Table 45.24 FIFO Interrupt Threshold and FIFO Depth Settings

	RFITH[2:0]/CFITH[2:0]							
FDS[2:0]	**111b (full)**	**110b (7/8)**	**101b (3/4)**	**100b (5/8)**	**011b (1/2)**	**010b (3/8)**	**001b (1/4)**	**000b (1/8)**
000b (0 messages)	Invalid (FIFO cannot be enabled)							
001b (4 messages)	Allowed	Prohibited	Allowed	Prohibited	Allowed	Prohibited	Allowed	Prohibited
010b (8 messages)	Allowed							
011b (16 messages)	Allowed							
100b (32 messages)	Allowed							
101b (48 messages)	Allowed							
110b (64 messages)	Allowed							
111b (128 messages)	Allowed							

45.6.2.2 FIFO Buffers Control

To enable the receive FIFO interrupt, set the RFIE or RFFIE bit in the RFCRn register (n = 0 to 7) to 1.
To enable the common FIFO interrupt, set either the CFRIE or CFTIE bit in the CFCRn register or the CFORIE or CFOTIE bit in the CFECRn register:
After configuration is complete, each FIFO can be enabled by setting the RFCRn.RFE bit and CFCRn.CFE bit to 1 to allow transmission and reception of messages.
When the CFECRn.CFBME bit is 1, the common FIFO is in buffering mode, and transmit data is stored in the common FIFO but is not transmitted. Transmission starts when the CFECRn.CFBME bit is set to 0.
When the CFCRn.CFE bit is 1, do not change the CFECRn.CFBME bit from 0 to 1.

45.7 Reception and Transmission

45.7.1 Reception

In the CANFDG module, messages received on any of the channels, will be stored in receive message buffers or in receive FIFOs or common FIFO configured in receive FIFO mode/gateway FIFO mode depending upon the Acceptance Filter List entries:

- up to 32 receive message buffers can be configured
- eight receive FIFOs available
- up to six common FIFOs can be configured in receive mode or gateway FIFO mode
- up to six transmit queues can be configured in gateway mode

45.7.1.1 Message Storage in Receive Message Buffers

When a message is successfully received and stored in a receive message buffer, the corresponding NDF[n] flag in the RMNDR0 register is set to 1.
The stored message can be read from the corresponding receive message buffer.
If a new message is stored into a receive message buffer before the previous message in this message buffer is read, the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the receive message buffer. If such a loss of messages is not acceptable, store related messages by using receive FIFO.

Note: Unused data bytes are filled with 00h depending on the DLC value.

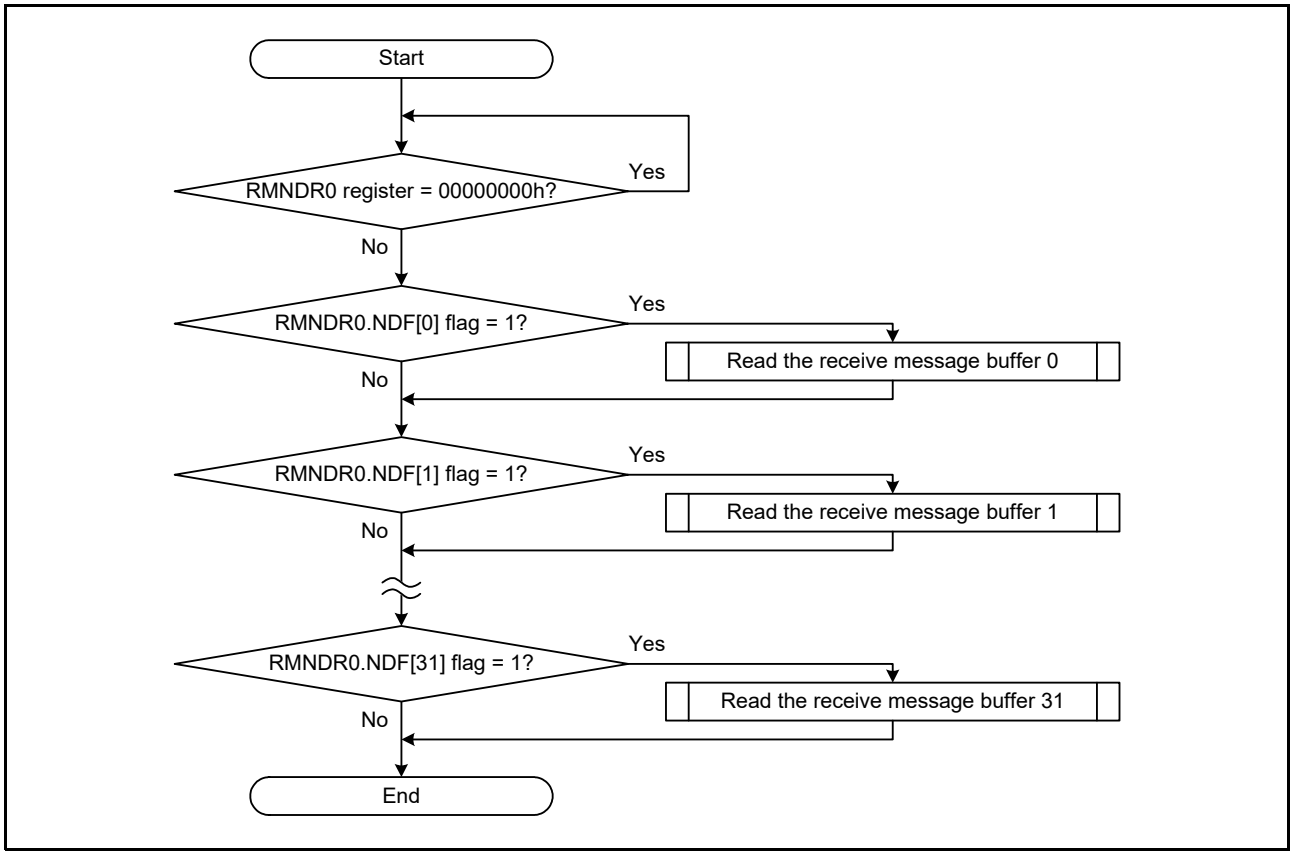

Figure 45.35 Receive Message Buffer Message Access Flow (Example for Polling Case)

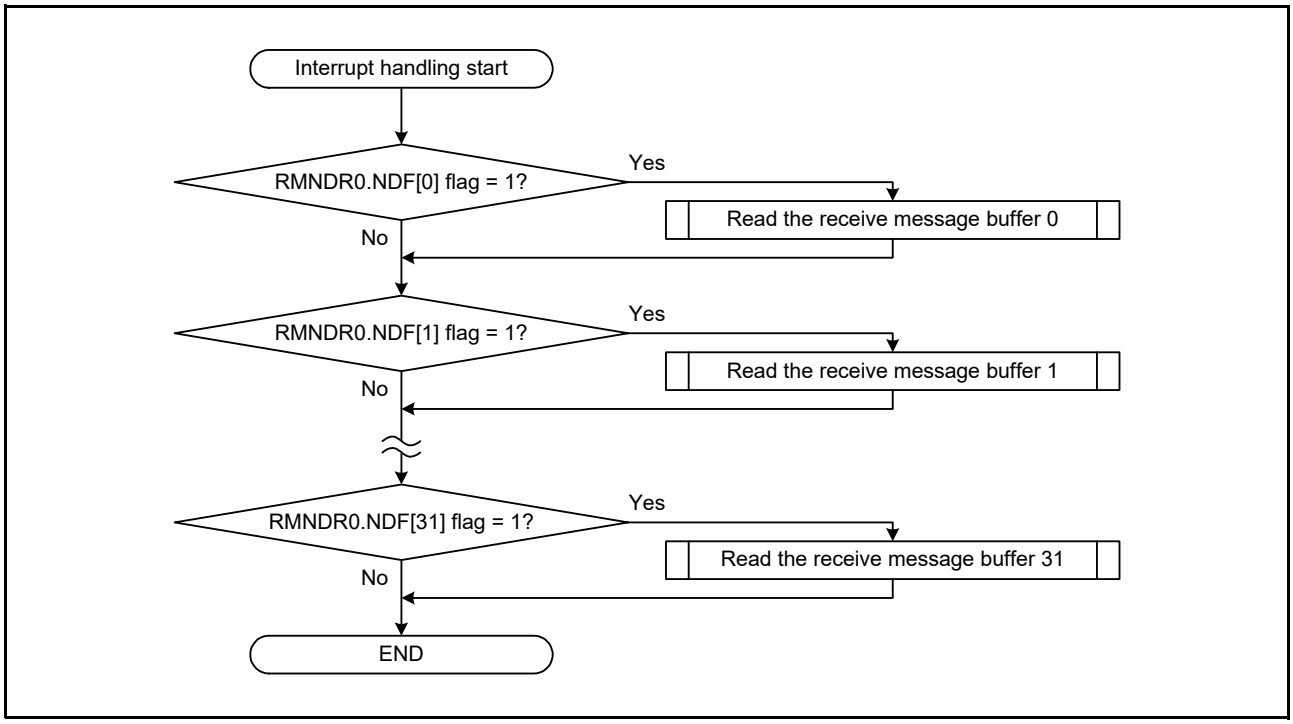

Figure 45.36 Receive Message Buffer Message Access Flow (Example for Interrupt Case)

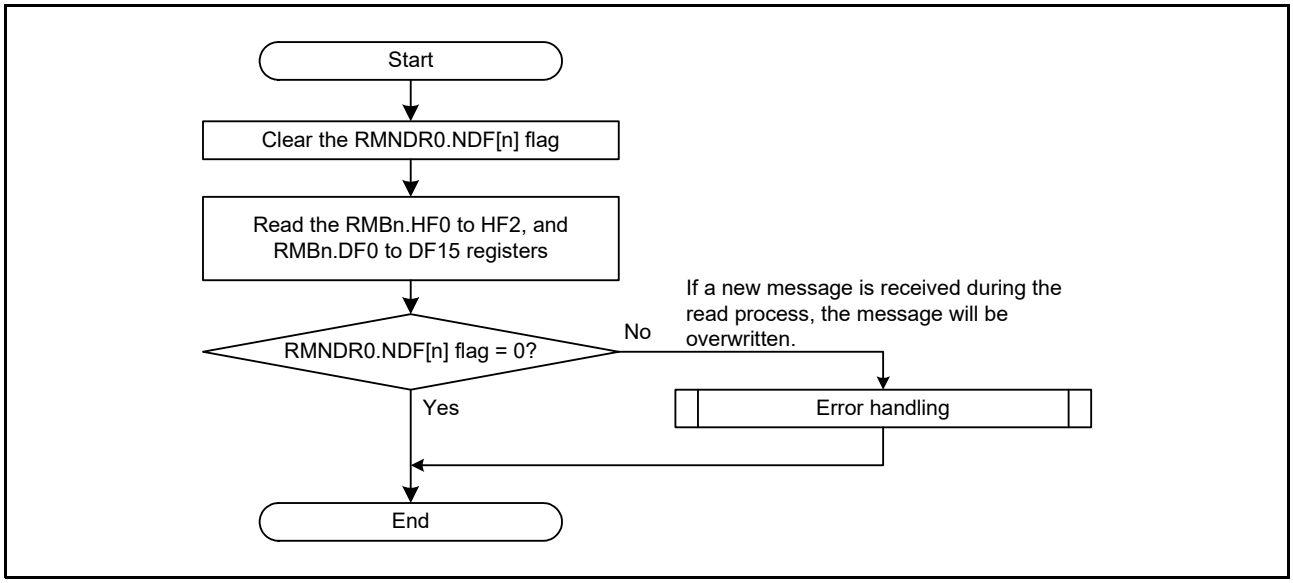

Figure 45.37 Receive Message Buffer n Read Flow

45.7.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to receive FIFOs or common FIFO configured in receive FIFO mode/ gateway FIFO mode should be configured based on the requirements of the system.
The AFLn.PTR1.RF0E to RF7E, or CF0E to CF5E bit in the matching AFL entry selects the FIFO buffers to which the related reception message will be stored.
When the received message is stored in one or more receive FIFOs or common FIFO configured in receive FIFO mode/ gateway FIFO mode, the message counter value is incremented in the corresponding Receive FIFO Status Register or Common FIFO Status Register.
Depending upon the configuration of the FIFO buffers, an interrupt may also be generated. The message can be read from the corresponding FIFO access registers.

Note: Since many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, then the FIFO full flag is set.
When the value 000000FFh is written to the corresponding FIFO Pointer Control Register, then the message count is decremented by 1.

Only write 000000FFh to the FIFO Pointer Control Register after completely reading the message from the FIFO Access Register of the corresponding FIFO.
When all the messages stored in the FIFO are read, then the FIFO empty flag is set.
If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO message lost flag is set and the new message will be lost (messages already stored will not be overwritten).
To prevent message loss due to overrun, set an appropriate interrupt generation threshold and generate an interrupt before the FIFO becomes full.

In gateway FIFO mode, if a new message is received and stored in a FIFO buffer that is already full, the existing message is overwritten or the received message is discarded, depending on the setting of the CFECRn.CFOWM bit, as follows:

- When the CFECRn.CFOWM bit is 0:
  The received message is discarded and the CFSRn.LOST flag is set to 1.
- When the CFECRn.CFOWM bit is 1:
  The oldest message in the buffer is overwritten with the received message, and the read pointer moves to the second oldest message. The CFSRn.CFOWF flag becomes 1, indicating that the message has been overwritten.

In addition, when a CAN bus error or arbitration-lost for the transmit message occurs in the FIFO buffer with full state, the message is discarded and retransmission for the message is not performed. The read pointer automatically moves to the next message.
When the CFCRn.CFE bit is 1, do not change the CFECRn.CFOWM bit.

The common FIFO can be configured to interrupt in the following cases:

- When CAN frame reception is completed
- When FIFO is in full status in receive FIFO mode or gateway FIFO mode

Note: The message lost flag is set by the CANFDG module only in receive FIFO mode or gateway mode, and the flag is not set when the FIFO buffer is overloaded by the CPU.

Note: When the AFLn.PTR0.RDS0 to RDS2 bits are set to 1 (a transmit queue is set as the routing destination) and the TQCRn.TQGWE bit is set to 1 (gateway mode of the transmit queue is enabled), received frames are routed to the specified transmit queue and stored as transmit data.

The receive FIFOs and the common FIFO configured in receive FIFO mode or gateway FIFO mode can be disabled at any time by clearing the RFCRn.RFE bit or CFCRn.CFE bit.

When the RFCRn.RFE bit or CFCRn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Hence, all messages in the FIFO buffers will be lost and no further messages can be stored into the FIFO.

When the receive FIFOs or common FIFO configured in receive FIFO mode is set to be read by DTC/DMA transfer, do not read the FIFO buffer on the CPU or write 000000FFh to the FIFO Pointer Control Register (the RFPCRn or CFPCRn register). The FIFO read pointer is automatically updated when read by DTC/DMA transfer.

Note: If the interrupt flag is set for a FIFO buffer and then the FIFO is disabled, then the interrupt flag will not be cleared automatically. The interrupt flag should be cleared before disabling the FIFO.

Note: When the next frame is received before clearing the receive interrupt flag, the receive interrupt flag is not set again.

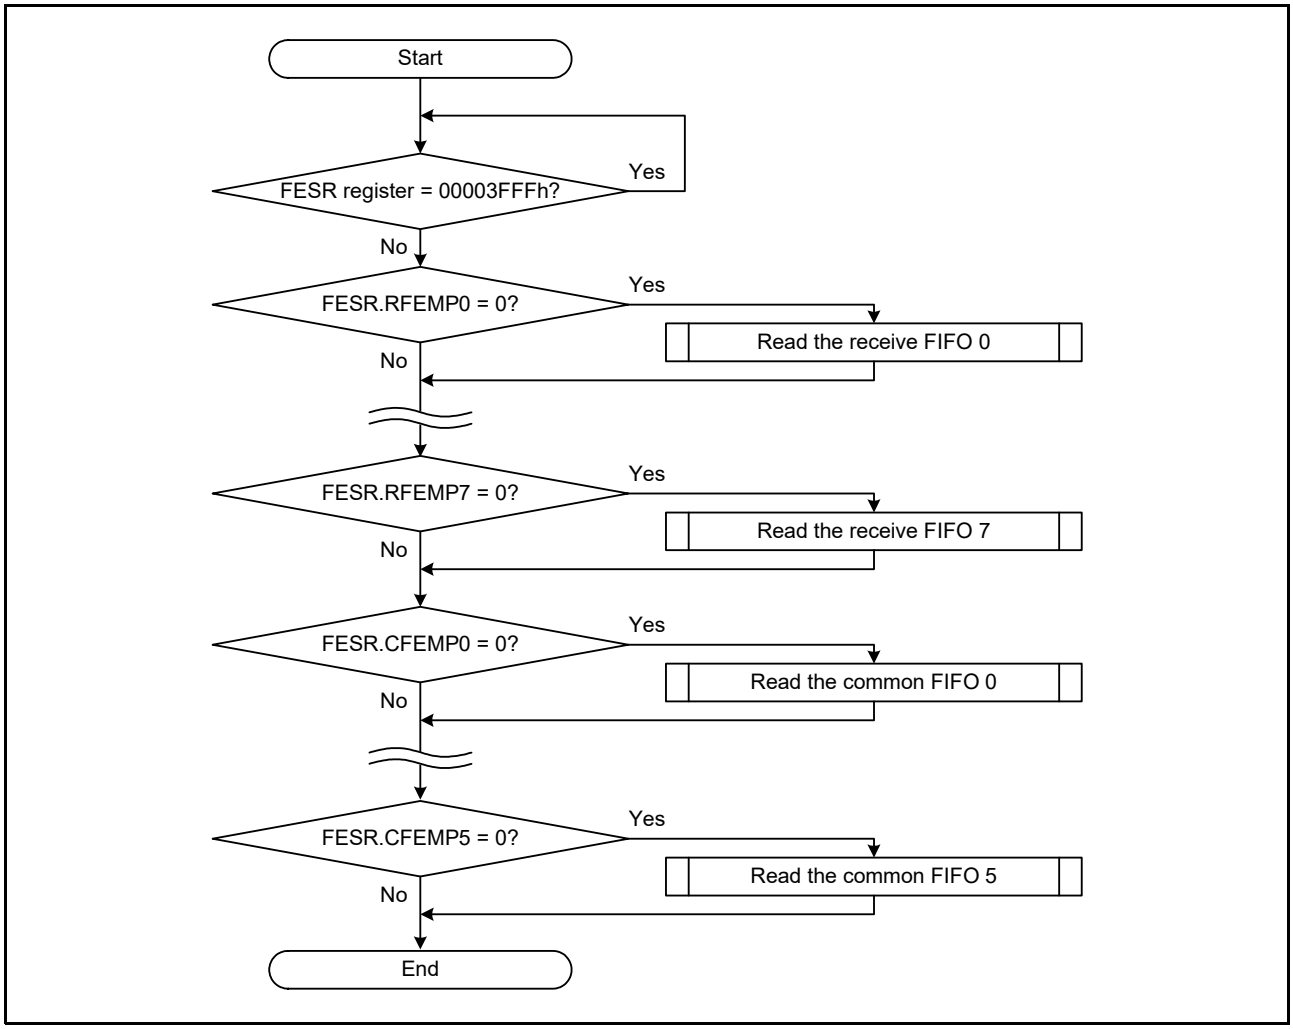

Figure 45.38 FIFO Buffer Message Access Flow (Example for Polling Case)

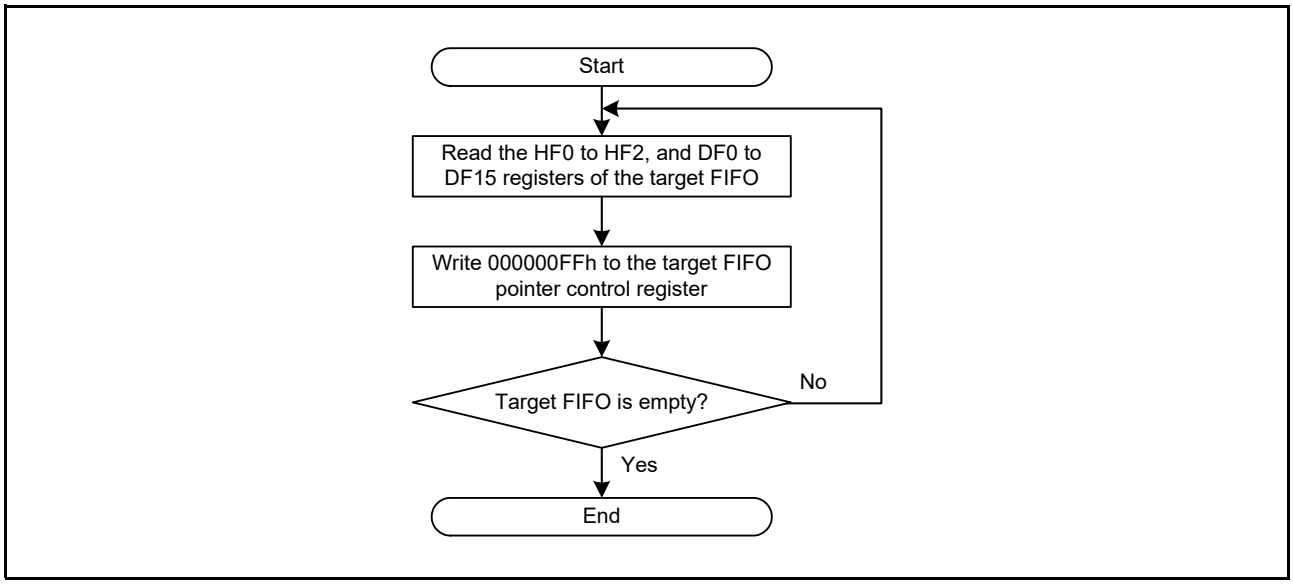

Figure 45.39 FIFO Buffer Read Flow (Example for Polling Case)

If the interrupt flag is cleared after the FIFO read process is completed, the interrupt flag is not set even if the next frame has already been received. The FIFO read process must be performed and the interrupt flag must be cleared before the reception of the next frame is completed. If the process is not in time, make sure the FIFO is empty, clear the interrupt flag, and make sure the FIFO is empty again.

45.7.1.3 Timestamp

The timestamp counter is a free-running counter that can be used to check reception time of a received message or transmission time of a successful transmitted message. The timestamp counter value will be captured based on the GFDCFG.TSCPS[1:0] bit setting (sample point of SOF, EOF when the frame is taken valid, or sample point of res bit following the FDF bit in case of a CAN FD frame). For reception the timestamp counter value is stored together with the message ID and data into the target receive message buffer, receive FIFO or gateway FIFO.
For transmit message the timestamp counter value is stored as part of the transmission history entry.
The counter can be clocked from PCLKA or the bit timing clock of the CAN channel. The counter clock source can be set with the GCFG.TSCS bit. If the GCFG.TSCS bit is 0, PCLKA is used. If it is 1, the bit time clock of CAN channel selected by the GCFG.TSBTCS[2:0] bits is used.
Care has to be taken when using the bit time clock as clock source. The timestamp counter stops when the selected channel enters CH_HALT or CH_RESET mode. So, also for other CAN channels the timestamp counter value will not be updated.
If PCLKA is selected as the timestamp counter clock source, time stamp counter function is not affected by the Channel mode.
The clock source of the timestamp counter can be divided by the coefficient defined by the GCFG.TSP[3:0] bits (timestamp prescaler).
The timestamp counter can be reset to 00000000h with the GCR.TSCR bit (timestamp counter reset).

45.7.2 Transmission

There are several possible transmission configurations for each channel:

- Normal transmission
- FIFO transmission
- Gateway transmission
- Transmit queue transmission

The CANFDG module has 16 transmit message buffers for each channel. These message buffers are only used for transmission and cannot be configured for reception.
Additionally transmission from transmit queue and/or common FIFO configured in transmit FIFO mode or gateway FIFO mode can be set in the following way (refer to Figure 45.40):

- Transmit queue
  Up to eight transmit message buffers in a channel can be grouped to form a transmit queue with a common access window. Each channel has four transmit queues.
  Transmit queue 0 and transmit queue 2 use the transmit message buffer from the lower level, and transmit queue 1 and transmit queue 3 use the transmit message buffer from the higher level.
  Do not access the TMCRn or TMSRn registers of the transmit message buffer used for the transmit queue.
  The access window for each transmit queue is as follows:
  – Transmit queue 0: Transmit message buffer 0
  – Transmit queue 1: Transmit message buffer 7
  – Transmit queue 2: Transmit message buffer 32
  – Transmit queue 3: Transmit message buffer 39
  When using transmit queue 0 and transmit queue 1 at the same time, set the total number of queue depth to 8 or less.
  When using transmit queue 2 and transmit queue 3 at the same time, set the total number of queue depth to 8 or less.
- Common FIFO (transmit FIFO mode or gateway FIFO mode)
  The CANFDG module has three common FIFO for each channel. Common FIFO configured in transmit FIFO mode or gateway FIFO mode is linked to any of the transmit message buffers 32 to 39.
  The linked transmit message buffer replaces the common FIFO. Do not access the TMCRn or TMSRn registers of the linked transmit message buffer.
  Refer to Figure 45.33 for information on the assignment of the common FIFO to each channel.

Note: Common FIFO should not be linked to transmit message buffers that are already part of a transmit queue.

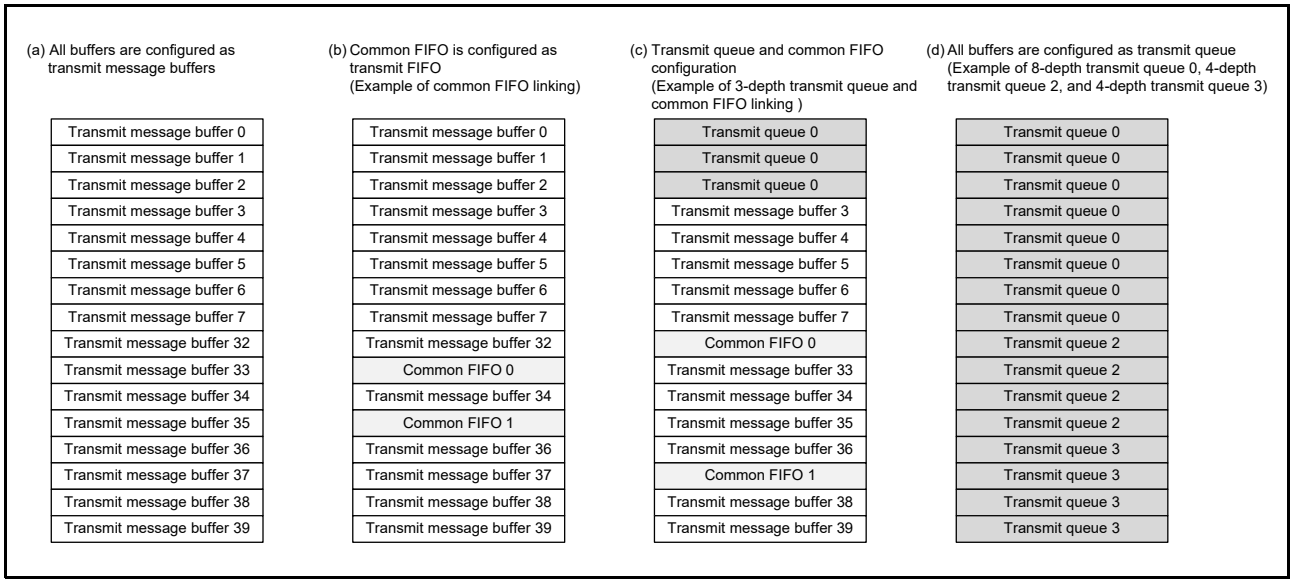

Figure 45.40 Channel Transmit Message Buffer Configuration

45.7.2.1 Transmission Priority

If two or more transmit message buffers are queued for transmission within a channel, messages are transmitted according to one of the following priorities.

- CAN ID priority
- Message buffer number priority

The transmission priority can be set using the GCFG.TPRI bit, and it applies to all message buffers and CAN channels.
For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the transmit message buffers linked to the common FIFO configured in transmit FIFO mode or gateway FIFO mode.
Do not select message buffer number priority when using the transmit queue.
For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All transmit message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the transmit message buffers linked to the common FIFO configured in transmit FIFO mode or gateway FIFO mode and includes the transmit queue message buffers.
If the ID of two or more message buffers is the same, then the smaller message buffer number will have higher priority for transmission.

Note: For common FIFO configured in transmit FIFO mode or gateway FIFO mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.
If the message is being transmitted from the FIFO, then the next pending message within the same FIFO will be considered in the transmission arbitration.
In contrast to this, all transmit message buffers of a transmit queue will participate in internal transmission arbitration.

Figure 45.41 below shows the transmission configuration flow.

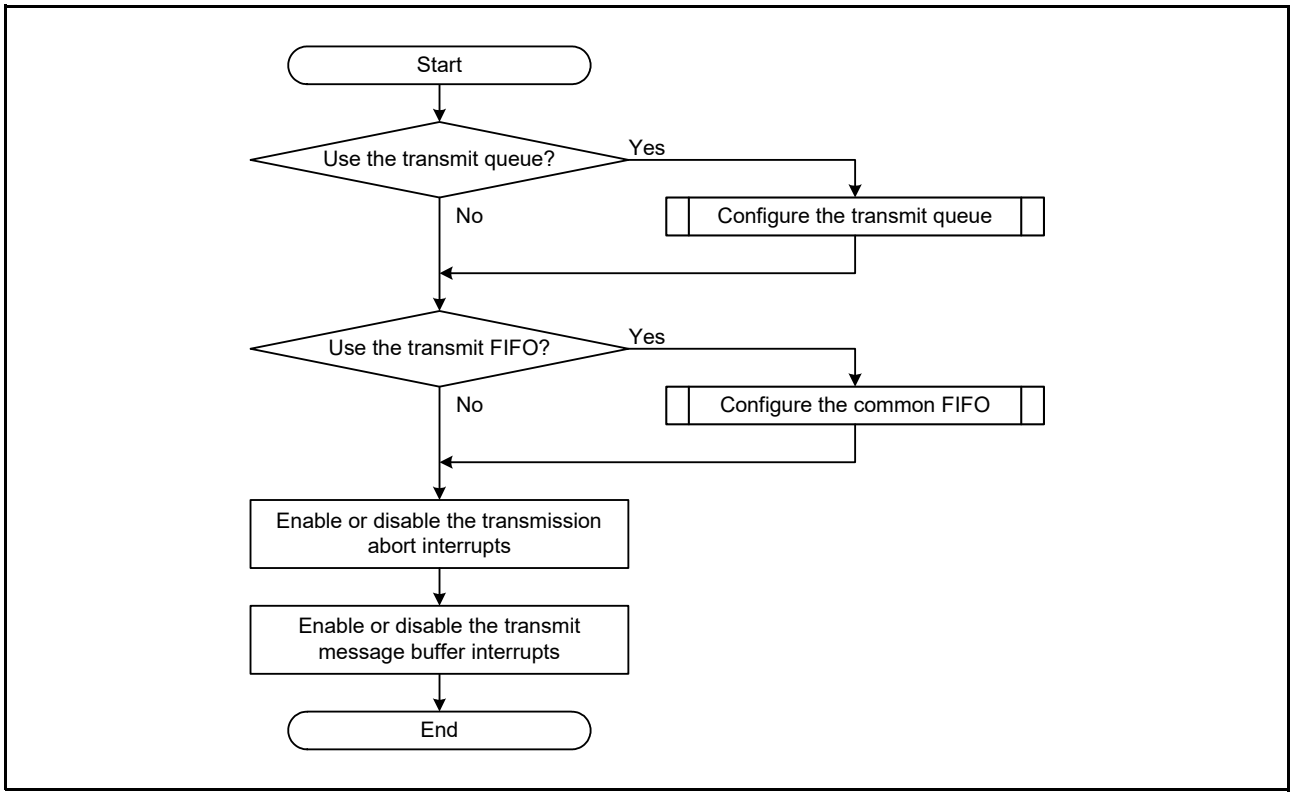

Figure 45.41 Transmission Configuration Flow

45.7.2.2 Message Transmission from Transmit Message Buffer

Each transmit message buffer has two modes of message transmission:

- Normal Transmission Mode
  When the message buffer is set to normal transmission mode, the data frames or remote frames set in that message buffer can be transmitted.
  Completion of normal transmission can be checked by the TMSRn.TXRF[1:0] flags. These flags are set to 10b or 11b when a normal transmission is successful.
  When arbitration is lost or an error occurs during transmission, the message transmission will be retried if no transmission abort request is set in the transmit message buffer.
  A new internal transmission arbitration is performed for all message buffers that have a transmission request.
- One-Shot Transmission Mode
  When the TMCRn.ONESHOT bit is set to 1, the message buffer is placed in one-shot transmission mode and attempts to transmit the message only once.
  Completion of one-shot transmission can be checked by the TMSRn.TXRF[1:0] flags. These flags are set to 10b or 11b when the one-shot transmission is successful.
  The TXRF[1:0] flags are set to 01b when arbitration is lost or an error occurs during transmission. In this case, message transmission will not be retried.

Figure 45.42 shows the transmission request procedure from transmit message buffer.

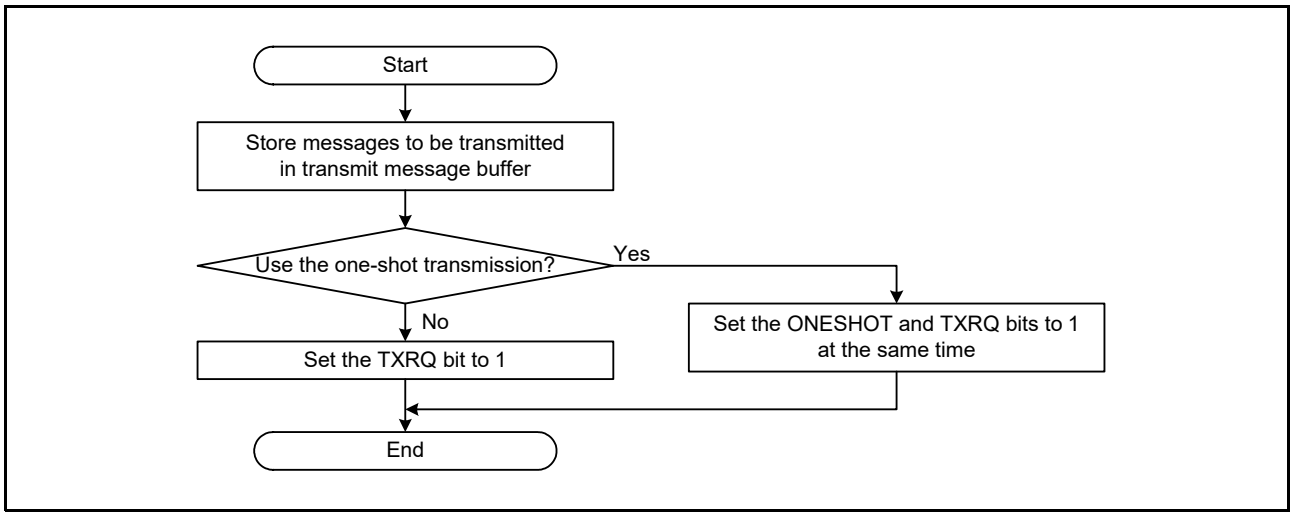

Figure 45.42 Transmission Request Procedure from Transmit Message Buffer

Table 45.25 shows configuration of the TMCRn register.

Table 45.25 Configuration of TMCRn Register

Transmission Request TXRQ Bit	Transmission Abort Request TARQ Bit	One-Shot Transmission Enable ONESHOT Bit	Message Buffer Status
0	0	0	Normal transmission is stopped.
0	0	1	One-shot transmission is stopped.
1	0	0	Data frames or remote frames are transmitted in normal transmission mode.
1	0	1	A data frame or a remote frame is transmitted in one-shot transmission mode.
1	1	0	Transmission abort is requested.
1	1	1	One-shot transmission abort is requested.

Figure 45.43 shows timings for successful transmission from two message buffers on one channel.

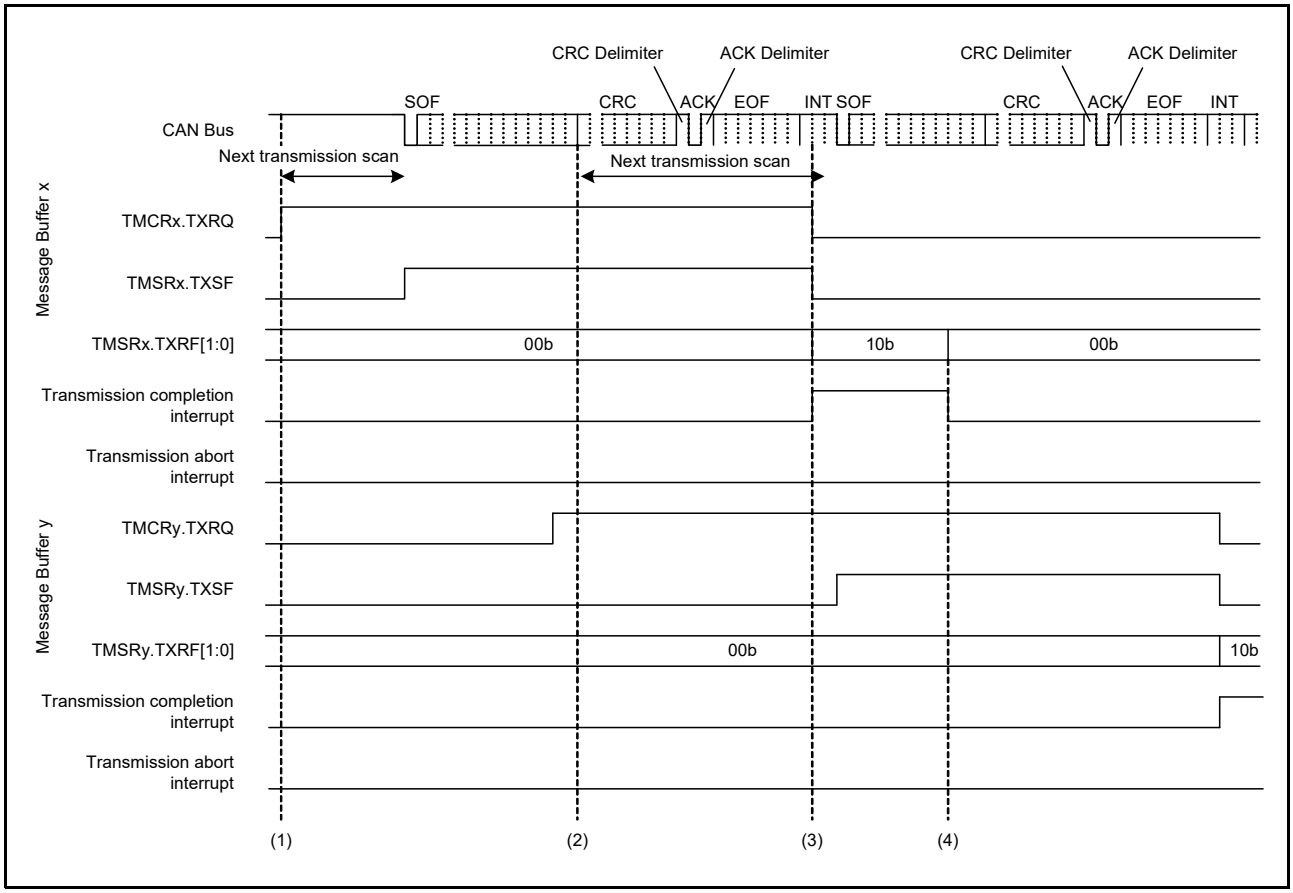

Figure 45.43 Timing of Request and Flag Bits for Successful Transmission

(1) If the TMCRx.TXRQ bit is set to 1 in the bus idle state, message buffer scanning procedure starts to decide the highest priority message buffer for transmission.
When the transmit message buffer is decided, the TMSRx.TXSF flag is set to 1 (transmitting), and CAN channel starts the transmission*1.

(2) At the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.

(3) If the message has been successfully transmitted, the TMSRx.TXRF[1:0] flags are set to 10b and the TMSRx.TXSF flag and the TMCRx.TXRQ bit are cleared.
When the corresponding TMIERm.TMIEj bit is set to 1 (transmit message buffer interrupt enabled), the successful transmission interrupt request is generated. To clear the related interrupt line the TMSRx.TXRF[1:0] flags have to be cleared.

(4) Before starting the next transmission, clear the TMSRx.TXRF[1:0] flags. Load the next message in the transmit message buffer and set the TMCRx.TXRQ bit to 1 again.
The TMCRx.TXRQ bit cannot be set to 1 again before TMSRx.TXRF[1:0] flags are cleared.

Note: The setting point of the TMSRx.TXSF flag is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the TMSRx.TXSF flag is cleared. Then the transmission scanning procedure is performed again to search for the highest priority transmit message buffer from the beginning of the first bit of CRC.
If an error occurs either during the transmission or following the loss of arbitration, the transmission scanning procedure is performed again during error frame to search for the highest priority transmit message buffer.

The Figure 45.44 shows timings for transmission abort for two message buffers on one channel.

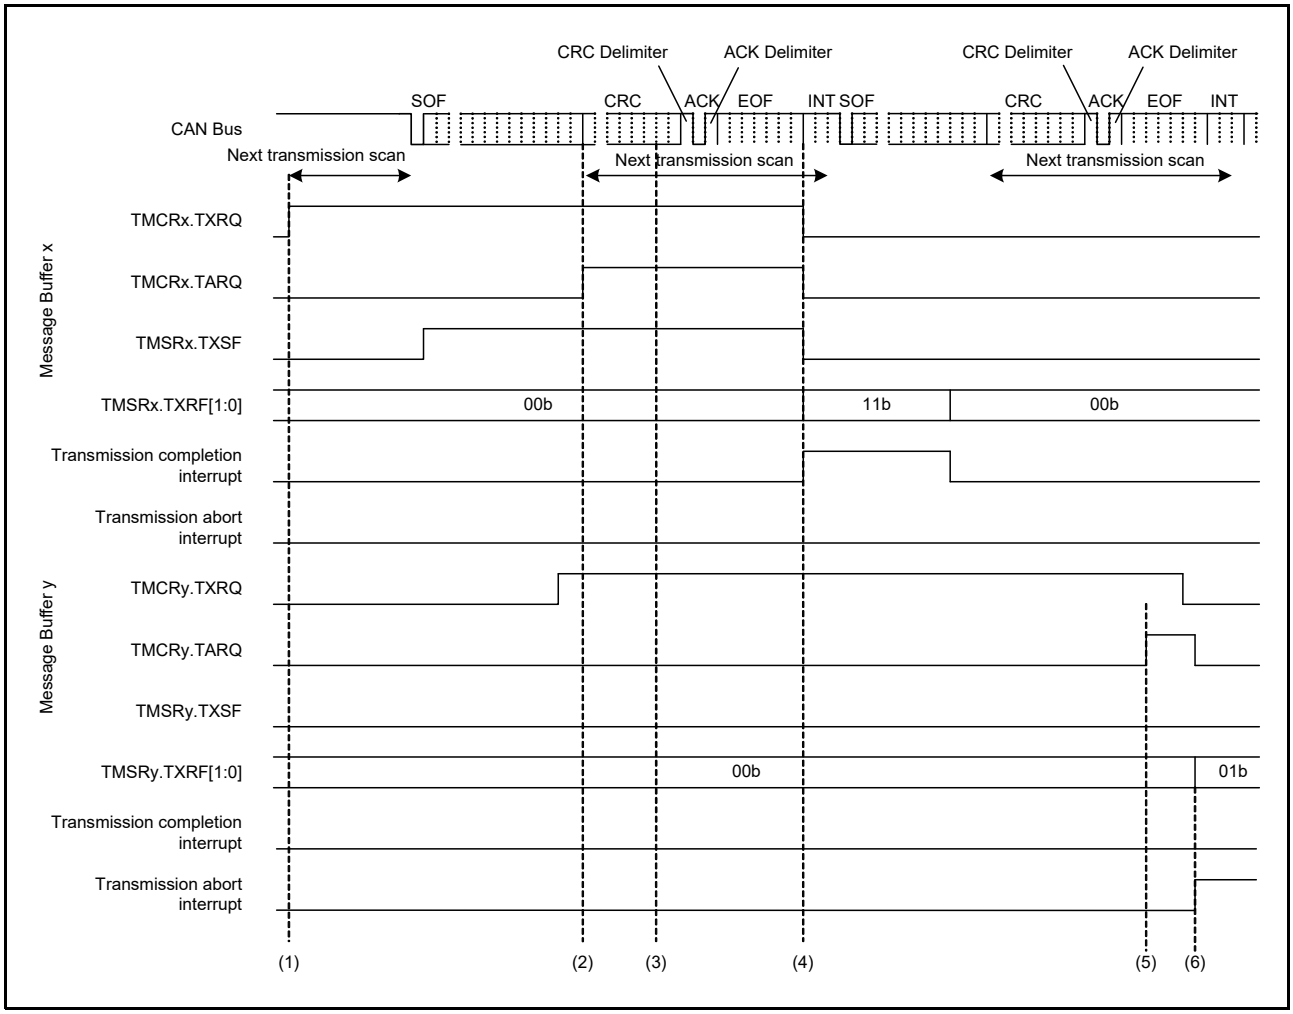

Figure 45.44 Timing of Request and Flag Bits for Transmission Abort

(1) If the TMCRx.TXRQ bit is set in the bus idle state, message buffer scanning procedure starts to decide the highest priority message buffer for transmission.
When the transmit message buffer is decided, the TMSRx.TXSF flag is set to 1 (transmitting), and CAN channel starts the transmission*1.

(2) If the TMCRx.TARQ bit is set to 1 when the related message buffer is already selected for transmission or currently transmitting, the message will not be aborted, if no error occurs or arbitration is lost.

(3) At the first bit of CRC, the transmission scanning procedure starts for the next transmission. In this example timing chart message buffer y is not selected as next transmit message buffer.

(4) If the message has been successfully transmitted, the TMSRx.TXRF[1:0] flags are set to 11b and the TMSRx.TXSF flag and TMCRx.TXRQ bit are cleared.
When the corresponding TMIERm.TMIEj bit is set to 1 (transmit message buffer interrupt enabled), the CAN successful transmission interrupt request is generated.
To clear the related interrupt line the TMSRx.TXRF[1:0] flags has to be cleared.

(5) Another CAN node is transmitting on the CAN bus (the TMSRy.TXSF flag is not set): if the TMCRy.TARQ bit is set to 1 when the related channel is under transmission scan, the transmission request cannot be cleared.

(6) After internal processing time the transmission is aborted and the TMSRy.TXRF[1:0] flags are set to 01b.
If the message buffer is not transmitting or selected as next transmit message buffer or under transmit scan, the abort is immediately accepted and the corresponding TMSRy.TXRF[1:0] flags are set to 01b.
In addition, the TMCRy.TXRQ and TMCRy.TARQ bits are cleared automatically.

When the CHCR.TAIE bit is set to 1 (transmission abort interrupt enabled), an interrupt is generated for successful transmission abort.
To clear the related interrupt the TMSRy.TXRF[1:0] flags have to be cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the TMSRx.TXSF flag is cleared. Then the transmission scanning procedure is performed again to search for the highest priority transmit message buffer from the beginning of the first bit of CRC.
If an error occurs, either during the transmission, or following the loss of arbitration, the transmission scanning procedure is performed again during error frame to search for the highest priority transmit message buffer.

45.7.2.3 Message Transmission from FIFO Buffer

The CANFDG module has three common FIFOs for each channel. The common FIFO can be linked to the transmit message buffer by the CFCRn.LTM[4:0] bits if configured in transmit FIFO mode or gateway FIFO mode.
When a transmission scan is started and the common FIFO corresponding to that transmit message buffer is enabled, the relevant message in the common FIFO will participate in the transmission scan.
Do not configure the transmit message buffer linked to the common FIFO configured in transmit FIFO mode.

(1) Transmit FIFO Operation

Messages can be written into the transmit FIFO by writing to the common FIFO buffer n (CFBn) (n = 0 to 5).
When the value 000000FFh is written into the CFPCRn register, the message count of the FIFO is incremented by 1.
Before writing to the CFPCRn register, wait until the message has been completely written to the CFBn. If the message count matches the FIFO depth, the CFSRn.FULL flag is set to 1.
The oldest message in the transmit FIFO is included in the scan for transmission.
When a message is successfully transmitted from the transmit FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the CFSRn.EMPTY flag is set to 1.
The interrupt generation conditions for the transmit FIFO buffers can be set by the CFCRn.CFIM bit.
If the CFCRn.CFIM bit is set to 0, interrupt is generated when last message is successfully transmitted from the transmit FIFO buffer. If the CFCRn.CFIM bit is set to 1, interrupt is generated for every successfully transmitted message from the transmit FIFO buffer.
Common FIFO can set interrupt, when CAN frame transmission is completed.
The common FIFO configured in transmit FIFO mode can be disabled by setting the CFCRn.CFE bit to 0. If this bit is set to 0, the CFSRn.EMPTY flag is set to 1 as described below:

- immediately if the message from the transmit FIFO is neither scheduled for the next transmission nor in transmission
- following the transmission completion, the detection of an error on the CAN bus, arbitration lost or transition to CH_HALT or GL_HALT mode if the transmission from the transmit FIFO is already scheduled for transmission or already in transmission.

Note: The common FIFO is considered as disabled after setting the CFCRn.CFE bit to 0 only when the CFSRn.EMPTY flag is set to 1 for the corresponding common FIFO.

If there are other pending messages in the transmit FIFO buffer, they will be lost and the transmission needs to be requested again. Before the CFCRn.CFE bit is set to 1 again ensure that the CFSRn.EMPTY flag is set to 1 and that there is no pending abort request from the transmit FIFO.
When the CFCRn.CFE bit is set to 0, the message read and write pointers of the FIFO are cleared and are no longer active. Hence, all messages in the FIFO buffers will be lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after a configuration is shown in Figure 45.45.

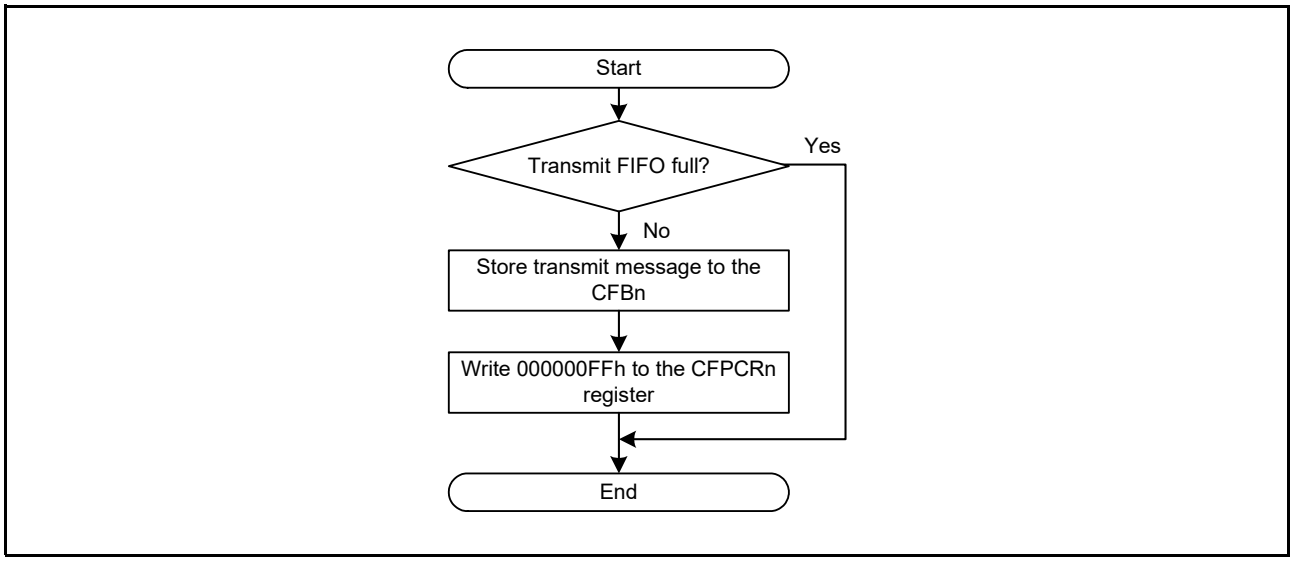

Figure 45.45 Transmit FIFO Transmission Request Procedure

(2) Gateway FIFO Operation

The AFL entry that routes received messages to the gateway FIFO must be configured according to the system requirements. The matching AFL entry selects the gateway FIFO of any CAN channel and stores the received message.
When a message is successfully received and stored in the gateway FIFO, the message count of the FIFO is incremented by 1.
If the message count matches the FIFO depth, the CFSRn.FULL flag is set to 1.
The oldest message in the gateway FIFO is included in the scan for transmission.
When a message is successfully transmitted from the gateway FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the CFSRn.EMPTY flag is set to 1
In gateway FIFO mode, if a new message is received and stored in a FIFO buffer that is already full, the existing message is overwritten or the received message is discarded, depending on the setting of the CFECRn.CFOWM bit, as follows:

- When the CFECRn.CFOWM bit is 0:
  The received message is discarded and the CFSRn.LOST flag is set to 1.
- When the CFECRn.CFOWM bit is 1:
  The oldest message in the buffer is overwritten with the received message, and the read pointer moves to the second oldest message. The CFSRn.CFOWF flag becomes 1, indicating that the message has been overwritten.

In addition, when a CAN bus error or arbitration-lost for the transmit message occurs in the FIFO buffer with full state, the message is discarded and retransmission for the message is not performed. The read pointer automatically moves to the next message.

The common FIFO can be configured to interrupt when CAN frame transmission or reception is completed.
The common FIFO can be configured to interrupt when FIFO is in full status in receive FIFO mode or gateway FIFO mode.
The interrupt generation conditions for the gateway FIFO can be set by the CFCRn.CFIM bit.
If the CFCRn.CFIM bit is set to 0, the number of stored messages is incremented and the receive interrupt flag is set when it reaches the value set in the CFCRn.CFITH[2:0] bits, and the transmit interrupt flag is set when the last message from the FIFO is successfully transmitted.

Setting the CFECRn.CFBME bit to 1 switches to FIFO buffering mode, stores transmit data in the common FIFO, and stops transmission. Transmission starts when the CFECRn.CFBME bit is set to 0.
A common FIFO configured in Gateway FIFO mode can be disabled by setting the CFCRn.CFE bit to 0. When this bit is

set to 0, the CFSRn.EMPTY flag becomes 1 at the following conditions:

- Condition for immediate setting to 1: When there is no next transmission scheduled from the gateway FIFO and no transmission is in progress
- After transmission is completed, after a CAN bus error is detected, after arbitration is lost, or after transition to CH_HALT mode or GL_HALT mode: If the next transmission is scheduled from the gateway FIFO or if transmission is currently in progress

If there are any other messages pending transmission in the gateway FIFO, those messages are lost.
Before setting the CFCRn.CFE bit to 1 again, make sure that the CFSRn.EMPTY flag is 1 and that there are no pending abort requests from the gateway FIFO.
When the CFCRn.CFE bit is set to 0 and the CFSRn.EMPTY flag becomes 1, the message read and write pointers in the gateway FIFO are cleared and become inactive. As a result, all messages in the gateway FIFO are lost and no further messages can be stored in that gateway FIFO.
For applications intended to use CAN-to-CAN gateways, it may be preferable not to replace the value of the ESI (Error State Indication) bit of the routed message with the value of the ESI bit of the transmitter node. For this reason, each channel can use the FDCFG.TESI bit to replace its own node's ESI bit with the value of the ESI bit in the routing message.

Note: If the transmitter node is error passive, the ESI bit is transmitted as error passive (ESI = 1).

(3) Interval Timer for FIFO Transmission

For the common FIFO in transmit mode or gateway FIFO mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFCRn.CFE bit is set to 1.
When the common FIFO in transmit mode or gateway FIFO mode is enabled, then the first message will be transmitted without considering this interval time.
The interval timer will stop counting when:

- FIFO is disabled by set the CFCRn.CFE bit to 0
- CAN channel is in CH_RESET mode.

The interval time is specified by the value of the CFCRn.TINT[7:0] bits and can be specified from 0 to 255 timer units. The timer unit can be defined based on two different clock sources for the interval timer. Select the value 0 to disable the interval timer for FIFO transmission.
The clock source can be selected by the CFCRn.ITCS bit. For the clock source the CAN bit timing clock of the related channel or a reference clock could be selected.
If CAN channel bit time clock is configured as clock source and the CAN channel enters CH_HALT, CH_RESET, or CH_SLEEP mode, then the interval timer is stopped for that channel.
If the reference clock is selected as interval timer clock source, then the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.
The reference clock can be used to configure the interval time in fixed time units. It is based on the PCLKA. The GCFG.ITP[15:0] bits define the relation between the PCLKA frequency/period and the reference clock period.
Refer to Table 45.26 for configuration values of the GCFG.ITP[15:0] bits to achieve different reference clock periods based on the PCLKA frequency/period.

Table 45.26 Configuration Example for Interval Timer Prescaler

	Reference clock period		
PCLKA frequency (period)	**1 µs**	**100 µs**	**500 µs**
16 MHz (62.5 ns)	16	1600	8000
20 MHz (50 ns)	20	2000	10000
32 MHz (31.25 ns)	32	3200	16000
50 MHz (20 ns)	50	5000	25000
60 MHz (16.67 ns)	60	6000	30000
80 MHz (12.5 ns)	80	8000	40000
100 MHz (10 ns)	100	10000	50000
120 MHz (8.33 ns)	120	12000	60000
150 MHz (6.67 ns)	150	15000	—

Additionally the reference clock resolution can be specified by the CFCRn.ITR bit.
The interval time is based on the reference clock period multiplied by the configured value (×1 or ×10).
The reference clock based interval timer can be used to follow the requirements of the ISO 15765-2 Separation Time.
The whole range for the separation time from 100 µs to 127 ms can be covered.
The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).
When the interval time has elapsed, the next transmission request is raised by the related transmit FIFO. Hence, the interval time defines the minimum time between two messages transmitted from one FIFO.
The next message will earliest be sent after this interval time. The Figure 45.46 shows an example timing of the internal processing.

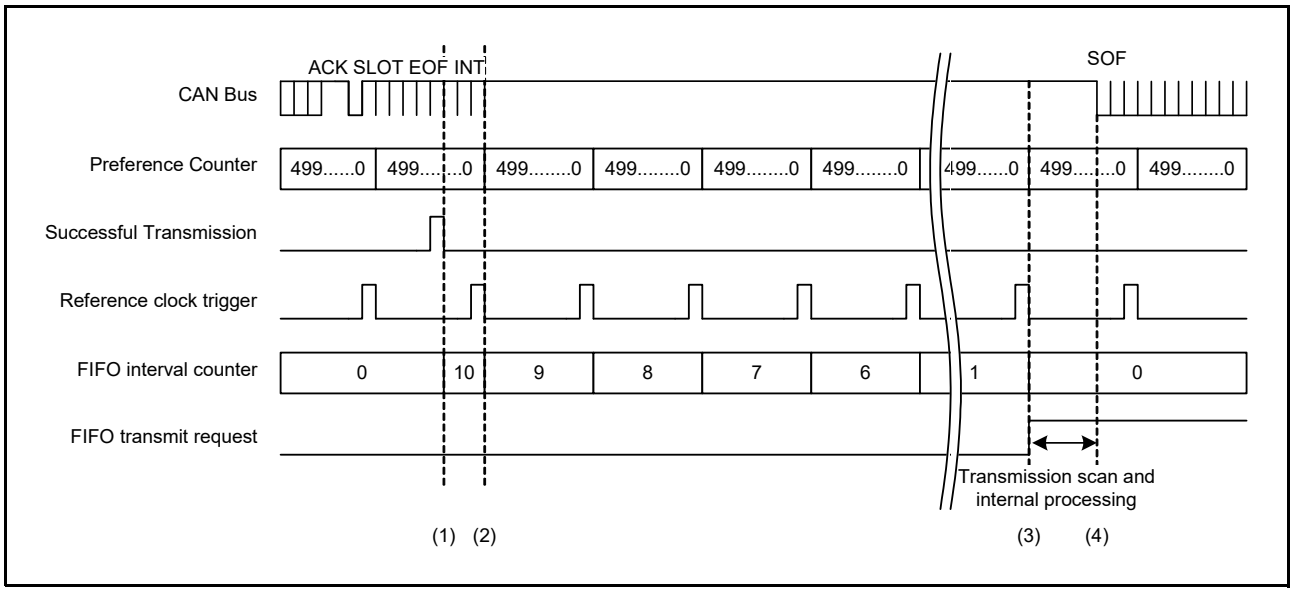

Figure 45.46 Example for Interval Processing Time

The configuration for this timing above is following:

- PCLKA frequency = 50 MHz
- Interval timer prescaler (GCFG.ITP[15:0]) = Divided by 500
- Reference clock due to the settings above = 10 µs
- Common FIFO interval timer clock source selection (CFCRn.ITCS) = 0
- Common FIFO interval timer resolution (CFCRn.ITR) = 0

- Common FIFO transmission interval (CFCRn.TINT[7:0]) = 10 counts
- Theoretical message separation interval = 100 µs

(1) Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore the first interval is counting less or equal to one reference clock interval.
(2) With the next reference clock trigger the FIFO interval timer is decremented.
(3) When the FIFO interval timer reached the value 0, the FIFO transmit request is set.
(4) When the FIFO is selected for transmission then the transmission will start soon. Due to internal processing this usually takes less than 3 bit time, between internal FIFO transmit request set 3. (shown above) and actual transmission.
When multiple events occur simultaneously, such as receive scanning, internal message routing, transmit scanning on all channels, it could take up to 432 PCLKA cycles.

As shown in Figure 45.46, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure the CFCRn.TINT[7:0] bits to required minimum value + 1.
If transmit message buffers, transmit FIFOs or gateway FIFO are configured for transmission for the channel the real delay between two messages transmitted from a transmit FIFO can be much longer than specified by the interval time due to higher priority message transmission from these transmit message buffers or transmit FIFOs.
Figure 45.47 shows a block diagram of the FIFO interval timer.

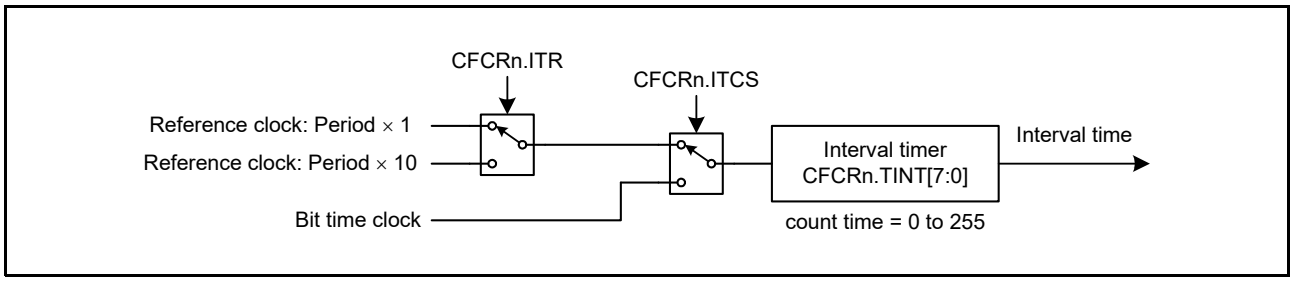

Figure 45.47 Block Diagram of FIFO Interval Timer

45.7.2.4 Transmit Queue

Each channel's enabled transmit queue consists of three to eight transmit message buffers, which are accessed via one access window. There are four transmit queues per channel. The depth in each transmit queue can be set to a value between 3 and 8.
The access window for each transmit queue (hereafter TXQ) is as follows:

- TXQ0: transmit message buffer 0
- TXQ1: transmit message buffer 7
- TXQ2: transmit message buffer 32
- TXQ3: transmit message buffer 39

For the transmit message buffer to be used as the access window, refer to the corresponding message buffer register (TMBn.HF0, TMBn.HF1, TMBn.HF2, TMBn.DF0 to TMBn.DF15).

All the messages in TXQ0 to TXQ3 enter the priority comparison for the transmission, which should be ID priority (GCFG.TPRI = 0).
The registers for TXQ are as follows:

- TXQ0: TQCR0, TQSR0, TQPCR0
- TXQ1: TQCR1, TQSR1, TQPCR1
- TXQ2: TQCR2, TQSR2, TQPCR2
- TXQ3: TQCR3, TQSR3, TQPCR3

The depth of each TXQ buffer can be configured by writing to the QDS[4:0] bits of the corresponding transmit queue configuration register. Each TXQ can set up to one of the following transmit message buffers as a queue buffer.

- TXQ0: transmit message buffer 0 to transmit message buffer 7
- TXQ1: transmit message buffer 7 to transmit message buffer 0
- TXQ2: transmit message buffer 32 to transmit message buffer 39
- TXQ3: transmit message buffer 39 to transmit message buffer 32

The available options for depth configuration of each TXQ buffer are:

- 00000b: 0 messages (transmission queue disabled)
- 00010b: 3 messages
- 00011b: 4 messages
  :
- 00111b: 8 messages

When using TXQ0 and TXQ1 at the same time, set the total number of queue depth to 8 or less.
When using TXQ2 and TXQ3 at the same time, set the total number of queue depth to 8 or less.

Do not access all transmit message buffers that configure the transmit queue, except transmit message buffer 0, transmit message buffer 7, transmit message buffer 32, and transmit message buffer 39, which function as the access window. Also, do not access the TMCRn registers that correspond to the transmit message buffers that configure the transmit queue.
When the AFLn.PTR0.RDS0 to AFLn.PTR0.RDS2 bits are set to 1 and the TQGWE bit for the corresponding transmit queue is set to 1, the received frame is stored as transmit data in the transmit queue specified as the routing destination. In gateway mode, if the transmit queue is accessed by routing when it is full, the transmit data is discarded and the TQSRn.LOST flag becomes 1.

When writing data to TXQ, check the status of TXQ before writing the data to be transmitted.
The messages stored to the transmit queue access window are internally stored to a free buffer of the transmit queue.

When the TXQ buffer is full, do not access the queue anymore. If the transmit data is written when the TXQ is full, the transmit data will be overwritten.
The transmit queue can be disabled by setting the TQE bit in the corresponding transmit queue setting register to 0. If this bit is set to 0, the TQSRn.EMPTY flag is set as described below:

- immediately: if a message from the transmit queue is not scheduled for the next transmission and is not being transmitted
- after the transmission completion, error detection on the CAN bus, loss of arbitration, or transition to CH_HALT or GL_HALT mode: if a message from the transmit queue is scheduled for transmission or is being transmitted.

Note: The transmit queue is disabled only when the TQSRn.EMPTY flag is set to 1 after setting the TQCRn.TQE bit to 0.

If there are other pending messages in the transmit queue, they will be lost, so their transmission needs to be requested again.
Before the TQCRn.TQE bit is set to 1 again, ensure that the TQSRn.EMPTY flag is set to 1 and that there is no pending abort request from the transmit queue.
When the TQE bit is set to 0, all messages in the transmit queue buffers will be lost and no further message can be stored in the transmit queue.
When a message has been stored to the transmit queue, 000000FFh must be written in to the TQPCRn register. This will set the transmit request automatically and change the internal message buffer pointer to the next free message buffer location of the transmit queue.

Note: If two messages with the same ID are stored in the transmit queue, then the order of transmission of these messages could be different from the order in which they were stored in the transmit queue.
To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same ID is stored in the transmit queue.

For the transmit queue a dedicated interrupt can be enabled by setting the TQCRn.TQIE bit.
The interrupt mode can be configured with the TQCRn.TQIM bit either to generate an interrupt for every transmitted message or for the last transmitted message.
The transmit queue transmission request procedure after configuration is shown in Figure 45.48.

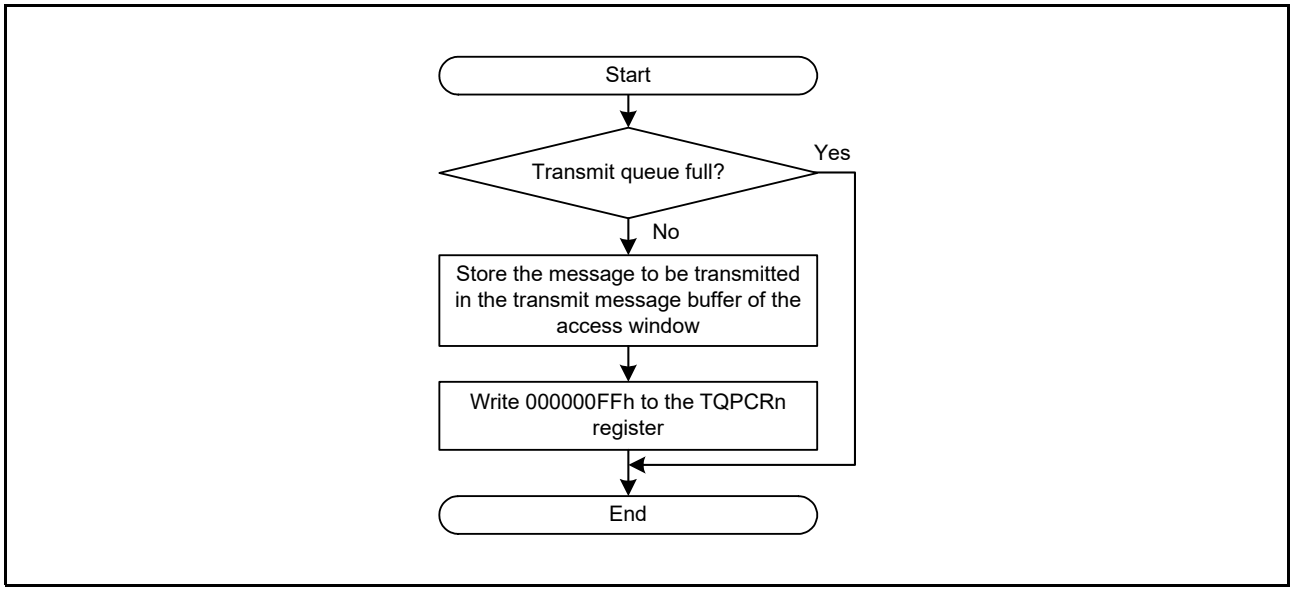

Figure 45.48 Transmit Queue Transmission Request

Table 45.27 shows the access points that can be used with transmit queues.
Do not use HW routing access, CPU access, and DTC/DMA access at the same time. Only one of the access methods is selected.

Table 45.27 Transmit Queue and Available Access Points

Transmit Queue	Access Window	Transmit Queue Depth*1	Message Buffer Direction	Hardware Routing Access Point	CPU Access Point	DMA Access Point
TXQ0	Transmit message buffer 0	0, 3 to 8	0 → 7	Yes	Yes	Yes
TXQ1	Transmit message buffer 7	0, 3 to 8	7 → 0	Yes	Yes	No
TXQ2	Transmit message buffer 32	0, 3 to 8	32 → 39	Yes	Yes	No
TXQ3	Transmit message buffer 39	0, 3 to 8	39 → 32	No	Yes	Yes

Note 1. When using TXQ0 and TXQ1 at the same time, set the total number of queue depth to 8 or less. When using TXQ2 and TXQ3 at the same time, set the total number of queue depth to 8 or less.

45.7.2.5 Transmission History

The transmission history function records the information of the successfully transmitted message in the transmission history buffer. Each channel has one transmission history buffer, and each transmission history buffer can store up to 32 transmission history entries.
The THCR.THRC bit can select whether to store information only for messages transmitted from transmit FIFO and transmit queue, or also for messages transmitted from the transmit message buffers.
When the THCR.THRGC bit is 1, information about all messages transmitted in gateway mode is stored in the transmission history.
Each transmit message can be individually configured for acceptance to the transmission history by the CFBn.HF0.THENT bit.
The message information is stored to the transmission history buffer of a CAN channel after the message is successfully transmitted on that CAN channel.
Storing to the list is not synchronized with the status of TMSRn.TXRF[1:0] flags.
Due to internal processing, the storage to the list could happen with a delay after the successful transmission indication.
Storing the transmission history data can be recognized by the condition that the THSR.THIF flag is set to 1 when the THCR.THIE bit is set to 1 or when the transmission history counter (THSR.FLVL[5:0]) is increased.
Multiple events could occur, such as reception scans and internal message routing.
Maximum delay time from setting the TMSRn.TXRF[1:0] flags to storing the transmission history data is 200 PCLKA cycles.

The transmission history records following information of the transmitted message:

- Transmitted Buffer type:
  - 001: Transmit message buffer
  - 010: Common FIFO in transmit FIFO mode (hereinafter referred to as transmit FIFO)
  - 100: Transmit queue
- Transmitted Buffer number:
  Transmit message buffer, transmit queue message buffer or transmit message buffer link for the common FIFO from which the transmission occurred. The number depends upon the buffer type, refer to Table 45.28.
- Transmitted pointer:
  Pointer set in header field 2 of transmit message (HF2.PTR[15:0])
- Transmitted timestamp:
  Message timestamp captured at capture point as set by the GFDCFG.TSCPS[1:0] bits
- Transmitted information label:
  Information label set in header field 2 of transmit message (HF2.IFL[1:0])
- Transmit gateway identification:
  When the message is transmitted through a gateway, the THACR0.GWMF bit is set to 1.

Table 45.28 Transmission History Buffer Number Entry

Transmitted Buffer Number (THACR0.BN[6:0])	Transmitted Buffer Type (THACR0.BT[2:0])		
	001b	010b	100b
	Transmit Message Buffer	Transmit FIFO	Transmit Queue
0000000b	TMB0	The value of the BN[6:0] bits corresponds to the setting of the CFCRn.LTM[4:0] bits.	The value of the BN[6:0] bits indicates the number of the transmit message buffer from which the message was transmitted.
:	:		
0000111b	TMB7		
0100000b	TMB32		
:	:		
0100111b	TMB39		
1000000b	TMB64		
:	:		
1000111b	TMB71		
1100000b	TMB96		
:	:		
1100111b	TMB103		

The transmitted pointer is used to identify which message of a transmit FIFO or transmit queue has been successfully transmitted because the transmit FIFO or transmit queue number alone is not sufficient.
Therefore, a unique number (pointer) can be attached to each transmit message stored in a transmit FIFO or transmit queue. This unique pointer should be written to the CFBn.HF2.PTR[15:0] bits for a transmit FIFO or to the TMBn.HF2.PTR[15:0] bits of the transmit queue.
When the message is successfully transmitted then this pointer is stored together with the other message related information to the transmission history and can be read via the transmitted pointer field (PTR[15:0]) in the Transmission History Access Register.
Also for normal transmit message buffers, the TMBn.HF2.PTR[15:0] bits will be stored in the transmission history. An information label is the same.
Read access to the Transmission History Access Register will be done for every single entry.
After reading one entry, 000000FFh has to be written to the THPCR register to be able to access the next entry until transmission history is empty.
Figure 45.49 shows an example flow for processing the transmission history.
The transmission history has dedicated interrupts, which can be configured with the THCR.THIM bit and enabled with the THCR.THIE bit, either to generate an interrupt when the transmission history reached a filling level of 75% or for every new transmission history entry.
Loss of transmission history is indicated by the THSR.LOST flag. Status of this flag is also shown by the GESR.THLDF flag.

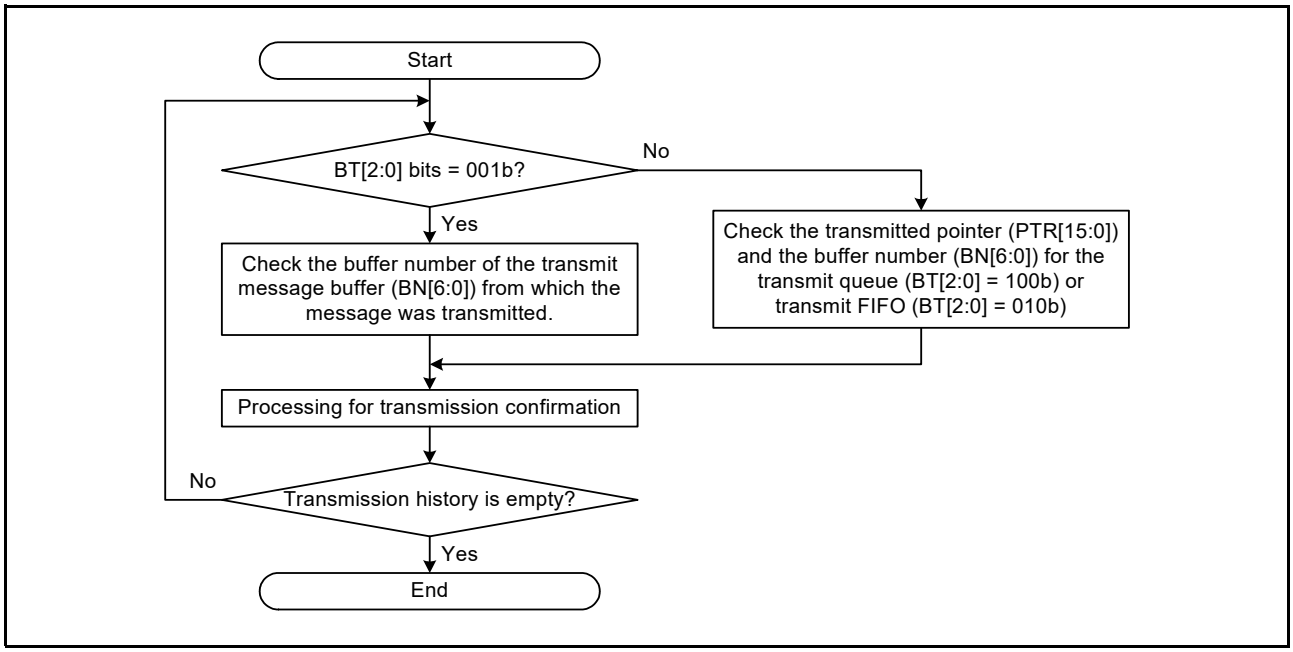

Figure 45.49 Example of Transmission History Processing Flow

45.7.2.6 Transmit Data Padding

If the data length code (DLC) of the transmit message is higher number of data bytes than the buffer size, the data bytes beyond the restricted range will be replaced by bytes with the value of CCh.

This could occur for common FIFO configured in transmit FIFO mode or gateway FIFO mode when the DLC of the transmit message is larger than the payload size set in the CFCRn.PLS[2:0] bits.

This can also occur in FD only mode, if the DLC value for a Classical CAN frame is greater than 8.

45.8 ECC Check

Message buffer RAM has ECC function of the 2-bit error detection and 1-bit error detection/correction.*1 The ECC module appends 7-bit ECC data to 32-bit RAM data.

Note 1. The ECC module cannot detect errors of 3 bits or more. In this case, the ECC module detects a 1-bit or 2-bit error, does not detect the error, or corrects the error bit to error data by configuration. If all RAM data is fixed at 0 or 1, it will be detected as a 2-bit ECC error.

45.8.1 ECC Function Setting

Figure 45.50 shows a procedure for ECC function setting.

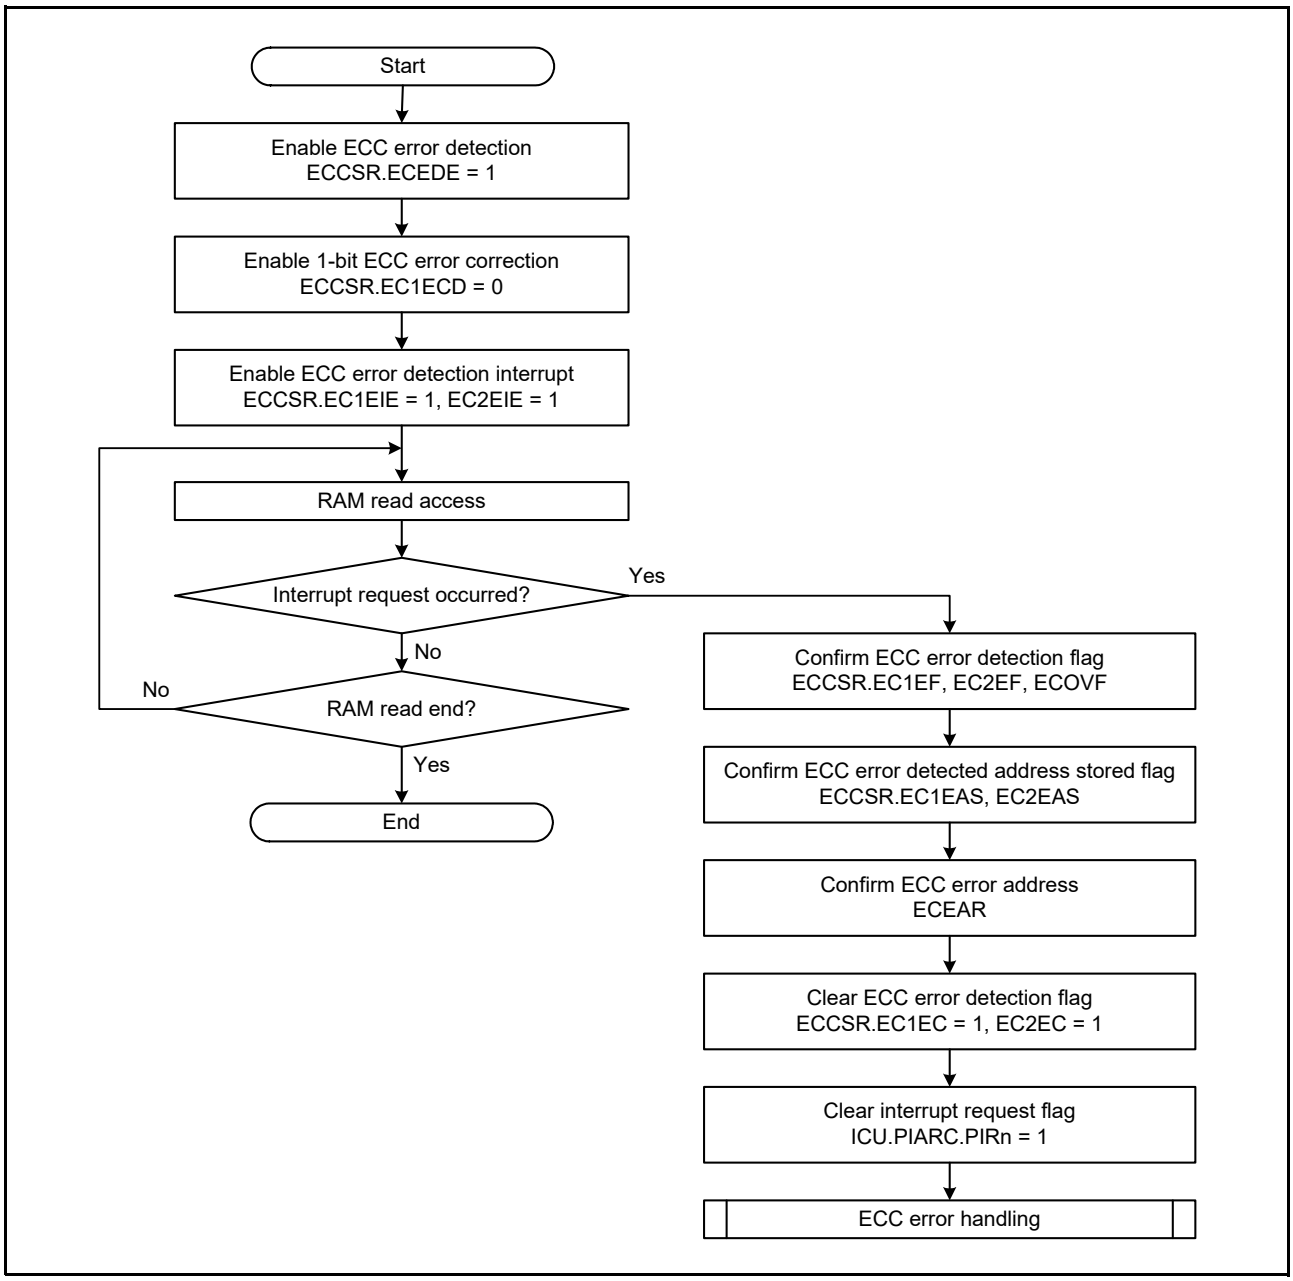

Figure 45.50 Setting Procedure for ECC Function

45.8.2 ECC Decoder Testing

ECC interrupts can be intentionally generated by ECC test mode. Figure 45.51 shows a procedure for ECC decoder testing.

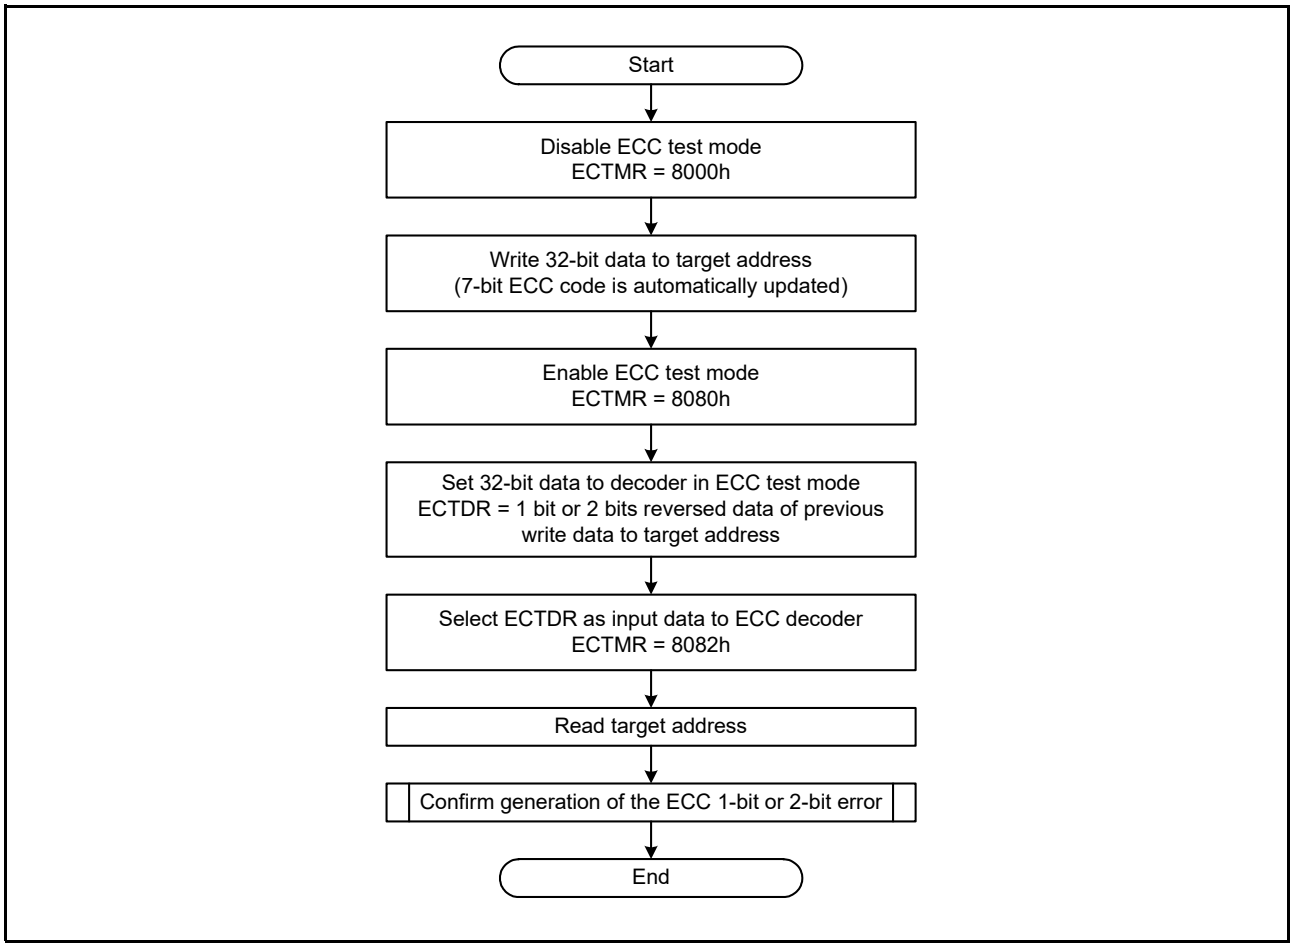

Figure 45.51 Testing Procedure for ECC Decoder

45.9 Test Mode

The CANFDG module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CANFDG module in the test modes.

Note: All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combinations of the various test modes specified in this section.
The test modes can be broadly split into two groups:

- Channel specific test modes
- Global test modes

45.9.1 Channel Specific Test Modes

CAN channel can be configured into following test modes:

- Basic test mode
- Listen-only mode
- Self test mode 0 (external loop-back mode)
- Self test mode 1 (internal loop-back mode)
- Restricted operation mode

45.9.1.1 Basic Test Mode

The basic test mode should be used when a particular test setting needs to be enabled other than when in listen-only and self-test modes.

45.9.1.2 Listen-Only Mode

The ISO 11898-1 recommends an optional bus monitoring mode. In this mode, the CAN channel can receive valid data frames and valid remote frames. However, it transmits only recessive bits on the CAN bus and is not allowed to transmit. If the CAN engine is required to transmit a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the CAN engine monitors this dominant bit, although the CTX pin remain in recessive state.
This mode can be used for bit rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.
In this mode, it is not permitted to request transmission from any transmit message buffer, transmit queue, or common FIFO.

Note: If messages are stored in a common FIFO set to gateway FIFO mode or to a transmit queue set to gateway mode, make sure the transmission channel is not in listen-only mode to avoid requests to transmit to the channel.

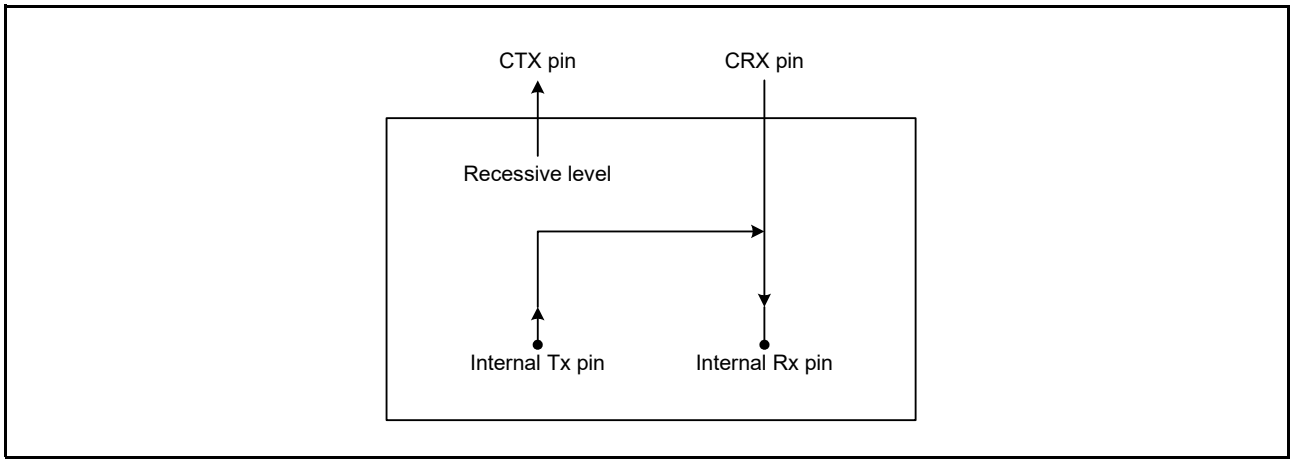

Figure 45.52 Listen-only Mode Configuration

45.9.1.3 Self Test Mode 0 (External Loop-Back Mode)

In self test mode 0, the CAN engine treats its own transmitted messages as received messages via the CAN transceiver and can store them into its receive message buffers.
To be independent of external stimulation the engine generates its own acknowledge bit. This test can be used for CAN transceiver tests.
The CRX and CTX pins should be connected to the transceiver.

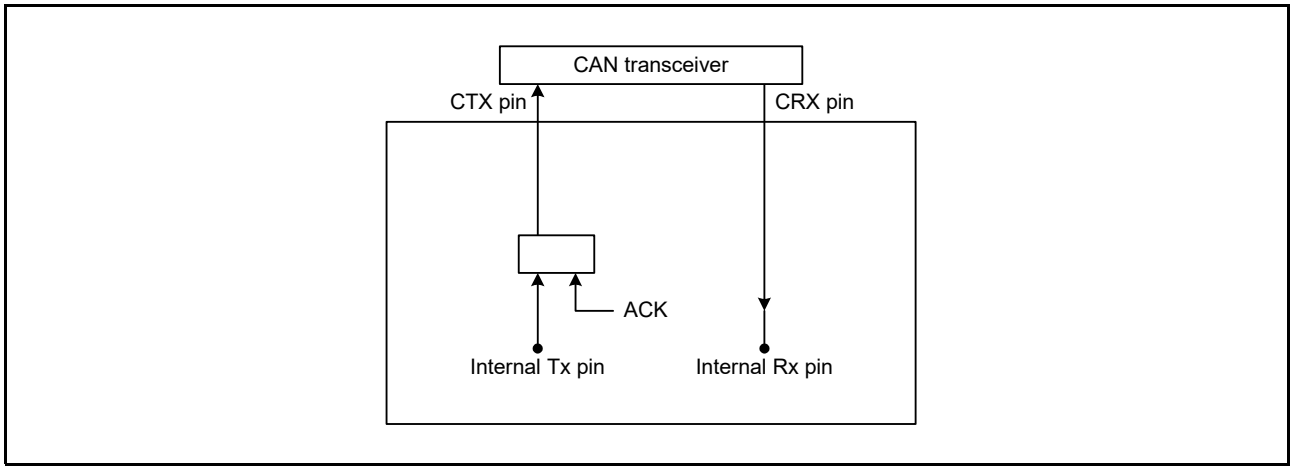

Figure 45.53 Self Test Mode 0 Configuration

45.9.1.4 Self Test Mode 1 (Internal Loop-Back Mode)

In self test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent of external stimulation the CAN engine generates its own acknowledge bit. In this mode the CAN engine performs an internal feedback from internal Tx pin to internal Rx pin. The actual input level of the CRX pin is disregarded by the CAN engine.
The CTX pin is driven high. The CRX and CTX pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the Internal CAN bus communication line.

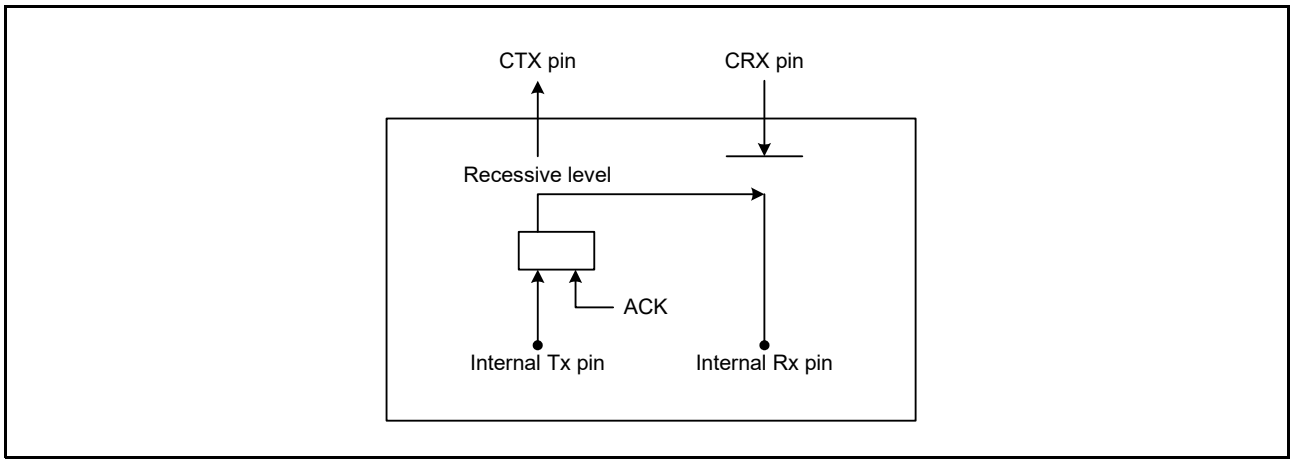

Figure 45.54 Self Test Mode 1 Configuration

45.9.1.5 Restricted Operation Mode

In restricted operation mode the CAN node is able to receive valid data and remote frames generating the acknowledge bit.
Active error and overload frames cannot be transmitted instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.
Moreover the receive error counter (CHSR.REC[7:0]) and transmit error counter (CHSR.TEC[7:0]) are frozen independently of the occurrence of errors.
The mode is specified as in ISO 11898-1; however it is permitted to set any transmit requested.

45.9.2 Global Test Modes

The CANFDG module can be configured into following test modes:

- RAM test mode
- Internal CAN bus communication mode
- CRC error test

The following test mode is protected by a special software procedure to enable the mode. This software procedure enables the write access to the test mode by specific unlock key, the related unlock key can be seen in the table below:

Table 45.29 Test Mode Unlock Key

Test Mode	Unlock Key 1	Unlock Key 2
RAM Test Mode	00007575h	00008A8Ah

If the software sequence of the two consecutive unlock key write accesses is interrupted by any other write access to the registers or if incorrect data is written to the Global Test Mode Lock Key Register then the corresponding test mode cannot be set and the sequence should be re-started.
After the two unlock key write accesses, the next write access should be to set the corresponding test mode enable bit. If this is not followed, the unlock mechanism resets and the test mode enable bit cannot be set and then the unlock sequence should be restarted.

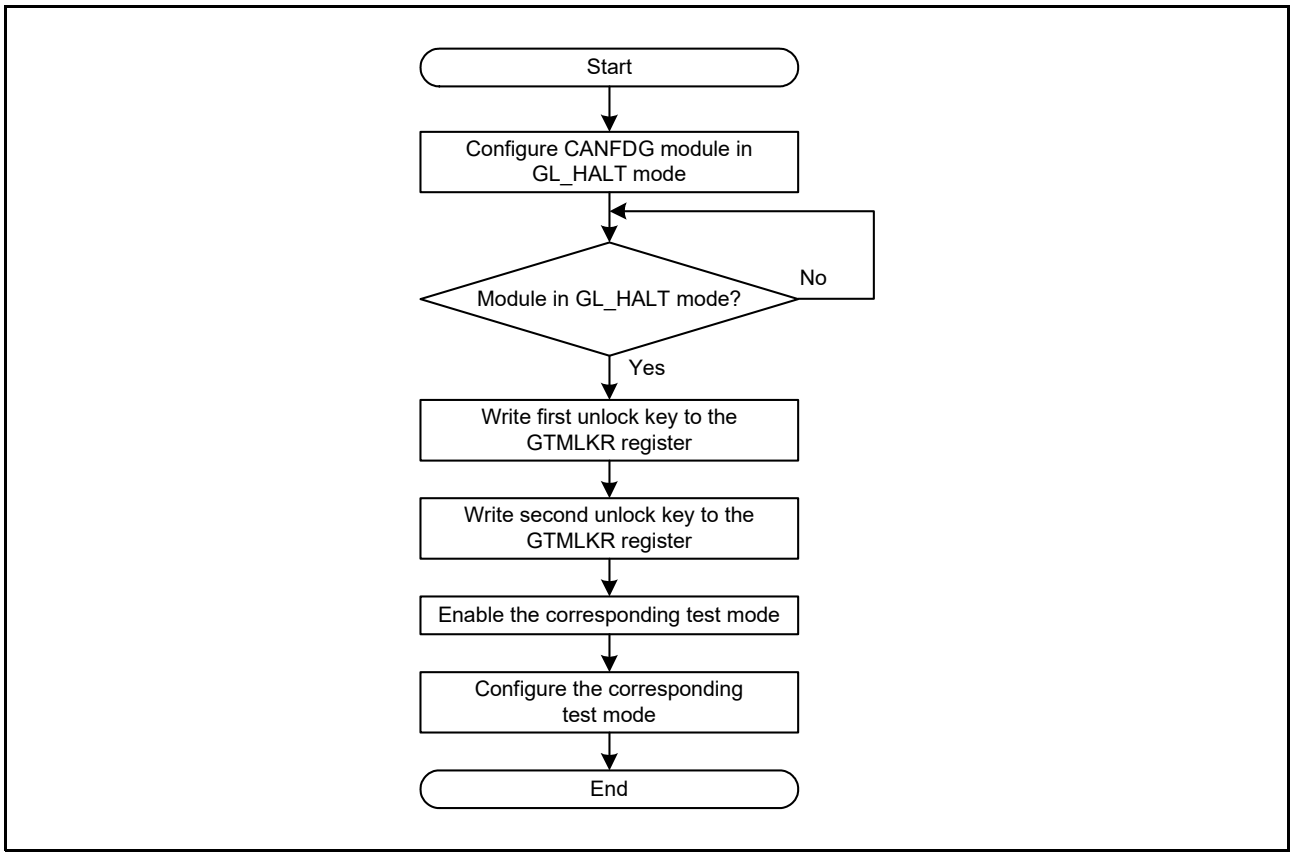

Figure 45.55 Unlock Software Protection Routine

45.9.2.1 RAM Test Mode

The CANFDG module can be configured in RAM test mode by setting the GTMER.RTME bit when the corresponding lock key is written before. This is a special test mode, in which, the complete RAM area can be accessed.

Note: The actual RAM size is bigger than the RAM area initialized after MCU reset. Hence, ECC error flag (of the ECC macro) may be set if CPU reads data from this uninitialized RAM area while CANFDG module is in RAM test mode.

In this mode, the RAM area is split into number of pages of 256 bytes each. Which can be accessed via RTPARk register (k = 0 to 63).
The page should be selected for read/write access by writing to the GTMCR.RTPS[9:0] bits. Then, data can be read from or written in to the RAM Test Page Access Register.
Figure 45.56 shows the structure of the pages in the RAM when performing a RAM test mode.

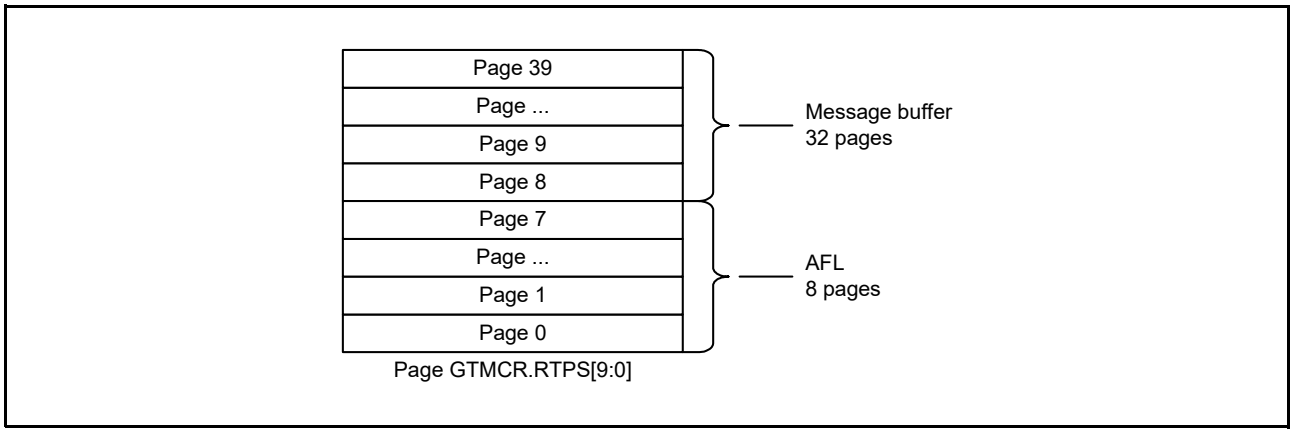

Figure 45.56 RAM Page Structure

The total available RAM size is, 2048 bytes for the AFLRAM and 8128 bytes for the message buffer RAM.
AFLRAM 0/1 can be treated as one RAM in RAM test mode.
Total number of pages for the RAMs and the GTMCR.RTPS[9:0] values are calculated in the following way:

Total number of pages = ceil (total RAM size in bytes / number of bytes per page)

- AFLRAM:
  Total number of pages = ceil (2048 / 256) = 8 pages
  GTMCR.RTPS[9:0] = 0 to 7
- Message buffer RAM:
  Total number of pages = ceil (8128 / 256) = 32 pages
  GTMCR.RTPS[9:0] = 8 to 39

Figure 45.57 shows the software flow for RAM test mode.

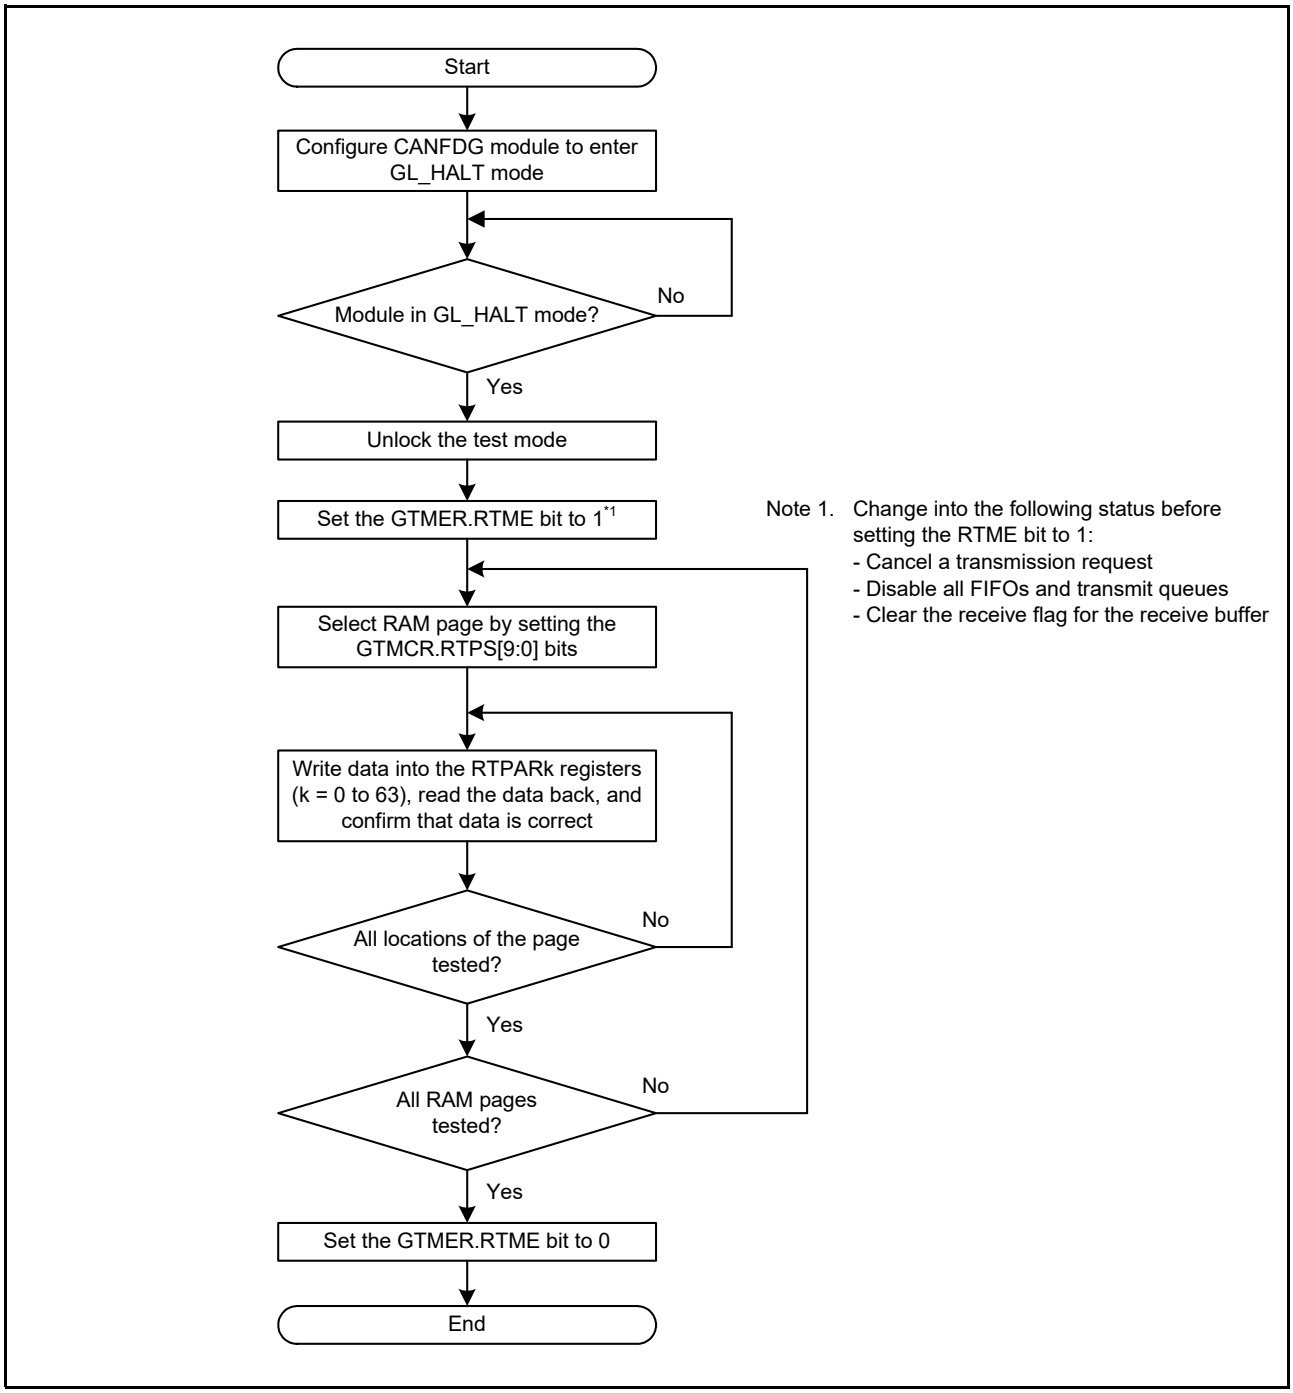

Figure 45.57 RAM Test Mode Software Flow

To exit RAM test mode, set the GTMER.RTME bit to 0.
The GTMER.RTME bit is automatically set to 0 when the CANFDG module enters GL_RESET mode from the test mode.

45.9.2.2 Internal CAN Bus Communication Test Mode

The CANFDG module can be configured in internal CAN bus communication test mode by setting the GTMER.ICBTME bit to 1. This is a special test mode in which the CAN channels are internally connected to create a CAN cluster within the CANFDG module.
Use the following procedure to enter internal CAN bus communication test mode:

(1) Set all channels to CH_HALT mode and confirm that all channels have transitioned to CH_HALT mode (GL_HALT mode).
(2) Set the GTMCR.ICBTMCi bit to select the channel on which to test the internal CAN bus communications.
(3) Set the GTMER.ICBTME bit to 1.
(4) Confirm that the GTMER.ICBTME bit is set to 1.

In this mode, the CTX pin outputs of channels set to internal CAN bus communication mode are logically ORed and connected to the internal CAN bus. This output is connected to the CRX inputs of all desired channels to create a CAN cluster within the CANFDG module. During this test mode the channel is isolated from the external CAN bus.
The AFL, receive message buffer, FIFO buffer, transmit message buffer and various registers can be configured as usual and communication between the channels can be started.
Set channels that do not participate in internal CAN bus communication to CH_HALT mode.

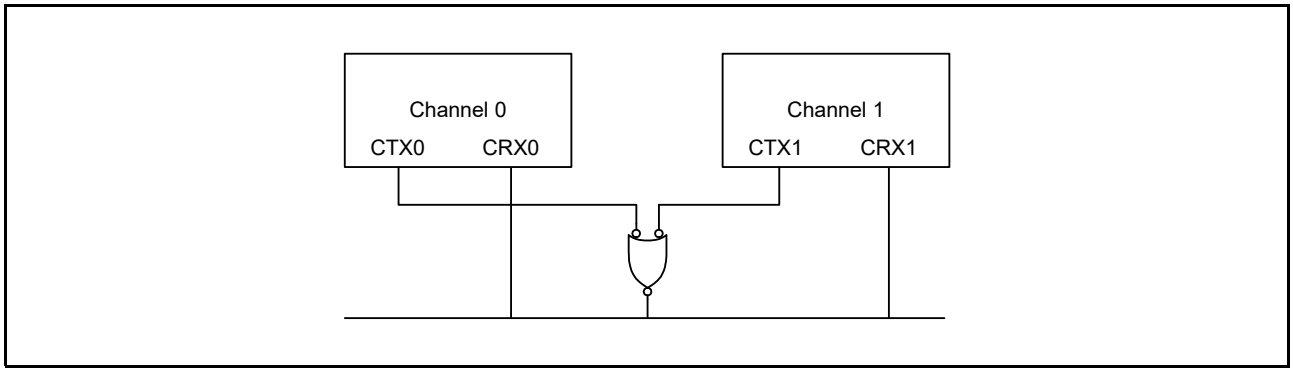

Figure 45.58 Internal CAN Bus Connections

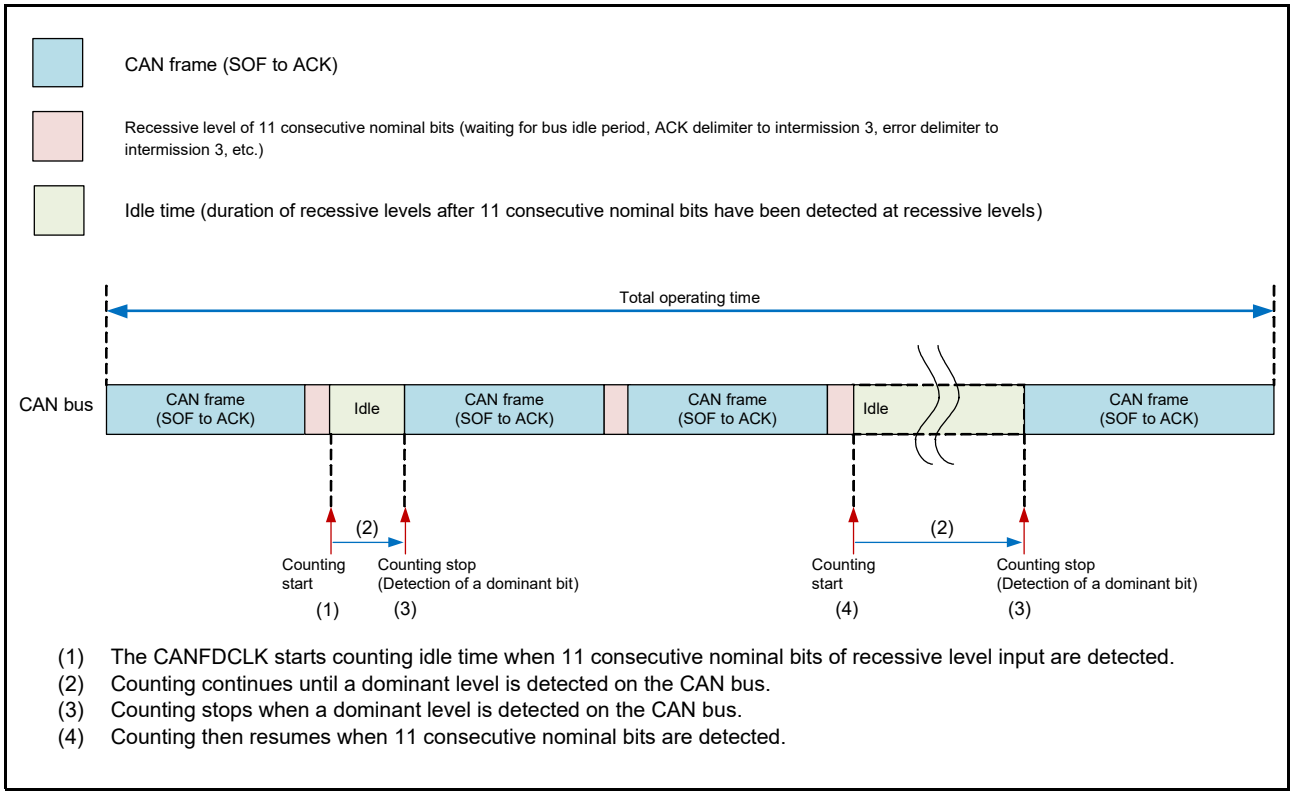
(1) CRC Error Test

CRC error testing can be performed by enabling the bit-flip test function at the receiver node. Enabling the bit flip test allows you to flip the first bit of the received stream (the first bit of the ID).
To perform a CRC error test, follow the steps below after setting the CANFDG module to the internal CAN bus communication test mode.
In the following sequence, channel x is the reference transmitter node and channel y is the receiver node (x = 0, y = 1 or x = 1, y = 0).

1. Configure the channel x node to transmit a reference message.
2. Set the CANFDy.CHCR.BFT bit to 1 to invert the first bit of the bit stream input from channel x.
3. Set the CANFDx.TMCRn.TXRQ bit to 1.
4. Wait for the channel error interrupt on channel y to become 1.
5. Read either the CANFDy.CHESR.CRC15[14:0] bits (Classic CAN frame) or the CANFDy.FDCRC.CRC21[20:0] bits (CAN FD frame). This value must be different from the received CRC value of the reference message from channel x.
6. Confirm that the CANFDy.CHESR.CEDF bit is 1.



The CRC generator logic is shared between receive and transmit, so there is no need to create a separate transmit CRC error test.

45.10 Bus Load Measurement

The CAN bus idle time can be measured using CANFDCLK or CANFDMCLK. The bus load is calculated based on the measurement results.

45.10.1 How to Count the CAN Bus Idle Time

Figure 45.59 shows a conceptual diagram of measuring CAN bus idle time.

(1) The CANFDCLK starts counting idle time when 11 consecutive nominal bits of recessive level input are detected.
(2) Counting continues until a dominant level is detected on the CAN bus.
(3) Counting stops when a dominant level is detected on the CAN bus.
(4) Counting then resumes when 11 consecutive nominal bits are detected.

Figure 45.59 Conceptual Diagram of Measuring CAN Bus Idle Time

45.10.2 Measurement Procedure

The following procedure shows the steps for measuring idle time of the CAN bus.

(1) Set the channel to be measured to CH_OPERATION mode and confirm that the transition was successful.
(2) Write 1 to BLCCR.BLCE bit to set the measuring counter to operating mode.
(3) Write 1 to BLCCR.BLCLD bit to reset the bus load count.
(4) Starts counting bus idle time when it detects 11 consecutive recessive bits at the nominal bit rate.
(5) When a dominant is detected, the bus load counter stops.
(6) Starts counting bus idle time when it detects 11 consecutive recessive bits at the nominal bit rate.
(7) Write 1 to the BLCCR.BLCLD bit to reset the counter register and load the counter value into the BLCR register.
(8) Reads the value of the BLCR register.

The counter is enabled when the channel to be measured is in CH_OPERATION mode. If the channel is in CH_RESET mode, the counter does not operate. Additionally, accurate measurements cannot be made in test mode.
Write 0 to the BLCCR.BLCE bit to stop the counter.
To initialize the counter, write 1 to the BLCCR.BLCLD bit. The counter is reset and the counter value is loaded into the BLCR register at the same time.
The lower three bits of the BLCR register are fixed to 0.
Based on the counter value, software calculates the CAN bus load according to the following formula:

$$\text{Bus occupancy rate} = \frac{\text{Total operating time} - \text{total idle time}}{\text{Total operating time}} = \frac{\text{Bus operating time}}{\text{Total operating time}}$$

Total idle time: Value read from the BLCR register × CANFDCLK clock cycles
Total operating time: BLCCR.BLCLD bit setting interval

A calculation example under the following conditions is shown below.

- Nominal bit rate: 1 Mbps
- CANFDCLK: 40 MHz (= 25 ns)
- BLCCR.BLCLD bit setting interval: cycle of 1 ms
- Read value of the BLCR register: 4E20h (20000)

$$\frac{\text{Total operating time} - \text{total idle time}}{\text{Total operating time}} = \frac{1000000\text{ns} - 20000 \times 25\text{ns}}{1000000} = 50\%$$

45.11 Interrupts and DTC/DMA Requests

45.11.1 CANFDG Interrupts

The CANFDG module generates several interrupts. The interrupt output, which is connected to the interrupt controller, can be controlled by the corresponding interrupt enable bit.
The status flags will be set independently of these enable bits.
The channel transmit interrupt has an additional status flag register; these status bits will only be set when the corresponding interrupt enables are set.
This register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.
The interrupts in the CANFDG module can be classified into two groups: global interrupts and channel interrupts.

(1) Global Interrupts

The CANFDG module can generate the following two global interrupts.

- Receive FIFO interrupt
- Global error interrupt

(2) Channel Interrupts

The CAN channel can generate the following three channel interrupts.

- Channel transmit interrupt
  (a) Successful transmission interrupt
  (b) Transmission abort interrupt
  (c) Transmit queue interrupt
  (d) Common FIFO transmission interrupt
  (e) Transmission history interrupt
- Channel receive interrupt
  (a) Common FIFO receive interrupt
  (b) Transmit queue receive interrupt
- Channel error interrupt

To clear each interrupt request, clear all flags set to 1 from among the sources for which interrupts are enabled. The interrupt request can also be cleared by setting all corresponding interrupt enable bits to 0.

Table 45.30 lists the interrupt sources for CANFDG module.

Table 45.30 Interrupt Sources

Interrupt Name			Interrupt Source Flag
Global interrupts	Receive FIFO interrupt (RFRI)	Receive FIFO interrupt	RFSRn.RFIF
		Receive FIFO full interrupt	RFSRn.RFFIF
	Global error interrupt (GLEI)		GESR.DEDF GESR.MLDF GESR.THLDF GESR.PODF GESR.TQMLDF GESR.CFOWDF
Channel interrupts	Channel transmit interrupt (CHTI)	Transmission successful interrupt*1	TMSRn.TXRF[1]
		Transmission abort interrupt*1	TMSRn.TXRF[1:0] (TXRF[1:0] = 01b)
		Transmit queue interrupt	TQSRn.TQIF
		Transmission history interrupt	THSR.THIF
		Common FIFO transmission interrupt	CFSRn.CFTIF
		Common FIFO one frame transmit interrupt	CFSRn.CFOTIF
		Transmit queue one frame transmit interrupt	TQSRn.TQOTIF
	Channel receive interrupt (CHRI)	Common FIFO receive interrupt	CFSRn.CFRIF
		Common FIFO one frame reception interrupt	CFSRn.CFORIF
		Common FIFO full interrupt	CFSRn.CFFIF
		Transmit queue one frame receive interrupt	TQSRn.TQORIF
		Transmit queue full interrupt	TQSRn.TQFIF
	Channel error interrupt (CHEI)		CHESR.BEDF CHESR.EWDF CHESR.EPDF CHESR.BOEDF CHESR.BORDF CHESR.OLDF CHESR.BLDF CHESR.ALDF FDSTS.ECOV FDSTS.SCOV FDSTS.TDCV

Note 1. These interrupts are only generated for transmit message buffers that are not part of a valid transmit queue and are not linked to a common FIFO. The common FIFO and the transmit queue have other interrupts respectively.

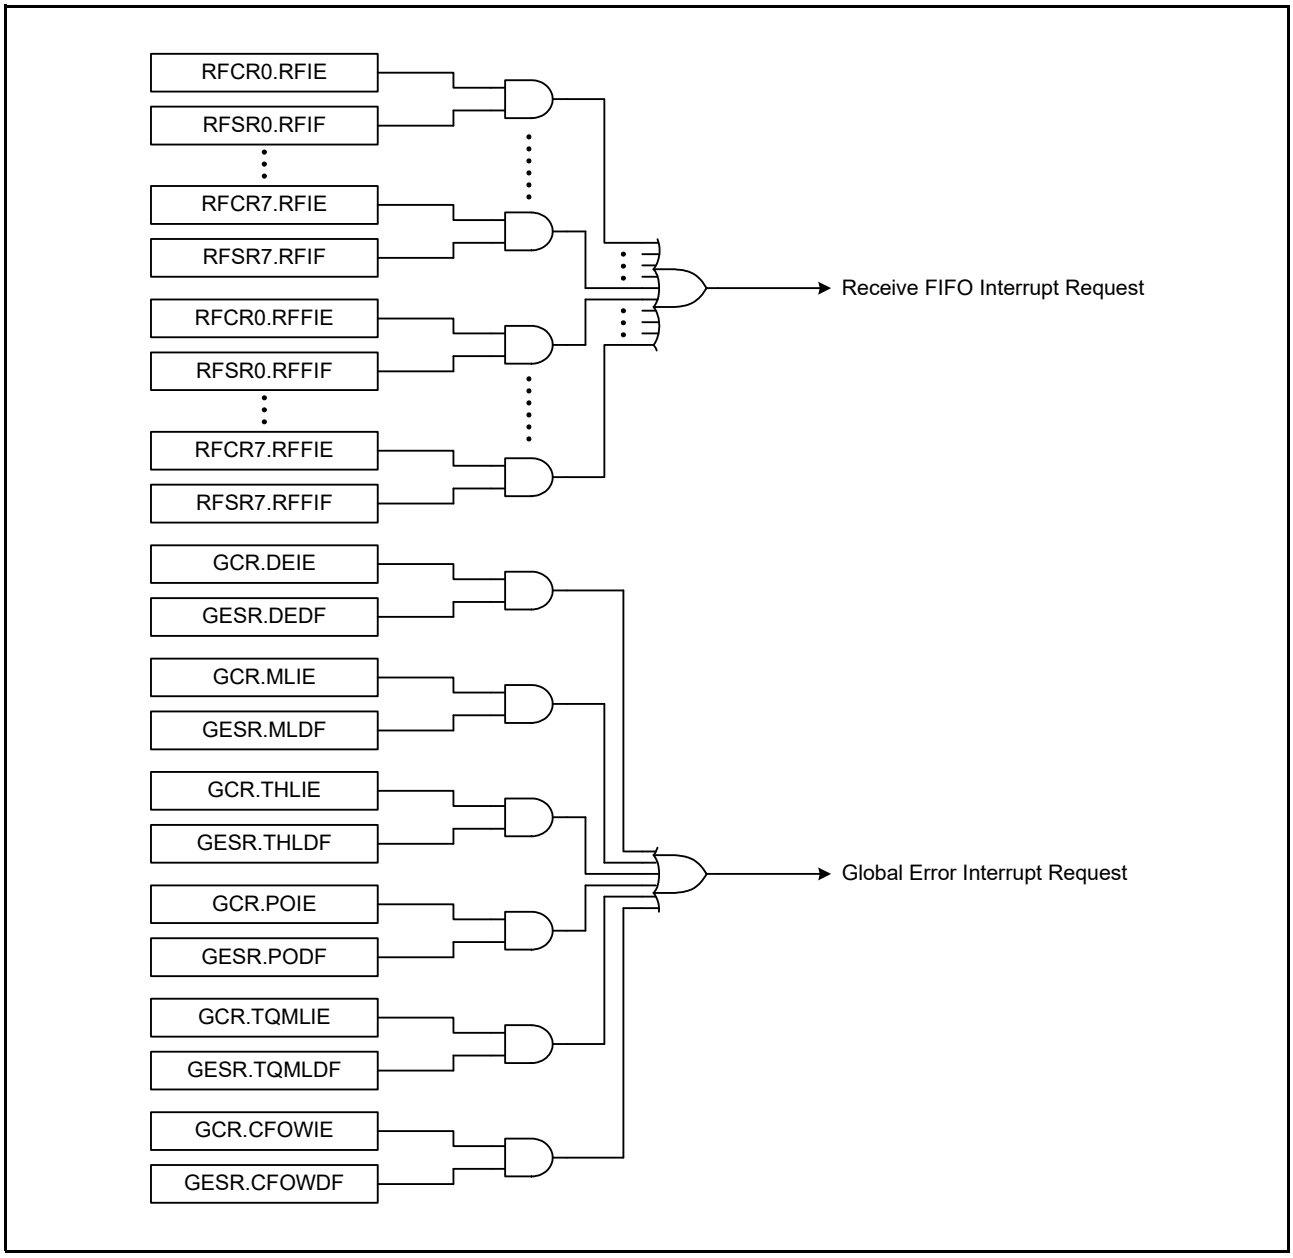


Figure 45.60 Global Interrupt Block Diagram

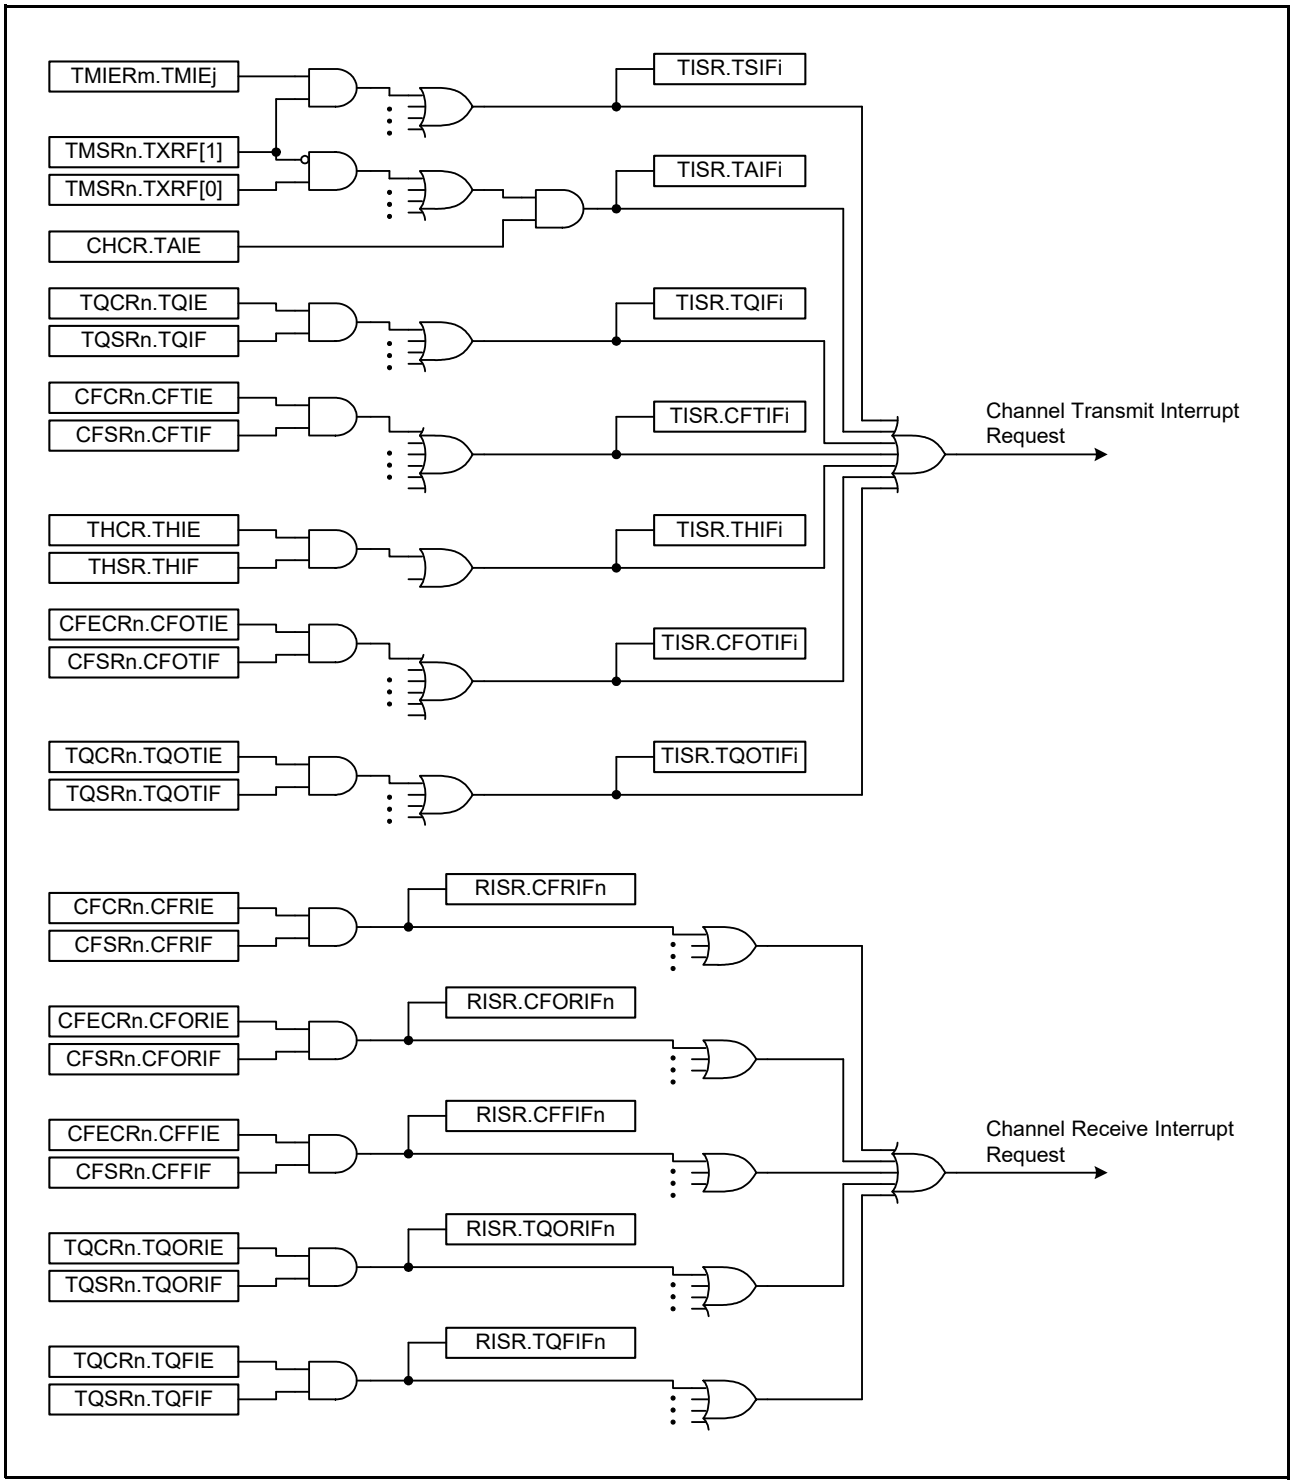

Figure 45.61 Channel Interrupt Block Diagram (1)

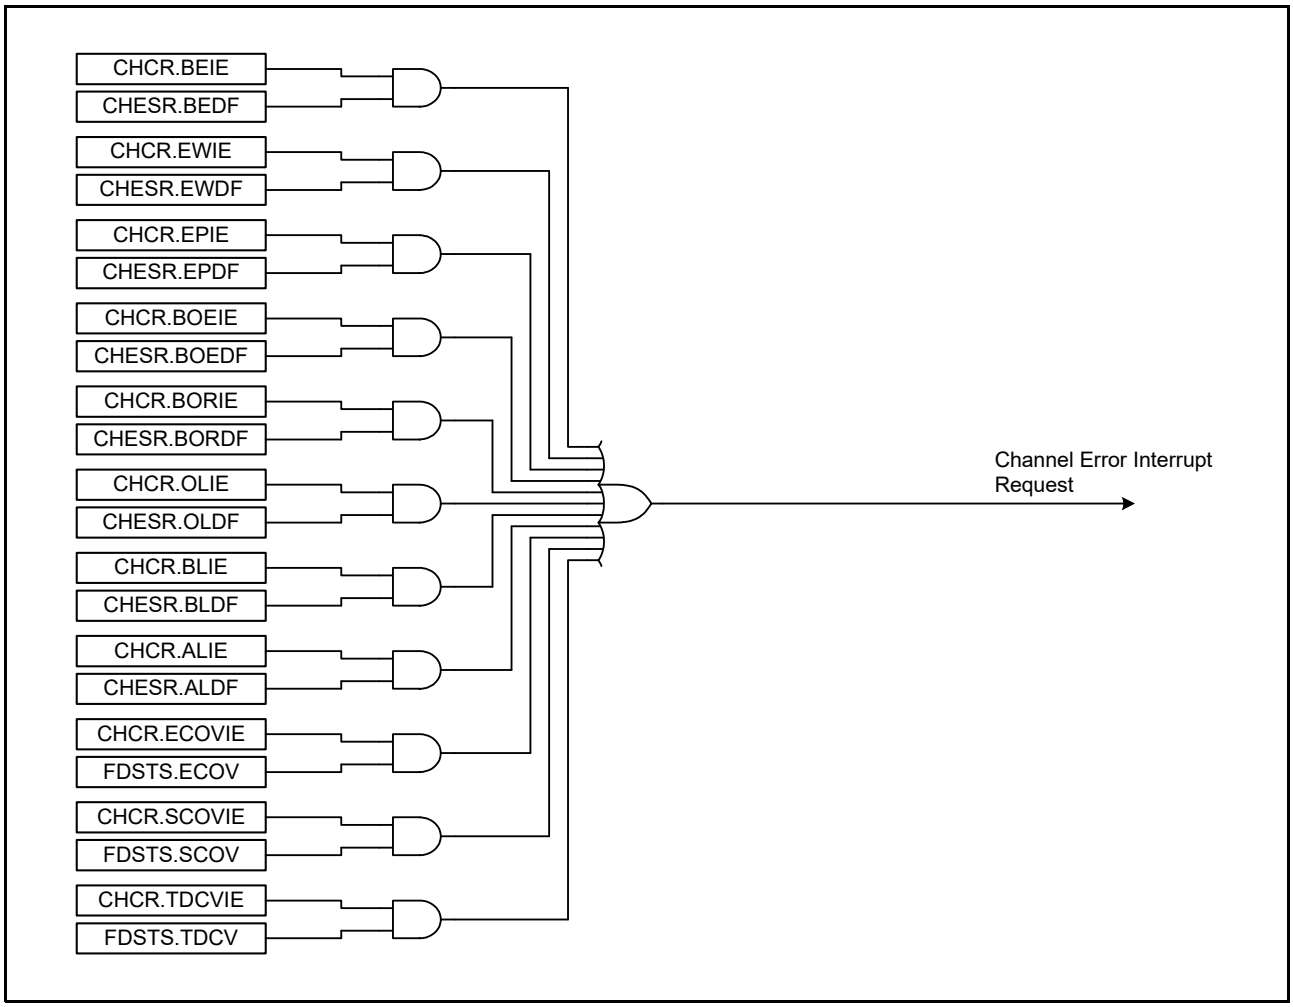

Figure 45.62 Channel Interrupt Block Diagram (2)

45.11.2 ECC Interrupts

The ECC decoder generates ECC error interrupts (AFLRAM0EI, AFLRAM1EI, MBRAMEI). There are three types of interrupt sources for the ECC error interrupt:

- 1-bit ECC error
- 2-bit ECC error
- ECC overflow.

45.11.3 DTC/DMA Transfer Requests

(1) Receive DTC/DMA Transfer

The CANFDG module has message buffers that can be read by DTC/DMA transfer:

- Eight receive FIFO message buffers
- Two common FIFO message buffers (common FIFO 0, common FIFO 3)

A DTC/DMA transfer request is generated when the DTCR.RFDTEn (n = 0 to 7), or CFDTEi (i = 0, 1) bits are set to 1 and the corresponding FIFO is not empty.
For FIFOs with DTC/DMA transfer enabled, disable receive FIFO interrupts (the RFCRn.RFIE (n = 0 to 7) or CFCRn.CFRIE bits (n = 0 to 5) are set to 0).

When the data of the specified payload size (the RFCRn.PLS[2:0] bits (n = 0 to 7) or CFCRn.PLS[2:0] bits (n = 0 to 5)) is read*1, the FIFO read pointer is automatically updated.
When DTC/DMA transfer is permitted, do not write to the FIFO pointer control register (RFPCRn (n = 0 to 7), or CFPCRn (n = 0 to 5)).

Note 1. The DTC/DMA should read the exact length of the specified data payload size (the RFCRn.PLS[2:0] or CFCRn.PLS[2:0] bits).

The permission for DTC/DMA transfer (the DTCR.RFDTEn (n = 0 to 7), or CFDTEi (i = 0, 1) bits) can be set to 1 at any time. Figure 45.63 shows the DTC/DMA transfer configuration flow.

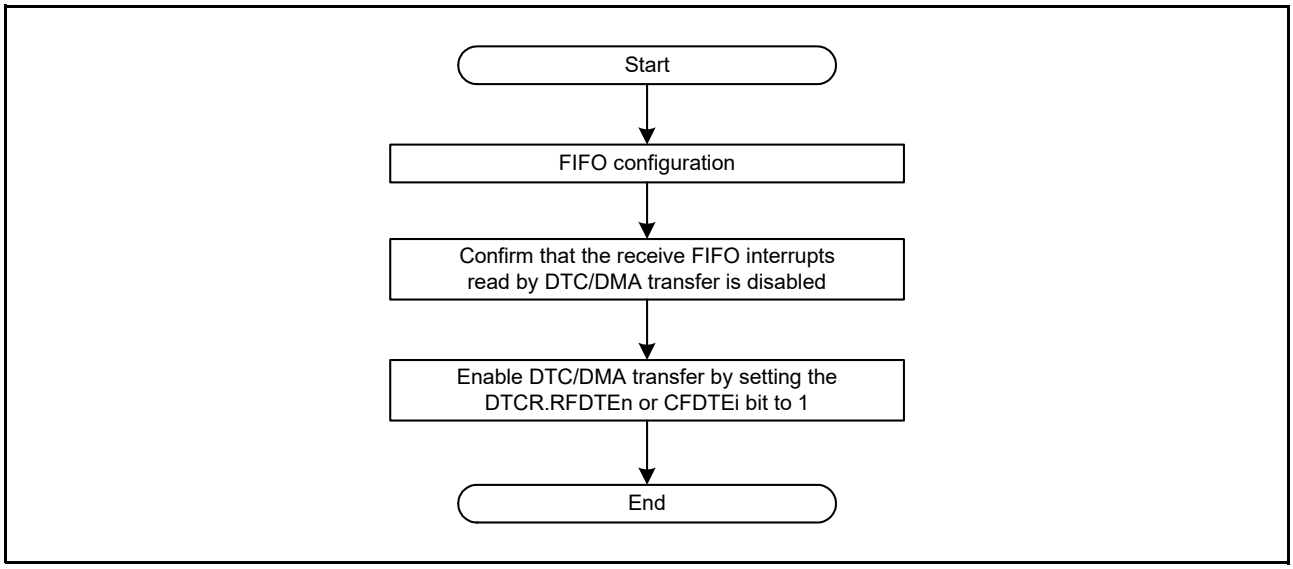

Figure 45.63 DTC/DMA Transfer Enable Flow

To disable the DTC/DMA transfer, set the corresponding DMA transfer enable bit (the DTCR.RFDTEn or CFDTEi bit)

to 0. If the disable is made during a DTC/DMA transfer, wait until the ongoing transfer is complete before performing the following operations. The transfer status can be confirmed by the DTSR.RFDTSn (n = 0 to 7) or CFDTSi (i = 0, 1) bit. Figure 45.64 shows the DTC/DMA transfer disable flow.
When the DTC/DMA transfer is disabled then consider what to do with the remaining or new incoming messages to this particular reception FIFOs. When the FIFO is not disabled then reception to the FIFO will continue.

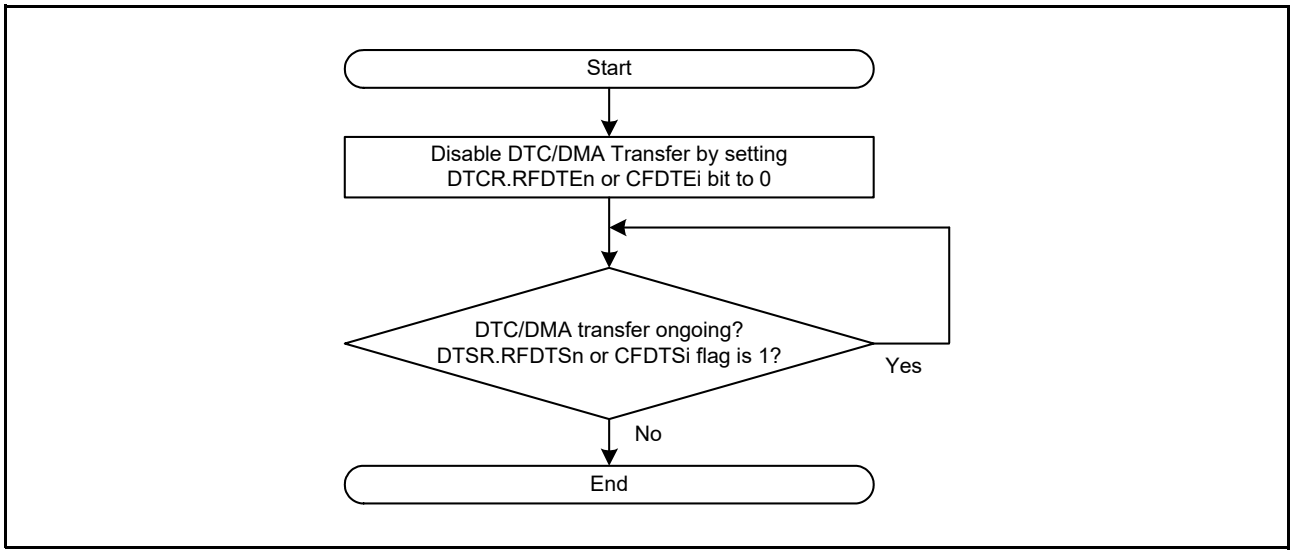

Figure 45.64 DTC/DMA Transfer Disable Flow

(2) Transmit DTC/DMA Transfer

The CANFDG module has message buffers to which data can be written by DTC/DMA transfer:

- Four transmit queue buffers
- Two common FIFO message buffers (common FIFO 2, common FIFO 5)

When the TDTCR.TQDTEi0, TQDTEi3 bit (i = 0, 1) or CFDTEi bit (i = 0, 1) is set to 1, a transmit message can be transferred to the corresponding transmit queue or common FIFO using the DTC/DMAC.
To transfer data to a transmit queue or common FIFO using DTC/DMAC transfer, follow the procedure below.

1. Confirm that the transmit queue or common FIFO is not full.
2. After preparing a message to be transmitted, enable DTC/DMA transfer.
   When using the common FIFO, transmit data is written to the CFBn.HF0, CFBn.HF1, CFBn.HF2, and CFBn.DFp registers. When using a transmit queue, transmit data is written to the TMBn.HF0, TMBn.HF1, TMBn.HF2, and TMBn.DFp registers.
3. For common FIFOs, the common FIFO pointer is automatically incremented when the DTC/DMAC writes the last data of the payload size set by the CFCRn.PLS[2:0] bits.
   For transmit queues, writing 64 bytes of payload data automatically increments the transmit queue pointer. If the payload size is less than 64 bytes, dummy data must be added to make it 64 bytes.

Note: DTC/DMA transfers can only be written in 32-bit units.

To disable DTC/DMA transfers, set the corresponding DMA transfer enable bit (TDTCR.TQDTEi0, TQDTEi3 or CFDTEi bit) to 0.

45.12 Usage Notes

45.12.1 Setting the Module Stop Function

The CANFDG operation can be disabled or enabled by module stop control register C (MSTPCRC). After a reset, the CANFDG module is stopped. The registers of the module become accessible when it is released from the module stop state. For details, refer to section 11, Low Power Consumption.

45.12.2 Notes on the DLL Clock Settings

Set the DLL clock to be used before releasing the module-stop state. For details on the DLL clock settings, refer to section 9, Clock Generation Circuit.
Release the module-stop state after the oscillation of the DLL clock has been stabilized.

45.12.3 Note on Configuration of Receive Message Buffers and FIFO Buffers

The maximum memory size available for receive message buffers and FIFO buffers is 4864 bytes.
For example, if all payload sizes are set to 64 bytes, each message size becomes 76 bytes, so the total number of messages must be 64 or less. If 32 receive message buffers are reserved, the total FIFO depth must be 32 or less. Operation is not guaranteed if the setting exceeds 4864 bytes.

45.12.4 Transition to Software Standby Mode

To reduce power consumption, power to the acceptance filter list RAMs and the message buffer RAM is turned off in software standby mode. Therefore, the respective sets of operations listed below must be performed before a transition to and after a return from software standby mode.

(1) Before a Transition to Software Standby Mode

Before a transition to software standby mode, perform the following operations.

1. Put the CANFDG module into GL_SLEEP mode.
2. Read the GTMLKR register and verify that its value is 00000000h.
3. Perform the following operations for AFLRAM0, AFLRAM1, and the MBRAM, respectively.
   (a) Set the ECCSR.EC1EC and ECCSR.EC2EC bits to 1 to clear the ECC error detection flags.
   (b) Set the ECCSR.ECEDE bit to 0 to disable ECC error detection.

(2) After a Return from Software Standby Mode 1

After a return from software standby mode 1, the CANFDG module is not reset, meaning that the RAMs are not initialized. Use RAM test mode to initialize the RAMs. After having initialized the RAMs, initialize the CANFDG module by following the standard procedure. For details on RAM test mode, refer to section 45.9.2.1, RAM Test Mode.

(3) After a Return from Software Standby Mode 2

After a return from software standby mode 2, the CANFDG module is reset. Initialize the CANFDG module through the same procedure as when the MCU is released from the reset state.

46. CAN FD Module (CANFD)

46.1 Overview

This MCU implements one channel of the CAN FD (Controller Area Network with Flexible Data Rate) module that complies with the ISO 11898-1:2015 standard.

Table 46.1 lists the specifications of the CANFD module, and Figure 46.1 shows a block diagram of the CANFD module.

Table 46.1 CANFD Module Specifications

Item	Description
Protocol	ISO 11898-1:2015 compliant
Data transfer rate	Arbitration phase: up to 1 Mbps Data phase: up to 8 Mbps*1, *2
Operating frequency*3	Register block: up to 150 MHz (PCLKA) Message buffer RAM: up to 300 MHz (PCLKE)
Operating clock for data link layer (DLL clock)	Up to 80 MHz (either CANFDMCLK or CANFDCLK can be selected)
Frame types	Classic CAN (CAN 2.0) • Data frame in base format (11-bit ID) • Data frame in extended format (29-bit ID) • Remote frame in base format (11-bit ID) • Remote frame in extended format (29-bit ID) CAN FD*1 • Data frame in base format (11-bit ID) • Data frame in extended format (29-bit ID)
Data length	Classic CAN: 0 to 8 bytes CAN FD: 0 to 8, 12, 16, 20, 24, 32, 48, or 64 bytes*1
Message buffers	• 16 receive message buffers • Four transmit message buffers • One transmit queue Messages can be automatically transferred to the transmit queue.
FIFOs	Variable size FIFO buffers • Two receive FIFOs • One common FIFO that can be configured as a receive FIFO or transmit FIFO
Automatic transmission interval adjustment	Available when the common FIFO is configured as a transmit FIFO The interval between messages sent from the FIFO can be adjusted.
Acceptance filter	Filterable in the following fields: • IDE bit (base format, extended format, or both) • ID field • RTR bit (data frame or remote frame) (only for Classic CAN) • DLC field (data length) Protection function when the payload size is exceeded Acceptance filter list (AFL) entries can be updated during communication.
Software support	Label information is automatically added to received messages
Timer	Transmission and reception timestamp function
Power down function	Module start/stop function for each CAN node (CH_SLEEP and GL_SLEEP mode) Transition to module stop state is possible.
RAM	RAM with ECC protection
Protect Zone filter	Security attribute can be set.*4

Note 1. This is only available for products that support the CAN FD protocol.
Note 2. The bit rate for communications depends on the board design and external environment. Determine it following sufficient evaluation.
Note 3. The frequency ratio of PCLKE and PCLKA should be 2 : 1. Also, the frequency of PCLKA should be equal to or higher than that of the DLL clock.
Note 4. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

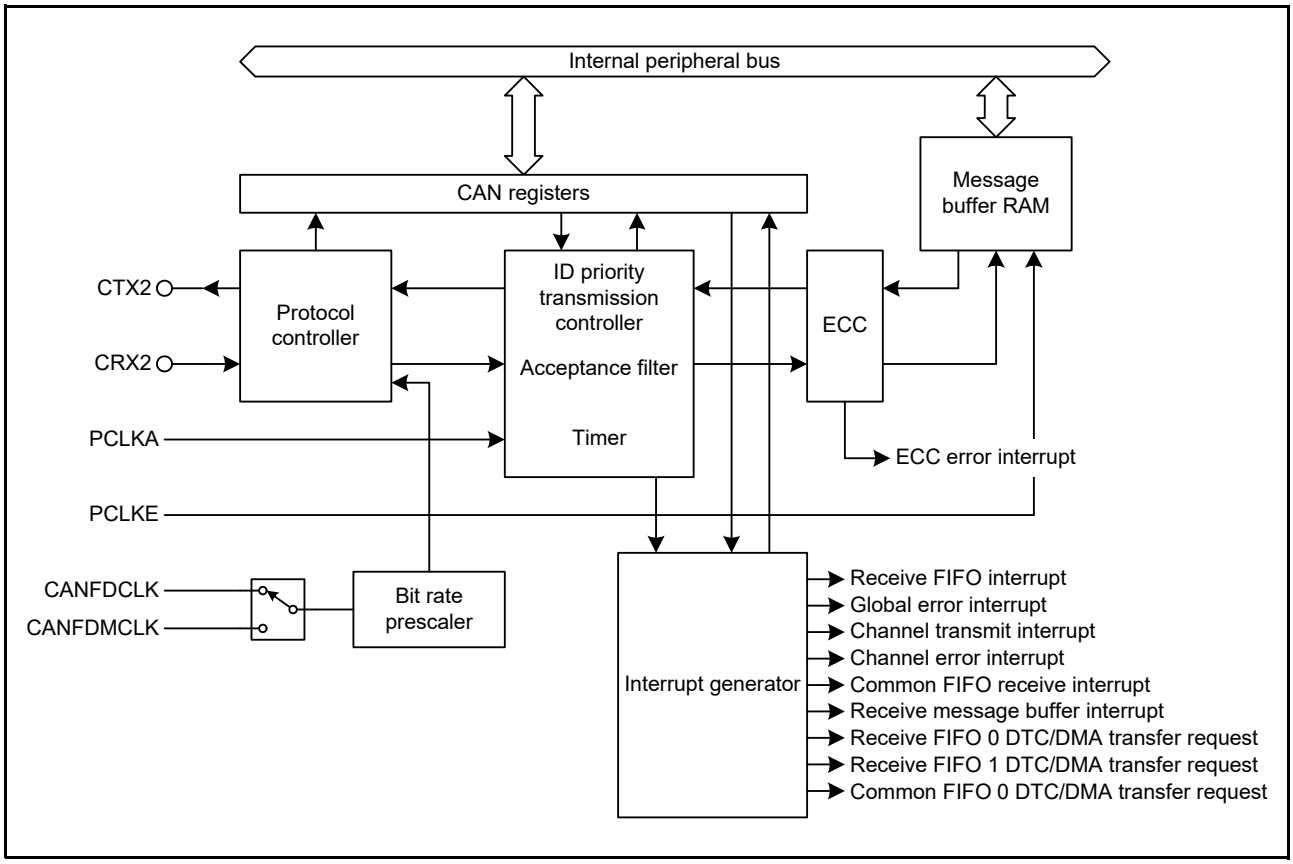

Figure 46.1 CANFD Module Block Diagram

- CRX2, CTX2
  I/O pins of the CANFD module
- Protocol controller
  Handles CAN FD protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, error handling, etc.
- Message buffer RAM
  Used for message buffers or FIFOs for transmitting and receiving messages. Each message has an individual identifier, data length code, a data field, a message pointer for upper layer application, and a timestamp.
- Acceptance filter
  Performs filtering of received messages. The entries set in the acceptance filter list are used for the filtering process.
- Timers
  Two timers: one used for the receive timestamp function and the other for adjusting the message transmission interval from the transmit FIFO.

Table 46.2 lists the pin configuration of the CANFD module.

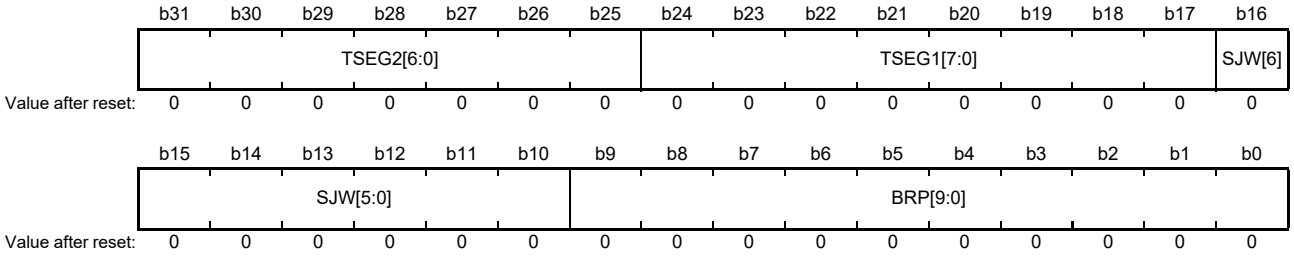

Table 46.2 CANFD Module Pin Configuration

Pin Name	I/O	Function
CRX2	Input	Receive data input
CTX2	Output	Transmit data output

46.2 Register Descriptions

46.2.1 Nominal Bit Rate Configuration Register (NBCR)

Address(es): CANFD2.NBCR 8747 0000h, CANFD2_NS.NBCR 0747 0000h

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	BRP[9:0]	Bit Rate Prescaler Setting	000h: No division 001h: Divided by 2 : : 3FEh: Divided by 1023 3FFh: Divided by 1024	R/W
b16 to b10	SJW[6:0]	Resynchronization Jump Width Control	00h: 1 Tq 01h: 2 Tq : : 7Eh: 127 Tq 7Fh: 128 Tq	R/W
b24 to b17	TSEG1[7:0]	Time Segment 1 Control	00h: Setting prohibited 01h: 2 Tq 02h: 3 Tq 03h: 4 Tq : : FEh: 255 Tq FFh: 256 Tq	R/W
b31 to b25	TSEG2[6:0]	Time Segment 2 Control	00h: Setting prohibited 01h: 2 Tq 02h: 3 Tq : : 7Eh: 127 Tq 7Fh: 128 Tq	R/W

This register is used to set the nominal bit rate during transmission and reception.
The value cannot be changed in CH_OPERATION or CH_SLEEP mode. Rewrite this register in CH_RESET or CH_HALT mode.
For details on the setting values, refer to section 46.4.1.2, Bit Timing.

BRP[9:0] Bits (Bit Rate Prescaler Setting)

These bits are used to define a period of 1 Tq (Time Quantum) that is the basis for CAN communication. Set the division ratio for the operating clock of the data link layer (DLL clock) selected by the GCFG.DLLCS bit. If the set value is n, the bit rate prescaler divides the DLL clock by n + 1.

SJW[6:0] Bits (Resynchronization Jump Width Control)

These bits are used to specify the resynchronization jump width with a Tq value. A value from 1 to 128 Tq can be set. Set a value less than or equal to that of the TSEG2[6:0] bits.

TSEG1[7:0] Bits (Time Segment 1 Control)

These bits are used to specify the total value (TSEG1) of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1) with a Tq value. A value from 2 to 256 Tq can be set.

TSEG2[6:0] Bits (Time Segment 2 Control)

These bits are used to specify the value (TSEG2) of the phase buffer segment 2 (PHASE_SEG2) with a Tq value. A value from 2 to 128 Tq can be set. Set a value less than that of the TSEG1[7:0] bits.

46.2.2 Channel Control Register (CHCR)

Address(es): CANFD2.CHCR 8747 0004h, CANFD2_NS.CHCR 0747 0004h

Note 1. Set this bit in CH_OPERATION mode.
Note 2. Rewrite these bits in CH_RESET mode.
Note 3. Do not set this bit to 1 in Classic Only mode.
Note 4. Set this bit in CH_RESET or CH_HALT mode.
Note 5. Set these bits in CH_HALT mode.

This register controls the modes of the channel. It is also used to enable interrupt generation when an error is detected on the CAN bus and to set the test mode.
In CH_SLEEP mode, values other than the SLPRQ bit cannot be changed.

MDC[1:0] Bits (Channel Mode Control)

The MDC[1:0] bits are used to specify the mode of the CAN channel. For the CAN mode transition, refer to section 46.3.2, Channel Modes.
When the CANFD module is in GL_HALT mode, these bits can only be set to 10b (CH_HALT mode) or 01b (CH_RESET mode).
These bits automatically become 10b when the mode is changed to CH_HALT mode by the setting of the CHCR.BOM[1:0] bits.
When writing to these bits and transition to CH_HALT mode (at the entry to bus-off state when the CHCR.BOM[1:0] bits are 01b, and at the end of bus-off state when the CHCR.BOM[1:0] bits are 10b) occur at the same time, priority is given to writing from the CPU. The value of these bits are automatically updated only if the above event occurs when these bits are 00b (CH_OPERATION mode).

SLPRQ Bit (CH_SLEEP Mode Request)

This bit is used to control the transition to CH_SLEEP mode and the return from CH_SLEEP mode.
Setting this bit to 1 in CH_RESET mode requests the channel to transition to CH_SLEEP mode. Setting this bit to 0 in CH_SLEEP mode requests the channel to transition to CH_RESET mode. These bits cannot be changed in other modes.

RTBO Bit (Forced Recovery from Bus-Off)

This bit is used to forcibly recover from the bus-off state. Use this bit only when the CHCR.BOM[1:0] bits are 00b.
This bit is automatically set to 0 after being set to 1. The read value is always 0.
When this bit is set to 1 during bus-off state, the channel transitions from bus-off state to integrating state within 1 bit time. Also the CHSR.REC[7:0] and TEC[7:0] bits are set to 00h and the CHSR.BOST flag is set to 0. Other registers and

bits do not change. In this case, even if the bus-off recovery interrupt is enabled, the bus-off recovery interrupt does not generated.
If this bit is set to 1 except in the bus-off state, nothing occurs.

BEIE Bit (Bus Error Interrupt Enable)

When the CHESR.BEDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

EWIE Bit (Error Warning Interrupt Enable)

When the CHESR.EWDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

EPIE Bit (Error Passive Interrupt Enable)

When the CHESR.EPDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

BOEIE Bit (Bus-Off Entry Interrupt Enable)

When the CHESR.BOEDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

BORIE Bit (Bus-Off Recovery Interrupt Enable)

When the CHESR.BORDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

OLIE Bit (Overload Interrupt Enable)

When the CHESR.OLDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

BLIE Bit (Bus Lock Interrupt Enable)

When the CHESR.BLDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

ALIE Bit (Arbitration Lost Interrupt Enable)

When the CHESR.ALDF flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

TAIE Bit (Transmission Abort Interrupt Enable)

When the transmission from the transmit message buffer of the channel is successfully aborted while this bit is 1, a channel transmit interrupt request is generated.

ECOVIE Bit (Error Occurrence Counter Overflow Interrupt Enable)

When the FDSTS.ECOV flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

SCOVIE Bit (Success Occurrence Counter Overflow Interrupt Enable)

When the FDSTS.SCOV flag is set to 1 while this bit is 1, a channel error interrupt request is generated.

TDCVIE Bit (Transceiver Delay Compensation Violation Interrupt Enable)

When the FDSTS.TDCV flag is set to 1 while this bit is 1, a channel error interrupt request is generated. Do not set this bit to 1 in Classic only mode.

BOM[1:0] Bits (Bus-Off Recovery Mode Select)

These bits control the recovery timing from the bus-off state.

EDM Bit (Error Display Mode Select)

This bit controls the indication mode of the error flags (b14 to b8) in the CHESR register.
When this bit is 0, only the flag corresponding to the first error detected becomes 1. If multiple errors are detected at the

same time, all corresponding flags become 1. The other flags do not become 1 until all the flags in b14 to b8 have been cleared.
When this bit is 1, the error flags are updated each time an error is detected.

CTME Bit (Channel Test Mode Enable)

This bit is used to enable the channel test mode.
When the channel transitions to CH_RESET mode, this bit becomes 0.

CTMS[1:0] Bits (Channel Test Mode Select)

These bits are used to select the test mode.
When the channel transitions to CH_RESET mode, these bits become 00b.

BFT Bit (Bit Flip Test)

This bit is used to check the CRC generator in the protocol controller.
Setting this bit to 1 inverts the first bit of the message data stream (ID bit) so that the result of the internally generated CRC does not match the received CRC value.
Note that as a result of bit inversion, a stuff error may be detected instead of a CRC error. Refer to the bit stuffing rule when using this function.
The CRC value generated internally can be checked in the following bits.

- The CHESR.CRC15[14:0] bits (for Classical CAN frames)
- The FDCRC.CRC21[20:0] bits (for CAN FD frames)

When using the BFT bit, it is necessary to have another CAN node transmit a reference message.

Note: Since the transmit and receive modes share the same CRC generator, there is no need to test for CRC errors in transmit mode separately.

Bit flip test mode is enabled when both the BFT and CTME bits are 1 and the CTMS[1:0] bits are 00b (basic test mode).
Using this function on the transmitter node causes a bit error or arbitration lost.
When the channel transitions to CH_RESET mode, this bit becomes 0.

ROME Bit (Restricted Operation Mode Enable)

When both this bit and the CTME bit are 1, the limited operation mode is enabled. Use this mode only in basic test mode (CTMS[1:0] bits = 00b). Also, do not set this bit to 1 in Classic only mode.
When the channel transitions to CH_RESET mode, this bit becomes 0.

46.2.3 Channel Status Register (CHSR)

Address(es): CANFD2.CHSR 8747 0008h, CANFD2_NS.CHSR 0747 0008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TEC[7:0]								REC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RESI	CRDY	RECST	TRMST	BOST	EPST	SLPST	HLTST	RSTST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	RSTST	CH_RESET Status Flag	0: Not in CH_RESET mode 1: In CH_RESET mode	R
b1	HLTST	CH_HALT Status Flag	0: Not in CH_HALT mode 1: In CH_HALT mode	R
b2	SLPST	CH_SLEEP Status Flag	0: Not in CH_SLEEP mode 1: In CH_SLEEP mode	R
b3	EPST	Error Passive Status Flag	0: Not in error passive state 1: In error passive state	R
b4	BOST	Bus-Off Status Flag	0: Not in bus-off state 1: In bus-off state	R
b5	TRMST	Transmit Status Flag	0: Channel is not transmitting 1: Transmission in progress	R
b6	RECST	Receive Status Flag	0: Channel is not receiving 1: Reception in progress	R
b7	CRDY	Communication Ready Flag	0: Channel is not ready for communication 1: Channel is ready for communication	R
b8	RESI	Receive ESI Flag*1	0: No message with ESI flag set to 1 was received. 1: At least 1 message with ESI flag set to 1 was received.	R/(W) *2
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	REC[7:0]	Reception Error Count	These bits increment or decrement the counter value according to error status of the CAN channel during reception.	R
b31 to b24	TEC[7:0]	Transmission Error Count	These bits increment or decrement the counter value according to error status of the CAN channel during transmission.	R

Note 1. This flag can be set to 0 only in CH_OPERATION or CH_HALT mode.
Note 2. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the mode, error and transmission or reception status of the CAN channel together with its reception and transmission error count values.

RSTST Flag (CH_RESET Status Flag)

The RSTST flag indicates whether the CAN channel is in CH_RESET mode.
This flag is automatically set to 1 when the CAN channel enters CH_RESET mode, and is automatically set to 0 when the CAN channel exits CH_RESET mode. When the mode is changed from CH_RESET mode to CH_SLEEP mode, the RSTST flag remains 1.

HLTST Flag (CH_HALT Status Flag)

The HLTST flag indicates whether the CAN channel is in CH_HALT mode.
This flag is automatically set to 1 when the CAN channel enters CH_HALT mode, and is automatically set to 0 when the CAN channel exits CH_HALT mode.

SLPST Flag (CH_SLEEP Status Flag)

The SLPST flag indicates whether the CAN channel is in CH_SLEEP mode.
This flag is automatically set to 1 when the CAN channel enters CH_SLEEP mode, and is automatically set to 0 when the CAN channel exits CH_SLEEP mode.

EPST Flag (Error Passive Status Flag)

The EPST flag indicates whether the CAN channel has entered the error passive state.
This flag is automatically set to 1 when the value of the REC[7:0] or TEC[7:0] bits exceeds 127.
This flag is automatically set to 0 when the CAN channel exits the error passive state or enters CH_RESET mode.

BOST Flag (Bus-Off Status Flag)

The BOST flag indicates whether the CAN channel has entered the bus-off state.
This flag is automatically set to 1 when the value of the TEC[7:0] bits exceeds 255 and the CAN channel is in the bus-off state.
This flag is automatically set to 0 when the CAN channel exits bus-off state.

TRMST Flag (Transmit Status Flag)

The TRMST flag indicates whether the CAN channel is transmitting a message.
This flag is automatically set to 1 when the CAN channel is operating as a transmitter node or is in the bus-off state, and is automatically set to 0 when the CAN channel is in the idle state or starts operating as a receiver node.

RECST Flag (Receive Status Flag)

The RECST flag indicates whether the CAN channel is receiving a message.
This flag is automatically set to 1 when the CAN channel is operating as a receiver node, and is automatically set to 0 when the CAN channel is in the idle state or starts operating as a transmitter node.

CRDY Flag (Communication Ready Flag)

The CRDY flag indicates whether the CAN channel is ready for communication.
This flag is automatically set to 1 when the CAN channel is ready to perform communication following the detection of 11 consecutive recessive bits after exiting CH_RESET or CH_HALT mode.
This flag is automatically set to 0 when the CAN channel enters CH_RESET or CH_HALT mode.

Note: This flag is 1 in the bus-off state.

RESI Flag (Receive ESI Flag)

The RESI flag is set to 1 when the ESI bit is sampled recessively for a received message without any error. When in loop-back or mirror mode, the self-transmitted messages are considered reception messages.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is cleared by writing 0 to it. This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
Do not use the bit clear instruction to clear this flag. Set only this flag to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

REC[7:0] Bits (Reception Error Count)

The REC[7:0] bits indicate the value of the reception error counter.
The value in bus-off state is indeterminate.
These bits are automatically set to 00h when the CANFD module enters GL_RESET or the CAN channel enters CH_RESET mode.

TEC[7:0] Bits (Transmission Error Count)

The TEC[7:0] bits indicate the value of the transmission error counter.
These bits are automatically set to 00h when CANFD module enters GL_RESET or CAN channel enters CH_RESET mode.

46.2.4 Channel Error Status Register (CHESR)

Address(es): CANFD2.CHESR 8747 000Ch, CANFD2_NS.CHESR 0747 000Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	CRC15[14:0]

b14	ADEDF	ACK Delimiter Error Detect Flag*1	0: Acknowledge delimiter error is not detected 1: Acknowledge delimiter error is detected	R/(W) *2
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b30-b16	CRC15[14:0]	CRC_15 Test	These bits show the CRC_15 value calculated for the CAN2.0 CAN frame.	R
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. This flag can be set to 0 only in CH_OPERATION or CH_HALT mode.
Note 2. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of various error conditions detectable regardless of the interrupt enable/disable setting of the Channel Control Register (CHCR). It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) for the conditions under which each error occurs.

Only a single bit can be cleared at a time. Do not use the bit clear instruction to clear the flag. Set only the flag to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

BEDF Flag (Bus Error Detect Flag)

The BEDF flag indicates a detection of an error state, flagged by b14 to b8 in this register.
This flag is automatically set to 1 when a bus error is detected, and is automatically set to 0 when the CAN channel enters CH_RESET mode.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

EWDF Flag (Error Warning Detect Flag)

The EWDF flag indicates whether an error warning condition has been detected for the CAN channel.
This flag is automatically set to 1 when the value of either the CHSR.TEC[7:0] or REC[7:0] bits exceeds 95.
The setting of this flag only occurs when the value of the TEC[7:0] or REC[7:0] bits initially exceeds 95. Therefore, if the TEC[7:0] or REC[7:0] bits remains > 95 and the EWDF flag is cleared by software, it is not set to 1 again until the value of both the TEC[7:0] and REC[7:0] bits go below 96 and either TEC[7:0] or REC[7:0] bits crosses over again from a value ≤ 95 to a value > 95.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. It is automatically set to 0 when the CAN channel enters CH_RESET mode.

EPDF Flag (Error Passive Detect Flag)

The EPDF flag indicates a detection of a CAN channel error passive state.
This flag is automatically set to 1 when the CAN error state becomes error passive state.
The setting of this flag only occurs when the value of either the CHSR.TEC[7:0] or REC[7:0] bits initially exceeds 127. Therefore, if the value of either the TEC[7:0] or REC[7:0] bits remains > 127 and the flag is cleared by software, it is not set to 1 again until the value of both the TEC[7:0] and REC[7:0] bits go below 128 and either TEC[7:0] or REC[7:0] bits crosses over again from a value ≤ 127 to a value > 127.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. It is automatically set to 0 when the CAN channel enters CH_RESET mode.

BOEDF Flag (Bus-Off Entry Detect Flag)

The BOEDF flag indicates a detection of a CAN channel bus-off entry state.
This flag is automatically set to 1 when the CAN error state enters the bus-off state.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the flag is set to 1.

BORDF Flag (Bus-Off Recovery Detect Flag)

The BORDF flag indicates a detection of a CAN channel bus-off recovery state.
This flag is automatically set to 1 if CAN channel recovers from bus-off state in the following conditions:

- When the CHCR.BOM[1:0] bits are 00b and normal recovery (128 occurrence of 11 consecutive recessive bits are detected) occurs
- When the CHCR.BOM[1:0] bits are 10b and normal recovery (128 occurrence of 11 consecutive recessive bits are detected) occurs
- When the CHCR.BOM[1:0] bits are 11b and normal recovery (128 occurrence of 11 consecutive recessive bits are detected) occurs.

The flag is not set to 1 if CAN channel recovers from bus-off state in the following conditions:

- When the CH_RESET mode is requested
- When setting the CHCR.RTBO bit to 1 (the CAN channel returns to error active)
- When the CHCR.BOM[1:0] bits are 01b

- When the CHCR.BOM[1:0] bits are 11b and a halt request is asserted before the CAN channel reaches the end of the bus-off state.

This flag is automatically set to 0 when the CAN channel enters CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set to 1.

OLDF Flag (Overload Detect Flag)

The OLDF flag indicates a detection of a CAN channel overload state.
This flag is automatically set to 1 when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.

BLDF Flag (Bus Lock Detect Flag)

The BLDF flag indicates a detection of a CAN channel bus lock condition.
This flag is automatically set to 1 when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in CH_OPERATION mode.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.

ALDF Flag (Arbitration Lost Detect Flag)

The ALDF flag indicates a detection of a CAN channel bus arbitration lost condition.
The flag is automatically set to 1 when an arbitration lost condition is detected on the CAN bus while the CAN channel is in CH_OPERATION mode.
If a set condition occurs simultaneously with a clear condition, then the flag is set to 1. This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.

SEDF Flag (Stuff Error Detect Flag)

The SEDF flag indicates a detection of a CAN stuff error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a stuff error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

FEDF Flag (Form Error Detect Flag)

The FEDF flag indicates a detection of a CAN form error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a form error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

AEDF Flag (Acknowledge Error Detect Flag)

The AEDF flag indicates a detection of a CAN acknowledge error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.

This flag is automatically set to 1 when an acknowledge error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

CEDF Flag (CRC Error Detect Flag)

The CEDF flag indicates a detection of a CAN CRC error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a CRC error is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

B1EDF Flag (Bit 1 Error Detect Flag)

The B1EDF flag indicates a detection of a recessive bit error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a recessive bit error (expected recessive bit, sampled as dominant bit) is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

B0EDF Flag (Bit 0 Error Detect Flag)

The B0EDF flag indicates a detection of a dominant bit error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a dominant bit error (expected dominant bit, sampled as recessive bit) is detected. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

ADEDF Flag (ACK Delimiter Error Detect Flag)

The ADEDF flag indicates a detection of an acknowledge delimiter bit error.
After clearing this flag, confirm that the flag is actually changed to 0 and execute subsequent instructions.
This flag is automatically set to 1 when a form error is detected during the acknowledge delimiter state of frame transmission. If the CHCR.EDM bit is 1 and if a set condition occurs simultaneously with a clear condition, then the flag is set to 1.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode. If the CHCR.EDM bit is 0 and if a set condition occurs simultaneously with a clear condition, then this flag is set to 0 if even one of the error flags (b14 to b8) in the CHESR register is already 1. Otherwise, this flag is set to 1 if the setting of the error flags (b14 to b8) in the CHESR register is 0000000b.

CRC15[14:0] Bits (CRC_15 Test)

The CRC15[14:0] bits indicate the calculated CRC_15 value when the CHCR.CTME bit is 1 (channel test mode enabled). If the CHCR.CTME bit is 0, then these bits are always read as 0000h.
The CRC_15 value which is read from these bits show the CAN2.0 CRC value calculated by the CAN channel logic.
The value of the CRC15[14:0] bits is updated in the first bit of the CRC field of the Classical CAN frame.
These bits are automatically set to 0000h when the CAN channel enters CH_RESET mode.

46.2.5 Data Bit Rate Configuration Register (DBCR)

Address(es): CANFD2.DBCR 8747 0100h, CANFD2_NS.DBCR 0747 0100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b23 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b24	SJW[3:0]	Resynchronization Jump Width Control	0h: 1 Tq 1h: 2 Tq : : Fh: 16 Tq	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Set this register in CH_RESET or CH_HALT mode.

This register configures the transmission/reception data bit rate parameters of the channel.
In Classic only mode, there is no need to configure this register.

BRP[7:0] Bits (Bit Rate Prescaler Setting)

The BRP[7:0] bits define the number of the DLL clock contained in 1 Tq (Time Quantum).

TSEG1[4:0] Bits (Time Segment 1 Control)

The TSEG1[4:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. A value from 2 to 32 Tq can be set.
The TSEG1[4:0] bits are also used to set the propagation time segment.
Do not write any other value to these bits. Refer to section 46.4.1.2, Bit Timing for more details.

TSEG2[3:0] Bits (Time Segment 2 Control)

The TSEG2[3:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. A

value from 2 to 16 Tq can be set.
Do not write any other value to these bits.

SJW[3:0] Bits (Resynchronization Jump Width Control)

The SJW[3:0] bits set the resynchronization jump width. A value from 1 to 16 Tq can be set.

46.2.6 CAN FD Configuration Register (FDCFG)

Address(es): CANFD2.FDCFG 8747 0104h, CANFD2_NS.FDCFG 0747 0104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	SSPC	Secondary Sample Point Configuration*2	0: Measured + offset 1: Offset-only	R/W
b9	TDCE	Transceiver Delay Compensation Enable*2	0: Transceiver delay compensation is disabled 1: Transceiver delay compensation is enabled	R/W
b10	TESI	Transmit ESI Configuration*2	0: The ESI flag in the transmission frame reflects the error status of the node itself. 1: The ESI flag in the transmission frame reflects the ESI bit in the message buffer if the node is not error passive, and the error status of the node itself If the node is error passive.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	TDCO[7:0]	Transceiver Delay Compensation Offset*2	Sets the offset value for the transceiver delay compensation	R/W
b27 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b28	FDOE	FD Only Mode Enable*3	0: FD only mode is disabled 1: FD only mode is enabled	R/W
b29	REFE	Receive Edge Filter Enable*3	0: Reception edge filter is disabled 1: Reception edge filter is enabled	R/W
b30	CLOE	Classic Only Mode Enable*3, *4	0: Classic only mode is disabled 1: Classic only mode is enabled	R/W
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. The value after reset is 0 for products that support the CAN FD protocol, and 1 for products that support only CAN 2.0 protocol.
Note 2. Set these bits in CH_RESET or CH_HALT mode.
Note 3. Set these bits in CH_RESET mode.
Note 4. This bit can only be written for products that support the CAN FD protocol. For products that support only CAN 2.0 protocol, this bit is reserved and fixed to 1.

This register configures which communication direction (transmitter/receiver) errors are counted.

ECC[2:0] Bits (Error Occurrence Counter Configuration)

The ECC[2:0] bits select which type of CAN frame the protocol errors should be counted for.

SSPC Bit (Secondary Sample Point Configuration)

The SSPC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CAN channel. If the bit is 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.
Do not set this bit to 1 in Classic only mode.

TDCE Bit (Transceiver Delay Compensation Enable)

The TDCE bit enables the transceiver delay compensation for the CAN channel.
Do not set this bit to 1 in Classic only mode.

TESI Bit (Transmit ESI Configuration)

The TESI bit selects whether to reflect the error status of the node itself or the value of the ESI bit in the message buffer (CFB0.HF2.ESI bit or TMBn.HF2.ESI bit) in the ESI flag of the transmit message.
Do not set this bit to 1 in Classic only mode.

TDCO[7:0] Bits (Transceiver Delay Compensation Offset)

The TDCO[7:0] bits set the offset of the secondary sample point. How this value is used, depends on the SSPC setting. If the SSPC bit is 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in the TDCO[7:0] bits, rounded down to the nearest integer number of Tq. Otherwise, the result is equal to the value in the TDCO[7:0] bits. Refer to section 46.4.1.5, Transceiver Delay Compensation for details.
The actual offset value is interpreted as TDCO[7:0] + 1. For example, if 4 is set in TDCO[7:0], the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.
Do not set to these bits in Classic only mode.

FDOE Bit (FD Only Mode Enable)

The FDOE bit enables the transmission and reception of CAN FD frames only. If enabled, communication in Classical CAN frame format is disabled. The value of the FDF bit in the message buffer (CFB0.HF2.FDF bit or TMBn.HF2.FDF bit) is arbitrary because transmission of Classical CAN frames is not possible.
If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and responds with error frames. If a Classical CAN frame is configured for transmission, the FDF bit is transmitted recessive, therefore a CAN FD frame is transmitted. If the data length code (DLC) is configured to be 9 bytes or more, the remaining data bytes are padded with CCh.
Do not set the FDOE and CLOE bits to 1 simultaneously.

REFE Bit (Receive Edge Filter Enable)

The REFE bit enables the reception edge filter during the integrating state. When this bit is 1, two or more consecutive dominant Tq are required to detect an edge for hard synchronization.
Do not set this bit to 1 in Classic only mode.

CLOE Bit (Classic Only Mode Enable)

The CLOE bit enables the Classic only mode. If this bit is set to 1, the protocol controller can only transmit Classical CAN frames and responds to CAN FD frames with a form error or CRC error.
Do not set the CLOE and FDOE bits to 1 simultaneously.

Table 46.3 Operation Mode Configuration

CLOE bit	FDOE bit	Operation mode
0	0	CAN FD mode
0	1	FD only mode
1	0	Classic only mode
1	1	Setting prohibited

46.2.7 CAN FD Control Register (FDCTR)

Address(es): CANFD2.FDCTR 8747 0108h, CANFD2_NS.FDCTR 0747 0108h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SCCL	ECCL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECCL	Error Occurrence Counter Clear	When 1 is written to this bit, the error occurrence counter is cleared. This bit is read as 0.	R/W
b1	SCCL	Success Occurrence Counter Clear	When 1 is written to this bit, the success occurrence counter is cleared. This bit is read as 0.	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the error and success occurrence counters.

ECCL Bit (Error Occurrence Counter Clear)

The ECCL bit is used to clear the error occurrence counter.
This bit cannot be written in CH_SLEEP or CH_RESET mode.
This bit is automatically set to 0 and is also set to 0 when the CAN channel enters CH_RESET mode.

SCCL Bit (Success Occurrence Counter Clear)

The SCCL bit is used to clear the success occurrence counter.
This bit cannot be written in CH_SLEEP or CH_RESET mode.
This bit is automatically set to 0 and is also set to 0 when the CAN channel enters CH_RESET mode.

46.2.8 CAN FD Status Register (FDSTS)

Address(es): CANFD2.FDSTS 8747 010Ch, CANFD2_NS.FDSTS 0747 010Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SC[7:0]								EC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TDCV	—	—	—	—	—	SCOV	ECOV	TDCR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TDCR[7:0]	Transceiver Delay Compensation Result	Indicates the transceiver delay compensation result when the transceiver delay has been measured	R
b8	ECOV	Error Occurrence Counter Overflow Flag*1	0: Error occurrence counter has not overflowed 1: Error occurrence counter has overflowed	R/(W) *2
b9	SCOV	Success Occurrence Counter Overflow Flag*1	0: Success occurrence counter has not overflowed 1: Success occurrence counter has overflowed	R/(W) *2
b14 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	TDCV	Transceiver Delay Compensation Violation Flag*1	0: Transceiver delay compensation violation has not occurred 1: Transceiver delay compensation violation has occurred	R/(W) *2
b23 to b16	EC[7:0]	Error Occurrence Counter	These bits show the error occurrence counter value.	R
b31 to b24	SC[7:0]	Success Occurrence Counter	These bits show the success occurrence counter value.	R

Note 1. Set this flag to 0 only in CH_OPERATION or CH_HALT mode.
Note 2. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register indicates the transceiver compensation delay result and its related FIFO message lost status.

TDCR[7:0] Bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.
The measured delay is represented by the number of the DLL clock cycles. The result depends on the configuration of the FDCFG.SSPC bit and the offset value in the FDCFG.TDCO[7:0] bits. Refer to section 46.4.1.5, Transceiver Delay Compensation for details.
The TDCR[7:0] bits are updated at the falling edge between the FDF bit and res bit when the FDCFG.SSPC bit is 0 and the FDCFG.TDCE bit is 1 (transceiver delay compensation is enabled).
These bits are automatically set to 0 when the CAN channel enters CH_RESET mode.

ECOV Flag (Error Occurrence Counter Overflow Flag)

The ECOV flag indicates whether the CAN channel error occurrence counter has overflowed.
This flag is set to 1 if a CAN bus error specified in the FDCFG.ECC[2:0] bits is detected when the EC[7:0] bits are FFh.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

SCOV Flag (Success Occurrence Counter Overflow Flag)

The SCOV flag indicates whether the CAN channel success occurrence counter has overflowed.

This flag is set to 1 if a successful message reception or successful message transmission occurs when the SC[7:0] bits are FFh.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
Do not use the bit clear instruction to clear this flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

TDCV Flag (Transceiver Delay Compensation Violation Flag)

The CANFD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.
The transceiver delay has some variations depending on the physical parameters such as temperature. The TDCR[7:0] bits are updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCV flag captures this violation.
This flag is set to 1 when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times – 2 DLL clocks) and the internal bit overruns.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is automatically set to 0 when the CAN channel enters CH_RESET mode.
Do not use the bit clear instruction to clear this flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

EC[7:0] Bits (Error Occurrence Counter)

The EC[7:0] bits are used together with the SC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.
This higher error rate can be detected depending on the configuration of the FDCFG.ECC[2:0] bits.
The EC[7:0] bits are set only by CANFD module logic. These bits are cleared by writing 1 to the FDCTR.ECCL bit.
These bits are updated when an error occurs, according to the configuration of the FDCFG.ECC[2:0] bits. When the counter reaches the value of FFh, the update stops.
These bits are automatically set to 00h when the CAN channel enters CH_RESET mode.

SC[7:0] Bits (Success Occurrence Counter)

The SC[7:0] bits are used together with the EC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.
The SC[7:0] bits are set only by CANFD module logic. These bits are cleared by writing 1 to the FDCTR.SCCL bit.
These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of FFh, the update stops.
These bits are automatically set to 00h when the CAN channel enters CH_RESET mode.

Note: In loop-back mode, the counter is incremented twice.

46.2.9 CAN FD CRC Register (FDCRC)

Address(es): CANFD2.FDCRC 8747 0110h, CANFD2_NS.FDCRC 0747 0110h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	SBC[3:0]				—	—	—	CRC21[20:16]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CRC21[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b20 to b0	CRC21[20:0]	CRC_21 Test	These bits show the CRC_17 value or CRC_21 value calculated for the CAN FD frame.	R
b23 to b21	—	Reserved	These bits are read as 0.	R
b27 to b24	SBC[3:0]	Stuff Bit Counter	These bits shows the stuff bit count (Mod 8) for the CAN FD frame.	R
b31 to b28	—	Reserved	These bits are read as 0.	R

This register holds the CRC value calculated for the CAN FD frame.

CRC21[20:0] Bits (CRC_21 Test)

The calculated CRC_17 value or CRC_21 value can be read from this bits when the CHCR.CTME bit is 1 (channel test mode).
When the CHCR.CTME bit is 0, the CRC21[20:0] bits are read as 000000h.
The CRC21[20:0] bits is updated in the first bit of the CRC field of the CAN FD frame.
When the CRC_17 field is used, the CRC21[20:17] bits are read as 0.
These bits are automatically set to 000000h when the CAN channel enters CH_RESET mode.

SBC[3:0] Bits (Stuff Bit Counter)

The SBC[3:0] bits contain the stuff count value of the CAN FD frame. These bits indicate the number of inserted stuff bits (modulo 8, Gray-coded) for a CAN FD frame when the CHCR.CTME bit is enabled in SBC[3:1]. SBC[0] is the parity bit.
When the CHCR.CTME bit is 0, the SBC[3:0] bits are always read as 0000b.
The value of the SBC[3:0] bits is updated in the first bit of CRC field of the CAN FD frame. These bits are automatically set to 0000b when the CAN channel enters CH_RESET mode.

46.2.10 Global Configuration Register (GCFG)

Address(es): CANFD.GCFG 8747 0014h, CANFD_NS.GCFG 0747 0014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ITP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	TSCS	TSP[3:0]				—	—	OMRC	DLLCS	MME	DRE	DCE	TPRI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TPRI	Transmission Priority Setting	0: ID priority 1: Message buffer number priority	R/W
b1	DCE	DLC Check Enable	0: DLC check is disabled 1: DLC check is enabled	R/W
b2	DRE	DLC Replacement Enable	0: DLC replacement is disabled 1: DLC replacement is enabled	R/W
b3	MME	Mirror Mode Enable	0: Mirror mode is disabled 1: Mirror mode is enabled	R/W
b4	DLLCS	DLL Clock Select	0: CANFDCLK 1: CANFDMCLK	R/W
b5	OMRC	Payload-Overflowed Message Reception Configuration	0: The message is discarded. 1: The message payload is cut to fit the specified message size	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b8	TSP[3:0]	Timestamp Counter Prescaler Setting	b11 b8 0 0 0 0: No division 0 0 0 1: Divide-by-2 (= 2^1) 0 0 1 0: Divide-by-4 (= 2^2) 0 0 1 1: Divide-by-8 (= 2^3) : : 1 1 0 1: Divide-by-8192 (= 2^{13}) 1 1 1 0: Divide-by-16384 (= 2^{14}) 1 1 1 1: Divide-by-32768 (= 2^{15})	R/W
b12	TSCS	Timestamp Counter Source Select	0: Clock source for timestamp counter is peripheral module clock (PCLKA) 1: Clock source for timestamp counter is bit time clock	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b16	ITP[15:0]	Interval Timer Prescaler Setting	FIFO interval timer prescaler value. Set the divided value for the peripheral module clock (PCLKA)	R/W

This register is used to select the transmission priority to be used for all the transmit message buffers and the clock source for the CAN protocol engine. The GCFG register is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

TPRI Bit (Transmission Priority Setting)

The TPRI bit selects the transmission priority for the CAN channel.

This bit cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode. Do not select message buffer number priority when using the transmit queue.

DCE Bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for the CAN channel.
This bit cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode.

DRE Bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE bit is 1, the CANFD module stores the configured value (AFLn.PTR0.DLC[3:0]) of the DLC in the destination receive message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination receive message buffer or FIFO buffer is unchanged.
This bit cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode.

MME Bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for the CAN channel.
This bit cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode.

DLLCS Bit (DLL Clock Select)

The DLLCS bit selects the clock source for CAN communication.
This bit cannot be written in GL_SLEEP or GL_OPERATION mode. Write to this bit only in GL_RESET mode.

OMRC Bit (Payload-Overflowed Message Reception Configuration)

The OMRC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size (RMCR.PLS[2:0], RFCRn.PLS[2:0], and CFCR0.PLS[2:0]). The received message payload is always compared with the available message payload size in the message buffer.
This bit cannot be written in GL_SLEEP or GL_OPERATION mode. Write to this bit only in GL_RESET mode.
When this bit is set to 1 and payload overflow occurs, the DLC value is stored in the receive message buffer or FIFO buffer unchanged.

TSP[3:0] Bits (Timestamp Counter Prescaler Setting)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter.
These bits cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode.

TSCS Bit (Timestamp Counter Source Select)

The TSCS bit allows the selection of the clock source for the timestamp counter.
This bit cannot be written in GL_SLEEP mode. Write to this bit only in GL_RESET mode. Additionally, do not set this bit to 1 when CAN FD communication is used.

Note: The bit time clock varies depending on the nominal bit rate and data bit rate configuration.

ITP[15:0] Bits (Interval Timer Prescaler Setting)

The ITP[15:0] bits allow the definition of a reference clock for the FIFO interval timer clock source. When these bits are 0000h, the timer is disabled.
These bits cannot be written in GL_SLEEP mode. Write to these bits only in GL_RESET mode.

46.2.11 Global Control Register (GCR)

Address(es): CANFD.GCR 8747 0018h, CANFD_NS.GCR 0747 0018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSCR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	POIE	THLIE	MLIE	DEIE	—	—	—	—	—	SLPRQ	MDC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b1, b0	MDC[1:0]	Global Mode Control	b1 b0 0 0: Request transition to GL_OPERATION mode 0 1: Request transition to GL_RESET mode 1 0: Request transition to GL_HALT mode 1 1: Keep current value	R/W
b2	SLPRQ	GL_SLEEP Mode Request	0: Request to release GL_SLEEP 1: Request transition to GL_SLEEP	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	DEIE	DLC Error Interrupt Enable	0: DLC error interrupt is disabled 1: DLC error interrupt is enabled	R/W
b9	MLIE	Message Lost Interrupt Enable	0: Message lost interrupt is disabled 1: Message lost interrupt is enabled	R/W
b10	THLIE	Transmission History Entry Lost Interrupt Enable	0: Transmission history entry lost interrupt is disabled 1: Transmission history entry lost interrupt is enabled	R/W
b11	POIE	Payload Overflow Interrupt Enable	0: Payload overflow interrupt is disabled 1: Payload overflow interrupt is enabled	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	TSCR	Timestamp Counter Reset	When 1 is written to this bit, the timestamp counter is reset. This bit is read as 0.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the Global mode of the CANFD module and the timestamp function. The register also enables and disables the global error interrupts.

MDC[1:0] Bits (Global Mode Control)

The MDC[1:0] bits are used to specify the modes of the CANFD module. For the mode transition of the CANFD module, refer to section 46.3.1, Global Modes.

These bits cannot be written in GL_SLEEP mode.

To request the CANFD module to transition to GL_SLEEP mode, first set these bits to 01b to enter GL_RESET mode, then set the GCR.SLPRQ bit to 1.

SLPRQ Bit (GL_SLEEP Mode Request)

The SLPRQ bit is used to control the transition to GL_SLEEP mode and the return from GL_SLEEP mode.

When this bit is set to 1, the transition to CH_SLEEP mode is also requested for CAN channel.

This bit can only be written in GL_RESET or GL_SLEEP mode.

DEIE Bit (DLC Error Interrupt Enable)

When the DEIE bit is 1, an interrupt is generated if a DLC error is detected in the received frames.

This bit cannot be written in GL_SLEEP mode.

MLIE Bit (Message Lost Interrupt Enable)

When the MLIE bit is 1, an interrupt is generated if a message lost condition occurs.
This bit cannot be written in GL_SLEEP mode.

THLIE Bit (Transmission History Entry Lost Interrupt Enable)

When the THLIE bit is 1, an interrupt is generated if a transmission history entry lost condition occurs.
This bit cannot be written in GL_SLEEP mode.

POIE Bit (Payload Overflow Interrupt Enable)

When the POIE bit is 1, an interrupt is generated when a message payload overflow condition occurs.
This bit cannot be written in GL_SLEEP mode.

TSCR Bit (Timestamp Counter Reset)

When the TSCR bit is 1, the Timestamp Counter Register (TSCR) is reset to 00000000h.
This bit cannot be written in GL_SLEEP mode. Do not write to this bit in GL_RESET mode.
This bit is automatically set to 0.

46.2.12 Global Status Register (GSR)

Address(es): CANFD.GSR 8747 001Ch, CANFD_NS.GSR 0747 001Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	RAMST	SLPST	HLTST	RSTST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	RSTST	GL_RESET Status Flag	0: Not in GL_RESET mode 1: In GL_RESET mode	R
b1	HLTST	GL_HALT Status Flag	0: Not in GL_HALT mode 1: In GL_HALT mode	R
b2	SLPST	GL_SLEEP Status Flag	0: Not in GL_SLEEP mode 1: In GL_SLEEP mode	R
b3	RAMST	RAM Initialization Status Flag	0: RAM initialization is completed 1: RAM initialization is in progress	R
b31 to b4	—	Reserved	These bits are read as 0.	R

This register indicates the global status of the CANFD module.

RSTST Flag (GL_RESET Status Flag)

The RSTST flag indicates the status of the CANFD module in GL_RESET mode.
This flag is automatically set to 1 when the CANFD module enters GL_RESET mode. When the mode changes from GL_RESET mode to GL_SLEEP mode, this bit remains 1. This flag is automatically set to 0 when the CANFD module enters GL_HALT or GL_OPERATION mode.

HLTST Flag (GL_HALT Status Flag)

The HLTST flag indicates the status of the CANFD module in GL_HALT mode.
This flag is automatically set to 1 when the CANFD module enters GL_HALT mode. This flag is automatically set to 0 when the CANFD module exits the GL_HALT mode.

SLPST Flag (GL_SLEEP Status Flag)

The SLPST flag indicates the status of the CANFD module in GL_SLEEP mode.
This flag is automatically set to 1 when the CANFD module enters GL_SLEEP mode. This flag is automatically set to 0 when the CANFD module exits the GL_SLEEP mode.

RAMST Flag (RAM Initialization Status Flag)

The RAMST flag indicates the status of the CANFD module's RAM initialization.
This flag is automatically set to 1 when the CANFD module enters GL_SLEEP mode by resetting the MCU. This flag is automatically set to 0 when the CANFD module completed RAM initialization.

46.2.13 Global Error Status Register (GESR)

Address(es): CANFD.GESR 8747 0020h, CANFD_NS.GESR 0747 0020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EEDF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PODF	THLDF	MLDF	DEDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DEDF	DLC Error Detect Flag	0: DLC error is not detected 1: DLC error is detected	R/(W) *1
b1	MLDF	Message Lost Detect Flag	0: Message lost error is not detected 1: Message lost error is detected	R
b2	THLDF	Transmission History Entry Lost Detect Flag	0: Transmission history entry lost is not detected 1: Transmission history entry lost is detected	R
b3	PODF	Payload Overflow Detect Flag	0: Payload overflow is not detected 1: Payload overflow is detected	R/(W) *1
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	EEDF0	ECC Error Detect Flag	0: ECC error is not detected during transmission scan 1: ECC error is detected during transmission scan	R/(W) *1
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register indicates the detection of global errors.

DEDF Flag (DLC Error Detect Flag)

The DEDF flag indicates the error status of the DLC.
This flag cannot be written in GL_SLEEP or GL_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is automatically set to 1 when a DLC error is detected in a received frame.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The flag is cleared by writing 0 to it. This flag is automatically set to 0 when the CANFD module enters GL_RESET mode.

MLDF Flag (Message Lost Detect Flag)

The MLDF flag indicates the status of the message lost error.
This flag is automatically set to 1 when a FIFO message lost error is detected.
This flag is automatically set to 0 when:

- All FIFO message lost flags (RFSRn.LOST, CFSR0.LOST) are cleared
- The CANFD module enters GL_RESET mode.

THLDF Flag (Transmission History Entry Lost Detect Flag)

The THLDF flag indicates the status of the transmission history entry lost error.
This flag is automatically set to 1 when a transmission history entry lost error is detected.
This flag is automatically set to 0 when:

- The transmission history lost flag (THSR.LOST) is cleared
- The CANFD module enters GL_RESET mode.

PODF Flag (Payload Overflow Detect Flag)

The PODF flag is automatically set to 1 when a message payload overflow is detected on at least one channel.
This flag cannot be written in GL_SLEEP or GL_RESET mode.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is automatically set to 0 when the CANFD module enters GL_RESET mode.

EEDF0 Flag (ECC Error Detect Flag)

The EEDF0 flag indicates whether an ECC error has occurred.
This flag cannot be written in GL_SLEEP or GL_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This bit is automatically set to 0 when the CANFD module enters GL_RESET mode.

46.2.14 Transmit Interrupt Status Register (TISR)

Address(es): CANFD.TISR 8747 00A4h, CANFD_NS.TISR 0747 00A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	THIF0	CFTIF0	TQIF0	TAIF0	TSIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TSIF0	Transmission Successful Interrupt Flag	0: Transmission successful interrupt is not generated. 1: Transmission successful interrupt is generated.	R
b1	TAIF0	Transmission Abort Interrupt Flag	0: Transmission abort interrupt is not generated. 1: Transmission abort interrupt is generated.	R
b2	TQIF0	Transmit Queue Interrupt Flag	0: Transmit queue interrupt is not generated. 1: Transmit queue interrupt is generated.	R
b3	CFTIF0	Common FIFO Transmission Interrupt Flag	0: Common FIFO transmission interrupt is not generated. 1: Common FIFO transmission interrupt is generated.	R
b4	THIF0	Transmission History Interrupt Flag	0: Transmission history interrupt is not generated. 1: Transmission history interrupt is generated.	R
b31 to b5	—	Reserved	These bits are read as 0.	R

This register indicates the detection of transmit specific interrupts.

TSIF0 Flag (Transmission Successful Interrupt Flag)

The TSIF0 flag becomes 1 if transmission from the transmit message buffer n is successful when the transmit message buffer n interrupt is enabled.

This flag is automatically set to 0:

- When the interrupt is disabled (TMIER0.TMIEn bits = 0)
- When the transmission result flag (TMSRn.TXRF[1:0]) is cleared
- When in GL_RESET or CH_RESET mode.

TAIF0 Flag (Transmission Abort Interrupt Flag)

The TAIF0 flag becomes 1 if transmission from the transmit message buffer n is aborted when the transmission abort interrupt is enabled.

This flag is automatically set to 0:

- When the interrupt is disabled (CHCR.TAIE bit = 0)
- When the transmission result flag (TMSRn.TXRF[1:0]) is cleared
- When in GL_RESET or CH_RESET mode.

TQIF0 Flag (Transmit Queue Interrupt Flag)

The TQIF0 flag becomes 1 if the Transmit Queue Interrupt flag is set to 1 when the transmit queue interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (TQCR0.TQIE bit = 0)
- When the transmission queue interrupt flag (TQSR0.TQIF) is cleared
- When in GL_RESET or CH_RESET mode.

CFTIF0 Flag (Common FIFO Transmission Interrupt Flag)

The CFTIF0 flag becomes 1 if the Common FIFO Transmit Interrupt flag (CFSR0.CFTIF) is set to 1 when the common FIFO transmit interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (CFCR0.CFTIE bit = 0)
- When the common transmit FIFO interrupt flag (CFSR0.CFTIF) is cleared
- When in GL_RESET or CH_RESET mode.

THIF0 Flag (Transmission History Interrupt Flag)

The THIF0 flag becomes 1 if the Transmission History Interrupt flag (THSR.THIF) is set to 1 when the transmission history interrupt is enabled.
This flag is automatically set to 0:

- When the interrupt is disabled (THCR.THIE bit = 0)
- When the transmission history interrupt flag (THSR.THIF) is cleared
- When in GL_RESET or CH_RESET mode.

46.2.15 Timestamp Counter Register (TSCR)

Address(es): CANFD.TSCR 8747 0024h, CANFD_NS.TSCR 0747 0024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is a read-only register that stores a timestamp based on the selected configuration.
The timestamp value is stored in the TSCR register based on the configuration of the GCFG.TSCS bit and GCFG.TSP[3:0] bits. The accuracy of the timestamp counter cannot be guaranteed when transitioning to GL_HALT state.
This register is automatically set to 00000000h in GL_RESET mode.

46.2.16 Acceptance Filter List Control Register (AFCR)

Address(es): CANFD.AFCR 8747 0028h, CANFD_NS.AFCR 0747 0028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	AFLWE	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	AFLWE	AFL Write Enable	0: Acceptance Filter List data access is disabled 1: Acceptance Filter List data access is enabled	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to select the Acceptance Filter List page for reading or writing entries into the Acceptance Filter List.

AFLWE Bit (AFL Write Enable)

The AFLWE bit allows writing to the Acceptance Filter List.

Setting this bit to 1 enables writing to the Acceptance Filter List. Setting this bit to 0 after configuring the Acceptance Filter List prevents writing to the Acceptance Filter List.

Data can be read from the Acceptance Filter List independent of the status of this bit.

This bit cannot be written in GL_SLEEP mode.

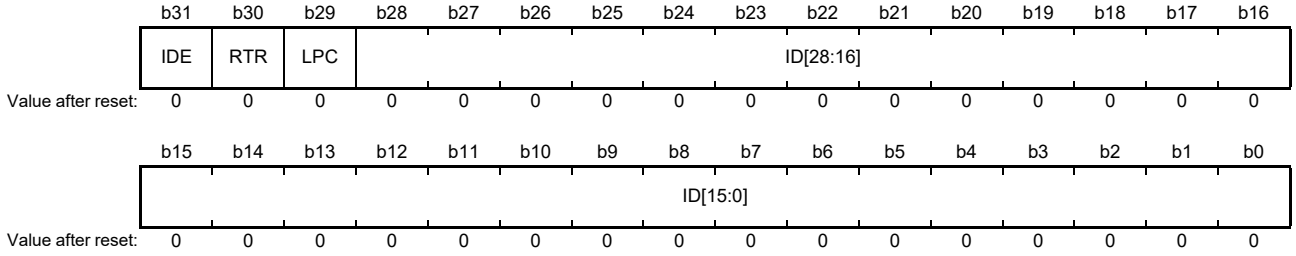
46.2.17 Acceptance Filter List Configuration Register (AFCFG)

Address(es): CANFD.AFCFG 8747 002Ch, CANFD_NS.AFCFG 0747 002Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	RN0[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	RN0[4:0]	Number of Rules Setting	Number of rules in the Acceptance Filter List	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W



This register is used to define the number of rules for entry in the Acceptance Filter List.
The maximum number of available entries in the Acceptance Filter List is 16.

RN0[4:0] Bits (Number of Rules Setting)

The RN0[4:0] bits define the number of rules in the Acceptance Filter List. Set a value of 16 or less.
These bits can only be written in GL_RESET mode.

46.2.18 Acceptance Filter List n ID Register (AFLn.IDR) (n = 0 to 15)

Address(es): CANFD.AFL0.IDR 8747 0120h, CANFD.AFL1.IDR 8747 0130h, CANFD.AFL2.IDR 8747 0140h, CANFD.AFL3.IDR 8747 0150h, CANFD.AFL4.IDR 8747 0160h, CANFD.AFL5.IDR 8747 0170h, CANFD.AFL6.IDR 8747 0180h, CANFD.AFL7.IDR 8747 0190h, CANFD.AFL8.IDR 8747 01A0h, CANFD.AFL9.IDR 8747 01B0h, CANFD.AFL10.IDR 8747 01C0h, CANFD.AFL11.IDR 8747 01D0h, CANFD.AFL12.IDR 8747 01E0h, CANFD.AFL13.IDR 8747 01F0h, CANFD.AFL14.IDR 8747 0200h, CANFD.AFL15.IDR 8747 0210h, CANFD_NS.AFL0.IDR 0747 0120h, CANFD_NS.AFL1.IDR 0747 0130h, CANFD_NS.AFL2.IDR 0747 0140h, CANFD_NS.AFL3.IDR 0747 0150h, CANFD_NS.AFL4.IDR 0747 0160h, CANFD_NS.AFL5.IDR 0747 0170h, CANFD_NS.AFL6.IDR 0747 0180h, CANFD_NS.AFL7.IDR 0747 0190h, CANFD_NS.AFL8.IDR 0747 01A0h, CANFD_NS.AFL9.IDR 0747 01B0h, CANFD_NS.AFL10.IDR 0747 01C0h, CANFD_NS.AFL11.IDR 0747 01D0h, CANFD_NS.AFL12.IDR 0747 01E0h, CANFD_NS.AFL13.IDR 0747 01F0h, CANFD_NS.AFL14.IDR 0747 0200h, CANFD_NS.AFL15.IDR 0747 0210h

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	ID Field	ID part of the Acceptance Filter List entry	R/W
b29	LPC	Loop-Back Configuration	0: Perform normal processing of received messages 1: Only accept its own transmitted messages	R/W
b30	RTR	RTR	0: Data frame 1: Remote frame	R/W
b31	IDE	IDE	0: Standard ID 1: Extended ID	R/W

Note: Set these registers in CH_RESET or CH_HALT mode. However, using the AFIGSR and AFIGER registers allows these registers to be rewritten even in CH_OPERATION mode. For details, refer to section 46.5.10, Updating AFL Entry during Communication.

These registers are used to configure the ID field in the rule entry of the Acceptance Filter List.
When rewriting these registers, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

ID[28:0] Bits (ID Field)

The ID[28:0] bits indicate the CAN identifier (ID) field of each entry in the Acceptance Filter List.
The acceptance filter process compares this field against the ID of a received message. For alignment of these bits in base and extended formats, refer to section 46.2.60, Identifier Bits Alignment.

LPC Bit (Loop-Back Configuration)

The LPC bit specifies the processing of received messages in loop-back mode and mirror mode for each entry in the Acceptance Filter List. For normal received messages, set this bit to 0.
Entries with this bit set to 1 only match its own transmitted messages in loop-back mode or mirror mode. Entries with this bit set to 0 match all messages transmitted by other nodes, and its own transmitted messages in loop-back mode.
For details, refer to section 46.5.8, Loop-Back Configuration.

RTR Bit (RTR)

The RTR bit allows the configuration of the specified frame format (data frame or remote frame) for each entry of the Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the RTR bit of the received message.

IDE Bit (IDE)

The IDE bit allows the configuration of the ID format (standard ID or extended ID) for each entry in the Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the IDE bit of the received message.

46.2.19 Acceptance Filter List n Mask Register (AFLn.MASK) (n = 0 to 15)

Address(es): CANFD.AFL0.MASK 8747 0124h, CANFD.AFL1.MASK 8747 0134h, CANFD.AFL2.MASK 8747 0144h, CANFD.AFL3.MASK 8747 0154h, CANFD.AFL4.MASK 8747 0164h, CANFD.AFL5.MASK 8747 0174h, CANFD.AFL6.MASK 8747 0184h, CANFD.AFL7.MASK 8747 0194h, CANFD.AFL8.MASK 8747 01A4h, CANFD.AFL9.MASK 8747 01B4h, CANFD.AFL10.MASK 8747 01C4h, CANFD.AFL11.MASK 8747 01D4h, CANFD.AFL12.MASK 8747 01E4h, CANFD.AFL13.MASK 8747 01F4h, CANFD.AFL14.MASK 8747 0204h, CANFD.AFL15.MASK 8747 0214h,
CANFD_NS.AFL0.MASK 0747 0124h, CANFD_NS.AFL1.MASK 0747 0134h, CANFD_NS.AFL2.MASK 0747 0144h, CANFD_NS.AFL3.MASK 0747 0154h, CANFD_NS.AFL4.MASK 0747 0164h, CANFD_NS.AFL5.MASK 0747 0174h, CANFD_NS.AFL6.MASK 0747 0184h, CANFD_NS.AFL7.MASK 0747 0194h, CANFD_NS.AFL8.MASK 0747 01A4h, CANFD_NS.AFL9.MASK 0747 01B4h, CANFD_NS.AFL10.MASK 0747 01C4h, CANFD_NS.AFL11.MASK 0747 01D4h, CANFD_NS.AFL12.MASK 0747 01E4h, CANFD_NS.AFL13.MASK 0747 01F4h, CANFD_NS.AFL14.MASK 0747 0204h, CANFD_NS.AFL15.MASK 0747 0214h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IDEM	RTRM	IFL1	IDM[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	IDM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	IDM[28:0]	ID Mask Field	0: Corresponding ID bit is not used for ID matching 1: Corresponding ID bit is used for ID matching	R/W
b29	IFL1	Information Label 1	Configure an information label 1 to be attached to a received message	R/W
b30	RTRM	RTR Mask	0: RTR bit is not used for ID matching 1: RTR bit is used for ID matching	R/W
b31	IDEM	IDE Mask	0: IDE bit is not used for ID matching 1: IDE bit is used for ID matching	R/W

Note: Set these registers in CH_RESET or CH_HALT mode. However, using the AFIGSR and AFIGER registers allows these registers to be rewritten even in CH_OPERATION mode. For details, refer to section 46.5.10, Updating AFL Entry during Communication.

These registers are used to configure the mask field of each rule for entries in the Acceptance Filter List.
When rewriting these registers, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

IDM[28:0] Bits (ID Mask Field)

The IDM[28:0] bits are the filter mask bits for the related bits in the CAN Identifier field of each Acceptance Filter List entry.

IFL1 Bit (Information Label 1)

The IFL1 bit is the upper bit of a 2-bit information label to be attached to a received message accepted by the associated entry in the Acceptance Filter List.
This bit is stored in the upper bit of the Information Label Field (RMBn.HF2.IFL[1], RFBn.HF2.IFL[1], CFB0.HF2.IFL[1]) of the storage location of a received message.

RTRM Bit (RTR Mask)

The RTRM bit is the RTR mask bit for each entry in the Acceptance Filter List.

IDEM Bit (IDE Mask)

The IDEM bit is the IDE mask bit for each entry in the Acceptance Filter List.
When the IDE mask bit is 0, the ID comparison depends on the IDE bit of the received message.

- If the IDE bit of the received message is 0, the standard ID comparison takes place.
- If the IDE bit of the received message is 1, the extended ID comparison takes place.

46.2.20 Acceptance Filter List n Pointer 0 Register (AFLn.PTR0) (n = 0 to 15)

Address(es): CANFD.AFL0.PTR0 8747 0128h, CANFD.AFL1.PTR0 8747 0138h, CANFD.AFL2.PTR0 8747 0148h, CANFD.AFL3.PTR0 8747 0158h, CANFD.AFL4.PTR0 8747 0168h, CANFD.AFL5.PTR0 8747 0178h, CANFD.AFL6.PTR0 8747 0188h, CANFD.AFL7.PTR0 8747 0198h, CANFD.AFL8.PTR0 8747 01A8h, CANFD.AFL9.PTR0 8747 01B8h, CANFD.AFL10.PTR0 8747 01C8h, CANFD.AFL11.PTR0 8747 01D8h, CANFD.AFL12.PTR0 8747 01E8h, CANFD.AFL13.PTR0 8747 01F8h, CANFD.AFL14.PTR0 8747 0208h, CANFD.AFL15.PTR0 8747 0218h, CANFD_NS.AFL0.PTR0 0747 0128h, CANFD_NS.AFL1.PTR0 0747 0138h, CANFD_NS.AFL2.PTR0 0747 0148h, CANFD_NS.AFL3.PTR0 0747 0158h, CANFD_NS.AFL4.PTR0 0747 0168h, CANFD_NS.AFL5.PTR0 0747 0178h, CANFD_NS.AFL6.PTR0 0747 0188h, CANFD_NS.AFL7.PTR0 0747 0198h, CANFD_NS.AFL8.PTR0 0747 01A8h, CANFD_NS.AFL9.PTR0 0747 01B8h, CANFD_NS.AFL10.PTR0 0747 01C8h, CANFD_NS.AFL11.PTR0 0747 01D8h, CANFD_NS.AFL12.PTR0 0747 01E8h, CANFD_NS.AFL13.PTR0 0747 01F8h, CANFD_NS.AFL14.PTR0 0747 0208h, CANFD_NS.AFL15.PTR0 0747 0218h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	DMBE	—	—	DMB[4:0]					IFL0	—	—	—	DLC[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	DLC[3:0]	DLC Field	Configure a minimum DLC value of received message	R/W
b6 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	IFL0	Information Label 0	Configure an information label 0 to be attached to a received message	R/W
b12 to b8	DMB[4:0]	Destination Message Buffer Setting	Configure the receive message buffer number for storage of received messages	R/W
b14 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	DMBE	Destination Message Buffer Setting Enable	0: The Destination Message Buffer Setting bit is disabled 1: The Destination Message Buffer Setting bit is enabled	R/W
b31 to b16	PTR[15:0]	Pointer	Configure a 16-bit pointer to be attached to a received message	R/W

Note: Set these registers in CH_RESET or CH_HALT mode. However, using the AFIGSR and AFIGER registers allows these registers to be rewritten even in CH_OPERATION mode. For details, refer to section 46.5.10, Updating AFL Entry during Communication.

These registers are used to configure the data length code (DLC), software pointer, and destination message buffer for each rule entry in the Acceptance Filter List.
When rewriting these registers, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

DLC[3:0] Bits (DLC Field)

The DLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Acceptance Filter List (automatic DLC filter function).
DLC filter process is only passed if the DLC value of the message accepted by an entry in the Acceptance Filter List is equal to or higher than the DLC value configured for this associated Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding rule entry when this field is set to 0000b.

IFL0 Bit (Information Label 0)

The IFL0 bit is the lower bit of a 2-bit information label that can be attached to a received message accepted by the Acceptance Filter List entry.
This bit is stored in the lower bit of the Information Label Field (RMBn.HF2.IFL[0], RFBn.HF2.IFL[0], CFB0.HF2.IFL[0]) of the storage location of a received message.

DMB[4:0] Bits (Destination Message Buffer Setting)

The DMB[4:0] bits allow the configuration of a message buffer as the destination for a received message that passes the acceptance check of the Acceptance Filter List entry. Configure the destination message buffer number.
Write the RMCR.NMB[4:0] bits to configure the number of receive message buffers. The value to be entered in the DMB[4:0] bits should only be between 00000b and 'NMB[4:0] – 1'.
If the RMCR.NMB[4:0] bits are 00000b, set the DMBE bit to 0.

DMBE Bit (Destination Message Buffer Setting Enable)

The DMBE bit allows the enabling or disabling of the receive message buffer as the destination message buffer for a received message that passes the acceptance check of the Acceptance Filter List entry.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits allow the configuration of a 16-bit pointer to be attached to a received message accepted by the Acceptance Filter List entry. The pointer is added during message storage in the message buffer area and can be used by the application as a support function. The pointer information can be used for example, to support PDU Identifier allocation for the received message in AUTOSAR systems.

46.2.21 Acceptance Filter List n Pointer 1 Register (AFLn.PTR1) (n = 0 to 15)

Address(es): CANFD.AFL0.PTR1 8747 012Ch, CANFD.AFL1.PTR1 8747 013Ch, CANFD.AFL2.PTR1 8747 014Ch, CANFD.AFL3.PTR1 8747 015Ch, CANFD.AFL4.PTR1 8747 016Ch, CANFD.AFL5.PTR1 8747 017Ch, CANFD.AFL6.PTR1 8747 018Ch, CANFD.AFL7.PTR1 8747 019Ch, CANFD.AFL8.PTR1 8747 01ACh, CANFD.AFL9.PTR1 8747 01BCh, CANFD.AFL10.PTR1 8747 01CCh, CANFD.AFL11.PTR1 8747 01DCh, CANFD.AFL12.PTR1 8747 01ECh, CANFD.AFL13.PTR1 8747 01FCh, CANFD.AFL14.PTR1 8747 020Ch, CANFD.AFL15.PTR1 8747 021Ch, CANFD_NS.AFL0.PTR1 0747 012Ch, CANFD_NS.AFL1.PTR1 0747 013Ch, CANFD_NS.AFL2.PTR1 0747 014Ch, CANFD_NS.AFL3.PTR1 0747 015Ch, CANFD_NS.AFL4.PTR1 0747 016Ch, CANFD_NS.AFL5.PTR1 0747 017Ch, CANFD_NS.AFL6.PTR1 0747 018Ch, CANFD_NS.AFL7.PTR1 0747 019Ch, CANFD_NS.AFL8.PTR1 0747 01ACh, CANFD_NS.AFL9.PTR1 0747 01BCh, CANFD_NS.AFL10.PTR1 0747 01CCh, CANFD_NS.AFL11.PTR1 0747 01DCh, CANFD_NS.AFL12.PTR1 0747 01ECh, CANFD_NS.AFL13.PTR1 0747 01FCh, CANFD_NS.AFL14.PTR1 0747 020Ch, CANFD_NS.AFL15.PTR1 0747 021Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	—	CF0E	—	—	—	—	—	—	RF1E	RF0E
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RF0E	Receive FIFO 0 Destination Enable	0: Do not select receive FIFO 0 as the message storage destination 1: Selects receive FIFO 0 as the message storage destination	R/W
b1	RF1E	Receive FIFO 1 Destination Enable	0: Do not select receive FIFO 1 as the message storage destination 1: Selects receive FIFO 1 as the message storage destination	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	CF0E	Common FIFO 0 Destination Enable	0: Do not select common FIFO 0 as the message storage destination 1: Selects common FIFO 0 as the message storage destination	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Set these registers in CH_RESET or CH_HALT mode. However, using the AFIGSR and AFIGER registers allows these registers to be rewritten even in CH_OPERATION mode. For details, refer to section 46.5.10, Updating AFL Entry during Communication.

These registers are used to configure the destination FIFO buffer for each rule entry in the Acceptance Filter List.
Up to two storage destinations can be specified for received messages. Two FIFO buffers, or one FIFO buffer and one receive message buffer are valid.
When rewriting these registers, set the AFCR.AFLWE bit to 1. When the AFLWE bit is 0, it cannot be rewritten.

RF0E Bit (Receive FIFO 0 Destination Enable)

The RF0E bit allows the configuration of the receive FIFO 0 as a storage destination of a received message that passes the acceptance check of the Acceptance Filter List entry.

RF1E Bit (Receive FIFO 1 Destination Enable)

The RF1E bit allows the configuration of the receive FIFO 1 as a storage destination of a received message that passes the acceptance check of the Acceptance Filter List entry.

CF0E Bit (Common FIFO 0 Destination Enable)

The CF0E bit allows the configuration of the common FIFO 0 as a storage destination of a received message that passes the acceptance check of the Acceptance Filter List entry.

The common FIFO 0 must be configured as the receive FIFO.

46.2.22 Receive Message Buffer Configuration Register (RMCR)

Address(es): CANFD.RMCR 8747 0030h, CANFD_NS.RMCR 0747 0030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PLS[2:0]			—	—	—	NMB[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	NMB[4:0]	Number of Message Buffer Setting	Configure the number of receive message buffers	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b10 to b8	PLS[2:0]	Payload Size Setting	b10 b8 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to configure the total number of receive message buffers allocated to a channel.

NMB[4:0] Bits (Number of Message Buffer Setting)

The NMB[4:0] bits are used to configure the number of receive message buffers.
These bits can only be written in GL_RESET mode.
Set a value between 0 and 16. A value of 0 indicates that no receive message buffer is allocated.

PLS[2:0] Bits (Payload Size Setting)

The PLS[2:0] bits are used to configure the message buffer payload size.
These bits can only be written in GL_RESET mode.

46.2.23 Receive Message Buffer New Data Register (RMNDR)

Address(es): CANFD.RMNDR 8747 0034h, CANFD_NS.RMNDR 0747 0034h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	NDF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	NDF[15:0]	New Data Flag	0: New data is not stored in corresponding receive message buffer 1: New data is stored in corresponding receive message buffer	R/(W) *1

Note 1. Writing 1 has no effect. These flags are cleared by writing 0 to them.

This register specifies the new data storage status of the receive message buffers.
The bit number of this register corresponds to the buffer number of the receive message buffer.

NDF[15:0] Flags (New Data Flag)

The NDF[15:0] flags indicate that the new data is stored in the corresponding receive message buffer. The NDF[0] flag corresponds to receive message buffer 0.
These flags are automatically set to 1 when storage of new messages are in the corresponding receive message buffer. When RMCR.PLS[2:0] = 000b (payload size is 8 bytes), the time required to store a message is 6 PCLKA cycles. When RMCR.PLS[2:0] > 000b, the time increases by 1 PCLKA cycle for every 4 bytes of payload size (20 PCLKA cycles for 64 bytes).
Do not write to these flags in GL_RESET or GL_SLEEP mode.
These flags are automatically set to 0 when the CANFD module enters GL_RESET mode.
These flags cannot be cleared when message storage in the corresponding receive message buffer is in progress.
Do not use the bit clear instruction to clear the flags. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 16-bit units using MOV instruction.

46.2.24 Receive FIFO n Configuration Register (RFCRn) (n = 0, 1)

Address(es): CANFD.RFCR0 8747 003Ch, CANFD.RFCR1 8747 0040h, CANFD_NS.RFCR0 0747 003Ch, CANFD_NS.RFCR1 0747 0040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RFITH[2:0]			RFIM	—	FDS[2:0]			—	PLS[2:0]			—	—	RFIE	RFE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFE	Receive FIFO Enable	0: FIFO is disabled 1: FIFO is enabled	R/W
b1	RFIE	Receive FIFO Interrupt Enable	0: FIFO interrupt generation is disabled 1: FIFO interrupt generation is enabled	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6 to b4	PLS[2:0]	Payload Size Setting	b6 b4 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10 to b8	FDS[2:0]	FIFO Depth Setting	b10 b8 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages Settings other than above are prohibited.	R/W
b11	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b12	RFIM	Receive FIFO Interrupt Mode Setting	0: Interrupt is generated when the number of messages stored in the receive FIFO reaches the value of the RFITH[2:0] bits from a value smaller than the RFITH[2:0] bits 1: Interrupt is generated at the end of every received message storage	R/W
b15 to b13	RFITH[2:0]	Receive FIFO Interrupt Threshold Setting	b15 b13 0 0 0: Interrupt generated when FIFO is 1/8 full 0 0 1: Interrupt generated when FIFO is 1/4 full 0 1 0: Interrupt generated when FIFO is 3/8 full 0 1 1: Interrupt generated when FIFO is 1/2 full 1 0 0: Interrupt generated when FIFO is 5/8 full 1 0 1: Interrupt generated when FIFO is 3/4 full 1 1 0: Interrupt generated when FIFO is 7/8 full 1 1 1: Interrupt generated when FIFO is full	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

These registers are used to configure and control the two receive FIFOs.

RFE Bit (Receive FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the receive FIFO is cleared to empty.
This bit can only be written in GL_HALT or GL_OPERATION mode.
This bit can be set to 1 only when the FIFO depth is 4 to 48 (001b ≤ FDS[2:0] ≤ 101b).
Set the RFE bit to 1 with a separate write access to the RFCRn register, after all the other flags in the RFCRn register are set.
This bit is automatically set to 0 when the CANFD module enters GL_RESET mode.

RFIE Bit (Receive FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.
This bit cannot be written in GL_SLEEP mode.

PLS[2:0] Bits (Payload Size Setting)

The PLS[2:0] bits define the message data payload size in the RAM.
This is the maximum number of bytes which can be received by this FIFO.
These bits can only be written in GL_RESET mode.

FDS[2:0] Bits (FIFO Depth Setting)

The FDS[2:0] bits select the depth of the FIFO in units of the number of messages. If the FIFO depth is set to 0, the FIFO cannot be used.
These bits can only be written in GL_RESET mode.

RFIM Bit (Receive FIFO Interrupt Mode Setting)

The RFIM bit selects the interrupt generation condition for the FIFO.
This bit cannot be written in GL_SLEEP mode.
Write to this bit only in GL_RESET mode.

RFITH[2:0] Bits (Receive FIFO Interrupt Threshold Setting)

The RFITH[2:0] bits select the counter value of the FIFO for generation of receive FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.
These bits cannot be written in GL_SLEEP mode.
The setting of the RFITH[2:0] bits is restricted by the value of the FDS[2:0] bits. For details, refer to section 46.6.2.1, FIFO Buffers Configuration.
Write to these bits only in GL_RESET mode.

46.2.25 Receive FIFO n Status Register (RFSRn) (n = 0, 1)

Address(es): CANFD.RFSR0 8747 0044h, CANFD.RFSR1 8747 0048h, CANFD_NS.RFSR0 0747 0044h, CANFD_NS.RFSR1 0747 0048h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	FLVL[5:0]						—	—	—	—	RFIF	LOST	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Receive FIFO Empty Flag	0: Message in receive FIFO 1: No message in receive FIFO (empty)	R
b1	FULL	Receive FIFO Full Flag	0: Receive FIFO not full 1: Receive FIFO full	R
b2	LOST	Message Lost Flag	0: Receive FIFO message lost has not occurred 1: Receive FIFO message lost has occurred	R/(W) *1
b3	RFIF	Receive FIFO Interrupt Flag	0: Receive FIFO interrupt condition is not satisfied 1: Receive FIFO interrupt condition is satisfied	R/(W) *1
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	FLVL[5:0]	Receive FIFO Fill Level	Indicate the number of messages stored in receive FIFO	R
b31 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

These registers show the status of messages stored in the corresponding FIFO buffers.

EMPTY Flag (Receive FIFO Empty Flag)

The EMPTY flag is automatically set to 1 when:

- The FLVL[5:0] flags are 00000b
- The RFCRn.RFE bit is set to 0 (receive FIFO is disabled)
- The CANFD module enters GL_RESET mode.

The EMPTY flag is automatically set to 0 when the first message is stored in the receive FIFO.

FULL Flag (Receive FIFO Full Flag)

The FULL flag is automatically set to 1 when the number of messages stored in the FIFO buffer matches the configured FIFO depth.

The FULL flag is automatically set to 0 when:

- The number of messages stored in the FIFO buffer is less than the configured FIFO depth
- The RFCRn.RFE bit is set to 0 (receive FIFO is disabled)
- The CANFD module enters GL_RESET mode.

LOST Flag (Message Lost Flag)

The LOST flag is automatically set to 1 whenever a message is lost due to attempted storage when the FIFO buffer is already full. This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

The flag is set to 0:

- By writing 0 to it

- When the CANFD module enters GL_RESET mode.

This flag can only be written in GL_HALT or GL_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

RFIF Flag (Receive FIFO Interrupt Flag)

The RFIF flag is automatically set to 1 when the configured interrupt condition is satisfied. This flag is not automatically cleared when the receive FIFO is disabled.
The flag is set to 0:

- By writing 0 to it
- When the CANFD module enters GL_RESET mode.

This flag can only be written in GL_HALT or GL_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.

FLVL[5:0] Bits (Receive FIFO Fill Level)

The FLVL[5:0] bits indicate the number of messages stored in the receive FIFO that can be read by the CPU. These bits are automatically set to 000000b when the FIFO is disabled or when the CANFD module enters GL_RESET mode.

46.2.26 Receive FIFO n Pointer Control Register (RFPCRn) (n = 0, 1)

Address(es): CANFD.RFPCR0 8747 004Ch, CANFD.RFPCR1 8747 0050h, CANFD_NS.RFPCR0 0747 004Ch, CANFD_NS.RFPCR1 0747 0050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register can be used to increment the read pointer of the corresponding receive FIFOs.
When the value 000000FFh is written to this register, the pointer of the corresponding receive FIFO is moved to the next FIFO entry. Write to this register only when the corresponding receive FIFO is enabled and not empty.
The read value from this register is always 00000000h.
This register can only be written in GL_HALT or GL_OPERATION mode.
Do not write to this register when DTC/DMA transfer is enabled (DTCR.RFDTEn bit = 1).

46.2.27 Common FIFO 0 Configuration Register (CFCR0)

Address(es): CANFD.CFCR0 8747 0054h, CANFD_NS.CFCR0 0747 0054h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TINT[7:0]								FDS[2:0]			—	—	—	LTM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b11	ITR	Interval Timer Resolution Select	0: Reference clock period × 1 1: Reference clock period × 10	R/W
b12	CFIM	Common FIFO Interrupt Mode Setting	Receive FIFO mode: 0: Reception interrupt generated when the number of messages stored in the common FIFO reaches CFITH[2:0] value from a lower value 1: Reception interrupt generated at the end of every received message storage Transmit FIFO mode: 0: Transmission interrupt generated when common FIFO transmits the last message successfully 1: Transmission interrupt generated for every successfully transmitted message	R/W
b15 to b13	CFITH[2:0]	Common FIFO Receive Interrupt Threshold Setting	b15 b13 0 0 0: Interrupt is generated when FIFO is 1/8 full 0 0 1: Interrupt is generated when FIFO is 1/4 full 0 1 0: Interrupt is generated when FIFO is 3/8 full 0 1 1: Interrupt is generated when FIFO is 1/2 full 1 0 0: Interrupt is generated when FIFO is 5/8 full 1 0 1: Interrupt is generated when FIFO is 3/4 full 1 1 0: Interrupt is generated when FIFO is 7/8 full 1 1 1: Interrupt is generated when FIFO is full	R/W

Bit	Symbol	Bit Name	Description	R/W
b17 to b16	LTM[1:0]	Linked Transmit Message Buffer Select	Transmission scan link position of the corresponding channel	R/W
b20 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b21	FDS[2:0]	FIFO Depth Setting	b23 b21 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages Settings other than the above are prohibited.	R/W
b31 to b24	TINT[7:0]	Transmission Interval Setting	Delay the start of transmission from the FIFO if configured in transmit mode, delay is a multiple of basic interval timer clock source unit	R/W

CFE Bit (Common FIFO Enable)

Setting the CFE bit to 1 enables the FIFO. The FIFO is disabled when this bit is set to 0.
This bit can also be used, by clearing it, to abort transmission from common FIFO when configured in transmit FIFO mode, or to stop reception into the common FIFO in receive FIFO mode.
This bit can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
This bit can only be set to 1 when the FIFO depth is between 4 and 48 (001b ≤ FDS[2:0] ≤ 101b).
Set the CFE bit to 1 with a separate write access to the CFCR0 register, after setting all the other bits in this register.
This bit is automatically set to 0 when the CANFD module enters GL_RESET mode. Also, if the common FIFO is configured as transmit FIFO mode, this bit is automatically set to 0 when the CAN channel enters CH_RESET mode.

CFRIE Bit (Common FIFO Receive Interrupt Enable)

The CFRIE bit enables or disables generation of common FIFO receive interrupt. If this flag is 1, common FIFO receive interrupt is generated when the common FIFO receive interrupt flag is set to 1 after reception of a frame in the corresponding FIFO buffer.
Do not write to this bit in GL_SLEEP mode.

CFTIE Bit (Common FIFO Transmit Interrupt Enable)

The CFTIE bit enables or disables generation of common FIFO transmit interrupt. If this flag is 1, common FIFO transmit interrupt is generated when the common FIFO transmit interrupt flag is set to 1 after transmission of a frame from the corresponding FIFO buffer.
Do not write to this bit in GL_SLEEP mode.

PLS[2:0] Bits (Payload Size Setting)

The PLS[2:0] bits define the message data payload size in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.
For details, refer to section 46.6, FIFO Buffers and Message Buffer Configuration.
These bits can only be written in GL_RESET mode.

MODE Bit (Operation Mode Setting)

The MODE bit is used to select the operation mode of the common FIFO. When the MCU reset is applied, all the common FIFO are configured in receive FIFO mode.
This bit cannot be written in GL_OPERATION or GL_SLEEP mode.
Write to this bit only in GL_RESET mode.

ITCS Bit (Interval Timer Clock Source Select)

The ITCS bit is used to select the clock source for the transmission interval timer.
Do not write to this bit in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.
Do not write 1 to this bit when CAN FD communication is used.

Note: The bit time clock can vary depending on the nominal bit rate and data bit rate configuration.

ITR Bit (Interval Timer Resolution Select)

The ITR bit is used to select the resolution of the reference clock for the transmission interval timer.
This bit cannot be written in GL_SLEEP mode. Do not write to this bit when the CFE bit is set to 1.

CFIM Bit (Common FIFO Interrupt Mode Setting)

The CFIM bit is used to select the condition for the generation of common FIFO interrupts.
This bit cannot be written in GL_SLEEP mode.
Write to this bit only in GL_RESET mode.

CFITH[2:0] Bits (Common FIFO Receive Interrupt Threshold Setting)

The CFITH[2:0] bits are used to select the message counter value for the generation of common FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.
These bits cannot be written in GL_SLEEP mode.
The setting of the CFITH[2:0] bits is restricted by the value of the FDS[2:0] bits. For details, refer to section 46.6.2.1, FIFO Buffers Configuration.
Write to these bits only in GL_RESET mode.

LTM[1:0] Bits (Linked Transmit Message Buffer Select)

The LTM[1:0] bits are used to select the number of the transmit message buffer that links common FIFO configured in transmit FIFO mode, for transmission scanning.
These bits cannot be written in GL_OPERATION or GL_SLEEP mode.
Write to these bits only in GL_RESET mode.

FDS[2:0] Bits (FIFO Depth Setting)

The FDS[2:0] bits are used to select the FIFO depth in units of the number of messages. If the FIFO depth is configured to 0, the FIFO cannot be used.
These bits can only be written in GL_RESET mode.

TINT[7:0] Bits (Transmission Interval Setting)

The TINT[7:0] bits are used to select the delay in the start of transmission for all messages transmitted from the common FIFO configured in transmit FIFO mode. The delay is an integral multiple of the clock source cycle of the interval timer (reference clock period × 1, reference clock period × 10, or bit-time clock period).
These bits cannot be written in GL_SLEEP mode.
Do not write to these bits when the CFE bit is set to 1.
When the GCFG.ITP[15:0] bits are set to 0000h, set the TINT[7:0] bits to 00h.

46.2.28 Common FIFO 0 Status Register (CFSR0)

Address(es): CANFD.CFSR0 8747 0058h, CANFD_NS.CFSR0 0747 0058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	FLVL[5:0]						—	—	—	CFTIF	CFRIF	LOST	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Common FIFO Empty Flag	0: Message in common FIFO 1: No message in common FIFO (empty)	R
b1	FULL	Common FIFO Full Flag	0: Common FIFO is not full 1: Common FIFO is full	R
b2	LOST	Message Lost Flag	0: No message lost in common FIFO 1: Common FIFO message lost	R/(W) *1
b3	CFRIF	Common FIFO Receive Interrupt Flag	0: Common FIFO receive interrupt condition is not satisfied 1: Common FIFO receive interrupt condition is satisfied	R/(W) *1
b4	CFTIF	Common FIFO Transmit Interrupt Flag	0: Common FIFO transmit interrupt condition is not satisfied 1: Common FIFO transmit interrupt condition is satisfied	R/(W) *1
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	FLVL[5:0]	Common FIFO Fill Level	Indicate the number of messages stored in common FIFO	R
b31 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of messages stored in the corresponding FIFO buffers.

EMPTY Flag (Common FIFO Empty Flag)

The EMPTY flag is automatically set to 1 when:

- The CPU has read all messages from the FIFO buffer in receive FIFO mode
- All messages have been transmitted from the FIFO buffer in transmit FIFO mode
- The common FIFO is disabled by setting the CFCR0.CFE bit to 0
- The CANFD module enters GL_RESET mode
- The CAN channel enters CH_RESET mode in transmit FIFO mode.

The EMPTY flag is automatically set to 0 when:

- The first reception message is stored in the FIFO buffer in receive FIFO mode
- The first message to be transmitted is stored in the FIFO buffer in transmit FIFO mode.

FULL Flag (Common FIFO Full Flag)

The FULL flag is automatically set to 1 when the number of messages stored in the FIFO matches the configured FIFO depth.

The FULL flag is automatically set to 0 when:

- The number of messages stored in the FIFO is less than the configured FIFO depth
- The common FIFO is disabled by setting the CFCR0.CFE bit to 0
- The CANFD module enters GL_RESET mode
- The CAN channel enters CH_RESET mode in transmit FIFO mode.

LOST Flag (Message Lost Flag)

The LOST flag is automatically set to 1 whenever a message is lost due to attempted storage of a new message when FIFO buffer is already full in receive FIFO mode.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
The LOST flag is set to 0:

- By writing 0 to it
- When the CANFD module enters GL_RESET mode
- When the CAN channel enters CH_RESET mode in transmit FIFO mode.

CFRIF Flag (Common FIFO Receive Interrupt Flag)

The CFRIF flag is set to 1 when the configured interrupt condition is satisfied in receive FIFO mode.
The CFRIF flag is not cleared automatically if the common FIFO is disabled.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The CFRIF flag is set to 0:

- By writing 0 to it
- When the CANFD module enters GL_RESET mode.

CFTIF Flag (Common FIFO Transmit Interrupt Flag)

The CFTIF flag is set to 1 when the configured interrupt condition is satisfied in transmit FIFO mode.
The CFTIF flag is not cleared automatically if the common FIFO is disabled.
This flag can only be written in GL_HALT or GL_OPERATION mode. Also, if the common FIFO is configured as transmit FIFO mode, this bit can only be written when the CAN channel is not in CH_RESET mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The CFTIF flag is set to 0:

- By writing 0 to it
- When the CANFD module enters GL_RESET mode
- When the CAN channel enters CH_RESET mode in transmit FIFO mode.

FLVL[5:0] Bits (Common FIFO Fill Level)

The FLVL[5:0] bits indicate the following:

- The number of messages stored by the CPU and waiting to be transmitted in the transmit FIFO mode

- The number of CPU-readable messages stored by CANFD in receive FIFO mode.

The FLVL[5:0] bits are automatically set to 000000b when:

- The CFCR0.CFE bit is set to 0 (common FIFO is disabled)
- The CANFD module enters GL_RESET mode
- The CAN channel enters CH_RESET mode in transmit FIFO mode.

46.2.29 Common FIFO 0 Pointer Control Register (CFPCR0)

Address(es): CANFD.CFPCR0 8747 005Ch, CANFD_NS.CFPCR0 0747 005Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register can be used to increment the read or write pointer of the corresponding common FIFO.
When the value 000000FFh is written into this register, the read pointer of the corresponding common FIFO in receive FIFO mode, or the write pointer of the corresponding common FIFO in transmit FIFO mode moves to the next FIFO entry.
The read value from this register is always 00000000h.
This register can only be written in GL_HALT or GL_OPERATION mode.
Write to this register only when:

- The common FIFO is enabled and is not empty in receive FIFO mode
- The common FIFO is enabled and is not full in transmit FIFO mode.

Do not write to the CFPCR0 register when DTC/DMA transfer is enabled (DTCR.CFDTE0 bit = 1).

46.2.30 FIFO Empty Status Register (FESR)

Address(es): CANFD.FESR 8747 0060h, CANFD_NS.FESR 0747 0060h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFEMP0	—	—	—	—	—	—	RFEMP1	RFEMP0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	RFEMP0	Receive FIFO 0 Empty Flag	0: Message in corresponding receive FIFO 0 1: No message in corresponding receive FIFO 0 (empty)	R
b1	RFEMP1	Receive FIFO 1 Empty Flag	0: Message in corresponding receive FIFO 1 1: No message in corresponding receive FIFO 1 (empty)	R
b7 to b2	—	Reserved	These bits are read as 0.	R
b8	CFEMP0	Common FIFO 0 Empty Flag	0: Message in corresponding common FIFO 0 1: No message in corresponding common FIFO 0 (empty)	R
b31 to b9	—	Reserved	These bits are read as 0.	R

This register shows the status of the empty flags of the FIFO buffers.

RFEMP0 Flag (Receive FIFO 0 Empty Flag)

The RFEMP0 flag is set to 1 when the RFSR0.EMPTY flag is set to 1, and is set to 0 when the RFSR0.EMPTY flag is set to 0.

The RFEMP0 flag is set to 1 when the CANFD module enters GL_RESET mode.

RFEMP1 Flag (Receive FIFO 1 Empty Flag)

The RFEMP1 flag is set to 1 when the RFSR1.EMPTY flag is set to 1, and is set to 0 when the RFSR1.EMPTY flag is set to 0.

The RFEMP1 flag is set to 1 when the CANFD module enters GL_RESET mode.

CFEMP0 Flag (Common FIFO 0 Empty Flag)

The CFEMP0 flag is set to 1 when the CFSR0.EMPTY flag is set to 1, and is set to 0 when the CFSR0.EMPTY flag is set to 0.

The CFEMP0 flag is set to 1 when the CANFD module enters GL_RESET mode.

46.2.31 FIFO Full Status Register (FFSR)

Address(es): CANFD.FFSR 8747 0064h, CANFD_NS.FFSR 0747 0064h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFFUL0	—	—	—	—	—	—	RFFUL1	RFFUL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFFUL0	Receive FIFO 0 Full Flag	0: Corresponding receive FIFO 0 is not full 1: Corresponding receive FIFO 0 is full	R
b1	RFFUL1	Receive FIFO 1 Full Flag	0: Corresponding receive FIFO 1 is not full 1: Corresponding receive FIFO 1 is full	R
b7 to b2	—	Reserved	These bits are read as 0.	R
b8	CFFUL0	Common FIFO 0 Full Flag	0: Common FIFO 0 is not full 1: Common FIFO 0 is full	R
b31 to b9	—	Reserved	These bits are read as 0.	R

This register shows the status of the full flags of the FIFO buffers.

RFFUL0 Flag (Receive FIFO 0 Full Flag)

The RFFUL0 flag is set to 1 when the RFSR0.FULL flag is set to 1, and is set to 0 when the RFSR0.FULL flag is set to 0.

The RFFUL0 flag is set to 0 when the CANFD module enters GL_RESET mode.

RFFUL1 Flag (Receive FIFO 1 Full Flag)

The RFFUL1 flag is set to 1 when the RFSR1.FULL flag is set to 1, and is set to 0 when the RFSR1.FULL flag is set to 0.

The RFFUL1 flag is set to 0 when the CANFD module enters GL_RESET mode.

CFFUL0 Flag (Common FIFO 0 Full Flag)

The CFFUL0 flag is set to 1 when the CFSR0.FULL flag is set to 1 is set to 0 when the CFSR0.FULL flag is set to 0.

The CFFUL0 flag is set to 0 when the CANFD module enters GL_RESET mode.

46.2.32 FIFO Message Lost Status Register (FMLSR)

Address(es): CANFD.FMLSR 8747 0068h, CANFD_NS.FMLSR 0747 0068h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFML0	—	—	—	—	—	—	RFML1	RFML0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFML0	Receive FIFO 0 Message Lost Flag	0: No message lost has occurred in receive FIFO 0 1: Message lost has occurred in receive FIFO 0	R
b1	RFML1	Receive FIFO 1 Message Lost Flag	0: No message lost has occurred in receive FIFO 1 1: Message lost has occurred in receive FIFO 1	R
b7 to b2	—	Reserved	These bits are read as 0.	R
b8	CFML0	Common FIFO 0 Message Lost Flag	0: No message lost has occurred in common FIFO 0 1: Message lost has occurred in common FIFO 0	R
b31 to b9	—	Reserved	These bits are read as 0.	R

This register shows the status of the message lost flags of the FIFO buffers.

RFML0 Flag (Receive FIFO 0 Message Lost Flag)

The RFML0 flag is set to 1 when the RFSR0.LOST flag is set to 1, and is set to 0 when the RFSR0.LOST flag is set to 0. The RFML0 flag is cleared when the CANFD module enters GL_RESET mode.

RFML1 Flag (Receive FIFO 1 Message Lost Flag)

The RFML1 flag is set to 1 when the RFSR1.LOST flag is set to 1, and is set to 0 when the RFSR1.LOST flag is set to 0. The RFML1 flag is cleared when the CANFD module enters GL_RESET mode.

CFML0 Flag (Common FIFO 0 Message Lost Flag)

The CFML0 flag is set to 1 when the CFSR0.LOST flag is set to 1, and is set to 0 when the CFSR0.LOST flag is set to 0. The CFML0 flag is cleared when the CANFD module enters GL_RESET mode.

46.2.33 Receive FIFO Interrupt Status Register (RFISR)

Address(es): CANFD.RFISR 8747 006Ch, CANFD_NS.RFISR 0747 006Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFIF1	RFIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFIF0	Receive FIFO 0 Interrupt Flag	0: Receive FIFO 0 interrupt condition is not satisfied 1: Receive FIFO 0 interrupt condition is satisfied	R
b1	RFIF1	Receive FIFO 1 Interrupt Flag	0: Receive FIFO 1 interrupt condition is not satisfied 1: Receive FIFO 1 interrupt condition is satisfied	R
b31 to b2	—	Reserved	These bits are read as 0.	R

This register shows the status of the interrupt flags of the receive FIFOs.

RFIF0 Flag (Receive FIFO 0 Interrupt Flag)

The RFIF0 flag is set to 1 when the RFSR0.RFIF flag is set to 1, and is set to 0 when the RFSR0.RFIF flag is set to 0. The RFIF0 flag is cleared when the CANFD module enters GL_RESET mode.

RFIF1 Flag (Receive FIFO 1 Interrupt Flag)

The RFIF1 flag is set to 1 when the RFSR1.RFIF flag is set to 1, and is set to 0 when the RFSR1.RFIF flag is set to 0. The RFIF1 flag is cleared when the CANFD module enters GL_RESET mode.

46.2.34 DMA Transfer Control Register (DTCR)

Address(es): CANFD.DTCR 8747 00C8h, CANFD_NS.DTCR 0747 00C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFDTE0	—	—	—	—	—	—	RFDTE1	RFDTE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFDTE0	Receive FIFO 0 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b1	RFDTE1	Receive FIFO 1 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	CFDTE0	Common FIFO 0 DMA Transfer Enable	0: DTC/DMA transfer request is disabled 1: DTC/DMA transfer request is enabled	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the start and stop of DTC/DMA transfer operation.

RFDTE0 Bit (Receive FIFO 0 DMA Transfer Enable)

The RFDTE0 bit enables or disables DTC/DMA transfer request for receive FIFO 0.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFD module enters GL_RESET mode.

RFDTE1 Bit (Receive FIFO 1 DMA Transfer Enable)

The RFDTE1 bit enables or disables DTC/DMA transfer request for receive FIFO 1.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
This bit is set to 0 when the CANFD module enters GL_RESET mode.

CFDTE0 Bit (Common FIFO 0 DMA Transfer Enable)

The CFDTE0 bit enables or disables DTC/DMA transfer request for common FIFO.
This bit cannot be set to 1 in GL_SLEEP or GL_RESET mode.
Do not enable DTC/DMA transfer for the common FIFO that is configured as transmit FIFO.
This bit is set to 0 when the CANFD module enters GL_RESET mode.

46.2.35 DMA Transfer Status Register (DTSR)

Address(es): CANFD.DTSR 8747 00CCh, CANFD_NS.DTSR 0747 00CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CFDTS0	—	—	—	—	—	—	RFDTS1	RFDTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFDTS0	Receive FIFO 0 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b1	RFDTS1	Receive FIFO 1 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b7 to b2	—	Reserved	These bits are read as 0.	R
b8	CFDTS0	Common FIFO 0 DMA Transfer Status Flag	0: DTC/DMA transfer is stopped state 1: DTC/DMA transfer is in progress	R
b31 to b9	—	Reserved	These bits are read as 0.	R

This register shows the status of the DTC/DMA transfer.

RFDTS0 Flag (Receive FIFO 0 DMA Transfer Status Flag)

The RFDTS0 flag is automatically set to 1 when the DTCR.RFDTE0 bit is set to 1 and the receive FIFO 0 is not empty. This flag is automatically set to 0 when the DTC/DMA transfer stops either because the DTCR.RFDTE0 bit is set to 0 or the receive FIFO 0 is empty.

When the DTCR.RFDTE0 bit is set to 0 while DTC/DMA transfer for the receive FIFO 0 is in progress, the RFDTS0 flag becomes 0 when the DTC/DMA transfer is completed.

This flag is set to 0 when the CANFD module enters GL_RESET mode.

RFDTS1 Flag (Receive FIFO 1 DMA Transfer Status Flag)

The RFDTS1 flag is automatically set to 1 when the DTCR.RFDTE1 bit is set to 1 and the receive FIFO 1 is not empty. This flag is automatically set to 0 when the DTC/DMA transfer stops either because the DTCR.RFDTE1 bit is set to 0 or the receive FIFO 1 is empty.

When the DTCR.RFDTE1 bit is set to 0 while DTC/DMA transfer for the receive FIFO 1 is in progress, the RFDTS1 flag becomes 0 when the DTC/DMA transfer is completed.

This flag is set to 0 when the CANFD module enters GL_RESET mode.

CFDTS0 Flag (Common FIFO 0 DMA Transfer Status Flag)

The CFDTS0 flag is automatically set to 1 when the DTCR.CFDTE0 bit is set to 1 and the common FIFO 0 is not empty. This flag is automatically set to 0 when the DTC/DMA transfer stops either because the DTCR.CFDTE0 bit is set to 0 or the common FIFO 0 is empty.

When the DTCR.CFDTE0 bit is set to 0 while DTC/DMA transfer for the common FIFO 0 is in progress, the CFDTS0 flag becomes 0 when the DTC/DMA transfer is complete.

This flag is set to 0 when the CANFD module enters GL_RESET mode.

46.2.36 Transmit Message Buffer n Control Register (TMCRn) (n = 0 to 3)

Address(es): CANFD.TMCR0 8747 0070h, CANFD.TMCR1 8747 0071h, CANFD.TMCR2 8747 0072h, CANFD.TMCR3 8747 0073h, CANFD_NS.TMCR0 0747 0070h, CANFD_NS.TMCR1 0747 0071h, CANFD_NS.TMCR2 0747 0072h, CANFD_NS.TMCR3 0747 0073h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	ONESHOT	TARQ	TXRQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXRQ	Transmission Request	0: Do not request a message transmission 1: Request a message transmission	R/W
b1	TARQ	Transmission Abort Request	0: Do not request to abort a message transmission 1: Request to abort a message transmission	R/W
b2	ONESHOT	One-shot Transmission Enable	0: One-shot transmission is disabled. 1: One-shot transmission is enabled.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register configures the transmit message buffer functions.

TXRQ Bit (Transmission Request)

When the TXRQ bit is set to 1, the CANFD module logic requests transmitting the message stored in the corresponding message buffer.

This bit can only be written in CH_HALT or CH_OPERATION mode.

This bit cannot be set to 1 if the corresponding transmit message buffer is linked to the common FIFO configured in transmit FIFO or is a part of the transmit queue.

This bit can be set to 1 only when the TMSRn.TXRF[1:0] flags are set to 00b.

This bit cannot be directly cleared by a CPU write access. The TXRQ bit is automatically set to 0:

- At the end of a successful transmission
- At the end of a transmission abort, requested by the TARQ bit
- When a CAN bus error or arbitration lost is detected if the ONESHOT bit is set to 1
- When the CANFD module enters GL_RESET or the CAN channel enters CH_RESET mode.

TARQ Bit (Transmission Abort Request)

When the TARQ bit is set to 1, the CANFD module logic requests aborting the transmission of the frame stored in the corresponding message buffer.

In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame will be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (pin for reception) before it starts transmission from the selected message buffer.

This bit can only be written in CH_HALT or CH_OPERATION mode. This bit can be set to 1 only when the TXRQ bit is set to 1.

This bit cannot be set to 0 by a CPU write access. This bit is set to 0 if writing 1 by CPU and clearing by the CAN channel occur at the same time.

The TARQ bit is automatically set to 0:

- At the end of a successful transmission
- At the end of a transmission abort

- When a CAN bus error or arbitration lost is detected
- When the CANFD module enters GL_RESET or the CAN channel enters CH_RESET mode.

ONESHOT Bit (One-shot Transmission Enable)

When the ONESHOT bit is set to 1, the CANFD module logic request transmitting the message only once.
If the transmission is successful, the TMSRn.TXRF[1:0] flags are set to 10b or 11b. Otherwise, the transmission is automatically aborted and TMSRn.TXRF[1:0] flags are set to 01b due to a bus error or an arbitration lost detection.
The ONESHOT bit remains 1 if the transmission has completed successfully or aborted due to a CAN bus error or an arbitration lost detection.
This bit can only be written in CH_HALT or CH_OPERATION mode.
Set this bit at the same time as the TXRQ bit. Clear this bit with a write access.
If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.
The ONESHOT bit is automatically set to 0 when the CANFD module enters GL_RESET or the CAN channel enters CH_RESET mode.

46.2.37 Transmit Message Buffer n Status Register (TMSRn) (n = 0 to 3)

Address(es): CANFD.TMSR0 8747 0074h, CANFD.TMSR1 8747 0075h, CANFD.TMSR2 8747 0076h, CANFD.TMSR3 8747 0077h, CANFD_NS.TMSR0 0747 0074h, CANFD_NS.TMSR1 0747 0075h, CANFD_NS.TMSR2 0747 0076h, CANFD_NS.TMSR3 0747 0077h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	TARQS	TXRQS	TXRF[1:0]		TXSF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXSF	Transmission Status Flag	0: No transmission is in progress. 1: Transmission is in progress.	R
b2, b1	TXRF[1:0]	Transmission Result Flag	b2 b1 0 0: No result (transmission is not requested or in progress) 0 1: Transmission was aborted. 1 0: Transmission was successful and transmission abort is not requested. 1 1: Transmission was successful and transmission abort is requested.	R/W
b3	TXRQS	Transmission Request Status Flag	0: Transmission is not requested. 1: Transmission is requested.	R
b4	TARQS	Transmission Abort Request Status Flag	0: Transmission abort is not requested. 1: Transmission abort is requested.	R
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register shows the status of the transmission and transmission abort for the transmit message buffers.

TXSF Flag (Transmission Status Flag)

The TXSF flag is automatically set to 1 at the start of the transmission from the corresponding transmit message buffer. This flag is automatically set to 0 when:

- Transmission stops
- The CANFD module enters GL_RESET mode
- The CAN channel enters CH_RESET mode.

TXRF[1:0] Flags (Transmission Result Flag)

The TXRF[1:0] flags show the transmission result for the transmit message buffer.
These flags can only be written in CH_HALT or CH_OPERATION mode.
Each bit of these flags is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
The TXRF[1:0] flags are automatically set to 00b when the CANFD module enters GL_RESET or the CAN channel enters CH_RESET mode.

TXRQS Flag (Transmission Request Status Flag)

The TXRQS flag reflects the value of the TMCRn.TXRQ bit.
The TXRQS flag is set to 1 when the TMCRn.TXRQ bit is set to 1. This flag is set to 0 when the TMCRn.TXRQ bit is set to 0.

TARQS Flag (Transmission Abort Request Status Flag)

The TARQS flag reflects the value of the TMCRn.TARQ bit.
The TARQS flag is set to 1 when the TMCRn.TARQ bit is set to 1. This flag is set to 0 when the TMCRn.TARQ bit is set to 0.

46.2.38 Transmit Message Buffer Transmission Request Status Register 0 (TMTRSR0)

Address(es): CANFD.TMTRSR0 8747 0078h, CANFD_NS.TMTRSR0 0747 0078h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	TXRQS3	TXRQS2	TXRQS1	TXRQS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXRQS0	Transmit Message Buffer 0 Transmission Request Status Flag	0: Transmission is not requested for the transmit message buffer 0. 1: Transmission is requested for the transmit message buffer 0	R
b1	TXRQS1	Transmit Message Buffer 1 Transmission Request Status Flag	0: Transmission is not requested for the transmit message buffer 1. 1: Transmission is requested for the transmit message buffer 1.	R
b2	TXRQS2	Transmit Message Buffer 2 Transmission Request Status Flag	0: Transmission is not requested for the transmit message buffer 2. 1: Transmission is requested for the transmit message buffer 2.	R
b3	TXRQS3	Transmit Message Buffer 3 Transmission Request Status Flag	0: Transmission is not requested for the transmit message buffer 3. 1: Transmission is requested for the transmit message buffer 3.	R
b31 to b4	—	Reserved	These bits are read as 0.	R

This register shows the status of the transmission request in each transmit message buffer.

TXRQSn Flag (Transmit Message Buffer n Transmission Request Status Flag) (n = 0 to 3)

The TXRQSn flag indicates status of the TMCRn.TXRQ bit.

Each flag is set to 1 only when the TMCRn.TXRQ bit is set to 1 and the message buffer does not belong to a transmit queue.

Each flag is automatically set to 0 when:

- The TMCRn.TXRQ bit is set to 0
- The CANFD module enters GL_RESET mode
- The CAN channel enters CH_RESET mode.

46.2.39 Transmit Message Buffer Transmission Abort Request Status Register 0 (TMARSR0)

Address(es): CANFD.TMARSR0 8747 007Ch, CANFD_NS.TMARSR0 0747 007Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TARQS0	Transmit Message Buffer 0 Transmission Abort Request Status Flag	0: Transmission abort is not requested for the transmit message buffer 0 1: Transmission abort is requested for the transmit message buffer 0	R
b1	TARQS1	Transmit Message Buffer 1 Transmission Abort Request Status Flag	0: Transmission abort is not requested for the transmit message buffer 1 1: Transmission abort is requested for the transmit message buffer 1	R
b2	TARQS2	Transmit Message Buffer 2 Transmission Abort Request Status Flag	0: Transmission abort is not requested for the transmit message buffer 2 1: Transmission abort is requested for the transmit message buffer 2	R
b3	TARQS3	Transmit Message Buffer 3 Transmission Abort Request Status Flag	0: Transmission abort is not requested for the transmit message buffer 3 1: Transmission abort is requested for the transmit message buffer 3	R
b31 to b4	—	Reserved	These bits are read as 0.	R

This register shows the status of the transmission abort request in each transmit message buffer.

TARQSn Flag (Transmit Message Buffer n Transmission Abort Request Status Flag) (n = 0 to 3)

The TARQSn flag indicates status of the TMCRn.TARQ bit.

Each flag is set to 1 when the TMCRn.TARQ bit is set to 1 or the message buffer belongs to a transmit queue.

Each flag is automatically set to 0 when:

- The TMCRn.TARQ bit is set to 0
- The CANFD module enters GL_RESET mode
- The CAN channel enters CH_RESET mode.

46.2.40 Transmit Message Buffer Transmission Completion Status Register 0 (TMTCSR0)

Address(es): CANFD.TMTCSR0 8747 0080h, CANFD_NS.TMTCSR0 0747 0080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	TXCF3	TXCF2	TXCF1	TXCF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXCF0	Transmit Message Buffer 0 Transmission Complete Flag	0: Transmission is not completed for the transmit message buffer 0 1: Transmission is completed for the transmit message buffer 0	R
b1	TXCF1	Transmit Message Buffer 1 Transmission Complete Flag	0: Transmission is not completed for the transmit message buffer 1 1: Transmission is completed for the transmit message buffer 1	R
b2	TXCF2	Transmit Message Buffer 2 Transmission Complete Flag	0: Transmission is not completed for the transmit message buffer 2 1: Transmission is completed for the transmit message buffer 2	R
b3	TXCF3	Transmit Message Buffer 3 Transmission Complete Flag	0: Transmission is not completed for the transmit message buffer 3 1: Transmission is completed for the transmit message buffer 3	R
b31 to b4	—	Reserved	These bits are read as 0.	R

This register shows the transmission completion status for each transmit message buffer.

TXCFn Flag (Transmit Message Buffer n Transmission Completion Status) (n = 0 to 3)

The TXCFn flag indicates the transmission completion status for the transmit message buffer n.

Each flag is automatically set to 1 when the TMSRn.TXRF[1] bit is set to 1.

Each flag is automatically set to 0 when:

- The TMSRn.TXRF[1] bit is set to 0
- The CANFD module enters GL_RESET mode
- The CAN channel enters CH_RESET mode.

46.2.41 Transmit Message Buffer Transmission Abort Status Register 0 (TMTASR0)

Address(es): CANFD.TMTASR0 8747 0084h, CANFD_NS.TMTASR0 0747 0084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	TAF3	TAF2	TAF1	TAF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TAF0	Transmit Message Buffer 0 Transmission Abort Status Flag	0: Transmission is not aborted for the transmit message buffer 0. 1: Transmission is aborted for the transmit message buffer 0.	R
b1	TAF1	Transmit Message Buffer 1 Transmission Abort Status Flag	0: Transmission is not aborted for the transmit message buffer 1. 1: Transmission is aborted for the transmit message buffer 1.	R
b2	TAF2	Transmit Message Buffer 2 Transmission Abort Status Flag	0: Transmission is not aborted for the transmit message buffer 2. 1: Transmission is aborted for the transmit message buffer 2.	R
b3	TAF3	Transmit Message Buffer 3 Transmission Abort Status Flag	0: Transmission is not aborted for the transmit message buffer 3. 1: Transmission is aborted for the transmit message buffer 3.	R
b31 to b4	—	Reserved	These bits are read as 0.	R

This register shows the transmission abort status for each transmit message buffer.

TAFn Flag (Transmit Message Buffer n Transmission Abort Status Flag) (n = 0 to 3)

The TAFn flag indicates the transmission abort status for the transmit message buffer n.

Each flag is automatically set to 1 when the TMSRn.TXRF[1:0] flags are set to 01b.

Each flag is automatically set to 0 when:

- The TMSRn.TXRF[1:0] flags are set to 00b
- The CANFD module enters GL_RESET mode
- The CAN channel enters CH_RESET mode.

46.2.42 Transmit Message Buffer Interrupt Enable Register (TMIER0)

Address(es): CANFD.TMIER0 8747 0088h, CANFD_NS.TMIER0 0747 0088h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	TMIE3	TMIE2	TMIE1	TMIE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMIE0	Transmit Message Buffer 0 Interrupt Enable	0: Interrupt for transmit message buffer 0 is disabled. 1: Interrupt for transmit message buffer 0 is enabled.	R/W
b1	TMIE1	Transmit Message Buffer 1 Interrupt Enable	0: Interrupt for transmit message buffer 1 is disabled. 1: Interrupt for transmit message buffer 1 is enabled.	R/W
b2	TMIE2	Transmit Message Buffer 2 Interrupt Enable	0: Interrupt for transmit message buffer 2 is disabled. 1: Interrupt for transmit message buffer 2 is enabled.	R/W
b3	TMIE3	Transmit Message Buffer 3 Interrupt Enable	0: Interrupt for transmit message buffer 3 is disabled. 1: Interrupt for transmit message buffer 3 is enabled.	R/W
b31 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register enables or disables the interrupt for each transmit message buffer.

TMIEn Bit (Transmit Message Buffer n Interrupt Enable) (n = 0 to 3)

If the TMIEn bit is set to 1, an interrupt is generated when transmission from the transmit message buffer n is completed successfully.

Refer to section 46.10, Interrupts and DTC/DMA Requests for the specification of the interrupt for transmit message buffer.

This bit cannot be written in GL_SLEEP mode.

Do not write to the TMIEn bit when:

- The CAN channel is in CH_SLEEP mode
- The transmit message buffer n is part of a transmit queue
- The transmit message buffer n is linked to a common FIFO by the CFCR0.LTM[1:0] bits.

46.2.43 Transmit Queue 0 Configuration Register (TQCR0)

Address(es): CANFD2.TQCR0 8747 008Ch, CANFD2_NS.TQCR0 0747 008Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	QDS[1:0]		TQIM	—	TQIE	—	—	—	—	TQE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TQE	Transmit Queue Enable	0: Transmit queue is disabled. 1: Transmit queue is enabled.	R/W
b4 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	TQIE	Transmit Queue Interrupt Enable	0: Transmit queue transmission interrupt is disabled. 1: Transmit queue transmission interrupt is enabled.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	TQIM	Transmit Queue Interrupt Mode Setting	0: When the last message is successfully transmitted 1: At every successful transmission	R/W
b9, b8	QDS[1:0]	Queue Depth Setting	b9 b8 0 0: 0 messages (disabled) 0 1: Setting prohibited 1 0: 3 messages (transmit message buffer 0 to 2) 1 1: 4 messages (transmit message buffer 0 to 3)	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to configure the transmit queue 0.

TQE Bit (Transmit Queue Enable)

The TQE bit enables the transmit queue. When the TQE bit is set to 1, the transmit message buffer is used to configure the transmit queue.

The TQE bit cannot be set to 1 if the configured transmit queue depth is 0 (QDS[1:0] = 00b).

This bit cannot be written in GL_SLEEP mode.

Also, this bit cannot be written in CH_RESET or CH_SLEEP mode.

The TQE bit is automatically set to 0 when the CAN channel enters CH_RESET mode.

TQIE Bit (Transmit Queue Interrupt Enable)

When the TQIE bit is set to 1, an interrupt is generated based on the setting of the TQIM bit.

This bit cannot be written in GL_SLEEP mode.

Do not write to this bit when the CAN channel is in CH_SLEEP mode.

TQIM Bit (Transmit Queue Interrupt Mode Setting)

The TQIM bit selects the interrupt generation condition for the transmit queue.

This bit cannot be written in GL_SLEEP mode.

Do not write to this bit when the CAN channel is in CH_SLEEP, CH_HALT, or CH_OPERATION mode.

QDS[1:0] Bits (Queue Depth Setting)

The QDS[1:0] bits select the depth of the transmission queue.

When these bits are set to 10b, the message buffers 0 to 2 are used, and when these bits are set to 11b, the message buffers 0 to 3 are used.
These bits cannot be written in GL_SLEEP mode.
Also, these bits cannot be written in CH_HALT or CH_OPERATION mode.
Do not write to these bits when the CAN channel is in CH_SLEEP mode.

46.2.44 Transmit Queue 0 Status Register (TQSR0)

Address(es): CANFD2.TQSR0 8747 0090h, CANFD2_NS.TQSR0 0747 0090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FLVL[2:0]			—	—	—	—	—	TQIF	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Transmit Queue Empty Flag	0: There is at least one message in transmit queue 1: No message in transmit queue (empty)	R
b1	FULL	Transmit Queue Full Flag	0: Transmit queue is not full 1: Transmit queue is full	R
b2	TQIF	Transmit Queue Interrupt Flag	0: Transmit queue interrupt condition is not satisfied 1: Transmit queue interrupt condition is satisfied	R/(W) *1
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b10 to b8	FLVL[2:0]	Transmit Queue Fill Level	Indicates the number of messages in the transmit queue	R
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of the transmit queue 0.

EMPTY Flag (Transmit Queue Empty Flag)

This flag is automatically set to 1 when:

- The TQCR0.TQE bit is set to 0 (transmit queue is disabled)
- No messages are stored in the transmit queue
- The last message is transmitted from the transmit queue
- The CAN channel enters CH_RESET mode.

This flag is automatically set to 0 when the first message to be transmitted is stored in the transmit queue.

FULL Flag (Transmit Queue Full Flag)

The FULL flag is automatically set to 1 when the number of messages stored in the transmit queue matches the configured transmit queue depth.

This flag is automatically set to 0 when:

- The number of messages stored in the transmit queue is less than the configured transmit queue depth
- The CAN channel enters CH_RESET mode.

TQIF Flag (Transmit Queue Interrupt Flag)

The TQIF flag is not cleared automatically if the transmit queue is disabled.

When stopping the transmit queue, this flag should be cleared, after setting the TQCR0.TQE bit to 0 and checking an empty state of transmit queue.

Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.

This flag is automatically set to 1 when the configured interrupt condition is satisfied for the transmit queue.

This flag is set to 0:

- By writing 0 to it
- When the CAN channel enters CH_RESET mode.

This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag cannot be written in CH_SLEEP or CH_RESET mode.

FLVL[2:0] Bits (Transmit Queue Fill Level)

The FLVL[2:0] bits indicates the number of messages in the transmit queue.
These bits are automatically set to 000b when the CAN channel enters CH_RESET mode.

46.2.45 Transmit Queue 0 Pointer Control Register (TQPCR0)

Address(es): CANFD2.TQPCR0 8747 0094h, CANFD2_NS.TQPCR0 0747 0094h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to increment the write pointer to the transmit queue.
When the value 000000FFh is written to this register, the write pointer to the transmit queue is updated and transmission of the existing message is requested.
The read value from this register is always 00000000h.
This register cannot be written in CH_SLEEP or CH_RESET mode.
Write to this register only when:

- The transmit queue is enabled and not full.

46.2.46 Transmission History Configuration Register (THCR)

Address(es): CANFD2.THCR 8747 0098h, CANFD2_NS.THCR 0747 0098h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	THRC	THIM	THIE	—	—	—	—	—	—	—	THE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	THE	Transmission History Enable	0: Transmission history buffer is disabled 1: Transmission history buffer is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	THIE	Transmission History Interrupt Enable	0: Transmission history interrupt is disabled 1: Transmission history interrupt is enabled	R/W
b9	THIM	Transmission History Interrupt Mode Setting	0: Interrupt is generated if transmission history level reaches 3/4 of the transmission history depth 1: Interrupt is generated for every successfully stored entry	R/W
b10	THRC	Transmission History Recording Condition Setting	0: Transmit FIFO + Transmit queue 1: Transmit message buffer + Transmit FIFO + Transmit queue	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register configures the transmission history functions.

THE Bit (Transmission History Enable)

The THE bit enables the transmission history buffer when it is set to 1.
This bit cannot be written in CH_RESET or CH_SLEEP mode.
This bit is automatically set to 0 when the CAN channel enters CH_RESET mode.

THIE Bit (Transmission History Interrupt Enable)

The THIE bit enables the generation of the transmission history interrupt when it is set to 1.
This bit cannot be written in GL_SLEEP mode.

THIM Bit (Transmission History Interrupt Mode Setting)

The THIM bit selects the transmission history interrupt generation condition.
This bit cannot be written in GL_SLEEP mode.
Do not write to this bit in GL_HALT or GL_OPERATION mode.

THRC Bit (Transmission History Recording Condition Setting)

The THRC bit selects the condition for storing an entry in the transmission history buffer after successful transmission.
This bit cannot be written in GL_SLEEP mode.
Do not write to this bit in GL_HALT or GL_OPERATION mode.

46.2.47 Transmission History Status Register (THSR)

Address(es): CANFD2.THSR 8747 009Ch, CANFD2_NS.THSR 0747 009Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	FLVL[3:0]				—	—	—	—	THIF	LOST	FULL	EMPTY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	EMPTY	Transmission History Empty Flag	0: There is a transmission history in the transmission history buffer 1: There is no transmission history in the transmission history buffer (empty)	R
b1	FULL	Transmission History Full Flag	0: Transmission history buffer is not full 1: Transmission history buffer is full	R
b2	LOST	Transmission History Lost Flag	0: Transmission history has not been lost 1: Transmission history has been lost	R/(W) *1
b3	THIF	Transmission History Interrupt Flag	0: Transmission history interrupt condition is not satisfied 1: Transmission history interrupt condition is satisfied	R/(W) *1
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b8	FLVL[3:0]	Transmission History Fill Level	Number of transmission histories stored in transmission history buffer	R
b31 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing 1 has no effect. This flag is cleared by writing 0 to it.

This register shows the status of data stored in the transmission history buffer.

EMPTY Flag (Transmission History Empty Flag)

This flag is automatically set to 0 when the first transmission history is stored to the transmission history buffer.
This flag is automatically set to 1 when:

- The CPU has read all the transmission histories from the transmission history buffer
- The THCR.THE bit is set to 0 (transmission history buffer is disabled)
- The CAN channel enters CH_RESET mode.

FULL Flag (Transmission History Full Flag)

The FULL flag is automatically set to 1 when the number of transmission histories in the transmission history buffer is eight.
This flag is automatically set to 0 when:

- The number of transmission histories in the transmission history buffer is less than eight
- The THCR.THE bit is set to 0 (transmission history buffer is disabled)
- The CAN channel enters CH_RESET mode.

LOST Flag (Transmission History Lost Flag)

The LOST flag is set to 1 when a new transmission history cannot be stored because the related transmission history buffer is already full.

This flag can only be written in CH_HALT or CH_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is set to 0:

- By writing 0 to it
- When the CAN channel enters CH_RESET mode.

THIF Flag (Transmission History Interrupt Flag)

The THIF flag is set to 1 when the configured interrupt condition is satisfied.
This flag can only be written in CH_HALT or CH_OPERATION mode.
Do not use the bit clear instruction to clear the flag. Set only the flags to be cleared to 0 and the other flags to 1, and write the data in 32-bit units using MOV instruction.
This flag is set to 1 if clearing by write access and setting by the CAN channel occur at the same time.
This flag is set to 0:

- By writing 0 to it
- When the CAN channel enters CH_RESET mode.

FLVL[3:0] Bits (Transmission History Fill Level)

The FLVL[3:0] bits show the number of transmission histories stored in the transmission history buffer.
These bits are automatically set to 0000b when the CAN channel enters CH_RESET mode.

46.2.48 Transmission History Access Register 0 (THACR0)

Address(es): CANFD2.THACR0 8747 0740h, CANFD2_NS.THACR0 0747 0740h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	BN[1:0]		BT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BT[2:0]	Transmitted Buffer Type	b2 b0 0 0 1: Transmit message buffer 0 1 0: Common FIFO 1 0 0: Transmit Queue	R
b4, b3	BN[1:0]	Transmitted Buffer Number	Number of the message buffer	R
b15 to b5	—	Reserved	These bits are read as 0.	R
b31 to b16	TS[15:0]	Transmitted Timestamp	Transmit timestamp value	R

This register is used to access to the histories in the transmission history buffer based on the read pointer value.

BT[2:0] Bits (Transmitted Buffer Type)

The BT[2:0] bits indicate which type of buffer the read history came from.

BN[1:0] Bits (Transmitted Buffer Number)

The BN[1:0] bits indicate which buffer number the read history came from.
For a common FIFO, these bits indicate the number of the linked transmit message buffer.

TS[15:0] Bits (Transmitted Timestamp)

The TS[15:0] bits indicate the timestamp used by the software driver.

46.2.49 Transmission History Access Register 1 (THACR1)

Address(es): CANFD2.THACR1 8747 0744h, CANFD2_NS.THACR1 0747 0744h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	PTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	PTR[15:0]	Transmitted Pointer	Stores the value of the PTR[15:0] field attached to the transmit message	R
b17, b16	IFL[1:0]	Transmitted Information Label	Stores the value of the IFL[1:0] field attached to the transmit message	R
b31 to b18	—	Reserved	These bits are read as 0.	R

This register is used to access to the histories in the transmission history buffer based on the read pointer value.

PTR[15:0] Bits (Transmitted Pointer)

The PTR[15:0] bits store the value of the pointer field (TMBn.HF2.PTR[15:0] bits or CFB0.HF2.PTR[15:0] bits) attached to the transmit message.

IFL[1:0] Bits (Transmitted Information Label)

The IFL[1:0] bits store the value of the information label field (TMBn.HF2.IFL[1:0] bits or CFB0.HF2.IFL[1:0] bits) attached to the transmit message.

46.2.50 Transmission History Pointer Control Register (THPCR)

Address(es): CANFD2.THPCR 8747 00A0h, CANFD2_NS.THPCR 0747 00A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to increment the read pointer of the transmission history buffer.
When 000000FFh is written to this register, the read pointer of the transmission history buffer is moved to the next history.
The read value from this register is 00000000h.
This register can only be written in CH_HALT or CH_OPERATION mode.
Write 000000FFh to this register only when the transmission history buffer is enabled and not empty.

46.2.51 Global Reset Control Register (GRCR)

Address(es): CANFD.GRCR 8747 00D8h, CANFD_NS.GRCR 0747 00D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	SRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SRST	Software Reset	0: Releases the software reset 1: Initiates the software reset	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits control rewriting of the SRST bit. These bits are read as 00h.	W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SRST Bit (Software Reset)

When the SRST bit is set to 1, the CANFD module is in the same state as the MCU reset. When a reset is required, write 1 to this bit and then 0.

When the software reset is released, the CANFD module is in GL_SLEEP mode.

After a software reset, the RAM initialization sequence is not performed. Initialize the RAM with software.

Similarly, if a software reset is performed during RAM initialization, the RAM is not initialized. Initialize the RAM with software.

KEY[7:0] Bits (Key Code)

When rewriting the value of the SRST bit, set these bits to C4h at the same time (write this register in 32 bits).

46.2.52 Global Test Mode Configuration Register (GTMCR)

Address(es): CANFD.GTMCR 8747 00A8h, CANFD_NS.GTMCR 0747 00A8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	RTPS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b19 to b16	RTPS[3:0]	RAM Test Page Select	Select the page of RAM to be tested	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to specify the page number of the RAM to be tested in RAM test mode.

RTPS[3:0] Bits (RAM Test Page Select)

The RTPS[3:0] bits select the RAM page number that the CPU reads and writes when the CANFD module is in RAM test mode. Specify the page number in the range of 0 to 8.

Refer to section 46.9.2.1, RAM Test Mode for the specifications of the RAM test mode.

These bits cannot be written in GL_RESET or GL_SLEEP mode. Write to these bits only in GL_HALT mode.

These bits are automatically set to 0000b when the CAN channel enters GL_RESET mode.

46.2.53 Global Test Mode Enable Register (GTMER)

Address(es): CANFD.GTMER 8747 00ACh, CANFD_NS.GTMER 0747 00ACh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	RTME	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b2	RTME	RAM Test Mode Enable	0: RAM Test mode is disabled. 1: RAM Test mode is enabled.	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to control the global test modes of the CANFD module.

RTME Bit (RAM Test Mode Enable)

When the RTME bit is set to 1, the CANFD module is in RAM test mode. Refer to section 46.9.2.1, RAM Test Mode for the specifications of the RAM test mode.

This bit can only be set to 1 in GL_HALT mode. To exit the RAM test mode, set this bit to 0 in GL_HALT mode.

This bit is automatically set to 0 when the CANFD module enters GL_RESET mode.

46.2.54 Global CAN FD Configuration Register (GFDCFG)

Address(es): CANFD.GFDCFG 8747 00B0h, CANFD_NS.GFDCFG 0747 00B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TSCPS[1:0]		—	—	—	—	—	—	—	PXEDIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PXEDIS	Protocol Exception Event Detection Disable	0: Protocol exception event detection is enabled. 1: Protocol exception event detection is disabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	TSCPS[1:0]	Timestamp Capturing Point Select	b9 b8 0 0: Sample point of SOF (start of frame) 0 1: EOF (end of frame) when frame is taken valid 1 0: Sample point of SOF (Classical CAN frame), or sample point of res bit following the FDF bit (CAN FD frame) 1 1: Setting prohibited	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

PXEDIS Bit (Protocol Exception Event Detection Disable)

The PXEDIS bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is set to 1, protocol exception event detection is disabled, and an error frame is transmitted if a protocol exception (a recessive reserved bit following the FDF bit) is detected.

This bit can only be written in GL_RESET mode.

TSCPS[1:0] Bits (Timestamp Capturing Point Select)

The TSCPS[1:0] bits selects the capture point of the timestamps for transmitted and received messages.

When the TSCPS[1:0] bits are 10b, the timestamp is captured at the reserved bit following the FDF bit in CAN FD frames and at the SOF in Classical CAN frames.

These bits can only be written in GL_RESET mode.

46.2.55 Global Test Mode Lock Key Register (GTMLKR)

Address(es): CANFD.GTMLKR 8747 00B8h, CANFD_NS.GTMLKR 0747 00B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to unlock the protection for RAM test mode. Refer to section 46.9.2, Global Test Modes for the specification of the lock key.
To put the CANFD module into RAM test mode, two unlock keys must be written to this register in consecutive bus cycles.
The read value from this register is always 00000000h.
This register cannot be written in GL_SLEEP or GL_RESET mode.
Do not write to this register in GL_OPERATION mode.

46.2.56 RAM Test Page Access Register k (RTPARk) (k = 0 to 63)

Address(es): CANFD.RTPAR0 8747 0280h to CANFD.RTPAR63 8747 037Ch,
CANFD_NS.RTPAR0 0747 0280h to CANFD_NS.RTPAR63 0747 037Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register can be read or written in RAM test mode.
This register can only be written in GL_HALT mode when RAM test mode is enabled.

46.2.57 Acceptance Filter List Ignore Entry Setting Register (AFIGSR)

Address(es): CANFD.AFIGSR 8747 00C0h, CANFD_NS.AFIGSR 0747 00C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—		—	IGES[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	IGES[3:0]	Ignore Entry Select	Set the rule number to be ignored during acceptance filtering.	R/W
b31 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

IGES[3:0] Bits (Ignore Entry Select)

The IGES[3:0] bits are used to specify the rule number to update when updating the acceptance filter.

Write to these bits only when the AFIGER.IGEE bit is 0.

These bits cannot be written in GL_SLEEP mode.

46.2.58 Acceptance Filter List Ignore Entry Enable Register (AFIGER)

Address(es): CANFD.AFIGER 8747 00C4h, CANFD_NS.AFIGER 0747 00C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	IGEE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IGEE	Ignore Entry Enable	0: The value of the AFIGSR.IGES[3:0] bits is invalid. 1: The value of the AFIGSR.IGES[3:0] bits is valid.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits control rewriting of the IGEE bit. These bits are read as 00h.	W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

IGEE Bit (Ignore Entry Enable)

When the IGEE bit is set to 1, the entry selected by the AFIGSR.IGES[3:0] bits is ignored.

This bit is automatically set to 0 when the CANFD module enters GL_RESET mode.

KEY[7:0] Bits (Key Code)

When rewriting the value of the IGEE bit, set these bits to C4h at the same time (write this register in 32 bits).

46.2.59 Receive Message Buffer Interrupt Enable Register (RMIER)

Address(es): CANFD.RMIER 8747 0038h, CANFD_NS.RMIER 0747 0038h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RMIE15	RMIE14	RMIE13	RMIE12	RMIE11	RMIE10	RMIE9	RMIE8	RMIE7	RMIE6	RMIE5	RMIE4	RMIE3	RMIE2	RMIE1	RMIE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RMIE0	Receive Message Buffer 0 Interrupt Enable	0: Interrupt for receive message buffer 0 is disabled. 1: Interrupt for receive message buffer 0 is enabled.	R/W
b1	RMIE1	Receive Message Buffer 1 Interrupt Enable	0: Interrupt for receive message buffer 1 is disabled. 1: Interrupt for receive message buffer 1 is enabled.	R/W
b2	RMIE2	Receive Message Buffer 2 Interrupt Enable	0: Interrupt for receive message buffer 2 is disabled. 1: Interrupt for receive message buffer 2 is enabled.	R/W
b3	RMIE3	Receive Message Buffer 3 Interrupt Enable	0: Interrupt for receive message buffer 3 is disabled. 1: Interrupt for receive message buffer 3 is enabled.	R/W
b4	RMIE4	Receive Message Buffer 4 Interrupt Enable	0: Interrupt for receive message buffer 4 is disabled. 1: Interrupt for receive message buffer 4 is enabled.	R/W
b5	RMIE5	Receive Message Buffer 5 Interrupt Enable	0: Interrupt for receive message buffer 5 is disabled. 1: Interrupt for receive message buffer 5 is enabled.	R/W
b6	RMIE6	Receive Message Buffer 6 Interrupt Enable	0: Interrupt for receive message buffer 6 is disabled. 1: Interrupt for receive message buffer 6 is enabled.	R/W
b7	RMIE7	Receive Message Buffer 7 Interrupt Enable	0: Interrupt for receive message buffer 7 is disabled. 1: Interrupt for receive message buffer 7 is enabled.	R/W
b8	RMIE8	Receive Message Buffer 8 Interrupt Enable	0: Interrupt for receive message buffer 8 is disabled. 1: Interrupt for receive message buffer 8 is enabled.	R/W
b9	RMIE9	Receive Message Buffer 9 Interrupt Enable	0: Interrupt for receive message buffer 9 is disabled. 1: Interrupt for receive message buffer 9 is enabled.	R/W
b10	RMIE10	Receive Message Buffer 10 Interrupt Enable	0: Interrupt for receive message buffer 10 is disabled. 1: Interrupt for receive message buffer 10 is enabled.	R/W
b11	RMIE11	Receive Message Buffer 11 Interrupt Enable	0: Interrupt for receive message buffer 11 is disabled. 1: Interrupt for receive message buffer 11 is enabled.	R/W
b12	RMIE12	Receive Message Buffer 12 Interrupt Enable	0: Interrupt for receive message buffer 12 is disabled. 1: Interrupt for receive message buffer 12 is enabled.	R/W
b13	RMIE13	Receive Message Buffer 13 Interrupt Enable	0: Interrupt for receive message buffer 13 is disabled. 1: Interrupt for receive message buffer 13 is enabled.	R/W
b14	RMIE14	Receive Message Buffer 14 Interrupt Enable	0: Interrupt for receive message buffer 14 is disabled. 1: Interrupt for receive message buffer 14 is enabled.	R/W
b15	RMIE15	Receive Message Buffer 15 Interrupt Enable	0: Interrupt for receive message buffer 15 is disabled. 1: Interrupt for receive message buffer 15 is enabled.	R/W

This register enables or disables the interrupt for each receive message buffer.

RMIEn Bit (Receive Message Buffer n Interrupt Enable) (n = 0 to 15)

If the RMIEn bit is set to 1, an interrupt is generated when reception to the receive message buffer n is completed successfully.

Refer to section 46.10, Interrupts and DTC/DMA Requests for the specification of the receive message buffer interrupt.

This bit cannot be written in GL_SLEEP mode.

46.2.60 Identifier Bits Alignment

Base format (11-bit length identifier): ID-28 to ID-18 are located in b10 to b0, and b28 to b11 are 0.
Extended format (29-bit length identifier): ID-28 to ID-0 are located in b28 to b0

Table 46.4 Standard Identifier (11-bit format)

46.2.61 Message Buffer Structure

The message buffer configuration consists of four types of message buffers:

- Receive message buffer (RMBn)
- Receive FIFO (RFBn)
- Common FIFO (CFB0)
- Transmit message buffer (TMBn)

“n” is a message buffer number whose range changes depending on the type of message buffer.
Refer to Figure 46.32 for an overview of this configuration. For more information on the number and types of message buffers, refer to section 46.6, FIFO Buffers and Message Buffer Configuration.

46.2.61.1 Start Addresses

The start address of each message buffer is calculated using the number of related message buffer components.
The start addresses for each register in the message buffer are listed in Table 46.6.

Table 46.6 Start Address for Each Register of the Message Buffer Component

Message Buffer	Symbol	n	Register	p	Start Address (Only Secure Addresses Are Listed)
Receive Message Buffer	RMBn	0 to 7	HF0	—	8747 0920h + n × 4Ch
			HF1	—	8747 0924h + n × 4Ch
			HF2	—	8747 0928h + n × 4Ch
			DFp	0 to 15	8747 092Ch + n × 4Ch + p × 4
	RMBn	8 to 15	HF0	—	8747 0D20h + (n – 8) × 4Ch
			HF1	—	8747 0D24h + (n – 8) × 4Ch
			HF2	—	8747 0D28h + (n – 8) × 4Ch
			DFp	0 to 15	8747 0D2Ch + (n – 8) × 4Ch + p × 4
Receive FIFO	RFBn	0, 1	HF0	—	8747 0520h + n × 4Ch
			HF1	—	8747 0524h + n × 4Ch
			HF2	—	8747 0528h + n × 4Ch
			DFp	0 to 15	8747 052Ch + n × 4Ch + p × 4
Common FIFO	CFB0	0	HF0	—	8747 05B8h
			HF1	—	8747 05BCh
			HF2	—	8747 05C0h
			DFp	0 to 15	8747 05C4h + p × 4
Transmit Message Buffer	TMBn	0 to 3	HF0	—	8747 0604h + n × 4Ch
			HF1	—	8747 0608h + n × 4Ch
			HF2	—	8747 060Ch + n × 4Ch
			DFp	0 to 15	8747 0610h + n × 4Ch + p × 4

46.2.61.2 Receive Message Buffer n (RMBn) (n = 0 to 15)

The total number of the receive message buffers (RMB) is 16, as shown in Figure 46.32.
The receive message buffer consists of the following registers:

- RMBn.HF0
- RMBn.HF1
- RMBn.HF2
- RMBn.DF0 to RMBn.DF15

Table 46.7 shows the structure of this buffer.

Table 46.7 Structure of Receive Message Buffer

Address Offset	Symbol	Register Name	Contents
+00h	RMBn.HF0	Receive Message Buffer n Header Field 0	IDE, RTR, ID

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	Identifier	Standard ID/extended ID field	R
b29	—	Reserved	This bit is read as 0.	R
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R

This register stores the ID field, IDE bit, and RTR bit of the received message.

ID[28:0] Bits (Identifier)

The ID[28:0] bits store the standard or extended identifier field of message stored in the receive message buffer.
For alignment of these bits in base and extended format, refer to section 46.2.60, Identifier Bits Alignment.

RTR Bit (Remote Transmission Request)

The RTR bit stores the value of the RTR bit of the received message.
The RTR bit indicates whether the receive message buffer stores a data frame or a remote frame.

Note: There are no remote frames in CAN FD format. When a CAN FD frame is received, this bit reflects the value of the RRS bit.

IDE Bit (Identifier Extension)

The IDE bit stores the value of the IDE bit of the received message.
The IDE bit indicates whether the message stored in the receive message buffer has a standard identifier or extended identifier.

46.2.61.4 Receive Message Buffer n Header Field 1 (RMBn.HF1) (n = 0 to 15)

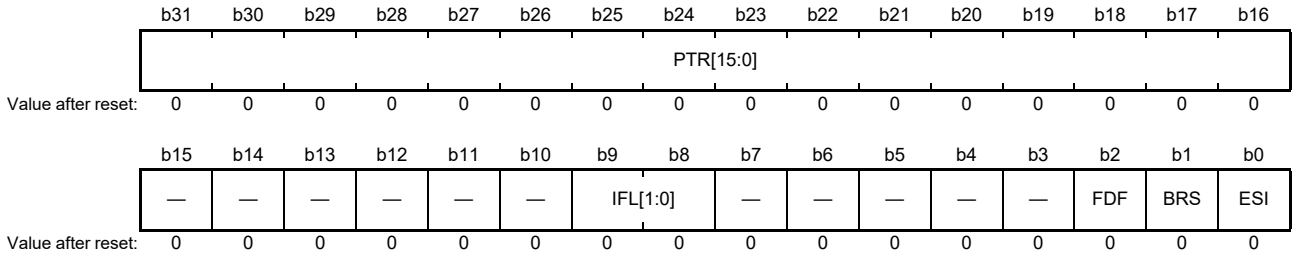
Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TS[15:0]	Timestamp	Timestamp value stored for the message in the receive message buffer	R
b27 to b16	—	Reserved	These bits are read as 0.	R
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes received in a CAN frame.	R

This register stores the data length code (DLC) and timestamp of the received message.

TS[15:0] Bits (Timestamp)

The TS[15:0] bits store the timestamp of the received message captured at the point specified by the GFDCFG.TSCPS[1:0] bits.



DLC[3:0] Bits (Data Length Code)

The DLC[3:0] bits store the number of data bytes of the received message.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

Note: The maximum number of data bytes in the buffer is specified by the RMCR.PLS[2:0] bits.

46.2.61.5 Receive Message Buffer n Header Field 2 (RMBn.HF2) (n = 0 to 15)

Address(es): CANFD.RMB0.HF2 8747 0928h, CANFD.RMB1.HF2 8747 0974h, CANFD.RMB2.HF2 8747 09C0h, CANFD.RMB3.HF2 8747 0A0Ch, CANFD.RMB4.HF2 8747 0A58h, CANFD.RMB5.HF2 8747 0AA4h, CANFD.RMB6.HF2 8747 0AF0h, CANFD.RMB7.HF2 8747 0B3Ch, CANFD.RMB8.HF2 8747 0D28h, CANFD.RMB9.HF2 8747 0D74h, CANFD.RMB10.HF2 8747 0DC0h, CANFD.RMB11.HF2 8747 0E0Ch, CANFD.RMB12.HF2 8747 0E58h, CANFD.RMB13.HF2 8747 0EA4h, CANFD.RMB14.HF2 8747 0EF0h, CANFD.RMB15.HF2 8747 0F3Ch,

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator Flag	0: CAN FD frame received from error active node 1: CAN FD frame received from error passive node	R
b1	BRS	Bit Rate Switch Flag	0: CAN FD frame received with no bit rate switch 1: CAN FD frame received with bit rate switch	R
b2	FDF	FD Format Indicator Flag	0: Non CAN FD frame received 1: CAN FD frame received	R
b7 to b3	—	Reserved	These bits are read as 0.	R
b9, b8	IFL[1:0]	Information Label	A field that stores the information label attached by the Acceptance Filter	R
b15 to b10	—	Reserved	These bits are read as 0.	R
b31 to b16	PTR[15:0]	Pointer	A field that stores the pointer attached by the Acceptance Filter	R

This register stores the FDF bit, BRS bit, and ESI flag of the received message, and pointer for the received message.

ESI Flag (Error State Indicator Flag)

The ESI flag stores the value of the ESI flag of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

BRS Flag (Bit Rate Switch Flag)

The BRS flag stores the value of the BRS bit of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

FDF Flag (FD Format Indicator Flag)

The FDF flag stores the value of the FDF bit of the received CAN FD frame.

IFL[1:0] Bits (Information Label)

The IFL[1:0] bits store the information label value set in the corresponding entry in the acceptance filter list.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits store the pointer value set in the corresponding entry in the acceptance filter list.

46.2.61.6 Receive Message Buffer n Data Field p (RMBn.DFp) (n = 0 to 15; p = 0 to 15)

These registers are read-only registers that store the data bytes of the received message.
Unused data bytes are filled with 00h.

46.2.61.8 Receive FIFO n (RFBn) (n = 0, 1)

The total number of the receive FIFOs (RFB) is two, as shown in Figure 46.32.
The receive FIFO consists of the following registers:

- RFBn.HF0
- RFBn.HF1
- RFBn.HF2
- RFBn.DF0 to RFBn.DF15

Table 46.8 shows the structure of this buffer.

Table 46.8 Structure of Receive FIFO

Address Offset	Symbol	Register Name	Contents
+00h	RFBn.HF0	Receive FIFO n Header Field 0	IDE, RTR, ID
+04h	RFBn.HF1	Receive FIFO n Header Field 1	DLC, timestamp

+48h	RFBn.DF15	Receive FIFO n Data Field 15	DATA60 to DATA63

46.2.61.9 Receive FIFO n Header Field 0 (RFBn.HF0) (n = 0, 1)

Address(es): CANFD.RFB0.HF0 8747 0520h, CANFD.RFB1.HF0 8747 056Ch,
CANFD_NS.RFB0.HF0 0747 0520h, CANFD_NS.RFB1.HF0 0747 056Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IDE	RTR	—	ID[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28-b0	ID[28:0]	Identifier	Standard ID/extended ID field	R
b29	—	Reserved	This bit is read as 0.	R
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R

This register stores the ID field, IDE bit, and RTR bit of the received message.

ID[28:0] Bits (Identifier)

The ID[28:0] bits store the standard or extended identifier field of message stored in the receive FIFO.
For alignment of these bits in base and extended format, refer to section 46.2.60, Identifier Bits Alignment.

RTR Bit (Remote Transmission Request)

The RTR bit stores the value of the RTR bit of the received message.

Note: There are no remote frames in CAN FD format. When a CAN FD frame is received, this bit reflects the value of the RRS bit.

IDE Bit (Identifier Extension)

The IDE bit stores the value of the IDE bit of the received message.

46.2.61.10 Receive FIFO n Header Field 1 (RFBn.HF1) (n = 0, 1)

Address(es): CANFD.RFB0.HF1 8747 0524h, CANFD.RFB1.HF1 8747 0570h,
CANFD_NS.RFB0.HF1 0747 0524h, CANFD_NS.RFB1.HF1 0747 0570h

	TS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TS[15:0]	Timestamp	Timestamp value of the received CAN frame	R
b27 to b16	—	Reserved	These bits are read as 0.	R
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes received in a CAN frame	R

This register stores the data length code (DLC) and timestamp of the received message.

TS[15:0] Bits (Timestamp)

The TS[15:0] bits store the timestamp of the received message captured at the point specified by the GFDCFG.TSCPS[1:0] bits.

DLC[3:0] Bits (Data Length Code)

The DLC[3:0] bits store the number of data bytes of the received message.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

Note: The maximum number of data bytes in the buffer is specified by the RFCRn.PLS[2:0] bits.

46.2.61.11 Receive FIFO n Header Field 2 (RFBn.HF2) (n = 0, 1)

Address(es): CANFD.RFB0.HF2 8747 0528h, CANFD.RFB1.HF2 8747 0574h,
CANFD_NS.RFB0.HF2 0747 0528h, CANFD_NS.RFB1.HF2 0747 0574h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	IFL[1:0]		—	—	—	—	—	FDF	BRS	ESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator Flag	0: CAN FD frame received from error active node 1: CAN FD frame received from error passive node	R
b1	BRS	Bit Rate Switch Flag	0: CAN FD frame received with no bit rate switch 1: CAN FD frame received with bit rate switch	R
b2	FDF	FD Format Indicator Flag	0: Non CAN FD frame received 1: CAN FD frame received	R
b7 to b3	—	Reserved	These bits are read as 0.	R
b9, b8	IFL[1:0]	Information Label	A field that stores the information label attached by the Acceptance Filter	R
b15 to b10	—	Reserved	These bits are read as 0.	R
b31 to b16	PTR[15:0]	Pointer	A field that stores the pointer attached by the Acceptance Filter	R

This register stores the FDF bit, BRS bit, and ESI flag of the received message, and pointer for the received message.

ESI Flag (Error State Indicator Flag)

The ESI flag stores the value of the ESI flag of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

BRS Flag (Bit Rate Switch Flag)

The BRS flag stores the value of the BRS bit of the received CAN FD frame.
When the received FDF bit is 0, this means a Classical CAN frame is received and 0 is stored to this flag.

FDF Flag (FD Format Indicator Flag)

The FDF flag stores the value of the FDF bit of the received CAN FD frame.

IFL[1:0] Bits (Information Label)

The IFL[1:0] bits store the information label value set in the corresponding entry in the acceptance filter list.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits store the pointer value set in the corresponding entry in the acceptance filter list.

46.2.61.12 Receive FIFO n Data Field p (RFBn.DFp) (n = 0, 1; p = 0 to 15)

Address(es): CANFD.RFB0.DF0 8747 052Ch to CANFD.RFB0.DF15 8747 0568h,
CANFD.RFB1.DF0 8747 0578h to CANFD.RFB1.DF15 8747 05B4h,
CANFD_NS.RFB0.DF0 0747 052Ch to CANFD_NS.RFB0.DF15 0747 0568h,
CANFD_NS.RFB1.DF0 0747 0578h to CANFD_NS.RFB1.DF15 0747 05B4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

These registers are read-only registers that store the data byte (p × 4 + 3) to data byte (p × 4) of the received message. Unused data bytes are filled with 00h.

46.2.61.13 Receive FIFO n Data k (RFBn.DATAk) (n = 0, 1; k = 0 to 63)

Address(es): CANFD.RFB0.DATA0 8747 052Ch to CANFD.RFB0.DATA63 8747 056Bh,
CANFD.RFB1.DATA0 8747 0578h to CANFD.RFB1.DATA63 8747 05B7h,
CANFD_NS.RFB0.DATA0 0747 052Ch to CANFD_NS.RFB0.DATA63 0747 056Bh,
CANFD_NS.RFB1.DATA0 0747 0578h to CANFD_NS.RFB1.DATA63 0747 05B7h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

These registers are read-only registers that store the data bytes of the received message.
Unused data bytes are filled with 00h.

46.2.61.14 Common FIFO 0 (CFB0)

The total number of the common FIFO (CFB) is one, as shown in Figure 46.32.
The common FIFO consists of the following registers:

- CFB0.HF0
- CFB0.HF1
- CFB0.HF2
- CFB0.DF0 to CFB0.DF15

Table 46.9 shows the structure of this buffer.

Table 46.9 Structure of Common FIFO

Address Offset	Symbol	Register Name	Contents
+00h	CFB0.HF0	Common FIFO 0 Header Field 0	IDE, RTR, ID
+04h	CFB0.HF1	Common FIFO 0 Header Field 1	DLC, timestamp
+08h	CFB0.HF2	Common FIFO 0 Header Field 2	Pointer, information label, FDF, BRS, ESI
+0Ch	CFB0.DF0	Common FIFO 0 Data Field 0	DATA0 to DATA3
+10h	CFB0.DF1	Common FIFO 0 Data Field 1	DATA4 to DATA7
+14h	CFB0.DF2	Common FIFO 0 Data Field 2	DATA8 to DATA11
+18h	CFB0.DF3	Common FIFO 0 Data Field 3	DATA12 to DATA15
+1Ch	CFB0.DF4	Common FIFO 0 Data Field 4	DATA16 to DATA19
+20h	CFB0.DF5	Common FIFO 0 Data Field 5	DATA20 to DATA23
+24h	CFB0.DF6	Common FIFO 0 Data Field 6	DATA24 to DATA27

+44h	CFB0.DF14	Common FIFO 0 Data Field 14	DATA56 to DATA59
+48h	CFB0.DF15	Common FIFO 0 Data Field 15	DATA60 to DATA63

46.2.61.15 Common FIFO 0 Header Field 0 (CFB0.HF0)

Address(es): CANFD.CFB0.HF0 8747 05B8h, CANFD_NS.CFB0.HF0 0747 05B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	IDE	RTR	THENT	ID[28:16]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	Identifier	Standard ID/extended ID field	R/W
b29	THENT	Transmission History Entry	Receive FIFO mode: Reserved. This bit is read as 0. Transmit FIFO mode: 0: Entry is not stored to the Transmission History after successful transmission. 1: Entry is stored to the Transmission History after successful transmission.	R/W
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R/W
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R/W

In receive FIFO mode, this register is a read-only register for reading the ID field, IDE bit, and RTR bit of the received message from the beginning of the FIFO buffer.
In transmit FIFO mode, this register is a read/write register for writing the ID field, IDE bit, and RTR bit of the message to be transmitted at the end of the FIFO buffer.

ID[28:0] Bits (Identifier)

In receive FIFO mode, the ID[28:0] bits store the standard or extended identifier field of the received message.
In transmit FIFO mode, the ID[28:0] bits are used to set the value of the standard or extended identifier field of the message to be transmitted.
For alignment of these bits in base and extended format, refer to section 46.2.60, Identifier Bits Alignment.

THENT Bit (Transmission History Entry)

This bit is valid only in transmit FIFO mode.
The THENT bit controls whether the corresponding entry is stored in the transmission history after a successful transmission of the message.

RTR Bit (Remote Transmission Request)

In receive FIFO mode, the RTR bit stores the value of the RTR bit of the received message.
In transmit FIFO mode, the RTR bit is used to specify the value of the RTR bit of the message to be transmitted.

Note: There are no remote frames in CAN FD format. When a CAN FD frame was received (receive mode), this bit reflects the value of the RRS bit. When transmitting a CAN FD frame (CFB0.HF2.FDF = 1), this bit is transmitted dominant regardless of the value of this bit.

IDE Bit (Identifier Extension)

In receive FIFO mode, the IDE bit stores the value of the IDE bit of the received message.
In transmit FIFO mode, the IDE bit is used to specify the value of the IDE bit of the message to be transmitted.

46.2.61.16 Common FIFO 0 Header Field 1 (CFB0.HF1)

Address(es): CANFD.CFB0.HF1 8747 05BCh, CANFD_NS.CFB0.HF1 0747 05BCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DLC[3:0]				—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TS[15:0]	Timestamp	Timestamp value of the received CAN frame (in receive FIFO mode)	R/W
b27 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes received in a CAN frame, or to be transmitted in a CAN frame	R/W

In receive FIFO mode, this register is a read-only register for reading the data length code (DLC) and timestamp of the received message from the beginning of the FIFO buffer.
In transmit FIFO mode, this register is a read/write register for writing the data length code (DLC) of the message to be transmitted at the end of the FIFO buffer.

TS[15:0] Bits (Timestamp)

These bits are valid only in receive FIFO mode.
The TS[15:0] bits store the timestamp of the received message captured at the point specified by the GFDCFG.TSCPS[1:0] bits.

DLC[3:0] Bits (Data Length Code)

In receive FIFO mode, the DLC[3:0] bits store the number of data bytes of the received message.
In transmit FIFO mode, The DLC[3:0] bits are used to specify the number of data bytes of the message to be transmitted.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

Note: The maximum number of data bytes in the buffer is specified by the CFCR0.PLS[2:0] bits.

46.2.61.17 Common FIFO 0 Header Field 2 (CFB0.HF2)

Address(es): CANFD.CFB0.HF2 8747 05C0h, CANFD_NS.CFB0.HF2 0747 05C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	IFL[1:0]		—	—	—	—	—	FDF	BRS	ESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator	0: CAN FD frame received or to transmit by error active node 1: CAN FD frame received or to transmit by error passive node	R/W
b1	BRS	Bit Rate Switch	0: CAN FD frame received or to transmit with no bit rate switch 1: CAN FD frame received or to transmit with bit rate switch	R/W
b2	FDF	FD Format Indicator	0: Non CAN FD frame received or to transmit 1: CAN FD frame received or to transmit	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	IFL[1:0]	Information Label	A field that stores the information label attached by the Acceptance Filter or sets the information label to be stored in the Transmission History	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b16	PTR[15:0]	Pointer	A field that stores the pointer attached by the Acceptance Filter or sets the pointer to be stored in the Transmission History	R/W

In receive FIFO mode, this register is a read-only register for reading the FDF bit, BRS bit, and ESI flag of the received message, and information label and pointer for the received message from the beginning of the FIFO buffer.
In transmit FIFO mode, this register is a read/write register for writing the FDF bit, BRS bit, and ESI flag of the message to be transmitted, and the information label and pointer to be stored in the transmission history at the end of the FIFO buffer.

ESI Bit (Error State Indicator)

In receive FIFO mode, the ESI bit stores the value of the ESI flag of the received CAN FD frame. When the received FDF bit is 0 (Classical CAN frame), 0 is stored to this bit.
In transmit FIFO mode, the ESI bit is used to specify the value of the ESI flag of the CAN FD frame to be transmitted. If the channel is not in error passive, the ESI flag of the transmitted message equals the value of this bit. If the channel is in error passive, this bit is transmitted recessive regardless of the value of this bit.

BRS Bit (Bit Rate Switch)

In receive FIFO mode, the BRS bit stores the value of the BRS bit of the received CAN FD frame. When the received FDF bit is 0 (Classical CAN frame), 0 is stored to this bit.
In transmit FIFO mode, the BRS bit is used to specify the value of the BRS bit of the CAN FD frame to be transmitted.

FDF Bit (FD Format Indicator)

In receive FIFO mode, the FDF bit stores the value of the FDF bit of the received CAN FD frame.
In transmit FIFO mode, the FDF bit is used to specify the value of the FDF bit of the CAN FD frame to be transmitted.

IFL[1:0] Bits (Information Label)

In receive FIFO mode, the IFL[1:0] bits store the information label value set in the corresponding entry in the acceptance filter list.
In transmit FIFO mode, the IFL[1:0] bits are used to specify the information label value to be stored in the transmission history after a successful transmission of the message.

PTR[15:0] Bits (Pointer)

In receive FIFO mode, the PTR[15:0] bits store the pointer value set in the corresponding entry in the acceptance filter list.
In transmit FIFO mode, the PTR[15:0] bits are used to specify the pointer value to be stored in the transmission history after a successful transmission of the message.

46.2.61.18 Common FIFO 0 Data Field p (CFB0.DFp) (p = 0 to 15)

Address(es): CANFD.CFB0.DF0 8747 05C4h to CANFD.CFB0.DF15 8747 0600h,
CANFD_NS.CFB0.DF0 0747 05C4h to CANFD_NS.CFB0.DF15 0747 0600h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

In receive FIFO mode, these registers are read-only registers for reading the data byte (p × 4 + 3) to data byte (p × 4) of the received message from the beginning of the FIFO buffer. Unused data bytes are filled with 00h.
In transmit FIFO mode, these registers are read/write registers for storing data byte (p × 4 + 3) to data byte (p × 4) of the message to be transmitted.

46.2.61.19 Common FIFO 0 Data k (CFB0.DATAk) (k = 0 to 63)

Address(es): CANFD.CFB0.DATA0 8747 05C4h to CANFD.CFB0.DATA63 8747 0603h,
CANFD_NS.CFB0.DATA0 0747 05C4h to CANFD_NS.CFB0.DATA63 0747 0603h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

In receive FIFO mode, these registers are read-only registers for reading the data bytes of the received message from the beginning of the FIFO buffer. Unused data bytes are filled with 00h.
In transmit FIFO mode, these registers are read/write registers for storing the data bytes of the message to be transmitted.

46.2.61.20 Transmit Message Buffer n (TMBn) (n = 0 to 3)

The total number of transmit message buffers (TMB) is four, as shown in Figure 46.32.
The transmit message buffer consists of the following registers:

- TMBn.HF0
- TMBn.HF1
- TMBn.HF2
- TMBn.DF0 to TMBn.DF15

Table 46.10 shows the structure of this buffer.

Table 46.10 Structure of Transmit Message Buffer

Address Offset	Symbol	Register Name	Contents
+00h	TMBn.HF0	Transmit Message Buffer n Header Field 0	IDE, RTR, ID
+04h	TMBn.HF1	Transmit Message Buffer n Header Field 1	DLC
+08h	TMBn.HF2	Transmit Message Buffer n Header Field 2	Pointer, information label, FDF, BRS, ESI
+0Ch	TMBn.DF0	Transmit Message Buffer n Data Field 0	DATA0 to DATA3
+10h	TMBn.DF1	Transmit Message Buffer n Data Field 1	DATA4 to DATA7
+14h	TMBn.DF2	Transmit Message Buffer n Data Field 2	DATA8 to DATA11
+18h	TMBn.DF3	Transmit Message Buffer n Data Field 3	DATA12 to DATA15
+1Ch	TMBn.DF4	Transmit Message Buffer n Data Field 4	DATA16 to DATA19
+20h	TMBn.DF5	Transmit Message Buffer n Data Field 5	DATA20 to DATA23
+24h	TMBn.DF6	Transmit Message Buffer n Data Field 6	DATA24 to DATA27
+28h	TMBn.DF7	Transmit Message Buffer n Data Field 7	DATA28 to DATA31
+2Ch	TMBn.DF8	Transmit Message Buffer n Data Field 8	DATA32 to DATA35
+30h	TMBn.DF9	Transmit Message Buffer n Data Field 9	DATA36 to DATA39
+34h	TMBn.DF10	Transmit Message Buffer n Data Field 10	DATA40 to DATA43
+38h	TMBn.DF11	Transmit Message Buffer n Data Field 11	DATA44 to DATA47
+3Ch	TMBn.DF12	Transmit Message Buffer n Data Field 12	DATA48 to DATA51
+40h	TMBn.DF13	Transmit Message Buffer n Data Field 13	DATA52 to DATA55
+44h	TMBn.DF14	Transmit Message Buffer n Data Field 14	DATA56 to DATA59
+48h	TMBn.DF15	Transmit Message Buffer n Data Field 15	DATA60 to DATA63

46.2.61.21 Transmit Message Buffer n Header Field 0 (TMBn.HF0) (n = 0 to 3)

Address(es): CANFD.TMB0.HF0 8747 0604h, CANFD.TMB1.HF0 8747 0650h, CANFD.TMB2.HF0 8747 069Ch, CANFD.TMB3.HF0 8747 06E8h, CANFD_NS.TMB0.HF0 0747 0604h, CANFD_NS.TMB1.HF0 0747 0650h, CANFD_NS.TMB2.HF0 0747 069Ch, CANFD_NS.TMB3.HF0 0747 06E8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	ID[28:0]	Identifier	Standard ID/extended ID field	R/W
b29	THENT	Transmission History Entry	0: Entry is not stored in transmission history after successful transmission. 1: Entry is stored in transmission history after successful transmission.	R/W
b30	RTR	Remote Transmission Request	0: Data frame 1: Remote frame	R/W
b31	IDE	Identifier Extension	0: Standard ID 1: Extended ID	R/W

This register is used to store the ID field, IDE bit, and RTR bit of the message to be transmitted, and to specify whether to store it in the transmission history.
Do not write to this register in CH_SLEEP mode.

ID[28:0] Bits (Identifier)

The ID[28:0] bits are used to set the value of the standard or extended identifier field of the message stored in the transmit message buffer.
For alignment of these bits in base and extended format, refer to section 46.2.60, Identifier Bits Alignment.

THENT Bit (Transmission History Entry)

The THENT bit controls whether the corresponding entry is stored in the transmission history after a successful transmission of the message stored in the transmit message buffer.

RTR Bit (Remote Transmission Request)

The RTR bit is used to specify the value of the RTR bit of the message to be transmitted.

Note: There are no remote frames in CAN FD format. When transmitting a CAN FD frame (TMBn.HF2.FDF = 1), this bit is transmitted dominant regardless of the value of this bit.

IDE Bit (Identifier Extension)

The IDE bit is used to specify the value of the IDE bit of the message to be transmitted.

46.2.61.22 Transmit Message Buffer n Header Field 1 (TMBn.HF1) (n = 0 to 3)

Address(es): CANFD.TMB0.HF1 8747 0608h, CANFD.TMB1.HF1 8747 0654h, CANFD.TMB2.HF1 8747 06A0h, CANFD.TMB3.HF1 8747 06ECh, CANFD_NS.TMB0.HF1 0747 0608h, CANFD_NS.TMB1.HF1 0747 0654h, CANFD_NS.TMB2.HF1 0747 06A0h, CANFD_NS.TMB3.HF1 0747 06ECh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b27 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b28	DLC[3:0]	Data Length Code	Number of data bytes to be transmitted in a CAN frame.	R/W

This register is used to store the data length code (DLC) fields of the message to be transmitted.
Do not write to this register in CH_SLEEP mode.

DLC[3:0] Bits (Data Length Code)

The DLC[3:0] bits are used to specify the number of data bytes of the message to be transmitted when the corresponding TMBn.HF0.RTR bit is set to 0.
Refer to Table 5 in ISO 11898-1:2015 Standard for details on defining the number of data bytes.

46.2.61.23 Transmit Message Buffer n Header Field 2 (TMBn.HF2) (n = 0 to 3)

Address(es): CANFD.TMB0.HF2 8747 060Ch, CANFD.TMB1.HF2 8747 0658h, CANFD.TMB2.HF2 8747 06A4h, CANFD.TMB3.HF2 8747 06F0h, CANFD_NS.TMB0.HF2 0747 060Ch, CANFD_NS.TMB1.HF2 0747 0658h, CANFD_NS.TMB2.HF2 0747 06A4h, CANFD_NS.TMB3.HF2 0747 06F0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	IFL[1:0]		—	—	—	—	—	FDF	BRS	ESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESI	Error State Indicator	0: CAN FD frame to transmit by error active node 1: CAN FD frame to transmit by error passive node	R/W
b1	BRS	Bit Rate Switch	0: CAN FD frame to transmit with no bit rate switch 1: CAN FD frame to transmit with bit rate switch	R/W
b2	FDF	FD Format Indicator	0: Non CAN FD frame to transmit 1: CAN FD frame to transmit	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	IFL[1:0]	Information Label	A field that sets the information label to be stored in the Transmission History	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b16	PTR[15:0]	Pointer	A field that sets the pointer to be stored in the Transmission History	R/W

This register is used to store the FDF bit, BRS bit, and ESI flag of the message to be transmitted, and the information label and pointer to be stored in the transmission history.
Do not write to this register in CH_SLEEP mode.

ESI Bit (Error State Indicator)

The ESI bit is used to specify the value of the ESI flag of the CAN FD frame to be transmitted.
If the channel is not in error passive, the ESI flag of the transmitted message equals the value of this bit. If the channel is in error passive, this bit is transmitted recessive regardless of the value of this bit.

BRS Bit (Bit Rate Switch)

The BRS bit is used to specify the value of the BRS bit of the CAN FD frame to be transmitted.

FDF Bit (FD Format Indicator)

The FDF bit is used to specify the value of the FDF bit of the CAN FD frame to be transmitted.

IFL[1:0] Bits (Information Label)

The IFL[1:0] bits are used to specify the information label value to be stored in the transmission history after a successful transmission of the message.

PTR[15:0] Bits (Pointer)

The PTR[15:0] bits are used to specify the pointer value to be stored in the transmission history after a successful transmission of the message.

46.2.61.24 Transmit Message Buffer n Data Field p (TMBn.DFp) (n = 0 to 3; p = 0 to 15)

Address(es): CANFD.TMB0.DF0 8747 0610h to CANFD.TMB0.DF15 8747 064Ch,
CANFD.TMB1.DF0 8747 065Ch to CANFD.TMB1.DF15 8747 0698h,
CANFD.TMB2.DF0 8747 06A8h to CANFD.TMB2.DF15 8747 06E4h,
CANFD.TMB3.DF0 8747 06F4h to CANFD.TMB3.DF15 8747 0730h,
CANFD_NS.TMB0.DF0 0747 0610h to CANFD_NS.TMB0.DF15 0747 064Ch,
CANFD_NS.TMB1.DF0 0747 065Ch to CANFD_NS.TMB1.DF15 0747 0698h,
CANFD_NS.TMB2.DF0 0747 06A8h to CANFD_NS.TMB2.DF15 0747 06E4h,
CANFD_NS.TMB3.DF0 0747 06F4h to CANFD_NS.TMB3.DF15 0747 0730h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

These registers are read/write registers for storing data byte (p × 4 + 3) to data byte (p × 4) of the message to be transmitted.
Do not write to these registers in CH_SLEEP mode.

46.2.61.25 Transmit Message Buffer n Data k (TMBn.DATAk) (n = 0 to 3; k = 0 to 63)

Address(es): CANFD.TMB0.DATA0 8747 0610h to CANFD.TMB0.DATA63 8747 064Fh,
CANFD.TMB1.DATA0 8747 065Ch to CANFD.TMB1.DATA63 8747 069Bh,
CANFD.TMB2.DATA0 8747 06A8h to CANFD.TMB2.DATA63 8747 06E7h,
CANFD.TMB3.DATA0 8747 06F4h to CANFD.TMB3.DATA63 8747 0733h,
CANFD_NS.TMB0.DATA0 0747 0610h to CANFD_NS.TMB0.DATA63 0747 064Fh,
CANFD_NS.TMB1.DATA0 0747 065Ch to CANFD_NS.TMB1.DATA63 0747 069Bh,
CANFD_NS.TMB2.DATA0 0747 06A8h to CANFD_NS.TMB2.DATA63 0747 06E7h,
CANFD_NS.TMB3.DATA0 0747 06F4h to CANFD_NS.TMB3.DATA63 0747 0733h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

These registers are read/write registers for storing the data bytes of the message to be transmitted.
Do not write to these registers in CH_SLEEP mode.

46.2.62 ECC Control/Status Register (ECCSR)

Address(es): CANFD.ECCSR 8746 F200h, CANFD_NS.ECCSR 0746 F200h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EC2EAS	EC1EAS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ECEDWC[1:0]		—	—	ECOVF	EC2EC	EC1EC	—	—	ECEDE	EC1ECD	EC2EIE	EC1EIE	EC2EF	EC1EF	ECEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECEF	ECC Error Flag	0: There is no ECC error in the last RAM data read. 1: There is an ECC error in the last RAM data read.	R
b1	EC1EF	1-Bit ECC Error Detection Flag	0: 1-bit ECC error is not detected. 1: 1-bit ECC error is detected.	R
b2	EC2EF	2-Bit ECC Error Detection Flag	0: 2-bit ECC error is not detected. 1: 2-bit ECC error is detected.	R
b3	EC1EIE	1-Bit ECC Error Detection Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b4	EC2EIE	2-Bit ECC Error Detection Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b5	EC1ECD	1-Bit ECC Error Correction Disable	0: Perform error correction when 1-bit ECC error is detected. 1: Does not perform error correction when 1-bit ECC error is detected.	R/W
b6	ECEDE	ECC Error Detection Enable	0: ECC error detection is disabled. 1: ECC error detection is enabled.	R/W
b8, b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9	EC1EC	EC1EF Flag Clear	Writing 1 to this bit clears the EC1EF flag. Writing 0 to this bit is ignored. This bit is read as 0.	R/W
b10	EC2EC	EC2EF Flag Clear	Writing 1 to this bit clears the EC2EF flag. Writing 0 to this bit is ignored. This bit is read as 0.	R/W
b11	ECOVF	ECC Overflow Detection Flag	0: The ECEAR register overflow has not occurred. 1: The ECEAR register overflow has occurred.	R
b13, b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	ECEDWC[1:0]	ECEDE Bit Write Control	Enables or disables write access to the ECEDE bit.	R/W
b16	EC1EAS	1-Bit ECC Error Detected Address Stored Flag	0: No valid address is stored in the ECEAR register. 1: The address where 1-bit ECC error occurred is stored in the ECEAR register.	R
b17	EC2EAS	2-Bit ECC Error Detected Address Stored Flag	0: No valid address is stored in the ECEAR register. 1: The address where 2-bit ECC error occurred is stored in the ECEAR register.	R
b31 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ECEF Flag (ECC Error Flag)

The ECEF flag indicates whether there is an ECC error in the last RAM data read. This flag is updated every time the RAM is read.

If the ECEDE bit is set to 1 without initializing the RAM, the value of this flag has no meaning.

[Setting condition]

- If there is an ECC error in read RAM data when the ECEDE bit is set to 1 (ECC error detection is enabled)

[Clearing condition]

- Under the condition that there is no ECC error in read RAM data
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

EC1EF Flag (1-Bit ECC Error Detection Flag)

The EC1EF flag indicates that a 1-bit ECC error is detected in the data read from RAM.
When this flag is set to 1 while the interrupt is enabled, an ECC error interrupt (ECCEI) is generated.
If a 1-bit ECC error is detected again while this flag is 1, no further interrupt is generated.

[Setting condition]

- When a 1-bit ECC error is detected in the data read from RAM while the ECEDE bit is set to 1 (ECC error detection is enabled)

[Clearing condition]

- Writing 1 to the EC1EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If a 1-bit ECC error is detected at the same time that the EC1EC bit is set to 1, the EC1EF flag becomes 0.

EC2EF Flag (2-Bit ECC Error Detection Flag)

The EC2EF flag indicates that a 2-bit ECC error is detected in the data read from RAM.
When this flag is set to 1 while the interrupt is enabled, an ECC error interrupt (ECCEI) is generated.
If a 2-bit ECC error is detected again while this flag is 1, no further interrupt is generated.

[Setting condition]

- When a 2-bit ECC error is detected in the data read from RAM while the ECEDE bit is set to 1 (ECC error detection is enabled)

[Clearing condition]

- Writing 1 to the EC2EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If a 2-bit ECC error is detected at the same time that the EC2EC bit is set to 1, the EC2EF flag becomes 0.

EC1EIE Bit (1-Bit ECC Error Detection Interrupt Enable)

The EC1EIE bit enables or disables the interrupt generated by 1-bit ECC error detection.
When the EC1EF flag is set to 1 while this bit is 1, an ECC error interrupt (ECCEI) is generated.

EC2EIE Bit (2-Bit ECC Error Detection Interrupt Enable)

The EC2EIE bit enables or disables the interrupt generated by 2-bit ECC error detection.
When the EC2EF flag is set to 1 while this bit is 1, an ECC error interrupt (ECCEI) is generated.

EC1ECD Bit (1-Bit ECC Error Correction Disable)

The EC1ECD bit sets whether 1-bit ECC error correction is performed when the ECEDE bit is set to 1 (ECC error detection is enabled). When this bit is set to 1, the RAM output data is not corrected even if a 1-bit ECC error is detected.

ECEDE Bit (ECC Error Detection Enable)

Setting this bit to 1 enables the ECC error detection.
Writing to this bit is valid only when the ECEDWC[1:0] bits are set to 01b.

EC1EC Bit (EC1EF Flag Clear)

The EC1EC bit is used to clear the EC1EF flag.
The EC1EF flag is cleared by writing 1 to this bit while the EC1EF flag is set to 1. Additionally, the ECOVF flag, EC1EAS flag, and EC2EAS flag are also cleared.
If a 1-bit ECC error is detected at the same time that the EC1EC bit is set to 1, the EC1EF flag becomes 0.

EC2EC Bit (EC2EF Flag Clear)

The EC2EC bit is used to clear the EC2EF flag.
The EC2EF flag is cleared by writing 1 to this bit while the EC2EF flag is set to 1. Additionally, the ECOVF flag, EC1EAS flag, and EC2EAS flag are also cleared.
If a 2-bit ECC error is detected at the same time that the EC2EC bit is set to 1, the EC2EF flag becomes 0.

ECOVF Flag (ECC Overflow Detection Flag)

If a new ECC error is detected and the address is overwritten when an address is already stored in the ECEAR register, the ECOVF flag is set to 1 and an ECC error interrupt (ECCEI) is generated.
If a new ECC error is detected while this flag is 1, an ECC error interrupt is generated again.

[Setting condition]

- When new error address is captured under the condition that error address is already captured in the ECEAR register.

[Clearing condition]

- When the EC1EC bit is set to 1
- When the EC2EC bit is set to 1
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If the ECOVF flag is cleared by the EC1EC or EC2EC bit and the setting condition of the ECOVF flag occurs at the same time, the ECOVF flag becomes 0.

ECEDWC[1:0] Bits (ECEDE Bit Write Control)

The ECEDWC[1:0] bits are used to enable or disable write access to the ECEDE bit. The read value is always 00b.
When the value of these bits is 01b, it is possible to have write access to the ECEDE bit. If these bits are other than 01b, write access to the ECEDE bit is ignored and the value does not change.

EC1EAS Flag (1-Bit ECC Error Detected Address Stored Flag)

The EC1EAS flag indicates that the address where the 1-bit ECC error occurred is stored in the ECEAR register when the ECEDE bit is set to 1 (ECC error detection is enabled).
When 1-bit ECC error is detected while the 2-bit ECC error address has already been captured in the ECEAR register, the ECEAR register is not updated and this flag is not updated.

[Setting condition]

- When a 1-bit ECC error is detected under the condition that the ECEDE bit is set to 1 (ECC error detection is enabled), and the address is stored in the ECEAR register

[Clearing condition]

- Writing 1 to the EC1EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If the EC1EAS flag is cleared by the EC1EC bit and the setting factor of the EC1EAS flag occurs at the same time, the EC1EAS flag becomes 0.

EC2EAS Flag (2-Bit ECC Error Detected Address Stored Flag)

The EC2EAS flag indicates that the address where the 2-bit ECC error occurred is stored in the ECEAR register when

the ECEDE bit is set to 1 (ECC error detection is enabled).
When 2-bit ECC error is detected while the 1-bit ECC error address has already been captured in the ECEAR register, the ECEAR register is updated and this flag becomes 1.

[Setting condition]

- When a 2-bit ECC error is detected under the condition that the ECEDE bit is set to 1 (ECC error detection is enabled), and the address is stored in the ECEAR register

[Clearing condition]

- Writing 1 to the EC2EC bit
- When the ECEDE bit is set to 0 (ECC error detection is disabled)

If the EC2EAS flag is cleared by the EC2EC bit and the setting factor of the EC2EAS flag occurs at the same time, the EC2EAS flag becomes 0.

46.2.63 ECC Test Mode Register (ECTMR)

Address(es): CANFD.ECTMR 8746 F204h, CANFD_NS.ECTMR 0746 F204h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ECTMWC[1:0]		—	—	—	—	—	—	ECTME	—	—	—	—	—	ECDIS	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	ECDIS	ECC Decoder Input Select	0: Input RAM output data to data input of decode circuit 1: Select the ECTDR register to data input of decode circuit	R/W
b6 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	ECTME	ECC Test Mode Enable	0: Access to the ECDIS bit and the ECTDR register is disabled 1: Access to the ECDIS bit and the ECTDR register is enabled	R/W
b13 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15, b14	ECTMWC[1:0]	ECTME Bit Write Control	Enable or disable write access to the ECTME bit.	R/W

ECDIS Bit (ECC Decoder Input Select)

The ECDIS bit selects which of the data value read from RAM and the value of the ECTDR register is used as input data to the ECC decoder.

The write access to this bit is enabled when the ECTME bit is set to 1. It is also possible to set them at the same time.

This bit is cleared by setting the ECTME bit to 0.

ECTME Bit (ECC Test Mode Enable)

The ECTME bit is used to enable or disable the access to the ECDIS bit and the ECTDR register.

This bit can be written only when the ECTMWC[1:0] bits is set to 10b.

ECTMWC[1:0] Bits (ECTME Bit Write Control)

The ECTMWC[1:0] bits are used to enable or disable the write access to the ECTME bit. The read value is always 00b.

When the value of these bits is 10b, it is possible to have write access to the ECTME bit. If these bits are other than 10b, write access to the ECTME bit is ignored and the value does not change.

46.2.64 ECC Decoder Test Data Register (ECTDR)

Address(es): CANFD.ECTDR 8746 F20Ch, CANFD_NS.ECTDR 0746 F20Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to set the data for testing the ECC decode.
When the ECTMR.ECTME bit is set to 1, this register can be read and written.
When the ECTMR.ECTME bit is set to 0, the value of this register becomes 00000000h.
When the ECTMR.ECDIS bit is set to 1, the value set in this register is used as the input data of the ECC decoder instead of the data read from RAM.

46.2.65 ECC Error Address Register (ECEAR)

Address(es): CANFD.ECEAR 8746 F210h, CANFD_NS.ECEAR 0746 F210h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register holds the address where the ECC error occurred.
If an ECC error is detected when the ECCSR.ECEDE bit is 1 (ECC error detection is enabled), b11 to b2 of the RAM address are stored in b9 to b0 of this register.
If the same error occurred again, this register is not updated.
If a 2-bit ECC error is detected while the address where the 1-bit ECC error occurred is already stored, the ECEAR register is overwritten with the new address and the ECCSR.EC2EAS flag is set to 1.
If a 1-bit ECC error is detected while the address where the 2-bit ECC error occurred is already stored, the ECEAR register is not updated and the ECCSR.EC1EAS flag is not updated.

46.3 Operating Mode

The operating modes of the CANFD module can be classified into two groups:

- Global modes
- Channel modes

46.3.1 Global Modes

These modes are applicable for the complete CANFD module and therefore are called Global modes.
The Global modes of the CANFD module are:

- GL_SLEEP
- GL_RESET
- GL_HALT
- GL_OPERATION

Figure 46.2 shows the possible transitions between the Global modes.

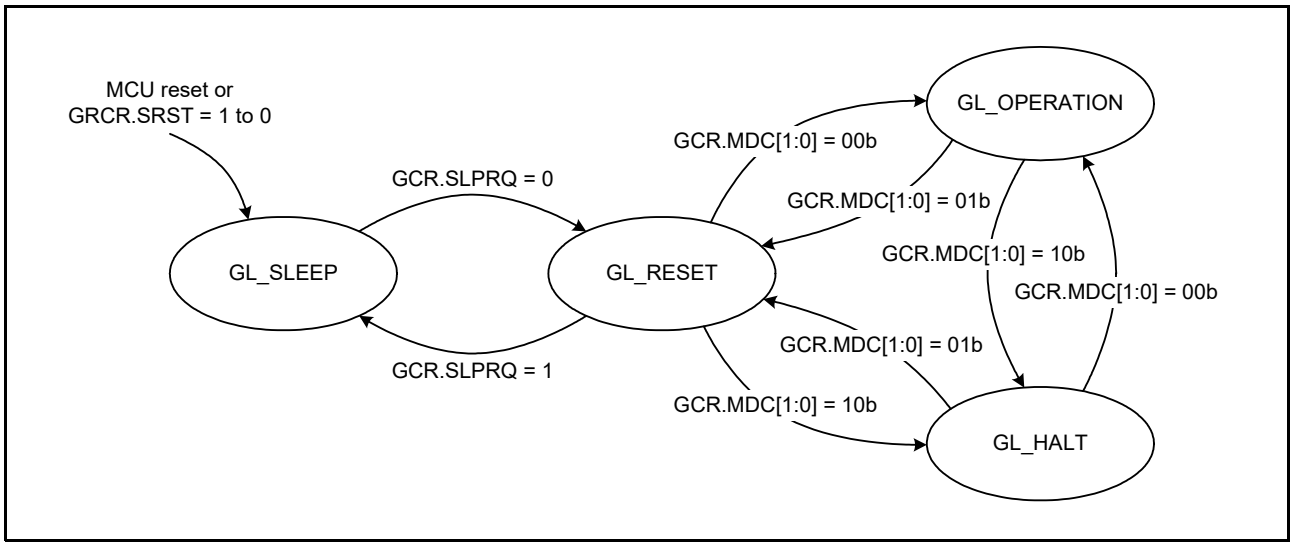

Figure 46.2 Transition between CANFD Global Modes

Change in the Global mode can affect the Channel mode. For details, refer to section 46.3.3, Global Mode and Channel Mode Transition Interactions.

46.3.1.1 GL_SLEEP Mode

The CANFD module automatically enters GL_SLEEP mode when the MCU reset is released or the software reset bit (GRCR.SRST) is changed from 1 to 0.
The CANFD module also enters the GL_SLEEP mode when the GCR.SLPRQ bit is set to 1 while it is in GL_RESET mode. The SLPRQ bit cannot be set to 1 in GL_HALT or GL_OPERATION mode.
Setting the GCR.SLPRQ bit to 1 sets the CHCR.SLPRQ bit to 1 and forces CAN channel into the CH_SLEEP mode.
GL_SLEEP mode is used for power saving purpose. When CANFD module is in GL_SLEEP mode, only the clock for writing to the SLPRQ bit is active. All other clocks are stopped and all other functions of the CANFD module are suspended.
Read access from all registers is still possible and all register values are preserved.
After setting the GCR.SLPRQ bit to 1, it is necessary to confirm the GSR.SLPST flag that the GL_SLEEP status has been updated, indicating successful transition to GL_SLEEP mode before the GCR.SLPRQ bit can be cleared again.

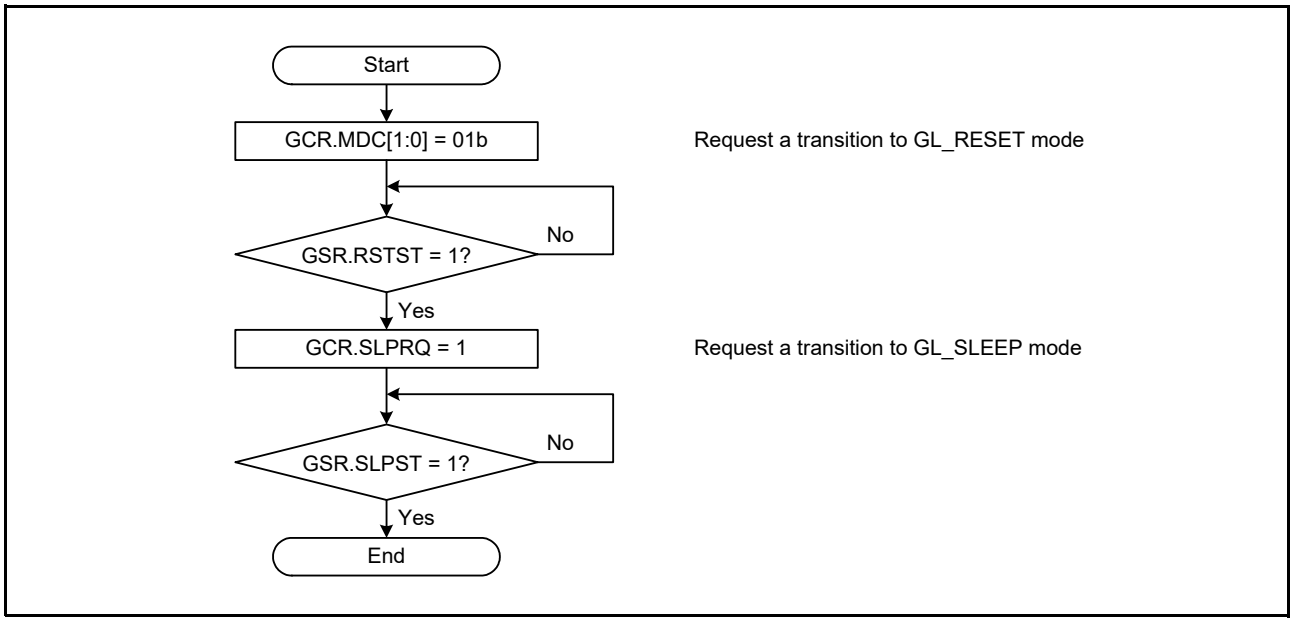

Figure 46.3 Procedure for Entering GL_SLEEP Mode

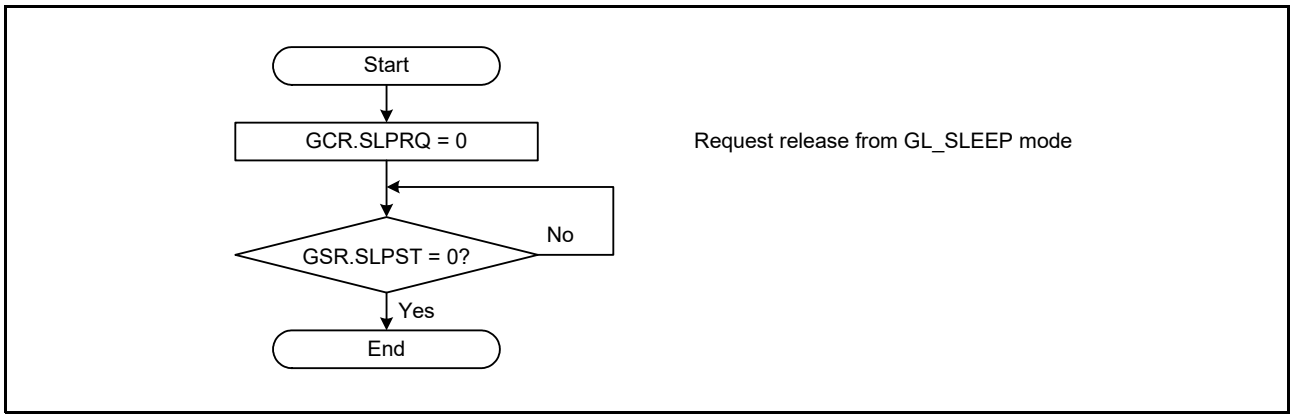

Figure 46.4 Procedure for Exiting GL_SLEEP Mode

46.3.1.2 GL_RESET Mode

The CANFD module enters GL_RESET mode in the following ways:

- The GCR.MDC[1:0] bits are set to 01b while the CANFD module is in GL_HALT or GL_OPERATION mode.
- The GCR.SLPRQ bit is set to 0 while the CANFD module is in GL_SLEEP mode.

In GL_RESET mode, all CANFD module functions are suspended and all status and flag registers are initialized. Additionally all FIFOs and all transmit queues are disabled and transmission control bits are cleared.
In this mode, configuration registers other than the GTMCR register and interrupt enable registers are not initialized, so the CANFD module can be configured.
Setting the Global mode to GL_RESET by setting the GCR.MDC[1:0] bits to 01b sets the CHCR.MDC[1:0] bits to 01b and forces the channel into the CH_RESET mode.
If the channel is already in CH_RESET mode or CH_SLEEP mode, the channel mode remains unchanged.
After setting the GCR.MDC[1:0] bits to 01b (GL_RESET mode), it is necessary to confirm that the GSR.RSTST flag has been updated, indicating successful transition to GL_RESET mode before the GCR.MDC[1:0] bits can be changed again.

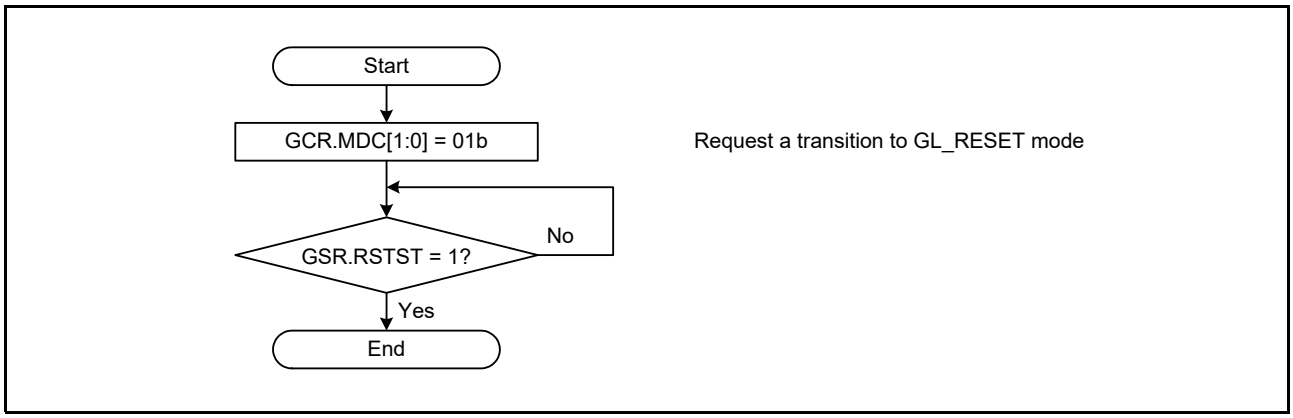

Figure 46.5 Procedure for Entering GL_RESET Mode

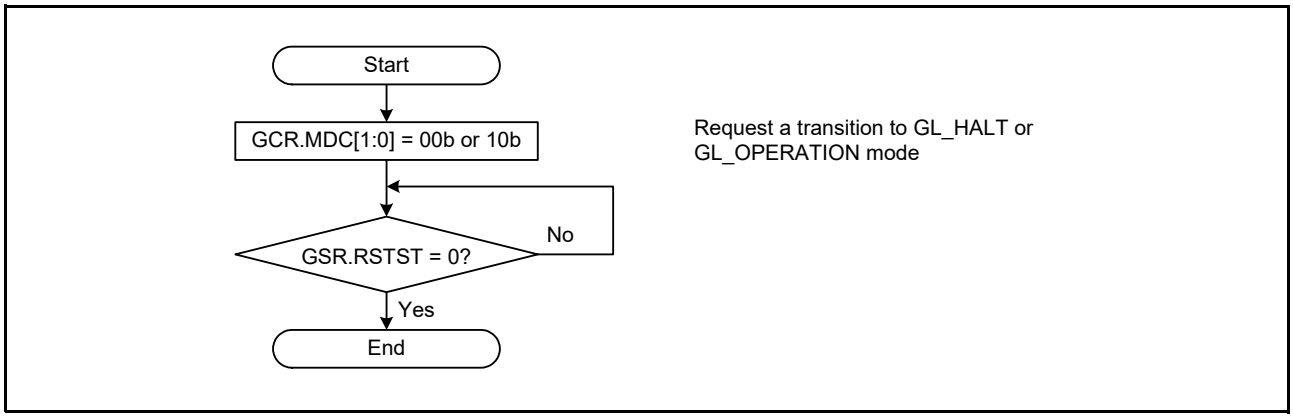

Figure 46.6 Procedure for Exiting GL_RESET Mode

46.3.1.3 GL_HALT Mode

The CANFD module enters GL_HALT mode in the following ways:

- Set the GCR.MDC[1:0] bits to 10b while the CANFD module is in GL_RESET mode:
  - The CAN channel is in either CH_RESET or CH_SLEEP mode and remains in that mode.
- Set the GCR.MDC[1:0] bits to 10b while the CANFD module is in GL_OPERATION mode:
  - If the CAN channel is in CH_RESET, CH_HALT, or CH_SLEEP mode, it remains in that mode.
  - If the CAN channel is in CH_OPERATION mode, it transits to CH_HALT mode.
  - the GSR.HLTST flag is set to 1 when the CAN channel exits CH_OPERATION mode.

If a transmission or reception is in progress for a CAN channel, the channel enters CH_HALT mode after waiting for completion of the communication.
Similarly, if a CAN channel is in the bus-off state, the channel may not enter CH_HALT mode until the bus-off recovery sequence is completed, depending on the channel configuration.
In GL_HALT mode, all communications are suspended and the status and flag registers do not change (only when a channel is in the bus-off state, its CHSR.REC[7:0] and TEC[7:0] bits are set to 00h).
Additionally, the GTMCR register and GTMER register are not initialized in this mode. The GL_HALT mode is used to configure Global Test Modes.
Setting the Global mode to GL_HALT by setting the GCR.MDC[1:0] bits to 10b sets the CHCR.MDC[1:0] bits to 10b and forces the channel into the CH_HALT mode.
If the channel is already in CH_RESET, CH_HALT, or CH_SLEEP mode, the channel mode remains unchanged.
Therefore, the GL_HALT mode request can be used to shut down all CAN channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channel).
After setting the GCR.MDC[1:0] bits to 10b (GL_HALT mode), it is necessary to confirm that the GSR.HLTST flag has been updated to indicate a successful transition to GL_HALT mode. Do not set any other registers until confirming the GSR.HLTST flag is set.

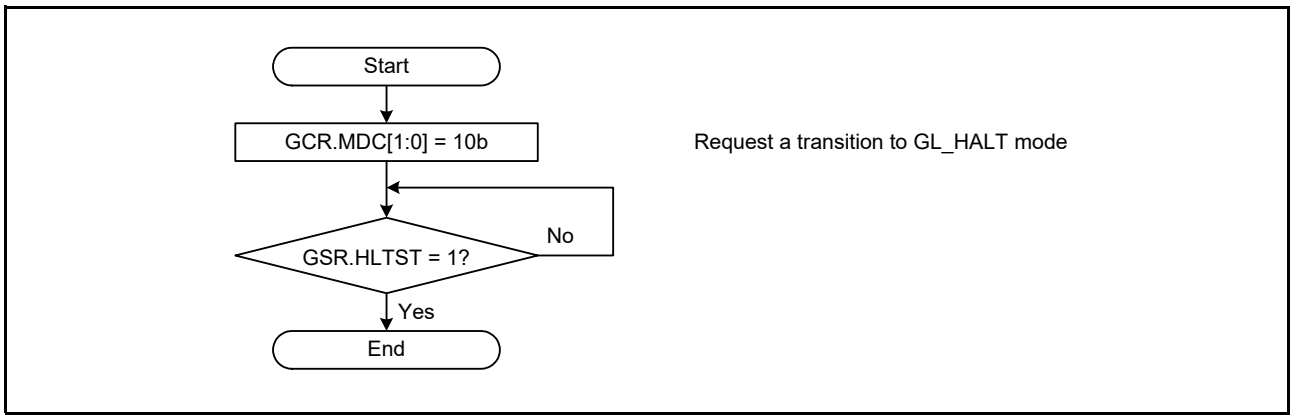

Figure 46.7 Procedure for Entering GL_HALT Mode

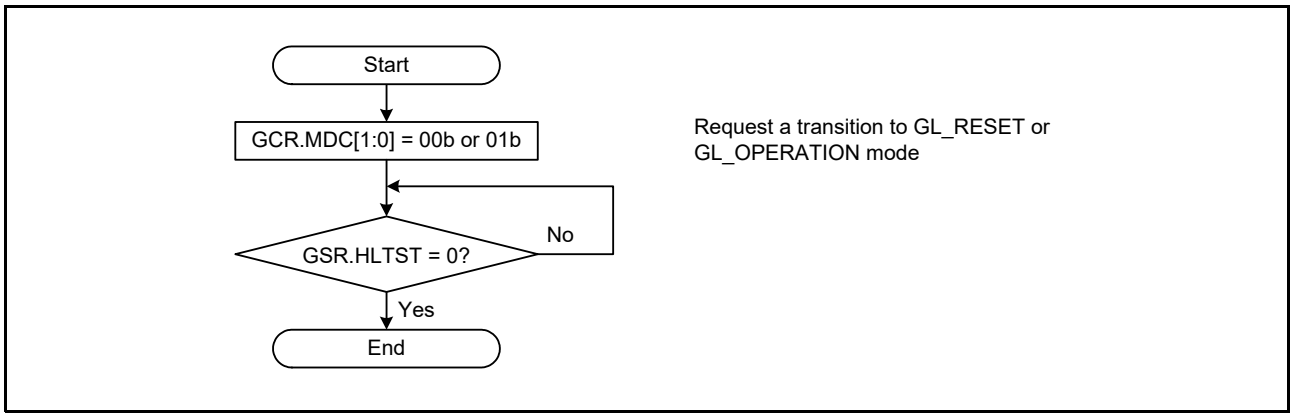

Figure 46.8 Procedure for Exiting GL_HALT Mode

46.3.1.4 GL_OPERATION Mode

The CANFD module enters this mode when the GCR.MDC[1:0] bits are set to 00b.
The CAN channel can be set to CH_OPERATION mode and start CAN communication only when the CANFD module is in GL_OPERATION mode.
After setting the GCR.MDC[1:0] bits to 00b (GL_OPERATION mode), it is necessary to confirm that the GSR.RSTST flag and the GSR.HLTST flag have been set to 0 to indicate a successful transition to GL_OPERATION mode before the GCR.MDC[1:0] bits can be modified again.

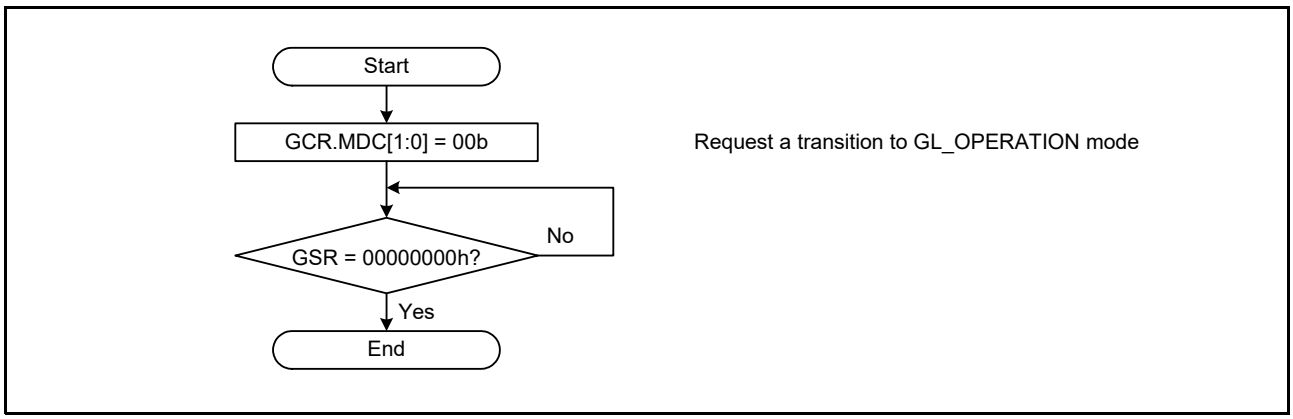

Figure 46.9 Procedure for Entering GL_OPERATION Mode

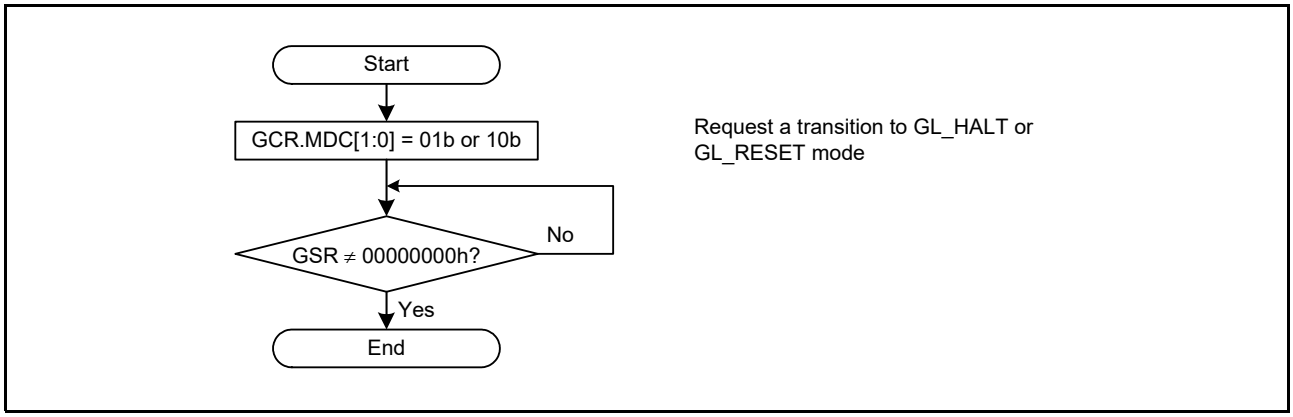

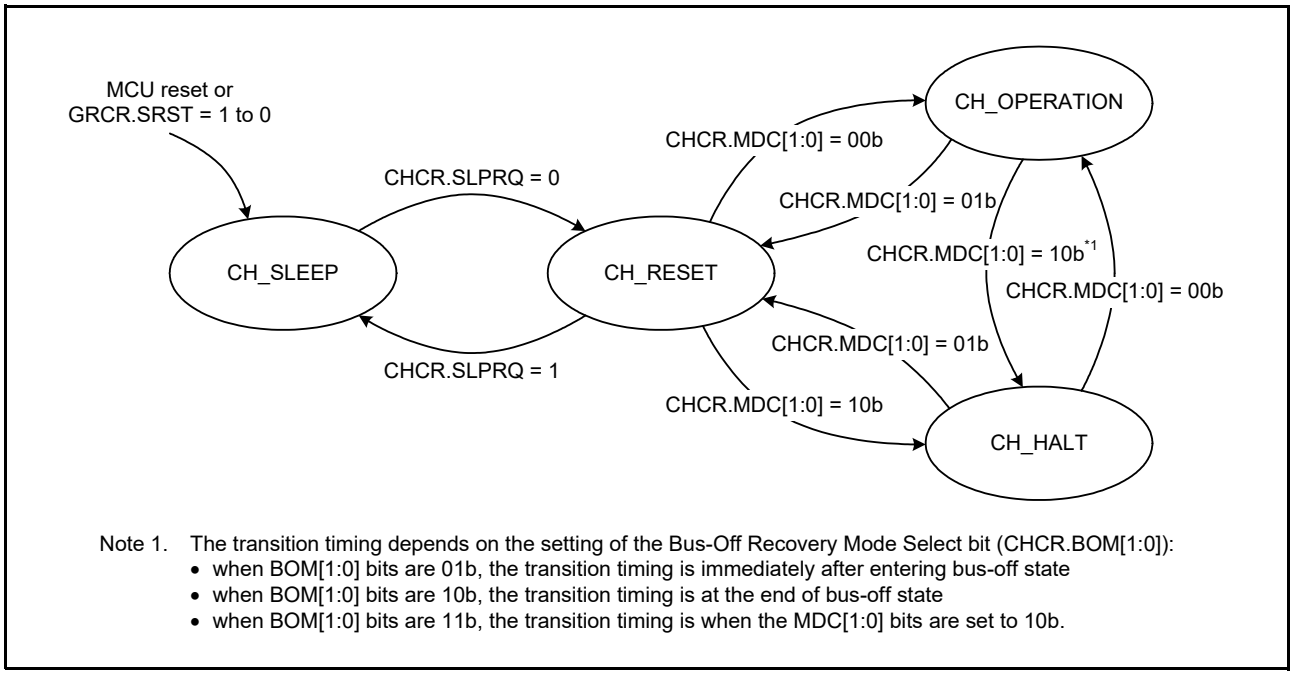

Figure 46.10 Procedure for Exiting GL_OPERATION Mode

46.3.2 Channel Modes

The Channel modes of the CANFD module are:

- CH_RESET
- CH_HALT
- CH_OPERATION
- CH_SLEEP

Figure 46.11 shows the possible transitions between the channel modes.

Note 1. The transition timing depends on the setting of the Bus-Off Recovery Mode Select bit (CHCR.BOM[1:0]):
- when BOM[1:0] bits are 01b, the transition timing is immediately after entering bus-off state
- when BOM[1:0] bits are 10b, the transition timing is at the end of bus-off state
- when BOM[1:0] bits are 11b, the transition timing is when the MDC[1:0] bits are set to 10b.

Figure 46.11 Transition between CAN Channel Modes

46.3.2.1 CH_SLEEP Mode

The CAN channel of the CANFD module automatically enters CH_SLEEP mode when the MCU reset is released or the software reset bit (GRCR.SRST) is changed from 1 to 0.
The CAN channel also enters CH_SLEEP mode when the CHCR.SLPRQ bit is set to 1 while the CAN channel is in CH_RESET mode. The CHCR.SLPRQ bit cannot be set to 1 in CH_HALT or CH_OPERATION mode.
Entering CH_SLEEP mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.
After setting the CHCR.SLPRQ bit to 1 and before setting it to 0 again, it is necessary to use the CHSR.SLPST flag to confirm that transition to CH_SLEEP mode was successful.
During CH_SLEEP mode, do not write to channel related registers. Read operation is still possible.

46.3.2.2 CH_RESET Mode

The CAN channel of CANFD module enters this mode in the following ways:

- The CHCR.MDC[1:0] bits are set to 01b while the CAN channel is in CH_HALT or CH_OPERATION mode
- The CHCR.SLPRQ bit is set to 0 while the CAN channel is in CH_SLEEP mode
- The GCR.MDC[1:0] bits are set to 01b while the CAN channel is not in CH_SLEEP or CH_RESET mode.

In CH_RESET mode, all CAN channel status and flags are initialized.
In addition, all transmission-related control bits of the channel are cleared, and the transmit queue of the channel is also disabled.
In this mode, the configuration registers except for the bits related to the channel test mode are not initialized, so the CAN channel can be configured for communication.
After setting the CHCR.MDC[1:0] bits to 01b (CH_RESET mode) and before modifying these bits again, it is necessary to use the CHSR.RSTST flag to confirm that transition to CH_RESET mode was successful.
Refer to Table 46.11 for the behavior of transitioning to CH_RESET mode while CAN communication is in progress.

46.3.2.3 CH_HALT Mode

The CAN channel of CANFD module enters this mode in the following ways:

- The CHCR.MDC[1:0] bits are set to 10b while the CAN channel is in CH_RESET or CH_OPERATION mode
- The GCR.MDC[1:0] bits are set to 10b while the CAN channel is in CH_OPERATION mode.

In CH_HALT mode, all CAN communication of the channel is suspended, but all statuses and flags remain unchanged during CH_HALT mode (except for the bus-off state where the CHSR.REC[7:0] and TEC[7:0] bits for the channel are set to 00h).
In addition, in this mode, the bits related to the channel test mode are not initialized. Use CH_HALT mode to configure the channel test mode.
After setting the CHCR.MDC[1:0] bits to 10b (CH_HALT mode) and before modifying these bits again, it is necessary to use the CHSR.HLTST flag to confirm that transition to CH_HALT mode was successful.
Refer to Table 46.11 for the transition behavior to CH_HALT mode while CAN communication is in progress.

Table 46.11 Transition Behavior in CH_RESET Mode and CH_HALT Mode

Mode	State		
	Receiver	Transmitter	Bus-Off
CH_RESET mode (CHCR.MDC[1:0] = 01b)	The CAN channel transits to CH_RESET mode without waiting for the completion of the ongoing reception.*1	The CAN channel transits to CH_RESET mode without waiting for the completion of the ongoing transmission.*1	The CAN channel transits to CH_RESET mode without waiting for the completion of the bus-off recovery.
CH_HALT mode (CHCR.MDC[1:0] = 10b)	CAN channel transits to CH_HALT mode at the end of the ongoing reception or when an error occurs.*2	CAN channel transits to CH_HALT mode after completion of the ongoing transmission.	When the CHCR.BOM[1:0] bits are 00b, a CH_HALT mode request is accepted only after the completion of the full bus-off recovery sequence. When the CHCR.BOM[1:0] bits are 10b, the CAN channel transits automatically to CH_HALT mode after waiting for the completion of the bus-off recovery. When the CHCR.BOM[1:0] bits are 01b, the CAN channel transits automatically to CH_HALT mode without waiting for the completion of the bus-off recovery. When the CHCR.BOM[1:0] bits are 11b, the CAN channel transits to CH_HALT mode as soon as CH_HALT mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to CH_RESET mode is required only at the end of an ongoing communication, then CH_HALT mode can be requested first to prevent interruption of CAN communication by direct transition to CH_RESET mode. After the CAN channel enters CH_HALT mode, the CH_RESET mode can be requested.

Note 2. If CAN communication is locked at dominant level after an error flag, software can detect this situation by monitoring the channel related BusLock flag and resolve lock condition by setting the CAN channel to CH_RESET mode.

46.3.2.4 CH_OPERATION Mode (in Other than Bus-Off State)

The CH_OPERATION mode is activated by setting the CHCR.MDC[1:0] bits to 00b. If 11 consecutive recessive bits are detected after entering the CH_OPERATION mode, the CHSR.CRDY flag is set to 1 and the CAN channel:

- Enables the functions of the communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters.

At this point, the CAN channel can start transmission and reception of messages.
Within the CH_OPERATION mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (refer to Figure 46.12):

- Idle mode: The CAN channel is neither receiving nor transmitting
- Receive mode: The channel is receiving a message transmitted by another CAN node
- Transmit mode: The channel is transmitting a message
  (The channel may receive its own message simultaneously when Self Test mode is enabled.)
- Bus-off mode: The CAN channel is cut-off from CAN bus communication

After setting the CHCR.MDC[1:0] bits to 00b (CH_OPERATION mode) and before modifying these bits again, it is necessary to use the CHSR.RSTST flag and the CHSR.HLTST flag to confirm that transition to CH_OPERATION mode was successful.

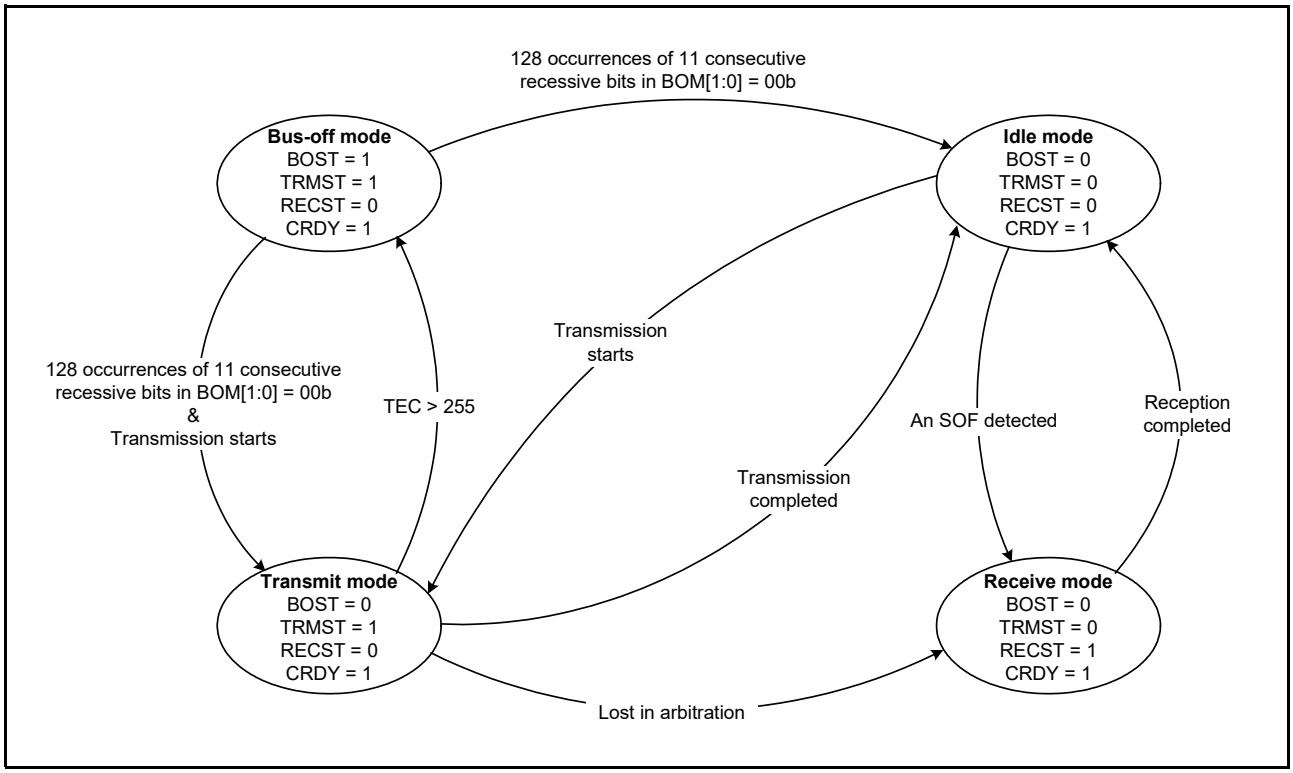

Figure 46.12 Sub-modes of CH_OPERATION Mode (only when CHCR.BOM[1:0] = 00b)

46.3.2.5 CH_OPERATION Mode (in Bus-Off State)

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CH_OPERATION mode from the bus-off state:

- CHCR.BOM[1:0] = 00b:
  Bus-off recovery is compliant to ISO 11898-1. The CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h, and the CHESR.BORDF flag is set to 1 in this case.
- CHCR.BOM[1:0] = 01b:
  When entering bus-off state, the CAN channel changes the value of the CHCR.MDC[1:0] bits to 10b and enters CH_HALT mode automatically. The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h and the CHESR.BORDF flag is not set to 1 in this case.
- CHCR.BOM[1:0] = 10b:
  When entering bus-off state, the CAN channel changes the value of the CHCR.MDC[1:0] bits to 10b and enters CH_HALT mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h and the CHESR.BORDF flag is set to 1 in this case.
- CHCR.BOM[1:0] = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter CH_HALT mode when still in bus-off state if a request is made to enter CH_HALT mode. The CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h and the CHESR.BORDF flag is not set to 1.
  Without setting CHCR.MDC[1:0] = 10b and when 11 consecutive recessive bits are detected 128 times, transition conditions become the same as CHCR.BOM[1:0] = 00b.

If the recovery from bus-off occurs normally in this mode (after waiting for 128 occurrences of 11 consecutive recessive bits), and no CH_HALT request has been generated during this period, then the CHESR.BORDF flag is set to 1.
When software writes to the CHCR.MDC[1:0] bits at the same time as the CAN channel enters CH_HALT mode (at the start of bus-off when CHCR.BOM[1:0] = 01b, or at the end of bus-off when CHCR.BOM[1:0] = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CHCR.MDC[1:0] bits to CH_HALT mode request is performed when the CHCR.MDC[1:0] bits value is previously 00b (CH_OPERATION mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting the CHCR.RTBO bit to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The CHESR.BORDF flag is not set to 1 in this case, and the CHSR.TEC[7:0] and REC[7:0] bits are initialized to 00h.
Before setting the CHCR.RTBO bit to 1, all pending transmissions from the transmit message buffers, transmit queues and/or common FIFO in transmit mode should be disabled.
The disable of the pending transmit message buffer, transmit queue or common FIFO must be confirmed by the corresponding acknowledge flags (TMSRn.TXRF[1:0] flags, TQSR0.EMPTY flag, and CFSR0.EMPTY flag).
The CHCR.RTBO bit should be used for bus-off recovery only when the CHCR.BOM[1:0] bits are set to 00b.
Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.
Table 46.12 lists the behavior of the bus-off entry detect flag (CHESR.BOEDF) and the bus-off recovery detect flag (CHESR.BORDF) according to the CHCR.BOM[1:0] bit settings.

Table 46.12 Behavior of Bus-off Entry and Recovery Flags

CHCR.BOM[1:0] Bits	CHESR.BOEDF Flag	CHESR.BORDF Flag
00b	Becomes 1 on entry to bus-off state.	Becomes 1 on exit from bus-off state.
00b Set the CHCR.RTBO bit to 1		Becomes 1 only if normal bus-off recovery occurs before setting the CHCR.RTBO bit to 1.
01b		Does not become 1.
10b		Becomes 1 on exit from bus-off state.
11b		Becomes 1 only if normal bus-off recovery occurs before requesting a transition to CH_HALT mode.

To make efficient software, it is not necessary to wait for the bus-off recovery sequence to end.
It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in Figure 46.13.

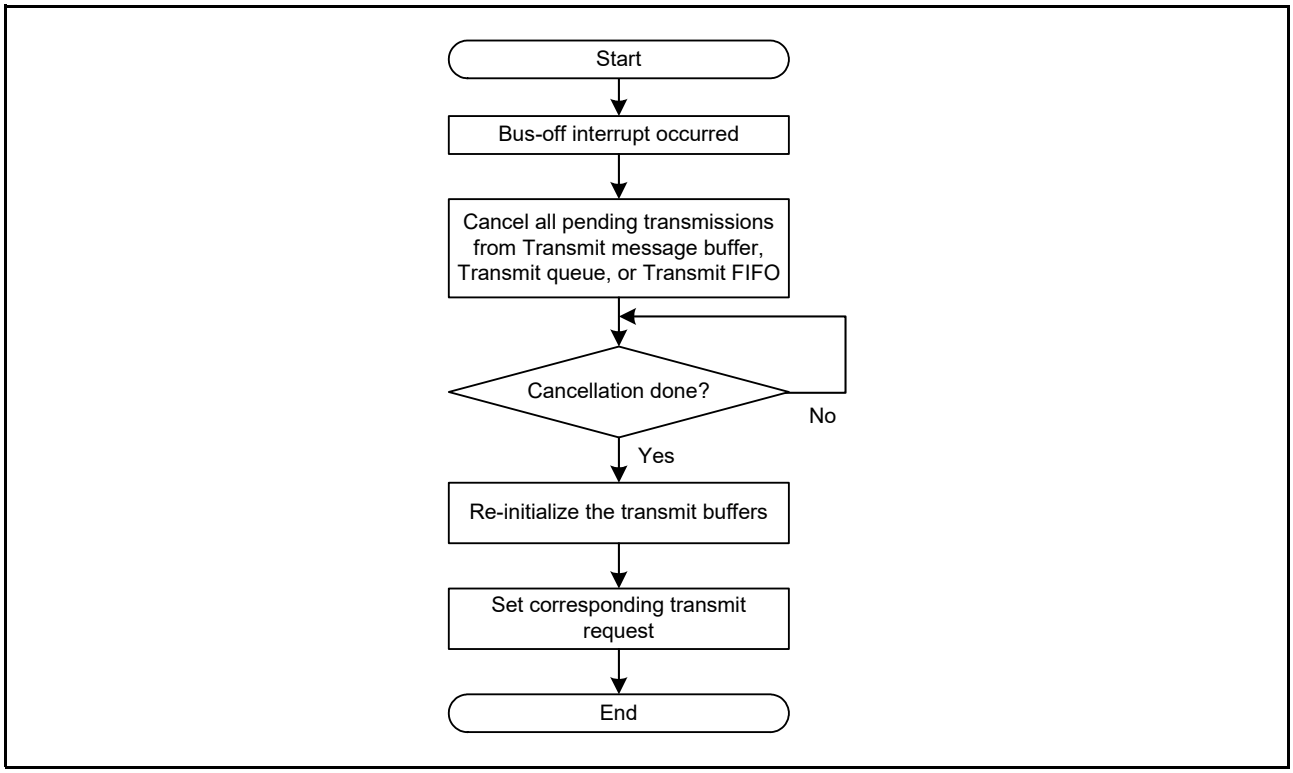

Figure 46.13 Transmission Re-Initialization During Bus-Off

46.3.3 Global Mode and Channel Mode Transition Interactions

The interaction between Global mode setting and Channel mode setting is as follows:

- Changing the CHCR.MDC[1:0] bits does not affect the GCR.MDC[1:0] bits.
- Changing the GCR.MDC[1:0] bits affects the channel mode control as described in Table 46.13.

Table 46.13 Interaction between Global Mode and Channel Mode Transition

Global Mode Change	Channel Mode before Changing Global Mode	Channel Mode after Changing Global Mode
GL_SLEEP → GL_RESET	CH_SLEEP	CH_SLEEP (no changes)
GL_RESET → GL_SLEEP	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_SLEEP
GL_RESET → GL_HALT	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
GL_RESET → GL_OPERATION	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
GL_HALT → GL_RESET	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
	CH_HALT	CH_RESET
GL_HALT → GL_OPERATION	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
	CH_HALT	CH_HALT (no changes)
GL_OPERATION → GL_RESET	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
	CH_HALT	CH_RESET
	CH_OPERATION	CH_RESET
GL_OPERATION → GL_HALT	CH_SLEEP	CH_SLEEP (no changes)
	CH_RESET	CH_RESET (no changes)
	CH_HALT	CH_HALT (no changes)
	CH_OPERATION	After communication ends, CH_HALT

46.3.3.1 Transition Time for Global Mode Change

Table 46.14 shows the transition times when changing the global mode.

Table 46.14 Maximum Transition Times for Global Mode Changes

From	To	Maximum Transition Time
GL_SLEEP	GL_RESET	3 × PCLKA*2
GL_RESET	GL_SLEEP	3 × PCLKA
GL_RESET	GL_HALT	10 × PCLKA
GL_RESET	GL_OPERATION	10 × PCLKA
GL_HALT	GL_RESET	2 bit times (1 Tq + 16 × PCLKA + 2 DLL clock cycles)
GL_HALT	GL_OPERATION	3 × PCLKA
GL_OPERATION	GL_RESET	2 bit times (1 Tq + 16 × PCLKA + 2 DLL clock cycles)
GL_OPERATION	GL_HALT	3 CAN frames (1 CAN frame + 3424 × PCLKA)*1

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked receive lines or continued error conditions.

Note 2. Exit GL_SLEEP mode only when the GSR.RAMST flag is cleared.

46.3.3.2 Transition Time for Channel Mode Change

Table 46.15 shows the transition times when changing the channel mode.

Table 46.15 Maximum Transition Times for Channel Mode Changes

From	To	Maximum Transition Time
CH_SLEEP	CH_RESET	3 × PCLKA
CH_RESET	CH_SLEEP	3 × PCLKA
CH_RESET	CH_HALT	3 bit times (1 CAN bit + 2 Tq + 8 × PCLKA + 2 DLL clock cycles)
CH_RESET	CH_OPERATION	4 bit times (2 CAN bits + 1 TSEG1 + 12 × PCLKA + 2 DLL clock cycles)
CH_HALT	CH_RESET	2 bit times (1 Tq + 10 × PCLKA + 2 DLL clock cycles)
CH_HALT	CH_OPERATION	4 bit times (< 4 CAN bits)*3
CH_OPERATION	CH_RESET	2 bit times (1 Tq + 10 × PCLKA + 2 DLL clock cycles)
CH_OPERATION	CH_HALT	2 CAN frames (1 CAN frame + 13 CAN bits)*1, *2

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CHCR.BOM[1:0] bits.

Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked receive lines or continued error conditions.

Note 3. In general, if the bit rate prescaler value (NBCR.BRP[9:0]) is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the Tq clock, and new BRP value is captured when the counter reaches the value 0.

46.4 Initialization of CANFD Module

Before starting CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data bit rate)
- Bit Rate setting (nominal and data bit rate)
- CANFD setting
- Acceptance Filter setting (configuration of Acceptance Filter List)
- Receive FIFO and Transmit FIFO setting
- CAN operating mode setting.

46.4.1 Initialization of CAN Clock, Bit Timing and Bit Rate

46.4.1.1 Bit Timing Conditions

The following lines describe the settings for each segment and the limitations that apply to those settings.

1. Each segment setting
   SS = Fixed to 1 Tq
   TSEG1 = 2 Tq to 256 Tq (NBCR), 2 Tq to 32 Tq (DBCR)
   TSEG2 = 2 Tq to 128 Tq (NBCR), 2 Tq to 16 Tq (DBCR)
   SJW = 1 Tq to 128 Tq (NBCR), 1 Tq to 16 Tq (DBCR)
   SS + TSEG1 + TSEG2 = 8 Tq to 385 Tq (NBCR), 5 Tq to 49 Tq (DBCR)
2. Limitations on TSEG1, TSEG2 and SJW
   NBCR register: TSEG1 > TSEG2 ≥ SJW
   DBCR register: TSEG1 ≥ TSEG2 ≥ SJW

Table 46.16 shows an example of how to set the bit timing to achieve the required sample point settings.

Table 46.16 Bit Timing Examples

1 Bit	Set Value (Tq)				Sample Point (%)
	SS	TSEG1	TSEG2	SJW	
5 Tq	1	2	2	1	60.00
8 Tq	1	4	3	1	62.50
	1	5	2	1	75.00
10 Tq	1	6	3	1	70.00
	1	7	2	1	80.00
12 Tq	1	8	3	1	75.00
	1	9	2	1	83.33
15 Tq	1	10	4	1	73.33
	1	11	3	1	80.00
16 Tq	1	10	5	1	68.75
	1	11	4	1	75.00
20 Tq	1	12	7	1	65.00
	1	13	6	1	70.00
24 Tq	1	15	8	1	66.66
	1	16	7	1	70.83
50 Tq	1	39	10	4	80.00

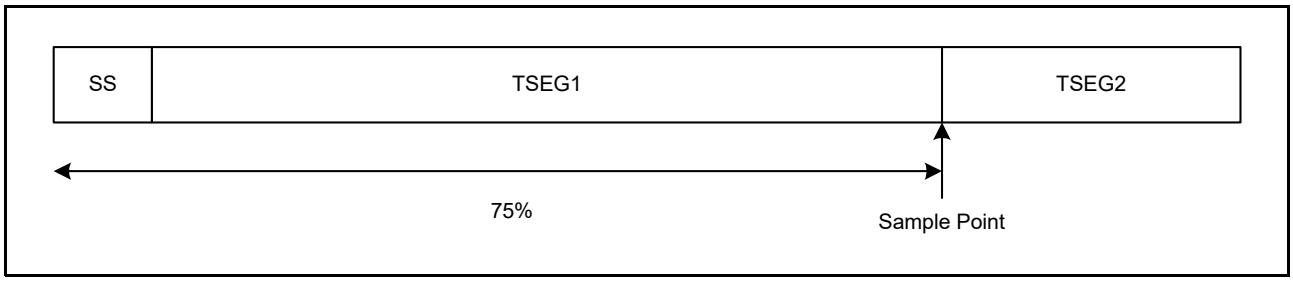

Figure 46.14 The Sample Point (in Case of 75%)

46.4.1.2 Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured using the NBCR and DBCR registers.

Figure 46.15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (Tq), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the bit rate prescaler (nominal and data bit rate).

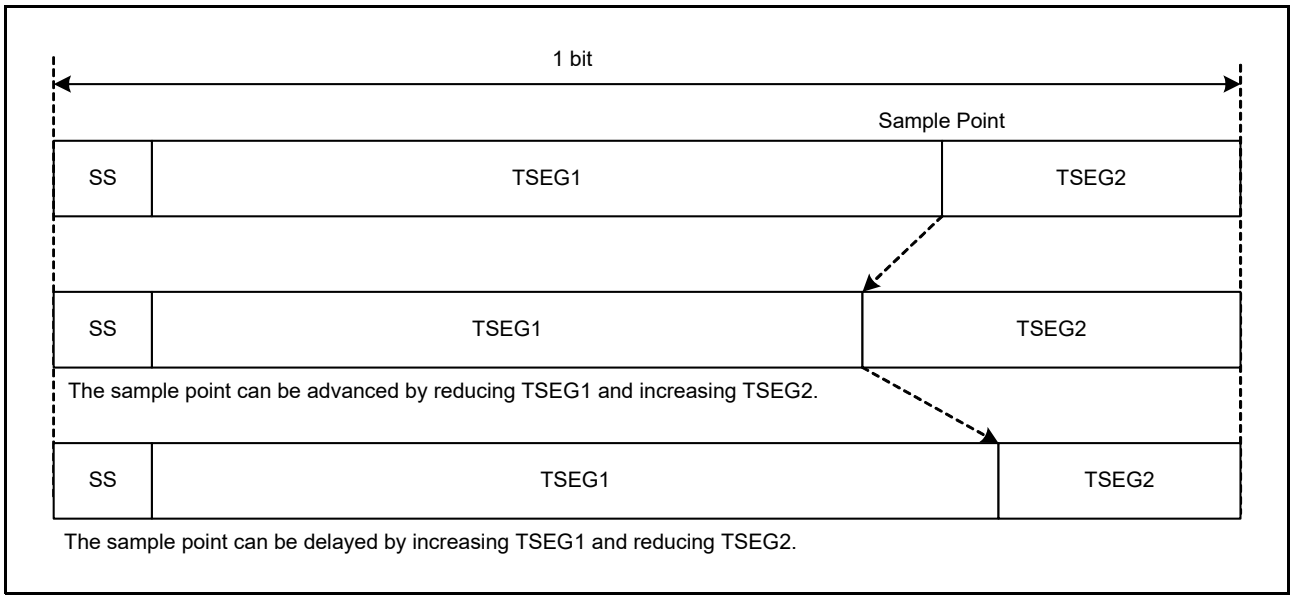

Figure 46.15 Segment Composition of A Bit and The Sample Point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. The interframe space consists of the intermission, suspend transmission, and bus idle fields; during the bus idle field, all nodes may begin transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While transmitting or receiving a message, communication frames between some nodes may get out of sync due to a drift

in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.

4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 46.15 shows an example of a typical sample point.

46.4.1.3 Bit Rate

The CAN communication clocks are generated by dividing the operating clock for data link layer (DLL clock). The DLL clock can be selected from either the internal clock (CANFDCLK) or the external clock (CANFDMCLK).
Figure 46.16 shows a block diagram of the circuit that generates the CAN communication clock.

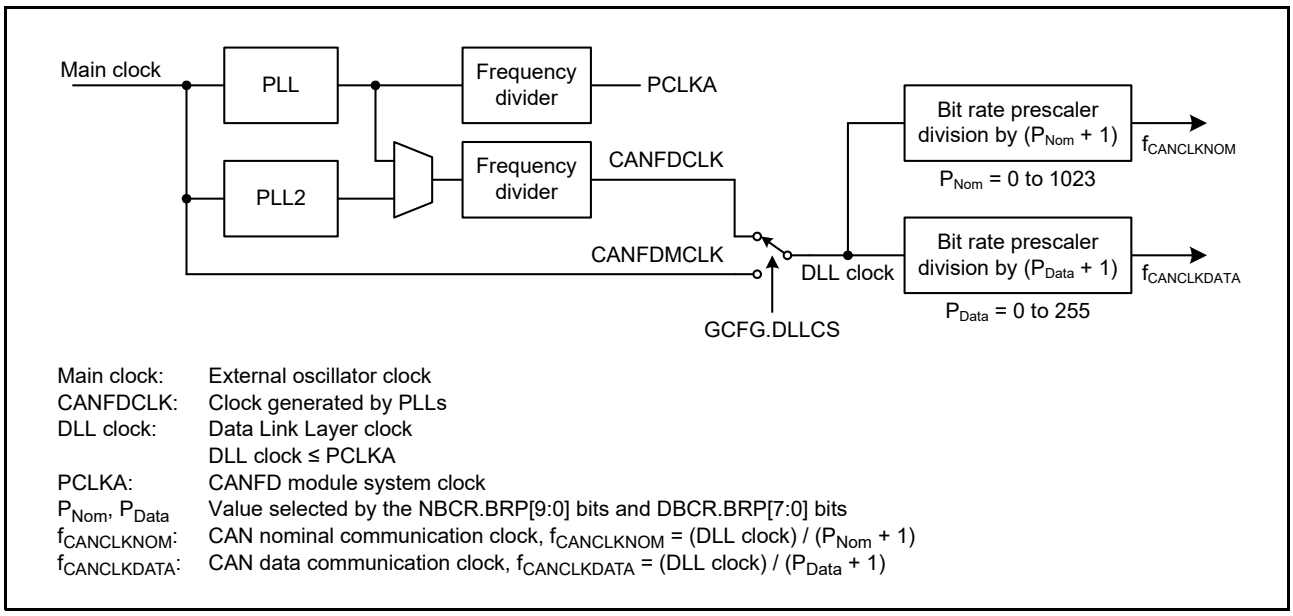

Figure 46.16 Block Diagram of the Circuit that Generates the CAN Communication Clock

The bit rate is determined by the DLL clock frequency, the division value of the bit rate prescaler (P + 1), and the number of Tq per bit.

$$\text{Bit rate} = \frac{\text{DLL clock frequency}}{\text{Number of Tq per bit} \times (\text{P} + 1)} = \frac{\text{CAN communication clock frequency}}{\text{Number of Tq per bit}}$$

Table 46.17 lists examples of setting the nominal bit rate for Classical CAN frame.

Table 46.17 Nominal Bit Rate Setting Examples for Classical CAN Frame

Bit Rate	DLL Clock Frequency																	
	80 MHz		40 MHz		32 MHz		30 MHz		24 MHz		20 MHz		16 MHz		10 MHz		8 MHz*1	
	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1	No. of Tq	P+1

Note 1. Minimum frequency to achieve a nominal bit rate of 1 Mbps.

For optimum clock tolerance in networks using the CAN FD frame, the length of the time quantum should be the same in nominal bit time and in data bit time. This means NBCR.BRP[9:0] = DBCR.BRP[7:0].
In addition, do not set the DBCR.BRP[7:0] bits greater than 1 when using transceiver delay compensation.
Table 46.18 lists examples of setting the nominal and data bit rate for CAN FD frame.

Table 46.18 Nominal and Data Bit Rate Setting Examples for CAN FD Frame

Bit Rate		DLL Clock Frequency											
		80 MHz			40 MHz			30 MHz			20 MHz		
		No. of Tq			No. of Tq			No. of Tq			No. of Tq		
Nominal	Data	Nom.	Data	P+1	Nom.	Data	P+1	Nom.	Data	P+1	Nom.	Data	P+1

46.4.1.4 Setting of CAN Clock, Bit Timing and Bit Rate

Figure 46.17 shows the procedure for setting the bit timing and the bit rate.
These settings should be configured when the CAN channel is in CH_RESET mode.
The bit rate must be configured before moving to the channel communication state. Otherwise the mode does not switch correctly.

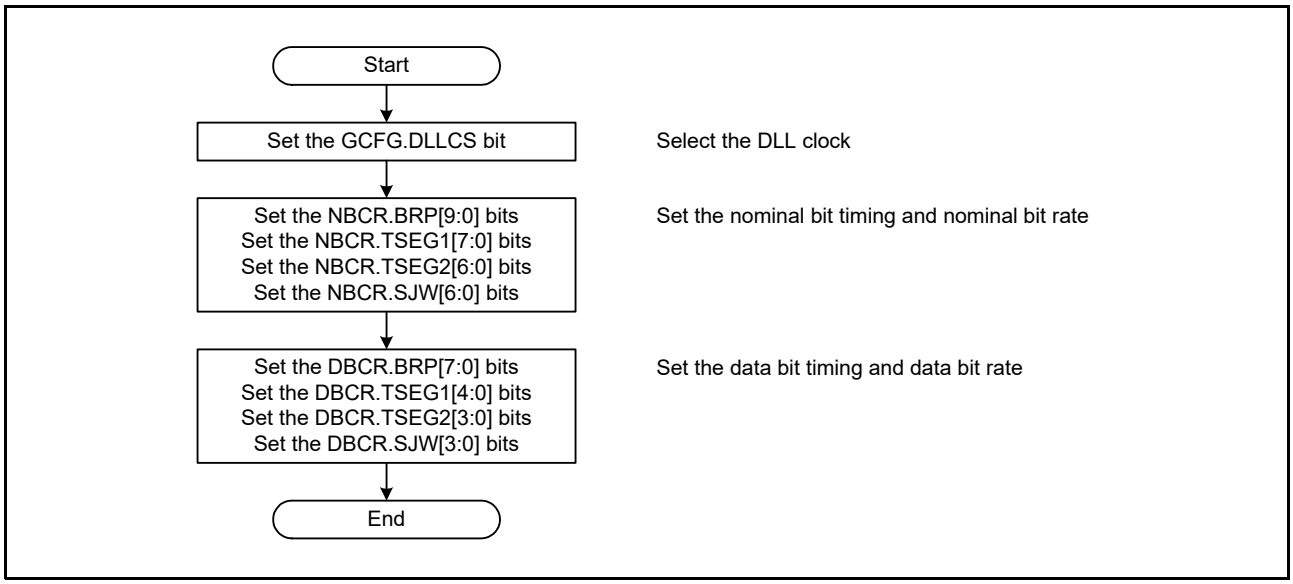

Figure 46.17 Procedure for Setting the Bit Timing and Bit Rate

46.4.1.5 Transceiver Delay Compensation

When a high bit rate is used such as 5 to 8 Mbps for the data phase, the transceiver delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CAN FD frame. The transceiver delay compensation function compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.
There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CAN FD frames. This is derived from the Transceiver Delay Compensation Result bit (FDSTS.TDCR[7:0]) as shown in Figure 46.18.
The resolution of the configuration, measured and offset values is based on the CAN channel DLL clock.

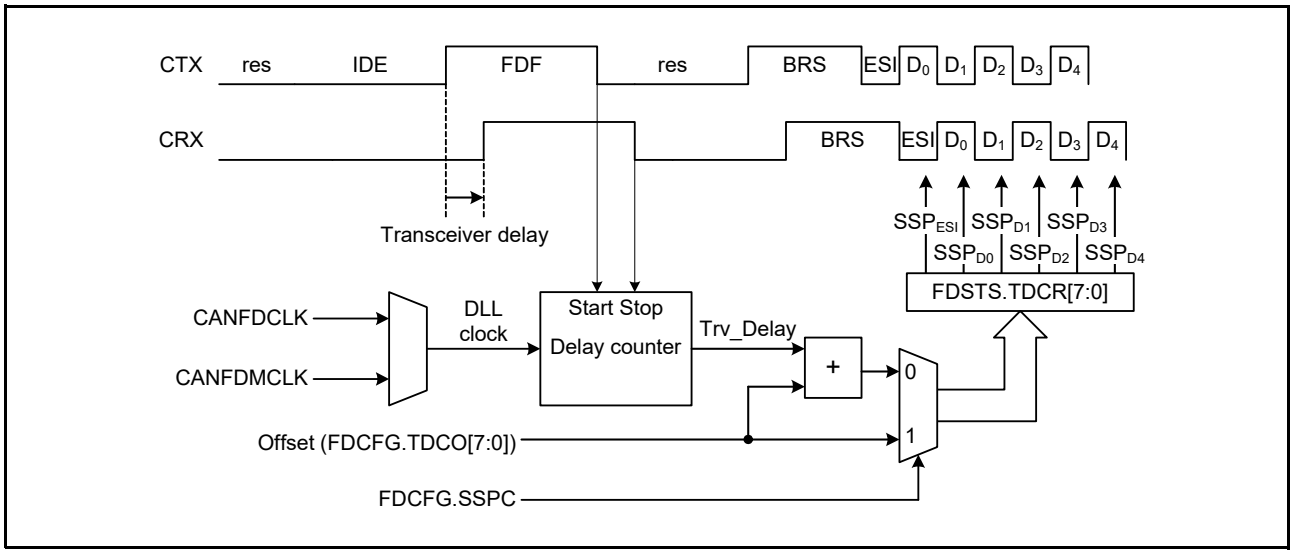

Figure 46.18 Transceiver Delay Compensation

The measured Trv_Delay is based on the number of DLL clock cycles. It counts up by one for each start clock until the dominant value can be observed at the CRX pin. Figure 46.19 shows the measurement example. Trv_Delay is counted up to 127 on each DLL clock.

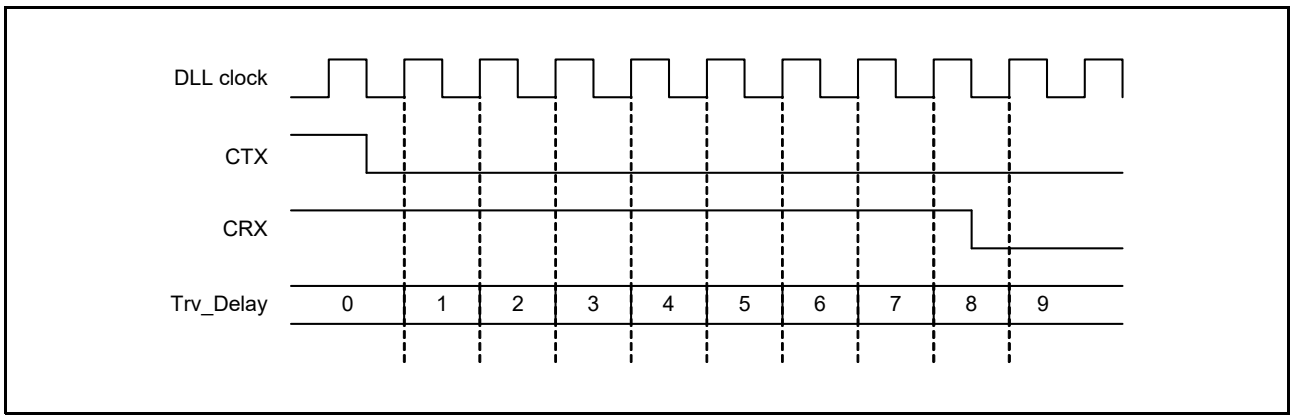

Figure 46.19 Trv_Delay Measurement Example

The SSP is calculated by taking the result from the FDSTS.TDCR[7:0] bits and rounding the value down to the nearest integer number of data Tq.

Figure 46.20 shows the positioning of the secondary sample point (SSP). When the FDCFG.SSPC bit is set to 0, the SSP is equal to the Trv_Delay (measured delay) + FDCFG.TDCO[7:0], rounded down to the nearest integer number of Tq. Normally, the TDCO[7:0] value has the magnitude of SS + TSEG1 in the data phase to position the SSP to a theoretical location of the sample point.

If the FDCFG.SSPC bit is set to 1, the SSP is defined by the FDCFG.TDCO[7:0] bits. If the DBCR.BRP[7:0] bits are greater than 00h, the value is also rounded down to the nearest integer number of Tq.

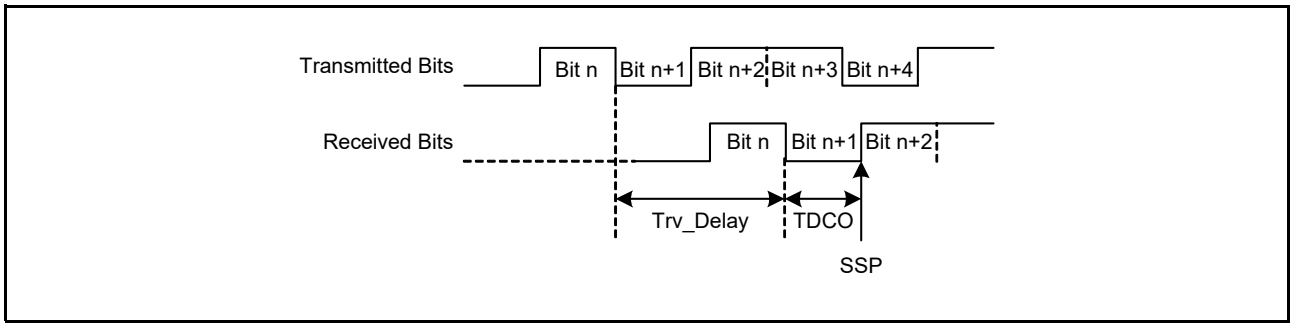

Figure 46.20 Positioning of the Secondary Sample Point (SSP)

The maximum delay time (Trv_Delay + TDCO[7:0]) which can be compensated by the CANFD module is (6 data bit times – 2 DLL clocks). The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.
If different values are used for the NBCR.BRP[9:0] bits and DBCR.BRP[7:0] bits, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in Figure 46.21.
The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means NBCR.BRP[9:0] = DBCR.BRP[7:0].
The bit rate can be changed by selecting different settings for the time segments. The nominal bit rate can be set from 8 to 385 Tqs and the data bit rate from 5 to 49 Tqs.

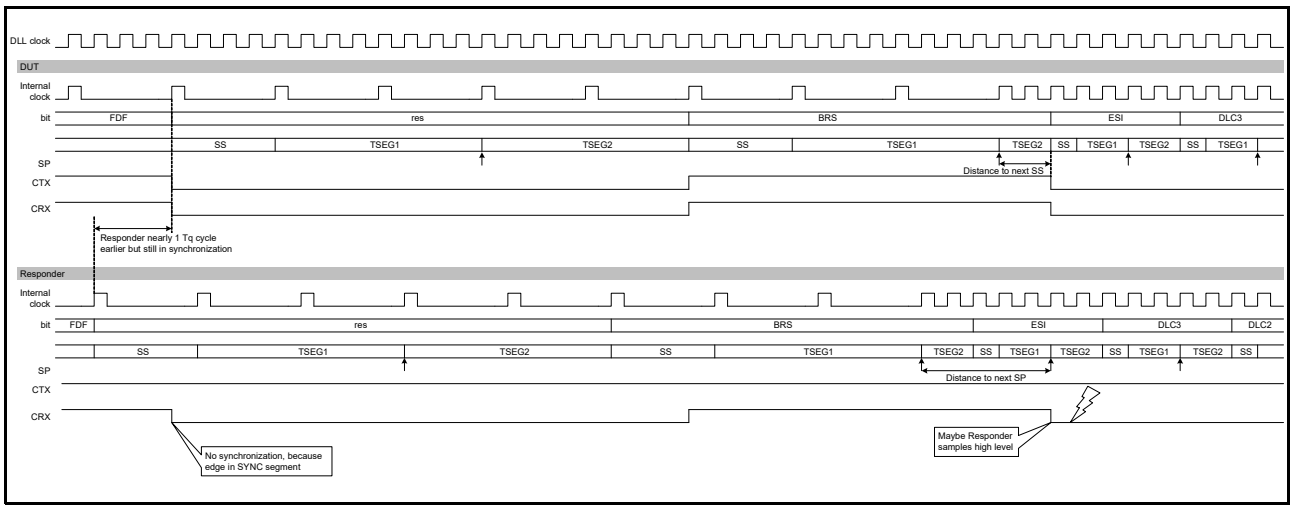

Figure 46.21 Loss of Synchronization Between Two CAN Nodes

The transceiver delay compensation measurement result is updated at the falling edge from FDF bit to res bit when configured accordingly (FDCFG.TDCE = 1, FDCFG.SSPC = 0).
Figure 46.22 shows the read flow to get the measured transceiver delay compensation result.

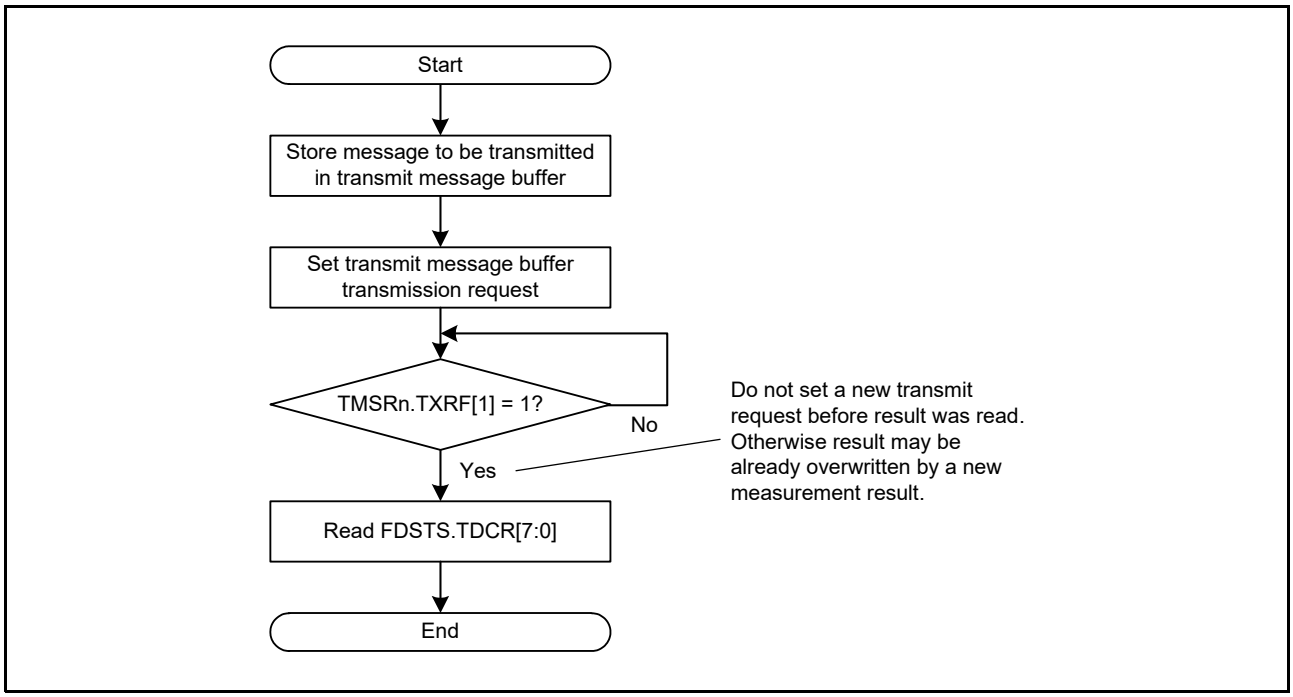

Figure 46.22 Transceiver Delay Compensation Result Read Flow

46.4.2 CANFD Module Configuration after a Reset

After resetting the MCU or applying a software reset using the GRCR.SRST bit, the CANFD module automatically enters GL_SLEEP mode.

To configure the CANFD module, set the GCR.SLPRQ bit to 0 to exit GL_SLEEP mode.

After resetting the MCU, the CANFD module starts RAM initialization when the module-stop state is released and clocks are supplied. At this time, the GSR.RAMST flag is automatically set to 1, indicating that the CANFD module is initializing the RAM.

After RAM initialization is complete, this flag is automatically set to 0.

RAM initialization is necessary to prevent false detection of ECC errors due to undefined data in RAM after MCU reset. Do not access (read or write) any other CANFD registers until the RAM initialization is complete and the RAMST flag is set to 0.

Before entering communication mode, the Acceptance Filter List and message FIFO buffers must be configured. In addition, the CAN channel settings such as CAN bit timing must be configured. To make this configuration, the CAN channel must be released from CH_SLEEP mode and configured for communication in CH_RESET mode (configuration mode).

Figure 46.23 shows the configuration procedure. For details about each step, refer to section 46.5, Filtering Using Acceptance Filter List (AFL), section 46.6, FIFO Buffers and Message Buffer Configuration, section 46.10, Interrupts and DTC/DMA Requests, and section 46.4.1.3, Bit Rate.

The CANFD module does not perform the RAM initialization sequence after executing a software reset by setting the GRCR.SRST bit to 1.

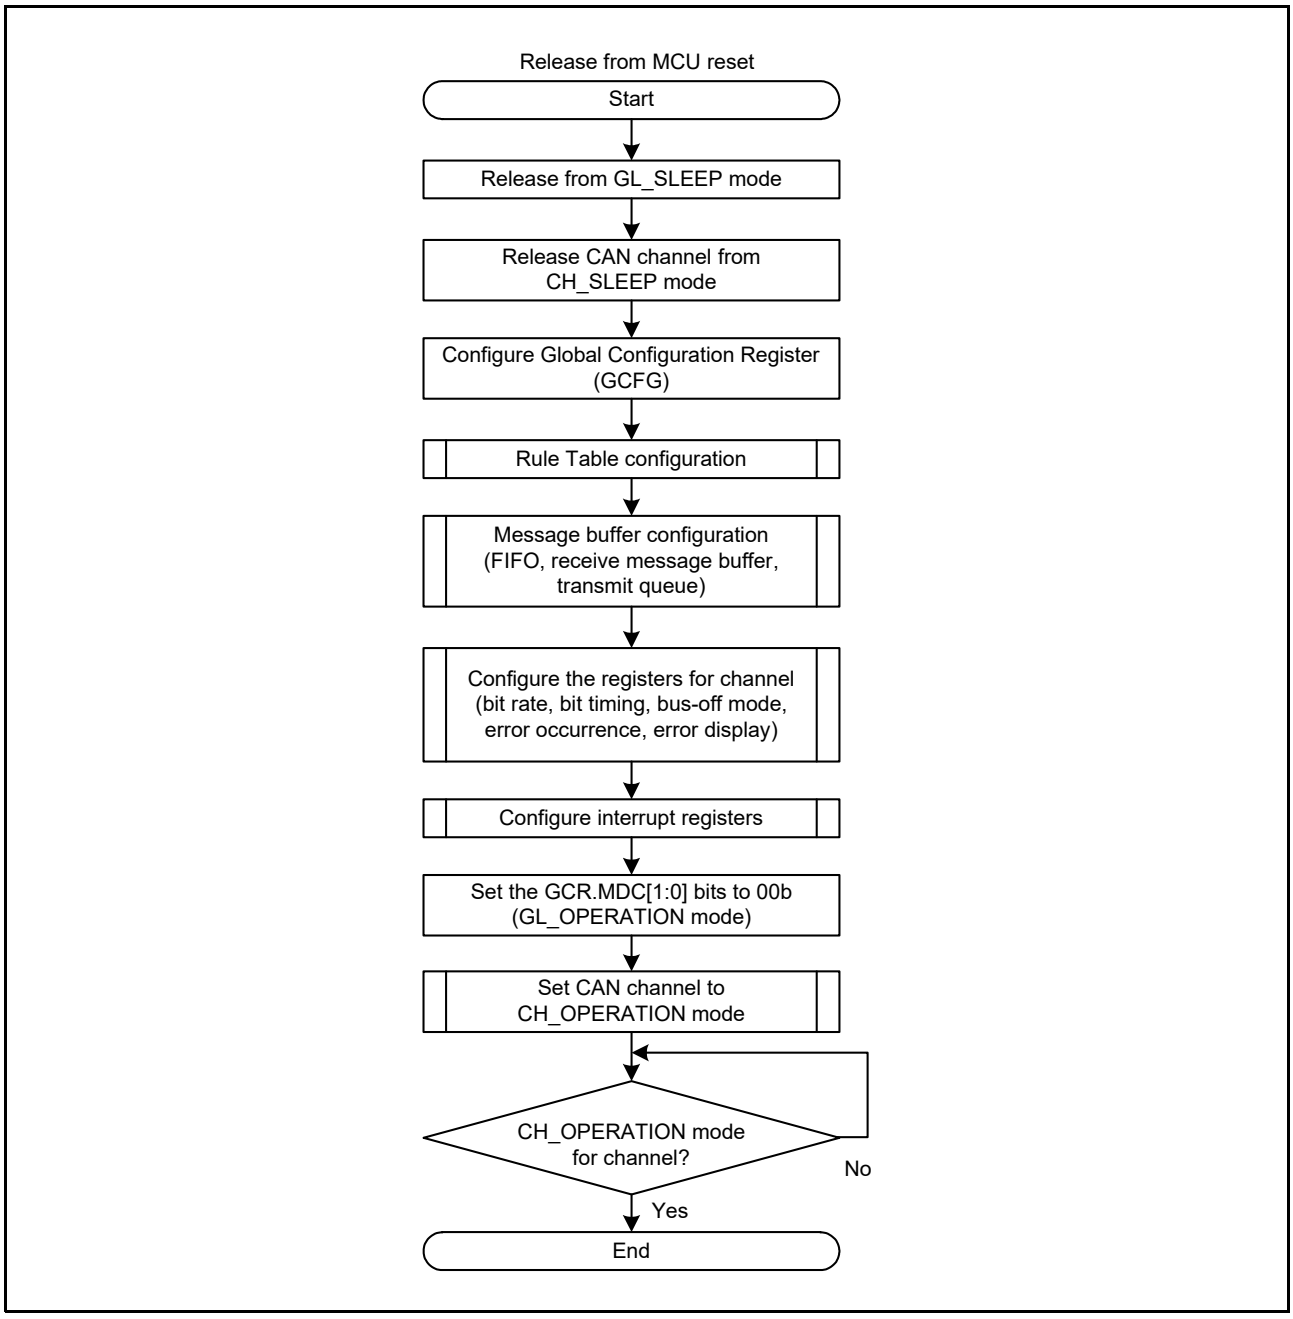

Figure 46.23 Configuration Procedure After An MCU Reset

46.5 Filtering Using Acceptance Filter List (AFL)

The CANFD module can use the Acceptance Filter List (AFL) to filter messages for acceptance. Each entry in the AFL defines a filtering rule for received messages.
The followings are performed based on the AFL entries:

- Acceptance filtering based on the RTR value, IDE value, and ID value of received message
- DLC filtering based on DLC value of received message
- Payload overflow based on the GCFG.OMRC bit
- Storage of accepted messages in the specified message buffer/FIFO buffer
- Attaching a 16-bit pointer to the stored messages, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages.

The CANFD module allows a maximum of 16 AFL entries.

46.5.1 Acceptance Filtering Process

Acceptance filtering matches each AFL entry with the received message. Matching starts with the lowest AFL entry number.
The AFL search stops when the received message ID matches the specified ID/mask combination, or when the received message ID has been matched against all defined AFL entries. If no match occurs, then the received message is discarded. No notification is given to the application in this case.

46.5.2 DLC Filtering Process

DLC filtering is performed for each accepted message if DLC check is enabled (GCFG.DCE bit = 1). If the DLC value of the received message is equal to or higher than the DLC value specified for the AFL entry whose ID matches in the Acceptance Filtering process (the matching AFL entry), the DLC check is passed.
If DLC replacement is enabled (GCFG.DRE bit = 1), DLC value configured in the matching AFL entry is greater than 0000b and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination receive message buffer (RMBn) or FIFO buffer. If DLC value of the received message is greater than the DLC value specified in the matching AFL entry, the excess data bytes are not stored in the RMBn/FIFO buffer. These excess data bytes are stored as 00h in the RMBn/FIFO buffer.
If DLC replacement is enabled and the DLC value specified in the matching AFL entry is 0000b (DLC filter function is disabled), the DLC value of the received message is stored in the RMBn/FIFO buffer.
If DLC replacement is disabled (GCFG.DRE bit = 0) and DLC check passes, the DLC value of the received message is stored in the RMBn/FIFO buffer. If the DLC value of the received message is greater than the DLC value specified in the matching AFL entry, the excess data bytes are also stored in the RMBn/FIFO buffer.
If DLC value of the received message is less than the DLC value specified in the matching AFL entry, DLC check fails. In this case, the received message is discarded and is not stored anywhere.
Additionally, when the DLC check fails, the GESR.DEDF flag is set to 1. If interrupts are enabled, an error interrupt is also generated. If the DLC check fails, the DLC replacement setting has no effect.

46.5.3 Message Storage

If a received message has passed both acceptance filtering and DLC filtering, the message is stored in receive message buffers 0 to 15, receive FIFO 0, 1, or common FIFO 0 configured in receive FIFO mode.
This message storage target information is also defined in the AFL entry. Do not set a target at the AFL entry which is not configured.
Up to two message storage destinations can be specified. Do not specify more than 3 destinations.

46.5.4 Payload Overflow Process

There is a protection mechanism in case the received message contains data with a payload size that is longer than the size that can be stored in the storage (RMCR.PLS[2:0], RFCR0.PLS[2:0], RFCR1.PLS[2:0], or CFCR0.PLS[2:0]).
If GCFG.OMRC = 0 (message is discarded), the message with data bytes that exceed the specified payload size are discarded and not stored. In this case, even if the FIFO is full, the corresponding FMLSR.RFML0, RFML1, or CFML0 flag is not set to 1.
If GCFG.OMRC = 1 (cut to specified size), only data bytes that exceed the specified payload size are discarded. In this case, if the FIFO is full, the corresponding FMLSR.RFML0, RFML1, or CFML0 flag is set to 1 (message lost has occurred).
Depending on the GCFG.DRE bit setting, either the DLC value of the received message or the DLC value specified in the AFL entry is stored.
Regardless of the GCFG.OMRC bit setting, the GESR.PODF flag is set to 1 if a payload overflow condition is detected.
The DLC filtering is performed before the payload overflow processing. Therefore, for each received frame, only one of the GESR.DEDF and GESR.PODF flags is set to 1.

46.5.5 Allocation of AFL Entries

The number of AFL entries (number of rules) can be configured using the AFCFG.RN0[4:0] bits (refer to Figure 46.24).

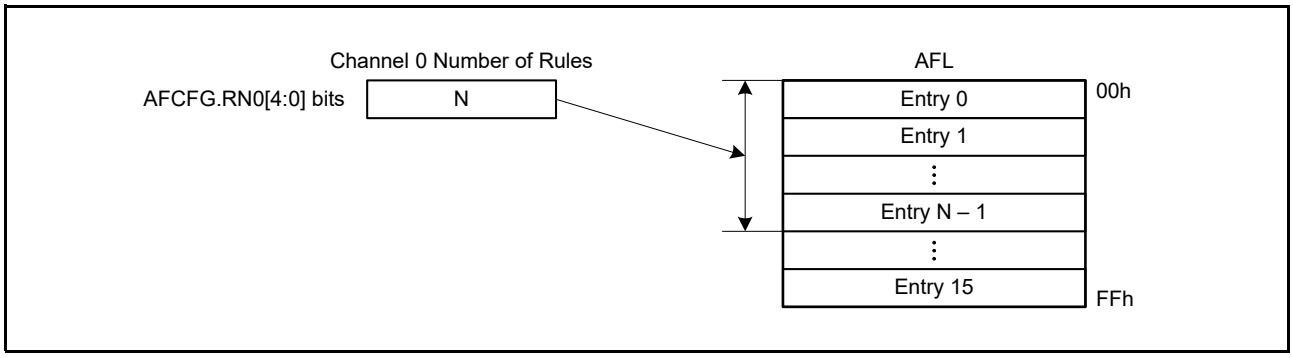

Figure 46.24 Configuration of AFL

The minimum number of entries is 0 (no entries defined for the channel) and the maximum number of entries is 16.
The CANFD module does not flag errors related to the configuration of the AFL.

46.5.6 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.
Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier field (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit matches this field with the identifier field of the received message (29 bits of identifier field can be masked individually, refer to the description of Mask for Identifier field below).
- IDE bit:
  Acceptance filter unit matches this bit with the IDE bit of the received message and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, refer to the description of Mask for IDE bit below).
- RTR bit:
  Acceptance filter unit only accepts data frames (RTR = 0) or remote frames (RTR = 1) according to the setting of this bit (masking of RTR bit is possible, refer to the description of Mask for RTR bit below).
- Loop-Back Configuration bit:
  This bit can enable or disable the AFL entry depending on the loop-back configuration or mirror mode condition.
- Mask for Identifier field (29 bits):
  Each bit in the identifier mask field can mask the corresponding identifier bit in the AFL entry (refer to Figure 46.25).
- Mask for IDE bit:
  If this Mask bit masks the IDE bit of an AFL entry, the AFL entry can accept messages in both Standard Identifier format and Extended Identifier format. For messages in Standard Identifier format, the Standard Identifier part of the AFL entry is compared, and for messages in Extended Identifier format, the Extended Identifier part of the AFL entry is compared.
- Mask for RTR bit:
  If this Mask bit masks the RTR bit of an AFL entry, the AFL entry can accept frame formats in both data frame and remote frame.
- Pointer (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added when storing a message in the message buffer area and can be used as a support function in the application.
  For example, the pointer information can be used to support the assignment of PDU IDs to the received message in AUTOSAR systems.
- Information label (2 bits):
  This 2-bit label is attached to a message accepted by the related AFL entry. This label is added when storing a message in the message buffer area and can be used as support function in the application.
- DLC field:
  If the DLC value of the received message is equal to or higher than the value set in this field, the DLC check is passed.
  If the DLC value of an AFL entry is set to 0000b, the DLC filtering for this entry is effectively disabled (all accepted messages pass DLC filtering).

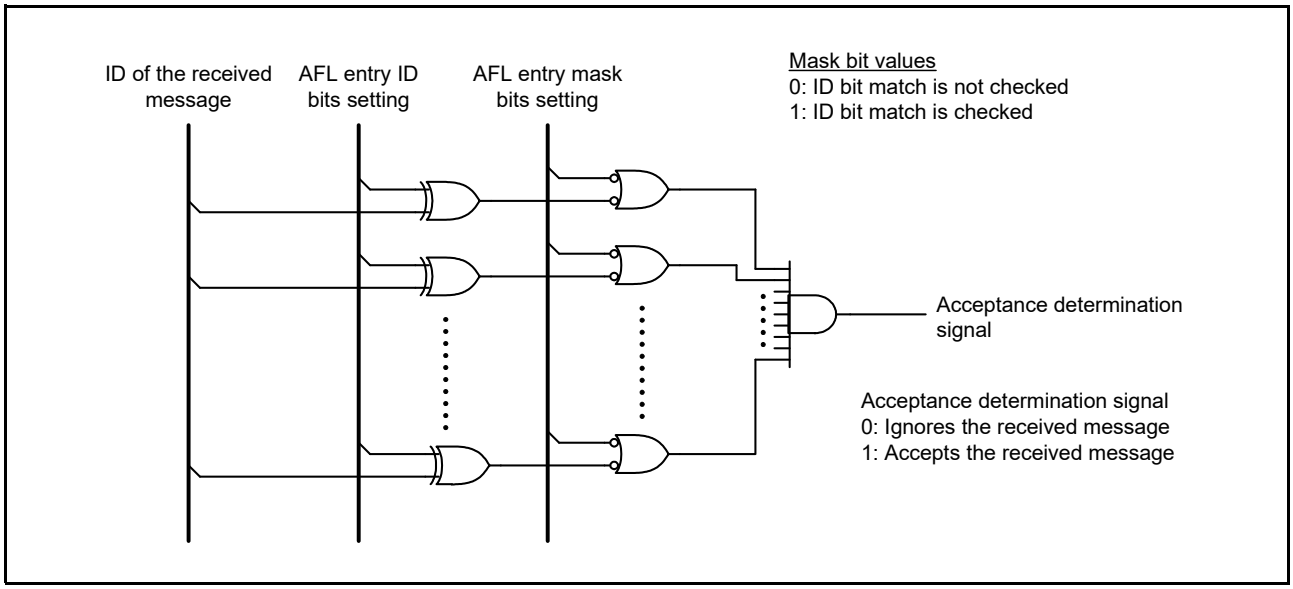

Figure 46.25 Acceptance Filter Function

Each AFL entry contains the following information for processing the received messages:

- Message buffer number of the receive message buffer used as the storage destination for received messages
- The Destination Message Buffer Setting Enable bit to specify the receive message buffer as the storage destination for received messages
- The FIFO Destination Enable bit to specify the FIFO as the storage destination for received messages.

There is no protection function for storing messages. Therefore, the FIFO Destination Enable bit must be set carefully.

46.5.7 Entering Entries in the AFL

One complete entry can be entered into AFL via the following registers:

- AFLn.IDR register: First part of the AFL entry
- AFLn.MASK register: Second part of the AFL entry
- AFLn.PTR0 register: Third part of the AFL entry
- AFLn.PTR1 register: Fourth part of the AFL entry

Follow the flow shown in Figure 46.26 to configure the AFL.
After entering all the entries, writing to the AFL must be disabled to prevent unnecessary write access to the AFL.
If the AFCR.AFLWE bit is set to 0, write protection is enabled during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION).
Even if the AFCR.AFLWE bit is set to 0, reading from AFL is possible during all Global modes (the consistency of AFL contents can be checked during execution).

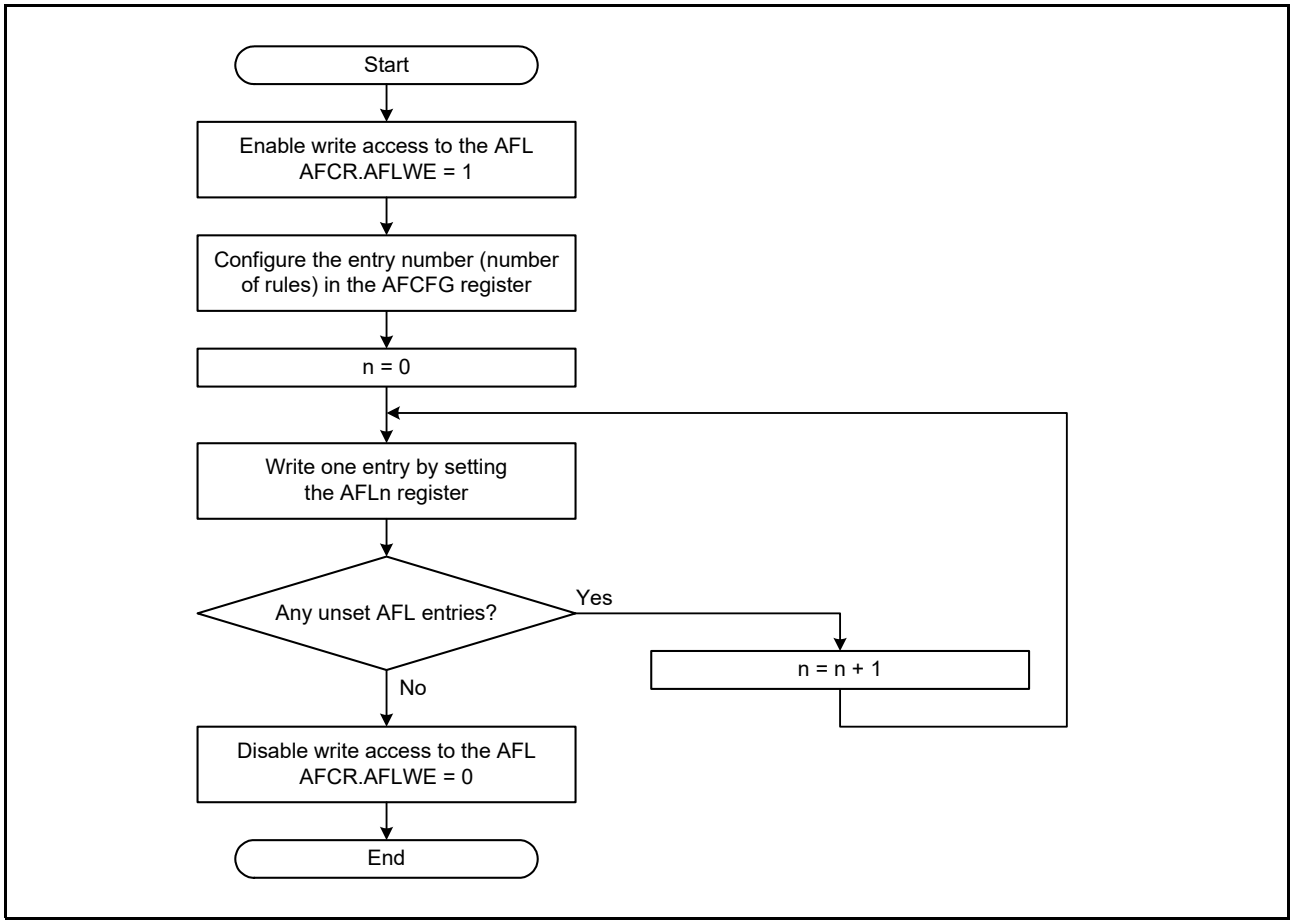

Figure 46.26 AFL Configuration Flow

46.5.8 Loop-Back Configuration

AFL entries with the AFLn.IDR.LPC bit set to 1 are used only in loop-back mode (self-test mode 0 or self-test mode 1) or mirror mode. If a message transmitted by another node on the CAN bus is received while in loop-back mode, the AFL entry will not be used.
AFL entries with the LPC bit set to 0 are used only when the following messages are received.

- Messages transmitted by other nodes
- Messages transmitted by the CAN channel itself in loop-back mode

The mirror mode can be enabled with the GCFG.MME bit. If the message is successfully transmitted when the GCFG.MME bit is 1, the message is stored in the receive message buffer or FIFO buffer if there is a matching entry in the AFL. The AFLn.IDR.LPC bit in the matching AFL entry must be set to 1 to store this message.
If mirror mode and loop-back mode are set at the same time, the loop-back mode behavior is applied. Table 46.19 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 46.19 Behavior of Acceptance Filter Based on the Loop-Back Setting in AFL Entry

Mirror Mode (MME Bit)	Loop-Back Mode (Self-Test Mode 0 or Self-Test Mode 1)	Channel Mode	LPC Bit	AFL Entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

46.5.9 IDE Masking

The IDE bit set in the AFL entry with the AFLn.MASK.IDEM bit set to 0 is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is selected based on the received IDE bit.
The following lines show the examples.

- The ID and mask fields of an AFL entry x is configured as follows:
  - AFLx.IDR = C0553A20h → IDE = 1, RTR = 1, LPC = 0, ID[10:0] = 220h/ID[28:0] = 00553A20h
  - AFLx.MASK = 0000FFFFh → IDEM = 0, RTRM = 0, IDM[10:0] = 7FFh/IDM[28:0] = 0000FFFFh
- The comparison result for the four different received IDs with AFL entry x is described as follows:
  - If a frame with IDE = 0 and ID = 220h is received, this is considered as a match
  - If a frame with IDE = 0 and ID = 320h is received, this is not a match
  - If a frame with IDE = 1 and ID = 1FFF3A20h is received, this is considered as a match
  - If a frame with IDE = 1 and ID = 08803220h is received, this is not a match.

46.5.10 Updating AFL Entry during Communication

The AFL entry can be updated without disabling CAN communications.
Set the AFL entry number to update to the ignore entry select bits and set the ignore entry enable bit to 1.
The entry number specified here is ignored by AFL matching while the entry is being updated.
Figure 46.27 shows the update flow for an AFL entry.

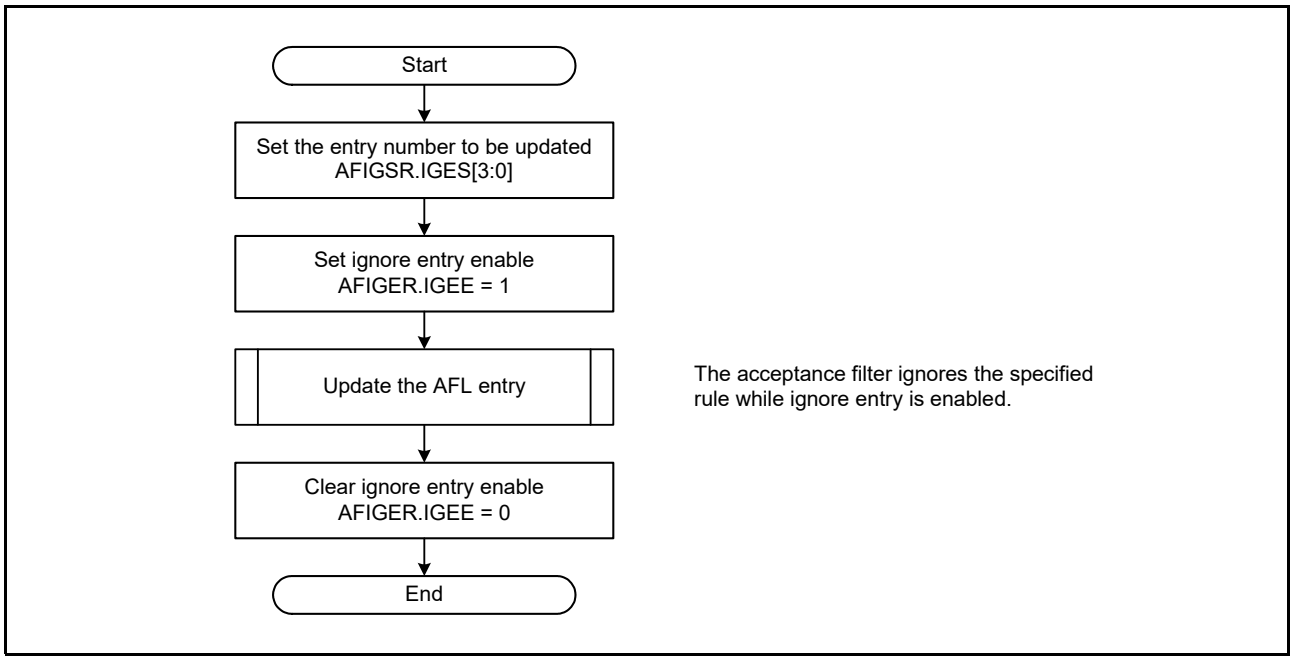

Figure 46.27 Update Flow for An AFL Entry

The method to update an AFL entry is as follows:
(1) Set the entry number*1 to be updated to the AFIGSR.IGES[3:0] bits.
(2) Set the value 0000C401h (key code and ignore entry enabled) to the AFIGER register.
(3) Set the AFCR.AFLWE bit to 1.
(4) Set the new rule to the AFLn.IDR, AFLn.MASK, AFLn.PTR0, AFLn.PTR1 registers.
(5) The AFCR.AFLWE bit is set to 0.
(6) Set the value 0000C400h (key code and ignore entry disabled) to the AFIGER register.

Note 1. The specified entry is not used for acceptance filtering between (2) and (5).

(1) Example 1: Deleting an Entry

The following describes how to delete entry 3 when the total number of entries is 6.

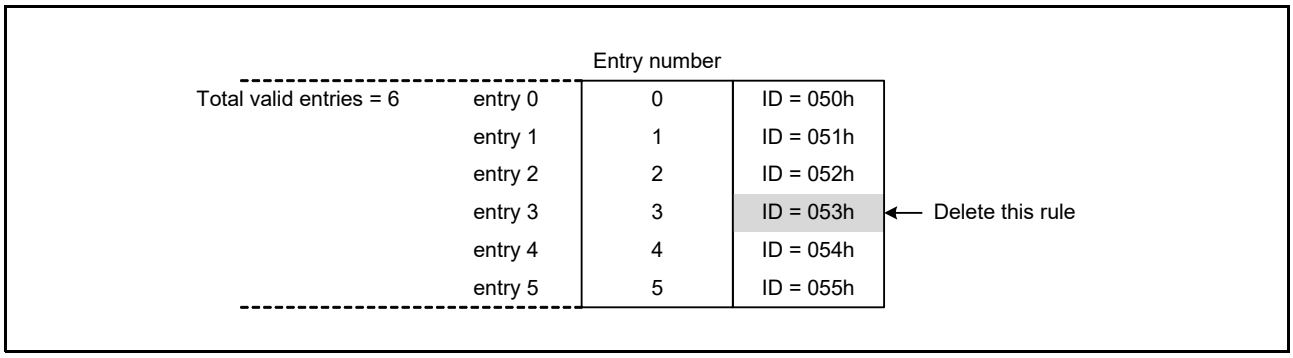

Figure 46.28 Example of Deleting an Entry (Before Deleting Entry 3)

[How to delete an entry]

(1) Set 00000003h to the AFIGSR register.
(2) Set 0000C401h to the AFIGER register.
(3) Set 00000100h to the AFCR register.
(4) Set the same rule as the previous entry by accessing the AFL3.IDR, AFL3.MASK, AFL3.PTR0, AFL3.PTR1 registers.
(5) Set 00000000h to the AFCR register.
(6) Set 0000C400h to the AFIGER register.

Entry 3 is now deleted.

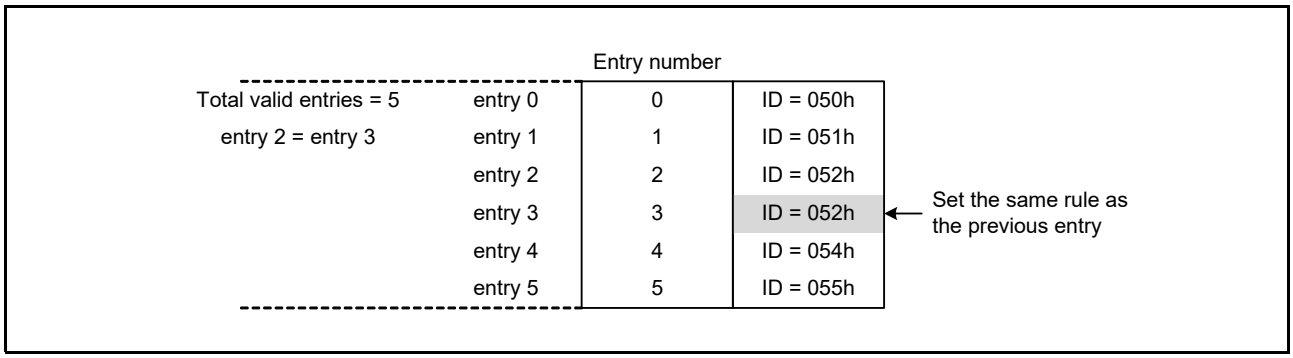

Figure 46.29 Example of Deleting an Entry (After Deleting Entry 3)

(2) Example 2: Adding an Entry (Update Unused Entry)

The following describes how to add a new rule to entry 3 when the total number of entries is 6.

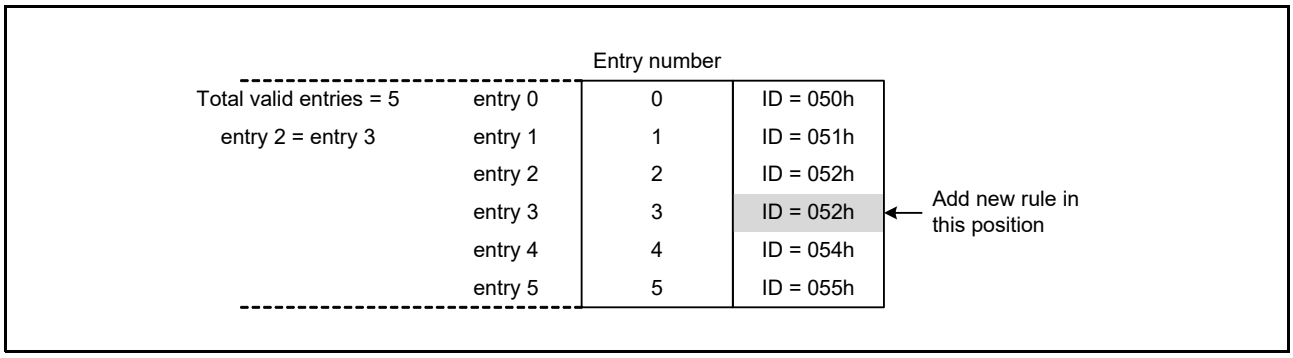

Figure 46.30 Example of Adding an Entry (Before Updating Entry 3)

[How to add an entry]

(1) Set 00000003h to the AFIGSR register.
(2) Set 0000C401h to the AFIGER register.
(3) Set 00000100h to the AFCR register.
(4) Set the new rule by accessing the AFL3.IDR, AFL3.MASK, AFL3.PTR0, AFL3.PTR1 registers.
(5) Set 00000000h to the AFCR register.
(6) Set 0000C400h to the AFIGER register.

The new entry is now added.

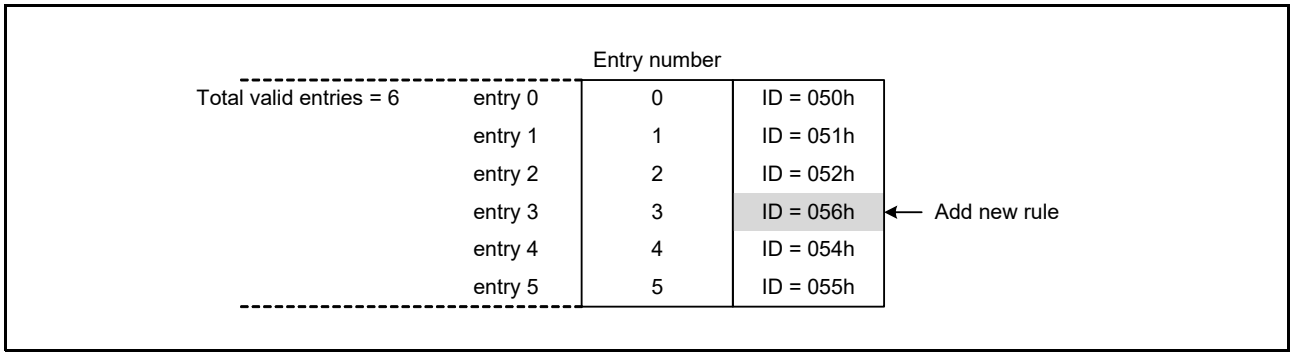

Figure 46.31 Example of Adding an Entry (After Updating Entry 3)

The acceptance filter can use entries in the range of value set in the AFCFG register and entries can be added/deleted within that range. Therefore, the AFCFG register should be set to the maximum number of entries to use.

46.6 FIFO Buffers and Message Buffer Configuration

This section describes the process for configuring the number of receive message buffers, the FIFO buffers, and the transmit message buffers in the CANFD module. The message buffers are mapped as shown in Figure 46.32.
The receive message buffers can be accessed with the RMBn register (n = 0 to 15).
The receive FIFOs can be accessed with the RFBn register (n = 0, 1).
The common FIFO can be accessed with the CFB0 register.
When the common FIFO is configured in transmit FIFO mode, data can only be written to the FIFO buffer via the CFB0 register.
When the common FIFO is configured in receive FIFO mode, data can only be read via the CFB0 register.
The transmit message buffers can be accessed with the TMBn register (n = 0 to 3).
Reading an unused message buffer results in reading an undefined value.

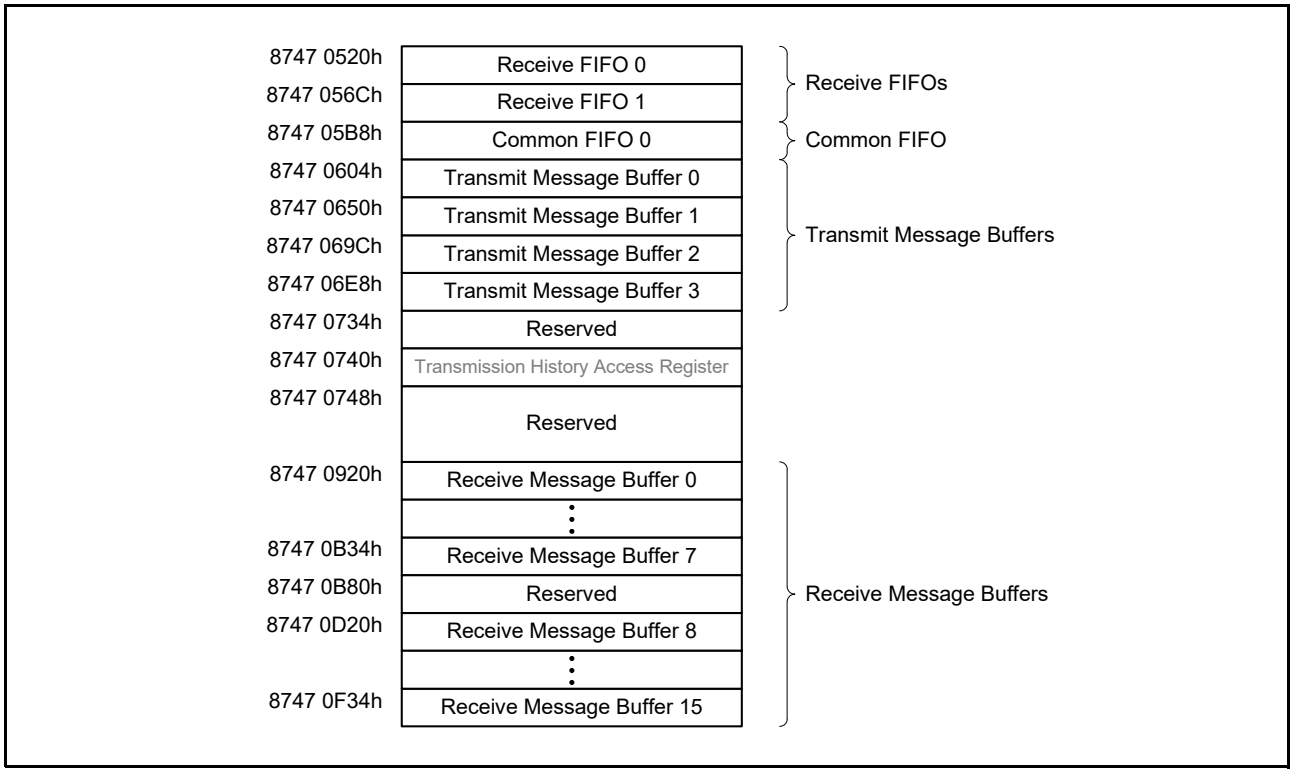

Figure 46.32 Message Buffer Configuration

46.6.1 Receive Message Buffers

In CANFD module, the received frames can be stored in receive message buffers based on the configuration of the AFL entries.
Additionally, the number of receive message buffers required by the system can be selected from 0 to 16.

46.6.1.1 Receive Message Buffer Configuration

The number of receive message buffers in CANFD module can be configured by writing to the RMCR.NMB[4:0] bits. Set the number of message buffers in the range 0 (no receive message buffers) to 16. Do not set a value larger than this.
The AFL entries for routing the received messages to receive message buffers must be configured to match the requirements of the system.
The AFL entries must also be configured properly, and an AFL entry for receive message buffers should not exceed the number of message buffers configured in the RMCR.NMB[4:0] bits.

Note: There is no internal check procedure provided in CANFD module against wrong configuration of the AFL.

The payload size of the receive message buffer can be configured with the RMCR.PLS[2:0] bits. The default size is 8 bytes and the maximum size is 64 bytes.
If the payload size of the received frame exceeds the specified payload size, the message is discarded or the payload is cut according to the setting of the GCFG.OMRC bit.

46.6.2 FIFO Buffers

The CANFD module provides FIFO buffers for storing received frames and frames to be transmitted, respectively.
There are two receive-only FIFOs, but common FIFO can be configured to store messages for transmission or reception.
These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- FIFO depth
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the transmit FIFO

If the payload size of the received frame exceeds the specified payload size, the message is discarded or the payload is cut according to the setting of the GCFG.OMRC bit.

46.6.2.1 FIFO Buffers Configuration

In CANFD module, the FIFO buffers can be configured to match the system requirements.
The total number of FIFO buffers is three (two receive FIFOs + one common FIFO).

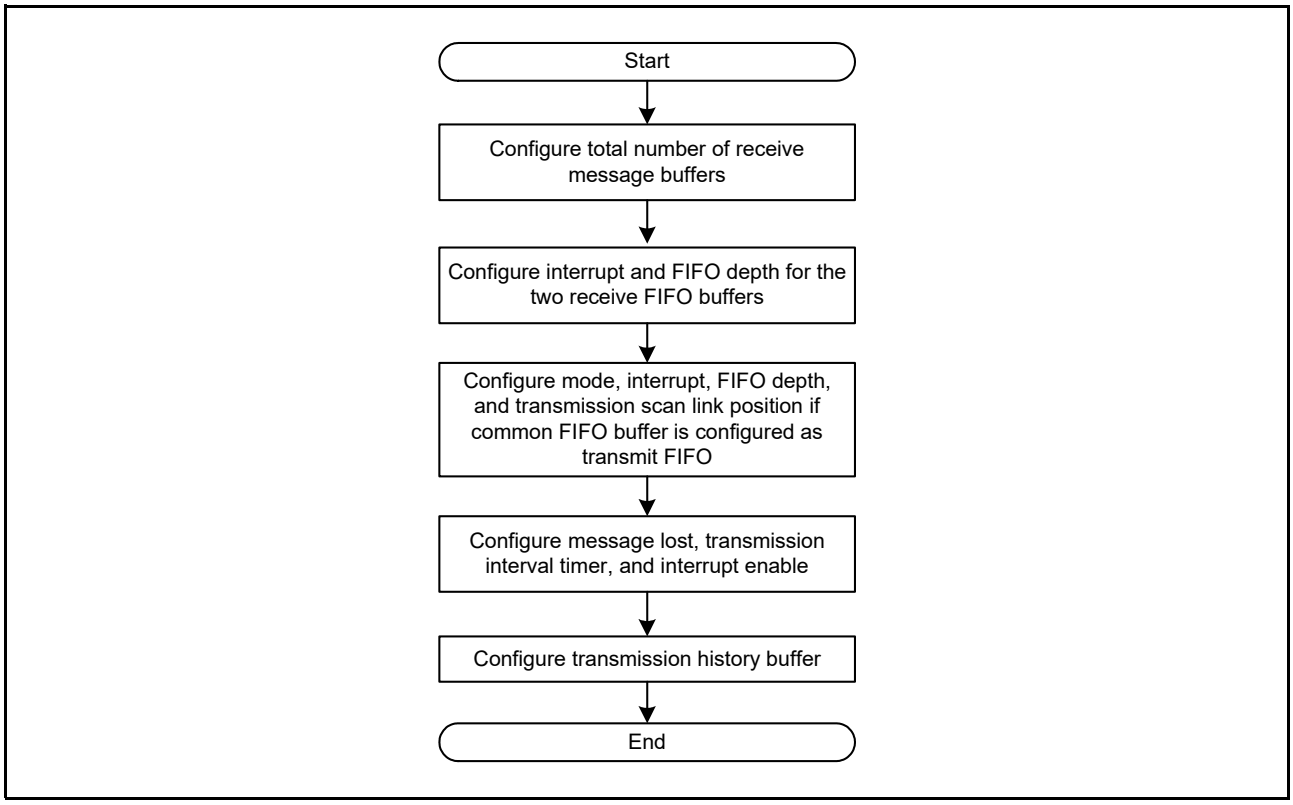

Figure 46.33 FIFO Buffer Configuration Flow in CANFD Module

As shown in Figure 46.33, the various FIFO buffers can be configured by writing to the RFCRn registers and the CFCR0 register (n = 0, 1).

For the two receive FIFOs, the following parameters can be configured:

- Interrupts
- FIFO depth
- Payload size

For the common FIFO, the following parameters can be configured:

- Mode
- Interrupts
- FIFO depth
- Payload size
- Transmission scan link position

(1) FIFO mode configuration of common FIFO

The mode of the common FIFO can be configured by writing to the CFCR0.MODE bit. The modes that can be configured in the common FIFO are as follows:

- 00b: Receive FIFO mode (default mode after an MCU reset)
- 01b: Transmit FIFO mode.

Messages can only be read from the receive FIFOs and the common FIFO configured in receive FIFO mode. Messages are stored by the CANFD module in these FIFO buffers based on the AFL entries.
Messages can be read and written into the common FIFO configured in transmit FIFO mode.
The pointers can be incremented only when a new message is stored in the FIFO buffer and decremented only when a message is transmitted on the corresponding CAN channel by the CANFD module.
After an MCU reset, all the common FIFO is configured in receive FIFO mode by default. Only enable the FIFO buffers after configuring the common FIFO in the required modes.

(2) FIFO transmit message buffer link configuration

When the common FIFO is configured as transmit FIFO, the FIFO buffer must be linked to a normal transmit message buffer to participate in the transmission scan of a CAN channel.
Do not write data into a transmit message buffer that is linked to a common FIFO. Also, the transmit message buffer linked to a common FIFO should not be a part of the transmit queue.
The link to the transmit message buffer of common FIFO can be configured by writing to the CFCR0.LTM[1:0] bits. The options available for linking the transmit message buffer are:

- 00b: Transmit message buffer 0
- 01b: Transmit message buffer 1
- 10b: Transmit message buffer 2
- 11b: Transmit message buffer 3.

(3) FIFO depth configuration

The depth of each FIFO buffer can be configured by writing to the RFCRn.FDS[2:0] bits and CFCR0.FDS[2:0] bits. The six available options for depth configuration are:

- 000b: 0 messages (FIFO buffer cannot be used)
- 001b: 4 messages
- 010b: 8 messages
- 011b: 16 messages
- 100b: 32 messages
- 101b: 48 messages.

The RAM allocated to the receive message buffers and FIFO buffers is limited to 16 messages (1216 bytes) when the payload size is set to 64 bytes. Do not configure the receive message buffers and FIFO buffers that exceed this maximum limit. CANFD module does not have the function to check the validity of the configuration.

Note: If the FIFO depth of the common FIFO is 4 messages or more (CFCR0.FDS[2:0] > 000b), the link between the common FIFO and the transmit message buffer is valid regardless of whether the FIFO is disabled or enabled. If the FIFO depth is 0 messages, the link between the common FIFO and transmit message buffer is invalid regardless of whether the FIFO is disabled or enabled.

(4) FIFO payload size configuration

The payload size of each FIFO buffer can be configured by writing to the RFCRn.PLS[2:0] bits and CFCR0.PLS[2:0] bits. The eight available options for payload size configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes.

The RAM allocated to the receive message buffers and FIFO buffers is limited to 16 messages (1216 bytes) when the payload size is set to 64 bytes. Do not configure the receive message buffers and FIFO buffers that exceed this maximum limit. CANFD module does not have the function to check the validity of the configuration.

(5) FIFO interrupt configuration

The interrupt generation conditions for the FIFO buffers can be configured by writing to the RFCRn.RFIM bit and CFCR0.CFIM bit. The two available options are:

- RFIM/CFIM = 0:
  - Receive FIFO mode: An interrupt is generated when the FIFO fill level reaches RFCRn.RFITH[2:0] or CFCR0.CFITH[2:0] value
  - Transmit FIFO mode: An interrupt is generated when the FIFO transmits the last message successfully
- RFIM/CFIM = 1:
  - Receive FIFO mode: An interrupt is generated each time the received message is stored
  - Transmit FIFO mode: An interrupt is generated each time a message is successfully transmitted.

If the RFCRn.RFIM bit for the receive FIFO is 0, an interrupt is generated based on the setting of the RFCRn.RFITH[2:0] bits.
Similarly, if the CFCR0.CFIM bit for a common FIFO set to receive FIFO mode is 0, an interrupt is generated based on the setting of the CFCR0.CFITH[2:0] bits.
The eight options available to set the FIFO fill level for generating interrupts are:

- 000b: Interrupt generated when FIFO is 1/8 Full
- 001b: Interrupt generated when FIFO is 1/4 Full
- 010b: Interrupt generated when FIFO is 3/8 Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8 Full
- 101b: Interrupt generated when FIFO is 3/4 Full
- 110b: Interrupt generated when FIFO is 7/8 Full
- 111b: Interrupt generated when FIFO is Full.

In this case, an interrupt is generated when the message fill level matches the set value.
However, as shown in Table 46.20, there are some restrictions on the RFITH[2:0] and CFITH[2:0] bit settings, depending on the FDS[2:0] bits (FIFO depth setting) of each register.

Table 46.20 FIFO Interrupt Threshold and FIFO Depth Settings

	RFITH[2:0]/CFITH[2:0]							
FDS[2:0]	**111b (full)**	**110b (7/8)**	**101b (3/4)**	**100b (5/8)**	**011b (1/2)**	**010b (3/8)**	**001b (1/4)**	**000b (1/8)**
000b (0 messages)	Invalid (FIFO cannot be enabled)							
001b (4 messages)	Allowed	Prohibited	Allowed	Prohibited	Allowed	Prohibited	Allowed	Prohibited
010b (8 messages)	Allowed							
011b (16 messages)	Allowed							
100b (32 messages)	Allowed							
101b (48 messages)	Allowed							

46.6.2.2 FIFO Buffers Control

To enable the receive FIFO interrupt, set the RFIE bit in the RFCRn register to 1 (n = 0, 1).
To enable the common FIFO interrupt, set either the CFRIE or CFTIE bit in the CFCR0 register:
After configuration is complete, each FIFO can be enabled by setting the RFCRn.RFE bit and CFCR0.CFE bit to 1 to allow transmission and reception of messages.

46.7 Reception and Transmission

46.7.1 Reception

In the CANFD module, received messages are stored in the receive message buffers, the receive FIFOs, or the common FIFO configured in receive FIFO mode, depending on the entries in the Acceptance Filter List:

- up to 16 receive message buffers can be configured
- two receive FIFOs available
- up to one common FIFO can be configured in receive mode

46.7.1.1 Message Storage in Receive Message Buffers

When a message is successfully received and stored in a receive message buffer, the corresponding NDF[n] flag in the RMNDR register is set to 1.
The stored message can be read from the corresponding receive message buffer.
If a new message is stored into a receive message buffer before the previous message in this message buffer is read, the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the receive message buffer. If such a loss of messages is not acceptable, store related messages by using receive FIFO.

Note: Unused data bytes are filled with 00h depending on the DLC value.

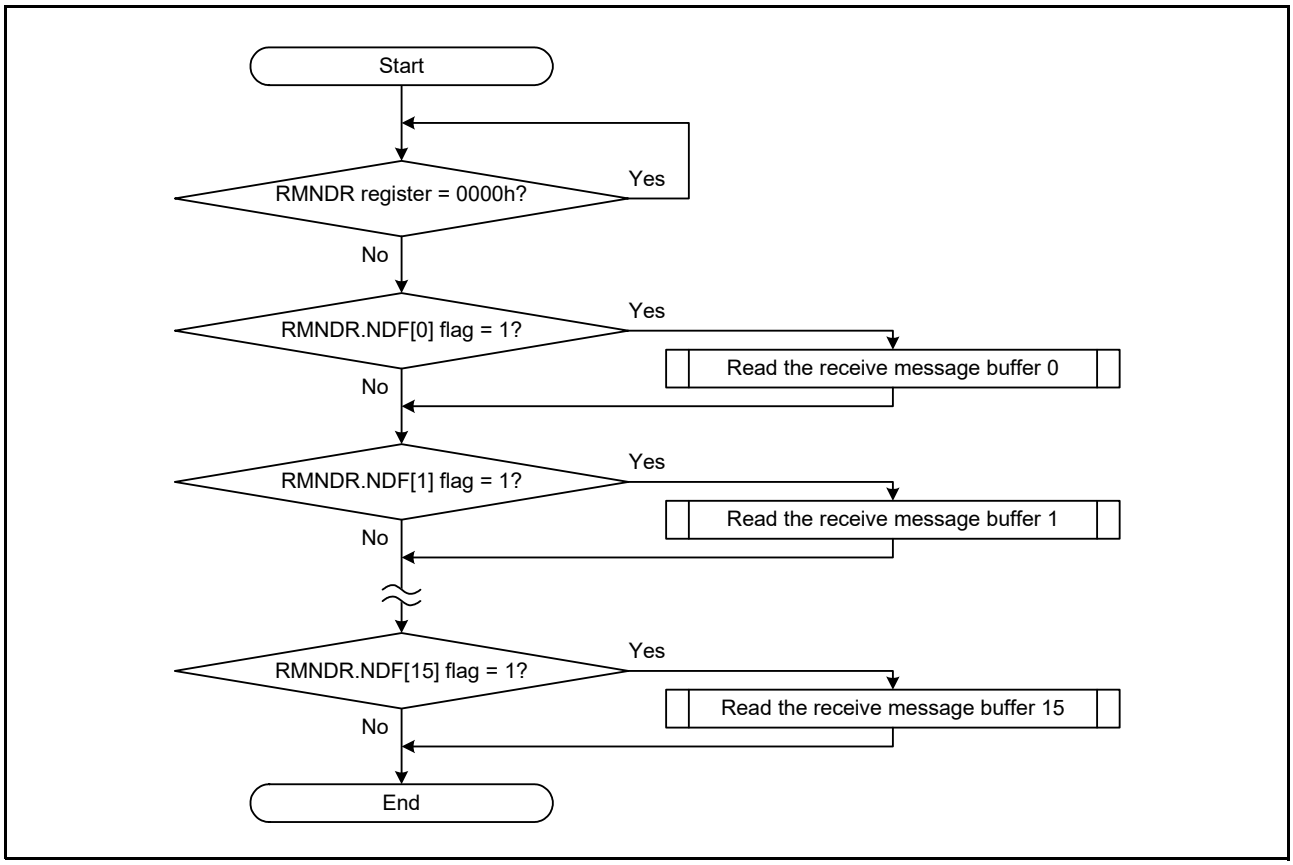

Figure 46.34 Receive Message Buffer Message Access Flow (Example for Polling Case)

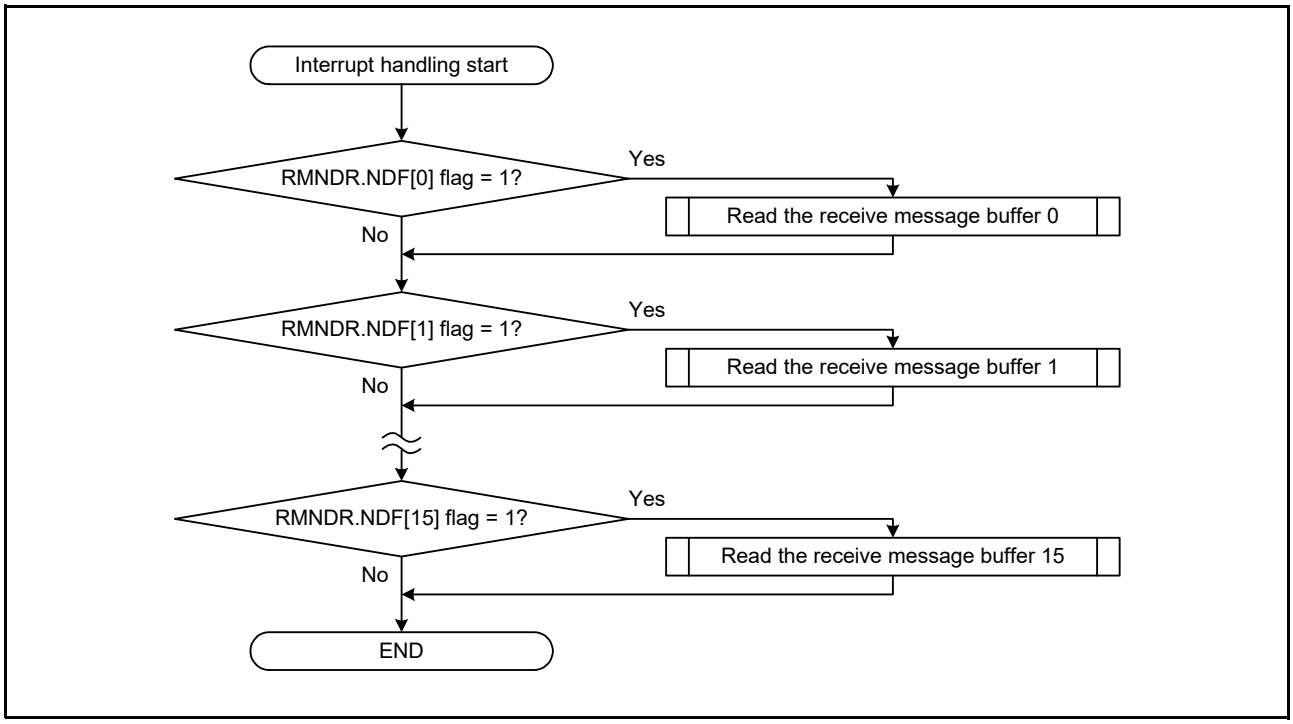

Figure 46.35 Receive Message Buffer Message Access Flow (Example for Interrupt Case)

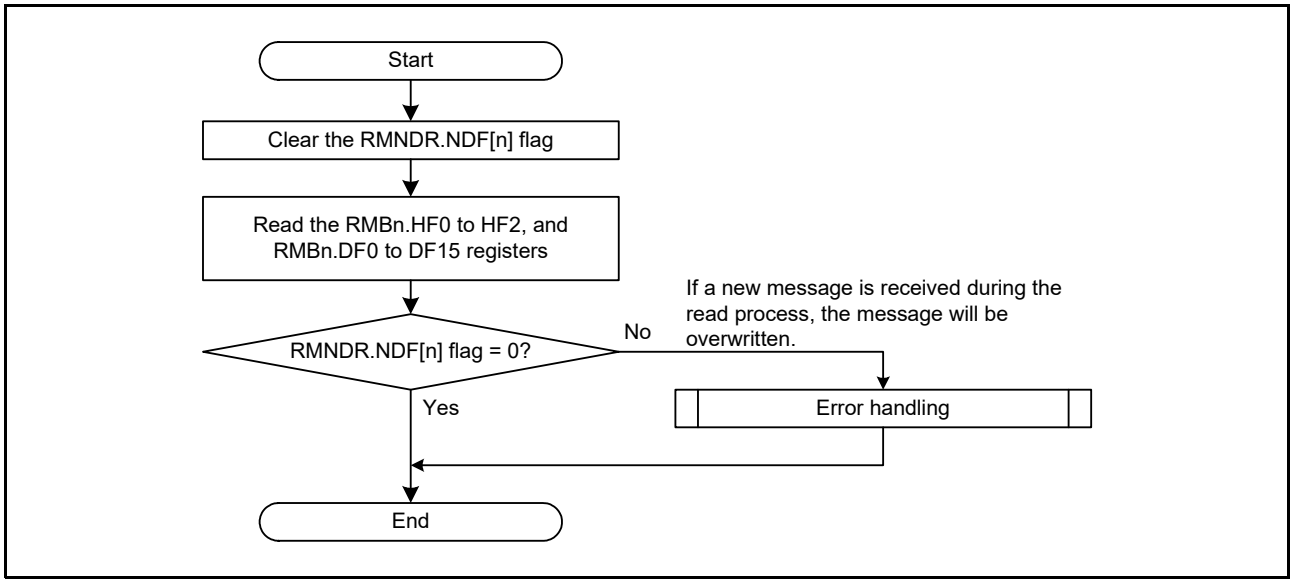

Figure 46.36 Receive Message Buffer n Read Flow

46.7.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to receive FIFOs or common FIFO configured in receive mode should be configured based on the requirements of the system.
The AFLn.PTR1.RF0E, RF1E, or CF0E bit in the matching AFL entry selects the FIFO buffers to which the related reception message will be stored.
When the received message is stored in one or more receive FIFOs or common FIFO configured in receive FIFO mode, the message counter value is incremented in the corresponding Receive FIFO Status Register or Common FIFO Status Register.
Depending upon the configuration of the FIFO buffers, an interrupt may also be generated. The message can be read from the corresponding FIFO access registers.

Note: Since many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, then the FIFO full flag is set.
When the value 000000FFh is written to the corresponding FIFO Pointer Control Register, then the message count is decremented by 1.

Only write 000000FFh to the FIFO Pointer Control Register after completely reading the message from the FIFO Access Register of the corresponding FIFO.
When all the messages stored in the FIFO are read, then the FIFO empty flag is set.
If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO message lost flag is set and the new message will be lost (messages already stored will not be overwritten).
To prevent message loss due to overrun, set an appropriate interrupt generation threshold and generate an interrupt before the FIFO becomes full.

The receive FIFOs and the common FIFO configured in receive FIFO mode can be disabled at any time by clearing the RFCRn.RFE bit or CFCR0.CFE bit.
When the RFCRn.RFE bit or CFCR0.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Hence, all messages in the FIFO buffers will be lost and no further messages can be stored into the FIFO.
When the receive FIFOs or common FIFO configured in receive FIFO mode is set to be read by DTC/DMA transfer, do not read the FIFO buffer on the CPU or write 000000FFh to the FIFO Pointer Control Register (RFPCR0, RFPCR1, or CFPCR0). The FIFO read pointer is automatically updated when read by DTC / DMA transfer.

Note: If the interrupt flag is set for a FIFO buffer and then the FIFO is disabled, then the interrupt flag will not be cleared automatically. The interrupt flag should be cleared before disabling the FIFO.

Note: When the next frame is received before clearing the receive interrupt flag, the receive interrupt flag is not set again.

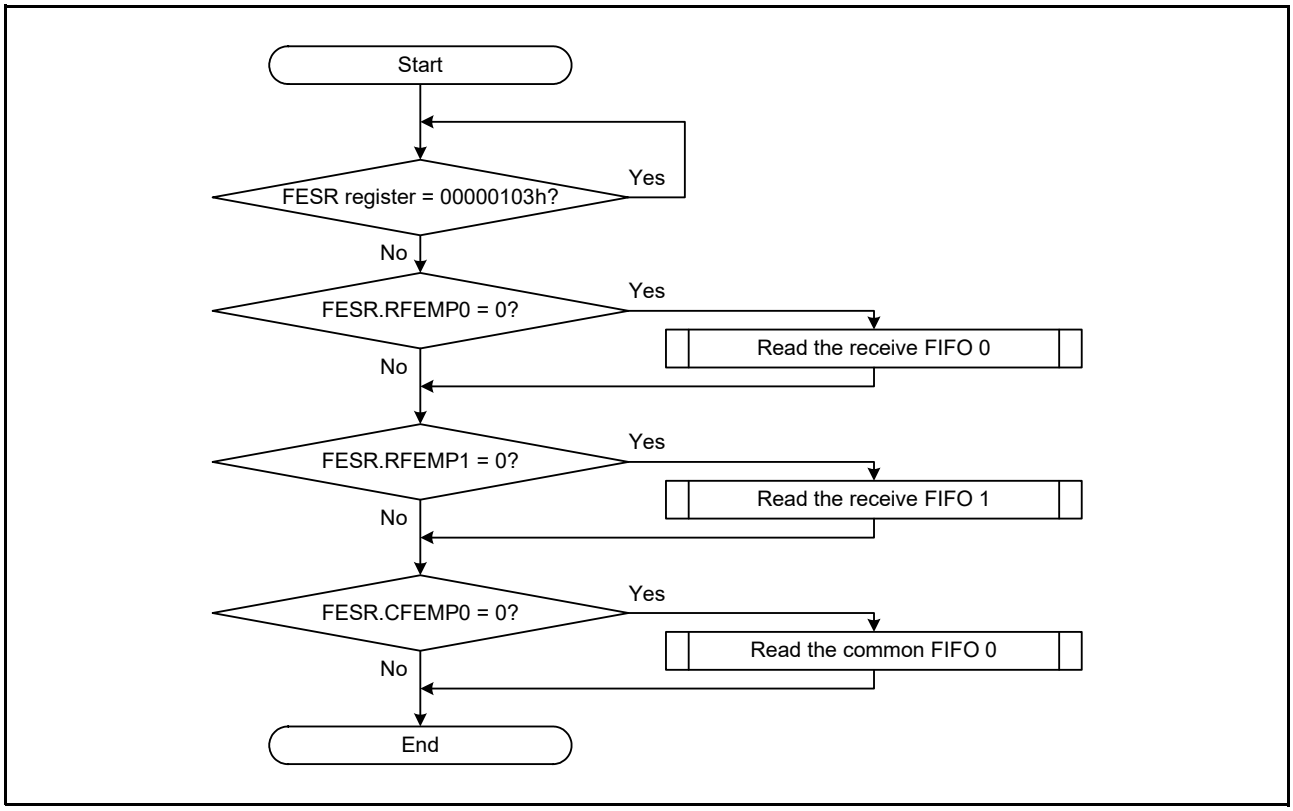

Figure 46.37 FIFO Buffer Message Access Flow (Example for Polling Case)

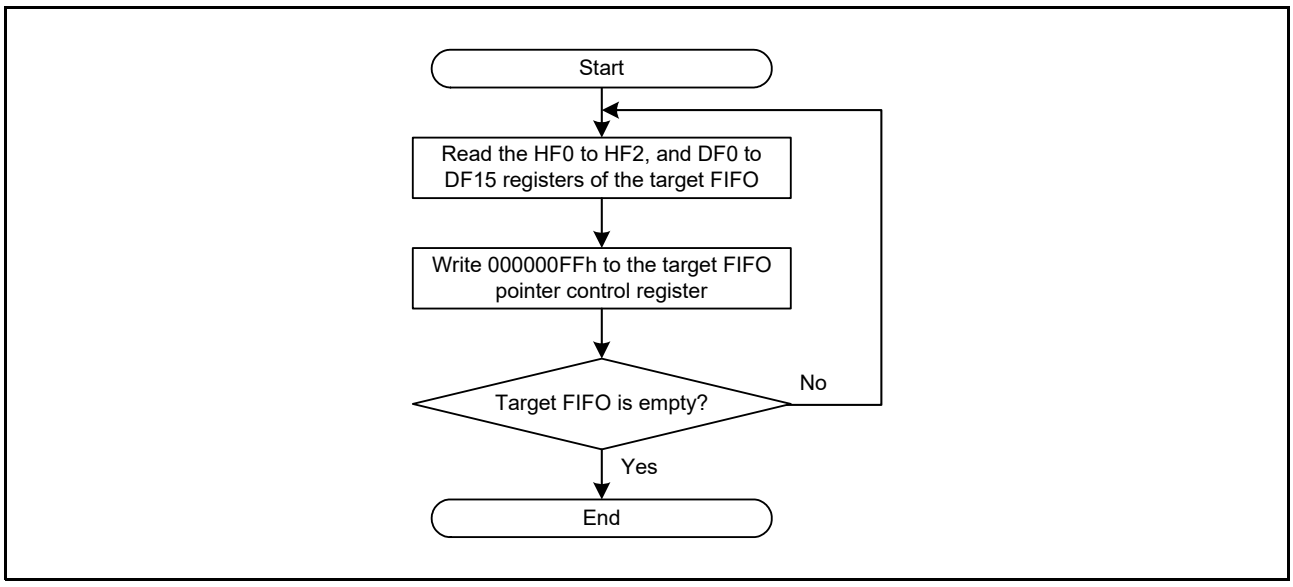

Figure 46.38 FIFO Buffer Read Flow (Example for Polling Case)

If the interrupt flag is cleared after the FIFO read process is completed, the interrupt flag is not set even if the next frame has already been received. The FIFO read process must be performed and the interrupt flag must be cleared before the reception of the next frame is completed. If the process is not in time, make sure the FIFO is empty, clear the interrupt flag, and make sure the FIFO is empty again.

46.7.1.3 Timestamp

The timestamp counter is a free-running counter that can be used to check reception time of a received message or transmission time of a successful transmitted message. The timestamp counter value will be captured based on the GFDCFG.TSCPS[1:0] bit setting (sample point of SOF, EOF when the frame is taken valid, or sample point of res bit following the FDF bit in case of a CAN FD frame). For reception the timestamp counter value is stored together with the message ID and data into the target receive message buffer or receive FIFO.
For transmit message the timestamp counter value is stored as part of the transmission history entry.
The counter can be clocked from PCLKA or the bit timing clock of the CAN channel. The counter clock source can be set with the GCFG.TSCS bit. If the GCFG.TSCS bit is 0, PCLKA is used. If it is 1, the bit time clock of CAN channel is used.
The clock source of the timestamp counter can be divided by the coefficient defined by the GCFG.TSP[3:0] bits (timestamp prescaler).
The timestamp counter can be reset to 0000h with the GCR.TSCR bit (timestamp counter reset).

46.7.2 Transmission

There are several possible transmission configurations:

- Normal transmission
- FIFO transmission
- Transmit queue transmission

The CANFD module has four transmit message buffers. These message buffers are only used for transmission and cannot be configured for reception.
Additionally transmission from transmit queue and/or common FIFO configured in transmit FIFO mode can be set in the following way (refer to Figure 46.39):

- Transmit queue
  3 or 4 transmit message buffers can be grouped to form a transmit queue with a common access window.
  Transmit message buffer 0 acts as an access window for transmit queue 0 (TXQ0).
- Common FIFO (transmit FIFO mode)
  The CANFD module has one common FIFO. Common FIFO configured in transmit FIFO mode is linked to any of the transmit message buffers 0 to 3.
  The linked transmit message buffer replaces the common FIFO. Do not access the TMCRn or TMSRn registers of the linked transmit message buffer.

Note: Common FIFO should not be linked to transmit message buffers that are already part of a transmit queue.

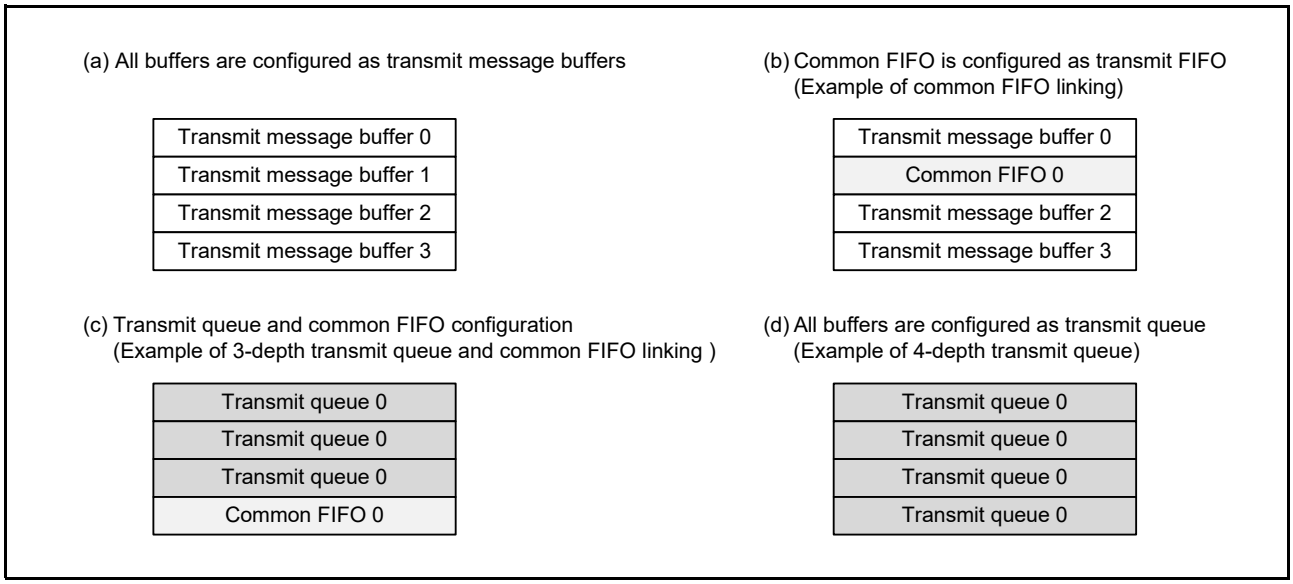

Figure 46.39 Channel Transmit Message Buffer Configuration

46.7.2.1 Transmission Priority

If two or more transmit message buffers are queued for transmission within a channel, messages are transmitted according to one of the following priorities.

- CAN ID priority
- Message buffer number priority

The transmission priority can be set using the GCFG.TPRI bit, and it applies to all message buffers.
For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the transmit message buffers linked to the common FIFO configured in transmit FIFO mode.
Do not select message buffer number priority when using the transmit queue.
For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All transmit message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the transmit message buffers linked to the common FIFO configured in transmit FIFO mode and includes the transmit queue message buffers.
If the ID of two or more message buffers is the same, then the smaller message buffer number will have higher priority for transmission.

Note: For common FIFO configured in transmit FIFO mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.
If the message is being transmitted from the FIFO, then the next pending message within the same FIFO will be considered in the transmission arbitration.
In contrast to this, all transmit message buffers of a transmit queue will participate in internal transmission arbitration.

Figure 46.40 below shows the transmission configuration flow.

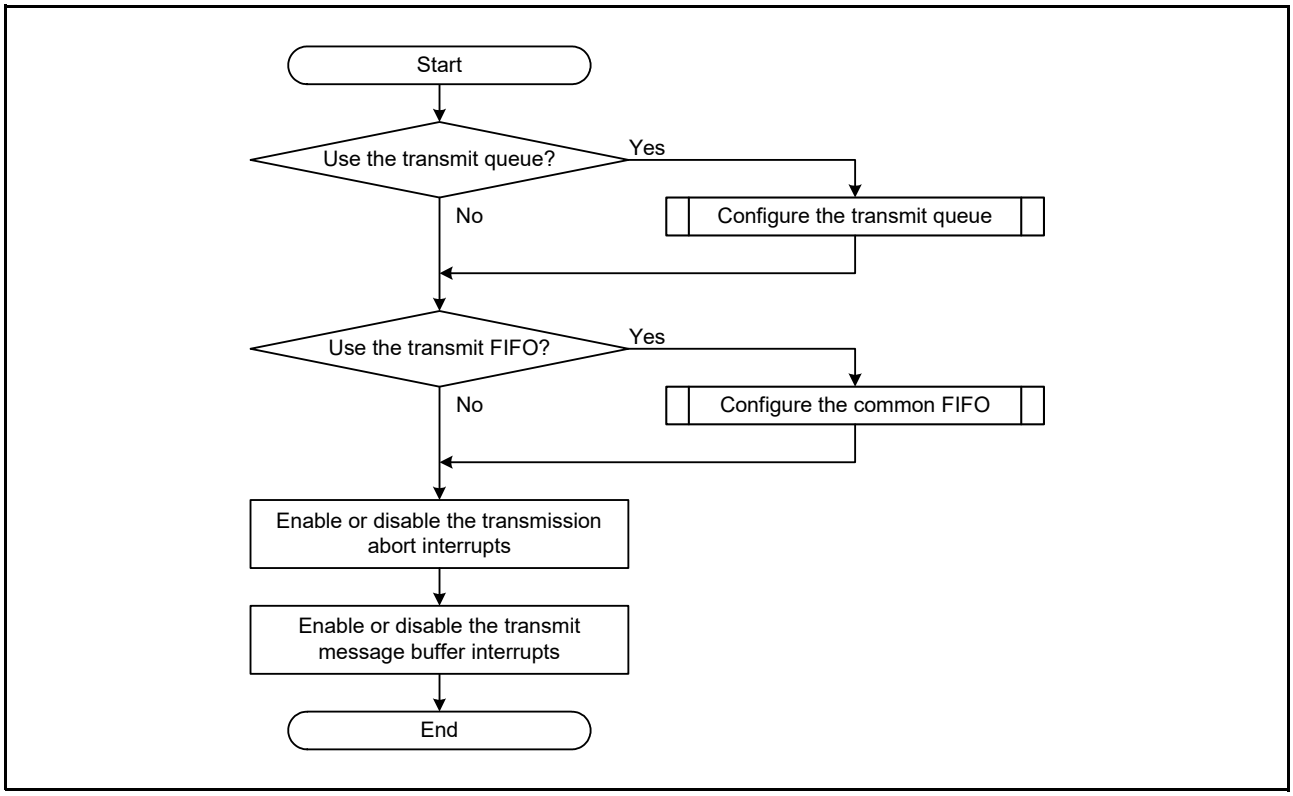

Figure 46.40 Transmission Configuration Flow

46.7.2.2 Message Transmission from Transmit Message Buffer

Each transmit message buffer has two modes of message transmission:

- Normal Transmission Mode
  When the message buffer is set to normal transmission mode, the data frames or remote frames set in that message buffer can be transmitted.
  Completion of normal transmission can be checked by the TMSRn.TXRF[1:0] flags. These flags are set to 10b or 11b when a normal transmission is successful.
  When arbitration is lost or an error occurs during transmission, the message transmission will be retried if no transmission abort request is set in the transmit message buffer.
  A new internal transmission arbitration is performed for all message buffers that have a transmission request.
- One-Shot Transmission Mode
  When the TMCRn.ONESHOT bit is set to 1, the message buffer is placed in one-shot transmission mode and attempts to transmit the message only once.
  Completion of one-shot transmission can be checked by the TMSRn.TXRF[1:0] flags. These flags are set to 10b or 11b when the one-shot transmission is successful.
  The TXRF[1:0] flags are set to 01b when arbitration is lost or an error occurs during transmission. In this case, message transmission will not be retried.

Figure 46.41 shows the transmission request procedure from transmit message buffer.

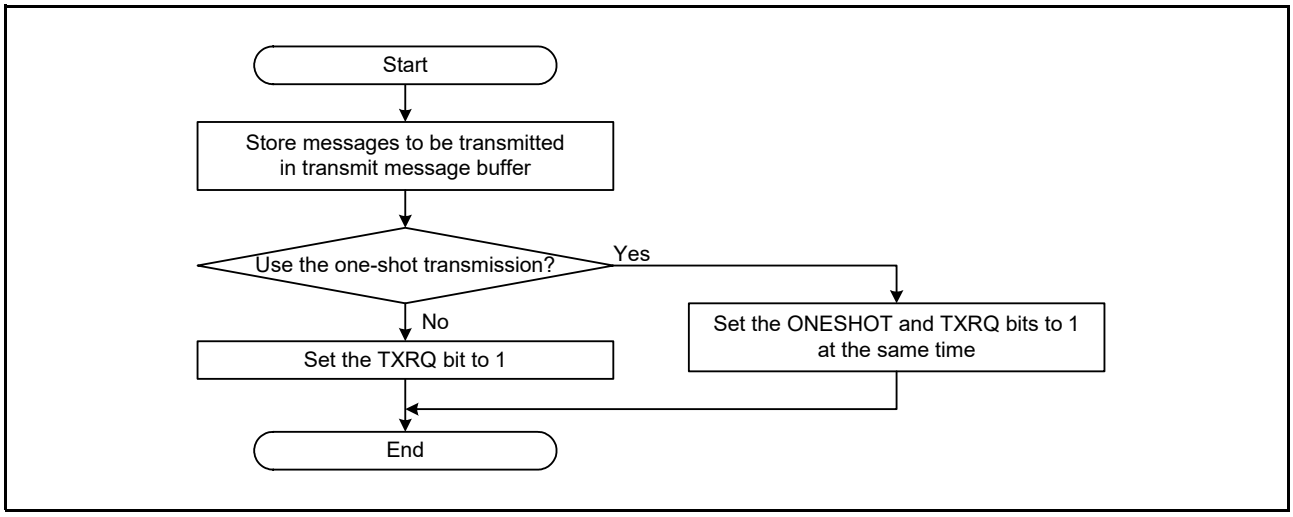

Figure 46.41 Transmission Request Procedure from Transmit Message Buffer

Table 46.21 shows configuration of the TMCRn register.

Table 46.21 Configuration of TMCRn Register

Transmission Request TXRQ Bit	Transmission Abort Request TARQ Bit	One-Shot Transmission Enable ONESHOT Bit	Message Buffer Status
0	0	0	Normal transmission is stopped.
0	0	1	One-shot transmission is stopped.
1	0	0	Data frames or remote frames are transmitted in normal transmission mode.
1	0	1	A data frame or a remote frame is transmitted in one-shot transmission mode.
1	1	0	Transmission abort is requested.
1	1	1	One-shot transmission abort is requested.

Figure 46.42 shows timings for successful transmission from two message buffers.

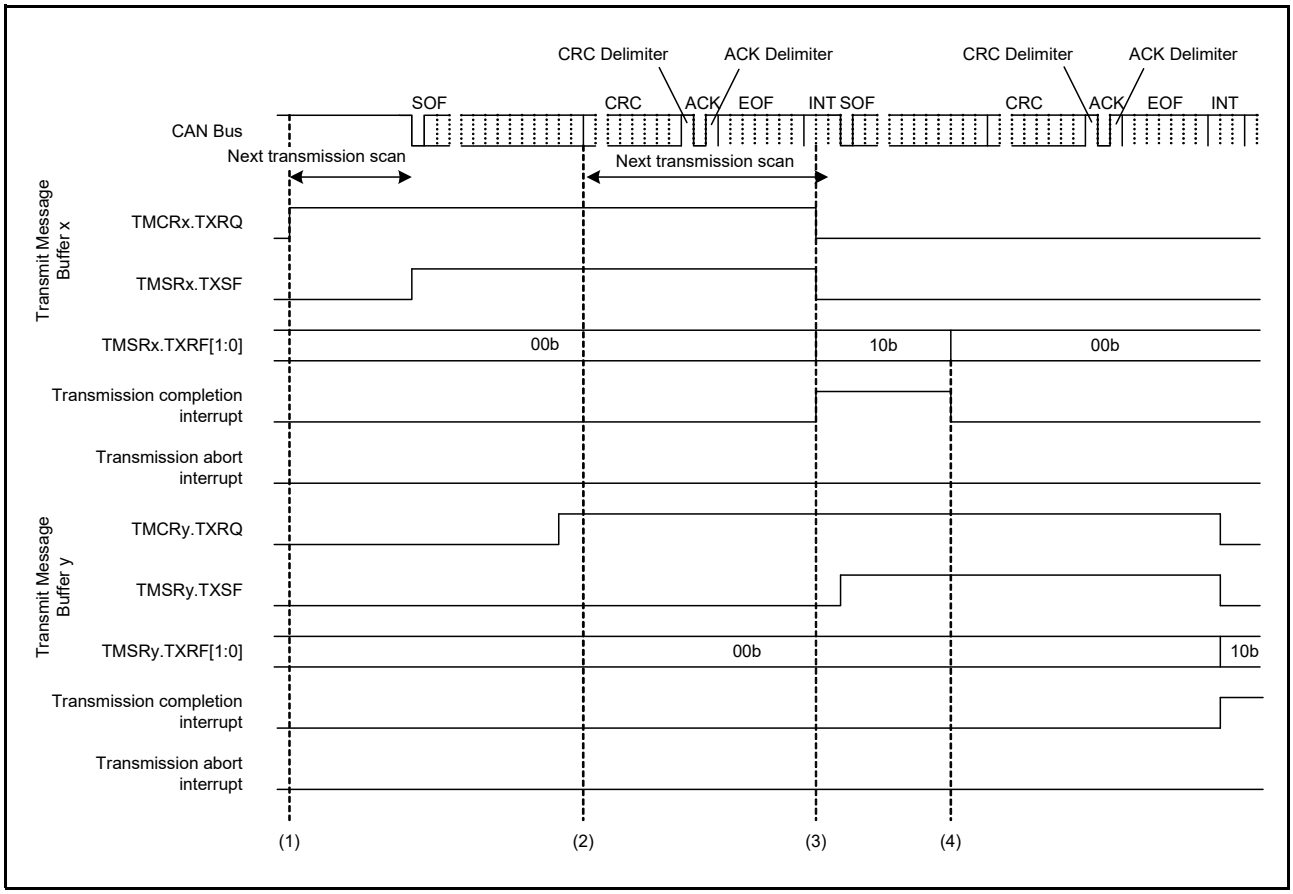

Figure 46.42 Timing of Request and Flag Bits for Successful Transmission

(1) If the TMCRx.TXRQ bit is set to 1 in the bus idle state, message buffer scanning procedure starts to decide the highest priority message buffer for transmission.
When the transmit message buffer is decided, the TMSRx.TXSF flag is set to 1 (transmitting), and CAN channel starts the transmission*1.

(2) At the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.

(3) If the message has been successfully transmitted, the TMSRx.TXRF[1:0] flags are set to 10b and the TMSRx.TXSF flag and the TMCRx.TXRQ bit are cleared.
When the TMIER0.TMIEx bit is set to 1 (transmit message buffer interrupt enabled), the successful transmission interrupt request is generated. To clear the related interrupt line the TMSRx.TXRF[1:0] flags have to be cleared.

(4) Before starting the next transmission, clear the TMSRx.TXRF[1:0] flags. Load the next message in the transmit message buffer and set the TMCRx.TXRQ bit to 1 again.
The TMCRx.TXRQ bit cannot be set to 1 again before TMSRx.TXRF[1:0] flags are cleared.

Note: The setting point of the TMSRx.TXSF flag is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the TMSRx.TXSF flag is cleared. Then the transmission scanning procedure is performed again to search for the highest priority transmit message buffer from the beginning of the first bit of CRC.
If an error occurs either during the transmission or following the loss of arbitration, the transmission scanning procedure is performed again during error frame to search for the highest priority transmit message buffer.

The Figure 46.43 shows timings for transmission abort for two message buffers.

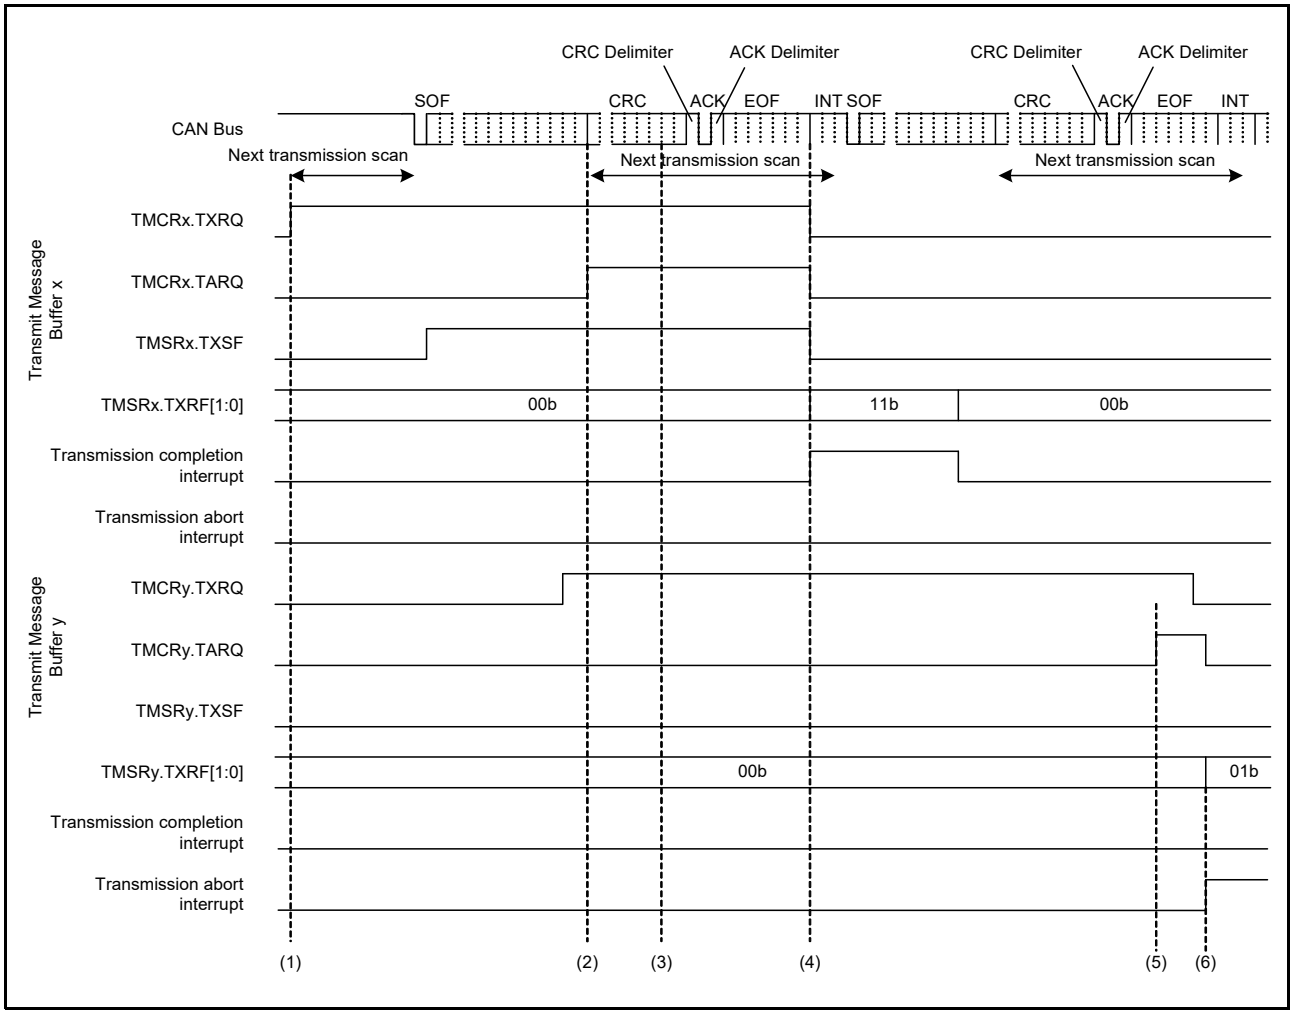

Figure 46.43 Timing of Request and Flag Bits for Transmission Abort

(1) If the TMCRx.TXRQ bit is set in the bus idle state, message buffer scanning procedure starts to decide the highest priority message buffer for transmission.
When the transmit message buffer is decided, the TMSRx.TXSF flag is set to 1 (transmitting), and CAN channel starts the transmission*1.

(2) If the TMCRx.TARQ bit is set to 1 when the related message buffer is already selected for transmission or currently transmitting, the message will not be aborted, if no error occurs or arbitration is lost.

(3) At the first bit of CRC, the transmission scanning procedure starts for the next transmission. In this example timing chart message buffer y is not selected as next transmit message buffer.

(4) If the message has been successfully transmitted, the TMSRx.TXRF[1:0] flags are set to 11b and the TMSRx.TXSF flag and TMCRx.TXRQ bit are cleared.
When the TMIER0.TMIEx bit is set to 1 (transmit message buffer interrupt enabled), the CAN successful transmission interrupt request is generated.
To clear the related interrupt line the TMSRx.TXRF[1:0] flags has to be cleared.

(5) Another CAN node is transmitting on the CAN bus (the TMSRy.TXSF flag is not set): if the TMCRy.TARQ bit is set to 1 when the related channel is under transmission scan, the transmission request cannot be cleared.

(6) After internal processing time the transmission is aborted and the TMSRy.TXRF[1:0] flags are set to 01b.
If the message buffer is not transmitting or selected as next transmit message buffer or under transmit scan, the abort is immediately accepted and the corresponding TMSRy.TXRF[1:0] flags are set to 01b.
In addition, the TMCRy.TXRQ and TMCRy.TARQ bits are cleared automatically.

When the CHCR.TAIE bit is set to 1 (transmission abort interrupt enabled), an interrupt is generated for successful transmission abort.
To clear the related interrupt the TMSRy.TXRF[1:0] flags have to be cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the TMSRx.TXSF flag is cleared. Then the transmission scanning procedure is performed again to search for the highest priority transmit message buffer from the beginning of the first bit of CRC.
If an error occurs, either during the transmission, or following the loss of arbitration, the transmission scanning procedure is performed again during error frame to search for the highest priority transmit message buffer.

46.7.2.3 Message Transmission from FIFO Buffer

The CANFD module has one common FIFO. The common FIFO can be linked to the transmit message buffer by the CFCR0.LTM[1:0] bits if configured in transmit FIFO mode.
When a transmission scan is started and the common FIFO corresponding to that transmit message buffer is enabled, the relevant message in the common FIFO will participate in the transmission scan.
Do not configure the transmit message buffer linked to the common FIFO configured in transmit FIFO mode.

(1) Transmit FIFO Operation

Messages can be written into the transmit FIFO by writing to the common FIFO buffer 0 (CFB0).
When the value 000000FFh is written into the CFPCR0 register, the message count of the FIFO is incremented by 1.
Before writing to the CFPCR0 register, wait until the message has been completely written to the CFB0. If the message count matches the FIFO depth, the CFSR0.FULL flag is set to 1.
The oldest message in the transmit FIFO is included in the scan for transmission.
When a message is successfully transmitted from the transmit FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the CFSR0.EMPTY flag is set to 1.
The interrupt generation conditions for the transmit FIFO buffers can be set by the CFCR0.CFIM bit.
If the CFCR0.CFIM bit is set to 0, interrupt is generated when last message is successfully transmitted from the transmit FIFO buffer. If the CFCR0.CFIM bit is set to 1, interrupt is generated for every successfully transmitted message from the transmit FIFO buffer.
Common FIFO can set interrupt, when CAN frame transmission is completed.
The common FIFO configured in transmit FIFO mode can be disabled by setting the CFCR0.CFE bit to 0. If this bit is set to 0, the CFSR0.EMPTY flag is set to 1 as described below:

- immediately if the message from the transmit FIFO is neither scheduled for the next transmission nor in transmission
- following the transmission completion, the detection of an error on the CAN bus, arbitration lost or transition to CH_HALT or GL_HALT mode if the transmission from the transmit FIFO is already scheduled for transmission or already in transmission.

Note: The common FIFO is considered as disabled after setting the CFCR0.CFE bit to 0 only when the CFSR0.EMPTY flag is set to 1 for the corresponding common FIFO.

If there are other pending messages in the transmit FIFO buffer, they will be lost and the transmission needs to be requested again. Before the CFCR0.CFE bit is set to 1 again ensure that the CFSR0.EMPTY flag is set to 1 and that there is no pending abort request from the transmit FIFO.
When the CFCR0.CFE bit is set to 0, the message read and write pointers of the FIFO are cleared and are no longer active. Hence, all messages in the FIFO buffers will be lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after a configuration is shown in Figure 46.44.

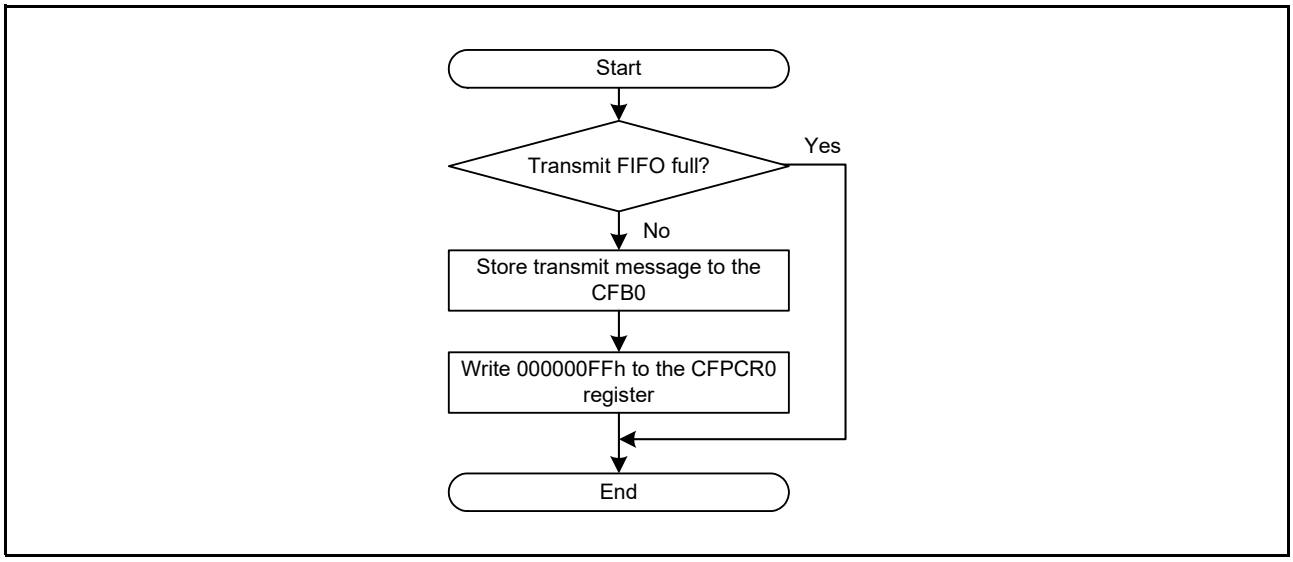

Figure 46.44 Transmit FIFO Transmission Request Procedure

(2) Interval Timer for FIFO Transmission

For the common FIFO in transmit mode it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFCR0.CFE bit is set to 1.
When the common FIFO in transmit mode is enabled, then the first message will be transmitted without considering this interval time.
The interval timer will stop counting when:

- FIFO is disabled by set the CFCR0.CFE bit to 0
- CAN channel is in CH_RESET mode.

The interval time is specified by the value of the CFCR0.TINT[7:0] bits and can be specified from 0 to 255 timer units. The timer unit can be defined based on two different clock sources for the interval timer. Select the value 0 to disable the interval timer for FIFO transmission.
The clock source can be selected by the CFCR0.ITCS bit. For the clock source the CAN bit timing clock of the related channel or a reference clock could be selected.
If CAN channel bit time clock is configured as clock source and the CAN channel enters CH_HALT, CH_RESET, or CH_SLEEP mode, then the interval timer is stopped for that channel.
If the reference clock is selected as interval timer clock source, then the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.
The reference clock can be used to configure the interval time in fixed time units. It is based on the PCLKA. The GCFG.ITP[15:0] bits define the relation between the PCLKA frequency/period and the reference clock period.
Refer to Table 46.22 for configuration values of the GCFG.ITP[15:0] bits to achieve different reference clock periods based on the PCLKA frequency/period.

Table 46.22 Configuration Example for Interval Timer Prescaler

	Reference clock period		
PCLKA frequency (period)	**1 µs**	**100 µs**	**500 µs**
16 MHz (62.5 ns)	16	1600	8000
20 MHz (50 ns)	20	2000	10000
32 MHz (31.25 ns)	32	3200	16000
50 MHz (20 ns)	50	5000	25000
60 MHz (16.67 ns)	60	6000	30000
80 MHz (12.5 ns)	80	8000	40000
100 MHz (10 ns)	100	10000	50000
120 MHz (8.33 ns)	120	12000	60000
150 MHz (6.67 ns)	150	15000	—

Additionally the reference clock resolution can be specified by the CFCR0.ITR bit.
The interval time is based on the reference clock period multiplied by the configured value (×1 or ×10).
The reference clock based interval timer can be used to follow the requirements of the ISO 15765-2 Separation Time.
The whole range for the separation time from 100 µs to 127 ms can be covered.
The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).
When the interval time has elapsed, the next transmission request is raised by the related transmit FIFO. Hence, the interval time defines the minimum time between two messages transmitted from one FIFO.
The next message will earliest be sent after this interval time. The Figure 46.45 shows an example timing of the internal processing.

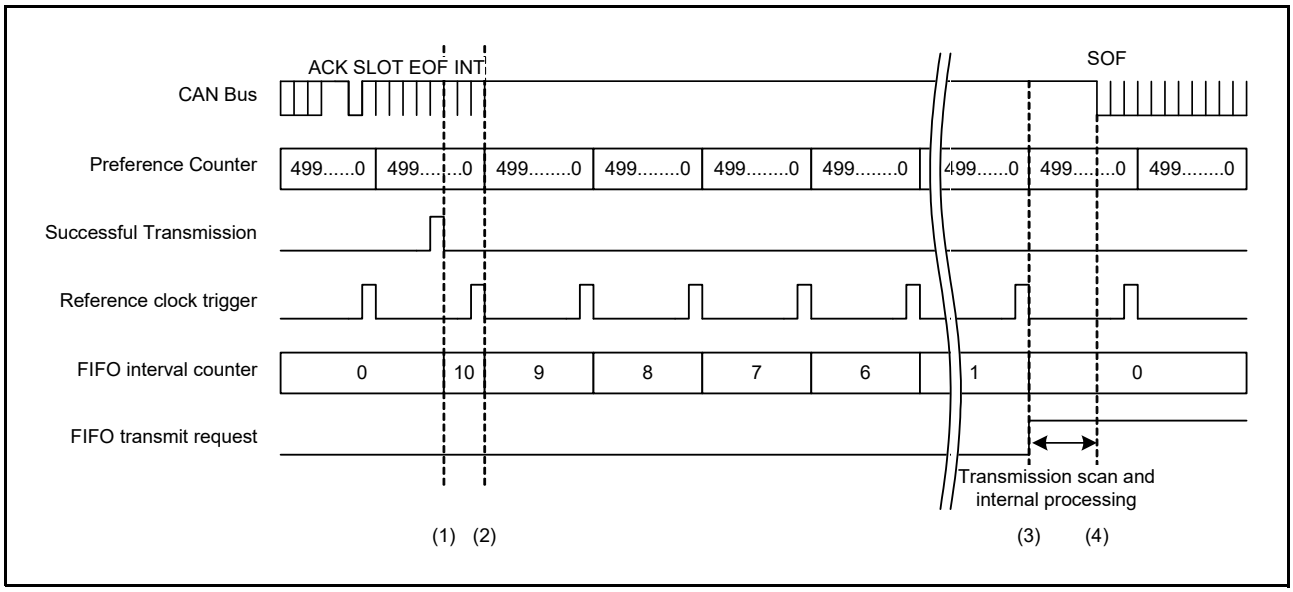

Figure 46.45 Example for Interval Processing Time

The configuration for this timing above is following:

- PCLKA frequency = 50 MHz
- Interval timer prescaler (GCFG.ITP[15:0]) = Divided by 500
- Reference clock due to the settings above = 10 µs
- Common FIFO interval timer clock source selection (CFCR0.ITCS) = 0
- Common FIFO interval timer resolution (CFCR0.ITR) = 0

- Common FIFO transmission interval (CFCR0.TINT[7:0]) = 10 counts
- Theoretical message separation interval = 100 µs

(1) Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore the first interval is counting less or equal to one reference clock interval.
(2) With the next reference clock trigger the FIFO interval timer is decremented.
(3) When the FIFO interval timer reached the value 0, the FIFO transmit request is set.
(4) When the FIFO is selected for transmission then the transmission will start soon. Due to internal processing this usually takes less than 3 bit time, between internal FIFO transmit request set (3) (shown above) and actual transmission.
When multi events like reception scan, internal message routing, transmit scan happen, then it could take up to 120 PCLKA cycles.

As shown in Figure 46.45, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure the CFCR0.TINT[7:0] bits to required minimum value + 1.
If transmit message buffers or transmit FIFOs are configured for transmission for the channel the real delay between two messages transmitted from a transmit FIFO can be much longer than specified by the interval time due to higher priority message transmission from these transmit message buffers or transmit FIFOs.
Figure 46.46 shows a block diagram of the FIFO interval timer.

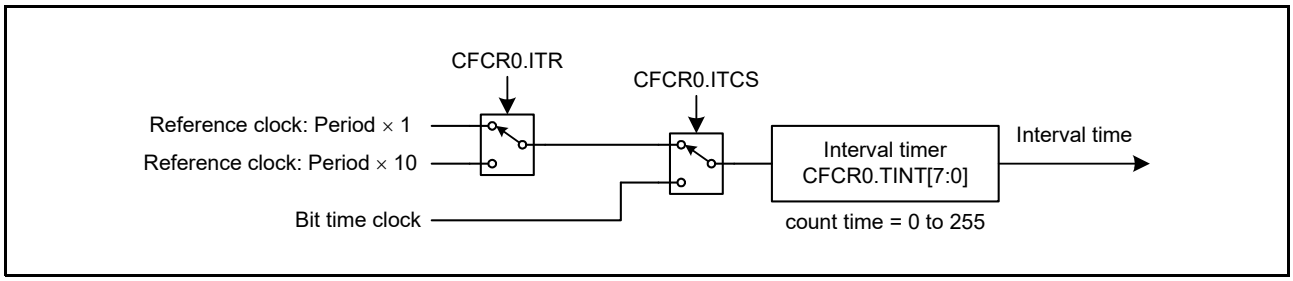

Figure 46.46 Block Diagram of FIFO Interval Timer

46.7.2.4 Transmit Queue

Each enabled transmit queue consists of three or four transmit message buffers, which are accessed via one access window.
The transmit queue 0 (hereafter TXQ0) can be configured with a depth of three to four, and it is using the transmit message buffer 0 as access window. All the message of TXQ0 enter the priority comparison for the transmission, which should be ID priority (GCFG.TPRI = 0).
The registers for TXQ0 are TQCR0, TQSR0, and TQPCR0.
As access window transmit message buffer 0 (TXQ0) is used, refer to related access registers TMB0.HF0, TMB0.HF1, TMB0.HF2, and TMB0.DF0 to TMB0.DF15.
The depth of each TXQ0 buffer can be configured by writing to the TQCR0.QDS[1:0] bits. TXQ0 can be set from TMB0 to TMB3 as a queue buffer at the maximum.
The available options for depth configuration are:

- 10b: 3 messages
- 11b: 4 messages.

Do not access all transmit message buffers except transmit message buffer 0 that configure the transmit queue. Also, do not access the TMCRn registers that correspond to the transmit message buffers that configure the transmit queue.
When writing data to TXQ0, check the status of TXQ0 before writing the data to be transmitted.

The messages stored to the transmit queue access window are internally stored to a free buffer of the transmit queue.
When the TXQ0 buffer is full, do not access the queue anymore. If the transmit data is written when the TXQ0 is full, the transmit data will be overwritten.
The transmit queue can be disabled by setting the TQCR0.TQE bit to 0. If this bit is set to 0, the TQSR0.EMPTY flag is set as described below:

- immediately: if a message from the transmit queue is not scheduled for the next transmission and is not being transmitted
- after the transmission completion, error detection on the CAN bus, loss of arbitration, or transition to CH_HALT or GL_HALT mode: if a message from the transmit queue is scheduled for transmission or is being transmitted.

Note: The transmit queue is disabled only when the TQSR0.EMPTY flag is set to 1 after setting the TQCR0.TQE bit to 0.

If there are other pending messages in the transmit queue, they will be lost, so their transmission needs to be requested again.
Before the TQCR0.TQE bit is set to 1 again, ensure that the TQSR0.EMPTY flag is set to 1 and that there is no pending abort request from the transmit queue.
When the TQE bit is set to 0, all messages in the transmit queue buffers will be lost and no further message can be stored in the transmit queue.
When a message has been stored to the transmit queue, 000000FFh must be written in to the TQPCR0 register. This will set the transmit request automatically and change the internal message buffer pointer to the next free message buffer location of the transmit queue.

Note: If two messages with the same ID are stored in the transmit queue, then the order of transmission of these messages could be different from the order in which they were stored in the transmit queue.
To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same ID is stored in the transmit queue.

For the transmit queue a dedicated interrupt can be enabled by setting the TQCR0.TQIE bit.
The interrupt mode can be configured with the TQCR0.TQIM bit either to generate an interrupt for every transmitted message or for the last transmitted message.
The transmit queue transmission request procedure after configuration is shown in Figure 46.47.

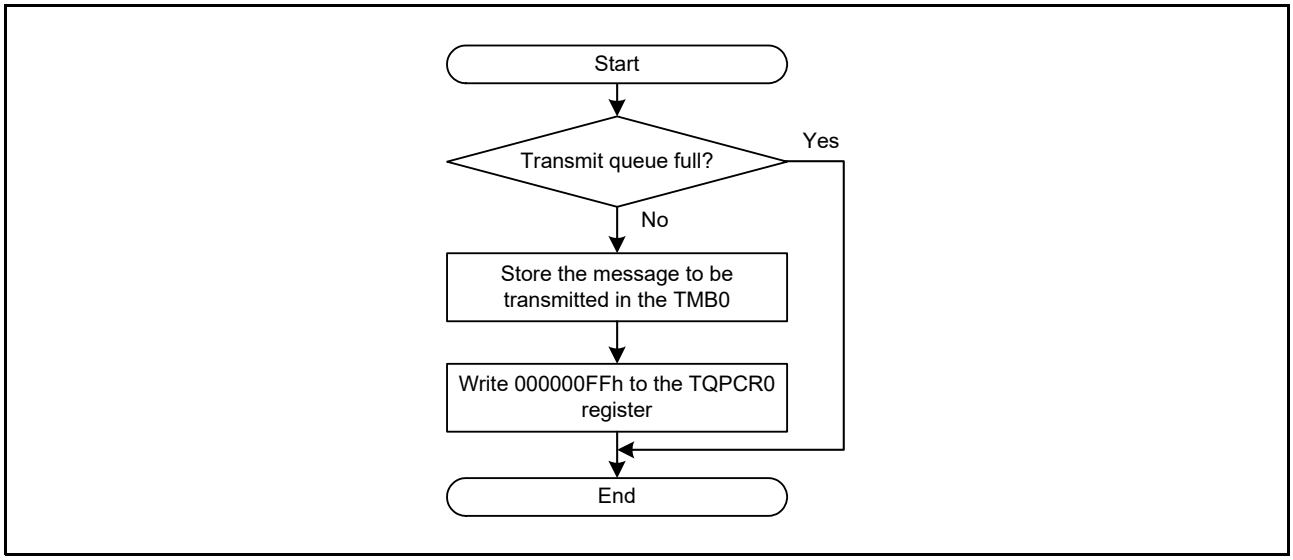

Figure 46.47 Transmit Queue Transmission Request

46.7.2.5 Transmission History

The transmission history function records the information of the successfully transmitted message in the transmission history buffer. The transmission history buffer can store up to eight transmission history entries.
The THCR.THRC bit can select whether to store information only for messages transmitted from transmit FIFO and transmit queue, or also for messages transmitted from the transmit message buffers.
Each transmit message can be individually configured for acceptance to the transmission history by the CFB0.HF0.THENT bit.
The message information is stored to the transmission history buffer of a CAN channel after the message is successfully transmitted on that CAN channel.
Storing to the list is not synchronized with the status of TMSRn.TXRF[1:0] flags.
Due to internal processing, the storage to the list could happen with a delay after the successful transmission indication.
Storing the transmission history data can be recognized by the condition that the THSR.THIF flag is set to 1 when the THCR.THIE bit is set to 1 or when the transmission history counter (THSR.FLVL[3:0]) is increased.
Multiple events could occur, such as reception scans and internal message routing.
Maximum delay time from setting the TMSRn.TXRF[1:0] flags to storing the transmission history data is 70 PCLKA cycles.

The transmission history records following information of the transmitted message:

- Transmitted Buffer type:
  - 001: Transmit message buffer
  - 010: Common FIFO in transmit FIFO mode (hereinafter referred to as transmit FIFO)
  - 100: Transmit queue
- Transmitted Buffer number:
  Transmit message buffer, transmit queue message buffer or transmit message buffer link for the common FIFO from which the transmission occurred. The number depends upon the buffer type, refer to Table 46.23.
- Transmitted pointer:
  Pointer set in header field 2 of transmit message (HF2.PTR[15:0])
- Transmitted timestamp:
  Message timestamp captured at capture point as set by the GFDCFG.TSCPS[1:0] bits
- Transmitted information label:
  Information label set in header field 2 of transmit message (HF2.IFL[1:0])

Table 46.23 Transmission History Buffer Number Entry

Transmitted Buffer Number (THACR0.BN[1:0])	Transmitted Buffer Type (THACR0.BT[2:0])		
	001b	010b	100b
	Transmit Message Buffer	Transmit FIFO	Transmit Queue
00b	TMB0	The value of the BN[1:0] bits corresponds to the setting of the CFCR0.LTM[1:0] bits.	The value of the BN[1:0] bits indicates the number of the transmit message buffer from which the message was transmitted.
01b	TMB1		
10b	TMB2		
11b	TMB3		

The transmitted pointer is used to identify which message of a transmit FIFO or transmit queue has been successfully transmitted because the transmit FIFO or transmit queue number alone is not sufficient.
Therefore, a unique number (pointer) can be attached to each transmit message stored in a transmit FIFO or transmit queue. This unique pointer should be written to the CFB0.HF2.PTR[15:0] bits for a transmit FIFO or to the TMB0.HF2.PTR[15:0] bits of the transmit queue.
When the message is successfully transmitted then this pointer is stored together with the other message related

information to the transmission history and can be read via the transmitted pointer field (PTR[15:0]) in the Transmission History Access Register.
Also for normal transmit message buffers, the TMBn.HF2.PTR[15:0] bits will be stored in the transmission history. An information label is the same.
Read access to the Transmission History Access Register will be done for every single entry.
After reading one entry, 000000FFh has to be written to the THPCR register to be able to access the next entry until transmission history is empty.
Figure 46.48 shows an example flow for processing the transmission history.
The transmission history has dedicated interrupts, which can be configured with the THCR.THIM bit and enabled with the THCR.THIE bit, either to generate an interrupt when the transmission history reached a filling level of 75% or for every new transmission history entry.
Loss of transmission history is indicated by the THSR.LOST flag. Status of this flag is also shown by the GESR.THLDF flag.

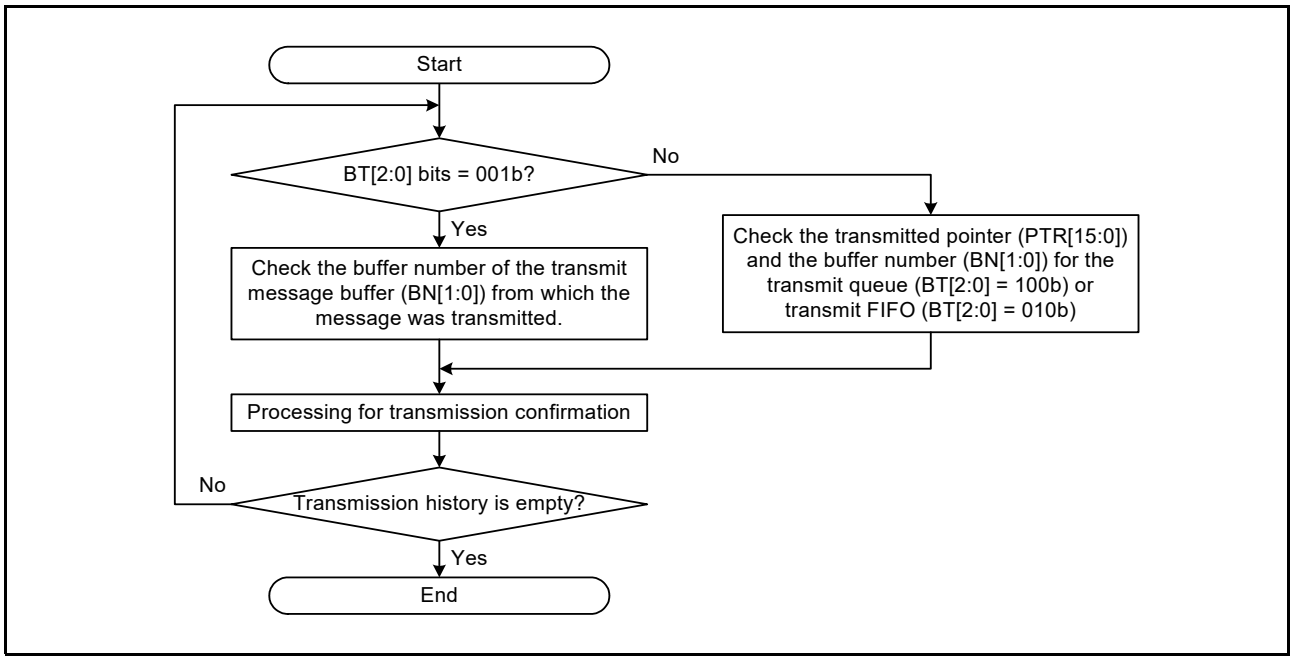

Figure 46.48 Example of Transmission History Processing Flow

46.7.2.6 Transmit Data Padding

If the data length code (DLC) of the transmit message is higher number of data bytes than the buffer size, the data bytes beyond the restricted range will be replaced by bytes with the value of CCh.
This could occur for common FIFO configured in transmit FIFO mode when the DLC of the transmit message is larger than the payload size set in the CFCR0.PLS[2:0] bits.
This can also occur in FD only mode, if the DLC value for a Classical CAN frame is greater than 8.

46.8 ECC Check

Message buffer RAM has ECC function of the 2-bit error detection and 1-bit error detection/correction.*1 The ECC module appends 7-bit ECC data to 32-bit RAM data.

Note 1. The ECC module cannot detect errors of 3 bits or more. In this case, the ECC module detects a 1-bit or 2-bit error, does not detect the error, or corrects the error bit to error data by configuration. If all RAM data is fixed at 0 or 1, it will be detected as a 2-bit ECC error.

46.8.1 ECC Function Setting

Figure 46.49 shows a procedure for ECC function setting.

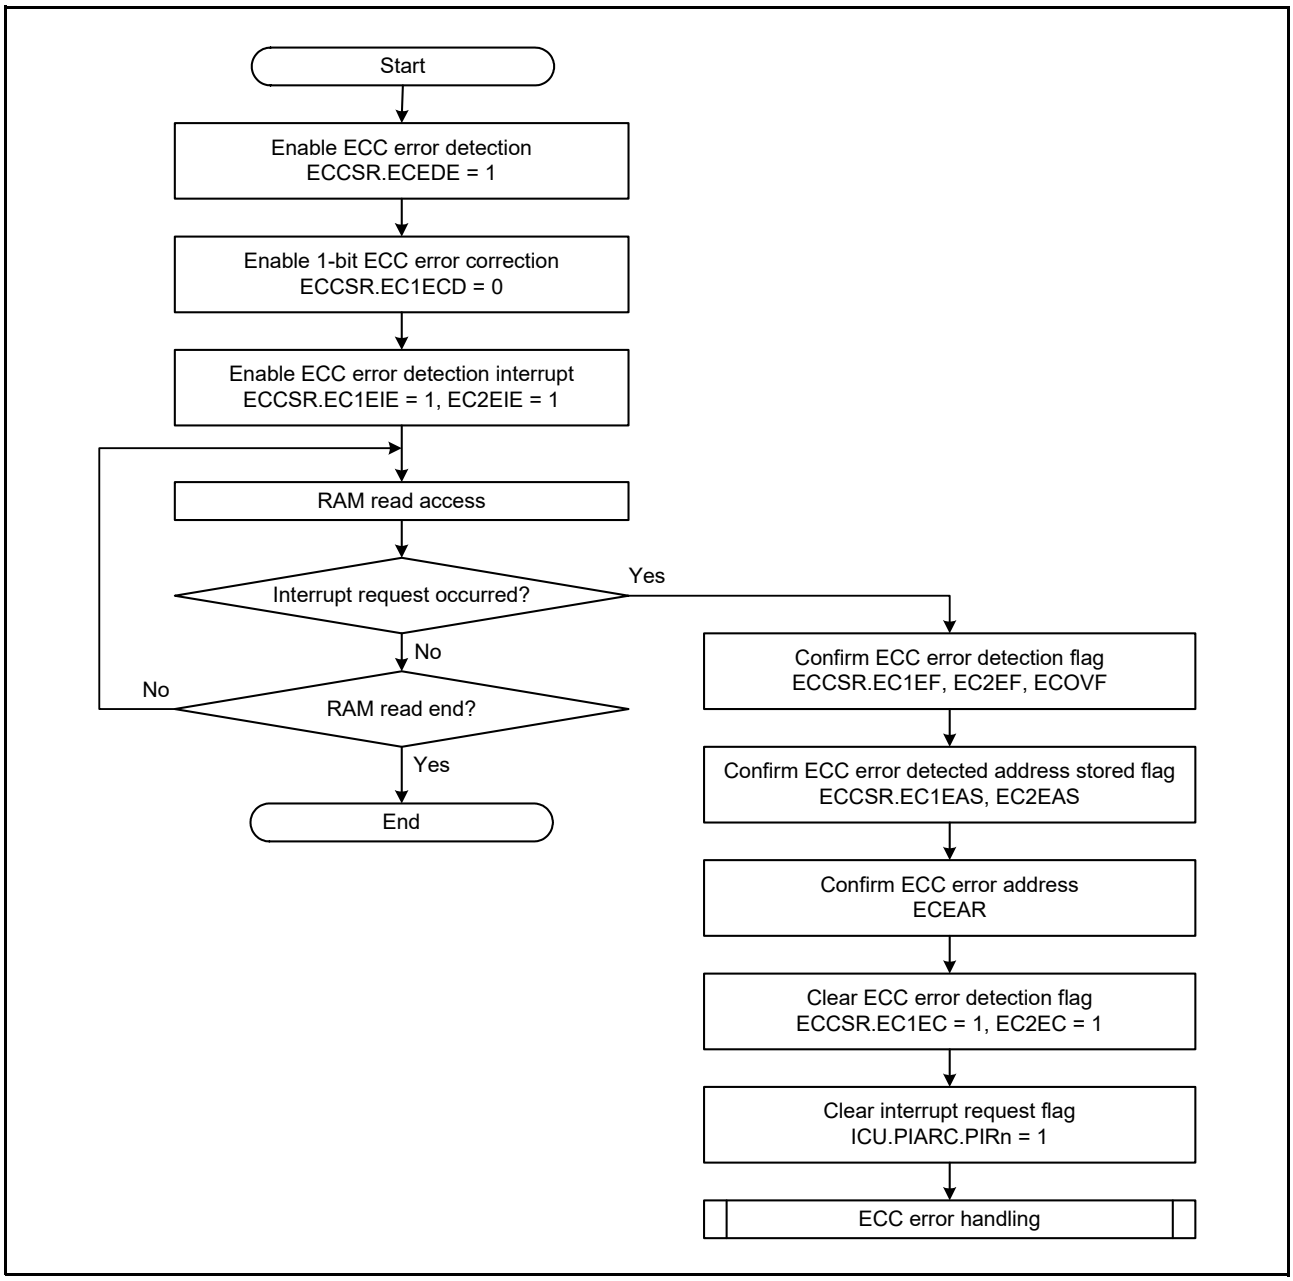

Figure 46.49 Setting Procedure for ECC Function

46.8.2 ECC Decoder Testing

ECC interrupts can be intentionally generated by ECC test mode. Figure 46.50 shows a procedure for ECC decoder testing.

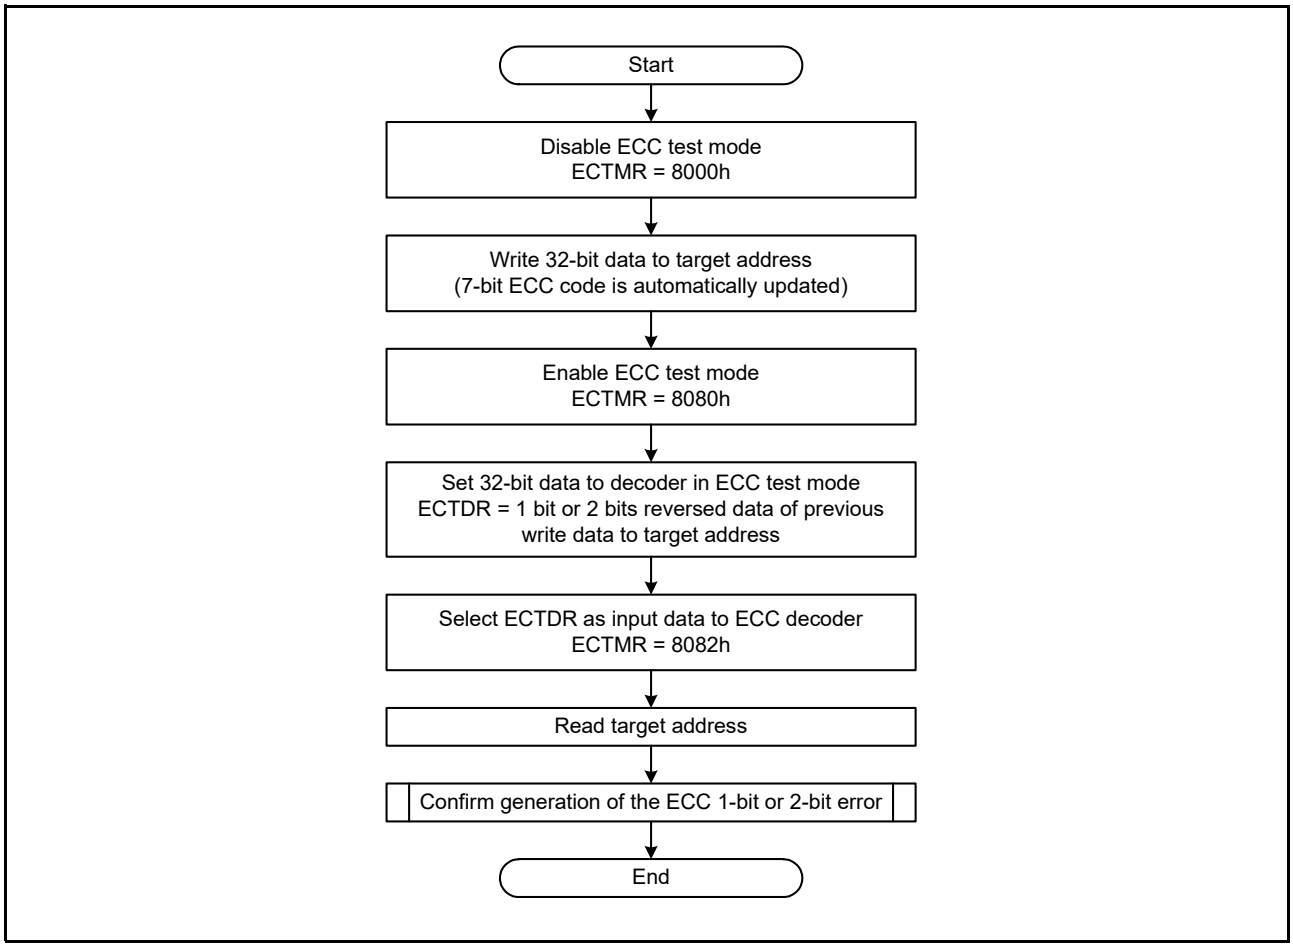

Figure 46.50 Testing Procedure for ECC Decoder

46.9 Test Mode

The CANFD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CANFD module in the test modes.

Note: All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combinations of the various test modes specified in this section.
The test modes can be broadly split into two groups:

- Channel specific test modes
- Global test modes

46.9.1 Channel Specific Test Modes

CAN channel can be configured into following test modes:

- Basic test mode
- Listen-only mode
- Self test mode 0 (external loop-back mode)
- Self test mode 1 (internal loop-back mode)
- Restricted operation mode

46.9.1.1 Basic Test Mode

The basic test mode should be used when a particular test setting needs to be enabled other than when in listen-only and self-test modes.

46.9.1.2 Listen-Only Mode

The ISO 11898-1 recommends an optional bus monitoring mode. In this mode, the CAN channel can receive valid data frames and valid remote frames. However, it transmits only recessive bits on the CAN bus and is not allowed to transmit. If the CAN engine is required to transmit a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the CAN engine monitors this dominant bit, although the CTX pin remain in recessive state.
This mode can be used for bit rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.
In this mode, it is not permitted to request transmission from any transmit message buffer, transmit queue, or common FIFO.

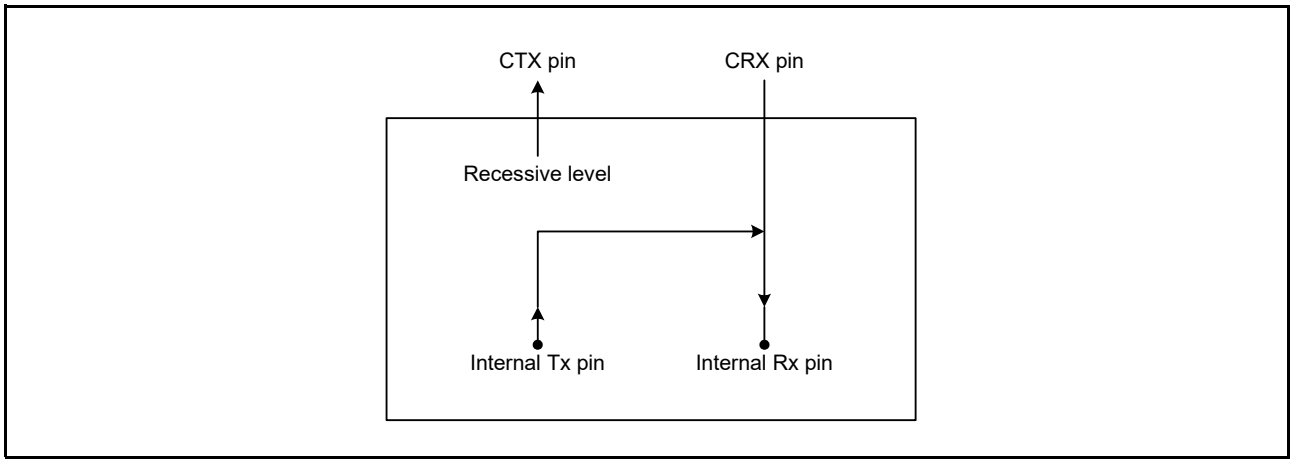

Figure 46.51 Listen-only Mode Configuration

46.9.1.3 Self Test Mode 0 (External Loop-Back Mode)

In self test mode 0, the CAN engine treats its own transmitted messages as received messages via the CAN transceiver and can store them into its receive message buffers.
To be independent of external stimulation the engine generates its own acknowledge bit. This test can be used for CAN transceiver tests.
The CRX and CTX pins should be connected to the transceiver.

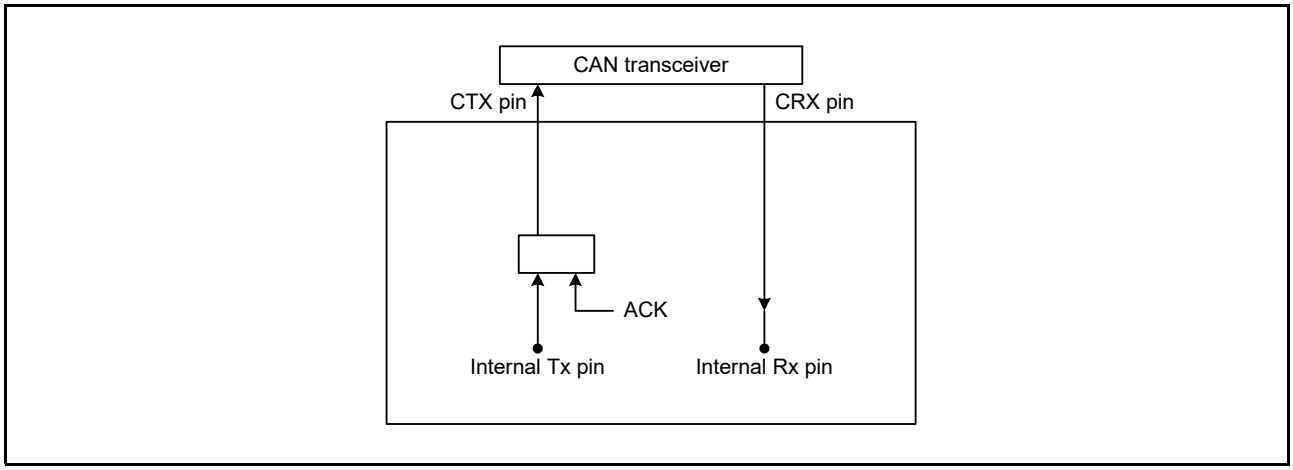

Figure 46.52 Self Test Mode 0 Configuration

46.9.1.4 Self Test Mode 1 (Internal Loop-Back Mode)

In self test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent of external stimulation the CAN engine generates its own acknowledge bit. In this mode the CAN engine performs an internal feedback from internal Tx pin to internal Rx pin. The actual input level of the CRX pin is disregarded by the CAN engine.
The CTX pin is driven high. The CRX and CTX pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the Internal CAN bus communication line.

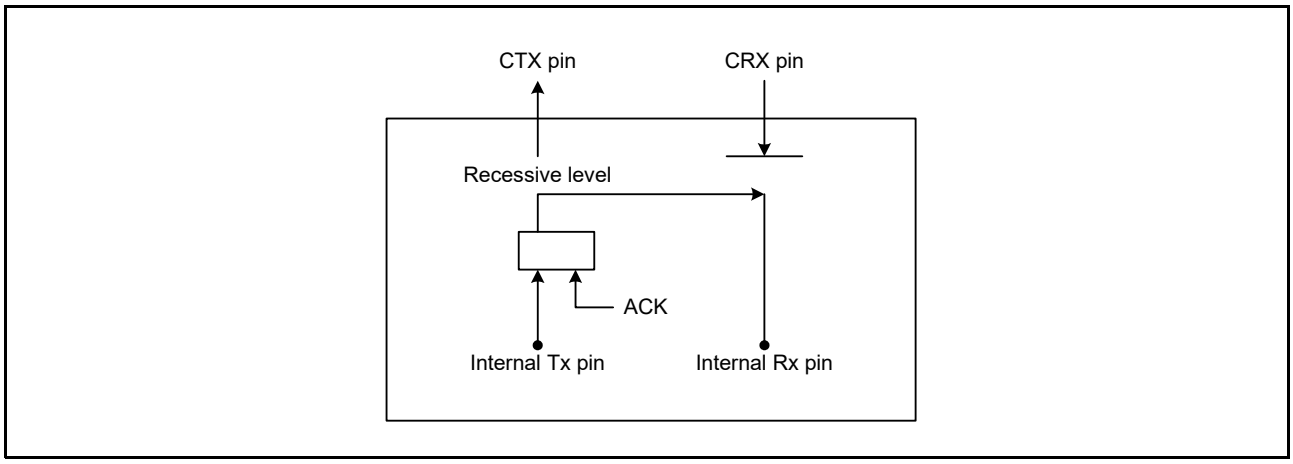

Figure 46.53 Self Test Mode 1 Configuration

46.9.1.5 Restricted Operation Mode

In restricted operation mode the CAN node is able to receive valid data and remote frames generating the acknowledge bit.
Active error and overload frames cannot be transmitted instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.
Moreover the receive error counter (CHSR.REC[7:0]) and transmit error counter (CHSR.TEC[7:0]) are frozen independently of the occurrence of errors.
The mode is specified as in ISO 11898-1; however it is permitted to set any transmit requested.

46.9.2 Global Test Modes

The CANFD module can be configured into following test modes:

- RAM test mode
- Bit flip test

The following test mode is protected by a special software procedure to enable the mode. This software procedure enables the write access to the test mode by specific unlock key, the related unlock key can be seen in the table below:

Table 46.24 Test Mode Unlock Key

Test Mode	Unlock Key 1	Unlock Key 2
RAM Test Mode	00007575h	00008A8Ah

If the software sequence of the two consecutive unlock key write accesses is interrupted by any other write access to the SFR or if incorrect data is written to the Global Test Mode Lock Key Register then the corresponding test mode cannot be set and the sequence should be re-started.
After the two unlock key write accesses, the next write access should be to set the corresponding test mode enable bit. If this is not followed, the unlock mechanism resets and the test mode enable bit cannot be set and then the unlock sequence should be restarted.

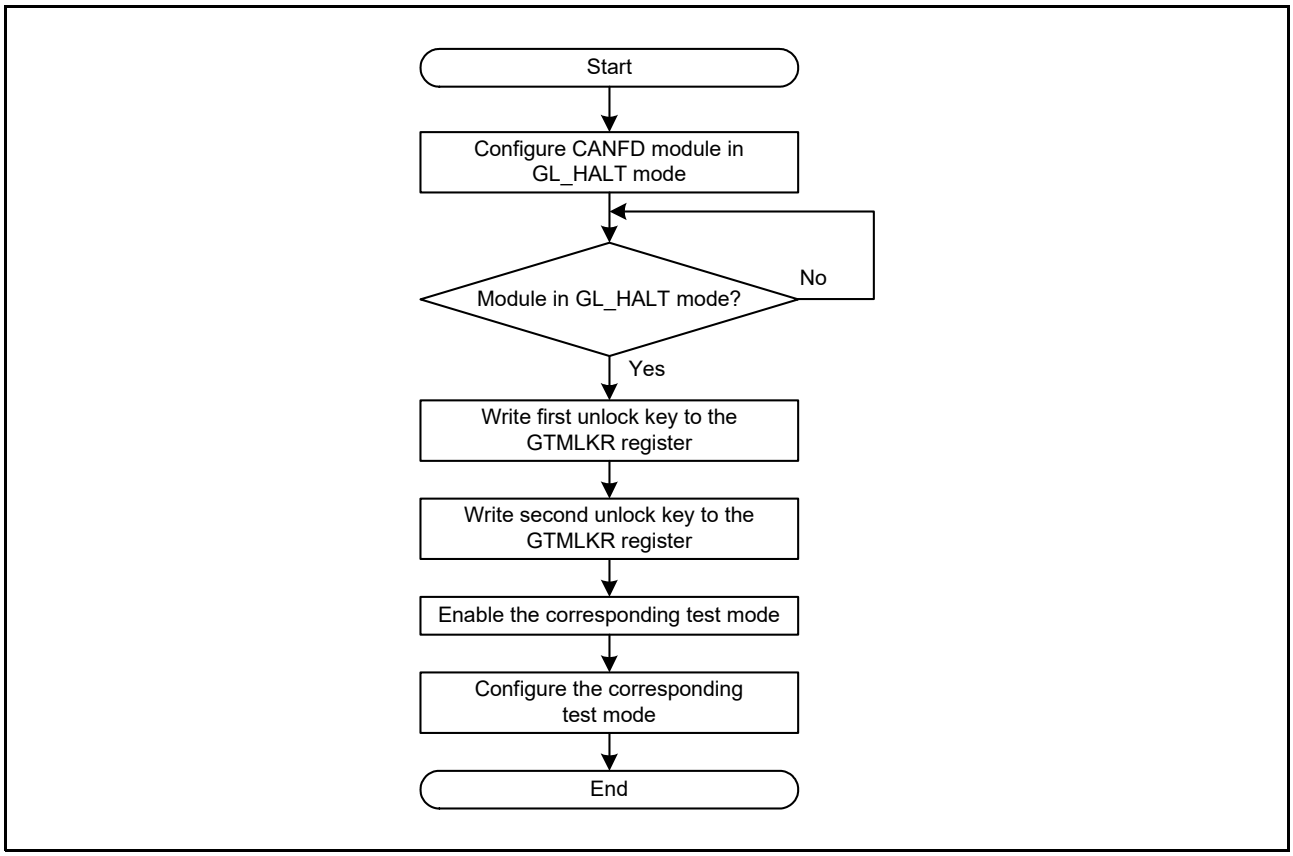

Figure 46.54 Unlock Software Protection Routine

46.9.2.1 RAM Test Mode

The CANFD module can be configured in RAM test mode by setting the GTMER.RTME bit when the corresponding lock key is written before. This is a special test mode, in which, the complete RAM area can be accessed.

Note: The actual RAM size is bigger than the RAM area initialized after MCU reset. Hence, ECC error flag (of the ECC macro) may be set if CPU reads data from this uninitialized RAM area while CANFD module is in RAM test mode.

In this mode, the RAM area is split into number of pages of 256 bytes each. Which can be accessed via RTPARk register (k = 0 to 63).
The page should be selected for read/write access by writing to the GTMCR.RTPS[3:0] bits. Then, data can be read from or written in to the RAM Test Page Access Register.
Figure 46.55 shows the structure of the pages in the RAM when performing a RAM test mode.

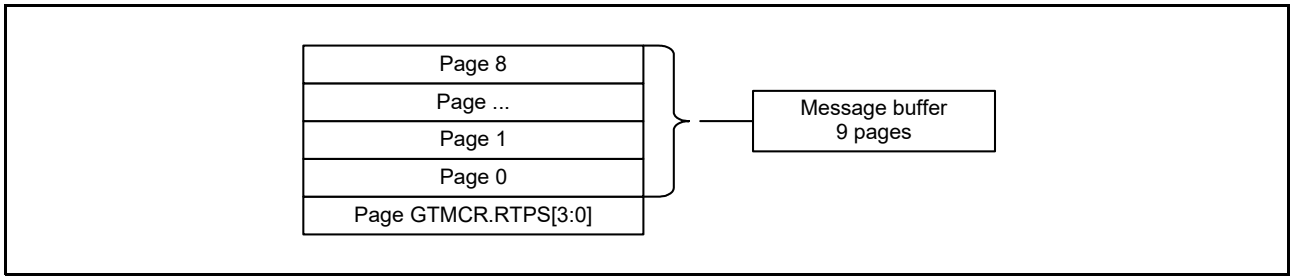

Figure 46.55 RAM Page Structure

The total available RAM size is, 2072 bytes for the message buffer RAM.
Total number of pages for the RAMs and the GTMCR.RTPS[3:0] values are calculated in the following way:

Total number of pages = ceil (total RAM size in bytes / number of bytes per page)

Message buffer RAM:

Total number of pages = ceil (2072 / 256) = 9 pages
GTMCR.RTPS[3:0] = 0 to 8

Figure 46.56 below shows the software flow for RAM test mode.

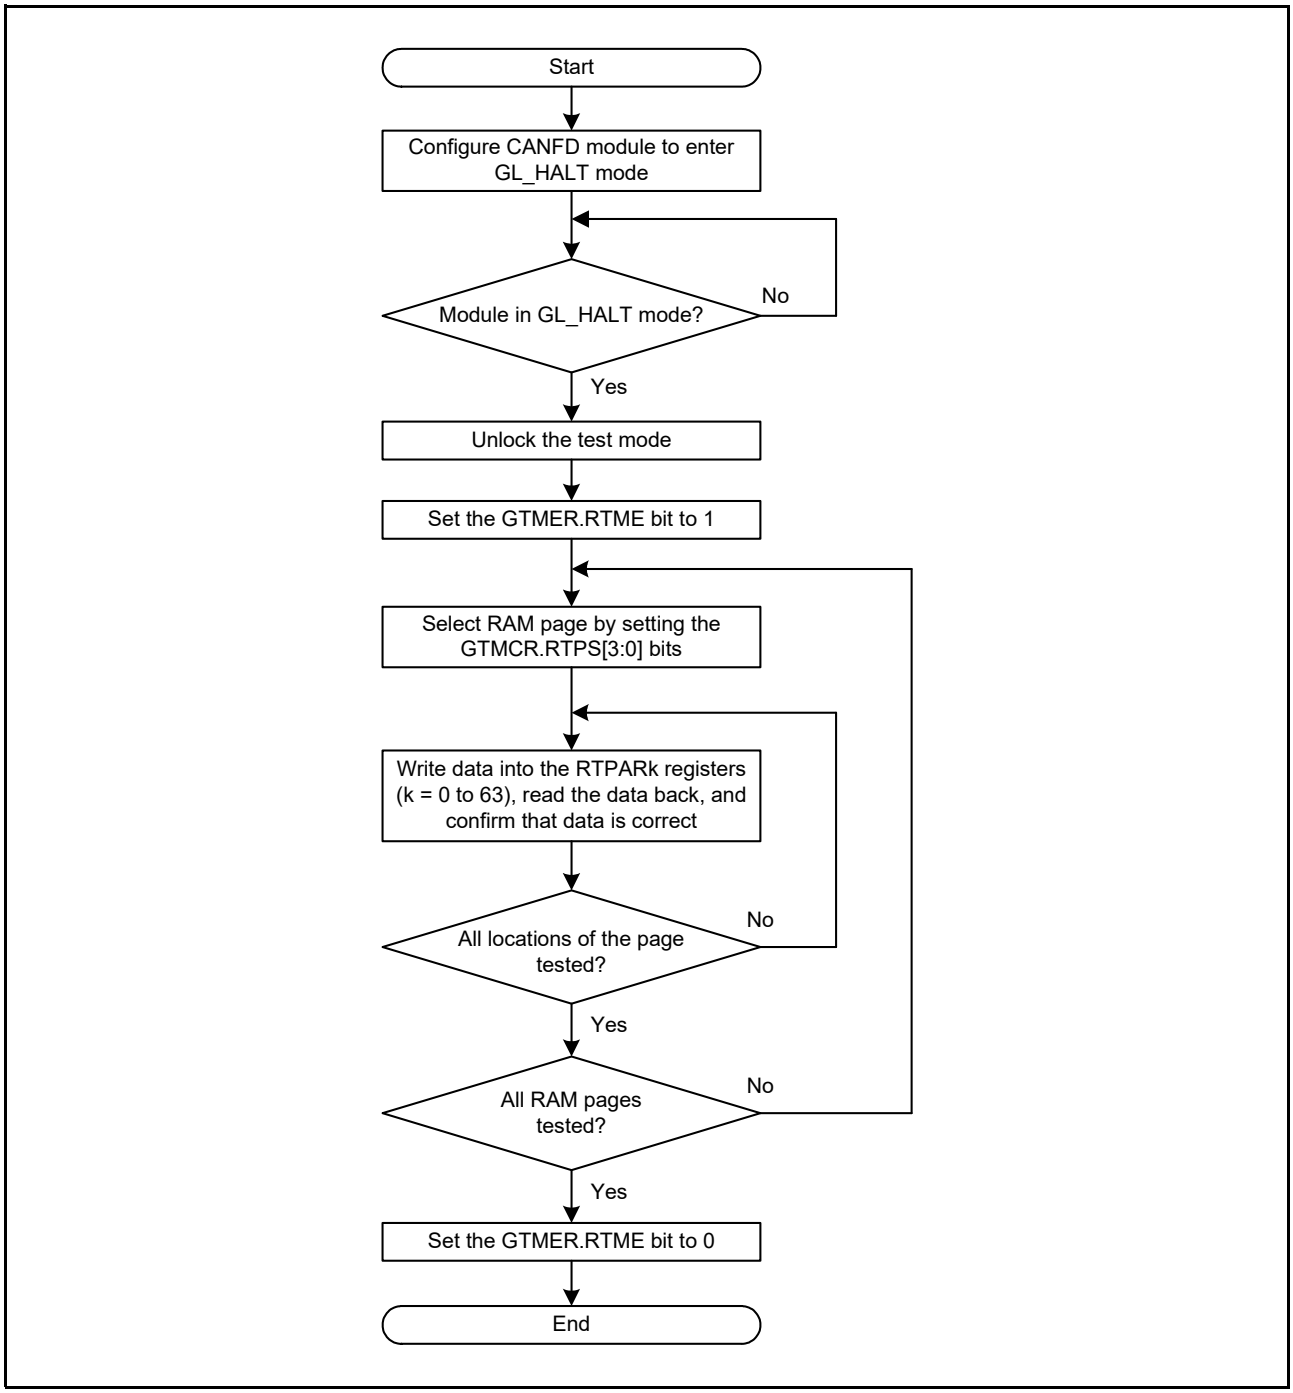

Figure 46.56 RAM Test Mode Software Flow

To exit RAM test mode, set the GTMER.RTME bit to 0.
The GTMER.RTME bit is automatically set to 0 when the CANFD module enters GL_RESET mode from the test mode.

46.9.2.2 Bit Flip Test

Bit flip test can invert the bit (the first bit of ID) of the beginning of the bit stream to receive.
If this function is used by a transmitter node, a bit error or an arbitration lost will occur.
If this function is used by a receiver node, a CRC error or a stuff error will occur.
Users should refer to the bit stuffing rule when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.
The following sequence should be used to perform CRC error testing. In the sequence below CANFD module is the receiver.

(1) Set the CHCR.BFT bit to 1, in order to invert the first bit of the incoming bit stream from transmitter node.
(2) Wait for the can_cherr_int output signal to set to 1.
(3) Read either the CHESR.CRC15[14:0] or FDCRC.CRC21[20:0] bits (depending on the received frame type: Classical CAN or CAN FD). The value should be different from the received CRC value of the reference message from transmitter node.
(4) Check that CHESR.CEDF is 1.
As the CRC generator logic is shared for receive and transmit there is no need to create a separate transmit CRC error test.

46.10 Interrupts and DTC/DMA Requests

46.10.1 CANFD Interrupts

The CANFD module generates several interrupts. The interrupt output, which is connected to the interrupt controller, can be controlled by the corresponding interrupt enable bit.
The status flags will be set independently of these enable bits.
The channel transmit interrupt has an additional status flag register; these status bits will only be set when the corresponding interrupt enables are set.
This register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.
The interrupts in the CANFD module can be classified into two groups: global interrupts and channel interrupts.

(1) Global Interrupts

The CANFD module can generate the following three global interrupts.

- Receive FIFO interrupt
- Global error interrupt
- Receive message buffer interrupt

(2) Channel Interrupts

The CAN channel can generate the following three channel interrupts.

- Channel transmit interrupt
  (a) Successful transmission interrupt
  (b) Transmission abort interrupt
  (c) Transmit queue interrupt
  (d) Common FIFO transmission interrupt
  (e) Transmission history interrupt
- Channel error interrupt
- Common FIFO receive interrupt

Table 46.25 lists the interrupt sources for CANFD module.
To clear each interrupt request, clear all flags set to 1 from among the sources for which interrupts are enabled. The interrupt request can also be cleared by setting all corresponding interrupt enable bits to 0.

Table 46.25 Interrupt Sources

Interrupt Name			Interrupt Source Flag	Interrupt Enable Bit	Interrupt Status Flag
Global interrupts	Receive FIFO interrupt (RFRI)		RFSRn.RFIF	RFCRn.RFIE	—
	Global error interrupt (GLEI)		GESR.DEDF GESR.MLDF GESR.THLDF GESR.PODF	GCR.DEIE GCR.MLIE GCR.THLIE GCR.POIE	—
	Receive message buffer interrupt (RMRI)		RMNDR.NDF[n]	RMIER.RMIEn	—
Channel interrupts	Channel transmit interrupt (CHTI)	Transmission successful interrupt*1	TMSRn.TXRF[1]	TMIER0.TMIEn	TISR.TSIF0
		Transmission abort interrupt*1	TMSRn.TXRF[1:0] (TXRF[1:0] = 01b)	CHCR.TAIE	TISR.TAIF0
		Transmit queue interrupt	TQSR0.TQIF	TQCR0.TQIE	TISR.TQIF0
		Common FIFO transmission interrupt	CFSR0.CFTIF	CFCR0.CFTIE	TISR.CFTIF0
		Transmission history interrupt	THSR.THIF	THCR.THIE	TISR.THIF0
	Channel error interrupt (CHEI)		CHESR.BEDF CHESR.EWDF CHESR.EPDF CHESR.BOEDF CHESR.BORDF CHESR.OLDF CHESR.BLDF CHESR.ALDF FDSTS.ECOV FDSTS.SCOV FDSTS.TDCV	CHCR.BEIE CHCR.EWIE CHCR.EPIE CHCR.BOEIE CHCR.BORIE CHCR.OLIE CHCR.BLIE CHCR.ALIE CHCR.ECOVIE CHCR.SCOVIE CHCR.TDCVIE	—
	Common FIFO receive interrupt (CFRI)		CFSR0.CFRIF	CFCR0.CFRIE	—

Note 1. These interrupts are only generated for transmit message buffers that are not part of a valid transmit queue and are not linked to a common FIFO. The common FIFO and the transmit queue have other interrupts respectively.

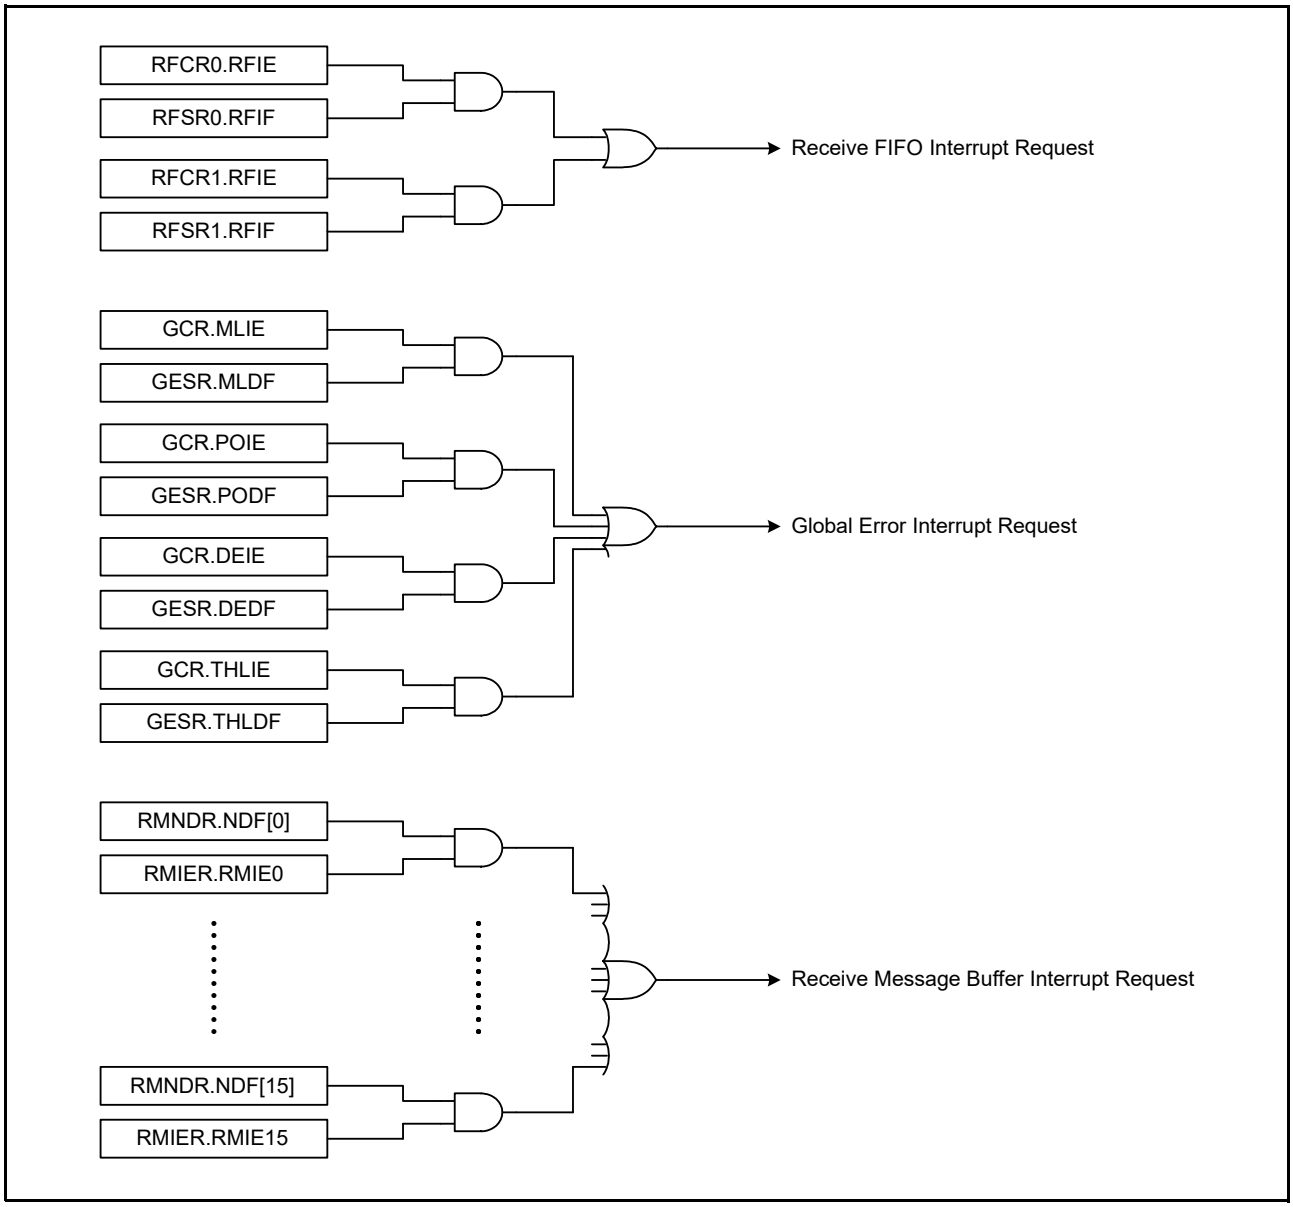

Figure 46.57 Global Interrupt Block Diagram

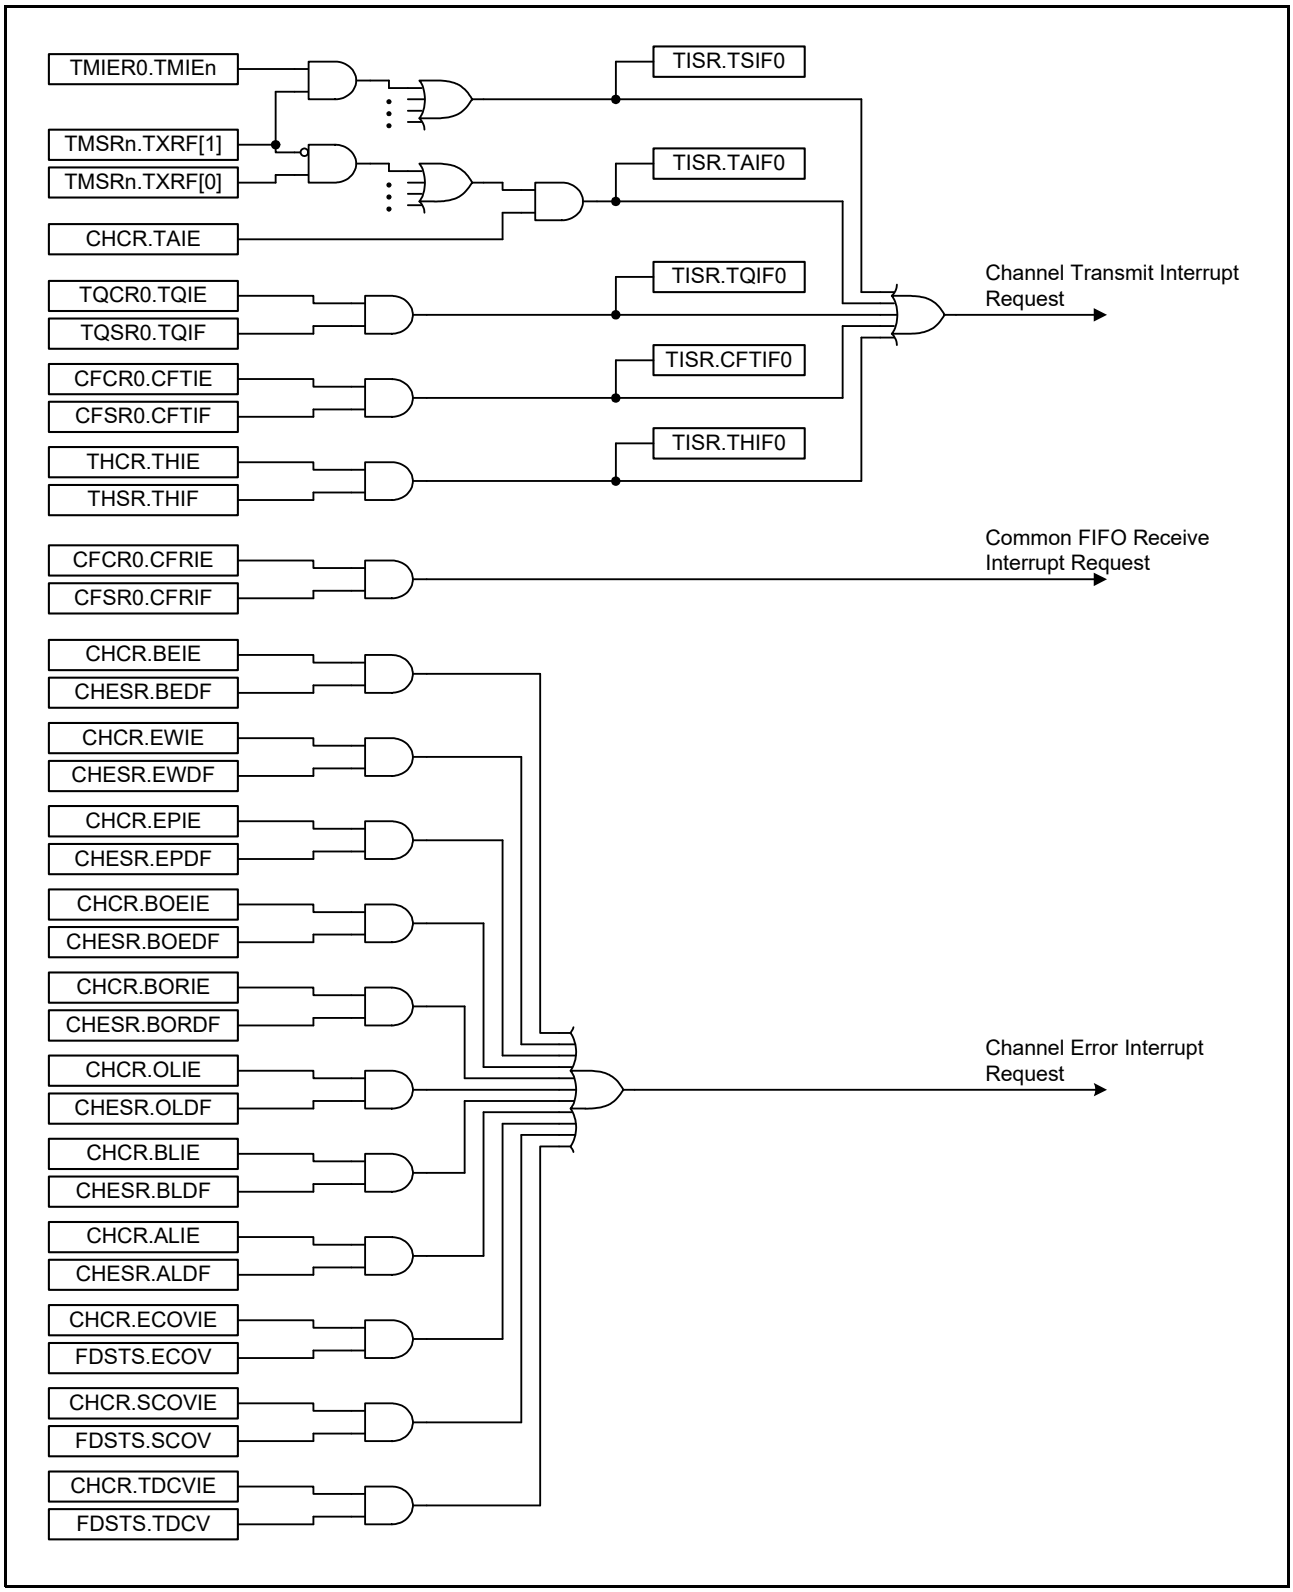

Figure 46.58 Channel Interrupt Block Diagram

46.10.2 ECC Interrupts

The ECC decoder generates an ECC error interrupt (ECCEI). There are three types of interrupt sources for the ECC error interrupt:

- 1-bit ECC error
- 2-bit ECC error
- ECC overflow.

46.10.3 DTC/DMA Transfer Requests

The CANFD module has message buffers that can be read by DTC/DMA transfer:

- Two receive FIFO message buffers
- Common FIFO message buffer

A DTC/DMA transfer request is generated when the DTCR.RFDTE0, RFDTE1, or CFDTE0 bit is set to 1 and the corresponding FIFO is not empty.
For FIFOs with DTC / DMA transfer enabled, disable receive FIFO interrupts (the RFCR0.RFIE, RFCR1.RFIE, or CFCR0.CFRIE bit).

When the data of the specified payload size (the RFCR0.PLS[2:0], RFCR1.PLS[2:0], or CFCR0.PLS[2:0] bits) is read*1, the FIFO read pointer is automatically updated.
When DTC/DMA transfer is permitted, do not write to the FIFO pointer control register (the RFPCR0, RFPCR1, or CFPCR0 register).

Note 1. The DTC/DMA should read the exact length of the specified data payload size (the RFCR0.PLS[2:0], RFCR1.PLS[2:0], or CFCR0.PLS[2:0] bits).

The permission for DTC/DMA transfer (the DTCR.RFDTE0, RFDTE1, or CFDTE0 bit) can be set to 1 at any time. Figure 46.59 shows the DTC/DMA transfer configuration flow.

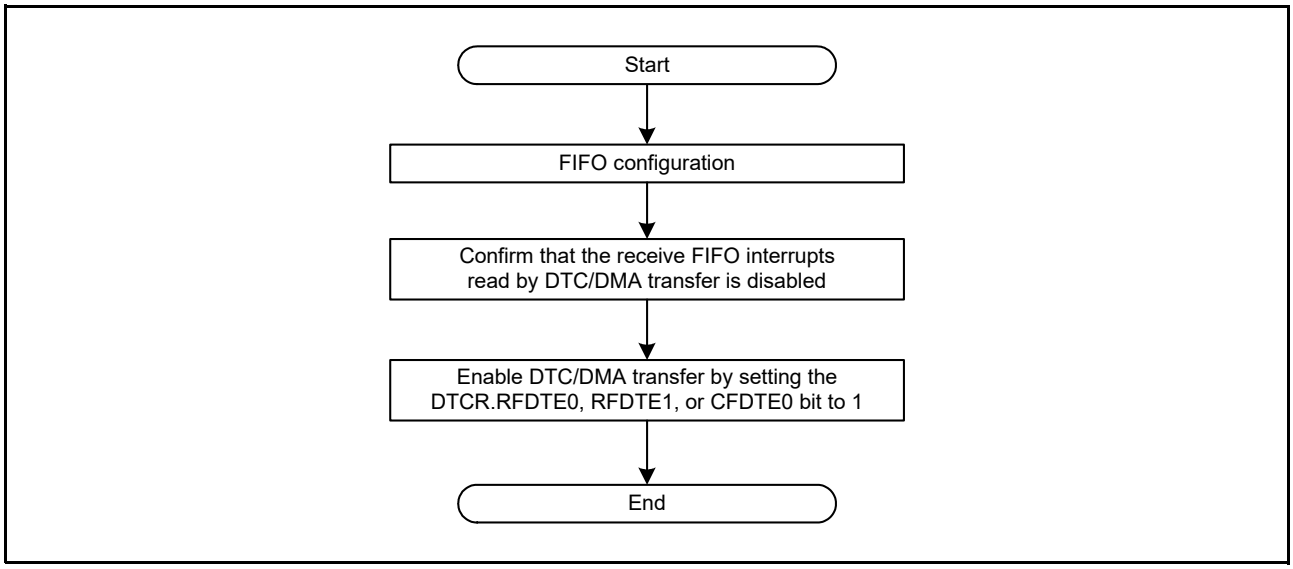

Figure 46.59 DTC/DMA Transfer Enable Flow

To disable the DTC/DMA transfer, set the corresponding DMA transfer enable bit (the DTCR.RFDTE0, RFDTE1, or CFDTE0 bit) to 0. If the disable is made during a DTC/DMA transfer, wait until the ongoing transfer is complete before

performing the following operations. The transfer status can be confirmed by the DTSR.RFDTS0, RFDTS1, or CFDTS0 flag. Figure 46.60 shows the DTC/DMA transfer disable flow.
When the DTC/DMA transfer is disabled then consider what to do with the remaining or new incoming messages to this particular reception FIFOs. When the FIFO is not disabled then reception to the FIFO will continue.

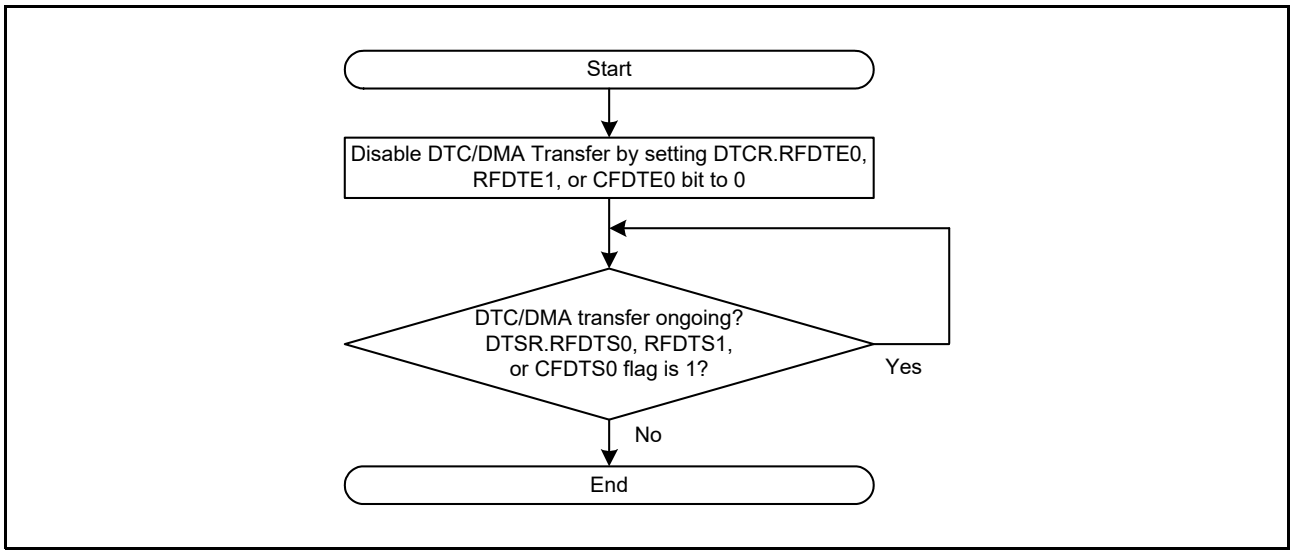

Figure 46.60 DTC/DMA Transfer Disable Flow

46.11 Usage Notes

46.11.1 Setting the Module Stop Function

The CANFD module operation can be enabled or disabled by module stop control register C (MSTPCRC). After a reset, the CANFD module is stopped. The registers of the module become accessible when it is released from the module stop state. For details, refer to section 11, Low Power Consumption.

46.11.2 Notes on the DLL Clock Settings

Set the DLL clock to be used before releasing the module-stop state. For details on the DLL clock settings, refer to section 9, Clock Generation Circuit.
Release the module-stop state after the oscillation of the DLL clock has been stabilized.

46.11.3 Note on Configuration of Receive Message Buffers and FIFO Buffers

The maximum memory size available for receive message buffers and FIFO buffers is 1216 bytes.
For example, if all payload sizes are set to 8 bytes, each message size becomes 20 bytes, so the total number of messages must be 60 or less. If 16 receive message buffers are reserved, the total FIFO depth must be 44 or less.
Similarly, if all payload sizes are set to 64 bytes, each message size becomes 76 bytes, so the total number of messages must be 16 or less. If all FIFO depths are set to 4 messages, up to four receive message buffers can be used.
Operation is not guaranteed if the setting exceeds 1216 bytes.

46.11.4 Transition to Software Standby Mode

To reduce power consumption, power to the message buffer RAM is turned off in software standby mode. Therefore, the respective sets of operations listed below must be performed before a transition to and after a return from software standby mode.

(1) Before a Transition to Software Standby Mode

Before a transition to software standby mode, perform the following operations.

1. Put the CANFD module into GL_SLEEP mode.
2. Read the GTMLKR register and verify that its value is 00000000h.
3. Set the ECCSR.EC1EC and ECCSR.EC2EC bits to 1 to clear the ECC error detection flags.
4. Set the ECCSR.ECEDE bit to 0 to disable ECC error detection.

(2) After a Return from Software Standby Mode 1

After a return from software standby mode 1, the CANFD module is not reset, meaning that the RAM is not initialized. Use RAM test mode to initialize the RAM. After having initialized the RAM, initialize the CANFD module by following the standard procedure. For details on RAM test mode, refer to section 46.9.2.1, RAM Test Mode.

(3) After a Return from Software Standby Mode 2

After a return from software standby mode 2, the CANFD module is reset. Initialize the CANFD module through the same procedure as when the MCU is released from the reset state.

47. Serial Peripheral Interface (RSPIA)

This MCU incorporates three channels of serial peripheral interface (RSPIA0, RSPIA1, RSPIA2).
The RSPIA supports high-speed, full-duplex or simplex synchronous serial communications with multiple processors and peripheral devices.

47.1 Overview

Table 47.1 lists the specifications of the RSPIA and Figure 47.1 shows a block diagram of the RSPIA.

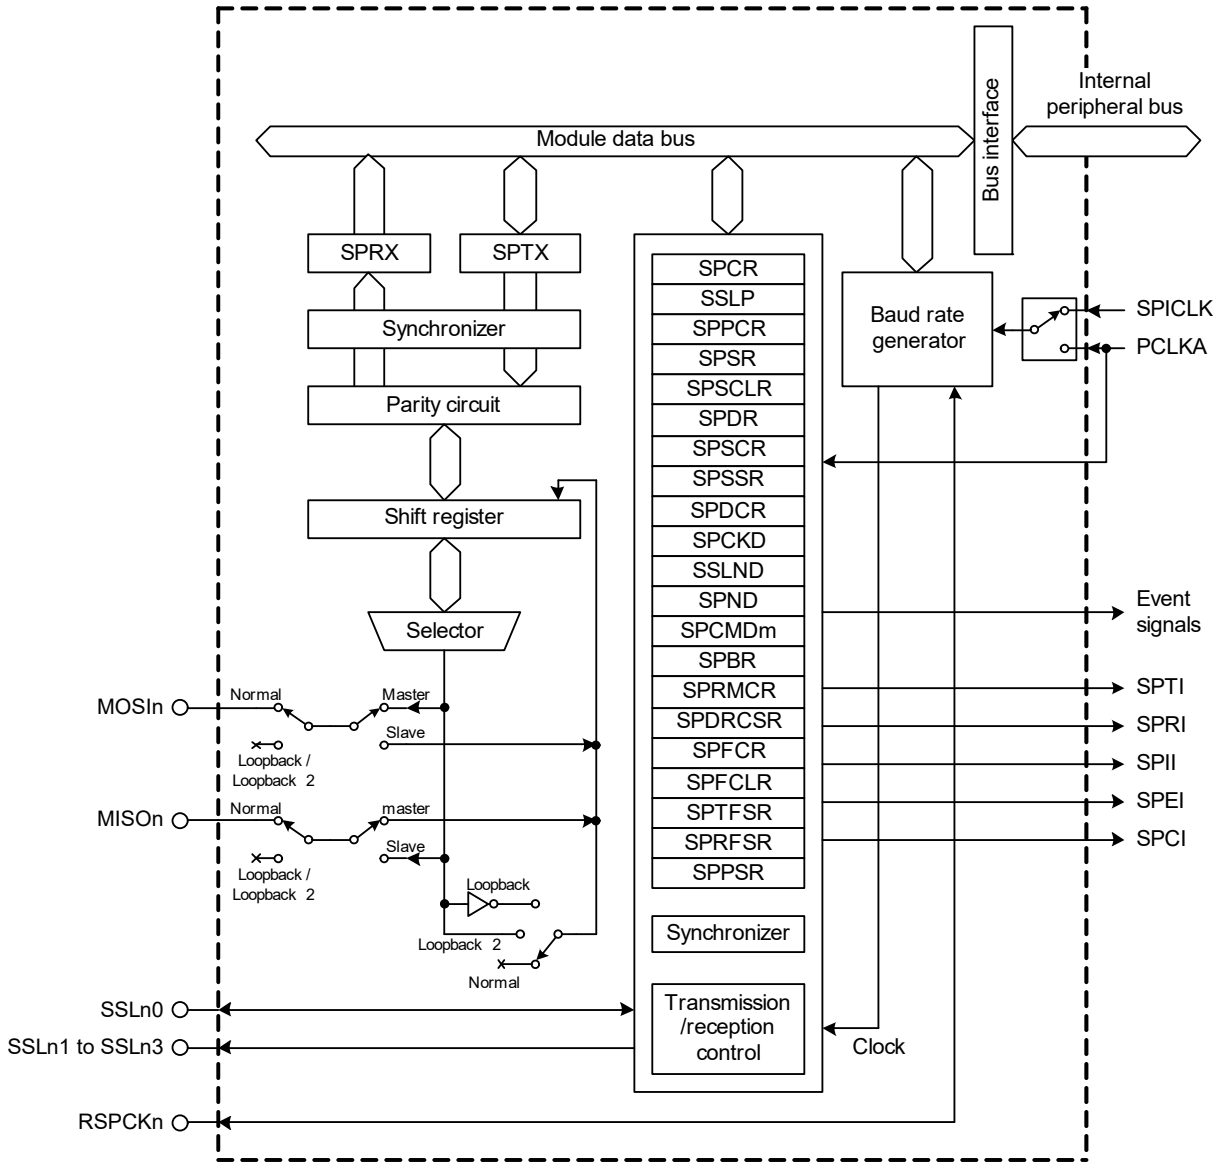

Table 47.1 RSPIA Specifications (1/2)

Item	Description
Transfer functions	• Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (RSPI clock) signals allows serial communications through SPI operation (4-wire method) or clock synchronous operation (3-wire method). • Full-duplex or simplex (transmit-only or receive-only) communications can be selected. • Serial communication is possible in master mode and slave mode. • Polarity of RSPCK can be selected. • Phase of RSPCK can be selected.
Data format	• MSB first/LSB first selectable • Transfer bit length can be changed to 4 through 32 bits. • Transmit buffer size/receive buffer size: 32 bits × 4 stages FIFO • Up to four frames can be transferred in one round of transmission/reception (each frame consisting of up to 32 bits). • Byte swapping of transmit and receive data is selectable. • Logic level of transmit and receive data can be inverted.
Operating clock (TCLK)	Selectable from peripheral module clock (PCLKA) or SPI clock (SPICLK)
Bit rate	• In master mode, the on-chip baud rate generator generates RSPCK by frequency-dividing TCLK. The division ratio ranges from divided by 2 to divided by 4096. • In slave mode, an external input clock is used as a serial clock. The maximum frequency of RSPCK is that of TCLK divided by 2 (width at high level: 1 cycle of TCLK; width at low level: 1 cycle of TCLK).
Buffer configuration	Transmit buffer and receive buffer are configured independently.
Error detection	• Mode fault error detection • Underrun error detection • Overrun error detection • Parity error detection • Receive data ready detection
SSL control function	[Motorola SPI] • Four SSL signals per RSPIA channel (SSLn0 to SSLn3) • In single-master mode, the SSLn0 to SSLn3 signals are output. • In multi-master mode: The SSLn0 signal is input and the SSLn1 to SSLn3 signals are output or Hi-Z. • In slave mode: The SSLn0 signal is input and the SSLn1 to SSLn3 signals are Hi-Z (not used). • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Function for changing SSL polarity

Table 47.1 RSPIA Specifications (2/2)

Item	Description
SSL control function	[TI SSP] • Four SSL signals per RSPIA channel (SSLn0 to SSLn3) • In single-master mode, the SSLn0 to SSLn3 signals are output. • In multi-master mode: The SSLn0 signal is input and the SSLn1 to SSLn3 signals are output or Hi-Z. • In slave mode: The SSLn0 signal is input and the SSLn1 to SSLn3 signals are Hi-Z (not used). • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 0 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to OE output negation (OE negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Function for changing SSL polarity
Communication Protocol	• Motorola SPI • TI SSP (synchronous serial protocol)
Control in master transfer	[Motorola SPI] • A transfer of up to eight commands can be executed sequentially in looped execution. • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity/phase, transmit data length, MSB/LSB first, burst, RSPCK delay, SSL negation delay, and next-access delay • A transfer can be initiated by writing to the transmit buffer. • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function (enabled or disabled by setting) • Delay between data bytes under burst transfer can be reduced. [TI SSP] • A transfer of up to eight commands can be executed sequentially in looped execution. • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity/phase, transmit data length, MSB/LSB first, burst, RSPCK delay, SSL negation delay (OE negation delay), and next-access delay • A transfer can be initiated by writing to the transmit buffer. • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function (enabled or disabled by setting) • Delay between data bytes under burst transfer can be reduced.
Interrupt sources	Five interrupt sources • Receive buffer full/receive data ready interrupt • Transmit buffer empty interrupt • Communication end interrupt • Error interrupt (mode fault error, underrun error, overrun error, parity error, or receive data ready) • Idle interrupt
Event link function	Five event types can be output to the event link controller. • Receive buffer full/receive data ready event signal • Transmit buffer empty event signal • Mode fault error, underrun error, overrun error, parity error, or receive data ready event signal • Idle event signal • Communication end event signal
Others	• Function for disabling (initializing) the RSPIA • Loopback mode • SPE bit status polling function
Low power consumption function	Module stop state can be set.
Protect Zone filter	Security attribute can be set for each channel.*1

Note 1. When each channel is set to the secure attribute, registers in the channel are accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When each channel is set to the non-secure attribute, registers in the channel are accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

SPCR: RSPI control register
SSLP: RSPI slave select polarity register
SPPCR: RSPI pin control register
SPSR: RSPI status register
SPSCLR: RSPI status clear register
SPDR: RSPI data register
SPSCR: RSPI sequence control register

Figure 47.1 RSPIA Block Diagram

Table 47.2 lists the I/O pins used in the RSPIA.
The RSPIA automatically switches the I/O direction of the SSLn0 pin. SSLn0 is set as an output when the RSPIA is a single master and as an input when the RSPIA is a multi-master or a slave. Pins RSPCKn, MOSIn, and MISOn are automatically set as inputs or outputs according to the setting of master or slave, the SPI operation (4-wire method) or clock synchronous operation (3-wire method), and the level input on the SSLn0 pin. Refer to section 47.3.2, Controlling RSPI Pins for details.

Table 47.2 RSPIA Pin Configuration

Channel	Pin Name	I/O	Function
RSPIA0	RSPCK0	I/O	Clock I/O
	MOSI0	I/O	Master transmit data I/O
	MISO0	I/O	Slave transmit data I/O
	SSL00	I/O	Slave selection I/O
	SSL01	Output	Slave selection output
	SSL02	Output	Slave selection output
	SSL03	Output	Slave selection output
RSPIA1	RSPCK1	I/O	Clock I/O
	MOSI1	I/O	Master transmit data I/O
	MISO1	I/O	Slave transmit data I/O
	SSL10	I/O	Slave selection I/O

The SPDR register is the interface with the buffers that hold data for transmission and reception by the RSPI. The transmit buffer and receive buffer are independent. Figure 47.2 shows the configuration of the SPDR register.

Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 47.2 Configuration of SPDR Register

The transmit and receive buffers each have 32 bits × 4 stages of FIFO. The eight stages of FIFO are all mapped to the single address of the SPDR register. Data written to the SPDR register are written to a transmit-buffer stage (SPTXn, n = 0 to 3) and then transmitted from the buffer. The receive buffer (SPRXn, n = 0 to 3) holds received data on completion of reception. The receive buffer is not updated if an overrun is generated.

(1) Bus Interface

The SPDR register is the interface with 32-bit wide transmit buffer (SPTXn, n = 0 to 3) and receive buffer (SPRXn, n = 0 to 3), each of which has four stages, for a total of 32 bytes. In other words, the 32 bytes are mapped to the 4-byte address space for the SPDR register.
Data for transmission should be flush with the LSB end of the register. Received data are stored flush with the LSB end.
Operations involved in writing to and reading from the SPDR register are described below.

(a) Writing

The transmit buffer includes a transmit buffer write pointer which is automatically updated to indicate the next stage each time data are written to the SPDR register. Figure 47.3 shows the configuration of the bus interface with the transmit buffer in the case of writing to the SPDR register.

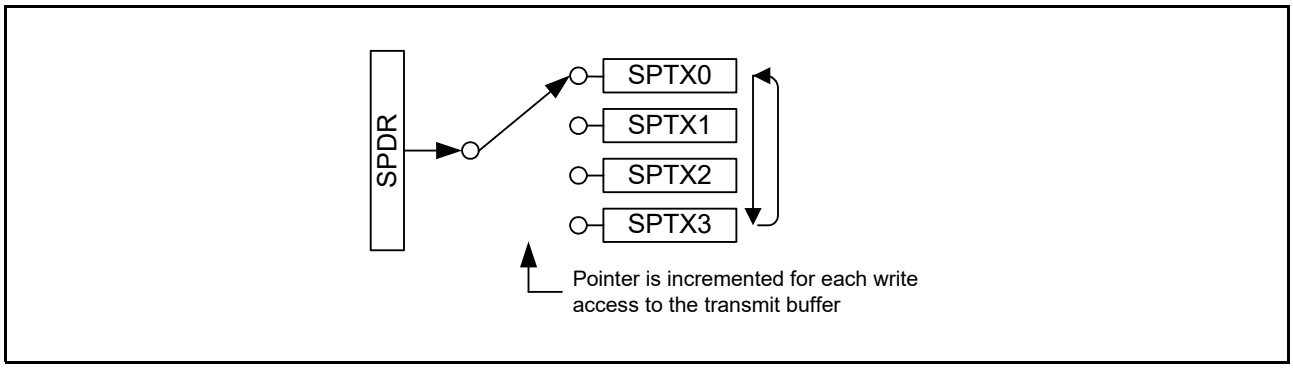

Figure 47.3 Configuration of SPDR Register (Writing)

Sequence of switching the pointer among SPTX0 to SPTX3:
SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …

When writing to the transmit buffer (SPTXn) after generation of the transmit buffer empty interrupt (after the SPSR.SPTEF flag becomes 1), write the number of frames + 1 set by the transmission FIFO threshold setting bits of RSPI FIFO control register (SPFCR.TTRG[1:0]). Writing to the transmit buffer (SPTXn, n = 0 to 3) in the state where there is no empty stages in the transmit FIFO does not update the buffer value.

(b) Reading

The SPDR register can be read to read the value of a receive buffer (SPRXn, n = 0 to 3) or a transmit buffer (SPTXn, n = 0 to 3). The setting of the RSPI receive/transmit data select bit in the RSPI data control register (SPDCR.SPRDTD) selects whether reading is of the receive or transmit buffer.
The sequence of reading the SPDR register is controlled by independent pointers, receive buffer read pointer and transmit buffer read pointer.
Figure 47.4 shows the configuration of the bus interface with the receive and transmit buffers in the case of reading from the SPDR register.

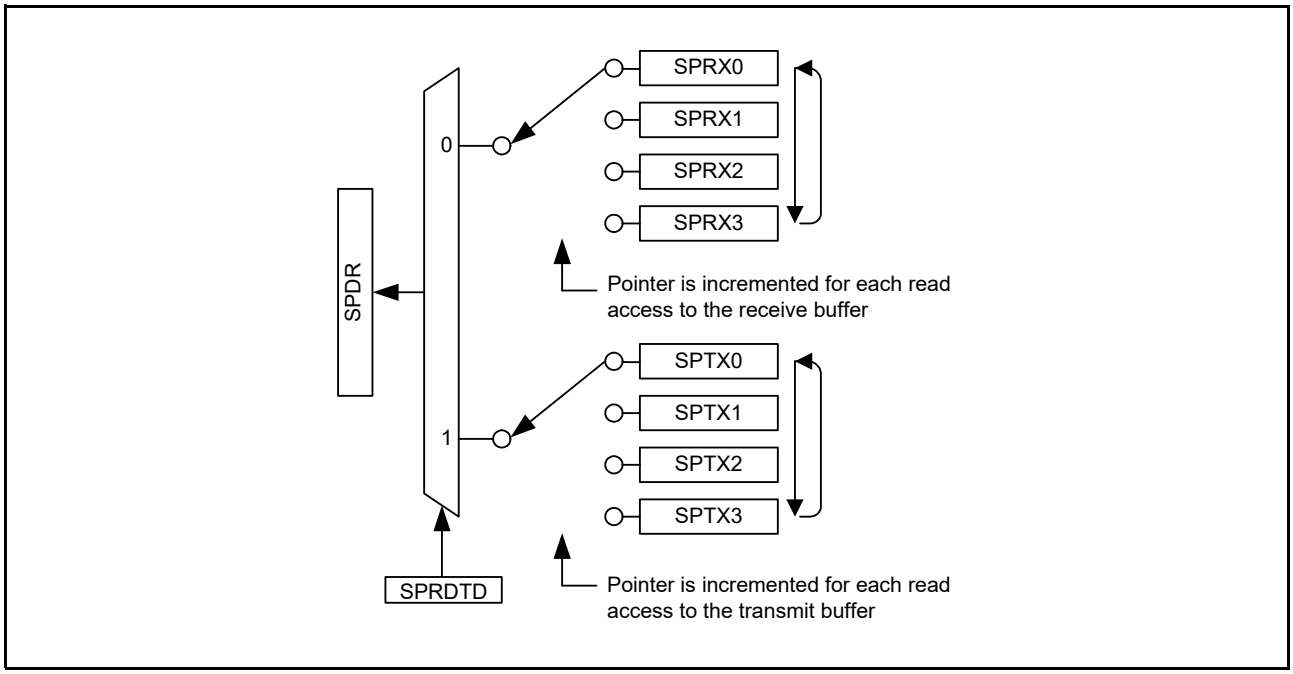

Figure 47.4 Configuration of SPDR (Reading)

Reading the receive buffer switches the receive buffer read pointer to the next buffer automatically.
The sequence of switching the receive buffer read pointer is the same as that for the transmit buffer write pointer.
The transmit buffer read pointer is updated when writing to the SPDR register, and not updated when reading from the transmit buffer. When reading from the transmit buffer, the value most recently written to the SPDR register is read.

47.2.2 RSPI Clock Delay Register (SPCKD)

Address(es): RSPIA0.SPCKD 8745 C004h, RSPIA1.SPCKD 8745 C104h, RSPIA2.SPCKD 8745 C204h, RSPIA0_NS.SPCKD 0745 C004h, RSPIA1_NS.SPCKD 0745 C104h, RSPIA2_NS.SPCKD 0745 C204h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SCKDL[2:0]	RSPCK Delay Setting	b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

[Motorola SPI]
The SPCKD register sets a period from the beginning of SSLni signal assertion to RSPCK oscillation (RSPCK delay) when the SPCMDm.SCKDEN bit is 1. If the value of the SPCKD register is changed while both the SPCR.MSTR and SPCR.SPE bits are 1, subsequent operation is not guaranteed.

[TI SSP]
The SPCKD register sets a period from the beginning of SSLni signal assertion to RSPCK oscillation (RSPCK delay) when the SPCMDm.SCKDEN bit is 1, and also sets a period until the SSLni signal is negated. If the value of the SPCKD register is changed while both the SPCR.MSTR and SPCR.SPE bits are 1, subsequent operation is not guaranteed.

SCKDL[2:0] Bits (RSPCK Delay Setting)

The SCKDL[2:0] bits set an RSPCK delay value when the SPCMDm.SCKDEN bit is 1.
When using the RSPIA in slave mode, set the SCKDL[2:0] bits to 000b.

47.2.3 RSPI Slave Select Negation Delay Register (SSLND)

Address(es): RSPIA0.SSLND 8745 C005h, RSPIA1.SSLND 8745 C105h, RSPIA2.SSLND 8745 C205h, RSPIA0_NS.SSLND 0745 C005h, RSPIA1_NS.SSLND 0745 C105h, RSPIA2_NS.SSLND 0745 C205h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SLNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SLNDL[2:0]	SSL Negation Delay Setting	[In master mode] b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK [In TI SSP slave mode] b2 b0 0 0 0: 1 TCLK 0 0 1: 2 TCLK 0 1 0: 3 TCLK 0 1 1: 4 TCLK 1 0 0: 5 TCLK 1 0 1: 6 TCLK 1 1 0: 7 TCLK 1 1 1: 8 TCLK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

[Motorola SPI]
The SSLND register sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the SSLni signal during a serial transfer by the RSPIA in master mode when the SPCMDm.SLNDEN bit is 1. If the value of the SSLND register is changed while both the SPCR.MSTR and SPCR.SPE bits are 1, subsequent operation is not guaranteed.

[TI SSP]
The SSLND register sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the OE signal during a serial transfer by the RSPIA in master mode, or from the detection of a final RSPCK edge to the negation of the OE signal during a serial transfer by the RSPIA in slave mode. If the value of the SSLND register is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

SLNDL[2:0] Bits (SSL Negation Delay Setting)

[Motorola SPI]
The SLNDL[2:0] bits set an SSL negation delay value when the SPCMDm.SLNDEN bit is 1.
When using the RSPIA in slave mode, set the SLNDL[2:0] bits to 000b.

[TI SSP]
The SLNDL[2:0] bits set an OE negation delay value when the SPCMDm.SLNDEN bit is 1.

[Clock synchronous]
When using the RSPIA in slave mode, set the SLNDL[2:0] bits to 000b.

47.2.4 RSPI Next-Access Delay Register (SPND)

Address(es): RSPIA0.SPND 8745 C006h, RSPIA1.SPND 8745 C106h, RSPIA2.SPND 8745 C206h, RSPIA0_NS.SPND 0745 C006h, RSPIA1_NS.SPND 0745 C106h, RSPIA2_NS.SPND 0745 C206h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPNDL[2:0]	RSPI Next-Access Delay Setting	b2 b0 0 0 0: 1 RSPCK + 5 TCLK 0 0 1: 2 RSPCK + 5 TCLK 0 1 0: 3 RSPCK + 5 TCLK 0 1 1: 4 RSPCK + 5 TCLK 1 0 0: 5 RSPCK + 5 TCLK 1 0 1: 6 RSPCK + 5 TCLK 1 1 0: 7 RSPCK + 5 TCLK 1 1 1: 8 RSPCK + 5 TCLK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPND register sets a non-active period (next-access delay) of the SSLni signal after termination of a serial transfer when the SPCMDm.SPNDEN bit is 1. If the value of the SPND register is changed while both the SPCR.MSTR and SPCR.SPE bits are 1, subsequent operation is not guaranteed.

SPNDL[2:0] Bits (RSPI Next-Access Delay Setting)

The SPNDL[2:0] bits set a next-access delay when the SPCMDm.SPNDEN bit is 1.
When using the RSPIA in slave mode, set the SPNDL[2:0] bits to 000b.

47.2.5 RSPI Control Register (SPCR)

Address(es): RSPIA0.SPCR 8745 C008h, RSPIA1.SPCR 8745 C108h, RSPIA2.SPCR 8745 C208h, RSPIA0_NS.SPCR 0745 C008h, RSPIA1_NS.SPCR 0745 C108h, RSPIA2_NS.SPCR 0745 C208h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	MODFEN	SCKDDIS	SCKASE	PTE	—	SPOE	SPPE	—	—	—	—	—	—	—	SPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPE	RSPI Function Enable	0: Disables the RSPI function 1: Enables the RSPI function	R/W
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	SPPE	Parity Enable	0: Does not add a parity bit to transmit data and does not check the parity bit of received data 1: Adds a parity bit to transmit data and checks the parity bit of received data	R/W
b9	SPOE	Parity Mode	0: Even parity is used for transmission and reception. 1: Odd parity is used for transmission and reception.	R/W
b10	—	Reserved	This bit is read as 0. The write value should be 0.	R
b11	PTE	Parity Self-Diagnosis	0: Disables the self-diagnosis function of the parity circuit 1: Enables the self-diagnosis function of the parity circuit	R/W
b12	SCKASE	RSPCK Auto-Stop Function Enable	0: Disables the RSPCK auto-stop function 1: Enables the RSPCK auto-stop function	R/W
b13	SCKDDIS	RSPCK Delay Between Frames Disable	0: Inter-frame delay is inserted during burst transfer. 1: Inter-frame delay is not inserted during burst transfer.	R/W
b14	MODFEN	Mode Fault Error Detection Enable	0: Disables the detection of mode fault error 1: Enables the detection of mode fault error	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R
b16	SPEIE	Error Interrupt Enable	0: Disables the error interrupt 1: Enables the error interrupt	R/W
b17	SPRIE	Receive Buffer Full Interrupt Enable	0: Disables the receive buffer full interrupt 1: Enables the receive buffer full interrupt	R/W
b18	SPIIE	Idle Interrupt Enable	0: Disables the idle interrupt 1: Enables the idle interrupt	R/W
b19	RDRIS	Receive Data Ready Interrupt Select	0: Receive buffer full interrupt 1: Error interrupt	R/W
b20	SPTIE	Transmit Buffer Empty Interrupt Enable	0: Disables the transmit buffer empty interrupt 1: Enables the transmit buffer empty interrupt	R/W
b21	SPCIE	Communication End Interrupt Enable	0: Disables the communication end interrupt 1: Enables the communication end interrupt	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R
b24	SPMS	RSPI Mode Select	0: SPI operation (4-wire method) 1: Clock synchronous operation (3-wire method)	R/W
b25	FRFS	Frame Format Select*1	0: Motorola SPI 1: TI SSP	R/W
b27, b26	—	Reserved	These bits are read as 0. The write value should be 0.	R

Bit	Symbol	Bit Name	Description	R/W
b29, b28	CMMD[1:0]	Communication Mode Select	b29 b28 0 0: Transmit-receive mode (full-duplex) 0 1: Transmit-only mode (simplex, receiver disabled) 1 0: Receive-only mode (simplex, transmitter disabled) 1 1: Setting prohibited	R/W
b30	MSTR	RSPI Master/Slave Mode Select	0: Slave mode 1: Master mode	R/W
b31	SYNDIS	Synchronizer Disable	0: TCLK = SPICLK, synchronizer enabled 1: TCLK = PCLKA, synchronizer disabled	R/W

Note 1. This bit is only valid when the SPMS bit is 0.

The SPCR register is used to specify the operating mode of the RSPIA. If the value of the SPPE, SPOE, PTE, SCKASE, SCKDDIS, MODFEN, SPMS, FRFS, CMMD[1:0], MSTR, or SYNDIS bit is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

SPE Bit (RSPI Function Enable)

This bit enables or disables the RSPI function. Setting this bit to 1 enables the RSPI function. When the SPSR.MODF flag is 1, this bit is set to 0. This bit cannot be set to 1 until the MODF flag is cleared. For details, refer to section 47.3.10, Error Detection.

Setting this bit to 0 disables the RSPI function, and initializes a part of the module function. For details, refer to section 47.3.12, Initializing RSPIA.

SPPE Bit (Parity Enable)

This bit enables or disables the parity function.

SPOE Bit (Parity Mode)

This bit specifies even or odd parity.

In even parity mode, the parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an even number. In the same way, in odd parity mode, a parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an odd number. The SPOE bit is effective only when the SPCR.SPPE bit is set to 1.

PTE Bit (Parity Self-Diagnosis)

This bit is used to enable or disable self-diagnosis of the parity circuit to confirm that the parity function is normal.

SCKASE Bit (RSPCK Auto-Stop Function Enable)

This bit is used to enable or disable the RSPCK auto-stop function. When this function is enabled, the RSPCK stops immediately before an overrun error occurs during data reception in master mode. For details, refer to section 47.3.10.1, Overrun Error.

SCKDDIS Bit (RSPCK Delay Between Frames Disable)

This bit controls whether or not a delay is inserted between frames during burst transfer.

This bit is valid for frames with the SPCMDm.SSLKP bit set to 1 in master mode (SPCR.MSTR = 1).

Set this bit to 0 in slave mode (SPCR.MSTR = 0). Table 47.3 shows the usage of SSL delay control in frame transmission. For details, refer to (4) Burst Transfer in section 47.3.13.1, Master Mode Operation.

Table 47.3 Usage of SSL Delay Control in Frame Transmission (in Master Mode)

Case		SPCMDm.SSLKP bit	SPCR.SCKDDIS bit	RSPCK delay, SSL negation delay, next access delay
Non-burst transfers		0	0	RSPCK delay, SSL negation delay, and next access delay are controlled according to the register settings*1.
Burst transfer with delay between frames	From the first frame to before the last frame	1	0	
	The last frame	0	0	
Burst transfer with no delay between frames	From the first frame to before the last frame	1	1	Each delay control is only performed in the following cases. • RSPCK delay of the first frame • SSL negation delay and next access delay of the last frame
	The last frame	0	1	

Note 1. RSPCK delay is controlled by the SPCKD.SCKDL[2:0] bits and SPCMDm.SCKDEN bit.
SSL negation delay is controlled by the SSLND.SLNDL[2:0] bits and SPCMDm.SLNDEN bit.
Next access delay is controlled by the SPND.SPNDL[2:0] bits and SPCMDm.SPNDEN bit.

Table 47.4 Operation Example in Motorola SPI (SCKDDIS = 1)

Setting	Operation
SPCMD0.SSLKP = 1	Between frames 0 and 1: burst transfer and no inter-frame delay (SSLni pin remains asserted)
SPCMD1.SSLKP = 1	Between frames 1 and 2: burst transfer and no inter-frame delay (SSLni pin remains asserted)
SPCMD2.SSLKP = 1	Between frames 2 and 3: burst transfer and no inter-frame delay (SSLni pin remains asserted)
SPCMD3.SSLKP = 1	Between frames 3 and 4: burst transfer and no inter-frame delay (SSLni pin remains asserted)
SPCMD4.SSLKP = 0	Burst transfer is not performed and the SSLni pin is negated once.*1
SPCMD5.SSLKP = 1	Between frames 5 and 6: burst transfer and no inter-frame delay (SSLni pin remains asserted)
SPCMD6.SSLKP = 1	Between frames 6 and 7: burst transfer and no inter-frame delay (SSLni pin remains asserted)
SPCMD7.SSLKP = 0	Burst transfer is not performed and the SSLni pin is negated once.*1

Note 1. The SCKDDIS bit setting is invalid because burst transfer is not performed.

MODFEN Bit (Mode Fault Error Detection Enable)

This bit is used to enable or disable detection of a mode fault error. (Refer to section 47.3.10, Error Detection.) The RSPIA determines SSLn0 pin input or output direction according to the combination of the MODFEN and MSTR bits (refer to section 47.3.2, Controlling RSPI Pins).

SPEIE Bit (Error Interrupt Enable)

This bit is used to enable or disable an error interrupt request.
When the SPSR.MODF, OVRF, or PERF flag is set to 1 while this bit is 1, an error interrupt request is generated (refer to section 47.3.10, Error Detection).

SPRIE Bit (Receive Buffer Full Interrupt Enable)

This bit is used to enable or disable a receive buffer full interrupt request.

SPIIE Bit (Idle Interrupt Enable)

This bit is used to enable or disable an idle interrupt requests.
When the SPSR.IDLNF flag changes from 1 to 0 while this bit is 1, an idle interrupt request is generated.

RDRIS Bit (Receive Data Ready Interrupt Select)

This bit is used to select the SPRI interrupt request or SPEI interrupt request to be generated when the receive data ready is detected (SPSR.RRDYF = 1).

SPTIE Bit (Transmit Buffer Empty Interrupt Enable)

This bit is used to enable or disable a transmit buffer empty interrupt request.

SPCIE Bit (Communication End Interrupt Enable)

This bit controls generation of a communication end interrupt request.

SPMS Bit (RSPI Mode Select)

This bit is used to select SPI operation (4-wire method) or clock synchronous operation (3-wire method).
For clock synchronous operation, the SSLni pin is not used but three pins RSPCKn, MOSIn, and MISOn are used for communication. When SPMS = 1 (clock synchronous operation (3-wire)), the setting of the FRFS bit is invalid.
To perform clock synchronous operation in master mode (SPCR.MSTR = 1), the SPCMDm.CPHA bit can be set to 0 or 1. To perform clock synchronous operation in slave mode (SPCR.MSTR = 0), set the CPHA bit to 1. If this bit is set to 0 for clock synchronous operation in slave mode (SPCR.MSTR = 0), the operation is not guaranteed.
Table 47.5 lists the communication status according to the settings of the MSTR bit, CMMD[1:0] bits, FRFS bit, and SPMS bit of the RSPI control register (SPCR) as follows.

Table 47.5 RSPI Communication Status

SPCR. MSTR	SPCR. CMMD[1:0]	SPCR. FRFS	SPCR. SPMS	Communication Status	Communi-cation Status No.
1	00b	0	0	Transmit-Receive Master mode/Motorola SPI/SPI operation (4-wire)	1-1
1	00b	1	0	Transmit-Receive Master mode/TI SSP/SPI operation (4-wire)	1-2
1	00b	—	1	Transmit-Receive Master mode/Clock synchronous operation (3-wire)	1-3
1	01b	0	0	Transmit-only Master mode/Motorola SPI/SPI operation (4-wire)	1-4
1	01b	1	0	Transmit-only Master mode/TI SSP/SPI operation (4-wire)	1-5
1	01b	—	1	Transmit-only Master mode/Clock synchronous operation (3-wire)	1-6
1	10b	0	0	Receive-only Master mode/Motorola SPI/SPI operation (4-wire)	1-7
1	10b	1	0	Receive-only Master mode/TI SSP/SPI operation (4-wire)	1-8
1	10b	—	1	Receive-only Master mode/Clock synchronous operation (3-wire)	1-9
0	00b	0	0	Transmit-Receive Slave mode/Motorola SPI/SPI operation (4-wire) (default)	0-1
0	00b	1	0	Transmit-Receive Slave mode/TI SSP/SPI operation (4-wire)	0-2
0	00b	—	1	Transmit-Receive Slave mode/Clock synchronous operation (3-wire)	0-3
0	01b	0	0	Transmit-only Slave mode/Motorola SPI/SPI operation (4-wire)	0-4
0	01b	1	0	Transmit-only Slave mode/TI SSP/SPI operation (4-wire)	0-5
0	01b	—	1	Transmit-only Slave mode/Clock synchronous operation (3-wire)	0-6
0	10b	0	0	Receive-only Slave mode/Motorola SPI/SPI operation (4-wire)	0-7
0	10b	1	0	Receive-only Slave mode/TI SSP/SPI operation (4-wire)	0-8
0	10b	—	1	Receive-only Slave mode/Clock synchronous operation (3-wire)	0-9

—: don't care

FRFS Bit (Frame Format Select)

This bit selects the communication protocol. The format of the RSPI pin (RSPCKn, SSLni (i = 0 to 3) can be set according to the set communication protocol.
When the SPMS bit is 1 (clock synchronous operation (3-wire method)), this bit is invalid because SSLni pin is not used.

CMMD[1:0] Bits (Communication Mode Select)

This bit is used to select the transmit-receive, transmit-only, and receive-only serial communication.
When CMMD[1:0] is set to 01b for communication, transmit-only is performed without reception.
When CMMD[1:0] is set to 10b for communication, receive-only is performed without transmission.
When CMMD[1:0] is set to 01b for communication, a receive buffer full interrupt request cannot be used.

When CMMD[1:0] is set to 10b for communication, a transmit buffer empty interrupt request cannot be used.
Refer to section 47.3.6, Communication Mode.

MSTR Bit (RSPI Master/Slave Mode Select)

This bit is used to select master mode or slave mode of the RSPIA. The RSPIA determines input/output directions of pins RSPCKn, MOSIn, MISOn, and SSLn1 to SSLn3 according to the MSTR bit setting.

SYNDIS Bit (Synchronizer Disable)

This bit is used to bypass the synchronizers for clock domain crossing. When this bit is set to 1, the peripheral module clock (PCLKA) is selected as the operating clock (TCLK) and the synchronizers are bypassed. For details, refer to section 47.3.19, Synchronizer Bypass Function.

47.2.6 RSPI Receive-Only Mode Control Register (SPRMCR)

Address(es): RSPIA0.SPRMCR 8745 C00Ch, RSPIA1.SPRMCR 8745 C10Ch, RSPIA2.SPRMCR 8745 C20Ch, RSPIA0_NS.SPRMCR 0745 C00Ch, RSPIA1_NS.SPRMCR 0745 C10Ch, RSPIA2_NS.SPRMCR 0745 C20Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	START	TERM	—	RFC[4:0]				
Value after reset:	0	0	0	0	0	0	0	0

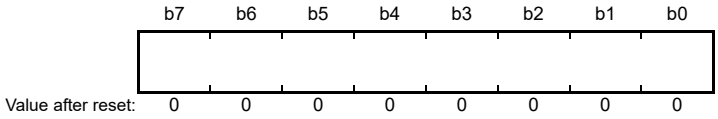
Bit	Symbol	Bit Name	Description	R/W
b4 to b0	RFC[4:0]	Receive Frame Count Select	The number of received frames can be adjusted in receive-only master mode. b4 b0 0 0 0 0 0: This function is not used. 0 0 0 0 1: Automatically stop communication after processing 1 received frame : 1 1 1 1 1: Automatically stop communication after processing 31 received frames Settings are not effective except in receive-only master mode.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R
b6	TERM	Reception Terminate	1: Receive End (Writable only in receive-only master mode) The read value is always 0.	W
b7	START	Reception Start	1: Receive Start (Writable only in receive-only master mode) The read value is always 0.	W

The SPRMCR register is used to control the start and completion of communication for receive-only master mode. If the RFC[4:0] bits are changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

RFC[4:0] Bits (Receive Frame Count Select)

The number of received frames can be adjusted when operating in receive-only master mode. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.CMMD[1:0]) are 10b. After reception is started by the START bit, the communication is automatically stopped after processing frames according to the value set in these bits.

TERM Bit (Reception Terminate)



This bit is used to end reception in receive-only master mode. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.CMMD[1:0]) are 10b.

START Bit (Reception Start)

This bit is used to start reception in receive-only master mode. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.CMMD[1:0]) are 10b.
Writing 1 to this bit during reception is not accepted. Write again after reception is completed.

47.2.7 RSPI Receive Data Ready Detect Condition Setting Register (SPDRCSR)

Address(es): RSPIA0.SPDRCSR 8745 C00Dh, RSPIA1.SPDRCSR 8745 C10Dh, RSPIA2.SPDRCSR 8745 C20Dh, RSPIA0_NS.SPDRCSR 0745 C00Dh, RSPIA1_NS.SPDRCSR 0745 C10Dh, RSPIA2_NS.SPDRCSR 0745 C20Dh

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	—	0h: Disables receive data ready detection function 1h: Performs receive data ready detection after 1 TCLK : FFh: Performs receive data ready detection after 255 TCLK	R/W

The SPDRCSR register is used to set the RSPI receive data ready detection function. If the setting value is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

The receive data ready detection function can be disabled or, if used, the period until detection can be set from 1 to 255 TCLK. The value set in the SPDRCSR register is used to 1 set the RRDYF flag. For details, see the description of the RRDYF flag in section 47.2.16, RSPI Status Register (SPSR).

47.2.8 RSPI Pin Control Register (SPPCR)

Address(es): RSPIA0.SPPCR 8745 C00Eh, RSPIA1.SPPCR 8745 C10Eh, RSPIA2.SPPCR 8745 C20Eh, RSPIA0_NS.SPPCR 0745 C00Eh, RSPIA1_NS.SPPCR 0745 C10Eh, RSPIA2_NS.SPPCR 0745 C20Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MOIFE	MOIFV	—	—	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPLP	RSPI Loopback	0: Normal mode 1: Loopback mode (data is inverted for transmission)	R/W
b1	SPLP2	RSPI Loopback 2	0: Normal mode 1: Loopback mode (data is not inverted for transmission)	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b4	MOIFV	MOSI Idle Fixed Value	0: The fixed value during MOSI idling corresponds to low 1: The fixed value during MOSI idling corresponds to high	R/W
b5	MOIFE	MOSI Idle Value Fixing Enable	0: MOSI output value equals final data from previous transfer 1: MOSI output value equals the value set in the MOIFV bit	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPPCR register is used to set pin mode of the RSPIA. If this register is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

SPLP Bit (RSPI Loopback)

When the SPLP bit is set to 1, the RSPIA shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects (inverts) the input path and output path for the shift register (loopback mode).

SPLP2 Bit (RSPI Loopback 2)

When the SPLP2 bit is set to 1, the RSPIA shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path for the shift register (loopback mode).
If this bit is set to 1 together with the SPLP bit, setting this bit takes precedence.

MOIFV Bit (MOSI Idle Fixed Value)

If the MOIFE bit is 1 in master mode, the MOIFV bit determines the MOSIn pin output value during the SSL negation period (including the SSL retention period during a burst transfer).

MOIFE Bit (MOSI Idle Value Fixing Enable)

The MOIFE bit fixes the MOSIn output value when the RSPIA in master mode is in an SSL negation period (including the SSL retention period during a burst transfer). When the MOIFE bit is 0, the RSPIA outputs the last data from the previous serial transfer during the SSL negation period to the MOSIn pin. When the MOIFE bit is 1, the RSPIA outputs the fixed value set in the MOIFV bit to the MOSIn pin.

47.2.9 RSPI Slave Select Polarity Register (SSLP)

Address(es): RSPIA0.SSLP 8745 C010h, RSPIA1.SSLP 8745 C110h, RSPIA2.SSLP 8745 C210h, RSPIA0_NS.SSLP 0745 C010h, RSPIA1_NS.SSLP 0745 C110h, RSPIA2_NS.SSLP 0745 C210h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SSL3P	SSL2P	SSL1P	SSL0P
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SSL0P	SSL0 Signal Polarity Setting	[Motorola SPI] 0: The SSLn0 signal is active low. 1: The SSLn0 signal is active high. [TI SSP] 0: The SSLn0 signal is active high. 1: The SSLn0 signal is active low.	R/W
b1	SSL1P	SSL1 Signal Polarity Setting	[Motorola SPI] 0: The SSLn1 signal is active low. 1: The SSLn1 signal is active high. [TI SSP] 0: The SSLn1 signal is active high. 1: The SSLn1 signal is active low.	R/W
b2	SSL2P	SSL2 Signal Polarity Setting	[Motorola SPI] 0: The SSLn2 signal is active low. 1: The SSLn2 signal is active high. [TI SSP] 0: The SSLn2 signal is active high. 1: The SSLn2 signal is active low.	R/W
b3	SSL3P	SSL3 Signal Polarity Setting	[Motorola SPI] 0: The SSLn3 signal is active low. 1: The SSLn3 signal is active high. [TI SSP] 0: The SSLn3 signal is active high. 1: The SSLn3 signal is active low.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The SSLP register is used to set the polarity of SSLni signals (i = 0 to 3) of the RSPIA. If this register is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

SSLiP Bits (SSLi Signal Polarity Setting) (i = 0 to 3)

These bits are used to specify the active level of the SSLni signals.

Note: The SSLn0 signal functions as an input signal in slave or multi-master mode, unlike the SSLn1 to SSLn3 signals. For details, refer to section 47.3.3.2, Single Master/Single Slave (with This MCU Acting as Slave), and section 47.3.3.5, Multi-Master/Multi-Slave (with This MCU Acting as Master).

47.2.10 RSPI Bit Rate Register (SPBR)

Address(es): RSPIA0.SPBR 8745 C011h, RSPIA1.SPBR 8745 C111h, RSPIA2.SPBR 8745 C211h, RSPIA0_NS.SPBR 0745 C011h, RSPIA1_NS.SPBR 0745 C111h, RSPIA2_NS.SPBR 0745 C211h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

The SPBR register is used to set the bit rate in master mode. If the SPBR register is changed while both the SPCR.MSTR and SPCR.SPE bits are 1, subsequent operation is not guaranteed.

The bit rate is determined by combinations of the SPBR register setting and the SPCMDm.BRDV[1:0] bit setting.

When the RSPIA is used in slave mode, the bit rate depends on the frequency of the input clock (bit rate satisfying the electrical characteristics should be used) regardless of the settings of the SPBR register and the SPCMDm.BRDV[1:0] bits.

The equation for calculating the bit rate is given below. In the equation, n denotes the SPBR register setting (0, 1, 2, …, 255), and N denotes the BRDV[1:0] bit setting (0, 1, 2, 3).

$$\text{Bit rate} = \frac{f(TCLK)}{2 \times (n + 1) \times 2^{N}}$$

Table 47.6 lists examples of the relationship among the SPBR register settings, the BRDV[1:0] bit settings, and bit rates.

Table 47.6 Relationship among SPBR Register Settings, BRDV[1:0] Bit Settings, and Bit Rates

SPBR Register (n)	BRDV[1:0] Bits (N)	Division Ratio	Bit Rate						
			TCLK = 32 MHz	TCLK = 36 MHz	TCLK = 40 MHz	TCLK = 50 MHz	TCLK = 100 MHz	TCLK = 120 MHz	TCLK = 150 MHz

47.2.11 RSPI Sequence Control Register (SPSCR)

Address(es): RSPIA0.SPSCR 8745 C013h, RSPIA1.SPSCR 8745 C113h, RSPIA2.SPSCR 8745 C213h, RSPIA0_NS.SPSCR 0745 C013h, RSPIA1_NS.SPSCR 0745 C113h, RSPIA2_NS.SPSCR 0745 C213h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPSLN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPSLN[2:0]	RSPI Sequence Length Setting	b2 b0 Sequence Length Referenced SPCMD0 to SPCMD7 (No.) 0 0 0: 1 0→0→… 0 0 1: 2 0→1→0→… 0 1 0: 3 0→1→2→0→… 0 1 1: 4 0→1→2→3→0→… 1 0 0: 5 0→1→2→3→4→0→… 1 0 1: 6 0→1→2→3→4→5→0→… 1 1 0: 7 0→1→2→3→4→5→6→0→… 1 1 1: 8 0→1→2→3→4→5→6→7→0→… The order in which the SPCMD0 to SPCMD7 registers are to be referenced is changed according to the sequence length that is set in these bits. The relationship among the setting of these bits, sequence length, and SPCMD0 to SPCMD7 registers referenced by the RSPIA is shown above. In slave mode, the SPCMD0 register is referenced.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPSCR register is used to set the sequence length when the RSPIA operates in master mode. When changing the SPSCR.SPSLN[2:0] bits while both the SPCR.MSTR and SPCR.SPE bits are 1, the bits should be changed while the SPSR.IDLNF flag is 0.

SPSLN[2:0] Bits (RSPI Sequence Length Setting)

The SPSLN[2:0] bits specify a sequence length when the RSPIA in master mode performs sequential operations. The RSPIA in master mode changes SPCMD0 to SPCMD7 registers to be referenced and the order in which they are referenced according to the sequence length that is set in the SPSLN[2:0] bits. For details, refer to (3) Sequence Control in section 47.3.13.1, Master Mode Operation.

In slave mode, the SPCMD0 register is referenced.

47.2.12 RSPI Command Register m (SPCMDm) (m = 0 to 7)

Address(es): RSPIA0.SPCMD0 8745 C014h, RSPIA0.SPCMD1 8745 C018h, RSPIA0.SPCMD2 8745 C01Ch, RSPIA0.SPCMD3 8745 C020h, RSPIA0.SPCMD4 8745 C024h, RSPIA0.SPCMD5 8745 C028h, RSPIA0.SPCMD6 8745 C02Ch, RSPIA0.SPCMD7 8745 C030h, RSPIA1.SPCMD0 8745 C114h, RSPIA1.SPCMD1 8745 C118h, RSPIA1.SPCMD2 8745 C11Ch, RSPIA1.SPCMD3 8745 C120h, RSPIA1.SPCMD4 8745 C124h, RSPIA1.SPCMD5 8745 C128h, RSPIA1.SPCMD6 8745 C12Ch, RSPIA1.SPCMD7 8745 C130h, RSPIA2.SPCMD0 8745 C214h, RSPIA2.SPCMD1 8745 C218h, RSPIA2.SPCMD2 8745 C21Ch, RSPIA2.SPCMD3 8745 C220h, RSPIA2.SPCMD4 8745 C224h, RSPIA2.SPCMD5 8745 C228h, RSPIA2.SPCMD6 8745 C22Ch, RSPIA2.SPCMD7 8745 C230h, RSPIA0_NS.SPCMD0 0745 C014h, RSPIA0_NS.SPCMD1 0745 C018h, RSPIA0_NS.SPCMD2 0745 C01Ch, RSPIA0_NS.SPCMD3 0745 C020h, RSPIA0_NS.SPCMD4 0745 C024h, RSPIA0_NS.SPCMD5 0745 C028h, RSPIA0_NS.SPCMD6 0745 C02Ch, RSPIA0_NS.SPCMD7 0745 C030h, RSPIA1_NS.SPCMD0 0745 C114h, RSPIA1_NS.SPCMD1 0745 C118h, RSPIA1_NS.SPCMD2 0745 C11Ch, RSPIA1_NS.SPCMD3 0745 C120h, RSPIA1_NS.SPCMD4 0745 C124h, RSPIA1_NS.SPCMD5 0745 C128h, RSPIA1_NS.SPCMD6 0745 C12Ch, RSPIA1_NS.SPCMD7 0745 C130h, RSPIA2_NS.SPCMD0 0745 C214h, RSPIA2_NS.SPCMD1 0745 C218h, RSPIA2_NS.SPCMD2 0745 C21Ch, RSPIA2_NS.SPCMD3 0745 C220h, RSPIA2_NS.SPCMD4 0745 C224h, RSPIA2_NS.SPCMD5 0745 C228h, RSPIA2_NS.SPCMD6 0745 C22Ch, RSPIA2_NS.SPCMD7 0745 C230h

b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

Bit	Symbol	Bit Name	Description	R/W
b26 to b24	SSLA[2:0]	SSL Signal Assertion Setting	b26 b24 0 0 0: SSLn0 0 0 1: SSLn1 0 1 0: SSLn2 0 1 1: SSLn3 Settings other than above are prohibited.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPCMDm register is used to set a transfer format for the RSPIA in master mode. Each channel has eight RSPI command registers (SPCMD0 to SPCMD7). Some of the bits in SPCMD0 register is used to set a transfer mode for the RSPIA in slave mode. The RSPIA in master mode sequentially references SPCMDm register according to the settings in the SPSCR.SPSLN[2:0] bits, and executes the serial transfer that is set in the referenced SPCMDm register.
The SPCMDm register should be set while the transmit buffer is empty (data for the next transfer is not set) and before setting of the data that is to be transmitted when that SPCMDm register is referenced.
SPCMDm that is referenced by the RSPIA in master mode can be checked by means of the SPSSR.SPCP[2:0] bits. If this register is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

CPHA Bit (RSPCK Phase Setting)

The CPHA bit is used to set an RSPCK phase of the RSPIA in master mode or slave mode. Data communications between RSPIA modules require the same RSPCK phase setting between the modules.
When the SPCR.SPMS is 0 and the SPCR.FRFS bit is 1 in TI SSP protocol, setting the CPHA bit to 0 is not effective.

CPOL Bit (RSPCK Polarity Setting)

The CPOL bit is used to set an RSPCK polarity of the RSPIA in master mode or slave mode. Data communications between RSPIA modules require the same RSPCK polarity setting between the modules.

BRDV[1:0] Bits (Bit Rate Division Setting)

The BRDV[1:0] bits are used to determine the bit rate. A bit rate is determined by combinations of the settings in the BRDV[1:0] bits and the SPBR register (refer to section 47.2.10, RSPI Bit Rate Register (SPBR)). The settings in the SPBR register determine the base bit rate. The settings in the BRDV[1:0] bits are used to select a bit rate which is obtained by dividing the base bit rate by 1, 2, 4, or 8. In the SPCMDm register, different BRDV[1:0] bit settings can be specified. This enables execution of serial transfers at a different bit rate for each command.

SSLKP Bit (SSL Signal Level Keeping)

When the RSPIA in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLni signal level for the current command is to be kept or negated between the SSLni negation timing associated with the current command and the SSLni assertion timing associated with the next command (i = 0 to 3).
Setting the SSLKP bit to 1 enables a burst transfer. For details, refer to section 47.3.13.1, Master Mode Operation (4) Burst Transfer.
When using the RSPIA in slave mode, the SSLKP bit should be set to 0.

LSBF Bit (RSPI LSB First)

The LSBF bit is used to set the data format of the RSPIA in master mode or slave mode to MSB first or LSB first.

SPNDEN Bit (RSPI Next-Access Delay Enable)

The SPNDEN bit is used to set the period from the time the RSPIA in master mode terminates a serial transfer and sets the SSLni signal inactive until the RSPIA enables the SSLni signal assertion for the next access (next-access delay). If the SPNDEN bit is 0, the RSPIA sets the next-access delay to 1 RSPCK + 5 TCLK. If the SPNDEN bit is 1, the RSPIA inserts a next-access delay in compliance with the SPND setting.

When using the RSPIA in slave mode, the SPNDEN bit should be set to 0.

SLNDEN Bit (SSL Negation Delay Setting Enable)

[Motorola SPI]
The SLNDEN bit is used to set the period from the time the RSPIA in master mode stops RSPCK oscillation until the RSPIA sets the SSL signal inactive (SSL negation delay). If the SLNDEN bit is 0, the RSPIA sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the RSPIA negates the SSL signal at an SSL negation delay in compliance with the SSLND setting.
When using the RSPIA in slave mode, set the SLNDL[2:0] bits to 000b.

[TI SSP]
The SLNDEN bit is used to set the period from the time the RSPIA in master mode stops RSPCK oscillation until the RSPIA sets the OE signal inactive, or from the detection of a final RSPCK edge to the negation of the OE signal by the RSPIA in slave mode. If the SLNDEN bit is 0, the SSL negation delay is 1 RSPCK in master mode and 1 TCLK in slave mode. If the SLNDEN bit is 1, the RSPIA negates the SSL signal at an SSL negation delay in compliance with the SSLND setting.

[Clock synchronous]
When using the RSPIA in slave mode, set this bit to 0.

SCKDEN Bit (RSPCK Delay Setting Enable)

[Motorola SPI]
The SCKDEN bit is used to set the period from the point when the RSPIA in master mode activates the SSL signal until the RSPCK starts oscillation (RSPCK delay). If the SCKDEN bit is 0, the RSPIA sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the RSPIA starts the oscillation of RSPCK at an RSPCK delay in compliance with the SPCKD setting.

[TI SSP]
The SCKDEN bit is used to set the period from the point when the RSPIA in master mode activates the SSL signal until the RSPCK starts oscillation (RSPCK delay) and to the negation of the SSLni signal. If the SCKDEN bit is 0, the RSPIA does not set the RSPCK delay. If the SCKDEN bit is 1, the RSPIA starts the oscillation of RSPCK at an RSPCK delay in compliance with the SPCKD setting.
When using the RSPIA in slave mode, the SCKDEN bit should be set to 0.

SPB[4:0] Bits (RSPI Data Length Setting)

The SPB[4:0] bits are used to set a transmit data length for the RSPIA in master mode or slave mode.

SSLA[2:0] Bits (SSL Signal Assertion Setting)

The SSLA[2:0] bits control the SSLni signal assertion when the RSPIA performs serial transfers in master mode. Setting the SSLA[2:0] bits controls the assertion for the SSLni signal (i = 0 to 3). When an SSLni signal is asserted, its polarity is determined by the set value in the corresponding SSLP. When the SSLA[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLn0 pin acts as input).
When using the RSPIA in slave mode, set the SSLA[2:0] bits to 000b.

47.2.13 RSPI Data Control Register (SPDCR)

Address(es): RSPIA0.SPDCR 8745 C040h, RSPIA1.SPDCR 8745 C140h, RSPIA2.SPDCR 8745 C240h, RSPIA0_NS.SPDCR 0745 C040h, RSPIA1_NS.SPDCR 0745 C140h, RSPIA2_NS.SPDCR 0745 C240h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SPFC[1:0]		—	—	—	DINV	SPRDTD	—	—	BYSW
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BYSW	Byte Swap	0: Byte swapping of SPDR data disabled 1: Byte swapping of SPDR data enabled	R/W
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b3	SPRDTD	RSPI Receive/Transmit Data Select	0: SPDR values are read from the receive buffer 1: SPDR values are read from the transmit buffer	R/W
b4	DINV	Transfer Data Invert	0: Not invert serial data 1: Invert serial data	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9, b8	SPFC[1:0]	Number of Frames Setting	b9 b8 0 0: 1 frame 0 1: 2 frames 1 0: 3 frames 1 1: 4 frames	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPDCR register is used to control the data format of the RSPIA. If this register is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

BYSW Bit (Byte Swap)

The BYSW bit is used to swap a transmit/receive data in byte units. A data alignment after byte swap is different by a data length (setting of SPCMDm.SPB[4:0]).

When using byte swap, set the data length (setting of SPCMDm.SPB[4:0]) to 32 bits or 16 bits. For other data length (i.e. 4 to 15, 17 to 31-bit length), byte swap operation is not guaranteed. For the arrangement of data before and after swapping data lengths of 32 bits and 16 bits, refer to section 47.3.4.4, Byte Swap Transmission and section 47.3.4.5, Byte Swap Reception.

The operation is also not guaranteed when the parity function is enabled (the SPCR.SPPE bit is 1).

SPRDTD Bit (RSPI Receive/Transmit Data Select)

The SPRDTD bit is used to whether the SPDR register reads values from the receive buffer or from the transmit buffer. If reading is from the transmit buffer, the value written to the SPDR register immediately beforehand is read.

DINV Bit (Transfer Data Invert)

The DINV bit is used to invert transmit data and receive data.

When the DINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/reception data.

SPFC[1:0] Bits (Number of Frames Setting)

The SPFC[1:0] bits are used for the condition to set the SPSR.SPCF flag in slave receive-only mode.

For details on the SPCF flag setting conditions, refer to [Setting condition] of the SPCF flag in section 47.2.16.

Note that these bits are not effective except in the slave receive-only mode.

47.2.14 RSPI FIFO Control Register (SPFCR)

Address(es): RSPIA0.SPFCR 8745 C044h, RSPIA1.SPFCR 8745 C144h, RSPIA2.SPFCR 8745 C244h, RSPIA0_NS.SPFCR 0745 C044h, RSPIA1_NS.SPFCR 0745 C144h, RSPIA2_NS.SPFCR 0745 C244h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TTRG[1:0]		—	—	—	—	—	—	RTRG[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	RTRG[1:0]	Receive FIFO Threshold Setting	b1 b0 0 0: When the receive FIFO fill level is 0. 0 1: When the receive FIFO fill level is 1. 1 0: When the receive FIFO fill level is 2. 1 1: When the receive FIFO fill level is 3.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R
b9, b8	TTRG[1:0]	Transmit FIFO Threshold Setting	b9 b8 0 0: When the transmit FIFO free level is 0. 0 1: When the transmit FIFO free level is 1. 1 0: When the transmit FIFO free level is 2. 1 1: When the transmit FIFO free level is 3.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPFCR register is used to control the FIFO threshold. If this register is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

RTRG[1:0] Bits (Receive FIFO Threshold Setting)

The RTRG[1:0] bits are used to select receive FIFO threshold. When the number of data stored in the receive FIFO is greater than the threshold value set by RTRG[1:0], the receive buffer full flag is set.

TTRG[1:0] Bits (Transmit FIFO Threshold Setting)

The TTRG[1:0] bits are used to select transmit FIFO threshold. When the number of empty stages in the transmit FIFO is greater than the threshold value set in TTRG[1:0], the transmit buffer empty flag is set.

47.2.15 RSPI Sequence Status Register (SPSSR)

Address(es): RSPIA0.SPSSR 8745 C051h, RSPIA1.SPSSR 8745 C151h, RSPIA2.SPSSR 8745 C251h, RSPIA0_NS.SPSSR 0745 C051h, RSPIA1_NS.SPSSR 0745 C151h, RSPIA2_NS.SPSSR 0745 C251h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	SPECM[2:0]			—	SPCP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPCP[2:0]	RSPI Command Pointer	b2 b0 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
b3	—	Reserved	This bit is read as 0.	R
b6 to b4	SPECM[2:0]	RSPI Error Command	b6 b4 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
b7	—	Reserved	This bit is read as 0.	R

The SPSSR register indicates the sequence control status when the RSPIA operates in master mode.
Any writing to the SPSSR register is ignored.

SPCP[2:0] Bits (RSPI Command Pointer)

The SPCP[2:0] bits indicate the SPCMDm register that is currently pointed to by the pointer during sequence control by the RSPIA.
For the RSPIA's sequence control, refer to section 47.3.13.1, Master Mode Operation.

SPECM[2:0] Bits (RSPI Error Command)

The SPECM[2:0] bits indicate the SPCMDm register that is specified by the SPCP[2:0] bits when an error is detected during sequence control by the RSPIA. The RSPIA updates the SPECM[2:0] bits only when an error is detected. If the SPSR.OVRF, MODF, and PERF flags are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning.
For the RSPIA's error detection function, refer to section 47.3.10, Error Detection. For the RSPIA's sequence control, refer to section 47.3.13.1, Master Mode Operation.

47.2.16 RSPI Status Register (SPSR)

Address(es): RSPIA0.SPSR 8745 C052h, RSPIA1.SPSR 8745 C152h, RSPIA2.SPSR 8745 C252h, RSPIA0_NS.SPSR 0745 C052h, RSPIA1_NS.SPSR 0745 C152h, RSPIA2_NS.SPSR 0745 C252h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SPRF	SPCF	SPTEF	UDRF	PERF	MODF	IDLNF	OVRF	RRDYF	—	—	—	—	—	—	—
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0.	R
b7	RRDYF	Receive Data Ready Flag	0: Receive data ready is not detected 1: Receive data ready is detected	R
b8	OVRF	Overrun Error Flag	0: No overrun error occurs 1: An overrun error occurs	R
b9	IDLNF	Idle Flag	0: RSPIA is in the idle state 1: RSPIA is in the transfer state	R
b10	MODF	Mode Fault Error Flag	0: Neither a mode fault error nor an underrun error occurs 1: A mode fault error or an underrun error occurs	R
b11	PERF	Parity Error Flag	0: No parity error occurs 1: A parity error occurs	R
b12	UDRF	Underrun Error Flag	This flag is used with the MODF flag to check the state in terms of mode fault errors and underrun errors. MODF UDRF 0 x: Neither a mode fault error nor an underrun error occurs 1 0: A mode fault error occurs 1 1: An underrun error occurs	R
b13	SPTEF	Transmit Buffer Empty Flag	0: The number of empty stages in the transmit FIFO ≤ the value set by the SPFCR.TTRG[1:0] bits 1: The number of empty stages in the transmit FIFO > the value set by the SPFCR.TTRG[1:0] bits	R
b14	SPCF	Communication End Flag	0: RSPIA is not communicating or communicating 1: RSPIA communication is completed	R
b15	SPRF	Receive Buffer Full Flag	0: The number of data stored in the receive FIFO ≤ number of frames set by the SPFCR.RTRG[1:0] bits 1: The number of data stored in the receive FIFO > number of frames set by the SPFCR.RTRG[1:0] bits	R

x: don't care

The SPSR register is used to store flags that indicate RSPIA's operating status.

RRDYF Flag (Receive Data Ready Flag)

The RRDYF flag indicates a certain period of time has elapsed while the number of data stored in the receive FIFO during communication (SPCR.SPE = 1) is equal to or less than the receive FIFO threshold value.
This flag is set to 0 when the receive operation is not performed (SPCR.CMMD[1:0] = 01b).

[Setting condition]

When all the following conditions are satisfied.

- SPDRCSR register ≠ 00h.
- After the receive FIFO has been written, when the number of data stored in the receive FIFO is equal to or less than the receive FIFO threshold value and the value set by the SPDRCSR register has elapsed

[Clearing condition]
When 1 is written to the SPSCLR.RRDYFC bit.

OVRF Flag (Overrun Error Flag)
The OVRF flag indicates the occurrence of an overrun error. In master mode (when the SPCR.MSTR bit is 1) and when the RSPCK auto-stop function is enabled (the SPCR.SCKASE bit is 1), an overrun error does not occur; accordingly this flag does not become 1. For details, refer to section 47.3.10.1, Overrun Error.

[Setting condition]
When serial transfer is completed with no free space in the receive FIFO under any of the following conditions.

- The SPCR.CMMD[1:0] bits are 00b (transmit-receive master mode or transmit-receive slave mode).
- The SPCR.CMMD[1:0] bits are 10b (receive-only master mode or receive-only slave mode).

[Clearing condition]
When 1 is written to the SPSCLR.OVRFC bit

IDLNF Flag (Idle Flag)
The IDLNF flag indicates the transfer status of the RSPIA.

[Setting condition]
(1) Transmit-receive master mode or transmit-only master mode

- When none of the conditions are satisfied in transmit-receive master mode or transmit-only master mode under the [Clearing condition] below.

(2) Transmit-only master mode

- When 1 is written to the SPRMCR.START bit.

(3) Slave mode

- The SPCR.SPE bit is 1 (enables the RSPI function)

[Clearing condition]
(1) Transmit-receive master mode or transmit-only master mode
Communication status: No. 1-1 to 1-6 (for details, refer to Table 47.5 RSPI Communication Status)

- When the SPCR.SPE bit is set to 0 (disables the RSPI function)
- When all of the following conditions are satisfied.
  (a) The the next transmit data is not set in the transmit buffer (SPTX)
  (b) The SPSSR.SPCP[2:0] bits are 000b (beginning of sequence control)
  (c) The operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(2) Transmit-only master mode
Communication status: No. 1-7 to 1-9 (for details, refer to Table 47.5 RSPI Communication Status)

- When the SPCR.SPE bit is set to 0 (disables the RSPI function)
- When any of the following conditions is satisfied.
  (a) When the SPRMCR.RFC[4:0] bits are 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(b) When the SPRMCR.RFC[4:0] bits are other than 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(c) When the SPRMCR.RFC[4:0] bits are other than 00000b, after the operation is completed for the number of received frames set by the SPRMCR.RFC[4:0] bits, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(3) Slave mode

Communication status: No. 0-1 to 0-9 (for details, refer to Table 47.5 RSPI Communication Status)

- When the SPCR.SPE bit is set to 0 (disables the RSPI function)

MODF Flag (Mode Fault Error Flag)

Indicates the occurrence of a mode fault error or an underrun error. The UDRF flag indicates whether the error is a mode fault error or an underrun error.

[Setting condition]

(1) Multi-master mode

- When the input level of the SSLn0 pin changes to the active level while the SPCR.MSTR bit is 1 (master mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPIA detects a mode fault error

(2) Slave mode (SPI operation, Motorola SPI)

When any of the following conditions are satisfied.

- When the SSLn0 pin is negated before the RSPCK cycle necessary for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPIA detects a mode fault error
- When the serial transfer starts while the SPCR.SPE bit is 1 (enables the RSPI function) and the transmit data are not ready for output, the RSPIA detects an underrun error

(3) Slave mode (SPI operation, TI SSP)

When any of the following conditions are satisfied.

- When the SSLn0 pin is asserted before the RSPCK cycle necessary for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPIA detects a mode fault error
- When the serial transfer starts while the SPCR.SPE bit is 1 (enables the RSPI function) and the transmit data are not ready for output, the RSPIA detects an underrun error

The active level of the SSLni signal is determined by the SSLP.SSLiP bit (SSL signal polarity setting bit).

[Clearing condition]

When 1 is written to the SPSCLR.MODFC bit

PERF Flag (Parity Error Flag)

Indicates the occurrence of a parity error.

[Setting condition]

When the serial transfer ends and a parity error is detected while the SPCR.SPPE bit is 1 under any of the following conditions.

- The SPCR.CMMD[1:0] bits are 00b (transmit-receive master mode or transmit-receive slave mode)
- The SPCR.CMMD[1:0] bits are 10b (receive-only master mode or receive-only slave mode)

[Clearing condition]
When 1 is written to the SPSCLR.PERFC bit

UDRF Flag (Underrun Error Flag)
When a mode fault error or an underrun error has occurred, the UDRF flag indicates whether the error is a mode fault error or an underrun error.

[Setting condition]
When the serial transfer starts while the SPCR.MSTR bit is 0, the SPCR.CMMD[1:0] bits are 00b or 01b (transmit-receive slave mode or transmit-only slave mode), the SPCR.SPE bit is 1 (enables the RSPI function) and the transmit data are not ready for output, the RSPIA detects an underrun error

[Clearing condition]
When 1 is written to the SPSCLR.UDRFC bit

SPTEF Flag (Transmit Buffer Empty Flag)
Indicates whether the transmit buffer (SPTXn, n = 0 to 3) in the RSPI data register (SPDR) has valid data.

[Setting condition]
When any of the following conditions are satisfied.

- When the SPCR.SPE bit is 0 (disables the RSPI function)
- When the number of empty transmission FIFO stages is greater than the threshold value set in SPFCR.TTRG[1:0]
- When 1 is written to the SPFCLR.FCLR bit

[Clearing condition]
When any of the following conditions are satisfied.

- At the final access when transmit data is written to SPDR (SPTXn) in one processing routine using DTC/DMAC
- When 1 is written to the SPSCLR.SPTEFC bit

The SPDR register can be set only when the SPSR.SPTEF flag is 1. The data in the transmit buffer (SPTXn) is not updated when the SPDR register is set while the SPSR.SPTEF flag is 0.

SPCF Flag (Communication End Flag)
Indicates communication end status of RSPI. It turns 1 at communication end and turns 0 at starting next communication.

[Setting condition]
(1) Transmit-receive master mode or transmit-only master mode
Communication status: No. 1-1 to 1-6 (for details, refer to Table 47.5 RSPI Communication Status)
When all of the following conditions are satisfied.

- The next transmit data is not set in the transmission buffer (SPTXn)
- The SPSSR.SPCP[2:0] bits are 000b (beginning of sequence control)
- The operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(2) Transmit-only master mode
Communication status: No. 1-7 to 1-9 (for details, refer to Table 47.5 RSPI Communication Status)
When any of the following conditions are satisfied.

- When the SPRMCR.RFC[4:0] bits are 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the

next-access delay have finished (the master main state machine has entered the idle state)

- When the SPRMCR.RFC[4:0] bits are other than 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)
- When the SPRMCR.RFC[4:0] bits are other than 00000b, after the operation is completed for the number of received frames set by the SPRMCR.RFC[4:0] bits, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(3) Transmit-receive slave mode or transmit-only slave mode (SPI operation, Motorola SPI)
Communication status: No. 0-1, 0-4 (for details, refer to Table 47.5 RSPI Communication Status)
When all of the following conditions are satisfied.

- The next transmit data is not set in the transmission buffer (SPTXn)
- The transmission shift register is empty (RSPIA does not perform serial transfer)
- The SSLn0 input is negated

(4) Transmit-receive slave mode or transmit-only slave mode (SPI operation, TI SSP)
Communication status: No. 0-2, 0-5 (for details, refer to Table 47.5 RSPI Communication Status)
When all of the following conditions are satisfied.

- The next transmit data is not set in the transmission buffer (SPTXn)
- The transmission shift register is empty (RSPIA does not perform serial transfer)
- When the SSL negation delay is completed

(5) Transmit-receive slave mode or transmit-only slave mode (clock synchronous operation)
Communication status: No. 0-3, 0-6 (for details, refer to Table 47.5 RSPI Communication Status)
When all of the following conditions are satisfied.

- The next transmit data is not set in the transmission buffer (SPTXn)
- The transmission shift register is empty (RSPIA does not perform serial transfer)
- The last even edge of RSPCK of the frame was detected (SPCMDm.CPHA = 1)

(6) Receive-only slave mode (SPI operation, Motorola SPI)
Communication status: No. 0-7 (for details, refer to Table 47.5 RSPI Communication Status)

- SSLn0 input was negated after getting frames for SPDCR.SPFC[1:0] set value in the receive buffer (SPRX)

(7) Receive-only slave mode (SPI operation, TI SSP)
Communication status: No. 0-8 (for details, refer to Table 47.5 RSPI Communication Status)

- SSL negation delay is completed after getting frames for SPDCR.SPFC[1:0] set value in the receive buffer (SPRX).

(8) Receive-only slave mode (clock synchronous operation)
Communication status: No. 0-9 (for details, refer to Table 47.5 RSPI Communication Status)

- The last even edge of RSPCK of the last frame received for SPFC[1:0] set value was detected (SPCMDm.CPHA = 1)

[Clearing condition]
(1) Transmit-receive master mode or transmit-only master mode
Communication status: No. 1-1 to 1-6 (for details, refer to Table 47.5 RSPI Communication Status)
When any of the following conditions are satisfied.

- The next transmit data is set in the transmission buffer (SPTXn)
- When 1 is written to the SPSCLR.SPCFC bit

(2) Transmit-only master mode

Communication status: No. 1-7 to 1-9 (for details, refer to Table 47.5 RSPI Communication Status)

When any of the following conditions are satisfied.

- When 1 is written to the SPRMCR.START bit while the SPCR.SPE bit is 1
- When 1 is written to the SPSCLR.SPCFC bit

(3) Transmit-receive slave mode or transmit-only slave mode

Communication status: No. 0-1 to 0-6 (for details, refer to Table 47.5 RSPI Communication Status)

When any of the following conditions are satisfied.

- The next transmit data is set in the transmission buffer (SPTXn)
- When 1 is written to the SPSCLR.SPCFC bit

(4) Receive-only slave mode (SPI operation)

Communication status: No. 0-7, 0-8 (for details, refer to Table 47.5 RSPI Communication Status)

When any of the following conditions are satisfied.

- The SSLn0 input assertion of next data is detected
- When 1 is written to the SPSCLR.SPCFC bit

(5) Receive-only slave mode (clock synchronous operation)

Communication status: No. 0-9 (for details, refer to Table 47.5 RSPI Communication Status)

When any of the following conditions are satisfied.

- The first edge of RSPCK of the next data was detected
- When 1 is written to the SPSCLR.SPCFC bit

SPRF Flag (Receive Buffer Full Flag)

Indicates whether the receive buffer (SPRX) in the RSPI data register has valid data.

[Setting condition]

When the number of data stored in the receive FIFO is greater than the number of frames set in the SPFCR.RTRG[1:0] bits in transmit-receive mode or receive-only mode.

Note that the SPRF flag does not become 1 when the OVRF flag is 1 (Refer to section 47.3.10, Error Detection, for details).

[Clearing condition]

When any of the following conditions are satisfied.

- At the final access when receive data is read from SPDR register (SPRXn, n = 0 to 3) in one processing routine using DTC/DMAC
- When 1 is written to the SPSCLR.SPRFC bit
- When 1 is written to the SPFCLR.FCLR bit

47.2.17 RSPI Transmit FIFO Status Register (SPTFSR)

Address(es): RSPIA0.SPTFSR 8745 C058h, RSPIA1.SPTFSR 8745 C158h, RSPIA2.SPTFSR 8745 C258h, RSPIA0_NS.SPTFSR 0745 C058h, RSPIA1_NS.SPTFSR 0745 C158h, RSPIA2_NS.SPTFSR 0745 C258h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FREE[2:0]		
Value after reset:	0	0	0	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	FREE[2:0]	Transmit FIFO Free Level	b2 b0 0 0 0: Number of empty stages 0 0 0 1: Number of empty stages 1 0 1 0: Number of empty stages 2 0 1 1: Number of empty stages 3 1 0 0: Number of empty stages 4	R
b7 to b3	—	Reserved	These bits are read as 0.	R

FREE[2:0] Bits (Transmit FIFO Free Level)

Indicate the number of empty transmit FIFO stages. By setting the SPCR.SPE bit to 0, the FREE[2:0] bits will be 100b.

47.2.18 RSPI Receive FIFO Status Register (SPRFSR)

Address(es): RSPIA0.SPRFSR 8745 C05Ch, RSPIA1.SPRFSR 8745 C15Ch, RSPIA2.SPRFSR 8745 C25Ch, RSPIA0_NS.SPRFSR 0745 C05Ch, RSPIA1_NS.SPRFSR 0745 C15Ch, RSPIA2_NS.SPRFSR 0745 C25Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FILL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

b2 to b0	FILL[2:0]	Receive FIFO Fill Level	b2 b0 0 0 0: Number of stored stages 0 0 0 1: Number of stored stages 1 0 1 0: Number of stored stages 2 0 1 1: Number of stored stages 3 1 0 0: Number of stored stages 4	R
b7 to b3	—	Reserved	These bits are read as 0.	R

FILL[2:0] Bits (Receive FIFO Fill Level)

Indicate the number of stored receive FIFO stages. By setting the SPCR.SPE bit to 0, the FILL[2:0] bits will be 000b.

47.2.19 RSPI Polling Status Register (SPPSR)

Address(es): RSPIA0.SPPSR 8745 C060h, RSPIA1.SPPSR 8745 C160h, RSPIA2.SPPSR 8745 C260h, RSPIA0_NS.SPPSR 0745 C060h, RSPIA1_NS.SPPSR 0745 C160h, RSPIA2_NS.SPPSR 0745 C260h

Bit	Symbol	Bit Name	Description	R/W
b0	SPEPS	SPE Polling Status Flag	0: The value of the SPCR.SPE bit after synchronization with TCLK is 0 1: The value of the SPCR.SPE bit after synchronization with TCLK is 1	R
b31 to b1	—	Reserved	These bits are read as 0.	R

SPEPS Flag (SPE Polling Status Flag)

This flag indicates the status after synchronizing the value of the SPCR.SPE bit with the operating clock (TCLK). In other words, this flag indicates whether the RSPI function is enabled or disabled within the transmitter/receiver. When the SPE bit is changed from 1 to 0 while the SPCR.SYNDIS bit is 0, confirm that this flag is set to 0, and then proceed to the next processing.

47.2.20 RSPI Status Clear Register (SPSCLR)

Address(es): RSPIA0.SPSCLR 8745 C06Ah, RSPIA1.SPSCLR 8745 C16Ah, RSPIA2.SPSCLR 8745 C26Ah, RSPIA0_NS.SPSCLR 0745 C06Ah, RSPIA1_NS.SPSCLR 0745 C16Ah, RSPIA2_NS.SPSCLR 0745 C26Ah

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	RRDYFC	Receive Data Ready Flag Clear	Writing 1 to this bit clears the receive data ready flag. The read value is always 0.	W
b8	OVRFC	Overrun Error Flag Clear	Writing 1 to this bit clears the overrun error flag. The read value is always 0.	W
b9	—	Reserved	This bit is read as 0. The write value should be 0.	R
b10	MODFC	Mode Fault Error Flag Clear	Writing 1 to this bit clears the mode fault error flag. The read value is always 0.	W*1
b11	PERFC	Parity Error Flag Clear	Writing 1 to this bit clears the parity error flag. The read value is always 0.	W
b12	UDRFC	Underrun Error Flag Clear	Writing 1 to this bit clears the underrun error flag. The read value is always 0.	W*1, *2
b13	SPTEFC	Transmit Buffer Empty Flag Clear	Writing 1 to this bit clears the transmit buffer empty flag. The read value is always 0.	W
b14	SPCFC	Communication End Flag Clear	Writing 1 to this bit clears the communication end flag. The read value is always 0.	W
b15	SPRFC	Receive Buffer Full Flag Clear	Writing 1 to this bit clears the receive buffer full flag. The read value is always 0.	W

Note 1. Before writing 1 to the MODFC bit, make sure that the SPSR.MODF flag is set to 1. Before writing 1 to the UDRFC bit, make sure that the SPSR.UDRF flag is set to 1.

Note 2. When clearing the UDRF flag, be sure to clear the MODF flag at the same time (write 1 to both UDRFC and MODFC bits simultaneously).

The SPSCLR register is used to clear each status flag in the SPSR register, which indicates the operating state of the RSPIA.

47.2.21 RSPI FIFO Clear Register (SPFCLR)

Address(es): RSPIA0.SPFCLR 8745 C06Ch, RSPIA1.SPFCLR 8745 C16Ch, RSPIA2.SPFCLR 8745 C26Ch, RSPIA0_NS.SPFCLR 0745 C06Ch, RSPIA1_NS.SPFCLR 0745 C16Ch, RSPIA2_NS.SPFCLR 0745 C26Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	FCLR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FCLR	FIFO Clear	By writing 1, the pointer in the FIFO and the stored data are initialized. The read value is always 0.	W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPFCLR register is used to clear the FIFO. If this register is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

FCLR Bit (FIFO Clear)

Writing 1 to this bit initializes the pointer and stored data in the transmit/receive FIFO.

47.3 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data.

47.3.1 Overview of RSPI Operations

The RSPIA is capable of serial transfers in the following five modes.

(1) Slave mode (SPI operation)
(2) Single-master mode (SPI operation)
(3) Multi-master mode (SPI operation)
(4) Slave mode (clock synchronous operation)
(5) Master mode (clock synchronous operation).

A particular mode of the RSPIA can be selected by using the MSTR, MODFEN, SPMS, and FRFS bits in SPCR. Table 47.7 lists the relationship between RSPI modes and SPCR settings, and a description of each mode.

Table 47.7 Relationship between RSPI Modes and SPCR Settings and Description of Each Mode

	SPI Operation			Clock Synchronous Operation	
Mode	**Slave**	**Single-Master**	**Multi-Master**	**Slave**	**Master**
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
FRFS bit setting	Enabled	Enabled	Enabled	Disabled	Disabled
RSPCKn signal	Input	Output	Output/Hi-Z*1	Input	Output
MOSIn signal	Input	Output	Output/Hi-Z*1	Input	Output
MISOn signal	Output/Hi-Z*2	Input	Input	Output	Input
SSLn0 signal	Input	Output	Input	Hi-Z (not used)	Hi-Z (not used)
SSLn1 to SSLn3 signals	Hi-Z (not used)	Output	Output/Hi-Z*1	Hi-Z (not used)	Hi-Z (not used)
Output pin mode	CMOS/open-drain				
SSL polarity change function	Supported	Supported	Supported	—	—
Transfer rate	Up to TCLK/2				
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	Two				
Clock phase	Two*3	Two*3	Two*3	One (CPHA = 1)	Two
First transfer bit	MSB/LSB				
Transmit data length	4 to 32 bits				
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0,1)	Possible (CPHA = 0,1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported*4	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported
Transfer activation method	SSL input active or RSPCK oscillation	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1	RSPCK oscillation	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmit buffer empty detection	Supported*5	Supported	Supported	Supported*5	Supported
Receive buffer full detection	Supported*6				
Overrun error detection	Supported*6	Supported*6, *7	Supported*6, *7	Supported*6	Supported*6, *7
Parity error detection	Supported*6, *8				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported
Underrun error detection	Supported*5	Not supported	Not supported	Supported*5	Not supported

Note 1. Motorola SPI: When SSLn0 is asserted by another master device, the pin becomes Hi-Z.
TI SSP: When the SPCR.SPE bit is 1, the pin becomes Hi-Z from the time SSLn0 is asserted by another master device until the end of communication.

Note 2. Motorola SPI: When SSLn0 is negated or the SPCR.SPE bit is 0, the pin becomes Hi-Z.
TI SSP: The pin becomes Hi-Z when the RSPIA is not communicating (from the end of communication to the next assertion of SSLn0) or when the SPCR.SPE bit is 0.

Note 3. In TI SSP protocol, setting the SPCMDm.CPHA bit to 0 is not effective.

Note 4. Available only in TI SSP protocol.

Note 5. When RSPIA is receive-only slave mode (refer to Table 47.5 RSPI Communication Status), transmit buffer empty error detection and underrun error detection are not performed.

Note 6. When RSPIA is transmit-only master mode or transmit-only slave mode (refer to Table 47.5 RSPI Communication Status), receiver buffer full detection, overrun error detection, and parity error detection are not performed.

Note 7. When the SPCR.SCKASE bit is 1, overrun error detection does not proceed.

Note 8. When the SPCR.SPPE bit is 0, parity error detection is not performed.

47.3.2 Controlling RSPI Pins

The RSPIA in single-master mode (SPI operation) or multi-master mode (SPI operation) determines MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) according to MOIFE and MOIFV bit settings in SPPCR, as listed in Table 47.8.

Table 47.8 MOSI Signal Value Determination during SSL Negation Period

MOIFE Bit	MOIFV Bit	MOSI Signal Value during SSL Negation Period
0	0, 1	Final data from previous transfer
1	0	Low
1	1	High

47.3.3 RSPI System Configuration Examples

This configuration example describes that the low level of SSLni signals is the active level.
When connecting and using in a multi-slave or multi-master mode, the transfer format of the connected device should be unified to either Motorola SPI or TI SSP.

47.3.3.1 Single Master/Single Slave (with This MCU Acting as Master)

Figure 47.5 shows a single-master/single-slave RSPI system configuration example when this MCU is used as a master. In the single-master/single-slave configuration, the SSLn0 to SSLn3 output of this MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in a select state. In the transfer format corresponding to the case where the SPCMDm.CPHA bit is 0, there are slave devices for which the SSL signal cannot be fixed to the active level. In situations where the SSL signal cannot be fixed, the SSLni output of this MCU should be connected to the SSL input of the slave device.
This MCU (master) drives the RSPCKn and MOSIn. The SPI slave drives the MISO.

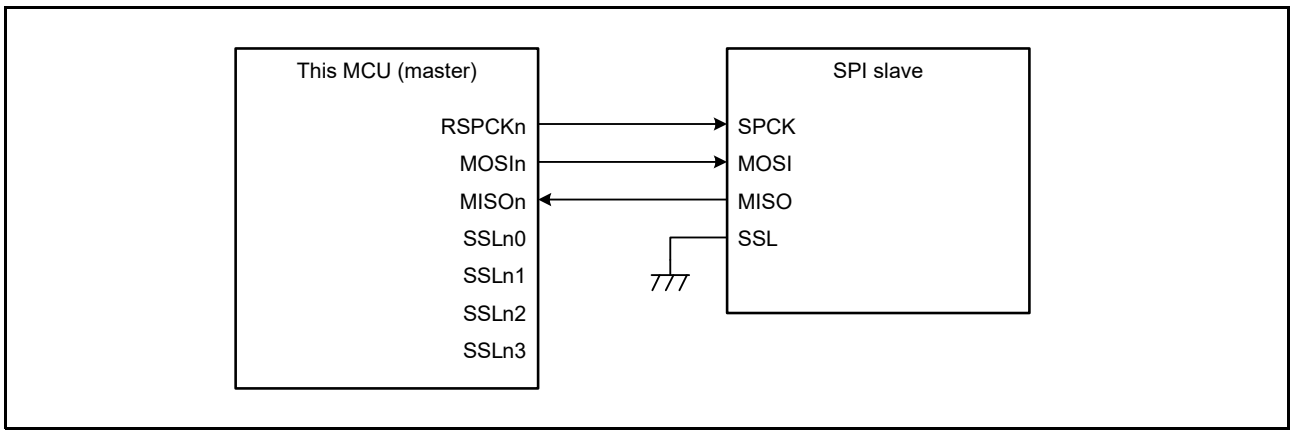

Figure 47.5 Single-Master/Single-Slave Configuration Example (This MCU = Master)

47.3.3.2 Single Master/Single Slave (with This MCU Acting as Slave)

Figure 47.6 shows a single-master/single-slave RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave, the SSLn0 pin is used as SSL input. The SPI master drives the SPCK and MOSI. This MCU (slave) drives the MISOn. When SSLn0 is at the non-active level, the pin state is Hi-Z.
In the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, set the SPCR.FRFS bit to 0, and set the SPCR.SPMS bit to 0, the SSLn0 input of this MCU (slave) is fixed to the low level, this MCU (slave) is maintained in a select state, and in this manner it is possible to execute serial transfer (Figure 47.7). Note that the communication end event and the communication end interrupt do not output when SSLn0 input was fixed as Figure 47.7.

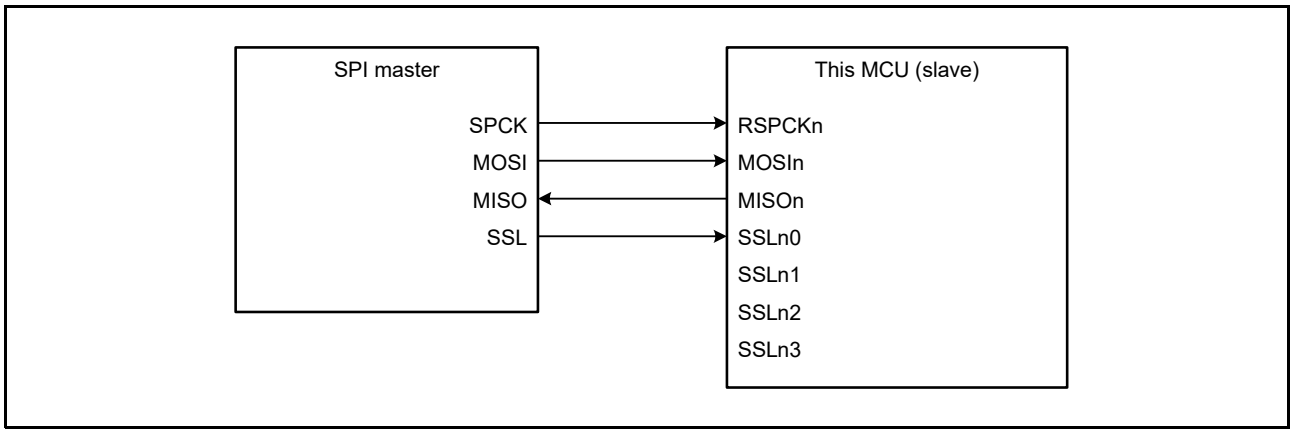

Figure 47.6 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 0)

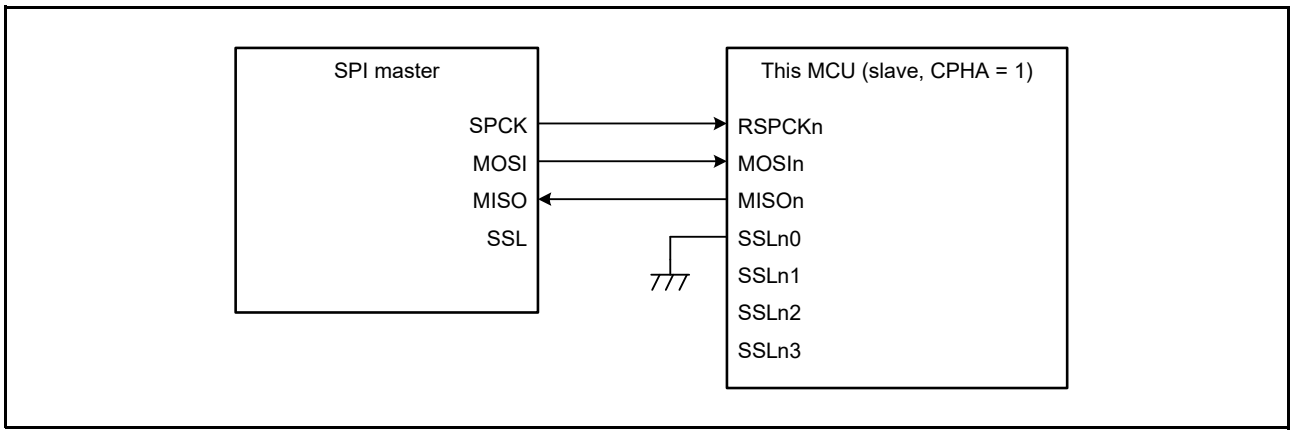

Figure 47.7 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 1)

47.3.3.3 Single Master/Multi-Slave (with This MCU Acting as Master)

Figure 47.8 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 47.8, the RSPI system is comprised of this MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKn and MOSIn outputs of this MCU (master) are connected to the SPCK and MOSI inputs of SPI slave 0 to SPI slave 3. The MISO outputs of SPI slave 0 to SPI slave 3 are all connected to the MISOn input of this MCU (master). SSLn0 to SSLn3 outputs of this MCU (master) are connected to the SSL inputs of SPI slave 0 to SPI slave 3, respectively.

This MCU (master) drives RSPCKn, MOSIn, and SSLn0 to SSLn3. Of the SPI slave 0 to SPI slave 3, the slave that receives low-level input into the SSL input drives MISO.

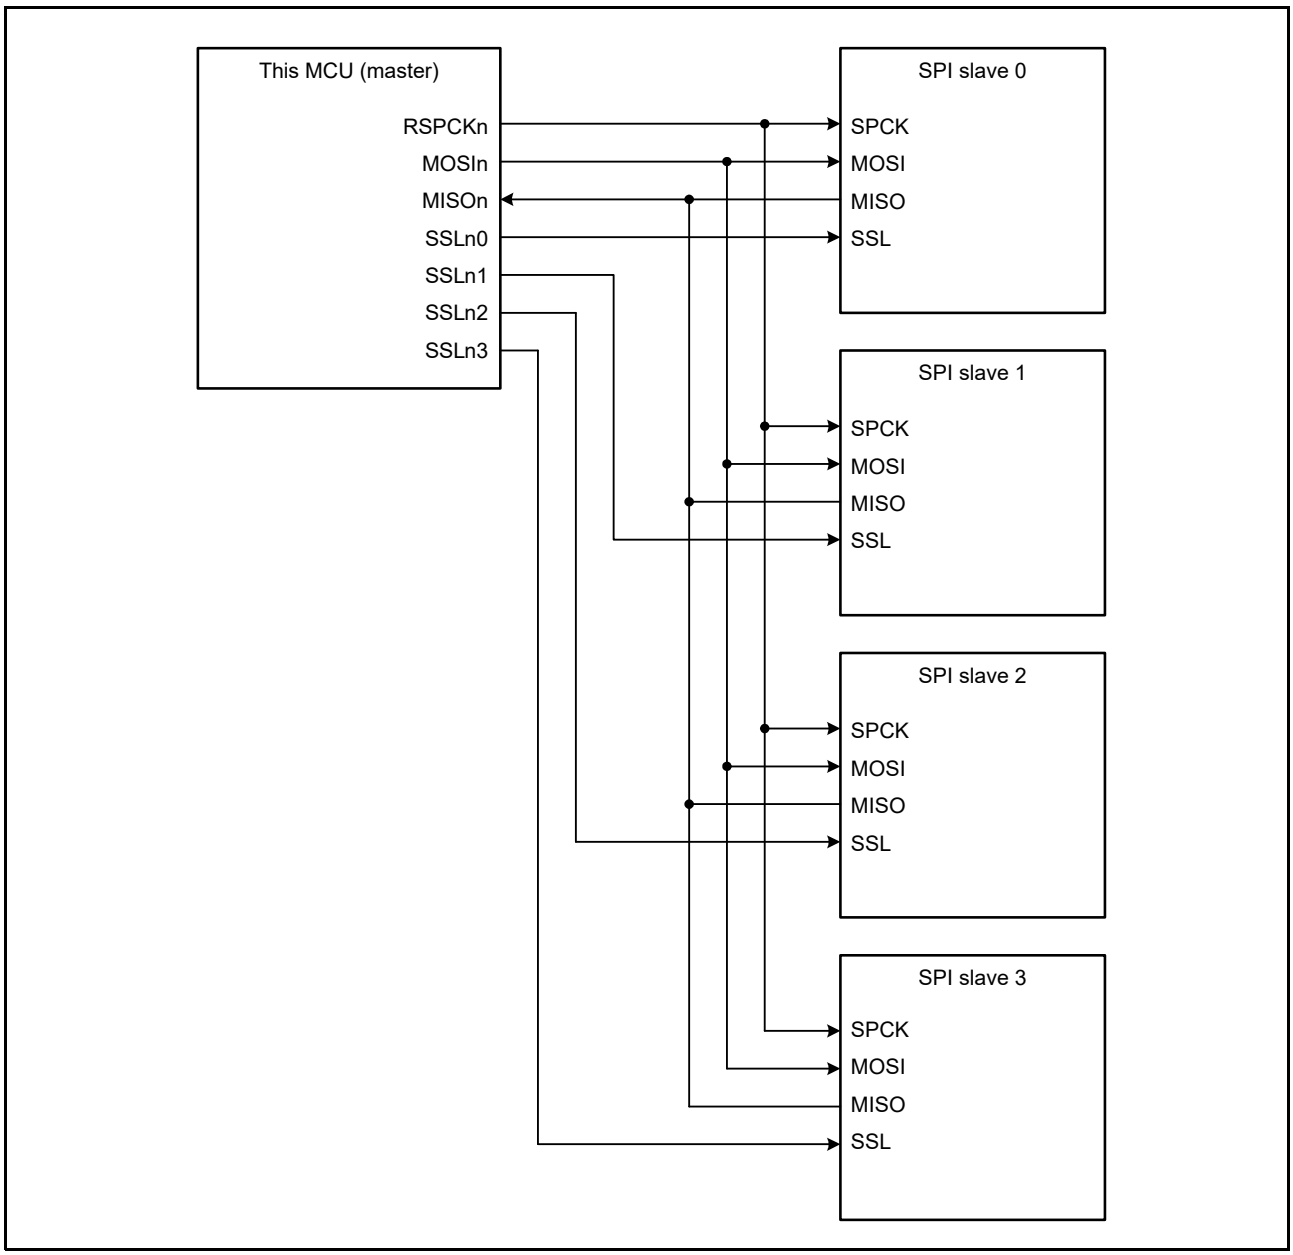

Figure 47.8 Single-Master/Multi-Slave Configuration Example (This MCU = Master)

47.3.3.4 Single Master/Multi-Slave (with This MCU Acting as Slave)

Figure 47.9 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a slave. In the example of Figure 47.9, the RSPI system is comprised of an SPI master and two MCUs (slave X and slave Y). The SPCK and MOSI outputs of the SPI master are connected to the RSPCKn and MOSIn inputs of the MCUs (slave X and slave Y). The MISOn outputs of the MCUs (slave X and slave Y) are all connected to the MISO input of the SPI master. SSLX and SSLY outputs of the SPI master are connected to the SSLn0 inputs of the MCUs (slave X and slave Y), respectively.

The SPI master always drives SPCK, MOSI, SSLX, and SSLY. Of the MCUs (slave X and slave Y), the slave that receives low-level input into the SSLn0 input drives MISOn.

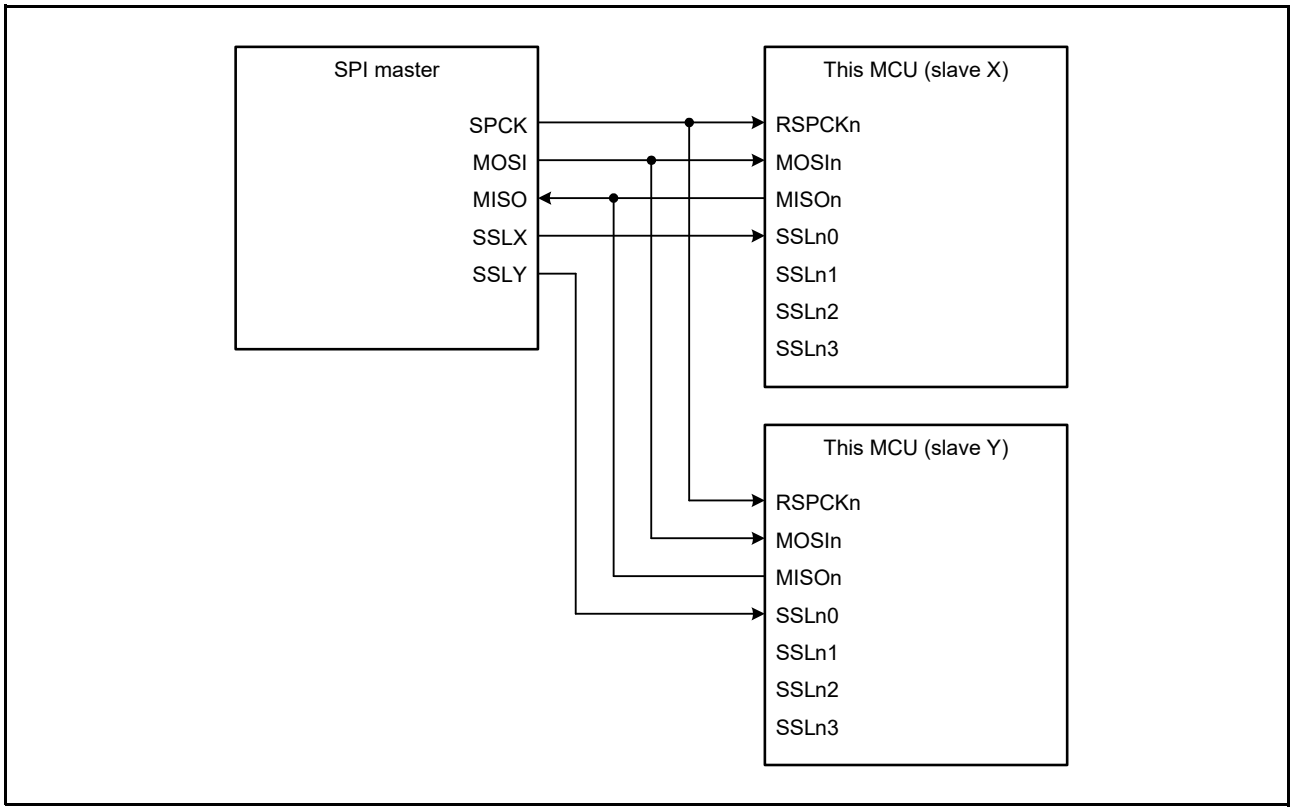

Figure 47.9 Single-Master/Multi-Slave Configuration Example (This MCU = Slave)

47.3.3.5 Multi-Master/Multi-Slave (with This MCU Acting as Master)

Figure 47.10 shows a multi-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 47.10, the RSPI system is comprised of two MCUs (master X and master Y) and two SPI slaves (SPI slave 1 and SPI slave 2).

The RSPCKn and MOSIn outputs of the MCUs (master X and master Y) are connected to the SPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOn inputs of the MCUs (master X and master Y). Any generic port Y output from this MCU (master X) is connected to the SSLn0 input of this MCU (master Y). Any generic port X output of this MCU (master Y) is connected to the SSLn0 input of this MCU (master X). The SSLn1 and SSLn2 outputs of the MCUs (master X and master Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, since the system can be comprised solely of SSLn0 input, and SSLn1 and SSLn2 outputs for slave connections, the SSLn3 output of this MCU is not required.

This MCU drives RSPCKn, MOSIn, SSLn1, and SSLn2 when the SSLn0 input level is high. When the SSLn0 input level is low, this MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the RSPI bus right to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives MISO.

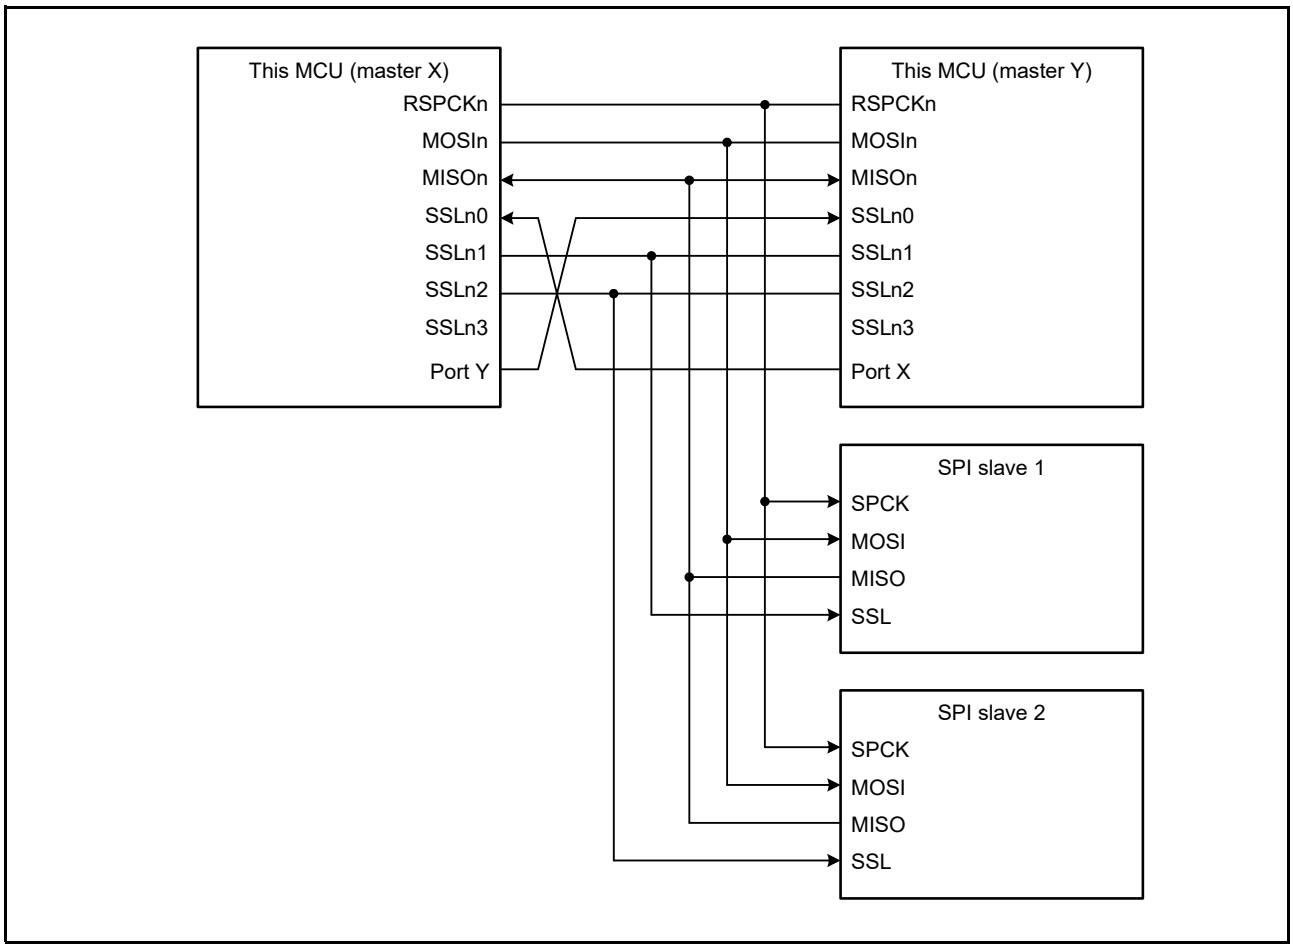

Figure 47.10 Multi-Master/Multi-Slave Configuration Example (This MCU = Master)

When setting TI SSP, enter the following levels for port X and port Y.

- Start of communication: the value of SSLP.SSL0P of the other master
- End of communication: the inverted value of SSLP.SSL0P of the other master

47.3.3.6 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Master)

Figure 47.11 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a master. In the master (clock synchronous operation)/slave (clock synchronous operation) configuration, SSLn0 to SSLn3 of this MCU (master) are not used.
This MCU (master) drives the RSPCKn and MOSIn. The SPI slave drives the MISO.

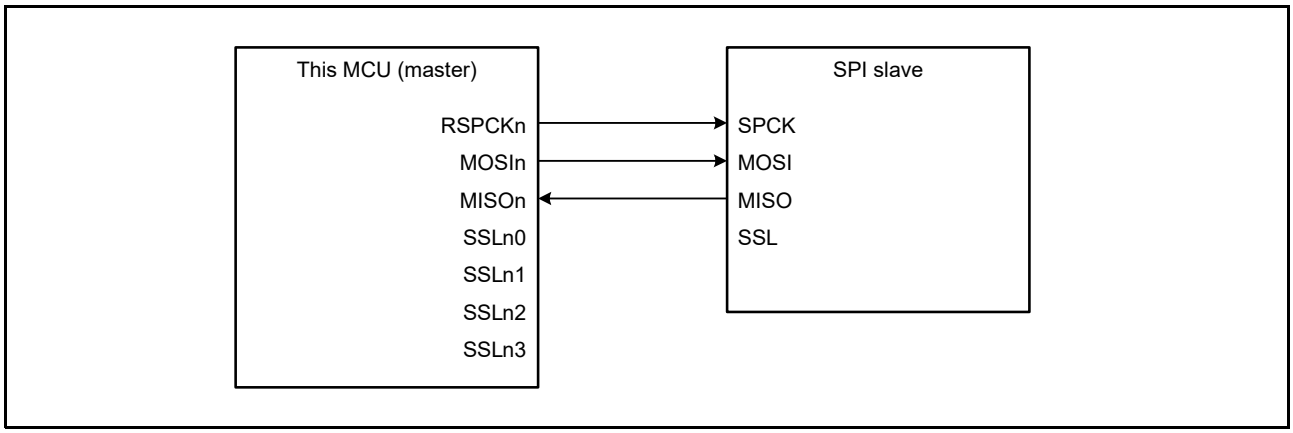

Figure 47.11 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Master)

47.3.3.7 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Slave)

Figure 47.12 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave (clock synchronous operation), this MCU (slave) drives the MISOn and the SPI master drives the SPCK and MOSI. In addition, SSLn0 to SSLn3 of this MCU (slave) are not used.
Only in the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, this MCU (slave) can execute serial transfer.

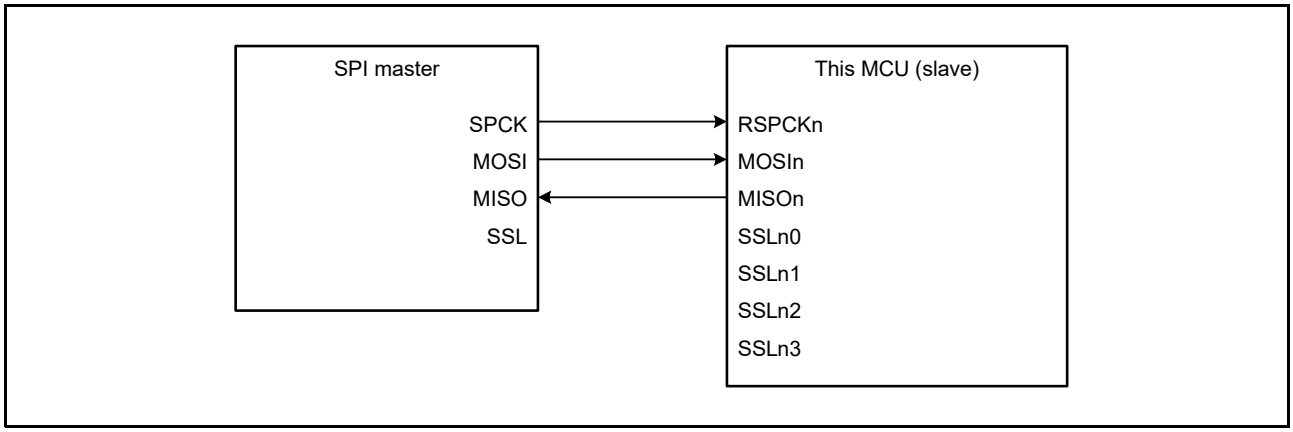

Figure 47.12 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Slave, CPHA = 1)

47.3.4 Data Format

The RSPIA's data format depends on the settings in RSPI command register m (SPCMDm) (m = 0 to 7) and the parity enable bit in RSPI control register (SPCR.SPPE). Regardless of whether the MSB or LSB is first, the RSPIA treats the range from the LSB bit in the RSPI data register (SPDR) to the selected data length as transmit data.

47.3.4.1 Data Format of One Frame

The format of one frame of data before or after transfer is shown below.

(a) With Parity Disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[4:0]).

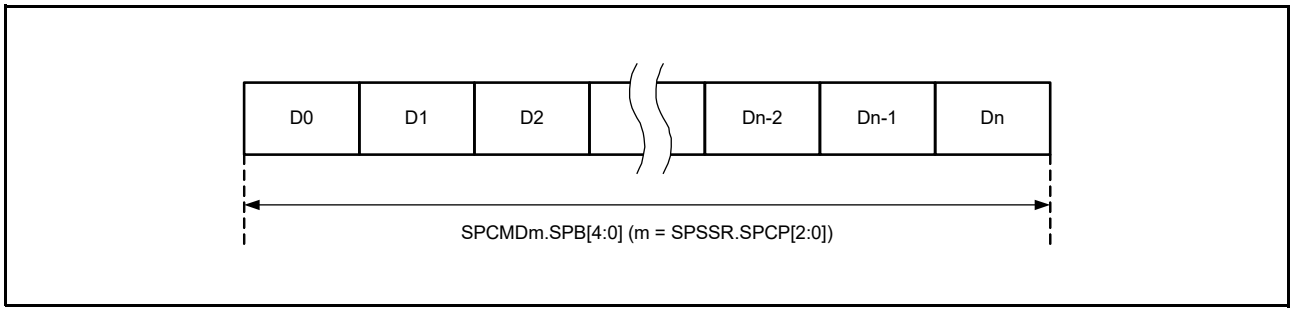

Figure 47.13 Outline of the Data Format (with Parity Disabled)

(b) With Parity Enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[4:0]). In this case, however, the last bit is a parity bit.

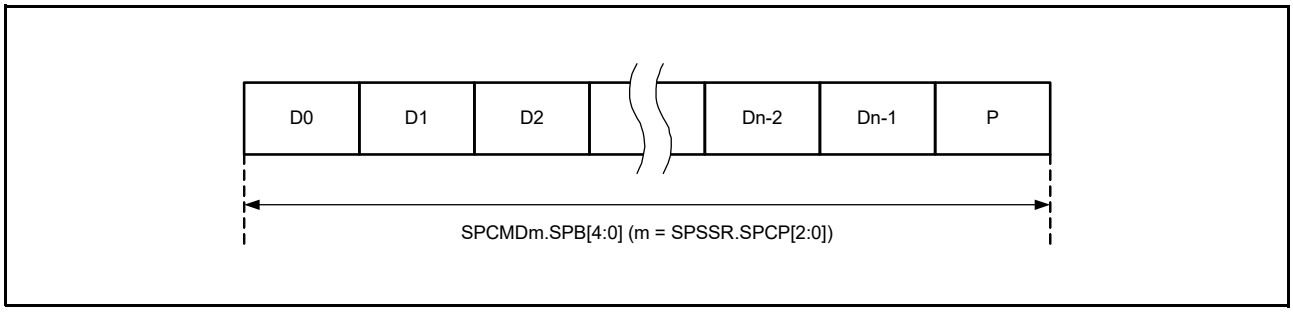

Figure 47.14 Outline of the Data Format (with Parity Enabled)

47.3.4.2 When Parity is Disabled (SPCR.SPPE = 0)

When parity is disabled, data for transmission are copied to the shift register with no prior processing. A description of the connection between the RSPI data register (SPDR) and the shift register in terms of the combination of MSB or LSB first and data length is given below.

(1) MSB First Transfer (32-Bit Data)

Figure 47.15 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and MSB first selected.
In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T31, through T30, and so on to T00.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

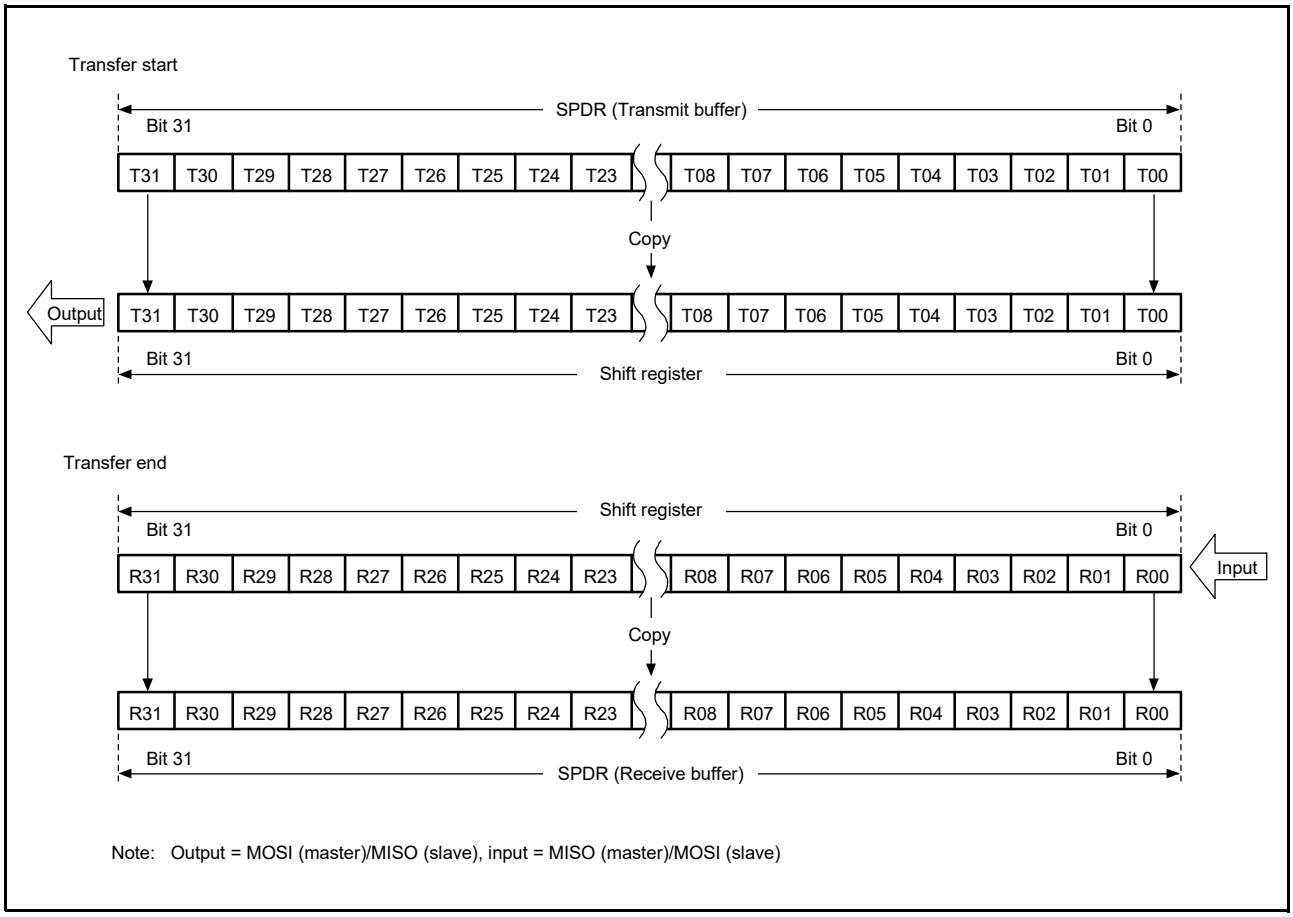

Figure 47.15 MSB First Transfer (32-Bit Data, Parity Disabled)

(2) MSB First Transfer (24-Bit Data)

Figure 47.16 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.
In transmission, the lower-order 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T23, through T22, and so on to T00.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

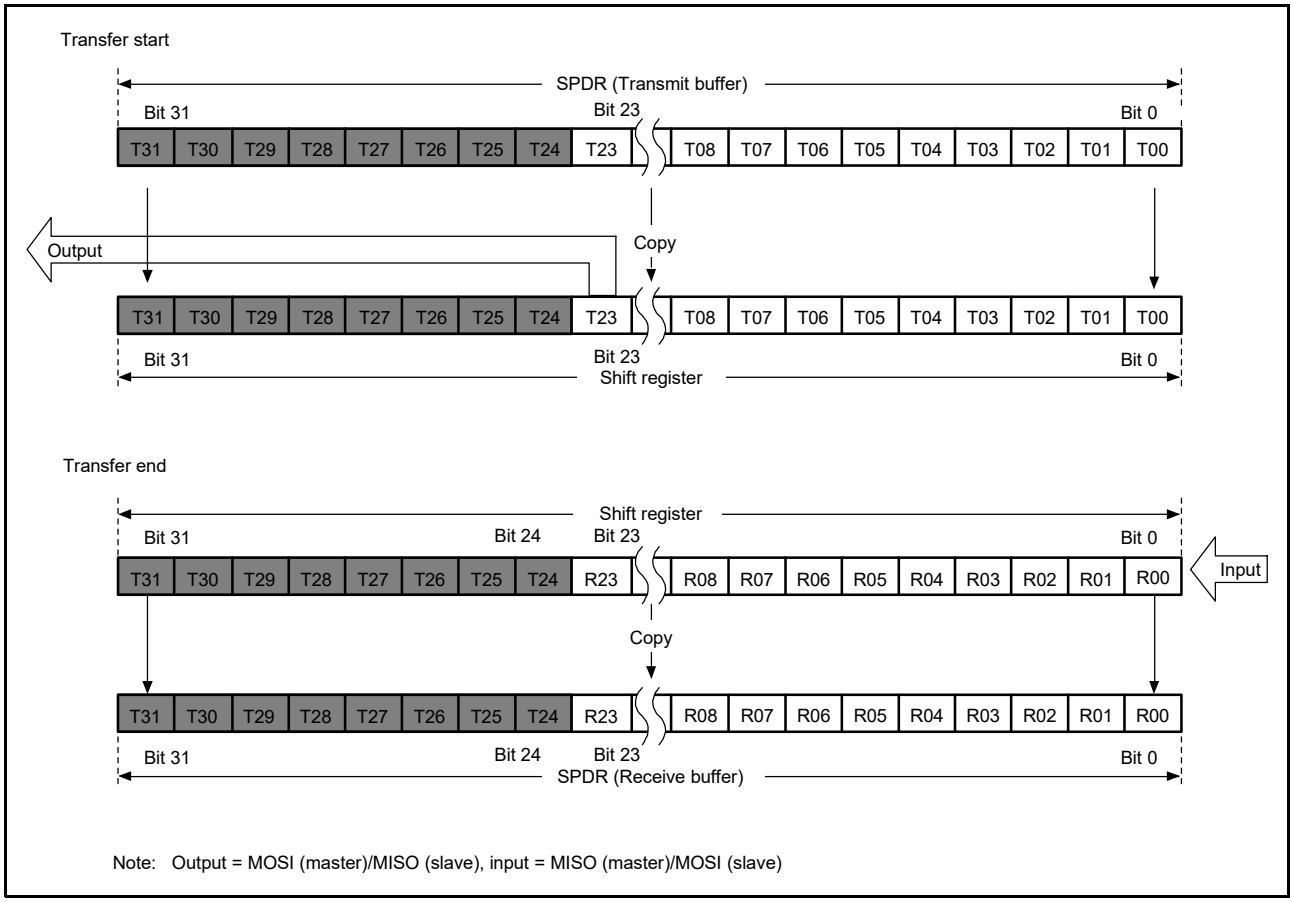

Figure 47.16 MSB First Transfer (24-Bit Data, Parity Disabled)

(3) LSB First Transfer (32-Bit Data)

Figure 47.17 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T31.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to R31 have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order R31 to R00 for copying to the receive buffer.

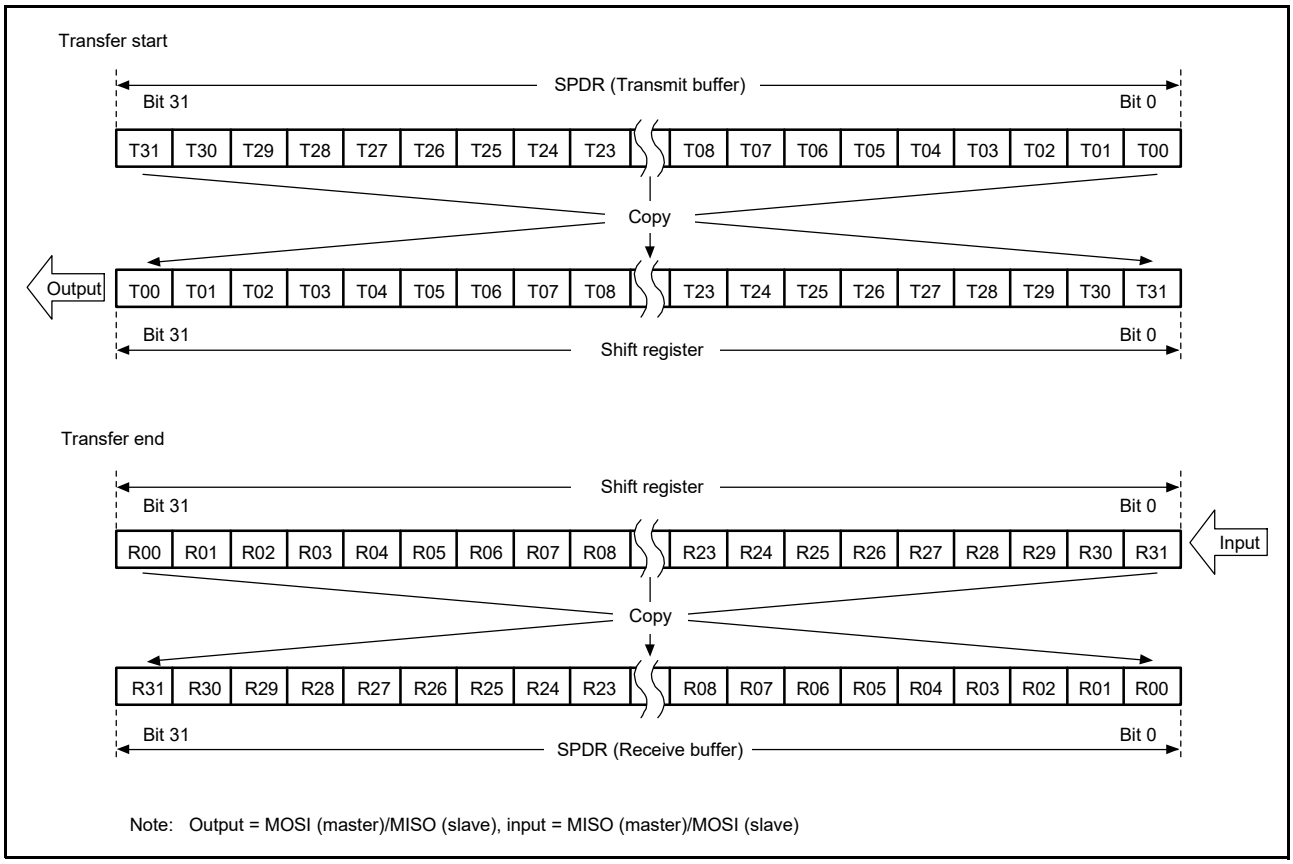

Figure 47.17 LSB First Transfer (32-Bit Data, Parity Disabled)

(4) LSB First Transfer (24-Bit Data)

Figure 47.18 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.

In transmission, the lower-order 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T23.

In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to R23 have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order R23 to R00 for copying to the receive buffer.

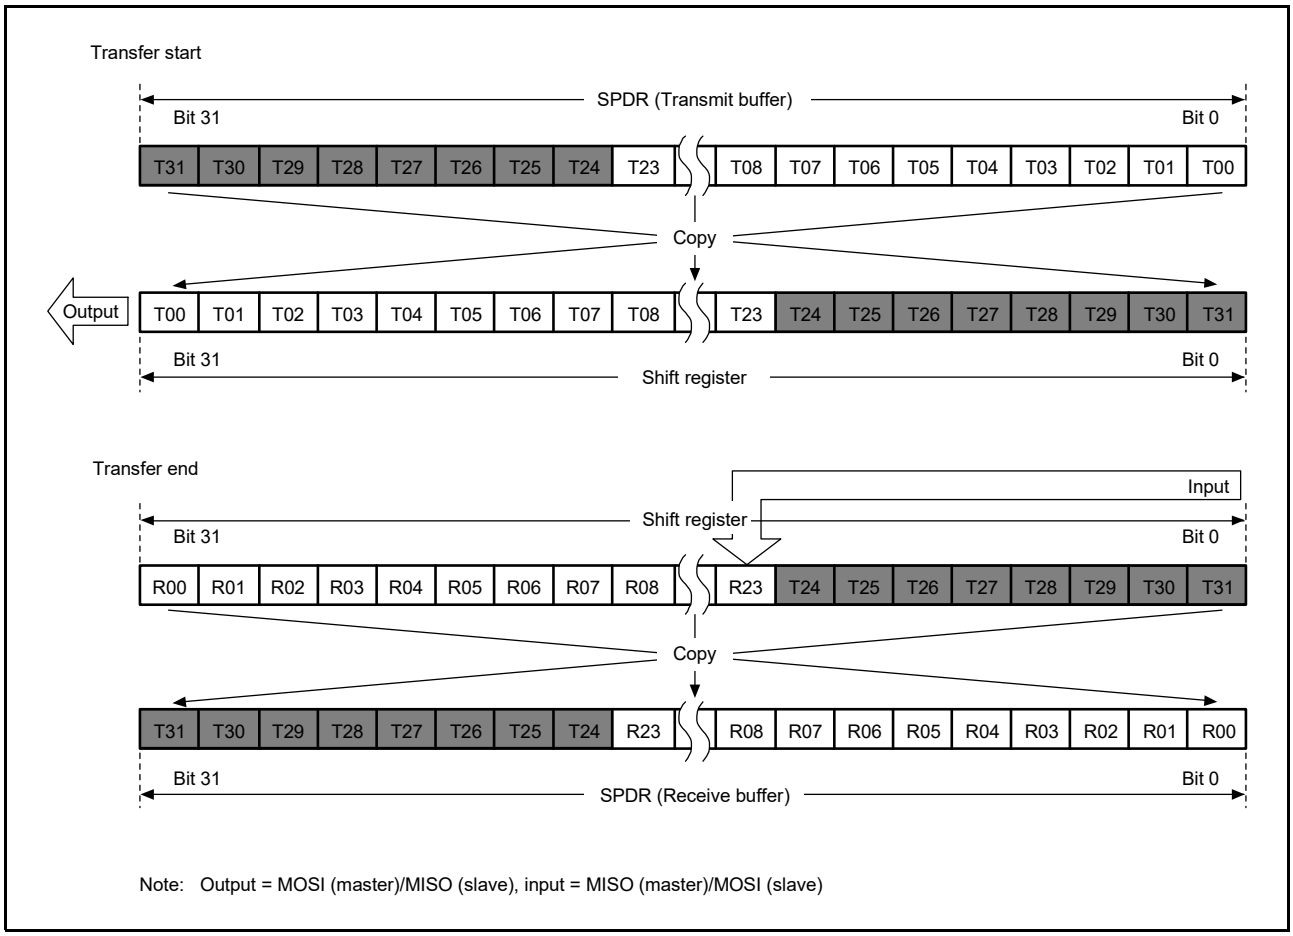

Figure 47.18 LSB First Transfer (24-Bit Data, Parity Disabled)

47.3.4.3 When Parity is Enabled (SPCR.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB First Transfer (32-Bit Data)

Figure 47.19 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and MSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T31, T30, …, T01, and P.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the receive buffer, the data from R31 to P are checked to judge the parity error.

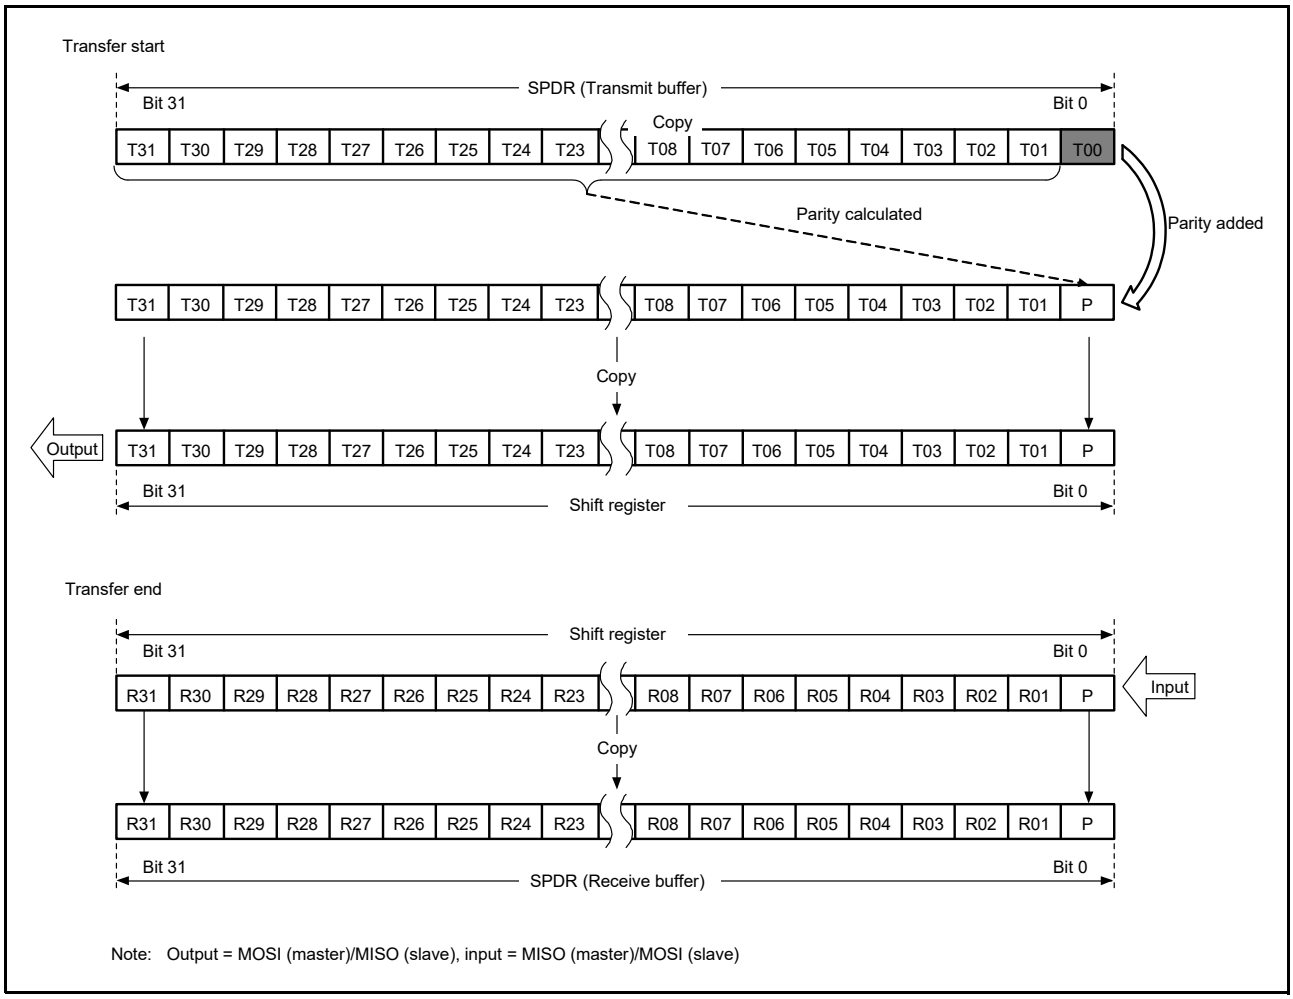

Figure 47.19 MSB First Transfer (32-Bit Data, Parity Enabled)

(2) MSB First Transfer (24-Bit Data)

Figure 47.20 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T23, T22, …, T01, and P.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the receive buffer, the data from R23 to P are checked to judge the parity error.

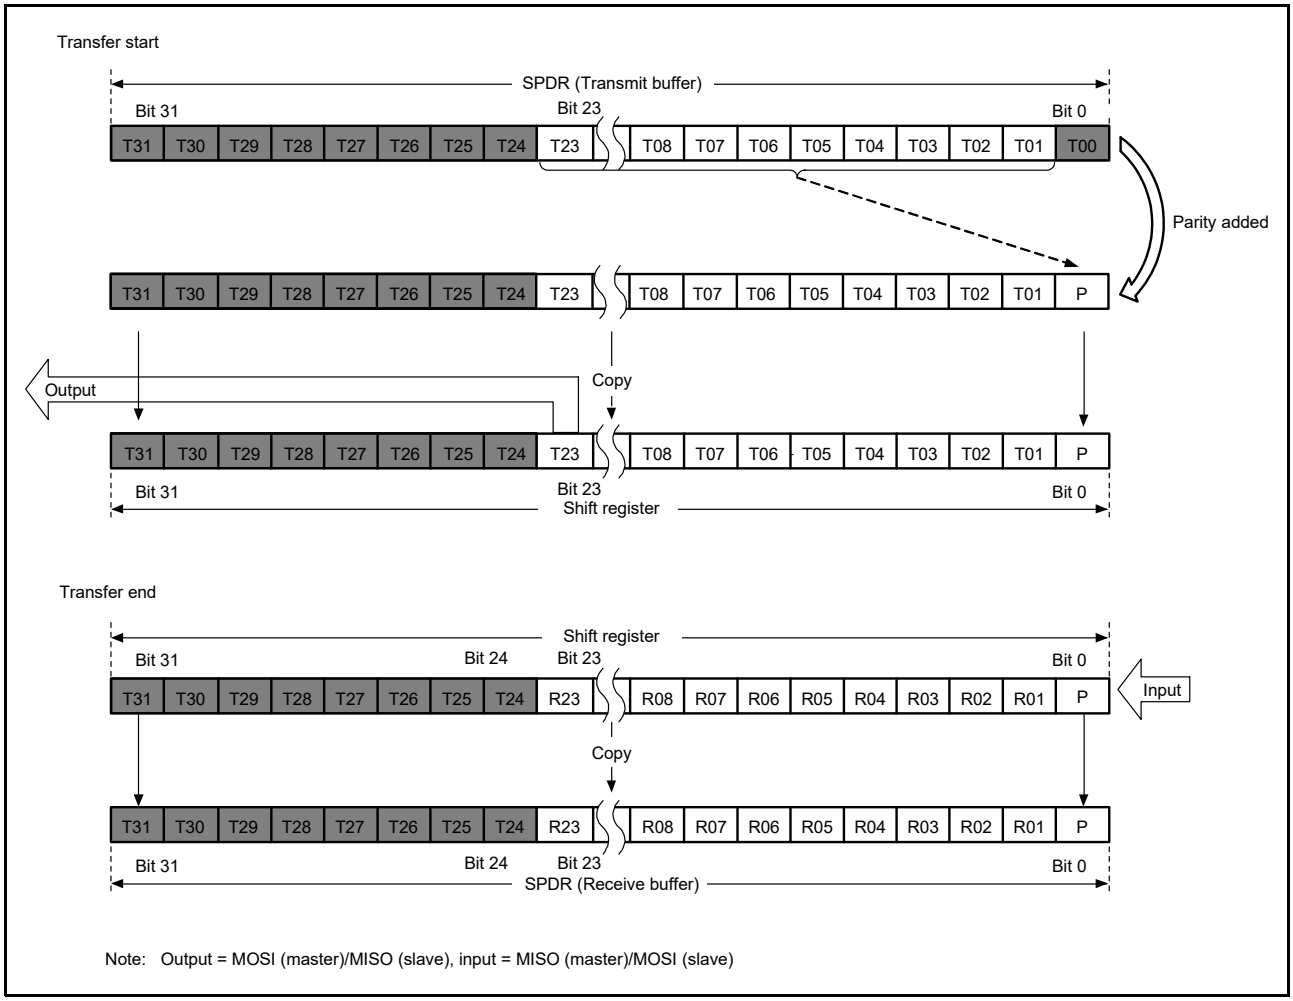

Figure 47.20 MSB First Transfer (24-Bit Data, Parity Enabled)

(3) LSB First Transfer (32-Bit Data)

Figure 47.21 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T30, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order P to R00 for copying to the receive buffer. On copying of data to the receive buffer, the data from R00 to P are checked to judge the parity error.

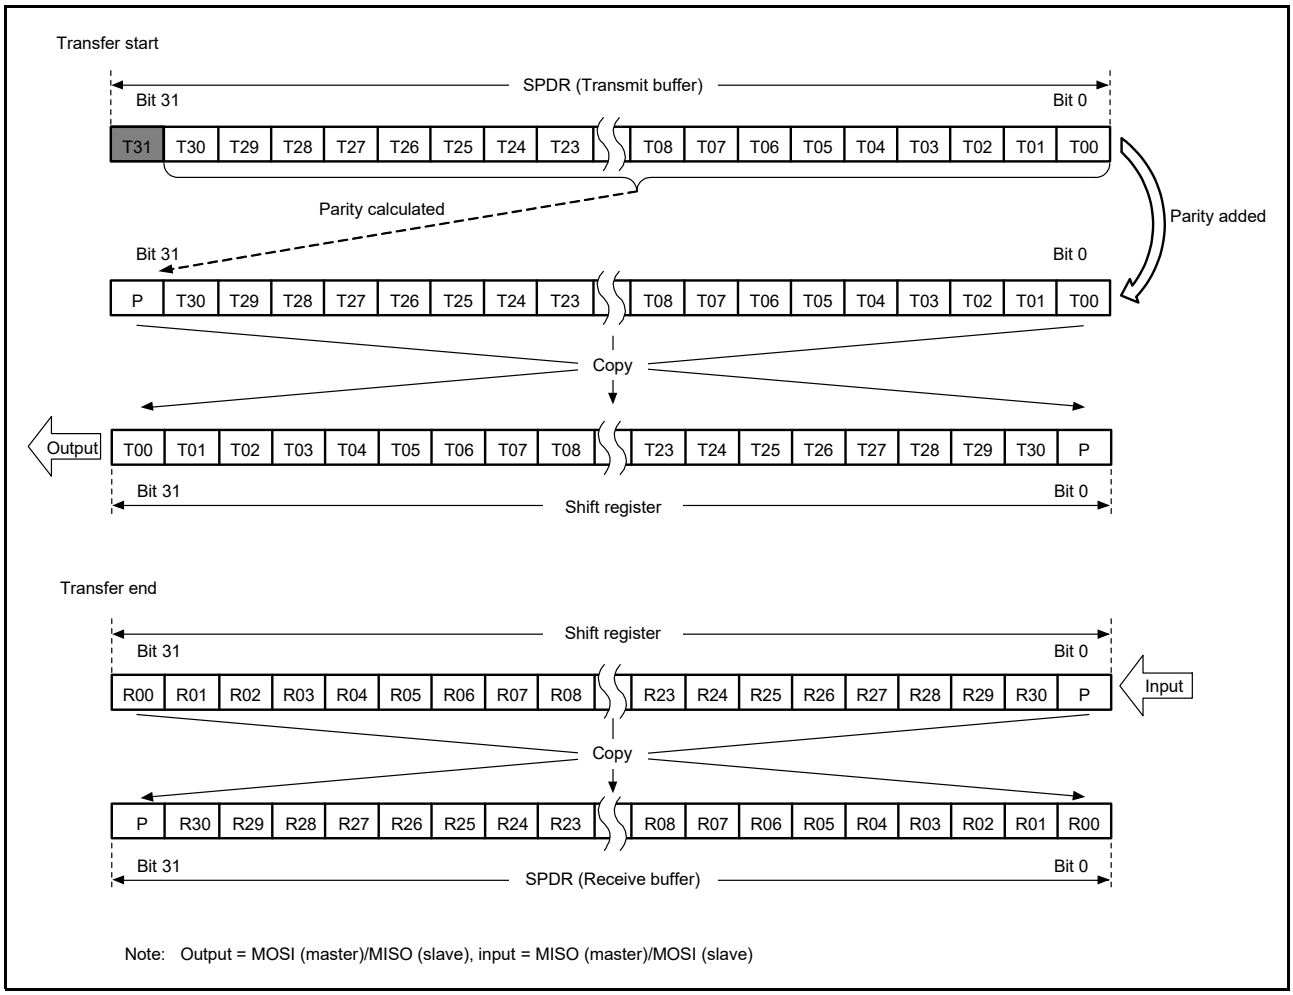

Figure 47.21 LSB First Transfer (32-Bit Data, Parity Enabled)

(4) LSB First Transfer (24-Bit Data)

Figure 47.22 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T22, and P.
In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order P (bit 23) to R00 (bit 0) for copying to the receive buffer. On copying of data to the receive buffer, the data from R00 to P are checked to judge the parity error.

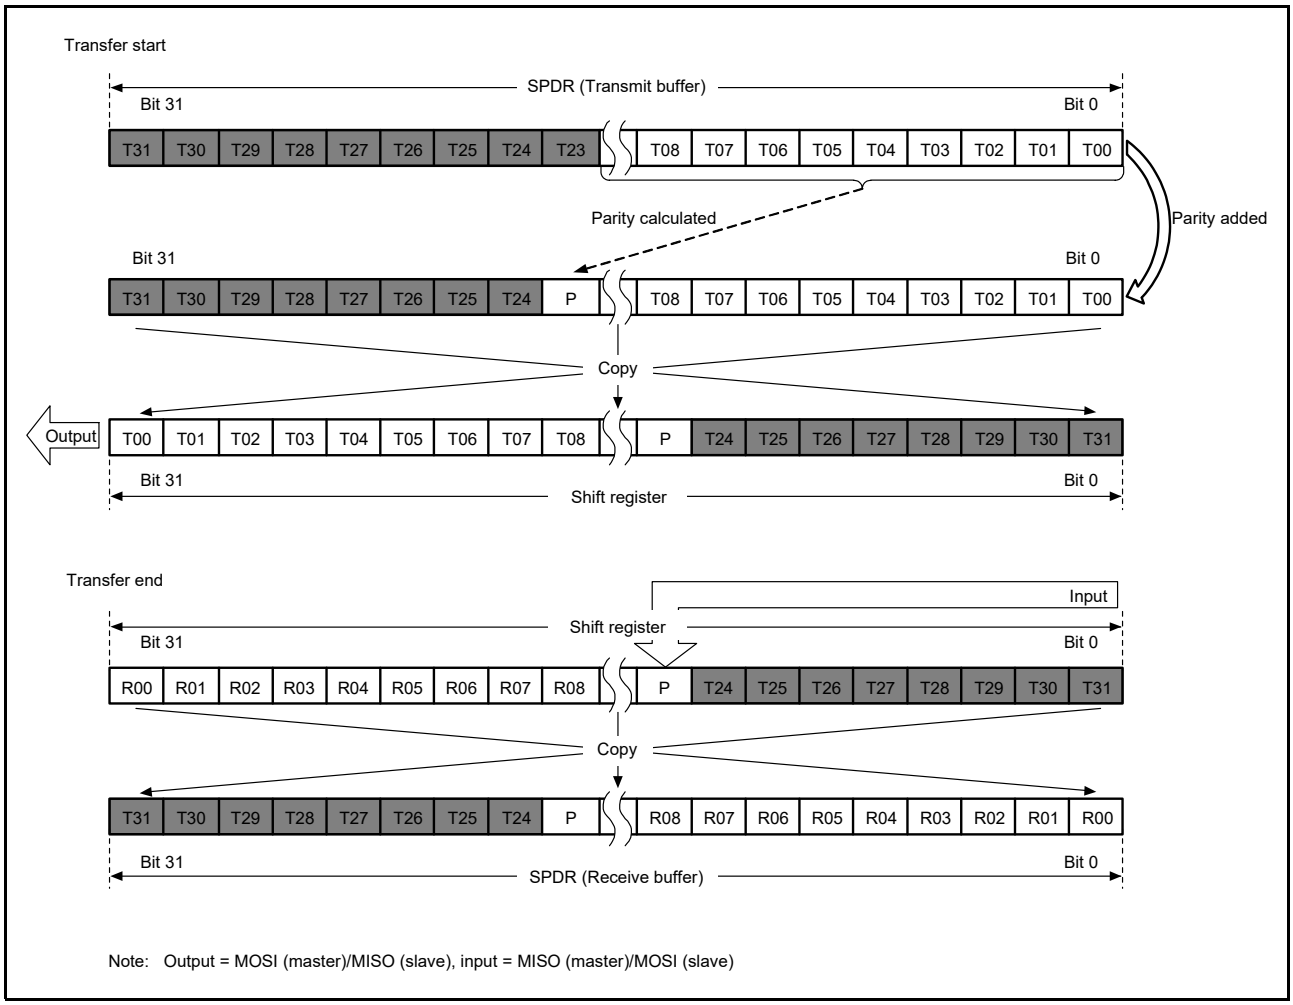

Figure 47.22 LSB First Transfer (24-Bit Data, Parity Enabled)

47.3.4.4 Byte Swap Transmission

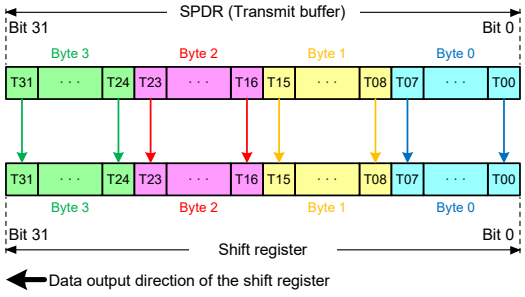
When the SPDCR.BYSW bit is 1 (byte swapping of SPDR data enabled), data bytes written in the transmit buffer (SPDR) will be swapped (in 8 bit units) when the data is transferred to the shift register. Figure 47.23 shows data transfer between the SPDR register and the shift register when data length is 32 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

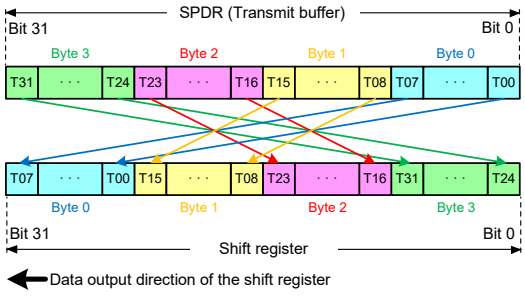
(1) MSB first transfer (when the byte swap is disabled)
Data (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T31, T30, …, and T00 as transmit data.

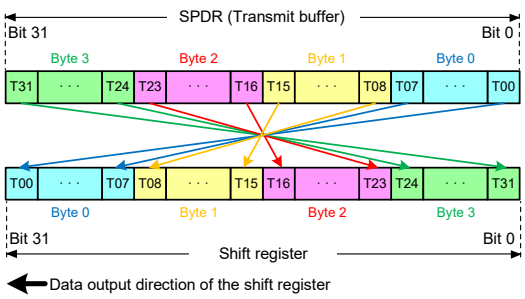
(2) MSB first transfer (when the byte swap is enabled)
Byte values of the transmit buffer (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte 0 [T07 to T00] to Byte 3 [T31 to T24].
Bit values in the shift register are shifted and transmitted in the order of T07, T06, …, T00, T15, T14, …, T08, T23, T22, …, T16, T31, T30, …, and T24 as transmit data.

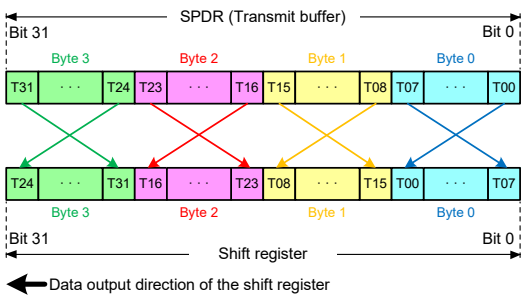
(3) LSB first transfer (when the byte swap is disabled)
Bit values of the transmit buffer (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 0 [T00 to T07] to Byte 3 [T24 to T31].
Bit values in the shift register are shifted and transmitted in the order of T00, T01, …, and T31 as transmit data.

(4) LSB first transfer (when the byte swap is enabled)
Bit values of each byte of the transmit buffer (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 3 [T24 to T31] to Byte 0 [T00 to T07].
Bit values in the shift register are shifted and transmitted in the order of T24, T25, …, T31, T16, T17, …, T23, T08, T09, …, T15, T00, T01, …, and T07 as transmit data.









32-bit Byte Swap Specifications	Byte Swap is Disabled (BYSW = 0)	Byte Swap is Enabled (BYSW = 1)
MSB-first (LSBF = 0)		
LSB-first (LSBF = 1)		

Figure 47.23 Transmit Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 32 bits)

Figure 47.24 shows data transfer between the SPDR register and the shift register when data length is 16 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

(1) MSB first transfer (when the byte swap is disabled)
Data (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) in the transmit buffer are copied to the shift register in the order of Byte 1 [T15 to T08] to Byte 0 [T07 to T00]. Bit values in the shift register are shifted and transmitted in the order of T15, T14, …, and T00 as transmit data.

(2) MSB first transfer (when the byte swap is enabled)
Byte values of the transmit buffer (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte 0 [T07 to T00] to Byte 1 [T15 to T08]. Bit values in the shift register are shifted and transmitted in the order of T07, T06, …, T00, T15, T14, …, T08 as transmit data.

(3) LSB first transfer (when the byte swap is disabled)
Bit values of the transmit buffer (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 0 [T00 to T07] to Byte 1 [T15 to T08]. Bit values in the shift register are shifted and transmitted in the order of T00, T01, …, and T15 as transmit data.

(4) LSB first transfer (when the byte swap is enabled)
Bit values of each byte of the transmit buffer (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 1 [T08 to T15] to Byte 0 [T00 to T07].
Bit values in the shift register are shifted and transmitted in the order of T08, T09, …, T15, T00, T01, …, and T07 as transmit data.

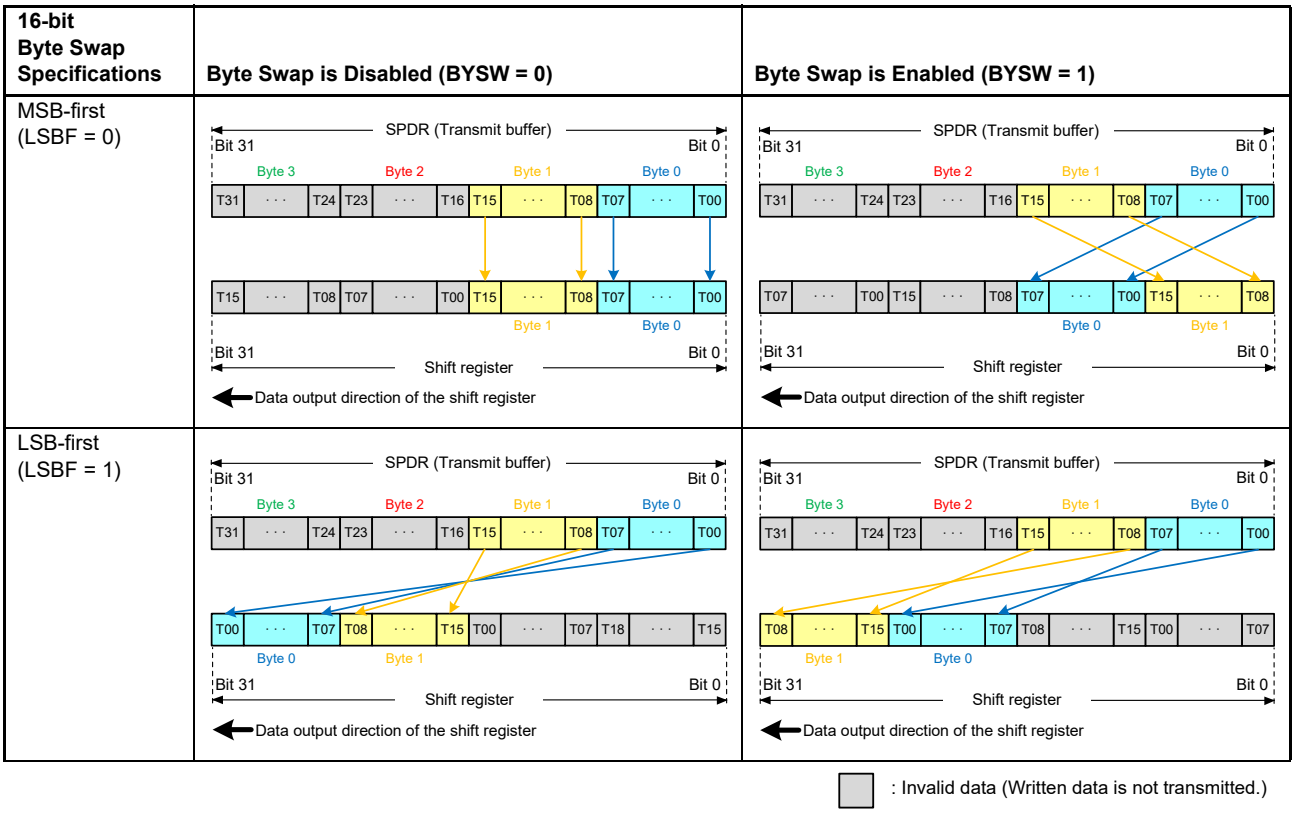


Figure 47.24 Transmit Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 16 bits)

Note 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length (4 to 15 or 17 to 31 bits), the operation is not guaranteed.

Note 2. When the byte swap is enabled, disable the parity function (SPCR.SPPE = 0). If the parity function is enabled (SPCR.SPPE = 1), the operation is not guaranteed.
Note 3. Set the SPDCR.BYSW bit, while the SPCR.SPE bit is 0. If the value of the SPDCR.BYSW bit is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

47.3.4.5 Byte Swap Reception

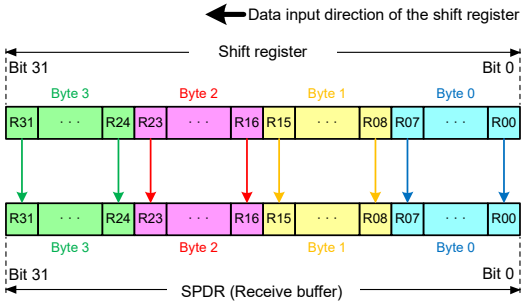
When the SPDCR.BYSW bit is 1 (byte swapping of SPDR data enabled), data bytes in the shift register will be swapped (in 8 bit units) when the data is transferred to the receive buffer (SPDR). Figure 47.25 shows data transfer between the shift register and the SPDR register when data length is 32 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

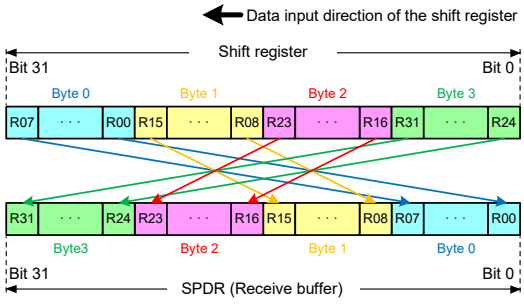
(1) MSB first transfer (when the byte swap is disabled)
The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31, R30, …, and R00. When necessary RSPCK cycles are input and data is stored from Byte 3 [R31 to R24] to Byte 0 [R07 to R00], the shift register value is copied to the receive buffer.

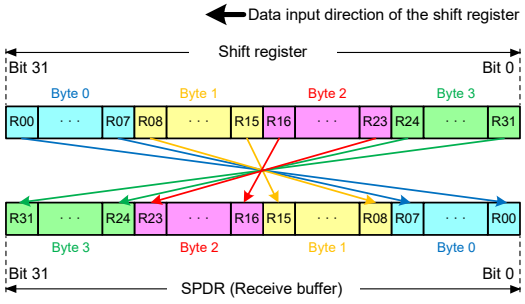
(2) MSB first transfer (when the byte swap is enabled)
The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07, R06, …, R00, R15, R14, …, R08, R23, R22, …, R16, R31, R30, …, and R24. When necessary RSPCK cycles are input and data is stored from Byte 0 [R07 to R00] to Byte 3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

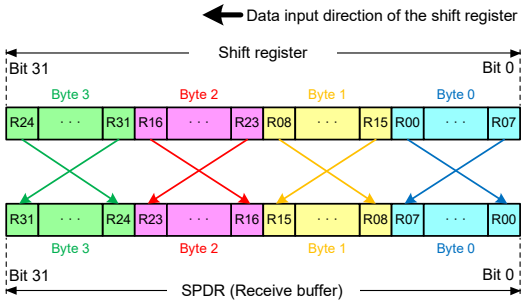
(3) LSB first transfer (when the byte swap is disabled)
The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00, R01, …, and R31. When necessary RSPCK cycles are input and data is stored from Byte 0 [R00 to R07] to Byte 3 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(4) LSB first transfer (when the byte swap is enabled)
The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24, R25, …, R31, R16, R17, …, R23, R08, R09, …, R15, R00, R01, …, and R07. When necessary RSPCK cycles are input and data is stored from Byte 3 [R24 to R31] to Byte 0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].









32-bit Byte Swap Specifications	Byte Swap is Disabled (BYSW = 0)	Byte Swap is Enabled (BYSW = 1)
MSB-first (LSBF = 0)		
LSB-first (LSBF = 1)		

Figure 47.25 Receive Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 32 bits)

Figure 47.26 shows data transfer between the shift register and the SPDR register when data length is 16 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

(1) MSB first transfer (when the byte swap is disabled)
The first received data (R15) is stored in bit 0 of the shift register, and received data is shifted in the order of R15, R14, …, and R00. When necessary RSPCK cycles are input and data is stored from Byte 3 [R31 to R24] to Byte 0 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB first transfer (when the byte swap is enabled)
The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07, R06, …, R00, R15, R14, …, and R08. When necessary RSPCK cycles are input and data is stored from Byte 0 [R07 to R00] to Byte 1 [R15 to R08], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(3) LSB first transfer (when the byte swap is disabled)
The first received data (R00) is stored in bit 15 of the shift register, and received data is shifted in the order of R00, R01, …, R07, R08, R09, …, and R15. When necessary RSPCK cycles are input and data is stored from Byte 0 [R00 to R07] to Byte 1 [R08 to R15], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(4) LSB first transfer (when the byte swap is enabled)
The first received data (R08) is stored in bit 15 of the shift register, and received data is shifted in the order of R08, R09, …, R15, R00, R01, …, and R15. When necessary RSPCK cycles are input and data is stored from Byte 1 [R08 to R15] to Byte 0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

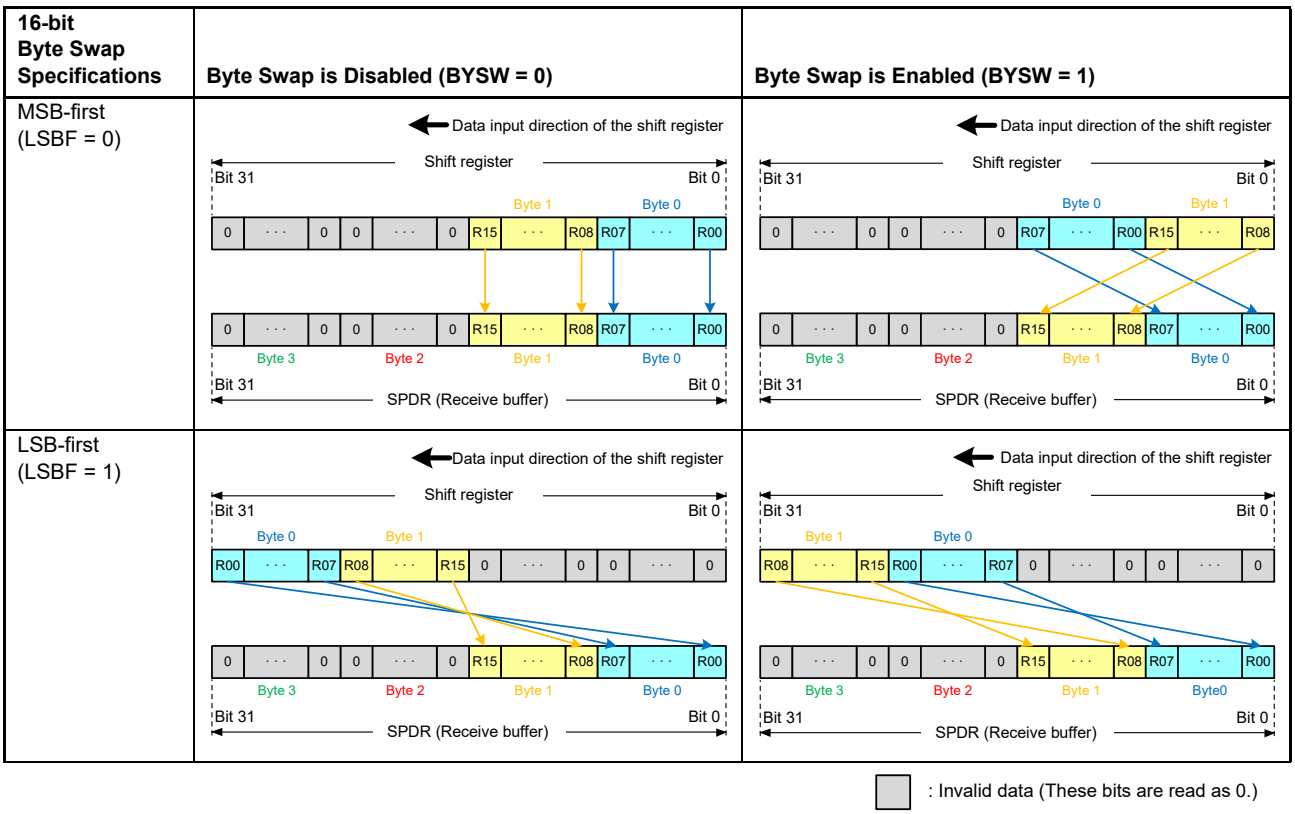


Figure 47.26 Receive Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 16 bits)

Note 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length (4 to 15 or 17 to 31 bits), the operation is not guaranteed.

Note 2. When the byte swap is enabled, disable the parity function (SPCR.SPPE = 0). If the parity function is enabled (SPCR.SPPE = 1), the operation is not guaranteed.

Note 3. Set the SPDCR.BYSW bit, while the SPCR.SPE bit is 0. If the value of the SPDCR.BYSW bit is changed while the SPCR.SPE bit is 1, subsequent operation is not guaranteed.

47.3.5 Transfer Format (Frame Format)

47.3.5.1 When CPHA = 0

Figure 47.27 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Note that clock synchronous operation (the SPCR.SPMS bit is 1) should not performed when the RSPIA operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 47.27, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0; RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPIA fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPIA settings. For details, refer to section 47.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOn signals commences at an SSLni signal assertion timing. The first RSPCKn signal change timing that occurs after the SSLni signal assertion becomes the first transfer data fetch timing. After this timing, data is sampled at every 1 RSPCK cycle. The change timing for MOSIn and MISOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCKn signal operation timing; it only affects the signal polarity.

t1 denotes a period from an SSLni signal assertion to RSPCKn oscillation (RSPCK delay). t2 denotes a period from the termination of RSPCKn oscillation to an SSLni signal negation (SSL negation delay). t3 denotes a period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the RSPI system. For a description of t1, t2, and t3 when the RSPIA of this MCU is in master mode, refer to section 47.3.13.1, Master Mode Operation.

[Motorola SPI]

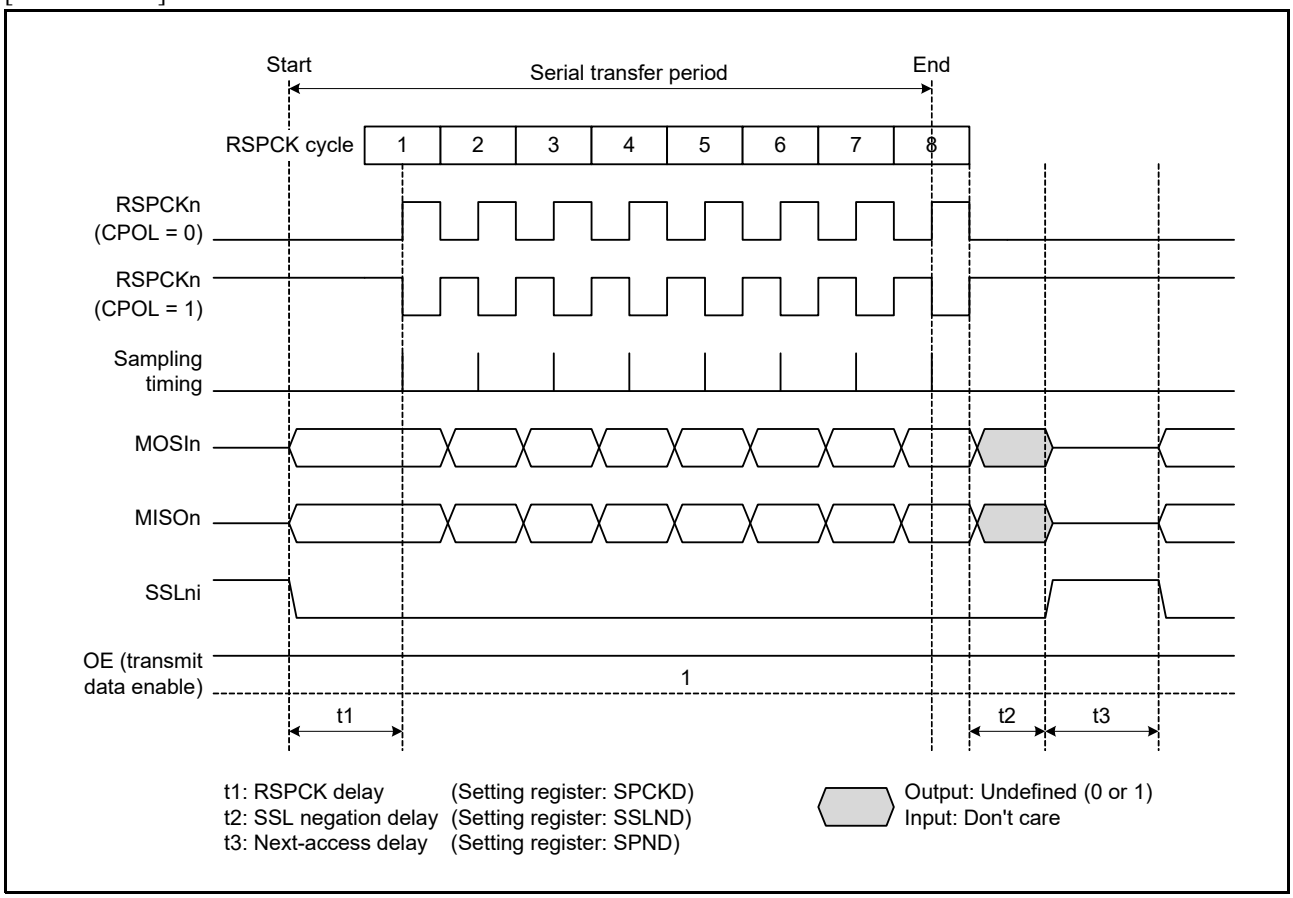

Figure 47.27 RSPI Transfer Format (CPHA = 0, FRFS = 0)

[TI SSP]

In TI SSP protocol, setting the CPHA bit to 0 is not effective.

47.3.5.2 When CPHA = 1

Figure 47.28 and Figure 47.29 show sample transfer formats for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISOn handle communications. In Figure 47.28, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0; RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPIA fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI mode (master or slave). For details, refer to section 47.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOn signal commences at an SSLni signal assertion timing. The output of valid data to the MOSIn and MISOn signals commences at the first RSPCKn signal change timing that occurs after the SSLni signal assertion. After this timing, data is updated at every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing; it only affects the signal polarity.

t1, t2, and t3 are the same as those in the case of CPHA = 0. For a description of t1, t2, and t3 when the RSPIA of this MCU is in master mode, refer to section 47.3.13.1, Master Mode Operation.

[Motorola SPI]

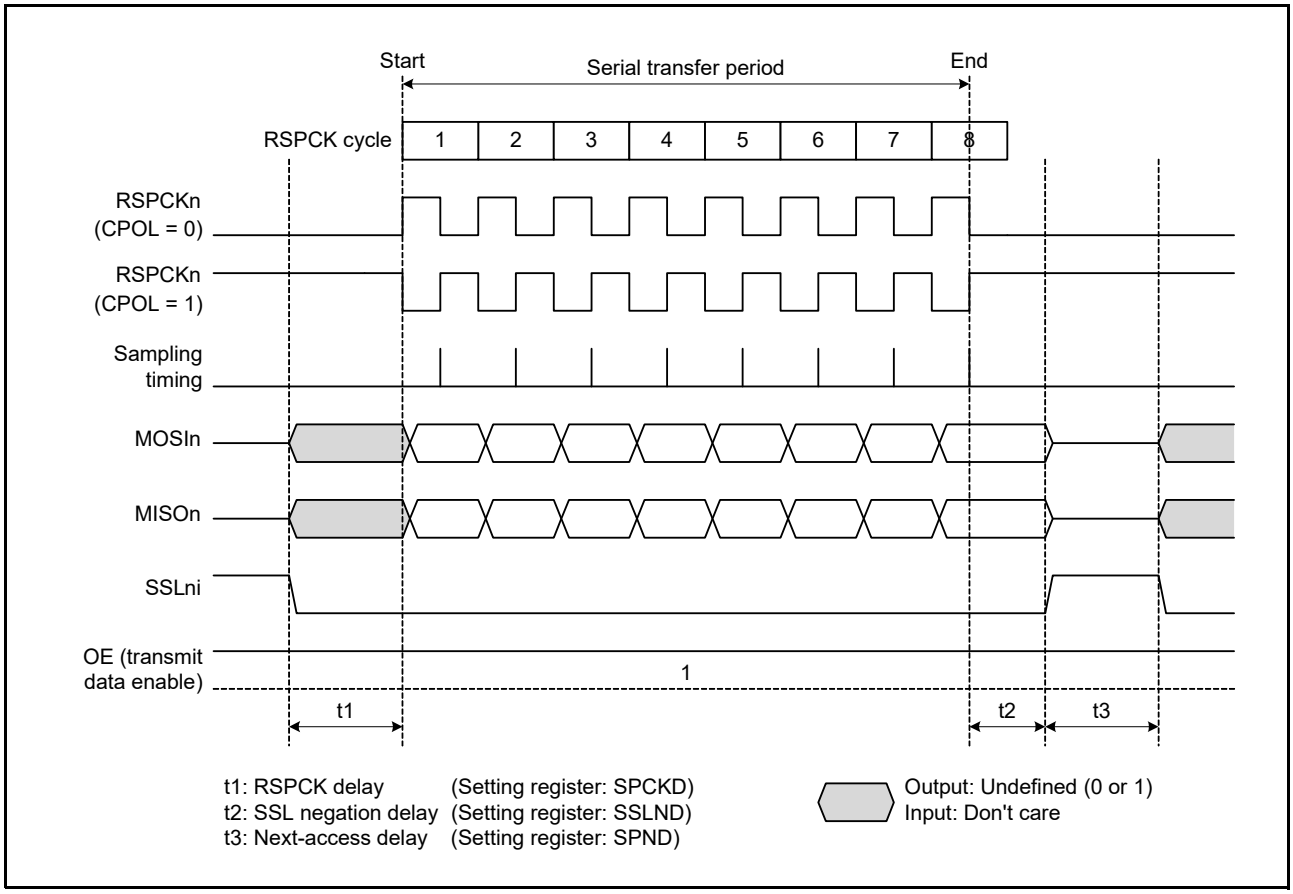

Figure 47.28 RSPI Transfer Format (CPHA = 1, FRFS = 0)

[TI SSP]

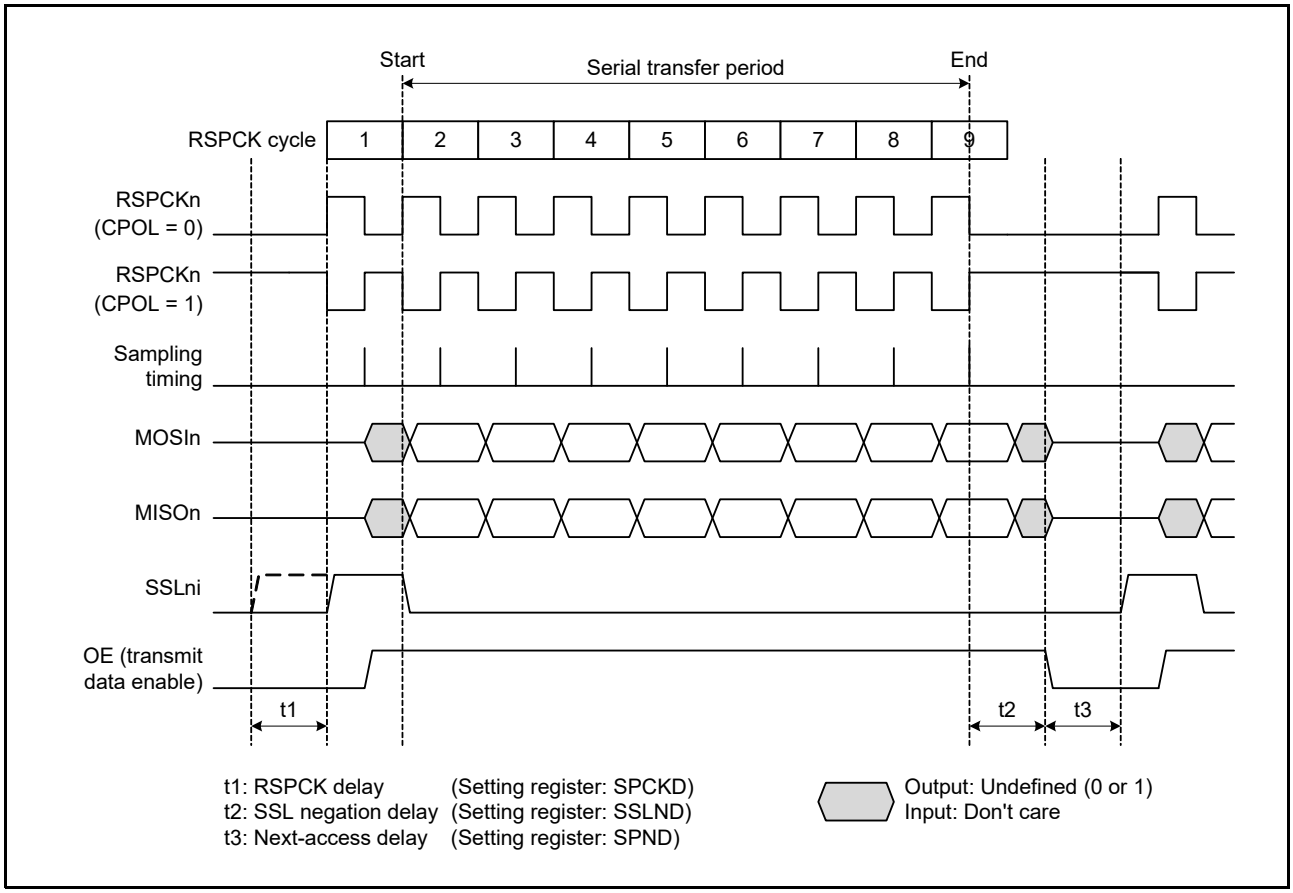

Figure 47.29 RSPI Transfer Format (CPHA = 1, FRFS = 1)

47.3.6 Communication Mode

Transmit-receive mode, transmit-only mode, and receive-only mode can be selected by the communication mode select bit (SPCR.CMMD[1:0]).

The SPDR register access shown in Figure 47.30, Figure 47.31 and Figure 47.32 indicate the condition of access to the SPDR register, where W denotes a write cycle.

47.3.6.1 Transmit-Receive Mode (SPCR.CMMD[1:0] = 00b)

Figure 47.30 shows an example of operation when the communication mode select bits (SPCR.CMMD[1:0]) are set to 00b. In the example in Figure 47.30, the RSPIA performs an 8-bit serial transfer in which SPFCR.TTRG[1:0] = 00b, SPFCR.RTRG[1:0] = FIFO stage – 1, SPCMDm.CPHA = 1, and SPCMDm.CPOL = 0. The numbers given under the RSPCKn waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

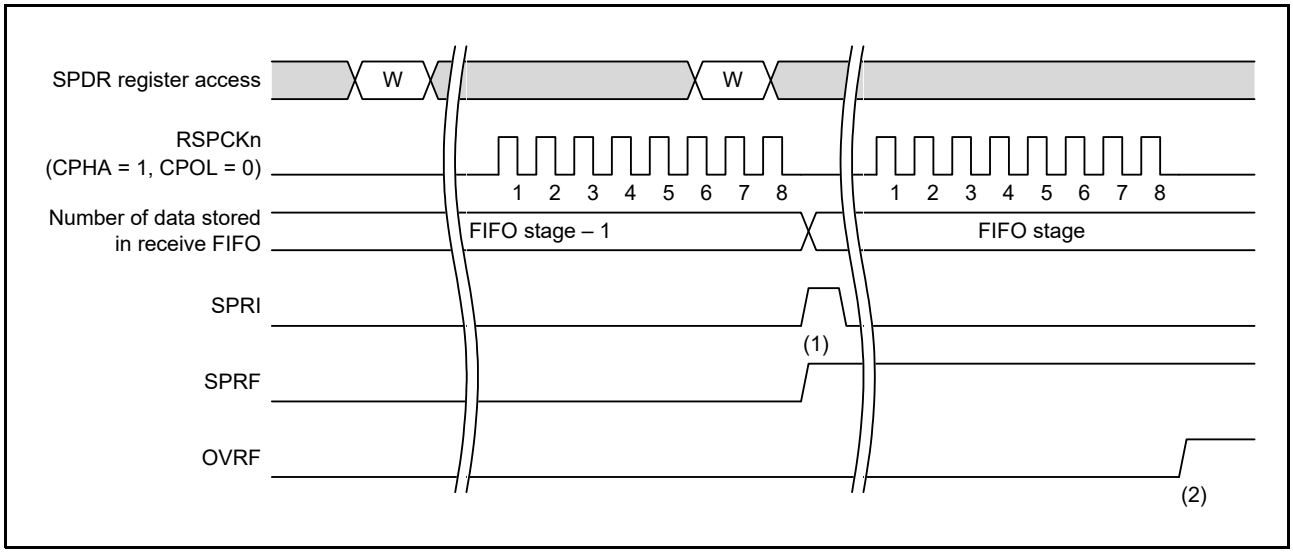

Figure 47.30 Operation Example of SPCR.CMMD[1:0] = 00b

The operation of the flags at timings shown in steps (1) and (2) in the figure is described below.

(1) When a serial transfer ends while the number of data stored in the SPDR receive buffer matches the number of frames set in SPFCR.RTRG[1:0] bits, the RSPIA generates a receive buffer full interrupt request (SPRI) (sets the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When a serial transfer ends with data for the number of FIFO stages is stored in the SPDR receive buffer, the RSPIA sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

When transmit-receive mode (CMMD[1:0] = 00b) is selected, reception occurs simultaneously with transmit operations. As such, the SPRF and OVRF flags in the SPSR register become 1 at the timing described in (1) and (2), respectively, according to the state of the receive buffer.

47.3.6.2 Transmit-Only Mode (SPCR.CMMD[1:0] = 01b)

Figure 47.31 shows an example of operation when the communication mode select bits (SPCR.CMMD[1:0]) are set to 01b. In the example in Figure 47.31, the RSPIA performs an 8-bit serial transfer in which SPFCR.TTRG[1:0] = 00b, SPFCR.RTRG[1:0] = 00b, SPCMDm.CPHA = 1, and SPCMDm.CPOL = 0. The numbers given under the RSPCKn waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

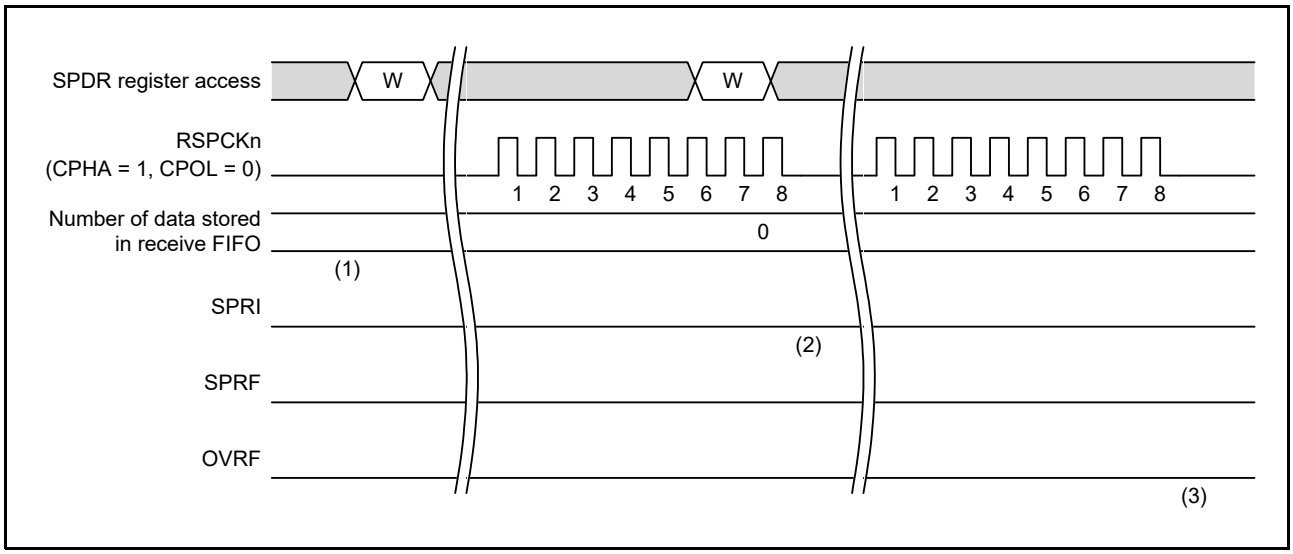

Figure 47.31 Operation Example of SPCR.CMMD[1:0] = 01b

The operation of the flags at timings shown in steps (1) to (3) in the figure is described below.

(1) Make sure there is no data left in the receive buffer and the SPSR.SPRF, OVRF flags are 0 before entering the mode of transmit operations only (SPCR.CMMD[1:0] = 01b).

(2) When a serial transfer ends without received data in the receive FIFO of SPDR, if transmit-only mode is selected (SPCR.CMMD[1:0] = 01b), the SPRF flag remains 0 and the RSPIA does not copy the data from the shift register to the receive buffer.

(3) Since the receive buffer of SPDR does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

When transmit-only mode (SPCR.CMMD[1:0] = 01b) is selected, the RSPIA transmits data but does not receive data. Therefore, the SPSR.SPRF, OVRF flags remain 0 at the timings of (1) to (3).

47.3.6.3 Receive-Only Mode (SPCR.CMMD[1:0] = 10b)

Figure 47.32 shows an example of operation when the communication mode select bits (SPCR.CMMD[1:0]) are set to 10b. In the example in Figure 47.32, the RSPIA performs an 8-bit serial transfer in which SPFCR.TTRG[1:0] = 00b, SPFCR.RTRG[1:0] = FIFO stage – 1, SPCMDm.CPHA = 1, and SPCMDm.CPOL = 0. The numbers given under the RSPCKn waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

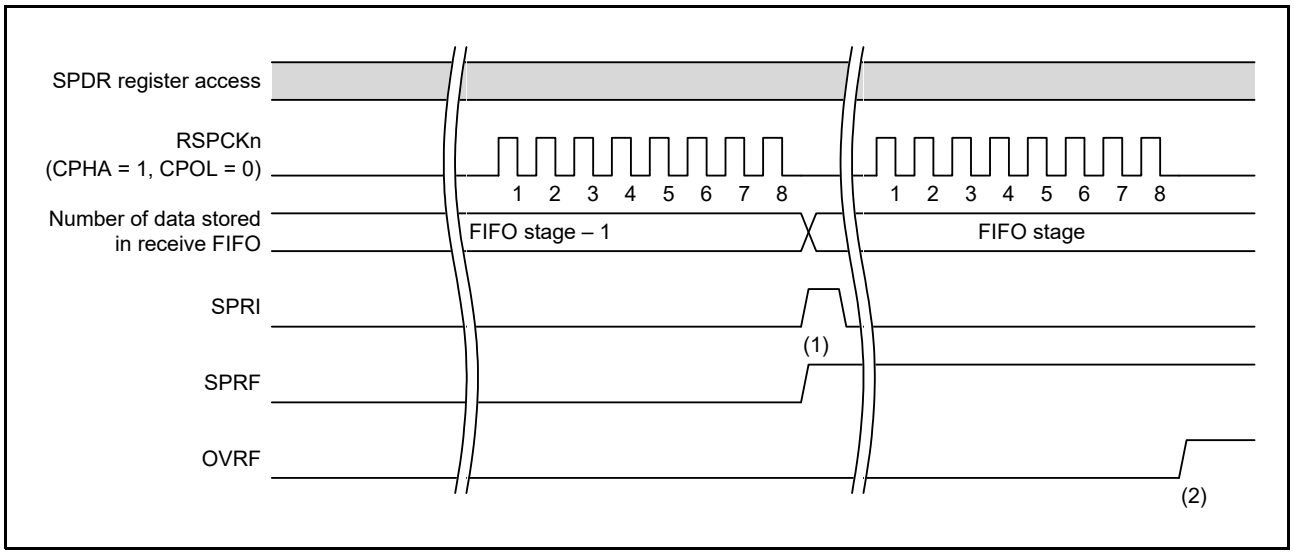

Figure 47.32 Operation Example of SPCR.CMMD[1:0] = 10b

The operation of the flags at timings shown in steps (1) to (2) in the figure is described below.

(1) When a serial transfer ends while the number of data stored in the SPDR receive buffer matches the number of frames set in SPFCR.RTRG[1:0] bits, the RSPIA generates a receive buffer full interrupt request (SPRI) (sets the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When a serial transfer ends with data for the number of FIFO stages is stored in the SPDR receive buffer, the RSPIA sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

47.3.7 Transmit Buffer Empty/Receive Buffer Full Interrupts

Figure 47.33 shows an example of operation of the transmit buffer empty interrupt (SPTI) and the receive buffer full interrupt (SPRI). The SPDR register access shown in Figure 47.33 indicate the conditions of access to the SPDR register, where W denotes a write cycle, and R a read cycle. In the examples in Figure 47.33, the RSPIA performs an 8-bit serial transfer in which the SPCR.CMMD[1:0] bits are 00b, SPFCR.TTRG[1:0] bits are 00b, the SPFCR.RTRG[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKn waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

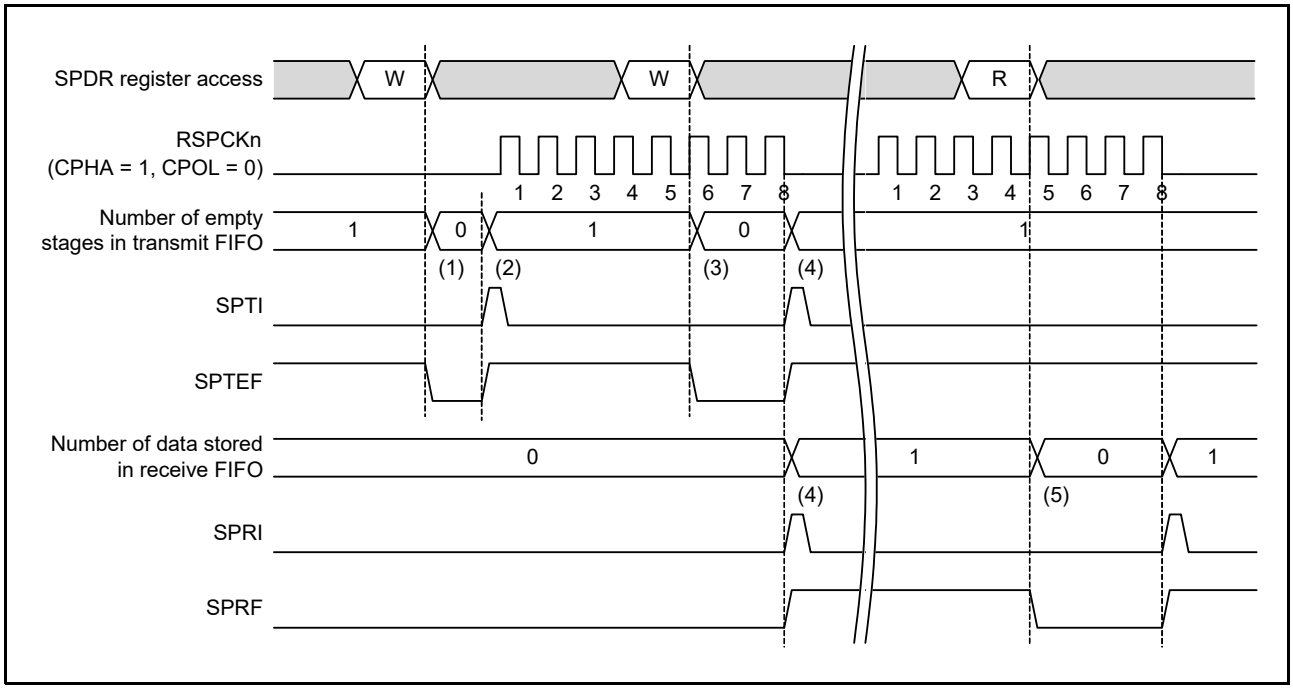

Figure 47.33 Operation Example of SPTI and SPRI Interrupts

The operation of the interrupts at timings shown in steps (1) to (5) in the figure is described below.

(1) If transmit data is written to SPDR when the next transmit data is not set in the transmit FIFO, the RSPIA writes data to the transmit buffer. When transmit data is written to SPDR in one processing routine using DTC/DMAC, the SPSR.SPTEF flag becomes 0 at the last access.

(2) If the shift register is empty, the RSPIA copies the data from the transmit buffer to the shift register. If the number of empty stage of the transmit FIFO is greater than the threshold value, the RSPIA generates a transmit buffer empty interrupt request (SPTI) and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the mode of the RSPIA. For details, refer to section 47.3.13, SPI Operation, and section 47.3.14, Clock Synchronous Operation.

(3) When transmit data is written to SPDR in the transmit buffer empty interrupt routine or in the transmit buffer empty detecting process by polling the SPTEF flag, the data is transferred to the transmit buffer. When transmit data is written to SPDR in one processing routine using DTC/DMAC, the SPSR.SPTEF flag becomes 0 at the last access. Because the data being transmitted is stored in the shift register, the RSPIA does not copy the data from the transmit buffer to the shift register.

(4) If the serial transfer ends (data sampling clock edge in the final bit is detected) when the data stored in the receive FIFO of SPDR < the number of FIFO stages, the RSPIA copies the receive data from the shift register to the receive buffer. At this time, if the data stored in the receive FIFO is greater than the threshold value, the RSPIA generates a receive buffer full interrupt request (SPRI), and sets the SPSR.SPRF flag to 1. Since the shift register becomes empty upon completion of the serial transfer, when the next transmit data had been set in the transmit FIFO before the serial transfer ended, the RSPIA sets the SPSR.SPTEF flag to 1 and copies the data from the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun

error status, upon completion of the serial transfer, the RSPIA determines that the shift register is empty, thus data transfer from the transmit buffer to the shift register is enabled.

(5) When SPDR is read in the receive buffer full interrupt (SPRI) routine or in the receive buffer full detecting process by polling the SPRF flag, the receive data can be read. If the received data is read from SPDR in one processing routine using DTC/DMAC, the SPRF flag becomes 0 at the last access.

If transmit data is written to SPDR while no empty stages in the transmit FIFO, the RSPIA does not update the data in the transmit buffer. Transmit data should be written to SPDR in the transmit buffer empty interrupt request routine or in the transmit buffer empty detecting process by polling the SPTEF flag.

When setting the SPCR.SPE bit to 0 (RSPI function disabled), if the SPCR.SPTIE is 1, a transmit buffer empty interrupt request will occur. However, transmit buffer empty interrupt is inhibited by disabling transmit buffer empty interrupt (the SPTIE bit is 0) at the same time as SPE bit setting.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the RSPIA does not copy data from the shift register to the receive buffer, and detects an overrun error (refer to section 47.3.10, Error Detection). To prevent a receive data overrun error, read the received data before the next serial transfer ends.

Transmit buffer empty interrupt and receive buffer full interrupt or the corresponding IRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers. The status of the transmit and receive buffers can be also confirmed by the SPTEF and SPRF flags.

47.3.8 Idle Interrupts

When the SPSSR.SPCP[2:0] bits becomes 000b, if the next transmit data is not set, the SPSR.IDLNF flag is set to 0 and an idle interrupt request is generated. An interrupt request is also made by setting the SPCR.SPE bit to 0.

[Motorola SPI]

Figure 47.34 shows an example of idle interrupt operation during normal operation.

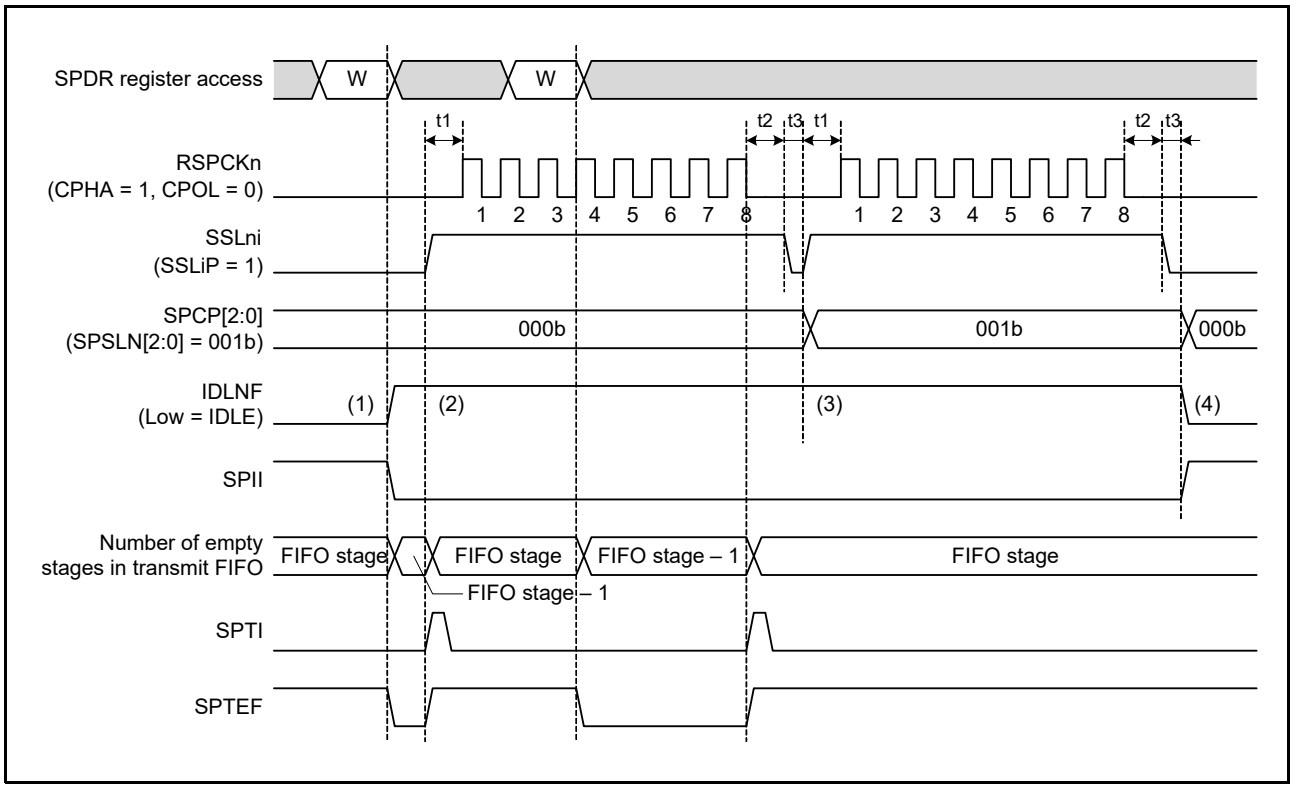

Figure 47.34 Operation Example of Idle Interrupts (Master Mode, Motorola SPI)

(1) At the start of transmission, if the next transmit data is not set in the transmission buffer, the SPSR.IDLNF flag becomes 0 (IDLE). Writing transmit data sets the SPSR.IDLNF flag to 1 (BUSY). When the SPCR.SPIIE bit is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPCR.SPIIE bit to 0 before starting transmission.

(2) After transmission has started, the SPSR.IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.

(3) The SPSSR.SPCP[2:0] bits change the command to the next one at the end of t3 cycle. When the next command is not 000b, the SPSR.IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The SPSR.IDLNF flag becomes 0 (IDLE) at the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPCR.SPIIE bit is 1, an SPII interrupt is output.

[TI SSP]

Figure 47.35 shows an example of idle interrupt operation during normal operation.

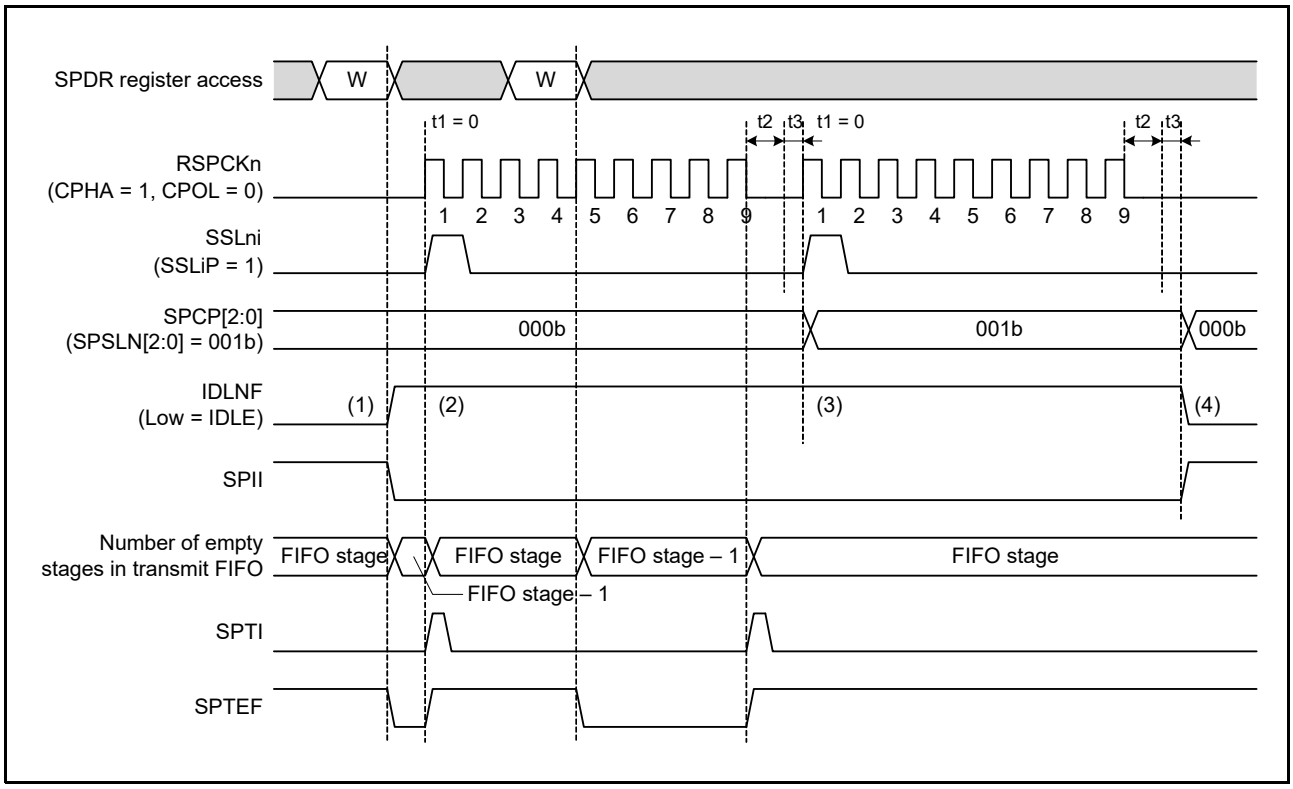

Figure 47.35 Operation Example of Idle Interrupts (Master Mode, TI SSP)

(1) At the start of transmission, if the next transmit data is not set in the transmission buffer, the SPSR.IDLNF flag becomes 0 (IDLE). Writing transmit data sets the SPSR.IDLNF flag to 1 (BUSY). When the SPCR.SPIIE bit is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPCR.SPIIE bit to 0 before starting transmission.

(2) After transmission has started, the SPSR.IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.

(3) The SPSSR.SPCP[2:0] bits change the command to the next one at the end of t3 cycle. When the next command is not 000b, the SPSR.IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The SPSR.IDLNF flag becomes 0 (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPCR.SPIIE bit is 1, an SPII interrupt is output.

An idle interrupt during slave mode operation depends only on the value of the SPCR.SPE bit.

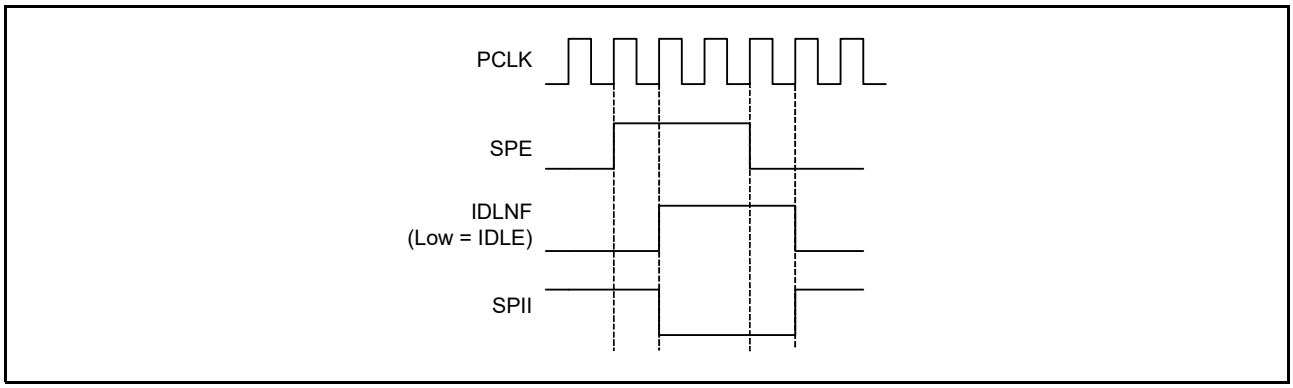

Figure 47.36 Operation Example of Idle Interrupts (Slave Mode)

47.3.9 Communication End Interrupts

47.3.9.1 Transmit-Receive Master Mode or Transmit-Only Master Mode

Refer to the description of the SPCF Flag (Communication End Flag) in section 47.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during transmit-receive master mode or transmit-only master mode.

[Motorola SPI]

Figure 47.37 shows an example of the SPCI interrupt operation during transmit-receive master mode/transmit-only master mode.

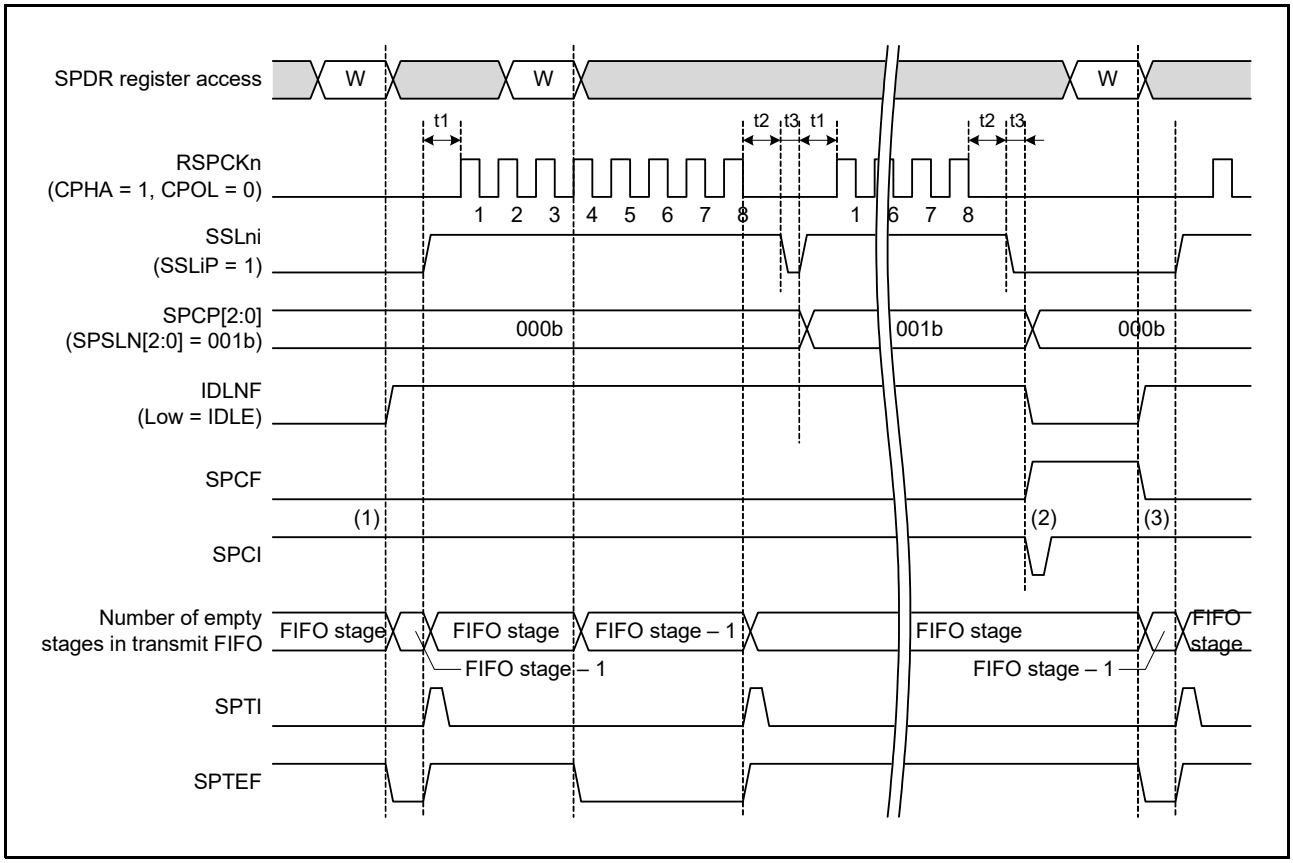

Figure 47.37 Operation Example of SPCI Interrupts (Transmit-Receive Master Mode/Transmit-Only Master Mode, Motorola SPI)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. And then the SPCI interrupt outputs with 1 PCLKA cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

[TI SSP]

Figure 47.38 shows an example of the SPCI interrupt operation during transmit-receive master mode/transmit-only master mode.

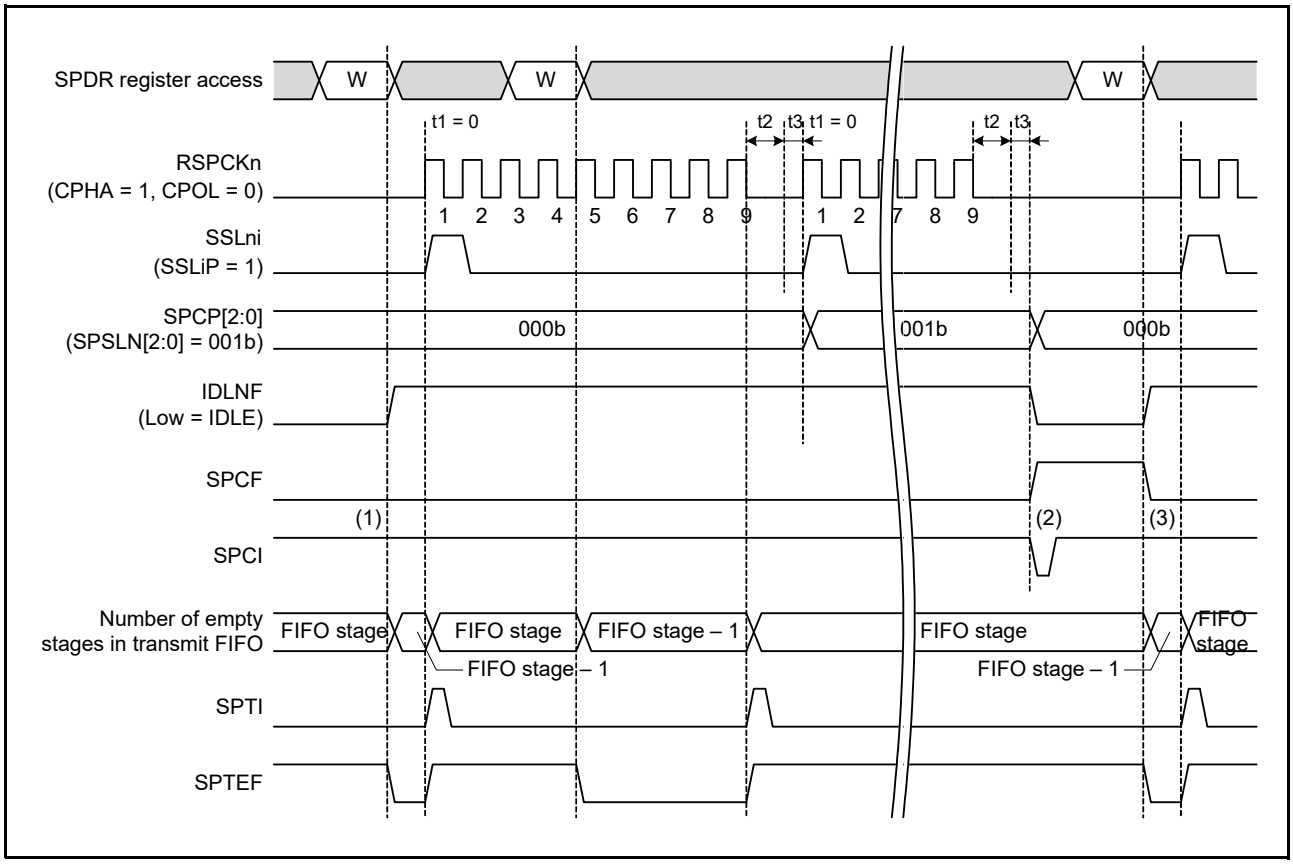

Figure 47.38 Operation Example of SPCI Interrupts (Transmit-Receive Master Mode/Transmit-Only Master Mode, TI SSP)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. And then the SPCI interrupt outputs with 1 PCLKA cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

47.3.9.2 Receive-Only Master Mode

Refer to the description of the SPCF Flag (Communication End Flag) in section 47.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during receive-only master mode.

Figure 47.39 shows an example of the SPCI interrupt operation during receive-only master mode when the SPRMCR.RFC[4:0] bits are 00000b.

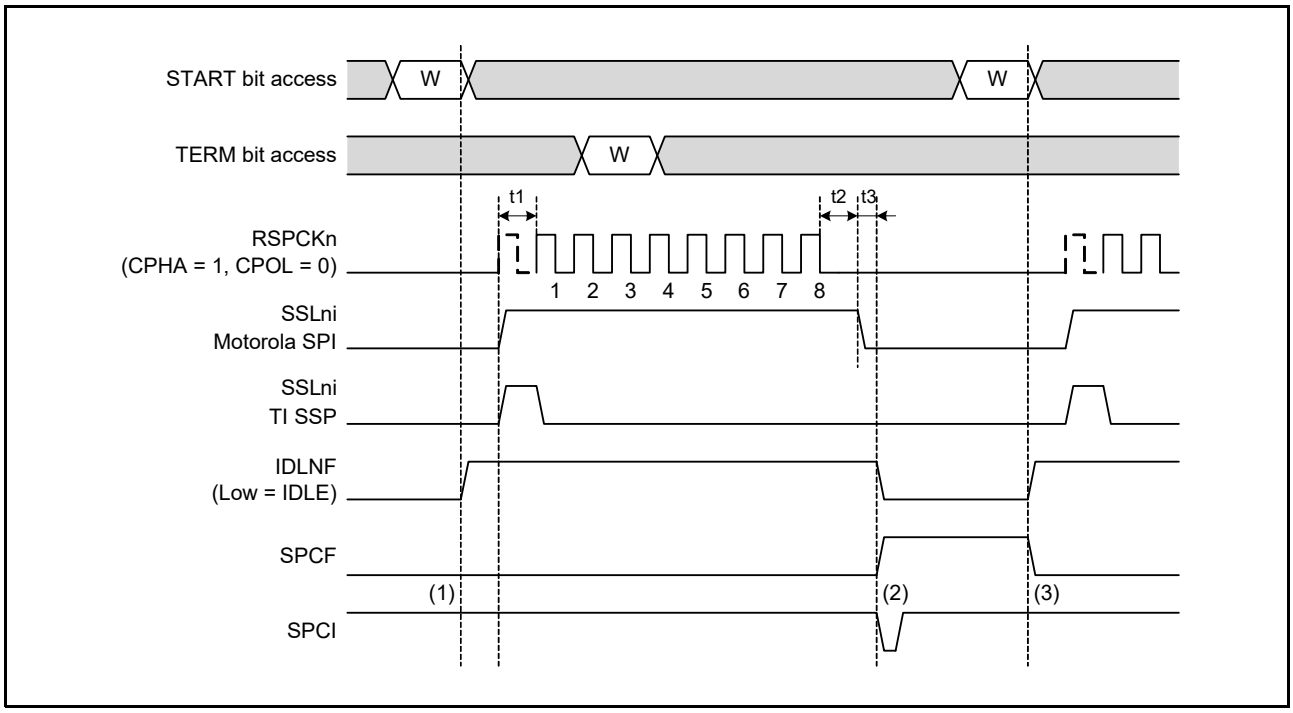

Figure 47.39 Operation Example of SPCI Interrupts (RFC[4:0] = 00000b) (Receive-Only Master Mode)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) When the SPRMCR.TERM bit is set to 1 during communication, the SPCF flag becomes 1 (communication end) at the end of t3 cycle. And then the SPCI interrupt outputs with 1 PCLKA cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when 1 is written to the SPRMCR.START bit. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

Figure 47.40 shows an example of the SPCI interrupt operation during receive-only master mode when the SPRMCR.RFC[4:0] bits are not 00000b.

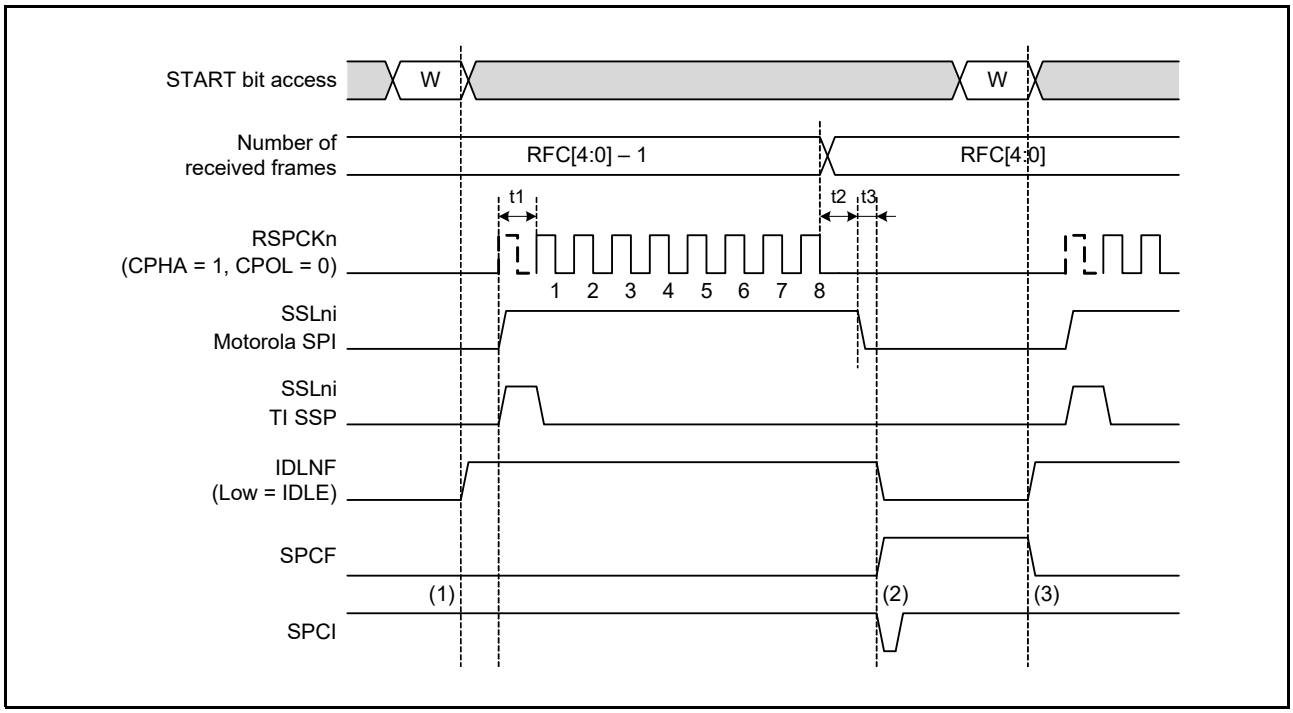

Figure 47.40 Operation Example of SPCI Interrupts (RFC[4:0] ≠ 00000b) (Receive-Only Master Mode)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the end of t3 cycle after receiving the number of frames set by the SPRMCR.RFC[4:0] bits. And then the SPCI interrupt outputs with 1 PCLKA cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when 1 is written to the SPRMCR.START bit. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

In slave mode operation, the output timing of the SPCI interrupt is different due to the value of the SPCR.SPMS bit (RSPI mode select bit). And the clear timing of the communication end interrupt is different due to the communication mode (transmit-receive, transmit-only, or receive-only).

47.3.9.3 Transmit-Receive Slave Mode or Transmit-Only Slave Mode on SPI Operation

Refer to the description of the SPCF Flag (Communication End Flag) in section 47.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during transmit-receive slave mode or transmit-only slave mode on SPI operation (4-wire method).

[Motorola SPI]

Figure 47.41 shows an example of the SPCI interrupt operation during transmit-receive slave mode/transmit-only slave mode on SPI operation.

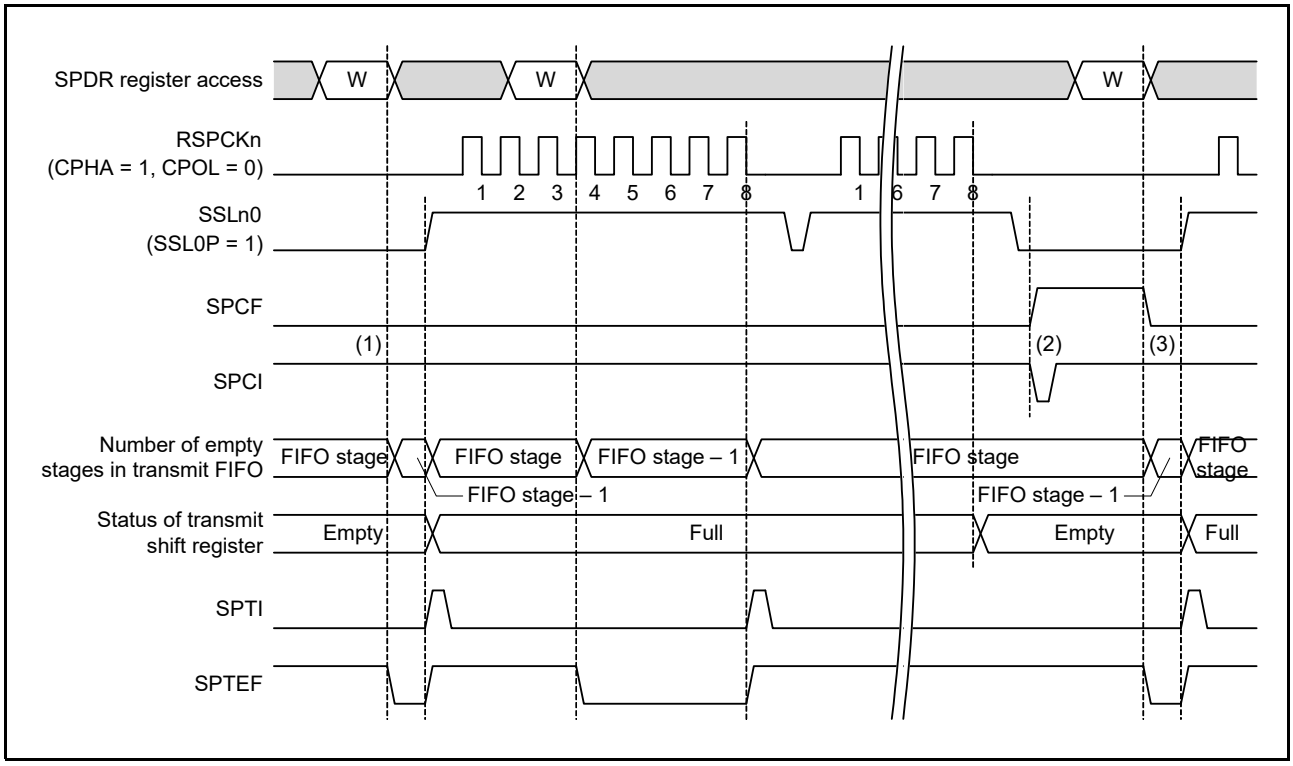

Figure 47.41 Operation Example of SPCI Interrupts (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Motorola SPI)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the timing of SSLni negation, when the next transmit data is not set in the transmit FIFO and the transmit shift register is empty. And then the SPCI interrupt outputs with 1 PCLKA cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

[TI SSP]

Figure 47.42 shows an example of the SPCI interrupt operation during transmit-receive slave mode/transmit-only slave mode on SPI operation.

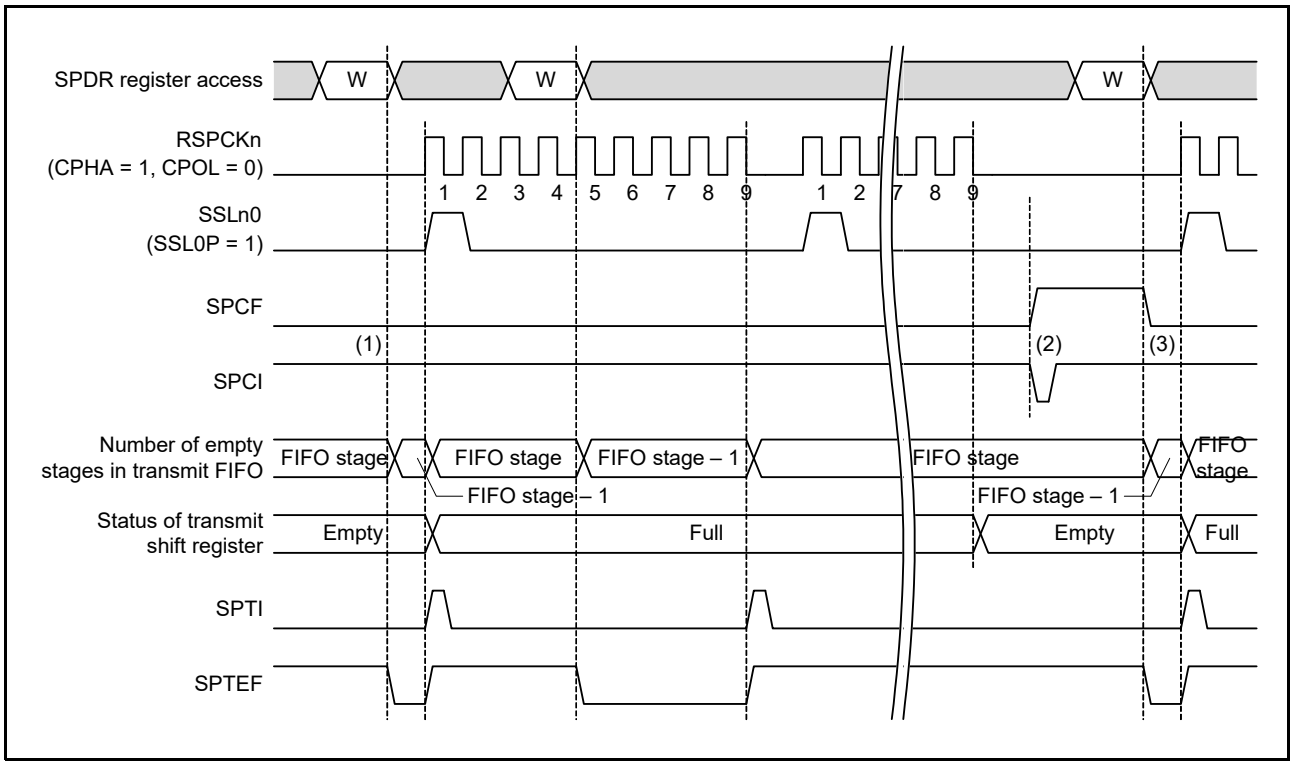

Figure 47.42 Operation Example of SPCI Interrupts (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, TI SSP)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) when the next transmit data is not set in the transmit FIFO, the transmit shift register is empty, and SSL negation delay is completed. And then the SPCI interrupt outputs with 1 PCLKA cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

47.3.9.4 Receive-Only Slave Mode on SPI Operation

Refer to the description of the SPCF Flag (Communication End Flag) in section 47.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during receive-only slave mode on SPI operation (4-wire method).

[Motorola SPI]

Figure 47.43 shows an example of the SPCI interrupt operation during receive-only slave mode on SPI operation.

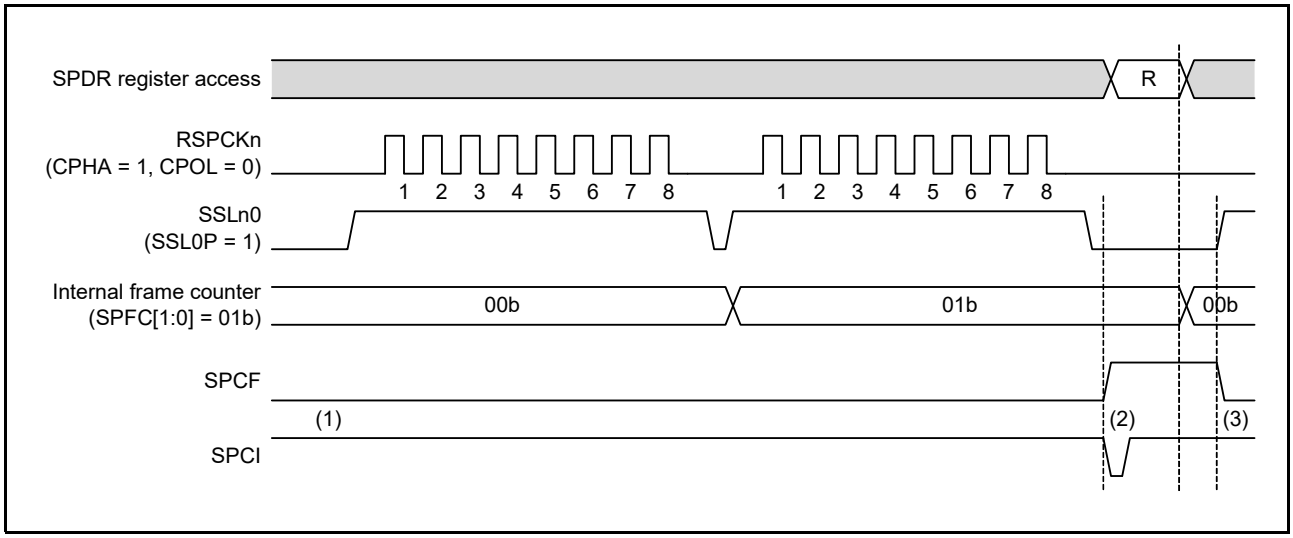

Figure 47.43 Operation Example of SPCI Interrupts (Receive-Only Slave Mode, Motorola SPI)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) After the frames of the value set in the SPDCR.SPFC[1:0] bits are stored in the receive buffer, the SPCF flag becomes 1 (communication end) at the timing of SSLn0 negation. And then the SPCI interrupt outputs with 1 PCLKA cycle width if the SPCIE bit is 1.

(3) The SPCF flag becomes 0 at the SSLn0 assertion when the next transmission start. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

[TI SSP]

Figure 47.44 shows an example of the SPCI interrupt operation during receive-only slave mode on SPI operation.

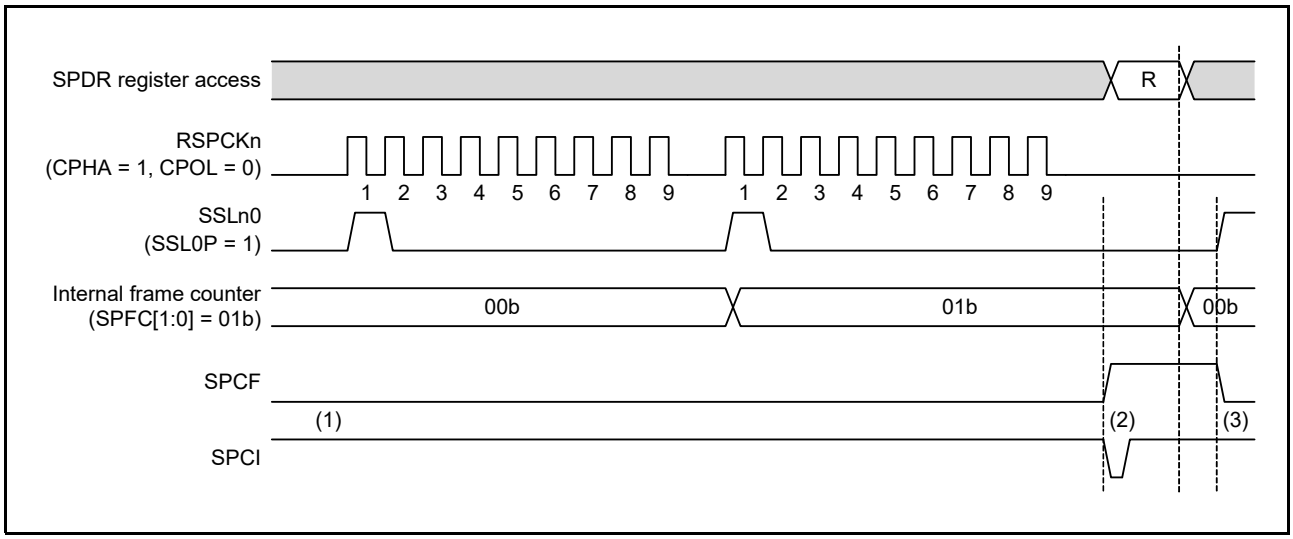

Figure 47.44 Operation Example of SPCI Interrupts (Receive-Only Slave Mode, TI SSP)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) After the frames of the value set in the SPDCR.SPFC[1:0] bits are stored in the receive buffer, the SPCF flag becomes 1 (communication end) at the timing when SSLn0 negation delay is completed. And then the SPCI interrupt outputs with 1 PCLKA cycle width if the SPCIE bit is 1.

(3) The SPCF flag becomes 0 at the SSLn0 assertion when the next transmission start. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

47.3.9.5 Transmit-Receive Slave Mode or Transmit-Only Slave Mode on Clock Synchronous Operation

Refer to the description of the SPCF Flag (Communication End Flag) in section 47.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during transmit-receive slave mode or transmit-only slave mode on clock synchronous operation (3-wire method).

Figure 47.45 shows an example of the SPCI interrupt operation during transmit-receive slave mode/transmit-only slave mode on clock synchronous operation.

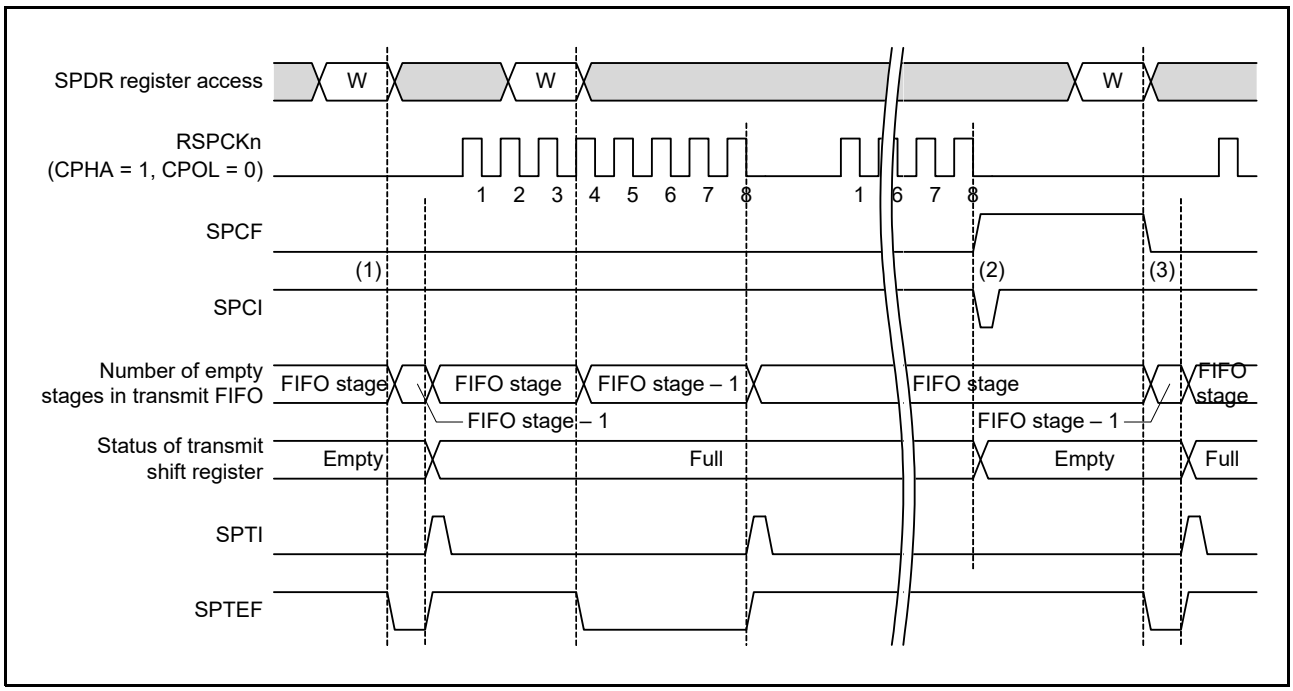

Figure 47.45 Operation Example of SPCI Interrupts (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Clock Synchronous Operation)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the sampling timing of the final data bit of RSPCKn, when the next transmit data is not set in the transmit buffer and the transmit shift register is empty. And then the SPCI interrupt outputs with 1 PCLKA cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

47.3.9.6 Receive-Only Slave Mode on Clock Synchronous Operation

Refer to the description of the SPCF Flag (Communication End Flag) in section 47.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during receive-only slave mode on clock synchronous operation (3-wire method).

Figure 47.46 shows an example of the SPCI interrupt operation during receive-only slave mode on clock synchronous operation.

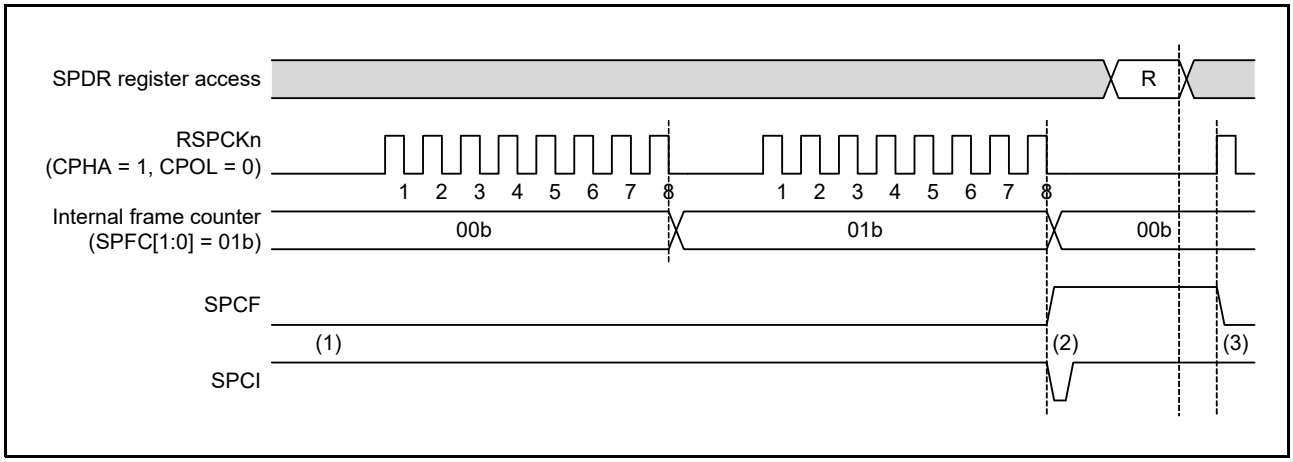

Figure 47.46 Operation Example of SPCI Interrupts (Receive-Only Slave Mode, Clock Synchronous Operation)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the sampling timing of the last data bit of RSPCKn in the last frame when the number of frames set in the SPDCR.SPFC[1:0] bits is received. And then the SPCI interrupt outputs with 1 PCLKA cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 at the first edge of RSPCKn for the next transmission. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

47.3.10 Error Detection

In the normal serial transfer of the RSPIA, the data written to the transmit buffer of SPDR is transmitted, and the received data can be read from the receive buffer of SPDR. If access is made to SPDR, depending on the status of the transmit/receive buffer or the status of the RSPIA at the beginning or end of serial transfer, in some cases non-normal transfers can be executed.

If a non-normal transfer operation occurs, the RSPIA detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 47.9 lists the relationship between non-normal transfer operations and the RSPIA's error detection function.

Table 47.9 Relationship between Non-Normal Transfer Operations and Error Detection Function of RSPIA

	Occurrence Condition	RSPI Operation	Error Detection
1	The SPDR register is written while no empty stages in the transmit FIFO.	• The contents of the transmit buffer are kept. • Missing write data.	None
2	The SPDR register is read while no empty stages in the receive FIFO.	If reception has completed, then the received data is output to the bus. Otherwise, data received previously is output instead.	None
3	Serial transfer is started in transmit-receive slave mode or transmit-only slave mode when transmit data is not ready to output.	• Serial transfer is suspended • Transmit/receive data is missing • The MISOn output signal is disabled • RSPI function is disabled	Underrun error Refer to section 47.3.10.4, Underrun Error for underrun error.
4	Serial transfer terminates when data is stored in the receive FIFO with no empty FIFO stage.	• The contents of the receive FIFO are kept • Missing receive data	Overrun error Refer to section 47.3.10.1, Overrun Error for overrun error.
5	An incorrect parity bit is received with the parity function enabled in the transmit-receive mode or receive-only mode	The parity error flag is asserted.	Parity error Refer to section 47.3.10.2, Parity Error for parity error.
6	The SSLn0 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped. • RSPI function is disabled.	Mode fault error Refer to section 47.3.10.3, Mode Fault Error for mode fault error.
7	The SSLn0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped. • RSPI function is disabled.	
8	The SSLn0 input signal is negated during serial transfer in slave mode. [Motorola SPI]	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the MISOn output signal is stopped. • RSPI function is disabled.	
9	The SSLn0 input signal is asserted during serial transfer in slave mode. [TI SSP]	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the MISOn output signal is stopped. • RSPI function is disabled.	
10	After data is stored in the receive FIFO with RDRIS = 1, the number of stored data is less than the threshold value and no receive data is written for the set value of the SPDRCSR register.	• The receive data ready flag is asserted.	Receive data ready Refer to section 47.3.11, Received Data Ready Detection for receive data ready

On operation 1 in Table 47.9, the RSPIA does not detect an error. To prevent data omission during the writing to SPDR, the SPDR register should be written when a transmit buffer empty interrupt request occurs or while the SPSR.SPTEF flag is 1.

Likewise, the RSPIA does not detect an error on operation 2. To prevent extraneous data from being read, the SPDR register should be read when a receive buffer full interrupt request occurs or while the SPSR.SPRF flag is 1.

For the transmit and receive interrupts, refer to section 47.3.7, Transmit Buffer Empty/Receive Buffer Full Interrupts.

47.3.10.1 Overrun Error

If a serial transfer ends while no empty stages in the receive FIFO, the RSPIA detects an overrun error, and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the RSPIA does not copy data from the shift register to the receive buffer so that the data prior to the occurrence of the error is retained in the receive buffer. To set the SPSR.OVRF flag to 0, issue a system reset or write 1 to the SPSCLR.OVRFC bit.

Figure 47.47 shows an example of operations of the SPSR.SPRF and OVRF flags. The SPSCLR register access and SPDR register access shown in Figure 47.47 indicate the condition of accesses to SPSCLR and SPDR, respectively, where W denotes a write cycle, and R a read cycle. In the example in Figure 47.47, the RSPIA performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKn waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

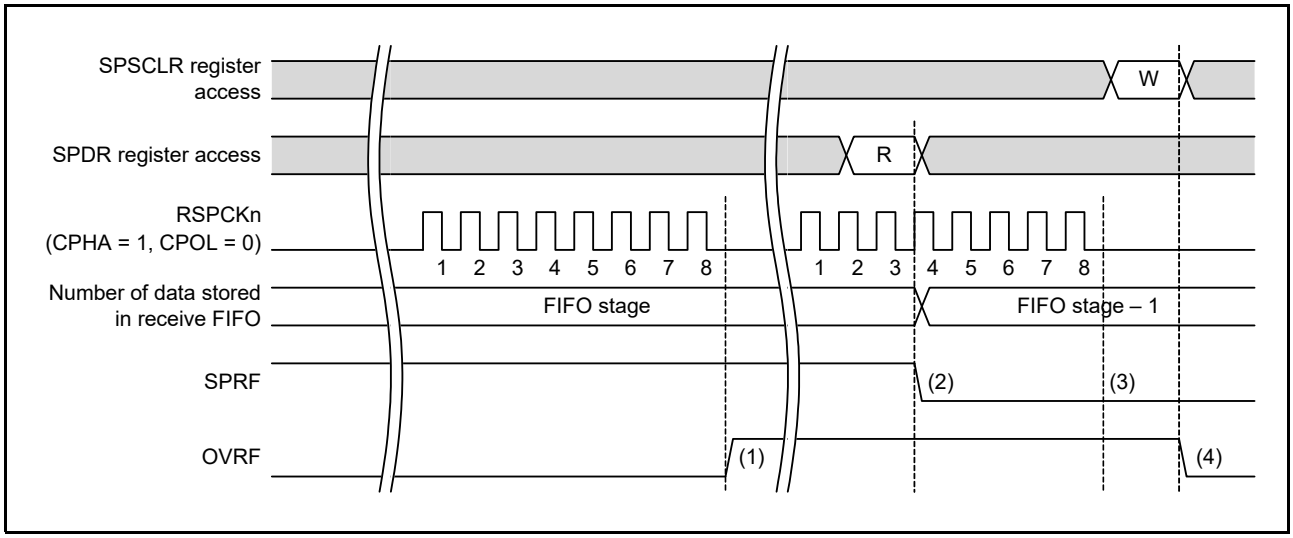

Figure 47.47 Operation Example of SPRF and OVRF Flags

The operation of the flags at the timing shown in steps (1) to (4) in the figure is described below.

(1) If a serial transfer terminates while no empty stages in the receive FIFO, the RSPIA detects an overrun error, and sets the OVRF flag to 1. The RSPIA does not copy the data in the shift register to the receive buffer. Even if the SPPE bit is 1, parity errors are not detected. In master mode, the RSPIA copies the pointer value to SPCMDm register to the SPSSR.SPECM[2:0] bits.

(2) When SPDR is read, the RSPIA outputs the data in the receive buffer. At this time the SPRF flag becomes 0 at the last access when the received data is read from the SPDR register in one processing routine using DTC/DMAC. Even if the receive buffer becomes empty, the OVRF flag does not become 0.

(3) If the serial transfer ends with the OVRF flag being 1 (an overrun error occurs), the RSPIA does not copy the data in the shift register to the receive buffer (the SPRF flag remains 0). A receive buffer full interrupt is not generated. Even if the SPPE bit is 1, parity errors are not detected. When in master mode, the RSPIA does not update the SPSSR.SPECM[2:0] bits. When in an overrun error state and the RSPIA does not copy the received data from the shift register to the receive buffer, upon termination of the serial transfer, the RSPIA determines that the shift register is empty; in this manner, data transfer from the transmit buffer to the shift register is enabled.

(4) When 1 is written to the SPSCLR.OVRFC bit, the OVRF flag is set to 0.

The occurrence of an overrun can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. When executing a serial transfer without using an error interrupt, measures should be taken to ensure the early detection of overrun errors, such as reading the SPSR register immediately after SPDR is read. When the RSPIA is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits. If an overrun error occurs and the OVRF flag is set to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. Figure 47.48 and Figure 47.49 show the clock stop waveform when a serial transfer continues while no empty stages in the receive FIFO in master mode.

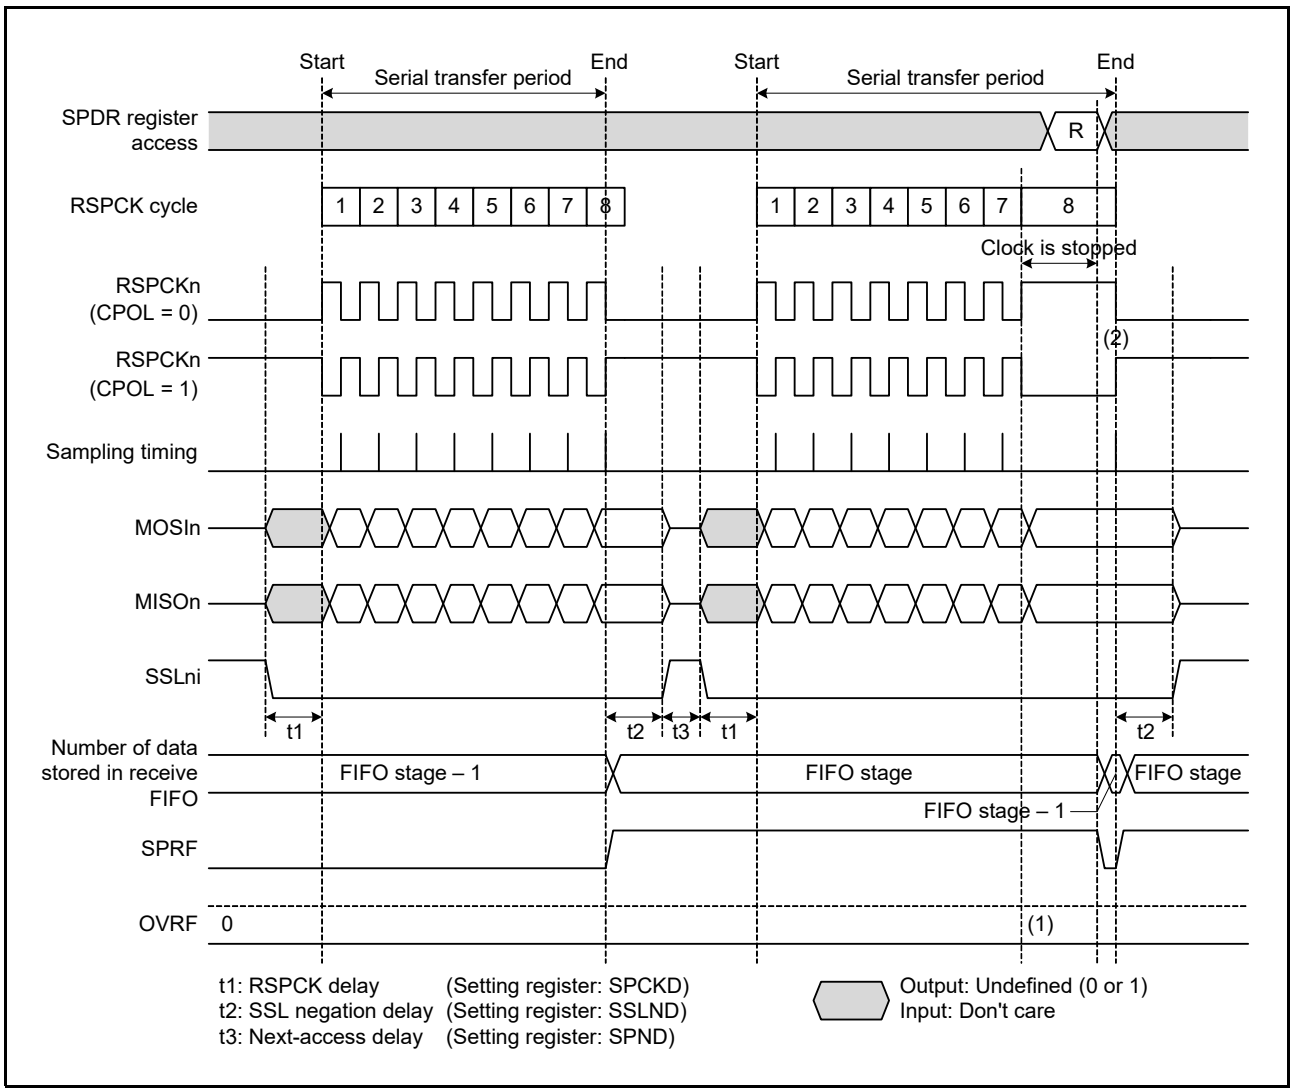

Figure 47.48 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (CPHA = 1)

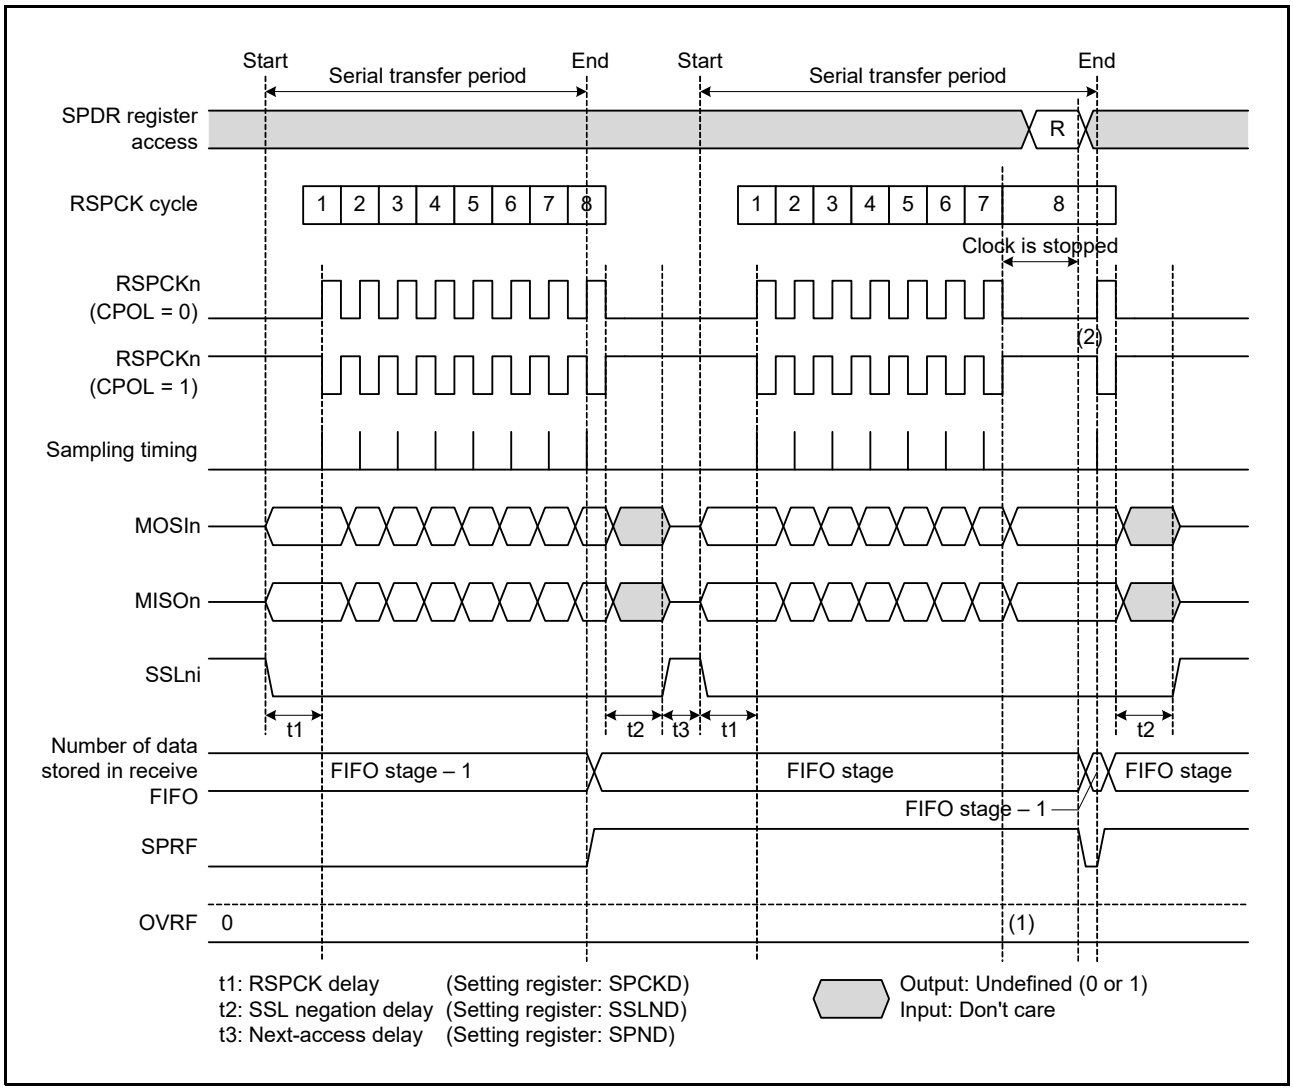

Figure 47.49 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (CPHA = 0)

The operation of the flags at the timings shown in steps (1) and (2) in the figure is described below.

(1) When no empty stages in the receive FIFO, an overrun error does not occur because the RSPCKn is stopped.

(2) If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCKn restarts after reading the receive buffer.

When the RSPCK auto-stop function is enabled for transfer with no delay of between frames during burst transfer in master mode, an overrun error does not occur. Figure 47.50 and Figure 47.51 show the clock stop waveform when there is no delay between frames during burst transfer and a serial transfer continues while no empty stages in the receive FIFO in master mode.

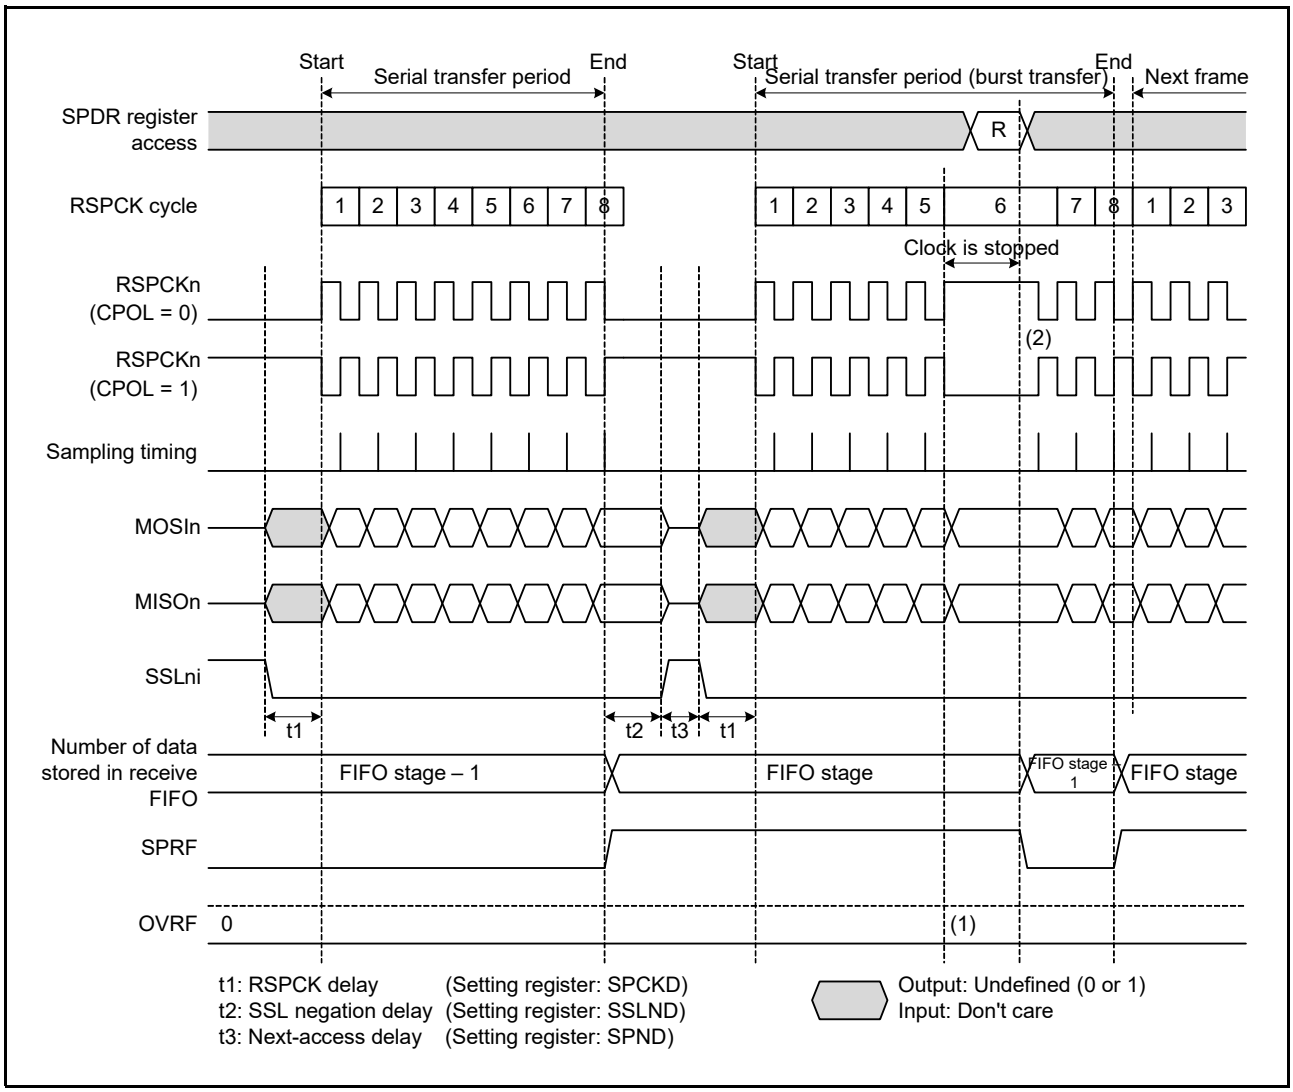

Figure 47.50 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (No Delay between Frames at Burst Transfer, CPHA = 1)

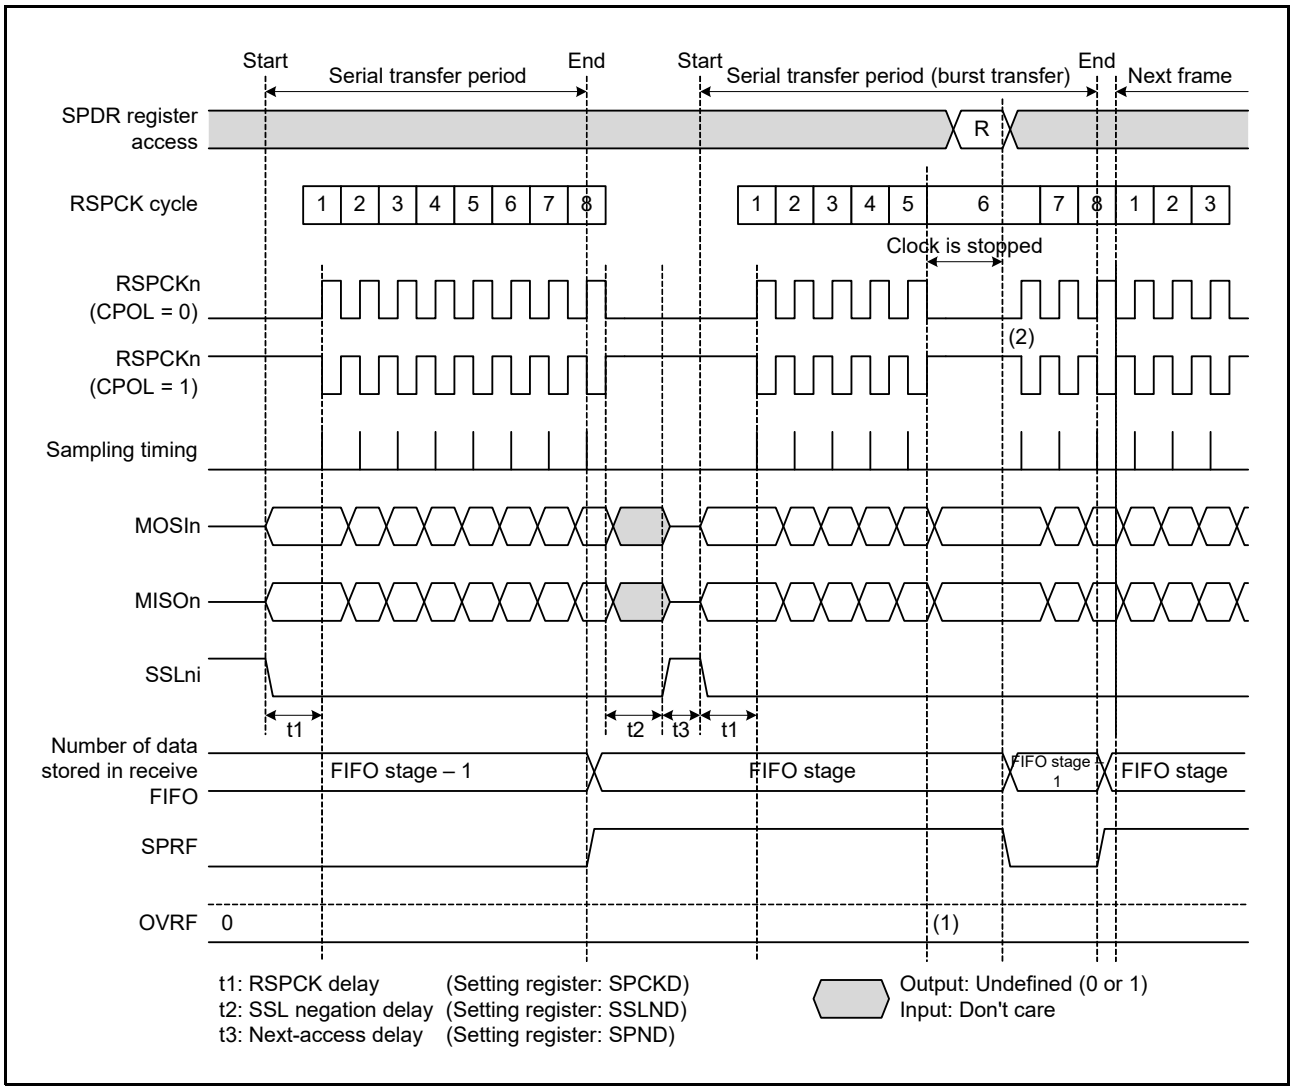

Figure 47.51 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (No Delay between Frames at Burst Transfer, CPHA = 0)

The operation of the flags at the timings shown in steps (1) and (2) in the figure is described below.

(1) When no empty stages in the receive FIFO, an overrun error does not occur because the RSPCKn is stopped.

(2) If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCKn restarts after reading the receive buffer.

47.3.10.2 Parity Error

If the SPCR.SPPE bit set to 1, when serial transfer in transmit-receive mode or receive-only mode terminates, the RSPIA checks whether there are parity errors. Upon detecting a parity error in the received data, the RSPIA sets the SPSR.PERF flag to 1. Since the RSPIA does not copy the data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, issue a system reset or write 1 to the SPSCLR.PERFC bit.

Figure 47.52 shows an example of operation of the OVRF and PERF flags. The SPSCLR register access shown in Figure 47.52 indicates the condition of access to SPSCLR register, where W denotes a write cycle. In the example of Figure 47.52, serial communications is performed while the SPCR.SPPE bit is 1. The RSPIA performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKn waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

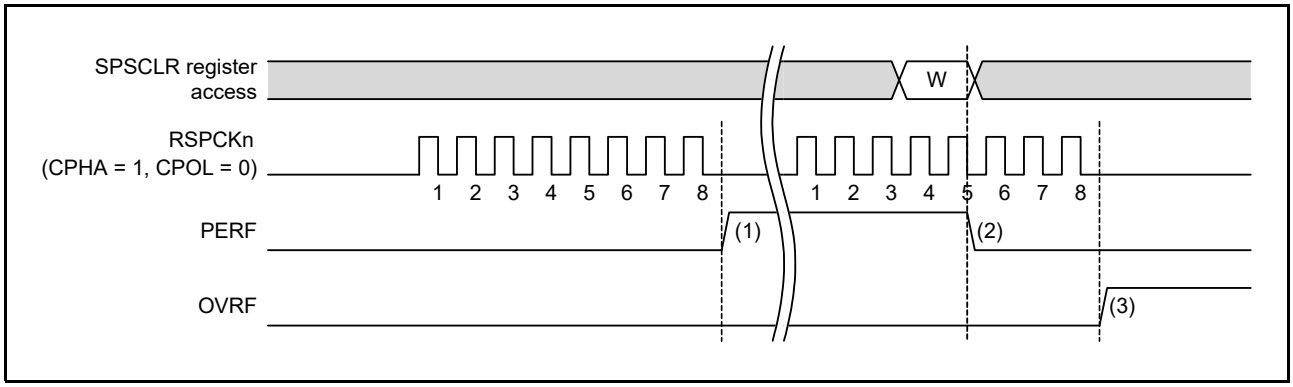

Figure 47.52 Operation Example of PERF Flag

The operation of the flags at the timing shown in steps (1) to (3) in the figure is described below.

(1) If a serial transfer terminates with the RSPIA not detecting an overrun error, the RSPIA copies the data in the shift register to the receive buffer. The RSPIA judges the received data at this timing, and sets the PERF flag to 1 if a parity error is detected. In master mode, the RSPIA copies the pointer value to SPCMDm register to the SPSSR.SPECM[2:0] bits.

(2) When 1 is written to the SPSCLR.PERFC bit, the PERF flag is set to 0.

(3) When the RSPIA detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The RSPIA does not perform parity error detection at this timing.

The occurrence of a parity error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. To use an error interrupt, set the SPCR.SPEIE bit to 1. When executing a serial transfer without using an error interrupt, measures should be taken to ensure the early detection of parity errors, such as reading the SPSR register. When the RSPIA is used in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

47.3.10.3 Mode Fault Error

The RSPIA operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input with respect to the SSLn0 input signal of the RSPIA in multi-master mode, the RSPIA detects a mode fault error irrespective of the status of the serial transfer, and sets the SPSR.MODF flag to 1. Upon detecting the mode fault error, the RSPIA copies the value of the pointer to SPCMDm to the SPSSR.SPECM[2:0] bits. The active level of the SSLn0 signal is determined by the SSLP.SSL0P bit.
When the MSTR bit is 0, the RSPIA operates in slave mode. The RSPIA detects a mode fault error if the MODFEN bit of the RSPIA in slave mode is 1, and the SPMS bit is 0, and the following conditions are satisfied during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

- In the Motorola SPI protocol, when the SSLn0 input signal is negated during the serial transfer period
- In the TI SSP protocol, when the SSLn0 input signal is asserted during the serial transfer period
  However, during a burst transfer, no error is detected even if the SSLn0 input signal is asserted during the last bit of frame.

Upon detecting a mode fault error, the RSPIA stops driving of the output signals and sets the SPCR.SPE bit to 0. When the SPE bit is cleared, the RSPI function is disabled (refer to section 47.3.12, Initializing RSPIA). In the case of multi-master configuration, detection of a mode fault error is used to stop driving of the output signals and the RSPI function, which allows the master right to be released.
The occurrence of a mode fault error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. Detecting mode fault errors without utilizing the error interrupt requires polling of the SPSR register. When using the RSPIA in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.
When the MODF flag is set to 1, writing 1 to the SPE bit is ignored. To enable the RSPI function after a mode fault error has been detected, clear the MODF flag and then set the SPE bit to 1.

47.3.10.4 Underrun Error

If RSPIA operates in slave mode (the SPCR.MSTR bit is 0) and the communication mode select bits (CMMD[1:0]) in the RSPI control register (SPCR) is set to 00b or 01b, when serial transfer is started before transmit data output is ready with the SPCR.SPE bit is 1 (RSPI function is enabled), the RSPIA detects an underrun error, and sets the SPSR.MODF and SPSR.UDRF flags to 1.
Upon detecting an underrun error, the RSPIA stops driving of the output signals and sets the SPCR.SPE bit to 0. Clearing of the SPE bit disables the RSPI function. (Refer to section 47.3.12, Initializing RSPIA).
The occurrence of an underrun error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. Detecting underrun errors without utilizing the error interrupt requires polling of the SPSR register.
When the MODF flag is set to 1, writing 1 to the SPE bit is ignored. To enable the RSPI function after an underrun error has been detected, clear both the MODF and UDRF flags simultaneously, and then set the SPE bit to 1.

47.3.11 Received Data Ready Detection

When the SPCR.CMMD[1:0] bits are 00b, 01b or 11b, and the value of the SPDRCSR register is not 00h, after receiving data in the receive FIFO during communication (SPE = 1), the SPSR.RRDYF flag is set to 1 when the received data is not stored even after the number of received FIFOs is equal to or less than the threshold value and the value set in the SPDRCSR register has elapsed.

When the receive data ready is detected, the interrupt and event link output can be selected as SPRI or SPEI with the SPCR.RDRIS bit.

Figure 47.53 shows an example of received data ready detection operation.

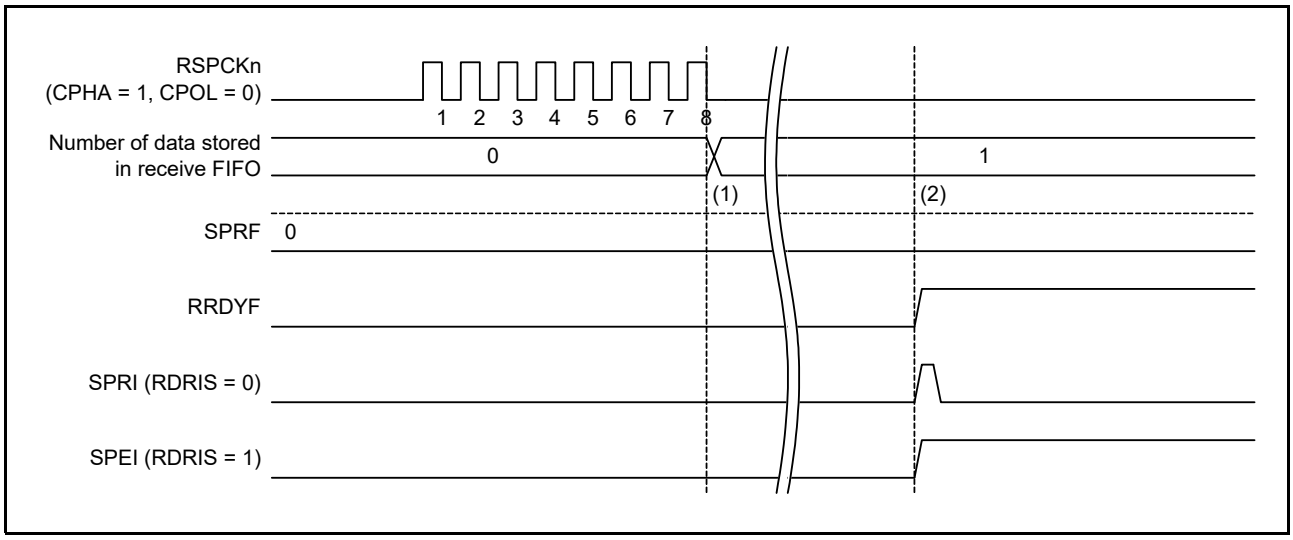

Figure 47.53 Received Data Ready Detection

The operation at the timing shown in steps (1) and (2) in the figure is described below.

(1) Store the received data to the receive FIFO. The SPSR.SPRF flag is 0, because the number of data stored in the receive FIFO is equal to or less than the value of the SPFCR.RTRG[1:0] bits.

(2) Set the RRDYF flag and assert SPRI or SPEI because data is not written to the receive FIFO for the value of the SPDRCSR register from (1).

47.3.12 Initializing RSPIA

If 0 is written to the SPCR.SPE bit or the RSPIA sets the SPE bit to 0 because of the detection of a mode fault error or an underrun error, the RSPIA disables the RSPI function, and initializes some of the module functions. When a system reset is generated, the RSPIA initializes all of the module functions. The following describes initialization by the clearing of the SPCR.SPE bit and initialization by a system reset.

47.3.12.1 Initialization by Clearing the SPE Bit

When the SPCR.SPE bit is set to 0, the RSPIA performs the following initialization:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the RSPIA
- Set the SPSR.SPTEF flag to 1

Initialization by the clearing of the SPE bit does not initialize the control bits of the RSPIA. For this reason, the RSPIA can be started in the same transfer mode as prior to the initialization if the SPE bit is set to 1 again.
The SPSR.SPCF, SPRF, OVRF, MODF, PERF, and UDRF flags are not initialized, nor is the value of the RSPI sequence status register (SPSSR) initialized. For this reason, even after the RSPIA is initialized, data from the receive buffer, the communication end status, and the error status during RSPI transfer can be read to check them.
The SPSR.SPTEF flag is initialized to 1. Therefore, if the SPCR.SPTIE bit is set to 1 after RSPIA initialization, a transmit buffer empty interrupt is generated. When the CPU initializes the RSPIA, in order to disable any transmit buffer empty interrupt, 0 should be written to the SPTIE bit simultaneously with the writing of 0 to the SPE bit.

47.3.12.2 System Reset

The initialization by a system reset completely initializes the RSPIA through the initialization of all bits for controlling the RSPIA, initialization of the status bits, and initialization of data registers, in addition to the requirements described in section 47.3.12.1, Initialization by Clearing the SPE Bit.

47.3.13 SPI Operation

47.3.13.1 Master Mode Operation

The only difference between single-master mode operation and multi-master mode operation lies in mode fault error detection (refer to section 47.3.10, Error Detection). When operating in single-master mode, the RSPIA does not detect mode fault errors whereas the RSPIA running in multi-master mode does detect mode fault errors. This section explains operations that are common to single-master mode and multi-master mode.

(1) Starting a Serial Transfer

The RSPIA updates the data in the transmit buffer (SPTXn, n = 0 to 3) when data is written to the RSPI data register (SPDR) with the transmit buffer being empty (data for the next transfer is not set). When the shift register is empty the RSPIA copies data from the transmit buffer to the shift register and starts serial transfer. Upon copying transmit data to the shift register, the RSPIA changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 47.3.5, Transfer Format (Frame Format). The polarity of the SSLni output pins depends on the SSLP register settings.

(2) Terminating a Serial Transfer

[Except receive-only operation in master mode]
Irrespective of the SPCMDm.CPHA bit, the RSPIA terminates the serial transfer after transmitting an RSPCKn edge corresponding to the final sampling timing. If the number of data stored in the receive FIFO is less than the number of FIFO stages, after the termination of serial transfer, the RSPIA copies data from the shift register to the receive buffer of the SPDR register.
It should be noted that the final sampling timing varies depending on the bit length of transmit data. In master mode, the RSPI data length depends on the SPCMDm.SPB[4:0] bits setting. The polarity of the SSLni output pin depends on the SSLP register settings.
For details on the RSPI transfer format, refer to section 47.3.5, Transfer Format (Frame Format).

[Receive-only operation in master mode]
The RSPIA terminates the serial transfer when any of the following conditions is satisfied.

- After the RSPIA detects the RSPCKn edge corresponding to the final sampling timing irrespective of the SPCMDm.CPHA bit
- When writing 1 to the SPRMCR.TERM bit during the serial transfer period

If the number of data stored in the receive FIFO is less the number of FIFO stages, after termination of serial transfer, the RSPIA copies data from the shift register to the receive buffer of the SPDR register.
It should be noted that the final sampling timing varies depending on the bit length of transmit data. In master mode, the RSPI data length depends on the SPCMDm.SPB[4:0] bits setting. The polarity of the SSLni output pin depends on the SSLP register settings.
For details on the RSPI transfer format, refer to section 47.3.5, Transfer Format (Frame Format).

(3) Sequence Control

The transfer format that is employed in master mode is determined by the following registers.

- RSPI sequence control register (SPSCR)
- RSPI command register m (SPCMDm) (m = 0 to 7)
- RSPI bit rate register (SPBR)
- RSPI clock delay register (SPCKD)
- RSPI slave select negation delay register (SSLND)
- RSPI next-access delay register (SPND)

SPSCR is a register used to determine the sequence configuration for serial transfers that are executed by the RSPIA in master mode. The following items are set in the SPCMDm register: SSLni pin output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. The SPBR register holds some of the bit rate settings; the SPCKD register, an RSPI clock delay value; the SSLND register, an SSL negation delay; and the SPND register, a next-access delay value.

According to the sequence length that is assigned to the SPSCR register, the RSPIA makes up a sequence comprised of a part or all of the SPCMDm register. The RSPIA contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPIA loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The RSPIA increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPIA sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

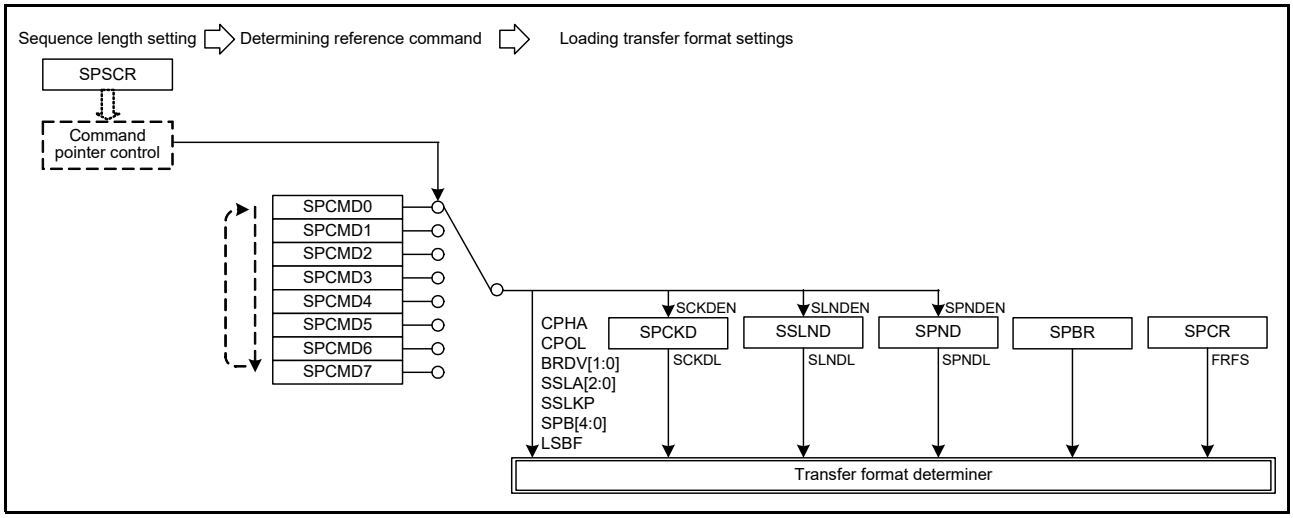

Figure 47.54 Procedure for Determining the Form of Serial Transfer in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

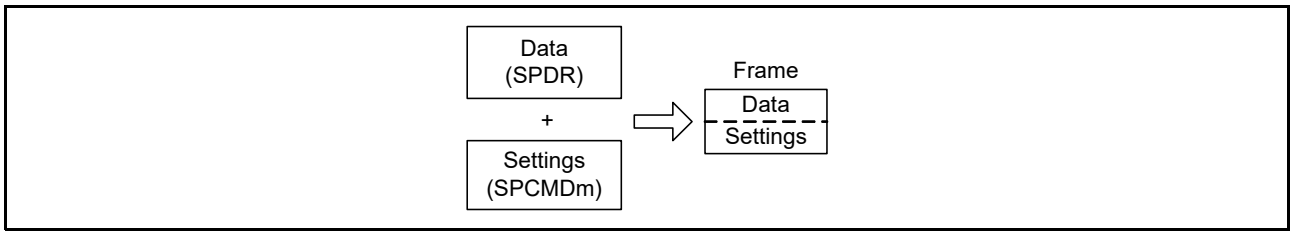

Figure 47.55 Concept of a Frame

Figure 47.56 shows the relationship between the command and the transmit buffer (SPTXn, n = 0 to 3) and receive buffer (SPRXn, n = 0 to 3) in sequence operations.

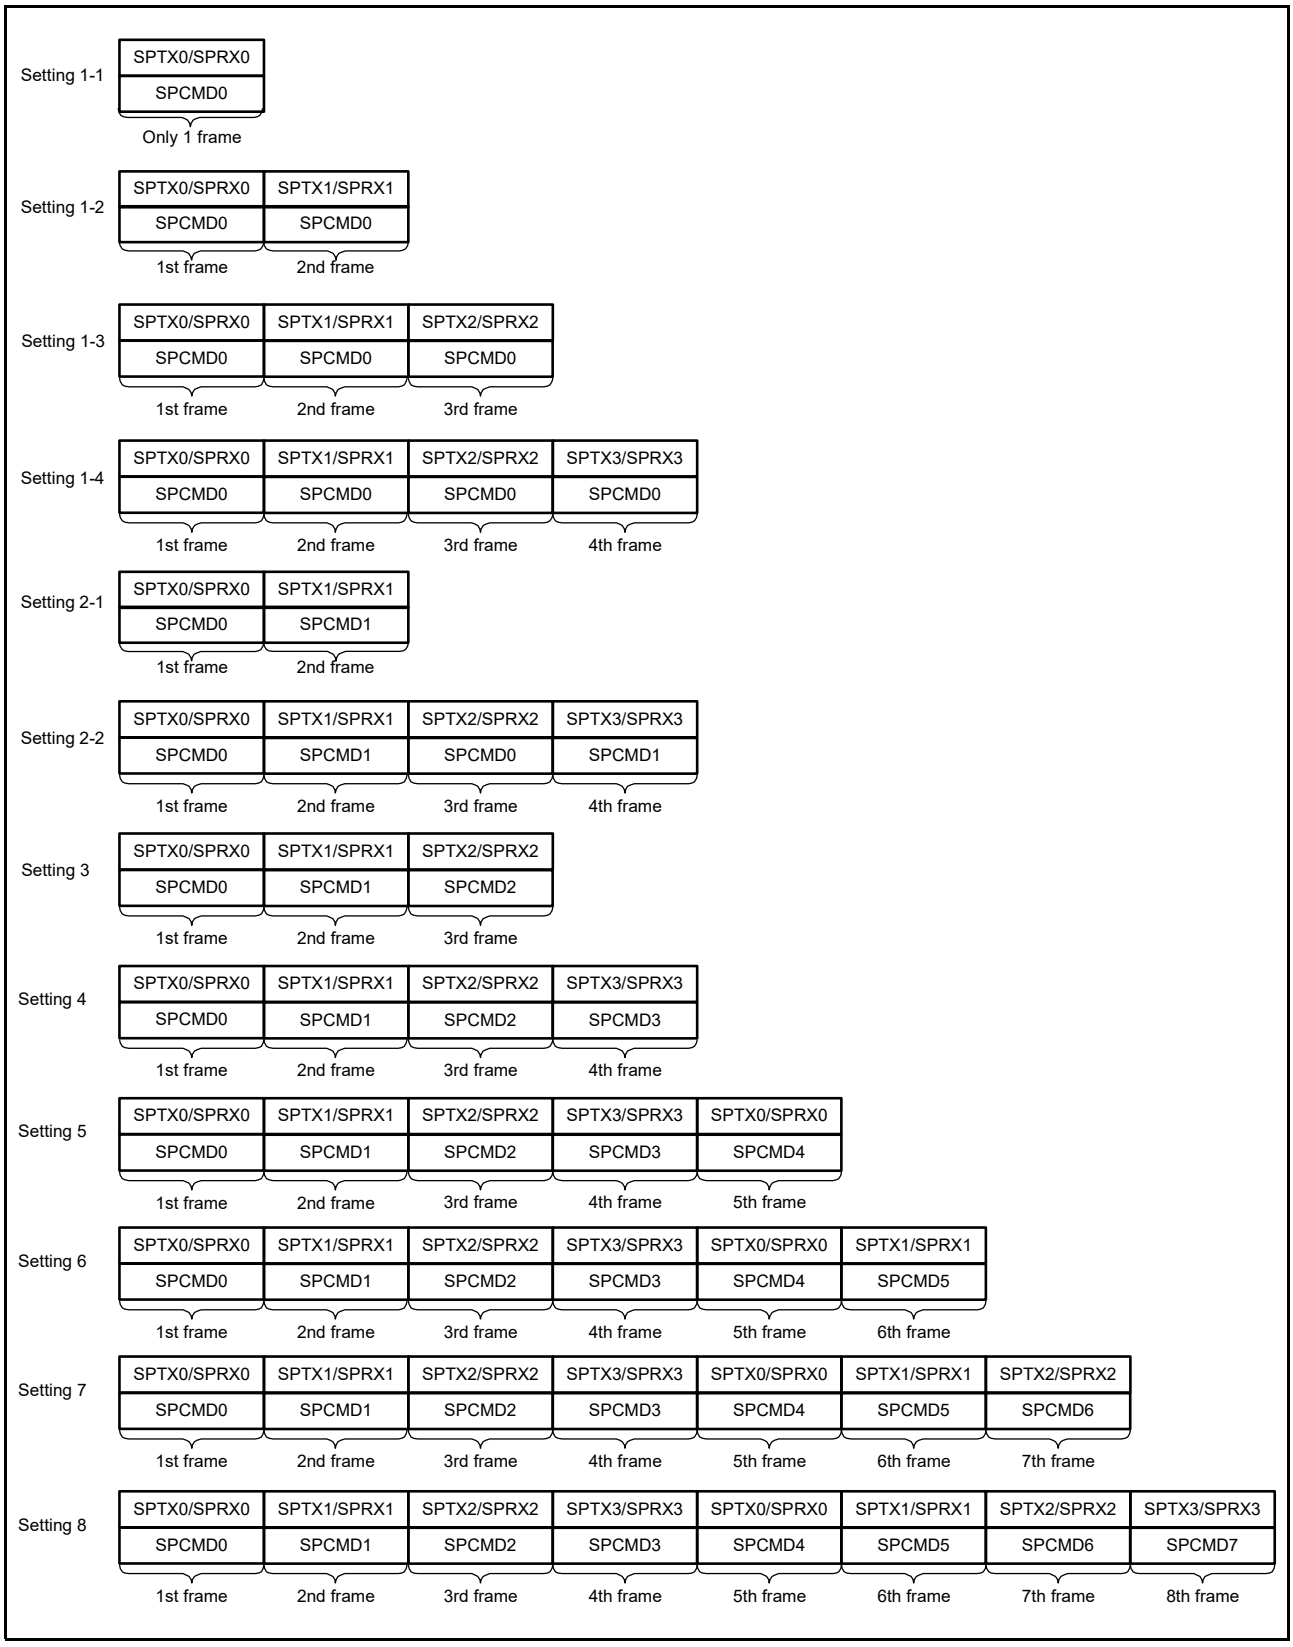

Figure 47.56 Correspondence between the RSPI Command Register m and Transmit/Receive Buffers in Sequence Operations

(4) Burst Transfer

[Motorola SPI]

If the SPCMDm.SSLKP bit that the RSPIA references during the current serial transfer is 1, the RSPIA keeps the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the RSPIA can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

- When the SPCR.SCKDDIS bit (RSPCK delay between data bytes disable bit) is 0

Figure 47.57 shows an example of an SSLni signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (8) as shown in Figure 47.57. It should be noted that the polarity of the SSLni output signal depends on the SSLP register settings.

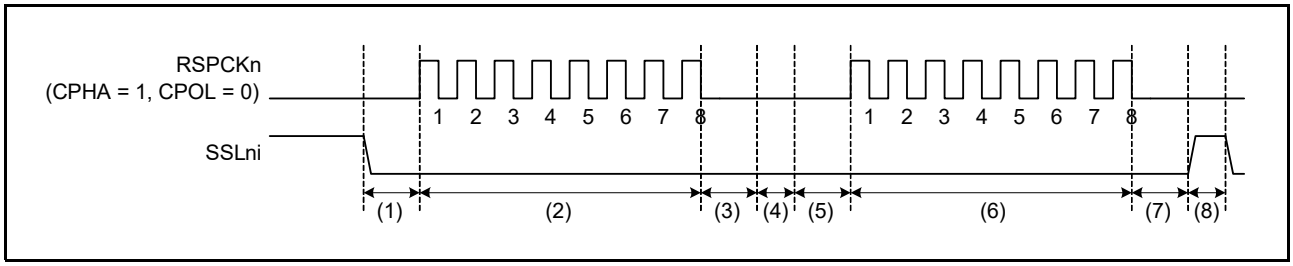

Figure 47.57 Example of Burst Transfer Operation Using SSLKP Bit (SCKDDIS = 0, FRFS = 0)

(1) Based on SPCMD0, the RSPIA asserts the SSLni signal and inserts RSPCK delays.
(2) The RSPIA executes serial transfers according to SPCMD0.
(3) The RSPIA inserts SSL negation delays.
(4) In transmit-receive mode or transmit-only mode, since the SPCMD0.SSLKP bit is 1, the RSPIA keeps the SSLni signal value on SPCMD0. This period is sustained, at the shortest, for a period equal to the next-access delay of SPCMD0 and additional 5 TCLK cycles. If the shift register is empty after the passage of a minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
In receive-only mode, since the SPCMD0.SSLKP bit is 1, the RSPIA keeps the SSLni signal value on SPCMD0. This period is sustained for a period equal to the next-access delay of SPCMD0 and additional 5 TCLK cycles.
(5) Based on SPCMD1, the RSPIA asserts the SSLni signal and inserts RSPCK delays.
(6) The RSPIA executes serial transfers according to SPCMD1.
(7) The RSPIA inserts SSL negation delays.
(8) Since the SPCMD1.SSLKP bit is 0, the RSPIA negates the SSLni signal. In addition, a next-access delay is inserted according to SPCMD1.

Note: If the SSLni signal output settings in the SPCMDm register in which 1 is assigned to the SSLKP bit (to use for burst transfer) are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the RSPIA switches the SSLni signal status to SSLni signal assertion ((5) in Figure 47.57) corresponding to the command for the next transfer. Note that if such an SSLni signal switching occurs, the slaves that drive the MISOn signal compete, and collision of signal levels may occur.

The RSPIA in master mode references the SSLni signal operation within the module for the case where the SSLKP bit is not used. Even when the SPCMDm.CPHA bit is 0, the RSPIA can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally. For this reason, burst transfer in master mode is enabled regardless of the CPHA bit setting. (Refer to section 47.3.13, SPI Operation.)

- When the SPCR.SCKDDIS bit (RSPCK delay between data bytes disable bit) is 1

Figure 47.58 shows an example of an SSLni signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (6) as shown in Figure 47.58. It should be noted that the polarity of the SSLni output signal depends on the SSLP register settings.

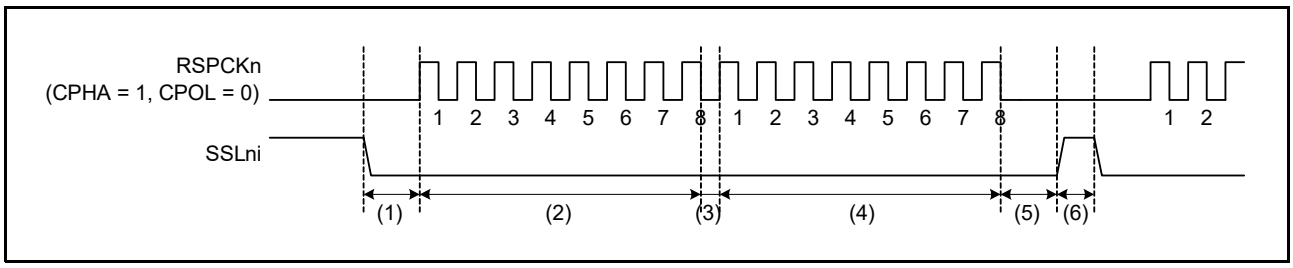

Figure 47.58 Example of Burst Transfer Operation Using SSLKP Bit (SCKDDIS = 1, FRFS = 0)

(1) Based on the SPCMD0 register, the RSPIA asserts the SSLni signal and inserts RSPCK delays.
The RSPCK delay is inserted only the first frame of burst transfer.

(2) In transmit-receive mode or transmit-only mode, the RSPIA executes serial transfers according to the SPCMD0 register. The RSPIA waits for the last clock output until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
In receive-only mode, the RSPIA executes serial transfers according to the SPCMD0 register.

(3) In transmit-receive mode or transmit-only mode, since the SPCMD0.SSLKP bit is 1, the RSPIA keeps the SSLni signal value on the SPCMD0 register. If the shift register is not empty, RSPCK negate period between frames is 0.5 RSPCK.
In receive-only mode, since it is not the last frame*1, the RSPIA keeps the SSLni signal value on the SPCMD0 register. RSPCK negate period between frames is 0.5 RSPCK.

(4) The RSPIA executes serial transfers according to the SPCMD1 register.

(5) The RSPIA inserts SSL negation delays.

(6) In transmit-receive mode or transmit-only mode, since the SPCMD1.SSLKP bit is 0, the RSPIA negates the SSLni signal. In addition, a next-access delay is inserted according to the SPCMD1 register.
In receive-only mode, the RSPIA negates the SSLni signal. In addition, a next-access delay is inserted according to the SPCMD1 register.

Note 1. In receive-only mode, the last frame is a frame set by the SPRMCR.RFC[4:0] bits when SPRMCR.RFC[4:0] ≠ 00000b or a frame in which SPRMCR.TERM = 1 has been accepted.

[TI SSP]
The RSPIA asserts the SSLni signal for one cycle at the start of serial transfer.
The RSPIA can execute continuous serial transfers by asserting the SSLni signal for one cycle at the start of serial transfer (burst transfer).

- When the SPCMDm.SSLKP bit (SSL signal level keeping bit) is 1, and the SPCR.SCKDDIS bit (RSPCK delay between data bytes disable bit) is 1

Figure 47.59 shows an example of an SSLni signal operation and the serial data MISOn/MOSIn for the case where a burst transfer is implemented using the SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (6) as shown in Figure 47.59. It should be noted that the polarity of the SSLni output signal depends on the SSLP register settings.

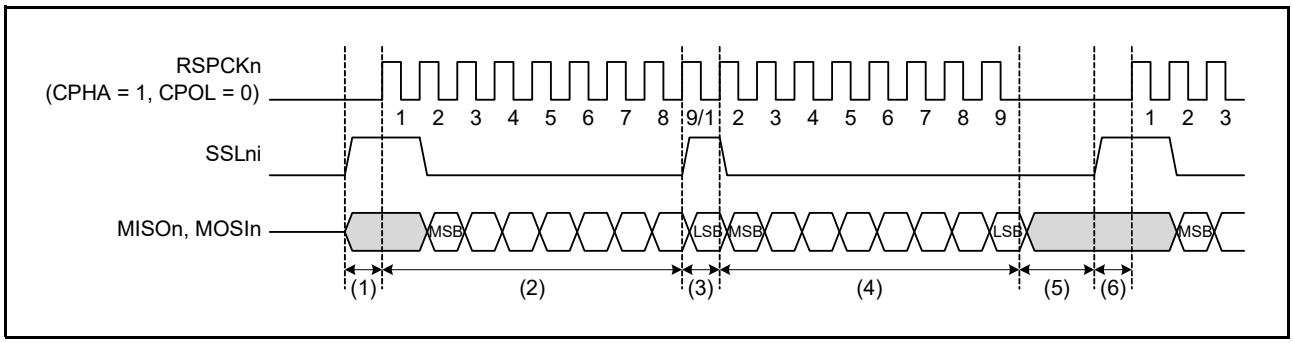

Figure 47.59 Example of Burst Transfer Operation (FRFS = 1)

(1) Based on the SPCMD0 register, the RSPIA asserts the SSLni signal and inserts RSPCK delays.
The RSPCK delay is inserted only the first frame of burst transfer.
(2) The RSPIA executes serial transfers according to the SPCMD0 register.
(3) Final data transfer and the SSLni assertion are performed simultaneously.
During transmit-receive/transmit-only operation, the RSPIA waits for the last clock output until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
(4) The RSPIA executes serial transfers according to the SPCMD1 register.
(5) The RSPIA inserts SSLni negation delays at the last frame*1.
(6) A next-access delay is inserted according to the SPCMD1 register.

Note 1. In receive-only mode, the last frame is a frame set by the SPRMCR.RFC[4:0] bits when SPRMCR.RFC[4:0] ≠ 00000b or a frame in which SPRMCR.TERM = 1 has been accepted.
Note: If the SSLni signal output settings in the SPCMDm register in which 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the RSPIA switches the SSLni signal status to SSLni signal assertion ((5) in Figure 47.59) corresponding to the command for the next transfer. Note that if such an SSLni signal switching occurs, the slaves that drive the MISOn signal compete, and collision of signal levels may occur.

(5) RSPCK Delay (t1)

The RSPCK delay value of the RSPIA in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD register setting. The RSPIA determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an RSPCK delay value during serial transfer by using the SPCMDm.SCKDEN bit and the SPCKD.SCKDL[2:0] bits, as listed in Table 47.10. For a definition of RSPCK delay, refer to section 47.3.5, Transfer Format (Frame Format).

The RSPCK delay is inserted only the first frame of burst transfer when data transfer is performed without delay between frames in burst transfer (SPCMDm.SSLKP = 1, SPCR.SCKDDIS = 1).

Table 47.10 Relationship among SCKDEN Bit, SCKDL[2:0] Bits, and RSPCK Delay Value

SPCMDm.SCKDEN Bit	SPCKD.SCKDL[2:0] Bits	RSPCK Delay Value	
		Motorola SPI	TI SSP
0	000b to 111b	1 RSPCK	0 RSPCK
1	000b	1 RSPCK	1 RSPCK
	001b	2 RSPCK	2 RSPCK
	010b	3 RSPCK	3 RSPCK
	011b	4 RSPCK	4 RSPCK
	100b	5 RSPCK	5 RSPCK
	101b	6 RSPCK	6 RSPCK
	110b	7 RSPCK	7 RSPCK
	111b	8 RSPCK	8 RSPCK

(6) SSL Negation Delay (t2)

The SSL negation delay value of the RSPIA in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND register setting. The RSPIA determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an SSL negation delay value during serial transfer by using the SPCMDm.SLNDEN bit and SSLND.SLNDL[2:0] bits, as listed in Table 47.11. For a definition of SSL negation delay, refer to section 47.3.5, Transfer Format (Frame Format).

The SSL negation delay is inserted only the last frame of burst transfer when data transfer is performed without delay between frames in burst transfer (SPCMDm.SSLKP = 1, SPCR.SCKDDIS = 1).

Table 47.11 Relationship among SLNDEN Bit, SLNDL[2:0] Bits, and SSL Negation Delay Value

SPCMDm.SLNDEN Bit	SSLND.SLNDL[2:0] Bits	SSL Negation Delay Value
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-Access Delay (t3)

The next-access delay value of the RSPIA in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND setting. The RSPIA determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines a next-access delay value during serial transfer by using the SPCMDm.SPNDEN bit and the SPND.SPNDL[2:0] bits, as listed in Table 47.12. For a definition of next-access delay, refer to section 47.3.5, Transfer Format (Frame Format).

The next-access delay is inserted only the last frame of burst transfer when data transfer is performed without delay between frames in burst transfer (SPCMDm.SSLKP = 1, SPCR.SCKDDIS = 1).

Table 47.12 Relationship among SPNDEN Bit, SPNDL[2:0], and Next-Access Delay Value

SPCMDm.SPNDEN Bit	SPND.SPNDL[2:0] Bits	Next-Access Delay Value
0	000b to 111b	1 RSPCK + 5 TCLK
1	000b	1 RSPCK + 5 TCLK
	001b	2 RSPCK + 5 TCLK
	010b	3 RSPCK + 5 TCLK
	011b	4 RSPCK + 5 TCLK
	100b	5 RSPCK + 5 TCLK
	101b	6 RSPCK + 5 TCLK
	110b	7 RSPCK + 5 TCLK
	111b	8 RSPCK + 5 TCLK

(8) Initialization Flowchart

Figure 47.60 is a flowchart illustrating an example of initialization in SPI operation when the RSPIA is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

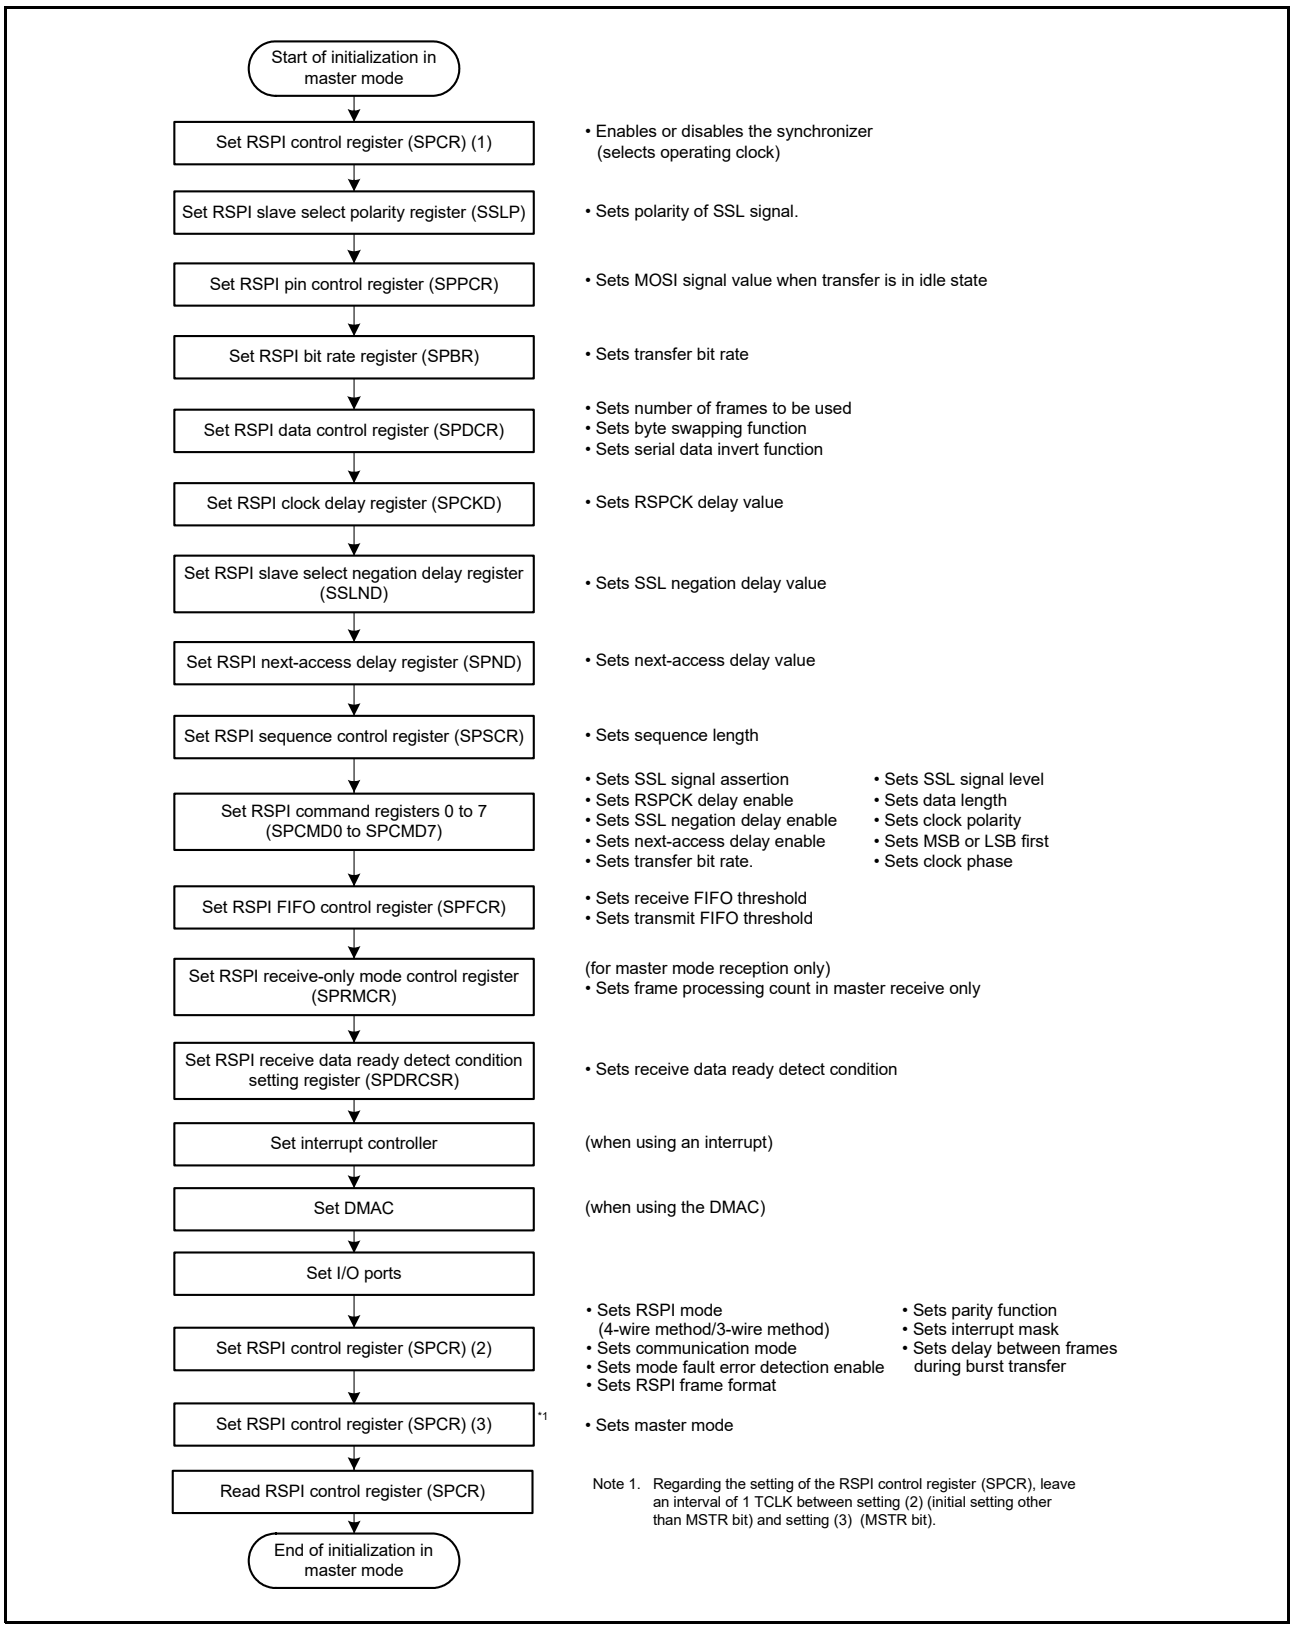

Figure 47.60 Example of Initialization Flowchart in Master Mode (SPI Operation)

(9) Software Processing Flow

Figure 47.61 to Figure 47.63 show examples of the flow of software processing.

(a) Transmit Processing Flow

Enabling SPII or SPCI interrupt after final transmit data is written makes it possible to notify the CPU that transmission of all data has been completed.

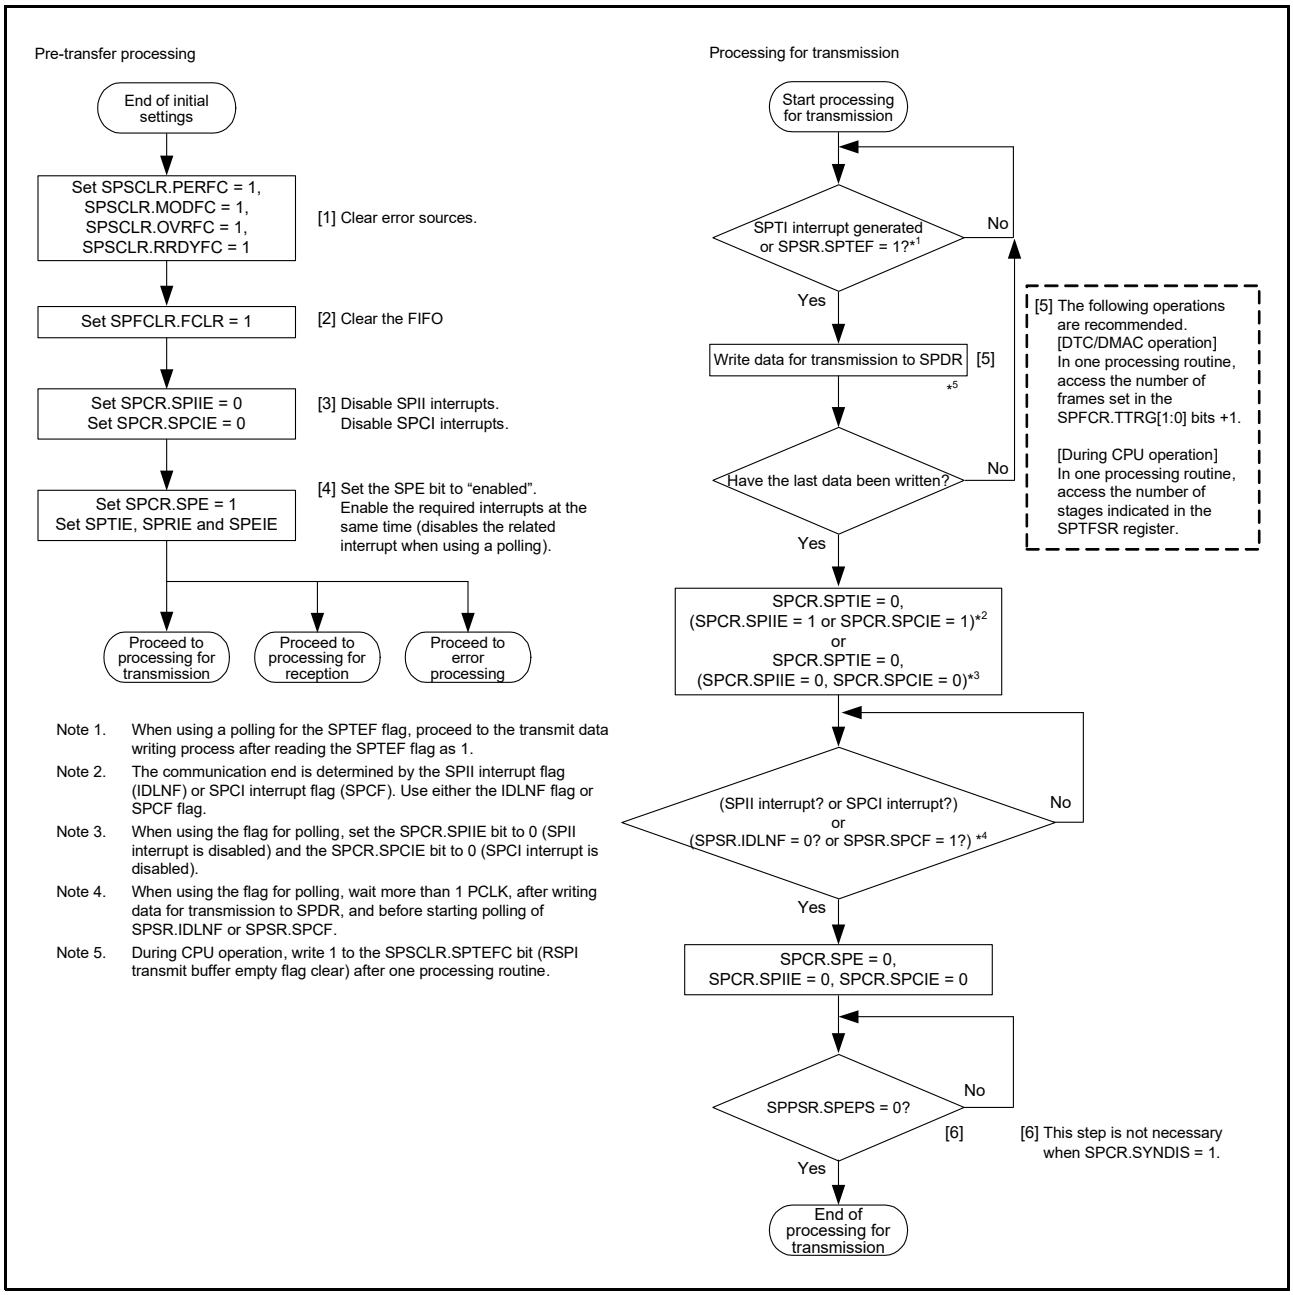

Figure 47.61 Flowchart in Master Mode (Transmission)

(b) Receive Processing Flow

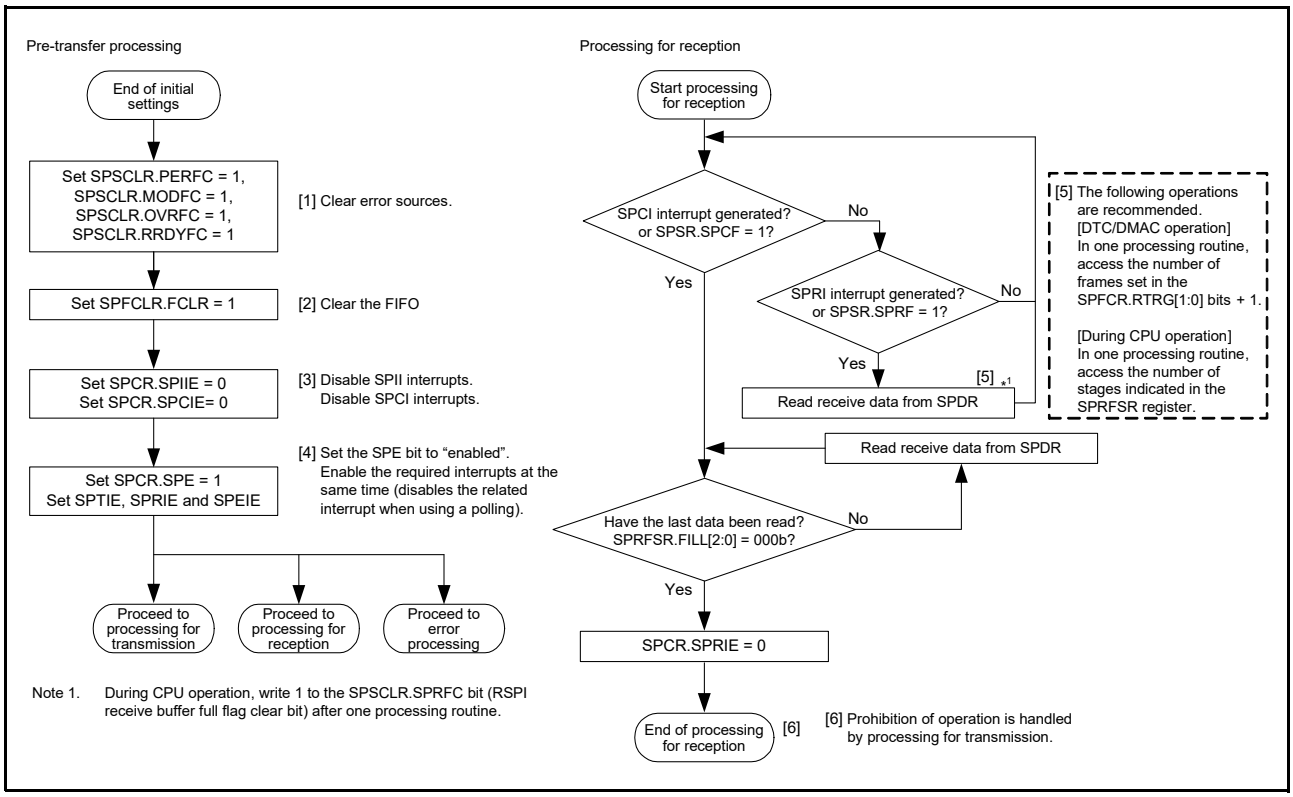

Figure 47.62 Flowchart in Master Mode (Reception)

(c) Receive-Only Processing Flow

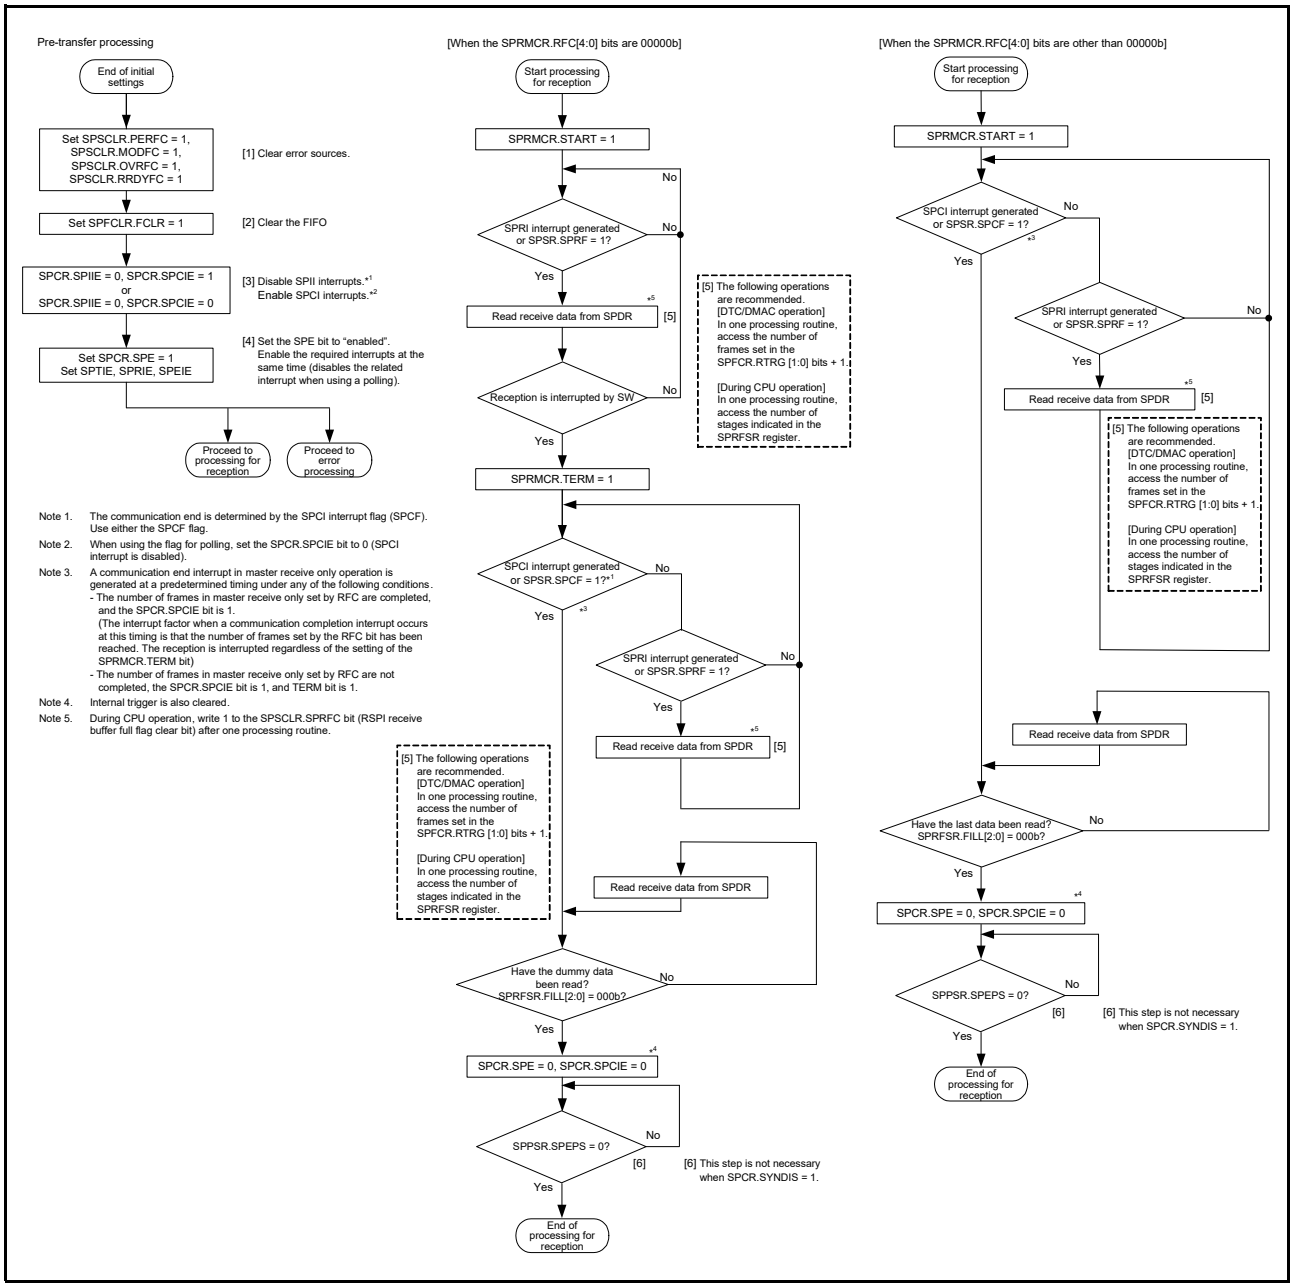

Figure 47.63 Flowchart in Master Mode (Receive-Only)

(d) Flow of Error Processing

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, however, the SPCR.SPE bit is not cleared and operations for transmission and reception continue; accordingly, we recommend clearing of the SPCR.SPE bit to stop operations in the case of errors other than mode fault errors. Not doing so will lead to updating of the SPSSR.SPECM[2:0] bits.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPIA.

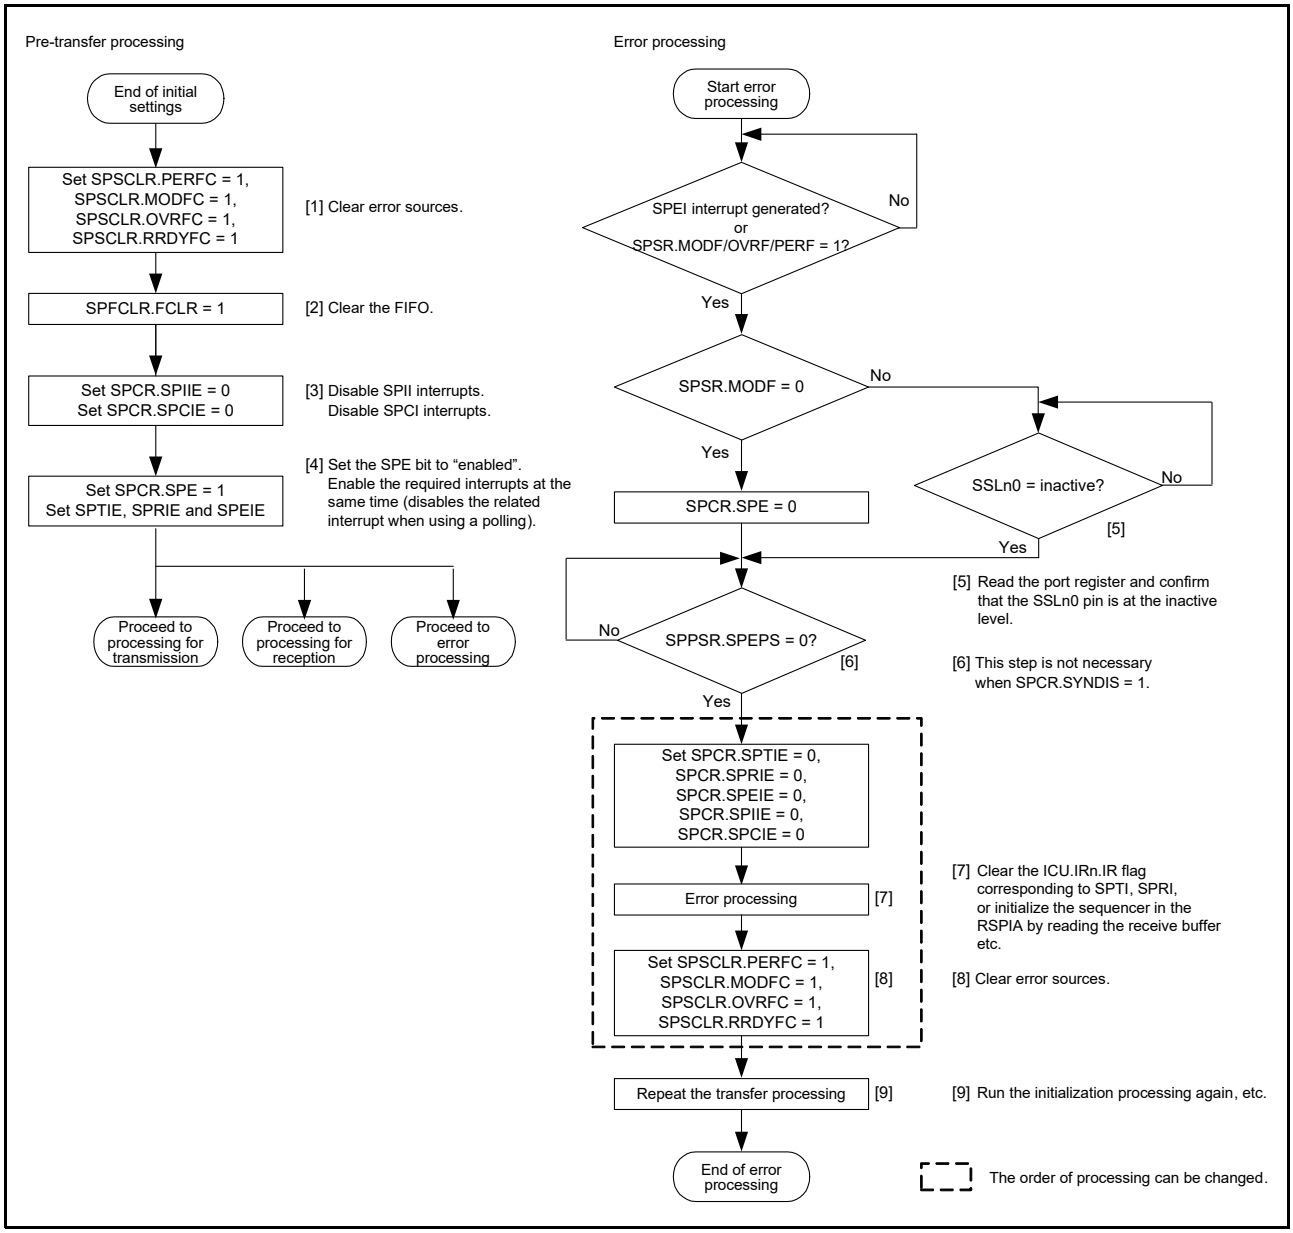

Figure 47.64 Flowchart for Master Mode (Error Processing)

47.3.13.2 Slave Mode Operation

(1) Starting a Serial Transfer

If the SPCMD0.CPHA bit is 0, when detecting an SSLn0 input signal assertion, the RSPIA needs to start driving valid data to the MISOn output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.
If the CPHA bit is 1, when detecting the first RSPCKn edge in an SSLn0 signal asserted condition, the RSPIA needs to start driving valid data to the MISOn output signal. For this reason, when the CPHA bit is 1, the first RSPCKn edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.
Irrespective of the CPHA bit setting, the timing at which the RSPIA starts driving of the MISOn output signal is the SSLn0 signal assertion timing. The data which is output by the RSPIA is either valid or invalid, depending on the CPHA bit setting.
For details on the RSPI transfer format, refer to section 47.3.5, Transfer Format (Frame Format). The polarity of the SSLn0 input signal depends on the setting of the SSLP.SSL0P bit.

(2) Terminating a Serial Transfer

Irrespective of the SPCMD0.CPHA bit, the RSPIA terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO is less than the number of FIFO stages, upon termination of serial transfer the RSPIA copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPIA changes the status of the shift register to “empty”, regardless of the receive buffer state. A mode fault error occurs if the RSPIA detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (refer to section 47.3.10, Error Detection).
The final sampling timing changes depending on the bit length of transmit data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[4:0] bit setting. The polarity of the SSLn0 input signal depends on the SSLP.SSL0P bit setting. For details on the RSPI transfer format, refer to section 47.3.5, Transfer Format (Frame Format).

(3) Notes on Single-Slave Operation

[Motorola SPI]
If the SPCMD0.CPHA bit is 0, when detecting an SSLn0 input signal assertion edge, the RSPIA starts a serial transfer. Upon the SSLn0 input signal is fixed to the active level when using the RSPIA in single slave mode in a configuration as shown in Figure 47.7, the RSPIA cannot start a serial transfer correctly while the CPHA bit is 0. To correctly perform transmission and reception of the RSPIA in slave mode in a configuration where the SSLn0 input signal is fixed to the active level, set the CPHA bit to 1. If the CPHA bit must be set to 0, do not fix the SSLn0 input signal to active level.

[TI SSP]
In the TI SSP protocol, upon the SSLn0 input signal is fixed to the inactive level when using the RSPIA in single slave mode in a configuration as shown in Figure 47.7, the RSPIA cannot start a serial transfer correctly.
When using the RSPIA in single slave mode, operate in a configuration as shown in Figure 47.6.

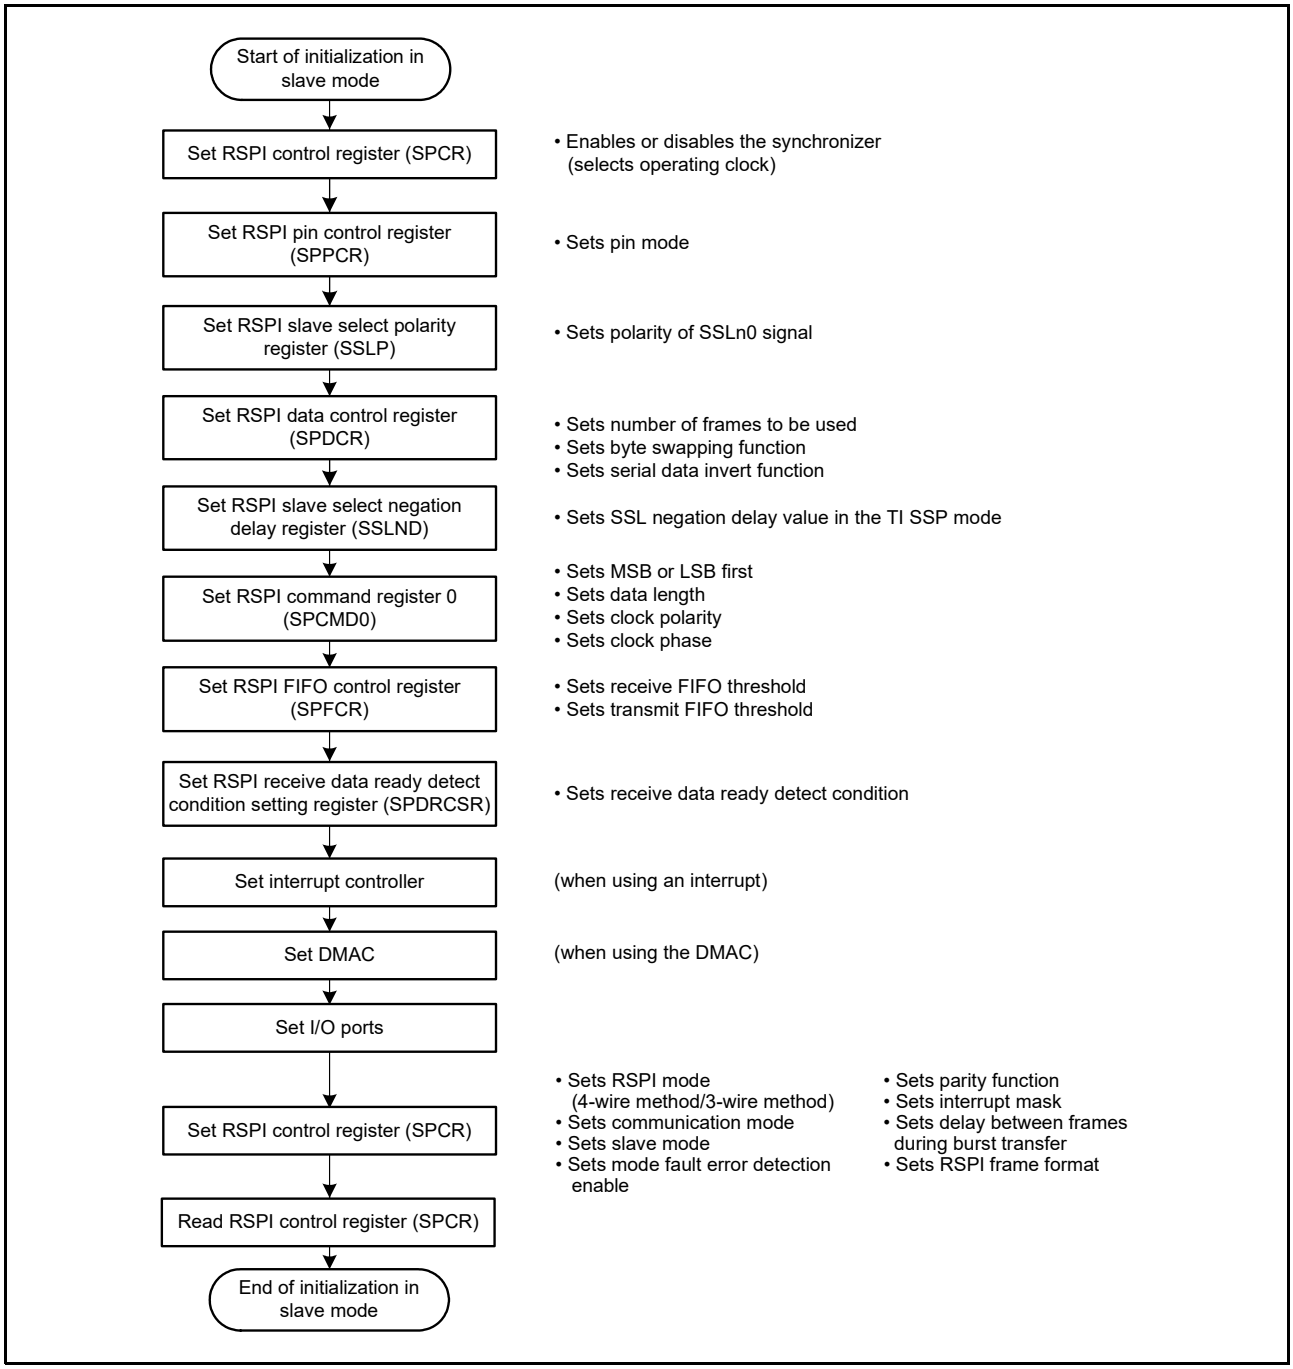
(4) Burst Transfer

[Motorola SPI]
When the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) is available while maintaining the SSLn0 input signal assertion state. When the CPHA bit is 1, the period (from the first RSPCKn edge in the SSLn0 input signal active state until the sampling timing for receiving the final bit) corresponds to the serial transfer period. Even if the SSLn0 input signal is always at the active level, start of an access can be detected, which allows burst transfer.
When the CPHA bit is 0, the second and subsequent serial burst transfers cannot be performed correctly for the same reason as (3).

[TI SSP]
In serial transfer, data transfer starts after the SSLni input signal is asserted for 1 RSPCK cycle. Since frame transfer starts from the SSLni input signal, SSL must be asserted between frames.

(5) Initialization Flowchart

Figure 47.65 shows an example of initialization flow when using the RSPIA in slave-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.



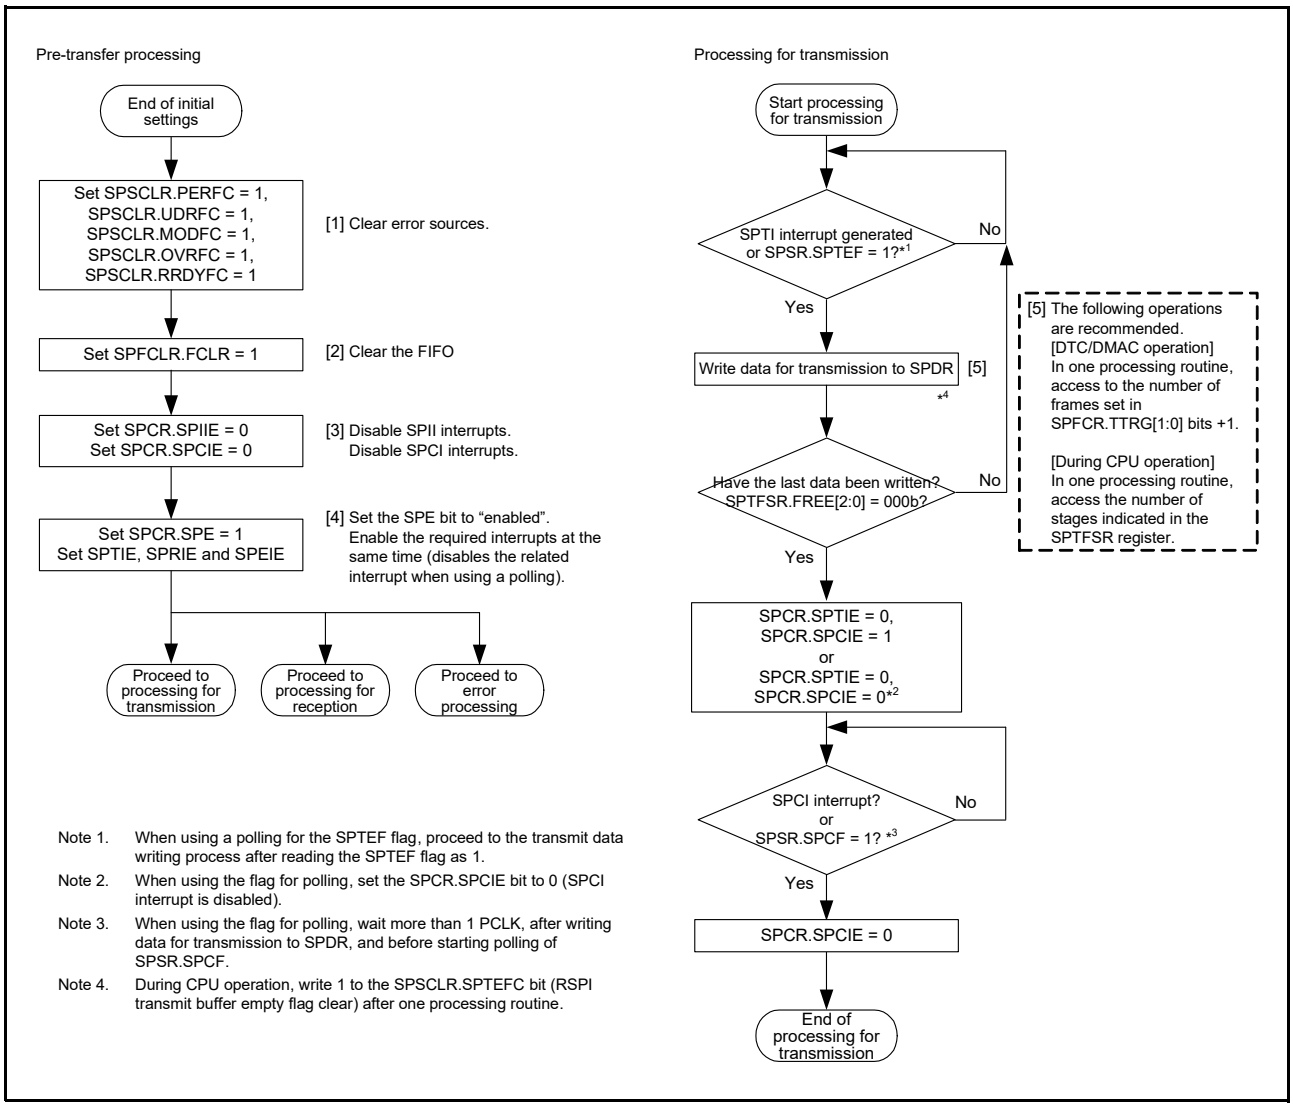


Figure 47.65 Example of Initialization Flow in Slave Mode

(6) Software Processing Flow

Figure 47.66 to Figure 47.69 show examples of the flow of software processing.

(a) Transmit Processing Flow

Note 1. When using a polling for the SPTEF flag, proceed to the transmit data writing process after reading the SPTEF flag as 1.

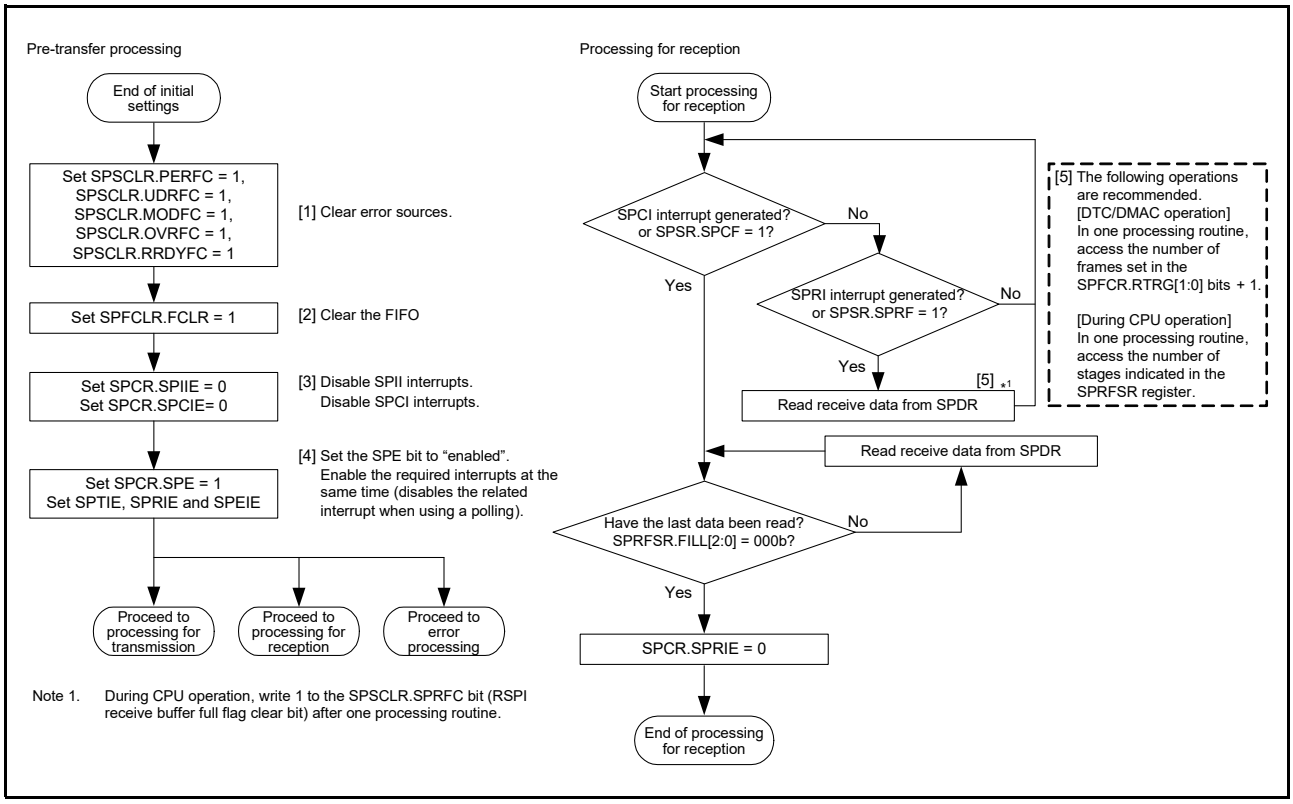
Note 2. When using the flag for polling, set the SPCR.SPCIE bit to 0 (SPCI interrupt is disabled).

Note 3. When using the flag for polling, wait more than 1 PCLK, after writing data for transmission to SPDR, and before starting polling of SPSR.SPCF.

Note 4. During CPU operation, write 1 to the SPSCLR.SPTEFC bit (RSPI transmit buffer empty flag clear) after one processing routine.

Figure 47.66 Flowchart in Slave Mode (Transmission)

(b) Receive Processing Flow



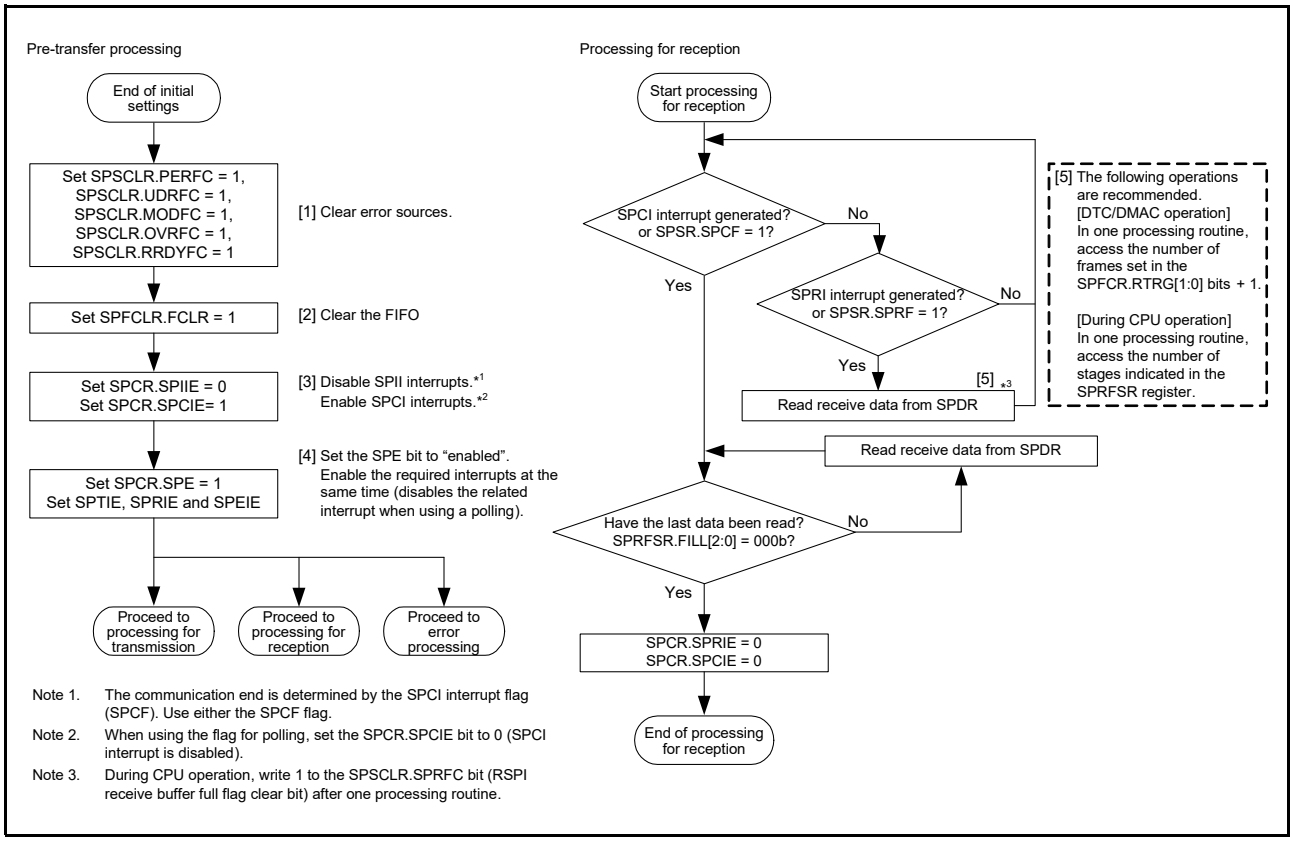


Figure 47.67 Flowchart in Slave Mode (Reception)

(c) Receive-Only Processing Flow

Note 1. The communication end is determined by the SPCI interrupt flag (SPCF). Use either the SPCF flag.
Note 2. When using the flag for polling, set the SPCR.SPCIE bit to 0 (SPCI interrupt is disabled).
Note 3. During CPU operation, write 1 to the SPSCLR.SPRFC bit (RSPI receive buffer full flag clear bit) after one processing routine.

Figure 47.68 Flowchart in Slave Mode (Receive-Only)

(d) Flow of Error Processing

In slave mode operation, the MODF flag can be cleared regardless of the SSLn0 pin status even when a mode fault error is generated.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPIA.

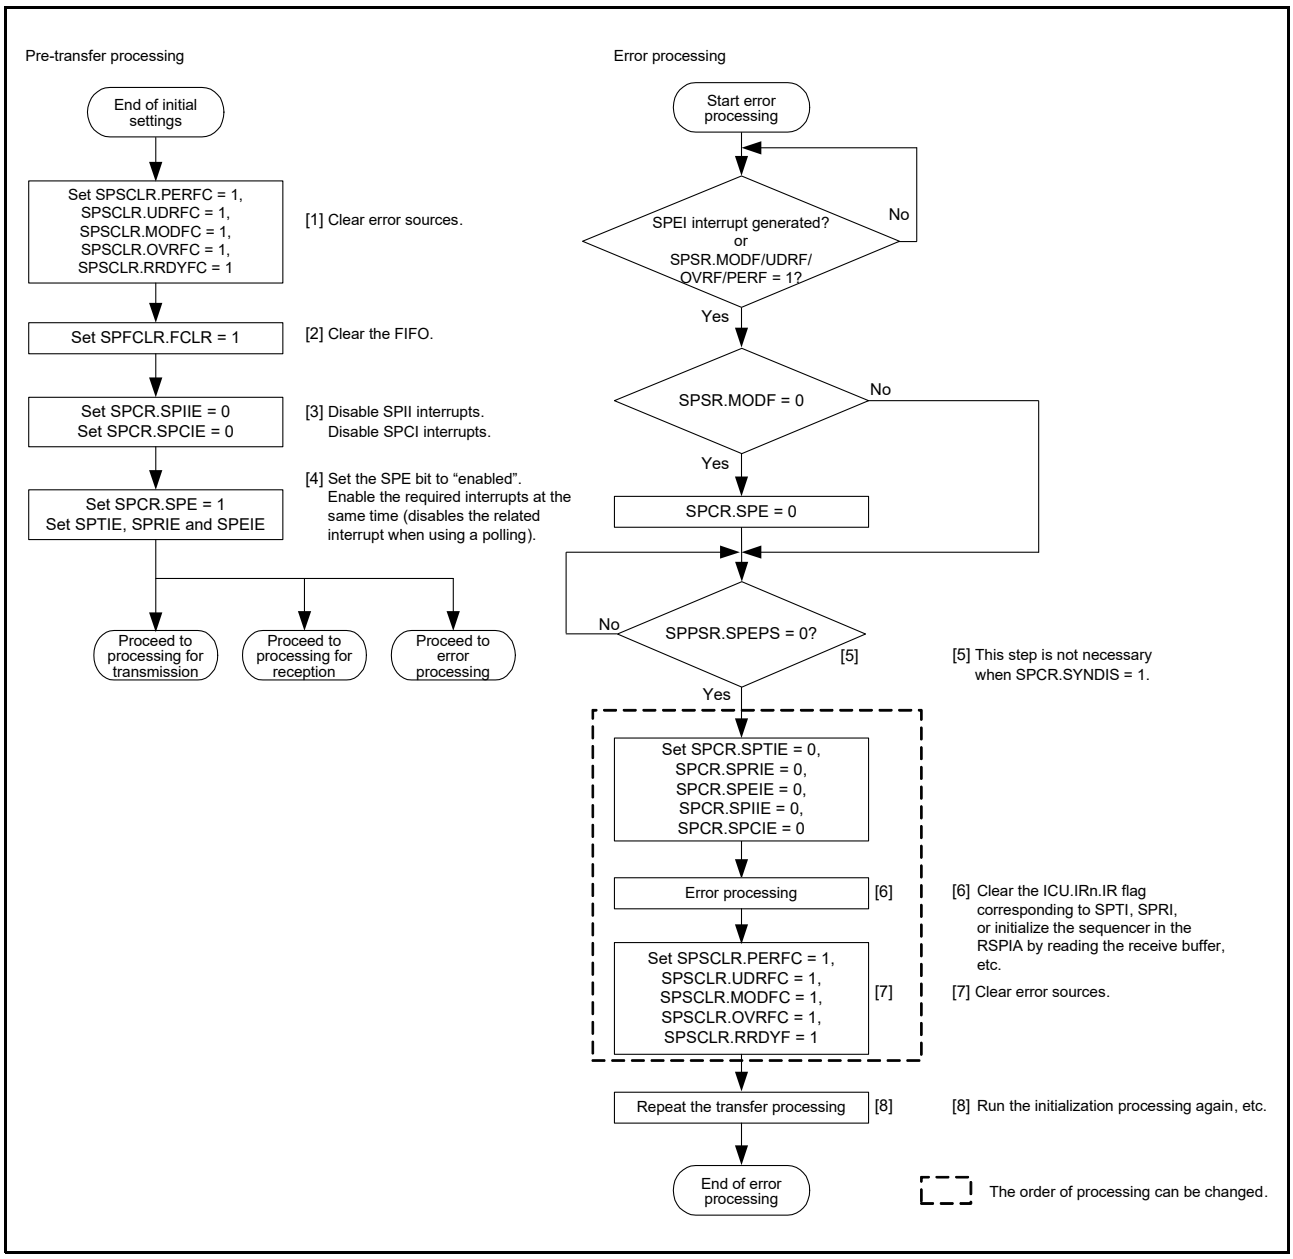

Figure 47.69 Flowchart in Slave Mode (Error Processing)

47.3.14 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the RSPIA. In clock synchronous operation, the SSLni pin is not used, and the three pins of RSPCKn, MOSIn, and MISOn handle communications. The SSLni pin is available as I/O port pins.
Although clock synchronous operation does not require use of the SSLni pin, operation of the module is the same as in SPI operation. That is, in both master and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected because the SSLni pin is not used.
Furthermore, do not set the SPCMDm.CPHA bit to 0 if clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0).

47.3.14.1 Master Mode Operation

(1) Starting a Serial Transfer

The RSPIA updates the data in the transmit buffer (SPTXn, n = 0 to 3) of the SPDR register when data is written to the SPDR register with the transmit buffer being empty (data for the next transfer is not set). When the shift register is empty, the RSPIA copies data from the transmit buffer to the shift register and starts serial transmission. Upon copying transmit data to the shift register, the RSPIA changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 47.3.5, Transfer Format (Frame Format).
However, transfer in clock synchronous operation is conducted without the SSLni output signal.

(2) Terminating a Serial Transfer

The RSPIA terminates the serial transfer after transmitting an RSPCKn edge corresponding to the final sampling timing. If the number of data stored in the receive FIFO is less than the number of FIFO stages, upon termination of serial transfer, the RSPIA copies data from the shift register to the receive buffer of the RSPI data register (SPDR).
It should be noted that the final sampling timing varies depending on the bit length of transmit data. In master mode, the RSPI data length depends on the SPCMDm.SPB[4:0] bit setting. For details on the RSPI transfer format, refer to section 47.3.5, Transfer Format (Frame Format).
However, transfer in clock synchronous operation is conducted without the SSLni output signal.

(3) Sequence Control

The transfer format employed in master mode is determined by the following registers:

- RSPI sequence control register (SPSCR)
- RSPI command register m (SPCMDm) (m = 0 to 7)
- RSPI bit rate register (SPBR)
- RSPI clock delay register (SPCKD)
- RSPI slave select negation delay register (SSLND)
- RSPI next-access delay register (SPND)

Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPSCR register is a register used to determine the sequence configuration for serial transfers that are executed by the RSPIA in master mode. The following items are set in the SPCMDm register: MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether the SPCKD register is to be referenced, whether the SSLND register is to be referenced, and whether the SPND register is to be referenced. The SPBR register holds some of the bit rate settings; the SPCKD register, an RSPI clock delay value; the SSLND register, an SSL negation delay; and the SPND register, a next-access delay value.
According to the sequence length that is assigned to the SPSCR register, the RSPIA makes up a sequence comprised of a part or all of the SPCMDm register. The RSPIA contains a pointer to the SPCMDm register that makes up the sequence.

The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPIA loads the pointer to the commands in the SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The RSPIA increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPIA sets the pointer in the SPCMD0 register, and in this manner the sequence is executed repeatedly.

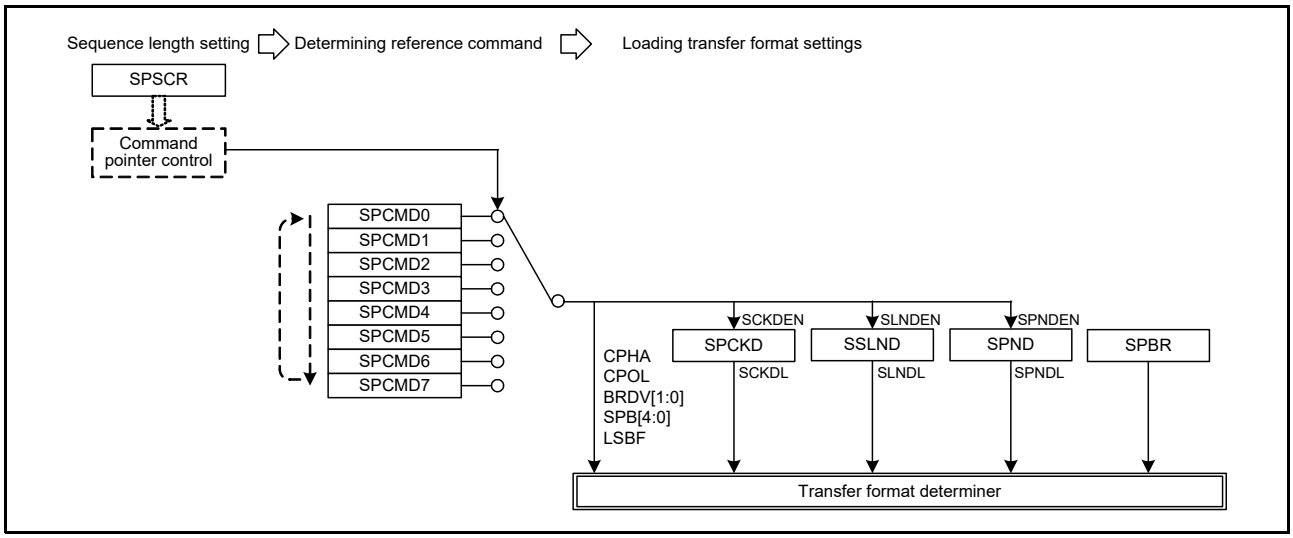

Figure 47.70 Procedure for Determining the Form of Serial Transfer in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

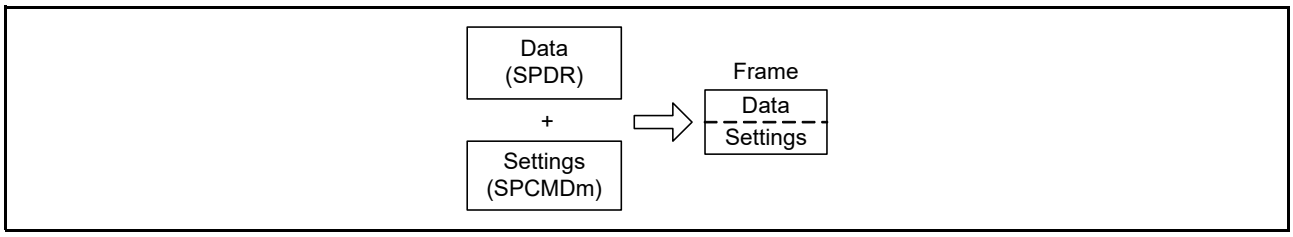

Figure 47.71 Concept of a Frame

Figure 47.72 shows the relationship between the command and the transmit buffer (SPTXn, n = 0 to 3) and receive buffer (SPRXn, n = 0 to 3) in the sequence of operations.

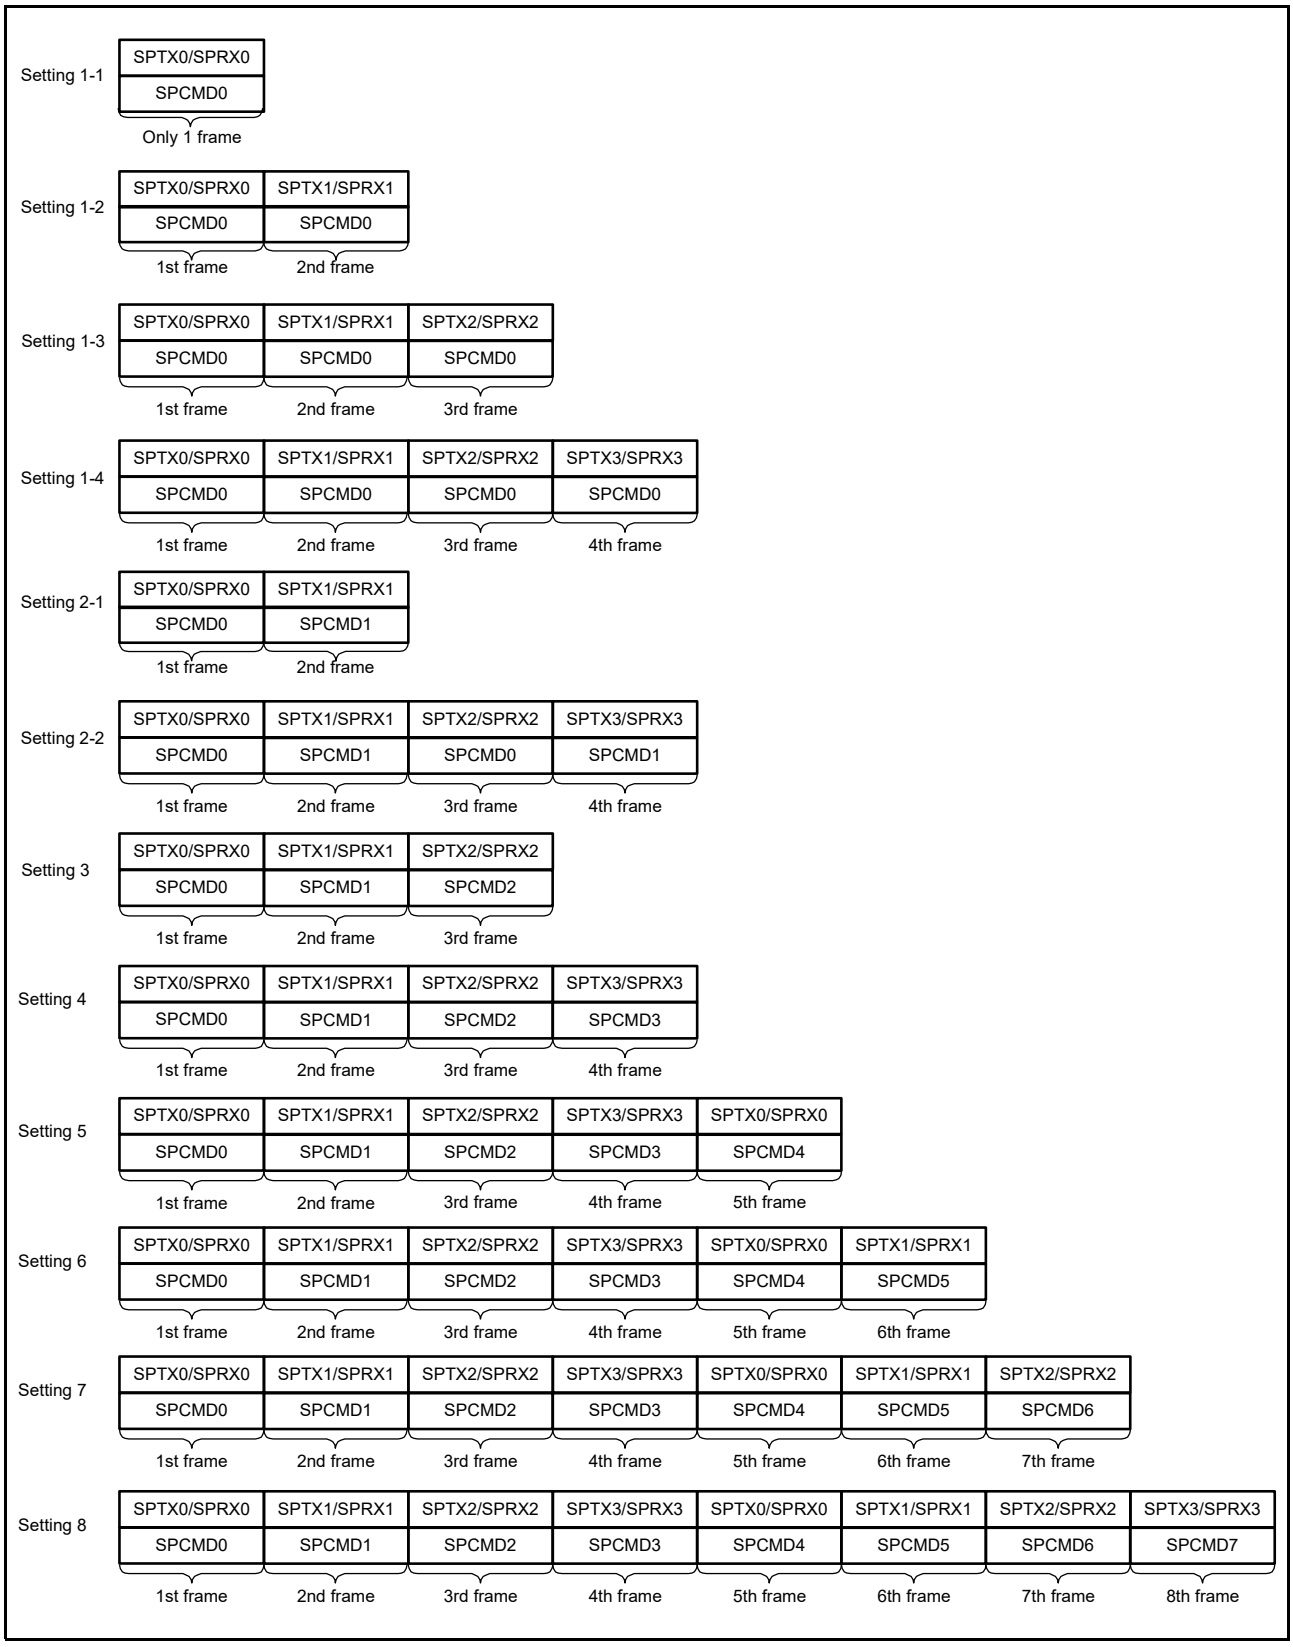

Figure 47.72 Correspondence between the RSPI Command Register m and Transmit/Receive Buffers in Sequence Operations

(4) Initialization Flowchart

Figure 47.73 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPIA is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

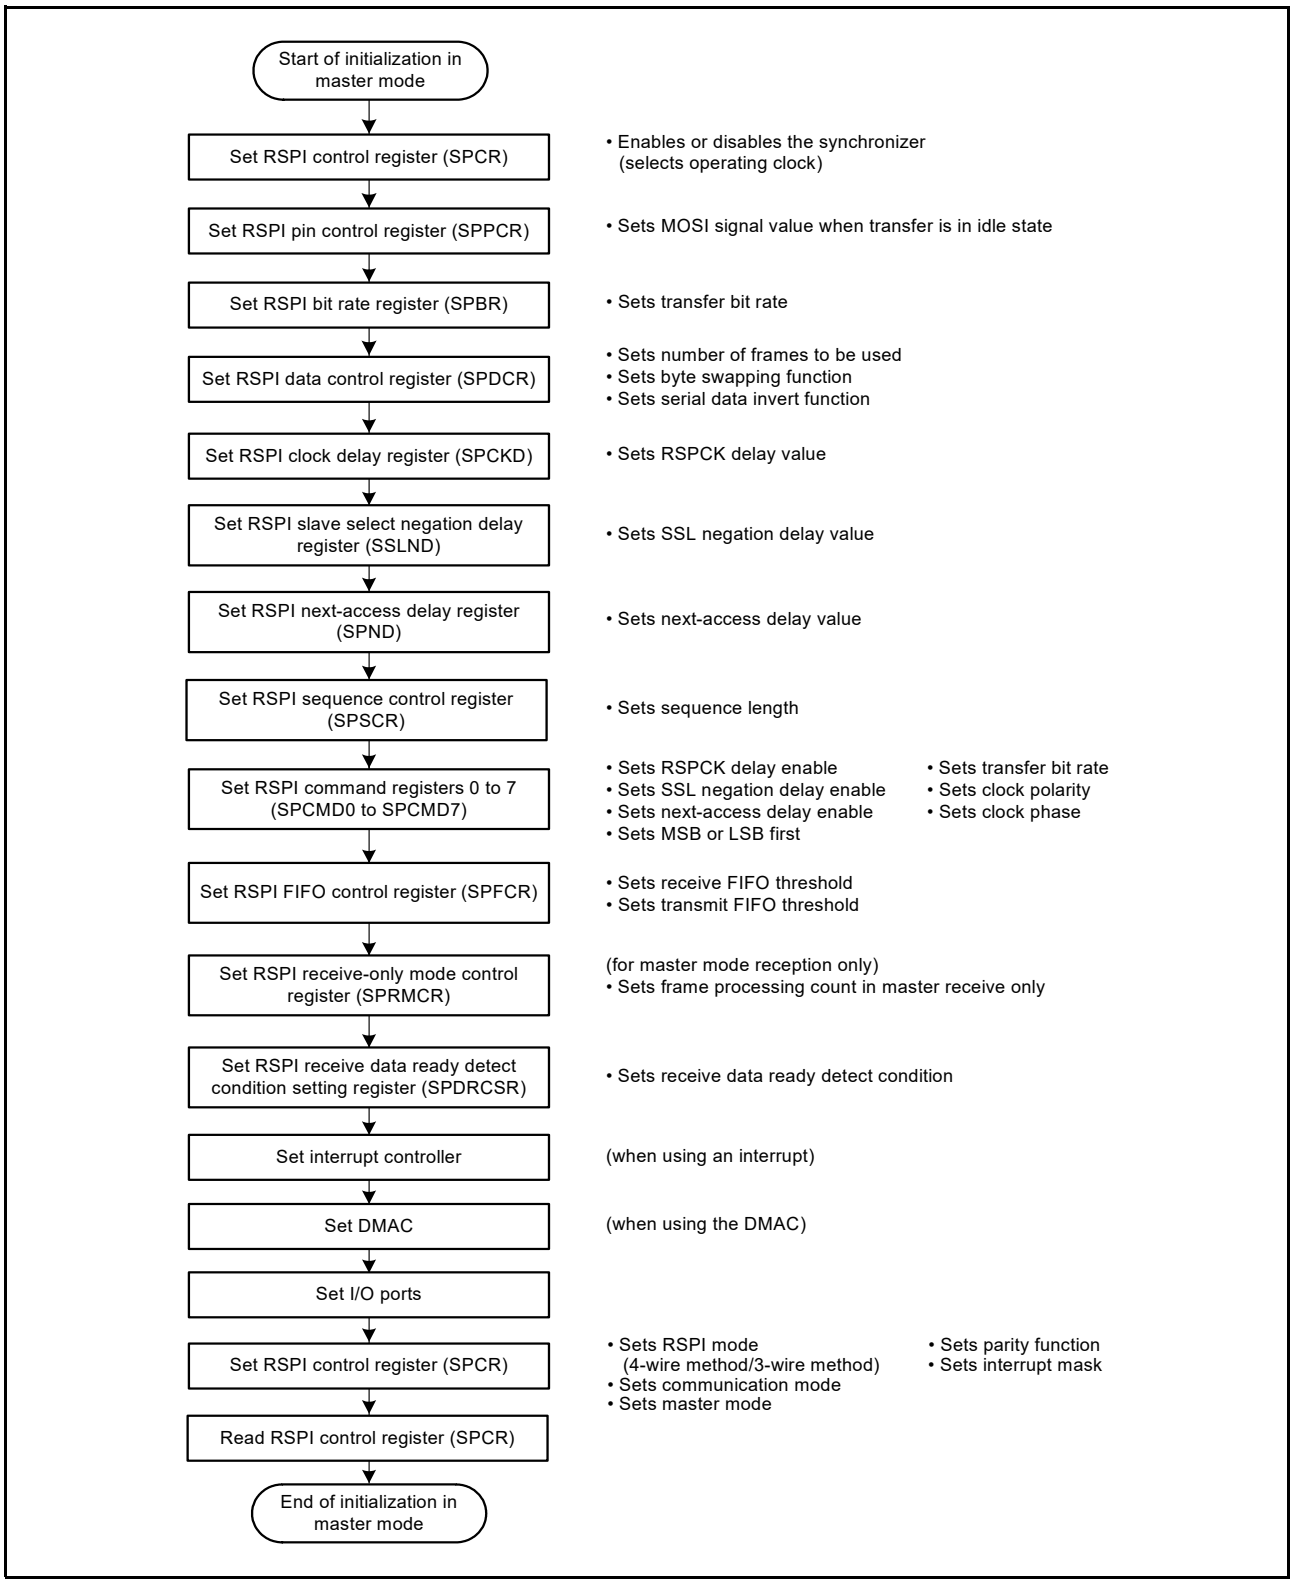

Figure 47.73 Example of Initialization Flowchart in Master Mode (Clock Synchronous Operation)

(5) Flow of Software Processing

Software processing during clock-synchronous operation when the RSPIA is used in master mode is the same as that for SPI master mode operation. For details, refer to section 47.3.13.1, (9) Software Processing Flow. Note that mode fault errors will not occur.

47.3.14.2 Slave Mode Operation

(1) Starting a Serial Transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the RSPIA.
When the SPMS bit is 1, the RSPIA drives the MISOn output signal.
For details on the RSPI transfer format, refer to section 47.3.5, Transfer Format (Frame Format).
It should be noted that the SSLn0 input signal is not used in clock synchronous operation.

(2) Terminating a Serial Transfer

The RSPIA terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO is less than the number of FIFO stages, upon termination of serial transfer the RSPIA copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPIA changes the status of the shift register to “empty” regardless of the receive buffer status. The final sampling timing changes depending on the bit length of transmit data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[4:0] bit setting.
For details on the RSPI transfer format, refer to section 47.3.5, Transfer Format (Frame Format).

(3) Initialization Flowchart

Figure 47.74 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPIA is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

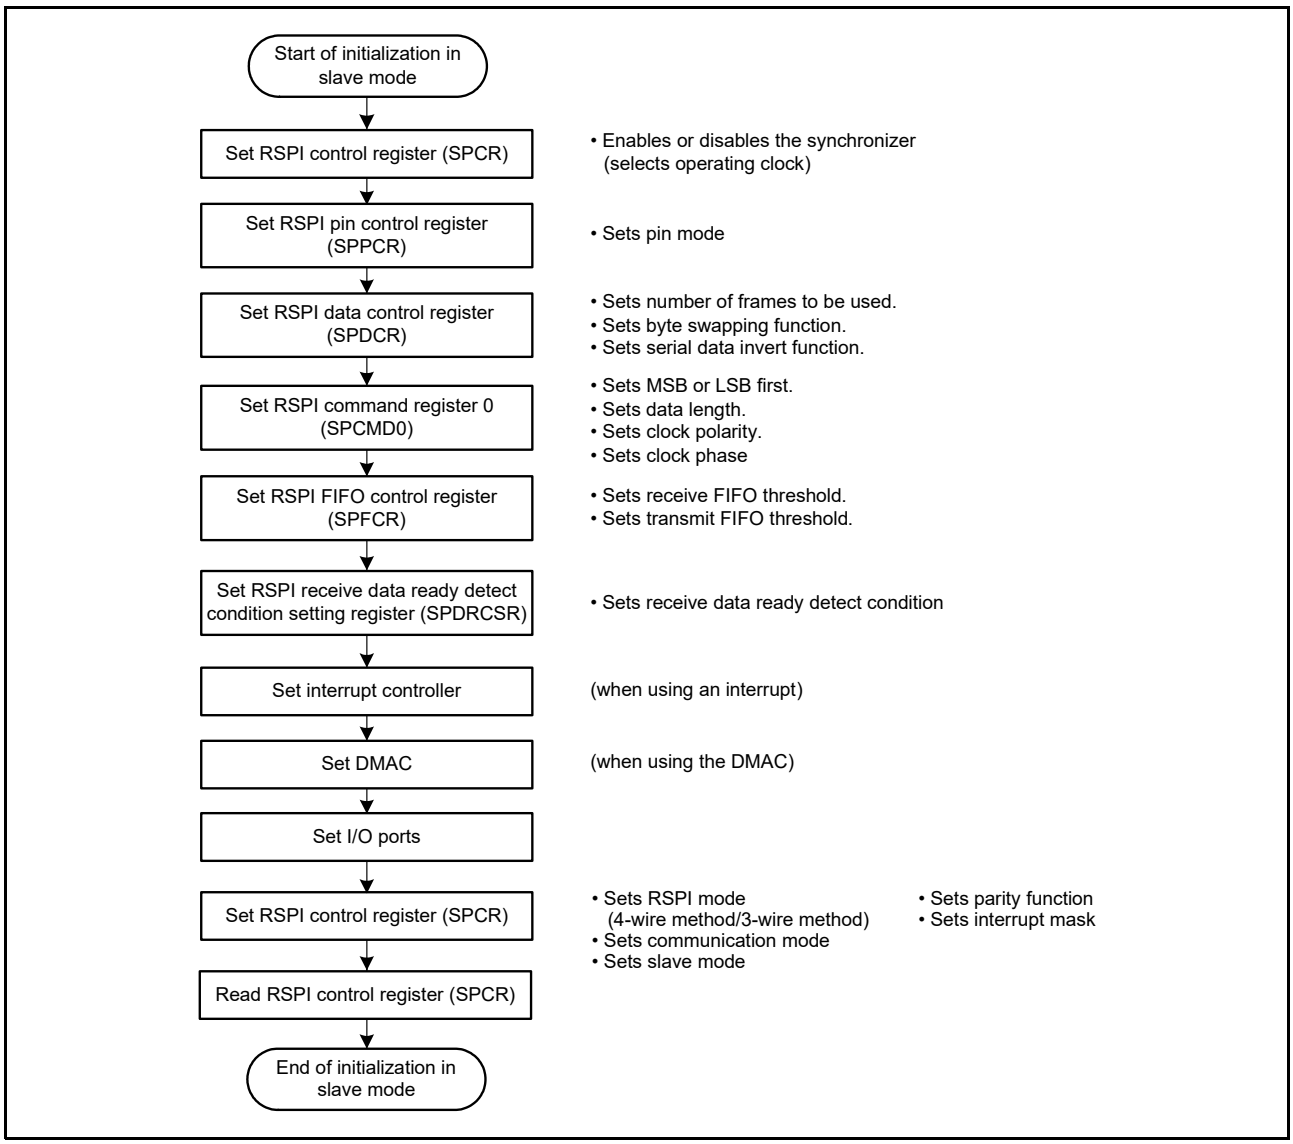

Figure 47.74 Example of Initialization Flowchart in Slave Mode (Clock Synchronous Operation)

(4) Flow of Software Processing

Software processing during clock-synchronous operation when the RSPIA is used in slave mode is the same as that for SPI slave mode operation. For details, refer to section 47.3.13.2, (6) Software Processing Flow. Note that mode fault errors will not occur.

47.3.15 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the RSPIA shuts off the path between the MISOn pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIn pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path of the shift register. The RSPIA does not shut off the path between the MOSIn pin and the shift register if the SPCR.MSTR bit is 1, and between the MISOn pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode.
When a serial transfer is executed in loopback mode, the transmit data for the RSPIA or the reversed transmit data becomes the received data for the RSPIA.
Table 47.13 lists the relationship among the SPLP2 and SPLP bits and the received data.

Table 47.13 SPLP2 and SPLP Bit Settings and Received Data

SPPCR.SPLP2 Bit	SPPCR.SPLP Bit	Received Data
0	0	Input data from the MOSIn pin or MISOn pin
0	1	Inverted transmit data
1	x	Transmit data

x: Don’t care.

Figure 47.75 shows the configuration of the shift register I/O paths in loopback mode.

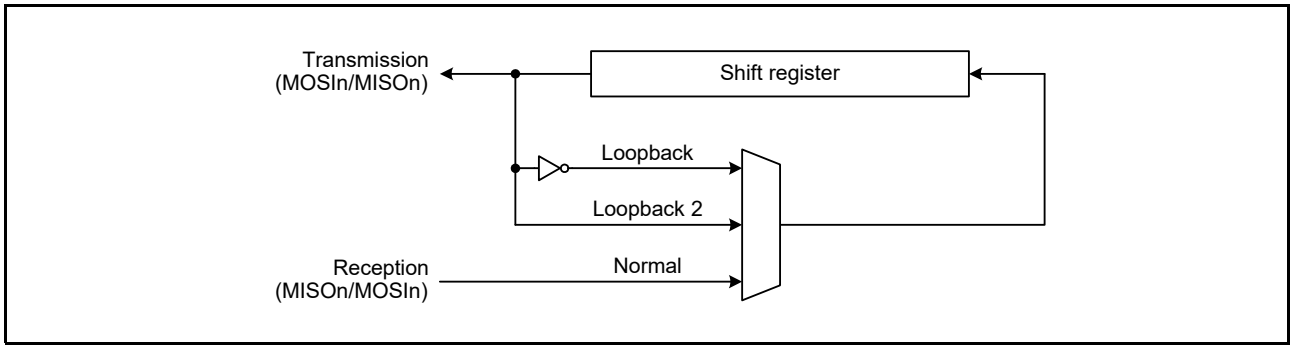

Figure 47.75 Configuration of Shift Register I/O Paths in Loopback Mode

47.3.16 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. In order to detect defects in the parity bit adding unit and error detecting unit of the parity circuit, self-diagnosis is executed for the parity circuit following the flowchart shown in Figure 47.76.

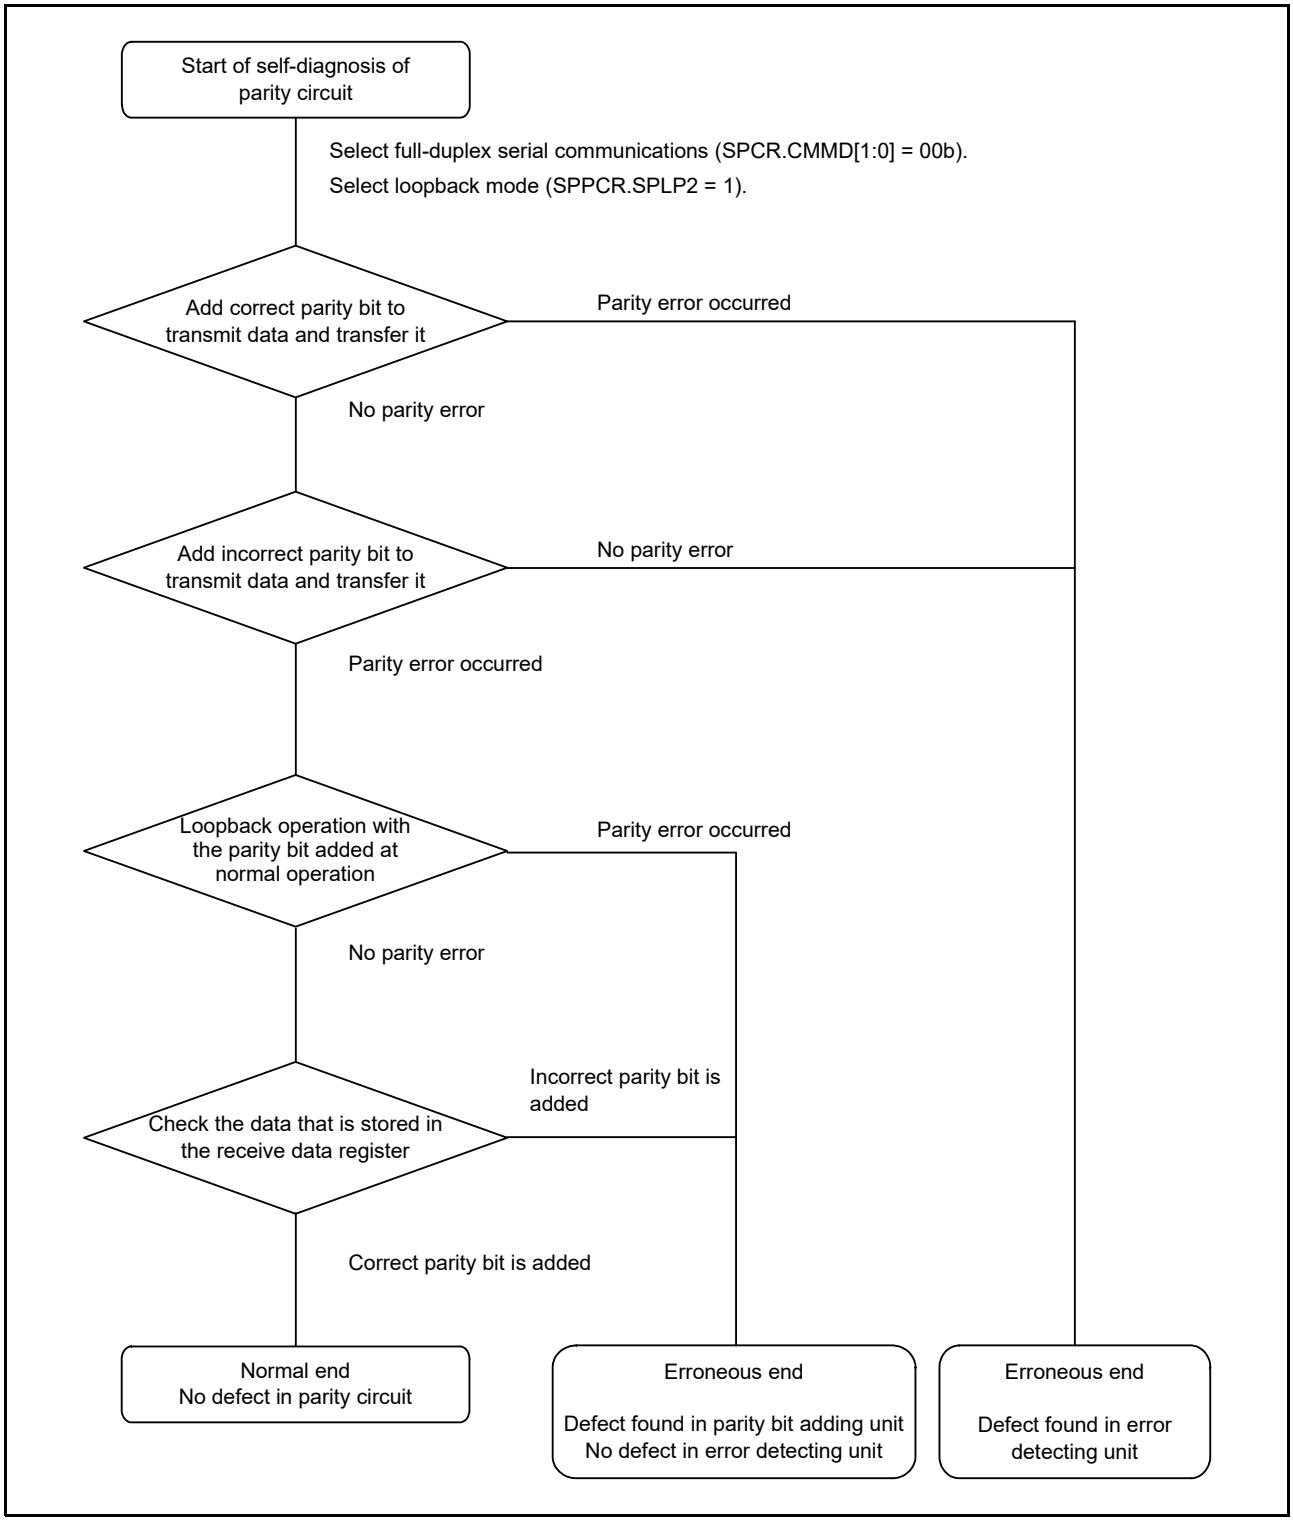

Figure 47.76 Flowchart for Self-Diagnosis of Parity Circuit

47.3.17 Interrupt Sources

The RSPIA has interrupt sources of receive buffer full, transmit buffer empty, error (mode fault, underrun, overrun, and parity error), idle, communication end, and receive data ready. In addition, the DTC or DMAC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Since the vector address for SPEI is allocated to interrupt requests due to mode fault, underrun, overrun, parity errors, and receive data ready (only when the RDRIS bit is 1), the actual interrupt source must be determined from the flags.

Interrupt sources for the RSPIA are listed in Table 47.14. An interrupt is generated on satisfaction of an interrupt condition in Table 47.14. Clear the receive buffer full and transmit buffer empty sources through data transfer.

When using the DTC or DMAC to perform data transmission/reception, the DTC or DMAC must be set up first to be in a status in which transfer is enabled before making the RSPIA settings. For the method for setting the DTC or DMAC, refer to section 18, DMA Controller (DMACAa), or section 20, Data Transfer Controller (DTCA).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt are generated while the ICU.IRn.IR flag is 1, the interrupt is not output as a request for ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IRn.IR flag becomes 0. A retained interrupt request is automatically discarded once it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be cleared to 0.

Table 47.14 Interrupt Sources of RSPIA

Interrupt Source	Symbol	Interrupt Condition	DMAC/DTC Activation
Receive buffer full Receive data ready	SPRI	The SPSR.SPRF flag is set to 1 while the SPCR.SPRIE bit is 1, or the RRDYF flag is set to 1 while the SPEIE is 1 and RDRIS bit is 0.	Possible
Transmit buffer empty	SPTI	The SPSR.SPTEF flag is set to 1 while the SPCR.SPTIE bit is 1.	Possible
Mode fault error Underrun error Overrun error Parity error Receive data ready	SPEI	The SPSR.MODF, OVRF, or PERF flag is set to 1 while the SPCR.SPEIE bit is 1, or the RRDYF flag is set to 1 while the SPEIE and RDRIS bits are 1.	Impossible
Idle	SPII	The SPSR.IDLNF flag is set to 0 while the SPCR.SPIIE bit is 1.	Impossible
Communication end	SPCI	The SPSR.SPCF flag is set to 1 while the SPCR.SPCIE bit is 1.	Impossible

47.3.18 Link Operation by Event Linking

The RSPIA supports the following event output for the event link controller (ELC). The event link output signal is output regardless of the interrupt enable bit setting.

47.3.18.1 Receive Buffer Full Event Output

This event signal is output when the number of data stored in the receive FIFO is greater than the threshold value, or when the SPCR.RDRIS bit = 0 and after writing to the receive FIFO, and the number of data stored in the receive FIFO is equal to or less than the threshold value, the value set in the SPDRCSR register has elapsed.
A receive buffer full event is output at the timing shown in Figure 47.77.

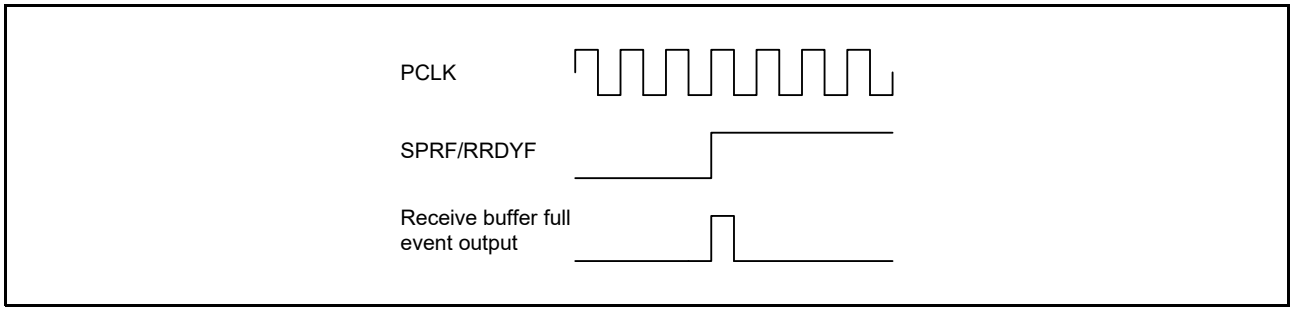

Figure 47.77 Event Output Timing of the Receive Buffer Full

47.3.18.2 Transmit Buffer Empty Event Output

This event signal is output when the number of empty stages in the transmit FIFO is greater than the threshold value or when the value of the SPCR.SPE bit has changed from 0 to 1.
A transmit buffer empty event is output at the timing shown in Figure 47.78.

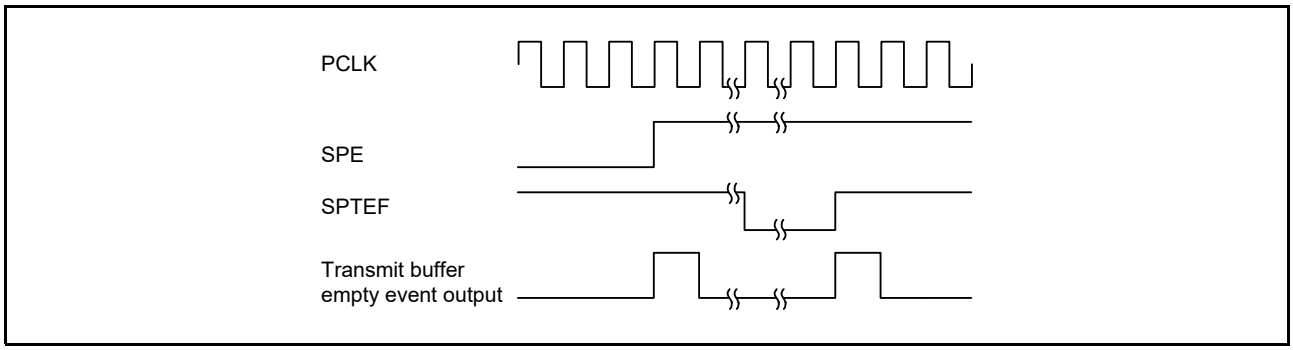

Figure 47.78 Event Output Timing of the Transmit Buffer Empty

47.3.18.3 Error Event Output

The error event signal is output due to five sources (mode fault, underrun, overrun, parity error, and receive data ready). For notes on error event output, see section 47.4.3, Note on Error Events Output.

(1) Mode Fault

A mode fault event occurs when all the following conditions are satisfied:

- SPI operation (SPCR.SPMS = 0)
- Slave mode (SPCR.MSTR = 0)
- The detection of mode fault error is enabled (SPCR.MODFEN = 1)
- Any of the following conditions are satisfied
  1. In the Motorola SPI protocol, the SSLn0 pin is deactivated during data transfer.
  2. In the TI SSP protocol, the SSLn0 pin is activated during data transfer.

(2) Underrun

The condition for this event signal being output in response to an underrun is the start of serial transfer while the value of the SPCR.MSTR bit is 0 (slave mode), the value of the SPCR.SPE bit is 1 (enables the RSPI function), and the transmit data are not ready for output.

(3) Overrun

The condition for this event signal being output in response to an overrun is completion of the serial transfer while the value of the SPCR.CMMD[1:0] bits are 00b or 10b, and the data is stored in the receive FIFO for the number of FIFO stages, in which case the SPSR.OVRF flag is set to 1.

(4) Parity Error

The condition for this event signal being output in response to a parity error is detection of a parity error on completion of the serial transfer while the value of the SPCR.CMMD[1:0] bits are 00b or 10b, and the value of the SPCR.SPE bit is 1.

(5) Receive Data Ready

The condition for this event signal being output in response to a receive data ready is elapsing of the value set by the SPDRCSR register when the number of data stored in the receive FIFO is less than or equal to the receive FIFO threshold value after the data has stored in the receive FIFO, while the value of the SPCR.CMMD[1:0] bits are 00b or 10b, the value of the SPCR.RDRIS bit is 1.

(6) Output Timing

Each error event signal is output at the timing shown in Figure 47.79.
Error event is output each time an error occurs.

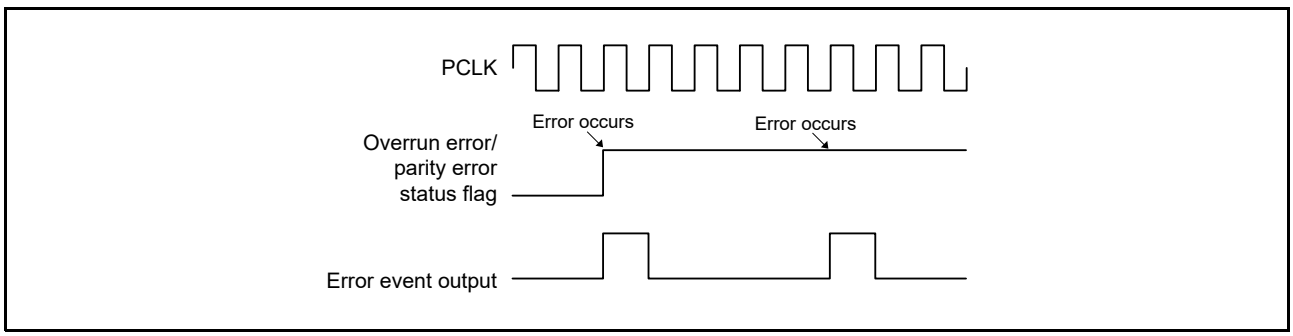

Figure 47.79 Error Event Output Timing

47.3.18.4 Idle Event Output

(1) In Master Mode

[Transmit-receive mode/transmit-only mode]

In transmit-receive master mode or transmit-only master mode, an event is output when the SPSR.IDLNF flag (idle flag) changes from 1 to 0.

The SPSR.IDLNF flag changes from 1 to 0 only when any of the following conditions are satisfied.

(a) The SPCR.SPE bit becomes 0 (RSPI is initialized) during transmission

(b) All the following conditions are satisfied:

- The next transmit data is not set in the transmission buffer (SPTXn, n = 0 to 3)
- The SPSSR.SPCP[2:0] bits are 000b (beginning of sequence control)
- The operations up to the next-access delay have finished (the master main state machine has entered the idle state)

[Receive-only mode]

In receive-only master mode, an event is output when any of the following conditions are satisfied.

(a) The SPCR.SPE bit is set to 0 (RSPI is initialized).

(b) Any the following conditions are satisfied:

- When the SPRMCR.RFC[4:0] bits are 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)
- When the SPRMCR.RFC[4:0] bits are other than 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)
- When the SPRMCR.RFC[4:0] bits are other than 00000b, after the operation is completed for the number of received frames set by the SPRMCR.RFC[4:0] bits, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(2) In Slave Mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (RSPI is initialized).

(3) Output Timing

An idle event is output at the timing shown in Figure 47.80.

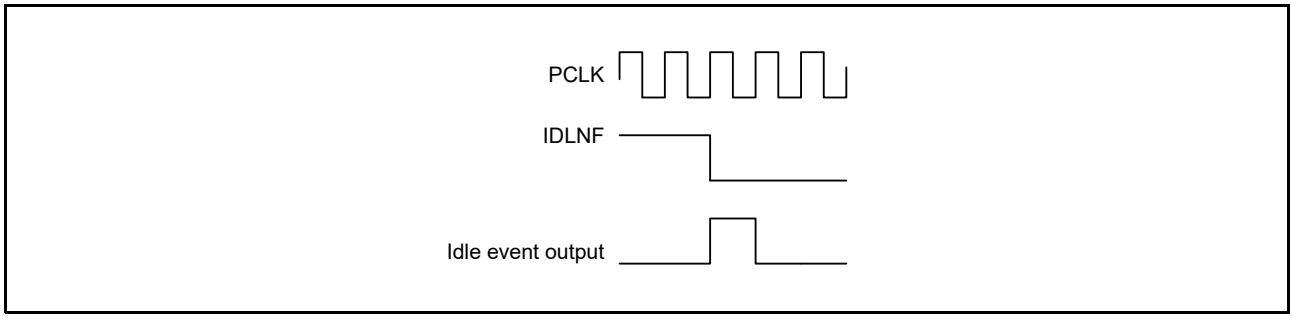

Figure 47.80 Idle Event Output Timing

47.3.18.5 Communication End Event Output

In master mode, an event is output under the condition for setting the SPSR.IDLNF flag (idle flag) from 1 to 0. In slave mode, an event is output under the conditions listed in Table 47.15 and Table 47.16.

Table 47.15 Generating Conditions of Communication End Event (Transmit-Receive Slave Mode/Transmit-Only Slave Mode)

RSPI Mode	Transmit Buffer State	Shift Register State	Others
SPI operation (SPMS = 0, FRFS = 0)	Empty	Empty	Negation of the SSLn0 input
SPI operation (SPMS = 0, FRFS = 1)	Empty	Empty	Completion of the SSL negation delay
Clock synchronous operation (SPMS = 1)	Empty	Empty	Even edge detection of the last RSPCKn for the last data

Table 47.16 Generating Conditions of Communication End Event (Receive-Only Slave Mode)

RSPI Mode	Condition
SPI operation (SPMS = 0, FRFS = 0)	Negation of the SSLn0 input after storing the number of frames set by the SPDCR.SPFC[1:0] bits in the receive buffer
SPI operation (SPMS = 0, FRFS = 1)	Completion of the SSL negation delay after storing the number of frames set by the SPDCR.SPFC[1:0] bits in the receive buffer
Clock synchronous operation (SPMS = 1)	Even edge detection of the last RSPCKn for the last frame set by the SPDCR.SPFC[1:0] bits

Whether the operation is in master mode or slave mode, an event is not output if 0 is written to the SPCR.SPE bit during communication or the SPCR.SPE bit is cleared by the mode fault error or underrun error.
A communication end event is output at timings shown in Figure 47.81 to Figure 47.86. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

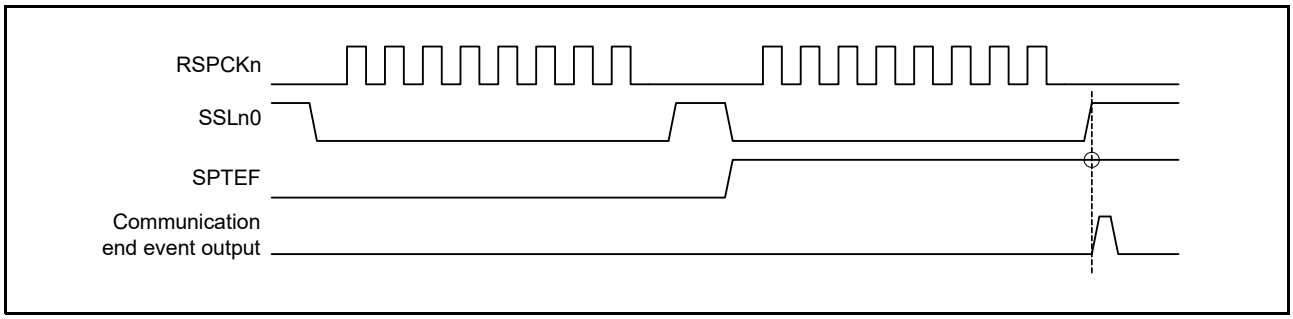

Figure 47.81 Communication End Event Output Timing (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Motorola SPI)

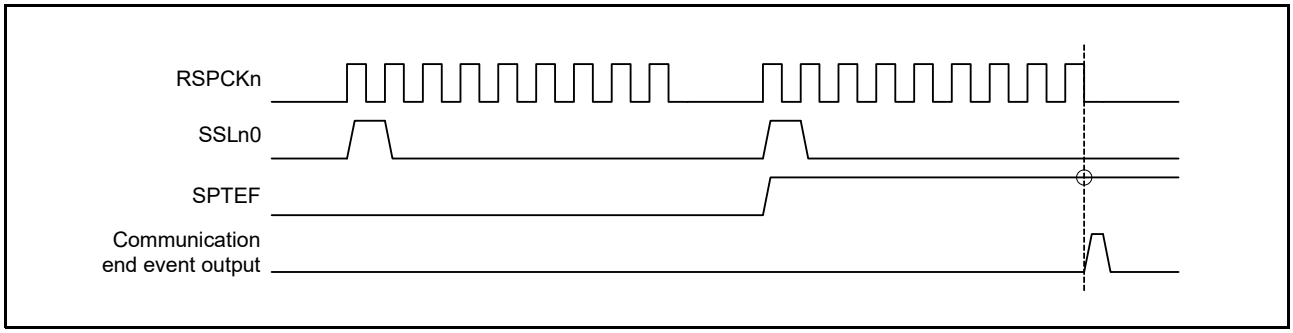

Figure 47.82 Communication End Event Output Timing (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, TI SSP)

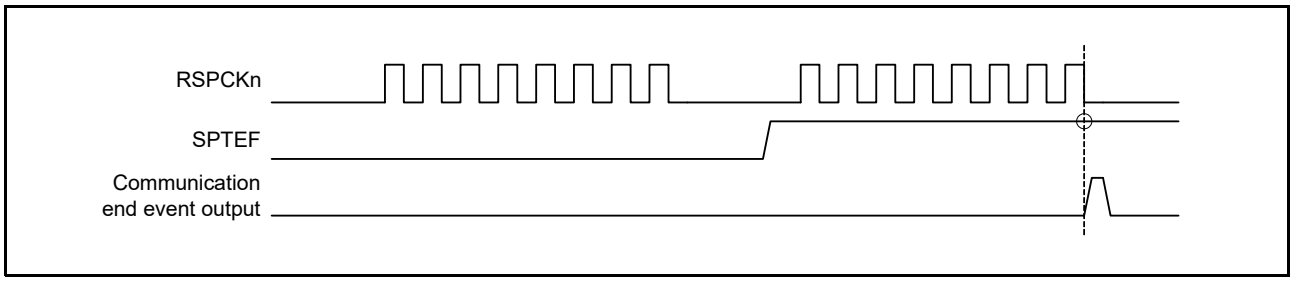

Figure 47.83 Communication End Event Output Timing (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Clock Synchronous Operation)

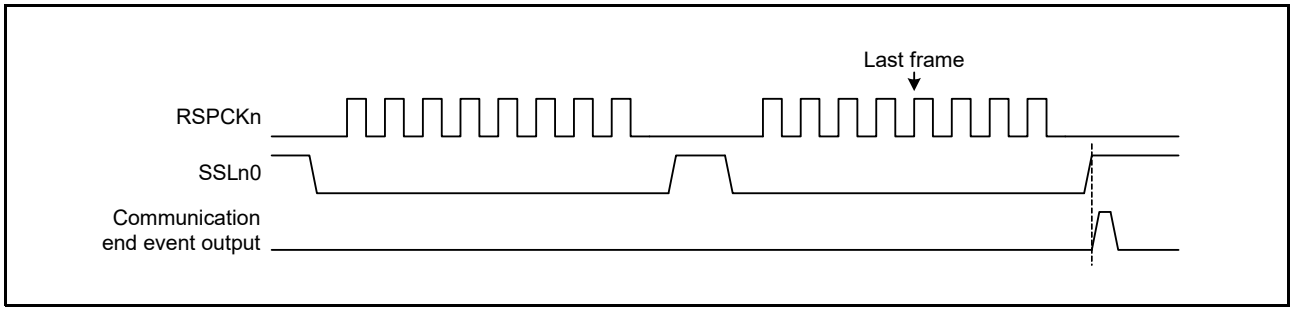

Figure 47.84 Communication End Event Output Timing (Receive-Only Slave Mode, Motorola SPI)

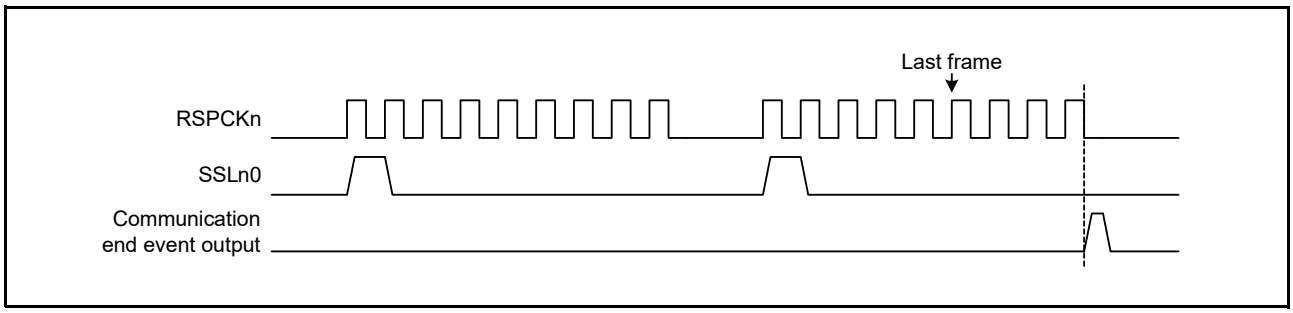

Figure 47.85 Communication End Event Output Timing (Receive-Only Slave Mode, TI SSP)

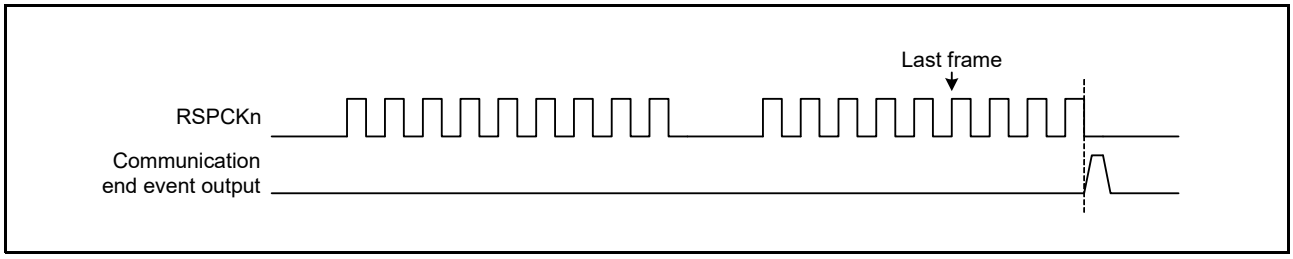

Figure 47.86 Communication End Event Output Timing (Receive-only slave mode, Clock Synchronous Operation)

47.3.19 Synchronizer Bypass Function

RSPIA has circuits that operate in synchronization with the peripheral module clock (PCLKA) and circuits that operate in synchronization with the operating clock (TCLK). A synchronizer is implemented to transfer signals across these two types of circuits, but the signals passing through the synchronizer are delayed by 2 to 3 PCLKA or 2 to 3 TCLK.
However, when the SPCR.SYNDIS bit is set to 1, the peripheral module clock is selected as the operating clock and the synchronizer is bypassed. In this case, the above delay is eliminated and responsiveness is improved.
Note that RSPIA also has a synchronizer between the circuits that operate in synchronization with the serial clock (RSPCK) and the circuits that operate in synchronization with the operating clock, but this synchronizer cannot be bypassed.

47.4 Usage Notes

47.4.1 Settings of the Module Stop Function

RSPIA operation can be disabled or enabled by the module stop control register B (MSTPCRB) for channels 0 and 1 or by the module stop control register C (MSTPCRC) for channel 2. After a reset, the operation of the RSPIA is stopped. The registers become accessible when it is released from the module stop state. For details, refer to section 11, Low Power Consumption.

47.4.2 Notes on Starting Transfer

When the ICU.IRn.IR flag is 1 at the time transfer is to start, follow the procedure below to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1).

1. Confirm that transfer has stopped (i.e. that the SPCR.SPE bit is 0).
2. Set the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) to 0.
3. Read the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IRn.IR flag to 0.

47.4.3 Note on Error Events Output

To enable SPI operation of the RSPIA in master mode in the multi-master environment (SPCR.SPMS bit = 0, SPCR.MSTR bit = 1, and SPCR.MODFEN bit = 1), do not use any output of error events.

47.4.4 Note on Low Power Consumption Functions

To reduce power consumption of this module by using the low power consumption functions, set the SPCR.SPE bit to 0 to terminate communication, and then use the low power consumption functions.

47.4.5 Note on the SPRF and SPTEF flags

When polling the SPSR.SPRF flag and/or SPSR.SPTEF flag, set the SPCR.SPRIE bit and/or SPCR.SPTIE bit to 0.

47.4.6 Notes on Burst Transfer in Master Mode

During burst transfer, changing the following settings between the SPCMDm register with the SSLKP bit set to 1 and the SPCMDm register used in the next transfer is prohibited.

- SSL Signal Assertion setting (SSLA[2:0] bits)
- RSPCK output setting (CPHA, CPOL, BRDV[1:0] bits)

47.4.7 Notes on Operating in TI SSP Slave Mode

In the TI SSP slave mode, the delay between frames must observe the following intervals. Secure the following intervals on the master side.

[Master side: interval from the RSPCK edge of last bit to the RSPCK edge of next SSL] > [Slave side: OE delay time = TCLK × (1 or 2) + SLNDL[2:0] setting value]

47.4.8 Notes on Data Length and Frequency Ratio

Table 47.17 shows whether RSPIA can operate for each combination of the frequency ratio of PCLKA and TCLK and the data length.

Table 47.17 Operation Possibilities Based on Frequency Ratio of PCLKA and TCLK and Data Length (SPCMDm.BRDV[1:0] = 00b, SPBR = 00h)

		Data Length										
RSPI Mode	**PCLKA:TCLK**	**4 bits**	**5 bits**	**6 bits**	**7 bits**	**8 bits**	**9 bits**	**10 bits**	**11 bits**	**12 bits**	**13 bits**	**14 bits**
SPCR. SYNDIS = 0	1:4	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Possible
	1:2	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Possible	Possible	Possible	Possible
	2:3	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Possible	Possible	Possible	Possible
	1:1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Possible	Possible	Possible	Possible	Possible	Possible
	150 MHz : 32 kHz	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Conditionally possible *1	Possible	Possible	Possible	Possible	Possible	Possible	Possible
SPCR. SYNDIS = 1	1:1	Conditionally possible *2	Conditionally possible *2	Conditionally possible *2	Possible	Possible	Possible	Possible	Possible	Possible	Possible	Possible

Possible: Operation is possible
Conditionally possible: Operation is possible under certain conditions.
Note 1. Operation is possible when the SPCR.SCKASE and SCKDDIS bits are 0.
Note 2. Operation is possible when the SPCR.SCKASE or SCKDDIS bit is 0.

47.4.9 Notes on Rewriting Registers

If the following registers or bits are rewritten while the SPCR.SPE bit is 1, subsequent operation is not guaranteed. When the SPCR.SPE bit is rewritten from 1 to 0 or the SPE bit becomes 0 because the SPSR.MODF flag is set to 1, while the SPCR.SYNDIS bit is 0, confirm that the SPPSR.SPEPS flag is set to 0, and then proceed to the next processing.

Table 47.18 List of Registers and Bits that Cannot Be Rewritten When the SPCR.SPE Bit Is 1 (1/2)

Register	**Bit**
SPCKD	SCKDL[2:0]
SSLND	SLNDL[2:0]
SPND	SPNDL[2:0]

Table 47.18 List of Registers and Bits that Cannot Be Rewritten When the SPCR.SPE Bit Is 1 (2/2)

Note 1. Rewriting is prohibited in slave mode. In master mode, rewriting is possible only when there is no next transmit data in the transmit FIFO.

48. Expanded Serial Peripheral Interface (XSPI)

This MCU incorporates two units of expanded serial peripheral interface (XSPI0, XSPI1) compliant with the xSPI (eXpanded SPI) standard.
XSPI consists of a controller module and a target module, and the software can select and use either module.

48.1 Overview

XSPI complies with JEDEC standards JESD251 (Profile 1.0, 2.0), JESD251-1, and JESD252.
JESD251 Profile 1.0 supports Octal xSPI. JESD251 Profile 2.0 supports HyperBus™ (HyperRAM™ and HyperFlash™).
Table 48.1 lists the specifications of the XSPI controller module, Table 48.2 lists the specifications of the XSPI target module, Figure 48.1 shows the block diagram of the XSPI controller module, Figure 48.2 shows the block diagram of the XSPI target module, and Table 48.3 lists the I/O pins.

Table 48.1 XSPI Controller Module Specifications

Item	Description
Number of units	Two units
Supported standards	JESD251 (xSPI) Profile 1.0 (Octal xSPI), 2.0 (HyperBus™) JESD251-1 (x4 Quad I/O with Data Strobe) JESD252 (Serial Flash Reset Signaling Protocol)
Number of target	Up to two target devices can be connected.
Operating clock	Register access: PCLKB Communication clock: XSPIDIVCLK (up to 133 MHz), XSPICLK (up to 266 MHz)
Transfer speed	Supports xSPI-266: up to 133 MHz, up to 266 MT/s
IO protocol mode	Transaction phase: Command–Modifier–Data Transfer bit width: 1 bit, 2 bits, 4 bits, or 8 bits Data rate: SDR, DDR Address: 8 bits, 16 bits, 24 bits, 32 bits, or 45 bits Initial access latency: Configurable within the range of 0 to 31 for each command Supports XIP mode
Protocol mode	Supports the following seven protocol modes: • 1S-1S-1S (xSPI) • 1S-2S-2S (legacy SPI) • 2S-2S-2S (legacy SPI) • 1S-4S-4S (legacy SPI) • 4S-4S-4S (legacy SPI) • 4S-4D-4D (xSPI) • 8D-8D-8D (xSPI)
Access mode	Memory-mapped mode • Up to 256 Mbytes per area • Prefetch function: 128-byte prefetch buffer • 128-byte write buffer • Supports on-the-fly decryption of read data*1 Indirect access mode • Sequential mode: Up to four transactions can be issued consecutively • Periodic mode: Allows periodic checking of the status of the xSPI device
Others	Supports DS signal compatible with read data strobe/write data mask Automatic calibration function for read data strobe signal Supports In-band Reset
Interrupt sources	Error interrupt Completion interrupt
Module stop function	Module-stop state can be set to reduce power consumption
Protect Zone filter	Security attribute can be set for each unit.*2 Security attribute of the XSPI area used in memory-mapped mode is fixed to Non-secure.

Note 1. For details on on-the-fly decryption, refer to section 49, Decryption On The Fly (DOTF).
Note 2. When each unit is set to the secure attribute, registers in the unit are accessible by secure transactions. Any access by non-

secure transaction is ignored, and a Protect Zone access error is generated.
When each unit is set to the non-secure attribute, registers in the unit are accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Table 48.2 XSPI Target Module Specifications

Item	Description
Number of units	Two units
Supported standards	JESD251 (xSPI) Profile 1.0 (Octal xSPI), 2.0 (HyperBus™) JESD251-1 (x4 Quad I/O with Data Strobe) JESD252 (Serial Flash Reset Signaling Protocol)
Operating clock	Register access: PCLKB Communication clock: XSPIn_CK (up to 100 MHz*1)
Transfer speed	Supports xSPI-200: up to 100 MHz, up to 200 MT/s
IO Protocol mode	Transaction phase: Command–Modifier–Data Transfer bit width: 1 bit, 4 bits, or 8 bits Data rate: SDR, DDR Address: 16 bits, 24 bits, or 32 bits Initial access latency: Configurable within the range of 11 to 31 for read and 0 to 31 for write
Protocol mode	Supports the following three protocol modes: • 1S-1S-1S (xSPI) • 4S-4D-4D (xSPI) • 8D-8D-8D (xSPI)
Access mode	Register access • The xSPI controller can access registers within the XSPI target module. Memory access • The xSPI controller can access SRAM0 and SRAM1 via the XSPI target module. • 1 Kbyte of write/read buffer
Module stop function	Module-stop state can be set to reduce power consumption
Protect Zone filter	Security attribute can be set for each unit.*2, *3

Note 1. The frequency of the XSPIn_CK should be 90% or less of the frequency of ICLK.
Note 2. When each unit is set to the secure attribute, registers in the unit are accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When each unit is set to the non-secure attribute, registers in the unit are accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 3. The security attribute of the XSPI target module as a bus master is also the same as this setting.

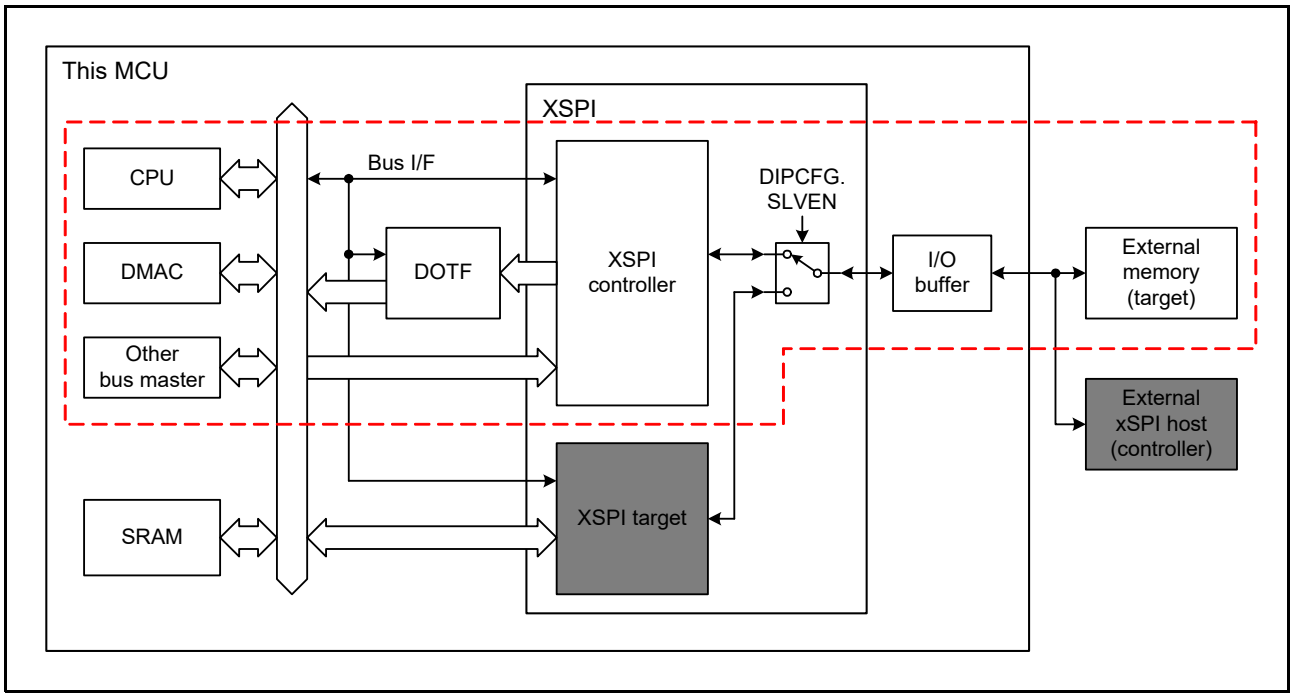

Figure 48.1 XSPI Controller Block Diagram

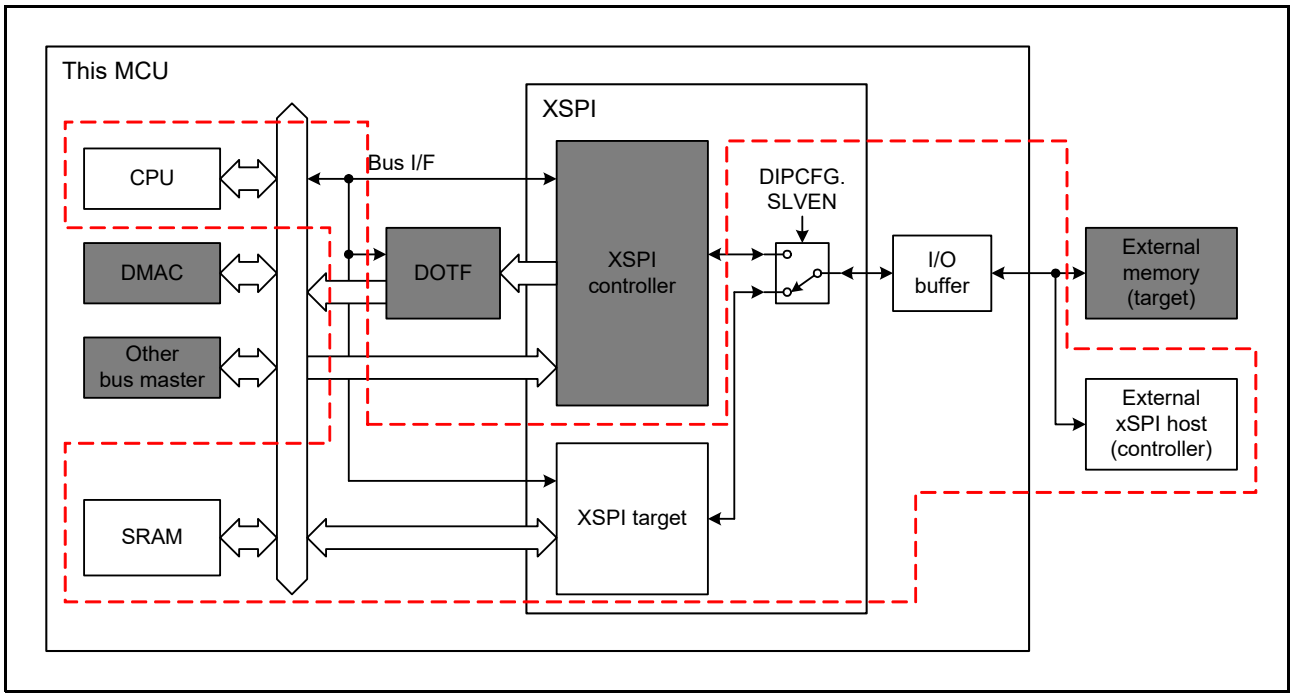

Figure 48.2 XSPI Target Block Diagram

Table 48.3 XSPI Pin Configuration

Unit	Pin Name	I/O		Description
		Controller	Target	
XSPI0	XSPI0_CK	Output	Input	Clock signal
	XSPI0_CKN	Output	—	Inverted clock signal when a differential clock is required
	XSPI0_CS0#	Output	Input	Chip select signal for target device 0
	XSPI0_CS1#	Output	—	Chip select signal for target device 1
	XSPI0_IO7 to XSPI0_IO0	I/O	I/O	Bidirectional data signal
	XSPI0_DS	I/O	I/O	Data strobe signal
	XSPI0_RESET0#	Output	Input	Reset signal for target device 0
	XSPI0_RESET1#	Output	—	Reset signal for target device 1
	XSPI0_RSTO0#	Input	Output	Signal indicating that target device 0 is resetting
	XSPI0_RSTO1#	Input	—	Signal indicating that target device 1 is resetting
	XSPI0_INT0#	Input	Output	Interrupt request signal from target device 0
	XSPI0_INT1#	Input	—	Interrupt request signal from target device 1
	XSPI0_ECS0#	Input	—	Signal indicating an ECC error occurred on target device 0
	XSPI0_ECS1#	Input	—	Signal indicating an ECC error occurred on target device 1
	XSPI0_WP0#	Output	—	Write protect signal for target device 0
	XSPI0_WP1#	Output	—	Write protect signal for target device 1
XSPI1	XSPI1_CK	Output	Input	Clock signal
	XSPI1_CKN	Output	—	Inverted clock signal when a differential clock is required
	XSPI1_CS0#	Output	Input	Chip select signal for target device 0
	XSPI1_CS1#	Output	—	Chip select signal for target device 1
	XSPI1_IO7 to XSPI1_IO0	I/O	I/O	Bidirectional data signal
	XSPI1_DS	I/O	I/O	Data strobe signal
	XSPI1_RESET0#	Output	Input	Reset signal for target device 0
	XSPI1_RESET1#	Output	—	Reset signal for target device 1
	XSPI1_RSTO0#	Input	Output	Signal indicating that target device 0 is resetting
	XSPI1_RSTO1#	Input	—	Signal indicating that target device 1 is resetting
	XSPI1_INT0#	Input	Output	Interrupt request signal from target device 0
	XSPI1_INT1#	Input	—	Interrupt request signal from target device 1
	XSPI1_ECS0#	Input	—	Signal indicating an ECC error occurred on target device 0
	XSPI1_ECS1#	Input	—	Signal indicating an ECC error occurred on target device 1
	XSPI1_WP0#	Output	—	Write protect signal for target device 0
	XSPI1_WP1#	Output	—	Write protect signal for target device 1

Note: Insert series termination registers of 30Ω ± 1% into the XSPIn_IO7 to XSPIn_IO0, XSPIn_CK, XSPIn_CKN, and XSPIn_DS pins (n = 0, 1).

48.2 Register Descriptions

48.2.1 Operating Mode Setting Register (DIPCFG)

Address(es): XSPI0.DIPCFG 8786 73FCh, XSPI1.DIPCFG 8786 77FCh, XSPI0_NS.DIPCFG 0786 73FCh, XSPI1_NS.DIPCFG 0786 77FCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SLVEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SLVEN	Target Mode Enable	0: Controller mode 1: Target mode	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the operating mode (controller/target) of the xSPI.

SLVEN Bit (Target Mode Enable)

This bit specifies whether XSPI is used in controller mode or target mode. It primarily switches the input/output direction of the pins.

Set this bit before an xSPI transaction begins. Changing this bit setting after an xSPI transaction has started is prohibited.

48.2.2 Controller Mode Registers

48.2.2.1 Timing Configuration Register (WRAPCFG)

Address(es): XSPI0.WRAPCFG 8786 8000h, XSPI1.WRAPCFG 8786 8400h, XSPI0_NS.WRAPCFG 0786 8000h, XSPI1_NS.WRAPCFG 0786 8400h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	DSSFTCS1[4:0]					—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DSSFTCS0[4:0]					—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12 to b8	DSSFTCS0[4:0]	DS Phase Shift Setting 0	Set the delay for the DS signal output by target device 0. b12 b8 00000: No delay 00001: Add a delay of 1 cell : : 11110: Add a delay of 30 cells 11111: Add a delay of 31 cells	R/W
b23 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b28 to b24	DSSFTCS1[4:0]	DS Phase Shift Setting 1	Set the delay for the DS signal output by target device 1. b28 b24 00000: No delay 00001: Add a delay of 1 cell : : 11110: Add a delay of 30 cells 11111: Add a delay of 31 cells	R/W
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions.

DSSFTCSi[4:0] Bits (DS Phase Shift Setting i) (i = 0, 1)

These bits configure the delay amount (phase shift amount) for the data strobe signal (XSPIn_DS signal (n = 0, 1)) output by target device i.

These bits are used to adjust the sampling timing in the protocol mode that uses a data strobe signal to sample read data.

Do not rewrite these bits when automatic calibration is enabled, as values are updated automatically.

48.2.2.2 Common Configuration Register (COMCFG)

Address(es): XSPI0.COMCFG 8786 8004h, XSPI1.COMCFG 8786 8404h, XSPI0_NS.COMCFG 0786 8004h, XSPI1_NS.COMCFG 0786 8404h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OENEGEX	OEASTEX
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	OEASTEX	Output Enable Assertion Delay	0: Does not delay the assertion timing of the IO[7:0] and DS signals. 1: Delays the assertion timing of IO[7:0] and DS signals by one cycle.	R/W
b17	OENEGEX	Output Enable Negation Delay	0: Does not delay the negation timing of the IO[7:0] and DS signals. 1: Delays the negation timing of IO[7:0] and DS signals by one cycle.	R/W
b31 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions.

This register configures the basic operation of the XSPI controller module.

OEASTEX Bit (Output Enable Assertion Delay)

This bit specifies the assertion timing of the output buffer control signal (OE: Output Enable). Setting this bit to 1 delays the start of output from the XSPIn_IO7 to XSPIn_IO0 pins and the XSPIn_DS pin by one cycle (n = 0, 1). In this case, the LIOCFGCSi.CSASTEX bit must also be set to 1 to extend the assertion period of the XSPIn_CSi# signal (i = 0, 1). Do not set this bit to 1 if there are no latency cycles, as this may cause output data to conflict with input data.

OENEGEX Bit (Output Enable Negation Delay)

This bit specifies the negation timing of the output buffer control signal (OE: Output Enable). Setting this bit to 1 delays the stop of output from the XSPIn_IO7 to XSPIn_IO0 pins and the XSPIn_DS pin by one cycle.
Do not set this bit to 1 if there are no latency cycles, as this may cause output data to conflict with input data.

48.2.2.3 Memory-Mapped Mode Configuration Register (BMCFGCH0)

Address(es): XSPI0.BMCFGCH0 8786 8008h, XSPI1.BMCFGCH0 8786 8408h,
XSPI0_NS.BMCFGCH0 0786 8008h, XSPI1_NS.BMCFGCH0 0786 8408h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CMBTIM[7:0]								—	—	—	—	—	—	—	PREEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WRMD	Internal Bus Write Cycle Response Mode Select*1	0: Responds after storing data to the write buffer 1: Responds after issuing a write transaction on the xSPI bus	R/W
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	MWRCOMB	Write Data Combination Mode Enable	0: Write data combination mode is disabled. 1: Write data combination mode is enabled.	R/W
b15 to b8	MWRSIZE[7:0]	Write Data Size Select	00h: 4 bytes 01h: 8 bytes : : 0Eh: 60 bytes 0Fh: 64 bytes FFh: 2 bytes Settings other than above are prohibited	R/W
b16	PREEN	Prefetch Function Enable	0: Prefetch function is disabled. 1: Prefetch function is enabled.	R/W
b23 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b24	CMBTIM[7:0]	Combination Timer Timeout Period Setting	These bits specify the timeout period for write data combination mode	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions.
Note 1. When setting the WRMD bit to 1, set the MWRCOMB bit to 0.

This register configures the operation of the memory-mapped mode within the basic operation of the XSPI controller module.

WRMD Bit (Internal Bus Write Cycle Response Mode Select)

This bit selects the response timing for the write cycle from the internal bus in memory-mapped mode. When this bit is set to 1, a response is returned after one frame is transmitted on the xSPI bus.

MWRCOMB Bit (Write Data Combination Mode Enable)

This bit is used to combine multiple write cycles from the internal bus into a single xSPI frame in memory-mapped mode.
When this bit is set to 0, one xSPI frame is generated for each write cycle on the internal bus.
When this bit is set to 1, an xSPI frame of the data size specified by the MWRSIZE[7:0] bits is generated. The xSPI transaction is not issued and is held internally within the XSPI until data of the specified size is available.

MWRSIZE[7:0] Bits (Write Data Size Select)

These bits specify the data size of the xSPI frame to be generated in memory-mapped mode. While write cycles to consecutive addresses are issued, xSPI frames of the specified data size are transmitted. If a read cycle or a write cycle to non-consecutive addresses is issued before the specified size is reached, an xSPI frame is generated using the data that

was reserved up to that point and transmitted on the xSPI bus.

PREEN Bit (Prefetch Function Enable)

This bit enables the prefetch function for read transactions in memory-mapped mode, which has the effect of reducing the latency of xSPI transactions when reading from consecutive addresses.

CMBTIM[7:0] Bits (Combination Timer Timeout Period Setting)

This bit specifies the number of ICLK cycles for which frame transmission is suspended internally for data integration in write data combination mode.
When the timer value reaches 00h, an xSPI frame is generated using the data accumulated up to that point and transmitted onto the xSPI bus. When 00h is set, no timeout occurs.

48.2.2.4 CSi Area Memory-Mapped Mode Configuration Register 0 (CMCFG0CSi) (i = 0, 1)

Address(es): XSPI0.CMCFG0CS0 8786 8010h, XSPI0.CMCFG0CS1 8786 8020h, XSPI1.CMCFG0CS0 8786 8410h, XSPI1.CMCFG0CS1 8786 8420h, XSPI0_NS.CMCFG0CS0 0786 8010h, XSPI0_NS.CMCFG0CS1 0786 8020h, XSPI1_NS.CMCFG0CS0 0786 8410h, XSPI1_NS.CMCFG0CS1 0786 8420h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	FFMT[1:0]	Frame Format Setting	b1 b0 0 0: Normal format 0 1: 8D-8D-8D profile 1.0 format 1 0: 8D-8D-8D profile 2.0 command modifier format 1 1: 8D-8D-8D profile 2.0 extended command modifier format	R/W
b3, b2	ADDSIZE[1:0]	Address Size Setting	b3 b2 0 0: 1 byte (256-Byte address space) 0 1: 2 bytes (64-Kbyte address space) 1 0: 3 bytes (16-Mbyte address space) 1 1: 4 bytes (4-Gbyte address space)	R/W
b4	WPBSTMD	WRAP Burst Mode Setting	0: Separate xSPI transfer at the wrap boundary 1: Not separate xSPI transfer at the wrap boundary	R/W
b5	ARYAMD	Array Address Mode Setting	0: Normal address mode 1: Array address mode	R/W
b15 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	ADDRPEN[7:0]	Address Replace Enable	These bits are used to specify, on a bit-by-bit basis, whether to replace the value of each of the 8 higher-order bits of the address output to the xSPI bus with the value specified by the corresponding ADDRPCD[7:0] bits. 0: Do not replace the corresponding address bit. 1: Replace the corresponding address bit.	R/W
b31 to b24	ADDRPCD[7:0]	Address to be Replaced	Set the value with which the 8 higher-order bits of the address output to the xSPI bus are to be replaced where this is selected by the corresponding ADDRPEN[7:0] bits.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions.

This register configures the operation of the memory-mapped mode within the basic operation of the XSPI controller module.

FFMT[1:0] Bits (Frame Format Setting)

These bits configure the xSPI frame format in memory-mapped mode. Table 48.4 shows the frame format for each setting value.

Table 48.4 FFMT[1:0] Bit Settings and xSPI Frame

FFMT[1:0]	Protocol Mode	xSPI Frame Format
00b	Except for the following	Command (1 byte) + Address (1 to 4 bytes) + Data
01b	8D-8D-8D Profile 1.0	Command (1 byte) + Command extension (1 byte) + Address (1 to 4 bytes) + Data
10b	8D-8D-8D Profile 2.0	Command (1 byte) + Command modifier (5 bytes) + Data
11b	8D-8D-8D Profile 2.0	Command (1 byte) + Command modifier (5 bytes) + Command extension (1 byte) + Data

ADDSIZE[1:0] Bits (Address Size Setting)

These bits specify the number of bytes in the address field in memory-mapped mode.
When setting the FFMT[1:0] bits to 10b or 11b (8D-8D-8D Profile 2.0), set this bit to 11b (4 bytes).

WPBSTMD Bit (WRAP Burst Mode Setting)

This bit configures the separation of xSPI transfers at the wrap boundary.
When this bit is set to 1, the wrap boundary for internal bus access aligns with the wrap boundary for xSPI memory.

ARYAMD Bit (Array Address Mode Setting)

This bit is used for Profile 1.0 commands.
When this bit is set to 1, the CPU address bits A[31:26] are ignored and the bits sent are A[25:18], A[17:10], A[9:4] + 00b, and 0000b + A[3:0] in that order.

ADDRPEN[7:0] Bits (Address Replace Enable)

These bits are used to select which of the 8 higher-order bits of the address output to the xSPI bus are to be replaced with the corresponding bit values of the ADDRPCD[7:0] bits in memory-mapped mode.

ADDRPCD[7:0] Bits (Address to be Replaced)

The values of these bits are set as the 8 higher-order bits of the address output to the xSPI bus in memory-mapped mode when replacement is selected by the corresponding ADDRPEN[7:0] bits.
The address bits to be replaced also depend on the setting of the ADDSIZE[1:0] bits. For example, if the ADDSIZE[1:0] bits are set to 11b (for 4-byte addresses), A[31:24] of the CPU address are to be replaced; if the ADDSIZE[1:0] bits are set to 10b (for 3-byte addresses), A[23:16] of the CPU address are to be replaced.
The value of the address bit corresponding to any bit in the ADDRPEN[7:0] bits that has the value 1 is replaced with that of the corresponding bit of the ADDRPCD[7:0] bits.
The XSPI area is allocated to the address range from 2000 0000h to 5FFF FFFFh. Accordingly, when using 4-byte addresses, you can access any address in the 4-Gbyte space by setting the ADDRPEN[7:0] bits to F0h and varying the value of the ADDRPCD[7:4] bits within the range from 0h to Fh.

48.2.2.5 CSi Area Memory-Mapped Mode Configuration Register 1 (CMCFG1CSi) (i = 0, 1)

Address(es): XSPI0.CMCFG1CS0 8786 8014h, XSPI0.CMCFG1CS1 8786 8024h, XSPI1.CMCFG1CS0 8786 8414h, XSPI1.CMCFG1CS1 8786 8424h, XSPI0_NS.CMCFG1CS0 0786 8014h, XSPI0_NS.CMCFG1CS1 0786 8024h, XSPI1_NS.CMCFG1CS0 0786 8414h, XSPI1_NS.CMCFG1CS1 0786 8424h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	RDLATE[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RDCMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	RDCMD[15:0]	Read Command Setting	This field configures the value of the command field for read transactions issued in memory-mapped mode.	R/W
b20 to b16	RDLATE[4:0]	Read Latency Cycle Setting	b20 b16 00000: No latency 00001: 1 cycle : : 11110: 30 cycles 11111: 31 cycles	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions.

This register configures the read command in the memory-mapped mode within the basic operation of the XSPI controller module.

RDCMD[15:0] Bits (Read Command Setting)

These bits are used to set the command code specified in the command field for read transactions that are automatically generated in memory-mapped mode.

Set the appropriate value according to the selected frame format. For the normal format and 8D-8D-8D Profile 2.0 format, set the command code in the RDCMD[15:8] bits and set the RDCMD[7:0] bits to 00h. For the 8D-8D-8D Profile 1.0 format, set the command code in the RDCMD[15:8] bits and the command extension in the RDCMD[7:0] bits.

RDLATE[4:0] Bits (Read Latency Cycle Setting)

These bits specify the number of latency cycles to insert during read transactions in memory-mapped mode.

48.2.2.6 CSi Area Memory-Mapped Mode Configuration Register 2 (CMCFG2CSi) (i = 0, 1)

Address(es): XSPI0.CMCFG2CS0 8786 8018h, XSPI0.CMCFG2CS1 8786 8028h, XSPI1.CMCFG2CS0 8786 8418h, XSPI1.CMCFG2CS1 8786 8428h, XSPI0_NS.CMCFG2CS0 0786 8018h, XSPI0_NS.CMCFG2CS1 0786 8028h, XSPI1_NS.CMCFG2CS0 0786 8418h, XSPI1_NS.CMCFG2CS1 0786 8428h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	WRLATE[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WRCMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	WRCMD[15:0]	Write Command Setting	This field configures the value of the command field for write transactions issued in memory-mapped mode.	R/W
b20 to b16	WRLATE[4:0]	Write Latency Cycle Setting	b20 b16 00000: No latency 00001: 1 cycle : : 11110: 30 cycles 11111: 31 cycles	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions.

This register configures the write command in the memory-mapped mode within the basic operation of the XSPI controller module.

WRCMD[15:0] Bits (Write Command Setting)

These bits are used to set the command code specified in the command field for write transactions that are automatically generated in memory-mapped mode.
Set the appropriate value according to the selected frame format. For the normal format and 8D-8D-8D Profile 2.0 format, set the command code in the WRCMD[15:8] bits and set the WRCMD[7:0] bits to 00h. For the 8D-8D-8D Profile 1.0 format, set the command code in the WRCMD[15:8] bits and the command extension in the WRCMD[7:0] bits.

WRLATE[4:0] Bits (Write Latency Cycle Setting)

These bits specify the number of latency cycles to insert during write transactions in memory-mapped mode.

48.2.2.7 CSi Area I/O Signal Configuration Register (LIOCFGCSi) (i = 0, 1)

Address(es): XSPI0.LIOCFGCS0 8786 8050h, XSPI0.LIOCFGCS1 8786 8054h, XSPI1.LIOCFGCS0 8786 8450h, XSPI1.LIOCFGCS1 8786 8454h, XSPI0_NS.LIOCFGCS0 0786 8050h, XSPI0_NS.LIOCFGCS1 0786 8054h, XSPI1_NS.LIOCFGCS0 0786 8450h, XSPI1_NS.LIOCFGCS1 0786 8454h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b21	CSNEGEX	CS Negation Delay	0: No delay 1: 1 cycle delay	R/W
b22	SDRDRV	SDR Data Output Timing Setting	0: Data is output on the falling edge of the XSPIDIVCLK. 1: Data is output on the rising edge of the XSPIDIVCLK.	R/W
b23	SDRSMPMD	SDR Data Sampling Timing Setting	0: Data is sampled on the falling edge of the CK or DS signal. 1: Data is sampled on the rising edge of the CK or DS signal.	R/W
b27 to b24	SDRSMPSFT[3:0]	SDR Data Sampling Timing Delay	b27 b24 0 0 0 0: No delay 0 0 0 1: Delay sampling timing by one cycle : : 0 1 1 0: Delay sampling timing by six cycles 0 1 1 1: Delay sampling timing by seven cycles Settings other than above are prohibited.	R/W

Bit	Symbol	Bit Name	Description	R/W
b31 to b28	DDRSMPEX[3:0]	DDR Data Sampling Period Extension	b31 b28 0 0 0 0: No extension 0 0 0 1: Expand by one cycle : : 0 1 1 0: Expand by six cycles 0 1 1 1: Expand by seven cycles Settings other than above are prohibited.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions.

This register configures the timing of input and output signals within the basic operation of the XSPI controller module.

PRTMD[9:0] Bits (Protocol Mode Setting)

These bits specify the IO protocol mode.
In 4S-4D-4D protocol mode and 8D-8D-8D protocol mode, the DS signal is used for data sampling. In other protocol modes, the CK signal is used.

LATEMD Bit (Latency Mode Select)

This bit selects the behavior of the initial access latency phase. Setting this bit to 0 inserts the specified number of latency cycles after the address field is transmitted.
Setting this bit to 1 causes the latency cycle count to start from the middle of the address field. Furthermore, the inserted latency cycles are doubled when the XSPIn_DS signal is high during the command & command modifier phase (n = 0, 1). This bit is used only during the 8D-8D-8D Profile 2.0 format.

WRMSKMD Bit (Write Data Mask Enable)

This bit configures whether to use the XSPIn_DS signal as a mask signal for each byte in the write data.
The write data mask function is only used in 8D-8D-8D protocol mode.

CSMIN[3:0] Bits (CS Minimum High Width Setting)

These bits are used to set the minimum high width of the XSPIn_CSi# signal (the shortest number of cycles between xSPI frames) (n = 0, 1; i = 0, 1).

CSASTEX Bit (CS Assertion Delay)

This bit is used to delay the assertion timing of the XSPIn_CSi# signal by one cycle.

CSNEGEX Bit (CS Negation Delay)

This bit is used to delay the negation timing of the XSPIn_CSi# signal by one cycle.

SDRDRV Bit (SDR Data Output Timing Setting)

This bit is used to delay the data output timing by 0.5 cycles during SDR transfer.
To prevent potential collisions between output and input data, do not set this bit to 1 if there is no latency cycle.

SDRSMPMD Bit (SDR Data Sampling Timing Setting)

This bit is used to select the input data sampling edge during SDR transfer. When this bit is set to 1, sampling occurs half a cycle earlier than when it is set to 0.

SDRSMPSFT[3:0] Bits (SDR Data Sampling Timing Delay)

This bit is used to delay the sampling timing during SDR transfer in one cycle units.
Set this bit to 0 during DDR transfer.

DDRSMPEX[3:0] Bits (DDR Data Sampling Period Extension)

This bit is used to extend the data phase during DDR transfer.

During DDR transfer, data is sampled within the data phase following the latency cycle. XSPI determines the timing to end the data phase by estimating the number of read data bits. However, depending on the delay of the signal output by the target device, valid data may fall outside the data phase range and risk not being sampled. In such cases, use this bit to extend the data phase.

48.2.2.8 Memory Access Extension Configuration Register (MEMEXTCFG)

Address(es): XSPI0.MEMEXTCFG 8786 805Ch, XSPI1.MEMEXTCFG 8786 845Ch, XSPI0_NS.MEMEXTCFG 0786 805Ch, XSPI1_NS.MEMEXTCFG 0786 845Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DSVLDMDCS1	—	—	—	DSEXTMDCS1	—	—	—	DSVLDMDCS0	—	—	—	DSEXTMDCS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DSEXTMDCS0	DS Receive Wait Extension Mode 0	Extends the acceptance time for the DS signal driven by target device 0 0: DS receive wait extension is disabled 1: DS receive wait extension is enabled	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	DSVLDMDCS0	DS Valid Cycle Setting 0	Delays the start position for accepting the DS signal driven by target device 0 0: DS is valid from the first cycle 1: DS is valid from the second cycle	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	DSEXTMDCS1	DS Receive Wait Extension Mode 1	Extends the acceptance time for the DS signal driven by target device 1 0: DS receive wait extension is disabled 1: DS receive wait extension is enabled	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	DSVLDMDCS1	DS Valid Cycle Setting 1	Delays the start position for accepting the DS signal driven by target device 1 0: DS is valid from the first cycle 1: DS is valid from the second cycle	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions.

This register configures the basic operation of the XSPI controller module.

DSEXTMDCSi Bit (DS Receive Wait Extension Mode i) (i = 0, 1)

This bit is used to configure whether the XSPI accepts DS signals after the scheduled receive cycle has elapsed in 8D-8D-8D Profile 2.0 mode.

When this bit is set to 1, the XSPI waits for DS input for each frame until the expected number of data is reached.

DSVLDMDCSi Bit (DS Valid Cycle Setting i) (i = 0, 1)

When in 8D-8D-8D Profile 1.0 mode, this bit configures the DS valid cycle.

When this bit is 0, the DS input is enabled starting from the first cycle.

When this bit is 1, the DS signal's first cycle (both rising and falling edges) is ignored, and it is used starting from the second cycle.

48.2.2.9 Memory-Mapped Mode Control Register 0 (BMCTL0)

Address(es): XSPI0.BMCTL0 8786 8060h, XSPI1.BMCTL0 8786 8460h, XSPI0_NS.BMCTL0 0786 8060h, XSPI1_NS.BMCTL0 0786 8460h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	CH0CS1ACC[1:0]		CH0CS0ACC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CH0CS0ACC[1:0]	Target Device 0 Memory Access Enable	b1 b0 0 0: Read/Write disabled 0 1: Read enabled, Write disabled 1 0: Read disabled, Write enabled 1 1: Read/Write enabled	R/W
b3, b2	CH0CS1ACC[1:0]	Target Device 1 Memory Access Enable	b3 b2 0 0: Read/Write disabled 0 1: Read enabled, Write disabled 1 0: Read disabled, Write enabled 1 1: Read/Write enabled	R/W
b7 to b4	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions. If you need to change the settings of this register after starting an xSPI transaction, stop all write/read transactions before rewriting it.

This register configures the operation of the memory-mapped mode within the basic operation of the XSPI controller module.

CH0CSiACC[1:0] Bits (Target Device i Memory Access Enable) (i = 0, 1)

These bits are used to configure protection when accessing the CSi area using memory-mapped mode. Protection should be disabled at the end of the initialization process.

48.2.2.10 Memory-Mapped Mode Control Register 1 (BMCTL1)

Address(es): XSPI0.BMCTL1 8786 8064h, XSPI1.BMCTL1 8786 8464h, XSPI0_NS.BMCTL1 0786 8064h, XSPI1_NS.BMCTL1 0786 8464h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PBUFCLRCH0	—	MWRPUSHCH0	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	The write value should be 0.	W
b8	MWRPUSHCH0	Write Data Push*1	Writing 1 to this bit will generate an xSPI frame with the previously pending data.	W
b9	—	Reserved	The write value should be 0.	W
b10	PBUFCLRCH0	Prefetch Buffer Clear*1	Writing 1 to this bit clears the prefetch buffer.	W
b31 to b11	—	Reserved	The write value should be 0.	W

Note 1. If an access from the internal bus occurs at the same time that this bit is written to 1, it is undefined whether a prefetch or write data combination will be performed.

This register controls the operation of the XSPI controller module in memory-mapped mode.

MWRPUSHCH0 Bit (Write Data Push)

In write data combination mode, if there is data reserved without generating an xSPI frame, writing 1 to this bit will force a transaction to be issued.

PBUFCLRCH0 Bit (Prefetch Buffer Clear)

This bit is used to request clearing of the prefetch buffer when the prefetch function is enabled.

48.2.2.11 Memory-Mapped Mode Command Control Register (CMCTLCH0)

Address(es): XSPI0.CMCTLCH0 8786 8068h, XSPI1.CMCTLCH0 8786 8468h, XSPI0_NS.CMCTLCH0 0786 8068h, XSPI1_NS.CMCTLCH0 0786 8468h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	XIPEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	XIPEXCODE[7:0]								XIPENCODE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	XIPENCODE[7:0]	XIP Mode Enter Code Setting	Set the code to enter XIP mode in these bits.	R/W
b15 to b8	XIPEXCODE[7:0]	XIP Mode Exit Code Setting	Set the code to exit XIP mode in these bits.	R/W
b16	XIPEN	XIP Mode Enable*1	0: Disable XIP mode 1: Enable XIP mode	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Do not set this bit to 1 when the 8D-8D-8D Profile 2.0 format is selected.

This register controls the operation of the XSPI controller module in memory-mapped mode.

XIPEN Bit (XIP Mode Enable)

This bit is used to enable XIP mode.

When this bit is set to 1, the XIP enter code specified in the XIPENCODE[7:0] bits is inserted into the latency field of the read transaction. The command field is omitted from subsequent read transactions.

When writing 0 to this bit, the XIP exit code specified in the XIPEXCODE[7:0] bits is inserted into the latency field of the read transaction, and then this bit is set to 0. While this bit is set to 1, XIP mode has not ended.

48.2.2.12 Indirect Access Mode Control Register 0 (CDCTL0)

Address(es): XSPI0.CDCTL0 8786 8070h, XSPI1.CDCTL0 8786 8470h, XSPI0_NS.CDCTL0 0786 8070h, XSPI1_NS.CDCTL0 0786 8470h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	PERREP[3:0]				—	—	—	PERITV[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	TRNUM[1:0]		CSSEL	—	PERMD	TRREQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TRREQ	Transaction Request	0: Transaction aborted or transaction completed 1: Request transaction issuance	R/W
b1	PERMD	Periodic Mode Setting	0: Sequential mode 1: Periodic mode	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	CSSEL	Chip Select	0: Target device 0 (CS0) 1: Target device 1 (CS1)	R/W
b5, b4	TRNUM[1:0]	Transaction Number Setting	b5 b4 0 0: One (using command buffer 0) 0 1: Two (using command buffers 0 and 1) 1 0: Three (using command buffers 0 to 2) 1 1: Four (using command buffers 0 to 3)	R/W
b15 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	PERITV[4:0]	Transaction Interval Setting	b20 b16 00000: 2^1 cycles (2 cycles) 00001: 2^2 cycles (4 cycles) : : 11110: 2^{31} cycles (2,147,483,648 cycles) 11111: 2^{32} cycles (4,294,967,296 cycles)	R/W
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b24	PERREP[3:0]	Transaction Repetition Count Setting	b27 b24 0 0 0 0: 2^0 time (1 time) 0 0 0 1: 2^1 times (2 times) : : 1 1 1 0: 2^{14} times (16,384 times) 1 1 1 1: 2^{15} times (32,768 times)	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the operation of the XSPI controller module in indirect access mode.

TRREQ Bit (Transaction Request)

This bit controls the issuance of transactions.

When this bit is set to 1, the transactions specified in the command buffers are issued. When all transactions have been issued, this bit is automatically set to 0.

Writing 0 to this bit while a transaction is being issued aborts the transaction.

PERMD Bit (Periodic Mode Setting)

This bit is used to enable periodic mode.

When this bit is set to 1, the read transaction specified in command buffer 0 is repeated periodically and the read value is compared with the expected value. This can be used for status polling of external memory.

CSSEL Bit (Chip Select)

This bit selects the target device to issue the transaction.

TRNUM[1:0] Bits (Transaction Number Setting)

This bit is used to set the number of transactions to issue in sequential mode.
In periodic mode, this bit should normally be set to 00b. If a value other than 00b is set, the read data of the last transaction is compared with the expected value.

PERITV[4:0] Bits (Transaction Interval Setting)

These bits are used to set the transaction issuance interval in periodic mode.
If this interval is too short compared to the CPU bus cycle, the read value may not be stored in the data buffer. Ensure the interval is at least four times longer than the CPU bus cycle.

PERREP[3:0] Bits (Transaction Repetition Count Setting)

These bits are used to set the number of times to repeat a specified transaction in periodic mode.
If the read value does not match the expected value even after the number of times set in these bits have been reached, it is considered a timeout.

48.2.2.13 Indirect Access Mode Control Register 1 (CDCTL1)

Address(es): XSPI0.CDCTL1 8786 8074h, XSPI1.CDCTL1 8786 8474h, XSPI0_NS.CDCTL1 0786 8074h, XSPI1_NS.CDCTL1 0786 8474h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to set the expected value for comparison with the read value in the periodic mode of indirect access mode. Set the expected value right-justified. For example, when performing a 1-byte comparison, set the value in bits b7 to b0.

48.2.2.14 Indirect Access Mode Control register 2 (CDCTL2)

Address(es): XSPI0.CDCTL2 8786 8078h, XSPI1.CDCTL2 8786 8478h, XSPI0_NS.CDCTL2 0786 8078h, XSPI1_NS.CDCTL2 0786 8478h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to set the mask value for comparing the read value with the expected value in the periodic mode of indirect access mode. Bits set to 1 in this register will not be compared.
For example, this register is used to compare only one byte when the protocol mode that cannot read in units of one byte is selected.

48.2.2.15 Command Buffer m Transaction Type Register (CDTBUFm) (m = 0 to 3)

Address(es): XSPI0.CDTBUF0 8786 8080h, XSPI0.CDTBUF1 8786 8090h, XSPI0.CDTBUF2 8786 80A0h, XSPI0.CDTBUF3 8786 80B0h, XSPI1.CDTBUF0 8786 8480h, XSPI1.CDTBUF1 8786 8490h, XSPI1.CDTBUF2 8786 84A0h, XSPI1.CDTBUF3 8786 84B0h, XSPI0_NS.CDTBUF0 0786 8080h, XSPI0_NS.CDTBUF1 0786 8090h, XSPI0_NS.CDTBUF2 0786 80A0h, XSPI0_NS.CDTBUF3 0786 80B0h, XSPI1_NS.CDTBUF0 0786 8480h, XSPI1_NS.CDTBUF1 0786 8490h, XSPI1_NS.CDTBUF2 0786 84A0h, XSPI1_NS.CDTBUF3 0786 84B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TRTYPE	—	LATE[4:0]					DATASIZE[3:0]				ADDSIZE[2:0]			CMDSIZE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CMDSIZE[1:0]	Command Size Setting	b1 b0 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes 1 1: Setting prohibited	R/W
b4 to b2	ADDSIZE[2:0]	Address Size Setting	b4 b2 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Settings other than above are prohibited.	R/W
b8 to b5	DATASIZE[3:0]	Data Size Setting	b8 b5 0 0 0 0: 0 bytes (No data phase) 0 0 0 1: 1 byte : : 0 1 1 1: 7 bytes 1 0 0 0: 8 bytes Settings other than above are prohibited.	R/W
b13 to b9	LATE[4:0]	Latency Cycle Setting	b13 b9 00000: No latency 00001: 1 cycle : : 11110: 30 cycles 11111: 31 cycles	R/W
b14	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b15	TRTYPE	Transaction Type Select	0: Read transaction 1: Other than read transaction	R/W
b31 to b16	CMD[15:0]	Command Field Setting	Set the command field (1 to 2 bytes)	R/W

This register configures the transaction to be issued in indirect access mode. This register specifies the command type and the size of each field, etc.

CMDSIZE[1:0] Bits (Command Size Setting)

These bits are used to set the size of the command field.

If 8D-8D-8D protocol mode is selected, these bits must be set to 10b.

Setting both the command size and address size to 0 bytes is prohibited.

ADDSIZE[2:0] Bits (Address Size Setting)

These bits are used to set the size of the address field.

DATASIZE[3:0] Bits (Data Size Setting)

These bits are used to set the size of the data field.
When 8D-8D-8D protocol mode is selected, data bytes are transferred only in byte pairs (16-bit units). For example, even if an odd-numbered byte is set to read, an even-numbered byte of data is received. In this case, the last byte is ignored.
Do not set 0 bytes for a read transaction.

LATE[4:0] Bits (Latency Cycle Setting)

These bits are used to set the latency cycle.

TRTYPE Bit (Transaction Type Select)

These bits are used to set the type of the transaction.

CMD[15:0] Bits (Command Field Setting)

These bits are used to set the command field as one or two bytes.
The command with the number of bytes specified by CMDSIZE[1:0] bits is transferred.

Table 48.5 CMD[15:0] Bit Setting Value for Each Frame Format

Frame Format	CMD[15:8] Bits	CMD[7:0] Bits
1S-1S-1S	Command code	Not used
4S-4D-4D	Command code	Not used
8D-8D-8D Profile 1.0 format	Command code	Command extension
8D-8D-8D Profile 2.0 command modifier format	Command code	First byte of the command modifier
8D-8D-8D Profile 2.0 extended command modifier format	Command code + command extension	First byte of the command modifier

48.2.2.16 Command Buffer m Address Register (CDABUFm) (m = 0 to 3)

Address(es): XSPI0.CDABUF0 8786 8084h, XSPI0.CDABUF1 8786 8094h, XSPI0.CDABUF2 8786 80A4h, XSPI0.CDABUF3 8786 80B4h, XSPI1.CDABUF0 8786 8484h, XSPI1.CDABUF1 8786 8494h, XSPI1.CDABUF2 8786 84A4h, XSPI1.CDABUF3 8786 84B4h, XSPI0_NS.CDABUF0 0786 8084h, XSPI0_NS.CDABUF1 0786 8094h, XSPI0_NS.CDABUF2 0786 80A4h, XSPI0_NS.CDABUF3 0786 80B4h, XSPI1_NS.CDABUF0 0786 8484h, XSPI1_NS.CDABUF1 0786 8494h, XSPI1_NS.CDABUF2 0786 84A4h, XSPI1_NS.CDABUF3 0786 84B4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to configure the transaction to be issued in indirect access mode. Set the address field in this register. The address of the number of bytes specified by the CDTBUFm.ADDSIZE[2:0] bits is transferred in order from the most significant byte. If the address size is less than 4 bytes, set the lower byte to 00h.

Table 48.6 Address Field Setting Value for Each Frame Format

Frame Format	Address Field
1S-1S-1S	Address
4S-4D-4D	Address
8D-8D-8D Profile 1.0 format	Address
8D-8D-8D Profile 2.0 command modifier format	Second to fifth bytes of the command modifier
8D-8D-8D Profile 2.0 extended command modifier format	Second to fifth bytes of the command modifier

48.2.2.17 Command Buffer m Data Register 0 (CDD0BUFm) (m = 0 to 3)

Address(es): XSPI0.CDD0BUF0 8786 8088h, XSPI0.CDD0BUF1 8786 8098h, XSPI0.CDD0BUF2 8786 80A8h, XSPI0.CDD0BUF3 8786 80B8h, XSPI1.CDD0BUF0 8786 8488h, XSPI1.CDD0BUF1 8786 8498h, XSPI1.CDD0BUF2 8786 84A8h, XSPI1.CDD0BUF3 8786 84B8h, XSPI0_NS.CDD0BUF0 0786 8088h, XSPI0_NS.CDD0BUF1 0786 8098h, XSPI0_NS.CDD0BUF2 0786 80A8h, XSPI0_NS.CDD0BUF3 0786 80B8h, XSPI1_NS.CDD0BUF0 0786 8488h, XSPI1_NS.CDD0BUF1 0786 8498h, XSPI1_NS.CDD0BUF2 0786 84A8h, XSPI1_NS.CDD0BUF3 0786 84B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to configure the transaction to be issued in indirect access mode.
For a write transaction, set the first 4 bytes of the data field in this register. The data of the number of bytes specified by the CDTBUFm.DATASIZE[3:0] bits is transferred in order from the most significant byte. If the data size is less than 4 bytes, set the lower byte to 00h.
For a read transaction, the first 4 bytes of the read data are stored in this register.

48.2.2.18 Command Buffer m Data Register 1 (CDD1BUFm) (m = 0 to 3)

Address(es): XSPI0.CDD1BUF0 8786 808Ch, XSPI0.CDD1BUF1 8786 809Ch, XSPI0.CDD1BUF2 8786 80ACh, XSPI0.CDD1BUF3 8786 80BCh, XSPI1.CDD1BUF0 8786 848Ch, XSPI1.CDD1BUF1 8786 849Ch, XSPI1.CDD1BUF2 8786 84ACh, XSPI1.CDD1BUF3 8786 84BCh, XSPI0_NS.CDD1BUF0 0786 808Ch, XSPI0_NS.CDD1BUF1 0786 809Ch, XSPI0_NS.CDD1BUF2 0786 80ACh, XSPI0_NS.CDD1BUF3 0786 80BCh, XSPI1_NS.CDD1BUF0 0786 848Ch, XSPI1_NS.CDD1BUF1 0786 849Ch, XSPI1_NS.CDD1BUF2 0786 84ACh, XSPI1_NS.CDD1BUF3 0786 84BCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is used to configure the transaction to be issued in indirect access mode.
For a write transaction, set the last 4 bytes of the data field in this register. The data of the number of bytes specified by the CDTBUFm.DATASIZE[3:0] bits is transferred in order from the most significant byte. If the data size is less than 8 bytes, set the lower byte to 00h.
For a read transaction, the last 4 bytes of the read data are stored in this register.

48.2.2.19 Signal Pattern Control Register 0 (LPCTL0)

Address(es): XSPI0.LPCTL0 8786 8100h, XSPI1.LPCTL0 8786 8500h, XSPI0_NS.LPCTL0 0786 8100h, XSPI1_NS.LPCTL0 0786 8500h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	XD2VAL	—	—	XD2LEN[4:0]					XD1VAL	—	—	XD1LEN[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	XDPIN[1:0]		CSSEL	—	—	PATREQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PATREQ	XIP Disable Pattern Generation Request	0: Do not generate XIP disable pattern/Generation complete 1: Request generation of XIP disable pattern	R/W
b2, b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	CSSEL	Chip Select	0: Target device 0 (CS0) 1: Target device 1 (CS1)	R/W
b5, b4	XDPIN[1:0]	XIP Disable Pattern Output Pin Select	b5 b4 0 0: 1 pin 0 1: 2 pins 1 0: 4 pins 1 1: 8 pins	R/W
b15 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	XD1LEN[4:0]	XIP Disable Pattern 1st Phase Length Setting*1	b20 b16 00000: 0 cycles 00001: 1 cycle : : 11110: 30 cycles 11111: 31 cycles	R/W
b22, b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23	XD1VAL	XIP Disable Pattern 1st Phase Output Level Select	0: Low 1: High	R/W
b28 to b24	XD2LEN[4:0]	XIP Disable Pattern 2nd Phase Length Setting*1	b28 b24 00000: 0 cycles 00001: 1 cycle : : 11110: 30 cycles 11111: 31 cycles	R/W
b30 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	XD2VAL	XIP Disable Pattern 2nd Phase Output Level Select	0: Low 1: High	R/W

Note 1. Setting both of these bits to 00000b is prohibited.

This register controls the generation of the XIP disable pattern by the XSPI controller module.

PATREQ Bit (XIP Disable Pattern Generation Request)

This bit is used to request generation of the XIP disable pattern.

Writing 1 to this bit initiates generation of the XIP disable pattern. It automatically returns to 0 when pattern generation is complete.

CSSEL Bit (Chip Select)

This bit selects the target device for which the XIP disable pattern is generated.

XDPIN[1:0] Bits (XIP Disable Pattern Output Pin Select)

These bits select the number of data pins to be used to generate the XIP disable pattern.

XD1LEN[4:0] Bits (XIP Disable Pattern 1st Phase Length Setting)

These bits set the length of the first phase of the XIP disable pattern in number of XSPIDIVCLK cycles.

XD1VAL Bit (XIP Disable Pattern 1st Phase Output Level Select)

These bits select the signal level output during the first phase of the XIP disable pattern.

XD2LEN[4:0] Bits (XIP Disable Pattern 2nd Phase Length Setting)

These bits set the length of the second phase of the XIP disable pattern in number of XSPIDIVCLK cycles.

XD2VAL Bit (XIP Disable Pattern 2nd Phase Output Level Select)

These bits select the signal level output during the second phase of the XIP disable pattern.

48.2.2.20 Signal Pattern Control Register 1 (LPCTL1)

Address(es): XSPI0.LPCTL1 8786 8104h, XSPI1.LPCTL1 8786 8504h, XSPI0_NS.LPCTL1 0786 8104h, XSPI1_NS.LPCTL1 0786 8504h

b11	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b14 to b12	RSTSU[2:0]	Reset Pattern Data Output Hold Time Setting	b14 b12 0 0 0: 1 cycle 0 0 1: 2 cycles : : 1 1 0: 7 cycles 1 1 1: 8 cycles	R/W
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the generation of special signal patterns by the XSPI controller module.

PATREQ[1:0] Bits (Signal Pattern Generation Request)

These bits are used to request generation of a signal pattern.

Writing 01b or 10b to these bits initiates generation of the corresponding signal pattern. It automatically returns to 00b when pattern generation is complete.

CSSEL Bit (Chip Select)

This bit selects the target device for which the signal pattern is generated.

RSTREP[1:0] Bits (Reset Pattern Repetition Count Select)

These bits select how many times the CS# signal toggles. The number specified in JESD252 is four times.

RSTWID[2:0] Bits (Reset Pattern Width Select)

These bits select the high width (tCSH) and low width (tCSL) of the CS# signal in the reset pattern or the low width (tCSL) of the CS# signal in the CS only pattern, in number of XSPIDIVCLK cycles.
Set these widths to at least 500 ns.

RSTSU[2:0] Bits (Reset Pattern Data Output Hold Time Setting)

These bits select the hold time of the IO[0] signal relative to the rising edge of the CS# signal in the reset pattern, in number of XSPIDIVCLK cycles.
Set these bits to ensure a hold time of at least 5 ns, including output buffer delay*1. Also, set these bits so that the hold time does not exceed the high width of the CS# signal specified by the RSTWID[2:0] bits.

Note 1. Set these bits so that the hold time also meets the specifications required by the target device.

48.2.2.21 I/O Signal Control Register (LIOCTL)

Address(es): XSPI0.LIOCTL 8786 8108h, XSPI1.LIOCTL 8786 8508h, XSPI0_NS.LIOCTL 0786 8108h, XSPI1_NS.LIOCTL 0786 8508h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	WPCS0	WP0# Signal Output Control	0: Output low 1: Output high	R/W
b1	WPCS1	WP1# Signal Output Control	0: Output low 1: Output high	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	RSTCS0	RESET0# Signal Output Control	0: Output low 1: Output high	R/W
b17	RSTCS1	RESET1# Signal Output Control	0: Output low 1: Output high	R/W
b31 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the output signal of the XSPI controller module.

WPCSi Bit (WPi# Signal Output Control) (i = 0, 1)

This bit controls the signal level output from the XSPIn_WPi# pin (n = 0, 1).

This bit setting is only effective when a target device with a write protect pin is connected.

RSTCSi Bit (RESETi# Signal Output Control) (i = 0, 1)

This bit controls the signal level output from the XSPIn_RESETi# pin.

This bit setting is only effective when a target device with a reset pin is connected.

48.2.2.22 CSi Area Calibration Control Register 0 (CCCTL0CSi) (i = 0, 1)

Address(es): XSPI0.CCCTL0CS0 8786 8130h, XSPI0.CCCTL0CS1 8786 8150h, XSPI1.CCCTL0CS0 8786 8530h, XSPI1.CCCTL0CS1 8786 8550h, XSPI0_NS.CCCTL0CS0 0786 8130h, XSPI0_NS.CCCTL0CS1 0786 8150h, XSPI1_NS.CCCTL0CS0 0786 8530h, XSPI1_NS.CCCTL0CS1 0786 8550h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	CASFTEND[4:0]					—	—	—	CASFTSTA[4:0]				
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	CAITV[4:0]					—	—	—	—	—	—	CANOWR	CAEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CAEN	Automatic Calibration Enable	0: Automatic calibration is disabled. 1: Automatic calibration is enabled.	R/W
b1	CANOWR	Read-Only Calibration Mode	0: Write-read calibration 1: Read-only calibration	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12 to b8	CAITV[4:0]	Calibration Interval Select	b12 b8 00000: 2^1 cycle (2 cycles) 00001: 2^2 cycle (4 cycles) : : 11110: 2^{31} cycles (2,147,483,648 cycles) 11111: 2^{32} cycles (4,294,967,296 cycles)	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	CASFTSTA[4:0]	Initial DS Delay Setting	These bits configure the initial value for the DS signal delay.	R/W
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b28 to b24	CASFTEND[4:0]	Maximum DS Delay Setting	These bits configure the maximum value for the DS signal delay.	R/W
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to automatically adjust the delay time of the DS signal for the XSPI controller module.

CAEN Bit (Automatic Calibration Enable)

This bit enables the automatic calibration.

Setting this bit to 1 periodically transmits a calibration sequence to adjust the delay time of the DS signal using delay elements. If this bit is written to 0 during execution of the calibration sequence, it is set to 0 after the currently executing calibration sequence completes.

CANOWR Bit (Read-Only Calibration Mode)

This bit selects the calibration method. Set this bit to 1 when calibration can be performed without writing to the target device.

When this bit is set to 0, calibration is performed to ensure values written to the target device can be read correctly. When this bit is set to 1, calibration is performed to ensure the calibration pattern originally written to the target device can be read correctly.

This bit can be used when the target device has a calibration pattern.

CAITV[4:0] Bits (Calibration Interval Select)

These bits select the calibration interval.

CASFTSTA[4:0] Bits (Initial DS Delay Setting)

These bit specify the initial value for calibration.
XSPI begins calibration using the DS signal delay time (number of delay cells) set in these bits as the initial delay time.

CASFTEND[4:0] Bits (Maximum DS Delay Setting)

These bit specify the maximum value for calibration.
When the delay time of the DS signal reaches the delay time (number of delay cells) set in these bits, the calibration sequence for that cycle ends.

48.2.2.23 CSi Area Calibration Control Register 1 (CCCTL1CSi) (i = 0, 1)

Address(es): XSPI0.CCCTL1CS0 8786 8134h, XSPI0.CCCTL1CS1 8786 8154h, XSPI1.CCCTL1CS0 8786 8534h, XSPI1.CCCTL1CS1 8786 8554h, XSPI0_NS.CCCTL1CS0 0786 8134h, XSPI0_NS.CCCTL1CS1 0786 8154h, XSPI1_NS.CCCTL1CS0 0786 8534h, XSPI1_NS.CCCTL1CS1 0786 8554h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CADATASIZE[3:0]				CAADDSIZE[2:0]			CACMDSIZE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CACMDSIZE[1:0]	Command Size Setting	b1 b0 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes 1 1: Setting prohibited	R/W
b4 to b2	CAADDSIZE[2:0]	Address Size Setting	b4 b2 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Settings other than above are prohibited.	R/W
b8 to b5	CADATASIZE[3:0]	Data Size Setting	b8 b5 0 0 0 0: 1 byte 0 0 0 1: 2 bytes : : 1 1 1 0: 15 bytes 1 1 1 1: 16 bytes	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	CAWRLATE[4:0]	Write Latency Cycle Setting	b20 b16 00000: No latency 00001: 1 cycle : : 11110: 30 cycles 11111: 31 cycles	R/W
b23 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b28 to b24	CARDLATE[4:0]	Read Latency Cycle Setting	b28 b24 00000: No latency 00001: 1 cycle : : 11110: 30 cycles 11111: 31 cycles	R/W
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set when the CCCTL0CSi.CAEN bit is 0 (automatic calibration is disabled).

This register is used to configure the frame format for automatic calibration in the XSPI controller module.

CACMDSIZE[1:0] Bits (Command Size Setting)

These bits configures the size of the command field.

When selecting 8D-8D-8D protocol mode, set these bit to 10b.

Setting both the command size and address size to 0 bytes is prohibited.

CAADDSIZE[2:0] Bits (Address Size Setting)

These bits configures the size of the address field.

CADATASIZE[3:0] Bits (Data Size Setting)

These bits configures the size of the data field.

When selecting 8D-8D-8D protocol mode, ensure the byte count is even.

CAWRLATE[4:0] Bits (Write Latency Cycle Setting)

These bits configures the latency cycle during write operation.

CARDLATE[4:0] Bits (Read Latency Cycle Setting)

These bits configures the latency cycle during read operation.

48.2.2.24 CSi Area Calibration Control Register 2 (CCCTL2CSi) (i = 0, 1)

Address(es): XSPI0.CCCTL2CS0 8786 8138h, XSPI0.CCCTL2CS1 8786 8158h, XSPI1.CCCTL2CS0 8786 8538h, XSPI1.CCCTL2CS1 8786 8558h, XSPI0_NS.CCCTL2CS0 0786 8138h, XSPI0_NS.CCCTL2CS1 0786 8158h, XSPI1_NS.CCCTL2CS0 0786 8538h, XSPI1_NS.CCCTL2CS1 0786 8558h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CARDCMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CAWRCMD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CAWRCMD[15:0]	Write Command Setting	Sets the value of the command field in the write transaction issued during automatic calibration.	R/W
b31 to b16	CARDCMD[15:0]	Read Command Setting	Sets the value of the command field in the read transaction issued during automatic calibration.	R/W

Note: This register should be set when the CCCTL0CSi.CAEN bit is 0 (automatic calibration is disabled).

This register is used to configure the command code used for automatic calibration in the XSPI controller module.

48.2.2.25 CSi Area Calibration Control Register 3 (CCCTL3CSi) (i = 0, 1)

Address(es): XSPI0.CCCTL3CS0 8786 813Ch, XSPI0.CCCTL3CS1 8786 815Ch, XSPI1.CCCTL3CS0 8786 853Ch, XSPI1.CCCTL3CS1 8786 855Ch, XSPI0_NS.CCCTL3CS0 0786 813Ch, XSPI0_NS.CCCTL3CS1 0786 815Ch, XSPI1_NS.CCCTL3CS0 0786 853Ch, XSPI1_NS.CCCTL3CS1 0786 855Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register should be set when the CCCTL0CSi.CAEN bit is 0 (automatic calibration is disabled).

This register is used to configure the address used for automatic calibration in the XSPI controller module.

48.2.2.26 CSi Area Calibration Control Register 4 (CCCTL4CSi) (i = 0, 1)

Address(es): XSPI0.CCCTL4CS0 8786 8140h, XSPI0.CCCTL4CS1 8786 8160h, XSPI1.CCCTL4CS0 8786 8540h, XSPI1.CCCTL4CS1 8786 8560h, XSPI0_NS.CCCTL4CS0 0786 8140h, XSPI0_NS.CCCTL4CS1 0786 8160h, XSPI1_NS.CCCTL4CS0 0786 8540h, XSPI1_NS.CCCTL4CS1 0786 8560h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register should be set when the CCCTL0CSi.CAEN bit is 0 (automatic calibration is disabled).

This register is used to configure the data used for automatic calibration in the XSPI controller module.
Set data bytes 0 through 3 to this register.

48.2.2.27 CSi Area Calibration Control Register 5 (CCCTL5CSi) (i = 0, 1)

Address(es): XSPI0.CCCTL5CS0 8786 8144h, XSPI0.CCCTL5CS1 8786 8164h, XSPI1.CCCTL5CS0 8786 8544h, XSPI1.CCCTL5CS1 8786 8564h, XSPI0_NS.CCCTL5CS0 0786 8144h, XSPI0_NS.CCCTL5CS1 0786 8164h, XSPI1_NS.CCCTL5CS0 0786 8544h, XSPI1_NS.CCCTL5CS1 0786 8564h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register should be set when the CCCTL0CSi.CAEN bit is 0 (automatic calibration is disabled).

This register is used to configure the data used for automatic calibration in the XSPI controller module.
Set data bytes 4 through 7 to this register.

48.2.2.28 CSi Area Calibration Control Register 6 (CCCTL6CSi) (i = 0, 1)

Address(es): XSPI0.CCCTL6CS0 8786 8148h, XSPI0.CCCTL6CS1 8786 8168h, XSPI1.CCCTL6CS0 8786 8548h, XSPI1.CCCTL6CS1 8786 8568h, XSPI0_NS.CCCTL6CS0 0786 8148h, XSPI0_NS.CCCTL6CS1 0786 8168h, XSPI1_NS.CCCTL6CS0 0786 8548h, XSPI1_NS.CCCTL6CS1 0786 8568h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register should be set when the CCCTL0CSi.CAEN bit is 0 (automatic calibration is disabled).

This register is used to configure the data used for automatic calibration in the XSPI controller module.
Set data bytes 8 through 11 to this register.

48.2.2.29 CSi Area Calibration Control Register 7 (CCCTL7CSi) (i = 0, 1)

Address(es): XSPI0.CCCTL7CS0 8786 814Ch, XSPI0.CCCTL7CS1 8786 816Ch, XSPI1.CCCTL7CS0 8786 854Ch, XSPI1.CCCTL7CS1 8786 856Ch, XSPI0_NS.CCCTL7CS0 0786 814Ch, XSPI0_NS.CCCTL7CS1 0786 816Ch, XSPI1_NS.CCCTL7CS0 0786 854Ch, XSPI1_NS.CCCTL7CS1 0786 856Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register should be set when the CCCTL0CSi.CAEN bit is 0 (automatic calibration is disabled).

This register is used to configure the data used for automatic calibration in the XSPI controller module.
Set data bytes 12 through 15 to this register.

48.2.2.30 Common Status Register (COMSTT)

Address(es): XSPI0.COMSTT 8786 8184h, XSPI1.COMSTT 8786 8584h, XSPI0_NS.COMSTT 0786 8184h, XSPI1_NS.COMSTT 0786 8584h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	MEMACCCH0	Memory Access Status Flag	0: XSPI controller is not accessing memory. 1: XSPI controller is accessing memory.	R
b1	—	Reserved	This bit is undefined when read.	R
b3, b2	—	Reserved	These bits are read as 0.	R
b4	PBUFNECH0	Prefetch Buffer Not Empty Flag	0: Prefetch buffer is empty. 1: Data is present in the prefetch buffer.	R
b5	—	Reserved	This bit is read as 0.	R
b6	WRBUFNECH0	Write Buffer Not Empty Flag	0: Write buffer is empty. 1: Data is present in the write buffer.	R
b15 to b7	—	Reserved	These bits are read as 0.	R
b16	ECSCS0	ECS0# Signal Monitor Flag	0: Low 1: High	R
b17	INTCS0	INT0# Signal Monitor Flag	0: Low 1: High	R
b18	RSTOCS0	RSTO0# Signal Monitor Flag	0: Low 1: High	R
b19	—	Reserved	This bit is read as 0.	R
b20	ECSCS1	ECS1# Signal Monitor Flag	0: Low 1: High	R
b21	INTCS1	INT1# Signal Monitor Flag	0: Low 1: High	R
b22	RSTOCS1	RSTO1# Signal Monitor Flag	0: Low 1: High	R
b31 to b23	—	Reserved	These bits are read as 0.	R

This register indicates the status of the XSPI controller module.

MEMACCCH0 Flag (Memory Access Status Flag)

This flag indicates the memory access state.

This flag is only valid in the (2) Communication Stop Flow and (6) Stop Flow for Memory-Mapped Mode described in section 48.3.1.7, Operation Flows.

PBUFNECH0 Flag (Prefetch Buffer Not Empty Flag)

This flag indicates that data is present in the prefetch buffer.

WRBUFNECH0 Flag (Write Buffer Not Empty Flag)

This flag indicates that data remains in the write buffer.
This flag is only valid in the (2) Communication Stop Flow and (6) Stop Flow for Memory-Mapped Mode described in section 48.3.1.7, Operation Flows.

ECSCSi Flag (ECSi# Signal Monitor Flag) (i = 0, 1)

This flag indicates the input level of the XSPIn_ECSi# pin (n = 0, 1).

INTCSi Flag (INTi# Signal Monitor Flag) (i = 0, 1)

This flag indicates the input level of the XSPIn_INTi# pin.

RSTOCSi Flag (RSTOi# Signal Monitor Flag) (i = 0, 1)

This flag indicates the input level of the XSPIn_RSTOi# pin.

48.2.2.31 CSi Area Calibration Status Register (CASTTCSi) (i = 0, 1)

Address(es): XSPI0.CASTTCS0 8786 8188h, XSPI0.CASTTCS1 8786 818Ch, XSPI1.CASTTCS0 8786 8588h, XSPI1.CASTTCS1 8786 858Ch, XSPI0_NS.CASTTCS0 0786 8188h, XSPI0_NS.CASTTCS1 0786 818Ch, XSPI1_NS.CASTTCS0 0786 8588h, XSPI1_NS.CASTTCS1 0786 858Ch

b28	CASUC28	Read Comparison Result Flag 28		R
b29	CASUC29	Read Comparison Result Flag 29		R
b30	CASUC30	Read Comparison Result Flag 30		R
b31	CASUC31	Read Comparison Result Flag 31		R

This register indicates the result of automatic calibration in the XSPI controller module.

CASUCm Flag (Read Comparison Result Flag m) (m = 0 to 31)

This flag indicates that the written and read values match when the DS signal delay (number of delay cells) is m. This flag is updated each time the calibration sequence is performed.
If any one of the CASUCm flags is set to 1 at the end of the calibration sequence, the INTS.CASUCCSi flag is set to 1; if all are 0, the INTS.CAFAILCSi flag is set to 1.

48.2.2.32 Interrupt Status Register (INTS)

Address(es): XSPI0.INTS 8786 8190h, XSPI1.INTS 8786 8590h, XSPI0_NS.INTS 0786 8190h, XSPI1_NS.INTS 0786 8590h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMDCMP	Command Issuance Completion Flag	0: Command issuance not complete 1: Command issuance completed	R
b1	PATCMP	Signal Pattern Generation Completion Flag	0: Signal pattern generation not completed 1: Signal pattern generation completed	R
b2	—	Reserved	This bit is read as 0.	R
b3	PERTO	Periodic Transaction Timeout Flag	0: No timeout detected 1: Timeout detected	R
b4	DSTOCS0	DS Timeout Flag 0	0: No DS timeout on target device 0 1: DS timeout occurred on target device 0	R
b5	DSTOCS1	DS Timeout Flag 1	0: No DS timeout on target device 1 1: DS timeout occurred on target device 1	R
b7, b6	—	Reserved	These bits are read as 0.	R
b8	ECSCS0	ECC Error Detection Flag 0	0: No ECC errors on target device 0 1: ECC error occurred on target device 0	R
b9	ECSCS1	ECC Error Detection Flag 1	0: No ECC errors on target device 1 1: ECC error occurred on target device 1	R
b11, b10	—	Reserved	These bits are read as 0.	R
b12	INTCS0	INT0 Detection Flag	0: No interrupt request from target device 0 1: An interrupt is requested from target device 0	R
b13	INTCS1	INT1 Detection Flag	0: No interrupt request from target device 1 1: An interrupt is requested from target device 1	R
b19 to b14	—	Reserved	These bits are read as 0.	R
b20	BUSERRCH0	Internal Bus Error Flag	0: No bus error 1: Bus error occurred	R
b27 to b21	—	Reserved	These bits are read as 0.	R
b28	CAFAILCS0	Calibration Failure Flag 0	0: Calibration for target device 0 has not failed. 1: Calibration for target device 0 has failed.	R
b29	CAFAILCS1	Calibration Failure Flag 1	0: Calibration for target device 1 has not failed. 1: Calibration for target device 1 has failed.	R
b30	CASUCCS0	Calibration Success Flag 0	0: Calibration for target device 0 has not succeeded. 1: Calibration for target device 0 has succeeded.	R
b31	CASUCCS1	Calibration Success Flag 1	0: Calibration for target device 1 has not succeeded. 1: Calibration for target device 1 has succeeded.	R

This register indicates the interrupt status of the XSPI controller module.
Each flag can be cleared by writing 1 to the corresponding bit in the INTC register.

CMDCMP Flag (Command Issuance Completion Flag)

This flag indicates that the issuance of the specified number of transactions has been completed in indirect access mode.

In sequential mode, it means that the issuance of all transactions specified by the CDCTL0.TRNUM[1:0] bits has been completed. In periodic mode, it means that the read value matched the expected value within the number of times specified by the CDCTL0.PERREP[3:0] bits.

PATCMP Flag (Signal Pattern Generation Completion Flag)

This flag indicates that generation of the requested signal pattern (XIP disable pattern, reset pattern, CS only pattern) has been completed.

PERTO Flag (Periodic Transaction Timeout Flag)

This flag indicates that, in periodic mode, the read value did not match the expected value even if the count specified by the CDCTL0.PERREP[3:0] bits is reached.

DSTOCSi Flag (DS Timeout Flag i) (i = 0, 1)

This flag indicates that the DS signal was not input in a read transaction that uses the DS signal.
This means that data was not received within the expected data phase. In this case, the XSPI aborts this read transaction and any subsequent transactions.
This error may issue an error response to the internal bus.

ECSCSi Flag (ECC Error Detection Flag i) (i = 0, 1)

This flag indicates that an ECC error has occurred on target device i.
This flag becomes 1 when the falling edge of the XSPIn_ECSi# signal is detected (n = 0, 1).
This flag is used for target devices that have ECC error detection capability.

INTCSi Flag (INTi Detection Flag) (i = 0, 1)

This flag indicates that an interrupt request has been received from target device i.
This flag becomes 1 when the falling edge of the XSPIn_INTi# signal is detected.
This flag is used for target devices that have interrupt functionality.

BUSERRCH0 Flag (Internal Bus Error Flag)

This flag indicates that a internal bus error has occurred.

CAFAILCSi Flag (Calibration Failure Flag i) (i = 0, 1)

This flag indicates that calibration has failed.
When the calibration sequence ends, this flag becomes 1 if all CASTTCSi.CASUCm flags are 0.

CASUCCSi Flag (Calibration Success Flag i) (i = 0, 1)

This flag indicates that calibration has succeeded.
When the calibration sequence ends, this flag becomes 1 if any of the CASTTCSi.CASUCm flags are 1.

48.2.2.33 Interrupt Clear Register (INTC)

Address(es): XSPI0.INTC 8786 8194h, XSPI1.INTC 8786 8594h, XSPI0_NS.INTC 0786 8194h, XSPI1_NS.INTC 0786 8594h

Bit	Symbol	Bit Name	Description	R/W
b0	CMDCMPC	Command Issuance Completion Flag Clear	Writing 1 to this bit clears the INTS.CMDCMP flag. Writing 0 has no effect.	W
b1	PATCMPC	Signal Pattern Generation Completion Flag Clear	Writing 1 to this bit clears the INTS.PATCMP flag. Writing 0 has no effect.	W
b2	—	Reserved	The write value should be 0.	W
b3	PERTOC	Periodic Transaction Timeout Flag Clear	Writing 1 to this bit clears the INTS.PERTO flag. Writing 0 has no effect.	W
b4	DSTOCS0C	DS Timeout Flag 0 Clear	Writing 1 to this bit clears the INTS.DSTOCS0 flag. Writing 0 has no effect.	W
b5	DSTOCS1C	DS Timeout Flag 1 Clear	Writing 1 to this bit clears the INTS.DSTOCS1 flag. Writing 0 has no effect.	W
b7, b6	—	Reserved	The write value should be 0.	W
b8	ECSCS0C	ECC Error Detection Flag 0 Clear	Writing 1 to this bit clears the INTS.ECSCS0 flag. Writing 0 has no effect.	W
b9	ECSCS1C	ECC Error Detection Flag 1 Clear	Writing 1 to this bit clears the INTS.ECSCS1 flag. Writing 0 has no effect.	W
b11, b10	—	Reserved	The write value should be 0.	W
b12	INTCS0C	INT0 Detection Flag Clear	Writing 1 to this bit clears the INTS.INTCS0 flag. Writing 0 has no effect.	W
b13	INTCS1C	INT1 Detection Flag Clear	Writing 1 to this bit clears the INTS.INTCS1 flag. Writing 0 has no effect.	W
b19 to b14	—	Reserved	The write value should be 0.	W
b20	BUSERRCH0C	Internal Bus Error Flag Clear	Writing 1 to this bit clears the INTS.BUSERRCH0 flag. Writing 0 has no effect.	W
b27 to b21	—	Reserved	The write value should be 0.	W
b28	CAFAILCS0C	Calibration Failure Flag 0 Clear	Writing 1 to this bit clears the INTS.CAFAILCS0 flag. Writing 0 has no effect.	W
b29	CAFAILCS1C	Calibration Failure Flag 1 Clear	Writing 1 to this bit clears the INTS.CAFAILCS1 flag. Writing 0 has no effect.	W
b30	CASUCCS0C	Calibration Success Flag 0 Clear	Writing 1 to this bit clears the INTS.CASUCCS0 flag. Writing 0 has no effect.	W
b31	CASUCCS1C	Calibration Success Flag 1 Clear	Writing 1 to this bit clears the INTS.CASUCCS1 flag. Writing 0 has no effect.	W

This register clears the interrupt status flags of the XSPI controller module.
Writing 1 to each bit clears the corresponding flag in the INTS register.

48.2.2.34 Interrupt Enable Register (INTE)

Address(es): XSPI0.INTE 8786 8198h, XSPI1.INTE 8786 8598h, XSPI0_NS.INTE 0786 8198h, XSPI1_NS.INTE 0786 8598h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMDCMPE	Command Issuance Completion Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b1	PATCMPE	Signal Pattern Generation Completion Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	PERTOE	Periodic Transaction Timeout Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b4	DSTOCS0E	DS Timeout Interrupt 0 Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b5	DSTOCS1E	DS Timeout Interrupt 1 Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	ECSCS0E	ECC Error Detection Interrupt 0 Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b9	ECSCS1E	ECC Error Detection Interrupt 1 Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	INTCS0E	INT0 Detection Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b13	INTCS1E	INT1 Detection Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b19 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20	BUSERRCH0E	Internal Bus Error Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b27 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b28	CAFAILCS0E	Calibration Failure Interrupt 0 Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b29	CAFAILCS1E	Calibration Failure Interrupt 1 Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b30	CASUCCS0E	Calibration Success Interrupt 0 Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b31	CASUCCS1E	Calibration Success Interrupt 1 Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W

This register enables each interrupt generated by the XSPI controller module.
If the corresponding flag in the INTS register becomes 1 while a bit in this register is 1, an interrupt request is generated.

48.2.3 Target Mode Registers

48.2.3.1 L1.5 Configuration Register 0 (L15CFG0)

Address(es): XSPI0.L15CFG0 8786 7000h, XSPI1.L15CFG0 8786 7400h, XSPI0_NS.L15CFG0 0786 7000h, XSPI1_NS.L15CFG0 0786 7400h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OEASTEX
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	WRMSKMD	—	PRTMD[9:0]									
Value after reset:	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	PRTMD[9:0]	Protocol Mode Setting	000h: 1S-1S-1S 3B2h: 4S-4D-4D 3FFh: 8D-8D-8D Settings other than above are prohibited.	R/W
b10	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b11	WRMSKMD	Write Data Mask Enable	0: Write data mask is disabled. 1: Write data mask is enabled.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	OEASTEX	Output Enable Signal Assertion Period Extension	0: Do not extend the output enable signal 1: Extend the output enable signal by one cycle	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions. If you need to change the settings of this register after starting an xSPI memory write/read transaction, stop all write/read transactions before rewriting it.

This register specifies the communication protocol for the XSPI target module.

PRTMD[9:0] Bits (Protocol Mode Setting)

These bits specify the IO protocol mode.
In 1S-1S-1S protocol modes, the CK signal is used for data sampling. In 4S-4D-4D protocol mode and 8D-8D-8D protocol mode, the DS signal is used for data sampling.

WRMSKMD Bit (Write Data Mask Enable)

This bit configures whether to use the XSPIn_DS signal as a mask signal for each byte in the write data (n = 0, 1).
The write data mask function is only used in 8D-8D-8D protocol mode.

OEASTEX Bit (Output Enable Signal Assertion Period Extension)

This bit specifies the negation timing of the output buffer control signal (OE: Output Enable). When this bit is set to 1, the output of the XSPIn_IO7 to XSPIn_IO0 pins and the XSPIn_DS pin is extended by one cycle (n = 0, 1).
To prevent potential collisions between output and input data, do not set this bit to 1 if there is no latency cycle.

48.2.3.2 L1.5 Configuration Register 1 (L15CFG1)

Address(es): XSPI0.L15CFG1 8786 7004h, XSPI1.L15CFG1 8786 7404h, XSPI0_NS.L15CFG1 0786 7004h, XSPI1_NS.L15CFG1 0786 7404h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	RDLATE[7:0]								WRLATE[7:0]							
Value after reset:	0	0	0	0	1	0	1	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	WRLATE[7:0]	Write Latency Cycle Setting	00h: No latency 01h: 1 cycle : : 1Eh: 30 cycles 1Fh: 31 cycles Settings other than above are prohibited.	R/W
b15 to b8	RDLATE[7:0]	Read Latency Cycle Setting	Set these bits to 0Fh (15 cycles).	R/W
b17, b16	FFMT[1:0]	Frame Format Setting	b17 b16 0 0: Normal format 0 1: 8D-8D-8D profile 1.0 format 1 0: 8D-8D-8D profile 2.0 command modifier format 1 1: 8D-8D-8D profile 2.0 extended command modifier format	R/W
b19, b18	ADDSIZE[1:0]	Address Size	b19 b18 0 1: 2 bytes (64-Kbyte address space) 1 0: 3 bytes (16-Mbyte address space) 1 1: 4 bytes (4-Gbyte address space) Settings other than above are prohibited.	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions. If you need to change the settings of this register after starting an xSPI memory write/read transaction, stop all write/read transactions before rewriting it.

This register specifies the frame format for the XSPI target module.

WRLATE[7:0] Bits (Write Latency Cycle Setting)

These bits specify the number of latency cycles to insert during write transactions when accessing memory.

RDLATE[7:0] Bits (Read Latency Cycle Setting)

These bits specify the number of latency cycles to insert during read transactions when accessing memory.

FFMT[1:0] Bits (Frame Format Setting)

These bits configure the xSPI frame format when accessing memory. Table 48.4 shows the frame format for each setting value.

ADDSIZE[1:0] Bits (Address Size)

These bits configure the number of bytes in the address field when accessing memory.
When setting the FFMT[1:0] bits to 10b or 11b (8D-8D-8D Profile 2.0), set this bit to 11b (4 bytes).

48.2.3.3 L1.5 Configuration Register 2 (L15CFG2)

Address(es): XSPI0.L15CFG2 8786 7008h, XSPI1.L15CFG2 8786 7408h, XSPI0_NS.L15CFG2 0786 7008h, XSPI1_NS.L15CFG2 0786 7408h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	MRDFSIZE[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	MWRFSIZE[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	MWRFSIZE[10:0]	Maximum Write Frame Size Setting	These bits specify the maximum data size for the write frame.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b16	MRDFSIZE[10:0]	Maximum Read Frame Size Setting	These bits specify the maximum data size for the read frame.	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions. If you need to change the settings of this register after starting an xSPI memory write/read transaction, stop all write/read transactions before rewriting it.

This register specifies the frame format for the XSPI target module.

MWRFSIZE[10:0] Bits (Maximum Write Frame Size Setting)

These bits are used to set the maximum data size in bytes for the write frame when accessing memory.
When the xSPI controller writes data to SRAM, the data size must match this size except for the last write data frame.
The value set for these bits must be less than or equal to the buffer size indicated by the TBI.BUFSIZE[12:0] bits.
The possible values are 8, 16, 32, 64, 128, 256, and 512.

MRDFSIZE[10:0] Bits (Maximum Read Frame Size Setting)

These bits are used to set the maximum data size in bytes for the read frame when accessing memory.
When the xSPI controller reads data from SRAM, the data size must match this size except for the last read data frame.
The value set for these bits must be less than or equal to the buffer size indicated by the TBI.BUFSIZE[12:0] bits.
The possible values are 8, 16, 32, 64, 128, 256, and 512.

48.2.3.4 L2 Configuration Register 0 (L2CFG0)

Address(es): XSPI0.L2CFG0 8786 7040h, XSPI1.L2CFG0 8786 7440h, XSPI0_NS.L2CFG0 0786 7040h, XSPI1_NS.L2CFG0 0786 7440h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Note: This register should be set during the initialization phase before issuing xSPI transactions. If you need to change the settings of this register after starting an xSPI memory write/read transaction, stop all write/read transactions before rewriting it.

This register specifies the address space of the XSPI target module.

Set the highest address (= memory size – 1) of the memory space exposed externally as an xSPI target. Set the lower 12 bits to 1.

Only the nine values shown in Table 48.7 are configurable.

Table 48.7 xSPI Target Address Space and Register Setting

xSPI Address Space	Memory Size	L2CFG0 Register Setting Value
0000 0000h to 0000 0FFFh	4 Kbytes	00000FFFh
0000 0000h to 0000 1FFFh	8 Kbytes	00001FFFh
0000 0000h to 0000 3FFFh	16 Kbytes	00003FFFh
0000 0000h to 0000 7FFFh	32 Kbytes	00007FFFh
0000 0000h to 0000 FFFFh	64 Kbytes	0000FFFFh
0000 0000h to 0001 FFFFh	128 Kbytes	0001FFFFh
0000 0000h to 0003 FFFFh	256 Kbytes	0003FFFFh
0000 0000h to 0007 FFFFh	512 Kbytes	0007FFFFh
0000 0000h to 000F FFFFh	1 Mbyte	000FFFFFh

48.2.3.5 L2 Configuration Register 1 (L2CFG1)

Address(es): XSPI0.L2CFG1 8786 7044h, XSPI1.L2CFG1 8786 7444h, XSPI0_NS.L2CFG1 0786 7044h, XSPI1_NS.L2CFG1 0786 7444h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	WRMCMD[7:0]								WRRCMD[7:0]							
Value after reset:	0	0	1	1	1	1	1	1	0	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RDMCMD[7:0]								RDRCMD[7:0]							
Value after reset:	1	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	RDRCMD[7:0]	Command Code for Read Register Linear*1	Set the command code for the Read Register Linear command.	R/W
b15 to b8	RDMCMD[7:0]	Command Code for Read Memory Linear*1	Set the command code for the Read Memory Linear command.	R/W
b23 to b16	WRRCMD[7:0]	Command Code for Write Register Linear*1	Set the command code for the Write Register Linear command.	R/W
b31 to b24	WRMCMD[7:0]	Command Code for Write Memory Linear*1	Set the command code for the Write Memory Linear command.	R/W

Note: This register should be set during the initialization phase before issuing xSPI transactions. If you need to change the settings of this register after starting an xSPI memory write/read transaction, stop all write/read transactions before rewriting it.

Note 1. For Profile 2.0 commands with extended command modifier, lower 5 bits are ignored.

This register specifies the commands processed by the XSPI target module.

48.2.3.6 Target Write Address Register (TWADR)

Address(es): XSPI0.TWADR 8786 7100h, XSPI1.TWADR 8786 7500h, XSPI0_NS.TWADR 0786 7100h, XSPI1_NS.TWADR 0786 7500h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register specifies the absolute address when the xSPI controller writes data to the memory of this MCU.
When using DDR mode, specify an even address.

48.2.3.7 Target Write Length Register (TWLEN)

Address(es): XSPI0.TWLEN 8786 7104h, XSPI1.TWLEN 8786 7504h, XSPI0_NS.TWLEN 0786 7104h, XSPI1_NS.TWLEN 0786 7504h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register specifies the total data size when the xSPI controller writes data to the memory of this MCU.
The configurable value range is 0000 0001h to 0010 0000h. When using DDR mode, specify an even value.

48.2.3.8 Target Write Control Register (TWCNT)

Address(es): XSPI0.TWCNT 8786 7108h, XSPI1.TWCNT 8786 7508h, XSPI0_NS.TWCNT 0786 7108h, XSPI1_NS.TWCNT 0786 7508h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WEN	Write Enable	Writing 1 to this bit starts a write transfer. Writing 0 has no effect. The read value has no meaning.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register enables write transfers to the XSPI target module.

WEN Bit (Write Enable)

Writing 1 to this bit starts a write transfer, using the value in the TWADR register as the start address and the value in the TWLEN register as the data size. Do not set this bit to 1 at the same time as the TRCNT.REN bit.

48.2.3.9 Target Read Address Register (TRADR)

Address(es): XSPI0.TRADR 8786 7140h, XSPI1.TRADR 8786 7540h, XSPI0_NS.TRADR 0786 7140h, XSPI1_NS.TRADR 0786 7540h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register specifies the absolute address when the xSPI controller reads data from the memory of this MCU.
When using DDR mode, specify an even address.

48.2.3.10 Target Read Length Register (TRLEN)

Address(es): XSPI0.TRLEN 8786 7144h, XSPI1.TRLEN 8786 7544h, XSPI0_NS.TRLEN 0786 7144h, XSPI1_NS.TRLEN 0786 7544h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register specifies the total data size when the xSPI controller read data from the memory of this MCU.
The configurable value range is 0000 0001h to 0010 0000h. When using DDR mode, specify an even value.

48.2.3.11 Target Read Control Register (TRCNT)

Address(es): XSPI0.TRCNT 8786 7148h, XSPI1.TRCNT 8786 7548h, XSPI0_NS.TRCNT 0786 7148h, XSPI1_NS.TRCNT 0786 7548h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	REN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	REN	Read Enable	Writing 1 to this bit starts a read transfer. Writing 0 has no effect. The read value has no meaning.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register enables write transfers to the XSPI target module.

REN Bit (Read Enable)

Writing 1 to this bit starts a read transfer, using the value in the TRADR register as the start address and the value in the TRLEN register as the data size. Do not set this bit to 1 at the same time as the TWCNT.WEN bit.

48.2.3.12 Transfer Control Register (TRNSC)

Address(es): XSPI0.TRNSC 8786 7180h, XSPI1.TRNSC 8786 7580h, XSPI0_NS.TRNSC 0786 7180h, XSPI1_NS.TRNSC 0786 7580h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	RSMSTB	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b30 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	RSMSTB	Software Standby Mode Transition Setting	0: Operation enabled 1: Operation disabled (transition to software standby mode possible)	R/W

This register controls the data transfer of the XSPI target module.

RSMSTB Bit (Software Standby Mode Transition Setting)

This bit is used to transition to and return from software standby mode.

Before transitioning to software standby mode, set this bit to 1 while no communication is being performed. When this bit is 1, communication functions will stop. After returning from software standby mode, set this bit to 0 before resuming operation.

48.2.3.13 Target Write Buffer Status Register (TWBS)

Address(es): XSPI0.TWBS 8786 7200h, XSPI1.TWBS 8786 7600h, XSPI0_NS.TWBS 0786 7200h, XSPI1_NS.TWBS 0786 7600h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ERR	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	VACSIZE[12:0]												
Value after reset:	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b12 to b0	VACSIZE[12:0]	Write Buffer Free Size	These bits indicate the free space in the write buffer. The xSPI controller can only write data up to the value indicated by these bits.	R
b30 to b13	—	Reserved	These bits are read as 0.	R
b31	ERR	Error Flag	This flag indicates that any of the error flags in the TS register (SBERR, MFSEERR, UNKCERR, BUDFERR, BOVFERR) is set to 1.	R

This register indicates the status of write transfer in the XSPI target module.

48.2.3.14 Target Write Transfer Status Register (TWTS)

Address(es): XSPI0.TWTS 8786 7204h, XSPI1.TWTS 8786 7604h, XSPI0_NS.TWTS 0786 7204h, XSPI1_NS.TWTS 0786 7604h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	LWDSIZE[20:16]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LWDSIZE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b20 to b0	LWDSIZE[20:0]	Remaining Write Data Size	These bits indicate the remaining data size for the write transfer. Immediately after setting the TWCNT.WEN bit to 1, these bits indicate the data size set in the TWLEN register. After the write transfer completes, these bits indicate 000000h.	R
b31 to b21	—	Reserved	These bits are read as 0.	R

This register indicates the status of write transfer in the XSPI target module.

48.2.3.15 Target Read Buffer Status Register (TRBS)

Address(es): XSPI0.TRBS 8786 7240h, XSPI1.TRBS 8786 7640h, XSPI0_NS.TRBS 0786 7240h, XSPI1_NS.TRBS 0786 7640h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ERR	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DATSIZE[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b12 to b0	DATSIZE[12:0]	Read Buffer Data Size	These bits indicate the data size stored in the read buffer. The xSPI controller can only read data up to the value indicated by these bits.	R
b30 to b13	—	Reserved	These bits are read as 0.	R
b31	ERR	Error Flag	This flag indicates that any of the error flags in the TS register (SBERR, MFSEERR, UNKCERR, BUDFERR, BOVFERR) is set to 1.	R

This register indicates the status of read transfer in the XSPI target module.

48.2.3.16 Target Read Transfer Status Register (TRTS)

Address(es): XSPI0.TRTS 8786 7244h, XSPI1.TRTS 8786 7644h, XSPI0_NS.TRTS 0786 7244h, XSPI1_NS.TRTS 0786 7644h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	LRDSIZE[20:16]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LRDSIZE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b20 to b0	LRDSIZE[20:0]	Remaining Read Data Size	These bits indicate the remaining data size for the read transfer. Immediately after setting the TRCNT.REN bit to 1, these bits indicate the data size set in the TRLEN register. After the read transfer completes, these bits indicate 000000h.	R
b31 to b21	—	Reserved	These bits are read as 0.	R

This register indicates the status of read transfer in the XSPI target module.

48.2.3.17 Target Status Register (TS)

Address(es): XSPI0.TS 8786 7280h, XSPI1.TS 8786 7680h, XSPI0_NS.TS 0786 7280h, XSPI1_NS.TS 0786 7680h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	SBERR	—	—	MFSEERR	UNKCERR	—	—	BUDFERR	BOVFERR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	EV1	EV0	—	—	SRSTO	SRST	—	—	—	TCMP	—	—	—	TIP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TIP	Transfer Status Flag	0: No transfer 1: Transfer exist	R
b3 to b1	—	Reserved	These bits are read as 0.	R
b4	TCMP	Transfer Complete Flag	0: Transfer not complete 1: Transfer complete	R
b7 to b5	—	Reserved	These bits are read as 0.	R
b8	SRST	SPI Reset Detection Flag	0: No reset detected 1: Reset detected	R
b9	SRSTO	SPI Reset Indication Output Flag	0: No reset indication is output 1: Reset indication is output	R
b11, b10	—	Reserved	These bits are read as 0.	R
b12	EV0	Event 0 Flag	0: No event 1: Event present	R
b13	EV1	Event 1 Flag	0: No event 1: Event present	R
b15, b14	—	Reserved	These bits are read as 0.	R
b16	BOVFERR	Buffer Overflow Flag	0: No buffer overflow 1: Buffer overflow	R
b17	BUDFERR	Buffer Underflow Flag	0: No buffer underflow 1: Buffer underflow	R
b19, b18	—	Reserved	These bits are read as 0.	R
b20	UNKCERR	Unknown Command Error Flag	0: No unknown command error 1: Unknown command error	R
b21	MFSEERR	Maximum Frame Size Exceeded Flag	0: No maximum frame size exceeded 1: Maximum frame size exceeded	R
b23, b22	—	Reserved	These bits are read as 0.	R
b24	SBERR	Internal Bus Error Flag	0: No internal bus error 1: Internal bus error present	R
b31 to b25	—	Reserved	These bits are read as 0.	R

This register indicates the status the XSPI target module.

TIP Flag (Transfer Status Flag)

This flag indicates the transfer status, including internal bus transfers. If an error is detected, wait until this flag becomes 1 before starting the next transfer.

SRSTO Flag (SPI Reset Indication Output Flag)

This flag indicates the status of a reset output. Setting this flag to 1 drives the RSTO0# signal low.

EV0 Flag (Event 0 Flag)

This flag indicates the status of a software event. This flag assumes events from the controller to the target.

EV1 Flag (Event 1 Flag)

This flag indicates the status of a software event. This flag assumes events from the target to the controller.

BOVFERR Flag (Buffer Overflow Flag)

This flag indicates the presence of a buffer overflow. This flag is set to 1 when the xSPI controller writes the data larger than the free size indicated by the TWBS.VACSIZE[12:0] bits.

BUDFERR Flag (Buffer Underflow Flag)

This flag indicates the presence of a buffer underflow. This flag is set to 1 when the xSPI controller reads the data larger than the data size indicated by the TRBS.DATSIZE[12:0] bits.

UNKCERR Flag (Unknown Command Error Flag)

This flag indicates that the XSPI target received an unknown command as listed below.

- When the L2CFG1 register is not configured.
- When a Read Memory command is issued while the TRCNT.REN bit is 0.
- When a Write Memory command is issued while the TWCNT.WEN bit is 0.
- When the inverted command is not matched with the expected value in 8D-8D-8D profile1.0 protocol mode.

MFSEERR Flag (Maximum Frame Size Exceeded Flag)

This flag indicates whether the maximum frame size has been exceeded. The maximum frame size is specified as follows: 4 bytes for register accesses, the L15CFG2.MRDFSIZE[10:0] bits for memory read accesses, and the MWRFSIZE[10:0] bits for memory write accesses.

SBERR Flag (Internal Bus Error Flag)

This flag indicates that the internal bus returned an error response or an unexpected response.

48.2.3.18 Target Status Clear Register (TSC)

Address(es): XSPI0.TSC 8786 7284h, XSPI1.TSC 8786 7684h, XSPI0_NS.TSC 0786 7284h, XSPI1_NS.TSC 0786 7684h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	—	Reserved	The write value should be 0.	W
b9	SRSTOS	SRSTO Flag Set	Writing 1 to this bit sets the TS.SRSTO flag to 1. Writing 0 has no effect.	W
b11, b10	—	Reserved	The write value should be 0.	W
b12	EV0S	EV0 Flag Set	Writing 1 to this bit sets the TS.EV0 flag to 1. Writing 0 has no effect.	W
b13	EV1S	EV1 Flag Set	Writing 1 to this bit sets the TS.EV1 flag to 1. Writing 0 has no effect.	W
b31 to b14	—	Reserved	The write value should be 0.	W

This register sets the status flags of the XSPI target module.
Writing 1 to each bit sets the corresponding flag in the TS register.

48.2.3.20 Target Status xSPI Interrupt Enable Register (TSXIE)

Address(es): XSPI0.TSXIE 8786 728Ch, XSPI1.TSXIE 8786 768Ch, XSPI0_NS.TSXIE 0786 728Ch, XSPI1_NS.TSXIE 0786 768Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	SBERRXIE	—	—	MFSEERRXIE	UNKCERRXIE	—	—	BUDFERRXIE	BOVFERRXIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	EV1XIE	EV0XIE	—	—	SRSTOXIE	—	—	—	—	TCMPXIE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	TCMPXIE	Transfer Complete Interrupt Enable	0: INT0# output is disabled. 1: INT0# output is enabled.	R/W
b8 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9	SRSTOXIE	SPI Reset Output Enable	0: RSTO0# output is disabled. 1: RSTO0# output is enabled.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	EV0XIE	Event 0 Interrupt Enable	0: INT0# output is disabled. 1: INT0# output is enabled.	R/W
b13	EV1XIE	Event 1 Interrupt Enable	0: INT0# output is disabled. 1: INT0# output is enabled.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	BOVFERRXIE	Buffer Overflow Interrupt Enable	0: INT0# output is disabled. 1: INT0# output is enabled.	R/W
b17	BUDFERRXIE	Buffer Underflow Interrupt Enable	0: INT0# output is disabled. 1: INT0# output is enabled.	R/W
b19, b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20	UNKCERRXIE	Unknown Command Error Interrupt Enable	0: INT0# output is disabled. 1: INT0# output is enabled.	R/W
b21	MFSEERRXIE	Maximum Frame Size Exceed Interrupt Enable	0: INT0# output is disabled. 1: INT0# output is enabled.	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	SBERRXIE	Internal Bus Error Interrupt Enable	0: INT0# output is disabled. 1: INT0# output is enabled.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register enables each interrupt generated by the XSPI target module.
If the corresponding flag in the TS register is set to 1 while a bit in this register is 1, an interrupt request (reset status signal) is output from the INT0# pin (RSTO0# pin).

48.2.3.21 Target Status System Interrupt Enable Register (TSSIE)

Address(es): XSPI0.TSSIE 8786 7290h, XSPI1.TSSIE 8786 7690h, XSPI0_NS.TSSIE 0786 7290h, XSPI1_NS.TSSIE 0786 7690h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	EV1SIE	EV0SIE	—	—	—	SRSTSIE	—	—	—	TCMPSIE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	TCMPSIE	Transfer Complete Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	SRSTSIE	SPI Reset Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	EV0SIE	Event 0 Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b13	EV1SIE	Event 1 Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	BOVFERRSIE	Buffer Overflow Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b17	BUDFERRSIE	Buffer Underflow Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b19, b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20	UNKCERRSIE	Unknown Command Error Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b21	MFSEERRSIE	Maximum Frame Size Exceeded Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	SBERRSIE	Internal Bus Error Interrupt Enable	0: Interrupt is disabled. 1: Interrupt is enabled.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register enables each interrupt generated by the XSPI target module.
If the corresponding flag in the TS register becomes 1 while a bit in this register is 1, an interrupt request is generated.

48.2.3.22 Target Basic Information Register (TBI)

Address(es): XSPI0.TBI 8786 72C0h, XSPI1.TBI 8786 76C0h, XSPI0_NS.TBI 0786 72C0h, XSPI1_NS.TBI 0786 76C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	VER[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	BUFSIZE[12:0]												
Value after reset:	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b12 to b0	BUFSIZE[12:0]	Buffer Size	These bits indicates the size of the write/read buffer installed. This product has a 1-Kbyte buffer installed.	R
b15 to b13	—	Reserved	These bits are read as 0.	R
b31 to b16	VER[15:0]	Version Register	These bits indicates the version of the IP installed.	R

This register indicates information about the XSPI target module.

48.3 Operation

48.3.1 XSPI Controller Module

The XSPI controller has the function to issue transactions to external memory devices equipped with an xSPI target interface.

The XSPI controller has two modes for issuing transactions. One is indirect access mode, which accesses external memory via XSPI registers. After setting all fields of the xSPI frame, the transaction is initiated by a software request. The other is memory-mapped mode. Reading or writing any address within the XSPI area (addresses 2000 0000h to 5FFF FFFFh) is automatically converted into an xSPI transaction. Each access occurs without needing to manipulate XSPI registers, allowing access to external memory as if it were directly connected to the internal bus.

48.3.1.1 xSPI Bus

Figure 48.3 shows an example of the connection between the XSPI controller and the memory devices.
In this figure, the XSPI0_CS0 pin is connected to the RAM device, and the XSPI0_CS1 pin is connected to the Flash memory device.
Specify the pull-up resistor values according to the instructions for each device.

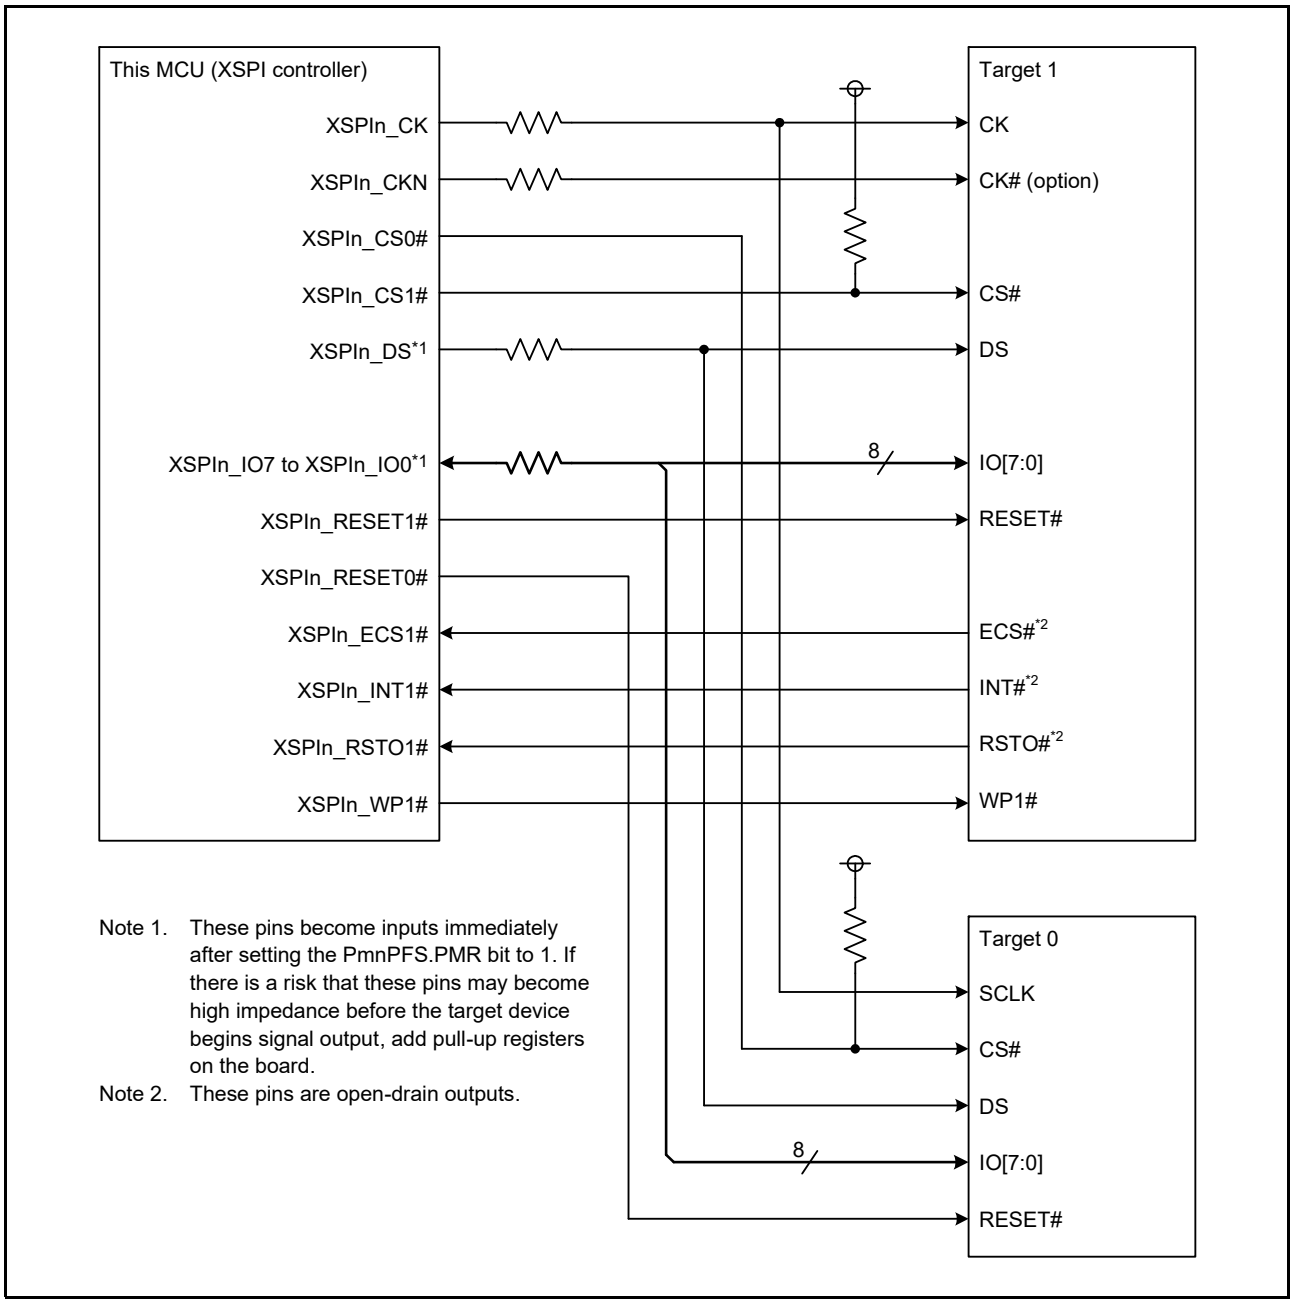

Figure 48.3 Example of Connection between XSPI Controller and Memory Devices (n = 0, 1)

(1) Supported Protocol Mode

The XSPI controller supports various protocol modes. Protocol mode is set by the LIOCFGCSi.PRTMD[9:0] bits (i = 0, 1). Table 48.8 provides an overview of each protocol mode.

Table 48.8 Supported Protocol Mode (n = 0, 1; i = 0, 1)

Protocol Mode	Function	LIOCFGCSi.PRTMD[9:0] Bit Setting	Note
1S-1S-1S	Command, Address and Data field are transferred at SDR with using 1data input pin and 1 data output pin. Read data is sampled with the XSPIn_CK signal.	000h	Specified by JESD251
4S-4D-4D	Command field is transferred at SDR with using 4 data pins. Address and Data field are transferred at DDR with using 4 data pins. Read data is sampled with the XSPIn_DS signal.	3B2h	Specified by JESD251-1
8D-8D-8D	Command, Address and Data fields are transferred at DDR with using 8 data pins. Read data is sampled with the XSPIn_DS signal.	3FFh	Specified by JESD251
1S-2S-2S	Command field is transferred at SDR with using 1 data pin. Address and Data fields are transferred at SDR with using 2 data pins. Read data is sampled with the XSPIn_CK signal.	048h	—
2S-2S-2S	Command, Address and Data fields are transferred at SDR with using 2 data pins. Read data is sampled with the XSPIn_CK signal.	049h	—
1S-4S-4S	Command field is transferred at SDR with using 1 data pin. Address and Data fields are transferred at SDR with using 4 data pins. Read data is sampled with the XSPIn_CK signal.	090h	—
4S-4S-4S	Command, Address and Data field are transferred at SDR with using 4 data pins. Read data is sampled with the XSPIn_CK signal.	092h	—

Note: When XIP mode is enabled in memory-mapped mode, XIP code is inserted into Latency field.

Bytes in the command field and address field are transferred in highest order to lowest order sequence. Sequential bytes in the data field are transferred in lowest address to highest address order. When using multiple pins, the least significant bit of each byte is assigned to the XSPIn_IO0 pin with each higher order bit on the successively higher numbered XSPIn_IOm pins (n = 0, 1).

Figure 48.4 shows the timing chart for the 1S-1S-1S protocol mode. The XSPIn_IO0 signal is used for output data and the XSPIn_IO1 signal is used for input data (n = 0, 1).

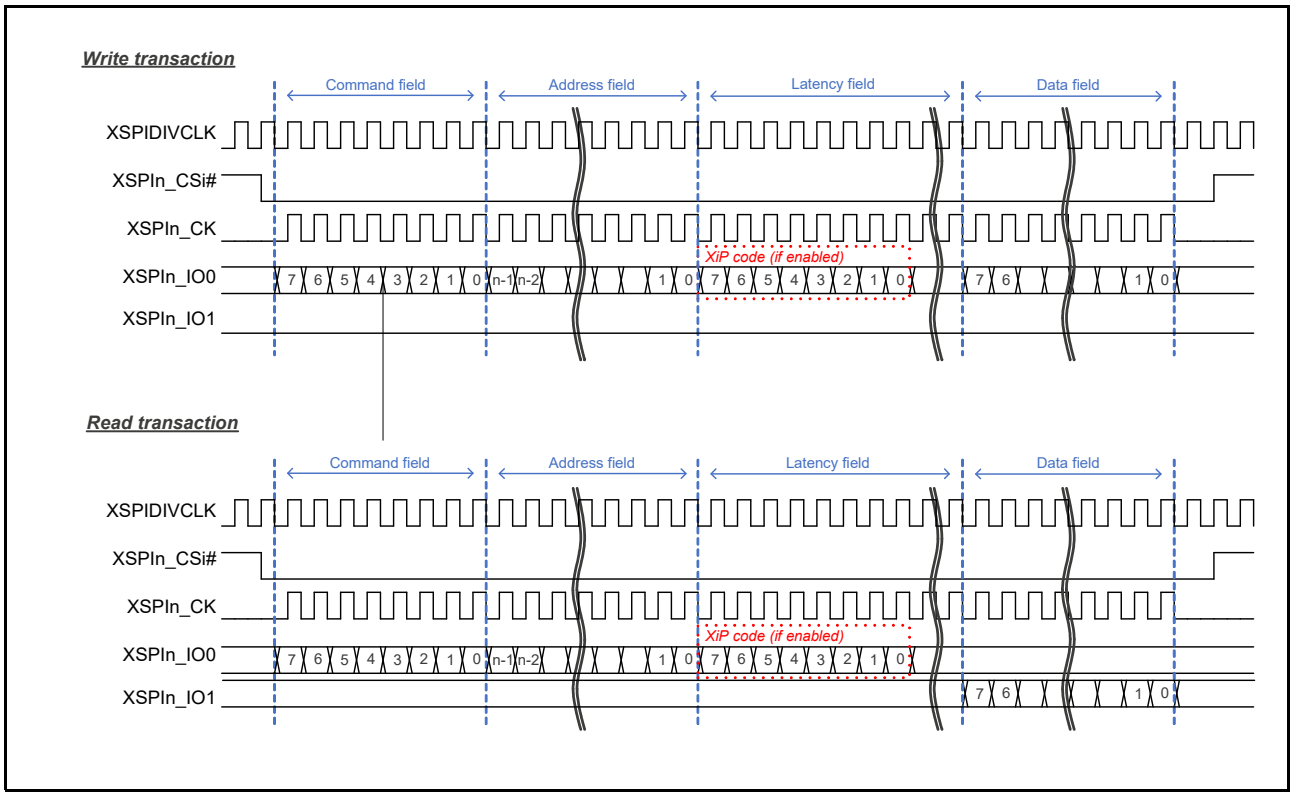

Figure 48.4 1S-1S-1S Timing Chart (n = 0, 1; i = 0, 1)

Figure 48.5 shows the timing chart for 1S-2S-2S protocol mode.

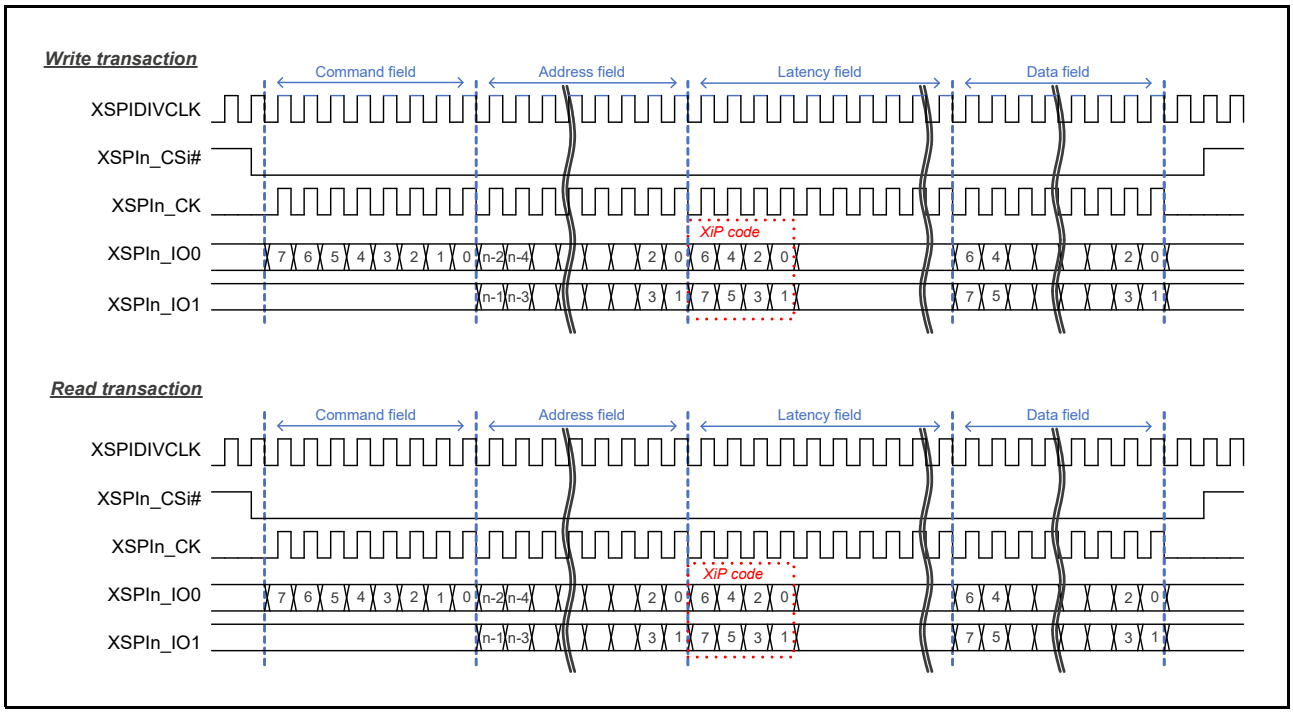

Figure 48.5 1S-2S-2S Timing Chart (n = 0, 1; i = 0, 1)

Figure 48.6 shows the timing chart for 4S-4D-4D protocol mode.

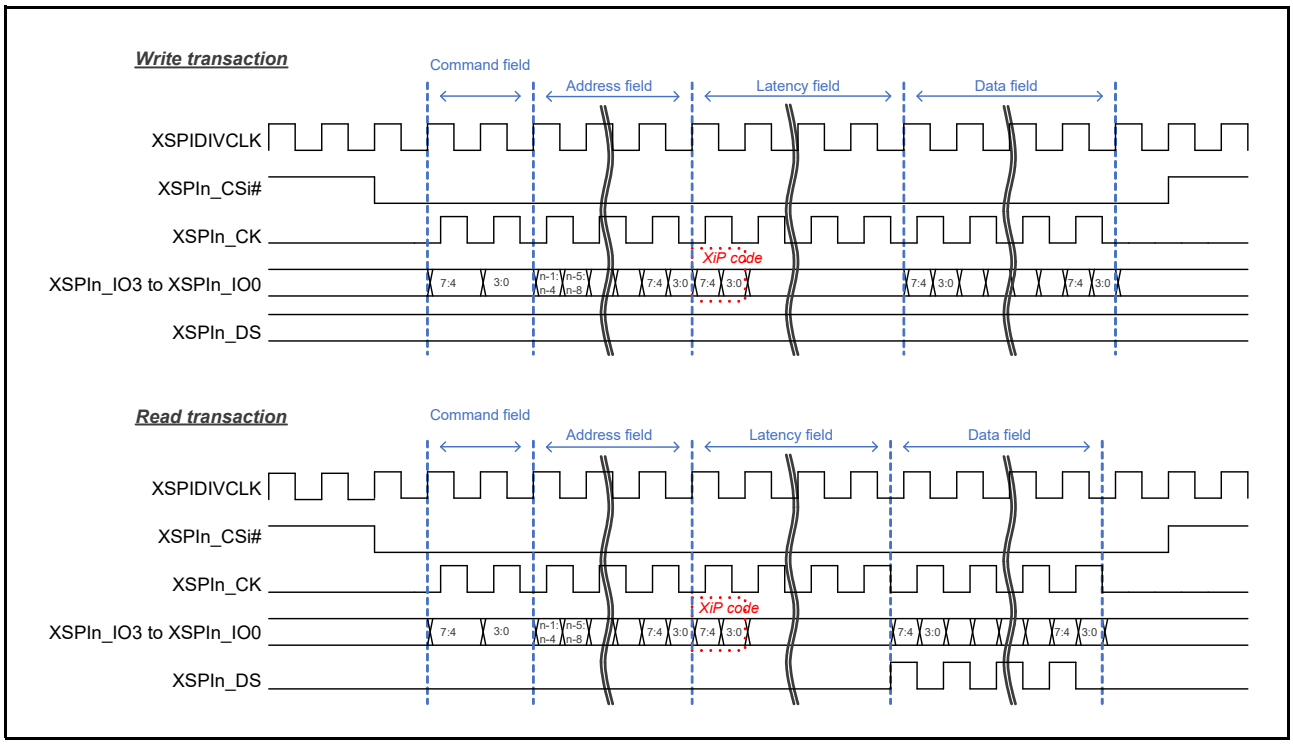

Figure 48.6 4S-4D-4D Timing Chart (n = 0, 1; i = 0, 1)

Figure 48.7 shows the timing chart for 8D-8D-8D profile1.0 protocol mode. In 8D-8D-8D mode, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

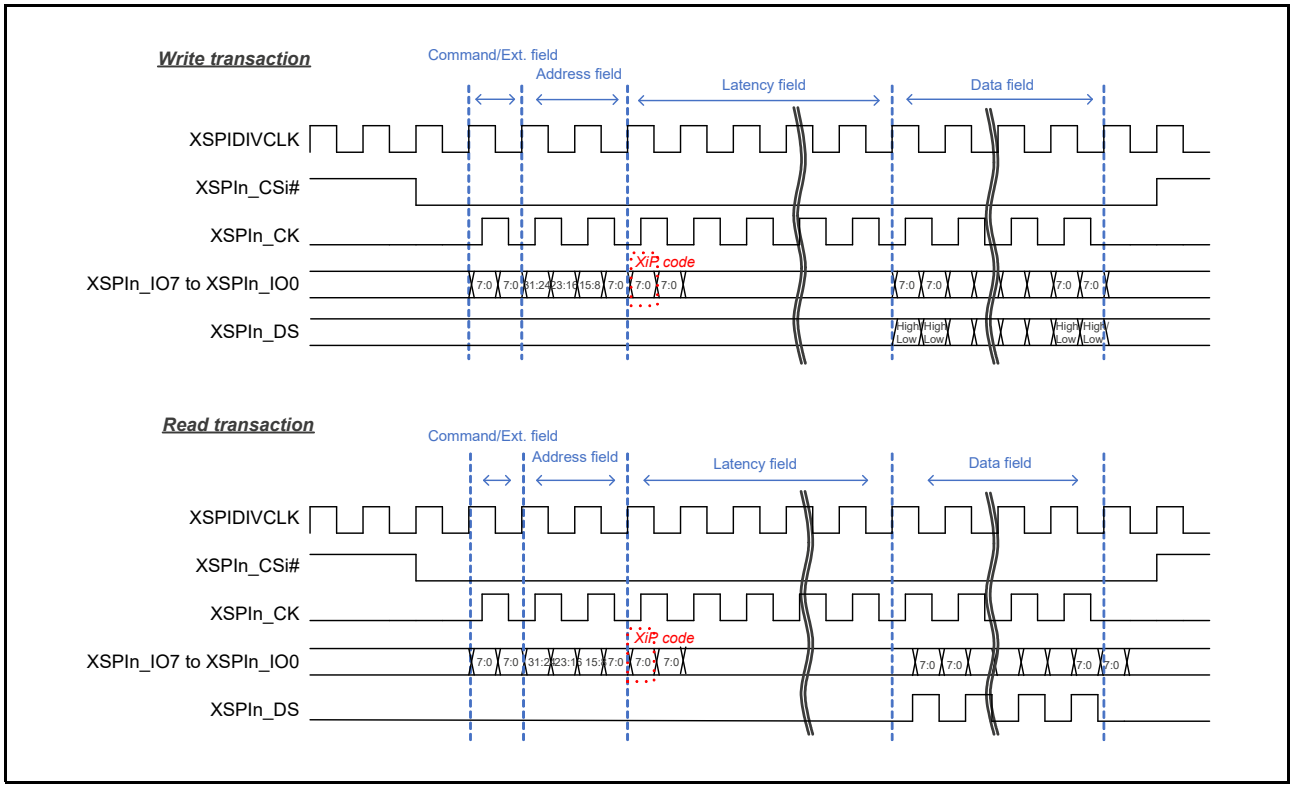

Figure 48.7 8D-8D-8D Profile 1.0 Timing Chart (n = 0, 1; i = 0, 1)

Figure 48.8 shows the timing chart for 8D-8D-8D profile2.0 protocol mode. In 8D-8D-8D mode, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

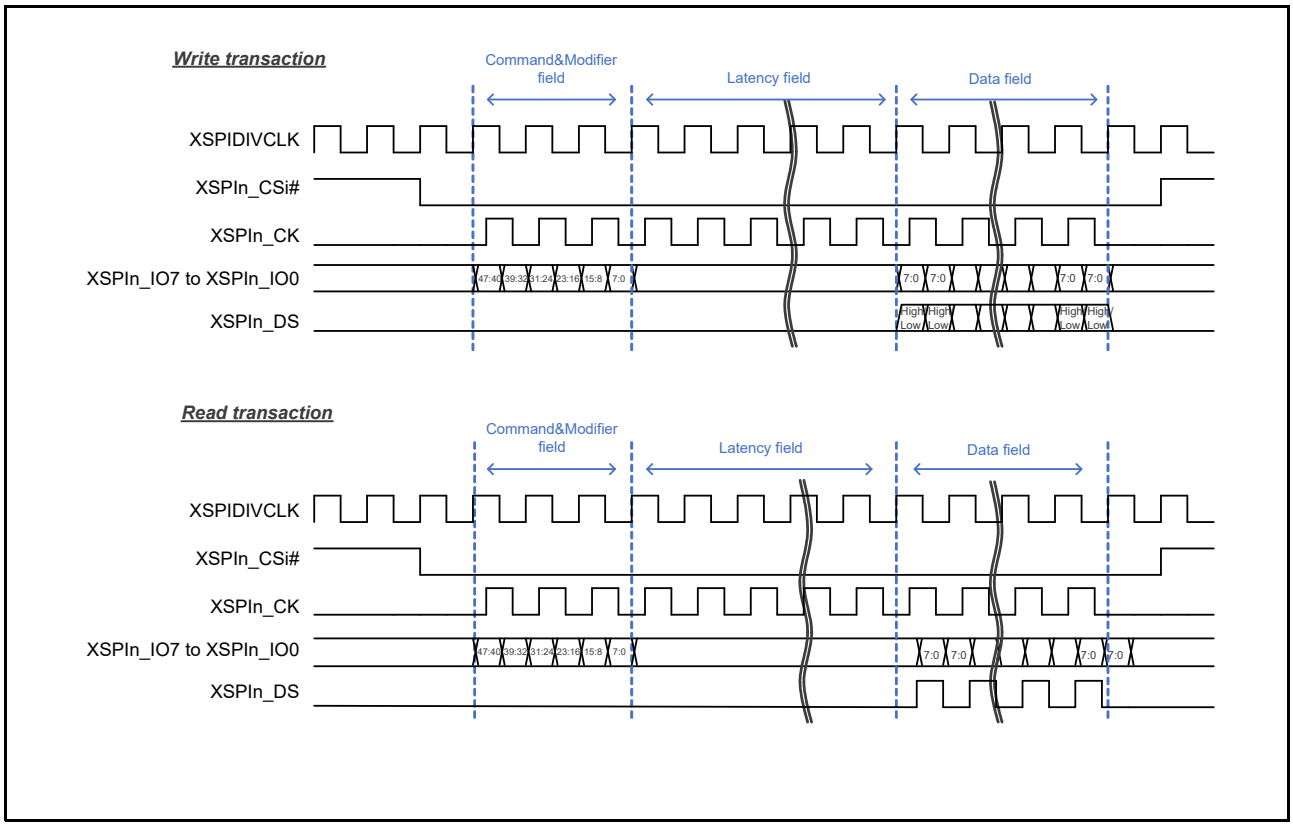

Figure 48.8 8D-8D-8D Profile 2.0 Timing Chart (n = 0, 1; i = 0, 1)

(2) xSPI Frame Interval

The interval between xSPI frames is set by the LIOCFGCSi.CSMIN[3:0] bits (i = 0, 1). The setting value depends on the specifications of the xSPI target device.

(3) Timing Control of xSPI Signals

The XSPI controller supports both SDR transfer and DDR transfer. For SDR transfers, input data is sampled with the XSPIn_CK signal, and for DDR transfers, it is sampled with the XSPIn_DS signal (n = 0, 1). The XSPI controller can statically adjust the output timing/sampling timing of the xSPI interface signals. Table 48.9 summarizes the timing control for the xSPI interface signals.

Table 48.9 Summary of Timing Control for the xSPI Signals (n = 0, 1; i = 0, 1)

Signal	I/O	Mode	Default Operation	Timing Control
XSPIn_CS0, XSPIn_CS1	Output	—	Asserted one cycle before the rising edge of the first XSPIn_CK signal	Assertion timing can be delayed one cycle by the LIOCFGCSi.CSASTEX bit.
			Negated 1.5 cycles after the falling edge of the last XSPIn_CK signal	Negation timing can be delayed one cycle by the LIOCFGCSi.CSNEGEX bit.
XSPIn_CK		SDR transfer	Reference signal	—
		DDR transfer	Reference signal	—
XSPIn_IO0 to XSPIn_IO7		SDR transfer	Output on the falling edge of XSPIDIVCLK	Output timing can be changed to the rising edge of XSPIDIVCLK (0.5 cycles delay) by the LIOCFGCSi.SDRDRV bit.
		DDR transfer	Output on both edges of XSPIDIVCLK	—
XSPIn_IO0 to XSPIn_IO7	Input	SDR transfer	Sampled at the falling edge of the XSPIn_CK signal within the expected data size	Sampling timing can be delayed 0 to 7 cycles by LIOCFGCSi.SDRSMPSFT[3:0] bits. Sampling timing can be changed to the rising edge of the XSPIn_CK signal (0.5 cycle earlier) by the LIOCFGCSi.SDRSMPMD bit.
		DDR transfer	Sampled at both edges of the XSPIn_DS signal within the expected data size	The phase of the XSPIn_DS signal can be shifted 0 to 1 cycle by the WRAPCFG.DSSFTCSi[4:0] bits. Sampling period can be extended from 0 to 7 cycles by the LIOCFGCSi.DDRSMPEX[3:0] bits.

Figure 48.9 shows the default operation and timing control for SDR transfer.

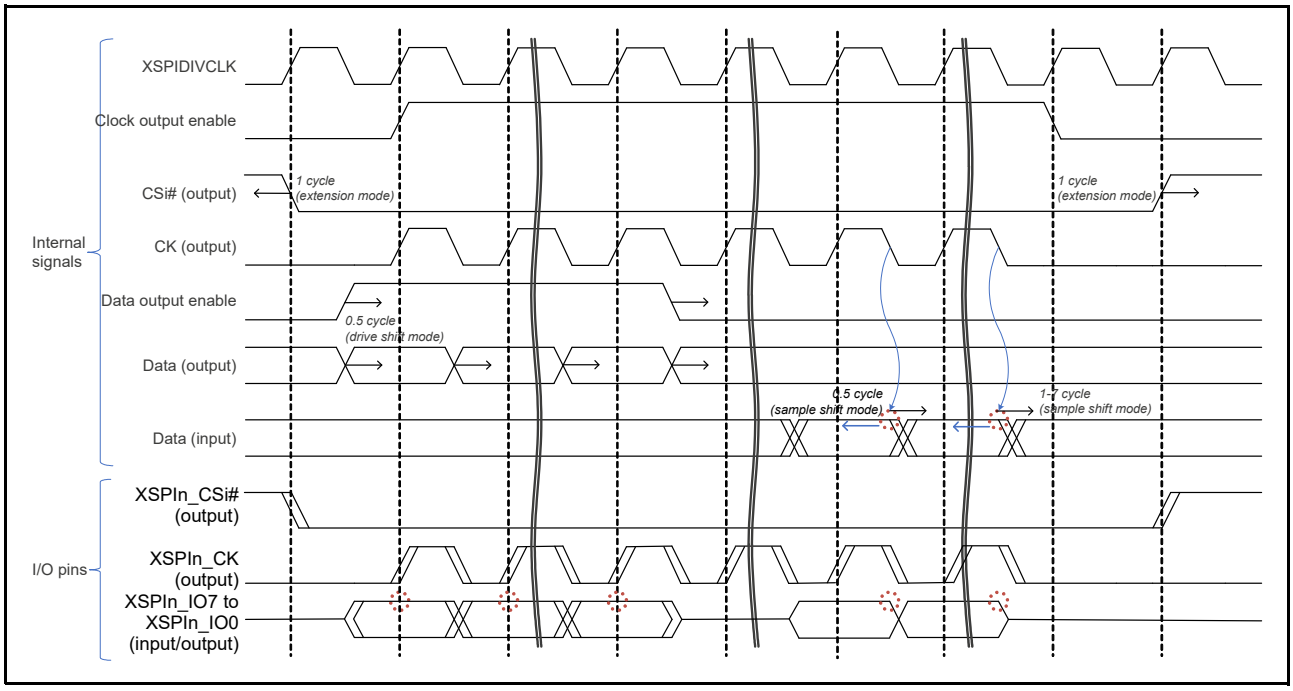

Figure 48.9 Timing Control for SDR Transfer (n = 0, 1; i = 0, 1)

Figure 48.10 shows the default operation and timing control for DDR transfer.

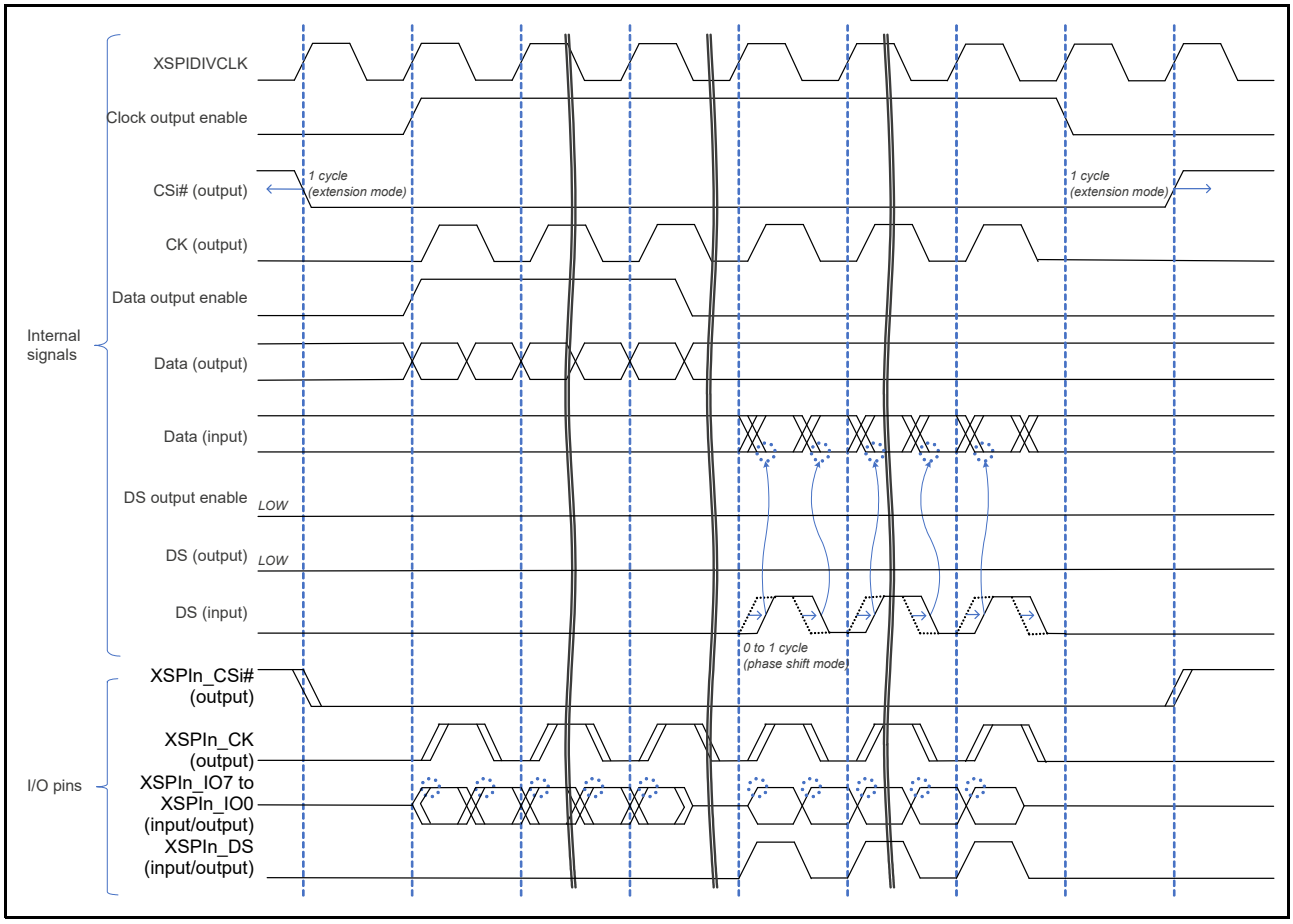

Figure 48.10 Timing Control for DDR Transfer (n = 0, 1; i = 0, 1)

(4) Automatic Calibration

The XSPI controller has a function to automatically adjust the phase shift amount of the DS signal.
This function is enabled by setting the CCCTL0CSi.CAEN bit to 1, and the XSPI controller periodically transmits calibration sequences and automatically adjusts the value of the WRAPCFG.DSSFTCSi[4:0] bits (phase shift amount) (i = 0, 1).
During read transactions in the calibration sequence, if all read comparison results are mismatched, the INTS.CAFAILCSi flag is set to 1 (calibration failed), and the value of the DSSFTCSi[4:0] bits is not updated. If at least one read comparison result matches, the INTS.CASUCCSi flag is set to 1 (calibration success), and the value of the DSSFTCSi[4:0] bits is updated. The success or failure of each phase shift amount can be confirmed by the corresponding flag in the CASTTCSi register.
Figure 48.11 shows the operation of automatic calibration.

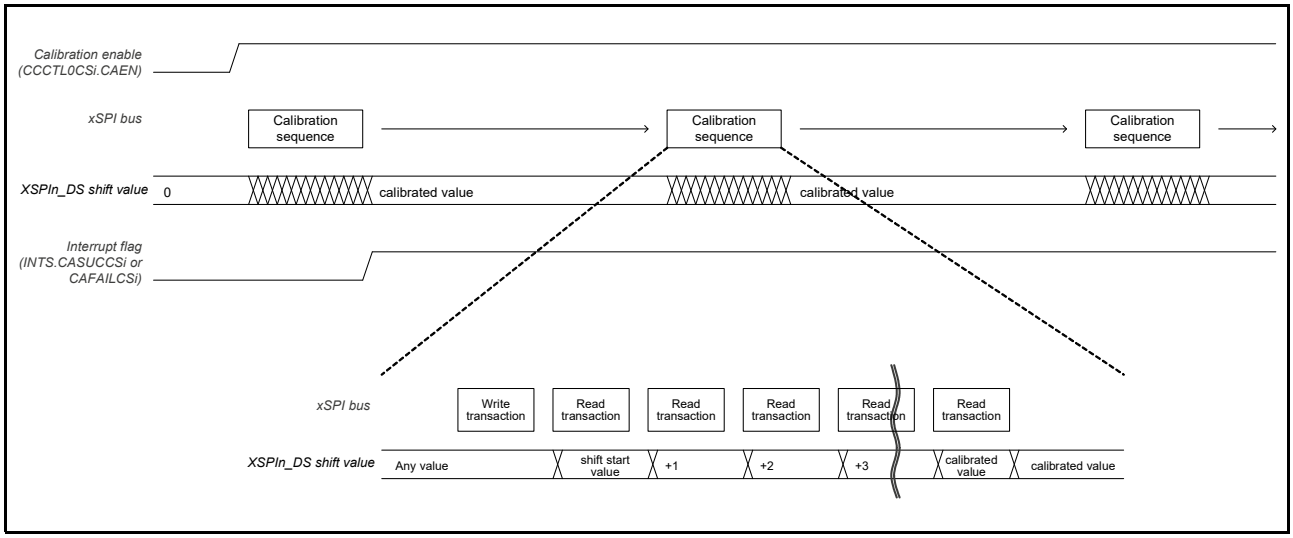

Figure 48.11 Automatic Calibration (n = 0, 1; i = 0, 1)

48.3.1.2 Indirect Access Mode

The indirect access mode has two functional modes: sequential mode and periodic mode.

(1) Sequential Mode

This mode sequentially issues up to four xSPI transactions as configured and requested by software. It can be used to change the mode or to read the status of the xSPI target device. This mode is enabled by setting the CDCTL0.PERMD bit to 0.

Set each transaction in the CDTBUFm, CDABUFm, CDD0BUFm, and CDD1BUFm registers (m = 0 to 3), and set the number of transactions to be issued in the CDCTL0.TRNUM[1:0] bits. After that, when the CDCTL0.TRREQ bit is set to 1, the specified number of transactions are issued sequentially starting from buffer number 0.

Table 48.10 lists the registers and bits used to set the transactions.

Table 48.10 Transaction Settings for Sequential Mode

Transaction	Transaction Type	Command	Command Size	Address	Address Size	Data	Data Size	Latency Cycle
1st Transaction	CDTBUF0. TRTYPE	CDTBUF0. CMD[15:0]	CDTBUF0. CMDSIZE[1:0]	CDABUF0	CDTBUF0. ADDSIZE[2:0]	CDD0BUF0, CDD1BUF0	CDTBUF0. DATASIZE[3:0]	CDTBUF0. LATE[4:0]
2nd Transaction	CDTBUF1. TRTYPE	CDTBUF1. CMD[15:0]	CDTBUF1. CMDSIZE[1:0]	CDABUF1	CDTBUF1. ADDSIZE[2:0]	CDD0BUF1, CDD1BUF1	CDTBUF1. DATASIZE[3:0]	CDTBUF1. LATE[4:0]
3rd Transaction	CDTBUF2. TRTYPE	CDTBUF2. CMD[15:0]	CDTBUF2. CMDSIZE[1:0]	CDABUF2	CDTBUF2. ADDSIZE[2:0]	CDD0BUF2, CDD1BUF2	CDTBUF2. DATASIZE[3:0]	CDTBUF2. LATE[4:0]
4th Transaction	CDTBUF3. TRTYPE	CDTBUF3. CMD[15:0]	CDTBUF3. CMDSIZE[1:0]	CDABUF3	CDTBUF3. ADDSIZE[2:0]	CDD0BUF3, CDD1BUF3	CDTBUF3. DATASIZE[3:0]	CDTBUF3. LATE[4:0]

(2) Periodic Mode

This mode periodically issues a single xSPI read transaction configured and requested by software, and compares up to 4 bytes of received data with the expected value. It can be used for status polling of the xSPI target device. This mode is enabled by setting the CDCTL0.PERMD bit to 1.

Set the transaction to be issued in the CDTBUF0, CDABUF0, CDD0BUF0, and CDD1BUF0 registers, the expected value of the received data in the CDCTL1 and CDCTL2 registers, the transaction interval in the CDCTL0.PERITV[4:0] bits, and the repetition count in the PERREP[3:0] bits. After that, when the CDCTL0.TRREQ bit is set to 1, the specified transaction is repeated up to the specified number of times at the specified interval. When the received data matches the expected value, the INTS.CMDCMP flag is set to 1 and transaction issuance stops.

Table 48.11 lists the registers and bits used to set the transactions.

Table 48.11 Transaction Settings for Periodic Mode

Transaction	Transaction Type	Command	Command Size	Address	Address Size	Data	Data Size	Latency Cycle
Read Transaction	CDTBUF0. TRTYPE = 0	CDTBUF0. CMD[15:0]	CDTBUF0. CMDSIZE[1:0]	CDABUF0	CDTBUF0. ADDSIZE[2:0]	CDD0BUF0, CDD1BUF0	CDTBUF0. DATASIZE[3:0]	CDTBUF0. LATE[4:0]

48.3.1.3 Memory-Mapped Mode

This mode automatically converts internal bus accesses to predefined memory regions into xSPI transactions.

(1) Configuration

In memory-mapped mode, the payload for the address and data fields is obtained from the internal bus signals, and information such as the command field and sizes is obtained from pre-configured registers.
Table 48.12 lists the registers and bits used in memory-mapped mode.

Table 48.12 Memory-Mapped Mode Configuration (i = 0, 1)

Internal Bus Transaction	Frame Format	Command	Command Size	Address*1	Address Size	Data	Latency Cycle
Writing to the memory area of target device i	Normal	CMCFG2CSi.WRCMD[15:8]	1 byte	A[x:0]	CMCFG0CSi.ADDSIZE[1:0]	D[x:0]	CMCFG2CSi.WRLATE[4:0]
	8D-8D-8D Profile 1.0	CMCFG2CSi.WRCMD[15:0]	2 bytes				
	8D-8D-8D Profile 2.0 Command Modifier	CMCFG2CSi.WRCMD[15:8]	1 byte	A[27:20], A[19:12], A[11:4], 00h, 00000b+A[3:1]	5 bytes		
	8D-8D-8D Profile 2.0 Extended Command Modifier	CMCFG2CSi.WRCMD[15:13]	3 bits	0b+A[31:28], A[27:20], A[19:12], A[11:4], 00h, 00000b+A[3:1]	45 bits (5 bits + 5 bytes)		
Reading from the memory area of target device i	Normal	CMCFG1CSi.RDCMD[15:8]	1 byte	A[x:0]	CMCFG0CSi.ADDSIZE[1:0]	D[x:0]	CMCFG1CSi.RDLATE[4:0]
	8D-8D-8D Profile 1.0	CMCFG1CSi.RDCMD[15:0]	2 bytes				
	8D-8D-8D Profile 2.0 Command Modifier	CMCFG1CSi.RDCMD[15:8]	1 byte	A[27:20], A[19:12], A[11:4], 00h, 00000b+A[3:1]	5 bytes		
	8D-8D-8D Profile 2.0 Extended Command Modifier	CMCFG1CSi.RDCMD[15:13]	3 bits	0b+A[31:28], A[27:20], A[19:12], A[11:4], 00h, 00000b+A[3:1]	45 bits (5 bits + 5 bytes)		

Note 1. The most significant byte of the address (A[31:24]) can be replaced using the CMCFG0CSi.ADDRPEN[7:0] and CMCFG0CSi.ADDRPCD[7:0] bits.

(2) Write Access

When accepting a write access from the internal bus to the XSPI area, the XSPI controller stores all payload data in an internal bridge buffer and then issues a write transaction to the XSPI target.
Figure 48.12 shows an overview of the write access operation.

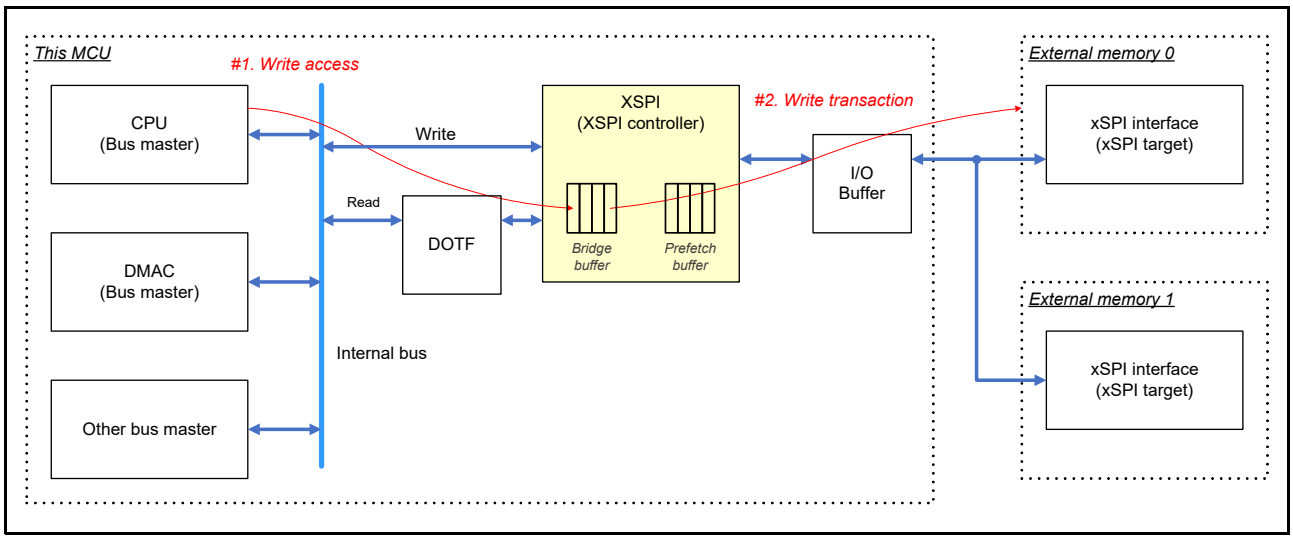

Figure 48.12 Write Access to Memory Area

The operation of xSPI bus changes depending on internal bus burst type. When the burst type is single type or incremental type, one internal bus transaction triggers for one xSPI frame. When the burst type is wrap type and the CMCFG0CSi.WPBSTMD is 0, one internal bus transaction triggers two xSPI frames (i = 0, 1).
Figure 48.13 shows the relationship between AXI and xSPI frame.

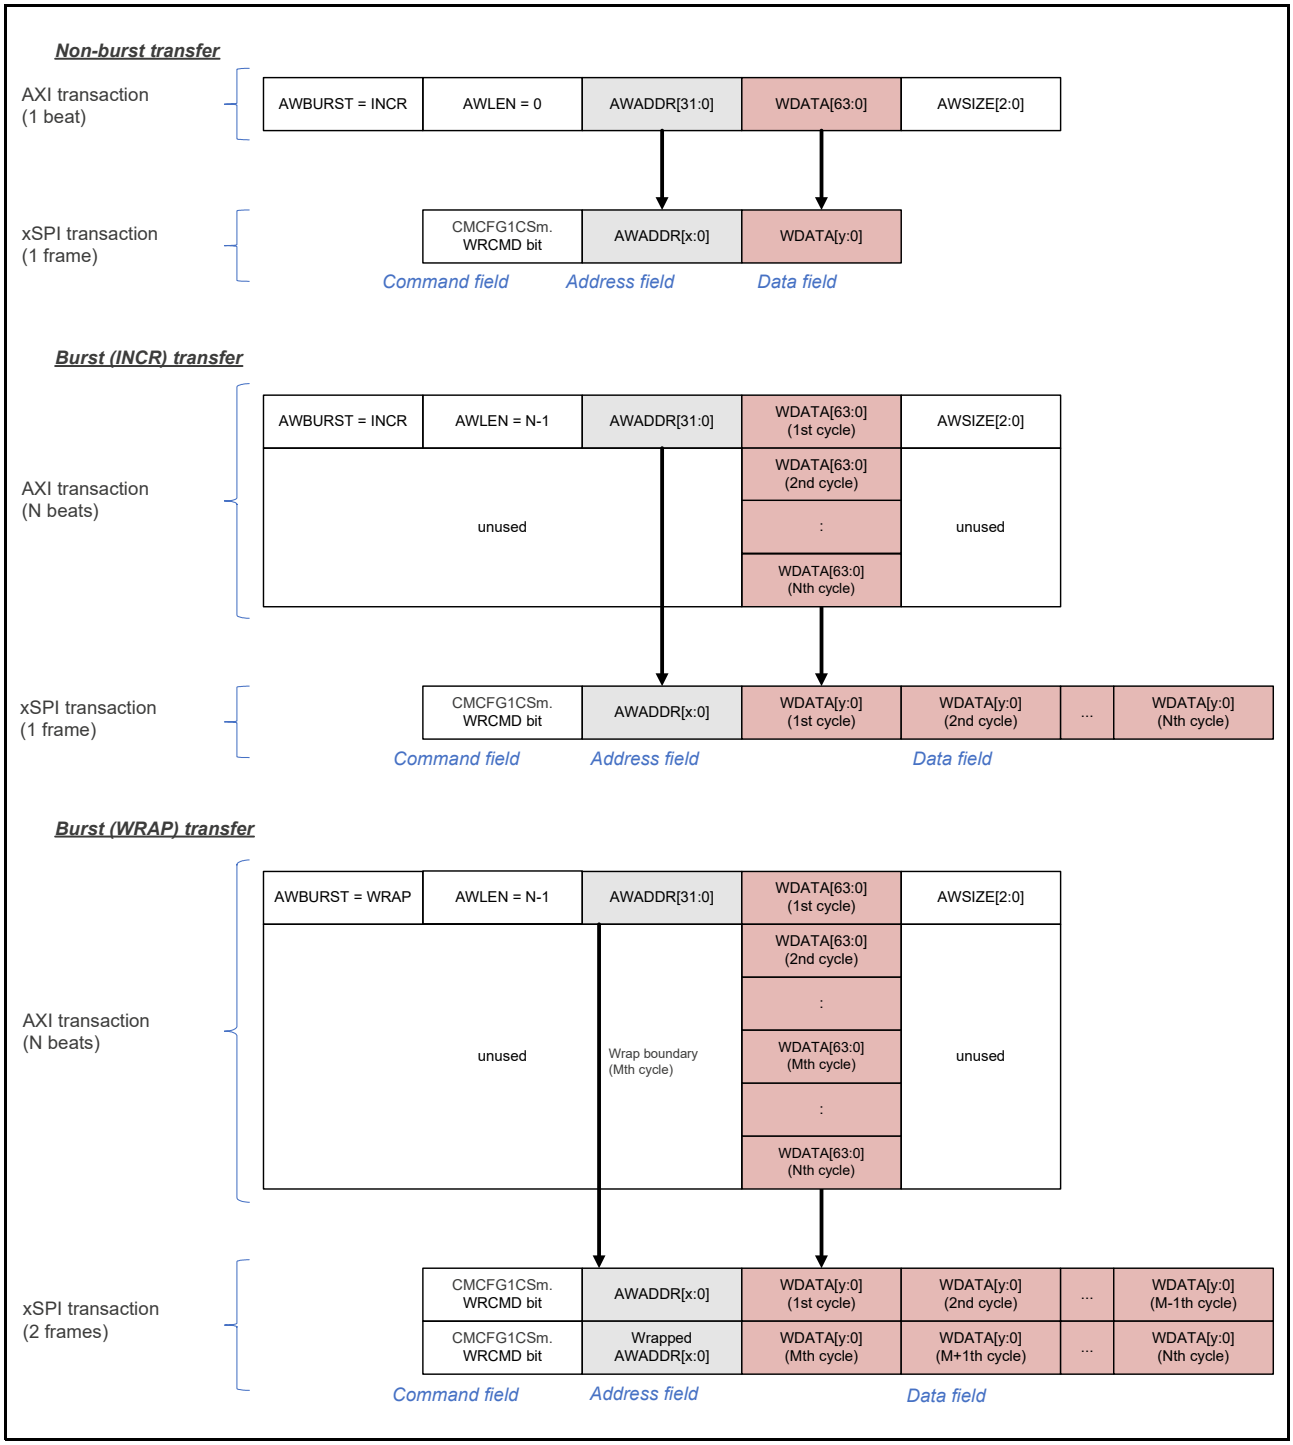

Figure 48.13 xSPI Frame Format in Write Access (Normal Format) (i = 0, 1)

(3) Write Data Combination Function

To achieve high throughput on the xSPI bus during internal bus write accesses to the XSPI area, the XSPI controller incorporates a function to combine write data. When the BMCFGCH0.MWRCOMB bit is set to 1, this function is enabled and the XSPI controller transmits xSPI frames at the selected size while the addresses are incrementally consecutive*1.

Note 1. The access which comply all below condition is considered as incremental address.
- Transaction type is INCR.
- The starting address of the access is consecutive with the last write address.
  - The starting position of WSTRB access is treated as the starting address
  - The last WSTRB of the previous access is treated as the last write address

When any of the following conditions is detected, the XSPI controller transmits pending data to the xSPI bus even if the target size set in the BMCFGCH0.MWRSIZE[7:0] bits has not been reached.

- Non-incremental address is detected.
- Different burst type is detected.
- Read transaction is detected.
- Access for different target is detected.
- Memory Write Data Push bit (BMCTL1.MWRPUSHCH0) is set to 1.

This function is useful when the target device requests large amount of data at once. In this case, the internal bus master must continue to provide fixed-size data blocks at incremental addresses.
Figure 48.14 shows the operation when enable the combination function.

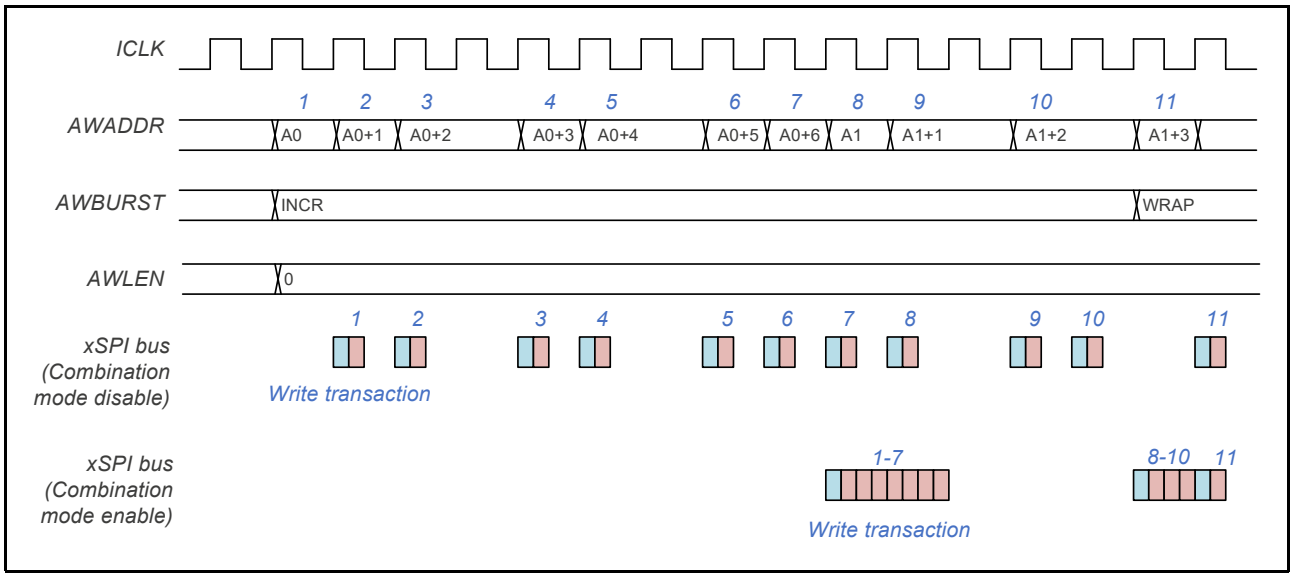

Figure 48.14 Write Data Combination Function

Figure 48.15 shows an example of write data combination in AXI access.

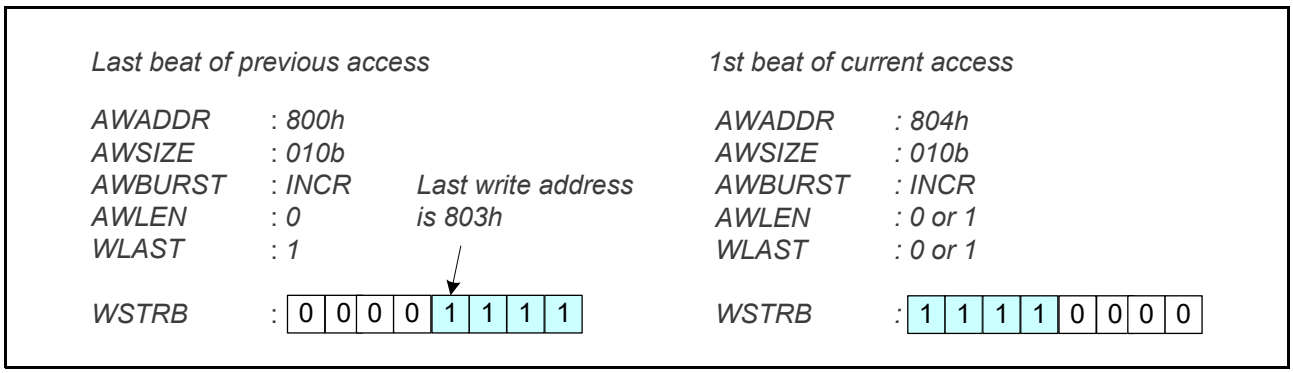

Figure 48.15 Example of Write Data Combination in AXI Access

(4) Read Access

When a read access to the XSPI area from the internal bus is detected, the XSPI controller immediately issues a read transaction to the xSPI target.

Figure 48.16 shows an overview of the read access operation.

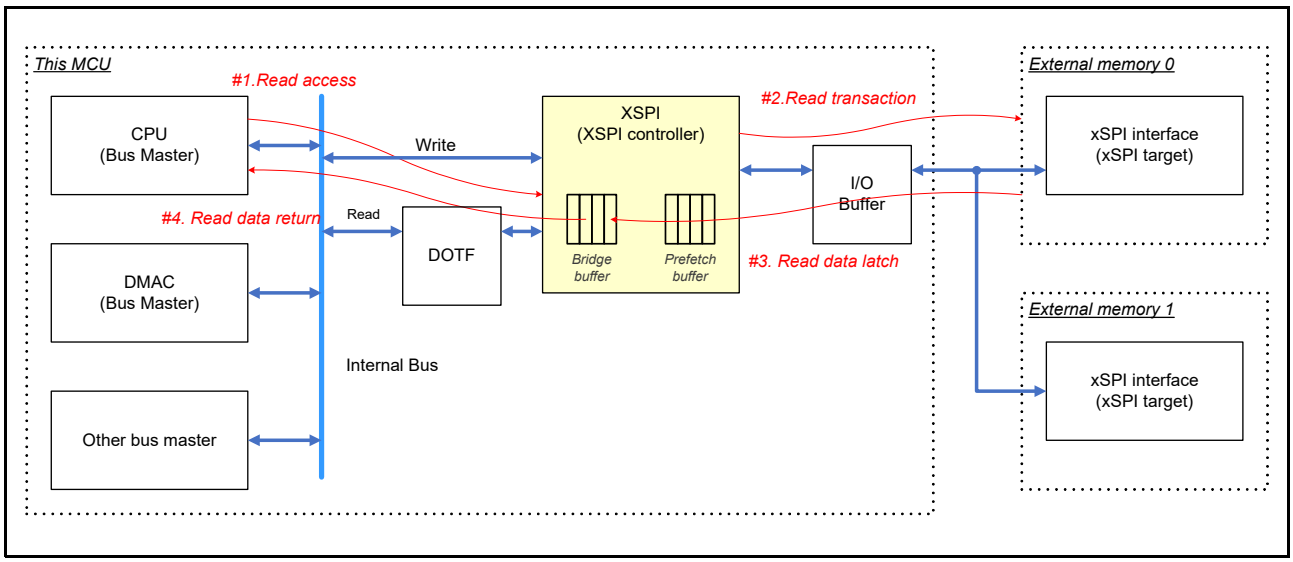

Figure 48.16 Read Access to Memory Area

The operation of xSPI bus changes depending on burst type. When the type is single or increment type, one internal bus's read transaction triggers one xSPI frame. When the type is wrap type and the CMCFG0CSi.WPBSTMD is 0, one system bus read transactions triggers two xSPI frame (i = 0, 1).
Figure 48.17 shows the relationship between AXI and xSPI frame.

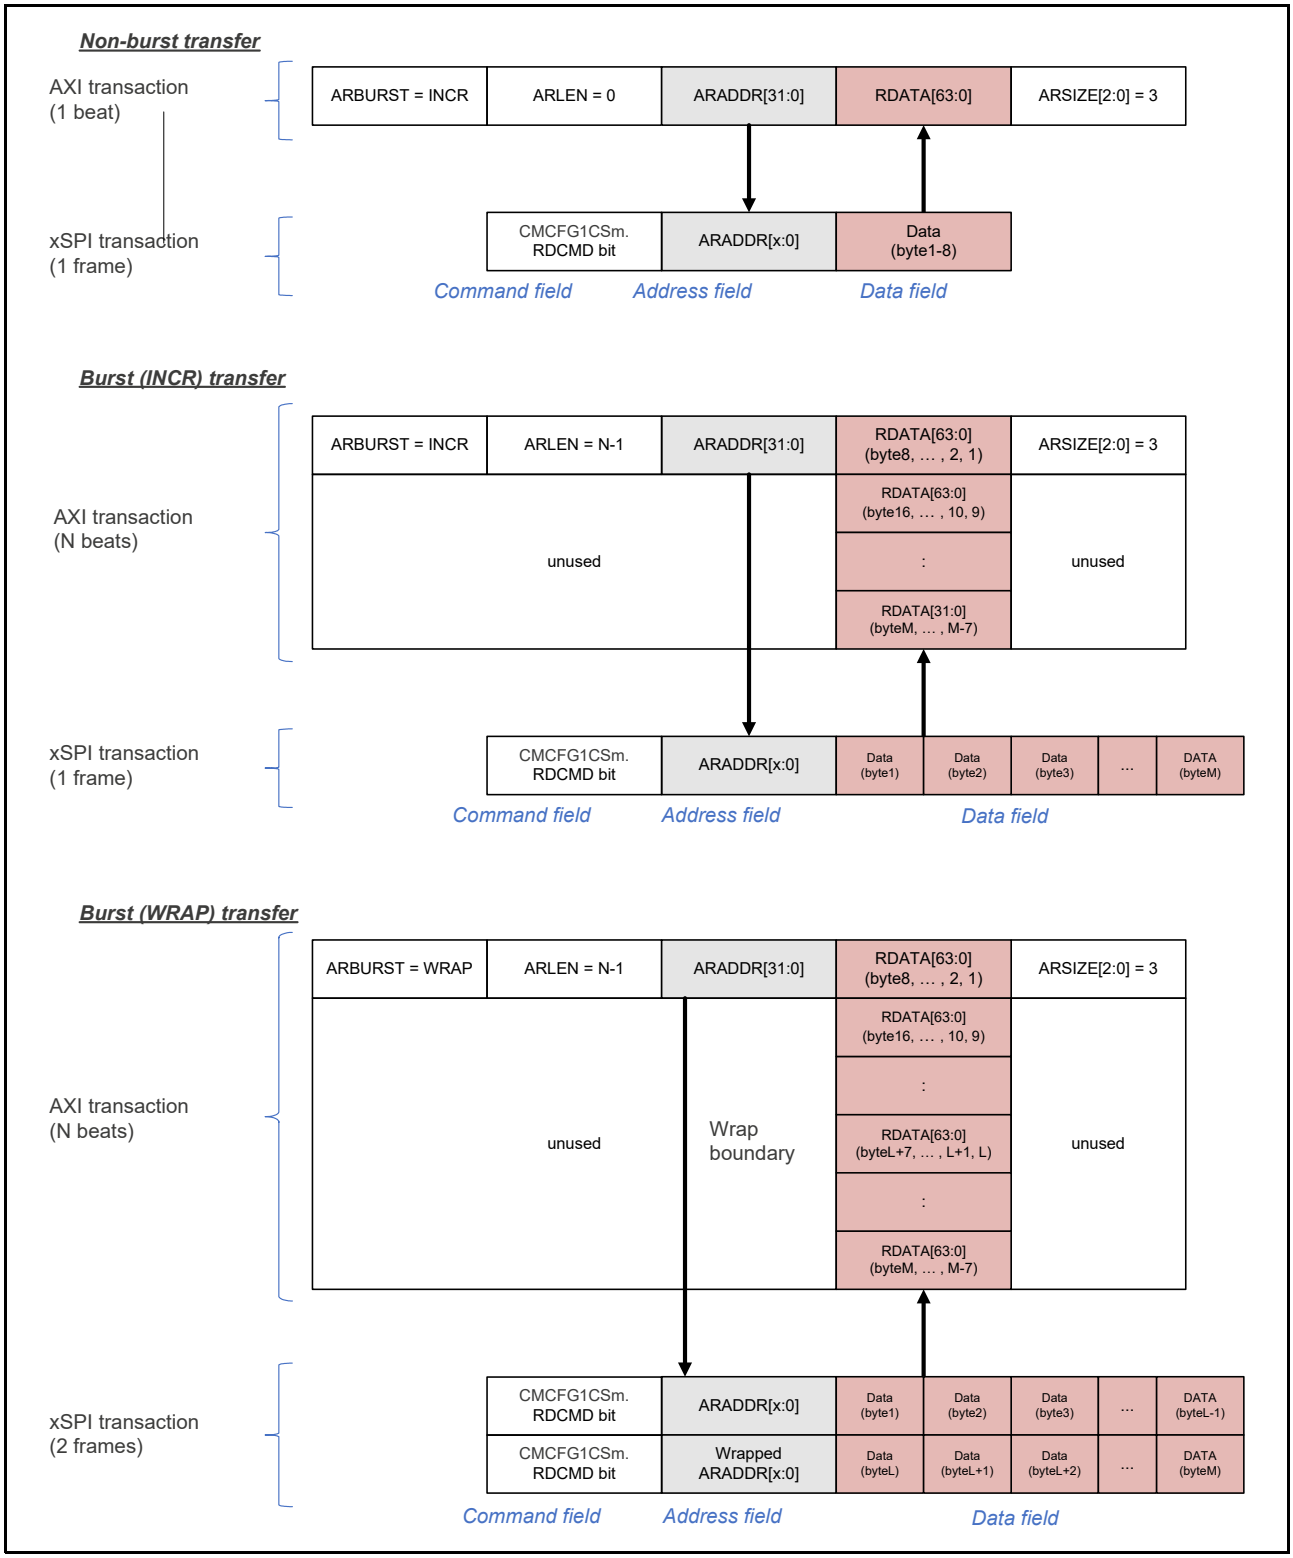

Figure 48.17 xSPI Frame Format in Read Access (Normal Format) (i = 0, 1)

(5) Prefetch Function

The XSPI controller has a function that prefetches read data to reduce latency for read accesses to the XSPI area from the internal bus. Setting the BMCFGCHi.PREEN bit to 1 enables this function, and the XSPI controller continuously reads data from subsequent addresses from the xSPI target and stores it in the internal prefetch buffer (i = 0, 1). When the next read access from the internal bus is detected, the XSPI controller searches the prefetch buffer. If the desired read data is found in the prefetch buffer, the XSPI controller returns the data from the prefetch buffer. If not found, the prefetch buffer is cleared and a new read transaction is issued to the xSPI target.

This function is effective in applications that read adjacent areas consecutively. It is ineffective if the addresses to be read are not consecutive.

Figure 48.18 shows the operation when enable the prefetch function.

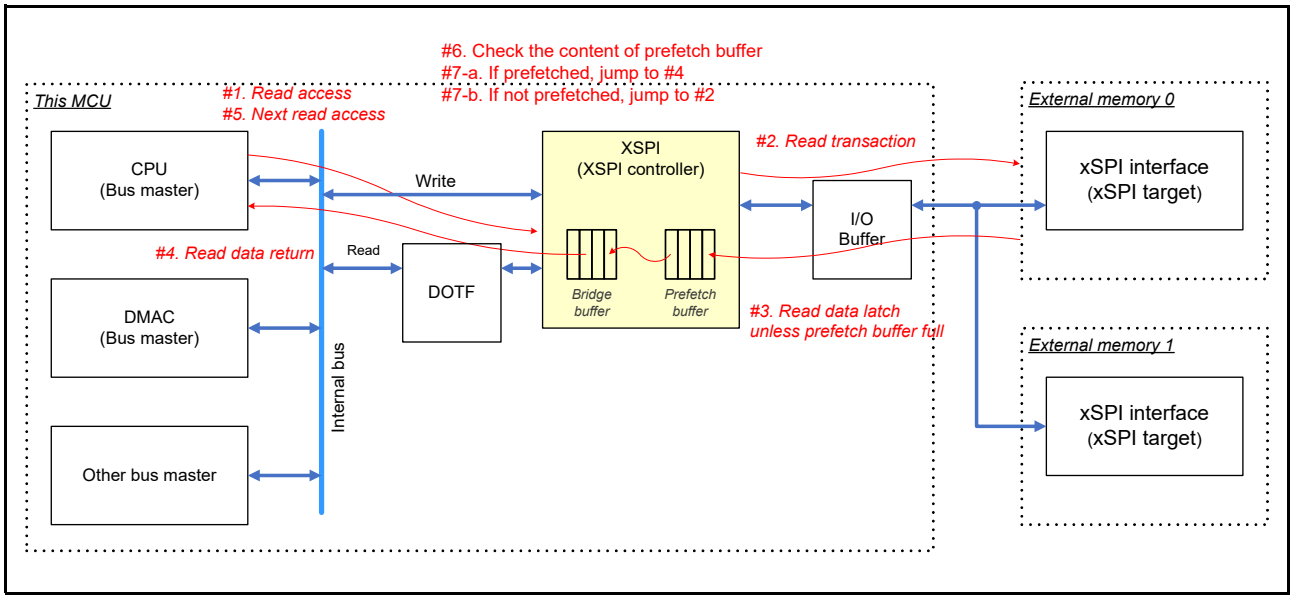

Figure 48.18 Read Access to Memory Area with Prefetch Function Enabled

(6) XIP Mode

Some target devices can reduce latency by omitting the command phase. To support such devices, the XSPI controller supports XIP mode.
When the CMCTLCH0.XIPEN bit is set to 1 (XIP mode enabled), the XSPI controller inserts the XIP enter code specified by the CMCTLCH0.XIPENCODE[7:0] bits into the latency field. When the XIPEN bit is set to 0 (XIP mode disabled), the XSPI controller inserts the XIP exit code specified by the CMCTLCH0.XIPEXCODE[7:0] bits into the latency field. This function is only available in memory-mapped mode.
The XIPEN bit also becomes 0 and XIP mode is disabled when the XSPI controller sends an XIP disable pattern by setting the LPCTL0.PATREQ bit to 1. It is not possible to disable XIP mode on only one channel using the XIP disable pattern.

Note: If there are not enough latency cycles for the XIP code to be inserted, the XIP code cannot be inserted.

48.3.1.4 Signal Pattern Control

This xSPI controller has the function to transmit three types of signal patterns that are not in xSPI frame format. Transmission of signal patterns is triggered by setting the signal pattern generation request bits (LPCTL0.PATREQ, LPCTL1.PATREQ[1:0]).

(1) XIP Disable Pattern

The XIP disable pattern is a signal pattern with the length and level set by the XD1LEN[4:0], XD1VAL, XD2LEN[4:0], and XD2VAL bits in the LPCTL0 register. The XSPIn_CK and XSPIn_IO7 to XSPIn_IO0 signals are used, and the number of output pins is specified by the LPCTL0.XDPIN[1:0] bits (n = 0, 1).
The XIP disable pattern can be used to disable XIP mode in Legacy SPI.
Figure 48.19 shows the timing chart for the XIP disable pattern.

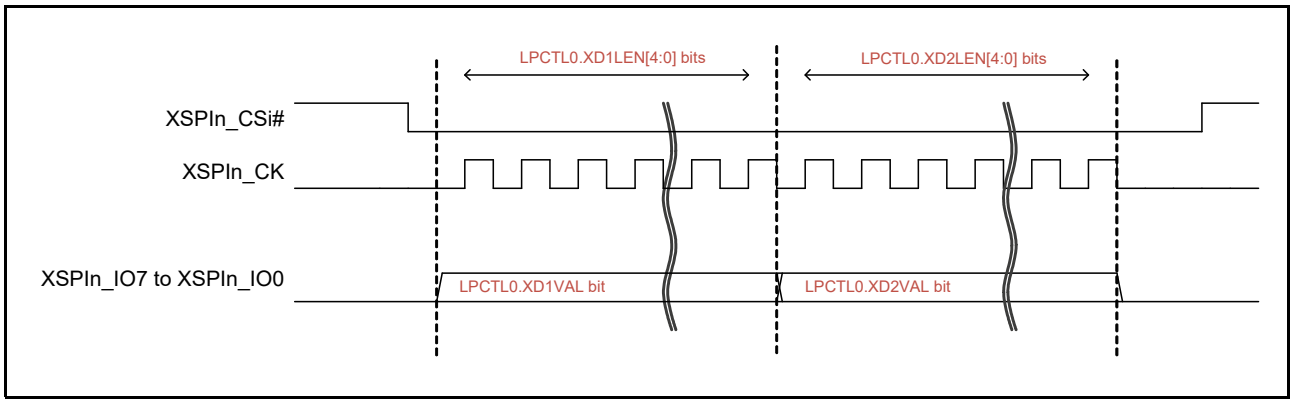

Figure 48.19 XIP Disable Pattern (n = 0, 1; i = 0, 1)

(2) Reset Pattern

The Reset pattern is a signal pattern specified in JESD252.
Figure 48.20 shows the timing chart for the reset pattern.
The low and high width of the XSPIn_CSi# signal is configured with the LPCTL1.RSTWID[2:0] bits (n = 0, 1; i = 0, 1).
The xSPI target samples data on the rising edge of the XSPIn_CSi# signal. The setup time for data output is configured with the LPCTL1.RSTSU[2:0] bits. The setup time must be shorter than the reset pattern width.

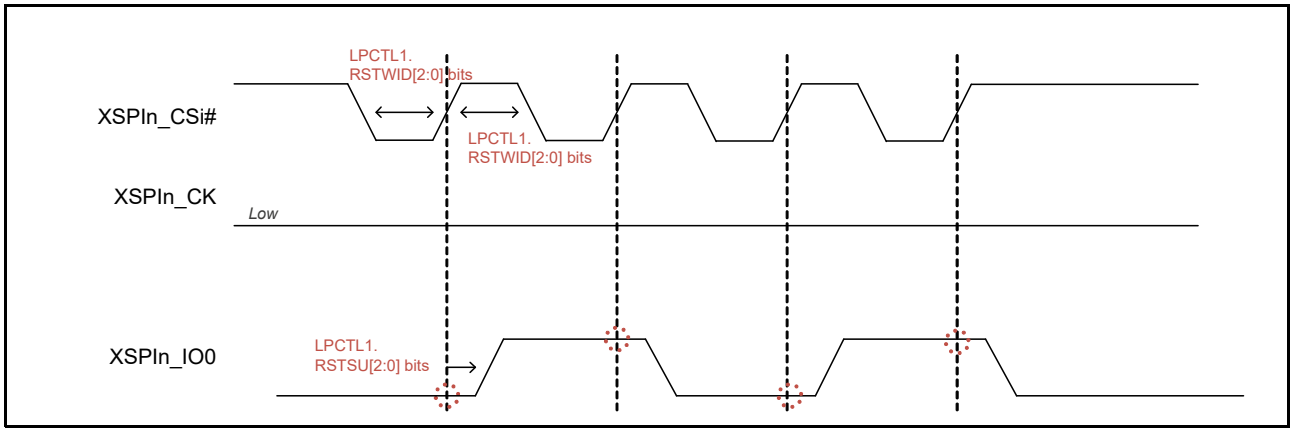

Figure 48.20 Reset Pattern (n = 0, 1; i = 0, 1)

(3) CS Only Pattern

CS only pattern asserts the XSPIn_CSi# pin with the pulse width configured with the LPCTL1.RSTWID[2:0] bits (n = 0, 1; i = 0, 1). It can be used to resume from deep power-down state.

Figure 48.21 shows the timing chart for the CS only pattern.

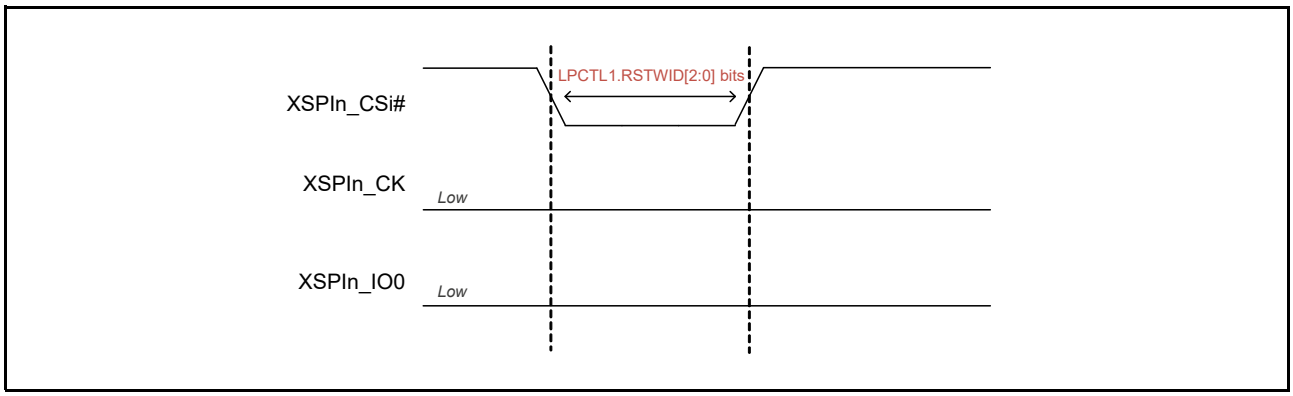

Figure 48.21 CS Only Pattern (n = 0, 1; i = 0, 1)

48.3.1.5 Error Detection

The xSPI controller can detect the errors shown in Table 48.13.

Table 48.13 Error List (n = 0, 1; i = 0, 1)

Name	Error Source	Detection Flag	Remarks
Calibration failed	The read data did not match the expected value during automatic calibration.	INTS.CAFAILCSi	Unexpected data is written to the xSPI target.
Internal bus error	An error occurred on the internal bus during memory-mapped mode.	INTS.BUSERRCH0	Due to a fatal error, the XSPI controller must be reset.
ECC error detection	The XSPIn_ECSi# pin changed from high to low (valid only if the xSPI target has ECC detection capability).	INTS.ECSCSi	Just a notification of an error event from the xSPI target
DS timeout	The XSPIn_DS signal did not toggle during a read transaction that uses the XSPIn_DS signal.	INTS.DSTOCSi	Due to a fatal error, both the XSPI controller and the xSPI target must be reset.
Periodic transaction timeout	The read value did not match the expected value in periodic mode of indirect access mode.	INTS.PERTO	

48.3.1.6 Interrupt Sources

This XSPI controller has two types of interrupt sources: CMP interrupt and ERR interrupt as shown in Table 48.14. Each interrupt can be monitored using the INTS register, and its enable/disable setting can be changed using the INTE register.

Note: Even if the corresponding bit in the INTE register is set to 1 after the flag in the INTS register is set to 1, the interrupt signal will not be output.

Table 48.14 XSPI Controller Interrupt Sources

Name	Interrupt Source	Interrupt Flag	Interrupt Enable Bit	Interrupt Clear Bit	DTC/DMAC Triggerable
CMP*1	Target 1 calibration success	INTS.CASUCCS1	INTE.CASUCCS1E	INTC.CASUCCS1C	No
	Target 0 calibration success	INTS.CASUCCS0	INTE.CASUCCS0E	INTC.CASUCCS0C	
	Signal pattern generation completion	INTS.PATCMP	INTE.PATCMPE	INTC.PATCMPC	
	Command issuance completion	INTS.CMDCMP	INTE.CMDCMPE	INTC.CMDCMPC	
ERR*1	Target 1 calibration failure	INTS.CAFAILCS1	INTE.CAFAILCS1E	INTC.CAFAILCS1C	No
	Target 0 calibration failure	INTS.CAFAILCS0	INTE.CAFAILCS0E	INTC.CAFAILCS0C	
	Internal bus error	INTS.BUSERRCH0	INTE.BUSERRCH0E	INTC.BUSERRCH0C	
	Target 1 interrupt detection	INTS.INTCS1	INTE.INTCS1E	INTC.INTCS1C	
	Target 0 interrupt detection	INTS.INTCS0	INTE.INTCS0E	INTC.INTCS0C	
	Target 1 ECC error detection	INTS.ECSCS1	INTE.ECSCS1E	INTC.ECSCS1C	
	Target 0 ECC error detection	INTS.ECSCS0	INTE.ECSCS0E	INTC.ECSCS0C	
	Target 1 DS timeout	INTS.DSTOCS1	INTE.DSTOCS1E	INTC.DSTOCS1C	
	Target 0 DS timeout	INTS.DSTOCS0	INTE.DSTOCS0E	INTC.DSTOCS0C	
	Periodic transaction timeout	INTS.PERTO	INTE.PERTOE	INTC.PERTOC	

Note 1. The interrupts from the XSPI target are each logically ORed and output to the interrupt controller (ICU).

48.3.1.7 Operation Flows

(1) Initial Configuration Flow

Figure 48.22 shows the initial configuration flow.

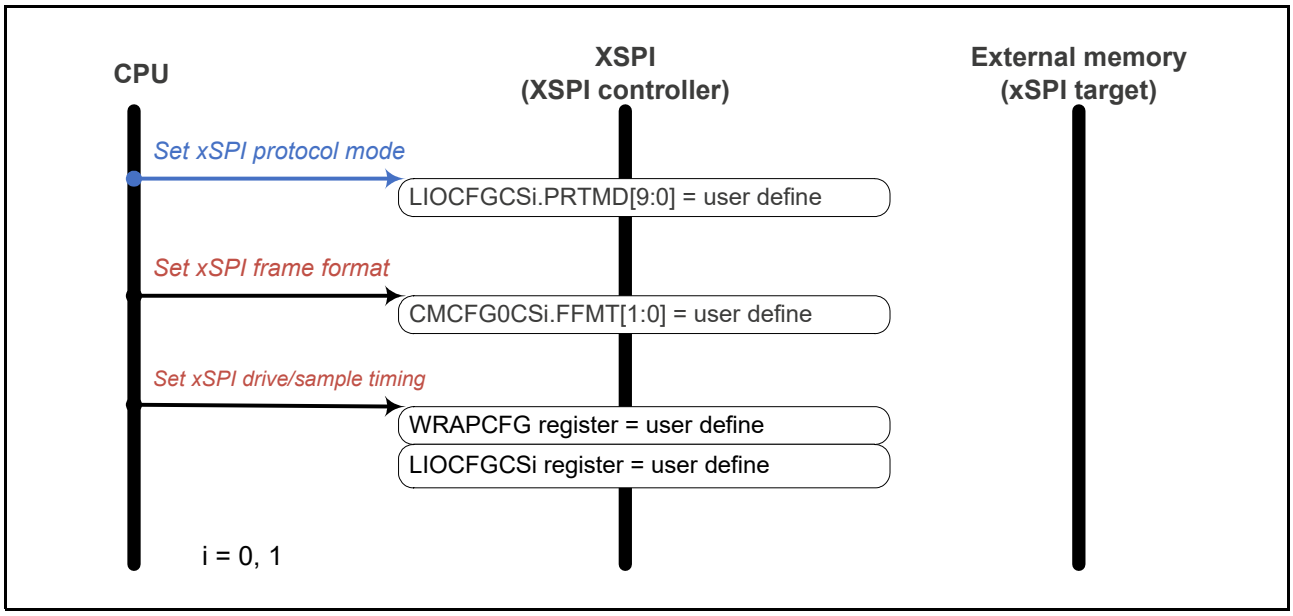

Figure 48.22 Initial Configuration Flow

(2) Communication Stop Flow

Figure 48.23 shows communication stop flow.

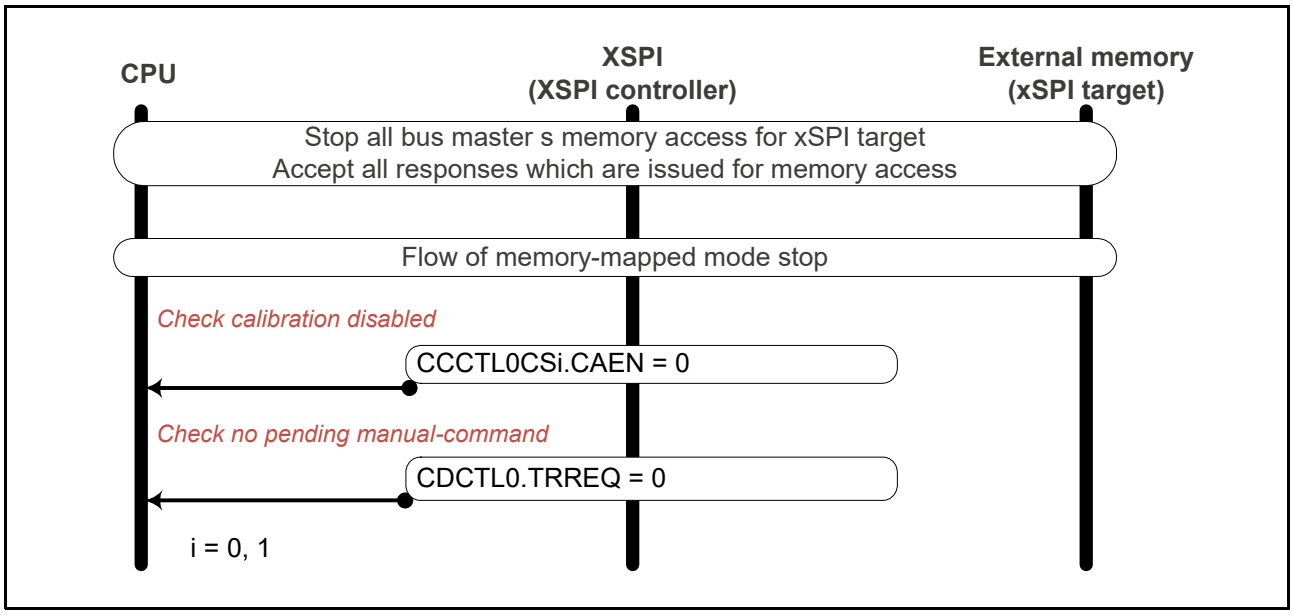

Figure 48.23 Communication Stop Flow

Note: When reconfiguring any of the configuration registers, all communication with the xSPI target must be stopped to avoid conflicts between register settings and memory accesses. This means automatic calibration is disabled, there are no pending commands in indirect access mode, and there are no accesses in memory-mapped mode.

(3) Automatic Calibration Flow

Figure 48.24 shows automatic calibration flow.

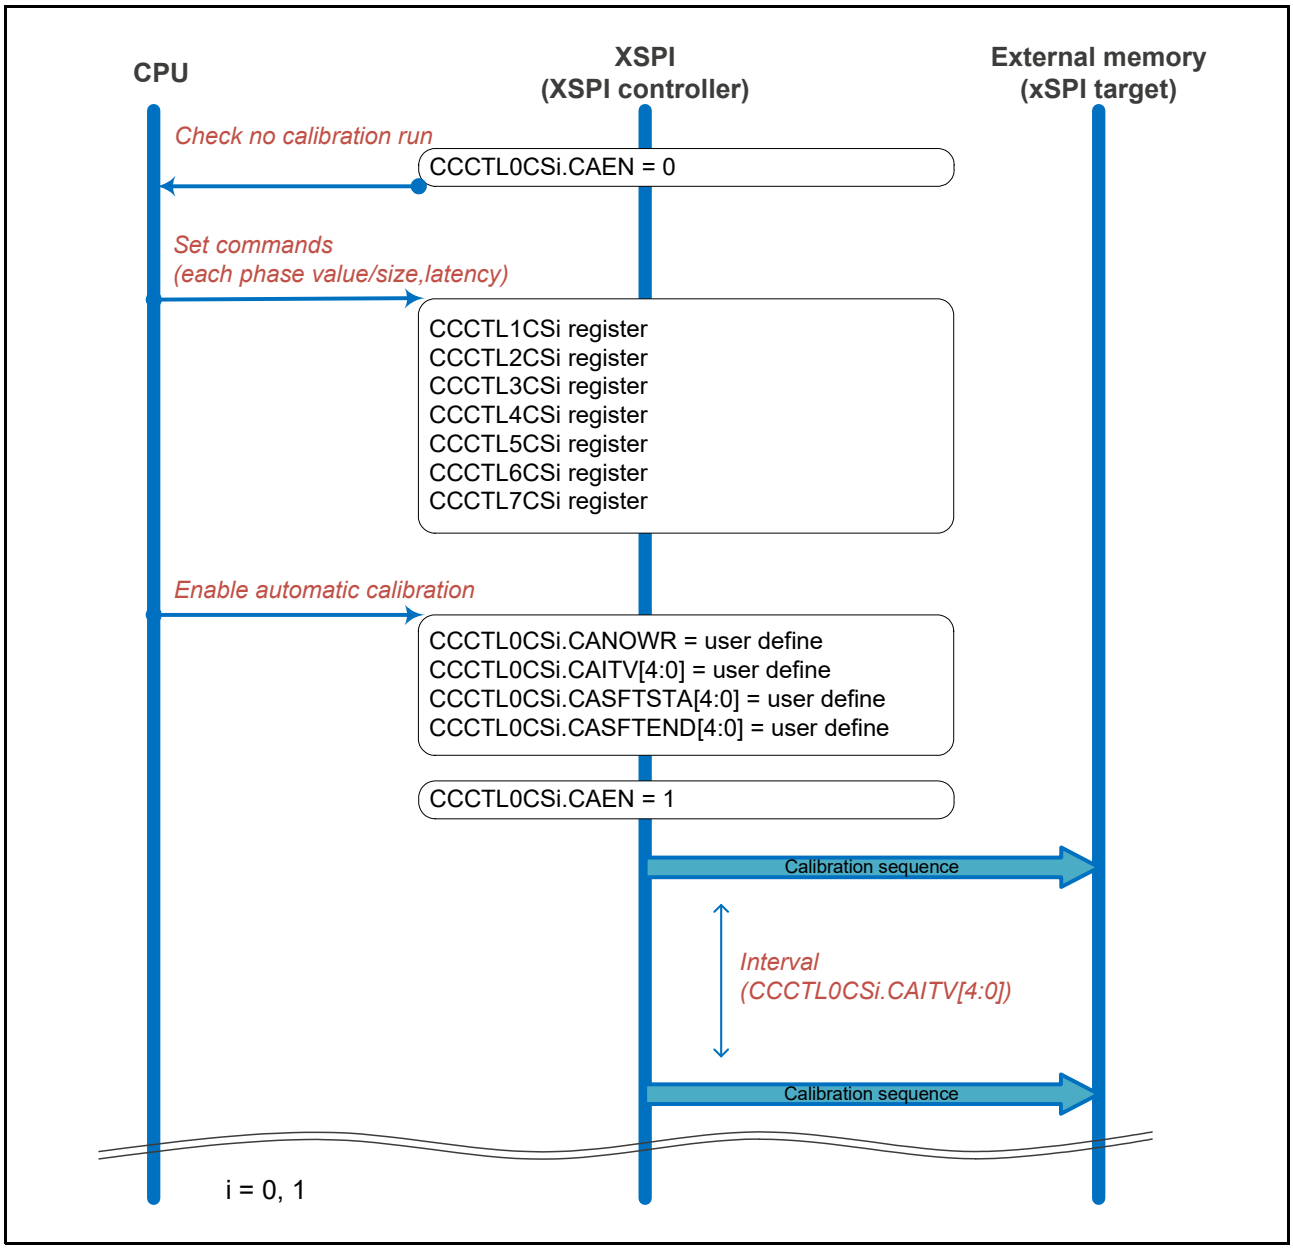

Figure 48.24 Automatic Calibration Flow

(4) Command Issuance Flow in Indirect Access Mode

Figure 48.25 shows the flow of command issuance procedure in sequential mode.

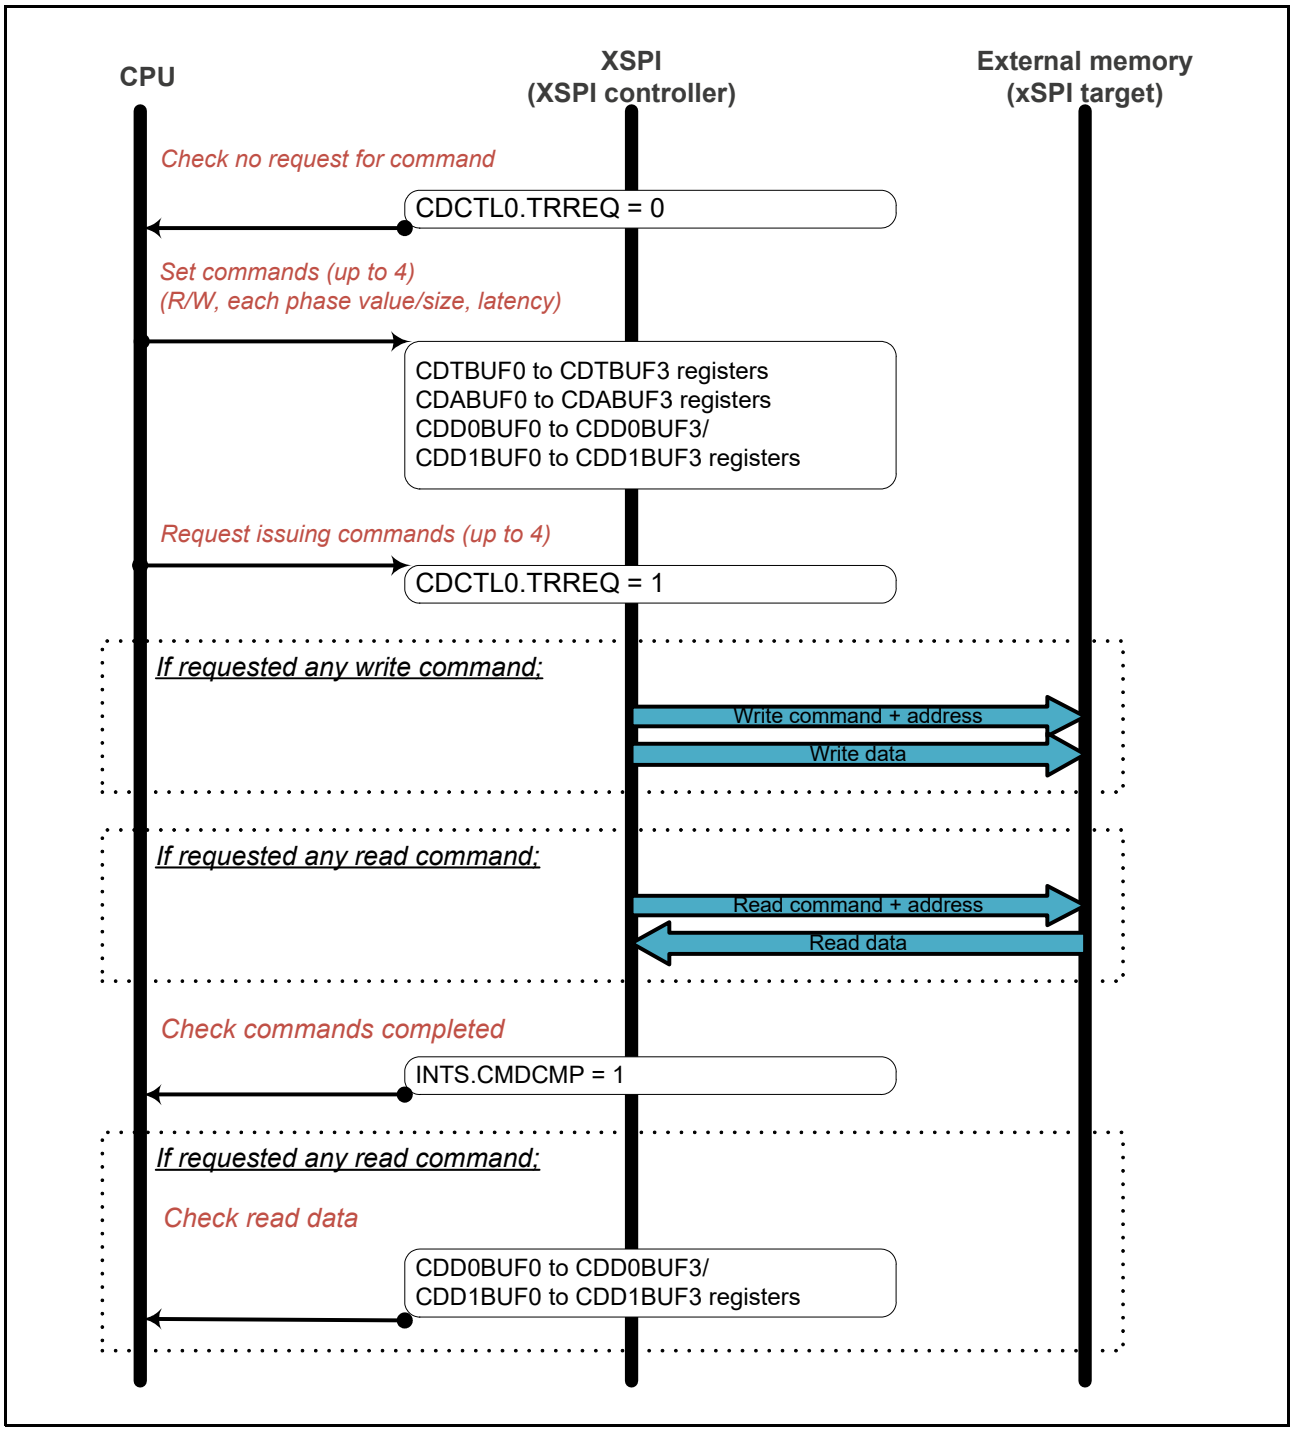

Figure 48.25 Command Issuance Procedure in Indirect Access Mode (Sequential Mode)

Figure 48.26 shows the flow of command issuance procedure in periodic mode.

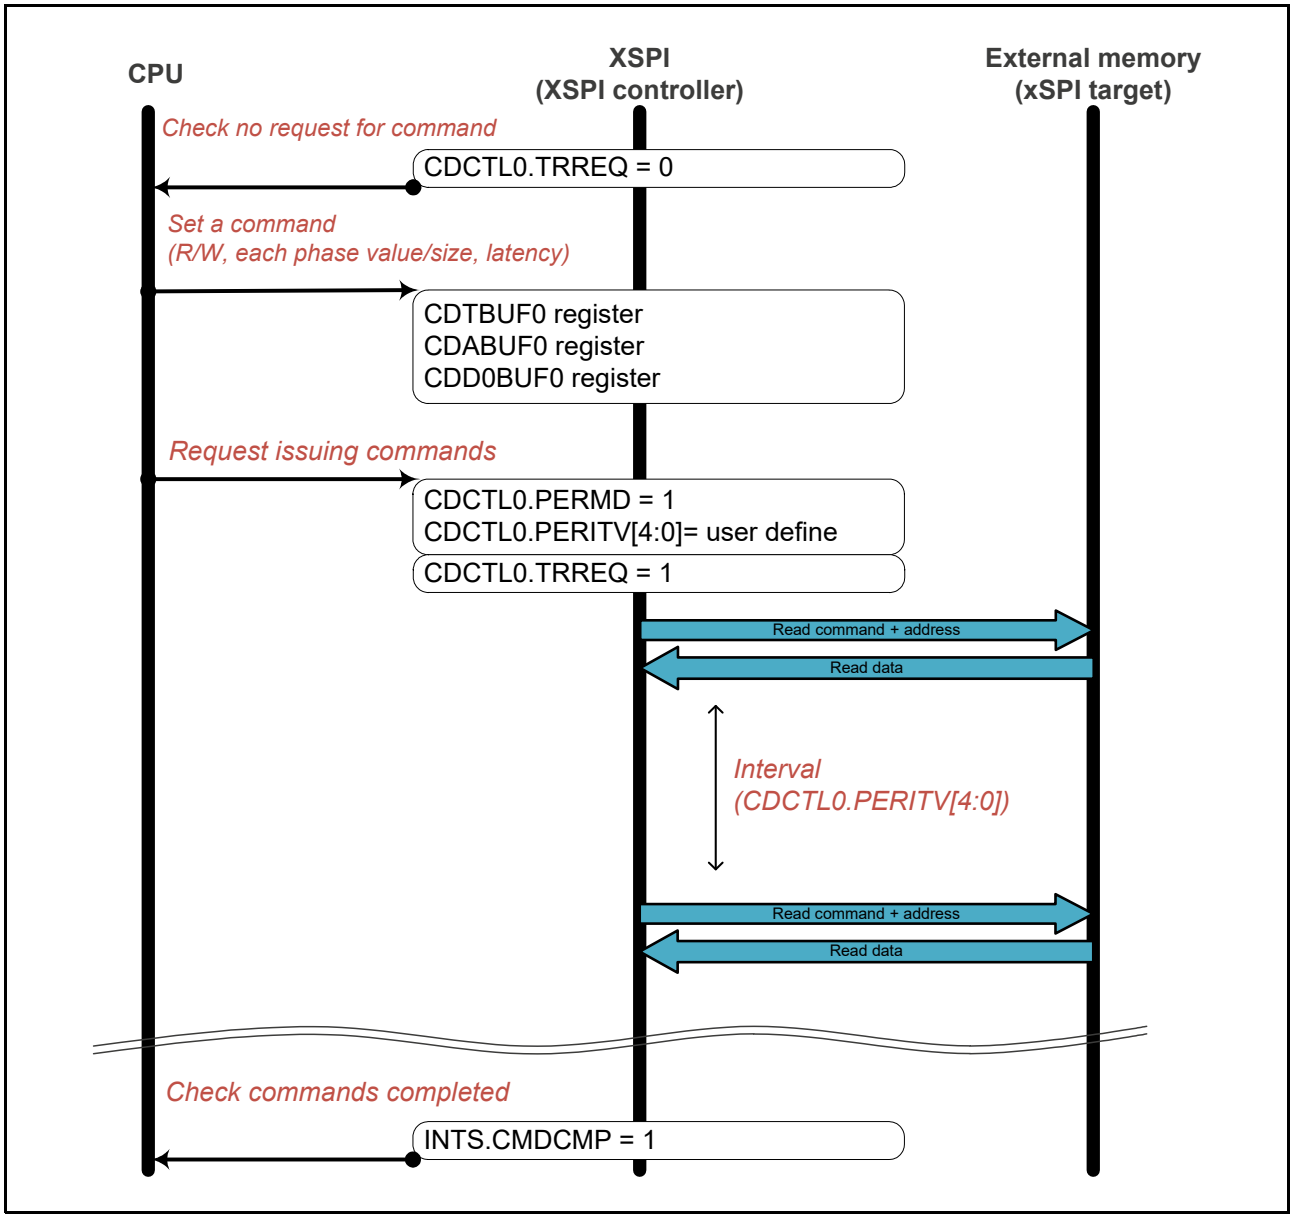

Figure 48.26 Command Issuance Procedure in Indirect Access Mode (Periodic Mode)

(5) Execution Flow in Memory-Mapped Mode

Figure 48.27 shows the execution flow in memory-mapped mode.

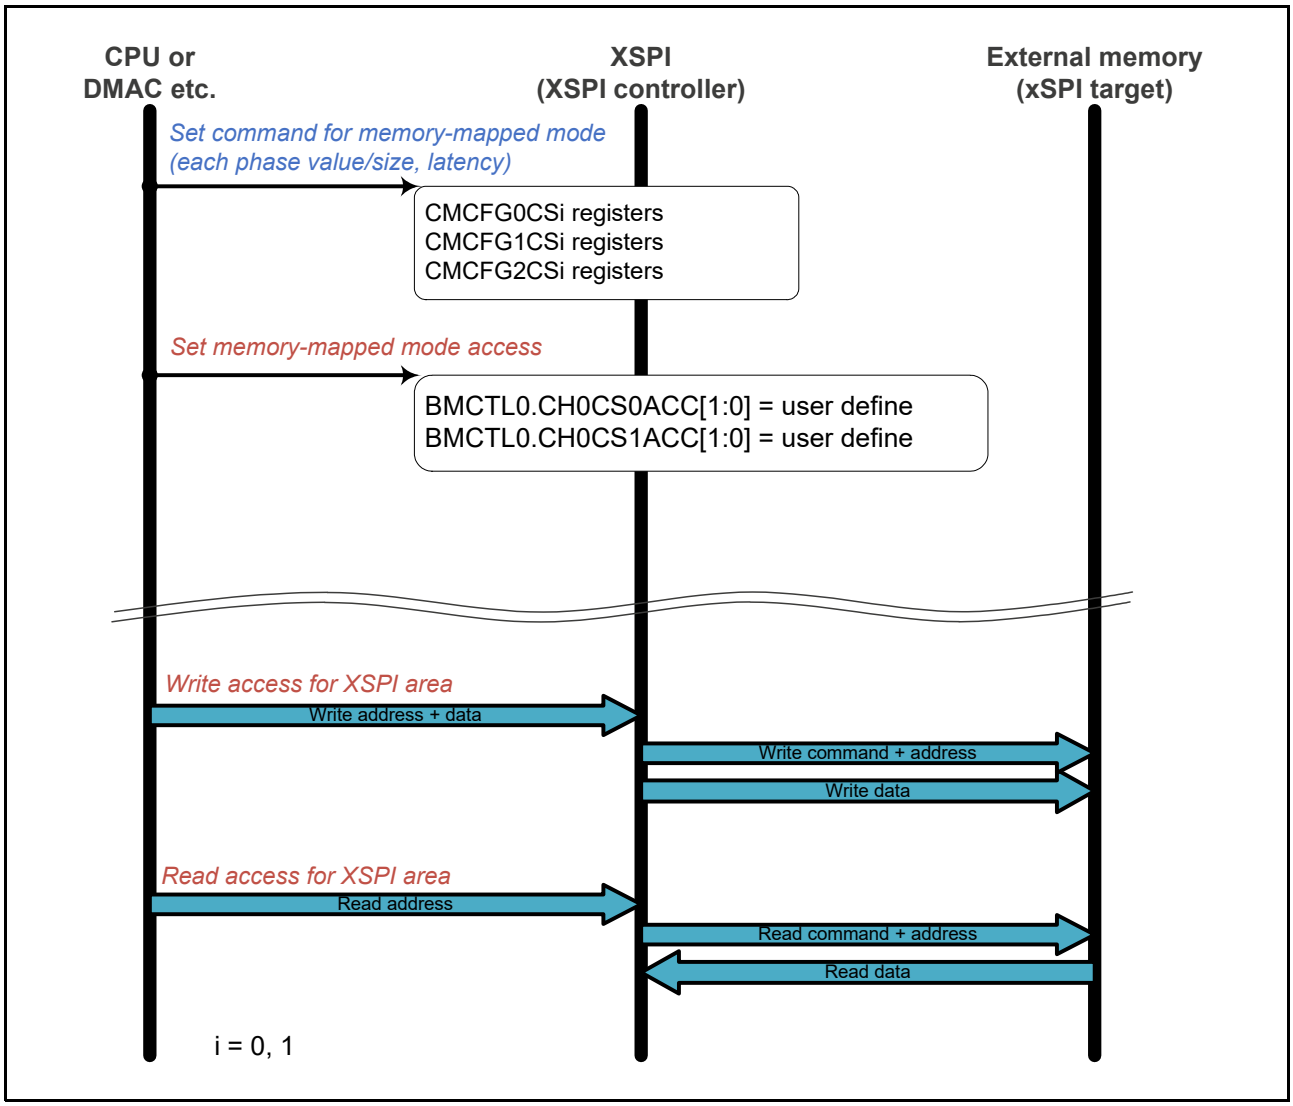

Figure 48.27 Memory-Mapped Mode Execution Flow

(6) Stop Flow for Memory-Mapped Mode

Figure 48.28 shows the stop flow for memory-mapped mode.

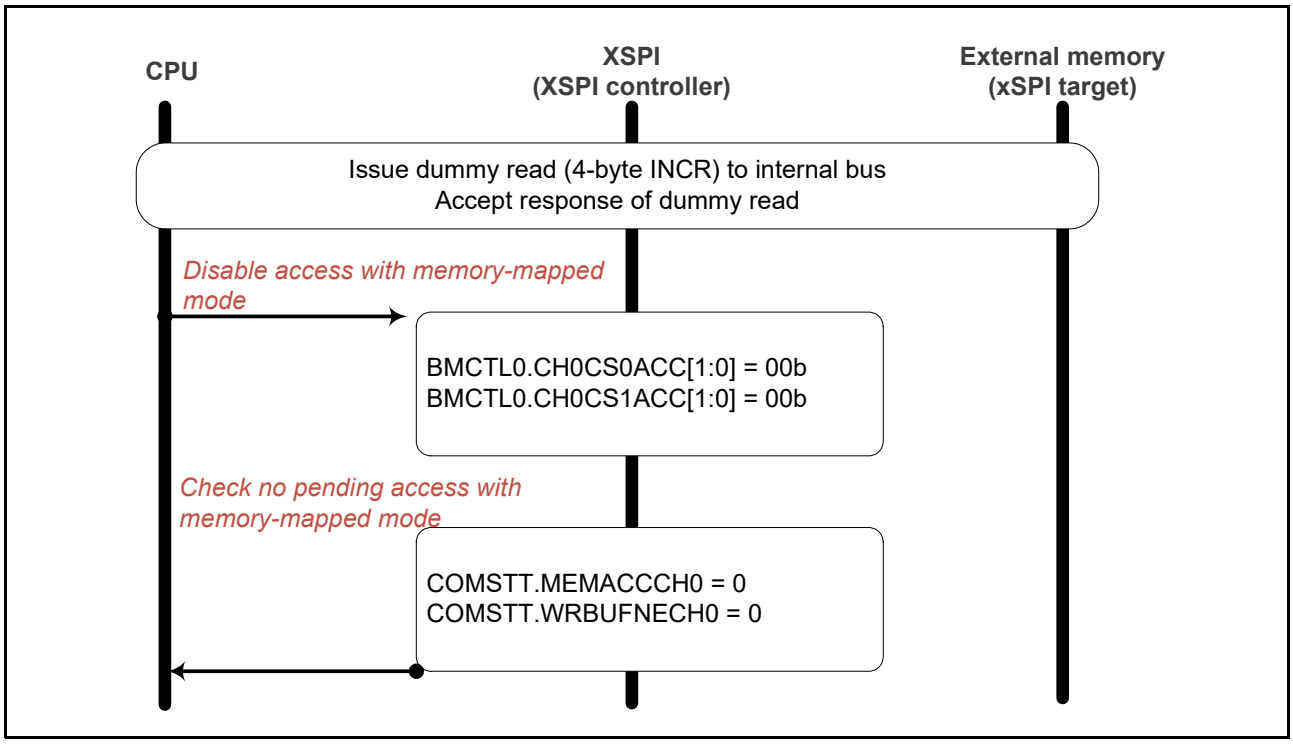

Figure 48.28 Memory-Mapped Mode Stop Flow

(7) Signal Pattern Generation Request Flow

Figure 48.29 shows the flow for requesting signal pattern generation. Before requesting a pattern, complete or cancel any commands that are being executed.

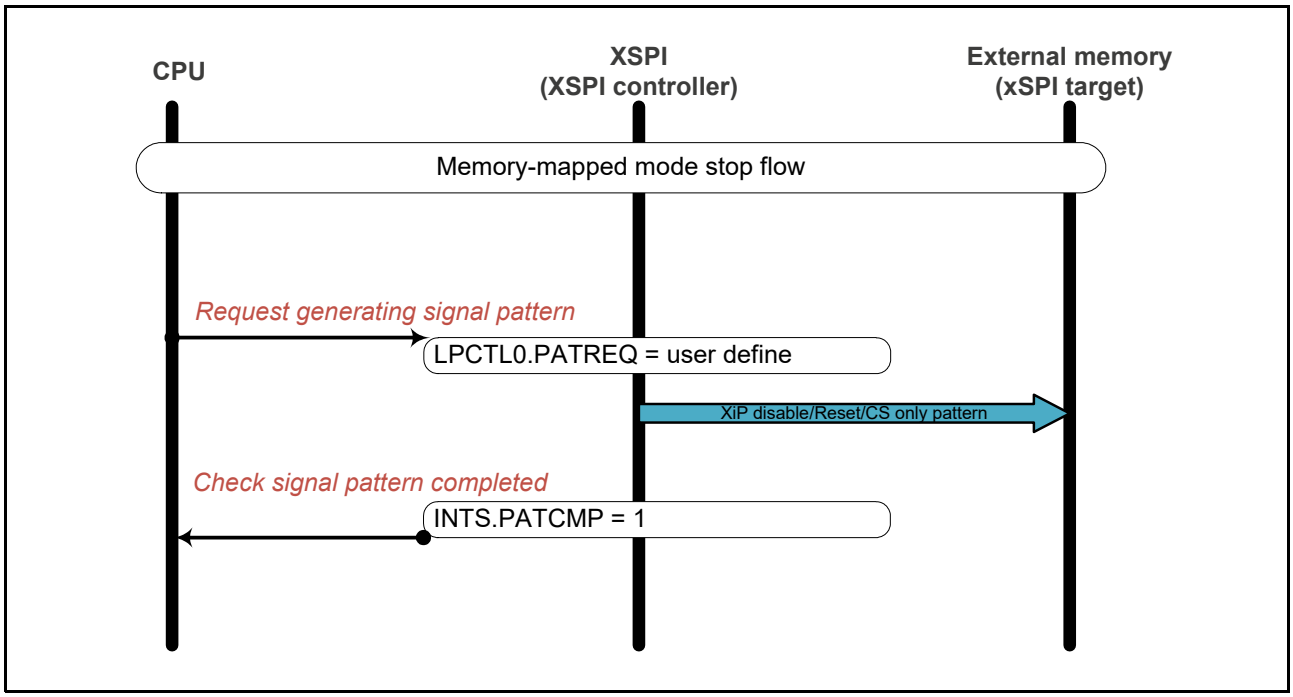

Figure 48.29 Signal Pattern Generation Request Flow

(8) XIP Mode Enable/Disable Flow

Figure 48.30 shows the flow to enable/disable XIP mode.

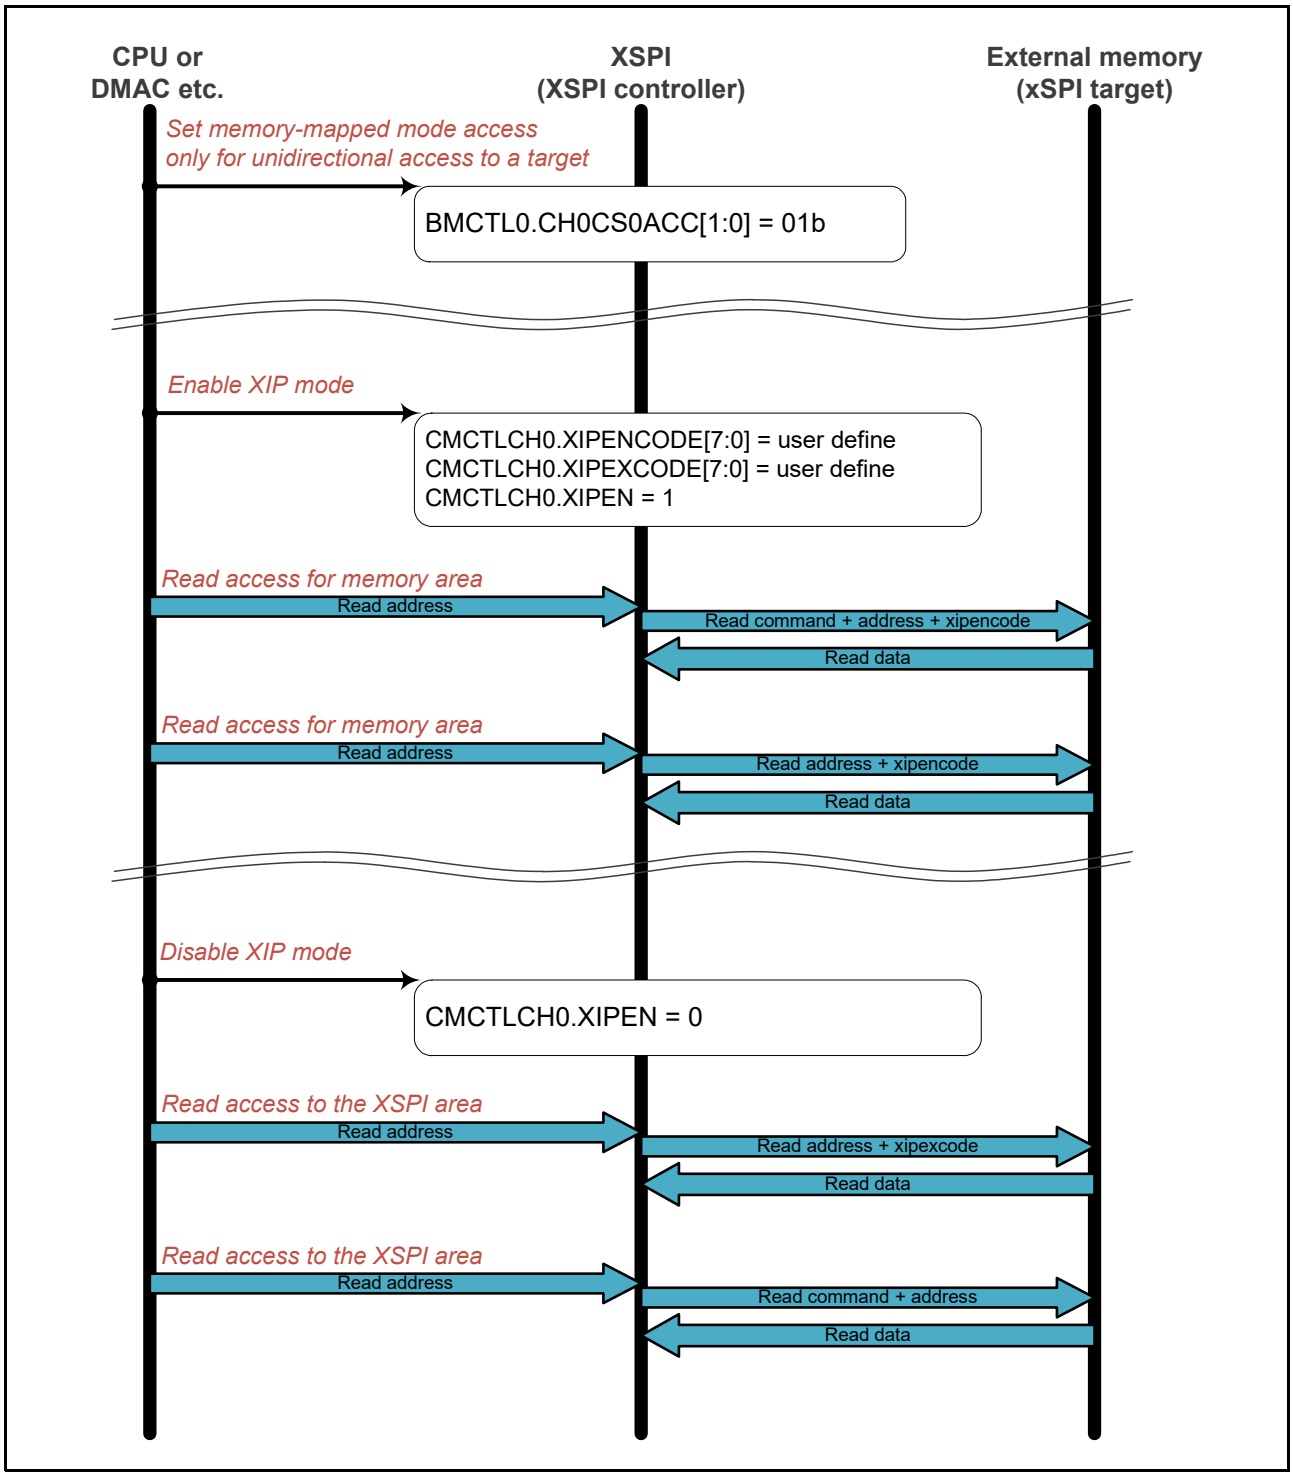

Figure 48.30 XIP Mode Enable/Disable Flow

(9) XSPI Module Stop Flow

Figure 48.31 shows the stop flow of the XSPI module.

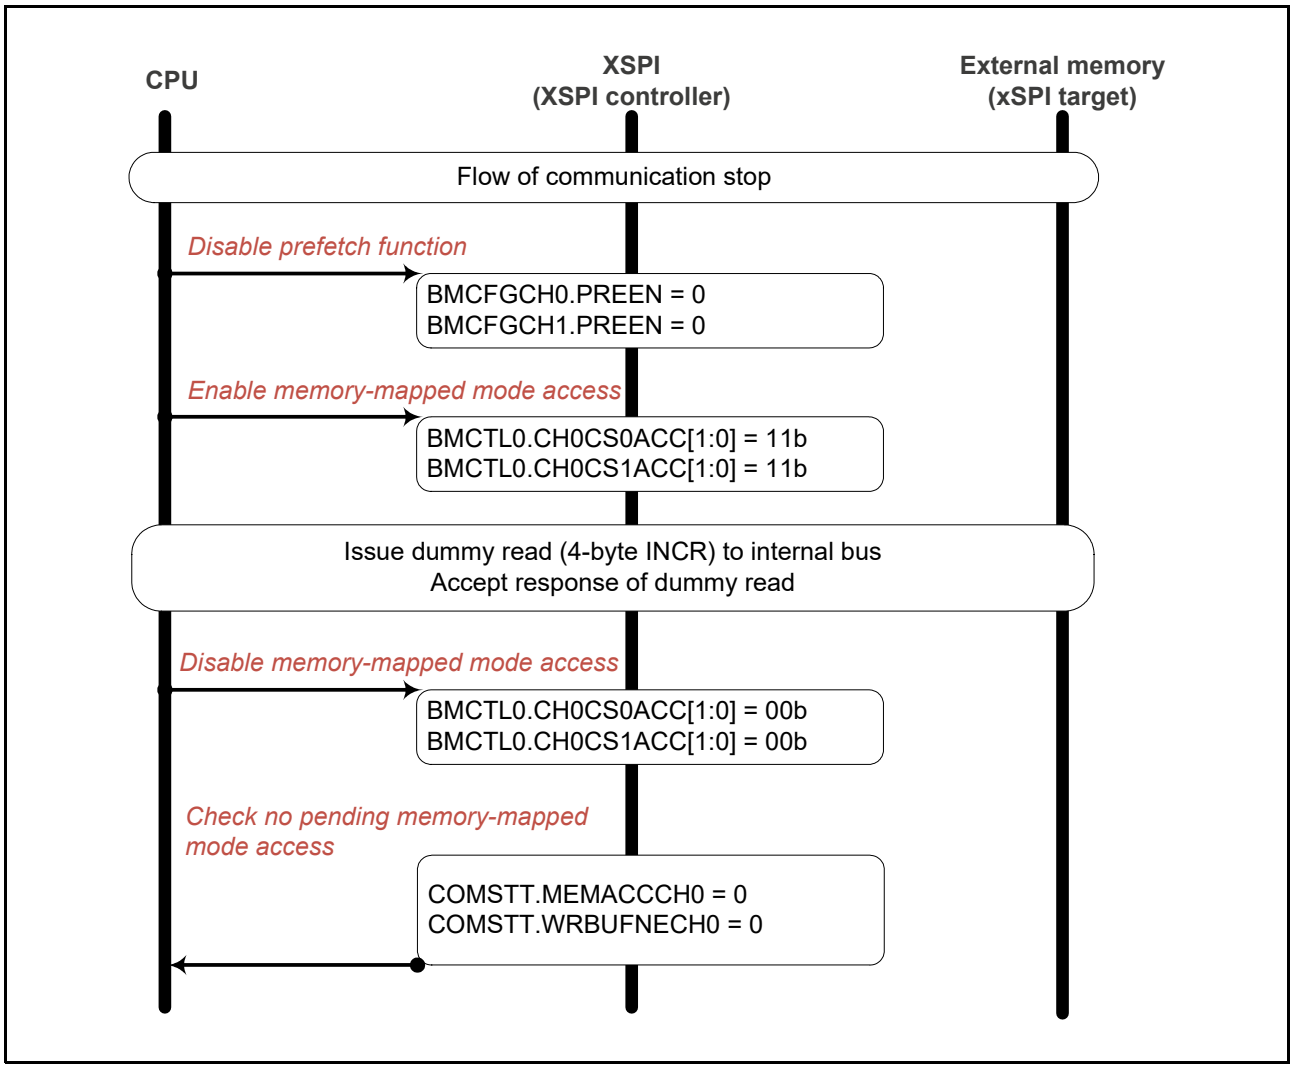

Figure 48.31 XSPI Module Stop Flow

48.3.2 XSPI Target Module

The XSPI target converts write/read accesses from the xSPI controller into write/read accesses to the internal bus. The xSPI controller must set the transfer address and transfer size in the registers of the XSPI target. The xSPI controller can then perform the intended data transfer.
The XSPI target operates in 8D-8D-8D protocol mode after reset is released. The xSPI controller can specify other protocol modes (1S-1S-1S or 4S-4D-4D) by register settings.
This section describes register access, memory write/read transfers, and protocol mode change.

48.3.2.1 XSPI Target Configuration

To enable the XSPI target function, set the DIPCFG.SLVEN bit to 1. After enabling the target function, access to the XSPI area and the registers of the XSPI controller is prohibited. Accessing these areas after setting the target mode will cause the XSPI operation to become undefined.

48.3.2.2 Register Access

The xSPI controller can access all registers of the XSPI target described in section 48.2.3, Target Mode Registers using the xSPI register write/read commands.
The register write command is defined by the L2CFG1.WRRCMD[7:0] bits, and the register read command is defined by the L2CFG1.RDRCMD[7:0] bits. The default frame format is 8D-8D-8D Profile 2.0 (specified by the L15CFG0.PRTMD[9:0] bits and L15CFG1.ADDSIZE[1:0], FFMT[1:0] bits). The register access size is 4 bytes only; other access sizes are prohibited.

Note: From this point on, register writes from the xSPI controller will be denoted as RegWrite(RegName, Value), and register reads as Value = RegRead(RegName). RegName can be L15CFG0, L15CFG1, L15CFG2, L2CFG0, L2CFG1, TWADR, TWLEN, TWCNT, TRADR, TRLEN, TRCNT, TRNSC, TWBS, TWTS, TRBS, TRTS, TS, TSC, TSS, TSXIE, TSSIE, or TBI. Value is the write or read value.

48.3.2.3 Memory Access

(1) Memory Map Configuration

Before initiating memory access from the xSPI controller, it is necessary to configure the address space of the XSPI target.
The xSPI controller must issue xSPI frames targeting the address space configured in the L2CFG0 register. Additionally, the maximum write frame size and maximum read frame size must be set to the MWRFSIZE[10:0] bits and MRDFSIZE[10:0] bits in the L15CFG2 register, respectively.
When accessing the XSPI target, the xSPI controller must ensure a minimum interval of 4 cycles between CS and the next CS.

(2) Write Access

The xSPI controller must set the transfer start address and transfer data size in the TWADR and TWLEN registers, respectively. The maximum transfer size is 1 Mbytes. Then, set the TWCNT.WEN bit to 1 to start the transfer.
Next, the xSPI controller polls the TWBS.VACSIZE[12:0] bits, and when the free space in the write buffer reaches or exceeds the size specified by the L15CFG2.MWRFSIZE[10:0] bits, it issues a write transaction of the size specified by the MWRFSIZE[10:0] bits. Only the final write frame will be a write transaction with a size equal to or less than the MWRFSIZE[10:0] bits.
The xSPI controller must transfer all write data of the size set in the TWLEN register, even if the TWBS.ERR flag is set to 1.
Figure 48.32 shows the memory write transfer from xSPI controller.

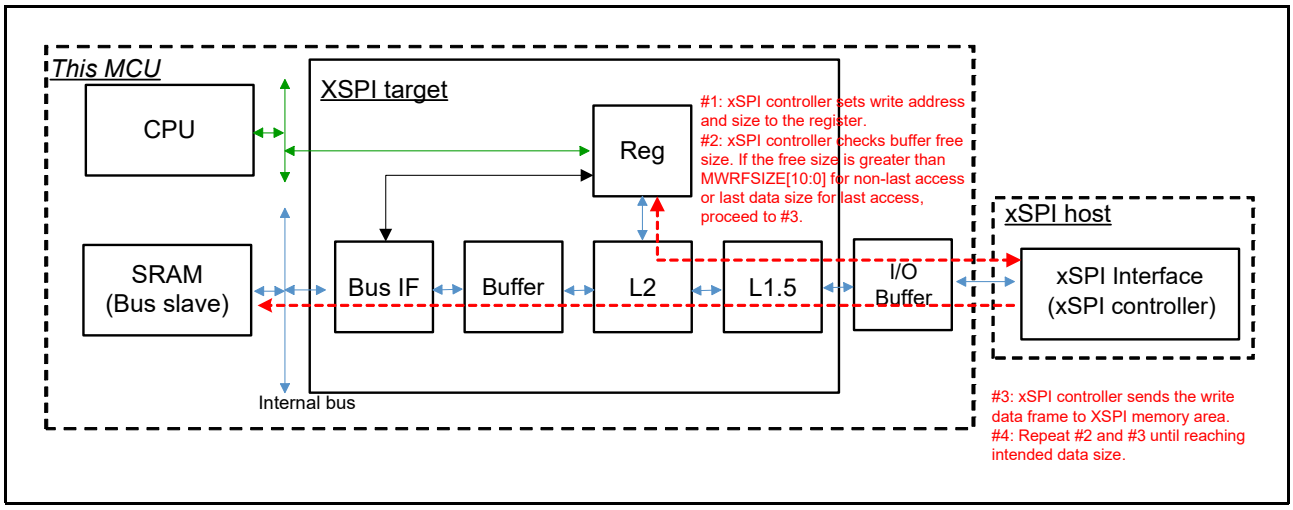

Figure 48.32 Memory Write Transfer from xSPI Controller

Figure 48.33 shows the flow of a write transfer as seen from the xSPI controller. The variables and functions used in the figure are defined as follows.

ValTargetWriteAddress: Write address in system memory of the XSPI target.
ValTransferSize: Total size of write data.
ValWrSize: Write size per frame.
ValVac: Variable to hold the read value of the TWBS register.
MemWrite: A function that issues a write transaction, with address, data size, and write data as arguments.
ValWrAdr: Address of the write frame. This value must be less than or equal to the value in the L2CFG0 register.
WriteData: Write data. This size must be less than or equal to ValVac.
ValTs: Variable to hold the read value of the TS register.

Note: Write access from the xSPI controller must be performed consecutively using frames with the data size specified by the L15CFG2.MWRFSIZE[10:0] bits. The XSPI target writes the received data sequentially starting from the address specified in the TWADR register, regardless of the address specified in the received frame. The XSPI target cannot rewind the address and rewrite data.

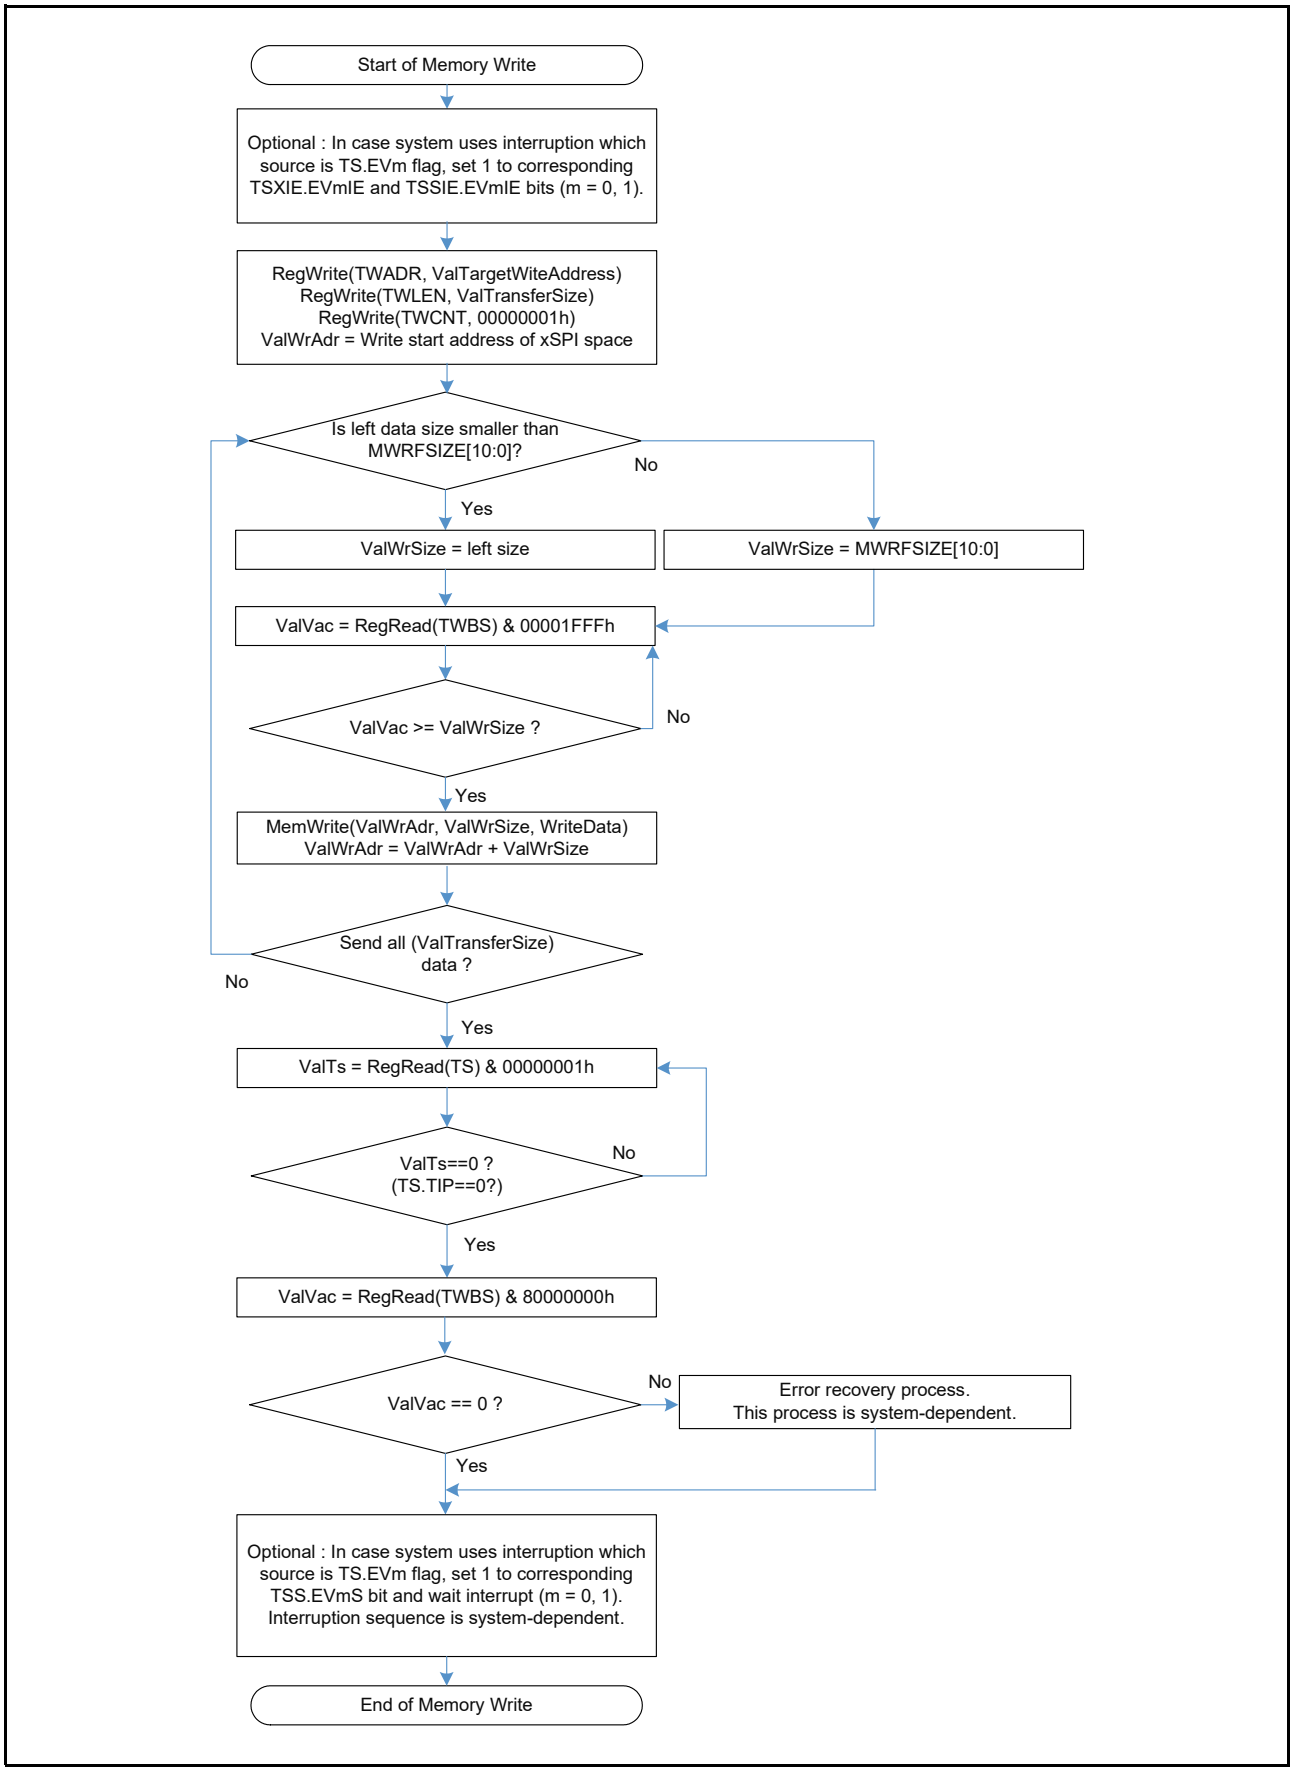

Figure 48.33 Memory Write Transfer Flow as Seen from xSPI Controller

(3) Read Access

The xSPI controller must set the transfer start address and transfer data size in the TRADR and TRLEN registers, respectively. The maximum transfer size is 1 Mbytes. Then, set the TRCNT.REN bit to 1 to start the transfer.
Next, the xSPI controller polls the TRBS.DATSIZE[12:0] bits, and when data equal to or more than the size specified by the L15CFG2.MRDFSIZE[10:0] bits is stored in the read buffer, it issues a read transaction of the size specified by the MRDFSIZE[10:0] bits. Only the final read frame will be a read transaction with a size equal to or less than the MRDFSIZE[10:0] bits (i.e., the size of the DATSIZE[12:0] bits).
The xSPI controller must transfer all data of the size set in the TRLEN register, even if the TRBS.ERR flag is set to 1.
Figure 48.34 shows the memory read transfer from xSPI controller.

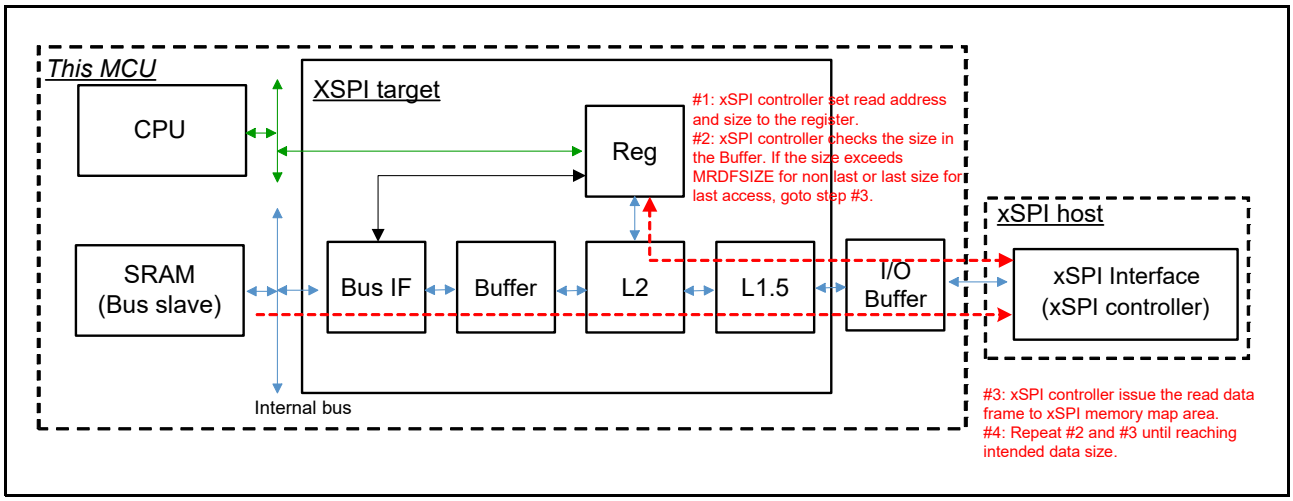

Figure 48.34 Memory Read Transfer from xSPI Controller

Figure 48.35 shows the flow of a read transfer as seen from the xSPI controller. The variables and functions used in the figure are defined as follows.

ValTargetReadAddress: Read address in the system memory of the XSPI target.
ValTransferSize: Total size of read data.
ValRdSize: Read size per frame.
ValDat: Variable to hold the read value of the TRBS register.
MemRead: A function that issues a read transaction, with address, data size, and storage address of read data as arguments.
ValRdAdr: Address of the read frame. This value must be less than or equal to the value in the L2CFG0 register.
&ReadData: Area for storing read data.

Note: Read access from the xSPI controller must be performed consecutively using frames with the data size specified by the L15CFG2.MRDFSIZE[10:0] bits. The XSPI target reads data sequentially starting from the address specified in the TRADR register, regardless of the address specified in the received frame. The XSPI target cannot rewind the address and reread data.

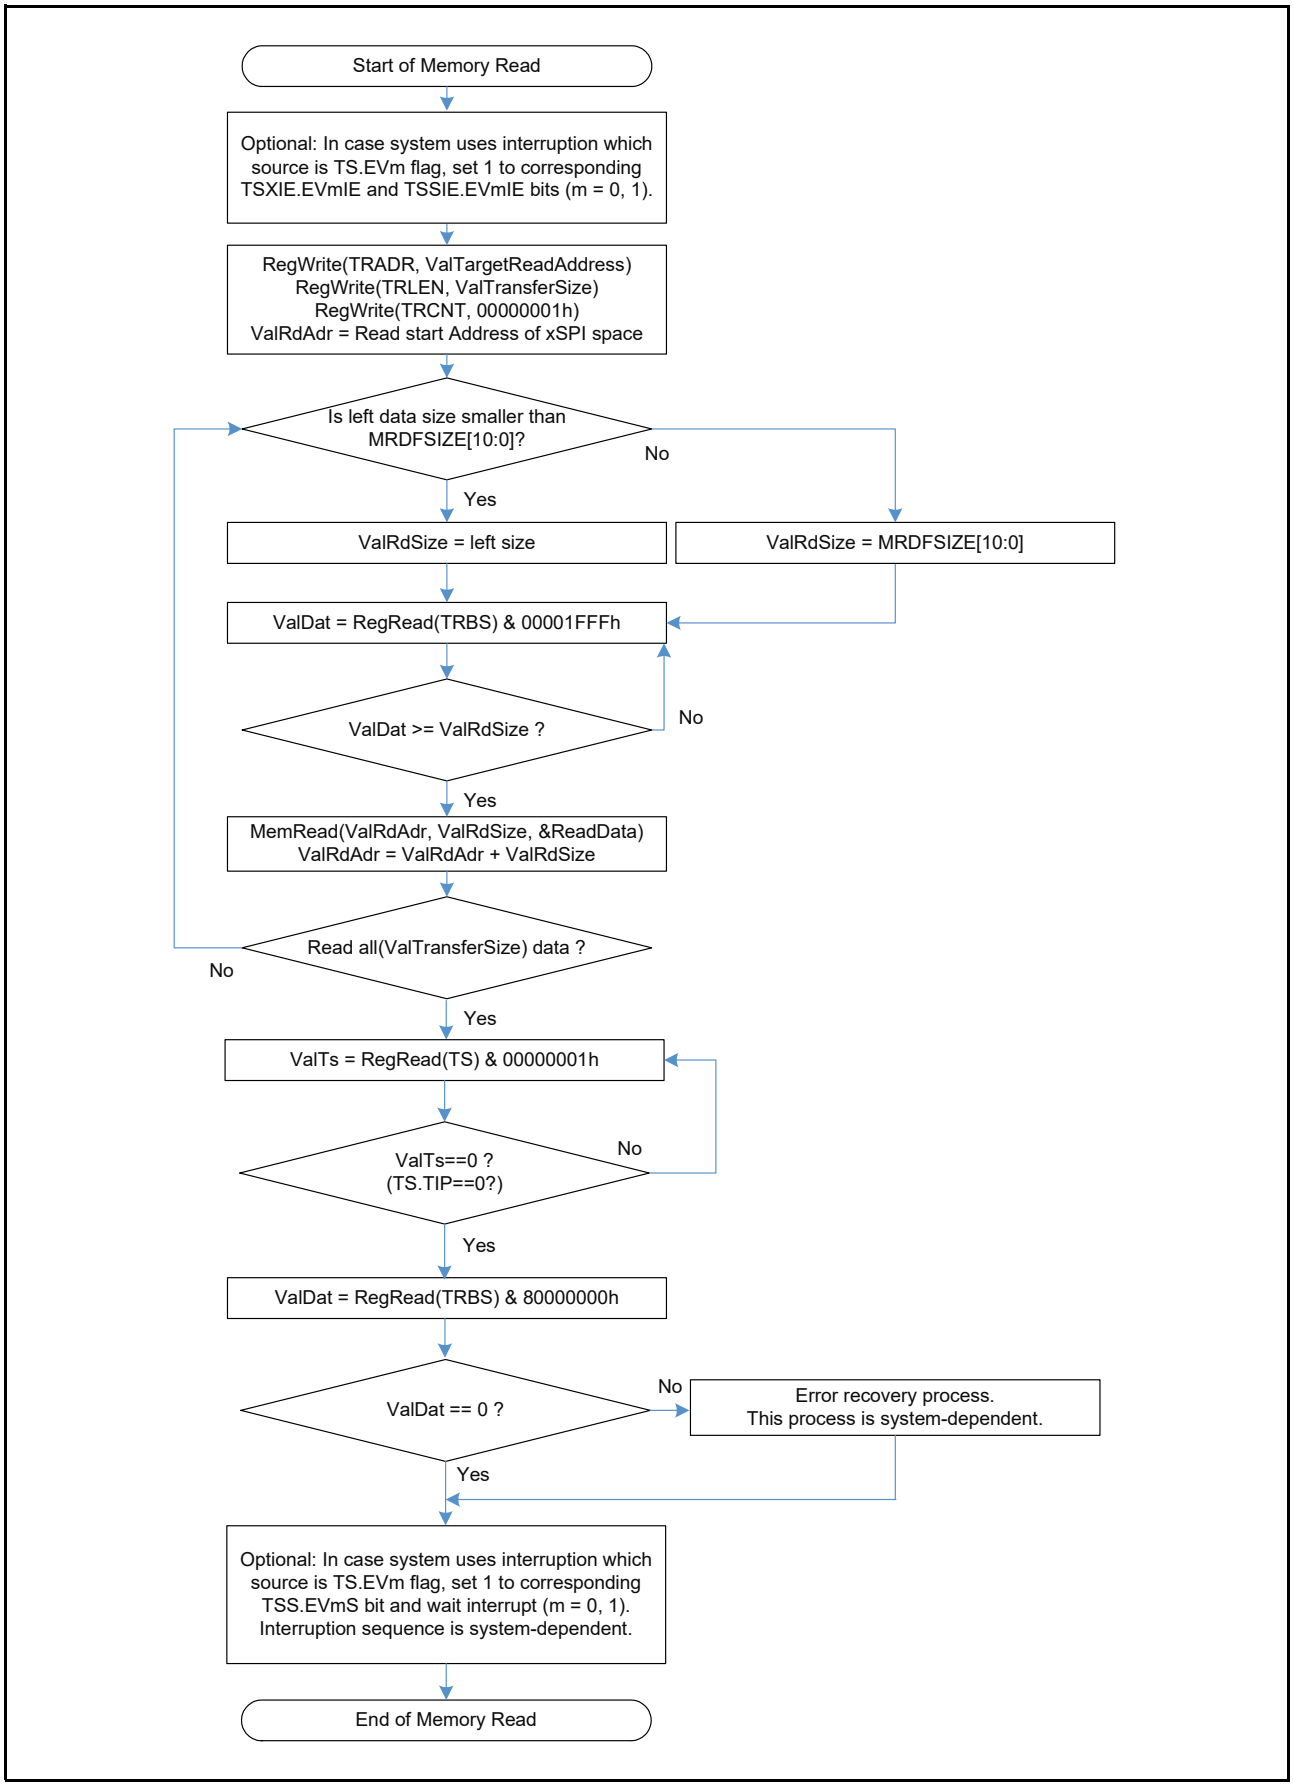

Figure 48.35 Memory Read Transfer Flow as seen from xSPI Controller

48.3.2.4 Changing IO Protocol Mode

Parameters related to the IO protocol mode of the XSPI target (such as protocol mode, address size, frame format, latency, etc.) can be changed. Before changing the IO protocol mode, the xSPI controller must ensure that no transfers are currently in progress.

Figure 48.36 shows the flow for changing these parameters. After sending the xSPI frame corresponding to the RegWrite(L15CFG1, ValL15CFG1Setting) in the flow below, the IO protocol for subsequent xSPI frames must follow the new settings. The definitions of the variables in the figure are as follows.

ValL15CFG0Setting: Setting value for the L15CFG0 register (user-defined)

ValL15CFG1Setting: Setting value for the L15CFG1 register (user-defined)

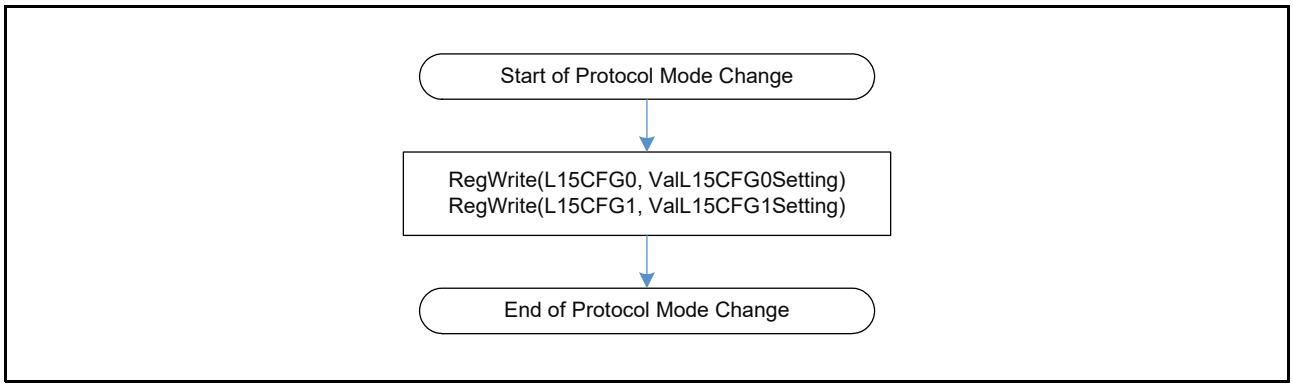

Figure 48.36 IO Protocol Mode Change Flow from xSPI Controller

48.3.2.5 xSPI Reset

The XSPI target has xSPI reset pins corresponding to the RESET# and RSTO# signals defined in the xSPI standard. The XSPI target has a reset information propagation mechanism shown in Figure 48.37.

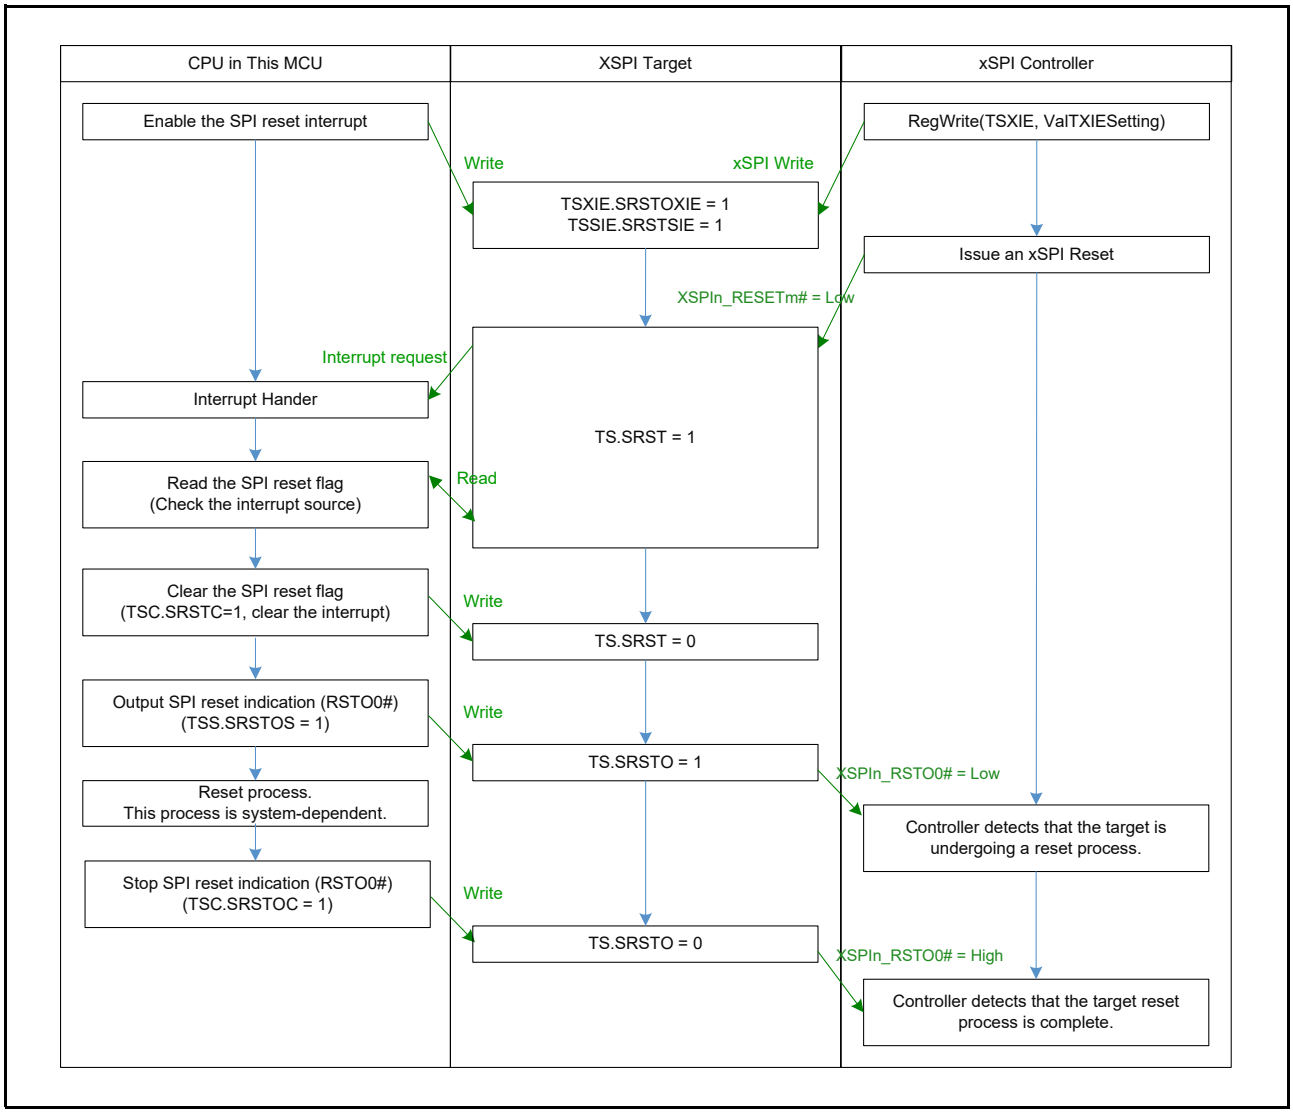

Figure 48.37 XSPI Target Reset Flow

48.3.2.6 Error Detection

The xSPI target can detect the errors shown in Table 48.15.

Table 48.15 Error List

Name	Error Source	Detection Flag	Remarks
Internal bus error	An error occurred on the internal bus when the XSPI target accessed an internal resource of this MCU.	TS.SBERR	Fatal error. This IP needs reset for recovery after this error.
Maximum frame size exceeded	The xSPI controller issued a transaction with a data size exceeding 4 bytes when accessing a register, or issued a transaction with a data size exceeding the size specified in the L15CFG2 register when accessing memory.	TS.MFSEERR	
Unknown command error	The command code in the transaction issued by the xSPI controller was undefined, or the xSPI controller issued an unauthorized transaction, or there was an error in the command extension.	TS.UNKCERR	
Buffer overflow	The xSPI controller issued a write transaction with a data size that exceeds the free space in the write buffer.	TS.BOVFERR	
Buffer underflow	The xSPI controller issued a read transaction with a data size that exceeds the data stored in the read buffer.	TS.BUDFERR	

48.3.2.7 Interrupt Sources

The XSPI target has two types of interrupts: internal bus interrupt that is notified to the CPU, and xSPI interrupt that is notified to the xSPI controller. The internal bus interrupt include the CMP interrupt and ERR interrupt, as shown in Table 48.16, and the xSPI interrupt has eight types of interrupt sources, as shown in Table 48.17.
Each interrupt can be monitored using the TS register, and the enable/disable setting can be changed using the TSSIE register (internal bus interrupt) or TSXIE register (xSPI interrupt).

Table 48.16 Internal Bus Interrupt Sources for XSPI Target

Name	Interrupt Source	Interrupt Flag	Interrupt Enable Bit	Interrupt Clear Bit	DTC/DMAC Triggerable
CMP*1	Event 0 detection	TS.EV0	TSSIE.EV0SIE	TSC.EV0C	No
	Event 1 detection	TS.EV1	TSSIE.EV1SIE	TSC.EV1C	
	SPI reset detection	TS.SRST	TSSIE.SRSTSIE	TSC.SRSTC	
	Transfer complete	TS.TCMP	TSSIE.TCMPSIE	TSC.TCMPC	
ERR*1	Internal bus error	TS.SBERR	TSSIE.SBERRSIE	TSC.SBERRC	No
	Maximum frame size exceeded	TS.MFSEERR	TSSIE.MFSEERRSIE	TSC.MFSEERRC	
	Unknown command error	TS.UNKCERR	TSSIE.UNKCERRSIE	TSC.UNKCERRC	
	Buffer underflow	TS.BUDFERR	TSSIE.BUDFERRSIE	TSC.BUDFERRC	
	Buffer overflow	TS.BOVFERR	TSSIE.BOVFERRSIE	TSC.BOVFERRC	

Note 1. The interrupts from the XSPI controller are each logically ORed and output to the interrupt controller (ICU).

Table 48.17 xSPI Interrupt Sources for XSPI Target (n = 0, 1)

Pin	Interrupt Source	Interrupt Flag	Interrupt Enable Bit	Interrupt Clear Bit
XSPIn_INT0#	Event 0 detection	TS.EV0	TSXIE.EV0XIE	TSC.EV0C
	Event 1 detection	TS.EV1	TSXIE.EV1XIE	TSC.EV1C
	Transfer complete	TS.TCMP	TSXIE.TCMPXIE	TSC.TCMPC
	Internal bus error	TS.SBERR	TSXIE.SBERRXIE	TSC.SBERRC
	Maximum frame size exceeded	TS.MFSEERR	TSXIE.MFSEERRXIE	TSC.MFSEERRC
	Unknown command error	TS.UNKCERR	TSXIE.UNKCERRXIE	TSC.UNKCERRC
	Buffer underflow	TS.BUDFERR	TSXIE.BUDFERRXIE	TSC.BUDFERRC
	Buffer overflow	TS.BOVFERR	TSXIE.BOVFERRXIE	TSC.BOVFERRC

48.4 Usage Notes

48.4.1 Settings of the Module Stop Function

XSPI operation can be disabled or enabled by the module stop control register B (MSTPCRB). After a reset, the operation of the XSPI is stopped. The registers become accessible when it is released from the module stop state. For details, refer to section 11, Low Power Consumption.

48.4.2 Notes on the XSPI Controller

48.4.2.1 Software Standby Mode

To transition to software standby mode, stop communication according to the communication stop flow and then stop the XSPI module according to the module stop flow.
Place the programs before and after the transition to software standby mode and the interrupt processing program used to return from software standby mode in the memory in this MCU, not on the xSPI target.
After returning from software standby mode, enable the settings that were disabled before transitioning to software standby mode, and if using automatic calibration, perform calibration before accessing the xSPI target.

48.4.2.2 Restrictions Regarding the Prefetch Function

When the prefetch function is enabled, do not access the last 128 bytes of the memory device. Accessing this area will issue transactions to addresses that do not exist on the memory device.

48.4.2.3 Note on the Prefetch Function

If all of the following conditions are met, prefetching does not proceed even if the prefetch function is enabled.

- Instruction caching is enabled and the XSPI area is subject to instruction caching, or data caching is enabled and the XSPI area is subject to data caching.
- Access by the CPU is to an XSPI area outside the decryption area for use with the DOTF unit.

48.4.2.4 Note on Using Special Memory Devices

In 8D-8D-8D protocol mode, the XSPI controller writes to and reads from memory in the order Data 0 – Data 1 – Data 2 – Data 3 –…. However, some memory devices input or output data in the order Data 1 – Data 0 – Data 3 – Data 2 –….
When reading data, which were written other than in 8D-8D-8D protocol mode, from such a device, in 8D-8D-8D protocol mode, change the order of writing the data to the device so that they are to be read in the order Data 0 – Data 1 – Data 2 – Data 3 –….

48.4.3 Notes on the XSPI Target

48.4.3.1 Software Standby Mode

When transitioning to software standby mode, ensure all operations on the XSPI target have stopped. Then, set the TRNSC.RSMSTB bit to 1 to stop communication functions.
After resuming from software standby mode, set the TRNSC.RSMSTB bit to 0.

48.4.3.2 Endian Setting

Regardless of the CPU's endian setting, the XSPI target is fixed to little endian. If the CPU is big endian, the xSPI controller must issue transactions with data sizes that are multiples of 4, starting from addresses that are multiples of 4.

49. Decryption On The Fly (DOTF)

49.1 Overview

This MCU has two units of on-the-fly decryption circuits (DOTF0, DOTF1) built into the expanded serial peripheral interfaces (XSPI0, XSPI1).
DOTF can decrypt data read by XSPI in memory-mapped mode at high speed using the AES core.
Table 49.1 lists the specifications of the DOTF.

Table 49.1 DOTF Specifications

Item	Description
Number of units	1 unit for each XSPI*1, total 2 units
Operating clock	Register clock: PCLKB AES core clock: ICLK
AES core function	• Utilize for on-the-fly decryption of encrypted software stored in external memory • Block size: 128 bits • Key sizes: 128, 192, or 256 bits • Block cipher mode of operation CTR: Compliant with NIST SP800-38A • Supports side-channel attack countermeasures • Supports self-test function
Tamper Resistance	Countermeasures against side-channel attacks, including SPA/DPA and timing attacks, are available.
Low power consumption	Module stop state can be set for each unit (simultaneously with XSPI)
ProtectZone filter	Security attribute can be set for each unit (same attribute with XSPI)*2

Note 1. For more information on XSPI, refer to section 48, Expanded Serial Peripheral Interface (XSPI).
Note 2. When each unit is set to the secure attribute, registers in the unit are accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When each unit is set to the non-secure attribute, registers in the unit are accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Figure 49.1 shows a block diagram of the DOTF. For a block diagram including XSPI, refer to section 48, Expanded Serial Peripheral Interface (XSPI).

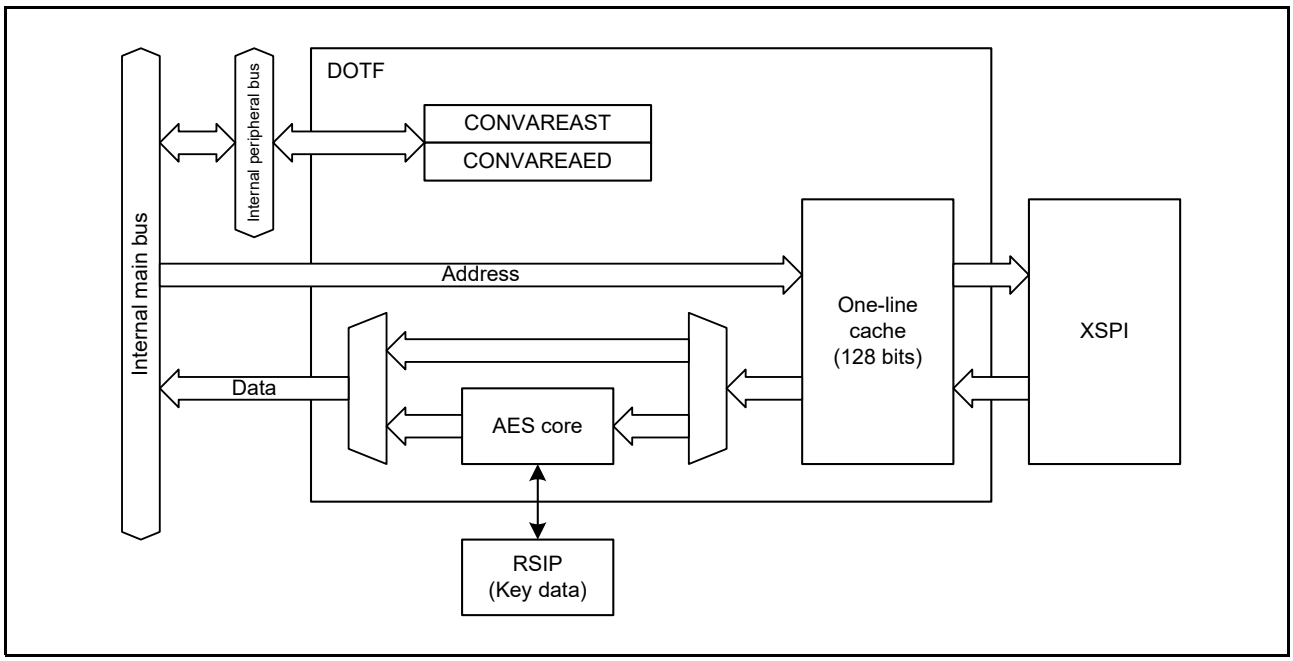

Figure 49.1 DOTF Block Diagram

49.2 Register Descriptions

49.2.1 Decryption Area Start Address Register (CONVAREAST)

Address(es): DOTF0.CONVAREAST 8786 8800h, DOTF1.CONVAREAST 8786 8900h, DOTF0_NS.CONVAREAST 0786 8800h, DOTF1_NS.CONVAREAST 0786 8900h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CONVAREAST register specifies the start address of the decryption area. The lower 12 bits are fixed at 000h. Set this register to a value less than the value of the CONVAREAED register.
Set this register before reading data from the XSPI area and do not change it thereafter.

49.2.2 Decryption Area End Address Register (CONVAREAED)

Address(es): DOTF0.CONVAREAED 8786 8804h, DOTF1.CONVAREAED 8786 8904h, DOTF0_NS.CONVAREAED 0786 8804h, DOTF1_NS.CONVAREAED 0786 8904h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

The CONVAREAED register specifies the end address of the decryption area. The lower 12 bits are fixed at FFFh. Set this register to a value larger than the value of the CONVAREAST register.
Set this register before reading data from the XSPI area and do not change it thereafter.

49.3 Operation

When a bus master such as the CPU or DMAC performs a read access to XSPI in memory-mapped mode, the data read from the xSPI target device is transferred to the bus master via DOTF.
DOTF determines whether decryption is required based on the address issued by the bus master, and if necessary, it decrypts the data using the AES core. If decryption is not required, the read data is output as is.
The area where the decryption process by DOTF is performed (decryption area) is limited to the range from the address set in the CONVAREAST register to the address set in the CONAREAED register.

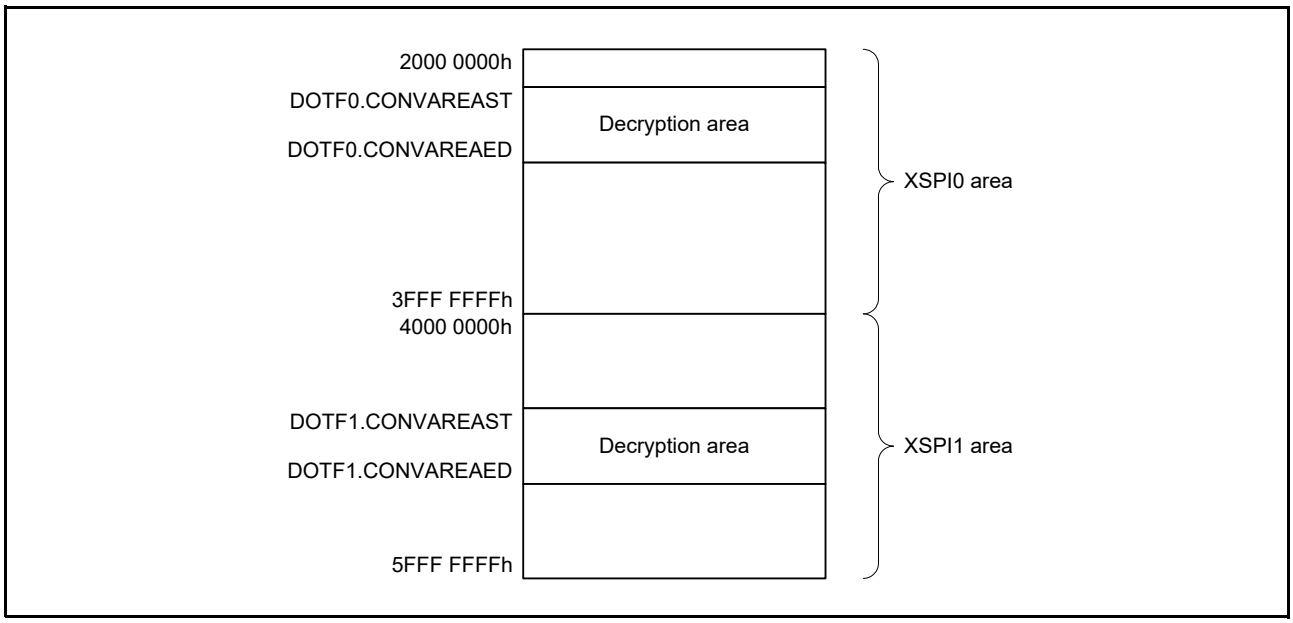

Figure 49.2 Decryption Area Setting

49.3.1 Initialization Flow

Figure 49.3 shows the initialization flow after hardware reset.

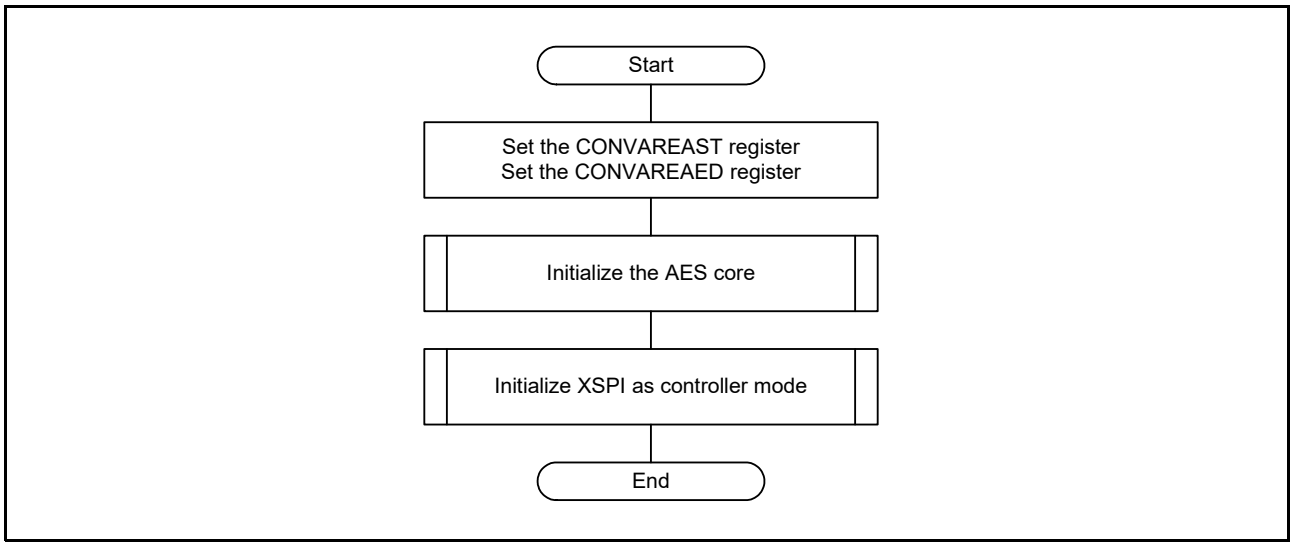

Figure 49.3 Initialization Flow

49.4 Usage Notes

49.4.1 Module Stop Function Setting

Operation of the DOTF module can be disabled or enabled using the module stop control register B (MSTPCRB). The DOTF is initially stopped after a reset. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

50. CRC Calculator (CRCA)

The CRC (Cyclic Redundancy Check) calculator generates CRC codes.

50.1 Overview

Table 50.1 lists the specifications of the CRC calculator, and Figure 50.1 shows a block diagram of the CRC calculator.

Table 50.1 CRC Specifications

Item	Description	
Data size	8 bits	32 bits
Data for CRC calculation*1	CRC codes are generated for any desired data in 8n-bit units (where n is a whole number)	CRC codes are generated for any desired data in 32n-bit units (where n is a whole number)
CRC processor unit	8-bit parallel processing	32-bit parallel processing
CRC generating polynomial	One of three generating polynomials is selectable • 8-bit CRC $X^8 + X^2 + X + 1$ • 16-bit CRC $X^{16} + X^{15} + X^2 + 1$ $X^{16} + X^{12} + X^5 + 1$	One of two generating polynomials is selectable • 32-bit CRC $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$
CRC calculation switching	The order of the bits produced by CRC calculation can be switched for LSB first or MSB first communication	
Low power consumption	Module stop state can be set.	
Protect Zone filter	Security attribute can be set.*2	

Note 1. The circuit does not have a function to divide data for calculation into CRC calculation units. Write data in 8-bit or 32-bit units.
Note 2. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

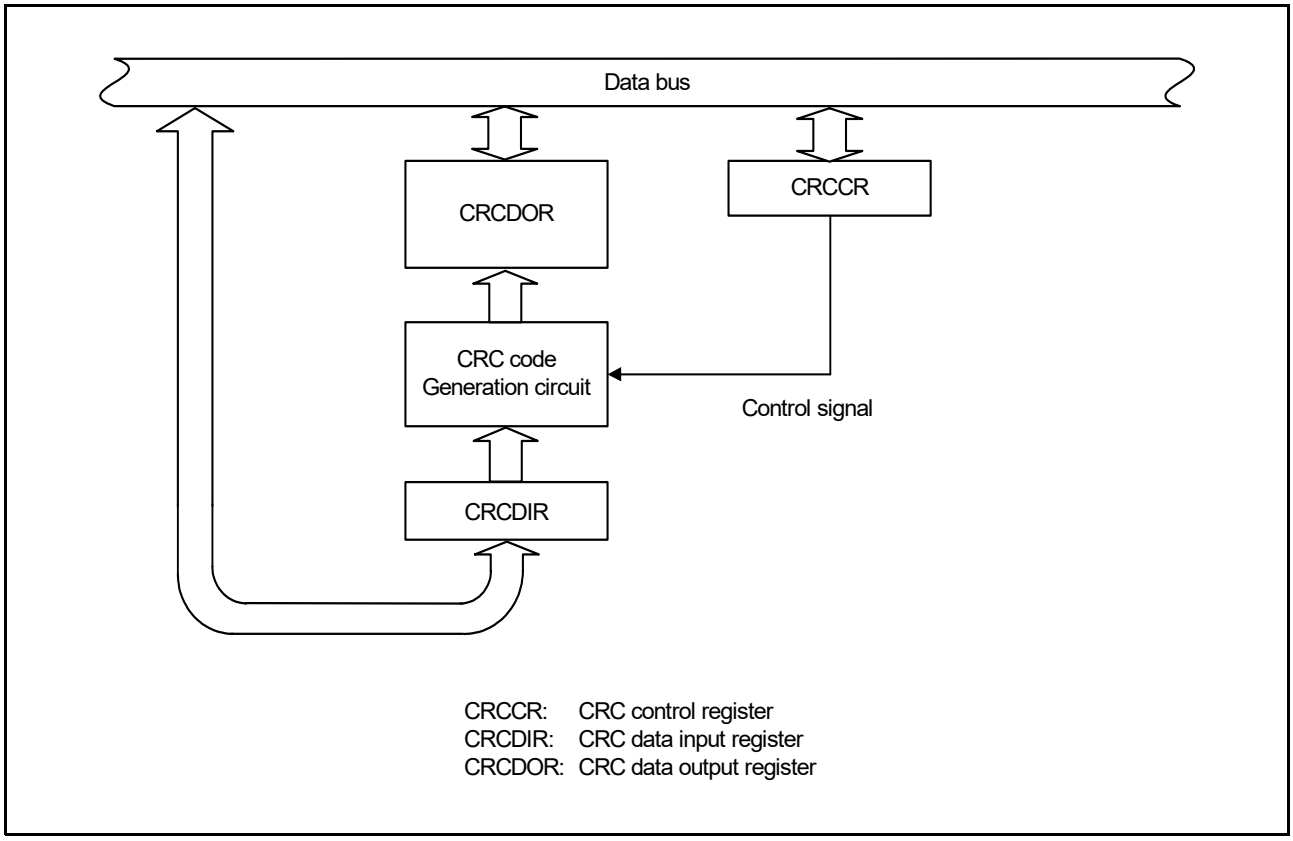

Figure 50.1 CRC Block Diagram

50.2 Register Descriptions

50.2.1 CRC Control Register (CRCCR)

Address(es): CRC.CRCCR 8741 0000h, CRC_NS.CRCCR 0741 0000h

	b7	b6	b5	b4	b3	b2	b1	b0
	DORCLR	LMS	—	—	—	GPS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	GPS[2:0]	CRC Generating Polynomial Switching	b2 b1 b0 0 0 0: No calculation is executed. 0 0 1: 8-bit CRC ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) 1 1 0: No calculation is executed. 1 1 1: No calculation is executed.	R/W
b5 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	LMS	CRC Calculation Switching	0: Generates CRC for LSB first communication. 1: Generates CRC for MSB first communication.	R/W
b7	DORCLR	CRCDOR Register Clear	1: Clears the CRCDOR register. This bit is read as 0.	W*1

Note 1. Only 1 can be written.

LMS Bit (CRC Calculation Switching)

The setting this bit selects the order of the bits of generated CRC codes. The bit selects transmission of the lower-order byte of the CRC code first for LSB first communication, or the higher-order byte first for MSB first communication. For details on the transmission and reception of CRC codes, refer to section 50.3, Operation.

DORCLR Bit (CRCDOR Register Clear)

Write 1 to this bit so that the CRCDOR register is set to 0000 0000h.
This bit is read as 0. Writing 0 to this bit has no effect.

50.2.2 CRC Data Input Register (CRCDIR)

- When 32-bit CRC is selected

Address(es): CRC.CRCDIR 8741 0004h, CRC_NS.CRCDIR 0741 0004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When 16-bit or 8-bit CRC is selected

Address(es): CRC.CRCDIR 8741 0004h, CRC_NS.CRCDIR 0741 0004h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

The CRCDIR register is a readable and writable register. Write data for CRC calculation to this register.
When generating a 32-bit CRC, the CRCDIR register should be accessed in longword units. When generating a 8-bit or 16-bit CRC, the CRCDIR register should be accessed in byte units.

50.2.3 CRC Data Output Register (CRCDOR)

- When 32-bit CRC is selected

Address(es): CRC.CRCDOR 8741 0008h, CRC_NS.CRCDOR 0741 0008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When 16-bit CRC is selected

Address(es): CRC.CRCDOR 8741 0008h, CRC_NS.CRCDOR 0741 0008h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When 8-bit CRC is selected

Address(es): CRC.CRCDOR 8741 0008h, CRC_NS.CRCDOR 0741 0008h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

The CRCDOR register is a readable and writable register.
The value after a reset is 0000 0000h. When calculating with the initial value set to a value other than 0000 0000h, rewrite the CRCDOR register.
Writing data to the CRCDIR register stores result of calculation in the CRCDOR register. In addition, following communication data, when a CRC code is written to the CRCDIR register and if the calculation result is 0000 0000h, there is no error in the communication data.
When a 32-bit CRC is selected, the CRCDOR register should be accessed in longword units. When a 16-bit CRC is selected, the CRCDOR register should be accessed in word units. When an 8-bit CRC is selected, the CRCDOR register should be accessed in byte units.

50.3 Operation

The CRC calculator generates CRC codes for use in LSB first or MSB first communication.
The following shows examples of generating the CRC code for input data (F0h) using the 16-bit CRC generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC data output register (CRCDOR) is cleared by setting the DORCLR bit to 1 to set the initial value for CRC calculation to 0000 0000h.

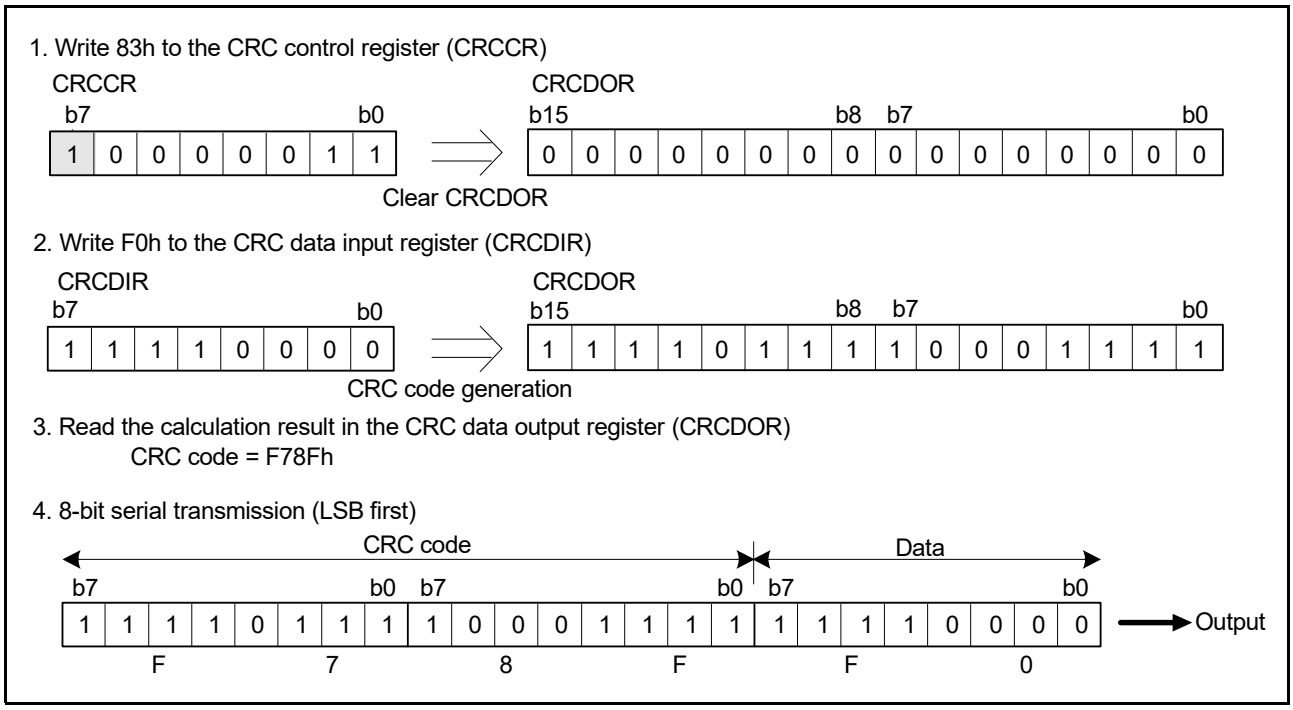

Figure 50.2 LSB First Data Transmission

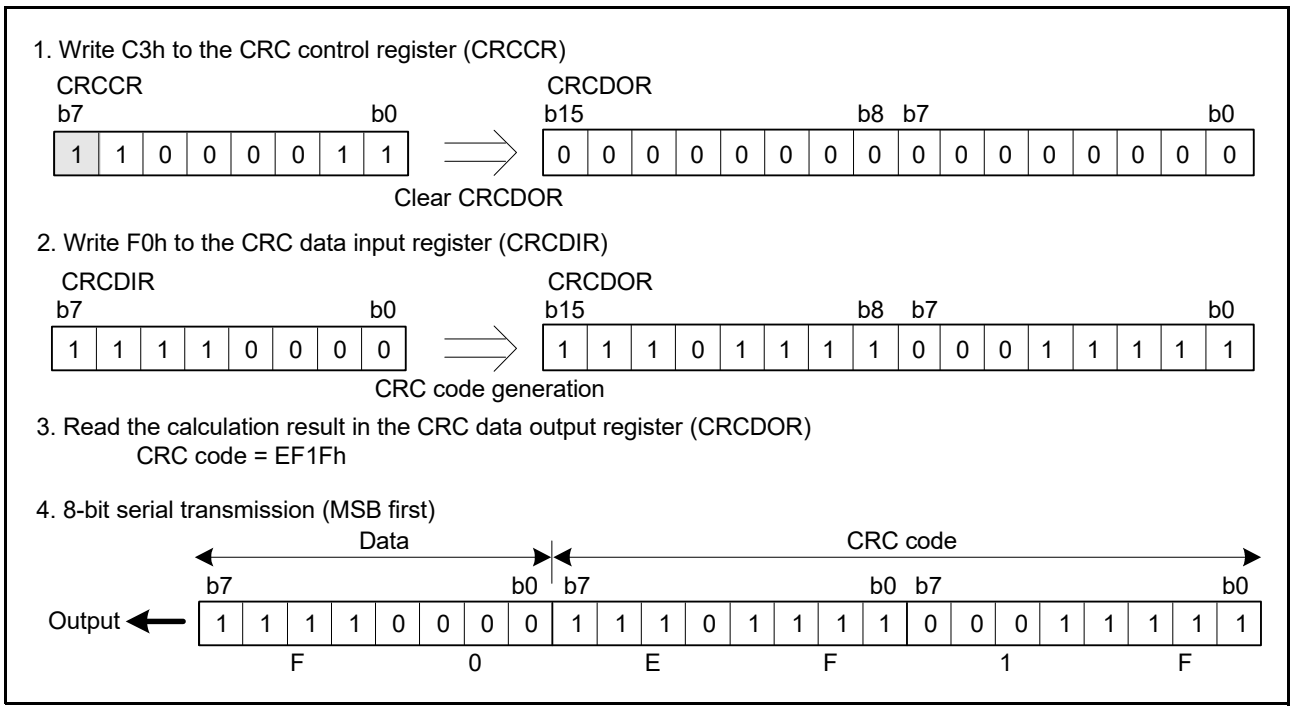

Figure 50.3 MSB First Data Transmission

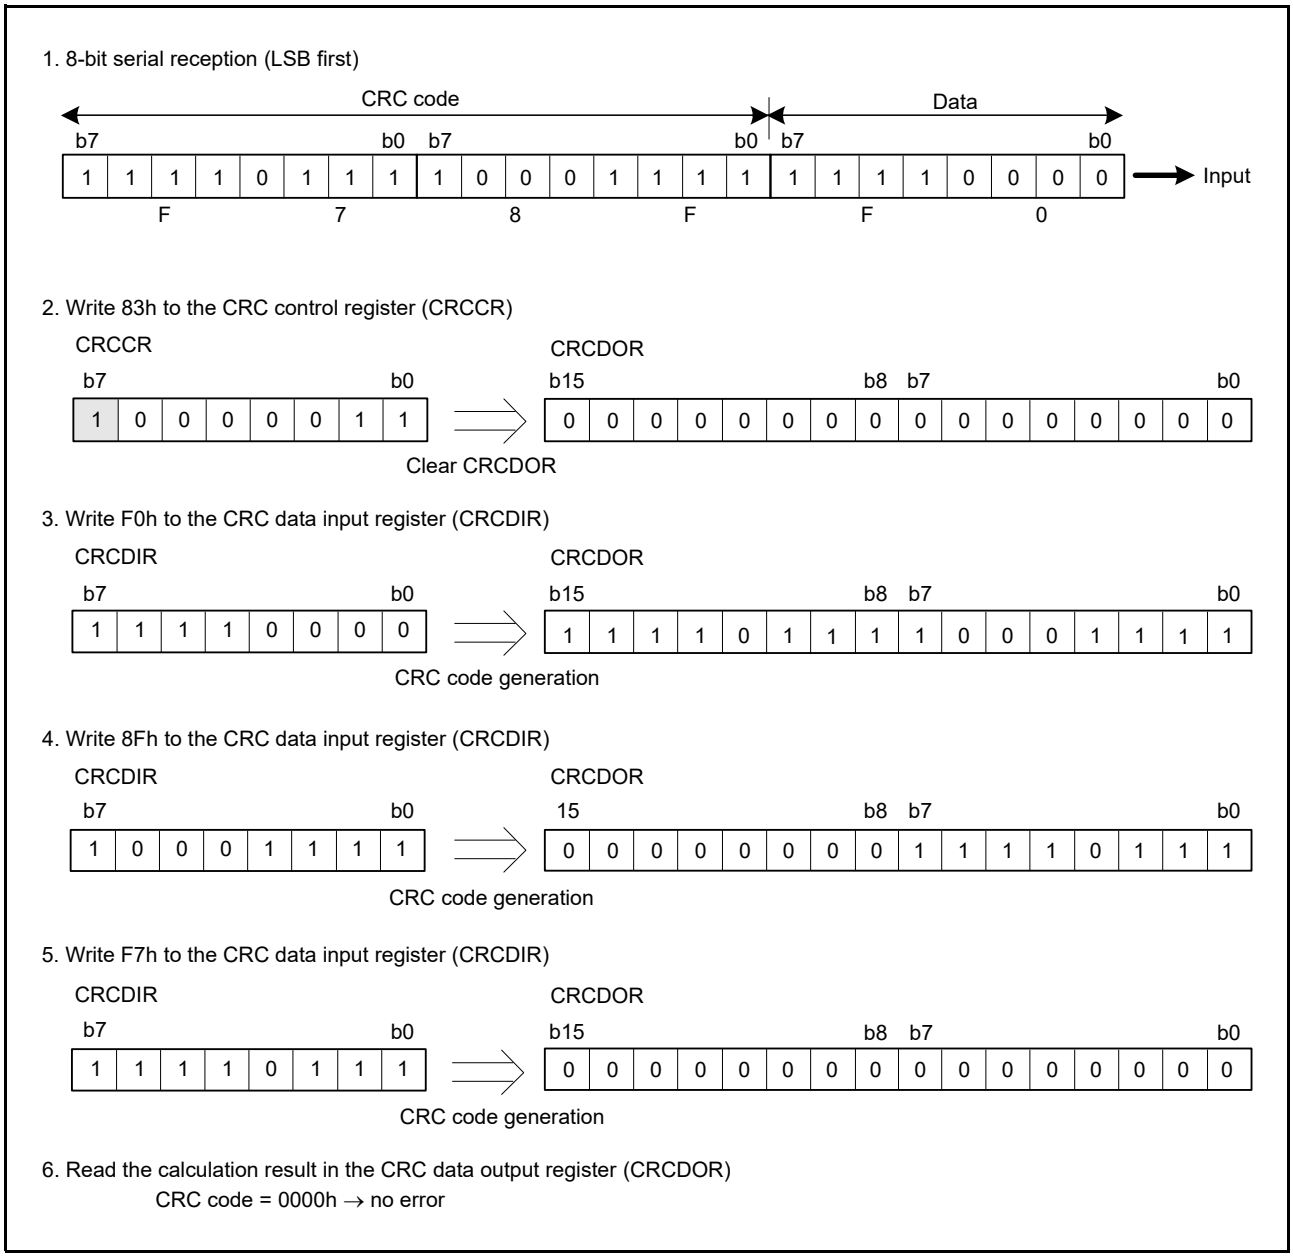

Figure 50.4 LSB First Data Reception

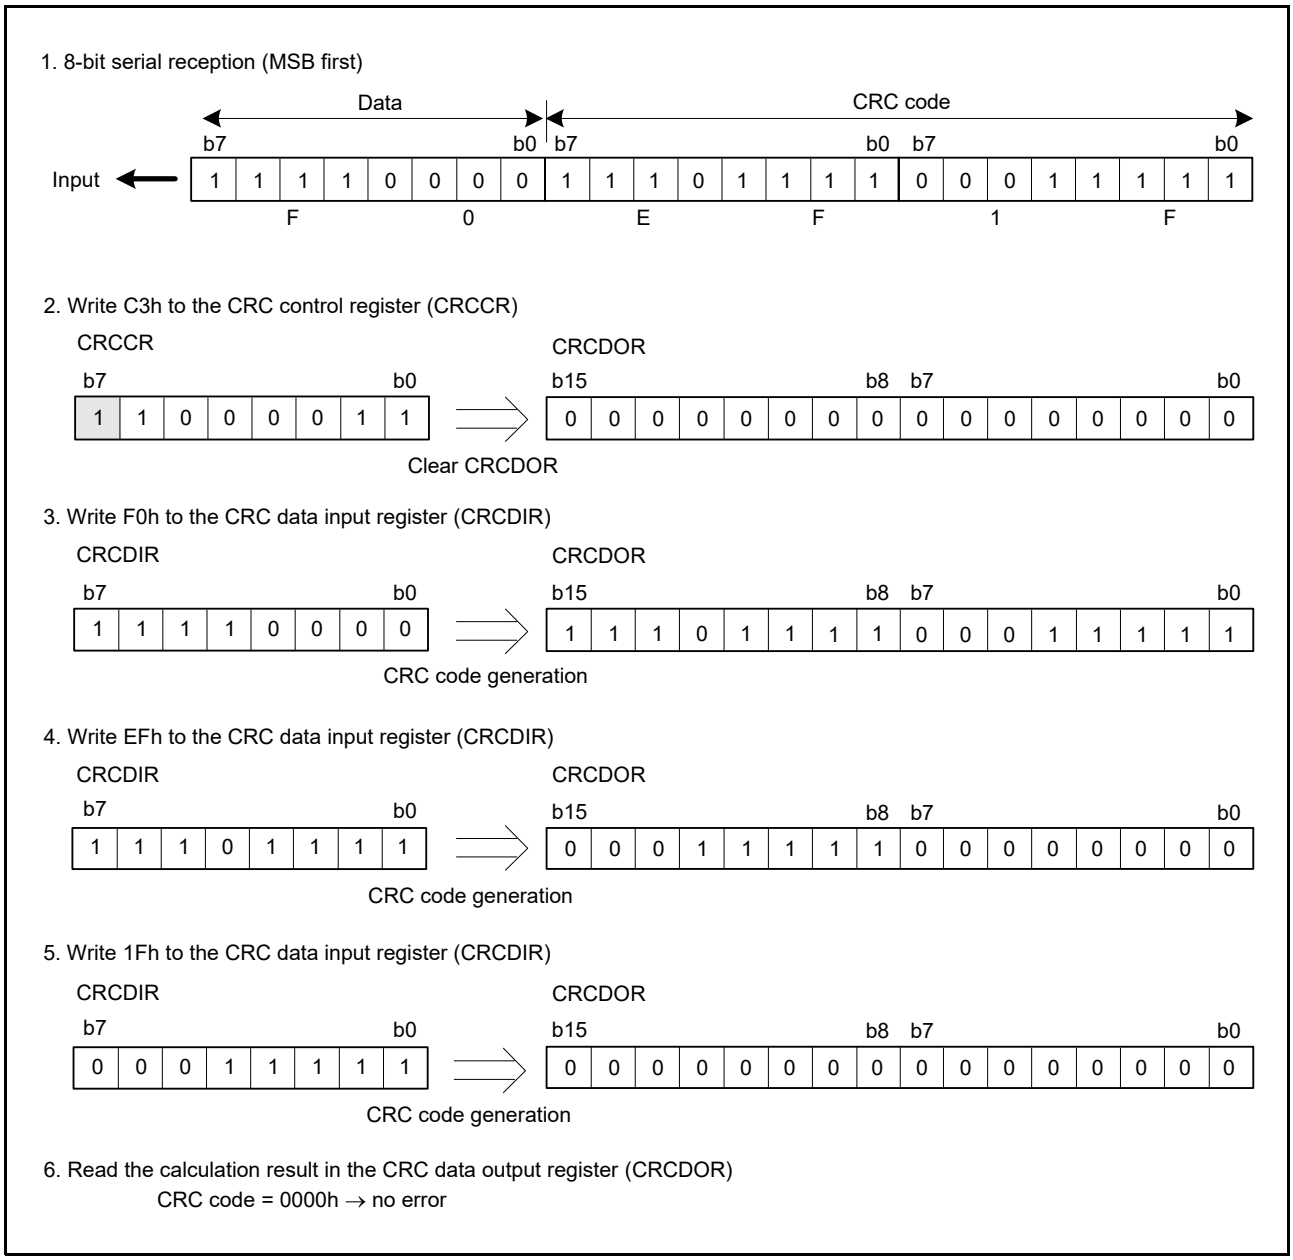

Figure 50.5 MSB First Data Reception

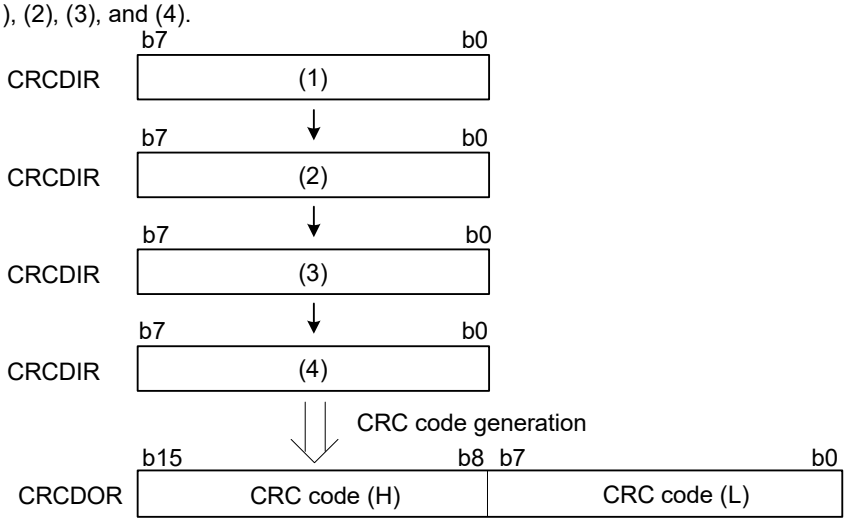
50.4 Usage Notes

50.4.1 Module Stop Function Setting

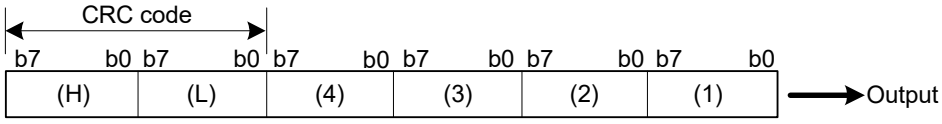
Operation of the CRC calculator can be disabled or enabled using the module stop control register C (MSTPCRC). After a reset, the CRC is in the module stop state. Register access is enabled by releasing the module stop state.
For details, refer to section 11, Low Power Consumption.



50.4.2 Note on Transmission

Note that the sequence of transmission for the CRC code differs according to whether transmission is LSB first or MSB first.

When transmitting 32-bit data



1. CRC code

After specifying the method for generation calculation, write data to the CRCDIR register in the order of (1), (2), (3), and (4).

2. Transmit data

(i) When transmission is LSB first

(ii) When transmission is MSB first

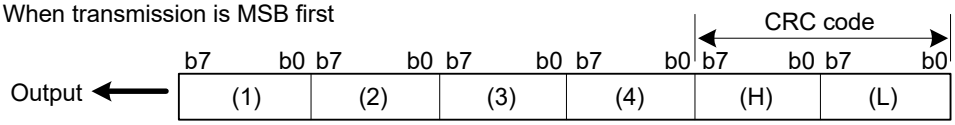


Figure 50.6 LSB First and MSB First Data Transmission

51. Serial Sound Interface (SSIE)

This MCU has two serial sound interfaces (SSIE0 and SSIE1). Each SSIE supports monaural and time-division multiplexed (TDM) formats in addition to standard audio data formats such as I²S, left-justified, and right-justified.

51.1 Overview

Table 51.1 lists the specifications of the SSIE. Table 51.2 lists and Figure 51.1 shows the terms and the definitions used in this chapter. Figure 51.2 shows a block diagram of the SSIE.

Table 51.1 Features of SSIE

Item		Description
Number of channels		Two channels, SSIE0 and SSIE1
Transfer mode		• Master/slave • Transmission, reception, or transception
Data format		• I²S format • Left-justified format • Right-justified format • Monaural format • TDM format
Serial data		• Fixed to MSB first • System word length: Selectable from among 8, 16, 24, 32, 48, 64, 128, or 256 bits • Data word length: Selectable from among 8, 16, 18, 20, 22, 24, or 32 bits • The level of padding bits is programmable. • Mute function
Master clock (MCK)		Clock source: AUDIO_CLK or GTIOC14A
Bit clock (BCK)	In master mode	• Frequency: Selectable from among 1/1, 1/2, 1/4, 1/6, 1/8, 1/12, 1/16, 1/24, 1/32, 1/48, 1/64, 1/96, or 1/128 of the MCK frequency • Continued supply or stopping while data transfer is halted is selectable.
	In master and slave modes	• Polarity is selectable as rising edges or falling edges.
LR clock (LRCK)		• Polarity is selectable as low or high. • Continued supply or stopping while data transfer is halted is selectable.
FIFO	Capacity	• Transmit FIFO: 4 bytes × 32 stages • Receive FIFO: 4 bytes × 32 stages
	Data alignment	• Alignment of data (left-justified or right-justified) in the FIFO is selectable.
Interrupts		• Data transfer error/idle state • Receive data full • Transmit data empty
Low power consumption function		• Module stop function • Master clock (MCK) supply stopping function
Protect Zone filter		Security attribute can be set for each channel.*1, *2

Note 1. If the security attributes for each channel are different, there are some notes regarding the input of AUDIO_CLK. Refer to section 51.5.2, Notes on AUDIO_CLK for details.

Note 2. When each channel is set to the secure attribute, registers in the channel are accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When each channel is set to the non-secure attribute, registers in the channel are accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Table 51.2 Definitions of Terms

Term	Definition
Start trigger	First edge of the type specified by the SSICR.LRCKP bit of the signal on the SSILRCK pin after the start of data transfer
Frame boundary	Point where SSIE starts transferring the first data of a frame or the point where SSIE ends transferring the last data of the frame
Frame word length	Number of system words per frame (number of channels)
System word length	Number of transferred bits per channel
Data word length	Number of effective bits per channel

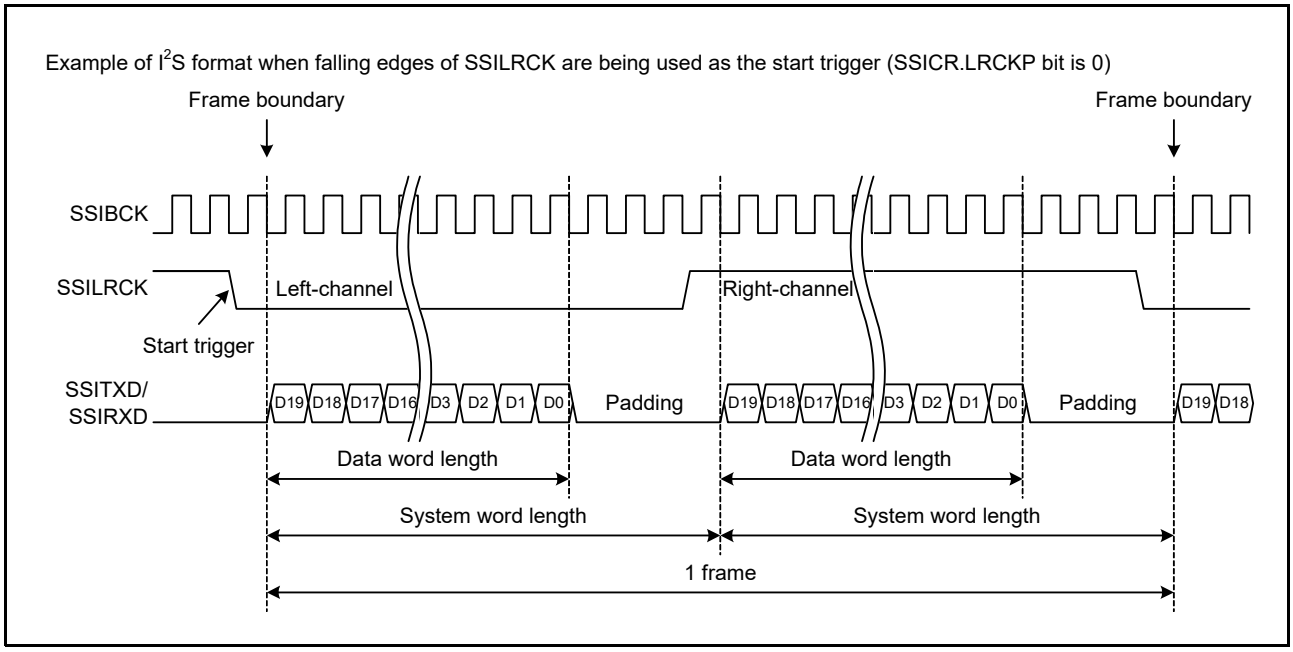

Figure 51.1 Definitions of Terms Related to Data Format

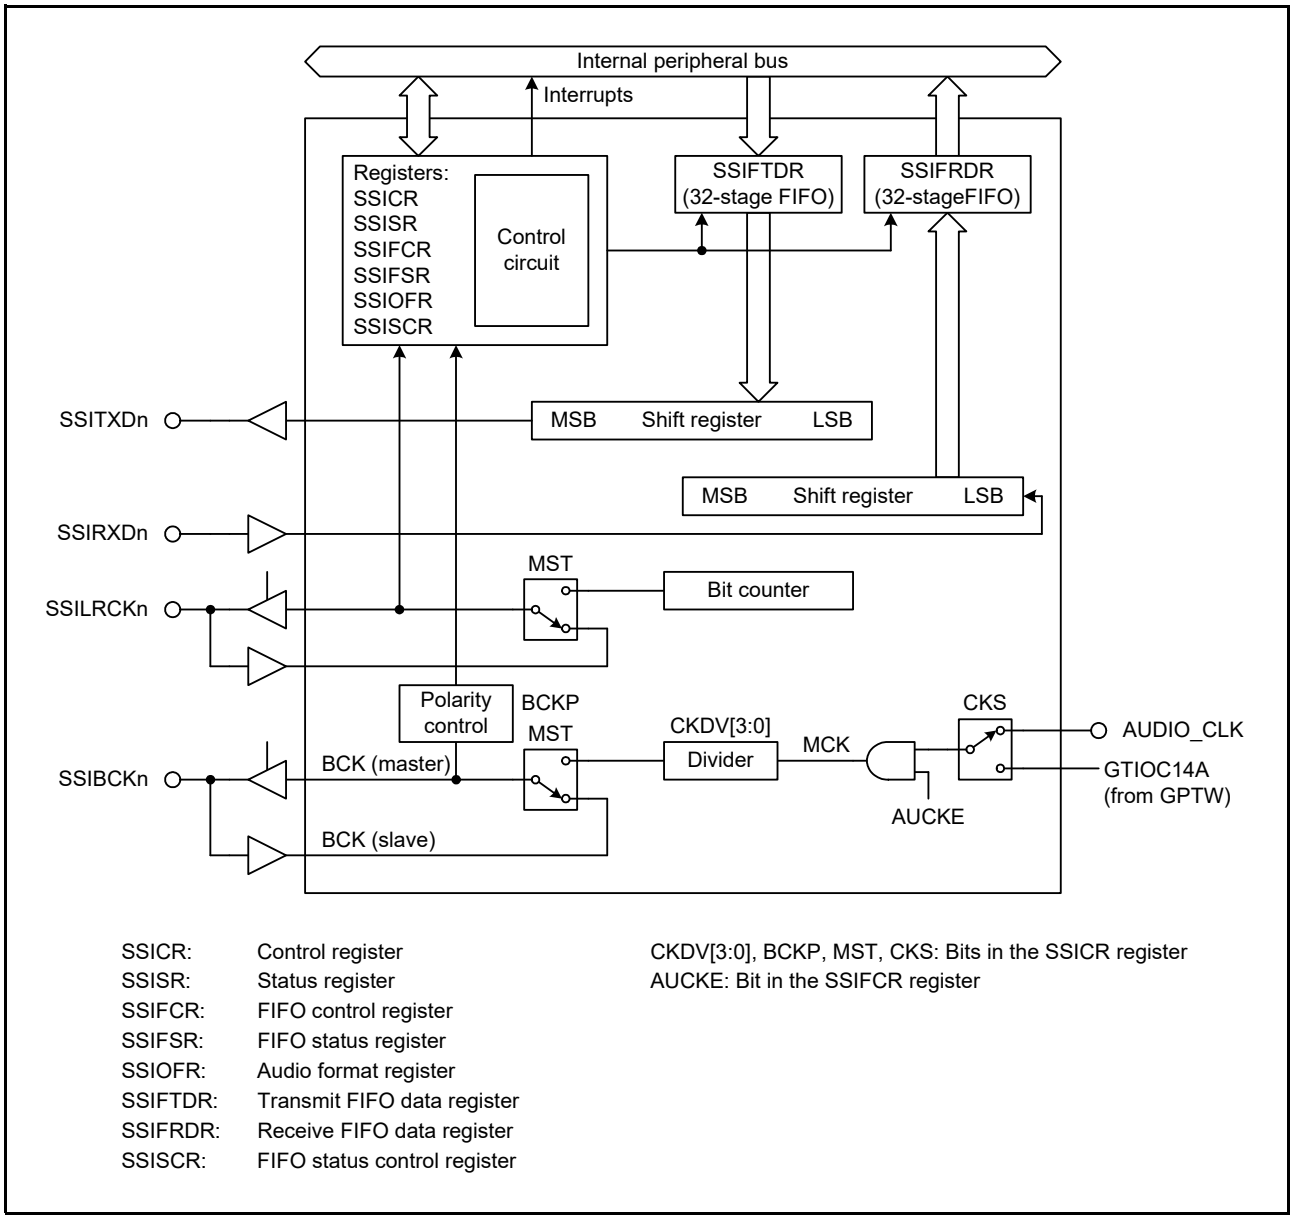

Figure 51.2 SSIE Block Diagram (n = 0, 1)

Table 51.3 lists the I/O pins of the SSIEs.

Table 51.3 I/O pins of SSIE

Pin Name	I/O	Function
AUDIO_CLK	Input	Audio clock input
SSIBCK0	I/O	Channel 0 bit-clock input/output
SSILRCK0	I/O	Channel 0 LR clock input/output
SSITXD0	Output	Channel 0 data output
SSIRXD0	Input	Channel 0 data input
SSIBCK1	I/O	Channel 1 bit-clock input/output
SSILRCK1	I/O	Channel 1 LR clock input/output
SSITXD1	Output	Channel 1 data output
SSIRXD1	Input	Channel 1 data input

51.2 Register Descriptions

51.2.1 Control Register (SSICR)

Address(es): SSIE0.SSICR 8785 D000h, SSIE1.SSICR 8785 D100h, SSIE0_NS.SSICR 0785 D000h, SSIE1_NS.SSICR 0785 D100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b23, b22	FRM[1:0]	Frame Word Length Select*2	Set a number of system words per a frame. b23 b22 0 0: 2 system words (I^2S, left-justified, or right-justified) or 1 system word (monaural) 0 1: 4 system words (TDM format only) 1 0: 6 system words (TDM format only) 1 1: 8 system words (TDM format only)	R/W
b24	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b25	IIEN	Idle State Interrupt Enable	0: Idle state interrupt disabled 1: Idle state interrupt enabled	R/W
b26	ROIEN	Receive Overflow Interrupt Enable	0: Receive overflow interrupt disabled 1: Receive overflow interrupt enabled	R/W
b27	RUIEN	Receive Underflow Interrupt Enable	0: Receive underflow interrupt disabled 1: Receive underflow interrupt enabled	R/W
b28	TOIEN	Transmit Overflow Interrupt Enable	0: Transmit overflow interrupt disabled 1: Transmit overflow interrupt enabled	R/W
b29	TUIEN	Transmit Underflow Interrupt Enable	0: Transmit underflow interrupt disabled 1: Transmit underflow interrupt enabled	R/W
b30	CKS	Master Clock Select*2, *3	0: Input signal from the AUDIO_CLK pin 1: The GTIOC14A signal from GPTW	R/W
b31	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. After the TEN or REN bit is rewritten, confirm that the SSISR.IIRQ flag is in the desired status (when transmission or reception is enabled, confirm that the IIRQ flag is 0; when transmission and reception are disabled, confirm that the IIRQ flag is 1).
Note 2. Rewrite these bits while SSIE is in idle state (SSISR.IIRQ flag = 1). If the value of these bits is changed while data transfer is in progress, the operation after the change is not guaranteed.
Note 3. Rewrite these bits while the SSIFCR.AUCKE bit is 0.

TEN Bit (Transmission Enable) and REN Bit (Reception Enable)

These bits enable/disable transmission and reception. When one of these bits is set to 1, the given type of data transfer starts in synchronization with a start trigger of the SSILRCK signal. When the bit is set to 0, the data transfer stops at the next frame boundary. To use an SSIE for both transmission and reception, set both the TEN and REN bits to 1 simultaneously. To stop the data transfer, set both the TEN and REN bits to 0 simultaneously.
To switch among transmission, reception, and transception, do so in the idle state.

MUEN Bit (Mute)

This bit is used to mute audio output by driving the SSITXD pin low. When this bit is changed during a frame, the setting takes effect at the next frame boundary.
The MUEN bit only controls fixing of the SSITXD pin. Status flags are set and interrupt signals are generated regardless of the setting of the MUEN bit.
Changing the value of this bit must be performed after setting the data format to be used.

CKDV[3:0] Bits (Bit Clock Division Ratio Select)

These bits specify the divisor for the generation of a bit clock (BCK) from the master clock (MCK). This bit is disabled in slave mode.
Set these bits while the SSIFCR.AUCKE bit is 0.

DEL Bit (Serial Data Delay Select)

When this bit is 0, a delay of one cycle of the bit clock is inserted between edges of SSILRCK and SSITXD and SSIRXD. When 1, no delay is inserted.
Set this bit to 0 for the I^{2}S format and to 1 for the left-justified or right-justified format. Set this bit in conformance with the other party device for the monaural and TDM formats.When the monaural format is used, setting of this bit changes the high width of SSILRCK.

PDTA Bit (Data Alignment Select)

This bit specifies the alignment of the effective bits in the SSIFTDR and SSIFRDR registers. This bit is valid when the data word length 18 to 24 bits (the DWL[2:0] bits = 010b to 101b). Set this bit to 0, when the other data word length is selected.
Figure 51.3 shows the data alignment of the SSIFTDR and SSIFRDR registers.

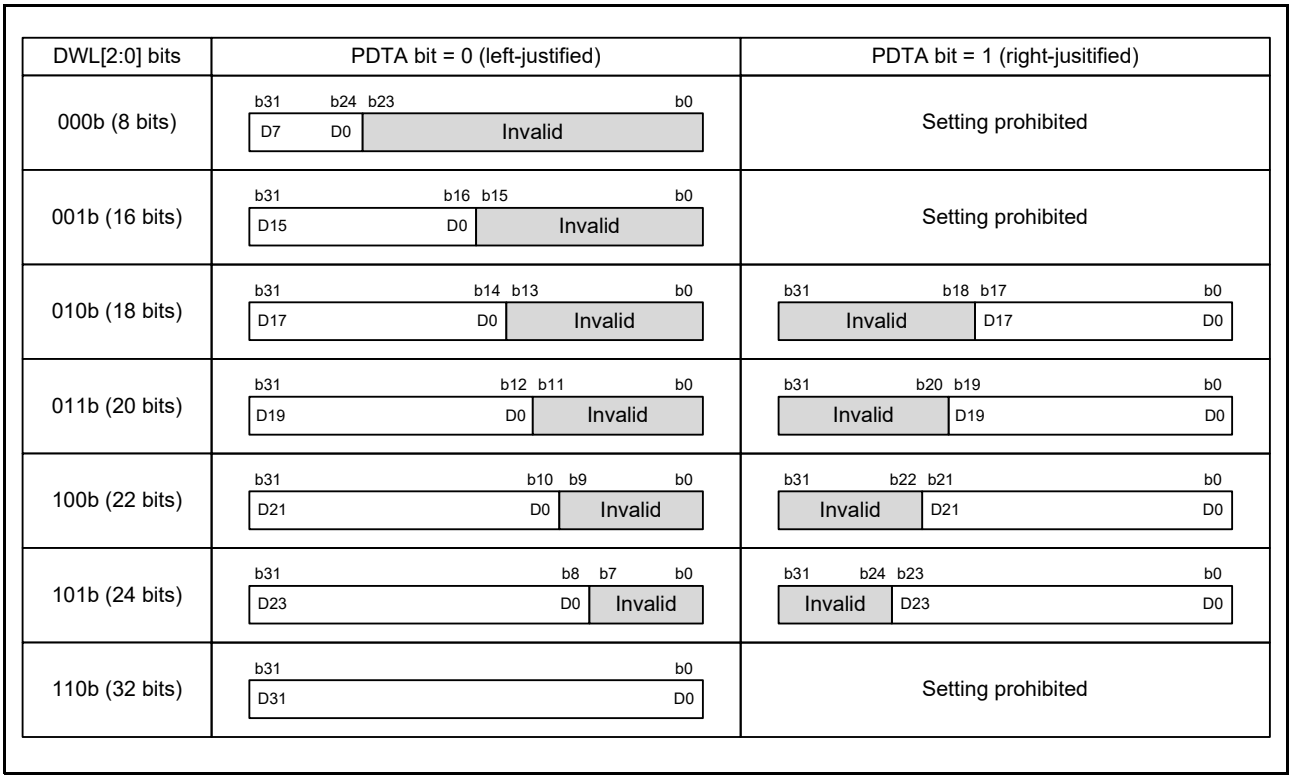

Figure 51.3 Data Alignment in the SSIFTDR and SSIFRDR Registers

SDTA Bit (Serial Data Alignment Select)

This bit specifies the order of data bits and padding bits for transception in system words. SSIE transmits and receives data bits first and then padding bits when this bit is 0 and padding bits first and then data bits when this bit is 1. This bit is invalid for data format without padding bits.

LRCKP Bit (LR Clock Polarity Select)

This bit specifies the initial status and polarity of the SSILRCK pin. Table 51.4 lists the settings of this bit and the corresponding states of the LR clock. SSIE uses the SSILRCK signal as a start trigger in slave mode.
Set this bit to 0 when the I^2S format is selected and 1 when the other data formats are selected.

Table 51.4 The Value of the LRCKP Bit and Responses to the States of the LR clock

LRCKP bit	Initial State of SSILRCK pin	Left Channel	Right Channel	Frame Boundary
0	High	Low	High	Falling edge
1	Low	High	Low	Rising edge

BCKP Bit (Bit Clock Polarity Select)

This bit specifies the polarity of the bit clock. Table 51.5 lists the settings of this bit and the corresponding timings of the respective signals.
Set this bit while the SSIFCR.AUCKE bit is 0.

Table 51.5 The Value of the BCKP bit and the Bit Clock Polarity

BCKP bit	Output of SSILRCK SSITXD	Input of SSILRCK SSIRXD
0	The signals change on falling edges of SSIBCK.	The signals are sampled on rising edges of SSIBCK.
1	The signals change on rising edges of SSIBCK.	The signals are sampled on falling edges of SSIBCK.

SWL[2:0] Bits (System Word Length Select)

These bits specify the number of bits in a system word. The setting of these bits determines the frequency ratio of the bit clock to the LR clock. Then number of the padding bits is obtained from the difference in the SWL[2:0] and DWL[2:0] bits. Refer to Table 51.8 for details.

DWL[2:0] Bits (Data Word Length Select)

These bits specify the number of bits of valid data in a system word. The data word length must not exceed the system word length. For details, refer to Table 51.8.

FRM[1:0] Bits (Frame Word Length Select)

These bits specify the number of system words in a frame.
Set these bits to 00b when the I^{2}S, left-justified, right-justified, or monaural format is selected. Do not set these bits to 00b when the TDM format is selected.

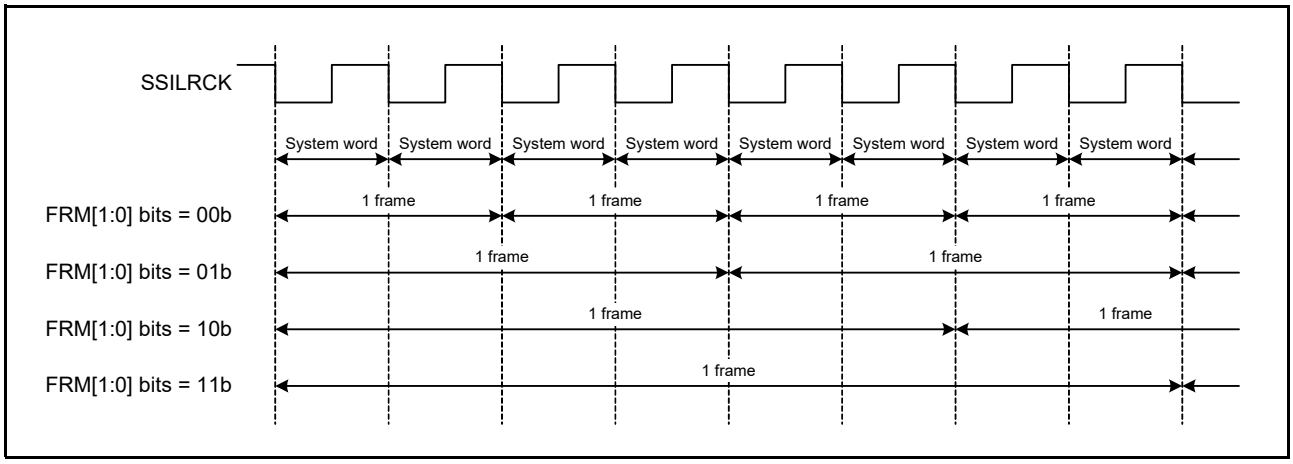

Figure 51.4 Frame Word Length

IIEN Bit (Idle State Interrupt Enable)

This bit enables or disables the idle state interrupts.
While this bit is 1, an interrupt request is output when the SSISR.IIRQ flag becomes 1. An interrupt request is also output when this bit is changed from 0 to 1 while the IIRQ flag is 1.

ROIEN Bit (Receive Overflow Interrupt Enable)

This bit enables or disables interrupts receive overflow interrupts.
While this bit is 1, an interrupt request is output when the SSISR.ROIRQ flag becomes 1. An interrupt request is also output when this bit is changed from 0 to 1 while the ROIRQ flag is 1.

RUIEN Bit (Receive Underflow Interrupt Enable)

This bit enables/disables the receive underflow interrupts.
While this bit is 1, an interrupt request is output when the SSISR.RUIRQ flag becomes 1. An interrupt request is also output when this bit is changed from 0 to 1 while the RUIRQ flag is 1.

TOIEN Bit (Transmit Overflow Interrupt Enable)

This bit enables/disables the transmit overflow interrupts.
While this bit is 1, an interrupt request is output when the SSISR.TOIRQ flag becomes 1. An interrupt request is also output when this bit is changed from 0 to 1 while the TOIRQ flag is 1.

TUIEN Bit (Transmit Underflow Interrupt Enable)

This bit enables/disables the transmit underflow interrupts.
While this bit is 1, an interrupt request is output when the SSISR.TUIRQ flag becomes 1. An interrupt request is also output when this bit is changed from 0 to 1 while the TUIRQ flag is 1.

51.2.2 Status Register (SSISR)

Address(es): SSIE0.SSISR 8785 D004h, SSIE1.SSISR 8785 D104h, SSIE0_NS.SSISR 0785 D004h, SSIE1_NS.SSISR 0785 D104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	TUIRQ	TOIRQ	RUIRQ	ROIRQ	IIRQ	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b24 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25	IIRQ	Idle State Flag	0: Transfer state 1: Idle state	R
b26	ROIRQ	Receive Overflow Flag	0: No receive overflows occurred. 1: A receive overflow has occurred.	R/W
b27	RUIRQ	Receive Underflow Flag	0: No receive underflows occurred. 1: A receive underflow has occurred.	R/W
b28	TOIRQ	Transmit Overflow Flag	0: No transmit overflows occurred. 1: A transmit overflow has occurred.	R/W
b29	TUIRQ	Transmit Underflow Flag	0: No transmit underflows occurred. 1: A transmit underflow has occurred.	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register indicates the SSIE status.

IIRQ Flag (Idle State Flag)

This flag indicates whether SSIE is in the idle state or transfer state.

[Setting condition]

- When a transmission of a frame is completed after changing the SSICR.TEN bit from 1 to 0.
- When a reception of a frame is completed after changing the SSICR.REN bit from 1 to 0.
- When a transmission of a frame is completed after changing the SSICR.TEN and SSICR.REN bits from 1 to 0.

[Clearing condition]

- When a start trigger is generated by writing a transmit data in the SSIFTDR register, while the SSICR.TEN bit is 1.
- When a start trigger is detected while the SSICR.REN bit is 1.
- When a start trigger is generated by writing a transmit data to the SSIFTDR register, while the SSICR.TEN and SSICR.REN bits are 1.

ROIRQ Flag (Receive Overflow Flag)

This flag indicates a receive overflow. This flag indicates that the data processing of the received data is delayed. The received data is not transferred to the receive FIFO if a receive overflow occurs. This flag is not cleared by resetting a receive FIFO.

[Priority order for setting and clearing]

Setting is prioritized.

[Setting condition]

- When a reception of the next data is completed while the receive FIFO is full.

[Clearing condition]

- When 0 is written to this flag after confirming this flag is 1.
- When the SSICR.REN bit is changed from 0 to 1.

RUIRQ Flag (Receive Underflow Flag)

This flag indicates a receive underflow. This flag indicates that the SSIFRDR register is read while the receive FIFO is empty. Data read from the SSIFRDR register is invalid if a receive underflow occurs. This flag is not cleared by resetting a receive FIFO. Reading the SSIFRDR register while resetting the receive FIFO does not lead to setting of this flag.

[Priority order for setting and clearing]

Setting is prioritized.

[Setting condition]

- When the SSIFRDR register is read while the receive FIFO is empty.

[Clearing condition]

- When 0 is written to this flag after confirming this flag is 1.
- When the SSICR.REN bit is changed from 0 to 1.

TOIRQ Flag (Transmit Overflow Flag)

This flag indicates a transmit overflow. This flag indicates that a data is written to the SSIFTDR register while the transmit FIFO is full. The written data is discarded. This flag is not cleared by resetting a transmit FIFO.

[Priority order for setting and clearing]

Setting is prioritized.

[Setting condition]

- When a data is written to the SSIFTDR register while the transmit FIFO is full.

[Clearing condition]

- When 0 is written to this flag after confirming this flag is 1.
- When the SSICR.TEN bit is changed from 0 to 1.

TUIRQ Flag (Transmit Underflow Flag)

This flag indicates a transmit underflow. This flag indicates that supply of the transmit data was not enough to the transmission of the frame. The SSITXD pin becomes low if a transmit underflow occurs, and remain low even if the flag is cleared. This flag is not cleared by resetting a transmit FIFO.

[Priority order for setting and clearing]

Setting is prioritized.

[Setting condition]

- When a data transfer to the transmit shift register occurs while the transmit FIFO is empty.

[Clearing condition]

- When 0 is written to this flag after confirming this flag is 1.
- When the SSICR.TEN bit is changed from 0 to 1.

51.2.3 FIFO Control Register (SSIFCR)

Address(es): SSIE0.SSIFCR 8785 D010h, SSIE1.SSIFCR 8785 D110h, SSIE0_NS.SSIFCR 0785 D010h, SSIE1_NS.SSIFCR 0785 D110h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	AUCKE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SSIRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	BSW	—	—	—	—	—	—	—	TIE	RIE	TFRST	RFRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFRST	Receive FIFO Reset*1	0: The receive FIFO is released from the reset state. 1: The receive FIFO is reset.	R/W
b1	TFRST	Transmit FIFO Reset*1	0: The transmit FIFO is released from the reset state. 1: The transmit FIFO is reset.	R/W
b2	RIE	Receive Data Full Interrupt Enable	0: Receive data full interrupt is disabled. 1: Receive data full interrupt is enabled.	R/W
b3	TIE	Transmit Data Empty Interrupt Enable	0: Transmit data empty interrupt is disabled. 1: Transmit data empty interrupt is enabled.	R/W
b10 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	BSW	Byte Swap*1	0: Byte swapping is disabled 1: Byte swapping is enabled	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	SSIRST	Software Reset	0: The software reset is released. 1: A software reset is applied.	R/W
b30 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	AUCKE	MCK Supply Enable*1	0: MCK is stopped. 1: MCK is supplied.	R/W

Note 1. Rewrite these bits while SSIE is in idle state (SSISR.IIRQ flag = 1). If the value of these bits is changed while data transfer is in progress, the operation after the change is not guaranteed.

RFRST Bit (Receive FIFO Reset)

This bit is used to reset the receive FIFO. Writing 1 to this bit resets the receive FIFO and initializes the RDC[5:0] bits and RDF flag in the SSIFSR register. Since this bit is not automatically cleared, write 0 to this bit to release from the reset state. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedure.
This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, this bit cannot be set to 1 when the SSIRST bit is 1.

TFRST Bit (Transmit FIFO Reset)

This bit is used to reset the transmit FIFO. Writing 1 to this bit resets the transmit FIFO and initializes the TDC[5:0] bits and TDE flag in the SSIFSR register. Since this bit is not automatically cleared, write 0 to this bit to release from the reset state. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedure.
This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, this bit cannot be set to 1 when the SSIRST bit is set.

RIE Bit (Receive Data Full Interrupt Enable)

This bit enables or disables a receive data full interrupt. Set this bit to 1 after specifying the condition for generating a receive data full interrupt in the SSISCR.RDFS[4:0] bits.

TIE Bit (Transmit Data Empty Interrupt Enable)

This bit enables or disables a transmit data empty interrupt. Set this bit to 1 after specifying the condition for generating a transmit data empty interrupt in the SSISCR.TDES[4:0] bits.

BSW Bit (Byte Swap)

The BSW bit enables or disables byte swapping when the SSIFTDR is written and the SSIFRDR register is read. This bit is valid only when the SSIFTDR and SSIFRDR register are accessed in 16-bit or 32-bit units. For details, refer to Figure 51.5.

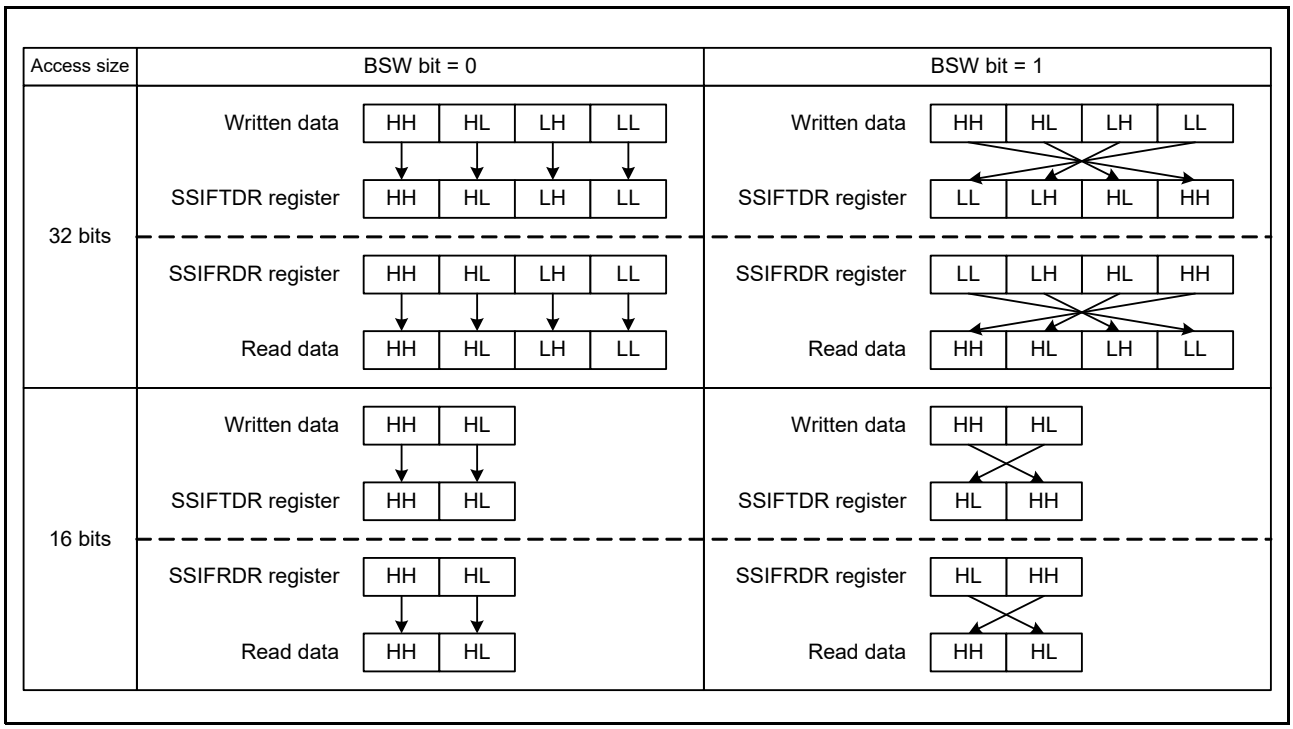

Figure 51.5 Examples of Byte-Swapping Operations

SSIRST Bit (Software Reset)

This bit is used to reset SSIE. Writing 1 to this bit initializes the internal state of SSIE. The registers and bits to be reset by setting this bit are listed below.

- SSICR.MUEN, TEN, and REN bits
- SSISR register
- SSIFCR.TFRST and RFRST bits
- SSIFSR register
- SSIFTDR register
- SSIFRDR register

Because this bit is not automatically cleared, write 0 to this bit to release from the reset state. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedure.

Because writing 1 to this bit during data transfer leads to initialization by software reset regardless of the bit clock, be careful to stop data transfer by using this bit.

AUCKE Bit (MCK Supply Enable)

This bit enables/disables supply of MCK while in master-mode. The setting value of this bit is reflected at the timing shown in Figure 51.6.

Changes to settings related to MCK (the settings of the CKS, MST, BCKP, and CKDV[3:0] bits in the SSICR register) should only proceed while this bit is 0.

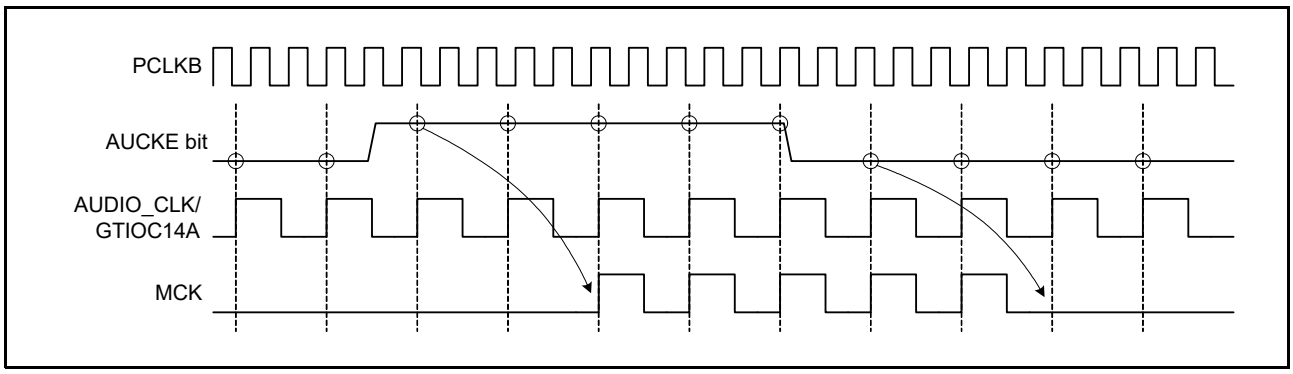

Figure 51.6 Supplying and Stopping MCK

51.2.4 FIFO Status Register (SSIFSR)

Address(es): SSIE0.SSIFSR 8785 D014h, SSIE1.SSIFSR 8785 D114h, SSIE0_NS.SSIFSR 0785 D014h, SSIE1_NS.SSIFSR 0785 D114h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	TDC[5:0]						—	—	—	—	—	—	—	TDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	RDC[5:0]						—	—	—	—	—	—	—	RDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RDF	Receive Data Full Flag	0: The number of received data stored in the receive FIFO does not exceed the value of the SSISCR.RDFS[4:0] bits. 1: The number of received data stored in the receive FIFO exceeds the value of the RDFS[4:0] bits.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	RDC[5:0]	Receive FIFO Data Count	Number of data stored in the receive FIFO	R
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	TDE	Transmit Data Empty Flag	0: The number of spaces available in the transmit FIFO does not exceed the value of the SSISCR.TDES[4:0] bits 1: The number of spaces available in the transmit FIFO exceeds the value of TDES[4:0] bits.	R/W
b23 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b29 to b24	TDC[5:0]	Transmit FIFO Data Count	Number of data stored in the transmit FIFO	R
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register indicates the status of the transmit FIFO and the receive FIFO.

RDF Flag (Receive Data Full Flag)

This flag indicates that the number of unread data in the receive FIFO is more than the value of the SSISCR.RDFS[4:0] bits.

[Priority order for setting and clearing]

Clearing is prioritized.

[Setting condition]

- When the number of data stored in the receive FIFO exceeds the value of the SSISCR.RDFS[4:0] bits.

[Clearing condition]*1

- When 0 is written to this flag after confirming this flag is 1.
- When a received data is read from the SSIFRDR register by DMA/DTC transfer (the last transfer of the block if using block transfer).

Note 1. This flag is cleared by a software reset and receive FIFO reset.

RDC[5:0] Bits (Receive FIFO Data Count)

These bits indicate the number of valid data that are stored in the receive FIFO. When this bit is 00h, there is no received data. When 20h, the receive FIFO is full and there is no space available.

TDE Flag (Transmit Data Empty Flag)

This flag indicates that the number of spaces available in the transmit FIFO is more than the value of the SSISCR.TDES[4:0] bits.
[Priority order for setting and clearing]
Clearing is prioritized.
[Setting condition]

- When the number of spaces available in the transmit FIFO exceeds the value of the SSISCR.TDES[4:0] bits.

[Clearing condition]*1

- When 0 is written to this flag after confirming this flag is 1.
- When a transmit data is written to the SSIFTDR register by DMA/DTC transfer (the last transfer of the block if using block transfer).

Note 1. This flag is cleared by a software reset and transmit FIFO reset.

TDC[5:0] Bits (Transmit FIFO Data Count)

These bits indicate the number of valid data that are stored in the transmit FIFO. When this bit is 00h, there is no data to be transmitted. When 20h, the transmit FIFO is full and there is no space available.

51.2.5 Transmit FIFO Data Register (SSIFTDR)

- When accessing in longword size

Address(es): SSIE0.SSIFTDR 8785 D018h, SSIE1.SSIFTDR 8785 D118h, SSIE0_NS.SSIFTDR 0785 D018h, SSIE1_NS.SSIFTDR 0785 D118h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When accessing in word size

Address(es): SSIE0.SSIFTDR.H 8785 D018h, SSIE1.SSIFTDR.H 8785 D118h,
SSIE0_NS.SSIFTDR.H 0785 D018h, SSIE1_NS.SSIFTDR.H 0785 D118h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
									H							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When accessing in byte size

Address(es): SSIE0.SSIFTDR.HH 8785 D018h, SSIE1.SSIFTDR.HH 8785 D118h,
SSIE0_NS.SSIFTDR.HH 0785 D018h, SSIE1_NS.SSIFTDR.HH 0785 D118h

	b7	b6	b5	b4	b3	b2	b1	b0
					HH			
Value after reset:	0	0	0	0	0	0	0	0

This register is a write-only register used to write a transmit data to the 32-stage and 4-byte-wide transmit FIFO. Access to this register according to the access size listed in Table 51.6.

Table 51.6 Access Size to the SSIFTDR and SSIFRDR Registers

		Access Size		
SSICR.DWL[2:0] Bits	**Data Word Length**	**Byte**	**Word**	**Longword**
000b	8	Available	Not available	Not available
001b	16	Not available	Available	Not available
010b	18	Not available	Not available	Available
011b	20	Not available	Not available	Available
100b	22	Not available	Not available	Available
101b	24	Not available	Not available	Available
110b	32	Not available	Not available	Available

51.2.6 Receive FIFO Data Register (SSIFRDR)

- When accessing in longword size

Address(es): SSIE0.SSIFRDR 8785 D01Ch, SSIE1.SSIFRDR 8785 D11Ch, SSIE0_NS.SSIFRDR 0785 D01Ch, SSIE1_NS.SSIFRDR 0785 D11Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When accessing in word size

Address(es): SSIE0.SSIFRDR.H 8785 D01Ch, SSIE1.SSIFRDR.H 8785 D11Ch,
SSIE0_NS.SSIFRDR.H 0785 D01Ch, SSIE1_NS.SSIFRDR.H 0785 D11Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	H															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When accessing in byte size

Address(es): SSIE0.SSIFRDR.HH 8785 D01Ch, SSIE1.SSIFRDR.HH 8785 D11Ch,
SSIE0_NS.SSIFRDR.HH 0785 D01Ch, SSIE1_NS.SSIFRDR.HH 0785 D11Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	HH							
Value after reset:	0	0	0	0	0	0	0	0

This register is a read-only register used to read a received data from the 32-stage and 4-byte-wide receive FIFO. Access to this register according to the access size listed in Table 51.6.

51.2.7 Audio Format Register (SSIOFR)

Address(es): SSIE0.SSIOFR 8785 D020h, SSIE1.SSIOFR 8785 D120h, SSIE0_NS.SSIOFR 0785 D020h, SSIE1_NS.SSIOFR 0785 D120h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	BCKASTP	LRCONT	—	—	—	—	—	—	OMOD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	OMOD[1:0]	Data Format Select*1	b1 b0 0 0: I²S, left-justified, or right-justified format 0 1: TDM format 1 0: Monaural format 1 1: Setting prohibited	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	LRCONT	LRCK Continuous Output Enable*2, *3	0: LRCK stops in the idle state. 1: Output of LRCK continues in the idle state.	R/W
b9	BCKASTP	BCK Continuous Output Disable*2, *3	0: BCK is always output. 1: BCK stops in idle state.	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewrite these bits while SSIE is in idle state (SSISR.IIRQ flag = 1). If the value of these bits is changed while data transfer is in progress, the operation after the change is not guaranteed.
Note 2. This bit is valid only in master-mode. The setting is invalid in slave-mode.
Note 3. Do not set both of the BCKASTP and LRCONT bits to 1.

This register is used to set an audio format (which includes the settings of data format, LR clock continuous output mode, and BCK continuous output disable).

LRCONT Bit (LRCK Continuous Output Enable)

This bit enables or disables the output from SSILRCK pin when SSIE is in the idle state. This bit is effective only in master mode.

BCKASTP Bit (BCK Continuous Output Disable)

This bit enables or disables the output from SSIBCK pin when SSIE is in the idle state. This bit is effective only in master mode.

Set this bit to 0 to output BCK from the SSIBCK pin before starting data transfer. If this bit is set to 1 during data transfer, BCK output from the SSIBCK pin stops when the SSIE enters the idle state.

Set this bit after the data format to be used is specified. Do not rewrite this bit while the supply of MCK stops.

51.2.8 FIFO Status Control Register (SSISCR)

Address(es): SSIE0.SSISCR 8785 D024h, SSIE1.SSISCR 8785 D124h, SSIE0_NS.SSISCR 0785 D024h, SSIE1_NS.SSISCR 0785 D124h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	TDES[4:0]					—	—	—	RDFS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	RDFS[4:0]	Receive Data Full Condition Setting*1	Specifies the condition for setting the RDF flag to 1. b4 b0 00000: When receive FIFO has unread received data. 00001: When receive FIFO has two or more unread received data. ... 11110: When receive FIFO has 31 or more unread received data. 11111: When receive FIFO is full.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12 to b8	TDES[4:0]	Transmit Data Empty Condition Setting*1	Specifies the condition for setting the TDE flag to 1. b12 b8 00000: When transmit FIFO has space available. 00001: When transmit FIFO has at least two stages available. ... 11110: When transmit FIFO has at least 31 stages available. 11111: When transmit FIFO is empty.	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewrite these bits while SSIE is in idle state (SSISR.IIRQ flag = 1). If the value of these bits is changed while data transfer is in progress, the operation after the change is not guaranteed.

51.3 Operation

51.3.1 Data Formats

SSIE supports five data formats. Table 51.7 lists the supported data formats.

Table 51.7 Supported Data Formats and Bit Setting

Data Format	SSIOFR.OMOD[1:0] Bits	SSICR.DEL Bit	SSICR.LRCKP Bit	SSICR.SDTA Bit
I²S format	00b	0	0	0
Left-justified format	00b	1	1	0
Right-justified format	00b	1	1	1
TDM format	01b	0 or 1	1	0 or 1
Monaural format	10b	0 or 1	1	0 or 1

The following describes the serial data structure shared by data formats.
A serial data structure is defined by the system word length (set in the SSICR.SWL[2:0] bits) and the data word length (set in the SSICR.DWL[2:0] bits). If the data word length is shorter than the system word length, padding bits are inserted (Figure 51.7).

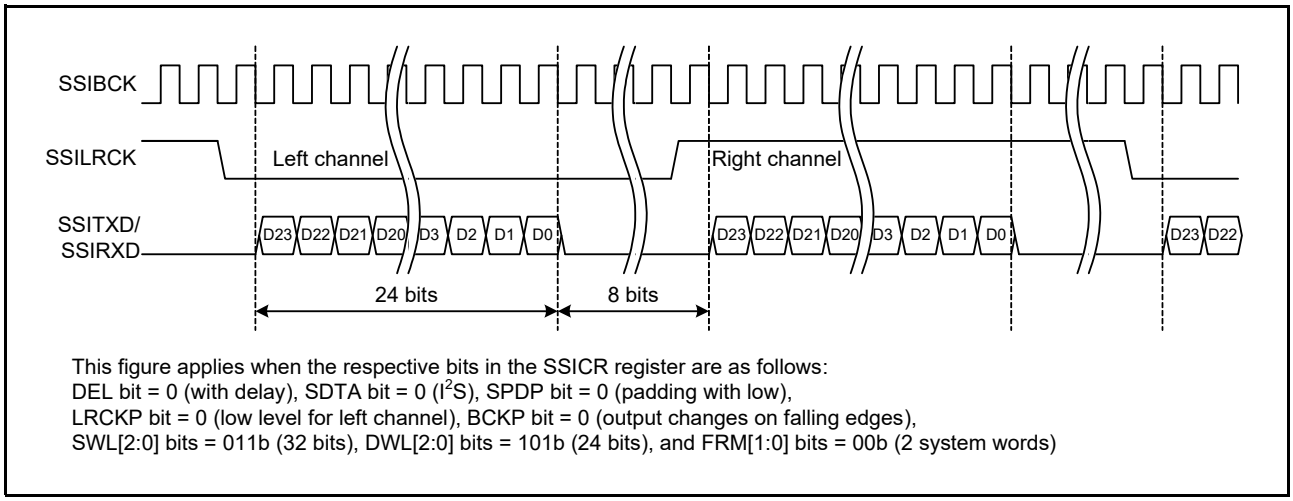

Figure 51.7 Example of Padding Bit Insertion (I²S Format, System Word Length > Data Word Length)

The number of padding bits is calculated from the system word length minus the data word length.
Table 51.8 lists the number of padding bits to be inserted with each combination of system word length (SWL[2:0] bits) and data word length (DWL[2:0] bits).

Table 51.8 Number of Padding Bits

System Word Length (SSICR.SWL[2:0] Bits)	Data Word Length (SSICR.DWL[2:0] Bits)						
	8 (000b)	16 (001b)	18 (010b)	20 (011b)	22 (100b)	24 (101b)	32 (110b)
8 (000b)	0	Prohibited setting	Prohibited setting	Prohibited setting	Prohibited setting	Prohibited setting	Prohibited setting
16 (001b)	8	0	Prohibited setting	Prohibited setting	Prohibited setting	Prohibited setting	Prohibited setting
24 (010b)	16	8	6	4	2	0	Prohibited setting
32 (011b)	24	16	14	12	10	8	0
48 (100b)	40	32	30	28	26	24	16
64 (101b)	56	48	46	44	42	40	32
128 (110b)	120	112	110	108	106	104	96
256 (111b)	248	240	238	236	234	232	224

51.3.1.1 I²S Format

The I²S format configures a frame with two system words of left channel and right channel. The SSILRCK signals becomes low for left channel and high for right channel. The effective data are output one bit clock period after the SSILRCK changes and then the padding bits are output.
Figure 51.8 shows an example of I²S format.

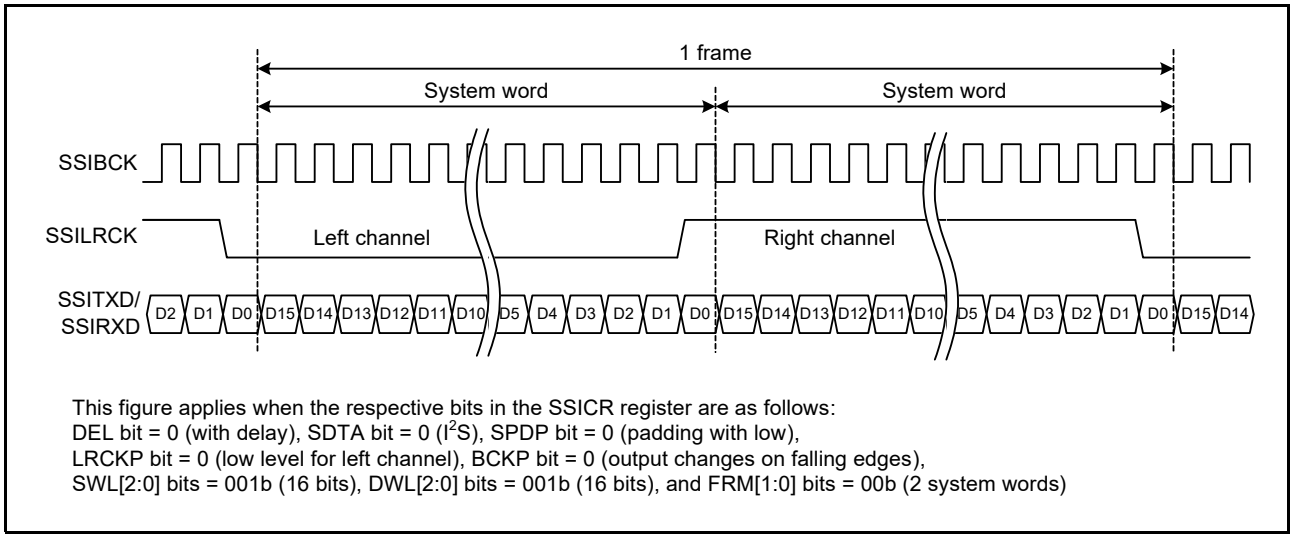

Figure 51.8 Example of I²S Format

51.3.1.2 Left-Justified Format

The left-justified format configures a frame with two system words of left channel and right channel. The SSILRCK signals becomes high for left channel and low for right channel. The effective data are output at the same time as the SSILRCK changes and then the padding bits are output.
Figure 51.9 shows an example of left-justified format.

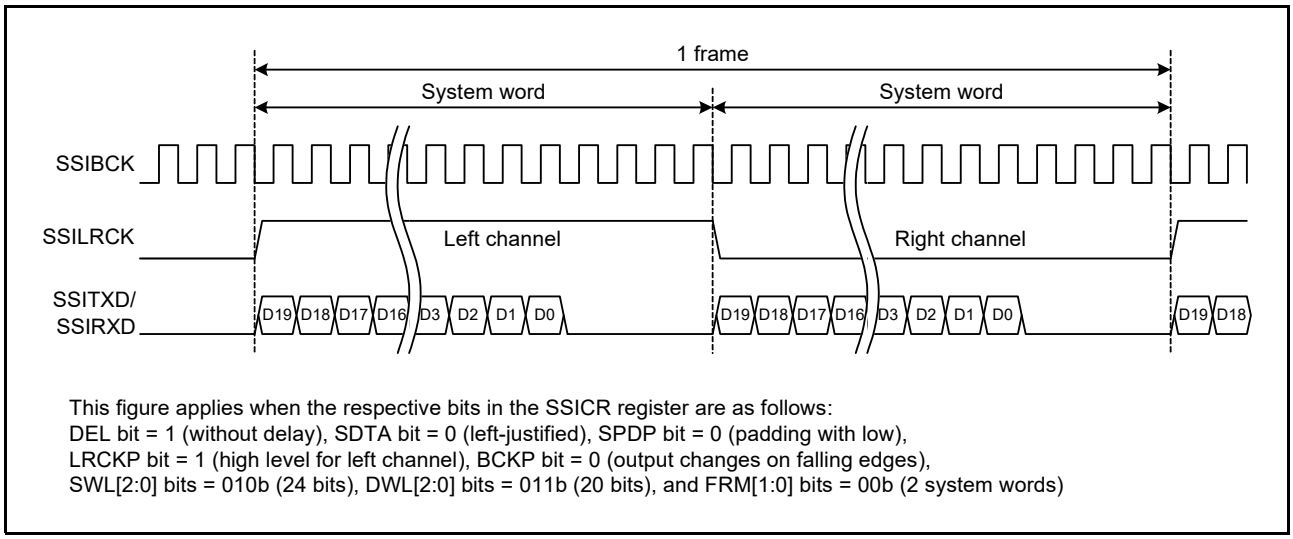

Figure 51.9 Example of Left-Justified Format

51.3.1.3 Right-Justified Format

The right-justified format configures a frame with two system words of left channel and right channel. The SSILRCK signals becomes high for left channel and low for right channel. The padding bits are output at the same time as the SSILRCK changes and then the effective data are output.
Figure 51.10 shows an example of right-justified format.

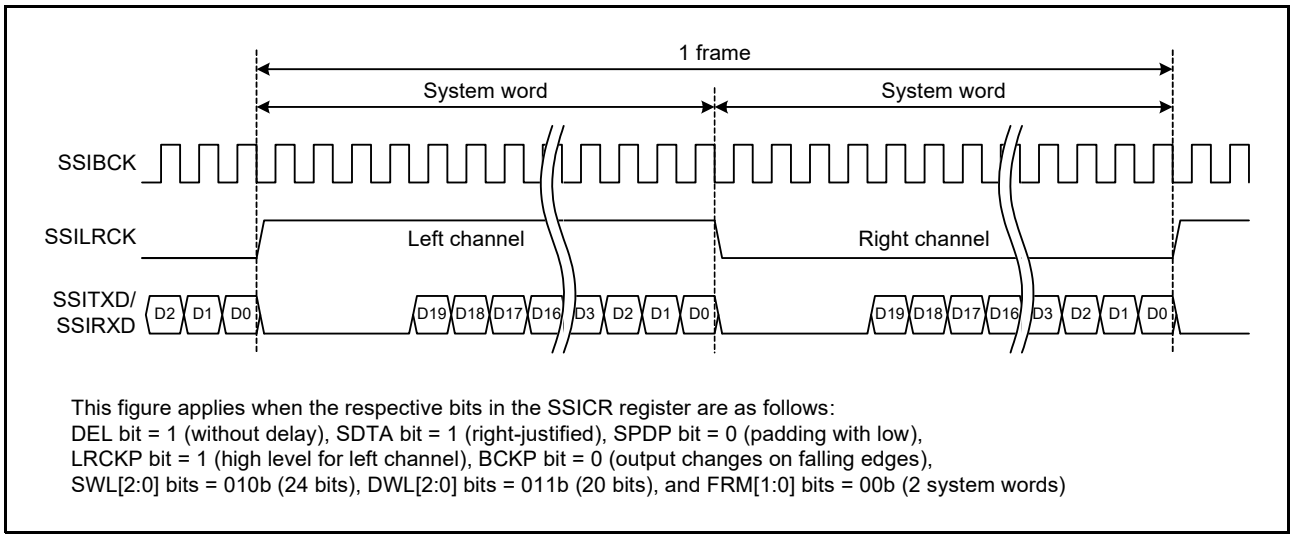

Figure 51.10 Example of Right-Justified Format

51.3.1.4 Monaural Format

The monaural format configures a frame with one system word. The SSILRCK signal is used as a transfer start trigger. Figure 51.11, Figure 51.12, and Figure 51.13 show examples of monaural formats with 0 as the value of the SSICR.DEL bit and no padding bits, with 0 as the value of the DEL bit and padding bits, and with 1 as the value of the DEL bit and no padding bits, respectively.

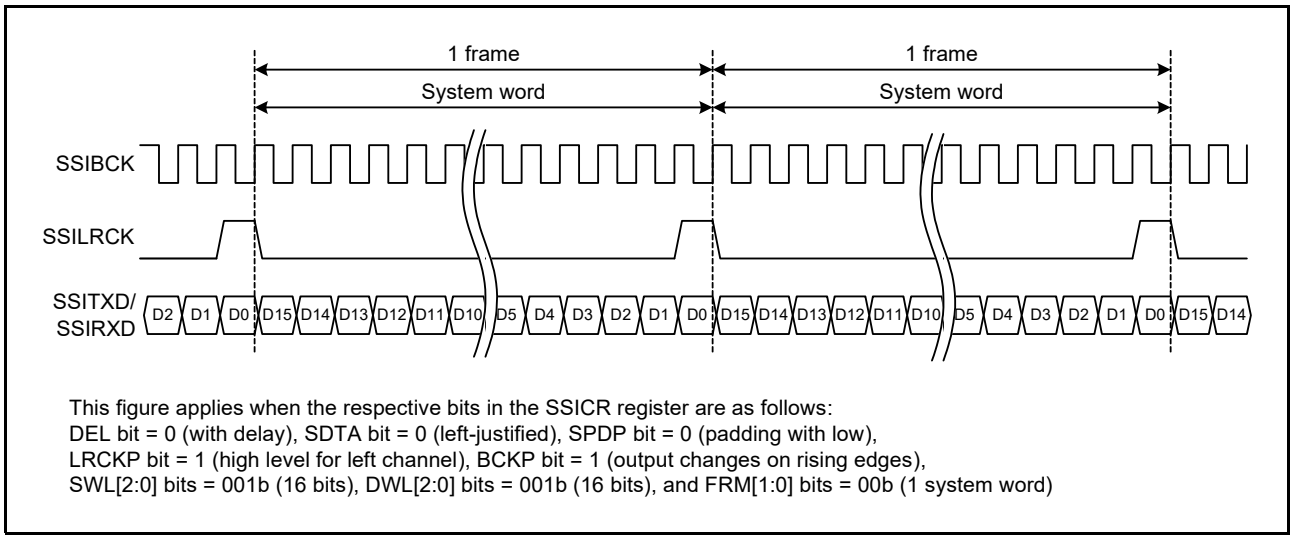

Figure 51.11 Example of Monaural Format (1): SSICR.DEL Bit = 0 and No Padding

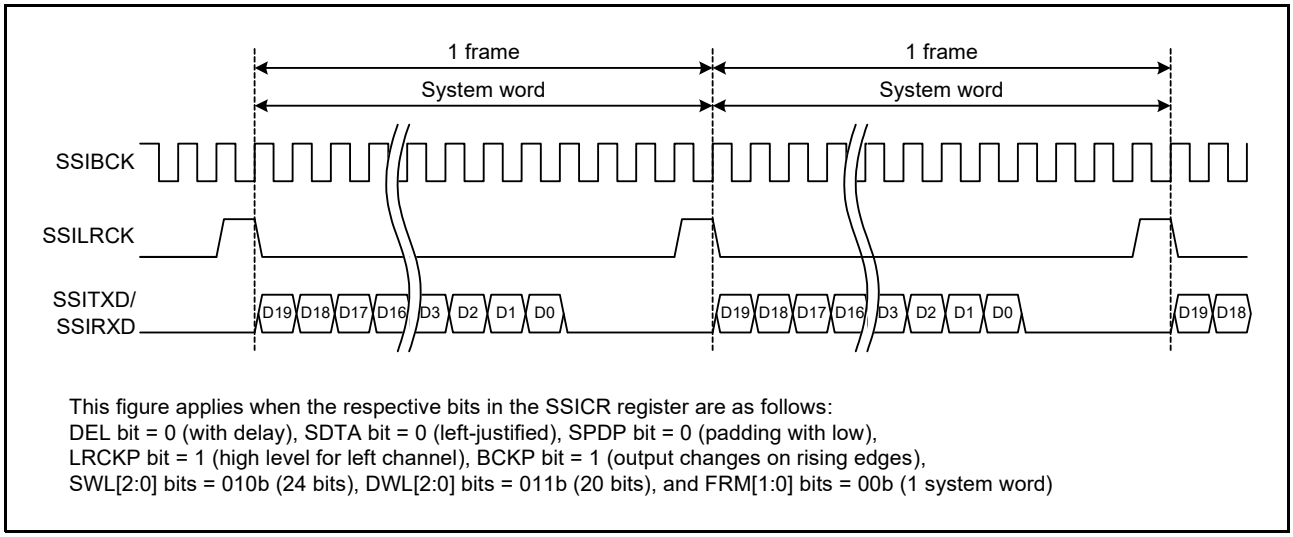

Figure 51.12 Example of Monaural Format (2): SSICR.DEL Bit = 0 and Padding Bits

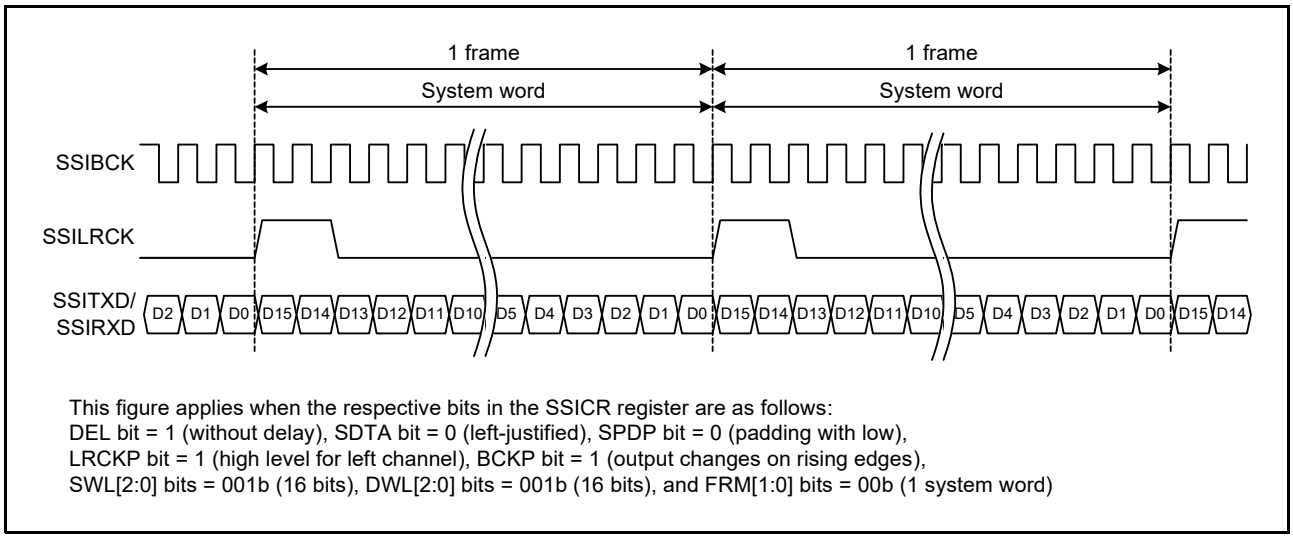

Figure 51.13 Example of Monaural Format (3): SSICR.DEL Bit = 1 and No Padding

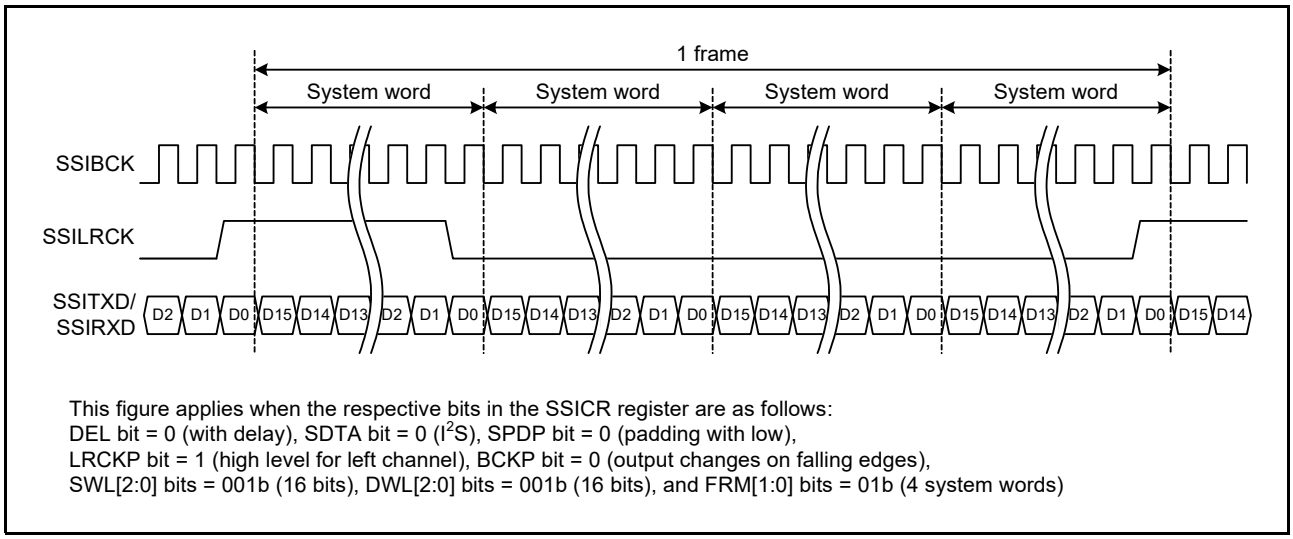
51.3.1.5 TDM Format

The TDM format configures a frame with four to eight system words. The SSILRCK signals become high for the first system word and low for the other system words. The SSILRCK signal is defined as the synchronous pulse and its rising edge means a start of a frame.

Figure 51.14 and Figure 51.15 show examples of the TDM formats with 0 as the value of the SSICR.DEL bit and no padding bits, and with 1 as the value of the SSICR.DEL bit and padding bits, respectively.



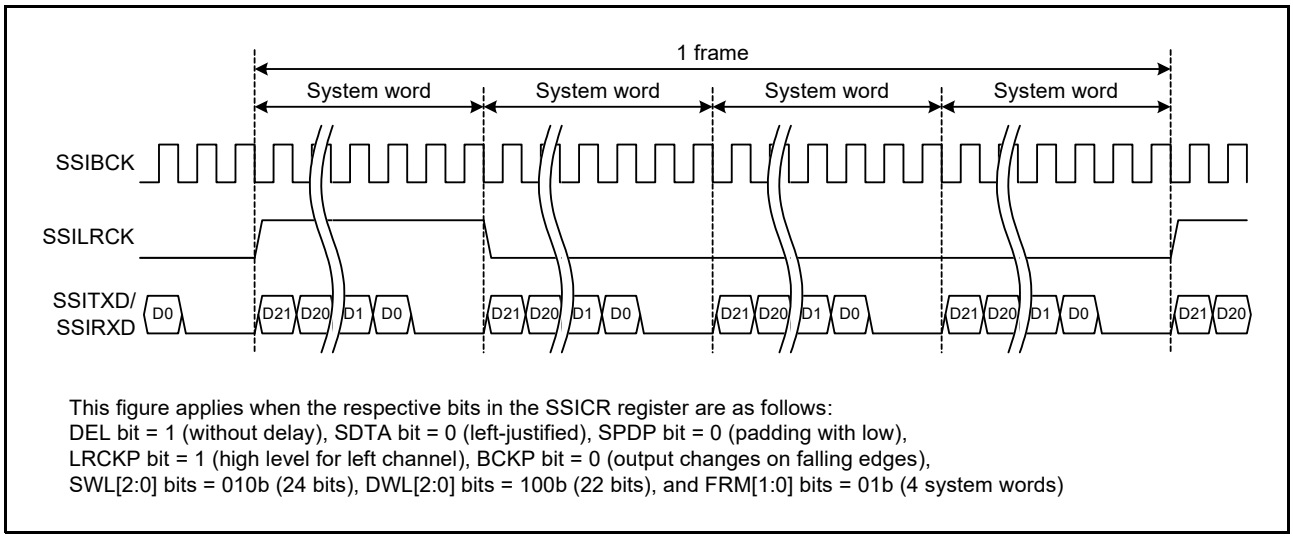


Figure 51.14 Example of TDM Format (1): SSICR.DEL Bit = 0 and No Padding

This figure applies when the respective bits in the SSICR register are as follows:
DEL bit = 1 (without delay), SDTA bit = 0 (left-justified), SPDP bit = 0 (padding with low),
LRCKP bit = 1 (high level for left channel), BCKP bit = 0 (output changes on falling edges),
SWL[2:0] bits = 010b (24 bits), DWL[2:0] bits = 100b (22 bits), and FRM[1:0] bits = 01b (4 system words)

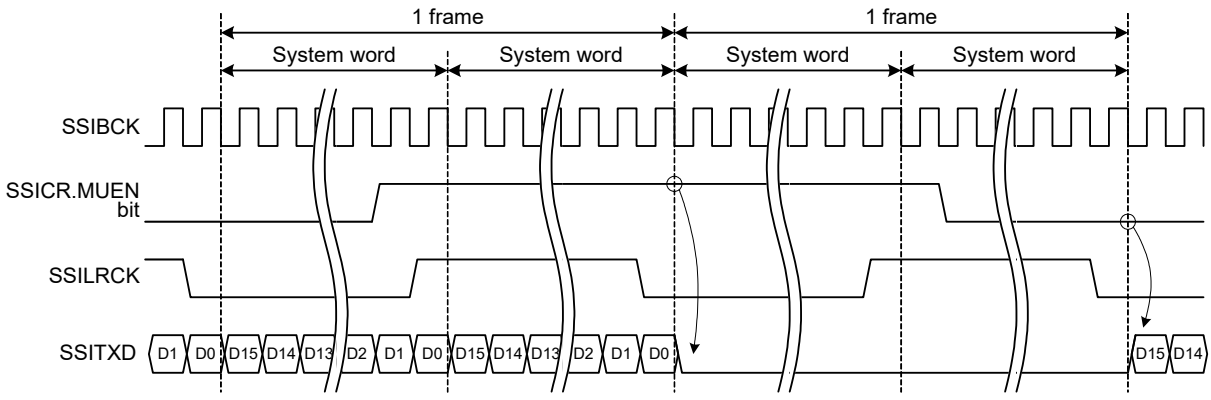

Figure 51.15 Example of TDM Format (2): SSICR.DEL Bit = 1 and Padding Bits

51.3.2 Output Control

SSIE has functions to control the outputs of data and clocks such as mute function, LRCK continuous output function, and BCK continuous output disable function.

51.3.2.1 Mute Function

The output from the SSITXD pin can be fixed to the low level by using the mute function. If the SSICR.MUEN bit is changed during a frame, the setting takes effect at the next frame boundary. Even while the MUEN bit is set to 1, status flags are updated and interrupt request signals are generated.
Figure 51.16 shows an example of the mute operation.

This figure applies when the respective bits in the SSICR register are as follows:
DEL bit = 0 (with delay), SDTA bit = 0 (I^2S), SPDP bit = 0 (padding with low),
LRCKP bit = 0 (low level for left channel), BCKP bit = 0 (output changes on falling edges),
SWL[2:0] bits = 001b (16 bits), DWL[2:0] bits = 001b (16 bits), and FRM[1:0] bits = 00b (2 system words)

Figure 51.16 Example of Mute Operation

51.3.2.2 LRCK Continuous Output Function

LRCK can be output from the SSILRCK pin even in the idle state by using the LRCK continuous output function. It is controlled by the SSIOFR.LRCONT bit.

Figure 51.17 shows an example of the operation with LRCK continuous output function.

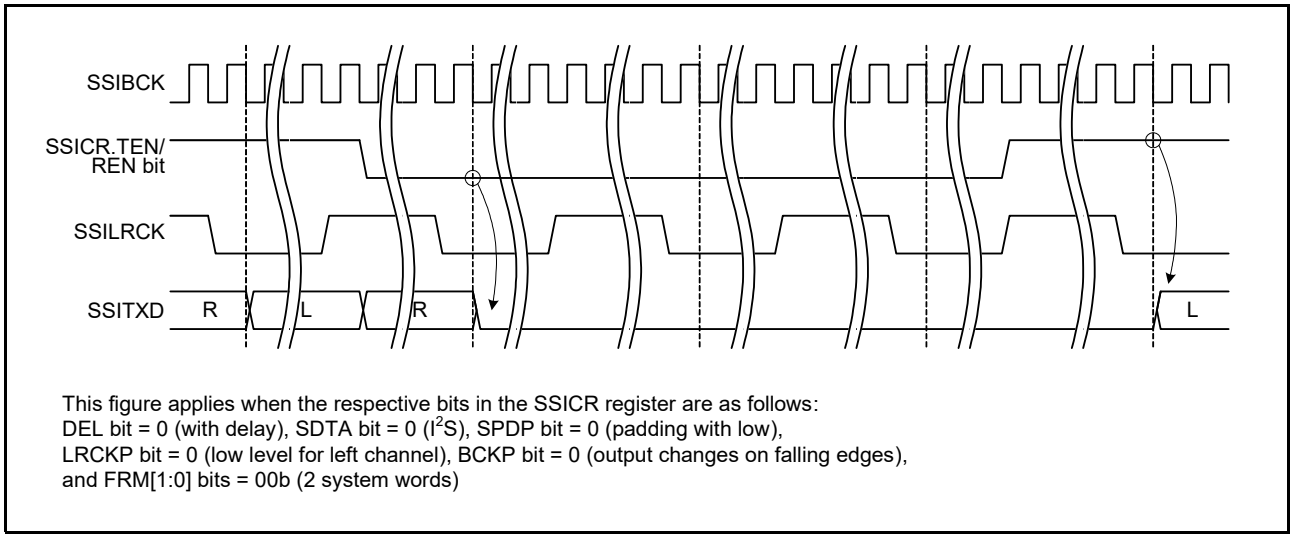

Figure 51.17 Example of Operation with LRCK Continuous Output Function

51.3.2.3 BCK Continuous Output Disable Function

BCK output from the SSIBCK pin can be stopped in the idle state by using the BCK continuous output disable function. It is controlled by the SSIOFR.BCKASTP bit. When the BCKASTP bit is set to 1, BCK stops in the idle state.

Set the BCKASTP bit to 0 and then start data transfer. If this bit is set to 1 during data transfer, BCK stops when SSIE enters the idle state. To resume the data transfer, set the BCKASTP bit to 0 to output BCK and then set the SSICR.TEN/REN bit to 1.

Figure 51.18 shows an example of the operation with BCK continuous output disable function.

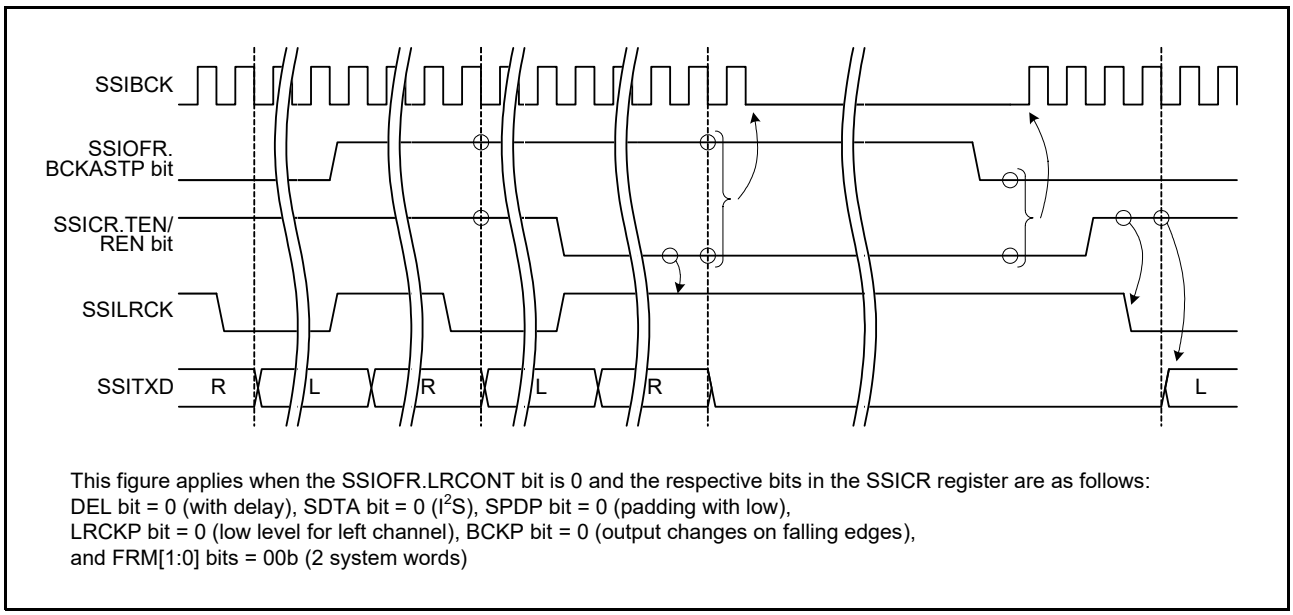

Figure 51.18 Example of Operation with BCK Continuous Output Disable Function

51.3.3 Transfer Modes

SSIE supports the transfer modes listed in Table 51.9. Table 51.10 lists the control bits valid in each transfer mode.

Table 51.9 Transfer Modes

Transfer Mode	SSICR.MST Bit	SSICR.REN Bit	SSICR.TEN Bit
Slave-mode transmission	0	0	1
Slave-mode reception	0	1	0
Slave-mode transception	0	1	1
Master-mode transmission	1	0	1
Master-mode reception	1	1	0
Master-mode transception	1	1	1

Table 51.10 Control Bits Valid in Each Transfer Mode*1

Control Bit		Transfer Mode					
Register	Bit	Slave-mode Reception	Slave-mode Transmission	Slave-mode Transception	Master-mode Reception	Master-mode Transmission	Master-mode Transception
SSICR	CKS	Ineffective	Ineffective	Ineffective	Effective	Effective	Effective
	CKDV[3:0]	Ineffective	Ineffective	Ineffective	Effective	Effective	Effective
	MUEN	Ineffective	Effective	Effective	Ineffective	Effective	Effective
SSIFCR	AUCKE	Ineffective	Ineffective	Ineffective	Effective	Effective	Effective
	TIE	Ineffective	Effective	Effective	Ineffective	Effective	Effective
	RIE	Effective	Ineffective	Effective	Effective	Ineffective	Effective
	TFRST	Ineffective	Effective	Effective	Ineffective	Effective	Effective
	RFRST	Effective	Ineffective	Effective	Effective	Ineffective	Effective
SSIOFR	BCKASTP	Ineffective	Ineffective	Ineffective	Effective	Effective	Effective
	LRCONT	Ineffective	Ineffective	Ineffective	Effective	Effective	Effective
	OMOD[1:0]	Effective	Effective	Effective	Effective	Effective	Effective
SSISCR	TDES[4:0]	Ineffective	Effective	Effective	Ineffective	Effective	Effective
	RDFS[4:0]	Effective	Ineffective	Effective	Effective	Ineffective	Effective

Note 1. “Ineffective” means that the setting of the bits does not affect operation.

51.3.3.1 Slave Mode

The SSIE operates in slave mode when the SSICR.MST bit is 0. The SSIBCK and SSILRCK signals must be supplied from an external device.

51.3.3.2 Master Mode

The SSIE operates in master mode when the SSICR.MST bit is 1. The SSIBCK and SSILRCK signals are internally generated from the master clock (MCK).

51.3.3.3 Transmission

The SSIE operates as a transmitter when the SSICR.TEN bit is 1 and the SSICR.REN bit is 0. Receive circuits do not operate.

51.3.3.4 Reception

The SSIE operates as a receiver when the SSICR.TEN bit is 0 and the SSICR.REN bit is 1. Transmit circuits do not operate.

51.3.3.5 Transception

The SSIE operates as a transceiver when both of the SSICR.TEN and SSICR.REN bits are 1.

51.3.4 State Transition

SSIE has the two main operation states: idle state and transfer state. The SSICR.TEN and SSICR.REN bits switch between these states. The SSISR.IIRQ flag can be used to confirm in which state SSIE is.
Figure 51.19 shows the state transition of the SSIE.

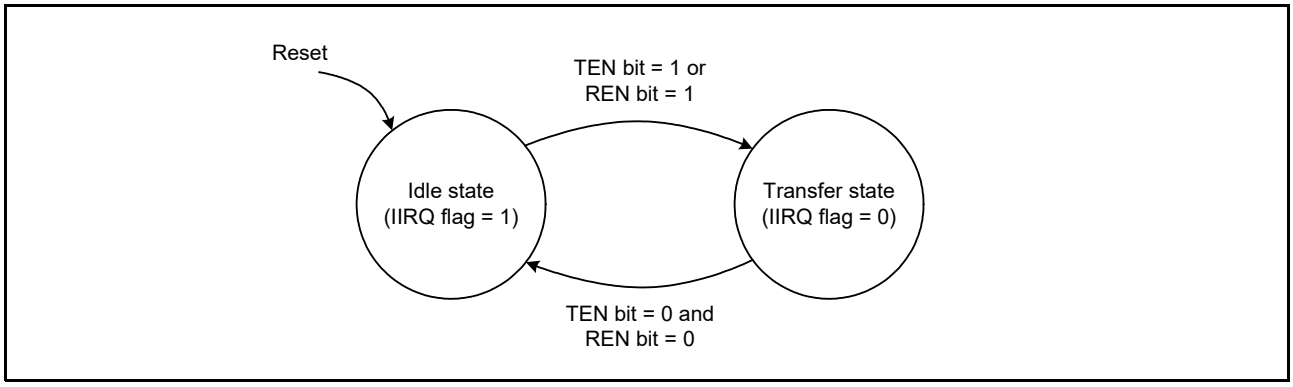

Figure 51.19 State Transition of the SSIE

51.3.4.1 Idle State

In the idle state, SSIE stops data transfer. When both or either of the SSICR.TEN and SSICR.REN bits are/is set to 1, the SSIE enters the transfer state.
Outputs of the BCK and LRCK in master mode can be controlled by the SSIOFR.BCKASTP and SSIOFR.LRCONT bits, respectively. For details, refer to Table 51.11.

Table 51.11 Output of Clock/Data in the Idle State

SSICR.MST Bit	SSIOFR.BCKASTP Bit	SSIOFR.LRCONT Bit	SSIBCK	SSILRCK	SSITXD
0	Invalid	Invalid	— (input)	— (input)	Stop
1	0	0	Supply	Stop	Stop
1	0	1	Supply	Supply	Stop
1	1	0	Stop	Stop	Stop
1	1	1	Stop	Supply	Stop

51.3.4.2 Transfer States

In this state, SSIE continues data transfer. When the SSICR.TEN and SSICR.REN bit is set to 0, SSIE enters the idle state.

For details, refer to Figure 51.20.

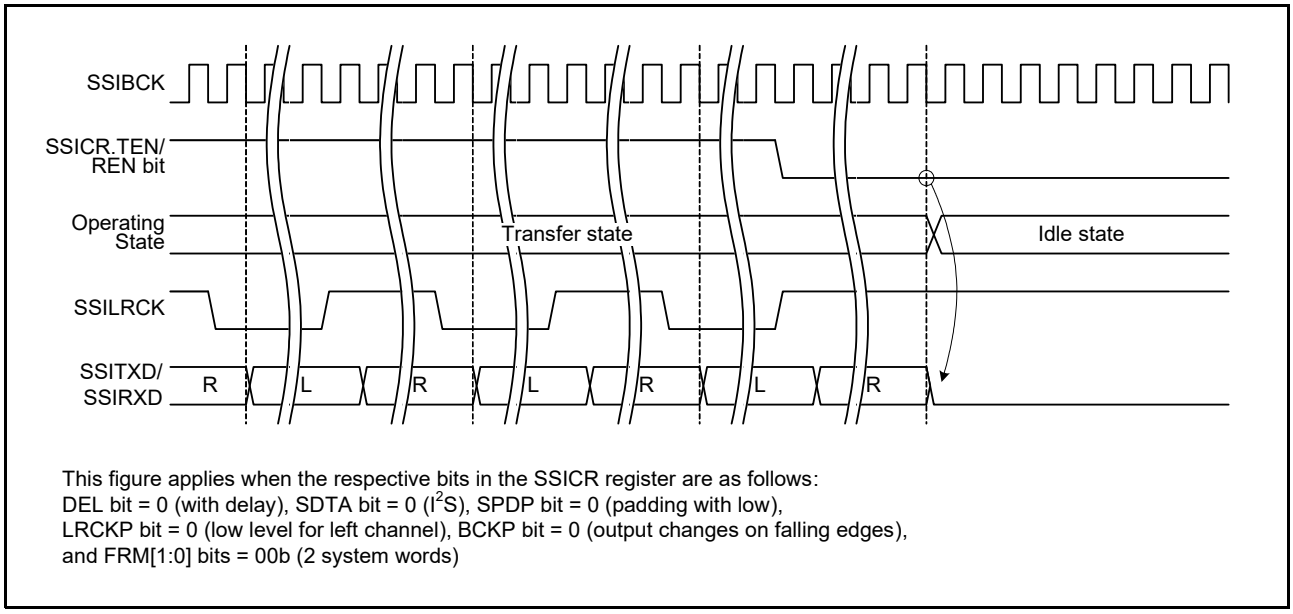

Figure 51.20 Transfer State and Transition to Idle State

51.3.5 SSIE Initialization

Figure 51.21 shows an example of the flow to initialize SSIE.

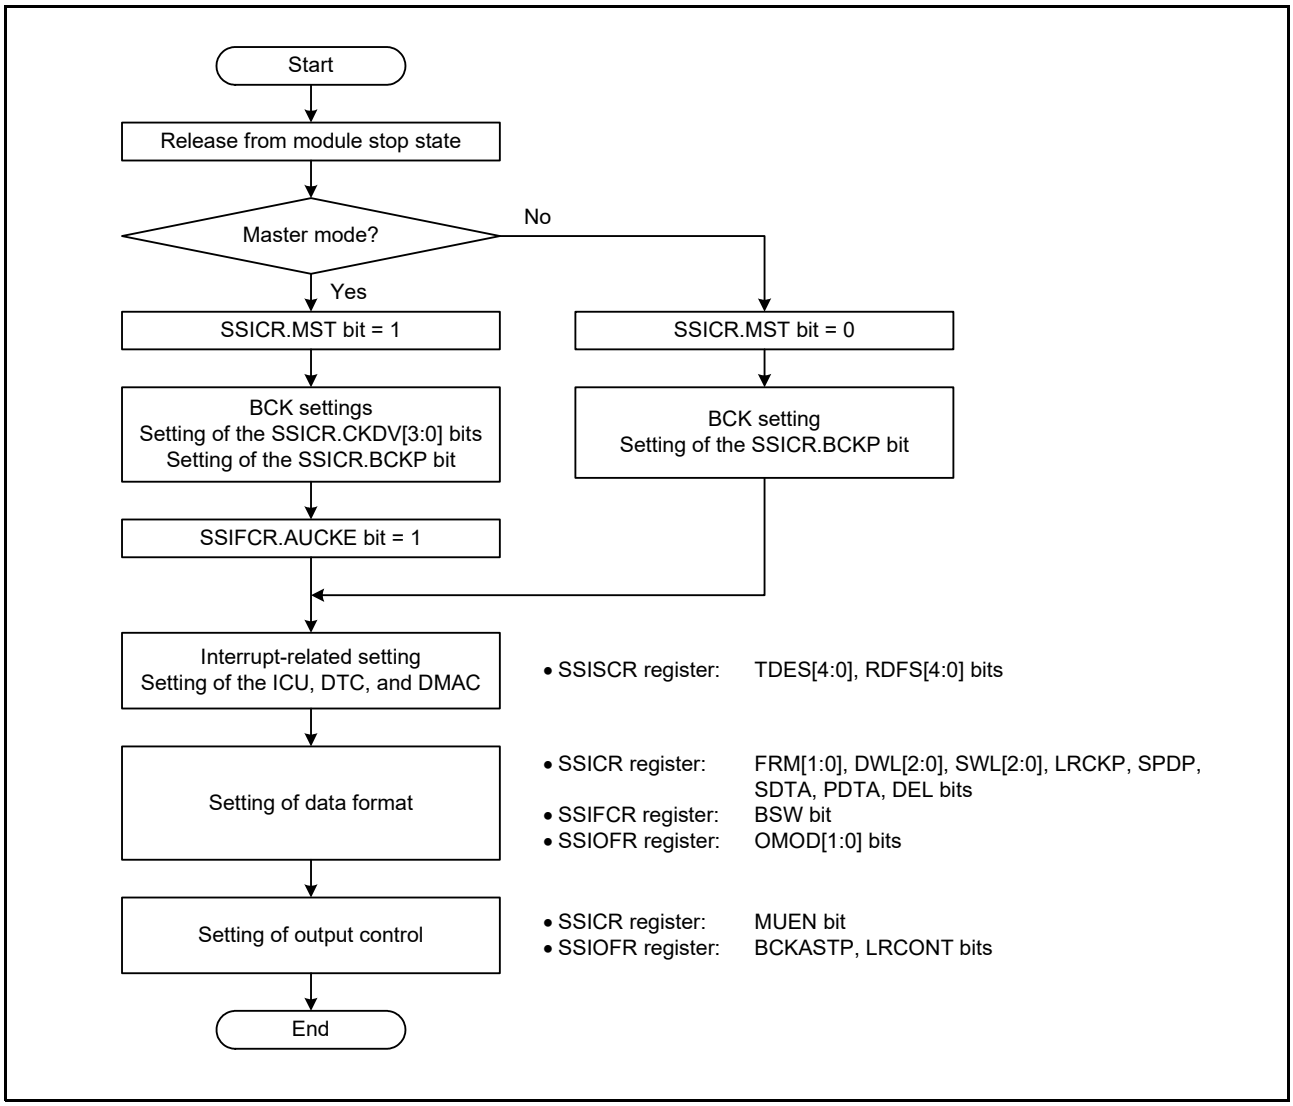

Figure 51.21 Example Flowchart of SSIE Initialization

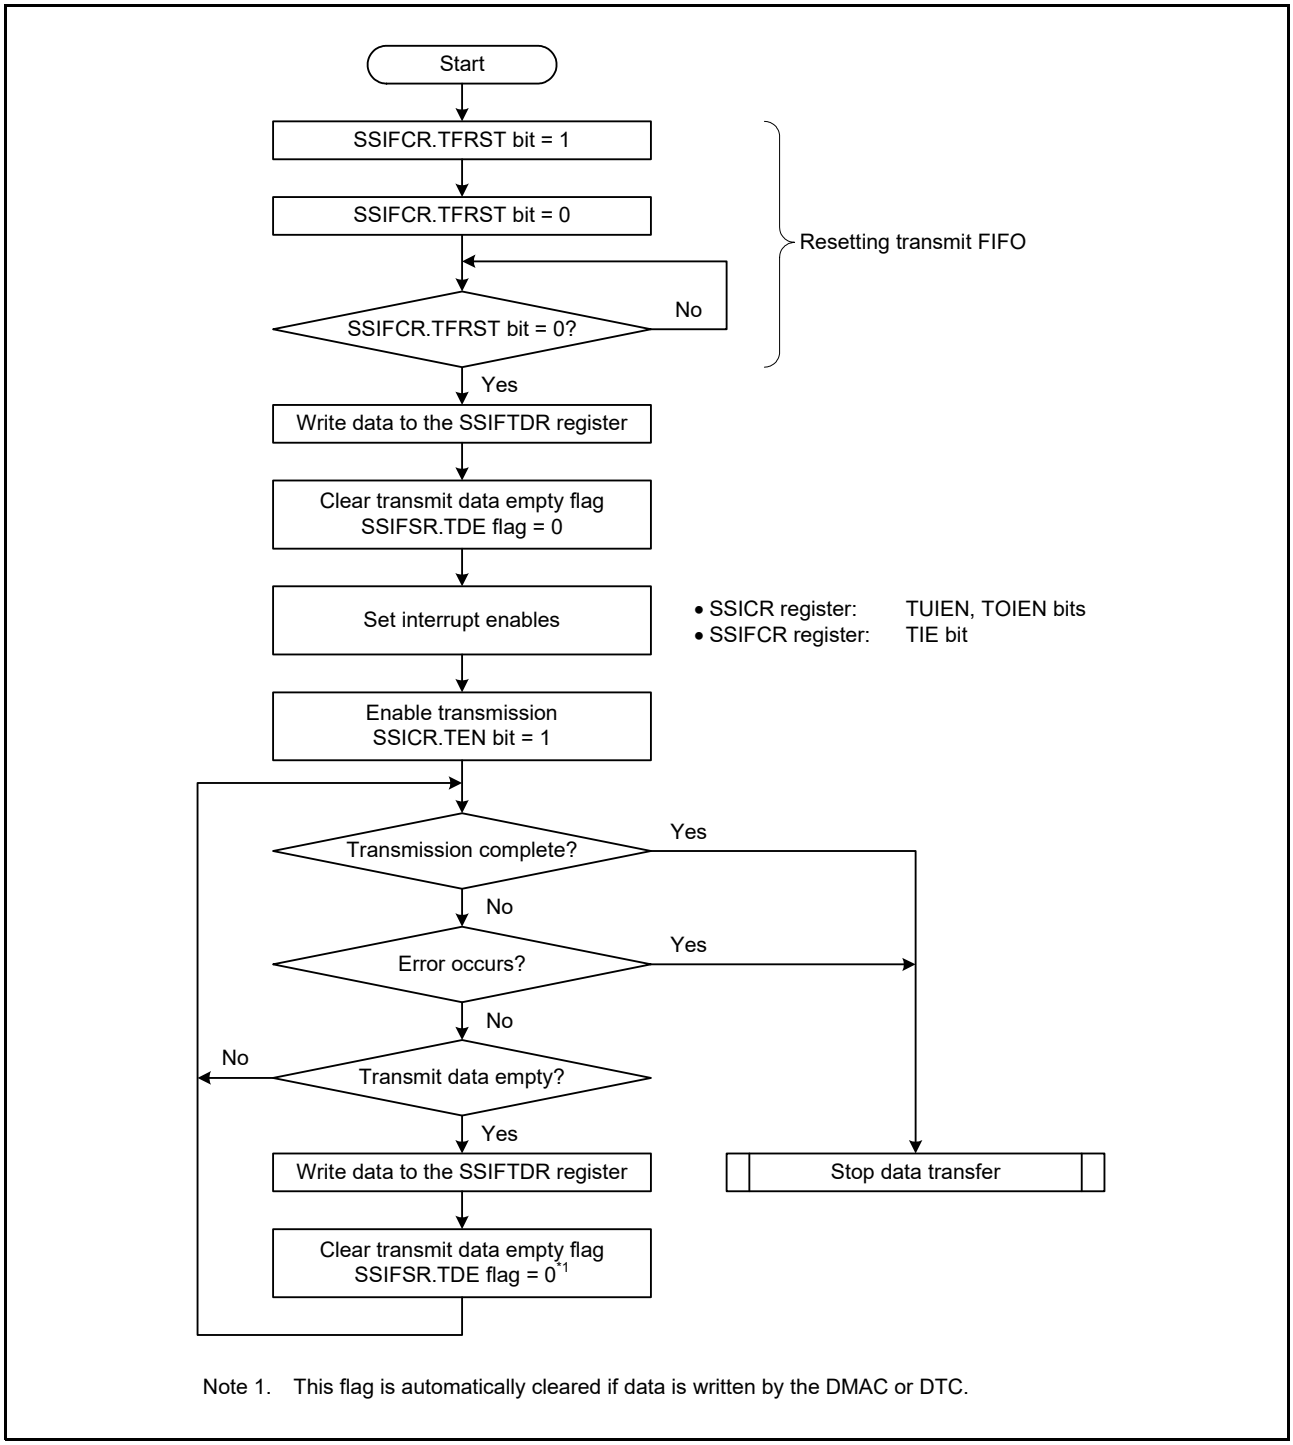
51.3.6 Transmission

Figure 51.22 shows an example of the flow to transmit data.
When the SSICR.TEN bit is set to 1 after setting the data for one frame in the SSIFTDR register, the SSIE starts transmission. When the number of spaces available in the transmit FIFO reaches the value specified by the SSISCR.TDES[4:0] bits while the SSIFCR.TIE bit is 1, a transmit data empty interrupt occurs. The number of data to be written to the SSIFTDR register should be determined in accordance with the space available in the transmit FIFO specified by the TDES[4:0] bits.



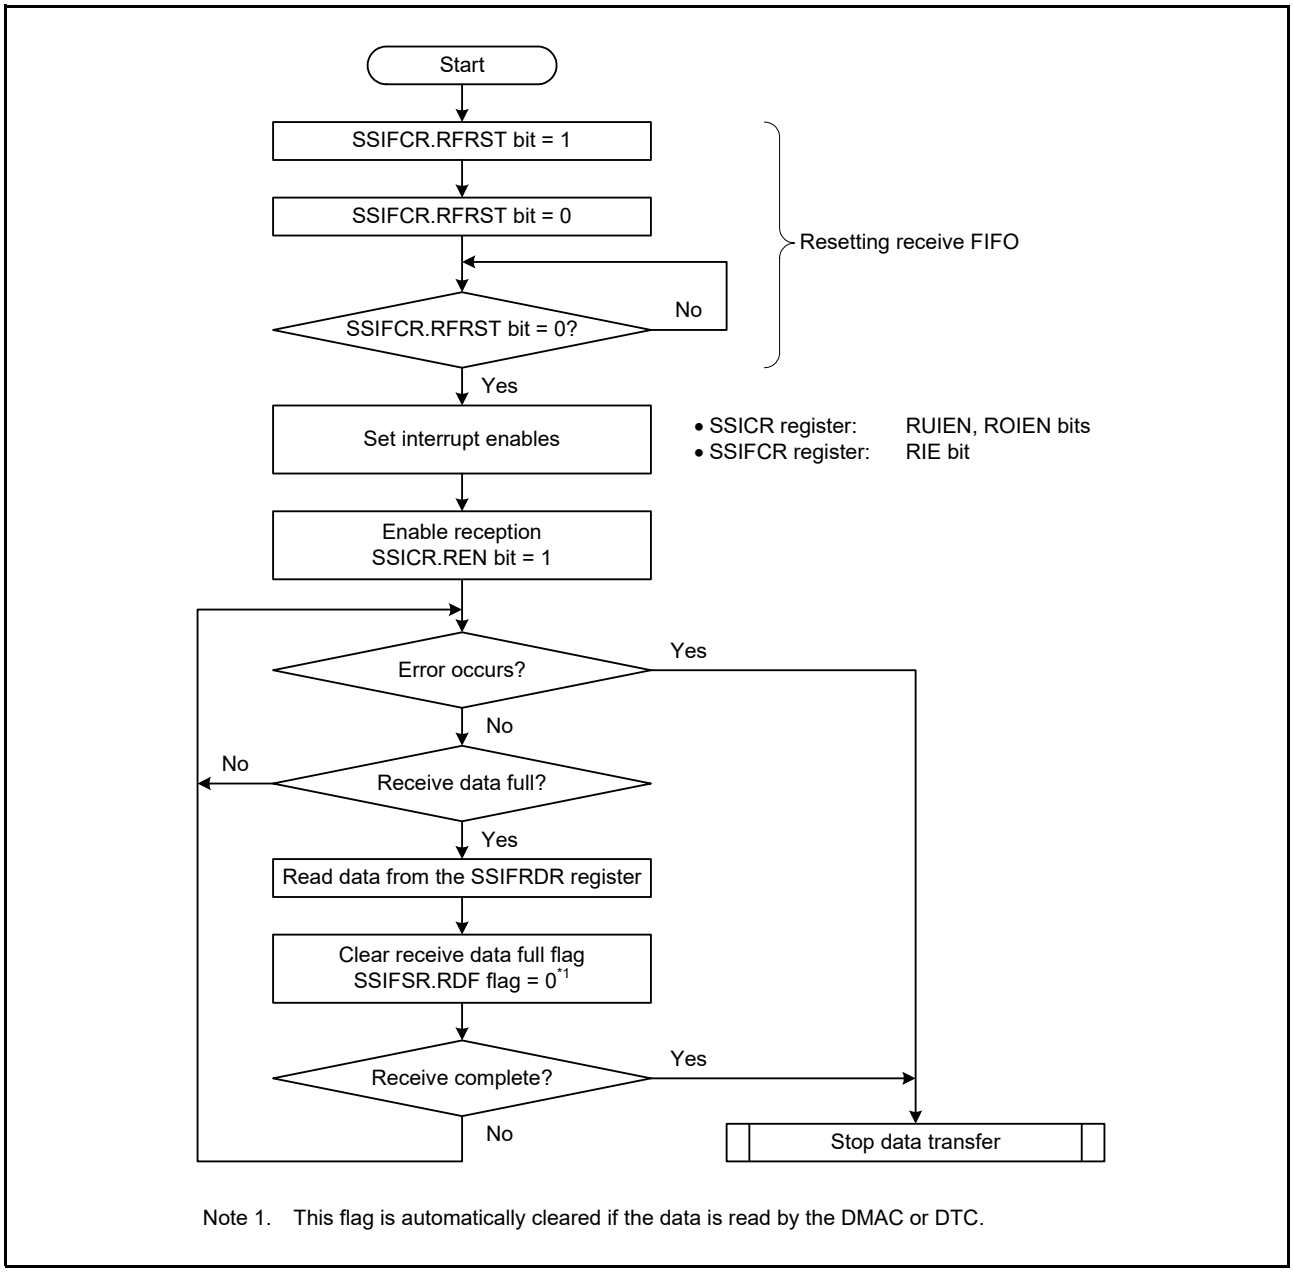


Figure 51.22 Example Flowchart of Transmission

51.3.7 Reception

Figure 51.23 shows an example of the flow to receive data.
When the SSICR.REN bit is set to 1, SSIE starts reception. When the number of data stored in the receive FIFO reaches to the value specified by the SSISCR.RDFS[4:0] bits while the SSIFCR.RIE bit is 1, a receive data full interrupt occurs. The number of data to be read from the SSIFRDR register should be determined in accordance with the number of data stored in the receive FIFO specified by the RDFS[4:0] bits.

Note 1. This flag is automatically cleared if the data is read by the DMAC or DTC.

Figure 51.23 Example Flowchart of Reception

51.3.8 Stop Data Transfer

Figure 51.24 shows an example of the flow to stop data transfer.

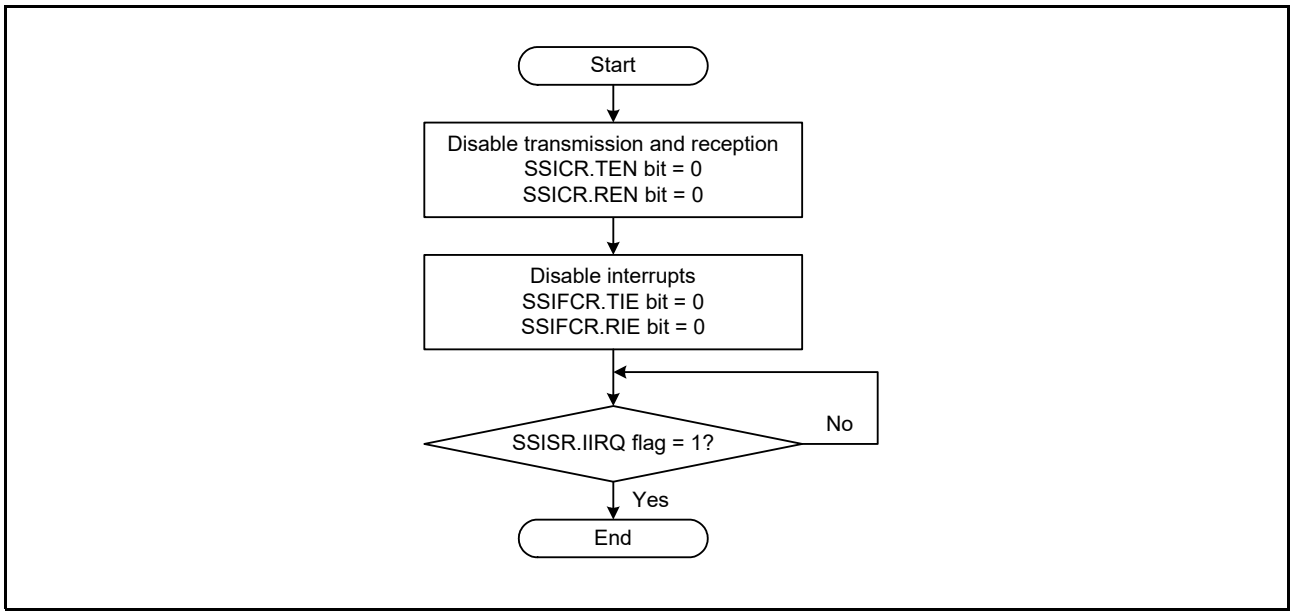

Figure 51.24 Example Flowchart of Stopping Data Transfer

To resume data transfer, conform with the example flowcharts of transmission and reception in Figure 51.22 and Figure 51.23, respectively. When changing the settings of clocks or switching a transfer mode between master and slave, start from initialization.

51.3.9 Error Processing

SSIE has the following four errors.

- Transmit underflow
- Transmit overflow
- Receive underflow
- Receive overflow

If an error has occurred, follow the procedure to stop data transfer shown in Figure 51.24 and then clear the corresponding flag. When an error has occurred while the corresponding interrupt enable bit in the SSICR register is 1, an interrupt is generated.

(1) Transmit Underflow

When a data transfer from the transmit FIFO to transmit shift register has performed while the transmit FIFO is empty, a transmit underflow is informed. If a transmit underflow has occurred, the SSITXD pin is driven low.

(2) Transmit Overflow

When a data is written to the SSIFTDR register while the transmit FIFO is full, a transmit overflow is informed. The data to be written is discarded.

(3) Receive Underflow

When a data is read from the SSIFRDR register while the receive FIFO is empty, a receive underflow is informed. The read data is undefined.

(4) Receive Overflow

When a data transfer from receive shift register to the receive FIFO has performed while the receive FIFO is full, a receive overflow is informed. The data to be transferred is discarded and is not stored in the receive FIFO.

51.4 Interrupts

Table 51.12 lists the interrupt sources. Figure 51.25 shows an block diagram for interrupts.

Table 51.12 SSIE Interrupt Sources

Channel	Name	Interrupt Source	Interrupt Request Flag	Interrupt Enable Bit	DMAC/DTC Triggerable
SSIE0	SSIF0	Transmit underflow interrupt Transmit overflow interrupt Receive underflow interrupt Receive overflow interrupt Idle state interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	SSICR.TUIEN SSICR.TOIEN SSICR.RUIEN SSICR.ROIEN SSICR.IIEN	No
	SSIRXI0	Receive data full interrupt	SSIFSR.RDF	SSIFCR.RIE	Yes
	SSITXI0	Transmit data empty interrupt	SSIFSR.TDE	SSIFCR.TIE	Yes
SSIE1	SSIF1	Transmit underflow interrupt Transmit overflow interrupt Receive underflow interrupt Receive overflow interrupt Idle state interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	SSICR.TUIEN SSICR.TOIEN SSICR.RUIEN SSICR.ROIEN SSICR.IIEN	No
	SSIRXI1	Receive data full interrupt	SSIFSR.RDF	SSIFCR.RIE	Yes
	SSITXI1	Transmit data empty interrupt	SSIFSR.TDE	SSIFCR.TIE	Yes

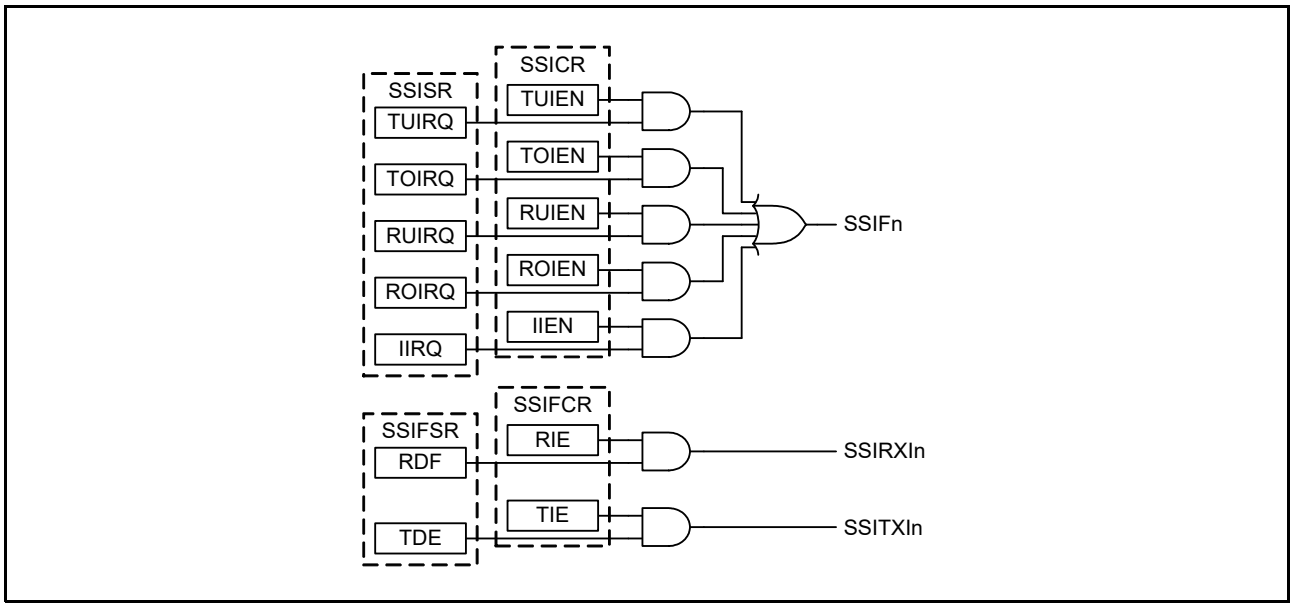

Figure 51.25 Interrupt System Block Diagram (n = 0, 1)

51.4.1 SSIFn Interrupt

Each SSIFn interrupt combines five interrupt sources (n = 0, 1). Each interrupt source has a status flag and an interrupt enable bit, so the interrupt can be enabled or disabled individually.

If an SSIFn interrupt occurs, read the SSISR register in the interrupt handling routine to check the source of the interrupt request, and then perform proper operation. To clear the interrupt request, set the corresponding interrupt enable bit to 0 or clear the interrupt request flag.

51.4.2 SSITXIn Interrupt

The SSITXIn interrupt (channel n transmit data empty interrupt) is an edge detection interrupt. This interrupt request is generated when either of the following conditions is satisfied.

- The SSIFSR.TDE flag has changed from 0 to 1 while the SSIFCR.TIE bit is 1.
- The SSIFCR.TIE bit has been changed from 0 to 1 while the SSIFSR.TDE flag is 1.

Figure 51.26 shows a timing chart when an interrupt request is generated when the TDE flag changes.

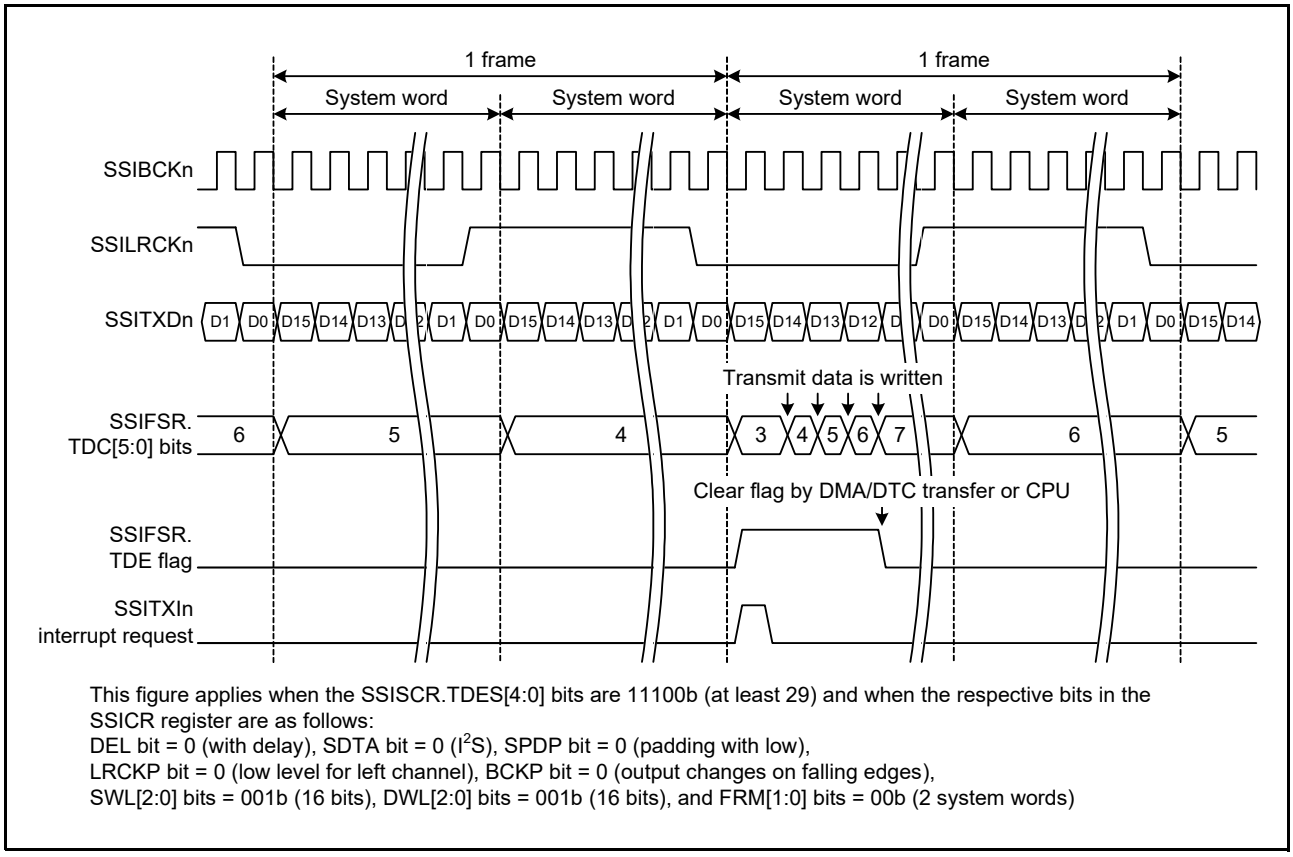

Figure 51.26 SSITXIn Interrupt Timing Chart (n = 0, 1)

51.4.3 SSIRXIn Interrupt

The SSIRXIn interrupt (channel n receive data full interrupt) is an edge detection interrupt. This interrupt request is generated when either of the following conditions is satisfied.

- The SSIFSR.RDF flag has changed from 0 to 1 while the SSIFCR.RIE bit is 1.
- The SSIFCR.RIE bit has been changed from 0 to 1 while the SSIFSR.RDF flag is 1.

Figure 51.27 shows a timing chart when an interrupt request is generated when the RDF flag changes.

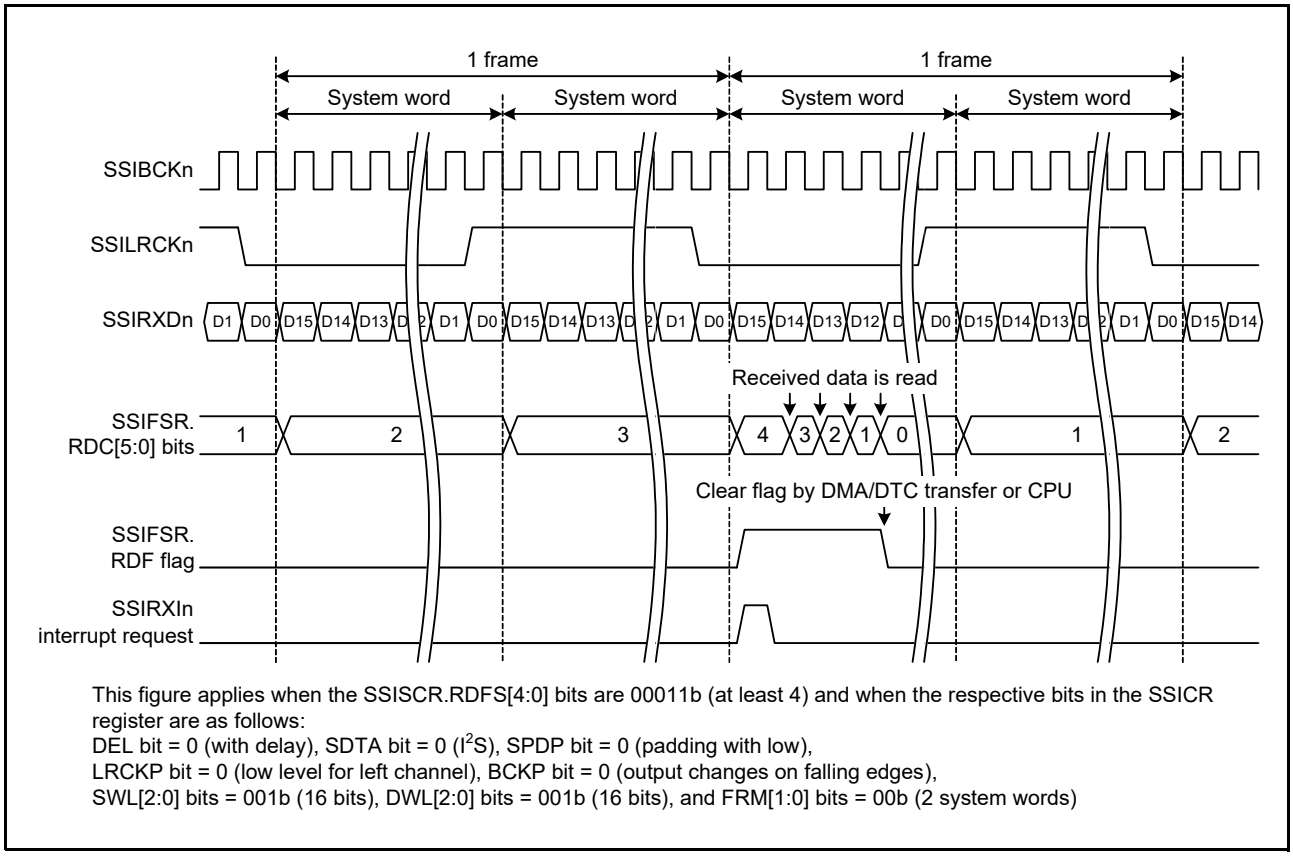

Figure 51.27 SSIRXIn Interrupt Timing Chart (n = 0, 1)

51.5 Notes

51.5.1 Setting the Module Stop Function

Operation of the SSIE can be enabled or disabled by setting a bit in the module stop control register C (MSTPCRC). The SSIE is initially disabled after a reset. Registers in the SSIE only become accessible after it has been released from the module stop state. For details, refer to section 11, Low Power Consumption.

51.5.2 Notes on AUDIO_CLK

In this MCU, the ProtectZone function allows signal input and output only when the security attributes of the peripheral function and the I/O pins match. The SSIE can change the security attribute for each channel. However, if the security attributes of SSIE0 and SSIE1 are different, using AUDIO_CLK on both channels results in the following specification mismatch.

- When the security attribute of the I/O pin is secure, if the security attribute of one channel is secure, AUDIO_CLK is input even if the other channel is non-secure.
- When the security attribute of the I/O pin is non-secure, even if the security attribute of one channel is non-secure, AUDIO_CLK is not input if the other channel is secure.

When setting different security attributes for SSIE0 and SSIE1, use them with the above understanding.
If there is a channel that is not used or does not use AUDIO_CLK, the above problem can be avoided by setting the SSICR.CKS bit of that channel to 1.

51.5.3 Note on LRCK in Slave Mode

The SSIE uses the SSILRCK signal as a start trigger in slave mode. Neither valid edges after the start trigger nor signal levels are used, so if a bit slippage occurs by a noise, the bit slippage cannot be repaired even at a frame boundary.

51.5.4 Transition to Software Standby Mode

Before transitioning to software standby mode, stop communication by following the procedure described in section 51.3.8, Stop Data Transfer. Additionally, if the SSIE is set to master mode, stop the clock output by setting the SSIOFR.BCKASTP bit to 1 and the SSIOFR.LRCONT bit to 0. After returning from software standby mode, set the BCKASTP and LRCONT bits before resuming communication.

52. SD/MMC Host Interface (SDHIc)

This MCU incorporates an SD/MMC host interface (SDHI) which is compliant with the SD Specifications and the *e*•MMC standard (JESD84-B451). When developing host devices that are compliant with the SD Specifications, the user must enter into the SD Host/Ancillary Product License Agreement (SD HALA).

52.1 Overview

Table 52.1 lists the SDHI specifications.

Table 52.1 SDHI Specifications

Item	Description
SD bus interface	• Compatible with SD memory card and SDIO card*1 • Transfer bus mode selectable from 4-bit wide bus mode or 1-bit default bus mode • Compatible with SD, SDHC, and SDXC formats • Selectable from default speed mode, high-speed mode, SDR12, or SDR25
MMC bus interface*2	• Supports *e*•MMC device • Transfer bus width selectable from 1, 4, or 8 bits • Selectable from backward compatible mode or high-speed SDR mode
SDHI clock	The SDHI clock is generated by dividing peripheral module clock B (PCLKB) by *n*, where *n* = 1, 2, 4, 8, 16, 32, 64, 128, 256, or 512
Error check functions	• CRC7 (command/response) • CRC16 (transfer data)
Interrupt sources	• Card access interrupt (CACI) • SDIO access interrupt (SDACI) • Card detection interrupt (CDETI) • SD buffer access interrupt (SBFAI)
DMA transfer sources	• DMAC and DTC triggerable by the SBFAI interrupt • SD buffer is read and write accessible using the DMAC and DTC
Other functions	• Card detection • Write protection
Low power consumption function	Module stop state can be set.
Protect Zone filter	Security attributes can be set.*3

Note 1. SPI bus interface, embedded SDIO shared bus, 8-bit SD bus, and SDIO suspend/resume functions are not supported.
Note 2. Stream read/write, high priority interrupt (HPI), boot operation, alternative boot operation, and open-ended multi block read/write are not supported.
Note 3. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Figure 52.1 shows a block diagram of the SDHI.

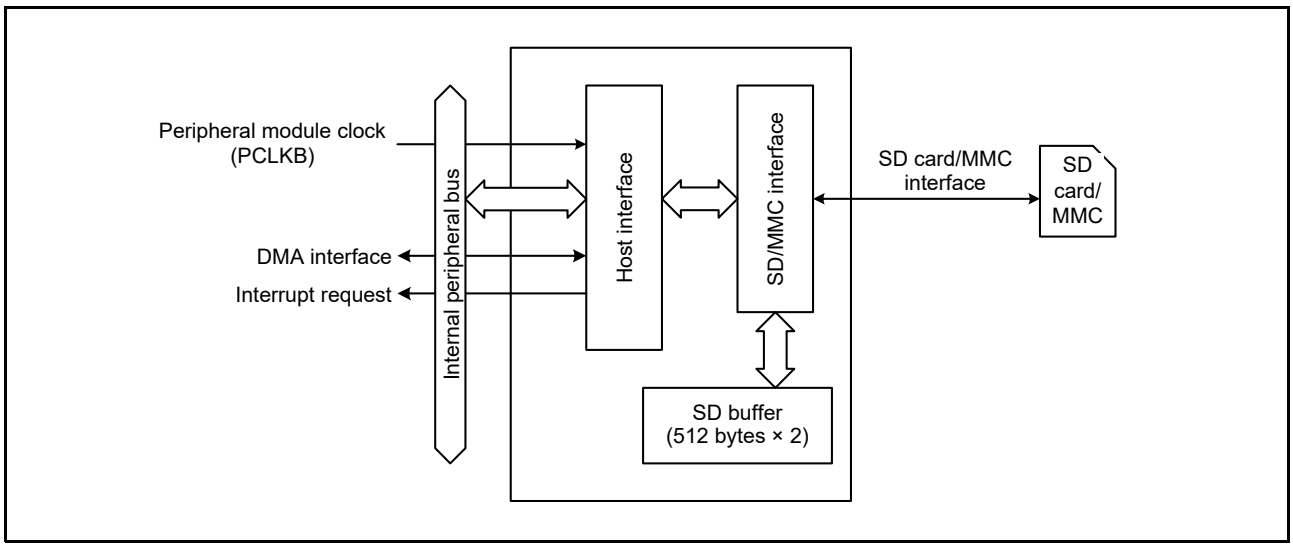

Figure 52.1 Block Diagram of the SDHI

Table 52.2 lists the pin configuration of the SDHI.

Table 52.2 Pin Configuration of the SDHI

Pin Name	I/O	Description
SD0_CLK	Output	SDHI clock
SD0_CMD	I/O	Command output, response input
SD0_DAT0	I/O	Data 0 (DAT0)
SD0_DAT1	I/O	Data 1 (DAT1), SDIO access interrupt
SD0_DAT2	I/O	Data 2 (DAT2), read wait
SD0_DAT3	I/O	Data 3 (DAT3), SD card detection
SD0_DAT4 to SD0_DAT7	I/O	Data 4 (DAT4) to Data 7 (DAT7) for MMC
SD0_CD	Input	SD card/MMC detection
SD0_WP	Input	SD card/MMC write protection

52.2 Register Descriptions

52.2.1 Command Register (SDCMD)

Address(es): SDHI.SDCMD 8785 2000h, SDHI_NS.SDCMD 0785 2000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMD12AT[1:0]		TRSTP	CMDRW	CMDTP	RSPTP[2:0]			ACMD[1:0]		CMDIDX[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	CMDIDX[5:0]	Command Index Field Value Select	These bits configure the command index field value. The examples below include the bit values for the ACMD[1:0] bits. b7 b0 0 0 0 0 0 1 1 0: CMD6 0 0 0 1 0 0 1 0: CMD18 0 1 0 0 1 1 0 1: ACMD13	R/W
b7, b6	ACMD[1:0]	Command Type Select	b7 b6 0 0: CMD 0 1: ACMD Only set the values listed above.	R/W
b10 to b8	RSPTP[2:0]	Response Type Select*1	b10 b8 0 0 0: Normal mode. Depending on the command, the response type and transfer method are selected by setting the ACMD[1:0] bits and CMDIDX[5:0] bits. At this time, the values for b15 to b11 in this register are invalid. 0 1 1: Expansion mode and no response 1 0 0: Expansion mode and R1, R5, R6, or R7 response 1 0 1: Expansion mode and R1b response 1 1 0: Expansion mode and R2 response 1 1 1: Expansion mode and R3 or R4 response Only set the values listed above.	R/W
b11	CMDTP	Data Transfer Select*2	0: Command does not include data transfer (bc, bcr, or ac) 1: Command includes data transfer (adtc)	R/W
b12	CMDRW	Data Transfer Direction Select*3	0: Write data to the SD card/MMC 1: Read data from the SD card/MMC	R/W
b13	TRSTP	Block Transfer Select*3	0: Single block transfer 1: Multiple blocks transfer	R/W
b15, b14	CMD12AT[1:0]	CMD12 Automatic Issue Select*4	b15 b14 0 0: CMD12 is automatically issued during multi-block transfer 0 1: CMD12 is not automatically issued during multi-block transfer Only set the values listed above.	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Some commands cannot be used in normal mode. Refer to Table 52.3 and set the RSPTP[2:0] bits.
Note 2. The CMDTP bit is valid only when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b.
Note 3. Bits CMDRW and TRSTP are valid only when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the CMDTP bit is 1.
Note 4. The CMD12AT[1:0] bits are valid only when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the TRSTP bit is 1.

The command type and response type are set in the SDCMD register. The command type and transfer mode must be set when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b. The sequence starts when a value is written to this register. Refer to Table 52.3 and Table 52.4 for setting examples. Do not write to the SDCMD register when the

SDSTS2.CBSY flag is 1.

Table 52.3 and Table 52.4 list examples of SDCMD register settings.

Table 52.3 Examples of SDCMD Register Settings (SD Card)

Type	Command Symbol	SDCMD Register Setting	Remarks
CMD	CMD0	0000 0000h	
	CMD2	0000 0002h	
	CMD3	0000 0003h	
	CMD4	0000 0004h	
	CMD5	0000 0705h or 0000 0005h	
	CMD6	0000 1C06h or 0000 0006h	
	CMD7	0000 0007h	When the card is deselected, the SD card does not return a response, so the SDSTS2.RSPTO flag becomes 1.
	CMD8	0000 0408h or 0000 0008h	
	CMD9	0000 0009h	
	CMD10	0000 000Ah	
	CMD11	0000 040Bh or 0000 000Bh	
	CMD12	0000 000Ch	
	CMD13	0000 000Dh	
	CMD15	0000 000Fh	
	CMD16	0000 0010h	
	CMD17	0000 0011h	
	CMD18	0000 0012h	Auto CMD12 enabled
	CMD20	0000 0514h or 0000 0014h	
	CMD24	0000 0018h	
	CMD25	0000 0019h	Auto CMD12 enabled
	CMD27	0000 001Bh	
	CMD28	0000 001Ch	
	CMD29	0000 001Dh	
	CMD30	0000 001Eh	
	CMD32	0000 0020h	
	CMD33	0000 0021h	
	CMD38	0000 0026h	
	CMD42	0000 002Ah	
	CMD52	0000 0434h or 0000 0034h	
	CMD53	0000 1C35h	Single block read
		0000 0C35h	Single block write
		0000 7C35h	Multi-block read
		0000 6C35h	Multi-block write
		0000 0035h	The setting to the left can be used regardless of the transfer being single block or multi-block. However, the MSB in the SDARG register (RW flag) must be set to 0 when reading and 1 when writing.
	CMD55	0000 0037h	
	CMD56	0000 0038h	
ACMD	ACMD6	0000 0046h

Table 52.4 Examples of SDCMD Register Settings (MMC)

Type	Command Symbol	SDCMD Register Setting	Remarks
CMD	CMD0	0000 0000h	
	CMD1	0000 0701h	
	CMD2	0000 0002h	
	CMD3	0000 0003h	
	CMD4	0000 0004h	
	CMD5	0000 0505h	
	CMD6	0000 0506h or 0000 0406h	
	CMD7	0000 0007h	When the card is deselected, the MMC does not return a response, so the SDSTS2.RSPTO flag becomes 1.
	CMD8	0000 1C08h	
	CMD9	0000 0009h	
	CMD10	0000 000Ah	
	CMD12	0000 000Ch	
	CMD13	0000 000Dh	
	CMD14	0000 1C0Eh	Set the SDIFMD.NOCHKCR bit to 1 (CRC check is disabled).
	CMD15	0000 000Fh	
	CMD16	0000 0010h	
	CMD17	0000 0011h	
	CMD18	0000 7C12h	Pre-defined block count
	CMD19	0000 0C13h	Set the SDIFMD.NOCHKCR bit to 1 (CRC check is disabled).
	CMD21	0000 1C15h	
	CMD23	0000 0017h	
	CMD24	0000 0018h	
	CMD25	0000 6C19h	Pre-defined block count
	CMD26	0000 0C1Ah	
	CMD27	0000 001Bh	
	CMD28	0000 001Ch	
	CMD29	0000 001Dh	
	CMD30	0000 001Eh	
	CMD31	0000 1C1Fh	
	CMD35	0000 0423h	
	CMD36	0000 0424h	
	CMD38	0000 0026h	
	CMD39	0000 0427h	
	CMD40	0000 0428h	
	CMD42	0000 002Ah	
	CMD49	0000 0C31h	
	CMD53	0000 7C35h	
	CMD54	0000 6C36h	
	CMD55	0000 0037h	
	CMD56	0000 0038h	

52.2.2 Argument Register (SDARG)

Address(es): SDHI.SDARG 8785 2008h, SDHI_NS.SDARG 0785 2008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The SDARG register is used for setting the argument field value. Set the SDARG register before setting the SDCMD register. The argument field value of the automatically issued CMD12 is 0000 0000h regardless of the SDARG register value.

52.2.3 Data Stop Register (SDSTOP)

Address(es): SDHI.SDSTOP 8785 2010h, SDHI_NS.SDSTOP 0785 2010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SDBLKCNTEN	—	—	—	—	—	—	—	STP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STP	Transfer Stop	Data transfer stops when this bit is set to 1.	R/W
b7 to b1	—	Reserved	These bits are 0 when read and cannot be modified.	R
b8	SDBLKCNTEN	Block Count Register Value Select*1	0: SDBLKCNT register value is invalid 1: SDBLKCNT register value is valid	R/W
b31 to b9	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY flag is 1.

The SDSTOP register stops data transfer. During a multi-block transfer sequence, the SDBLKCNT register value (number of blocks to be transferred) can be set to valid or invalid by setting the SDSTOP register.

STP Bit (Transfer Stop)

When setting the STP bit to 1, set it after the SDSTS1.RSPEND flag becomes 1; when setting the STP bit to 0, set it after the SDSTS1.ACEND flag becomes 1. After a command sequence is complete, the SDHI does not issue CMD12 and the SDSTS1.ACEND flag does not become 1 even if the STP bit is set to 1. When the SDHI is in the busy state after receiving the R1b response, the SDHI does not issue CMD12 even if the STP bit is 1, and after the SDHI is released from the busy state, the SDSTS1.ACEND flag becomes 1.

- Performing a multi-block transfer
  When the STP bit is set to 1, the SDHI issues CMD12, and the command sequence is stopped. The SD buffer can be accessed even after the STP bit is set to 1, but a buffer access error occurs and the SDSTS2.ILW flag or SDSTS2.ILR flag becomes 1. If the command sequence stops due to a communication error or a timeout, the SDHI does not issue CMD12.
- Performing a single block transfer
  When the STP bit is set to 1 during a single block write access, if there is no data in the SD buffer, the SDSTS1.ACEND flag becomes 1. If there is data in the SD buffer, after the SDHI is released from the busy state, the SDSTS1.ACEND flag becomes 1. When the STP bit is set to 1 during a single block read access, the SDSTS1.ACEND flag becomes 1. Also, CMD12 is not issued even if the STP bit is set to 1 during a single block read access or single block write access.

SDBLKCNTEN Bit (Block Count Register Value Select)

If the SDBLKCNTEN bit is 1 during a multi-block transfer sequence, the SDHI automatically issues CMD12. When the SDCMD.RSPTP[2:0] bits are set to 000b and CMD18 or CMD25 is issued, or if the SDCMD.RSPTP[2:0] bits are set to 011b, 100b, 101b, 110b, or 111b and the SDCMD.TRSTP bit is 1 (multiple blocks transferred), if the SDCMD.CMD12AT[1:0] bits are 00b (CMD12 is automatically issued during multi-block transfer), and the number of transfer blocks reaches the value set in the SDBLKCNT register, the SDHI automatically issues CMD12.
If the command sequence is stopped by a communication error or a timeout, CMD12 is not automatically issued.

52.2.4 Block Count Register (SDBLKCNT)

Address(es): SDHI.SDBLKCNT 8785 2014h, SDHI_NS.SDBLKCNT 0785 2014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

When performing a multi-block transfer, SDBLKCNT is a readable/writable register used to set the number of blocks to be transferred. For example, when the register value is 0000 0001h, 1 block is transferred; when the register value is 0000 FFFFh, 65,535 blocks are transferred; and when the register value is FFFF FFFFh, 4,294,967,295 blocks are transferred. Do not set this register to 0000 0000h. Do not rewrite the SDBLKCNT register when the SDSTS2.CBSY flag is 1.

52.2.5 Response Register 10 (SDRSP10), Response Register 32 (SDRSP32), Response Register 54 (SDRSP54), Response Register 76 (SDRSP76)

- SDRSP10, SDRSP32, SDRSP54

Address(es): SDHI.SDRSP10 8785 2018h, SDHI.SDRSP32 8785 2020h, SDHI.SDRSP54 8785 2028h, SDHI_NS.SDRSP10 0785 2018h, SDHI_NS.SDRSP32 0785 2020h, SDHI_NS.SDRSP54 0785 2028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- SDRSP76

Address(es): SDHI.SDRSP76 8785 2030h, SDHI_NS.SDRSP76 0785 2030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Registers SDRSP10, SDRSP32, SDRSP54, and SDRSP76 are read-only registers that store the response from the SD card/MMC. Depending on the type of response from the SD card/MMC, the SDHI divides and stores the response among the four registers.
Table 52.5 lists the correspondence between the response type and its storage destination.

Table 52.5 Correspondence Between the Response Type and Its Storage Destination

Response Type	SDRSP76 Register	SDRSP54 Register	SDRSP32 Register	SDRSP10 Register
R1	—	[39:8] *1	—	[39:8]
R1b	—	[39:8] *1	—	[39:8]
R2	[127:104]	[103:72]	[71:40]	[39:8]
R3	—	—	—	[39:8]
R4	—	—	—	[39:8]
R5	—	—	—	[39:8]
R6	—	—	—	[39:8]
R7	—	—	—	[39:8]

Note 1. The responses for CMD18 and CMD25 are stored in registers SDRSP10 and SDRSP54. Therefore, even if the SDRSP10 register is overwritten with the response for the automatically transmitted CMD12, the response for CMD18 or CMD25 can be confirmed by reading the SDRSP54 register.

52.2.6 SD Status Register 1 (SDSTS1)

Address(es): SDHI.SDSTS1 8785 2038h, SDHI_NS.SDSTS1 0785 2038h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SDD3MON	SDD3IN	SDD3RM	SDWPMON	—	SDCDMON	SDCDIN	SDCDRM	ACEND	—	RSPEND
Value after reset:	0	0	0	0	0	x	0	0	x	0	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	RSPEND	Response End Detection Flag	0: Response end is not detected 1: Response end is detected	R/(W) *1
b1	—	Reserved	This bit is 0 when read and cannot be modified.	R
b2	ACEND	Access End Detection Flag	0: Access end is not detected 1: Access end is detected	R/(W) *1
b3	SDCDRM	SD0_CD Removal Flag	0: SD card/MMC removal not detected by the SD0_CD pin 1: SD card/MMC removal detected by the SD0_CD pin	R/(W) *1
b4	SDCDIN	SD0_CD Insertion Flag	0: SD card/MMC insertion not detected by the SD0_CD pin 1: SD card/MMC insertion detected by the SD0_CD pin	R/(W) *1
b5	SDCDMON	SD0_CD Pin Monitor Flag	0: SD0_CD pin level is high *2 1: SD0_CD pin level is low *2	R
b6	—	Reserved	This bit is 0 when read and cannot be modified.	R
b7	SDWPMON	SD0_WP Pin Monitor Flag	0: SD0_WP pin level is high 1: SD0_WP pin level is low	R
b8	SDD3RM	SD0_DAT3 Removal Flag	0: SD card/MMC removal not detected by the SD0_DAT3 pin 1: SD card/MMC removal detected by the SD0_DAT3 pin	R/(W) *1
b9	SDD3IN	SD0_DAT3 Insertion Flag	0: SD card/MMC insertion not detected by the SD0_DAT3 pin 1: SD card/MMC insertion detected by the SD0_DAT3 pin	R/(W) *1
b10	SDD3MON	SD0_DAT3 Pin Monitor Flag	0: SD0_DAT3 pin level is low 1: SD0_DAT3 pin level is high	R
b31 to b11	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.
Note 2. The flag changes when the pin level continues for the period set in the SDOPT.CTOP[3:0] bits or longer.

The SDSTS1 register indicates the detection of a response end or access end for a command sequence. The SDSTS1 register also indicates the detection SD card/MMC insertion/removal, and indicates the write protection status.
During a multi-block transfer sequence, if CMD12 or CMD52 (SDIO abort) is issued, the ACEND flag becomes 1, but the RSPEND flag remains set to 0.
If the command sequence is stopped due to a communication error or timeout, the ACEND flag or RSPEND flag becomes 1.
After a reset is released, the SDD3MON flag, SDD3IN flag, and SDD3RM flag values are changed according to the status of the SD0_DAT3 pin, and their values are changed when data is being transferred in wide bus mode.
Flags to be cleared should be set to 0; flags not being cleared should be set to 1.

RSPEND Flag (Response End Detection Flag)

— This flag becomes 1 under any of the following conditions:

- A response is received.
- A command that does not have a response is issued.
- After the R1b response is received, the SDHI is released from the busy state.
- During a multi-block transmission, after the SDIOMD.C52PUB bit is set to 1, the CMD52 response is received.
- A communication error or timeout causes the command sequence to abort.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

Note: When a command is issued that is absent of data transfer, the RSPEND flag becomes 1 after the command sequence ends.

ACEND Flag (Access End Detection Flag)

— This flag becomes 1 under any of the following conditions:

- During a single block read sequence, the SD buffer read access is completed.
- During a multi-block read sequence, the last block is read from the SD buffer.
- During a multi-block read sequence, if CMD12 is automatically issued, data is read from the SD buffer, and the response for CMD12 is received.
- During a single block write sequence, after a CRC status token is received, the SDHI is released from the busy state.
- During a multi-block write sequence, after a CRC status token is received for the last block, the SDHI is released from the busy state.
- During a multi-block write sequence, when CMD12 is automatically issued, a response busy of the automatically issued CMD12 is received.
- During a multi-block read sequence, when CMD12 is automatically issued, after setting the SDSTOP.STP bit to 1, a response of the automatically issued CMD12 is received.
- During a multi-block write sequence, when CMD12 is automatically issued, after setting the SDSTOP.STP bit to 1, a response busy of the automatically issued CMD12 is received.
- During a multi-block read sequence, after the SDIOMD.IOABT bit is set to 1, the response for CMD52 is received.
- During a multi-block write sequence, after the SDIOMD.IOABT bit is set to 1, the response for CMD52 is received.
- A communication error or timeout causes the command sequence to abort.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

Note: The ACEND flag becomes 1 after the command sequence ends.

SDCDRM Flag (SD0_CD Removal Flag)

— This flag becomes 1 under the following condition:

- The SD0_CD pin changes from low to high, and the high period is the period set in the SDOPT.CTOP[3:0] bits or longer.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDCDIN Flag (SD0_CD Insertion Flag)

— This flag becomes 1 under the following condition:

- The SD0_CD pin changes from high to low, and the low period is the period specified in the SDOPT.CTOP[3:0] bits or longer.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDD3RM Flag (SD0_DAT3 Removal Flag)

— This flag becomes 1 under the following condition:

- The SD0_DAT3 pin changes from high to low, and the low period is at least two PCLKB cycles.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDD3IN Flag (SD0_DAT3 Insertion Flag)

— This flag becomes 1 under the following condition:

- The SD0_DAT3 pin changes from low to high, and the high period is at least two PCLKB cycles.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

52.2.7 SD Status Register 2 (SDSTS2)

Address(es): SDHI.SDSTS2 8785 203Ch, SDHI_NS.SDSTS2 0785 203Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ILA	CBSY	SDCLKCREN	—	—	—	BWE	BRE	SDD0MON	RSPTO	ILR	ILW	DTO	ENDE	CRCE	CMDE
Value after reset:	0	0	1	0	0	0	0	0	x	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	CMDE	Command Error Detection Flag	0: Command error not detected 1: Command error detected	R/(W) *1
b1	CRCE	CRC Error Detection Flag	0: CRC error not detected 1: CRC error detected	R/(W) *1
b2	ENDE	End Bit Error Detection Flag	0: End bit error not detected 1: End bit error detected	R/(W) *1
b3	DTO	Data Timeout Detection Flag	0: Data timeout not detected 1: Data timeout detected	R/(W) *1
b4	ILW	SDBUFR Illegal Write Access Detection Flag	0: Illegal write access to the SDBUFR register not detected 1: Illegal write access to the SDBUFR register detected	R/(W) *1
b5	ILR	SDBUFR Illegal Read Access Detection Flag	0: Illegal read access to the SDBUFR register not detected 1: Illegal read access to the SDBUFR register detected	R/(W) *1
b6	RSPTO	Response Timeout Detection Flag	0: Response timeout not detected 1: Response timeout detected	R/(W) *1
b7	SDD0MON	SD0_DAT0 Pin Status Flag	0: SD0_DAT0 pin is low 1: SD0_DAT0 pin is high	R
b8	BRE	SDBUFR Read Enable Flag	0: Read access to the SDBUFR register disabled 1: Read access to the SDBUFR register enabled	R/(W) *1
b9	BWE	SDBUFR Write Enable Flag	0: Write access to the SDBUFR register disabled 1: Write access to the SDBUFR register enabled	R/(W) *1
b10	—	Reserved	This bit is 0 when read and cannot be modified.	R
b11	—	Reserved	This bit is 0 when read. Set it to 1 when writing.	R/W
b12	—	Reserved	This bit is 0 when read and cannot be modified.	R
b13	SDCLKCREN	SDCLKCR Write Enable Flag	0: SD/MMC bus (CMD and DAT lines) is busy, so write access to the SDCLKCR.CLKEN bit and CLKSEL[7:0] bits is disabled. 1: SD/MMC bus (CMD and DAT lines) is not busy, so write access to the SDCLKCR.CLKEN bit and CLKSEL[7:0] bits is enabled.	R
b14	CBSY	Command Sequence Status Flag	0: Command sequence completed 1: Command sequence in progress (busy)	R
b15	ILA	Illegal Access Error Detection Flag	0: Illegal access error not detected 1: Illegal access error detected	R/(W) *1
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.

The SDSTS2 register indicates the status of the SD buffer and the status of the SD card/MMC. Flags to be cleared should be set to 0; flags not being cleared should be set to 1.

CMDE Flag (Command Error Detection Flag)

The command sequence is stopped when a command error occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 52.3.6.9 or section 52.3.6.10 and complete the command sequence.

— This flag becomes 1 under any of the following conditions:

- The command index field value for the command transmitted differs from the command index field value for the response received.
- The command index field value for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer) differs from the command index field value for the response received.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

CRCE Flag (CRC Error Detection Flag)

The command sequence is stopped when a CRC error occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 52.3.6.9 or section 52.3.6.10 and complete the command sequence.

— This flag becomes 1 under any of the following conditions:

- The received CRC status token is in error (the value of the CRC status is a value other than 010b).
- The read data contains a CRC error.
- The response contains a CRC error.
- The response for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer) contains a CRC error.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

ENDE Flag (End Bit Error Detection Flag)

The command sequence is stopped when an end bit error occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 52.3.6.9 or section 52.3.6.10 and complete the command sequence.

— This flag becomes 1 under any of the following conditions:

- The response length is in error (the end bit could not be detected).
- The read data length is in error (the end bit of the enabled bit could not be detected).
- The CRC status token length is in error (the end bit could not be detected).
- The response length for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer) contains an error (the end bit could not be detected).

— This flag becomes 0 under the following condition:

- The flag is set to 0.

DTO Flag (Data Timeout Detection Flag)

This flag indicates that the data expected to be received during the period specified (set in the SDOPT.TOP[3:0] bits) was not received. However, response timeouts are excluded. The command sequence stops when a data timeout occurs.

— This flag becomes 1 under any of the following conditions:

- After the R1b response is received, the SDHI is busy for the period specified or longer.
- After the CRC status token is received, the SDHI is busy for the period specified or longer.
- After data is written, the CRC status token is not received even after the period specified elapsed.
- After a read command is issued, the read data is not received even after the period specified elapsed.
- After CMD12 is issued during a command sequence, the SDHI is busy for the period specified or longer.
- After the read data is received, the next read data is not received even after the period specified elapsed.
- After the SDHI exits the read wait state, the next read data is not received even after the period specified elapsed.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

ILW Flag (SDBUFR Illegal Write Access Detection Flag)

— This flag becomes 1 under any of the following conditions:

- A value is written to the SDBUFR register while the SDHI is not in the data read or data write command state.
- A value is written to the SDBUFR register while the SD buffer is full.
- A value is written to the SDBUFR register while the CRC status token or CRC status token length is in error.
- After the CRC status token is received, a value is written to the SDBUFR register if the SDHI is busy for the period set in bits SDOPT.TOP[3:0] or longer.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

ILR Flag (SDBUFR Illegal Read Access Detection Flag)

— This flag becomes 1 under any of the following conditions:

- The SDBUFR register is read while the SD buffer is empty.
- The value read from the SDBUFR register includes a CRC error or end bit error.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

RSPTO Flag (Response Timeout Detection Flag)

The command sequence is stopped when a response timeout occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 52.3.6.9 or section 52.3.6.10 and complete the command sequence.

— This flag becomes 1 under the following condition:

- A response is not received even after 640 SDHI clock cycles or more have elapsed (including the response for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer)).

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDD0MON Flag (SD0_DAT0 Pin Status Flag)

This flag indicates the status of the SD0_DAT0 pin. After an erase command is issued, if the DTO flag is 1 and the RSPTO flag is 0, polling can be used to monitor the SDD0MON flag change from 0 to 1, and check that the erase command sequence is complete. If a communication error or timeout occurs during the write sequence, the SD0_DAT0 pin may remain low. When the SDHI clock is stopped, the value before the SDHI clock was stopped is retained.

BRE Flag (SDBUFR Read Enable Flag)

— This flag becomes 1 under any of the following conditions:

- During a single block transfer, the data size set in the SDSIZE.LEN[9:0] bits is stored in the SD buffer.
- During a multi-block transfer, the data size set in the SDSIZE.LEN[9:0] bits is stored in one of the two SD buffers.

— This flag becomes 0 under any of the following conditions:

- The bit is set to 0.
- DMA transfer is used to read 1 block of data from the SD buffer.

If the CPU is used to read data from the SDBUFR register, set the BRE flag to 0 before reading the data size *1 set in the SDSIZE.LEN[9:0] bits. Even if the block of data read contains a CRC error or end bit error, the data is stored in the SD buffer and the BRE flag becomes 1.

Note 1. If the transfer data size set in the SDSIZE.LEN[9:0] bits is an odd number, the remaining byte is ignored. Refer to section 52.5.2, SDBUFR Register Illegal Write Error for details.

BWE Flag (SDBUFR Write Enable Flag)

— This flag becomes 1 under any of the following conditions:

- During a single block transfer, the SD buffer is empty.
- During a multi-block transfer, bank 1 or bank 2 of the SD buffer is empty.

— This flag becomes 0 under any of the following conditions:

- The flag is set to 0.
- DMA transfer is used to write 1 block of data to the SD buffer.

If the CPU is used to write data to the SDBUFR register, set the BWE flag to 0 before writing the data size *1 set in the SDSIZE.LEN[9:0] bits.

Note 1. If the transfer data size set in the SDSIZE.LEN[9:0] bits is an odd number, the remaining byte is ignored. Refer to section 52.5.2, SDBUFR Register Illegal Write Error for details.

SDCLKCREN Flag (SDCLKCR Write Enable Flag)

When a value is written to the SDCMD register, the SDHI starts the command sequence, the SDSTS2.CBSY flag becomes 1, and the SDSTS2.SDCLKCREN flag becomes 0. When the command sequence is complete, after the SDSTS2.CBSY flag becomes 0, eight cycles of the SDHI clock elapse and then the SDSTS2.SDCLKCREN flag becomes 1.

ILA Flag (Illegal Access Error Detection Flag)

— This flag becomes 1 under any of the following conditions:

- A value is written to the SDCMD register when the SDSTS2.CBSY flag is 1.
- The SDCMD.CMDTP bit is set to 1 (command accompanying data transfer), the SDCMD.ACMD[1:0] bits are set to 00b, and the SDCMD.CMDIDX[5:0] bits are set to 001100b (CMD12).

— This flag becomes 0 under the following condition:

- The flag is set to 0.

52.2.8 SD Interrupt Mask Register 1 (SDIMSK1)

Address(es): SDHI.SDIMSK1 8785 2040h, SDHI_NS.SDIMSK1 0785 2040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SDD3INM	SDD3RMM	—	—	—	SDCDINM	SDCDRMM	ACENDM	—	RSPENDM
Value after reset:	0	0	0	0	0	0	1	1	0	0	0	1	1	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	RSPENDM	Response End Interrupt Request Mask	0: Response end interrupt request is not masked 1: Response end interrupt request is masked	R/W
b1	—	Reserved	This bit is 0 when read and cannot be modified.	R
b2	ACENDM	Access End Interrupt Request Mask	0: Access end interrupt request is not masked 1: Access end interrupt request is masked	R/W
b3	SDCDRMM	SD0_CD Removal Interrupt Request Mask	0: SD card/MMC removal interrupt request by the SD0_CD pin not masked 1: SD card/MMC removal interrupt request by the SD0_CD pin masked	R/W
b4	SDCDINM	SD0_CD Insertion Interrupt Request Mask	0: SD card/MMC insertion interrupt request by the SD0_CD pin not masked 1: SD card/MMC insertion interrupt request by the SD0_CD pin masked	R/W
b7 to b5	—	Reserved	These bits are 0 when read and cannot be modified.	R
b8	SDD3RMM	SD0_DAT3 Removal Interrupt Request Mask	0: SD card/MMC removal interrupt request by the SD0_DAT3 pin not masked 1: SD card/MMC removal interrupt request by the SD0_DAT3 pin masked	R/W
b9	SDD3INM	SD0_DAT3 Insertion Interrupt Request Mask	0: SD card/MMC insertion interrupt request by the SD0_DAT3 pin not masked 1: SD card/MMC insertion interrupt request by the SD0_DAT3 pin masked	R/W
b31 to b10	—	Reserved	These bits are 0 when read and cannot be modified.	R

The SDIMSK1 register enables and disables the interrupt requests from the status flags in the SDSTS1 register. Refer to Table 52.9, Interrupt Sources for details on the relationship between the status flags and the requested interrupt source.

52.2.9 SD Interrupt Mask Register 2 (SDIMSK2)

Address(es): SDHI.SDIMSK2 8785 2044h, SDHI_NS.SDIMSK2 0785 2044h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ILAM	—	—	—	—	—	BWEM	BREM	—	RSPTOM	ILRM	ILWM	DTTOM	ENDEM	CRCEM	CMDEM
Value after reset:	1	0	0	0	1	0	1	1	0	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	CMDEM	Command Error Interrupt Request Mask	0: Command error interrupt request not masked 1: Command error interrupt request masked	R/W
b1	CRCEM	CRC Error Interrupt Request Mask	0: CRC error interrupt request not masked 1: CRC error interrupt request masked	R/W
b2	ENDEM	End Bit Error Interrupt Request Mask	0: End bit detection error interrupt request not masked 1: End bit detection error interrupt request masked	R/W
b3	DTTOM	Data Timeout Interrupt Request Mask	0: Data timeout interrupt request not masked 1: Data timeout interrupt request masked	R/W
b4	ILWM	SDBUFR Register Illegal Write Interrupt Request Mask	0: Illegal write detection interrupt request for the SDBUFR register not masked 1: Illegal write detection interrupt request for the SDBUFR register masked	R/W
b5	ILRM	SDBUFR Register Illegal Read Interrupt Request Mask	0: Illegal read detection interrupt request for the SDBUFR register not masked 1: Illegal read detection interrupt request for the SDBUFR register masked	R/W
b6	RSPTOM	Response Timeout Interrupt Request Mask	0: Response timeout interrupt request not masked 1: Response timeout interrupt request masked	R/W
b7	—	Reserved	This bit is 0 when read and cannot be modified.	R
b8	BREM	BRE Interrupt Request Mask*1	0: Read enable interrupt request for the SDBUFR register not masked 1: Read enable interrupt request for the SDBUFR register masked	R/W
b9	BWEM	BWE Interrupt Request Mask*1	0: Write enable interrupt request for the SDBUFR register not masked 1: Write enable interrupt request for the SDBUFR register masked	R/W
b10	—	Reserved	This bit is 0 when read and cannot be modified.	R
b11	—	Reserved	This bit is 1 when read. Set it to 1 when writing.	R/W
b14 to b12	—	Reserved	These bits are 0 when read and cannot be modified.	R
b15	ILAM	Illegal Access Error Interrupt Request Mask	0: Illegal access error interrupt request not masked 1: Illegal access error interrupt request masked	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. When the SDIMSK2.BWEM bit is 0 or the SDIMSK2.BREM bit is 0, set the SDDMAEN.DMAEN bit to 0. When the SDDMAEN.DMAEN bit is 1, set the SDIMSK2.BWEM bit to 1 and the SDIMSK2.BREM bit to 1.

The SDIMSK2 register enables and disables the interrupt requests from the status flags in the SDSTS2 register. Refer to Table 52.9 for details on the relationship between the status flags and the requested interrupt source.

52.2.10 SDHI Clock Control Register (SDCLKCR)

Address(es): SDHI.SDCLKCR 8785 2048h, SDHI_NS.SDCLKCR 0785 2048h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CLKCTRLEN	CLKEN	CLKSEL[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CLKSEL[7:0]	SDHI Clock Frequency Select	b7 b0 0 0 0 0 0 0 0 0: PCLKB divided by 2 0 0 0 0 0 0 0 1: PCLKB divided by 4 0 0 0 0 0 0 1 0: PCLKB divided by 8 0 0 0 0 0 1 0 0: PCLKB divided by 16 0 0 0 0 1 0 0 0: PCLKB divided by 32 0 0 0 1 0 0 0 0: PCLKB divided by 64 0 0 1 0 0 0 0 0: PCLKB divided by 128 0 1 0 0 0 0 0 0: PCLKB divided by 256 1 0 0 0 0 0 0 0: PCLKB divided by 512 1 1 1 1 1 1 1 1: PCLKB *2 Only set the values listed above.	R/W*1
b8	CLKEN	SDHI Clock Output Control	0: SDHI clock output is disabled (SD0_CLK signal fixed low) 1: SDHI clock output enabled	R/W*1
b9	CLKCTRLEN	SDHI Clock Output Automatic Control Select	0: Automatic control of SDHI clock output disabled 1: Automatic control of SDHI clock output enabled	R/W
b31 to b10	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Bits CLKSEL[7:0] and CLKEN cannot be write accessed when the SDSTS2.SDCLKCREN flag is 0.
Note 2. When setting the CLKSEL[7:0] bits to 11111111b or when changing the CLKSEL[7:0] bit values from 11111111b to another value, perform the following steps:
(1) Set the CLKEN bit to 0. Do not change the other bit values.
(2) Change the CLKSEL[7:0] bit values. Do not change the other bit values.
(3) Set the CLKEN bit to 1. Do not change the other bit values.

The SDCLKCR register controls the SDHI clock frequency settings and output. Set the CLKEN bit to 1 before writing to the SDCMD register to start a command sequence. Do not write access the SDCLKCR register when the SDSTS2.SDCLKCREN flag is 0.

CLKCTRLEN Bit (SDHI Clock Output Automatic Control Select)

The SDHI clock output automatic control is a function for starting and stopping SDHI clock output only during a command sequence. When this function is enabled, the SDHI starts outputting the SDHI clock after a value is set to the SDCMD register. After the command sequence is complete and eight cycles of the SDHI clock elapse, the SDHI stops outputting the SDHI clock. When the SDCLKCR.CLKEN bit is 0, output from the SD0_CLK pin becomes low regardless of the CLKCTRLEN bit setting.

52.2.11 Transfer Data Size Register (SDSIZE)

Address(es): SDHI.SDSIZE 8785 204Ch, SDHI_NS.SDSIZE 0785 204Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	LEN[9:0]									
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	LEN[9:0]	Transfer Data Size Setting*1	Set the transfer data size.	R/W
b11 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R
b31 to b12	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite these bits when the SDSTS2.CBSY flag is 1.

The SDSIZE register is used to set the transfer data size.

LEN[9:0] Bits (Transfer Data Size Setting)

When using single block transfer, the transfer data size can be set from 1 byte to 512 bytes. When CMD12 is automatically issued during a multi-block transfer sequence (CMD18 and CMD25), the transfer data size can only be set to 512 bytes. When CMD12 is not automatically issued during a multi-block transfer sequence, the transfer data size can be set to 32, 64, 128, 256, or 512 bytes. However, a 32-, 64-, 128-, or 256-byte multi-block read transfer can only be performed during an SDIO multi-block transfer (CMD53). Do not set these bits to 0 when using a command that includes data transfer.

52.2.12 Card Access Option Register (SDOPT)

Address(es): SDHI.SDOPT 8785 2050h, SDHI_NS.SDOPT 0785 2050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WIDTH	—	WIDTH8	—	—	—	—	TOUTMASK	TOP[3:0]				CTOP[3:0]			
Value after reset:	0	1	0	0	0	0	0	0	1	1	1	0	1	1	1	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CTOP[3:0]	Card Detection Time Counter*1	b3 b0 0 0 0 0: PCLKB × 2^{10} 0 0 0 1: PCLKB × 2^{11} 0 0 1 0: PCLKB × 2^{12} 0 0 1 1: PCLKB × 2^{13} 0 1 0 0: PCLKB × 2^{14} 0 1 0 1: PCLKB × 2^{15} 0 1 1 0: PCLKB × 2^{16} 0 1 1 1: PCLKB × 2^{17} 1 0 0 0: PCLKB × 2^{18} 1 0 0 1: PCLKB × 2^{19} 1 0 1 0: PCLKB × 2^{20} 1 0 1 1: PCLKB × 2^{21} 1 1 0 0: PCLKB × 2^{22} 1 1 0 1: PCLKB × 2^{23} 1 1 1 0: PCLKB × 2^{24} 1 1 1 1: Do not set this value.	R/W
b7 to b4	TOP[3:0]	Timeout Counter*1	b7 b4 0 0 0 0: SDHI clock × 2^{13} 0 0 0 1: SDHI clock × 2^{14} 0 0 1 0: SDHI clock × 2^{15} 0 0 1 1: SDHI clock × 2^{16} 0 1 0 0: SDHI clock × 2^{17} 0 1 0 1: SDHI clock × 2^{18} 0 1 1 0: SDHI clock × 2^{19} 0 1 1 1: SDHI clock × 2^{20} 1 0 0 0: SDHI clock × 2^{21} 1 0 0 1: SDHI clock × 2^{22} 1 0 1 0: SDHI clock × 2^{23} 1 0 1 1: SDHI clock × 2^{24} 1 1 0 0: SDHI clock × 2^{25} 1 1 0 1: SDHI clock × 2^{26} 1 1 1 0: SDHI clock × 2^{27} 1 1 1 1: Do not set this value.	R/W
b8	TOUTMASK	Timeout Mask	0: Timeout detection is enabled. 1: Timeout detection is disabled.	R/W
b12 to b9	—	Reserved	These bits are 0 when read and cannot be modified.	R
b13	WIDTH8	MMC Bus Width Select*1	0: Wide bus mode (4 bits) 1: Wide bus mode (8 bits)	R/W
b14	—	Reserved	This bit is 1 when read and cannot be modified.	R
b15	WIDTH	SD Bus Width Select*1	0: Selected by the WIDTH8 bit 1: Default bus mode (1 bit)	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite these bits when the SDSTS2.CBSY flag is 1.

The SD/MMC bus width and timeout counter are set in the SDOPT register.

TOUTMASK Bit (Timeout Mask)

This bit is used to disable the timeout detect function.
When this bit is set to 1, the RSPTO and DTO flags in the SDSTS2 register and each flag in the SDERSTS2 register are not set to 1.

WIDTH8 Bit (MMC Bus Width Select)

This bit is used to select the bus width of the MMC bus in combination with the WIDTH bit.

WIDTH Bit	WIDTH8 Bit	Bus Width
0	0	4 bits
0	1	8 bits
1	0	1 bit
1	1	1 bit

52.2.13 SD Error Status Register 1 (SDERSTS1)

Address(es): SDHI.SDERSTS1 8785 2058h, SDHI_NS.SDERSTS1 0785 2058h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	CRCTK[2:0]			CRCTKE	RDCRCE	RSPCRCE1	RSPCRCE0	—	—	CRCLENE	RDLENE	RSPLENE1	RSPLENE0	CMDE1	CMDE0
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMDE0	Command Error Flag 0	0: Command index field value for a command *1 response is error free 1: Command index field value for a command *1 response is in error	R
b1	CMDE1	Command Error Flag 1	0: Command index field value for a command *2 response is error free 1: Command index field value for a command *2 response is in error (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the CMDE0 flag)	R
b2	RSPLENE0	Response Length Error Flag 0	0: Command *1 response length is error free 1: Command *1 response length is in error	R
b3	RSPLENE1	Response Length Error Flag 1	0: Command *2 response length is error free 1: Command *2 response length is in error (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the RSPLENE0 flag)	R
b4	RDLENE	Read Data Length Error Flag	0: Read data length error did not occur 1: Read data length error occurred	R
b5	CRCLENE	CRC Status Token Length Error Flag	0: CRC status token length error did not occur 1: CRC status token length error occurred	R
b7, b6	—	Reserved	These bits are 0 when read.	R
b8	RSPCRCE0	Response CRC Error Flag 0	0: No CRC error detected in command *1 response 1: CRC error detected in command *1 response	R
b9	RSPCRCE1	Response CRC Error Flag 1	0: No CRC error detected in command *2 response 1: CRC error detected in command *2 response (the error that occurs for CMD12 with the setting of the SDCMD.CMDIDX[5:0] bits is indicated by the RSPCRCE0 flag)	R
b10	RDCRCE	Read Data CRC Error Flag	0: No CRC error detected in read data 1: CRC error detected in read data	R
b11	CRCTKE	CRC Status Token Error Flag	0: No error detected in CRC status token 1: Error detected in CRC status token	R
b14 to b12	CRCTK[2:0]	CRC Status Token	Store the CRC status token value (normal value is 010b)	R
b15	—	Reserved	This bit is 0 when read.	R
b31 to b16	—	Reserved	These bits are undefined when read.	R

Note 1. Command other than CMD12 or CMD52 which are automatically issued to stop data transfer.
Note 2. CMD12 or CMD52 which are automatically issued to stop data transfer.

The SDERSTS1 register indicates the CRC status token, CRC error, end bit error, and command error.

52.2.14 SD Error Status Register 2 (SDERSTS2)

Address(es): SDHI.SDERSTS2 8785 205Ch, SDHI_NS.SDERSTS2 0785 205Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	CRCBSYTO	CRCTO	RDTO	BSYTO1	BSYTO0	RSPTO1	RSPTO0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RSPTO0	Response Timeout Flag 0	0: After a command *1 was issued, a response was received in less than 640 cycles of the SDHI clock. 1: After a command *1 was issued, a response was not received even after 640 cycles or more of the SDHI clock elapsed.	R
b1	RSPTO1	Response Timeout Flag 1	0: After a command *2 was issued, a response was received in less than 640 cycles of the SDHI clock. 1: After a command *2 was issued, a response was not received even after 640 cycles or more of the SDHI clock elapsed (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the RSPTO0 flag).	R
b2	BSYTO0	Busy Timeout Flag 0	0: After the R1b response was received, the SDHI was released from the busy state during the specified period *3. 1: After the R1b response was received, the SDHI was in the busy state even after the specified period *3 elapsed.	R
b3	BSYTO1	Busy Timeout Flag 1	0: After CMD12 was automatically issued, the SDHI was released from the busy state during the specified period *3. 1: After CMD12 was automatically issued, the SDHI was in the busy state even after the specified period *3 elapsed (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the BSYTO0 flag).	R
b4	RDTO	Read Data Timeout Flag	After a read command is issued, this flag becomes 1 when read data is not received even after the specified period *3 elapses. After read data is received, this flag becomes 1 when the next block of read data is not received even after the specified period *3 elapses. After the SDHI exits the read wait state, this flag becomes 1 when the next block of read data is not received even after the specified period *3 elapses.	R
b5	CRCTO	CRC Status Token Timeout Flag	0: After data was written to the SD card/MMC, a CRC status token was received during the specified period *3. 1: After CRC data was written to the SD card/MMC, a CRC status token was not received even after the specified period *3 elapsed.	R
b6	CRCBSYTO	CRC Status Token Busy Timeout Flag	0: After a CRC status token was received, the SDHI was released from the busy state during the specified period *3. 1: After a CRC status token was received, the SDHI is in the busy state even after the specified period *3 elapsed.	R
b31 to b7	—	Reserved	These bits are 0 when read.	R

Note 1. Command other than CMD12 or CMD52 which are automatically issued to stop data transfer.
Note 2. CMD12 or CMD52 which are automatically issued to stop transfer.
Note 3. Set the SDOPT.TOP[3:0] bits to select the number of *n* cycles.

The SDERSTS2 register indicates the timeout status.

52.2.15 SD Buffer Register (SDBUFR)

Address(es): SDHI.SDBUFR 8785 2060h, SDHI_NS.SDBUFR 0785 2060h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

The SDBUFR register is used when writing data to the SD card/MMC and when reading data from the SD card/MMC. The SDBUFR register is connected to the SDHI's internal SD buffer. Refer to section 52.3.1, Data Block Format of the SD Card/MMC for details on the configuration of the SDBUFR register and the SD buffer.

52.2.16 SDIO Mode Control Register (SDIOMD)

Address(es): SDHI.SDIOMD 8785 2068h, SDHI_NS.SDIOMD 0785 2068h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	C52PUB	IOABT	—	—	—	—	—	RWREQ	—	INTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	INTEN	SDIO Interrupt Acceptance Enable*1	0: SDIO interrupt accept disabled 1: SDIO interrupt accept enabled	R/W
b1	—	Reserved	This bit is 0 when read and cannot be modified.	R
b2	RWREQ	Read Wait Request	0: SDHI exits read wait state 1: Request for SDHI to enter read wait state	R/W
b7 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R
b8	IOABT	SDIO Abort	If this bit is set to 1 during multi-block transfer triggered by CMD53, CMD52 is immediately issued, and the command sequence is aborted.	R/W
b9	C52PUB	SDIO None Abort	If this bit is set to 1 during multi-block transfer triggered by CMD53, CMD52 is issued before the transfer process is complete, and the command sequence is completed.	R/W
b31 to b10	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY flag is 1.

The SDIOMD register controls reception of the SDIO interrupt, controls CMD52 issuance during multi-block transfer, and controls the read wait request. Do not set bits C52PUB and IOABT to 1 at the same time.

RWREQ Bit (Read Wait Request)

If the RWREQ bit is set to 1 during a multi-block read sequence triggered by issuing CMD53, when the current block is done being read, the SDHI enters the read wait state. The method for exiting the read wait state is as follows.

- If the RWREQ bit is set to 0 while the SDHI is in the read wait state, the SDHI exits the read wait state.
- If the IOABT bit is set to 1 while the SDHI is in the read wait state, after CMD52 is issued, the RWREQ bit becomes 0 and the SDHI exits the read wait state.
- If bits C52PUB and RWREQ are simultaneously set to 1 during a multi-block read sequence triggered by issuing CMD53 *1, the SDHI does not automatically exit the read wait state, so after receiving the CMD52 response, set the RWREQ bit to 0.

Note 1. Set bits RWREQ and C52PUB to 1 simultaneously.

If the RWREQ bit is set to 1 while the last block is being transferred during a multi-block read sequence triggered by issuing CMD53, the SDHI will not enter the read wait state, the SDSTS1.ACEND flag becomes 1, and the RWREQ bit becomes 0. Set the RWREQ bit to 1 after the SDSTS1.RSPEND flag becomes 1.

IOABT Bit (SDIO Abort)

- If the IOABT bit is set to 1 during a multi-block transfer sequence triggered by issuing CMD53, the SDHI stops the CMD53 command sequence, and CMD52 is issued. If the command sequence is stopped due to a communication error or timeout, the SDHI does not issue CMD52. The SD buffer can be accessed even after the IOABT bit is set to 1, but the SDSTS2.ILR flag or ILW flag becomes 1, and a buffer access error occurs. Write a value to the SDARG register before setting the IOABT bit to 1.
- During a single block write, if there is no data in the SD buffer when the IOABT bit is set to 1, the SDHI does not issue CMD52, and the SDSTS1.ACEND flag becomes 1. If there is data in the SD buffer when the IOABT bit is set to 1, the SDHI does not issue CMD52, and after the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1.
- If the IOABT bit is set to 1 during a single block read, the SDHI does not issue CMD52, and the SDSTS1.ACEND flag immediately becomes 1.
- If the SDHI is in the busy state after the R1b response is received and the IOABT bit is set to 1, the SDHI does not issue CMD52, and after the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1.
- If the IOABT bit is set to 1 after the command sequence is completed, the SDHI does not issue CMD52, and the SDSTS1.ACEND flag does not become 1.
- Set the IOABT bit to 1 after the SDSTS1.RSPEND flag becomes 1.
- Set the IOABT bit to 0 after the SDSTS1.ACEND flag becomes 1.

C52PUB Bit (SDIO None Abort)

- If the C52PUB bit is set to 1 during a multi-block write sequence triggered by issuing CMD53, CMD52 is automatically issued when the SD buffer is empty and the current block write access is complete. The C52PUB bit becomes 0 after the response for CMD52 is received. If the C52PUB bit is 1 while the last block is being transferred, the SDHI does not issue CMD52, and after the SDSTS1.RSPEND flag becomes 1, the C52PUB bit is set to 0.
- If the C52PUB bit and RWREQ bit are set to 1 during a multi-block read sequence triggered by issuing CMD53, the SDHI enters the read wait state after the current block read access is complete, and the SDHI automatically issues CMD52. The C52PUB bit becomes 0 after the response for CMD52 is received. If the C52PUB bit is set to 1 while the last block is being transferred, the SDHI does not issue CMD52, and after the SDSTS1.RSPEND flag becomes 1, the C52PUB bit is set to 0.
- During a multi-block read sequence triggered by issuing CMD53, if the C52PUB bit is set to 1, also set the RWREQ bit to 1.
- Write a value to the SDARG register before setting the C52PUB bit to 1.
- Set the C52PUB bit to 1 after the SDSTS1.RSPEND flag becomes 1.

52.2.17 SDIO Status Register (SDIOSTS)

Address(es): SDHI.SDIOSTS 8785 206Ch, SDHI_NS.SDIOSTS 0785 206Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EXWT	EXPUB52	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IOIRQ	SDIO Interrupt Status Flag	0: SDIO interrupt not accepted 1: SDIO interrupt accepted	R/(W) *1
b2, b1	—	Reserved	These bits are undefined when read. Set them to 1 when writing.	R/W
b13 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R
b14	EXPUB52	EXPUB52 Status Flag	Indicates the status of the EXPUB52	R/(W) *1
b15	EXWT	EXWT Status Flag	Indicates the status of the EXWT	R/(W) *1
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. The flag value does not change even when set to 1. If 0 is written to this flag, it becomes 0.

The SDIOSTS register indicates the status of the SDIO card access. When clearing a flag, bits to be cleared should be set to 0; bits not being cleared should be set to 1.

IOIRQ Flag (SDIO Interrupt Status Flag)

— This flag becomes 1 under the following condition:

- The SDIO interrupt from the SDIO card is accepted while the SDIOMD.INTEN bit is 1.

— This flag becomes 0 under the following condition:

- The flag is set to 0. *1

Note 1. Access the SDIO card, negate the SDIO interrupt from the SDIO card, and then set the IOIRQ flag to 0. If the SDIO interrupt from the SDIO card is not negated, the IOIRQ flag might become 1 again.

EXPUB52 Flag (EXPUB52 Status Flag)

— This flag becomes 1 under any of the following conditions:

- When multi-block transfer is triggered by CMD53 being issued, the SDIOMD.C52PUB bit is set to 1 while the last block is being transferred.
- When multi-block write is triggered by CMD53 being issued, the SDIOMD.C52PUB bit remains set to 1 while the last block is being transferred.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

EXWT Flag (EXWT Status Flag)

— This flag becomes 1 under the following condition:

- During a multi-block read sequence triggered by CMD53 being issued, the SDIOMD.RWREQ bit is set to 1 while the last block is being transferred.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

52.2.18 SDIO Interrupt Mask Register (SDIOIMSK)

Address(es): SDHI.SDIOIMSK 8785 2070h, SDHI_NS.SDIOIMSK 0785 2070h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EXWTM	EXPUB52M	—	—	—	—	—	—	—	—	—	—	—	—	—	IOIRQM
Value after reset:	1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	IOIRQM	IOIRQ Interrupt Mask Control	0: IOIRQ interrupt not masked 1: IOIRQ interrupt masked	R/W
b2, b1	—	Reserved	These bits are 1 when read. Set them to 1 when writing.	R/W
b13 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R
b14	EXPUB52M	EXPUB52 Interrupt Request Mask Control	0: EXPUB52 interrupt request not masked 1: EXPUB52 interrupt request masked	R/W
b15	EXWTM	EXWT Interrupt Request Mask Control	0: EXWT interrupt request not masked 1: EXWT interrupt request masked	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

The SDIOIMSK register enables and disables the interrupt requests from the status flags in the SDIOSTS register. Refer to Table 52.9, Interrupt Sources for details on the relationship between the status flags and the requested interrupt source.

52.2.19 DMA Transfer Enable Register (SDDMAEN)

Address(es): SDHI.SDDMAEN 8785 21B0h, SDHI_NS.SDDMAEN 0785 21B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMAEN	—
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b1	DMAEN	DMA Transfer Enable*1 *2	0: Using DMAC and DTC to access the SDBUFR register is disabled 1: Using DMAC and DTC to access the SDBUFR register is enabled	R/W
b3, b2	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R
b4	—	Reserved	This bit is 1 when read. Set it to 1 when writing.	R
b5	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b7, b6	—	Reserved	These bits are 0 when read and cannot be modified.	R
b9, b8	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b11, b10	—	Reserved	These bits are 0 when read and cannot be modified.	R
b12	—	Reserved	This bit is 1 when read. Set it to 1 when writing.	R
b31 to b13	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY bit is 1.
Note 2. When the SDIMSK2.BWEM bit is 0 or the SDIMSK2.BREM bit is 0, set the SDDMAEN.DMAEN bit to 0. When the SDDMAEN.DMAEN bit is 1, set the SDIMSK2.BWEM bit to 1 and the SDIMSK2.BREM bit to 1.

The SDDMAEN register enables and disables DMA transfer.

DMAEN Bit (DMA Transfer Enable)

When using DMA transfer to access the SD buffer, set the DMAEN bit to 1 before setting the SDCMD register.

52.2.20 SDHI Software Reset Register (SDRST)

Address(es): SDHI.SDRST 8785 21C0h, SDHI_NS.SDRST 0785 21C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SDRST	SDHI Software Reset Control	0: SDHI software reset 1: SDHI software reset released	R/W
b2, b1	—	Reserved	These bits are 1 when read. Set them to 1 when writing.	R
b31 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R

Table 52.6 lists the bits and flags initialized by the SDHI software reset.

Table 52.6 Bits and Flags Initialized by the SDHI Software Reset

Register	Bit/Flag
SDSTOP	SDBLKCNTEN
SDSTS1	RSPEND, ACEND
SDSTS2	CMDE, CRCE, ENDE, DTO, ILW, ILR, RSPTO, SDD0MON, BRE, BWE, SDCLKCREN, ILA
SDCLKCR	CLKEN
SDOPT	CTOP[3:0], TOP[3:0], TOUTMASK, WIDTH8, WIDTH
SDERSTS1	CMDE0, CMDE1, RSPLENE0, RSPLENE1, RDLENE, CRCLENE, RSPCRCE0, RSPCRCE1, RDCRCE, CRCTKE, CRCTK[2:0]
SDERSTS2	RSPTO0, RSPTO1, BSYTO0, BSYTO1, RDTO, CRCTO, CRCBSYTO
SDIOSTS	IOIRQ, EXPUB52, EXWT
SDIFMD	NOCHKCR

52.2.21 SD/MMC Interface Mode Register (SDIFMD)

Address(es): SDHI.SDIFMD 8785 21CCh, SDHI_NS.SDIFMD 0785 21CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	NOCHKCR	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b7 to b1	—	Reserved	These bits are 0 when read and cannot be modified.	R
b8	NOCHKCR	CRC Check Mask*1	0: CRC check is enabled 1: CRC check is disabled	R/W
b9	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b31 to b10	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY flag is 1.

The SDIFMD register is used to specify the operation mode of the SD/MMC interface.

NOCHKCR Bit (CRC Check Mask)

This bit is used to support MMC test commands.

When this bit is set to 1, the CRC16 field in the received data is not checked on read commands and the CRC status token is not detected on write commands.

52.2.22 Swap Control Register (SDSWAP)

Address(es): SDHI.SDSWAP 8785 21E0h, SDHI_NS.SDSWAP 0785 21E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	BRSWP	BWSWP	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is 0 when read and cannot be modified.	R
b1	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b2	—	Reserved	This bit is 0 when read and cannot be modified.	R
b4, b3	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b5	—	Reserved	This bit is 0 when read and cannot be modified.	R
b6	BWSWP	SDBUFR Swap Write*1	0: Normal write operation 1: Swap the byte endian before writing to the SDBUFR register	R/W
b7	BRSWP	SDBUFR Swap Read*1	0: Normal read operation 1: Swap the byte endian before reading the SDBUFR register	R/W
b10 to b8	—	Reserved	These bits are 0 when read and cannot be modified.	R
b12, b11	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b14, b13	—	Reserved	These bits are 0 when read and cannot be modified.	R
b15	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY flag is 1.

The SDSWAP register is used to select whether or not the byte endian is swapped when accessing the SDBUFR register. Refer to section 52.3.1 for details on the differences in accessing the SDBUFR register based on the SDSWAP register value.

52.3 SDHI Operation

52.3.1 Data Block Format of the SD Card/MMC

The SDHI has a default bus mode (1-bit width) that uses just the SD0_DAT0 pin as a data line, a wide bus mode (4-bit width) that uses pins SD0_DAT0 to SD0_DAT3, and an MMC-only wide bus mode (8-bit width) that uses pins SD0_DAT0 to SD0_DAT7. Figure 52.2 shows the transfer format in default bus mode, Figure 52.3 shows the transfer format in wide bus mode (4-bit width), and Figure 52.4 shows the transfer format in wide bus mode (8-bit width).

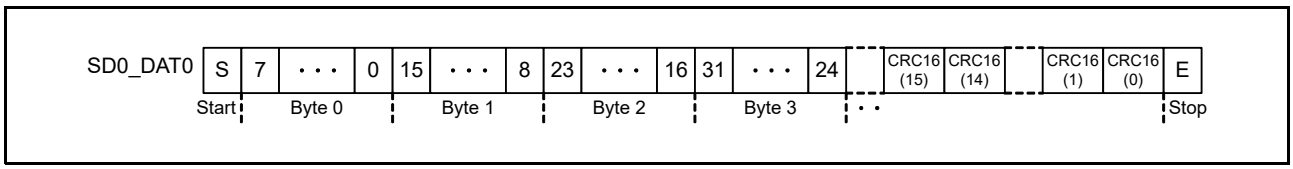

Figure 52.2 Transfer Format in Default Bus Mode (When the SDOPT.WIDTH Bit Is 1)

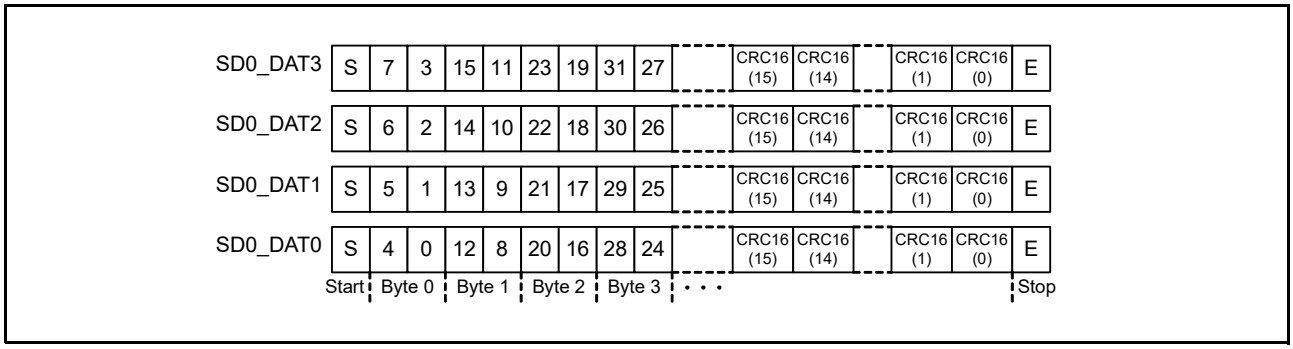

Figure 52.3 Transfer Format in Wide Bus Mode (4-bit Width) (When the SDOPT.WIDTH and WIDTH8 Bits Are 0)

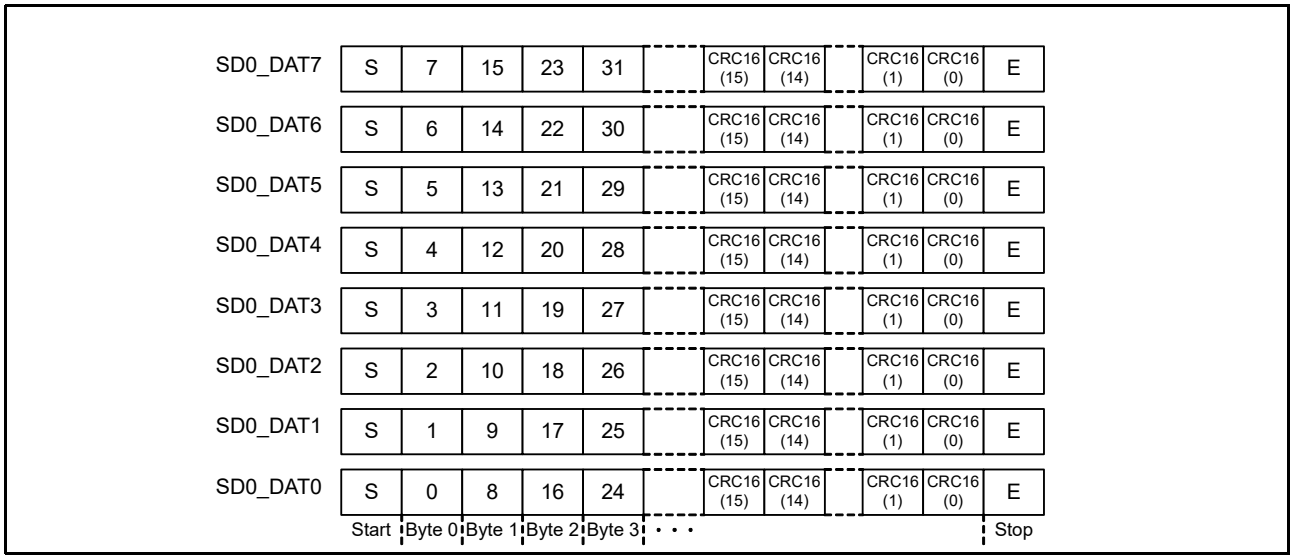

Figure 52.4 Transfer Format in Wide Bus Mode (8-bit Width) (When the SDOPT.WIDTH Bit Is 0 and WIDTH8 Bit Is 1)

52.3.2 SD Buffer and the SDBUFR Register

The SDHI transfers data to an SD card/MMC via its internal SD buffer. The SD buffer is comprised of a double buffer, and each buffer is 512 bytes. Figure 52.5 shows the data configuration of a single buffer of the SD buffer's double buffer.

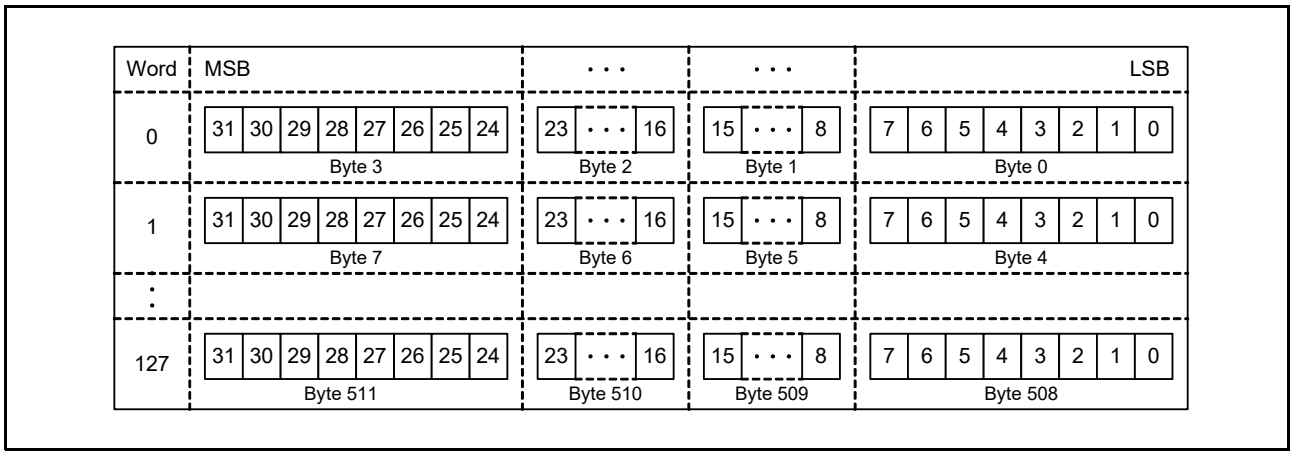

Figure 52.5 Data Configuration of Single Buffer in the SD Buffer

Access to the SD buffer is done via the SDBUFR register. If data is written to the SDBUFR register while the SDSWAP.BWSWP bit is 1, the SDHI swaps the endian for the byte, and stores the data in the SDBUFR register. If data is read from the SDBUFR register while the SDSWAP.BRSWP bit is 1, the data of the endian for the byte that was swapped can be read. Figure 52.6 shows the data alignment when reading the SDBUFR register.

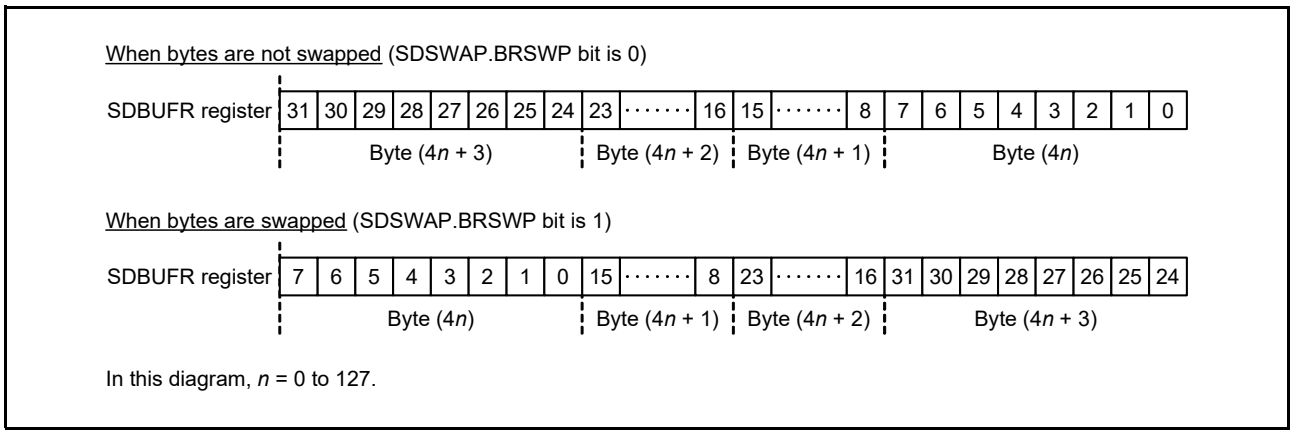

Figure 52.6 Data Alignment When Reading the SDBUFR Register

52.3.3 SD Card/MMC Detection

The SDHI can detect an SD card/MMC using either the SD0_CD pin or SD0_DAT3 pin.

52.3.3.1 Using the SD0_CD Pin to Detect an SD Card/MMC

Figure 52.7 shows the timing chart for SD card/MMC detection using the SD0_CD pin. The SD0_CD pin is connected to the card detection switch of the SD card/MMC connector, and is pulled-up by the MCU. The pull-up resistance value is determined by the specifications of the host device. Note that there are some SD card/MMC sockets whose card detection switches become open when the card is inserted.

- Detecting SD card/MMC insertion
  The signal from the SD0_CD pin becomes low when an SD card/MMC is inserted. This causes the SDSTS1.SDCDIN flag to become 1 if the SD0_CD pin is low for the number of cycles set in the SDOPT.CTOP[3:0] bits. The SDSTS1.SDCDIN flag is cleared by setting it to 0.
- Detecting SD card/MMC removal
  The signal from the SD0_CD pin becomes high when the SD card/MMC is removed. This causes the SDSTS1.SDCDRM flag to become 1 if the SD0_CD pin is high for the number of cycles set in the SDOPT.CTOP[3:0] bits. The SDSTS1.SDCDRM flag is cleared by setting it to 0.

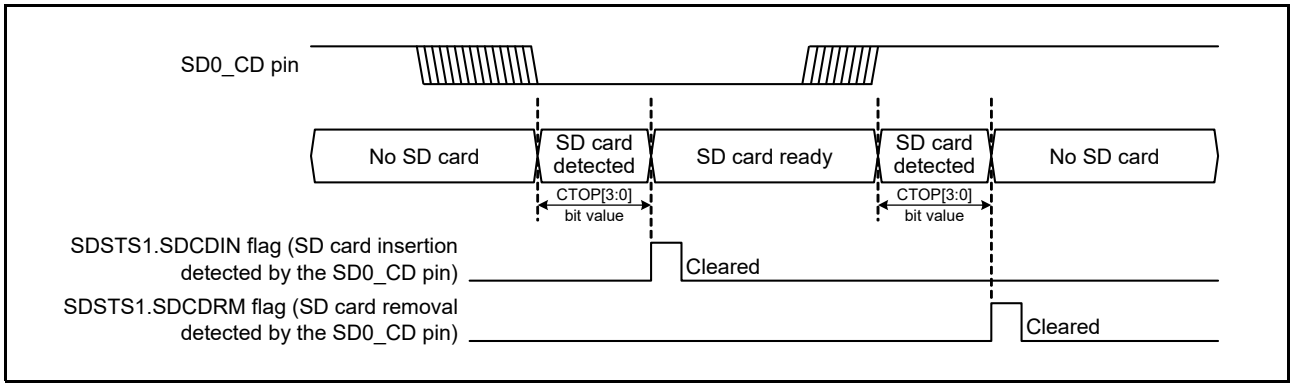

Figure 52.7 SD Card/MMC Detection Using the SD0_CD Pin

52.3.3.2 Using the SD0_DAT3 Pin to Detect an SD Card

Figure 52.8 shows the timing chart for SD card detection using the SD0_DAT3 pin. The SD0_DAT3 pin is pulled-down by the MCU. The pull-down resistance value is determined by the specifications of the host device.

- Detecting SD card insertion
  The signal from the SD0_DAT3 pin becomes high when an SD card is inserted. This causes the SDSTS1.SDD3IN flag to become 1. The SDSTS1.SDD3IN flag is cleared by setting it to 0.
- Detecting SD card removal
  The signal from the SD0_DAT3 pin becomes low when the SD card is removed. This causes the SDSTS1.SDD3RM flag to become 1. The SDSTS1.SDD3RM flag is cleared by setting it to 0.

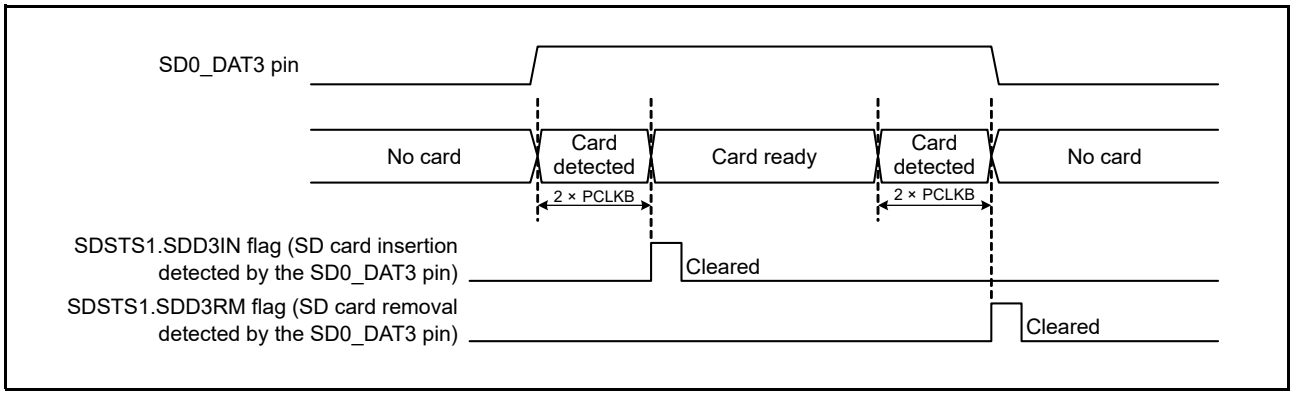

Figure 52.8 SD Card Detection Using the SD0_DAT3 Pin

52.3.4 SD Card/MMC Write Protection

The SDHI can disable writing to an SD card/MMC via the SD0_WP pin or a command.

52.3.4.1 Using the SD0_WP Pin to Enable Write Protection

The SD0_WP pin is connected to the WP detection switch of the SD card/MMC connector, and the SD0_WP pin is pulled-down or pulled-up when a card is inserted. The resistance value and whether the SD0_WP pin is pulled-up or pulled-down are determined by the specifications of the host device. The status of the SD0_WP pin is reflected in the SDSTS1.SDWPMON flag. After a card is inserted, read the SDSTS1.SDWPMON flag to check if write protection is enabled or disabled.

52.3.4.2 Using a Command to Enable Write Protection

The SDHI uses the write protect command or the lock command to disable writing to the SD card/MMC.

52.3.5 Communication Errors and Timeouts

When a communication error or timeout error occurs, depending on the type of error, the corresponding status flag in the SDSTS2 register becomes 1. Also, depending on the source of the error, the corresponding flag in the SDERSTS1 or SDERSTS2 register becomes 1.

The status flags in registers SDERSTS1 and SDERSTS2 become 0 by writing to the SDCMD register, or by setting the SDRST.SDRST bit to 0.

Table 52.7 Communication Errors

Communication Error	Interrupt Flag Register		Error Status Register		This Occurs When...
	Register	Bit	Register	Bit	
End bit error	SDSTS2	ENDE	SDERSTS1	CRCLENE	The CRC status token length is in error
				RDLENE	The read data length is in error
				RSPLENE1	The response length is in error *1
				RSPLENE0	The response length is in error *2
CRC error		CRCE		CRCTKE	The CRC status token is in error
				RDCRCE	There is a CRC error in the read data
				RSPCRCE1	There is a CRC error in the response *1
				RSPCRCE0	There is a CRC error in the response *2
Command error		CMDE		CMDE1	The command index field value for the transmitted command and received response do not match *1
				CMDE0	The command index field value for the transmitted command and received response do not match *2

Note 1. CMD12 or CMD52 which are automatically issued to stop transfer.
Note 2. A command other than CMD12 or CMD52 which are automatically issued to stop transfer.

Table 52.8 Timeouts

Timeout	Interrupt Flag Register		Error Status Register		This Occurs When...
	Register	Bit	Register	Bit	
Response timeout	SDSTS2	RSPTO	SDERSTS2	RSPTO1	A response is not received even after a minimum of 640 SDHI clock cycles elapse *1
				RSPTO0	A response is not received even after a minimum of 640 SDHI clock cycles elapse *2
Data timeout (excluding response timeout)		DTO		CRCBSYTO	After the CRC status token is received, the SDHI is busy for at least the period set *3
				CRCTO	After the write data is transmitted, the CRC status token is not received even after at least the period set *3 elapses
				RDTO	After the read command is issued, the read data is not received even after at least the period set *3 elapses
					After the read data is received, the next block read data is not received even after at least the period set *3 elapses
					After the SDHI exits the read wait state, the next block read data is not received even after at least the period set *3 elapses
				BSYTO1	After CMD12 is issued during the command sequence, the SDHI is busy for at least the period set *3
				BSYTO0	After the R1b response is received, the SDHI is busy for at least the period set *3 (a command other than CMD12 is issued during the command sequence)

Note 1. CMD12 or CMD52 which are automatically issued to stop transfer.
Note 2. A command other than CMD12 or CMD52 which are automatically issued to stop transfer.
Note 3. The period is set in the SDOPT.TOP[3:0] bits.

52.3.6 Examples of Issuing a Command

52.3.6.1 Command Absent of Response Reception and Data Transfer

Figure 52.9 shows an example of no response being received and no data being transferred after the SDHI issues a command.

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 52.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value to the SDARG register, write the command information to be sent to the SDCMD register. The SDHI issues a command when a value is written to the SDCMD register.
4. After a command is issued, the SDSTS1.RSPEND flag becomes 1, and a response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0.

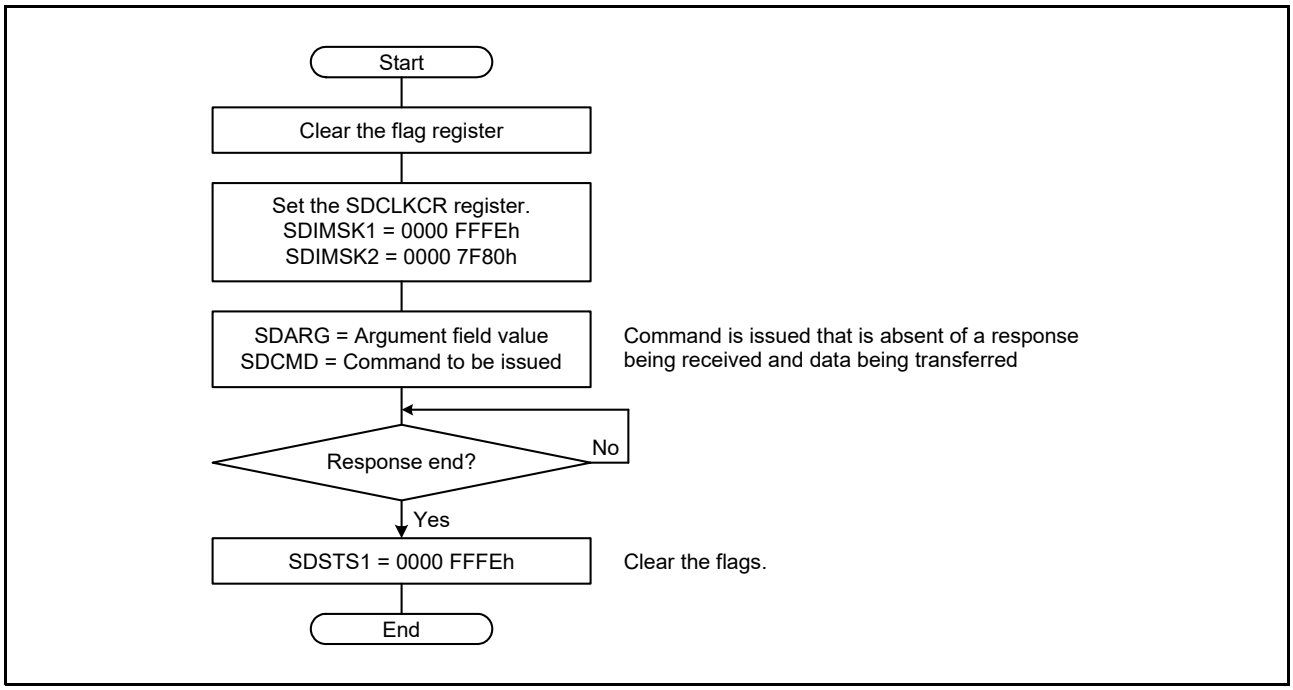

Figure 52.9 Command Issued That Is Absent of Response Reception and Data Transfer

52.3.6.2 Command Absent of Data Transfer

Figure 52.10 shows an example of no data being transferred after the SDHI issues a command.

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 52.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value in the SDARG register, write the information of the command to be issued to the SDCMD register. The SDHI issues a command when a value is written to the SDCMD register.
4. After a response is received, the SDSTS1.RSPEND flag becomes 1, and a response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0, and read the response stored in the SDRSP10 register.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

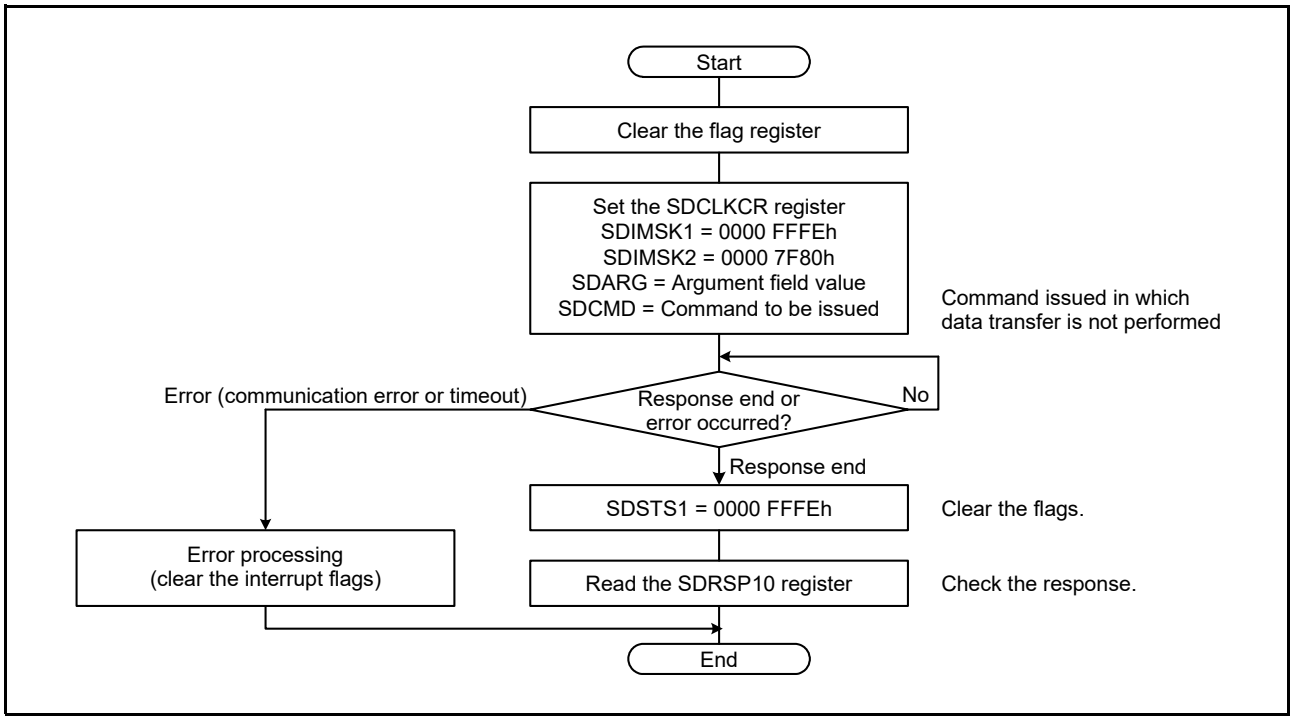

Figure 52.10 Command Issued That Is Absent of Data Transfer

52.3.6.3 Single Block Read Command (CMD17)

Figure 52.11 shows an example of issuing the single block read command (CMD17).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 52.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value for CMD17 to the SDARG register, write 0000 0011h to the SDCMD register. The SDHI issues CMD17 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and a response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0, and read the response stored in the SDRSP10 register. If the response read is in error, set the SDSTOP.STP bit or SDIOMD.IOABT bit to 1, and the command sequence can be stopped. When the command sequence is stopped, the SDSTS1.ACEND flag becomes 1. Note that CMD12 and CMD52 are not automatically issued by stopping this command sequence.
6. After the response is received, set the SDIMSK1.ACENDM bit to 0 and set the SDIMSK2.BREM bit to 0.
7. After the amount of data set in the SDSIZE.LEN[9:0] bits is received from the SD card/MMC, the SDSTS2.BRE flag becomes 1, and the BRE interrupt request is generated.
8. Set the SDSTS2.BRE flag to 0, and read the amount of data set in the SDSIZE.LEN[9:0] bits from the SDBUFR register.
9. After data has been read from the SDBUFR register, the SDSTS1.ACEND flag becomes 1, and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

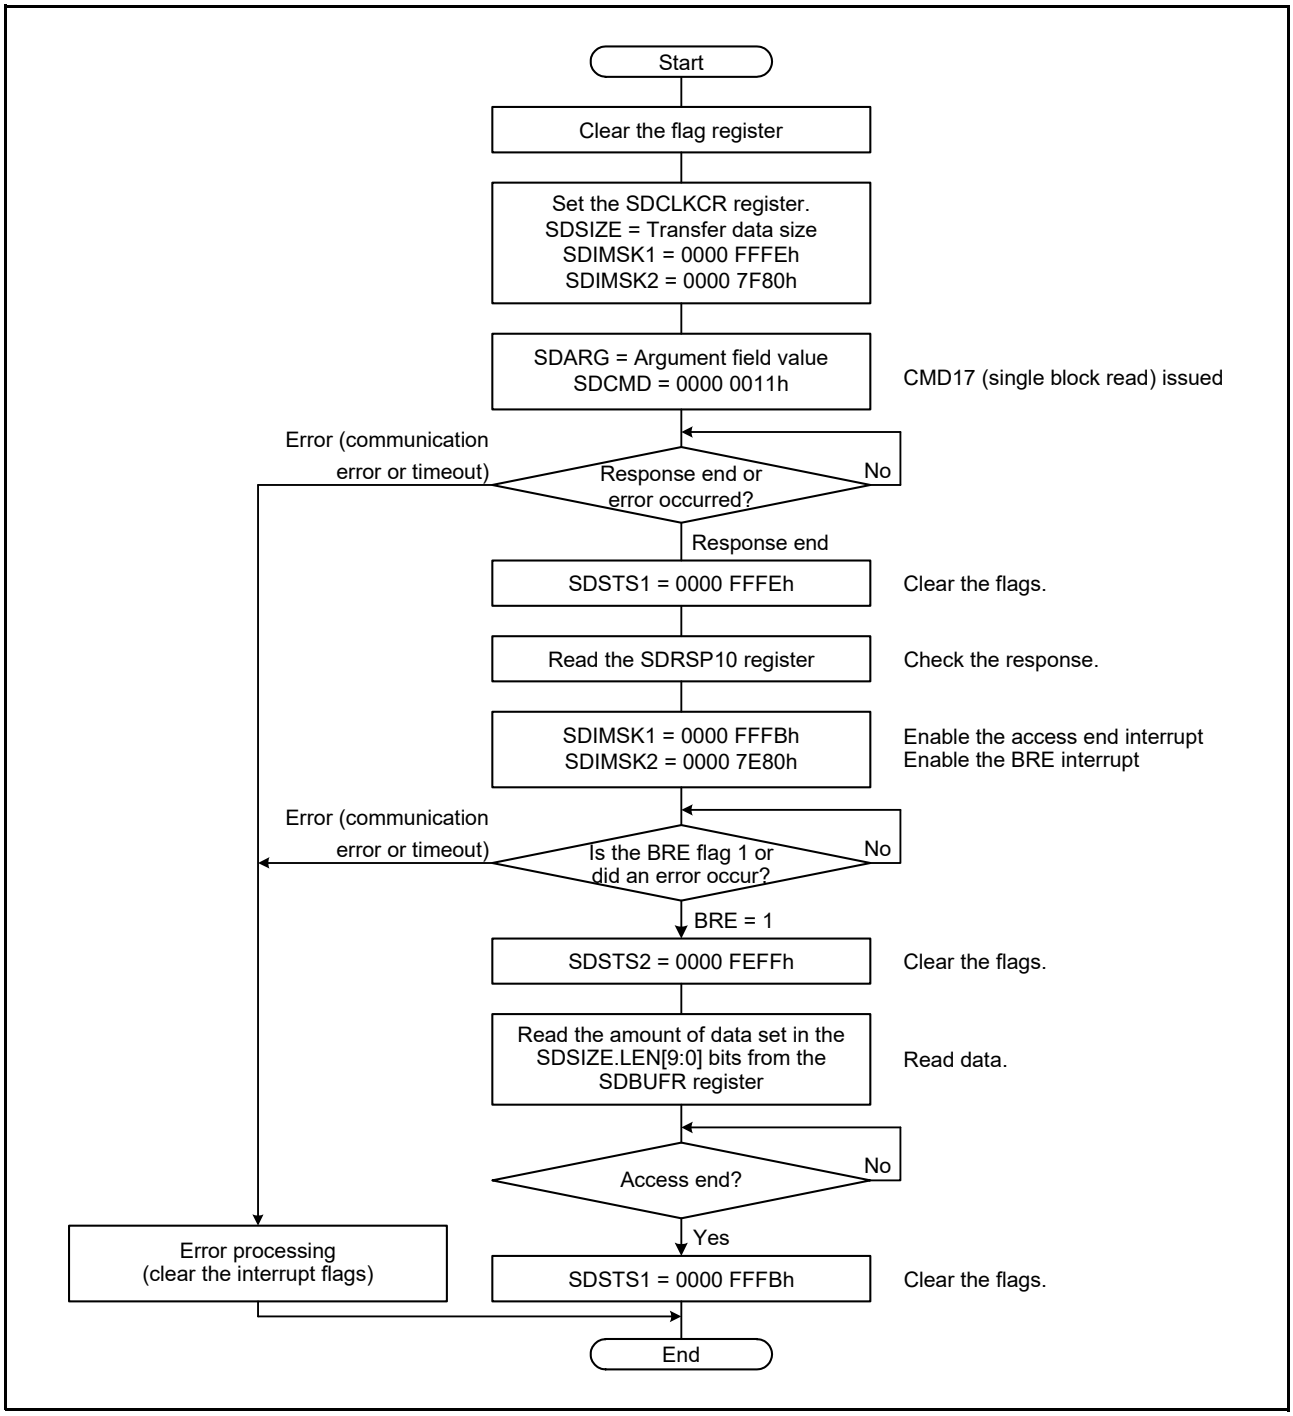

Figure 52.11 Issuing the Single Block Read Command

52.3.6.4 Single Block Write Command (CMD24)

Figure 52.12 shows an example of issuing the single block write command (CMD24).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 52.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value for CMD24 to the SDARG register, write 0000 0018h to the SDCMD register. The SDHI issues CMD24 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and the response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0 and read the response stored in the SDRSP10 register. If the read response is in error, set the SDSTOP.STP bit or SDIOMD.IOABT bit to 1, and the command sequence can be stopped. When the command sequence is stopped, the SDSTS1.ACEND flag becomes 1. Note that when this command sequence is stopped, CMD12 and CMD52 are not automatically issued.
6. After the response is received, set the SDIMSK1.ACENDM bit to 0, and set the SDIMSK2.BWEM bit to 0.
7. When the SDBUFR register becomes write accessible, the SDSTS2.BWE flag becomes 1, and the BWE interrupt request is generated.
8. Set the SDSTS2.BWE flag to 0, and write the amount of data set in the SDSIZE.LEN[9:0] bits to the SDBUFR register. After writing to the SDBUFR register, the SDHI transmits write data to the SD card/MMC. Also, after writing to the SDBUFR register, data transmission may cause a communication error or timeout to occur.
9. After all data has been written to the SD card/MMC, the SDHI receives the CRC status token, and the SD0_DAT0 pin line becomes busy (low). Then, when the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1, and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

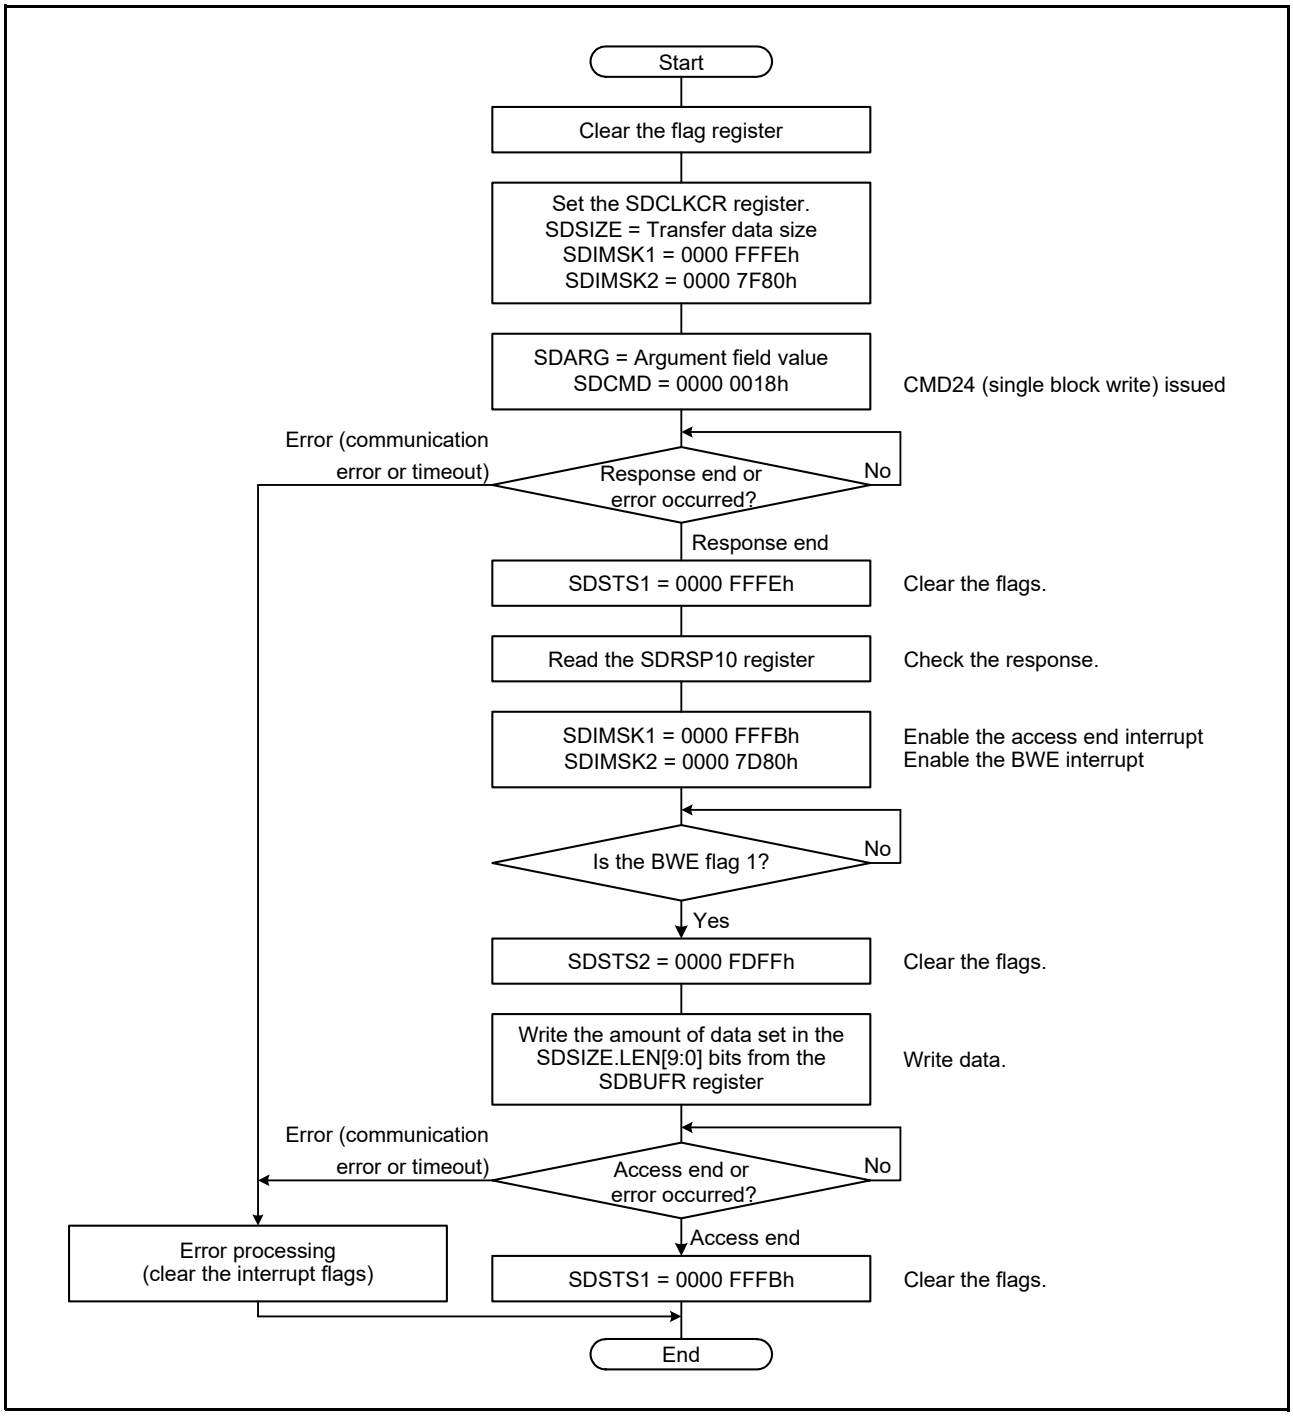

Figure 52.12 Issuing the Single Block Write Command

52.3.6.5 Multi-Block Read Command (CMD18)

Figure 52.13 shows an example of issuing the multi-block read command (CMD18).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 52.5.5 for details on setting the SDCLKCR register. Set the SDSTOP.SDBLKCNTEN bit to 1, and set the number of transfer blocks in the SDBLKCNT register.
3. After setting the argument field value for CMD18 to the SDARG register, write 0000 0012h to the SDCMD register. The SDHI issues CMD18 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and the response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0 and read the response stored in the SDRSP54 register. If the read response is in error, set the SDSTOP.STP bit to 1, and the command sequence can be stopped. When the SDSTOP.STP bit is set to 1, the SDHI automatically issues CMD12, and the response is received. At this point, the SDSTS1.ACEND flag becomes 1, and if the access end interrupt request is enabled, the access end interrupt request is generated. Next, set the SDSTS1.ACEND flag to 0 and read the response.
6. After the response is received, set the SDIMSK1.ACENDM bit to 0, and set the SDIMSK2.BREM bit to 0.
7. After receiving one block of data from the SD card/MMC, the SDSTS2.BRE bit becomes 1, and the BRE interrupt request is generated.
8. Set the SDSTS2.BRE flag to 0, and read the amount of data set in the SDSIZE.LEN[9:0] bits from the SDBUFR register. The read access to the SDBUFR register repeats for the amount of transfer blocks set in the SDBLKCNT register. Also, while reading the SDBUFR register, data reception may cause a communication error or timeout to occur. After the amount of transfer blocks set in the SDBLKCNT register have been read, the SDHI automatically issues CMD12, and the response is received. At this time, the SDHI automatically writes 0000 0000h to the SDARG register.
9. When all blocks have been received and the CMD12 response is received, the SDSTS1.ACEND flag becomes 1 and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0 and read the response.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

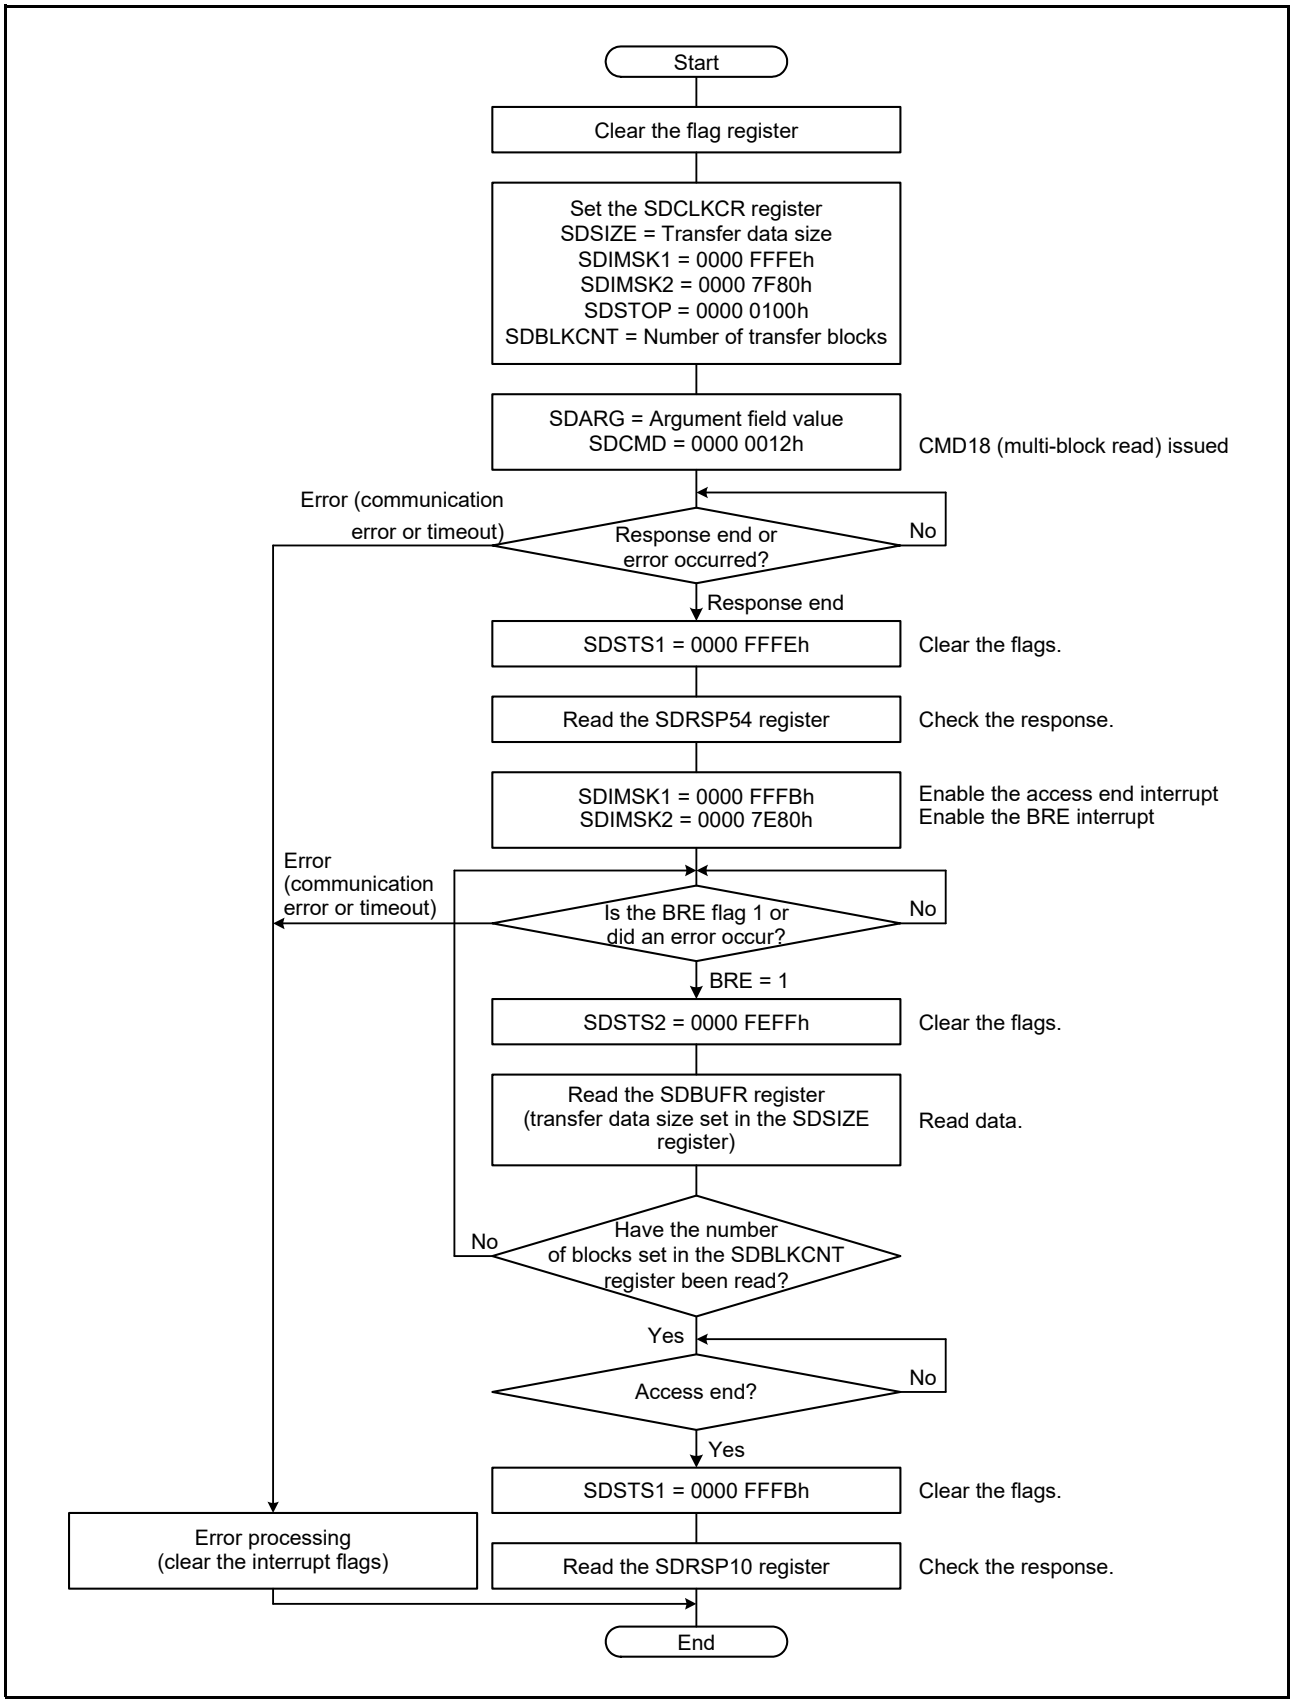

Figure 52.13 Issuing the Multi-Block Read Command

52.3.6.6 Multi-Block Write Command (CMD25)

Figure 52.14 shows an example of issuing the multi-block write command (CMD25).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 52.5.5 for details on setting the SDCLKCR register. Set the SDSTOP.SDBLKCNTEN bit to 1, and set the number of transfer blocks in the SDBLKCNT register.
3. After setting the argument field value for CMD25 to the SDARG register, write 0000 0019h to the SDCMD register. The SDHI issues CMD25 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and the response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0 and read the response stored in the SDRSP54 register. If the read response is in error, set the SDSTOP.STP bit to 1, and the command sequence can be stopped. When the SDSTOP.STP bit is set to 1, the SDHI automatically issues CMD12, and the response is received. At this point, the SDSTS1.ACEND flag becomes 1, and if the access end interrupt request is enabled, the access end interrupt request is generated. Next, set the SDSTS1.ACEND flag to 0 and read the response.
6. After the response is received, configure the SDIMSK1 register to enable the access end interrupt request, and configure the SDIMSK2 register to enable the BWE interrupt request.
7. When the SDBUFR register becomes write accessible, the SDSTS2.BWE flag becomes 1, and the BWE interrupt request is generated.
8. Set the SDSTS2.BWE flag to 0, and write the amount of data set in the SDSIZE.LEN[9:0] bits to the SDBUFR register. After writing to the SDBUFR register, and after the SDHI transmits write data to the SD card/MMC, the CRC status token is received, and the SD0_DAT0 pin line becomes busy (low). The write access to the SDBUFR register and CRC status token reception repeat for the amount of transfer blocks set in the SDBLKCNT register. Also, after writing to the SDBUFR register, data transmission may cause a communication error or timeout to occur. After the amount of transfer blocks set in the SDBLKCNT register have been written, the SDHI automatically issues CMD12, and the response is received. At that time, the SDHI automatically writes 0000 0000h to the SDARG register.
9. When all blocks have been transmitted and the CRC status token is received, the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1, and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0 and read the response.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

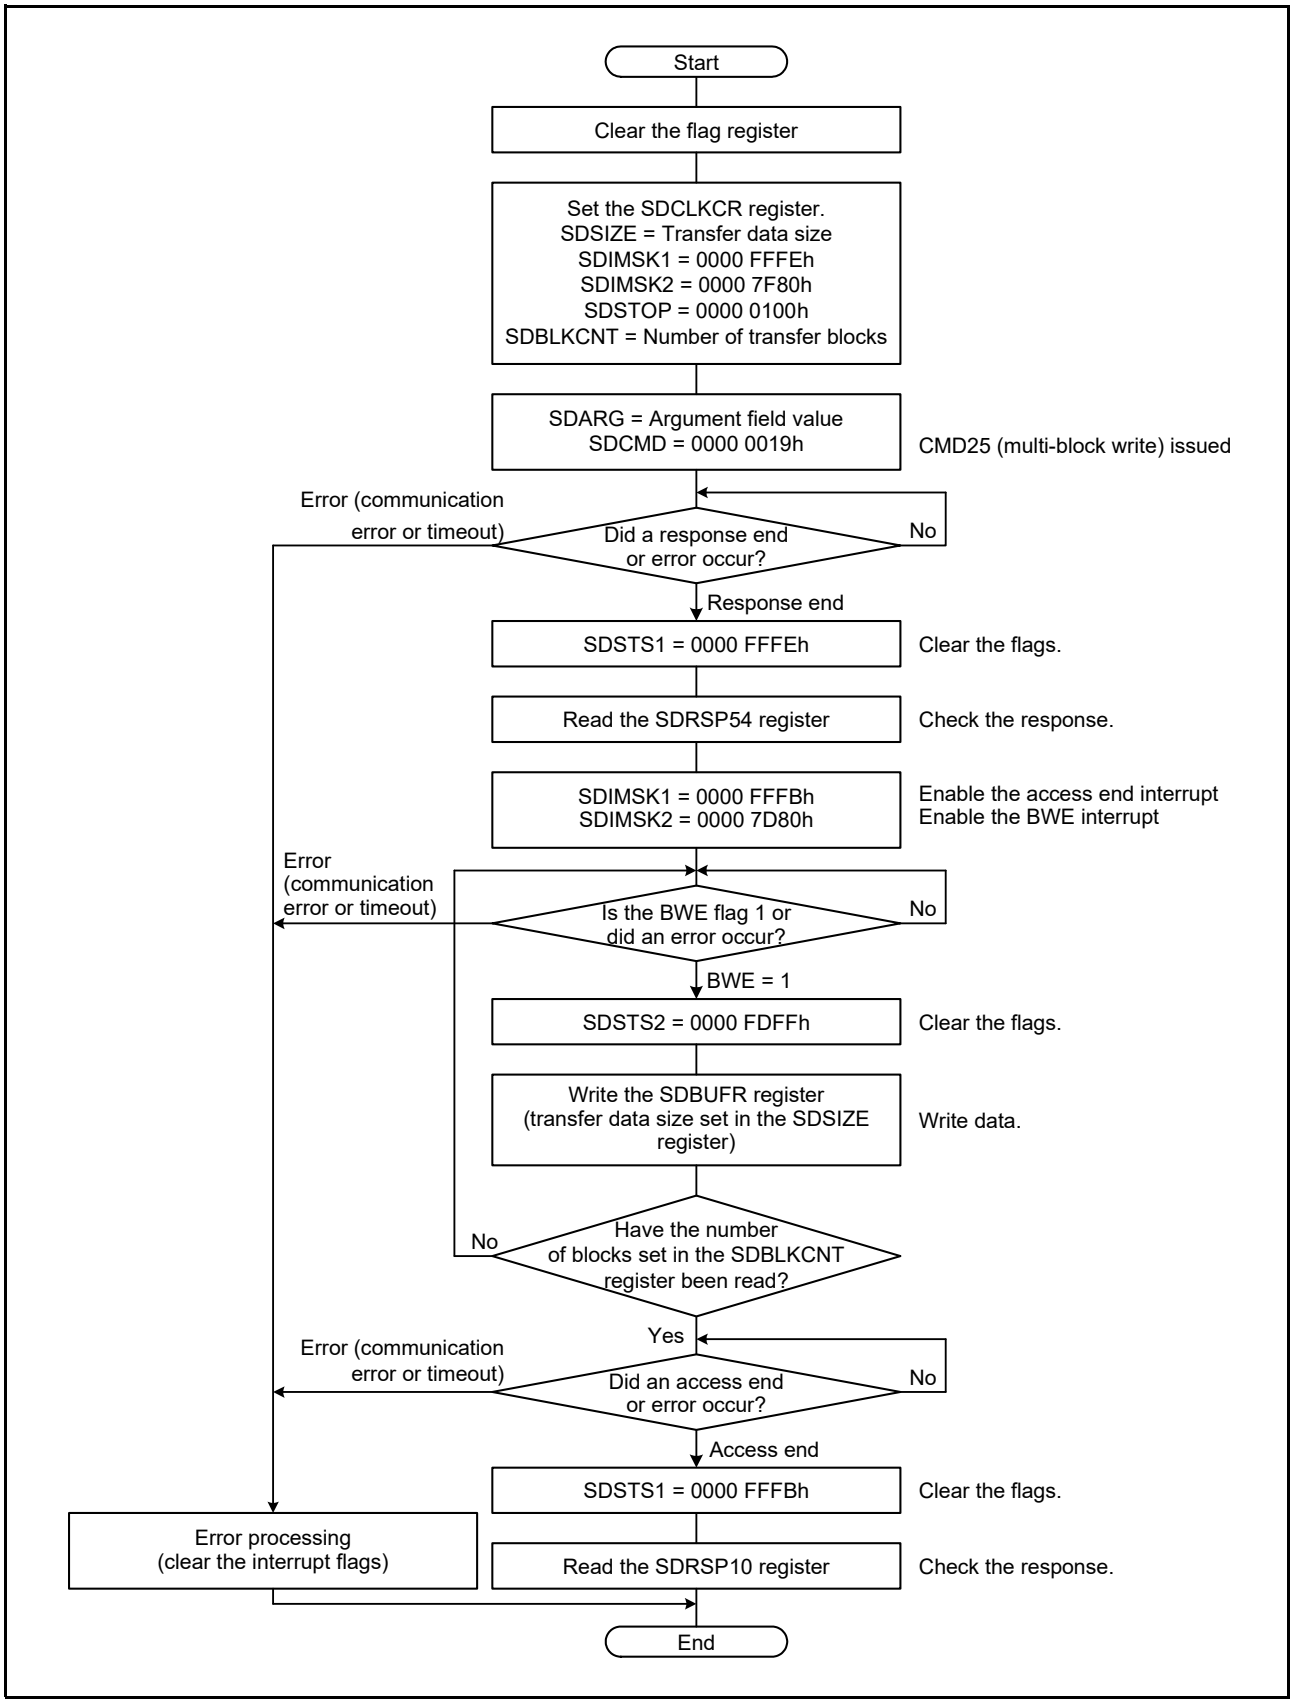

Figure 52.14 Issuing the Multi-Block Write Command

52.3.6.7 Multi-Block Write Command (CMD54)

Figure 52.15 shows an example of issuing the multi-block write command (CMD54).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 52.5.5 for details on setting the SDCLKCR register. Set the SDSTOP.SDBLKCNTEN bit to 1, and set the number of transfer blocks in the SDBLKCNT register.
3. After setting the argument field value for CMD54 to the SDARG register, write 0000 6C36h to the SDCMD register. The SDHI issues CMD54 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and the response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0 and read the response stored in the SDRSP54 register. If the read response is in error, set the SDSTOP.STP bit to 1, and the command sequence can be stopped. When the SDSTOP.STP bit is set to 1, the SDHI automatically issues CMD12, and the response is received. At this point, the SDSTS1.ACEND flag becomes 1, and if the access end interrupt request is enabled, the access end interrupt request is generated. Next, set the SDSTS1.ACEND flag to 0 and read the response.
6. After the response is received, configure the SDIMSK1 register to enable the access end interrupt request, and configure the SDIMSK2 register to enable the BWE interrupt request.
7. Set the SDOPT.TOUTMASK bit to 1 to disable timeout detection by the internal timer and start a timer outside the SDHI to be used for timeout measurement.
8. When the SDBUFR register becomes write accessible, the SDSTS2.BWE flag becomes 1, and the BWE interrupt request is generated.
9. Set the SDSTS2.BWE flag to 0, and write the 512 bytes of data to the SDBUFR register. After writing to the SDBUFR register, and after the SDHI transmits write data to the MMC, the CRC status token is received, and the SD0_DAT0 pin line becomes busy (low). The write access to the SDBUFR register and CRC status token reception repeat for the amount of transfer blocks set in the SDBLKCNT register. Also, after writing to the SDBUFR register, data transmission may cause a communication error or timeout to occur.
10. When all blocks have been transmitted and the CRC status token is received, the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1, and the access end interrupt request is generated.
11. Set the SDSTS1.ACEND flag to 0 and read the response.

Perform error processing (clear the interrupt flag) if a communication error occurs. Perform a software reset if a timeout occurs.

52.3.6.11 DMA Transfer

Figure 52.23 shows an example of data being transferred from the SDBUFR register after the CMD18 multi-block read command is issued.

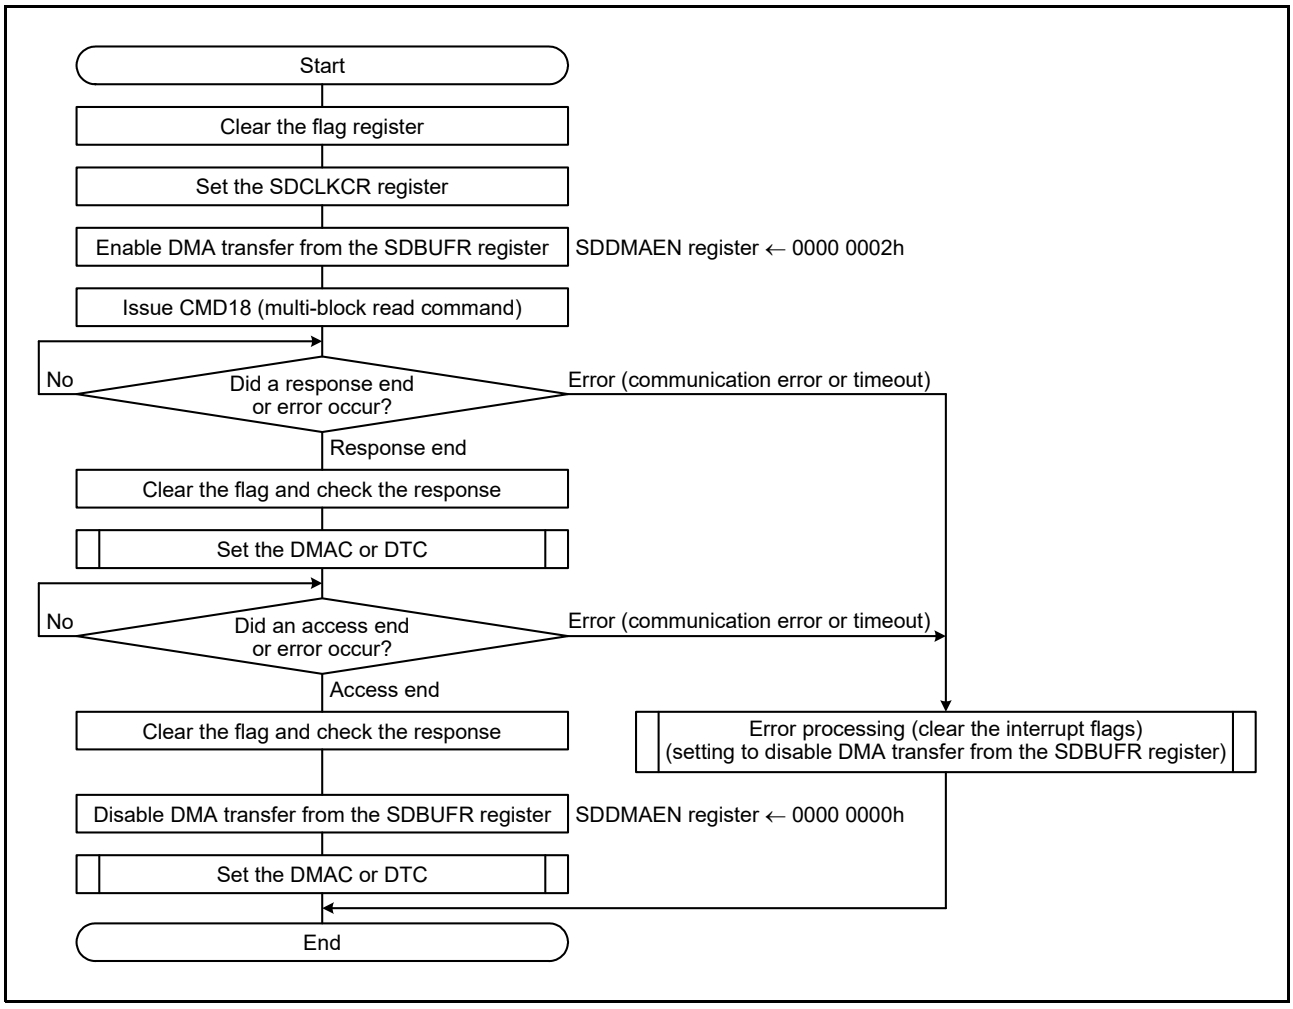

Figure 52.23 DMA Transfer After CMD18 is Issued

Figure 52.24 shows an example of data being DMA transferred to the SDBUFR register after the CMD25 multi-block write command is issued.

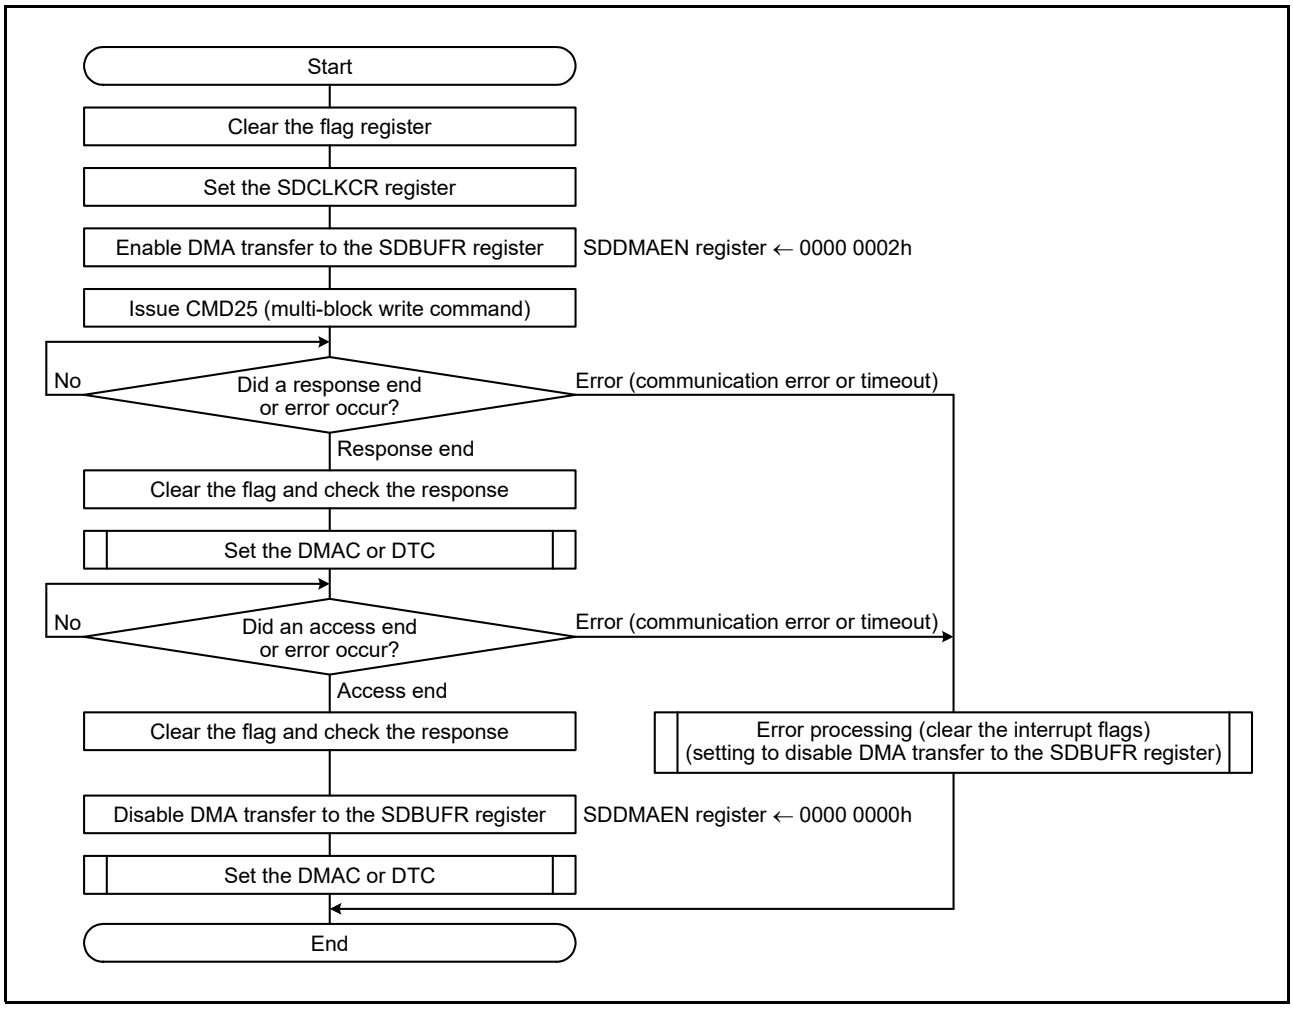

Figure 52.24 DMA Transfer After CMD25 is Issued

52.4 Interrupts

Table 52.9 lists the SDHI interrupt sources. When the status flags in registers SDSTS1, SDSTS2, and SDIOSTS become 1, if the corresponding bits in registers SDIMSK1, SDIMSK2, and SDIOIMSK are 0, the SDHI requests an interrupt. When clearing the status flags in registers SDSTS1, SDSTS2, and SDIOSTS, write 0 to the status flags to be cleared and write 1 to the states flags not being cleared.

Table 52.9 Interrupt Sources

Interrupt Source	Status Flag Register		Interrupt Mask/Enable Register		DMAC/DTC Triggerable
	Register	Bit	Register	Bit	
Card access interrupt (CACI)	SDSTS1	ACEND	SDIMSK1	ACENDM	No
		RSPEND		RSPENDM	
	SDSTS2	ILA	SDIMSK2	ILAM	
		BWE		BWEM	
		BRE		BREM	
		RSPTO		RSPTOM	
		ILR		ILRM	
		ILW		ILWM	
		DTO		DTTOM	
		ENDE		ENDEM	
		CRCE		CRCEM	
		CMDE		CMDEM	
SDIO access interrupt (SDACI)	SDIOSTS	EXWT	SDIOIMSK	EXWTM	No
		EXPUB52		EXPUB52M	
		IOIRQ		IOIRQM	
Card detection interrupt (CDETI)	SDSTS1	SDD3IN	SDIMSK1	SDD3INM	No
		SDD3RM		SDD3RMM	
		SDCDIN		SDCDINM	
		SDCDRM		SDCDRMM	
SD buffer access interrupt (SBFAI)	SDSTS2	BWE	SDDMAEN	DMAEN	Yes
		BRE			

52.4.1 DMA Transfer Triggered by Interrupt Requests

When the SBFAI interrupt is requested, DMA/DTC transfer can be used to write to or read the SDBUFR register. When using the SBFAI interrupt, set the SDDMAEN.DMAEN bit to 1, the SDIMSK2.BWEM bit to 1, and SDIMSK2.BREM bit to 1.

When the SDDMAEN.DMAEN bit is 1, if a write command is issued, the SDSTS2.BWE flag becomes 1; if a read command is issued, the SDSTS2.BRE flag becomes 1. At this point, the SBFAI interrupt request is output. When the last data of a block is transferred (one block is the transfer data size set in the SDSIZE.LEN[9:0] bits), the SBFAI interrupt request is cleared, and the SDSTS2.BWE flag or the SDSTS2.BRE flag becomes 0.

The SBFAI interrupt request is also cleared by following:

- The SDRST.SDRST bit is set to 0 (SDHI software reset).
- The SDSTOP.STP bit is set to 1.
- The SDIOMD.IOABT bit is set to 1.
- The SDDMAEN.DMAEN bit is set to 0.
  However, if the DMAEN bit is set to 1 again before the next command is written to the SDCMD register, the SBFAI interrupt request is output again.

The SBFAI interrupt request will not be cleared when a communication error or timeout occurs during DMA transfer. Perform error processing by software.

The SDSTS2.BWE flag and BRE flag will not become 0 when a communication error or timeout occurs, nor will they become 0 when the SDSTOP.STP bit and SDIOMD.IOABT bit are set to 1. If the SDSTS2.BWE flag or BRE flag remain set to 1, even if a write command or read command is issued, the SBFAI interrupt request will not be output, and the SDSTS2.BWE flag and BRE flag must be set to 0 before issuing the next command.

Table 52.10 lists the DMAC and DTC settings when performing DMA transfer.

Table 52.10 DMAC and DTC Settings When Performing DMA Transfer

Item		Setting Description
Transfer mode		Block transfer mode
Transfer data	1 data	32 bits
	Block size	Size set in the SDSIZE.LEN[9:0] bits divided by 4
Number of block transfers		Number of transfers set in the SDBLKCNT register

52.5 Notes on Using the SDHI

52.5.1 Illegal Read Access During a Multi-Block Read and How To Avoid It

When the multi-block read command (CMD18) is issued to read one or two blocks, if the response to CMD18 stored in the SDRSP10 register is read, the timing of the read access may cause the response to be read incorrectly.
Figure 52.25 shows examples of a normal read and an illegal read when using CMD18 to read two blocks.

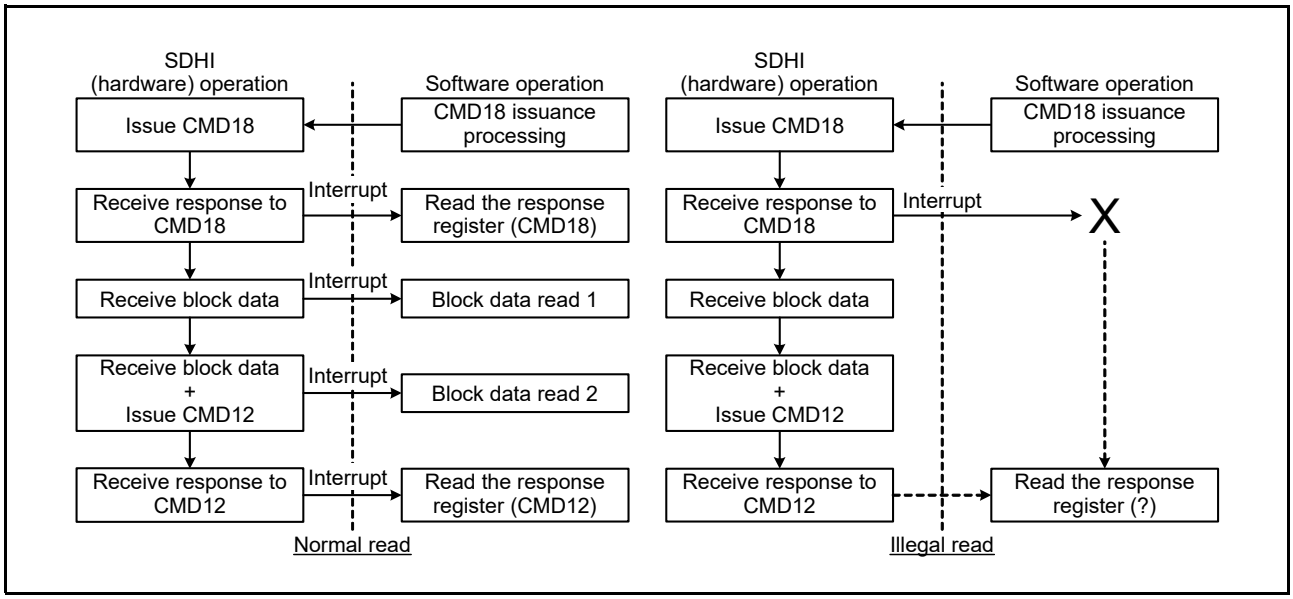

Figure 52.25 Multi-Block Read Processing When Reading Two Blocks

In the example of the illegal read, when the interrupt is generated by receiving the response to CMD18, the timing for reading the SDRSP10 register during the interrupt handling is delayed, and instead of the response for CMD18 being read, the response for CMD12 or the data during the response for CMD12 may be read.
This problem can be avoided by performing either of the following:

- When reading one block or two blocks, use a single block read command instead of a multi-block read command.
- When reading the response for CMD18, read the SDRSP54 register instead of the SDRSP10 register.

When using a multi-block read command to read three or more blocks, CMD12 will not be issued if no block data is read, which will prevent this problem from happening. Also, when using a multi-block write command, the above problem can be avoided by transmitting block data after reading the response to CMD25.

52.5.2 SDBUFR Register Illegal Write Error

When writing to the SDBUFR register after issuing a single block write command or a multi-block write command, write data for the size set by the SDSIZE.LEN[9:0] bits. If the amount of data written to the SDBUFR register is greater than the size set by the SDSIZE.LEN[9:0] bits, an illegal write error occurs in the SDBUFR register, and the SDSTS2.ILW flag becomes 1. However, the padding data included in the data being written to the SDBUFR register is ignored, so this error does not occur. For example, if the data size set by the SDSIZE.LEN[9:0] bits is an odd number, of the data written to the SDBUFR register, there is a remainder of 1 byte or 3 bytes. Although the extra data is written to the register, no error occurs. If the data size set by the SDSIZE.LEN[9:0] bits is an even number, and there is a remainder of 2 bytes, no error occurs even if these 2 bytes are written to the SDBUFR register.
If data written to the SDBUFR register is not transmitted, the SDSTS2.SDCLKCREN flag may remain set to 0. In this case, in order to set the SDSTS2.SDCLKCREN flag to 1, the SDRST.SDRST bit must be set to 0 and then set back to 1.

52.5.3 Automatic Control of the SDHI Clock Output

As per the SD card/MMC specifications, after MCU power-on, 74 cycles of the SDHI clock must be output from the host to the SD card/MMC before the card initialization command (CMD0) can be issued. Therefore, 74 cycles of the SDHI clock should be output from the SDHI to the SD card/MMC before enabling automatic control of the SDHI clock output. When automatic control of the SDHI clock output is enabled, clock output from the SD0_CLK pin stops if the command sequence is ended by a communication error or timeout. Therefore, if it is necessary to change the internal status of the SD card/MMC even after the command sequence ends, disable automatic control of the SDHI clock output and output the SDHI clock to the SD card/MMC.

52.5.4 Restrictions on Setting the C52PUB Bit During a Multi-Block Write Sequence

During a CMD53 multi-block write sequence, if the SDIOMD.C52PUB bit is set to 1, the SDHI issues CMD52 after the SD buffer becomes empty. To immediately issue CMD52, perform one of the procedures below to suspend writing to the SD buffer, and set the C52PUB bit to 1.

Procedure to suspend writing to the SD buffer when not performing DMA transfer (interrupt used)

1. Set the SDIMSK2.BWEM bit to 1 to disable the interrupt, and suspend writing to the SDBUFR register.
2. Set the SDIOMD.C52PUB bit to 1. Then, when the SD buffer becomes empty, the SDHI issues CMD52.
3. After receiving the response for CMD52, set the SDIMSK2.BWEM bit to 0 to enable the interrupt, and resume writing to the SDBUFR register.

Procedure to suspend writing to the SD buffer when performing DMA transfer

1. Configure settings to perform DMA transfer every [SDSIZE register setting value × *n* blocks], and suspend writing to the SDBUFR register before setting the SDIOMD.C52PUB bit (*n* = 1, 2, ...).
2. Set the SDIOMD.C52PUB bit to 1. Then, when the SD buffer becomes empty, the SDHI issues CMD52.
3. After receiving the response for CMD52, resume DMA transfer to the SDBUFR register.

52.5.5 Note on Setting the SDCLKCR Register

The SDCLKCR register cannot be written when the SDSTS2.SDCLKCREN flag is 0. Set the SDSTS2.SDCLKCREN flag to 1 before writing to the SDCLKCR register.

52.5.6 Writing to the SDSTOP Register During a Multi-Block Read Sequence

When the SDSTOP.SDBLKCNTEN bit is 1 during a multi-block read sequence, if the SDSTOP.STP bit is set to 1 and the command sequence is stopped, the command sequence may not be completed depending on when the SDSTOP.STP bit is set to 1. To avoid this problem, set the SDSTOP.STP bit and the SDSTOP.SDBLKCNTEN bit to 0 simultaneously. Note that at this time, the SDSTOP.SDBLKCNTEN bit should be set to 0 even if the SDSTS2.SDCLKCREN bit is 0. If the SDSTOP.SDBLKCNTEN bit is not set to 0, the command sequence can be completed by setting the SDRST.SDRST bit to 0.
During a CMD53 multi-block transfer, when stopping data transfer by setting the SDIOMD.IOABT bit to 1, the SDSTOP.SDBLKCNTEN bit should remain set to 1.

52.5.7 Controlling Module Operation

SDHI operation is controlled by setting the MSTPCRC.MSTPC12 bit. Setting the MSTPC12 bit to 0 enables the SDHI; setting the MSTPC12 bit to 1 disables the SDHI. The SDHI is disabled after a reset. Registers in the SDHI can be accessed by setting the MSTPC12 bit to 0. Refer to section 11, Low Power Consumption for details.

53. Parallel Data Capture Unit (PDC)

53.1 Overview

This MCU includes a single parallel data capture unit (PDC).
The PDC has the function of communicating with the external I/O devices including image sensors, and specifically transferring parallel data such as an image output from the external I/O devices via the DTC or DMAC to the on-chip RAM and external address spaces (the CS, SDRAM and XSPIareas).

Table 53.1 PDC Specifications

Item	Description
Capture Range	• Desired amounts of parallel data within the following ranges in the vertical and horizontal directions. Vertical direction: 1 to 4095 lines Horizontal direction: 4 to 4095 bytes
Parallel data transfer clock (PIXCLK)	• Operating frequency: 1 to 27 MHz*1
Interrupt Sources	• Receive data ready • Frame end • Overrun • Underrun • Error in the setting for the number of lines • Error in setting for the number of bytes per line
Startup of DTC/DMAC	• The receive data ready interrupt is capable of starting the DTC or DMAC
Parallel data transfer clock output (PCKO)	• Operating frequency: 1 to 37.5 MHz*2 • Clock source: Peripheral module clock B (PCLKB) • Frequency division ratio: Selectable from 2, 4, 6, 8, 10, 12, 14, and 16.
Others	• PDC reset function • Selectable active sense for the VSYNC and HSYNC signals • Monitoring of the VSYNC and HSYNC signals • Endian selection
Reducing Power Consumption	• The PDC can be placed in the module stop state.
Protect Zone filter	• Security attribution can be set.*3

Note 1. The frequency of the parallel data transfer clock (PIXCLK) should be equal to or less than 0.6 × PCLKB (peripheral module clock).
Note 2. The operating frequency is 37.5 MHz when that of the peripheral module clock B (PCLKB) is 75 MHz and the frequency division ratio is 2.
Note 3. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

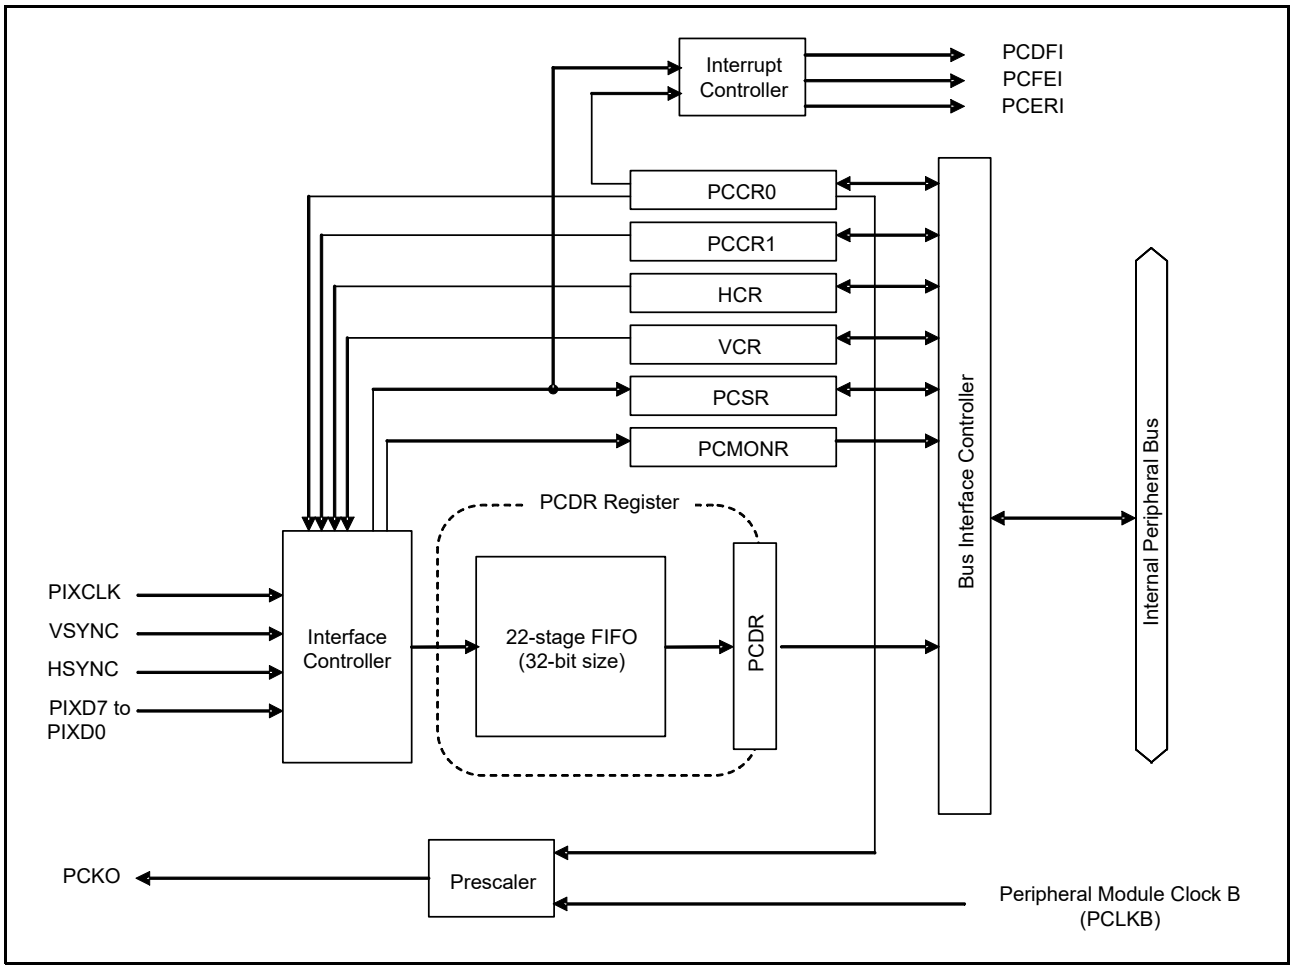

Figure 53.1 Block Diagram of the PDC

Table 53.2 Input and Output Pins of the PDC

Pin Name	Input/Output	Description
PIXCLK	Input	Parallel data transfer clock
VSYNC	Input	Vertical synchronization signal
HSYNC	Input	Horizontal synchronization signal
PIXD7 to PIXD0	Input	8-bit data
PCKO	Output	Output of the parallel data transfer clock

53.2 Register Descriptions

53.2.1 PDC Control Register 0 (PCCR0)

Address(es): PDC.PCCR0 8784 1000h, PDC_NS.PCCR0 0784 1000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	EDS	PCKDIV[2:0]			PCKOE	HERIE	VERIE	UDRIE	OVIE	FEIE	DFIE	PRST	HPS	VPS	PCKE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PCKE	PIXCLK Input Enable	0: PIXCLK input is disabled. 1: PIXCLK input is enabled.	R/W
b1	VPS	VSYNC Signal Polarity Select	0: VSYNC signal is active high. 1: VSYNC signal is active low.	R/W
b2	HPS	HSYNC Signal Polarity Select	0: HSYNC signal is active high. 1: HSYNC signal is active low.	R/W
b3	PRST	PDC Reset	0: PDC reset is not applied. 1: PDC is reset.	R/(W) *1
b4	DFIE	Receive Data Ready Interrupt Enable	0: Generation of receive data ready interrupt requests is disabled. 1: Generation of receive data ready interrupt requests is enabled.	R/W
b5	FEIE	Frame End Interrupt Enable	0: Generation of frame end interrupt requests is disabled. 1: Generation of frame end interrupt requests is enabled.	R/W
b6	OVIE	Overrun Interrupt Enable	0: Generation of overrun interrupt requests is disabled. 1: Generation of overrun interrupt requests is enabled.	R/W
b7	UDRIE	Underrun Interrupt Enable	0: Generation of underrun interrupt requests is disabled. 1: Generation of underrun interrupt requests is enabled.	R/W
b8	VERIE	Vertical Line Number Setting Error Interrupt Enable	0: Generation of vertical line number setting error interrupt requests is disabled. 1: Generation of vertical line number setting error interrupt requests is enabled.	R/W
b9	HERIE	Horizontal Byte Number Setting Error Interrupt Enable	0: Generation of horizontal byte number setting error interrupt requests is disabled. 1: Generation of horizontal byte number setting error interrupt requests is enabled.	R/W
b10	PCKOE	PCKO Output Enable	0: PCKO output is disabled (fixed to the high level) 1: PCKO output is enabled.	R/W
b13 to b11	PCKDIV[2:0]	PCKO Frequency Division Ratio Select	b13 b11 0 0 0: PCKO/2 0 0 1: PCKO/4 0 1 0: PCKO/6 0 1 1: PCKO/8 1 0 0: PCKO/10 1 0 1: PCKO/12 1 1 0: PCKO/14 1 1 1: PCKO/16	R/W
b14	EDS	Endian Select	0: Little endian 1: Big endian	R/W
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 1 can be written to this bit.

The PCCR0 register should only be set while the PCE bit in the PCCR1 register is 0.

PCKE Bit (PIXCLK Input Enable)

This bit enables and disables the input through the PIXCLK pin.
Set this bit to 1 before enabling reception. After enabling input through the PIXCLK pin, use the PRST bit to initialize the PDC.
When setting this bit to 0, do so after disabling reception operations.

VPS Bit (VSYNC Signal Polarity Select)

This bit selects the active sense of the VSYNC signal.

HPS Bit (HSYNC Signal Polarity Select)

This bit selects the active sense of the HSYNC signal.

PRST Bit (PDC Reset)

This bit initializes the internal status of the PDC and the target registers of the PDC reset. Refer to section 53.3.11, Reset State for the target registers.
The PDC should be reset after setting the PCKE bit to 1.
When 1 is written to the PRST bit, initialization is started in synchronization with the PIXCLK. After completion of the initialization, the PRST bit is automatically cleared to 0. When the PDC is reset, ensure that the PIXCLK pin has an input signal. Also, after 1 has been written to the PRST bit, do not proceed to the next step until verifying that the bit has returned to 0.
In the case of consecutive PDC resets, wait for at least one cycle of PIXCLK after verifying that the PRST bit has returned to 0.

DFIE Bit (Receive Data Ready Interrupt Enable)

This bit enables and disables the generation of receive data ready interrupt requests.

FEIE Bit (Frame End Interrupt Enable)

This bit enables and disables the generation of frame end interrupt requests.

OVIE Bit (Overrun Interrupt Enable)

This bit enables and disables the generation of overrun interrupt requests.

UDRIE Bit (Underrun Interrupt Enable)

This bit enables and disables the generation of underrun interrupt requests.

VERIE Bit (Vertical Line Number Setting Error Interrupt Enable)

This bit enables and disables the generation of vertical line number setting error interrupt requests.

HERIE Bit (Horizontal Byte Number Setting Error Interrupt Enable)

This bit enables and disables the generation of horizontal byte number setting error interrupt requests.

PCKOE Bit (PCKO Output Enable)

This bit enables and disables an output from PCKO.
When the PCKOE bit is cleared to 0 during low output of PCKO, it may cause high output at the time of clearing, resulting in spoiling the duty factor.

PCKDIV[2:0] Bits (PCKO Frequency Division Ratio Select)

This bit selects the frequency division ratio of the PCKO.
The PCKO output is a clock signal derived by dividing the PCLKB clock signal by the value from 2 to 16 corresponding to the setting of the PCKDIV[2:0] bits.
The operating frequency should be set in accord with that of PCLKB to a value within the range from 1 to 37.5 MHz.

EDS Bit (Endian Select)

This bit selects an endian for the captured data.

53.2.2 PDC Control Register 1 (PCCR1)

Address(es): PDC.PCCR1 8784 1004h, PDC_NS.PCCR1 0784 1004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PCE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PCE	PDC Operation Enable	0: Operations for reception are disabled. 1: Operations for reception are enabled.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

PCE Bit (PDC Operation Enable)

This bit enables and disables operations for reception.
When the PCE bit is set to 1 during assertion of the VSYNC signal, the PDC starts operations for reception from the next effective edge of the VSYNC signal.
The PCE bit should only be cleared to 0 while operations for reception or continued reception are stopped, including the frame end interrupt and so on. Regarding operations for continued reception, refer to section 53.3.6, Operations for Continued Reception at the Time of Frame End.

53.2.3 PDC Status Register (PCSR)

Address(es): PDC.PCSR 8784 1008h, PDC_NS.PCSR 0784 1008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	HERF	VERF	UDRF	OVRF	FEF	FEMPF	FBSY
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	FBSY	Frame Busy Flag	0: Operations for reception are stopped. 1: Operations for reception are ongoing.	R
b1	FEMPF	FIFO Empty Flag	0: FIFO is not empty. 1: FIFO is empty.	R
b2	FEF	Frame End Flag	0: Frame end has not been generated. 1: Frame end has been generated.	R/(W) *1
b3	OVRF	Overrun Flag	0: FIFO overrun has not been generated. 1: FIFO overrun has been generated.	R/(W) *1
b4	UDRF	Underrun Flag	0: Underrun has not been generated. 1: Underrun has been generated.	R/(W) *1
b5	VERF	Vertical Line Number Setting Error Flag	0: Vertical line number setting error has not been generated. 1: Vertical line number setting error has been generated.	R/(W) *1
b6	HERF	Horizontal Byte Number Setting Error Flag	0: Horizontal byte number setting error has not been generated. 1: Horizontal byte number setting error has been generated.	R/(W) *1
b31 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. 0 can only be written to these bits to clear these flags after they have been read out as 1.

FBSY Flag (Frame Busy Flag)

This flag indicates the state of PDC operations.

[Setting Condition]

- Detection of the effective edge of the VSYNC signal after the enabling of operations for reception.

[Clearing Conditions]

- Reception of one-frame of data according to the settings of the VCR and HCR registers being completed.*1
- When an error (overrun, underrun, vertical line number setting error, or horizontal byte number setting error) occurs
- When the PCCR1.PCE bit is 0

Note 1. This flag is 0 during operations for continued reception.

FEMPF Flag (FIFO Empty Flag)

This flag indicates the state of the FIFO.

This flag indicates the state of the FIFO at the time when a vertical line number setting error or a horizontal byte number setting error occurs and is 0 following an overrun and undefined following an underrun.

[Setting Conditions]*1

- Reading of the PCDR register while the FIFO is empty.

- Detection of an effective edge of the VSYNC signal.
- The PDC being reset.

[Clearing Condition]*1

- Storage of the data captured in the FIFO.

Note 1. This flag is undefined following an underrun, and is set to either 0 or 1.

FEF Flag (Frame End Flag)

This flag indicates the end of a frame.

[Setting Condition]

- Reception of one frame of data in accord with the settings of the VCR and HCR registers.*1

[Clearing Conditions]

- The PDC being reset.
- Writing of 0 to the bit after it has been read as 1.

Note 1. In the case of operations for continued reception, this flag will be 1 after their completion.

OVRF Flag (Overrun Flag)

This flag indicates an overrun.

[Setting Condition]

- Data for reception arriving while the FIFO is full.

[Clearing Conditions]

- The PDC being reset.
- Writing of 0 to the bit after it has been read as 1.

UDRF Flag (Underrun Flag)

This flag indicates an underrun.

[Setting Condition]

- Reading of the PCDR register while the FIFO is empty.

[Clearing Conditions]

- The PDC being reset.
- Writing of 0 to the bit after it has been read as 1.

VERF Flag (Vertical Line Number Setting Error Flag)

This flag indicates an error in the setting for the number of lines.

[Setting Condition]

- The VSYNC signal is negated because fewer lines have been captured than the value in the VCR register.

[Clearing Conditions]

- The PDC being reset.
- Writing of 0 to the bit after it has been read as 1.

HERF Flag (Horizontal Byte Number Setting Error Flag)

This flag indicates an error in the setting for the number of bytes in a line.

[Setting Condition]

- The HSYNC signal is negated because fewer bytes in a line have been captured than the value in the HCR register.

[Clearing Conditions]

- The PDC being reset.
- Writing of 0 to the bit after it has been read as 1.

53.2.4 PDC Pin Monitor Register (PCMONR)

Address(es): PDC.PCMONR 8784 100Ch, PDC_NS.PCMONR 0784 100Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HSYNC	VSYNC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	VSYNC	VSYNC Signal Status Flag	0: VSYNC signal is at the low level. 1: VSYNC signal is at the high level.	R
b1	HSYNC	HSYNC Signal Status Flag	0: HSYNC signal is at the low level. 1: HSYNC signal is at the high level.	R
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

VSYNC Flag (VSYNC Signal Status Flag)

This flag indicates the state of the VSYNC signal.

HSYNC Flag (HSYNC Signal Status Flag)

This flag indicates the state of the HSYNC signal.

53.2.5 PDC Receive Data Register (PCDR)

Address(es): PDC.PCDR 8784 1010h, PDC_NS.PCDR 0784 1010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The PDC includes a 32-bit, 22-stage FIFO buffer for the storage of captured data. The FIFO buffer is mapped to the 4-byte PCDR register, and captured data are read from this register in 4-byte units. The receive data ready flag is set for every 32 bytes of received data, and this also leads to a receive data ready interrupt if the DFIE bit in the PCCR0 register is set to 1. When a receive data ready interrupt is generated, read the PCDR register eight times. Figure 53.2 shows a schematic view of the PCDR register.

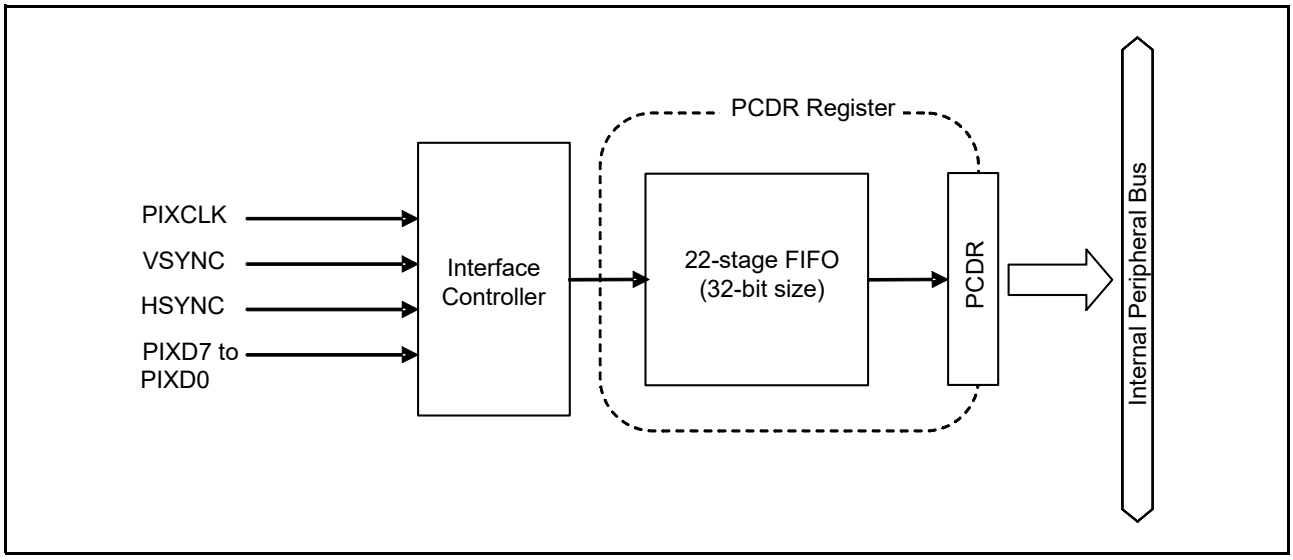

Figure 53.2 Schematic View of the PCDR Register

For the format of the captured data, either big or little endian can be selected by the EDS bit of the PCCR0 register. Figure 53.3 shows the arrangements of data according to the endian formats.

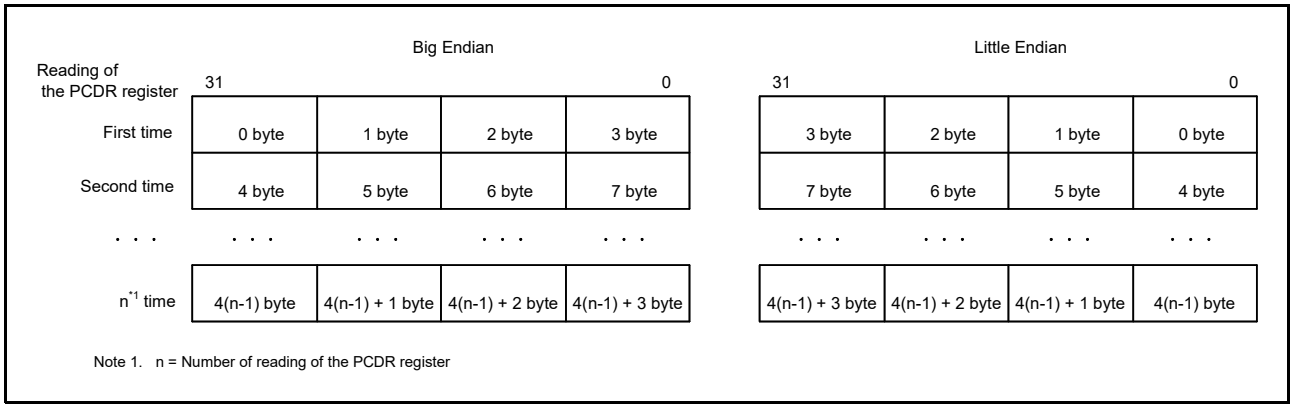

Figure 53.3 Endian Formats

53.2.6 Vertical Capture Register (VCR)

Address(es): PDC.VCR 8784 1014h, PDC_NS.VCR 0784 1014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	VSZ[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	VST[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	VST[11:0]	Vertical Capture Start Line Position	Number of the line where capture is to start.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b16	VSZ[11:0]	Vertical Capture Size	Number of lines to be captured.	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

For the relationship between the VCR register setting and the captured range, refer to section 53.3.3, Settings of the VCR and HCR Registers and the Captured Range.
The VCR register should be set while the PCE bit in the PCCR1 register is 0.

VST[11:0] Bits (Vertical Capture Start Line Position)

These bits set the number of the line where capture is to start.
To set the first line, these bits should be 000h; to set the 4095th line, they should be FFEh.
The setting of the VST[11:0] bits should be within the range from 000h to FFEh and, in combination with that of the VSZ[11:0] bits, satisfy the following relation:
Setting range of the VST[11:0] bits: $1 \leq VST[11:0] + VSZ[11:0] \leq FFFh$.

VSZ[11:0] Bits (Vertical Capture Size)

These bits set the number of lines to be captured.
To set one line, these bits should be 001h; to set 4095 lines, they should be FFFh.
The setting of the VSZ[11:0] bits should be within the range from 001h to FFFh and, in combination with that of the VST[11:0] bits, satisfy the following relation:
Setting range of the VSZ[11:0] bits: $1 \leq VST[11:0] + VSZ[11:0] \leq FFFh$.

53.2.7 Horizontal Capture Register (HCR)

Address(es): PDC.HCR 8784 1018h, PDC_NS.HCR 0784 1018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	HSZ[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	HST[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	HST[11:0]	Horizontal Capture Start Byte Position	Horizontal position in bytes where capture is to start.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b16	HSZ[11:0]	Horizontal Capture Size	Number of bytes to be captured horizontally.	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

For the relationship between the HCR register setting and the captured range, refer to section 53.3.3, Settings of the VCR and HCR Registers and the Captured Range.
The HCR register should be set while the PCE bit in the PCCR1 register is 0.

HST[11:0] Bits (Horizontal Capture Start Byte Position)

These bits set the horizontal position in bytes where capture is to start.
To set the first byte, these bits should be 000h; to set the 4092th byte, they should be FFBh.
The setting of the HST[11:0] bits should be within the range from 000h to FFBh and, in combination with that of the HSZ[11:0] bits, satisfy the following relation:
Setting range of the HST[11:0] bits: $4 \leq HST[11:0] + HSZ[11:0] \leq FFFh$.

HSZ[11:0] Bits (Horizontal Capture Size)

These bits set the number of bytes to be captured per line.
To set four bytes, these bits should be 004h; to set 4095 bytes, they should be FFFh.
The setting of the HSZ[11:0] bits should be within the range from 004h to FFFh and, in combination with that of the HST[11:0] bits, satisfy the following relation:
Setting range of the HSZ[11:0] bits: $4 \leq HST[11:0] + HSZ[11:0] \leq FFFh$.

53.3 Operation

53.3.1 Transfer Formats

The PDC supports the four transfer formats shown in Figure 53.4 to Figure 53.7. The format is determined by the setting of the VPS and HPS bits in the PCCR0 register.

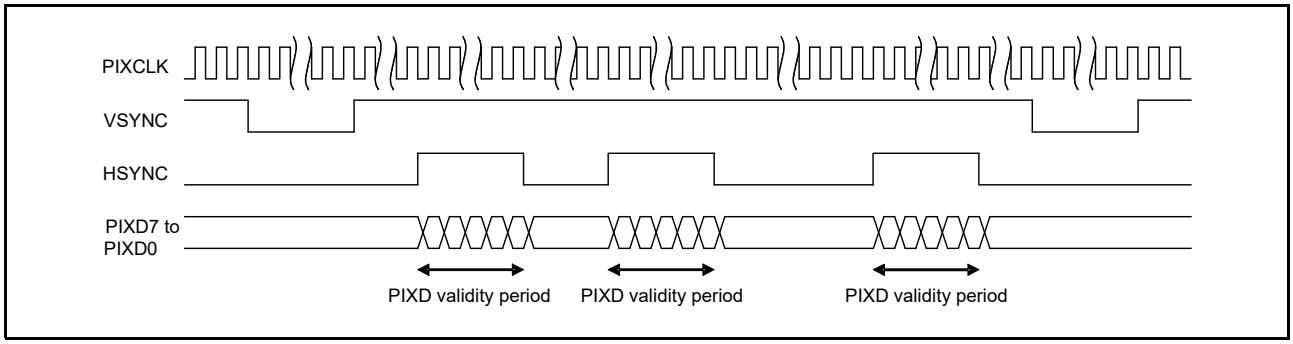

Figure 53.4 PDC Transfer Format (for VPS=0, HPS=0)

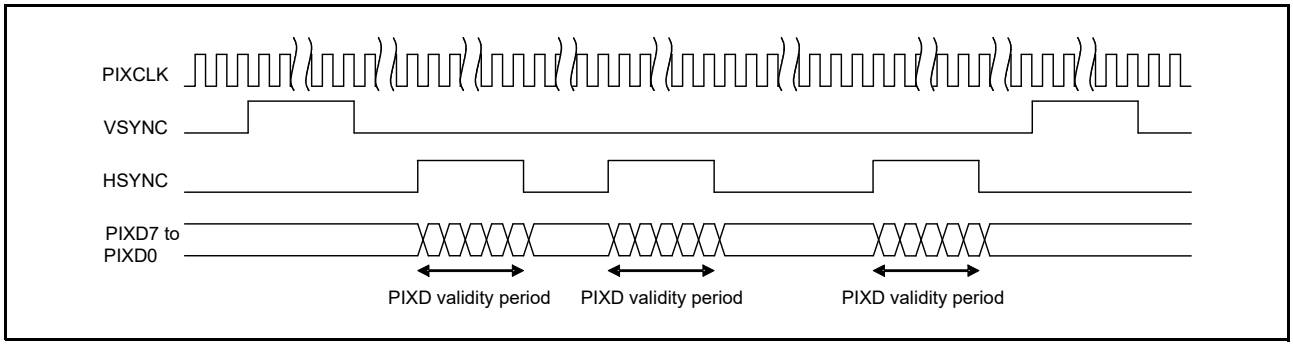

Figure 53.5 PDC Transfer Format (for VPS=1, HPS=0)

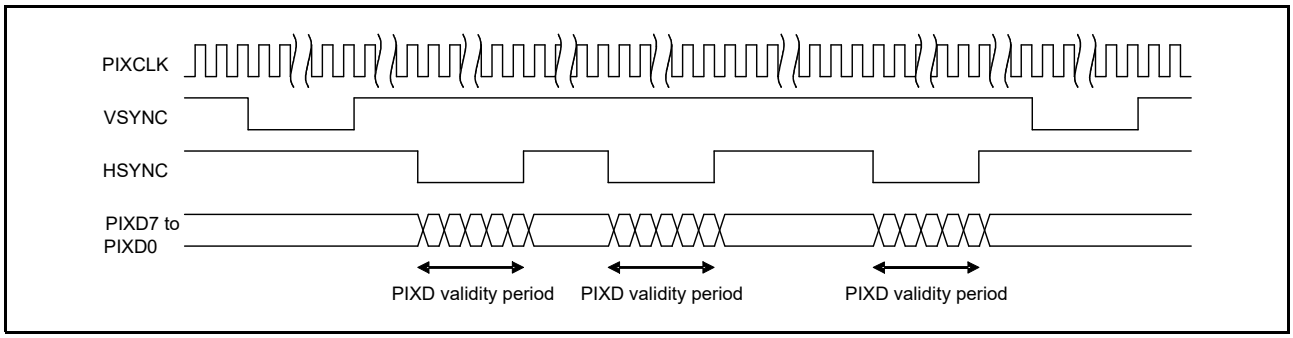

Figure 53.6 PDC Transfer Format (for VPS=0, HPS=1)

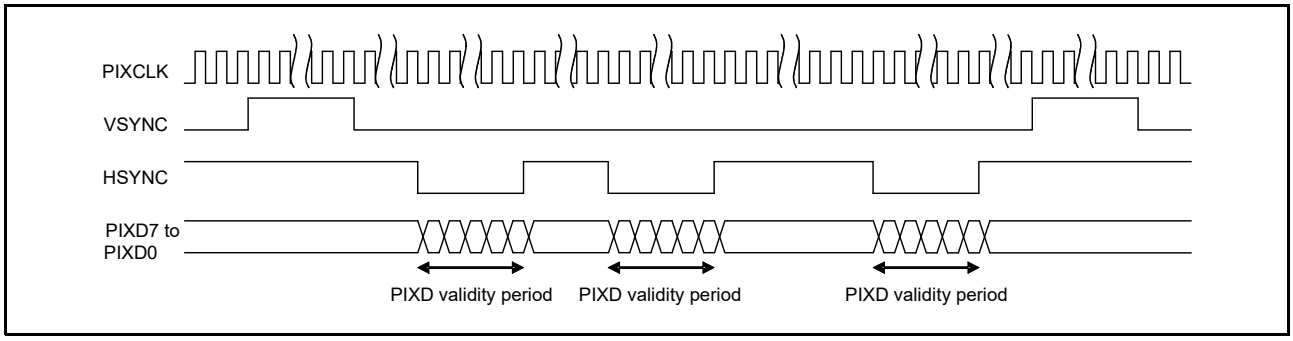

Figure 53.7 PDC Transfer Format (for VPS=1, HPS=1)

53.3.2 Transfer Timing

Figure 53.8 and Table 53.3 show the timing of transfer by the PDC.

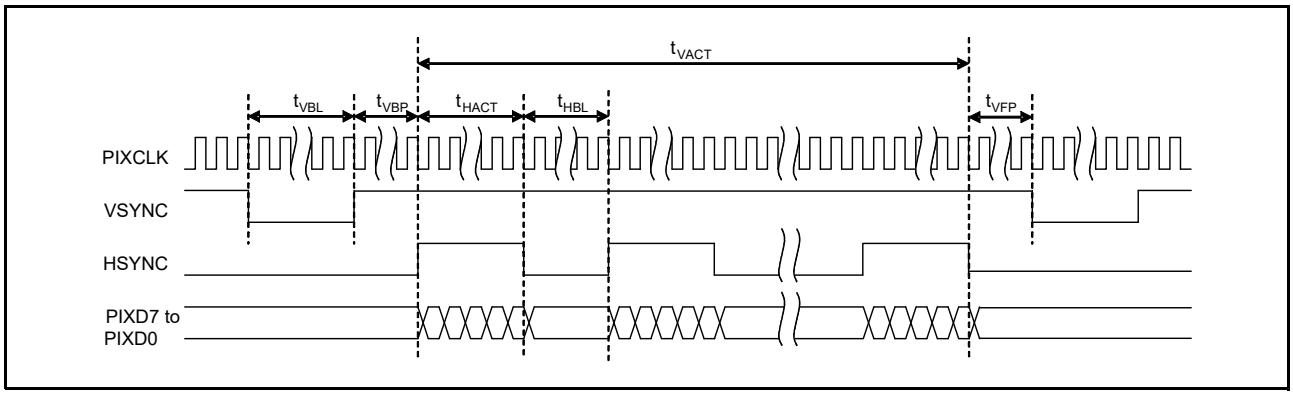

Figure 53.8 PDC Transfer Timing

Table 53.3 PDC Transfer Timing

Item	Symbol	Min*1	Max	Unit
Vertical Blanking Period	t_{VBL}	128	—	PIXCLK
Vertical Backporch	t_{VBP}	10	—	PIXCLK
Horizontal Valid Period	t_{HACT}	4	4095	PIXCLK
Horizontal Blanking Period	t_{HBL}	128	—	PIXCLK
Vertical Frontporch	t_{VFP}	10	—	PIXCLK
Vertical Valid Period	t_{VACT}	1	4095	Line

Note 1. The minimum values are the lowest of which this MCU circuit is capable. They are not values which guarantee the avoidance of overruns, vertical line number setting errors, or horizontal byte number setting errors.

53.3.3 Settings of the VCR and HCR Registers and the Captured Range

Figure 53.9 and Figure 53.10 show the relationship between the settings of the VCR and HCR registers and the captured range.

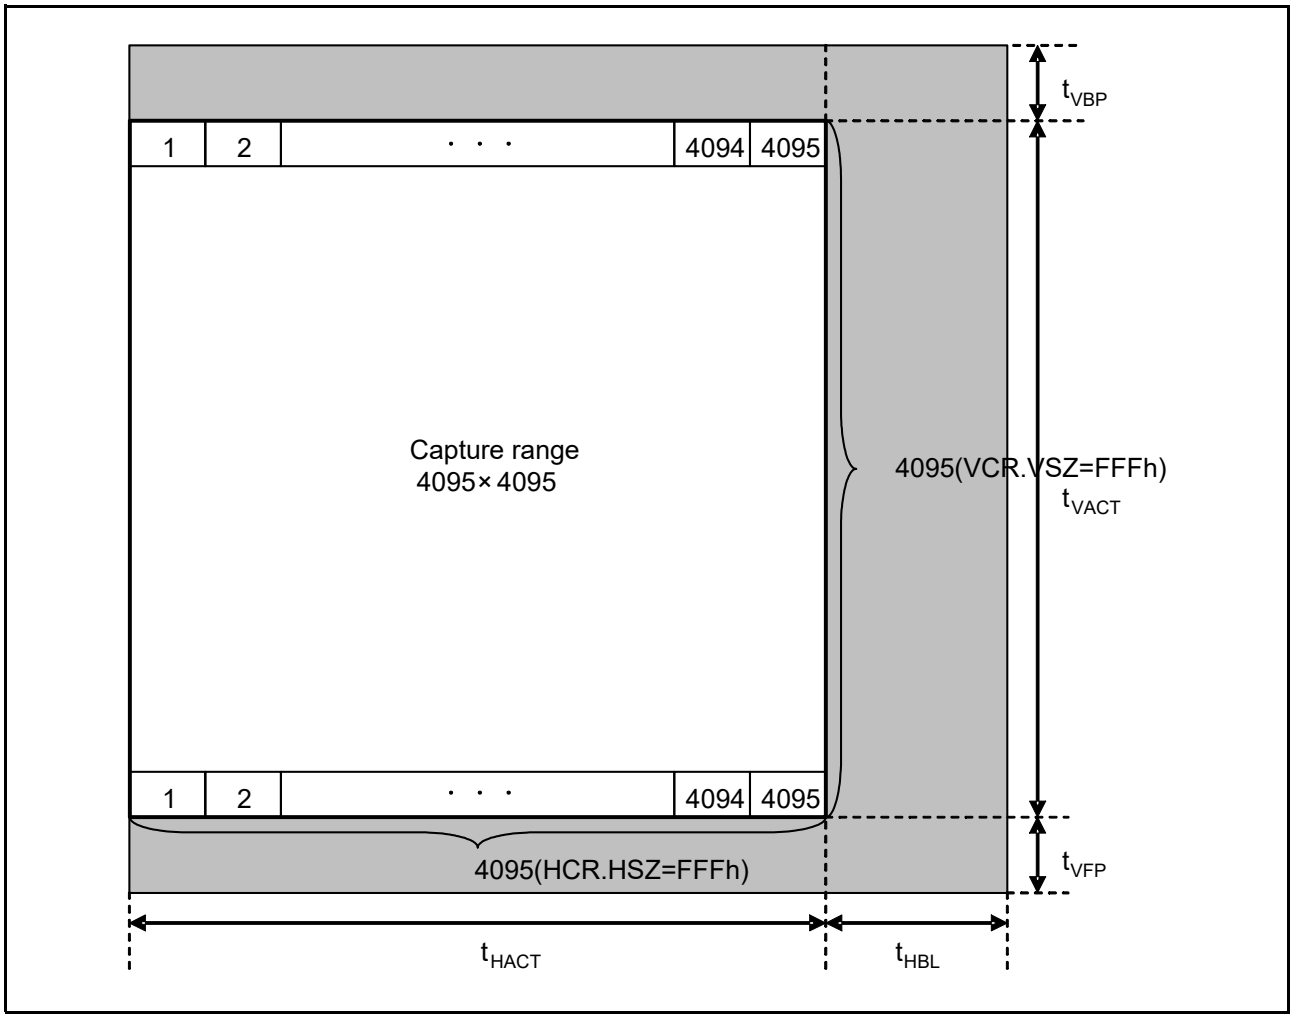

Figure 53.9 Settings of the VCR and HCR Registers and the Captured Range (VCR = 0FFF 0000h, HCR = 0FFF 0000h)

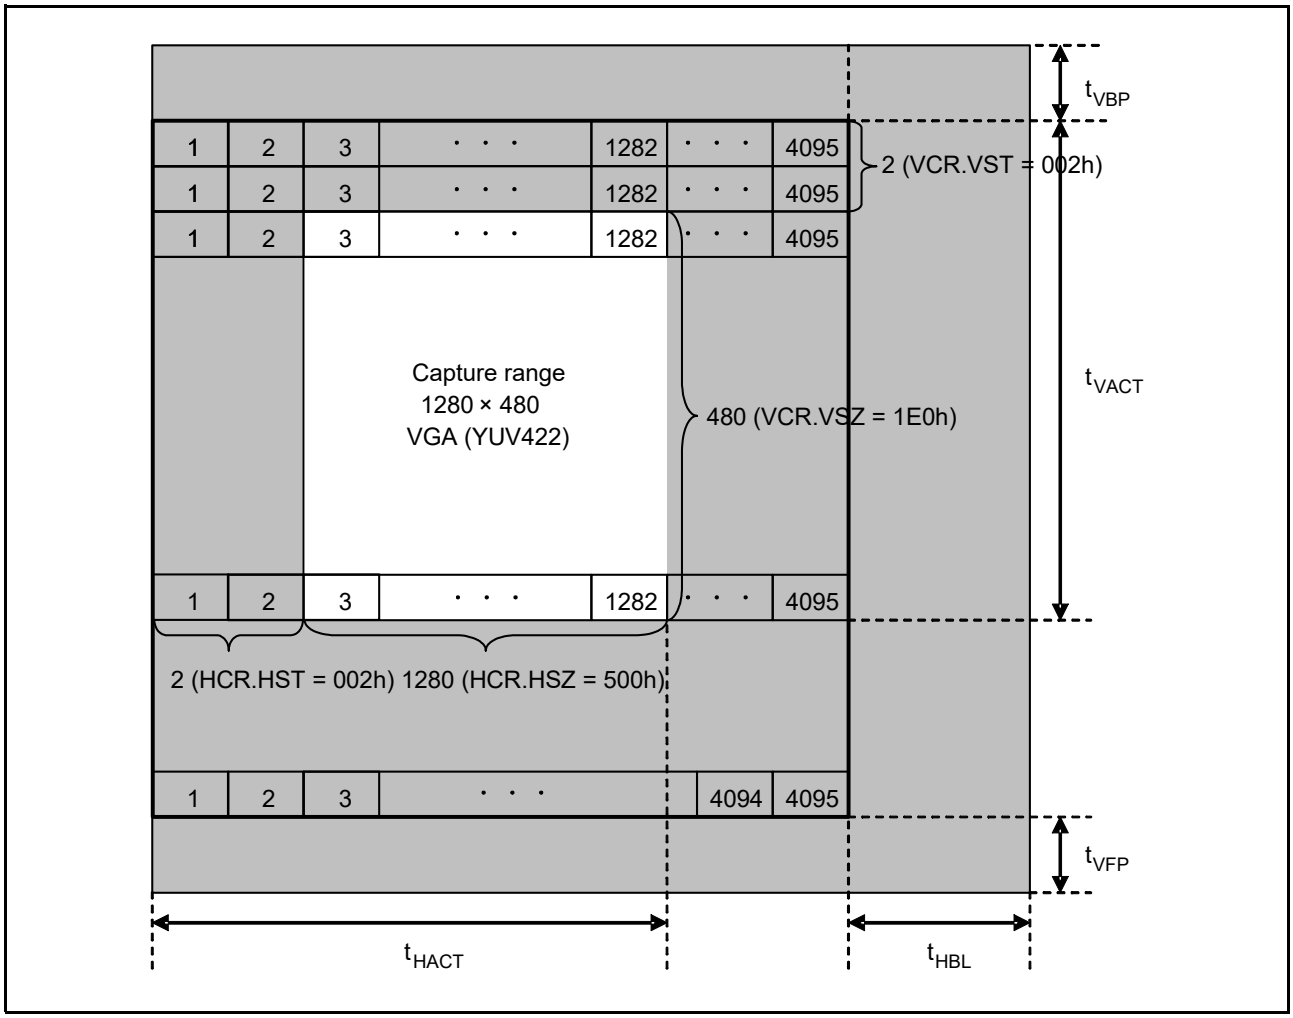

Figure 53.10 Settings of the VCR and HCR Registers and the Captured Range (VCR = 01E0 0002h, HCR = 0500 0002h)

53.3.4 Operations for Reception

Figure 53.11 shows an example of operations for reception when receive data ready interrupts (to start up the DTC or DMAC) and frame end interrupts are in use.

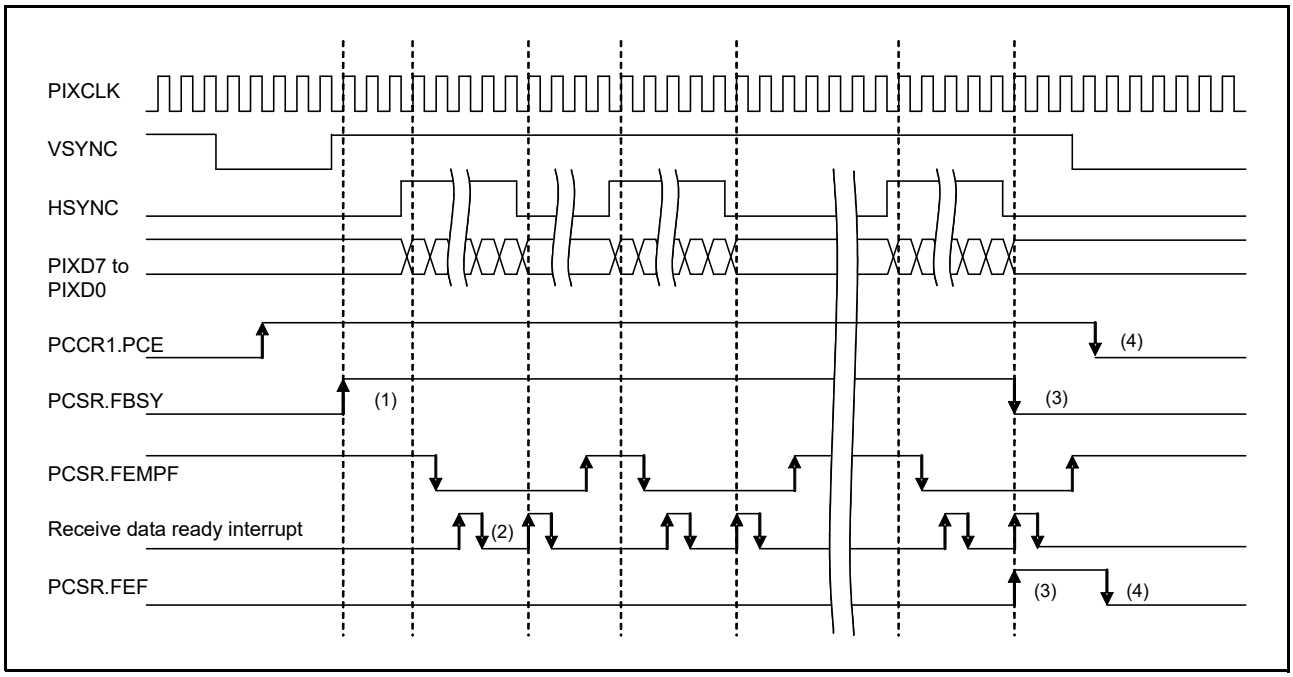

Figure 53.11 Example of Operations for Reception

The actual operations at the times indicated by (1), (2), (3), and (4) in Figure 53.11 are described below.

(1) When an effective edge of the VSYNC signal is detected after the PCE bit in the PCCR1 register is set to 1, the FEMPF flag in the PCSR register is set to 1 and the FIFO is initialized. Concurrently, the FBSY flag in the PCSR register is set to 1 and operations for reception start.

(2) When data within the range for capture set in the VCR and HCR registers is received, the data are stored in the FIFO. The PDC generates a receive data ready interrupt every time it receives 32 bytes of data, and the interrupt starts transfer of the captured data by the DTC or DMAC to the on-chip RAM or an external address space. The FIFO is likely to overrun if reading of the PCDR register takes more time than reception of the data. Check the OVRF flag in the PCSR register to verify an overrun.

(3) After reception of the last byte of data is completed, the FBSY flag in the PCSR register is cleared to 0 and the FEF flag in the PCSR register is set to 1 so that a receive data ready interrupt and frame end interrupt are generated.

(4) The FEMPF flag in the PCSR register is polled by the frame end interrupt, after which the completion of data transfer by the DTC or DMAC should be verified. After the PCE bit in the PCCR1 register is cleared to 0, the FEF flag in the PCSR register is also cleared to 0, and the reception of one frame of data is complete.
If an underrun occurs while the PCSR.FEMPF flag is being polled, setting of the PCSR.FEMPF flag may not proceed. Accordingly, also check the PCSR.UDRF flag during polling, and if an underrun occurs, run appropriate error processing.

If the FEF flag in the PCSR register has been set to 1 before the PCE bit in the PCCR1 register is set to 1, effective edges of the VSYNC signal are not detected and operations for reception will not be started. Clear the FEF flag in the PCSR register to 0 to start operations for data reception.

53.3.5 Operation during the Horizontal Blanking Period

If the horizontal blanking period begins but the number of the received data bytes has not reached 32 bytes since the previous receive data ready, the count of the number of received data bytes is retained and carried over to the next horizontal valid period. Figure 53.12 shows an example of operation during the horizontal blanking period.

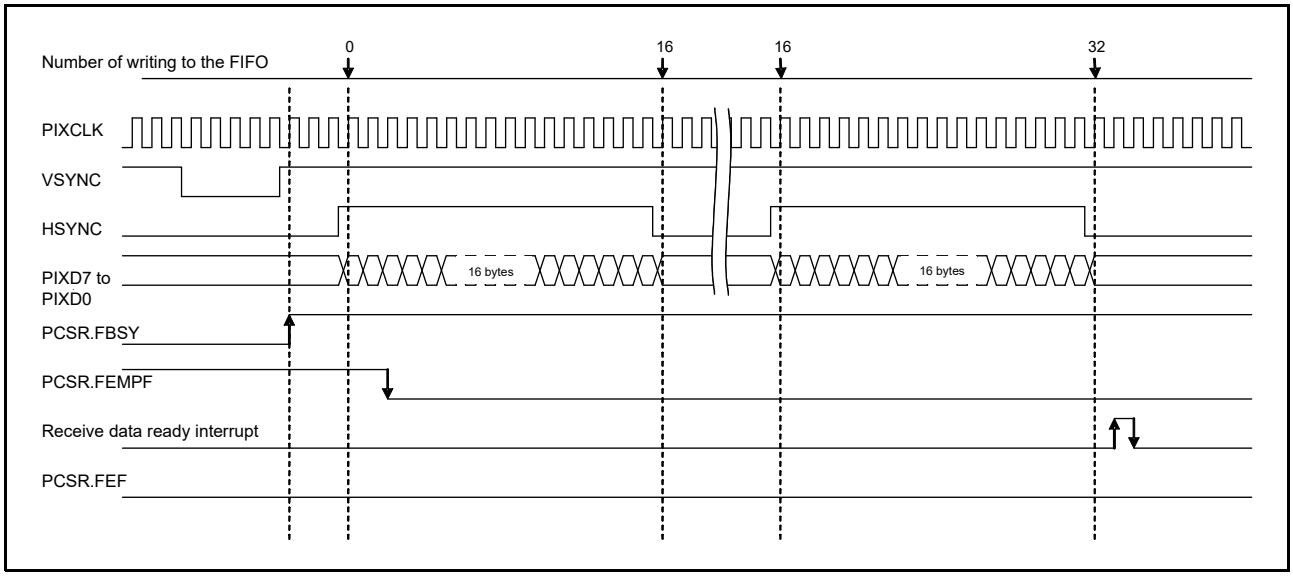

Figure 53.12 Example of Operation during the Horizontal Blanking Period

53.3.6 Operations for Continued Reception at the Time of Frame End

When the last of the data have been received but the number of bytes of data received since the previous receive data ready has not reached 32, the PDC continues to receive data (hereinafter referred to as “continued reception”) until the number reaches 32. After that, it generates a receive data ready and a frame end. The PIXCLK should be input during operations for continued reception. If the data stored in the FIFO are read out during operations for continued reception, the values read are undefined. Figure 53.13 shows an example of operations at the time of frame end.

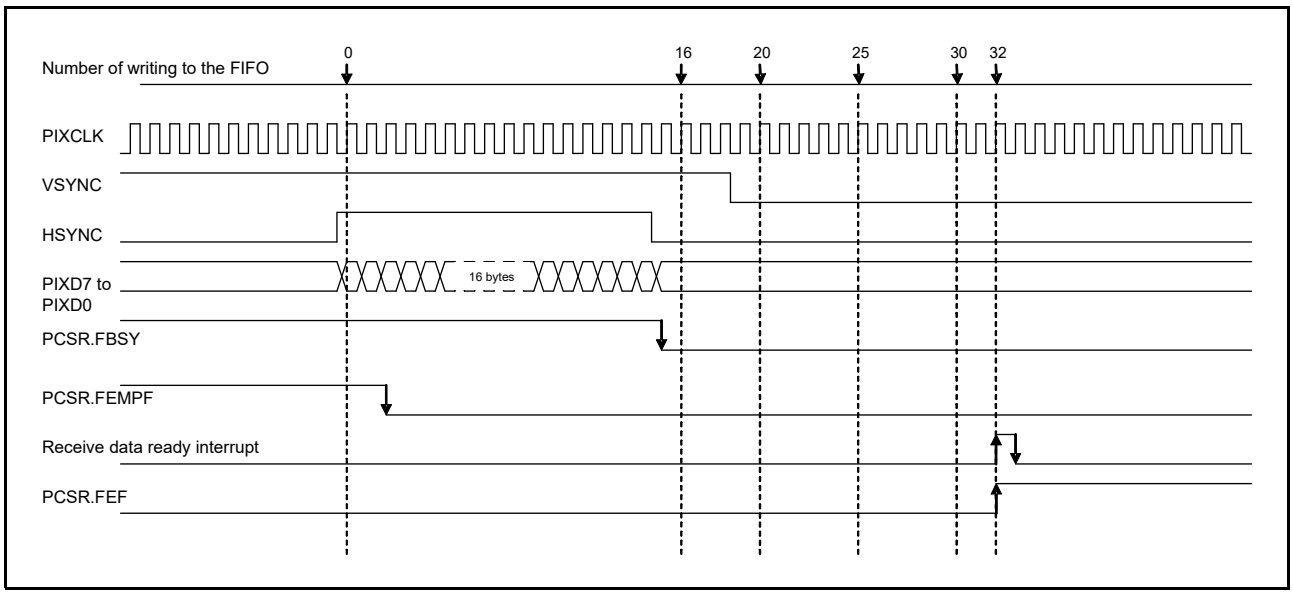

Figure 53.13 Example of Continued Reception at the Time of Frame End

53.3.7 Error Detection

The PDC has functions for error detection so that the software can apply control in response to errors during operations for reception. Table 53.4 summarizes the conditions under which each type of error is detected and the interrupt flags set in response.

Table 53.4 Error Detection

Error Factor	Conditions of Error Detection	Interrupt Flag	Example of Operation
Overrun	Data for reception arriving while the FIFO is full.*1	PCSR.OVRF	Figure 53.14
Underrun	The PCDR register being read while the FIFO is empty.	PCSR.UDRF	Figure 53.15
Vertical line number setting error	Negation of the VSYNC signal when the number of captured lines is less than the value set in the VCR register.	PCSR.VERF	Figure 53.16
Horizontal byte number setting error	Negation of the HSYNC signal when the number of bytes captured in a line is less than the value set in the HCR register.	PCSR.HERF	Figure 53.17

Note 1. This includes data reception during operations for continued reception.

When an error is detected, the PDC sets the corresponding interrupt flag to 1 to stop operations for reception. While the interrupt flag is set to 1, the PDC does not detect effective edges of the VSYNC signal and does not start operations for reception. Clear all error source interrupt flags to 0 to start operations for reception.
In addition, when an error occurs, data stored in the FIFO is disabled.

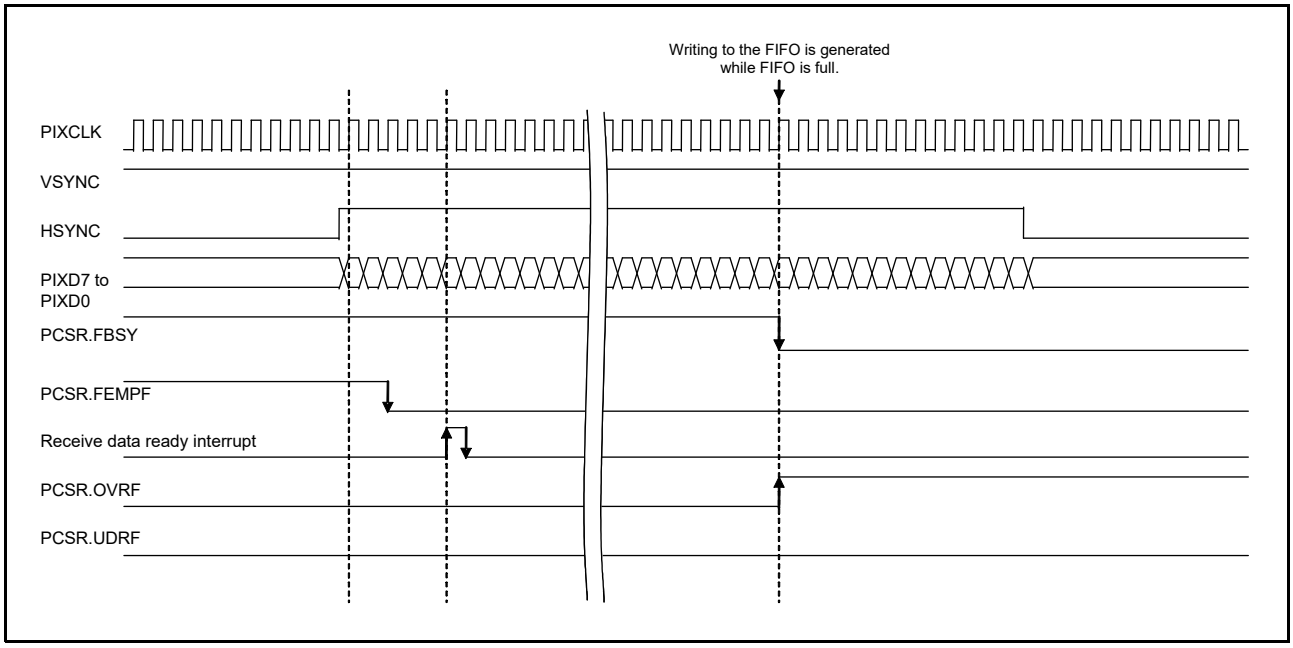

Figure 53.14 Overrun Detected

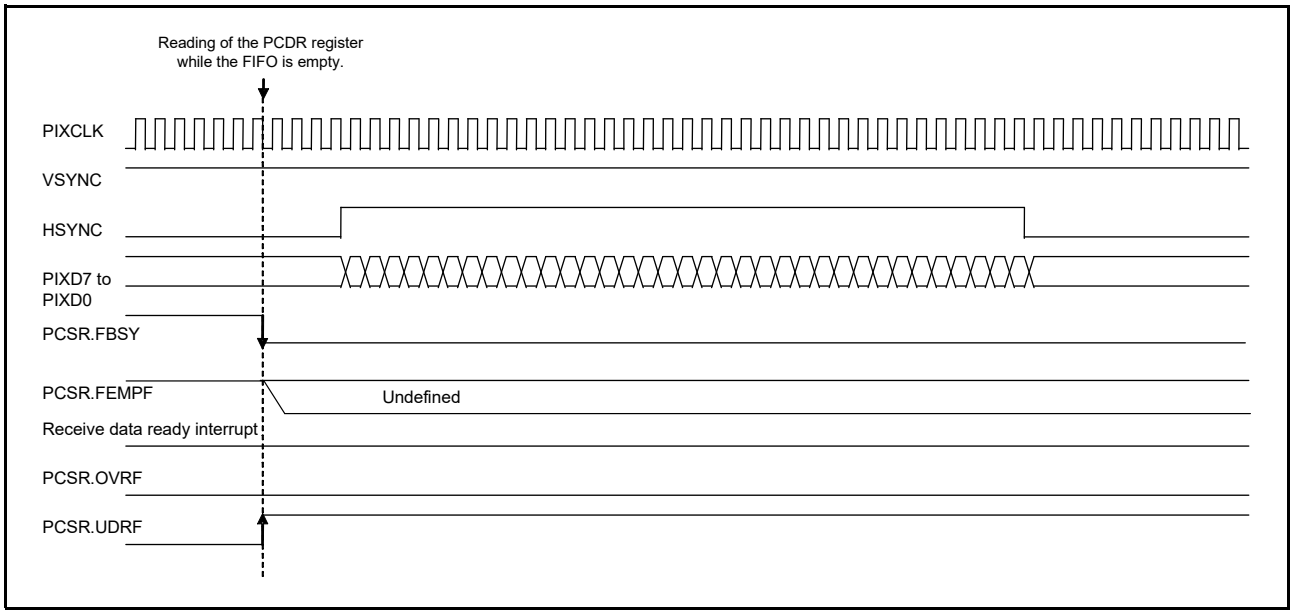

Figure 53.15 Underrun Detected

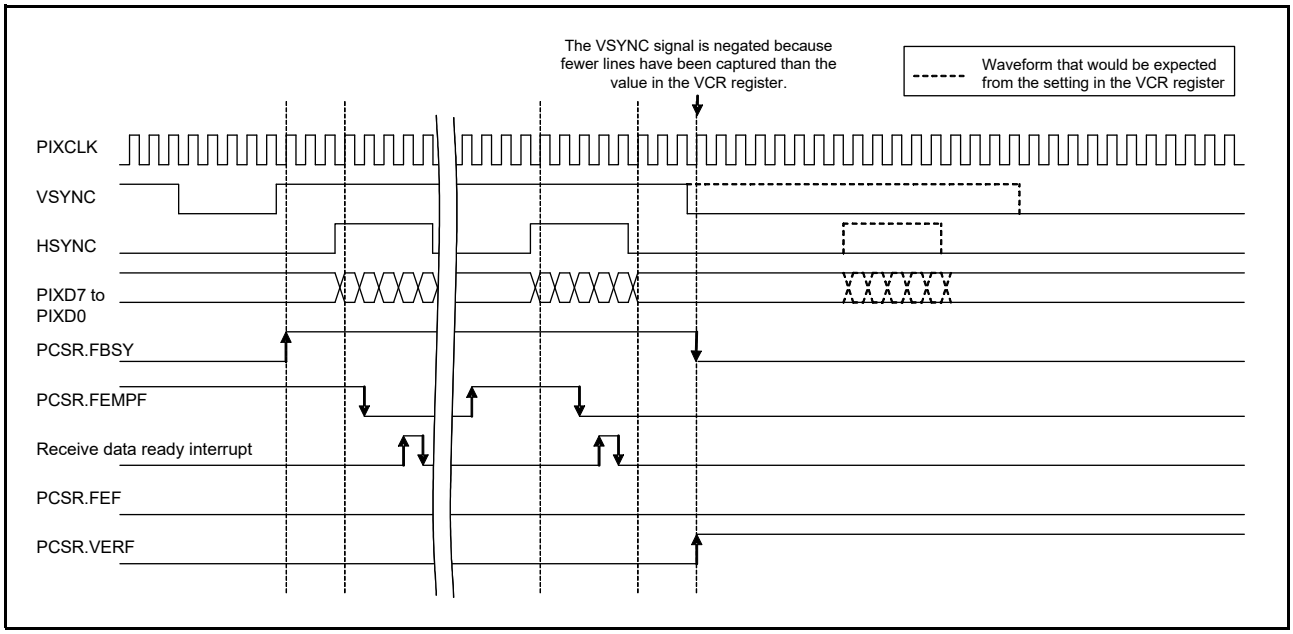

Figure 53.16 Vertical Line Number Setting Error Detected

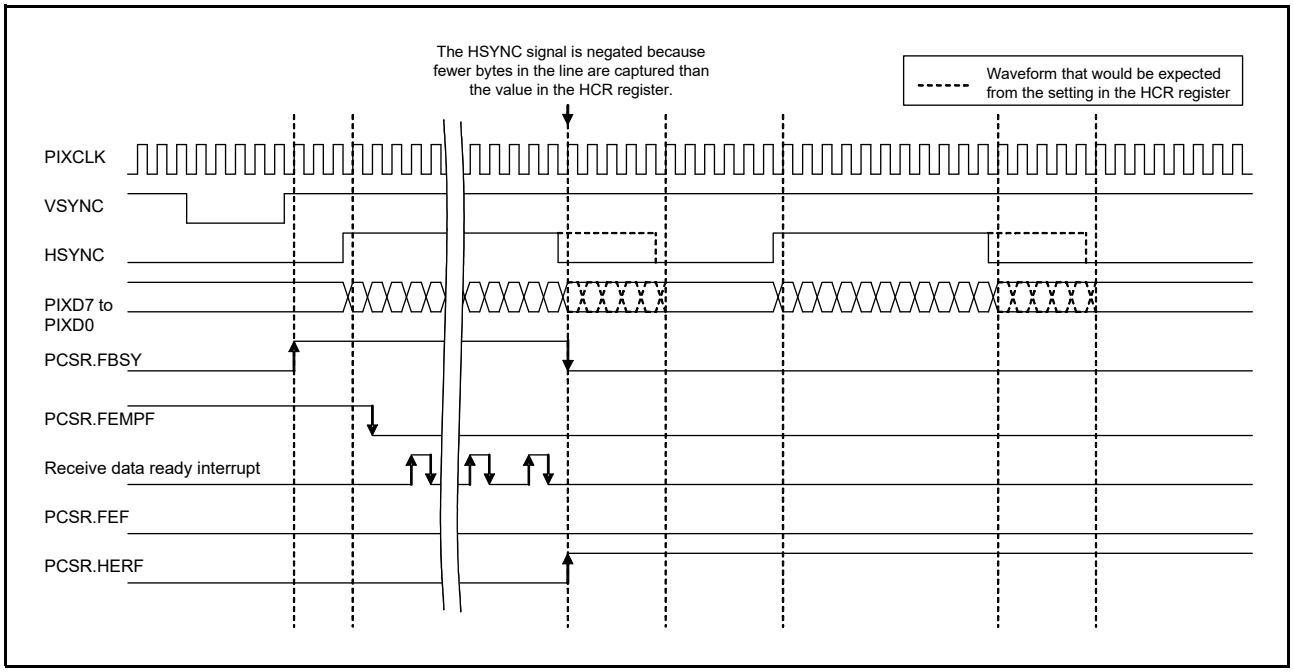

Figure 53.17 Horizontal Byte Number Setting Error Detected

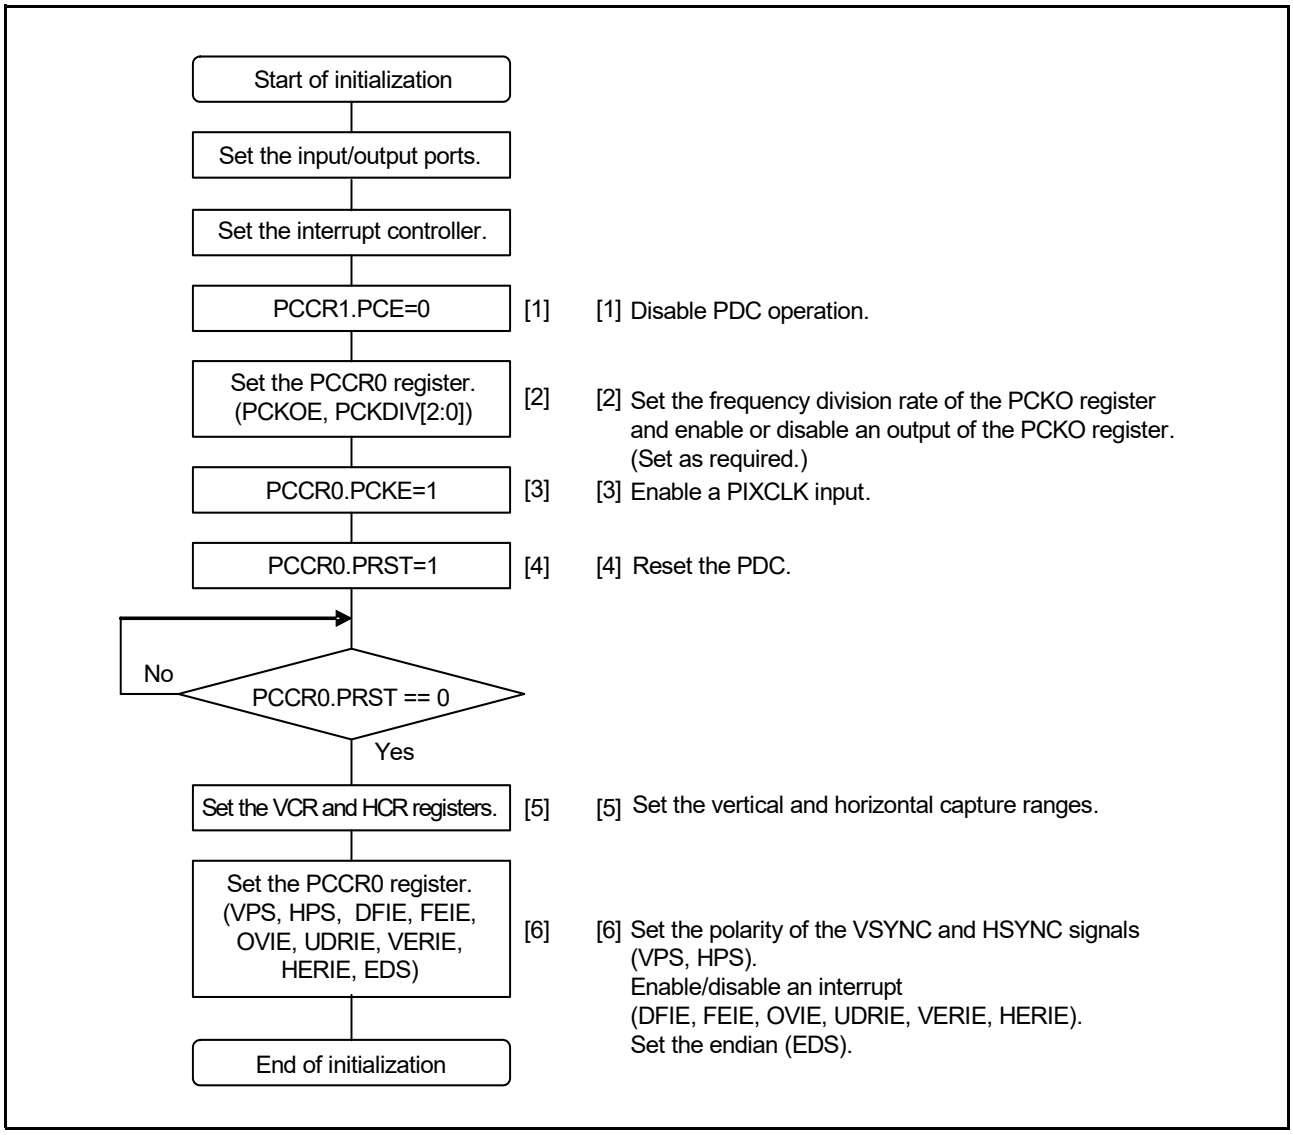
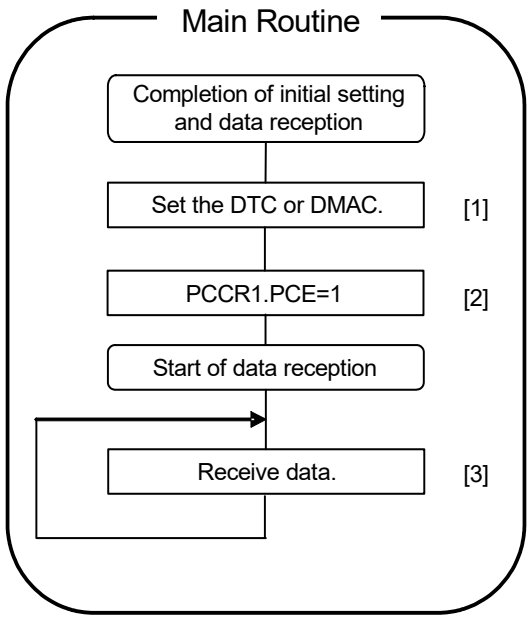
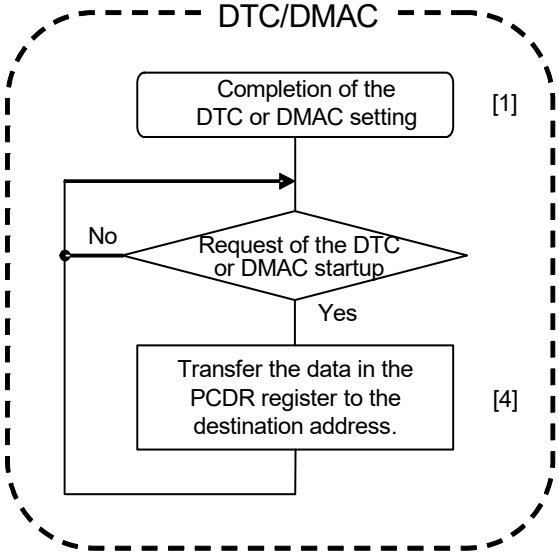
53.3.8 Initial Settings

Figure 53.18 is a sample flowchart for initial settings. For a description of how to set up the input and output ports and the interrupt controller, refer to the descriptions given in the sections on the relevant blocks.







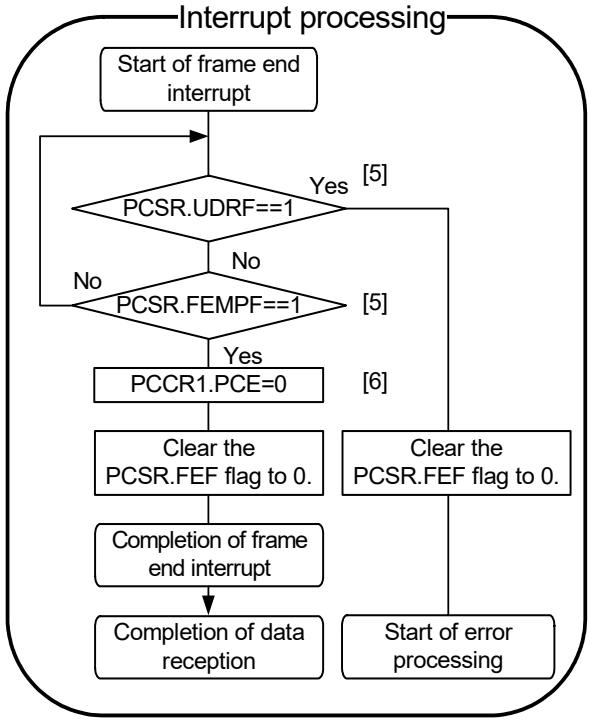


Figure 53.18 Sample Flowchart for Initial Setting of the PDC

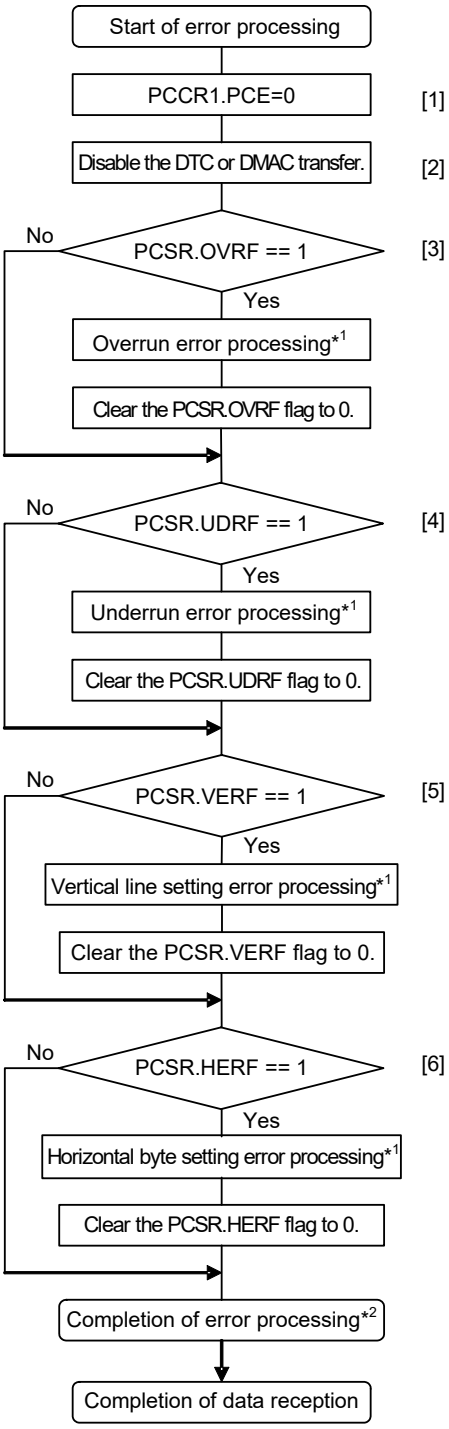
53.3.9 Flows of Operations

Figure 53.19 shows an example of the flows of operations when the receive data ready interrupt (to start up the DTC or DMAC) and frame end interrupt are in use. For a description of how to set up the DTC or DMAC, refer to section 18, DMA Controller (DMACAa) and section 20, Data Transfer Controller (DTCA).

[1] Setting of the DTC or DMAC:
Set the DTC or DMAC according to the size of the captured image.

[2] Enabling of PDC operation:
Set the PCE bit in the PCCR1 register to 1 to enable PDC operation.

[3] Data reception:
Receive the data from the external I/O and wait for generation of a receive data ready interrupt (DTC/DMAC startup) or a frame end interrupt.



[4] Transfer by the DTC or DMAC:
Transfer the data in the PCDR register to the destination address in response to a receive data ready interrupt (DTC/DMAC startup).
Read the PCDR register in longword access and transfer 32 bytes of data per receive data ready interrupt.

[5] Frame end interrupt:
Read the FEMPF flag in the PCSR register and verify completion of the DTC or DMAC transfer.
If an underrun occurs during DTC or DMAC transfer, setting of the FEMPF flag may not proceed. When an underrun occurs, clear the FEF flag to 0 and branch to the appropriate error processing routine.

[6] Completion of data reception:
After completion of the transfer, clear the PCE bit in the PCCR1 register to 0, and then clear the FEF flag in the PCSR register to 0. This completes handling of the frame end interrupt and data reception.

Figure 53.19 Example of Flows of Operations

Figure 53.20 shows an example of the flow of operations in response to an error interrupt.

[1] Disabling of PDC operation:
Clear the PCE bit in the PCCR1 register to 0 to disable PDC operation.

[2] Disabling of the DTC or DMAC transfer:
Disable the transfer of the DTC or DMAC.

[3] Checking the overrun flag:
Read the PCSR register to check the state of the OVRF flag. If the flag is set, processing to handle the overrun error proceeds and the flag is then cleared.

[4] Checking the underrun flag:
Read the PCSR register to check the state of the UDRF flag. If the flag is set, processing to handle the underrun error proceeds and the flag is then cleared.

[5] Checking the vertical line setting error flag:
Read the PCSR register to check the state of the VERF flag. If the flag is set, processing to handle the vertical line setting error proceeds and the flag is then cleared.

[6] Checking the horizontal byte setting error flag:
Read the PCSR register to check the status of the HERF flag. If the flag is set, processing to handle the horizontal byte setting error proceeds and the flag is then cleared.

Note 1. Processing for each type of error is defined by the user, so the user needs to prepare error processing for each.

Note 2. If the CPU, DTC, or DMAC reads the PCDR register after an error interrupt has occurred in response to an interrupt source other than an underrun, an underrun may occur. If an underrun occurs on completion of error processing, run the error processing again and clear the UDRF flag.
Since an underrun after error processing still requires detection, do not prohibit the underrun interrupt before the error processing.

Figure 53.20 Example of Error Processing Flow

53.3.10 Interrupt Source

The interrupt sources of the PDC are receive data ready, frame end, overrun, underrun, vertical line number setting error, and horizontal byte number setting error. The PDC can start up the DTC or DMAC in response to a receive data ready interrupt request for the transfer of data.

Table 53.5 summarizes the interrupt sources of the PDC. When an interrupt condition listed in Table 53.5 is satisfied, the corresponding interrupt is generated. In the case of receive data ready, the interrupt source flag is cleared by reading of the PCDR register. For the interrupt source flag for frame end, the FEF flag in the PCSR register is cleared. For an overrun, underrun, vertical line number setting error, or a horizontal byte number setting error, the flags must be checked to identify the error source flag because their interrupt vectors are allocated to the same address by the PCERI. Once identified, the corresponding error interrupt source flag (the OVRF, UDRF, VERF, or HERF flag) in the PCSR register should be cleared.

When the DTC or DMAC is to handle data transfer, whichever is selected should be set up first. After enabling the block to handle transfer, set up the PDC. For descriptions of how to set up the DTC and DMAC, refer to section 18, DMA Controller (DMACAa) and section 20, Data Transfer Controller (DTCA).

In addition, for receive data ready, if the ICU.IRn.IR flag is 1, the interrupt request signal is retained internally but an interrupt request is not output to the ICU, even if the interrupt condition is satisfied. In this case, however, only one interrupt request signal can be retained internally. If the ICU.IRn.IR flag is 0, the retained interrupt request signal is output to the ICU. After completion of output, the request flag is automatically cleared. An interrupt request signal retained internally can also be cleared by setting the corresponding interrupt enable bit (the DFIE bit in the PCCR0 register) to 0.

When the receive data ready interrupt is disabled from the enabled state, set the ICU.IRn.IR flag to 0 according to the following procedure.

1. Set the IERn.IENj bit to the value that disables interrupt requests.
2. Set the receive data ready interrupt enable bit (the DFIE bit) to “disabled” and read out the register after writing to verify that the bit has the new value.
3. Set the ICU.IRn.IR flag to 0.

Table 53.5 PDC Interrupt Source

Interrupt Source	Abbre -viation	Interrupt Conditions	DTC/DMAC Startup
Receive Data Ready	PCDFI	Receive data ready occurring while the DFIE bit in the PCCR0 register is 1.	Possible
Frame End	PCFEI	Frame end occurring while the FEIE bit in the PCCR0 register is 1.	Impossible
Errors	PCERI	An overrun occurring while the OVIE bit in the PCCR0 register is 1. An underrun occurring while the UDRIE bit in the PCCR0 register is 1. A vertical line number setting error occurring while the VERIE bit in the PCCR0 register is 1. A horizontal byte number setting error occurring while the HERIE bit in the PCCR0 register is 1.	Impossible

53.3.11 Reset State

Resetting of the PDC is divided into two types, PDC reset and other reset. Other resets include RES# pin reset, power-on reset, voltage-monitoring 0 reset, voltage-monitoring 1 reset, voltage-monitoring 2 reset, voltage-monitoring 4 reset, voltage-monitoring 5 reset, core voltage monitoring reset, temperature monitoring reset, independent watchdog timer rese, watchdog timer reset, bus error reset, common memory error reset, local memory error reset, deep software standby reset, and software reset. Table 53.6 lists the range and states following the two types of reset.

Table 53.6 Reset State

	PDC Reset	Other reset
PCCR0	Retained	Reset
PCCR1	Retained	Reset
PCSR	Reset	Reset
PCMONR	Retained	Reset
PCDR	Retained	Reset
VCR	Retained	Reset
HCR	Retained	Reset

53.4 Usage Notes

53.4.1 Setting of the Module Stop Function

The module stop control register C (MSTPCRC) enables or disables operation of the PDC. Operation of the PDC is stopped when the value is that following a reset. The register becomes accessible following release from the module stop state. For details, refer to section 11, Low Power Consumption.

53.4.2 Notes on the Power Consumption Reduction Function

The following steps are required in advance of using the power consumption reduction function to reduce power consumption by the PDC.

- Set the PCE bit in the PCCR1 register to 0 to disable operations for reception.
- Set the PCKE bit in the PCCR0 register to 0 to disable input through the PIXCLK pin.
- After that, clear the flags in the PCSR register.

If the setting of the PCKOE bit in the PCCR0 register is 1, the following steps are required in advance of using the power consumption reduction function.

- Set the PCKOE bit to 0 to stop output of the PCKO signal.
- Disable input through the PIXCLK pin in the same way as stated above.
- After that, clear the flags in the PCSR register.

On return from the low power consumption state, set the PCKE bit to 1, and after enabling input through the PIXCLK pin, use the PRST bit to initialize the PDC.

53.4.3 Notes on Error Interrupts

When an error interrupt occurs, there is a possibility that the DTC or DMAC might be transmitting parallel data depending on their operation state. Therefore, transmitting executed by the DTC or DMAC should be prohibited after the PDC operation is prohibited at the top of the error interrupt processing routine (PCCR1.PCE = 0).

53.4.4 Notes on Use of the DTC

When the DTC is used with the receive data ready interrupt, set the DISEL bit in the MRB register to 0 and the SZ bit in the MRA register to 10b.
The maximum number of blocks the DTC can transfer in block transfer mode is 65536. If 32 bytes are transferred per block transfer, this represents a total of up to 2097152 bytes. If more data are to be transferred, set up the DTC again during the horizontal blanking period.

53.4.5 Notes on Use of the DMAC

When the DMAC is used with the receive data ready interrupt, set the DISEL bit in the DMCSL register to 0, set the SZ bit in the DMTMD register to 10b, and set the IPRn.IPR[3:0] bit responding to an ICU receive data ready interrupt to level 0 (the interrupt is prohibited).
The maximum number of blocks the DMAC can transfer in block transfer mode is 65536. If 32 bytes are transferred per block transfer, this represents a total of up to 2097152 bytes. If more data are to be transferred, set up the DMAC again during the horizontal blanking period.

53.4.6 Notes on Start of Transfer

When transfer starts while the ICU.IRn.IR flag is 1, an interrupt request signal is internally retained after the start of transfer. This may cause the ICU.IRn.IR flag to behave in an unexpected way.
In such cases, therefore, clear the interrupt request flag by following the procedures below before enabling operations (i.e. before setting the PCE bit in the PCCR1 to 1).

(1) Ensure that transfer is stopped (the PCE bit in the PCCR1 is 0).
(2) Set the corresponding interrupt enable bit (the DFIE bit in the PCCR0 register) to 0.
(3) Read out the corresponding interrupt enable bit (the DFIE bit in the PCCR0 register) to ensure that it is 0.
(4) Set the ICU.IRn.IR flag to 0.

54. Boundary Scan

This MCU has boundary scan function.
The boundary scan is a serial I/O interface based on the JTAG (Joint Test Action Group, IEEE Std.1149.1 and IEEE Standard Test Access Port and Boundary-Scan Architecture).

54.1 Overview

Table 54.1 lists the specifications of boundary scan.
Figure 54.1 shows a block diagram of the boundary scan function.

Table 54.1 Specifications of Boundary Scan

Item	Description
Prerequisite for execution	Run the boundary scan while the signal on the RES# pin is at the low level.
Six test modes	• BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode

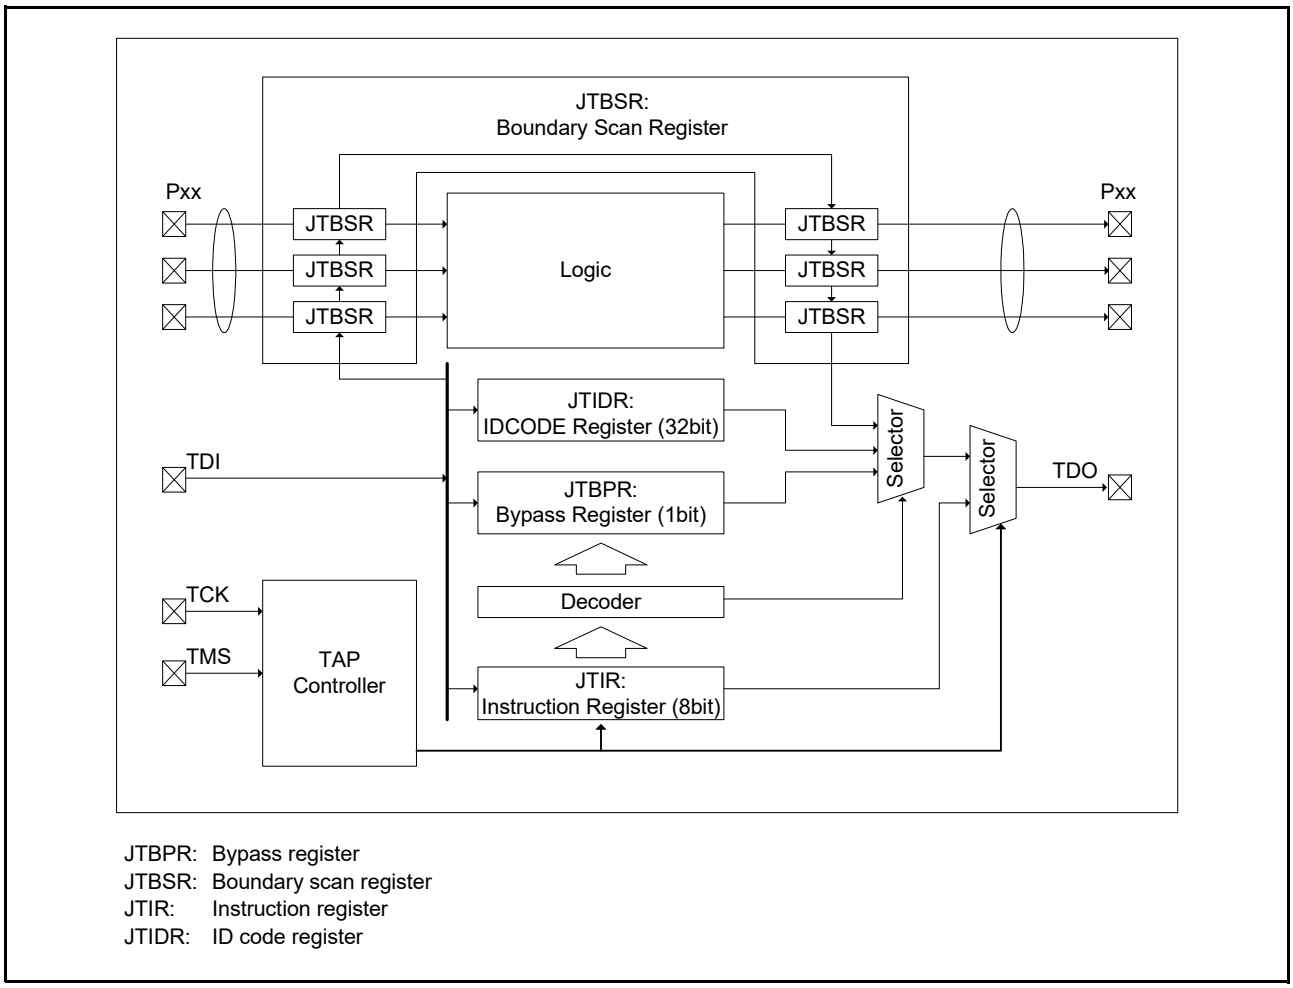


Figure 54.1 Block Diagram of JTAG

Table 54.2 lists the I/O pins used in the boundary scan function.

Table 54.2 Pin Configuration

Pin Name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. Input the clock the duty cycle of which is 50 percent when boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin

54.2 Register Descriptions

Table 54.3 lists the boundary scan registers.

Table 54.3 List of Boundary Scan Registers

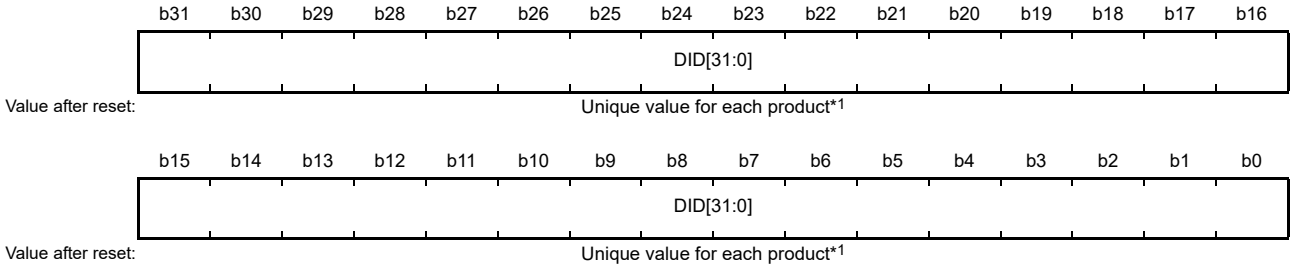
Register Name	Symbol	Value after Reset
Instruction register	JTIR	55h
ID code register	JTIDR	0867 C447h
Bypass register	JTBPR	Undefined
Boundary scan register	JTBSR	Undefined

Instructions can be input to the JTIR register via the TDI pin by serial transfer.
The JTBPR register, which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
The JTBSR register, which is configured according to Table 54.6 to Table 54.11, is connected between the TDI and TDO pins when test data are being shifted in.
None of the registers is accessible from the CPU.
Table 54.4 lists the availability of serial transfer for the registers.

Table 54.4 Serial Transfer for the Registers

Register Name	Serial Input	Serial Output
Instruction register (JTIR)	Available	Available
ID code register (JTIDR)	Available	Available
Bypass register (JTBPR)	Available	Available
Boundary scan register (JTBSR)	Available	Available

54.2.1 Instruction Register (JTIR)



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TS[7:0]	Test Bit Set	The command configuration is as listed in Table 54.5.	—

Table 54.5 Command Configuration

TS7	TS6	TS5	TS4	TS3	TS2	TS1	TS0	Instruction
0	0	0	0	0	0	0	0	EXTEST
0	1	0	0	0	0	0	0	SAMPLE/PRELOAD
0	1	0	1	0	1	0	1	IDCODE (initial value)
1	1	0	1	0	0	0	0	CLAMP
1	0	0	0	0	0	0	0	HIGHZ
1	1	1	1	1	1	1	1	BYPASS
Other than above								Reserved

JTAG instructions can be transferred to the JTIR register by serial input from the TDI pin.
The JTIR register is initialized when a power-on reset occurs, or when the TAP controller is in the Test-Logic-Reset state.

54.2.2 ID Code Register (JTIDR)

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	DID[31:0]	Reserved	JTIDR is a register with the fixed value that indicates the device IDCODE.	—

Note 1. For the ID code for each product, refer to Table 54.3, List of Boundary Scan Registers.

JTIDR data is output from the TDO pin when the IDCODE instruction has been executed.

54.2.3 Bypass Register (JTBPR)

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode.
The JTBPR register cannot be read from or written to by the CPU.

54.2.4 Boundary Scan Register (JTBSR)

The JTBSR register is a shift register to control the external input and output pins of this MCU and is distributed across the pads.
The EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ instructions are issued to apply the JTBSR register in boundary-scan testing.
Table 54.6 to Table 54.11 list the correspondence between the JTBSR bits and the pins of this MCU.
The value after reset is undefined.

54.3 Operations

While the signal on the RES# pin is asserted, the port pins multiplexed with the JTAG functions are assigned to TCK, TMS, TDI, and TDO by default, and the internal pull-up resistors are enabled for the TCK, TMS, and TDI pins. After the power-on reset signal is deasserted, the boundary scan test can be executed once the setup time has elapsed while the RES# signal is at the low level.

54.3.1 TAP Controller

Figure 54.2 shows the state transition diagram of the TAP controller.

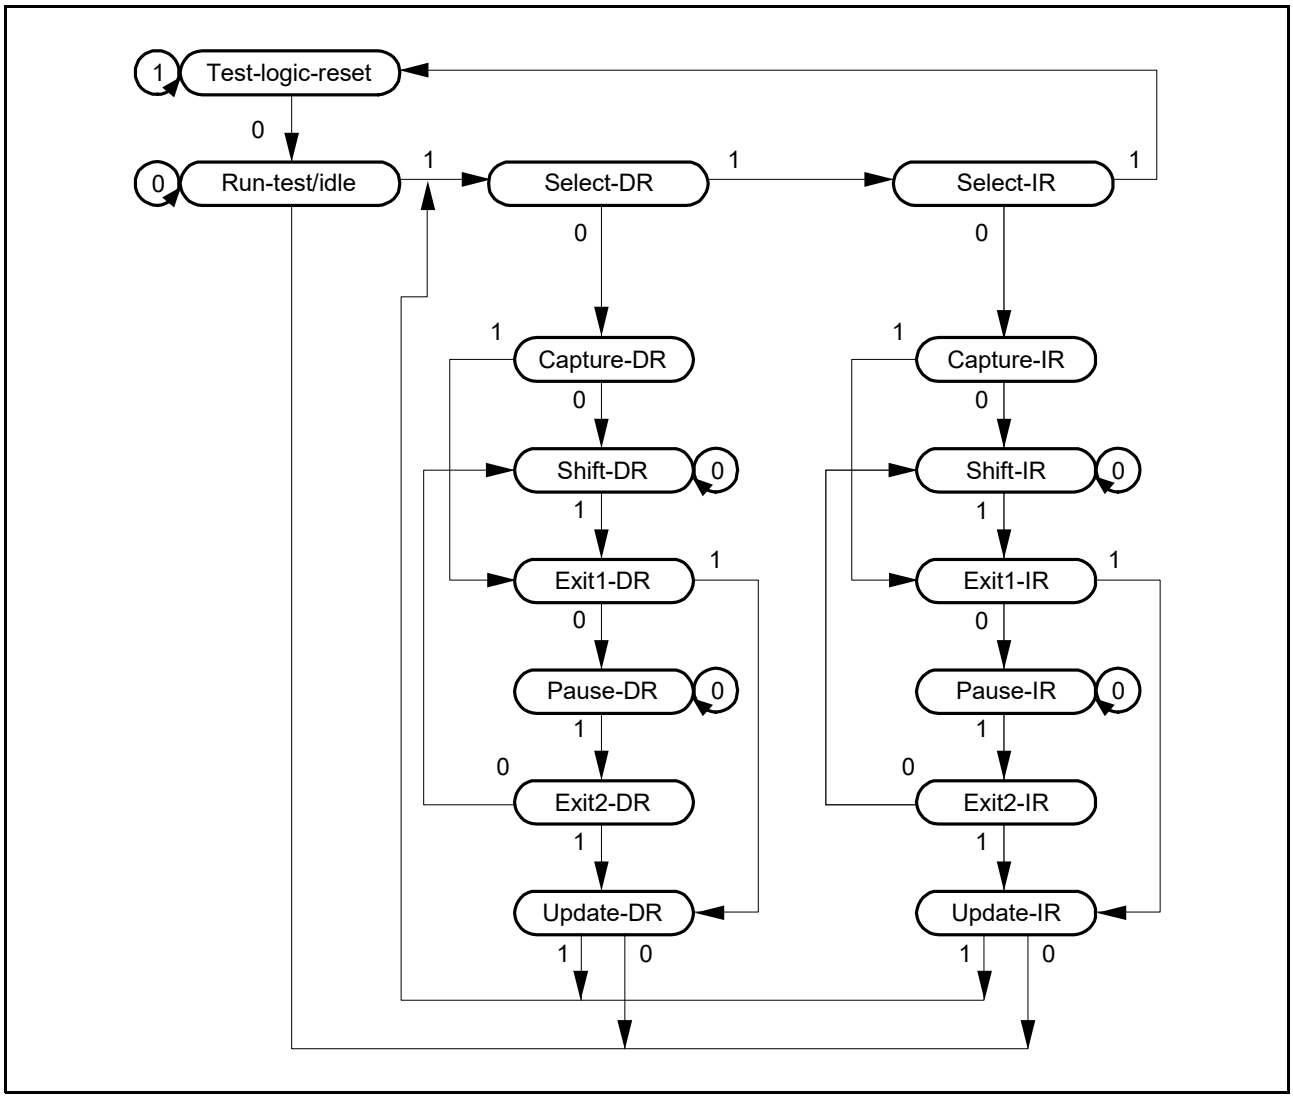

Figure 54.2 State Transition Diagram of TAP Controller

54.3.2 List of Commands

(1) BYPASS [Instruction Code: 1111 1111b]

The BYPASS instruction is an instruction that drives the bypass register (JTBPR). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed-circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.
The bypass register (JTBPR) is connected between the TDI and TDO pins. Bypass operation is initiated from shift-DR operation. The TDO is low in the first clock cycle in the shift-DR state; in the subsequent clock cycles, the TDI signal is output on the TDO pin.

(2) EXTEST [Instruction Code: 0000 0000b]

The EXTEST instruction is used to test external circuits when this LSI is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified by the SAMPLE/PRELOAD instruction) from the boundary scan register to the print circuit board, and input pins are used to input test result.

(3) SAMPLE/PRELOAD [Instruction Code: 0100 0000b]

The SAMPLE/PRELOAD instruction is used to input data from the LSI internal circuits to the boundary scan register, output data from scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to the LSI and output signals are also directly output to the external circuits. The LSI system circuit is not affected by this instruction.
In SAMPLE operation, the boundary scan register latches the snap shot of data transferred from input pins to internal circuit or data transferred from internal circuit to output pins. The latched data is read from the scan path. The scan register latches the snap data at the rising edge of the TCK in Capture-DR state. The scan register latches snap shot without affecting the LSI normal operation.
In PRELOAD operation, initial value is written from the scan path to the parallel output latch of the boundary scan register prior to the EXTEST instruction execution. If the EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In EXTEST instruction, output parallel latches are output to the output pins.)

(4) IDCODE [Instruction Code: 0101 0101b]

When the IDCODE instruction is selected, IDCODE register value is output to the TDO in Shift-DR state of the TAP controller. In this case, IDCODE register value is output from the LSB. During this instruction execution, test circuit does not affect the system circuit. JTIR is initialized by the IDCODE instruction in Test-Logic-Reset state of the TAP controller.

(5) CLAMP [Instruction Code: 1101 0000b]

When the CLAMP instruction is selected, output pins output the boundary scan register value which was specified by the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of boundary scan register is maintained regardless of the TAP controller state.
BYPASS is connected between TDI and TDO, the same operation as BYPASS instruction can be achieved.

(6) HIGHZ [Instruction Code: 1000 0000b]

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the status of boundary scan register is maintained regardless of the state of the TAP controller.
BYPASS is connected between TDI and TDO pins, leading to the same operation as when the BYPASS instruction has been selected.

54.4 Usage Notes

(1) Pin serial transfer, data are input or output in LSB order (refer to Figure 54.3).

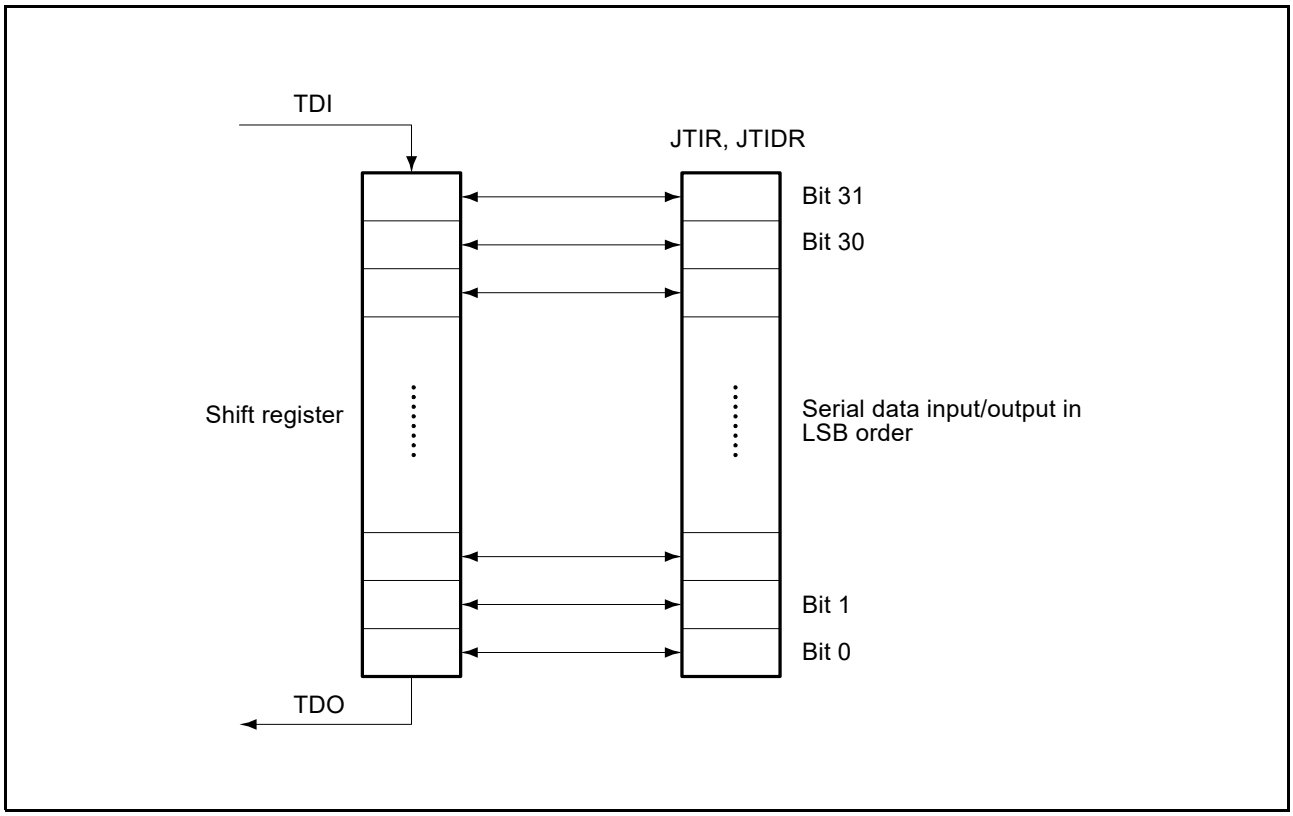

Figure 54.3 Serial Data Input/Output

(2) Power supply pins (VCC, VCC2, VCC_DCDC, VCL, VSS, VSS_DCDC, VLO, VBATT, AVCC0, AVSS0, VCC_USB,VCC_USBHS, AVCC_USBHS, VSS_USB, VSS_USBHS, and AVSS_USBHS) cannot be boundary-scanned.
(3) Analog reference pins (VREFH0, VREFL0) cannot be boundary-scanned.
(4) Clock pins (EXTAL, XTAL, XCIN, and XCOUT) cannot be boundary-scanned.
(5) Reset signal (RES#) cannot be boundary-scanned.
(6) USB dedicated pins (USBHS_DP, USBHS_DM, USB0_DP, and USB0_DM) cannot be boundary-scanned.
(7) The boundary-scan pins (TCK, TMS, TDI, and TDO) cannot be boundary-scanned.

55. Arithmetic Unit for Trigonometric Functions (TFUv2)

This MCU has an arithmetic unit for trigonometric functions (TFUv2). TFUv2 has an upward compatible architecture with TFUv1 and supports fixed-point numbers as well as floating-point numbers.

The TFU has hardware processing functionality for sin, cos, atan, and hypot_k calculations that provide sinθ, cosθ, atan(y/x), and $\sqrt{x^2 + y^2}/k$, respectively. For the value of k, see section 55.3.1, Arithmetic Processing.

55.1 Overview

Table 55.1 lists the specifications of the TFU.

Table 55.1 TFU specifications

Item	Description				
Arithmetic Processing	Calculation of sine, cosine, arctangent, and hypotenuse • A sine and cosine can be simultaneously calculated. • An arctangent and hypotenuse can be simultaneously calculated.				
Range and Unit of Values	With the input and output of floating-point numbers	I/O		Range	Unit
	Calculating sine	Input	Angle θ	–float_max ≤ θ ≤ float_max*1	radians
		Output	sinθ	–1.0 ≤ sinθ ≤ 1.0	—
	Calculating cosine	Input	Angle θ	–float_max ≤ θ ≤ float_max*1	radians
		Output	cosθ	–1.0 ≤ cosθ ≤ 1.0	—
	Calculating arctangent	Input	x and y coordinates	–float_max ≤ x ≤ float_max*1 –float_max ≤ y ≤ float_max*1	—
		Output	atan(y/x)	$-\pi \le \text{atan}(y/x) \le \pi$	radians
	Calculating hypotenuse	Input	x and y coordinates	–float_max ≤ x ≤ float_max*1 –float_max ≤ y ≤ float_max*1	—
		Output	$\sqrt{x^2 + y^2}/k$	$0 \le \sqrt{x^2 + y^2}/k \le \infty$	—
	With the input and output of fixed-point numbers	I/O		Range	Unit
	Calculating sine	Input	Angle θ	–1.0 ≤ θ < 1.0	turns
				–4.0 ≤ θ < 4.0	radians
		Output	sinθ	–1.0 ≤ sinθ ≤ 1.0	—
	Calculating cosine	Input	Angle θ	–1.0 ≤ θ < 1.0	turns
				–4.0 ≤ θ < 4.0	radians
		Output	cosθ	–1.0 ≤ cosθ ≤ 1.0	—
	Calculating arctangent	Input	x and y coordinates	–1.0 ≤ x < 1.0	—
				–1.0 ≤ y < 1.0	
		Output	atan(y/x)	–0.5 ≤ atan(y/x) ≤ 0.5	turns
				$-\pi \le \text{atan}(y/x) \le \pi$	radians
	Calculating hypotenuse	Input	x and y coordinates	–1.0 ≤ x < 1.0	—
				–1.0 ≤ y < 1.0	
		Output	$\sqrt{x^2 + y^2}/k$	$0 \le \sqrt{x^2 + y^2}/k \le \sqrt{2}/k$	—
Data Type for Processing	Single-precision floating-point, fixed-point two's-complement				
Number of cycles for calculation	Sine: 5 Cosine: 5 Arctangent: 14 Hypotenuse: 14				
Protect Zone filter	Security attribute can be set.*2				

Note 1. float_max is the maximum value that can be expressed as single-precision floating-point: $(2 - 2^{-23}) \times 2^{127}$.

Note 2. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

55.2 Register Descriptions

55.2.1 Fixed-Point Sincos Input and Output Setting Register (FXSCIOC)

Address(es): TFU.FXSCIOC 8100 1004h, TFU_NS.FXSCIOC 0100 1004h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	OF[1:0]		—	—	—	IUF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IUF	Input Unit and Format Setting	0: Unit of turns, Q1.31 format 1: Unit of radians, Q3.29 format	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5, b4	OF[1:0]	Output Format Setting	b5 b4 0 0: Q1.31 0 1: Q2.30 1 0: Q3.29 1 1: Setting prohibited	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Set this register before starting a calculation. Operation cannot be guaranteed if writing to this register is attempted during a calculation.

IUF Bit (Input Unit and Format Setting)

The IUF bit is used to set the unit and format of the input values in fixed-point sincos operations.

OF[1:0] Bits (Output Format Setting)

The OF[1:0] bits are used to set the format of the output values in fixed-point sincos operations. Exactly expressing the value +1.0 is not possible in Q1.31 format. When the exact value of $\sin\theta$ or $\cos\theta$ should be +1.0 in Q1.31 format, the value read from the FXSCDT0 or FXSCDT1 register is $+1.0 - 2^{-31}$ instead.

55.2.2 Fixed-Point Atanhypot_k Input and Output Setting Register (FXATIOC)

Address(es): TFU.FXATIOC 8100 1005h, TFU_NS.FXATIOC 0100 1005h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	OUF	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	OUF	Output Unit and Format Setting	0: Unit of turns, Q1.31 format 1: Unit of radians, Q3.29 format	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Set this register before starting a calculation. Operation cannot be guaranteed if writing to this register is attempted during a calculation.

OUF Bit (Output Unit and Format Setting)

The OUF bit is used to set the unit and format of the output values of atan calculations in fixed-point atanhypot_k operations. Note that the format of the output value of every hypot_k calculation simultaneous with an atan calculation is Q3.29 regardless of the value of this bit.

55.2.3 Trigonometric Status Register (TRGSTS)

Address(es): TFU.TRGSTS 8100 1008h, TFU_NS.TRGSTS 0100 1008h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	ERRF	BSYF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BSYF	Calculation in Progress Flag	0: No calculating 1: Calculating	R/W *1
b1	ERRF	Input Error Flag	0: No input error occurred 1: Input error occurred	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to this flag is invalid.

BSYF Flag (Calculation in Progress Flag)

The BSYF flag indicates whether a calculation is in progress. Writing to this flag is ignored.

[Setting condition]

- When calculation started

[Clearing condition]

- When calculation completed

ERRF Flag (Input Error Flag)

The ERRF flag indicates whether an input error occurred during a calculation. Follow the procedure for restoring the error flag described in section 55.4.2, How to Use Interrupts, to write to this register.

[Setting condition]

- When input error occurred*1 or this flag is set to 1

[Clearing condition]

- When the next calculation started or this flag is set to 0

Note 1. For details on input error, see section 55.3.5, Relationship Between Input and Output Values for Atan Operation.

55.2.4 Floating-Point Sincos Data Register 0 (FPSCDT0)

Address(es): TFU.FPSCDT0 8100 1010h, TFU_NS.FPSCDT0 0100 1010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FPSCDT0 register is used to read the output value of cosθ in a floating-point sincos operation. For details, see Table 55.2. For how to use this register, see section 55.4.1, Procedures for Using the TFU.
Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.
Only write to or read from this register in a floating-point sincos operation. Writing to any other data register 0, that is, to the FPATDT0, FXSCDT0, or FXATDT0 register, makes the value of this register undefined. Writing to data saving and restoring register 0 (DTSR0) makes the value of this register the same as that written to the DTSR0 register.

55.2.5 Floating-Point Sincos Data Register 1 (FPSCDT1)

Address(es): TFU.FPSCDT1 8100 1014h, TFU_NS.FPSCDT1 0100 1014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FPSCDT1 register is used to input an angle value θ and to read the output value of sinθ in a floating-point sincos operation. For details, see Table 55.2. Writing to this register starts a floating-point sincos operation. For how to use this register, see section 55.4.1, Procedures for Using the TFU.
Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.
Only write to or read from this register in a floating-point sincos operation. Writing to any other data register 1, that is, to the FPATDT1, FXSCDT1, or FXATDT1 register, makes the value of this register undefined. Writing to data saving and restoring register 1 (DTSR1) makes the value of this register the same as that written to the DTSR1 register.

Table 55.2 Input/Output value of FPSCDT0 and FPSCDT1

Register	Input value	Output value
FPSCDT0	Not used	cosθ
FPSCDT1	Angleθ	sinθ

55.2.6 Floating-Point Atanhypot_k Data Register 0 (FPATDT0)

Address(es): TFU.FPATDT0 8100 1018h, TFU_NS.FPATDT0 0100 1018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FPATDT0 register is used to input a coordinate value x and to read the output value of $\sqrt{x^2 + y^2}/k$ in a floating-point atanhypot_k operation. For details, see Table 55.3. For how to use this register, see section 55.4.1, Procedures for Using the TFU.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

Only write to or read from this register in a floating-point atanhypot_k operation. Writing to any other data register 0, that is, to the FPSCDT0, FXSCDT0, or FXATDT0 register, makes the value of this register undefined. Writing to data saving and restoring register 0 (DTSR0) makes the value of this register the same as that written to the DTSR0 register.

55.2.7 Floating-Point Atanhypot_k Data Register 1 (FPATDT1)

Address(es): TFU.FPATDT1 8100 101Ch, TFU_NS.FPATDT1 0100 101Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FPATDT1 register is used to input a coordinate value y and to read the output value of atan(y/x) in a floating-point atanhypot_k operation. For details, see Table 55.3. Writing to this register starts a floating-point atanhypot_k operation. For how to use this register, see section 55.4.1, Procedures for Using the TFU.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

Only write to or read from this register in a floating-point atanhypot_k operation. Writing to any other data register 1, that is, to the FPSCDT1, FXSCDT1, or FXATDT1 register, makes the value of this register undefined. Writing to data saving and restoring register 1 (DTSR1) makes the value of this register the same as that written to the DTSR1 register.

Table 55.3 Input/Output value of FPATDT0 and FPATDT1

Register	Input value	Output value
FPATDT0	Input coordinates x	$\sqrt{x^2 + y^2}/k$
FPATDT1	Input coordinates y	atan(y/x)

55.2.8 Fixed-Point Sincos Data Register 0 (FXSCDT0)

Address(es): TFU.FXSCDT0 8100 1020h, TFU_NS.FXSCDT0 0100 1020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FXSCDT0 register is used to read the output value of cosθ in a fixed-point sincos operation. For details, see Table 55.4. For how to use this register, see section 55.4.1, Procedures for Using the TFU.
Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.
Only write to or read from this register in a fixed-point sincos operation. Writing to any other data register 0, that is, to the FPSCDT0, FPATDT0, or FXATDT0 register, makes the value of this register undefined. Writing to data saving and restoring register 0 (DTSR0) makes the value of this register the same as that written to the DTSR0 register.

55.2.9 Fixed-Point Sincos Data Register 1 (FXSCDT1)

Address(es): TFU.FXSCDT1 8100 1024h, TFU_NS.FXSCDT1 0100 1024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FXSCDT1 register is used to input an angle value θ and to read the output value of sinθ in a fixed-point sincos operation. For details, see Table 55.4. Writing to this register starts a fixed-point sincos operation. For how to use this register, see section 55.4.1, Procedures for Using the TFU.
Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.
Only write to or read from this register in a fixed-point sincos operation. Writing to any other data register 1, that is, to the FPSCDT1, FPATDT1, or FXATDT1 register, makes the value of this register undefined. Writing to data saving and restoring register 1 (DTSR1) makes the value of this register the same as that written to the DTSR1 register.

Table 55.4 Input/Output value of FXSCDT0 and FXSCDT1

Register	Input value	Unit and format of the input values	Output value	Output value formats
FXSCDT0	Not used	—	cosθ	Q1.31, Q2.30, or Q3.29 in accordance with the value of FXSCIOC.OF[1:0] bits
FXSCDT1	Angleθ	FXSCIOC.IUF = 0: turns, Q1.31 FXSCIOC.IUF = 1: radians, Q3.29	sinθ	

Exactly expressing the value +1.0 is not possible when the output value format is Q1.31. When the exact value of sinθ or cosθ should be +1.0 in Q1.31 format, the value read from the FXSCDT0 or FXSCDT1 register is $+1.0 - 2^{-31}$ instead.

55.2.10 Fixed-Point Atanhypot_k Data Register 0 (FXATDT0)

Address(es): TFU.FXATDT0 8100 1028h, TFU_NS.FXATDT0 0100 1028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FXATDT0 register is used to input a coordinate value x and to read the output value of $\sqrt{x^2+y^2}/k$ in a fixed-point atanhypot_k operation. For details, see Table 55.5. For how to use this register, see section 55.4.1, Procedures for Using the TFU.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

Only write to or read from this register in a fixed-point atanhypot_k operation. Writing to any other data register 0, that is, to the FPSCDT0, FPATDT0, or FXSCDT0 register, makes the value of this register undefined. Writing to data saving and restoring register 0 (DTSR0) makes the value of this register the same as that written to the DTSR0 register.

55.2.11 Fixed-Point Atanhypot_k Data Register 1 (FXATDT1)

Address(es): TFU.FXATDT1 8100 102Ch, TFU_NS.FXATDT1 0100 102Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FXATDT1 register is used to input a coordinate value y and to read the output value of atan(y/x) in a fixed-point atanhypot_k operation. For details, see Table 55.5. Writing to this register starts a fixed-point atanhypot_k operation. For how to use this register, see section 55.4.1, Procedures for Using the TFU.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

Only write to or read from this register in a fixed-point atanhypot_k operation. Writing to any other data register 1, that is, to the FPSCDT1, FPATDT1, or FXSCDT1 register, makes the value of this register undefined. Writing to data saving and restoring register 1 (DTSR1) makes the value of this register the same as that written to the DTSR1 register.

Table 55.5 Input/Output value of FXATDT0 and FXATDT1

Register	Input value	Input value formats	Output value	Unit and format of the output values
FXATDT0	Input coordinates x	Q1.31	$\sqrt{x^2 + y^2}/k$	—, Q3.29
FXATDT1	Input coordinates y	Q1.31	atan(y/x)	FXATIOC.OUF = 0: turns, Q1.31 FXATIOC.OUF = 1: radians, Q3.29

55.2.12 Data Saving and Restoring Register 0 (DTSR0)

Address(es): TFU.DTSR0 8100 1030h, TFU_NS.DTSR0 0100 1030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DTSR0 register is used to save and restore the data in data registers 0 that are FPSCDT0, FPATDT0, FXSCDT0, or FXATDT0 registers. The value read from this register is either that most recently written to any of data registers 0 or the latest result of arithmetic processing in any of data registers 0. Writing to this register makes the values of all data registers 0 the same as that written to this register.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

For how to use this register, see section 55.4.2, How to Use Interrupts.

55.2.13 Data Saving and Restoring Register 1 (DTSR1)

Address(es): TFU.DTSR1 8100 1034h, TFU_NS.DTSR1 0100 1034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DTSR1 register is used to save and restore the data in data registers 1 that are FPSCDT1, FPATDT1, FXSCDT1, or FXATDT1 registers. The value read from this register is either that most recently written to any of data registers 1 or the latest result of arithmetic processing in any of data registers 1. Writing to this register makes the values of all data registers 1 the same as that written to this register.

Writing to this register during operation is prohibited. If read access is made to this register during the calculation, the result is read after the calculation is completed. At this time, the bus access is forced to wait until the operation is completed.

For how to use this register, see section 55.4.2, How to Use Interrupts.

55.2.14 TFU Security Attribution Register (TFUSAR)

Address(es): CPSCU.TFUSAR 8701 8140h, CPSCU_NS.TFUSAR 0701 8140h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TFUSA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TFUSA	TFU Security Attribution	0: Secure 1: Non-secure	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.
Note: This register is write-protected by the PRCR_S.PRC4 bit.

This register is used to configure the security attribute of the TFU.

55.3 Operation

55.3.1 Arithmetic Processing

The trigonometric function unit has two arithmetic operations, the sincos operation and the atanhypot_k operation. Here, “sincos operation” means simultaneous sin and cos calculations and “atanhypot_k operation” means simultaneous atan and hypot_k calculations. For details, see Table 55.6.

Table 55.6 Arithmetic Processing

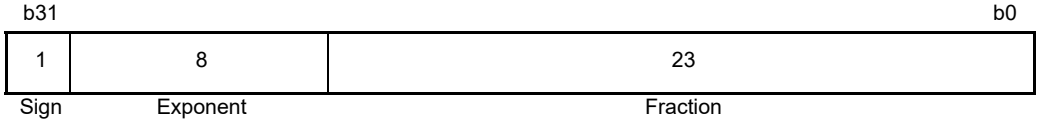
Operation	Input value	Output value
sincos	Angle value θ	cosθ and sinθ
atanhypot_k	Coordinates x and y	atan(y/x) and $\sqrt{x^2+y^2}/k$

Note: The value of scaling factor *k* is:

$$k = \prod_{i=0}^{\infty} \frac{1}{\sqrt{1+2^{-2i}}} \fallingdotseq 0.607252935008881256169 4$$

Multiplying the output value of the TFU $\sqrt{x^2+y^2}/k$ by k provides $\sqrt{x^2+y^2}$.

55.3.2 Input and Output Value Formats



The TFU supports single-precision floating-point numbers and fixed-point numbers as its input and output values. For details on single-precision floating-point numbers and fixed-point numbers, see section 55.3.2.1, Single-Precision Floating-Point Numbers, and section 55.3.2.2, Fixed-Point Numbers, respectively. Note that the precision of fixed-point calculations is lower than 32 bits, although the input and output values are fixed-point numbers in 32-bit format.

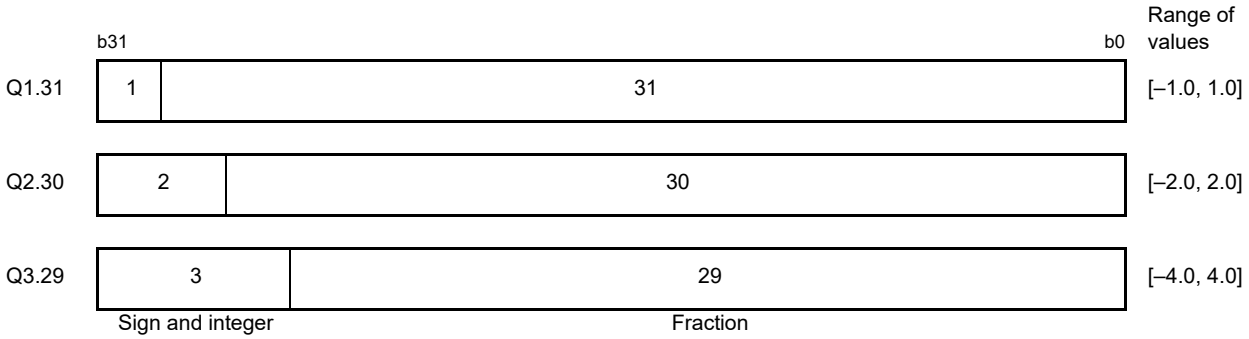
55.3.2.1 Single-Precision Floating-Point Numbers

Floating-Point Number

The TFU supports the format for single-precision floating-point numbers specified in the IEEE754 standard.

- Single-Precision Floating-Point Number

Sign: sign field (1-bit)
Exponent: exponent field (8-bit)
Fraction: significand field (23-bit)



Numerical = $(-1)^S \times (1 + F \times 2^{-23}) \times 2^{(E-127)}$ (normalized value)
Numerical = $(-1)^S \times (0 + F \times 2^{-23}) \times 2^{-126}$ (denormalized value)

The TFU supports the numerical formats of single-precision floating-point numbers listed below.

S	E	F	Numerical
Any value	0 < E < 255	Any value	$(-1)^S \times 1.F \times 2^{(E-127)}$ (Normal Numbers)
Any value	E = 0	F > 0	$(-1)^S \times 0.F \times 2^{-126)}$ (Subnormal Numbers)
S = 0	E = 0	F = 0	$(-1)^0 \times 0.0$ (Positive zero: +0)
S = 1	E = 0	F = 0	$(-1)^{-1} \times 0.0$ (Negative zero: –0)
S = 0	E = 255	F = 0	Positive infinity: +∞
S = 1	E = 255	F = 0	Negative infinity: –∞
Any value	E = 255	400000h > F > 0	SNaN (Signaling Not a Number)
Any value	E = 255	F ≥ 400000h	QNaN (Quiet Not a Number)

55.3.2.2 Fixed-Point Numbers

The TFU supports the two’s-complement formats shown below.

55.3.3 Units of Angles

The TFU supports radians and turns as the units for angles. 0 to 2π radians and 0 to 1 turns respectively represent 0- to 360-degree rotations.

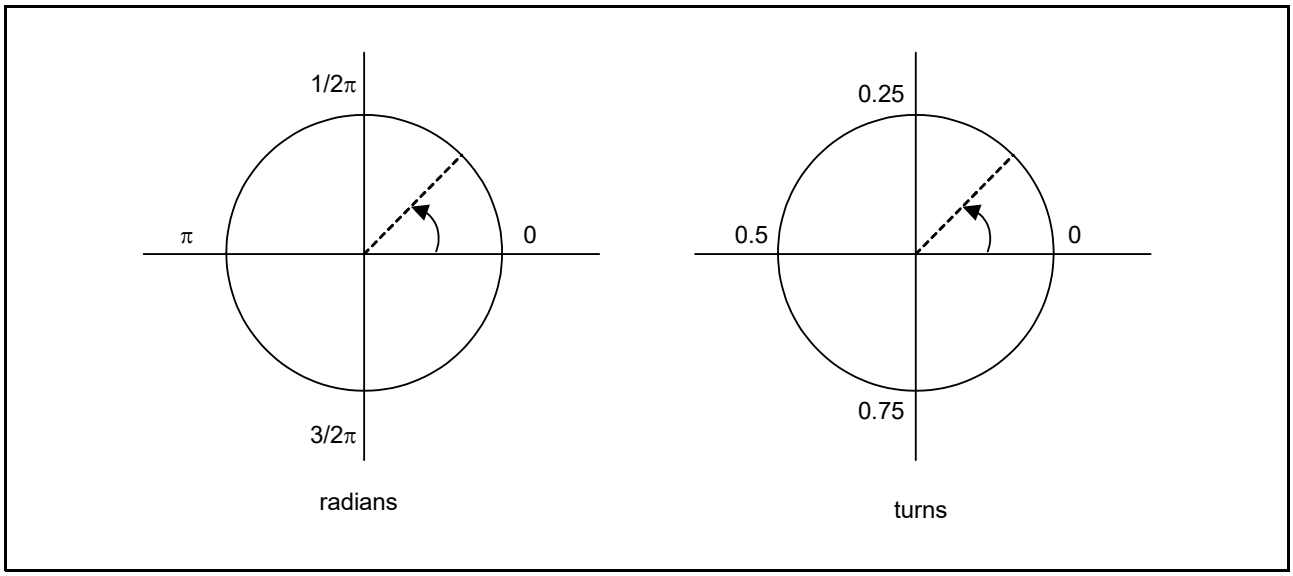


Figure 55.1 Units of Angles

55.3.4 Relationship Between Input and Output Values for Sincos Operation

The output value of a floating-point sin or cos calculation is specified as listed in Table 55.7 when the input value is ±0, ±∞, SNaN (Signaling Not a Number), or QNaN (Quiet Not a Number).

Table 55.7 Relationship Between Special Input Value and Its Output Value (for Sincos Operation)

Input (*θ*)	Output (cos)	Output (sin)
–∞	QNaN	QNaN
–0	+1	–0
+0	+1	+0
+∞	QNaN	QNaN
SNaN/QNaN	QNaN	QNaN

Note: The output value of QNaN is FFC0 0000h.

55.3.5 Relationship Between Input and Output Values for Atan Operation

The output value of a floating-point atan calculation is specified as listed in Table 55.8 when either of the input values x or y is ±0, ±∞, SNaN (Signaling Not a Number), or QNaN (Quiet Not a Number). An input error is detected when both of the input values x and y are ±0.

Table 55.8 Relationship Between Special Input Value and Its Output Value (for Floating-Point Atan Operation)

y \ x	−∞	Negative value	−0	+0	Positive value	+∞	SNaN/QNaN
−∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
Negative value	QNaN	—	−π/2	−π/2	—	QNaN	QNaN
−0	QNaN	−π	QNaN*1	QNaN*1	−0	QNaN	QNaN
+0	QNaN	+π	QNaN*1	QNaN*1	+0	QNaN	QNaN
Positive value	QNaN	—	+π/2	+π/2	—	QNaN	QNaN
+∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
SNaN/QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN

Note 1. An input error occurs for the special input value, and the input error flag (TRGSTS.ERRF) is set.

An input error is detected when both of the input values x and y of a fixed-point atan calculation are 0, even for the values other than 0 in 32-bit fixed-point format that are handled as 0 by the TFU. The output value of an atan calculation is 0 when an input error has occurred.

55.3.6 Relationship Between Input and Output Values for hypot_k Operation

The output value of a floating-point hypot_k calculation is specified as listed in Table 55.9 in either of the following cases: when either of the input values x or y is ±∞, SNaN (Signaling Not a Number), or QNaN (Quiet Not a Number), or when both of the input values x and y are ±0. An input error is detected when both of the input values x and y are ±0. The reason is that such values cause errors in atan calculations although hypot_k calculations are possible.

Table 55.9 Relationship Between Special Input Value and Its Output Value (for hypot_k Operation)

y \ x	−∞	Negative value	−0	+0	Positive value	+∞	SNaN/QNaN
−∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
Negative value	QNaN	—	—	—	—	QNaN	QNaN
−0	QNaN	—	+0*1	+0*1	—	QNaN	QNaN
+0	QNaN	—	+0*1	+0*1	—	QNaN	QNaN
Positive value	QNaN	—	—	—	—	QNaN	QNaN
+∞	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN
SNaN/QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN	QNaN

Note 1. An input error occurs for the special input value, and the input error flag (TRGSTS.ERRF) is set.

An input error is detected when both of the input values x and y of a fixed-point hypot_k calculation are 0, even for the values other than 0 in 32-bit fixed-point format that are handled as 0 by the TFU. The reason is that such values cause errors in atan calculations although hypot_k calculations are possible. The output value of a hypot_k calculation is 0 when an input error has occurred.

55.4 Usage Procedures

55.4.1 Procedures for Using the TFU

There are two procedures for reading the result of an operation: reading the data register after the operation is completed (Procedure 1) and reading the data register without waiting for the operation to be completed (Procedure 2). Table 55.10 shows the advantages and disadvantages of each procedure. Figure 55.2 shows the procedures for sincos operations and Figure 55.3 shows the procedures for atanhypot_k operations. Read SCDTn (n = 0, 1) in Figure 55.2 as FPSCDTn and FXSCDTn in the case of floating-point sincos operations and fixed-point sincos operations, respectively. Read ATDTn in Figure 55.3 as FPATDTn and FXATDTn in the case of floating-point atanhypot_k operations and fixed-point atanhypot_k operations, respectively.

Table 55.10 Advantages and Disadvantages of Procedures for Sincos and Atanhypot_k Operations

Method	Advantages	Disadvantages
Procedure 1: reading the data register after the operation is completed	The bus is not occupied.	Detecting completion of a calculation by checking the TRGSTS.BSYF flag is required.
Procedure 2: reading the data register without waiting for the operation to be completed	Detecting completion of a calculation by checking the TRGSTS.BSYF flag is not required, resulting in fewer cycles being required for execution.	The bus is occupied until completion of the calculation.

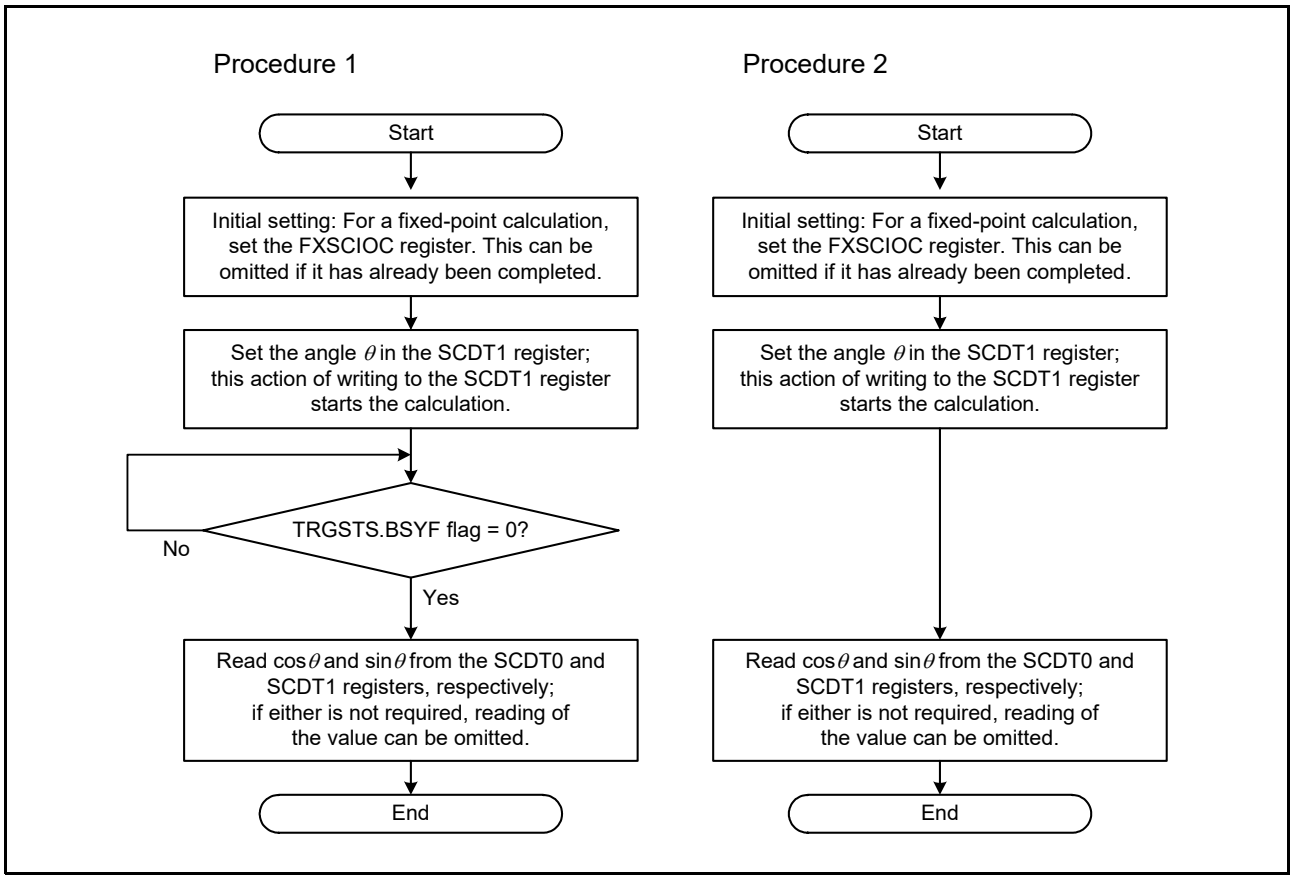

Figure 55.2 Procedure for Using TFU (Sincos Operation)

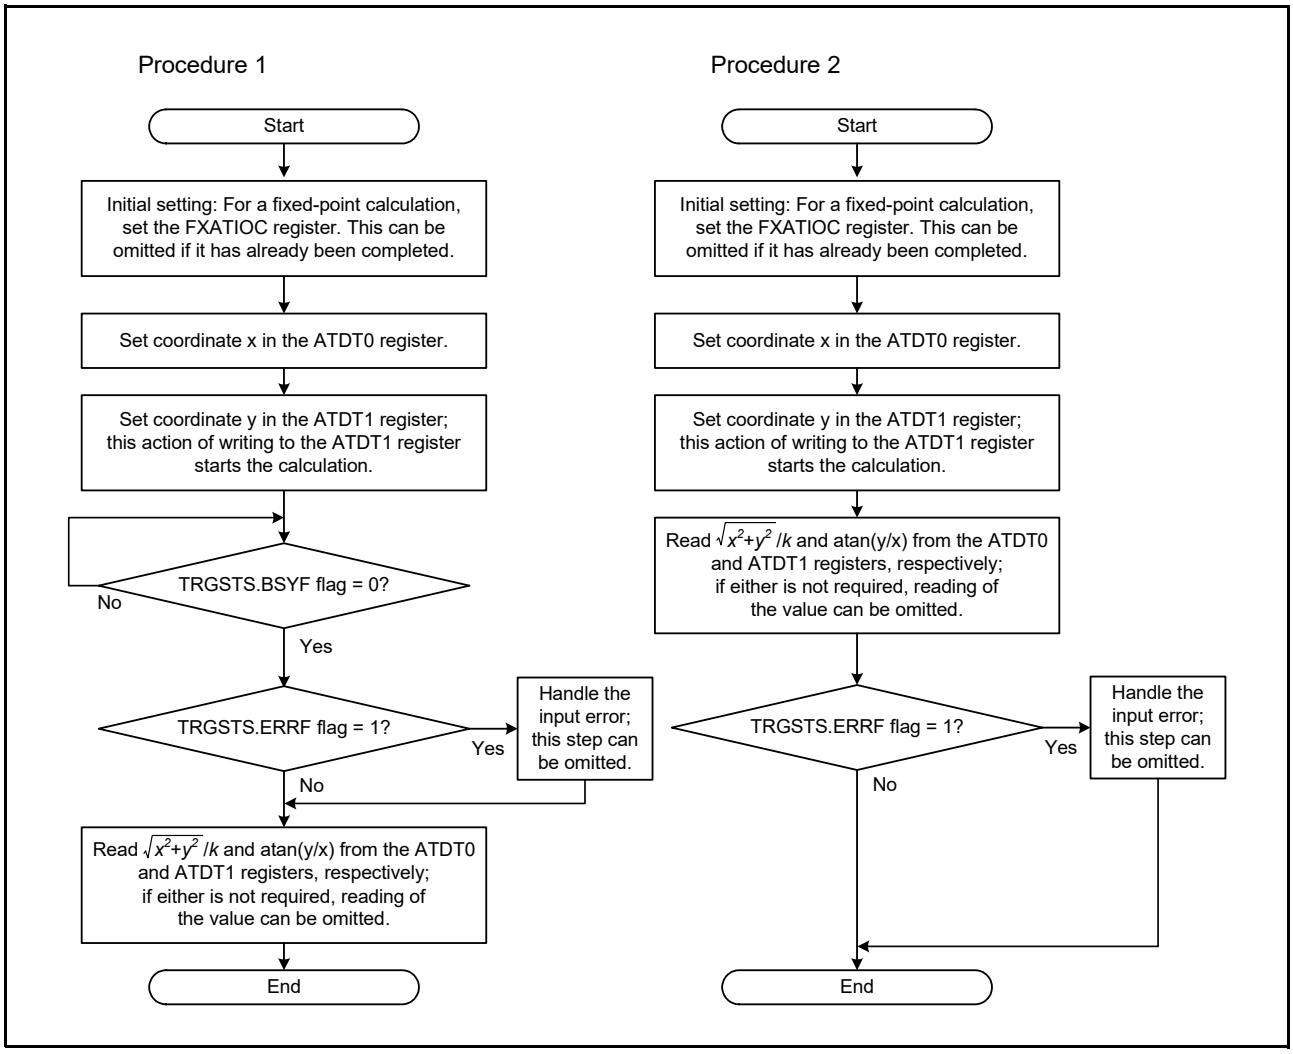

Figure 55.3 Procedure for Using TFU (Atanhypot_k Operation)

55.4.2 How to Use Interrupts

If an interrupt is accepted in the following order, the values stored in the data registers and the error flag prior to the acceptance of the interrupt may become incorrect in terms of the software after execution is returned from the interrupt handler.

1. The interrupt is accepted between writing to the data registers and reading of the data registers and the error flag during any of the procedures described in section 55.4.1, Procedures for Using the TFU.
2. The TFU is used to execute any calculation in the handler.

Accordingly, avoid such incorrect operation when, for example, using the TFU with multiple interrupts and their handlers by taking either of the following measures.

(1) Disabling interrupts that otherwise may disrupt processing between writing to the data registers and reading of the data registers and the error flag

(2) Saving and restoring data registers and the error flag in interrupt handlers that may disrupt processing*1, *2

Note 1. Regardless of the type of operation executed in the interrupt handler or the type of operation executed before accepting an interrupt, use the DTSR0, DTSR1, and TRGSTS registers to save and restore data registers and error flags. Figure 55.4 shows the save/restore procedure in an interrupt handler. By following this procedure, after returning from the interrupt handler, the processing that was being performed before accepting the interrupt can be continued without malfunctioning.

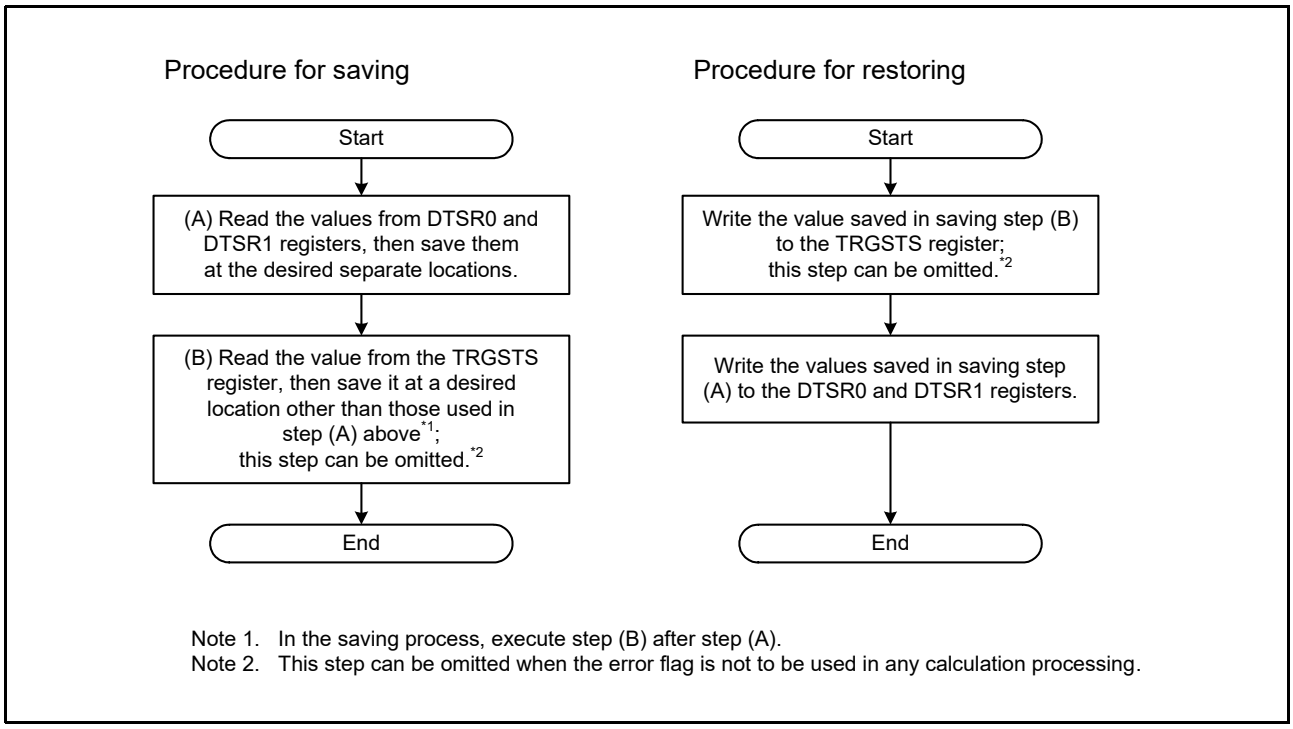

Figure 55.4 Procedures for Saving and Restoring in Interrupt Handlers

Note 2. As well as the data registers and the error flag, interrupt handlers that may change the values of the setting registers (FXSCIOC and FXATIOC) also require saving and restoring of the setting register values. Accordingly, save and restore the values of the setting registers as required. Saving of the setting registers must be executed after step (A) of the saving process in Figure 55.4.

56. Security Features

56.1 Features

- Protect Zone security
  - CPU core
    - Security technology based on a three-world structure
  - Bus access and address space
    - Divides slave resources into secure and non-secure.
  - Implements the Security Attribution Unit (SAU).
    - Divides the address space into secure and non-secure.
    - Manages security attributes and detects security violations for CPU bus access.
    - Implements the Master Security Attribution Unit (MSAU) (SAU for bus masters other than the CPU).
  - Interrupts
    - The destination can be configured to be secure or non-secure for each interrupt vector.
  - Code MRAM
    - Up to two regions (secure/non-secure) in linear mode
    - Up to four regions (two secure regions and two non-secure regions) in dual mode
  - Data MRAM
    - Up to two regions (secure/non-secure)
  - SRAM
    - Up to two regions (secure/non-secure) for each SRAM
  - Backup Registers
    - Up to two regions (secure/non-secure)
  - Peripherals
    - Security attributes can be set individually for each unit/channel.
- Device lifecycle management
- Three debug levels
  - AL2: Non-secure and secure debug functions are enabled and accessible from the debugger.
  - AL1: Only the non-secure debug function is enabled, and the debugger can access only defined non-secure debug accessible regions.
  - AL0: No debug functions are available.
- Secure key injection
- Secure factory programming
  - Supports programming of on-chip MRAM in ciphertext format.
- Secure boot

  Supports up to four expirable Roots of Trust (RoTs) with OTP. This is the SHA-256 hash digest of the RoT public key.
  - Verification of the integrity and authenticity of the image to be programmed
  - Before executing the image, the immutable (OTP) first-stage bootloader (FSBL) and user boot loader verify the integrity and authenticity of the executable image.
- Cryptographic accelerator
  - See section 57, Renesas Secure IP (RSIP-E50D).

- Secure pin multiplexing
  - All I/O ports can be individually configured as secure or non-secure.
  - The peripheral pin function is valid when the security attributes of the peripheral function and I/O port match. See section 22, I/O Ports.
- Decryption on the fly
  - The circuits for decryption on the fly (DOTFs) decrypt encrypted contents of external memory in real time. See section 49, Decryption On The Fly (DOTF).

Note: The external address spaces do not have Protect Zone filters. For this reason, even if these spaces are specified as secure with the settings by the SAU, they are accessible by non-secure masters other than the CPU.

56.2 Detection of Tampering

This device has I/O ports that are capable of detecting external tampering.
For tamper events

- Time stamp processing
  - The RTC can be used to obtain time stamps, record events, and generate interrupts. See section 30, Realtime Clock (RTCBb).
- Hardware unique key
  - Zeroization (setting 0) is applied to the hardware unique key (HUK) following the detection of a tamper event. See section 65, MRAM.
- Backup registers
  - Zeroization (setting 0) is applied to the backup registers following the detection of a tamper event. See section 12, Battery Backup Function (VBATTBa).

56.3 Protect Zone Feature

56.3.1 Protect Zone Technology

The RXv3e CPU core has three security states called worlds. These are called root world, secure world, and non-secure world, respectively. Programs executed in the secure world and the non-secure world, as well as the resources they can access, can be separated. A program cannot be moved directly between the secure world and non-secure world; it can be moved only via the root world. Some resources of the CPU core, such as control registers, are separated by the CPU core's hardware, but other resources are separated by a program in the root world.
The world after a reset is the root world.

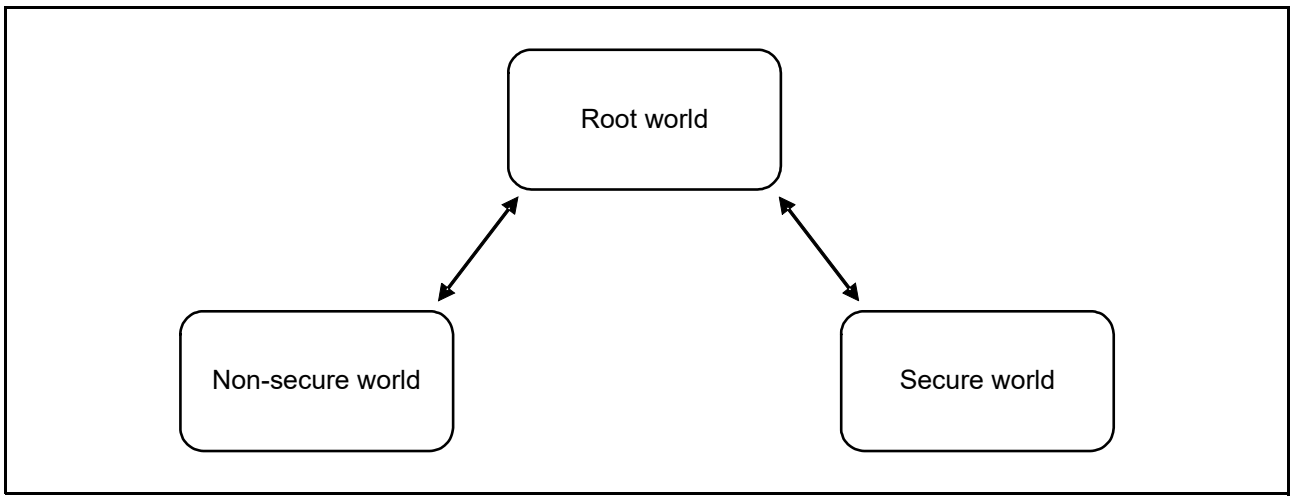

Figure 56.1 Three Worlds of the Protect Zone

56.3.2 Flat-Project and Non-Flat-Project

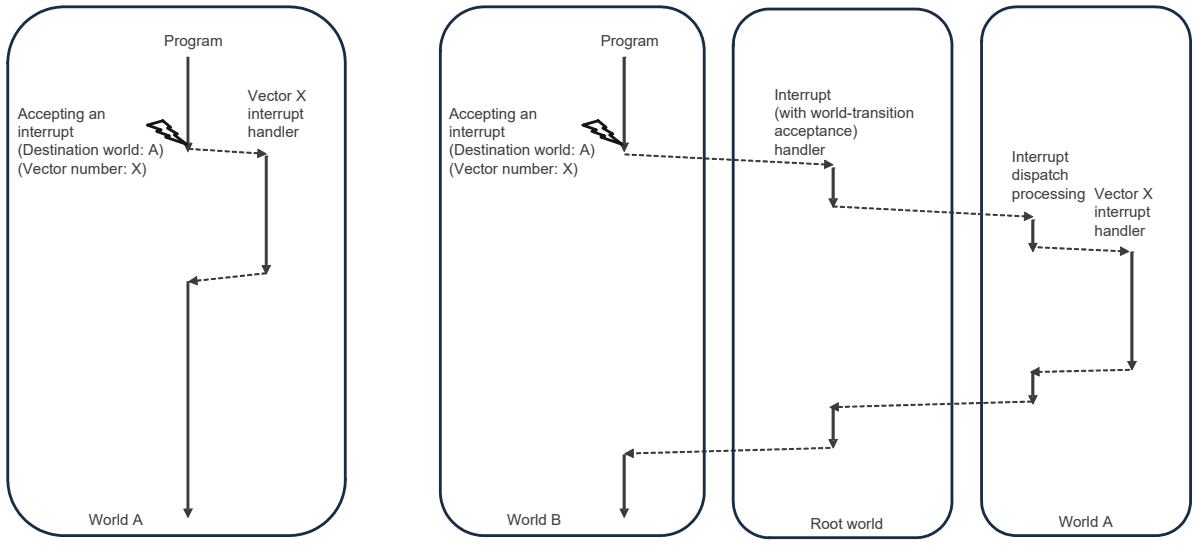
Running programs is also possible without taking the other worlds into account. Such software projects are called Flat-Projects*1. A Flat-Project is only used in the root world and programs can be executed without taking the other worlds into account.
In contrast with Flat-Projects, all software projects that use the Protect Zone's worlds are called a Non-Flat-Project. A Non-Flat Project consists of multiple software projects. These are software projects for the root and secure worlds and software projects for the non-secure world.
Table 56.1 lists the functions that require operation switching depending on whether software is developed as a Flat-Project or a Non-Flat-Projec. These operations can be switched using the CPSCU.PRTZCR register and the SAU.AAS register. The operation for a Flat-Project is selected after release from the reset state. To use a Non-Flat-Project, appropriately set the registers so that the operation for a Non-Flat-Project proceeds.

Note 1. This term is used in the descriptions of development tools provided by Renesas.

Table 56.1 Register Settings for Operation for a Flat-Project and Operation for a Non-Flat-Project

Item	Register Setting	Description
Operation for Flat-Project	CPSCU.PRTZCR.PRTZC = 0	The destination world for all interrupts and non-maskable interrupts is the root world.
	SAU.AAS.NS = 0	Instruction fetch from the non-secure address space is enabled in the root world and secure world.
Operation for Non-Flat-Project	CPSCU.PRTZCR.PRTZC = 1	The destination world for interrupts can be set to either the secure world or non-secure world for each vector. The destination world for non-maskable interrupts can also be set to either the secure world or non-secure world.
	SAU.AAS.NS = 1	Instruction fetch from the non-secure address space is disabled in the root world and secure world and generates an exception.

56.3.3 Relationship Between Interrupts and Worlds



An interrupt notified from the ICU to the CPU contains information about the world that is the destination of the interrupt. Interrupt acceptance is determined based on the CPU status (world where the program is being executed, PSW.IPL, etc.) and interrupt information from the ICU (interrupt priority level and interrupt destination world). For details on acceptance conditions, see section 2, CPU.

An interrupt vector table exists independently for each world.

When an interrupt is accepted, the following occurs.

If the world where the program is being executed is the same as the interrupt destination world, the CPU references the vector table within that world and moves on to the interrupt handler processing (Figure 56.2 (a)).

If the world where the program is being executed is different from the interrupt destination world, the CPU moves on to the interrupt (with world-transition acceptance) handler of the root world. The handler in the root world calls the interrupt dispatch processing of the destination world. Interrupts can be handled by referencing the vector table within the interrupt dispatch processing and calling the interrupt handler (Figure 56.2 (b)). Note that the handler in the root world and the interrupt dispatch processing software must be prepared in advance. The hardware performs only the minimum necessary processing. The handler in the root world should perform operations such as saving resources that need to be hidden or protected between worlds.

(a) When the world where the program is being executed and the interrupt destination world are the same

(b) When the world where the program is being executed and the interrupt destination world are different

Figure 56.2 Operation When Accepting an Interrupt

56.3.3.1 When Set for Operation for Non-Flat-Project

For each vector, the secure or non-secure world can be selected as the interrupt destination world. The secure or non-secure world can be selected as the destination world for non-maskable interrupts. The root world cannot be selected as the destination.
The interrupt priority level for interrupts destined for the secure world can be set from 0 to 31. The interrupt priority level for interrupts destined for the non-secure world can be set from 0 to 15.

56.3.3.2 When Set for Operation for Flat-Project

The destination world for all interrupts and non-maskable interrupts is the root world.
The interrupt priority level for interrupts can be set from 0 to 31.

56.3.4 Protect Zone Initial State

In the initial state after resetting, operation starts in the root world.
The reset vector and the initial value of the EXTB register are changed to match the program execution start area.

Table 56.2 Reset Vector and the Initial Value of the EXTB Register

Program Execution Start Area	Reset Vector	EXTB Initial Value
User area	FFFF FFFCh	FFFF FF80h
User extra MRAM area	86D8 007Ch	86D8 0000h

All spaces in the root world become accessible for instruction fetching and data access.

56.4 Bus Access and Address Space

The bus master (CPU, DMAC, etc.) has security attributes as information for issuing bus transactions, and is classified into “secure bus master” and “non-secure bus master” depending on the transaction to be issued. The security attributes of the CPU are determined by the world that executes the bus transaction. Security attributes for bus masters other than the CPU are configurable. For resources with selectable security attributes, the default setting after a reset is “secure”.
The address space accessible to the bus master is broadly divided into “secure access region” and “non-secure access region.” Bit 31 of the address determines which region is accessible. The SAU (Security Attribution Unit) associated with the CPU or the SAU (MSAU) of a bus master other than the CPU determines whether access is permitted based on the security attributes of the transaction issued by the bus master and the address of the access destination, and then determines the security attributes of the transaction to be issued to the bus slave. Except for some regions such as external bus regions, a bus slave is mapped to both the secure access region and non-secure access region.
Bus-accessible resources (slave resources) such as memory and registers are classified as either “secure” or “non-secure”. As a general rule, secure resources can only be accessed by secure transactions, and non-secure resources can only be accessed by non-secure transactions. The PZF (Protect Zone Filter) associated with each slave module transmits only access-enabled transactions to the slave. Note that there are some exceptional resources that can be accessed by both secure and non-secure transactions, but the PZF also determines whether such resources can be accessed.
The security attributes (assignment to secure/non-secure) of slave resources are either fixed in advance as hardware specifications or selectable through settings. In addition, some read-only slave resources are not subject to access control by security attributes. For resources with selectable security attributes, the default setting after a reset is “secure”. For details, see the descriptions of the peripheral security attribution registers (PSARx, x = B to F) in this section and the security attribution registers in other sections.

Figure 56.3 shows how transactions are processed from the master to the slave according to security attributes. There are two types of processing methods in the SAU for the secure bus master. See Table 56.3 for the security attributes and types of each bus master.
Also, for some register resources, read access is not subject to access control, while write access is subject to security access control, meaning that read and write access are handled differently. In addition, whether or not a Protect Zone access error is generated when an access violation is detected by the PZF depends on the register. For details, see the description for each register.

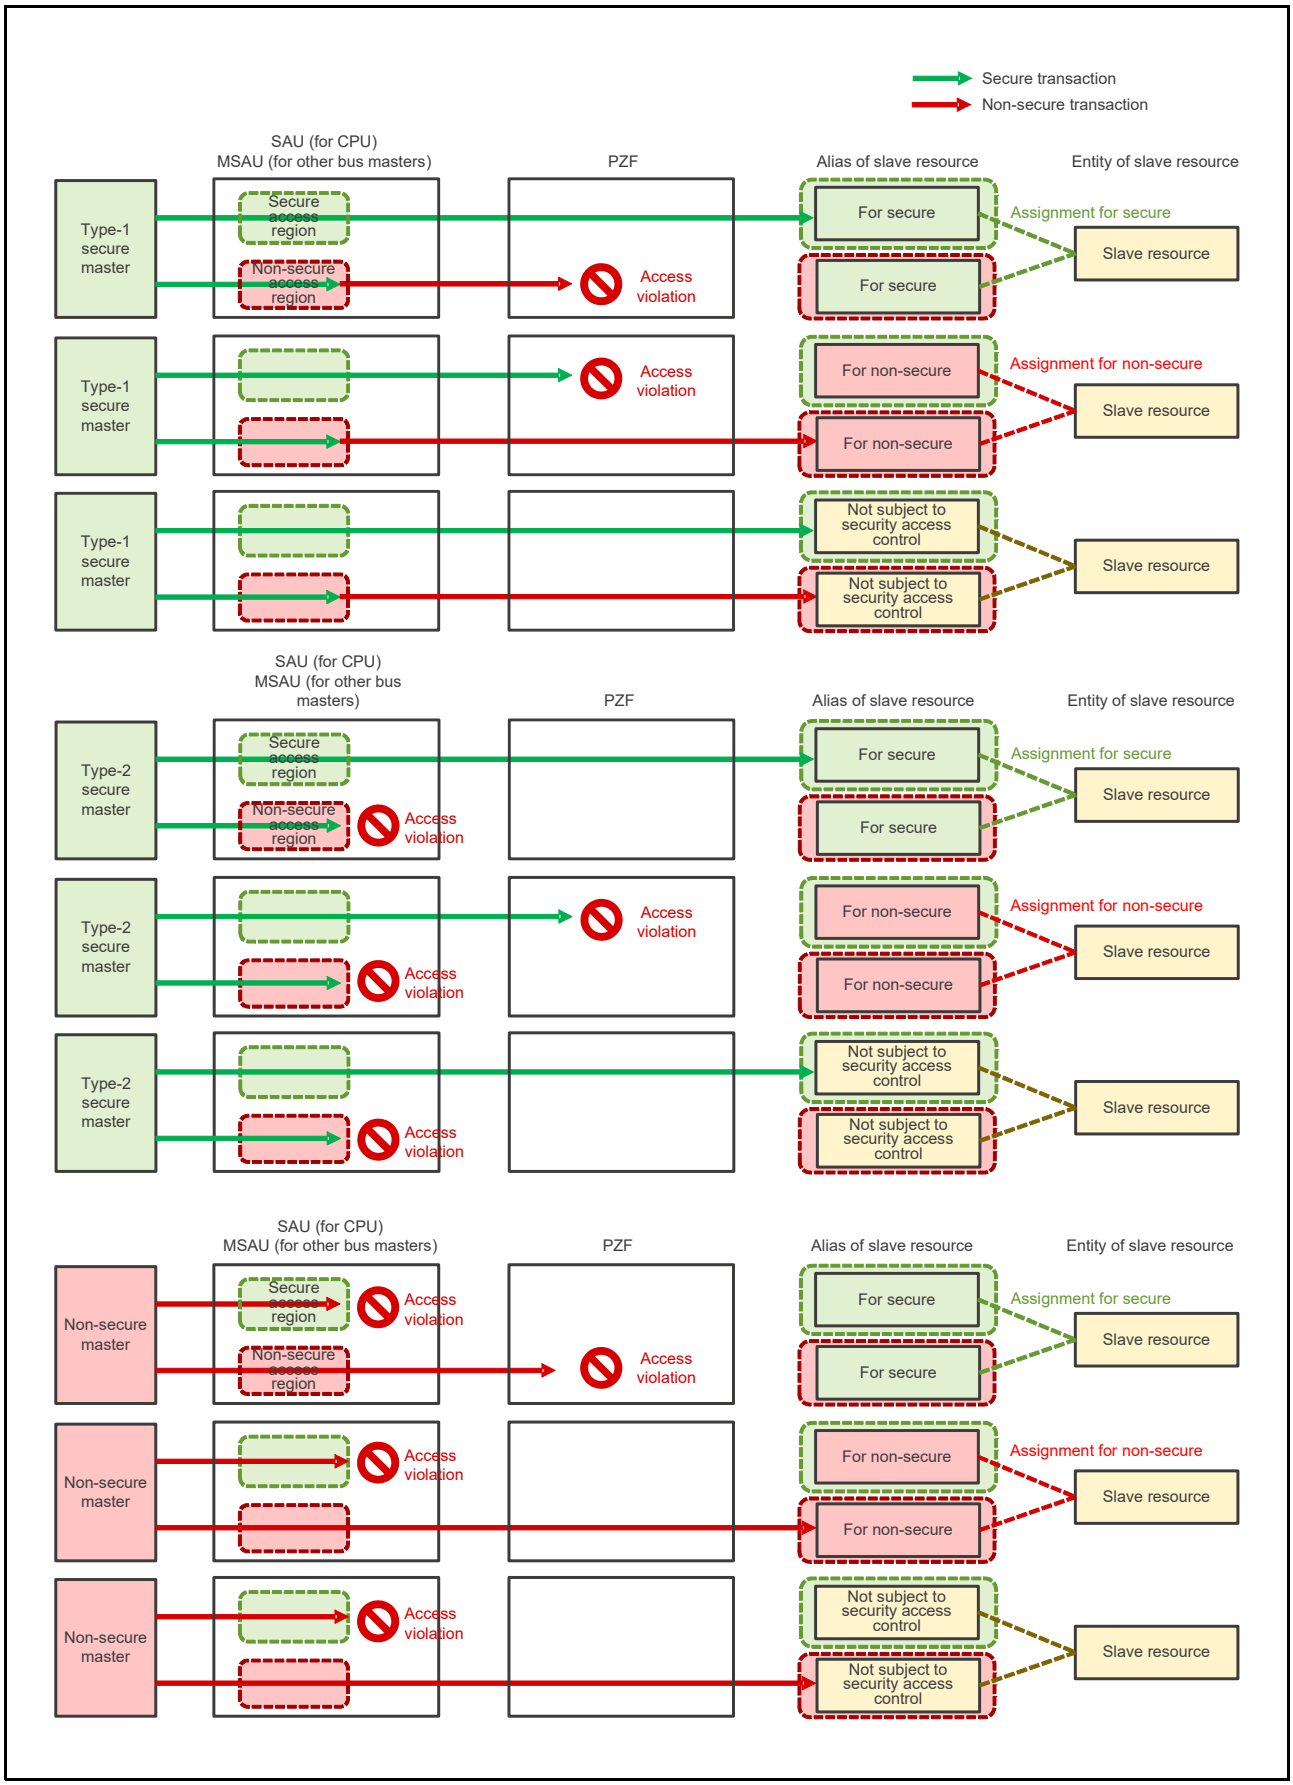


Figure 56.3 Processing of Transactions from Each Master

Table 56.3 Security Attributes of Each Bus Master

Bus Master	Security Attribute
CPU (root world) operand access	Secure*1
CPU (root world) instruction fetch	Secure*2
CPU (secure world) operand access	Secure*1
CPU (secure world) instruction fetch	Secure*2
CPU (non-secure world) operand access	Non-secure
CPU (non-secure world) instruction fetch	Non-secure
DMAC	Select secure*1/non-secure for each channel.
DTC	Select secure*1/non-secure.
EXDMAC	Select secure*1/non-secure for each channel.
XSPI0/XSPI1	Select secure*1/non-secure for each channel.

Note 1. Type-1 secure
Note 2. Type-1 secure when operation for a Flat-Project is selected. Type-2 secure when operation for a Non-Flat-Project is selected.

56.5 Security Attribution Unit (SAU)

This MCU has a built-in address-space Security Attribution Unit (SAU) that manages security attributes for CPU bus access.
The SAU manages security attributes by generating secure exceptions based on the CPU access type and the security attributes of the access target. All attribute management is effective regardless of the CPU's secure/non-secure state or user/supervisor mode.
Table 56.4 shows the specifications for the Security Attribution Unit.

Table 56.4 Specifications for the Security Attribution Unit (SAU)

Specification	Description
Address-space security attribute	The address space has the following fixed security attributes: 0000 0000h to 7FFF FFFFh: Non-secure attribute 8000 0000h to FFFF FFFFh: Secure attribute
Secure violation detection function	Detects violations by comparing CPU access types and address space security attributes. (secure exception generation) In the case of operand access, stores the address that caused the violation in the secure exception address register (SEA). It also stores the cause in the secure exception status register (SESTS).
Transaction issuance function	If no violations are detected, issue a transaction with attributes corresponding to the address-space security attributes.

56.5.1 Types of CPU Access

The CPU has security attributes of secure (root world, secure world) and non-secure (non-secure world) corresponding to the world where the program is currently being executed. In order to perform instruction access and data access in each state, there are four types of CPU access: "instruction access (secure)", "data access (secure)", "instruction access (non-secure)", and "data access (non-secure)".

56.5.2 Address-Space Security Attribute

Each address has two security attributes: Secure space and non-secure space. The security attributes for addresses 0000 0000h to 7FFF FFFFh are fixed as non-secure space, and addresses 8000 0000h to FFFF FFFFh are fixed as secure space.

56.5.3 Transaction Types Issued

For CPU access, a secure transaction or a non-secure transaction is issued in accordance with the address-space security attribute. In addition, cache attributes are added to each issued transaction based on the MPU and background cache settings.

56.5.4 Access Across Different Security Attribute Spaces

If access occurs across different security attribute spaces, a secure violation is detected.

56.5.5 Functions

56.5.5.1 Secure Memory Protection Function

The secure memory protection function monitors whether the program in the secure or non-secure state is only accessing what is permitted in each state. If an access violation (secure memory protection error) is detected, the SAU notifies the CPU of this information, and the CPU starts secure exception handling.
The secure memory protection function is always enabled after a reset.
If a violation is detected, the corresponding transaction will not occur and a secure exception will occur. If no violations are detected, transactions are issued according to the security attributes of the address space being accessed.

Table 56.5 Secure Memory Protection and Issued Transactions

Types of CPU Access	Security Attribute of the Address Space to Be Accessed	Violation Detection (Exception Occurs)	Issued Transaction
Instruction access (secure)	Secure	Not detected	Secure
	Non-secure	Detected (secure exception)*1	Not detected
Instruction access (non-secure)	Secure	Detected (secure exception)	Not detected
	Non-secure	Not detected	Non-secure
Data access (secure)	Secure	Not detected	Secure
	Non-secure	Not detected	Non-secure
Data access (non-secure)	Secure	Detected (secure exception)	Not detected
	Non-secure	Not detected	Non-secure

Note 1. This is the behavior when operation for a Non-Flat-Project is selected (AAS.NS = 1). When operation for a Flat-Project is selected (AAS.NS = 0), violation detection = none and issued transaction = non-secure in the same way as data access (secure).

56.5.5.2 Protection of Security Attribution Management Registers

The AAS, SESTS, SECLR, and SEA registers cannot be accessed by any means other than CPU operand access in secure state and Supervisor mode (instruction fetch, DMA). When the user-mode CPU accesses an operand, a data memory protection error occurs regardless of whether memory protection is enabled. If the CPU attempts to access data in non-secure state and supervisor mode, a secure exception occurs.

56.5.5.3 Access Determination Flow for the Secure Memory Protection Function

Figure 56.4 shows the instruction access determination flow when operation for a Non-Flat-Project is selected (AAS.NS = 1). When operation for a Flat-Project is selected (AAS.NS = 0), secure access to the non-secure space is possible in the same way as the data access determination flow shown in Figure 56.5.

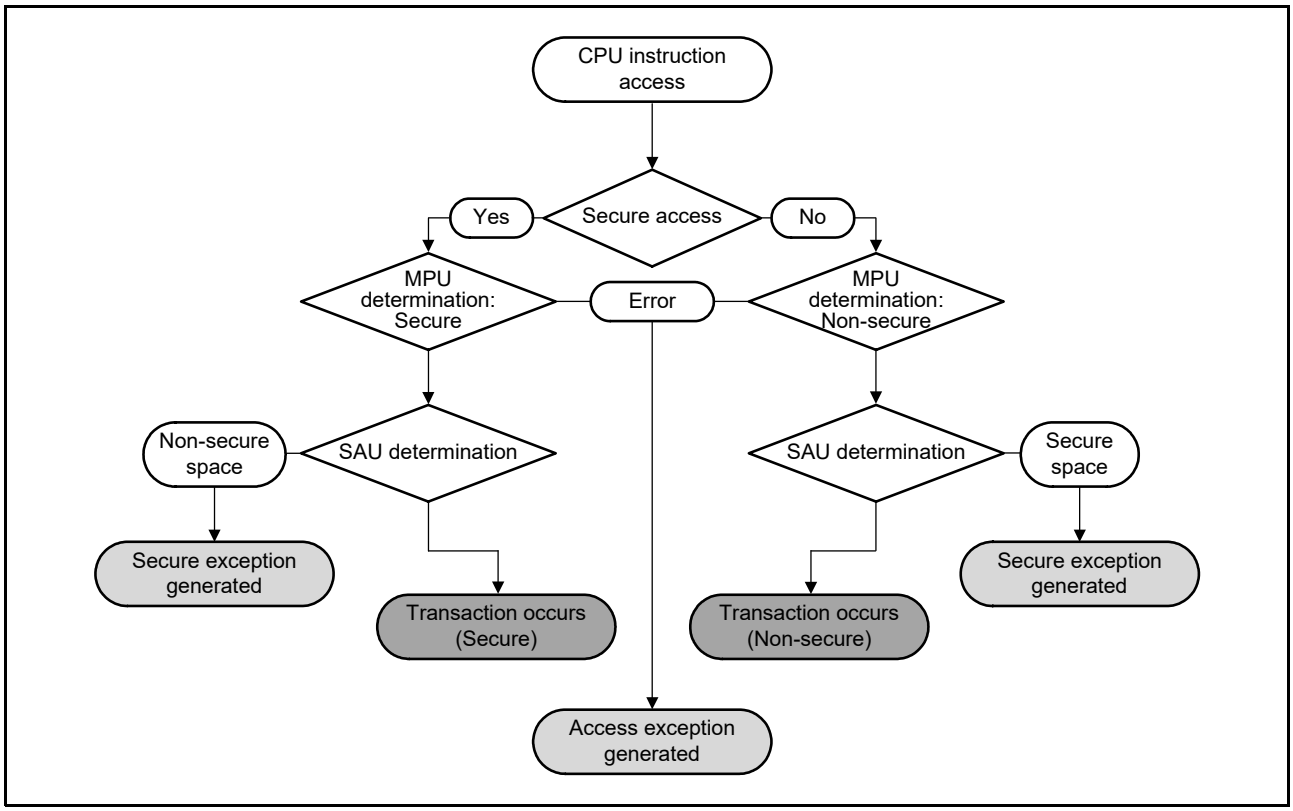

Figure 56.4 Access Determination Flow During Instruction Access (AAS.NS = 1)

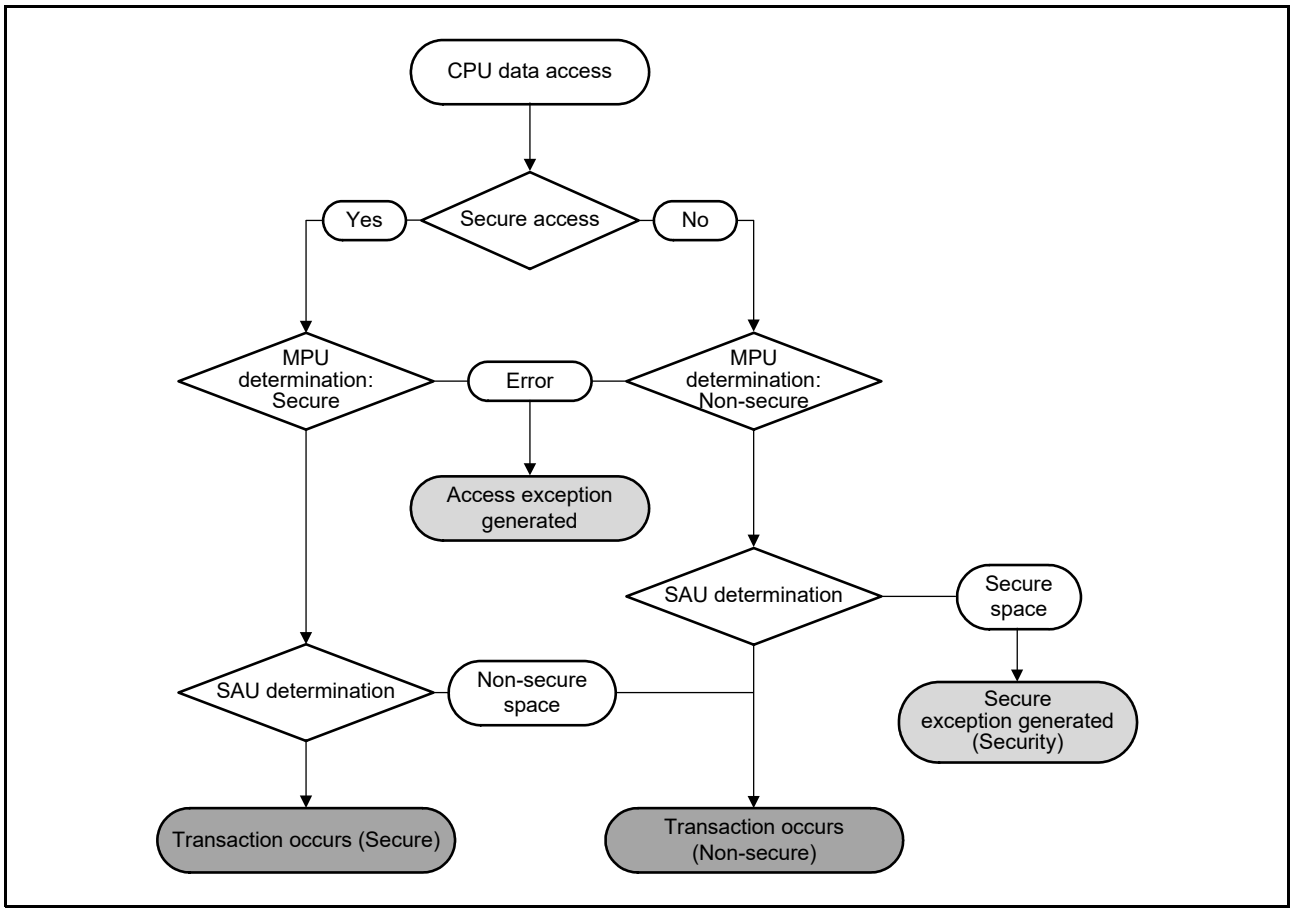

Figure 56.5 Access Determination Flow During Data Access

56.5.6 Instructions for Use

56.5.6.1 Handling Secure Exceptions

When a secure memory protection error is detected, the CPU starts secure exception handling. In addition, the cause of the secure exception is stored in the secure exception status register (SESTS), and in the case of a secure memory protection error caused by operand access, the operand access address that caused the exception is stored in the secure exception address register (SEA). For details on CPU operations for secure exception handling, see section 14, Exception Handling.

56.6 Memory Security Attributes

Memory is divided into secure and non-secure regions. The memory security attributes of code MRAM and data MRAM are stored into nonvolatile memory by a boot command when the device lifecycle is in the OEM state and the authentication level is AL2. These memory security attributes are applied before application execution. They cannot be updated by the application but are readable using dedicated registers. The memory security attributes of SRAM are set by a dedicated security attribution register writable only by secure access.

The code MRAM can be divided into up to two regions in linear mode and four regions in dual mode. The partitioning is the same between bank0 and bank1 in the dual mode. The data MRAM can be divided into up to two regions. The SRAM can be divided into up to two regions.

Figure 56.6 shows the memory mapping. Table 56.6 shows the sizes of the memory regions and Table 56.7 shows access permission of the memory regions.

It is prohibited to place secure regions in a block swappable area in linear mode because the secure application would be placed in the non-secure region after block swapping.

The contents in secure regions must be the same in both bank0 and bank1 in the dual mode. If they are not the same, the contents of the secure regions or non-secure regions may not match after the firmware update in the field. See section 56.13, Field Updating in Dual Mode.

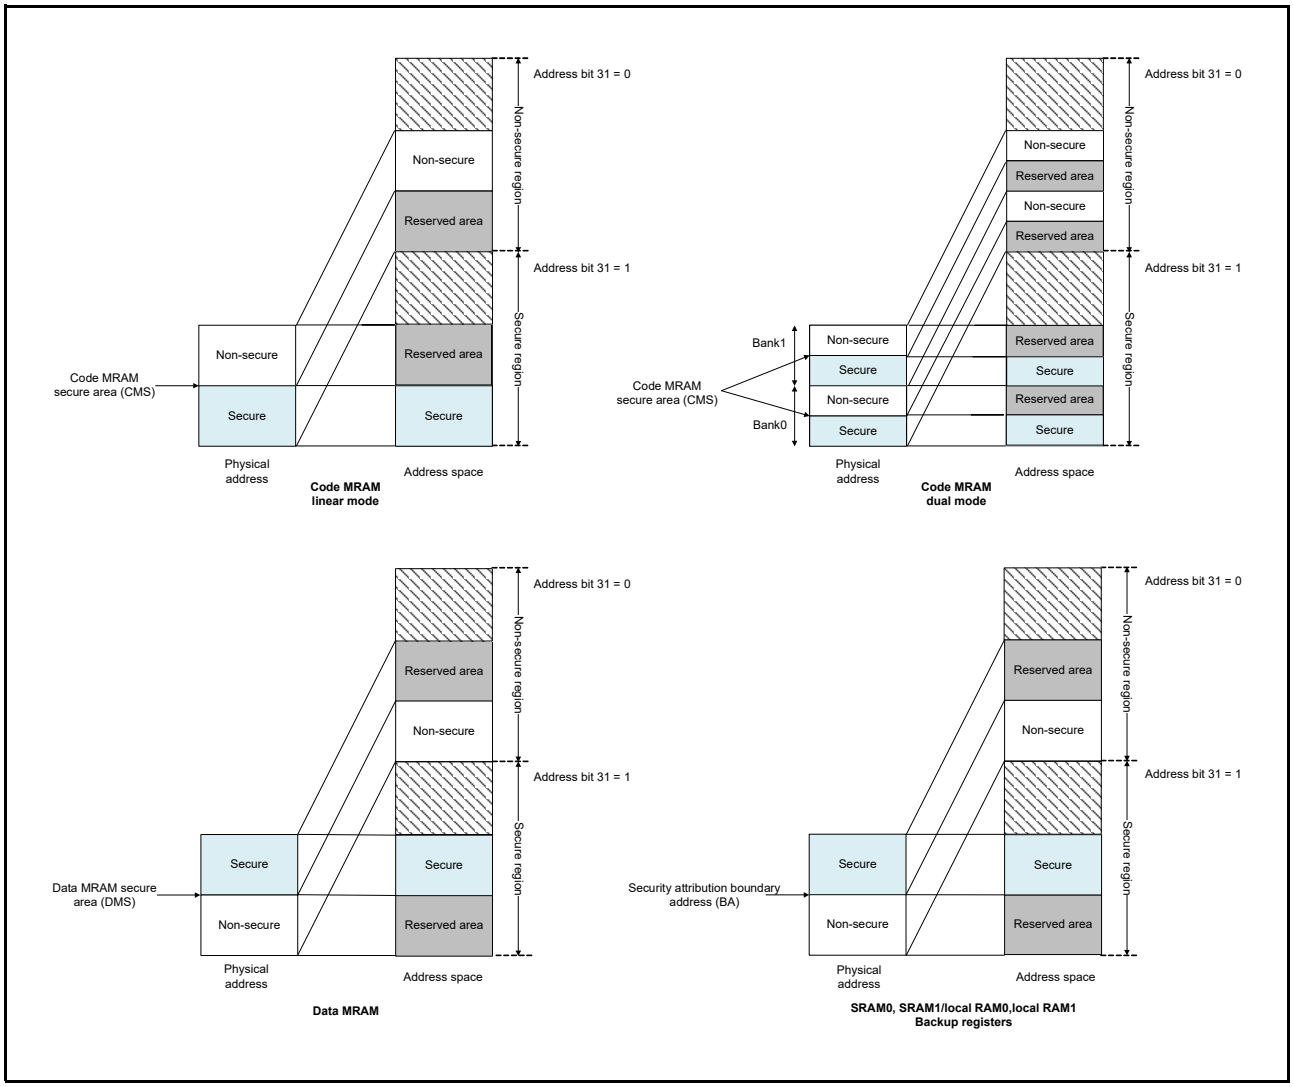

Figure 56.6 Memory Mapping

Table 56.6 Sizes of Memory Regions

Memory Region		Start Address	Size
Linear mode	Code MRAM secure	FFF0 0000h + ((20h – CMS) × 32 KB)	CMS × 32 KB
	Code MRAM non-secure	7FF0 0000h	((20h – CMS) × 32 KB)
Dual mode	Code MRAM bank0 secure	FFF8 0000h + ((10h – CMS) × 32 KB)	CMS × 32 KB
	Code MRAM bank0 non-secure	7FF8 0000h	((10h – CMS) × 32 KB)
	Code MRAM bank1 secure	FFB8 0000h + ((10h – CMS) × 32 KB)	CMS × 32 KB
	Code MRAM bank1 non-secure	7FB8 0000h	((10h – CMS) × 32 KB)
Data MRAM secure		8690 0000h	DMS × 2 KB
Data MRAM non-secure		0690 0000h + (DMS × 2 KB)	(1Bh – DMS) × 2 KB
SRAM0 secure		8200 0000h	BA*1
SRAM0 non-secure		0200 0000h + BA*1	SRAM0 size – BA*1
SRAM1 secure		8210 0000h	BA*1
SRAM1 non-secure		0210 0000h + BA*1	SRAM1 size – BA*1
Local RAM0 secure		8000 0000h + BA*2: Access address from CPU 8280 0000h + BA*2: Access address from bus masters other than CPU	BA*2
Local RAM0 non-secure		0000 0000h + BA*2: Access address from CPU 0280 0000h + BA*2: Access address from bus masters other than CPU	Local RAM0 size – BA*2
Local RAM1 secure		8002 0000h + BA*2: Access address from CPU 8282 0000h + BA*2: Access address from bus masters other than CPU	BA*2
Local RAM1 non-secure		0002 0000h + BA*2: Access address from CPU 0282 0000h + BA*2: Access address from bus masters other than CPU	Local RAM1 size – BA*2
Backup registers secure		8701 9D00h	BA*3
Backup registers non-secure		8701 0000h + BA*3	Backup register size – BA*3

Note 1. Boundary address specified by CPSCU.SRAMSABARn (n = 0, 1)
Note 2. Boundary address specified by CPSCU.LRMSABARn (n = 0, 1)
Note 3. Boundary address specified by SYSC.BKRSABR

Table 56.7 Access Permission of Memory Regions

Memory Region	Secure Transaction	Non-secure Transaction
Each memory region configured as secure	Permitted	Write ignored/Read ignored Protect Zone access error is generated.
Each memory region configured as non-secure	Write ignored/Read ignored Protect Zone access error is generated.	Permitted

56.7 Security Attribution of Peripherals

Each peripheral can be set to secure or non-secure by configuring the security attribution register. Peripherals are classified into two types based on the registers to be used for security attribution. Type-1 peripherals have one security attribute. Access to all registers is controlled by one security attribute. Type-1 peripheral security attributes are set in the PSARx (x = B to F) register by the secure application. Type-2 peripherals have a security attribute for each register or for a bit. Among the type-2 peripherals, the TFU only has one security attribute for the module. Access to each register or bit field is controlled according to these security attributes. Type-2 peripheral security attributes are set in the security attribution register in each module by the secure application. For the security attribution register, see sections in the user's manual for each peripheral. Table 56.8 shows the classification of peripheral types.

Table 56.8 Classification of Peripheral Types

Type	Peripheral and CPU Acceleration Function
1	RSCI, RSPIA, XSPI, DOTF, USBHS, USB, RIICHS, RI3C, RSIP-E50D, ESWM, CANFDG, CANFD, PDMIF, DOC, CRC, CAC, TEMPS, ADC16H, DAC12R, POEG, HRPWM, GPTW, RTC, IWDT, WDT, PDC, TMR, CMTW, CMT, PIO, PCIF, SSIE, SDHI, ETHPHYCLK
2	System control (Resets, PVD, Clock Generation Circuit, Low Power Consumption Function, Battery Backup Function, Register Write Protection Function), CPU acceleration function (IFU and caches), MRAM Controller, SRAM Controller, Local RAM Controller, DMAC, DTC, EXDMAC, ICU, MPU, BUS, Security Setting, ELC, TFU, and I/O Ports

Table 56.9 shows the access permission of type-1 peripherals. The access permissions of type-2 peripherals vary depending on the peripheral. See the register description for each peripheral.

Table 56.9 Access Permissions of Type-1 Peripherals

	Secure Access	Non-secure Access
Peripheral configured as secure	Permitted	Write ignored/Read ignored Protect Zone access error is generated.
Peripheral configured as non-secure	Write ignored/Read ignored Protect Zone access error is generated.	Permitted

56.8 Protect Zone Access Error

Table 56.10 shows the operation when a Protect Zone access error occurs. The operation varies depending on the master. This operation does not apply to bufferable write access. For more information on the operations when a bufferable write access error is detected, see section 16.8.2, Operations When a Bus Error Occurs.

Table 56.10 Operations When a Protect Zone Access Error Occurs

CPU	DMAC/DTC/EXDMAC	ESWM
• An instruction secure exception is generated for an error in instruction fetch.*1 • An interrupt or reset*2 can be issued.	• Transfer is stopped. • An interrupt or reset*2 can be issued.	• An interrupt or reset*2 can be issued.

Note 1. A secure exception is not generated for an error in operand access.
Note 2. The operation after error detection is selected by the BUSOAD.SLERROAD bit.

56.9 Register Descriptions

56.9.1 Secure Address-Space Attribute Setting Register (AAS)

Address(es): SAU.AAS 8100 0400h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	NS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	NS	Non-secure Address Space Setting	0: Instruction access (secure) to 0000 0000h to 7FFF FFFFh is enabled. 1: Instruction access (secure) to 0000 0000h to 7FFF FFFFh is disabled.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

NS Bit (Non-secure Address Space Setting)

This bit disables subsequent instruction access (secure) to the non-secure address space (0000 0000h to 7FFF FFFFh) after the CPU is shifted from a secure state (operation for a Flat-Project is selected) to a mixed secure/non-secure state (operation for a Non-Flat Project is selected). When this bit is set to 1, instruction access (secure) to 0000 0000h to 7FFF FFFFh cannot be executed, and a secure exception occurs.

It is initialized to 0 when reset, and can be written to 1, but cannot be cleared afterwards.

56.9.2 Secure Exception Status Register (SESTS)

Address(es): SAU.SESTS 8100 0404h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSER	ISER
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ISER	Instruction Access Secure Exception Occurrence Flag	0: No secure exceptions occurred by instruction access. 1: A secure exception occurred by instruction access.	R
b1	DSER	Data Access Secure Exception Occurrence Flag	0: No secure exceptions occurred by data access. 1: A secure exception occurred by data access.	R
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

ISER Flag (Instruction Access Secure Exception Occurrence Flag)

This flag indicates that a secure exception has occurred due to instruction execution.

The ISER flag is set to 0 only when the exception status clear bit (CLR) of the secure exception status clear register (SECLR) is set to 1.

DSER Flag (Data Access Secure Exception Occurrence Flag)

This flag indicates that a secure exception has occurred due to operand access.

The DSER flag is set to 0 only when the exception status clear bit (CLR) of the secure exception status clear register (SECLR) is set to 1.

56.9.3 Secure Exception Status Clear Register (SECLR)

Address(es): SAU.SECLR 8100 0408h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CLR	Exception Status Clear	[When read] 0: Fixed value for reading [When written] 0: No operation 1: Sets the SESTS.DSER and SESTS.ISER flags to 0.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

CLR Bit (Exception Status Clear)

This bit sets the data access secure exception flag (DSER) and instruction access secure exception flag (ISER) in the secure exception status register (SESTS) to 0.

56.9.4 Secure Exception Address Register (SEA)

Address(es): SAU.SEA 8100 040Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SEA[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SEA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	SEA[31:0]	Secure Exception Address	Address of the access that caused a secure exception	R

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

SEA[31:0] Bits (Secure Exception Address)

These bits hold the address of the access that caused a secure exception due to operand access. They are not updated when a secure exception occurs due to instruction access.

56.9.5 Peripheral Security Attribution Register B (PSARB)

Address(es): PSCU.PSARB 8780 4004h,
PSCU_NS.PSARB 0780 4004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PSARB31	PSARB30	PSARB29	PSARB28	PSARB27	PSARB26	PSARB25	PSARB24	PSARB23	PSARB22	PSARB21	PSARB20	PSARB19	PSARB18	PSARB17	PSARB16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	PSARB12	PSARB11	—	—	PSARB8	PSARB7	—	—	PSARB4	—	—	—	PSARB0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PSARB0	Serial Communications Interface 12 Security Attribution	Target module: RSCI12 and the MSTPCRB.MSTPB0 bit 0: Secure 1: Non-secure	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	PSARB4	I3C Bus Interface 0 Security Attribution	Target module: RI3C0 and the MSTPCRB.MSTPB4 bit 0: Secure 1: Non-secure	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	PSARB7	High-Speed I^2C-bus Interface 2 Security Attribution	Target module: RIICHS2 and the MSTPCRB.MSTPB7 bit 0: Secure 1: Non-secure	R/W
b8	PSARB8	High-Speed I^2C-bus Interface 1 Security Attribution	Target module: RIICHS1 and the MSTPCRB.MSTPB8 bit 0: Secure 1: Non-secure	R/W
b10, b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	PSARB11	USB 2.0 FS Host/Function Module 0 Security Attribution	Target module: USB0 and the MSTPCRB.MSTPB11 bit 0: Secure 1: Non-secure	R/W
b12	PSARB12	USB 2.0 High-Speed Host/Function Module Security Attribution	Target module: USBHS and the MSTPCRB.MSTPB12 bit 0: Secure 1: Non-secure	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	PSARB16	Expanded Serial Peripheral Interface 0 Security Attribution	Target module: XSPI0 (plus DOTF0), the bus master MPU for XSPI0, and the MSTPCRB.MSTPB16 bit 0: Secure 1: Non-secure	R/W
b17	PSARB17	Expanded Serial Peripheral Interface 1 Security Attribution	Target module: XSPI1 (plus DOTF1), the bus master MPU for XSPI1, and the MSTPCRB.MSTPB17 bit 0: Secure 1: Non-secure	R/W
b18	PSARB18	Serial Peripheral Interface 1 Security Attribution	Target module: RSPIA1 and the MSTPCRB.MSTPB18 bit 0: Secure 1: Non-secure	R/W
b19	PSARB19	Serial Peripheral Interface 0 Security Attribution	Target module: RSPIA0 and the MSTPCRB.MSTPB19 bit 0: Secure 1: Non-secure	R/W
b20	PSARB20	Serial Communications Interface 11 Security Attribution	Target module: RSCI11 and the MSTPCRB.MSTPB20 bit 0: Secure 1: Non-secure	R/W
b21	PSARB21	Serial Communications Interface 10 Security Attribution	Target module: RSCI10 and the MSTPCRB.MSTPB21 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Bit Name	Description	R/W
b22	PSARB22	Serial Communications Interface 9 Security Attribution	Target module: RSCI9 and the MSTPCRB.MSTPB22 bit 0: Secure 1: Non-secure	R/W
b23	PSARB23	Serial Communications Interface 8 Security Attribution	Target module: RSCI8 and the MSTPCRB.MSTPB23 bit 0: Secure 1: Non-secure	R/W
b24	PSARB24	Serial Communications Interface 7 Security Attribution	Target module: RSCI7 and the MSTPCRB.MSTPB24 bit 0: Secure 1: Non-secure	R/W
b25	PSARB25	Serial Communications Interface 6 Security Attribution	Target module: RSCI6 and the MSTPCRB.MSTPB25 bit 0: Secure 1: Non-secure	R/W
b26	PSARB26	Serial Communications Interface 5 Security Attribution	Target module: RSCI5 and the MSTPCRB.MSTPB26 bit 0: Secure 1: Non-secure	R/W
b27	PSARB27	Serial Communications Interface 4 Security Attribution	Target module: RSCI4 and the MSTPCRB.MSTPB27 bit 0: Secure 1: Non-secure	R/W
b28	PSARB28	Serial Communications Interface 3 Security Attribution	Target module: RSCI3 and the MSTPCRB.MSTPB28 bit 0: Secure 1: Non-secure	R/W
b29	PSARB29	Serial Communications Interface 2 Security Attribution	Target module: RSCI2 and the MSTPCRB.MSTPB29 bit 0: Secure 1: Non-secure	R/W
b30	PSARB30	Serial Communications Interface 1 Security Attribution	Target module: RSCI1 and the MSTPCRB.MSTPB30 bit 0: Secure 1: Non-secure	R/W
b31	PSARB31	Serial Communications Interface 0 Security Attribution	Target module: RSCI0 and the MSTPCRB.MSTPB31 bit 0: Secure 1: Non-secure	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The PSARB register is used to set the security attributes of each module and the corresponding module stop control register's bits.

56.9.6 Peripheral Security Attribution Register C (PSARC)

Address(es): PSCU.PSARC 8780 4008h,
PSCU_NS.PSARC 0780 4008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PSARC31	PSARC30	—	PSARC28	PSARC27	—	PSARC25	PSARC24	PSARC23	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	PSARC13	PSARC12	—	—	—	PSARC8	PSARC7	—	—	—	—	PSARC2	PSARC1	PSARC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PSARC0	Clock Frequency Accuracy Measurement Circuit Security Attribution	Target module: CAC0/1/2 and the MSTPCRC.MSTPC0 bit 0: Secure 1: Non-secure	R/W
b1	PSARC1	CRC Calculator Security Attribution	Target module: CRC and the MSTPCRC.MSTPC1 bit 0: Secure 1: Non-secure	R/W
b2	PSARC2	Parallel Data Capture Unit Security Attribution	Target module: PDC and the MSTPCRC.MSTPC2 bit 0: Secure 1: Non-secure	R/W
b6 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	PSARC7	Serial Sound Interface 1 Security Attribution	Target module: SSIE1 and the MSTPCRC.MSTPC7 bit 0: Secure 1: Non-secure	R/W
b8	PSARC8	Serial Sound Interface 0 Security Attribution	Target module: SSIE0 and the MSTPCRC.MSTPC8 bit 0: Secure 1: Non-secure	R/W
b11 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	PSARC12	SD/MMC Host Interface Security Attribution	Target module: SDHI and the MSTPCRC.MSTPC12 bit 0: Secure 1: Non-secure	R/W
b13	PSARC13	Data Operation Circuit Security Attribution	Target module: DOC and the MSTPCRC.MSTPC13 bit 0: Secure 1: Non-secure	R/W
b22 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23	PSARC23	Serial Peripheral Interface 2 Security Attribution	Target module: RSPIA2 and the MSTPCRC.MSTPC23 bit 0: Secure 1: Non-secure	R/W
b24	PSARC24	Pulse-Density Modulation Interface Security Attribution	Target module: PDMIF and the MSTPCRC.MSTPC24 bit 0: Secure 1: Non-secure	R/W
b25	PSARC25	CANFDG Module Security Attribution	Target module: CANFDG and the MSTPCRC.MSTPC25 bit 0: Secure 1: Non-secure	R/W
b26	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b27	PSARC27	CANFD Module Security Attribution	Target module: Controller area network with CANFD and the MSTPCRC.MSTPC27 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Bit Name	Description	R/W
b28	PSARC28	Ether-PHY Clock Security Attribution	Target module: ETHPHYCLK and the MSTPCRC.MSTPC28 bit 0: Secure 1: Non-secure	R/W
b29	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b30	PSARC30	Ethernet Module Security Attribution	Target module: ESWM and the MSTPCRC.MSTPC30 bit 0: Secure 1: Non-secure	R/W
b31	PSARC31	Renesas Secure IP Security Attribution	Target module: RSIP-E50D and the MSTPCRC.MSTPC31 bit 0: Secure 1: Non-secure	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The PSARC register is used to set the security attributes of each module and the corresponding module stop control register's bits.

56.9.7 Peripheral Security Attribution Register D (PSARD)

Address(es): PSCU.PSARD 8780 400Ch,
PSCU_NS.PSARD 0780 400Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	PSARD22	PSARD21	PSARD20	PSARD19	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	PSARD14	PSARD13	PSARD12	PSARD11	—	—	—	—	PSARD6	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	PSARD6	High Resolution PWM Waveform Generation Circuit Security Attribution	Target module: HRPWM and the MSTPCRD.MSTPD6 bit 0: Secure 1: Non-secure	R/W
b10 to b7	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	PSARD11	Port Output Enable for GPTW Group D Security Attribution	Target module: POEG Group D and the MSTPCRD.MSTPD11 bit 0: Secure 1: Non-secure	R/W
b12	PSARD12	Port Output Enable for GPTW Group C Security Attribution	Target module: POEG Group C and the MSTPCRD.MSTPD12 bit 0: Secure 1: Non-secure	R/W
b13	PSARD13	Port Output Enable for GPTW Group B Security Attribution	Target module: POEG Group B and the MSTPCRD.MSTPD13 bit 0: Secure 1: Non-secure	R/W
b14	PSARD14	Port Output Enable for GPTW Group A Security Attribution	Target module: POEG Group A and the MSTPCRD.MSTPD14 bit 0: Secure 1: Non-secure	R/W
b18 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b19	PSARD19	12-Bit D/A Converter 1 Security Attribution	Target module: DAC1 and the MSTPCRD.MSTPD19 bit 0: Secure 1: Non-secure	R/W
b20	PSARD20	12-Bit D/A Converter 0 Security Attribution	Target module: DAC0 and the MSTPCRD.MSTPD20 bit 0: Secure 1: Non-secure	R/W
b21	PSARD21	16-Bit A/D Converter Security Attribution	Target module: ADC16H and the MSTPCRD.MSTPD21 bit 0: Secure 1: Non-secure	R/W
b22	PSARD22	Temperature Sensor Security Attribution	Target module: TEMPS and the MSTPCRD.MSTPD22 bit 0: Secure 1: Non-secure	R/W
b31 to b23	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The PSARD register is used to set the security attributes of each module and the corresponding module stop control register's bits.

56.9.8 Peripheral Security Attribution Register E (PSARE)

Address(es): PSCU.PSARE 8780 4010h,
PSCU_NS.PSARE 0780 4010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PSARE31	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PSARE15	—	—	—	—	—	—	—	—	—	—	—	PSARE3	PSARE2	PSARE1	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	PSARE1	Watchdog Timer Security Attribution	Target module: WDT 0: Secure 1: Non-secure	R/W
b2	PSARE2	Independent Watchdog Timer Security Attribution	Target module: IWDT 0: Secure 1: Non-secure	R/W
b3	PSARE3	Real Time Clock Security Attribution	Target module: RTC 0: Secure 1: Non-secure	R/W
b14 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	PSARE15	General PWM Timer Common Security Attribution	Target module: GPTW GTCLKCR register 0: Secure 1: Non-secure	R/W
b30 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	PSARE31	General PWM Timer Channel 15 to 0 Security Attribution	Target module: GPTW15 to GPTW0 and the MSTPCRE.MSTPE31 bit 0: Secure 1: Non-secure	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.

The PSARE register is used to set the security attributes of each module and the corresponding module stop control register's bits.

56.9.9 Peripheral Security Attribution Register F (PSARF)

Address(es): PSCU.PSARF 8780 4040h,
PSCU_NS.PSARF 0780 4040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	*1	*1	*1	*1

Note 1. The value is 0100b in a blank product. The value of these bits depends on the DLM status.

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	DLMMON[3:0]	Device Lifecycle Management State Monitor	Indicate the DLM status value. b3 b0 0 1 0 0: OEM 0 1 1 0: LCK_BOOT 0 1 1 1: RMA_REQ 1 0 0 0: RMA_ACK 1 0 0 1: RMA_RET Other than above: Reserved	R
b31 to b4	—	Reserved	These bits are read as 0.	R

56.9.14 Master Security Attribution Operation-After-Detection Register (MSAOAD)

Address(es): BUS.MSAOAD 8701 E010h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OAD	Operation after access violation detection	0: Interrupt 1: Reset	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key code	These bits enable or disable writing to the OAD bit.	W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

OAD Bit (Operation after access violation detection)

The OAD bit specifies operation when the access violation is detected. When OAD = 0, the error response is returned to the bus master. When BUSIRQFN<Master Name>.EN = 1, an interrupt request is generated. For details, see section 16.3.35, Bus Error Interrupt Enable Register (BUSINTENCPU0IF, BUSINTENCPU0OA, BUSINTENDMAC0, BUSINTENEXDMAC, BUSINTENEDMAC, BUSINTENXSPI0, BUSINTENXSPI1). Also, bus errors can be used as non-masukable interrupts. For details, see the specifications for the ICU.NMIER register.
When OAD = 1, a reset request is generated.

KEY[7:0] Bits (Key code)

The KEY[7:0] bits are used to enable or disable writing to the OAD bit. When writing to the OAD bit, use 16-bit access to write A5h to the KEY[7:0] bits at the same time. If this value is not written to the KEY[7:0] bits, the OAD bit is not updated.

56.9.15 Master Security Attribution Protect Register (MSAPT)

Address(es): BUS.MSAPT 8701 E014h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	PROTECT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PROTECT	Register Write Protection	0: Disables write protection. 1: Enables write protection. Reading is possible.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	These bits enable or disable writing to the PROTECT bit.	W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

PROTECT Bit (Register Write Protection)

The PPROTECT bit enables or disables writes to the associated register to be protected. The MSAPT.PROTECT bit controls the MSAOAD register.

KEY[7:0] Bits (Key Code)

The KEY[7:0] bits enable or disable writing to the PROTECT bit. When writing to the PROTECT bit, use 16-bit access to write A5 to KEY[7:0] bits at the same time. If this value is not written to the KEY[7:0] bits, the PROTECT bit is not updated.

56.10 Secure Key Injection

To inject a user key into the MCU, perform the following steps.
Renesas provides the Security Key Management Tool, available on the Renesas website, to assist with key injection preparation.

1. Create a 256-bit installation key.
   This key is called the user factory programming key (UFPK) and is used to wrap a user key.
2. Get the wrapped version (W-UFPK) of the UFPK through the Renesas key wrapping service.
3. Wrap the user key using the UFPK.
4. Send the W-UFPK and the wrapped user key to the MCU using a boot firmware interface.
   First, the user key is unwrapped. Then, it is wrapped with the MCU's unique hardware key and stored in non-volatile memory. DLM keys are stored in MRAM that is not memory-mapped. An application key is stored at the address specified with the key injection command.

Figure 56.7 shows an example of key injection and Table 56.11 shows the keys that can be injected.

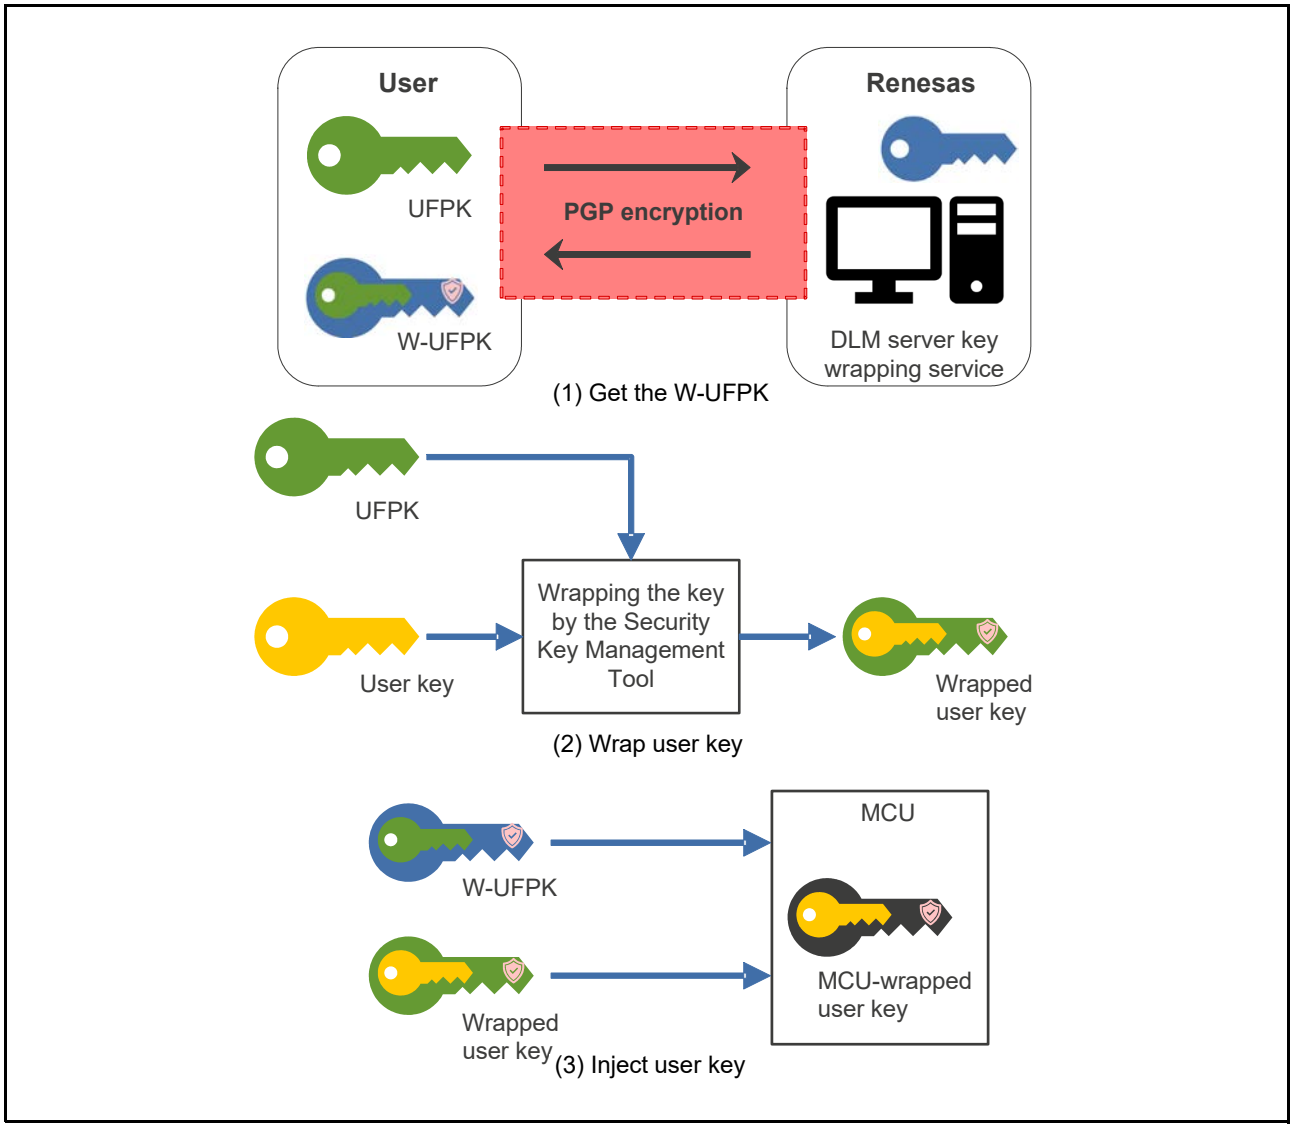

Figure 56.7 Key Injection

Table 56.11 Keys That Can Be Injected

DLM Transition	RMA_KEY (up to four)
AL Transition	AL2_KEY and AL1_KEY (up to four of each)
AES	AES-128, AES-192, AES-256, AES-XTS-128, AES-XTS-256
ChaCha20-Poly-1305	ChaCha20-Poly-1305
RSA	RSA-1024, RSA-2048, RSA-3072, RSA-4096 (public and private keys) RSA-2048 Public key for TLS
ECC	secp192r1, secp224r1, secp256r1, secp384r1, secp521r1 (public and private keys) Brainpool P256r1, Brainpool P384r1, Brainpool P512r1, Koblitz secp256k1 (public and private keys)
HMAC	HMAC-SHA224, HMAC-SHA256, HMAC-SHA384, HMAC-SHA512, HMAC-SHA512/224, HMAC-SHA512/256, HMAC-SHA3-224, HMAC-SHA3-256, HMAC-SHA3-384, HMAC-SHA3-512
EdDSA	Ed25519 (public and private keys)
Secure Boot	OEM_ROOT_PK (Up to 4)
Others	Key-update key

56.11 Secure Factory Programming

Secure factory programming is to program a firmware image in ciphertext format to prevent asset leakage during production programming. This MCU supports secure factory programming in addition to supporting secure injection of the DLM keys, debug authentication keys, application keys, and secure boot keys shown in Table 56.11. This enables programming in an environment that is not secure. This function is implemented in the boot program. Figure 56.8 shows an example of secure factory programming of an encrypted image. The user should encrypt the firmware image with AES128-CCM by using the firmware image encryption key (called the image encryption key). The image encryption key should be wrapped with the UFPK. When the user sends the W-UFPK, the wrapped image encryption key, and encrypted image to the MCU through the serial programming interface, the MCU decrypts and programs the image.

To support secure factory programming in an environment that is not secure, the DLM state, protection level, and authentication keys can all be set via a single boot command. Points to note about this boot command include:

- Execution of the boot command that supports secure factory programming is only possible when the MCU is in the OEM state.
- This command will change the protection level of the MCU. The initial PL of the device is PL2. Set the final PL to PL0.
- If the DLM state will remain in the OEM state, AL2_KEY must be injected. AL1_KEY can also be injected optionally.
- The MCU can be transitioned to the LCK_BOOT state. In this case, AL keys cannot be injected.
- AL keys must be wrapped with the same UFPK as for the image encryption key.
- This command will erase all code MRAM areas and data MRAM areas except option-setting memory before programming an encrypted image. Therefore, if the permanent block protection function has been applied to any area, this command cannot be executed.
- This command will not be executed if the current register settings or the write values to the registers related to startup area selection and startup bank selection are other than the following:
  - SAS2.BTFLG = 1b
  - BANKSEL_NS.BANKSWP[2:0] = 111b
  - BANKSEL_S.BANKSWP[2:0] = 111b

- All option-setting memory values must be included in the encrypted image, including settings that are not used with default values. However, if the following areas are write-protected, the write data in these areas should not be included in the image. If included, this command will terminate with an error.
  - Configuration setting area protected by the POFSPSSn registers
  - Configuration setting area protected by the POFSPSNS0 registers

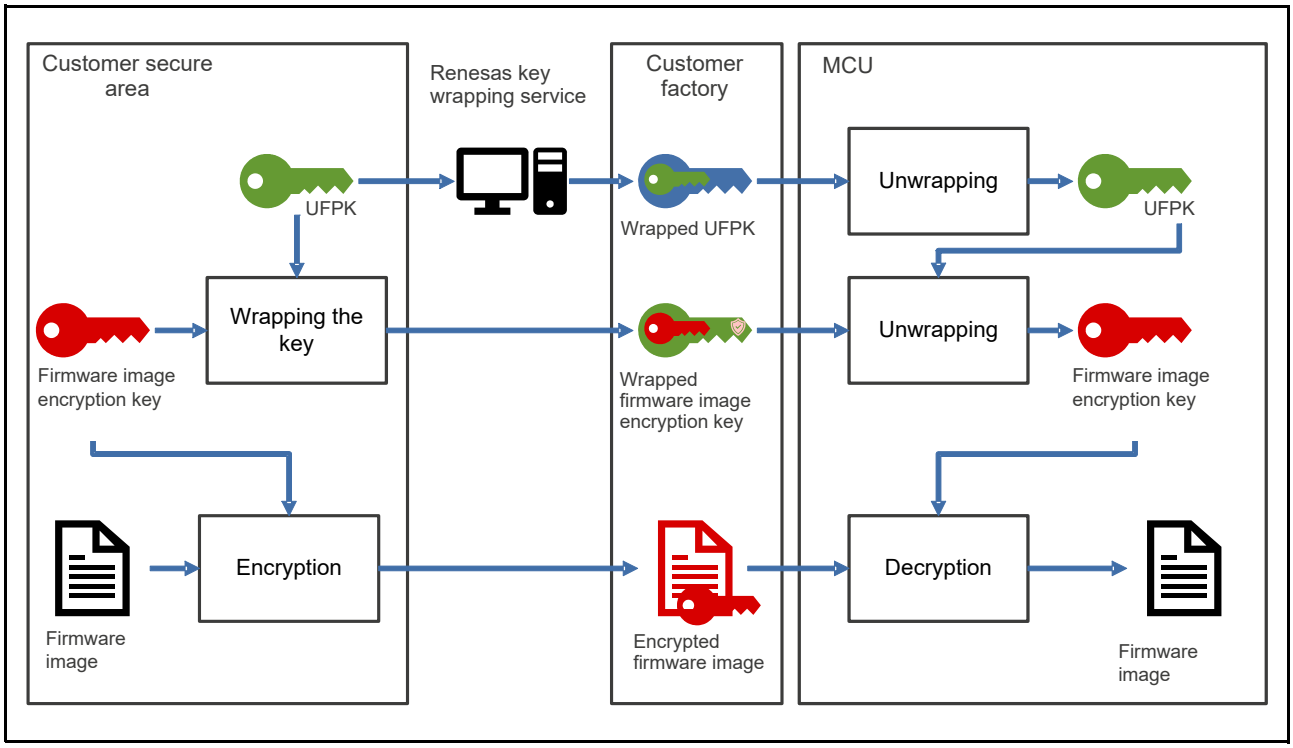

Figure 56.8 Secure Factory Programming of Encrypted Image

56.12 Secure Boot

Secure boot verifies the integrity and authenticity of an OEM boot loader (called OEM_BL) starting at the beginning of the user program.
The OEM_BL is verified when it is programmed and before it is excecuted.
It is verified when it is programmed using the boot firmware. Two certificates are used for validation. One is the key certificate, which is used to certify the OEM_BL verification key (called the OEM_BL_PK, the public key of the OEM_BL verification key pair). The key certificate is signed by the secret key of OEM_BL verification root key pair (called OEM_ROOT_SK). The public key of OEM_BL verification root key pair (called OEM_ROOT_PK) is registered with the MCU as the root of trust key using secure key injection as described in section 56.10, Secure Key Injection.
The OEM_ROOT_SK and OEM_ROOT_PK are a 256-bit ECC (secp256r1 curve) key pair. The SHA2-256 hash of the OEM_ROOT_PK is stored during the secure key injection process.
The other certificate for validation during programming is the code certificate, which is used to certify the OEM_BL. The code certificate is signed by the secret key of OEM_BL verification key pair (called OEM_BL_SK). After successful validation of the OEM_BL, the HMAC value of OEM_BL and the code certificate (called OEM_BL_digest) is generated and programmed into MRAM. HMAC SHA2-256 is used as the HMAC value. A key derived from the HUK is used in HMAC generation, so the HMAC value is unique in each MCU.
In single-chip mode, the first-stage boot loader (FSBL) stored in the area that cannot be rewritten is executed after a reset when the FSBL is enabled in the FSBLCTRL0 register. When HMAC authentication is selected in FSBLCTRL1 register, the FSBL generates the HMAC value of the OEM_BL and the code certificate, and compares it to the expected HMAC value. When the HMAC values match, the FSBL jumps to the OEM_BL. When CRC validation is selected in the FSBLCTRL1 register, the FSBL calculates the CRC of the OEM_BL and compares it to the expected CRC value, which is located in the code certificate. If the CRC values match, the FSBL jumps to the OEM_BL.
The code certificate must be programmed into MRAM, and its location in MRAM must be programmed into the SACC0 register or SACC1 register. The SACC0 register specifies the start address of the code certificate when BANKSWP[2:0] = 111b in dual mode or when BTFLG = 1 in linear mode. The SACC1 register specifies the start address of the code certificate when BANKSWP[2:0] = 000b in dual mode or when BTFLG = 0 in linear mode. The SACC0n and SACC1n registers are in the OTP area and cannot be erased. Therefore, each set consists of four registers allocated to four locations for use in updating the start address of the code certificate. The FSBL reads the values of the given registers in order, starting with the one with the highest number n, and uses the first register that includes non-1 bits as the start address of the code certificate. Accordingly, write to the registers of each set in order, starting with the register having the lowest number n.
When measurement reporting is enabled in the FSBLCTRL1 register, the FSBL stores the measurement report at the SRAM address specified by the SAMR register.
FSBL execution can be skipped after a software reset or deep software standby reset, as configured by the FSBLCTRL0 register. If the generated HMAC or CRC value is different from the expected value, a high level is output to the port set by the FSBLCTRL2 register and the MCU transitions to CPU sleep mode.

	Value	32	SHA2-256 hash value of OEM_BL_PK
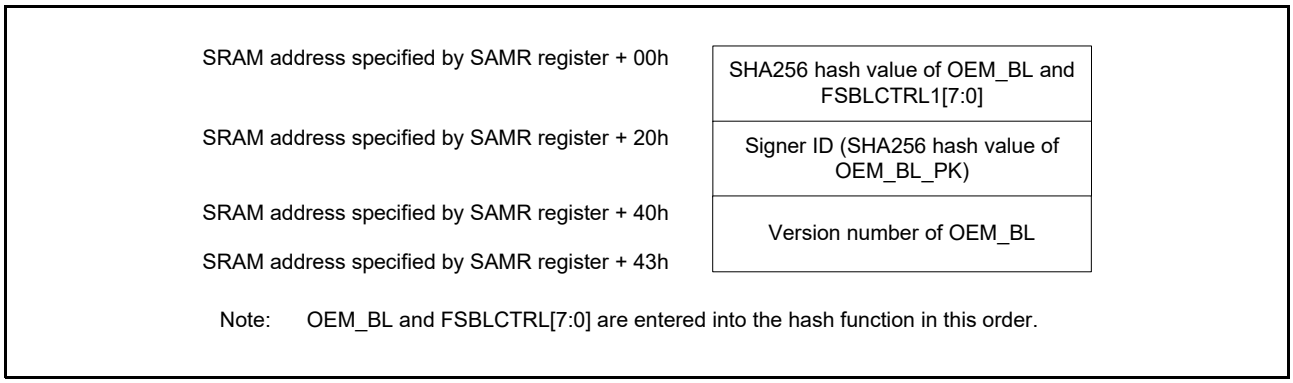
TLV EXPECTED_SIG	Type & length	4	Set to 25088410h
	Value	64	OEM_BL signed by signature OEM_BL_SK in [code certificate] When generating the signature, enter the code certificate and OEM_BL in the hash function in this order.

Table 56.14 Details of OEM_BL_digest

Field		Size (Bytes)	Description
TLV EXPECTED_MAC	Type & length	4	Fixed value 30184008h
	Value	32	Unique OEM_BL_digest in each MCU

Note: OEM_BL_digest should be programmed in the area contiguous with the code certificate.



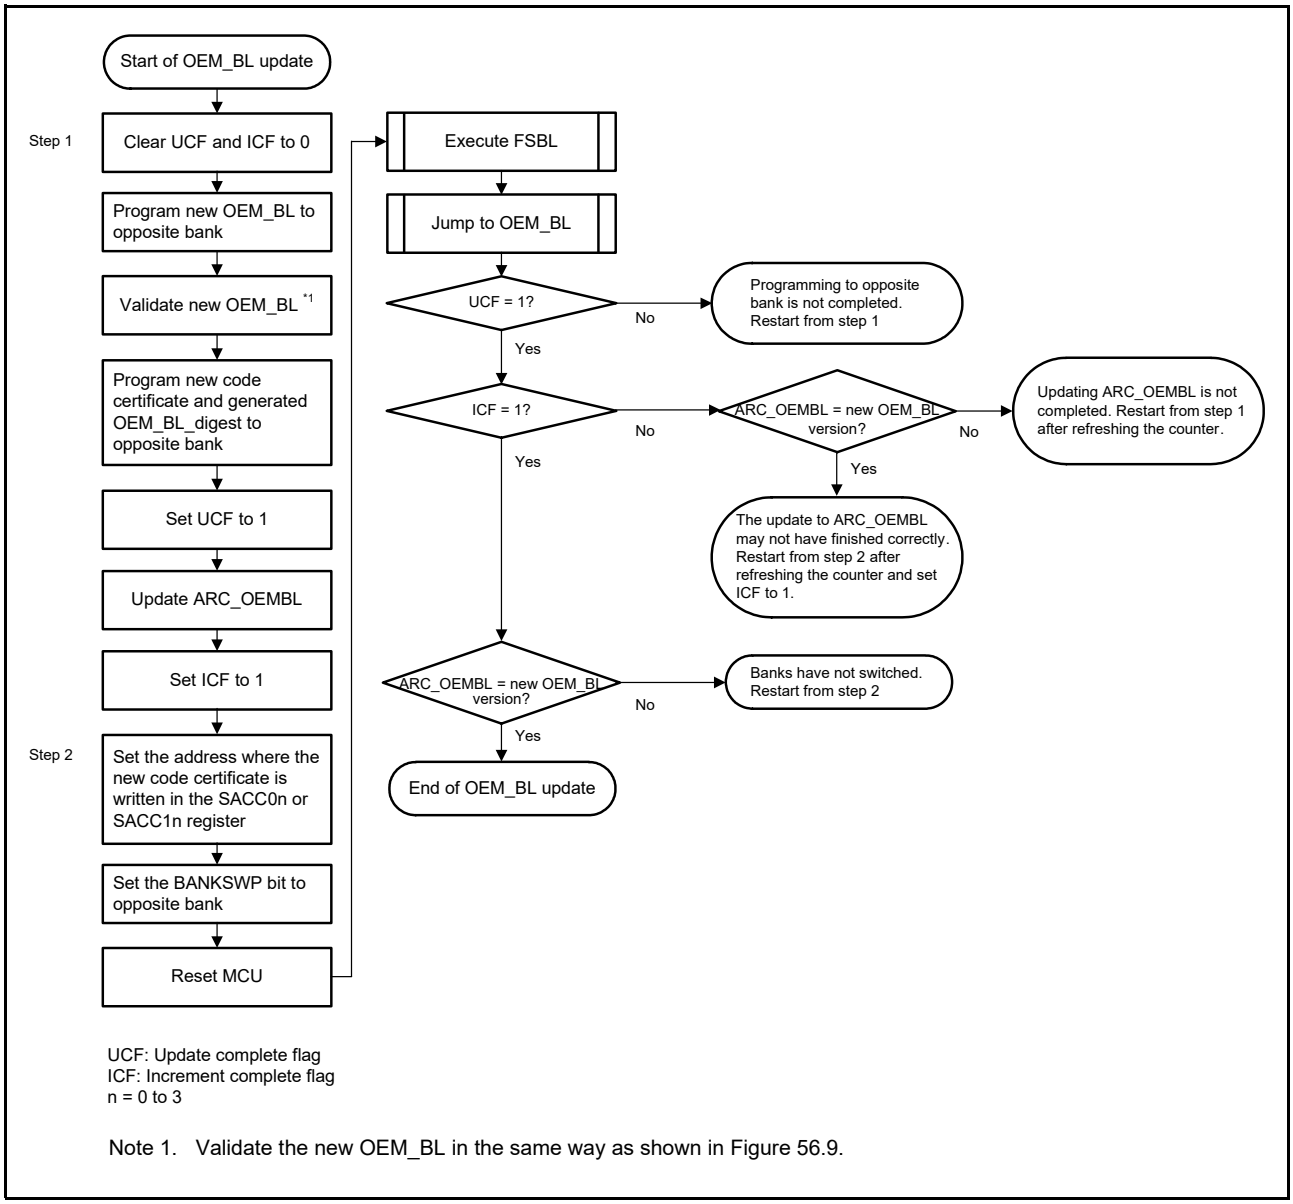


Figure 56.12 Format and Location of the Measurement Report

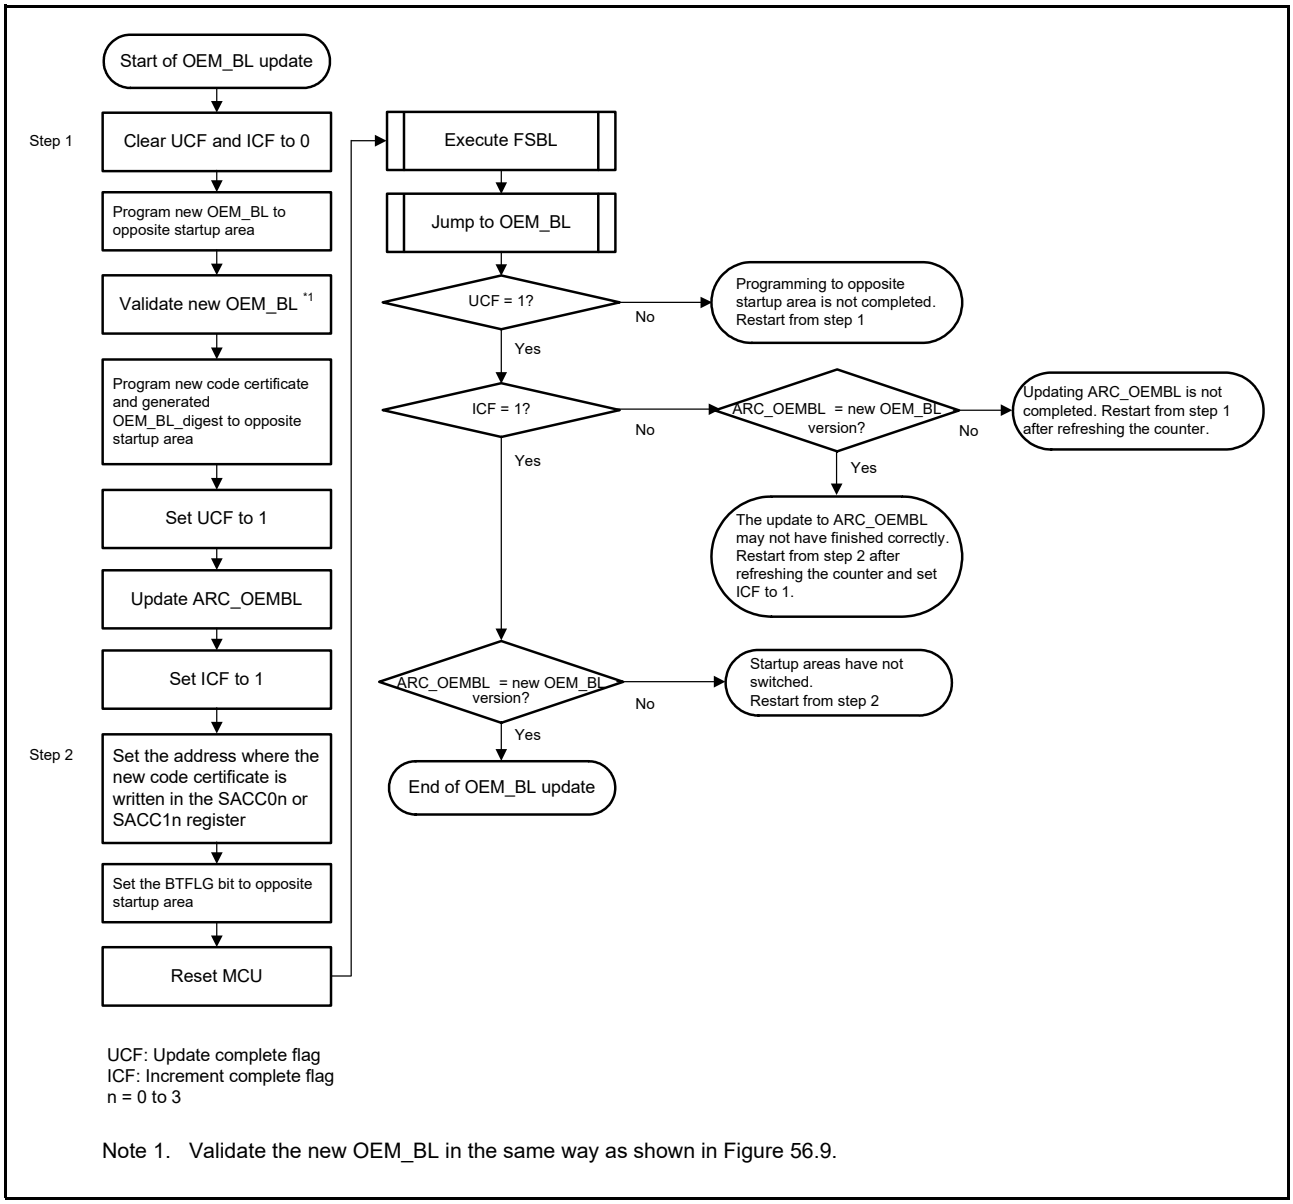

OEM_BL can be updated by application code. In this case, the application code must validate the updated bootloader, generate the OEM_BL_digest, and store it immediately after the new code certificate, as per the flow described by Figure 56.12. Figure 56.13 and Figure 56.14 show the OEM_BL update flow in dual mode and linear mode. When using linear mode, if the total size of OEM_BL, code certificate, and OEM_BL_digest is larger than the startup area size of 8 KB, this update flow cannot be used. It is recommended to use dual mode.

The implementation of the OEM_BL is user defined and application specific. However, it is recommended to implement status flags such as Update Complete Flag (UCF) and Increment Complete Flag (ICF) in code MRAM as a countermeasure against update errors due to unexpected power failure. If an update error occurs, recovery from the error is possible as shown in the following figures. If an update error occurs, the current OEM_BL is executed after FSBL execution. Note that the update error determination program is required for both the current OEM_BL and the new OEM_BL.

Note 1. Validate the new OEM_BL in the same way as shown in Figure 56.9.

Figure 56.13 OEM_BL Update Flow in Dual Mode

Note 1. Validate the new OEM_BL in the same way as shown in Figure 56.9.

Figure 56.14 OEM_BL Update Flow in Linear Mode

56.13 Field Updating in Dual Mode

Be careful when performing field firmware update to keep the contents of secure (S) or non-secure (NS) regions after bank swapping in the dual mode. Figure 56.15 and Figure 56.16 show the field update execution flow for secure and non-secure regions in dual mode.

Figure 56.15 and Figure 56.16 show the information update flow for the secure area and non-secure regions in dual bank mode in the field. Initially, bank0 contains Version 1 of the firmware, and bank1 is blank. As shown in Figure 56.15, to update the secure firmware (S firmware) to Version 2, first copy the Version 1 non-secure firmware (NS firmware) in bank0 to bank1, update the S firmware to Version 2, and then execute the start-up bank switch.

As shown in Figure 56.16, to update the NS firmware to Version 2, first copy the Version 1 S firmware from bank0 to bank1. Note that this process must be done by a secure service. After that, non-secure users should update the NS firmware to Version 2 and execute the start-up bank switch.

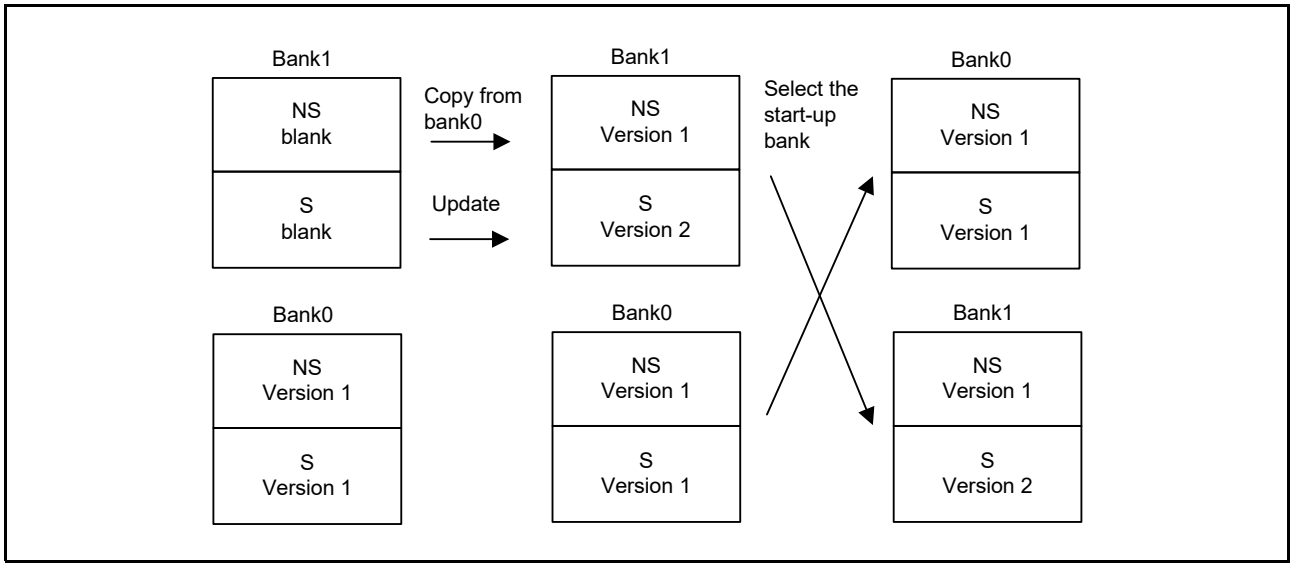

Figure 56.15 Field Updating Flow of Secure Region

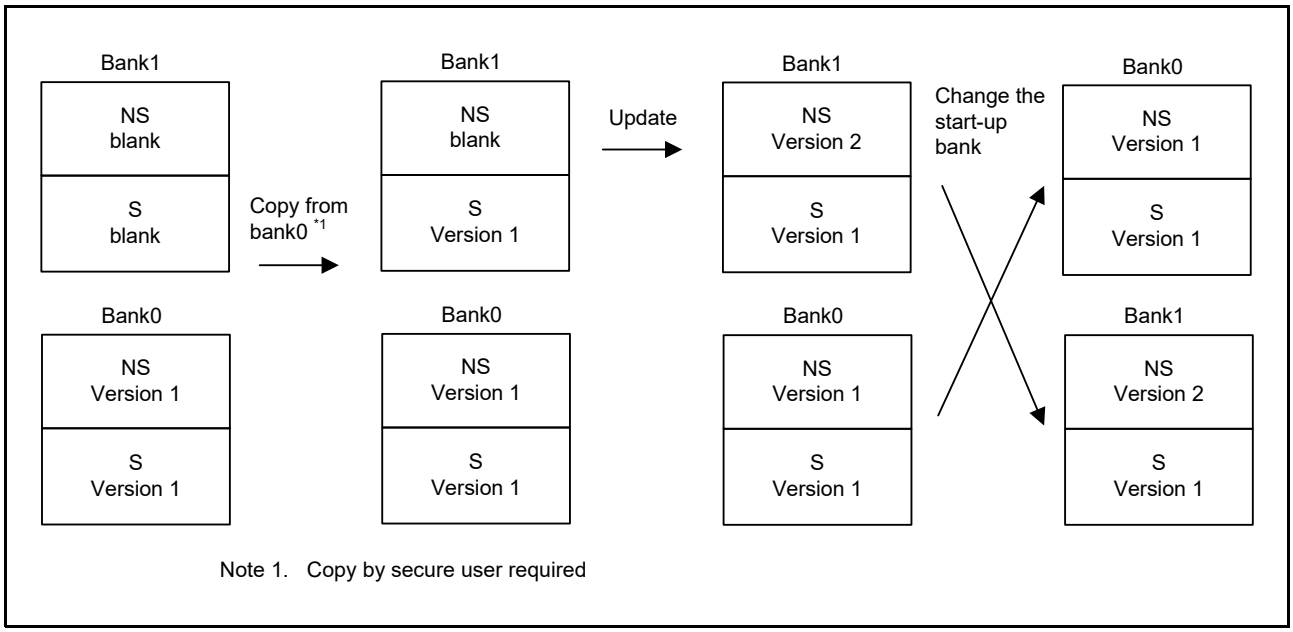

Figure 56.16 Field Updating Flow of Non-Secure Region

56.14 Device Lifecycle Management

Device Lifecycle Management (DLM) identifies the current development/production/deployment phase of the device and controls the capabilities of the debug function, the serial programming interface, and Renesas test mode. Figure 56.17 shows the available device lifecycle states and Table 56.15 shows the lifecycle state definitions and capabilities in each state.

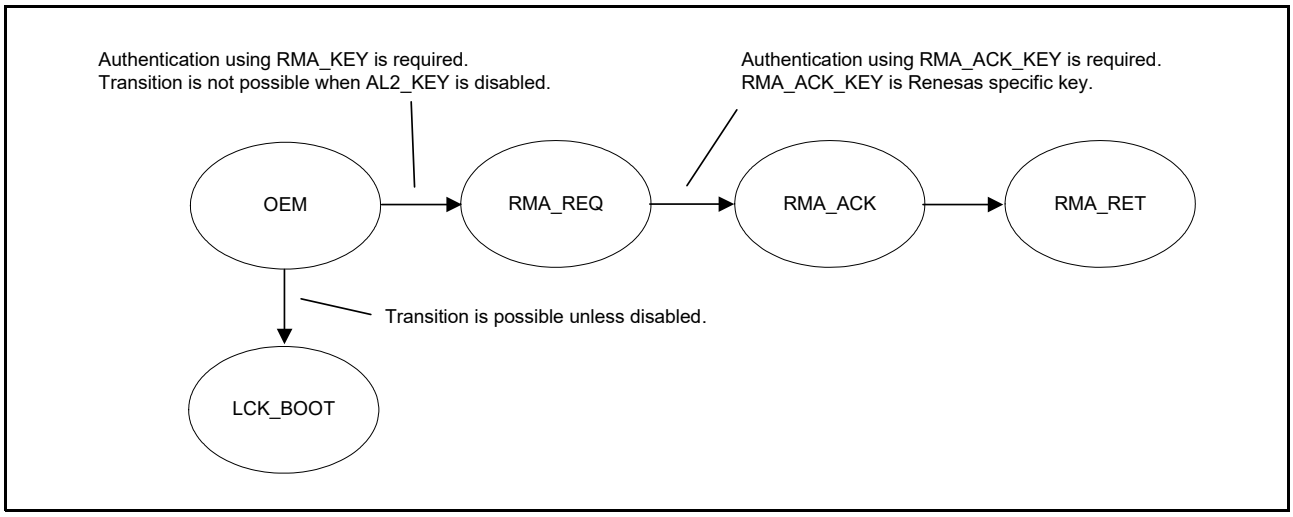

Figure 56.17 Device Lifecycle States

Table 56.15 Lifecycle State Definitions and Functions in Each State

Lifecycle	Definition	Protection Level	Debug Function	Serial Programming	Renesas Test Mode
OEM	Original Equipment Manufacturer The device is owned by the customer.	PL2, PL1 or PL0	Depends on the authentication level.		Not available
LCK_BOOT	LoCKed BOOT interface (Boot interface locked) The debug interface and the serial programming interface are permanently disabled.	PL0	Not available	Not available	Not available
RMA_REQ	Return Material Authorization REQuest (RMA request) RMA request. The customer must send the device to Renesas in this state.	PL0	Not available	Available Access to code MRAM area and data MRAM area not possible	Not available
RMA_ACK	Return Material Authorization ACKnowledged (RMA acknowledged) Failure analysis in Renesas	PL2	Non-secure and secure debug functions are enabled.	Available Access to code MRAM area and data MRAM area not possible	Available
RMA_RET	Return Material Authorization ACKnowledged (RMA return) This device has been returned to the customer. The device does not boot.	PL0	Not available	Not available	Not available

56.14.1 Changing Lifecycle States

Use the boot commands to change the device lifecycle state. The lifecycle state cannot be updated by an application, but the current lifecycle state can be read through the dedicated registers.
As shown in Figure 56.18, each transition is one-way and the state cannot be regressed.
Transition from OEM to RMA_REQ requires key authentication using the RMA_KEY which must have been previously injected by the user. The key length of the RMA_KEY is 128 bits. Inject the RMA_KEY as shown in section 56.10, Secure Key Injection.
The key authentication uses challenge and response authentication or authentication using the MCU's unique ID. The response (challenge and response authentication) or the authentication code (using the MCU's unique ID) can be calculated as follows:
Response = AES-128 CMAC (RMA_KEY, 128-bit challenge)
Authentication code = AES-128 CMAC (RMA_KEY, 128-bit MCU unique ID)
The contents of the code MRAM and data MRAM except permanently locked blocks or registers are erased when transitioning to RMA_REQ. The contents of the permanently locked blocks or registers can be read by Renesas at failure analysis. MRAM blocks can be permanently locked by setting the PBPS_NS and PBPS_S registers or PBPSD_NS and PBPSD_S registers to permanently disable rewriting of the code and data MRAM blocks. The SAS and SAS2 registers can be permanently locked by using the FSPRS and FSPR bits, which permanently disable programming and erasure of the registers. Transition to RMA_REQ is not possible if the AL2_KEY is disabled. The MCU does not respond after changing the device lifecycle state to RMA_REQ. To continue to use boot commands, re-transition back to boot mode is required after a reset.
Transition from OEM to LCK_BOOT is possible unless it has been explicitly disabled. Use the parameter setting command at authentication level AL2 or AL1 to prohibit the transition to LCK_BOOT. The transition to LCK_BOOT is a permanently disabled and cannot be reversed. The debug interface and serial programming interface are permanently disabled in LCK_BOOT.

56.14.2 Protection and Authentication Levels

The protection level (PL) and the authentication level (AL) determine the availability of the debug function and the serial programming interface. PL and AL are fixed except in the OEM state. In OEM mode, three levels can be set for PL and AL. AL indicates a temporary authentication status and is initialized to PL after an MCU power-on reset. Both PL and AL can be changed only by the boot firmware and cannot be changed by the application. Figure 56.18 shows the available protection level and authentication level states and transitions. Table 56.16 shows the availability of the debug function and the serial programming interface in each level.

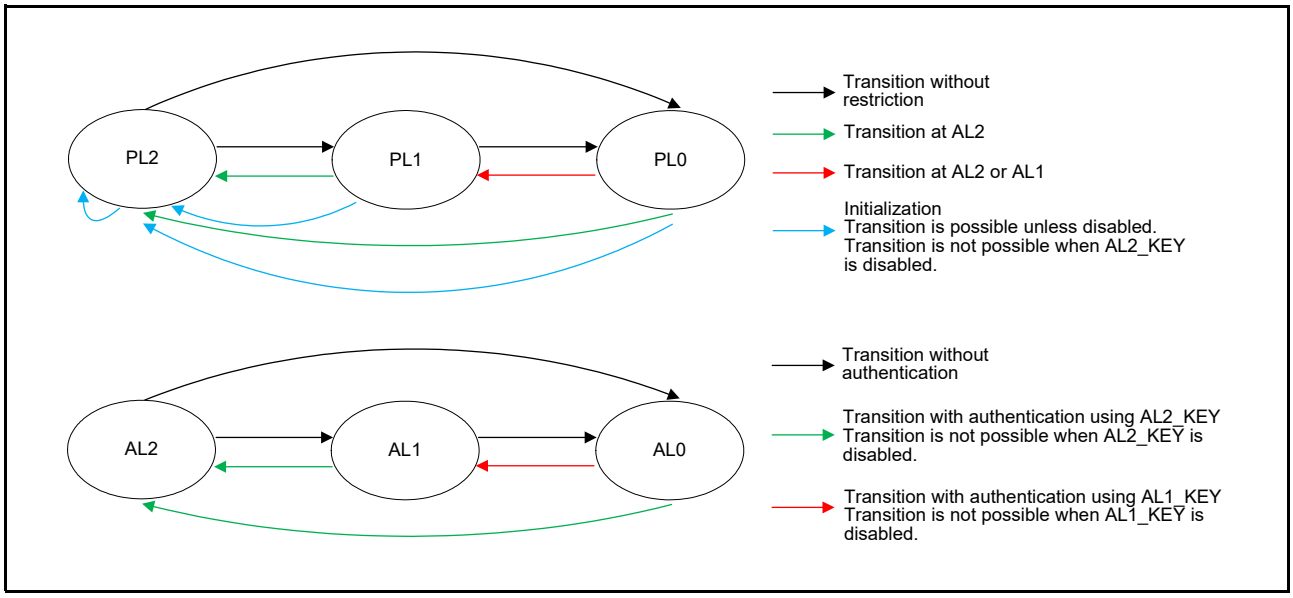

Figure 56.18 PL and AL States and Transitions

Table 56.16 Availability of the Debug Function and the Serial Programming Interface in Each Authentication Level

AL	Debug Function	Serial Programming Interface
AL2	Non-secure and secure debug functions are enabled and accessible from the debugger.	All functions are available
AL1	Only the non-secure debug function is enabled, and the debugger can access only defined non-secure debug accessible regions.	Available, but programming, erasing, and reading of the secure region of code MRAM and data MRAM are not possible.
AL0	No debug functions are available.	Available, but access to code MRAM and data MRAM is not possible.

Use the boot commands to change the PL and AL.

Changing to a lower PL can be done with no restriction. Changing to a higher PL requires that the MCU be at that AL or higher. For example, when the current AL is AL1, changing to PL1 is possible but changing to PL2 is impossible. The PL can be reset with an Initialize command as long as the command itself is not invalid. The PL is back to PL2 and the contents on MRAM are erased. If the OTP area is not empty, the Initialize command will not be executed. The Initialize command can be disabled permanently in all AL states by the parameter setting command to prevent users from erasing the contents of MRAM.

The Initialize command is disabled also when AL2_KEY is disabled. The MCU does not respond after executing the Initialize command. To continue to use the boot commands, re-transition back to boot mode is required after a reset.

Changing to a lower AL can be done without authentication. Changing to a higher AL requires key authentication using AL2_KEY or AL1_KEY, as appropriate. These keys are 128-bit keys. Injection of AL2_KEY or AL1_KEY is performed as shown in section 56.10, Secure Key Injection. AL2_KEY can be injected at authentication level AL2. AL1_KEY can be injected at authentication level AL2 or AL1. The key authentication uses challenge and response authentication. The response can be calculated as follows:

Response = AES-128 CMAC (KEY, 128-bit challenge)

AL2_KEY can be disabled permanently at authentication level AL2 with the parameter setting command. AL1_KEY can be disabled permanently at authentication level AL2 or AL1 with the parameter setting command.

56.14.3 Serial Programming

Whether a serial programmer can be connected and the range of MRAM that can be accessed depends on the device lifecycle state and AL as shown in Table 56.15 and Table 56.16. In addition, the acceptable serial programming commands differ depending on the device lifecycle state and AL.

56.14.4 Device Lifecycle States and PL Change Examples

This section describes typical device lifecycle states and PL change examples.

- Secure developers
  - Set the memory security attributes of the code MRAM and data MRAM using the boot commands.
  - Program and debug the secure application.
  - If the AL2_KEY and RMA_KEY are required, inject them using the boot commands.
  - Inject application AES, ChaCha20-Poly1305, RSA, ECC, HMAC, EdDSA keys listed in Table 56.11 (if required).
  - MCU preparations for non-secure developers
    - If the non-secure developer will not be permitted to use the Initialize command, disable it using the boot commands.
    - If the AL2_KEY will not be used and the non-secure developer will not be permitted to use the Initialize function, disable the AL2_KEY using the boot commands.
    - Change the PL from PL2 to PL1 using the boot commands.
- Non-secure developers
  - Program and debug non-secure applications.
  - If the AL1_KEY is required, inject it using the boot commands.
  - Inject application AES, RSA, ECC, HMAC keys listed in Table 56.11 (if required).
  - MCU preparations for end-product deployment
    - Disable the Initialize command using the boot commands (if required).
    - If the AL1_KEY will not be used, disable it using the boot commands.
    - Change the PL state from PL1 to PL0 using the boot commands.

56.14.5 Failure Analysis

If the user requests failure analysis by Renesas, it is necessary to send the device after changing the device lifecycle state to RMA_REQ. If the device lifecycle state is not RMA_REQ, Renesas cannot perform the failure analysis. After failure analysis, Renesas changes the lifecycle to RMA_RET and returns the device to the user.

Note: RMA_KEY is required to change the device lifecycle state to RMA_REQ or the MCU's Unique ID must be used as part of the authentication code. For details, see section 56.14.1, Changing Lifecycle States.

56.15 Usage Notes

56.15.1 Notes on Settings of the Security Attribution Bits

Program execution begins in the root world after release from a reset. Before shifting to another world, set the security attribute for each resource of the memory and peripheral modules. Specify the security attribute for a resource before using the resource and do not change the setting. Determine the security attribute for a memory address before accessing the address.

56.15.2 Security Attribution Bit Write Timing

When writing a security attribution bit, confirm that the write is complete by reading the security attribution register until it matches the value written. The protection is not effective until the write to the security attribution register is complete.

56.15.3 Executing the WAIT Instruction in Non-Flat-Project Operation

When CPSCU.PRTZCR.PRTZC is set to 1 (Non-Flat-Project operation), do not execute the WAIT instruction in the root world. In this state, the root world does not accept interrupts destined for the secure or non-secure world, so the MCU cannot be released from the low-power state by these interrupts.

57. Renesas Secure IP (RSIP-E50D)

This MCU incorporates a Renesas Secure IP (RSIP-E50D) module to provide security functions. The module consists of an access management circuit, encryption engine, and random number generator. In combination with the RSIP library, the RSIP can prevent eavesdropping (confidentiality), falsification of information (integrity), and impersonation (authenticity).

Key information to be used in encrypting and decrypting data is only stored within the RSIP, and any external access can be shut out to obtain a system with strong security.

57.1 Overview

Table 57.1 summarizes the specifications of the RSIP. Figure 57.1 shows a block diagram of the RSIP.

Table 57.1 Specifications of RSIP (1/2)

Item	Description
Access control	Access management circuit • In case of irregular access to the RSIP due to a falsified program or runaway execution of a program, this circuit blocks all subsequent access and stops the output of data from the RSIP.
Symmetric-key cryptography	AES: Compliant with NIST FIPS PUB 197 algorithm • Key sizes: 128, 192, or 256 bits • Block sizes: 128 bits • Block cipher mode of operation ECB, CBC, CTR: Compliant with NIST SP 800-38A CCM: Compliant with NIST SP 800-38C GCM: Compliant with NIST SP 800-38D XTS: Compliant with IEEE 1619-2007 • Message Authentication Code Algorithm CMAC: Compliant with NIST SP 800-38B GMAC: Compliant with NIST SP 800-38D ChaCha20-Poly1305: Compliant with RFC7539 • Key sizes: 256 bits • Block sizes: 512 bits • ChaCha20 algorithm ChaCha20-Poly1305
Public-key cryptography	RSA • Key sizes: 1024, 2048, 3072, or 4096 bits • Block sizes: Up to 4224 bits • Signing, Signature verification, public-key encryption, private-key decryption ECC • Key sizes: Up to 521 bits • Block sizes: Up to 576 bits • Signing, Signature verification, Key generation
Message digest function	HASH • Secure hash algorithm SHA-1, SH-224, SHA-256, SHA-512/224, SHA-512/256, SHA-384, SHA-512: Compliant with FIPS PUB 180-4 SHA3-224, SHA3-256, SHA3-384, SHA3-512, SHAKE128, SHAKE256: Compliant with FIPS PUB 202 • Message authentication algorithm HMAC: Compliant with FIPS PUB 198 • Key sizes: Up to 512-bit • Block sizes: 512 bits (SHA-1, SHA-224, SHA-256) 1024 bits (SHA-512/224, SHA-512/256, SHA-384, SHA-512) 1152 bits (SHA3-224) 1088 bits (SHA3-256) 832 bits (SHA3-384) 576 bits (SHA3-512) 1344 bits (SHAKE128) 1088 bits (SHAKE256)
Generation of random numbers	128-bit true random number generator

Table 57.1 Specifications of RSIP (2/2)

Item	Description
Hardware unique key (HUK)	• 256-bit read-only key unique to each individual MCU • HUK is wrapped with unique ID and stored in an area isolated from CPU. • HUK can only be read from the access management circuit through the dedicated bus. HUK is not accessible from CPU.
Unique ID	• 128-bit read-only ID code to identify individual MCUs. • Unique ID is accessible from the access management circuit through the dedicated bus. • Unique ID is used to unwrap the HUK.
Key management	• User key can be securely stored in MRAM or RAM by wrapping with HUK. Raw key is not stored. • Keys wrapped with HUK are valid only within the corresponding RSIP. Even if the wrapped key is leaked, it cannot be unwrapped by RSIP on other MCUs.
Supervisor mode	• The supervisor mode signal is connected to the access management circuit and is used to limit control of the RSIP module to supervisor mode only.
OEM boot loader version	• The RSIP outputs the OEM boot loader version (OEM BL Ver.). • The MRAM sequencer supports Anti-Rollback Counter Protection using the OEM boot loader version, which is protected by the RSIP.
On-the-fly decryption	The RSIP outputs key data for on-the-fly decryption (DOTF) through a dedicated bus.
Preventing tampering	Countermeasures against side channel attacks, including SPA/DPA and timing attacks, are available.
Low power consumption	Setting of the module stop state is possible.
Protect Zone filter	Security attribution can be set.

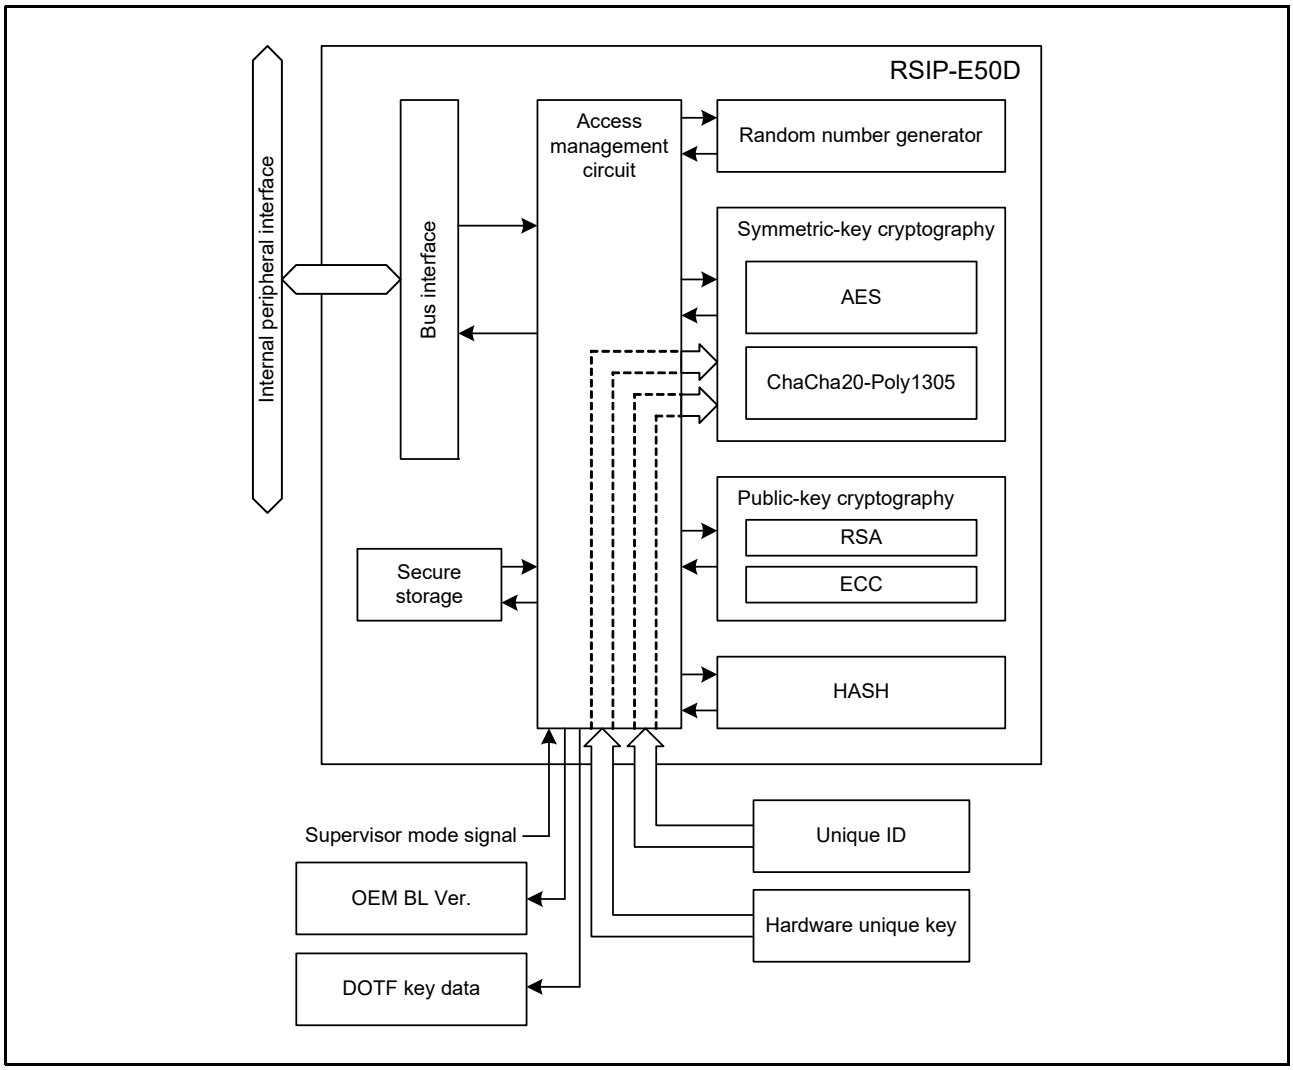

Figure 57.1 RSIP Block Diagram

57.2 Operation

57.2.1 Encryption Engine

Figure 57.2 shows processes of the encryption engine integrated in the RSIP.
The encryption engine, using the wrapped user key, performs plaintext to ciphertext encryption and ciphertext to plaintext decryption by hardware.
In no part of the encryption or decryption process, is user key or intermediate data ever exposed outside of the RSIP.

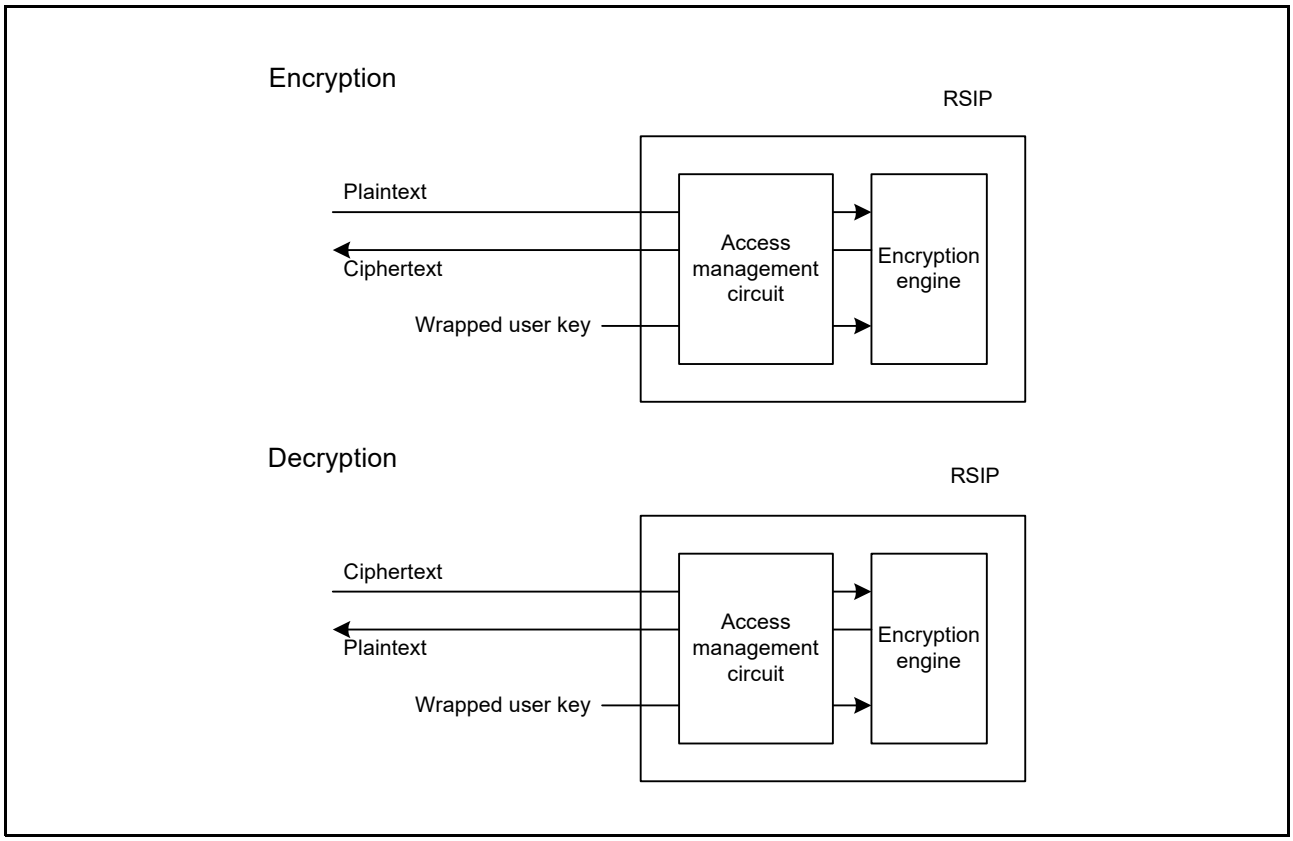

Figure 57.2 Encryption and Decryption processes by Encryption Engine

57.2.2 Encryption and Decryption

The procedures for encrypting and decrypting data are given below.

(1) Input the wrapped user key into the RSIP, and recover the user key.
(2) Input the data to encrypt or decrypt into the RSIP. This converts plaintext into ciphertext, and ciphertext into plaintext.
(3) Read the converted data.

The encryption engine has an input buffer and an output buffer, enabling encryption/decryption to proceed in parallel with data input/output.
Figure 57.3 shows the timing diagram.

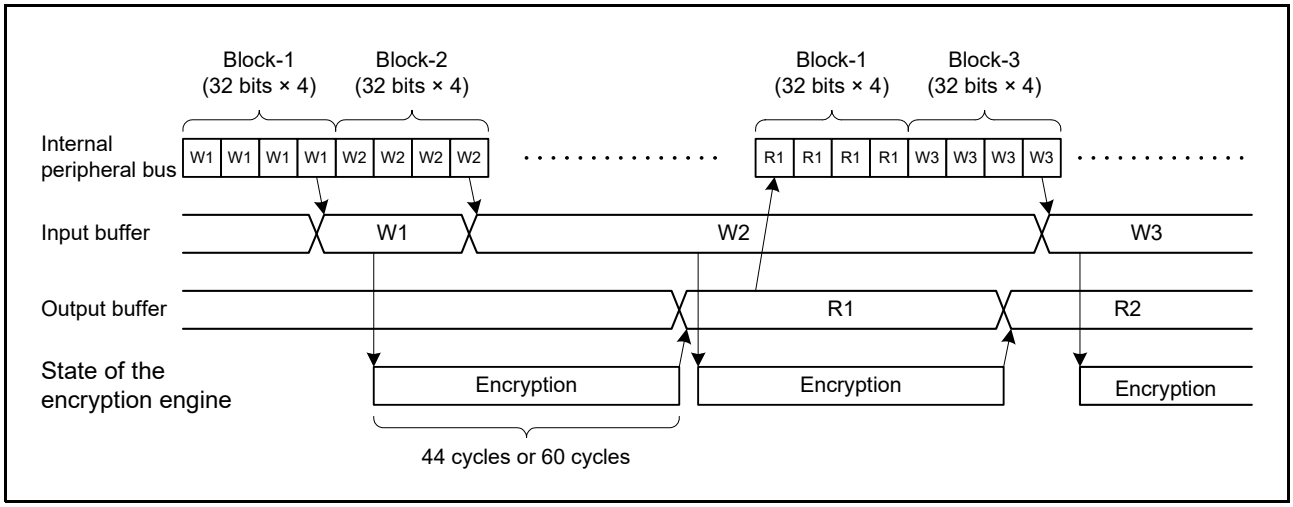

Figure 57.3 Encryption and Decryption Timing Diagram

57.3 Usage Notes

57.3.1 Standby Mode

When standby mode is entered while the encryption engine is in processing, proper processing cannot be resumed after standby mode is exited. Standby mode should therefore be entered only when the encryption engine is stopped.

57.3.2 Setting the Module Stop Function

The module stop control register C (MSTPCRC) enables or disables operation of the RSIP. After a reset, the RSIP is stopped. After exiting the module stop state, the RSIP can be accessed. Refer to section 11, Low Power Consumption for details.

57.3.3 Protection against SPA/DPA

Protection against SPA/DPA can be enabled in the encryption/decryption process.

57.3.4 RSIP Library

Use of the RSIP requires the RSIP library provided by Renesas Electronics.

58. Pulse-Density Modulation Interface (PDM-IF)

58.1 Overview

This MCU has a built-in, one-channel pulse-density modulation interface (PDM-IF). It outputs pulse-density modulation signals that can be connected to an external microphone.
The PDM-IF filters a 1-bit digital data stream with its pulse density modulated at a high sampling rate and converts it into 20-bit or 16-bit digital data at a lower sampling rate.
In this section, PCLK refers to PCLKB.
Table 58.1 lists the specifications for the PDM-IF. Figure 58.1 shows a block diagram of the PDM-IF.

Table 58.1 PDM-IF Specifications

Item	Description
Number of channels	1 channel
Clock	Core clock: PDMIFCLK Bus clock: PCLK
Functions	• Filters a 1-bit digital input data stream (PDMDAT0) and converts it into 20-bit or 16-bit digital data. The bit order is little-endian. • Supports audio active detection. • Contains programmable filters such as a 4th-order Sinc filter, high-pass filter (for DC bias suppression), compensation filter (for Sinc passband distortion), and half-band decimation filter (for aliasing distortion). – The decimation ratio is flexibly programmable. – A Sinc filter can be selected from 1st, 2nd, 3rd, and 4th order. • DMA transfer via the APB is possible. • Internal buffer – The buffer size is 32-stage. – Audio data can be stored in low power consumption mode. • Error detection function available for debugging
Interrupt sources	Three sources • Data receive interrupt • Audio detection interrupt • Error detection interrupt
Lower power consumption function	• Supports low power consumption configuration (low clock speed) of microphones. Can switch to high-speed clock after audio detection. • Bus clock can be stopped in low power consumption mode*1.
Protect Zone filter	Security attribution can be set*2.

Note 1. When performing audio detection in software standby mode, set the SYSC.MOCOSCR.MOCOSOKP bit to 1 to enable the core clock to operate even in software standby mode.
Note 2. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The PDM-IF consists of the following blocks:

- Clock control: Generates PDMCLK0 for the microphone and internal timing signals for the Sinc filter.
- Data input control: Receives data input from the microphone to the PDMDAT0 pin.
- Sinc filter: Converts a 1-bit digital data stream input from the PDMDAT0 pin into 34-bit signed data, and then clips the 34-bit signed data into 20-bit signed data.
- High-pass filter: Filter for suppressing DC bias
- Compensation filter: Filter for Sinc passband distortion
- Low-pass (half-band decimation) filter: Filter for aliasing distortion
- Moving average filter: Simple filter for reducing noise before audio detection
- Audio detection: Generates a wake-up interrupt and returns from low power consumption mode.
- Data buffer: Stores filtered 20-bit or 16-bit data.

- Short-circuit detection: Detects a short-circuit error indicating a continuous input of 0 or 1 from the PDMDAT0 pin.
- Overvoltage detection: Detects overvoltage errors.
- Error control: Generates error flags from other blocks.

The 1-bit digital data stream input from the PDMDAT0 pin is converted to 34-bit signed data by a Sinc filter and then clipped to 20-bit signed data. The 20-bit signed data is used for audio detection and data storage in the buffer.
The audio detection block receives the 20-bit signed data through a high-pass filter block and a moving average filter block. This block compares the received data with the set threshold values and generates a wake-up interrupt when the data exceeds the upper threshold or falls below the lower threshold.
The data buffer block receives 20-bit signed data through a high-pass filter, compensation filter, and low-pass filter. The block stores 20-bit signed data or clipped 16-bit signed data. Then, when an APB read access occurs, the block sends 20-bit signed data or 16-bit signed data to the APB-IF.

Table 58.2 PDM-IF I/O Pins

Pin Name	I/O	Function
PDMCLK0	Output	Clock output pin
PDMDAT0	Input	Data input pins

PDMIF	1E4h	PDDCRCH0	Data Clear Register Channel 0	W	00000000h	—	—	✓	—	—
PDMIF	1E8h	PDDRRCH0	Data Read Register Channel 0	R	00000000h	—	—	—	—	—
PDMIF	1ECh	PDDSRCH0	Data Status Register Channel 0	R	00000000h	—	—	—	—	—

Note: The 10 registers with offset addresses 000h to 080h are common registers. Common registers, excluding the Version Register, are registers used for synchronous control in multi-channel products and have mirroring registers for each channel. For more information on the mirroring registers, see section 58.2.67, Mirroring Registers.

Note 1. The base address of the PDMIF is 8785 6000h.

Note 2. For details on writing to each register, see section 58.4, Setting Flows.

58.2.2 Channel Software Start Trigger Register (PDCSTRTR)

Address(es): PDMIF.PDCSTRTR 8785 6000h, PDMIF_NS.PDCSTRTR 0785 6000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STRTRG0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STRTRG0	Channel 0 Start Trigger	0: No operation 1: Starts channel 0.	W
b31 to b1	—	Reserved	The write value should be 0.	W

This register is used to set the start trigger.

58.2.3 Channel Software Stop Trigger Register (PDCSTPTR)

Address(es): PDMIF.PDCSTPTR 8785 6004h, PDMIF_NS.PDCSTPTR 0785 6004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STPTRG0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STPTRG0	Channel 0 Stop Trigger	0: No operation 1: Stops channel 0.	W
b31 to b1	—	Reserved	The write value should be 0.	W

This register is used to set the stop trigger.

58.2.4 Channel Software Change Trigger Register (PDCCHGTR)

Address(es): PDMIF.PDCCHGTR 8785 6008h, PDMIF_NS.PDCCHGTR 0785 6008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CHGTRG0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CHGTRG0	Channel 0 Change Trigger	0: No operation 1: Changes the clock (PDMCLK0) settings.	W
b31 to b1	—	Reserved	The write value should be 0.	W

This register is used to set the change trigger for the clock (PDMCLK0) settings.

58.2.5 Channel Interrupt Control Register (PDCICR)

Address(es): PDMIF.PDCICR 8785 600Ch, PDMIF_NS.PDCICR 0785 600Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	IEDE0	—	—	—	—	—	—	—	IDRE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ISDE0	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	ISDE0	Channel 0 Audio Detection Interrupt Enable	0: Disables interrupt output. 1: Enables interrupt output.	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	IDRE0	Channel 0 Data Receive Interrupt Enable	0: Disables interrupt output. 1: Enables interrupt output.	R/W
b23 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	IEDE0	Channel 0 Error Detection Interrupt Enable	0: Disables interrupt output. 1: Enables interrupt output.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to control the interrupt outputs.

58.2.6 Channel Status Register (PDCSR)

Address(es): PDMIF.PDCSR 8785 6010h, PDMIF_NS.PDCSR 0785 6010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	EDF0	—	—	—	—	—	—	—	DRF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SDF0	—	—	—	—	—	—	—	STATE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STATE0	Channel 0 Status Flag	0: Stopped 1: Operating	R
b7 to b1	—	Reserved	These bits are read as 0.	R
b8	SDF0	Channel 0 Audio Detection Flag	0: No audio detected above the threshold 1: Audio detected above the threshold	R
b15 to b9	—	Reserved	These bits are read as 0.	R
b16	DRF0	Channel 0 Data Receive Flag	0: The amount of data stored in the buffer is less than the threshold. 1: The amount of data stored in the buffer exceeds the threshold.	R
b23 to b17	—	Reserved	These bits are read as 0.	R
b24	EDF0	Channel 0 Error Detection Flag	0: No error detected 1: Error detected	R
b31 to b25	—	Reserved	These bits are read as 0.	R

This status register indicates the channel status.

STATE0 Flag (Channel 0 Status Flag)

This flag indicates the operating status of channel 0. For details, see section 58.3.2, Channel Start and Channel Stop.

[Setting condition]

- When 1 is written to the PDCSTRTR.STRTRG0 bit

[Clearing condition]

- When 1 is written to the PDCSTPTR.STPTRG0 bit

SDF0 Flag (Channel 0 Audio Detection Flag)

This flag indicates the audio detection status of channel 0. For details, see section 58.3.5, Audio Detection.

[Setting conditions]

- When the moving average filter result is greater than or equal to the value of the PDSDUTR.SDETU[19:0] bits with PDCSDCR.SDE0 = 1
- When the moving average filter result is less than or equal to the value of the PDSDLTR.SDETL[19:0] bits with PDCSDCR.SDE0 = 1

[Clearing condition]

- When 1 is written to the PDCSCR.SDFC0 bit

DRF0 Flag (Channel 0 Data Receive Flag)

This flag indicates the data receive status of channel 0. For details, see section 58.3.6, Data Buffer.

[Setting condition]

- When the value of the PDDSRCH0.DATNUM[7:0] bits is greater than or equal to the threshold set by the PDDBCRCH0.DATRITHR[2:0] bits with PDCDRCR.DATRE0 = 1

[Clearing condition]

- When PDCDRCR.DATRE0 = 0 or the value of the PDDSRCH0.DATNUM[7:0] bits is less than the threshold

EDF0 Flag (Channel 0 Error Detection Flag)

This flag indicates the error detection status of channel 0.

[Setting condition]

- When an error has occurred For error types, see section 58.2.17, Status Register Channel 0 (PDSRCH0).

[Clearing condition]

- When all error flags are cleared by writing to the PDSCRCH0 register

58.2.7 Channel Status Clear Register (PDCSCR)

Address(es): PDMIF.PDCSCR 8785 6014h, PDMIF_NS.PDCSCR 0785 6014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SDFC0	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	The write value should be 0.	W
b8	SDFC0	Channel 0 Audio Detection Flag Clear	0: No operation 1: Clears the PDCSR.SDF0 flag.	W
b31 to b9	—	Reserved	The write value should be 0.	W

This register is used to clear the audio detection flag of channel 0.

58.2.8 Channel Audio Detection Control Register (PDCSDCR)

Address(es): PDMIF.PDCSDCR 8785 6020h, PDMIF_NS.PDCSDCR 0785 6020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SDE0	Channel 0 Audio Detection Enable	0: Disables audio detection. 1: Enables audio detection.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to control audio detection.

58.2.9 Channel Data Read Control Register (PDCDRCR)

Address(es): PDMIF.PDCDRCR 8785 6024h, PDMIF_NS.PDCDRCR 0785 6024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DATRE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DATRE0	Channel 0 Data Read Enable	0: Disables reading from the data buffer. 1: Enables reading from the data buffer.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to control the reading of data.

58.2.10 Channel Data Clear Register (PDCDCR)

Address(es): PDMIF.PDCDCR 8785 6028h, PDMIF_NS.PDCDCR 0785 6028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DATC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DATC0	Channel 0 Data Clear	0: No operation 1: Clears data.	W
b31 to b1	—	Reserved	The write value should be 0.	W

This register is used to clear the data of channel 0.

58.2.11 Version Register (PDVR)

Address(es): PDMIF.PDVR 8785 6080h, PDMIF_NS.PDVR 0785 6080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	VER[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	VER[11:0]	Version	Indicates the version of the PDM-IF.	R
b31 to b12	—	Reserved	These bits are read as 0.	R

This register indicates the IP version of the PDM-IF.

58.2.12 Software Start Trigger Register Channel 0 (PDSTRTRCH0)

Address(es): PDMIF.PDSTRTRCH0 8785 6100h, PDMIF_NS.PDSTRTRCH0 0785 6100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STRTRG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STRTRG	Start Trigger	0: No operation 1: Starts the channel.	W
b31 to b1	—	Reserved	The write value should be 0.	W

This register is a mirroring register of the PDCSTRTR register that is used to set the start trigger.
For more information on the mirroring register, see section 58.2.67, Mirroring Registers.

58.2.13 Software Stop Trigger Register Channel 0 (PDSTPTRCH0)

Address(es): PDMIF.PDSTPTRCH0 8785 6104h, PDMIF_NS.PDSTPTRCH0 0785 6104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STPTRG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STPTRG	Stop Trigger	0: No operation 1: Stops the channel.	W
b31 to b1	—	Reserved	The write value should be 0.	W

This register is a mirroring register of the PDCSTPTR register that is used to set the stop trigger.
For more information on the mirroring register, see section 58.2.67, Mirroring Registers.

58.2.14 Software Change Trigger Register Channel 0 (PDCHGTRCH0)

Address(es): PDMIF.PDCHGTRCH0 8785 6108h, PDMIF_NS.PDCHGTRCH0 0785 6108h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CHGTRG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CHGTRG	Change Trigger	0: No operation 1: Changes the clock (PDMCLK0) settings.	W
b31 to b1	—	Reserved	The write value should be 0.	W

This register is a mirroring register of the PDCCHGTR register that is used to change the clock settings.
For more information on the mirroring register, see section 58.2.67, Mirroring Registers.

58.2.15 Interrupt Control Register Channel 0 (PDICRCH0)

Address(es): PDMIF.PDICRCH0 8785 610Ch, PDMIF_NS.PDICRCH0 0785 610Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	IEDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	IDRE	ISDE	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	ISDE	Audio Detection Interrupt Enable	0: Disables interrupt output. 1: Enables interrupt output.	R/W
b2	IDRE	Data Receive Interrupt Enable	0: Disables interrupt output. 1: Enables interrupt output.	R/W
b15 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	IEDE	Error Detection Interrupt Enable	0: Disables interrupt output. 1: Enables interrupt output.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is a mirroring register of the PDCICR register that is used to control the interrupt outputs.
For more information on the mirroring register, see section 58.2.67, Mirroring Registers.

58.2.16 Status Detection Control Register Channel 0 (PDSDCRCH0)

Address(es): PDMIF.PDSDCRCH0 8785 6110h, PDMIF_NS.PDSDCRCH0 0785 6110h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	BFOWDE	—	—	—	—	—	—	—	—	OVUDE	OVLDE	SCDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDE	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	SDE	Audio Detection Enable	0: Disables audio detection. 1: Enables audio detection.	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	SCDE	Short-Circuit Detection Enable	0: Disables short-circuit detection on the PDMDAT0 pin. 1: Enables short-circuit detection on the PDMDAT0 pin.	R/W
b17	OVLDE	Overvoltage Less-Than-Lower-Limit Detection Enable	0: Disables detection of less-than-lower-limit data. 1: Enables detection of less-than-lower-limit data.	R/W
b18	OVUDE	Overvoltage Upper-Limit-Exceeded Detection Enable	0: Disables detection of data exceeding the upper limit. 1: Enables detection of data exceeding the upper limit.	R/W
b26 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27	BFOWDE	Buffer Overwrite Detection Enable	0: Disables buffer overwrite detection. 1: Enables buffer overwrite detection.	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is a mirroring register of the PDCSDCR register that is used to control the audio detection, and it is also used to control the error detection functions.
For more information on the mirroring register, see section 58.2.67, Mirroring Registers.

58.2.17 Status Register Channel 0 (PDSRCH0)

Address(es): PDMIF.PDSRCH0 8785 6114h, PDMIF_NS.PDSRCH0 0785 6114h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	BFOWDF	—	—	—	—	—	—	—	—	OVUDF	OVLDF	SCDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STATE	Status Flag	0: Stopped 1: Operating	R
b1	SDF	Audio Detection Flag	0: No audio detected above the threshold 1: Audio detected above the threshold	R
b2	DRF	Data Receive Flag	0: The amount of data stored in the buffer is less than the threshold. 1: The amount of data stored in the buffer exceeds the threshold.	R
b15 to b3	—	Reserved	These bits are read as 0.	R
b16	SCDF	Short-Circuit Detection Flag	0: No short circuit detected at the PDMDAT0 pin 1: Short circuit detected at PDMDAT0 pin	R
b17	OVLDF	Overvoltage Less-Than-Lower-Limit Detection Flag	0: Data is not less than the lower limit. 1: Data is less than the lower limit.	R
b18	OVUDF	Overvoltage Upper-Limit-Exceeded Detection Flag	0: Data is not exceeding the upper limit. 1: Data is exceeding the upper limit.	R
b26 to b19	—	Reserved	These bits are read as 0.	R
b27	BFOWDF	Buffer Overwrite Detection Flag	0: No buffer overwrites have occurred. 1: Buffer overwrite has occurred.	R
b31 to b28	—	Reserved	These bits are read as 0.	R

This register is a mirroring register of the PDCSR register that indicates the channel status.
For more information on the mirroring register, see section 58.2.67, Mirroring Registers.

STATE Flag (Status Flag)

This flag indicates the operating status. For details, see section 58.3.2, Channel Start and Channel Stop.
[Setting condition]

- When 1 is written to the PDSTRTRCH0.STRTRG bit

[Clearing condition]

- When 1 is written to the PDSTPTRCH0.STPTRG bit

SDF Flag (Audio Detection Flag)

This flag indicates the audio detection status. For details, see section 58.3.5, Audio Detection.
[Setting conditions]

- When the moving average filter result is greater than or equal to the value of the PDSDUTRCH0.SDETU[19:0] bits with PDSDCRCH0.SDE = 1
- When the moving average filter result is less than or equal to the value of the PDSDLTRCH0.SDETL[19:0] bits with PDSDCRCH0.SDE = 1

[Clearing condition]

- When 1 is written to the PDSCRCH0.SDFC bit

DRF Flag (Data Receive Flag)

This flag indicates the data receive status. For details, see section 58.3.6, Data Buffer.
[Setting condition]

- When the value of the PDDSRCH0.DATNUM[7:0] bits is greater than or equal to the threshold set by the PDDBCRCH0.DATRITHR[2:0] bits with PDDRCRCH0.DATRE = 1

[Clearing condition]

- When PDDRCRCH0.DATRE = 0 or the value of the PDDSRCH0.DATNUM[7:0] bits is less than the threshold set by the PDDBCRCH0.DATRITHR[2:0] bits

SCDF Flag (Short-Circuit Detection Flag)

This flag indicates that a short circuit has been detected at the PDMDAT0 pin. For details, see section 58.3.7, Short-Circuit Detection.
[Setting conditions]

- When the number of times that 1 is input consecutively to the PDMDAT0 pin exceeds the number set by PDSCTSRCH0.SCDH[12:0] bits with PDSDCRCH0.SCDE = 1
- When the number of times that 0 is input consecutively to the PDMDAT0 pin exceeds the number set by PDSCTSRCH0.SCDL[12:0] bits with PDSDCRCH0.SCDE = 1

[Clearing condition]

- When 1 is written to the PDSCRCH0.SCDFC bit

OVLDF Flag (Overvoltage Less-Than-Lower-Limit Detection Flag)

This flag indicates that the clipped Sinc filter result is below the lower limit for overvoltage detection. For details, see section 58.3.8, Overvoltage Detection.
[Setting condition]

- When the clipped Sinc filter result is smaller than the lower limit value (PDOVLTRCH0.OVDL[19:0]) with PDSDCRCH0.OVLDE = 1

[Clearing condition]

- When 1 is written to the PDSCRCH0.OVLDFC bit

OVUDF Flag (Overvoltage Upper-Limit-Exceeded Detection Flag)

This flag indicates that the clipped Sinc filter result exceeded the upper limit for overvoltage detection. For details, see section 58.3.8, Overvoltage Detection.
[Setting condition]

- When the clipped Sinc filter result is greater than the upper limit value (PDOVUTRCH0.OVDU[19:0]) with PDSDCRCH0.OVUDE = 1

[Clearing condition]

- When 1 is written to the PDSCRCH0.OVUDFC bit

BFOWDF Flag (Buffer Overwrite Detection Flag)

This flag indicates whether a buffer overwrite has occurred. For details, see section 58.3.6, Data Buffer.
[Setting condition]

- When data is written without reading data from the buffer when the buffer is full while PDSDCRCH0.BFOWDE = 1

[Clearing condition]

- When 1 is written to the PDSCRCH0.BFOWDFC bit

58.2.18 Status Clear Register Channel 0 (PDSCRCH0)

Address(es): PDMIF.PDSCRCH0 8785 6118h, PDMIF_NS.PDSCRCH0 0785 6118h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	The write value should be 0.	W
b1	SDFC	Audio Detection Flag Clear	0: No operation 1: Clears the PDSRCH0.SDF flag.	W
b15 to b2	—	Reserved	The write value should be 0.	W
b16	SCDFC	Short-Circuit Detection Flag Clear	0: No operation 1: Clears the PDSRCH0.SCDF flag.	W
b17	OVLDFC	Overvoltage Less-Than-Lower-Limit Detection Clear	0: No operation 1: Clears the PDSRCH0.OVLDF flag.	W
b18	OVUDFC	Overvoltage Upper-Limit-Exceeded Detection Flag Clear	0: No operation 1: Clears the PDSRCH0.OVUDF flag.	W
b26 to b19	—	Reserved	The write value should be 0.	W
b27	BFOWDFC	Buffer Overwrite Detection Flag Clear	0: No operation 1: Clears the PDSRCH0.BFOWDF flag.	W
b31 to b28	—	Reserved	The write value should be 0.	W

This register is used to clear each error detection flag of the PDSRCH0 register.
Note that the SDFC bit is a mirroring register of the PDCSCR.SDFC0 bit.
For more information on the mirroring register, see section 58.2.67, Mirroring Registers.

58.2.19 Mode Setting Register Channel 0 (PDMDSRCH0)

Address(es): PDMIF.PDMDSRCH0 8785 6120h, PDMIF_NS.PDMDSRCH0 0785 6120h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HFS[15:0]															
Value after reset:	0	0	1	1	1	1	1	1	0	1	1	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	HFS[15:0]	High-Pass Filter Coefficient s (0)	16-bit signed data (fractional bits [13:0])	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to set a high-pass filter coefficient.

58.2.22 High-Pass Filter Coefficient k (1) Register Channel 0 (PDHFCK1RCH0)

Address(es): PDMIF.PDHFCK1RCH0 8785 612Ch, PDMIF_NS.PDHFCK1RCH0 0785 612Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	HFK[15:0]															
Value after reset:	0	0	1	1	1	1	1	1	0	1	1	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	HFK[15:0]	High-Pass Filter Coefficient k (1)	16-bit signed data (fractional bits [13:0])	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to set a high-pass filter coefficient.

58.2.23 High-Pass Filter Coefficient h (0) Register Channel 0 (PDHFCH0RCH0)

Address(es): PDMIF.PDHFCH0RCH0 8785 6130h, PDMIF_NS.PDHFCH0RCH0 0785 6130h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	LFH1[12:0]												
Value after reset*1:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b12 to b0	LFH1[12:0]	Low-Pass (Half-Band Decimation) Filter Coefficient h1 (18)	13-bit signed data (fractional bits [10:0])	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Low-pass filter cut-off frequency = 7 kHz

This register is used to set a low-pass filter coefficient.

58.2.56 Low-Pass Filter Coefficient h1 (19) Register Channel 0 (PDLFCH119RCH0)

Address(es): PDMIF.PDLFCH119RCH0 8785 61B4h, PDMIF_NS.PDLFCH119RCH0 0785 61B4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	LFH1[12:0]												
Value after reset*1:	0	0	0	1	1	1	1	1	1	1	1	1	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b12 to b0	LFH1[12:0]	Low-Pass (Half-Band Decimation) Filter Coefficient h1 (19)	13-bit signed data (fractional bits [10:0])	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Low-pass filter cut-off frequency = 7 kHz

This register is used to set a low-pass filter coefficient.

58.2.57 Audio Detection Lower Threshold Register Channel 0 (PDSDLTRCH0)

Address(es): PDMIF.PDSDLTRCH0 8785 61B8h, PDMIF_NS.PDSDLTRCH0 0785 61B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	SDETL[19:16]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SDETL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b19 to b0	SDETL[19:0]	Audio Detection Lower Limit Setting	Set the lower limit for audio detection (20-bit signed data).	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to set the lower limit for audio detection.

58.2.58 Audio Detection Upper Threshold Register Channel 0 (PDSDUTRCH0)

Address(es): PDMIF.PDSDUTRCH0 8785 61BCh, PDMIF_NS.PDSDUTRCH0 0785 61BCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	SDETU[19:16]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SDETU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b19 to b0	SDETU[19:0]	Audio Detection Upper Limit Setting	Set the upper limit for audio detection (20-bit signed data).	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to set the upper limit for audio detection.

58.2.59 Data Buffer Control Register Channel 0 (PDDBCRCH0)

Address(es): PDMIF.PDDBCRCH0 8785 61C0h, PDMIF_NS.PDDBCRCH0 0785 61C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	DATRITHR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	DATRITHR[2:0]	Data Receive Interrupt Threshold Setting	b2 b0 0 0 0: Outputs an interrupt when one or more pieces of data are received. 0 0 1: Outputs an interrupt when two or more pieces of data are received. 0 1 0: Outputs an interrupt when four or more pieces of data are received. 0 1 1: Outputs an interrupt when eight or more pieces of data are received. Other than above: Outputs an interrupt when 16 or more pieces of data are received.	W
b31 to b3	—	Reserved	The write value should be 0.	W

This register is used to set the threshold for data reception interrupt output.

58.2.60 Short-Circuit Threshold Setting Register Channel 0 (PDSCTSRCH0)

Address(es): PDMIF.PDSCTSRCH0 8785 61C4h, PDMIF_NS.PDSCTSRCH0 0785 61C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	SCDH[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SCDL[12:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b12 to b0	SCDL[12:0]	Short-Circuit Detection Low Consecutive Detection Count Setting	Set the upper limit for the number of times 0 is input consecutively to the PDMDAT0 pin.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b28 to b16	SCDH[12:0]	Short-Circuit Detection High Consecutive Detection Count Setting	Set the upper limit for the number of times 1 is input consecutively to the PDMDAT0 pin.	R/W
b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to set the thresholds for the number of consecutive lows/highs for short-circuit detection.

58.2.61 Overvoltage Lower Threshold Register Channel 0 (PDOVLTRCH0)

Address(es): PDMIF.PDOVLTRCH0 8785 61C8h, PDMIF_NS.PDOVLTRCH0 0785 61C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	OVDL[19:16]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVDL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b19 to b0	OVDL[19:0]	Overvoltage Detection Lower Limit Setting	Set the lower limit of the effective voltage for overvoltage detection (20-bit signed data).	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to set the lower limit of the effective voltage for overvoltage detection.

58.2.62 Overvoltage Upper Threshold Register Channel 0 (PDOVUTRCH0)

Address(es): PDMIF.PDOVUTRCH0 8785 61CCh, PDMIF_NS.PDOVUTRCH0 0785 61CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	OVDU[19:16]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVDU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b19 to b0	OVDU[19:0]	Overvoltage Detection Upper Limit Setting	Set the upper limit of the effective voltage for overvoltage detection (20-bit signed data).	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to set the upper limit of the effective voltage for overvoltage detection.

58.2.63 Data Read Control Register Channel 0 (PDDRCRCH0)

Address(es): PDMIF.PDDRCRCH0 8785 61E0h, PDMIF_NS.PDDRCRCH0 0785 61E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DATRE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DATRE	Data Read Enable	0: Disables reading from the data buffer. 1: Enables reading from the data buffer.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is a mirroring register of the PDCDRCR register that is used to control data read.
For more information on the mirroring register, see section 58.2.67, Mirroring Registers.

58.2.64 Data Clear Register Channel 0 (PDDCRCH0)

Address(es): PDMIF.PDDCRCH0 8785 61E4h, PDMIF_NS.PDDCRCH0 0785 61E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DATC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DATC	Data Clear	0: No operation 1: Clears data.	W
b31 to b1	—	Reserved	The write value should be 0.	W

This register is a mirroring register of the PDCDCR register that is used to clear data.
For more information on the mirroring register, see section 58.2.67, Mirroring Registers.

58.2.65 Data Read Register Channel 0 (PDDRRCH0)

Address(es): PDMIF.PDDRRCH0 8785 61E8h, PDMIF_NS.PDDRRCH0 0785 61E8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	DAT[19:16]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DAT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b19 to b0	DAT[19:0]	Data	20-bit or 16-bit signed audio data is read. In 20-bit mode (PDMDSRCH0.DBIS[3:0] = 0xxxb), the sign bit is [19]. In 16-bit mode (PDMDSRCH0.DBIS[3:0] = 1xxxb), the sign bits are [19:15].	R
b31 to b20	—	Reserved	These bits are read as 0.	R

This register is used to read audio data.

58.2.66 Data Status Register Channel 0 (PDDSRCH0)

Address(es): PDMIF.PDDSRCH0 8785 61ECh, PDMIF_NS.PDDSRCH0 0785 61ECh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	DATNUM[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	DATNUM[7:0]	Number of Data Stored in Buffer	When PDDRCRCH0.DATRE = 0, 0 is read. When PDDRCRCH0.DATRE = 1, the number of data stored in the buffer is read. The maximum value is 31.	R
b31 to b8	—	Reserved	These bits are read as 0.	R

This register is used to read the number of data stored in the buffer.

58.2.67 Mirroring Registers

Common registers, excluding the Version Register, have mirroring registers for each channel.
The PDCSR.EDF0 flag is set by ORing all error flags in the mirroring registers of each channel.
Common registers are used for synchronous control of multiple-channel products. For single-channel products, use either common registers or channel-specific mirroring registers.
Table 58.4 shows the common registers and corresponding mirroring registers.

Table 58.4 Mirroring Registers

Common Register		Mirroring Register of Each Channel	
Register Name	**Bit Name**	**Register Name**	**Bit Name**
PDCSTRTR	STRTRG0	PDSTRTRCH0	STRTRG
PDCSTPTR	STPTRG0	PDSTPTRCH0	STPTRG
PDCCHGTR	CHGTRG0	PDCHGTRCH0	CHGTRG
PDCICR	ISDE0	PDICRCH0	ISDE
	IDRE0		IDRE
	IEDE0		IEDE
PDCSR	STATE0	PDSRCH0	STATE
	SDF0		SDF
	DRF0		DRF
PDCSCR	SDFC0	PDSCRCH0	SDFC
PDCSDCR	SDE0	PDSDCRCH0	SDE
PDCDRCR	DATRE0	PDDRCRCH0	DATRE
PDCDCR	DATC0	PDDCRCH0	DARC

58.3 Operation

58.3.1 Clock Specifications

The core clock is divided and output to PDMCLK0.
Table 58.5 shows the clock frequencies and clock modes guaranteed by the PDM-IF. Note that PDMIFCLK and PCLK are asynchronous.

Table 58.5 Guaranteed Clock Frequencies and Clock Modes

PDMIFCLK Frequency (MHz)	PCLK Frequency (MHz)	PDMCLK0 Frequency (MHz)	Supported Core Clock Division Ratio	PDSFCRCH0.CKDIV[3:0] Setting
8	1 to 75*1	4	2	0000
		2	4	0001
		1.33	6	0010
		1	8	0011
		0.8	10	0100
		0.67	12	0101
		0.57	14	0110
		0.5	16	0111
		0.44	18	1000
		0.4	20	1001
		0.36	22	1010
		0.33	24	1011
		0.31	26	1100
		0.29	28	1101
		0.27	30	1110
		0.25	32	1111

Note 1. Although the PDM-IF can operate at frequencies below 1 MHz, the guaranteed frequency range is 1 to 75 MHz.

58.3.1.1 Output Sampling Frequency

PDM-IF output sampling frequency is shown by the following formula:
$F_{out} = F_{clk} / (M \times 2)$

- F_{out}: PDM-IF output sampling frequency
- F_{clk}: PDMCLK0 frequency
- M: Sinc filter decimation ratio (PDSFCRCH0.SINCDEC[7:0] + 1)

58.3.2 Channel Start and Channel Stop

The channel start and channel stop are controlled by the registers shown in Table 58.6. When synchronizing multiple channels, use common registers to simultaneously set the bits of the target channels to 1.
Set channel start according to section 58.4.1, Start Flow and channel stop according to section 58.4.2, Stop Flow.

Table 58.6 Channel Start Trigger and Channel Stop Trigger

	Register and Bit Name	
Channel Control	**Common Register**	**Channel Register**
Channel start	PDCSTRTR.STRTRG0	PDSTRTRCH0.STRTRG
Channel stop	PDCSTPTR.STPTRG0	PDSTPTRCH0.STPTRG

58.3.3 Changing the PDMCLK0 Frequency

The external microphone switches the power mode according to the input clock frequency. The PDM-IF enables transition of the microphone's power mode by changing the operating frequency of the PDMCLK0 clock output to the microphone during operation. The operating frequency of PDMCLK0 can be changed with the PDSFCRCH0.CKDIV[3:0] bits. When the frequency is changed, the decimation ratio of the Sinc filter must also be changed. Set the PDSFCRCH0.SINCDEC[7:0] bits so that the sampling frequency after decimation is 32 kHz*1. In addition, changing the decimation ratio changes the output range of the Sinc filter. Also change the PDSFCRCH0.SINCRNG[4:0] bits according to the output range. For details, see section Table 58.7, Clipping the Sinc Filter Output.
After changing these register settings, the PDF-IF must wait for the settling time of the microphone and PDM-IF channels. For details, see sections section 58.4.4, Low Power Consumption Mode Transition Flow and section 58.4.5, Normal Mode Transition Flow.

Note 1. If the sampling frequency differs from 32 kHz, the filter characteristics after the Sinc filter may change.

58.3.4 Filters

58.3.4.1 Data Clipping and Shifting Among Filters

Audio sample data is clipped or shifted among filters.

Figure 58.2 shows how data is clipped and shifted among filters.

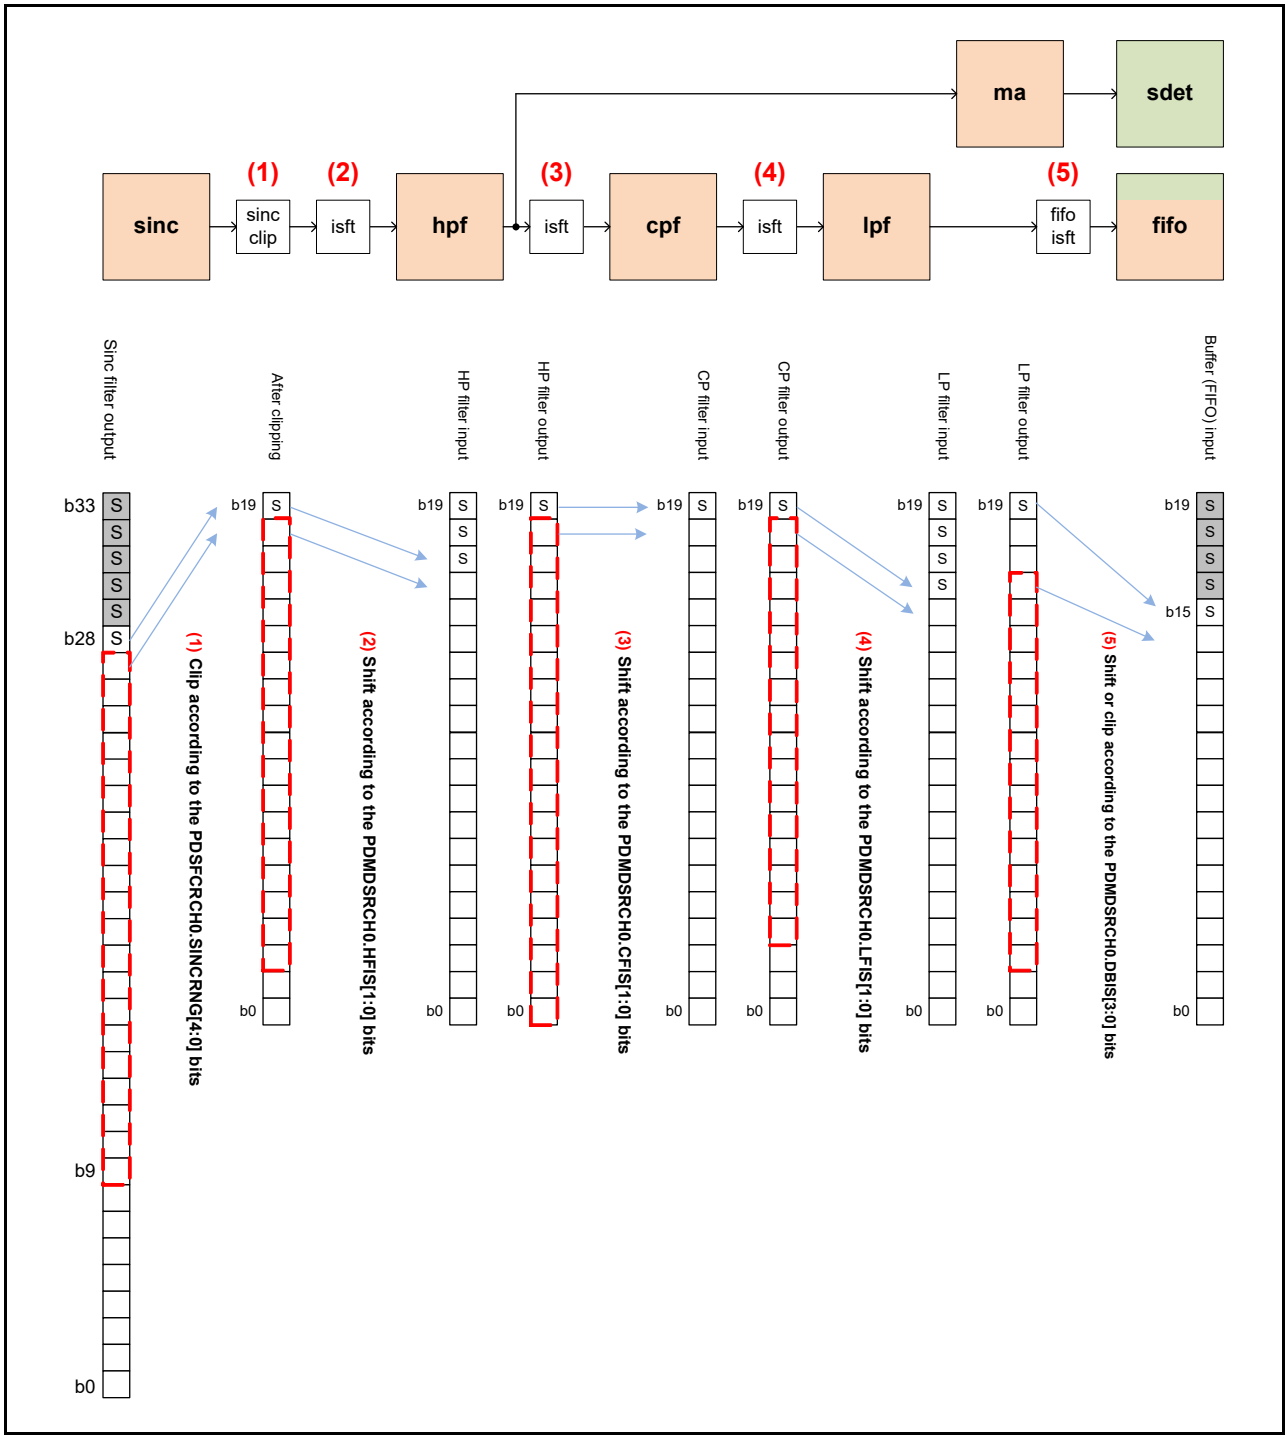

Figure 58.2 Data Clipping and Shifting Among Filters

(1) Clipping the Sinc filter output

Table 58.7 shows the available settings for the Sinc filter and data clipping. These settings are controlled by the PDSFCRCH0.SINCRNG[4:0] bits.

Table 58.7 Clipping the Sinc Filter Output (1/2)

PDMIFCLK (MHz)	Sinc Filter Order	PDMDSRCH0.SFMD[2:0]	PDMCLK Division Ratio	PDSFCRCH0.CKDIV[3:0]	Sinc Filter Decimation Ratio	PDSFCRCH0.SINCDEC[7:0]	Sinc Filter Output Effective Bits	Sinc Filter Output Clipping (20 Bits)	PDSFCRCH0.SINCRNG[4:0]	Resolution	PDMCLK0 Frequency (MHz)	Sinc Filter Output Sampling Frequency (kHz)	PDM-IF Output Sampling Frequency (kHz)

			24	1011	10	09h	b4 to b0	b4 to b0, 000000000000000	11101	5	0.33	33.33	16.67
			26	1100	9	08h	b4 to b0	b4 to b0, 000000000000000	11101	5	0.31	34.19	17.09
			28	1101	9	08h	b4 to b0	b4 to b0, 000000000000000	11101	5	0.29	31.75	15.87
			30	1110	8	07h	b4 to b0	b4 to b0, 000000000000000	11101	5	0.27	33.33	16.67
			32	1111	8	07h	b4 to b0	b4 to b0, 000000000000000	11101	5	0.25	31.25	15.63

When the PDMDSRCH0.SFMD[2:0], PDSFCRCH0.CKDIV[3:0], PDSFCRCH0.SINCDEC[7:0], and PDSFCRCH0.SINCRNG[4:0] bits are set in the combinations shown in Table 58.7, no overflows or underflows will occur. However, if other combinations are set, an overflow or underflow may occur. When an overflow occurs, 7FFFFh is output. When an underflow occurs, 80000h is output. To check whether an overflow or underflow has occurred, use the overvoltage detection function.

(2) Shifting the high-pass filter input

The clipped output of the Sinc filter is shifted to the right and fed into a high-pass filter.
The high-pass filter input shift is controlled by the PDMDSRCH0.HFIS[1:0] bits.

Table 58.8 Shifting the High-Pass Filter Input

PDMDSRCH0.HFIS[1:0]	Function	Shifted Data*1
00	No shift	S, b18 to b0
01	Right-shifted by 1 bit	S, S, b18 to b1
10	Right-shifted by 2 bits	S, S, S, b18 to b2
11	Right-shifted by 3 bits	S, S, S, S, b18 to b3

Note 1. S: Signed bit (b19)

(3) Shifting the compensation filter input

The output of the high-pass filter is shifted to the right and input to a compensation filter.
The compensation filter input shift is controlled by the PDMDSRCH0.CFIS[1:0] bits.

Table 58.9 Shifting the Compensation Filter Input

PDMDSRCH0.CFIS[1:0]	Function	Shifted Data*1
00	No shift	S, b18 to b0
01	Right-shifted by 1 bit	S, S, b18 to b1
10	Right-shifted by 2 bits	S, S, S, b18 to b2
11	Right-shifted by 3 bits	S, S, S, S, b18 to b3

Note 1. S: Signed bit (b19)

(4) Shifting the low-pass filter input

The output of the compensation filter is shifted to the right and input to a low-pass (half-band decimation) filter.
The low-pass (half-band decimation) filter input shift is controlled by the PDMDSRCH0.LFIS[1:0] bits.

Table 58.10 Shifting the Low-Pass Filter Input

PDMDSRCH0.LFIS[1:0]	Function	Shifted Data*1
00	No shift	S, b18 to b0
01	Right-shifted by 1 bit	S, S, b18 to b1
10	Right-shifted by 2 bits	S, S, S, b18 to b2
11	Right-shifted by 3 bits	S, S, S, S, b18 to b3

Note 1. S: Signed bit (b19)

(5) Shifting or clipping buffer input

The compensation filter output is shifted to the right or clipped by 16 bits. After that, the shifted or clipped data is input to a buffer.
The buffer input shift is controlled by the PDMDSRCH0.DBIS[3:0] bits.

Table 58.11 Shifting or Clipping Buffer Input

PDMDSRCH0.DBIS[3:0]	Function	Effective Data Width	Shifted or Clipped Data*1
0000	No shift	20 bits	S, b18 to b0
0001	Right-shifted by 1 bit	20 bits	S, S, b18 to b1
0010	Right-shifted by 2 bits	20 bits	S, S, S, b18 to b2
0011	Right-shifted by 3 bits	20 bits	S, S, S, S, b18 to b3
1000	Signed bit and bits 18 to 4 are clipped.	16 bits	S, b18 to b4
1001	Signed bit and bits 17 to 3 are clipped.*2	16 bits	S, b17 to b3
1010	Signed bit and bits 16 to 2 are clipped.*2	16 bits	S, b16 to b2
1011	Signed bit and bits 15 to 1 are clipped.*2	16 bits	S, b15 to b1
1100	Signed bit and bits 14 to 0 are clipped.*2	16 bits	S, b14 to b0

Note 1. S: Signed bit (bit 19)
Note 2. When an overflow occurs, 7FFFh is input to the buffer, When an underflow occurs, 8000h is input to the buffer.

58.3.4.2 Sinc Filter

The operating clock for the Sinc filter is PDMIFCLK. The Sinc filter operates using 1-bit stream data latched at the rising or falling edge of PDMCLK0. Figure 58.3 shows the timing and configuration of data input control.

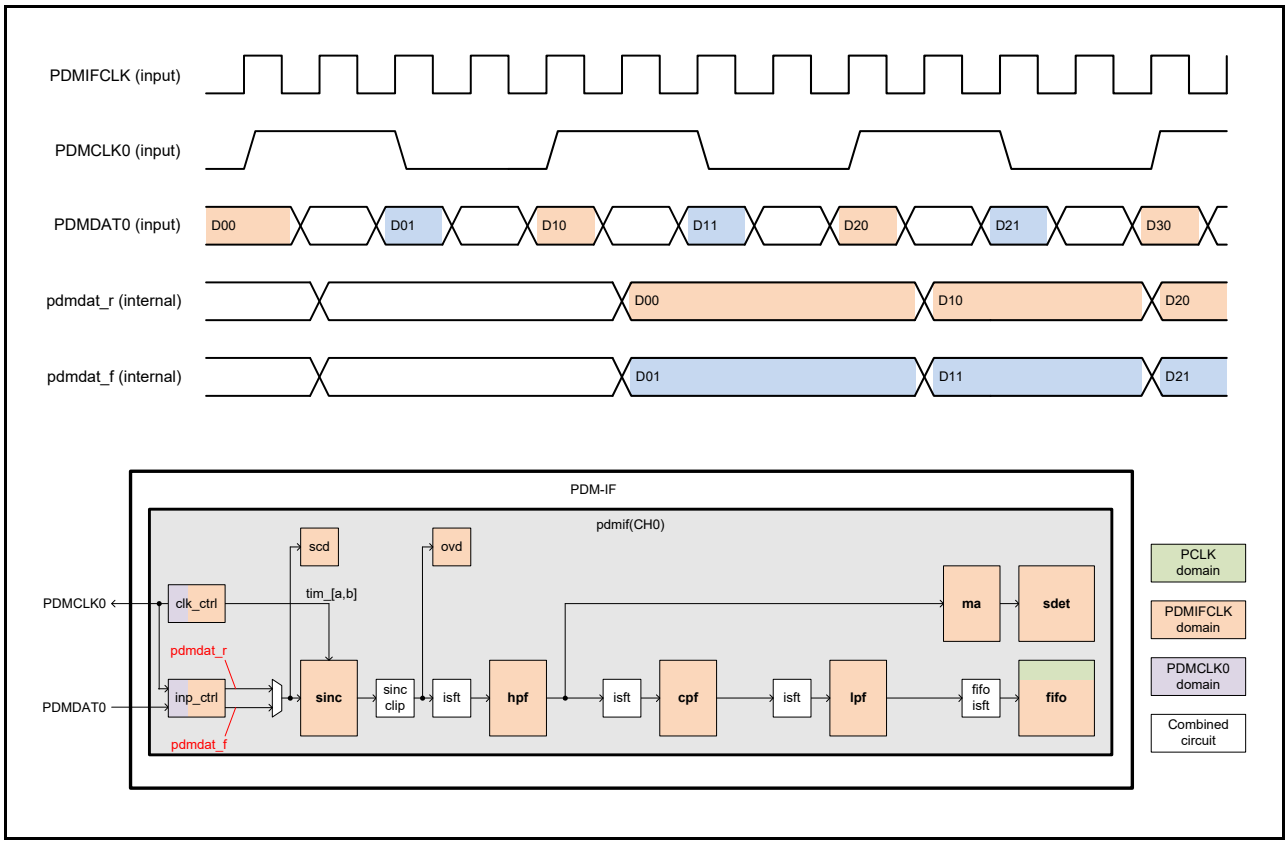

Figure 58.3 Data Input Control

Figure 58.4 shows a block diagram of the Sinc filter.

The differentiation stage operates using a decimation clock (frequency is 1/M of PDMCLK0). M is the decimation ratio and is set by the PDSFCRCH0.SINCDEC[7:0] bits. The filter results are output to the register for each decimation clock.

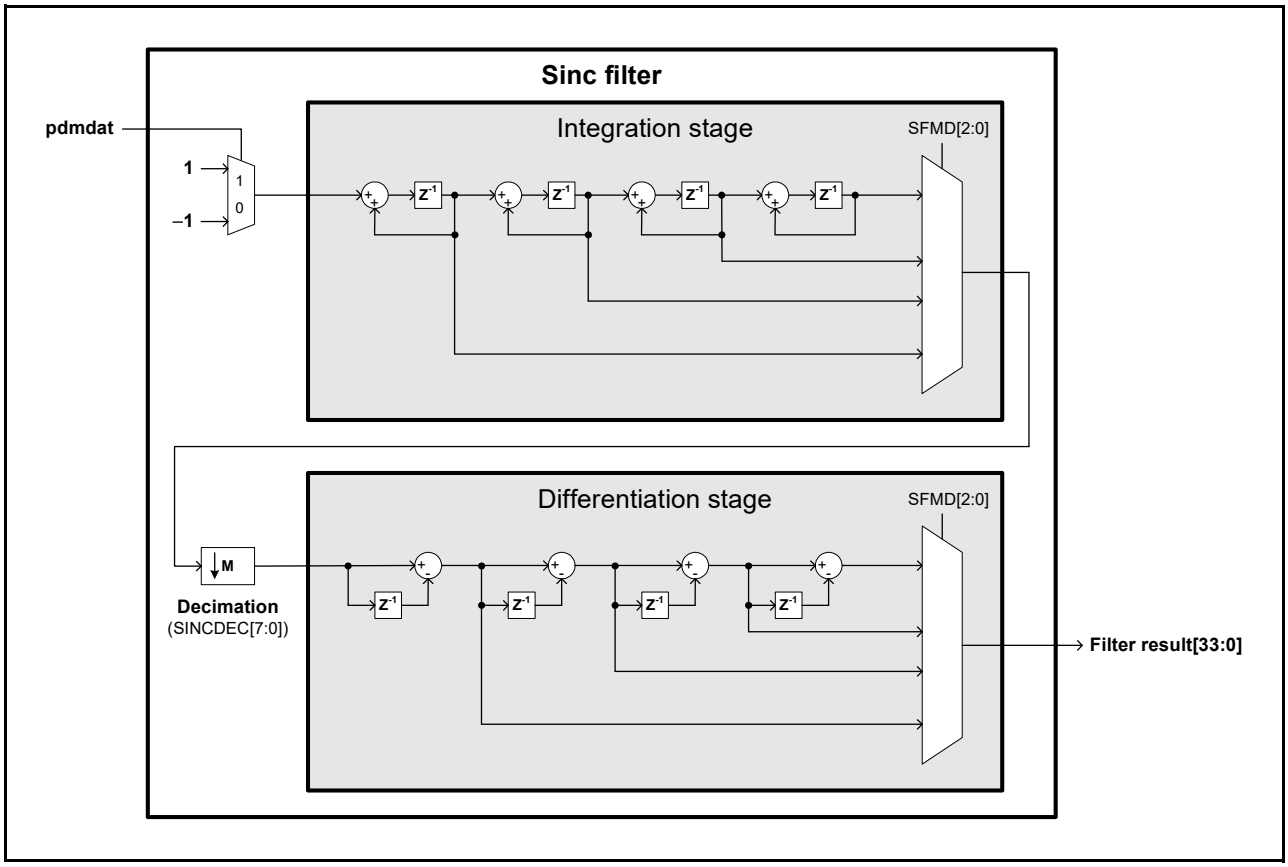

Figure 58.4 Sinc Filter Block Diagram

58.3.4.3 High-Pass Filter

The operating clock for the high-pass filter is PDMIFCLK. The high-pass filter operates using the results of the Sinc filter.

Figure 58.5 shows a block diagram of the high-pass filter, and Table 58.12 lists the specifications for the high-pass filter.

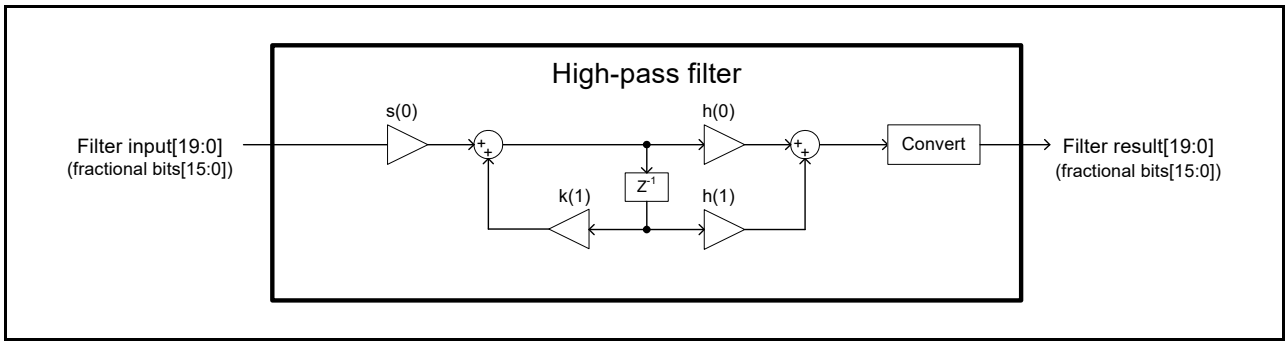

Figure 58.5 High-Pass Filter Block Diagram

Table 58.12 High-Pass Filter Specifications

Function		Specification
Input	Bit width	Signed 20 bits (16 fractional bits)
Output	Bit width	Signed 20 bits (16 fractional bits)
Coefficient	Bit width	Signed 16 bits (14 fractional bits) For details, see the following sections: • section 58.2.21, High-Pass Filter Coefficient s (0) Register Channel 0 (PDHFCS0RCH0) • section 58.2.22, High-Pass Filter Coefficient k (1) Register Channel 0 (PDHFCK1RCH0) • section 58.2.23, High-Pass Filter Coefficient h (0) Register Channel 0 (PDHFCH0RCH0)
Delay Z	Bit width	Signed 32 bits (18 fractional bits)
Multiplier	Bit width of input A	Signed 32 bits (18 fractional bits)
	Bit width of input B	Signed 16 bits (14 fractional bits)
	Output bit width	Signed 47 bits (32 fractional bits)
Adder	Bit width of input A	Signed 32 bits (18 fractional bits)
	Bit width of input B	Signed 32 bits (18 fractional bits)
	Output bit width	Signed 33 bits (18 fractional bits)
Output conversion	Input bit width	Signed 32 bits (18 fractional bits)
	Output bit width	Signed 20 bits (16 fractional bits)
Excessive fractional bit processing		Excessive fractional bits are truncated at the function unit input or final output.

58.3.4.4 Compensation Filter

The operating clock for the compensation filter is PDMIFCLK. The compensation filter operates using the results of the high-pass filter.

Figure 58.6 shows a block diagram of the compensation filter, and Table 58.13 lists the specifications for the compensation filter.

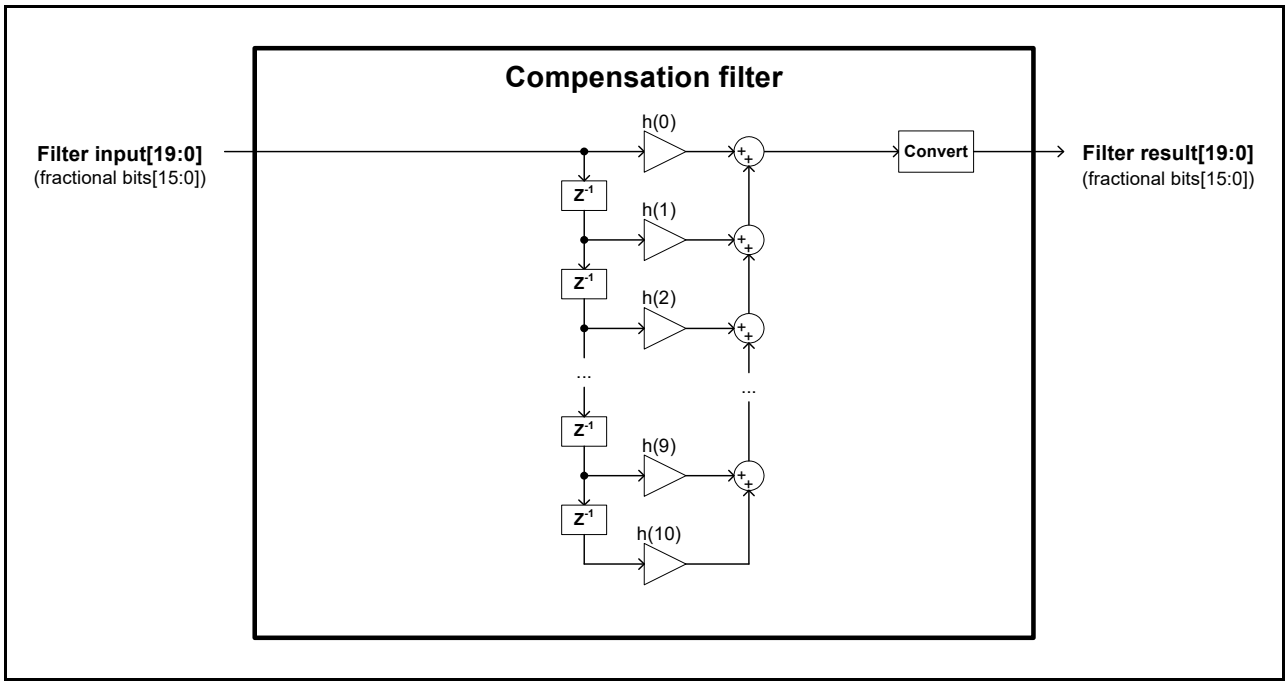

Figure 58.6 Compensation Filter Block Diagram

Table 58.13 Compensation Filter Specifications

Function		Specification
Input	Bit width	Signed 20 bits (16 fractional bits)
Output	Bit width	Signed 20 bits (16 fractional bits)
Coefficient	Bit width	Signed 13 bits (11 fractional bits) For details, see the following sections: • section 58.2.25, Compensation Filter Coefficient h (0) Register Channel 0 (PDCFCH00RCH0)
Delay Z	Bit width	Signed 20 bits (16 fractional bits)
Multiplier	Bit width of input A	Signed 20 bits (16 fractional bits)
	Bit width of input B	Signed 13 bits (11 fractional bits)
	Output bit width	Signed 32 bits (27 fractional bits)
Adder	Bit width of input A	Signed 22 bits (18 fractional bits)
	Bit width of input B	Signed 22 bits (18 fractional bits)
	Output bit width	Signed 23 bits (18 fractional bits)
Output conversion	Input bit width	Signed 22 bits (18 fractional bits)
	Output bit width	Signed 20 bits (16 fractional bits)
Excessive fractional bit processing		Excessive fractional bits are truncated at the function unit input or final output.

58.3.4.5 Low-Pass (Half-Band Decimation) Filter

The operating clock for the low-pass (half-band decimation) filter is PDMIFCLK. The low-pass filter operates using the results of the compensation filter. The output data is decimated to half of the input data. As a result, the output data frequency is reduced to half the input frequency, and the output data frequency becomes equal to the sampling rate of the data stored in the FIFO.

Figure 58.7 shows a block diagram of the low-pass filter, and Table 58.14 lists the specifications for the low-pass filter.

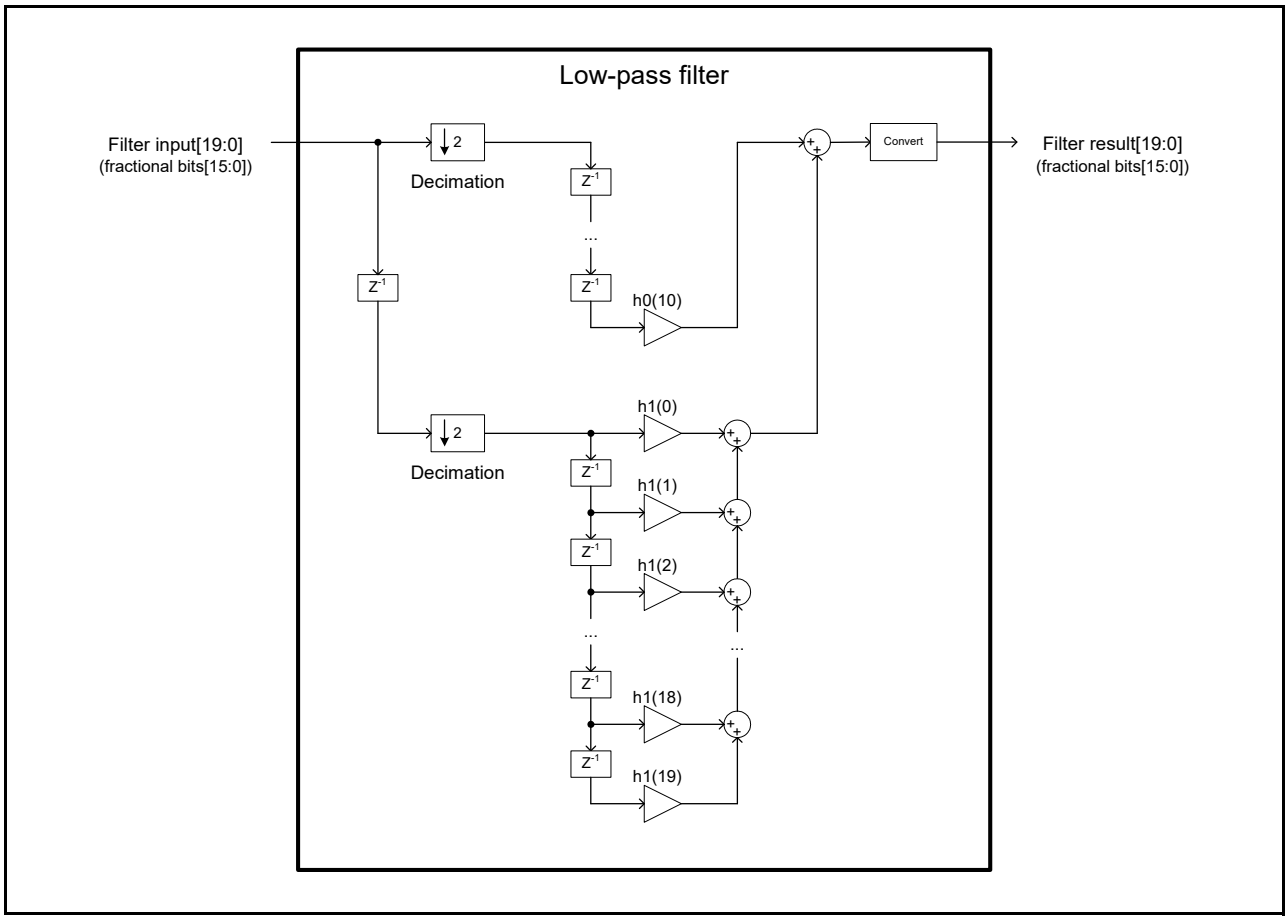

Figure 58.7 Low-Pass Filter Block Diagram

Table 58.14 Low-Pass Filter Specifications

Function		Specification
Input	Bit width	Signed 20 bits (16 fractional bits)
Output	Bit width	Signed 20 bits (16 fractional bits)
Coefficient	Bit width	Signed 13 bits (11 fractional bits) For details, see the following sections: • section 58.2.36, Low-Pass Filter Coefficient h0 (10) Register Channel 0 (PDLFCH010RCH0) • section 58.2.37, Low-Pass Filter Coefficient h1 (0) Register Channel 0 (PDLFCH100RCH0)
Delay Z	Bit width	Signed 20 bits (16 fractional bits)
Multiplier	Bit width of input A	Signed 20 bits (16 fractional bits)
	Bit width of input B	Signed 13 bits (11 fractional bits)
	Output bit width	Signed 32 bits (27 fractional bits)
Adder	Bit width of input A	Signed 22 bits (18 fractional bits)
	Bit width of input B	Signed 22 bits (18 fractional bits)
	Output bit width	Signed 23 bits (18 fractional bits)
Output conversion	Input bit width	Signed 22 bits (18 fractional bits)
	Output bit width	Signed 20 bits (16 fractional bits)
Excessive fractional bit processing		Excessive fractional bits are truncated at the function unit input or final output.

58.3.4.6 Moving Average Filter

The operating clock for the moving average filter is PDMIFCLK. The moving average filter operates using the results of the high-pass filter.

The order of the moving average filter can be changed by setting the PDMDSRCH0.SDMAMD[1:0] bits.

Figure 58.8 shows a block diagram of the moving average filter, and Table 58.15 lists the specifications for the moving average filter.

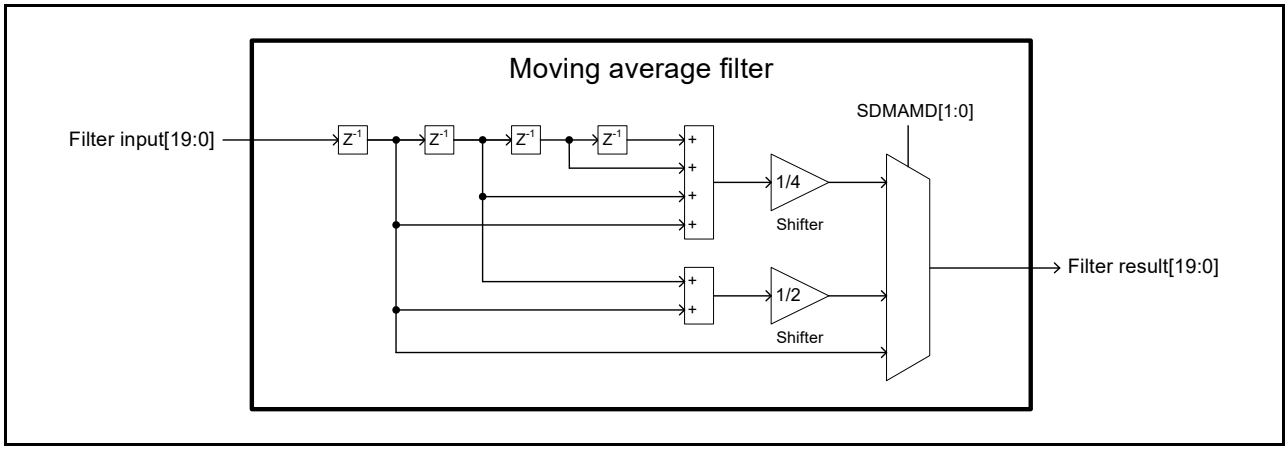

Figure 58.8 Moving Average Filter Block Diagram

Table 58.15 Moving Average Filter Specifications

Function		Specification
Input	Bit width	Signed 20 bits (16 fractional bits)
Output	Bit width	Signed 20 bits (16 fractional bits)
Delay Z	Bit width	Signed 20 bits (16 fractional bits)
Excessive fractional bit processing		Excessive fractional bits are truncated by a shifter.

58.3.4.7 Settling Times of Channel Start and Setting Change

The channel start settling time is the time from when the start trigger PDCSTRTR.STRTRG0 (or PDSTRTRCH0.STRTRG) bit is set until the filter results are output stably. The settling time for channel setting changes is the time from when the change trigger PDCCHGTR.CHGTRG0 (or PDCHGTRCH0.CHGTRG) bit is set until the filter results are output stably.

Figure 58.9 shows the measurement points for settling time, and Table 58.16 shows the settling time for channel start/setting changes.

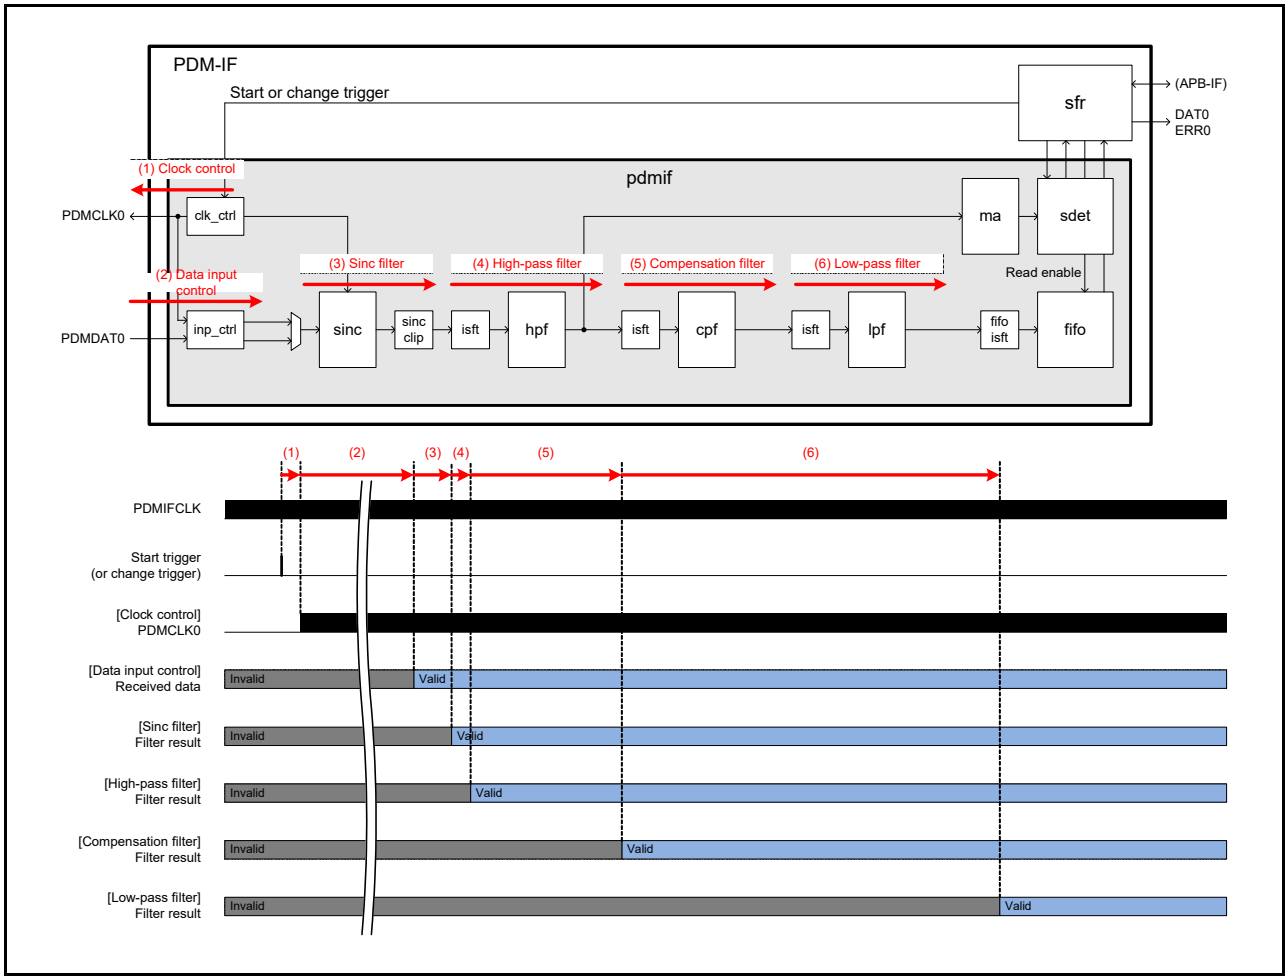

Figure 58.9 Channel Start Settling Time

Table 58.16 Channel Start and Setting Change Settling Times

No.	Function	Settling Time	
		Channel Start	Channel Setting Change
(1)	Clock control	(4 + (D / 2)) × Cp	(3 + Do + (D / 2)) × Cp
(2)	Data input control	(D /2) × Cp + (Microphone stabilization time*1)	
(3)	Sinc filter	(K × D × M) × Cp	
(4)	High-pass filter	(D × M + 5) × Cp	
(5)	Compensation filter	(10× D × M + 12) × Cp	
(6)	Low-pass filter	(38× D × M + 22) × Cp	

Note 1. Wake-up time from low power consumption mode, switching time, etc. For details, see the Data Sheet for the microphone.
Cp: PDMIFCLK period
D: PDMCLK0 division ratio
Do: PDMCLK0 division ratio (previous setting)
K: Sinc filter order
M: Decimation ratio of Sinc filter

58.3.5 Audio Detection

The operating clock for the audio detection function is PDMIFCLK. When the PDSDCRCH0.SDE bit is set to 1, audio detection is determined using the result of the moving average filter. When the result exceeds the upper limit (PDSDUTRCH0.SDETU[19:0]) or falls below the lower limit (PDSDLTRCH0.SDETL[19:0]), the audio detection flag (PDSRCH0.SDF) is set to 1. The audio detection flag is cleared to 0 by writing 1 to the PDSCRCH0.SDFC bit.
Figure 58.10 shows a block diagram of the audio detection function.

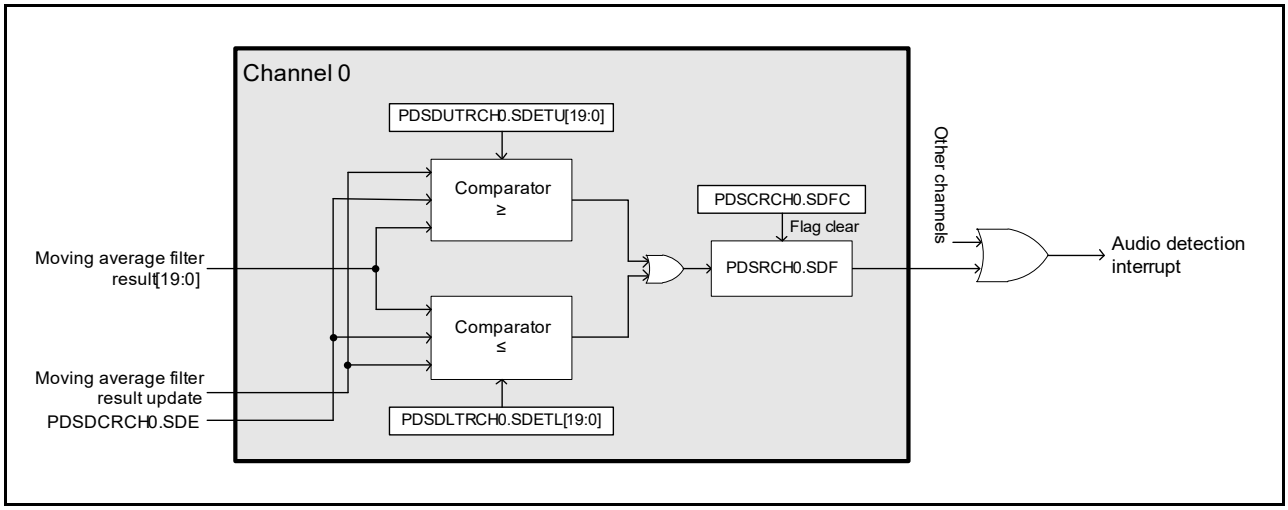

Figure 58.10 Audio Detection Function Block Diagram

58.3.6 Data Buffer

The data buffer writes audio data to the FIFO in synchronization with PDMIFCLK and reads audio data from the FIFO in synchronization with PCLK. The data buffer stores audio data in the FIFO until it is read out.

While the PDDSRCH0.DATRE bit is 0, the PDDSRCH0.DATNUM[7:0] bits indicate 0, and the PDM-IF does not allow reading of audio data. When the DATRE bit is changed to 1, the DATNUM[7:0] bits indicate the value of “buffer size - 2”, and the PDM-IF allows reading of audio data. While the DATRE bit is 1, the data buffer increments the DATNUM[7:0] bits when data is written and decrements the DATNUM[7:0] bits when data is read.

If the DATNUM[7:0] bits are set to a value greater than or equal to the threshold set by the PDDBCRCH0.DATRITHR[2:0] bits, the PDSRCH0.DRF flag is set to 1. When the value of the DATNUM[7:0] bits falls below the threshold due to data readout, the DRF flag is cleared to 0. When the value of the DATNUM[7:0] bits is set to “buffer size - 2” and data is written to the data buffer without being read, the oldest data is overwritten with the new data, and the buffer overwrite detection flag (PDSRCH0.BFOWDF) is set to 1. After overwriting, the value of the DATNUM[7:0] bits is reset to the value of “buffer size - 2”. However, the data buffer will be overwritten until the first data is read after the DATRE bit changes from 0 to 1, but the BFOWDF flag will not be set to 1.

Figure 58.11 shows a block diagram of the data buffer function.

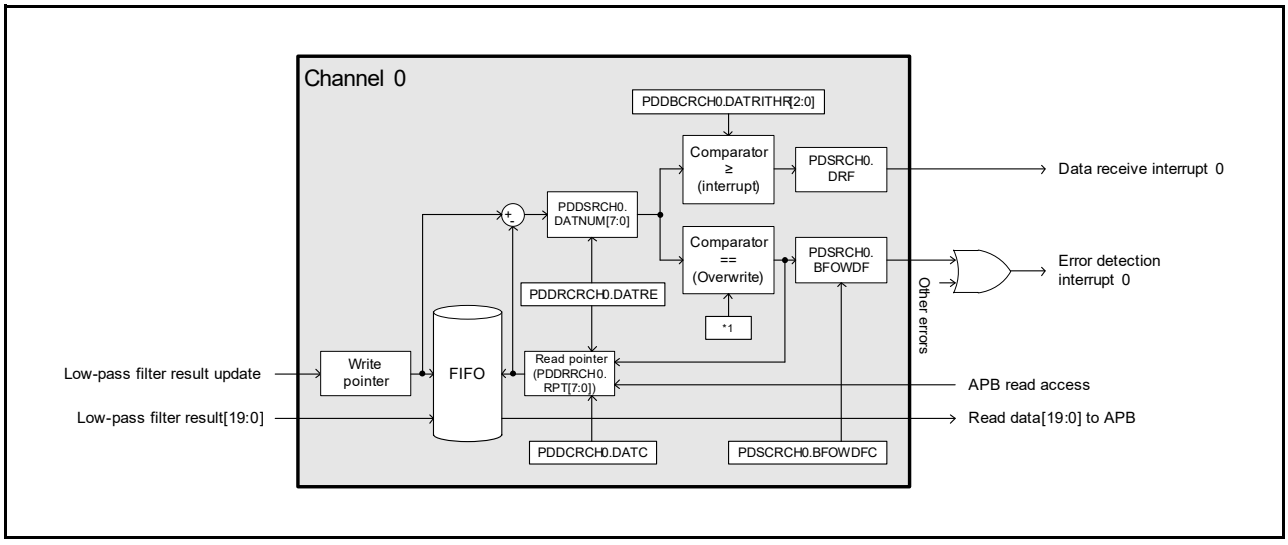

Figure 58.11 Data Buffer Function Block Diagram

58.3.7 Short-Circuit Detection

Short-circuit detection is enabled when the short-circuit detection enable bit (PDSDCRCH0.SCDE) is set to 1.
A dedicated 13-bit counter counts the consecutive 0s or 1s from pdmdat output by the data input control block of channel 0.
When the number of consecutive 0s exceeds the value set in the PDSCTSRCH0.SCDL[12:0] bits, or the number of consecutive 1s exceeds the value set in the PDSCTSRCH0.SCDH[12:0] bits, a short-circuit detection interrupt request is generated.
Figure 58.12 shows a block diagram of the short-circuit detection function.

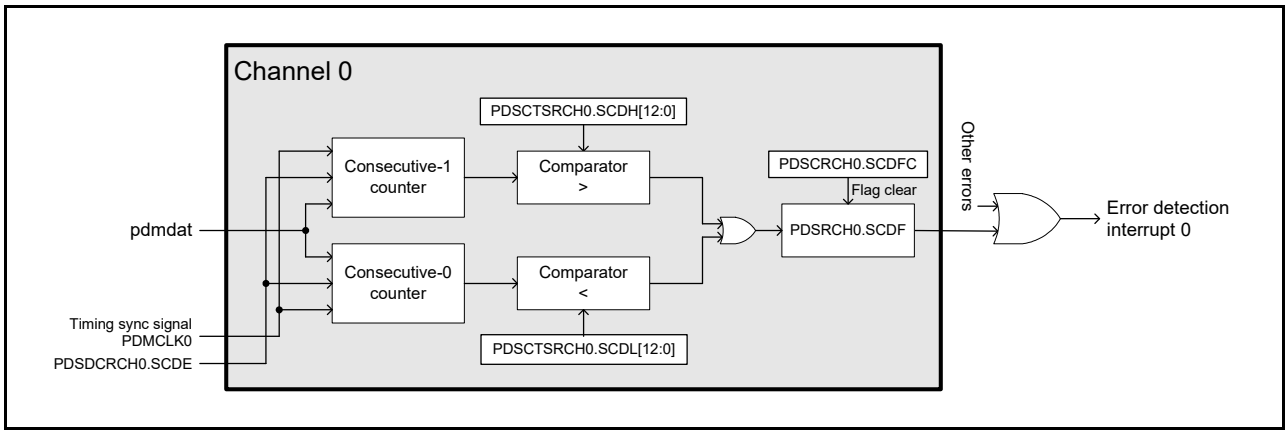

Figure 58.12 Short-Circuit Detection Function Block Diagram

58.3.8 Overvoltage Detection

When the overvoltage upper-limit-exceeded detection enable bit (PDSDCRCH0.OVUDE) is set to 1, overvoltage upper-limit-exceeded detection operates. In addition, when the overvoltage less-than-lower-limit detection enable bit (PDSDCRCH0.OVLDE) is set to 1, overvoltage less-than-lower-limit detection operates.
The audio data is clipped to 20 bits from the 34-bit data output from the Sinc filter by setting the PDSFCRCH0.SINCRNG[4:0] bits. For details, see section Table 58.7, Clipping the Sinc Filter Output.
When the clipped audio data exceeds the setting value of the PDOVUTRCH0.OVDU[19:0] bits, the overvoltage upper-limit-exceeded detection flag (PDSRCH0.OVUDF) is set to 1. When the clipped audio data falls below the value of the PDOVLTRCH0.OVDL[19:0] bits, the overvoltage less-than-lower-limit detection flag (PDSRCH0.OVLDF) is set to 1.
Figure 58.13 shows a block diagram of the overvoltage detection function.

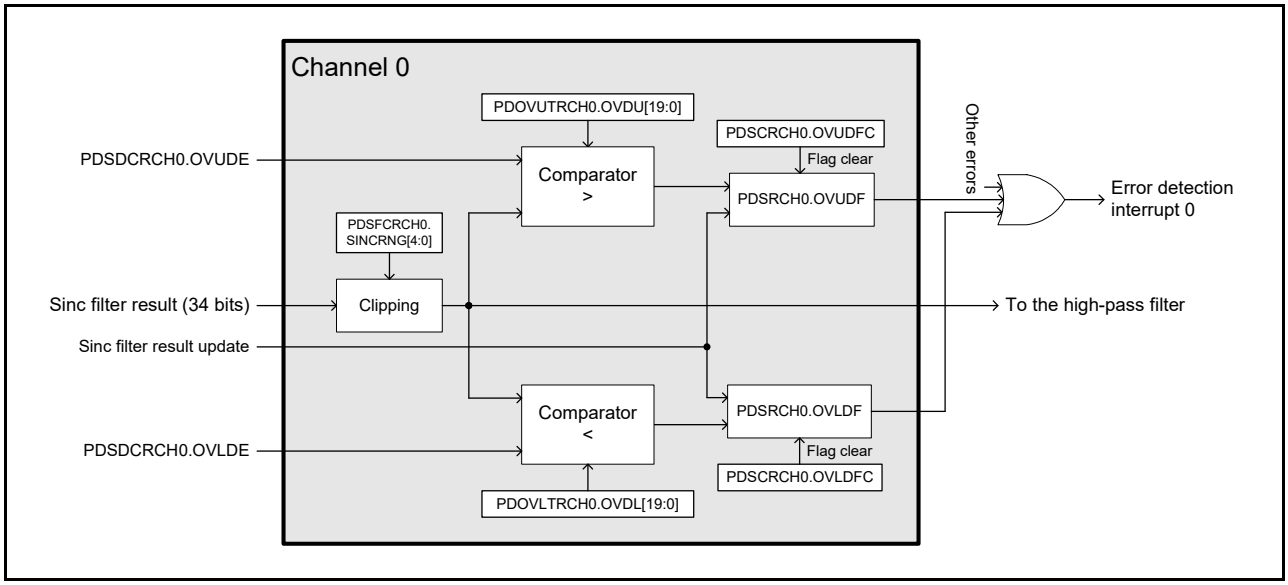

Figure 58.13 Overvoltage Detection Function Block Diagram

58.3.9 Errors

Table 58.17 lists errors with the PDM-IF.

Table 58.17 PDM-IF Error List

No	Register and Bit Symbol	Bit Name	Comment	Function (Reference)
1	PDSRCH0.SCDF	Short-circuit detection flag	—	section 58.3.7, Short-Circuit Detection
2	PDSRCH0.OVLDF	Overvoltage less-than-lower-limit detection flag	—	section 58.3.8, Overvoltage Detection
3	PDSRCH0.OVUDF	Overvoltage upper-limit-exceeded detection flag	—	section 58.3.8, Overvoltage Detection
4	PDSRCH0.BFOWDF	Buffer overwrite detection flag	For debugging	section 58.3.6, Data Buffer

The buffer overwrite detection error is for debugging purposes. Before operating the PDM-IF, the registers must be set so that these errors do not occur in the software. If any of these errors occur, stop the PDM-IF according to section 58.4.2, Stop Flow and change the settings.

58.3.10 Interrupt Functions

Table 58.18 shows the interrupt functions of the PDM-IF.

Table 58.18 List of PDM-IF Interrupts

No.	Signal Name	Interrupt Name	Number of Signals	Pulse or Level	Related Registers and Bit Names		Function (Reference)
					Common Register	Channel Register	
1	DAT0	Data receive interrupt 0	1	Pulse	PDCSR.DRF0	PDSRCH0.DRF	section 58.3.6, Data Buffer
2	SDET	Audio detection interrupt	1	Level	PDCSR.SDF0	PDSRCH0.SDF	section 58.3.5, Audio Detection
3	ERR0	Error detection interrupt 0	1	Level	PDCSR.EDF0	PDSRCH0.SCDF	section 58.3.7, Short-Circuit Detection
						PDSRCH0.OVLDF	section 58.3.8, Overvoltage Detection
						PDSRCH0.OVUDF	section 58.3.8, Overvoltage Detection
						PDSRCH0.BFOWDF	section 58.3.6, Data Buffer

58.4 Setting Flows

Figure 58.14 shows an example of PDM-IF operation, and Figure 58.15 shows the main flow of PDM-IF settings with transition to low power consumption mode.

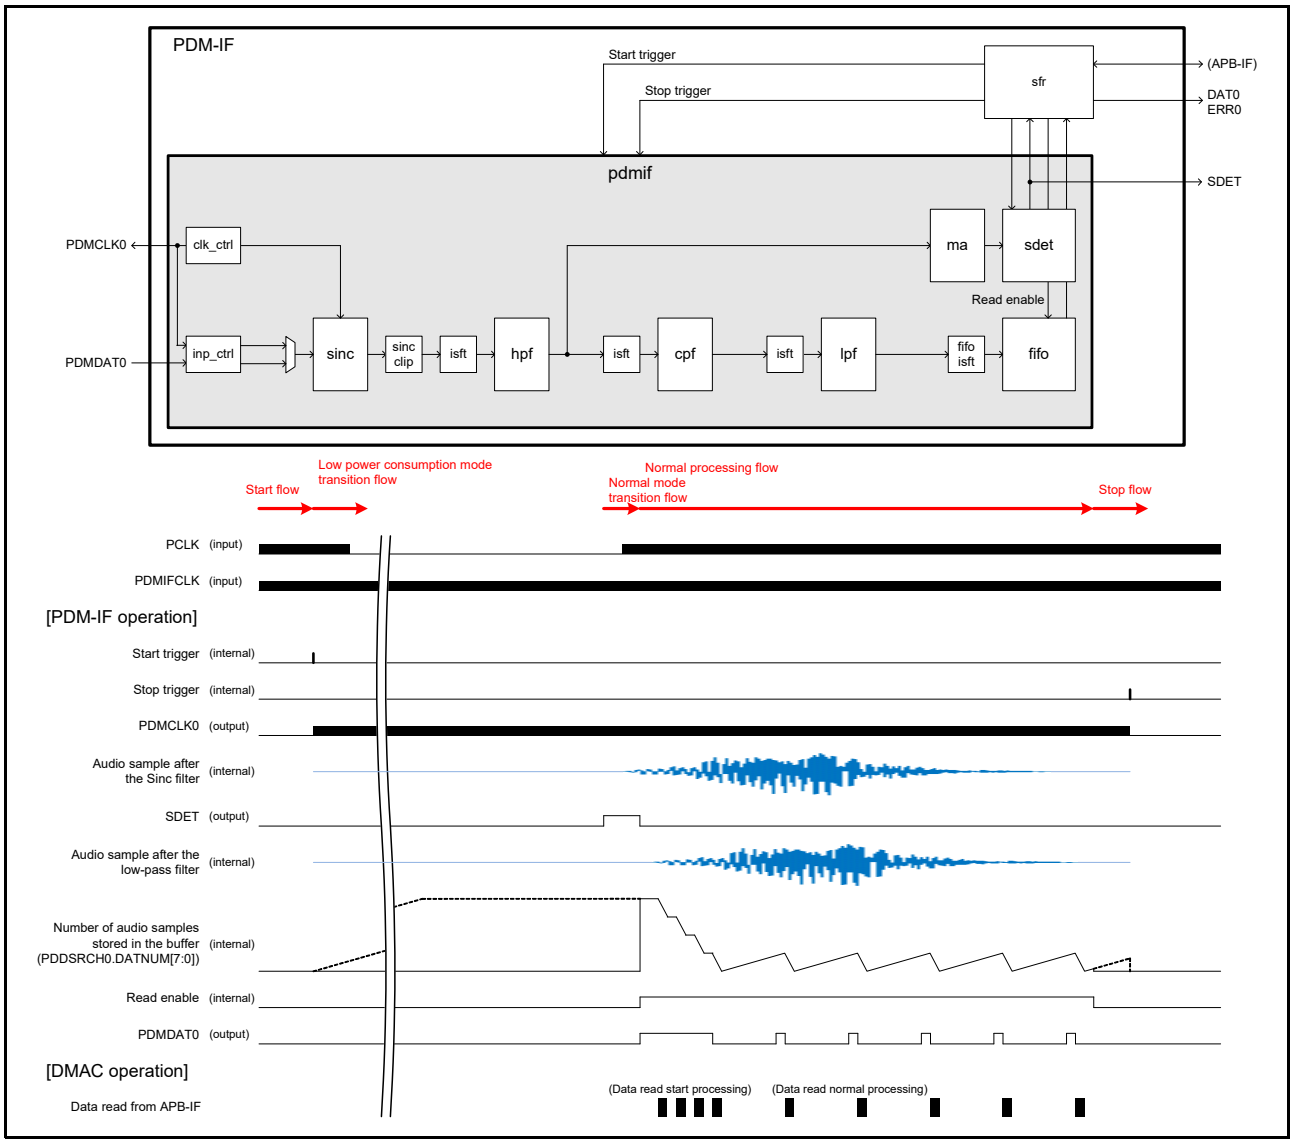

Figure 58.14 Example of PDM-IF Operation

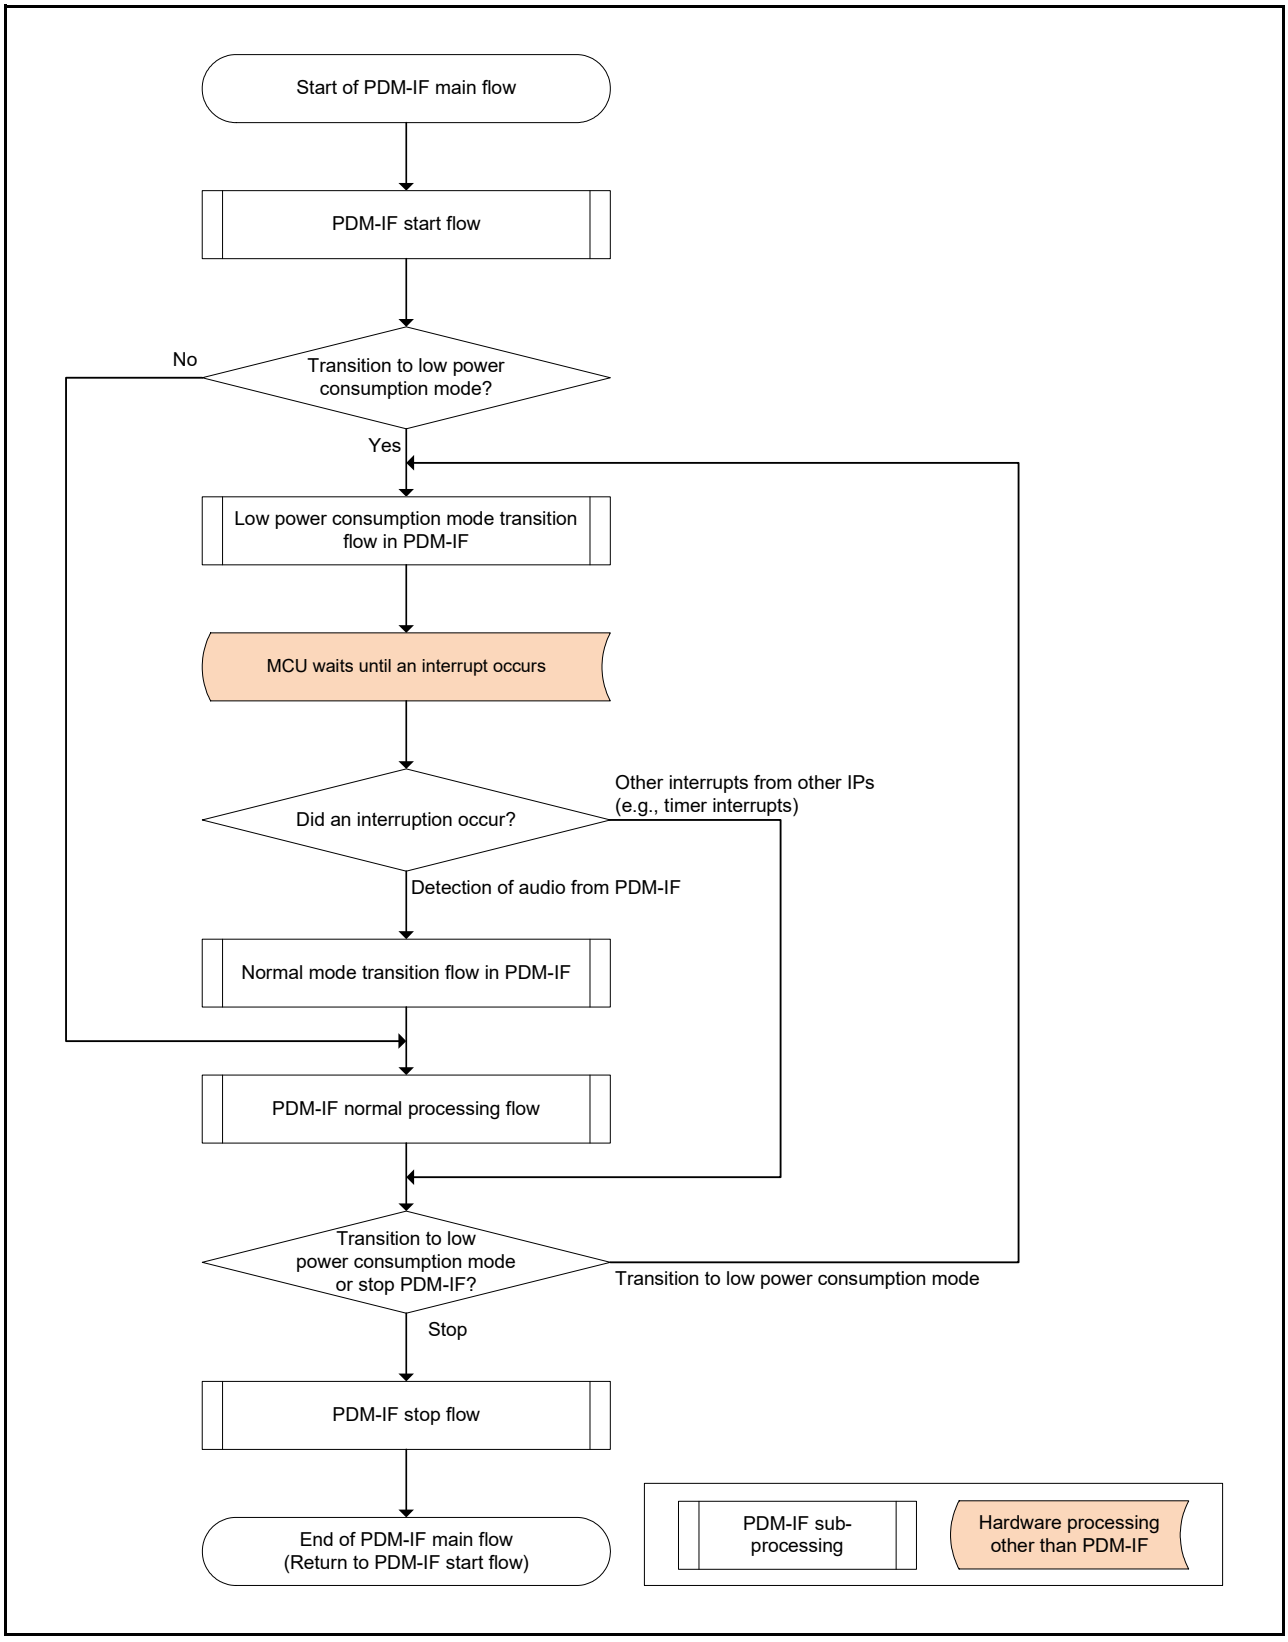

Figure 58.15 Main Flow of PDM-IF Settings with Transition to Low Power Consumption Mode

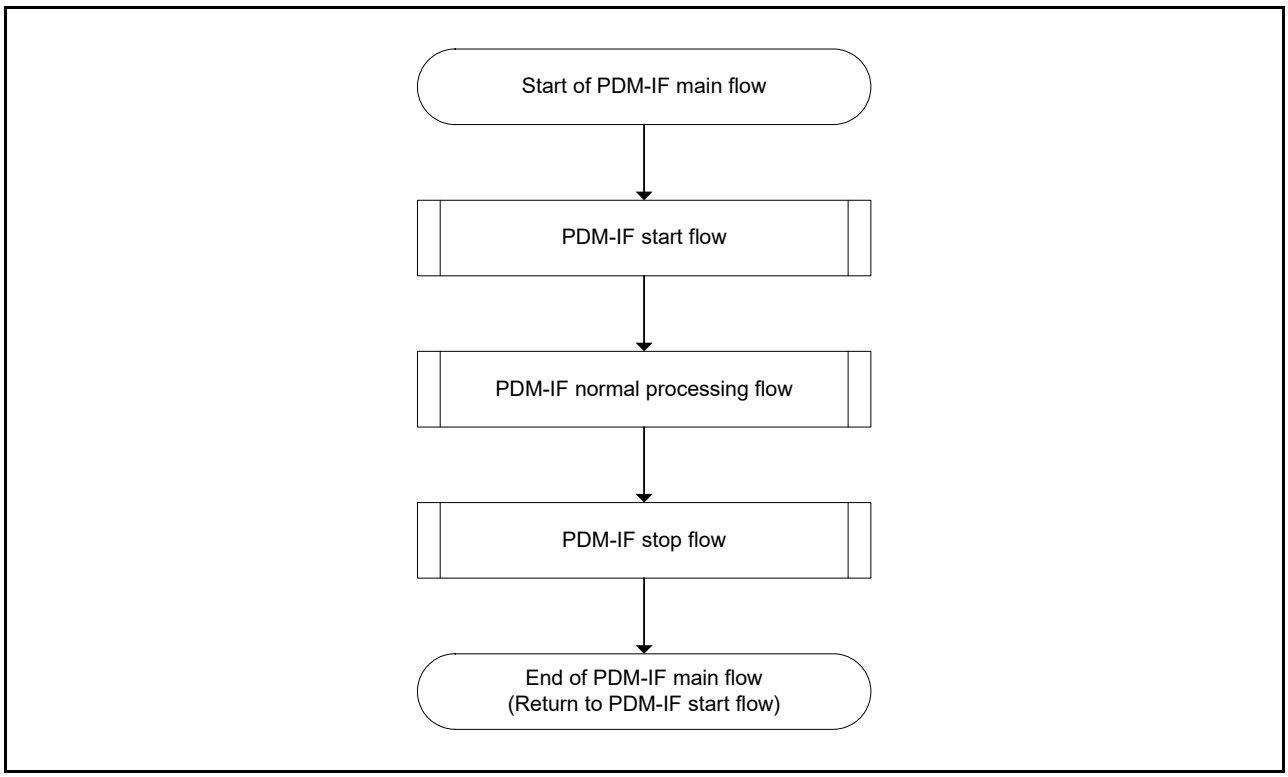
Figure 58.16 shows the main flow of PDM-IF settings without transition to low power consumption mode.



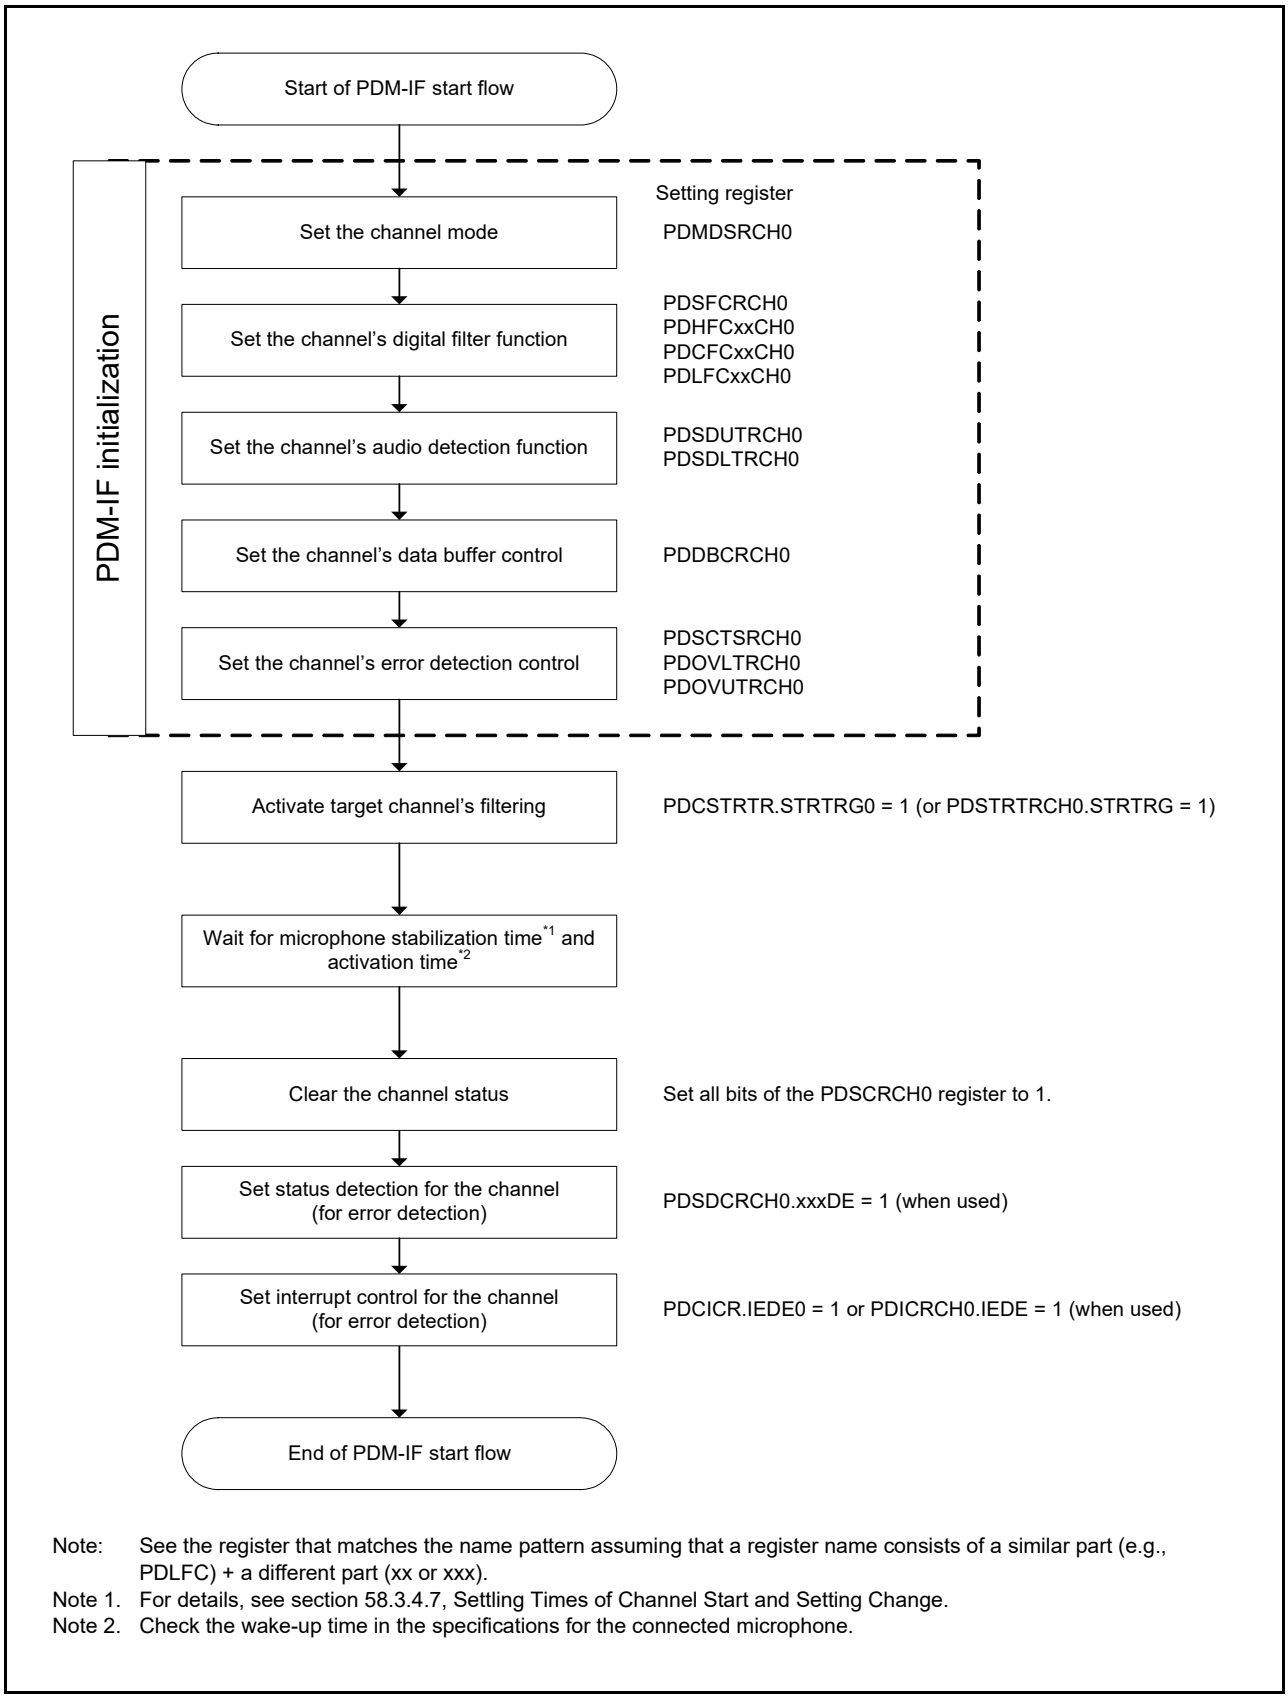


Figure 58.16 Main Flow of PDM-IF Settings without Transition to Low Power Consumption Mode

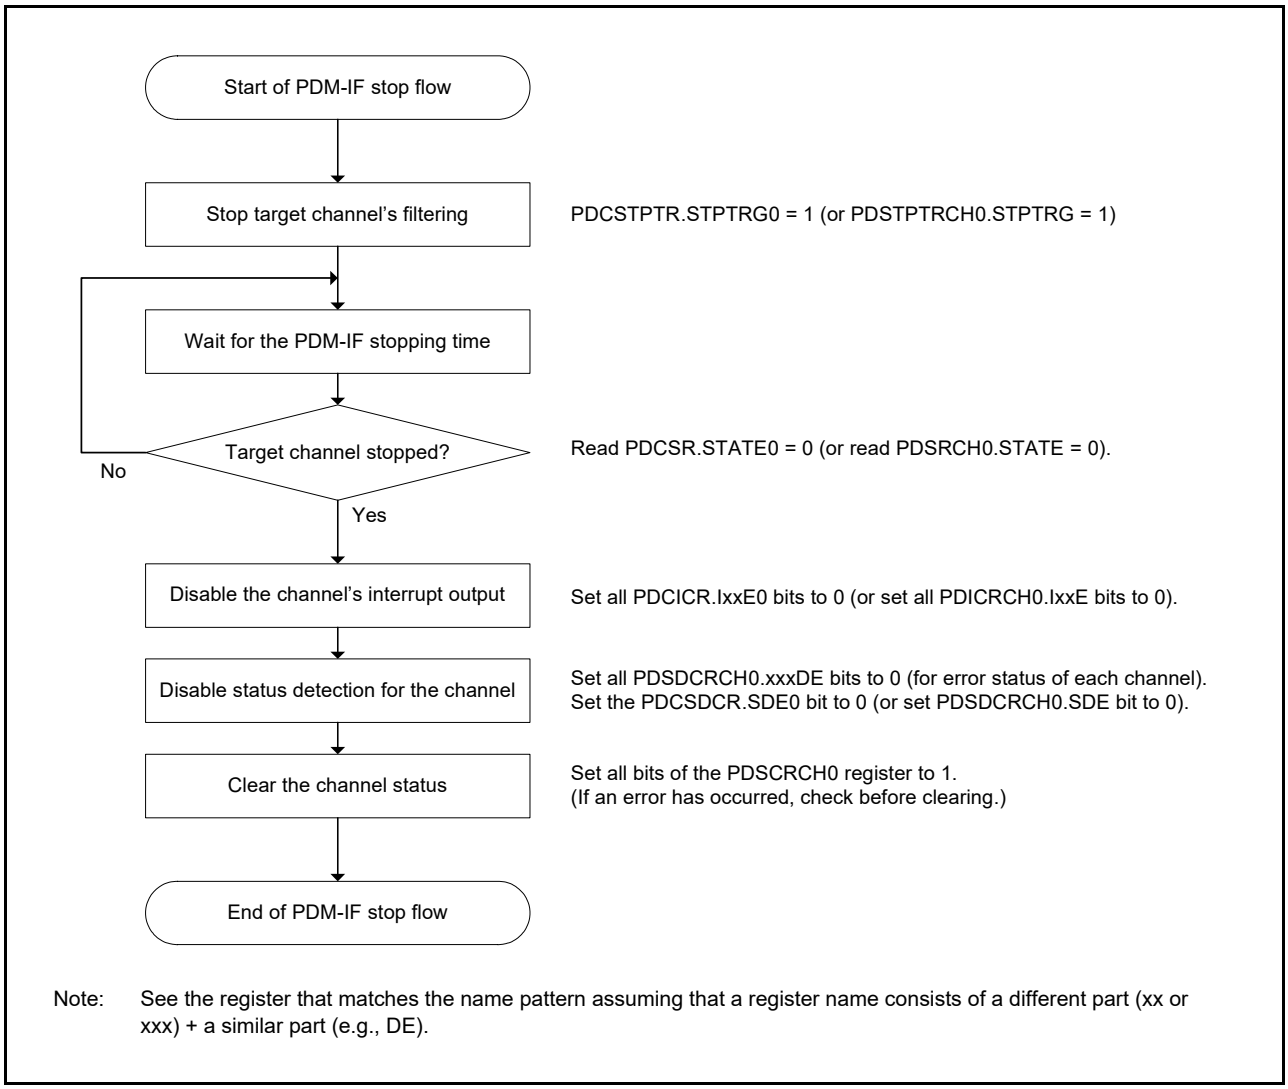
58.4.1 Start Flow

Figure 58.17 shows an example of a start procedure for the PDM-IF.

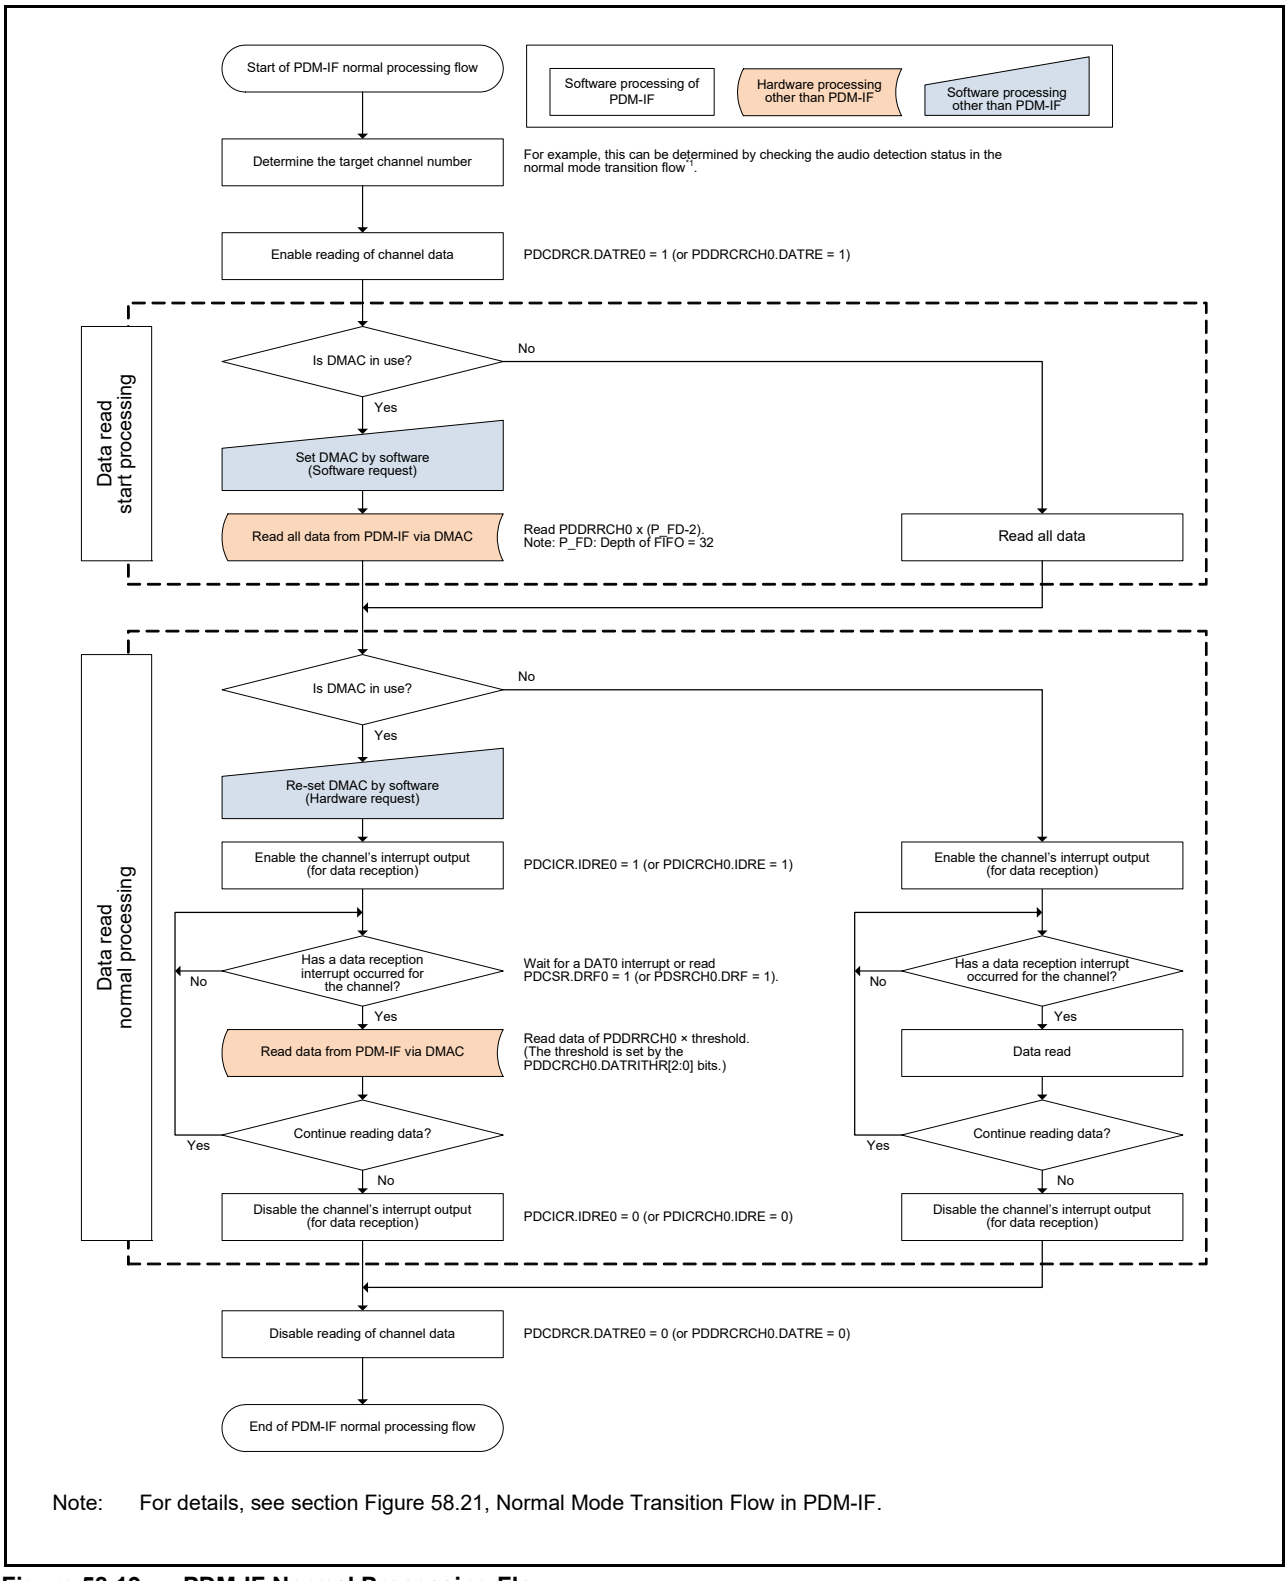


Note: See the register that matches the name pattern assuming that a register name consists of a similar part (e.g., PDLFC) + a different part (xx or xxx).
Note 1. For details, see section 58.3.4.7, Settling Times of Channel Start and Setting Change.
Note 2. Check the wake-up time in the specifications for the connected microphone.

Figure 58.17 PDM-IF Start Flow

58.4.2 Stop Flow

Figure 58.18 shows an example of a stop procedure for the PDM-IF.

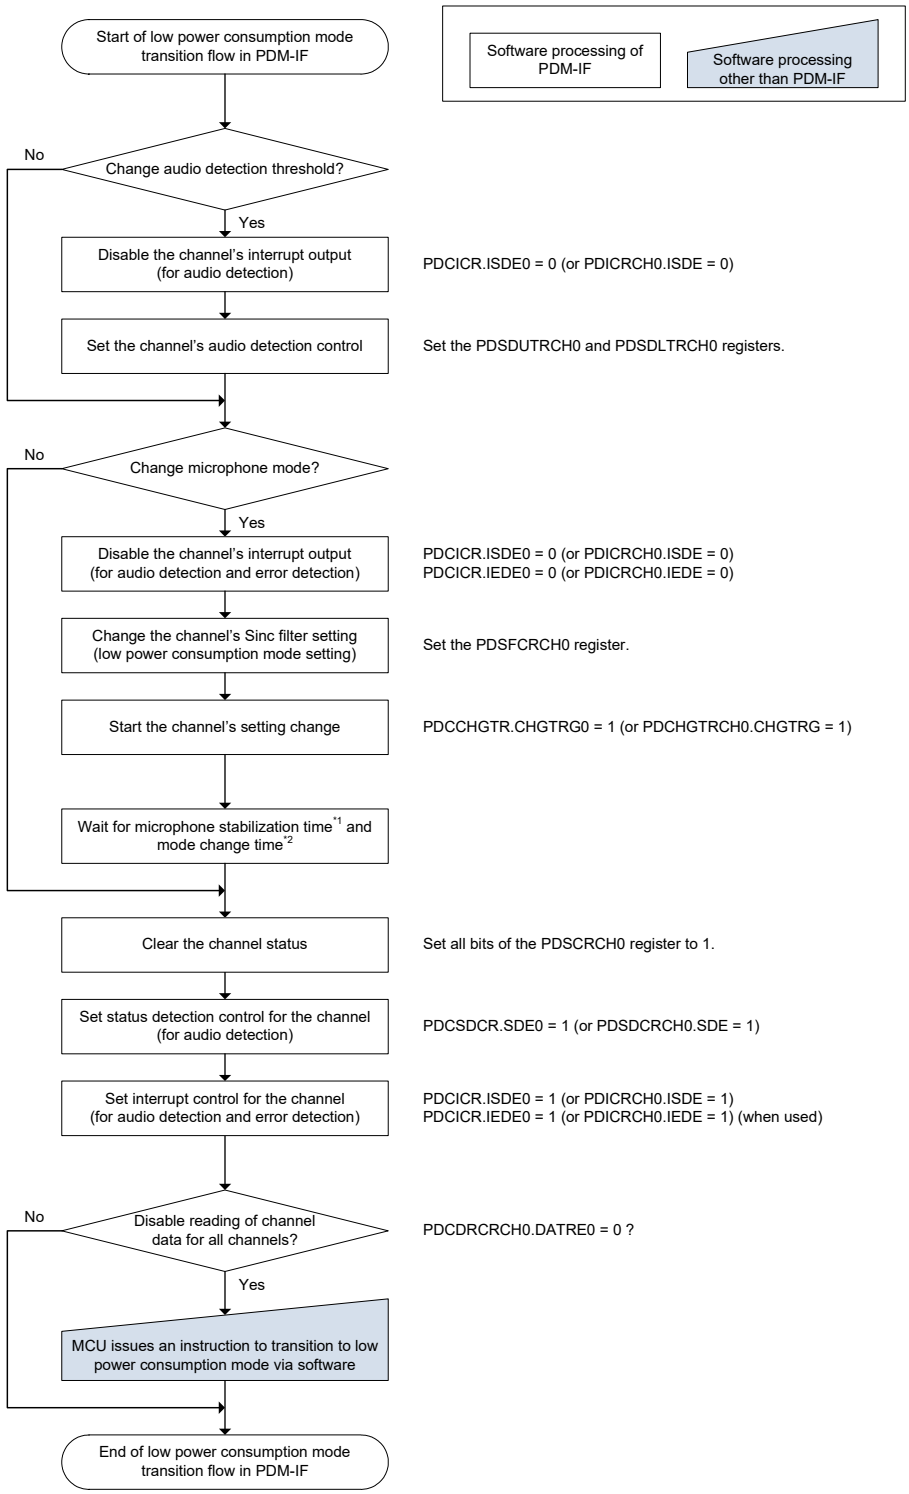


Note: See the register that matches the name pattern assuming that a register name consists of a different part (xx or xxx) + a similar part (e.g., DE).

Figure 58.18 PDM-IF Stop Flow

58.4.3 Normal Processing Flow

Figure 58.19 shows an example of a normal processing procedure for the PDM-IF.

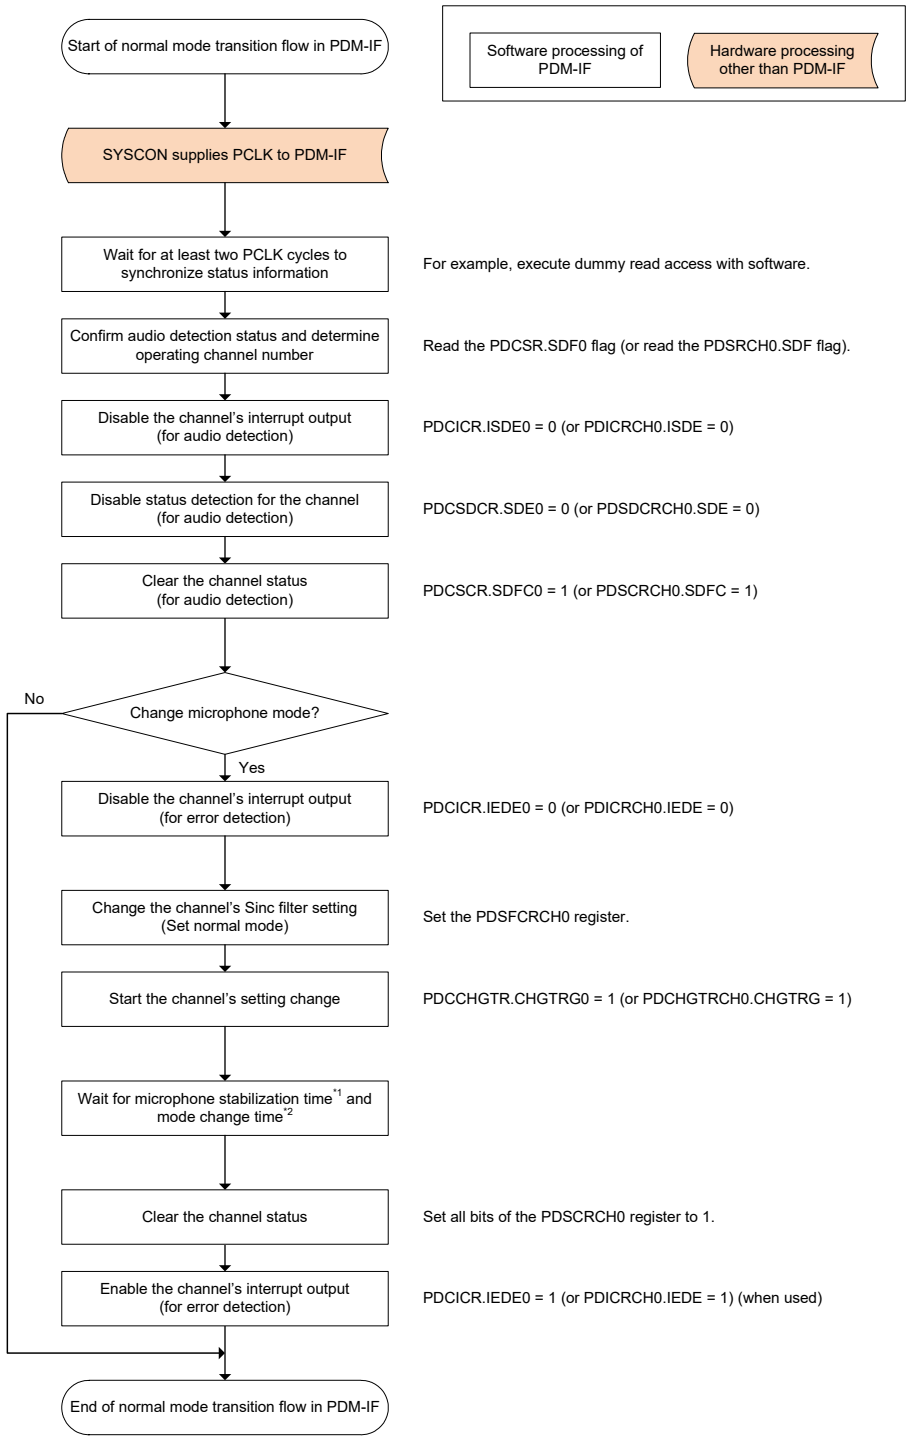


Note: For details, see section Figure 58.21, Normal Mode Transition Flow in PDM-IF.

Figure 58.19 PDM-IF Normal Processing Flow

58.4.4 Low Power Consumption Mode Transition Flow

Figure 58.20 shows an example of a transition procedure to low power consumption mode in the PDM-IF.



Note 1. For details, see section 58.3.4.7, Settling Times of Channel Start and Setting Change.
Note 2. For the PDM microphone mode frequency and mode change time, check the specifications for the connected microphone.

Figure 58.20 Low Power Consumption Mode Transition Flow in PDM-IF

58.4.5 Normal Mode Transition Flow

Figure 58.21 shows an example of a transition procedure to normal mode in the PDM-IF.

Note 1. For details, see section 58.3.4.7, Settling Times of Channel Start and Setting Change.
Note 2. For the PDM microphone mode frequency and mode change time, check the specifications for the connected microphone.

Figure 58.21 Normal Mode Transition Flow in PDM-IF

58.5 Usage Notes

58.5.1 Setting the Data Receive Interrupt Threshold

When data read by DMA is complete, if the number of data items stored in the buffer that have not yet been read exceeds the data reception interrupt threshold (hereinafter referred to as the threshold) set by PDDBCRCH0.DATRITHR[2:0] bits, the data reception interrupt (DAT0) that should normally be issued is not issued, and the next data read cannot be requested by the interrupt controller. This occurs when the time required to read the data exceeds [sampling rate at which data is stored in the data buffer × threshold value]. Set the threshold appropriately to avoid loss of interrupt requests. If this cannot be avoided even by setting the threshold value, check the number of data stored in the buffer when data read is complete using the PDDSRCH0.DATNUM[7:0] bits, and then start DMA by software to read the confirmed number of data.

58.5.2 Default Filter Frequency Characteristics

Figure 58.22 and Table 58.19 show the default filter frequency characteristics for reference.

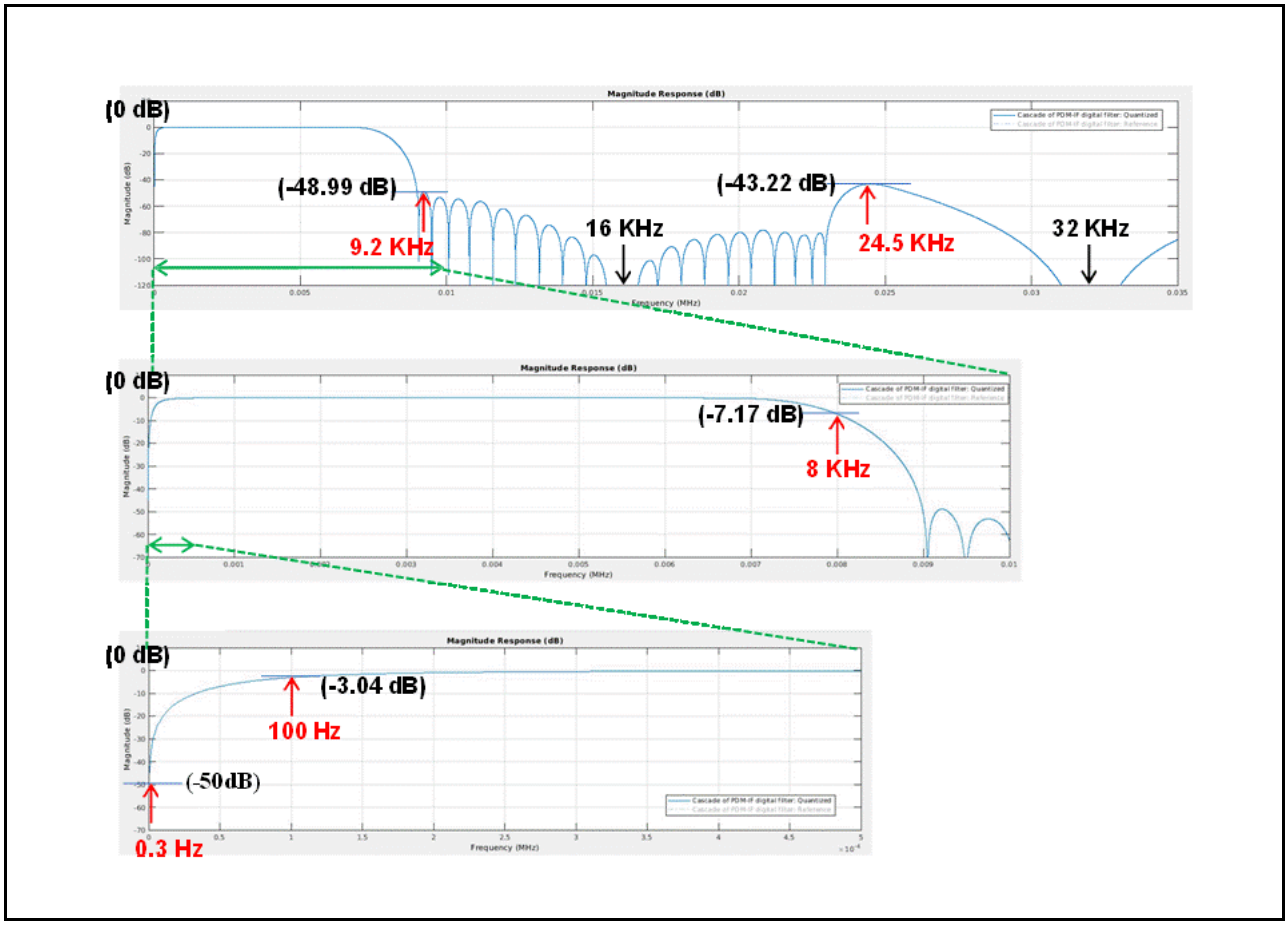


Figure 58.22 Default Filter Frequency Characteristics

Table 58.19 Default Filter Frequency Characteristics

Frequency (Hz)		Amplitude (dB)
LPF cut-off frequency	24.5 kHz	–43.22
	…	…
	9.2 kHz	–48.99
	8 kHz	–7.17
Passband	7 kHz	–0.39
	6 kHz	–0.07
	…	…
	150 Hz	–1.63
	100 Hz	–3.04
HPF cut-off frequency	50 Hz	–7.02
	0.3 Hz	–50.00

59. Phase-Counting Interface (PCIF)

This MCU has two phase-counting interfaces (PCIF0 and PCIF1). In this section, “PCLK” is used to refer to PCLKB.

59.1 Overview

The PCIF outputs A-phase, B-phase, and Z-phase signals according to phase information. There are two PCIF modes: phase counting mode and incremental mode.
In phase counting mode, the edge count and carrier period event are input according to the register settings from the CPU, and then the PCIF calculates the change timing of each phase and generates ABZ-phase outputs.
In incremental mode, A-, B-, and Z-phase signals are directly input from an incremental encoder, and then the PCIF generates ABZ-phase outputs by reducing the resolution of the input to the desired value.
Table 59.1 lists the PCIF specifications, and Figure 59.1 shows a block diagram of the PCIF.

Table 59.1 PCIF Specifications

Item	Description
Core clock (CCLK)	Clock for receiving event trigger input Selectable from two types of clocks: PCLK and GPTCLK
Frequency-divided clock (CCLK_DIV)	Clock with which ABZ-phase output is synchronized. Selectable from division rates of 1, 2, 3, 4, 5 … 32.
Reset	Hardware reset or software reset
Phase counting mode	ABZ-phase signals are output for the number of edges set in the carrier period. • Number of edges per rotation: 16 to 65,536 (multiple of 4) • Carrier period: 10 µs to CCLK_DIV period × 65,535 • Carrier period control function supporting two ways of stopping outputs in this mode, two modes for generating the carrier period start timing (carrier period event) • Automatic edge count clearing function • Function for changing the synchronization phase and output width of Z-phase • Four types of errors can be detected.
Incremental mode	ABZ-phase signals are output by changing the resolution of ABZ-phase input • Supporting five types of I/O protocols • Resolution changing function • Five ways of clearing the internal counters • Five ways of generating Z-phase signals • Four Z-phase synchronization modes
Output controller	ABZ-phase output inversion function
Event link function (input)	• Carrier period event input (ELC_IN) • Crest/trough event trigger input (PEK_IN or VLY_IN) initializes the internal counters to clear the AB-phase outputs. • Crest/trough event trigger input (PEK_IN or VLY_IN) generates Z-phase output.
Protect Zone filter	Security attribute can be set for each channel.*1

Note 1. When each channel is set to the secure attribute, registers in the channel are accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When each channel is set to the non-secure attribute, registers in the channel are accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

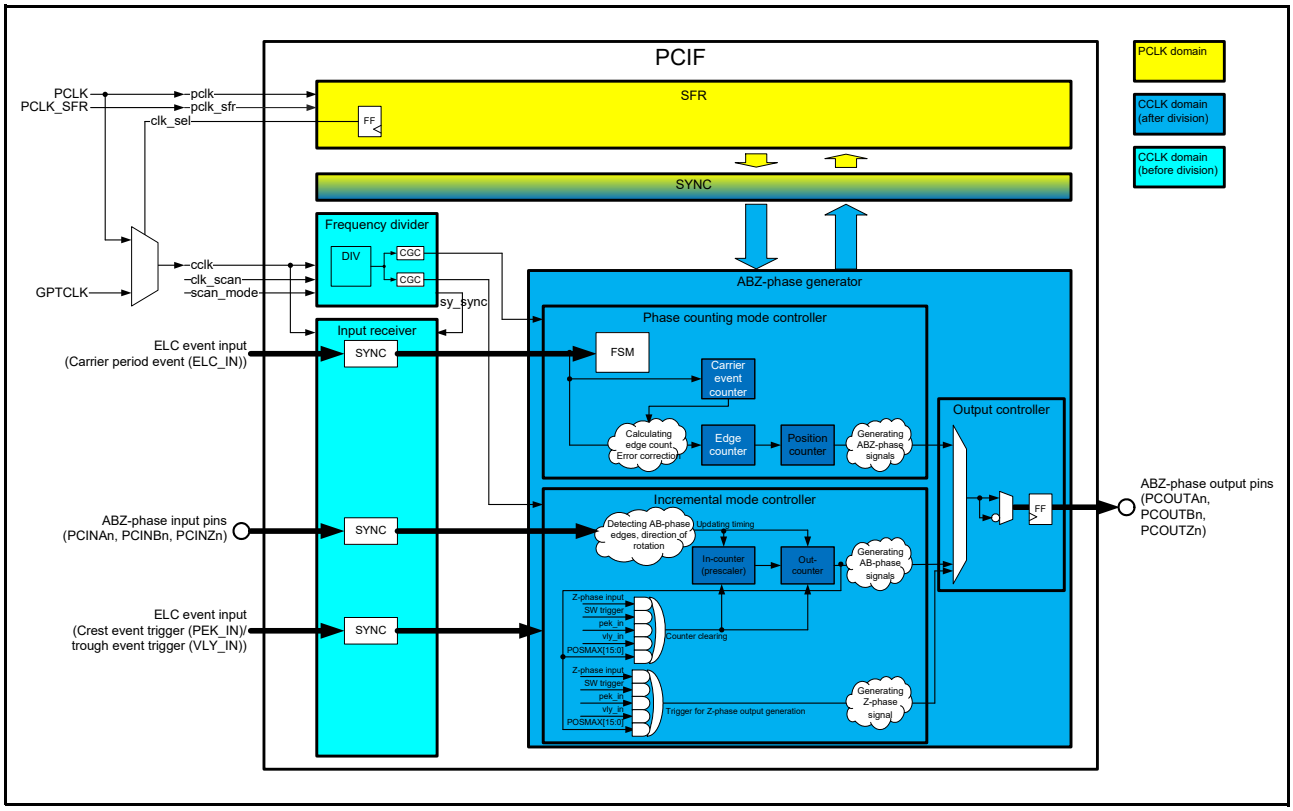

Figure 59.1 PCIF Block Diagram (n = 0, 1)

Table 59.2 shows the clock frequency range used for the PCIF and the usage conditions, and Figure 59.2 shows the clock configuration diagram of the PCIF.

Table 59.2 List of PCIF Clocks

Clock Name	Minimum Frequency (MHz)	Maximum Frequency (MHz)
PCLK	—	75
CCLK*1	—	200
CCLK_DIV*2	10	20

Note 1. If the asynchronous clock (GPTCLK) is to be selected as the CCLK clock source, make sure that this satisfies the condition for frequency GPTCLK ≤ 8 × PCLK.
Note 2. Make sure that this satisfies the condition for frequency CCLK_DIV ≤ 1/2 × PCLK.

[Clock frequency setting examples]

- For the maximum frequency: PCLK = 75 MHz, CCLK = 200 MHz, CCLK_DIV = 20 MHz
- For the minimum frequency: PCLK = 20 MHz, CCLK = 10 MHz, CCLK_DIV = 10 MHz
- For an unbalance frequency: PCLK = 20 MHz, CCLK = 160 MHz*1, CCLK_DIV = 10 MHz

Note 1. Setting of CCLK > 160 MHz is prohibited.

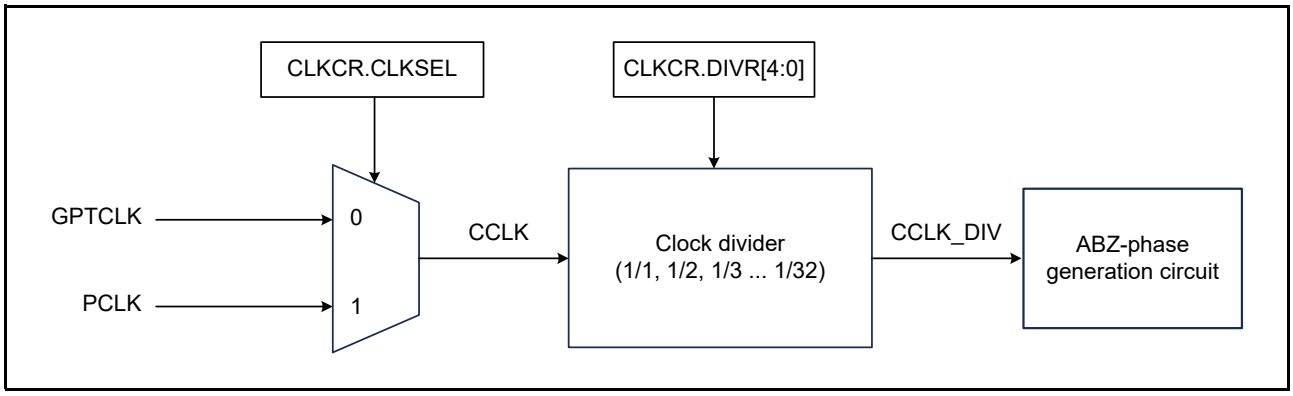

Figure 59.2 PCIF Clock Configuration Diagram

In phase counting mode, the CPU obtains position information from the encoder for each period of the current loop and position control loop notified by the timer module (carrier period event), and then calculates the difference from the previous position information. After the CPU initializes the PCIF, the PCIF generates ABZ-phase outputs by periodically updating the calculated value.
Carrier period events can be input to the PCIF via the ELC (carrier period input). It is also possible to generate a carrier period event within the PCIF.

In incremental mode, the CPU only initializes the PCIF. The PCIF generates ABZ-phase outputs from AB(Z)-phase signals directly input from the incremental encoder after startup or by using the timer module's crest/trough interrupts that are input through the ELC as events.
Table 59.3 lists the I/O pins used in the PCIF, and Figure 59.3 shows a system configuration example using the PCIF (n = 0, 1).

Table 59.3 I/O Pins of PCIF (n = 0, 1)

Interface	Pin Name	I/O	Function
PCIFn	PCINAn	Input	A-phase input pin of PCIFn
	PCINBn	Input	B-phase input pin of PCIFn
	PCINZn	Input	Z-phase input pin of PCIFn
	PCOUTAn	Output	A-phase output pin of PCIFn
	PCOUTBn	Output	B-phase output pin of PCIFn
	PCOUTZn	Output	Z-phase output pin of PCIFn

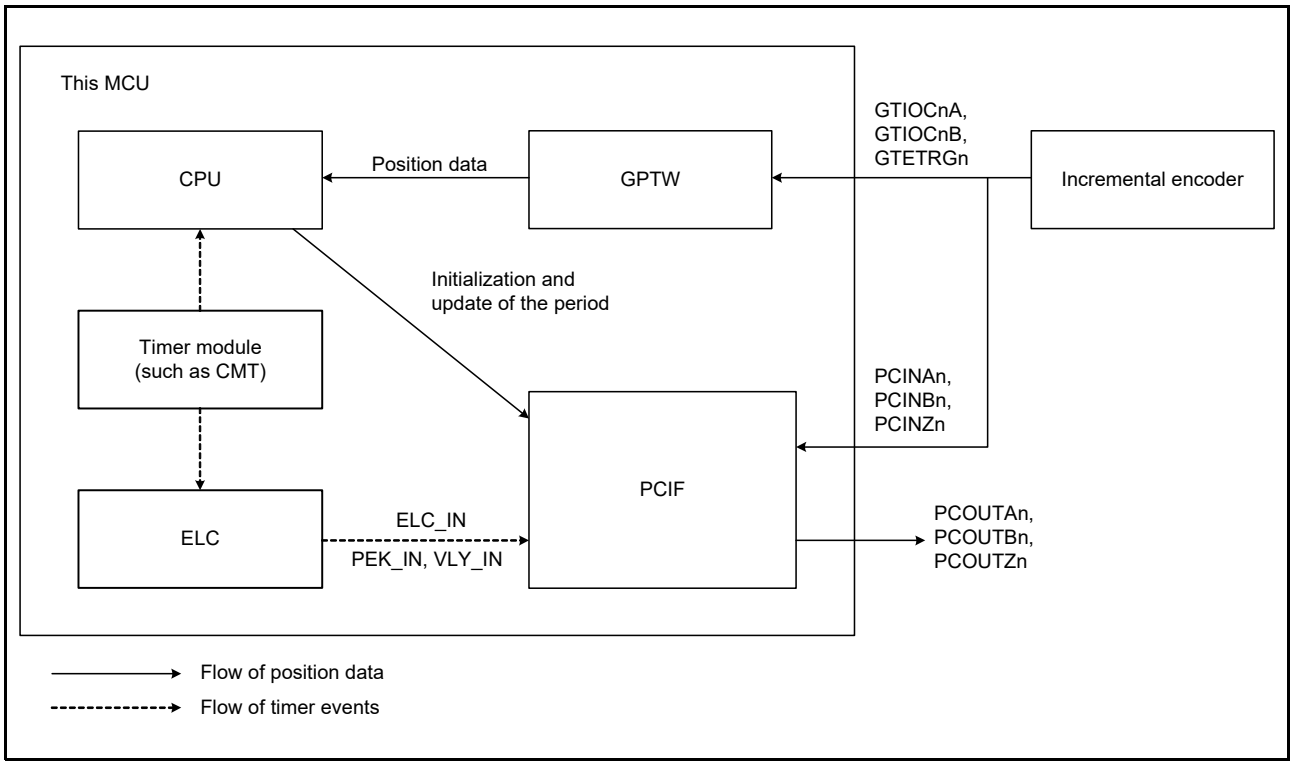

Figure 59.3 Example of System Configuration Using PCIF (n = 0, 1)

59.2 Register Descriptions

59.2.1 PCIF Clock Enable Register (CLKER)

Address(es): PCIF0.CLKER 8782 7000h, PCIF1.CLKER 8782 7080h,
PCIF0_NS.CLKER 0782 7000h, PCIF1_NS.CLKER 0782 7080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLKEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CLKEN	Frequency-Divided Clock Enable	0: Frequency-divided clock operation disabled 1: Frequency-divided clock operation enabled	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register enables or disables operation of the frequency-divided clock (CCLK_DIV).

CLKEN Bit (Frequency-Divided Clock Enable)

This bit enables operation of the frequency-divided clock (CCLK_DIV).

After a reset is released, make the setting of this bit according to the procedure in Figure 59.44 Overall Operating Flow for PCIF.

59.2.2 PCIF Clock Status Register (CLKSR)

Address(es): PCIF0.CLKSR 8782 7004h, PCIF1.CLKSR 8782 7084h,
PCIF0_NS.CLKSR 0782 7004h, PCIF1_NS.CLKSR 0782 7084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLKS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CLKS	Frequency-Divided Clock Status Flag	0: Frequency-divided clock stopped 1: Frequency-divided clock operating	R
b31 to b1	—	Reserved	These bits are read as 0.	R

This register indicates the state of the frequency-divided clock (CCLK_DIV).

CLKS Flag (Frequency-Divided Clock Status Flag)

This status flag indicates whether the frequency-divided clock (CCLK_DIV) is operating or stopped.

59.2.3 PCIF Clock Control Register (CLKCR)

Address(es): PCIF0.CLKCR 8782 7008h, PCIF1.CLKCR 8782 7088h,
PCIF0_NS.CLKCR 0782 7008h, PCIF1_NS.CLKCR 0782 7088h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DIVR[4:0]					—	—	—	—	—	—	—	CLKSEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CLKSEL	CCLK Clock Source Select	0: Asynchronous clock (GPTCLK) 1: Synchronous clock (PCLK)	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12 to b8	DIVR[4:0]	Frequency-Divided Clock Ratio Select	b12 b8 0 0 0 0 0: Divided by 1 0 0 0 0 1: Divided by 2 (duty cycle 1:1) 0 0 0 1 0: Divided by 3 (duty cycle 2:1) 0 0 0 1 1: Divided by 4 (duty cycle 2:2) 0 0 1 0 0: Divided by 5 (duty cycle 3:2) 0 0 1 0 1: Divided by 6 (duty cycle 3:3) : : 1 1 1 1 1: Divided by 32 (duty cycle 16:16)	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register selects the CCLK clock source and the division ratio of the frequency-divided clock (CCLK_DIV).

CLKSEL Bit (CCLK Clock Source Select)

Selects the CCLK clock source.

If the asynchronous clock (GPTCLK) is to be selected as the CCLK clock source, make sure that this satisfies the condition for frequency GPTCLK ≤ 8 × PCLK.

Rewriting is prohibited when the frequency-divided clock is in operation (CLKSR.CLKS flag = 1).

DIVR[4:0] Bits (Frequency-Divided Clock Ratio Select)

Select the division ratio of the frequency-divided clock (CCLK_DIV).

Make sure that this satisfies the condition for frequency CCLK_DIV ≤ 1/2 × PCLK.

The setting can be changed only when CCLK_DIV is stopped (CLKER.CLKEN bit = 0).

Rewriting is prohibited when the frequency-divided clock is in operation (CLKSR.CLKS flag = 1).

59.2.4 PCIF Control Register (CTLR)

Address(es): PCIF0.CTLR 8782 700Ch, PCIF1.CTLR 8782 708Ch,
PCIF0_NS.CTLR 0782 700Ch, PCIF1_NS.CTLR 0782 708Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	ZPOL	BPOL	APOL	—	—	—	—	—	—	—	PCIFMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PCIFMD	PCIF Mode Select	0: Phase counting mode 1: Incremental mode	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	APOL	A-Phase Output Active Sense Select	0: Positive 1: Negative	R/W
b9	BPOL	B-Phase Output Active Sense Select	0: Positive 1: Negative	R/W
b10	ZPOL	Z-Phase Output Active Sense Select	0: Positive 1: Negative	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register selects the mode and the active senses of ABZ-phase signals.

PCIFMD Bit (PCIF Mode Select)

Selects the mode of the PCIF.
Rewriting is prohibited when the frequency-divided clock is in operation (CLKSR.CLKS flag = 1).

APOL Bit (A-Phase Output Active Sense Select)

Selects the active sense of A-phase output.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).
For details on this function, refer to section 59.3.3.1, ABZ-Phase Output Inversion Function.

BPOL Bit (B-Phase Output Active Sense Select)

Selects the active sense of B-phase output.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).
For details on this function, refer to section 59.3.3.1, ABZ-Phase Output Inversion Function.

ZPOL Bit (Z-Phase Output Active Sense Select)

Selects the active sense of Z-phase output.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).
For details on this function, refer to section 59.3.3.1, ABZ-Phase Output Inversion Function.

59.2.5 PCIF Maximum Position Setting Register (POSMAXR)

Address(es): PCIF0.POSMAXR 8782 7010h, PCIF1.POSMAXR 8782 7090h,
PCIF0_NS.POSMAXR 0782 7010h, PCIF1_NS.POSMAXR 0782 7090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	POSMAX[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	POSMAX[15:0]	Maximum Position Setting	In phase counting mode: The set value is used as the maximum value of the position counter (PHCPCMR.PHCPOSCNTM[15:0] bits). In incremental mode: The set value is used as the maximum value of the output counter (INCPCMR.INCOCNTM[15:0] bits) when the internal counters are cleared (INCZGCTLR.INCZAGE bit = 1). A value that meets “4 × N – 1 (N is an integer equal to or greater than 4)” can be set in these bits.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register sets the maximum position of the output counter.
Rewriting this register is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

59.2.6 PCIF Start/Stop Trigger Register (TRGR)

Address(es): PCIF0.TRGR 8782 7014h, PCIF1.TRGR 8782 7094h,
PCIF0_NS.TRGR 0782 7014h, PCIF1_NS.TRGR 0782 7094h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	PHCSTPT	—	—	—	—	—	—	—	PCIFSTPT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PCIFSTRT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PCIFSTRT	PCIF Start Trigger	0: Does not operate. 1: Starts outputs by the PCIF.	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	PCIFSTPT	PCIF Stop Trigger	0: Does not operate. 1: Immediately stops outputs by the PCIF.	R/W
b23 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	PHCSTPT	Phase Counting Mode Stop Trigger	0: Does not operate. 1: Stops outputs by the PCIF after generating ABZ-phase signals set in the PHCECR.PHCEDGCNT[15:0] bits.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register controls the start and stop of outputs by the PCIF and stop of outputs exclusively for use in phase counting mode.

PCIFSTRT Bit (PCIF Start Trigger)

This bit is a PCIF start trigger bit for use in phase counting mode and incremental mode. This bit is read as 0. Setting this bit to 1 at the same time as other bits is prohibited.

PCIFSTPT Bit (PCIF Stop Trigger)

This bit is a PCIF stop trigger bit for use in phase counting mode and incremental mode. In phase counting mode, setting this bit to 1 immediately stops outputs by the PCIF.
This bit is read as 0. Setting this bit to 1 at the same time as other bits is prohibited.
For details on how to stop outputs in phase counting mode, refer to (1) Immediate Stop Function in section 59.3.1.2, Stop Control. For details on how to stop outputs in incremental mode, refer to section 59.3.2.1, Startup/Stop Control.

PHCSTPT Bit (Phase Counting Mode Stop Trigger)

This bit is a PCIF stop trigger bit for use in phase counting mode. Setting this bit to 1 stops outputs by the PCIF in synchronization with the carrier period.
Carrier period events will not be accepted until the PCIFSTRT bit is set to 1.
This bit is read as 0. Setting this bit to 1 at the same time as other bits is prohibited.
For details on how to stop outputs by using this bit, refer to (2) Carrier Period-Synchronized Stop Function in section 59.3.1.2, Stop Control.

59.2.7 PCIF Status Register (SR)

Address(es): PCIF0.SR 8782 7018h, PCIF1.SR 8782 7098h,
PCIF0_NS.SR 0782 7018h, PCIF1_NS.SR 0782 7098h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PCIFPS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PCIFPS	PCIF Operation Status Flag	0: PCIF is stopped. 1: PCIF is in operation.	R
b31 to b1	—	Reserved	These bits are read as 0.	R

This register is a status register that indicates the PCIF operating state.

59.2.8 PCIF Phase Counting Mode Control Register (PHCCTLR)

Address(es): PCIF0.PHCCTLR 8782 7020h, PCIF1.PHCCTLR 8782 70A0h, PCIF0_NS.PHCCTLR 0782 7020h, PCIF1_NS.PHCCTLR 0782 70A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	PHCECACMD	—	—	—	—	—	—	—	PHCCEDAMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PHCZOS	PHCZW[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	PHCZW[2:0]	Z-Phase Pulse Width Select in Phase Counting Mode	b2 b0 0 0 0: Z-phase output is prohibited. 0 0 1: Pulse output when the PHCPCMR.PHCPOSCNTM[15:0] bits are set to 0 0 1 0: Pulse output when the PHCPCMR.PHCPOSCNTM[15:0] bits are set to –1 or 0 (sync to A-phase) or set to 0 or 1 (sync to B-phase) 0 1 1: Pulse output when the PHCPCMR.PHCPOSCNTM[15:0] bits are set to –1, 0, or 1 1 0 0: Pulse output when the PHCPCMR.PHCPOSCNTM[15:0] bits are set to –1, 0, 1, or 2 (sync to A-phase) or set to –2, –1, 0, or 1 (sync to B-phase) Settings other than the above are prohibited.	R/W
b3	PHCZOS	Z-Phase Output Synchronization Phase Select in Phase Counting Mode	0: A-phase 1: B-phase	R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	PHCCEDAMD	Carrier Period Event Difference Adjustment Mode Select in Phase Counting Mode	0: Event-based mode 1: Register-based mode	R/W
b23 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	PHCECACMD	Automatic Edge Count Clear Mode Select in Phase Counting Mode	0: Automatic clearing is not performed. 1: Automatic clearing is performed.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register selects the operating mode in phase counting mode.

PHCZW[2:0] Bits (Z-Phase Pulse Width Select in Phase Counting Mode)

These bits set the pulse width of Z-phase output in phase counting mode. Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

For details on this function, refer to section 59.3.1.5, Generating A-, B-, and Z-Phase Signals.

PHCZOS Bit (Z-Phase Output Synchronization Phase Select in Phase Counting Mode)

This bit selects the phase with which the Z-phase output is to be synchronized in phase counting mode. Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

For details on this function, refer to section 59.3.1.5, Generating A-, B-, and Z-Phase Signals.

PHCCEDAMD Bit (Carrier Period Event Difference Adjustment Mode Select in Phase Counting Mode)

This bit selects the processing to be performed if the intervals between carrier period events differ from the carrier period. In event-based mode, A-phase and B-phase are generated when a carrier period event is input. In register-based mode, A-phase and B-phase are generated for each carrier period set in the PHCPERIODR.PHCPERIOD[15:0] bits. In both modes, the AB-phase change intervals are generated according to the setting of the PHCPERIOD[15:0] bits. Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

For details on the event-based mode, refer to section 59.3.1.3, Carrier Period Control, (1) Event-Based Mode. For details on the register-based mode, refer to section 59.3.1.3, Carrier Period Control, (2) Register-Based Mode.

PHCECACMD Bit (Automatic Edge Count Clear Mode Select in Phase Counting Mode)

This bit selects the automatic clear mode for the PHCECR.PHCEDGCNT[15:0] bits. Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

For details on the automatic clearing function, refer to section 59.3.1.4, Position Counter Controll, (2) Automatic Edge Count Clearing Function.

59.2.9 Carrier Period Event Difference Threshold Select Register for PCIF Phase Counting Mode (PHCCEDTHR)

Address(es): PCIF0.PHCCEDTHR 8782 7024h, PCIF1.PHCCEDTHR 8782 70A4h, PCIF0_NS.PHCCEDTHR 0782 7024h, PCIF1_NS.PHCCEDTHR 0782 70A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PHCCEDTH[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	PHCCEDTH[15:0]	Carrier Period Event Difference Threshold in Phase Counting Mode	Set the tolerance of difference between the interval at which the carrier period event is generated and the carrier period setting.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register sets the carrier period event difference threshold in phase counting mode.

PHCCEDTH[15:0] Bits (Carrier Period Event Difference Threshold in Phase Counting Mode)

These bits set the tolerance of difference between the interval at which the carrier period event is generated and the carrier period setting (PHCPERIODR.PHCPERIOD[15:0] bits). Setting a value no less than the PHCPERIOD[15:0] bit value is prohibited.

If either of the following conditions is satisfied, an error occurs (PHCSR.PHCCEES flag = 1).

Carrier period event generation interval < PHCPERIOD[15:0] bits – PHCCEDTH[15:0] bits, or

Carrier period event generation interval > PHCPERIOD[15:0] bits + PHCCEDTH[15:0] bits

Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

59.2.10 PCIF Phase Counting Mode Carrier Period Setting Register (PHCPERIODR)

Address(es): PCIF0.PHCPERIODR 8782 7028h, PCIF1.PHCPERIODR 8782 70A8h,
PCIF0_NS.PHCPERIODR 0782 7028h, PCIF1_NS.PHCPERIODR 0782 70A8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PHCPERIOD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	PHCPERIOD[15:0]	Phase Counting Mode Carrier Period Setting	Set the carrier period.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register sets the carrier period in phase counting mode.

PHCPERIOD[15:0] Bits (Phase Counting Mode Carrier Period Setting)

These bits set the carrier period in cycles of the frequency-divided clock (CCLK_DIV) in accordance with the average period of event input from the ELC or an expected interval at which the carrier period event is generated. Specify the setting so that the carrier period is 10 µs or longer (maximum value is CCLK_DIV period × 65,535). If the average period of event input from the ELC is not divisible by the frequency-divided clock (CCLK_DIV) cycle, set the nearest value of the quotient.

Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

59.2.11 PCIF Phase Counting Mode Edge Count Setting Register (PHCECR)

Address(es): PCIF0.PHCECR 8782 702Ch, PCIF1.PHCECR 8782 70ACh,
PCIF0_NS.PHCECR 0782 702Ch, PCIF1_NS.PHCECR 0782 70ACh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PHCEDGCNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	PHCEDGCNT[15:0]	Edge Count Setting in Phase Counting Mode	Set the number of output edges for the next carrier period.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register sets the number of output edges for the next carrier period in phase counting mode.

PHCEDGCNT[15:0] Bits (Edge Count Setting in Phase Counting Mode)

Set the number of output edges for the next carrier period.
For reverse rotation, set a negative value by using the two's-complement format. The range of settable values is from – PHCPERIOD[15:0] bits to PHCPERIOD[15:0] bits.

If the automatic clear mode is disabled (PHCCTLR.PHCECACMD bit = 0), the value is retained even when a carrier period event is received. If the automatic clear mode is enabled (PHCCTLR.PHCECACMD bit = 1), the value is set to 0000h when a carrier period event is received.
Writing to these bits causes the status flag corresponding to the edge count setting register (PHCSR.PHCECUS) to be set to 1.

59.2.12 PCIF Phase Counting Mode Position Count Monitor Register (PHCPCMR)

Address(es): PCIF0.PHCPCMR 8782 7030h, PCIF1.PHCPCMR 8782 70B0h,
PCIF0_NS.PHCPCMR 0782 7030h, PCIF1_NS.PHCPCMR 0782 70B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PHCPOSCNTM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	PHCPOSCNTM[15:0]	Position Count Monitor in Phase Counting Mode	Position count monitor in phase counting mode	R
b31 to b16	—	Reserved	These bits are read as 0.	R

This register monitors the position count in phase counting mode.

PHCPOSCNTM[15:0] Bits (Position Count Monitor in Phase Counting Mode)

These bits indicate the current position information in phase counting mode.
The available range is from 0 to the POSMAXR.POSMAX[15:0] bit setting. The value of these bits is not guaranteed in incremental mode.

59.2.13 PCIF Phase Counting Mode Position Counter Write Register (PHCPCWDR)

Address(es): PCIF0.PHCPCWDR 8782 7034h, PCIF1.PHCPCWDR 8782 70B4h,
PCIF0_NS.PHCPCWDR 0782 7034h, PCIF1_NS.PHCPCWDR 0782 70B4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PHCPOSCNTWD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	PHCPOSCNTWD[15:0]	Position Counter Write Data in Phase Counting Mode	Set the current position information.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is the position counter write register in phase counting mode.

PHCPOSCNTWD[15:0] Bits (Position Counter Write Data in Phase Counting Mode)

These bits are used to write data to the position counter in phase counting mode.
The available range is from 0 to the POSMAXR.POSMAX[15:0] bit setting.
The value written to this register is reflected to the PHCPCMR.PHCPOSCNTM[15:0] bits. Writing to these bits during operation causes the status flag corresponding to the position counter write register (PHCSR.PHCPCUS) to be set to 1.
The timing at which the value written to these bits is reflected to the PHCPOSCNTM[15:0] bits varies depending on the PCIF state. If the PCIF is stopped (until the phase counting mode startup processing flow*1), the value written to these bits is immediately reflected to the PHCPOSCNTM[15:0] bits. If the PCIF is operating (during main processing flow*2), the value written to these bits is reflected to the PHCPOSCNTM[15:0] bits when the next carrier period event is generated. For internal fetch timing, refer to Figure 59.16 PHCOENS Flag Waveform.

Note 1. Even during main processing, if the carrier period event generation intervals are extremely long, as shown in Figure 59.20, the input delay might exceed the sum of the PHCPERIOD[15:0] and PHCCEDTH[15:0] bits. In this case, the value written to these bits is immediately reflected to the PHCPOSCNTM[15:0] bits in the same way as when the PCIF is stopped.
Note 2. Once the flow of stop processing has started, writing to these bits after the previous carrier period event is ignored. If necessary, repeat the writing.

59.2.14 PCIF Phase Counting Mode Status Register (PHCSR)

Address(es): PCIF0.PHCSR 8782 7038h, PCIF1.PHCSR 8782 70B8h,
PCIF0_NS.PHCSR 0782 7038h, PCIF1_NS.PHCSR 0782 70B8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	PHCOECUES	PHCIECOES	PHCIECES	PHCCEES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PHCECUS	PHCPCUS	—	—	—	—	—	—	—	PHCOENS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PHCOENS	Output Edge Count Status Flag in Phase Counting Mode	0: The number of edges specified in the PHCECR.PHCEDGCNT[15:0] bits has been output. 1: The number of edges specified in the PHCECR.PHCEDGCNT[15:0] bits is being output.	R
b7 to b1	—	Reserved	These bits are read as 0.	R
b8	PHCPCUS	Position Count Available Status Flag in Phase Counting Mode	0: The current PHCPCWDR.PHCPOSCNTWD[15:0] value has been written to the PHCPCMR.PHCPOSCNTM[15:0] bits (including the state in which writing is not required after a reset and immediate write when PCIF is not operating). 1: Data was written to the PHCPCWDR.PHCPOSCNTWD[15:0] bits during PCIF operation, but was not written to the PHCPCMR.PHCPOSCNTM[15:0] bits.	R
b9	PHCECUS	Edge Count Available Status Flag in Phase Counting Mode	0: The current PHCECR.PHCEDGCNT[15:0] bits have been or are being used for the ABZ-phase output processing. 1: The current PHCECR.PHCEDGCNT[15:0] bits have not been used for the ABZ-phase output processing.	R
b15 to b10	—	Reserved	These bits are read as 0.	R
b16	PHCCEES	Carrier Period Event Error Status Flag in Phase Counting Mode	0: The carrier period event is normal. 1: The carrier period event has an error. This bit is set to 1 when either of the following conditions is met: Carrier period event generation interval < PHCPERIODR.PHCPERIOD[15:0] bits – PHCCEDTHR.PHCCEDTH[15:0] bits, or Carrier period event generation interval > PHCPERIODR.PHCPERIOD[15:0] bits + PHCCEDTHR.PHCCEDTH[15:0] bits	R
b17	PHCIECES	Internal Edge Count Error Status Flag in Phase Counting Mode	0: The number of remaining edges is normal. 1: Error in the number of remaining edges (number of remaining edges > PHCPERIODR.PHCPERIOD[15:0] bits)	R
b18	PHCIECOES	Internal Edge Count Overflow Error Status Flag in Phase Counting Mode	0: The number of remaining edges is normal. 1: Error in the number of remaining edges (overflow)	R
b19	PHCOECUES	Old Edge Count Usage Error Status Flag in Phase Counting Mode	0: Normal PHCECR.PHCEDGCNT[15:0] bits 1: PHCECR.PHCEDGCNT[15:0] bit error (when processing was started with the PHCEDGCNT[15:0] bits not updated)	R
b31 to b20	—	Reserved	These bits are read as 0.	R

This register is a status register in phase counting mode.

For details on each status flag, refer to section 59.3.1.6, States.

59.2.15 PCIF Phase Counting Mode Status Clear Register (PHCSCR)

Address(es): PCIF0.PHCSCR 8782 703Ch, PCIF1.PHCSCR 8782 70BCh, PCIF0_NS.PHCSCR 0782 703Ch, PCIF1_NS.PHCSCR 0782 70BCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	PHCCEESC	Carrier Period Event Error Status Clear in Phase Counting Mode	Writing 1 to this bit clears the PHCSR.PHCCEES flag. This bit is read as 0.	R/W
b17	PHCIECESC	Internal Edge Count Error Status Clear in Phase Counting Mode	Writing 1 to this bit clears the PHCSR.PHCIECES flag. This bit is read as 0.	R/W
b18	PHCIECOESC	Internal Edge Count Overflow Error Status Clear in Phase Counting Mode	Writing 1 to this bit clears the PHCSR.PHCIECOES flag. This bit is read as 0.	R/W
b19	PHCOECUESC	Old Edge Count Usage Error Status Clear in Phase Counting Mode	Writing 1 to this bit clears the PHCSR.PHCOECUES flag. This bit is read as 0.	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is a status clear register in phase counting mode.

59.2.16 PCIF Phase Counting Mode Status Enable Register (PHCSER)

Address(es): PCIF0.PHCSER 8782 7040h, PCIF1.PHCSER 8782 70C0h,
PCIF0_NS.PHCSER 0782 7040h, PCIF1_NS.PHCSER 0782 70C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	PHCOECUESE	PHCIECOESE	PHCIECESE	PHCCEESE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	PHCCEESE	Carrier Period Event Error Status Enable in Phase Counting Mode	0: The PHCSR.PHCCEES flag is disabled (fixed to 0). 1: The PHCSR.PHCCEES flag is enabled.	R/W
b17	PHCIECESE	Internal Edge Count Error Status Enable in Phase Counting Mode	0: The PHCSR.PHCIECES flag is disabled (fixed to 0). 1: The PHCSR.PHCIECES flag is enabled.	R/W
b18	PHCIECOESE	Internal Edge Count Overflow Error Status Enable in Phase Counting Mode	0: The PHCSR.PHCIECOES flag is disabled (fixed to 0). 1: The PHCSR.PHCIECOES flag is enabled.	R/W
b19	PHCOECUESE	Old Edge Count Usage Error Status Enable in Phase Counting Mode	0: The PHCSR.PHCOECUES flag is disabled (fixed to 0). 1: The PHCSR.PHCOECUES flag is enabled.	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register enables or disables the status flags in phase counting mode.
Rewriting this register is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

59.2.17 PCIF Incremental Mode Control Register (INCCTLR)

Address(es): PCIF0.INCCTLR 8782 7050h, PCIF1.INCCTLR 8782 70D0h,

b5, b4	INCZOS[1:0]	Z-Phase Output Synchronous Phase Select in Incremental Mode	b5 b4 0 0: Immediate output 0 1: Synchronized with A-phase (output protocol mode 0 only) 1 0: Synchronized with B-phase (output protocol mode 0 only) 1 1: Synchronized with pulse (output protocol modes 1 and 2 only)	R/W
b15 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	INCZOMIN[7:0]	Z-Phase Output Minimum Cycle Setting in Incremental Mode	00h: 1 cycle 01h: 2 cycles 02h: 3 cycles : : FFh: 256 cycles	R/W
b29 to b24	INCRSL[5:0]	Incremental Mode Resolution Ratio Select	00h: Same size 01h: ×1/2 02h: ×1/3 03h: ×1/4 : : 3Fh: ×1/64	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is a control register in incremental mode.

INCIMD[1:0] Bits (ABZ-Phase Input Mode Select in Incremental Mode)

These bits are used to select the AB-phase input protocol mode.

Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

For details on input protocol modes, refer to section 59.3.2.2, Generating A- and B-Phase Signals, (1) I/O Protocol Change Function.

INCOMD Bit (ABZ-Phase Output Mode Select in Incremental Mode)

This bit selects the AB-phase output protocol mode.

Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

For details on output protocol modes, refer to section 59.3.2.2, Generating A- and B-Phase Signals, (1) I/O Protocol Change Function.

INCZOS[1:0] Bits (Z-Phase Output Synchronous Phase Select in Incremental Mode)

These bits are used to select the phase to be synchronized with Z-phase output.
Setting 11b is prohibited in output protocol mode 0. Setting 01b or 10b is prohibited in output protocol modes 1 and 2.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).
For details on this function, refer to section 59.3.2.3, Generating Z-Phase Signals, (2) Selecting the Z-Phase Output Synchronization Method. Table 59.4 lists the output protocol modes that can be used with the INCZOS[1:0] bits.

Table 59.4 Output Protocol Modes Available with the INCZOS[1:0] Bits

INCIMD[1:0] Bits	INCOMD Bit	Output Protocol Mode	INCZOS[1:0] Bit Settings			
			00b	01b	10b	11b
00b	×	Mode 0	Available	Available	Available	Not available
01b	0	Mode 1	Available	Not available	Not available	Available
01b	1	Mode 0	Available	Available	Available	Not available
10b	0	Mode 2	Available	Not available	Not available	Available
10b	1	Mode 0	Available	Available	Available	Not available

×: Don’t care

INCZOMIN[7:0] Bits (Z-Phase Output Minimum Cycle Setting in Incremental Mode)

These bits are used to set the minimum number of cycles for Z-phase output.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).
For details on this function, refer to section 59.3.2.3, Generating Z-Phase Signals, (3) Setting the Minimum Pulse Width of Z-Phase Output.

INCRSL[5:0] Bits (Incremental Mode Resolution Ratio Select)

These bits are used to select the resolution ratio of the AB(Z)-phase input and AB(Z)-phase output.
For details on this function, refer to section 59.3.2.2, Generating A- and B-Phase Signals, (2) Internal Counter Operation, (b) Resolution Changing Function.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

59.2.18 PCIF Incremental Mode Z-Phase Generation Control Register (INCZGCTLR)

Address(es): PCIF0.INCZGCTLR 8782 7054h, PCIF1.INCZGCTLR 8782 70D4h, PCIF0_NS.INCZGCTLR 0782 7054h, PCIF1_NS.INCZGCTLR 0782 70D4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	INCSWZGE	INCVIZGE	INCPIZGE	INCZIZGE	INCZAGE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	INCZAGE	Incremental Mode Z-Phase Automatic Generation Enable	0: Z-phase generation with the INCPCMR.INCOCNTM[15:0] bits is disabled. 1: Z-phase generation with the INCPCMR.INCOCNTM[15:0] bits is enabled.	R/W
b1	INCZIZGE	Incremental Mode Z-Phase Generation with Z-Phase Input Enable	0: Z-phase generation by using Z-phase input is disabled. 1: Z-phase generation by using Z-phase input is enabled.	R/W
b2	INCPIZGE	Incremental Mode Z-Phase Generation with Crest Event Trigger Input Enable	0: Z-phase generation with crest event trigger input is disabled. 1: Z-phase generation with crest event trigger input is enabled.	R/W
b3	INCVIZGE	Incremental Mode Z-Phase Generation with Trough Event Trigger Input Enable	0: Z-phase generation with trough event trigger input is disabled. 1: Z-phase generation with trough event trigger input is enabled.	R/W
b4	INCSWZGE	Incremental Mode Z-Phase Generation with Software Trigger Enable	0: Z-phase generation with software trigger is disabled. 1: Z-phase generation with software trigger is enabled.	R/W
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is a control register for Z-phase generation in incremental mode.

INCZAGE Bit (Incremental Mode Z-Phase Automatic Generation Enable)

This is the enable bit for Z-phase automatic generation with the internal counter INCOCNTM[15:0] bits.

Setting 1 is prohibited when the INCZIZGE bit = 1.

When the INCOCNTM[15:0] bit setting is equal to the POSMAX[15:0] bit setting, the INCOCNTM[15:0] bits are automatically set to 0000h.

Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

INCZIZGE Bit (Incremental Mode Z-Phase Generation with Z-Phase Input Enable)

This is the enable bit for Z-phase generation by using Z-phase input.

Setting 1 is prohibited when the INCZAGE bit = 1.

Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

INCPIZGE Bit (Incremental Mode Z-Phase Generation with Crest Event Trigger Input Enable)

This is the enable bit for Z-phase generation with crest event trigger input.

Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

INCVIZGE Bit (Incremental Mode Z-Phase Generation with Trough Event Trigger Input Enable)

This is the enable bit for Z-phase generation with trough event trigger input.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

INCSWZGE Bit (Incremental Mode Z-Phase Generation with Software Trigger Enable)

This is the enable bit for Z-phase generation with a software trigger.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

59.2.19 PCIF Incremental Mode Position Counter Clear Enable Register (INCPCCER)

Address(es): PCIF0.INCPCCER 8782 7058h, PCIF1.INCPCCER 8782 70D8h, PCIF0_NS.INCPCCER 0782 7058h, PCIF1_NS.INCPCCER 0782 70D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	INCSW CLRE	INCVIC LRE	INCPIC LRE	INCZIC LRE	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	INCZICLRE	Incremental Mode Z-Phase Input Position Counter Clear Enable	0: The counter is not cleared. 1: The counter is cleared.	R/W
b2	INCPICLRE	Incremental Mode Crest Event Trigger Input Position Counter Clear Enable	0: The counter is not cleared. 1: The counter is cleared.	R/W
b3	INCVICLRE	Incremental Mode Trough Event Trigger Input Position Counter Clear Enable	0: The counter is not cleared. 1: The counter is cleared.	R/W
b4	INCSWCLRE	Incremental Mode Software Trigger Position Counter Clear Enable	0: The counter is not cleared. 1: The counter is cleared.	R/W
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register clears the position counter (INCPCMR.INCOCNTM[15:0] bits) in incremental mode.

INCZICLRE Bit (Incremental Mode Z-Phase Input Position Counter Clear Enable)

This bit clears the INCOCNTM[15:0] bits with Z-phase input. Setting 1 is prohibited when the INCZGCTLR.INCZAGE bit = 1. Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

INCPICLRE Bit (Incremental Mode Crest Event Trigger Input Position Counter Clear Enable)

This bit clears the INCOCNTM[15:0] bits with crest event trigger input.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

INCVICLRE Bit (Incremental Mode Trough Event Trigger Input Position Counter Clear Enable)

This bit clears the INCOCNTM[15:0] bits with trough event trigger input.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

INCSWCLRE Bit (Incremental Mode Software Trigger Position Counter Clear Enable)

This bit clears the INCOCNTM[15:0] bits with a software trigger.
Rewriting is prohibited when the PCIF is in operation (SR.PCIFPS flag = 1).

59.2.20 PCIF Incremental Mode Software Trigger Register (INCSWTRGR)

Address(es): PCIF0.INCSWTRGR 8782 705Ch, PCIF1.INCSWTRGR 8782 70DCh, PCIF0_NS.INCSWTRGR 0782 705Ch, PCIF1_NS.INCSWTRGR 0782 70DCh

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	INCOCNTM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	INCOCNTM[15:0]	Incremental Mode Output Position Counter Monitor	Monitor bits of the output counter	R
b23 to b16	—	Reserved	These bits are read as 0.	R
b29 to b24	INCICNTM[5:0]	Incremental Mode Input Position Counter Monitor	Monitor bits of the input counter	R
b30	—	Reserved	This bit is read as 0.	R
b31	INCROTM	Incremental Mode Rotation Direction Monitor	0: Forward direction (clockwise (CW)) 1: Reverse direction (counterclockwise (CCW))	R

This register monitors the I/O counters and rotation direction in incremental mode.

INCOCNTM[15:0] Bits (Incremental Mode Output Position Counter Monitor)

These are monitor bits of the output counter.

A- and B-phase signals are output based on the 2 lower-order bits of this register. The counter is incremented when the INCICNTM[5:0] setting changes from the maximum value (INCCTLR.INCRSL[5:0] bits) to 0, and is decremented when the INCICNTM[5:0] setting changes from 0 to the maximum value (INCRSL[5:0] bits).

Operation of these bits is not guaranteed in phase counting mode.

INCICNTM[5:0] Bits (Incremental Mode Input Position Counter Monitor)

These are monitor bits of the input counter.

The INCOCNTM[15:0] bit value is incremented and decremented based on this register and the resolution is changed.

Position information for the AB(Z)-phase input can be obtained with the following formula.

Position information for AB(Z)-phase input = INCOCNTM[15:0] bits × (INCRSL[5:0] bits + 1) + INCICNTM[5:0] bits

INCROTM Bit (Incremental Mode Rotation Direction Monitor)

This monitor bit indicates the current rotation direction.

Operation of this bit is not guaranteed in phase counting mode.

59.2.22 PCIF Software Reset Register (SWRSTR)

Address(es): PCIF0.SWRSTR 8782 7070h, PCIF1.SWRSTR 8782 70F0h, PCIF0_NS.SWRSTR 0782 7070h, PCIF1_NS.SWRSTR 0782 70F0h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SWRST	Software Reset	0: Releases the registers from the software reset state. 1: Applies a software reset to the registers.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register performs a software reset.

SWRST Bit (Software Reset)

This bit applies a software reset to registers that operate with the frequency-divided clock (CCLK_DIV). Table 59.5 lists the registers that can be cleared by a software reset.

Table 59.5 Registers That Can be Cleared by Software Reset

Register Name	Bit Name	Clearing by Software Reset	Value following a Software Reset
CLKSR	CLKS	Not applicable	The previous value is retained.
SR	PCIFPS	Applicable	0
PHCECR	PHCEDGCNT[15:0]	Applicable	0000h
PHCPCMR	PHCPOSCNTM[15:0]	Applicable	0000h
PHCPCWDR	PHCPOSCNTWD[15:0]	Applicable	0000h
PHCSR	PHCOENS	Applicable	0
	PHCPCUS	Applicable	0
	PHCECUS	Applicable	0
	PHCCEES	Not applicable	The previous value is retained.
	PHCIECES	Not applicable	The previous value is retained.
	PHCIECOES	Not applicable	The previous value is retained.
	PHCOECUES	Not applicable	The previous value is retained.
INCPCMR	INCOCNTM[15:0]	Applicable	0000h
	INCICNTM[5:0]	Applicable	00h
	INCROTM	Applicable	0
Other than above	—	Not applicable	The previous value is retained.

59.3 Operation

59.3.1 Phase Counting Mode

When the CTLR.PCIFMD bit is set to 0, the PCIF operates in phase counting mode.
In phase counting mode, ABZ-phase signals are output according to the register settings from the CPU that obtained the motor position information.
In this mode, A-, B-, and Z-phase signals are generated by using two types of information: a carrier period event and the edge count setting register (PHCECR.PHCEDGCNT[15:0] bits).
A carrier period event is a signal that is asserted at the unit time interval for measuring the number of edges. The PHCEDGCNT[15:0] bits indicate the number of edges in the AB-phase inputs generated by rotating the motor during the interval between the carrier period events.
If a carrier period event is generated after setting the PHCEDGCNT[15:0] bits, counting is performed at regular intervals until the value of the position counter (PHCPCMR.PHCPOSCNTM[15:0] bits) reaches the value of (*2) in the following expression after PHCPERIODR.PHCPERIOD[15:0] × CCLK_DIV cycles.
Figure 59.4 shows details of the values of (*1) to (*3) in the following expression. For details, refer to section 59.3.1.4, Position Counter Control.

PHCPOSCNTM[15:0] bits (*2) = PHCPOSCNTM[15:0] bits (*1) + PHCEDGCNT[15:0] bits (*3)

Figure 59.4 shows the basic operation waveforms in phase counting mode.

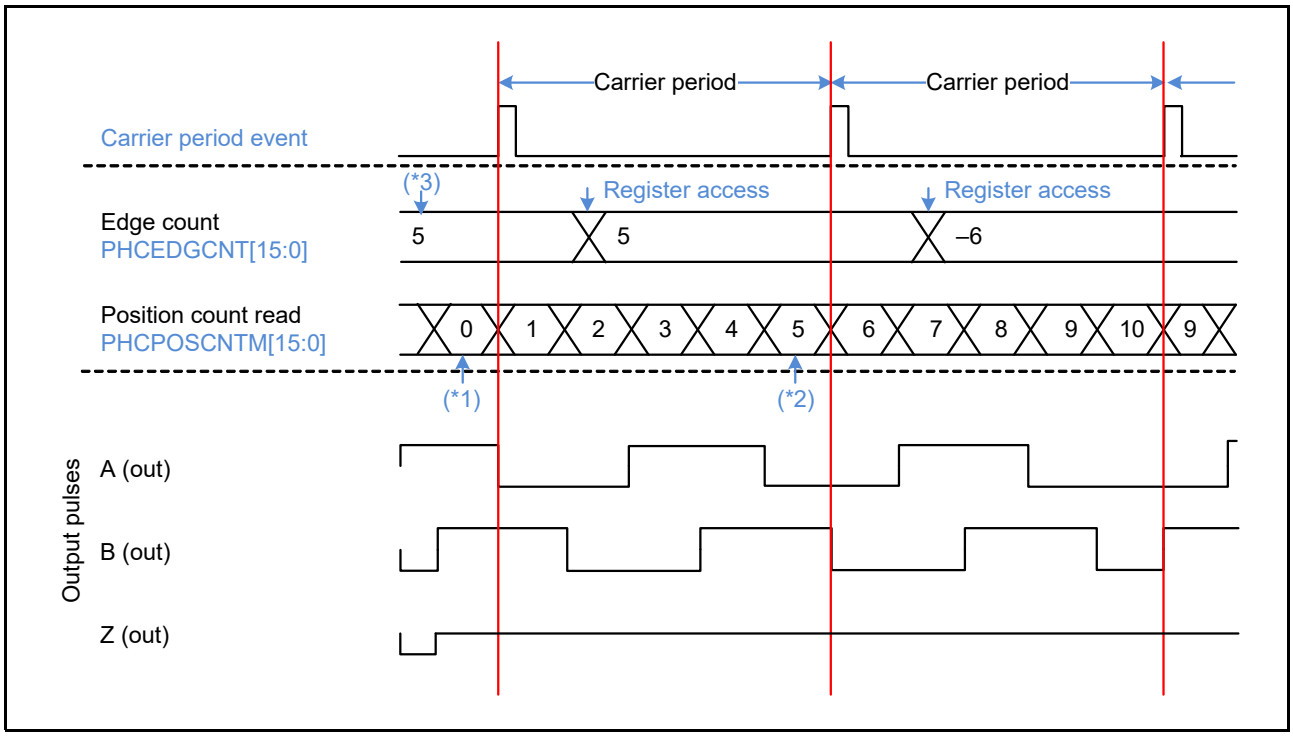

Figure 59.4 Basic Operation Waveforms in Phase Counting Mode

59.3.1.1 Startup Control

The phase counting mode is started by using the TRGR.PCIFSTRT bit. When the CTLR.PCIFMD bit = 0, setting the PCIFSTRT bit to 1 starts the phase counting mode and sets the SR.PCIFPS flag to 1. When the phase counting mode is started, A-, B-, and Z -phase signals are output in accordance with the position counter (PHCPCMR.PHCPOSCNTM[15:0] bits). When a carrier period event is generated, the position counter operates and then the ABZ-phase outputs change according to the counter value.
For details on the startup processing flow, refer to section 59.3.4.3, Flows of Phase Counting Mode.

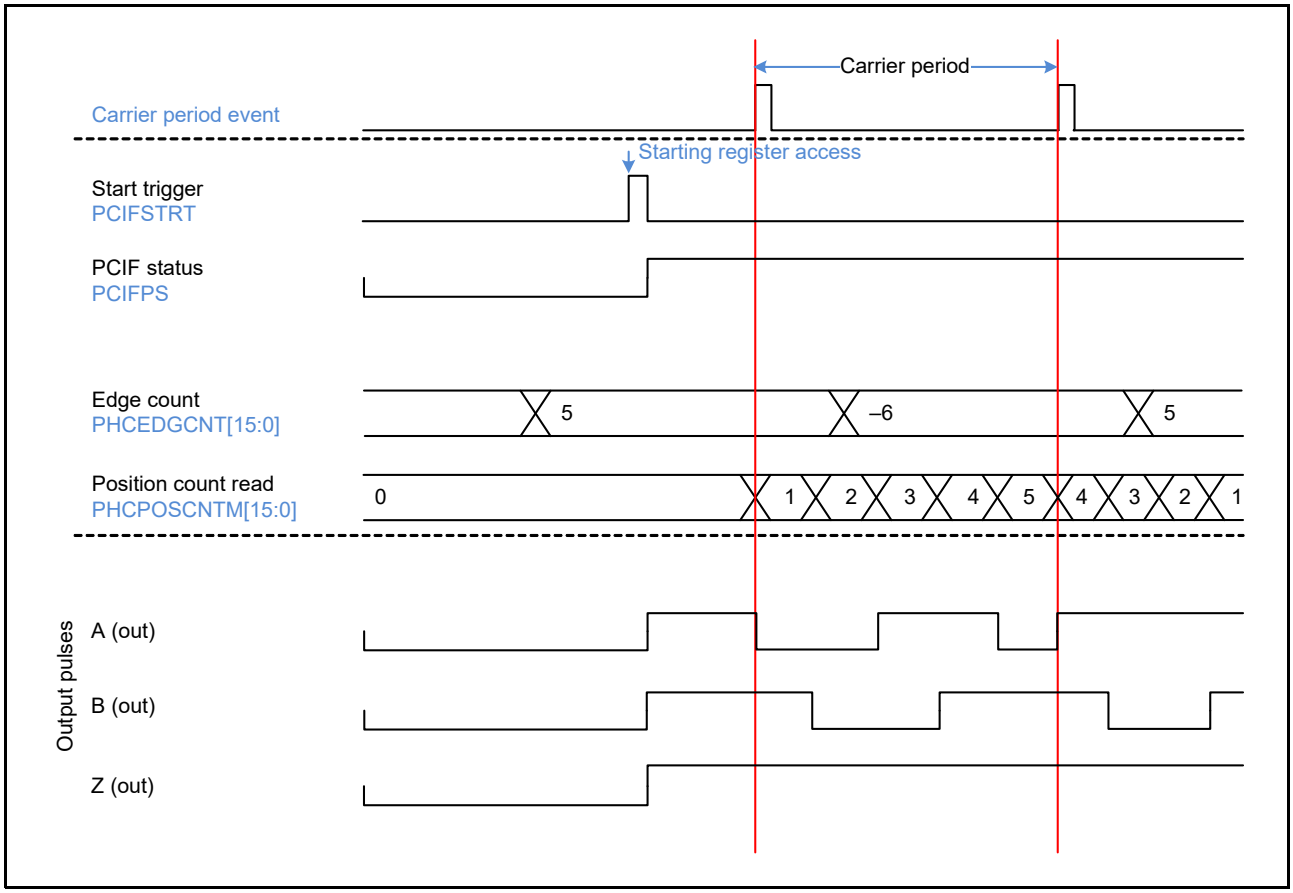

Figure 59.5 Startup Waveforms in Phase Counting Mode

59.3.1.2 Stop Control

The phase counting mode can be stopped in two ways. One way uses the immediate stop function with the TRGR.PCIFSTPT bit. The other way uses the carrier period-synchronized stop function with the TRGR.PHCSTPT bit. The following explains stop control. For details on the stop processing flow, refer to section 59.3.4.3, Flows of Phase Counting Mode.

(1) Immediate Stop Function

If the PCIFSTPT bit is set to 0 in phase counting mode, the SR.PCIFPS flag is set to 0 and ABZ-phase outputs stop irrespective of the current processing.

Figure 59.6 shows the operation waveforms at the time of immediate stop.

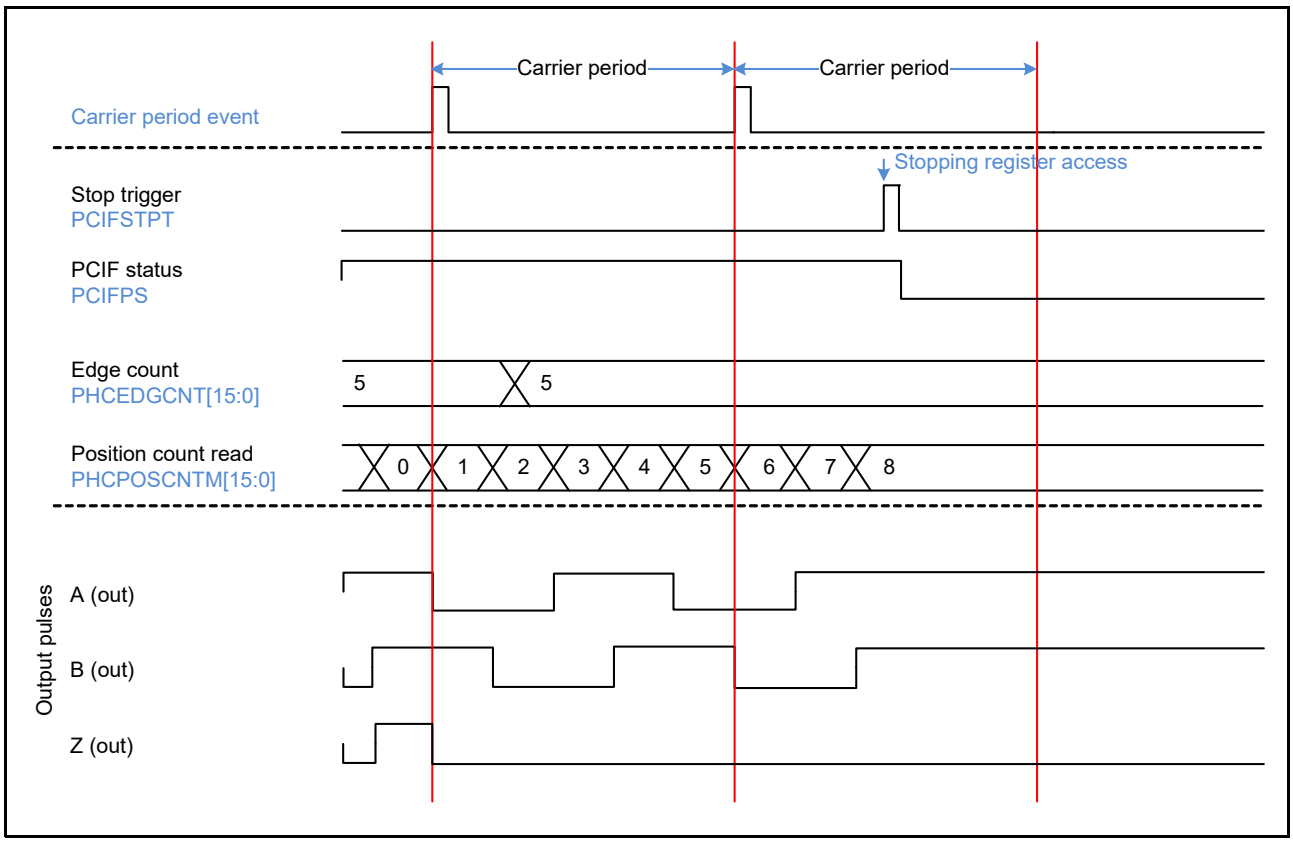

Figure 59.6 Operation Waveforms at Immediate Stop of Phase Counting Mode

(2) Carrier Period-Synchronized Stop Function

If the TRGR.PHCSTPT bit is set to 1 in phase counting mode, the SR.PCIFPS flag is set to 0 and ABZ-phase outputs stop after the current edge count operation ends. For details on how to calculate the total number of edges, refer to section 59.3.1.3, Carrier Period Control, (1) Event-Based Mode.

Figure 59.7 shows the operation waveforms of the carrier period-synchronized stop function.

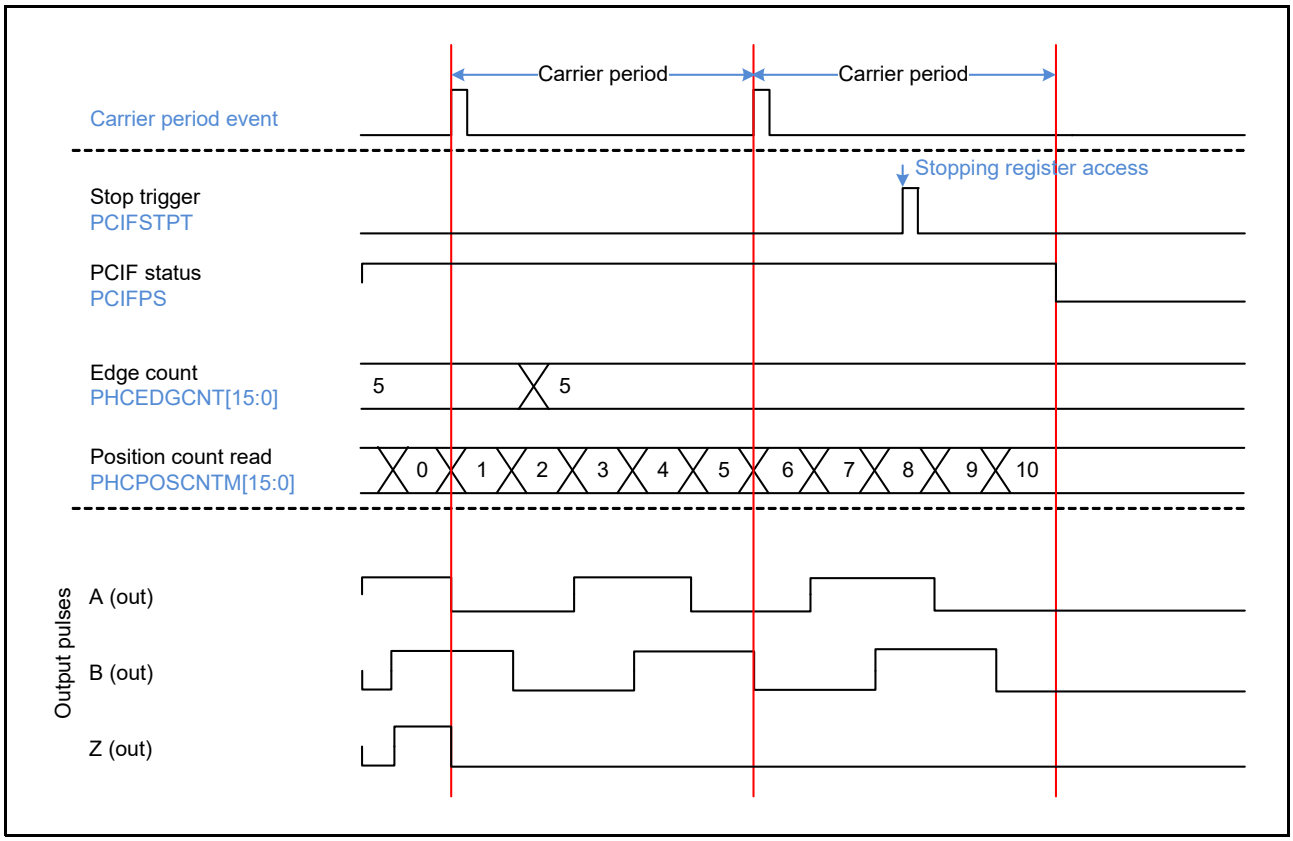

Figure 59.7 Operation Waveforms of the Carrier Period-Synchronized Stop Function in Phase Counting Mode

59.3.1.3 Carrier Period Control

The carrier period is determined by the interval at which a carrier period event is generated.
There are two methods of controlling the carrier periods: event-based mode that uses input pins as carrier period events, and register-based mode that uses register settings. These modes can be switched by using the PHCCTLR.PHCCEDAMD bit.

(1) Event-Based Mode

Setting the PHCCEDAMD bit to 0 sets event-based mode.
In event-based mode, the edge count set in the PHCECR.PHCEDGCNT[15:0] bits is processed within the carrier period set in the PHCPERIODR.PHCPERIOD[15:0] bits from the time of notification of a carrier period input by the ELC.
Figure 59.8 shows the operation waveforms in event-based mode.

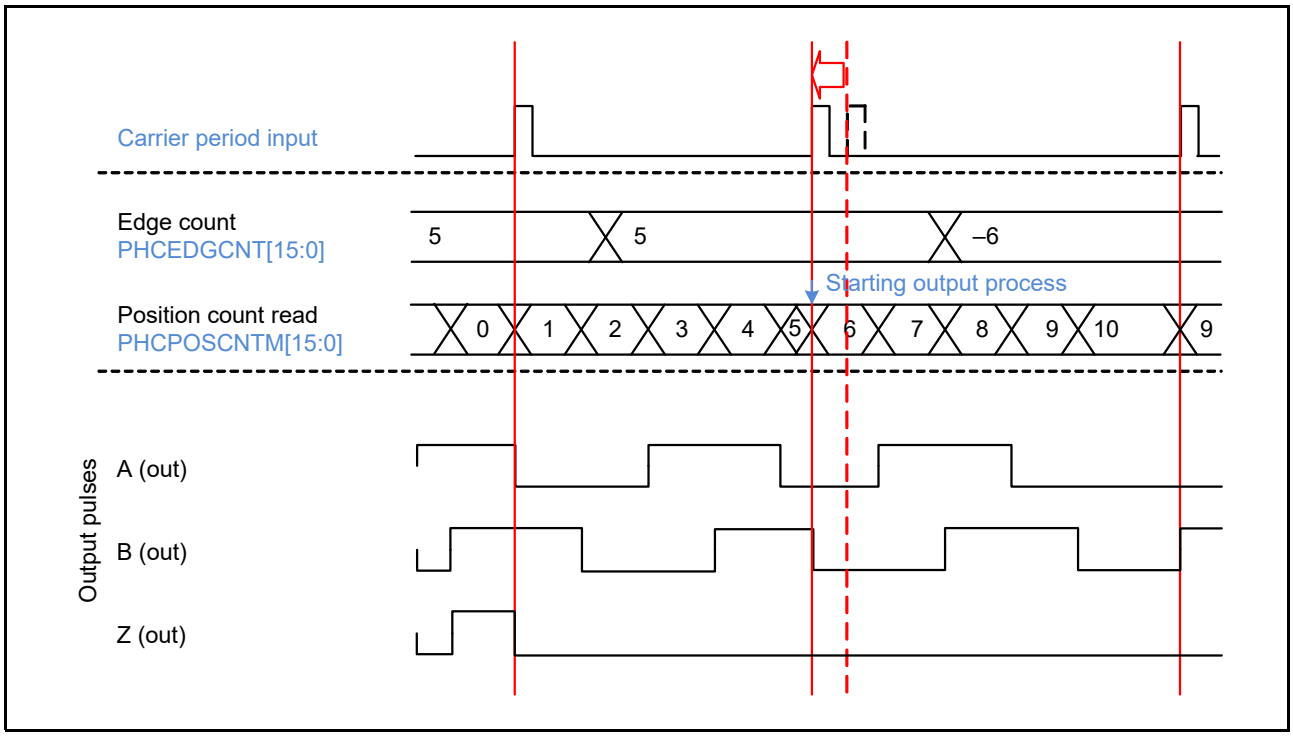

Figure 59.8 Operation Waveforms in Event-Based Mode

If the next carrier period event is received before completion of edge count output set in the PHCECR.PHCEDGCNT[15:0] bits, the current processing is suspended. Then, the next processing is performed with the total edge count calculated from the following expression.

Total edge count = current PHCEDGCNT[15:0] bits + number of unprocessed edges when processing was suspended

Each parameter has a sign indicating the rotation direction. There might be cases in which the rotation direction differs before and after suspension. In such cases, ABZ-phase signals are output for the difference obtained by the above expression. For example, if the number of unprocessed edges when processing was suspended is +2 and the current PHCEDGCNT[15:0] bits value is –5, the total edge count is –3. As a result, 3 edges in reverse direction will be generated.
Figure 59.9 shows the waveforms when the next carrier period event is received before completion of edge count output.

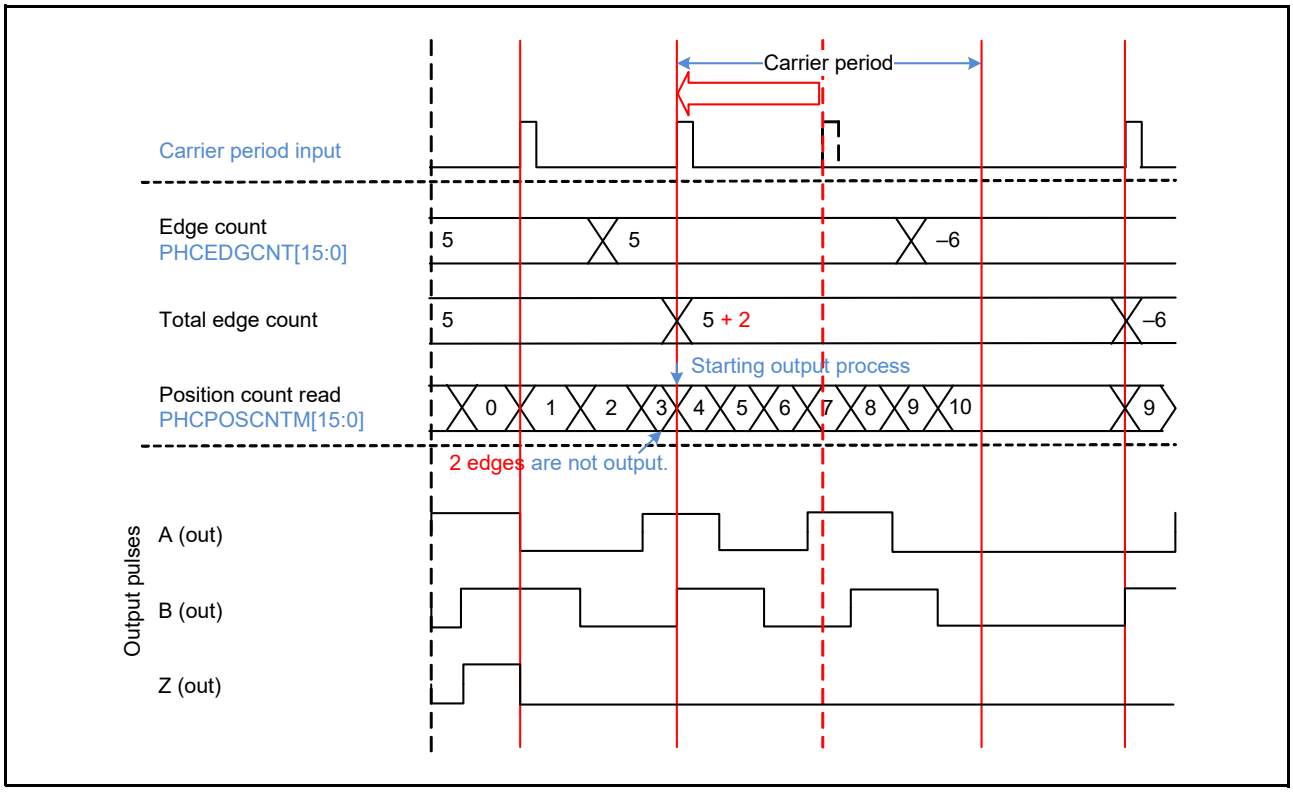

Figure 59.9 Event-Based Mode Waveforms 1 (When the Next Carrier Period Event is Received before Completion of Edge Count Output)

If a carrier period input is delayed, processing stops until a notification of the next carrier period input. Figure 59.10 shows the waveforms in event-based mode when a carrier period input is delayed.

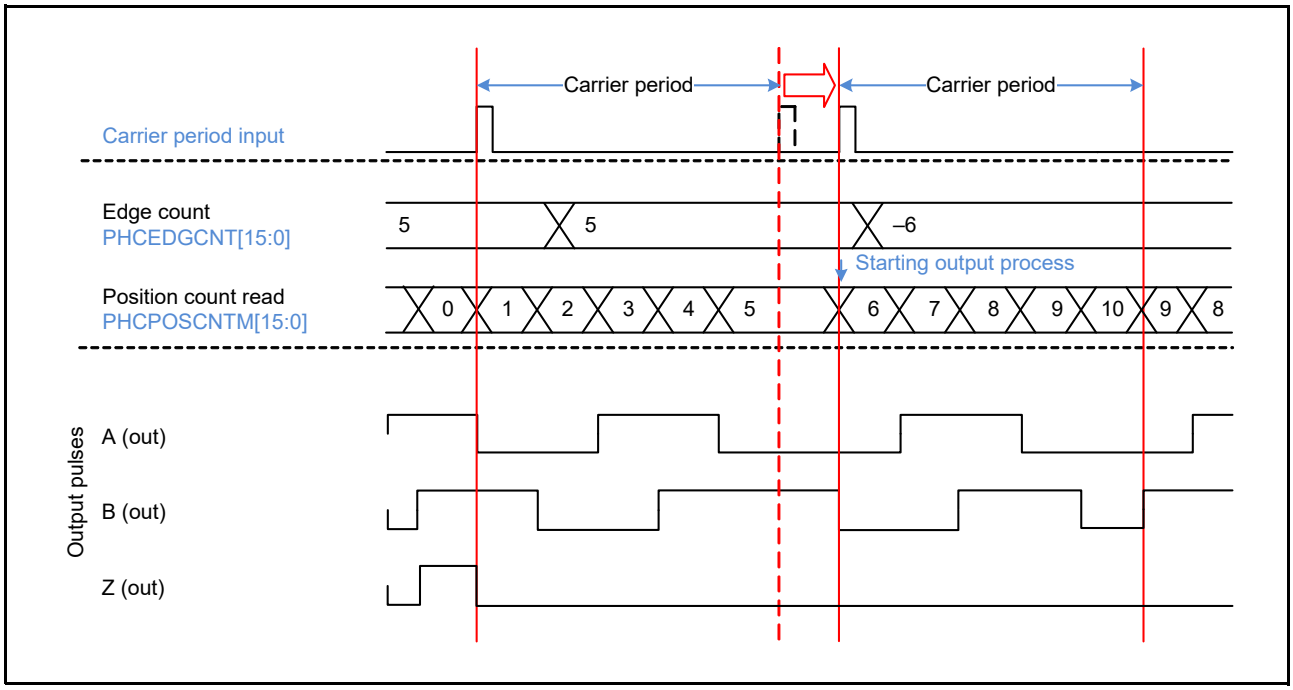

Figure 59.10 Event-Based Mode Waveforms 2 (When a Carrier Period Input is Delayed)

(2) Register-Based Mode

Setting the PHCCTLR.PHCCEDAMD bit to 1 sets the register-based mode.
In register-based mode, carrier period input is not used. Instead, the edge count set in the PHCECR.PHCEDGCNT[15:0] bits is processed at the carrier period intervals set in the PHCPERIODR.PHCPERIOD[15:0] bits. Measurement of the carrier period starts when the PCIF operation is started by setting the TRGR.PCIFSTRT bit to 1 in booting of the PCIF.
Figure 59.11 shows the waveforms in register-based mode.

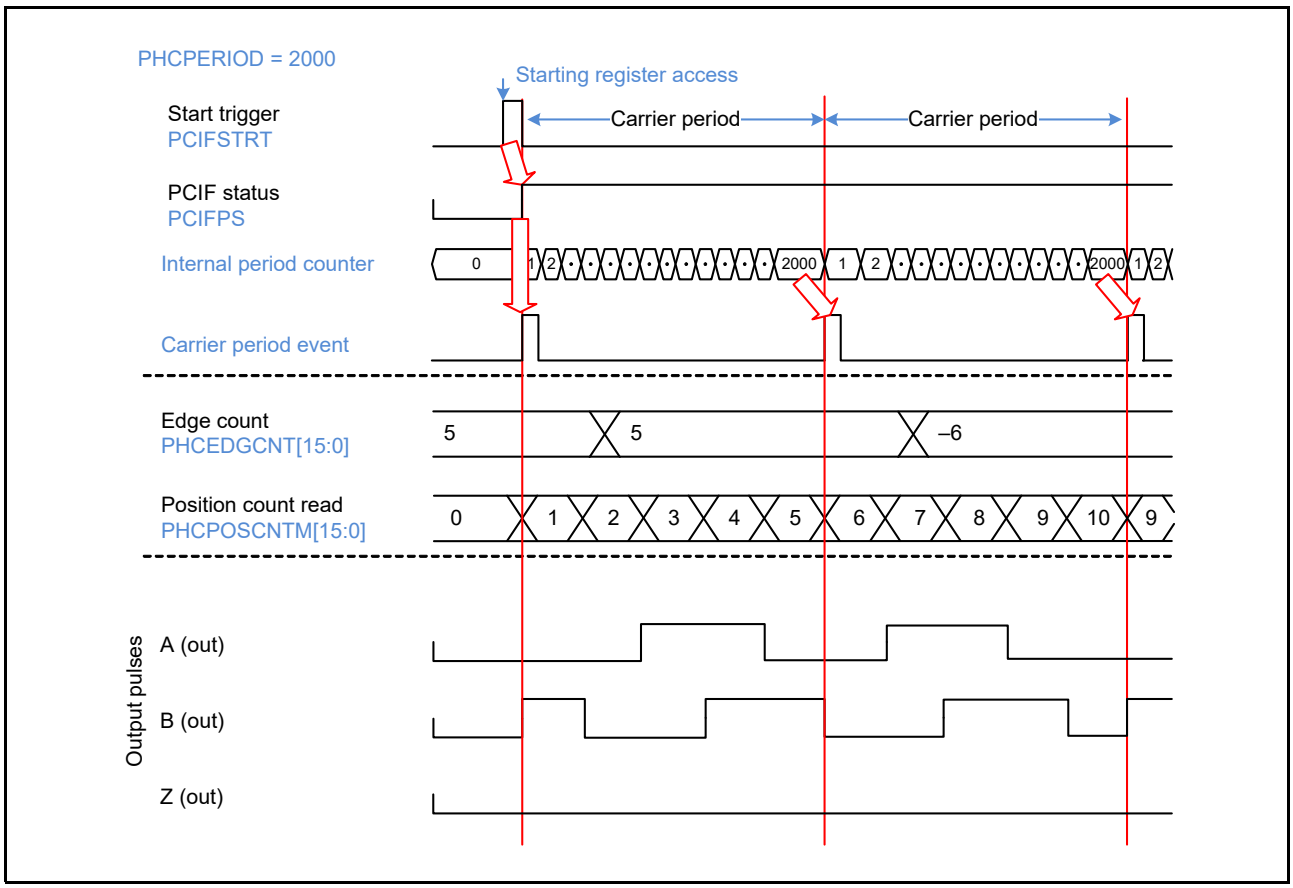

Figure 59.11 Register-Based Mode Waveforms

59.3.1.4 Position Counter Control

(1) Edge Processing for Carrier Periods

The following describes the position counter (PHCPCMR.PHCPOSCNTM[15:0] bits) and how to output the edge count set in the PHCECR.PHCEDGCNT[15:0] bits.

For each carrier period, the total edge count (X) calculated from the PHCEDGCNT[15:0] bits (as described in section 59.3.1.3, Carrier Period Control) is processed. When a carrier period event is generated, the position counter (PHCPOSCNTM[15:0] bits) starts counting. The counting is performed at regular intervals until the position counter (PHCPOSCNTM[15:0] bits) reaches “PHCPOSCNTM[15:0] setting + X” by the carrier period set in the PHCPERIODR.PHCPERIOD[15:0] bits. The position count change intervals (edge intervals) change at (PHCPERIOD[15:0] bits/X) cycles. The fractional parts of the change intervals are distributed to each edge interval to adjust the position counter. The adjusted position counter is used to output the corresponding AB-phase signals.

Figure 59.12 shows the total edge count X and the A-phase and B-phase output change timing for forward rotation (X > 0). Figure 59.13 shows the total edge count X and the A-phase and B-phase output change timing for reverse rotation (X < 0).

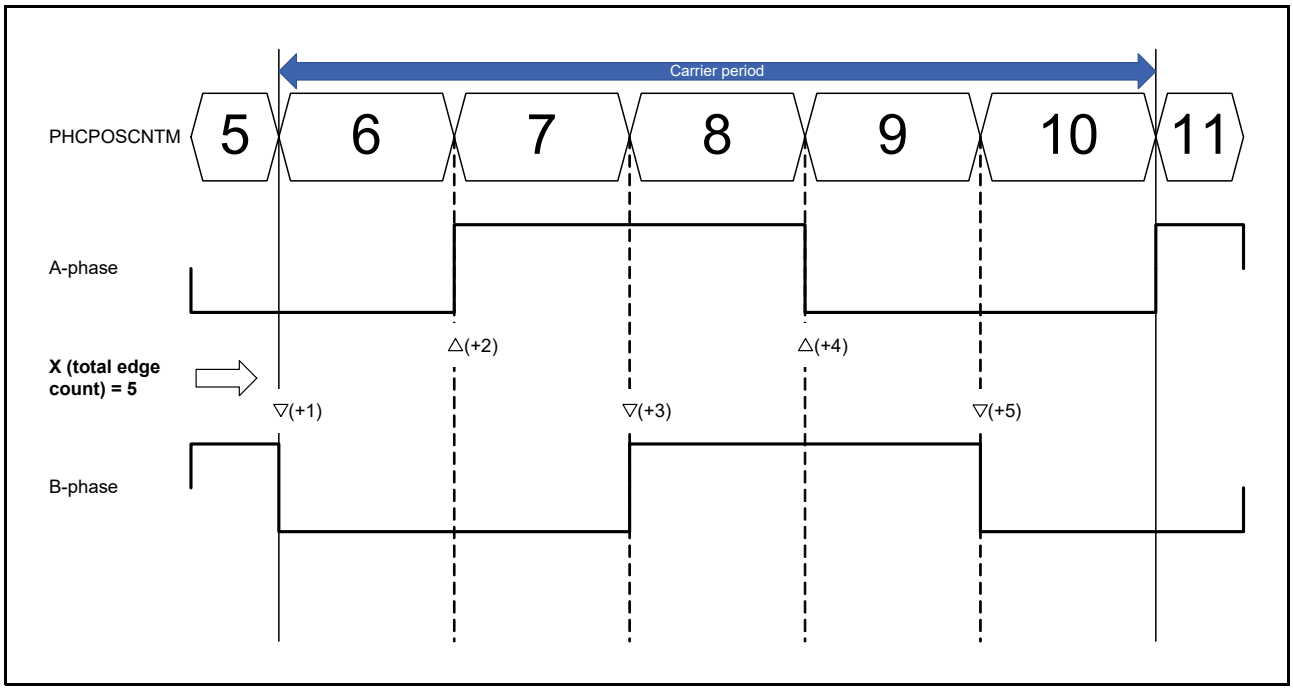

Figure 59.12 AB-Phase Outputs after Setting the PHCEDGCNT[15:0] Bits (Forward Rotation)

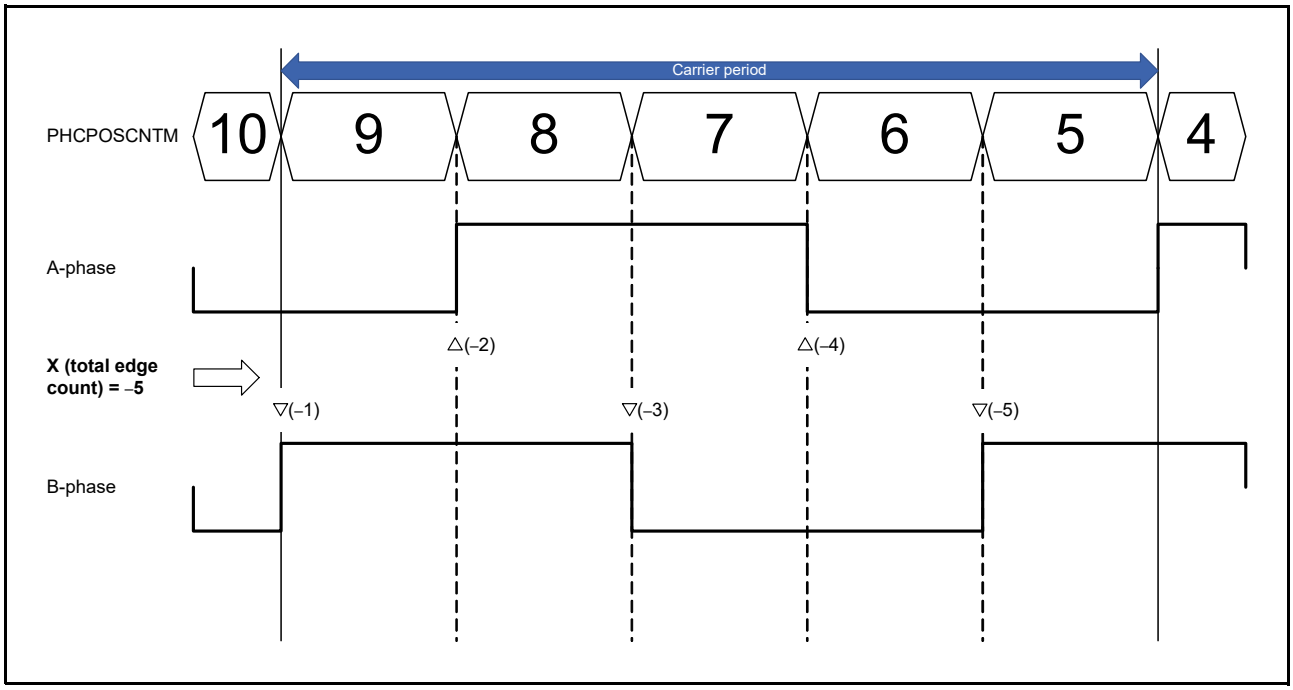

Figure 59.13 AB-Phase Outputs after Setting the PHCEDGCNT[15:0] Bits (Reverse Rotation)

(2) Automatic Edge Count Clearing Function

The automatic edge count clearing function automatically clears the PHCECR.PHCEDGCNT[15:0] bits when a carrier period event is generated. When this function is enabled, if the next carrier period event is generated without updating the PHCEDGCNT[15:0] bits, ABZ-phase outputs stop because processing is performed with the value after clearing (PHCEDGCNT[15:0] bits = 0000h). This function is enabled by setting the PHCCTLR.PHCECACMD bit to 1. Figure 59.14 shows the waveforms of the automatic edge count clearing function.

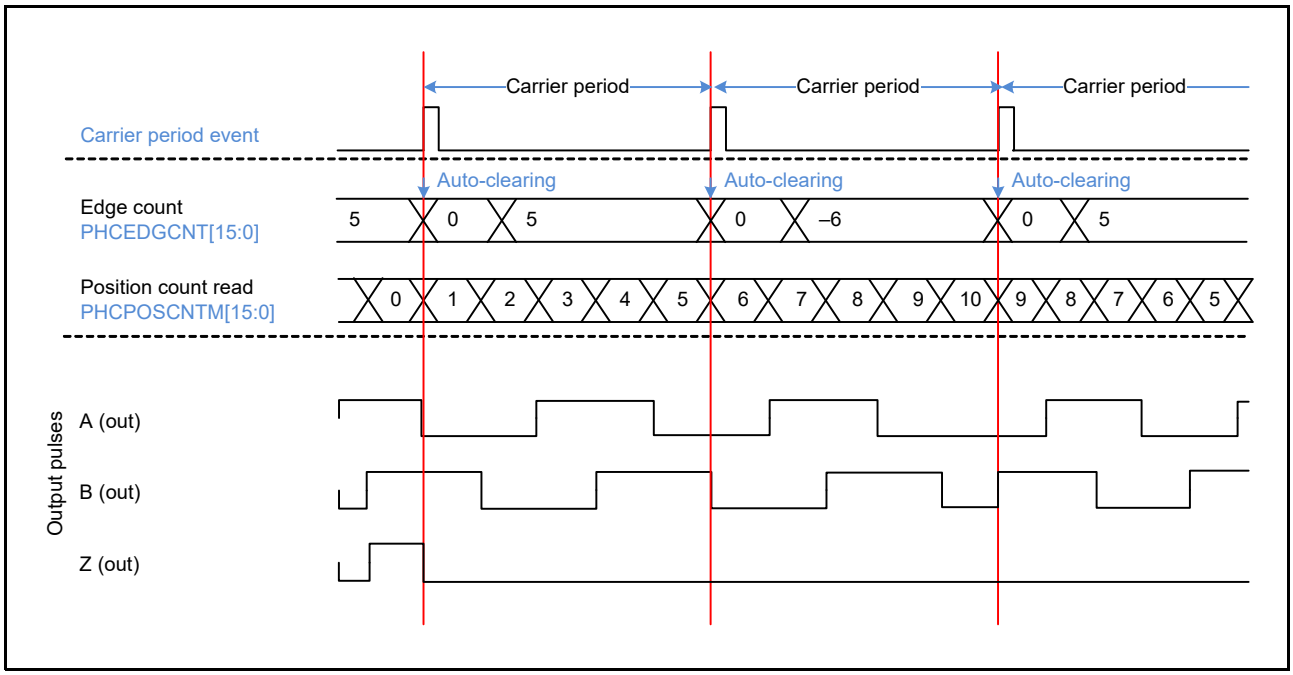

Figure 59.14 Waveforms of the Automatic Edge Count Clearing Function

59.3.1.5 Generating A-, B-, and Z-Phase Signals

A-phase and B-phase signals are uniquely output according to the register settings and the two lower-order bits of the position counter (PHCPCMR.PHCPOSCNTM[1:0] bits). For negative phase output, set the CTLR.APOL and BPOL bits to 1.

Table 59.6 shows the A- and B-phase output patterns.

Table 59.6 A- and B-Phase Output Patterns in Phase Counting Mode

PHCPOSCNTM[1:0] Bits	00b	01b	10b	11b
A-phase output (APOL bit = 0: Positive phase)	1	0	0	1
A-phase output (APOL bit = 1: Negative phase)	0	1	1	0
B-phase output (BPOL bit = 0: Positive phase)	1	1	0	0
B-phase output (BPOL bit = 1: Negative phase)	0	0	1	1

Figure 59.15 shows the correspondence between the PHCPOSCNTM[15:0] bit value and the ABZ-phase output waveforms.

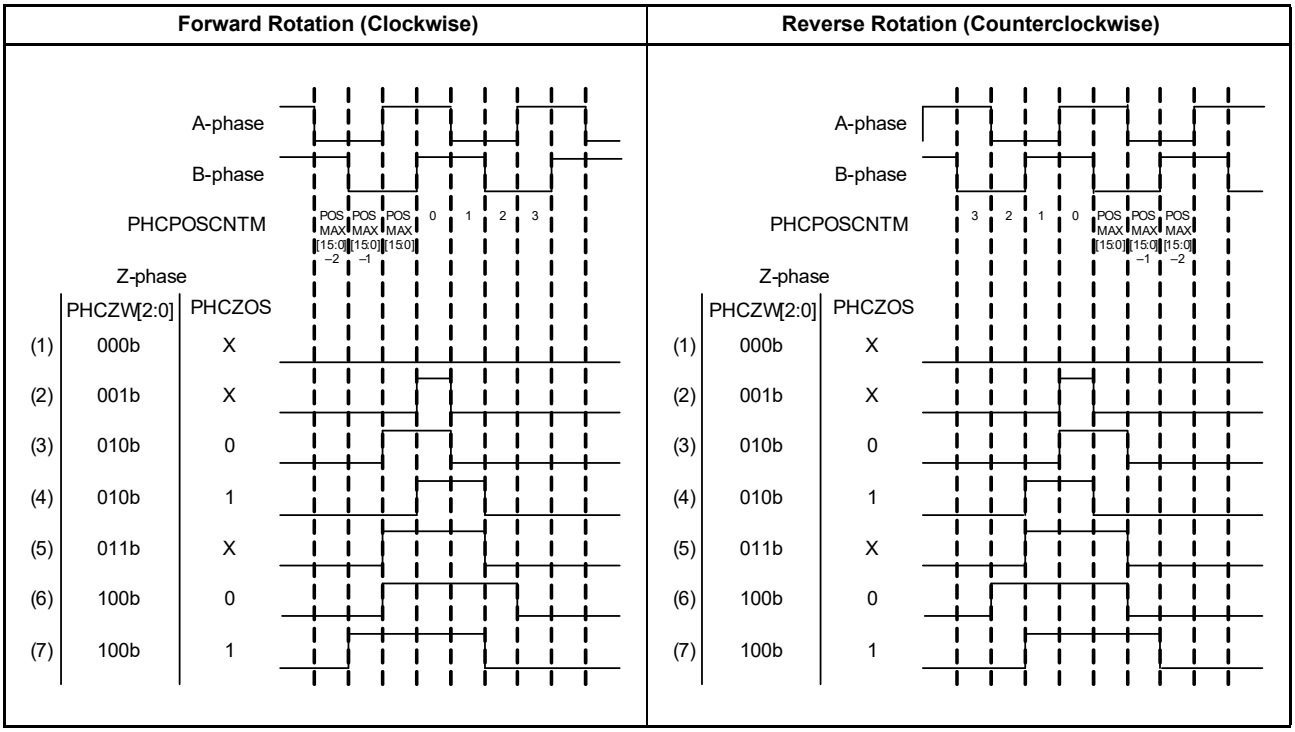

Figure 59.15 ABZ-Phase Output Waveforms in Phase Counting Mode

59.3.1.6 States

(1) Normal Operation

The phase counting mode has three types of status flags.

- Output Edge Count Status Flag in Phase Counting Mode (PHCOENS)
  This status flag indicates whether any edges have not been output yet.

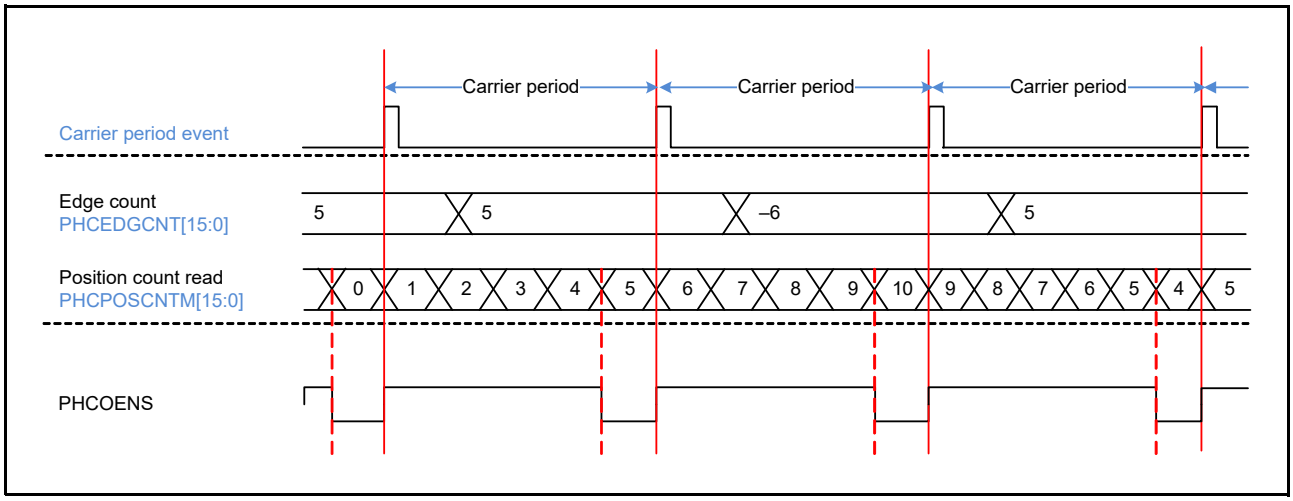

Figure 59.16 PHCOENS Flag Waveform

- Position Count Available Status Flag in Phase Counting Mode (PHCPCUS)
  The PHCSR.PHCPCUS flag indicates that the values written to the PHCPCWDR.PHCPOSCNTWD[15:0] bits have not been reflected to the PHCPCMR.PHCPOSCNTM[15:0] bits.
  When the PCIF is not operating (other than the main processing flow), this flag always indicates 0 because the value written to the PHCPOSCNTWD[15:0] bits is immediately reflected to the PHCPOSCNTM[15:0] bits. When the PCIF is operating (in the main processing flow), this flag is set by writing to the PHCPOSCNTWD[15:0] bits, and is cleared when a carrier period event is generated.

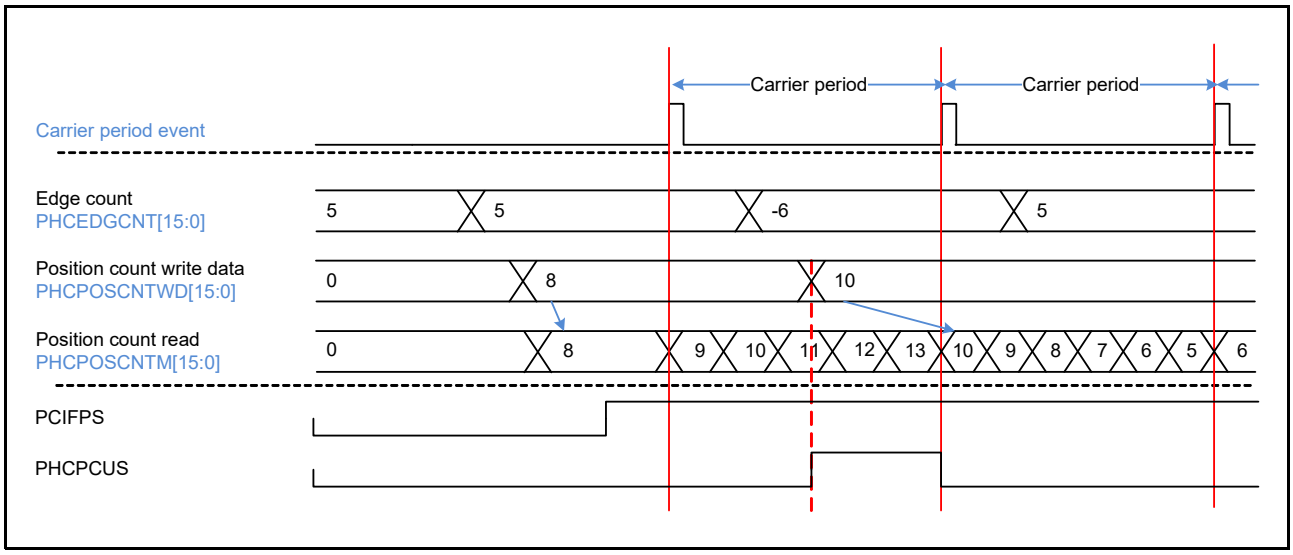

Figure 59.17 PHCPCUS Flag Waveform

Note: If the PCIF is stopped (PCIFPS flag = 0) when the PHCPCUS flag is 1, the PHCPCUS flag is set to 0.

- Edge Count Available Status Flag in Phase Counting Mode (PHCECUS)
  The PHCSR.PHCECUS flag indicates the period over which the value written to the PHCECR.PHCEDGCNT[15:0] bits is held pending until it is used for ABZ-phase output.
  This flag is set by writing to the PHCEDGCNT[15:0] bits, and is cleared when a carrier period event is generated.

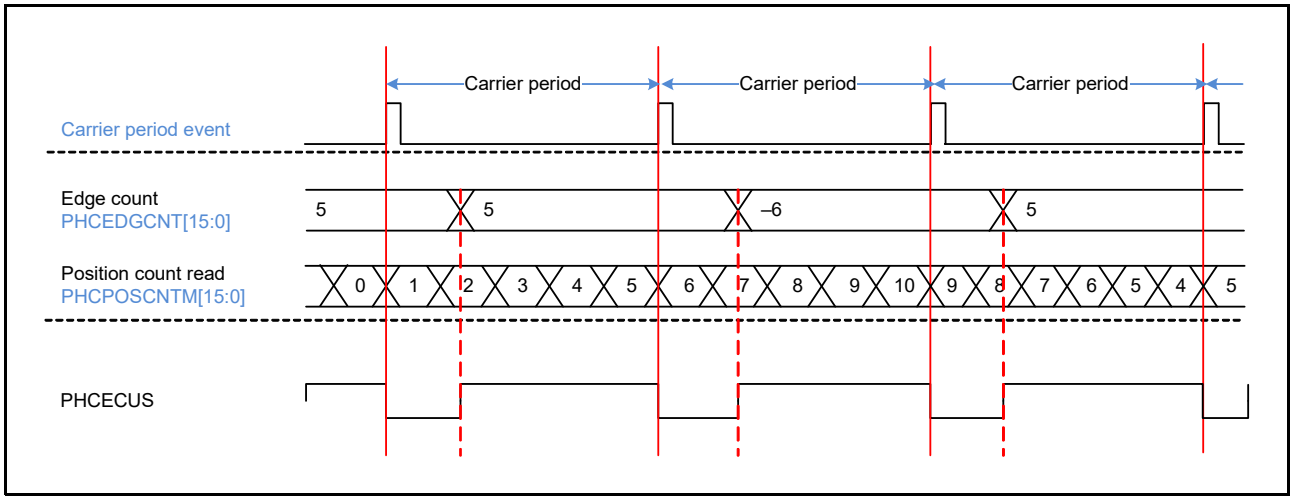

Figure 59.18 PHCECUS Flag Waveform

Note: If the PCIF is stopped (PCIFPS flag = 0) when the PHCECUS flag is 1, the PHCECUS flag is retained as 1.

(2) Error Operations

The phase counting mode has four types of error status flags.

Table 59.7 shows the error determination timings of each of the error status flags and the processing to be performed if an error occurs.

If an error indicated in this section has occurred, operation is not guaranteed. Apply a software reset to clear the error states, and then confirm the register settings.

Table 59.7 Processing When an Error Occurs

Error Status Flag	Error Determination Timing	Processing When Error Occurs
PHCCEES	A carrier period event is generated at an interval shorter than the number of cycles obtained by "PHCPERIOD[15:0] setting – PHCCEDTH[15:0] setting" since the last carrier period event.	The carrier period event is not accepted and processing resumes from the next carrier period event.
	The number of cycles obtained by "PHCPERIOD[15:0] setting + PHCCEDTH[15:0] setting" has elapsed before a carrier period event is input.	Processing resumes from the delayed carrier period event.
PHCIECES	A carrier period event is generated.	Unprocessed edges are taken over to the next carrier period event.
PHCIECOES	A carrier period event is generated.	Edges for the overflow are lost and processing is performed with the maximum value.
PHCOECUES	A carrier period event is generated.	—

Note: Setting the error status flags is delayed relative to the error determination timings.

- Carrier Period Event Error Status Flag in Phase Counting Mode (PHCCEES)
  The PHCSR.PHCCEES flag indicates that the interval at which carrier period events are generated is extremely long or short. This flag is set when the absolute value of the difference between the carrier period event interval and the carrier period (PHCPERIODR.PHCPERIOD[15:0] bits) is greater than the number of cycles set in the PHCCEDTHR.PHCCEDTH[15:0] bits.
  If this error occurs when the interval at which carrier period events are generated is extremely short, the carrier period event that caused the error is not accepted.

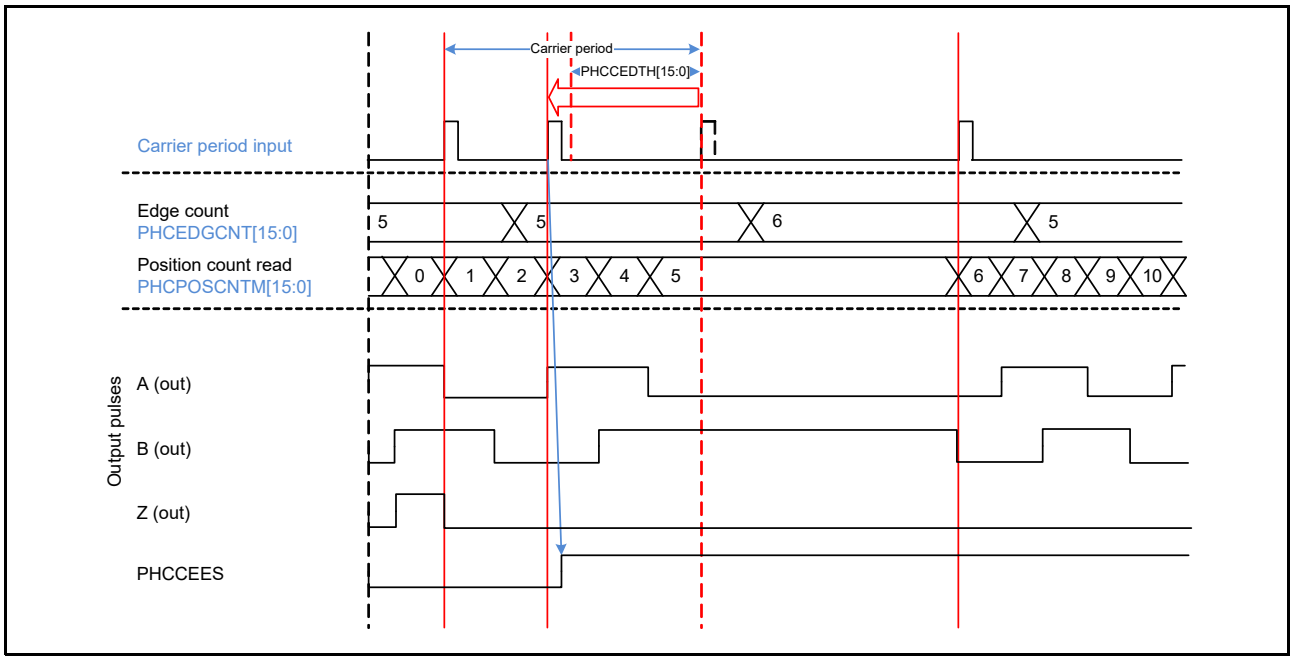

Figure 59.19 Waveforms for Occurrence of a PHCCEES Error Caused by Early Carrier Period Input

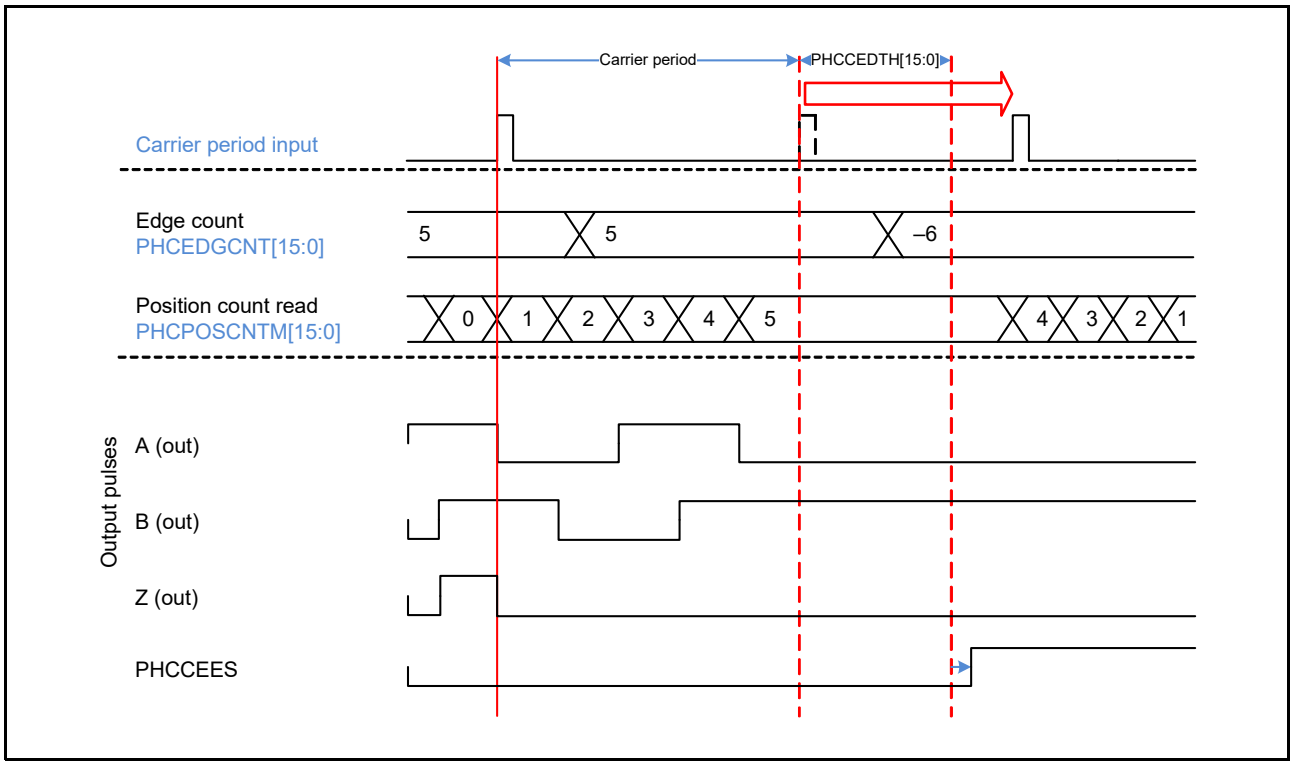

Figure 59.20 Waveforms for Occurrence of a PHCCEES Error Caused by Delayed Carrier Period Input

- Internal Edge Count Error Status Flag in Phase Counting Mode (PHCIECES)
  The PHCSR.PHCIECES flag indicates that pulses for the number of output edges set in the PHCECR.PHCEDGCNT[15:0] bits cannot be output within the carrier period.
  This flag is set when the carrier period event is generated at a short interval and the total edge count exceeds the carrier period (PHCPERIODR.PHCPERIOD[15:0] bits).
  If this error occurs and pulses for the current total edge count cannot be processed within the carrier period, the unprocessed edges are taken over to the next carrier period.

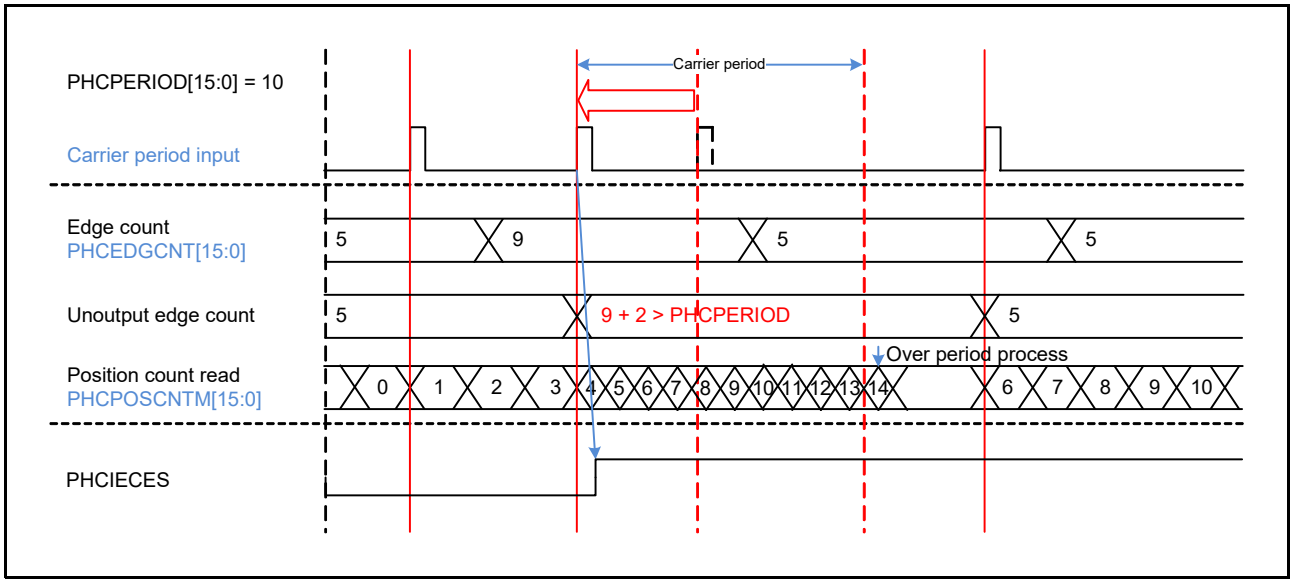

Figure 59.21 Waveforms for Occurrence of a PHCIECES Error

- Internal Edge Count Overflow Error Status Flag in Phase Counting Mode (PHCIECOES)
  The PHCSR.PHCIECOES flag indicates that output edges were lost due to an overflow or underflow of the total edge count to be output within the carrier period.
  This flag is set when the total edge count exceeding 32,767 resulted in an overflow. This flag is also set when the total edge count less than –32,768 resulted in an underflow.
  If this error is caused by an overflow, the total edge count is processed as 32,767. If this error is caused by an underflow, the total edge count is processed as –32,768.

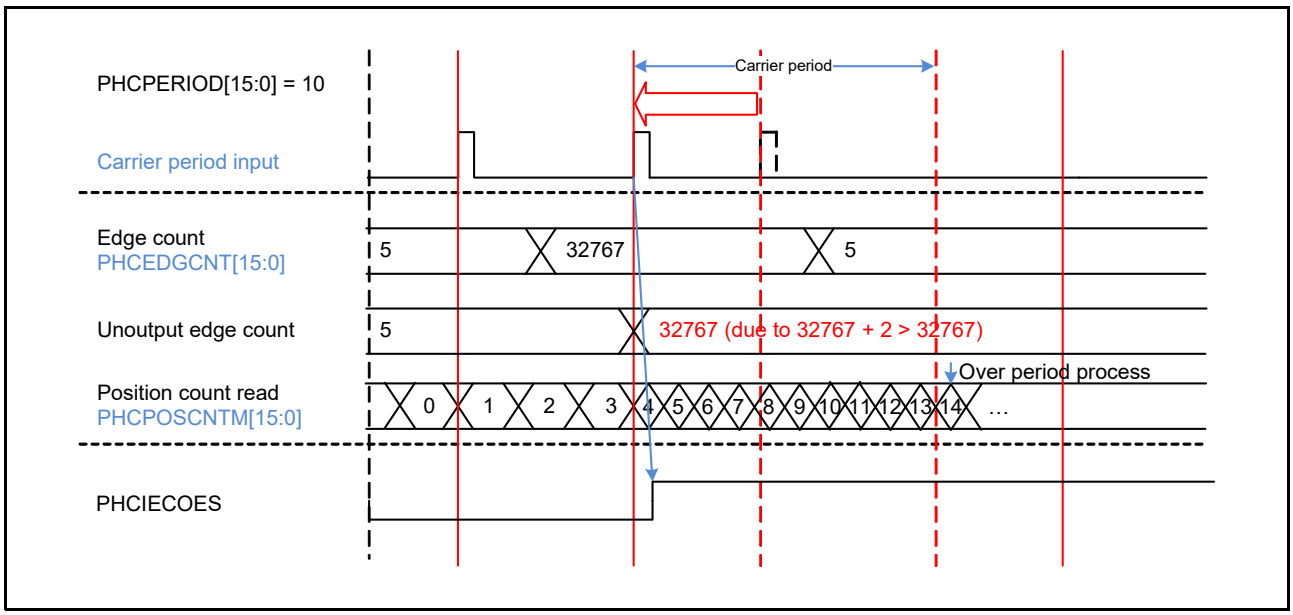

Figure 59.22 Waveforms for Occurrence of a PHCIECOES Error

- Old Edge Count Usage Error Status Flag in Phase Counting Mode (PHCOECUES)
  The PHCSR.PHCOECUES flag is set when, after a carrier period event is generated, the next carrier period event is generated without updating the PHCECR.PHCEDGCNT[15:0] bits.
  If this error occurs, the current value of the PHCEDGCNT[15:0] bits is used for the processing after occurrence of the error.
  If the automatic clearing function (PHCCTLR.PHCECACMD bit = 1) is used, the PHCEDGCNT[15:0] bits = 0000h is assumed for the processing and the ABZ-phase outputs stop.

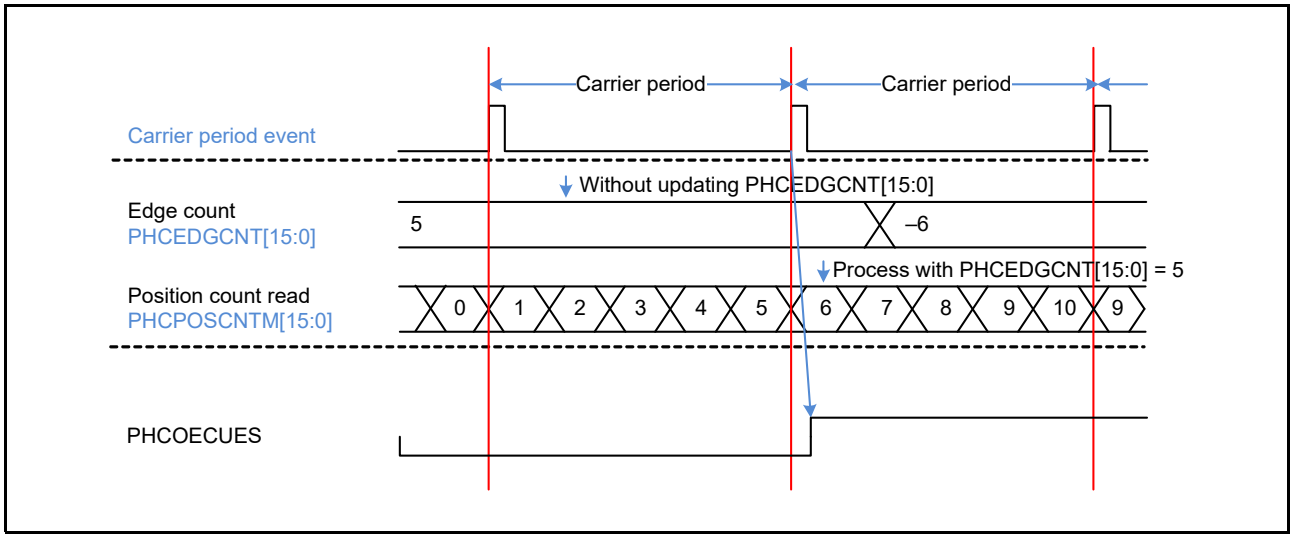

Figure 59.23 Waveforms for Occurrence of a PHCOECUES Error

59.3.2 Incremental Mode

When the CTLR.PCIFMD bit is set to 1, the PCIF operates in incremental mode.
In incremental mode, ABZ-phase output values are generated based on the ABZ-phase signals directly input from the motor without using the CPU. This mode also provides the resolution changing function and three types of I/O protocols to support various motors and host controllers.
Figure 59.24 shows the basic operation waveforms in incremental mode.

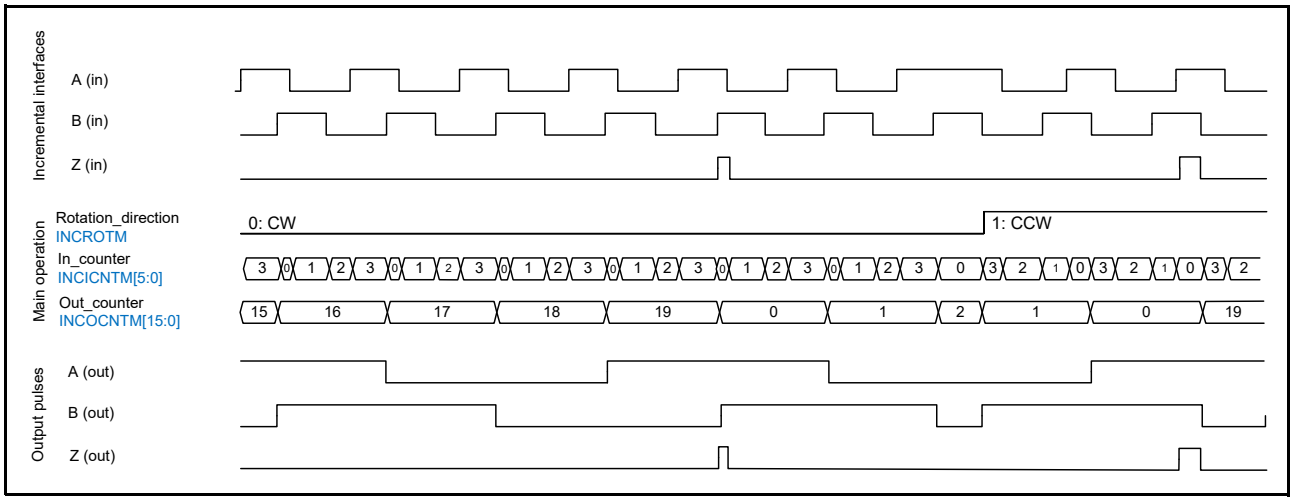

Figure 59.24 Basic Operation Waveforms in Incremental Mode

59.3.2.1 Startup/Stop Control

The incremental mode is started by using the TRGR.PCIFSTRT bit. When the CTLR.PCIFMD bit = 1, setting the PCIFSTRT bit to 1 starts the incremental mode and sets the SR.PCIFPS flag to 1. When the incremental mode is started, ABZ-phase input reception starts and ABZ-phase outputs begin in accordance with the output counter (INCPCMR.INCOCNTM[15:0] bits).

If AB(Z)-phase input is toggled, the output counter changes, and the corresponding A-, B-, and Z-phase signals are output.

For details on the start and stop operation flows, refer to section 59.3.4.4, Flows of Incremental Mode. Figure 59.25 and Figure 59.26 show the waveforms when starting and stopping the incremental mode, respectively.

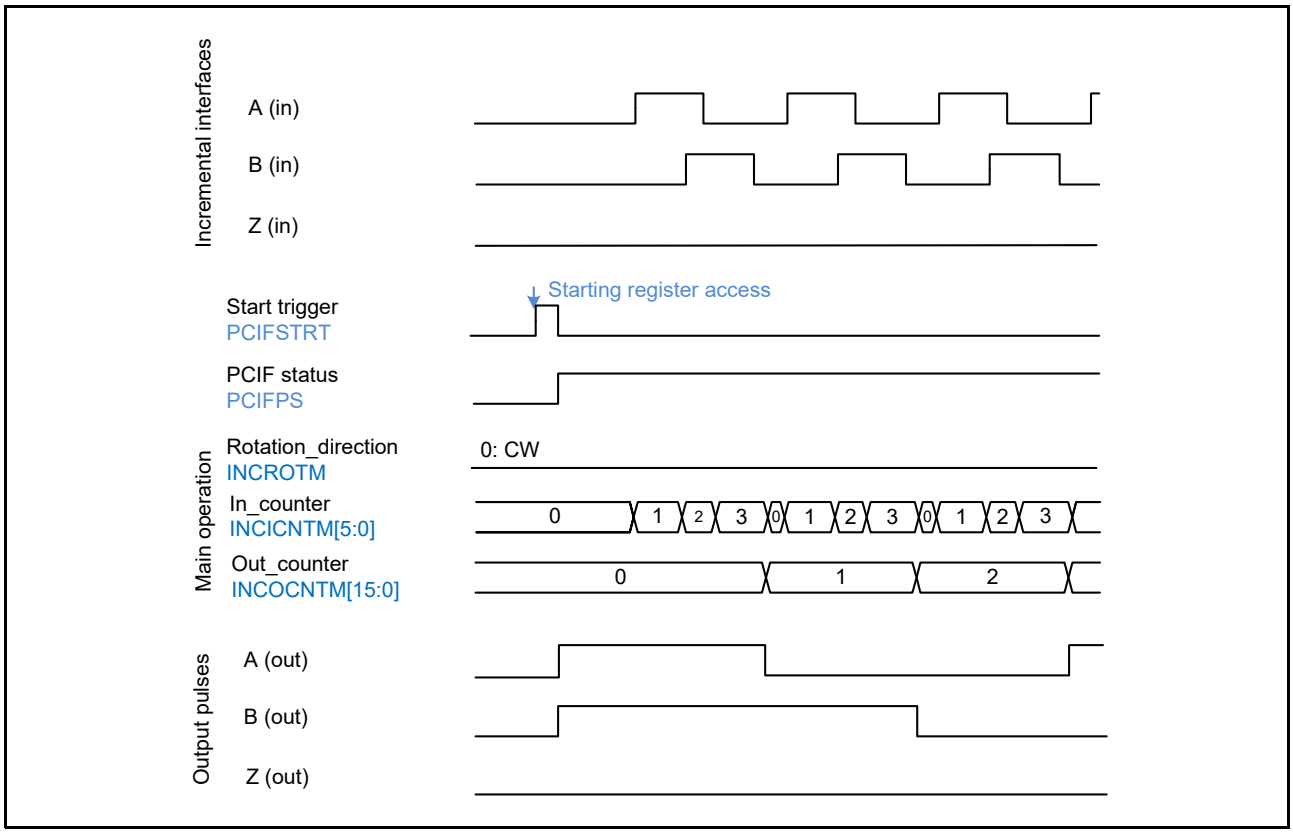

Figure 59.25 Waveforms when Starting Incremental Mode

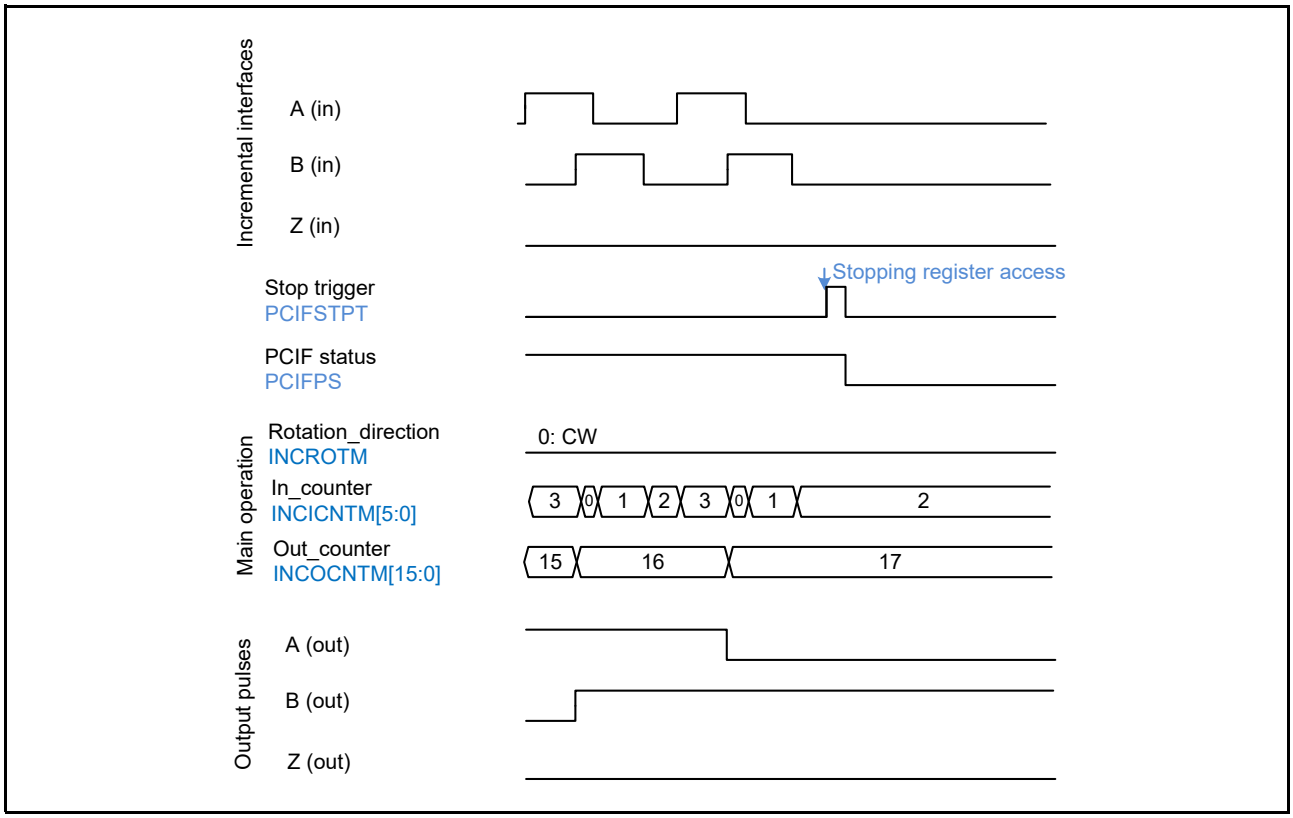

Figure 59.26 Waveforms when Stopping Incremental Mode

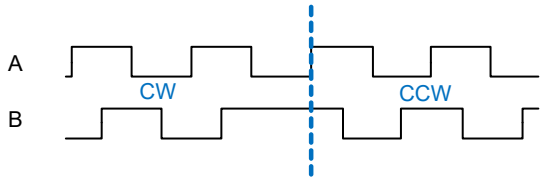

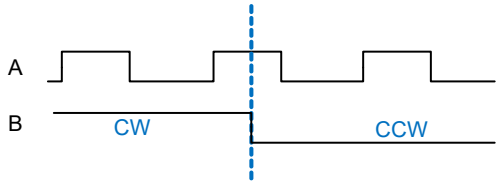

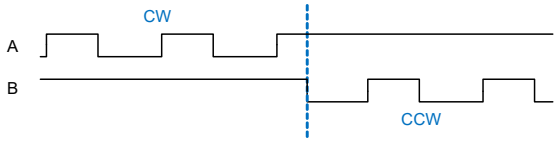

59.3.2.2 Generating A- and B-Phase Signals

This section describes generating AB-phase outputs.
First, the number of edges in AB-phase inputs is counted by the input counter (INCPCMR.INCICNTM[5:0] bits). Then, based on the input counter, the output counter (INCPCMR.INCOCNTM[15:0] bits) operates for each edge count appropriate for the resolution ratio. Finally, A- and B-phase signals corresponding to the output counter are output.

(1) I/O Protocol Change Function

In incremental mode, three types of AB-phase input protocols can be accepted. Furthermore, A- or B-phase signals converted to a different protocol from the input protocol can be output. The INCCTLR.INCIMD[1:0] bits are used to control input protocols, and the INCOMD bit is used to control output protocols.
Table 59.8 shows the five available combinations of I/O protocols.
When the incremental mode is started, the rotation direction of each protocol is determined by toggling input signals, and the output changes according to the protocol mode.

Table 59.8 Correspondence between Register Settings and I/O Protocols

INCIMD[1:0] Bits	INCOMD Bit	Input Protocol Mode	Output Protocol Mode	Waveforms
00b	x	Mode 0: AB-phase pulses 	Mode 0: AB-phase pulses	Figure 59.24
01b	0	Mode 1: A-phase pulse (B-phase rotation direction) 	Mode 1: A-phase pulse (B-phase rotation direction)	Figure 59.27
	1		Mode 0: AB-phase pulses	Figure 59.28
10b	0	Mode 2: Pulse switching 	Mode 2: Pulse switching	Figure 59.29
	1		Mode 0: AB-phase pulses	Figure 59.30

x: Don't care

In mode 0, both A-phase and B-phase are toggled and the rotation direction is determined by the phase relation. After edge counting ends, the combination of A- and B-phases is in one-to-one correspondence with the two lower-order bits of the output counter.
In mode 1, toggling A-phase changes the edge, and the B-phase value determines the rotation direction. A-phase corresponds to the one lower-order bit of the output counter.
In mode 2, the edge changes in the forward rotation direction when A-phase is toggled and in the reverse rotation direction when B-phase is toggled. The toggled phase corresponds to the one lower-order bit of the output counter.

The basic operation of each function is indicated with the INCCTLR.INCIMD[1:0] bits = 00b (mode 0: AB-phase pulses). Each function of the incremental mode supports all I/O protocols. Figure 59.24 shows the operation example

when the INCIMD[1:0] bits = 00b. Figure 59.27 to Figure 59.30 show operation examples in other cases.

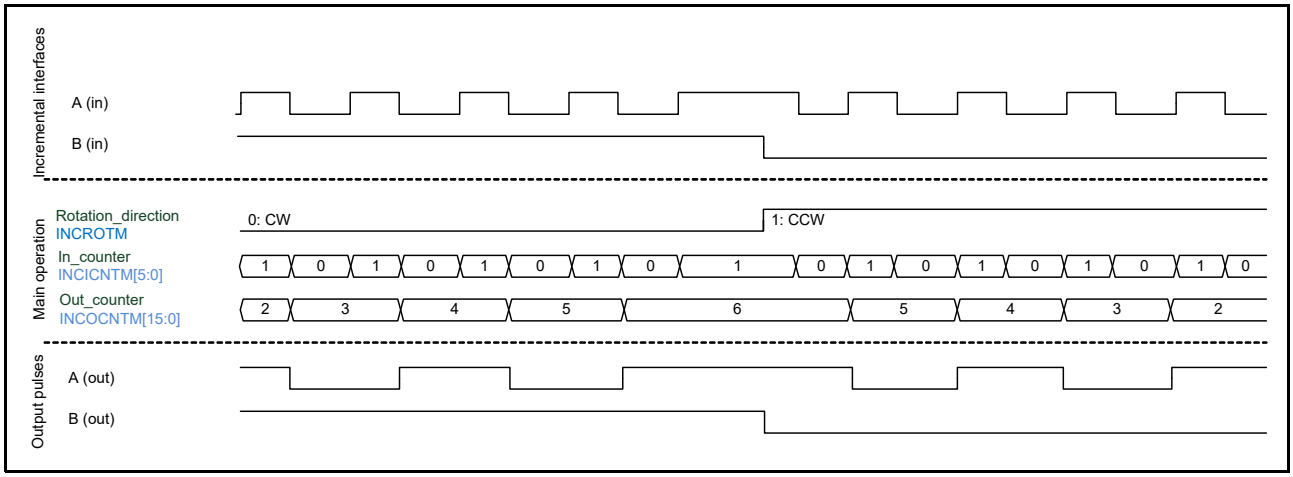

Figure 59.27 Incremental Mode Operation Waveforms 1 (INCIMD[1:0] Bits = 01b, INCOMD Bit = 0)

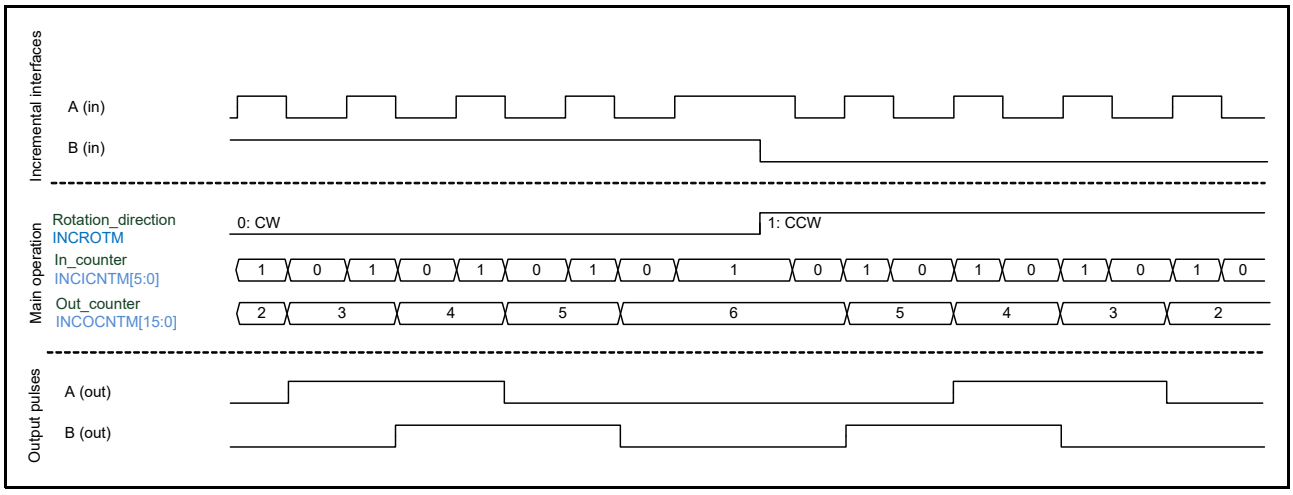

Figure 59.28 Incremental Mode Operation Waveforms 2 (INCIMD[1:0] Bits = 01b, INCOMD Bit = 1)

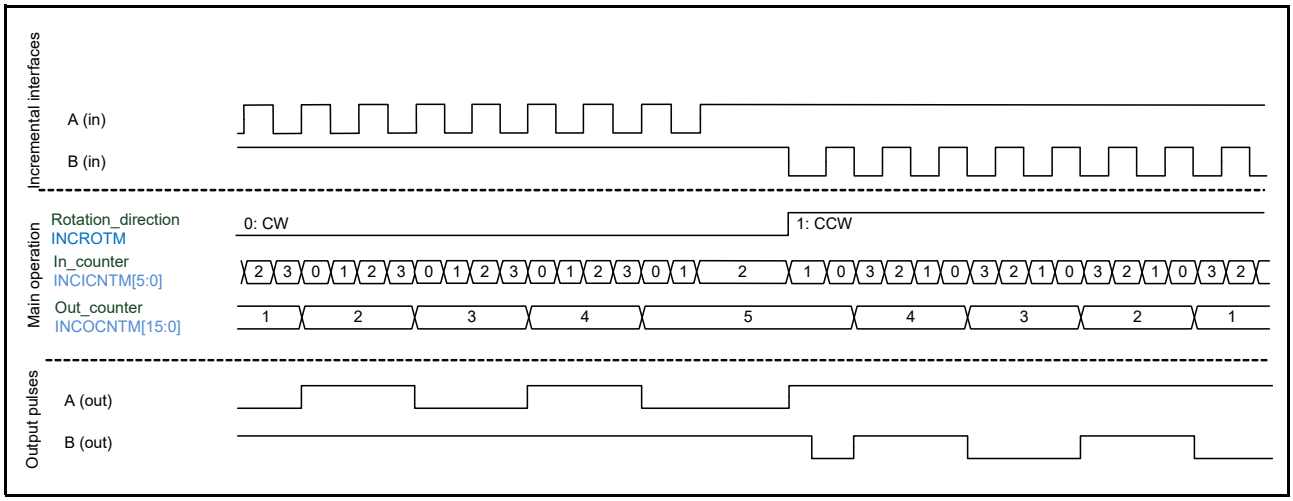

Figure 59.29 Incremental Mode Operation Waveforms 3 (INCIMD[1:0] Bits = 10b, INCOMD Bit = 0)

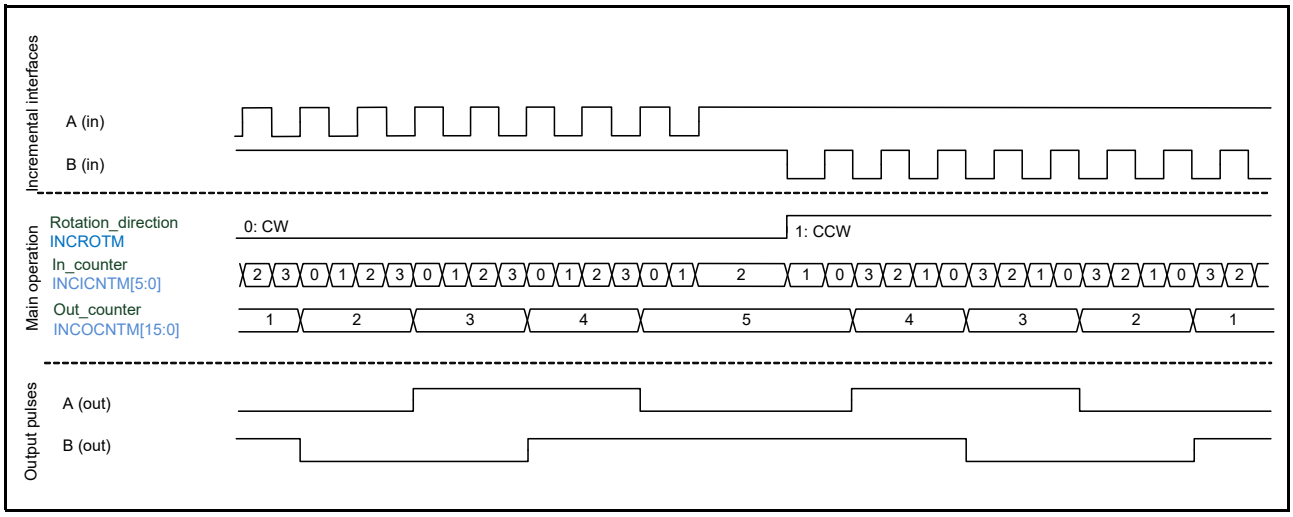

Figure 59.30 Incremental Mode Operation Waveforms 4 (INCIMD[1:0] Bits = 10b, INCOMD Bit = 1)

(2) Internal Counter Operation

In incremental mode, two internal counters, input counter (INCICNT[5:0]) and output counter (INCOCNT[15:0]), are used to generate AB-phase outputs through the following steps 1 to 3.

1. Conversion from AB-phase input to the input counter (INCICNT[5:0]) (AB-phase reception)
2. Conversion from the input counter to the output counter (resolution change)
3. AB-phase output from the output counter (INCOCNT[15:0]) (AB-phase generation)

The following describes details of each processing.

(a) AB-Phase Reception

In AB-phase reception, edges in the AB-phase inputs are detected and the number of edges in the AB-phase inputs is counted by the input counter (INCICNT[5:0]).
Table 59.9, Table 59.10, and Table 59.11 show the methods of counting by the input counter when AB-phase input is in mode 0, mode 1, and mode 2, respectively.

Operation is not guaranteed if "Unexpected protocol" in Table 59.9 to Table 59.11 is executed.

Table 59.9 Method of Counting by the Input Counter When AB-Phase Input is in Mode 0

Rising	Rising			Unexpected protocol
Rising	Falling			Unexpected protocol
Falling	Rising			Unexpected protocol
Falling	Falling			Unexpected protocol

(b) Resolution Changing Function

The resolution changing function outputs AB-phase signals by reducing the resolution of AB-phase input to allow host controllers to receive data. The resolution can be changed in the range from 1/1 (same size) to 1/64.
The resolution changing function is implemented with the input counter (INCICNT[5:0]) and output counter (INCOCNT[15:0]).
Figure 59.31 shows the operation waveforms when changing the resolution to 1/4.

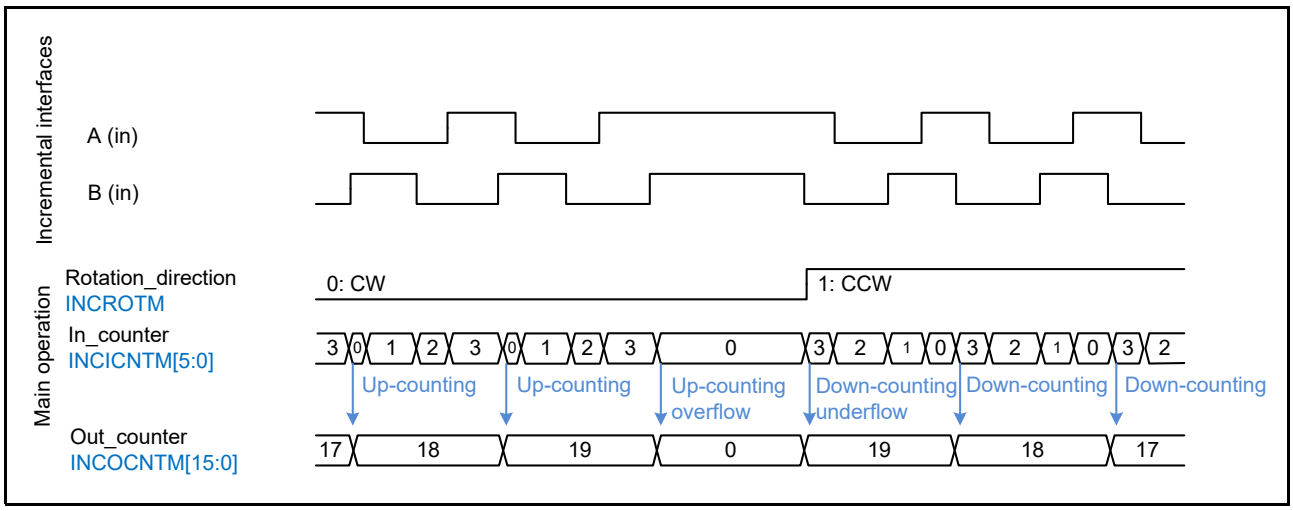

Figure 59.31 Waveforms of Resolution Changing Function (INCCTLR.INCRSL[5:0] Bits = 03h, POSMAXR.POSMAX[15:0] Bits = 0013h)

The input counter (INCICNT[5:0]) has a prescaler function. If the input counter overflows, the output counter performs up-counting. If the input counter underflows, the output counter performs down-counting. The maximum value of the input counter is the value set in the INCCTLR.INCRSL[5:0] bits. If the output counter (INCOCNT[15:0]) overflows, it is cleared to zero. If the output counter underflows, the maximum value is set.
The maximum value of the output counter is shown in Table 59.12. Figure 59.32 shows waveforms when the output counter exceeds the value of the POSMAXR.POSMAX[15:0] bits, causing the INCOCNTM[15:0] bits to be cleared.

Table 59.12 Maximum Value of the Output Counter (INCOCNT[15:0])

INCZGCTLR.INCZAGE Bit	Maximum Value of the Output Counter (INCOCNT[15:0])
0	FFFFh
1	POSMAX[15:0] setting

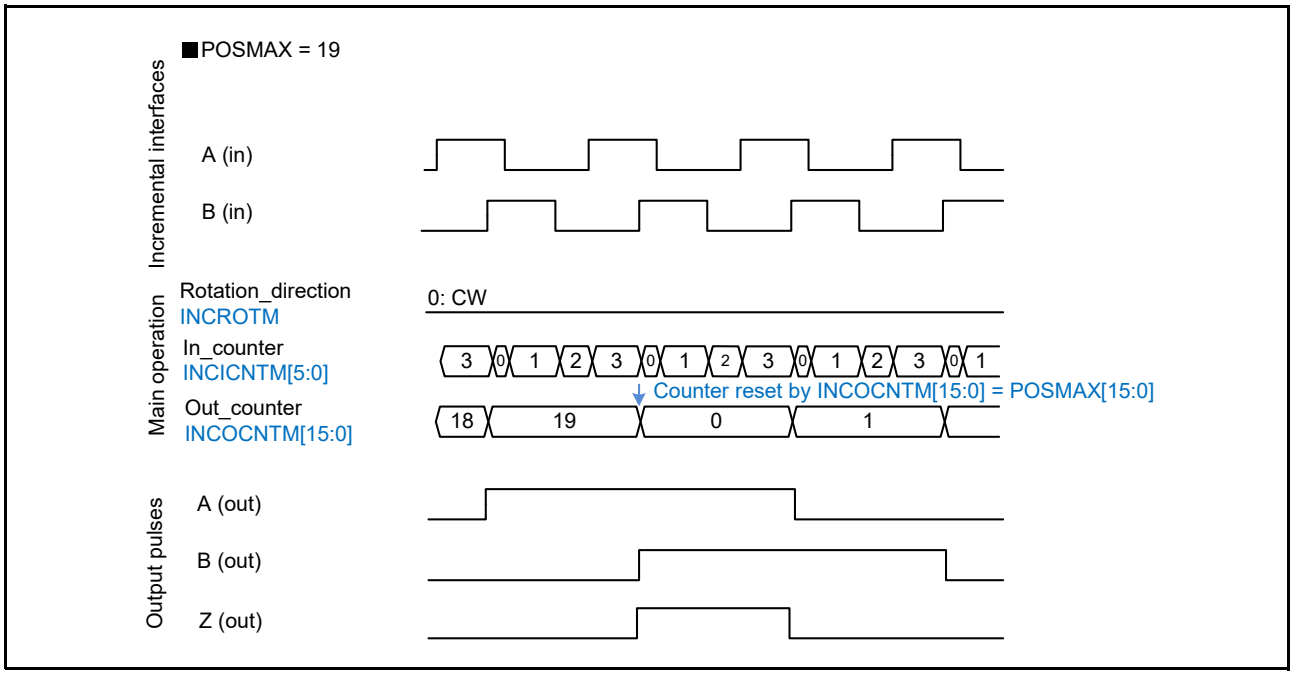

Figure 59.32 Waveforms When the Output Counter (INCOCNT[15:0]) is Cleared by the POSMAX[15:0] Setting

(c) AB-Phase Generation

The following describes how AB-phase outputs are generated based on the position information indicated by the output counter (INCOCNT[15:0]).

The AB-phase output generation method when the INCCTLR.INCIMD[1:0] bits = 00b or the INCCTLR.INCOMD bit = 1 (mode 0 output) is shown in Table 59.13. The AB-phase output generation method when the INCIMD[1:0] bits = 01b and the INCOMD bit = 0 (mode 1 output) is shown in Table 59.14. The AB-phase output generation method when the INCIMD[1:0] bits = 10b and the INCOMD bit = 0 (mode 2 output) is shown in Table 59.15.

Table 59.13 Truth Table for Generating AB-Phase Outputs by Using the Output Counter (Mode 0)

INCOCNT[1:0]	00b	01b	10b	11b
A-phase output	1	0	0	1
B-phase output	1	1	0	0

Table 59.14 Truth Table for Generating AB-Phase Outputs by Using the Output Counter (Mode 1)

INCOCNT[0]	0	1	0	1
INCROTM Bit	0 (Forward Rotation)	0 (Forward Rotation)	1 (Reverse Rotation)	1 (Reverse Rotation)
A-phase output	1	0	1	0
B-phase output	1	1	0	0

Table 59.15 Truth Table for Generating AB-Phase Outputs by Using the Output Counter (Mode 2)

INCOCNT[0]	0	1	0	1
INCROTM Bit	0 (Forward Rotation)	0 (Forward Rotation)	1 (Reverse Rotation)	1 (Reverse Rotation)
A-phase output	1	0*1	1	1
B-phase output	1	1	1	0*1

Note 1. If the value of the INCROTM bit changes, the AB-phase outputs are always placed at the high level for one cycle of CCLK_DIV irrespective of the above setting. Example waveforms are shown in Figure 59.33, Example of Changing the Rotation Direction in Mode 2.

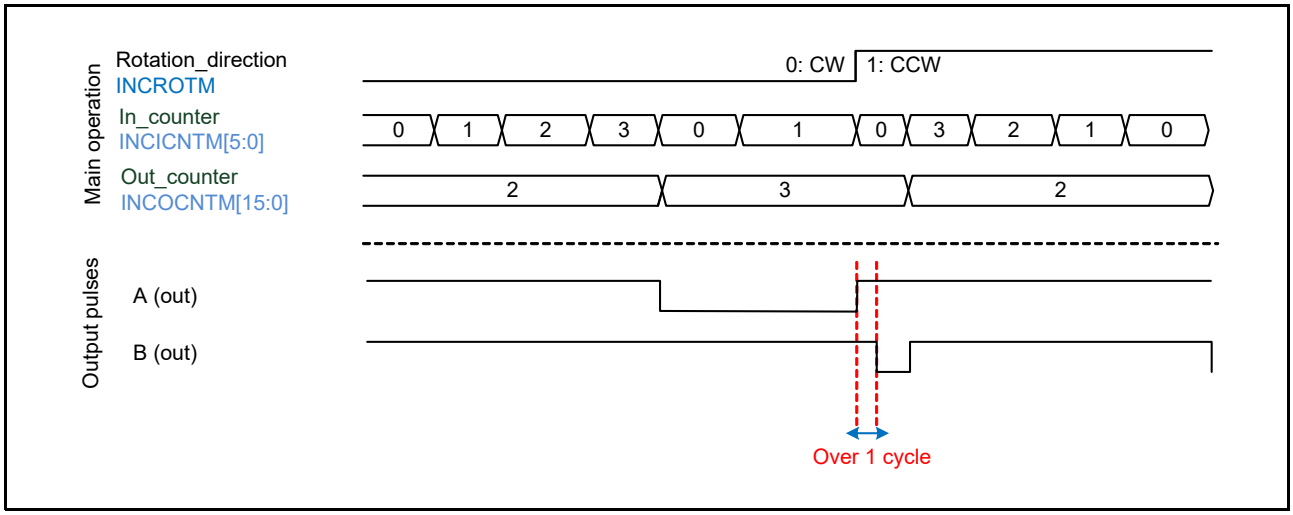

Figure 59.33 Example of Changing the Rotation Direction in Mode 2

(3) Internal Counter Clearing Function

As shown in (2), AB-phase output corresponds to the output counter (INCPCMR.INCOCNTM[1:0] bits). In addition to the clearing function for the INCOCNTM[15:0] bits, the PCIF has the following four types of internal counter clearing functions that allow AB-phase outputs to be cleared on the system side. When any of the conditions for clearing is met, the internal counters (INCOCNT[15:0] and INCICNT[5:0]) are initialized.

- Clearing by a Z-phase input*1
- Clearing by a crest event trigger (PEK_IN)
- Clearing by a trough event trigger (VLY_IN)
- Clearing by a software trigger

You can control any combination of these functions by setting the INCPCCER register.*2

Note 1. When the internal counters are cleared by a Z-phase input, note that the counter value might be incremented by 1 due to the deviation in the timing of input between the AB-phase and Z-phase signals.
Note 2. When the internal counters are cleared by setting the POSMAXR.POSMAX[15:0] bits (INCZGCTLR.INCZAGE bit = 1), clearing the counters by a Z-phase input is prohibited.

For details on the waveforms for internal counter clearing by a Z-phase input, refer to Figure 59.24. Figure 59.34 shows the waveforms for internal counter clearing by a software trigger.

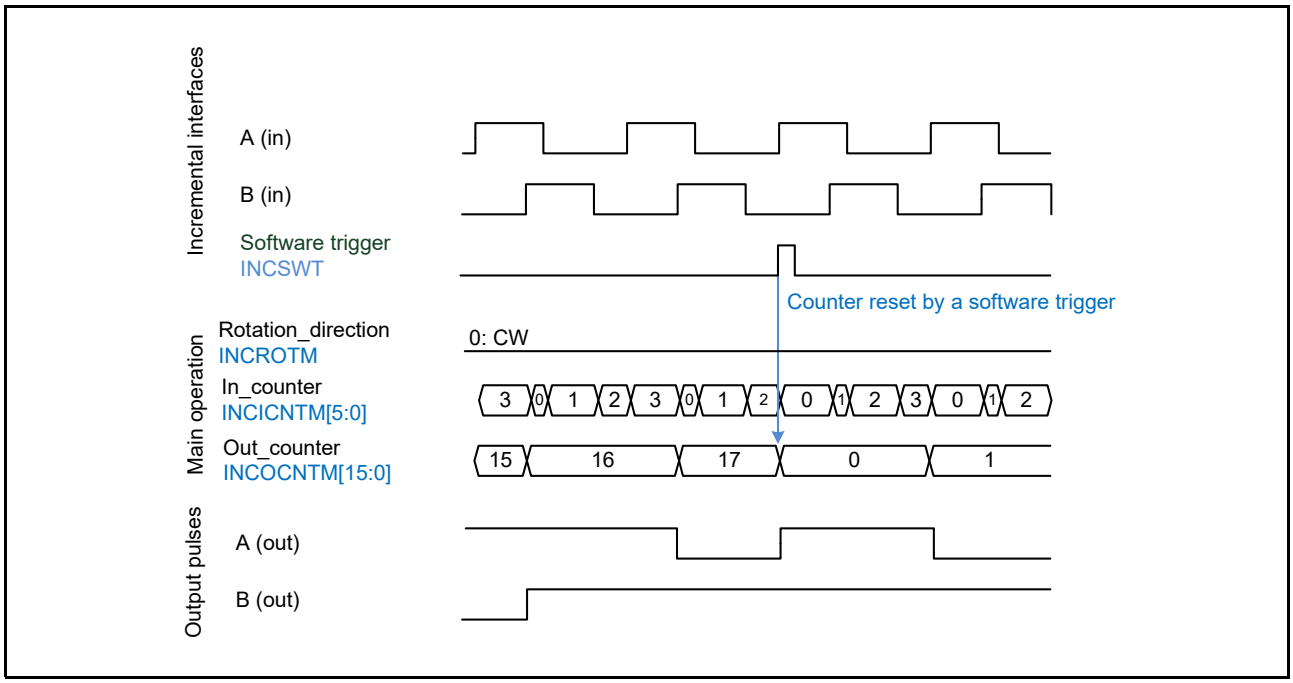

Figure 59.34 Waveforms for Internal Counter Clearing by a Software Trigger

59.3.2.3 Generating Z-Phase Signals

Z-phase output is a signal indicating that the motor rotates one round. Z-phase output is generated by using the output counter, a Z-phase input, crest/trough event trigger, or software trigger. In addition, you can select whether to output Z-phase signals synchronized with AB-phase output or output immediately.

(1) Selecting the Z-Phase Output Trigger

Z-phase signals can be output by using one of the following five ways:

- Generation with the output counter ...(a)
- Generation by a Z-phase input ...(b)
- Generation by a crest event trigger ...(c)
- Generation by a trough event trigger ...(c)
- Generation by a software trigger ...(c)

You can control any combination of these methods by setting the INCZGCTLR register.

(a) Generation with the Output Counter

Z-phase output can be generated by using the output counter (INCPCMR.INCOCNTM[15:0] bits) for AB-phase operations.
If the INCZGCTLR.INCZAGE bit is set to 1, Z-phase output is asserted when the INCOCNTM[15:0] bits = 0000h. The maximum value of the counter (INCOCNTM[15:0] bits) is set in the POSMAXR.POSMAX[15:0] bits. If an overflow or underflow occurs, the count wraps around within the range from 0 to the POSMAX[15:0] bit setting.
Figure 59.35 shows example waveforms for Z-phase output generation with the output counter.

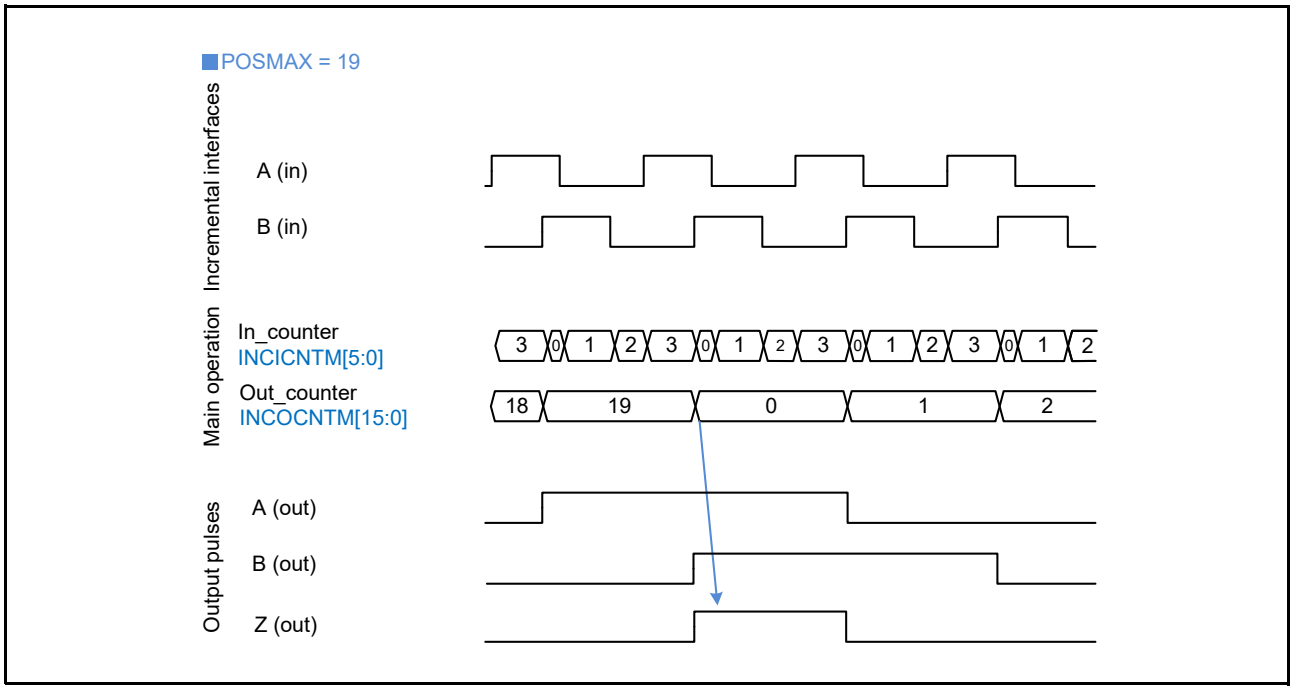

Figure 59.35 Example of Z-Phase Output Generation with the Output Counter (INCOCNTM[15:0] Bits) (INCZGCTLR.INCZAGE Bit = 1, INCCTLR.INCZOS[1:0] Bits = 00b)

(b) Generation by a Z-Phase Input

Z-phase output can be generated in synchronization with Z-phase input. If the INCZGCTLR.INCZIZGE bit is set to 1, when the Z-phase input is asserted, Z-phase output is also asserted.
Refer to Figure 59.24 for an example of Z-phase output generation in response to a Z-phase input when the INCZGCTLR.INCZIZGE bit = 1 and the INCCTLR.INCZOS[1:0] bits = 00b.

(c) Generation by Crest/Trough Event Triggers and Software Triggers

Besides the previously mentioned generation methods using the output counter and a Z-phase input, Z-phase output can also be generated by using triggers. When the INCZGCTLR.INCPIZGE bit, INCVIZGE bit, and INCSWZGE bit are set to 1, Z-phase output is asserted when a crest event trigger (PEK_IN), a trough event trigger (VLY_IN), or a software trigger is executed, respectively.
Figure 59.36 shows an example of Z-phase output generation by a software trigger (INCZGCTLR.INCSWZGE bit = 1, INCCTLR.INCZOS[1:0] bits = 00b).

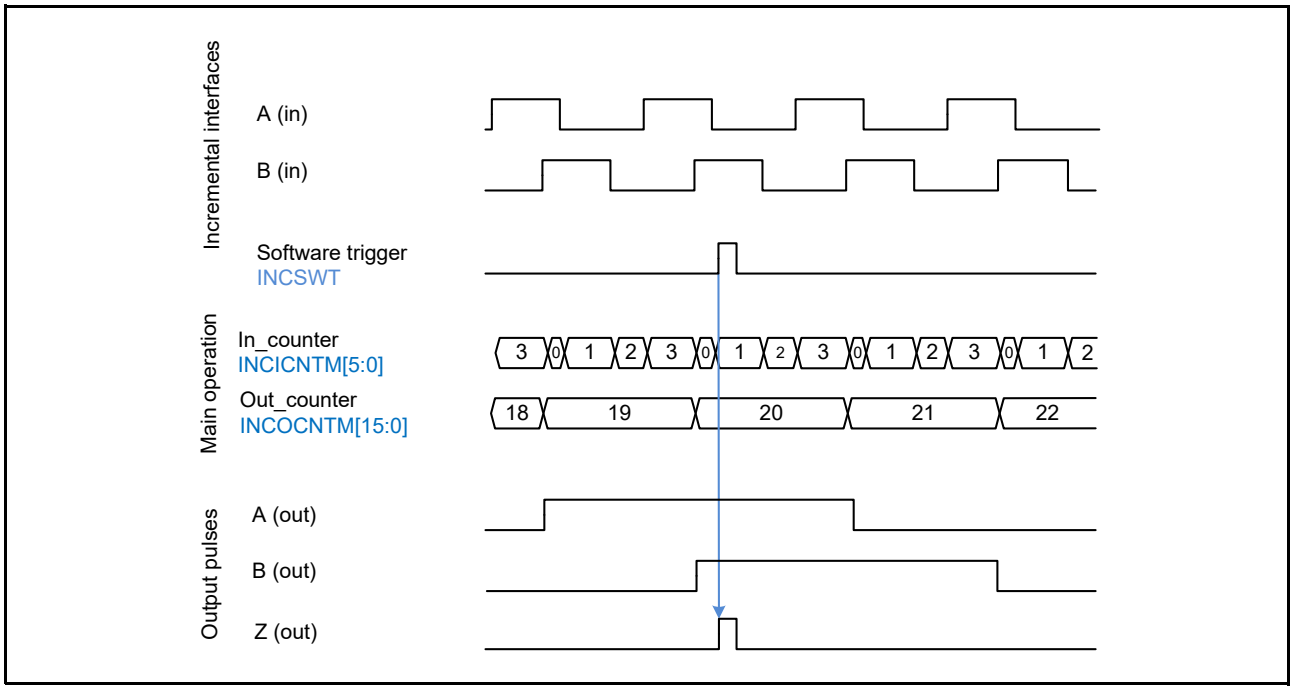

Figure 59.36 Example of Z-Phase Output Generation by a Software Trigger (INCZGCTLR.INCSWZGE Bit = 1, INCCTLR.INCZOS[1:0] Bits = 00b)

(2) Selecting the Z-Phase Output Synchronization Method

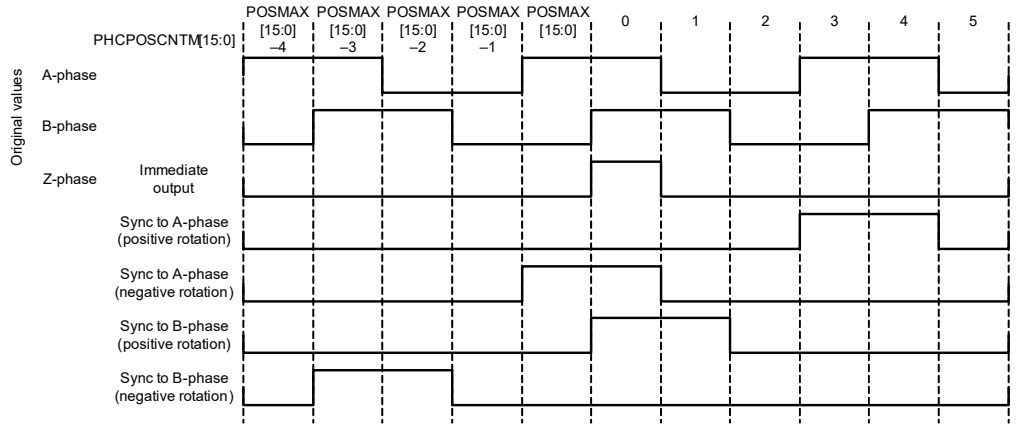
For the PCIF, you can select whether to generate Z-phase output when any of the Z-phase output conditions is met as described in (1) Selecting the Z-Phase Output Trigger, or to synchronize the Z-phase output generation to AB-phase output.

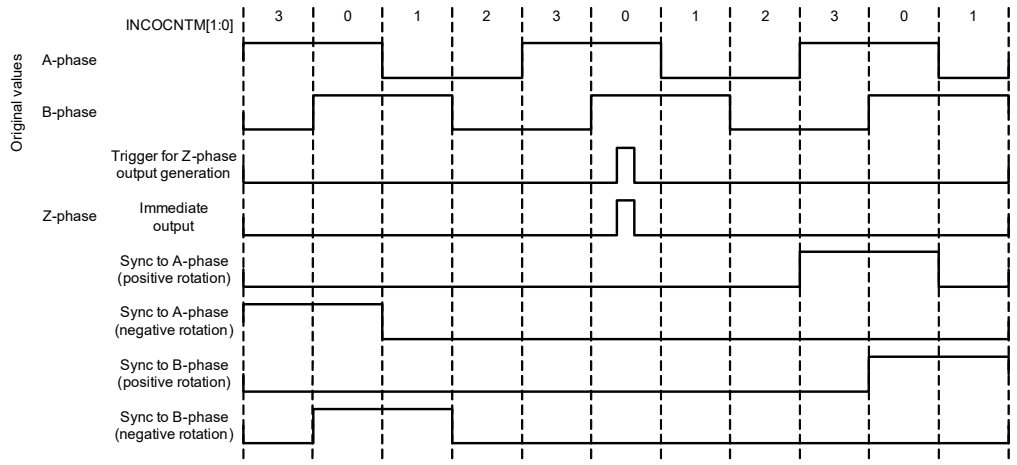
Table 59.16 shows the types of synchronization methods. Figure 59.37 shows the Z-phase output timing in mode 0, Figure 59.38 shows the Z-phase output timing in mode 1, and Figure 59.39 shows the Z-phase output timing in mode 2.

Table 59.16 Types of Z-Phase Output Synchronization Methods

Z-Phase Sync Condition	INCCTLR. INCZOS[1:0] Bits	Assertion Timing	De-assertion Timing	Remarks
Immediate output	00b	When a Z-phase generation condition is met.	When no Z-phase generation conditions are met.	The Z-phase generation conditions are as follows. • When the INCZGCTLR.INCZAGE bit = 1, INCPCMR.INCOCNTM[15:0] bits = 0000h • When the INCZGCTLR.INCZIZGE bit = 1, Z-phase input = 1 • When the INCZGCTLR.INCPIZGE bit = 1, PEK_IN = 1 • When the INCZGCTLR.INCVIZGE bit = 1, VLY_IN = 1 • When the INCZGCTLR.INCSWZGE bit = 1, 1 is written to the INCSWTRGR.INCSWT bit.
Synchronization with the A-phase	01b	Rising edge of A-phase before the next inversion of the active sense when a Z-phase generation condition is met	Falling edge of A-phase before the inversion of the active sense	Available only when the output protocol is mode 0
Synchronization with the B-phase	10b	Rising edge of B-phase before the next inversion of the active sense when a Z-phase generation condition is met	Falling edge of B-phase before the inversion of the active sense	Available only when the output protocol is mode 0
Synchronization with the pulse	11b	Rising edge of the pulse output signal*1 before the next inversion of the active sense when a Z-phase generation condition is met	Falling edge of the pulse output signal*1 before the inversion of the active sense	Available only when the output protocol is mode 1 or 2

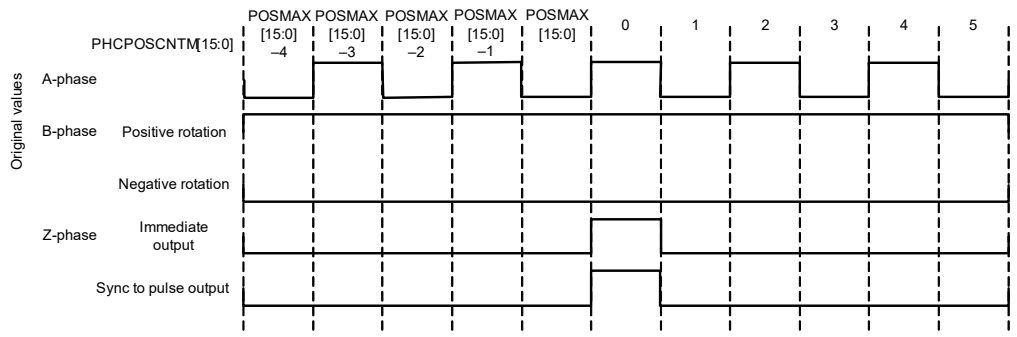
Note 1. A-phase in mode 1, and A-phase or B-phase in mode 2.

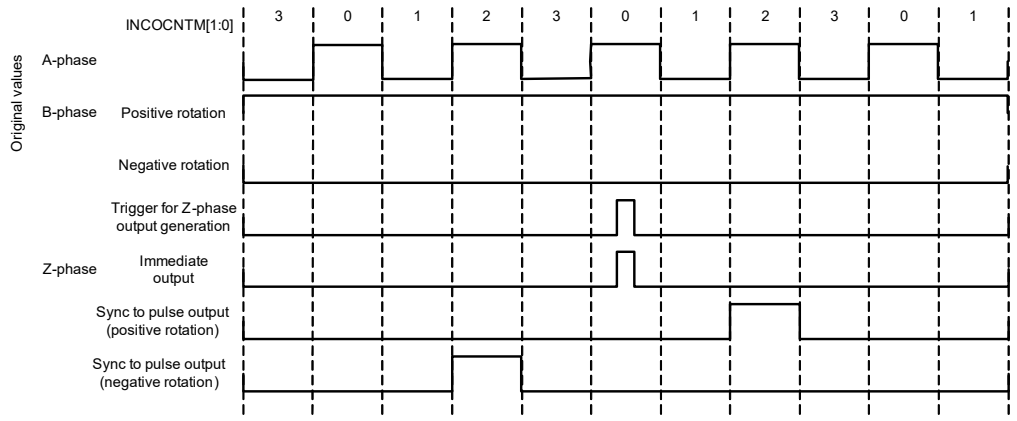




Z-phase generation with the output counter (INCZAGE = 1)	
Other than above	

Figure 59.37 Synchronized Z-Phase Output Timing (Mode 0)





Z-phase generation with the output counter (INCZAGE = 1)	
Other than above	

Figure 59.38 Synchronized Z-Phase Output Timing (Mode 1)

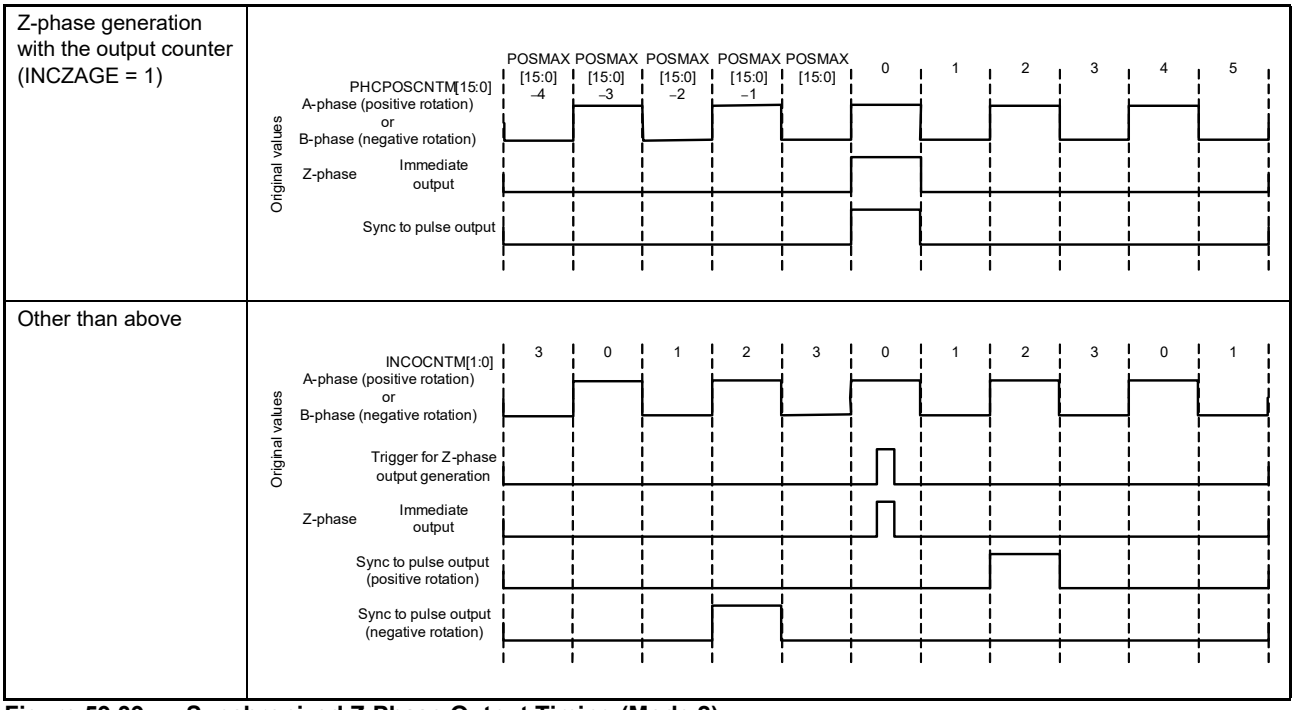


Figure 59.39 Synchronized Z-Phase Output Timing (Mode 2)

In synchronization with pulse output in mode 2, if a Z-phase output trigger is generated when the rotation direction changes, the Z-phase output might be synchronized with different phases at rising and falling edges. Figure 59.40 shows an example.

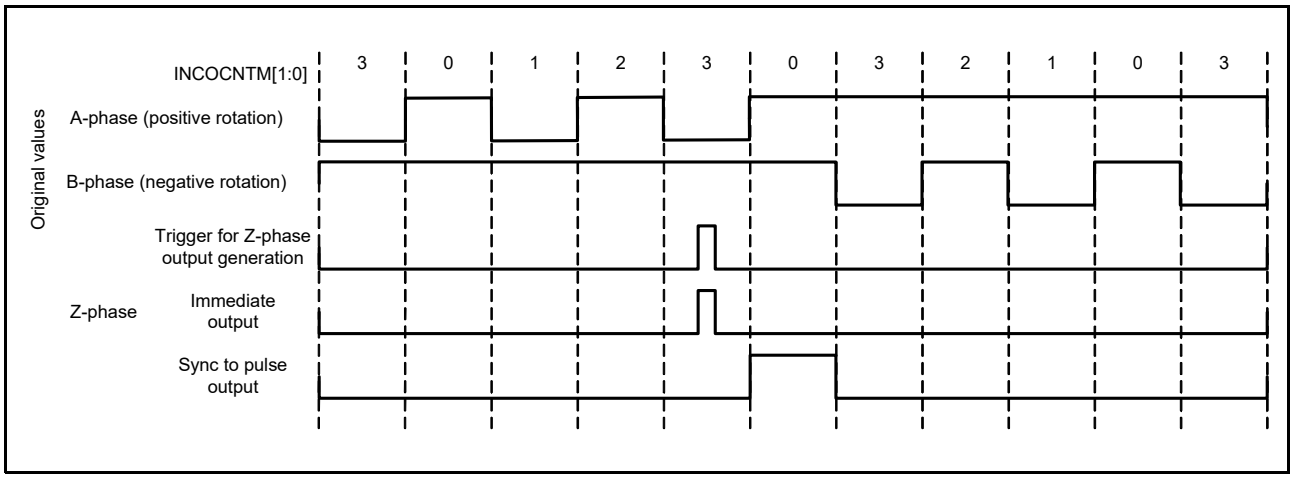

Figure 59.40 Synchronized Z-Phase Output Timing When the Rotation Direction Changes (Mode 2)

(3) Setting the Minimum Pulse Width of Z-Phase Output

The minimum assertion period of Z-phase output is one cycle of CCLK_DIV. The assertion period can be extended by up to 256 cycles of CCLK_DIV by setting the INCCTLR.INCZOMIN[7:0] bits. While the Z-phase output assertion period is being extended, any other Z-phase output conditions are ignored even if they are met. A new Z-phase output condition can be accepted after the extension is complete.

Figure 59.41 shows the Z-phase generation waveforms when setting the minimum pulse width by a software trigger.

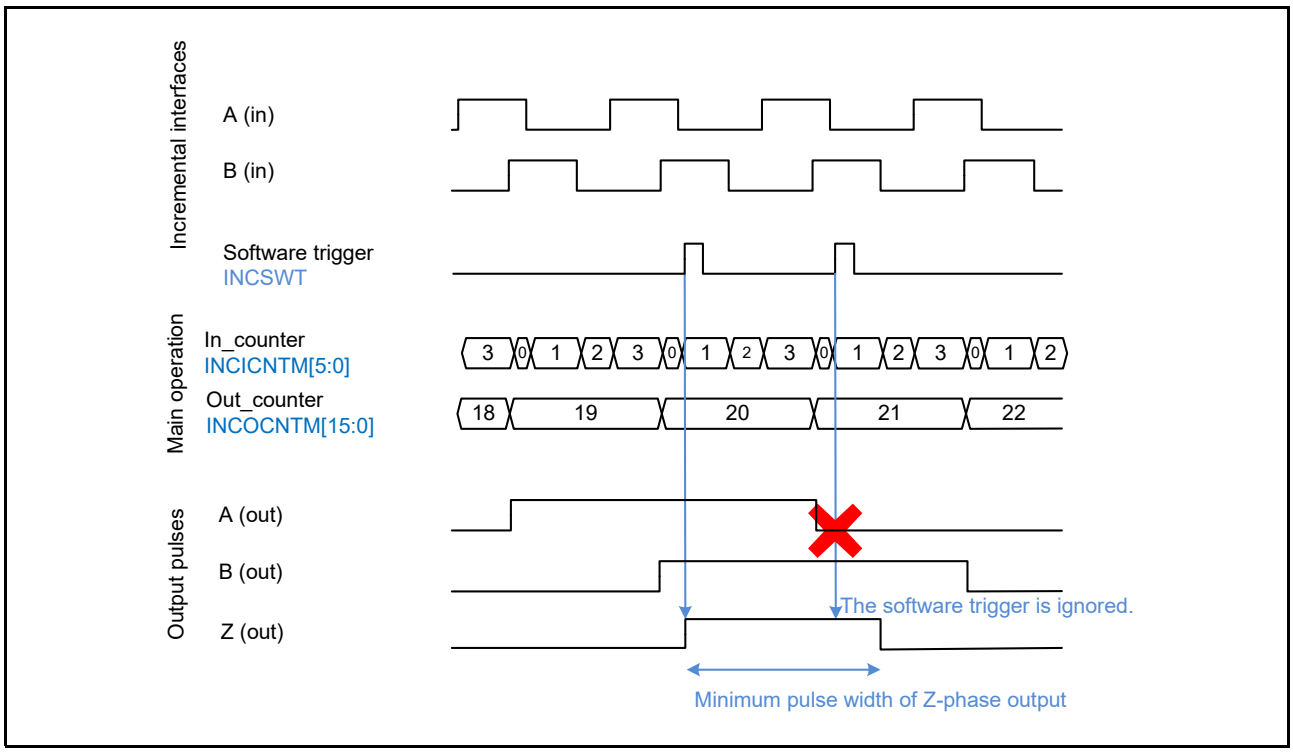

Figure 59.41 Z-Phase Generation Waveforms when Setting the Minimum Pulse Width

However, if the extended Z-phase output assertion period overlaps with a Z-phase output condition, the Z-phase signal will be output according to the longer period.

Figure 59.42 shows the waveforms for the extended Z-phase output.

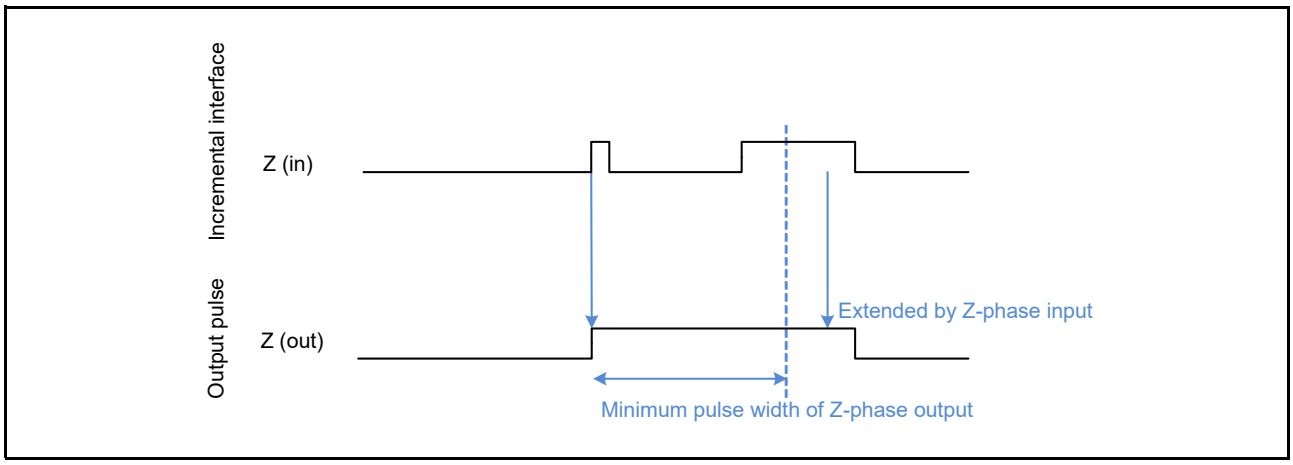

Figure 59.42 Waveforms for Extended Z-Phase Output

59.3.3 Output Controller

The following describes the function that inverts and outputs A-, B-, and Z-phase signals generated in phase counting mode or incremental mode.

59.3.3.1 ABZ-Phase Output Inversion Function

Table 59.17 shows the output values of ABZ-phase output signals. The ABZ-phase outputs can be inverted by setting the CTLR.APOL, BPOL, and ZPOL bits, respectively.
Figure 59.43 shows example waveforms when A-phase output is inverted and Z-phase output is synchronized with A-phase.

Table 59.17 Output Values of ABZ-Phase Output Signals

SWRSTR.SWRST Bit	SR.PCIFPS Flag	CTLR.PCIFMD Bit	CTLR.XPOL Bit*1	Operation	X-Phase
1	—	—	—	Software reset is in progress.	0
0	0	—	—	Stopped	The previous value is retained.
0	1	0	0	Phase counting mode	Generated value*2
0	1	0	1	Phase counting mode	Inverted value*3
0	1	1	0	Incremental mode	Generated value*4
0	1	1	1	Incremental mode	Inverted value*3

Note 1. XPOL indicates each of the APOL, BPOL, and ZPOL bits.
Note 2. ABZ-phase signals generated in phase counting mode (Refer to section 59.3.1.5.)
Note 3. ABZ-phase signals generated by inverting the values generated in the corresponding mode
Note 4. ABZ-phase signals generated in incremental mode (Refer to section 59.3.2.2 and section 59.3.2.3.)

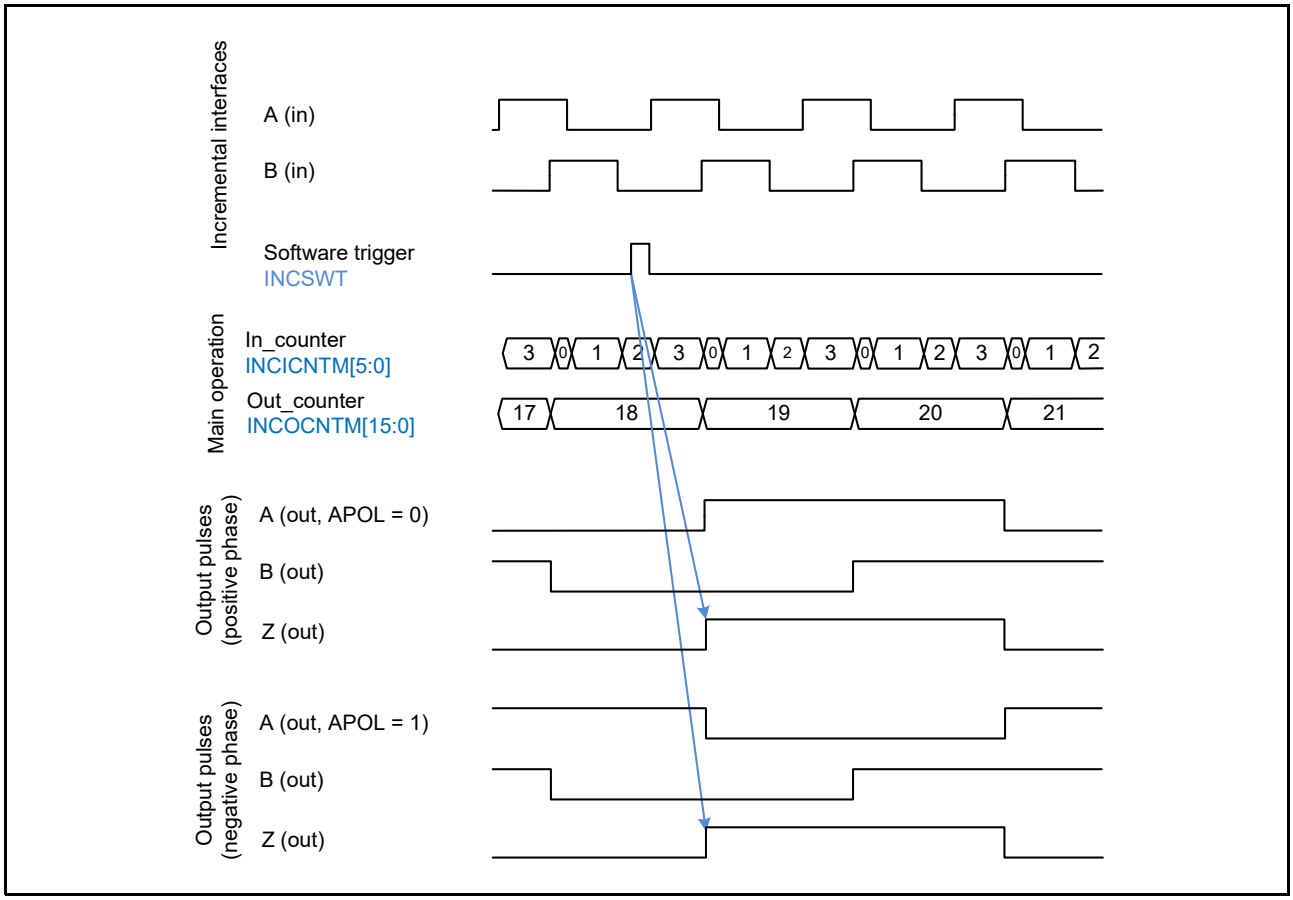

Figure 59.43 Example Waveforms for Z-Phase Output Synchronized with A-Phase (Positive/Negative Phase)

59.3.4 Operating Flows

This section describes the PCIF operating flows.

59.3.4.1 Overall Operation

Figure 59.44 shows the overall operating flow for the PCIF.

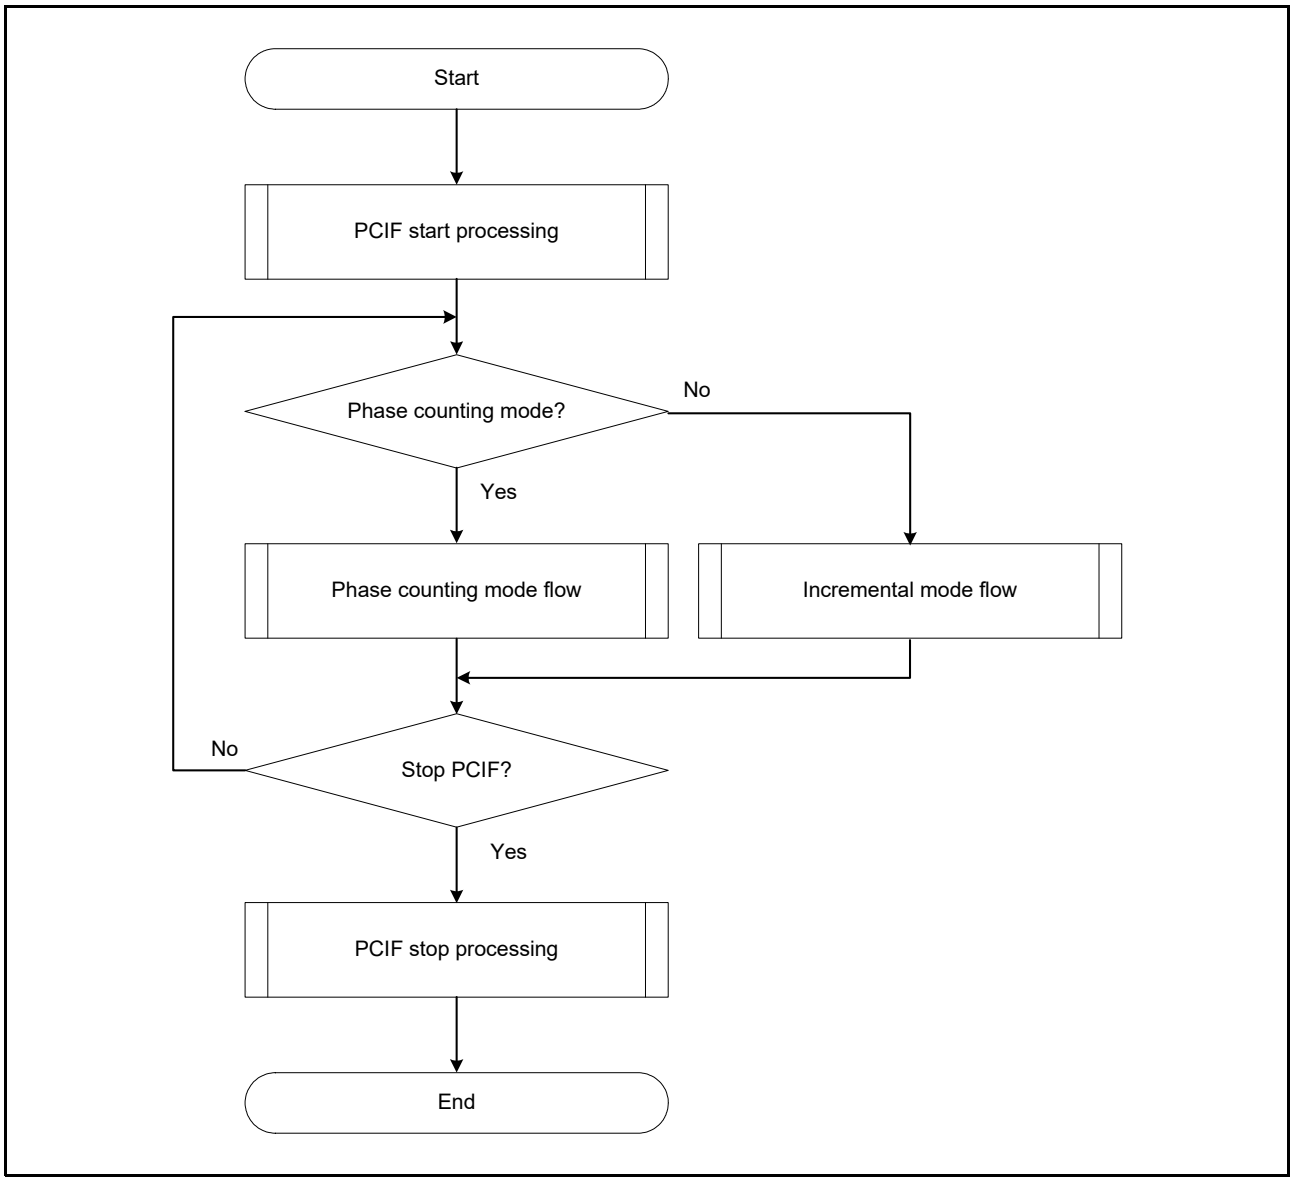

Figure 59.44 Overall Operating Flow for PCIF

59.3.4.2 PCIF Startup Processing

Figure 59.45 shows the startup processing flow.

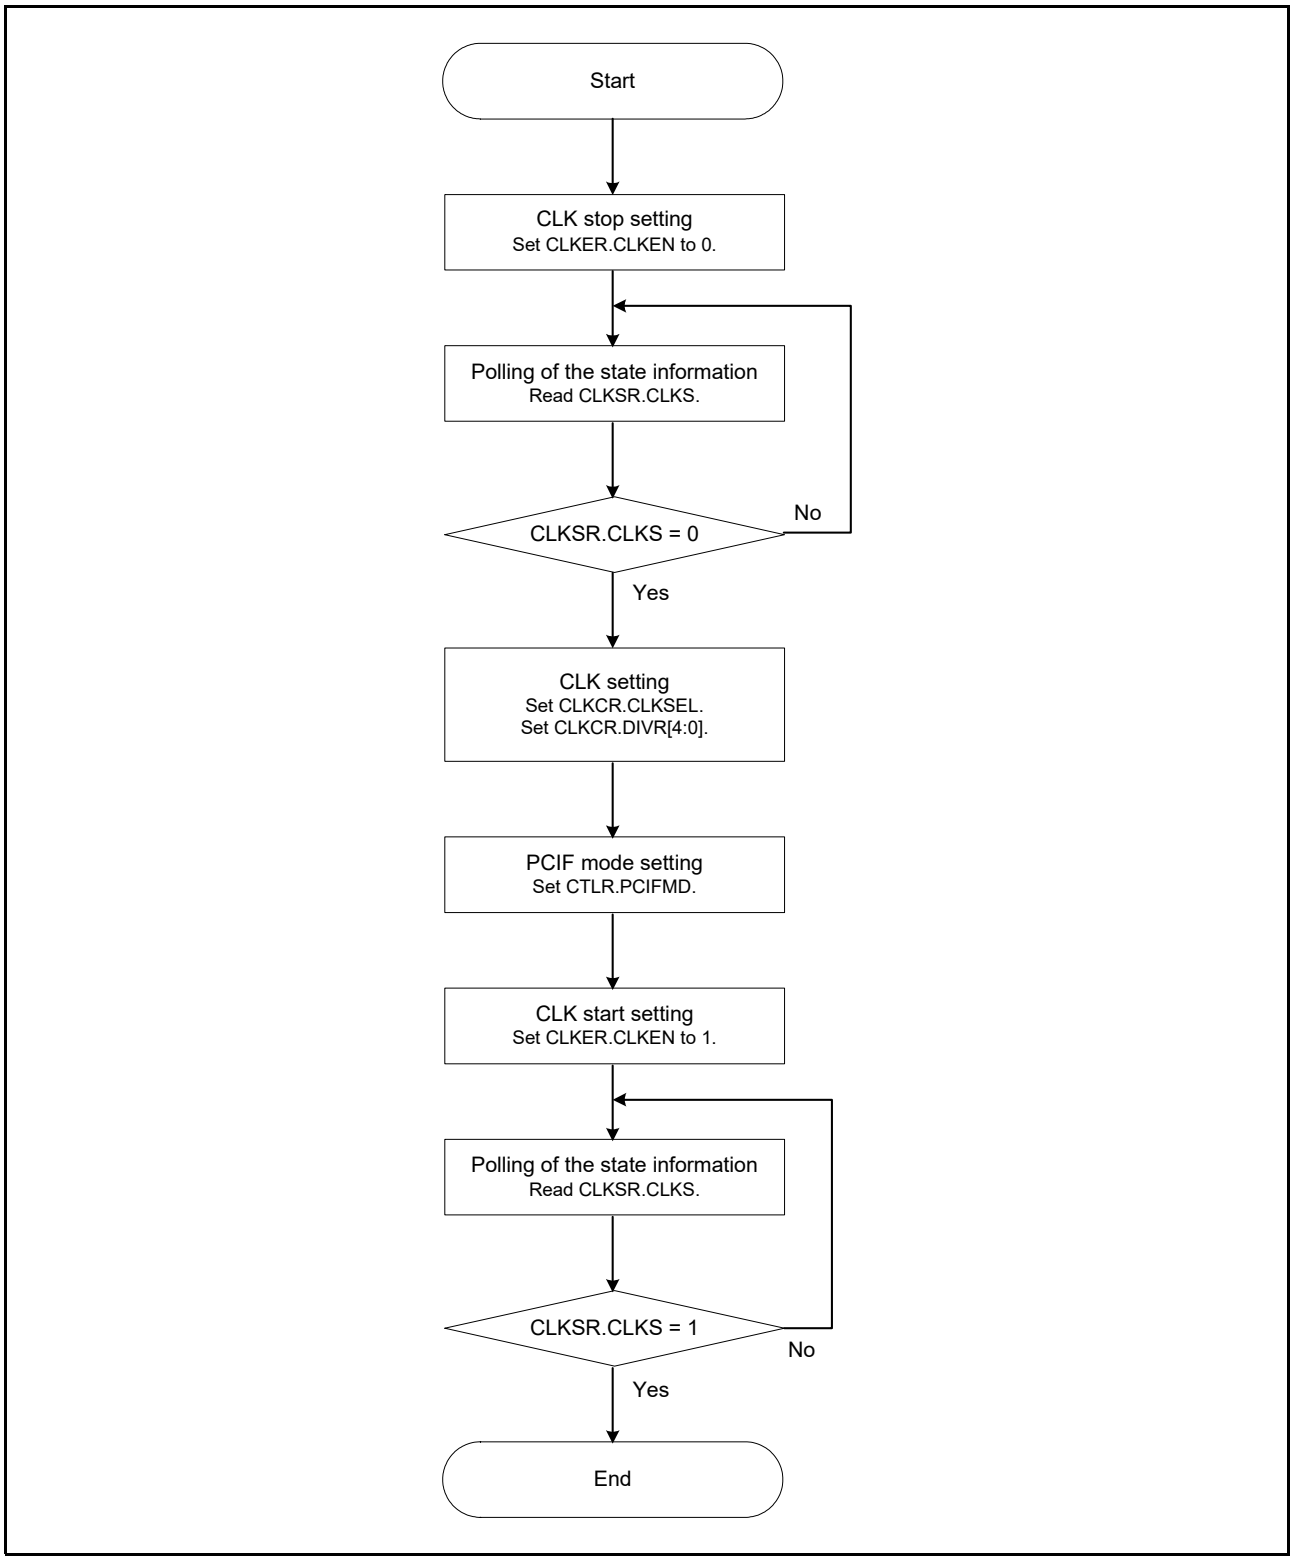

Figure 59.45 PCIF Startup Processing Flow

59.3.4.3 Flows of Phase Counting Mode

Figure 59.46 shows the processing flow of the phase counting mode.

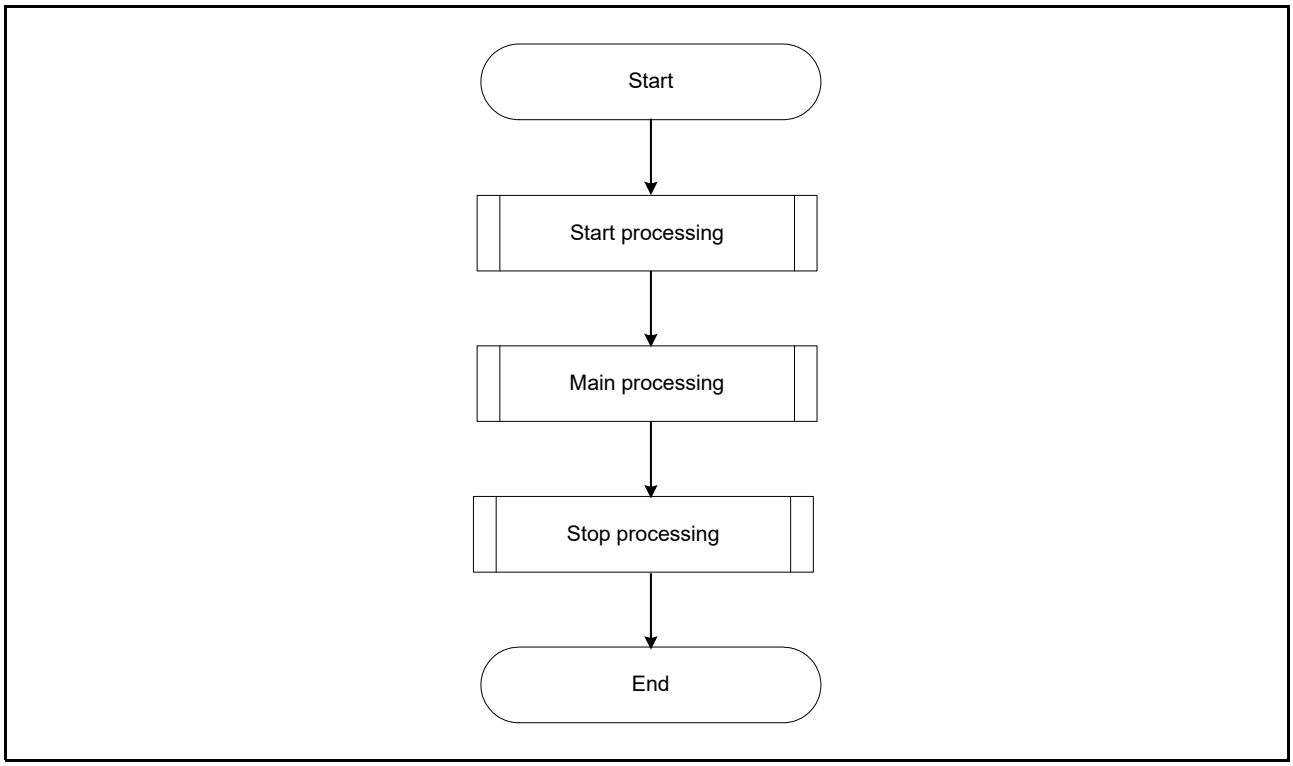

Figure 59.46 Processing Flow of Phase Counting Mode

(1) Startup Processing

Figure 59.47 shows the startup processing flow of the phase counting mode. Operation of carrier period input is not guaranteed during the startup processing flow. Start carrier period generation by the ELC after the startup processing flow ends.

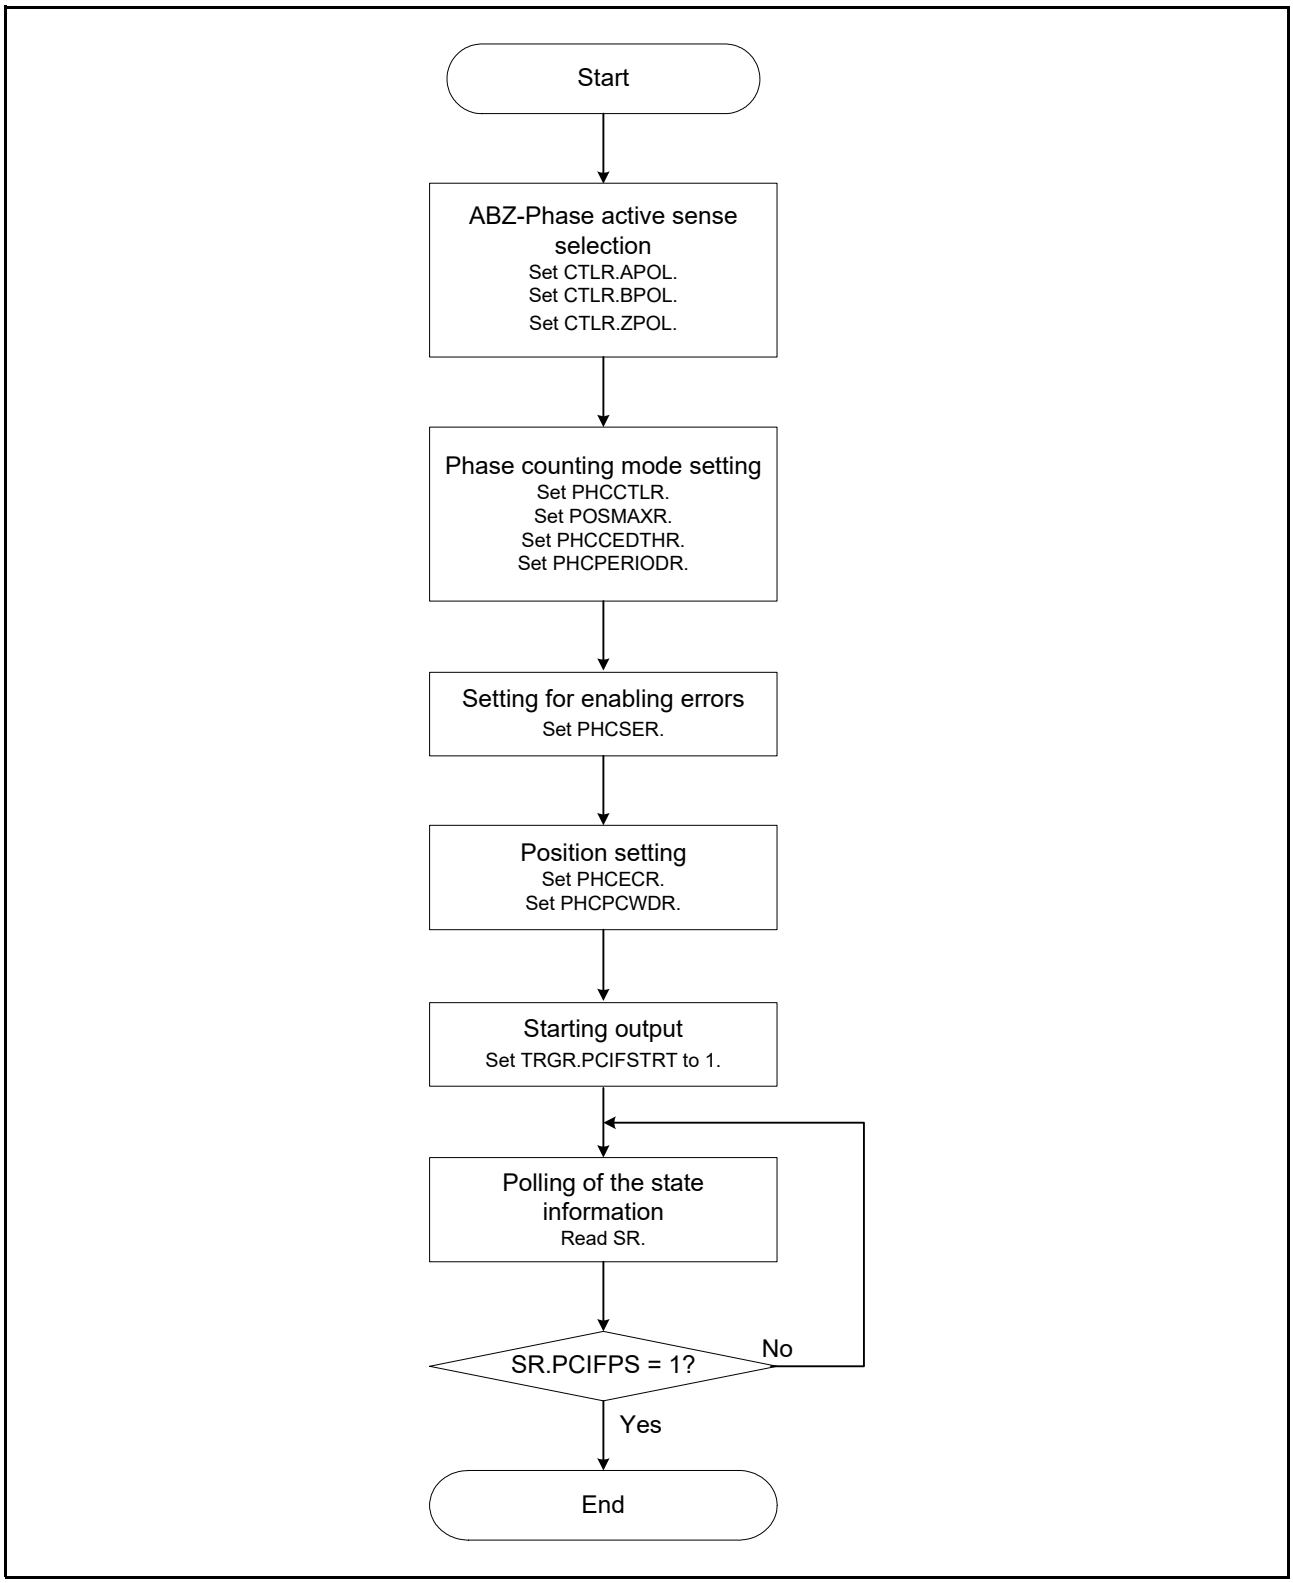

Figure 59.47 Startup Processing Flow of Phase Counting Mode

(2) Main Processing

Figure 59.48 shows the main processing flow of the phase counting mode.

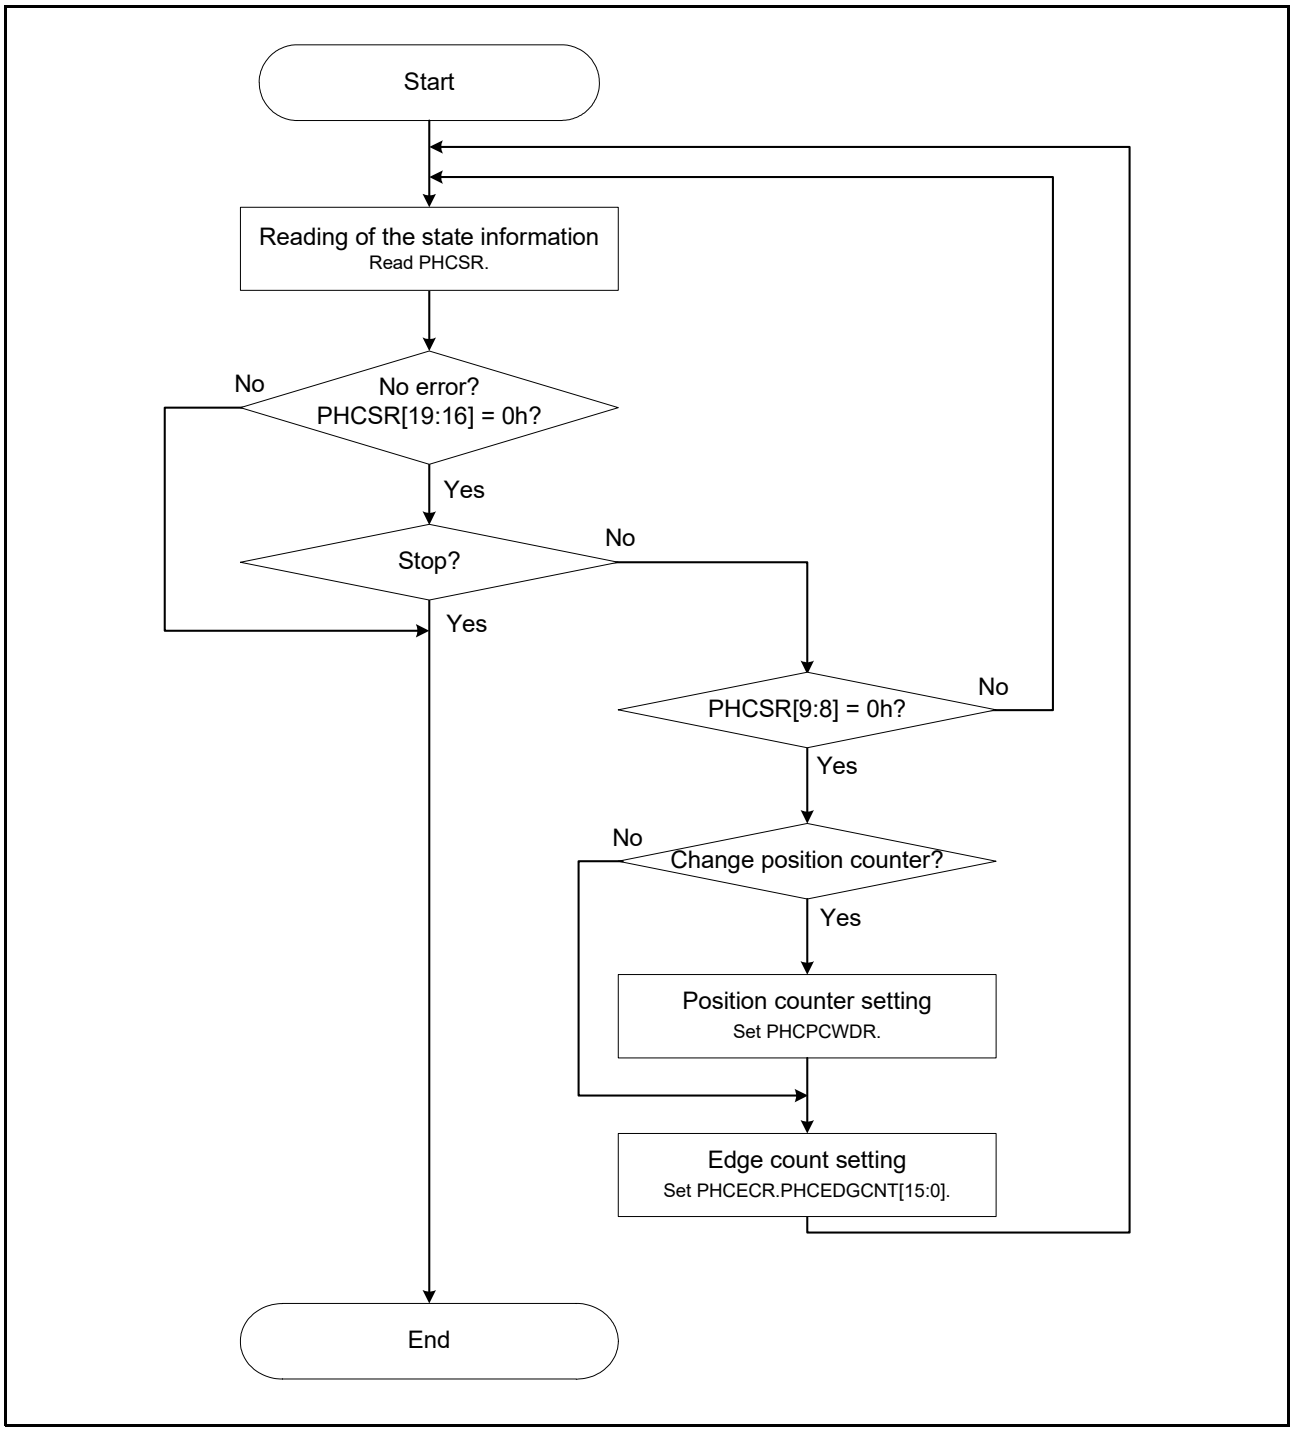

Figure 59.48 Main Processing Flow of Phase Counting Mode

(3) Stop Processing

Figure 59.49 shows the stop processing flow of the phase counting mode.
To immediately stop the phase counting mode, apply a software reset to clear the internal information such as the total edge count.

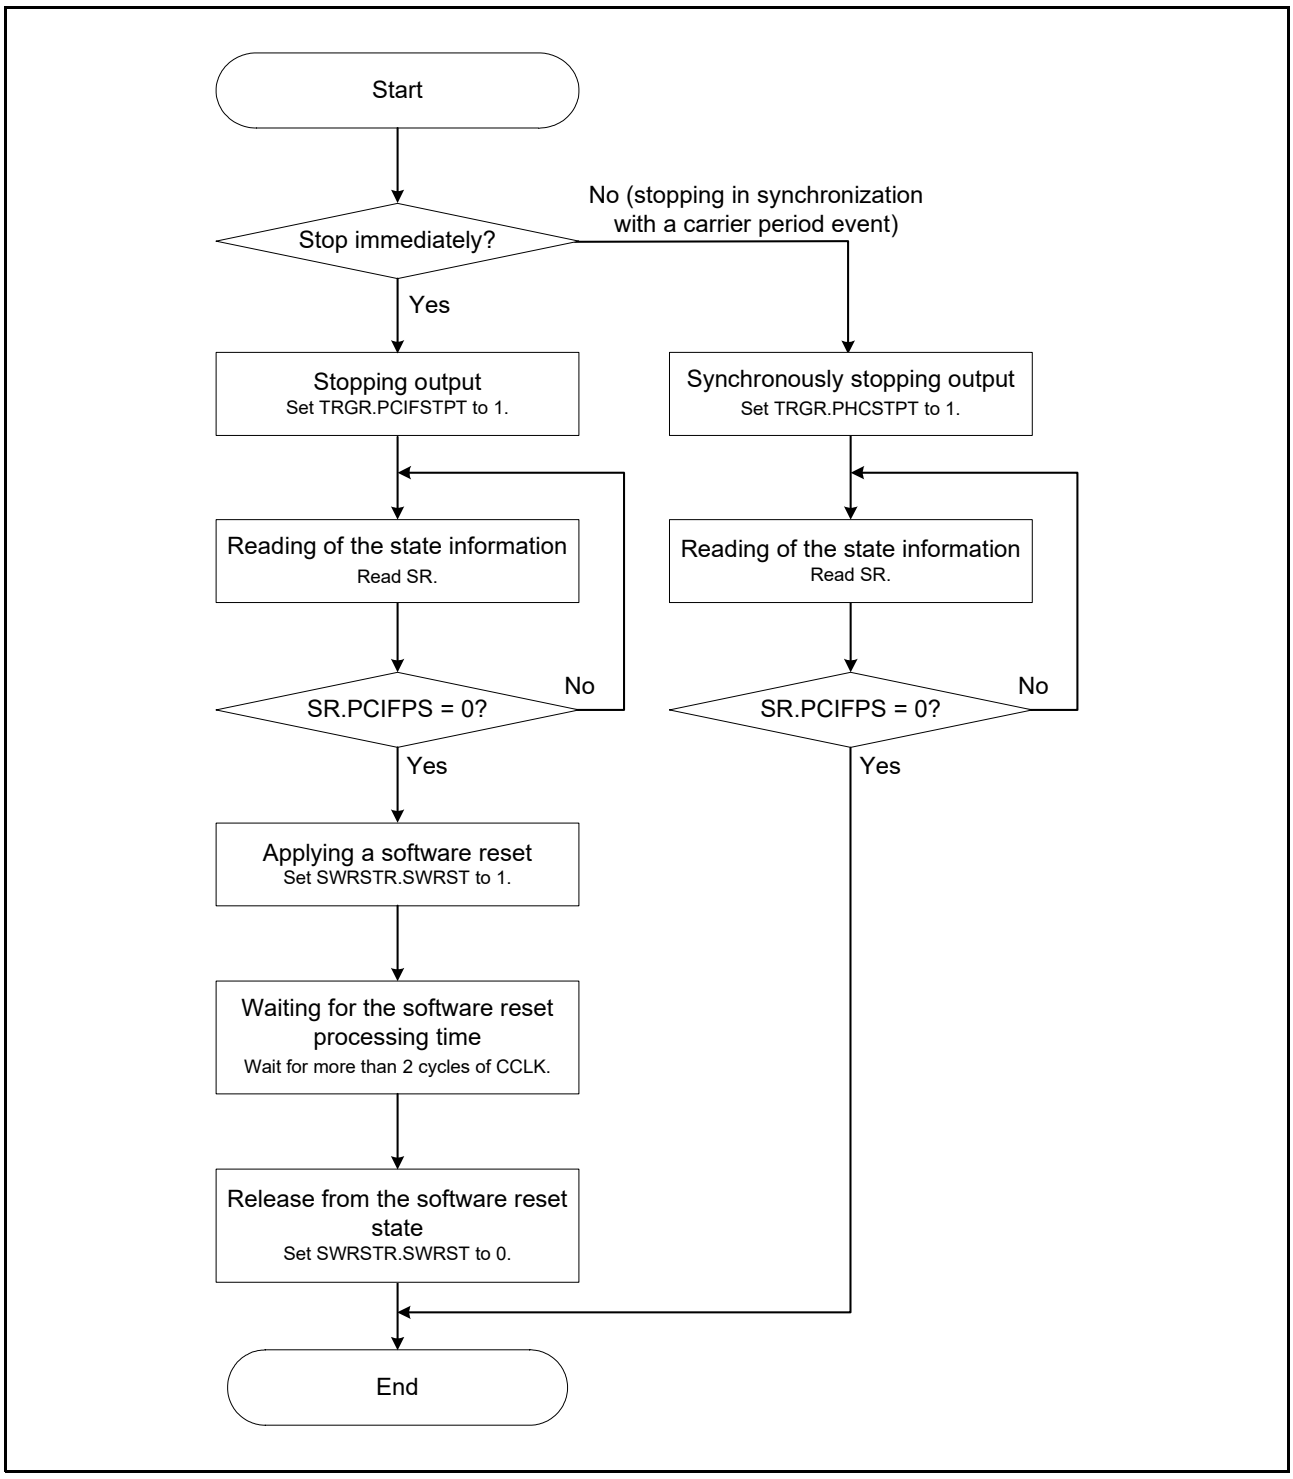

Figure 59.49 Stop Processing Flow of Phase Counting Mode

59.3.4.4 Flows of Incremental Mode

Figure 59.50 shows the processing flow of incremental mode.

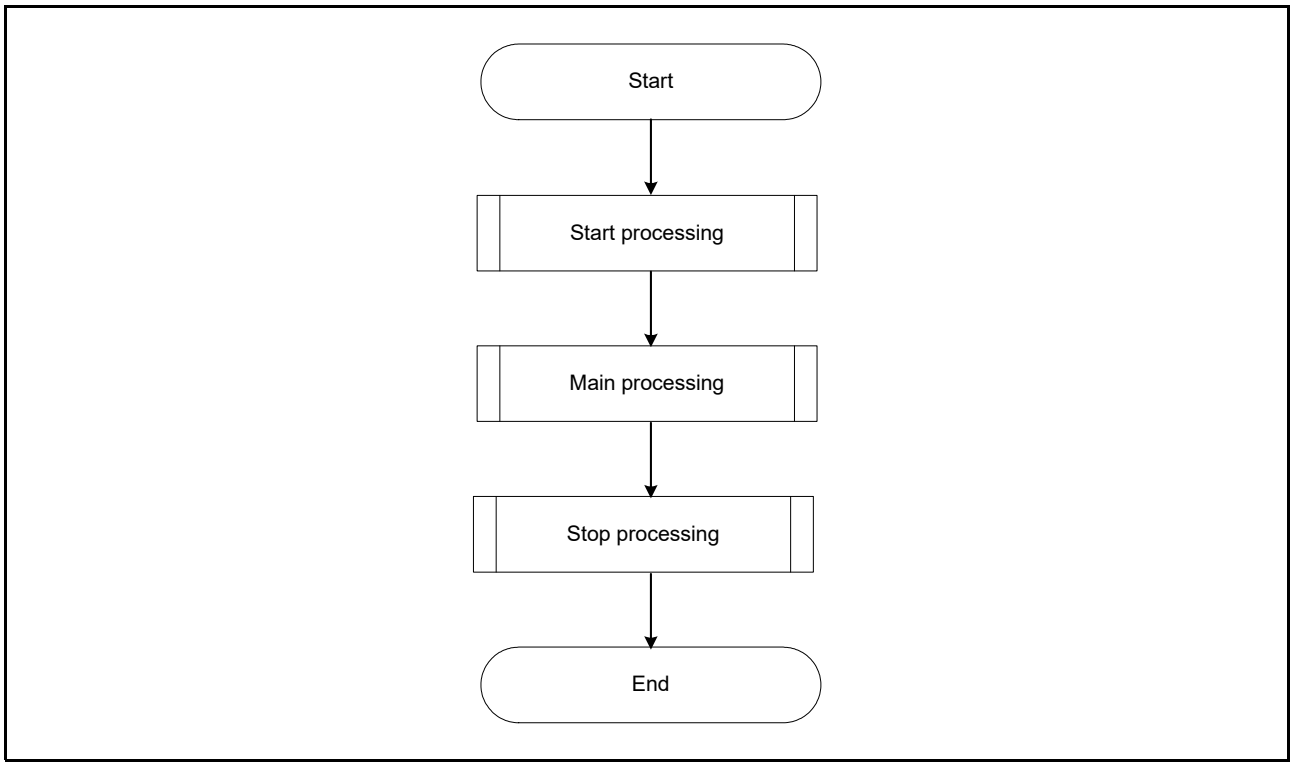

Figure 59.50 Processing Flow of Incremental Mode

(1) Startup Processing

Figure 59.51 shows the startup processing flow of the incremental mode. To restart the PCIF after changing register settings, initialize the internal information by using a software reset (SWRSTR.SWRST bit = 1) immediately before the startup processing flow.

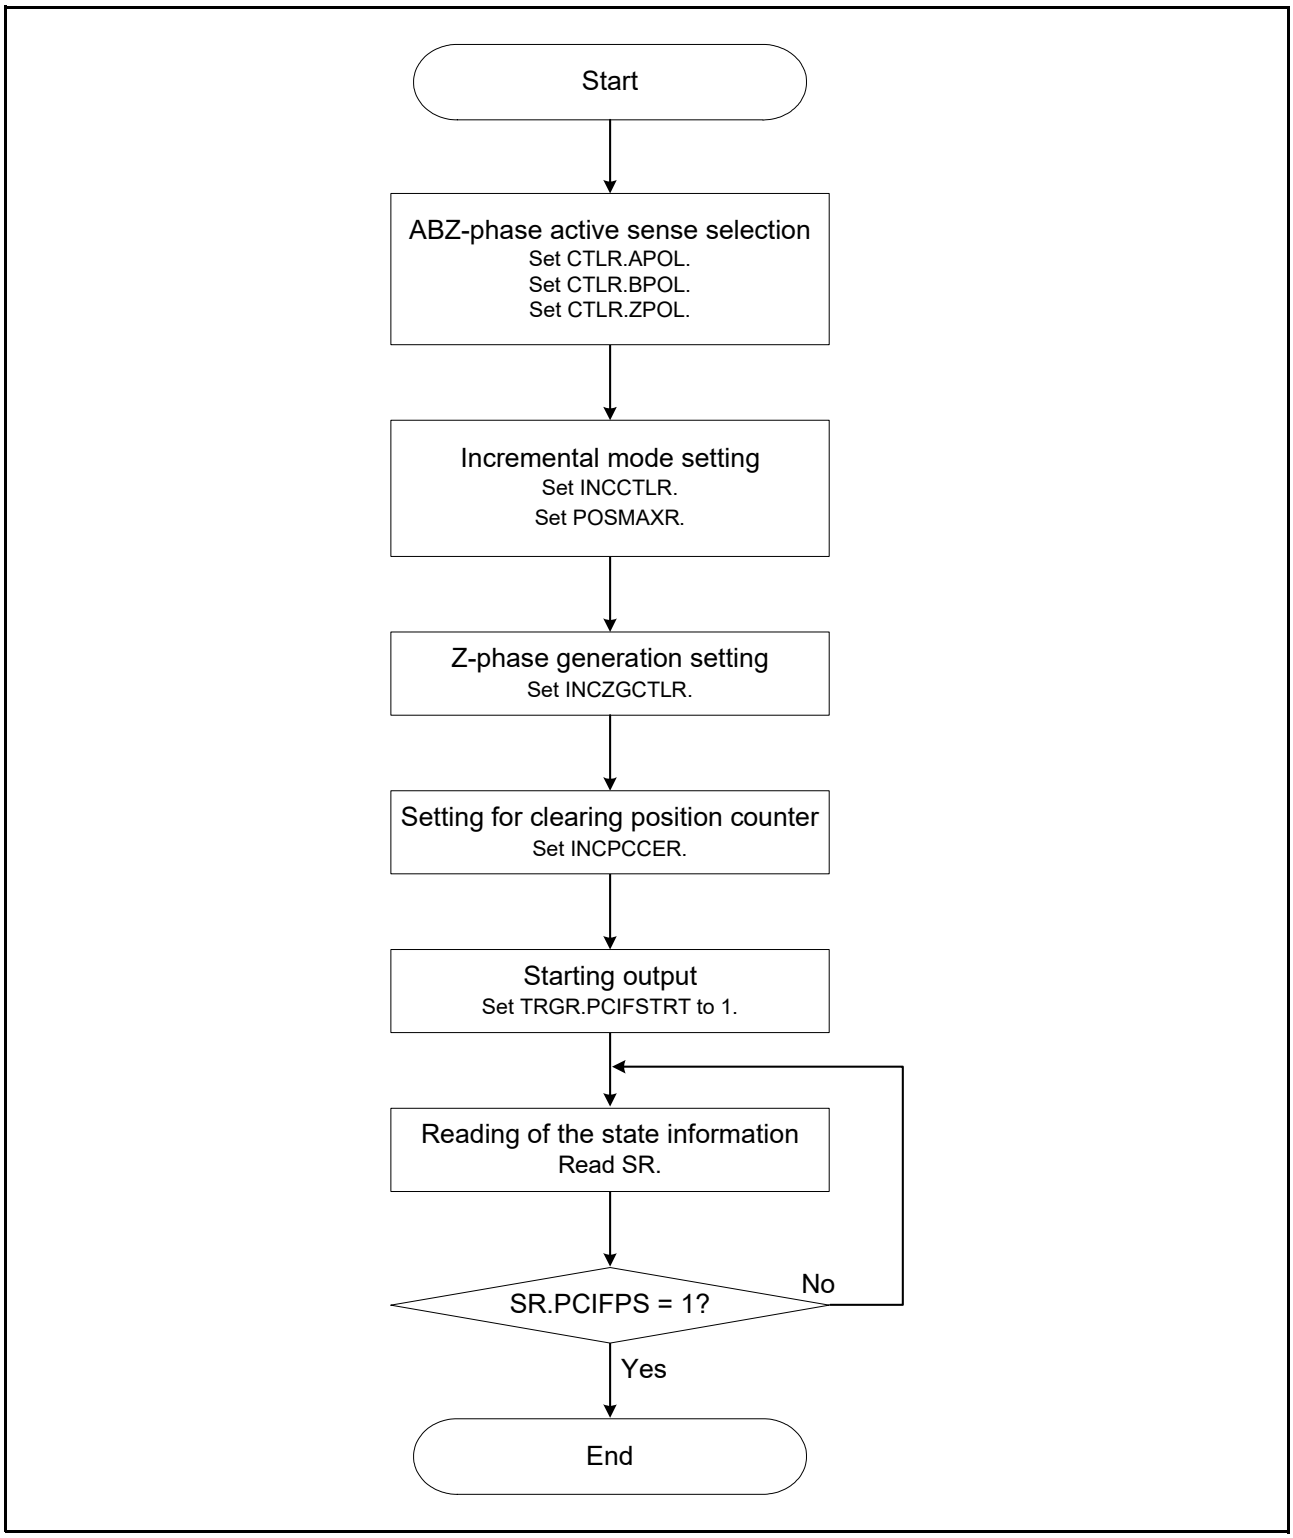

Figure 59.51 Startup Processing Flow of Incremental Mode

(2) Main Processing

Software operation is not required during main processing. ABZ-phase outputs are automatically generated from the external input of the PCIF. Based on AB-phase inputs, AB-phase signals are output according to the resolution ratio, and the Z-phase signal is output by using a Z-phase input, crest event trigger, trough event trigger, or software trigger input, or when the output counter's maximum value (POSMAXR.POSMAX[15:0] bits) is reached.
For details, refer to section 59.3.2, Incremental Mode.

(3) Stop Processing

Figure 59.52 shows the stop processing flow of the incremental mode.

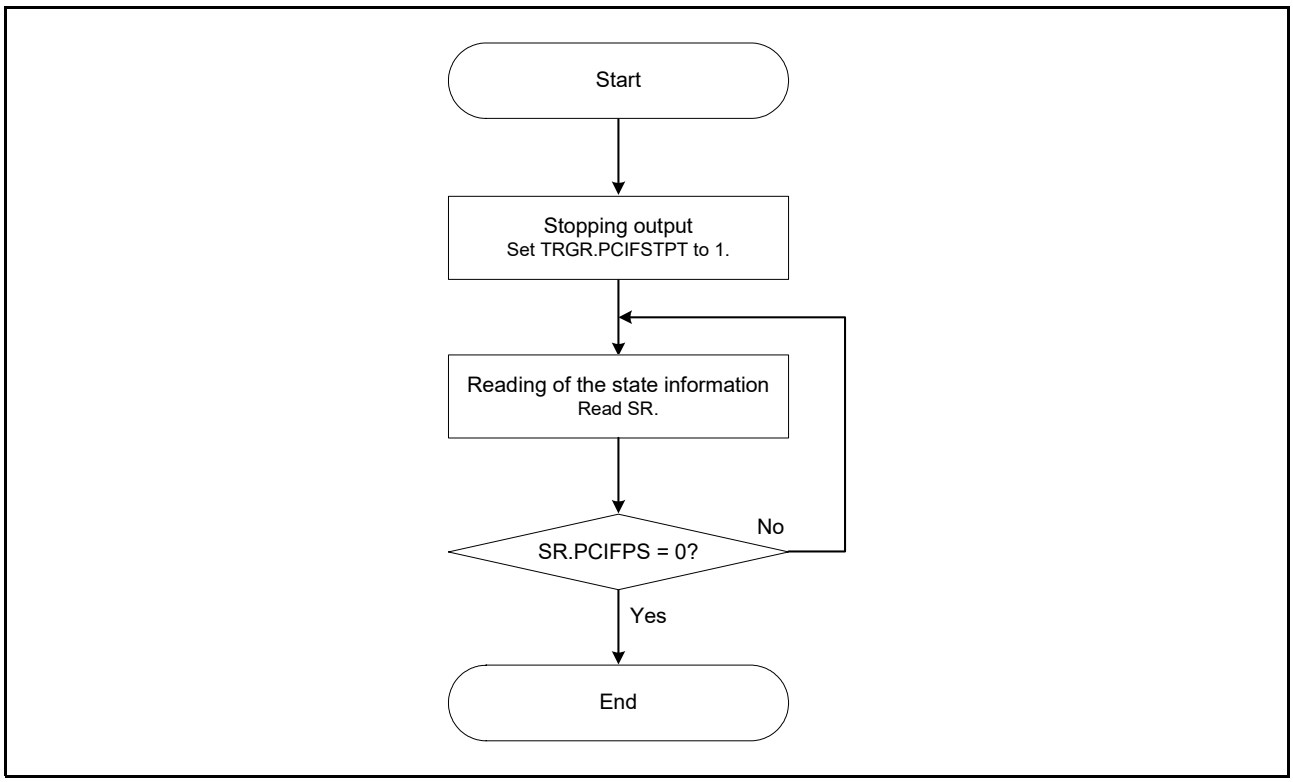

Figure 59.52 Stop Processing Flow of Incremental Mode

59.3.4.5 PCIF Stop Processing

Figure 59.53 shows the stop processing flow.

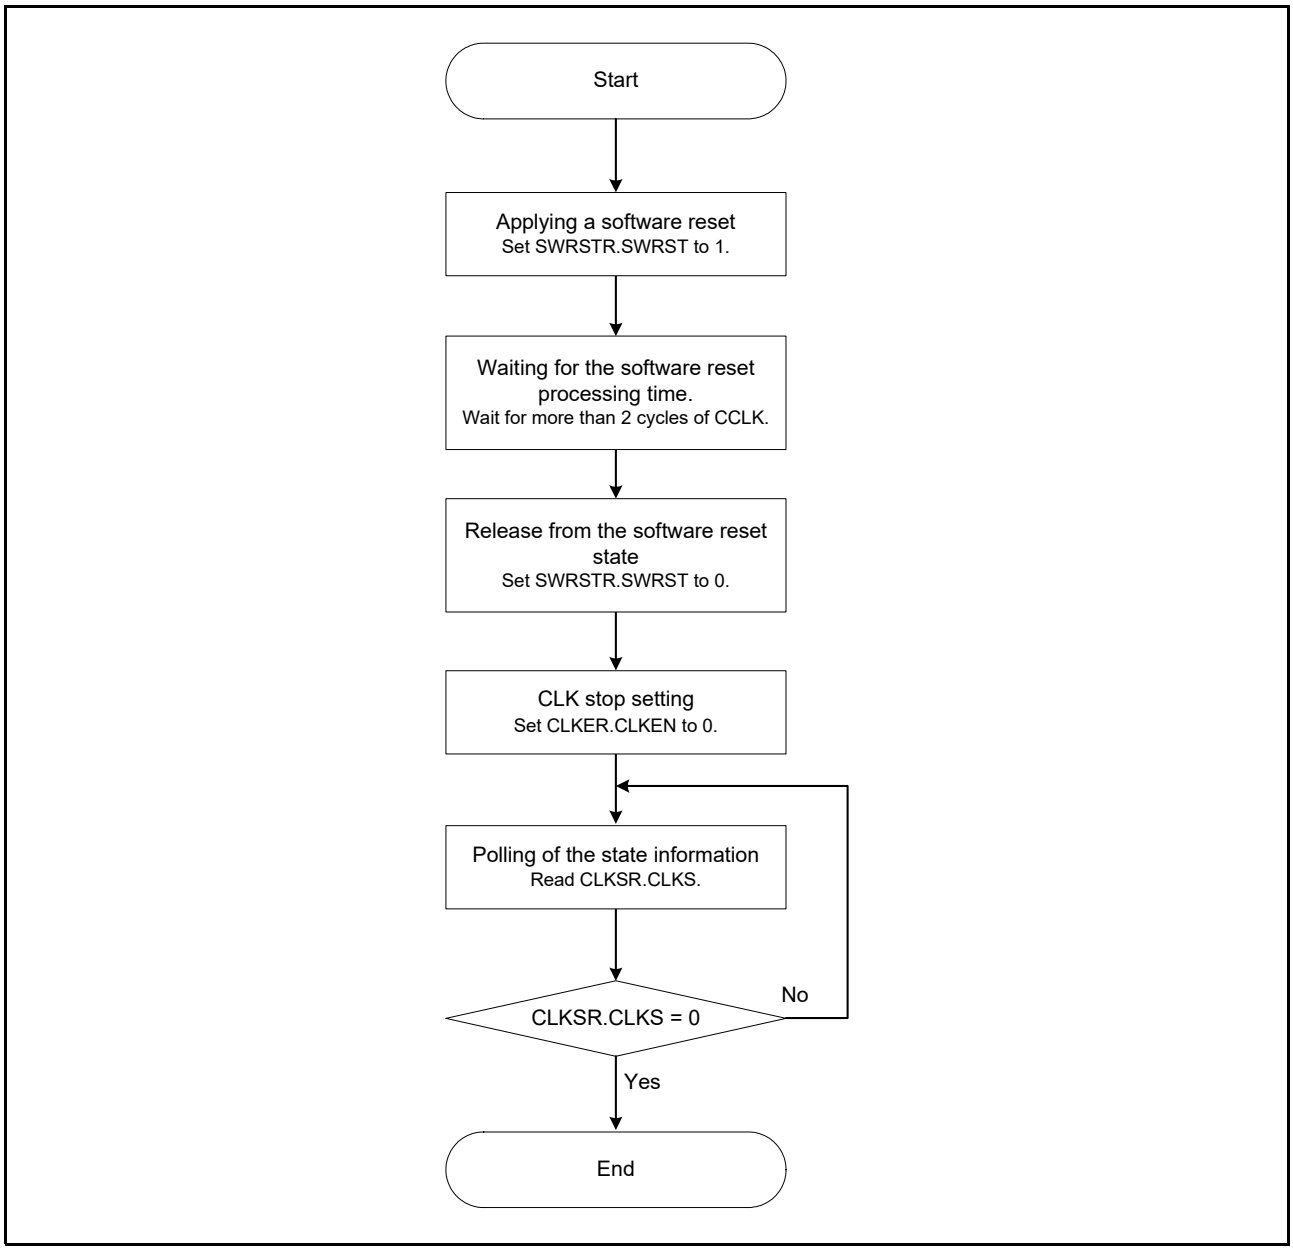

Figure 59.53 PCIF Stop Processing Flow

59.4 Event Link Function

59.4.1 Carrier Period Event Input (ELC_IN)

You can control the carrier period by setting the event-based mode (PHCCTLR.PHCCEDAMD bit = 0) and using the carrier period event (ELC_IN) output from the ELC.
For details, refer to section 59.3.1.3, Carrier Period Control, (1) Event-Based Mode.

59.4.2 Clearing the Internal Counters by Crest/Trough Event Trigger Input (PEK_IN, VLY_IN)

Input of a crest event trigger (PEK_IN) or trough event trigger (VLY_IN) from the ELC can initialize the internal counters (INCOCNTM[15:0] and INCICNTM[5:0] bits) to clear the AB-phase outputs.
For details, refer to section 59.3.2.2, Generating A- and B-Phase Signals, (3) Internal Counter Clearing Function.

59.4.3 Generating Z-Phase Output by Crest/Trough Event Trigger Input (PEK_IN, VLY_IN)

Input of a crest event trigger (PEK_IN) or trough event trigger (VLY_IN) from the ELC can assert the Z-phase output.
For details, refer to section 59.3.2.3, Generating Z-Phase Signals, (1) Selecting the Z-Phase Output Trigger.

59.5 Usage Notes

59.5.1 Restrictions on Input Pins

- Minimum toggle intervals for ABZ-phase inputs

Table 59.18 shows the minimum toggle intervals for ABZ-phase inputs. The toggle intervals in the table mean the intervals for toggling of A-phase or B-phase inputs for use in switching between counting up and counting down in Table 59.9 to Table 59.11. For mode 2 (when the rotation direction changes), the minimum toggle interval means the period indicated by a blue double-headed arrow in Figure 59.54.

Table 59.18 Minimum Toggle Intervals for ABZ-Phase Inputs

Input Protocol Mode and Condition	Minimum Required Toggle Interval
Mode 0	1 CCLK cycle + 1 CCLK_DIV cycle
Mode 1	1 CCLK cycle + 1 CCLK_DIV cycle
Mode 2 (when the rotation direction is constant)	1 CCLK cycle + 1 CCLK_DIV cycle
Mode 2 (when the rotation direction changes)	1 CCLK cycle + 2 CCLK_DIV cycles

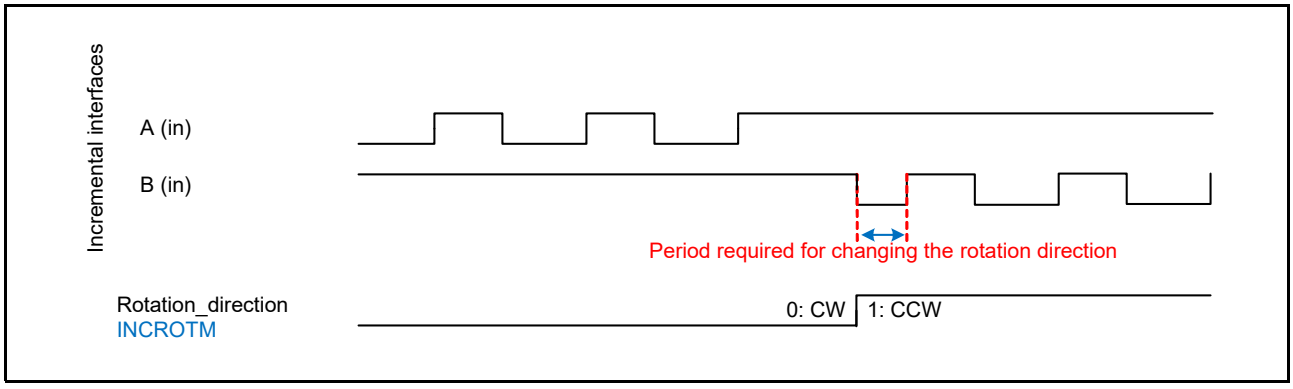

Figure 59.54 Waveforms When the Rotation Direction Changes in Mode 2

For modes 0 and 1 or mode 2 (when the rotation direction is constant), the number of cycles for synchronization (1 CCLK cycle) and the number of cycles that the CCLK_DIV domain circuit can receive (1 CCLK_DIV cycle) are required.

For mode 2 (when the rotation direction changes), in addition to the previously mentioned number of cycles, 1 CCLK_DIV cycle is required for the high-to-low period (first pulse) immediately after the rotation direction changes. This input restriction is provided to guarantee 1 CCLK_DIV cycle in the high-to-high period for output and 1 CCLK_DIV cycle in the high-to-low period of the first pulse. For details on this specification, refer to section 59.3.2.2, Generating A- and B-Phase Signals, (2) Internal Counter Operation, (c) AB-Phase Generation.
In any mode and condition, if the sufficient toggle intervals are not ensured, an edge might be lost when the rotation direction changes.

59.5.2 Restriction on Register Settings

- PHCPERIODR.PHCPERIOD[15:0] bit setting

Make sure to set the PHCPERIOD[15:0] bits to the mean value of the carrier period event intervals. If the mean value of the carrier period event intervals differs from the value set in the PHCPERIOD[15:0] bits, edges cannot be processed completely and will be lost during long-term operation.

59.5.3 Restrictions on Operation

- CTLR.PCIFMD bit setting timing

To switch the PCIF mode by changing the value of the PCIFMD bit, disable CCLK_DIV operation before writing to the bit in accord with the flow of startup processing in Figure 59.45.

- ELC startup timing

Operation of carrier period input is not guaranteed during the startup processing flow. Start carrier period generation by carrier period event input from the ELC after the startup processing flow ends.

- Action to be taken if an error occurs in phase counting mode

After an error specified in the PHCSR register occurs, operation is not guaranteed. If an error occurs, apply a software reset according to the stop processing flow in section 59.3.4.3, Flows of Phase Counting Mode, (3) Stop Processing. After the stop, use the PHCSCR register to clear the error state, and then review the register settings.

- Crest/trough event trigger input timing

If a crest event trigger (PEK_IN) or trough event trigger (VLY_IN) is input during the startup processing flow, operation is not guaranteed. Input the trigger after the startup processing flow ends.

59.5.4 Transition to Software Standby Mode

For phase counting mode, stop the PCIF according to Figure 59.49 Stop Processing Flow of Phase Counting Mode. After phase-counting by the PCIF has been stopped, stop the core clock according to Figure 59.53 PCIF Stop Processing Flow, and then initiate a transition to software standby mode. For incremental mode, stop the PCIF according to Figure 59.52 Stop Processing Flow of Incremental Mode. After incremental mode operation of the PCIF has been stopped, stop the core clock according to Figure 59.53 PCIF Stop Processing Flow, and then initiate a transition to software standby mode.

59.5.5 Return from Software Standby Mode

For phase counting mode, after a return from software standby mode, start the core clock according to Figure 59.45 PCIF Startup Processing Flow, and then start the PCIF operating in phase counting mode according to Figure 59.47 Startup Processing Flow of Phase Counting Mode. For incremental mode, after a return from software standby mode, start the core clock according to Figure 59.45 PCIF Startup Processing Flow, and then start the PCIF operating in incremental mode according to Figure 59.51 Startup Processing Flow of Incremental Mode.

60. 16-Bit A/D Converter (ADC16H)

60.1 Overview

This MCU contains three units of noise-shaping SAR-type A/D converters (ADC) that is the hybrid architecture with features of SAR-type and delta-sigma modulation-type. The A/D converter unit 0 (ADC0) can select up to 8 channels of analog inputs. The A/D converter unit 1 (ADC1) can select up to 28 channels of analog inputs. The A/D converter unit 2 (ADC2) can select up to 28 channels of analog inputs. The 28 channels of analog input shared by unit 1 and unit 2 use the same port. The temperature sensor, internal reference voltage, D/A converters, and VBATT 1/6 voltage monitor output can be A/D-converted by A/D converter unit 0, unit 1 or unit 2. A/D conversion data can be selected from 16-bit, 14-bit, 12-bit, and 10-bit length data formats.
The ADC has the following features.

- Resolution: Up to 16-bit
- Fast conversion: Up to 6.25 Msps (0.16 µs per channel) (when A/D conversion clock ADCLK = 50 MHz)
- Input channels: Up to 36 analog input channels
- Support single-ended input or differential inputs
- Self-calibration Function
- Built-in channel-dedicated sample-and-hold circuit (S&H)

Table 60.1 shows the ADC specifications, Table 60.2 shows the correspondence between ADC functions and ADC operation mode, and Table 60.3 shows the ADC I/O pins.
Figure 60.1 shows the block diagram of ADC. Figure 60.2 shows the analog channel structure for A/D converter unit 0. Figure 60.3 shows the analog channel structure for A/D converter unit 1. Figure 60.4 shows the analog channel structure for A/D converter unit 2.
Table 60.4 shows the ADC channel configuration of the analog inputs. Table 60.5 shows the ADC channel configuration of the extended analog function.

Table 60.1 ADC Specifications (1/4)

Item	Description
Number of units	Three units (unit 0, unit 1, and unit 2)
Input channels	• Support single-ended input or differential inputs • Up to 36 analog input channels • A/D converter unit 0: Up to 8 analog input channels at single-ended input, 8 analog input channels (4 pairs) of which support differential inputs. • A/D converter unit 1: Up to 28 analog input channels at single-ended input, 8 analog input channels (4 pairs) of which support differential inputs. • A/D converter unit 2: Up to 28 analog input channels at single-ended input, 8 analog input channels (4 pairs) of which support differential inputs. • 28 analog input channels are shared by A/D converter unit 1 and unit 2
Extended analog function	Self-diagnosis, temperature sensor, internal reference voltage, D/A converter (DA0 and DA1), VBATT 1/6 voltage monitor output
A/D conversion method	• Successive approximation register method in SAR mode • Noise-shaping successive approximation register method in oversampling mode and hybrid mode
Resolution of A/D converter	• Up to 12-bits in SAR mode • Up to 16-bits in oversampling mode or hybrid mode
Conversion time	0.16 µs per channel (when A/D conversion clock ADCLK = 50 MHz).
A/D conversion clock	The A/D conversion clock (ADCLK) can be set by selecting the clock source and the division ratio as follows: • The clock source: the peripheral module clock PCLKA*1, ADC clock ADCCLK*1, the GPT clock GPTCLK*1. • The division ratio: 1/2/3/4/5/6/7/8 A/D conversion clock (ADCLK) can operate between 25 MHz at a minimum and 60 MHz at a maximum.
A/D conversion data	• A/D conversion results are stored in data register or FIFO. • A/D conversion results are available in 16-, 14-, 12-, and 10-bit data formats.

Table 60.1 ADC Specifications (2/4)

<table>
<tr><th>Item</th><th>Description</th></tr>
<tr><td>Operating modes</td><td>
• SAR mode
  • A/D converter samples the signal source once, and convert by successive approximation register method
  • Fast A/D conversion
  • Support up to 8 channels per one scan group
  • Support only single-ended input (excluding self-diagnosis function)
• Oversampling mode
  • A/D converter oversamples the signal source, and converts analog-to-digital by noise shaping successive approximation register method
  • High-accuracy A/D conversion
  • Support up to 8 channels per one scan group
  • Support single-ended input and differential input
• Hybrid mode
  • A/D converter oversamples the signal source, and converts analog-to-digital by noise shaping successive approximation register method
  • High-accuracy A/D conversion
  • High data rate in continuous scanning operation
  • Support up to 4 channels per one scan group
  • Support single-ended input and differential input
</td></tr>
<tr><td>Scan mode</td><td>
• Single scan mode
  • Assign any selected analog input or analog channel of the extended analog function to any scan group, and convert the selected analog input only once per scan group for A/D conversion.
  • By selecting the scan start conditions for each scan group individually, A/D conversion for each scan group can be started at different times.
• Continuous scan mode
  • Assign any selected analog input or analog channel of the extended analog function to any scan group and repeat A/D conversion in scan group units.
• Background continuous scan mode
  • Assign any selected analog input or analog channel of the extended analog function to any scan group and repeat A/D conversion in scan group units.
  • The A/D conversion is performed in the background and, if the A/D conversion start trigger is entered, the A/D conversion data at that point is acquired.
• Same channel continuous scan mode
  • Repeats A/D conversion of one analog channel assigned to any scan group
  • When an A/D conversion trigger is input during scanning, A/D conversion of the next analog channel begins
  • A/D conversion channel can be changed whenever an external factor occurs
• Fixed channel continuous scan mode
  • Analog channels designated as fixed channels are A/D converted in hybrid mode, and analog channels designated as non-fixed channels are A/D converted in SAR mode
  • The non-fixed channels to be A/D converted are switched every time the scan operation is completed, and A/D conversion of fixed and non-fixed channels is repeated
  • A larger number of channels can be converted than in normal hybrid mode
  • The scan interval can be adjusted by adding channels that are not converted (free channels) after scanning non-fixed channels
</td></tr>

Table 60.1 ADC Specifications (3/4)

Item	Description
Functions	• Virtual channel function (50 virtual channels) • Scan group function (up to 12 scan groups) • Variable sampling time (select from 16 tables per virtual channel) • Channel-dedicated sample-and-hold circuit (S&H) (3 SH units for A/D converter unit 0, constant sampling can be set) • Self-diagnosis function for A/D converter • Selectable A/D-converted value addition mode or average mode • Analog input disconnection detection assist function (discharge function/precharge function) • Selectable the data format from 16- / 14- / 12- / 10-bit. • Selectable the signed-data or the unsigned-data format • Limiter clip function (Up to 8 tables) • Compare match function (Up to 8 tables) • Self-calibration function • User's gain adjustment function • User's offset adjustment function • Built-in FIFO (16 stages per each scan group) • FIFO clear function (when scanning starts/resumes) • Built-in digital filter (2 type) (support only oversampling mode and hybrid mode) • A/D conversion data decimation function (only oversampling mode (same channel continuous scan mode) is supported) • Multiple A/D converters unit-to-unit synchronous operation function • GPT can be used for inter-unit sync signals • Accuracy priority function (High accuracy mode)
Interrupt sources	• A/D scan end interrupt • Generates the interrupt requests and the ELC events at the end of A/D scan operation for the scan group i (ADIi (i = 0 to 11)). The interrupt requests are independent for each scan group. • FIFO data read request interrupt • Generates the interrupt requests when the number of vacant stages of FIFO for the scan group i becomes less than or equal to the specified value (FIFOREQi (i = 0 to 11)). The interrupt requests are independent for each scan group. • FIFO data overflow interrupt • Generates the interrupt request when the overflow occurs in any of the FIFO for the scan groups 0 to 11 (FIFOOVF). • Limiter clip interrupt • Generates the interrupt request when the limiter clip using the limiter tables 0 to 7 is occurred for A/D conversion results (LIMCLPI). • Compare match interrupt • Generates the interrupt requests when the compare match using the compare match tables j are occurred for A/D conversion results (CMPIj (j = 0 to 7)). The interrupt requests are independent for each compare match table. • Composite compare match interrupt • Generates the interrupt requests and the ELC events when the compare match of the composite condition using compare match tables 0 to 7 occurs (CCMPMm (m = 0 to 7)). • Composite compare unmatch interrupt • Generates the interrupt requests and the ELC events when the compare unmatch of the composite condition using compare match tables 0 to 7 occurs (CCMPUMm (m = 0 to 7)). • A/D converter error interrupt • Generates the interrupt requests when the operational error is detected in A/D converter unit j (ERRj (j = 0 to 2)). • A/D conversion overflow interrupt • Generates the interrupt request when the A/D conversion result overflow is occurred (RESOVFj (j = 0 to 2)) The interrupt requests are independent for A/D converter unit j. • A/D converter calibration end interrupt • Generates the interrupt requests at the end of calibration operation of A/D converter unit j (CALENDj (j = 0 to 2)).
ELC interface	• Trigger Input • Scan can be started by the trigger from the ELC. • Event Generation • An event is generated at the end of each scan operation for the scan group 0 to 11. • An event is generated when composite compare match or composite compare unmatch is occurred.
Reference voltage	VREFH0 is the analog reference voltage. VREFL0 is the analog reference ground.
Module-stop function	Module-stop state can be set to reduce power consumption.*2 A/D converter units can be set to sleep mode independently

Table 60.1 ADC Specifications (4/4)

Item	Description
Protect Zone filter	Security attribute can be set.*3

Note 1. For details, see section 9, Clock Generation Circuit.
Note 2. For details, see section 11, Low Power Consumption
Note 3. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Table 60.2 Association between ADC Functions and ADC Operation Mode

Function			SAR Mode		Oversampling Mode			Hybrid Mode			
			Single Scan Mode	Continuous Scan Mode	Single Scan Mode	Continuous Scan Mode	Same Channel Continuous Scan Mode	Single Scan Mode	Continuous Scan Mode	Background Continuous Scan Mode	Fixed Channel Continuous Scan Mode
Analog input	Single-ended input		✓	✓	✓	✓	✓	✓	✓	✓	✓
	Differential input		✓	✓	✓	✓	✓	✓	✓	✓	✓
	Channel-dedicated sample-and-hold circuit		✓	—	—	—	—	✓	✓	✓	✓*1
Diagnosis function/ extended analog function	Disconnection detection assist function	Channel-dedicated sample-and-hold circuit disabled	✓	✓	—	—	—	✓	✓	—	—
		Channel-dedicated sample-and-hold circuit enabled	✓	—	—	—	—	—	—	—	—
	Self-diagnosis	Channel-dedicated sample-and-hold circuit disabled	✓	✓	✓	—	—	✓	—	—	—
		Channel-dedicated sample-and-hold circuit enabled	✓	—	—	—	—	—	—	—	—
	Internal reference voltage		✓	✓	✓	✓	✓	✓	✓	✓	✓
	VBATT 1/6 voltage monitor output		✓	✓	✓	✓	✓	✓	✓	✓	✓

	D/A converter (DA0, DA1)		✓	✓	✓	✓	✓	✓	✓	✓	✓
Scanning operation	Group priority operation		✓*2	✓*2	—	—	—	—	—	—	—
	Multiple A/D converter synchronous operation		✓	✓	✓	✓	✓	✓	✓	✓	✓
Digital calculation	Digital filter function		—	—	✓*3	✓*3	✓*3	✓*3	✓*3	✓*3	✓*3
	User's gain/offset adjustment function		✓	✓	✓	✓	✓	✓	✓	✓	✓
	Addition/average function		✓	✓	✓	✓	✓	✓	✓	✓	—
	Limiter clip function		✓	✓	✓	✓	✓	✓	✓	✓	✓
	Compare match function		✓	✓	✓	✓	✓	✓	✓	✓	✓
FIFO function			✓	✓	✓	✓	✓	✓	✓	✓	✓

Note 1. Fixed channels can be used when the number of fixed channels is set to 3 and all fixed channels are set to channel-dedicated sample-and-hold circuits. Non-fixed channels (SAR mode) cannot use the channel-dedicated sample-and-hold circuits.
Note 2. When group scan is enabled, only the highest priority group can use the channel-dedicated sample-and-hold circuits.
Note 3. Use of the digital filter function is required when in oversampling mode and hybrid mode.

Table 60.3 Input/Output Pins of ADC

Item	I/O	Function
AVCC0	Input	Analog block power supply pin
AVSS0	Input	Analog block ground pin
VREFH0	Input	Analog reference power supply pin
VREFL0	Input	Analog reference ground pin
AN000 to AN035	Input	Analog input pins
SHIN0P to SHIN2P	Input	Analog input pins for channel-dedicated sample-and-hold circuit • For single-ended input: Connect to signal source • For differential input: Functions as the non-inverting inputs (+) terminal for differential input
SHIN0N to SHIN2N	Input	Analog input pins for channel-dedicated sample-and-hold circuit • For single-ended input: Connect to signal source • For differential input: Functions as the inverting inputs (–) terminal for differential input
ADTRG0, ADTRG1, ADTRG2	Input	External trigger input pin for starting A/D conversion, active-low.
ADST0, ADST1, ADST2	Output	A/D conversion period monitor output
ADCNV0, ADCNV1, ADCNV2	Output	A/D comparison period monitor output
ADSYNC	Output	A/D converter unit inter-unit synchronous monitor output

34	AN034 (AN034P) *1	—	—	—	✓	—	✓	—
35	AN035 (AN034N) *1	—	—		✓		✓	

Note 1. Do not perform A/D conversions of the same signal source from both A/D converter unit 1 and unit 2.
Note 2. When the channel-dedicated sample-and-hold circuit is used with a single-ended input, the SHINxP (non-inverting input (+)) and SHINxN (inverting input (–)) channels should be assigned to different scan groups (x = 0 to 2), or assigned to the same scan group with one of them set as the bias path.
Note 3. When performing A/D conversion with differential-input, set the even-numbered channel as the A/D conversion target. For differential input, the even-numbered channels function as non-inverting inputs (+), and the odd-numbered channels function as inverting inputs (–).

Table 60.5 ADC Channel Configuration of the Extended Analog Function

Analog Channel Number	Source of Analog Signal	A/D Converter Unit 0		A/D Converter Unit 1		A/D Converter Unit 2	
	Analog Input	Single-Ended Input*2	Differential Input*3	Single-Ended Input*2	Differential Input*3	Single-Ended Input*2	Differential Input*3
96	Self-diagnosis Unit 0	—	✓	—	—	—	—
97	Self-diagnosis Unit 1	—	—	—	✓	—	—
98	Self-diagnosis Unit 2	—	—	—	—	—	✓
100	Temperature sensor*1	✓	—	✓	—	✓	—
101	Internal reference voltage*1	✓	—	✓	—	✓	—
102	VBATT 1/6*1	✓	—	✓	—	✓	—
104	D/A converter channel 0*1	✓	—	✓	—	✓	—
105	D/A converter channel 1*1	✓	—	✓	—	✓	—
112	Self-diagnosis S&H 0	—	✓	—	—	—	—
113	Self-diagnosis S&H 1	—	✓	—	—	—	—
114	Self-diagnosis S&H 2	—	✓	—	—	—	—

Note 1. Do not perform A/D conversions of the same signal source from multiple A/D converter units.
Note 2. The extend analog function (except for the self-diagnosis function) is only supported with the single-ended input. Do not set to the differential input.
Note 3. The self-diagnosis function is only supported with differential input.

60.2 Register Descriptions

60.2.1 A/D Conversion Clock Enable Register (ADCLKENR)

Address(es): ADC_B.ADCLKENR 8743 8000h, ADC_B_NS.ADCLKENR 0743 8000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLKEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CLKEN	ADCLK Operating Enable	0: Stop ADCLK 1: Supply ADCLK	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCLKENR controls the supply of the A/D conversion clock (ADCLK).

60.2.2 A/D Conversion Clock Status Register (ADCLKSR)

Address(es): ADC_B.ADCLKSR 8743 8004h, ADC_B_NS.ADCLKSR 0743 8004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SYLOCKSR	CLKSR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CLKSR	ADCLK Status	0: ADCLK is stopped 1: ADCLK is in supply	R
b1	SYLOCKSR	Sync Status	0: Not synchronized with an external signal (synchronization signal from GPT). 1: Synchronized with an external signal (synchronization signal from GPT).	R
b31 to b2	—	Reserved	These bits are read as 0.	R

The ADCLKSR register indicates the supply status of the A/D conversion clock (ADCLK).

CLKSR Bit (ADCLK Status)

The CLKSR bit indicates the supply status of the A/D converter operating clock (ADCLK).

SYLOCKSR Bit (Sync Status)

The SYLOCKSR bit indicates the synchronization status with an external signal (synchronization signal from the GPT). This bit is valid when the ADSYCR.ADSYEXTEN bit is 1 and one of the ADSYCR.ADSYDISm (m = 0 to 2) bits is 0. In all other cases, this bit is invalid and is always set to 0.

This bit is 1 when the ADC is synchronized to an external signal (sync signal from GPT). This bit is 0 when the clock is stopped (CLKSR = 0).

To detect the synchronization status with an external signal (synchronous signal from GPT), it takes a maximum of three ADCLK cycles after the clock status bit (CLKSR) becomes 1.

60.2.3 A/D Conversion Clock Control Register (ADCLKCR)

Address(es): ADC_B.ADCLKCR 8743 8008h, ADC_B_NS.ADCLKCR 0743 8008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	DIVR[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CLKSEL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CLKSEL[1:0]	ADCLK Clock Source Select	b1 b0 0 0: ADC clock (ADCCLK) 0 1: GPT clock (GPTCLK) 1 0: Peripheral module clock A (PCLKA) 1 1: Setting prohibited	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b18 to b16	DIVR[2:0]	Clock Division Ratio Select	b18 b16 0 0 0: 1/1 0 0 1: 1/2 0 1 0: 1/3 0 1 1: 1/4 1 0 0: 1/5 1 0 1: 1/6 1 1 0: 1/7 1 1 1: 1/8	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCLKCR register selects the frequency of A/D conversion clock (ADCLK). The frequency of ADCLK should be set within the range specified in the section 67, Electrical Characteristics.

CLKSEL[1:0] Bits (ADCLK Clock Source Select)

CLKSEL[1:0] bits select the clock source of A/D conversion clock (ADCLK).

DIVR[2:0] Bits (Clock Division Ratio Select)

DIVR[2:0] bits select the division ratio for the clock source selected by CLKSEL[1:0] bits. The clock divided by the clock source selected by CLKSEL[1:0] bits at the ratio set by DIVR[2:0] bits becomes the A/D conversion operating clock (ADCLK).

60.2.4 A/D Converter Synchronous Operation Control Register (ADSYCR)

Address(es): ADC_B.ADSYCR 8743 800Ch, ADC_B_NS.ADSYCR 0743 800Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	ADSYEXTEN	—	—	—	—	—	ADSYDIS2	ADSYDIS1	ADSYDIS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	ADSYCYC [7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	ADSYCYC [7:0]	Synchronous Operation Period Cycle	These bits should be set in the range from 5 to 255. The settings of 0 to 4 are prohibited.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	ADSYDIS0	ADC0 Synchronous Operation Select	0: Enable ADC0 synchronous operation 1: Disable ADC0 synchronous operation	R/W
b17	ADSYDIS1	ADC1 Synchronous Operation Select	0: Enable ADC1 synchronous operation 1: Disable ADC1 synchronous operation	R/W
b18	ADSYDIS2	ADC2 Synchronous Operation Select	0: Enable ADC2 synchronous operation 1: Disable ADC2 synchronous operation	R/W
b23 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b24	ADSYEXTEN	External Signal (GPT Sync Signal) Synchronization Enable	0: Do not synchronize the synchronization timing between the external signal (GPT synchronization signal) and the ADC unit. 1: Synchronize the synchronization timing between the external signal (GPT synchronization signal) and the ADC unit.	R/W
b31 to b25	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSYCR register controls the synchronous operation function. For more information, refer to section 60.3.20, Synchronous Operation.

ADSYCYC [7:0] Bits (Synchronous Operation Period Cycle)

These bits are selected the synchronous operation period cycles.
These bits set in the range from 5 to 255 regardless of whether the synchronous operation function is used or not. The settings of 0 to 4 are prohibited.

ADSYDIS0 Bit (ADC0 Synchronous Operation Select)

ADSYDIS0 bit selects enable/disable the synchronous operation of ADC0. If the synchronous operation is enabled, the ADC0 operates synchronously with other A/D converter that has synchronous operation enabled.

ADSYDIS1 Bit (ADC1 Synchronous Operation Select)

ADSYDIS1 bit selects enables/disables to the synchronous operation of ADC1. If the synchronous operation is enabled, the ADC1 operates synchronously with other A/D converter that has synchronous operation enabled.

ADSYDIS2 Bit (ADC2 Synchronous Operation Select)

ADSYDIS2 bit selects enables/disables to the synchronous operation of ADC2. If the synchronous operation is enabled, the ADC2 operates synchronously with other A/D converter that has synchronous operation enabled.

ADSYEXTEN Bit (External Signal (GPT Sync Signal) Synchronization Enable)

The ADSYEXTEN bit enables synchronization with an external signal (synchronization signal from GPT) when performing inter-unit synchronous operation. This bit is only valid for the ADC of a unit that has the ADSYDISx (x = 0 to 2) bit set to 0 when an external signal (synchronous signal from GPT) is being input.

Before setting this bit to 1, set the GPT registers and input an external signal (synchronous signal from the GPT) to the ADC. For the GPTW settings, refer to 24 General Purpose PWM Timer (GPTW).

When this bit is set to 1, A/D conversion is performed in synchronization with an external signal (synchronous signal from GPT).

This allows the synchronous operation wait time to be constant when A/D conversion is started from the GPT.

60.2.5 A/D Converter Unit Sleep Control Register 0 (ADUSLPCR0)

Address(es): ADC_B.ADUSLPCR0 8743 8010h, ADC_B_NS.ADUSLPCR0 0743 8010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADUSLP0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADUSLP0	ADC0 Sleep Setting	0: ADC0 is set in normal operation mode 1: ADC0 is set in sleep mode	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADUSLPCR0 register is used to control the A/D converter unit 0 Sleep mode.

60.2.6 A/D Converter Unit Sleep Control Register 1 (ADUSLPCR1)

Address(es): ADC_B.ADUSLPCR1 8743 8014h, ADC_B_NS.ADUSLPCR1 0743 8014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADUSLP1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADUSLP1	ADC1 Sleep Setting	0: ADC1 is set in normal operation mode 1: ADC1 is set in sleep mode	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADUSLPCR1 register is used to control the A/D converter unit 1 Sleep mode.

60.2.7 A/D Converter Unit Sleep Control Register 2 (ADUSLPCR2)

Address(es): ADC_B.ADUSLPCR2 8743 8018h, ADC_B_NS.ADUSLPCR2 0743 8018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADUSLP2
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADUSLP2	ADC2 Sleep Setting	0: ADC2 is set in normal operation mode 1: ADC2 is set in sleep mode	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADUSLPCR2 register is used to control the A/D converter unit 2 Sleep mode.

60.2.8 A/D Conversion Error Interrupt Enable Register (ADERINTCR)

Address(es): ADC_B.ADERINTCR 8743 8020h, ADC_B_NS.ADERINTCR 0743 8020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	ADEIE2	ADEIE1	ADEIE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADEIE0	ADC0 A/D Conversion Error Interrupt Enable	0: Disable A/D conversion error interrupt for ADC0 1: Enable A/D conversion error interrupt for ADC0	R/W
b1	ADEIE1	ADC1 A/D Conversion Error Interrupt Enable	0: Disable A/D conversion error interrupt for ADC1 1: Enable A/D conversion error interrupt for ADC1	R/W
b2	ADEIE2	ADC2 A/D Conversion Error Interrupt Enable	0: Disable A/D conversion error interrupt for ADC2 1: Enable A/D conversion error interrupt for ADC2	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADERINTCR register controls the enable/disable to the A/D conversion error interrupt.

60.2.9 A/D Conversion Overflow Interrupt Enable Register (ADOVFINTCR)

Address(es): ADC_B.ADOVFINTCR 8743 8024h, ADC_B_NS.ADOVFINTCR 0743 8024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	ADOVFIE2	ADOVFIE1	ADOVFIE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADOVFIE0	ADC0 A/D Conversion Overflow Interrupt Enable	0: Disable A/D conversion overflow interrupt for ADC0 1: Enable A/D conversion overflow interrupt for ADC0	R/W
b1	ADOVFIE1	ADC1 A/D Conversion Overflow Interrupt Enable	0: Disable A/D conversion overflow interrupt for ADC1 1: Enable A/D conversion overflow interrupt for ADC1	R/W
b2	ADOVFIE2	ADC2 A/D Conversion Overflow Interrupt Enable	0: Disable A/D conversion overflow interrupt for ADC2 1: Enable A/D conversion overflow interrupt for ADC2	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADOVFINTCR register controls the enable/disable to the A/D conversion overflow interrupt.

60.2.10 Calibration interrupt Enable Register (ADCALINTCR)

Address(es): ADC_B.ADCALINTCR 8743 8028h, ADC_B_NS.ADCALINTCR 0743 8028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	CALENDIE2	CALENDIE1	CALENDIE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	CALENDIE0	ADC0 Calibration End Interrupt Enable	0: Disable Calibration End Interrupt for ADC0 1: Enable Calibration End Interrupt for ADC0	R/W
b17	CALENDIE1	ADC1 Calibration End Interrupt Enable	0: Disable Calibration End Interrupt for ADC1 1: Enable Calibration End Interrupt for ADC1	R/W
b18	CALENDIE2	ADC2 Calibration End Interrupt Enable	0: Disable Calibration End Interrupt for ADC2 1: Enable Calibration End Interrupt for ADC2	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCALINTCR register controls the enable/disable to the Calibration End Interrupt.

60.2.11 A/D Converter Mode Selection Register (ADMDR)

Address(es): ADC_B.ADMDR 8743 8040h, ADC_B_NS.ADMDR 0743 8040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	ADMD2[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	ADMD1[3:0]				—	—	—	—	ADMD0[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ADMD0[3:0]	ADC0 Mode Selection	b3 b0 0 0 0 0: SAR mode – Single scan mode 0 0 0 1: SAR mode – Continuous scan mode 0 1 0 0: Oversampling mode – Single scan mode 0 1 0 1: Oversampling mode – Continuous scan mode 0 1 1 0: Oversampling mode – One-channel continuous scan mode 1 0 0 0: Hybrid mode – Single scan mode 1 0 0 1: Hybrid mode – Continuous scan mode 1 0 1 0: Hybrid mode – Background continuous scan mode 1 0 1 1: Hybrid mode – Fixed channel continuous scan mode Settings other than above are prohibited.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b8	ADMD1[3:0]	ADC1 Mode Selection	b11 b8 0 0 0 0: SAR mode – Single scan mode 0 0 0 1: SAR mode – Continuous scan mode 0 1 0 0: Oversampling mode – Single scan mode 0 1 0 1: Oversampling mode – Continuous scan mode 0 1 1 0: Oversampling mode – One-channel continuous scan mode 1 0 0 0: Hybrid mode – Single scan mode 1 0 0 1: Hybrid mode – Continuous scan mode 1 0 1 0: Hybrid mode – Background continuous scan mode 1 0 1 1: Hybrid mode – Fixed channel continuous scan mode Settings other than above are prohibited.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b19 to b16	ADMD2[3:0]	ADC2 Mode Selection	b19 b16 0 0 0 0: SAR mode – Single scan mode 0 0 0 1: SAR mode – Continuous scan mode 0 1 0 0: Oversampling mode – Single scan mode 0 1 0 1: Oversampling mode – Continuous scan mode 0 1 1 0: Oversampling mode – One-channel continuous scan mode 1 0 0 0: Hybrid mode – Single scan mode 1 0 0 1: Hybrid mode – Continuous scan mode 1 0 1 0: Hybrid mode – Background continuous scan mode 1 0 1 1: Hybrid mode – Fixed channel continuous scan mode Settings other than above are prohibited.	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADMDR register selects the operation mode and the scan mode for each A/D converter.

60.2.12 A/D Group scan Priority Control Register (ADGSPCR)

Address(es): ADC_B.ADGSPCR 8743 8044h, ADC_B_NS.ADGSPCR 0743 8044h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	GRP2	LGRRS2	RSCN2	PGS2
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	GRP1	LGRRS1	RSCN1	PGS1	—	—	—	—	GRP0	LGRRS0	RSCN0	PGS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PGS0	ADC0 Group Priority Control Setting	0: ADC0 operation is without group priority control 1: ADC0 operation is with group priority control in SAR mode. Setting prohibited when other than SAR mode.	R/W
b1	RSCN0	ADC0 Group Priority Control Setting 2	0: Set when PGS0 is set to 0. 1: Set when PGS0 is set to 1.	R/W
b2	LGRRS0	ADC0 Group Priority Control Setting 3	0: Set when PGS0 is set to 0. 1: Set when PGS0 is set to 1.	R/W
b3	GRP0	ADC0 Group Priority Control Setting 4	0: Set the following case: • When PGS0 is set to 0 • When PGS0 is set to 1 and ADC0 is SAR mode – Single scan mode. 1: Set when PGS0 is set to 1 and ADC0 is SAR mode – Continuous scan mode.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	PGS1	ADC1 Group Priority Control Setting	0: ADC1 operation is without group priority control 1: ADC1 operation is with group priority control in SAR mode. Setting prohibited when other than SAR mode.	R/W
b9	RSCN1	ADC1 Group Priority Control Setting 2	0: Set when PGS1 is set to 0. 1: Set when PGS1 is set to 1.	R/W
b10	LGRRS1	ADC1 Group Priority Control Setting 3	0: Set when PGS1 is set to 0. 1: Set when PGS1 is set to 1.	R/W
b11	GRP1	ADC1 Group Priority Control Setting 4	0: Set the following case: • When PGS1 is set to 0 • When PGS1 is set to 1 and ADC1 is SAR mode – Single scan mode. 1: Set when PGS1 is set to 1 and ADC1 is SAR mode – Continuous scan mode.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	PGS2	ADC2 Group Priority Control Setting	0: ADC2 operation is without group priority control 1: ADC2 operation is with group priority control in SAR mode. Setting prohibited when other than SAR mode.	R/W
b17	RSCN2	ADC2 Group Priority Control Setting 2	0: Set when PGS2 is set to 0. 1: Set when PGS2 is set to 1.	R/W
b18	LGRRS2	ADC2 Group Priority Control Setting 3	0: Set when PGS2 is set to 0. 1: Set when PGS2 is set to 1.	R/W
b19	GRP2	ADC2 Group Priority Control Setting 4	0: Set the following case: • When PGS2 is set to 0 • When PGS2 is set to 1 and ADC2 is SAR mode – Single scan mode. 1: Set when PGS2 is set to 1 and ADC2 is SAR mode – Continuous scan mode.	R/W
b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADGSPCR register controls the group priority operation to each A/D converter. For details on setting this register, see section 60.3.19, Group Priority Operation.

60.2.13 Scan Group Enable Register (ADSGER)

Address(es): ADC_B.ADSGER 8743 8048h, ADC_B_NS.ADSGER 0743 8048h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SGRE11	SGRE10	SGRE9	SGRE8	SGRE7	SGRE6	SGRE5	SGRE4	SGRE3	SGRE2	SGRE1	SGRE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	SGREn	Scan Group n Enable	The suffix number of each bit symbol corresponds to the scan group number n. 0: Disable the scan group n 1: Enable the scan group n	R/W
b31 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

n = 0 to 11

The ADSGER register selects the enable/disable to each scan group.

SGREn bit (Scan Group n Enable) (n = 0 to 11)

The SGREn bit selects the enable/disable to the scan group n. When SGREn is set to 1, A/D conversion with the scan group n is available. When SGREn is set to 0, A/D conversion with the scan group n is not available, even if the trigger corresponding to the scan group n is input.

60.2.14 Scan Group Control Register 0 (ADSGCR0)

Address(es): ADC_B.ADSGCR0 8743 804Ch, ADC_B_NS.ADSGCR0 0743 804Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	SGADS3[1:0]		—	—	—	—	—	—	SGADS2[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SGADS1[1:0]		—	—	—	—	—	—	SGADS0[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SGADS0[1:0]	Scan Group 0 A/D Converter Selection	b1 b0 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	SGADS1[1:0]	Scan Group 1 A/D Converter Selection	b9 b8 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	SGADS2[1:0]	Scan Group 2 A/D Converter Selection	b17 b16 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b23 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25, b24	SGADS3[1:0]	Scan Group 3 A/D Converter Selection	b25 b24 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSGCR0 register selects which A/D converter is used for each scan group.

60.2.15 Scan Group Control Register 1 (ADSGCR1)

Address(es): ADC_B.ADSGCR1 8743 8050h, ADC_B_NS.ADSGCR1 0743 8050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	SGADS7[1:0]		—	—	—	—	—	—	SGADS6[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SGADS5[1:0]		—	—	—	—	—	—	SGADS4[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SGADS4[1:0]	Scan Group 4 A/D Converter Selection	b1 b0 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	SGADS5[1:0]	Scan Group 5 A/D Converter Selection	b9 b8 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	SGADS6[1:0]	Scan Group 6 A/D Converter Selection	b17 b16 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b23 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25, b24	SGADS7[1:0]	Scan Group 7 A/D Converter Selection	b25 b24 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSGCR1 register selects which A/D converter is used for each scan group.

60.2.16 Scan Group Control Register 2 (ADSGCR2)

Address(es): ADC_B.ADSGCR2 8743 8054h, ADC_B_NS.ADSGCR2 0743 8054h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	SGADS11[1:0]		—	—	—	—	—	—	SGADS10[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	SGADS9[1:0]		—	—	—	—	—	—	SGADS8[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SGADS8[1:0]	Scan Group 8 A/D Converter Selection	b1 b0 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	SGADS9[1:0]	Scan Group 9 A/D Converter Selection	b9 b8 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	SGADS10[1:0]	Scan Group 10 A/D Converter Selection	b17 b16 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b23 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25, b24	SGADS11[1:0]	Scan Group 11 A/D Converter Selection	b25 b24 0 0: Select ADC0 0 1: Select ADC1 1 0: Select ADC2 1 1: Setting prohibited	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSGCR2 register selects which A/D converter is used for each scan group.

60.2.17 Scan End Interrupt Enable Register (ADINTCR)

Address(es): ADC_B.ADINTCR 8743 805Ch, ADC_B_NS.ADINTCR 0743 805Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	ADIE11	ADIE10	ADIE9	ADIE8	ADIE7	ADIE6	ADIE5	ADIE4	ADIE3	ADIE2	ADIE1	ADIE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	ADIE0 to ADIE11	Scan Group n Scan End Interrupt Enable	The suffix number of each bit symbol corresponds to the scan group number n. 0: Disable scan group n scan end interrupt 1: Enable scan group n scan end interrupt	R/W
b31 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

n = 0 to 11

The ADINTCR register enables/disables the scan end interrupt.

60.2.18 External Trigger Enable Register n (ADTRGEXTn) (n = 0 to 11)

Address(es): ADC_B.ADTRGEXT0 8743 80C0h, ADC_B.ADTRGEXT1 8743 80D0h, ADC_B.ADTRGEXT2 8743 80E0h, ADC_B.ADTRGEXT3 8743 80F0h, ADC_B.ADTRGEXT4 8743 8100h, ADC_B.ADTRGEXT5 8743 8110h, ADC_B.ADTRGEXT6 8743 8120h, ADC_B.ADTRGEXT7 8743 8130h, ADC_B.ADTRGEXT8 8743 8140h, ADC_B.ADTRGEXT9 8743 8150h, ADC_B.ADTRGEXT10 8743 8160h, ADC_B.ADTRGEXT11 8743 8170h, ADC_B_NS.ADTRGEXT0 0743 80C0h, ADC_B_NS.ADTRGEXT1 0743 80D0h, ADC_B_NS.ADTRGEXT2 0743 80E0h, ADC_B_NS.ADTRGEXT3 0743 80F0h, ADC_B_NS.ADTRGEXT4 0743 8100h, ADC_B_NS.ADTRGEXT5 0743 8110h, ADC_B_NS.ADTRGEXT6 0743 8120h, ADC_B_NS.ADTRGEXT7 0743 8130h, ADC_B_NS.ADTRGEXT8 0743 8140h, ADC_B_NS.ADTRGEXT9 0743 8150h, ADC_B_NS.ADTRGEXT10 0743 8160h, ADC_B_NS.ADTRGEXT11 0743 8170h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b0	TRGEXT0	External Trigger Input 0 (ADTRG0) Enable	0: Disable ADTRG0 1: Enable ADTRG0	R/W
b1	TRGEXT1	External Trigger Input 1 (ADTRG1) Enable	0: Disable ADTRG1 1: Enable ADTRG1	R/W
b2	TRGEXT2	External Trigger Input 2 (ADTRG2) Enable	0: Disable ADTRG2 1: Enable ADTRG2	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADTRGEXTn register enables/disables the External Trigger input 0, 1, and 2 (ADTRG0, ADTRG1, and ADTRG2) as the starting conditions for A/D conversion of scan group n.

60.2.19 ELC Trigger Enable Register n (ADTRGELCn) (n = 0 to 11)

Address(es): ADC_B.ADTRGELC0 8743 80C4h, ADC_B.ADTRGELC1 8743 80D4h, ADC_B.ADTRGELC2 8743 80E4h, ADC_B.ADTRGELC3 8743 80F4h, ADC_B.ADTRGELC4 8743 8104h, ADC_B.ADTRGELC5 8743 8114h, ADC_B.ADTRGELC6 8743 8124h, ADC_B.ADTRGELC7 8743 8134h, ADC_B.ADTRGELC8 8743 8144h, ADC_B.ADTRGELC9 8743 8154h, ADC_B.ADTRGELC10 8743 8164h, ADC_B.ADTRGELC11 8743 8174h, ADC_B_NS.ADTRGELC0 0743 80C4h, ADC_B_NS.ADTRGELC1 0743 80D4h, ADC_B_NS.ADTRGELC2 0743 80E4h, ADC_B_NS.ADTRGELC3 0743 80F4h, ADC_B_NS.ADTRGELC4 0743 8104h, ADC_B_NS.ADTRGELC5 0743 8114h, ADC_B_NS.ADTRGELC6 0743 8124h, ADC_B_NS.ADTRGELC7 0743 8134h, ADC_B_NS.ADTRGELC8 0743 8144h, ADC_B_NS.ADTRGELC9 0743 8154h, ADC_B_NS.ADTRGELC10 0743 8164h, ADC_B_NS.ADTRGELC11 0743 8174h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	TRGELC0 to TRGELC8	ELC Trigger m Enable	The suffix number of each bit symbol corresponds to the ELC trigger number m. 0: Disable ELC Trigger m 1: Enable ELC Trigger m	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

m = 0 to 8

The ADTRGELCn register enables/disables the ELC Trigger m as the starting conditions for A/D conversion of scan group n.

60.2.20 GPT Trigger Enable Register n (ADTRGGPTn) (n = 0 to 11)

Address(es): ADC_B.ADTRGGPT0 8743 80C8h, ADC_B.ADTRGGPT1 8743 80D8h, ADC_B.ADTRGGPT2 8743 80E8h, ADC_B.ADTRGGPT3 8743 80F8h, ADC_B.ADTRGGPT4 8743 8108h, ADC_B.ADTRGGPT5 8743 8118h, ADC_B.ADTRGGPT6 8743 8128h, ADC_B.ADTRGGPT7 8743 8138h, ADC_B.ADTRGGPT8 8743 8148h, ADC_B.ADTRGGPT9 8743 8158h, ADC_B.ADTRGGPT10 8743 8168h, ADC_B.ADTRGGPT11 8743 8178h, ADC_B_NS.ADTRGGPT0 0743 80C8h, ADC_B_NS.ADTRGGPT1 0743 80D8h, ADC_B_NS.ADTRGGPT2 0743 80E8h, ADC_B_NS.ADTRGGPT3 0743 80F8h, ADC_B_NS.ADTRGGPT4 0743 8108h, ADC_B_NS.ADTRGGPT5 0743 8118h, ADC_B_NS.ADTRGGPT6 0743 8128h, ADC_B_NS.ADTRGGPT7 0743 8138h, ADC_B_NS.ADTRGGPT8 0743 8148h, ADC_B_NS.ADTRGGPT9 0743 8158h, ADC_B_NS.ADTRGGPT10 0743 8168h, ADC_B_NS.ADTRGGPT11 0743 8178h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TRGGPTA15	TRGGPTA14	TRGGPTA13	TRGGPTA12	TRGGPTA11	TRGGPTA10	TRGGPTA9	TRGGPTA8	TRGGPTA7	TRGGPTA6	TRGGPTA5	TRGGPTA4	TRGGPTA3	TRGGPTA2	TRGGPTA1	TRGGPTA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TRGGPTA0 to TRGGPTA15	GPT Channel m A/D Conversion Starting Request A Enable	The suffix number of each bit symbol corresponds to the GPT channel number m. 0: Disable the A/D conversion stating request A from GPT channel m 1: Enable the A/D conversion stating request A from GPT channel m	R/W
b31 to b16	TRGGPTB0 to TRGGPTB15	GPT Channel m A/D Conversion Starting Request B Enable	The suffix number of each bit symbol corresponds to the GPT channel number m. 0: Disable the A/D conversion stating request B from GPT channel m 1: Enable the A/D conversion stating request B from GPT channel m	R/W

m = 0 to 15

The ADTRGGPTn register enables/disables the A/D conversion starting request A/B from GPT channel m as the starting conditions for A/D conversion of scan group n.

60.2.21 A/D Conversion Start Trigger Enable Register (ADTRGENR)

Address(es): ADC_B.ADTRGENR 8743 8C08h, ADC_B_NS.ADTRGENR 0743 8C08h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	STTRGEN11	STTRGEN10	STTRGEN9	STTRGEN8	STTRGEN7	STTRGEN6	STTRGEN5	STTRGEN4	STTRGEN3	STTRGEN2	STTRGEN1	STTRGEN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	STTRGEN0 to STTRGEN11	Scan Group n A/D Conversion Start Trigger Enable	The suffix number of each bit symbol corresponds to the scan group number n. 0: Disable the A/D conversion start trigger 1: Enable the A/D conversion start trigger	R/W
b31 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

n = 0 to 11

The ADTRGENR register enables/disables the trigger from the peripheral modules for starting the A/D conversion of Scan group n. The triggers for each scan group are selected in the ADTRGEXTn, ADTRGELCn, and ADTRGGPTn registers.

STTRGENn Bit (Scan Group n A/D Conversion Start Trigger Enable)

The STTRGENn bit selects whether the trigger inputs from the peripheral module, which are selected in the ADTRGEXTn, ADTRGELCn, and ADTRGGPTn registers, is used for the A/D conversion start condition.
When the STTRGENn bit is set to 1, the A/D conversion of scan group n can be started by trigger inputs from the peripheral module.
When the STTRGENn bit is set to 0, the A/D conversion of scan group n cannot be started by trigger inputs from the peripheral module. In this setting, the A/D conversion of scan group n can be only started by writing to the ADSYSTR or ADSTRn registers.

60.2.22 A/D Conversion Start Trigger Delay Register 0 (ADTRGDLR0)

Address(es): ADC_B.ADTRGDLR0 8743 81C0h, ADC_B_NS.ADTRGDLR0 0743 81C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	TRGDLY1[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TRGDLY0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TRGDLY0[7:0]	Scan Group 0	Trigger Input Delay Configuration	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	TRGDLY1[7:0]	Scan Group 1	Trigger Input Delay Configuration	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADTRGDLR0 register controls the input delay added to the external trigger inputs, ELC triggers and GPT triggers which are the starting conditions for the A/D conversion of each scan group. The input delay value is given as the register setting value × the cycle of the A/D conversion clock (ADCLK).

60.2.23 A/D Conversion Start Trigger Delay Register 1 (ADTRGDLR1)

Address(es): ADC_B.ADTRGDLR1 8743 81C4h, ADC_B_NS.ADTRGDLR1 0743 81C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	TRGDLY3[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TRGDLY2[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TRGDLY2[7:0]	Scan Group 2	Trigger Input Delay Configuration	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	TRGDLY3[7:0]	Scan Group 3	Trigger Input Delay Configuration	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADTRGDLR1 register controls the input delay added to the external trigger inputs, ELC triggers and GPT triggers which are the starting conditions for the A/D conversion of each scan group. The input delay value is given as the register setting value × the cycle of the A/D conversion clock (ADCLK).

60.2.24 A/D Conversion Start Trigger Delay Register 2 (ADTRGDLR2)

Address(es): ADC_B.ADTRGDLR2 8743 81C8h, ADC_B_NS.ADTRGDLR2 0743 81C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TRGDLY4[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TRGDLY4[7:0]	Scan Group 4	Trigger Input Delay Configuration	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	TRGDLY5[7:0]	Scan Group 5	Trigger Input Delay Configuration	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADTRGDLR2 register controls the input delay added to the external trigger inputs, ELC triggers and GPT triggers which are the starting conditions for the A/D conversion of each scan group. The input delay value is given as the register setting value × the cycle of the A/D conversion clock (ADCLK).

60.2.25 A/D Conversion Start Trigger Delay Register 3 (ADTRGDLR3)

Address(es): ADC_B.ADTRGDLR3 8743 81CCh, ADC_B_NS.ADTRGDLR3 0743 81CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	—	—	TRGDLY6[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TRGDLY6[7:0]	Scan Group 6	Trigger Input Delay Configuration	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	TRGDLY7[7:0]	Scan Group 7	Trigger Input Delay Configuration	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADTRGDLR3 register controls the input delay added to the external trigger inputs, ELC triggers and GPT triggers which are the starting conditions for the A/D conversion of each scan group. The input delay value is given as the register setting value × the cycle of the A/D conversion clock (ADCLK).

60.2.26 A/D Conversion Start Trigger Delay Register 4 (ADTRGDLR4)

Address(es): ADC_B.ADTRGDLR4 8743 81D0h, ADC_B_NS.ADTRGDLR4 0743 81D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	SWFIX0[1:0]	ADC0 Fixed Channel Count Setting	b17 b16 0 0: 1 Fixed channel 0 1: 2 Fixed channels 1 0: 3 Fixed channels 1 1: Setting prohibited	R/W
b23 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b24	SWNOFIX0[2:0]	ADC0 Non-Fixed Channel Count Setting	b26 b24 0 0 0: 1 channel Others: Setting prohibited	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSWNR0 register sets the A/D conversion period for the fixed channel scan of A/D converter Unit 0.
The ADSWNR0 register is valid only when ADC0 is set to hybrid mode (fixed channel continuous scan mode).

SWNUM0[2:0] Bits (ADC0 Fixed Channel Mode Scan Cycle Setting (Number of Conversions))

The SWNUM0[2:0] bits specify the A/D conversion cycle for fixed channel scan of A/D converter Unit 0.
The A/D conversion cycle is the value set by SWNUM0[2:0] + 1.

BCSSTSL0[3:0] Bits (Sampling State Setting Table Selection for Vacant Channels)

The BCSSTSL0[3:0] bits set the number of sampling states on blank channels that do not get the A/D conversion data.

Although analog input sampling is not performed on unused channels, a sampling time setting table is selected to set the number of channel states in the same way as for virtual channels. The sampling state value of the selected table is used.

SWFIX0[1:0] Bits (ADC0 Fixed Channel Count Setting)

The SWFIX0[1:0] bits set the number of fixed channels that are converted channels sweeping through each scan.

SWNOFIX0[2:0] Bits (ADC0 Non-Fixed Channel Count Setting)

The SWNOFIX0[2:0] bits set the number of non-fixed channels that are converted while switching channels in each scan.

60.2.29 Hybrid Mode (Fixed Channel Continuous Scan Mode) Conversion Count per Scan Register 1 (ADSWNR1)

Address(es): ADC_B.ADSWNR1 8743 8064h, ADC_B_NS.ADSWNR1 0743 8064h

b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSWNR1 register sets the A/D conversion period for the fixed channel scan of A/D converter Unit 1.
The ADSWNR1 register is valid only when ADC1 is set to hybrid mode (fixed channel continuous scan mode).

SWNUM1[2:0] Bits (ADC1 Fixed Channel Mode Scan Cycle Setting (Number of Conversions))

The SWNUM1[2:0] bits specify the A/D conversion cycle for fixed channel scan of A/D converter Unit 1.
The A/D conversion cycle is the value set by SWNUM1[2:0] + 1.

BCSSTSL1[3:0] Bits (Sampling State Setting Table Selection for Vacant Channels)

The BCSSTSL1[3:0] bits set the number of sampling states on blank channels that do not get the A/D conversion data. Although analog input sampling is not performed on unused channels, a sampling time setting table is selected to set the number of channel states in the same way as for virtual channels. The sampling state value of the selected table is used.

SWFIX1[1:0] Bits (ADC1 Fixed Channel Count Setting)

The SWFIX1[1:0] bits set the number of fixed channels that are converted channels sweeping through each scan.

SWNOFIX1[2:0] Bits (ADC1 Non-Fixed Channel Count Setting)

The SWNOFIX1[2:0] bits set the number of non-fixed channels that are converted while switching channels in each scan.

60.2.30 Hybrid Mode (Fixed Channel Continuous Scan Mode) Conversion Count per Scan Register 2 (ADSWNR2)

Address(es): ADC_B.ADSWNR2 8743 8068h, ADC_B_NS.ADSWNR2 0743 8068h

b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSWNR2 register sets the A/D conversion period for the fixed channel scan of A/D converter Unit 2.
The ADSWNR2 register is valid only when ADC2 is set to hybrid mode (fixed channel continuous scan mode).

SWNUM2[2:0] Bits (ADC2 Fixed Channel Mode Scan Cycle Setting (Number of Conversions))

The SWNUM2[2:0] bits specify the A/D conversion cycle for fixed channel scan of A/D converter Unit 2.
The A/D conversion cycle is the value set by SWNUM2[2:0] + 1.

BCSSTSL2[3:0] Bits (Sampling State Setting Table Selection for Vacant Channels)

The BCSSTSL2[3:0] bits set the number of sampling states on blank channels that do not get the A/D conversion data.

Although analog input sampling is not performed on unused channels, a sampling time setting table is selected to set the number of channel states in the same way as for virtual channels. The sampling state value of the selected table is used.

SWFIX2[1:0] Bits (ADC2 Fixed Channel Count Setting)

The SWFIX2[1:0] bits set the number of fixed channels that are converted channels sweeping through each scan.

SWNOFIX2[2:0] Bits (ADC2 Non-Fixed Channel Count Setting)

The SWNOFIX2[2:0] bits set the number of non-fixed channels that are converted while switching channels in each scan.

60.2.31 Oversampling Mode (Same Channel Continuous Scan Mode) Decimation Control Register (ADDECCR)

Address(es): ADC_B.ADDECCR 8743 8080h, ADC_B_NS.ADDECCR 0743 8080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	DCIM2[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DCIM1[4:0]					—	—	—	DCIM0[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	DCIM0[4:0]	ADC0 Output Decimation Constant	b4 b0 0 0 0 0 0: No decimation 0 0 0 1 1: Output data once for every 4 conversions (thinned 3 times) 0 0 1 1 1: Output data once for every 8 conversions (thinned 7 times) Settings other than above are prohibited.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12 to b8	DCIM1[4:0]	ADC1 Output Decimation Constant	b12 b8 0 0 0 0 0: No decimation 0 0 0 1 1: Output data once for every 4 conversions (thinned 3 times) 0 0 1 1 1: Output data once for every 8 conversions (thinned 7 times) Settings other than above are prohibited.	R/W
b15 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	DCIM2[4:0]	ADC2 Output Decimation Constant	b20 b16 0 0 0 0 0: No decimation 0 0 0 1 1: Output data once for every 4 conversions (thinned 3 times) 0 0 1 1 1: Output data once for every 8 conversions (thinned 7 times) Settings other than above are prohibited.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADDECCR register controls the data output decimation of each A/D converter. The ADDECCR register is only valid when the A/D converter unit is set to oversampling mode (same channel continuous scan mode).

60.2.32 A/D Converter Accuracy Mode Register (ADACMDR)

Address(es): ADC_B.ADACMDR 8743 8084h, ADC_B_NS.ADACMDR 0743 8084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADHACMD0	ADC0 High Accuracy Mode	0: High accuracy mode of A/D converter is disabled 1: High accuracy mode of A/D converter is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	ADHACMD1	ADC1 High Accuracy Mode	0: High accuracy mode of A/D converter is disabled 1: High accuracy mode of A/D converter is enabled	R/W
b15 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	ADHACMD2	ADC2 High Accuracy Mode	0: High accuracy mode of A/D converter is disabled 1: High accuracy mode of A/D converter is enabled	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADACMDR register controls the conversion precision mode for each A/D converter.

ADHACMDm Bit (ADCm High Accuracy Mode) (m = 0 to 2)

The ADHACMDm bit sets the accuracy of ADCm.
Setting the ADHACMDm bit to 1 enables A/D conversion in high precision mode.
Enabling high precision mode allows you to obtain A/D conversion results with higher accuracy than when high precision mode is disabled.
For details about accuracy, see section 67, Electrical Characteristics.

Enabling high precision mode adds setting restrictions to some registers.
For details, see section 60.10.17, Restrictions on the High Accuracy Mode.

60.2.33 A/D Conversion Channel Configuration Register n (ADCHCRn) (n = 0 to 49)

Address(es): ADC_B.ADCHCR0 8743 8600h, ADC_B.ADCHCR1 8743 8610h, ADC_B.ADCHCR2 8743 8620h, ADC_B.ADCHCR3 8743 8630h, ADC_B.ADCHCR4 8743 8640h, ADC_B.ADCHCR5 8743 8650h, ADC_B.ADCHCR6 8743 8660h, ADC_B.ADCHCR7 8743 8670h, ADC_B.ADCHCR8 8743 8680h, ADC_B.ADCHCR9 8743 8690h, ADC_B.ADCHCR10 8743 86A0h, ADC_B.ADCHCR11 8743 86B0h, ADC_B.ADCHCR12 8743 86C0h, ADC_B.ADCHCR13 8743 86D0h, ADC_B.ADCHCR14 8743 86E0h, ADC_B.ADCHCR15 8743 86F0h, ADC_B.ADCHCR16 8743 8700h, ADC_B.ADCHCR17 8743 8710h, ADC_B.ADCHCR18 8743 8720h, ADC_B.ADCHCR19 8743 8730h, ADC_B.ADCHCR20 8743 8740h, ADC_B.ADCHCR21 8743 8750h, ADC_B.ADCHCR22 8743 8760h, ADC_B.ADCHCR23 8743 8770h, ADC_B.ADCHCR24 8743 8780h, ADC_B.ADCHCR25 8743 8790h, ADC_B.ADCHCR26 8743 87A0h, ADC_B.ADCHCR27 8743 87B0h, ADC_B.ADCHCR28 8743 87C0h, ADC_B.ADCHCR29 8743 87D0h, ADC_B.ADCHCR30 8743 87E0h, ADC_B.ADCHCR31 8743 87F0h, ADC_B.ADCHCR32 8743 8800h, ADC_B.ADCHCR33 8743 8810h, ADC_B.ADCHCR34 8743 8820h, ADC_B.ADCHCR35 8743 8830h, ADC_B.ADCHCR36 8743 8840h, ADC_B.ADCHCR37 8743 8850h, ADC_B.ADCHCR38 8743 8860h, ADC_B.ADCHCR39 8743 8870h, ADC_B.ADCHCR40 8743 8880h, ADC_B.ADCHCR41 8743 8890h, ADC_B.ADCHCR42 8743 88A0h, ADC_B.ADCHCR43 8743 88B0h, ADC_B.ADCHCR44 8743 88C0h, ADC_B.ADCHCR45 8743 88D0h, ADC_B.ADCHCR46 8743 88E0h, ADC_B.ADCHCR47 8743 88F0h, ADC_B.ADCHCR48 8743 8900h, ADC_B.ADCHCR49 8743 8910h,

b31 to b20	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Select differential input when self-diagnosis is selected.
Note 2. When using a channel-dedicated sample-and-hold circuit, make sure that the setting of channel-dedicated sample-and-hold circuit unit n for the channel selected by CNVCS[6:0] matches the setting of ADSHCR0.SHMDn.

The ADCHCRn register selects the Virtual channel configuration for A/D conversion.

SGSEL[4:0] Bits (Scan Group Selection)

The SGSEL[4:0] bits select which scan group to assign the selected channel in CNVCS[6:0]. If SGSEL[4:0] is set to 00h, the channel selected by CNVCS[6:0] is not available for A/D conversion. If SGSEL[4:0] is set to other than 00h, the channel selected by CNVCS[6:0] is available for A/D conversion in the scan operation of the scan group corresponding to the setting value.

Up to 8 A/D conversion channels can be assigned per scan group in the SAR mode or oversampling mode; Up to 4 A/D conversion channels can be assigned per scan group in the hybrid mode. Do not assign more than specified number of A/D conversion channels per scan group.

In fixed channel continuous scan mode, the scan group setting of the virtual channel assigned to the fixed channel (hybrid mode) must be set to no setting (00h).

CNVCS[6:0] Bits (A/D Conversion Channel Selection)

The CNVCS[6:0] bits select the analog signal source for the A/D conversion. The CNVCS[6:0] bits should be set for the channel number corresponding to the analog input or the extended analog function. For A/D conversion of the analog signal source in differential input mode, the CNVCS[6:0] bits should be set the even-numbered channel; When the odd-numbered channel is set in differential input mode, A/D conversion is not guaranteed.

To A/D convert the channel selected by the CNVCS[6:0] bits, it should be assigned to one of the scan groups by the SGSEL[4:0] bits.

AINMD Bit (Analog Input Mode Selection)

The AINMD bit selects the input method for A/D conversion of the analog signal source selected by the CNVCS[6:0] bits. When the AINMD bit is set to 0, A/D conversion is performed in single-ended input. When the AINMD bit is set to 1, A/D conversion is performed in differential input.
If the self-diagnosis channel is selected with the CNVCS[6:0] bits, a differential input should be selected.

SSTSEL[3:0] Bits (Sampling State Table Selection)

The SSTSEL[3:0] bits select the sampling state table for A/D conversion of the analog signal source selected by the CNVCS[6:0] bits. The number of sampling states is the value set in the selected sampling state table.

Note 1. Whenever A/D conversion is performed in oversampling mode or hybrid mode, the digital filter must be used.
Note 2. Whenever A/D conversion is performed in SAR mode, the digital filter must not be used.

The ADDOPCRAn register is one of the registers that selects the data calculation function for the A/D conversion data of virtual channel n.

DFSEL[2:0] Bits (Digital Filter Selection)

The DFSEL[2:0] bits select the digital filter for inputting A/D converted data of virtual channel n. When 000b is set in the DFSEL[2:0] bits, the digital filter is not used. When 001b, 010b, 011b, or 100b is set in the DFSEL[2:0] bits, the digital filter corresponding to the setting of the DFSEL[2:0] bits is selected. The characteristics of the digital filters are specified by ADDFSRm (m = 0 to 2) register.
For SAR mode, select 000b for the DFSEL[2:0] bits. For oversampling mode or hybrid mode, set the DFSEL[2:0] bits to 001b, 010b, 011b, or 100b.

GAINSEL[3:0] Bits (User Gain Table Selection)

The GAINSEL[3:0] bits select the user gain table for adjusting the A/D conversion data of virtual channel n.
When the GAINSEL[3:0] bits are set to 0h, no gain adjustment is performed. When the GAINSEL[3:0] bits are set to any of 1h to 8h, the gain adjustment is performed according to the user gain table selected by the GAINSEL[3:0] bits.

OFSETSEL[3:0] Bits (User Offset Table Selection)

The OFSETSEL[3:0] bits select the user offset table for adjusting the A/D conversion data of virtual channel n. When the OFSETSEL[3:0] bits are set to 0h, no offset adjustment is performed. When the OFSETSEL[3:0] bits are set to any of 1h to 8h, the offset adjustment is performed according to the user offset table selected by the OFSETSEL[3:0] bits.

m = 0 to 7

The ADDOPCRBn register is one of the registers that selects the data calculation function for the A/D conversion data of virtual channel n.

AVEMD[1:0] Bits (Addition/Averaging Mode Selection)

The AVEMD[1:0] bits select the addition mode or the averaging mode for the A/D conversion of virtual channel n. When the AVEMD[1:0] bits are set to 00b, the addition/averaging operation is not performed. When the AVEMD[1:0] bits are set to 01b or 10b, the addition/averaging operation is performed according to the setting value of the ADC[3:0] bits.

ADC[3:0] Bits (Addition/Averaging Times Selection)

The ADC[3:0] bits select the number of times of addition/averaging for the A/D conversion of virtual channel n. If the addition mode or the averaging mode is selected in the AVEMD[1:0] bits, the A/D conversion is performed a number of times according to the setting value of the ADC[3:0] bits.

CMPTBLEm Bits (Compare Match Enable) (m = 0 to 7)

The CMPTBLEm bits enable/disable the compare match with the compare match table m for the A/D conversion data of virtual channel n.

60.2.36 A/D Conversion Data Operation Control C Register n (ADDOPCRCn) (n = 0 to 49)

Address(es): ADC_B.ADDOPCRC0 8743 860Ch, ADC_B.ADDOPCRC1 8743 861Ch, ADC_B.ADDOPCRC2 8743 862Ch, ADC_B.ADDOPCRC3 8743 863Ch, ADC_B.ADDOPCRC4 8743 864Ch, ADC_B.ADDOPCRC5 8743 865Ch, ADC_B.ADDOPCRC6 8743 866Ch, ADC_B.ADDOPCRC7 8743 867Ch, ADC_B.ADDOPCRC8 8743 868Ch, ADC_B.ADDOPCRC9 8743 869Ch, ADC_B.ADDOPCRC10 8743 86ACh, ADC_B.ADDOPCRC11 8743 86BCh, ADC_B.ADDOPCRC12 8743 86CCh, ADC_B.ADDOPCRC13 8743 86DCh, ADC_B.ADDOPCRC14 8743 86ECh, ADC_B.ADDOPCRC15 8743 86FCh, ADC_B.ADDOPCRC16 8743 870Ch, ADC_B.ADDOPCRC17 8743 871Ch, ADC_B.ADDOPCRC18 8743 872Ch, ADC_B.ADDOPCRC19 8743 873Ch, ADC_B.ADDOPCRC20 8743 874Ch, ADC_B.ADDOPCRC21 8743 875Ch, ADC_B.ADDOPCRC22 8743 876Ch, ADC_B.ADDOPCRC23 8743 877Ch, ADC_B.ADDOPCRC24 8743 878Ch, ADC_B.ADDOPCRC25 8743 879Ch, ADC_B.ADDOPCRC26 8743 87ACh, ADC_B.ADDOPCRC27 8743 87BCh, ADC_B.ADDOPCRC28 8743 87CCh, ADC_B.ADDOPCRC29 8743 87DCh, ADC_B.ADDOPCRC30 8743 87ECh, ADC_B.ADDOPCRC31 8743 87FCh, ADC_B.ADDOPCRC32 8743 880Ch, ADC_B.ADDOPCRC33 8743 881Ch, ADC_B.ADDOPCRC34 8743 882Ch, ADC_B.ADDOPCRC35 8743 883Ch, ADC_B.ADDOPCRC36 8743 884Ch, ADC_B.ADDOPCRC37 8743 885Ch, ADC_B.ADDOPCRC38 8743 886Ch, ADC_B.ADDOPCRC39 8743 887Ch, ADC_B.ADDOPCRC40 8743 888Ch, ADC_B.ADDOPCRC41 8743 889Ch, ADC_B.ADDOPCRC42 8743 88ACh, ADC_B.ADDOPCRC43 8743 88BCh, ADC_B.ADDOPCRC44 8743 88CCh, ADC_B.ADDOPCRC45 8743 88DCh, ADC_B.ADDOPCRC46 8743 88ECh, ADC_B.ADDOPCRC47 8743 88FCh, ADC_B.ADDOPCRC48 8743 890Ch, ADC_B.ADDOPCRC49 8743 891Ch,
ADC_B_NS.ADDOPCRC0 0743 860Ch, ADC_B_NS.ADDOPCRC1 0743 861Ch, ADC_B_NS.ADDOPCRC2 0743 862Ch, ADC_B_NS.ADDOPCRC3 0743 863Ch, ADC_B_NS.ADDOPCRC4 0743 864Ch, ADC_B_NS.ADDOPCRC5 0743 865Ch, ADC_B_NS.ADDOPCRC6 0743 866Ch, ADC_B_NS.ADDOPCRC7 0743 867Ch, ADC_B_NS.ADDOPCRC8 0743 868Ch, ADC_B_NS.ADDOPCRC9 0743 869Ch, ADC_B_NS.ADDOPCRC10 0743 86ACh, ADC_B_NS.ADDOPCRC11 0743 86BCh, ADC_B_NS.ADDOPCRC12 0743 86CCh, ADC_B_NS.ADDOPCRC13 0743 86DCh, ADC_B_NS.ADDOPCRC14 0743 86ECh, ADC_B_NS.ADDOPCRC15 0743 86FCh, ADC_B_NS.ADDOPCRC16 0743 870Ch, ADC_B_NS.ADDOPCRC17 0743 871Ch, ADC_B_NS.ADDOPCRC18 0743 872Ch, ADC_B_NS.ADDOPCRC19 0743 873Ch, ADC_B_NS.ADDOPCRC20 0743 874Ch, ADC_B_NS.ADDOPCRC21 0743 875Ch, ADC_B_NS.ADDOPCRC22 0743 876Ch, ADC_B_NS.ADDOPCRC23 0743 877Ch, ADC_B_NS.ADDOPCRC24 0743 878Ch, ADC_B_NS.ADDOPCRC25 0743 879Ch, ADC_B_NS.ADDOPCRC26 0743 87ACh, ADC_B_NS.ADDOPCRC27 0743 87BCh, ADC_B_NS.ADDOPCRC28 0743 87CCh, ADC_B_NS.ADDOPCRC29 0743 87DCh, ADC_B_NS.ADDOPCRC30 0743 87ECh, ADC_B_NS.ADDOPCRC31 0743 87FCh, ADC_B_NS.ADDOPCRC32 0743 880Ch, ADC_B_NS.ADDOPCRC33 0743 881Ch, ADC_B_NS.ADDOPCRC34 0743 882Ch, ADC_B_NS.ADDOPCRC35 0743 883Ch, ADC_B_NS.ADDOPCRC36 0743 884Ch, ADC_B_NS.ADDOPCRC37 0743 885Ch, ADC_B_NS.ADDOPCRC38 0743 886Ch, ADC_B_NS.ADDOPCRC39 0743 887Ch, ADC_B_NS.ADDOPCRC40 0743 888Ch, ADC_B_NS.ADDOPCRC41 0743 889Ch, ADC_B_NS.ADDOPCRC42 0743 88ACh, ADC_B_NS.ADDOPCRC43 0743 88BCh, ADC_B_NS.ADDOPCRC44 0743 88CCh, ADC_B_NS.ADDOPCRC45 0743 88DCh, ADC_B_NS.ADDOPCRC46 0743 88ECh, ADC_B_NS.ADDOPCRC47 0743 88FCh, ADC_B_NS.ADDOPCRC48 0743 890Ch, ADC_B_NS.ADDOPCRC49 0743 891Ch

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	LIMTBLS[3:0]	Limiter Clip Table Selection	b3 b0 0 0 0 0: Not use the limiter clip table 0 0 0 1: Use the limiter clip table 0 0 0 1 0: Use the limiter clip table 1 0 0 1 1: Use the limiter clip table 2 : : 1 0 0 0: Use the limiter clip table 7 Settings other than above are prohibited.	R/W
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	ADPRC[1:0]	A/D Conversion Data Format Selection	b17 b16 0 0: Store the A/D conversion result as 16-bit data format 0 1: Store the A/D conversion result as 14-bit data format 1 0: Store the A/D conversion result as 12-bit data format 1 1: Store the A/D conversion result as 10-bit data format	R/W
b19, b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20	SIGNSEL	A/D Conversion Data Signed/ Un-Signed Selection	0: Signed data format 1: Un-signed data format	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADDOPCRCn register is one of the registers that selects the data calculation function for the A/D conversion data of virtual channel n.

LIMTBLS[3:0] Bits (Limiter Clip Table Selection)

The LIMTBLS[3:0] bits select the limiter clip table for clipping the A/D conversion data of virtual channel n. When the LIMTBLS[3:0] bits are set to 0h, the A/D conversion data is not clipped. When the LIMTBLS[3:0] bits are set to any of 1h to 8h, the A/D conversion data is clipped according to the limiter clip table selected by the LIMTBLS[3:0] bits.

ADPRC[1:0] Bits (A/D Conversion Data Format Selection)

The ADPRC[1:0] bits select the data length of A/D conversion data. The A/D conversion data of virtual channel n is stored to the A/D data register or the FIFO with selected data length.

SIGNSEL Bit (A/D Conversion Data Signed/Un-Signed Selection)

The SIGNSEL bit selects the Signed/Unsigned data format of the A/D conversion data. The A/D conversion data of the virtual channel n is stored to the A/D data register or the FIFO with selected data format.
Select the signed data format (SIGNSEL = 0) whenever the A/D conversion of the self-diagnosis channel is performed. Select the unsigned data format (SIGNSEL = 1) whenever the A/D conversion in SAR mode, unless to convert the self-diagnosis channel, is performed. The signed data format or the unsigned data format is available for the A/D conversion in oversampling mode or hybrid mode unless converting to the self-diagnosis channel.

60.2.37 Scan Group Diagnosis Function Control Register n (ADSGDCRn) (n = 0 to 11)

Address(es): ADC_B.ADSGDCR0 8743 8200h, ADC_B.ADSGDCR1 8743 8204h, ADC_B.ADSGDCR2 8743 8208h, ADC_B.ADSGDCR3 8743 820Ch, ADC_B.ADSGDCR4 8743 8210h, ADC_B.ADSGDCR5 8743 8214h, ADC_B.ADSGDCR6 8743 8218h, ADC_B.ADSGDCR7 8743 821Ch, ADC_B.ADSGDCR8 8743 8220h, ADC_B.ADSGDCR9 8743 8224h, ADC_B.ADSGDCR10 8743 8228h, ADC_B.ADSGDCR11 8743 822Ch, ADC_B_NS.ADSGDCR0 0743 8200h, ADC_B_NS.ADSGDCR1 0743 8204h, ADC_B_NS.ADSGDCR2 0743 8208h, ADC_B_NS.ADSGDCR3 0743 820Ch, ADC_B_NS.ADSGDCR4 0743 8210h, ADC_B_NS.ADSGDCR5 0743 8214h, ADC_B_NS.ADSGDCR6 0743 8218h, ADC_B_NS.ADSGDCR7 0743 821Ch, ADC_B_NS.ADSGDCR8 0743 8220h, ADC_B_NS.ADSGDCR9 0743 8224h, ADC_B_NS.ADSGDCR10 0743 8228h, ADC_B_NS.ADSGDCR11 0743 822Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	—	—	—	—	—	—	—	DIAGVAL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	DIAGVAL[2:0]	Self-Diagnosis Mode Selection	b2 b0 0 0 0: Set when any self-diagnosis channel is not included. Setting prohibited when any self-diagnosis channels are included. 1 0 0: Self-diagnosis mode 1 1 0 1: Self-diagnosis mode 2 1 1 0: Self-diagnosis mode 3 Settings other than above are prohibited.	R/W
b15 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	ADDISEN	Disconnection Detection Assist Enable	0: Disable the disconnection detection assist function 1: Enable the disconnection detection assist function	R/W
b19 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20	ADDISP	Disconnection Detection Assist Mode Selection (for the Even-Numbered Analog Channel)	0: Discharge 1: Precharge	R/W
b21	ADDISN	Disconnection Detection Assist Mode Selection (for the Odd-Numbered Analog Channel)	0: Discharge 1: Precharge	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b24	ADNDIS[7:0]	Disconnection Detection Assist Period	b31 b24 0 0 0 0 0 0 0 0: Setting prohibited when the disconnection detection assist function is enabled 0 0 0 0 0 0 0 1: Setting prohibited 0 0 0 0 0 0 1 0: Setting prohibited 0 0 0 0 0 0 1 1 to 1 1 1 1 1 1 1 1: The number of states for the discharge or precharge period – 1	R/W

The ADSGDCRn register controls the diagnosis function at the scanning operation of scan group n.

DIAGVAL[2:0] Bits (Self-Diagnosis Mode Selection)

DIAGVAL[2:0] bits select the self-diagnosis mode for A/D converter.

The DIAGVAL[2:0] bits must be set to 000b when the scan group n does not include any virtual channels that selected the self-diagnosis channel. The DIAGVAL[2:0] bits must be set to 100b, 101b or 110b when the scan group n is including the virtual channel that selected the self-diagnosis channel.

ADDISEN Bit (Disconnection Detection Assist Enable)

The ADDISEN bit enables/disables the disconnection detection assist function. When the ADDISEN bit is set to 0, the disconnection detection assist operation is not performed. When the ADDISEN bit is set to 1, the disconnection detection assist operation according to the setting of the ADDISP bit and the ADDISN bit is performed at the scanning operation of scan group n.

ADDISP Bit (Disconnection Detection Assist Mode Selection (for the Even-Numbered Analog Channel))

The ADDISP bit select the discharge/precharge operation for the disconnection detection. The ADDISP bit selects the discharge/precharge operation for the even-numbered analog channel.

ADDISN Bit (Disconnection Detection Assist Mode Selection (for the Odd-Numbered Analog Channel)

The ADDISN bit select the discharge/precharge operation for the disconnection detection. The ADDISN bit selects the discharge/precharge operation for the odd-numbered analog channel.

ADNDIS[7:0] Bits (Disconnection Detection Assist Period)

The ADNDIS[7:0] bits select the discharge/precharge period. When the disconnection detection assist function is disabled (ADDISEN = 0), the ADNDIS[7:0] bits should be set to 00h. When the disconnection detection assist function is enabled (ADDISEN = 1), the ADNDIS[7:0] bits should be set the value within 03h to FFh as the number of state for the discharge/ precharge period. The number of states actually valid in the operation is the value of the register setting minus one.

60.2.38 Sampling State Table Register 0 (ADSSTR0)

Address(es): ADC_B.ADSSTR0 8743 8240h, ADC_B_NS.ADSSTR0 0743 8240h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	SST0[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	SST0[9:0]	Sampling State Table 0	These bits set the sampling time in the range from 2 to 1023 states.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25 to b16	SST1[9:0]	Sampling State Table 1	These bits set the sampling time in the range from 2 to 1023 states.	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSSTR0 register selects the sampling time at the A/D conversion that is using each sampling state table.

60.2.39 Sampling State Table Register 1 (ADSSTR1)

Address(es): ADC_B.ADSSTR1 8743 8244h, ADC_B_NS.ADSSTR1 0743 8244h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	SST10[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	SST10[9:0]	Sampling State Table 10	These bits set the sampling time in the range from 2 to 1023 states.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25 to b16	SST11[9:0]	Sampling State Table 11	These bits set the sampling time in the range from 2 to 1023 states.	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSSTR5 register selects the sampling time at the A/D conversion that is using each sampling state table.

60.2.44 Sampling State Table Register 6 (ADSSTR6)

Address(es): ADC_B.ADSSTR6 8743 8258h, ADC_B_NS.ADSSTR6 0743 8258h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	CST0[5:0]	A/D Converter Unit 0 (ADC0) A/D Successive Approximation Time Configuration	These bits set the successive approximation time in the range from 3 to 63 states.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	CST1[5:0]	A/D Converter Unit 1 (ADC1) A/D Successive Approximation Time Configuration	These bits set the successive approximation time in the range from 3 to 63 states.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b21 to b16	CST2[5:0]	A/D Converter Unit 2 (ADC2) A/D Successive Approximation Time Configuration	These bits set the successive approximation time in the range from 3 to 63 states.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCNVSTR register specifies the A/D successive approximation time, which required by the A/D converter Unit 0, Unit 1 or Unit 2 to convert the sampled analog input to the digital value, in the number of cycles based on A/D conversion clock (ADCLK). The A/D successive approximation time does not include the sampling time of the analog input.

The A/D successive approximation time must be set to meet the value specified in section 67, Electrical Characteristics. If the successive approximation time is set to a value over the range specified for the electrical characteristics, the A/D conversion result is not guaranteed. In addition, the A/D successive approximation time for each A/D converter should be set to be the same. (Set the same value to CST0[5:0] bits, CST1[5:0] bits, and CST2[5:0] bits).

60.2.47 Channel-Dedicated Sample-and-Hold Circuit Control Register 0 (ADSHCR0)

Address(es): ADC_B.ADSHCR0 8743 8280h, ADC_B_NS.ADSHCR0 0743 8280h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	SHMD2	SHMD1	SHMD0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	SHEN2	SHEN1	SHEN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SHEN0*1	Channel-Dedicated Sample-and-Hold Circuit Unit 0 Bypass Select	0: Bypass the circuit unit 0 1: Use the circuit unit 0	R/W
b1	SHEN1*1	Channel-Dedicated Sample-and-Hold Circuit Unit 1 Bypass Select	0: Bypass the circuit unit 1 1: Use the circuit unit 1	R/W
b2	SHEN2*1	Channel-Dedicated Sample-and-Hold Circuit Unit 2 Bypass Select	0: Bypass the circuit unit 2 1: Use the circuit unit 2	R/W
b15 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	SHMD0*2	Channel-Dedicated Sample-and-Hold Circuit Unit 0 Input Mode Select	0: Single-ended Input mode 1: Differential Input mode	R/W
b17	SHMD1*2	Channel-Dedicated Sample-and-Hold Circuit Unit 1 Input Mode Select	0: Single-ended Input mode 1: Differential Input mode	R/W
b18	SHMD2*2	Channel-Dedicated Sample-and-Hold Circuit Unit 2 Input Mode Select	0: Single-ended Input mode 1: Differential Input mode	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. When using a channel-dedicated sample-and-hold circuit, also set ADSHSBPCR (for single-ended input mode) or ADSHDBPCR (for differential input mode).
Note 2. When using a channel-dedicated sample-and-hold circuit, make sure that its polarity matches the setting of the ADCHCRn.AINMD bit of virtual channel n (n = 0 to 49) to which the channel-dedicated sample-and-hold circuit is assigned.

The ADSHCR0 register controls the channel-dedicated sample-and-hold circuits (unit 0, unit 1 and unit 2) connected to the A/D converter unit 0 (ADC0).

SHENn Bit (Channel-dedicated Sample-and-hold Circuit Bypass Select) (n = 0 to 2)

The SHENn bit selects whether to use or bypass the channel-dedicated sample-and-hold circuits unit n.
When the SHENn bit is set to 0, the channel-dedicated sample-and-hold circuits unit n is disabled. If A/D conversion of analog input channel which is connected to the channel-dedicated sample-and-hold circuit unit n is performed, the channel-dedicated sample-and-hold circuit is not used and is bypassed.
When the SHENn bit is set to 1, the channel-dedicated sample-and-hold circuits unit n is enabled. In this case, A/D conversion of analog input channel to which the channel-dedicated sample-and-hold circuit unit n is performed with the channel-dedicated sample-and-hold circuit used.

SHMDn Bit (Channel-dedicated Sample-and-hold Circuit Input Mode Select) (n = 0 to 2)

The SHMDn bit selects the input mode of the channel-dedicated sample-and-hold circuits unit n.
When the SHMDn bit is set to 0, the channel-dedicated sample-and-hold circuits unit n is in single-ended input mode.
When the SHMDn bit is set to 1, the channel-dedicated sample-and-hold circuits unit n is in differential input mode.

60.2.48 Channel-Dedicated Sample-and-Hold Circuit Diagnosis Control Register 0 (ADSHDCR0)

Address(es): ADC_B.ADSHDCR0 8743 8284h, ADC_B_NS.ADSHDCR0 0743 8284h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	SH0DIS	—	—	—	SH0DISEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SH0DISEN	Disconnection Detection Assist Enable	0: Disable the disconnection detection assist function 1: Enable the disconnection detection assist function	R/W
b3 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SH0DIS	Disconnection Detection Assist Mode Selection	0: Discharge 1: Precharge	R/W
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSHDCR0 register controls settings of the diagnosis function for the channel-dedicated sample-and-hold circuits (unit 0, unit 1 and unit 2) connected to the A/D converter unit 0 (ADC0).

SH0DISEN Bit (Disconnection Detection Assist Enable)

The SH0DISEN bit enables or disables the open-wire detection assist function of the channel-dedicated sample-and-hold circuit. When the SH0DISEN bit is set to 0, the open-wire detection assist operation is not performed. When the SH0DISEN bit is set to 1, the open-wire detection assist operation according to the setting of the SH0DIS bit is performed during the scan operation of scan group n.

SH0DIS Bit (Disconnection Detection Assist Mode Selection)

The SH0DIS bit selects whether to discharge or precharge when a disconnection is detected in the channel-specific sample-and-hold circuit.

60.2.49 Channel-Dedicated Sample-and-Hold Circuit State Register 0 (ADSHSTR0)

Address(es): ADC_B.ADSHSTR0 8743 8288h, ADC_B_NS.ADSHSTR0 0743 8288h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	SHHST[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	SHSST[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SHSST[7:0]	Sampling Time Setting	These bits set the sampling time in the range from 4 to 255 states	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b18 to b16	SHHST[2:0]	Hold Mode Switching Time Setting	These bits set the hold mode switching time in the range from 2 to 7 states.	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSHSTR0 register specifies the sampling time and the hold mode switching time for the channel-dedicated sample-and-hold circuits (unit 0, unit 1, and unit 2) connected to the A/D converter unit 0 (ADC0). The value set in this register should be set to meet the value specified in section 67, Electrical Characteristics.

60.2.50 Channel-Dedicated Sample-and-Hold Circuit Single-Ended Input Mode Bypass Control Register (ADSHSBPCR)

Address(es): ADC_B.ADSHSBPCR 8743 8310h, ADC_B_NS.ADSHSBPCR 0743 8310h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	SHSBN2	SHSBN1	SHSBN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	SHSBP2	SHSBP1	SHSBP0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SHSBP0	Channel-Dedicated Sample-and-Hold Circuit Unit 0 Single-Ended Input Bypass Selection (for the Even-Numbered Analog Channel)	0: Use the circuit unit 0 1: Bypass the circuit unit 0	R/W
b1	SHSBP1	Channel-Dedicated Sample-and-Hold Circuit Unit 1 Single-Ended Input Bypass Selection (for the Even-Numbered Analog Channel)	0: Use the circuit unit 1 1: Bypass the circuit unit 1	R/W
b2	SHSBP2	Channel-Dedicated Sample-and-Hold Circuit Unit 2 Single-Ended Input Bypass Selection (for the Even-Numbered Analog Channel)	0: Use the circuit unit 2 1: Bypass the circuit unit 2	R/W
b15 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	SHSBN0	Channel-Dedicated Sample-and-Hold Circuit Unit 0 Single-Ended Input Bypass Selection (for the Odd-Numbered Analog Channel)	0: Use the circuit unit 0 1: Bypass the circuit unit 0	R/W
b17	SHSBN1	Channel-Dedicated Sample-and-Hold Circuit Unit 1 Single-Ended Input Bypass Selection (for the Odd-Numbered Analog Channel)	0: Use the circuit unit 1 1: Bypass the circuit unit 1	R/W
b18	SHSBN2	Channel-Dedicated Sample-and-Hold Circuit Unit 2 Single-Ended Input Bypass Selection (for the Odd-Numbered Analog Channel)	0: Use the circuit unit 2 1: Bypass the circuit unit 2	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: Write access is permitted only if ADSHCR0.SHENn for the target sample-and-hold circuit is set to 0.
Note: If you set both the even-numbered and odd-numbered channels of the same unit to bypass using this register, do not set the two corresponding virtual channels to the same scan group.

The ADSHSBPCR register controls the bypass operation for even-numbered or odd-numbered analog channels individually when using the channel-dedicated sample-and-hold circuits (unit 0, unit 1, and unit 2) in single-ended input mode.

SHSBPn Bit (Channel-Dedicated Sample-and-Hold Circuit Unit n Single-Ended Input Bypass Selection (for the Even-Numbered Analog Channel)) (n = 0 to 2)

The SHSBPn bit control the analog input for A/D conversion when the channel-dedicated sample-and-hold circuit is enabled.

When the bit is set to 0, the analog output held by the channel-dedicated sample-and-hold circuit is A/D-converted.

When the bit is set to 1, the analog input of the channel-dedicated sample-and-hold circuit is A/D-converted.

SHSBNn Bit (Channel-Dedicated Sample-and-Hold Circuit Unit n Single-Ended Input Bypass Selection (for the Odd-Numbered Analog Channel)) (n = 0 to 2)

The SHSBNn bit control the analog input for A/D conversion when the channel-dedicated sample-and-hold circuit is enabled.

When the bit is set to 0, the analog output held by the channel-dedicated sample-and-hold circuit is A/D-converted.

When the bit is set to 1, the analog input of the channel-dedicated sample-and-hold circuit is A/D-converted.

60.2.51 Channel-Dedicated Sample-and-Hold Circuit Differential Input Mode Bypass Control Register (ADSHDBPCR)

Address(es): ADC_B.ADSHDBPCR 8743 8314h, ADC_B_NS.ADSHDBPCR 0743 8314h

b9	SHDBP9	Scan Group 9 Channel Dedicated Sample-and-Hold Circuit Differential Input Bypass Selection	0: Use the channel-dedicated sample-and-hold circuit 1: Bypass the channel-dedicated sample-and-hold circuit	R/W
b10	SHDBP10	Scan Group 10 Channel Dedicated Sample-and-Hold Circuit Differential Input Bypass Selection	0: Use the channel-dedicated sample-and-hold circuit 1: Bypass the channel-dedicated sample-and-hold circuit	R/W
b11	SHDBP11	Scan Group 11 Channel Dedicated Sample-and-Hold Circuit Differential Input Bypass Selection	0: Use the channel-dedicated sample-and-hold circuit 1: Bypass the channel-dedicated sample-and-hold circuit	R/W
b31 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSHDBPCR register controls the bypass operation of the channel-dedicated sample-and-hold circuits in differential input mode of scan group n.

SHDBPn Bit (Scan Group n Channel Dedicated Sample-and-Hold Circuit Differential Input Bypass Selection) (n = 0 to 11)

The SHDBPn bit selects whether to use or bypass the channel-dedicated sample-and-hold circuit of scan group n.
When the SHDBPn bit is set to 0, the output of the channel-dedicated sample-and-hold circuit is A/D converted.
When the SHDBPn bit is set to 1, the analog channel input can be A/D converted without going through the channel-dedicated sample-and-hold circuit.
If the A/D disconnection detection assist function is required when using the channel-dedicated sample-and-hold circuit in differential input mode, recalibration due to mode switching is not required if this bit is set to bypass.
For details, see section 60.3.17.2 (5) Advanced operation (in differential input mode) with the disconnection detection assist function in use in SAR mode.

60.2.52 Channel-Dedicated Sample-and-Hold Circuit Self-Diagnosis Control Register 0 (ADSHSDCR0)

R/W
b31 to b15	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADSHSDCR1 register controls the self-diagnostic function of the channel-dedicated sample-and-hold circuit.

60.2.54 Channel-Dedicated Sample-and-Hold Circuit Constant Sampling Control Register (ADSHCSCR)

Address(es): ADC_B.ADSHCSCR 8743 8C04h, ADC_B_NS.ADSHCSCR 0743 8C04h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SHCSST0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SHCSST0	Channel-Dedicated Sample-and-Hold Circuit Unit 0 Constant Sampling Enabled	0: Disable constant sampling 1: Enable constant sampling	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register should be set after self-calibration has been performed.
Note: Do not set this register if the channel-dedicated sample-and-hold circuit is not used.

The ADSHCSCR register controls the constant sampling function of channel-dedicated sample-and-hold circuit.
When constant sampling is enabled, sampling of the channel-dedicated sample-and-hold circuit begins.
For details about the constant sampling function, see section 60.3.17.2 (4) SAR mode (with constant sampling enabled).

60.2.55 Internal Reference Voltage Monitor Enable Register (ADREFCR)

Address(es): ADC_B.ADREFCR 8743 8320h, ADC_B_NS.ADREFCR 0743 8320h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	VDE	Internal Reference Voltage A/D Conversion Select	0: Disable A/D conversion of internal reference voltage 1: Enable A/D conversion of internal reference voltage	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADREFCR register controls the function of the internal reference voltage circuit. When the A/D conversion of the internal reference voltage is performed, the VDE bit must be set to 1.

60.2.56 A/D Converter Digital Filter Selection Register n (ADDFSRn) (n = 0 to 2)

Address(es): ADC_B.ADDFSR0 8743 8340h, ADC_B.ADDFSR1 8743 8344h, ADC_B.ADDFSR2 8743 8348h
ADC_B_NS.ADDFSR0 0743 8340h, ADC_B_NS.ADDFSR1 0743 8344h, ADC_B_NS.ADDFSR2 0743 8348h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	DFSEL3[1:0]		—	—	—	—	—	—	DFSEL2[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	DFSEL1[1:0]		—	—	—	—	—	—	DFSEL0[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	DFSEL0[1:0]	A/D Converter Unit n the 1st Digital Filter Characteristic Selection	b1 b0 0 1: Sinc filter Settings other than above are prohibited.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	DFSEL1[1:0]	A/D Converter Unit n the 2nd Digital Filter Characteristic Selection	b9 b8 0 1: Sinc filter Settings other than above are prohibited.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	DFSEL2[1:0]	A/D Converter Unit n the 3rd Digital Filter Characteristic Selection	b17 b16 0 1: Sinc filter Settings other than above are prohibited.	R/W
b23 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25, b24	DFSEL3[1:0]	A/D Converter Unit n the 4th Digital Filter Characteristic Selection	b25 b24 0 1: Sinc filter Settings other than above are prohibited.	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADDFSRn register selects the characteristics of the digital filter for the A/D converter unit n. The selection of the digital filter to be used at A/D conversion is specified by the ADDOPCRAm register (m = 0 to 49). If the digital filter function is used with prohibited values set to the ADDFSRn.DFSELx[1:0] (x = 0 to 3) bits, the A/D conversion characteristics and A/D conversion results are not guaranteed.

60.2.57 A/D Converter Self-Calibration State Register (ADCALSTCR)

Address(es): ADC_B.ADCALSTCR 8743 8264h, ADC_B_NS.ADCALSTCR 0743 8264h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	CALADCST[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CALADSST[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	CALADSST[9:0]	A/D Converter Self-Calibration Sampling Time Configuration	These bits set the sampling time in the range from 2 to 1023 states.	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b21 to b16	CALADCST[5:0]	A/D Converter Self-Calibration Successive Approximation Time Configuration	These bits set the successive approximation time in the range from 3 to 63 states.	R/W
b31 to b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCALSTCR register specifies the sampling and the A/D successive approximation times at the self-calibration operation for all A/D converter (ADC0, ADC1, ADC2). The sampling time and successive approximation time should be set by the number of clock cycles based on the A/D conversion clock (ADCLK) to meet the values specified in section 67, Electrical Characteristics.

60.2.58 Channel-Dedicated Sample-and-Hold Circuit Self-Calibration State Register (ADCALSHCR)

Address(es): ADC_B.ADCALSHCR 8743 82B0h, ADC_B_NS.ADCALSHCR 0743 82B0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	CALSHHST[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	CALSHSST[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CALSHSST[7:0]	Channel-Dedicated Sample-and-Hold Circuit Self-Calibration Sampling Time Configuration	These bits set the sampling time in the range from 4 to 255 states.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b18 to b16	CALSHHST[2:0]	Channel-Dedicated Sample-and-Hold Circuit Self-Calibration Hold Mode Switching Time Configuration	These bits set the hold mode switching time in the range from 2 to 7 states.	R/W
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCALSHCR register specifies the sampling time and the hold mode switching time at the self-calibration operation for all channel-dedicated sample-and-hold circuits (SH0 to SH2). The sampling time and the hold mode switching time should be set by the number of clock cycles based on the A/D conversion clock (ADCLK) to meet the values specified in section 67, Electrical Characteristics.

60.2.59 User Offset Table Register n (ADUOFTRn) (n = 0 to 7)

Address(es): ADC_B.ADUOFTR0 8743 8360h, ADC_B.ADUOFTR1 8743 8364h, ADC_B.ADUOFTR2 8743 8368h, ADC_B.ADUOFTR3 8743 836Ch, ADC_B.ADUOFTR4 8743 8370h, ADC_B.ADUOFTR5 8743 8374h, ADC_B.ADUOFTR6 8743 8378h, ADC_B.ADUOFTR7 8743 837Ch, ADC_B_NS.ADUOFTR0 0743 8360h, ADC_B_NS.ADUOFTR1 0743 8364h, ADC_B_NS.ADUOFTR2 0743 8368h, ADC_B_NS.ADUOFTR3 0743 836Ch, ADC_B_NS.ADUOFTR4 0743 8370h, ADC_B_NS.ADUOFTR5 0743 8374h, ADC_B_NS.ADUOFTR6 0743 8378h, ADC_B_NS.ADUOFTR7 0743 837Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	UOFSET[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	UOFSET[15:0]	User Offset Table n	7FFFh: +32767 7FFEh: +32766 : 0002h: +2 0001h: +1 0000h: 0 (without user offset) FFFFh: –1 FFFEh: –2 : 8001h: –32767 8000h: –32768	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADUOFTRn register specifies the offset value in the user offset table n.

60.2.60 User Gain Table Register n (ADUGTRn) (n = 0 to 7)

Address(es): ADC_B.ADUGTR0 8743 8380h, ADC_B.ADUGTR1 8743 8384h, ADC_B.ADUGTR2 8743 8388h, ADC_B.ADUGTR3 8743 838Ch, ADC_B.ADUGTR4 8743 8390h, ADC_B.ADUGTR5 8743 8394h, ADC_B.ADUGTR6 8743 8398h, ADC_B.ADUGTR7 8743 839Ch, ADC_B_NS.ADUGTR0 0743 8380h, ADC_B_NS.ADUGTR1 0743 8384h, ADC_B_NS.ADUGTR2 0743 8388h, ADC_B_NS.ADUGTR3 0743 838Ch, ADC_B_NS.ADUGTR4 0743 8390h, ADC_B_NS.ADUGTR5 0743 8394h, ADC_B_NS.ADUGTR6 0743 8398h, ADC_B_NS.ADUGTR7 0743 839Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	UGAIN[15:0]															
Value after reset:	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	UGAIN[15:0]	User Gain Table n	These bits set the gain value to be multiplied by the A/D conversion result. UGAIN[15:14]: Integer part of gain UGAIN[13:0]: Fractional part of gain	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADUGTRn register specifies the gain value in the user gain table n.

60.2.61 Limiter Clip Interrupt Enable Register (ADLIMINTCR)

Address(es): ADC_B.ADLIMINTCR 8743 83A0h, ADC_B_NS.ADLIMINTCR 0743 83A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	LIMIE11	LIMIE10	LIMIE9	LIMIE8	LIMIE7	LIMIE6	LIMIE5	LIMIE4	LIMIE3	LIMIE2	LIMIE1	LIMIE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	LIMIE0 to LIMIE11	Limiter Clip Interrupt n Enable	The suffix number of each bit symbol corresponds to the limiter clip interrupt number n. 0: Disable the limiter clip interrupt n 1: Enable the limiter clip interrupt n	R/W
b31 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

n = 0 to 11

The ADLIMINTCR register enables/disables the limiter clip interrupt n.

60.2.62 Limiter Clip Table Register n (ADLIMTRn) (n = 0 to 7)

Address(es): ADC_B.ADLIMTR0 8743 83A4h, ADC_B.ADLIMTR1 8743 83A8h, ADC_B.ADLIMTR2 8743 83ACh, ADC_B.ADLIMTR3 8743 83B0h, ADC_B.ADLIMTR4 8743 83B4h, ADC_B.ADLIMTR5 8743 83B8h, ADC_B.ADLIMTR6 8743 83BCh, ADC_B.ADLIMTR7 8743 83C0h, ADC_B_NS.ADLIMTR0 0743 83A4h, ADC_B_NS.ADLIMTR1 0743 83A8h, ADC_B_NS.ADLIMTR2 0743 83ACh, ADC_B_NS.ADLIMTR3 0743 83B0h, ADC_B_NS.ADLIMTR4 0743 83B4h, ADC_B_NS.ADLIMTR5 0743 83B8h, ADC_B_NS.ADLIMTR6 0743 83BCh, ADC_B_NS.ADLIMTR7 0743 83C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	LIMU[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LIML[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	LIML[15:0]	Limiter Clip Table n: Lower-side Limit Value		R/W
b31 to b16	LIMU[15:0]	Limiter Clip Table n: Upper-side Limit Value		R/W

The ADLIMTRn register specifies the lower- and upper-side limit value of the limiter clip table n.

60.2.63 Limiter Clip Scan Group Status Register (ADLIMGRSR)

Address(es): ADC_B.ADLIMGRSR 8743 8D28h, ADC_B_NS.ADLIMGRSR 0743 8D28h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	LIMGRF0 to LIMGRF11	Scan Group n Limiter Clip Flag	The suffix number of each bit symbol corresponds to the scan group number n. 0: Limiter clip for scan group n is not detected 1: Limiter clip for scan group n is detected	R
b31 to b12	—	Reserved	These bits are read as 0.	R

n = 0 to 11

The ADLIMGRSR register indicates whether the limiter clip occurred in the scanning operation for scan group n. Each flag can be cleared in the ADLIMGRSCR.

60.2.64 Limiter Clip Channel Status Register 0 (ADLIMCHSR0)

Address(es): ADC_B.ADLIMCHSR0 8743 8D2Ch, ADC_B_NS.ADLIMCHSR0 0743 8D2Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	LIMCHF32 to LIMCHF35	Analog Channel n: Limiter Clip Flag	The suffix number of each bit symbol corresponds to the analog channel number n. 0: Limiter clip is not detected 1: Limiter clip is detected	R
b31 to b4	—	Reserved	These bits are read as 0.	R

n = 32 to 35

The ADLIMCHSR1 register indicates whether the limiter clip occurred when the A/D conversion for the analog channel n is performed. Each flag can be cleared in ADLIMCHSCR1.

60.2.66 Extended Analog Limiter Clip Status Register (ADLIMEXSR)

Address(es): ADC_B.ADLIMEXSR 8743 8D38h, ADC_B_NS.ADLIMEXSR 0743 8D38h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	LIMEXF18	LIMEXF17	LIMEXF16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	LIMEXF9	LIMEXF8	—	LIMEXF6	LIMEXF5	LIMEXF4	—	LIMEXF2	LIMEXF1	LIMEXF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LIMEXF0	ADC0 Self-Diagnosis Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b1	LIMEXF1	ADC1 Self-Diagnosis Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b2	LIMEXF2	ADC2 Self-Diagnosis Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b3	—	Reserved	This bit is read as 0.	R
b4	LIMEXF4	Temperature Sensor Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b5	LIMEXF5	Internal Reference Voltage Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b6	LIMEXF6	VBATT1/6 Voltage Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b7	—	Reserved	This bit is read as 0.	R
b8	LIMEXF8	D/A Converter 0 Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b9	LIMEXF9	D/A Converter 1 Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b15 to b10	—	Reserved	These bits are read as 0.	R
b16	LIMEXF16	Channel-Dedicated Sample-and-Hold Circuit Unit 0 Self-Diagnosis Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b17	LIMEXF17	Channel-Dedicated Sample-and-Hold Circuit Unit 1 Self-Diagnosis Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b18	LIMEXF18	Channel-Dedicated Sample-and-Hold Circuit Unit 2 Self-Diagnosis Channel: Limiter Clip Flag	0: Limiter clip is not detected 1: Limiter clip is detected	R
b31 to b19	—	Reserved	These bits are read as 0.	R

The ADLIMEXSR register indicates whether the limiter clip occurred when the A/D conversion for the extended analog function (which channel no. is 96 to 98, 100 to 102, 104, 105, 112 to 114) is performed. Each flag can be cleared in the ADLIMEXSCR.

60.2.67 Limiter Clip Scan Group Status Clear Register (ADLIMGRSCR)

Address(es): ADC_B.ADLIMGRSCR 8743 8D3Ch, ADC_B_NS.ADLIMGRSCR 0743 8D3Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	LIMGRC0 to LIMGRC11	Scan Group n Limiter Clip Flag Clear	The suffix number of each bit symbol corresponds to the scan group number n. 0: No effect 1: ADLIMGRSR.LIMGRFn is cleared	W
b31 to b12	—	Reserved	The write value should be 0.	W

n = 0 to 11

The ADLIMGRSCR register clears the limiter clip flag for scan group n (ADLIMGRSR.LIMGRFn).

60.2.68 Limiter Clip Channel Status Clear Register 0 (ADLIMCHSCR0)

Address(es): ADC_B.ADLIMCHSCR0 8743 8D40h, ADC_B_NS.ADLIMCHSCR0 0743 8D40h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	LIMCHC0 to LIMCHC31	Analog Channel n Limiter Clip Flag Clear bit	The suffix number of each bit symbol corresponds to the analog channel number n. 0: No effect 1: ADLIMCHSR0.LIMCHFn is cleared	W

n = 0 to 31

The ADLIMCHSCR0 register clears the limiter clip flag for the analog channel n (ADLIMCHSR0.LIMCHFn).

60.2.69 Limiter Clip Channel Status Clear Register 1 (ADLIMCHSCR1)

Address(es): ADC_B.ADLIMCHSCR1 8743 8D44h, ADC_B_NS.ADLIMCHSCR1 0743 8D44h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	LIMCHC35	LIMCHC34	LIMCHC33	LIMCHC32
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	LIMCHC32 to LIMCHC35	Analog Channel n Limiter Clip Flag Clear bit	The suffix number of each bit symbol corresponds to the analog channel number n. 0: No effect 1: ADLIMCHSR1.LIMCHFn is cleared	W
b31 to b4	—	Reserved	The write value should be 0.	W

n = 32 to 35

The ADLIMCHSCR1 register clears the limiter clip flag for the analog channel n (ADLIMCHSR1.LIMCHFn).

60.2.70 Extended Analog Limiter Clip Status Clear Register (ADLIMEXSCR)

Address(es): ADC_B.ADLIMEXSCR 8743 8D4Ch, ADC_B_NS.ADLIMEXSCR 0743 8D4Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	LIMEXC18	LIMEXC17	LIMEXC16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LIMEXC0	ADC0 Self-Diagnosis Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF0 is cleared	W
b1	LIMEXC1	ADC1 Self-Diagnosis Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF1 is cleared	W
b2	LIMEXC2	ADC2 Self-Diagnosis Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF2 is cleared	W
b3	—	Reserved	The write value should be 0.	W
b4	LIMEXC4	Temperature Sensor Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF4 is cleared	W
b5	LIMEXC5	Internal Reference Voltage Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF5 is cleared	W
b6	LIMEXC6	VBATT1/6 Voltage Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF6 is cleared	W
b7	—	Reserved	The write value should be 0.	W
b8	LIMEXC8	D/A Converter 0 Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF8 is cleared	W
b9	LIMEXC9	D/A Converter 1 Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF9 is cleared	W
b15 to b10	—	Reserved	The write value should be 0.	W
b16	LIMEXC16	Channel-Dedicated Sample-and-Hold Circuit Unit 0 Self-Diagnosis Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF16 is cleared	W
b17	LIMEXC17	Channel-Dedicated Sample-and-Hold Circuit Unit 1 Self-Diagnosis Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF17 is cleared	W
b18	LIMEXC18	Channel-Dedicated Sample-and-Hold Circuit Unit 2 Self-Diagnosis Channel: Limiter Clip Flag Clear	0: No effect 1: ADLIMEXSR.LIMEXF18 is cleared	W
b31 to b19	—	Reserved	The write value should be 0.	W

The ADLIMEXSCR register clears the limiter clip flag for the extended analog function.

60.2.71 Compare Match Enable Register (ADCMPENR)

Address(es): ADC_B.ADCMPENR 8743 8400h, ADC_B_NS.ADCMPENR 0743 8400h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CMPEN0 to CMPEN7	Compare Match n Enable	The suffix number of each bit symbol corresponds to the compare match number n. 0: Disable the compare match n 1: Enable the compare match n	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

n = 0 to 7

The ADCMPENR register enables/disables the compare match n.

60.2.72 Compare Match Interrupt Enable Register (ADCMPINTCR)

Address(es): ADC_B.ADCMPINTCR 8743 8404h, ADC_B_NS.ADCMPINTCR 0743 8404h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CMPIE0 to CMPIE7	Compare Match Interrupt n Enable	The suffix number of each bit symbol corresponds to the compare match interrupt number n. 0: Disable the compare match interrupt n 1: Enable the compare match interrupt n	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

n = 0 to 7

The ADCMPINTCR register enables/disables the compare match interrupt n.

60.2.73 Composite Compare Match Configuration Register n (ADCCMPCRn) (n = 0 to 7)

Address(es): ADC_B.ADCCMPCR0 8743 8408h, ADC_B.ADCCMPCR1 8743 840Ch, ADC_B.ADCCMPCR2 8743 8410h, ADC_B.ADCCMPCR3 8743 8414h, ADC_B.ADCCMPCR4 8743 8418h, ADC_B.ADCCMPCR5 8743 841Ch, ADC_B.ADCCMPCR6 8743 8420h, ADC_B.ADCCMPCR7 8743 8424h, ADC_B_NS.ADCCMPCR0 0743 8408h, ADC_B_NS.ADCCMPCR1 0743 840Ch, ADC_B_NS.ADCCMPCR2 0743 8410h, ADC_B_NS.ADCCMPCR3 0743 8414h, ADC_B_NS.ADCCMPCR4 0743 8418h, ADC_B_NS.ADCCMPCR5 0743 841Ch, ADC_B_NS.ADCCMPCR6 0743 8420h, ADC_B_NS.ADCCMPCR7 0743 8424h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	CCMPTBL7	CCMPTBL6	CCMPTBL5	CCMPTBL4	CCMPTBL3	CCMPTBL2	CCMPTBL1	CCMPTBL0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CCMPCND[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CCMPCND[1:0]	Composite Compare Match Condition Selection	b1 b0 0 0: Logical disjunction (OR) conditions Settings other than above are prohibited.	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	CCMPTBL0 to CCMPTBL7	Composite Compare Match Condition Table Selection	0: Not use the compare match table m 1: Use the compare match table m	R/W
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

m = 0 to 7

The ADCCMPCRn register configures the conditions for the composite compare match interrupt n.

CCMPCND[1:0] Bits (Composite Compare Match Condition Selection)

The CCMPCND[1:0] bits select the generating condition for the composite compare match interrupt n.

CCMPTBLm Bits (Composite Compare Match Condition Table Selection) (m = 0 to 7)

The CCMPTBLm bits select whether to use or not to use the compare match table m as the generating conditions of the composite compare match interrupt.

60.2.74 Compare Match Mode Selection Register 0 (ADCMPMDR0)

Address(es): ADC_B.ADCMPMDR0 8743 8448h, ADC_B_NS.ADCMPMDR0 0743 8448h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	CMPMD3[1:0]		—	—	—	—	—	—	CMPMD2[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CMPMD1[1:0]		—	—	—	—	—	—	CMPMD0[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CMPMD0[1:0]	Compare Match 0: Match Mode Selection	b1 b0 0 0: Generate the match event when high-side level or more 0 1: Generate the match event when low-side level or less 1 0: Generate the match event when high-side level or more, or low-side level or less 1 1: Generate the match event when low-side level or more and high-side level or less	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	CMPMD1[1:0]	Compare Match 1: Match Mode Selection	b9 b8 0 0: Generate the match event when high-side level or more 0 1: Generate the match event when low-side level or less 1 0: Generate the match event when high-side level or more, or low-side level or less 1 1: Generate the match event when low-side level or more and high-side level or less	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	CMPMD2[1:0]	Compare Match 2: Match Mode Selection	b17 b16 0 0: Generate the match event when high-side level or more 0 1: Generate the match event when low-side level or less 1 0: Generate the match event when high-side level or more, or low-side level or less 1 1: Generate the match event when low-side level or more and high-side level or less	R/W
b23 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25, b24	CMPMD3[1:0]	Compare Match 3: Match Mode Selection	b25 b24 0 0: Generate the match event when high-side level or more 0 1: Generate the match event when low-side level or less 1 0: Generate the match event when high-side level or more, or low-side level or less 1 1: Generate the match event when low-side level or more and high-side level or less	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCMPMDR0 register selects the generating condition of each compare match event.

60.2.75 Compare Match Mode Selection Register 1 (ADCMPMDR1)

Address(es): ADC_B.ADCMPMDR1 8743 844Ch, ADC_B_NS.ADCMPMDR1 0743 844Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	CMPMD7[1:0]		—	—	—	—	—	—	CMPMD6[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CMPMD4[1:0]	Compare Match 4: Match Mode Selection	b1 b0 0 0: Generate the match event when high-side level or more 0 1: Generate the match event when low-side level or less 1 0: Generate the match event when high-side level or more, or low-side level or less 1 1: Generate the match event when low-side level or more and high-side level or less	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	CMPMD5[1:0]	Compare Match 5: Match Mode Selection	b9 b8 0 0: Generate the match event when high-side level or more 0 1: Generate the match event when low-side level or less 1 0: Generate the match event when high-side level or more, or low-side level or less 1 1: Generate the match event when low-side level or more and high-side level or less	R/W
b15 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b17, b16	CMPMD6[1:0]	Compare Match 6: Match Mode Selection	b17 b16 0 0: Generate the match event when high-side level or more 0 1: Generate the match event when low-side level or less 1 0: Generate the match event when high-side level or more, or low-side level or less 1 1: Generate the match event when low-side level or more and high-side level or less	R/W
b23 to b18	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25, b24	CMPMD7[1:0]	Compare Match 7: Match Mode Selection	b25 b24 0 0: Generate the match event when high-side level or more 0 1: Generate the match event when low-side level or less 1 0: Generate the match event when high-side level or more, or low-side level or less 1 1: Generate the match event when low-side level or more and high-side level or less	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADCMPMDR1 register selects the generating condition of each compare match event.

60.2.76 Compare Match Table Register n (ADCMPTBRn) (n = 0 to 7)

Address(es): ADC_B.ADCMPTBR0 8743 8458h, ADC_B.ADCMPTBR1 8743 845Ch, ADC_B.ADCMPTBR2 8743 8460h, ADC_B.ADCMPTBR3 8743 8464h, ADC_B.ADCMPTBR4 8743 8468h, ADC_B.ADCMPTBR5 8743 846Ch, ADC_B.ADCMPTBR6 8743 8470h, ADC_B.ADCMPTBR7 8743 8474h, ADC_B_NS.ADCMPTBR0 0743 8458h, ADC_B_NS.ADCMPTBR1 0743 845Ch, ADC_B_NS.ADCMPTBR2 0743 8460h, ADC_B_NS.ADCMPTBR3 0743 8464h, ADC_B_NS.ADCMPTBR4 0743 8468h, ADC_B_NS.ADCMPTBR5 0743 846Ch, ADC_B_NS.ADCMPTBR6 0743 8470h, ADC_B_NS.ADCMPTBR7 0743 8474h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CMPTBH[15:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMPTBL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CMPTBL[15:0]	Compare Match Table n: Low-Side Level	Set CMPTBH > CMPTBL	R/W
b31 to b16	CMPTBH[15:0]	Compare Match Table n: High-Side Level	Set CMPTBH > CMPTBL	R/W

The ADCMPTBRn register specifies the low-side level and the high-side level for the compare match table n.

60.2.77 Compare Match Table Status Register (ADCMPTBSR)

Address(es): ADC_B.ADCMPTBSR 8743 8D00h, ADC_B_NS.ADCMPTBSR 0743 8D00h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	CMPTBF7	CMPTBF6	CMPTBF5	CMPTBF4	CMPTBF3	CMPTBF2	CMPTBF1	CMPTBF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CMPTBF0 to CMPTBF7	Compare Match Table n Match Flag	The suffix number of each bit symbol corresponds to the compare match table number n. 0: Match event with compare match table n is not detected 1: Match event with compare match table n is detected	R
b31 to b8	—	Reserved	These bits are read as 0.	R

n = 0 to 7

The ADCMPTBSR register indicates whether the match event with the compare match table n occurred during the A/D conversion. Each flag can be cleared in the ADCMPTBSCR.

60.2.78 Compare Match Table Status Clear Register (ADCMPTBSCR)

Address(es): ADC_B.ADCMPTBSCR 8743 8D04h, ADC_B_NS.ADCMPTBSCR 0743 8D04h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	CMPTBC7	CMPTBC6	CMPTBC5	CMPTBC4	CMPTBC3	CMPTBC2	CMPTBC1	CMPTBC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CMPTBC0 to CMPTBC7	Compare Match Table n: Match Flag Clear	The suffix number of each bit symbol corresponds to the compare match table number n. 0: No effect 1: ADCMPTBSR.CMPTBFn is cleared	W
b31 to b8	—	Reserved	The write value should be 0.	W

n = 0 to 7

The ADCMPTBSCR register clears the match flag for the compare match n (ADCMPTBSR.CMPTBFn).

60.2.79 Compare Match Channel Status Register 0 (ADCMPCHSR0)

Address(es): ADC_B.ADCMPCHSR0 8743 8D08h, ADC_B_NS.ADCMPCHSR0 0743 8D08h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CMPCHF31	CMPCHF30	CMPCHF29	CMPCHF28	CMPCHF27	CMPCHF26	CMPCHF25	CMPCHF24	CMPCHF23	CMPCHF22	CMPCHF21	CMPCHF20	CMPCHF19	CMPCHF18	CMPCHF17	CMPCHF16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	CMPCHF15	CMPCHF14	CMPCHF13	CMPCHF12	CMPCHF11	CMPCHF10	CMPCHF9	CMPCHF8	CMPCHF7	CMPCHF6	CMPCHF5	CMPCHF4	CMPCHF3	CMPCHF2	CMPCHF1	CMPCHF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	CMPCHF0 to CMPCHF31	Analog Channel n: Compare Match Flag	The suffix number of each bit symbol corresponds to the analog channel number n. 0: Compare match is not detected 1: Compare match is detected	R

n = 0 to 31

The ADCMPCHSR0 register indicates whether the compare match event for the analog channel n is detected. Each flag can be cleared in ADCMPCHSCR0.

60.2.80 Compare Match Channel Status Register 1 (ADCMPCHSR1)

Address(es): ADC_B.ADCMPCHSR1 8743 8D0Ch, ADC_B_NS.ADCMPCHSR1 0743 8D0Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	CMPCHF35	CMPCHF34	CMPCHF33	CMPCHF32
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CMPCHF32 to CMPCHF35	Analog Channel n: Compare Match Flag	The suffix number of each bit symbol corresponds to the analog channel number n. 0: Compare match is not detected 1: Compare match is detected	R
b31 to b4	—	Reserved	These bits are read as 0.	R

n = 32 to 35

The ADCMPCHSR1 register indicates whether the compare match event for the analog channel n is detected. Each flag can be cleared in ADCMPCHSCR1.

60.2.81 Extended Analog Compare Match Status Register (ADCMPEXSR)

Address(es): ADC_B.ADCMPEXSR 8743 8D14h, ADC_B_NS.ADCMPEXSR 0743 8D14h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	CMPEXF18	CMPEXF17	CMPEXF16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPEXF0	ADC0 Self-Diagnosis Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b1	CMPEXF1	ADC1 Self-Diagnosis Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b2	CMPEXF2	ADC2 Self-Diagnosis Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b3	—	Reserved	This bit is read as 0.	R
b4	CMPEXF4	Temperature Sensor Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b5	CMPEXF5	Internal Reference Voltage Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b6	CMPEXF6	VBATT 1/6 Voltage Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b7	—	Reserved	This bit is read as 0.	R
b8	CMPEXF8	D/A Converter 0 Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b9	CMPEXF9	D/A Converter 1 Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b15 to b10	—	Reserved	These bits are read as 0.	R
b16	CMPEXF16	Channel-Dedicated Sample-and-Hold Circuit Unit 0 Self-Diagnosis Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b17	CMPEXF17	Channel-Dedicated Sample-and-Hold Circuit Unit 1 Self-Diagnosis Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b18	CMPEXF18	Channel-Dedicated Sample-and-Hold Circuit Unit 2 Self-Diagnosis Channel: Compare Match Flag	0: Compare match is not detected 1: Compare match is detected	R
b31 to b19	—	Reserved	These bits are read as 0.	R

The ADCMPEXSR register indicates whether the compare match event for the extended analog function channel is detected. Each flag can be cleared in ADCMPEXSCR.

60.2.82 Compare Match Channel Status Clear Register 0 (ADCMPCHSCR0)

Address(es): ADC_B.ADCMPCHSCR0 8743 8D18h, ADC_B_NS.ADCMPCHSCR0 0743 8D18h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	CMPCHC15	CMPCHC14	CMPCHC13	CMPCHC12	CMPCHC11	CMPCHC10	CMPCHC9	CMPCHC8	CMPCHC7	CMPCHC6	CMPCHC5	CMPCHC4	CMPCHC3	CMPCHC2	CMPCHC1	CMPCHC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	CMPCHC0 to CMPCHC31	Analog Channel n: Compare Match Flag Clear	The suffix number of each bit symbol corresponds to the analog channel number n. 0: No effect 1: ADCMPCHSR0.CMPCHFn is cleared	W

n = 0 to 31

The ADCMPCHSCR0 register clears the compare match flag for the analog channel n (ADCMPCHSR0.CMPCHFn).

60.2.83 Compare Match Channel Status Clear Register 1 (ADCMPCHSCR1)

Address(es): ADC_B.ADCMPCHSCR1 8743 8D1Ch, ADC_B_NS.ADCMPCHSCR1 0743 8D1Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	CMPCHC35	CMPCHC34	CMPCHC33	CMPCHC32
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CMPCHC32 to CMPCHC35	Analog Channel n: Compare Match Flag Clear	The suffix number of each bit symbol corresponds to the analog channel number n. 0: No effect 1: ADCMPCHSR1.CMPCHFn is cleared	W
b31 to b4	—	Reserved	The write value should be 0.	W

n = 32 to 35

The ADCMPCHSCR1 register clears the compare match flag for the analog channel n (ADCMPCHSR1.CMPCHFn).

60.2.84 Extended Analog Compare Match Status Clear Register (ADCMPEXSCR)

Address(es): ADC_B.ADCMPEXSCR 8743 8D24h, ADC_B_NS.ADCMPEXSCR 0743 8D24h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	CMPEXC18	CMPEXC17	CMPEXC16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPEXC0	ADC0 Self-Diagnosis Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF0 is cleared	W
b1	CMPEXC1	ADC1 Self-Diagnosis Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF1 is cleared	W
b2	CMPEXC2	ADC2 Self-Diagnosis Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF2 is cleared	W
b3	—	Reserved	The write value should be 0.	W
b4	CMPEXC4	Temperature Sensor Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF4 is cleared	W
b5	CMPEXC5	Internal Reference Voltage Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF5 is cleared	W
b6	CMPEXC6	VBATT 1/6 Voltage Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF6 is cleared	W
b7	—	Reserved	The write value should be 0.	W
b8	CMPEXC8	D/A Converter 0 Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF8 is cleared	W
b9	CMPEXC9	D/A Converter 1 Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF9 is cleared	W
b15 to b10	—	Reserved	The write value should be 0.	W
b16	CMPEXC16	Channel-Dedicated Sample-and-Hold Circuit Unit 0 Self-Diagnosis Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF16 is cleared	W
b17	CMPEXC17	Channel-Dedicated Sample-and-Hold Circuit Unit 1 Self-Diagnosis Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF17 is cleared	W
b18	CMPEXC18	Channel-Dedicated Sample-and-Hold Circuit Unit 2 Self-Diagnosis Channel: Compare Match Flag Clear	0: No effect 1: ADCMPEXSR.CMPEXF18 is cleared	W
b31 to b19	—	Reserved	The write value should be 0.	W

The ADCMPEXSCR register clears the compare match flag for the extended analog function channel (ADCMPEXSR.CMPEXFn).

60.2.85 A/D Converter Self-Calibration Start Register (ADCALSTR)

Address(es): ADC_B.ADCALSTR 8743 8C00h, ADC_B_NS.ADCALSTR 0743 8C00h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADCALST2[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	ADCALST1[1:0]		—	—	—	—	—	ADCALST0[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	ADCALST0[2:0]*1	A/D Converter Unit 0 (ADC0) Self-Calibration Start Control	[Function of each bit] b0: Start bit of the internal circuit calibration b1: Start bit of the gain and offset calibration b2: Start bit of the channel-dedicated sample-and-hold circuit calibration [Write value] 0: No effect (not start the calibration) 1: Start the calibration	W
b7 to b3	—	Reserved	The write value should be 0.	W
b9 to b8	ADCALST1[1:0]*1	A/D Converter Unit 1 (ADC1) Self-Calibration Start Control	[Function of each bit] b8: Start bit of the internal circuit calibration b9: Start bit of the gain and offset calibration [Write value] 0: No effect (not start the calibration) 1: Start the calibration	W
b15 to b10	—	Reserved	The write value should be 0.	W
b17 to b16	ADCALST2[1:0]*1	A/D Converter Unit 2 (ADC2) Self-Calibration Start Control	[Function of each bit] b16: Start bit of the internal circuit calibration b17: Start bit of the gain and offset calibration [Write value] 0: No effect (not start the calibration) 1: Start the calibration	W
b31 to b18	—	Reserved	The write value should be 0.	W

Note 1. To perform a calibration operation, write 1 to each of the calibration start bits simultaneously.

The ADCALSTR register controls the start of the self-calibration for each A/D converter.

ADCALST0[2:0] Bits (A/D Converter Unit 0 (ADC0) Self-Calibration Start Control)

The ADCALST0[2:0] bits control the start of the self-calibration operation of the A/D converter Unit 0. When any bit of ADCALST0[2:0] is set to 1, the self-calibration operation corresponding to each bit is started. When multiple bits of ADCALST0[2:0] are set to 1 simultaneously, each self-calibration operation is performed in the order as following:

1. Internal circuit calibration
2. A/D converter gain/offset calibration
3. Channel-specific sample-and-hold circuit gain/offset calibration

Note: The self-calibration operation corresponding to the bits set to 0 in ADCALST0[2:0] is skipped.

The ADCALST0[2:0] bits must be written when all A/D converters are stopped (ADSR.ADACTm = 0 and ADSR.CALACTm = 0 (m = 0 to 2));
Writing to the ADCALST0[2:0] bits are prohibited when A/D converters are operating.

ADCALST1[1:0] Bits (A/D Converter Unit 1 (ADC1) Self-Calibration Start Control)

The ADCALST1[1:0] bits control the start of the self-calibration operation of the A/D converter Unit 1. When any bit of ADCALST1[1:0] is set to 1, the self-calibration operation corresponding to each bit is started. When multiple bits of ADCALST1[1:0] are set to 1 simultaneously, each self-calibration operation is performed in the order as following:

1. Internal circuit calibration
2. A/D converter gain/offset calibration

Note: The self-calibration operation corresponding to the bits set to 0 in ADCALST1[1:0] is skipped.

The ADCALST1[1:0] bits must be written when all A/D converters are stopped (ADSR.ADACTm = 0 and ADSR.CALACTm = 0 (m = 0 to 2));
Writing to the ADCALST1[1:0] bits are prohibited when A/D converters are operating.

ADCALST2[1:0] Bits (A/D Converter Unit 2 (ADC2) Self-Calibration Start Control)

The ADCALST2[1:0] bits control the start of the self-calibration operation of the A/D converter Unit 2. When any bit of ADCALST2[1:0] is set to 1, the self-calibration operation corresponding to each bit is started. When multiple bits of ADCALST2[1:0] are set to 1 simultaneously, each self-calibration operation is performed in the order as following:

1. Internal circuit calibration
2. A/D converter gain/offset calibration

Note: The self-calibration operation corresponding to the bits set to 0 in ADCALST2[1:0] is skipped.

The ADCALST2[1:0] bits must be written when all A/D converters are stopped (ADSR.ADACTm = 0 and ADSR.CALACTm = 0 (m = 0 to 2));
Writing to the ADCALST2[1:0] bits are prohibited when A/D converters are operating.

60.2.86 A/D Conversion Synchronous Software Start Register (ADSYSTR)

Address(es): ADC_B.ADSYSTR 8743 8C10h, ADC_B_NS.ADSYSTR 0743 8C10h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	ADSYST0 to ADSYST11	Scan Group n: A/D Conversion Start	The suffix number of each bit symbol corresponds to the scan group number n. 0: No effect 1: Start the A/D conversion of scan group n	W
b31 to b12	—	Reserved	The write value should be 0.	W

n = 0 to 11

The ADSYSTR register controls the start of the A/D conversion of scan group n. This register is used to start the A/D conversions of several scan groups simultaneously by software.

ADSYSTn Bit (Scan Group n: A/D Conversion Start) (n = 0 to 11)

The ADSYSTn bit controls the start of the A/D conversion of scan group n. When the ADSYSTn bit is set to 1, the A/D conversion of scan group n is started. Setting 0 to the ADSYSTn bit has no effect on the operation. If the ADSYSTn bits for multiple scan groups are set to 1 at the same time, A/D conversion begins in sequence according to the priority levels of the scan groups.

60.2.87 A/D Conversion Software Start Register n (ADSTRn) (n = 0 to 11)

Address(es): ADC_B.ADSTR0 8743 8C20h, ADC_B.ADSTR1 8743 8C24h, ADC_B.ADSTR2 8743 8C28h, ADC_B.ADSTR3 8743 8C2Ch, ADC_B.ADSTR4 8743 8C30h, ADC_B.ADSTR5 8743 8C34h, ADC_B.ADSTR6 8743 8C38h, ADC_B.ADSTR7 8743 8C3Ch, ADC_B.ADSTR8 8743 8C40h, ADC_B.ADSTR9 8743 8C44h, ADC_B.ADSTR10 8743 8C48h, ADC_B.ADSTR11 8743 8C4Ch, ADC_B_NS.ADSTR0 0743 8C20h, ADC_B_NS.ADSTR1 0743 8C24h, ADC_B_NS.ADSTR2 0743 8C28h, ADC_B_NS.ADSTR3 0743 8C2Ch, ADC_B_NS.ADSTR4 0743 8C30h, ADC_B_NS.ADSTR5 0743 8C34h, ADC_B_NS.ADSTR6 0743 8C38h, ADC_B_NS.ADSTR7 0743 8C3Ch, ADC_B_NS.ADSTR8 0743 8C40h, ADC_B_NS.ADSTR9 0743 8C44h, ADC_B_NS.ADSTR10 0743 8C48h, ADC_B_NS.ADSTR11 0743 8C4Ch

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADST	Scan Group n A/D Conversion Start	0: No effect 1: Start the A/D conversion of scan group n	W
b31 to b1	—	Reserved	The write value should be 0.	W

The ADSTRn register controls the start of the A/D conversion of scan group n. This register is used to start the A/D conversion of a scan group by software.

If A/D conversions of several scan groups are to be started simultaneously by software, the ADSYSTR register should be used.

ADST Bit (Scan Group n A/D Conversion Start)

The ADST bit controls the start of the A/D conversion of scan group n. When the ADST bit is set to 1, the A/D conversion of the scan group n is started. Setting 0 to the ADST bit has no effect on the operation.

60.2.88 A/D Conversion Stop Register (ADSTOPR)

Address(es): ADC_B.ADSTOPR 8743 8C60h, ADC_B_NS.ADSTOPR 0743 8C60h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ADSTOP2
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ADSTOP1	—	—	—	—	—	—	—	ADSTOP0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADSTOP0	A/D Converter Unit 0 Force Stop	0: No effect 1: Force stop the operation of A/D converter unit 0	W
b7 to b1	—	Reserved	The write value should be 0.	W
b8	ADSTOP1	A/D Converter Unit 1 Force Stop	0: No effect 1: Force stop the operation of A/D converter unit 1	W
b15 to b9	—	Reserved	The write value should be 0.	W
b16	ADSTOP2	A/D Converter Unit 2 Force Stop	0: No effect 1: Force stop the operation of A/D converter unit 2	W
b31 to b17	—	Reserved	The write value should be 0.	W

The ADSTOPR register forces each A/D converter to stop the operation. When the A/D converter is stopped with this register, the A/D conversion results with that A/D converter are not guaranteed.

ADSTOP0 Bit (A/D Converter Unit 0 Force Stop)

The ADSTOP0 bit forces the A/D converter unit 0 to stop the A/D conversion operation. Setting 0 to the ADSTOP0 bit has no effect on the operation. When the ADSTOP0 bit is set to 1, the A/D converter unit 0 is forced to stop the operation. If the A/D converter unit 0 is forced to stop, the A/D conversion results with the A/D converter unit 0 are not guaranteed.

ADSTOP1 Bit (A/D Converter Unit 1 Force Stop)

The ADSTOP1 bit forces the A/D converter unit 1 to stop the A/D conversion operation. Setting 0 to the ADSTOP1 bit has no effect on the operation. When the ADSTOP1 bit is set to 1, the A/D converter unit 1 is forced to stop the operation. If the A/D converter unit 1 is forced to stop, the A/D conversion results with the A/D converter unit 1 are not guaranteed.

ADSTOP2 Bit (A/D Converter Unit 2 Force Stop)

The ADSTOP2 bit forces the A/D converter unit 2 to stop the A/D conversion operation. Setting 0 to the ADSTOP2 bit has no effect on the operation. When the ADSTOP2 bit is set to 1, the A/D converter unit 2 is forced to stop the operation. If the A/D converter unit 2 is forced to stop, the A/D conversion results with the A/D converter unit 2 are not guaranteed.

60.2.89 A/D Conversion Status Register (ADSR)

Address(es): ADC_B.ADSR 8743 8C80h, ADC_B_NS.ADSR 0743 8C80h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	CALACT2	CALACT1	CALACT0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—		ADACT2	ADACT1	ADACT0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADACT0	A/D Converter Unit 0 (ADC0) A/D Conversion Status	0: ADC0 is not in A/D conversion 1: ADC0 is in A/D conversion	R
b1	ADACT1	A/D Converter Unit 1 (ADC1) A/D Conversion Status	0: ADC1 is not in A/D conversion 1: ADC1 is in A/D conversion	R
b2	ADACT2	A/D Converter Unit 2 (ADC2) A/D Conversion Status	0: ADC2 is not in A/D conversion 1: ADC2 is in A/D conversion	R
b15 to b3	—	Reserved	These bits are read as 0.	R
b16	CALACT0	A/D Converter Unit 0 (ADC0): Calibration Status	0: ADC0 is not in the calibration operation 1: ADC0 is in the calibration operation	R
b17	CALACT1	A/D Converter Unit 1 (ADC1): Calibration Status	0: ADC1 is not in the calibration operation 1: ADC1 is in the calibration operation	R
b18	CALACT2	A/D Converter Unit 2 (ADC2): Calibration Status	0: ADC2 is not in the calibration operation 1: ADC2 is in the calibration operation	R
b31 to b19	—	Reserved	These bits are read as 0.	R

The ADSR register indicates the status for each A/D converter operation.

60.2.90 Scan Group Status Register (ADGRSR)

Address(es): ADC_B.ADGRSR 8743 8C84h, ADC_B_NS.ADGRSR 0743 8C84h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	ACTGR11	ACTGR10	ACTGR9	ACTGR8	ACTGR7	ACTGR6	ACTGR5	ACTGR4	ACTGR3	ACTGR2	ACTGR1	ACTGR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	ACTGR0 to ACTGR11	Scan Group n Status*1	The suffix number of each bit symbol corresponds to the scan group number n. 0: Scan group n is idle 1: Scan group n is in the scanning operation	R
b31 to b12	—	Reserved	These bits are read as 0.	R

n = 0 to 11

Note 1. In the group priority operation, if the scanning operation of a low priority group is interrupted, the ACTGRn bit of the corresponding scan group is set to 1.

The ADGRSR register indicates the operating status for each scan group.

60.2.91 Scan End Status Register (ADSCANENDSR)

Address(es): ADC_B.ADSCANENDSR 8743 8D50h, ADC_B_NS.ADSCANENDSR 0743 8D50h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	SCENDF0 to SCENDF11	Scan Group n Scan End Flag*1	The suffix number of each bit symbol corresponds to the scan group number n. 0: Scan group n has not been scanned 1: End of scan for scan group n is detected	R
b31 to b12	—	Reserved	These bits are read as 0.	R

n = 0 to 11

Note 1. If the A/D conversion operation is stopped with the ADSTOPR register, the SCENDFn bit of the scan group in which the scan operation was stopped is not changed. (It is not set to 1)

The ADSCANENDSR register indicates whether the scanning operation for each scan group has been done. Each flag can be cleared in ADSCANENDSCR register.

60.2.92 Scan End Status Clear Register (ADSCANENDSCR)

Address(es): ADC_B.ADSCANENDSCR 8743 8D54h, ADC_B_NS.ADSCANENDSCR 0743 8D54h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SCENDC11	SCENDC10	SCENDC9	SCENDC8	SCENDC7	SCENDC6	SCENDC5	SCENDC4	SCENDC3	SCENDC2	SCENDC1	SCENDC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	SCENDC0 to SCENDC11	Scan Group n Scan End Flag Clear	The suffix number of each bit symbol corresponds to the scan group number n. 0: No effect 1: ADSCANENDSR.SCENDFn is cleared	W
b31 to b12	—	Reserved	The write value should be 0.	W

n = 0 to 11

The ADSCANENDSCR register clears the scan end flag for the scan group n.

60.2.93 A/D Conversion Error Status Register (ADERSR)

Address(es): ADC_B.ADERSR 8743 8C88h, ADC_B_NS.ADERSR 0743 8C88h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	ADERF2	ADERF1	ADERF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADERF0	A/D Converter Unit 0 (ADC0) Error Flag	0: Error is not detected 1: Error is detected	R
b1	ADERF1	A/D Converter Unit 1 (ADC1) Error Flag	0: Error is not detected 1: Error is detected	R
b2	ADERF2	A/D Converter Unit 2 (ADC2) Error Flag	0: Error is not detected 1: Error is detected	R
b31 to b3	—	Reserved	These bits are read as 0.	R

The ADERSR register indicates whether the operating error has occurred in each A/D converter. Each flag can be cleared in ADERSCR register.
The A/D conversion data is not guaranteed in the A/D converter operation with an error detected.

60.2.94 A/D Conversion Error Status Clear Register (ADERSCR)

Address(es): ADC_B.ADERSCR 8743 8C8Ch, ADC_B_NS.ADERSCR 0743 8C8Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	ADERCLR2	ADERCLR1	ADERCLR0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADERCLR0	A/D Converter Unit 0 Error Flag Clear	0: No effect 1: ADERSR.ADERF0 is cleared	W
b1	ADERCLR1	A/D Converter Unit 1 Error Flag Clear	0: No effect 1: ADERSR.ADERF1 is cleared	W
b2	ADERCLR2	A/D Converter Unit 2 Error Flag Clear	0: No effect 1: ADERSR.ADERF2 is cleared	W
b31 to b3	—	Reserved	The write value should be 0.	W

The ADERSCR register clears the error flag for A/D converter unit 0, unit 1 or unit 2.

60.2.95 A/D Converter Calibration End Status Register (ADCALENDSR)

Address(es): ADC_B.ADCALENDSR 8743 8C98h, ADC_B_NS.ADCALENDSR 0743 8C98h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CALENDF0	A/D Converter Unit 0 Calibration End Flag	0: End of the calibration is not detected 1: End of the calibration is detected	R
b1	CALENDF1	A/D Converter Unit 1 Calibration End Flag	0: End of the calibration is not detected 1: End of the calibration is detected	R
b2	CALENDF2	A/D Converter Unit 2 Calibration End Flag	0: End of the calibration is not detected 1: End of the calibration is detected	R
b31 to b3	—	Reserved	These bits are read as 0.	R

The ADCALENDSR register indicates the end of the calibration operation for the A/D converter unit 0, unit 1 or unit 2. Each flag can be cleared in ADCALENDSCR register.

60.2.96 A/D Converter Calibration End Status Clear Register (ADCALENDSCR)

Address(es): ADC_B.ADCALENDSCR 8743 8C9Ch, ADC_B_NS.ADCALENDSCR 0743 8C9Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	CALENDC2	CALENDC1	CALENDC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CALENDC0	A/D Converter Unit 0 Calibration End Flag Clear	0: No effect 1: ADCALENDSR.CALENDF0 is cleared	W
b1	CALENDC1	A/D Converter Unit 1 Calibration End Flag Clear	0: No effect 1: ADCALENDSR.CALENDF1 is cleared	W
b2	CALENDC2	A/D Converter Unit 2 Calibration End Flag Clear	0: No effect 1: ADCALENDSR.CALENDF2 is cleared	W
b31 to b3	—	Reserved	The write value should be 0.	W

The ADCALENDSCR register clears the calibration end flag for the A/D converter unit 0, unit 1 or unit 2.

60.2.97 A/D Conversion Overflow Error Status Register (ADOVFERSR)

Address(es): ADC_B.ADOVFERSR 8743 8CA0h, ADC_B_NS.ADOVFERSR 0743 8CA0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	—	—	—	—	—	—	—	ADOVFEF2	ADOVFEF1	ADOVFEF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADOVFEF0	A/D Converter Unit 0 (ADC0) Overflow Error Flag	0: ADC0 overflow error is not detected 1: ADC0 overflow error is detected	R
b1	ADOVFEF1	A/D Converter Unit 1 (ADC1) Overflow Error Flag	0: ADC1 overflow error is not detected 1: ADC1 overflow error is detected	R
b2	ADOVFEF2	A/D Converter Unit 2 (ADC2) Overflow Error Flag	0: ADC2 overflow error is not detected 1: ADC2 overflow error is detected	R
b31 to b3	—	Reserved	These bits are read as 0.	R

The ADOVFERSR register indicates whether the overflow error has occurred in an A/D conversion using A/D converter unit 0, unit 1 or unit 2. Each flag can be cleared in ADOVFERSCR register.

60.2.98 A/D Conversion Overflow Channel Status Register 0 (ADOVFCHSR0)

Address(es): ADC_B.ADOVFCHSR0 8743 8CA4h, ADC_B_NS.ADOVFCHSR0 0743 8CA4h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ADOVFEC0	A/D Converter Unit 0 Overflow Error Flag Clear	0: No effect 1: ADOVFERSR.ADOVFEF0 is cleared	W
b1	ADOVFEC1	A/D Converter Unit 1 Overflow Error Flag Clear	0: No effect 1: ADOVFERSR.ADOVFEF1 is cleared	W
b2	ADOVFEC2	A/D Converter Unit 2 Overflow Error Flag Clear	0: No effect 1: ADOVFERSR.ADOVFEF2 is cleared	W
b31 to b3	—	Reserved	The write value should be 0.	W

The ADOVFERSCR register clears the overflow error flag for the A/D converter unit 0, unit 1 or unit 2.

60.2.102 A/D Conversion Overflow Channel Status Clear Register 0 (ADOVFCHSCR0)

Address(es): ADC_B.ADOVFCHSCR0 8743 8CB8h, ADC_B_NS.ADOVFCHSCR0 0743 8CB8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	OVFCHC0 to OVFCHC31	Analog Channel n: Overflow Flag Clear	The suffix number of each bit symbol corresponds to the analog channel number n. 0: No effect 1: ADOVFCHSR0.OVFCHFn is cleared	W

n = 0 to 31

The ADOVFCHSCR0 register clears the overflow flag for the analog channel n.

60.2.103 A/D Conversion Overflow Channel Status Clear Register 1 (ADOVFCHSCR1)

Address(es): ADC_B.ADOVFCHSCR1 8743 8CBCh, ADC_B_NS.ADOVFCHSCR1 0743 8CBCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	OVFCHC32 to OVFCHC35	Analog Channel n: Overflow Flag Clear	The suffix number of each bit symbol corresponds to the analog channel number n. 0: No effect 1: ADOVFCHSR1.OVFCHFn is cleared	W
b31 to b4	—	Reserved	The write value should be 0.	W

n = 32 to 35

The ADOVFCHSCR1 register clears the overflow flag for the analog channel n.

60.2.104 Extended Analog A/D Conversion Overflow Status Clear Register (ADOVFEXSCR)

Address(es): ADC_B.ADOVFEXSCR 8743 8CC4h, ADC_B_NS.ADOVFEXSCR 0743 8CC4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	OVFEXC18	OVFEXC17	OVFEXC16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	OVFEXC9	OVFEXC8	—	OVFEXC6	OVFEXC5	OVFEXC4	—	OVFEXC2	OVFEXC1	OVFEXC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OVFEXC0	ADC0 Self-diagnosis Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF0 is cleared	W
b1	OVFEXC1	ADC1 Self-diagnosis Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF1 is cleared	W
b2	OVFEXC2	ADC2 Self-diagnosis Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF2 is cleared	W
b3	—	Reserved	The write value should be 0.	W
b4	OVFEXC4	Temperature Sensor Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF4 is cleared	W
b5	OVFEXC5	Internal Reference Voltage Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF5 is cleared	W
b6	OVFEXC6	VBATT 1/6 Voltage Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF6 is cleared	W
b7	—	Reserved	The write value should be 0.	W
b8	OVFEXC8	D/A Converter 0 Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF8 is cleared	W
b9	OVFEXC9	D/A Converter 1 Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF9 is cleared	W
b15 to b10	—	Reserved	The write value should be 0.	W
b16	OVFEXC16	Channel-Dedicated Sample-and-Hold Circuit Unit 0 Self-Diagnosis Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF16 is cleared	W
b17	OVFEXC17	Channel-Dedicated Sample-and-Hold Circuit Unit 1 Self-Diagnosis Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF17 is cleared	W
b18	OVFEXC18	Channel-Dedicated Sample-and-Hold Circuit Unit 2 Self-Diagnosis Channel: Overflow Flag Clear	0: No effect 1: ADOVFEXSR.OVFEXF18 is cleared	W
b31 to b19	—	Reserved	The write value should be 0.	W

The ADOVFEXSCR register clears the overflow flag for the extended analog function channels.

60.2.105 FIFO Control Register (ADFIFOCR)

Address(es): ADC_B.ADFIFOCR 8743 84C0h, ADC_B_NS.ADFIFOCR 0743 84C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	FIFOCE11	FIFOCE10	FIFOCE9	FIFOCE8	FIFOCE7	FIFOCE6	FIFOCE5	FIFOCE4	FIFOCE3	FIFOCE2	FIFOCE1	FIFOCE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	FIFOEN11	FIFOEN10	FIFOEN9	FIFOEN8	FIFOEN7	FIFOEN6	FIFOEN5	FIFOEN4	FIFOEN3	FIFOEN2	FIFOEN1	FIFOEN0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	FIFOEN0 to FIFOEN11	Scan Group n FIFO Enable	The suffix number of each bit symbol corresponds to the scan group number n. 0: Disable scan group n FIFO function 1: Enable scan group n FIFO function	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27 to b16	FIFOCE0 to FIFOCE11	Scan Group n FIFO Clear Enable at Scan Start/Resume	The suffix number of each bit symbol corresponds to the scan group number n. 0: Disable scan group n FIFO clear function 1: Enable scan group n FIFO clear function	R/W
b31 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

n = 0 to 11

The ADFIFOCR register enables/disables the FIFO function of scan group n.

FIFOENn Bit (Scan Group n FIFO Enable) (n = 0 to 11)

The FIFOENn bit enables or disables the FIFO function of scan group n. When the FIFOENn bit is set to 1, the FIFO function of scan group n is enabled, and the result of A/D conversion is stored to the FIFO. When the FIFOENn bit is set to 0, the FIFO function of scan group n is disabled.
The A/D conversion result can also be read from the A/D data or extended data registers.

FIFOCEn Bit (Scan Group n FIFO Clear Enable at Scan Start/Resume) (n = 0 to 11)

The FIFOCEn bit controls whether the scan group n FIFO clear function is enabled or disabled. When the FIFOCEn bit is set to 1, FIFO clear for scan group n is enabled and the FIFO is cleared when the scan group n scan starts/resumes. When the FIFOCEn bit is set to 0, FIFO clear for scan group n is disabled.

60.2.106 FIFO Interrupt Control Register (ADFIFOINTCR)

Address(es): ADC_B.ADFIFOINTCR 8743 84C4h, ADC_B_NS.ADFIFOINTCR 0743 84C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	FIFOIE11	FIFOIE10	FIFOIE9	FIFOIE8	FIFOIE7	FIFOIE6	FIFOIE5	FIFOIE4	FIFOIE3	FIFOIE2	FIFOIE1	FIFOIE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	FIFOIE0 to FIFOIE11	Scan Group n FIFO Interrupt Enable	The suffix number of each bit symbol corresponds to the scan group number n. 0: Disable scan group n FIFO interrupt 1: Enable scan group n FIFO interrupt	R/W
b31 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

n = 0 to 11

The ADFIFOINTCR register enables/disables the FIFO data read request interrupt and FIFO overflow interrupt for scan group n.

60.2.107 FIFO Interrupt Generation Level Register 0 (ADFIFOINTLR0)

Address(es): ADC_B.ADFIFOINTLR0 8743 84C8h, ADC_B_NS.ADFIFOINTLR0 0743 84C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	FIFOILV1[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOILV0[4:0]	Scan Group 0 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	FIFOILV1[4:0]	Scan Group 1 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADFIFOINTLR0 register specifies the generation timing of the FIFO data read request interrupt for the scan group 0 and 1.

60.2.108 FIFO Interrupt Generation Level Register 1 (ADFIFOINTLR1)

Address(es): ADC_B.ADFIFOINTLR1 8743 84CCh, ADC_B_NS.ADFIFOINTLR1 0743 84CCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	FIFOILV3[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	FIFOILV2[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOILV2[4:0]	Scan Group 2 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	FIFOILV3[4:0]	Scan Group 3 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADFIFOINTLR1 register specifies the generation timing of the FIFO data read request interrupt for the scan group 2 and 3.

60.2.109 FIFO Interrupt Generation Level Register 2 (ADFIFOINTLR2)

Address(es): ADC_B.ADFIFOINTLR2 8743 84D0h, ADC_B_NS.ADFIFOINTLR2 0743 84D0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOILV4[4:0]	Scan Group 4 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	FIFOILV5[4:0]	Scan Group 5 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADFIFOINTLR2 register specifies the generation timing of the FIFO data read request interrupt for the scan group 4 and 5.

60.2.110 FIFO Interrupt Generation Level Register 3 (ADFIFOINTLR3)

Address(es): ADC_B.ADFIFOINTLR3 8743 84D4h, ADC_B_NS.ADFIFOINTLR3 0743 84D4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	FIFOILV7[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOILV6[4:0]	Scan Group 6 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	FIFOILV7[4:0]	Scan Group 7 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADFIFOINTLR3 register specifies the generation timing of the FIFO data read request interrupt for the scan group 6 and 7.

60.2.111 FIFO Interrupt Generation Level Register 4 (ADFIFOINTLR4)

Address(es): ADC_B.ADFIFOINTLR4 8743 84D8h, ADC_B_NS.ADFIFOINTLR4 0743 84D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	FIFOILV9[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	FIFOILV8[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOILV8[4:0]	Scan Group 8 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	FIFOILV9[4:0]	Scan Group 9 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADFIFOINTLR4 register specifies the generation timing of the FIFO data read request interrupt for the scan group 8 and 9.

60.2.112 FIFO Interrupt Generation Level Register 5 (ADFIFOINTLR5)

Address(es): ADC_B.ADFIFOINTLR5 8743 84DCh, ADC_B_NS.ADFIFOINTLR5 0743 84DCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOILV10[4:0]	Scan Group 10 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b15 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20 to b16	FIFOILV11[4:0]	Scan Group 11 FIFO Interrupt Output Timing Setting	These bits set the generation timing of FIFO interrupt. The FIFO data read request interrupt is generated when the number of vacant stages in FIFO becomes less than or equal to the value set by these bits. Set a value in the range from 0 to 15.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADFIFOINTLR5 register specifies the generation timing of the FIFO data read request interrupt for the scan group 10 and 11.

60.2.113 FIFO Status Register 0 (ADFIFOSR0)

Address(es): ADC_B.ADFIFOSR0 8743 8CD0h, ADC_B_NS.ADFIFOSR0 0743 8CD0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	FIFOST1[4:0]

	—	—	—	—	—	—	—	—	—	—	—	FIFOST0[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOST0[4:0]	Number of Vacant Stages in FIFO for Scan Group 0		R
b15 to b5	—	Reserved	These bits are read as 0.	R
b20 to b16	FIFOST1[4:0]	Number of Vacant Stages in FIFO for Scan Group 1		R
b31 to b21	—	Reserved	These bits are read as 0.	R

The ADFIFOSR0 register indicates the number of vacant stages in FIFO for scan group 0 and 1.

60.2.114 FIFO Status Register 1 (ADFIFOSR1)

Address(es): ADC_B.ADFIFOSR1 8743 8CD4h, ADC_B_NS.ADFIFOSR1 0743 8CD4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	FIFOST3[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	FIFOST2[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOST2[4:0]	Number of Vacant Stages in FIFO for Scan Group 2		R
b15 to b5	—	Reserved	These bits are read as 0.	R
b20 to b16	FIFOST3[4:0]	Number of Vacant Stages in FIFO for Scan Group 3		R
b31 to b21	—	Reserved	These bits are read as 0.	R

The ADFIFOSR1 register indicates the number of vacant stages in FIFO for scan group 2 and 3.

60.2.115 FIFO Status Register 2 (ADFIFOSR2)

Address(es): ADC_B.ADFIFOSR2 8743 8CD8h, ADC_B_NS.ADFIFOSR2 0743 8CD8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	FIFOST5[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	FIFOST4[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOST4[4:0]	Number of Vacant Stages in FIFO for Scan Group 4		R
b15 to b5	—	Reserved	These bits are read as 0.	R
b20 to b16	FIFOST5[4:0]	Number of Vacant Stages in FIFO for Scan Group 5		R
b31 to b21	—	Reserved	These bits are read as 0.	R

The ADFIFOSR2 register indicates the number of vacant stages in FIFO for scan group 4 and 5.

60.2.116 FIFO Status Register 3 (ADFIFOSR3)

Address(es): ADC_B.ADFIFOSR3 8743 8CDCh, ADC_B_NS.ADFIFOSR3 0743 8CDCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	FIFOST7[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	FIFOST6[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOST6[4:0]	Number of Vacant Stages in FIFO for Scan Group 6		R
b15 to b5	—	Reserved	These bits are read as 0.	R
b20 to b16	FIFOST7[4:0]	Number of Vacant Stages in FIFO for Scan Group 7		R
b31 to b21	—	Reserved	These bits are read as 0.	R

The ADFIFOSR3 register indicates the number of vacant stages in FIFO for scan group 6 and 7.

60.2.117 FIFO Status Register 4 (ADFIFOSR4)

Address(es): ADC_B.ADFIFOSR4 8743 8CE0h, ADC_B_NS.ADFIFOSR4 0743 8CE0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	FIFOST9[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	FIFOST8[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOST8[4:0]	Number of Vacant Stages in FIFO for Scan Group 8		R
b15 to b5	—	Reserved	These bits are read as 0.	R
b20 to b16	FIFOST9[4:0]	Number of Vacant Stages in FIFO for Scan Group 9		R
b31 to b21	—	Reserved	These bits are read as 0.	R

The ADFIFOSR4 register indicates the number of vacant stages in FIFO for scan group 8 and 9.

60.2.118 FIFO Status Register 5 (ADFIFOSR5)

Address(es): ADC_B.ADFIFOSR5 8743 8CE4h, ADC_B_NS.ADFIFOSR5 0743 8CE4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	FIFOST11[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	FIFOST10[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	FIFOST10[4:0]	Number of Vacant Stages in FIFO for Scan Group 10		R
b15 to b5	—	Reserved	These bits are read as 0.	R
b20 to b16	FIFOST11[4:0]	Number of Vacant Stages in FIFO for Scan Group 11		R
b31 to b21	—	Reserved	These bits are read as 0.	R

The ADFIFOSR5 register indicates the number of vacant stages in FIFO for scan group 10 and 11.

60.2.119 FIFO Data Clear Register (ADFIFODCR)

Address(es): ADC_B.ADFIFODCR 8743 8CF0h, ADC_B_NS.ADFIFODCR 0743 8CF0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	FIFODC11	FIFODC10	FIFODC9	FIFODC8	FIFODC7	FIFODC6	FIFODC5	FIFODC4	FIFODC3	FIFODC2	FIFODC1	FIFODC0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	FIFODC0 to FIFODC11	Scan Group n FIFO Data Clear	The suffix number of each bit symbol corresponds to the scan group number n. 0: No effect 1: Clear the data of scan group n FIFO	W
b31 to b12	—	Reserved	The write value should be 0.	W

n = 0 to 11

The ADFIFODCR register clears the data in FIFO for each scan group.

FIFODCn Bit (Scan Group n FIFO Data Clear) (n = 0 to 11)

The FIFODCn bit clears the data in FIFO for scan group n. Writing 1 to the FIFODCn clears the data in the FIFO of scan group n. Writing 0 has no effect on the operation, and the data in FIFO is not cleared

60.2.120 FIFO Error Status Register (ADFIFOERSR)

Address(es): ADC_B.ADFIFOERSR 8743 8CF4h, ADC_B_NS.ADFIFOERSR 0743 8CF4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	FIFOFLF11	FIFOFLF10	FIFOFLF9	FIFOFLF8	FIFOFLF7	FIFOFLF6	FIFOFLF5	FIFOFLF4	FIFOFLF3	FIFOFLF2	FIFOFLF1	FIFOFLF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	FIFOOVF11	FIFOOVF10	FIFOOVF9	FIFOOVF8	FIFOOVF7	FIFOOVF6	FIFOOVF5	FIFOOVF4	FIFOOVF3	FIFOOVF2	FIFOOVF1	FIFOOVF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	FIFOOVF0 to FIFOOVF11	Scan Group n FIFO Overflow Flag	The suffix number of each bit symbol corresponds to the scan group number n. 0: No overflow 1: FIFO overflow is detected	R
b15 to b12	—	Reserved	These bits are read as 0.	R
b27 to b16	FIFOFLF0 to FIFOFLF11	Scan Group n FIFO Data Read Request Flag	The suffix number of each bit symbol corresponds to the scan group number n. 0: FIFO Data Read Request is not detected. 1: FIFO Data Read Request is detected.	R
b31 to b28	—	Reserved	These bits are read as 0.	R

n = 0 to 11

The ADFIFOERSR register indicates the status of the FIFO. Each flag can be cleared in ADFIFOERSCR.

FIFOOVFn Bit (Scan Group n FIFO Overflow Flag) (n = 0 to 11)

The FIFOOVFn bit indicates whether the overflow occurred in the FIFO of the scan group n.
When FIFOOVFn = 0, an overflow is not detected in the FIFO. When FIFOOVFn = 1, an overflow occurred in the FIFO and the A/D conversion result cannot be stored to the FIFO. FIFOOVFn can be cleared in ADFIFOERSCR.

FIFOFLFn Bit (Scan Group n FIFO Data Read Request Flag) (n = 0 to 11)

The FIFOFLFn bit indicates whether a FIFO data read request in scan group n has been detected. The setting and clearing conditions of FIFOFLFn are shown as follows:
[Setting condition]

- When the condition of ADFIFOSRm.FIFOSTn[4:0] ≤ ADFIFOINTLRm.FIFOILVn[4:0] is detected.

[Clearing condition]

- When ADFIFOERSCR.FIFOFLCn is written to 1 under the condition of ADFIFOSRm.FIFOSTn[4:0] > ADFIFOINTLRm.FIFOILVn[4:0].
- When the condition of ADFIFOSRm.FIFOSTn[4:0] > ADFIFOINTLRm.FIFOILVn[4:0] is occurred by the read access to ADFIFODRn register with DMAC or DTC.

Note: m = 0 to 5, n = 0 to 11

60.2.121 FIFO Error Status Clear Register (ADFIFOERSCR)

Address(es): ADC_B.ADFIFOERSCR 8743 8CF8h, ADC_B_NS.ADFIFOERSCR 0743 8CF8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	FIFOOVFC0 to FIFOOVFC11	Scan Group n FIFO Overflow Flag Clear	The suffix number of each bit symbol corresponds to the scan group number n. 0: No effect 1: ADFIFOERSR.FIFOOVFn is cleared	W
b15 to b12	—	Reserved	The write value should be 0.	W
b27 to b16	FIFOFLC0 to FIFOFLC11	Scan Group n FIFO Data Read Request Flag Clear	The suffix number of each bit symbol corresponds to the scan group number n. 0: No effect 1: ADFIFOERSR.FIFOFLFn is cleared	W
b31 to b28	—	Reserved	The write value should be 0.	W

n = 0 to 11

ADFIFOERSCR clears the FIFO overflow flags and the FIFO data read request flags for scan group n.

60.2.122 A/D Data Register n (ADDRn) (n = 0 to 35)

Address(es): ADC_B.ADDR0 8743 A000h, ADC_B.ADDR1 8743 A004h, ADC_B.ADDR2 8743 A008h, ADC_B.ADDR3 8743 A00Ch, ADC_B.ADDR4 8743 A010h, ADC_B.ADDR5 8743 A014h, ADC_B.ADDR6 8743 A018h, ADC_B.ADDR7 8743 A01Ch, ADC_B.ADDR8 8743 A020h, ADC_B.ADDR9 8743 A024h, ADC_B.ADDR10 8743 A028h, ADC_B.ADDR11 8743 A02Ch, ADC_B.ADDR12 8743 A030h, ADC_B.ADDR13 8743 A034h, ADC_B.ADDR14 8743 A038h, ADC_B.ADDR15 8743 A03Ch, ADC_B.ADDR16 8743 A040h, ADC_B.ADDR17 8743 A044h, ADC_B.ADDR18 8743 A048h, ADC_B.ADDR19 8743 A04Ch, ADC_B.ADDR20 8743 A050h, ADC_B.ADDR21 8743 A054h, ADC_B.ADDR22 8743 A058h, ADC_B.ADDR23 8743 A05Ch, ADC_B.ADDR24 8743 A060h, ADC_B.ADDR25 8743 A064h, ADC_B.ADDR26 8743 A068h, ADC_B.ADDR27 8743 A06Ch, ADC_B.ADDR28 8743 A070h, ADC_B.ADDR29 8743 A074h, ADC_B.ADDR30 8743 A078h, ADC_B.ADDR31 8743 A07Ch, ADC_B.ADDR32 8743 A080h, ADC_B.ADDR33 8743 A084h, ADC_B.ADDR34 8743 A088h, ADC_B.ADDR35 8743 A08Ch, ADC_B_NS.ADDR0 0743 A000h, ADC_B_NS.ADDR1 0743 A004h, ADC_B_NS.ADDR2 0743 A008h, ADC_B_NS.ADDR3 0743 A00Ch, ADC_B_NS.ADDR4 0743 A010h, ADC_B_NS.ADDR5 0743 A014h, ADC_B_NS.ADDR6 0743 A018h, ADC_B_NS.ADDR7 0743 A01Ch, ADC_B_NS.ADDR8 0743 A020h, ADC_B_NS.ADDR9 0743 A024h, ADC_B_NS.ADDR10 0743 A028h, ADC_B_NS.ADDR11 0743 A02Ch, ADC_B_NS.ADDR12 0743 A030h, ADC_B_NS.ADDR13 0743 A034h, ADC_B_NS.ADDR14 0743 A038h, ADC_B_NS.ADDR15 0743 A03Ch, ADC_B_NS.ADDR16 0743 A040h, ADC_B_NS.ADDR17 0743 A044h, ADC_B_NS.ADDR18 0743 A048h, ADC_B_NS.ADDR19 0743 A04Ch, ADC_B_NS.ADDR20 0743 A050h, ADC_B_NS.ADDR21 0743 A054h, ADC_B_NS.ADDR22 0743 A058h, ADC_B_NS.ADDR23 0743 A05Ch, ADC_B_NS.ADDR24 0743 A060h, ADC_B_NS.ADDR25 0743 A064h, ADC_B_NS.ADDR26 0743 A068h, ADC_B_NS.ADDR27 0743 A06Ch, ADC_B_NS.ADDR28 0743 A070h, ADC_B_NS.ADDR29 0743 A074h, ADC_B_NS.ADDR30 0743 A078h, ADC_B_NS.ADDR31 0743 A07Ch, ADC_B_NS.ADDR32 0743 A080h, ADC_B_NS.ADDR33 0743 A084h, ADC_B_NS.ADDR34 0743 A088h, ADC_B_NS.ADDR35 0743 A08Ch

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DATA[15:0]	A/D Conversion Data		R
b30 to b16	—	Reserved	These bits are read as 0.	R
b31	ERR	A/D Conversion Data Error Status	0: No error (the A/D conversion data is valid) 1: Error is detected (the A/D conversion data is not guaranteed)	R

The ADDRn registers are read-only registers to read A/D conversion results.

DATA[15:0] Bits (A/D Conversion Data)

The DATA[15:0] bits indicate the data of the A/D conversion result for the analog input channel n.

The data format of the A/D conversion results is determined by the setting of the virtual channel m (m = 0 to 49) to which the analog input channel n is assigned.

ERR Bit (A/D Conversion Data Error Status)

The ERR bit indicates the error status in the A/D conversion for the analog input channel n.

When ERR = 0, the A/D conversion data is valid. When ERR = 1, the A/D conversion data is invalid, and the accuracy of the A/D conversion data is not guaranteed.

60.2.123 A/D Extended Analog Data Register n (ADEXDRn) (n = 0 to 2, 4 to 6, 8, 9, 16 to 18)

Address(es): ADC_B.ADEXDR0 8743 A180h, ADC_B.ADEXDR1 8743 A184h, ADC_B.ADEXDR2 8743 A188h, ADC_B.ADEXDR4 8743 A190h, ADC_B.ADEXDR5 8743 A194h, ADC_B.ADEXDR6 8743 A198h, ADC_B.ADEXDR8 8743 A1A0h, ADC_B.ADEXDR9 8743 A1A4h, ADC_B.ADEXDR16 8743 A1C0h, ADC_B.ADEXDR17 8743 A1C4h, ADC_B.ADEXDR18 8743 A1C8h, ADC_B_NS.ADEXDR0 0743 A180h, ADC_B_NS.ADEXDR1 0743 A184h, ADC_B_NS.ADEXDR2 0743 A188h, ADC_B_NS.ADEXDR4 0743 A190h, ADC_B_NS.ADEXDR5 0743 A194h, ADC_B_NS.ADEXDR6 0743 A198h, ADC_B_NS.ADEXDR8 0743 A1A0h, ADC_B_NS.ADEXDR9 0743 A1A4h, ADC_B_NS.ADEXDR16 0743 A1C0h, ADC_B_NS.ADEXDR17 0743 A1C4h, ADC_B_NS.ADEXDR18 0743 A1C8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ERR	—	—	—	—	DIAGSR[2:0]			—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DATA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DATA[15:0]	A/D Conversion Data		R
b23 to b16	—	Reserved	These bits are read as 0.	R
b26 to b24	DIAGSR[2:0]	Self-Diagnosis Status*1		R
b30 to b27	—	Reserved	These bits are read as 0.	R
b31	ERR	A/D Conversion Error Status	0: No error (the A/D conversion data is valid) 1: Error is detected (the A/D conversion data is not guaranteed)	R

Note 1. Only the ADEXDR0-2, ADEXDR16-18 register has the DIAGSR[2:0] bits. The DIAGSR[2:0] bits in the ADEXDRn register except for the ADEXDR0-2, ADEXDR16-18 register are reserved bits.

The ADEXDRn registers are read-only registers to read A/D conversion results of the extended analog function. The ADEXDRn registers and the extended analog functions are as follows:

- ADEXDR0: ADC0 self-diagnosis
- ADEXDR1: ADC1 self-diagnosis
- ADEXDR2: ADC2 self-diagnosis
- ADEXDR4: Temperature sensor
- ADEXDR5: Internal reference voltage
- ADEXDR6: VBATT 1/6 voltage
- ADEXDR8: D/A converter channel 0 output
- ADEXDR9: D/A converter channel 1 output
- ADEXDR16: Channel-dedicated sample-and-hold circuit unit 0 self-diagnosis channel
- ADEXDR17: Channel-dedicated sample-and-hold circuit unit 1 self-diagnosis channel
- ADEXDR18: Channel-dedicated sample-and-hold circuit unit 2 self-diagnosis channel

DATA[15:0] Bits (A/D Conversion Data)

The DATA[15:0] bits indicate the data of the A/D conversion result for the extended analog function channel. The data format of the A/D conversion results is determined by the setting of the virtual channel m (m = 0 to 49) to which the extended analog function channel is assigned.

DIAGSR[2:0] Bits (Self-Diagnosis Status)

The DIAGSR[2:0] bits indicate the voltage setting of the self-diagnosis channel. The DIAGSR[2:0] bits in the

ADEXDR0, ADEXDR1, and ADEXDR2 registers indicate the setting of the ADSGDCRm.DIAGVAL[2:0] bits (m = 0 to 11). The DIAGSR[2:0] bits in the ADEXDR16, ADEXDR17, and ADEXDR18 registers indicate the setting of the ADSHSDCRm.SHDIAGn[2:0] bits (m = 0, 1; n = 0 to 11) of the scan group to which the channel-dedicated sample-and-hold circuit is assigned.
The DIAGSR[2:0] bits are available in the ADEXDR0, ADEXDR1, ADEXDR2, ADEXDR16, ADEXDR17 and ADEXDR18 registers. The DIAGSR[2:0] bits in ADEXDRn except above are reserved.

ERR Bit (A/D Conversion Error Status)

The ERR bit indicates the error status in the A/D conversion for the extended analog functions.
When ERR = 0, the A/D conversion data is valid. When ERR = 1, the A/D conversion data is invalid, and the accuracy of the A/D conversion data is not guaranteed.

60.2.124 FIFO Data Register n (ADFIFODRn) (n = 0 to 11)

Address(es): ADC_B.ADFIFODR0 8743 A200h, ADC_B.ADFIFODR1 8743 A204h, ADC_B.ADFIFODR2 8743 A208h, ADC_B.ADFIFODR3 8743 A20Ch, ADC_B.ADFIFODR4 8743 A210h, ADC_B.ADFIFODR5 8743 A214h, ADC_B.ADFIFODR6 8743 A218h, ADC_B.ADFIFODR7 8743 A21Ch, ADC_B.ADFIFODR8 8743 A220h, ADC_B.ADFIFODR9 8743 A224h, ADC_B.ADFIFODR10 8743 A228h, ADC_B.ADFIFODR11 8743 A22Ch, ADC_B_NS.ADFIFODR0 0743 A200h, ADC_B_NS.ADFIFODR1 0743 A204h, ADC_B_NS.ADFIFODR2 0743 A208h, ADC_B_NS.ADFIFODR3 0743 A20Ch, ADC_B_NS.ADFIFODR4 0743 A210h, ADC_B_NS.ADFIFODR5 0743 A214h, ADC_B_NS.ADFIFODR6 0743 A218h, ADC_B_NS.ADFIFODR7 0743 A21Ch, ADC_B_NS.ADFIFODR8 0743 A220h, ADC_B_NS.ADFIFODR9 0743 A224h, ADC_B_NS.ADFIFODR10 0743 A228h, ADC_B_NS.ADFIFODR11 0743 A22Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ERR	CH[6:0]							—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DATA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DATA[15:0]	A/D Conversion Data		R
b23 to b16	—	Reserved	These bits are read as 0.	R
b30 to b24	CH[6:0]	A/D Conversion Channel Number		R
b31	ERR	A/D Conversion Data Error Status	0: No error (the A/D conversion data is valid) 1: Error is detected (the A/D conversion data is not guaranteed)	R

The ADFIFODRn register is used to read data stored in the FIFO of scan group n.

DATA[15:0] Bits (A/D Conversion Data)

The DATA[15:0] bits are read-only bits that read the A/D conversion data stored in the scan group n FIFO.

CH[6:0] Bits (A/D Conversion Channel Number)

The CH[6:0] bits indicate the channel number of the A/D conversion data that is read from the DATA[15:0] bits.

ERR Bit (A/D Conversion Data Error Status)

The ERR bit indicates the error status in the A/D conversion data of the analog channel indicated by the CH[6:0] bits. When ERR = 0, the A/D conversion data is valid. When ERR = 1, the A/D conversion data is invalid, and the accuracy of the A/D conversion data is not guaranteed.

60.3 Operation

60.3.1 A/D Conversion Clock

A/D conversion clock (ADCLK) is the operation clock of ADC. The A/D converters (ADC0, ADC1, and ADC2) are operated and controlled by ADCLK as the basic clock. Figure 60.5 shows clock structure of ADC.
ADCLK is generated from the clock source and the division ratio selected in ADCLKCR register. The frequency of ADCLK should be set so that PCLKA ≥ ADCLK. Also, the frequency of ADCLK should be set so that it is within the guaranteed operating range specified in the electrical characteristics. For details, see section 67, Electrical Characteristics.

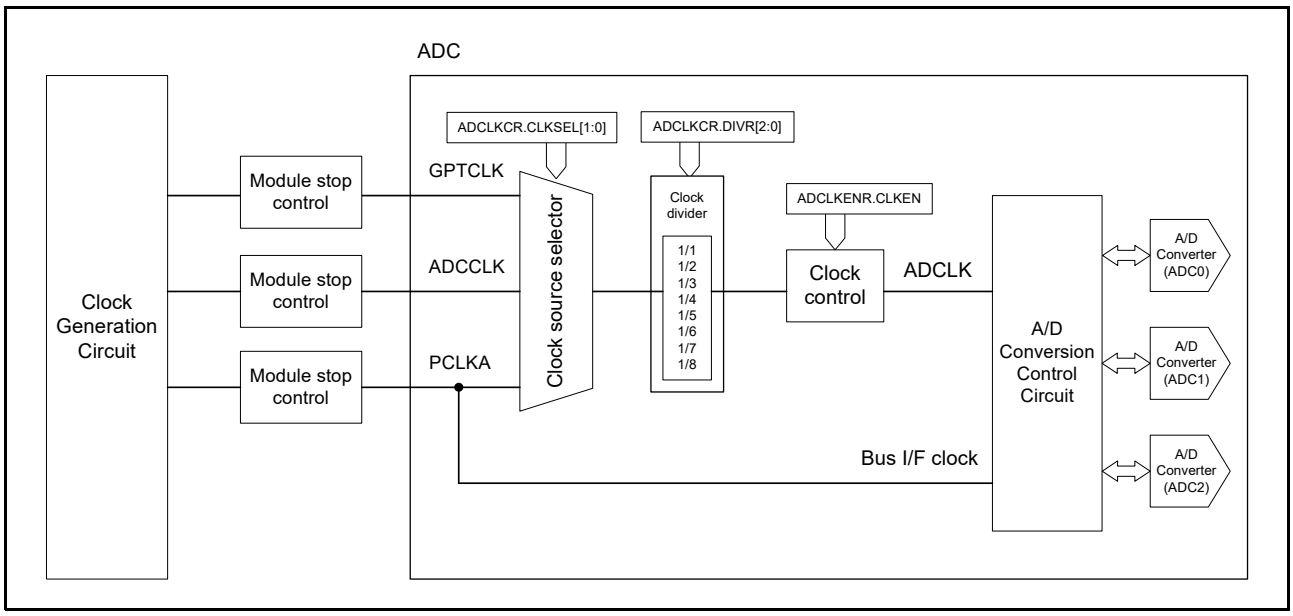

Figure 60.5 Clock Structure

60.3.2 A/D Converter Operation Mode

60.3.2.1 SAR Mode

In SAR mode, A/D converter operates as a nyquist type A/D converter. Analog channels are sampled one time and converted analog to digital by successive approximation register (SAR) method. The features of SAR mode are shown in the following:
[Features of SAR mode]

- Fast conversion: A/D conversion data can be acquired with the shortest group delay.
- A/D conversion of up to 8 analog channels (virtual channels) is possible per scan group.
- Single-ended input and differential input supported (digital filter functions not supported)

For details about operation of A/D conversion in SAR mode, see section 60.3.7, Scan Mode. For restrictions on SAR mode, see section 60.10.14, Restrictions on SAR Mode.

60.3.2.2 Oversampling Mode

In oversampling mode, A/D converter operates as oversampling-type A/D converter. Analog channels are oversampled and converted analog to digital by noise shaping successive approximation register method (NS-SAR). The features of oversampling mode are shown in the following:
[Features of oversampling mode]

- High accuracy conversion: A/D conversion data can be acquired with noise shaping technology and digital filter function.*1
- A/D conversion of up to 8 analog channels (virtual channels) is possible per scan group.
- Both of single-ended input and differential input are supported.

Note 1. Digital filter function must be used in oversampling mode. It is prohibited to operate without digital filter function in oversampling mode.

For details about operation of A/D conversion in oversampling mode, see section 60.3.7, Scan Mode. For restrictions on oversampling mode, see section 60.10.15, Restrictions on Oversampling Mode.

60.3.2.3 Hybrid Mode

Hybrid mode has both features of SAR mode and oversampling mode. In hybrid mode, A/D converter operates as oversampling-type A/D converter. Analog channels are oversampled and converted analog to digital by noise shaping successive approximation register (NS-SAR) method. In the hybrid mode, while switching channels for each sampling, multiple analog channels are oversampled. The features of hybrid mode are shown in the following:

[Features of hybrid mode]

- High accuracy conversion: A/D conversion data can be acquired with noise shaping technology and digital filter function.*1
- Fast conversion: A/D conversion data can be acquired with the shortest group delay when in the continuous scan mode and after initial delay time.
- A/D conversion of up to 4 analog channels (virtual channels) is possible per scan group.
- Both of single-ended input and differential input are supported.

Note 1. Digital filter function must be used in hybrid mode. It is prohibited to operate without digital filter function in hybrid mode.

For details about operation of A/D conversion in hybrid mode, see section 60.3.7, Scan Mode. For restrictions on hybrid mode, see section 60.10.16, Restrictions on Hybrid Mode.

60.3.3 Single-Ended Input and Differential Input

ADC supports single-ended input and differential input. The selection of single-ended input or differential input is specified in ADCHCRn.AINMD (n = 0 to 49) bit. For the analog channels that support differential input, see Table 60.4 and Table 60.5.

Single-ended Input

In single-ended input mode, the difference between the voltage of the analog channel (signal source) and the analog reference ground voltage (VREFL0) is A/D-converted.

Differential Input

In differential input mode, the even-numbered analog channel is used as the non-inverting input (+) (AINP) and the odd-numbered analog channel is used as the inverting input (−) (AINN), then the difference voltage between the non-inverting input (+) and the inverting input (−) (AINP − AINN) is A/D-converted.*1

For A/D conversion with differential input mode, select the non-inverting input (+) channel*2 of the target of differential pair in ADCHCRn.CNVCS[6:0] (n = 0 to 49) bits, and select the differential input mode in ADCHCRn.AINMD (n = 0 to 49) bit.

It is prohibited to perform A/D conversion for channels that do not support differential input with differential input mode. In that case, A/D conversion result is not guaranteed.

Note 1. The differential input pair is a combination of channels with analog channel number 2i and 2i + 1 (i = 0, 1, 2, 3, ...), and they are named ANxxxP and ANxxxN (xxx = 000, 002, 004, ...). The combination of discontinuous analog channel numbers or the combination of analog channel numbers 2i − 1 and 2i cannot be used as a

differential input pair.

Note 2. It is the even-numbered analog channel which is named as ANxxxP (xxx = 000, 002, 004, …).

60.3.4 Analog Channel

The analog channel is the source of the analog signal that is targeted for A/D conversion. The analog channels consist of the following elements:

- Analog input channels: A/D conversion channels for the analog input from MCU's I/O pin as the signal source.
- Extended analog channels: A/D conversion channels for the source of the analog signal inside the MCU.

To perform A/D conversion for the analog channels, assignments to the virtual channel and scan group are required. For each element, refer to each item.

60.3.5 Virtual Channel

The virtual channel is a group of registers that stores the A/D conversion configurations for an analog channel. The virtual channels can be specified the configurations for A/D conversion such as the selection of the analog channels, the optional settings for A/D conversion, the data processing method of the A/D conversion data, the assignment to scan groups, and so on.

To perform the A/D conversion of the analog channel, the analog channel should be assigned to any of the virtual channels. Then that virtual channel should be assigned to one of the scan groups. See Figure 60.6 for the relationship between the analog channels and the virtual channels and scan groups. Figure 60.7 shows the A/D conversion order in Figure 60.6 settings.

The virtual channel can be assigned to only one scan group. If the same analog channel is to be converted within the different scan group, or the same analog channel is to be converted several times within the same scan group, assign the analog channel to several virtual channels. When performing the A/D conversion more than once using more than one virtual channel within the same scan group for the same analog channel, the FIFO function should be used in combination.

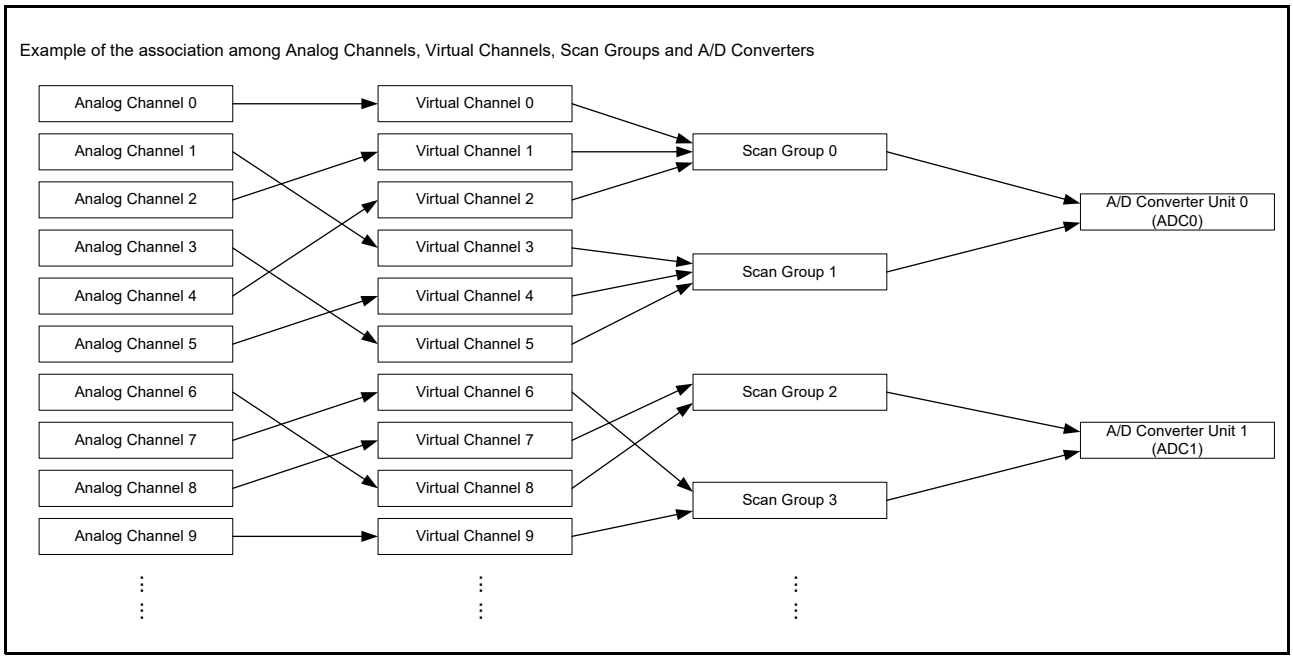

Figure 60.6 The Concept of Virtual Channel

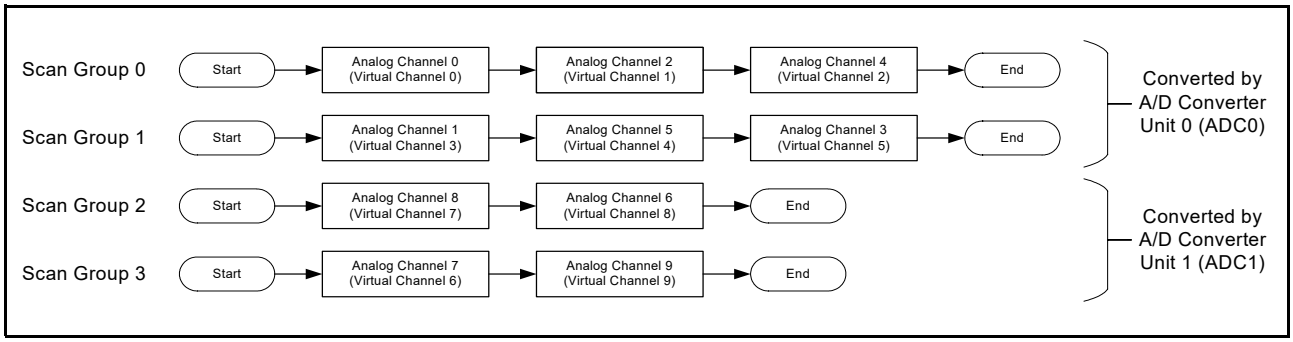

Figure 60.7 Example of A/D Conversion Order at the Scanning Operation

60.3.6 Scan Group

The scan group is a group of the analog channels that perform A/D conversion in a scanning operation. To perform the A/D conversion using the scan group, configure the following steps:

- Assign the analog channel for the A/D conversion to the virtual channel.
- Assign the virtual channel to the scan group.
- Assign the scan group to A/D converter.

See Figure 60.6 and Figure 60.7 for the relationship among the analog channels, the virtual channels, and the scan groups. A single scan group can be assigned virtual channels in the following ranges, according to its operation mode.

- SAR mode: up to 8 virtual channels per scan group
- Oversampling mode: up to 8 virtual channels per scan group
- Hybrid mode: from 2 to 4 virtual channels per scan group

If more than the maximum number of virtual channels are allocated to one scan group, A/D conversion is performed on the 8th (SAR mode or oversampling mode) or 4th (Hybrid mode) channels in ascending order of virtual channel numbers. Subsequent channels are not subject to A/D conversion.

Notes on the scan groups

The virtual channels assigned to one scan group should be assigned the analog channels that can be converted by the same A/D converter. If any analog channels cannot be converted by the specified A/D converter are included, the A/D conversion result of those channels are undefined.

In hybrid mode, you must assign at least 2 virtual channels to a scan group. Operation is not guaranteed when any virtual channel is not assigned or only 1 virtual channel is assigned.

60.3.7 Scan Mode

The scanning operation is the operation of sequential A/D conversion for the analog channels. The modes of the scanning operation are the followings:

- Single scan mode
- Continuous scan mode
- Background continuous scan mode
- Same channel continuous scan mode
- Fixed channels continuous scan mode

The scan modes supported by each operation mode are shown in Table 60.6.

Table 60.6 Scan Modes Supported by Each Operation Mode

	Operation Mode of A/D Converter		
Scan Mode	**SAR Mode**	**Oversampling Mode**	**Hybrid Mode**
Single scan mode	✓	✓	✓
Continuous scan mode	✓	✓	✓
Background continuous scan mode	—	—	✓
Same channel continuous scan mode	—	✓	—
Fixed channels continuous scan mode	—	—	✓ Only for fixed channels*1

✓: available, —: not available

Note 1. A/D conversion on non-fixed channels proceeds in SAR mode.

The scanning operations are performed on a scan group basis. When the scanning operation is started, A/D conversion is performed for each analog channel based on the virtual channel setting. If the scanning operation starts for 2 or more scan group assigned to the same A/D converter at the same time, the scanning operation of the group with the lowest scan group number is performed.

The A/D conversion order of the analog channel in the scanning operation is the ascending order of the virtual channel numbers assigned to the scan group. (The channels with the lowest virtual channel numbers are performed the A/D conversion at the forward end of the scan group. The channels with larger virtual channel numbers are performed the A/D conversion at the backward of the scan group.)

See Figure 60.6 and Figure 60.7 for the relationship of the conversion order of the respective analog channel in the scanning operation.

The scanning operations in each operation mode are shown in the following.

60.3.7.1 Single Scan Mode

- In single scan mode, one scan group is scanned once for each A/D conversion start trigger input.
- Each time an A/D conversion start trigger is input, A/D conversion is performed once for each analog channel assigned to that scan group.

60.3.7.2 Continuous Scan Mode

- The continuous scan mode repeats the scanning operation of one scan group.
- When an A/D conversion start trigger is input, A/D conversion of each analog channel assigned to that scan group is repeated until A/D conversion stop processing is performed.

60.3.7.3 Background Continuous Scan Mode

- The background continuous scan mode repeats the scanning operation of a single scanning group.
- Scanning operation starts when the first A/D conversion start trigger is input.
- A/D conversions of each analog channel assigned to that scan group are repeated until A/D conversion stop processing is performed. (Continuous scanning operation)
- When an A/D conversion start trigger is input during continuous scanning operation, the A/D conversion data at that point is output. (Unless an A/D conversion start trigger is input, the A/D conversion data are not output and the values of the A/D data registers and FIFO data registers are not updated.)

60.3.7.4 Same Channel Continuous Scan Mode

- In same channel continuous scan mode, A/D conversion on a single analog channel assigned to a desired scan group repeatedly proceeds. Changing the target channel for conversion in response to an A/D conversion start trigger stops the current A/D conversion and restarts A/D conversion for the new channel following the change.
- Scanning operation on the first analog channel assigned to a scan group starts in response to input of the first A/D conversion start trigger.
- The A/D conversion repeatedly proceeds until input of the next A/D conversion start trigger (continuous scanning operation).
- A/D conversion on the next analog channel assigned to the scan group starts in response to input of that next A/D conversion start trigger.
- The A/D conversion on the channel repeatedly proceeds until the input of a further A/D conversion start trigger. After that, the above operations are repeated in response to the input of A/D conversion start triggers.
- When an A/D conversion start trigger is input while A/D conversion on the last analog channel assigned to the scan group is repeated, A/D conversion is terminated and then restarted on the first channel in the group.
- In this mode, data outputs can be skipped so that only one result of conversion is output for every four or eight A/D conversions. See section 60.4.11, A/D Conversion Data Output Decimation for details.

60.3.7.5 Fixed Channels Continuous Scan Mode

- In fixed channels continuous scan mode, A/D conversion in hybrid mode proceeds on the up to three analog channels specified as the fixed channels and A/D conversion in SAR mode proceeds on the analog channels specified as non-fixed channels.
- A/D conversion proceeds on all of the fixed channels and then on one non-fixed channel in one round of scanning operation.
- A/D conversion is repeated on all of the fixed channels and one non-fixed channel as stated above while the target non-fixed channel is changed on each round until a next A/D conversion start trigger is input (continuous scanning operation).
- The output of converted data does not start until the number of times A/D conversion has been completed matches the number of taps in the digital filters for the fixed channels.
- The scan groups and virtual channels to which the individual fixed channels are assigned are specified per A/D converter unit. Only the settings listed in Table 60.7 are specifiable.
- For the constraints on the settings for this mode, see Table 60.8.

Table 60.7 Virtual Channel Numbers Which Should be Assigned as the Individual Fixed Channels

Unit	ADC0	ADC1	ADC2
Scan Group	Scan Group 0	Scan Group 1	Scan Group 2
First fixed channel	Virtual Channel 0	Virtual Channel 4	Virtual Channel 8
Second fixed channel	Virtual Channel 1	Virtual Channel 5	Virtual Channel 9
Third fixed channel	Virtual Channel 2	Virtual Channel 6	Virtual Channel 10

Table 60.8 Constraints on the Settings for the Fixed Channels Continuous Scan Mode

Description	Conditions
Number of fixed channels	ADSWNRm.SWFIXm = 1, 2, 3 (m = 0 to 2)
Number of non-fixed channels	ADSWNRm.SWNOFIXm = 1 (m = 0 to 2)
Number of conversions	ADSWNRm.SWNUMm ≥ number of fixed channels + number of non-fixed channels (m = 0 to 2) (The surplus of channels over the number of fixed channels + number of non-fixed channels corresponds to the number of idle channels.)
Scan groups of virtual channels to which the fixed channels are assigned	ADCHCRn.SGSEL[4:0] = 00h (scan group not selected) (n is replaced with the number of a destination scan group for assignment listed in Table 60.7.)
Filter settings for fixed channels	ADDOPCRAp.DFSEL[2:0]: Select filters with the same number of taps for the fixed channels in the same scan group. (p is replaced with the number of a destination virtual channel for assignment listed in Table 60.7.)
Number of sampling states for virtual channels to which individual non-fixed channels are assigned	ADSSTRx.SSTy[9:0] Set the same value for non-fixed channels.
Calculation of A/D converted data on fixed and non-fixed channels	Setting the addition or averaging function is prohibited.
Self-calibration	Self-calibration is required in both fixed channels continuous scan mode and SAR mode with single scan mode.

60.3.8 Example of the Scanning Operation

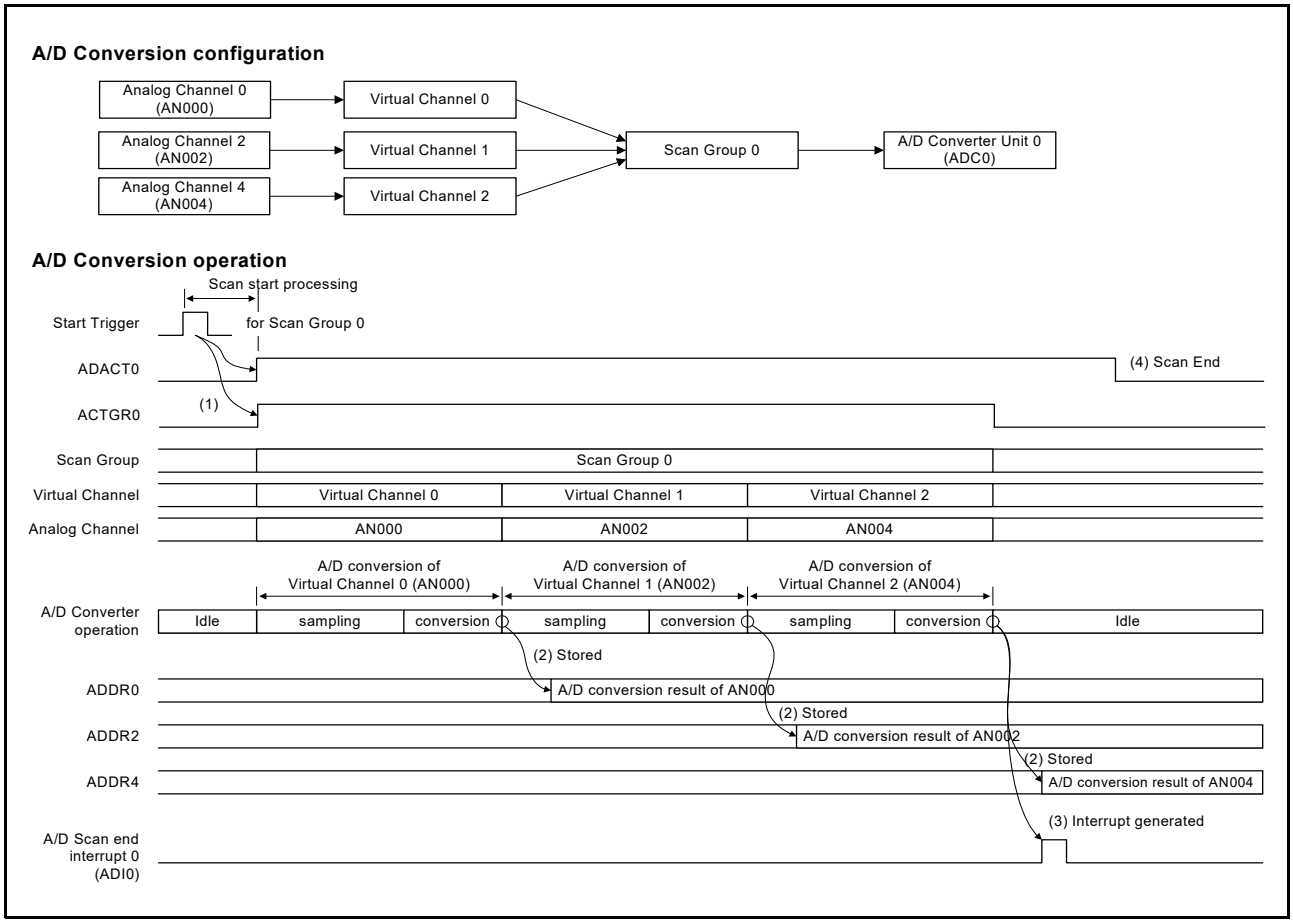
The scanning operations in each operation mode are shown in the following.

60.3.8.1 SAR Mode – Single Scan Mode

Table 60.9 and Figure 60.8 show the operation example in SAR mode – Single scan mode.

Table 60.9 Example of the Scanning Operation in SAR Mode – Single Scan Mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started.
2	Each time an A/D conversion of one analog channel is completed, A/D conversion result is stored to the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO is used, the A/D conversion result is also stored to the FIFO data register (ADFIFODRk (k = 0 to 11)).
3	If the scan end interrupt is enabled, the scan end interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
4	During the scanning operation, ADGRSR.ACTGRn (n = 0 to 11) bit corresponding to that scan group is set to 1. ADSR.ADACTm (m = 0 to 2) bit corresponding to the A/D converter performing the A/D conversion is also set to 1. When scanning operation is complete, each bit is cleared to 0 and A/D converter enters the idle state.



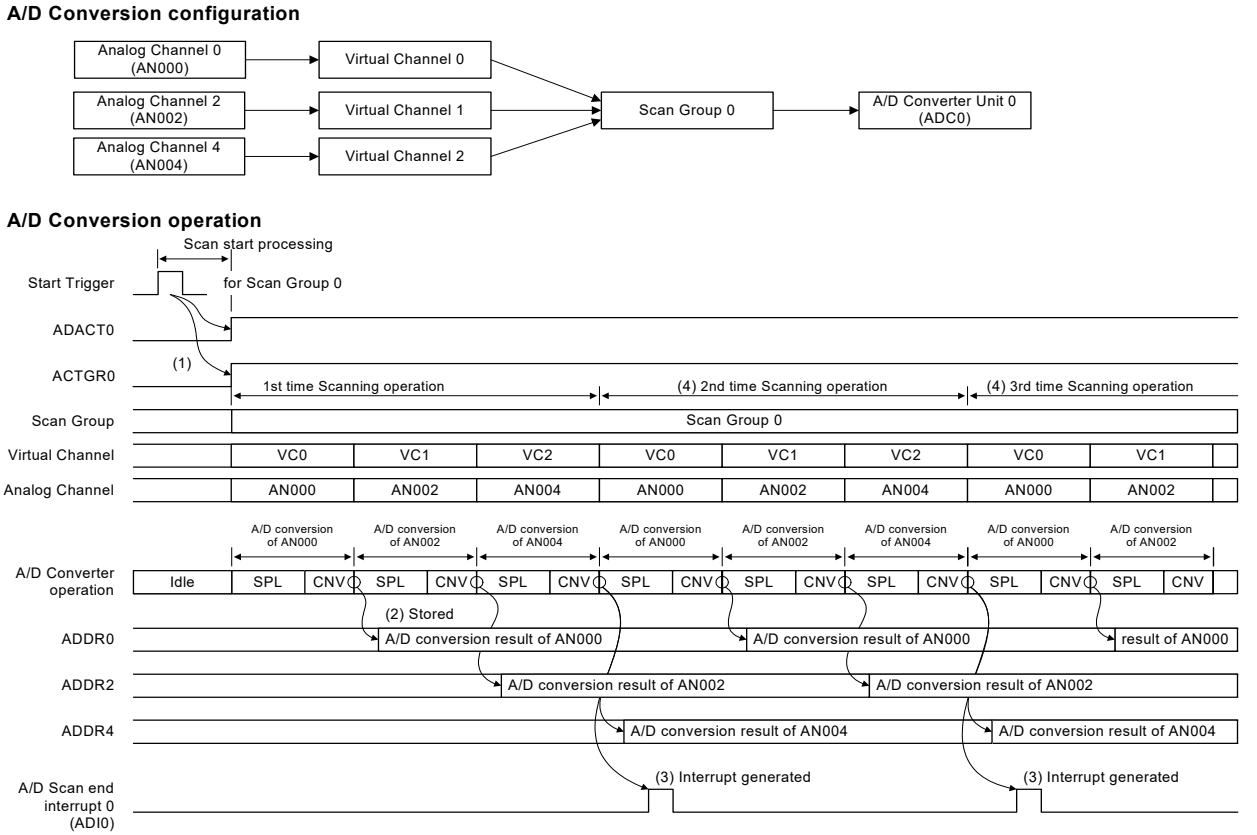


Figure 60.8 Example of the Scanning Operation in SAR Mode – Single Scan Mode

60.3.8.2 SAR Mode – Continuous Scan Mode

Table 60.10 and Figure 60.9 show the operation example in SAR mode – Continuous scan mode.

Table 60.10 Example of the Scanning Operation in SAR Mode – Continuous Scan Mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started. When scanning operation starts, ADGRSR.ACTGRn (n = 0 to 11) corresponding to that scan group is set to 1. ADSR.ADACTm (m = 0 to 2) bit corresponding to the A/D converter performing the A/D conversion is also set to 1.
2	Each time an A/D conversion of one analog channel is completed, A/D conversion result is stored to the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO is used, the A/D conversion result is also stored to the FIFO data register (ADFIFODRk (k = 0 to 11)).
3	If the scan end interrupt is enabled, the scan end interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
4	Until the A/D conversion stop process is performed, Step 2 to 3 are repeated, and the scanning operation continues. To stop the A/D conversion, you must follow to section 60.5.4, Force Stops the A/D Conversion Operation.

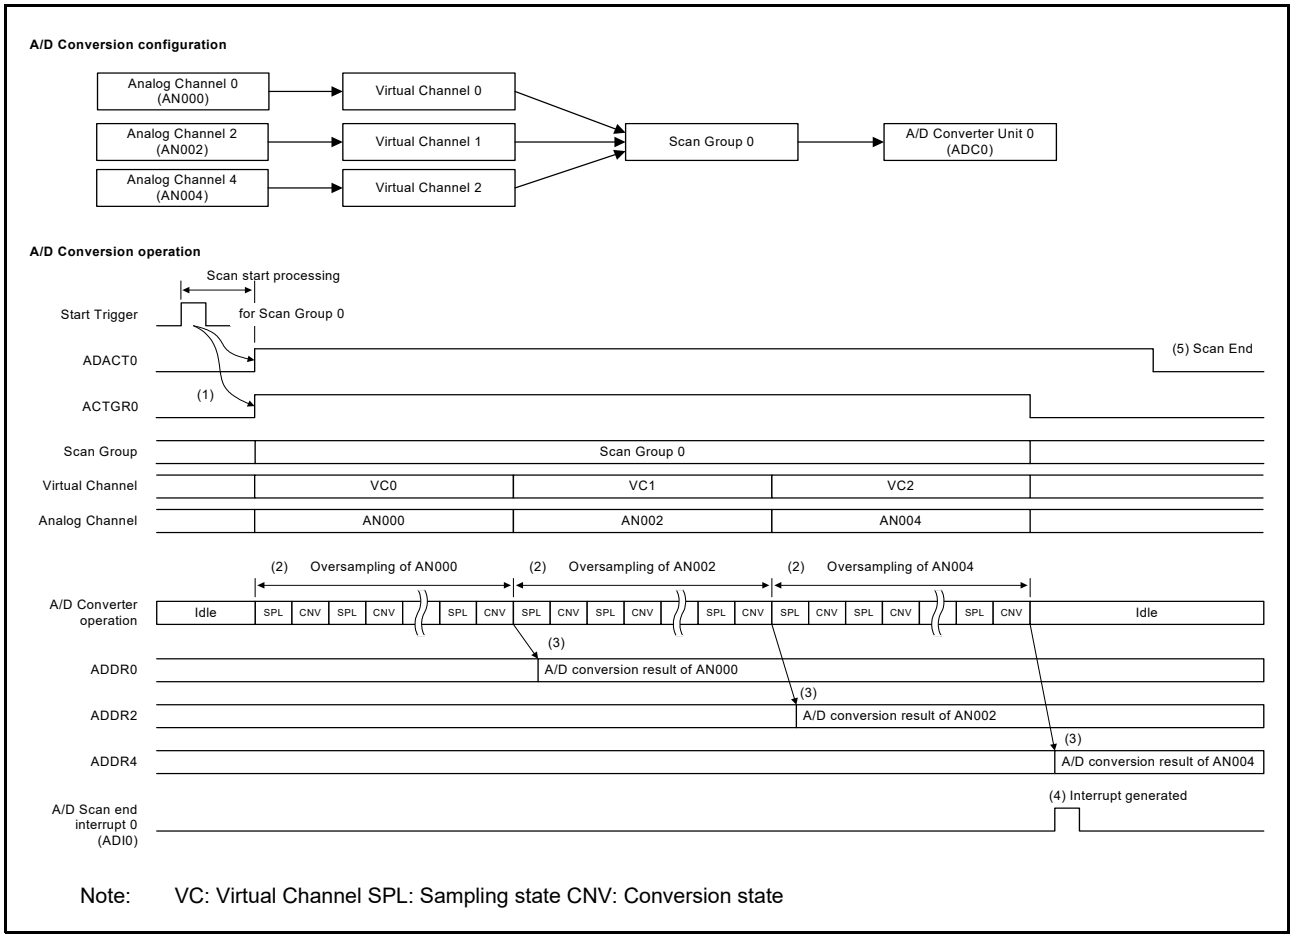

Figure 60.9 Example of the Scanning Operation in SAR Mode – Continuous Scan Mode

60.3.8.3 Oversampling Mode – Single Scan Mode

Table 60.11 and Figure 60.10 show the operation example in oversampling mode – single scan mode.

Table 60.11 Example of the Scanning Operation in Oversampling Mode – Single Scan Mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started.
2	Each analog channel is oversampled according to the number of TAPs in the digital filter and the number of A/D-converted value addition/averaging times. The oversampled data stored in the digital filter are discarded after the oversampling of each analog channel is completed.
3	A/D conversion data of each analog channel is output after oversampling. The A/D conversion data is stored in the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO is used, A/D conversion data is also stored in FIFO data register (ADFIFODRk (k = 0 to 11)).
4	If the scan end interrupt is enabled, the scan end interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
5	During the scanning operation, ADGRSR.ACTGRn (n = 0 to 11) bit corresponding to that scan group is set to 1. ADSR.ADACTm (m = 0 to 2)) bit corresponding to the A/D converter performing the A/D conversion is also set to 1. When scanning operation is complete, each bit is cleared to 0 and A/D converter enters the idle state.

Note: VC: Virtual Channel SPL: Sampling state CNV: Conversion state

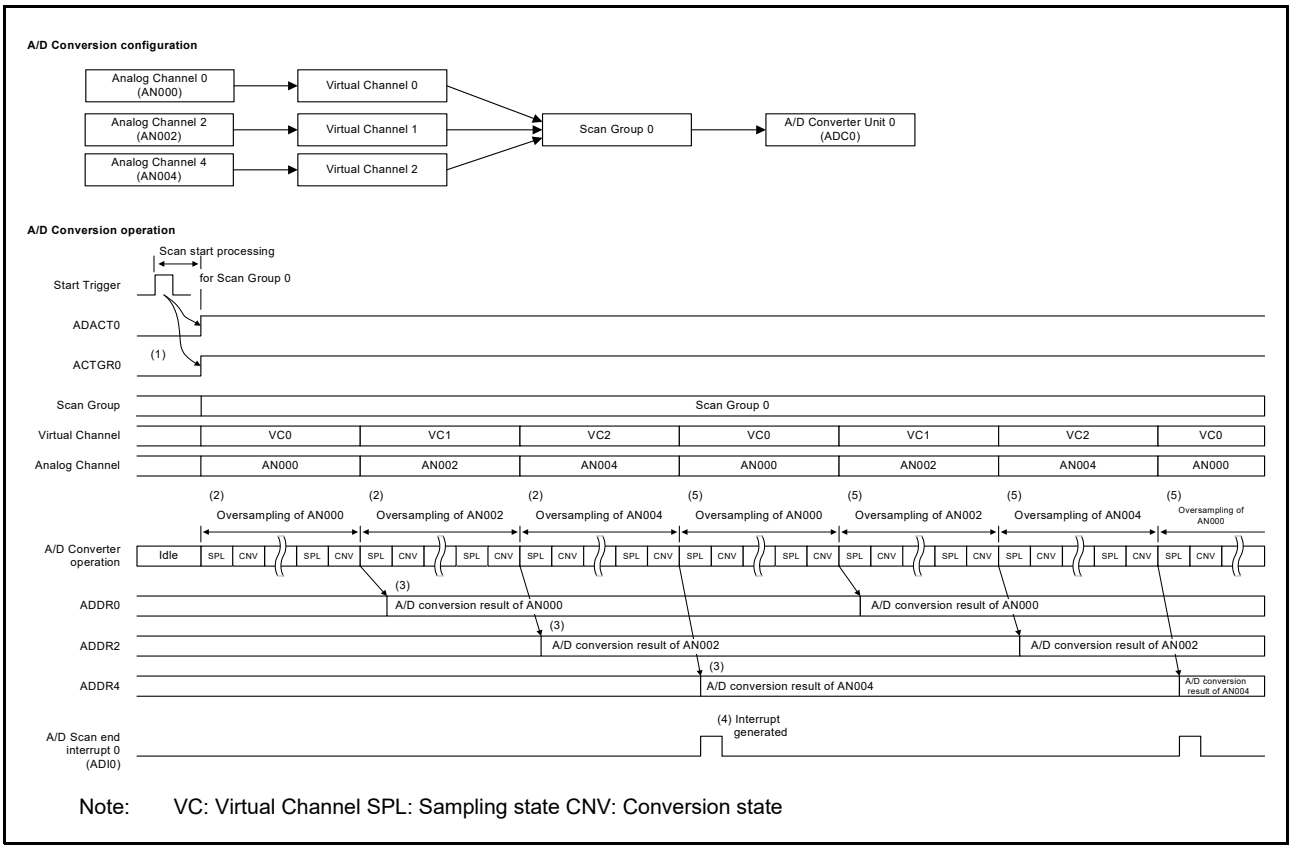

Figure 60.10 Example of the Scanning Operation in Oversampling Mode – Single Scan Mode

60.3.8.4 Oversampling Mode – Continuous Scan Mode

Table 60.12 and Figure 60.11 show the operation example in oversampling mode – continuous scan mode.

Table 60.12 Example of the Scanning Operation in Oversampling Mode – Continuous Scan Mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started. When scanning operation starts, ADGRSR.ACTGRn (n = 0 to 11) corresponding to that scan group is set to 1. ADSR.ADACTm (m = 0 to 2)) bit corresponding to the A/D converter performing the A/D conversion is also set to 1.
2	Each analog channel is oversampled according to the number of TAPs in the digital filter and the number of A/D-converted value addition/averaging times. The oversampled data stored in the digital filter are discarded after the oversampling of each analog channel is completed.
3	A/D conversion data of each analog channel is output after oversampling. The A/D conversion data is stored in the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO is used, A/D conversion data is also stored in FIFO data register (ADFIFODRk (k = 0 to 11)).
4	If the scan end interrupt is enabled, the scan end interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
5	Until the A/D conversion stop process is performed, Step 2 to 4 are repeated, and the scanning operation continues. To stop A/D conversion, you must follow to section 60.5.4, Force Stops the A/D Conversion Operation.

Note: VC: Virtual Channel SPL: Sampling state CNV: Conversion state

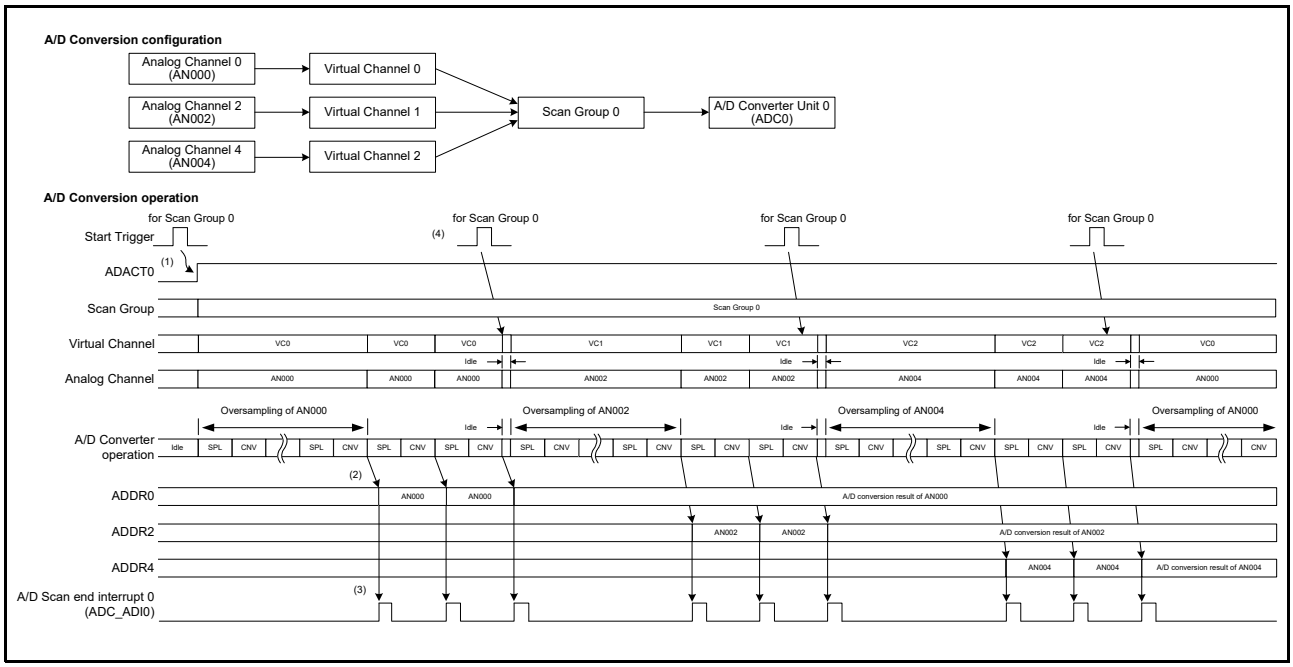
Figure 60.11 Example of the Scanning Operation in Oversampling Mode – Continuous Scan Mode

60.3.8.5 Oversampling Mode – Same Channel Continuous Scan Mode

Table 60.13 and Figure 60.12 show the operation example in oversampling mode – same channel continuous scan mode.

Table 60.13 Example of the Scanning Operation in Oversampling Mode – Same Channel Continuous Scan Mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started. When scanning operation starts, ADGRSR.ACTGRn (n = 0 to 11) corresponding to that scan group is set to 1. ADSR.ADACTm (m = 0 to 2)) bit corresponding to the A/D converter performing the A/D conversion is also set to 1.
2	Every time A/D conversion on a single channel is completed, the result of A/D conversion is stored in an A/D data register i (ADDRi (i = 0 to 35)) or A/D extended analog data register j (ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to18)). When the FIFO function is in use, the result of A/D conversion is also stored in a FIFO data register k (ADFIFODRk (k = 0 to 11)).
3	If the scan end interrupt is enabled, the scan end interrupt corresponding to the given scan group is generated in response to completion of A/D conversion on a single channel.
4	The scanning operation continues until input of the next trigger. To stop the A/D conversion, follow the procedure shown in section 60.5.4, Force Stops the A/D Conversion Operation.



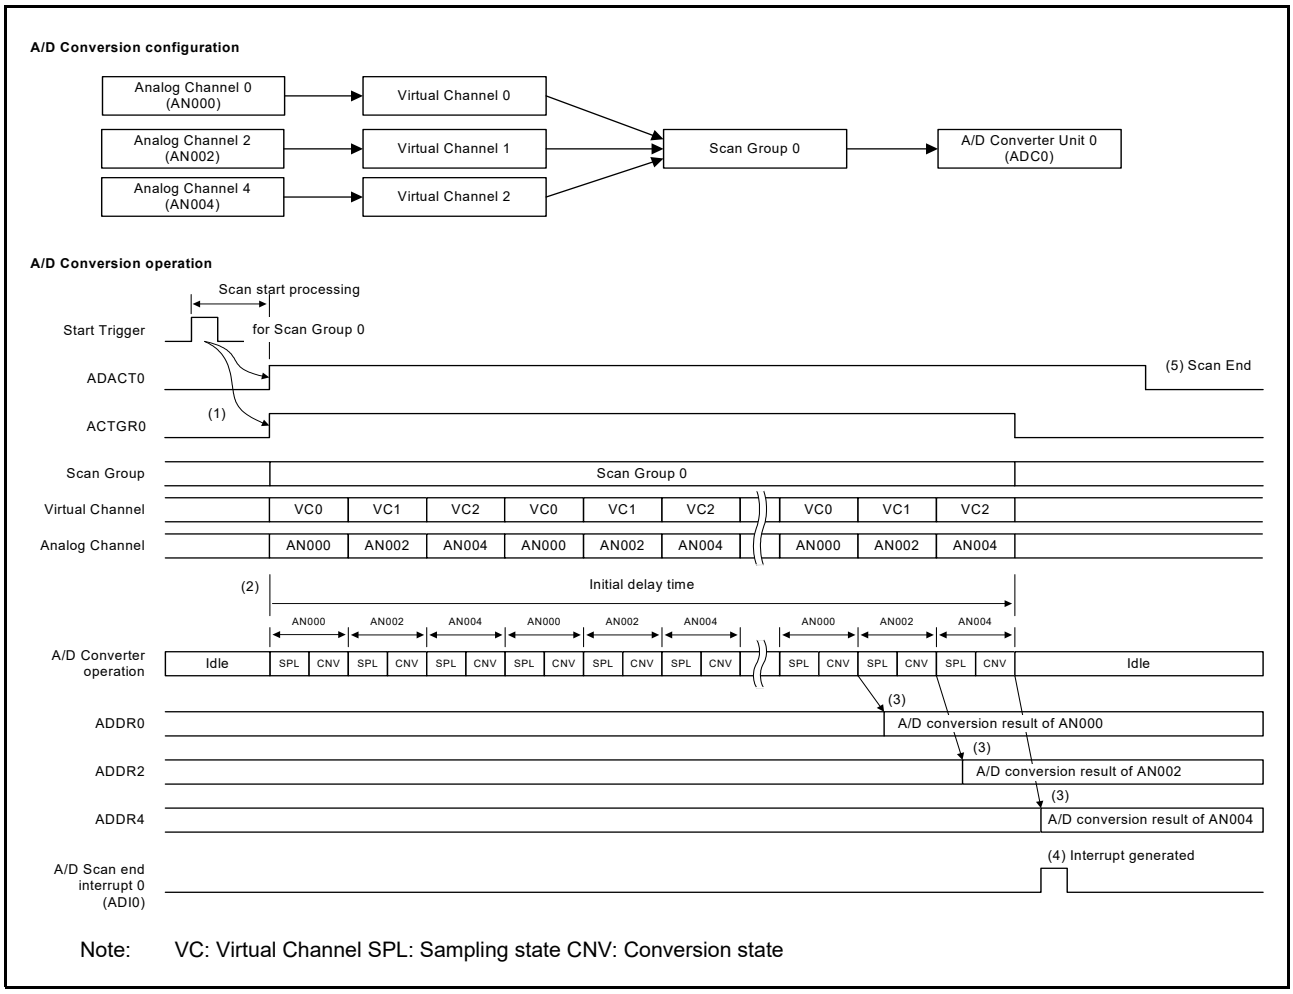


Figure 60.12 Example of the Scanning Operation in Oversampling Mode – Same Channel Continuous Scan Mode

60.3.8.6 Hybrid Mode – Single Scan Mode

Table 60.14 and Figure 60.13 show the operation example in hybrid mode – single scan mode.

Table 60.14 Example of the Scanning Operation in Hybrid Mode – Single Scan Mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started.
2	In Hybrid mode, the scanning operation is performed while switching analog channels every time oversampling is performed.
3	After the oversampling corresponding to the number of TAPs of the digital filter and the number of A/D-converted value addition/averaging times is performed to each analog channel, A/D conversion data is output. (The time taken for the oversampling required to obtain the first A/D conversion data is called the initial delay time.) The A/D conversion data is stored in the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO is used, A/D conversion data is also stored in FIFO data register (ADFIFODRk (k = 0 to 11)).
4	If the scan end interrupt is enabled, the scan end interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
5	During the scanning operation, ADGRSR.ACTGRn (n = 0 to 11) bit corresponding to that scan group is set to 1. ADSR.ADACTm (m = 0 to 2) bit corresponding to the A/D converter performing the A/D conversion is also set to 1. When scanning operation is complete, each bit is cleared to 0 and A/D converter enters the idle state. And the oversampled data in the digital filter are also discarded at the end of the scanning operation.

Note: VC: Virtual Channel SPL: Sampling state CNV: Conversion state

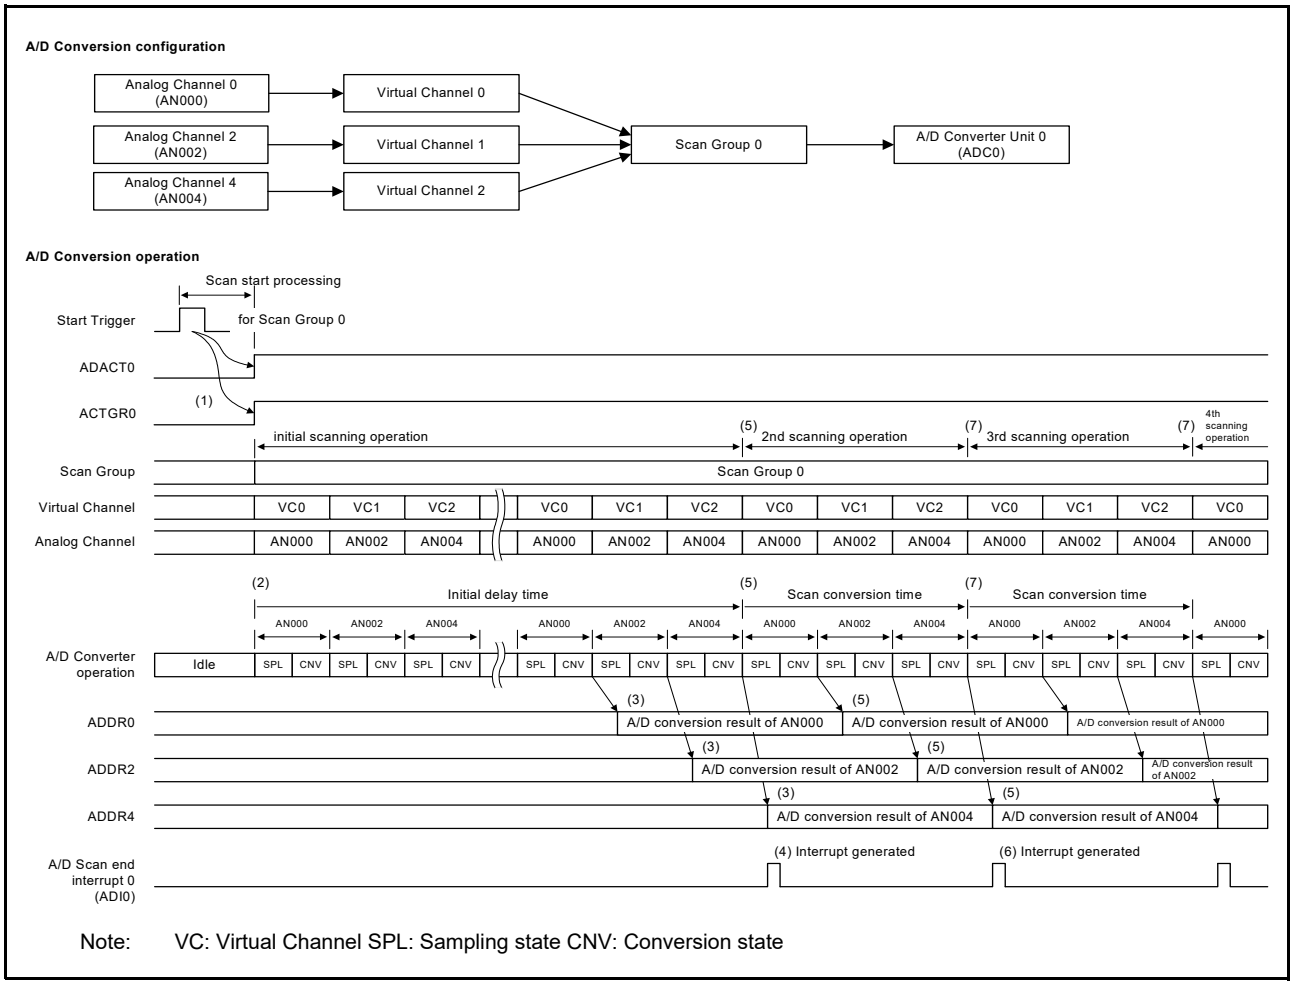

Figure 60.13 Example of the Scanning Operation in Hybrid mode – Single Scan Mode

60.3.8.7 Hybrid Mode – Continuous Scan Mode

Table 60.15 and Figure 60.14 show the operation example in hybrid mode – continuous scan mode.

Table 60.15 Example of the Scanning Operation in Hybrid Mode – Continuous Scan Mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started. When scanning operation starts, ADGRSR.ACTGRn (n = 0 to 11) corresponding to that scan group is set to 1. ADSR.ADACTm (m = 0 to 2) bit corresponding to the A/D converter performing the A/D conversion is also set to 1.
2	In Hybrid mode, the scanning operation is performed while switching analog channels every time oversampling is performed.
3	After the oversampling corresponding to the number of TAPs of the digital filter and the number of A/D-converted value addition/averaging times is performed to each analog channel, A/D conversion data is output. (The time taken for the oversampling required to obtain the first A/D conversion data is called the initial delay time.) The A/D conversion data is stored in the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO is used, A/D conversion data is also stored in FIFO data register (ADFIFODRk (k = 0 to 11)).
4	If the scan end interrupt is enabled, the scan end interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
5	In scanning operation after the initial delay time has elapsed, each time oversampling is performed for an analog channel, the data in the digital filter is updated. The updated A/D conversion data for an analog channel can be output for each one time oversampling or for each multiple times oversampling corresponding to the number of A/D-converted value addition/ averaging times that is performed. The A/D conversion data is stored in the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO is used, A/D conversion data is also stored in FIFO data register (ADFIFODRk (k = 0 to 11)).
6	If the scan end interrupt is enabled, the scan end interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
7	Thereafter, until the A/D conversion stop process is performed, Step 5 to 6 are repeated, and the scanning operation continues. To stop the A/D conversion, you must follow to section 60.5.4, Force Stops the A/D Conversion Operation.

Note: VC: Virtual Channel SPL: Sampling state CNV: Conversion state

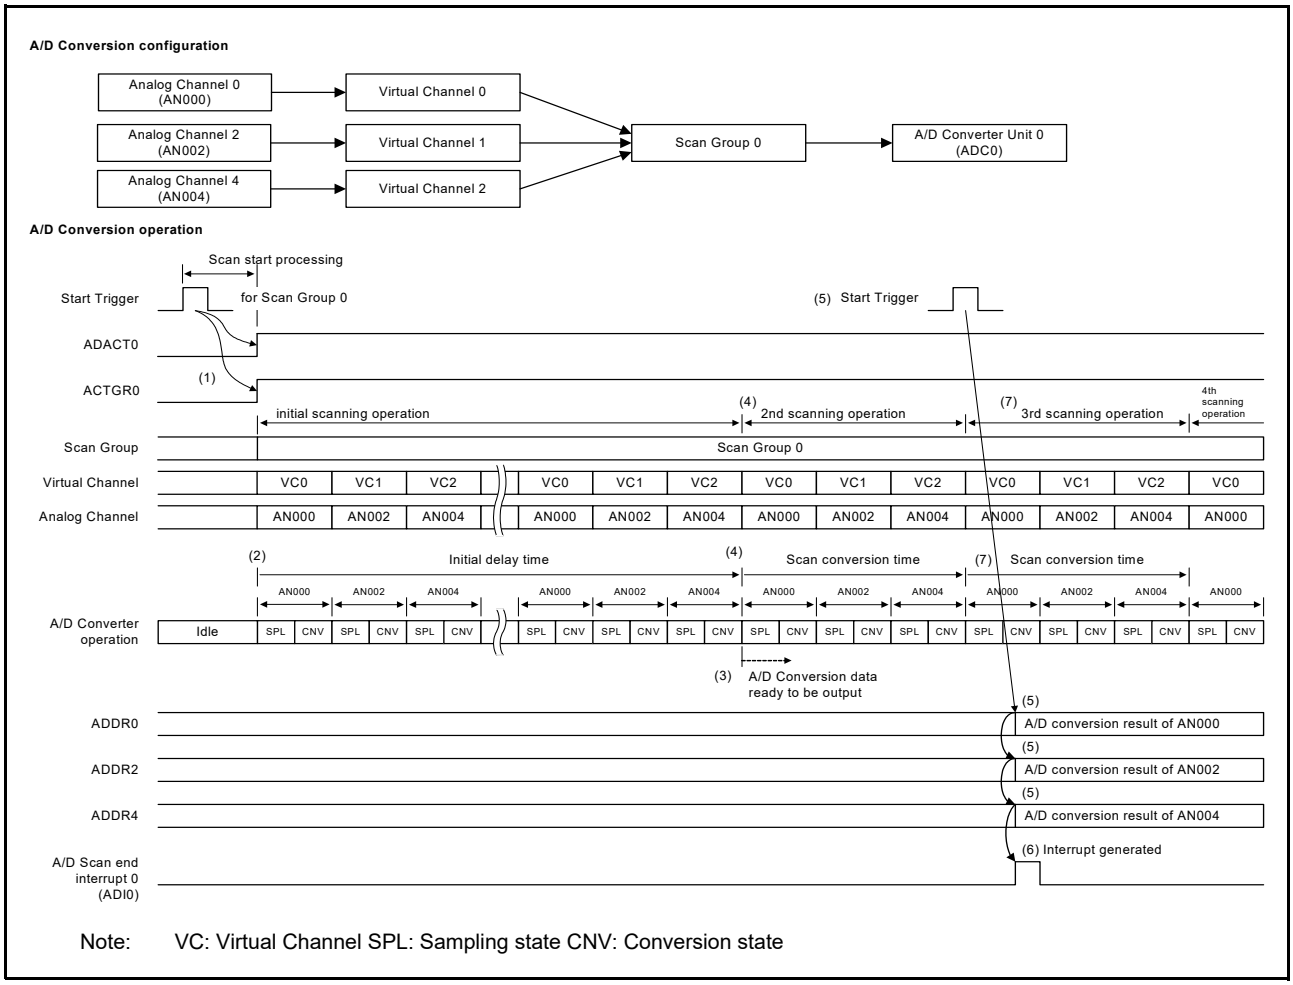
Figure 60.14 Example of the Scanning Operation in Hybrid Mode – Continuous Scan Mode

60.3.8.8 Hybrid Mode – Background Continuous Scan Mode

Table 60.16 and Figure 60.15 show the operation example in hybrid mode – background continuous scan mode.

Table 60.16 Example of the Scanning Operation in Hybrid Mode – Background Continuous Scan Mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started. When scanning operation starts, ADGRSR.ACTGRn (n = 0 to 11) corresponding to that scan group is set to 1. ADSR.ADACTm (m = 0 to 2) bit corresponding to the A/D converter performing the A/D conversion is also set to 1.
2	In Hybrid mode, the scanning operation is performed while switching analog channels every time oversampling is performed.
3	After the oversampling corresponding to the number of TAPs of the digital filter and the number of A/D-converted value addition/averaging times is performed to each analog channel, A/D conversion data becomes in ready to be output. (The time taken for the oversampling required to obtain the first A/D conversion data is called the initial delay time. In the background continuous scan operation, A/D conversion data can be obtained after the initial delay time has elapsed from the start of the scanning operation.)
4	In scanning operation after the initial delay time has elapsed, each time oversampling is performed for an analog channel, the data in the digital filter is updated. The updated A/D conversion data for an analog channel can be output for each one time oversampling or for each multiple times oversampling corresponding to the number of A/D-converted value addition/ averaging times that is performed.
5	When an A/D conversion start trigger is input during background continuous scanning operation, the most recent A/D conversion data at that time is stored in the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO function is set to enabled, A/D conversion data is also stored in the FIFO data register (ADFIFODRk (k = 0 to 11)).
6	If scan end interrupt is set to enable, scan end interrupt is generated.
7	Thereafter, until the A/D conversion stop process is performed, Background continuous scanning operation (Step 4) is repeated. And whenever the A/D conversion start trigger is input during Background continuous scanning operation, the A/D conversion data is output (Step 5 and Step 6). To stop A/D conversion, you must follow to section 60.5.4, Force Stops the A/D Conversion Operation.



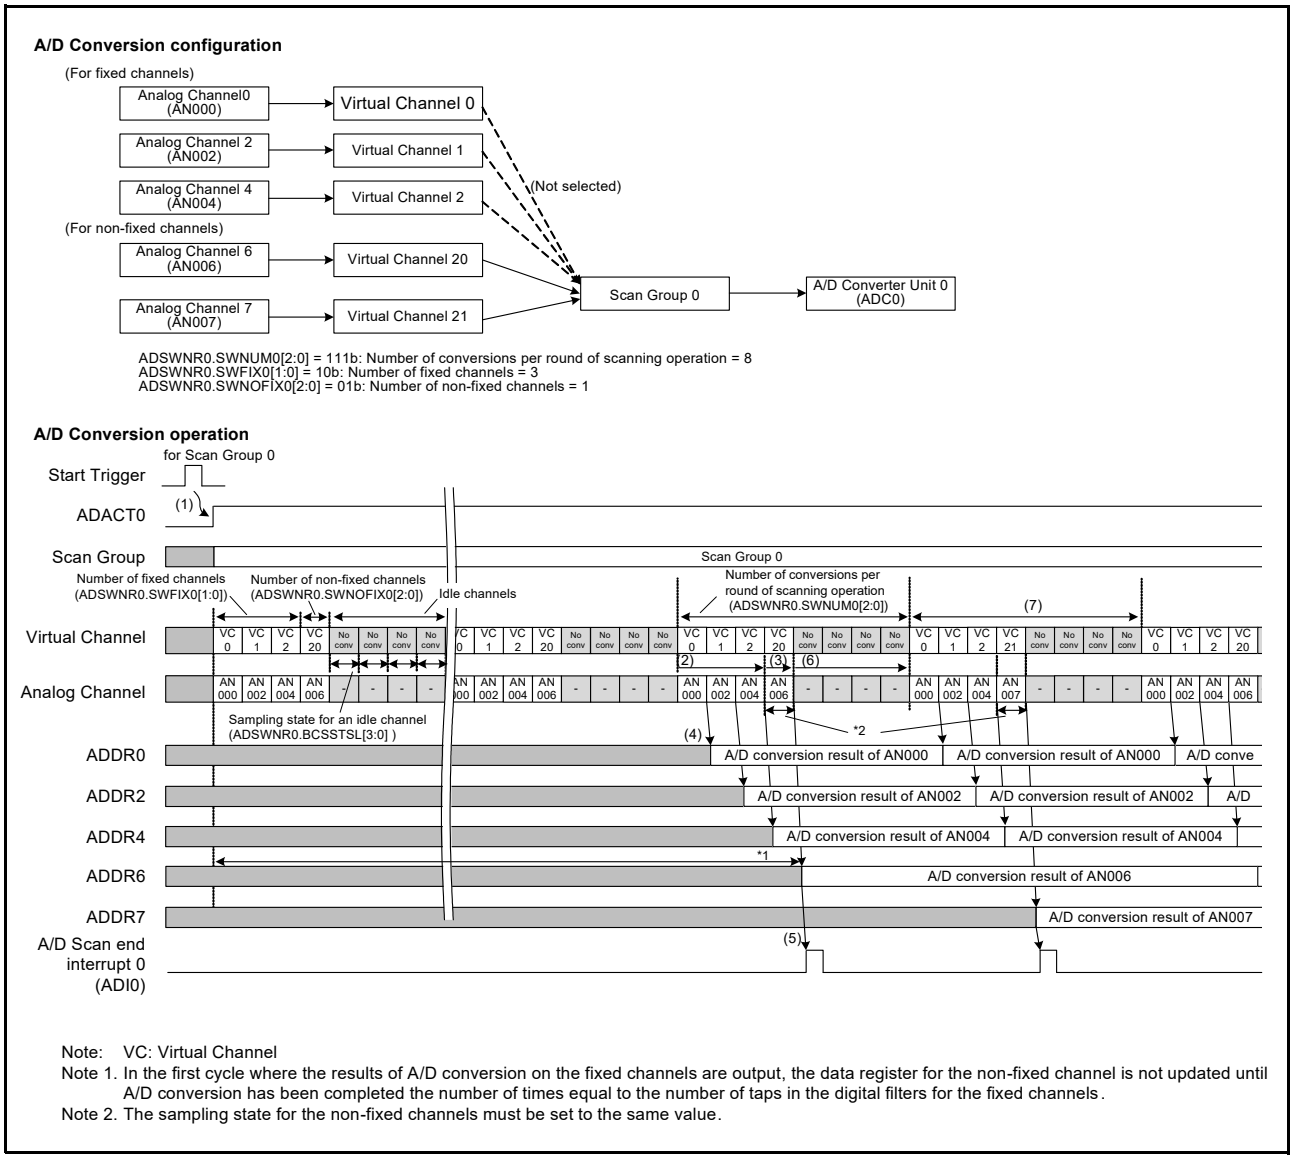


Figure 60.15 Example of the Scanning Operation in Hybrid Mode – Background Continuous Scan Mode

60.3.8.9 Hybrid Mode – Fixed Channels Continuous Scan Mode

Table 60.17 and Figure 60.16 show the operation example in hybrid mode – fixed channels continuous scan mode.

Table 60.17 Example of the Scanning Operation in Hybrid Mode – Fixed Channels Continuous Scan Mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started.
2	A/D conversion in hybrid mode proceeds on one to three fixed channels.
3	A/D conversion in SAR mode proceeds on one non-fixed channel. The non-fixed channel for conversion is selected from among the virtual channels assigned to the given scan group in ascending order of the channel number.
4	Every time A/D conversion on a single analog channel is completed, the result of A/D conversion is stored in an A/D data register i (ADDRi (i = 0 to 35)) or A/D extended analog data register j (ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to18)). When the FIFO function is in use, the result of A/D conversion is also stored in a FIFO data register k (ADFIFODRk (k = 0 to 11)).
5	If the scan end interrupt is enabled, the scan end interrupt for the given scan group is generated after the period for the round of scanning.
6	The period until the end of the round of scanning also includes the times for conversion on idle channels.
7	Until the A/D conversion stop processing proceeds, steps 2 to 6 are repeated, and the scanning operation continues. Specifically, A/D conversion is repeated on the same fixed channels and on one non-fixed channel, which is selected from among those assigned to the given scan group in ascending order of the channel number. When the last channel number is reached, the target for conversion of a non-fixed channel returns to the first channel and this operation is repeated. To stop the A/D conversion, follow the procedure shown in section 60.5.4, Force Stops the A/D Conversion Operation.

Note: VC: Virtual Channel
Note 1. In the first cycle where the results of A/D conversion on the fixed channels are output, the data register for the non-fixed channel is not updated until A/D conversion has been completed the number of times equal to the number of taps in the digital filters for the fixed channels.
Note 2. The sampling state for the non-fixed channels must be set to the same value.

Figure 60.16 Example of the Scanning Operation in Hybrid Mode – Fixed Channels Continuous Scan Mode

60.3.9 Self-Calibration

ADC has a built-in self-calibration function. Self-calibration function is used to calibrate the variations of characteristics caused by the chip-by-chip variations. Self-calibration function has the following operations.

1. Internal Circuit Calibration
   - Adjusts the operation of A/D converter's internal circuitry.
2. Gain and Offset Calibration
   - Measure the A/D converter's Gain Error and Offset Error.
   - The calibration processing of the A/D conversion result based on the measured error data is performed after the A/D conversion.
     For details, see section 60.4.3.1, Gain Error and Offset Error Calibration.
   - This self-calibration should be performed after Internal-circuit self-calibration is completed.
3. Channel-dedicated sample-and-hold circuit Gain and Offset Calibration
   - Measure the Gain Error and the Offset Error when using the channel-dedicated sample-and-hold circuit.
   - The calibration processing of the A/D conversion result based on the measured error data is performed after the A/D conversion.
     For details, see section 60.4.3.1, Gain Error and Offset Error Calibration.
   - This self-calibration should be performed after A/D converter Gain/Offset self-calibration is completed.

60.3.9.1 Conditions under Which Self-Calibration is Required

The conditions under which self-calibration is required are shown in Table 60.18. Under the conditions shown in Table 60.18, self-calibration should be performed before using the A/D converter. If A/D converter is operating, stop all A/D converters and perform the self-calibration again. If the required self-calibration is not performed, the A/D conversion result is not guaranteed.

Table 60.18 List of Conditions under Which Self-Calibration should be Performed

Conditions under Which Self-Calibration is Required	Internal-Circuit Calibration	Gain/Offset Calibration	Channel-Dedicated Sample-and-Hold Circuit Gain and Offset Calibration*1
After reset release	✓	✓	✓
After releasing the module stop	✓	✓	✓
When returning from software standby mode or deep software standby mode	✓	✓	✓
When changed the ADCLK setting (When clock source or frequency is changed)	✓	✓	✓
When changed the operation mode or the scan mode of the A/D converter (When changed ADMDR.ADMDm bit (m = 0 to 2))	✓	✓*2	✓
When changed A/D successive approximation time (When changed ADCNVSTR.CSTm bit (m = 0 to 2))	✓	✓	✓
When changed the operation setting of the channel-dedicated sample-and-hold circuit*1	—	—	✓

✓: available, —: not available

Note 1. When any of ADSHCR0.SHENn bits are set to 1, or any of ADSHCR0.SHENn bits are changed, perform the channel-dedicated sample-and-hold circuits self-calibration (n = 0 to 2). Not required if the channel-dedicated sample-and-hold circuits are not used.

Note 2. When the fixed channels continuous scan mode is in use, the gain/offset calibration in SAR mode with single scan mode is also required.

60.3.9.2 Self-Calibration Procedure

Table 60.19 shows the self-calibration procedures.

Table 60.19 Procedure for Self-Calibration

No.	Step	Description
1	Disable trigger input	Disables the trigger input from the peripheral module. (Write ADTRGENR.STTRGENn = 0)
2	Waiting for all A/D converters to stop	Check that all A/D converters are stopped. If A/D conversion is operating, wait until the A/D converter stops by either of the following: • Wait until all A/D conversions are complete • Force the A/D converter to stop the operation using the ADSTOPR register. For details on forced stopping of A/D conversion operation, see section 60.5.4, Force Stops the A/D Conversion Operation.
3	Setting the number of states for self-calibration	Set the number of states for the self-calibration of A/D converter to ADCALSTCR register. The values in ADCALSTCR register are commonly used for ADC0, ADC1, and ADC2. Set the value to be set in ADCALSTCR register to satisfy the range defined in section 67, Electrical Characteristics.
4	Clearing the error status flag	If error flags are detected, clear them before performing the self-calibration. (A/D converter error flag, A/D converter overflow flag, etc.)
5	Performing the self-calibration for ADC0	Performs the self-calibration for ADC0. • Internal-circuit calibration • Gain/offset calibration After starting the self-calibration, wait until it is completed.
6	Performing the self-calibration for ADC1	Performs the self-calibration for ADC1 in the same as Step 5.
7	Performing the self-calibration for ADC2	Performs the self-calibration for ADC2 in the same as Step 5.
8	Setting the self-calibration of channel-dedicated sample-and-hold circuit*1	Make settings for self-calibration of channel-dedicated sample-and-hold circuit. Enable channel-dedicated sample-and-hold circuit. Sets the number of states for channel-dedicated sample-and-hold self-calibration (ADCALSTCR register*2 and ADCALSHCR register).
9	Performing channel-dedicated sample-and-hold circuit self-calibration for SH0 to SH2.*1	Performs the self-calibration for channel-dedicated sample-and-hold circuit (SH0 to SH2) connected to ADC0. • Channel-dedicated sample-and-hold circuit gain/offset calibration after starting self-calibration, wait until it is completed.
10	Error status check*3	Check for errors in self-calibration. If no operating error occurs, self-calibration is complete.

Note: In order to increase the effectiveness of self-calibration, it is recommended to perform self-calibration for the A/D converters one by one.

Note: When the fixed channels continuous scan mode is to be used, execute steps 1 to 10 for non-fixed channels in SAR mode with single scan mode, and then change the scan mode to the fixed channels continuous scan mode and execute steps 1 to 10.

Note 1. Not required if the channel-dedicated sample-and-hold circuits are not used.

Note 2. When the self-calibration is performed for the channel-dedicated sample-and-hold circuitry, the number of sampling states at the self-calibration of the A/D converter (ADCALSTCR.CALADSST[9:0] bits) may also need to be changed. Set the value that satisfies the electrical characteristics.

Note 3. If the A/D converter error is detected by the self-calibration, it may be set outside the operation guaranteed range specified in the electric characteristics. Check the operation setting.

60.3.9.3 Restrictions on Self-Calibration

(1) Prohibition of the scanning operation during self-calibration

Do not start the scanning operation during self-calibration. When performing the scanning operation, start the scanning operation after self-calibration is completed. Operation is not guaranteed when the scanning operation is started during self-calibration.

(2) Prohibition of additional writes to the ADCALSTR register during self-calibration

After the self-calibration is started, writing to ADCALSTR register is prohibited until self-calibration is completed. Write to ADCALSTR register after self-calibration is completed. Operation is not guaranteed if this restriction is violated.

(3) Restrictions on self-calibration for channel-dedicated sample-and-hold circuit

To perform self-calibration of the channel-dedicated sample-and-hold circuits, set the corresponding SHENn bit in ADSHCR0 (n = 0 to 2) to 1 for the channel-dedicated sample-and-hold circuit unit to be used.

(4) Restrictions on the self-calibration

Self-calibration should be performed for the A/D converters one by one. During the self-calibration operation, the other A/D converters should be in idle (not in scan operation or self-calibration operation).
If this restriction is violated, the A/D conversion accuracy will be degraded due to noise during the self-calibration operation. In this case, the A/D converter characteristics are not guaranteed.
In addition, in order to enhance the effect of self-calibration, self-calibration operation should be performed under conditions with as little noise as possible.

(5) Restrictions on setting of the number of status for self-calibration

The number of states to be set in the ADCALSTCR and ADCALSHCR registers should be set to satisfy the values specified in the Electrical Characteristics. In addition, the number of states involved in self-calibration should be set to satisfy the following restrictions.
If these restrictions are violated, A/D conversion results are not guaranteed.

[Restrictions on setting of ADCALSTCR register]

- ADCALSTCR.CALADSST[9:0] bits
  - According to the type of self-calibration, set the values to satisfy those specified in the electrical characteristics.
  - If the setting value differs according to the type of self-calibration, change the register setting value for each self-calibration.
- ADCALSTCR.CALADCST[5:0] bits
  - Set the same value as ADCNVSTR.CSTm[5:0] (m = 0 to 2) bits. (ADCALSTCR.CALADCST[5:0] = ADCNVSTR.CSTm[5:0])

[Restrictions on setting of ADCALSHCR register] (only when channel-dedicated sample-and-hold circuit is used)

- ADCALSHCR.CALSHSST[7:0] bits
  - Set the same value as ADSHSTR0.SHSST[7:0] bits.
- ADCALSHCR.CALSHHST[2:0] bits
  - Set the same value as ADSHSTR0.SHHST[2:0] bits.

60.3.10 Analog Input Channel

For the correspondence between the analog input pins and the analog channel numbers, the A/D converters, and channel-dedicated sample-and-hold circuit, see Table 60.4.

60.3.11 Extended Analog Function

Extended analog function performs A/D conversion on the internal signal source of MCU. The available sources for extended analog function are shown in the following:

- Self-diagnosis voltage
- Internal reference voltage
- Temperature sensor
- D/A converter output
- VBATT1/6 voltage monitoring output

60.3.12 Self-Diagnosis Function

This A/D converter has a built-in self-diagnosis function. The self-diagnosis function inputs the self-diagnosis voltage to the A/D converter and performs A/D conversion. The A/D conversion result of the self-diagnosis voltage can be used to confirm that the A/D converter is operating normally.

60.3.12.1 Self-Diagnosis

This A/D converter has a built-in self-diagnosis function. The self-diagnosis function inputs the self-diagnosis voltage to the A/D converter and performs A/D conversion. The A/D conversion result of the self-diagnosis voltage can be used to confirm that the A/D converter is operating normally. Table 60.20 shows the operation mode in which the self-diagnostic function is available.

Table 60.20 List of Operation Mode for which the Self-Diagnostic Function is Available

Operation Mode – Scan Mode	Self-Diagnosis Function	
	With the Channel-Dedicated Sample-and-Hold Circuit Not in Use	With the Channel-Dedicated Sample-and-Hold Circuit in Use
SAR mode – Single scan mode	✓	✓
SAR mode – Continuous scan mode	✓	—
Oversampling mode – Single scan mode	✓	—
Oversampling mode – Continuous scan mode	—	—
Oversampling mode – Same channel continuous scan mode	—	—
Hybrid mode – Single scan mode	✓	—
Hybrid mode – Continuous scan mode	—	—
Hybrid mode – Background continuous scan mode	—	—
Hybrid mode – Fixed channels continuous scan mode	—	—

✓: available, —: not available

The procedure for performing self-diagnosis of A/D converter is shown in the following.

1. Assign the self-diagnosis channel to one of the virtual channels and configure the virtual channel settings.
2. Assign the virtual channel that the self-diagnosis channel is selected to one of the scan groups.
3. Set the self-diagnosis voltage in DIAGVAL[2:0] bits of ADSGDCRn (n = 0 to 11) register corresponding to the scan group assigned in 2 above. When the channel-dedicated sample-and-hold circuits are to be used, use the

SHDIAGx[2:0] bits in the ADSHSDCRy register (y = 0, 1; x = 0 to 11) to set the voltage for use in self-diagnosis.

4. Start the scanning operation by inputting the A/D conversion start trigger. The self-diagnosis operation is executed at the A/D conversion of the self-diagnosis channel.

60.3.12.2 Self-Diagnosis Mode

ADC has a total of nine self-diagnosis modes: three modes determined by the circuit to be used and three modes with different expected values for each of the selectable circuits. Proceed with self-diagnosis in an appropriate mode for the circuit you are using. We recommend proceeding with self-diagnosis with all three types of expected value.

- Self-diagnosis modes 1 to 3: Self-diagnosis only proceeds for the A/D converter itself.
- Self-diagnosis modes 4 to 6: Self-diagnosis proceeds for the channel-dedicated sample-and-hold circuit in differential input mode in combination with the A/D converter.
- Self-diagnosis modes 7 to 9: Self-diagnosis proceeds for the channel-dedicated sample-and-hold circuit in single-ended input mode in combination with the A/D converter.

Table 60.21, Table 60.22 lists the operation settings when the self-diagnosis function is used. When using the self-diagnosis function, follow the setting in Table 60.21, Table 60.22. If self-diagnosis operation is performed with settings other than those shown in Table 60.21, Table 60.22, the self-diagnosis result (A/D conversion result) is not guaranteed.

Table 60.21 List of Operation Setting and Expected Value for Self-Diagnosis Function

	Register Setting Value				Self-Diagnosis Operation
	ADSGDCRx	ADCHCRy		ADDOPCRCy	Expected Value of A/D Conversion Data*1, *2
Self-Diagnosis Mode	DIAGVAL[2:0]	CNVCS[6:0]	AINMD	SIGNSEL	
Self-diagnosis mode 1	100b	ADC0: 60h ADC1: 61h ADC2: 62h	1	0	0000h
Self-diagnosis mode 2	101b		1	0	8000h
Self-diagnosis mode 3	110b		1	0	7FFFh

Note: x = 0 to 8, y = 0 to 49

Note 1. Expected values indicate ideal values for results of A/D conversion to be stored in the ADEXDRn.DATA[15:0] (n = 0 to 2, 4 to 6, 8, 9, 16 to 18) or ADFIFODRx.DATA[15:0] bits. A result of A/D conversion is no less than the ideal value + 1 when a positive error is generated in terms of the precision of conversion and no greater than the ideal value - 1 when a negative error is generated.

Note 2. The A/D conversion data is the value when 16-bit data format (ADDOPCRCy.ADPRC[1:0] = 00b) is selected.

Table 60.22 List of Operation Setting and Expected Value for Self-Diagnosis Function (with the Channel-Dedicated Sample-and-Hold Circuit in Use)

	Register Setting Value					Self-Diagnosis Operation
	ADSHSDCRy	ADCHCRy		ADSHCR0	ADDOPCRCy	Expected Value of A/D Conversion Data*1, *2
Self-Diagnosis Mode	SHDIAGx[2:0]	CNVCS[6:0]	AINMD	SHMDz	SIGNSEL	
Self-diagnosis mode 4	001b	SH0: 70h SH1: 71h SH2: 72h	1	1	0	0000h
Self-diagnosis mode 5	010b		1	1	0	8000h
Self-diagnosis mode 6	011b		1	1	0	7FFFh
Self-diagnosis mode 7	100b		1	1	0	0000h
Self-diagnosis mode 8	101b		1	1	0	8000h
Self-diagnosis mode 9	110b		1	1	0	7FFFh

Note: x = 0 to 11, y = 0, 1, z = 0 to 2

Note 1. Expected values indicate ideal values for results of A/D conversion to be stored in the ADEXDRn.DATA[15:0] (n = 0 to 2, 4 to 6, 8, 9, 16 to 18) or ADFIFODRx.DATA[15:0] bits. A result of A/D conversion is no less than the ideal value + 1 when a positive error is generated in terms of the precision of conversion and no greater than the ideal value - 1 when a negative error is generated.

Note 2. The A/D conversion data is the value when 16-bit data format (ADDOPCRCy.ADPRC[1:0] = 00b) is selected.

60.3.12.3 Notes on Self-Diagnosis Function

(1) Notes on data format during self-diagnosis

When self-diagnosis modes 4 to 9 is performed, if a data format other than 16-bit length is set, an overflow occurs due to A/D conversion data rounding, and the A/D conversion data error is detected. To perform self-diagnosis, select the 16-bit data format.

(2) Self-diagnosis of channel-dedicated sample-and-hold circuits

Setting normal conversion and self-diagnosis for a single channel-dedicated sample-and-hold circuit in a scan group at the same time is prohibited.

60.3.13 Internal Reference Voltage

ADC can perform A/D conversion of internal reference voltage. Internal reference voltage outputs a constant voltage that is independent of the power supply voltage (VCC, VSS, AVCC0, AVSS0, VREFH0 and VREFL0). The monitoring of internal reference voltage can be used to detect variations in the analog reference supply voltage (VREFH0 and VREFL0), or abnormalities or faults in the system.
When performing A/D conversion of internal reference voltage, it is required to set the internal reference voltage monitor enable register (ADREFCR) and assign the analog channel of internal reference voltage to any of the virtual channels. See Table 60.5 for the correspondence between internal reference voltage function and the analog channels. For the sampling time when A/D conversion of internal reference voltage is performed, see section 67, Electrical Characteristics.

60.3.14 Temperature Sensor

ADC can perform A/D conversion of temperature sensor. The chip temperature can be estimated from the A/D conversion result of temperature sensor. For more details on temperature sensor, see section 62, Temperature Sensor (TEMPS).
When A/D conversion of temperature sensor is performed, temperature sensor should be configured and the analog channel of temperature sensor should be assigned to any of the virtual channels. See Table 60.5 for the correspondence between temperature sensor and analog channels. For the sampling time when A/D conversion of temperature sensor is performed, see section 67, Electrical Characteristics.

60.3.15 D/A Converter

ADC can perform A/D conversion of the voltage that is being output by a D/A converter. For details on the functionality of the D/A converter, see section 61, 12-Bit D/A Converter (DAC12R).
When A/D conversion is performed on the output of D/A converter (DA0 to DA1), the D/A converter should be configured and the analog channel of the D/A converter should be assigned to one of the virtual channels.
For the sampling time when A/D conversion is performed on the D/A converter output voltage, see section 67, Electrical Characteristics.

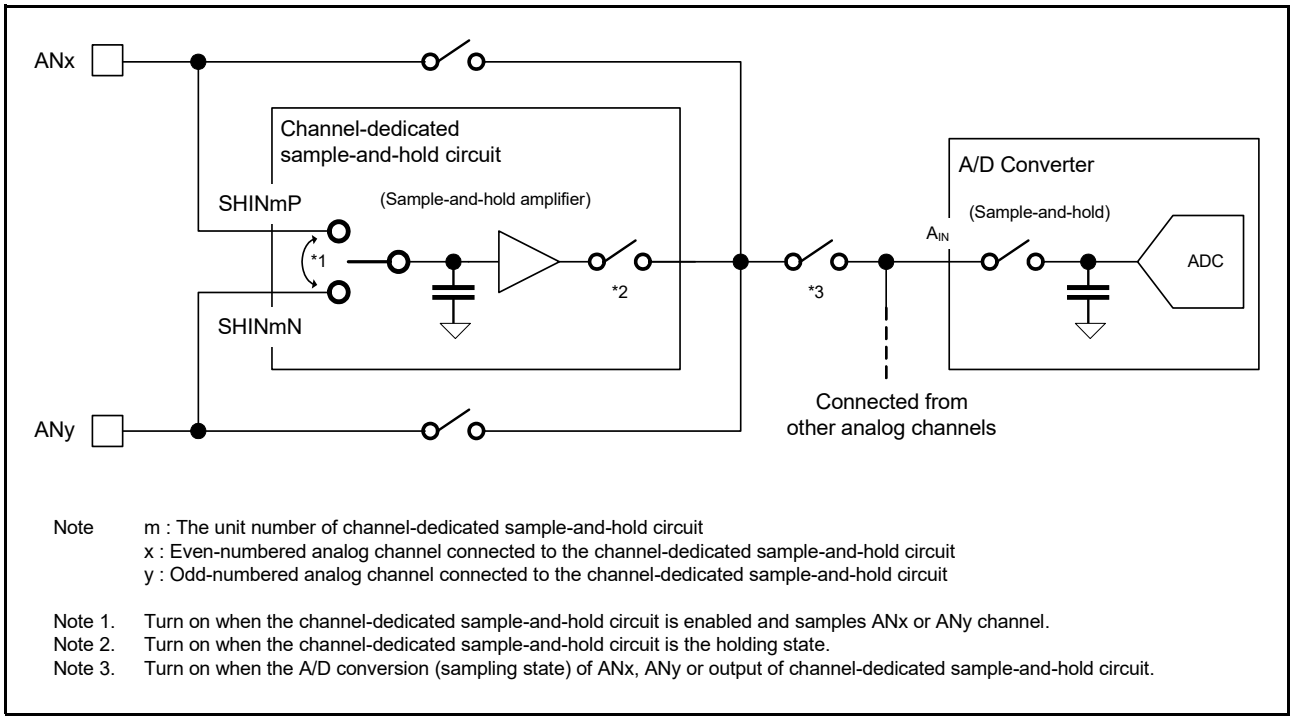
60.3.16 VBATT 1/6 Voltage Monitoring Output

ADC can perform A/D conversion of the VBATT 1/6 voltage monitoring output. The VBATT 1/6 voltage monitoring output is for the input voltage on the VBATT pin. For details on the VBATT pin, see section 12, Battery Backup Function (VBATTBa).
A/D converting the VBATT 1/6 voltage monitoring output requires setting the VBATTMNSELR.VBTTMNSEL bit to 1 and assigning an analog channel for the VBATT 1/6 voltage monitoring output to any of the virtual channels. For the correspondence between the VBATT 1/6 voltage monitoring output and analog channel, see Table 60.5.
For the sampling time when A/D conversion of the VBATT 1/6 voltage monitoring output is performed, see section 67, Electrical Characteristics.

60.3.17 Channel-Dedicated Sample-and-hold Circuit

ADC has a built-in channel-dedicated sample-and-hold circuit. By using multiple channel-dedicated sample-and-hold circuits, it is possible to sample multiple analog inputs simultaneously.
The conditions under which channel-dedicated sample-and-hold circuit can be used are shown in Table 60.23.

Table 60.23 Operation Mode in which Channel-Dedicated Sample-and-Hold Circuits can be Used



Operation Mode	Channel-Dedicated Sample-and-Hold Circuits
SAR mode – Single scan mode	✓*1
SAR mode – Continuous scan mode	—
Oversampling mode – Single scan mode	—
Oversampling mode – Continuous scan mode	—
Oversampling mode – Same channel continuous scan mode	—
Hybrid mode – Single scan mode	✓
Hybrid mode – Continuous scan mode	✓
Hybrid mode – Background continuous scan mode	✓
Hybrid mode – Fixed channels continuous scan mode	✓*2

✓: available, —: not available
Note 1. The constant sampling mode can be used.
Note 2. In this mode, fixed channels must satisfy the following conditions: the number of fixed channels is set to three and the channel-dedicated sample-and-hold circuits are specified for each of the fixed channels.

60.3.17.1 Configuration of Channel-Dedicated Sample-and-Hold Circuit

(1) Configuration in single-ended input mode

This section describes the internal configuration when using channel-dedicated sample-and-hold circuit with single-ended inputs.
Figure 60.17 shows the configuration of channel-dedicated sample-and-hold circuit in single-ended input mode.
Channel-dedicated sample-and-hold circuits are connected to two analog input channels. When channel-dedicated sample-and-hold circuit is operating in Single-ended input mode, one of the two analogue inputs (ANx or ANy) is sampled and held in one scanning operation, and output to the A/D converter. The A/D conversion setting should be set to convert a single-ended input signal source. (ADCHCRn.AINMD = 0 (n = 0 to 49))
If you want to perform A/D conversion of both ANx and ANy with single-ended inputs while the channel-specific sample-and-hold circuit is enabled, ANx and ANy must be assigned to different scan groups for conversion.
If you want to assign ANx and ANy to the same scan group, A/D convert one by using the channel-dedicated sample-and-hold circuit and the other with the channel-dedicated sample-and-hold circuit bypassed.

Note m : The unit number of channel-dedicated sample-and-hold circuit
x : Even-numbered analog channel connected to the channel-dedicated sample-and-hold circuit
y : Odd-numbered analog channel connected to the channel-dedicated sample-and-hold circuit

Note 1. Turn on when the channel-dedicated sample-and-hold circuit is enabled and samples ANx or ANy channel.
Note 2. Turn on when the channel-dedicated sample-and-hold circuit is the holding state.
Note 3. Turn on when the A/D conversion (sampling state) of ANx, ANy or output of channel-dedicated sample-and-hold circuit.

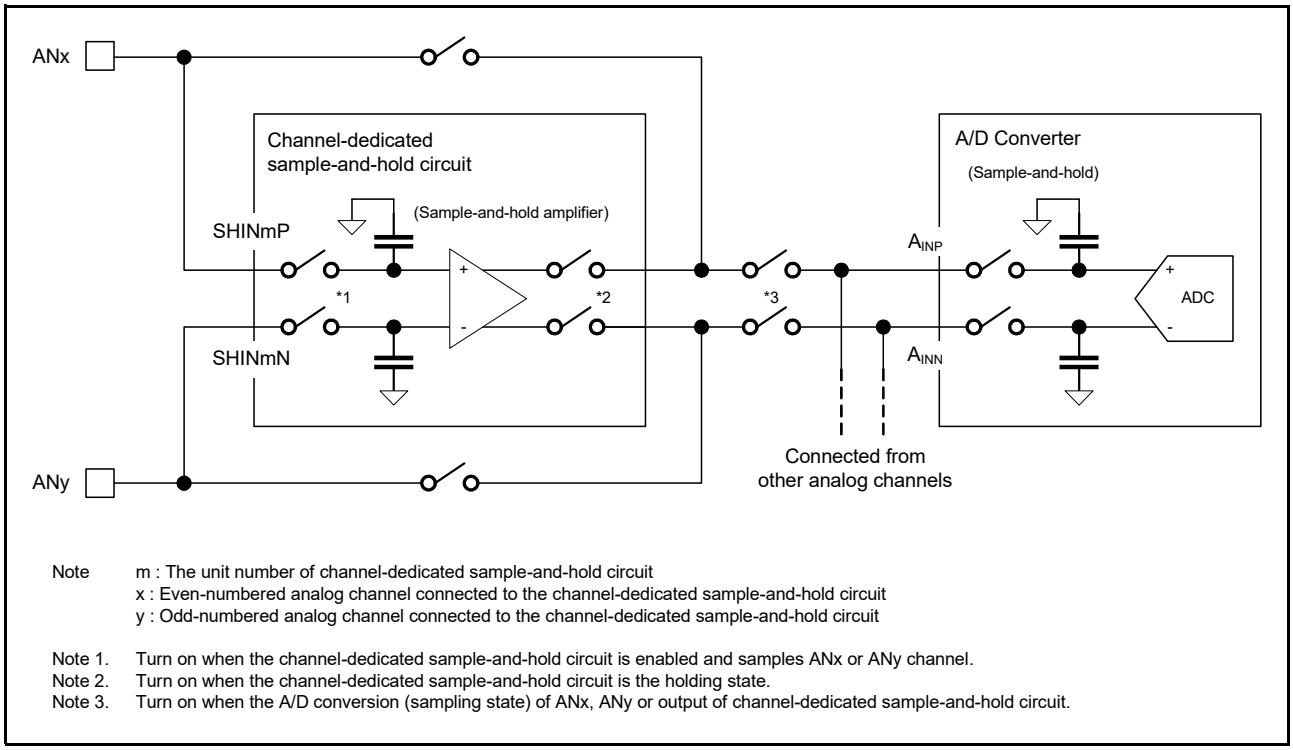


Figure 60.17 Internal Configuration of Channel-Dedicated Sample-and-Hold Circuit in Single-Ended Input Mode

(2) Configuration in differential input mode

This section describes the internal configuration when channel-dedicated sample-and-hold circuit is used with differential inputs.

Figure 60.18 shows the configuration of channel-dedicated sample-and-hold circuit in differential input mode.

When channel-dedicated sample-and-hold circuit is operating in differential input mode, the even analog channel is connected to the non-inverting input (+) (SHINmP) and the odd-numbered analog channel is connected to the inverting input (−) (SHINmN). Two analog inputs (differential input) are sampled and held in one scanning operation, and output to the A/D converter. The A/D conversion setting should be set to convert a differential input signal source. (ADCHCRn.AINMD = 1 (n = 0 to 49))

Note m : The unit number of channel-dedicated sample-and-hold circuit
x : Even-numbered analog channel connected to the channel-dedicated sample-and-hold circuit
y : Odd-numbered analog channel connected to the channel-dedicated sample-and-hold circuit

Note 1. Turn on when the channel-dedicated sample-and-hold circuit is enabled and samples ANx or ANy channel.
Note 2. Turn on when the channel-dedicated sample-and-hold circuit is the holding state.
Note 3. Turn on when the A/D conversion (sampling state) of ANx, ANy or output of channel-dedicated sample-and-hold circuit.

Figure 60.18 Internal Configuration of Channel-dedicated Sample-and-hold Circuit in Differential Input Mode

60.3.17.2 Operation in SAR Mode with Channel-Dedicated Sample-and-Hold Circuit

(1) Basic operation in SAR mode – Single scan mode (single-ended input mode)

This paragraph describes the basic operation of channel-dedicated sample-and-hold circuit in SAR mode. The configuration and behavior of example operation show in Table 60.24, Table 60.25 and Figure 60.19.

Table 60.24 Configuration of Example Operation for Channel-Dedicated Sample-and-Hold Circuit in SAR Mode – Single Scan Mode

Item	Configuration
A/D converter	Set ADC0 to SAR mode – single scan mode
Channel-dedicated sample-and-hold circuit	Set SH0 to SH2 to enabled and single-ended input mode. (AN000, AN002 and AN004 are subject to A/D conversion using channel-dedicated sample-and-hold circuit.)
Virtual channel*1	• Assign AN000, AN002, AN004 and AN006 to virtual channel 0 to 3, and set to Single-ended input mode.
Scan group*1	• Assign virtual channel 0 to 3 to scan group 0. • Set scan group 0 to convert with ADC0.

Note 1. When channel-dedicated sample-and-hold circuit is used, there are restrictions on the setting of virtual channels. For more details, see section 60.3.17.4, Restrictions on Channel-Dedicated Sample-and-Hold Circuit.

Table 60.25 Example Operation of Channel-Dedicated Sample-and-Hold Circuit in SAR Mode – Single Scan Mode

Step	Operation
1	The scanning operation of scan group 0 starts when a trigger for scan group 0 is input.
2	Channel-dedicated sample-and-hold circuit (SH0 to SH2) starts sampling the analog inputs (AN000, AN002, AN004) and holds them.
3	A/D conversion is performed on the voltages held by each channel-dedicated sample-and-hold circuit and on other analog input channels (AN006).
4	When A/D conversion of each channel completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
5	If scan end interrupt in scan group 0 is set to enabled, a scan end interrupt occurs.

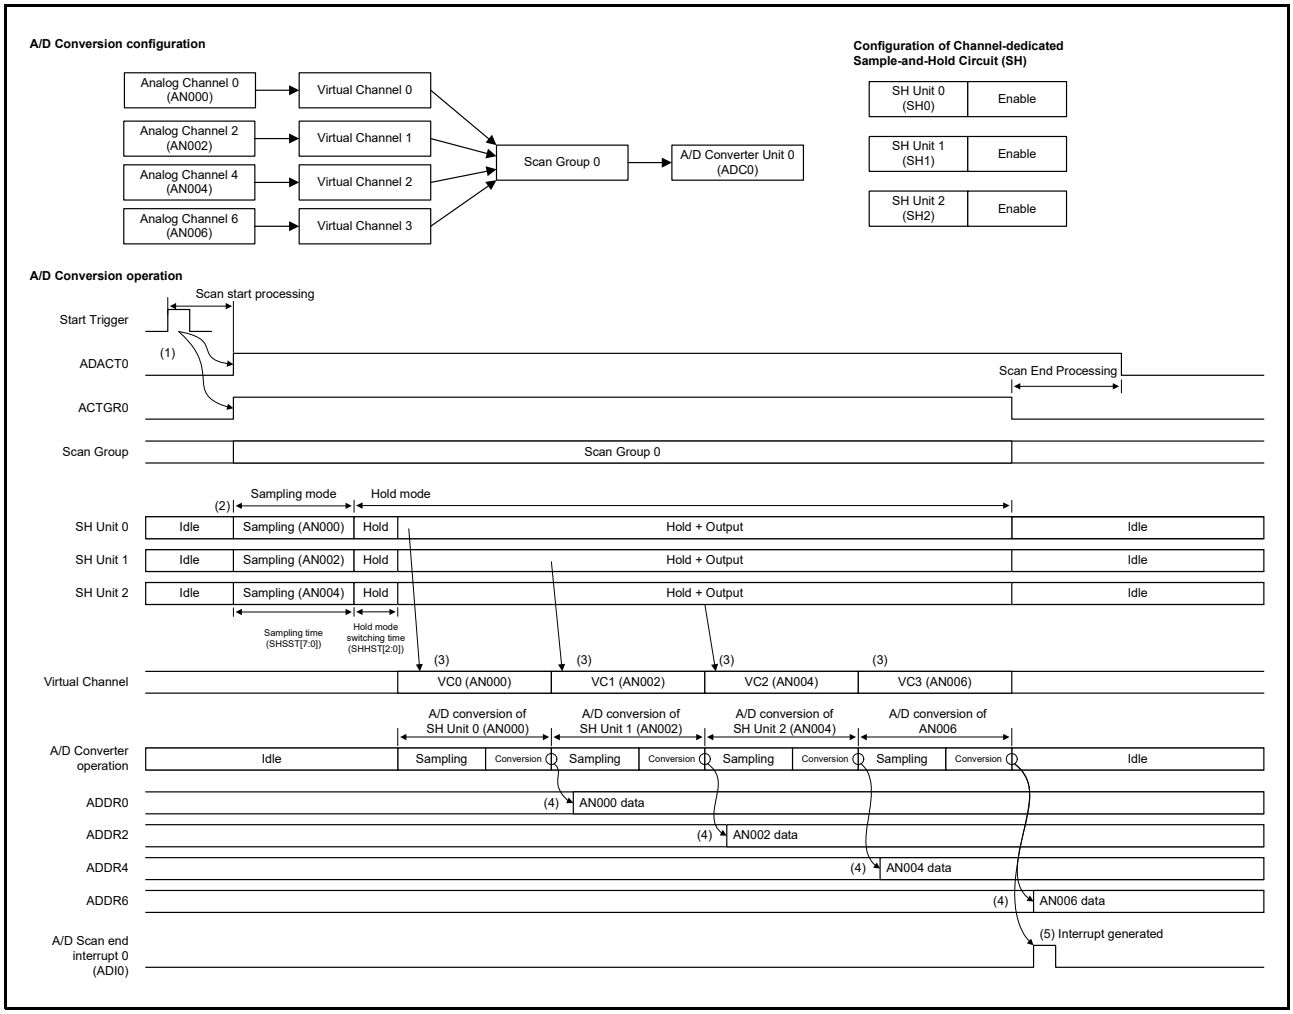

Figure 60.19 Basic Operation of Channel-Dedicated Sample-and-Hold Circuit in SAR Mode

(2) Advanced operation in SAR mode – Single scan mode

This paragraph describes the operation of A/D conversion that sharing one channel-dedicated sample-and-hold circuit between two analog channels. The operation shown in this paragraph is possible only when all of the following conditions are met.

[Operating Conditions]

- Operation mode: SAR mode – Single scan mode
- Input method: Single-ended input mode
- Others:

The following shows an example of A/D conversions of even-numbered analog channels and odd-numbered analog channels using channel-dedicated sample-and-hold circuit in SAR mode – single scan mode. The configuration example is shown in Table 60.26, and the operation detail is shown in Table 60.27 and Figure 60.20.

Table 60.26 Configuration Example of Advanced Operation for Channel-Dedicated Sample-and-Hold Circuit

Item	Configuration
A/D converter	Set ADC0 to SAR mode – single scan mode
Channel-dedicated sample-and-hold circuit	Set SH0 to SH2 to enabled and single-ended input mode. (AN000, AN002 and AN004 are subject to A/D conversion using channel-dedicated sample-and-hold circuit.)
Virtual channel*1	• Assign AN000, AN002 and AN004 to virtual channel 0 to 2, and set to single- ended input mode. • Assign AN001, AN003 and AN005 to virtual channel 3 to 5, and set to single- ended input mode.
Scan group*1	• Scan group 0: Assign AN000, AN002, AN004 (virtual channels 0 to 2). • Scan group 1: Assign AN001, AN003, AN005 (virtual channels 3 to 5). • Set scan group 0 and scan group 1 to convert with ADC0.

Note 1. When channel-dedicated sample-and-hold circuit is used, there are restrictions on the setting of virtual channels. For more details, see section 60.3.17.4, Restrictions on Channel-Dedicated Sample-and-Hold Circuit.

Table 60.27 Example Advanced Operation of Channel-Dedicated Sample-and-Hold Circuit

Step	Operation
1	The scanning operation of scan group 0 starts when a trigger for scan group 0 is input.
2	Channel-dedicated sample-and-hold circuit (SH0 to SH2) starts sampling the analog inputs (AN000, AN002, AN004) and holds them.
3	A/D conversion is performed on the voltages held by channel-dedicated sample-and-hold circuit.
4	When A/D conversion of each channel in scan group 0 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
5	If scan end interrupt in scan group 0 is set to enabled, a scan end interrupt occurs.
6	After scanning of scan group 0 is completed, the scanning operation of scan group 1 starts when a trigger for scan group 1 is input.
7	Channel-dedicated sample-and-hold circuit (SH0 to SH2) starts sampling the analog inputs (AN001, AN003, AN005) and holds them.
8	A/D conversion is performed on the voltages held by channel-dedicated sample-and-hold circuit.
9	When A/D conversion of each channel in scan group 1 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
10	If scan end interrupt for scan group 1 is set to enabled, a scan end interrupt occurs.

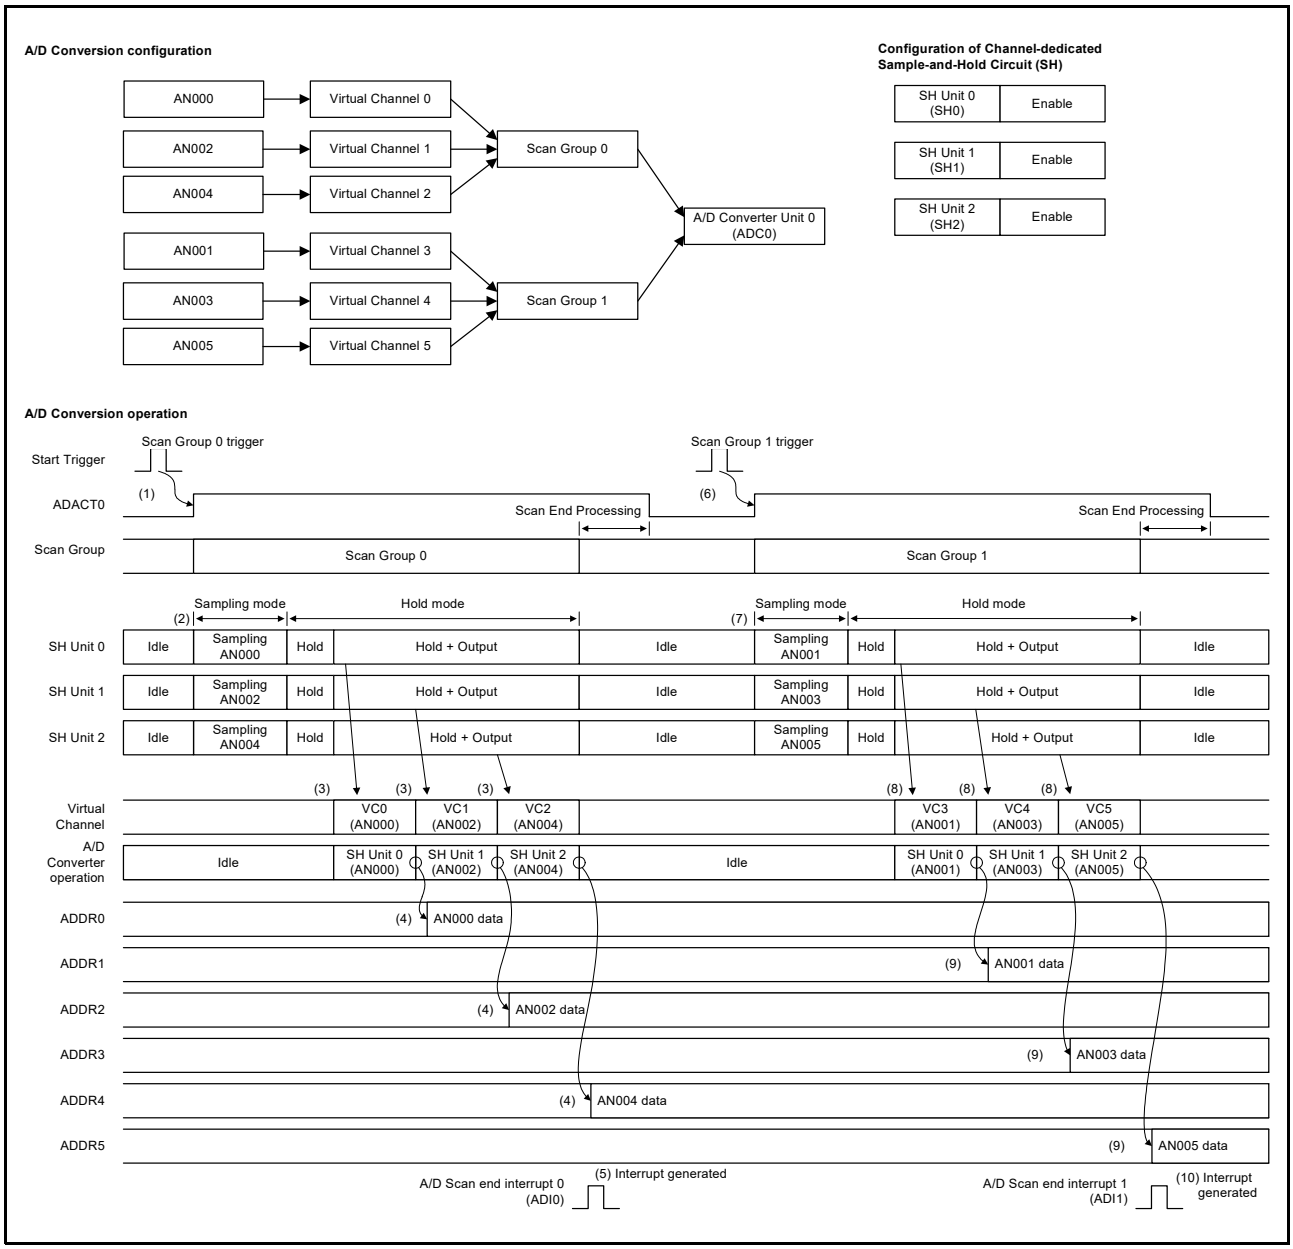

Figure 60.20 The Example Operation when Channel-Dedicated Sample-and-Hold Circuit is Shared with Two Analog Channels in SAR Mode

(3) Advanced operation 2 in SAR mode with single scan mode

The following passages describe the operation of A/D conversion when one of two analog channels is used with a channel-dedicated sample-and-hold circuit and the other bypasses the channel-dedicated sample-and-hold circuit. The operation shown in the passages is possible only when all of the following conditions are met.

[Operating Conditions]

- Operation mode: SAR mode – Single scan mode
- Input method: Single-ended input mode
- Other condition: Settings to use and to bypass the channel-dedicated sample-and-hold circuits in single-ended input mode (ADSHSBPCR.SHSBPn = 0, ADSHSBPCR.SHSBNn = 1 (n = 0 to 2))

The following tables and figure give an example of A/D conversion on even-numbered analog channels with the channel-dedicated sample-and-hold circuits in use and odd-numbered analog channels with the channel-dedicated sample-and-hold circuits bypassed in SAR mode with single scan mode. The steps for the example configuration are listed in Table 60.28, and details on the operation are given in Table 60.29 and Figure 60.21.

Table 60.28 Configuration Example of Advanced Operation for Channel-Dedicated Sample-and-Hold Circuit 2

Item	Configuration
A/D converter	Set ADC0 to SAR mode – single scan mode
Channel-dedicated sample-and-hold circuit	Set SH0 to SH2 to enabled and single-ended input mode. Make the settings to bypass the channel-dedicated sample-and-hold circuits in single-ended input mode for odd-numbered analog channels. (AN000, AN002, and AN004 signals are A/D converted with the channel-dedicated sample-and-hold circuits in use and AN001, AN003, and AN005 signals are A/D converted with the channel-dedicated sample-and-hold circuits bypassed.)
Virtual channel	• Assign AN000, AN002 and AN004 to virtual channel 0 to 2, and set to single- ended input mode. • Assign AN001, AN003 and AN005 to virtual channel 3 to 5, and set to single- ended input mode.
Scan group	• Scan group 0: Assign AN000, AN002, AN004, AN001, AN003, AN005 (virtual channels 0 to 5). • Set scan group 0 to convert with ADC0.

Table 60.29 Example Advanced Operation of Channel-Dedicated Sample-and-Hold Circuit 2

Step	Operation
1	The scanning operation of scan group 0 starts when a trigger for scan group 0 is input.
2	Channel-dedicated sample-and-hold circuit (SH0 to SH2) starts sampling the analog inputs (AN000, AN002, AN004) and holds them.
3	A/D conversion is performed on the voltages held by channel-dedicated sample-and-hold circuit.
4	Sampling of the odd-numbered analog inputs (AN001, AN003, AN005) is started and A/D conversion then proceeds.
5	When A/D conversion of each channel in scan group 0 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
6	If scan end interrupt in scan group 0 is set to enabled, a scan end interrupt occurs.

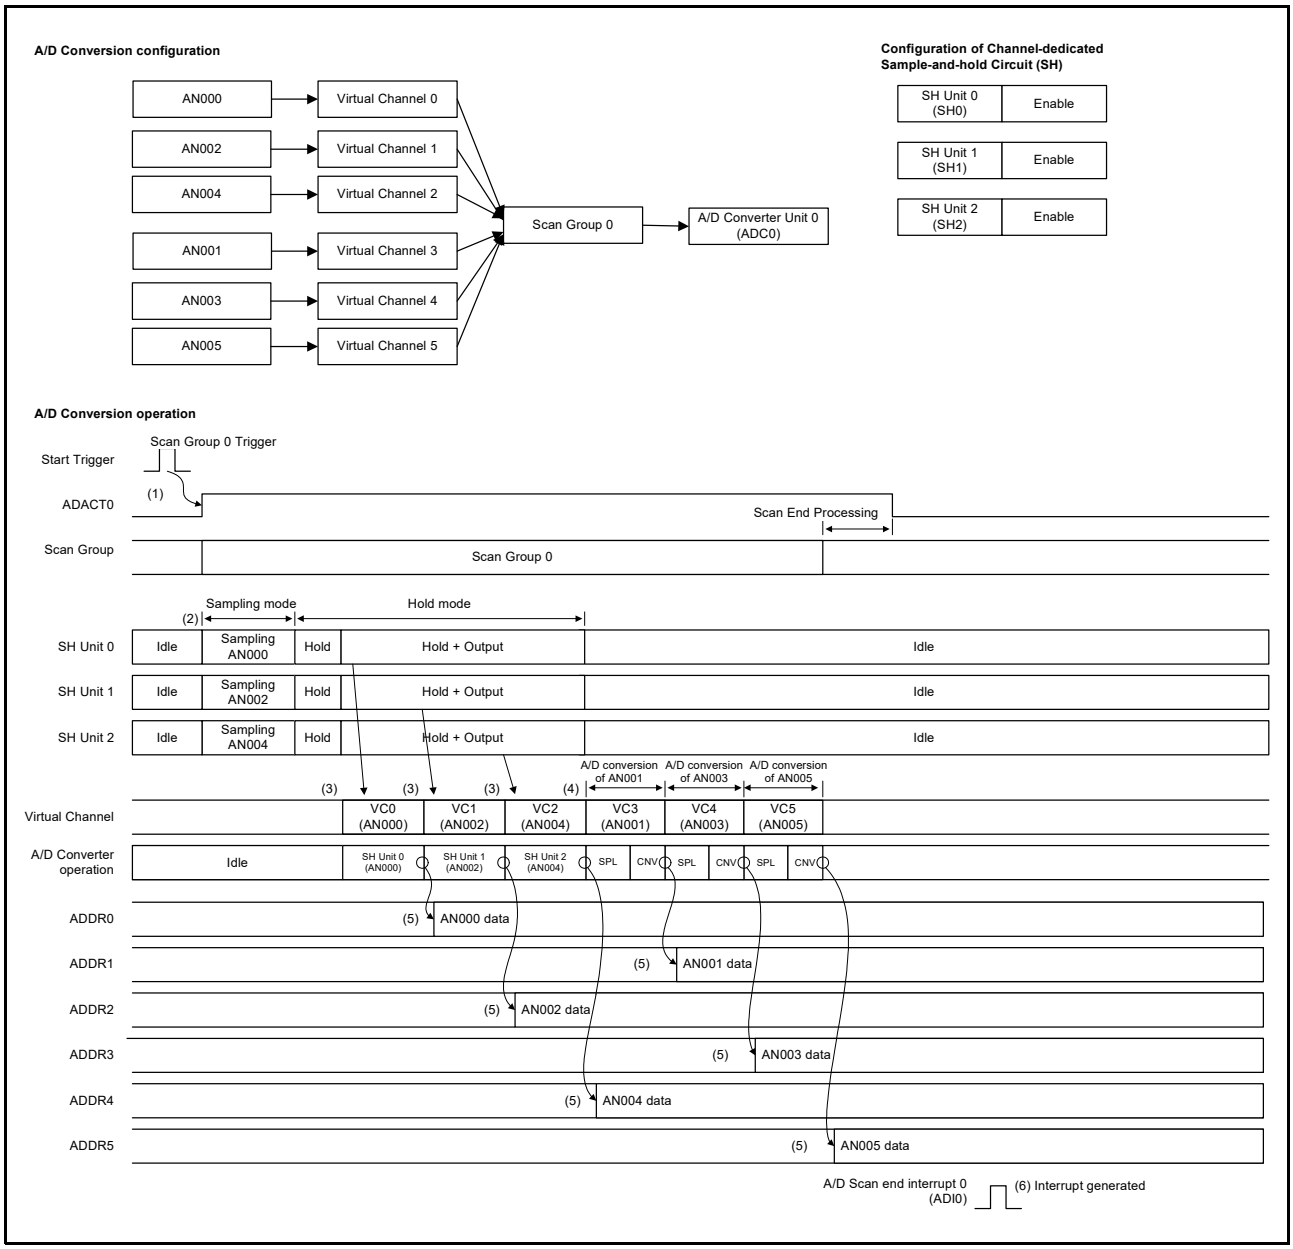

Figure 60.21 Example of A/D Conversion Operations in SAR Mode When the Channel-Dedicated Sample-and-Hold Circuits are Used with the Even-Numbered Analog Channels but Bypassed for the Odd-Numbered Analog Channels

(4) SAR mode (with constant sampling enabled)

When the constant sampling function is enabled, the channel-dedicated sample-and-hold circuits start sampling before A/D conversion proceeds. The circuits simultaneously proceed with sampling on multiple channels, so the results of A/D conversion are for voltages that were captured at the same time.
When the constant sampling function is in use, the channel-dedicated sample-and-hold circuits are assigned to the virtual channels specified for use in conversion. Only the settings listed in Table 60.30 are specifiable.

Table 60.30 Virtual Channel Numbers Which Should be Assigned as the Individual Fixed Channels

Item	Configuration
Channel-dedicated sample-and-hold circuit 0	Virtual channel 0
Channel-dedicated sample-and-hold circuit 1	Virtual channel 1
Channel-dedicated sample-and-hold circuit 2	Virtual channel 2

A comparison of operations with the constant sampling function enabled and disabled is given in Figure 60.22.

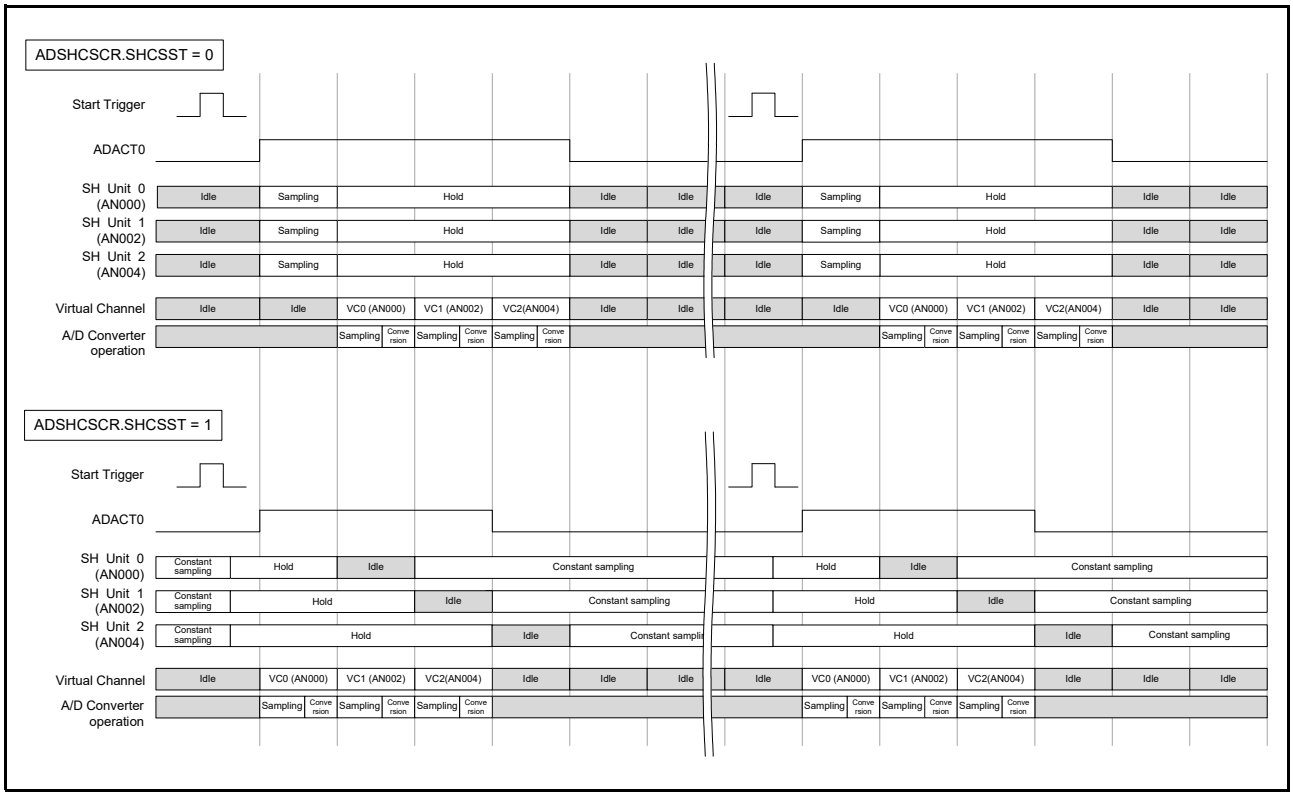

Figure 60.22 Comparison of Operations with the Constant Sampling Function Disabled (SHCSST = 0) and Enabled (SHCSST = 1)

The steps in an example of making the settings for operation are listed in Table 60.31, and an example of operation is given in Table 60.32 and Figure 60.23.

Table 60.31 Example of Making the Settings for Operation with the Constant Sampling Function Enabled

Item	Configuration
A/D converter	Set ADC0 to SAR mode – single scan mode
Channel-dedicated sample-and-hold circuit	Set SH0 to SH2 to enabled and single-ended input mode. (AN000, AN002 and AN004 are subject to A/D conversion using channel-dedicated sample-and-hold circuit.) Enable constant sampling of SH0 to SH2.
Virtual channel*1	• Assign AN000, AN002 and AN004 to virtual channel 0 to 2, and set to Single-ended input mode.
Scan group*1	• Assign virtual channel 0 to 2 to scan group 0. • Set scan group 0 to convert with ADC0.

Note 1. When channel-dedicated sample-and-hold circuit is used, there are restrictions on the setting of virtual channels. For more details, see section 60.3.17.4, Restrictions on Channel-Dedicated Sample-and-Hold Circuit.

Table 60.32 Example of Operation with the Constant Sampling Function Enabled

Step	Operation
1	Setting the SHCSST0 to SHCSST2 bits in the ADSHCSCR register to 1 starts constant sampling by the channel-dedicated sample-and-hold circuits (SH0 to SH2).
2	When a trigger for scan group 0 is input, holding of analog input voltages on the AN000, AN002, and AN004 pins starts.
3	After the stabilization time of the channel-dedicated sample and hold circuit has elapsed, A/D conversion is performed on the voltage held by the channel-dedicated sample and hold circuit.
4	When A/D conversion of each channel completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn). The channel-specific sample-and-hold circuitry resumes full-time sampling after an idle period.
5	If scan end interrupt in scan group 0 is set to enabled, a scan end interrupt occurs.
6	Setting the SHCSST0 to SHCSST2 bits in the ADSHCSCR register to 0 stops constant sampling by the channel-dedicated sample-and-hold circuits (SH0 to SH2).

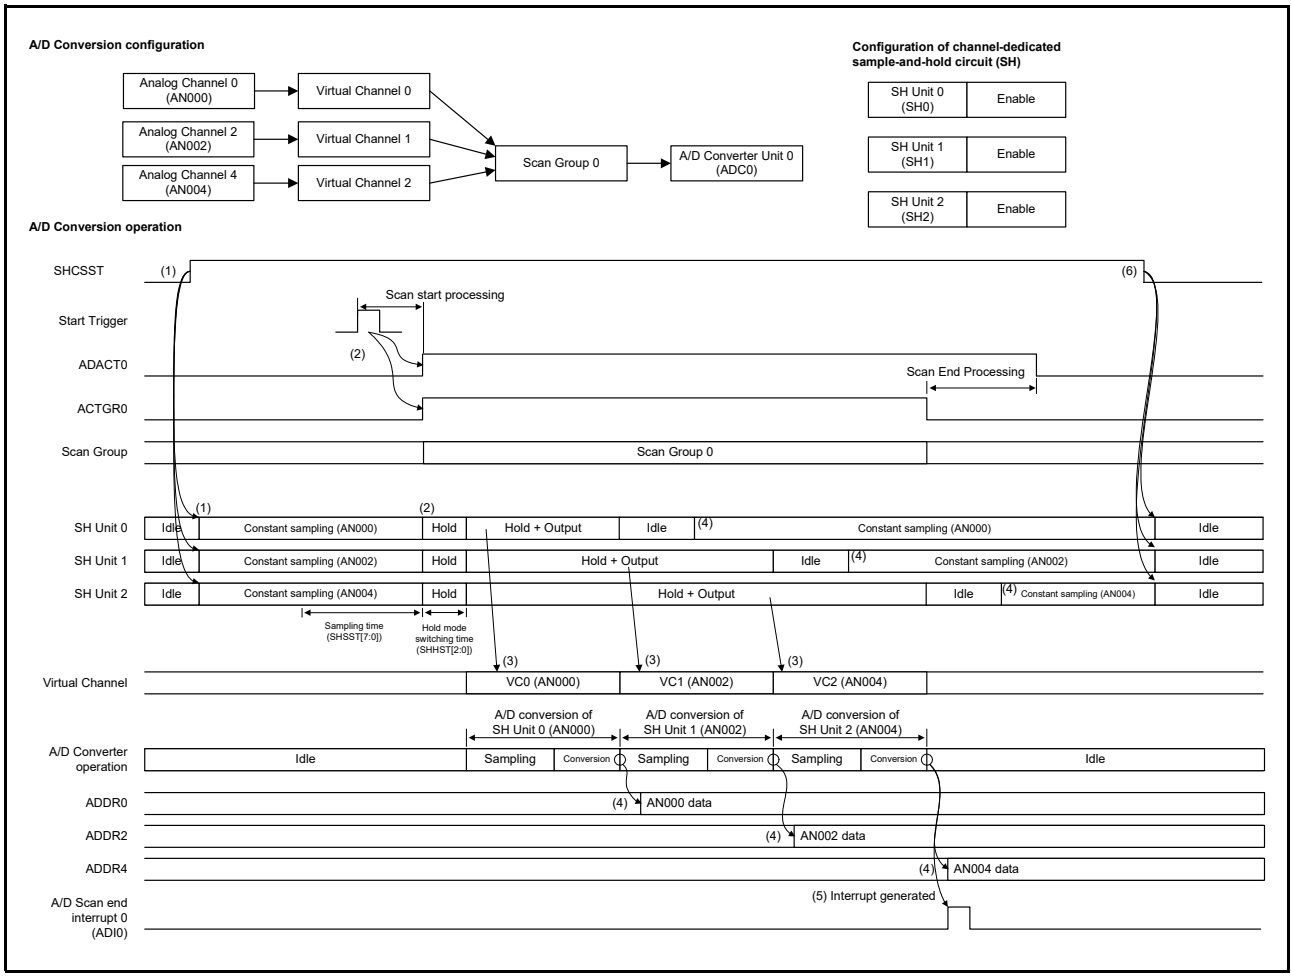

Figure 60.23 Constant Sampling Operation in SAR Mode

(5) Advanced operation (in differential input mode) with the disconnection detection assist function in use in SAR mode

When the differential input mode is selected for the channel-dedicated sample-and-hold circuits, using the differential bypass function allows the detection of disconnection by the disconnection detection assist function of the A/D converter (in single-ended input mode). This is intended to avoid the complicated self-calibration operations required in changing the channel-dedicated sample-and-hold circuits from differential input mode to single-ended input mode because the disconnection detection assist function is only supported in single-ended input mode.

The table below lists the steps in an example of making the settings for operation. In this example, A/D conversion with the use of the channel-dedicated sample-and-hold circuit proceeds in differential input mode in scan group 0, and the disconnection detection assist function is then executed in scan group 1 without changing the input mode.

Table 60.33 Example of Settings for Using the Disconnection Detection Assist Function of the A/D Converter with the Channel-Dedicated Sample-and-Hold Circuit (in Differential Input Mode)

Item	Configuration
A/D converter	Set ADC0 to SAR mode – single scan mode
Channel-dedicated sample-and-hold circuit	Set SH0 to enabled and differential input mode. (AN000 and AN001 are subject to A/D conversion using channel-dedicated sample-and-hold circuit.)
Virtual channel	• Assign AN000 to virtual channel 0, and set to differential input mode. (This will function AN000 as the non-inverting inputs (+) of the differential input, and AN001 as the inverting inputs (–) of the differential input.) • Assign AN000 and AN001 to virtual channel 1, 2, and set to Single-ended input mode.
Scan group	• Scan group 0: Virtual channel 0 • Scan group 1: Virtual channel 1, 2 • Make the settings to use ADC0 for A/D conversion of scan groups 0 and 1. • Scan group 0: Make the setting to use the channel-dedicated sample-and-hold circuits (ADSHDBPCR.SHDBP0 = 0) • Scan group 1: Make the setting to bypass the channel-dedicated sample-and-hold circuits (ADSHDBPCR.SHDBP1 = 1) • Scan group 1: Enable the disconnection detection assist function.

60.3.17.3 Operation in Hybrid Mode with Channel-Dedicated Sample-and-Hold Circuit

(1) Basic operation in hybrid mode – Single scan mode

This paragraph shows the basic operation of channel-dedicated sample-and-hold circuit in hybrid mode – single scan mode. Since differential input mode is supported in hybrid mode, this example describes a case that channel-dedicated sample-and-hold circuits are set to differential input mode. The configuration and behavior of example operation show in Table 60.34, Table 60.35 and Figure 60.24.

Table 60.34 Configuration of Example Operation for Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Single Scan Mode

Item	Configuration
A/D converter	Set ADC0 to hybrid mode – single scan mode
Channel-dedicated sample-and-hold circuit	Set SH0 to SH2 to enabled and differential input mode. (AN000 to AN005 are subject to A/D conversion using channel-dedicated sample-and-hold circuit.)
Virtual channel*1	• Assign AN000, AN002 and AN004 to virtual channel 0 to 2, and set to differential input mode. (This will function AN000, AN002 and AN004 as the non-inverting inputs (+) of the differential input, and AN001, AN003, and AN005 as the inverting inputs (–) of the differential input.)
Scan group*1	• Assign virtual channel 0 to 3 to scan group 0. • Set scan group 0 to convert with ADC0.

Note 1. When channel-dedicated sample-and-hold circuit is used, there are restrictions on the setting of virtual channels. For more details, see section 60.3.17.4, Restrictions on Channel-Dedicated Sample-and-Hold Circuit.

Table 60.35 Example Operation of Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Single Scan Mode

Step	Operation
1	The scanning operation of scan group 0 starts when a trigger for scan group 0 is input.
2	Channel-dedicated sample-and-hold circuit (SH0 to SH2) starts sampling the analog inputs (AN000, AN002, AN004) and holds them.
3	The A/D converter performs oversampling once for each output of channel-dedicated sample-and-hold circuit (SH0 to SH2).
4	After one oversampling for each analog channel, channel-dedicated sample-and-hold circuit releases the held voltage and enters the idle state.
5	Step 2 to 4 is repeated until oversampling corresponding to the number of TAPs of the digital filter and the number of A/D-converted value addition/average times is performed for each analog channel.
6	A/D conversion data corresponding to each analog channel is output. The A/D conversion data is stored in the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO is used, A/D conversion data is also stored in FIFO data register (ADFIFODRk (k = 0 to 11)).
7	If the scan end interrupt is enabled, the scan end interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
8	A/D converter and channel-dedicated sample-and-hold circuit enter the idle state when scanning operation is completed. The oversampling data in digital filter are discarded at the end of the scanning operation.

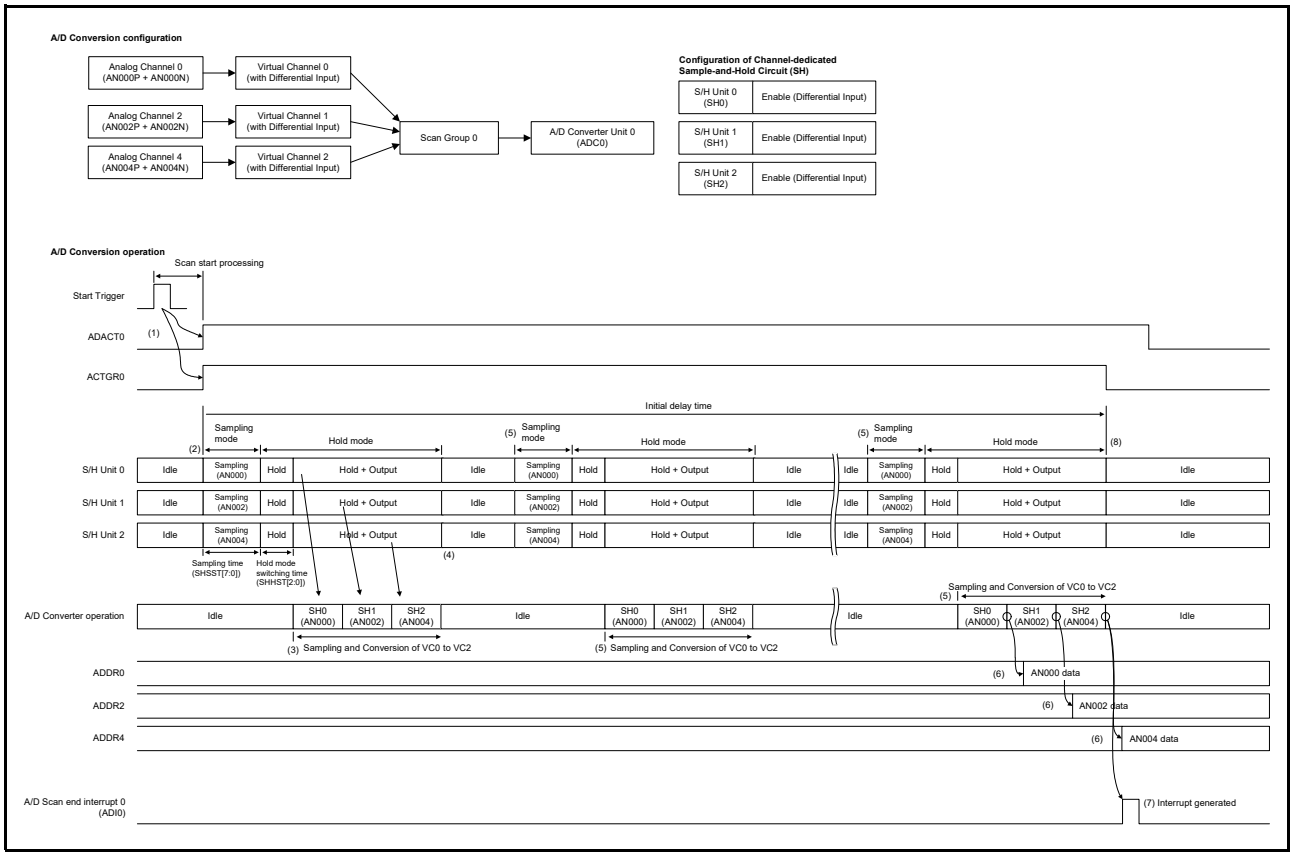

Figure 60.24 Basic Operation of Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Single Scan Mode

(2) Basic operation in hybrid mode – Continuous scan mode

This paragraph shows the basic operation of channel-dedicated sample-and-hold circuit in hybrid mode – continuous scan mode. Since differential input mode is supported in hybrid mode, this example describes a case that channel-dedicated sample-and-hold circuits are set to differential input mode. The configuration and behavior of example operation show in Table 60.36, Table 60.37 and Figure 60.25.

Table 60.36 Example Operation Setting of Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Continuous Scan Mode

Item	Configuration
A/D converter	Set ADC0 to hybrid mode – continuous scan mode
Channel-dedicated sample-and-hold circuit	Set SH0 to SH2 to enabled and differential input mode. (AN000 to AN005 are subject to A/D conversion using channel-dedicated sample-and-hold circuit.)
Virtual channel*1	• Assign AN000, AN002 and AN004 to virtual channel 0 to 2, and set to differential input mode. (This will function AN000, AN002 and AN004 as the non-inverting inputs (+) of the differential input, and AN001, AN003, and AN005 as the inverting inputs (–) of the differential input.)
Scan group*1	• Assign virtual channel 0 to 3 to scan group 0. • Set scan group 0 to convert with ADC0.

Note 1. When channel-dedicated sample-and-hold circuit is used, there are restrictions on the setting of virtual channels. For more details, see section 60.3.17.4, Restrictions on Channel-Dedicated Sample-and-Hold Circuit.

Table 60.37 Example Operation of Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Continuous Scan Mode

Step	Operation
1	The scanning operation of scan group 0 starts when a trigger for scan group 0 is input.
2	Channel-dedicated sample-and-hold circuit (SH0 to SH2) starts sampling the analog inputs (AN000, AN002, AN004) and holds them.
3	The A/D converter performs oversampling once for each output of channel-dedicated sample-and-hold circuit (SH0 to SH2).
4	After one oversampling for each analog channel, channel-dedicated sample-and-hold circuit releases the held voltage and enters the idle state.
5	Step 2 to 4 is repeated until oversampling corresponding to the number of TAPs of the digital filter and the number of A/D-converted value addition/average times is performed for each analog channel.
6	A/D conversion data corresponding to each analog channel is output. The A/D conversion data is stored in the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO is used, A/D conversion data is also stored in FIFO data register (ADFIFODRk (k = 0 to 11)).
7	If the scan end interrupt is enabled, the scan end interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
8	The second and subsequent rounds of scanning operations repeat the operation of Step 2 to 4, retaining the oversampling data stored in the digital filter. Each one time oversampling or each multiple times oversampling corresponding to the number of A/D-converted value addition/averaging times is performed for each analog channel, the next A/D conversion data is output. The A/D conversion data is stored in the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). If FIFO is used, A/D conversion data is also stored in FIFO data register (ADFIFODRk (k = 0 to 11)).
9	If the scan end interrupt is enabled, the scan end interrupt corresponding to that scan group is generated when the A/D conversion of all virtual channels assigned to that scan group is completed.
10	Thereafter, until the forcibly stop process is performed, Step 8 to 9 are repeated, and the scanning operation continues. To perform the forcibly stop, follow to section 60.5.4, Force Stops the A/D Conversion Operation. If scanning operation is aborted by the forcibly stop process, A/D converter and channel-dedicated sample-and-hold circuit enter the idle state. The oversampling data in digital filter are discarded at the end of the scanning operation.

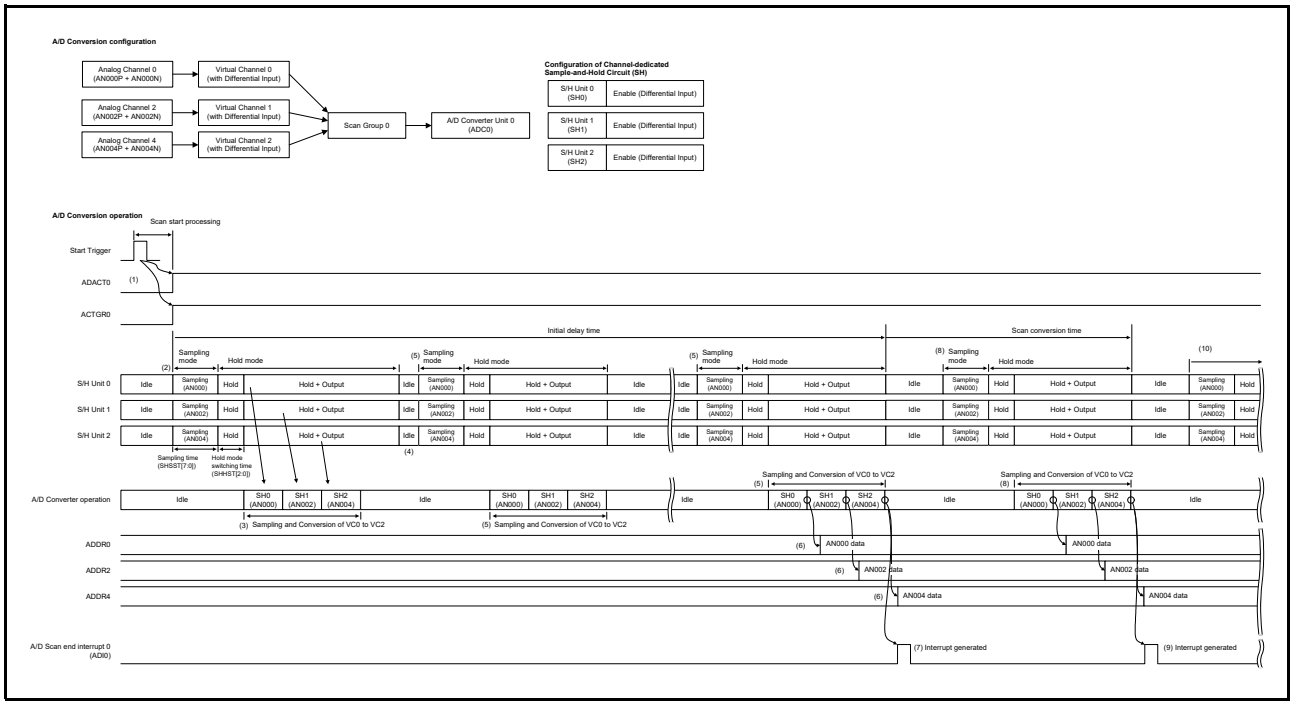

Figure 60.25 Basic Operation of Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Continuous Scan Mode

(3) Basic operation in hybrid mode – Background continuous scan mode

This paragraph shows the basic operation of channel-dedicated sample-and-hold circuit in hybrid mode – background continuous scan mode. Since differential input mode is supported in hybrid mode, this example describes a case that channel-dedicated sample-and-hold circuits are set to differential input mode. The configuration and behavior of example operation show in Table 60.38, Table 60.39 and Figure 60.26.

Table 60.38 Configuration of Example Operation for Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Background Continuous Scan Mode

Item	Configuration
A/D converter	Set ADC0 to hybrid mode – Background continuous scan mode
Channel-dedicated sample-and-hold circuit	Set SH0 to SH2 to enabled and differential input mode. (AN000 to AN005 are subject to A/D conversion using channel-dedicated sample-and-hold circuit.)
Virtual channel*1	• Assign AN000, AN002 and AN004 to virtual channel 0 to 2, and set to differential input mode. (This will function AN000, AN002 and AN004 as the non-inverting inputs (+) of the differential input, and AN001, AN003, and AN005 as the inverting inputs (–) of the differential input.)
Scan group*1	• Assign virtual channel 0 to 3 to scan group 0. • Set scan group 0 to convert with ADC0.

Note 1. When channel-dedicated sample-and-hold circuit is used, there are restrictions on the setting of virtual channels. For more details, see section 60.3.17.4, Restrictions on Channel-Dedicated Sample-and-Hold Circuit.

Table 60.39 Example Operation of Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Background Continuous Scan Mode

Step	Operation
1	The scanning operation of scan group 0 starts when a trigger for scan group 0 is input.
2	Channel-dedicated sample-and-hold circuit (SH0 to SH2) starts sampling the analog inputs (AN000, AN002, AN004) and holds them.
3	The A/D converter performs oversampling once for each output of channel-dedicated sample-and-hold circuit (SH0 to SH2) .
4	After one oversampling for each analog channel, channel-dedicated sample-and-hold circuit releases the held voltage and enters the idle state.
5	Step 2 to 4 is repeated. After the oversampling corresponding to the number of TAPs of the digital filter and the number of A/D-converted value addition/averaging times is performed to each analog channel, first A/D conversion data becomes in ready to be output. Step 2 to 4 is repeated until oversampling corresponding to the number of TAPs of the digital filter and the number of A/D-converted value addition/average times is performed for each analog channel.
6	The second and subsequent rounds of scanning operations repeat the operation of Step 2 to 4, retaining the oversampling data stored in the digital filter. Each time oversampling is performed for each analog channel, the data in the digital filter is updated. Each one time oversampling or each multiple times oversampling corresponding to the number of A/D-converted value addition/averaging times is performed for each analog channel, the next A/D conversion data becomes in ready to be output.
7	When an A/D conversion start trigger is input during background continuous scanning operation, the most recent A/D conversion data at that time is stored in the data register (ADDRi (i = 0 to 35), ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)). When FIFO function is set to enabled, A/D conversion data is also stored in the FIFO data register (ADFIFODRk (k = 0 to 11)). Also, if scan end interrupt is set to enable, scan end interrupt is generated. If FIFO interrupt is set to enable, FIFO data read request is generated when the condition for generating it is met.
8	Thereafter, until the forcibly stop process is performed, background continuous scanning operation (Step 6) is repeated. And whenever the A/D conversion start trigger is input during background continuous scanning operation, the A/D conversion data is output (Step 7). To perform the forcibly stop, follow to section 60.5.4, Force Stops the A/D Conversion Operation. If scanning operation is aborted by the forcibly stop process, A/D converter and channel-dedicated sample-and-hold circuit enter the idle state. The oversampling data in digital filter are discarded at the end of the scanning operation.

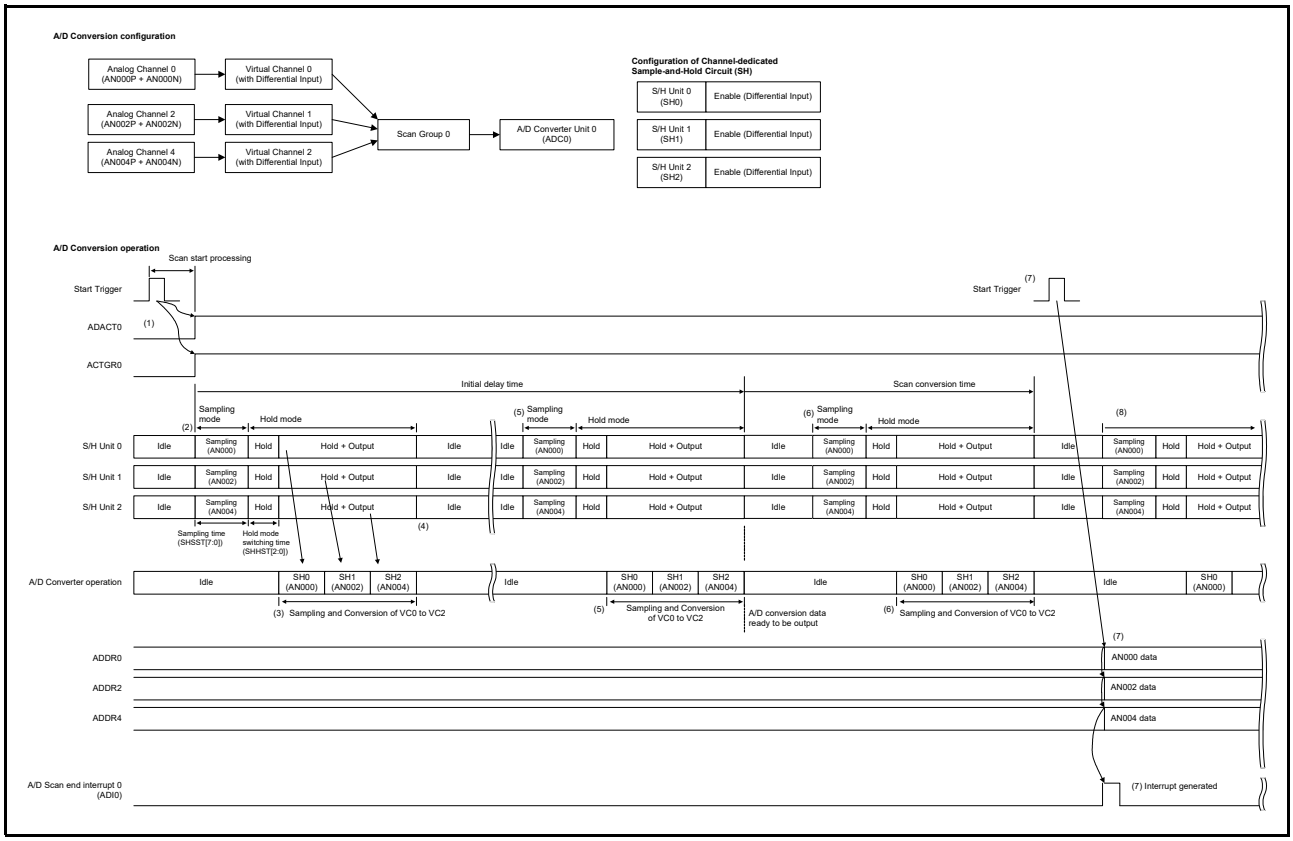

Figure 60.26 Basic Operation of Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Background Continuous Scan Mode

(4) Basic operation in hybrid mode with fixed channels continuous scan mode

The following passages describe the basic operation of the channel-dedicated sample-and-hold circuits in hybrid mode with fixed channels continuous scan mode. The steps in an example of making the settings for operation are listed in Table 60.40 and an example of operation is given in Table 60.41. This mode can only be used under the following conditions: the number of fixed channels is three and use of the channel-dedicated sample-and-hold circuits is only specified for the fixed channels.

Table 60.40 Configuration of Example Operation for Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Fixed Channels Continuous Scan Mode

Item	Configuration
A/D converter	Set ADC0 to hybrid mode – Fixed channels continuous scan mode
Channel-dedicated sample-and-hold circuit	Set SH0 to SH2 to enabled and differential input mode. (AN000 to AN005 are subject to A/D conversion using channel-dedicated sample-and-hold circuit.)
Virtual channel*1	• Assign AN000, AN002 and AN004 to virtual channel 0 to 2, and set to differential input mode. (This will function AN000, AN002 and AN004 as the non-inverting inputs (+) of the differential input, and AN001, AN003, and AN005 as the inverting inputs (–) of the differential input.)
Scan group*1	• Assign virtual channel 0 to 3 to scan group 0. • Set scan group 0 to convert with ADC0.

Note 1. When channel-dedicated sample-and-hold circuit is used, there are restrictions on the setting of virtual channels. For more details, see section 60.3.17.4, Restrictions on Channel-Dedicated Sample-and-Hold Circuit.

Table 60.41 Example Operation of Channel-Dedicated Sample-and-Hold Circuit in Hybrid Mode – Fixed Channels Continuous Scan Mode

Step	Operation
1	When a software trigger or a trigger from a peripheral module is input, the scanning operation of the scan group corresponding to the trigger is started.
2	The three channel-dedicated sample-and-hold circuits (SH0 to SH2) specified as the fixed channels start sampling the analog inputs (AN000, AN002, AN004) and hold the voltages on those pins.
3	The output signals of the channel-dedicated sample-and-hold circuits (SH0 to SH2) are A/D converted in hybrid mode.
4	A/D conversion in SAR mode proceeds on one non-fixed channel. The non-fixed channel for conversion is selected from among the virtual channels assigned to the given scan group in ascending order of the channel number.
5	After A/D conversion on the three fixed channels and a single non-fixed channel, the channel-dedicated sample-and-hold circuits release the held voltages and enter the idle state.
6	Every time A/D conversion on a single analog channel is completed, the result of A/D conversion is stored in an A/D data register i (ADDRi (i = 0 to 35)) or A/D extended analog data register j (ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to18)). When the FIFO function is in use, the result of A/D conversion is also stored in a FIFO data register k (ADFIFODRk (k = 0 to 11)).
7	If the scan end interrupt is enabled, the scan end interrupt for the given scan group is generated after the period for the round of scanning.
8	The period until the end of the round of scanning also includes the times for conversion on idle channels.
9	Until the A/D conversion stop processing proceeds, steps 2 to 6 are repeated, and the scanning operation continues. Specifically, A/D conversion is repeated on the same fixed channels and on one non-fixed channel, which is selected from among those assigned to the given scan group in ascending order of the channel number. When the last channel number is reached, the target for conversion of a non-fixed channel returns to the first channel and this operation is repeated. To stop the A/D conversion, follow the procedure shown in section 60.5.4, Force Stops the A/D Conversion Operation.

60.3.17.4 Restrictions on Channel-Dedicated Sample-and-Hold Circuit

When using channel-dedicated sample-and-hold circuit, observe the following restrictions:

(1) Limitations on usage of channel-dedicated sample-and-hold circuit

Channel-dedicated sample-and-hold circuit is only available in the following:

- SAR mode – Single scan mode
- Hybrid mode – Single scan mode
- Hybrid mode – Continuous scan mode
- Hybrid mode – Background continuous scan mode
- Hybrid mode – Fixed channels continuous scan mode*1

In the operation mode other than above, channel-dedicated sample-and-hold circuit is prohibited.

Set the sampling time of the channel-dedicated sample-and-hold circuit to at least 3.5 times the sum of the following times:

- Hold mode switching time
- Sampling times of the A/D converter units that use the channel-dedicated sample-and-hold circuits in the same scan group
- A/D successive approximation times set for the virtual channel numbers to which the channel-dedicated sample-and-hold circuits are assigned

This relationship is expressed by the following equation:

$$ADSHSTR0.SHSST[7:0] \geq (ADSHSTR0.SHHST[2:0] + \Sigma_{i=1}^{n} ADSSTRx.SSTy[9:0] + \Sigma_{i=1}^{n-1} ADCNVSTR.CSTm[5:0]\ ) \times 3.5$$

(x = 0 to 7, y = 0 to 15, m = 0 to 2, i: Number of rounds of A/D conversion on the virtual channels that use the channel-dedicated sample-and-hold circuits in the same scan group (1 to n))

Note 1. Only fixed channels are supported when fixed channels are set to 3 channels and all fixed channels enable channel dedicated sample-and-hold circuit. Non-fixed channels cannot use channel-dedicated sample-and-hold circuit.

(2) Restrictions on self-calibration operation of channel-dedicated sample-and-hold circuit

Self-calibration operation is required when channel-dedicated sample-and-hold circuit is used. For more details on self-calibration procedures for channel-dedicated sample-and-hold circuit and the restrictions on it, see section 60.3.9, Self-Calibration.

(3) Restrictions on assigning virtual channels and scan groups

For analog channels using channel-dedicated sample-and-hold circuit, assign them to virtual channels so that A/D conversion is performed at the front of the scan group. Specifically, assign an analog channel that uses channel-dedicated sample-and-hold circuit from the virtual channel that has the smallest virtual channel number among the virtual channels assigned to that scan group. (Assign the analog channels of channel-dedicated sample-and-hold circuit to the front virtual channels in ascending order of the virtual channel number.)
If this restriction is violated, the operation of channel-dedicated sample-and-hold circuit and A/D converter is not guaranteed.

(4) Prohibition of multiple assignments of channels using the same channel-dedicated sample-and-hold circuit in the same scan group

It is prohibited to assign more than one virtual channel that uses the same channel-dedicated sample-and-hold circuit to a single scan group. Specific restrictions are the followings:

[Restrictions]

- When not using the bypass function, the virtual channel whose signal source is selected as the even-numbered analog channel connected to channel- dedicated sample-and-hold circuit and the virtual channel whose signal source is selected as the odd-numbered analog channel must not be assigned to the same scan group.
- It is prohibited to assign the even-numbered analog channels or odd-numbered analog channels connected to channel- dedicated sample-and-hold circuit to multiple virtual channels, and assign them to the same scan group.

Operation is not guaranteed if this restriction is violated.
To avoid this restriction, assign virtual channels that use the same channel-dedicated sample-and-hold circuit to separate scan groups. This restriction can be avoided by preventing A/D conversion from occurring more than once for the same channel-dedicated sample-and-hold circuit during one scanning operation. For the example workaround for this restriction, see (2) Advanced operation in SAR mode – Single scan mode in section 60.3.17.2, Operation in SAR Mode with Channel-Dedicated Sample-and-Hold Circuit in SAR Mode.

(5) Restriction on the differential bypass function

When a scan group uses the channel-dedicated sample-and-hold circuits with the use of differential bypass inputs, the disconnection detection assist function and constant sampling function for use with the channel-dedicated sample-and-hold circuits cannot be used in any of the channel-dedicated sample-and-hold circuits, including in cases where they are in use by another scan group.

(6) Restrictions on group priority operation

Only a scan group with the highest priority can use the channel-dedicated sample-and-hold circuits in group priority operation.

(7) Restrictions on the constant sampling function

The constant sampling function can only be used in SAR mode with single scan mode.
Set the constant sampling function after self-calibration and before A/D conversion.
The constant sampling function is only available for the virtual channels listed in Table 60.30.
Set the sampling time of the channel-dedicated sample-and-hold circuit which uses the constant sampling function as follows.

- When synchronization between units is disabled:
  ADSHSTR0.SHSST[7:0] = 04h (initial value)
- When synchronization between units is enabled:
  Set the sampling time and hold mode switching time of the channel-dedicated sample-and-hold circuit so that the sum of the two is equal to the synchronous operation period. In addition, set the synchronous operation period to at least 6 cycles of ADCLK, which is the minimum value of sum of the sampling time and hold mode switching time.
  ADSHSTR0.SHSST[7:0] + ADSHSTR0.SHHST[2:0] = ADSYCR.ADSYCYC[7:0]
  ADSYCR.ADSYCYC[7:0] ≥ 6 ADCLK

When the constant sampling function is to be used, the sampling period of the channel-dedicated sample-and-hold circuit is from completion of conversion of the signal from a channel-dedicated sample-and-hold circuit until conversion of the next signal from the channel-dedicated sample-and-hold circuit starts. Therefore, in cases of the input of successive conversion start triggers, secure sufficient intervals between the triggers to ensure that the sampling period of the channel-dedicated sample-and-hold circuit is secured.

(8) Restriction on hybrid mode with fixed channels continuous scan mode

The fixed channels continuous scan mode for the channel-dedicated sample-and-hold circuits can only be used under the following conditions: the number of fixed channels is three and use of the channel-dedicated sample-and-hold circuits is only specified for the fixed channels.

60.3.18 Disconnection Detection Assist Function

The disconnection detection assist function is the function that fixes the charges of the sampling capacitance of the A/D converter or of the channel-dedicated sample-and-hold circuits to a specified condition prior to starting A/D conversion. This function can be used to detect the wiring disconnection connected to analog input.
Table 60.42 shows the operation modes in which the disconnection detection assist function is available. In addition, when this function is to be used, the use of the high accuracy mode is recommended.

Table 60.42 List of Operation Mode for which Disconnection Detection Assist Function is Available

Operation Mode – Scan Mode	Disconnection Detection Assist Function	
	With the Channel-Dedicated Sample-and-Hold Circuit Not in Use	With the Channel-Dedicated Sample-and-Hold Circuit in Use
SAR mode – Single scan mode	✓	✓
SAR mode – Continuous scan mode	✓	—
Oversampling mode – Single scan mode	—	—
Oversampling mode – Continuous scan mode	—	—
Oversampling mode – Same channel continuous scan mode	—	—
Hybrid mode – Single scan mode	✓	—
Hybrid mode – Continuous scan mode	✓	—
Hybrid mode – Background continuous scan mode	—	—
Hybrid mode – Fixed channels continuous scan mode	—	—

✓: Available, —: Not Available

Figure 60.27 shows an example operation of A/D conversion when disconnection detection assist function is used.
Figure 60.28 shows an example operation of A/D conversion when disconnection detection assist function and channel-dedicated sample-and-hold circuit are used.
Figure 60.29 shows an example of the disconnection detection when precharge is selected, and Figure 60.30 shows an example of the disconnection detection when discharge is selected.

Note 1. 3 to 254 cycles of ADCLK (value of ADNDIS[7:0] – 1)

Figure 60.28 Operation of A/D Conversion when the Disconnection Detection Assist Function and Channel-Dedicated Sample-and-Hold Circuit are Used

Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.
Note 2. Turn off when precharge, and turn on when sampling the Analog input ANn.
Note 3. For the 320-pin LFBGA, use VREFH00, VREFH01, and VREFH02 for ADC0, ADC1, and ADC2, respectively.

Figure 60.29 Example of Disconnection Detection when Precharge is Selected

Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.
Note 2. Turn off when discharge and turn on when sampling the Analog input ANn.
Note 3. For the 320-pin LFBGA, use VREFL00, VREFL01, and VREFL02 for ADC0, ADC1, and ADC2, respectively.

Figure 60.30 Example of Disconnection Detection when Discharge is Selected

60.3.19 Group Priority Operation

Group priority operation function is the function that performs the scanning operation (A/D conversion) for a scan group with a higher priority based on the priority of scan group.
The priority of scan groups is group 0 > group 1 > … > group n. (n: the number of maximum scan group - 1)
Table 60.43 shows the conditions when group priority operation can be used and the corresponding register settings. Set the operation according to Table 60.43.

Table 60.43 Group Priority Operation Usable Conditions and Corresponding Register Settings

Operating Conditions		Group Priority Operation				
Operation mode of A/D converter		Operation	Setting for ADGSPCR register*1			
			PGSm	RSCNm	LGRRSm	GRPm
SAR mode	Single scan mode	✓	1	1	1	0
	Continuous scan mode	✓	1	1	1	1
Oversampling mode		—	0	0	0	0
Hybrid mode		—	0	0	0	0

✓: Available, —: Not Available
m = 0 to 2
Note 1. Settings other than the specified value are prohibited.

60.3.19.1 Group Priority Operation in SAR Mode – Single Scan Mode

In group priority operation in SAR mode – Single scan mode, the single scanning operation is performed according to the priority of scan group.
If an A/D conversion start trigger for the high priority group is input during a scanning operation of the low priority group, the scanning operation of the low priority group is interrupted, and the scanning operation of the high priority group is started. After the scanning operation of the high priority group is completed, the scanning operation of the low priority group is resumed.
When an A/D conversion start trigger of the low priority group during a scanning operation of the high priority group is input, the scanning operation of the low priority group is performed after the scanning operation of the high priority group is completed.

Example of the Group Priority Operation in SAR Mode – Single Scan Mode

Table 60.44 and Figure 60.31 show the example of group priority operation in SAR mode – Single scan mode when analog channel 0 (AN000) is assigned to scan group 0 (high priority) and analog channel 1 to 3 (AN001 to AN003) are assigned to scan group 1 (low priority).

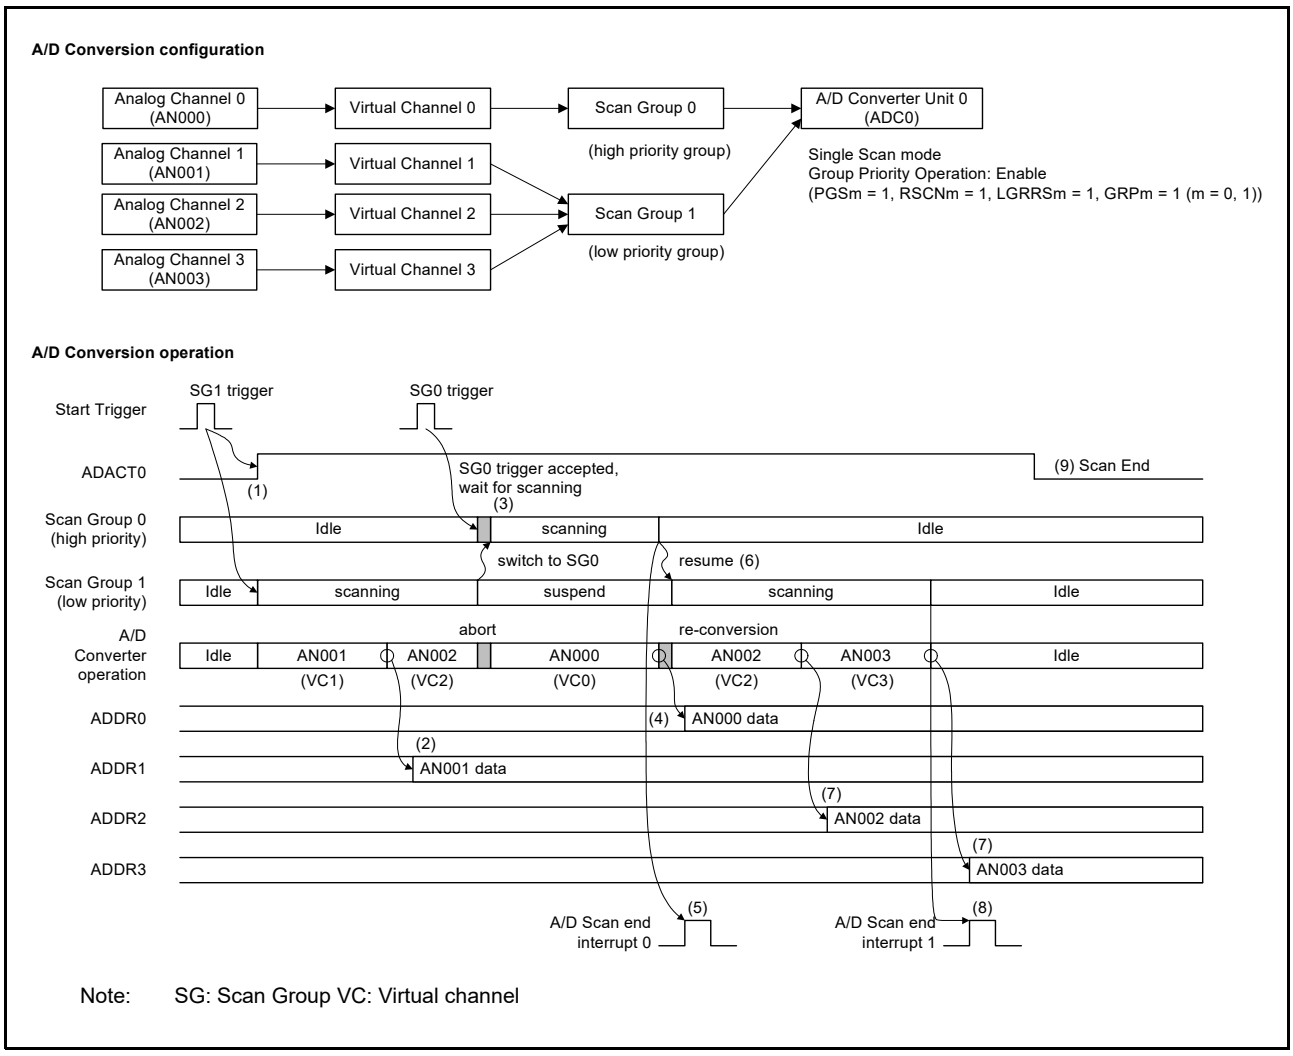

Table 60.44 Example of the Group Priority Operation in SAR Mode – Single Scan Mode (2 groups) (1/2)

Step	Operation
1	The scanning operation of scan group 1 starts when a trigger for scan group 1 is input.
2	When A/D conversion of each channel in scan group 1 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
3	If a trigger for scan group 0 is input during A/D conversion for scan group 1, the scanning operation of scan group 1 is suspended and the scanning operation of scan group 0 is started.*1
4	When A/D conversion of each channel in scan group 0 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
5	If a scan end interrupt for scan group 0 is enabled, a scan end interrupt occurs.
6	The scanning operation of scan group 1 is resumed after scanning of scan group 0 is completed. The scanning operation is resumed from the A/D conversion incomplete channel.*1
7	When A/D conversion of each channel in scan group 1 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).

Table 60.44 Example of the Group Priority Operation in SAR Mode – Single Scan Mode (2 groups) (2/2)

Step	Operation
8	If a scan end interrupt for scan group 1 is enabled, a scan end interrupt occurs.
9	When all scanning operations are completed, ADSR.ADACTm (m = 0, 1) bits are cleared and the A/D converter enters the idle status.

Note 1. The timing of interruption and restart of scanning operation depends on the operating conditions. For details, see section 60.3.19.3, Restrictions on Group Priority Operation.

Note: SG: Scan Group VC: Virtual channel

Figure 60.31 Example of Group Priority Operation in SAR Mode – Single Scan Mode (2 Groups)

60.3.19.2 Group Priority Operation in SAR Mode – Continuous Scan Mode

In group priority operation in SAR mode – Continuous scan mode, the continuous scanning operation is performed for the scan group (continuous-scan group) in which scanning operation was first started. If an A/D conversion start trigger of another scan group (interrupt-scan group) is input during the continuous scanning operation of the continuous-scan group, the following operations are performed according to the priority of the interrupt-scan group.

1. Priority: When Interrupt-scan group (high) > Continuous-scan group (low)

- The scanning operation of the continuous-scan group is interrupted, and the single scanning operation of the interrupt-scan group is started.
- The continuous scanning operation of the continuous-scan group is restarted after the single scanning operation of the interrupt-scan group is completed.

2. Priority: When Continuous-scan group (high) > Interrupt-scan group (low)

- This operation is prohibited. Operation is not guaranteed.

In case 1. above, if an A/D conversion start trigger for another scan group (interrupt-scan group B) is input during the single scanning operation of the interrupt-scan group (interrupt-scan group A), the following operation is performed according to the priority of interrupt-scan group B.

3. Priority: When Interrupt-scan group B (high) > Interrupt-scan group A (middle) > Continuous-scan group (low)

- The single scanning operation of interrupt-scan group A is suspended, and the single scanning operation of interrupt-scan group B is started.
- After the single scanning operation of interrupt-scan group B is completed, the single scanning operation of interrupt-scan group A is resumed.
- After the scanning operation of interrupt-scan group A is completed, the continuous scanning operation of the continuous-scan group is resumed.

4. Priority: When interrupt-scan group A (high) > interrupt-scan group B (medium) > continuous-scan group (low)

- After the single scanning operation of interrupt-scan group A is completed, the single scanning operation of interrupt-scan group B is started.
- After the single scanning operation of interrupt-scan group B is completed, the continuous scanning operation of the continuous-scan group is resumed.

5. Priority: When interrupt-scan group A (high) > continuous-scan group (medium) > interrupt-scan group B (low)

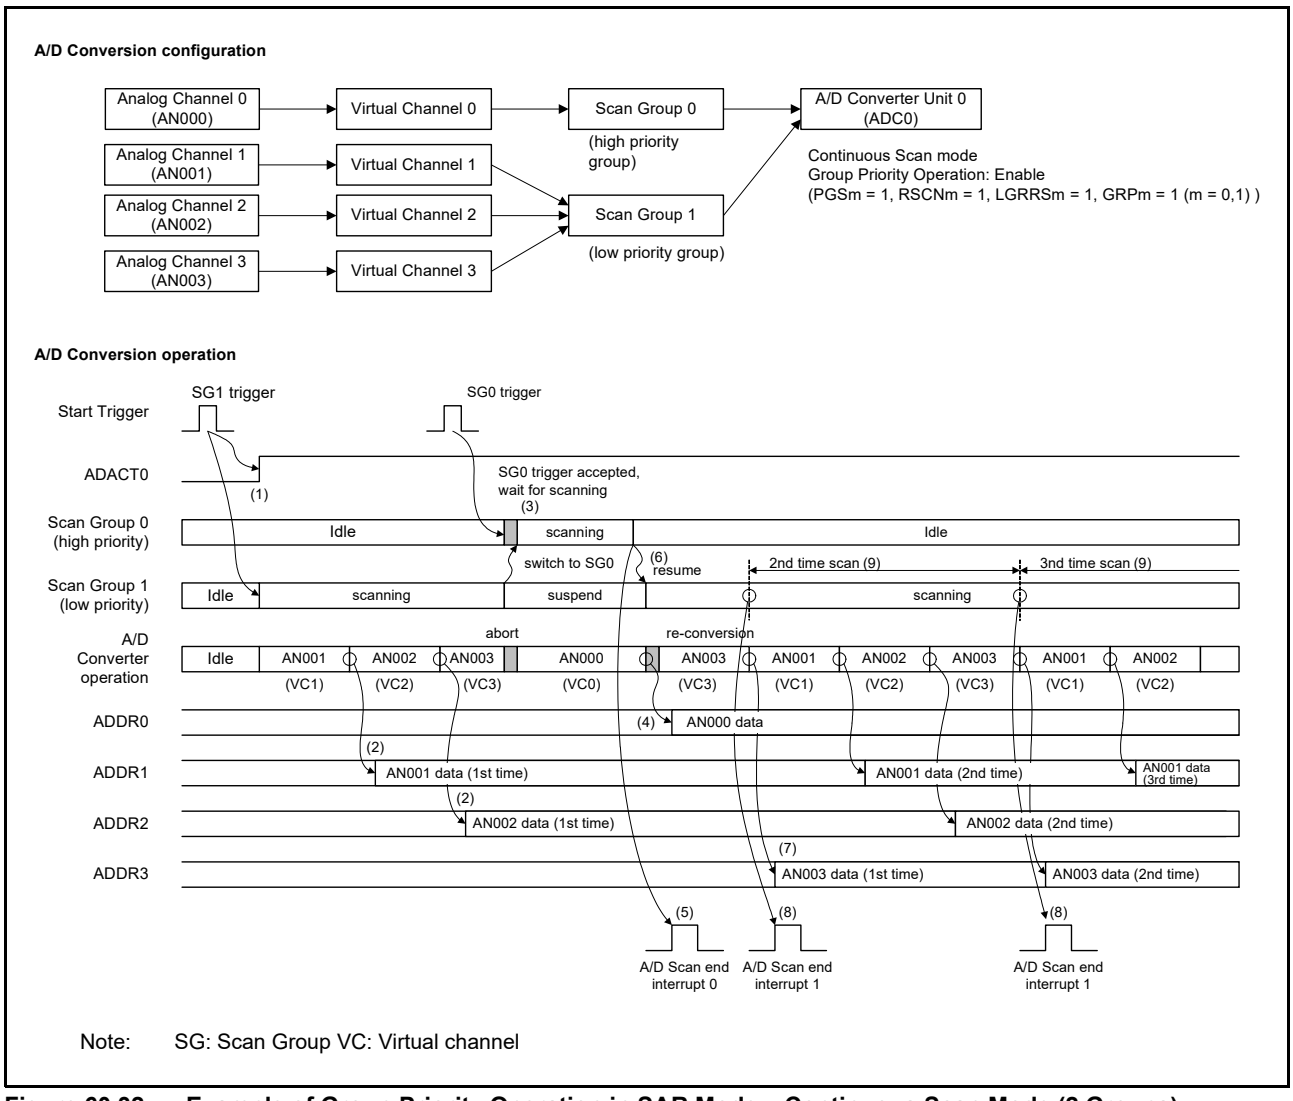
- This operation is prohibited. Operation is not guaranteed.

Example operations are shown in the followings:

(1) Example of two-group priority operation in SAR mode – Continuous scan mode

Table 60.45 and Figure 60.32 show the example of group priority operation in SAR mode – Continuous scan mode when analog channel 0 (AN000) is assigned to scan group 0 (high-priority group) and analog channel 1 to 3 (AN001 to AN003) is assigned to scan group 1 (low-priority group).

Table 60.45 Example of the Group Priority Operation in SAR Mode – Continuous Scan Mode (2 Groups) (1/2)



Step	Operation
1	The continuous scanning operation of scan group 1 (low priority group) is started by the trigger input of scan group 1.
2	When A/D conversion of each channel in scan group 1 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
3	If a trigger for scan group 0 is input during A/D conversion for scan group 1, the scanning operation of scan group 1 is suspended and scanning operation of scan group 0 is started.*1
4	When A/D conversion of each channel in scan group 0 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
5	If a scan end interrupt for scan group 0 is enabled, a scan end interrupt occurs.
6	The scanning operation of scan group 1 is resumed after scanning of scan group 0 is completed. The scanning operation is resumed from the A/D conversion incomplete channel.*1

Table 60.45 Example of the Group Priority Operation in SAR Mode – Continuous Scan Mode (2 Groups) (2/2)

Step	Operation
7	When A/D conversion of each channel in scan group 1 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
8	If a scan end interrupt for scan group 1 is enabled, a scan end interrupt occurs.
9	Scan group 1 continues the continuous scanning operation.*2

Note 1. The timing of interruption and restart of scanning operation depends on the operating conditions. For details, see section 60.3.19.3, Restrictions on Group Priority Operation.

Note 2. To stop the continuous scanning operation, follow the procedures described in section 60.5.4, Force Stops the A/D Conversion Operation.

Note: SG: Scan Group VC: Virtual channel

Figure 60.32 Example of Group Priority Operation in SAR Mode – Continuous Scan Mode (2 Groups)

(2) Example of three-groups priority operation in SAR mode – Continuous scan mode

Table 60.46 and Figure 60.33 show the example of group priority operation when analog channel 0 (AN000) is assigned to scan group 0 (high priority), analog channels 1 and 2 (AN001 and AN002) are assigned to scan group 1 (middle priority), and analog channel 3 to 5 (AN003 to AN005) are assigned to scan group 2 (low priority).

Table 60.46 Example of the Group Priority Operation in SAR Mode – Continuous Scan Mode (3 Groups)

Step	Operation
1	The continuous scanning operation of scan group 2 is started by the trigger input of scan group 2.
2	When A/D conversion of each channel in scan group 2 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
3	If a trigger for scan group 1 is input during A/D conversion on scan group 2, the scanning operation of scan group 2 is suspended and the scanning operation of scan group 1 is started.*1
4	When A/D conversion of each channel in scan group 1 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
5	If a trigger for scan group 0 is input during A/D conversion for scan group 1, the scanning operation of scan group 1 is suspended and the scanning operation of scan group 0 is started.*1
6	When A/D conversion of each channel in scan group 0 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
7	If a scan end interrupt for scan group 0 is enabled, a scan end interrupt occurs.
8	The scanning operation of scan group 1 is resumed after scanning of scan group 0 is completed. The scanning operation is restarted from the A/D conversion incomplete channel.*1
9	When A/D conversion of each channel in scan group 1 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
10	If a scan end interrupt for scan group 1 is enabled, a scan end interrupt occurs.
11	Scan group 2 is resumed after scanning of scan group 1 is completed. The scanning operation is resumed from the A/D conversion incomplete channel.*1
12	When A/D conversion of each channel in scan group 2 completes, the A/D conversion result is stored in the corresponding A/D data register n (ADDRn).
13	If a scan end interrupt for scan group 2 is enabled, a scan end interrupt occurs.
14	Scan group 1 continues the continuous scanning operation.*2

Note 1. The timing of interruption and restart of scanning operation depends on the operating conditions. For details, see section 60.3.19.3, Restrictions on Group Priority Operation.

Note 2. To stop the continuous scanning operation, follow the procedures described in section 60.5.4, Force Stops the A/D Conversion Operation.

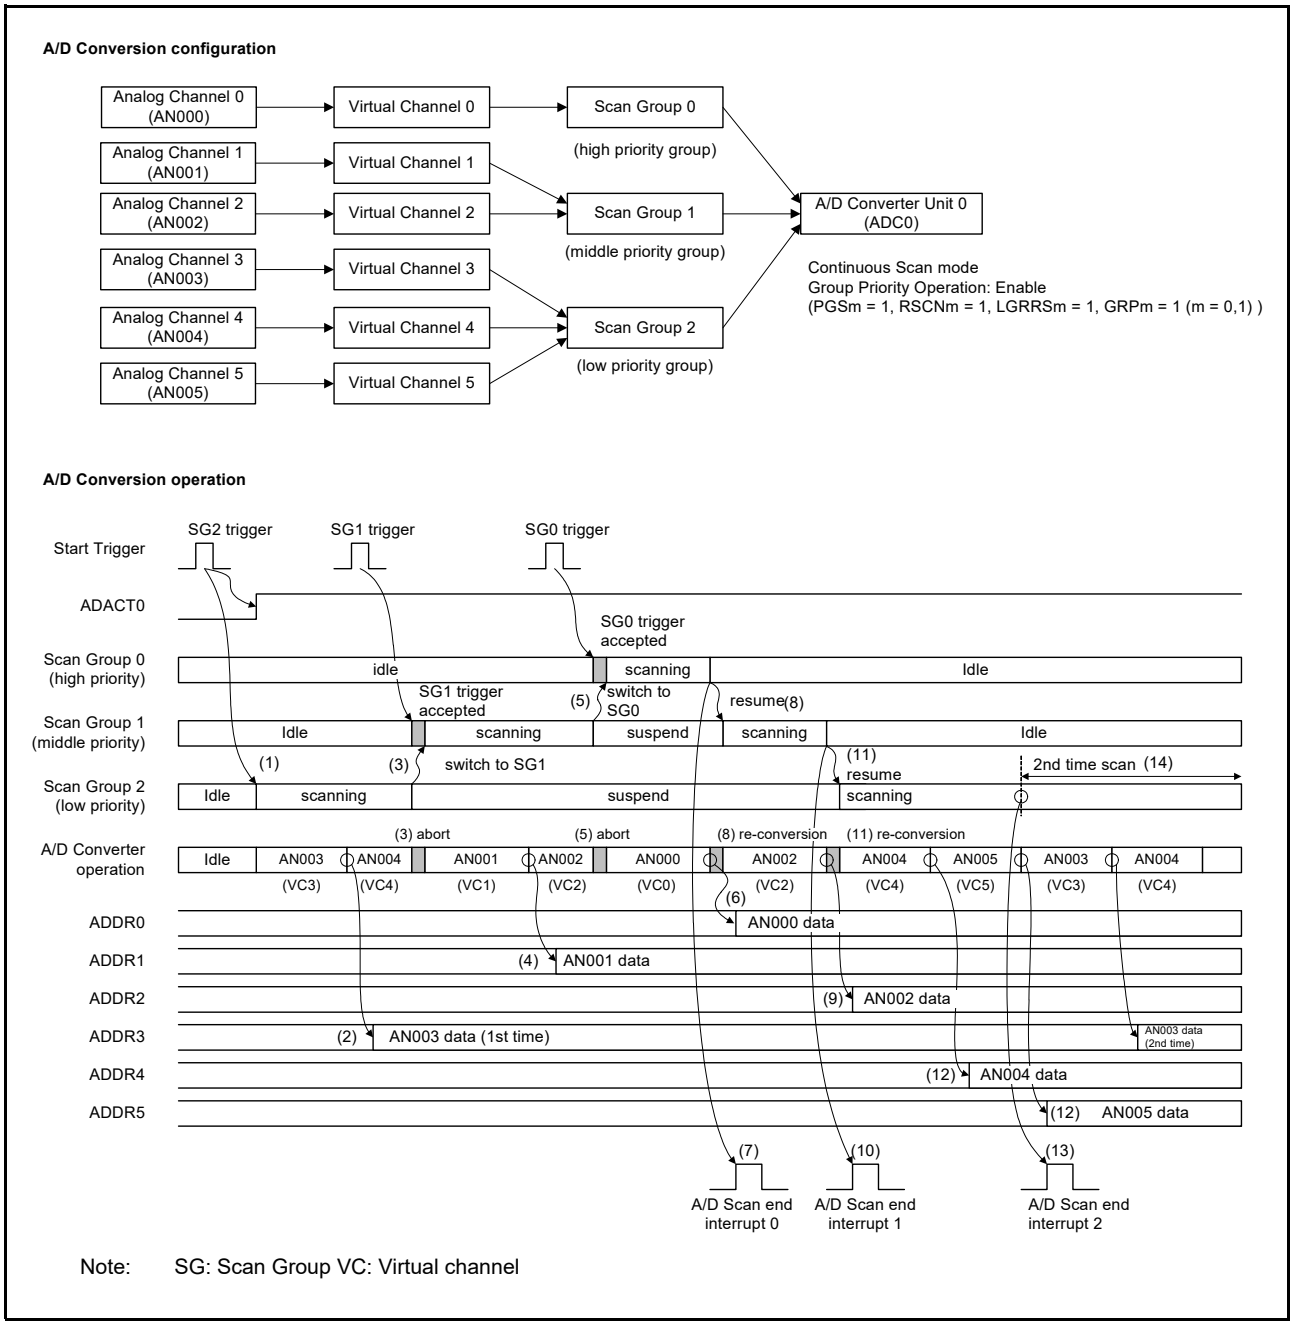


Figure 60.33 Example of Group Priority Operation in SAR Mode – Continuous Scan Mode (3 Groups)

60.3.19.3 Restrictions on Group Priority Operation

(1) Channel-dedicated sample-and-hold circuit restrictions

Only a scan group with the highest priority can use the channel-dedicated sample-and-hold circuits in group priority operation.

(2) Restrictions on the operation mode and operation setting of the A/D converter

Group priority operation is only available in SAR mode; Group priority operation is prohibited in oversampling mode or hybrid mode.

For details, see Table 60.43.

If these restrictions are violated, operation is not guaranteed.

(3) Restrictions on group priority operation in SAR mode – Continuous scan mode

In group priority operation in SAR mode – continuous scan mode, do not input A/D conversion start triggers for scan groups that have a lower priority than the scan group that started continuous scanning operation. If this restriction is violated, the operation is not guaranteed.

(4) Restrictions on trigger input for the same scan group

Input the A/D conversion start triggers for the same scan group in group priority operation for the following periods.

[When synchronous operation is disabled (ADSYCR.ADSYDISm = 1)]

- 2 ADCLK + 2 PCLK cycles after the scan end flag is set*1

[When synchronous operation is enabled (ADSYCR.ADSYDISm = 0)]

- Synchronous operation period cycle × 2 after the scan end flag is set*1

Note: m = 0 to 2

Note 1. ADSCANENDSR.SCENDFn = 1 (n = 0 to 11)

If A/D conversion start triggers are input without waiting for the above period, the A/D conversion start triggers may be lost. To accept A/D conversion start triggers reliably, input the trigger after the above period has elapsed.

(5) Restrictions on suspend and resume for scanning operation of low-priority groups

When an A/D conversion start trigger for the high priority group is input during scanning of the low priority group in group priority operation, the scanning operation of the low priority group is interrupted at the timing shown in the following:

[Scan interruption timing of low priority group]

- When synchronous operation is enabled
  - After the A/D conversion start trigger of the high-priority group is accepted, the scanning operation of the low-priority group is suspended after waiting until the next synchronous operation period timing.
- When synchronous operation is disabled
  - The scanning operation of the low-priority group is immediately suspended after the A/D conversion start trigger of the high-priority group is accepted.

If A/D conversion is being performed on channels for which A/D-converted value addition/averaging function is to be used at the timing of scan interruption of a low-priority group, the midway result of A/D-converted value addition/averaging value at that time is discarded. When the scanning operation of the low-priority group is resumed, A/D conversion starts over from the beginning of the number of times specified for A/D-converted value addition/averaging function.

If the scanning operation is suspended by group priority operation, ADGRSR.ACTGRn (n = 0 to 11) bit of the suspended scan group remains set to 1.

60.3.20 Synchronous Operation

Synchronous operation is the function that controls the operations of multiple A/D converters so that they are synchronized. The synchronization signal can be selected from between an internal signal of the ADC and the external signal from the GPT.

60.3.20.1 Synchronous Operation Examples

(1) Basic synchronous operation

The basic operation of synchronous operation is shown in the following. The configuration example is shown in Table 60.47, and the detail of operation is shown in Table 60.48 and Figure 60.34.

Table 60.47 Configuration Example of Basic Synchronous Operation

Item	Configuration
A/D converter	• ADC0: Set to SAR mode – single scan mode • ADC1: Set to SAR mode – single scan mode
Virtual channel	• Virtual channel 0 to 2: Assign AN000 to AN002 and set to single-ended input mode. • Virtual channel 8 to 10: Assign AN008 to AN010 and set to single-ended input mode.
Scan group	[Scan Group 0] • Assign AN000 to AN002 (virtual channel 0 to 2) • Set to convert with ADC0 [Scan Group 1] • Assign AN008 to AN010 (virtual channel 8 to 10) • Set to convert with ADC1
Synchronous operation setting	• Enable ADC0 synchronous operation • Enable ADC1 synchronous operation • Set the synchronous operation period cycles

Table 60.48 Example of Basic Synchronous Operation

Step	Detail Behavior of Example Operation
1	When a trigger of scan group 0 is input, a wait is inserted until the A/D conversion synchronization timing.
2	At the timing of synchronous operation period, the trigger input of scan group 0 is accepted, and the scanning operation of scan group 0 (for ADC0) starts.
3	When a trigger of scan group 1 is input, a wait is inserted until the A/D conversion synchronization timing.
4	At the timing of synchronous operation period, the trigger input of scan group 1 is accepted, and the scanning operation of scan group 1 (for ADC1) starts.
5	During synchronous operation, the A/D converter starts the sampling operation in accordance with synchronous operation period.

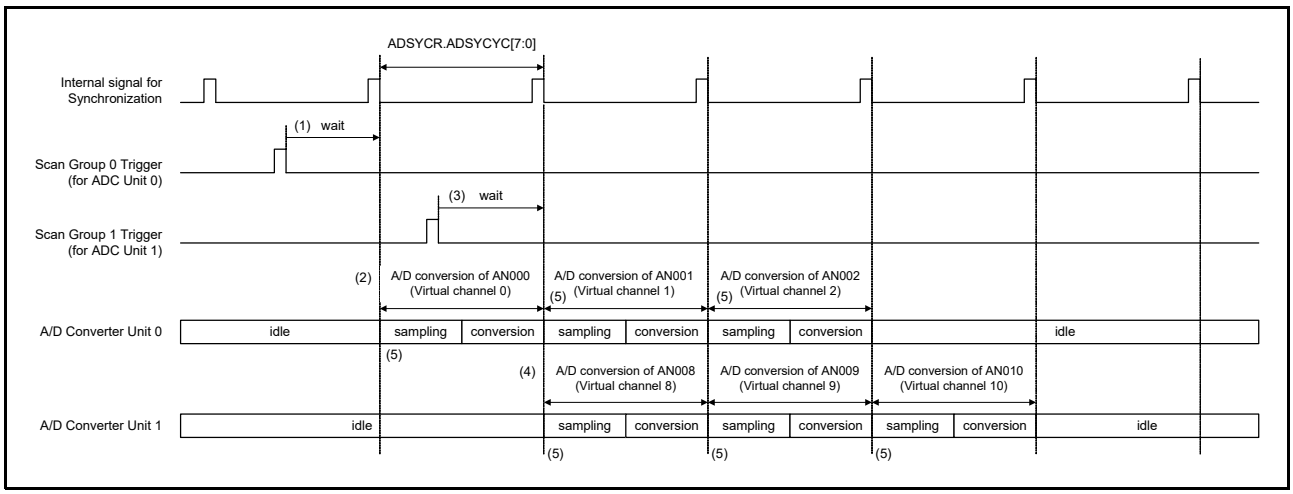

Figure 60.34 Example of Synchronous Operation in SAR Mode – Single Scan Mode

(2) Example of synchronous operation using an external signal (the synchronization signal from the GPT)

Table 60.49 Configuration Example

Item	Configuration
A/D converter	• ADC0: Set to SAR mode – single scan mode • ADC1: Set to SAR mode – single scan mode
Virtual channel	• Virtual channel 0 to 2: Assign AN000 to AN002 and set to single-ended input mode. • Virtual channel 8 to 10: Assign AN008 to AN010 and set to single-ended input mode.
Scan group	[Scan Group 0] • Assign AN000 to AN002 (virtual channel 0 to 2) • Set to convert with ADC0 [Scan Group 1] • Assign AN008 to AN010 (virtual channel 8 to 10) • Set to convert with ADC1
Synchronous operation setting	• Enable ADC0 synchronous operation • Enable ADC1 synchronous operation • Set the synchronous operation period cycles • Enable synchronization with an external signal (the synchronization signal from the GPT)

Table 60.50 Example of Basic Synchronous Operation

Step	Detail Behavior of Example Operation
1	When a GPT trigger of scan group 0 is input, a wait is inserted until the A/D conversion synchronization timing.
2	At the timing of synchronous operation period, the trigger input of scan group 0 is accepted, and the scanning operation of scan group 0 (for ADC0) starts.
3	When a trigger of scan group 1 is input, a wait is inserted until the A/D conversion synchronization timing.
4	At the timing of synchronous operation period, the trigger input of scan group 1 is accepted, and the scanning operation of scan group 1 (for ADC1) starts.
5	During synchronous operation, the A/D converter starts the sampling operation in accordance with synchronous operation period.

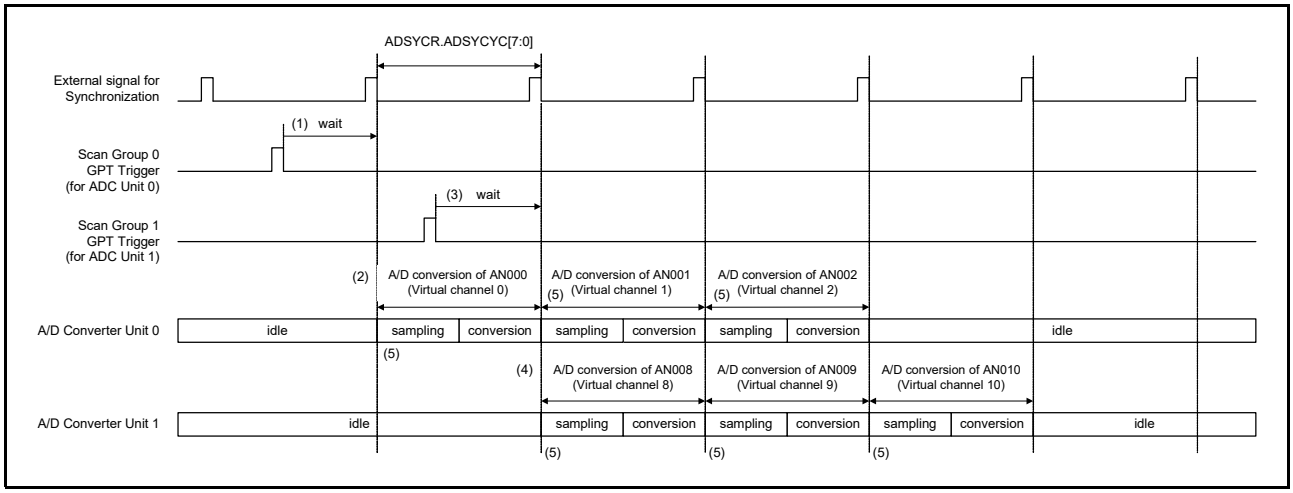

Figure 60.35 Example of Synchronous Operation Using an External Signal (the Synchronization Signal from the GPT)

60.3.20.2 Restrictions on Synchronous Operation

When synchronous operation is used, observe the following restrictions. If the following restrictions are violated, operations are not guaranteed.

(1) Basic restrictions

- Set the synchronous operation period to a value larger than successive approximation time of ADCm (m = 0 to 2).
  - ADSYCR.ADSYCYC[7:0] ≥ ADCNVSTR.CSTm[5:0] + 1 (m = 0 to 2)
- Set so that the sum of the sampling times of the analog channels and successive approximation time of ADCm (m = 0 to 2) is an integral multiple of the synchronous operation period.
  - ADSSTRx.SSTy[9:0] + ADCNVSTR.CSTm[5:0] = ADSYCR.ADSYCYC[7:0] × i
    (x = 0 to 7, y = 0 to 15, m = 0 to 2, i: Any integer greater than or equal to 1 (i = 1, 2, 3…))
- Set the synchronous operation period to a value larger than successive approximation time at self-calibration.*1
  - ADSYCR.ADSYCYC[7:0] ≥ ADCALSTCR.CALADCST[5:0] + 1
- Set the sampling time and successive approximation time at self-calibration to be integral multiples of the synchronous operation period.*1
  - ADCALSTCR.CALADSST[9:0] + ADCALSTCR.CALADCST[5:0] = ADSYCR.ADSYCYC[7:0] × i (i: Any integer greater than or equal to 1 (i = 1, 2, 3…))

(2) Restrictions when using channel-dedicated sample-and-hold circuit

- Set the synchronous operation period to a value greater than the hold mode switching time of channel-dedicated sample-and-hold circuit.
  - ADSYCR.ADSYCYC[7:0] ≥ ADSHSTR0.SHHST[2:0] + 1
- Set the sum of channel-dedicated sample-and-hold circuit sampling time and the hold mode switching time to be an integral multiple of the synchronous operation period.
  - ADSHSTR0.SHSST[7:0] + ADSHSTR0.SHHST[2:0] = ADSYCR.ADSYCYC[7:0] × i (i: Any integer greater than or equal to 1 (i = 1, 2, 3…))
- Set the hold mode switching time of channel-dedicated sample-and-hold circuit so that it is the same as successive approximation time of ADC0.
  - ADSHSTR0.SHHST[2:0] = ADCNVSTR.CSTm[5:0]
- Set the synchronous operation period to a value greater than the hold mode switching time in channel-dedicated sample-and-hold circuit's self-calibration operation.*1
  - ADSYCR.ADSYCYC[7:0] ≥ ADCALSHCR.CALSHHST[2:0] + 1
- Set so that the sum of channel-dedicated sample-and-hold circuit sampling time and the hold mode switching time in self-calibration operation is an integral multiple of the synchronous operation period.*1
  - ADCALSHCR.CALSHSST[7:0] + ADCALSHCR.CALSHHST[2:0] = ADSYCR.ADSYCYC[7:0] × i (i: Any integer greater than or equal to 1 (i = 1, 2, 3…))

(3) Restrictions when using disconnection detection assist function

- Set Disconnection Detection Assist period so that it is the same as the synchronous operation period.
  - ADSGDCRn.ADNDIS[7:0] = ADSYCR.ADSYCYC[7:0] (n = 0 to 11)

(4) Restrictions when using an external signal (the synchronization signal from the GPT)

- Select GPTCLK as the clock source for ADCLK.
- Release the GPT module-stop state using the Module Stop Register E (MSTPCRE) before enabling using an external signal (the synchronization signal from the GPT) and selecting the clock source for ADCLK.

(5) Restriction when using high accuracy mode

- The synchronous operation period should be set as follows.
  - ADSYCR.ADSYCYC[7:0] × i = ADSSTRx.SSTy[9:0] + ADCNVSTR.CSTm[5:0]
    (x = 0 to 7, y = 0 to 15, m = 0 to 2, i: 1, 2 × n (n = 1, 2, 3…))

Note 1. In relation to this restriction, the restrictions on the settings of self-calibration should be satisfied at the same time.
For restrictions on the setting of self-calibration, see section 60.3.9.3, Restrictions on Self-Calibration.

60.3.21 A/D Conversion Operation Monitor Function

The timing of A/D conversion operations can be monitored by observing the internal operation signals output from pins of the A/D converter. When this function is to be used, see section 22, I/O Ports to specify the signals to be monitored. The following signals can be monitored.

- ADSYNC

ADSYNC is the synchronization signal for A/D conversion operations. This signal indicates the synchronous timing of the synchronization function for A/D conversion. When this function is enabled, an A/D conversion operation is executed in synchronization with this signal. When this function is disabled, this signal is generated but ignored in A/D conversion operations. See section 60.3.20, Synchronous Operation for more details about synchronous operation of A/D conversion.

- ADCNVn (n = 0 to 2)

ADCNVn indicates the period of the A/D conversion of A/D converter units 0, 1, and 2. This signal is asserted during A/D conversion.

- ADSTn (n = 0 to 2)

ADSTn indicates the period of A/D scanning of A/D converter units 0, 1, and 2. This signal is asserted during A/D scanning.

Figure 60.36 shows the operation timing of each signal.

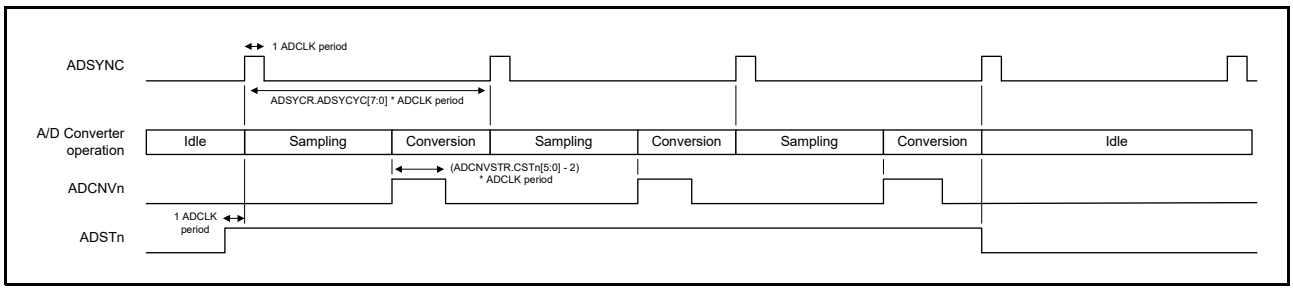

Figure 60.36 Monitor Signal Waveforms

60.4 A/D Conversion Data

This section describes the internal processing for A/D conversion data. For details about the operation of A/D conversion, see section 60.3, Operation.

60.4.1 Internal Data Processing Flow

Figure 60.37 shows the internal processing-flow of A/D conversion data.
The A/D conversion data output from the A/D converter is temporarily stored in the data buffer. And then, various data processing is performed based on the register setting. If the function that corresponds to each data processing is not used, its data processing is skipped.

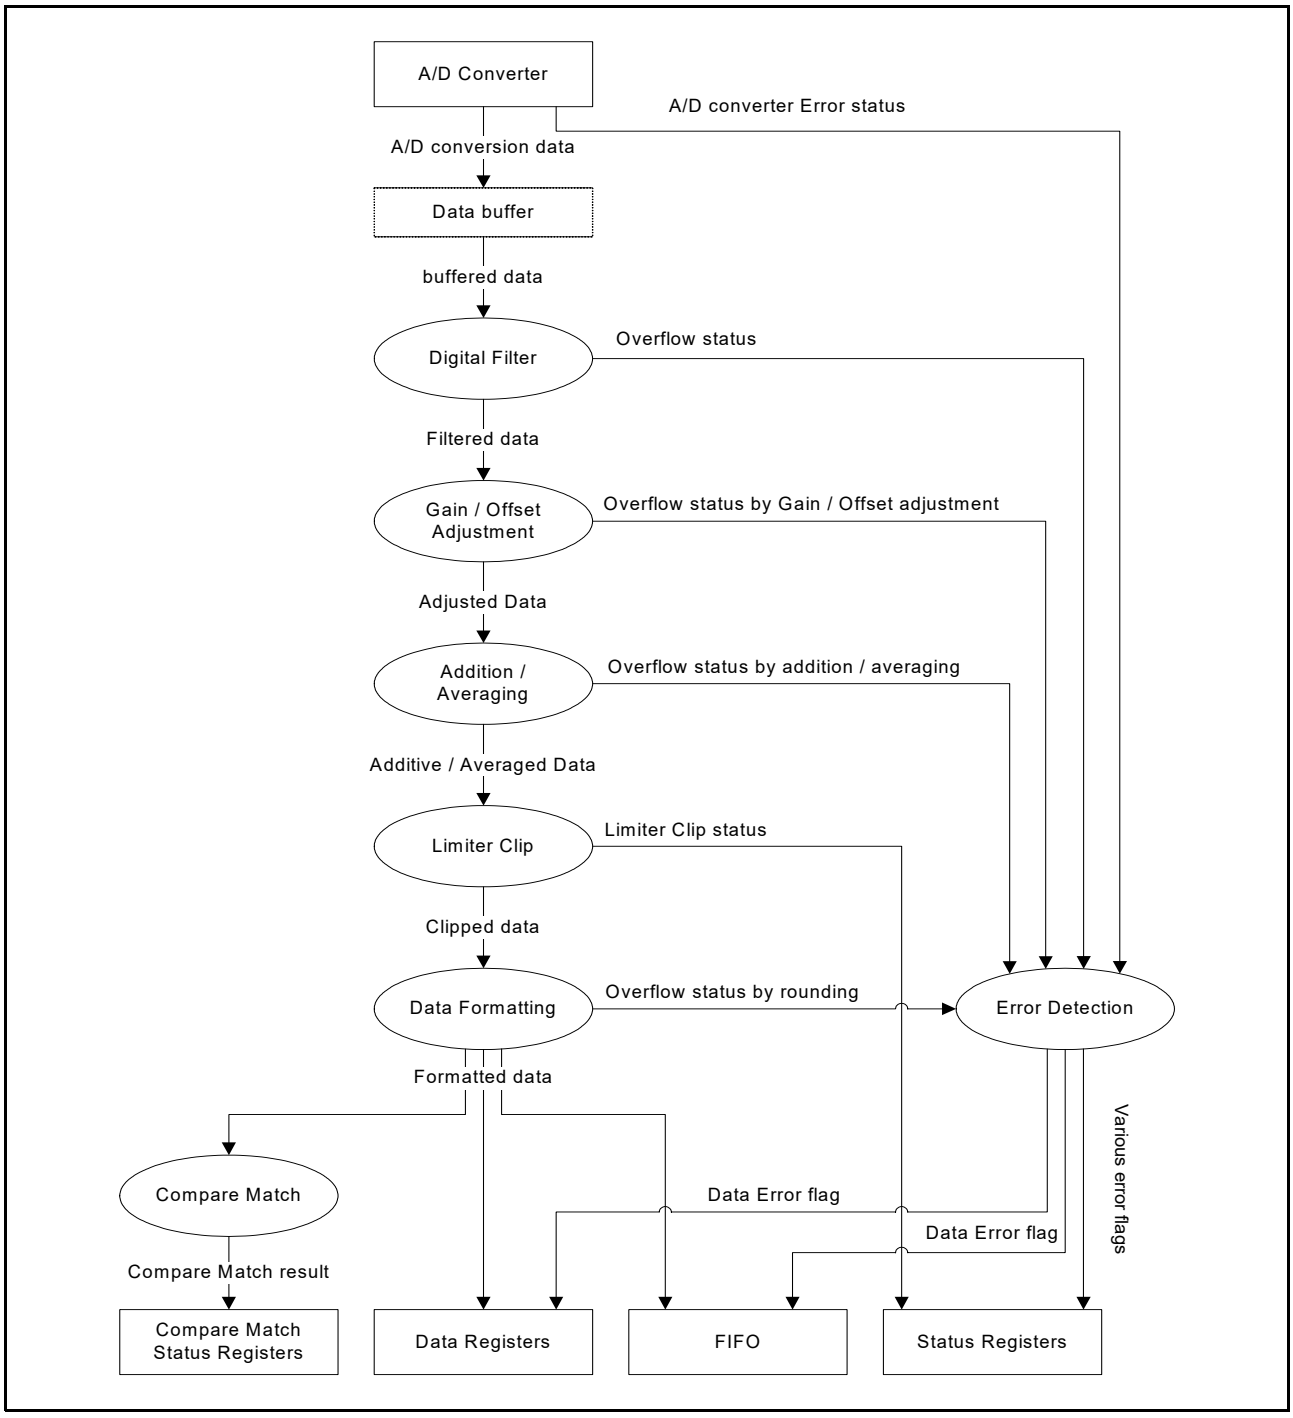

Figure 60.37 Internal Data Flow Diagram of A/D Conversion Data

60.4.2 Digital Filter Function

ADC has 4 digital filters per 1 unit of A/D converter. High-precision A/D conversion results can be obtained by using a digital filter. The digital filter function must be used in oversampling mode or hybrid mode. The digital filter function in SAR mode is prohibited.

60.4.2.1 Configuration and Characteristics

The digital filter consists of a FIR type filter with 22 taps. The digital filter is set by ADDOPCRAn.DFSEL[2:0] (n = 0 to 49) and ADDFSRm (m = 0 to 2) registers. The configuration of the digital filter is shown in Figure 60.38.
The type of the digital filter (FIR filter) can be selected from the following. For the characteristics of the digital filters, see section 67, Electrical Characteristics.
[List of digital filter characteristics]

- Sinc filter

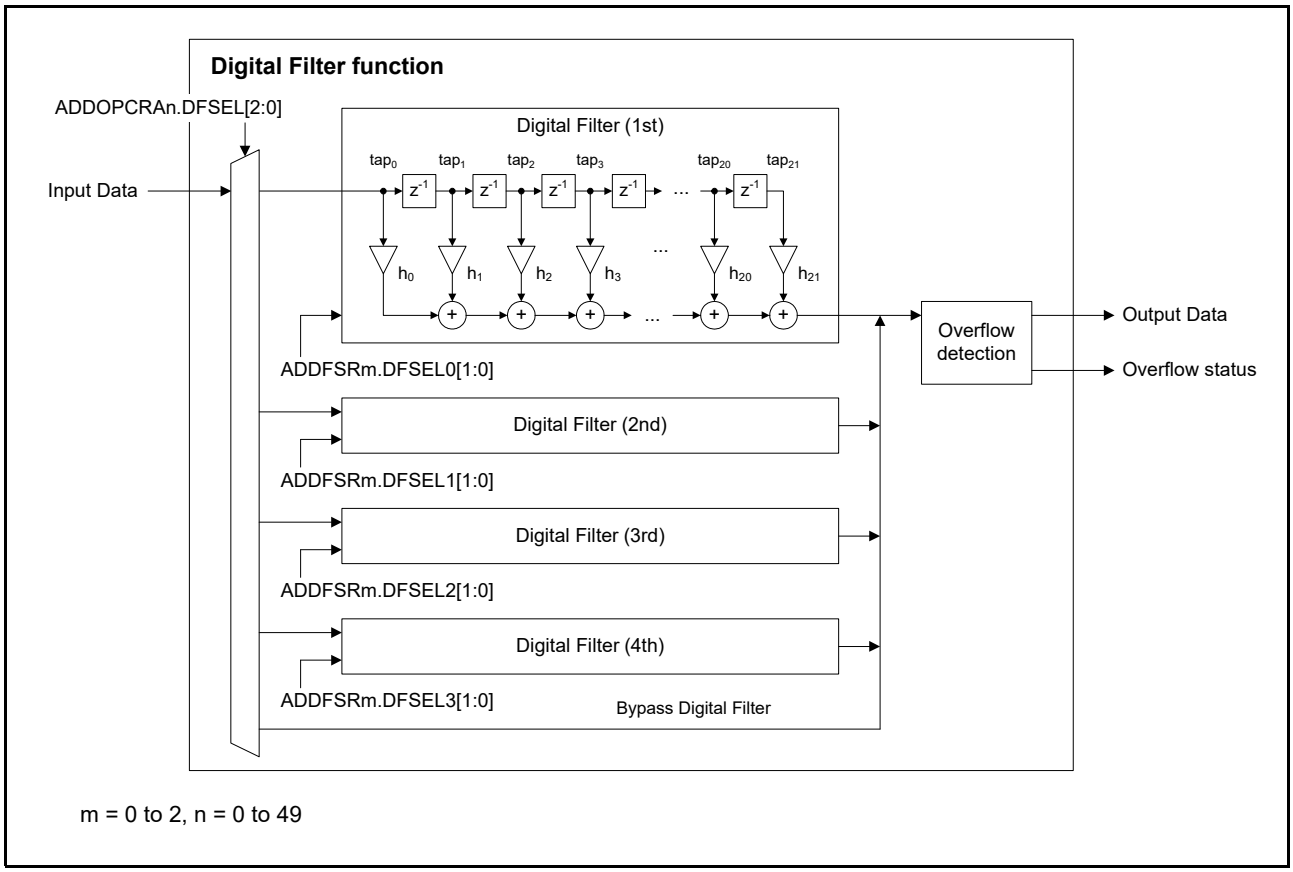

Figure 60.38 Block Diagram of Digital Filter

60.4.2.2 Operation of Digital Filter Function

When the digital filter function is enabled, A/D conversion data is sequentially input to the digital filter. When all the taps in the digital filter are filled with data, the calculation result is output and sent to the next data processing.
The operation of the digital filters in oversampling mode and hybrid mode is shown in the followings.

(1) Digital filter operation in oversampling mode

In oversampling mode, oversampling (A/D conversion) is performed continuously for one analog channel. Each time oversampling is performed, A/D conversion data is sequentially input to the digital filter. When all the taps in the digital filter are filled with data, the calculation result is output and sent to the next data processing.
In oversampling mode, the data of the taps in the digital filter is discarded when the A/D conversion data is output to the next data processing. However, when A/D-converted value addition/averaging function is used, the data of taps in the digital filter is kept until the data required to calculate the addition value or average value of the A/D converted value is collected. When the A/D-converted value addition/averaging value is calculated, the tap data in the digital filter is discarded.

(2) Digital filter operation in hybrid mode

Hybrid mode can process oversampled data (A/D converted data) of up to four analog channels in parallel by using several digital filter circuits at the same time. Each time oversampling is performed, A/D conversion data is sequentially input to the digital filter. When all the taps in the digital filter are filled with data, the calculation result is output and sent to the next data processing.
In hybrid mode – single scan mode, taps in the digital filter are discarded at the end of scanning operation.
In hybrid mode – continuous scan mode, the data of the taps in the digital filter continues to be updated as long as the continuous scanning operation is continued. Therefore, after the data is filled in all taps in the digital filter, a new calculation result is output for each oversampling. When scanning operation is aborted due to a forced stop of A/D conversion, the data of taps in the filter is discarded.
The operation of the digital filter in hybrid mode – background continuous scan mode is the same as in hybrid mode – continuous scan mode. During the background continuous scanning operation, the digital filters and other data processing continue to take place in the background. When scanning operation is aborted due to a forced stop of A/D conversion, the data of taps in the filter is discarded.

60.4.3 Calibration and Adjustment

In this process, the following processing is performed for the results output from the A/D converter or for the data output from Digital Filter.

1. Calibrate Gain Error and Offset Error
2. Adjust User's Gain
3. Adjust User's Offset

For details on each process, refer to each item.

60.4.3.1 Gain Error and Offset Error Calibration

This process calibrates the A/D converter's Gain Error and Offset Error due to by chip-by-chip characteristic variations. Calibration for the A/D converter's Gain Error and Offset Error is performed by calculation based on error data measured inside the ADC by self-calibration operation.

Using gain error and offset error calibration when the input to the A/D converter is near the VREFH0 upper limit or VREFL0 lower limit, an overflow of A/D conversion data may occur.

60.4.3.2 User's Gain Adjustment

User's Gain adjusting function multiplies the A/D conversion data by an arbitrary coefficient value.

The coefficient value of User's Gain is set in ADUGTRn.UGAIN[15:0] (n = 0 to 7). User's Gain can be set for each virtual channel. The User's Gain Table to be used is selected in ADDOPCRAm.GAINSEL[3:0] (m = 0 to 49). The coefficient value of User's Gain is the sum of the gain corresponding to the bits that are set to 1 in ADUGTRn.UGAIN[15:0]. Table 60.51 shows the gain factors corresponding to the respective bit in ADUGTRn.UGAIN[15:0]. An example of setting User's Gain is shown in Table 60.52. Figure 60.39 and Figure 60.40 show the relationship between before adjustment (input) and after adjustment (output) to the A/D conversion result when User's Gain adjustment function is used.

The overflow of A/D conversion data may occur when User's Gain adjusting function is used.

Table 60.51 List of Gains Corresponding to Each Gain Setting Bit in User's Gain Setting Table Register

UGAIN[15:8]	Gain Value	UGAIN[7:0]	Gain Value
b15	2^{1} = 2.0	b7	2^{-7} = 7.813E–03
b14	2^{0} = 1.0	b6	2^{-8} = 3.906E–03
b13	2^{-1} = 0.5	b5	2^{-9} = 1.953E–03
b12	2^{-2} = 0.25	b4	2^{-10} = 9.766E–04
b11	2^{-3} = 0.125	b3	2^{-11} = 4.883E–04
b10	2^{-4} = 0.0625	b2	2^{-12} = 2.441E–04
b9	2^{-5} = 0.03125	b1	2^{-13} = 1.221E–04
b8	2^{-6} = 1.563E-02	b0	2^{-14} = 6.104E–04

Table 60.52 Example of User's Gain Settings (1/2)

ADUGTRn.UGAIN[15:0] (n = 0 to 7)	Gain Value
0000h	x0.0000

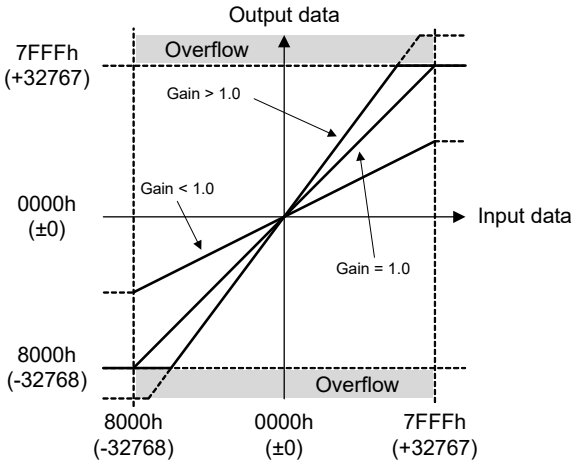

Figure 60.40 User's Gain Adjustment (16-Bit Data Length Format and Signed Data Format)

60.4.3.3 User's Offset Adjustment

User's Offset adjustment function adds or subtracts any constant value to or from the A/D conversion data.
The constant value of User's Offset is set in ADUOFTRn.UOFSET[15:0] (n = 0 to 7). User's Offset can be set for each virtual channel. User's Offset Table to be used is selected in ADDOPCRAm.OFSETSEL[3:0] (m = 0 to 49). Table 60.53 shows the relationship between the register setting value of User's Offset and the offset value. Figure 60.41 and Figure 60.42 show the relationship between before adjustment (input) and after adjustment (output) to the A/D conversion result when User's Offset adjustment function is used.
When User's Offset adjusting function is used, overflow of A/D conversion data may occur.

Table 60.53 Relationship between User's Offset Register Value and Offset Value

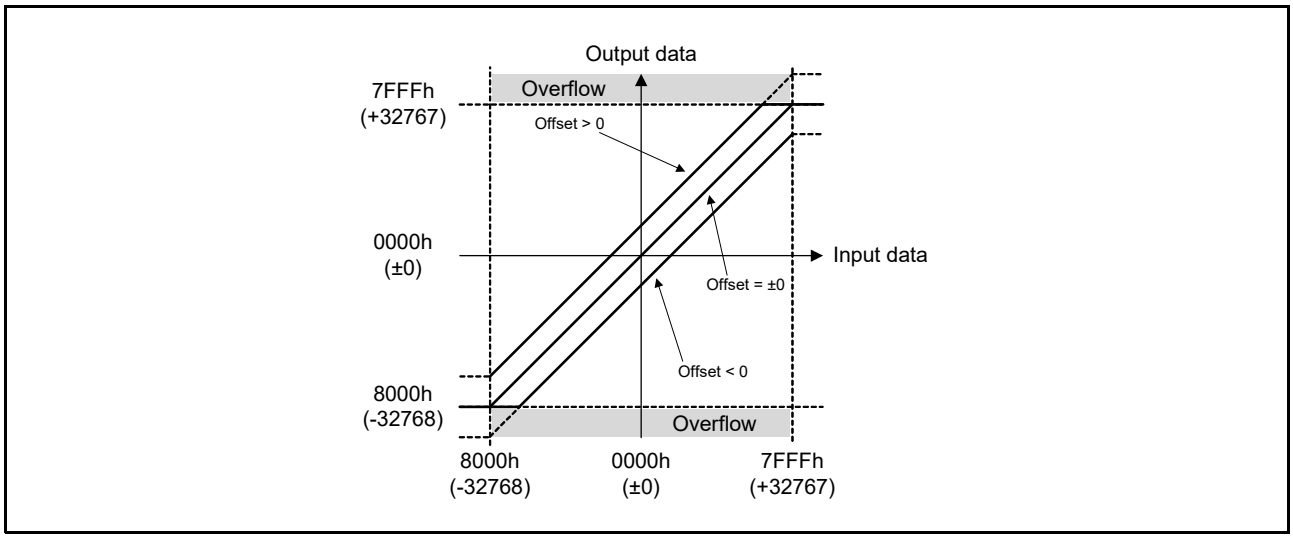

Figure 60.42 User's Offset Adjustment (16-Bit Data Length Format and Signed Data Format)

60.4.4 A/D-Converted Value Addition/Averaging Function

A/D-converted value addition/averaging function is a function to calculate the sum value or average value of the result of A/D conversion of analog channels continuously for the specified number of times. A/D-converted value addition/averaging function can be configured for each virtual channel in ADDOPCRBn.AVEMD[1:0] bits and ADDOPCRBn.ADC[3:0] bits (n = 0 to 49).

A/D-converted value addition/averaging function inputs the output of the previous data processing. When the specified number of times of data is input, the added value or average value is calculated, and the result is output to the next data processing. When A/D-converted value addition/averaging function is used, the A/D converter repeats the A/D conversion until the data is collected for the number of times specified by the ADDOPCRBn.ADC[3:0] (n = 0 to 49) bits. One calculation result (total value or average value) is output every time the specified number of times of data is input to A/D-converted value addition/averaging. Figure 60.43 shows the operation of A/D-converted value addition/averaging function in SAR mode or oversampling mode. Figure 60.44 shows the operation of A/D-converted value addition/averaging function in hybrid mode.

When the A/D-converted value addition/averaging function is used, overflow of the A/D-converted data may occur. However, A/D conversion overflow may not be detected under certain conditions. For more information on A/D conversion overflow, see section 60.6.2, A/D Conversion Overflow.

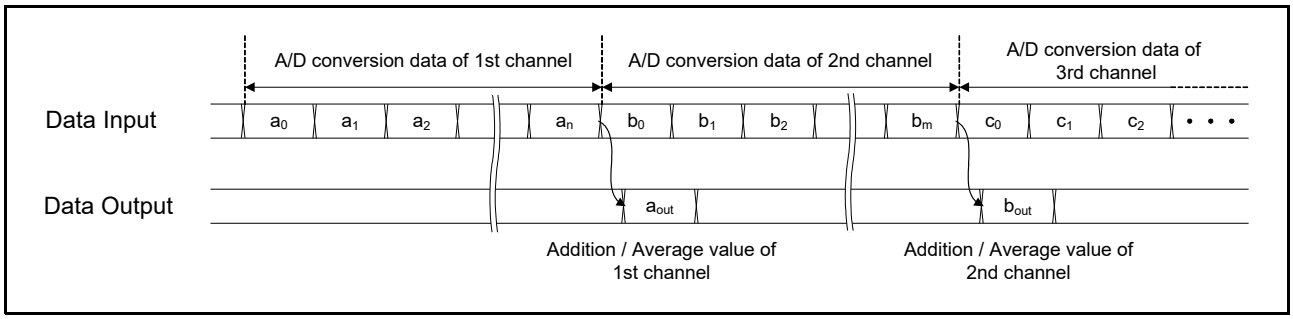

Figure 60.43 Example Operation of A/D-Converted Value Addition/Averaging Function (SAR Mode or Oversampling Mode)

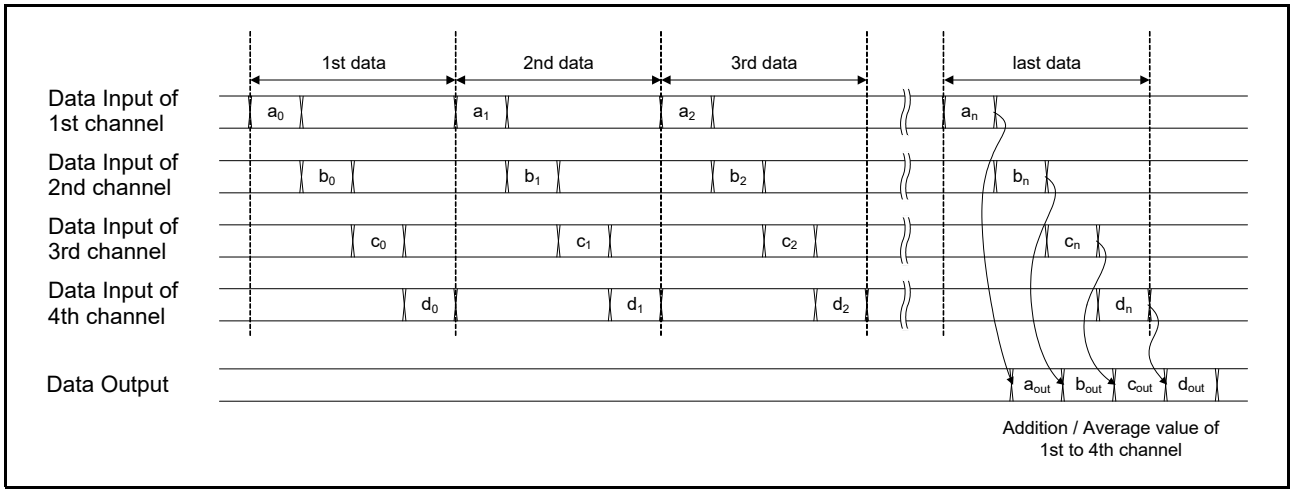

Figure 60.44 Example Operation of A/D-Converted Value Addition/Averaging Function (Hybrid Mode)

60.4.5 Limiter Clip Function

Limiter Clip Function is the function to set the upper and lower limits of A/D conversion data. When the A/D conversion data exceeds the specified upper limit value, it is clipped to the upper limit value. If the A/D conversion data falls below the specified lower limit, it is clipped to the lower limit value. Figure 60.45 shows an example of Limiter Clip Function operation.

The upper and lower limits of Limiter Clip Function can be specified in ADLIMTRn.LIMU[15:0] (n = 0 to 7) and ADLIMTRn.LIML[15:0] (n = 0 to 7). The Limiter Clip Function can be selected use or not (enable or disable) for each virtual channel in ADDOPCRCm.LIMTBLS[3:0] (m = 0 to 49).

Limiter Clip Function is processed by 16-bit length. When 14-/12-/10-bit is selected as the data length of the A/D conversion data (when ADDOPCRCm.ADPRC[1:0] = 01b, 10b, or 11b (m = 0 to 49)), the rounding to the specified data length is performed after the clipping by Limiter Clip Function. For details, see section 60.4.6, Data Formatting process.

The upper and lower limits of the limiter clip are treated as signed or unsigned depending on the setting of the sign selection bit (ADDOPCRCm.SIGNSEL (m = 0 to 49)) in the A/D conversion data.

For Limiter Clip Function, the upper limit value should be greater than the lower limit value (ADLIMTRn.LIMU[15:0] > ADLIMTRn.LIML[15:0] (n = 0 to 7)). If the upper limit value is less than or equal to the lower limit value, the A/D conversion data always becomes 0000h.

If a limiter clip occurs, the flags are set in the following status registers:

- ADLIMGRSR: The flag is set to the bit corresponding to the scan group where the limiter clip occurred.
- ADLIMCHSR0: If a limiter clip occurs during A/D conversion of an analog input channel, the flag is set to the corresponding bit.
- ADLIMCHSR1: If a limiter clip occurs during A/D conversion of an Extended Analog input channels, the flag is set to the corresponding bit.
- ADLIMEXSR: If a limiter clip occurs during A/D conversion of Extended Analog Function, the flag is set to the corresponding bit.

To clear the flags in the status registers, write 1 to the corresponding bit in ADLIMGRSCR, ADLIMCHSCR0, ADLIMCHSCR1, ADLIMEXSCR.

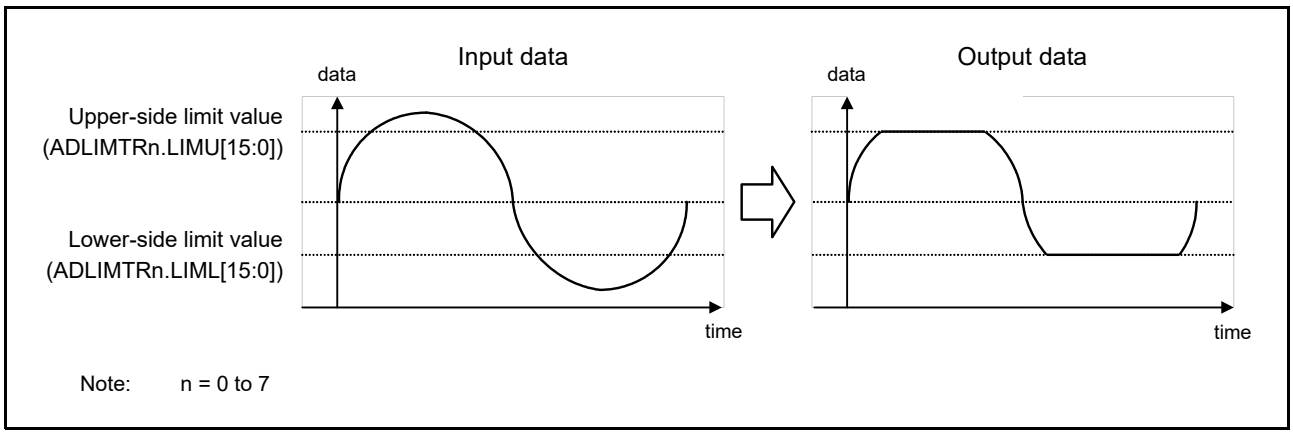

Figure 60.45 Example of Limiter Clip Function Operation

60.4.6 Data Formatting process

In this process, the following formatting is performed on the A/D conversion data.

- Signed/Unsigned data processing
- Data Rounding process

The data formatted in this process is stored to DATA[15:0] bits of the A/D data register (ADDRi (i = 0 to 35)), the extended A/D data register (ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18), and the FIFO data register (ADFIFODRk (k = 0 to 11)) as the result of A/D conversion.
For details on the data format, see section 60.4.7, Data Format.

60.4.6.1 Signed/Unsigned Data Process

The A/D conversion data is formatted into signed or unsigned data format based on the setting of the ADDOPCRCn.SIGNSEL (n = 0 to 49) bits. Select the signed data format (SIGNSEL = 0) for differential input mode and the unsigned format (SIGNSEL = 1) for single-ended input mode.

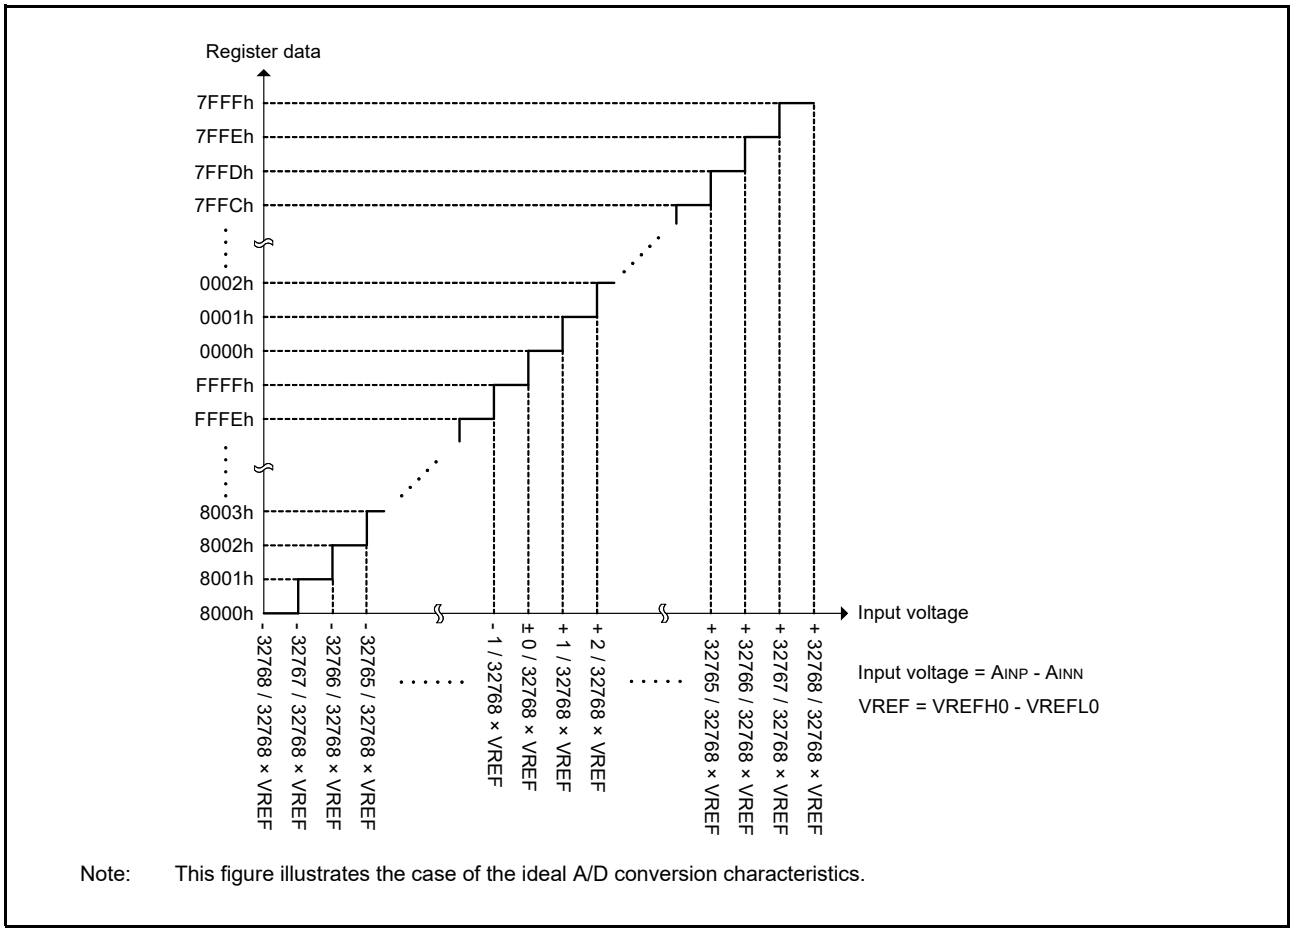
60.4.6.2 Data Rounding Process

The A/D conversion data is processed as a fraction of the data length based on the setting of the ADDOPCRCn.ADPRC[1:0] (n = 0 to 49) bits. If 14-/12-/10-bit data format is selected (ADPRC[1:0] = 01b, 10b, 11b), the lower bits of the A/D conversion data will be rounding. (If the most significant bit of the digit to be cut off is 0, the digit is rounded down; if it is 1, the digit is rounded up.) If the 16-bit data format is selected (ADPRC[1:0] = 00b), the A/D conversion data is not rounded.

60.4.7 Data Format

This section describes the data format of the A/D conversion result stored in the DATA[15:0] bits of the A/D data register (ADDRi (i = 0 to 35)), extended A/D data register (ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)), and FIFO data register (ADFIFODRk (k = 0 to 11)).

Note: The data format does not guarantee the resolution and accuracy of the A/D converter itself. See section 67, Electrical Characteristics of the A/D converter.



(1) 16-bits data length format

Table 60.54 shows the alignment of A/D conversion data on 16-bit data format. Figure 60.46 and Figure 60.47 show the data range for 16-bit data format.

For 16-bit data length signed data format, the differential input voltage is A/D-converted in the range of 8000h (-VREFH0) to 7FFFh (+VREFH0). In 16-bit data length unsigned data format, the single-ended input voltage is A/D-converted in the range of 0000h (VREFL0) to FFFFh (VREFH0).

Table 60.54 Alignment of A/D Conversion Result Data (16-Bit Data Length)

Bit number:	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

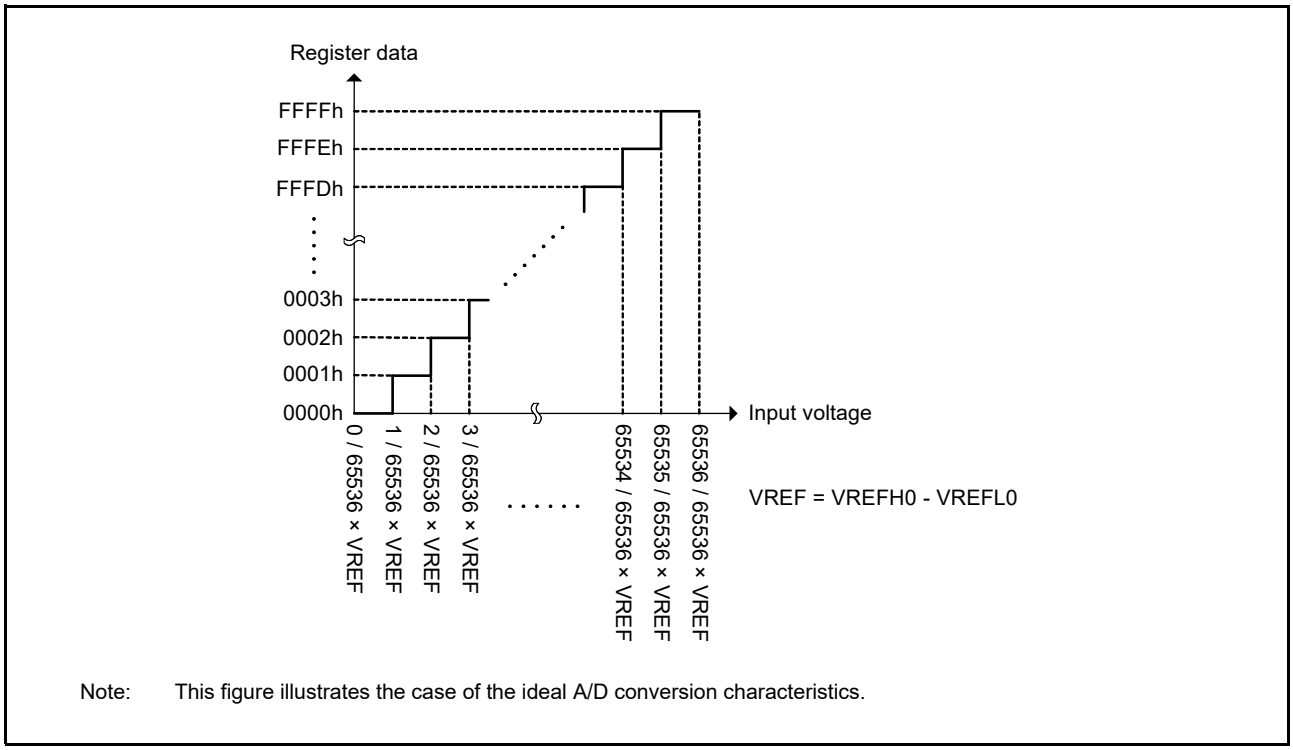

Figure 60.47 Data Range of A/D Conversion Result (16-Bit Data Length, Unsigned Data, Single-Ended Input)

(2) 14-bits data length format

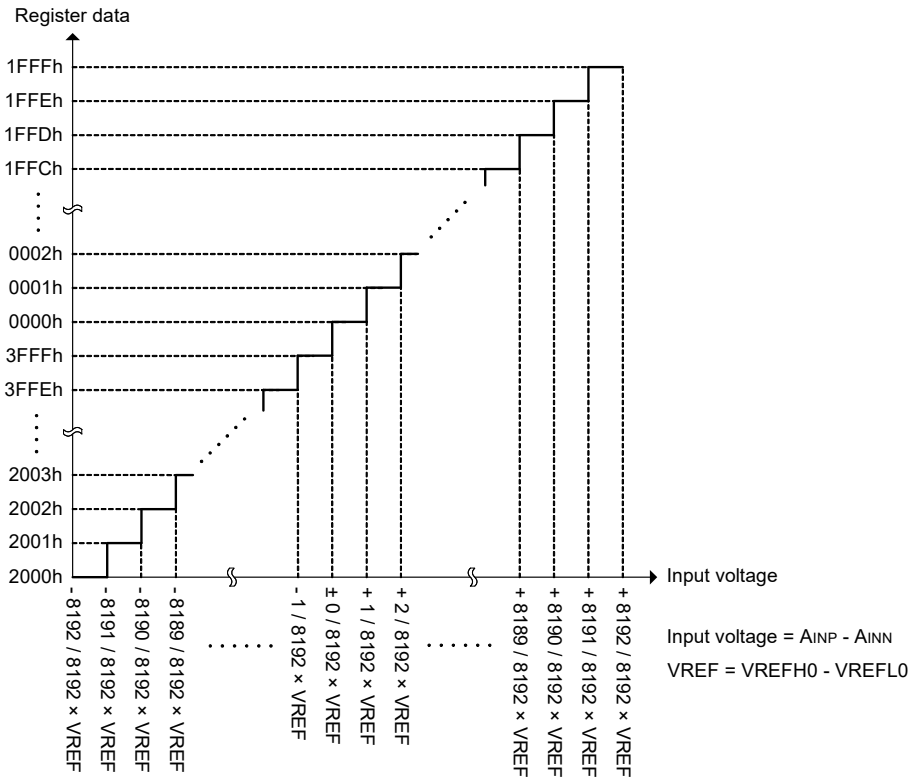

Table 60.55 shows the alignment of A/D conversion data on 14-bit data format. Figure 60.48 and Figure 60.49 show the data range for 14-bit data format.

For 14-bit data length signed data format, the differential input voltage is A/D-converted in the range of 2000h (-VREFH0) to 1FFFh (+VREFH0). In 14-bit data length unsigned data format, the single-ended input voltage is A/D-converted in the range of 0000h (VREFL0) to 3FFFh (VREFH0).

For 14-bit data length, the upper 2 bits (bit15 to bit14) are always 0.

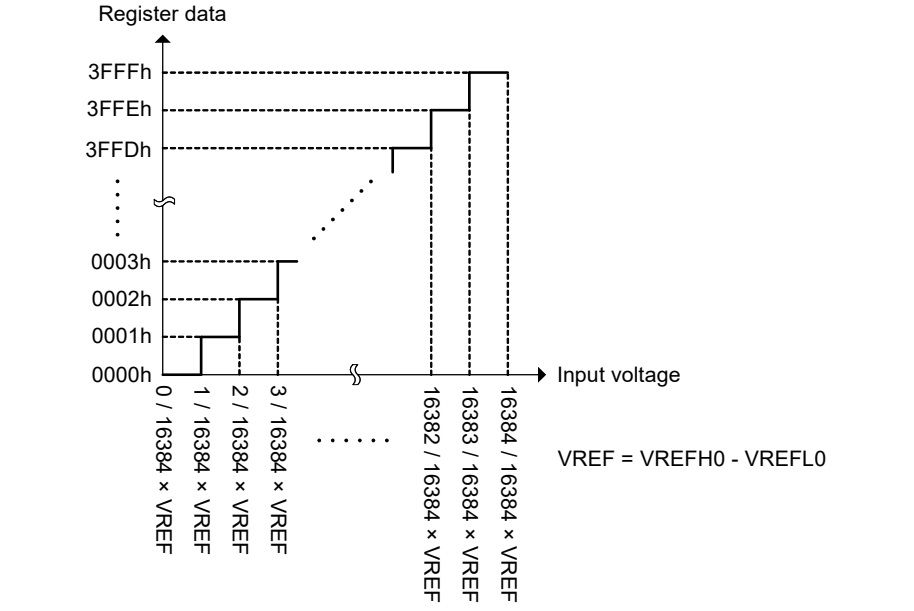

Table 60.55 Alignment of A/D Conversion Result Data (14-Bit Data Length)

Figure 60.49 Data Range of A/D Conversion Result (14-Bit Data Length, Unsigned Data, Single-Ended Input)

(3) 12-bits data length format

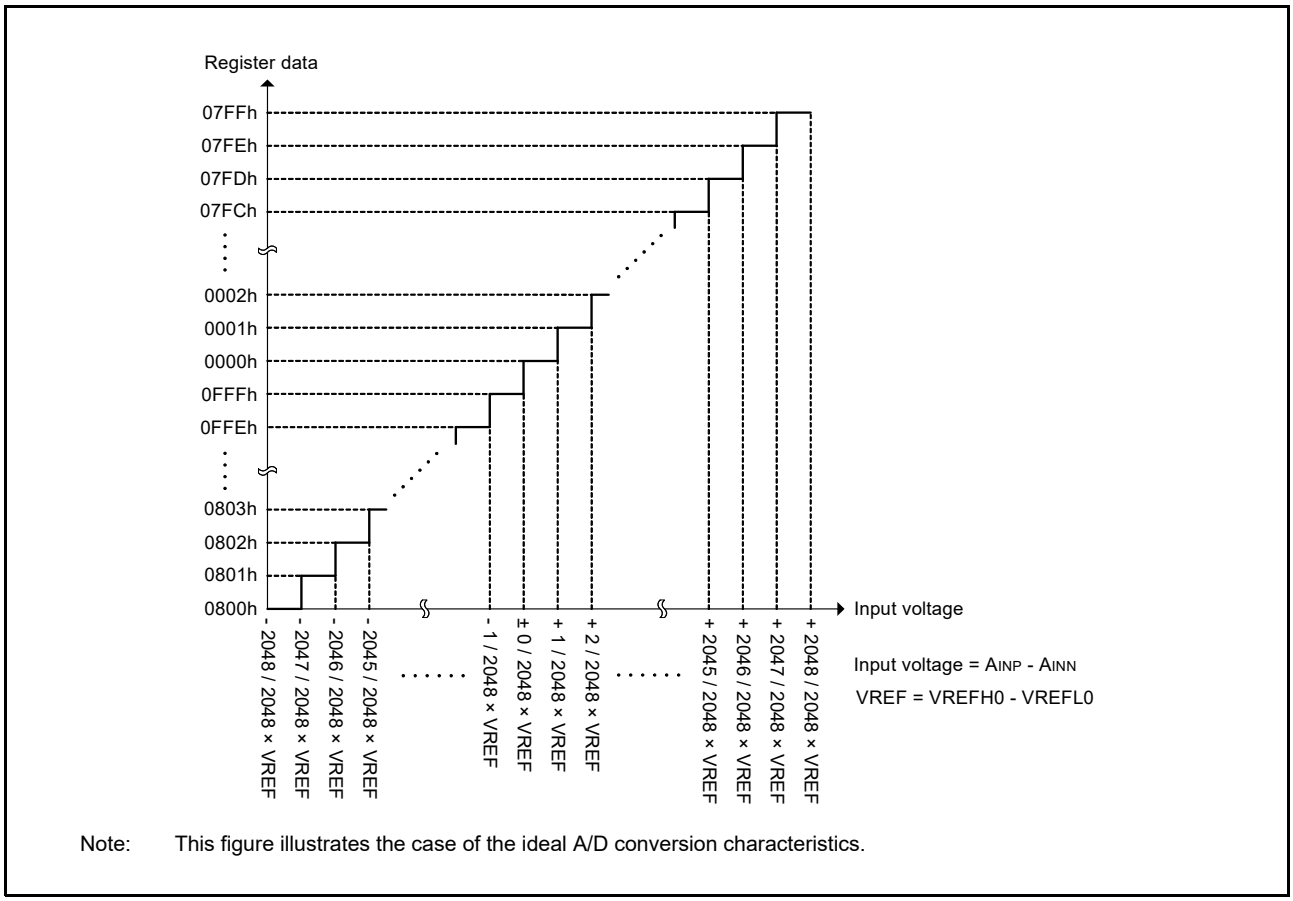

Table 60.56 shows the alignment of A/D conversion data on 12-bit data format. Figure 60.50 and Figure 60.51 show the data range for 12-bit data format.

For 12-bit data length signed data format, the differential input voltage is A/D-converted in the range of 0800h (-VREFH0) to 07FFh (+VREFH0). In 12-bit data length unsigned data format, the single-ended input voltage is A/D-converted in the range of 0000h (VREFL0) to 0FFFh (VREFH0).

For 12-bit data length, the upper 4 bits (bit15 to bit12) are always 0.

Table 60.56 Alignment of A/D Conversion Result Data (12-Bit Data Length)

Bit number:	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

60.4.8 Compare Match Function

60.4.8.1 Compare Match

The compare match function compares the A/D conversion result with the reference value set in the compare match table register (ADCMPTBRn (n = 0 to 7). The compare match function compares the A/D conversion data after the data formatting process.

(1) Compare match mode

The comparison mode for detecting the compare match is selected in ADCMPMDRm.CMPMDn[1:0] (m = 0, 1. n = 0 to 7). The comparison mode can be selected from the following four modes.

1. Compare match is detected when the A/D conversion value is greater than or equal to the specified upper limit value.
2. Compare match is detected when the A/D conversion value is less than or equal to the specified lower limit.
3. Compare match is detected when the A/D conversion value is greater than or equal to the specified upper limit value, or less than or equal to the lower limit value.
4. Compare match is detected when the A/D conversion value is within the specified upper and lower limit values (when the value is lower than or equal to the upper limit value and greater than or equal to the lower limit value).

Figure 60.54 shows an example of compare match detection.

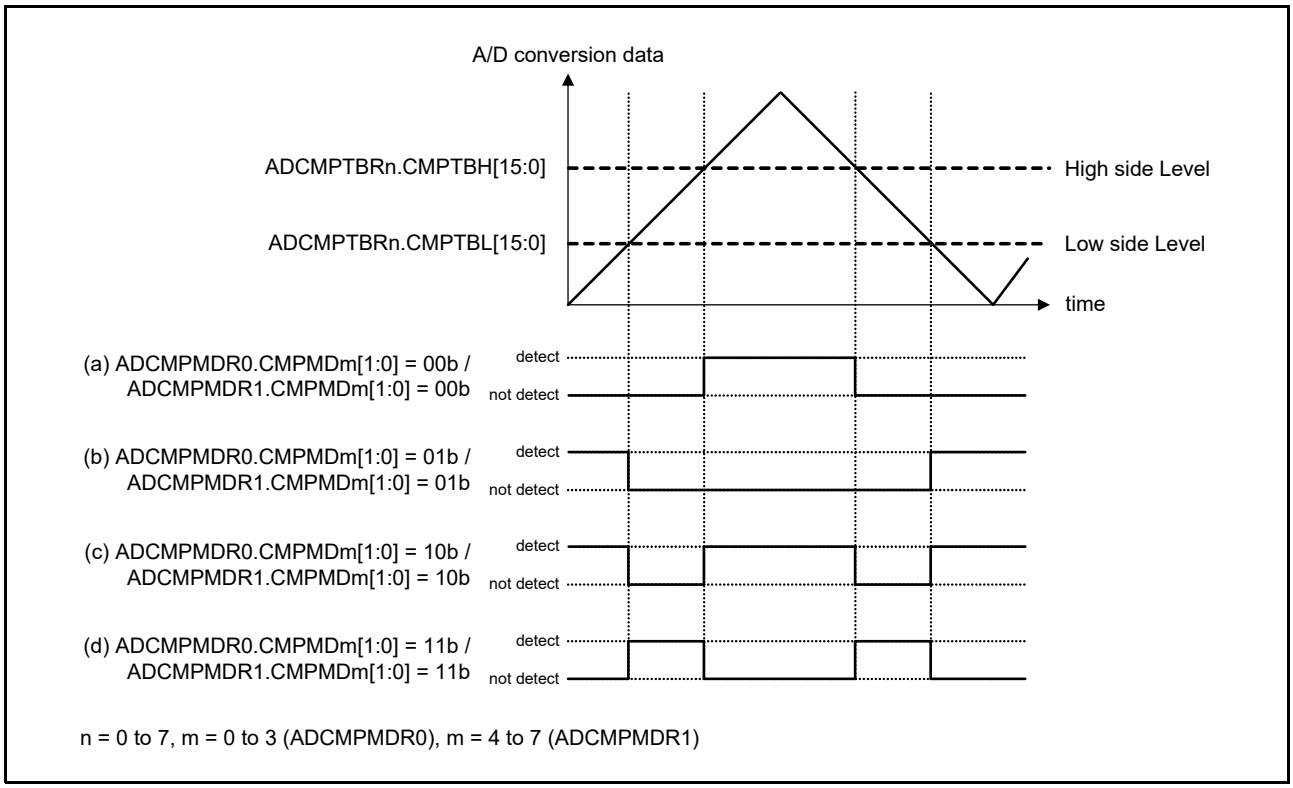

Figure 60.54 Compare Match Detection

(2) Compare match detection

To use the compare match function, enable the compare match table used in ADCMPENR register, and select the compare match table in ADDOPCRBn.CMPTBLEm (n = 0 to 49, m = 0 to 7) for each virtual channel.
When A/D conversion is performed on a virtual channel for which the compare match function is enabled, a compare match is judged based on the A/D conversion result of its channel.
When a compare match is detected, the flags are set in the following status registers:

- ADCMPTBSR: The flag is set to the bit corresponding to the compare match table used when a compare match is detected.
- ADCMPCHSR0, ADCMPCHSR1: The flag is set to the bit corresponding to the analog input channel that detected the compare match.
- ADCMPEXSR: The flag is set to the bit corresponding to Extended Analog Function where a compare match is detected.

To clear the flag of each status register, write 1 to the corresponding bit of ADCMPTBSCR, ADCMPCHSCR0, ADCMPCHSCR1, ADCMPEXSCR.
If compare match interrupt is enabled in ADCMPINTCR register and a compare match using compare match table 0 to 7 is detected, the corresponding interrupt is generated.

60.4.8.2 Composite Compare Match

The composite compare match function generates interrupts and ELC events by combining the comparison results of multiple compare match tables. The combinations and conditions for the compare match table for the composite compare match function can be set using ADCCMPCRn (n = 0 to 7).
Composite compare match interrupt is generated when a compare match is detected that matches the specified condition. Also, if a compare match is not detected, a composite compare unmatch interrupt is generated.
Figure 60.55 shows the relationship between composite compare match and compare match function. Table 60.58 shows the relationship between the composite compare match function and the control register.

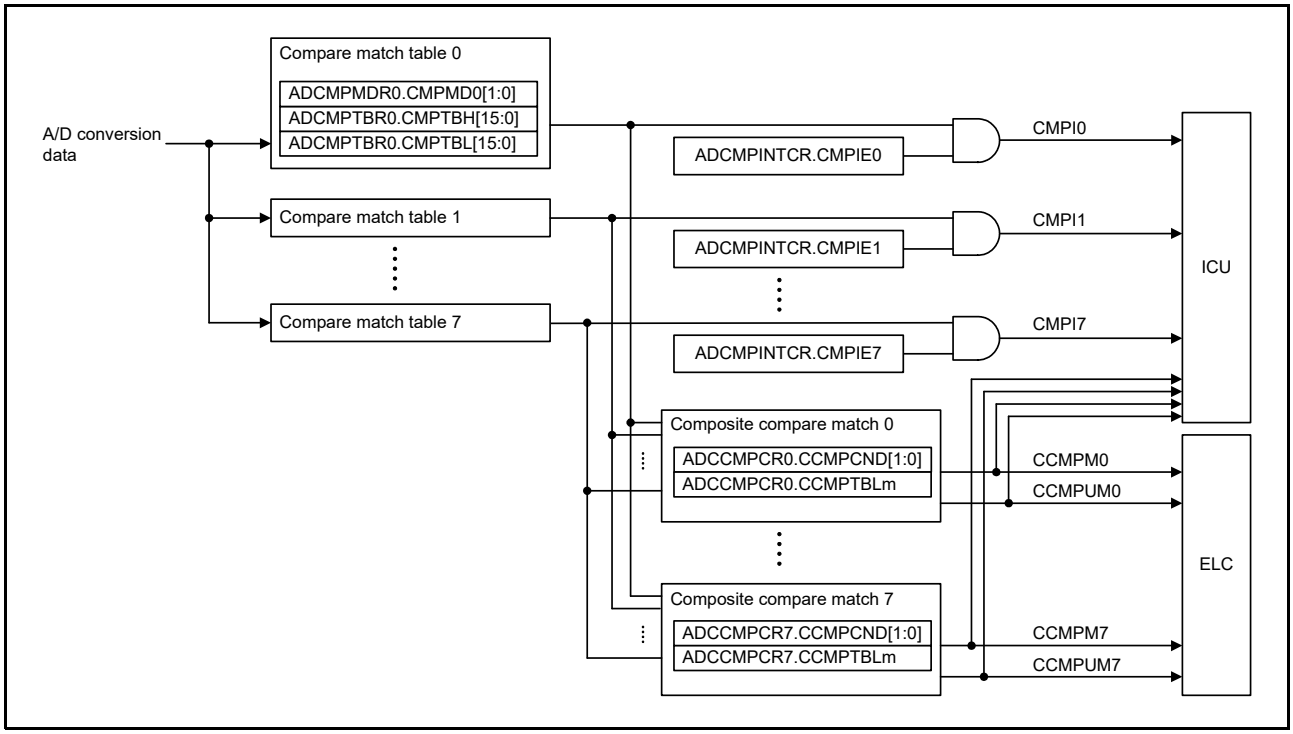

Figure 60.55 Relationship between Composite Compare Match Function and Compare Match Function

Table 60.58 Composite Compare Match and Control Register (m = 0 to 7)

Function Name	Enable Composite Compare Function	Composite Compare Mode Selection	Composite Compare Match Interrupt
Composite compare match 0	ADCCMPCR0.CCMPTBLm	ADCCMPCR0.CCMPCND[1:0]	CCMPM0, CCMPUM0
Composite compare match 1	ADCCMPCR1.CCMPTBLm	ADCCMPCR1.CCMPCND[1:0]	CCMPM1, CCMPUM1
Composite compare match 2	ADCCMPCR2.CCMPTBLm	ADCCMPCR2.CCMPCND[1:0]	CCMPM2, CCMPUM2
Composite compare match 3	ADCCMPCR3.CCMPTBLm	ADCCMPCR3.CCMPCND[1:0]	CCMPM3, CCMPUM3
Composite compare match 4	ADCCMPCR4.CCMPTBLm	ADCCMPCR4.CCMPCND[1:0]	CCMPM4, CCMPUM4
Composite compare match 5	ADCCMPCR5.CCMPTBLm	ADCCMPCR5.CCMPCND[1:0]	CCMPM5, CCMPUM5
Composite compare match 6	ADCCMPCR6.CCMPTBLm	ADCCMPCR6.CCMPCND[1:0]	CCMPM6, CCMPUM6
Composite compare match 7	ADCCMPCR7.CCMPTBLm	ADCCMPCR7.CCMPCND[1:0]	CCMPM7, CCMPUM7

60.4.9 Data Registers

A/D data register (ADDRi (i = 0 to 35)) and Extended A/D data register (ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to 18)) store the A/D conversion data of the analog channels corresponding to each register. These registers are updated (overwritten) when A/D conversion for the analog channel corresponding to each register is completed.

60.4.10 FIFO Function

FIFO consists of 16-stage registers and can hold up to 16 A/D conversion data. One FIFO is implemented for each scan group. The A/D conversion data stored in FIFO can be read from ADFIFODRn register (n = 0 to 11).
FIFO acts as a ring buffer. Writing and reading A/D conversion data to and from FIFO is controlled by the write pointer and read pointer inside FIFO. The block diagram of FIFO is shown in Figure 60.56.

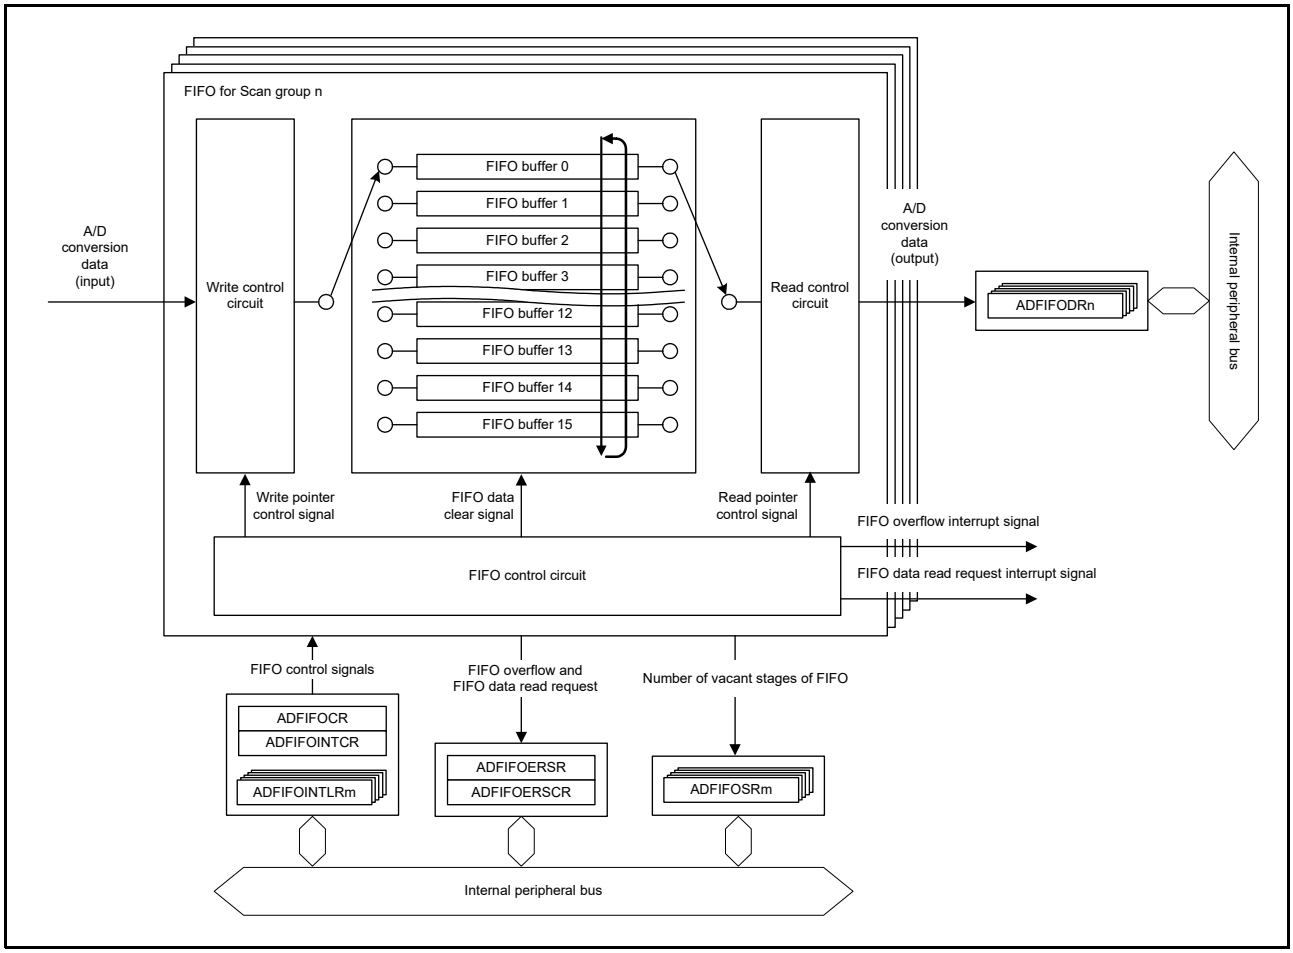

Figure 60.56 The Block Diagram of FIFO (m = 0 to 5, n = 0 to 11)

60.4.10.1 Operation When Writing A/D Conversion Data to FIFO

The A/D conversion data is stored sequentially to the register pointed by the write pointer. When A/D conversion data is written to a register in FIFO, the write pointer is switched to the next register. At this time, the number of vacant stages (ADFIFOSRm.FIFOSTn[4:0] (m = 0 to 5, n = 0 to 11) bits) is decreased 1.
A FIFO overflow occurs when FIFO is full (ADFIFOSRm.FIFOSTn[4:0] bits are 00000b) and an additional A/D conversion data is written to FIFO. When a FIFO overflow occurs, the A/D conversion data is not written and the write pointer does not change.

60.4.10.2 Operation When Reading A/D Conversion Data from FIFO

When A/D conversion data is read from FIFO data register (ADFIFODRn (n = 0 to 11)), the data in the register pointed to by FIFO read pointer is read. When A/D conversion data is read from FIFO, the read pointer is switched to the next register. At this time, the number of vacant stages (ADFIFOSRm.FIFOSTn[4:0] (m = 0 to 5, n = 0 to 11) bits) is increased 1.
If FIFO is empty (ADFIFOSRm.FIFOSTn[4:0] bits are 11111b) and the reading from the FIFO is occurred, an invalid data is read. (If FIFO is read after a reset or after FIFO data is cleared, 00000000h is read. If data had been written to register in FIFO, the previous data is read.) The read pointer does not change in the read operation when FIFO is empty.
Read A/D conversion data from FIFO data register (ADFIFODRn) by 32-bit access. For details, see section 60.4.10.6, Usage Notes on FIFO.

60.4.10.3 FIFO Data Read Request and Overflow

When A/D conversion data is written to or read from FIFO, the write pointer or read pointer changes. Depending on the state of the write pointer and the read pointer, the number of vacant stages in FIFO is reflected in ADFIFOSRm.FIFOSTn[4:0] (m = 0 to 5, n = 0 to 11).
FIFO data read request flag is set (ADFIFOERSR.FIFOFLFn = 1 (n = 0 to 11)) when the number of vacant stages become less than or equal to the value specified in ADFIFOINTLRm.FIFOILVn[4:0] (m = 0 to 5, n = 0 to 11) bit. If a FIFO data read request occurs, FIFO data read request interrupt can be generated.
When FIFO is full (ADFIFOSRm.FIFOSTn[4:0] bits are 00000b) and additional A/D conversion data are written, FIFO overflow flag is set (ADFIFOERSR.FIFOOVFn = 1 (n = 0 to 11)). If a FIFO overflow occurs, FIFO data overflow interrupt can be generated.

60.4.10.4 Clearing FIFO Data

The data stored in the registers in FIFO can be cleared by writing to ADFIFODCR.FIFODCn (n = 0 to 11) bit. When writing 1 to ADFIFODCR.FIFODCn bit, the registers, read pointer, and write pointer in FIFO of the scan group corresponding to FIFODCn bit are initialized. Clearing FIFO data using FIFODCn bit should be performed while A/D conversion is not being performed.

60.4.10.5 Clearing FIFO Data by Starting/Resuming Scanning

For clearing the unnecessary data stored in the registers in FIFO at the start of a scan group or at the restart of scanning after the stop of the previous scanning in group priority operation, write to ADFIFOCR.FIFOCEn (n = 0 to 11) bit. Clearing can be enabled or disabled individually for each scan group. When writing 1 to ADFIFOCR.FIFOCEn (n = 0 to 11) bit, the registers, read pointer, and write pointer in FIFO of the scan group corresponding to FIFOCEn bit are initialized.

60.4.10.6 Usage Notes on FIFO

Reading the A/D conversion data from the FIFO data register (ADFIFODRn (n = 0 to 11)) should be performed with a single 32-bit access; access to each bit of ADFIFODRn, 16-bit read access, and 8-bit read access are prohibited. If these restrictions are violated, the operation of FIFO is not guaranteed. (If these restrictions are violated, the read pointer may not change normally, and correct data may not be able to read. Alternatively, the read pointer may advance unintentionally, and A/D conversion data may be lost.)

If you want to restart scanning and rescan from the first channel during group priority operation, enable FIFO clearing (ADFIFOCR.FIFOCEn = 1 (n = 0 to 11)) for scan groups other than the highest priority group.

When FIFO clear is enabled using ADFIFOCR.FIFOCEn (n = 0 to 11), all data remaining in the FIFO at the start of scan is cleared. Control the scan start timing so that the FIFO is not cleared before the necessary FIFO data is read. When the clearing FIFO data function by starting/resuming scanning is enabled using ADFIFOCR.FIFOCEn (n = 0 to 11), all data remaining in the FIFO at the start of scan, or all data before the stop of the previous scanning at the restart of a scan, is cleared. Note that the usage of the clearing FIFO data function by starting/resuming scanning is prohibited for other than SAR mode and group priority operation.

60.4.11 A/D Conversion Data Output Decimation

In oversampling mode with same channel continuous scan mode, the output of A/D conversion data can be decimated (decimation). The A/D conversion data output interval can be set for each unit using ADDECCR.DCIMm (m = 0 to 2). When A/D conversion data output is decimated using this function, the interrupt output is decimated as well. When this function is used in addition/average mode, the A/D conversion data output interval is the period when the specified number of times the data has been added or averaged and then decimated by this function. In addition/average mode, the data to be decimated by this function is the data before addition/averaging. Figure 60.57 shows an example of operation when only one result of conversion is output for every four A/D conversions. Figure 60.58 shows an example of operation when only one result of conversion is output for every four A/D conversions with 4-time addition.

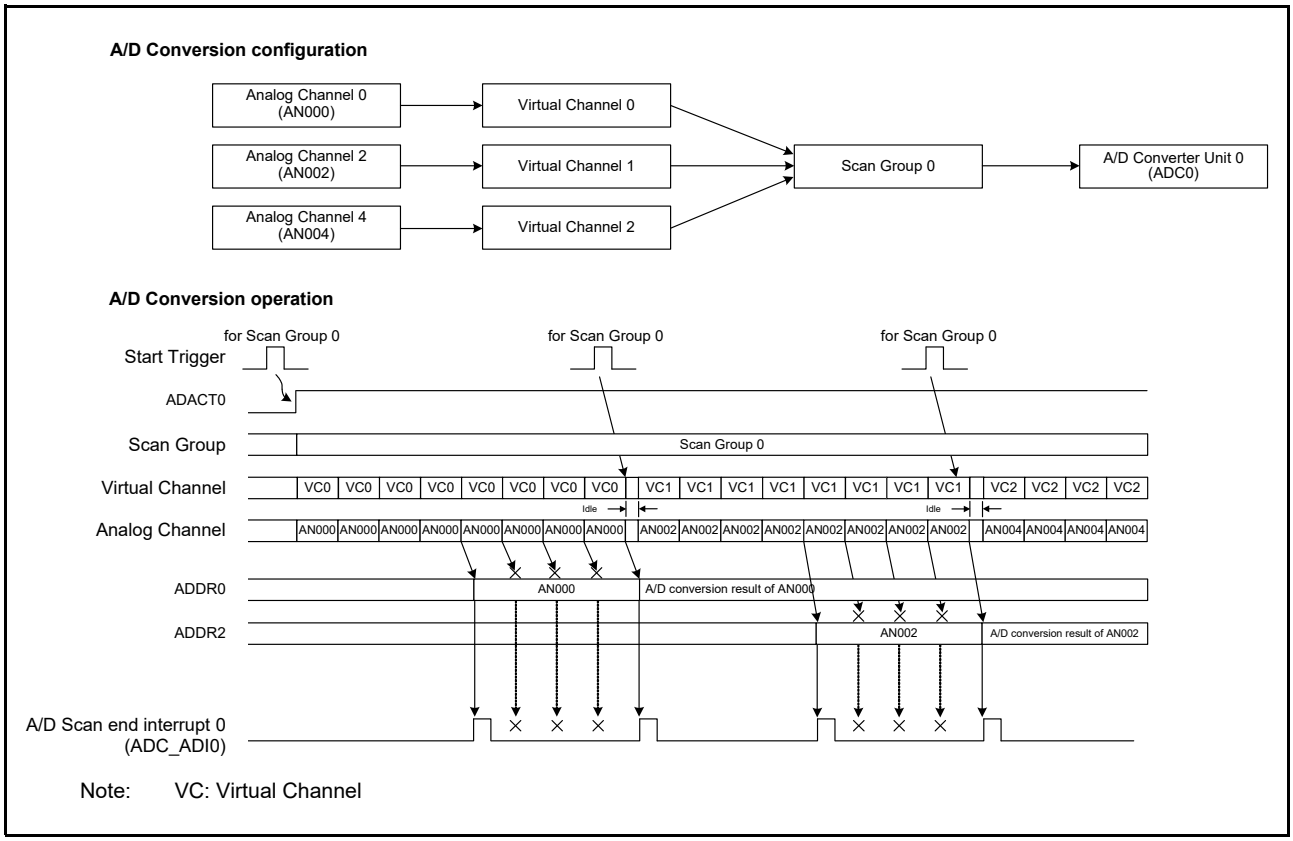

Figure 60.57 Example of the Decimation Function Operation When Only One Result of Conversion Is Output for Every Four A/D Conversions

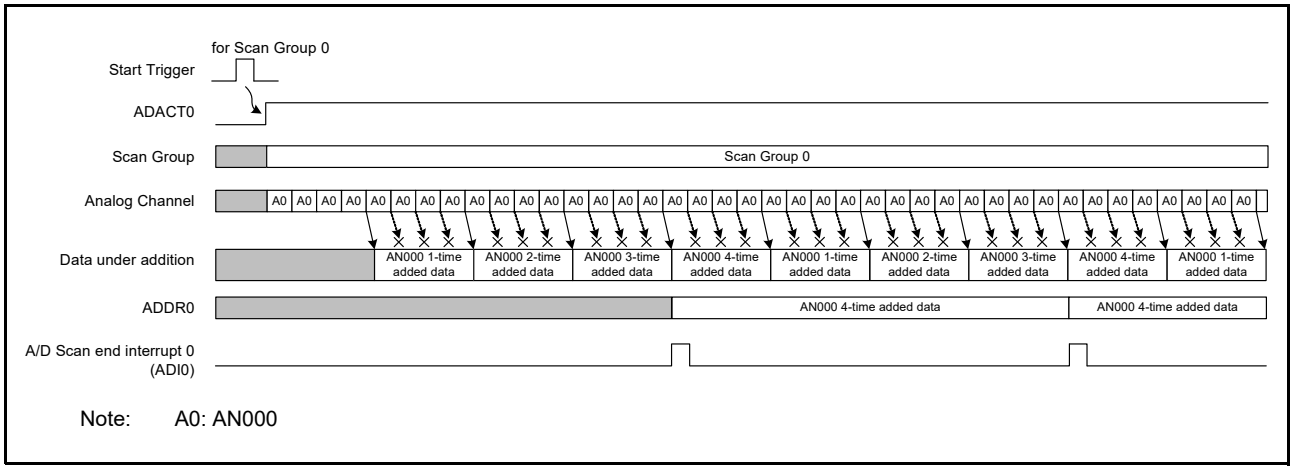

Figure 60.58 Example of the Decimation Function Operation When Only One Result of Conversion Is Output for Every Four A/D Conversions with 4-time Addition in the Addition Mode

60.4.12 A/D Conversion Data Error Detection

The ERR bit in A/D data register (ADDRi (i = 0 to 35)), Extended A/D data register (ADEXDRj (j = 0 to 2, 4 to 6, 8, 9, 16 to18)), and FIFO data register (ADFIFODRk (k = 0 to 11)) is a flag that indicates an A/D conversion data error. An A/D conversion data error indicates that an invalid A/D conversion data has been detected. If an A/D conversion data error occurs (ERR = 1), the A/D conversion data cannot be guaranteed.
A/D conversion data error is generated by the following factors.

- A/D converter error
- A/D conversion overflow

For more details about these errors, see section 60.6, Error Detection.

60.5 Start and Stop Control of A/D Conversion

60.5.1 Software Trigger

A/D conversion of scan group n can be started by writing 1 to ADSTRn.ADST (n = 0 to 11) bit or ADSYSTR.ADSYSTn (n = 0 to 11) bit.
ADSTRn.ADST bit is used to start A/D conversion individually for each scan group. ADSYSTR.ADSYSTn bit is used to start A/D conversion on the scan group assigned to ADC0, ADC1 or ADC2 at the same time.
Except when group priority operation, writing to ADSTRn.ADST bit or ADSYSTR.ADSYSTn bit for the scan groups, which use A/D converter that is in A/D conversion, is ignored.

60.5.2 Peripheral Module Triggers

A/D conversion can be started by triggers from the peripheral modules listed in the followings.

- ELC Trigger
- GPT Trigger
- External Trigger (I/O port)

To perform A/D conversion by a trigger from a peripheral module, configure the trigger for each scan group and enable the trigger input from the peripheral module in ADTRGENR register.

60.5.2.1 ELC Trigger

A/D conversion can be started by an event (ELC event) from Event Link Controller. To start A/D conversion using an ELC event, configure the scan group using the ELC event in ADTRGELCn (n = 0 to 11) register and enable the A/D conversion start trigger in ADTRGENR register. Table 60.59 shows the correspondence between ADTRGELCn register and ELC event.

Table 60.59 Correspondence between ELC Trigger Enable Register and ELC Event

Register Bit	Event Name
ADTRGELCn.TRGELC0	ELC_AD00
ADTRGELCn.TRGELC1	ELC_AD01
ADTRGELCn.TRGELC2	ELC_AD02
ADTRGELCn.TRGELC3	ELC_AD10
ADTRGELCn.TRGELC4	ELC_AD11
ADTRGELCn.TRGELC5	ELC_AD12
ADTRGELCn.TRGELC6	ELC_AD20
ADTRGELCn.TRGELC7	ELC_AD21
ADTRGELCn.TRGELC8	ELC_AD22

n = 0 to 11

60.5.2.2 GPT Trigger

A/D conversion can be started by an interrupt source from the general-purpose PWM Timer (GPT). To start A/D conversion using an interrupt source from the GPT, configure the scan group using the GPT interrupt source in ADTRGGPTn (n = 0 to 11) register and enable the A/D conversion start trigger in ADTRGENR register. Table 60.60 shows the correspondence between ADTRGGPTn register and GPT interrupt sources.

Table 60.60 Correspondence between GPT Trigger Enable Registers and GPT Interrupt Sources

Register Bit	Event Name

ADTRGGPTn.TRGGPTB6	GPT6_ADTRGB
ADTRGGPTn.TRGGPTB7	GPT7_ADTRGB
ADTRGGPTn.TRGGPTB8	GPT8_ADTRGB
ADTRGGPTn.TRGGPTB9	GPT9_ADTRGB
ADTRGGPTn.TRGGPTB10	GPT10_ADTRGB
ADTRGGPTn.TRGGPTB11	GPT11_ADTRGB
ADTRGGPTn.TRGGPTB12	GPT12_ADTRGB
ADTRGGPTn.TRGGPTB13	GPT13_ADTRGB
ADTRGGPTn.TRGGPTB14	GPT14_ADTRGB
ADTRGGPTn.TRGGPTB15	GPT15_ADTRGB

n = 0 to 11

60.5.2.3 External Trigger

A/D conversion can be started by the input from the external trigger pin (ADTRG0, ADTRG1 and ADTRG2). To start A/D conversion using an external trigger, configure the scan group using the external trigger in ADTRGEXTn (n = 0 to 11) register and enable the A/D conversion start trigger in ADTRGENR register.

External trigger is active low. Before setting to enable the external trigger (ADTRG0, ADTRG1 and ADTRG2), you should input the High level to the external trigger pin.

60.5.3 Trigger Delay

The trigger delay function adds a delay to the A/D conversion start trigger in order to adjust the A/D conversion start timing for each scan group. This function adds a delay to the internal trigger for each scan group generated by accepting an external trigger, ELC trigger or GPT trigger. This function cannot be used to add a delay to a software trigger.
The delay value to be added to the internal trigger is set for each scan group in ADTRGDLRi (i = 0 to 5) register. The delay value to be added is the register setting value × A/D conversion clock (ADCLK) cycle.

60.5.4 Force Stops the A/D Conversion Operation

The scanning operation of the A/D converter can be forcibly stopped by writing 1 to ADSTOPR.ADSTOPm (m = 0 to 2) bit during scanning operation. If the scanning operation is forcibly stopped, the A/D conversion data is not guaranteed.

60.5.4.1 Forced Stop Procedure

Table 60.61 shows the procedure for forced stop of A/D conversion operation. Observe Table 60.61 when performing the forced stop. If this procedure is violated, the A/D converter may not be able to stop and then it may not operate normally. In that case, a reset is required for recovery.

Table 60.61 Procedure for Forced Stop of A/D Conversion Operation

No.	Step Name	Description
1	Disable trigger input	Disables the trigger input from the peripheral module. (Write ADTRGENR.STTRGENn = 0)
2	Waiting time	After setting the above Step 1, a wait time is required to safely stop the A/D converter. Proceed to the next processing after the specified waiting time has elapsed. For details on the wait time, see section 60.5.4.2, Waiting Time after Disabling Trigger Input for Forced Stop Processing.
3	Checking the A/D converter status	Check if the A/D converter is operating after the waiting time of the above Step 2 has elapsed. If the A/D converter is running (ADSR.ADACTm = 1), proceed to Step 4. If the A/D converter is stopped (ADSR.ADACTm = 0), no further processing is required (proceed to Step 6).
4	Forced stop of A/D converter	Forcibly stop the A/D converter by ADSTOPR register. (Write ADSTOPR.ADSTOPm = 1)
5	Waiting for A/D converter to stop	Wait until the A/D converter stops. (ADSR.ADACTm = 0)
6	End	Processing of forced stop is completed.

m = 0 to 2, n = 0 to 11

Do not write to ADSYSTR register or ADSTRn register while this forced stop procedure is in progress.

60.5.4.2 Waiting Time after Disabling Trigger Input for Forced Stop Processing

In the forced stop procedure shown in Table 60.61, after disabling the trigger input from the peripheral module, a wait time is required to perform the forced stop (Step 2 of Table 60.61). This wait time is the time that must be secured to perform a forced stop safely.
The wait time after disabling the trigger input for forced stop processing is calculated as follows.
[Waiting time after disabling trigger input in forced stop processing]

- When synchronous operation is enabled (ADSYCR.ADSYDISm = 0)
  - (ADTRGDLRi.TRGDLYn[7:0] setting value + ADSYCR.ADCSYCYC[7:0] setting value × 2) × t_{ADCLK}
- When synchronous operation is disabled (ADSYCR.ADSYDISm = 1)
  - (4 + ADTRGDLRi.TRGDLYn[7:0] setting value) × t_{ADCLK}

Note: i = 0 to 5, n = 0 to 11, m = 0 to 2, t_{ADCLK}: ADCLK period

After the waiting time calculated by the above expressions has elapsed, proceed to the Step 3 in Table 60.61. There are two ways to generate the waiting time: (a) Use the timer function built into MCU. (b) Read the status register multiple times. If you choose (b), the number of register reads to generate the waiting time required is calculated by the following equation:

[Number of register reads to generate the waiting time]

N_{RD} = (Wait time after disabling trigger input ÷ (t_{PCLK} × N_{RDCYC})) + 1

N_{RD}: Number of register reads required to generate the trigger input disable wait time (truncate after the decimal point)

t_{PCLK}: The period of the Bus I/F clock (PCLKA)

N_{RDCYC}: Minimum number of register read access cycles (see section 5, I/O Registers.)

60.6 Error Detection

60.6.1 A/D Converter Error

An A/D converter error is detected when an abnormal operation of the A/D converter occurs. If an A/D converter error is detected, the A/D conversion result is not guaranteed.
An A/D converter error occurs in the following cases:

[A/D Converter Error Generation Conditions]

- When A/D conversion is performed without self-calibration.
- When the operating frequency of ADCLK exceeds the guaranteed operating frequency range specified in the electric characteristics.
- When the successive approximation time of the A/D converter exceeds the guaranteed operating range specified in the electric characteristics.
- When an accidental abnormal operation occurs in the A/D converter due to external factors.

If an A/D converter error is detected, the flag is set in ADERSR.ADERFn (n = 0 to 2) bit. To clear the A/D converter error flag, write 1 to the corresponding bit in ADERSCR register.

Notes on A/D Converter Error

The A/D converter error is an auxiliary function used to detect abnormal operation of the A/D converter. It does not guarantee the reliable detection of abnormal operation. Even under the A/D converter error occurrence conditions described above, an A/D converter error may not be detected depending on the individual chip differences and chip operating conditions.

60.6.2 A/D Conversion Overflow

A/D conversion overflow is detected when A/D conversion data exceeds the range that can be handled in the specified data format. If A/D conversion overflow occurs, the A/D conversion data becomes the upper or lower limit value of the specified data format. For the range that can be handled as A/D conversion data, see section 60.4.7, Data Format.
A/D conversion overflow is detected in the following cases:

- When the input to the A/D converter exceeds the range between VREFH0 to VREFL0
  - Single-ended input: When the input to the A/D converter exceeds VREFH0 or falls below VREFL0
  - Differential input: When the differential input to the A/D converter exceeds +VREFH0 or falls below -VREFH0
- When overflow occurs by the internal processing (calculation) for the A/D conversion data shown in the following:
  - Gain error and Offset error calibration
  - User's Gain/User's Offset adjustment function
  - When using A/D-converted value addition function
  - Data formatting process

When an A/D conversion overflow is detected, the flag is set in the following status register:

- ADOVFERSR: The flag is set to the bit corresponding to the A/D converter that detected the A/D conversion overflow.
- ADOVFCHSR0, ADOVFCHSR1: The flag is set to the bit corresponding to the analog input channel on which A/D conversion overflow is detected.
- ADOVFEXSR: The flag is set to the bit corresponding to the extended analog channel on which A/D conversion overflow is detected.

To clear the flags in the status registers, write 1 to the corresponding bit in ADOVFERSCR, ADOVFCHSCR0, ADOVFCHSCR1, ADOVFEXSCR.

60.6.3 FIFO Overflow

If A/D-converted data is written (added) to FIFO while FIFO is full, a FIFO overflow is detected. For more details about FIFO overflow, see section 60.4.10, FIFO Function.

60.7 Procedure for Setting up and Changing

60.7.1 Initial Setup Procedure

Table 60.62 shows the initial setup procedure.

Table 60.62 Initial Setup Procedure

No.	Step	Description
1	Release module-stop	Release the module-stop bit for ADC in MSTPCR register.*1
2	I/O port configuration	Set ASEL bit of the pin used as analog input to 1.
3	Synchronous operation configuration	Set the synchronous operation function. The synchronous operation function is disabled at the initial value of the ADSYCR register after reset released. If the synchronous operation function is used, be sure to enable the synchronous operation function (ADSYCR.ADSYDISm = 1 (m = 0 to 2))*2.
4	ADCLK configuration	Set the clock source and division ratio for ADCLK. Then, set ADCLKENR.CLKEN bit to 1, and wait for ADCLK to supply (ADCLKSR.CLKSR = 1)*3.
5	A/D conversion configuration	Configure the A/D conversion settings.
6	Wait for operation stabilization	Wait until the operating stabilization times specified in the Electrical Characteristics have elapsed.
7	Self-calibration	Self-calibration must be executed prior to starting A/D conversion. Set up for self-calibration and execute it. For details, see section 60.3.9, Self-Calibration.
8	Enabling constant sampling	When the constant sampling function is to be used, enable the function after self-calibration is completed.
9	Trigger configuration	To start A/D conversion by a trigger from peripheral modules, configure the triggers for each scan group.
10	Start of A/D conversion	When a software trigger or a trigger from peripheral modules is input, A/D conversion (scanning operation) starts.

Note: In either of the following cases, release the GPT module-stop state using the Module Stop Register E (MSTPCRE) before the corresponding step.
- An external signal (the synchronization signal from the GPT) is to be used in Step 3.
- GPTCLK is to be selected in Step 4.
For details, see section 11, Low Power Consumption.

Note 1. When the ADC units need to be stopped individually, set the corresponding ADUSLPCRm.ADUSLPm bits to 1 (m = 0 to 2).
Note 2. When an external signal (the synchronization signal from the GPT) is to be used, set the ADSYCR.ADSYEXTEN bit to 1.
Note 3. When an external signal (the synchronization signal from the GPT) is to be used, confirm that the setting of the ADCLKSR.SYLOCKSR bit is 1.

60.7.2 Procedure for Changing ADCLK Settings

Table 60.63 shows the procedure for changing ADCLK setting. Table 60.64 shows the procedure for changing ADCLK setting while an external signal (the synchronization signal from the GPT) is in use.

Table 60.63 Procedure for Changing ADCLK Setting (1/2)

No.	Step	Description
1	Disable trigger input	Disables the trigger input from the peripheral module. (Write ADTRGENR.STTRGENn = 0 (n = 0 to 11))
2	Stop A/D conversion	Check that all A/D converter is stopped. When A/D conversion is in progress, wait until all A/D conversion is completed or forcibly stop A/D conversion operation. For details about forcibly stop A/D conversion operation, see section 60.5.4, Force Stops the A/D Conversion Operation.
3	Stop ADCLK supplies	Set ADCLKENR.CLKEN bit to 0. Then, wait for ADCLK to stop (ADCLKSR.CLKSR = 0).
4	Change ADCLK setting	Change the clock-source and the division ratio for ADCLK.*1
5	Started supplying ADCLK	Set ADCLKENR.CLKEN bit to 1, and wait for ADCLK to supply (ADCLKSR.CLKSR = 1).

Table 60.63 Procedure for Changing ADCLK Setting (2/2)

No.	Step	Description
6	Change the A/D conversion configuration	Change the following settings according to the changed ADCLK frequency. • Successive approximation time for A/D converter • Number of sampling states for A/D conversion • Number of sampling states and hold mode switching states for channel- dedicated sample-and-hold circuit*2 • Number of states for self-calibration operation (A/D converter and channel- dedicated sample-and-hold circuit*2) • Synchronous operation period*3 • Disconnection detection assist period*4 If other settings related to A/D conversion are also to be changed, change them in this step.
7	Wait for operation stabilization	Wait until the operating stabilization times specified in the section 67, Electrical Characteristics have elapsed.
8	Self-calibration	Execute self-calibration operation prior to starting A/D conversion. For details, see section 60.3.9, Self-Calibration.
9	Enabling constant sampling	When the constant sampling function is to be used, enable the function after self-calibration is completed.
10	Trigger configuration	To start A/D conversion by a trigger from peripheral modules, configure the triggers for each scan group.
11	Start of A/D conversion	When a software trigger or a trigger from peripheral modules is input, A/D conversion (scanning operation) starts.

Note 1. When GPTCLK is selected, release the GPT module-stop state using the Module Stop Register E (MSTPCRE). For details, see section 11, Low Power Consumption.
Note 2. Setting is not required when channel-dedicated sample-and-hold circuit is not used.
Note 3. No change is required when synchronous operation setting is disabled (ADSYCR, ADSYDISm = 1 (m = 0 to 2))
Note 4. Setting is not required when disconnection detection assist function is not used.

Table 60.64 Procedure for Changing ADCLK Setting While an External Signal (the Synchronization Signal from the GPT) is in Use (ADSYCR.ADSYEXTEN = 1) (1/2)

No.	Step	Description
1	Disable trigger input	Disables the trigger input from the peripheral module. (Write ADTRGENR.STTRGENn = 0 (n = 0 to 11))
2	Stop A/D conversion	Check that all A/D converter is stopped. When A/D conversion is in progress, wait until all A/D conversion is completed or forcibly stop A/D conversion operation. For details about forcibly stop A/D conversion operation, see section 60.5.4, Force Stops the A/D Conversion Operation.
3	Stop of the synchronization signal from the GPT	Stop the synchronization signal from the GPT. After stopping the signal, wait for at least 3 ADCLK.
4	Stop ADCLK supplies	Set ADCLKENR.CLKEN bit to 0. Then, wait for ADCLK to stop (ADCLKSR.CLKSR = 0).
5	Change ADCLK setting	Change the clock-source and the division ratio for ADCLK.*1
6	Start of the synchronization signal from the GPT	Start the output of the synchronization signal from the GPT.
7	Started supplying ADCLK	Set ADCLKENR.CLKEN bit to 1, and wait for ADCLK to supply (ADCLKSR.CLKSR = 1)*2.
8	Confirmation of synchronization with an external signal (the synchronization signal from the GPT)	Confirm that the setting of the ADCLKSR.SYLOCKSR bit is 1.
9	Change the A/D conversion configuration	Change the following settings according to the changed ADCLK frequency. • Successive approximation time for A/D converter • Number of sampling states for A/D conversion • Number of sampling states and hold mode switching states for channel- dedicated sample-and-hold circuit*3 • Number of states for self-calibration operation (A/D converter and channel- dedicated sample-and-hold circuit*3) • Synchronous operation period • Disconnection detection assist period*4 If other settings related to A/D conversion are also to be changed, change them in this step.

Table 60.64 Procedure for Changing ADCLK Setting While an External Signal (the Synchronization Signal from the GPT) is in Use (ADSYCR.ADSYEXTEN = 1) (2/2)

No.	Step	Description
10	Wait for operation stabilization	Wait until the operating stabilization times specified in the section 67, Electrical Characteristics have elapsed.
11	Self-calibration	Execute self-calibration operation prior to starting A/D conversion. For details, see section 60.3.9, Self-Calibration.
12	Enabling constant sampling	When the constant sampling function is to be used, enable the function after self-calibration is completed.
13	Trigger configuration	To start A/D conversion by a trigger from peripheral modules, configure the triggers for each scan group.
14	Start of A/D conversion	When a software trigger or a trigger from peripheral modules is input, A/D conversion (scanning operation) starts.

Note 1. When GPTCLK is selected, release the GPT module-stop state using the Module Stop Register E (MSTPCRE). For details, see section 11, Low Power Consumption.
Note 2. The time until the supply of the clock is resumed is longer than that while the setting of the ADSYCR.ADSYEXTEN bit is 0 by up to 1 ADCLK.
Note 3. Setting is not required when channel-dedicated sample-and-hold circuit is not used.
Note 4. Setting is not required when disconnection detection assist function is not used.

60.7.3 Procedure for Changing the Settings of the A/D Converter

Table 60.65 shows the procedure for changing the A/D conversion configuration while an external signal (the synchronization signal from the GPT) is in use. If there is a change in ADCLK setting, follow the procedures in section 60.7.2, Procedure for Changing ADCLK Settings.

Table 60.65 Procedure for Changing the Settings of the A/D Converter while an External Signal (the Synchronization Signal from the GPT) is in Use (ADSYCR.ADSYEXTEN = 1)

No.	Step	Description
1	Disable trigger input	Disables the trigger input from the peripheral module. (Write ADTRGENR.STTRGENn = 0 (n = 0 to 11))
2	Stop A/D conversion	Check that all A/D converter is stopped. When A/D conversion is in progress, wait until all A/D conversion is completed or forcibly stop A/D conversion operation. For details about forcibly stop A/D conversion operation, see section 60.5.4, Force Stops the A/D Conversion Operation.
3	Stop of the synchronization signal from the GPT	Stop the synchronization signal from the GPT. After stopping the signal, wait for at least 3 ADCLK.
4	Change the A/D conversion configuration	Change the A/D conversion settings (except the settings for ADCLK).
5	Wait for operation stabilization	Wait until the operating stabilization times specified in the section 67, Electrical Characteristics have elapsed.
6	Self-calibration	Execute self-calibration operation prior to starting A/D conversion. For details, see section 60.3.9, Self-Calibration.
7	Enabling constant sampling	When the constant sampling function is to be used, enable the function after self-calibration is completed.
8	Trigger configuration	To start A/D conversion by a trigger from peripheral modules, configure the triggers for each scan group.
9	Start of A/D conversion	When a software trigger or a trigger from peripheral modules is input, A/D conversion (scanning operation) starts.

60.7.4 Procedure for the A/D Converter Entering to and Returning from the Software Standby Mode

Table 60.66 lists the procedure for the A/D converter returning from the software standby mode while an external signal (the synchronization signal from the GPT) is in use.

Table 60.66 Procedure for the A/D Converter Returning from the Software Standby Mode while the Synchronization Signal from the GPT is in Use (ADSYCR.ADSYEXTEN = 1)

No.	Step	Description
1	Disable trigger input	Disables the trigger input from the peripheral module. (Write ADTRGENR.STTRGENn = 0 (n = 0 to 11))
2	Stop A/D conversion	Check that all A/D converter is stopped. When A/D conversion is in progress, wait until all A/D conversion is completed or forcibly stop A/D conversion operation. For details about forcibly stop A/D conversion operation, see section 60.5.4, Force Stops the A/D Conversion Operation.
3	Stop of the synchronization signal from the GPT	Stop the synchronization signal from the GPT. After stopping the signal, wait for at least 3 ADCLK.
4	Stop ADCLK supplies	Set ADCLKENR.CLKEN bit to 0. Then, wait for ADCLK to stop (ADCLKSR.CLKSR = 0).
5	Entering to the software standby mode	Enter the software standby mode.
6	Returning from the software standby mode	Release the software standby mode.
7	ADCLK configuration	Set the clock source and division ratio for ADCLK.*1
8	Start of the synchronization signal from the GPT	Start the output of the synchronization signal from the GPT.
9	Started supplying ADCLK	Set ADCLKENR.CLKEN bit to 1, and wait for ADCLK to supply (ADCLKSR.CLKSR = 1)*2.
10	Confirmation of synchronization with an external signal (the synchronization signal from the GPT)	Confirm that the setting of the ADCLKSR.SYLOCKSR bit is 1.
11	A/D conversion configuration	Change the following settings according to the changed ADCLK frequency. • Successive approximation time for A/D converter • Number of sampling states for A/D conversion • Number of sampling states and hold mode switching states for channel- dedicated sample-and-hold circuit*3 • Number of states for self-calibration operation (A/D converter and channel- dedicated sample-and-hold circuit*3) • Synchronous operation period • Disconnection detection assist period*4 If other settings related to A/D conversion are also to be changed, change them in this step.
12	Wait for operation stabilization	Wait until the operating stabilization times specified in the ssection 67, Electrical Characteristics have elapsed.
13	Self-calibration	Execute self-calibration operation prior to starting A/D conversion. For details, see section 60.3.9, Self-Calibration.
14	Enabling constant sampling	When the constant sampling function is to be used, enable the function after self-calibration is completed.
15	Trigger configuration	To start A/D conversion by a trigger from peripheral modules, configure the triggers for each scan group.
16	Start of A/D conversion	When a software trigger or a trigger from peripheral modules is input, A/D conversion (scanning operation) starts.

Note 1. When GPTCLK is selected, release the GPT module-stop state using the Module Stop Register E (MSTPCRE). For details, see section 11, Low Power Consumption.
Note 2. The time until the supply of the clock is resumed is longer than that while the setting of the ADSYCR.ADSYEXTEN bit is 0 by up to 1 ADCLK.
Note 3. Setting is not required when channel-dedicated sample-and-hold circuit is not used.
Note 4. Setting is not required when disconnection detection assist function is not used.

60.8 Interrupt Sources

Table 60.67 lists ADC interrupt sources.

For more details about interrupts, see section 15, Interrupt Controller (ICUM) . For more details about ELC events, see section 21, Event Link Controller (ELC).

Table 60.67 Interrupt Sources (1/3)

Interrupt Request	Symbol	Description	Status Flag
A/D converter error interrupt	ERR0	Generated when abnormal operation of ADC0 is detected.	ADERSR.ADERF0
	ERR1	Generated when abnormal operation of ADC1 is detected.	ADERSR.ADERF1
	ERR2	Generated when abnormal operation of ADC2 is detected.	ADERSR.ADERF2
A/D converter self-calibration end interrupt	CALEND0	Generated when self-calibration operation of ADC0 is finished.	ADCALENDSR.CALENDF0
	CALEND1	Generated when self-calibration operation of ADC1 is finished.	ADCALENDSR.CALENDF1
	CALEND2	Generated when self-calibration operation of ADC2 is finished.	ADCALENDSR.CALENDF2
A/D scan end interrupt	ADI0	Generated at the scan end of scan group 0	ADSCANENDSR.SCENDF0
	ADI1	Generated at the scan end of scan group 1	ADSCANENDSR.SCENDF1
	ADI2	Generated at the scan end of scan group 2	ADSCANENDSR.SCENDF2
	ADI3	Generated at the scan end of scan group 3	ADSCANENDSR.SCENDF3
	ADI4	Generated at the scan end of scan group 4	ADSCANENDSR.SCENDF4
	ADI5	Generated at the scan end of scan group 5	ADSCANENDSR.SCENDF5
	ADI6	Generated at the scan end of scan group 6	ADSCANENDSR.SCENDF6
	ADI7	Generated at the scan end of scan group 7	ADSCANENDSR.SCENDF7
	ADI8	Generated at the scan end of scan group 8	ADSCANENDSR.SCENDF8
	ADI9	Generated at the scan end of scan group 9	ADSCANENDSR.SCENDF9
	ADI10	Generated at the scan end of scan group 10	ADSCANENDSR.SCENDF10
	ADI11	Generated at the scan end of scan group 11	ADSCANENDSR.SCENDF11
Limiter clip interrupt	LIMCLPI	Generated when a limiter clip using limiter table 0 to 7 is detected for A/D conversion.	ADLIMGRSR.LIMGRFn ADLIMCHSR0.LIMCHFi ADLIMCHSR1.LIMCHFi ADLIMEXSR.LIMEXFj
A/D conversion overflow interrupt	RESOVF0	Generated when the overflow is detected in A/D conversion result with ADC0.	ADOVFERSR.ADOVFEF0 ADOVFCHSR0.OVFCHFi ADOVFCHSR1.OVFCHFi ADOVFEXSR.OVFEXFj
	RESOVF1	Generated when the overflow is detected in A/D conversion result with ADC1.	ADOVFERSR.ADOVFEF1 ADOVFCHSR0.OVFCHFi ADOVFCHSR1.OVFCHFi ADOVFEXSR.OVFEXFj
	RESOVF2	Generated when the overflow is detected in A/D conversion result with ADC2.	ADOVFERSR.ADOVFEF2 ADOVFCHSR0.OVFCHFi ADOVFCHSR1.OVFCHFi ADOVFEXSR.OVFEXFj

Table 60.67 Interrupt Sources (2/3)

Interrupt Request	Symbol	Description	Status Flag
Compare match interrupt	CMPI0	Generated when a compare match with compare match table 0 is detected.	ADCMPTBSR.CMPTBF0
	CMPI1	Generated when a compare match with compare match table 1 is detected.	ADCMPTBSR.CMPTBF1
	CMPI2	Generated when a compare match with compare match table 2 is detected.	ADCMPTBSR.CMPTBF2
	CMPI3	Generated when a compare match with compare match table 3 is detected.	ADCMPTBSR.CMPTBF3
Compare match interrupt	CMPI4	Generated when a compare match with compare match table 4 is detected.	ADCMPTBSR.CMPTBF4
	CMPI5	Generated when a compare match with compare match table 5 is detected.	ADCMPTBSR.CMPTBF5
	CMPI6	Generated when a compare match with compare match table 6 is detected.	ADCMPTBSR.CMPTBF6
	CMPI7	Generated when a compare match with compare match table 7 is detected.	ADCMPTBSR.CMPTBF7
Composite compare match interrupt	CCMPM0 CCMPM1 CCMPM2 CCMPM3 CCMPM4 CCMPM5 CCMPM6 CCMPM7	Generated when a composite compare match with combined conditions using compare match table 0 to 7 is detected.	ADCMPTBSR.CMPTBF0 to ADCMPTBSR.CMPTBF7
	CCMPUM0 CCMPUM1 CCMPUM2 CCMPUM3 CCMPUM4 CCMPUM5 CCMPUM6 CCMPUM7	Generated when a composite compare match with combined conditions using compare match table 0 to 7 is not detected.	ADCMPTBSR.CMPTBF0 to ADCMPTBSR.CMPTBF7

Table 60.67 Interrupt Sources (3/3)

Interrupt Request	Symbol	Description	Status Flag
FIFO data read request interrupt	FIFOREQ0	Generated when the number of vacant stages in FIFO for scan group 0 become less than or equal to the specified value.	ADFIFOSR0.FIFOST0[4:0]
	FIFOREQ1	Generated when the number of vacant stages in FIFO for scan group 1 become less than or equal to the specified value.	ADFIFOSR0.FIFOST1[4:0]
	FIFOREQ2	Generated when the number of vacant stages in FIFO for scan group 2 become less than or equal to the specified value.	ADFIFOSR1.FIFOST2[4:0]
	FIFOREQ3	Generated when the number of vacant stages in FIFO for scan group 3 become less than or equal to the specified value.	ADFIFOSR1.FIFOST3[4:0]
	FIFOREQ4	Generated when the number of vacant stages in FIFO for scan group 4 become less than or equal to the specified value.	ADFIFOSR2.FIFOST4[4:0]
	FIFOREQ5	Generated when the number of vacant stages in FIFO for scan group 5 become less than or equal to the specified value.	ADFIFOSR2.FIFOST5[4:0]
	FIFOREQ6	Generated when the number of vacant stages in FIFO for scan group 6 become less than or equal to the specified value.	ADFIFOSR3.FIFOST6[4:0]
	FIFOREQ7	Generated when the number of vacant stages in FIFO for scan group 7 become less than or equal to the specified value.	ADFIFOSR3.FIFOST7[4:0]
	FIFOREQ8	Generated when the number of vacant stages in FIFO for scan group 8 become less than or equal to the specified value.	ADFIFOSR4.FIFOST8[4:0]
FIFO data read request interrupt	FIFOREQ9	Generated when the number of vacant stages in FIFO for scan group 9 become less than or equal to the specified value.	ADFIFOSR4.FIFOST9[4:0]
	FIFOREQ10	Generated when the number of vacant stages in FIFO for scan group 10 become less than or equal to the specified value.	ADFIFOSR5.FIFOST10[4:0]
	FIFOREQ11	Generated when the number of vacant stages in FIFO for scan group 11 become less than or equal to the specified value.	ADFIFOSR5.FIFOST11[4:0]
FIFO data overflow interrupt	FIFOOVF	Generated when FIFO overflow is detected in any of FIFO for scan group 0 to 11.	ADFIFOERSR.FIFOOVF0 to ADFIFOERSR.FIFOOVF11

Note: n = 0 to 11
i = 0 to 31 (ADLIMCHSR0, ADOVFCHSR0), i = 32 to 35 (ADLIMCHSR1, ADOVFCHSR1)
j = 0 to 2, 4 to 6, 8, 9, 16 to 18

(1) A/D converter error interrupt

A/D converter error interrupt can be generated when an A/D converter error is detected.

A/D converter error interrupt (ERRm (m = 0 to 2)) is generated when ADERINTCR.ADEIEm (m = 0 to 2) bit is 1 and ADERSR.ADERFm (m = 0 to 2) bit is 1.

(2) A/D converter self-calibration end interrupt

A/D converter self-calibration end interrupt can be generated at the end of A/D converter self-calibration operation.

A/D converter self-calibration end interrupt (CALENDm (m = 0 to 2)) is generated when ADCALINTCR.CALENDIEm (m = 0 to 2) bit is 1 and ADCALENDSR.CALENDFm (m = 0 to 2) bit is 1.

(3) A/D scan end interrupt

A/D scan end interrupt can be generated at the end of scanning operation of scan group n (n = 0 to 11).

A/D scan end interrupt for scan group 0 to 11 (ADI0 to ADI11) are generated when ADINTCR.ADIEn (n = 0 to 11) bit is set to 1 and ADSCANENDSR.SCENDFn (n = 0 to 11) bit is set to 1.
However, A/D scan end interrupt is not generated when A/D conversion operation (scanning operation) is forcibly stopped by ADSTOPR register.

(4) Limiter clip interrupt

Limiter clip interrupt (LIMCLPI) can be generated when a limiter clip with limiter table i (i = 0 to 7) is detected.
Limiter clip interrupt is generated when either ADLIMINTCR.LIMIEi (i = 0 to 11) bit is 1 and ADLIMGRSR.LIMGRFi (i = 0 to 11) bit is 1 is satisfied.

(5) A/D conversion overflow interrupt

A/D conversion overflow interrupt can be generated when A/D conversion overflow in the A/D conversion result using ADCm (m = 0 to 2) is detected. For details about A/D conversion overflow, see section 60.6.2, A/D Conversion Overflow.
A/D conversion overflow interrupt (RESOVFm (m = 0 to 2)) is generated when ADOVFINTCR.ADOVFIEm (m = 0 to 2) bit is 1 and ADOVFERSR.ADOVFEFm (m = 0 to 2) bit is 1.

(6) Compare match interrupt

Compare match interrupt can be generated when a compare match is detected.
Compare match interrupt (CMPIj (j = 0 to 7)) is generated when ADCMPINTCR.CMPIEj (j = 0 to 7) bit is 1 and ADCMPTBSR.CMPTBFj (j = 0 to 7) bit is 1.

(7) Composite compare match interrupt, Composite compare unmatch interrupt

Composite compare match interrupt (CCMPMk (k = 0 to 7)), compare unmatch interrupt (CCMPUMk (k = 0 to 7)) can be generated by combining the comparison results of two or more compare match tables. For details about composite compare match, see section 60.4.8.2, Composite Compare Match.

(8) FIFO data read request interrupt

FIFO data read request interrupt can be generated when the number of vacant stages in FIFO become less than or equal to the specified value.
FIFO data read request interrupt for scan group 0 to 11 (FIFOREQ0 to FIFOREQ11) are generated when ADFIFOINTCR.FIFOIEn (n = 0 to 11) is set to 1 and ADFIFOSRm.FIFOSTn[4:0] ≤ ADFIFOINTLRm.FIFOILVn[4:0] (m = 0 to 5, n = 0 to 11).
However, FIFO read request interrupt is not generated while the ADFIFOERSR.FIFOFLFn (n = 0 to 11) bit corresponding to its interrupt source is set to 1.

(9) FIFO data overflow interrupt

FIFO data overflow interrupt (FIFOOVF) can be generated when a FIFO overflow is detected in any of FIFO in scan groups 0 to 11.

60.9 Scan Conversion Time

60.9.1 Scan Start Processing Time

The processing time from the input of the A/D conversion start trigger to the start of the scanning operation is shown in Table 60.68 and Figure 60.59.

Table 60.68 Scan Start Processing Time

Item		Symbol	Processing Time
Peripheral module trigger input processing time*1		t_{D_TRG}	[When an external trigger is selected.] • 5 ADSRCCLK + (ADTRGDLRr.TRGDLYn[7:0] + 1) × ADCLK [Other than above] • 1 ADSRCCLK + (ADTRGDLRr.TRGDLYn[7:0] + 1) × ADCLK
Software trigger input processing time		t_{D_SW}	[When ADCLK = PCLKA/1]*2 • Number of access cycles to I/O registers*3 + 1 PCLKA [Other than above] • (Number of access cycles to I/O registers*3) + 1 PCLKA + (1 to 3 ADCLK)
Internal trigger processing time		t_{D_ITRG}	[When synchronous operation is disabled] (ADSYCR.ADSYDISm = 1) • 6 ADCLK [Idle start] • 7 to 13 ADCLK [Suspend start]*4 [When synchronous operation is enabled] (ADSYCR.ADSYDISm = 0) • 7 ADCLK [Idle start] • (3 + ADSYCR.ADSYCYC[7:0]) × ADCLK to (2 + 2 × ADSYCR.ADSYCYC[7:0]) × ADCLK [Suspend start]*5
Wait time for synchronous operation		t_{D_SYOP}	[When synchronous operation is disabled] (ADSYCR.ADSYDISm = 1) • 0 [When synchronous operation is enabled] (ADSYCR.ADSYDISm = 0) • 0 to ADSYCR.ADSYCYC[7:0] × ADCLK
Total scan start processing time	Started by peripheral module trigger	t_{D_ADST}	$t_{D_TRG} + t_{D_ITRG} + t_{D_SYOP}$
	Started by software trigger		$t_{D_SW} + t_{D_ITRG} + t_{D_SYOP}$

Note: ADSRCCLK: Clock source of ADCLK
n = 0 to 11, m = 0 to 2, r = 0 to 5

Note 1. It does not include the input delay time from the source of the peripheral module trigger to ADC.

Note 2. When ADCLKCR.CLKSEL[1:0] = 10b and ADCLKCR.DIVR[2:0] = 000b are set.

Note 3. It is the number of access cycles to ADSTRn register (n = 0 to 11) or ADSYSTR register. For more details about the number of access cycles for I/O registers, see section 5, I/O Registers.

Note 4. When constant sampling is enabled, it is 7 to (6 + ADSHSTRm.SHSST[7:0]) × ADCLK. When constant sampling is enabled, by setting the sampling time setting of the channel-dedicated sample-and-hold circuit to ADSHSTRm.SHSST[7:0] = 04h (reset value), the effect of the ADSHSTRm.SHSST[7:0] setting on the conversion start time can be ignored.

Note 5. When constant sampling is enabled, (3 + ADSYCR.ADSYCYC[7:0]) × ADCLK to (2 + ADSHSTRm.SHSST[7:0] + ADSYCR.ADSYCYC[7:0]) × ADCLK. When constant sampling is enabled, by setting the sampling time setting of the channel dedicated sample-and-hold circuit to ADSHSTRm.SHSST[7:0] = 04h (reset value), the effect of the ADSHSTRm.SHSST[7:0] setting on the conversion start time can be ignored.

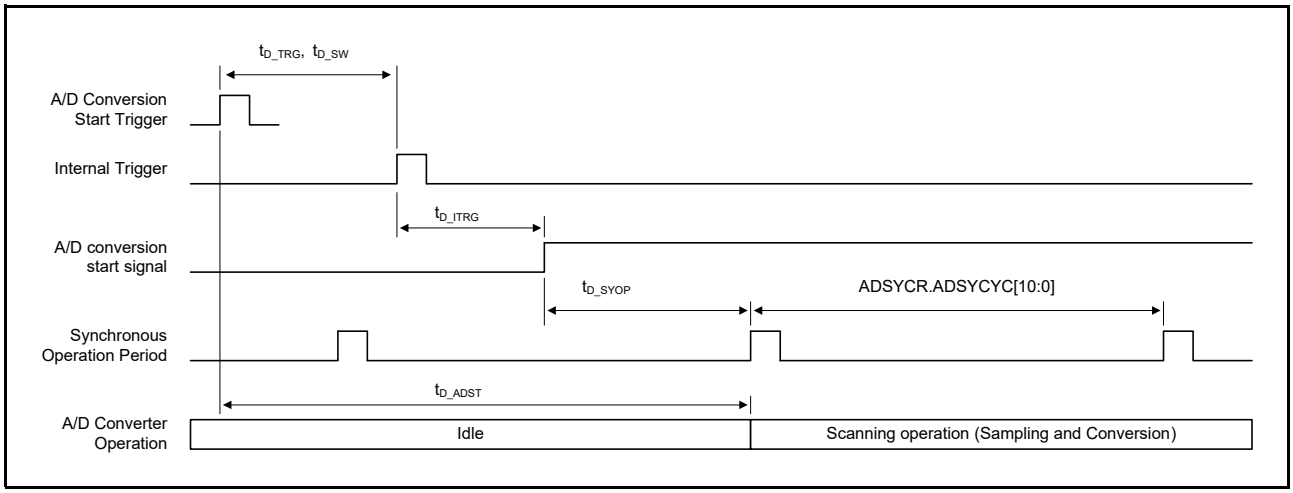

Figure 60.59 Scan Start Processing Time

60.9.2 Conversion Processing Time

The various processing times in the conversion operation are shown in Table 60.69 and Figure 60.60 to Figure 60.64.

Table 60.69 A/D Convert Processing Time (1/2)

Item			Symbol	Processing Time
Channel- dedicated sample-and-hold processing time	Sampling time		t_{SH_SPL}	ADSHSTR0.SHSST[7:0] × ADCLK
	Hold mode switching time		t_{SH_HLD}	ADSHSTR0.SHHST[2:0] × ADCLK
	Sampling mode switching time (only when hybrid mode)		t_{SH_D}	(ADSYCR.ADSYCYC[7:0] - 1) × ADCLK
A/D disconnection detect assist processing time			t_{DDA}	[When disconnection detect assist function is disabled] • 0 [When disconnection detect assist function is enabled] • ADSGDCRn.ADNDIS[7:0] × ADCLK
A/D conversion time	Sampling time		t_{AD_SPL}	ADSSTRp.SSTq[9:0] × ADCLK

	Channel conversion time		t_{ADCH_O}	$(t_{DDA} + t_{AD_SPL} + t_{AD_CNV}) \times (N_{TAP} + N_{ADC})$
	Scan conversion time*5		t_{SCAN_O}	Σt_{ADCH_O}

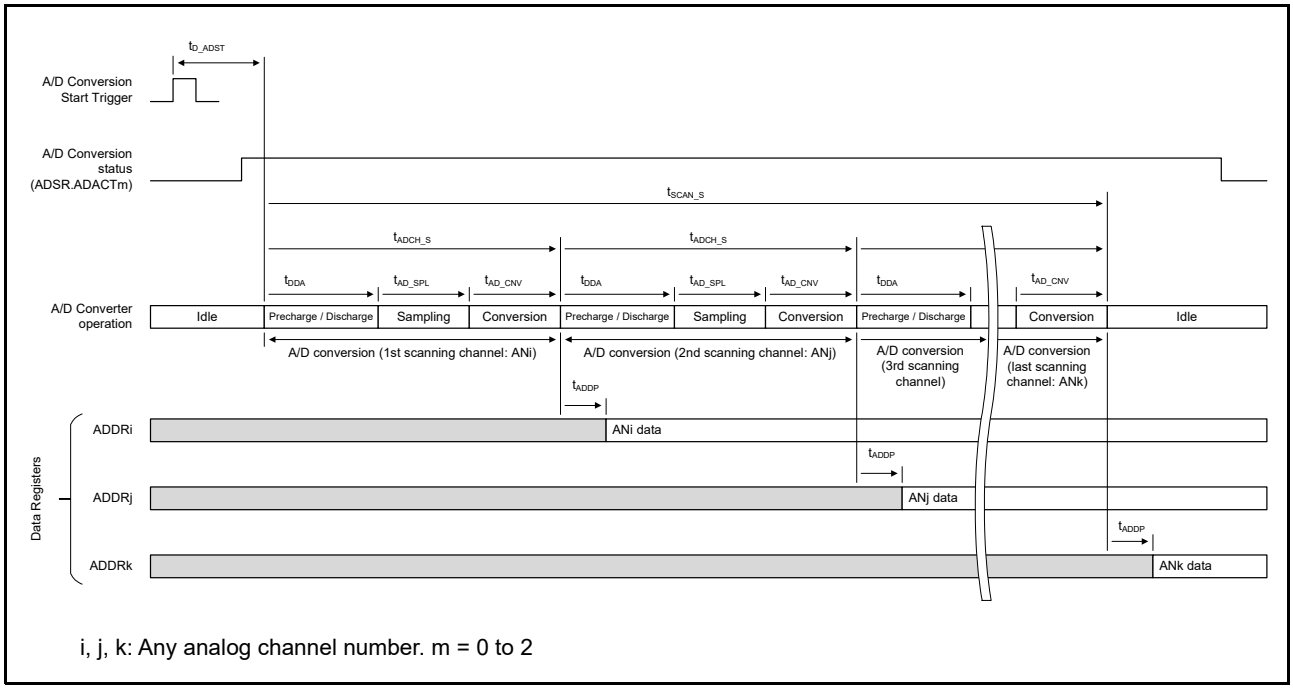
Table 60.69 A/D Convert Processing Time (2/2)

Item			Symbol	Processing Time
Total A/D conversion time (hybrid mode)*3	Channel-dedicated sample-and-hold processing time in hybrid mode		t_{HY_SH}	$t_{SH_SPL} + t_{SH_HLD} + t_{SH_D}$
	Oversampling period		t_{HY_OS}	$(t_{DDA} + t_{AD_SPL} + t_{AD_CNV})$
	Scan conversion time	Initial delay	t_{HY_ID}	[When channel-dedicated sample-and-hold circuit is not used] • $(N_{TAP} + N_{ADC}) \times \Sigma t_{HY_OS}$*6 [When channel-dedicated sample-and-hold circuit is used] • $(t_{HY_SH} \times (N_{ADC} + N_{TAP}) - t_{SH_D}) + (N_{TAP} + N_{ADC}) \times \Sigma t_{HY_OS}$*6
		After initial delay time	t_{SCAN_HY}	[When channel-dedicated sample-and-hold circuit is not used] • Σt_{HY_OS}*6 [When channel-dedicated sample-and-hold circuit is used] • $t_{HY_SH} + \Sigma t_{HY_OS}$*6

n = 0 to 11, m = 0 to 2, p = 0 to 7, q = 0 to 15

Note: N_{ADC}: This value is the number of the times of the addition/averaging according to the setting value of ADDOPCRBx.ADC[3:0] (x = 0 to 49). If A/D-converted value addition/averaging function is not used, this value is 1.
N_{TAP}: This value is the number of TAP of the digital filter that selected in ADDOPCRAx.DFSEL[2:0] (x = 0 to 49) and ADDFSRm.DFSELy[1:0] (m = 0 to 2, y = 0 to 4).
N_{SGCH}: This value is the number of the channels in the scan group.

Note 1. When ADCLKCR.CLKSEL[1:0] = 10b and ADCLKCR.DIVR[2:0] = 000b are set.



Note 2. It does not include the channel-dedicated sample-and-hold processing time.

Note 3. It does not include the A/D conversion data processing time.

Note 4. This is the sum of the channel conversion times (t_{ADCH_N}) that calculated from the conversion settings for each analog channel assigned to the scan group. If channel-dedicated sample-and-hold circuits are used, channel-dedicated sample-and-hold processing times (t_{SH_SPL} and t_{SH_HLD}) are also added.

Note 5. This is the sum of the channel conversion times (t_{ADCH_O}) that calculated from the conversion settings for each analog channel assigned to the scan group.

Note 6. This is the sum of the oversampling period (t_{HY_OS}) that calculated from the conversion settings for each analog channel assigned to the scan group.

i, j, k: Any analog channel number. m = 0 to 2

Figure 60.63 A/D Conversion Processing Time (Hybrid Mode)

i, j, k: Any analog channel number. m = 0 to 2

Figure 60.64 A/D Conversion Processing Time (Hybrid Mode with Channel-Dedicated Sample-and-Hold Circuit)

60.9.3 Scan End Processing Time

The scan end processing time and the forcibly stop processing time are shown in Table 60.70, Figure 60.65, Figure 60.66.

Table 60.70 Scan End Processing Time and the Forcibly Stop Processing Time

Item		Symbol	Processing Time
Scan end processing time	Until reflected in the status register*1	t_{ED1}	t_{ADDP}
	Until output the FIFO data read request interrupt	t_{ED2}	t_{ED1} + 2 PCLKA
Forcibly stop processing time	Forcibly stop trigger input processing time	t_{STOP_TRG}	[When ADCLK = PCLKA/1 is set]*2 • Number of access cycles to I/O registers*3 + 1 PCLKA [Other than above] • (Number of access cycles to I/O registers*3) + 1 PCLKA + (3 to 4 ADCLK)
	Wait time for synchronous operation	t_{STOP_SYNC}	[When synchronous operation is disabled] (ADSYCR.ADSYDISm = 1) • 0 [When synchronous operation is enabled] (ADSYCR.ADSYDISm = 0) • 0 to ADSYCR.ADSYCYC[7:0] × ADCLK
	Forcibly stop processing time	t_{STOP}	[When ADCLK = PCLKA/1 is set]*2 (ADSYCR.ADSYDISm = 1) • 4 PCLKA (ADSYCR.ADSYDISm = 0) • 3 PCLKA [Other than above] (ADSYCR.ADSYDISm = 1) • 4 PCLKA + (2 to 3 PCLKA) (ADSYCR.ADSYDISm = 0) • 3 PCLKA + (2 to 3 PCLKA)

m = 0 to 2

Note 1. This is the time it takes for ADSCANENDSR.SCENDFn = 1 (n = 0 to 11) or until an end-of-scan interrupt is generated.

Note 2. When ADCLKCR.CLKSEL[1:0] = 10b and ADCLKCR.DIVR[2:0] = 000b are set.

Note 3. It is the number of access cycles to ADSTOPR register. For more details about the number of access cycles for I/O registers, see section 5, I/O Registers.

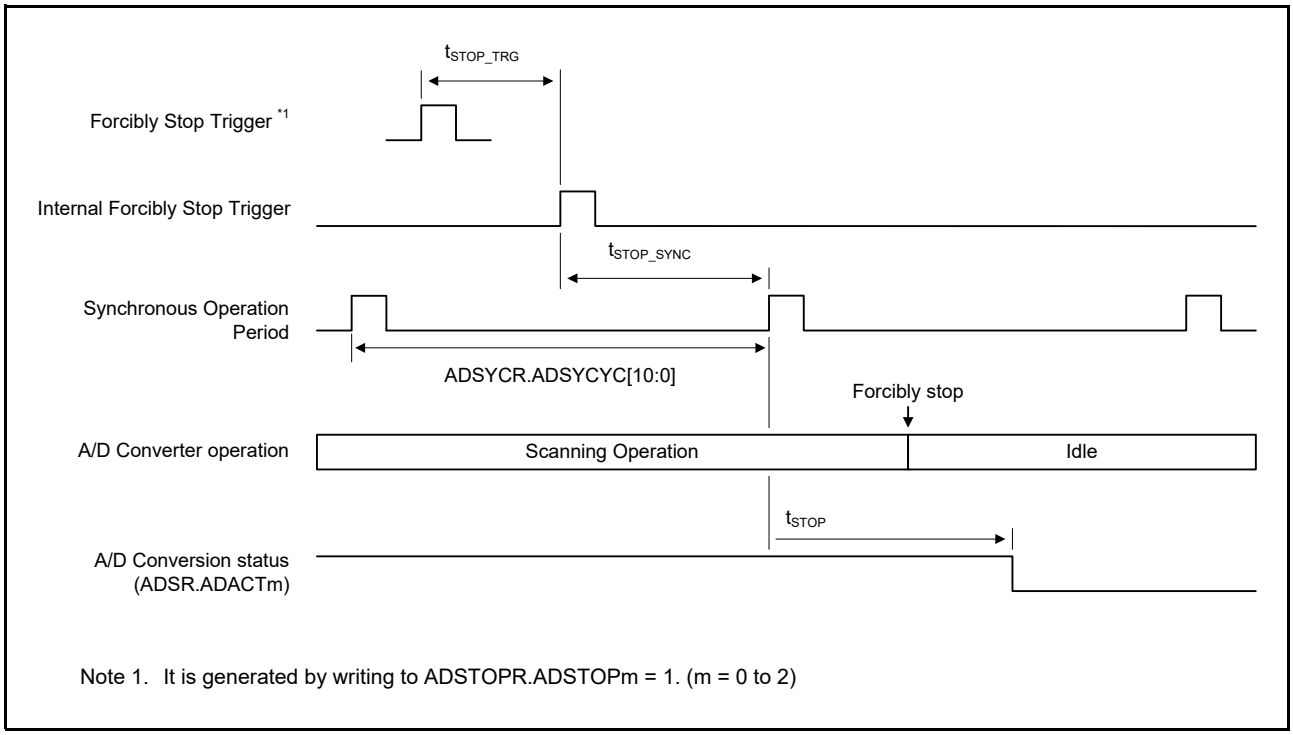

Figure 60.66 Forcibly Stop Processing Time (SAR/Oversampling/Hybrid Mode – Single Scan Mode)

60.10 Usage Notes

60.10.1 Prohibition of Changing the Operation Settings During A/D Conversion Operation

The registers related to the operation setting of the A/D converter should be set while all A/D converters are stopped (ADSR.ADACTm = 0 and ADSR.CALACTm = 0 (m = 0 to 2)). Changing (writing) of registers except for those listed below is prohibited during A/D conversion. If the operation setting is changed during A/D conversion, operation is not guaranteed.

[Registers that can be written while the A/D converter is operating]

- Status clear registers
  - Status clear registers related to A/D converter operation
    (ADERSCR, ADCALENDSCR, ADSCANENDSCR)
  - A/D conversion overflow status clear registers
    (ADOVFERSCR, ADOVFCHSCR0, ADOVFCHSCR1, ADOVFEXSCR)
  - Limiter clip status clear register
    (ADLIMGRSCR, ADLIMCHSCR0, ADLIMCHSCR1, ADLIMEXSCR)
  - Compare match status clear register
    (ADCMPTBSCR, ADCMPCHSCR0, ADCMPCHSCR1, ADCMPEXSCR)
  - FIFO error status clear register
    (ADFIFOERSCR)
- Software trigger register (ADSYSTR, ADSTRn (n = 0 to 11))
- A/D converter stop register (ADSTOPR)
- A/D converter start trigger enable register (ADTRGENR)*1

Note 1. Writing during operation is only permitted for disabling the trigger input (ADTRGENR.STTRGENn = 0 (n = 0 to 11)) in order to stop the A/D conversion. To avoid unintended operation, do not change the trigger input to Enable (ADTRGENR.STTRGENn = 1) during operation.

60.10.2 Usage Notes on Forced Stop of A/D Conversion

If you want to forcibly stop the A/D conversion operation, follow the procedure in section 60.5.4, Force Stops the A/D Conversion Operation.

60.10.3 Usage Notes on A/D Data Registers

When A/D conversion is performed multiple times on the same analog channel, A/D data register ADDRn (n = 0 to 35) or A/D extended analog data register ADEXDRm (m = 0 to 2, 4 to 6, 8, 9, 16 to 18) corresponding to that analog channel is overwritten at the later A/D conversion.
If you intend to keep the data for each A/D conversion for the same analog channel, perform one of the following methods.

- Read out data from registers at each scanning operation
  - At the end of scanning each scan group, read out the A/D conversion data of the analog channel that was subject to A/D conversion from ADDRn or ADEXDRm.
  - This method is effective if A/D conversion of the same analog channel is not performed more than once in the same scan group, and A/D conversion data can be read from the registers before the next scanning operation.
- Use FIFO function to hold data for each A/D conversion
  - By using FIFO, multiple A/D conversion data for the same analog channel can be kept.

– Read out the A/D conversion data before FIFO overflow.
– For the notes on using FIFOs, see section 60.4.10.6, Usage Notes on FIFO.

60.10.4 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC operation. The ADC is initially stopped after a reset. The registers become accessible on release from the module-stop state.
See section 60.10.6, Restrictions on Entering and Releasing the Low-Power States in connection with this usage note.

60.10.5 Settings for the Sleep Function

ADC0, ADC1, and ADC2 can individually be set to sleep operation mode using the A/D converter unit sleep control registers ADUSLPCRm (m = 0 to 2). Set these registers first after reset released in accordance with section 60.7.1, Initial Setup Procedure. For the units in the sleep state, do not execute self-calibration nor input A/D conversion start triggers. For the units in self-calibration or in A/D conversion, prevent the corresponding A/D converter unit sleep control registers m (m = 0 to 2) from setting the units to sleep operation mode.

60.10.6 Restrictions on Entering and Releasing the Low-Power States

(1) Module-stop state

Before entering the module-stop state, be sure to stop A/D conversion. When releasing the module-stop state again, make sure the shutdown time specified in the Electrical Characteristics has elapsed before releasing the module stop state. Then, follow to section 60.7.1, Initial Setup Procedure.

(2) Software standby mode

For entering and releasing the software standby mode, follow to section 60.7.4, Procedure for the A/D Converter Entering to and Returning from the Software Standby Mode.

(3) Low-power states

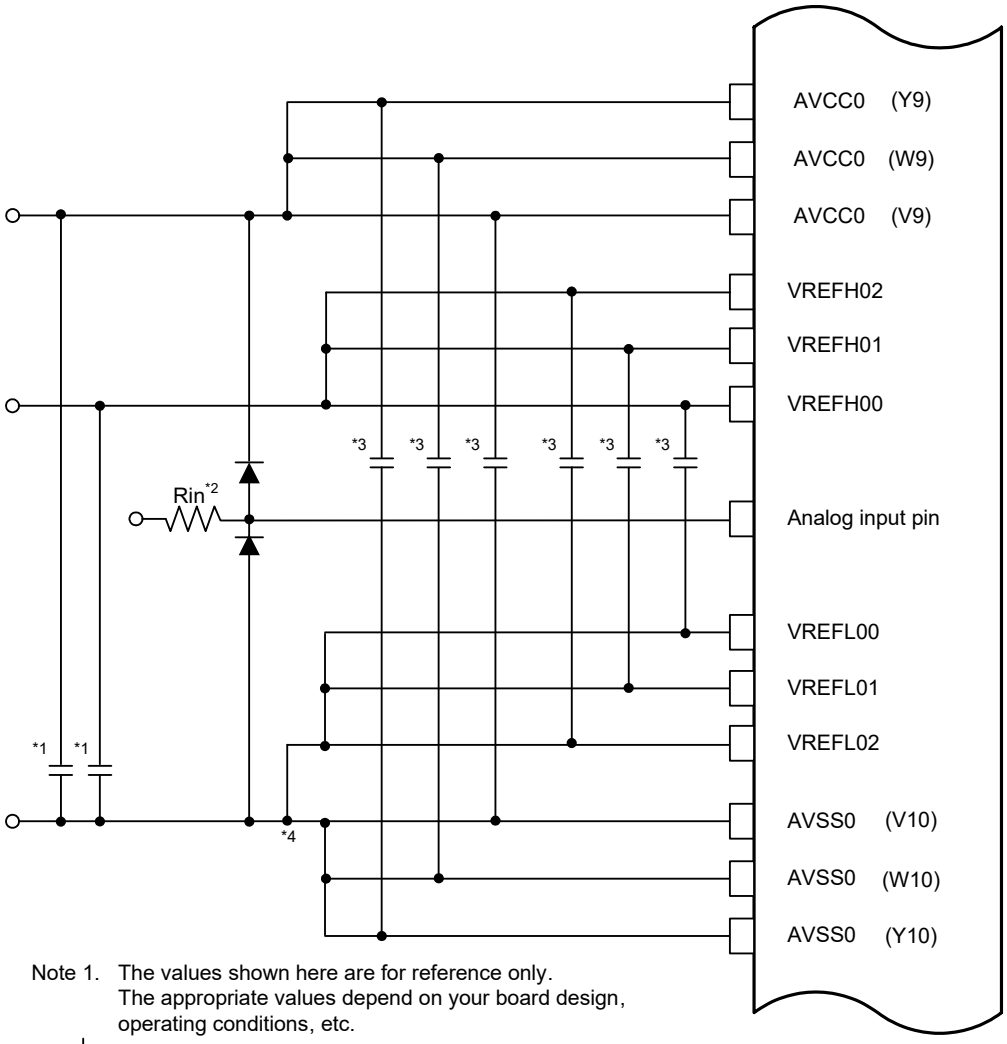
Configure the A/D conversion not to start during further entering a low-power state after entering the module-stop state.

60.10.7 Notes on Board Design

(1) Protection circuit

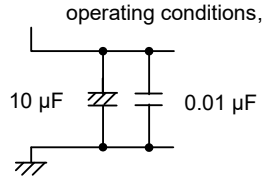
To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, take the following measures.

- Insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0.
- Connect a protection circuit to protect the analog input pins.



An example of a protection circuit is shown in Figure 60.67.

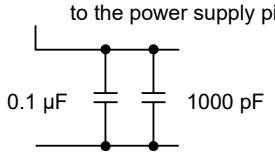
(2) Board design to ensure A/D conversion accuracy



In order to ensure the accuracy of A/D conversion, design the board considering the following:

- Analog circuits and digital circuits should be separated from each other as far as possible.
- Analog circuit signal lines and digital circuit signal lines should not intersect or be placed near each other.
- The analog input, analog reference power supply (VREFH0), analog reference ground (VREFL0), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0).

- The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).
- Place a capacitor for noise filters between AVCC0 pin and AVSS0 pin and between VREFH0 pin and VREFL0 pin close to the pin and connect them. Also, connect AVSS0 and VREFL0 pins to the analog ground on the board as close to the pins as possible. Figure 60.67 and Figure 60.68 show examples of connections. As shown in Figure 60.67, connect individual capacitors to each pin on 320-pin products.



Note 1. The values shown here are for reference only.
The appropriate values depend on your board design, operating conditions, etc.

Note 2. Rin: Signal source impedance

Note 3. To ensure the better A/D conversion accuracy, these capacitors must be placed as close as possible to the appropriate pins. Place the 1000-pF capacitor closer to the power supply pin than the 0.1-µF capacitor.

Note 4. Connect to the analog ground of the board at the position as close as possible to the capacitor for noise filtering that ensure the A/D conversion accuracy.

Figure 60.67 Example of Protection Circuit and Noise Prevention (320-pin products)

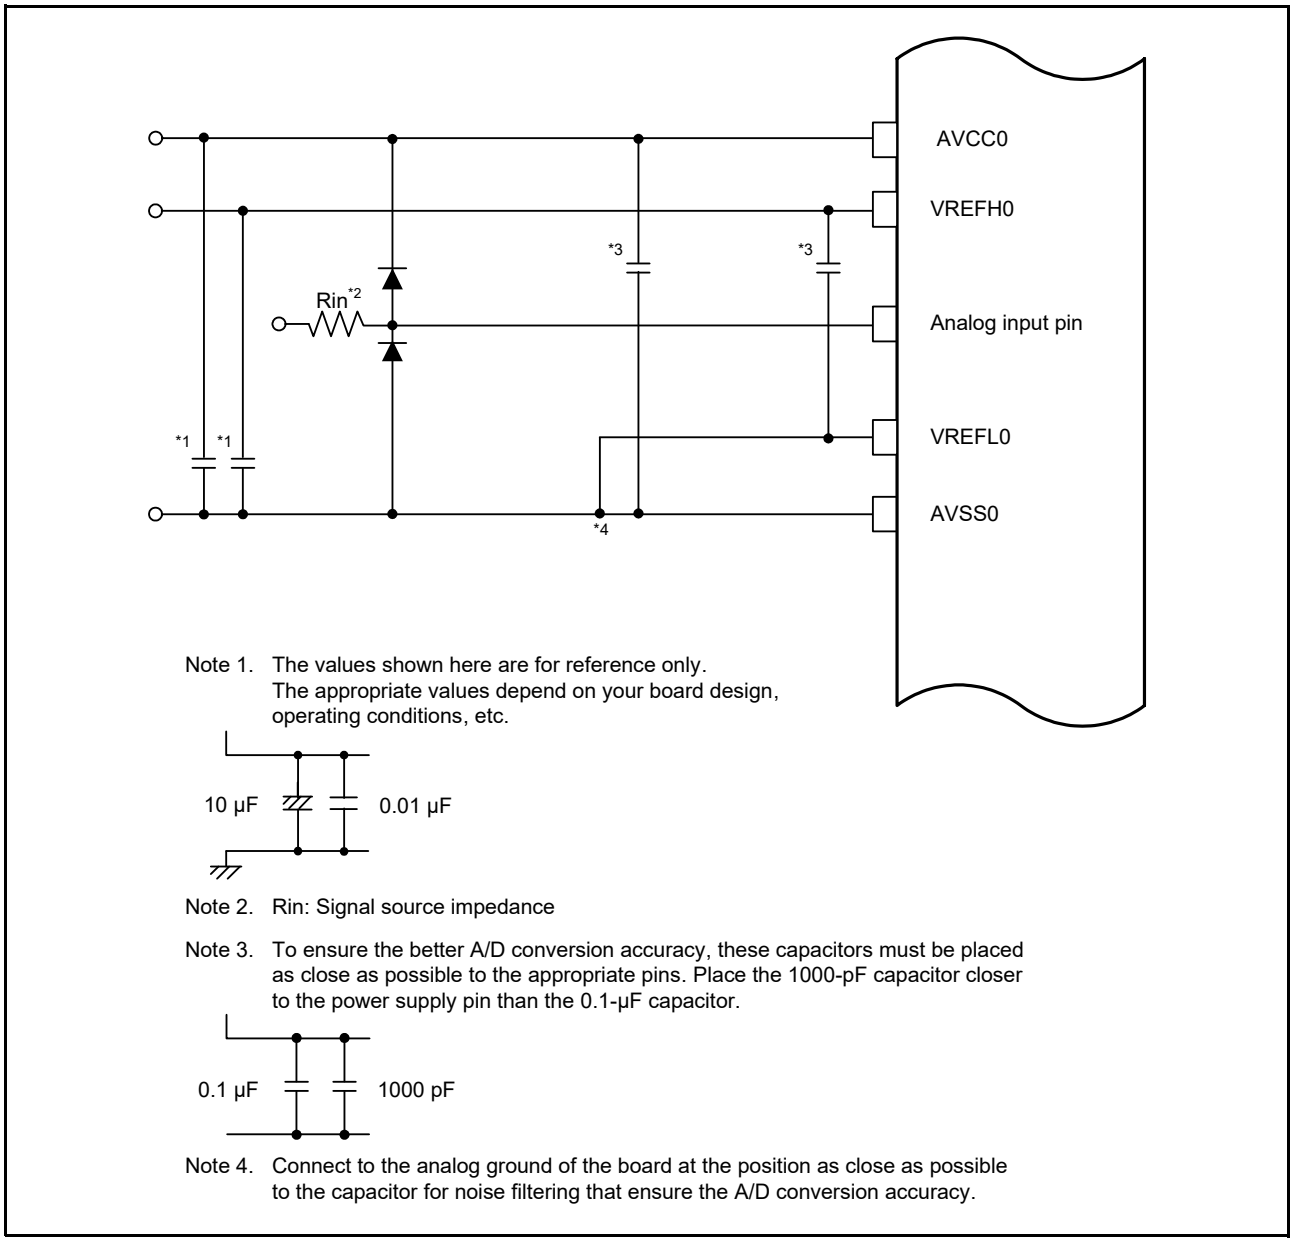


Figure 60.68 Example of Protection Circuit and Noise Prevention (Products Other than 320-pin)

60.10.8 Notes on Synchronous Operation

Synchronous operation function is disabled in the initial state after reset released. If using synchronous operation function with an external signal (the synchronization signal from the GPT), follow the restrictions described in section 60.3.20, Synchronous Operation.

60.10.9 Notes on Channel-Dedicated Sample-and-Hold Circuit

When using channel-dedicated sample-and-hold circuit, follow the restrictions. For details, see section 60.3.17.4, Restrictions on Channel-Dedicated Sample-and-Hold Circuit.

60.10.10 Restrictions on Analog Channel Shared Among Multiple A/D Converters

To avoid degradation of the accuracy of the A/D conversion result, A/D conversion of the same analog channel (same analog signal source) from both ADC1 and ADC2 is prohibited, except for the self-diagnosis channel.
If this restriction is violated, the A/D conversion results are not guaranteed because the A/D conversion accuracy of the target analog channel may deteriorate significantly.

60.10.11 Notes on A/D Conversion Start Trigger

(1) Notes on A/D conversion trigger for the same scan group

In modes other than same channel continuous scan mode or background continuous scan mode, A/D conversion start triggers for the same scan group are not accepted until scanning operation of the scan group is completed (in this case, A/D conversion start triggers are ignored).
An A/D conversion trigger for the same scan group should be input after the scanning operation of its scan group is completed (ADSCANENDSR.SCENDFn = 1 (n = 0 to 11)) and after a 6 PCLKA clock cycles or more has elapsed.

(2) Prohibition on calibration and A/D conversion

It is prohibited to start calibration and A/D conversion in the ADC unit during sleep operation. In addition, it is prohibited to set the ADC unit to Sleep mode during calibration and A/D conversion operations.

60.10.12 Notes on Self-Calibration

Observe the restrictions on self-calibration function. For details, see section 60.3.9, Self-Calibration.

60.10.13 Notes on Group Priority Operation

Observe the restrictions when using group priority operation. For details, see section 60.3.19, Group Priority Operation.

60.10.14 Restrictions on SAR Mode

(1) Notes on resolution and accuracy

In SAR mode, the A/D converter functions as a 12-bit A/D converter. Although the data output from the A/D converter is internally extended to 16-bit data length for calculation processing, even if 14-bit or 16-bit length data format is selected, the resolution and accuracy exceeding 12 bits are not guaranteed for that A/D conversion data. Select 14-bit or 16-bit length data format in SAR mode if you want to increase the computational resolution, such as when using A/D-converted value addition/averaging function or User's Gain/User's Offset function.

(2) Restrictions on digital filter function

The digital filter is prohibited in SAR mode. Operation is not guaranteed when the digital filter function is enabled.

60.10.15 Restrictions on Oversampling Mode

(1) Restrictions on digital filter function

In Oversampling mode, the use of the digital filter function is mandatory. If A/D conversion is performed without using the digital filter function, the A/D conversion characteristics are not guaranteed.

(2) Restrictions on trigger interval in same channel continuous scan mode

In oversampling mode with same channel continuous scan mode, A/D conversion start trigger should be input after the following interval or more.
[Required Interval for A/D Conversion Start Trigger Input]

- When trigger delay function is not used, or software trigger: 8 ADCLK, or more
- When trigger delay function is used: (8 + (the setting value of ADTRGDLRm.TRGDLYn[7:0])) × ADCLK, or more

Note: m = 0 to 5, n = 0 to 11

If this restriction is violated, the A/D conversion start trigger is not accepted and is ignored.

60.10.16 Restrictions on Hybrid Mode

In hybrid mode, observe the following restrictions.

(1) Prohibition of scanning operation with only one channel

In hybrid mode, be sure to assign two or more virtual channels to one scan group (up to 4 virtual channels). Scanning operation with only one virtual channel assigned to one scan group is prohibited. If this restriction is violated, operation is not guaranteed.

(2) Restrictions on virtual channel configuration

In hybrid mode, do not assign the same analog channel to multiple virtual channels that are assigned to the same scan group. If this restriction is violated, A/D conversion result is not guaranteed.

(3) Restrictions on digital filter configuration

In hybrid mode, the use of the digital filter function is mandatory. If A/D conversion in hybrid mode is performed without using the digital filter function, the A/D conversion characteristics are not guaranteed.
In addition, since multiple digital filters are used simultaneously in hybrid mode, the digital filters used for virtual channels in the same scan group must be set to be exclusive. The digital filters selected by the ADDOPCRAn.DFSEL[2:0] (n = 0 to 49) bits must be set to be exclusive among virtual channels in the same scan group. If the same digital filter is selected from multiple virtual channels in the same scan group, operation is not guaranteed.

(4) Restrictions on A/D-converted value addition/averaging function

When using A/D-converted value addition/averaging function in hybrid mode, set the number of addition/averaging times for all virtual channels in the same scan group to be the same. If this restriction is violated, operation is not guaranteed.

(5) Restrictions on trigger interval in background continuous scan mode

In Hybrid mode – background continuous scan mode, A/D conversion start trigger should be input after the following interval or more.
[Required interval for A/D conversion start trigger input]

- When trigger delay function is not used, or software trigger: 8 ADCLK, or more
- When trigger delay function is used: (8 + (the setting value of ADTRGDLRm.TRGDLYn[7:0])) × ADCLK, or more

Note: m = 0 to 5, n = 0 to 11
If this restriction is violated, the A/D conversion start trigger is not accepted and is ignored.

(6) Restrictions on fixed channels continuous scan mode

In hybrid mode with fixed channels continuous scan mode, observe the constraints on the settings. For details, see section 60.3.7.5, Fixed Channels Continuous Scan Mode.

60.10.17 Restrictions on the High Accuracy Mode

The high accuracy mode can be set using the A/D converter conversion accuracy mode register. In the high accuracy mode, observe the following restrictions. If the following restrictions are violated, operations are not guaranteed.

- A/D conversion modes with which the high accuracy mode can be set
  - SAR mode
  - Hybrid mode
- Restrictions on the sampling time of the analog channel of the ADCm (m = 0 to 2) for which the high accuracy mode is set
  - Set the value no less than 1.6 times the successive approximation time.
  - ADSSTRx.SSTy[9:0] ≥ ADCNVSTR.CSTm [5:0] ×1.6 (x = 0 to 9, y = 0 to 11, m = 0 to 2)
  - Set the number of states no less than four.
  - ADSSTRx.SSTy[9:0] ≥ 04h (x = 0 to 9, y = 0 to 11)
- When the high accuracy mode is set, the synchronous operation period should be set as follows.
  - ADSYCR.ADSYCYC[7:0] × i = ADSSTRx.SSTy[9:0] + ADCNVSTR.CSTm[5:0]
    (x = 0 to 7, y = 0 to 15, m = 0 to 2, i: 1, 2 × n (n = 1, 2, 3…))

The use of the high accuracy mode is recommended for the following function.

- Disconnection detection assist function

60.10.18 Restrictions on Composite Compare Match

The selection of a common compare match table for multiple ADCs is prohibited for composite compare match. If selected, the composite compare match interrupt is asserted when the condition is satisfied at any ADC. When the condition is not satisfied for all ADCs, the composite compare unmatch interrupt is asserted.

60.10.19 Estimating the Sampling Error and Sampling Time

This section describes how to estimate the sampling error and sampling time.
The sampling time required in A/D conversion for externally input analog signal is determined by the time for charging the sampling capacitance in A/D converter. The simplified model of the circuit is shown in Figure 60.69.

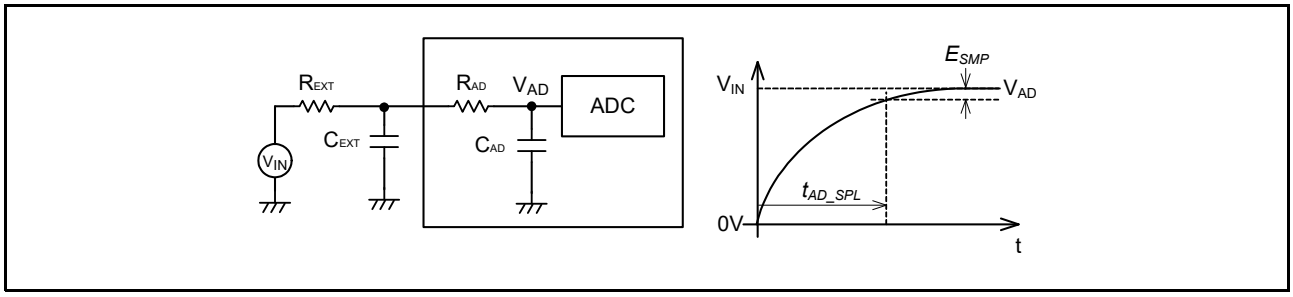

Figure 60.69 Simplified Model of Sample-and-Hold Circuit for A/D Converter

The sampling error can be roughly estimated by the following equation. Set the sampling time (t_{AD_SPL}) to ensure that the sampling error (E_{SMP}) falls within the expected range. The range of E_{SMP} is 0 to 1; the minimum value (0) indicates that there is no error and the error becomes the maximum (1) when the input voltage does not converge at all and V_{in} = VREFH0.

[Estimation Equation for Sampling Error]

$$E_{SMP}(t) = \frac{\frac{k_1 C_{AD}}{C_{EXT} + k_1 C_{AD}}}{1 - \frac{C_{EXT}}{C_{EXT} + k_1 C_{AD}} e^{\frac{-t_{SCAN_*} + t_{AD_SPL}/k_2 \left(1 - \frac{\tau_{EXT}}{\tau}\right)}{\tau_{EXT}}}} e^{\frac{-t_{AD_SPL}/k_2}{\tau}}$$

$$\tau = R_{EXT}(C_{EXT} + k_1 C_{AD}) + R_{AD} k_1 C_{AD}$$

$$\tau_{EXT} = R_{EXT} C_{EXT}$$

E_{SMP}: Estimated value of sampling error
t_{AD_SPL}: Sampling time
C_{EXT}: External capacitance (pin capacitance + PCB parasitic capacitance)
C_{AD}: Internal sampling capacitance
R_{EXT}: External input signal source impedance
R_{AD}: Internal resistance
k_1, k_2: Correction coefficients according to operation mode
t_{SCAN_*}: Channel scan interval (the sum of the scan conversion time) (* = S, O, HY)

Figure 60.70 shows the definition of the channel scan interval.

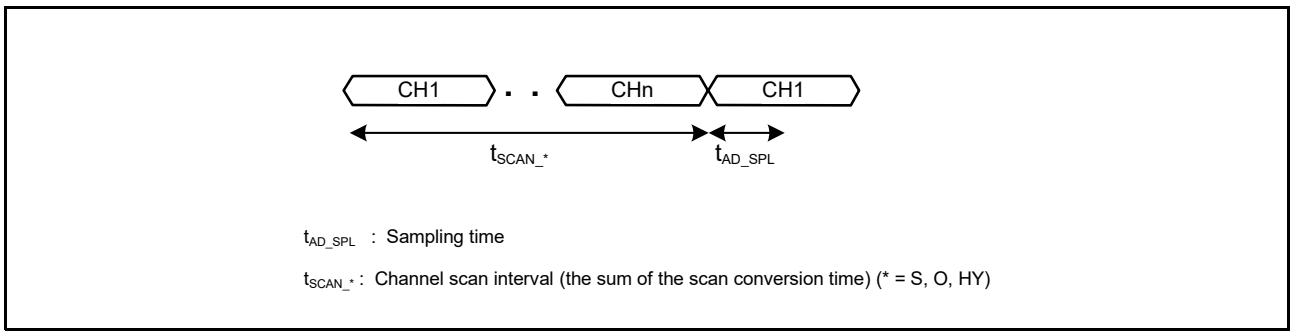

Figure 60.70 Definition of the Channel Scan Interval

The typical values for the parameters are as follows. These are reference values.

[Internal Sampling Capacitance (C_{AD}): 7 pF]

Table 60.71 k_1, k_2

Power Supply	Scan Mode	k_1 High-Speed Channels (AN000 to AN015) Low-Speed Channels (AN016 to AN035)	k_2
AVCC0: 2.7 to 3.63 V VCC: 2.7 to 3.63 V VREFH0: 2.7 V to AVCC	SAR mode (normal mode)	1.3	1.0
	SAR mode (high accuracy mode)	1.3	1.8
	Oversampling mode	1.0	1.0
	Hybrid mode	1.3	1.8
AVCC0: 1.62 to 2.7 V VCC: 1.62 to 2.7 V VREFH0: 1.62 V to AVCC	SAR mode (normal mode)	1.2	1.0
	SAR mode (high accuracy mode)	1.2	1.8
	Oversampling mode	1.0	1.0
	Hybrid mode	1.2	1.8

Table 60.72 R_{AD}

Power Supply	R_{AD}(Ω)	
	High-Speed Channels (AN000 to AN015)	Low-Speed Channels (AN016 to AN035)
AVCC0: 2.7 to 3.63 V VCC: 2.7 to 3.63 V VREFH0: 2.7 V to AVCC	700	3000
AVCC0: 1.62 to 2.7 V VCC: 1.62 to 2.7 V VREFH0: 1.62 V to AVCC	1500	5000

[Usage Notes]

- Set the sampling time to a value greater than or equal to the minimum value specified in the electrical characteristics.
- The equation described in this section is simplified in view of general use case. It does not guarantee the accurate sampling time. You should only use it to roughly estimate the sampling time.

60.10.20 Restriction on A/D Conversion Overflow in Single-Ended Input Mode

To use the A/D conversion overflow to determine whether the input to the A/D converter is lower than VREFL0 in single-ended input mode, make the following settings to disable both the user offset adjustment function and A/D-converted value addition or average function.

1. Disable the user offset adjustment function: Set the ADUOFTRn.UOFSET[15:0] bits to 0000h.
2. Disable the A/D-converted value addition or average function: Set the ADDOPCRBn.AVEMD[1:0] bits to 00b.

Note that if the user offset adjustment function is required, the limiter clip interrupt can be used instead of the overflow interrupt to detect an input lower than VREFL0 while the user offset adjustment function is enabled but the A/D-converted value addition or average function is disabled. In such a case, set the lower-side limit of the limiter clip function (ADLIMTRn.LIML[15:0] bits) to the code value corresponding to an input voltage that is below VREFL0 but cannot be detected as an overflow due to the user offset setting.

61. 12-Bit D/A Converter (DAC12R)

61.1 Overview

This MCU includes two channels of 12-bit D/A converters.
Table 61.1 lists the specifications of the 12-bit D/A converter, Figure 61.1 shows a block diagram of the 12-bit D/A converter.

Table 61.1 Specifications of 12-Bit D/A Converter

Item	Specifications
Resolution	12 bits
Output channels	Two channels
Output Control	Conversion result can be output to external pin, internal peripheral module (A/D converter), or both.
Event link function (input)	D/A conversion can be started in response to the input of an event signal.
Low power consumption function	Module stop state can be set.
Protect Zone filter	Security attribution can be set for each channel*1.

Note 1. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

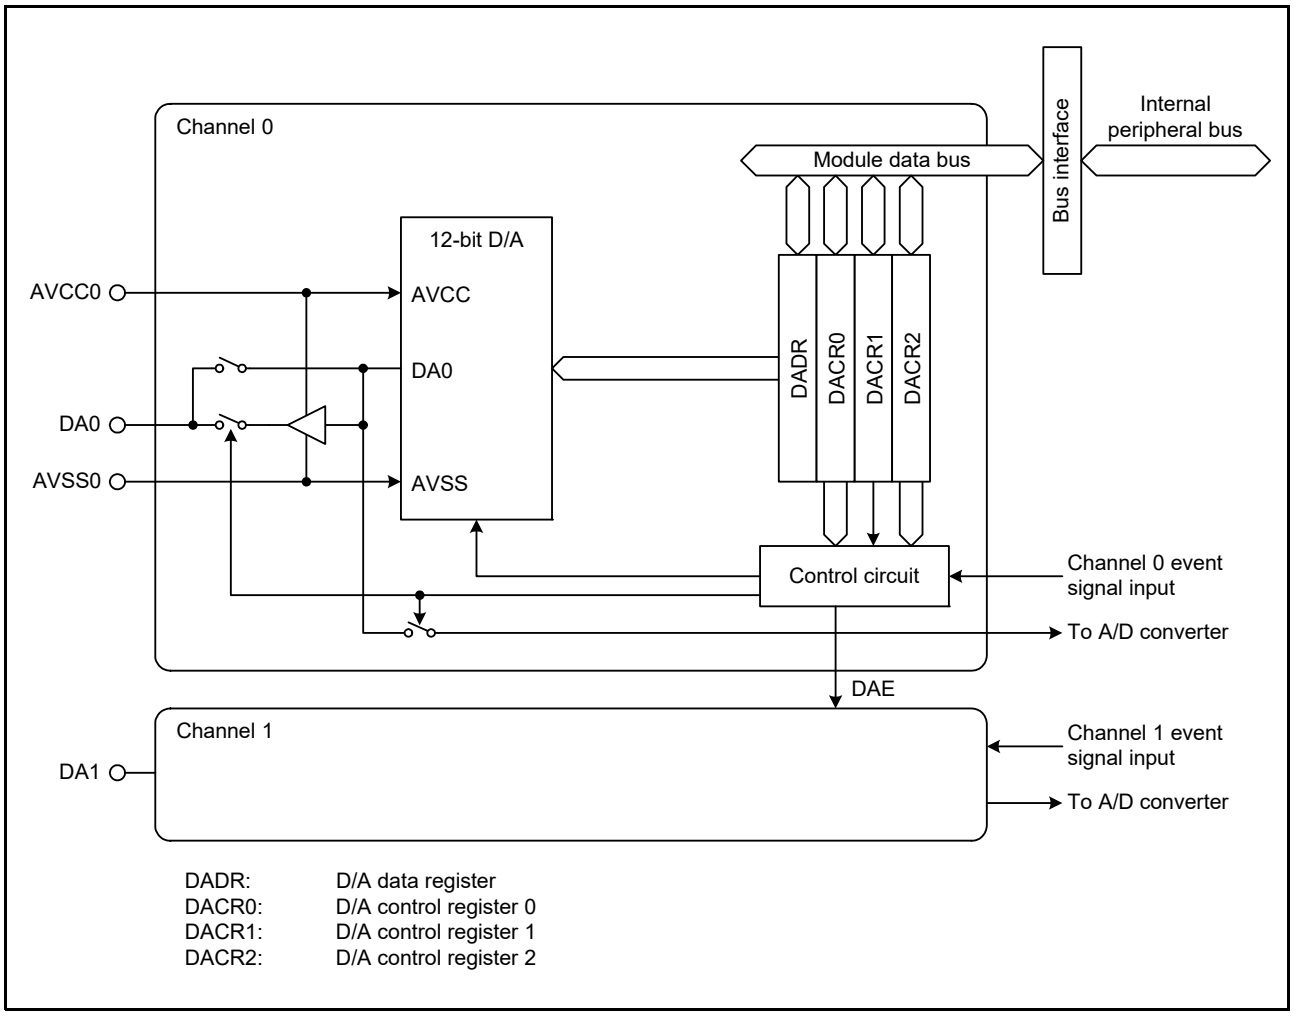

Figure 61.1 Block Diagram of 12-Bit D/A Converter

Table 61.2 lists the pin configuration of the 12-bit D/A converter.

Table 61.2 Pin Configuration of 12-Bit D/A Converter

Pin Name	I/O	Function
AVCC0	Input	Analog power supply pin and reference voltage input pin
AVSS0	Input	Analog ground pin and reference ground pin
DA0	Output	Channel 0 analog output pin
DA1	Output	Channel 1 analog output pin

61.2 Register Descriptions

Address(es): DAC12R0.DADR 8783 3000h, DAC12R1.DADR 8783 3100h, DAC12R0_NS.DADR 0783 3000h, DAC12R1_NS.DADR 0783 3100h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DADR register is a 16-bit readable/writable register, which stores data to which D/A conversion is to be performed. Access this register in 16-bit units.

When the DACR1.DPSEL bit is 0, the upper 4 bits are reserved. When the DPSEL bit is 1, the lower 4 bits are reserved. These reserved bits are read as 0. The write value should be 0.

When using the output buffer amplifier, the range of setting values is 0E0h to F1Fh when the DACR2.OFSSEL bit is 0, and 1F8h to E07h when the OFSSEL bit is 1.

When analog output is enabled, the value of the DADR register is converted and output to the analog output pin.

61.2.2 D/A Control Register 0 (DACR0)

Address(es): DAC12R0.DACR0 8783 3004h, DAC12R1.DACR0 8783 3104h, DAC12R0_NS.DACR0 0783 3004h, DAC12R1_NS.DACR0 0783 3104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DAOUTDIS	DAOUTEN	—	DAOE	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DAE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DACEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DACEN	D/A Conversion Enable	0: D/A conversion is disabled. 1: D/A conversion is enabled.	R/W
b14 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R
b15	DAE	Collective D/A Conversion Enable*1, *2	0: D/A conversion of channels 0 and 1 is controlled by the DACEN bit for each channel. 1: D/A conversion of channels 0 and 1 is enabled collectively.	R/W
b27 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R
b28	DAOE	D/A Output Enable	0: Analog output from the DAn pin is disabled (n = 0, 1). 1: Analog output from the DAn pin is enabled.	R/W
b29	—	Reserved	This bit is read as 0. The write value should be 0.	R
b30	DAOUTEN	DAn Pin Output Enable*3	0: Analog output from the DAn pin follows the setting of the DAOUTDIS bit. 1: Analog output from the DAn pin is enabled regardless of the setting of the DAOUTDIS bit.	R/W
b31	DAOUTDIS	DAn Pin Output Disable*3	0: Analog output from the DAn pin is enabled and analog output to internal peripheral modules is disabled. 1: Analog output from the DAn pin is disabled and analog output to internal peripheral modules is enabled.	R/W

Note 1. This bit is reserved on channel 1. This bit is read as 0. The write value should be 0.
Note 2. When using this bit, ensure that the security attributes for channels 0 and 1 are the same.
Note 3. This bit should be rewritten only when the DACEN bit for the same channel and DAE bit for channel 0 are both 0.

DACEN Bit (D/A Conversion Enable)

The DACEN bit controls the D/A conversion and output of the results of conversion. This bit is only valid when the DAE bit for channel 0 is set to 0.

When this bit is set to 0, D/A conversion is disabled and D/A output is also disabled. When this bit is set to 1, D/A conversion is performed, but D/A output is controlled by the DAOE, DAOUTEN, and DAOUTDIS bits.

The DACEN bit can also be set to 1 using the event link function.

DAE Bit (Collective D/A Conversion Enable)

This bit is used to control the D/A conversion for both channel 0 and channel 1 collectively. To control the D/A conversion for each channel individually, set the DAE bit for channel 0 to 0 and use the DACEN bit instead.

Table 61.3 Operation of D/A Converters

Bit Settings			Operation of D/A converters	
Channel 0		Channel 1		
DAE	DACEN	DACEN	Channel 0	Channel 1
0	0	0	Conversion stops. Analog output disabled (Hi-Z).	Conversion stops. Analog output disabled (Hi-Z).
0	1	0	D/A conversion is performed.	Conversion stops. Analog output disabled (Hi-Z).
0	0	1	Conversion stops. Analog output disabled (Hi-Z).	D/A conversion is performed.
0	1	1	D/A conversion is performed.	D/A conversion is performed.
1	x	x	D/A conversion is performed.	D/A conversion is performed.

DAOE Bit (D/A Output Enable)

This bit is used to enable analog output from the DAn pin (n = 0, 1). This bit does not affect analog output to internal peripheral modules.

DAOUTEN Bit (DAn Pin Output Enable)

This bit is used to enable analog output from the DAn pin even when the DAOUTDIS bit is set to 1 (n = 0, 1). Using this bit allows analog output from the DAn pins to be enabled while keeping analog output to internal peripheral modules enabled.

DAOUTDIS Bit (DAn Pin Output Disable)

This bit is used to disable analog output from the DAn pin (n = 0, 1). Setting this bit to 1 enables analog output to the internal peripheral modules.

Table 61.4 Analog Voltage Output Destination Specification (when the DACEN or DAE bit is set to 1)

Bit Settings				Analog Outputs	
DAOUTDIS	DAOUTEN	DAOE	DACR2.DAAMP	DAn Pin	Internal Peripheral Modules
0	x	0	x	Output disabled (Hi-Z)	Output disabled
0	x	1	0	Unbuffered output	Output disabled
0	x	1	1	Buffered output	Output disabled
1	0	x	x	Output disabled (Hi-Z)	Unbuffered output
1	1	0	x	Output disabled (Hi-Z)	Unbuffered output
1	1	1	x	Unbuffered output	Unbuffered output

61.2.3 D/A Control Register 1 (DACR1)

Address(es): DAC12R0.DACR1 8783 3008h, DAC12R1.DACR1 8783 3108h, DAC12R0_NS.DACR1 0783 3008h, DAC12R1_NS.DACR1 0783 3108h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DPSEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b16	DPSEL	Format Select	0: Data is right-justified. 1: Data is left-justified.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R

DPSEL Bit (Format Select)

This bit specifies the location of valid data in the DADR register.

Write data to bits 11 to 0, when this bit is set to 0. Write data to bits 15 to 4, when this bit is set to 1.

61.2.4 D/A Control Register 2 (DACR2)

Address(es): DAC12R0.DACR2 8783 300Ch, DAC12R1.DACR2 8783 310Ch, DAC12R0_NS.DACR2 0783 300Ch, DAC12R1_NS.DACR2 0783 310Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DAAMP	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	OFSSEL	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b8	OFSSEL	Offset Calibration Value Select *1	0: Offset calibration value for normal voltage (AVCC0 ≥ 2.7 V) 1: Offset calibration value for low voltage (AVCC0 < 2.7 V)	R/W
b30 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31	DAAMP	Output Buffer Amplifier Control *2	0: Output buffer amplifier is not used. 1: Output buffer amplifier is used.	R/W

Note 1. Set the same value in this bit for all channels.
Note 2. This bit should be rewritten only when the DACEN bit for the same channel and DAE bit for channel 0 are both set to 0.

OFSSEL Bit (Offset Calibration Value Select)

This bit is used to select the optimum offset calibration value based on the operating voltage of the D/A converter. When using AVCC0 below 2.7 V, set this bit to 1.

DAAMP Bit (Output Buffer Amplifier Control)

This bit selects whether the D/A converter output is output to the DAn pin via an output buffer amplifier (n = 0, 1). It is only valid when the DACR0.DAOUTDIS bit is 0. When the DAOUTDIS bit is 1, the setting of this bit is ignored and the output buffer amplifier is not used. Refer to Table 61.4 for details.

61.3 Operation

The 12-bit D/A converter features independent circuits for each channel, allowing the D/A conversion enable/disable status and the output destinations of the D/A conversion result to be set per channel. Channels 0 and 1 can be enabled or disabled for D/A conversion simultaneously. This section explains operation using channel 0 as an example.

61.3.1 D/A Conversion

When the DACR0.DAE or DACR0.DACEN bit is 1, D/A conversion is enabled and the results of conversion are output from the destination specified by the DAOE, DAOUTEN, and DAOUTDIS bits in the DACR0 register. Figure 61.2 shows the timing of this operation.
An example of the setting procedure for D/A conversion is shown below.

When Outputting from the DA0 Pin Bypassing the Output Buffer Amplifier

(1) Set the DACR0.DAOE bit to 1, the DAOUTDIS bit to 0, and the DACR2.DAAMP bit to 0.
(2) Set the data format in the DACR1.DPSEL bit.
(3) Set the DADR register to 0000h.
(4) Setting the DACR0.DACEN bit to 1 initiates D/A conversion, and after the recovery time ($t_{DSLPUP1}$) has elapsed, the voltage at the DA0 pin stabilizes at 0 V. Note that if a value other than 0000h is set in step (3), additional conversion time (t_{DCONV1}) is required before the output stabilizes.
(5) Updating the DADR register immediately initiates re-conversion, and after the conversion time (t_{DCONV1}) has elapsed, the output at the DA0 pin stabilizes at the voltage corresponding to the set value. The output of the D/A conversion results is held at this level until the DADR register is updated or the DACEN bit or DAOE bit is set to 0. The output voltage is expressed by the following formula:

$$\frac{\text{Value of the DADR register}}{4096} \times \text{AVCC0}$$

(6) Setting the DACEN bit to 0 stops D/A conversion and disables analog output.

When Outputting from the DA0 Pin Via the Output Buffer Amplifier

(1) Set the DACR0.DAOUTDIS bit to 0 and the DACR2.DAAMP bit to 1.
(2) Set the data format in the DACR1.DPSEL bit.
(3) When the DACR2.OFSSEL bit is 0, set the DADR register to 00E0h (for right-justified format) or 0E00h (for left-justified format). When the OFSSEL bit is 1, set the DADR register to 01F8h (for right-justified format) or 1F80h (for left-justified format).
(4) Setting the DACR0.DACEN bit to 1 initiates D/A conversion.
(5) After the output buffer amplifier startup time (t_{DISOUT}) has elapsed, setting the DACR0.DAOE bit to 1 enables the output from the DA0 pin, and after the recovery time ($t_{DSLPUP2}$) has elapsed, the voltage at the DA0 pin stabilizes at approximately 0 V. Note that if a value other than the above is set in step (3), additional conversion time (t_{DCONV2}) is required before the output stabilizes.
(6) Updating the DADR register immediately initiates re-conversion, and after the conversion time (t_{DCONV2}) has elapsed, the output at the DA0 pin stabilizes at the voltage corresponding to the set value. The output of the D/A conversion results is held at this level until the DADR register is updated or the DACEN bit or DAOE bit is set to 0. The output voltage is expressed by the following formula:

$$\frac{\text{Value of the DADR register}}{4096} \times \text{AVCC0}$$

Note that when using the output buffer amplifier, the lower and upper limits of the output voltage do not reach 0 V and AVCC0, respectively. For details, refer to section 67, Electrical Characteristics.
(7) Setting the DACEN bit to 0 stops D/A conversion and disables analog output.

When Outputting to Internal Peripheral Modules

(1) Set the DACR0.DAOUTDIS bit to 1, and the DACR2.DAAMP bit to 0.

(2) Set the data format in the DACR1.DPSEL bit.

(3) Set the DADR register to 0000h.

(4) Setting the DACR0.DACEN bit to 1 initiates D/A conversion, and after the recovery time ($t_{DSLPUP1}$) has elapsed, the output voltage stabilizes at 0 V. Note that if a value other than 0000h is set in step (3), additional conversion time (t_{DCONV3}) is required before the output stabilizes.

(5) Updating the DADR register immediately initiates re-conversion, and after the conversion time (t_{DCONV3}) has elapsed, the output stabilizes at the voltage corresponding to the set value. The output of the D/A conversion results is held at this level until the DADR register is updated or the DACEN bit is set to 0. The output voltage is expressed by the following formula:

$$\frac{\text{Value of the DADR register}}{4096} \times \text{AVCC0}$$

(6) Setting the DACEN bit to 0 stops D/A conversion and disables analog output.

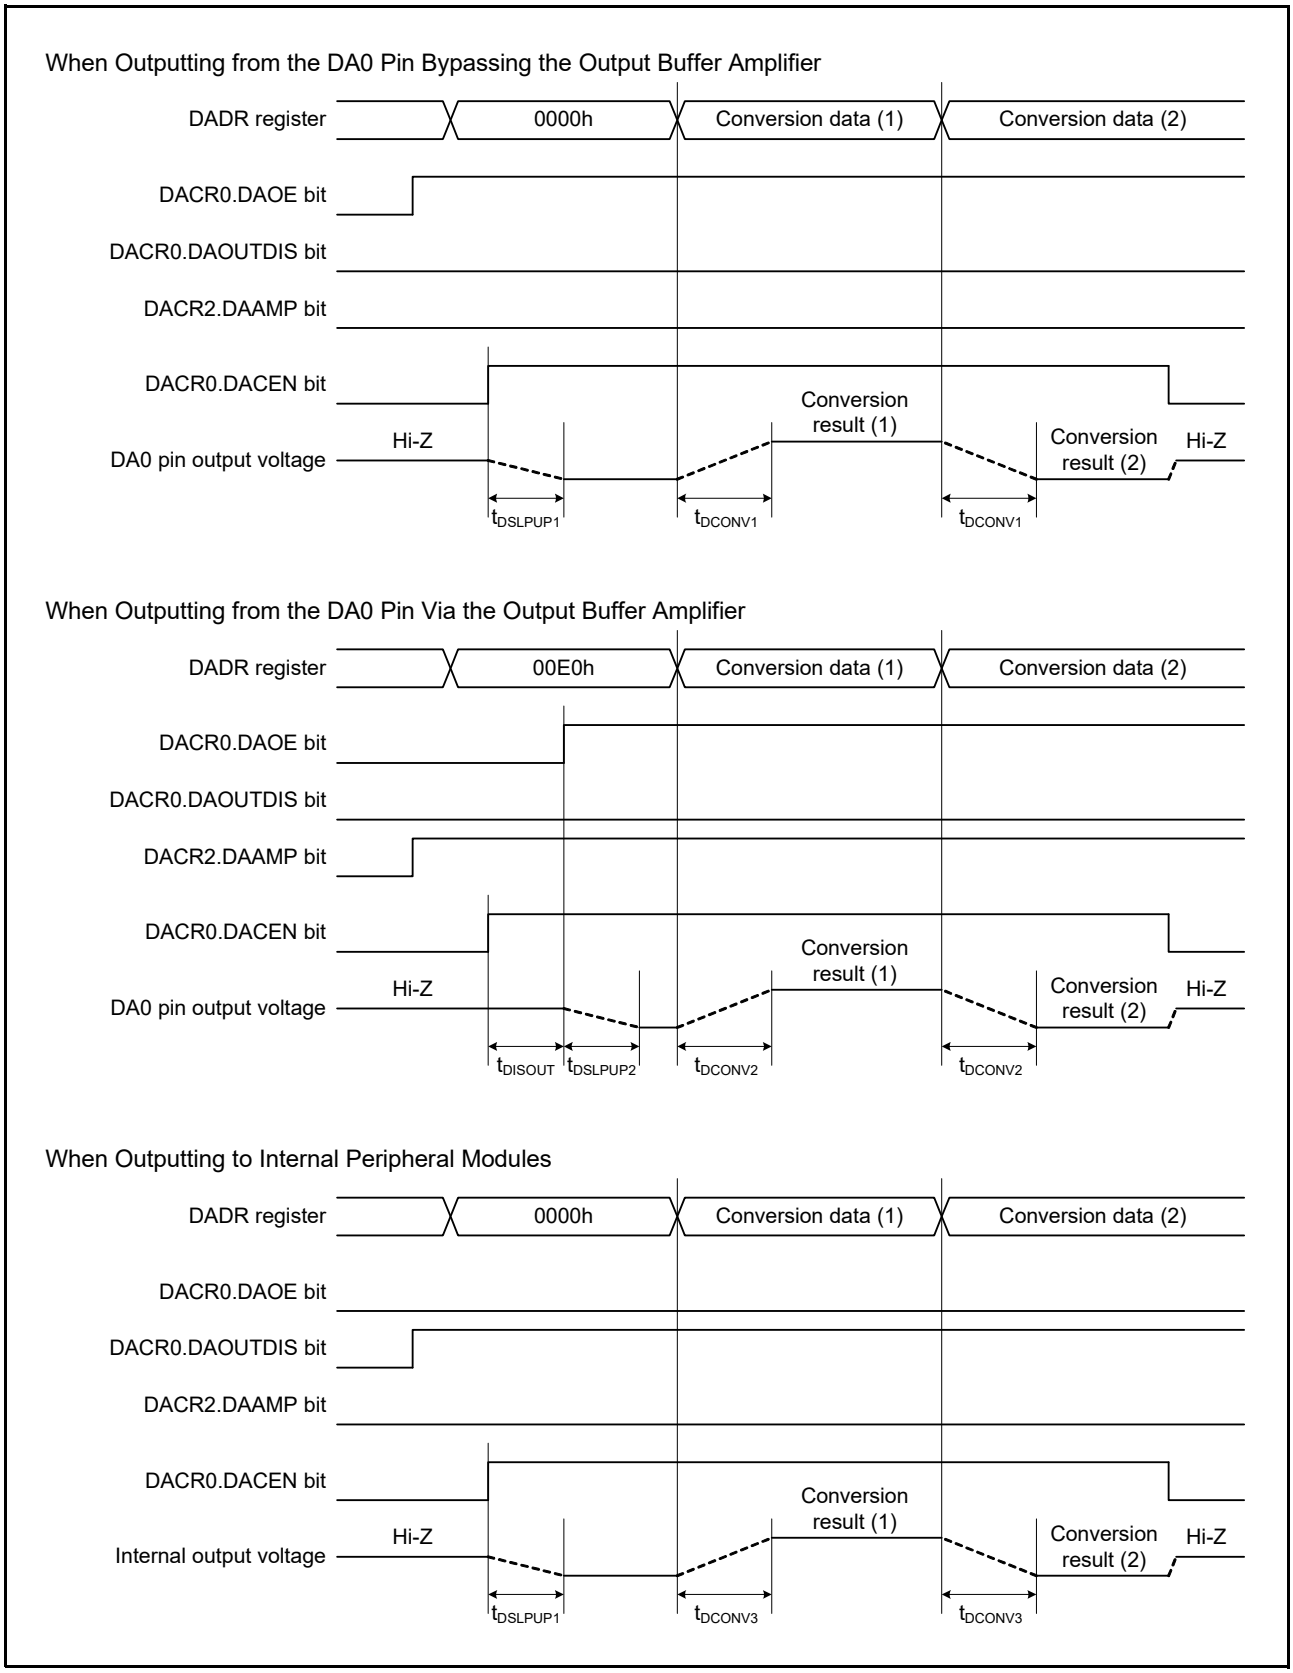

Figure 61.2 Example of 12-Bit D/A Converter Operation

61.4 Linked Operation with the Use of the Event Link Function

61.4.1 Action in Response to Receiving an Event Signal

The example of setting procedure for using event link operation is described below.
The event signal can only control the DACR0.DACEN bit; it cannot control the DAOE bit. Therefore, depending on the data for D/A conversion, an undefined voltage may be output before the D/A conversion output voltage has settled.

(1) Set the DACR0.DACEN bit to 0, DAE bit to 0, DAOE bit to 1, DAOUTDIS bit to 0, and the DACR2.DAAMP bit to 0.
(2) Set the data for D/A conversion in the DADR register.
(3) Set the number for the event signal to be linked in the ELSR46 register (DAC12R0) or ELSR47 register (DAC12R1) of the ELC.
(4) Set the ELCR.ELCON bit to 1. This procedure enables event link operation for all modules with the event link function selected.
(5) Set the event output source module and start it. After the event is output from the module, the DACR0.DACEN bit becomes 1, and D/A conversion starts.
(6) Set the ELSR46 and ELSR47 registers to 0000h to stop event link operation of 12-bit D/A converter. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

61.4.2 Usage Notes on Event Link Operation

- When the event link function is used, set the DACR0.DACEN, DAE, and DACR2.DAAMP bits to 0.
- If an event signal is asserted during writing to the DACR0.DACEN bit, setting 1 in the bit in response to the event signal takes priority.

61.5 Usage Notes

61.5.1 Module Stop Function Setting

Operation of the 12-bit D/A converter can be disabled or enabled using the module stop control register. The 12-bit D/A converter is initially disabled after a reset. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

61.5.2 Operation of the 12-Bit D/A Converter in Module Stop State

When the MCU enters the module stop state with D/A conversion enabled, the 12-bit D/A converter outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current has to be reduced in the module stop state, disable output from the 12-bit D/A converter by setting the DACR0.DACEN and DAE bits to 0.

61.5.3 Operation of the 12-Bit D/A Converter in Software Standby Mode or Deep Software Standby Mode

When the MCU enters software standby mode or deep software standby mode with D/A conversion enabled, the D/A converter outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current has to be reduced in software standby mode or deep software standby mode, disable output from the 12-bit D/A converter by setting the DACR0.DACEN and DAE bits to 0.

61.5.4 Notes on Output from the DAn Pin

When outputting D/A conversion result from the DAn pin, set the security attribute of the port multiplexed with the DAn pin to either the same security attribute as the corresponding channel, or to non-secure (n = 0, 1). If the channel is set to non-secure and the pin is set to secure, the D/A conversion result will not be output.

61.5.5 Notes on Simultaneous Output to the DAn Pin and Internal Peripheral Modules

If both the DACR0.DAOUTDIS and DAOUTEN bits are set to 1 to output the D/A conversion result simultaneously to the DAn pin and internal peripheral modules, the D/A conversion characteristics specified in the electrical characteristics may not be met (n = 0, 1). A full evaluation is recommended before use when using simultaneous output.

62. Temperature Sensor (TEMPS)

62.1 Overview

This MCU has a built-in temperature sensor. The temperature sensor outputs a voltage proportional to temperature. By converting the output voltage of the temperature sensor into a digital value with a 16-bit A/D converter and converting it into temperature, the internal temperature of the MCU can be obtained.
Table 62.1 lists the specifications of the temperature sensor, and Figure 62.1 shows a block diagram of the temperature sensor.

Table 62.1 Specifications of Temperature Sensor

Item	Description
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 16-bit A/D converter.
Low-power consumption function	Module stop state can be set.
Temperature Sensor Calibration Data	Reference data measured for each chip at factory shipment is stored.
Abnormal temperature detection	Abnormal high/low temperatures can be detected and a reset can be issued.
Protect Zone filter	Security attribution can be set.

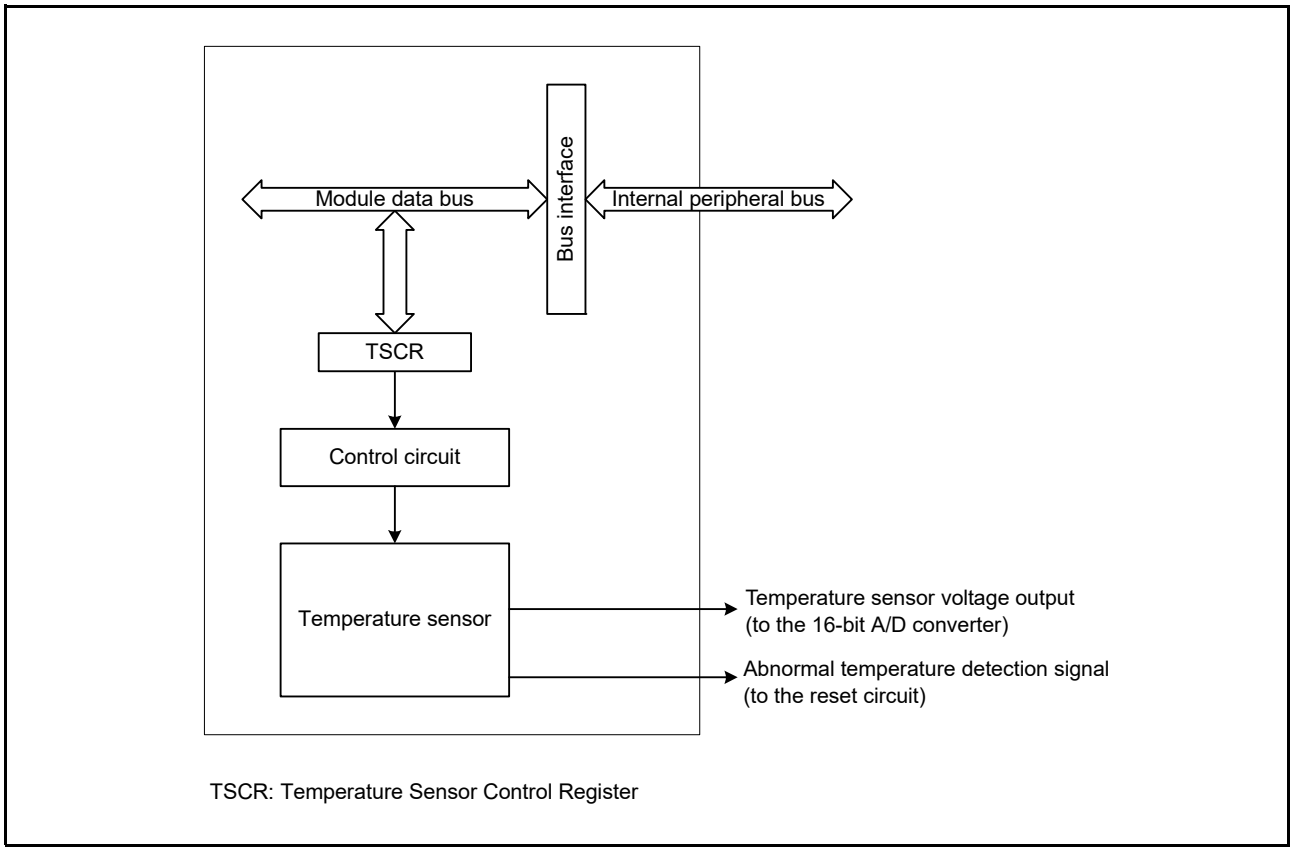

Figure 62.1 Block Diagram of Temperature Sensor

62.2 Register Descriptions

62.2.1 Temperature Sensor Control Register (TSCR)

Address(es): TEMPS.TSCR 8783 5000h, TEMPS_NS.TSCR 0783 5000h

	b7	b6	b5	b4	b3	b2	b1	b0
	TSEN	—	—	TSOE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	TSOE	Temperature Sensor Output Enable	0: Disables output from the temperature sensor to the 16-bit A/D converter. 1: Enables output from the temperature sensor to the 16-bit A/D converter	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TSEN	Temperature Sensor Enable	0: Stops the temperature sensor. 1: Starts the temperature sensor.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The settings of TSCR register have the timing restrictions shown in Figure 62.4.

62.2.2 Temperature Sensor Calibration Data Register (TSCDR)

Address(es): TEMPSCONST.TSCDR 86C1 2DA0h, TEMPSCONST_NS.TSCDR 06C1 2DA0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—												
Value after reset:	0	0	0	0	Unique value for each chip											

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment. The TSCDR register is a 32-bit read-only register and should be read in 32-bit units.
Temperature sensor calibration data is a digital value obtained using the 16-bit A/D converter to convert the voltage output by the temperature sensor under the condition of Tj = 125°C and AVCC0 = 3.3 V.
The voltage V1 output by the temperature sensor under the condition of Tj = 125°C can be calculated from the value of the TSCDR register according to the formula below.

V1 = 3.3 × value of the TSCDR register/4096 [V]

Note that the AVCC0 voltage does not affect voltage V1.

62.2.3 Temperature Sensor Calibration Data Register 2 (TSCDR2)

Address(es): TEMPSCONST.TSCDR2 86C1 2DA4h, TEMPSCONST_NS.TSCDR2 06C1 2DA4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—												
Value after reset:	0	0	0	0	Unique value for each chip											

The TSCDR2 register stores temperature sensor calibration data measured for each chip at factory shipment. The TSCDR2 register is a 32-bit read-only register and should be read in 32-bit units.
Temperature sensor calibration data is a digital value obtained using the 16-bit A/D converter to convert the voltage output by the temperature sensor under the condition of Tj = –40°C and AVCC0 = 3.3 V.
The voltage V1 output by the temperature sensor under the condition of Tj = –40°C can be calculated from the value of the TSCDR2 register according to the formula below.

V1 = 3.3 × value of the TSCDR2 register/4096 [V]

Note that the AVCC0 voltage does not affect voltage V1.

62.3 Using the Temperature Sensor

The temperature sensor outputs a voltage proportional to temperature. By converting this voltage into a digital value with a 16-bit A/D converter and converting it into temperature, the internal temperature of the MCU can be obtained.

62.3.1 Preparation for Using the Temperature Sensor

Perform a calibration of the temperature sensor as shown below. The voltage output by the temperature sensor is proportional to temperature, which can be calculated according to the following formula.

Formula for the temperature characteristic:
T = (Vs – V1)/Slope + T1

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
T1: Sample temperature measurement at first point (°C)
V1: Voltage output by the temperature sensor when T1 is measured (V)
T2: Sample temperature measurement at second point (°C)
V2: Voltage output by the temperature sensor when T2 is measured (V)
Slope: Temperature slope of the temperature sensor (V/°C); Slope = (V2 – V1)/(T2 – T1)

Since there are individual differences in temperature sensors, it is recommended to prepare a temperature slope by performing trial measurements at two different temperatures as shown below.
Use the 16-bit A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1.
Again, using the 16-bit A/D converter, measure the voltage V2 output by the temperature sensor at a different temperature T2. Obtain the temperature slope (Slope = (V2 – V1)/(T2 – T1)) from these results.
Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs – V1)/Slope + T1).

If you are using the temperature slope given in Table 67.130 of section 67, Electrical Characteristics, use the 16-bit A/D converter to measure the voltage V1 output by the temperature sensor at temperature T1, and then calculate the temperature characteristic by using the formula below.
However, this calibration gives less accurate temperatures than two-point calibration.

T = (Vs – V1)/Slope + T1

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
T1: Sample temperature measurement at first point (°C)
V1: Voltage output by the temperature sensor when T1 is measured (V)
Slope: Temperature slope given in Table 67.130 ÷ 1000 (V/°C)

In this MCU, the TSCDR register holds the temperature value (CAL_{125}) measured by the temperature sensor under the condition Tj = 125°C and AVCC0 = 3.3 V, and the TSCDR2 register holds the temperature value (CAL_{-40}) measured by the temperature sensor measured under the condition of Tj = –40°C and AVCC0 = 3.3 V. By using this value as the sample measurement result at the first point, preparation before using the temperature sensor can be omitted.
If V1 is calculated from CAL_{125} or CAL_{-40},

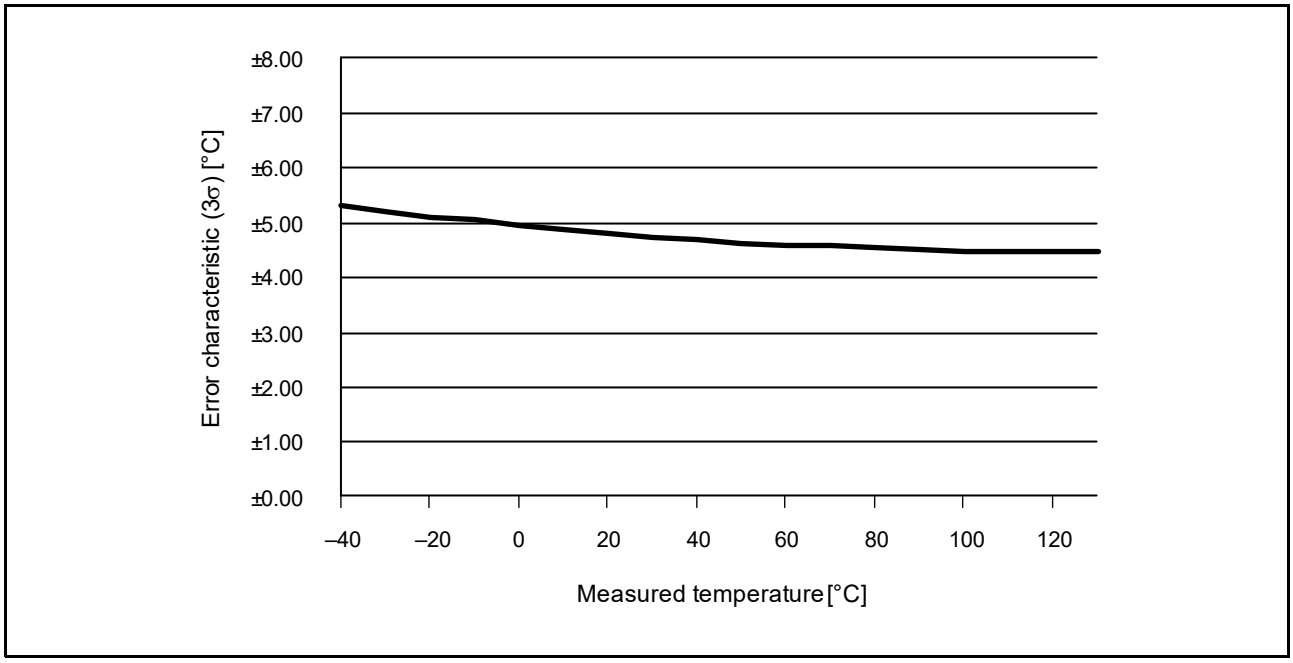
V1 = 3.3 × CAL_{125} or CAL_{-40}/4096 [V]
Using this, the measured temperature can be calculated according to the formula below.

T = (Vs – V1)/Slope + 125 or –40 [°C]

T: Measured temperature (internal temperature of the MCU) (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
V1: Voltage output by the temperature sensor when Tj = 125°C or –40°C and AVCC0 = 3.3 V (V)
Slope: Temperature slope given in Table 67.130 ÷ 1000 (V/°C)

The slope can also be obtained by using the value of the TSCDR or TSCDR2 register as the second result of measurement.

Error in the measured temperature (the range of variation is 3σ) is shown in Figure 62.2.



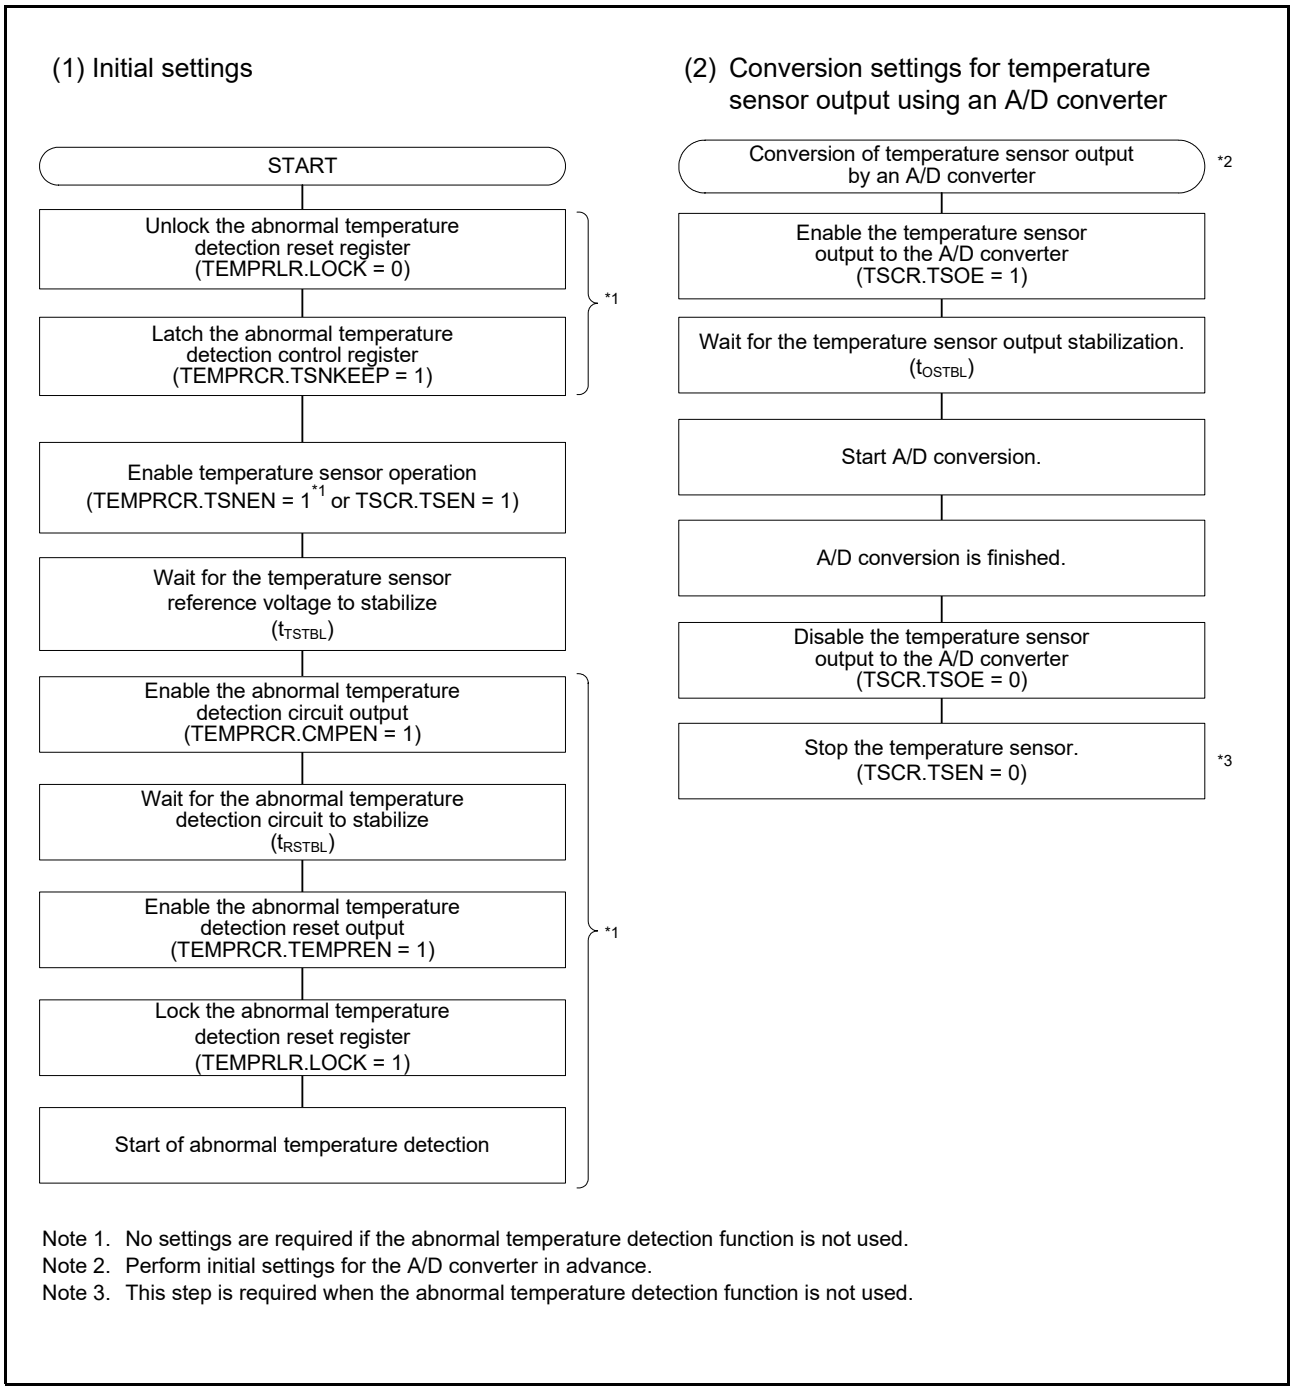


Figure 62.2 Error in the Measured Temperature

62.3.2 Procedure for Using the Temperature Sensor

Figure 62.3 shows the procedure for using the temperature sensor.

To use a temperature sensor, perform the initial settings (1) first. When converting temperature sensor output using an A/D converter, perform the initial settings (1) and then perform the procedure (2) to convert the temperature sensor output using the A/D converter.
For details on how to configure the A/D converter, see section 60, 16-Bit A/D Converter (ADC16H).
For details on registers TEMPRLR and TEMPRCR, see section 6, Resets.

Note 1. No settings are required if the abnormal temperature detection function is not used.
Note 2. Perform initial settings for the A/D converter in advance.
Note 3. This step is required when the abnormal temperature detection function is not used.

Figure 62.3 Procedure for Using the Temperature Sensor

62.3.3 Timing of A/D Conversion of Temperature Sensor Output

Figure 62.4 shows the timing from the start of temperature-sensor operation until the completion of A/D conversion when only the output from the temperature sensor is to be A/D converted and conversion is in single-scan mode. The times shown in the figure are described in Table 62.2.

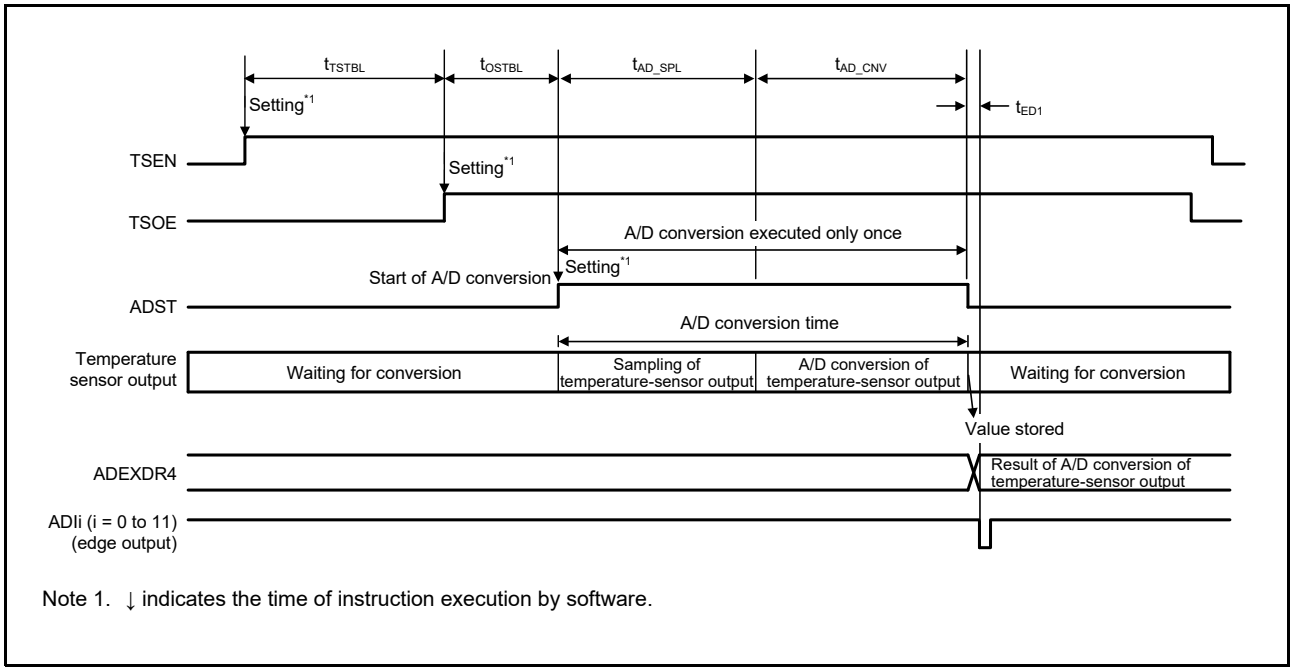

Figure 62.4 Timing from the Start of Temperature-Sensor Operation until Completion of A/D Conversion

Table 62.2 Time until Completion of A/D Conversion after the Start of Temperature-Sensor Operation

Item	Symbol	Time
Temperature-sensor reference-voltage stabilization wait time	t_{TSTBL}	Refer to section 67, Electrical Characteristics.
Temperature-sensor output stabilization wait time	t_{OSTBL}	Refer to section 67, Electrical Characteristics.
Abnormal temperature detection circuit stabilization waiting time	t_{RSTBL}	Refer to section 67, Electrical Characteristics.
16-bit A/D converter input sampling time	t_{AD_SPL}	Refer to “Table 60.69, A/D Convert Processing Time” in “section 60.9.2, Conversion Processing Time”.
16-bit A/D converter successive approximation time	t_{AD_CNV}	Refer to “Table 60.69, A/D Convert Processing Time” in “section 60.9.2, Conversion Processing Time”.
Scan end processing time	t_{ED1}	Refer to “Table 60.70, Scan End Processing Time and the Forcibly Stop Processing Time” in “section 60.9.3, Scan End Processing Time”.

62.4 Usage Note

62.4.1 Module-Stop Function Setting

The corresponding bit in module stop control register D (MSTPCRD) can be used to enable and disable the temperature sensor. The initial setting is for the temperature sensor to be stopped. The register becomes accessible by releasing from the module-stop state. For details, refer to section 11, Low Power Consumption.

62.4.2 Settings for the Software Standby Mode

Before placing the MCU in the software standby mode, stop A/D conversion and set the TSCR.TSOE bit to 0. After that, set the TSCR.TSEN bit to 0 to stop the temperature sensor. Figure 62.5 shows the procedure for a transition to the software standby mode, and Figure 62.6 shows the procedure for return from the software standby mode.

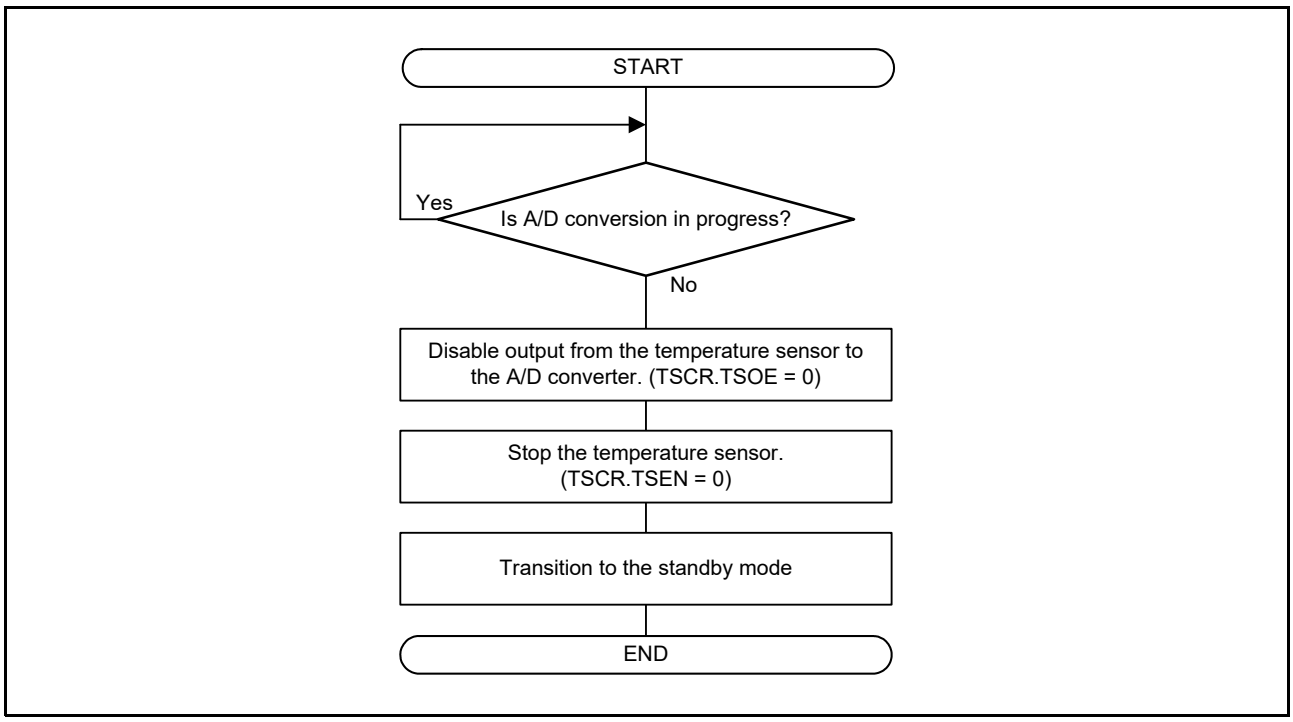

Figure 62.5 Procedure for a Transition to the Software Standby Mode

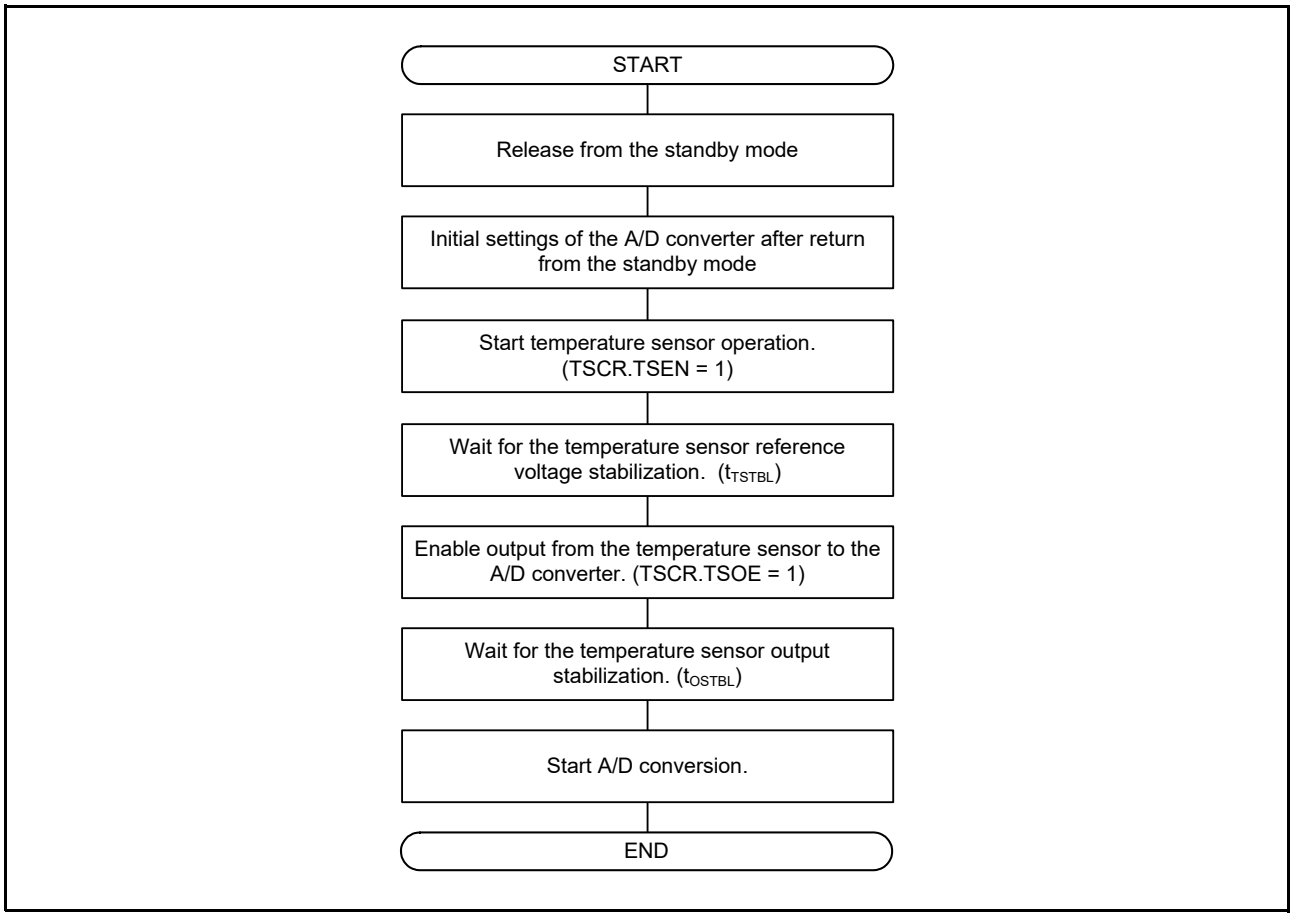

Figure 62.6 Procedure for Return from the Software Standby Mode

63. Data Operation Circuit (DOCA)

63.1 Overview

The data operation circuit (DOC) is used to compare, add, or subtract 16- or 32-bit values.
Table 63.1 lists the specifications of the DOC and Figure 63.1 is a block diagram of the DOC.
An interrupt can be generated if the result of 16- or 32-bit comparison meets one of the set interrupt conditions or if the result of the addition or subtraction result of 16- or 32-bit values is an overflow or underflow.

Table 63.1 DOC Specifications

Item	Description
Data operation function	• Comparison of 16- or 32-bit values (equal or not equal, greater or less than, or within or beyond a range) • Addition or subtraction of 16- or 32-bit values
Lower power consumption function	The DOC can be placed in a module-stop state.
Interrupts	• The result of data comparison meets the detection condition. • The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1), which is an overflow. • The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1), which is an underflow.
Event link function (output)	• The result of data comparison meets the detection condition. • The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1), which is an overflow. • The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1), which is an underflow.
Protect Zone filter	Security attribute can be set.*1

Note 1. When this module is set to the secure attribute, every register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this module is set to the non-secure attribute, every register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

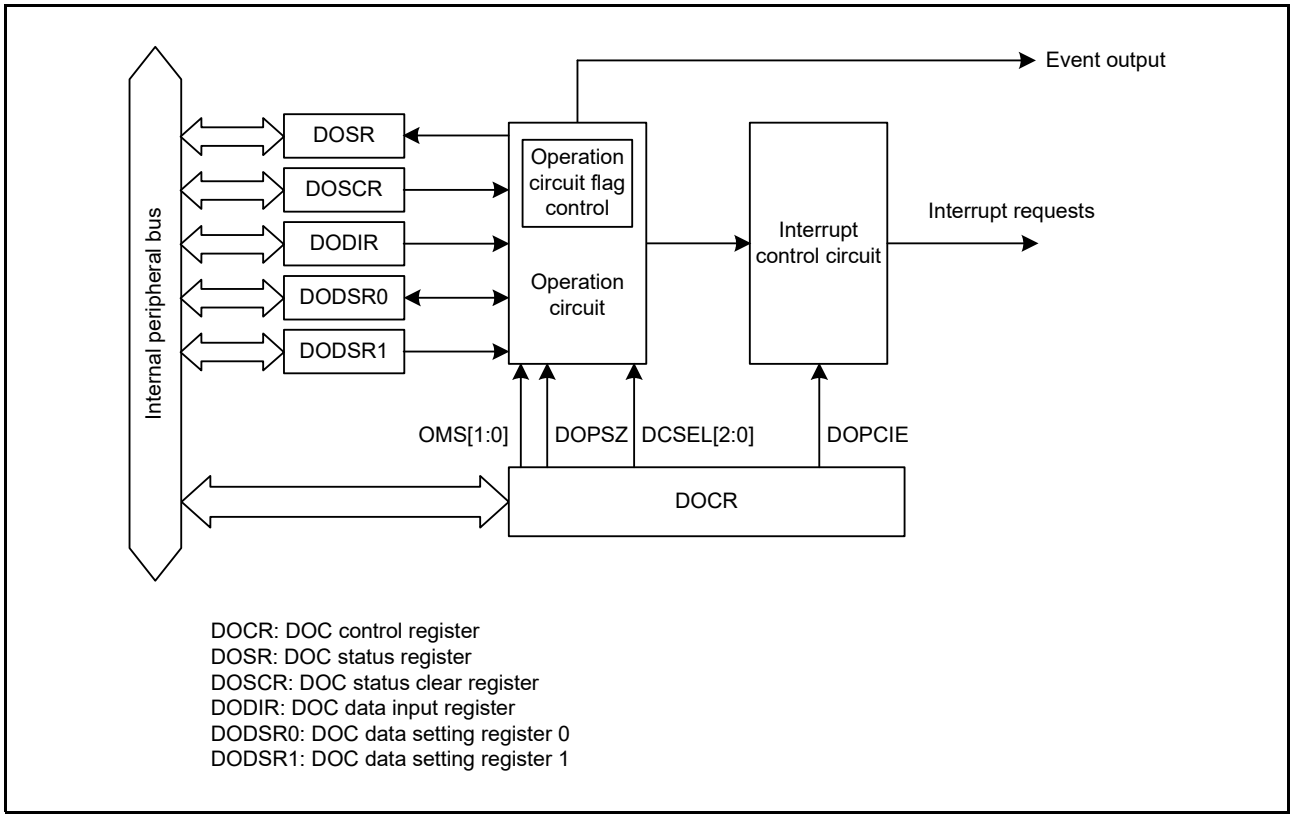

Figure 63.1 DOC Block Diagram

63.2 Register Descriptions

63.2.1 DOC Control Register (DOCR)

Address(es): DOC.DOCR 8741 1000h, DOC_NS.DOCR 0741 1000h

	b7	b6	b5	b4	b3	b2	b1	b0
	DOPCIE	DCSEL[2:0]			DOPSZ	—	OMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	OMS[1:0]	Operating Mode Select	b1 b0 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	DOPSZ	Data Operation Size Select	0: 16-bit width 1: 32-bit width	R/W
b6-b4	DCSEL[2:0]	Detection Condition Select*1	b6 b4 0 0 0: Not equal to (DODIR ≠ DODSR0) 0 0 1: Equal to (DODIR = DODSR0) 0 1 0: Less than (DODIR < DODSR0) 0 1 1: Greater than (DODIR > DODSR0) 1 0 0: Within the range (DODSR0 < DODIR < DODSR1) 1 0 1: Beyond the range (DODIR < DODSR0, DODSR1 < DODIR) Settings other than above are prohibited.	R/W
b7	DOPCIE	Data Operation Circuit Interrupt Enable	0: Interrupt disabled 1: Interrupt enabled	R/W

Note 1. Valid only when data comparison mode is selected.

The DOCR register specifies the operation of DOC, or enabling or disabling of the interrupt.

OMS[1:0] Bits (Operating Mode Select)

These bits select the operating mode of the DOC.

DOPSZ Bit (Data Operation Size Select)

This bit selects the size of the data operation.

DCSEL[2:0] Bits (Detection Condition Select)

This bit is valid only when data comparison mode is selected.
This bit selects the condition for detection in data comparison mode.

DOPCIE Bit (Data Operation Circuit Interrupt Enable)

Setting this bit to 1 enables interrupts from the DOC.

63.2.2 DOC Status Register (DOSR)

Address(es): DOC.DOSR 8741 1004h, DOC_NS.DOSR 0741 1004h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DOPCF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DOPCF	Data Operation Result Flag	Indicates the result of an operation.	R
b7-b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

The DOSR register indicates the results of data operation.

DOPCF Flag (Data Operation Result Flag)

[Setting conditions]

- The setting of the DOCR.OMS[1:0] bits is 00b (data comparison mode) and the result of data comparison meets the condition selected by the DOCR.DCSEL[2:0] bits.
- The setting of the DOCR.OMS[1:0] bits is 01b (data addition mode) and the result of addition was greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1).
- The setting of the DOCR.OMS[1:0] bits is 10b (data subtraction mode) and the result of subtraction is below 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1).

[Clearing condition]

- Writing 1 to the DOSCR.DOPCFCL bit

63.2.3 DOC Status Clear Register (DOSCR)

Address(es): DOC.DOSCR 8741 1008h, DOC_NS.DOSCR 0741 1008h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DOPCFCL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DOPCFCL	Data Operation Result Clear	0: Retain the value of the DOPCF flag. 1: Clears the DOPCF flag.	W
b7-b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

The DOSCR register is for clearing the DOPCF flag. It is always read as 00h.

DOPCFCL Bit (Data Operation Result Clear)

Writing 1 to this bit clears the DOSR.DOPCF flag.

63.2.4 DOC Data Input Register (DODIR)

Address(es): DOC.DODIR 8741 100Ch, DOC_NS.DODIR 0741 100Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DODIR register is a readable and writable register that holds values for use in operations.
Access the DODIR register with the data operation size selected by the DOCR.DOPSZ bit.

63.2.5 DOC Data Setting Register 0 (DODSR0)

Address(es): DOC.DODSR0 8741 1010h, DOC_NS.DODSR0 0741 1010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DODSR0 register is a readable and writable register that holds values for use in comparison or the results of other operations.
Access the DODSR0 register with the data operation size selected by the DOCR.DOPSZ bit.
In data comparison mode, store the standard value for use in comparison in this register. When either ‘within the range’ (DOCR.DCSEL[2:0] = 100b) or ‘beyond the range’ (DOCR.DCSEL[2:0] = 101b) is selected, specify the lower boundary of the range.
In data addition or data subtraction mode, this register holds the results of operations.

63.2.6 DOC Data Setting Register 1 (DODSR1)

Address(es): DOC.DODSR1 8741 1014h, DOC_NS.DODSR1 0741 1014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DODSR1 register is a readable and writable register that holds a value for use in range comparison.
Access the DODSR1 register with the data operation size selected by the DOCR.DOPSZ bit.
When either ‘within the range’ (DOCR.DCSEL[2:0] = 100b) or ‘beyond the range’ (DOCR.DCSEL[2:0] = 101b) is selected in data comparison mode, specify the upper boundary of the range.
This register is only used when either ‘within the range’ or ‘beyond the range’ is selected.

63.3 Operation

63.3.1 Data Comparison Mode

Figure 63.2 to Figure 63.7 show an example of the steps involved in data comparison mode operation by the DOC*1. An example of operation with the operation size of 32 bits is shown below.

(1) Writing 00b to the DOCR.OMS[1:0] bits places the DOC in the data comparison mode. At the same time, write to the DOCR.DCSEL[2:0] bits to select the condition to be detected.
(2) Specify the standard values for comparison in the DODSR0 and DODSR1 registers.*2
(3) Write the value for comparison in the DODIR register.
(4) If the value written to the DODIR register satisfies the condition set in the DOCR.DCSEL[2:0] bits, the DOSR.DOPCF flag becomes 1, and an ELC event is generated. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

Note 1. Comparison is made to proceed at the same time a value is written to the DODIR register. Writing values to the DODSR0 and DODSR1 registers does not make comparison proceed.
Note 2. Setting of the DODSR1 register is only required when either 'within the range' or 'beyond the range' is selected. Set a greater value for the DODSR1 register than that of the DODSR0 register.

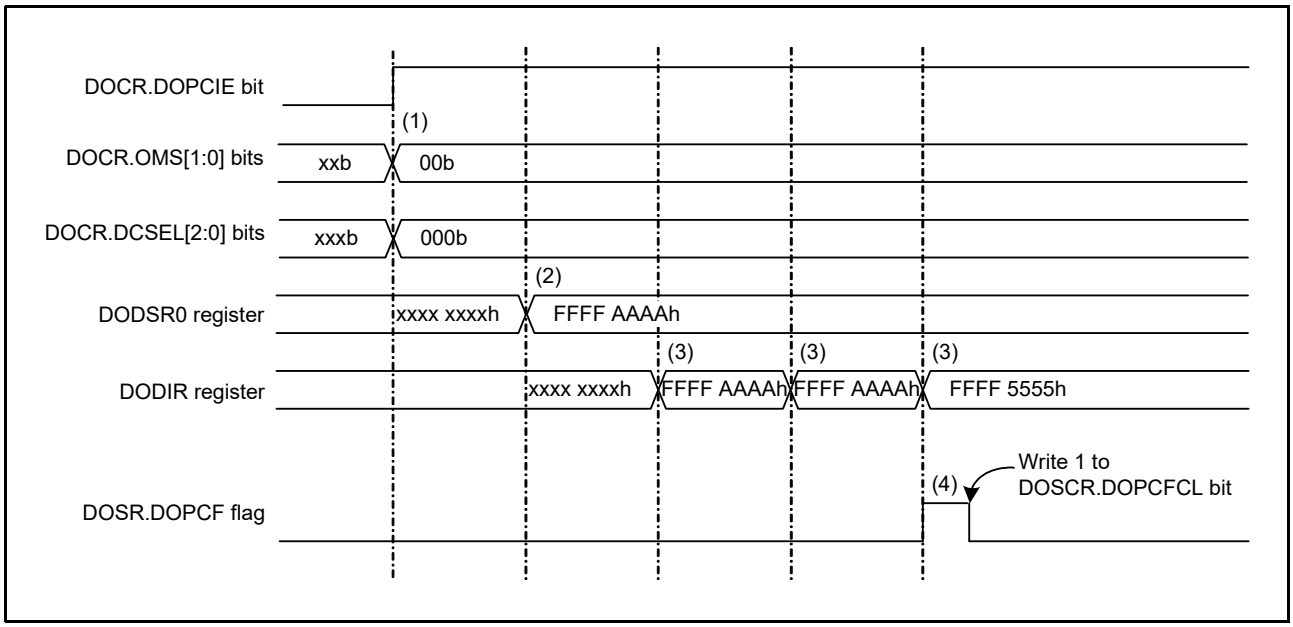

Figure 63.2 Example of the Operation of 'Not Equal to' as the Detection Condition in Data Comparison Mode

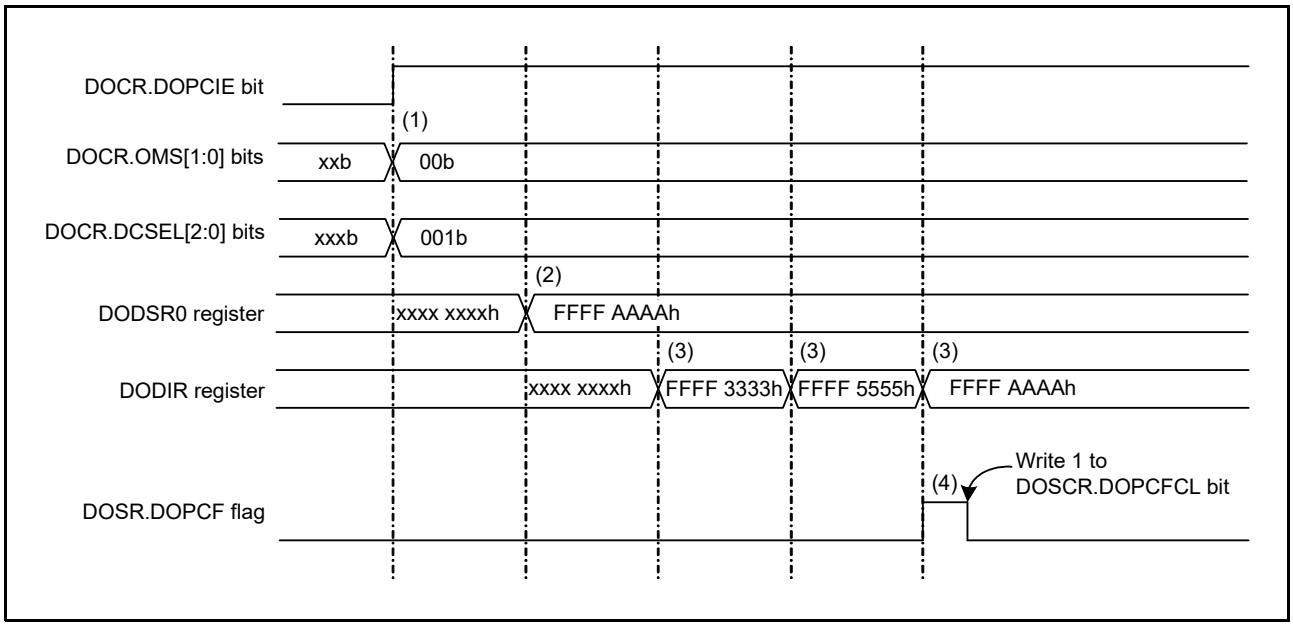

Figure 63.3 Example of the Operation of 'Equal to' as the Detection Condition in Data Comparison Mode

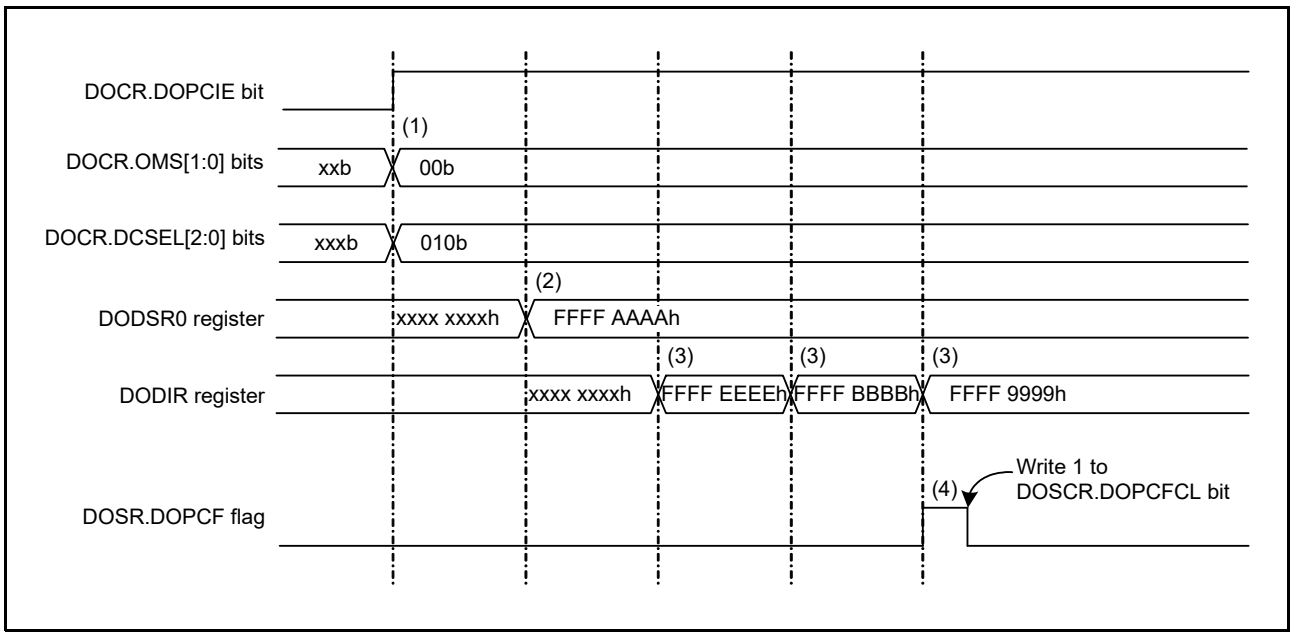

Figure 63.4 Example of the Operation of 'Less Than' as the Detection Condition in Data Comparison Mode

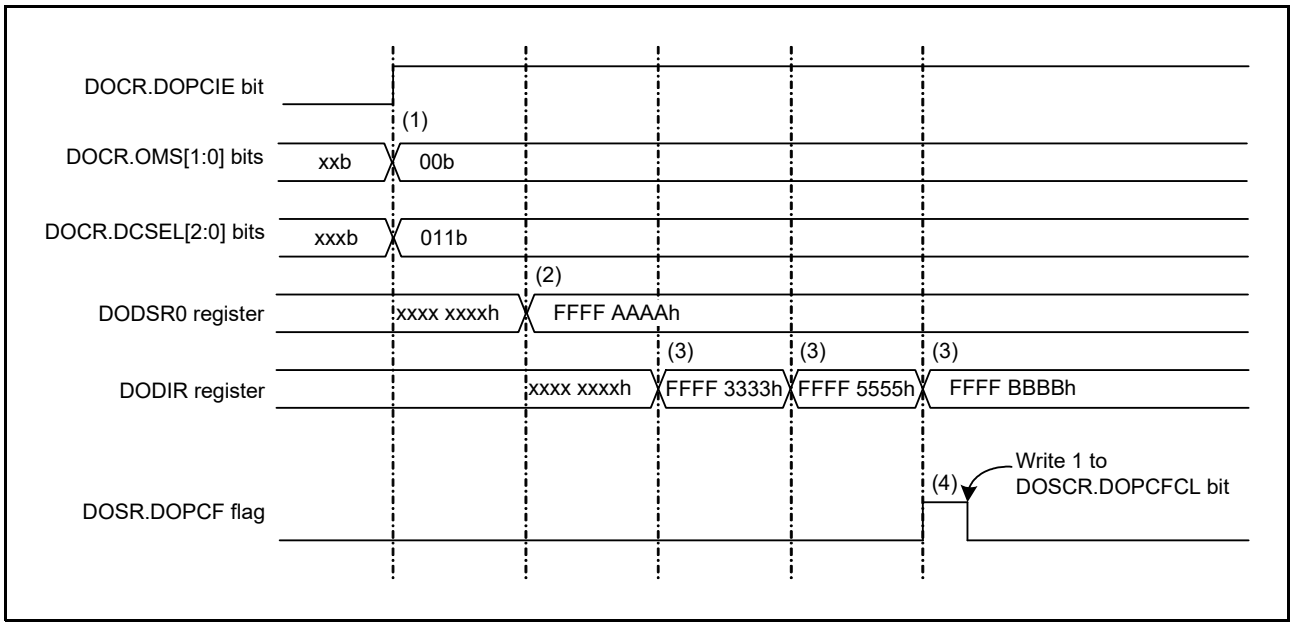

Figure 63.5 Example of the Operation of 'Greater Than' as the Detection Condition in Data Comparison Mode

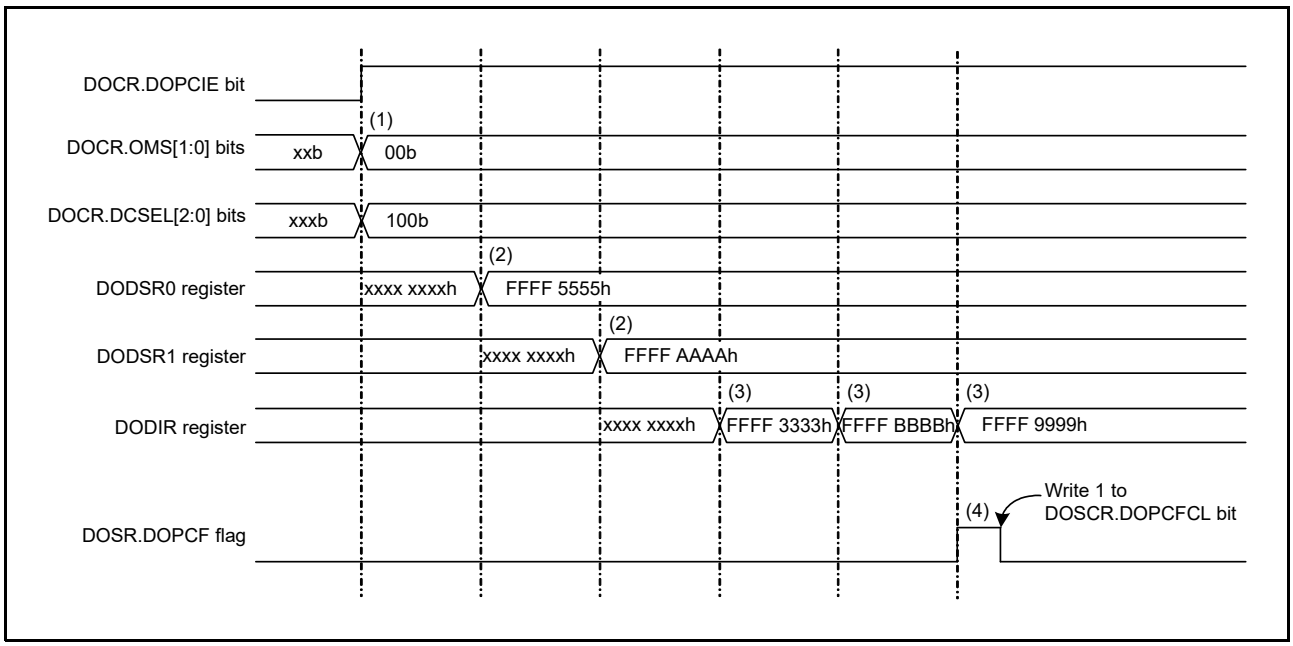

Figure 63.6 Example of the Operation of 'Within the Range' as the Detection Condition in Data Comparison Mode

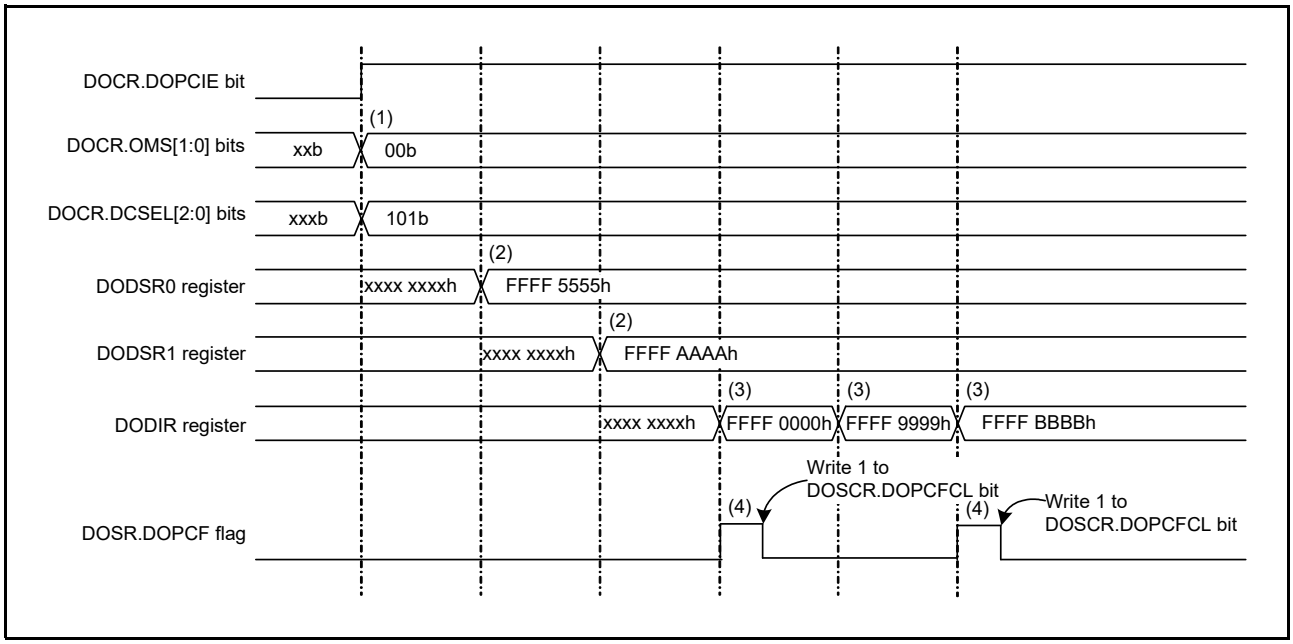

Figure 63.7 Example of the Operation of 'Beyond the Range' as the Detection Condition in Data Comparison Mode

63.3.2 Data Addition Mode

Figure 63.8 shows an example of the steps involved in data addition mode operation*1 by the DOC.
An example of operation when the data operation size is 32 bits is shown below.

(1) Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
(2) Set the initial value in the DODSR0 register.
(3) Write the value for addition in the DODIR register. The result of the operation is stored in DODSR0.
(4) Write all values for use in addition to the DODIR register.
(5) If the result of the operation is greater than FFFF FFFFh, the DOSR.DOPCF flag becomes 1, and an ELC event is generated. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

Note 1. Addition is made to proceed at the same time as a value is written to the DODIR register. Writing a value to the DODSR0 register does not make addition proceed.

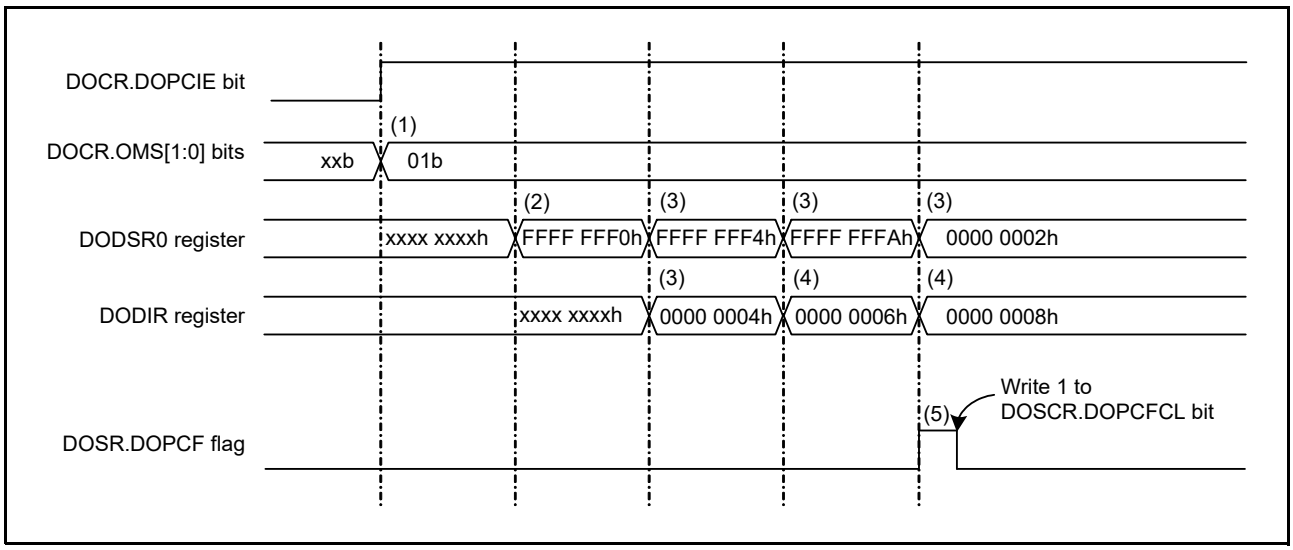

Figure 63.8 Example of Operation in Data Addition Mode

63.3.3 Data Subtraction Mode

Figure 63.9 shows an example of the steps involved in data subtraction mode operation*1 by the DOC.
An example of operation when the data operation size is 32 bits is shown below.

(1) Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
(2) Set the initial value in the DODSR0 register.
(3) Write the value for subtraction in the DODIR register. The result of the operation is stored in DODSR0.
(4) Write all values for use in subtraction to the DODIR register.
(5) If the result of the operation is less than 0000 0000h, the DOSR.DOPCF flag becomes 1, and an ELC event is generated. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

Note 1. Subtraction is made to proceed at the same time a value is written to the DODIR register. Writing a value to the DODSR0 register does not make subtraction proceed.

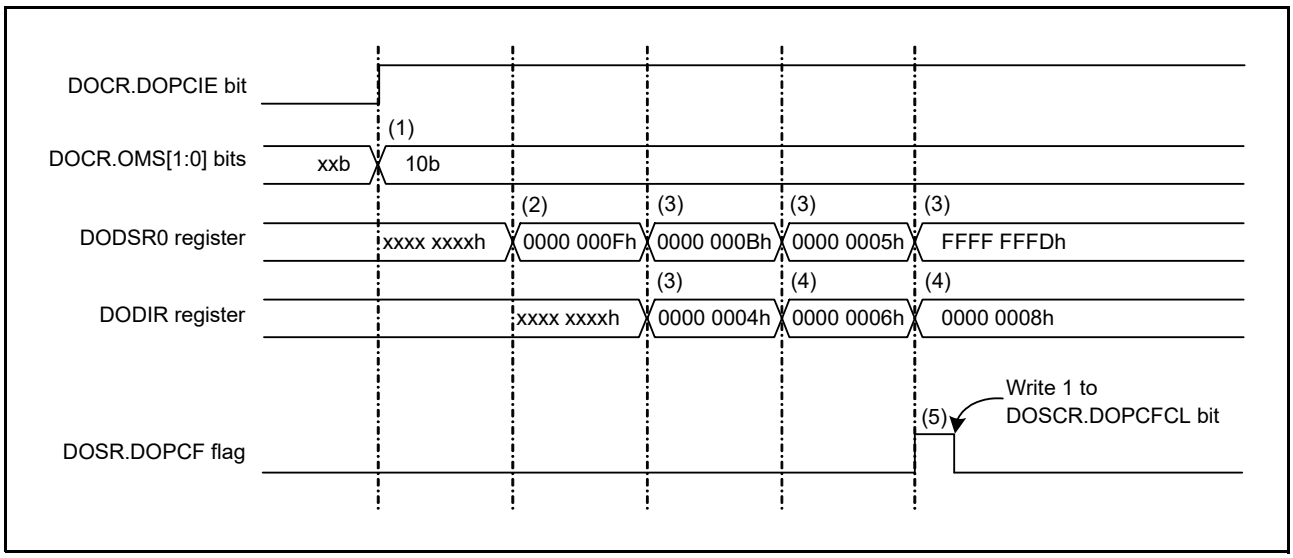

Figure 63.9 Example of Operation in Data Subtraction Mode

63.4 Interrupt Requests

The data operation circuit interrupt (DOPCI) is the interrupt request generated by the DOC. The DOSR.DOPCF flag becomes 1 when the interrupt source condition is satisfied, and an interrupt request is also issued if the DOCR.DOPCIE bit is 1.
Table 63.2 lists the details of the interrupt request.

Table 63.2 Interrupt Request from DOC

Interrupt Request	Data Operation Result Flag	Interrupt Generation Timing
Data operation circuit interrupt (DOPCI)	DOPCF	• The result of data comparison meets the detection condition. • The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1). • The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1).

63.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The result of data comparison meets the detection condition.
- The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1).
- The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1).

63.5.1 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. When an interrupt source condition is satisfied while the interrupt is enabled, the interrupt request signal is issued to the CPU.
In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

63.6 Usage Note

63.6.1 Module Stop Function Setting

Operation of the DOC can be enabled or disabled by setting the MSTPC13 bit in module stop control register C (MSTPCRC). The DOC is initially disabled after a reset. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

64. SRAM

64.1 Overview

The MCU provides an on-chip, SRAM module with parity checking or error correction code (ECC).
Table 64.1 lists the specifications of the SRAM.

Table 64.1 Specifications of the SRAM

Item		SRAM0	SRAM1
Capacity		1 Mbyte	512 Kbytes
Address Range	Secure Area	8200 0000h to 820F FFFFh	8210 0000h to 8217 FFFFh
	Non-secure Area	0200 0000h to 020F FFFFh	0210 0000h to 0217 FFFFh
Access		Supports wait state function. Wait states are not inserted into the access cycle by default. If the ICLK frequency is greater than 150 MHz, a wait state is required. If the ICLK frequency is less than or equal to 150 MHz, a wait state is not required. For details, see section 64.3.6, Access Cycle	
Data Retention		Data retention is not available on deep software standby.	
Low Power Consumption		The SRAM0 and SRAM1 are independently transferable to the module stop state.	
Error Checking		SEC-DED (Single-Error Correction and Double-Error Detection Code: 64-bit data with 8-bit ECC code)	
Security		Protect Zone Filter is integrated for memory access and register access. Access to the memory space is controlled by setting the memory Security Attribution. And access to register space is controlled by setting the register Security Attribution. See section 56, Security Features.	

64.2 Register Descriptions

64.2.1 SRAMn Security Attribute Boundary Address Register (SRAMSABARn) (n = 0, 1)

Address(es): CPSCU.SRAMSABAR0 8701 8400h, CPSCU.SRAMSABAR1 8701 8404h,
CPSCU_NS.SRAMSABAR0 0701 8400h, CPSCU_NS.SRAMSABAR1 0701 8404h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.
Note: This register is write-protected by the PRCR_S.PRC4 bit.

This register specifies the offset of the boundary between the secure and non-secure areas of each SRAMn (n = 0, 1).
Write the absolute address to this register. The register must be accessed in 32-bit units.
When writing to this register, writing from b31 to b21 is ignored and the write value to b12 to b0 must be 0.
The region lower than the boundary address is marked as secure area, and higher than or equal to the boundary address is marked as non-secure area.
The boundary address is as follows:
8200 0000h + SRAMSABARn (secure area)
0200 0000h + SRAMSABARn (non-secure area)

SRAMSABAR0

When the offset of the boundary address is 0000 0000h, whole SRAM0 is marked as non-secure area.
When the offset of the boundary address is 0010 0000h or greater, whole SRAM0 is marked as secure area.

SRAMSABAR1

When the offset of the boundary address is 0010 0000h or less, whole SRAM1 is marked as non-secure area.
When the offset of the boundary address is 0018 0000h or greater, whole SRAM1 is marked as secure area.

64.2.2 SRAM Security Attribution Register (SRAMSAR)

Address(es): CPSCU.SRAMSAR 8701 8010h, CPSCU_NS.SRAMSAR 0701 8010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SRAM WTSA	—	—	—	—	—	—	SRAMSA1	SRAMSA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SRAMSA0	SRAM0-Related Register Security Attribution	0: Secure 1: Non-secure	R/W
b1	SRAMSA1	SRAM1-Related Register Security Attribution	0: Secure 1: Non-secure	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	SRAMWTSA	SRAMWTSC Security Attribution	0: Secure 1: Non-secure	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.
Note: This register is write-protected by the PRCR_S.PRC4 bit.

This register controls the security attributes of SRAM registers.

SRAMSA0 Bit (SRAM0-Related Register Security Attribution)

This bit is used to specify the security attributes of the following SRAM0-related registers and bits.

- SRAMCR0
- SRAMECCRGN0
- SRAMESCLR.CLR00, SRAMESCLR.CLR01

SRAMSA1 Bit (SRAM1-Related Register Security Attribution)

This bit is used to specify the security attributes of the following SRAM1-related registers and bits.

- SRAMCR1
- SRAMECCRGN1
- SRAMESCLR.CLR10, SRAMESCLR.CLR11

SRAMWTSA Bit (SRAMWTSC Security Attribution)

This bit is used to specify the security attributes of the SRAMWTSC register.

64.2.3 SRAM Protection Control Register for Secure (SRAMPRCR_S)

Address(es): SRAM.SRAMPRCR_S 8701 C000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PR	Register Write Control	0: Writing to registers are disable. 1: Writing to registers are enable.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KW[7:0]	Write Key Code	Key code protection to the PR bit	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

Note: It is necessary to write by 16-bit access. 8-bit write access is prohibited. When 8-bit write access is executed, operation is not guaranteed.

This register controls writing to SRAM registers that are specified as secure.

PR Bit (Register Write Control)

This bit controls the write mode of the SRAMWTSC, SRAMCRn, and SRAMECCRGNn registers that are specified as secure by the SRAMSAR register.

When this bit is set to 1, writing to SRAMWTSC, SRAMCRn, and SRAMECCRGNn that are specified as secure is permitted.

Simultaneously with writing this bit, A5h must also be written to the KW[7:0] bits.

KW[7:0] Bits (Write Key Code)

These bits enable or disable writing to the PR bit.

When writing to the PR bit, write A5h to the KW[7:0] bits at the same time. If a value other than A5h is written, the PR bit is not updated. When read, it returns 00h.

64.2.4 SRAM Protection Control Register for Non-Secure (SRAMPRCR_NS)

Address(es): SRAM_NS.SRAMPRCR_NS 0701 C004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PR	Register Write Control	0: Writing registers are disable. 1: Writing registers are enable.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KW[7:0]	Write Key Code	Key code protection to the PR bit	R/W

Note: This register is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: It is necessary to write by 16-bit access. 8-bit write access is prohibited. When 8-bit write access is executed, operation is not guaranteed.

This register controls writing to SRAM registers that are specified as non-secure.

PR Bit (Register Write Control)

This bit controls the write mode of the SRAMWTSC, SRAMCRn, and SRAMECCRGNn registers that are specified as non-secure by the SRAMSAR register.

When this bit is set to 1, writing to SRAMWTSC, SRAMCRn, and SRAMECCRGNn that are specified as non-secure is permitted.

When writing to this bit, A5h must also be written to the KW[7:0] bits.

KW[7:0] Bits (Write Key Code)

These bits enable or disable writing to the PR bit.

When writing to the PR bit, write A5h to the KW[7:0] bits at the same time. If a value other than A5h is written, the PR bit is not updated. When read, it returns 00h.

64.2.5 SRAM Wait State Control Register (SRAMWTSC)

Address(es): SRAM.SRAMWTSC 8701 C008h, SRAM_NS.SRAMWTSC 0701 C008h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	WTEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	WTEN	SRAM wait enable	0: Do not add wait state in the access cycle to SRAMs. 1: Add wait state in the access cycle to SRAMs.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note: This register can be written only when the PR bit of the SRAMPRCR_S or SRAMPRCR_NS register is 1.

This register sets whether or not to insert wait cycles into SRAM access cycles.

WTEN Bit (SRAM wait enable)

This bit sets the wait cycle insertion to the access cycle of SRAM. When this bit is set to 1, one wait cycle is inserted to the read access cycle of SRAM. When this bit is 1 and there are consecutive accesses to the same area*1 and the same mat*2, one wait cycle is inserted in the second access cycle. When access frequency is greater than 150 MHz, set this bit to 1.

Note 1. The area of SRAM is divided to 128KB units.
Note 2. The mat is divided to 0h to 7h and 8h to Fh in the lower 4-bits of the address.

For example, in the case of SRAMn, the same area and same mat means 16 areas in the figure below. When one area is accessed consecutively, one wait cycle is inserted.
Figure 64.1 shows the mat configuration of each SRAM.

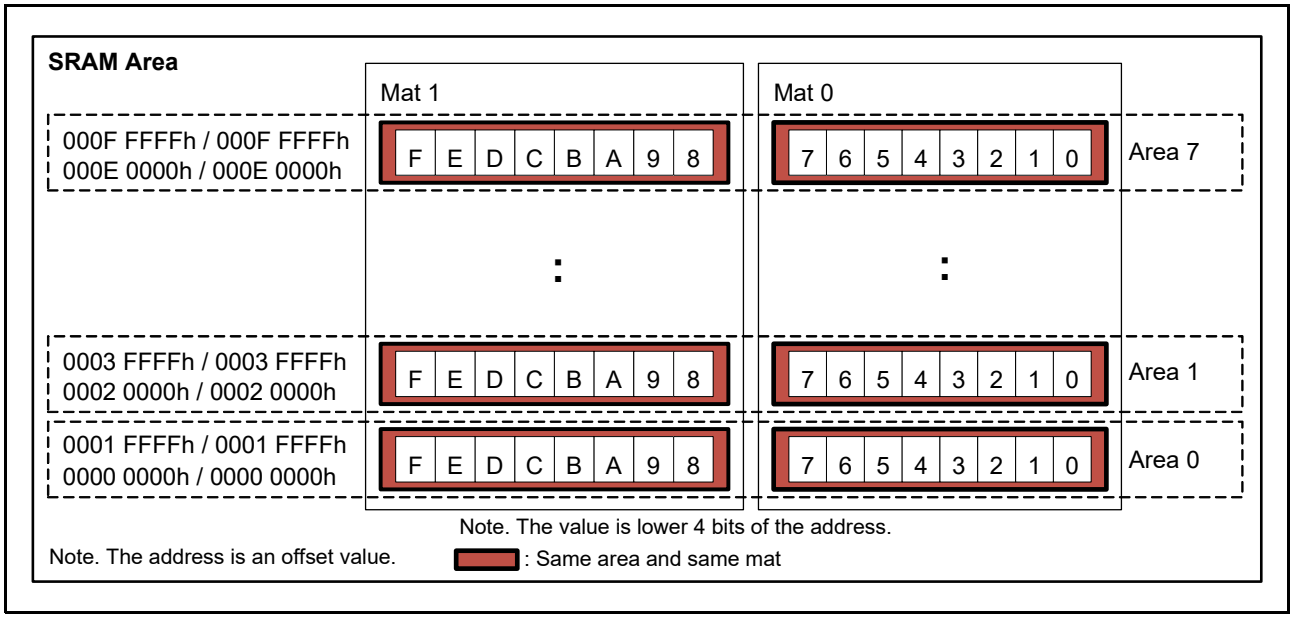

Figure 64.1 Mat configuration of each SRAMs

64.2.6 SRAM Control Register n (SRAMCRn) (n = 0, 1)

Address(es): SRAM.SRAMCR0 8701 C010h, SRAM.SRAMCR1 8701 C014h,
SRAM_NS.SRAMCR0 0701 C010h, SRAM_NS.SRAMCR1 0701 C014h

	b7	b6	b5	b4	b3	b2	b1	b0
	TSTBYP	—	—	E1STSEN	ECCMOD[1:0]		—	OAD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OAD	Operation after error detection	0: Interrupt 1: Reset	R/W
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3 to b2	ECCMOD[1:0]	ECC Operating Mode Select	b3 b2 0 0: Disable ECC function 0 1: Setting prohibited 1 0: Enable ECC function without error checking 1 1: Enable ECC function with error checking	R/W
b4	E1STSEN	ECC 1-bit Error Update Enable	0: Disable updating of 1-bit ECC error 1: Enable updating of 1-bit ECC error	R/W
b6 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TSTBYP	ECC Bypass Select	0: Disable ECC bypass 1: Enable ECC bypass	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

This register controls the functions related to the ECC operation of SRAMn (n = 0, 1).

OAD Bit (Operation after error detection)

Select whether to request a reset or an interrupt when an ECC error is detected.
For information about handling the interrupt (also selectable as a non-maskable interrupt), refer to section 15, Interrupt Controller (ICUM).

E1STSEN Bit (ECC 1-bit Error Update Enable)

This bit enables or disables updating of the ECC 1-bit error status bit in the SRAMESR register, in response to a 1-bit error.
This bit also functions as an interrupt or a reset mask.

TSTBYP Bit (ECC Bypass Select)

This bit enables direct access to ECC code by bypassing the ECC function. The ECC Bypass function is used along with setting the ECCMOD[1:0] bits to 00b.
The ECC must be accessed the same address. The ECC code is assigned to the lower 8 bits. When writing the ECC code, the bits above the ECC bits are ignored. When reading the ECC code, the bits above the ECC bits are invalid.
For details about ECC test, refer to section 64.3.3, ECC Decoder Testing.

64.2.7 SRAM ECC Region Control Register 0 (SRAMECCRGN0)

Address(es): SRAM.SRAMECCRGN0 8701 C030h, SRAM_NS.SRAMECCRGN0 0701 C030h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	ECCRGN[3:0]			
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ECCRGN[3:0]	ECC target region select	b3 b0 0 0 0 0: No ECC target area 0 0 0 1: 0200 0000h to 0201 FFFFh 8200 0000h to 8201 FFFFh (128 Kbytes) 0 0 1 0: 0200 0000h to 0203 FFFFh 8200 0000h to 8203 FFFFh (256 Kbytes) 0 0 1 1: 0200 0000h to 0205 FFFFh 8200 0000h to 8205 FFFFh (384 Kbytes) 0 1 0 0: 0200 0000h to 0207 FFFFh 8200 0000h to 8207 FFFFh (512 Kbytes) 0 1 0 1: 0200 0000h to 0209 FFFFh 8200 0000h to 8209 FFFFh (640 Kbytes) 0 1 1 0: 0200 0000h to 020B FFFFh 8200 0000h to 820B FFFFh (768 Kbytes) 0 1 1 1: 0200 0000h to 020D FFFFh 8200 0000h to 820D FFFFh (896 Kbytes) 1 0 0 0: 0200 0000h to 020F FFFFh 8200 0000h to 820F FFFFh (1 Mbyte) Settings other than above are prohibited. The ECC target area selected by these bits can be controlled by the SRAMCR0 register.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

This register selects the ECC target area of SRAM0.

64.2.8 SRAM ECC Region Control Register 1 (SRAMECCRGN1)

Address(es): SRAM.SRAMECCRGN1 8701 C034h, SRAM_NS.SRAMECCRGN1 0701 C034h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	ECCRGN[3:0]			
Value after reset:	0	0	0	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ECCRGN[3:0]	ECC target region select	b3 b0 0 0 0 0: No ECC target area 0 0 0 1: 0210 0000h to 0211 FFFFh 8210 0000h to 8211 FFFFh (128 Kbytes) 0 0 1 0: 0210 0000h to 0213 FFFFh 8210 0000h to 8213 FFFFh (256 Kbytes) 0 0 1 1: 0210 0000h to 0215 FFFFh 8210 0000h to 8215 FFFFh (384 Kbytes) 0 1 0 0: 0210 0000h to 0217 FFFFh 8210 0000h to 8217 FFFFh (512 Kbytes) Settings other than above are prohibited. The ECC target area selected by these bits can be controlled by the SRAMCR1 register.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note: This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

This register selects the ECC target area of SRAM1.

64.2.9 SRAM Error Status Register (SRAMESR)

Address(es): SRAM.SRAMESR 8701 C040h, SRAM_NS.SRAMESR 0701 C040h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	ERR11	ERR10	ERR01	ERR00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ERR00	SRAM0 1-bit ECC Error Status	0: 1-bit ECC error has not occurred. 1: 1-bit ECC error has occurred.	R
b1	ERR01	SRAM0 2-bit ECC Error Status	0: 2-bit ECC error has not occurred. 1: 2-bit ECC error has occurred.	R
b2	ERR10	SRAM1 1-bit ECC Error Status	0: 1-bit ECC error has not occurred. 1: 1-bit ECC error has occurred.	R
b3	ERR11	SRAM1 2-bit ECC Error Status	0: 2-bit ECC error has not occurred. 1: 2-bit ECC error has occurred.	R
b15 to b4	—	Reserved	These bits are read as 0	R

This register is the SRAM ECC error status register.
This register is cleared by the corresponding bit in the SRAMESCLR register, or by any reset other than a bus error reset or memory error reset. If an error and a clear occur at the same time, clear takes priority.

ERRn0 Flags (SRAMn 1-bit ECC Error Status) (n = 0, 1)

This flag indicates whether or not a 1-bit ECC error has occurred in SRAMn.
When the ECC function is enabled, error checking is enabled (SRAMCRn.ECCMOD[1:0] = 11b), and the SRAMCRn.E1STSEN bit is set to 1, the ERRn0 flag becomes 1 when a 1-bit error is detected. When the ERRn0 flag becomes 1, a reset or interrupt request occurs according to the SRAMCRn.OAD bit.

ERRn1 Flags (SRAMn 2-bit ECC Error Status) (n = 0, 1)

This flag indicates whether or not a 2-bit ECC error has occurred in SRAMn.
When the ECC function is enabled and error checking is performed (SRAMCRn.ECCMOD[1:0] = 11b), if a 2-bit error is detected, the ERRn1 flag becomes 1. When the ERRn1 flag becomes 1, a reset or interrupt request occurs according to the SRAMCRn.OAD bit.

64.2.10 SRAM Error Status Clear Register (SRAMESCLR)

Address(es): SRAM.SRAMESCLR 8701 C048h, SRAM_NS.SRAMESCLR 0701 C048h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	CLR11	CLR10	CLR01	CLR00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CLR00	SRAM0 1-bit ECC Error Status Clear	Setting this bit to 1 clears the SRAMESR.ERR00 flag. The read value is always 0.	R/W*1
b1	CLR01	SRAM0 2-bit ECC Error Status Clear	Setting this bit to 1 clears the SRAMESR.ERR01 flag. The read value is always 0.	R/W*1
b2	CLR10	SRAM1 1-bit ECC Error Status Clear	Setting this bit to 1 clears the SRAMESR.ERR10 flag. The read value is always 0.	R/W*1
b3	CLR11	SRAM1 2-bit ECC Error Status Clear	Setting this bit to 1 clears the SRAMESR.ERR11 flag. The read value is always 0.	R/W*1
b15 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: The security attributes for this register can be set for each bit.
When a bit is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, but no Protect Zone access errors are generated.
When a bit is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, but no Protect Zone access errors are generated.

Note 1. Only 1 can be written.

This register clears the ECC error status flags in the SRAMESR register.

If a flag is set due to an error and is also cleared by the SRAMESCLR register at the same time, the clear takes precedence.

64.2.11 SRAMn Error Address m Register (SRAMEARnm) (n = 0, 1; m = 0, 1)

Address(es): SRAM.SRAMEAR00 8701 C050h, SRAM.SRAMEAR01 8701 C054h, SRAM.SRAMEAR10 8701 C060h, SRAM.SRAMEAR11 8701 C064h, SRAM_NS.SRAMEAR00 0701 C050h, SRAM_NS.SRAMEAR01 0701 C054h, SRAM_NS.SRAMEAR10 0701 C060h, SRAM_NS.SRAMEAR11 0701 C064h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This register is a 32-bit read-only register that stores the offset of the error address when an SRAM error occurs.
It is cleared by clearing the ECC error status flag using the corresponding bit in the SRAMESCLR register, or by any reset other than a bus error reset or memory error reset. If the offset of the error address due to an error is stored and cleared at the same time, the clear takes priority.
The error address is as follows.
8200 0000h + SRAMEARnm (secure area)
0200 0000h + SRAMEARnm (non-secure area)

For SRAMEARn0 (n = 0, 1)

This register stores the offset of the error address where a 1-bit ECC error was detected. It holds the offset of the address where the first error occurred. It is cleared by clearing the 1-bit ECC error status flag by the SRAMESCLR.CLRn0 bit.

For SRAMEARn1 (n = 0, 1)

This register stores the offset of the error address where a 2-bit ECC error was detected. It holds the offset of the address where the first error occurred. It is cleared by clearing the 2-bit ECC error status flag by the SRAMESCLR.CLRn1 bit.

64.3 Operation

64.3.1 ECC Function

Enabling and disabling of ECC error correction can be selected through the SRAMCRn.ECCMOD[1:0] bits setting. In the initial state, ECC error correction is disabled. The ECC used in this device is SEC-DED (Single-Error Correction and Double-Error Detection Code).
When ECCs are enabled, an 8-bit ECC code is appended to 64-bit data for writing. For reading, 72-bit (data: 64 bits, ECC code: 8 bits) data is read out from the SRAM.

ECC Function with Error Checking Enable

When a 1-bit error occurs, error correction is performed, and when the SRAMCRn.E1STSEN bit is 1, the SRAMESR.ERRn0 flag is set to 1. When a 2-bit error occurs, error detection is performed, and the SRAMESR.ERRn1 flag is set to 1, but error correction is not performed.

ECC Function without Error Checking Enable

When a 1-bit error occurs, error correction is performed, but the SRAMESR.ERRn0 flag is not updated even if the SRAMCRn.E1STSEN bit is 1. When a 2-bit error occurs, error detection is performed, but the SRAMESR.ERRn1 flag is not updated, and error correction is not performed.

ECC Function Disabled

Even if a 1-bit or 2-bit error occurs, error correction and error detection are not performed. Therefore, the SRAMESR.ERRn0 and SRAMESR.ERRn1 flags are not updated.

When updating data after an error occurs, only 64-bit data writes are supported. Since the SRAM data is undefined after power-on or after waking up from deep software standby mode, an ECC error will occur when accessing the SRAM if ECC enabled and error check is selected. Therefore, before using the ECC function, enable ECC and perform an initial write with 64-bit data size, or enable ECC and perform an initial write without error check, for the area to be used in the SRAM.

64.3.2 ECC Error Interrupt Function

When ECC function with error checking is enabled, error checking is possible in the SRAMn. In the case of a 2-bit error, the ERRn1 flag in the SRAMESR register set to 1. In the case of a 1-bit error, the ERRn0 flag in the SRAMESR register set to 1 when SRAMCRn.E1STSEN bit is 1.
When the ECC 1-bit error is to be masked, it is necessary to set the SRAMCRn.E1STSEN bit to 0 to disable updating to 1 of the SRAMESR.ERRn0 flag. An ECC error will not be generated while ECC function is disabled or ECC function without error checking is enabled.
ECC error may result in interrupt or reset. When an ECC error occurs, a reset request is output if the SRAMCRn.OAD bit is 1. If the OAD bit is 0, an interrupt request is output to the ICU.
ECC Error interrupt occurs when one flag in the SRAMESR register is set. ECC Error interrupt continues to occur until the SRAMESR register flag is cleared.

64.3.3 ECC Decoder Testing

This MCU allows users to test the ECC decoder.
To test your ECC decoder, follow the steps below.

1. Wait for the previous access to complete.
2. Write A501h to the SRAMPRCR_S or SRAMPRCR_NS register and enable writing to SRAM-related registers.
3. Write 08h to the SRAMCRn register and set ECC function without error checking enabled, and ECC bypass disabled.
4. Wait for 08h to be written in the SRAMCRn register.
5. Writes 8 bytes of data to the target address. The 8-bit ECC code is updated automatically.
6. Wait for the previous access to complete.
7. Write 80h to the SRAMCRn register, set ECC disabled and ECC bypass enabled.
8. Wait for 80h to be written in the SRAMCRn register.
9. Read the target address and get the 8-bit ECC code.
10. To generate a 1-bit/2-bit ECC error, invert the 1-bit/2 bit of the data read in step 9 and write the data back to the target address.
11. Wait for the previous access to complete.
12. Write 1Ch to the SRAMCRn register and set the ECC function with error checking enabled, ECC 1-bit error information update enabled, and ECC bypass disabled.
13. Wait for 1Ch to be written in the SRAMCRn register.
14. Read the target address.
15. Wait for the previous access to complete.
16. Confirm the generation of the ECC error by the SRAMESR register.

64.3.4 Interrupt Source

The only SRAM interrupt source is an ECC error. The SRAMCRn.OAD bit can be used to set whether an ECC error causes a reset or an interrupt request. An SRAM interrupt request is generated when any error status flag in the SRAMESR register is set to 1, and remains active until the corresponding error status flag is cleared. If a common memory error occurs (NMISR.CMST = 1 or RSTSR1.CMRF = 1), read the SRAMESR register and check the cause of the SRAM interrupt. Table 64.2 lists the SRAM interrupt source.

Table 64.2 SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
ECCERR	ECC error (SRAMn with ECC)	Not possible	Not possible

64.3.5 Wait State

When the ICLK frequency is greater than 150 MHz, set the SRAMWTSC.WTEN bit to 1, as the wait cycle must be inserted into SRAM0 and SRAM1. When the wait cycles are not inserted, operation is not guaranteed.
The relationship between SRAM access weight setting and ICLK frequency is as follows:
[ICLK frequency]

- 300 MHz ≥ ICLK > 150 MHz : 1 wait
- 150 MHz ≥ ICLK : No wait

64.3.6 Access Cycle

The following shows the delay information of the access cycle.

- When the ECC function is enabled, writing through access that is not aligned or writing through access that is aligned but with a unit of less than 64 bits is delayed by two cycles relative to normal writing.
- Wait cycles are inserted according to the setting of the SRAMWTSC.WTEN bit. If the SRAMWTSC.WTEN bit is 1, reads are delayed by one cycle.

64.4 Usage Notes

64.4.1 Low Power Consumption Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to the SRAM.
When the MSTPCRA.MSTPA0 bit is set to 1, the clock supplied to SRAM0 will be stopped, and when the MSTPCRA.MSTPA1 bit is set to 1, the clock supplied to SRAM1 will be stopped. When the clock supply stops, the SRAM enters the module-stop state.
After reset, SRAM is in operation.
In the module stop state, SRAM cannot be accessed. Do not enter the module stop state while accessing SRAM. In the module stop state, access to the SRAM is prohibited. If accessed, operation cannot be guaranteed.
For details on the MSTPCRA register, refer to section 11, Low Power Consumption.

64.4.2 Instruction Fetch from SRAM Area

When executing programs using SRAM, initialize the SRAM area so that the CPU can properly prefetch data. ECC error might occur if the CPU prefetches from an area that is not initialized.
The SRAM must be initialized at an 8-byte boundary. When enabling the ECC function and executing a program on SRAM, initialize the SRAM taking into consideration that the CPU will perform instruction prefetching. Since instruction prefetching is performed up to 32 bytes, initialize an extra 24 to 31 bytes from the last address of the program.

64.4.3 Notes when using the SRAM error check function

Data in SRAM are undefined when the power is turned on. Therefore, an ECC error occurs if the data are read before initialization.
SRAM is read in 8-byte (64-bit) units. Initialize at an 8-byte boundary.

65. MRAM

This MCU incorporates a code MRAM, data MRAM, option-setting memory, and user extra MRAM. Instructions and operands can be stored in the code MRAM. Data can only be stored in the data MRAM. For option-setting memory, see section 7, Option-Setting Memory (OFSM). The user program and data can be stored in the user extra MRAM as required by the user's application. In this section, the data MRAM, option-setting memory, and user extra MRAM are collectively referred to as extra MRAM.

65.1 Overview

Table 65.1 lists the specification of MRAM, and Figure 65.1 shows a block diagram of the MRAM related modules. The programming sequencer controls programming of the code MRAM and extra MRAM. Two program sequencers are available: CPSEQ for the code MRAM and EPSEQ for the extra MRAM. The MRAM application command interface (MACI) controls EPSEQ for option-setting memory and user extra MRAM according to the specified MACI commands.

Table 65.1 Specifications of MRAM (1/2)

Item	Code MRAM	Extra MRAM		
		Data MRAM	Option-Setting Memory	User Extra MRAM
Memory capacity	User area: 1 Mbyte max	Data area: 48 Kbytes	See section 7, Option-Setting Memory (OFSM)	User area: 128 Kbytes GPOTP: 96 bytes
Switch to operate as OTP	Not possible	Not possible	See section 7, Option-Setting Memory (OFSM)	Possible
Read cycle	See section 65.5.2, Code MRAM Frequency Notifications Register (MRCFREQ)	See section 65.5.3, Extra MRAM Frequency Notifications Register (MREFREQ)		
Programming method	Write page buffer (32 bytes)	Write page buffer (16 bytes)	MACI command	
Protection	Protects against erroneous rewriting of the MRAM			
Dual bank function	The dual-bank structure makes a safe update possible in cases where programming is suspended. • Linear mode: The code MRAM is used as one area. • Dual mode: The code MRAM is divided into two areas (MRC0 area = bank 0 and MRC1 area = bank 1).	Not available		
Block swap function	Block swap block size: 8 Kbytes Block swapping allows safe updates to code in operations by exchanging working sectors	Not available		
Background operations (BGOs)	• The code MRAM can be read while the extra MRAM is being programmed. • The extra MRAM can be read while the code MRAM is being programmed. • A bank of the code MRAM can be read while another bank of the code MRAM is being programmed.			
Units of programming	1 to 32 bytes	1 to16 bytes	16 bytes	
MACI command	Not available	Not available	Program: 16 bytes Forced stop Status clear Configuration set: 16 bytes Increment counter: 1 bit Read counter: 8 bytes	

Table 65.1 Specifications of MRAM (2/2)

Item	Code MRAM	Extra MRAM		
		Data MRAM	Option-Setting Memory	User Extra MRAM
Security function	• Protect against illicit tampering with or reading out of data in MRAM • OFS area protection • Startup area select setting protection - BTFLG and MSUACR register are protected by the FSPR bit. - BTSIZE is protected by the FSPRS bit. • Permanent block protect setting protection - User area is permanently protected from programming operation by permanent block protect function. • MRAM protection for Protect Zone - Protection for MRAM area (program) - Protection for MRAM area (read) - Protection for register • Extra MRAM program mode entry protection • Anti-rollback counter • HUK protection			
Safety function	Software protection • MACI command protection by MENTRYR register • User area protection by MRCPCS and MRCPCNS registers • User area and data area protection by the block protect setting Error protection • Error is detected when unintended commands or prohibited settings occur. The MACI command is not accepted after an error detection. Startup area protection • The startup area select function allows the user to safely update the startup program, which is to be started after a reset. The size of the startup area can be selected from 8 Kbytes, 16 Kbytes or 32 Kbytes. ECC support for double-bit error correction and triple-bit error detection.			
Interrupt request	• MRCRDI (code MRAM ECC error) Enabled by the INTENBTC and INTENBDC bits • MRERDI (Extra MRAM ECC error) Enabled by the INTENBTE and INTENBDE bits • MRCPRI (code MRAM access error) Enabled by the MRCAEIE bit • MRDPRI (data MRAM access error) Enabled by the MRDAEIE bit • MREPRI (Extra MRAM access error) Enabled by the CMDLKIEE and MREAEIE bits • MRDYI (Extra MRAM ready) Enabled by the MRDYIE bit • MRPRRI (MRAM program ready) Enabled by the MRCPRRIE or MRDPRRIE bit			
Address translation	• The startup area select function is supported in linear mode. • The bank swap function is supported in dual mode. • The block swap function is supported in linear mode.			

Note 1. Once switched to operate as OTP (One Time Programmable), the specified area of the MRAM cannot be rewritten.

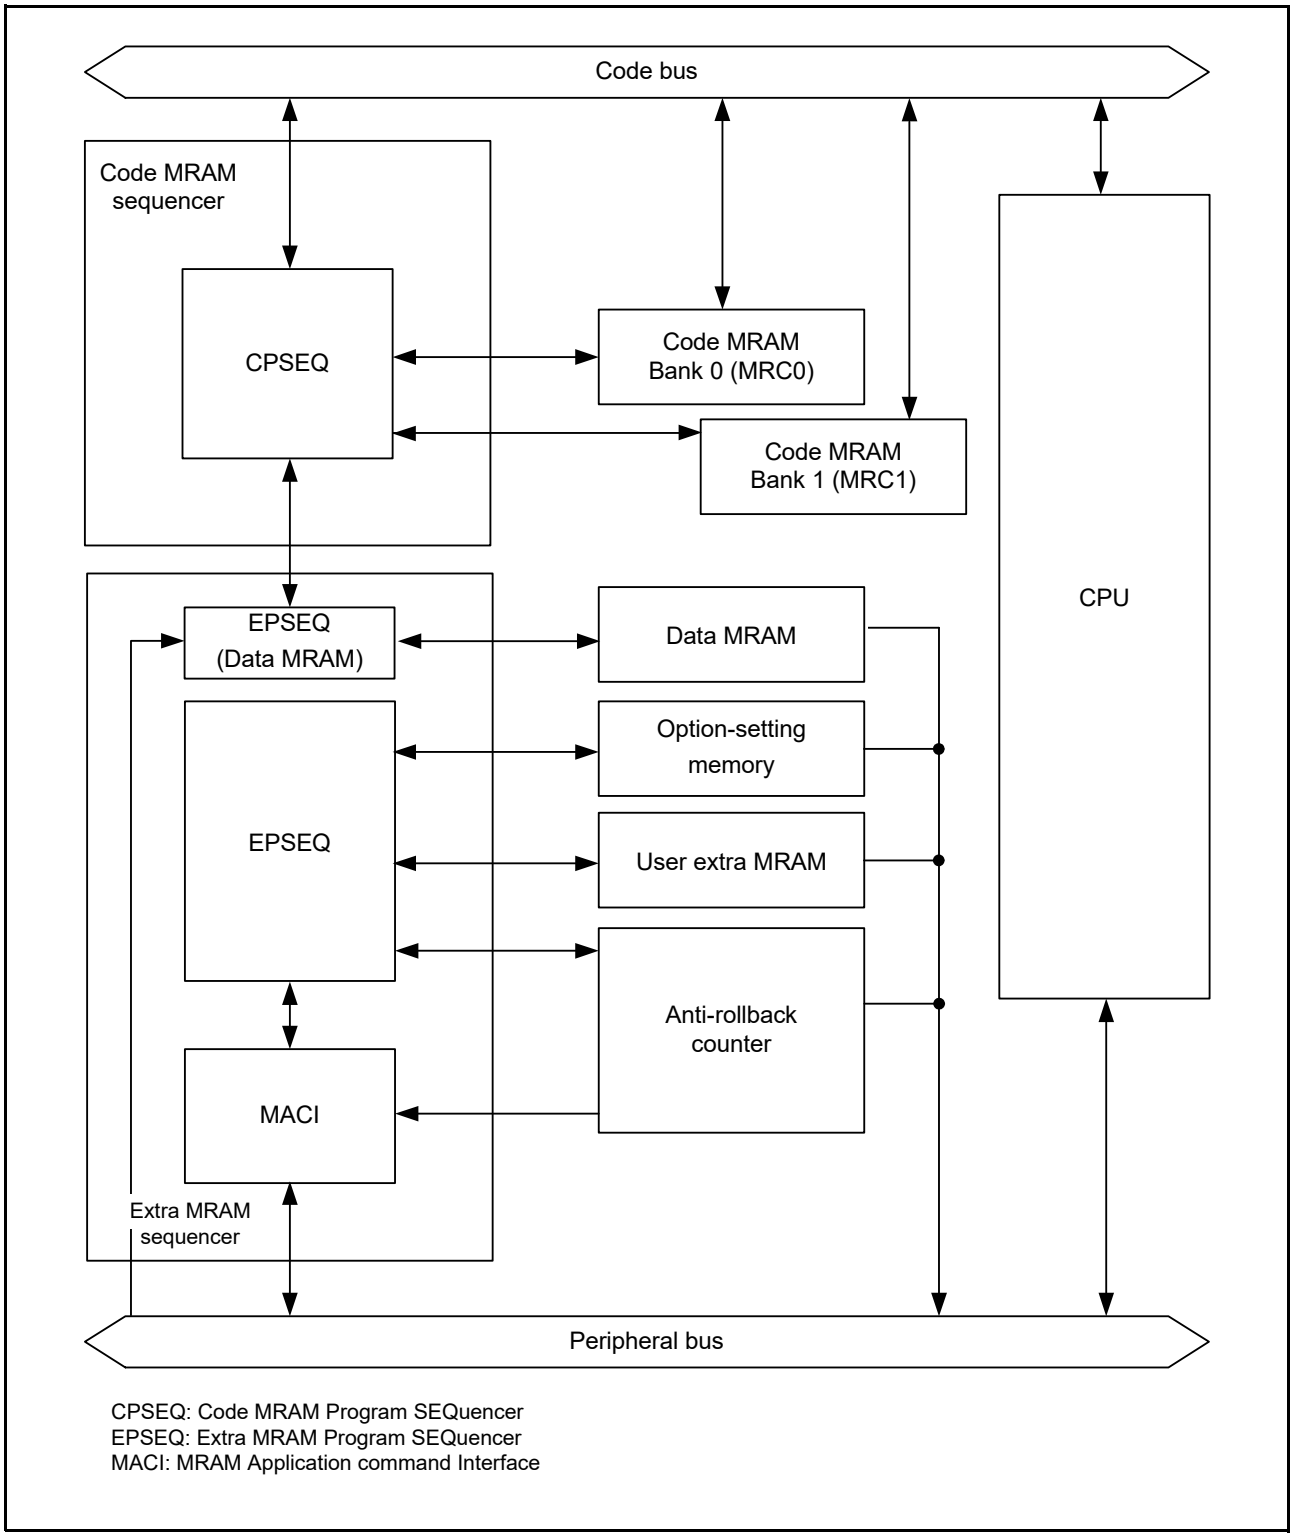

Figure 65.1 Block Diagram of MRAM Related Modules

65.2 Structure of Memory

Figure 65.2 shows the memory map of code MRAM in linear mode. Figure 65.3 shows the memory map of code MRAM in dual mode. The code MRAM can be used as 2 bank areas by using the dual bank function. This dual-bank structure allows a safe update of a program while a user program is running.

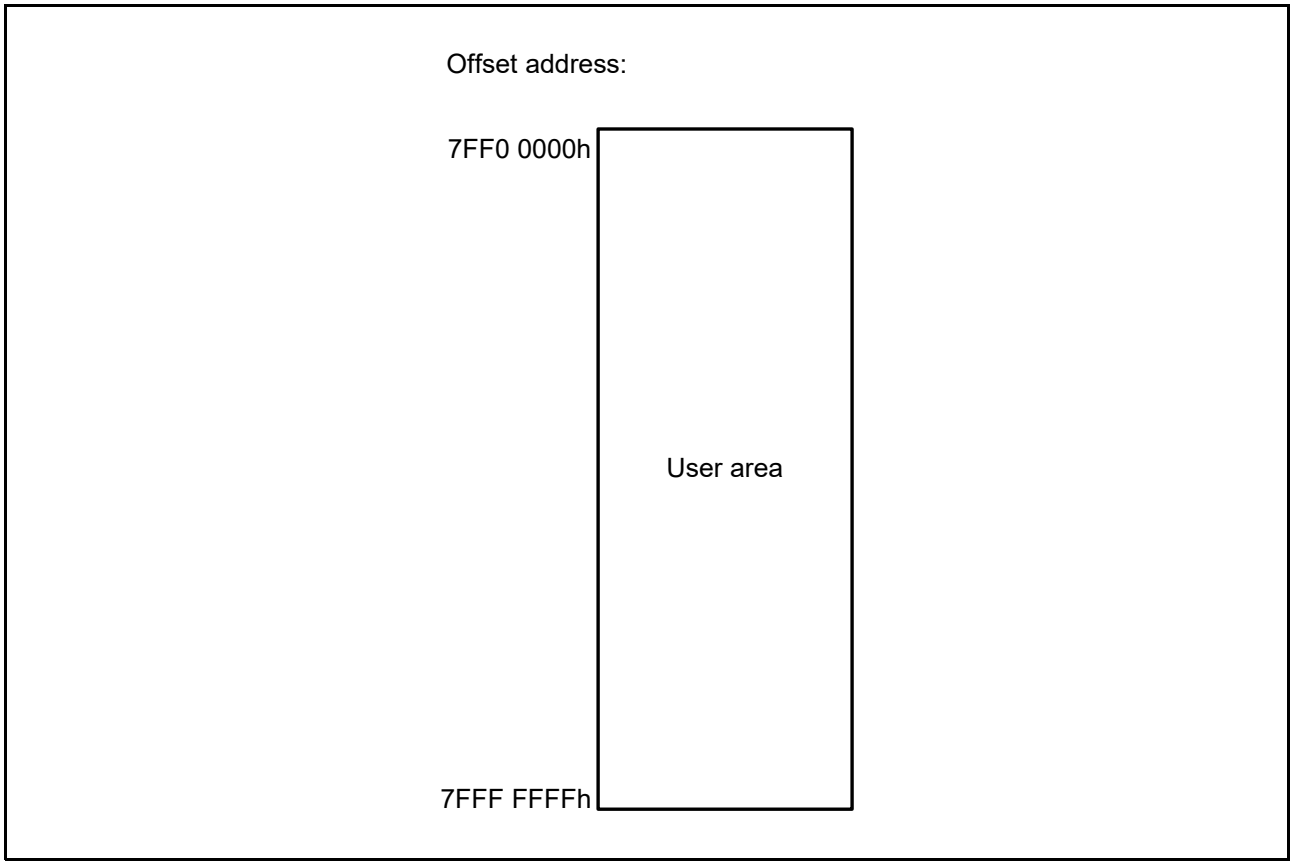

Figure 65.2 Memory Map of the Code MRAM in Linear Mode

Table 65.2 Read and Programming Address by Product for the Code MRAM (Linear Mode)

Code MRAM Memory Capacity	Address
1 Mbyte product	Secure area: FFF0 0000h to FFFF FFFFh MCR1: FFF0 0000h to FFF7 FFFFh MCR0: FFF8 0000h to FFFF FFFFh Non-secure area: 7FF0 0000h to 7FFF FFFFh MCR1: 7FF0 0000h to 7FF7 FFFFh MCR0: 7FF8 0000h to 7FFF FFFFh
512 Kbytes product	Secure area: FFF8 0000h to FFFF FFFFh MCR1: FFF8 0000h to FFFB FFFFh MCR0: FFFC 0000h to FFFF FFFFh Non-secure area: 7FF8 0000h to 7FFF FFFFh MCR1: 7FF8 0000h to 7FFB FFFFh MCR0: 7FFC 0000h to 7FFF FFFFh

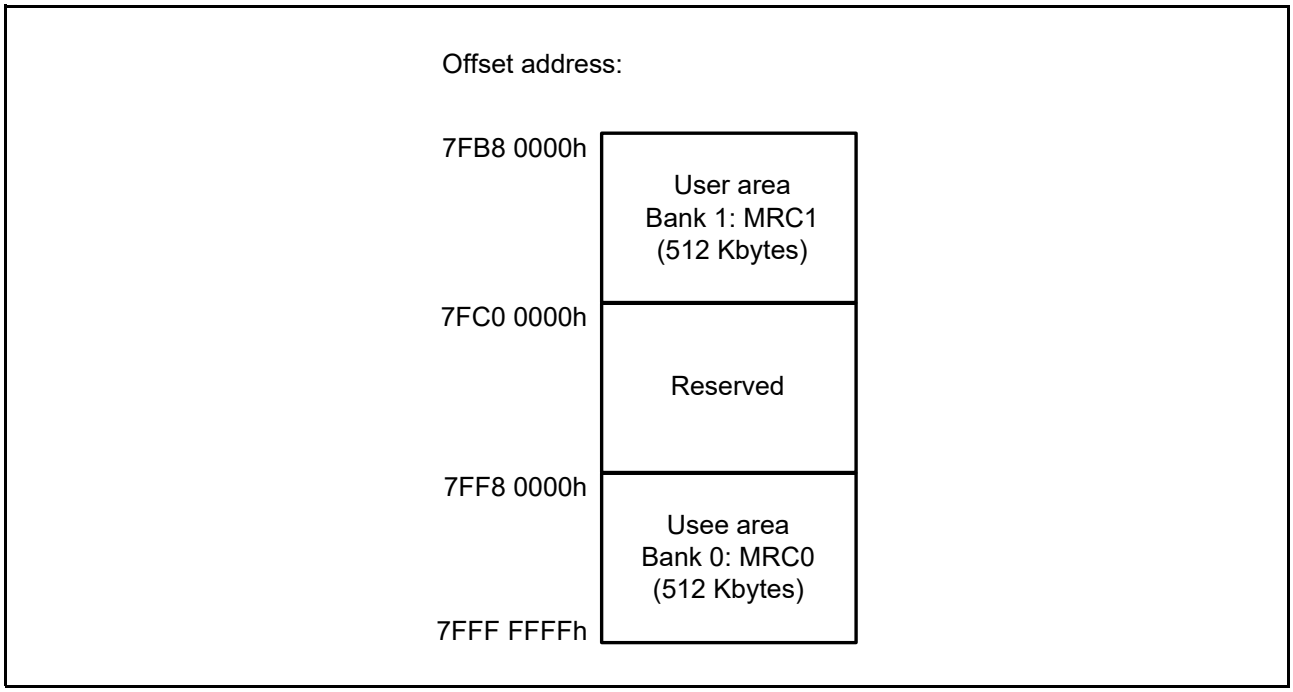

Figure 65.3 Memory Map of the Code MRAM in Dual Mode

Table 65.3 Read and Programming Address by Product for the Code MRAM (Dual Mode (BANKSEL.BANKSWP[2:0] = 111b))

Code MRAM Memory Capacity	Address
Products with 1 Mbyte of MRAM, Bank 1	Secure area (MRC1): FFB8 0000h to FFBF FFFFh Non-secure area (MRC1): 7FB8 0000h to 7FBF FFFFh
Products with 1 Mbyte of MRAM, Bank 0	Secure area (MRC0): FFF8 0000h to FFFF FFFFh Non-secure area (MRC0): 7FF8 0000h to 7FFF FFFFh
Products with 512 Kbytes of MRAM, Bank 1	Secure area (MRC1): FFBC 0000h to FFBF FFFFh Non-secure area (MRC1): 7FBC 0000h to 7FBF FFFFh
Products with 512 Kbytes of MRAM, Bank 0	Secure area (MRC0): FFFC 0000h to FFFF FFFFh Non-secure area (MRC0): 7FFC 0000h to 7FFF FFFFh

Figure 65.4 shows the memory map of the data MRAM and user extra MRAM. The user extra MRAM can only be accessed as a secure area. The user extra MRAM is divided into a 128-Kbyte user area and a 96-byte general-purpose OTP area (GPOTP).

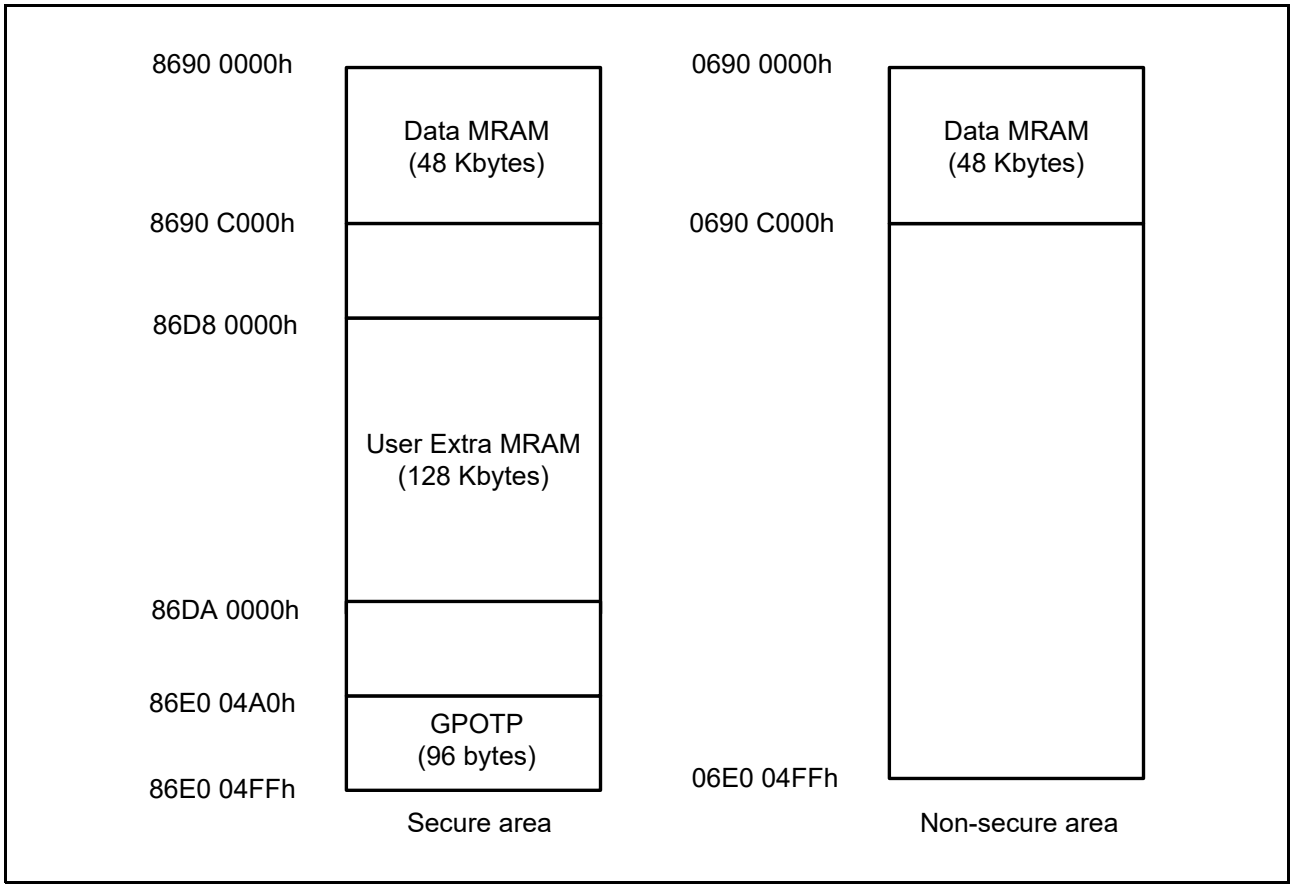

Figure 65.4 Memory Map of the Data MRAM and User Extra MRAM

65.3 Address Space

Using the hardware interface with MRAM requires access to all registers of the hardware. This is so that MACI commands can be issued. Table 65.4 to Table 65.6 list the base addresses.

Table 65.4 The Base Address of the Extra MRAM

Base Address Symbol	Address	Secure Alias
BASE_ME	8600 0000h or 0600 0000h	Secure or non-secure
BASE_MES	8600 0000h	Secure
BASE_MEN	0600 0000h	Non-secure

Table 65.5 The Base Address of the Code MRAM

Base Address Symbol	Address	Secure Alias
BASE_MC	FF00 0000h or 7F00 0000h	Secure or non-secure

Table 65.6 MACI Command Issuing Area

Area	Address	Capacity	Secure Alias
MACI command issuing area	8708 0000h	4 bytes	Secure
	0708 0000h		Non-secure

65.4 MRAM Read and Program Function

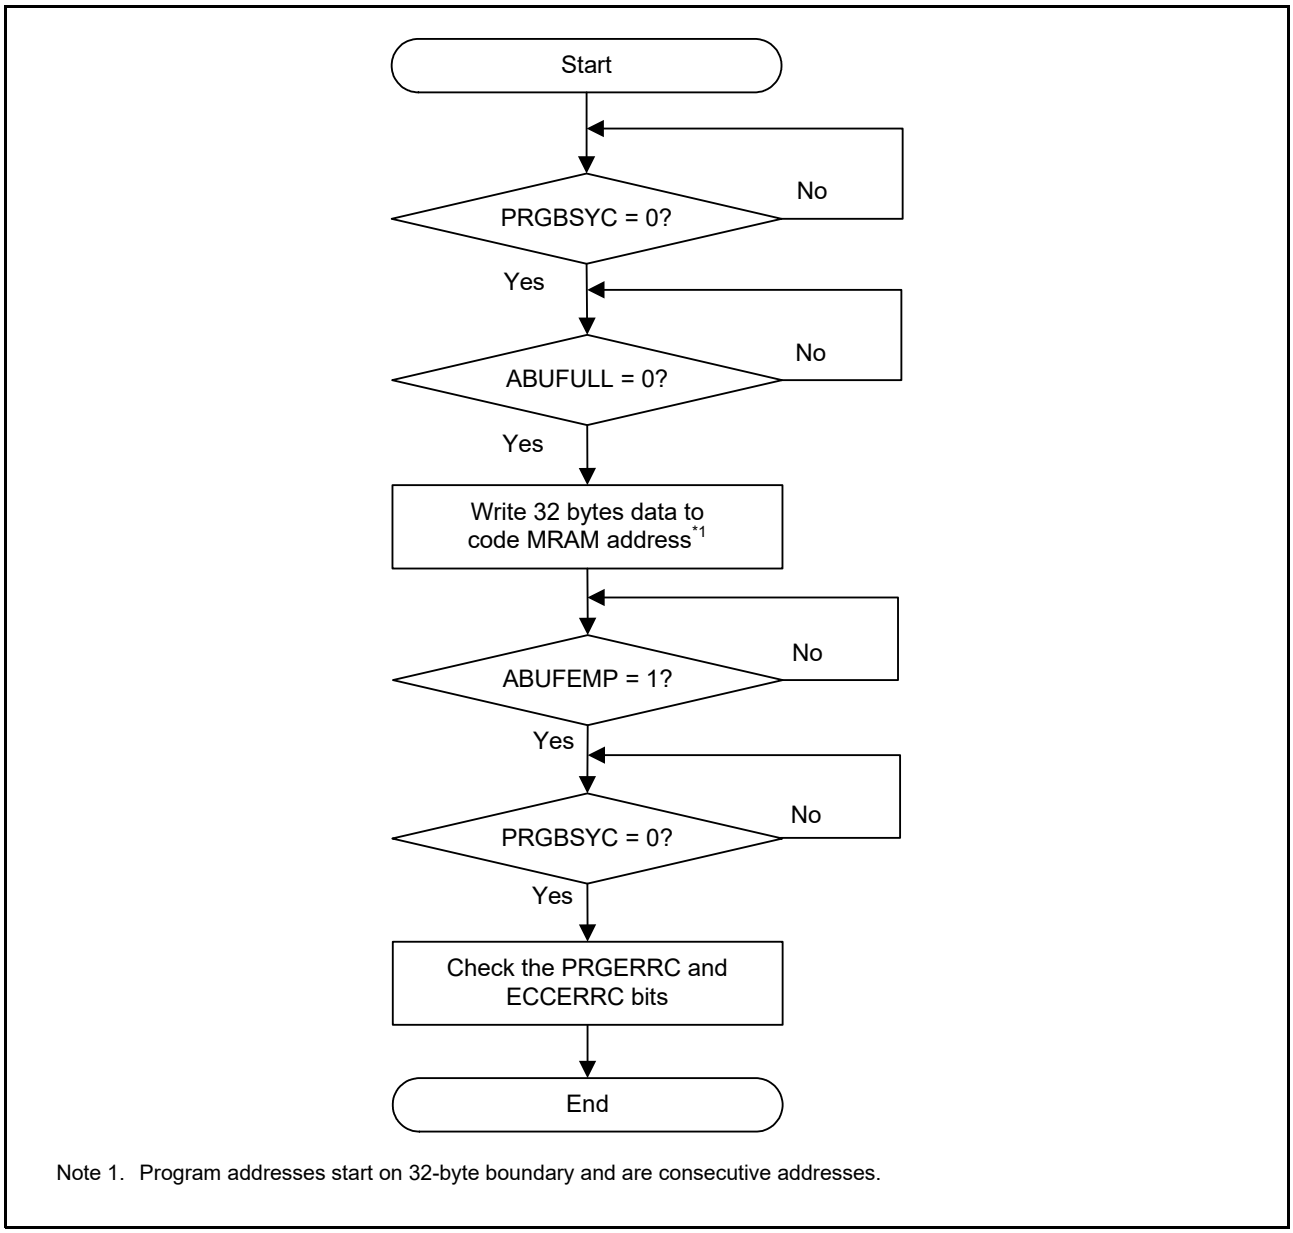
65.4.1 Prefetch Buffer

Prefetch buffer speeds up CPU instruction fetches from bus master to code MRAM.

Table 65.7 Prefetch Buffer Overview

Function	Implementation
Target Region	Linear mode: 7FF0 0000h to 7FFF FFFFh (1 Mbyte) FFF0 0000h to FFFF FFFFh (1 Mbyte) Dual mode: 7FB8 0000h to 7FBF FFFFh (512 Kbytes) 7FF8 0000h to 7FFF FFFFh (512 Kbytes) FFB8 0000h to FFBF FFFFh (512 Kbytes) FFF8 0000h to FFFF FFFFh (512 Kbytes)
Target Bus Master	CPU instruction fetch
Capacity	64 Bytes/CPU
Associativity	Full associative
	256 bits/entry (256 bits aligned data), 2 entries
Access Cycle	Hit: 0 wait Miss: See section 65.5.2, Code MRAM Frequency Notifications Register (MRCFREQ)

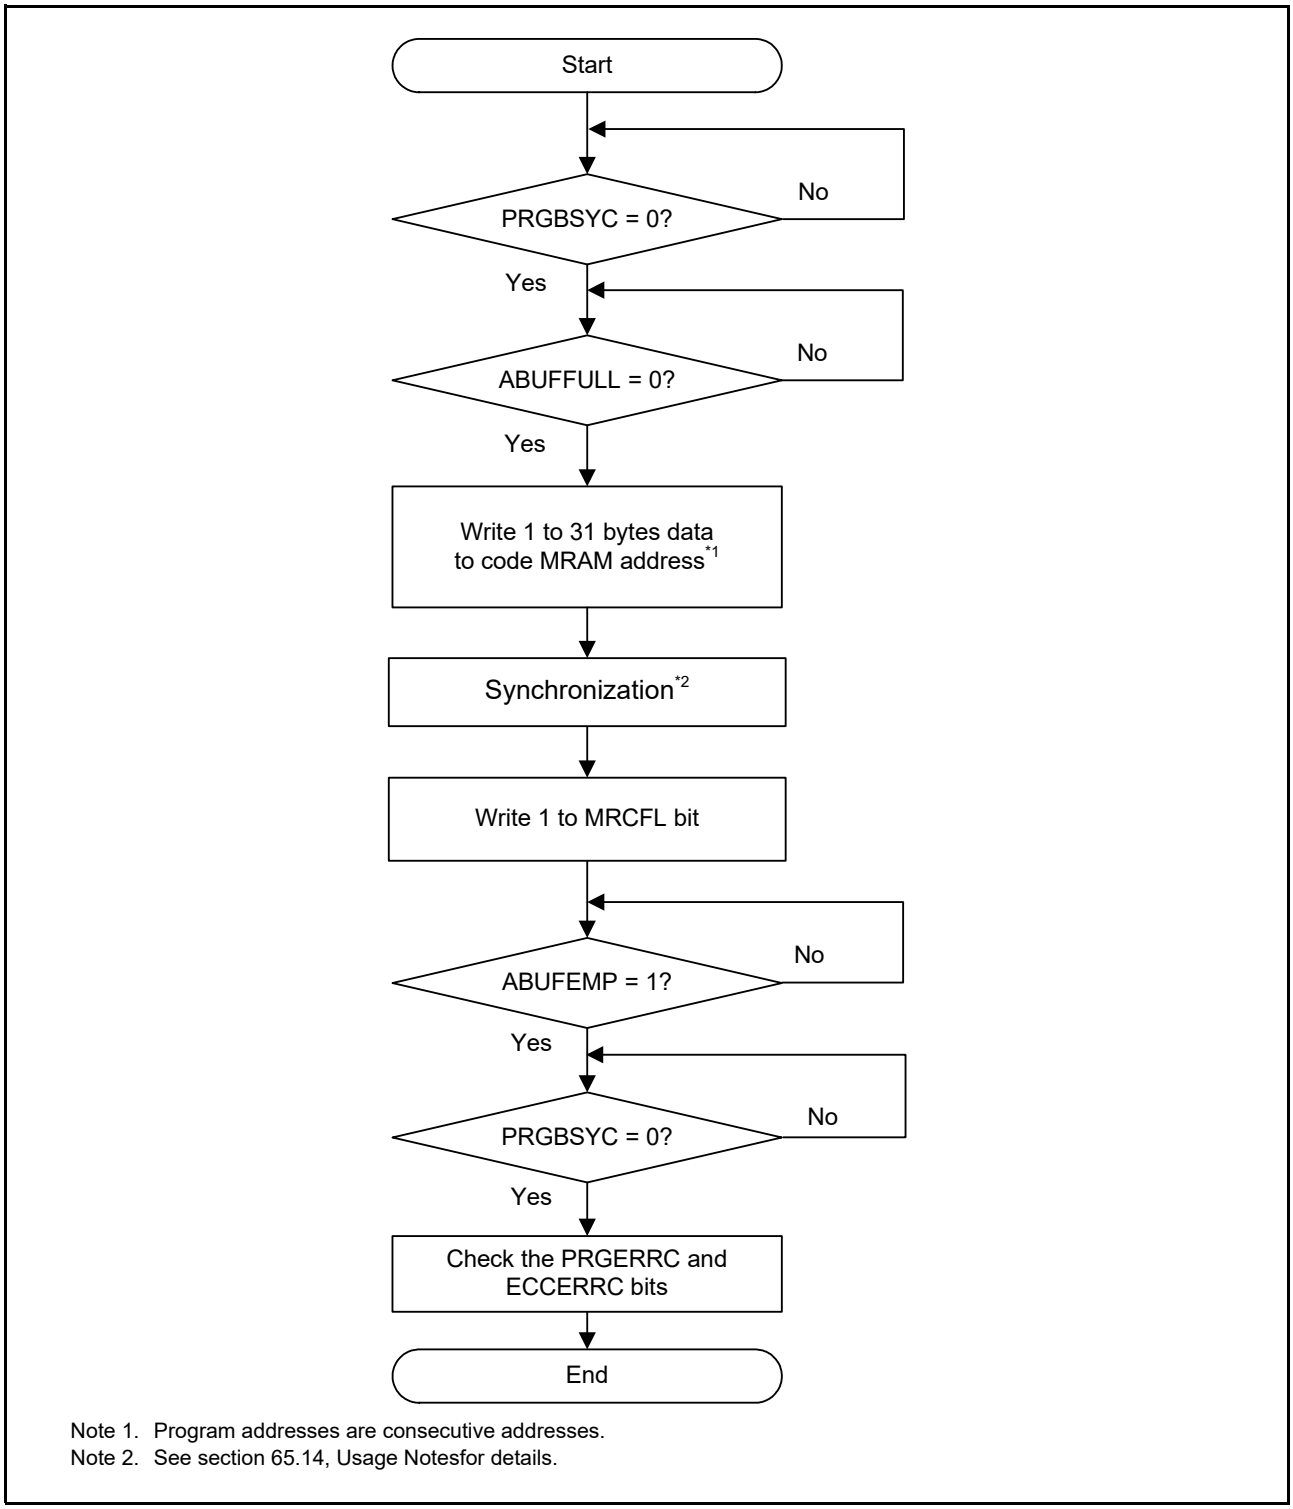
65.4.2 Code MRAM Programming Procedure



Program data for code MRAM is entered to program buffer by bus access and is written to code MRAM in 32 bytes units. It is recommended the following to avoid system bus stall while code MRAM program processing.

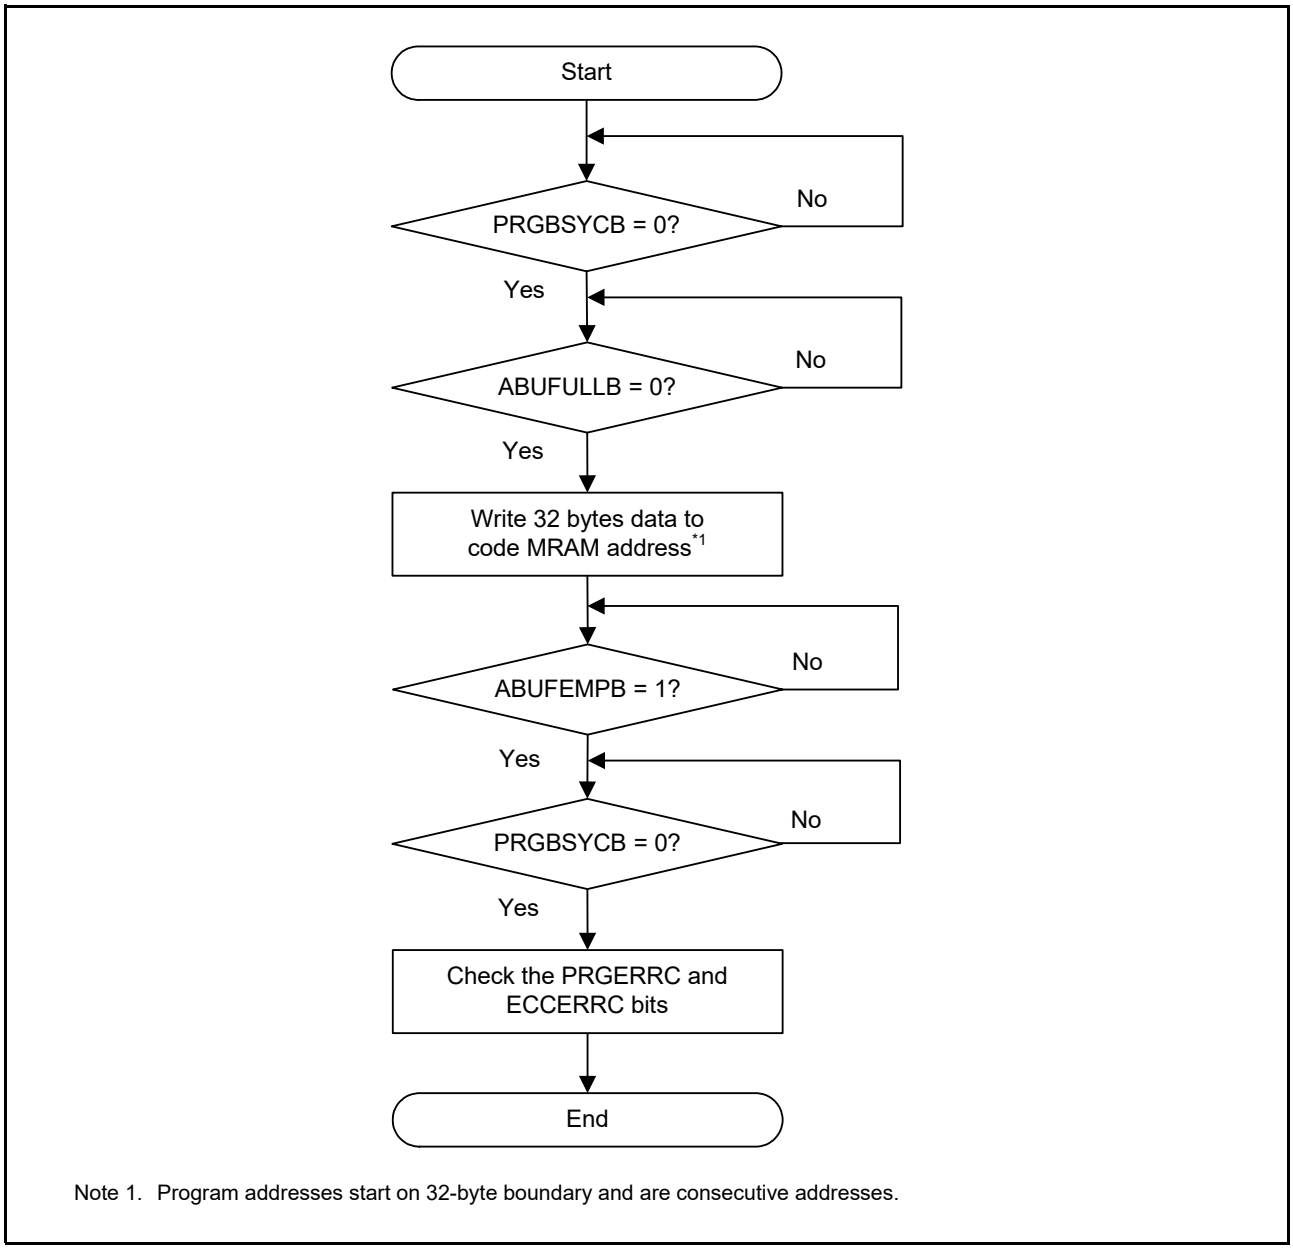
- Only one bus master can perform code MRAM write access
- Program data is 32 bytes or less in the same 32 bytes boundary.

The following describes the procedure for programming the MRC0 area. When programming the MRC1 area, replace the bit names in the description with those assigned to the MRC1 area. Figure 65.5 and Figure 65.6 show the procedure for programming the MRC0 area. Figure 65.7 and Figure 65.8 show the procedure for programming the MRC1 area. Before starting to program the MRC0 area, check the PRGBSYC and ABUFFULL flags in the MRCPS register to ensure that no other programming is in progress. The data to be written to the MRC0 area are stored in the 32-byte program data buffer and are written to the MRC0 area when any of the following conditions is satisfied.



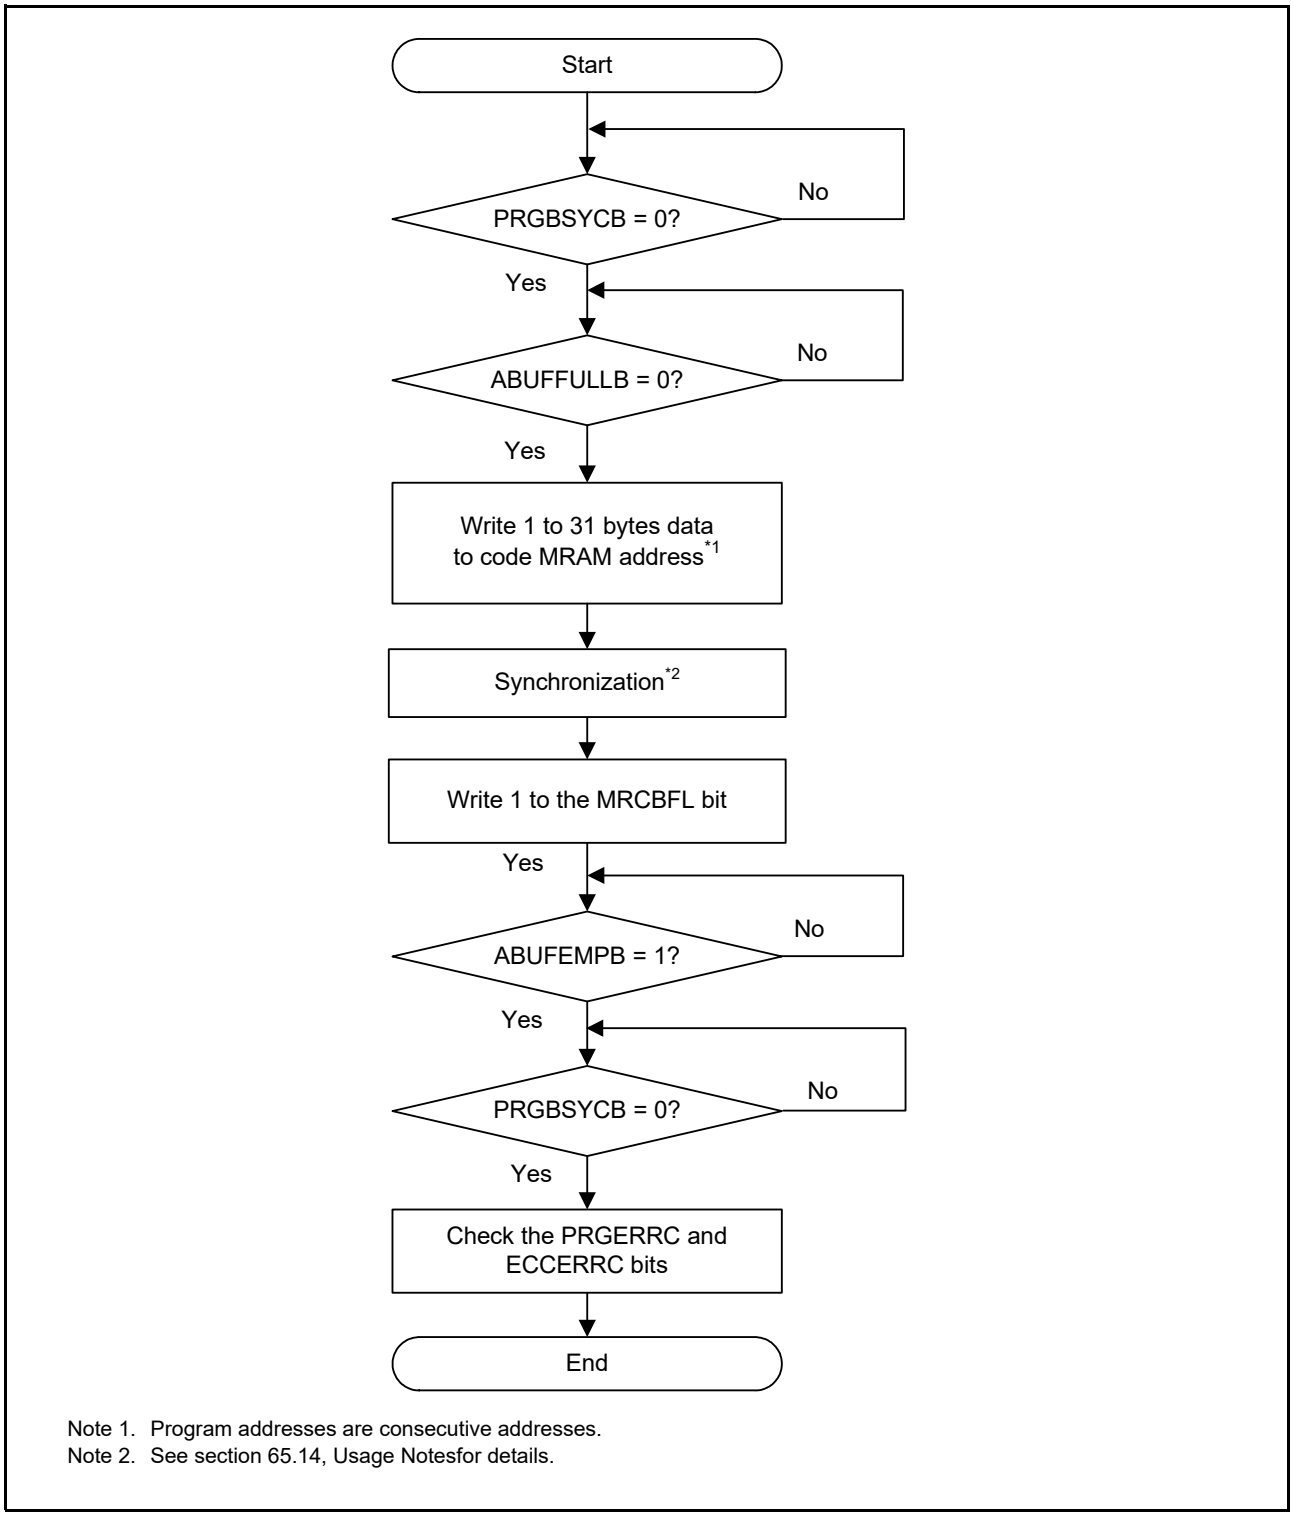
- Program data buffer is full (Figure 65.5)
- The address of the MRC0 area in the code MRAM to be written to is beyond the current 32-byte boundary.
- MRCFL bit in MRCFLR register is set to 1 (Figure 65.6)

Program processing error status can be confirmed by PRGERRC and ECCERRC bits in MRCPS register.



Note 1. Program addresses start on 32-byte boundary and are consecutive addresses.

Figure 65.5 Programming Procedure in MRC0 Area (32-Byte Programming)



Note 1. Program addresses are consecutive addresses.
Note 2. See section 65.14, Usage Notesfor details.

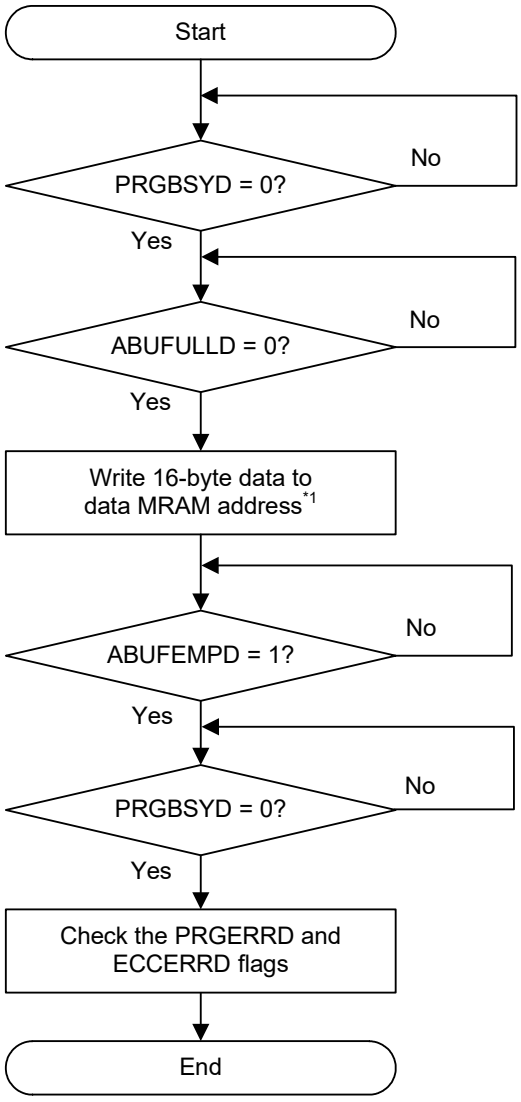
Figure 65.6 Programming Procedure in MRC0 Area (Smaller than 32-Byte Programming)

Note 1. Program addresses start on 32-byte boundary and are consecutive addresses.

Figure 65.7 Programming Procedure in MRC1 Area (32-Byte Programming)

Note 1. Program addresses are consecutive addresses.
Note 2. See section 65.14, Usage Notesfor details.

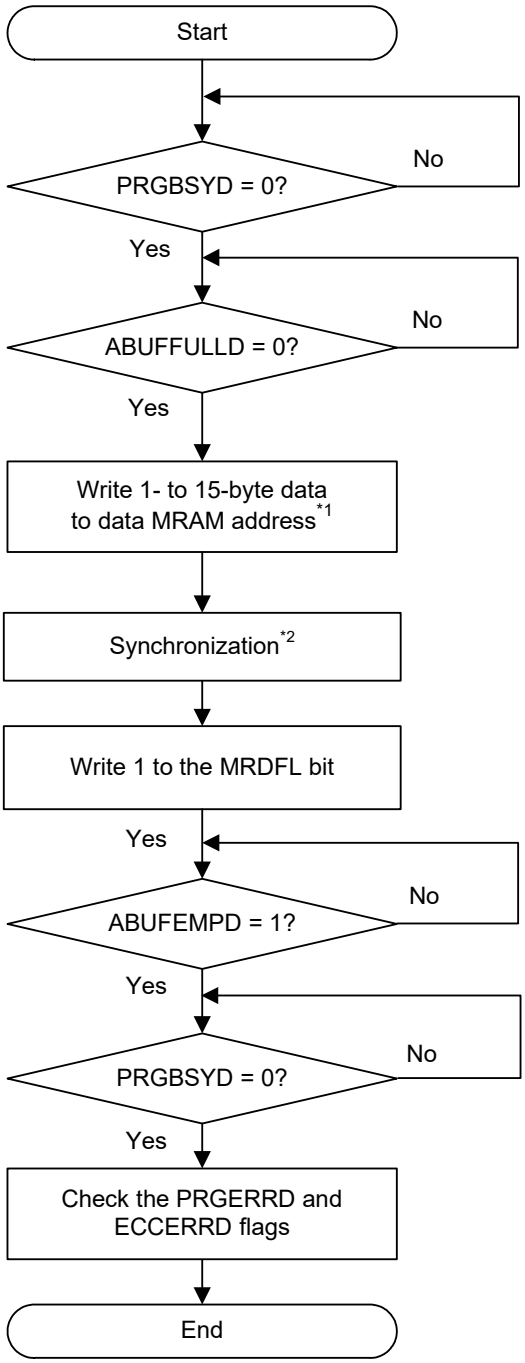
Figure 65.8 Programming Procedure in MRC1 Area (Smaller than 32-Byte Programming)



65.4.3 Data MRAM Programming Procedure

Program data for the data MRAM is input to the program buffer via bus access and written to the data MRAM in 16-byte units. The followings are recommended to avoid system bus stalls during the data MRAM programming operations:

- Only one bus master can perform write access to the data MRAM.
- Program data should be 16 bytes or less on the same 16-byte boundary.



The programming procedures of data MRAM are shown in Figure 65.9 and Figure 65.10. Before writing to data MRAM, confirm that other program processing is not performed by the PRGBSYD and ABUFFULLD flags in the MRDPS register. All program processing is performed by writing to the data MRAM and writing 1 to the MRDFL bit in the MRDFLR register. Completion of programming can be confirmed by checking the MRDFL bit in the MRDFLR register and the ABUFEMPD and PRGBSYD flags in the MRDPS register.

The program processing error status can be confirmed by the PRGERRD and ECCERRD flags in the MRDPS register.

Note 1. Program addresses start on 16-byte boundary and are consecutive addresses.

Figure 65.9 Programming Procedure in the Data MRAM (16-Byte Programming)

Note 1. Program addresses are consecutive addresses.
Note 2. See section 65.14, Usage Notes for details.

Figure 65.10 Programming Procedure in the Data MRAM (Smaller than16-Byte Programming)

65.4.4 MRAM Programming Procedure with MRAM Program Ready Interrupt

Figure 65.11, Figure 65.12, and Figure 65.13 show the procedure for programming the MRC or MRD using a DMA transfer start interrupt request. If the DMAC performs a write to MRAM during a code MRAM or data MRAM programming process, the system bus stalls until the code MRAM or data MRAM programming is complete.

Therefore, to perform efficient software operations (including the DMAC), it is recommended that you operate the DMAC according to the procedures in Figure 65.11, Figure 65.12, and Figure 65.13. However, these steps may still cause the system bus to stall when:

- Another bus master performs programming to the code MRAM or data MRAM regardless of the interrupt request
- Performing more than one DMA write transfer per interrupt request

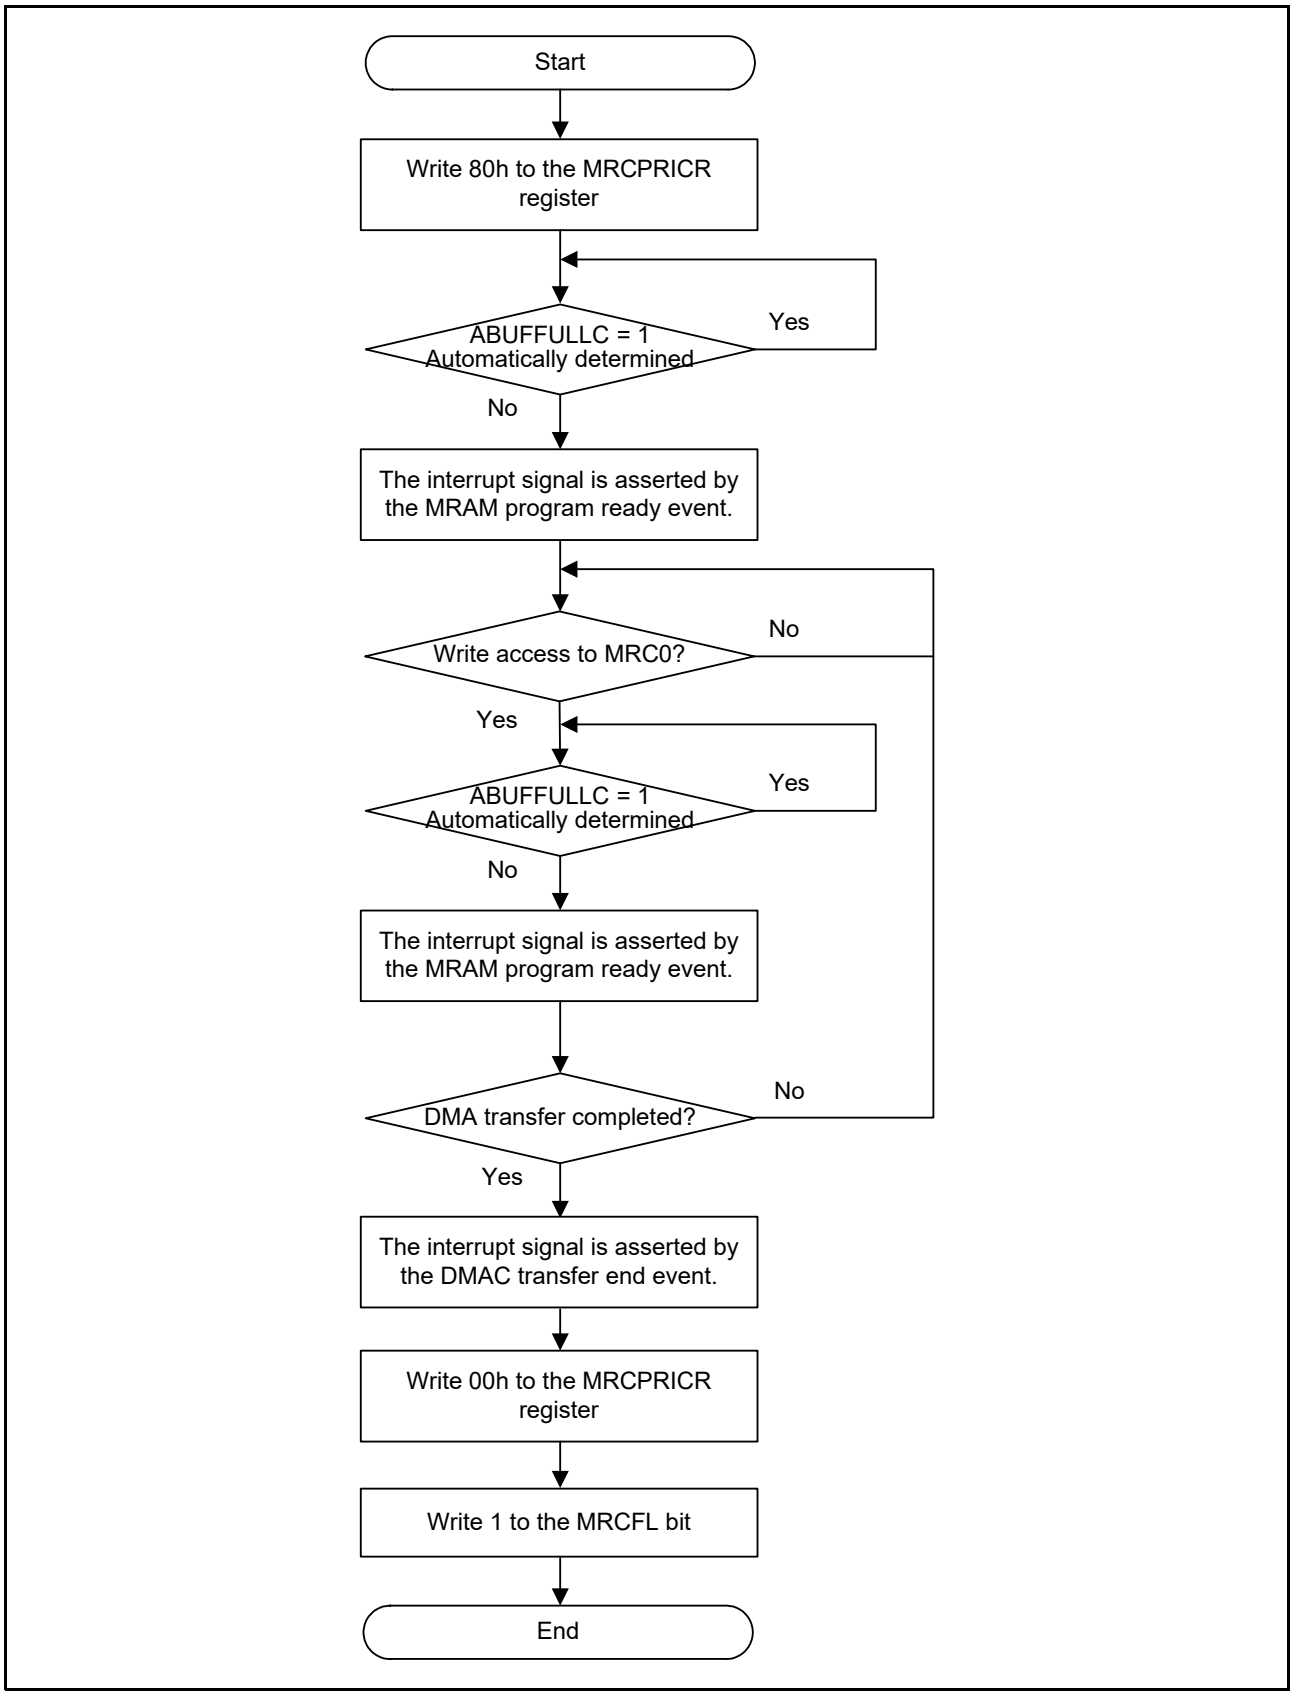


Figure 65.11 Code MRAM (MRC0) Programming Procedure with DMAC

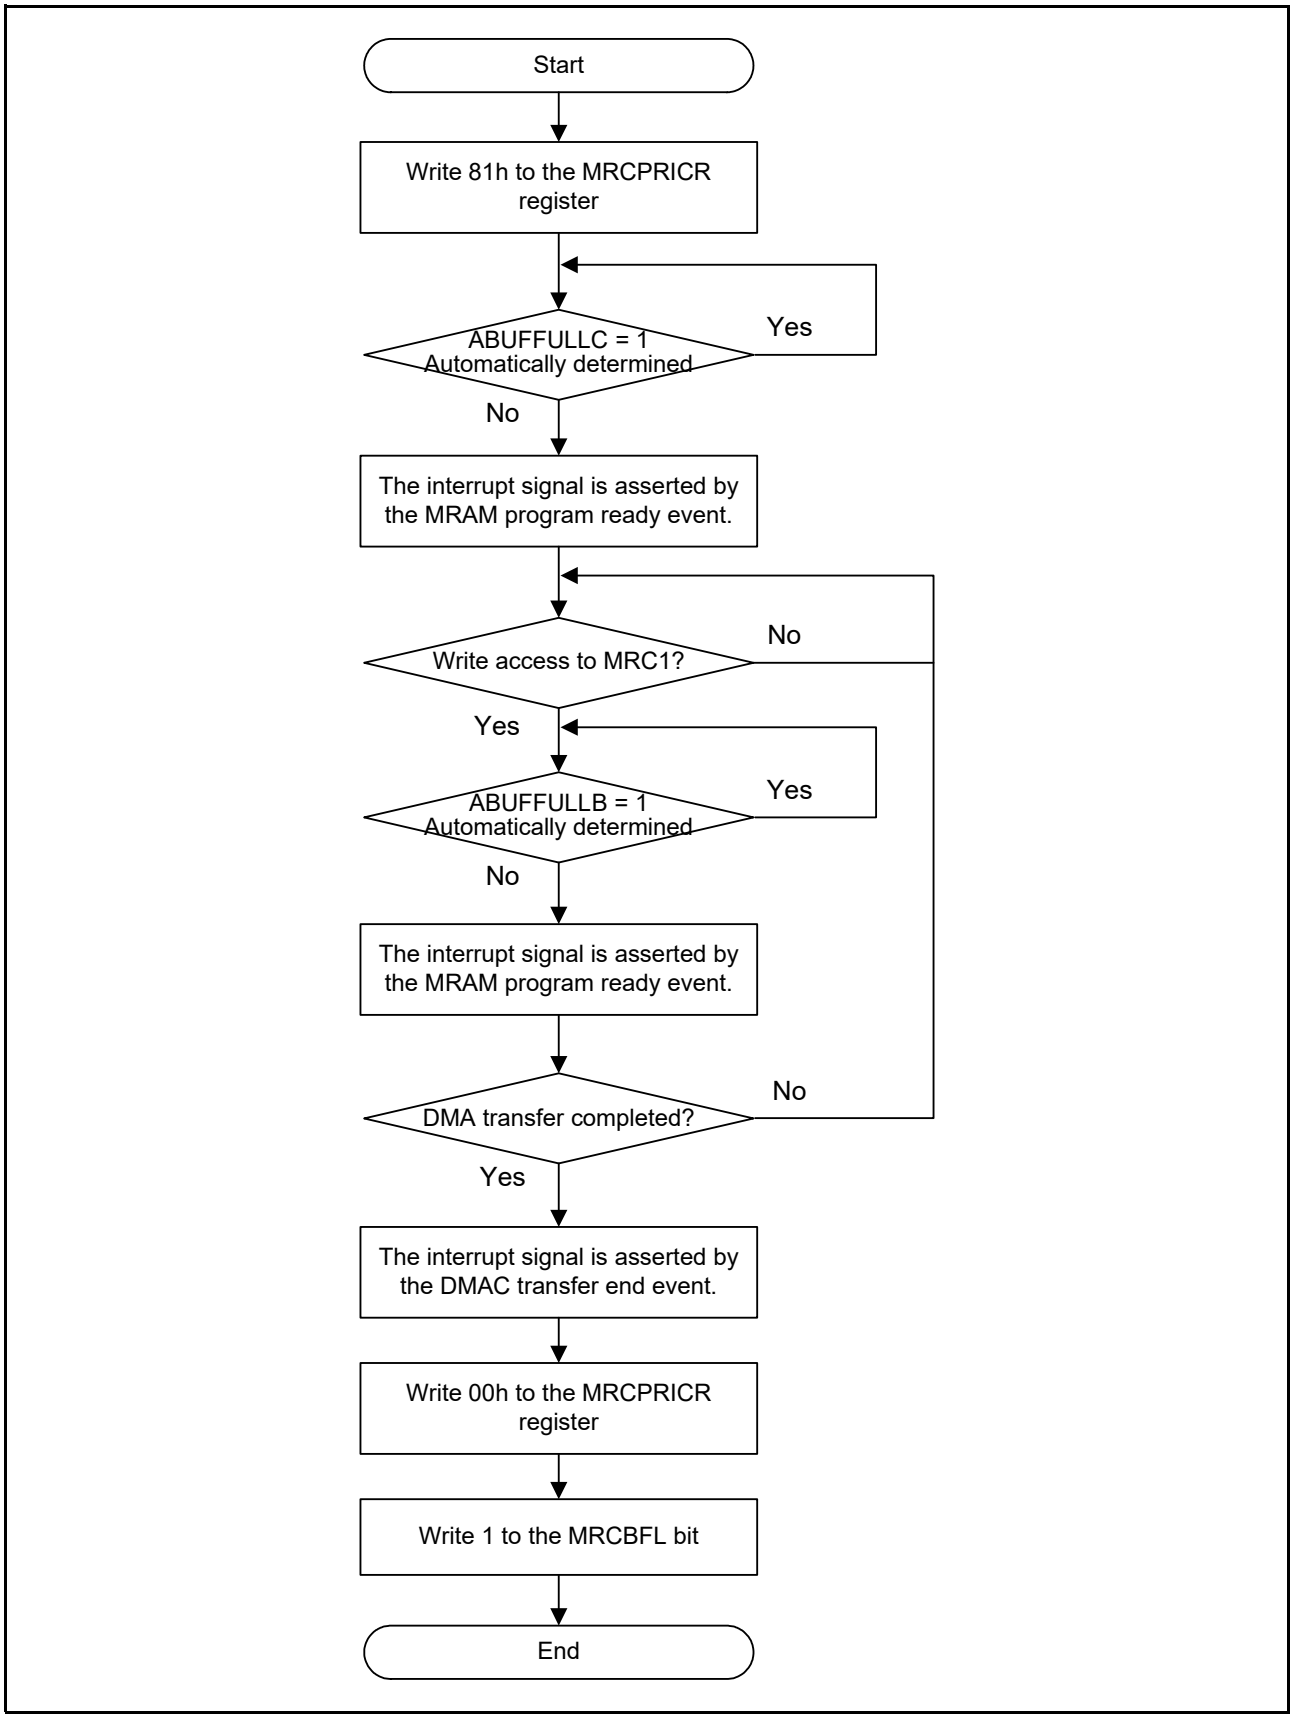

Figure 65.12 Code MRAM (MRC1) Programming Procedure with DMAC

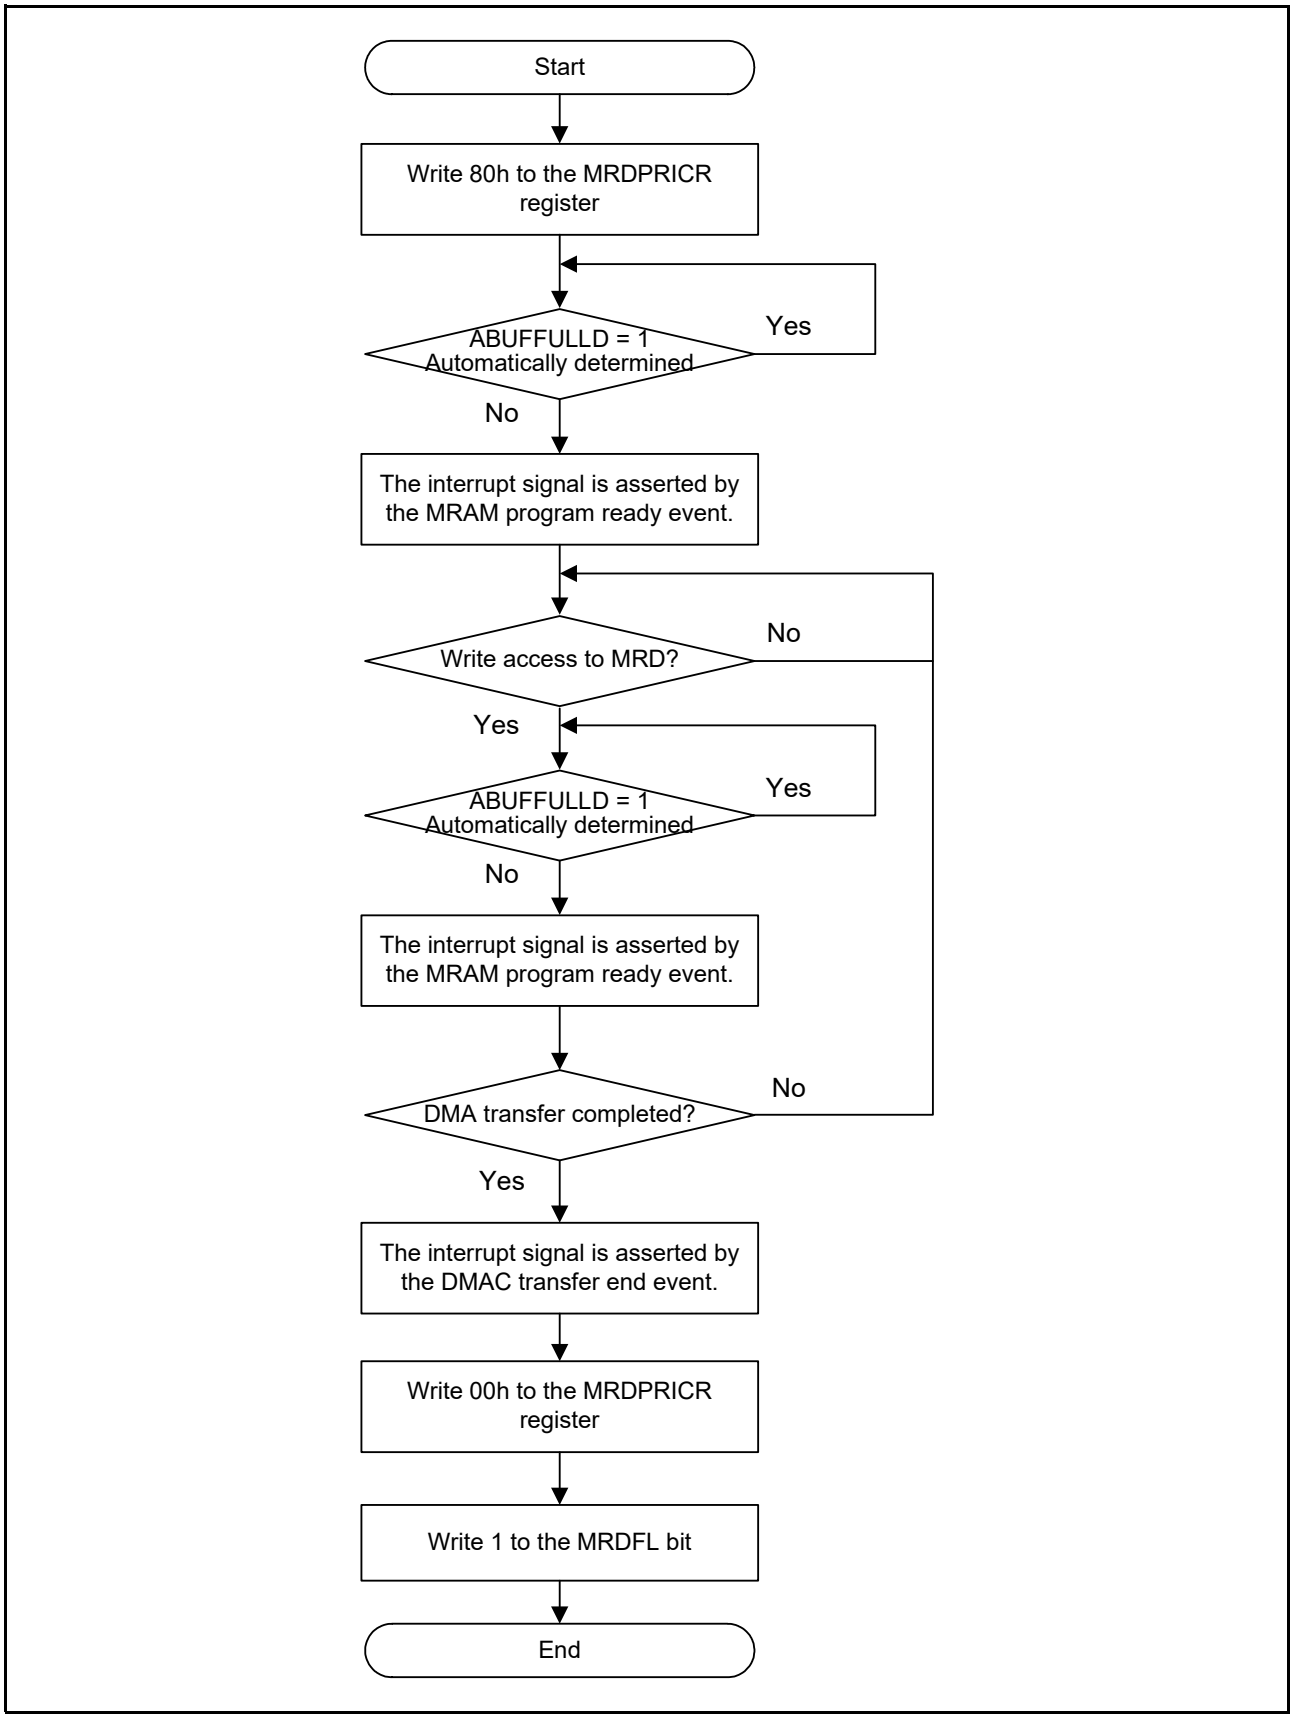

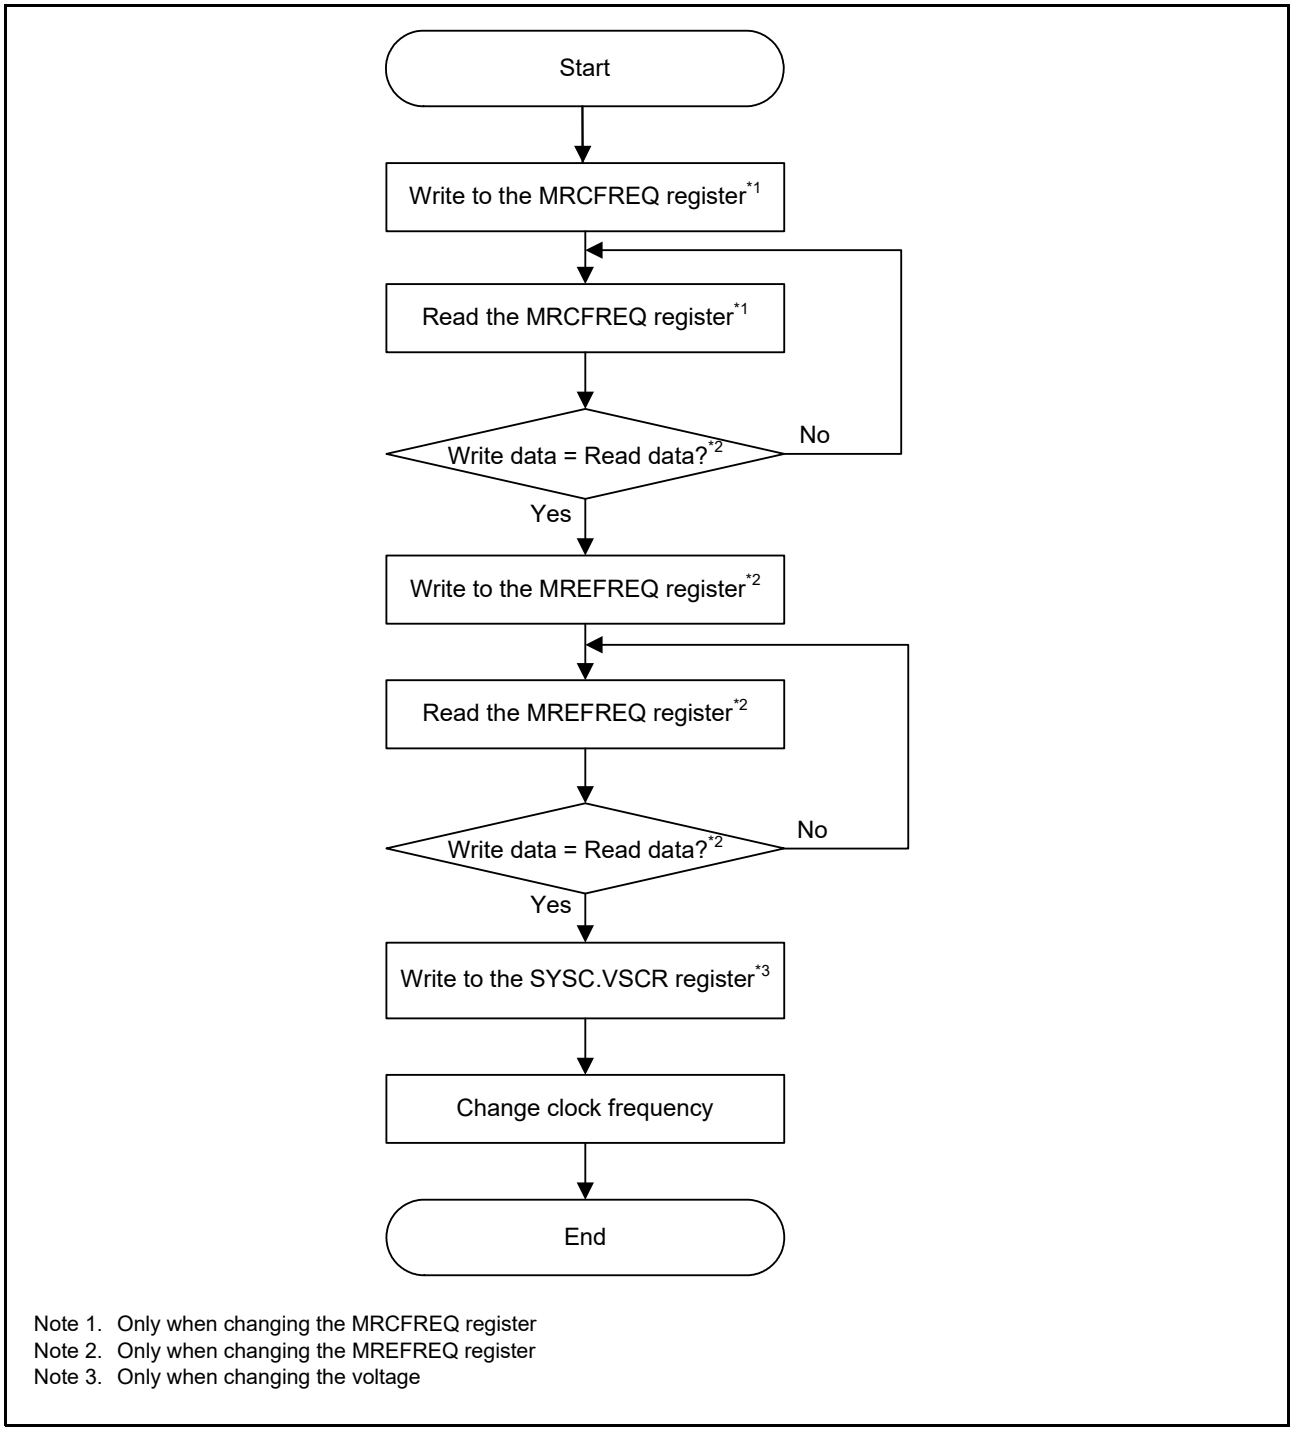

Figure 65.13 Data MRAM Programming Procedure with DMAC

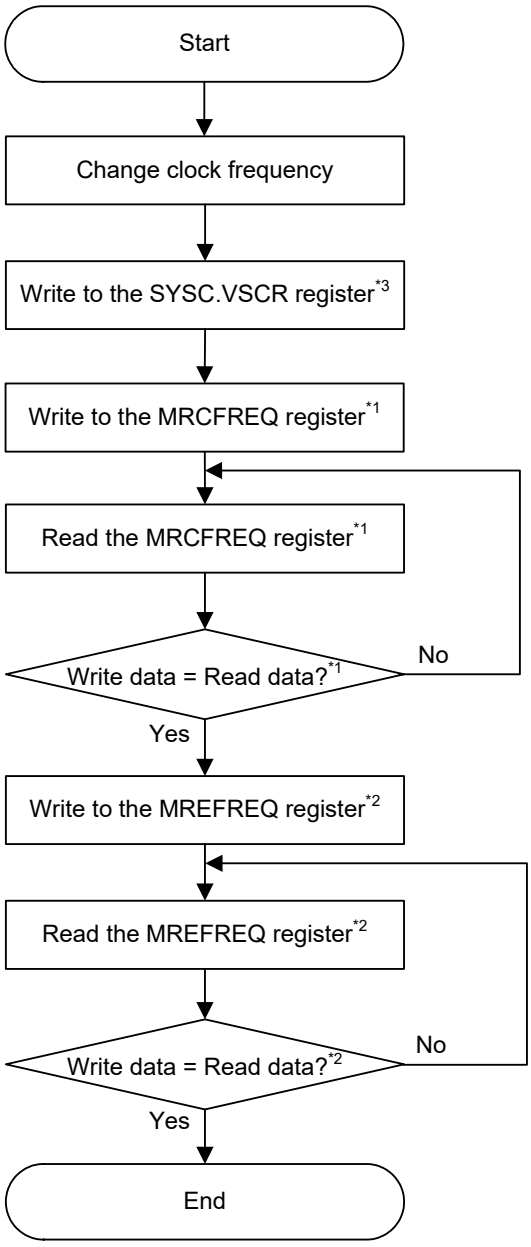


65.4.5 Frequency Change Procedure

The frequency setting is not reflected even if the register is written while programming or reading MRAM. To change the clock frequency, check that the register value is set to the write value before changing it. The frequency change procedures for code MRAM and extra MRAM are shown in Figure 65.14 and Figure 65.15.

Note 1. Only when changing the MRCFREQ register
Note 2. Only when changing the MREFREQ register
Note 3. Only when changing the voltage

Figure 65.14 Frequency Up Procedure

Note 1. Only when changing the MRCFREQ register
Note 2. Only when changing the MREFREQ register
Note 3. Only when changing the voltage

Figure 65.15 Frequency Down Procedure

65.5 Register Descriptions

65.5.1 Code MRAM Prefetch Buffer Enable Register (MRCPFB)

Address(es): MRAM.MRCPFB 8709 C000h, MRAM_NS.MRCPFB 0709 C000h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	MPFBEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MPFBEN	Code MRAM Prefetch Buffer Enable	0: Prefetch buffer is disabled 1: Prefetch buffer is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

MPFBEN Bit (Code MRAM Prefetch Buffer Enable)

This bit is used to enable or disable code MRAM prefetch buffer.

65.5.2 Code MRAM Frequency Notifications Register (MRCFREQ)

Address(es): MRAM.MRCFREQ 8709 C004h, MRAM_NS.MRCFREQ 0709 C004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	KEY[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	MRCMHZ[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	MRCMHZ[9:0]	Code MRAM Frequency Notifications	Set the operating frequency of the code MRAM by rounding it up in MHz and converting it to a binary number. MRCMHZ[9:0] ≤ 064h: No cycles of waiting 064h < MRCMHZ[9:0] ≤ 0C8h: 1 cycle of waiting 0C8h < MRCMHZ[9:0] ≤ 12Ch: 2 cycles of waiting Settings other than above are prohibited.	R/W*1
b23 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b24	KEY[7:0]	Key Code	Key code	R/W*2

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Writing to these bits is possible only when this register is written in 32-bit units with the KEY[7:0] bits set to 1Eh.
Note 2. Written values are not retained by these bits. These bits are read as 0.

The MRCFREQ register is used to set the read and program frequency for the code MRAM. For a faster clock frequency, set the MRCMHZ[9:0] bits before changing the clock frequency. To slow down the clock frequency, set the MRCMHZ[9:0] bits after changing the clock frequency. For information on the frequency setting, see section 65.4.5, Frequency Change Procedure.

MRCMHZ[9:0] Bits (Code MRAM Frequency Notifications)

These bits specify the operating frequency of the code MRAM. Specifically, convert the frequency represented in MHz into a binary number and set it in these bits. If the operating frequency is 32.768 KHz or less, set the MRCMHZ[9:0] bits to 000h.

Example 1: The desired frequency is 249.4 MHz.
Round up the first decimal place of 249.4 to obtain the nearest whole number (= 250). Specify the value in binary (0FAh) in these bits.

Example 2: The desired frequency is 0.4 MHz.
Round up the first decimal place of 0.4 to obtain the nearest whole number (= 1). Specify the value in binary (001h) in these bits.

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the MRCMHZ[9:0] bits.

65.5.3 Extra MRAM Frequency Notifications Register (MREFREQ)

Address(es): MRAM.MREFREQ 8709 C008h, MRAM_NS.MREFREQ 0709 C008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	KEY[7:0]								—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	MREMHZ[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	MREMHZ[7:0]	Extra MRAM Frequency Notifications	Set the operating frequency of the extra MRAM by rounding it up in MHz and converting it to a binary number. MREMHZ[7:0] ≤ 64h: No cycles of waiting 64h < MREMHZ[7:0] ≤ 96h: 1 cycle of waiting Settings other than above are prohibited.	R/W*1
b23 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b24	KEY[7:0]	Key Code	Key code	R/W*2

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Writing to these bits is possible only when this register is written in 32-bit units with the KEY[7:0] bits set to E1h.
Note 2. Written values are not retained by these bits. These bits are read as 0.

The MREFREQ register is used to set the read and program frequency of extra MRAM. For a faster clock frequency, set the MREMHZ[7:0] bits before changing the clock frequency. To slow down the clock frequency, set the MREMHZ[7:0] bits after changing the clock frequency. For information on the frequency setting, see section 65.4.5, Frequency Change Procedure.

MREMHZ[7:0] Bits (Extra MRAM Frequency Notifications)

These bits specify the operating frequency of the extra MRAM. Specifically, convert the frequency represented in MHz into a binary number and set it in these bits. If the operating frequency is 32.768 KHz or less, set the MREMHZ[7:0] bits to 000h.

Example 1: The desired frequency is 124.4 MHz.
Round up the first decimal place of 124.4 to obtain the nearest whole number (= 125). Specify the value in binary (7Dh) in these bits.

Example 2: The desired frequency is 0.4 MHz.
Round up the first decimal place of 0.4 to obtain the nearest whole number (= 1). Specify the value in binary (01h) in these bits.

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the MREMHZ[7:0] bits.

65.5.4 Code MRAM ECC Decoder Control Register (MRCDECC)

Address(es): MRAM.MRCDECC 8709 C010h, MRAM_NS.MRCDECC 0709 C010h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	ECCSELC	DECDISC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DECDISC	Code MRAM ECC Decoder Disable	0: ECC decoder is enabled 1: ECC decoder is disabled	R/W*1
b1	ECCSELC	Code MRAM ECC Bits Select	0: ECC bits unselect 1: ECC bits select	R/W*1
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key code	R/W*2

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Writing to this bit is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 5Ah.
Note 2. Written values are not retained by these bits. These bits are read as 0.

The MRCDECC register is used to test the ECC decoder circuits for the code MRAM. For information on the ECC decoder circuits test flow, see section 65.9.6, Fault Correction and Detection.

DECDISC Bit (Code MRAM ECC Decoder Disable)

This bit selects to enable or disable the ECC decoder circuit in code MRAM.
[Setting condition]

- When 1 is written while the write enabling condition is satisfied.

[Clearing condition]

- When 0 is written while the write enabling condition is satisfied.

ECCSELC Bit (Code MRAM ECC Bits Select)

When the setting of the ECCSELC bit is 1, the ECC bits of code MRAM are output to the [144:128] and [16:0] bits and 0 is output to the [255:145] and [127:17] bits of the read data. When an DEC error occurs, the corrected data is output. Read data is not guaranteed when a TED error is detected.
[Setting condition]

- When 1 is written while the write enabling condition is satisfied.

[Clearing condition]

- When 0 is written while the write enabling condition is satisfied.

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the DECDISC and ECCSELC bits.

65.5.5 Code MRAM Read Access Error Interrupt Enable Register (MRCRAEINT)

Address(es): MRAM.MRCRAEINT 8709 C014h, MRAM_NS.MRCRAEINT 0709 C014h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	INTENBTC	INTENBDC
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	INTENBDC	Code MRAM DEC Error Interrupt Enable	0: Generation of an MRCRDI interrupt request is disabled when the MRCRAES.DECERRC flag is set to 1. 1: Generation of an MRCRDI interrupt request is enabled when the MRCRAES.DECERRC flag is set to 1.	R/W
b1	INTENBTC	Code MRAM TED Error Interrupt Enable	0: Generation of an MRCRDI interrupt request is disabled when the MRCRAES.TEDERRC flag is set to 1. 1: Generation of an MRCRDI interrupt request is enabled when the MRCRAES.TEDERRC flag is set to 1.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MRCRAEINT register enables or disables generation of a code MRAM ECC error (MRCRDI) interrupt request.

INTENBDC Bit (Code MRAM DEC Error Interrupt Enable)

This bit enables or disables the generation of an MRCRDI interrupt request when a code MRAM read access violation occurs causing the DECERRC flag in the MRCRAES register to become 1.

INTENBTC Bit (Code MRAM TED Error Interrupt Enable)

This bit enables or disables the generation of an MRCRDI interrupt request when a code MRAM read access violation occurs causing the TEDERRC flag in the MRCRAES register to become 1.

65.5.6 Code MRAM Read Access Error Status Register (MRCRAES)

Address(es): MRAM.MRCRAES 8709 C018h, MRAM_NS.MRCRAES 0709 C018h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TEDERRC	DECERRC
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DECERRC	Code MRAM DEC Error Detect Flag	0: DEC error not detected 1: DEC error detected	R/W *1
b1	TEDERRC	Code MRAM TED Error Detect Flag	0: TED error not detected 1: TED error detected	R/W *1
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. 0 can be written to clear the flag only after 1 has been read.

DECERRC Flag (Code MRAM DEC Error Detect Flag)

This bit indicates the result of DEC error check for read data.

[Setting condition]

- Error is detected to read data of bus masters (This bit is not set when an error is detected to prefetched data).

[Clearing condition]

- 0 is written after reading 1 from this bit.

TEDERRC Flag (Code MRAM TED Error Detect Flag)

This bit indicates the result of TED error check for read data.

[Setting condition]

- Error is detected to read data of bus masters (This bit is not set when an error is detected to prefetched data).

[Clearing condition]

- 0 is written after reading 1 from this bit.

65.5.7 Code MRAM TED Error Address Register (MRCRTEA)

Address(es): MRAM.MRCRTEA 8709 C01Ch, MRAM_NS.MRCRTEA 0709 C01Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MRCRTEA[26:11]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRCRTEA[10:0]											—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	—	Reserved	These bits are read as 0.	R
b31 to b5	MRCRTEA[26:0]	Code MRAM Read Access TED Error Address	Indicates address when TED error occurs.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

This register stores the address when a TED error occurs during a code MRAM read. The address of ECC error is stored when the MRCRAES.TEDERRC flag is set to 1. The MRCRTEA[26:0] bits do not capture the error address when a TED error occurs until the MRCRAES.TEDERRC flag becomes 0.

MRCRTEA[26:0] Bits (Code MRAM Read Access TED Error Address)

[Setting condition]

- When the TEDERRC flag in the MRCRAES register changes from 0 to 1.

65.5.8 Code MRAM DEC Error Address Register (MRCRDEA)

Address(es): MRAM.MRCRDEA 8709 C020h, MRAM_NS.MRCRDEA 0709 C020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MRCRDEA[26:11]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRCRDEA[10:0]											—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	—	Reserved	These bits are read as 0.	R
b31 to b5	MRCRDEA[26:0]	Code MRAM Read Access DEC Error Address	Indicates address when DEC error occurs.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

This register stores the address when a DEC error occurs during a code MRAM read. The address of ECC error is stored when the MRCRAES.DECERRC flag is set to 1. The MRCRDEA[26:0] bits do not capture the error address when a DEC error occurs until the MRCRAES.DECERRC flag becomes 0.

MRCRDEA[26:0] Bits (Code MRAM Read Access DEC Error Address)

[Setting condition]

- When the DECERRC flag in the MRCRAES register changes from 0 to 1.

65.5.9 Extra MRAM ECC Decoder Control Register (MREDECC)

Address(es): MRAM.MREDECC 8709 C030h, MRAM_NS.MREDECC 0709 C030h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	ECCSELE	DECDISE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DECDISE	Extra MRAM ECC Decoder Disable	0: ECC decoder enable 1: ECC decoder disable	R/W*1
b1	ECCSELE	Extra MRAM ECC Bits Select	0: ECC bits unselect 1: ECC bits select	R/W*1
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key code	R/W*2

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Writing to this bit is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to A5h.
Note 2. Written values are not retained by these bits. These bits are read as 0.

DECDISE Bit (Extra MRAM ECC Decoder Disable)

When this bit is set to 1 and the MRE is read, the data before error correction is output.

ECCSELE Bit (Extra MRAM ECC Bits Select)

If the ECCSELE bit is 1, the ECC bits of the MRE are output to bits [16:0] as read data, and 0 is output to bits [127:17]. If a DEC error occurs, the data after the error correction is output. If a TED error is detected, the read data is not guaranteed.

65.5.10 Extra MRAM Read Access Error Interrupt Enable Register (MRERAEINT)

Address(es): MRAM.MRERAEINT 8709 C034h, MRAM_NS.MRERAEINT 0709 C034h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	INTENBTE	INTENBDE
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	INTENBDE	Extra MRAM DEC Error Interrupt Enable	0: Generation of an MRERDI interrupt request is disabled when the MRERAES.DECERRE flag is set to 1. 1: Generation of an MRERDI interrupt request is enabled when the MRERAES.DECERRC flag is set to 1.	R/W
b1	INTENBTE	Extra MRAM TED Error Interrupt Enable	0: Generation of an MRERDI interrupt request is disabled when the MRERAES.TEDERRE flag is set to 1. 1: Generation of an MRERDI interrupt request is enabled when the MRERAES.TEDERRE flag is set to 1.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MRERAEINT register enables or disables generation of a Extra MRAM ECC error (MRERDI) interrupt request.

INTENBDE Bit (Extra MRAM DEC Error Interrupt Enable)

This bit enables or disables generation of an MRERDI interrupt request when a extra MRAM read access violation occurs causing the DECERRE flag in the MRERAES register to become 1.

INTENBTE Bit (Extra MRAM TED Error Interrupt Enable)

This bit enables or disables generation of an MRERDI interrupt request when a extra MRAM read access violation occurs causing the TEDERRE flag in the MRERAES register to become 1.

65.5.11 Extra MRAM Read Access Error Status Register (MRERAES)

Address(es): MRAM.MRERAES 8709 C038h, MRAM_NS.MRERAES 0709 C038h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TEDERRE	DECERRE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DECERRE	Extra MRAM DEC Error Detected	0: DEC error not detected 1: DEC error detected	R/W*1
b1	TEDERRE	Extra MRAM TED Error Detected	0: TED error not detected 1: TED error detected	R/W*1
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. 0 can be written to clear the flag only after 1 has been read.

DECERRE Flag (Extra MRAM DEC Error Detected)

This bit indicates the result of DEC error check for read data.

[Setting condition]

- Error is detected to read data of bus masters (This flag is not set when error is detected to prefetched data).

[Clearing condition]

- 0 is written after reading 1 from this flag.

TEDERRE Flag (Extra MRAM TED Error Detected)

This bit indicates the result of TED error check for read data.

[Setting condition]

- Error is detected to read data of bus masters (This flag is not set when error is detected to prefetched data).

[Clearing condition]

- 0 is written after reading 1 from this flag.

65.5.12 Extra MRAM TED Error Address Register (MRERTEA)

Address(es): MRAM.MRERTEA 8709 C03Ch, MRAM_NS.MRERTEA 0709 C03Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MRERTEA[27:12]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRERTEA[11:0]												—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0.	R
b31 to b4	MRERTEA[27:0]	Extra MRAM Read Access TED Error Address	Indicates address when TED error occurs.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

This register stores the address when a TED error occurs during an extra MRAM read. The address of ECC error is stored when the MRERAES.TEDERRE flag is set to 1. The MRERTEA[27:0] bits do not capture the error address when a TED error occurs until the MRERAES.TEDERRE flag becomes 0.

MRERTEA[27:0] Bits (Extra MRAM Read Access TED Error Address)

[Setting condition]

- When the TEDERRE flag in the MRERAES register changes from 0 to 1.

65.5.13 Extra MRAM DEC Error Address Register (MRERDEA)

Address(es): MRAM.MRERDEA 8709 C040h, MRAM_NS.MRERDEA 0709 C040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MRERDEA[27:12]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRERDEA[11:0]												—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0.	R
b31 to b4	MRERDEA[27:0]	Extra MRAM Read Access DEC Error Address	Indicates address when DEC error occurs.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

This register stores the address when a DEC error occurs during an extra MRAM read. The address of ECC error is stored when the MRERAES.DECERRE flag is set to 1. The MRERDEA[27:0] bits do not capture the error address when a DEC error occurs until the MRERAES.DECERRE flag becomes 0.

MRERDEA[27:0] Bits (Extra MRAM Read Access DEC Error Address)

[Setting condition]

- When the DECERRE flag in the MRERAES register changes from 0 to 1.

65.5.14 MRAM Security Attribution Register (MSAR)

Address(es): MRAM.MSAR 8709 C100h, MRAM_NS.MSAR 0709 C100h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRCPSEQSA	MREPSEQSA	MRCPSA	MRDPSA	MACITRSA	MACICMRSA	MACICMISA	—	—	—	—	MPFBENSA	MRCFREQSA	MRCECCSA	MREFREQSA	MREECCSA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MREECCSA	Extra MRAM ECC Register Security Attribution	0: Secure 1: Non-secure	R/W
b1	MREFREQSA	MREFREQ Register Security Attribution	0: Secure 1: Non-secure	R/W
b2	MRCECCSA	Code MRAM ECC Register Security Attribution	0: Secure 1: Non-secure	R/W
b3	MRCFREQSA	MRCFREQ Register Security Attribution	0: Secure 1: Non-secure	R/W
b4	MPFBENSA	MRCPFB Register Security Attribution	0: Secure 1: Non-secure	R/W
b8 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9	MACICMISA	MACI Command Issuing Security Attribution	0: Secure 1: Non-secure	R/W
b10	MACICMRSA	MACI Command Registers Security Attribution	0: Secure 1: Non-secure	R/W
b11	MACITRSA	MACI Transfer Security Attribution	0: Secure 1: Non-secure	R/W
b12	MRDPSA	Data MRAM Program Register Security Attribution	0: Secure 1: Non-secure	R/W
b13	MRCPSA	Code MRAM Program Register Security Attribution	0: Secure 1: Non-secure	R/W
b14	MREPSEQSA	EPSEQ Area Register Security Attribution	0: Secure 1: Non-secure	R/W
b15	MRCPSEQSA	CPSEQ Area Register Security Attribution	0: Secure 1: Non-secure	R/W

Note: This register can only be written by secure transactions. Writes by non-secure transactions are ignored, but no Protect Zone access errors are generated. It can be read by any transaction.
Note: Write access is invalid when PRCR_S.PRC4*1 = 0
Note 1. Refer to the target specifications for the register write protection function of the PRCR_S.PRC4 bit.

MREECCSA Bit (Extra MRAM ECC Register Security Attribution)

This bit sets the security attribute of the MREDECC, MRERAEINT, MRERAES, MRERTEA, and MRERDEA registers.

MREFREQSA Bit (MREFREQ Register Security Attribution)

This bit sets the security attribute of the MREFREQ register.

MRCECCSA Bit (Code MRAM ECC Register Security Attribution)

This bit sets the security attribute of the MRCDECC, MRCRAEINT, MRCRAES, MRCRTEA, and MRCRDEA registers.

MRCFREQSA Bit (MRCFREQ Register Security Attribution)

This bit sets the security attribute of the MRCFREQ register.

MPFBENSA Bit (MRCPFB Register Security Attribution)

This bit sets the security attribute of the MCPFB register.

MACICMISA Bit (MACI Command Issuing Security Attribution)

This bit sets the security attribute of the MRAM access area.

MACICMRSA Bit (MACI Command Registers Security Attribution)

This bit sets the security attribute of the MASTAT, MREPAEINT, MRDYIE, MSADDR, MSTATR, MENTRYR, MSUINITR, MCMDR, and MSUASMON registers.

MACITRSA Bit (MACI Transfer Security Attribution)

This bit sets the security attribute of the MCTRCNTR, and MCTRSTATR registers.

MRDPSA Bit (Data MRAM Program Register Security Attribution)

This bit sets the security attribute of the MRDPS, MRDPAEINT, MRDPEA, and MRDPRICR registers.

MRCPSA Bit (Code MRAM Program Register Security Attribution)

This bit sets the security attribute of the MRCPCNS, MRCBPROTNS, MRCPS, MRCPAEINT, MRCPEA, and MRCPRICR registers.

MREPSEQSA Bit (EPSEQ Area Register Security Attribution)

This bit sets the security attribute of the MRPSC and MREEECC registers.

MRCPSEQSA Bit (CPSEQ Area Register Security Attribution)

This bit sets the security attribute of the MRCEECC register.

65.5.15 Extra MRAM Zeroization Status Register (MREZS)

Address(es): MRAM.MREZS 8709 C400h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	WHUKEXE	WHUKZF
Value after reset:	1	1	1	1	1	1	0	1/0*1

Bit	Symbol	Bit Name	Description	R/W
b0	WHUKZF	W-HUK Zero Status Flag	0: The W-HUK has been zeroized. 1: The W-HUK has not been zeroized.	R
b1	WHUKEXE	W-HUK Zeroization Executing Status Flag	0: W-HUK zeroization not performed 1: W-HUK zeroization in progress	R
b7 to b2	—	Reserved	These bits are read as 1.	R

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. The initial value is changed by the status of W-HUK.

WHUKZF Flag (W-HUK Zero Status Flag)

See section 65.8.6, HUK Protection for the update conditions of the WHUKZF flag.

[Setting condition]

- When W-HUK is released from the reset state without zeroing.

[Clearing condition]

- When W-HUK zeroization is complete.

WHUKEXE Flag (W-HUK Zeroization Executing Status Flag)

[Setting condition]

- When W-HUK zeroization is started.

[Clearing condition]

- When W-HUK zeroization is complete.

65.5.16 Extra MRAM Zeroization Control Register (MREZC)

Address(es): MRAM.MREZC 8709 C404h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	WHUKZE[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	WHUKZE[2:0]	W-HUK Zeroization Execute	0XX, X0X, XX0: W-HUK zeroization not performed 111: W-HUK zeroization performed	R/W *1, *2
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key code	R/W *3

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 3Ch.

Note 2. The MREZC register cannot be written in the following conditions.
- When the W-HUK pseudo-zeroing operation in Table 65.34 has already been completed and pseudo-zeroing is to be started again by register writing without any system resets.
- If the operation of W-HUK zeroing in Table 65.34 has already been completed.

Note 3. Written values are not retained by these bits. These bits are read as 0.

WHUKZE[2:0] Bits (W-HUK Zeroization Execute)

0 cannot be written to these bits.

[Setting condition]

- 1 is written to while write enabling conditions are satisfied.

[Clearing condition]

- When W-HUK zeroization is complete.

65.5.17 Extra MRAM Access Status Register (MASTAT)

Address(es): MRAM.MASTAT 8709 E010h, MRAM_NS.MASTAT 0709 E010h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	CMDLK	MREAE	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	MREAE	Extra MRAM Access Violation Flag	0: No extra MRAM access violation has occurred. 1: A extra MRAM access violation has occurred.	R/W *1
b4	CMDLK	Command Lock Flag	0: The MRAM sequencer is not in the command-locked state. 1: The MRAM sequencer is in the command-locked state.	R
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. 0 can be written to clear the flag only after 1 has been read.

The MASTAT register indicates whether extra MRAM access violation has occurred. If any of the CMDLK and MREAE flags is set to 1, the extra MRAM sequencer enters the command-locked state (see section 65.9.2, Error Protection). To release it from the command-locked state, the status clear or forced stop command must be issued to the extra MRAM sequencer.

MREAE Flag (Extra MRAM Access Violation Flag)

This flag indicates whether extra MRAM access violation occurred. When this flag is set to 1, the ILGLERR flag in the MSTATR register is set to 1, placing the extra MRAM sequencer in the command-locked state.

[Setting conditions]

In general, commands are issued in extra MRAM program mode as described below.

- When the area of extra MRAM beyond the address specified by the MSADDR register is treated as reserved
- When an MRAM sequencer command is issued to the non-secure attribute extra MRAM

[Clearing conditions]

- When 0 is written to this flag after this flag is set to 1.
- When the extra MRAM sequencer starts processing the status clear or forced stop command.

CMDLK Flag (Command Lock Flag)

This flag indicates that the extra MRAM sequencer is in the command-locked state.

[Setting condition]

- When the extra MRAM sequencer detects an error and enters the command-locked state.

[Clearing condition]

- When the extra MRAM sequencer starts processing the status clear or forced stop command.

65.5.18 Extra MRAM Access Error Interrupt Enable Register (MPAEINT)

Address(es): MRAM.MPAEINT 8709 E014h, MRAM_NS.MPAEINT 0709 E014h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	CMDLKIE	MREAEIE	—	—	—
Value after reset:	0	0	0	1	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	MREAEIE	Extra MRAM Access Violation Interrupt Enable	0: Generation of an MREPRI interrupt request is disabled when the MASTAT.MREAE flag is set to 1. 1: Generation of an MREPRI interrupt request is enabled when the MASTAT.MREAE flag is set to 1.	R/W
b4	CMDLKIE	Command Lock Interrupt Enable	0: Generation of an MREPRI interrupt request is disabled when the MASTAT.CMDLK flag is set to 1. 1: Generation of an MREPRI interrupt request is enabled when the MASTAT.CMDLK flag is set to 1.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MPAEINT register enables or disables generation of an extra MRAM access error (MREPRI) interrupt request.

MREAEIE Bit (Extra MRAM Access Violation Interrupt Enable)

This bit enables or disables generation of an MREPRI interrupt request when a extra MRAM access violation occur causing the MREAE flag in the MASTAT register to become 1.

CMDLKIE Bit (Command Lock Interrupt Enable)

This bit enables or disables generation of an MREPRI interrupt request when the extra MRAM sequencer enters the command-locked state causing the CMDLK flag in the MASTAT register to become 1.

65.5.19 Extra MRAM Ready Interrupt Enable Register (MRDYIE)

Address(es): MRAM.MRDYIE 8709 E018h, MRAM_NS.MRDYIE 0709 E018h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	MRDYIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRDYIE	Extra MRAM Ready Interrupt Enable	0: Generation of an MRDYI interrupt request is disabled 1: Generation of an MRDYI interrupt request is enabled	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MRDYIE register enables or disables generation of an extra MRAM ready (MRDYI) interrupt.

MRDYIE Bit (Extra MRAM Ready Interrupt Enable)

This bit is used to enable or disable generation of an MRDYI interrupt request when the MRDY flag in the MSTATR register is changed from 0 to 1 on completion of processing by the extra MRAM sequencer of program and configuration set command.

65.5.20 MACI Command Start Address Register (MSADDR)

Address(es): MRAM.MSADDR 8709 E030h, MRAM_NS.MSADDR 0709 E030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MSADDR[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MSADDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	MSADDR[31:0]	Start Address for MACI Command Processing	Start Address for MACI Command Processing	R/W*1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Writing to these bits is possible only when the MSTATR.MRDY flag is 1. Writing to these bits while the MSTATR.MRDY flag = 0 is ignored. The value of the lower 4 bits (b3 to b0) is fixed to 0000b.

The MSADDR register specifies the address where the target area for command processing starts when the MACI command for program or configuration set is issued.
The MSADDR register is initialized when the MSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

MSADDR[31:0] Bits (Start Address for MACI Command Processing)

These bits specify the start address for MACI command processing. Bits [30:25] are ignored in MACI command processing for extra MRAM. Bit [31] is used for the security area for extra MRAM sequencer command. When bit [31] is 1, the extra MRAM sequencer can update the secure area with secure access. When bit [31] is 0, the extra MRAM sequencer can update the non-secure area with secure and non-secure access. Bits corresponding to address bits of lower order than the corresponding boundary listed above are also ignored. Table 65.8 shows the address boundary for each command.
See the user's manual for information on the addresses of the extra MRAM.
See Table 65.17 and Table 65.18 for information on the addresses of program and configuration set commands.

Table 65.8 Address Boundary for Each of the Commands

Command	Address Boundary
Program (extra MRAM)	16-byte
Configuration set (extra MRAM)	16-byte

65.5.21 MRAM Counter Select Register (MCNTSELR)

Address(es): MRAM.MCNTSELR 8709 E048h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	CNTSEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CNTSEL[2:0]	Counter Select	b2 b0 0 0 0: Anti-rollback counter is not selected. 0 0 1: ARCS is selected. Counter size is 1024 bits. 0 1 0: ARCOEMBL is selected. Counter size is 64 bits. 0 1 1: Anti-rollback counter is not selected. 1 x x: ARCNS is selected. Counter configuration is 256 or 1024 bits. See Table 65.9 and Table 65.10 for details on counter select condition.	R/W *1, *2
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. This bit can be written when MSTATR.MRDY = 1. Writing to this bit is ignored when MSTATR.MRDY = 0.
Note 2. Writing to these bits is possible only when this register is written in 8-bit units.

CNTSEL[2:0] Bits (Counter Select)

The CNTSEL[2:0] bits specifies 3 types of anti-rollback counter (ARCS, ARCNS or ARCOEMBL) in the increment counter or read counter command.

The MCNTSELR value is initialized when the SUINIT bit in MSUINITR is set to 1.

Before using the ARCNS counter, it is necessary to set whether the counter is to be used with 4 lines × 256 bits or 1 line × 1024 bits using the program command. The bits to be set are CNFARCNS[1:0] bits. If the CNFARCNS[1] bit is set to 1, the ARCNS counter cannot be used. Once the counter type is decided, it cannot be changed.

Table 65.9 Select Condition of ARCNS (256 Bits) in Increment/Read Counter Command

MCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARCNS0[255:0]	Counter number is 4. Counter size is 256 bits.
101	ARCNS1[255:0]	
110	ARCNS2[255:0]	
111	ARCNS3[255:0]	

Table 65.10 Select Condition of ARCNS (1024 Bits) in Increment Counter Command

MCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARCNS[1023:0]	Counter number is 1. Counter size is 1024 bits.
101		
110		
111		

65.5.22 MRAM Counter Data Register n (MCNTDTRn) (n = 0, 1)

Address(es): MRAM.MCNTDTR0 8709 E04Ch, MRAM.MCNTDTR1 8709 E050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CNTRDAT[31:16]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CNTRDAT[15:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	CNTRDAT[31:0]	Counter Read Data	32 bits (LSB side of 64-bit counter value) of read data are output to MCNTDTR0. 32 bits (MSB side of 64-bit counter value) of read data are output to MCNTDTR1.	R

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

MCNTDTR0 and MCNTDTR1 indicate the 64-bit value that was read from the ARCOEMBL anti-rollback counter by the read counter command.

CNTRDAT[31:0] Bits (Counter Read Data)

[Condition for read data]

- MACI has accepted the read counter command.

[Clearing conditions]

- MACI has accepted extra MRAM sequencer command except for the read counter command.
- Extra MRAM sequencer enters command lock state.
- W-HUK zeroization is started.

65.5.23 MRAM Configuration Update Transfer Control Register (MCTRCNTR)

Address(es): MRAM.MCTRCNTR 8709 E060h, MRAM_NS.MCTRCNTR 0709 E060h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	TRTRG
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TRTRG	Transfer Start Trigger	0: Configuration update transfer process has not started. 1: Configuration update transfer process started	R/W *1, *2, *3
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key code	R/W*1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Written values are not retained in these bits. These bits are read as 0.
Note 2. This bit can be written when the MCTRSTATR register is 00h. Writing to this bit is ignored when the MCTRSTATR register is other than 00h or when W-HUK zeroing is in progress.
Note 3. Writing to this bit is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 45h.

The MCTRCNTR register is used to start the configuration update transfer process.

TRTRG Bit (Transfer Start Trigger)

The TRTRG bit is used to start the configuration update transfer process.

[Setting condition]

- When the MCTRCNTR register is in write-enabled state and “4501h” is written to the MCTRCNTR register

65.5.24 MRAM Configuration Update Transfer Status Register (MCTRSTATR)

Address(es): MRAM.MCTRSTATR 8709 E06Ch, MRAM_NS.MCTRSTATR 0709 E06Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	TRMD	—	TRBUSY
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TRBUSY	Transfer Busy Status	0: No configuration update transfer is in progress. 1: Configuration update transfer is in progress.	R
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R
b2	TRMD	Transfer Mode Setting Status	0: The MENTRYR register is in a setting that allows data transfer. 1: The MENTRYR register is not in a setting that allows data transfer.	R
b7 to b3	—	Reserved	These bits are read as 0.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

TRBUSY Bit (Transfer Busy Status)

Indicates configuration update transfer processing status.

[Setting condition]

- 1 is written to the MCTRCNTR.TRTRG bit.

[Clearing condition]

- Configuration update transfer processing is complete.

TRMD Bit (Transfer Mode Setting Status)

Indicates whether the MENTRYR register is in a state that allows a configuration update transfer to be started.

[Setting condition]

- The MENTRYR register is set to 0080h.
- When “AA80h” is written to the MENTRYR register during data MRAM programming processing

[Clearing condition]

- The MENTRYR register is set to 0000h.

65.5.25 Extra MRAM Status Register (MSTATR)

Address(es): MRAM.MSTATR 8709 E080h, MRAM_NS.MSTATR 0709 E080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	ILGCOMERR	—	—	OTERR	PZFERR	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MRDY	ILGLERR	—	PRGERR	—	—	—	—	—	—	CFGSETERR	PROTERR	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0.	R
b4	PROTERR	Protection Error Flag	0: Programming of and configuration settings for the protected area have been successfully completed. 1: An error occurred during programming of or configuration settings for the protected area.	R
b5	CFGSETERR	Configuration Set Error Flag	0: Configuration setting has been completed successfully. 1: An error has occurred during configuration setting.	R
b11 to b6	—	Reserved	These bits are read as 0.	R
b12	PRGERR	Programming Error Flag	0: Programming has been completed successfully. 1: An error has occurred during programming.	R
b13	—	Reserved	This bit is read as 0.	R
b14	ILGLERR	Illegal Command Error Flag	0: The extra MRAM sequencer has not detected an illegal MACI command or illegal extra MRAM access. 1: The extra MRAM sequencer has detected an illegal MACI command or illegal extra MRAM access.	R
b15	MRDY	Extra MRAM Ready Flag	0: Program, Configuration set, Increment Counter or Read Counter command processing is in progress. 1: None of the above is in progress.	R
b18 to b16	—	Reserved	These bits are read as 0.	R
b19	PZFERR	Protect Zone Filter Error Flag	0: A Protect Zone filter error has not been detected. 1: A Protect Zone filter error has been detected.	R
b20	OTERR	Other Error Flag	0: An error has not been detected. 1: An error has been detected.	R
b21	—	Reserved	This bit is undefined when read.	R
b22	—	Reserved	This bit is read as 0.	R
b23	ILGCOMERR	Illegal Command Error Flag	0: An illegal MACI command error has not been detected. 1: An illegal MACI command error has been detected.	R
b31 to b24	—	Reserved	These bits are read as 0.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MSTATR register indicates the state of the extra MRAM sequencer.

PROTERR Flag (Protection Error Flag)

The update area is permanently protected, and this flag indicates that there is a TED error in the data to be updated. If the PROTERR flag is 1, the extra MRAM sequencer is in a command lock state.
[Setting condition]

- Occurrence of an error while the extra MRAM sequencer was programming or making configuration settings for the protected area

[Clearing condition]

- After the extra MRAM sequencer starting to process a status clear or forced stop command

CFGSETERR Flag (Configuration Set Error Flag)

This flag indicates the result of the extra MRAM configuration setting. If this flag is 1, the extra MRAM sequencer is in the command-locked state.

[Setting condition]

- When the extra MRAM sequencer reads data not to update from configuration area during configuration setting.

[Clearing condition]

- After the extra MRAM sequencer starting to process a status clear or forced stop command

PRGERR Flag (Programming Error Flag)

This flag indicates the result of the extra MRAM programming. If this flag is 1, the extra MRAM sequencer is in the command-locked state.

[Setting condition]

- See Table 65.42, Error Protection Types.

[Clearing condition]

- After the extra MRAM sequencer starting to process a status clear or forced stop command

ILGLERR Flag (Illegal Command Error Flag)

This flag indicates that the extra MRAM sequencer has detected an illegal MACI command or extra MRAM access. If this flag is 1, the extra MRAM sequencer is in the command-locked state.

[Setting condition]

- See Table 65.42, Error Protection Types.

[Clearing condition]

- After the extra MRAM sequencer starting to process a status clear or forced stop command

MRDY Flag (Extra MRAM Ready Flag)

This flag indicates the command processing state of the extra MRAM sequencer.

[Setting conditions]

- After the extra MRAM sequencer completes command processing.
- After the extra MRAM sequencer starting to process a status clear or forced stop command
- When W-HUK zeroing is in processing

[Clearing conditions]

- After the extra MRAM sequencer has received the MACI command.
- The extra MRAM sequencer has received program and configuration set commands, and after the first write to the MACI command- issuing area
- For other commands, after the first write to the MACI command- issuing area.

PZFERR Flag (Protect Zone Filter Error Flag)

This flag indicates the Protect Zone filter error in the MACI command. If this flag is 1, the extra MRAM sequencer is in the command-locked state.

[Setting condition]

- See Table 65.42, Error Protection Types.

[Clearing condition]

- After the extra MRAM sequencer starting to process a status clear or forced stop command

OTERR Flag (Other Error Flag)

This flag indicates that an MACI command has been issued when the condition of accepting commands is not satisfied. If this flag is 1, the extra MRAM sequencer is in the command-locked state.

[Setting condition]

- See Table 65.42, Error Protection Types.

[Clearing condition]

- After the extra MRAM sequencer starting to process a status clear or forced stop command

ILGCOMERR Flag (Illegal Command Error Flag)

This flag indicates that the extra MRAM sequencer has detected an illegal MACI command. If this flag is 1, the extra MRAM sequencer is in the command-locked state.

[Setting condition]

- See Table 65.42, Error Protection Types.

[Clearing condition]

- After the extra MRAM sequencer starting to process a status clear or forced stop command

65.5.26 Extra MRAM Program Mode Entry Register (MENTRYR)

Address(es): MRAM.MENTRYR 8709 E084h, MRAM_NS.MENTRYR 0709 E084h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								MENTRY	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	MENTRY	Extra MRAM Program Mode Entry	0: Extra MRAM is in the read mode. 1: Extra MRAM is in the program mode.	R/W *1, *2, *3
b15 to b8	KEY[7:0]	Key Code	Key code	R/W*4

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. These bits can be written when the MRDY flag in the MSTATR register is 1. Writing to these bits are ignored when the MRDY flag is 0.

Note 2. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to AAh.

Note 3. The MENTRY bit cannot be set to 1 during configuration update, the MENTRYR register cannot be written to during W-HUK zeroing.

Note 4. Written values are not retained by these bits. These bits are read as 0.

The MENTRYR register is used to specify extra MRAM program mode. To enable the extra MRAM sequencer to accept MACI commands, the MENTRY bit must be set to 1 to put the extra MRAM sequencer into program mode.
The MENTRYR register is initialized when the MSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

MENTRY Bit (Extra MRAM Program Mode Entry)

This bit specifies extra MRAM program mode.
[Setting condition]

- When the MENTRYR register is in write-enabled state and the MENTRYR register is in the state of 0000h, AA80h is written to the MENTRYR register.

[Clearing conditions]

- The MENTRYR register is written in 8-bit units when the MSTATR.MRDY flag is set to 1.
- When the MSTATR.MRDY flag is set to 1 and a value other than AAh is specified for the KEY[7:0] bits and written to the MENTRYR register in 16-bit units
- Write AA00h to the MENTRYR register while writing to the MENTRYR register is enabled.
- Write to the MENTRYR register while writing is enabled and its value is other than 0000h.

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the MENTRY bit.

65.5.27 Extra MRAM Sequencer Set-Up Initialization Register (MSUINITR)

Address(es): MRAM.MSUINITR 8709 E08Ch, MRAM_NS.MSUINITR 0709 E08Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	SUINIT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

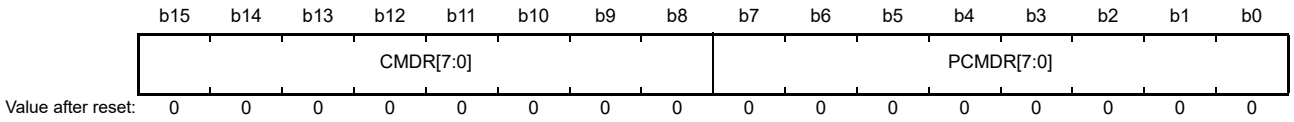
Bit	Symbol	Bit Name	Description	R/W
b0	SUINIT	Set-Up Initialization	0: The extra MRAM sequencer setting register values of the MSADDR, MENTRYR, and MCNTSELR registers are retained. 1: Initializes the extra MRAM sequencer settings in the MSADDR, MENTRYR, and MCNTSELR registers	R/W *1, *2
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key code	R/W *3

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. This bit can be written when the MRDY flag in the MSTATR register is 1. Writing to this bit is ignored when the MRDY flag is 0.
Note 2. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 2Dh.
Note 3. Written values are not retained by these bits. These bits are read as 0.

The MSUINITR register is used for initialization of the extra MRAM sequencer settings.

SUINIT Bit (Set-Up Initialization)

This bit initializes the following extra MRAM sequencer set-up registers.



- MSADDR
- MENTRYR
- MCNTSELR

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the SUINIT bit.

65.5.28 MACI Command Register (MCMDR)

Address(es): MRAM.MCMDR 8709 E0A0h, MRAM_NS.MCMDR 0709 E0A0h

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	PCMDR[7:0]	Pre-command Flag	The command just before the latest command is stored.	R
b15 to b8	CMDR[7:0]	Command Flag	The latest command is stored.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MCMDR register indicates the command accepted by MACI.

PCMDR[7:0] Flags (Pre-command Flag)

These flags indicate the command received immediately before the latest command received by MACI.

CMDR[7:0] Flags (Command Flag)

These flags indicate the latest command received by MACI.

Table 65.11 States of MCMDR after Receiving Commands

Command	CMDR[7:0] Flags	PCMDR[7:0] Flags
Program	E8h	Previous Command
Status Clear	50h	Previous Command
Forced Stop	B3h	Previous Command
Configuration set	40h	Previous Command
Increment Counter	D0h	35h
Read Counter	D0h	39h

65.5.29 MRAM Startup Area Select Monitor Register (MSUASMON)

Address(es): MRAM.MSUASMON 8709 E0DCh, MRAM_NS.MSUASMON 0709 E0DCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BTFLG	BTSIZE[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0/1	0/1	0/1	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FSPR	FSPRS	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0/1	0/1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	—	Reserved	These bits are read as 0.	R
b14	FSPRS	Protection Status Flag of Startup Area Size Selection	0: Protected state 1: Non-protected state	R
b15	FSPR	Protection Status Flag of Startup Area Selection	0: Protected state 1: Non-protected state	R
b28 to b16	—	Reserved	These bits are read as 0.	R
b30, b29	BTSIZE[1:0]	Startup Area Size Select	b30 b29 0 0: Reserved 0 1: Startup area size is set to 32 Kbytes 1 0: Startup area size is set to 16 Kbytes 1 1: Startup area size is set to 8 Kbytes	R
b31	BTFLG	Startup Area Select Flag*1	0: The startup area is the alternate block (block 1) 1: The startup area is the default block (block 0)	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. If the MSUACR.SAS[1:0] bits are changed to 1xb, the startup area follows the setting of the MSUACR.SAS[1:0] bits regardless of the setting of the SAS2.BTFLG bit.

The MSUASMON register is a register that contains a flag that indicates the write protection status for startup area size selection and startup area selection, and that indicates the startup area size selection value and the startup area selection flag value. When a reset or configuration setting command is executed, MACI transfers data from the extra MRAM to the MSUASMON register, and the extra MRAM settings become effective.

FSPRS Flag (Protection Status Flag of Startup Area Size Selection)

This flag indicates whether or not protection is enabled against writing configuration setting commands for the startup area size selection setting.

FSPR Flag (Protection Status Flag of Startup Area Selection)

This flag indicates whether or not protection is enabled against writing configuration setting commands for to startup area selection and writing to the MSUACR register.

BTSIZE[1:0] Bits (Startup Area Size Select)

These bits indicate the size of the startup area.

BTFLG Flag (Startup Area Select Flag)

This flag indicates whether the address of the startup area is exchanged for the boot swap function or not.

65.5.30 MRAM Startup Area Control Register (MSUACR)

Address(es): MRAM.MSUACR 8709 E0E8h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	SAS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SAS[1:0]	Startup Area Select	b1 b0 0 x: Startup area is selected by the SAS2.BTFLG bit 1 0: Startup area is temporarily switched to the default area regardless of the setting of the SAS2.BTFLG bit 1 1: Startup area is temporarily switched to the alternate area regardless of the setting of the SAS2.BTFLG bit	R/W *1, *2
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key code	R/W *3

x: Don't care.

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. Writing is possible only when the MSUASMON.FSPR flag is 1. Writing is ignored when the MSUASMON.FSPR flag is 0.

Note 2. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 66h.

Note 3. Written values are not retained by these bits. These bits are read as 0.

The MSUACR register is used to switch the startup area between the default area (block 0) and the alternative area (block 1) using the boot swap function.

SAS[1:0] Bits (Startup Area Select)

These bits are used to switch the startup area between the default area (block 0) and the alternate area (block 1).

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the SAS [1:0] bits.

65.5.31 MACI Reset Transfer Status Register (MRSTTRST)

Address(es): MRAM.MRSTTRST 8709 E0F0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RSTTRER
Value after reset:	0	0	0	0	0	0	0	x

x: Don’t care

Bit	Symbol	Bit Name	Description	R/W
b0	RSTTRER	MACI Reset Transfer Status	0: ECC error has not been detected. 1: ECC error has been detected.	R
b7 to b1	—	Reserved	These bits are read as 0.	R

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.

RSTTRER Bit (MACI Reset Transfer Status)

This bit indicates the MACI reset transfer status.

65.5.32 MRAM Program Speed Control Register (MRPSC)

Address(es): MRAM.MRPSC 8709 E800h, MRAM_NS.MRPSC 0709 E800h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	MHSPEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MHSPEN	MRAM High Speed Program Mode Enable	0: Normal program mode 1: High speed program mode	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

MHSPEN Bit (MRAM High Speed Program Mode Enable)

This bit is used to enable or disable high speed program mode of code MRAM or extra MRAM. After setting this bit to 1 and programming code MRAM or extra MRAM, the mode is changed to high-speed program mode. To change to normal program mode, set this bit to 0, read the MRPSC register once, and program or read the MRAM.

65.5.33 Extra MRAM ECC Encoder Control Register (MREEECC)

Address(es): MRAM.MREEECC 8709 E804h, MRAM_NS.MREEECC 0709 E804h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	ECCBYPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECCBYPE	Extra MRAM ECC encoder outputs bypass enable	0: ECC bypass is disabled. 1: ECC bypass is enabled.	R/W*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	The ECCBYPE bit protection key code	R/W*2

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to EFh.
Note 2. Written values are not retained by these bits. These bits are read as 0.

The MREEECC register is used to enable the bypass function of the ECC encoder output of the extra MRAM.
It is used to test the ECC decoder circuit of the extra MRAM. For information on the ECC decoder circuits test flow, see section 65.9.6, Fault Correction and Detection.

ECCBYPE Bit (Extra MRAM ECC encoder outputs bypass enable)

This bit enables the function to bypass the ECC encoder output of the extra MRAM.
When the ECCBYPE bit is 0, the ECC bits of the extra MRAM are the ECC encoder output.
When the ECCBYPE bit is 1, the ECC bits of the extra MRAM are bits [16:0] of the write data.

KEY[7:0] Bits (Key Code)

The KEY[7:0] bits control permission and prohibition of writing to the ECCBYPE bit.
To write to the ECCBYPE bit, write EFh to the KEY[7:0] at the same time. If a value other than EFh is written, the ECCBYPE bit will not be updated. When read, it will return 00h.

65.5.34 Code MRAM Program Control Register for Non-Secure Application (MRCPCNS)

Address(es): MRAM.MRCPCNS 8709 F000h, MRAM_NS.MRCPCNS 0709 F000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	MRCPEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRCPEN	Code MRAM Program Enable	0: Code MRAM non-secure areas are not programmable 1: Code MRAM non-secure areas are programmable	R/W *1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key code	R/W *2

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 86h.
Note 2. Written values are not retained by these bits. These bits are read as 0.

MRCPEN Bit (Code MRAM Program Enable)

This bit is used to enable programming to the non-secure area.

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the MRCPEN bit.

65.5.35 Code MRAM Program Control Register for Secure Application (MRCPCS)

Address(es): MRAM.MRCPCS 8709 F004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	MRCPEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRCPEN	Code MRAM Program Enable	0: Code MRAM secure areas are not programmable 1: Code MRAM secure areas are programmable	R/W *1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key code	R/W *2

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 68h.
Note 2. Written values are not retained by these bits. These bits are read as 0.

MRCPEN Bit (Code MRAM Program Enable)

This bit is used to enable programming to the secure area.

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the MRCPEN bit.

65.5.36 Code MRAM Block Protection Register for Non-Secure Application (MRCBPROTNS)

Address(es): MRAM.MRCBPROTNS 8709 F008h, MRAM_NS.MRCBPROTNS 0709 F008h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	BPCN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BPCN	Code MRAM Block Protection Cancel	0: Code MRAM block protection is enabled 1: Code MRAM block protection is disabled	R/W *1, *2
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	BPCN bit protection key code	R/W *3

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. This bit can be written when the MRCPCNS.MRCPEN bit is 1. Writing when the MRCPCNS.MRCPEN bit is 0 is ignored.
Note 2. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to 78h.
Note 3. Written values are not retained by these bits. These bits are read as 0.

The MRCBPROTNS register is used to disable the block protect function for non-secure. When the block protect setting is locked by permanent block setting, it cannot be disabled by this register.

BPCN Bit (Code MRAM Block Protection Cancel)

This bit disables the block protection function for the non-secure code MRAM area.

[Setting condition]

- When the MRCPCNS.MRCPEN bit is 1, 7801h is written to the MRCBPROTNS register.

[Clearing conditions]

- When the MRCPCNS.MRCPEN bit is 1, 7800h is written to the MRCBPROTNS register.
- When 0 is written to the MRCPCNS.MRCPEN bit.

KEY[7:0] Bits (Key Code)

This bit enables or disables writing to the BPCN bit.

When writing to the BPCN bit, write 78h to the KEY[7:0] bits at the same time. If a value other than 78h is written, the BPCN bit will not be updated. When read, it will return 00h.

65.5.37 Code MRAM Block Protection Register for Secure Application (MRCBPROTS)

Address(es): MRAM.MRCBPROTS 8709 F00Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	BPCN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BPCN	Code MRAM Block Protection Cancel	0: Code MRAM block protection is enabled 1: Code MRAM block protection is disabled	R/W *1, *2
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	BPCN1 bit protection key code	R/W *3

Note: This register is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. This bit can be written when the MRCPCS.MRCPEN bit is 1. Writing when the MRCPCS.MRCPEN bit is 0 is ignored.
Note 2. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to B1h.
Note 3. Written values are not retained by these bits. These bits are read as 0.

The MRCBPROTS register is used to disable the block protect function for secure. When the block protect setting is locked by permanent block setting, it cannot be disabled by this register.

BPCN Bit (Code MRAM Block Protection Cancel)

This bit disables the block protection function for the secure code MRAM area.
[Setting condition]

- When the MRCPCS.MRCPEN bit is 1, B101h is written to the MRCBPROTS register.

[Clearing condition]

- When the MRCPCS.MRCPEN bit is 1, B100h is written to the MRCBPROTS register.
- When 0 is written to the MRCPCS.MRCPEN bit.

KEY[7:0] Bits (Key Code)

This bit enables or disables writing to the BPCN bit.
When writing to the BPCN bit, write B1h to the KEY[7:0] bits at the same time. If a value other than B1h is written, the BPCN bit will not be updated. When read, it will return 00h.

65.5.38 Code MRAM Program Status Register (MRCPS)

Address(es): MRAM.MRCPS 8709 F010h, MRAM_NS.MRCPS 0709 F010h

	b7	b6	b5	b4	b3	b2	b1	b0
	PRGBSYC	ABUFFULL	ABUFEMP	PRGBSYCB	ABUFFULLB	ABUFEMPB	ECCERRC	PRGERRC
Value after reset:	0	0	1	0	0	1	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PRGERRC	Programming Error Flag	0: Programming has been completed successfully 1: An error has occurred during programming	R/W *1
b1	ECCERRC	ECC Error Flag	0: Programming has been completed successfully 1: An error has occurred during programming	R/W *1
b2	ABUFEMPB	MRC1 Address Buffer Empty Flag	0: The address buffer is not empty. Write data can be flushed. 1: The address buffer is empty. Write data cannot be flushed.	R
b3	ABUFFULLB	MRC1 Address Buffer Full Flag	0: Address buffer is not full. Write transactions are allowed. 1: Address buffer is full. Write transactions are not allowed.	R
b4	PRGBSYCB	MRC1 Programming Status Flag	0: Programming is not in progress 1: Programming is in progress	R
b5	ABUFEMP	MRC0 Address Buffer Empty Flag	0: The address buffer is not empty. Write data can be flushed. 1: The address buffer is empty. Write data cannot be flushed.	R
b6	ABUFFULL	MRC0 Address Buffer Full Flag	0: Address buffer is not full. Write transactions are allowed. 1: Address buffer is full. Write transactions are not allowed.	R
b7	PRGBSYC	MRC0 Programming Status Flag	0: Programming is not in progress 1: Programming is in progress	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. 0 can be written to clear the flag only after 1 has been read.

The MRCPS register indicates the status of the code MRAM programming sequencer.

PRGERRC Flag (Programming Error Flag)

This flag indicates the result of programming to the code MRAM. Writing 1 to this flag is ignored.

[Setting condition]

- An error has occurred during programming and the ECCERRC flag is 0.

[Clearing condition]

- 0 is written after reading 1 from this flag.

ECCERRC Flag (ECC Error Flag)

This flag indicates that an uncorrectable error has occurred when the programming data from the code bus is less than 32 bytes. Programming data to code MRAM is generated from data in the target address and data from code bus. If a TED error occurs when reading data from the target address, programming data to code MRAM cannot be correctly generated if the data from code bus is less than 32 bytes. To perform programming to an address with this flag set to 1, all 32 bytes data must be input from code bus.
This flag can only be written to 0 and writing 1 is ignored.
[Setting condition]

- Uncorrectable error occurred when programming data from code bus is less than 32 bytes and PRGERRC flag is 0.

[Clearing condition]

- 0 is written after reading 1 from this bit.

ABUFEMPB Flag (MRC1 Address Buffer Empty Flag)

This flag indicates the status of the programming address buffer for the code MRAM on the MRC1 side. When the address buffer is empty, this flag becomes 1. When this flag is 1, writing to the MRCFLR.MRCBFL bit is not possible, so programming data cannot be flashed.

ABUFFULLB Flag (MRC1 Address Buffer Full Flag)

This flag indicates the status of the address buffer for programming the code MRAM on the MRC1 side. When the address buffer is full, this flag becomes 1. When this flag is 1, new write transactions are not accepted until programming to the MRC1 area starts or ends.

PRGBSYCB Flag (MRC1 Programming Status Flag)

This flag indicates the programming status of the code MRAM on the MRC1 side. If CPSEQ executes the code MRAM programming processing, this flag is set to 1. When this flag is 1, a new read transaction to the MRC1 area cannot be accepted until the MRC1 area programming finishes.

ABUFEMP Flag (MRC0 Address Buffer Empty Flag)

This flag indicates the status of the programming address buffer for the code MRAM on the MRC0 side. When the address buffer is empty, this flag becomes 1. When this flag is 1, writing to the MRCFLR.MRCBFL bit is not possible, so programming data cannot be flashed.

ABUFFULL Flag (MRC0 Address Buffer Full Flag)

This flag indicates the status of the address buffer for programming the code MRAM on the MRC0 side. When the address buffer is full, this flag becomes 1. When this flag is 1, new write transactions are not accepted until programming to the MRC0 area starts or ends.

PRGBSYC Flag (MRC0 Programming Status Flag)

This flag indicates the programming status of the code MRAM on the MRC0 side. If CPSEQ executes the code MRAM programming processing, this flag is set to 1. When this flag is 1, a new read transaction to the MRC0 area cannot be accepted until the MRC0 area programming finishes.

65.5.39 Code MRAM Program Access Error Interrupt Enable Register (MRCPAEINT)

Address(es): MRAM.MRCPAEINT 8709 F014h, MRAM_NS.MRCPAEINT 0709 F014h

	b7	b6	b5	b4	b3	b2	b1	b0
	MRCAEIE	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	MRCAEIE	Program Access Error Interrupt Enable	0: Generation of an MRCPRI interrupt request is disabled 1: Generation of an MRCPRI interrupt request is enabled	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MRCPAEINT register enables or disables generation of a code MRAM access error (MRCPRI) interrupt request.

MRCAEIE Bit (Program Access Error Interrupt Enable)

This bit enables a code MRAM access error (MRCPRI) interrupt request to be generated when the MRCPS.PRGERRC flag or MRCPS.ECCERRC flag is 1.

When the MRCAEIE bit is 1, an MRCPRI interrupt request is generated. When the MRCAEIE bit is 0, an MRCPRI interrupt request is not generated.

65.5.40 Code MRAM Program Error Address Register (MRCPEA)

Address(es): MRAM.MRCPEA 8709 F018h, MRAM_NS.MRCPEA 0709 F018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MCPEA[26:11]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MCPEA[10:0]											—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31 to b5	MCPEA[26:0]	Code MRAM Program Error Address	Indicates address when a code MRAM program error occurs.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MRCPEA register stores the error address when a code MRAM program error occurs.

MCPEA[26:0] Bits (Code MRAM Program Error Address)

[Update condition]

- When a program error or ECC error occurs while the MRCPS.ECCERRC flag is 0 and the MRCPS.PROGERRC flag is 0, the error address is stored in the MRCPEA register.

65.5.41 Code MRAM Flush Register (MRCFLR)

Address(es): MRAM.MRCFLR 8709 F030h, MRAM_NS.MRCFLR 0709 F030h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	MRCBFL	MRCFL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRCFL	Flush Write Data Buffer for MRC0	0: Not execute to flush program data buffer 1: Execute to flush program data buffer	R/W *1, *3
b1	MRCBFL	Flush Write Data Buffer for MRC1	0: Not execute to flush program data buffer 1: Execute to flush program data buffer	R/W *2, *3
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	The MRCFL and MRCBFL bit protection key codes	R/W *4

Note 1. When the ABUFEMP flag in the MRCPS register is 1, it is not possible to write 1 to this bit.
Note 2. When the ABUFEMPB flag in the MRCPS register is 1, it is not possible to write 1 to this bit.
Note 3. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to C3h.
Note 4. Written values are not retained by these bits. These bits are read as 0.

The MRCFLR register is used for writing data less than 32 bytes.

MRCFL Bit (Flush Write Data Buffer for MRC0)

This bit is used for starting the programming operation to the code MRAM on the MRC0 side.
[Setting condition]

- When C301h or C303h is written to the MRCFLR register while the MRCPS.ABUFEMP flag is 0.

[Clearing condition]

- When the MRCPS.ABUFEMP flag is set to 1.

MRCBFL Bit (Flush Write Data Buffer for MRC1)

This bit is used for starting the programming operation to the code MRAM on the MRC1 side.
[Setting condition]

- When C302h or C303h is written to the MRCFLR register while the MRCPS.ABUFEMPB flag is 0.

[Clearing condition]

- When the MRCPS.ABUFEMPB flag is set to 1.

KEY[7:0] Bits (Key Code)

When writing to the MRCFL or MRCBFL bit, write C3h to the KEY[7:0] bits at the same time. If a value other than C3h is written, the MRCFL or MRCBFL bit will not be updated. When read, it will return 00h.

65.5.42 Code MRAM Program Ready Interrupt Control Register (MRCPRICR)

Address(es): MRAM.MRCPRICR 8709 F040h, MRAM_NS.MRCPRICR 0709 F040h

	b7	b6	b5	b4	b3	b2	b1	b0
	MRCPRRIE	—	—	—	—	—	—	MRCINTSEL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRCINTSEL	Program Ready Interrupt Request Source Select	0: Selects the program ready interrupt for the code MRAM on the MRC0 side 1: Selects the program ready interrupt for the code MRAM on the MRC1 side	R/W
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	MRCPRRIE	Program Ready Interrupt Enable	0: Generation of program ready interrupt requests is disabled. 1: Generation of program ready interrupt requests is enabled.	R/W *1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. It is prohibited to set the MRCPRICR.MRCPRRIE bit and the MRDPRICR.MRDPRRIE bit to 1 at the same time.

The MRCPRICR register is used to enable or disable the generation of MRAM program ready (MRPRRI) interrupt requests.

MRCINTSEL Bit (Program Ready Interrupt Request Source Select)

This bit is used to select the source of the MRAM program ready (MRPRRI) interrupt.

MRCPRRIE Bit (Program Ready Interrupt Enable)

This bit enables the generation of an MRAM program ready (MRPRRI) interrupt request.
When programming on the MRC0 side (MRCINTSEL bit = 0), a program ready interrupt request can be generated if the MRCPS.ABUFFULLC bit is 0. Writing 1 to this bit generates the first interrupt request. After that, when a write transaction to the MRC0 side is accepted, an interrupt request is generated.
When programming on the MRC1 side (MRCINTSEL bit = 1), a program ready interrupt request can be generated if the MRCPS.ABUFFULLCB bit is 0. Writing 1 to this bit generates the first interrupt request. After that, when a write transaction to the MRC1 side is accepted, an interrupt request is generated.

65.5.43 Data MRAM Program Status Register (MRDPS)

Address(es): MRAM.MRDPS 8709 F410h, MRAM_NS.MRDPS 0709 F410h

	b7	b6	b5	b4	b3	b2	b1	b0
	PRGBSYD	ABUFFULLD	ABUFEMPD	—	—	—	ECCERRD	PRGERRD
Value after reset:	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PRGERRD	Programming Error Flag	0: Programming has been completed successfully 1: An error has occurred during programming	R/W *1
b1	ECCERRD	ECC Error Flag	0: No error has occurred during programming 1: An error has occurred during programming	R/W *1
b4 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	ABUFEMPD	Data MRAM Address Buffer Empty Flag	0: The address buffer is not empty. Write data can be flushed. 1: The address buffer is empty. Write data cannot be flushed.	R
b6	ABUFFULLD	Data MRAM Address Buffer Full Flag	0: Address buffer is not full. Write transactions are allowed. 1: Address buffer is full. Write transactions are not allowed.	R
b7	PRGBSYD	Data MRAM Programming Status Flag	0: Programming is not in progress 1: Programming is in progress	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. 0 can be written to clear the flag only after 1 has been read.

The MRDPS register indicates the status of the data MRAM programming sequencer.

PRGERRD Flag (Programming Error Flag)

This flag indicates the result of programming to the data MRAM. Writing 1 to this flag is ignored.

[Setting condition]

- When an error occurs during programming and the ECCERRD flag is 0

[Clearing condition]

- 0 is written after reading 1 from this flag.

ECCERRD Flag (ECC Error Flag)

This flag indicates that an uncorrectable error has occurred when the programming data from the peripheral bus is less than 16 bytes. The programming data for the data MRAM is generated from the data at the target address and the data from the peripheral bus. If a TED error occurs when reading data from the target address and the data from the peripheral bus is less than 16 bytes, the programming data for the data MRAM cannot be generated correctly. When programming an address where this flag is set to 1, all 16 bytes of data must be input from the peripheral bus.

This flag can only be written as 0; writing 1 is ignored.

[Setting condition]

- When an uncorrectable error occurs, and the programming from the peripheral bus is less than 16 bytes, and the PRGERRD flag is 0

[Clearing condition]

- 0 is written after reading 1 from this flag.

ABUFEMPD Flag (Data MRAM Address Buffer Empty Flag)

This flag indicates the status of the programming address buffer for the data MRAM. When the address buffer is empty,

this flag becomes 1. When this flag is 1, writing to the MRDFLR.MRDFL bit is not possible, so programming data cannot be flashed.

ABUFFULLD Flag (Data MRAM Address Buffer Full Flag)

This flag indicates the status of the address buffer for programming the data MRAM. When the address buffer is full, this flag becomes 1. When this flag is 1, new write transactions are not accepted until programming to the data MRAM starts or ends.

PRGBSYD Flag (Data MRAM Programming Status Flag)

This flag indicates the programming status of the data MRAM. If CPSEQ executes the data MRAM programming processing, this flag is set to 1. When this flag is 1, a new read transaction to the data MRAM cannot be accepted until the data MRAM programming finishes.

65.5.44 Data MRAM Program Access Error Interrupt Enable Register (MRDPAEINT)

Address(es): MRAM.MRDPAEINT 8709 F414h, MRAM_NS.MRDPAEINT 0709 F414h

	b7	b6	b5	b4	b3	b2	b1	b0
	MRDAEIE	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	MRDAEIE	Data MRAM Program Access Error Interrupt Enable	0: Generation of MRDPRI interrupt requests is disabled. 1: Generation of MRDPRI interrupt requests is enabled.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MRDPAEINT register is used to enable or disable the generation of data MRAM access error (MRDPRI) interrupt requests.

MRDAEIE Bit (Data MRAM Program Access Error Interrupt Enable)

This bit is used to enable the generation of data MRAM access error (MRDPRI) interrupt requests.
When the MRDPS.PRGERRD flag or MRDPS.ECCERRD flag is 1, an MRDPRI interrupt request is generated if this bit is 1. If this bit is 0, an MRDPRI interrupt request is not generated.

65.5.45 Data MRAM Program Error Address Register (MRDPEA)

Address(es): MRAM.MRDPEA 8709 F418h, MRAM_NS.MRDPEA 0709 F418h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MDPEA[27:12]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MDPEA[11:0]												—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31 to b4	MDPEA[27:0]	Data MRAM Program Error Address	Stores the error address when a data MRAM program error occurs.	R

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MRDPEA register is used to store the error address when a data MRAM program error occurs.

MDPEA[27:0] Bits (Data MRAM Program Error Address)

[Update condition]

- When a program error or ECC error occurs while the MRDPS.PRGERRD flag is 0 and the MRDPS.ECCERRD flag is 0, the error address is stored in the MRDPEA register.

65.5.46 Data MRAM Flush Register (MRDFLR)

Address(es): MRAM.MRDFLR 8709 F430h, MRAM_NS.MRDFLR 0709 F430h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	MRDFL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MRDFL	Flush Write Data Buffer for Data MRAM	0: Not execute to flush program data buffer 1: Execute to flush program data buffer	R/W *1, *2
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	The MRDFL bit protection key code	R/W *3

Note 1. When the ABUFEMPD flag in the MRDPS register is 1, it is not possible to write 1 to this bit.
Note 2. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to C4h.
Note 3. Written values are not retained by these bits. These bits are read as 0.

The MRDFLR register is used for programming data less than 16 bytes.

MRDFL Bit (Flush Write Data Buffer for Data MRAM)

This bit is used for starting data MRAM programming operation.

[Setting condition]

- When C401h is written to the MRDFLR register while the MRDPS.ABUFEMPD flag is 0.

[Clearing condition]

- When the ABUFEMPD flag in the MRDPS register is set to 1.

KEY[7:0] Bits (Key Code)

The KEY[7:0] bits control permission and prohibition of writing to the MRDFL bit.

To write to the MRDFL bit, write C4h to the KEY[7:0] bits at the same time. If a value other than C4h is written, the MRDFL bit will not be updated. When read, it will read 00h.

65.5.47 Data MRAM Program Ready Interrupt Control Register (MRDPRICR)

Address(es): MRAM.MRDPRICR 8709 F440h, MRAM_NS.MRDPRICR 0709 F440h

	b7	b6	b5	b4	b3	b2	b1	b0
	MRDPRRIE	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	MRDPRRIE	Data MRAM Program Ready Interrupt Enable	0: Generation of program ready interrupt request is disabled. 1: Generation of program ready interrupt request is enabled.	R/W *1

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

Note 1. It is prohibited to set the MRCPRICR.MRCPRRIE bit and the MRDPRICR.MRDPRRIE bit to 1 at the same time.

The MRDPRICR register is used to enable or disable the generation of MRAM program ready (MRPRRI) interrupt requests.

MRDPRRIE Bit (Data MRAM Program Ready Interrupt Enable)

This bit is used to enable the generation of MRAM program ready (MRPRRI) interrupt requests.
When programming to the data MRAM, a program ready interrupt request can be generated if the MRDPS.ABUFFULLD flag is 0. Writing 1 to this bit generates the first interrupt request. After that, when a write transaction to the data MRAM is accepted, an interrupt request is generated.

65.5.48 Code MRAM ECC Encoder Control Register (MRCEECC)

Address(es): MRAM.MRCEECC 8709 F804h, MRAM_NS.MRCEECC 0709 F804h

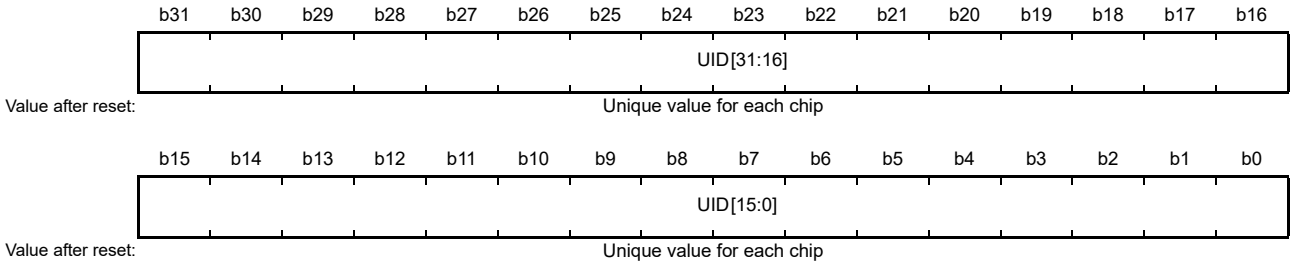
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	ECCBYPC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECCBYPC	Code MRAM ECC encoder outputs bypass enable	0: ECC bypass is disabled. 1: ECC bypass is enabled.	R/W*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	The ECCBYPC bit protection key code	R/W*2

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.
Note 1. Writing to these bits is possible only when this register is written in 16-bit units with the KEY[7:0] bits set to CDh.
Note 2. Written values are not retained by these bits. These bits are read as 0.

The MRCEECC register is used to enable the bypass function of the ECC encoder output of the code MRAM.
It is used to test the ECC decoder circuit of the code MRAM. For information on the ECC decoder circuits test flow, see section 65.9.6, Fault Correction and Detection.

ECCBYPC Bit (Code MRAM ECC encoder outputs bypass enable)



This bit enables the function to bypass the ECC encoder output of the code MRAM.
When the ECCBYPC bit is 0, the ECC bits of the code MRAM are the ECC encoder output.
When the ECCBYPC bit is 1, the ECC bits of the code MRAM are bits [144:128,16:0] of the write data.

KEY[7:0] Bits (Key Code)

The KEY[7:0] bits control permission and prohibition of writing to the ECCBYPC bit.
To write to the ECCBYPC bit, write CDh to the KEY[7:0] at the same time. If a value other than CDh is written, the ECCBYPC bit will not be updated. When read, it will return 00h.

65.5.49 Unique ID Register n (UIDRn) (n = 0 to 3)

Address(es): NVMCONST.UIDR0 86F0 1000h, NVMCONST.UIDR1 86F0 1004h, NVMCONST.UIDR2 86F0 1008h, NVMCONST.UIDR3 86F0 100Ch, NVMCONST_NS.UIDR0 06F0 1000h, NVMCONST_NS.UIDR1 06F0 1004h, NVMCONST_NS.UIDR2 06F0 1008h, NVMCONST_NS.UIDR3 06F0 100Ch

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	UID	Unique ID	Unique ID for individual identification	R

The UIDRn register is a read-only register that stores a 16-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units.

65.5.50 Part Numbering Register n (PNRn) (n = 0 to 3)

Address(es): NVMCONST.PNR0 86C1 2C38h, NVMCONST.PNR1 86C1 2C3Ch, NVMCONST.PNR2 86C1 2C40h, NVMCONST.PNR3 86C1 2C44h, NVMCONST_NS.PNR0 06C1 2C38h, NVMCONST_NS.PNR1 06C1 2C3Ch, NVMCONST_NS.PNR2 06C1 2C40h, NVMCONST_NS.PNR3 06C1 2C44h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PNR[31:16]															
Value after reset:	Unique value for each chip															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PNR[15:0]															
Value after reset:	Unique value for each chip															

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	PNR	Part Number	Part Number Information	R

The PNRn register is a read-only register that stores a 16-byte part numbering. The PNRn register should be read in 32-bit units. Each byte corresponds to the ASCII code representation of the product part number as detailed in Table 1.3, List of Products. The first character of the part number (ASCII code “R”, 52h) is stored in b0 to b7 of the PNR0 register. When reading with the signature request command of the serial programming interface, data is read in order from the lowest address data.

65.5.51 MCU Version Register (MCUVER)

Address(es): NVMCONST.MCUVER 86C1 2C48h, NVMCONST_NS.MCUVER 06C1 2C48h

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	MCUVE	MCU Version	MCU Version Information	R

The MCUVER is a read-only register that stores a MCU version. The MCUVER register should be read in 8-bit units.

65.5.52 MRAM-OTP Write Mode Control Register (MWMCR)

Address(es): SYSC.MWMCR 8701 9AB4h, SYSC_NS.MWMCR 0701 9AB4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	MWM[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	MWM[1:0]	MRAM-OTP Write Mode	b1 b0 0 0: Normal speed write mode 0 1: High speed write mode 0 1 0: High speed write mode 1 1 1: Prohibited	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: When this register is set to the secure attribute, it is accessible by secure transactions. Any access by non-secure transaction is ignored, and a Protect Zone access error is generated.
When this register is set to the non-secure attribute, it is accessible by non-secure transactions. Any access by secure transaction is ignored, and a Protect Zone access error is generated.

The MWMCR register controls the MRAM-OTP write mode when writing data to MRAM-OTP.

MWM[1:0] Bits (MRAM-OTP Write Mode)

1. MWM[1:0] = 00: MRAM-OTP is set to MRAM-OTP normal speed write mode.
   You can set MWM[1:0] to 00 in the case that 1.62V ≤ VCC ≤ 3.63V.
   Refer to the write period of MRAM-OTP normal speed write mode to section 67, Electrical Characteristics.
2. MWM[1:0] = 01: MRAM-OTP is set to MRAM-OTP high speed write mode 0.
   You can set MWM[1:0] to 01 in the case that 2.5V ≤ VCC ≤ 3.63V.
   Refer to the write period of MRAM-OTP high speed write mode 0 to section 67, Electrical Characteristics.
3. MWM[1:0] = 10: MRAM-OTP is set to MRAM-OTP high speed write mode 1.
   You can set MWM[1:0] to 10 in the case that 3.0V ≤ VCC ≤ 3.63V.
   Refer to the write period of MRAM-OTP high speed write mode 1 to section 67, Electrical Characteristics.

65.6 Operating Mode

65.6.1 MRAM Read/Program Mode

The code MRAM and extra MRAM have modes for reading and programming as shown in Figure 65.16.
A transition from code MRAM read mode to code MRAM program mode is started by a request for programming generated under one of the following conditions.

- The program data buffer has become full.
- The last address of the code MRAM where data have been written is beyond the 16-byte boundary of the addresses at which the data stored in the program data buffer are to be programmed.
- The MRCFLR.MRCFL bit is set to 1.

Programming of the code MRAM automatically begins after a transition to code MRAM program mode. When programming of the code MRAM is completed, operation automatically switches from code MRAM program mode to code MRAM read mode.

Transitions between extra MRAM read mode and extra MRAM program mode are initiated by changing the value of the MENTRYR register, by issuing a request for programming of the data MRAM, or by W-HUK zeroization (see section 65.8.6, HUK Protection).
The MRAM is in extra MRAM read mode when the MENTRYR register is set to 0000h, no request for programming of the data MRAM is issued, and W-HUK zeroization is not executed.
MRAM is in extra MRAM program mode in other cases.
Programming of the extra MRAM can be started by using an MACI command while the MENTRYR register is set to 0080h, by issuing a request for programming of the data MRAM while the MENTRYR register is set to 0000h, or by starting W-HUK zeroization.

A transition to extra MRAM program mode for programming of the data MRAM is started by a request for programming generated under one of the following conditions.

- The program data buffer has become full.
- The last address of the data MRAM where data have been written is beyond the 16-byte boundary of the addresses at which the data stored in the program data buffer are to be programmed.
- The MRDFLR.MRDFL bit is set to 1.

Programming of the data MRAM automatically begins after a transition to extra MRAM program mode. When programming of the data MRAM is completed, operation automatically switches from extra MRAM program mode to extra MRAM read mode.

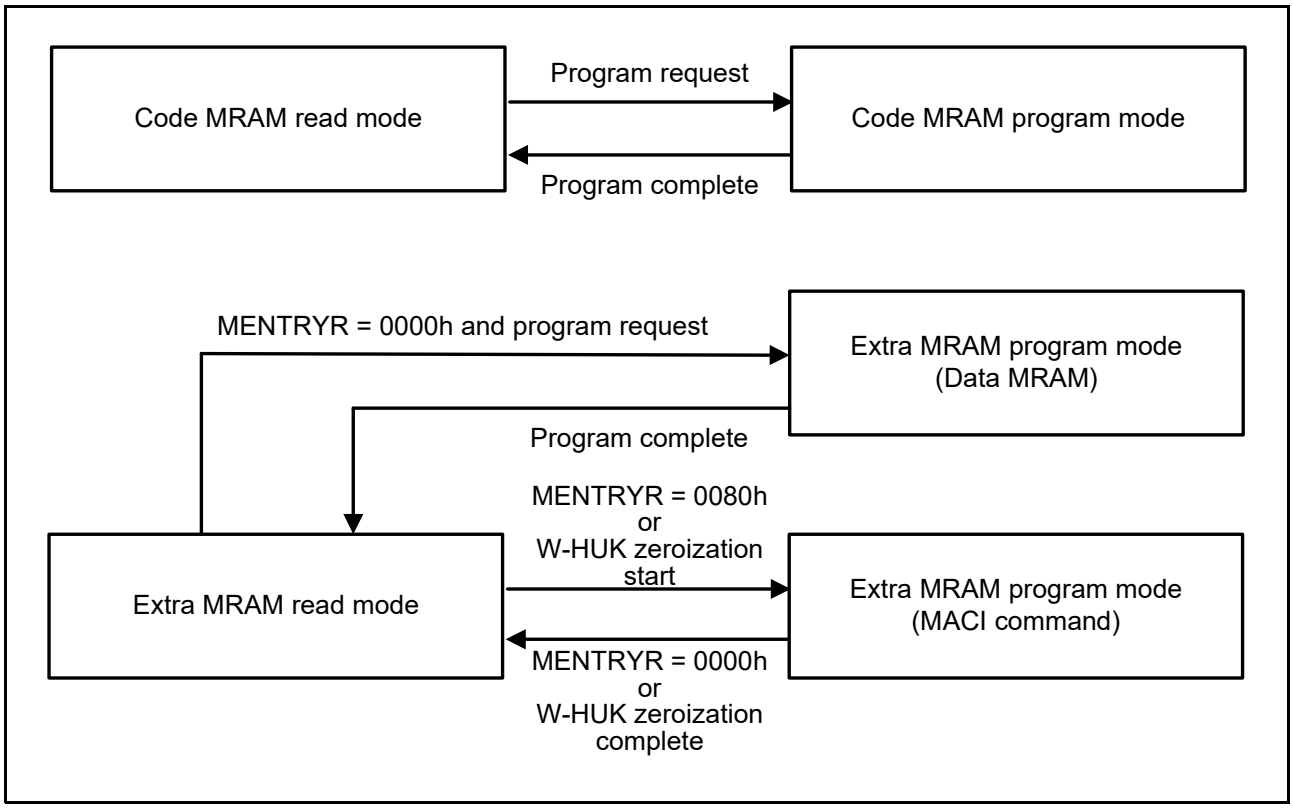


Figure 65.16 MRAM Read/Program Mode Transition

65.6.2 MRAM High-Speed Program Mode

MRAM has normal program mode and high-speed program mode, as shown in Figure 65.17, and the same mode settings apply to both code MRAM program mode and extra MRAM program mode.
In normal program mode, when the MHSPEN bit of the MRPSC register is set to 1 in the “MHSPM disabled” state, the system transitions to the MHSPM startup preparation state.
Executing an MRAM program once in the MHSPM startup preparation state transitions to high-speed program mode.
Setting the MHSPEN bit to 0 transitions from high-speed program mode to normal program mode.
The MRAM program mode enters the MHSPM startup preparation state when the MCU is in standby mode.
The setting of the MHSPEN bit is retained in standby mode, so after wake-up, programming MRAM or extra MRAM once transitions the MRAM program mode to high-speed program mode.

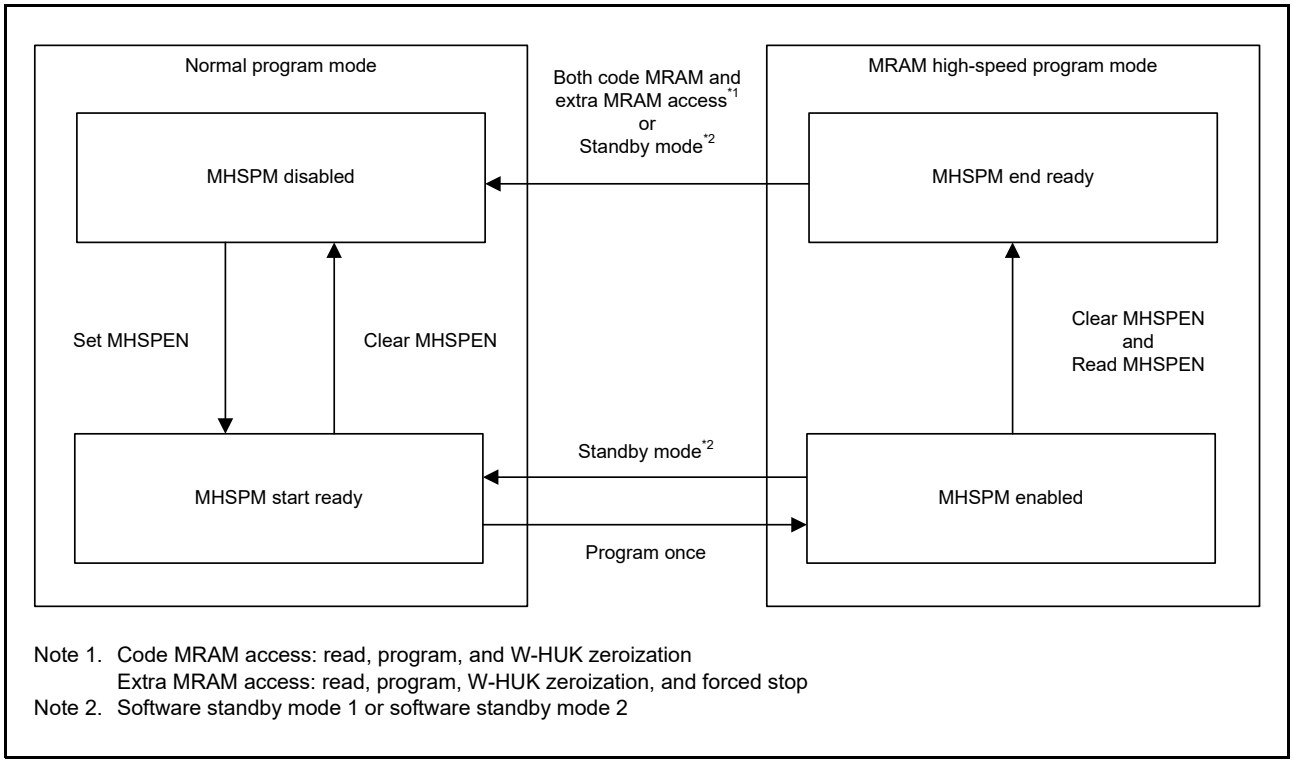

Figure 65.17 High-Speed Program Mode Transition

65.7 MACI Commands

65.7.1 Programmable Area with MACI Commands

Table 65.12 shows the MRAM and OTP areas in extra MRAM that can be programmed with the MACI command. These areas store setting data for security, safety, and system configuration. Each bit (both data and ECC) in OTP area is allowed to be programmed only one time from 1 to 0.

There are two types of OTP areas with ECC and without ECC as shown in Table 65.12. A unit of 16 bytes data can be programmed only once to OTP area with ECC. Reprogramming of different data cannot be retried because some bits of ECC may need to change from 0 to 1. Reliability of OTP area without ECC is secured by redundant data configuration. A unit of 16 bytes data can be programmed multiple times to OTP area without ECC in case that there is no bit changing from 0 to 1.

Table 65.12 Programmable Area with MACI Commands

Address (Offset address: BASE_ME)	Area Name	Memory Type	ECC
00C2 E820h to 00C2 E9FFh	Secure OFS configuration	MRAM	Use
00C4 EC20h to 00C4 EC7Fh	Non-secure OFS configuration	MRAM	Use
00C9 F050h to 00C9 F7FFh	Configuration	MRAM	Use
00D8 0000h to 00D9 FFFFh	User extra MRAM area	MRAM or OTP	Use
00E0 0400h to 00E0 040Fh	FSBL setting	OTP	Use
00E0 0410h to 00E0 049Fh	Start address of measurement report Start address of code certificate	OTP	Use
00E0 04A0h to 00E0 04FFh	General purpose OTP	OTP	Use
00E1 0610h to 00E1 061Fh	Secure OFS OTP memory type setting	OTP	Use
00E1 0620h to 00E1 06EFh	Secure OFS OTP setting	MRAM or OTP	Use
00E1 0710h to 00E1 07FFh	Secure OFS OTP setting	MRAM or OTP	Use
00E1 0A00h to 00E1 0A7Fh	Permanent block protect setting for secure*1	OTP	Don't use
00E1 0A80h to 00E1 0A9Fh	Data MRAM permanent block protection setting for secure	OTP	Don't use
00E2 0810h to 00E2 081Fh	Non-secure OFS OTP memory type setting	OTP	Use
00E2 0820h to 00E2 087Fh	Non-secure OFS OTP setting	MRAM or OTP	Use
00E2 0C00h to 00E2 0C7Fh	Permanent block protect setting for non-secure*2	OTP	Don't use
00E2 0C80h to 00E2 0C9Fh	Data MRAM permanent block protection setting for non-secure	OTP	Don't use
00E3 0E00h to 00E3 0E0Fh	Secure OFS OTP setting protect setting	OTP	Don't use
00E3 0E10h to 00E3 0E1Fh	REVOKE	OTP	Don't use
00E3 0E20h to 00E3 0E2Fh	Zeroization HUK in OTP enable	OTP	Don't use
00E3 0E30h to 00E3 0E3Fh	Anti-rollback counter setting	OTP	Don't use
00E3 0E50h to 00E3 0E5Fh	User Extra MRAM	OTP	Don't use
00E3 0E60h to 00E3 0E6Fh	Secure OFS setting protect setting	OTP	Don't use
00E3 0E80h to 00E3 0E8Fh	Non-secure OFS OTP setting protect setting	OTP	Don't use
00E3 0EE0h to 00E3 0EEFh	Non-secure OFS setting protect setting	OTP	Don't use
00E3 0EF0h to 00E3 0EFFh	Reserved	OTP	Don't use
—	Anti-rollback counter	OTP	Don't use

Note 1. The PBPSm_S[n] bit can be programmed to 0 when the BPSn_S.BPi[3:0] bits are 0000b.
Note 2. The PBPSm_NS[n] bit can be programmed to 0 when the BPSn_NS.BPi[3:0] bits are 0000b.

65.7.2 List of MACI Commands

Table 65.13 List of MACI Commands

MACI Command	Function
Program	This is used to program extra MRAM area except for the configuration area. The program unit is 16 bytes.
Status Clear	This initializes the ILGLERR, PRGERR, ILGCOMERR, OTERR, PZFERR, CFGPRGERR, and PROTERR flags in the MSTATR register and the CMDLK and MREAE flags in the MASTAT register, and the extra MRAM sequencer released from command-locked state.
Forced Stop	This forcibly stops processing of MACI commands and initializes the MSTATR and MASTAT register.
Configuration Set	This is used to program configuration area for setting security function and safety function Units of setting are 16 bytes.
Increment Counter (secure access only)	Anti-rollback counter value can be incremented. The target of counter is selected by the MCNTSELR register. Update data unit is 1 bit.
Read Counter (secure access only)	The value of the OFSM.ARCOEMBL register can be read. Reading data is output to the MCNTDTR0 and MCNTDTR1 registers. Read unit is 64 bit.

The MACI commands are issued by writing to the MACI command-issuing area (4 bytes starting at 8708 0000h). When write access as shown in Table 65.15 proceeds in the specified state, the extra MRAM sequencer executes the processing corresponding to the given command (see section 65.7.3, Relationship Between the Extra MRAM Sequencer State and MACI Commands).

Table 65.14 MACI Command Formats

MACI Commands	Number of Write Access	Write Data to the MACI Command-Issuing Area			
		1st Access	2nd Access	3rd to (N+2)th Access	(N+3)th Access
Program 16-byte programming: N = 8	N + 3	E8h	08h (= N)	WD1 to WDN	D0h
Status Clear	1	50h	—	—	—
Forced Stop	1	B3h	—	—	—
Configuration set N = 8 (16 Bytes)	N + 3	40h	08h (= N)	WD1-WDn	D0h
Increment Counter	2	35h	D0h	—	—
Read Counter	2	39h	D0h	—	—

Note: WDN (N = 1, 2,…): Nth 16-bit data to be programmed.

The extra MRAM sequencer clears the MSTATR.MRDY flag to 0 at the start of processing of a command other than the status clear command and sets this flag to 1 on completion of command processing.
If the setting of the MRDYIE.MRDYIE bit is 1, MRDYI interrupt is generated when the MSTATR.MRDY flag is set to 1.

65.7.3 Relationship Between the Extra MRAM Sequencer State and MACI Commands

The MACI commands are accepted according to the mode/state of the extra MRAM sequencer. MACI commands should be issued after the transition to the extra MRAM program mode and checking of the state of the extra MRAM sequencer. Use the MSTATR and MASTAT registers to check the state of the extra MRAM sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the MASTAT register; its value is the logical OR of the ILGLERR, ILGCOMERR, OTERR, PZFERR, PRGERR, CFGPRGERR, and PROTERR flags in the MSTATR register. Table 65.15 lists the available commands in each operating mode.

Table 65.15 Operating Mode and Available Commands

Operation Mode	MENTRYR	Available Commands
MRE/MRD read mode MRD program mode	0000h	None
Extra MRAM program mode (W-HUK zeroization is not executed)	0080h	Program Status Clear Forced Stop Configuration Increment Counter Read Counter
Extra MRAM program mode (W-HUK zeroization is executed)	0000h/0080h*1	None

Note 1. MRAM is in extra MRAM program mode when W-HUK zeroization is executed regardless of MENTRYR value.

Table 65.16 shows the state of the extra MRAM sequencer and acceptable MACI commands. An appropriate mode is assumed to have been set before the commands are executed.

Table 65.16 Acceptable MACI Commands and the State of the Extra MRAM Sequencer

	Program, Configuration Set, Increment Counter, Read Counter, Forced Stop Command Processing	Command-Locked State (MRDY = 1)	Command-Locked State (MRDY = 0)	W-HUK Zeroization is Executed	Other State
MRDY flag	0	1	0	0/1	1
CMDLK bit	0	1	1	0/1	0
Program	×	×	×	×	✓
Status Clear	×	✓	×	×	✓
Forced Stop	✓	✓	✓	×	✓
Configuration set	×	×	×	×	✓
Increment Counter	×	×	×	×	✓
Read Counter	×	×	×	×	✓

✓: Acceptable
×: Not acceptable (places the sequencer in the command-locked state)

65.7.4 Usage of MACI Commands

This section gives an overview of the usage of MACI commands.

65.7.4.1 Overview of Command Usage in Extra MRAM Program Mode

An overview of MACI command usage in extra MRAM program mode is shown below. For which commands are available in extra MRAM program mode, Table 65.15, Operating Mode and Available Commands.

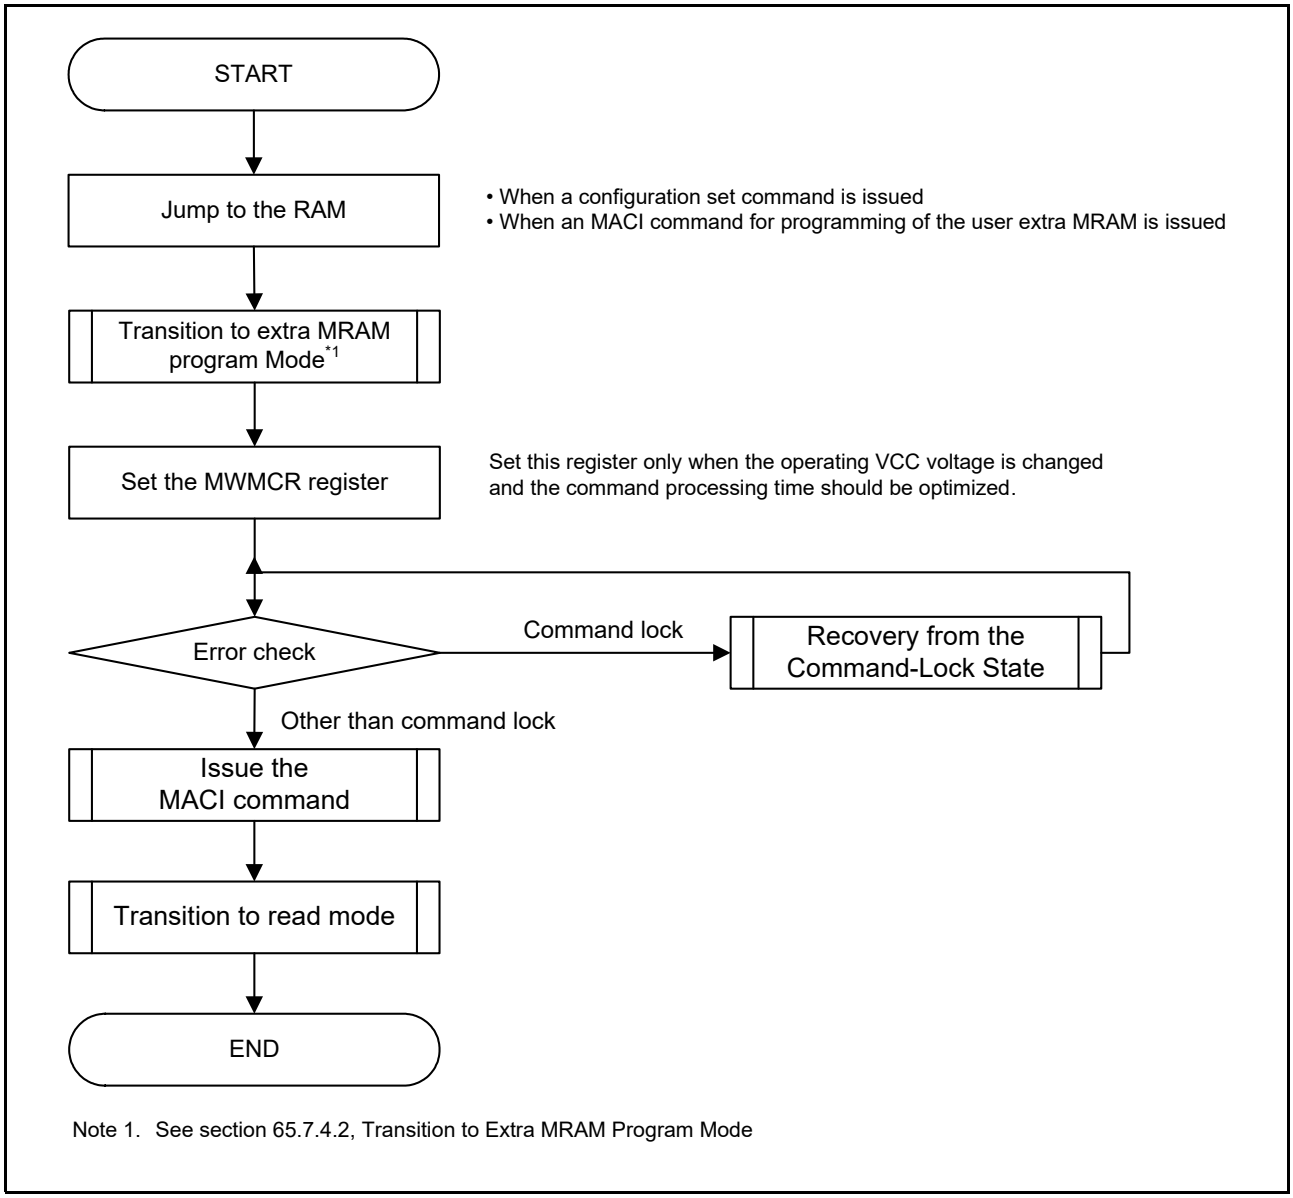

Figure 65.18 Overview of Command Usage in Extra MRAM Program Mode

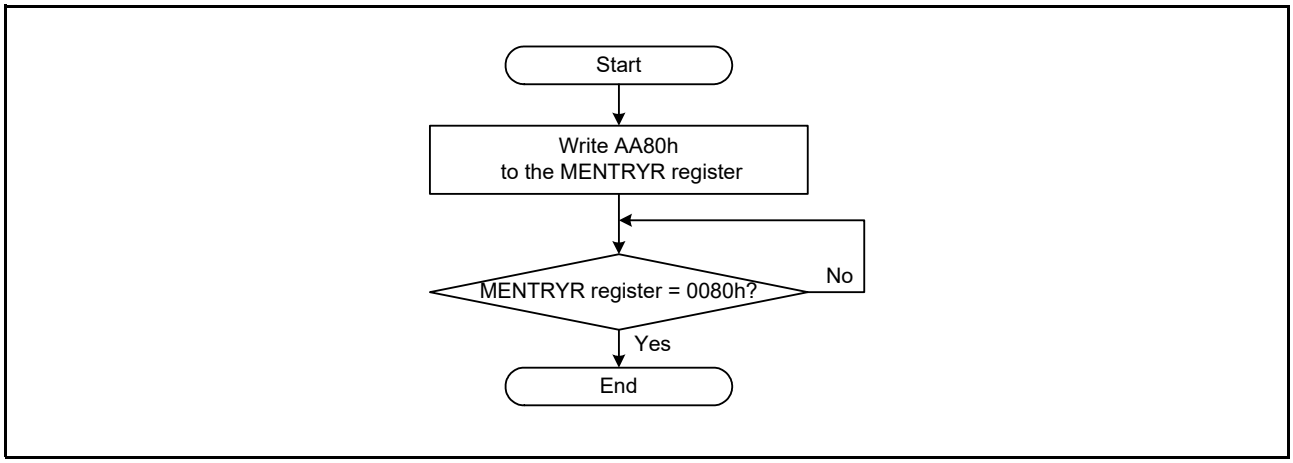
65.7.4.2 Transition to Extra MRAM Program Mode

To issue the MACI commands for the extra MRAM, a transition to extra MRAM program mode is required. To cause the transition to extra MRAM program mode, set the MENTRY bit in the MENTRYR register to 1.



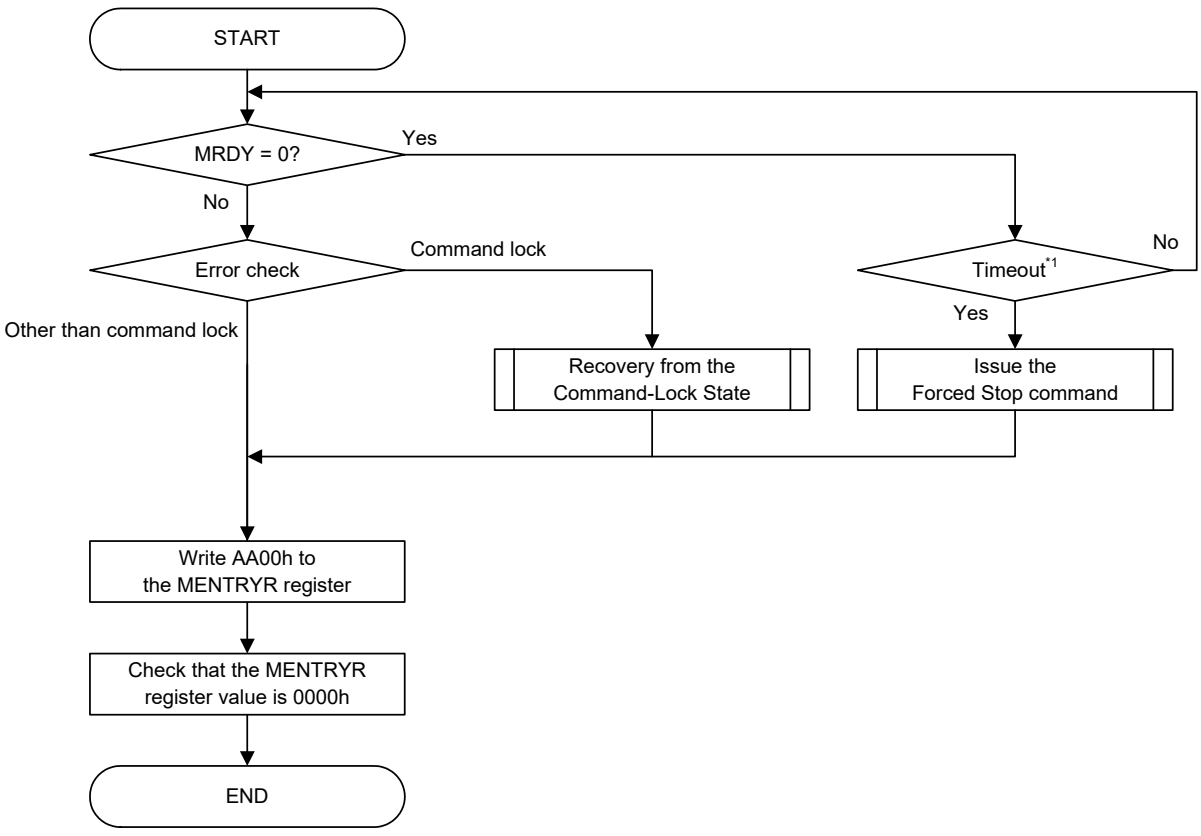


Figure 65.19 Procedure for Transition to Extra MRAM Program Mode

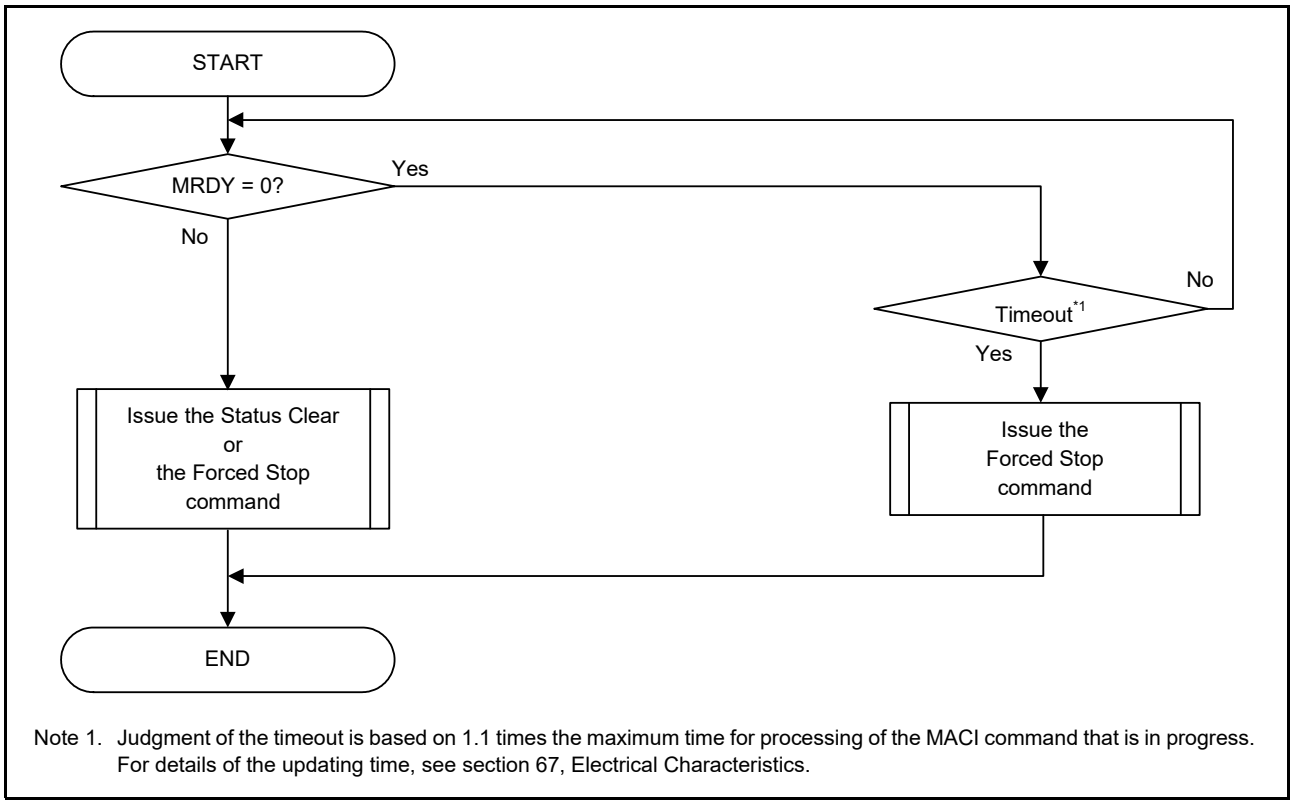
65.7.4.3 Transition to Read Mode

To read the extra MRAM, the MRDY flag in the MSTATR register must be set to 1 or a transition to read mode is required. To cause a transition to read mode, set the MENTRYR register to 0000h. The transition to read mode should be made while processing by the Extra MRAM sequencer is completed and the operation is in a state other than command locked.

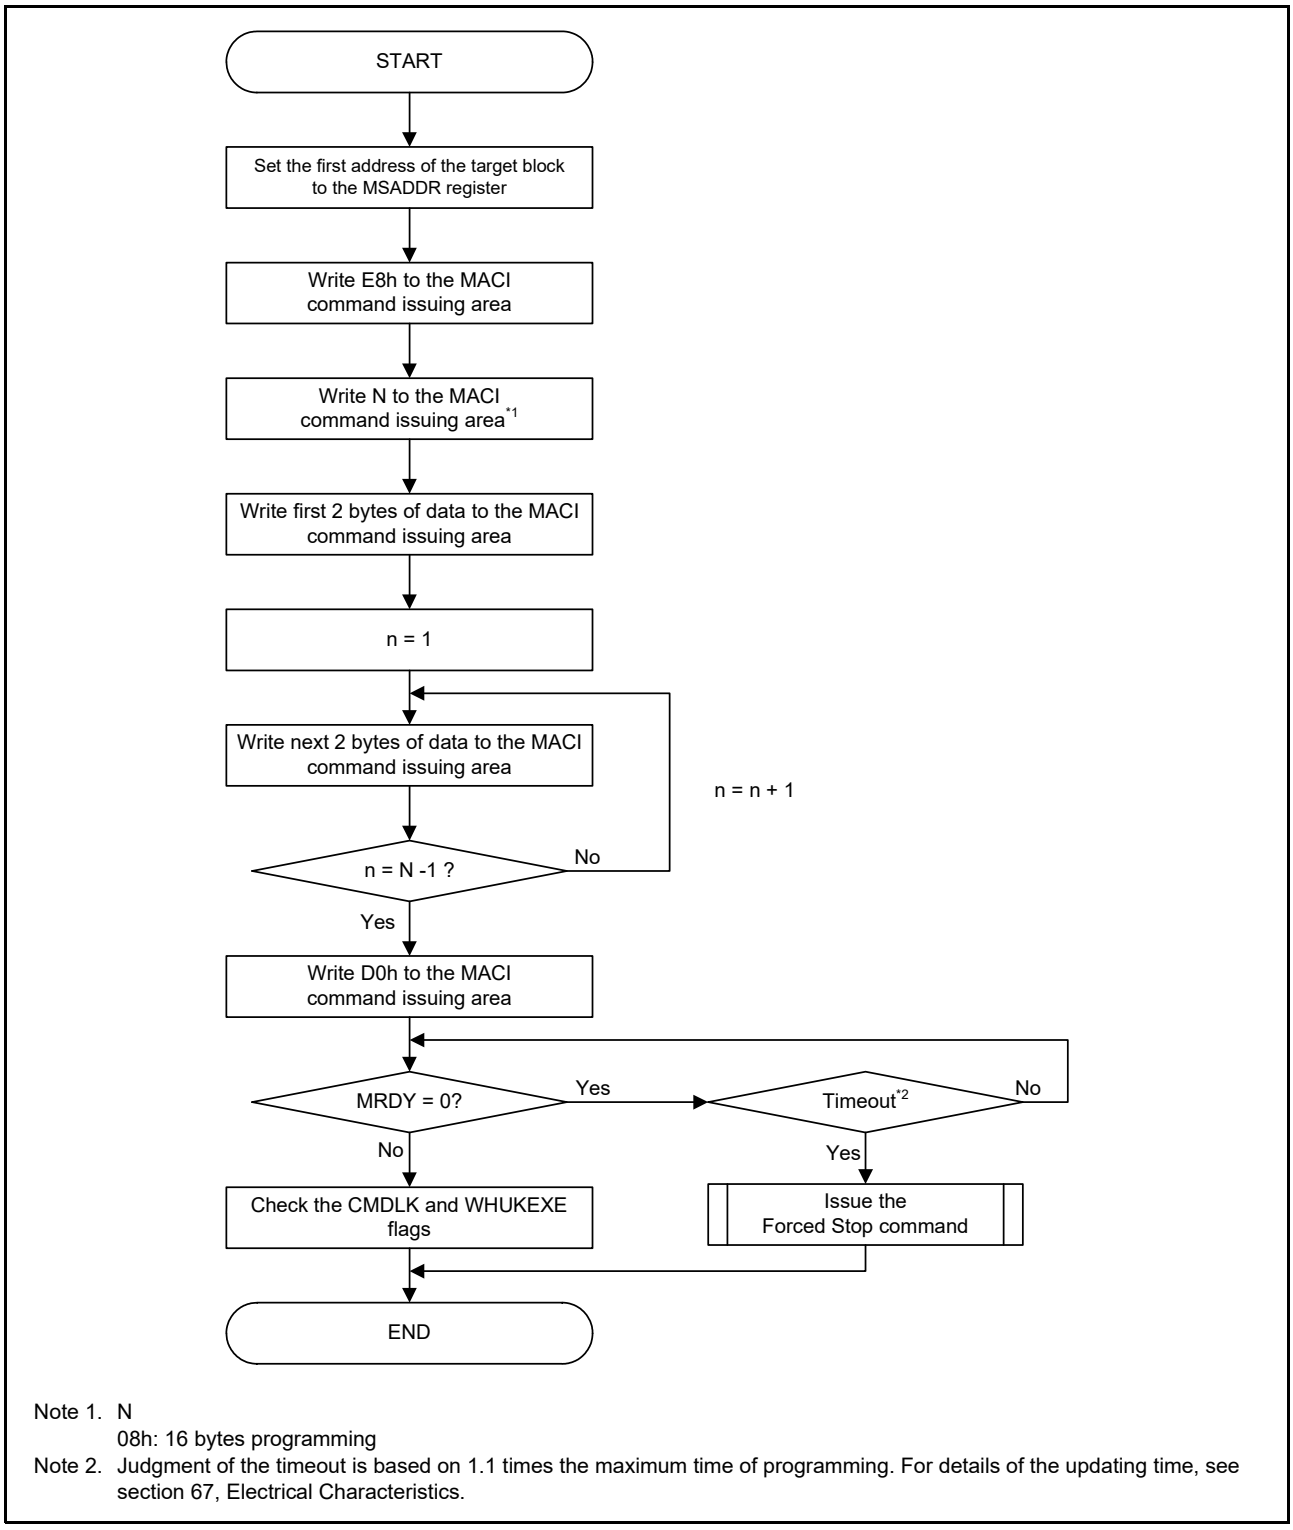


Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the MACI command that is in progress. For details of the updating time, see section 67, Electrical Characteristics.

Figure 65.20 Procedure for Transition to Read Mode

65.7.4.4 Recovery from the Command-Locked State

When the extra MRAM sequencer enters the command-locked state, MACI commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, forced stop command.
If processing is not completed in time beyond the maximum programming time specified in the electrical characteristics, this can be considered a timeout, and the extra MRAM sequencer should be stopped by the forced stop command.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the MACI command that is in progress. For details of the updating time, see section 67, Electrical Characteristics.

Figure 65.21 Recovery from the Command-Locked State

65.7.4.5 Program Command

The program command is used for programming to the extra MRAM area, excluding the configuration area. Before issuing the program command, set the first address of the target block in the MSADDR register.
Writing D0h to the MACI command-issuing area at the final access of the MACI command-issuing starts the program command processing.

Note 1. N
08h: 16 bytes programming
Note 2. Judgment of the timeout is based on 1.1 times the maximum time of programming. For details of the updating time, see section 67, Electrical Characteristics.

Figure 65.22 Usage of the Program Command

The correspondence between the possible target data and the address value set in the MSADDR register is shown in Table 65.17. For details on the MSADDR register, see section 65.5.20, MACI Command Start Address Register (MSADDR).

Table 65.17 Address Used by Program Command

Address	MSADDR Register Value	Setting Data	Timing when the Setting is Enabled
BASE_ME+00D8 0000h	BASE_MES + 00D8 0000h to BASE_MES + 00D9 FFF0h	User extra MRAM	—
BASE_ME+00E0 0400h	BASE_MES + 00E0 0400h	FSBL setting	At a reset
BASE_ME+00E0 0410h	BASE_MES + 00E0 0410h to BASE_MES + 00E0 0490h	Start address of measurement report Start address of code certificate	—
BASE_ME+00E0 04A0h	BASE_MES + 00E0 04A0h to BASE_MES + 00E0 04F0h	GPOTP	—
BASE_ME+00E1 0610h	BASE_MES + 00E1 0610h	Secure OFS OTP memory type selection	When a reset or command is executed
BASE_ME+00E1 0620h	BASE_MES + 00E1 0620h to BASE_MES + 00E1 06E0h	Secure OFS OTP setting	At a reset
BASE_ME+00E1 0710h	BASE_MES + 00E1 0710h to BASE_MES + 00E1 07F0h	Secure OFS OTP setting	At a reset
BASE_ME+00E1 0A00h	BASE_MES + 00E1 0A00h to BASE_MES + 00E1 0A70h	Permanent block protect setting for secure	When a reset or command is executed
BASE_ME+00E1 0A80h	BASE_MES + 00E1 0A80h to BASE_MES + 00E1 0A90h	Data MRAM permanent block protection setting for secure application	When a reset or command is executed
BASE_ME+00E2 0810h	BASE_MEN + 00E2 0810h	Non-secure OFS OTP memory type selection	When a reset or command is executed
BASE_ME+00E2 0820h	BASE_MEN + 00E2 0820h to BASE_MEN + 00E2 0870h	Non-secure OFS OTP setting	At a reset
BASE_ME+00E2 0C00h	BASE_MEN + 00E2 0C00h to BASE_MEN + 00E2 0C70h	Permanent block protect setting	When a reset or command is executed

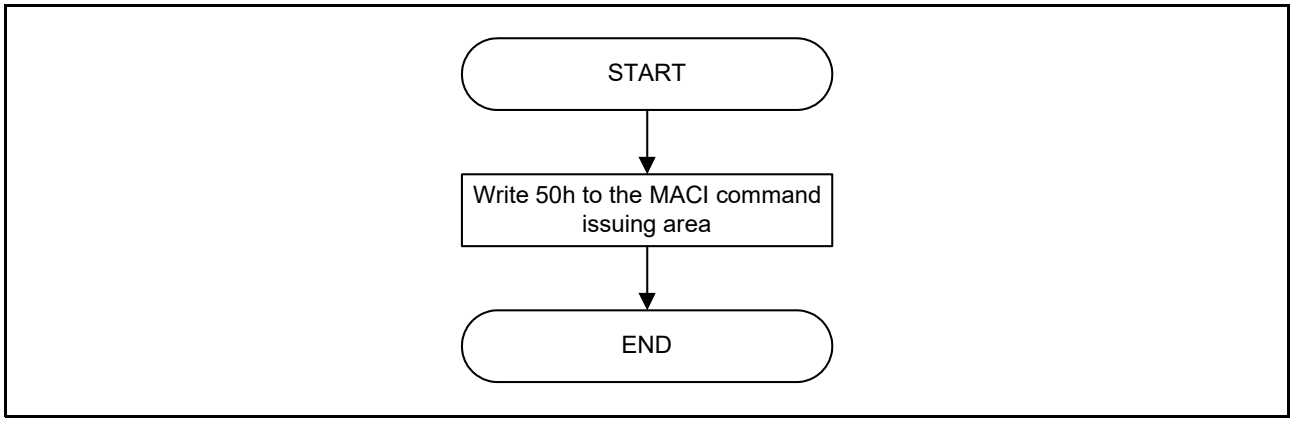
BASE_ME+00E3 0EF0h	BASE_MES + 00E3 0EF0h	Reserved	—

65.7.4.6 Status Clear Command

The Status Clear command is used to clear the command-locked state (see section 65.7.4.4, Recovery from the Command-Locked State). To clear the ILGLERR, ILGCOMERR, OTERR, PRGERR, PZFERR, CFGPRGERR, and PROTERR flags in the MSTATR register in the command-locked state, the Status Clear command is available.



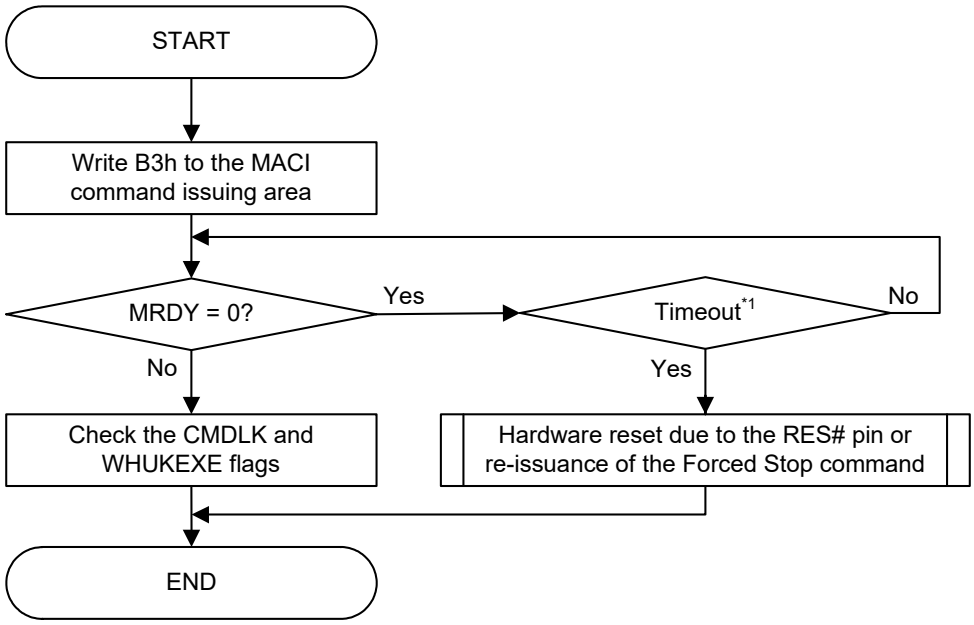


Figure 65.23 Usage of the Status Clear Command

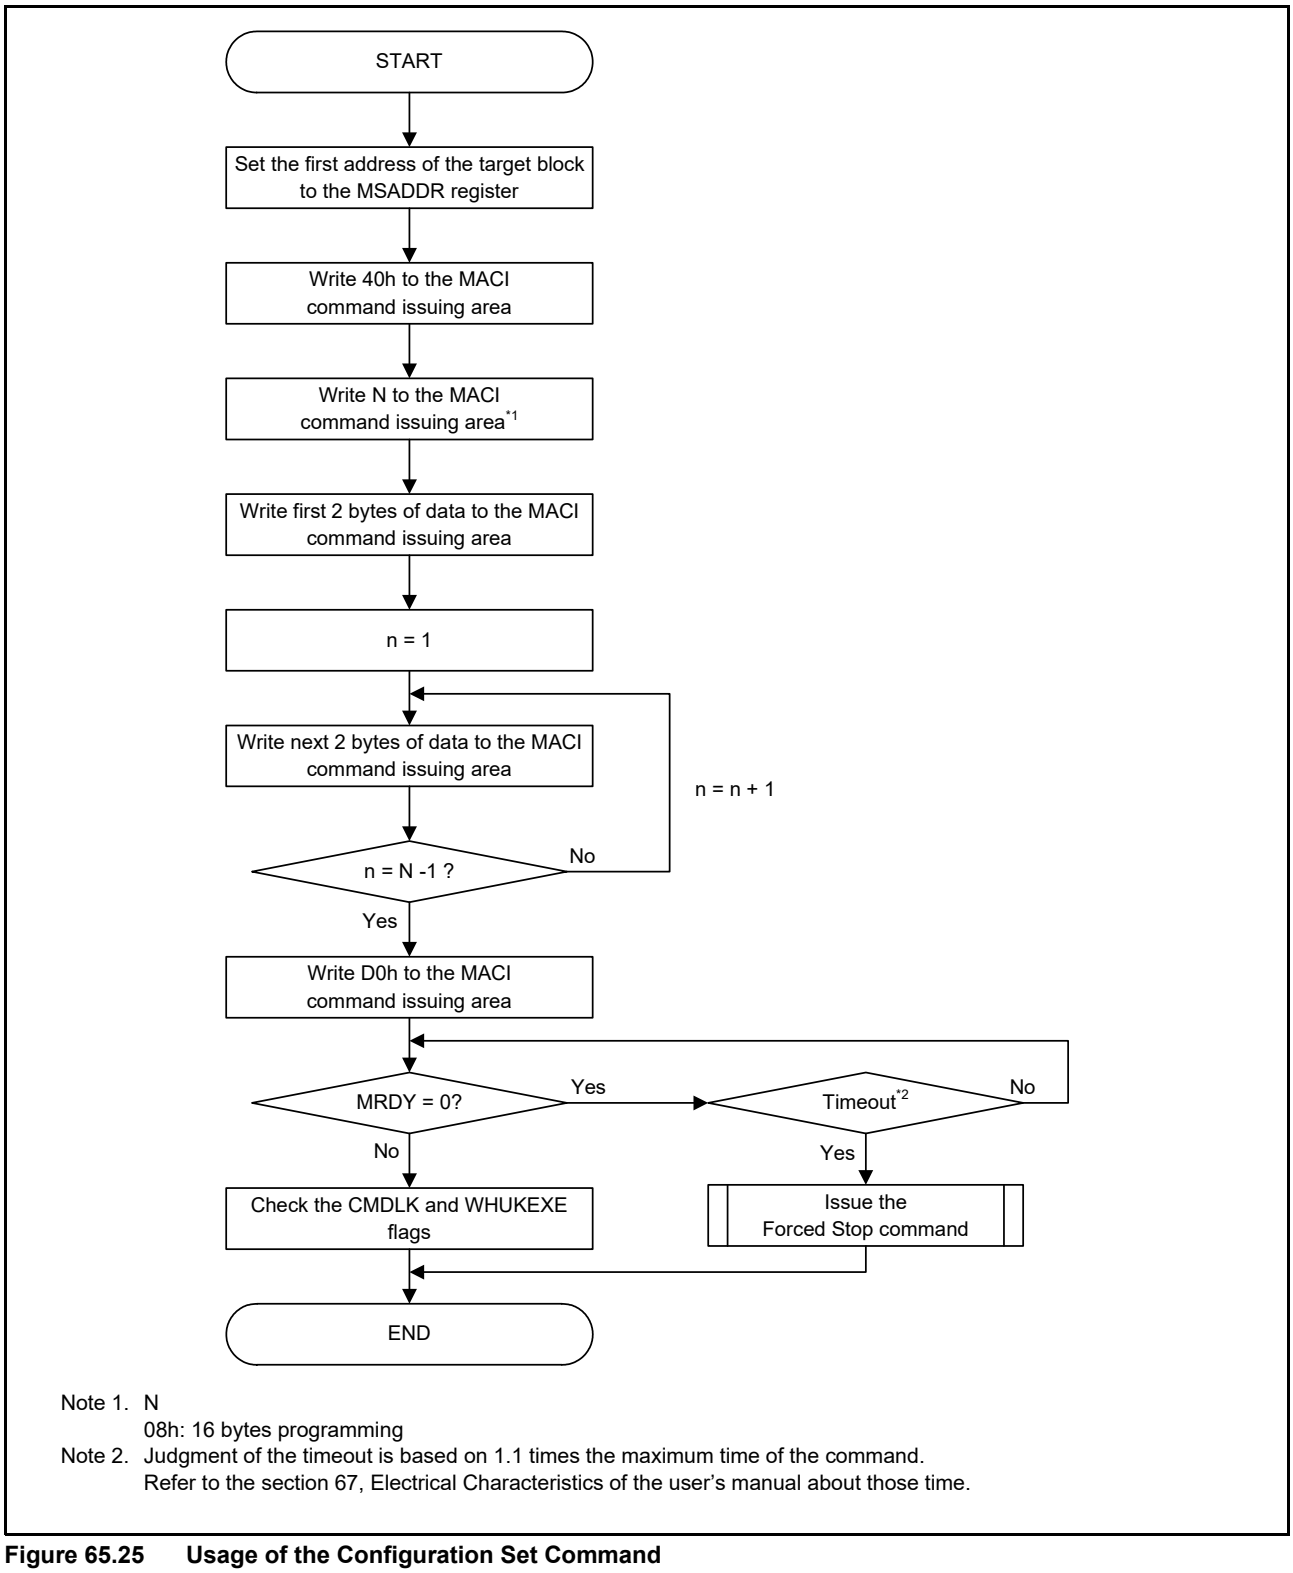
65.7.4.7 Forced Stop Command

The Forced stop command forcibly ends command processing by the extra MRAM sequencer. Although this command halts command processing, values from the programming that was in progress are not guaranteed. Furthermore, resumption of processing is not possible. Processing of programming that was halted by the Forced Stop command is also defined as one from the perspective of programming endurance.
Executing the Forced Stop command also initializes part of the MACI, the whole extra MRAM sequencer, the MSTATR register and the MASTAT register. Accordingly, this command can be used in the procedure for recovery from the command-locked state and in processing in response to a time-out of the extra MRAM sequencer (see section 65.7.4.4, Recovery from the Command-Locked State)



Note 1. Judgment of the timeout is based on 1.1 times the maximum time of the Forced Stop command latency. For details of the updating time, see section 67, Electrical Characteristics.

Figure 65.24 Usage of the Forced Stop Command

65.7.4.8 Configuration Set Command

The configuration set command is used to security function, safety function. Before issuing the configuration set command, set the specified address (shown in Table 65.18) in the MSADDR register. Writing D0h to the MACI command issuing area in the final access for issuing the MACI command starts MACI processing of the configuration set command.

Note 1. N
08h: 16 bytes programming
Note 2. Judgment of the timeout is based on 1.1 times the maximum time of the command.
Refer to the section 67, Electrical Characteristics of the user's manual about those time.

Figure 65.25 Usage of the Configuration Set Command

The correspondence between the possible target data for configuration setting and the address value set in the MSADDR register is shown in Table 65.18. For details on the MSADDR register, see section 65.5.20, MACI Command Start Address Register (MSADDR).

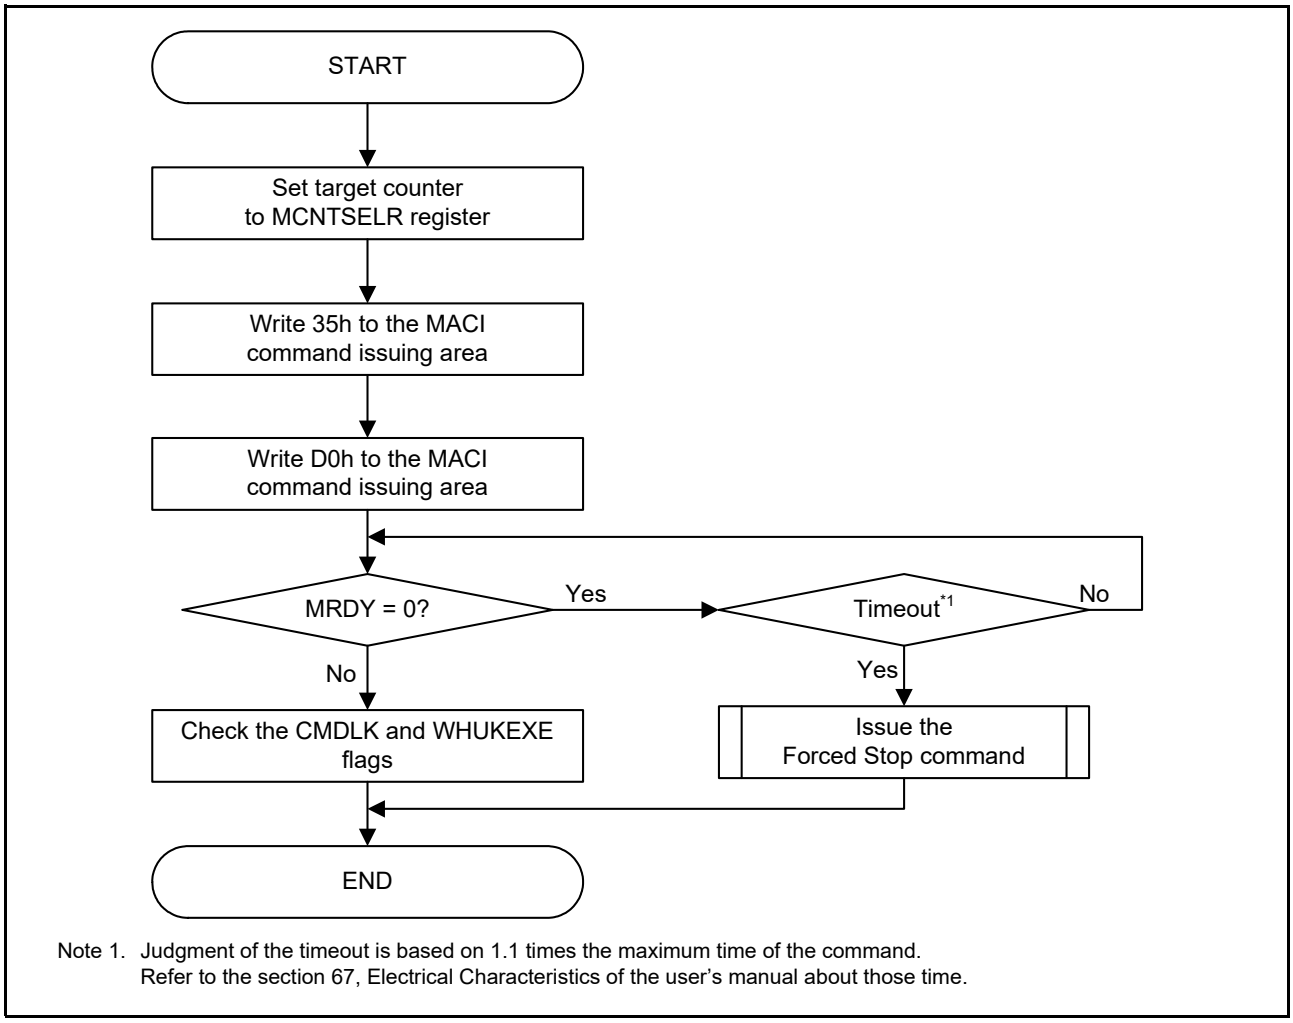


Table 65.18 Address Used by Configuration Set Command

Address	MSADDR Register Value	Setting Data	Operation of Additional Writing	Timing When the Setting is Enabled
BASE_ME + 00C2 E850h	BASE_MES + 00C2 E850h	Bank Mode Select Register (DUALSEL)	Writable*1	At a reset
BASE_ME + 00C2 E870h	BASE_MES + 00C2 E870h	Start-Up Area Setting Register (SAS)	Writable*1	When a reset or command is executed
BASE_ME + 00C2 E874h	BASE_MES + 00C2 E874h	Start-Up Area Setting Register 2 (SAS2)	Writable*1	When a reset or command is executed
BASE_ME + 00C2 E9B0h	BASE_MES + 00C2 E9B0h	Bank Select Register for Secure Application (BANKSEL_S)	Writable*1	At a reset
BASE_ME + 00C2 E9C0h	BASE_MES + 00C2 E9C0h	Block Select Register for Secure Application (BLSEL_S)	Writable*1	At a reset
BASE_ME + 00C2 E9E0h	BASE_MES + 00C2 E9E0h	BANKSEL Attribute Select Register (BANKSEL_SEL)	Writable*1	At a reset
BASE_ME + 00C2 E9F0h	BASE_MES + 00C2 E9F0h	BLSEL Attribute Select Register (BLSEL_SEL)	Writable*1	At a reset
BASE_ME + 00C4 EC60h	BASE_MEN + 00C2 EC60h	Bank Select Register for Non-secure Application (BANKSEL_NS)	Writable*2	At a reset
BASE_ME + 00C4 EC70h	BASE_MEN + 00C2 EC70h	Block Select Register for Non-Secure Application (BLSEL_NS)	Writable*2	At a reset
BASE_ME + 00C9 F050h	BASE_MES + 00C9 F050h	MRAM Security Attribute Boundary Register (MRAMSABR)	Writable	At a reset
BASE_ME + 00C9 F080h	BASE_MES + 00C9 F080h	Data MRAM Block Protect Register 0 for Secure Application (BPSD0_S)	Writable*3	When a reset or command is executed
BASE_ME+00 C9 F100h	BASE_MES + 00C9 F100h	Block Swap Setting Register n for Secure Application (BLKSWP_S)	Writable	At a reset
BASE_ME + 00C9 F200h	BASE_MES + 00C9 F200h to BASE_MES + 00C9 F330h	Block Protect Register n for Secure Application (BPSn_S)	Writable*5	When a reset or command is executed
BASE_ME + 00C9 F480h	BASE_MEN + 00C9 F480h	Data MRAM Block Protect Register 0 for Non-Secure Application (BPSD0_NS)	Writable*4	When a reset or command is executed
BASE_ME + 00C9 F500h	BASE_MEN + 00C9 F500h	Block Swap Setting Register for Non-Secure Application (BLKSWP_NS)	Writable	At a reset
BASE_ME + 00C9 F600h	BASE_MEN + 00C9 F600h to BASE_MEN + 00C9 F730h	Block Protect Register n for Non-Secure Application (BPSn_NS)	Writable*6	When a reset or command is executed

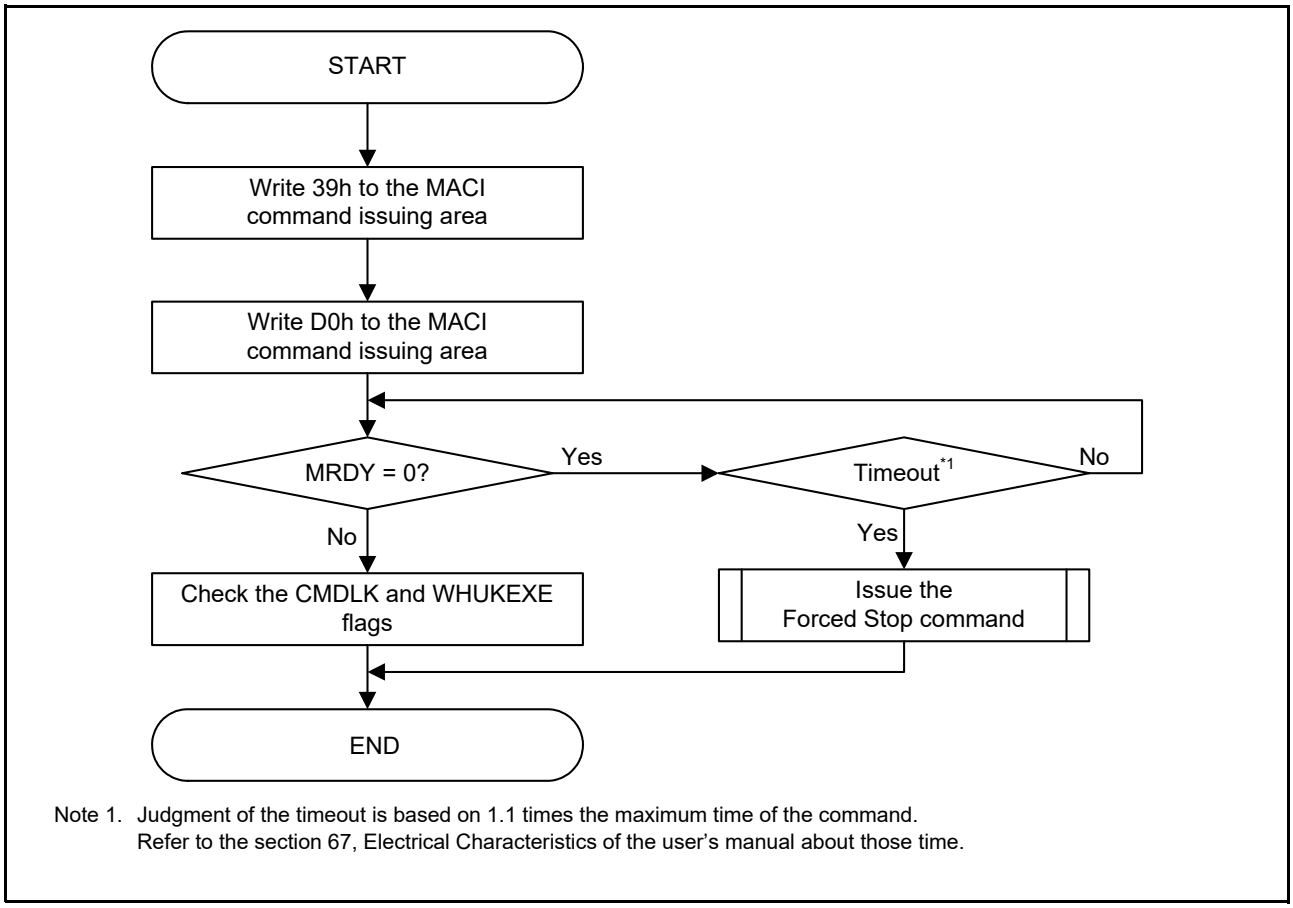
Note 1. This area can be protected by an individual bit in a POFSPSSn register. If the setting of the bit in the POFSPSSn register corresponding to an area for updating is 0, the area cannot be updated by the configuration setting command (n = 0 to 3).
Note 2. This area can be protected by each bit in the POFSPSNS0 register. If the bit in the POFSPSNS0 register corresponding to the update area is 0, it cannot be updated by the configuration set command.
Note 3. Once PBPSD0_S[n] bit is set to 0, the BPSD0_S[n] bit cannot be restored to 1 by using the Configuration set command.
Note 4. Once PBPSD0_NS[n] bit is set to 0, the BPSD0_NS[n] bit cannot be restored to 1 by using the Configuration set command.
Note 5. Once PBPSm_S[n] bit is set to 0, the BPSn_S.BPi[3:0] bits cannot be restored to 1111b by using the Configuration set command.
Note 6. Once PBPSm_NS[n] bit is set to 0, the BPSn_NS.BPi[3:0] bits cannot be restored to 1111b by using the Configuration set command.

65.7.4.9 Increment Counter Command

The Increment Counter command is used to security function, safety function. The increment counter command is used for updating 3 types of anti-rollback counter (ARCS, ARCNS, and ARCOEMBL). The counter update is executed increment processing and cannot be decrement processing.
Writing D0h at 2nd write access of extra MRAM sequencer command triggers MACI to start the increment counter command processing. Completion of command processing can be confirmed by the MRDY flag of MSTATR register.

Note 1. Judgment of the timeout is based on 1.1 times the maximum time of the command.
Refer to the section 67, Electrical Characteristics of the user's manual about those time.

Figure 65.26 Usage of the Increment Counter Command



Anti-rollback counter value is not increased the following conditions by the increment counter command.

- The value for updating the ARCOEMBL is equal to or greater than the OEM boot loader version (OEM BL Ver.) output by the RSIP when the ARCCS.ARCMD[1:0] bits are set to 01b (mode1).
- The value for updating the ARCS is equal to or greater than the version value output by the RSIP when the ARCCS.ARCMD[1:0] bits are set to 00b (mode2).
- The ARCCS.ARCMD[1:0] bits are set to an invalid value.
- Target counter value is maximum. (Error does not occur)
- Target counter is ARCNS when ARCCS.CNFARCNS[1:0] is invalid setting.

65.7.4.10 Read Counter Command

The read counter command is used to security function, safety function. The read counter command is used for reading the anti-rollback counter (ARCOEMBL). Extra MRAM sequencer reads 64 bits data, and stores to the MCNTDTR0 and MCNTDTR1 registers.

Writing D0h at 2nd write access of extra MRAM sequencer command triggers MACI to start the read counter command processing. Completion of command processing can be confirmed by the MRDY flag of MSTATR register.

Note 1. Judgment of the timeout is based on 1.1 times the maximum time of the command.
Refer to the section 67, Electrical Characteristics of the user's manual about those time.

Figure 65.27 Usage of the Read Counter Command

65.8 Security Function

The extra MRAM sequencer supports the following security functions in security enabled product:

- Permanent OFS protect setting
- Security flag for startup area and startup size
- Permanent block protect setting
- MRAM protection for Protect Zone
- Extra MRAM configuration area protection
- Anti-rollback counter
- HUK protection
- OEM_ROOT_KEY protection
- AUTH AL1 KEY, AUTH AL2 KEY, and AUTH RMA KEY protection

65.8.1 Permanent OFS Protect Setting

The secure OFS configuration area, non-secure OFS configuration area, secure OFS OTP area, and non-secure OFS OTP area can be permanently protected by the protection setting bits as listed in Table 65.19 to Table 65.22, respectively. See section 7, Option-Setting Memory (OFSM).

Table 65.19 Example of Protection Settings for the Secure OFS Configuration Area

Protect Register	MSADDR Register Value	Protection Size	Protection Setting Regster	Corresponding Bit	Remarks
DUALSEL	86C2 E820h	4 Bytes	MOFSPS0_S	bit 12	—
SAS	86C2 E820h	4 Bytes	MOFSPS0_S	bit 20	—
SAS2	86C2 E820h	4 Bytes	MOFSPS0_S	bit 21	—

BLSEL_S	86C2 E9A0h	4 Bytes	MOFSPS3_S	bit 8	—
BANKSEL_SEL	86C2 E9A0h	4 Bytes	MOFSPS3_S	bit 16	—
BLSEL_SEL	86C2 E9A0h	4 Bytes	MOFSPS3_S	bit 20	—

Table 65.20 Example of Protection Settings for the Non-Secure OFS Configuration Area

Protect Register	MSADDR Register Value	Protection Size	Protection Setting Regster	Corresponding Bit	Remarks
BANKSEL_NS	06C4 EC20h	4 Bytes	MOFSPS0_NS	bit 16	—
BLSEL_NS	00C4 EC20h	4 Bytes	MOFSPS0_NS	bit 20	—

Table 65.21 Example of Protection Settings for the Secure OFS OTP Area

Protect Register	MSADDR Register Value	Protection Size	Protection Setting Regster	Corresponding Bit	Remarks
OFS0	86E1 0620h	4 Bytes	SOFSOPS0_S	bit 8	—
OFS2	86E1 0620h	4 Bytes	SOFSOPS0_S	bit 9	—
MDE	86E1 0620h	4 Bytes	SOFSOPS0_S	bit 10	—
OFS1_S	86E1 07A0h	4 Bytes	SOFSOPS3_S	bit 0	—
OFS1_SEL	86E1 07A0h	4 Bytes	SOFSOPS3_S	bit 12	—

Table 65.22 Example of Protection Settings for the Non-Secure OFS OTP Area

Protect Register	MSADDR Register Value	Protection Size	Protection Setting Regster	Corresponding Bit	Remarks
OFS1_NS	06E2 0820h	4 Bytes	SOFSPS0_NS	bit 12	—

65.8.2 Security Flag for Startup Area and Startup Size Select

The security flag (POFSPSS0.POFSPSS0[21] and POFSPSS0.POFSPSS0[20]) for the startup area and startup size are located in the OTP area as the section 65.7.4.5, Program Command. The POFSPSS0[21] and POFSPSS0[20] bits can respectively be monitored by using the FSPR and FSPRS flags in the MSUASMON register. When the POFSPSS0[21] or POFSPSS0[20] bit is 0, issuing a configuration set command to respectively change the BTFLG or BTSIZE bit has no effect. Also, when the POFSPSS0[21] bit is 0, it is not possible to write the startup area select bits (SAS[1:0]) in the MSUACR register.
The POFSPSS0[21] and POFSPSS0[20] bits provide the protection. See section 7, Option-Setting Memory (OFSM).

65.8.3 Permanent Block Protect Setting

The permanent block protect setting disables updating of the block protection setting. The code MRAM and data MRAM can never be updated when the permanent block protect setting is enabled. See section 65.9.1.2, Block Protection of Code MRAM in details of the block protect setting.
The block protect setting and the permanent block protect setting cannot be updated by a configuration set command. Even if a configuration set command is issued, the extra MRAM sequencer does not detect an error. In addition, the protected blocks cannot be updated by a program command.
Figure 65.28, Table 65.23, and Table 65.24 show the protection against updating of the bits in block protect register n for non-secure application (BPSn_NS.BPi[3:0]) and permanent block protect register m for non-secure application (PBPSm_NS[n]).
Figure 65.29, Table 65.25, and Table 65.26 show the protection against updating of the bits in block protect register n for secure application (BPSn_S.BPi[3:0]) and permanent block protect register m for secure application m (PBPSm_S[n]).
Figure 65.30, Table 65.27, and Table 65.28 show the protection against updating of the bits in data MRAM block protect register 0 for non-secure application (BPSD0_NS[n]) and data MRAM permanent block protect register 0 for non-secure application (PBPSD0_NS[n]).
Figure 65.31, Table 65.29, and Table 65.30 show the protection against updating of the bits in data MRAM block protect register 0 for secure application (BPSD0_S[n]) and data MRAM permanent block protect register 0 for secure application (PBPSD0_S[n]).

The setting of the MRAM security attribute boundary register (MRAMSABR) determines which of the BPSn_S and BPSn_NS registers is effective for code MRAM block protection and which of the PBPSm_S and PBPSm_NS registers is effective for code MRAM permanent block protection.
For details of the permanent block protect registers (PBPSm_NS, PBPSm_S, PBPSD0_NS, and PBPSD0_S), see section 7, Option-Setting Memory (OFSM).

65.8.4 MRAM Protection for Protect Zone

MRAM has following 4 types of protect function against non-secure access to support the Protect Zone specification for MRAM. Descriptions of this section are focused on extra MRAM sequencer operation.

- Protection for the code MRAM and data MRAM areas (against programming)
- Protection for the extra MRAM area (against programming)
- Protection for the MRAM area (against reading)
- Protection for registers

65.8.4.1 Protection for Code MRAM and Data MRAM Areas (Program)

This function protects code MRAM and data MRAM from bus access such as CPU, DMAC. For details of protection, see section 56, Security Features.

65.8.4.2 Protection for extra MRAM Area (Program)

This function protects secure area of extra MRAM from MRAM sequencer command of non-secure developer. The condition of protection depends on extra MRAM sequencer command, access attribution.
See Table 65.31 in details of protection for extra MRAM area (Program).

Table 65.31 Protection for Extra MRAM Area (Program)

MACI Command		Target Area		Issuing MACI Command by Non-Secure Access	Issuing MACI Command by Secure Access
Program	Extra MRAM	MRAM and OTP area (non-secure area)	Secure area*1	×	×
			Non-secure area*2	✓	✓
		MRAM and OTP area (secure area)	Secure area*1	×	✓
			Non-secure area*2	×	×
Configuration set	Extra MRAM	Configuration area (non-secure area)	Secure area*1	×	×
			Non-secure area*2	✓	✓
		Configuration area (secure area)	Secure area*1	×	✓
			Non-secure area*2	×	×
Increment Counter Read Counter	Extra MRAM	Anti-rollback counter area (secure area only)	—	×	✓

✓: MACI command operation is not prohibited.
×: MACI command operation is prohibited.
Note 1. The secure area is judged when the address of MSADDR[31] is 1.
Note 2. The non-secure area is judged when the address of MSADDR[31] is 0.

Error occurs when the area is selected, and MACI command is executed.
The configuration areas are mapped to both the non-secure areas and secure areas. Figure 65.32 shows the non-secure and secure areas where the configuration areas are mapped.
The extra MRAM sequencer judges that target area is secure region from the MSADDR register setting.

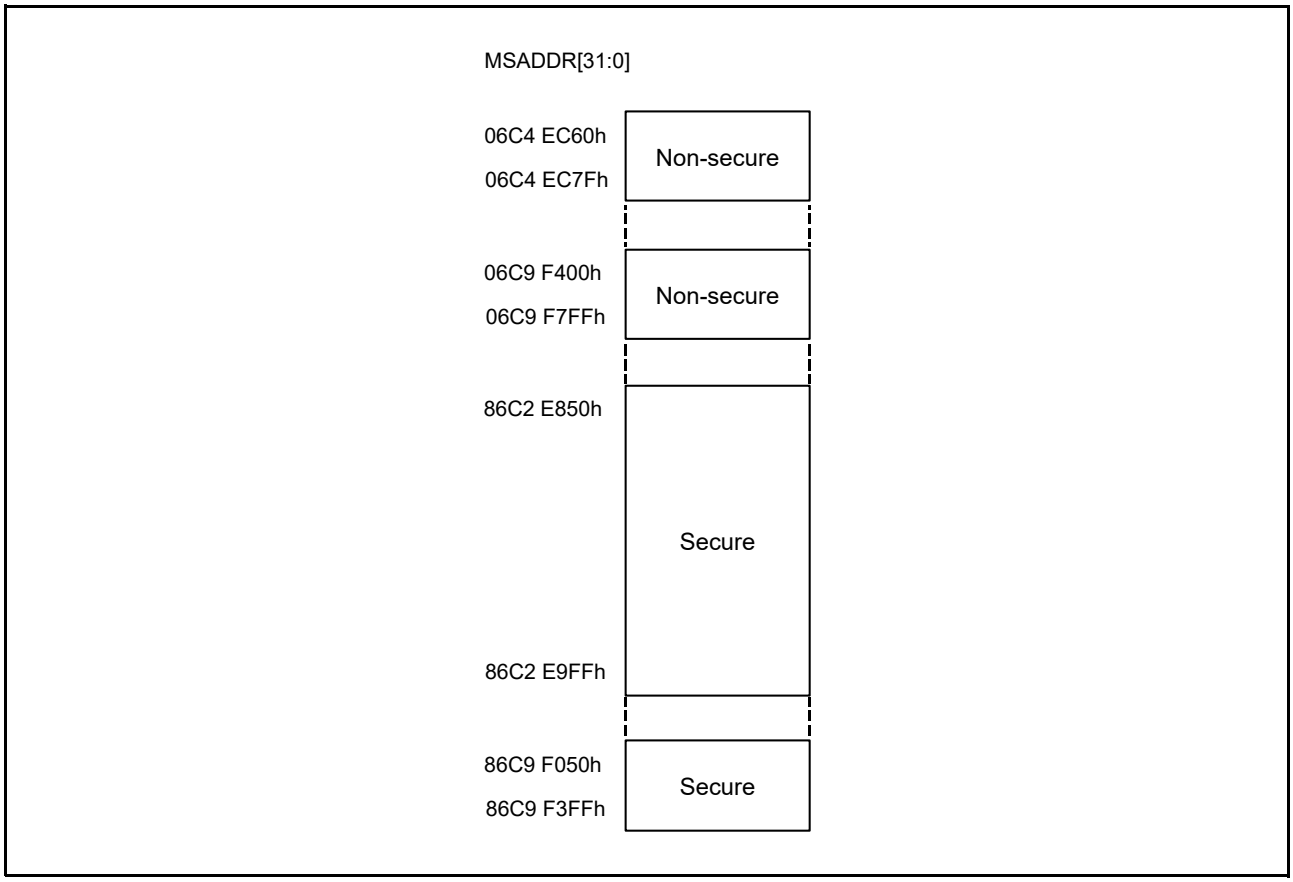

Figure 65.32 Secure/Non-secure Region in Configuration Area

65.8.4.3 Protection for MRAM Area (Read)

This function protects code MRAM, data MRAM, and extra MRAM from bus access (CPU, DMAC, etc.). For details of protection, see section 56, Security Features.

65.8.4.4 Protection for Registers

The MRAM registers have the write access protection against the non-secure access. See Table 65.32 in details of protected the MRAM registers.

Table 65.32 Protected MRAM Registers for Protect Zone (1/2)

Protection Target Register	Secure Attribute Setting	Remarks
MRCEECC	SA register setting (MSAR.MRBCPSA)	section 65.5.48, Code MRAM ECC Encoder Control Register (MRCEECC)

Note 1. The target MACI registers are MASTAT, MPAEINT, MRDYIE, MSADDR, MSTATR, MENTRYR, MSUINITR, MCMDR and MSUASMON.

65.8.5 Anti-Rollback Counter

Anti-rollback counter cannot be decremented and is used in the firmware update. Only secure applications are available. Anti-rollback counter shifts one bit to the left with the increment counter command from the initial value of 0. The least significant bit (bit 0) is set to 1. When anti-rollback counter is of maximum value, extra MRAM sequencer does not change counter by the Increment Counter command (does not occur error).
There are three commands that control the counters. See section 65.7.2, List of MACI Commands for details.
Figure 65.33 shows anti-rollback counter increment image when increment counter command is issued.

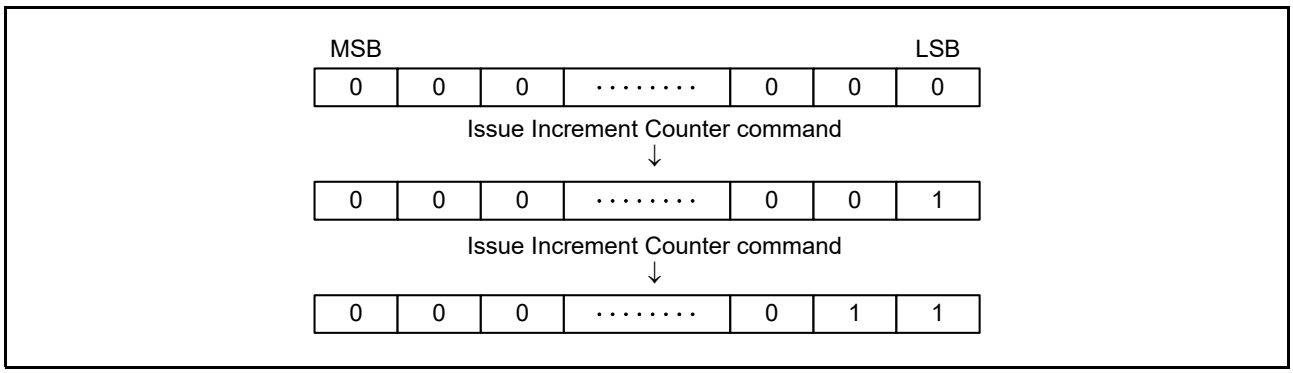

Figure 65.33 Increment Image of Anti-Rollback Counter

Anti-rollback counter has 3 types of counters (ARCS, ARCNS and ARCOEMBL). If ARCCS.ARCMD[1:0] bits are set to 11b, the increment counter command has no effect on any counters.
The ARCNS can be configured as 1 × 1024 bits or 4 × 256 bits by the ARCNS counter configuration select bits (ARCCS.CNFARCNS[1:0]) and cannot be updated to an invalid configuration.
The ARCOEMBL is protected by the RSIP and cannot be updated until the updated OEM boot loader has been successfully validated. After the successful validation, the ARCOEMBL can be updated to the current OEM boot loader version (OEM BL Ver.) that was output by the RSIP. The ARCOEMBL cannot be updated to a value greater than the OEM boot loader version (OEM BL Ver.).

65.8.6 HUK Protection

Zeroization of W-HUK is triggered when one of the ZHUKEN[3:0] bits (zeroization enable bit) is 0 and anti-tamper is detected or 07h is set to the WHUKWE[2:0] bits in MREZC register. Zeroing W-HUK disables the generation of HUK. Table 65.33 shows the combinations of enable bits and request signals. If a zeroing request is received during code MRAM, data MRAM, or extra MRAM program, the executing program is forcibly terminated, and the zeroing process is started. If code MRAM program request is received during zeroing, code MRAM program is started after zeroing is completed. MACI commands are not accepted during zeroing. During W-HUK zeroing, all MACI commands are not accepted and extra MRAM cannot be read.

Table 65.33 Combinations of Request Signals and Enable bits

Zeroization Request Signal				Zeroization Enable Bit				
	RTCIC			ZHUKEN				
WHUKZE[2:0]	2	1	0	3	2	1	0	Function
7h	—	—	—	0	—	—	—	O
7h	—	—	—	1	—	—	—	Oe
Except 7h	—	—	—	—	—	—	—	×
—	1	—	—	—	0	—	—	O
—	1	—	—	—	1	—	—	Oe
—	0	—	—	—	—	—	—	×
—	—	1	—	—	—	0	—	O
—	—	1	—	—	—	1	—	Oe
—	—	0	—	—	—	—	—	×
—	—	—	1	—	—	—	0	O
—	—	—	1	—	—	—	1	Oe
—	—	—	0	—	—	—	—	×

O: W-HUK zeroing.
Oe: W-HUK Pseudo-zeroing
×: Zeroization of W-HUK does not execute
—: Don't care

Table 65.34 shows differences of W-HUK pseudo-zeroing and W-HUK zeroing described in Table 65.33. If the zeroization enable bit is 1 and tamper is detected, the MREZS.WHUKZF bit is set to 0 to complete zeroing without physically zeroing W-HUK (W-HUK pseudo-zeroing). If the zeroization enable bit is 0 and a tamper is detected, physical zeroization of W-HUK is performed and the Zeroized Monitor register is set to 0 (W-HUK zeroing).

Table 65.34 Internal State at the Time of Zeroing Request

Table 65.33 Function	Operation Name	Zeroization Enable Bits	W-HUK	W-HUK Zeroized Monitor Register (MREZS)
Oe	W-HUK Pseudo-zeroing	Disable(1)	Not zeroed	Clear
O	W-HUK zeroing	Enable(0)	Zeroed	Clear flag after zeroization finished

65.8.7 OEM Root Key Protection

The REVOKE bit located in the OTP area is used to delete the OEM root key. When the REVOKE bit is 0, the read data of the target OEM root key is masked to 0.

65.9 Protection Function

65.9.1 Software Protection

Software protection function disables MRAM programming operation according to register and configuration area settings.

65.9.1.1 Code MRAM Program Protection

When MRCPCNS register is set to 0000h, programming of non-secure areas in code MRAM is prohibited. When MRCPCS register is set to 0000h, programming of secure areas in code MRAM is prohibited. Code MRAM program protection has higher priority than block protection and cannot be canceled by MRCBPROTNS or MRCBPROTS register.

65.9.1.2 Block Protection of Code MRAM

Each block in the code MRAM has a block protect register (BPSn_NS or BPSn_S) for that block. When the MRCBPROTNS or MRCBPROTS register is set to 0000h and the BPSn_NS.BPi[3:0] bits for the target block for protection are set to 0000b, access for programming of the non-secure area of the target block in the code MRAM is prohibited.
When the MRCBPROTS register is set to 0000h and the BPSn_S.BPi[3:0] bits for the target block for protection are set to 0000b, access for programming of the secure area of the target block in the code MRAM is prohibited. To program the block for which the BPSn_S.BPi[3:0] or BPSn_NS.BPi[3:0] bits are set to 0000b, set the MRCBPROTNS or MRCBPROTS register to 0001h.
The block protect setting can be locked by the permanent block protect register (PBPSm_S or PBPSm_NS). When a bit in the permanent block protect register or block protect register is set 0, program access to the corresponding block cannot be performed.
The setting of the MRAM security attribute boundary register (MRAMSABR) determines which of the BPSn_S and BPSn_NS registers is effective for the setting of the target block for block protection.
Likewise, the setting of the MRAMSABR register determines which of the PBPSm_S and PBPSm_NS registers is effective for the setting of the target block for permanent block protection.
See section 65.8.3, Permanent Block Protect Setting in details of the permanent block protect setting and block protect setting.
See section 65.5.36, Code MRAM Block Protection Register for Non-Secure Application (MRCBPROTNS) and section 65.5.37, Code MRAM Block Protection Register for Secure Application (MRCBPROTS) for the MRCBPROTNS and MRCBPROTS registers.
For details of block protect setting (BPS_S or BPS_NS), permanent block protect setting block (PBPS_S or PBPS_NS) and code MRAM boundary setting, see section 7, Option-Setting Memory (OFSM).
Table 65.35 to Table 65.40 show the correspondence between the block protect settings and the target blocks in some examples of function settings.

- In linear mode, BPSn_NS.BPi[3:0] or BPSn_S.BPi[3:0] are assigned to the blocks in the code MRAM (e.g., the addresses are the last block address to BASE_MC + 00FF FFFFh).
- BPSn_NS[31:0] and BPSn_S[31:0] are assigned to blocks in the code MRAM according to the settings of the startup area select bit (SAS2.BTFLG) and startup area size setting bits (SAS.BTSIZE[1:0]). For details, see section 65.9.3, Startup Program Protection.
- In dual mode, BPS0_NS.BP0[3:0] to BPS7_NS.BP7[3:0] or BPS0_S.BP0[3:0] to BPS7_S.BP7[3:0] are assigned to the blocks in bank 0 (MRC0) of the code MRAM.
  BPS64_NS.BP0[3:0] to BPS71_NS.BP7[3:0] or BPS64_S.BP0[3:0] to BPS71_S.BP7[3:0] are assigned to the blocks in bank 1 (MRC1) of the code MRAM. The offset addresses for bank 0 are F8 0000h to FF FFFFh and those

for bank 1 are B8 0000h to BF FFFFh in the products with 1-Mbyte code MRAM.
For details, see section 65.9.4, Dual Bank Function.

Table 65.35 to Table 65.40 show example of the block protect setting.

Table 65.35 Example of Block Protect Setting when SAS2.BTFLG bit is 1 and All Sizes (Code MRAM Size: 1 Mbyte)

Block Protect Setting	Address (Offset address)	Remarks

65.9.1.3 Block Protection of Data MRAM

Each block in the data area has data MRAM block protect register 0 (BPSD0_S or BPSD0_NS) for that block.
The block protect setting can be locked by data MRAM permanent block protect register 0 (PBPSD0_S or PBPSD0_NS).
Access for programming of a block cannot be performed when the corresponding bits in data MRAM permanent block protect register 0 and data MRAM block protect register 0 are set to 0.
The setting of the MRAM security attribute boundary register (MRAMSABR) determines which of the BPSD0_S and BPSD0_NS registers is effective for the setting of data MRAM block protection and which of the PBPSD0_S and PBPSD0_NS registers is effective for the setting of data MRAM permanent block protection.
See section 65.8.3, Permanent Block Protect Setting. For details of data MRAM block protect register 0 (BPSD0_S or BPSD0_NS), data MRAM permanent block protect register 0 (PBPSD0_S or PBPSD0_NS), and MRAM security attribute boundary register (MRAMSABR), see section 7, Option-Setting Memory (OFSM).
Table 65.41 shows an example of block protect settings for the data MRAM.

Table 65.41 Example of Block Protection Settings for Data MRAM

Data MRAM Block Protect Setting	Address (Offset address)
BPSD0_NS.BP23 or BPSD0_S.BP23	90 B800h to 90 BFFFh
:	:
BPSD0_NS.BP3 or BPSD0_S.BP3	90 1800h to 90 1FFFh
BPSD0_NS.BP2 or BPSD0_S.BP2	90 1000h to 90 17FFh
BPSD0_NS.BP1 or BPSD0_S.BP1	90 0800h to 90 0FFFh
BPSD0_NS.BP0 or BPSD0_S.BP0	90 0000h to 90 07FFh

65.9.2 Error Protection

Error protection detects the issuing of illegal MACI commands, illegal access, and extra MRAM sequencer malfunction. MACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The extra MRAM cannot be programmed while the extra MRAM sequencer is in the command-locked state. For release from the command-locked state, issue the status clear or forced stop command. The status clear command can only be used while the MRDY flag in the MSTATR register is 1. The forced stop command can be used regardless of the value of the MRDY flag. While the CMDLKIE bit in the MPAEINT register is 1, an extra MRAM access error (MREPRI) interrupt is generated if the extra MRAM sequencer enters the command-locked state (the CMDLK bit in the MASTAT register is set to 1).

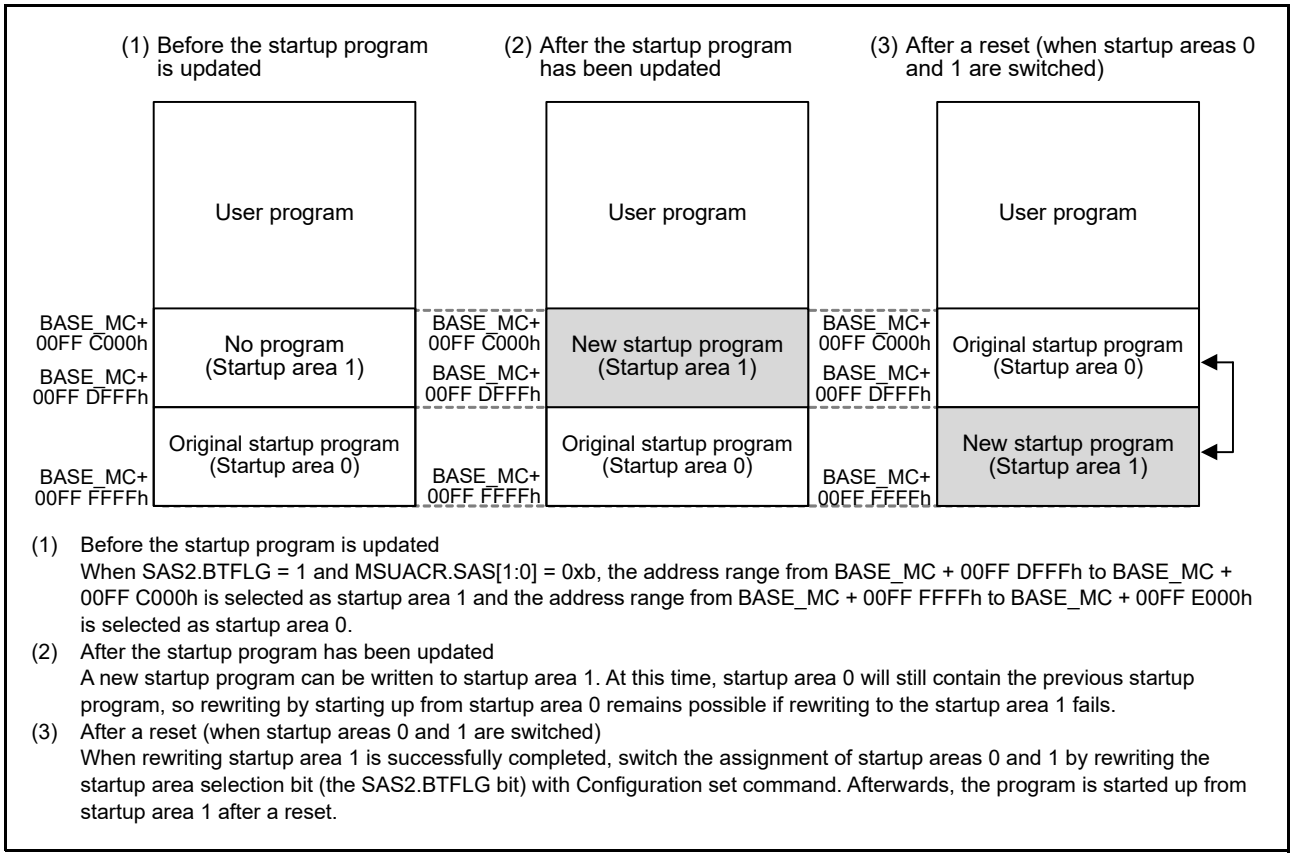
If the extra MRAM sequencer enters the command-locked state in response to a command, the extra MRAM sequencer continues the processing for programming. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set due to previous error detection.

Table 65.42 shows error protection types and status bit values after error detection.

Table 65.42 Error Protection Types (1/2)

Error Type	Description	ILGCO MERR	OTERR	PZFERR	ILGLERR	PRGERR	CFGPRGERR	PROTERR	MREAE
Illegal command error	An undefined size has been specified in the first cycle of command. (Not Byte write)	1	0	0	1	0	0	0	0
	An undefined code is written in the first access of the MACI command.	1	0	0	1	0	0	0	0
	The value specified in the last access of the multiple access MACI command is not D0h.	1	0	0	1	0	0	0	0
	The value (N) specified in the second write access of the MACI command in the program command or Configuration set command is wrong.	1	0	0	1	0	0	0	0
	Increment counter or read counter command has been issued with the ARCMD[1:0] bits or MCNTSLER[2:0] bits being set to an incorrect value. (Including the case where the CNFARCNS[1:0] setting is incorrect)	1	0	0	1	0	0	0	0
	The MACI command not acceptable in each mode has been issued (see Table 65.16).	1	0	0	1	0	0	0	0
	The MACI command has been issued when command acceptance conditions are not satisfied (see Table 65.17).	0/1	0/1	0	1	0/1	0/1	0	0/1
	Increment counter command for updating the version to an illegal value has been issued. (see section 65.8.5, Anti-Rollback Counter).	1	0	0	1	0	0	0	0
	A command has been issued against extra MRAM sequencer command illegal status (see Table 65.13).	0/1	0/1	0	1	0/1	0/1	0	0/1
Program error	An error occurs during programming. (When OTP area data is programmed from 0 to 1 or verify error)	0	0	0	0	1	0	0	0
Configuration set error	An error has occurred during configuration set.	0	0	0	0	0	1	0	0
Protection error	The area for updating is permanently protected and the data for updating contains a TED error.	0	0	0	0	0	0	1	0

Table 65.42 Error Protection Types (2/2)



Error Type	Description	ILGCO MERR	OTERR	PZFERR	ILGLERR	PRGERR	CFGPRGERR	PROTERR	MREAE
Access error	Program command has been issued to reserved area in extra MRAM program mode.	0/1	0	0	1	0	0	0	1
	Configuration set command has been issued to a reserved configuration area in extra MRAM program mode.	0/1	0	0	1	0	0	0	1
	Program command or configuration set command has been issued to Protect Zone protection area in extra MRAM program mode.	0/1	0	1	1	0	0	0	1
	Configuration set command has been issued to operation mode protection area in extra MRAM program mode.	0/1	0	0	1	0	0	0	1
Others	The MACI command-issuing area has been accessed in extra MRAM read mode.	0	1	0	1	0	0	0	0
	The MACI command-issuing area has been read in extra MRAM program mode.	0	1	0	1	0	0	0	0

65.9.3 Startup Program Protection

This is a function for protecting the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.
The startup area is 8 Kbytes, 16 Kbytes, or 32 Kbytes in size and is assigned to the user area in the code MRAM. The size of the startup area can be changed by the BTSIZE bits. When resizing the startup area, be careful not to destroy the software in use.
This function uses the values of the SAS2.BTFLG bit, the SAS.BTSIZE bits, and the MSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see Table 65.25 to Table 65.30).

In protection of the startup program, the selection of the startup area can be fixed by bit 21 of the MOFSPS0_S register and the size of the startup area can be fixed by bit 20 of the register. However, the POFSPS.POFSPS[21:20] bits are not restored to 1 once the flag is set to 0. Exercise extra caution when handling the POFSPS.POFSPS[21:20] bits.

Assign all startup areas (a total of 64 Kbytes of areas 0 and 1) to the secure area regardless of the BTSIZE bit setting.

(1) Before the startup program is updated
When SAS2.BTFLG = 1 and MSUACR.SAS[1:0] = 0xb, the address range from BASE_MC + 00FF DFFFh to BASE_MC + 00FF C000h is selected as startup area 1 and the address range from BASE_MC + 00FF FFFFh to BASE_MC + 00FF E000h is selected as startup area 0.

(2) After the startup program has been updated
A new startup program can be written to startup area 1. At this time, startup area 0 will still contain the previous startup program, so rewriting by starting up from startup area 0 remains possible if rewriting to the startup area 1 fails.

(3) After a reset (when startup areas 0 and 1 are switched)
When rewriting startup area 1 is successfully completed, switch the assignment of startup areas 0 and 1 by rewriting the startup area selection bit (the SAS2.BTFLG bit) with Configuration set command. Afterwards, the program is started up from startup area 1 after a reset.

Figure 65.34 Concept of Protection of the Startup Program

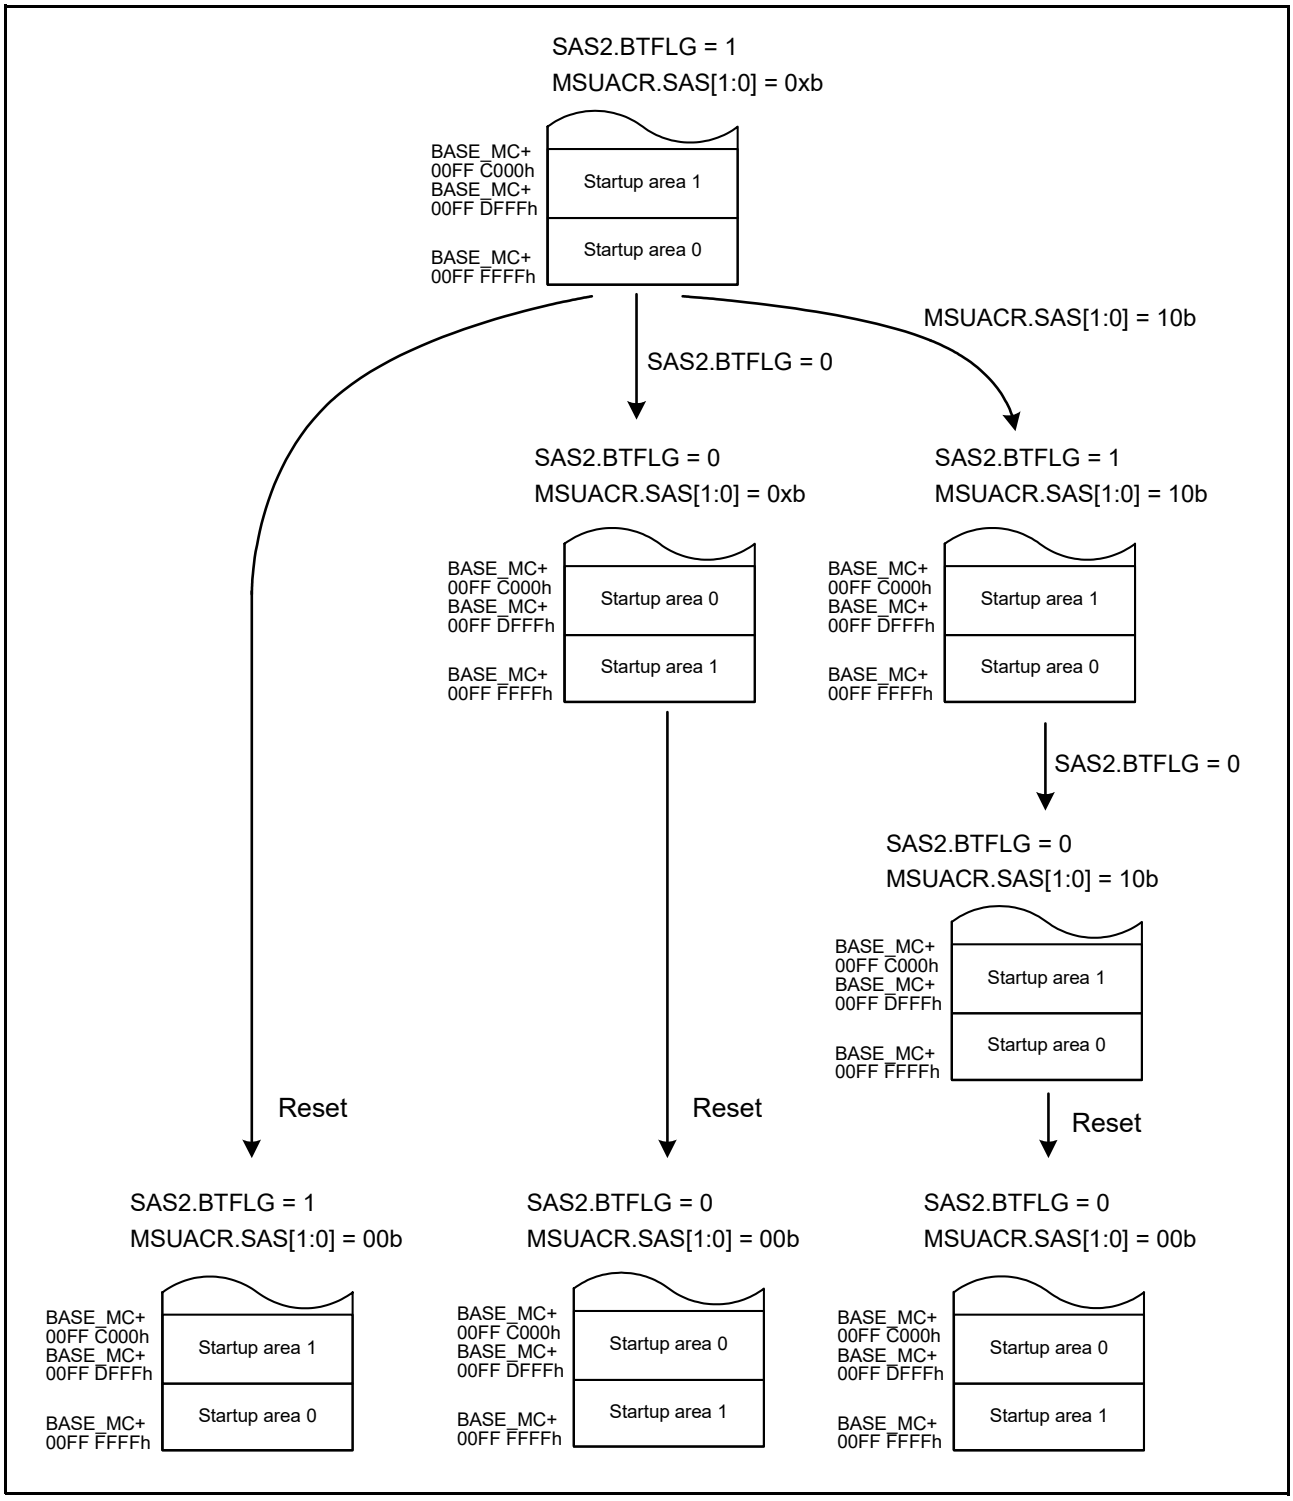


Figure 65.35 Example 1 of Transitions for Startup Program Protection Settings

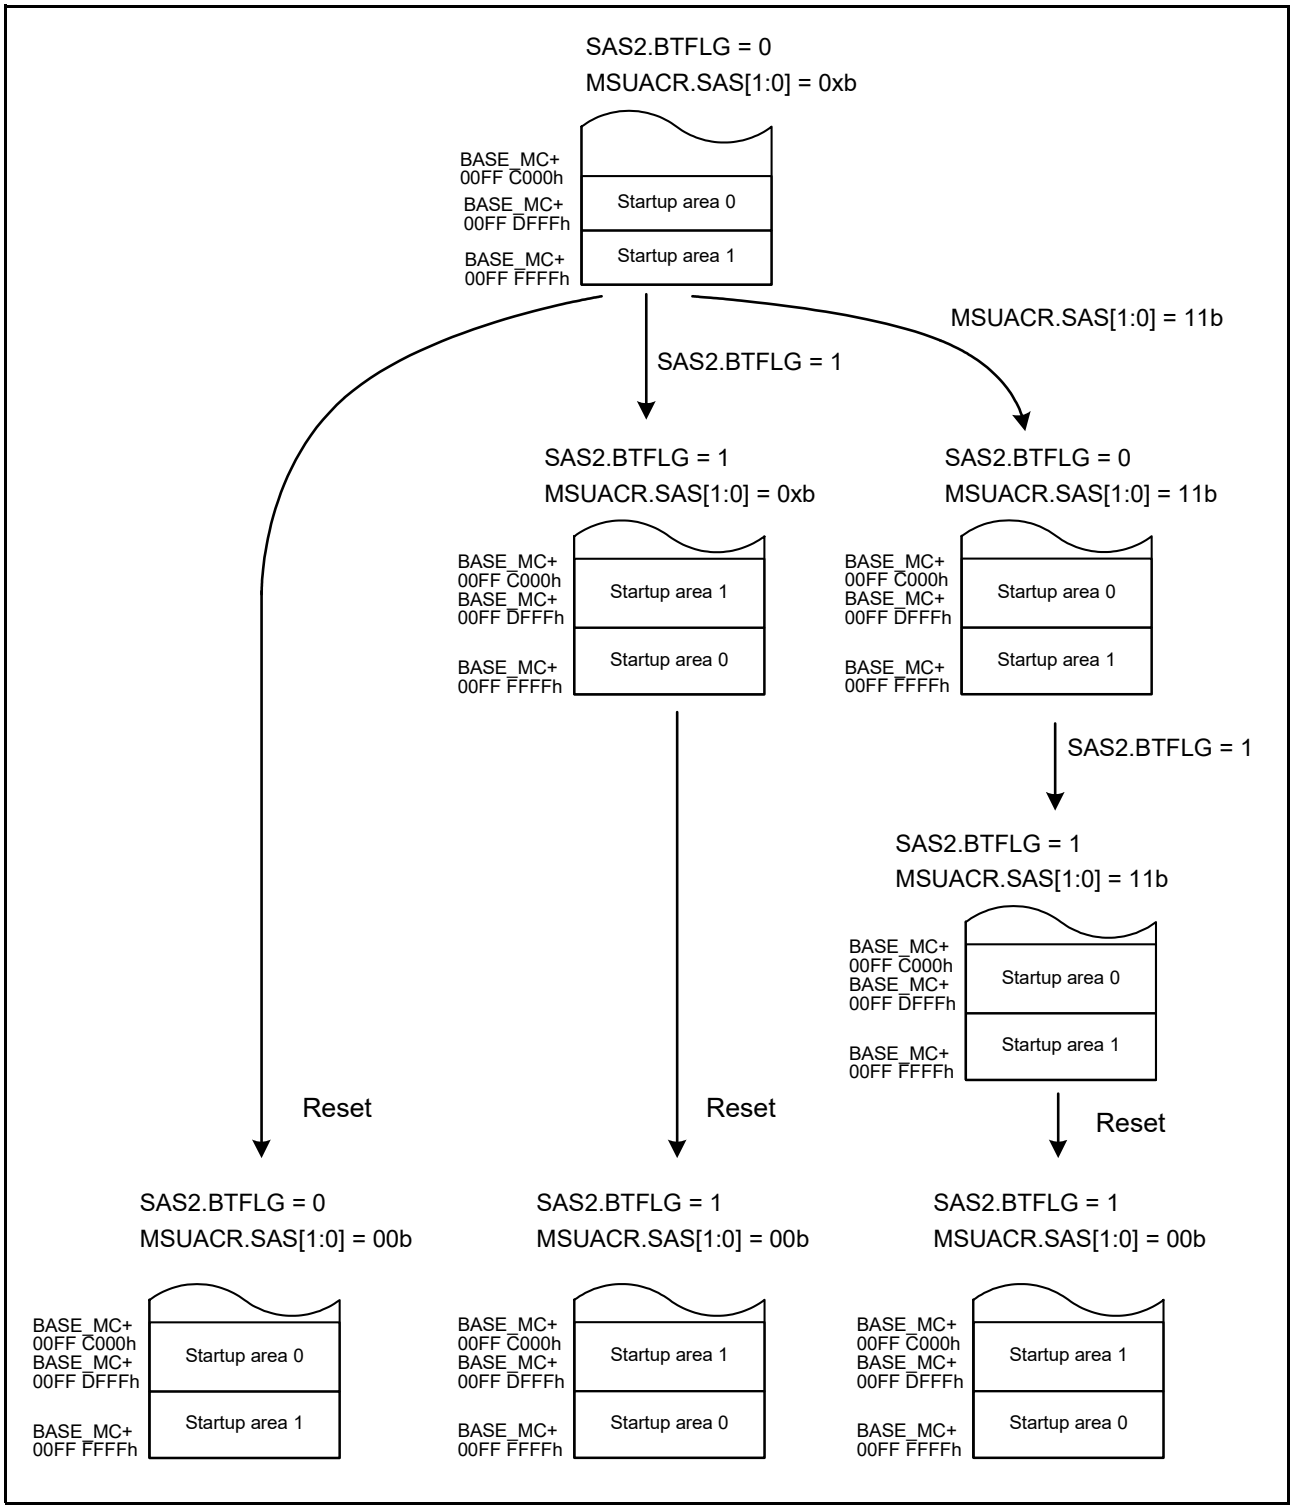

Figure 65.36 Example 2 of Transitions for Startup Program Protection Settings

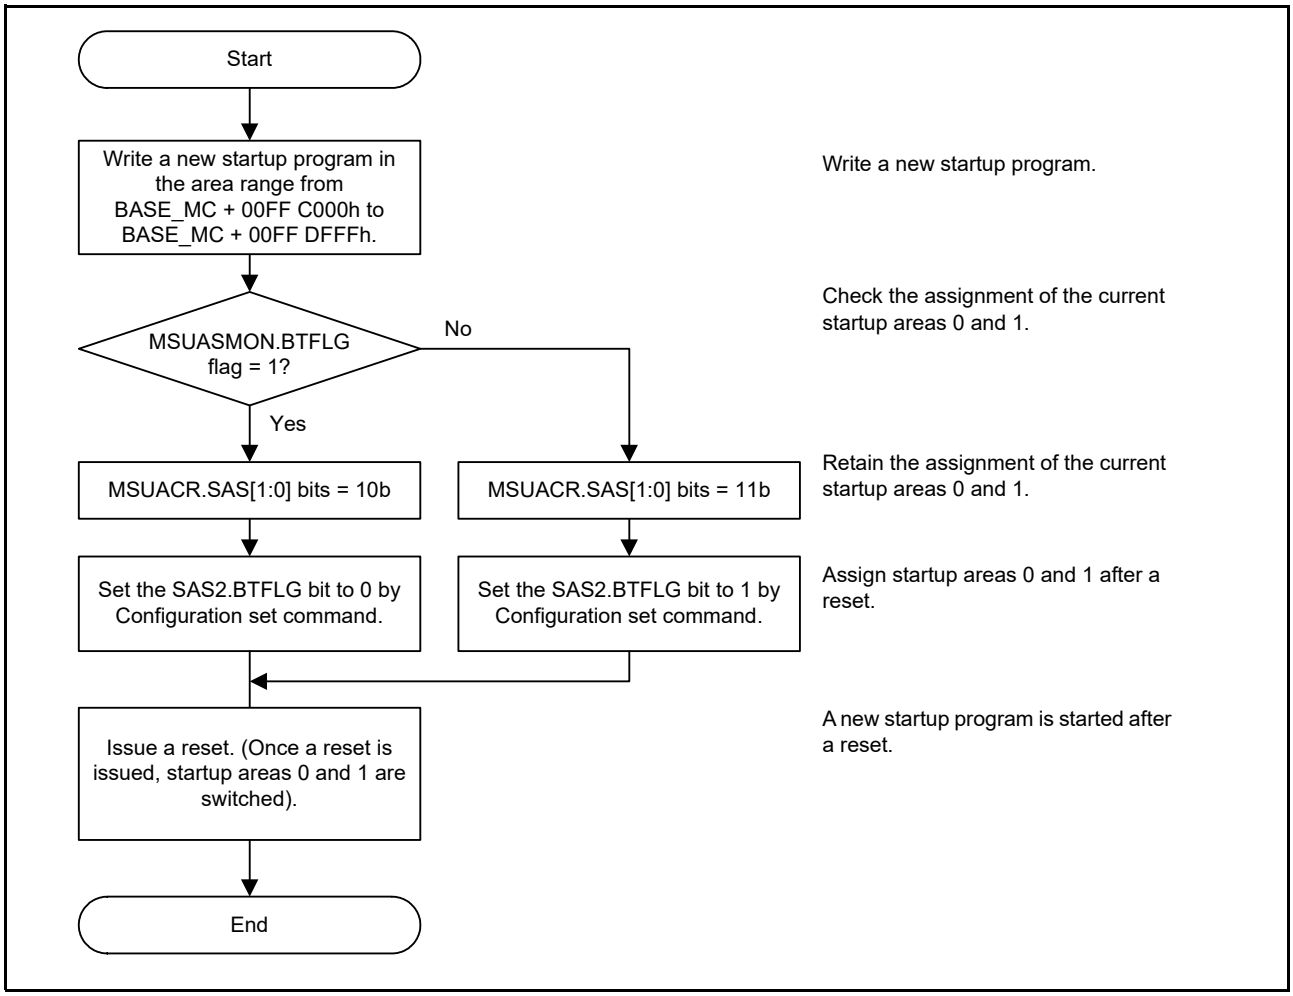

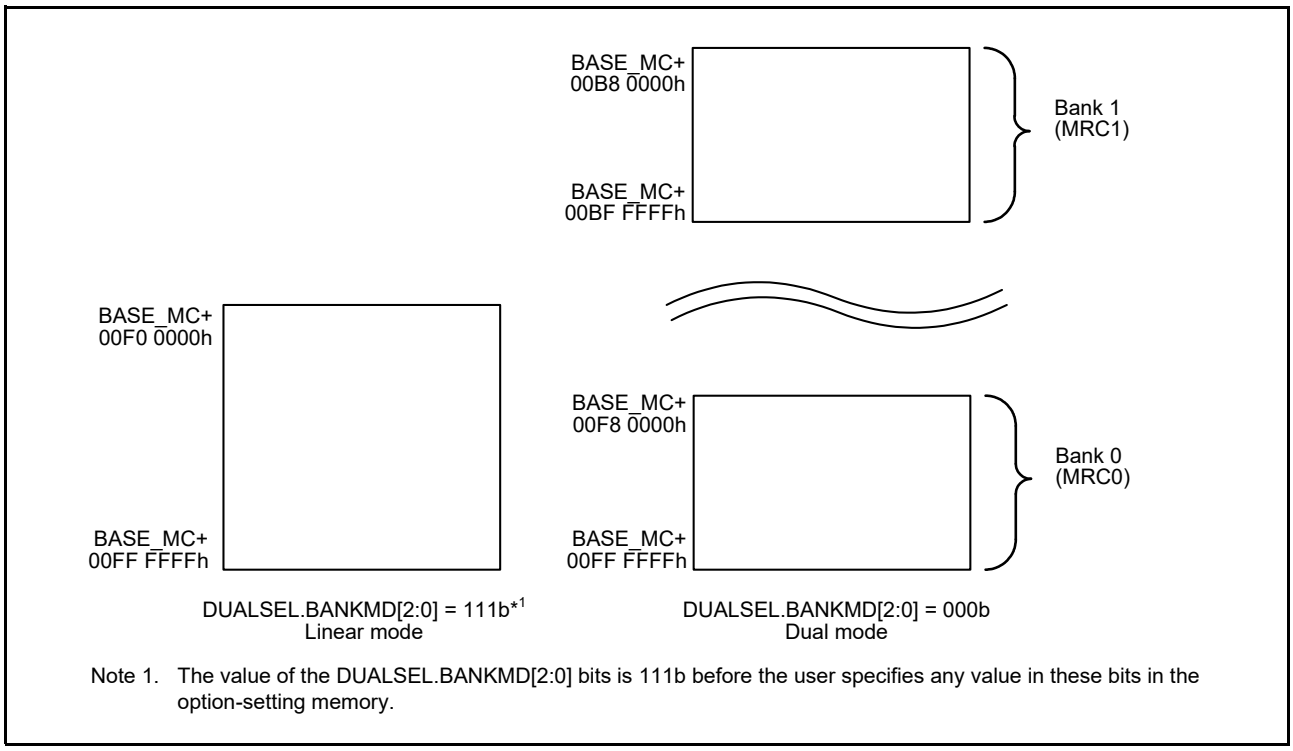

Figure 65.37 Concept of Protection of the Startup Program

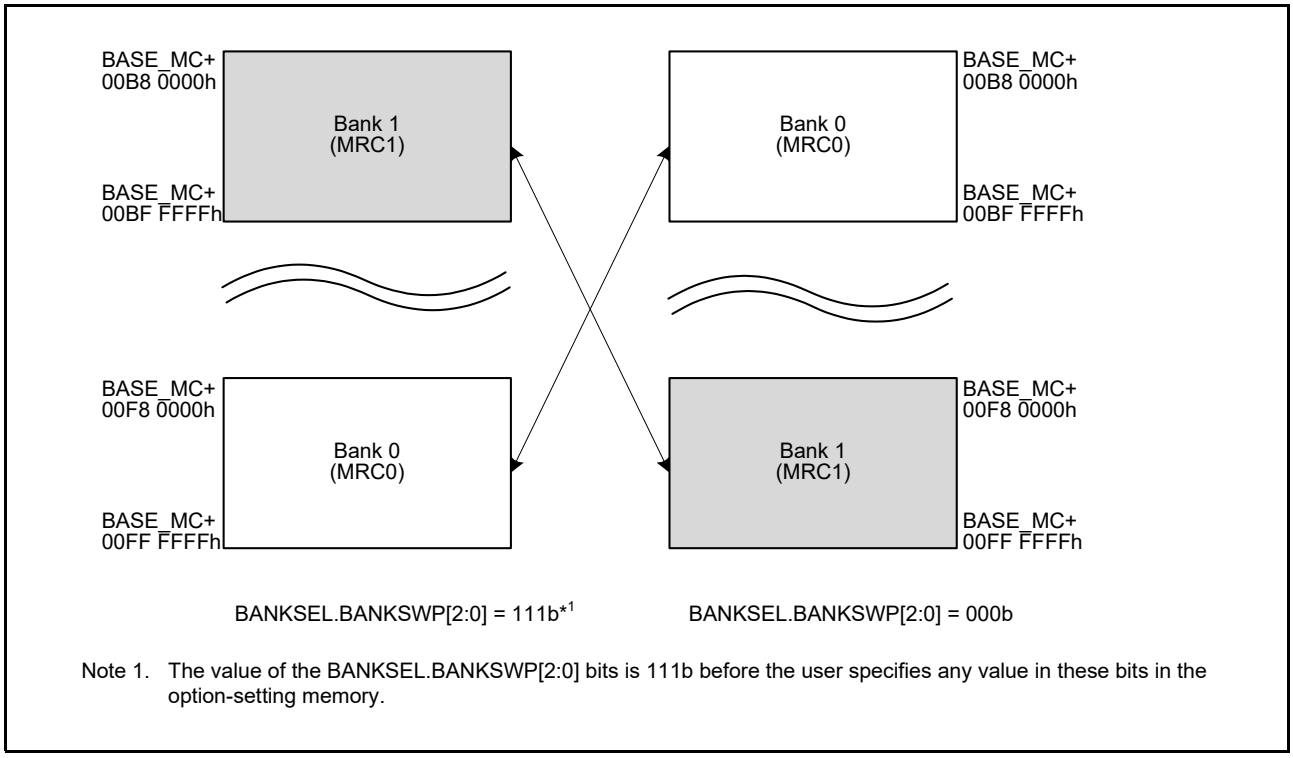
65.9.4 Dual Bank Function

The bank mode switching function and startup bank selection function can be used to update the user program while execution of the program is in progress.
These functions provide a way to safely update the program even if rewriting is suspended by a reset.

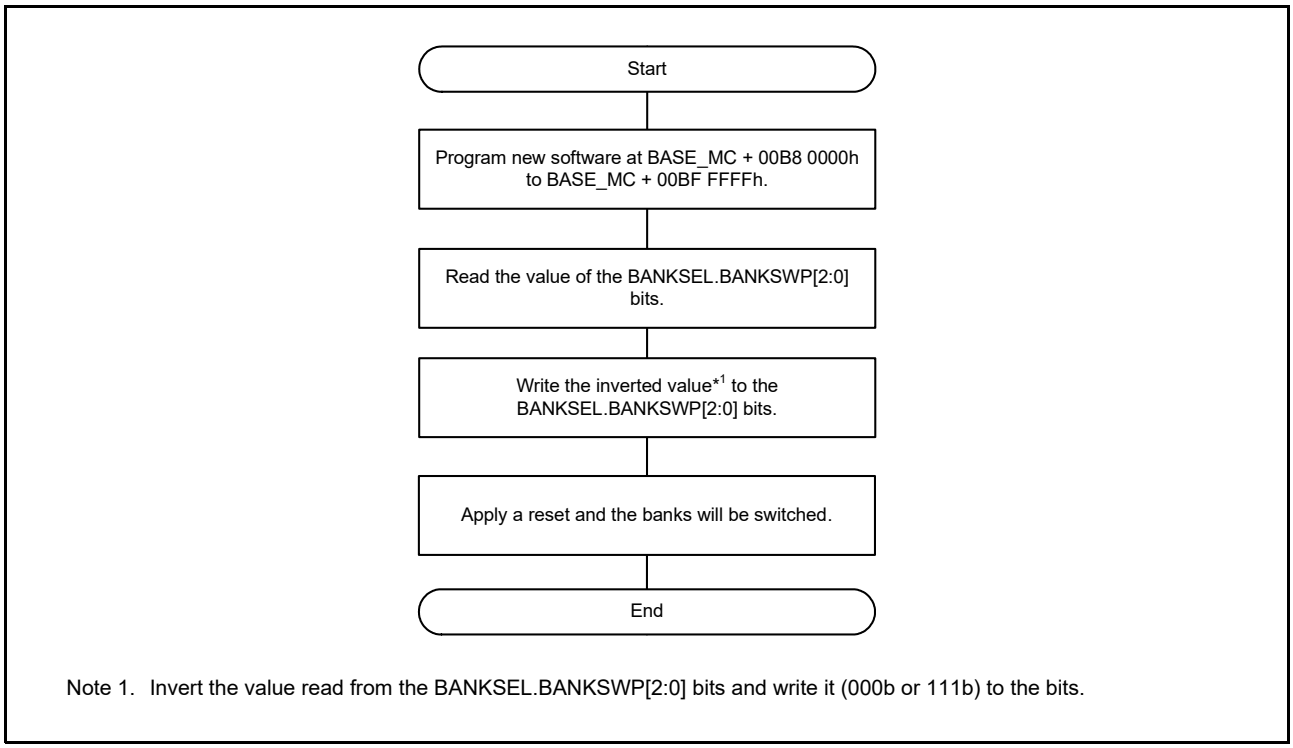
65.9.4.1 Bank Mode Switching Function

This function can be used to switch operations between two modes; linear mode, in which the user area in the code MRAM is handled as a single area, and dual mode, in which it is handled as two bank areas. Figure 65.38 shows the bank mode switching function. Setting the DUALSEL.BANKMD[2:0] bits in the option-setting memory and then applying a reset switches the bank mode. Selecting dual mode enables the startup bank selection function.
Note that the startup program protect function cannot be used when dual mode is selected (DUALSEL.BANKMD[2:0] = 000b).



Note 1. The value of the DUALSEL.BANKMD[2:0] bits is 111b before the user specifies any value in these bits in the option-setting memory.

Figure 65.38 Example of Bank Mode Switching (Example in the Product with 1-Mbyte Code MRAM)



65.9.4.2 Startup Bank Selection Function

This function can be used to select the bank area where program execution is started when dual mode is selected (DUALSEL.BANKMD[2:0] = 000b). This provides a way to safely update the program even if rewriting is suspended by a reset. Figure 65.39 shows the startup bank selection function and Figure 65.40 shows an example of startup bank selection flow. Setting the BANKSEL.BANKSWP[2:0] bits in the option-setting memory and then applying a reset switches the addresses between banks 0 and 1 and starts program execution from the updated area. This function is disabled when linear mode is selected.

Note 1. The value of the BANKSEL.BANKSWP[2:0] bits is 111b before the user specifies any value in these bits in the option-setting memory.

Figure 65.39 Example of Startup Bank Selection (Example in the Product with 1-Mbyte Code MRAM)

Note 1. Invert the value read from the BANKSEL.BANKSWP[2:0] bits and write it (000b or 111b) to the bits.

Figure 65.40 Example of Startup Bank Selection Flow (Example in the Product with 1-Mbyte Code MRAM)

65.9.5 Block Swap Function

This function can be used to update the user program while program execution is in progress. This provides a way to safely update the program even if rewriting is suspended by a reset.

A half or quarter of the code MRAM can be allocated as block swap areas. The total size of the block swap areas can be selected by the BLSEL.BLSWAREA bits. When resizing the block swap areas, be careful not to destroy the software in use.

Be sure to specify the same attribute (secure or non-secure area) to both block swap areas.

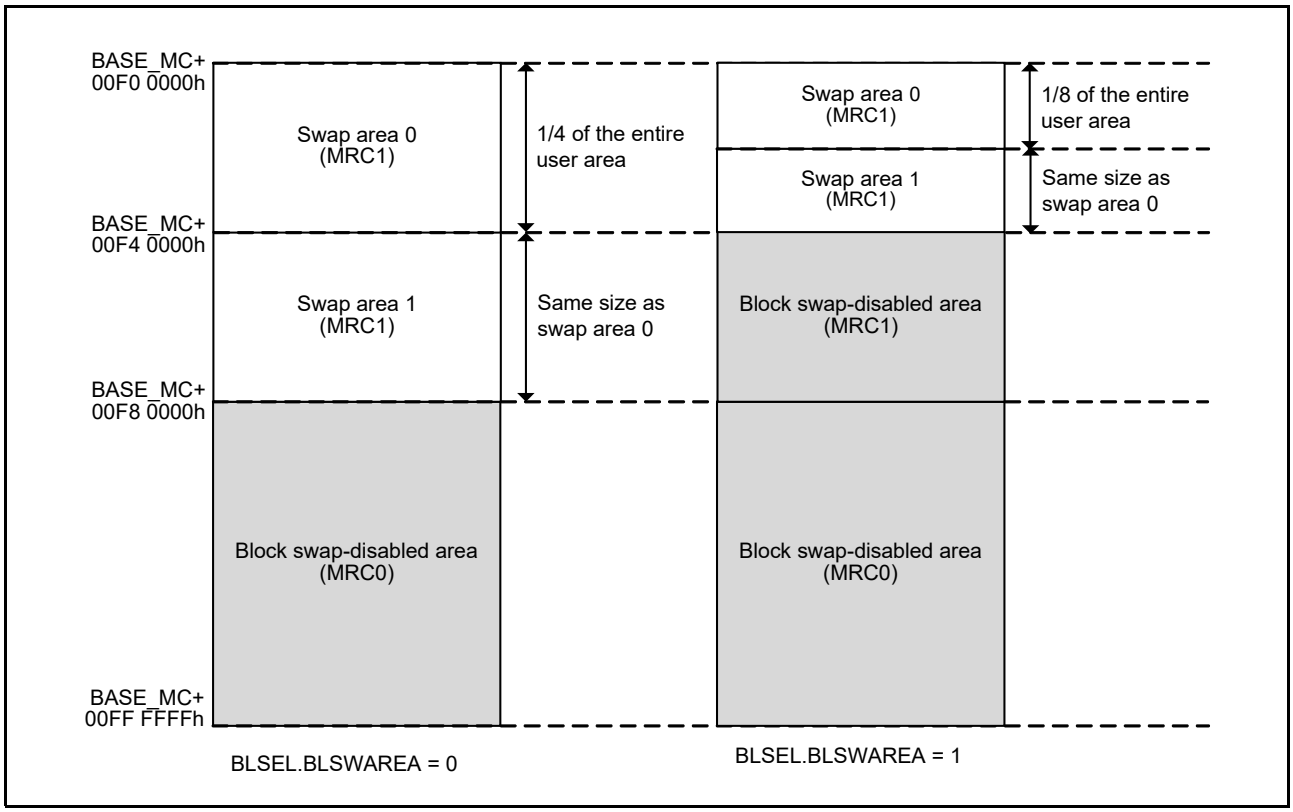


Figure 65.41 Sizes of the Source and Target Areas for Block Swap

65.9.5.1 Block Swap Selection

This function provides a way to safely update the program even if rewriting is suspended by a reset. Figure 65.42 and Figure 65.43 show examples of block swap selection and Figure 65.44 shows an example of block swap selection flow. Setting the BLKSWPn_S.SWPi[3:0] or BLKSWPn_NS.SWPi[3:0] bits in the option-setting memory to 0000b and then applying a reset swaps the addresses of the selected blocks between the source and target areas (swap areas 0 and 1). Note that the block swap selection function cannot be used when dual mode is selected (DUALSEL.BANKMD[2:0] = 000b).

For the correspondence between the BLKSWPn_S.SWPi[3:0] or BLKSWPn_NS.SWPi[3:0] bits and the target blocks (addresses) for block swap, refer to section 7.2.10, Block Swap Setting Register n for Secure Application (BLKSWPn_S) (n = 0 to 3), Block Swap Setting Register n for Non-Secure Application (BLKSWPn_NS) (n = 0 to 3).

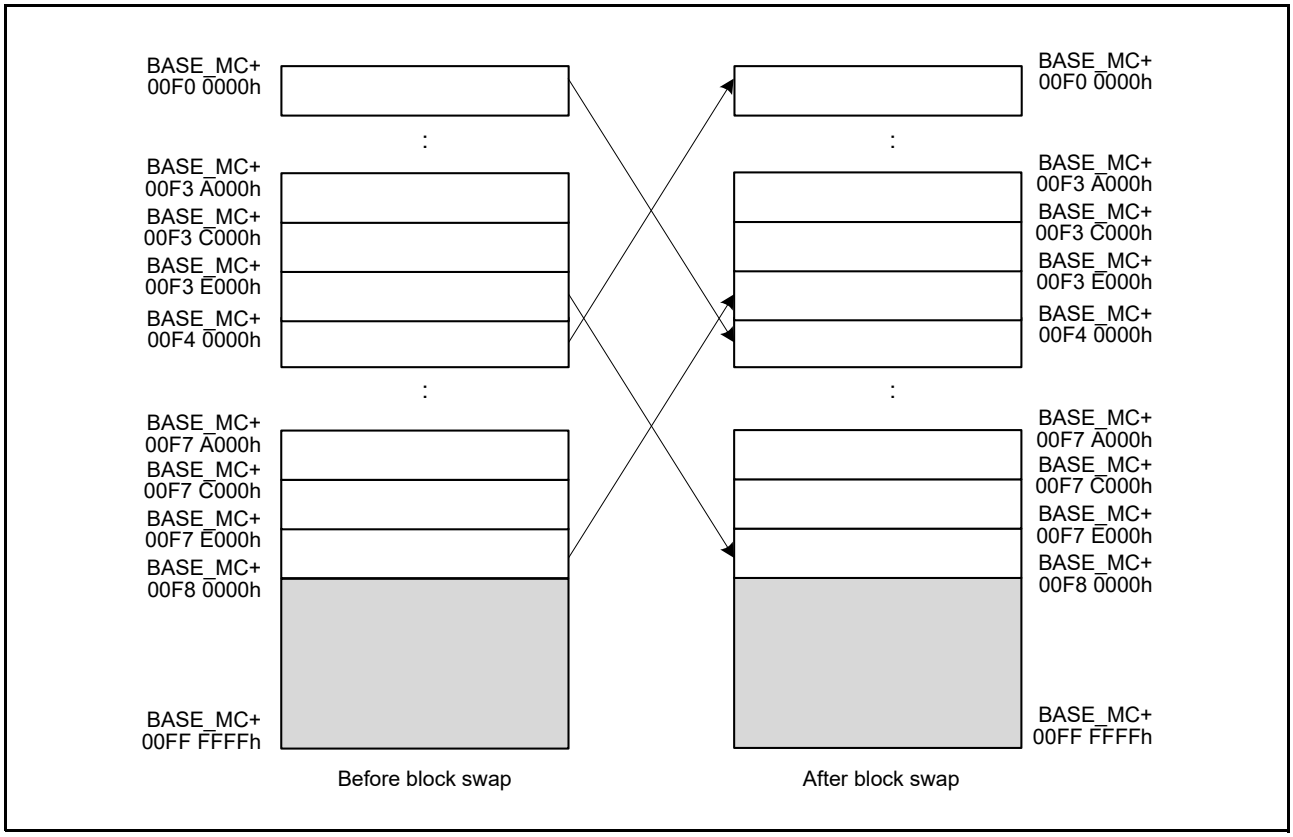

Figure 65.42 Example of Block Swap Selection when the Block Swap Areas are 1/2 (BLSEL.BLSWAREA = 0) of the Code MRAM (Example in the Product with 1-Mbyte Code MRAM)

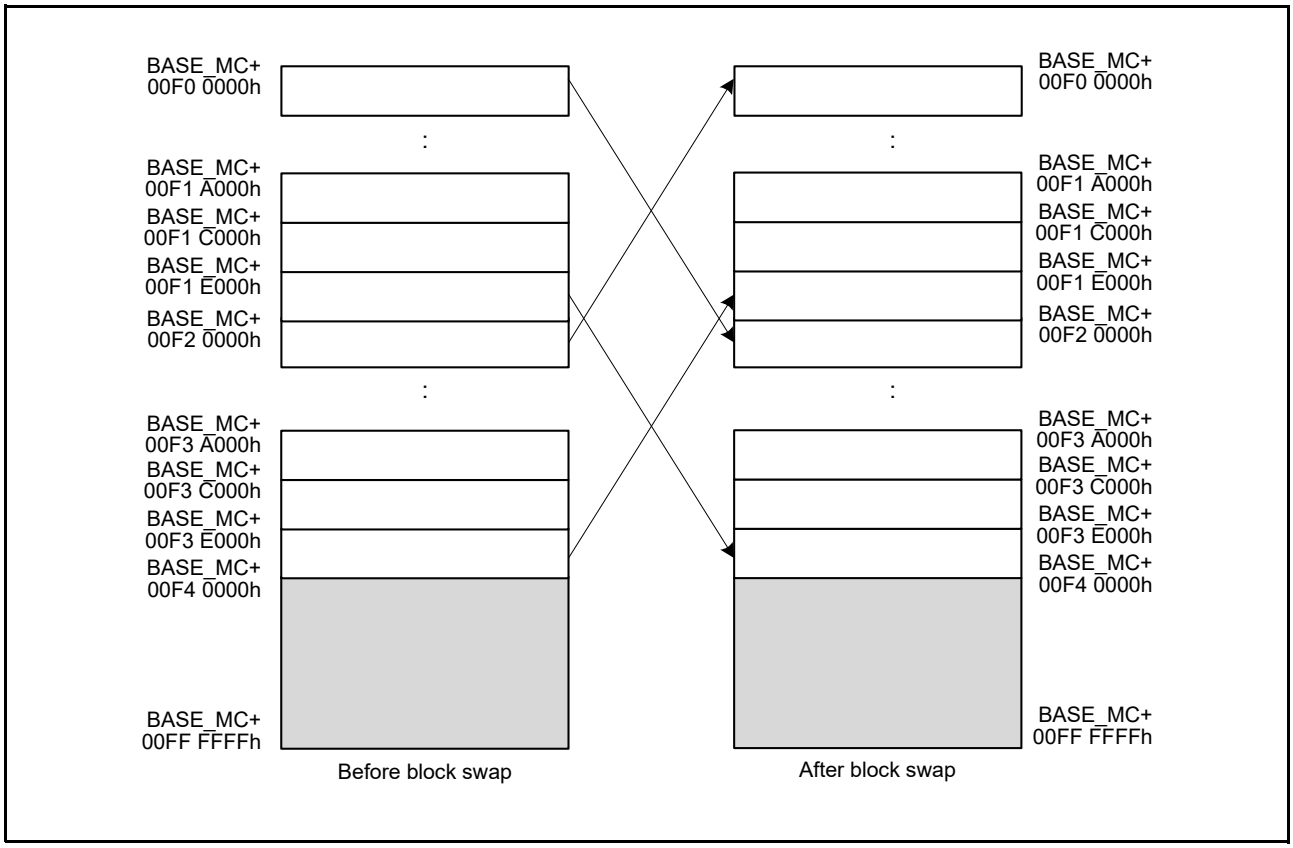

Figure 65.43 Example of Block Swap Selection when the Block Swap Areas are 1/4 (BLSEL.BLSWAREA = 1) of the Code MRAM (Example in the Product with 1-Mbyte Code MRAM)

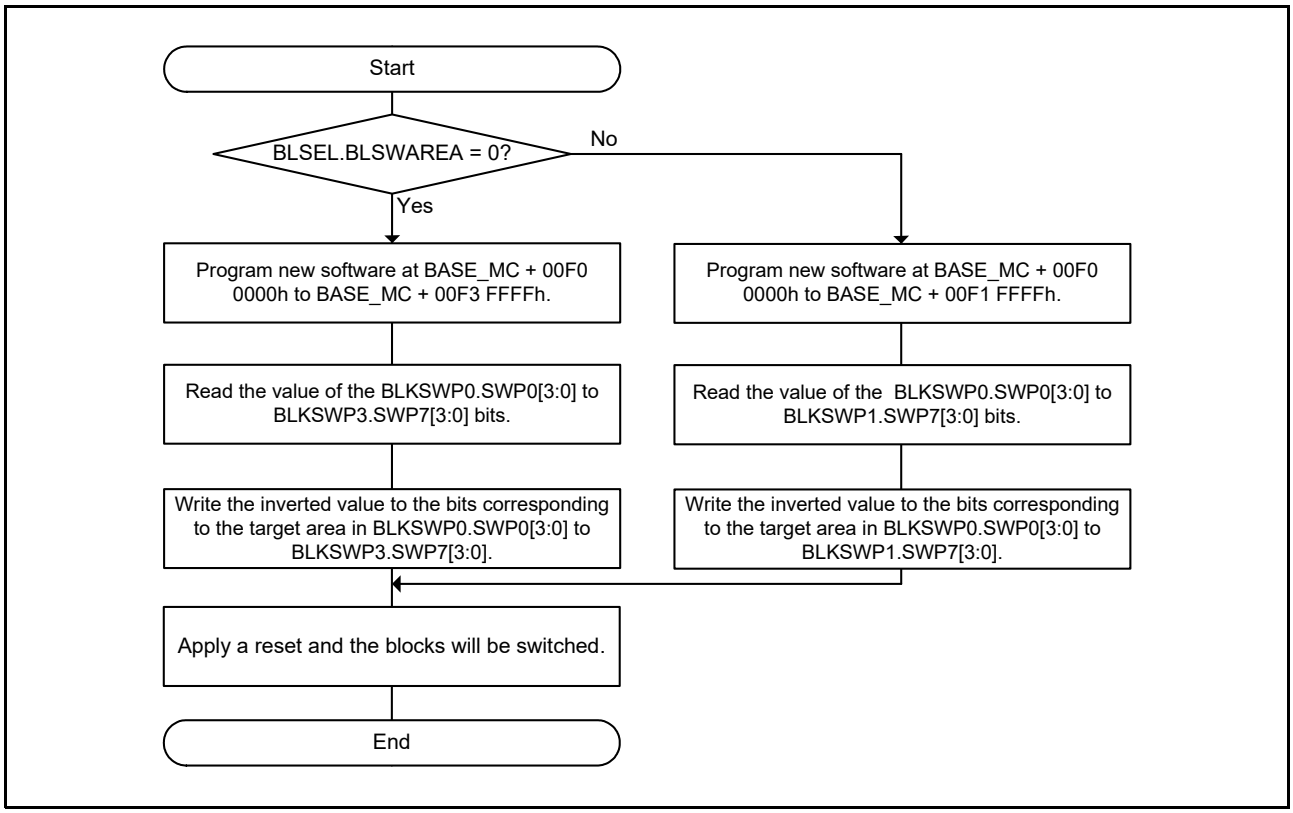

Figure 65.44 Example of Block Swap Selection Flow (Example in the Product with 1-Mbyte Code MRAM)

65.9.6 Fault Correction and Detection

MRAM systems are equipped with ECC circuitry to correct and detect errors. DEC-TED (double bit error correction and triple bit error detection) ECC corrects errors in 128-bit data units. Code MRAM uses two ECC circuits for 256 bit readout, and extra MRAM uses one ECC circuit for 128 bit readout.

If there is a DEC error in the code MRAM reading, error correction is performed and the MRCRAES.DECERRC flag is set to 1. If there is a TED error, the MRCRAES.TEDERRC flag is set to 1, but error correction is not possible. When an error is detected, the error address is stored in the MRCRDEA register for DEC error and in the MRCRTEA register for TED error.

If a DEC error occurs, read the data at the error address, and write back. If a TED error occurs, update all 32 bytes of data and overwrite with the correct data.

If there is a DEC error in the extra MRAM reading, error correction is performed and the MRERAES.DECERRE flag is set to 1. If there is a TED error, the MRERAES.TEDERRE flag is set to 1, but error correction is not possible. When an error is detected, the error address is stored in the MRERDEA register for DEC errors and in the MRERTEA register for TED errors. If a DEC error occurs, read the data at the error address, and write back. If a TED error occurs, update all 32 bytes of data and overwrite with the correct data.

65.9.6.1 Test Method for ECC Circuits

The ECC circuit can be tested by setting the program data and ECC data to desired values. A block diagram of the ECC test circuit is shown in Figure 65.45.

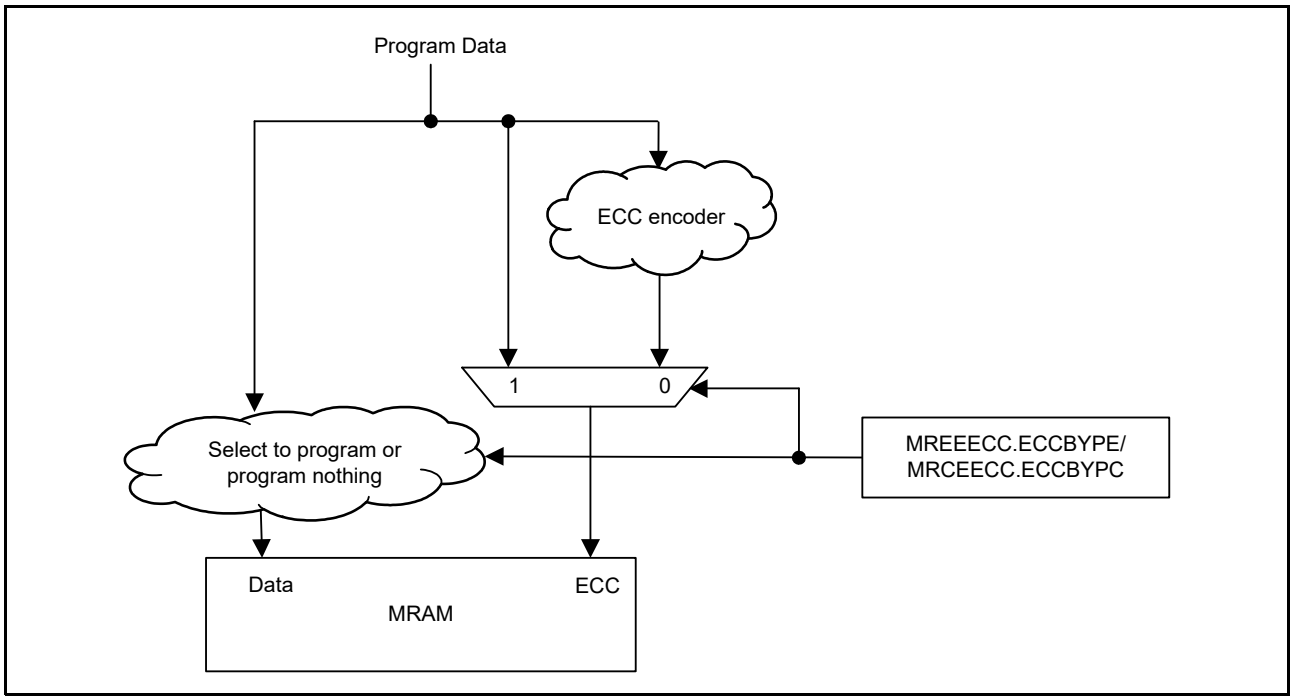

Figure 65.45 Block Diagram of the ECC Test Circuit

Table 65.43 Changes in Data Allocation Depending on the Value of MRCEECC.ECCBYPC

	Code MRAM	
MRCEECC.ECCBYPC	**Data[255:0]**	**ECC[33:0]**
0	Program data[255:0]	ECC code generated from program data[127:0]
1	Program nothing	{Program data[144:128], Program data[16:0]}

Table 65.44 Changes in Data Allocation Depending on the Value of MREEECC.ECCBYPE

	Extra MRAM	
MREEECC.ECCBYPE	**Data[127:0]**	**ECC[16:0]**
0	Program data[127:0]	ECC code generated from program data[127:0]
1	Program nothing	Program data[16:0]

Figure 65.46 shows the ECC decoder test flow for the code MRAM and Figure 65.47 shows the ECC decoder test flow for the data MRAM. The code MRAM has two ECC decoders and ECC errors are merged, so when testing the ECC decoder, test the ECC decoder circuits individually.

Note 1. To eliminate ECC errors in instruction fetching.
Note 2. If you get an error, try the test again at a different address.
Note 3. Invert the bits of the code according to the error condition you want to check (1 to 3)

Replace the bits shown in Table 65.43, Table 65.44with the code you created and write to the same address as DATA.

Note 4. See Table 65.45, Table 65.46 for how to check the result.

Table 65.45 Expected Value of Code MRAM Error Status

	Expected Value		
Check Results	**1-bit Invert**	**2-bit Invert**	**3-bit Invert**
MRCRAES.DECERRC	0	1	0
MRCRAES.TEDERRC	0	0	1

Table 65.46 Expected Value of Data MRAM Error Status

	Expected Value		
Check Results	**1-bit Invert**	**2-bit Invert**	**3-bit Invert**
MRERAES.DECERRE	0	1	0
MRERAES.TEDERRE	0	0	1

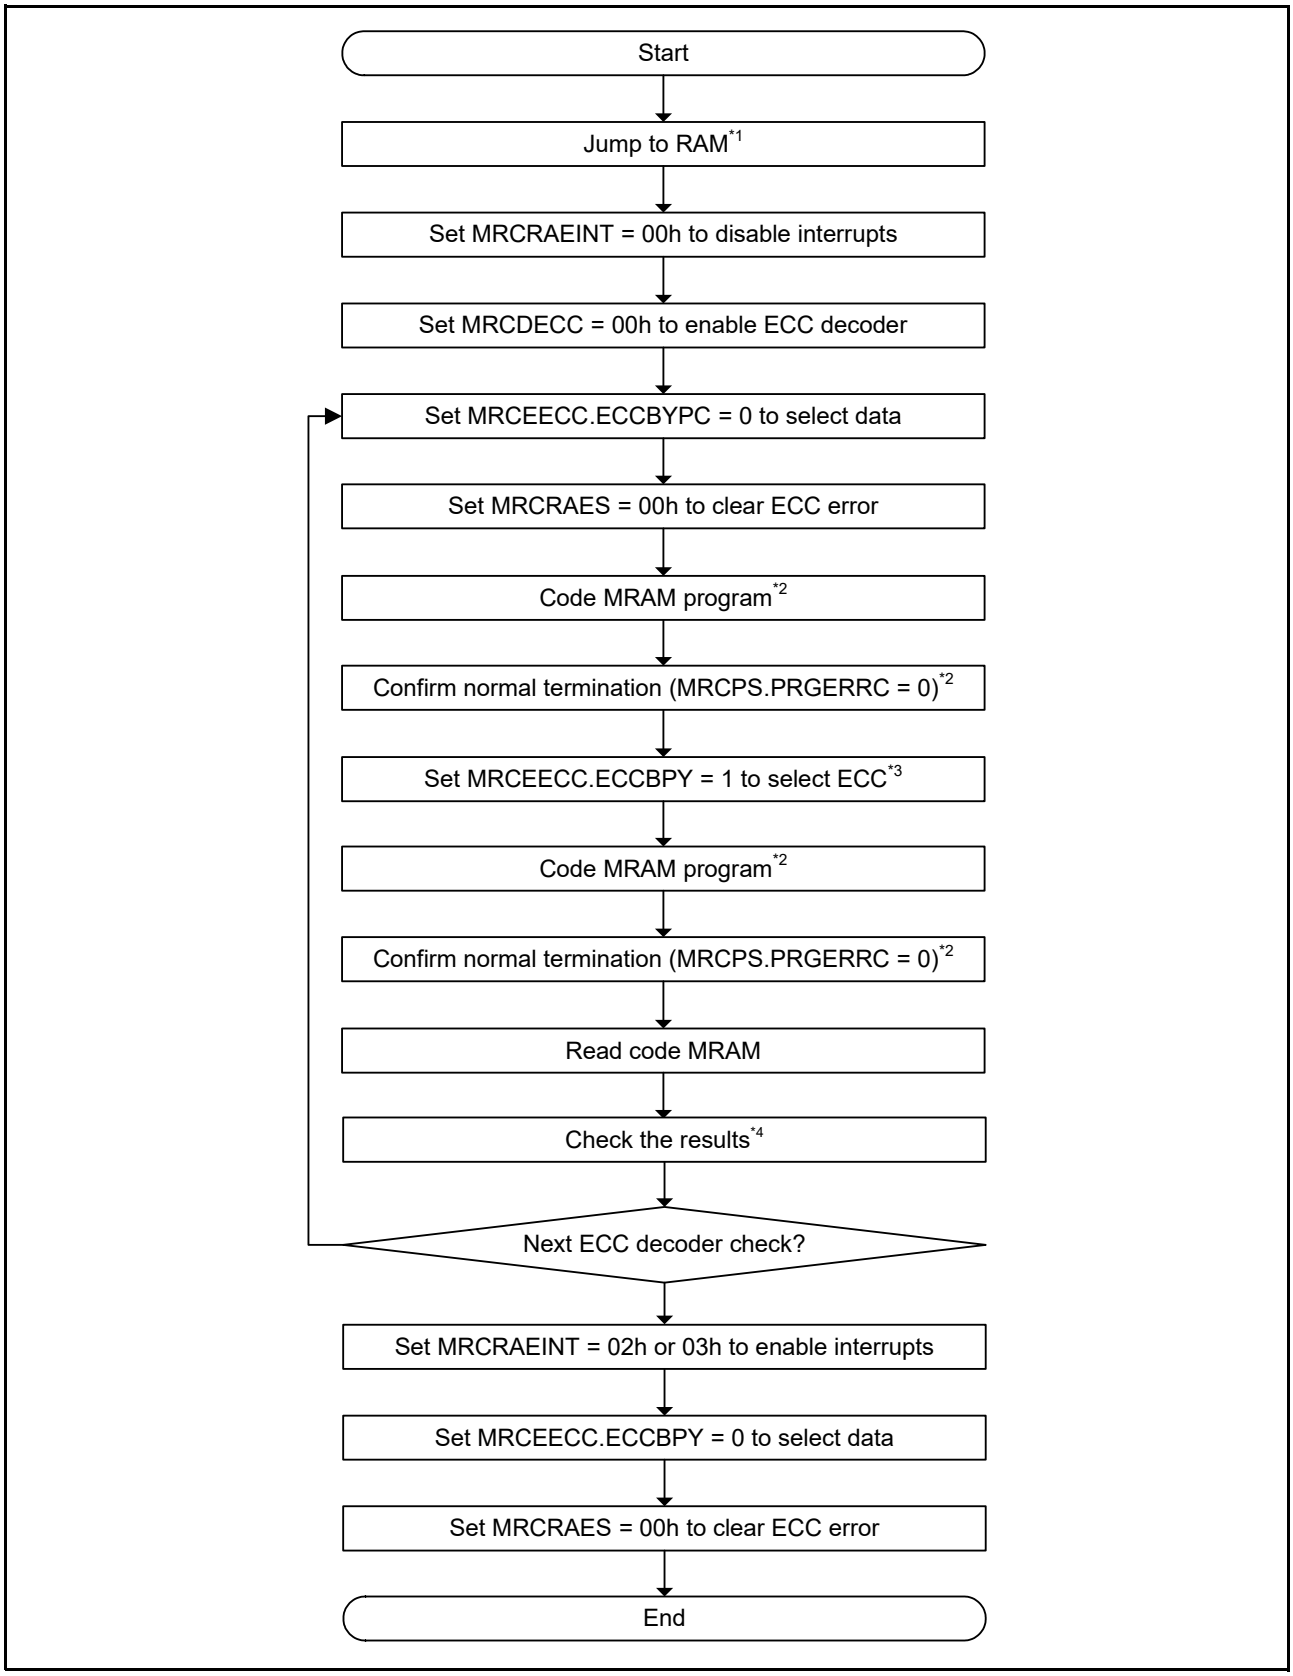

Figure 65.46 Code MRAM ECC Decoder Test Flow

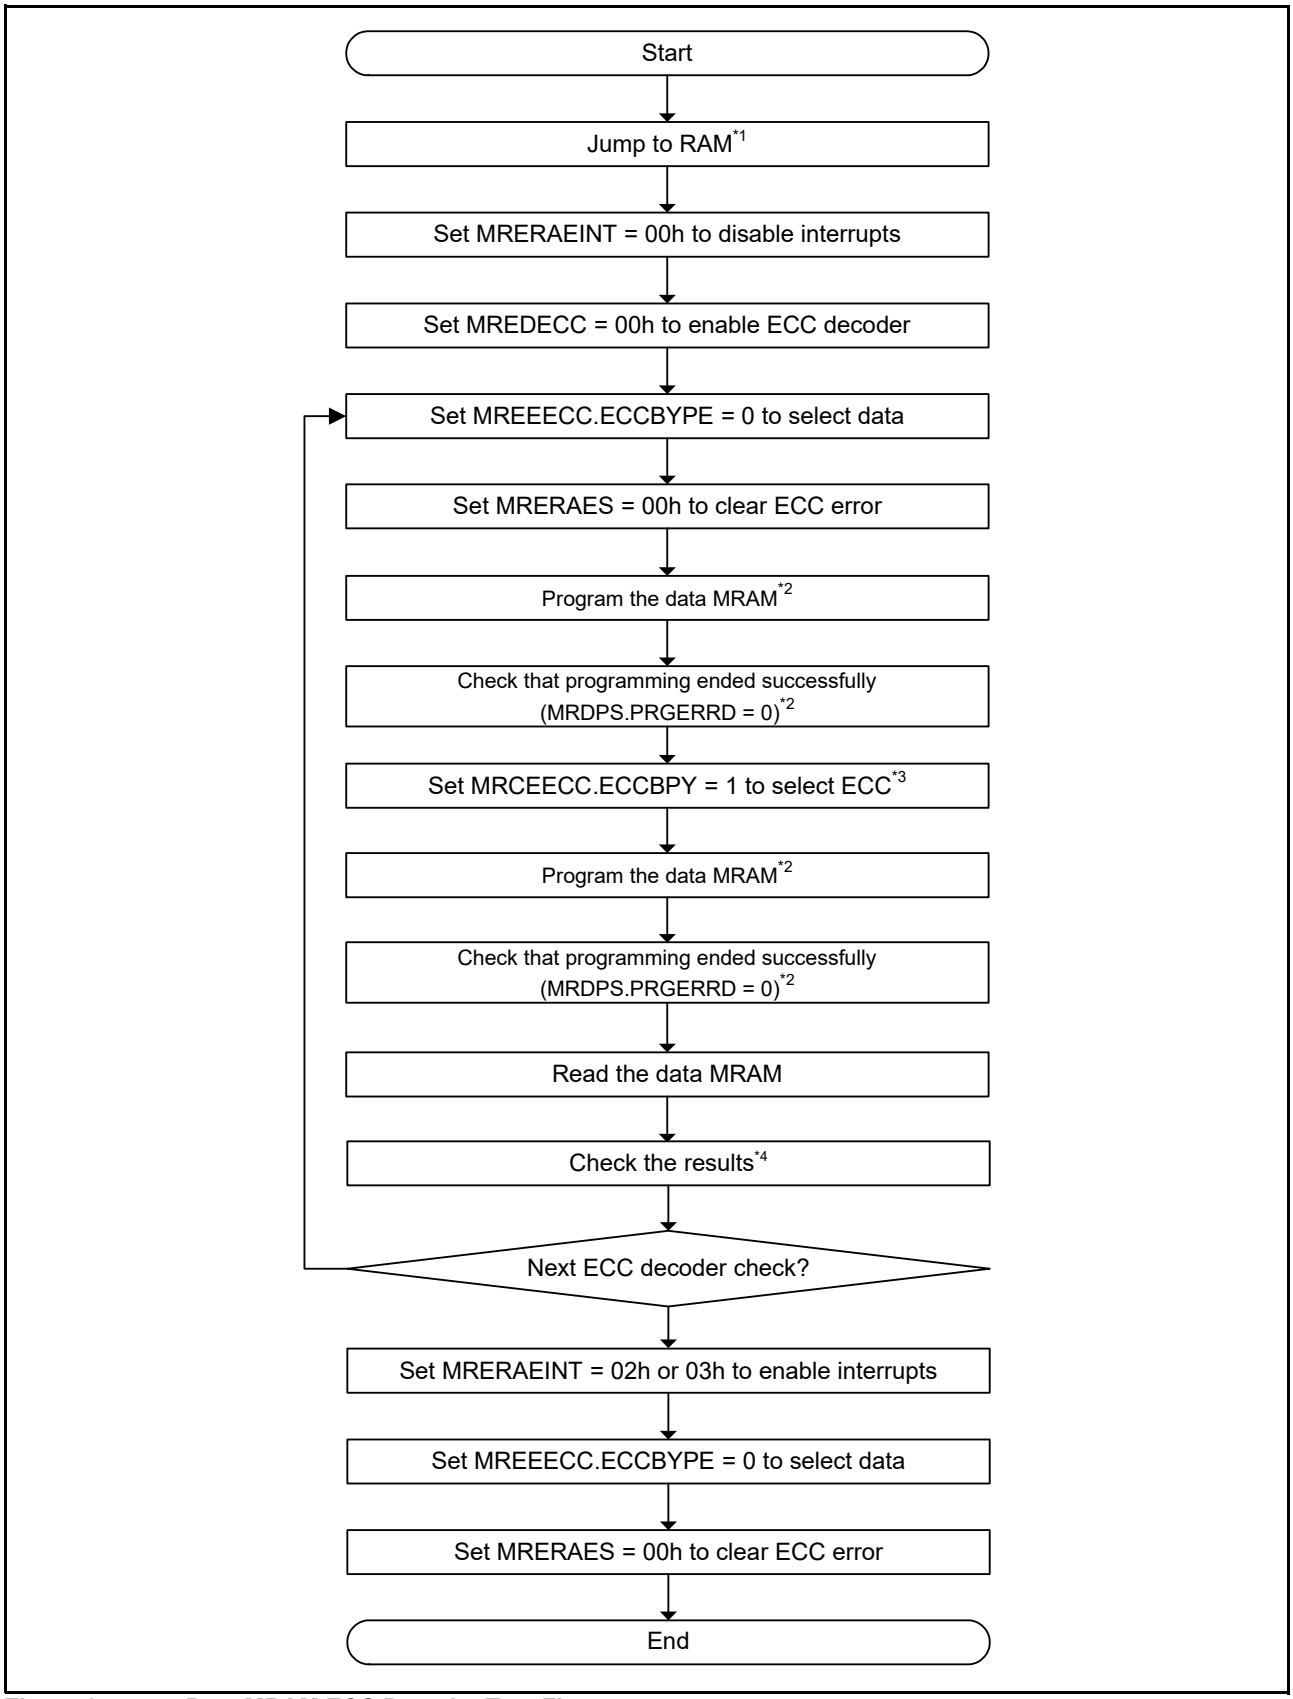

Figure 65.47 Data MRAM ECC Decoder Test Flow

65.10 Configuration Update Transfer

After the program or configuration set command operation, the system status can be updated by configuration update transfer without system reset. When 1 is written to the MCTRCNTR.TRTRG bit in the read mode (the MENTRYR register is 0000h and the WHUKEXE flag in MREZS register is 0), MACI transfers data from extra MRAM. The MCTRSTATR register can monitor to configuration update transfer processing status. Extra MRAM cannot be read during configuration data transfer.

Figure 65.48 shows configuration update transfer usage.

If the WHUKEXE flag in the MREZS register is set to 1 in the configuration update transfer flow, the configuration update transfer must be re-executed after the W-HUK zeroing is finished.

See section 65.5.23, MRAM Configuration Update Transfer Control Register (MCTRCNTR), and section 65.5.24, MRAM Configuration Update Transfer Status Register (MCTRSTATR) in details of the associated registers specifications (the MCTRCNTR and MCTRSTATR registers).

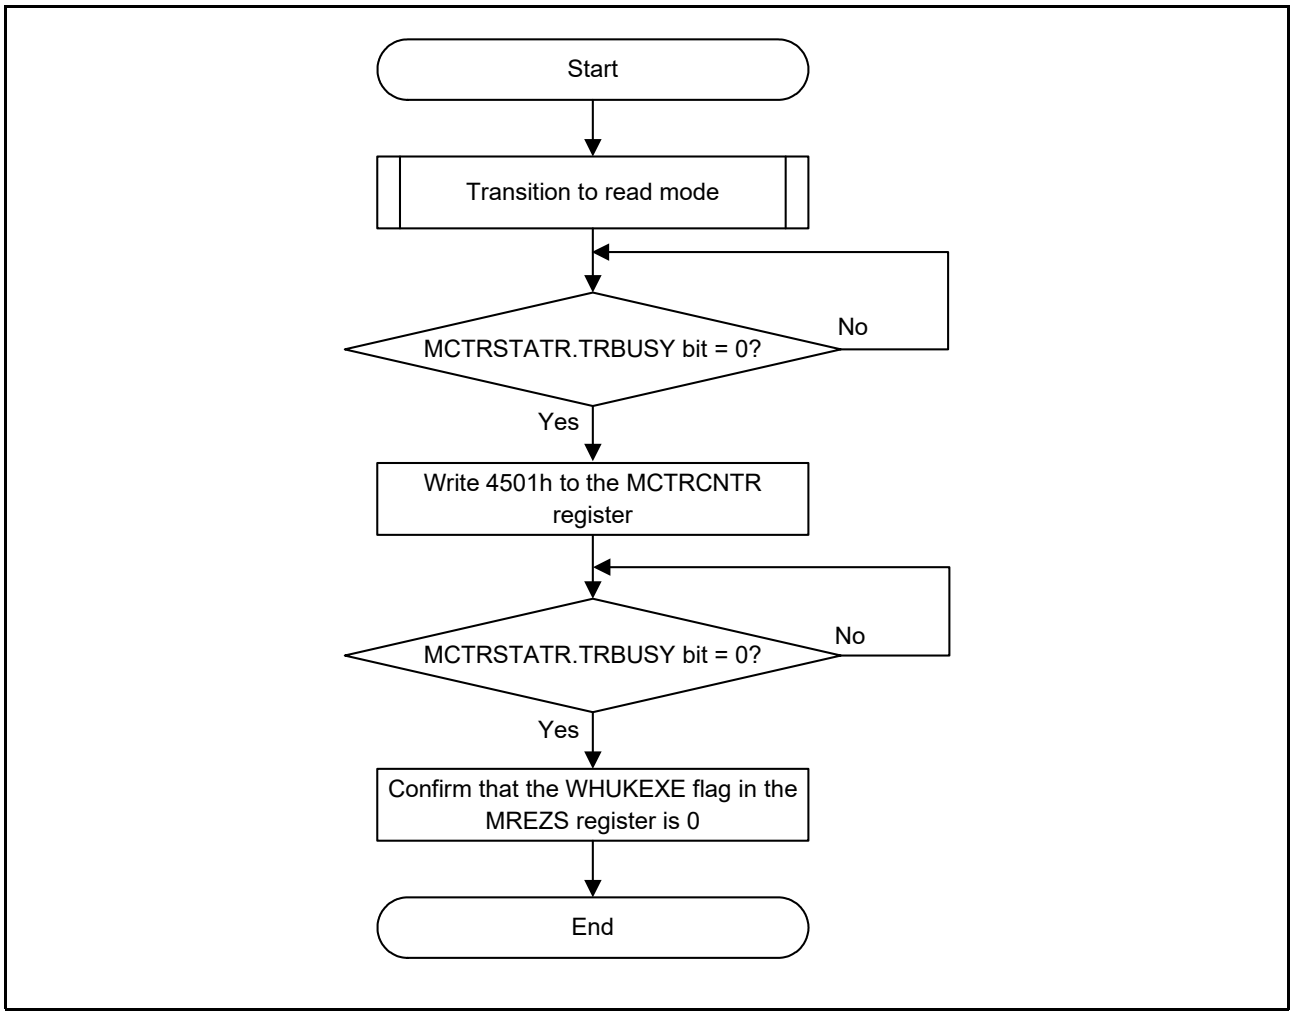

Figure 65.48 Configuration Update Transfer Usage

65.11 Boot Mode

There are four types of boot mode; boot mode (SCI interface), boot mode (USB interface), boot mode (JTAG/SWD interface), and boot mode (FINE interface).
Table 65.47 lists the I/O pins used in boot mode. Table 65.48 lists the available communication interface used in the boot mode.

Table 65.47 I/O Pins Used in Boot Mode

Pin Name	I/O	Mode to be Used	Use
MD/FINED	Input	Boot mode (SCI interface) Boot mode (USB interface)	Selection of operating mode
P303/RXD1	Input	Boot mode (SCI interface)	For host communication (to receive data through SCI)
P302/TXD1	Output		For host communication (to transmit data through SCI)
USB0_DP, USB0_DM	I/O	Boot mode (USB interface)	Data input/output of USB
P101/USB0_VBUS	Input		Detection of connection and disconnection of USB cables
P301/TCK [JTAG]	Input	Boot mode (JTAG/SWD interface)	On-chip emulator or boundary scan pins.
P300/TMS [JTAG]	Input		
P302/TDO [JTAG]	Output		
P303/TDI [JTAG]	Input		
P301/SWCLK [SWD]	Input		Serial wire clock
P300/SWDIO [SWD]	I/O		Serial wire debug data input/output
MD/FINED	I/O	Boot mode (FINE interface)	FINE data input/output

Table 65.48 Available Communication Interface Used in Boot Mode

Main clock oscillator or external clock is connected	Yes	No	No
Sub clock oscillator is connected*1	Yes or No	Yes	No
Available interface	SCI or USB	SCI or USB	SCI
Tool connection time*2	Up to 1 second	Up to 2 seconds	Up to 3 seconds

Note 1. The drive capability of the sub clock oscillator is set to standard by SOMCR.SODRV bit. Note that if you use the crystal corresponding the low drive capability on your board, the crystal may not oscillate in the boot mode.
Note 2. See the boot firmware manual for the detail connection time.

65.11.1 Boot Mode (SCI Interface)

In boot mode (SCI interface), the host sends control commands and data for programming, and the MRAM is programmed accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.
When this MCU is activated in boot mode (SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming by receiving control commands from the host.
Figure 65.49 shows the system configuration for operations in boot mode (SCI interface).

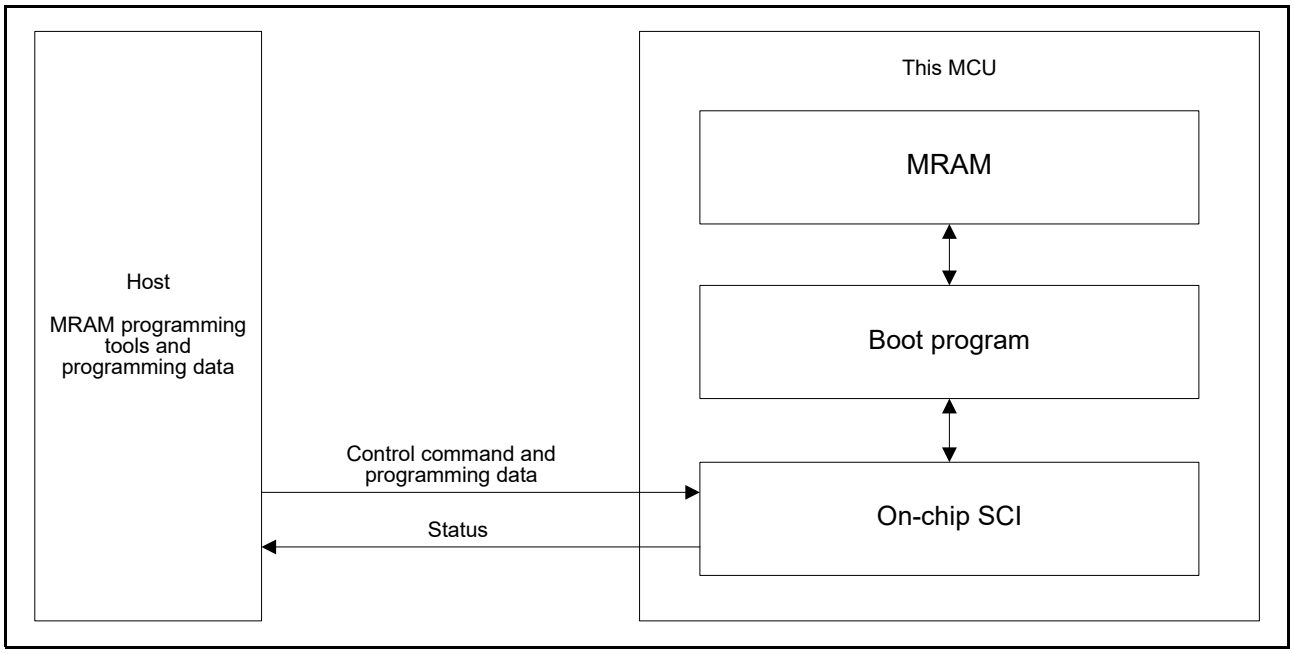

Figure 65.49 System Configuration for Operations in Boot Mode (SCI Interface)

65.11.2 Boot Mode (USB Interface)

In boot mode (USB interface), the MRAM can be programmed by sending control commands and program data from the host. An on-chip USB is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 65.50 shows the configuration of a system for use in boot mode (USB interface). The USB cable must be connected on reset release.

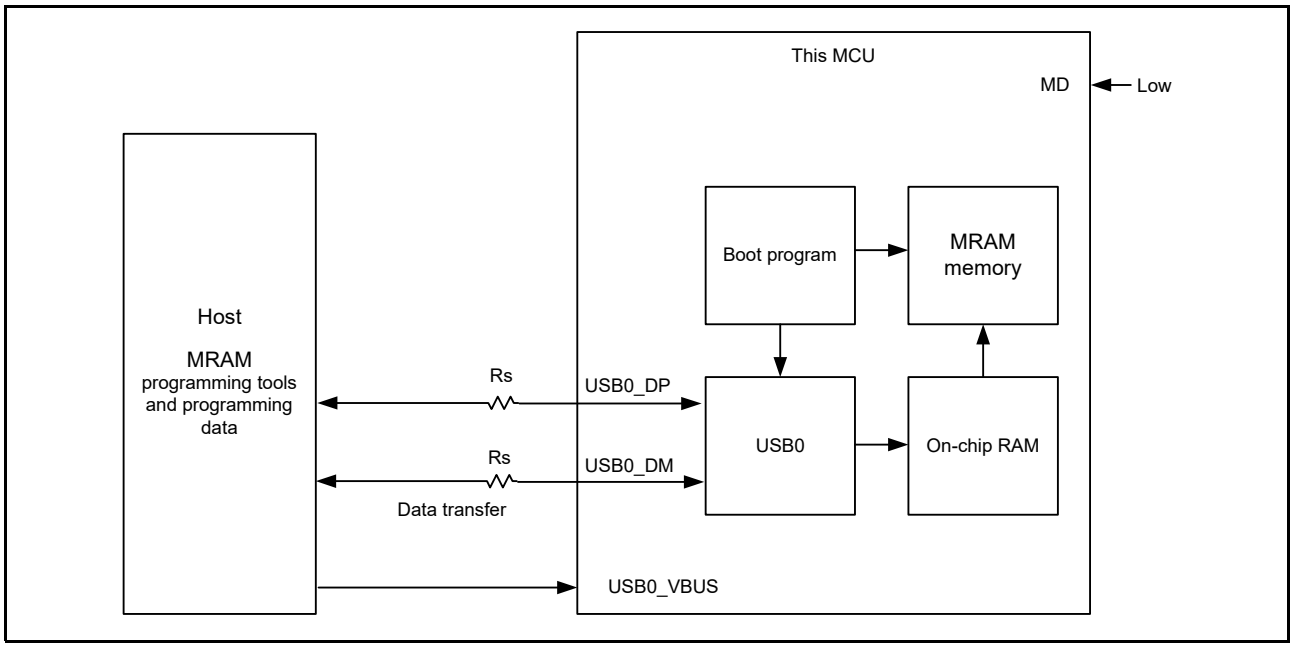

Figure 65.50 System Configuration in Boot Mode (USB Interface)

65.11.3 Boot Mode (FINE Interface)

The MRAM can be programmed using the FINE in boot mode (FINE interface). The MRAM can be rewritten.

65.11.3.1 Operating Conditions in Boot Mode (FINE Interface)

FINE is used to communicate with the serial programmer in boot mode (FINE Interface).
Figure 65.51 shows an Example of Pin Connections in Boot Mode (FINE Interface). Table 65.49 lists Pin Handling in Boot Mode (FINE Interface).
The example of pin connections shown in Figure 65.51 is a simplified circuit. Operations are not guaranteed in all systems.

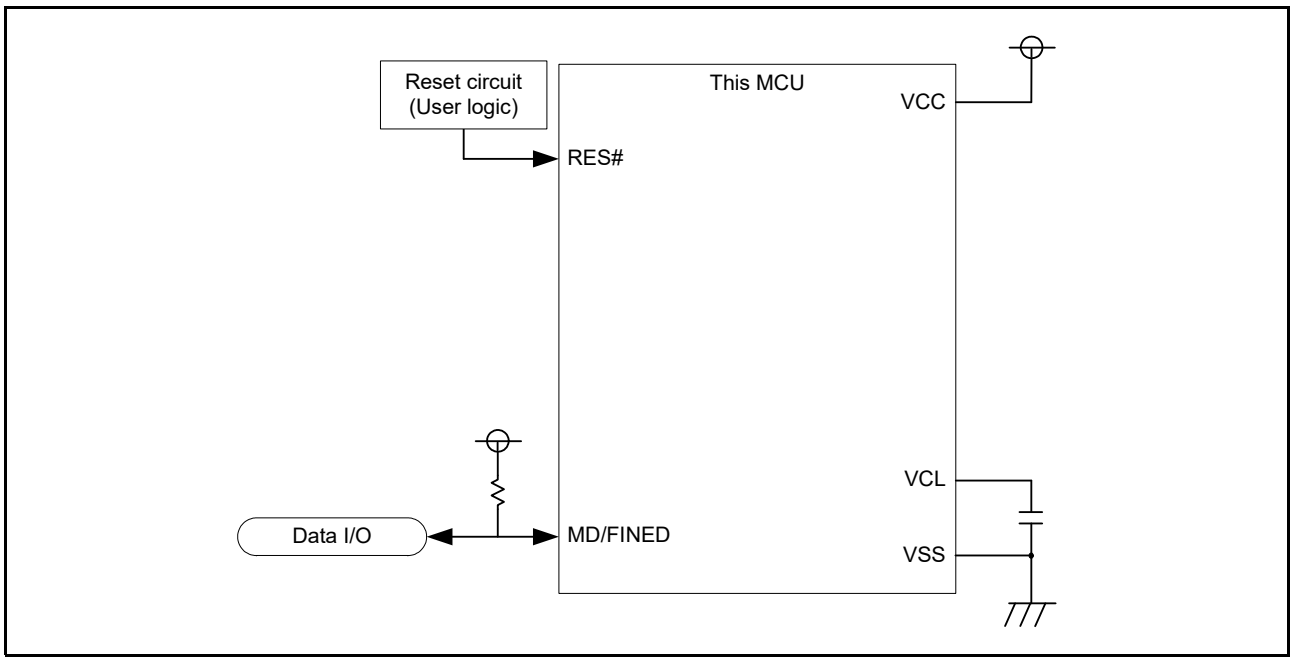

Figure 65.51 Example of Pin Connections in Boot Mode (FINE Interface)

Table 65.49 Pin Handling in Boot Mode (FINE Interface)

Pin Name	Name	I/O	Function
VCC, VSS	Power supply input	Input	Input 1.62 V or higher to the VCC pin. Input 0 V to the VSS pin.
VCL	Decoupling capacitor connect pin	—	Connect to the VSS pin via a 0.22-μF multilayer ceramic capacitor for stabilizing the internal voltage.
MD	Operating mode control/ data I/O	I/O	Connect the VCC pin via a resistor (pull up).
RES#	Reset input	Input	Reset pin. Connect to the reset circuit.

65.12 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite MRAM in boot mode.

(1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

65.12.1 Environments for Serial Programming

The recommended environments for rewriting the MRAM of the MCU with data are described below.

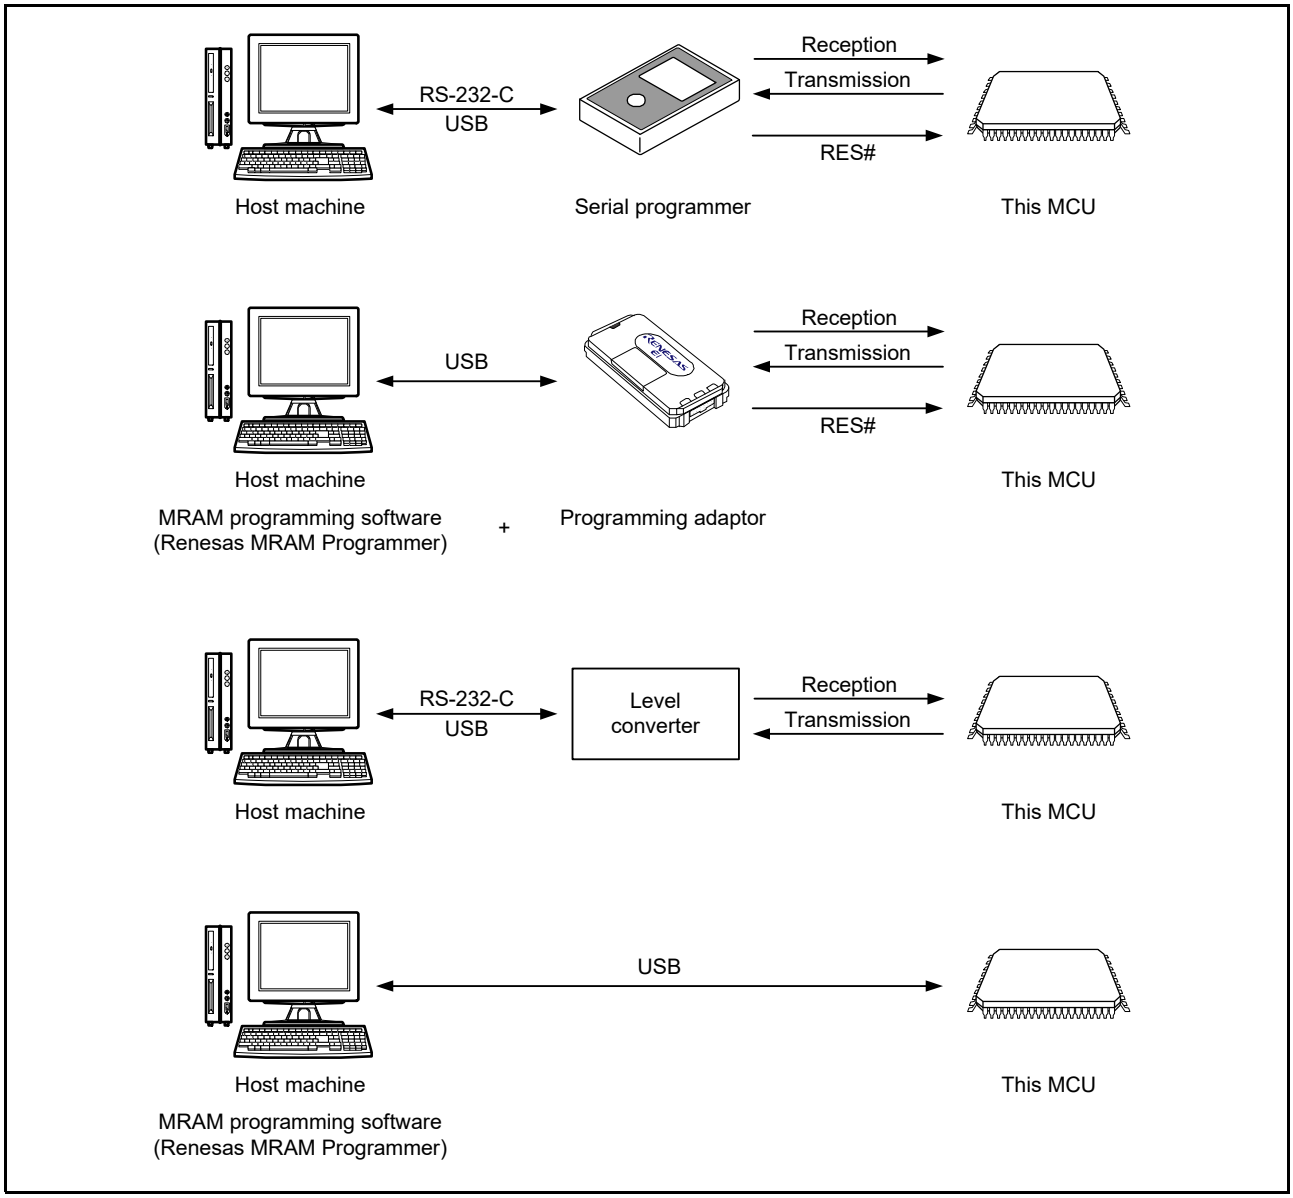

Figure 65.52 Environments for Rewriting the MRAM

65.13 Programming through Self-Programming

65.13.1 Overview

This MCU supports programming of the MRAM by the user program itself. The write page buffer or the MACI commands can be used with user programs for writing to the MRAM. This allows upgrading of user programs and rewriting of constant data fields.
The program for rewriting must be transferred to the internal RAM or external memory in advance when the BGO is not available or when rewriting the option-setting memory.

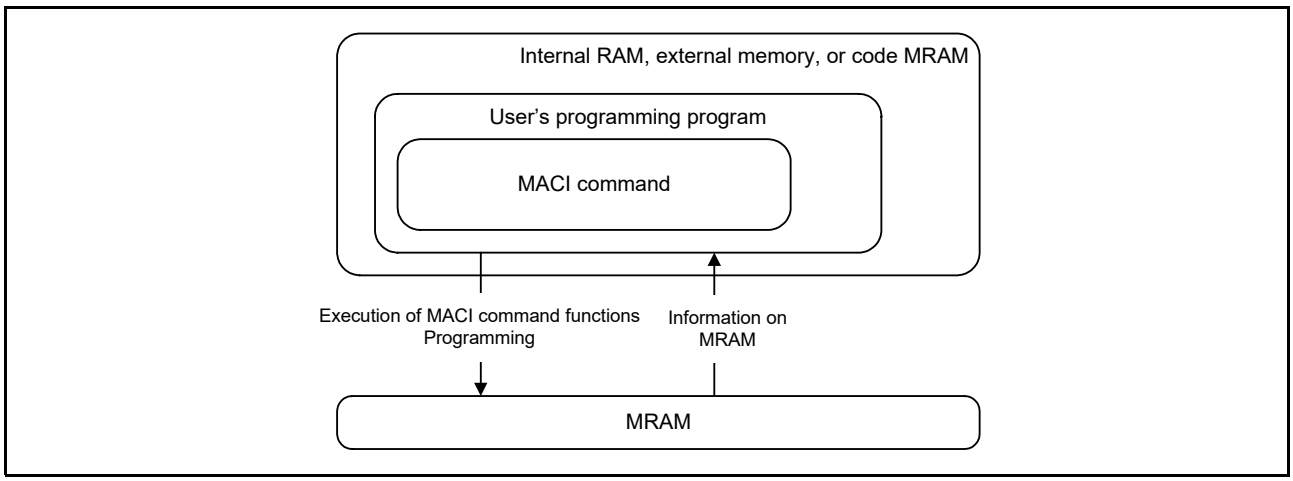

Figure 65.53 Schematic View of Self-Programming

For comprehensive information on the self-programming, see section 65.7, MACI Commands.

65.13.2 Parallel Accessibility

Parallel read and program accesses are possible in conditions shown in Table 65.50.
Read while program (background operation: BGO) is possible between different MRAM banks. Parallel read to different MRAM banks is possible. Only one MRAM bank can be programmed at the same time. W-HUK zeroing has highest priority among all MRAM programming requests. (See section 65.8.6, HUK Protection).
Programming of the code MRAM and extra MRAM cannot be done in parallel. A programming request issued later is kept waiting until previous programming is completed. If a request for programming of the code MRAM is issued while the MSTATR.MRDY flag is 0, programming begins after the flag becomes 1. If a request for programming of the extra MRAM (a program, configuration set, or increment counter command) is issued while the MRCPS.PRGBSYC flag is 1, programming begins after the flag becomes 0. Therefore, the programming time in these cases is the sum of the times of code MRAM programming and extra MRAM programming.
Reading from and programming of a given MRAM area cannot be done in parallel. The values shown in section 67.15, MRAM Characteristics, are the individual operation times in which no arbitration is performed between reading and programming operations.

Table 65.50 Parallel Accessibility

		Code MRAM Bank 0 (MRC0)		Code MRAM Bank 1 (MRC1)		Extra MRAM		
		Read	Program	Read	Program	Read	Program (Data MRAM)	MACI Command
Code MRAM Bank 0 (MRC0)	Read	X	X	O	X	O*1	O*1	O
	Program	X	X	O	X	O*1	X	X
Code MRAM Bank 1 (MRC1)	Read	O	X	X	X	O*1	O*1	O
	Program	O	X	X	X	O*1	X	X
Extra MRAM	Read	O*1	O*1	O*1	O*1	X	X	X
	Program (Data MRAM)	O*1	X	O*1	X	X	X	O*2
	MACI Command	O	X	O	X	X	X*2	X

O: Executable
X: Not executable
Note 1. The bus master cannot read or program the extra MRAM during configuration update transfer (see section 65.10, Configuration Update Transfer).
Note 2. When the MENTRYR.MENTRY bit is set to 1, a slave bus error always occurs and programming of the data MRAM fails.

65.13.3 Reading MRAM

Special settings are not required to read MRAM after release from the reset state. Data can simply be read out through access to addresses in the MRAM.
When reading MRAM that has not yet been programming (i.e. that is in the nonprogrammed state), all bits are read as 1.

65.14 Usage Notes

65.14.1 Area where Programming was Interrupted by W-HUK Zeroing

The data stored in the area where programming was suspended due to zeroing of the W-HUK is undefined. To prevent malfunctions due to reading undefined data, care should be taken not to fetch instructions or read data from the area where writing has been suspended.

65.14.2 Actions Prohibited during Programming

Do not reduce the power to less than operating voltage.

65.14.3 Prohibition of Additional Programming

An OTP area that uses ECC cannot be programmed twice with different data.

65.14.4 Resets During Programming

For a reset due to the signal on the RES# pin during programming of the MRAM, wait for at least t_{RESW} (see section 67, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

65.14.5 Allocation of Vectors for Interrupts and Other Exceptions During Programming

Generation of an interrupt or other exception during programming may lead to fetching of the vector from the code MRAM.
The vectors cannot be read from code MRAM until the program is finished. Code MRAM requires up t_{PMC} (see section 67, Electrical Characteristics) of time to program. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the code MRAM. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming.

65.14.6 Synchronization of Code MRAM Program Completion and Subsequent Instruction Generation

When CPU writes to code MRAM, there is a time lag from execution of MRAM programming by code MRAM program sequencer. Therefore, after programming is finished, appropriate processing for synchronization is required for executing subsequent instructions. The processing for synchronization is shown as follow:

1. Code MRAM programming.
2. Confirm that programming of the code MRAM is finished.
3. Flush the Code MRAM programming data (see Figure 65.2 and Figure 65.3).
4. Synchronization (wait for flushing process to finish).
5. Subsequent instruction.

If it is necessary to avoid CPU stall in step 4., completion of code MRAM programming should be checked by the PRGBSYC bit in the MRCPS register instead of dummy reading in step 3.

65.14.7 Constraints During Programming of MRAM

Frequency change, transition to software standby, and transition to deep standby are prohibited while MRAM is being programmed.

65.14.8 Power Supply in Any Type of Boot Mode

We recommend against rewriting MRAM while power is being supplied from a host*1 as a process that is part of mass production.
If power is to be supplied from a host, proceed with sufficient evaluation in the user environment before putting this into practice.

Note 1. “Power is being supplied from a host” means that power is supplied by a device such as an emulator or by a USB host through a USB cable (USB bus power).

66. Internal Voltage Regulator

66.1 Overview

This MCU supports three types of power supply for the core voltage.

- Switching regulator (DCDC)
- External power supply from an external power device (external VDD)
- Linear regulator (LDO); however, this is only usable with R5K574xxE4xx and R5K574xxF4xx products.

Table 66.1 shows the specifications of the internal voltage regulator.
One of the power supply modes is selected as follows in accord with the connection of the VCC_DCDC pin and the setting of the UMRECR.DCDCCTL bit in the option-setting memory.

- The DCDC mode is selected when VCC is connected to the VCC_DCDC pin and the setting of the UMRECR.DCDCCTL bit is 1.
- The external VDD mode is selected when VCC is connected to the VCC_DCDC pin and the setting of the UMRECR.DCDCCTL bit is 0.
- The LDO mode is selected when VSS is connected to the VCC_DCDC pin, regardless of the setting of the UMRECR.DCDCCTL bit.

Table 66.1 Selection of the Power Supply

VCC_DCDC Pin Connection	UMRECR.DCDCCTL Bit	Power Mode
VCC	1	DCDC mode
VCC	0	External VDD mode
VSS	Don't care	LDO mode

66.2 Operation

66.2.1 DCDC Mode

Table 66.2 lists the DCDC mode pin settings, and Figure 66.1 shows the DCDC mode settings.
In DCDC mode, VDD is supplied from VCL through VLO output and an external inductor and capacitor.

Table 66.2 DCDC Mode Pin Settings

Pin	Settings
All VCC and VCC2 pins	• Connect each pin to the system power supply. • Connect each pin to VSS through a 0.1-μF multilayer ceramic capacitor. Place the capacitor close to the pins.
VCC_DCDC pins	• Connect the pins to the system power supply. • Connect the pins to VSS_DCDC through a 22-μF and 0.1-μF multilayer ceramic capacitors in parallel. Place the capacitor close to the pins.
VCL pins	• Connect the each pin to VSS through a 0.22-μF*1 multilayer ceramic capacitor. Place the capacitor close to the pins. • Connect each pin to an external inductor and capacitor. Place the inductor and capacitor close to the pins (see Figure 66.1).
All VLO pins	Connect each pin to an external inductor and capacitor. Place the 2.2-μH inductor and 47-μF capacitor close to the pins. Connect the capacitor to VSS_DCDC.

Note 1. 0.47 μF for 100-pin products only

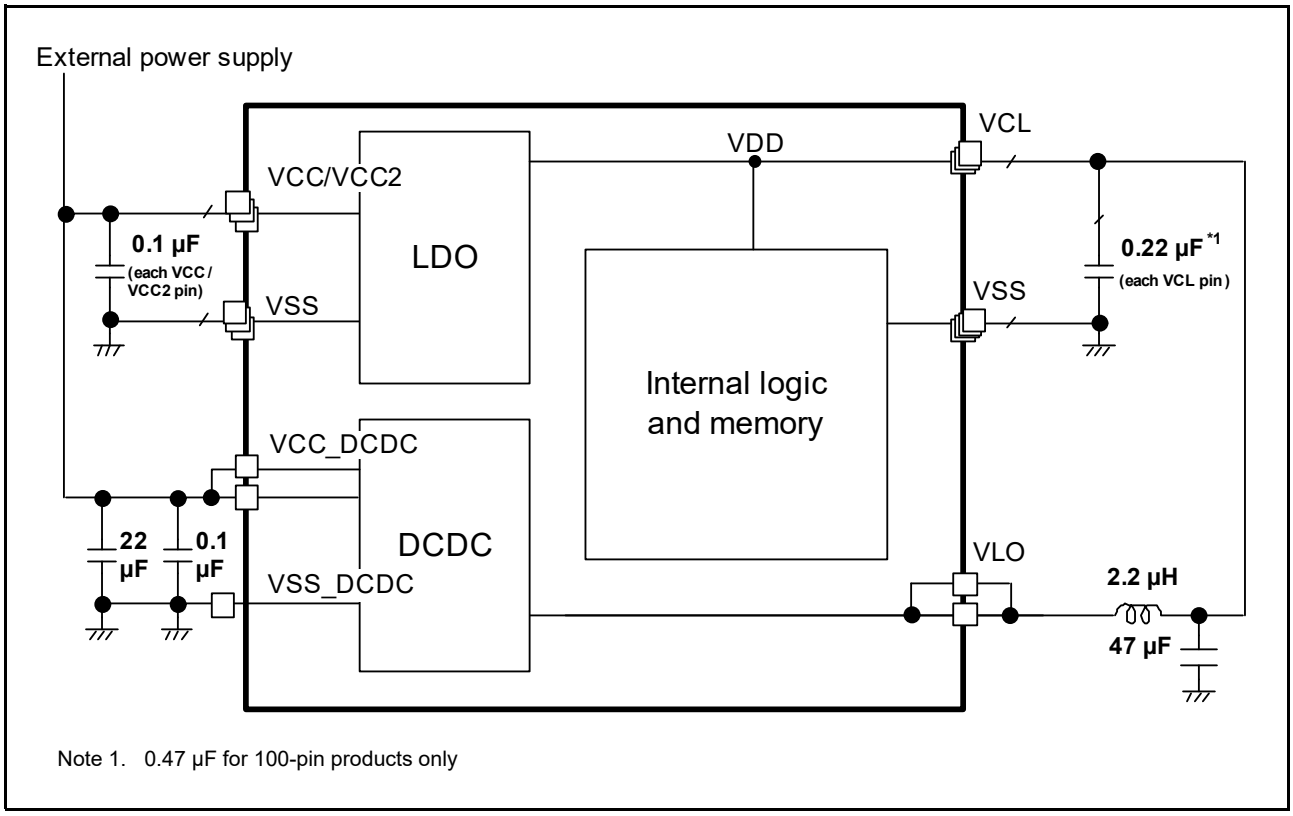

Figure 66.1 DCDC Mode Setting

66.2.2 External VDD Mode

Table 66.3 lists the external VDD mode pin settings, and Figure 66.2 shows the external VDD mode settings. VDD is supplied from the VCL pin.

Note: Software standby mode 1, 2, deep software standby mode 1, 2, 3, battery backup function, and voltage scaling control are not supported in this mode.

Table 66.3 External VDD Mode Settings

Pin	Settings
All VCC and VCC2 pins	• Connect each pin to the system power supply device for VCC. • Connect each pin to VSS through a 0.1-µF multilayer ceramic capacitor. Place the capacitor close to the pins.
VCC_DCDC pins	• Connect the pins to the system power supply.
VCL pins	• Connect each pin to the system power supply device for VDD. • Connect each pin to VSS through a 0.22-µF*1 multilayer ceramic capacitor. Place the capacitor close to the pins.
All VLO pins	Keep the pins open.

Note 1. 0.47 µF for 100-pin products only

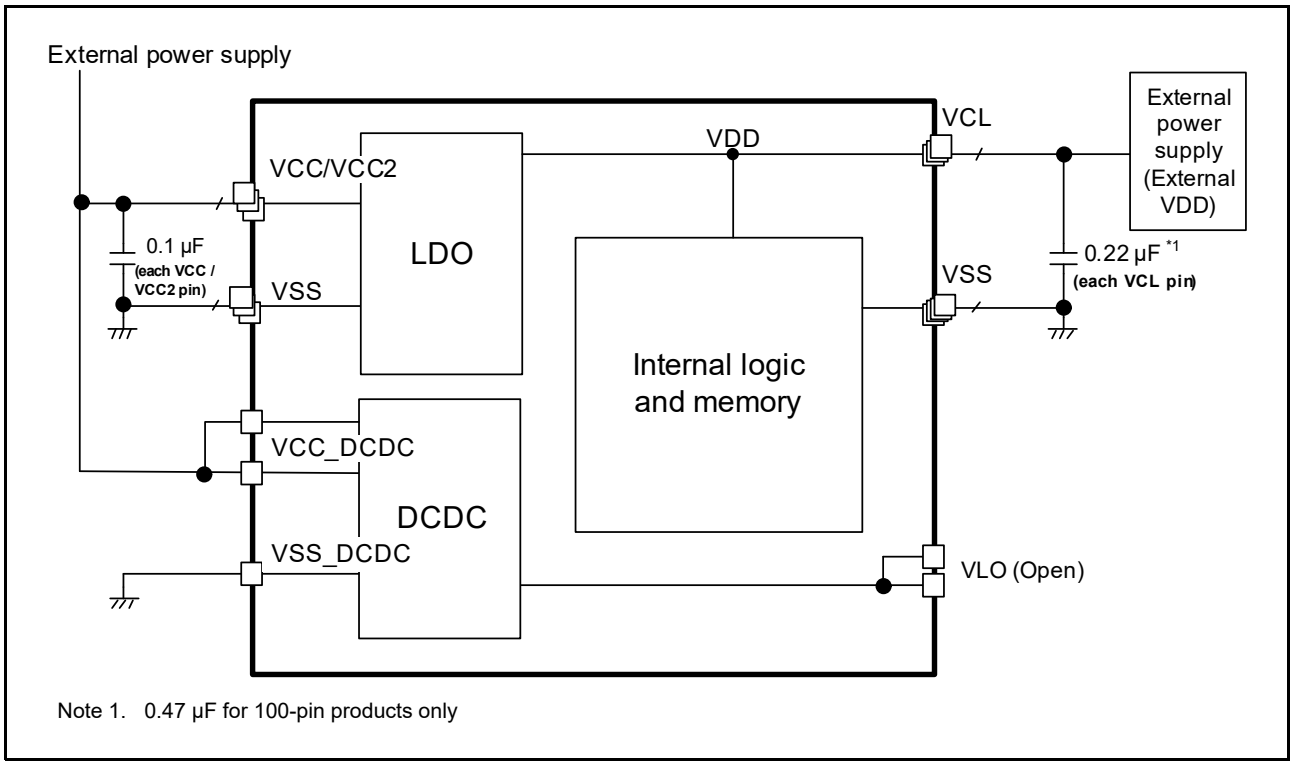

Figure 66.2 External VDD Mode Setting

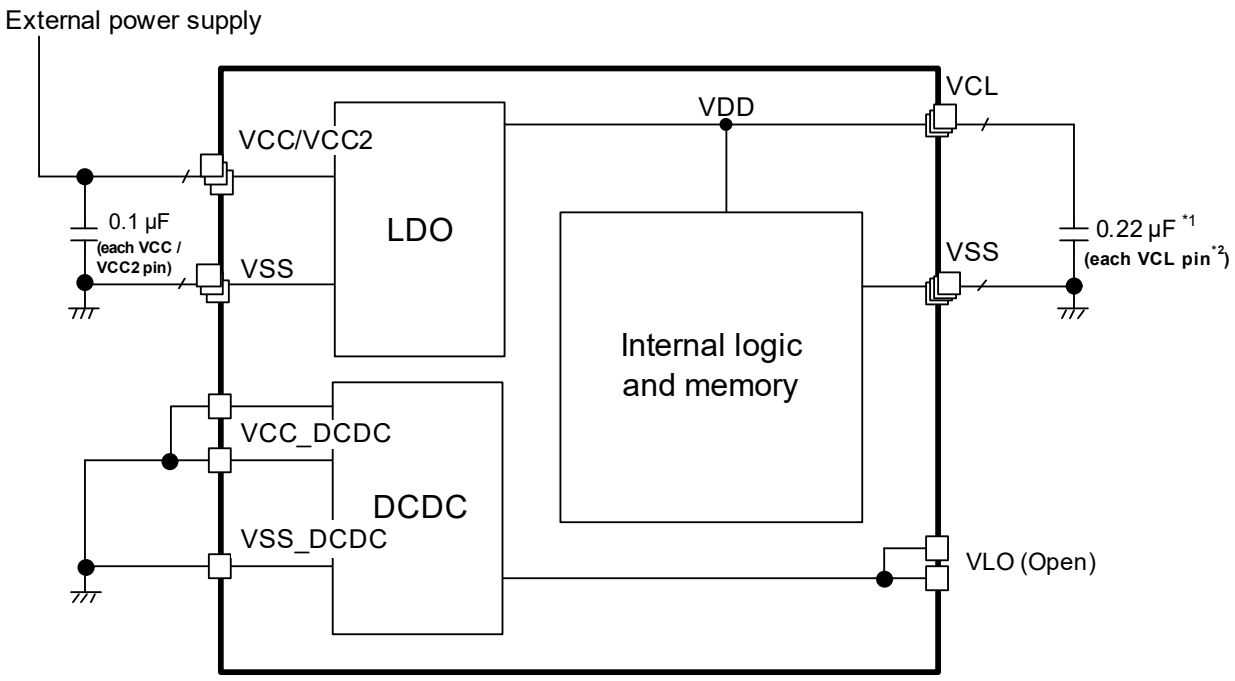

66.2.3 LDO Mode

Table 66.4 lists the LDO mode pin settings, and Figure 66.3 shows the LDO mode settings.
VDD is supplied from the LDO in LDO mode.

Table 66.4 LDO Mode Pin Settings

Pin	Settings
All VCC and VCC2 pins	• Connect each pin to the system power supply. • Connect each pin to VSS through a 0.1-µF multilayer ceramic capacitor. Place the capacitor close to the pins.
VCC_DCDC pins	• Connect the pins to VSS.
VCL pins	• Connect the pins*1 to VSS through a 0.22-µF*2 multilayer ceramic capacitor. Place the capacitor close to the pins.
All VLO pins	Keep the pins open.

Note 1. For products with more than 10 VCL pins, connect capacitors to no more than 10 VCL pins and leave the remaining pins open.
Note 2. 0.47 µF for 100-pin products only

Note 1. 0.47 µF for 100-pin products only
Note 2. For products with more than 10 VCL pins, connect capacitors to no more than 10 VCL pins and leave the remaining pins open.

Figure 66.3 LDO Mode Setting

66.3 Usage Notes

In DCDC mode, to minimize power loss and maximize efficiency, a 2.2-µH inductor with a DC resistance of 100 mΩ or less is recommended. Short VCC and VCC_DCDC.
In external VDD mode, the voltage of VDD should always be below the voltage of VCC including the power-on and power-off sequence. See section 67, Electrical Characteristics for more information.

67. Electrical Characteristics

67.1 Test Conditions

The supported peripheral functions and pins vary depending on the product model.
Unless otherwise specified, the electrical characteristics of the MCU are defined under the following conditions:

- VCC = VCC_DCDC = VBATT = 1.62 to 3.63 V
- VCC2 = 1.62 to 3.63 V
- AVCC0 = 1.62 to 3.63 V
- VCC_USB = VCC_USBHS = AVCC_USBHS = 3.0 to 3.6 V
- VREFH00/VREFH01/VREFH02/VREFH0 = 1.62 V to AVCC0
- VSS = VSS_DCDC = AVSS0 = VREFL00/VREFL01/VREFL02/VREFL0 = VSS_USB = VSS_USBHS = AVSS_USBHS = 0 V
- VCC voltage is lower than 2.7 V : LVOCR.LVO0E = 1, otherwise LVOCR.LVO0E = 0
- Tj = Topj
- V_{OH} = 0.7 × VCC/VCC2, V_{OL} = 0.3 ×VCC/VCC2
- V_{IH} = 0.7 × VCC/VCC2, V_{IL} = 0.3 ×VCC/VCC2
- Capacitive load C = 30 pF

67.1.1 Maximum and Minimum Values (Max./Min.)

Unless otherwise specified, minimum and maximum values are guaranteed by either design simulation, characterization results or test in production.

67.1.2 Typical Values (Typ.)

Unless otherwise specified, the following conditions were used in obtaining the typical (Typ.) values:

- Room temperature of 25°C
- VCC/VCC2 = VCC_DCDC = VCC_USB = VBATT = VCC_USBHS = AVCC_USBHS = AVCC0 = VREFH00/VREFH01/VREFH02/VREFH0 = 3.3 V

67.2 Absolute Maximum Ratings

Table 67.1 Absolute Maximum Rating

Item			Symbol	Value	Unit
Power supply voltage			VCC, VCC2, VCC_DCDC	–0.3 to +4.0	V
External power supply voltage			VCL	–0.3 to +1.2	V
VBATT power supply voltage			V_{BATT}	–0.3 to +4.0	V
USB power supply voltage			VCC_USB	–0.3 to +4.0	V
USBHS power supply voltage			VCC_USBHS	–0.3 to +4.0	V
USBHS analog power supply voltage			AVCC_USBHS	–0.3 to +4.0	V
Analog power supply voltage			AVCC0	–0.3 to +4.0	V
Reference power supply voltage			VREFH00, VREFH01, VREFH02, VREFH0	–0.3 to AVCC0 + 0.3	V
Input voltage for port pins that are not 5-V tolerant	P000 to P015, P108 to P115, P208 to P215, P300 to P307, P315, P500 to P515, P700 to P715, P800 to P807, PA00 to PA07, PB00 to PB07, PC00 to PC07, PE00 to PE07, PF02 to PF09, PG00 to PG15		V_{in}	–0.3 to VCC + 0.3	V
	P309	EXCIN (when the VCC power supply is selected)		–0.3 to VCC + 0.3	
		EXCIN (when the VBATT power supply is selected)		–0.3 to VBATT + 0.3	
		Other than above		–0.3 to VCC + 0.3	
	P310, P311, P312	RTCICn (n = 0 to 2)		–0.3 to +3.9	
		Other than above		–0.3 to VCC + 0.3 (up to 3.9)	
	P600 to P607, P900 to P907, PD00 to PD07			–0.3 to VCC2 + 0.3	
	P400 to P415			–0.3 to AVCC0 + 0.3	
	PF00, PF01			–0.3 to VCC_USB + 0.3	
	USBHS_DP, USBHS_DM			–0.3 to VCC_USBHS + 0.3	
Input voltage for port pins that are 5-V tolerant	P100 to P107, P200 to P207		V_{in}	–0.3 to VCC + 3.6 (up to 5.8)	V
Analog input voltage	P400 to P415		V_{AN}	–0.3 to AVCC0 + 0.3	V
	P000 to P007	AVCC0 ≤ VCC		–0.3 to AVCC0 + 0.3	
		VCC < AVCC0		–0.3 to VCC + 0.3	
	P900 to P903, PD00 to PD07	AVCC0 ≤ VCC2		–0.3 to AVCC0 + 0.3	
		VCC2 < AVCC0		–0.3 to VCC2 + 0.3	
Junction temperature			T_j	–40 to +125	°C
Storage temperature			T_{stg}	–55 to +125	°C

Caution: Permanent damage to the MCU may result if absolute maximum ratings are exceeded.

67.3 Recommended Operating Conditions

Table 67.2 Recommended Operating Conditions (1)

Item			Symbol	Min.	Typ.	Max.	Unit
Power supply voltage	When ESWM and SDRAM are not in use		VCC, VCC_DCDC	1.62	—	3.63	V
	When ESWM is in use			2.30	—	3.63	
	When SDRAM is in use			3.00	—	3.63	
	When ESWM and SDRAM are not in use		VCC2	1.62	—	3.63	
	When ESWM is in use*1			2.30	—	3.63	
	When SDRAM is in use*2			3.00	—	3.63	
	When external VDD is in use*3	Voltage range 1	VCL	0.920	0.950	0.990	
		Voltage range 2		0.870	0.925	0.990	
	When DCDC is in use	VSCR_1		—	0.950	—	
		VSCR_2		—	0.925	—	
		SVSCR_1		—	0.950	—	
		SVSCR_2		—	0.925	—	
		SVSCR_3		—	0.825	—	
		SVSCR_4		—	0.765		
		SVSCR_5		—	0.715	—	
			VSS, VSS_DCDC	—	0	—	
VBATT power supply voltage			V_{BATT}	1.62	—	3.63	V
USB power supply voltage	When USB is not in use		VCC_USB, VCC_USBHS, AVCC_USBHS	1.62	—	3.63	V
	When USB is in use			3.00	—	3.60	
			VSS_USB, VSS_USBHS, AVSS_USBHS	—	0	—	
Analog power supply voltage	Other than the following		AVCC0*4	1.62	—	3.63	V
	When sample-and-hold circuit is in use			2.70	—	3.63	
			AVSS0	—	0	—	

Note 1. When the pins for the ESWM with the VCC2 power supply are not in use, the voltage conditions differ from those when the ESWM is in use.
Note 2. When the pins for the SDRAM with the VCC2 power supply are not in use, the voltage conditions differ from those when the SDRAM is in use.
Note 3. Ensure that the VCL voltage is no higher than the VCC voltage.
Note 4. When the A/D converter, the D/A converter and the comparator are not in use, connect the AVCC0 and VREFH0 pins to VCC, and the AVSS0 and VREFL pins to VSS, respectively.

Table 67.3 Recommended Operating Conditions (2)

Item	Package	Symbol	Value	Required number of capacitors
Capacitance of a decoupling capacitor for stabilizing the internal voltage	BGA320	C_{VCL}	0.22 µF ± 30%	Nine or more
	BGA224			
	BGA176			
	LQFP176			Nine
	LQFP144			Eight
	LQFP100		0.47 µF ± 30%	Four

Note: Use a multilayer ceramic capacitor with a stated capacitance of 0.22 µF or 0.47µF and a capacitance tolerance within the range ±30%.

67.4 DC Characteristics

67.4.1 Characteristics of the Input Voltage of the I/O Pins

Table 67.4 Characteristics of the Input Voltage of the I/O Pins (V_{IH}/V_{IL}) (1/2)

Item		VCC/VCC2/ AVCC0/ VCC_USB	Symbol	Min.	Typ.	Max.	Unit
High- and low-level input voltage (except for Schmitt trigger input pins)	EXTAL (excluding usage with external clock input)	1.62 V or higher	V_{IH}	0.8 × VCC	—	—	V

Note 1. This is the driving ability as selected by the setting of the driving ability select (PmnPFS.DSCR[3:0]) bits.

67.4.3 Characteristics of the Other I/O Pins

Table 67.7 Characteristics of the Other I/O Pins

Item		Power supply voltage	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Input leakage current	RES# pin		$\lvert I_{in} \rvert$	—	—	5	μA	V_{in} = 0 V, V_{in} = 5.5 V
	NMI, XCIN, and XCOUT pins			—	—	1		V_{in} = 0 V, V_{in} = VCC
Three-state leakage current (off state)	Other than ports for 5-V tolerant		$\lvert I_{TSI} \rvert$	—	—	1	μA	V_{in} = 0 V, V_{in} = VCC, VCC2, AVCC0, VCC_USB
	Ports for 5-V tolerant*1			—	—	5		V_{in} = 0 V, V_{in} = 5.5 V
Input pull-up resistor current*2		2.70 V or higher	I_p	–300	—	–10	μA	VCC, VCC2, AVCC0, VCC_USB = 2.7 to 3.63 V V_{in} = 0 V
		1.62 V or higher		–300	—	–5		VCC, VCC2, AVCC0, VCC_USB = 1.62 to 3.63 V V_{in} = 0 V
Input capacitance	P414, P415		C_{in}	—	—	16	pF	Vbias = 0 V Vamp = 20 mV f = 1 MHz T_a = 25°C
	PF00, PF01, USB_DP, USB_DM			—	—	12		
	P102, P103, P106, P107, P200, P201			—	—	10		
	USBHS_DP, USBHS_DM			—	—	10		
	Other input pins			—	—	8		

Note 1. P100 to P107 and P200 to P207 are 5-V tolerant.
Note 2. The values are for pins excluding USB_DP, USB_DM, USBHS_DP, USBHS_DM, SDA00-A, SCL00-A, SDAHSn-A, and SCLHSn-A (n = 1, 2).

67.4.4 Operating and Standby Currents

The operating current and standby current depend on the product part number.
For the current characteristics of the products with part numbers of the form R5K574Nxy4xx (y = A, B, C, D), see section 67.4.4.1, Operating and Standby Currents for Product Part No. R5K574Nxy4xx (y = A, B, C, D).
For the current characteristics of the products with part numbers of the form R5K574Nxy4xx (y = E, F), see section 67.4.4.2, Operating and Standby Currents for Product Part No. R5K574Nxy4xx (y = E, F).
Unless otherwise specified, the supply current values were measured with all output pins load-free and all input pull-up resistors disabled.
The values for current given or used in this section do not include the current supplied for background operation (BGO).
The VCC current includes the VCC2 power supply current.

The currents were measured with the operating frequencies specified as shown in Table 67.8.

Table 67.8 Frequency Settings for the Individual Clocks

Item		ICLK	MRICLK	MRPCLK	BCLK	PCLKA	PCLKB, PCLKC	PCLKD	PCLKE	Unit
When the peripheral clock supplies are stopped*1	Frequency setting 1 (CPUCLK0 = 600 MHz)	300	300	150	Stopped	Stopped	Stopped	Stopped	Stopped	MHz
	Frequency setting 2 (CPUCLK0 = 480 MHz)	240	240	120	Stopped	Stopped	Stopped	Stopped	Stopped	
	Frequency setting 3 (CPUCLK0 = 300 MHz)	300	300	150	Stopped	Stopped	Stopped	Stopped	Stopped	
Other cases	Frequency setting 1 (CPUCLK0 = 600 MHz)	300	300	150	150	150	75	150	300	
	Frequency setting 2 (CPUCLK0 = 480 MHz)	240	240	120	120	120	60	120	240	
	Frequency setting 3 (CPUCLK0 = 300 MHz)	300	300	150	150	150	75	150	300	

Note 1. The frequencies of the clocks in the table are set for division by 64 in the SCKDIVCR register when the peripheral clock supplies are stopped.

The symbols shown in Figure 67.1, Supply Current Measurement Diagram (DCDC Mode), and Figure 67.2, Supply Current Measurement Diagram (LDO Mode), are used in the tables that follow the figures.

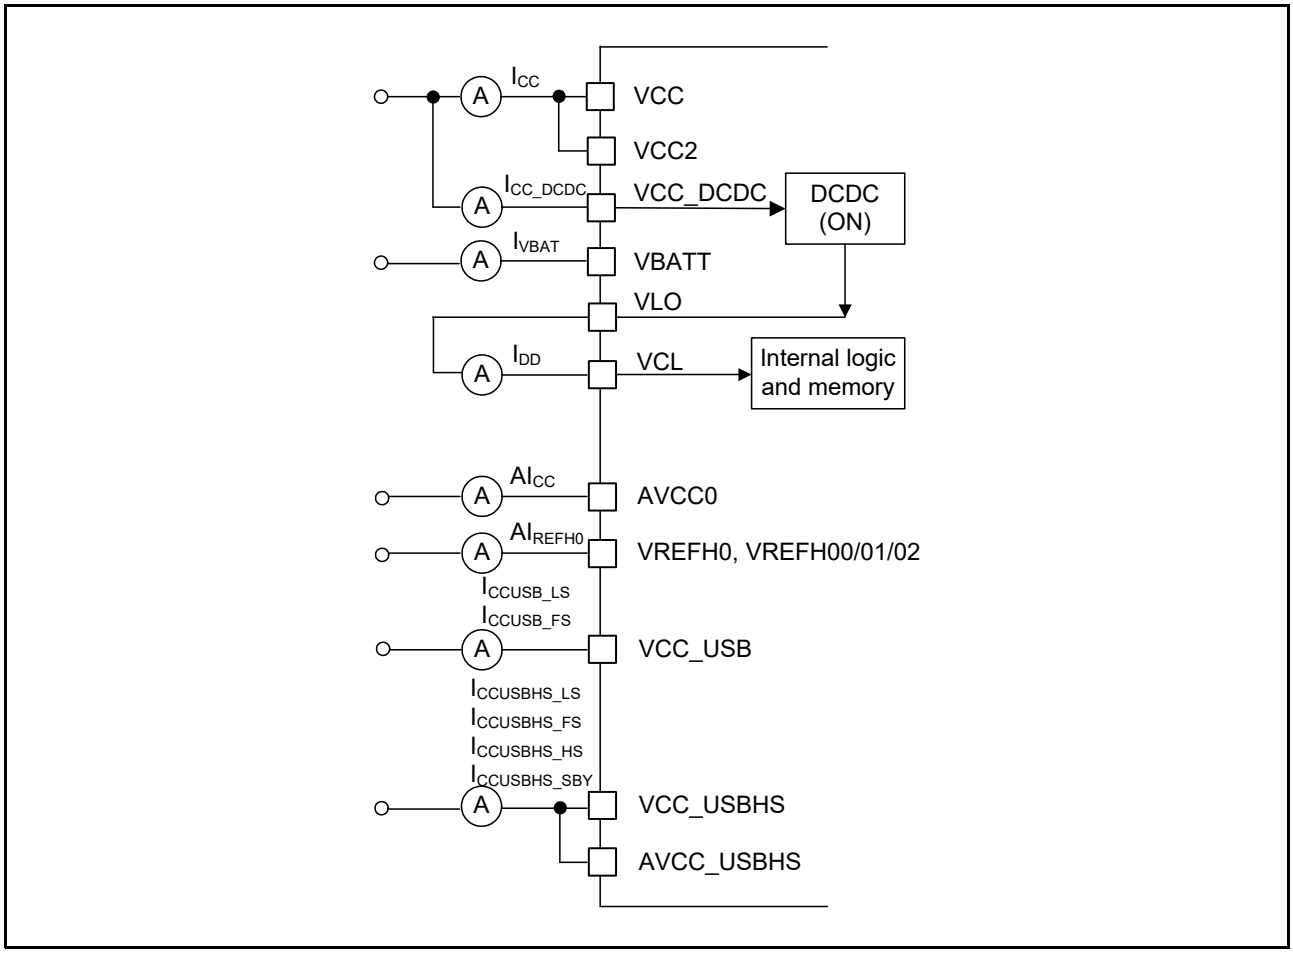

Figure 67.1 Supply Current Measurement Diagram (DCDC Mode)

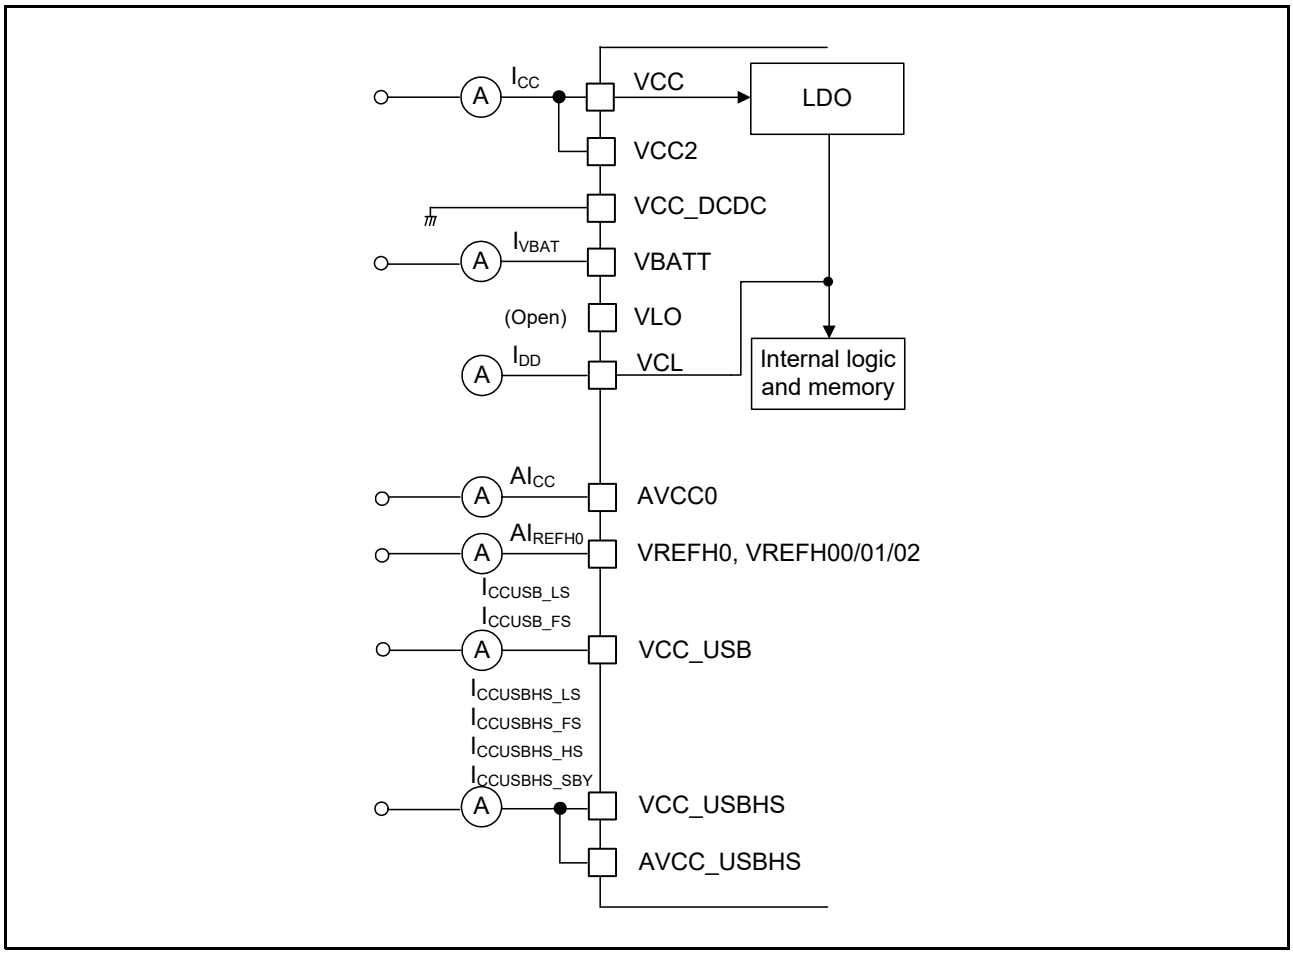

Figure 67.2 Supply Current Measurement Diagram (LDO Mode)

When the DCDC is in use, the efficiency of power conversion depends on the load currents, temperature, and VCC voltage. For reference, the results of conversion efficiency simulation are shown in Figure 67.3 to Figure 67.5.

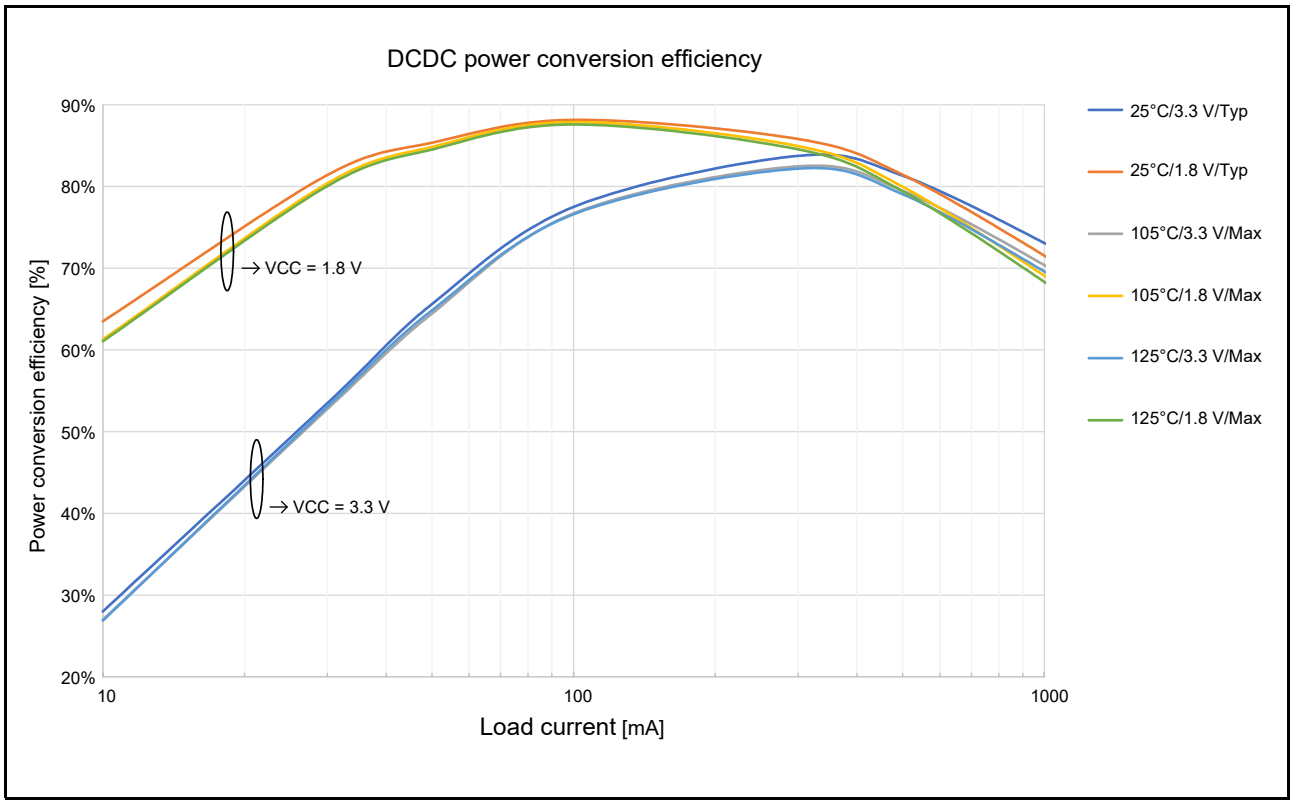

Figure 67.3 DCDC Power Conversion Efficiency in Normal Mode and Software Standby Mode (SSCR1.SS2LP = SS2LP_0) (Reference: Simulated Values)

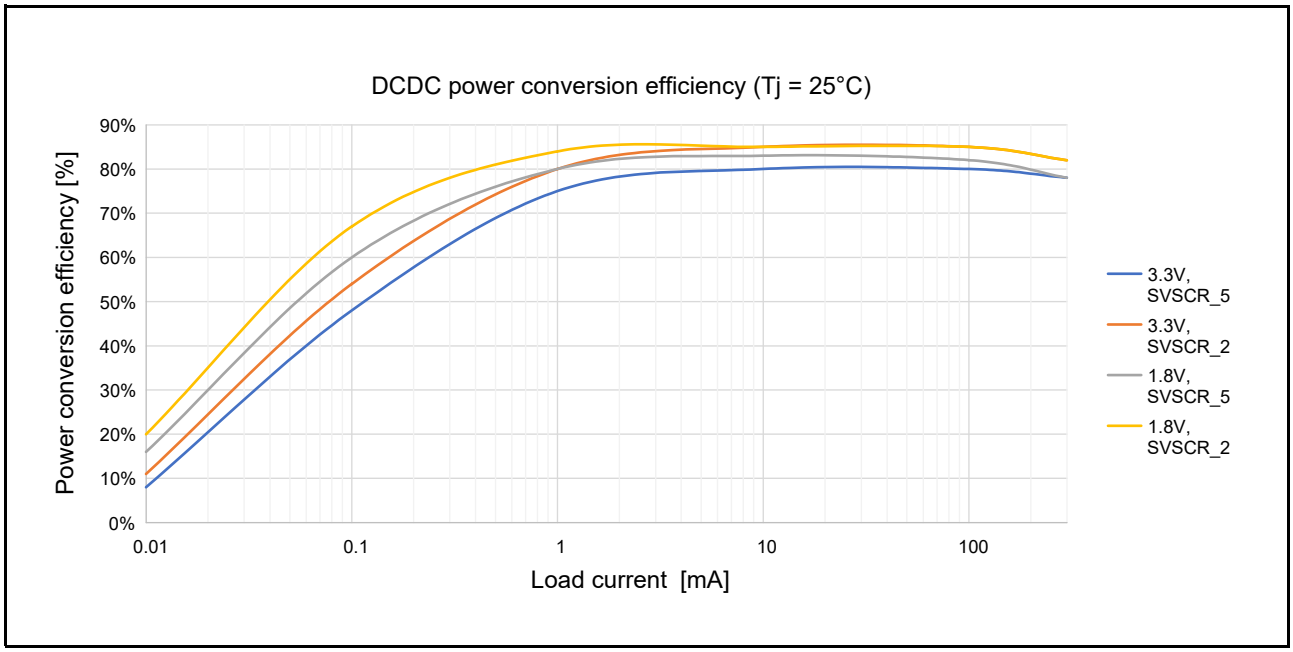

Figure 67.4 DCDC Power Conversion Efficiency in Software Standby Mode (SSCR1.SS2LP = SS2LP_1) at Tj = 25°C (Reference: Simulated Values)

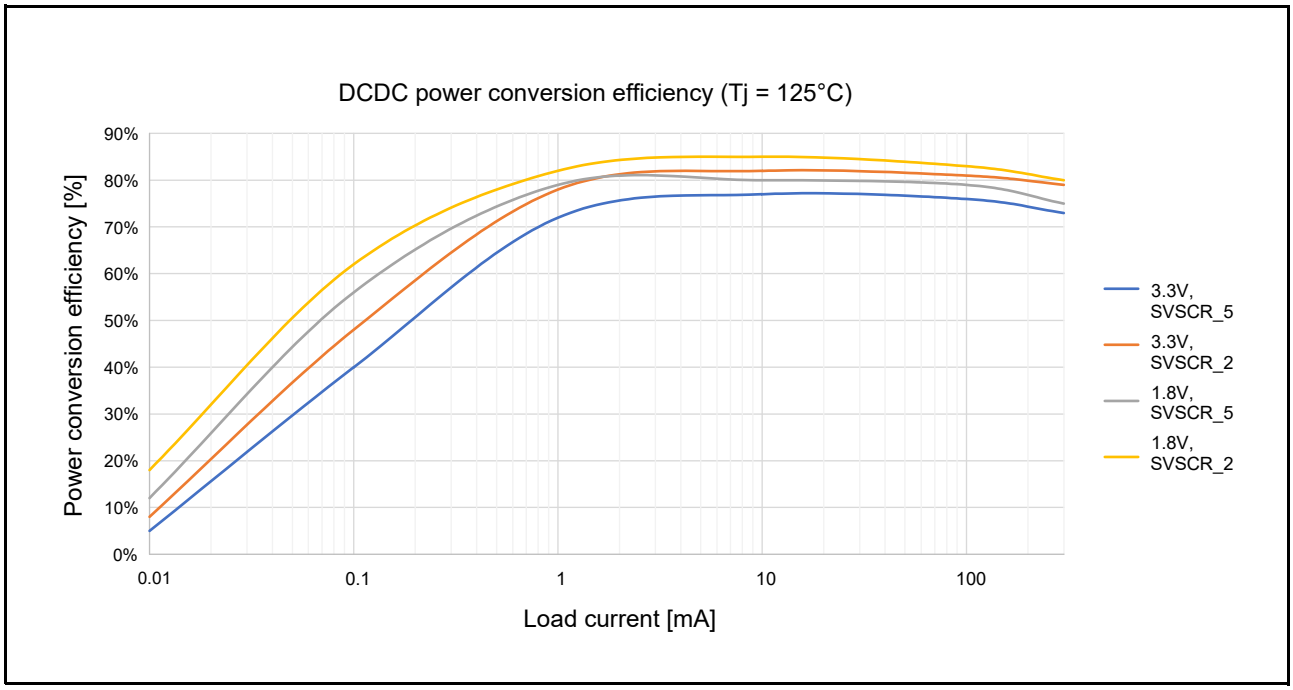

Figure 67.5 DCDC Power Conversion Efficiency in Software Standby Mode (SSCR1.SS2LP = SS2LP_1) at Tj = 125°C (Reference: Simulated Values)

67.4.4.1 Operating and Standby Currents for Product Part No. R5K574Nxy4xx (y = A, B, C, D)

Table 67.9 Supply Currents for Full Operation (DCDC Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max.*2 (Tj = 125°C)	Unit	Test Conditions
Supply current (full operation)	VCC_DCDC ≥ 2.5 V	Frequency setting 1 (CPUCLK0 = 600 MHz)	I_{CC_DCDC} *1	88	217	307	mA	VSCR_1 (VCL = 0.95 V) VCC_DCDC = 3.3 V
		Frequency setting 2 (CPUCLK0 = 480 MHz)		68	181	262		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 3.3 V
		Frequency setting 3 (CPUCLK0 = 300 MHz)		68	180	261		
	VCC_DCDC < 2.5 V	Frequency setting 1 (CPUCLK0 = 600 MHz)		153	396	568		VSCR_1 (VCL = 0.95 V) VCC_DCDC = 1.8 V
		Frequency setting 2 (CPUCLK0 = 480 MHz)		116	329	482		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 1.8 V
		Frequency setting 3 (CPUCLK0 = 300 MHz)		115	329	482		
	VCC current		I_{CC}	11	15	17		VCC = 3.3 V

Note: This table lists the values for current under the following operating conditions.
- The internal memory (SRAM and MRAM) is configured with wait settings that suit the operating frequency and kept as active as is possible through data transfer by the DMAC.
- The peripheral functions are supplied with clocks and kept as active as is possible.
- Unless otherwise specified, the clocks are set to the states that maximize the supply currents within the limits imposed by the specifications.
- The program is placed in the LRAM, the cache is enabled, and the CPU repeatedly executes multiply-and-accumulate instructions.
- Power to the ESWM domain is turned on.

Note 1. Value for I_{CC_DCDC} can be estimated by using the following formulae (units: I_{CC_DCDC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).

[When VCC_DCDC = 3.3 V]

I_{CC_DCDC} Typ.(VSCR_1) = 0.0498 × $f_{CPUCLK0}$ + 0.0895 × f_{ICLK} + 30.84
I_{CC_DCDC} Typ.(VSCR_2) = 0.0512 × $f_{CPUCLK0}$ + 0.0633 × f_{ICLK} + 28.49
I_{CC_DCDC} Max.(VSCR_1, 105°C) = 0.0654 × $f_{CPUCLK0}$ + 0.1276 × f_{ICLK} + 139.00
I_{CC_DCDC} Max.(VSCR_1, 125°C) = 0.0716 × $f_{CPUCLK0}$ + 0.1305 × f_{ICLK} + 225.16
I_{CC_DCDC} Max.(VSCR_2, 105°C) = 0.0604 × $f_{CPUCLK0}$ + 0.0810 × f_{ICLK} + 132.18
I_{CC_DCDC} Max.(VSCR_2, 125°C) = 0.0679 × $f_{CPUCLK0}$ + 0.0907 × f_{ICLK} + 207.32

[When VCC_DCDC = 1.8 V]

I_{CC_DCDC} Typ.(VSCR_1) = 0.0974 × $f_{CPUCLK0}$ + 0.1756 × f_{ICLK} + 42.07
I_{CC_DCDC} Typ.(VSCR_2) = 0.0927 × $f_{CPUCLK0}$ + 0.1180 × f_{ICLK} + 43.29
I_{CC_DCDC} Max.(VSCR_1, 105°C) = 0.1223 × $f_{CPUCLK0}$ + 0.2385 × f_{ICLK} + 251.34
I_{CC_DCDC} Max.(VSCR_1, 125°C) = 0.1363 × $f_{CPUCLK0}$ + 0.2484 × f_{ICLK} + 411.75
I_{CC_DCDC} Max.(VSCR_2, 105°C) = 0.1157 × $f_{CPUCLK0}$ + 0.1521 × f_{ICLK} + 237.43
I_{CC_DCDC} Max.(VSCR_2, 125°C) = 0.1280 × $f_{CPUCLK0}$ + 0.1714 × f_{ICLK} + 379.37

However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 2. For the LQFP100 package (products with part numbers of the form R5K574NxxxFP), control the number of peripheral functions to ensure that the maximum current does not exceed 710 mA (see section 67.4.5.2, Supply Currents for the Peripheral Functions).

Table 67.10 Supply Currents for Full Operation (External VDD Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max.*2 (Tj = 125°C)	Unit	Test Conditions
Supply current (full operation)	VCL = 0.92 to 0.99 V	Frequency setting 1 (CPUCLK0 = 600 MHz)	I_{DD}*1	256	597	800	mA	Voltage range 1 (VCL = 0.95 V)
	VCL = 0.87 to 0.99 V	Frequency setting 2 (CPUCLK0 = 480 MHz)		202	524	719		Voltage range 2 (VCL = 0.925 V)
		Frequency setting 3 (CPUCLK0 = 300 MHz)		201	523	718		
	VCC current		I_{CC}	11	15	17		VCC = 3.3 V

Note: This table lists the values for current under the following operating conditions.
- Unless otherwise specified, the clocks are set to the states that maximize the supply currents within the limits imposed by the specifications.
- The program is placed in the LRAM, the cache is enabled, and the CPU repeatedly executes multiply-and-accumulate instructions.
- The internal memory (SRAM and MRAM) is configured with wait settings that suit the operating frequency and kept as active as is possible through data transfer by the DMAC.
- Power to the ESWM domain is turned on.

Note 1. Value for I_{DD} can be estimated by using the following formulae (units: I_{DD} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
I_{DD} Typ.(VCL = 0.92 to 0.99 V) = 0.1584 × $f_{CPUCLK0}$ + 0.2852 × f_{ICLK} + 75.36
I_{DD} Typ.(VCL = 0.87 to 0.99 V) = 0.1588 × $f_{CPUCLK0}$ + 0.2007 × f_{ICLK} + 77.55
I_{DD} Max.(VCL = 0.92 to 0.99 V, 105°C) = 0.1600 × $f_{CPUCLK0}$ + 0.3120 × f_{ICLK} + 407.46
I_{DD} Max.(VCL = 0.92 to 0.99 V, 125°C) = 0.1565 × $f_{CPUCLK0}$ + 0.2849 × f_{ICLK} + 620.60
I_{DD} Max.(VCL = 0.87 to 0.99 V, 105°C) = 0.1622 × $f_{CPUCLK0}$ + 0.2122 × f_{ICLK} + 394.73
I_{DD} Max.(VCL = 0.87 to 0.99 V, 125°C) = 0.1615 × $f_{CPUCLK0}$ + 0.2126 × f_{ICLK} + 590.17
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 2. For the LQFP100 package (products with part numbers of the form R5K574NxxxFP), control the number of peripheral functions to ensure that the maximum current does not exceed 718 mA (see section 67.4.5.2, Supply Currents for the Peripheral Functions).

Table 67.11 Supply Currents for Maximum Data Processing with the Peripheral Clock Supplies Stopped (DCDC Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
Supply current (maximum data processing with the peripheral clock supplies stopped)	VCC_DCDC ≥ 2.5 V	Frequency setting 1 (CPUCLK0 = 600 MHz)	I_{CC_DCDC}*1	41	165	254	mA	VSCR_1 (VCL = 0.95 V) VCC_DCDC = 3.3 V
		Frequency setting 2 (CPUCLK0 = 480 MHz)		33	144	225		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 3.3 V
		Frequency setting 3 (CPUCLK0 = 300 MHz)		28	138	218		
	VCC_DCDC < 2.5 V	Frequency setting 1 (CPUCLK0 = 600 MHz)		66	299	467		VSCR_1 (VCL = 0.95 V) VCC_DCDC = 1.8 V
		Frequency setting 2 (CPUCLK0 = 480 MHz)		52	260	412		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 1.8 V
		Frequency setting 3 (CPUCLK0 = 300 MHz)		42	248	399		
	VCC current		I_{CC}	3.9	7.1	9.7		VCC = 3.3 V

Note: This table lists the values for current under the following operating conditions.
- Unless otherwise specified, the clocks are set to the states that maximize the supply currents within the limits imposed by the specifications.
- The program is placed in the LRAM, the cache is enabled, and the CPU repeatedly executes multiply-and-accumulate instructions.
- The clock-signal supplies to the peripheral functions are stopped.
- Power to the ESWM domain is turned off.

Note 1. Value for I_{CC_DCDC} can be estimated by using the following formulae (units: I_{CC_DCDC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When VCC_DCDC = 3.3 V]
I_{CC_DCDC} Typ.(VSCR_1) = 0.0352 × $f_{CPUCLK0}$ + 0.0163 × f_{ICLK} + 14.69
I_{CC_DCDC} Typ.(VSCR_2) = 0.0369 × $f_{CPUCLK0}$ + 0.0119 × f_{ICLK} + 12.17
I_{CC_DCDC} Max.(VSCR_1, 105°C) = 0.0454 × $f_{CPUCLK0}$ + 0.0180 × f_{ICLK} + 132.14
I_{CC_DCDC} Max.(VSCR_1, 125°C) = 0.0496 × $f_{CPUCLK0}$ + 0.0190 × f_{ICLK} + 218.27
I_{CC_DCDC} Max.(VSCR_2, 105°C) = 0.0443 × $f_{CPUCLK0}$ + 0.0162 × f_{ICLK} + 119.62
I_{CC_DCDC} Max.(VSCR_2, 125°C) = 0.0479 × $f_{CPUCLK0}$ + 0.0183 × f_{ICLK} + 197.45
[When VCC_DCDC = 1.8 V]
I_{CC_DCDC} Typ.(VSCR_1) = 0.0674 × $f_{CPUCLK0}$ + 0.0279 × f_{ICLK} + 17.22
I_{CC_DCDC} Typ.(VSCR_2) = 0.0646 × $f_{CPUCLK0}$ + 0.0223 × f_{ICLK} + 15.14
I_{CC_DCDC} Max.(VSCR_1, 105°C) = 0.0863 × $f_{CPUCLK0}$ + 0.0343 × f_{ICLK} + 237.02
I_{CC_DCDC} Max.(VSCR_1, 125°C) = 0.0935 × $f_{CPUCLK0}$ + 0.0359 × f_{ICLK} + 399.63
I_{CC_DCDC} Max.(VSCR_2, 105°C) = 0.0806 × $f_{CPUCLK0}$ + 0.0305 × f_{ICLK} + 214.33
I_{CC_DCDC} Max.(VSCR_2, 125°C) = 0.0897 × $f_{CPUCLK0}$ + 0.0343 × f_{ICLK} + 361.19
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Table 67.12 Supply Currents for Maximum Data Processing with the Peripheral Clock Supplies Stopped (External VDD Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
Supply current (maximum data processing with the peripheral clock supplies stopped)	VCL = 0.92 to 0.99 V	Frequency setting 1 (CPUCLK0 = 600 MHz)	I_{DD}*1	112	468	681	mA	Voltage range 1 (VCL = 0.95 V)
	VCL = 0.87 to 0.99 V	Frequency setting 2 (CPUCLK0 = 480 MHz)		90	426	631		Voltage range 2 (VCL = 0.925 V)
		Frequency setting 3 (CPUCLK0 = 300 MHz)		73	408	614		
	VCC current		I_{CC}	3.9	7.1	9.7		VCC = 3.3 V

Note: This table lists the values for current under the following operating conditions.
- Unless otherwise specified, the clocks are set to the states that maximize the supply currents within the limits imposed by the specifications.
- The program is placed in the LRAM, the cache is enabled, and the CPU repeatedly executes multiply-and-accumulate instructions.
- The clock-signal supplies to the peripheral functions are stopped.
- Power to the ESWM domain is turned off.
- The values given were measured with all output pins load-free and all input pull-up resistors disabled.
- The values given do not include the supply current for background operation (BGO).

Note 1. Value for I_{DD} can be estimated by using the following formulae (units: I_{DD} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
I_{DD} Typ.(VCL = 0.92 to 0.99 V) = 0.1181 × $f_{CPUCLK0}$ + 0.0469 × f_{ICLK} + 27.55
I_{DD} Typ.(VCL = 0.87 to 0.99 V) = 0.1153 × $f_{CPUCLK0}$ + 0.0405 × f_{ICLK} + 25.17
I_{DD} Max.(VCL = 0.92 to 0.99 V, 105°C) = 0.1192 × $f_{CPUCLK0}$ + 0.0469 × f_{ICLK} + 381.95
I_{DD} Max.(VCL = 0.92 to 0.99 V, 125°C) = 0.1148 × $f_{CPUCLK0}$ + 0.0437 × f_{ICLK} + 598.85
I_{DD} Max.(VCL = 0.87 to 0.99 V, 105°C) = 0.1192 × $f_{CPUCLK0}$ + 0.0448 × f_{ICLK} + 357.95
I_{DD} Max.(VCL = 0.87 to 0.99 V, 125°C) = 0.1182 × $f_{CPUCLK0}$ + 0.0449 × f_{ICLK} + 563.65
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Table 67.13 Supply Currents for while(1) Operation by the CPU with the Peripheral Clock Supplies Stopped and the ESWM Domain Turned Off

Item			Symbol	Typ.	Max.	Unit	Test Conditions
Supply current (DCDC mode)	VCC_DCDC ≥ 2.5 V	Frequency setting 1 (CPUCLK0 = 600 MHz)	I_{CC_DCDC} *1	28	—	mA	VSCR_1 (VCL = 0.95 V) VCC_DCDC = 3.3 V
		Frequency setting 2 (CPUCLK0 = 480 MHz)		23	—		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 3.3 V
		Frequency setting 3 (CPUCLK0 = 300 MHz)		22	—		
	VCC_DCDC < 2.5 V	Frequency setting 1 (CPUCLK0 = 600 MHz)		41	—		VSCR_1 (VCL = 0.95 V) VCC_DCDC = 1.8 V
		Frequency setting 2 (CPUCLK0 = 480 MHz)		33	—		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 1.8 V
		Frequency setting 3 (CPUCLK0 = 300 MHz)		30	—		
Supply current (external VDD mode)	VCL = 0.92 to 0.99 V	Frequency setting 1 (CPUCLK0 = 600 MHz)	I_{DD} *2	68	—	mA	Voltage range 1 (VCL = 0.95 V)
	VCL = 0.87 to 0.99 V	Frequency setting 2 (CPUCLK0 = 480 MHz)		56	—		Voltage range 2 (VCL = 0.925 V)
		Frequency setting 3 (CPUCLK0 = 300 MHz)		52	—		

Note: This table lists the values for current under the following operating condition.
- The program is placed in the LRAM, the cache is enabled, and the CPU executes a while(1) loop.

Note 1. Value for I_{CC_DCDC} can be estimated by using the following formulae (units: I_{CC_DCDC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When VCC_DCDC = 3.3 V]
I_{CC_DCDC} Typ.(VSCR_1) = 0.0145 × $f_{CPUCLK0}$ + 0.0149 × f_{ICLK} + 14.35
I_{CC_DCDC} Typ.(VSCR_2) = 0.0113 × $f_{CPUCLK0}$ + 0.0109 × f_{ICLK} + 14.76
[When VCC_DCDC = 1.8 V]
I_{CC_DCDC} Typ.(VSCR_1) = 0.0259 × $f_{CPUCLK0}$ + 0.0269 × f_{ICLK} + 17.25
I_{CC_DCDC} Typ.(VSCR_2) = 0.0236 × $f_{CPUCLK0}$ + 0.0218 × f_{ICLK} + 16.14
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 2. Value for I_{DD} can be estimated by using the following formulae (units: I_{DD} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
I_{DD} Typ.(VCL = 0.92 to 0.99 V) = 0.0448 × $f_{CPUCLK0}$ + 0.0469 × f_{ICLK} + 27.37
I_{DD} Typ.(VCL = 0.87 to 0.99 V) = 0.0440 × $f_{CPUCLK0}$ + 0.0406 × f_{ICLK} + 25.19
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Table 67.16 Supply Currents in CPU Sleep Mode with the Peripheral Clock Supplies Stopped and the ESWM Domain Turned Off

Item			Symbol	Typ.	Max.	Unit	Test Conditions
Supply current (DCDC Mode)	VCC_DCDC ≥ 2.5 V	Frequency setting 1 (CPUCLK0 = 600 MHz)	I_{CC_DCDC} *1	22	227	mA	VSCR_1 (VCL = 0.95 V) VCC_DCDC = 3.3 V
		Frequency setting 2 (CPUCLK0 = 480 MHz)		19	205		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 3.3 V
		Frequency setting 3 (CPUCLK0 = 300 MHz)		19	205		
	VCC_DCDC < 2.5 V	Frequency setting 1 (CPUCLK0 = 600 MHz)		31	416		VSCR_1 (VCL = 0.95 V) VCC_DCDC = 1.8 V
		Frequency setting 2 (CPUCLK0 = 480 MHz)		26	375		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 1.8 V
		Frequency setting 3 (CPUCLK0 = 300 MHz)		26	375		
Supply current (External VDD Mode)	VCL = 0.92 to 0.99 V	Frequency setting 1 (CPUCLK0 = 600 MHz)	I_{DD}*2	52	618	mA	Voltage range 1 (VCL = 0.95 V)
	VCL = 0.87 to 0.99 V	Frequency setting 2 (CPUCLK0 = 480 MHz)		43	582		Voltage range 2 (VCL = 0.925 V)
		Frequency setting 3 (CPUCLK0 = 300 MHz)		44	582		

Note 1. Value for I_{CC_DCDC} can be estimated by using the following formulae (units: I_{CC_DCDC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When VCC_DCDC = 3.3 V]
I_{CC_DCDC} Typ.(VSCR_1) = 0.0049 × $f_{CPUCLK0}$ + 0.0128 × f_{ICLK} + 15.37
I_{CC_DCDC} Typ.(VSCR_2) = 0.0051 × $f_{CPUCLK0}$ + 0.0109 × f_{ICLK} + 14.14
[When VCC_DCDC = 1.8 V]
I_{CC_DCDC} Typ.(VSCR_1) = 0.0098 × $f_{CPUCLK0}$ + 0.0260 × f_{ICLK} + 17.72

I_{CC_DCDC} Typ.(VSCR_2) = 0.0096 × $f_{CPUCLK0}$ + 0.0221 × f_{ICLK} + 15.88

However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 2. Value for I_{DD} can be estimated by using the following formulae (units: I_{DD} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).

I_{DD} Typ.(VCL = 0.92 to 0.99 V) = 0.0176 × $f_{CPUCLK0}$ + 0.0471 × f_{ICLK} + 27.25

I_{DD} Typ.(VCL = 0.87 to 0.99 V) = 0.0175 × $f_{CPUCLK0}$ + 0.0409 × f_{ICLK} + 25.14

However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Table 67.17 Supply Currents in CPU Deep Sleep Mode with the Peripheral Clock Supplies Stopped and the ESWM Domain Turned Off

Item			Symbol	Typ.	Max.	Unit	Test Conditions
Supply current (DCDC Mode)	VCC_DCDC ≥ 2.5 V	Frequency setting 1 (CPUCLK0 = 600 MHz)	I_{CC_DCDC} *1	20	186	mA	VSCR_1 (VCL = 0.95 V) VCC_DCDC = 3.3 V
		Frequency setting 2 (CPUCLK0 = 480 MHz)		17	168		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 3.3 V
		Frequency setting 3 (CPUCLK0 = 300 MHz)		18	169		
	VCC_DCDC < 2.5 V	Frequency setting 1 (CPUCLK0 = 600 MHz)		27	340		VSCR_1 (VCL = 0.95 V) VCC_DCDC = 1.8 V
		Frequency setting 2 (CPUCLK0 = 480 MHz)		22	307		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 1.8 V
		Frequency setting 3 (CPUCLK0 = 300 MHz)		23	308		
Supply current (External VDD Mode)	VCL = 0.92 to 0.99 V	Frequency setting 1 (CPUCLK0 = 600 MHz)	I_{DD}*2	43	520	mA	Voltage range 1 (VCL = 0.95 V)
	VCL = 0.87 to 0.99 V	Frequency setting 2 (CPUCLK0 = 480 MHz)		36	489		Voltage range 2 (VCL = 0.925 V)
		Frequency setting 3 (CPUCLK0 = 300 MHz)		38	491		

Note 1. Value for I_{CC_DCDC} can be estimated by using the following formulae (units: I_{CC_DCDC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).

[When VCC_DCDC = 3.3 V]

I_{CC_DCDC} Typ.(VSCR_1) = 0.0024 × $f_{CPUCLK0}$ + 0.0134 × f_{ICLK} + 14.33

I_{CC_DCDC} Typ.(VSCR_2) = 0.0029 × $f_{CPUCLK0}$ + 0.0122 × f_{ICLK} + 12.87

[When VCC_DCDC = 1.8 V]

I_{CC_DCDC} Typ.(VSCR_1) = 0.0049 × $f_{CPUCLK0}$ + 0.0265 × f_{ICLK} + 15.67

I_{CC_DCDC} Typ.(VSCR_2) = 0.0050 × $f_{CPUCLK0}$ + 0.0226 × f_{ICLK} + 13.98

However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 2. Value for I_{DD} can be estimated by using the following formulae (units: I_{DD} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).

I_{DD} Typ.(VCL = 0.92 to 0.99 V) = 0.0089 × $f_{CPUCLK0}$ + 0.0472 × f_{ICLK} + 23.68

I_{DD} Typ.(VCL = 0.87 to 0.99 V) = 0.0089 × $f_{CPUCLK0}$ + 0.0406 × f_{ICLK} + 22.00

However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Table 67.18 Increases in Supply Currents during BGO Programming of MRAM-OTP in the Case of Maximal Operation

Item		Symbol	Typ.	Max.	Unit	Test Conditions
Supply current	Normal speed write mode	I_{CC}	—	20	mA	VCC ≥ 1.62 V
		I_{DD}	—	0.5		
	High speed write mode 0	I_{CC}	—	25		VCC ≥ 2.5 V
		I_{DD}	—	5		
	High speed write mode 1	I_{CC}	—	80		VCC ≥ 3.0 V
		I_{DD}	—	0.5		

Note: The MWMCR register is used to select the mode for writing data to MRAM-OTP.

Table 67.19 Currents in Software Standby Mode 1 (DCDC Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
VCC current			I_{CC}	0.20	0.41	0.62	mA	VCC = 3.3 V
VCC_DCDC current	The SRAM and LRAM data are retained.*1, *2	VSCR_1 (VCL = 0.95 V)	I_{CC_DCDC}	10.5	86.3	135	mA	VCC_DCDC = 3.3 V
		VSCR_2 (VCL = 0.925 V)		9.76	79.2	124		
	The SRAM and LRAM data are not retained. *1, *2	VSCR_1 (VCL = 0.95 V)		10.3	85.7	134		
		VSCR_2 (VCL = 0.925 V)		9.63	78.7	123		

Note 1. When the PDRAMSCR0 register is set to 7FFFh, data in the SRAM are retained; when the register is set to 7000h, data in the SRAM are not retained.
Note 2. When the PDRAMSCR2.RKEEP0 bit is set to 1, data in the LRAM are retained; when the bit is set to 0, data in the LRAM are not retained.

Table 67.20 Currents in Software Standby Mode 2 (DCDC Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
VCC current	For SS2LP_0		I_{CC}	0.20	0.41	0.62	mA	VCC = 3.3 V
	For SS2LP_1			0.04	0.27	0.48		
SS2LP_0*1	SVSCR_1*2	The SRAM and LRAM data are retained.*3, *4	I_{CC_DCDC}	8.95	26.8	39.2	mA	VCC_DCDC = 3.3 V
		The SRAM and LRAM data are not retained.*3, *4		8.88	26.0	37.8		
	SVSCR_2*2	The SRAM and LRAM data are retained.*3, *4		8.89	24.7	36.0		
		The SRAM and LRAM data are not retained.*3, *4		8.74	24.2	35.1		
	SVSCR_3*2	The SRAM and LRAM data are retained.*3, *4		8.69	18.7	27.9		
		The SRAM and LRAM data are not retained.*3, *4		8.68	18.4	27.3		
	SVSCR_4*2	The SRAM and LRAM data are retained.*3, *4		8.62	16.6	24.7		
		The SRAM and LRAM data are not retained.*3, *4		8.59	16.1	23.6		
	SVSCR_5*2	The SRAM and LRAM data are retained.*3, *4		8.39	14.6	21.5		
		The SRAM and LRAM data are not retained.*3, *4		8.37	14.2	20.6		
SS2LP_1*1	SVSCR_2*2	The SRAM and LRAM data are retained.*3, *4	I_{CC_DCDC}	1.06	20.3	34.1	mA	VCC_DCDC = 3.3 V
		The SRAM and LRAM data are not retained.*3, *4		0.96	19.8	33.0		
	SVSCR_3*2	The SRAM and LRAM data are retained.*3, *4		0.69	14.9	25.5		
		The SRAM and LRAM data are not retained.*3, *4		0.65	14.6	24.8		
	SVSCR_4*2	The SRAM and LRAM data are retained.*3, *4		0.56	13.0	22.6		
		The SRAM and LRAM data are not retained.*3, *4		0.52	12.4	21.3		
	SVSCR_5*2	The SRAM and LRAM data are retained.*3, *4		0.46	11.2	19.6		
		The SRAM and LRAM data are not retained.*3, *4		0.43	10.7	18.5		

Note 1. Setting of the SS2LP[1:0] bits in the SSCR1 register: SS2LP_0 = default mode, SS2LP_1 = low power setting 1

Note 2. SVSCR_n (n = 1 to 5) is the target VDD voltage specified in the SVSCR register.
Note 3. When the PDRAMSCR0 register is set to 7FFFh, data in the SRAM are retained; when the register is set to 7000h, data in the SRAM are not retained.
Note 4. When the PDRAMSCR2.RKEEP0 bit is set to 1, data in the LRAM are retained; when the bit is set to 0, data in the LRAM are not retained.

67.4.4.2 Operating and Standby Currents for Product Part No. R5K574Nxy4xx (y = E, F)

Table 67.21 Supply Currents for Full Operation (DCDC Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
Supply current (full operation	VCC_DCDC ≥ 2.5 V	Frequency setting 3 (CPUCLK0 = 300 MHz)	I_{CC_DCDC} *1	62	144	210	mA	VSCR_2 (VCL = 0.925 V) VCC_DCDC = 3.3 V
	VCC_DCDC < 2.5 V	Frequency setting 3 (CPUCLK0 = 300 MHz)		104	260	384		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 1.8 V
	VCC current		I_{CC}	10	13	15		VCC = 3.3 V

Note: This table lists the values for current under the following operating conditions.
- The internal memory (SRAM and MRAM) is configured with wait settings that suit the operating frequency and kept as active as is possible through data transfer by the DMAC.
- The peripheral functions are supplied with clocks and kept as active as is possible.
- Unless otherwise specified, the clocks are set to the states that maximize the supply currents within the limits imposed by the specifications.
- The program is placed in the LRAM, the cache is enabled, and the CPU repeatedly executes multiply-and-accumulate instructions.
- Power to the ESWM domain is turned on.

Note 1. Value for I_{CC_DCDC} can be estimated by using the following formulae (units: I_{CC_DCDC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When VCC_DCDC = 3.3 V]
I_{CC_DCDC} Typ. = 0.0460 × $f_{CPUCLK0}$ + 0.0622 × f_{ICLK} + 29.28
I_{CC_DCDC} Max.(VSCR_2, 105°C) = 0.0456 × $f_{CPUCLK0}$ + 0.0702 × f_{ICLK} + 109.07
I_{CC_DCDC} Max.(VSCR_2, 125°C) = 0.0477 × $f_{CPUCLK0}$ + 0.0723 × f_{ICLK} + 173.67
[When VCC_DCDC = 1.8 V]
I_{CC_DCDC} Typ. = 0.0818 × $f_{CPUCLK0}$ + 0.1136 × f_{ICLK} + 45.27
I_{CC_DCDC} Max.(VSCR_2, 105°C) = 0.0854 × $f_{CPUCLK0}$ + 0.1322 × f_{ICLK} + 194.42
I_{CC_DCDC} Max.(VSCR_2, 125°C) = 0.0890 × $f_{CPUCLK0}$ + 0.1352 × f_{ICLK} + 316.79
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Table 67.22 Supply Currents for Full Operation (External VDD Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
Supply current (full operation	VCL = 0.87 to 0.99 V	Frequency setting 3 (CPUCLK0 = 300 MHz)	I_{DD}*1	181	425	594	mA	Voltage range 2 (VCL = 0.925 V)
	VCC current		I_{CC}	10	13	15		VCC = 3.3 V

Note: This table lists the values for current under the following operating conditions.
- The internal memory (SRAM and MRAM) is configured with wait settings that suit the operating frequency and kept as active as is possible through data transfer by the DMAC.
- The peripheral functions are supplied with clocks and kept as active as is possible.
- Unless otherwise specified, the clocks are set to the states that maximize the supply currents within the limits imposed by the specifications.
- The program is placed in the LRAM, the cache is enabled, and the CPU repeatedly executes multiply-and-accumulate instructions.
- Power to the ESWM domain is turned on.

Note 1. Value for I_{DD} can be estimated by using the following formulae (units: I_{DD} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
I_{DD} Typ. = 0.1408 × $f_{CPUCLK0}$ + 0.1942 × f_{ICLK} + 80.70
I_{DD} Max.(VCL = 0.87 to 0.99 V, 105°C) = 0.1267 × $f_{CPUCLK0}$ + 0.1933 × f_{ICLK} + 329.00
I_{DD} Max.(VCL = 0.87 to 0.99 V, 125°C) = 0.1200 × $f_{CPUCLK0}$ + 0.1800 × f_{ICLK} + 504.00
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Table 67.23 Supply Currents for Full Operation (LDO Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
Supply current (full operation)	LDO efficiency improvement function is disabled*2	Frequency setting 3 (CPUCLK0 = 300 MHz)	I_{CC}*1	192	432	600	mA	VCC = 3.3 V
	LDO efficiency improvement function is enabled*2, *3	Frequency setting 3 (CPUCLK0 = 300 MHz)		175	352*4	477*4		
				230	487*4	666*4		VCC = 1.8 V

Note: This table lists the values for current under the following operating conditions.
- The internal memory (SRAM and MRAM) is configured with wait settings that suit the operating frequency and kept as active as is possible through data transfer by the DMAC.
- The peripheral functions are supplied with clocks and kept as active as is possible.
- Unless otherwise specified, the clocks are set to the states that maximize the supply currents within the limits imposed by the specifications.
- The program is placed in the LRAM, the cache is enabled, and the CPU repeatedly executes multiply-and-accumulate instructions.
- Power to the ESWM domain is turned on.

Note 1. Value for I_{CC} can be estimated by using the following formulae (units: I_{CC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When LDO efficiency improvement function is disabled (LDOECR.EFUPE = 0)]
I_{CC} Typ. = 0.1431 × $f_{CPUCLK0}$ + 0.2051 × f_{ICLK} + 87.95
I_{CC} Max.(VSCR_2, 105°C) = 0.1333 × $f_{CPUCLK0}$ + 0.2000 × f_{ICLK} + 332.01
I_{CC} Max.(VSCR_2, 125°C) = 0.1400 × $f_{CPUCLK0}$ + 0.2000 × f_{ICLK} + 498.00
[When LDO efficiency improvement function is enabled (LDOECR.EFUPE = 1)] (VCC = 3.3 V)
I_{CC} Typ. = (0.0856 × $f_{CPUCLK0}$ + 0.1260 × f_{ICLK} + 95.97) × (correction coefficients 1.1)
I_{CC} Max.(VSCR_2, 105°C) = (0.1133 × $f_{CPUCLK0}$ + 0.1333 × f_{ICLK} + 246.02) × (correction coefficients 1.1)
I_{CC} Max.(VSCR_2, 125°C) = (0.0867 × $f_{CPUCLK0}$ + 0.1400 × f_{ICLK} + 365.99) × (correction coefficients 1.1)
[When LDO efficiency improvement function is enabled (LDOECR.EFUPE = 1)] (VCC = 1.8 V)
I_{CC} Typ. = (0.1456 × $f_{CPUCLK0}$ + 0.2042 × f_{ICLK} + 103.76) × (correction coefficients 1.1)
I_{CC} Max.(VSCR_2, 105°C) = (0.1267 × $f_{CPUCLK0}$ + 0.1867 × f_{ICLK} + 348.98) × (correction coefficients 1.1)
I_{CC} Max.(VSCR_2, 125°C) = (0.1000 × $f_{CPUCLK0}$ + 0.1733 × f_{ICLK} + 523.01) × (correction coefficients 1.1)
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 2. LDOECR.EFUPE = 0 (disabled) or LDOECR.EFUPE = 1 (enabled)

Note 3. When the LDO efficiency improvement function is enabled, the efficiency deteriorates and the supply current increases as the VCC voltage decreases. See Figure 67.6.

Note 4. The values are reference values.

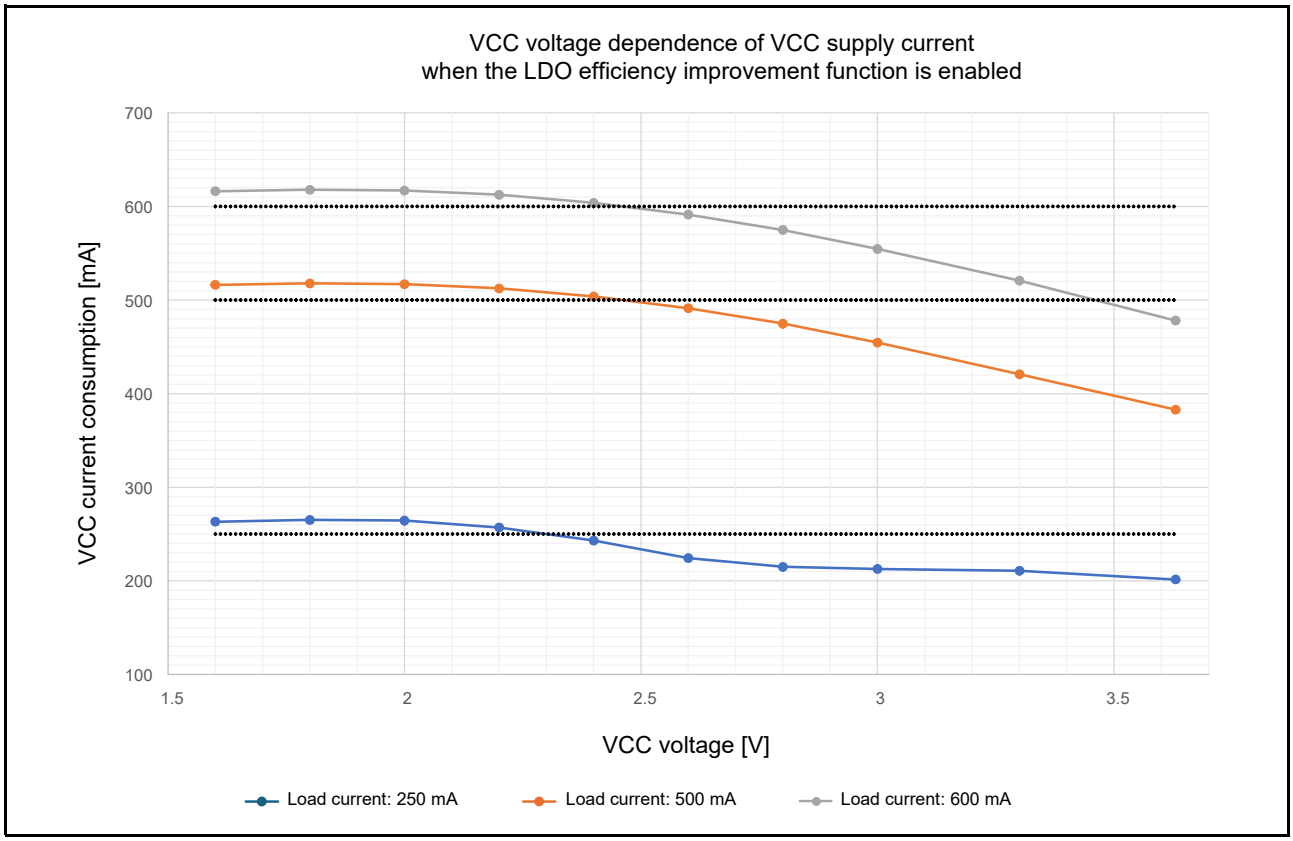

Figure 67.6 VCC Voltage Dependence of VCC Supply Current when the LDO Efficiency Improvement Function is Enabled

Table 67.24 Supply Currents for Maximum Data Processing with the Peripheral Clock Supplies Stopped (DCDC Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
Supply current	VCC_DCDC ≥ 2.5 V	Frequency setting 3 (CPUCLK0 = 300 MHz)	I_{CC_DCDC} *1	25	106	173	mA	VSCR_2 (VCL = 0.925 V) VCC_DCDC = 3.3 V
	VCC_DCDC < 2.5 V	Frequency setting 3 (CPUCLK0 = 300 MHz)		36	189	315		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 1.8 V
	VCC current		I_{CC}	3.9	6.2	8.3		VCC = 3.3 V

Note: This table lists the values for current under the following operating conditions.
- Unless otherwise specified, the clocks are set to the states that maximize the supply currents within the limits imposed by the specifications.
- The program is placed in the LRAM, the cache is enabled, and the CPU repeatedly executes multiply-and-accumulate instructions.
- The clock-signal supplies to the peripheral functions are stopped.
- Power to the ESWM domain is turned off.

Note 1. Value for I_{CC_DCDC} can be estimated by using the following formulae (units: I_{CC_DCDC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When VCC_DCDC = 3.3 V]
I_{CC_DCDC} Typ. = 0.0318 × $f_{CPUCLK0}$ + 0.0111 × f_{ICLK} + 12.00
I_{CC_DCDC} Max.(VSCR_2, 105°C) = 0.0210 × $f_{CPUCLK0}$ + 0.0070 × f_{ICLK} + 97.82
I_{CC_DCDC} Max.(VSCR_2, 125°C) = 0.0126 × $f_{CPUCLK0}$ + 0.0026 × f_{ICLK} + 168.35
[When VCC_DCDC = 1.8 V]
I_{CC_DCDC} Typ. = 0.0612 × $f_{CPUCLK0}$ + 0.0197 × f_{ICLK} + 12.07
I_{CC_DCDC} Max.(VSCR_2, 105°C) = 0.0387 × $f_{CPUCLK0}$ + 0.0129 × f_{ICLK} + 174.02
I_{CC_DCDC} Max.(VSCR_2, 125°C) = 0.0243 × $f_{CPUCLK0}$ + 0.0048 × f_{ICLK} + 306.77
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Table 67.25 Supply Currents for Maximum Data Processing with the Peripheral Clock Supplies Stopped (External VDD Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
Supply current	VCL = 0.87 to 0.99 V	Frequency setting 3 (CPUCLK0 = 300 MHz)	I_{DD}*1	62.5	320	501	mA	Voltage range 2 (VCL = 0.925 V)
	VCC current		I_{CC}	3.9	6.2	8.3		VCC = 3.3 V

Note: This table lists the values for current under the following operating conditions.
- Unless otherwise specified, the clocks are set to the states that maximize the supply currents within the limits imposed by the specifications.
- The program is placed in the LRAM, the cache is enabled, and the CPU repeatedly executes multiply-and-accumulate instructions.
- The clock-signal supplies to the peripheral functions are stopped.
- Power to the ESWM domain is turned off.
- The values given were measured with all output pins load-free and all input pull-up resistors disabled.
- The values given do not include the supply current for background operation (BGO).

Note 1. Value for I_{DD} can be estimated by using the following formulae (units: I_{DD} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
I_{DD} Typ. = 0.1124 × $f_{CPUCLK0}$ + 0.0351 × f_{ICLK} + 18.30
I_{DD} Max.(VCL = 0.87 to 0.99 V, 105°C) = 0.0600 × $f_{CPUCLK0}$ + 0.0200 × f_{ICLK} + 296.00
I_{DD} Max.(VCL = 0.87 to 0.99 V, 125°C) = 0.0333 × $f_{CPUCLK0}$ + 0.0067 × f_{ICLK} + 489.00
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Table 67.26 Supply Currents for Maximum Data Processing with the Peripheral Clock Supplies Stopped (LDO Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
Supply current	LDO efficiency improvement function is disabled*2	Frequency setting 3 (CPUCLK0 = 300 MHz)	I_{CC}*1	68.1	323	503	mA	VCC = 3.3 V
	LDO efficiency improvement function is enabled*2	Frequency setting 3 (CPUCLK0 = 300 MHz)		68.0	256*3	424*3		
				68.2	373*3	554*3		VCC = 1.8 V

Note: This table lists the values for current under the following operating conditions.
- The internal memory (SRAM and MRAM) is configured with wait settings that suit the operating frequency and kept as active as is possible through data transfer by the DMAC.
- The peripheral functions are supplied with clocks and kept as active as is possible.
- Unless otherwise specified, the clocks are set to the states that maximize the supply currents within the limits imposed by the specifications.
- The program is placed in the LRAM, the cache is enabled, and the CPU repeatedly executes multiply-and-accumulate instructions.
- Power to the ESWM domain is turned on.

Note 1. Value for I_{CC} can be estimated by using the following formulae (units: I_{CC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When LDO efficiency improvement function is disabled (LDOECR.EFUPE = 0)]
I_{CC} Typ. = 0.1115 × $f_{CPUCLK0}$ + 0.0349 × f_{ICLK} + 24.16
I_{CC} Max.(VSCR_2, 105°C) = 0.0800 × $f_{CPUCLK0}$ + 0.0333 × f_{ICLK} + 289.01
I_{CC} Max.(VSCR_2, 125°C) = 0.0800 × $f_{CPUCLK0}$ + 0.0400 × f_{ICLK} + 467.00
[When LDO efficiency improvement function is enabled (LDOECR.EFUPE = 1)] (VCC = 3.3 V)
I_{CC} Typ. = 0.1115 × $f_{CPUCLK0}$ + 0.0349 × f_{ICLK} + 24.08
I_{CC} Max.(VSCR_2, 105°C) = (0.0400 × $f_{CPUCLK0}$ + 0.0200 × f_{ICLK} + 215.00) × (correction coefficients 1.1)
I_{CC} Max.(VSCR_2, 125°C) = (0.0733 × $f_{CPUCLK0}$ + 0.2200 × f_{ICLK} + 297.01) × (correction coefficients 1.1)
[When LDO efficiency improvement function is enabled (LDOECR.EFUPE = 1)] (VCC = 1.8 V)
I_{CC} Typ. = 0.1115 × $f_{CPUCLK0}$ + 0.0349 × f_{ICLK} + 24.25
I_{CC} Max.(VSCR_2, 105°C) = (0.0327 × $f_{CPUCLK0}$ + 0.1029 × f_{ICLK} + 298.32) × (correction coefficients 1.1)
I_{CC} Max.(VSCR_2, 125°C) = (0.0333 × $f_{CPUCLK0}$ + 0.0200 × f_{ICLK} + 488.01) × (correction coefficients 1.1)
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 2. LDOECR.EFUPE = 0 (disabled) or LDOECR.EFUPE = 1 (enabled)

Note 3. The values are reference values.

Table 67.27 Supply Currents for while(1) Operation by the CPU with the Peripheral Clock Supplies Stopped and the ESWM Domain Turned Off

Item			Symbol	Typ.	Max.	Unit	Test Conditions
DCDC mode	VCC_DCDC ≥ 2.5 V	Frequency setting 3 (CPUCLK0 = 300 MHz)	I_{CC_DCDC}*2	16	—	mA	VSCR_2 (VCL = 0.925 V) VCC_DCDC = 3.3 V
	VCC_DCDC < 2.5 V	Frequency setting 3 (CPUCLK0 = 300 MHz)		24	—		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 1.8 V
External VDD mode	VCL = 0.87 to 0.99 V	Frequency setting 3 (CPUCLK0 = 300 MHz)	I_{DD}*3	41	—	mA	Voltage range 2 (VCL = 0.925 V)
LDO mode	LDO efficiency improvement function is disabled*1	Frequency setting 3 (CPUCLK0 = 300 MHz)	I_{CC}*4	47	—	mA	VCC = 3.3 V
	LDO efficiency improvement function is enabled*1	Frequency setting 3 (CPUCLK0 = 300 MHz)		47	—		

Note 1. LDOECR.EFUPE = 0 (disabled) or LDOECR.EFUPE = 1 (enabled)

Note 2. Value for I_{CC_DCDC} can be estimated by using the following formulae (units: I_{CC_DCDC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When VCC_DCDC = 3.3 V]
I_{CC_DCDC} Typ.(VSCR_2) = 0.0069 × $f_{CPUCLK0}$ + 0.0122 × f_{ICLK} + 10.71
[When VCC_DCDC = 1.8 V]
I_{CC_DCDC} Typ.(VSCR_2) = 0.0213 × $f_{CPUCLK0}$ + 0.0200 × f_{ICLK} + 11.63
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 3. Value for I_{DD} can be estimated by using the following formula (units: I_{DD} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
I_{DD} Typ.(VCL = 0.87 to 0.99 V) = 0.0420 × $f_{CPUCLK0}$ + 0.0353 × f_{ICLK} + 18.16
However, note that the above formula is only for use in estimation and values from it do not guarantee the actual supply currents.

Note 4. Value for I_{CC} can be estimated by using the following formulae (units: I_{CC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When LDO efficiency improvement function is disabled (LDOECR.EFUPE = 0)]
I_{CC} Typ. = 0.0425 × $f_{CPUCLK0}$ + 0.0351 × f_{ICLK} + 24.05
[When LDO efficiency improvement function is enabled (LDOECR.EFUPE = 1)]
I_{CC} Typ. = 0.0423 × $f_{CPUCLK0}$ + 0.0351 × f_{ICLK} + 23.78
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Table 67.31 Supply Currents in CPU Sleep Mode with the Peripheral Clock Supplies Stopped and the ESWM Domain Turned Off

Item		Symbol	Typ.	Max.	Unit	Test Conditions
DCDC mode	VCC_DCDC ≥ 2.5 V	I_{CC_DCDC} *2	17	188	mA	VSCR_2 (VCL = 0.925 V) VCC_DCDC = 3.3 V
	VCC_DCDC < 2.5 V		21	344		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 1.8 V
External VDD mode	VCL = 0.87 to 0.99 V	I_{DD}*3	34	540	mA	Voltage range 2 (VCL = 0.925 V)
LDO mode	LDO efficiency improvement function is disabled*1	I_{CC}*4	40	542	mA	VCC = 3.3 V
	LDO efficiency improvement function is enabled*1		40	406*5		
			40	595*5		VCC = 1.8 V

Note 1. LDOECR.EFUPE = 0 (disabled) or LDOECR.EFUPE = 1 (enabled)

Note 2. Value for I_{CC_DCDC} can be estimated by using the following formulae (units: I_{CC_DCDC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When VCC_DCDC = 3.3 V]
I_{CC_DCDC} Typ. = 0.0028 × $f_{CPUCLK0}$ + 0.0096 × f_{ICLK} + 12.80
[When VCC_DCDC = 1.8 V]
I_{CC_DCDC} Typ. = 0.0074 × $f_{CPUCLK0}$ + 0.0184 × f_{ICLK} + 12.82
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 3. Value for I_{DD} can be estimated by using the following formula (units: I_{DD} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
I_{DD} Typ.(VCL = 0.87 to 0.99 V) = 0.0169 × $f_{CPUCLK0}$ + 0.0351 × f_{ICLK} + 18.18
However, note that the above formula is only for use in estimation and values from it do not guarantee the actual supply currents.

Note 4. Value for I_{CC} can be estimated by using the following formulae (units: I_{CC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When LDO efficiency improvement function is disabled (LDOECR.EFUPE = 0)]
I_{CC} Typ. = 0.0171 × $f_{CPUCLK0}$ + 0.0352 × f_{ICLK} + 24.02
[When LDO efficiency improvement function is enabled (LDOECR.EFUPE = 1)]
I_{CC} Typ. = 0.0170 × $f_{CPUCLK0}$ + 0.0351 × f_{ICLK} + 24.50
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 5. The values are reference values.

Table 67.32 Supply Currents in CPU Deep Sleep Mode with the Peripheral Clock Supplies Stopped and the ESWM Domain Turned Off

Item		Symbol	Typ.	Max.	Unit	Test Conditions
DCDC mode	VCC_DCDC ≥ 2.5 V	I_{CC_DCDC} *2	15	154	mA	VSCR_2 (VCL = 0.925 V) VCC_DCDC = 3.3 V
	VCC_DCDC < 2.5 V		19	279		VSCR_2 (VCL = 0.925 V) VCC_DCDC = 1.8 V
External VDD mode	VCL = 0.87 to 0.99 V	I_{DD} *3	30	450	mA	Voltage range 2 (VCL = 0.925 V)
LDO mode	LDO efficiency improvement function is disabled*1	I_{CC} *4	36	453	mA	VCC = 3.3 V
	LDO efficiency improvement function is enabled*1		36	347*5		
			36	506*5		VCC = 1.8 V

Note 1. LDOECR.EFUPE = 0 (disabled) or LDOECR.EFUPE = 1 (enabled)

Note 2. Value for I_{CC_DCDC} can be estimated by using the following formulae (units: I_{CC_DCDC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When VCC_DCDC = 3.3 V]
I_{CC_DCDC} Typ.(VSCR_2) = 0.0016 × $f_{CPUCLK0}$ + 0.0062 × f_{ICLK} + 13.10
[When VCC_DCDC = 1.8 V]
I_{CC_DCDC} Typ.(VSCR_2) = 0.0039 × $f_{CPUCLK0}$ + 0.0156 × f_{ICLK} + 12.82
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 3. Value for I_{DD} can be estimated by using the following formula (units: I_{DD} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
I_{DD} Typ.(VCL = 0.87 to 0.99 V) = 0.0085 × $f_{CPUCLK0}$ + 0.0350 × f_{ICLK} + 17.37
However, note that the above formula is only for use in estimation and values from it do not guarantee the actual supply currents.

Note 4. Value for I_{CC} can be estimated by using the following formulae (units: I_{CC} = mA, $f_{CPUCLK0}$ = MHz, f_{ICLK} = MHz).
[When LDO efficiency improvement function is disabled (LDOECR.EFUPE = 0)]
I_{CC} Typ. = 0.0086 × $f_{CPUCLK0}$ + 0.0351 × f_{ICLK} + 23.25
[When LDO efficiency improvement function is enabled (LDOECR.EFUPE = 1)]
I_{CC} Typ. = 0.0085 × $f_{CPUCLK0}$ + 0.0352 × f_{ICLK} + 22.89
However, note that the above formulae are only for use in estimation and values from them do not guarantee the actual supply currents.

Note 5. The values are reference values.

Table 67.33 Increases in Supply Currents during BGO Programming of MRAM-OTP in the Case of Maximal Operation

Item		Symbol	Typ.	Max.	Unit	Test Conditions
Supply current	Normal speed write mode	I_{CC}	—	20	mA	VCC ≥ 1.62 V
		I_{DD}	—	0.5		
	High speed write mode 0	I_{CC}	—	25		VCC ≥ 2.5 V
		I_{DD}	—	5		
	High speed write mode 1	I_{CC}	—	80		VCC ≥ 3.0 V
		I_{DD}	—	0.5		

Note: The MWMCR register is used to select the mode for writing data to MRAM-OTP.

Table 67.34 Currents in Software Standby Mode 1 (DCDC Mode)

Item		Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
VCC current		I_{CC}	0.18	0.39	0.62	mA	VCC = 3.3 V
VCC_DCDC current	The SRAM and LRAM data are retained. *1, *2	I_{CC_DCDC}	9.76	77.4	122	mA	VCC_DCDC = 3.3 V
	The SRAM and LRAM data are not retained.*1, *2		9.63	76.7	121		

Note 1. When the PDRAMSCR0 register is set to 7FFFh, data in the SRAM are retained; when the register is set to 7000h, data in the SRAM are not retained.
Note 2. When the PDRAMSCR2.RKEEP0 bit is set to 1, data in the LRAM are retained; when the bit is set to 0, data in the LRAM are not retained.

Table 67.35 Currents in Software Standby Mode 1 (LDO Mode)

Item		Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
VCC current	The SRAM and LRAM data are retained.*1, *2	I_{CC}	9.94	223	353	mA	VCC = 3.3 V
	The SRAM and LRAM data are not retained. *1, *2		9.81	223	353		

Note: In software standby mode 1, disable the LDO efficiency improvement function (LDOECR.EFUPE = 0).
Note 1. When the PDRAMSCR0 register is set to 7FFFh, data in the SRAM are retained; when the register is set to 7000h, data in the SRAM are not retained.
Note 2. When the PDRAMSCR2.RKEEP0 bit is set to 1, data in the LRAM are retained; when the bit is set to 0, data in the LRAM are not retained.

Table 67.36 Currents in Software Standby Mode 2 (DCDC Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
VCC current	For SS2LP_0		I_{CC}	0.18	0.39	0.62	mA	VCC = 3.3 V
	For SS2LP_1			0.04	0.26	0.49		
SS2LP_0*1	SVSCR_2*2	The SRAM and LRAM data are retained.*3, *4	I_{CC_DCDC}	8.34	23.2	34.1	mA	VCC_DCDC = 3.3 V
		The SRAM and LRAM data are not retained.*3, *4		8.25	22.8	33.3		
	SVSCR_3*2	The SRAM and LRAM data are retained.*3, *4		7.99	17.8	26.2		
		The SRAM and LRAM data are not retained.*3, *4		7.94	17.6	25.7		
	SVSCR_4*2	The SRAM and LRAM data are retained.*3, *4		7.87	15.6	22.9		
		The SRAM and LRAM data are not retained.*3, *4		7.84	15.3	22.0		
	SVSCR_5*2	The SRAM and LRAM data are retained.*3, *4		7.79	13.6	19.8		
		The SRAM and LRAM data are not retained.*3, *4		7.77	13.4	19.1		
SS2LP_1*1	SVSCR_2*2	The SRAM and LRAM data are retained.*3, *4	I_{CC_DCDC}	0.84	18.7	31.5	mA	VCC_DCDC = 3.3 V
		The SRAM and LRAM data are not retained.*3, *4		0.73	18.3	30.5		
	SVSCR_3*2	The SRAM and LRAM data are retained.*3, *4		0.53	13.6	23.3		
		The SRAM and LRAM data are not retained.*3, *4		0.48	13.4	22.7		
	SVSCR_4*2	The SRAM and LRAM data are retained.*3, *4		0.42	11.7	20.3		
		The SRAM and LRAM data are not retained.*3, *4		0.39	11.3	19.4		
	SVSCR_5*2	The SRAM and LRAM data are retained.*3, *4		0.34	10.0	17.6		
		The SRAM and LRAM data are not retained.*3, *4		0.32	9.70	16.8		

Note 1. Setting of the SS2LP[1:0] bits in the SSCR1 register: SS2LP_0 = default mode, SS2LP_1 = low power setting 1
Note 2. SVSCR_n (n = 2 to 5) is the target VDD voltage specified in the SVSCR register.
Note 3. When the PDRAMSCR0 register is set to 7FFFh, data in the SRAM are retained; when the register is set to 7000h, data in the SRAM are not retained.
Note 4. When the PDRAMSCR2.RKEEP0 bit is set to 1, data in the LRAM are retained; when the bit is set to 0, data in the LRAM are not retained.

Table 67.37 Currents in Software Standby Mode 2 (LDO Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
SS2LP_0*1	SVSCR_2*2	The SRAM and LRAM data are retained.*3, *4	I_{CC}	4.46	57.2	95.9	mA	VCC = 3.3 V
		The SRAM and LRAM data are not retained.*3, *4		4.11	56.3	94.0		
	SVSCR_3*2	The SRAM and LRAM data are retained.*3, *4		3.66	47.2	80.3		
		The SRAM and LRAM data are not retained.*3, *4		3.49	46.5	78.7		
	SVSCR_4*2	The SRAM and LRAM data are retained.*3, *4		3.39	42.7	73.8		
		The SRAM and LRAM data are not retained.*3, *4		3.26	41.2	70.6		
	SVSCR_5*2	The SRAM and LRAM data are retained.*3, *4		3.14	38.6	67.3		
		The SRAM and LRAM data are not retained.*3, *4		3.05	37.3	64.4		
SS2LP_1*1	SVSCR_2*2	The SRAM and LRAM data are retained.*3, *4	I_{CC}	2.85	56.4	94.9	mA	VCC = 3.3 V
		The SRAM and LRAM data are not retained.*3, *4		2.51	55.6	93.1		
	SVSCR_3*2	The SRAM and LRAM data are retained.*3, *4		2.09	46.3	79.3		
		The SRAM and LRAM data are not retained.*3, *4		1.92	45.6	77.8		
	SVSCR_4*2	The SRAM and LRAM data are retained.*3, *4		1.78	41.6	72.6		
		The SRAM and LRAM data are not retained.*3, *4		1.65	40.4	69.6		
	SVSCR_5*2	The SRAM and LRAM data are retained.*3, *4		1.54	37.5	66.1		
		The SRAM and LRAM data are not retained.*3, *4		1.45	36.4	63.3		

Note: In software standby mode 2, disable the LDO efficiency improvement function (LDOECR.EFUPE = 0).
Note 1. Setting of the SS2LP[1:0] bits in the SSCR1 register: SS2LP_0 = default mode, SS2LP_1 = low power setting 1
Note 2. SVSCR_n (n = 2 to 5) is the target VDD voltage specified in the SVSCR register.
Note 3. When the PDRAMSCR0 register is set to 7FFFh, data in the SRAM are retained; when the register is set to 7000h, data in the SRAM are not retained.
Note 4. When the PDRAMSCR2.RKEEP0 bit is set to 1, data in the LRAM are retained; when the bit is set to 0, data in the LRAM are not retained.

67.4.4.3 Currents in Deep Software Standby Mode

Table 67.38 Currents in Deep Software Standby Mode (DCDC Mode or LDO Mode)

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
DSTBY1	VCC_DCDC current		I_{CC_DCDC}	0.16	1.24	2.45	µA	Condition for the Max. values: VCC = VCC_DCDC = 3.63 V Condition for the Typ. values: VCC = VCC_DCDC = 3.3 V
	VCC current		I_{CC}	7.10	185	332		
		Increase in the current when PVDn or VBATT power switching is enabled*1		See Table 67.40				
		Increase in the current when the LOCO is in use*2		3.42	4.50	5.20		
		Increase in the current during SOSC and RTC operation		See Table 67.41				
		Increase in the current during IWDT operation		0.01	0.02	0.02		
DSTBY2	VCC_DCDC current		I_{CC_DCDC}	0.16	1.24	2.45	µA	
	VCC current		I_{CC}	4.90	108	195		
		Increase in the current when PVDn or VBATT power switching is enabled*1		See Table 67.40				
		Increase in the current during SOSC and RTC operation		See Table 67.41				
DSTBY3	VCC_DCDC current		I_{CC_DCDC}	0.16	1.24	2.45	µA	
	VCC current		I_{CC}	4.40	106	193		
		Increase in the current during SOSC and RTC operation		See Table 67.41				
Increase in the current when the LDO regulator is in use			I_{CC}	0.10	7.42	26.1	µA	VCC = 3.3 V

DSTBY1: Deep software standby mode 1
DSTBY2: Deep software standby mode 2
DSTBY3: Deep software standby mode 3
PVDn: Programmable voltage detection module (n = 0, 1, 2, 4, 5)
LOCO: Low-speed on-chip oscillator
SOSC: Sub-clock oscillator
RTC: Realtime clock
Note 1. When the VBATTCR1.PSWDIS bit = 0 (initial value), VBATT power switching is enabled.
Note 2. The maximum value for this item is the result measured at VCC = VCC_DCDC = 3.3 V.

Table 67.39 RTC Operating Current with VCC Off (VCC = 0 V) and Only the RTC Operating through the Battery Backup Function

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
VBATT supply current	When a crystal resonator is in use	Low-power mode 2 (7 pF) *1	I_{VBAT}	0.57	—	—	µA	VBATT = 1.8 V
				0.98	—	—		VBATT = 3.3 V
		Low-power mode 1 (9 pF) *1		0.67	—	—		VBATT = 1.8 V
				1.08	—	—		VBATT = 3.3 V
		Standard mode (12.5 pF) *1		0.92	—	—		VBATT = 1.8 V
				1.34	—	—		VBATT = 3.3 V
	When the external sub-clock input pin (EXCIN) is in use			0.23	—	—		VBATT = 1.8 V
				0.57	—	—		VBATT = 3.3 V
	Increased in the current per channel when the RTCICn (n = 0 to 2) input is in use			0.01	—	—		VBATT = 1.8 V
				0.01	—	—		VBATT = 3.3 V

Note 1. This mode is selected by the SOMCR.SODRV[1:0] bits.

Table 67.40 Increases in the Current when the PVDn or VBATT Function is Enabled in DSTBY1 and DSTBY2

Item		Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
Increase in VCC current	Current in the common circuit of PVDn in DSTBY1*1	I_{CC}	3.60	—	—	µA	VCC = VCC_DCDC = 3.3 V
	Current in the common circuit of PVDn in DSTBY2*1		3.60	—	—		
	PVD1 is enabled		1.70	—	—		
	PVD2 is enabled		1.70	—	—		
	PVD4 is enabled		1.70	—	—		
	PVD5 is enabled		1.70	—	—		
	When VBATT power switching is enabled*2		1.70	—	—		

n = 0, 1, 2, 4, 5

Note 1. When PVDn is enabled and the low power consumption function of PVD0 is disabled (OFS1.DSBYLPSEL = 1)

Note 2. When the VBATTCR1.PSWDIS bit = 0 and PVD0 is not in use for VBATT voltage detection (OFS1.DSBYLPSEL = 1)

Table 67.41 Increase in the Current during Sub-Clock Oscillator and RTC Operation in DSTBY Mode

Item			Symbol	Typ.	Max. (Tj = 105°C)	Max. (Tj = 125°C)	Unit	Test Conditions
Increase in VCC current	When a crystal resonator is in use	Low-power mode 2 (7 pF) *1	I_{CC}	0.47	—	—	µA	VCC = VCC_DCDC = 3.3 V
		Low-power mode 1 (9 pF) *1		0.57	—	—		
		Standard mode (12.5 pF) *1		0.83	—	—		
	During RTC Operation			0.05	—	—		

Note 1. This mode is selected by the SOMCR.SODRV[1:0] bits.

Table 67.42 Inrush Currents

Item		Product Part No. (R5K574Nxy4zz)	DPSBYCR Register	Symbol	Typ.	Max.	Unit	Test Conditions
Inrush current of VCC_DCDC	Inrush current on power-on	y = A, B, C, D	—	I_{RUSH}	—	1200	mA	—
		y = E, F	—		—	1050		
	Inrush current on return from deep software standby mode	y = A, B, C, D	DCSSMODE[1:0] = 01b		—	1150		
			DCSSMODE[1:0] = 10b		—	1050		
			DCSSMODE[1:0] = 11b		—	1050		
		y = E, F	DCSSMODE[1:0] = 01b		—	1000		
			DCSSMODE[1:0] = 10b		—	900		
			DCSSMODE[1:0] = 11b		—	800		
Inrush current of VCC	Inrush current on power-on	zz = FP (LQFP100)		I_{RUSH}	—	495	mA	—
		zz = FB (LQFP144)			—	490		
		zz = FC (LQFP176)			—	500		
		zz = BG (BGA176)			—	500		
		zz = BD (BGA224)			—	500		
		zz = AE (BGA320)			—	511		*1
	Inrush current on return from deep software standby mode	zz = FP (LQFP100)	LDOSSMODE[1:0] = 01b		—	615		—
		zz = FB (LQFP144)			—	602		
		zz = FC (LQFP176)			—	626		
		zz = BG (BGA176)			—	626		
		zz = BD (BGA224)			—	626		
		zz = AE (BGA320)			—	650		*1
		zz = FP (LQFP100)	LDOSSMODE[1:0] = 10b		—	541		—
		zz = FB (LQFP144)			—	532		
		zz = FC (LQFP176)			—	548		
		zz = BG (BGA176)			—	548		
		zz = BD (BGA224)			—	548		
		zz = AE (BGA320)			—	563		*1
		zz = FP (LQFP100)	LDOSSMODE[1:0] = 11b		—	495		—
		zz = FB (LQFP144)			—	490		
		zz = FC (LQFP176)			—	500		
		zz = BG (BGA176)			—	500		
		zz = BD (BGA224)			—	500		
		zz = AE (BGA320)			—	511		*1

Note: The values are reference values.

Note 1. The VCL pins must be connected to the VSS pins via multilayer ceramic capacitors and no more than ten multilayer ceramic capacitors should be connected in LDO mode.
The values for the BGA320 package are for the case with ten multilayer ceramic capacitors connected.

67.4.4.4 Other Operating Currents

Table 67.43 Main Clock Oscillator Operating Current

Item		Symbol	Typ.	Max.	Unit
Main clock oscillator operating current	MOMCR.MODRV0[2:0] = 000b	I_{CC}	0.65	—	mA
	MOMCR.MODRV0[2:0] = 011b		0.76	—	
	MOMCR.MODRV0[2:0] = 101b		0.88	—	

Table 67.44 Analog Operating Currents

Item								Symbol	Typ.	Max.	Unit
	A/D Unit 0	S&H (3ch.)	A/D Unit 1	A/D Unit 2	D/A*1 AMP ON	D/A*2 AMP OFF	TEMPS				
Analog power supply current	Converting	Sleep	Sleep	Sleep	Stopped	Stopped	Stopped	AI_{CC}	2.4	3.2	mA
	Converting	Converting	Sleep	Sleep	Stopped	Stopped	Stopped		6.6	8.7	
	Waiting	Sleep	Sleep	Sleep	Stopped	Stopped	Stopped		1.6	2.0	
	Sleep	Sleep	Converting	Sleep	Stopped	Stopped	Stopped		2.4	3.2	
	Sleep	Sleep	Waiting	Sleep	Stopped	Stopped	Stopped		1.6	2.0	
	Sleep	Sleep	Sleep	Converting	Stopped	Stopped	Stopped		2.4	3.2	
	Sleep	Sleep	Sleep	Waiting	Stopped	Stopped	Stopped		1.6	2.0	
	Stopped	Stopped	Stopped	Stopped	Converting	Stopped	Stopped		0.5	1.5	
	Stopped	Stopped	Stopped	Stopped	Stopped	Converting	Stopped		0.1	0.2	
	Stopped	Stopped	Stopped	Stopped	Stopped	Stopped	Converting		0.1	0.2	
	Standby mode								0.3	7.3	µA
Reference power supply current	A/D conversion is in progress in all ADC16H units.			SAR mode				AI_{REFH0}	220	370	µA
				Oversampling mode or hybrid mode					580	880	
	All ADC16H units waiting for the start of A/D conversion								8.2	14	
	All ADC16H units in standby mode								0.1	0.5	

Stopped: The module is stopped.
Waiting: The module is operating but not performing A/D conversion.
Sleep: The module is in sleep mode. (ADUSLPCRn.ADUSLPn = 1 (n = 0, 1, or 2))
S&H: Channel-dedicated sample-and-hold circuit
Note 1. The load resistance is 5 kΩ when the amplifier is on.
Note 2. The load resistance is 2 MΩ when the amplifier is off.

Table 67.45 USB Operating Currents

Item				Symbol	Typ.	Max.	Unit
USB operating current	Low-speed operation	USBf		I_{CCUSB_LS}	2.90	4.00	mA
		USBHS	Classic-only mode is disabled	$I_{CCUSBHS_LS}$	11.5	14.6	
			Classic-only mode is enabled		5.04	6.80	
	Full-speed operation	USBf		I_{CCUSB_FS}	4.00	4.70	
		USBHS	Classic-only mode is disabled	$I_{CCUSBHS_FS}$	12.5	14.7	
			Classic-only mode is enabled		5.98	6.90	
	High-speed operation	USBHS		$I_{CCUSBHS_HS}$	45.7	55.3	
	Standby mode	USBHS		$I_{CCUSBHS_SBY}$	0.89	11.4	µA

Note: The power supplies to the USBHS are set as VCC_USBHS = AVCC_USBHS.
Note: Classic-only mode is disabled when the PHYSET.HSEB bit is 0 and enabled when the PHYSET.HSEB bit is 1.

67.4.4.5 Permissible Output Currents

Table 67.46 Permissible Output Currents (1/6)

Item				Symbol	Min.	Typ.	Max.	Unit
Permissible output low current (average value per pin)	I3C*1	I3C protocol mode*5	LVO0E = 0	I_{OL}	—	—	20	mA

		P708 to P711, PE00 to PE07, PF06 to PF09 (Total of 16 pins)		—	—	–80	

Table 67.46 Permissible Output Currents (6/6)

Item			Symbol	Min.	Typ.	Max.	Unit
Permissible output high current (total)	VCC2 IO	P600 to P607, P900 to P907, PD00 to PD07 (Total of 24 pins)	ΣI_{OH_VCC2}	—	—	–80	mA
	AVCC0 IO	P400 to P415 (Total of 16 pins)	ΣI_{OH_AVCC0}	—	—	–33	mA
	VCC_USB IO	PF00, PF01 (Total of 2 pins)*6	ΣI_{OH_VCCUSB}	—	—	–33	mA

Caution: To protect the MCU's reliability, the output current values should not exceed the values in Table 67.46.
The average output current is obtained from the values for current measured over a period of 100 µs.
Note 1. When SDA00-A and SCL00-A are selected for the P102 and P103 pins.
Note 2. When SDAHSn-A and SCLHSn-A (n = 1, 2) are selected for the P106, P107, P200, and P201 pins.
Note 3. This is the driving ability as selected by the setting of the driving ability select (PmnPFS.DSCR[3:0]) bits.
Note 4. The values are for pins excluding USB0_DP, USB0_DM, USBHS_DP, and USBHS_DM.
Note 5. This characteristics depends on the setting of the LVO0E bit in the low-voltage operating characteristics control register (LVOCR).
Note 6. When a function other than USB0_DP or USB0_DM is selected.
Note 7. When the module operates in Push-Pull mode

67.4.5 Thermal Characteristics

67.4.5.1 Thermal Resistance Value

Table 67.47 Thermal Resistance Value (Reference)

Item	Package	Symbol	Max.	Unit	Test Conditions
Thermal resistance	176-pin LQFP (PLQP0176KJ-A)	θ_{ja}	29.6	°C/W	JESD51-2 and JESD51-7 compliant
	144-pin LQFP (PLQP0144KA-B)		34.3		
	100-pin LQFP (PLQP0100KP-A)		31.6		
	320-pin BGA (PLBG0320GD-A)		20.3		JESD51-2 and JESD51-9 compliant
	224-pin BGA (PLBG0224GE-A)		20.4		
	176-pin BGA (PLBG0176GG-A)		24.7		
	176-pin LQFP (PLQP0176KJ-A)	Ψ_{jt}	0.45	°C/W	JESD51-2 and JESD51-7 compliant
	144-pin LQFP (PLQP0144KA-B)		0.36		
	100-pin LQFP (PLQP0100KP-A)		0.45		
	320-pin BGA (PLBG0320GD-A)		0.17		JESD51-2 and JESD51-9 compliant
	224-pin BGA (PLBG0224GE-A)		0.19		
	176-pin BGA (PLBG0176GG-A)		0.21		

Note: The values are reference values when the 4-layer board is used. Thermal resistance depends on the number of layers or size of the board. For details, refer to the JEDEC standards.

67.4.5.2 Supply Currents for the Peripheral Functions

Table 67.48 Operating Currents for the Peripheral Functions (Load Currents inside the Chip after Release from Module Stop State)

Item		Symbol	Max.	Unit	Register
SRAM1		I_{DD}	23.1	mA	MSTPCRA.MSTPA1
DMAC, DTC	DMACAa (8 channels), DTC	I_{DD}	7.04	mA	MSTPCRA.MSTPA22
	EXDMACAa (2 channels)		6.56		MSTPCRA.MSTPA29
Timers	GPTW (16 channels)	I_{DD}	5.54	mA	MSTPCRE.MSTPE31
	HRPWMb		0.09		MSTPCRD.MSTPD6
	TMRa (2 units)		0.07		MSTPCRF.MSTPF7, MSTPCRF.MSTPF6
	CMT (2 units)		0.06		MSTPCRF.MSTPF15, MSTPCRF.MSTPF14
	CMTW (2 units)		0.05		MSTPCRF.MSTPF13, MSTPCRF.MSTPF12
Communication interface	ESWM	I_{DD}	24.5	mA	MSTPCRC.MSTPC30
	USB		0.25		MSTPCRB.MSTPB11
	USBHS		0.35		MSTPCRB.MSTPB12
	RSCI (13 channels)		5.34		MSTPCRB.MSTPB31 to MSTPCRB.MSTPB20, MSTPCRB.MSTPB0
	RI3C		0.21		MSTPCRB.MSTPB4
	RIICHS (2 channels)		0.40		MSTPCRB.MSTPB8, MSTPCRB.MSTPB7
	CANFDG (2 channels)		0.30		MSTPCRC.MSTPC25
	CANFD		0.14		MSTPCRC.MSTPC27
	RSPIA (3 channels)		0.67		MSTPCRB.MSTPB19, MSTPCRB.MSTPB18, MSTPCRC.MSTPC23
	SDHIc		0.08		MSTPCRC.MSTPC12
	PDMIF		0.03		MSTPCRC.MSTPC24
	XSPI (2 units), DOTF		9.37		MSTPCRB.MSTPB17, MSTPCRB.MSTPB16
	PCIF (2 units)		0.44		MSTPCRF.MSTPF31, MSTPCRF.MSTPF30
	SSIE (2 channels)		0.08		MSTPCRC.MSTPC8, MSTPCRC.MSTPC7
Analog	ADC16H	I_{DD}	4.73	mA	MSTPCRD.MSTPD21
	R12DAB		0.02		MSTPCRD.MSTPD20, MSTPCRD.MSTPD19
	Temperature sensor		0.01		MSTPCRD.MSTPD22
Safety, security function	CRCA	I_{DD}	0.01	mA	MSTPCRC.MSTPC1
	DOCA		0.01		MSTPCRC.MSTPC13
	RSIP		0.67		MSTPCRC.MSTPC31
	POEGd (4 channels)		0.22		MSTPCRD.MSTPD14, MSTPCRD.MSTPD13, MSTPCRD.MSTPD12, MSTPCRD.MSTPD11
Image processing	PDC	I_{DD}	0.04	mA	MSTPCRC.MSTPC2

Note: This table lists the internal load currents flowing inside the chip; they are not the I_{CC_DCDC} current supplied to the DCDC.
Note: The values listed are the increases in the currents after release from the module stop state.

Table 67.49 Leakage Current of the Peripheral Functions (Load Current inside the Chip)

Item	Tj = 105°C	Tj = 125°C	Unit	Control register
ESWM	9.48	18.3	mA	PDCTRESWM.PDDE

Note: The value given is the leakage current when the ESWM power domain is turned on.

67.4.5.3 Example of Calculation of T_a

The estimated maximum operating temperature (i.e., maximum ambient temperature) can be calculated from the maximum junction temperature and the thermal resistance value by using the following formula.

Tamax = Tjmax – (Iccmax × VCC × θja)

- Tamax: Maximum ambient temperature (maximum operating temperature) [°C]
- Tjmax: Maximum junction temperature [°C]
- Iccmax: Maximum operating current [A]
- θja: Thermal resistance value

For example, for the BGA320 package, when the LDO efficiency improvement function is enabled and the ICC current in maximal operation is 211 mA (typ) with VCC = 3.3 V, the calculation can proceed as shown below. In this case, the MCU can operate at ambient temperatures up to 111°C.

Tamax = 125°C – (0.211 A × 3.3 V × 20.3°C/W) = Approximately 111°C

Figure 67.7 shows the VCC voltage dependence of the maximum ambient temperature with a load current of 250 mA when the LDO efficiency improvement function is disabled.

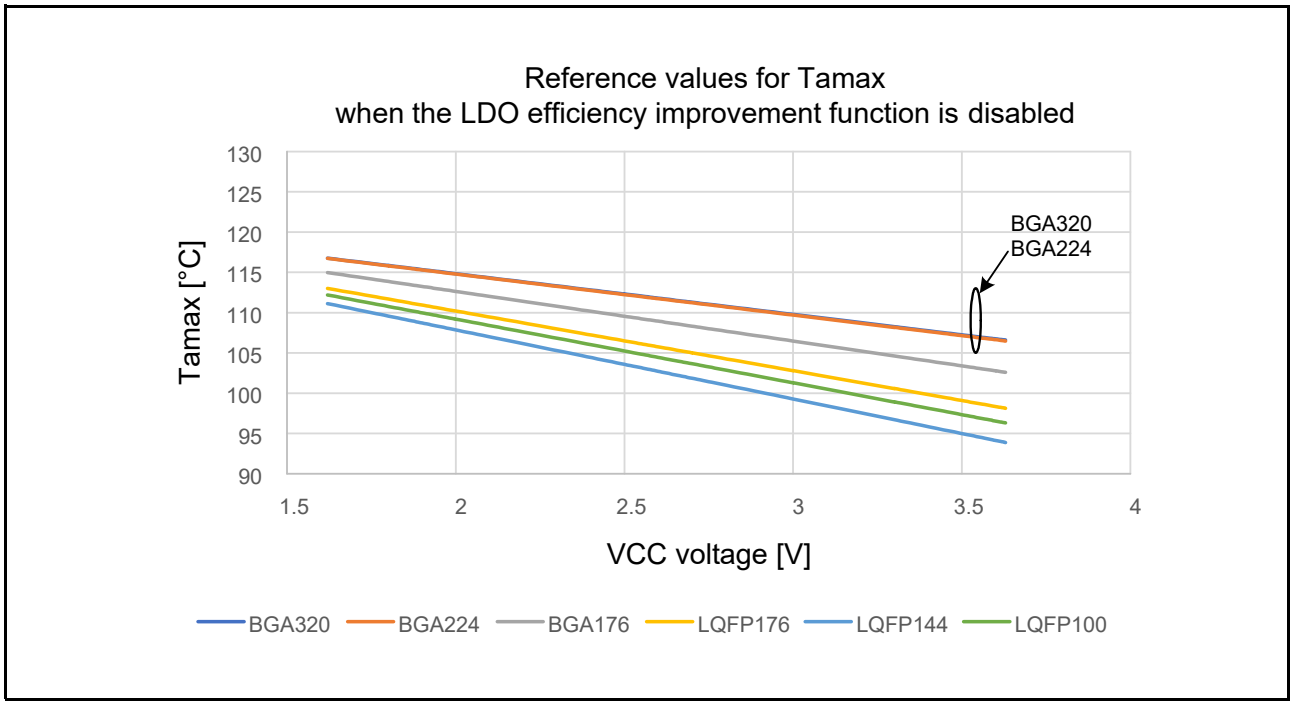

Figure 67.7 VCC Voltage Dependence of the Maximum Ambient Temperature with a Load Current of 250 mA When the LDO Efficiency Improvement Function Is Disabled

Figure 67.8 shows the VCC voltage dependence of the maximum ambient temperature with a load current of 250 mA when the LDO efficiency improvement function is enabled.

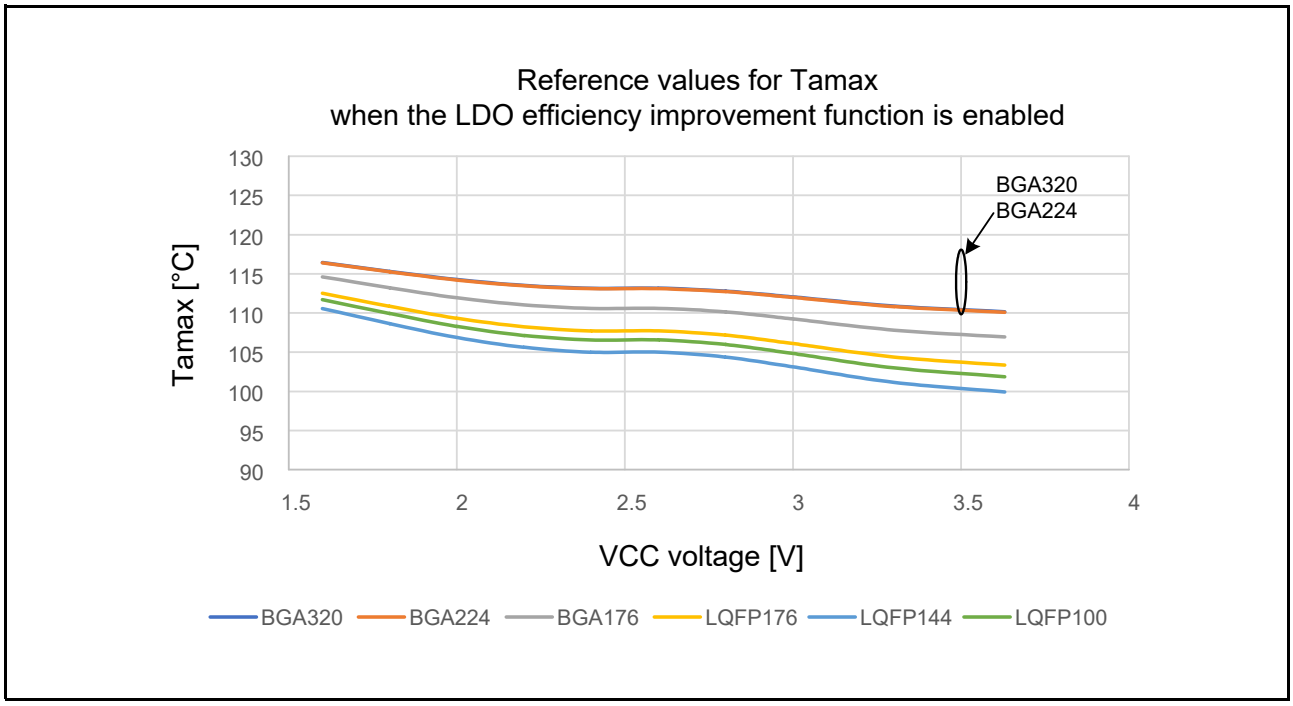

Figure 67.8 VCC Voltage Dependence of the Maximum Ambient Temperature with a Load Current of 250 mA When the LDO Efficiency Improvement Function Is Enabled

Figure 67.9 shows the VCC voltage dependence of the maximum ambient temperature with a load current of 200 mA when the DCDC supply is in use. Since the ICC current and power conversion efficiency of the DCDC supply vary with the VCC voltage, the values shown are only for reference and were calculated assuming a power conversion efficiency of approximately 70% at higher VCC voltages and approximately 85% at lower VCC voltages.

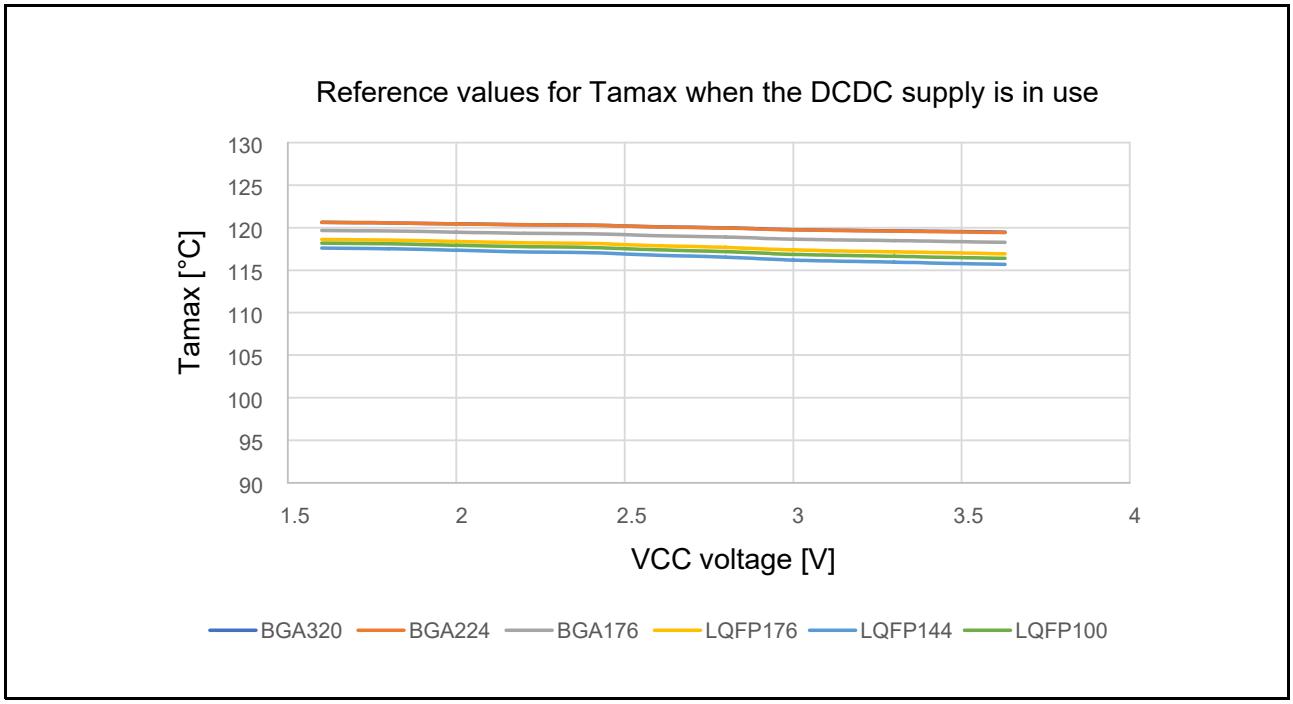

Figure 67.9 VCC Voltage Dependence of the Maximum Ambient Temperature with a Load Current of 200 mA When the DCDC Supply Is in Use

67.4.6 VCC Rising and Falling Slopes and Ripple Frequency

Table 67.50 Characteristics of VCC Rising and Falling Slopes When Power is Switched On and Off

Item		Symbol	Min.	Typ.	Max.	Unit	Test Conditions
VCC rising slope at power on*1		SrVCC	0.0084	—	4	ms/V	Figure 67.10
VCC falling slope at power off*2	VBATT function is disabled	SfVCC1	0.0084	—	—		
	VBATT function is enabled	SfVCC2	1.0000	—	—		

Note 1. When the VCC voltage changes from below V_{POR1} to above V_{POR1}
Note 2. When the VCC voltage changes from above V_{POR1} to below V_{POR1}

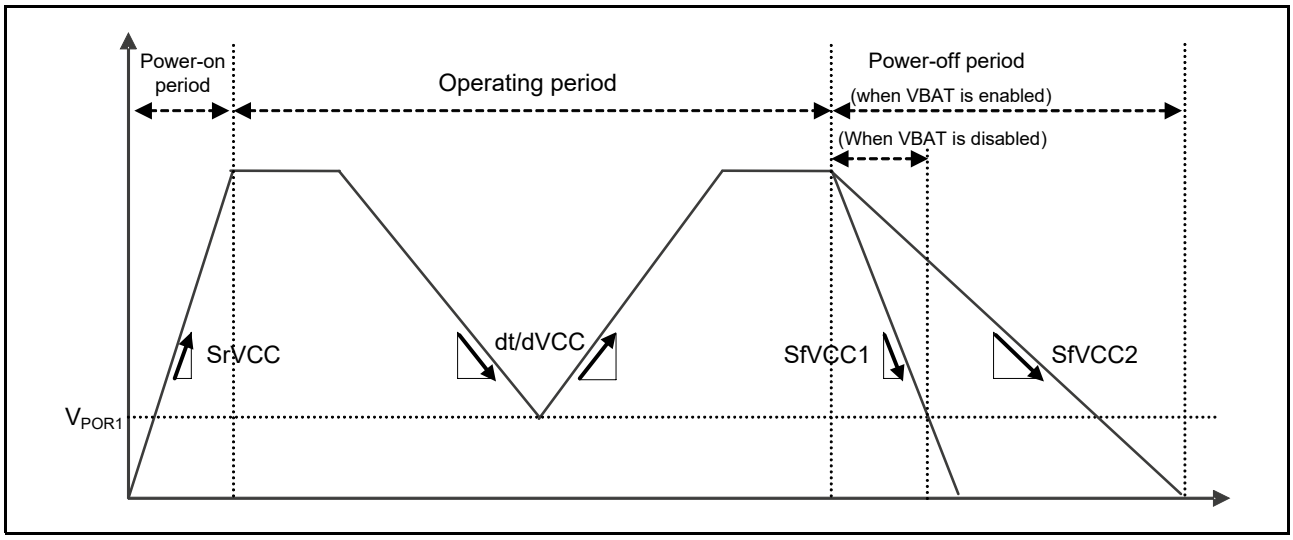

Figure 67.10 VCC Rising and Falling Slopes

Table 67.51 Characteristics of VCC Ripple Frequency and Rising and Falling Slope during Operation

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Allowable ripple frequency	$f_{r(VCC)}$	—	—	10	kHz	Figure 67.11 $V_{r(VCC)} \leq VCC \times 0.2$
		—	—	1	MHz	Figure 67.11 $V_{r(VCC)} \leq VCC \times 0.08$
		—	—	10		Figure 67.11 $V_{r(VCC)} \leq VCC \times 0.06$
Allowable voltage fluctuation rising and falling slope*1	dt/dVCC	1	—	—	ms/V	When the fluctuation in VCC exceeds VCC ± 10%

Note: The ripple voltage must be within the range between the upper (3.63 V) and lower (1.62 V) limits of VCC and satisfy the condition for allowable ripple frequency $f_{r(VCC)}$.
Note: When the fluctuation in VCC exceeds VCC ± 10%, the rate of change must be within the allowable voltage fluctuation rising and falling slope dt/dVCC.
Note 1. When the VCC voltage does not drop below V_{POR1}.

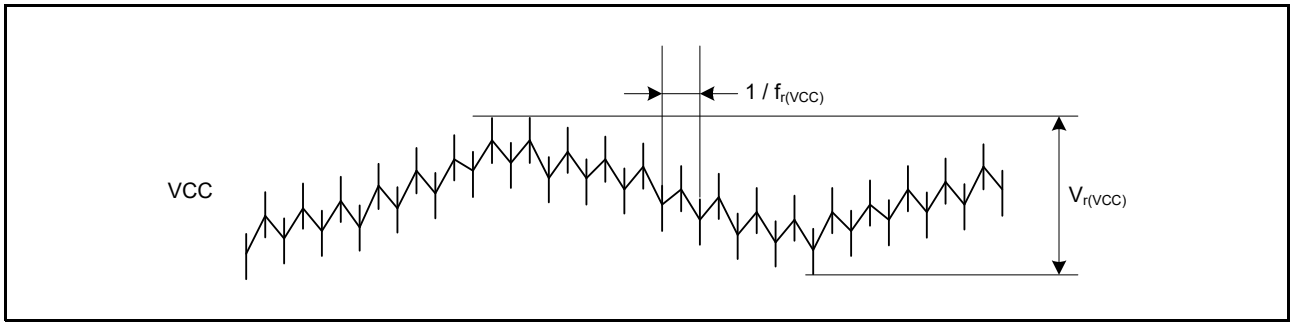

Figure 67.11 Ripple Waveform

67.5 AC Characteristics

67.5.1 Operating Frequency

Table 67.52 Operating Frequency

Item			Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Operating frequency	CPU clock (CPUCLK0)*1	For product part no. R5K574Nxy4xx (y = A, B)	f	—	—	600	MHz	VSCR_1 (DCDC mode) Voltage range 1 (external VDD mode)

Table 67.55 Main Clock Timing

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Main clock oscillation frequency	f_{MAIN}	8	—	48	MHz	
Main clock oscillation stabilization wait time (crystal)*1	$t_{MAINOSCWT}$	—	—	—	ms	Figure 67.14

Note 1. When using the main clock, request evaluation by the manufacturer of the oscillator. For the time until the oscillation is stabilized, confirm the evaluation result by the manufacturer and set a value in the MOSCWTCR register that exceeds the manufacturer's recommended value. After having set the MOSCCR.MOSTP bit to start the main clock operation, wait until the oscillation is stabilized before using the main clock.

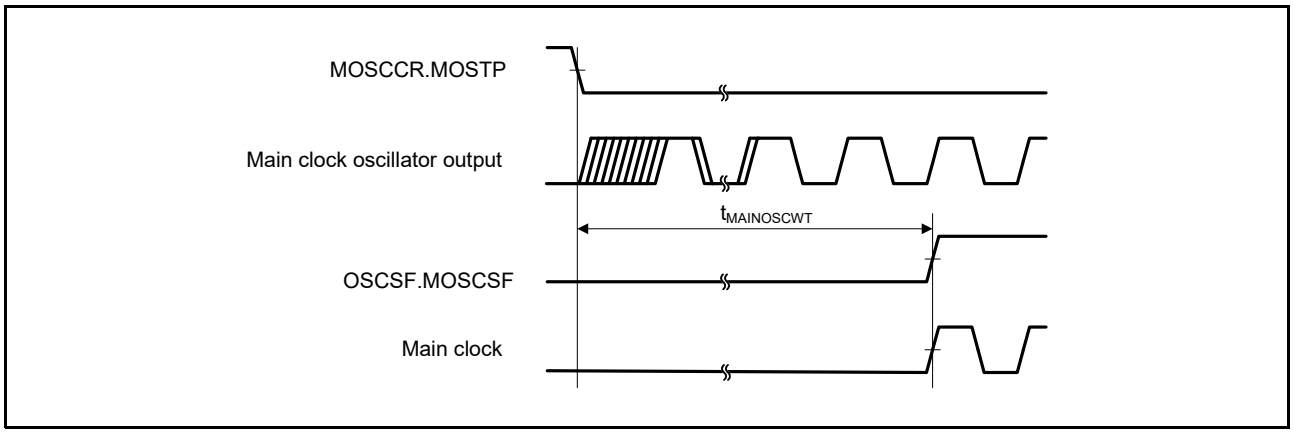

Figure 67.14 Main Clock Oscillator Start Timing

Table 67.56 LOCO and MOCO Clock Timing

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
LOCO clock oscillation frequency	f_{LOCO}	29.4912	32.768	36.0448	kHz	
LOCO clock oscillation stabilization wait time	t_{LOCOWT}	—	—	26.0	µs	Figure 67.15
MOCO clock oscillation frequency	f_{MOCO}	7.2	8.0	8.8	MHz	
MOCO clock oscillation stabilization wait time	t_{MOCOWT}	—	—	3.5	µs	Figure 67.16

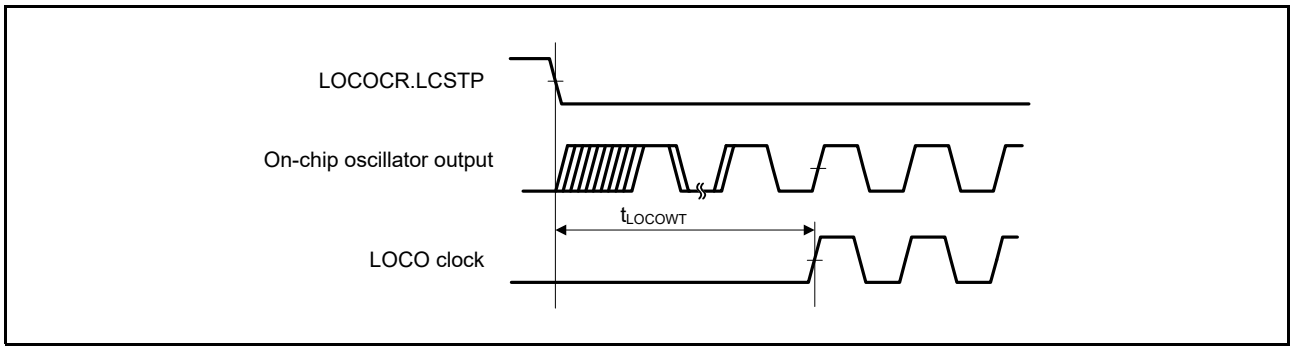

Figure 67.15 LOCO Clock Oscillation Start Timing

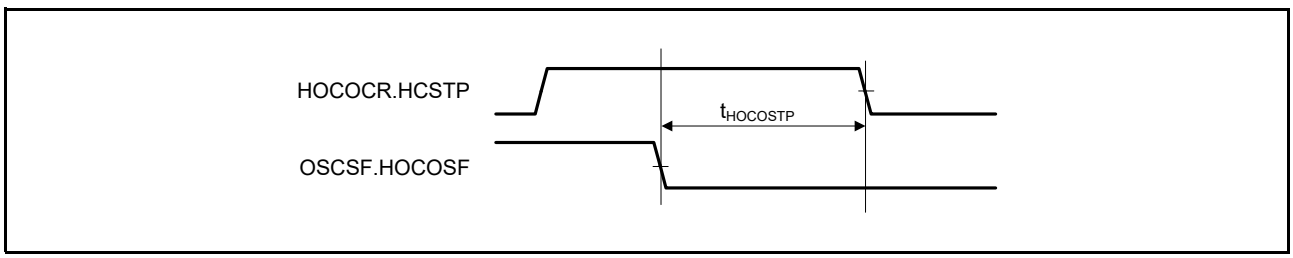

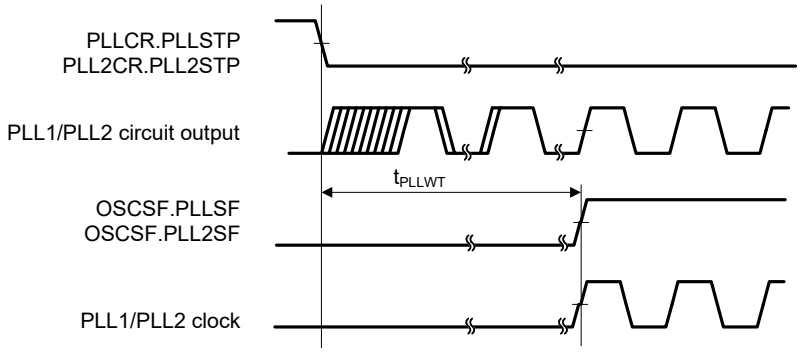

Figure 67.18 HOCO Stop Width Time

Table 67.58 PLL Clock Timing

Item			Symbol	Min.	Typ.	Max.	Unit	Test Conditions
PLL1 clock oscillation frequency	VCO frequency		f_{PLL_VCO}	960	—	2400	MHz	—
	PLL output clock P	Part no. type 1	f_{PLL_P}	60	—	600		VSCR_1 (DCDC mode) Voltage range 1 (external VDD mode)
				60	—	480		VSCR_2 (DCDC mode) Voltage range 2 (external VDD mode)
		Part no. type 2		60	—	480		VSCR_2 (DCDC mode) Voltage range 2 (external VDD mode)
		Part no. type 3		60	—	300		
	PLL output clock Q	Part no. types 1 and 2	f_{PLL_Q}	106.6	—	500		—
		Part no. type 3		106.6	—	300		—
	PLL output clock R		f_{PLL_R}	106.6	—	500		—
PLL2 clock oscillation frequency	VCO frequency		f_{PLL_VCO}	960	—	2400	MHz	—
	PLL output clock P	Part no. types 1 and 2	f_{PLL_P}	60	—	500		—
		Part no. type 3		60	—	300		—
	PLL output clock Q	Part no. types 1 and 2	f_{PLL_Q}	106.6	—	500		—
		Part no. type 3		106.6	—	300		—
	PLL output clock R		f_{PLL_R}	106.6	—	500		—
PLL1/PLL2 clock oscillation stabilization wait time			t_{PLLWT}	—	—	50	µs	Figure 67.19
PLL1/PLL2 period jitter			—	—	±52	—	ps	—
PLL1/PLL2 long term jitter			—	—	±300	—	ps	Term: 1 µs, 10 µs

Part no. type 1: Products with part numbers of the form R5K574Nxy4xx (y = A, B)
Part no. type 2: Products with part numbers of the form R5K574Nxy4xx (y = C, D)
Part no. type 3: Products with part numbers of the form R5K574Nxy4xx (y = E, F)

Note 1. The PLL only starts operation after the main clock oscillation is stabilized.

Figure 67.19 PLL1/PLL2 Clock Oscillation Start Timing

Table 67.59 Sub-Clock Timing

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Sub-clock oscillation frequency	f_{SUB}	—	32.768	—	kHz	
Sub-clock oscillation stabilization wait time*1	$t_{SUBOSCWT}$	—	—	—	s	Figure 67.20

Note 1. When using the sub-clock, request evaluation by the manufacturer of the oscillator. Regarding the oscillation stabilization wait time, refer to the resonator manufacturer's evaluation results and wait in the program for a time longer than the value recommended by the resonator manufacturer. After having set the SOSCCR.SOSTP bit to start the sub-clock operation, wait until the oscillation is stabilized before using the sub-clock.

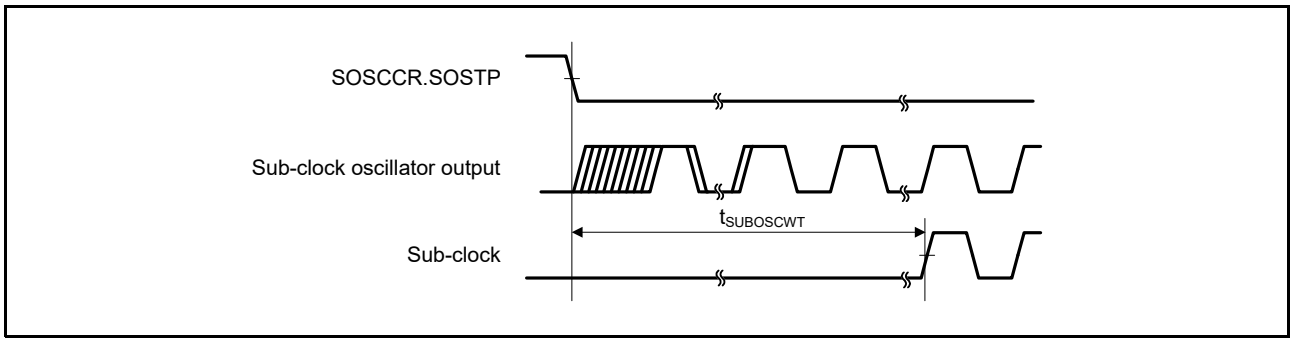

Figure 67.20 Sub-Clock Oscillation Start Timing

Table 67.60 EXCIN External Clock Timing

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
EXCIN external clock input cycle time	t_{EXcyc}	27.7	—	—	µs	Figure 67.21

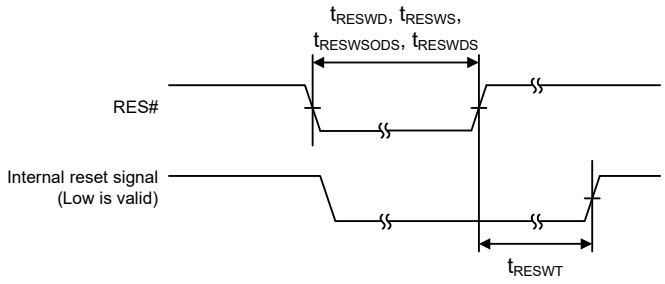
		OFS1.ROWSEL[2:0] = 111b		10.0	11.0	12.2		

Note 1. VCCmin is the minimum guaranteed voltage of the MCU.

Figure 67.23 Reset Input Timing at Power-On



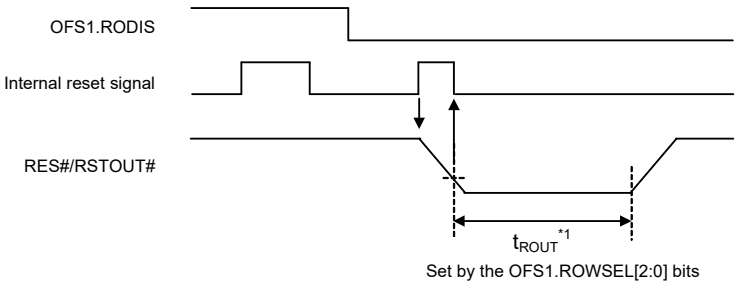


Figure 67.24 Reset Input Timing

Note 1. t_{ROUT} is the value counted for the time set by OFS1.ROWSEL[2:0] after the internal reset is released. After the count ends, the RSTOUT# output is released.

Figure 67.25 RSTOUT# Output Operation

67.5.4 Timing of Return from Low Power Consumption Modes

The following symbols are used in this section to represent the frequencies of the individual clocks.

f_{MOCO}: MOCO clock (8 MHz)
$f_{MOCOmin}$: Minimum frequency of the MOCO clock (7.2 MHz)
f_{SRCCLK}: System clock shown in Table 67.64 to Table 67.67
f_{PLL}: PLL1 circuit clock
f_{ICLK}: System clock ICLK
f_{MOSC}: MOSC clock
f_{HOCO}: HOCO clock
f_{SOSC}: SOSC clock (32.768 kHz)

Table 67.63 Time to Return from CPU Deep Sleep Mode

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Time to return from CPU deep sleep mode	t_{DSLP}	—	6.13	9.44	µs	ICLK = 300 MHz

Note: To calculate the time to return at a frequency that differs from the condition in testing, use the following formula.
t_{DSLP} (typ.) = 44 / f_{MOCO} + 9 / f_{ICLK} + 0.6 [µs], t_{DSLP} (max.) = 44 / $f_{MOCOmin}$ + 9 / f_{ICLK} + 3.3 [µs]
(f_{MOCO}: MOCO frequency [MHz], $f_{MOCOmin}$: Minimum frequency of MOCO [MHz], f_{ICLK}: ICLK frequency [MHz])

Table 67.64 Time to Return from Software Standby Mode 1

Item	Input Clock Source		Symbol	Min.	Typ.	Max.	Unit	Test Conditions
PLL1 output clock P	MOSC (Crystal resonator is connected.)	Oscillation continues.*1	t_{SBYPC}	—	132	194	µs	PLL1P = 300 MHz ICLK = MRICLK = PCLKE = 300 MHz PCLKA = PCLKD = MRPCLK = BCLK = 150 MHz PCLKB = 75 MHz (divide-by-4)
		Oscillation stops.*1		—	2209	2499		
	MOSC (External clock is connected.)		t_{SBYPE}	—	132.5	194		
	HOCO	Oscillation continues.*2	t_{SBYPH}	—	132.5	194		
		Oscillation stops.*2		—	142.7	205		
Main clock oscillator (MOSC)	Crystal resonator	Oscillation continues.*1	t_{SBYMC}	—	24.3	62.4	µs	Main clock = 48 MHz ICLK = 48 MHz
		Oscillation stops.*1		—	2091	2368		
	External clock		t_{SBYEX}	—	24.3	62.4		
High-speed on-chip oscillator (HOCO)		Oscillation continues.*2	t_{SBYHO}	—	22.9	25.7	µs	High-speed clock = 48 MHz ICLK = 48 MHz
		Oscillation stops.*2		—	25.4	70.1		
Sub-clock oscillator (SOSC)			t_{SBYSC}	—	569	569	µs	Sub-clock = 32.768 kHz ICLK = 32.768 kHz
Middle-speed on-chip oscillator (MOCO)			t_{SBYMO}	—	23.9	26.7	µs	Middle-speed clock = 8 MHz ICLK = 8 MHz

Note 1. The setting of the MOSCSOKP bit in the main clock oscillator standby control register (MOSCSCR) determines this. When MOSCSOKP = 1, oscillation will be continuing. When MOSCSOKP = 0, oscillation will be stopped.
Note 2. The setting of the HCSTP bit in the high-speed on-chip oscillator control register (HOCOCR) determines this. When HCSTP = 0, oscillation will be continuing. When HCSTP = 1, oscillation will be stopped.

Table 67.65 Formula for Calculating the Time to Return from Software Standby Mode 1

Item	Input Clock Source		Symbol	Formula (Typ.)	Formula (Max.)
PLL1 output clock P	MOSC (Crystal resonator is connected.)	Oscillation continues.*1	t_{SBYPC}	FG + MAX (oscillation stabilization time (129.8), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))	FG + MAX (oscillation stabilization time (190.7), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))
		Oscillation stops.*1		FG + MAX (($t_{MAINOSCWT}$ + 118.3), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))	FG + MAX (($t_{MAINOSCWT}$ + 178), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))
	MOSC (External clock is connected.)		t_{SBYPE}	FG + MAX (oscillation stabilization time (129.8), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))	FG + MAX (oscillation stabilization time (190.7), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))
	HOCO	Oscillation continues.*2	t_{SBYPH}	FG + MAX (oscillation stabilization time (129.8), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))	FG + MAX (oscillation stabilization time (190.7), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))
		Oscillation stops.*2		FG + MAX (140, B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))	FG + MAX (202, B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))
Main clock oscillator (MOSC)	Crystal resonator	Oscillation continues.*1	t_{SBYMC}	FG + MAX (oscillation stabilization time (11.5), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{MOSC}$))	FG + MAX (oscillation stabilization time (59.3), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{MOSC}$))
		Oscillation stops.*1		FG + MAX ($t_{MAINOSCWT}$, B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))	FG + MAX (($t_{MAINOSCWT}$ + 46.6), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))
	External clock		t_{SBYEX}	FG + MAX (oscillation stabilization time (11.5), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{MOSC}$))	FG + MAX (oscillation stabilization time (59.3), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{MOSC}$))
High-speed on-chip oscillator (HOCO)		Oscillation continues.*2	t_{SBYHO}	FG + MAX (oscillation stabilization time (0), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{HOCO}$))	
		Oscillation stops.*2		FG + MAX (20, B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))	FG + MAX (67, B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))
Sub-clock oscillator (SOSC)			t_{SBYSC}	FG + MAX (oscillation stabilization time (0), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{SOSC}$))	
Middle-speed on-chip oscillator (MOCO)			t_{SBYMO}	FG + MAX (oscillation stabilization time (0), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{MOCO}$))	

The symbols used in the table above represent the following value and calculation results.

n: The larger of the frequency division values set by the SCKDIVCR and SCKDIVCR2 registers.
Typ. value: FG = $14/f_{MOCO}$ + $2/f_{ICLK}$
Max. value: FG = $14/f_{MOCOmin}$ + $2/f_{ICLK}$
Typ. value: B = Oscillation stabilization time/f_{MOCO} + $158/f_{MOCO}$ + 0.3
Max. value: B = Oscillation stabilization time/$f_{MOCOmin}$ + $158/f_{MOCO}$ + 0.59
Typ. value: C = (10.5 + 2.5n)/f_{MOCO} + $2.5/f_{SRCCLK}$ + $2/f_{ICLK}$
Max. value: C is obtained by the same formula as for the typ. value.
Typ. value: D = $7/f_{MOCO}$ + $8/f_{ICLK}$
Max. value: D = $7/f_{MOCOmin}$ + $8/f_{ICLK}$
Typ. value: H = $2/f_{ICLK}$
Max. value: H is obtained by the same formula as for the typ. value.

$t_{MAINOSCWT}$: Main clock oscillation stabilization wait time

Note: In the formulae above, when no distinction is made between Typ. and Max., use the same formula for the calculation.

Note 1. The setting of the MOSCSOKP bit in the main clock oscillator standby control register (MOSCSCR) determines this. When MOSCSOKP = 1, oscillation will be continuing. When MOSCSOKP = 0, oscillation will be stopped.

Note 2. The setting of the HCSTP bit in the high-speed on-chip oscillator control register (HOCOCR) determines this. When HCSTP = 0, oscillation will be continuing. When HCSTP = 1, oscillation will be stopped.

Table 67.66 Time to Return from Software Standby Mode 2

Conditions: The SS2FR bit in software standby control register 1 (SSCR1) is set to 1 (fast return function is enabled) and the SS2LP[1:0] bits are set to SS2LP_1 (low power setting 1).
The VSCM[2:0] bits in the voltage scaling control register (VSCR) are set to 010b (0.90 V).
The SVMCM[2:0] bits in the SSTBY voltage scaling control register (SVSCR) are set to 010b (0.90 V).
The LDOSTP bits in both of the PLLn-LDO control registers (PLLnLDOCR, n = 1, 2) are set to 1 (LDO is stopped).

Item	Input Clock Source		Symbol	Min.	Typ.	Max.	Unit	Test Conditions
PLL1 output clock P	MOSC (Crystal resonator is connected.)	Oscillation continues.*1	t_{SBYPC}	—	294	355	µs	PLL1P = 300 MHz ICLK = MRICLK = PCLKE = 300 MHz PCLKA = PCLKD = MRPCLK = BCLK = 150 MHz PCLKB = 75 MHz (divide-by-4)
		Oscillation stops.*1		—	2370	2660		
	MOSC (External clock is connected.)		t_{SBYPE}	—	294	355		
	HOCO	Oscillation continues.*2	t_{SBYPH}	—	294	355		
		Oscillation stops.*2		—	304	367		
Main clock oscillator (MOSC)	Crystal resonator	Oscillation continues.*1	t_{SBYMC}	—	202	251	µs	Main clock = 48 MHz ICLK = 48 MHz
		Oscillation stops.*1		—	2252	2529		
	External clock		t_{SBYEX}	—	202	251		
High-speed on-chip oscillator (HOCO)		Oscillation continues.*2	t_{SBYHO}	—	200	243	µs	High-speed clock = 48 MHz ICLK = 48 MHz
		Oscillation stops.*2		—	203	252		
Sub-clock oscillator (SOSC)			t_{SBYSC}	—	729	729	µs	Sub-clock = 32.768 kHz ICLK = 32.768 kHz
Middle-speed on-chip oscillator (MOCO)			t_{SBYMO}	—	201	244	µs	Middle-speed clock = 8 MHz ICLK = 8 MHz

Note 1. The setting of the MOSCSOKP bit in the main clock oscillator standby control register (MOSCSCR) determines this. When MOSCSOKP = 1, oscillation will be continuing. When MOSCSOKP = 0, oscillation will be stopped.
Note 2. The setting of the HCSTP bit in the high-speed on-chip oscillator control register (HOCOCR) determines this. When HCSTP = 0, oscillation will be continuing. When HCSTP = 1, oscillation will be stopped.

Main clock oscillator (MOSC)	Crystal resonator	Oscillation continues.*1	t_{SBYMC}	FG + MAX (oscillation stabilization time (11.5), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{MOSC}$))	FG + MAX (oscillation stabilization time (59.3), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{MOSC}$))
		Oscillation stops.*1		FG + MAX ($t_{MAINOSCWT}$, B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))	FG + MAX (($t_{MAINOSCWT}$ + 46.6), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))
	External clock		t_{SBYEX}	FG + MAX (oscillation stabilization time (11.5), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{MOSC}$))	FG + MAX (oscillation stabilization time (59.3), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{MOSC}$))
High-speed on-chip oscillator (HOCO)		Oscillation continues.*2	t_{SBYHO}	FG + MAX (oscillation stabilization time (0), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{HOCO}$))	
		Oscillation stops.*2		FG + MAX (20, B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))	FG + MAX (67, B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{PLL}$))
Sub-clock oscillator (SOSC)			t_{SBYSC}	FG + MAX (oscillation stabilization time (0), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{SOSC}$))	
Middle-speed on-chip oscillator (MOCO)			t_{SBYMO}	FG + MAX (oscillation stabilization time (0), B, C) + MAX (D, H + ($2/f_{ICLK}$ + $2n/f_{MOCO}$))	

The symbols used in the table above represent the following value and calculation results.

n: The larger of the frequency division values set by the SCKDIVCR and SCKDIVCR2 registers.
Typ. value: FG = CYC + $2/f_{ICLK}$
Max. value: FG = CYC + $2/f_{ICLK}$ (See Table 67.68 for CYC values.)
Typ. value: B = Oscillation stabilization time/f_{MOCO} + $193/f_{MOCO}$ + 11.6
Max. value: B = Oscillation stabilization time/$f_{MOCOmin}$ + $193/f_{MOCO}$ + 51
Typ. value: C = $(10.5 + 2.5n)/f_{MOCO}$ + $2.5/f_{SRCCLK}$ + $2/f_{ICLK}$
Max. value: C is obtained by the same formula as for the typ. value.
Typ. value: D = $18/f_{MOCO}$ + $9/f_{ICLK}$
Max. value: D = $18/f_{MOCOmin}$ + $9/f_{ICLK}$
Typ. value: H = $2/f_{ICLK}$
Max. value: H is obtained by the same formula as for the typ. value.

$t_{MAINOSCWT}$: Main clock oscillation stabilization wait time

Note: In the formulae above, when no distinction is made between Typ. and Max., use the same formula for the calculation.

Note 1. The setting of the MOSCSOKP bit in the main clock oscillator standby control register (MOSCSCR) determines this. When MOSCSOKP = 1, oscillation will be continuing. When MOSCSOKP = 0, oscillation will be stopped.

Note 2. The setting of the HCSTP bit in the high-speed on-chip oscillator control register (HOCOCR) determines this. When HCSTP = 0, oscillation will be continuing. When HCSTP = 1, oscillation will be stopped.

Table 67.68 CYC Value

SSCR1.SS2LP[1:0]	VSCR.VSCM[2:0]	SVSCR.SVSCM[2:0]	CYC	Unit	Remarks
SS2LP_0	VSCR_1	SVSCR_1	237	Cycles	*1
		SVSCR_2	379		—
		SVSCR_3	591		
		SVSCR_4	696		
		SVSCR_5	802		
	VSCR_2	SVSCR_1	379		—
		SVSCR_2	237		*1
		SVSCR_3	538		—
		SVSCR_4	643		
		SVSCR_5	749		
SS2LP_1	VSCR_1	SVSCR_2	514	Cycles	—
		SVSCR_3	726		
		SVSCR_4	831		
		SVSCR_5	937		
	VSCR_2	SVSCR_2	459		*2
		SVSCR_3	673		—
		SVSCR_4	778		
		SVSCR_5	884		

Note 1. When the LDOSTP bits in both of the PLLn-LDO control registers (PLLnLDOCR, n = 1, 2) are set to 1 (LDO is stopped) or the SKEEP bits in both registers are set to 1 (the PLLn-LDO state before software standby mode 2 is retained), CYC is 56 if both the LDOSTP bit and SKEEP bit in the HOCO/LCO control register (HOCOLDOCR) are set to 0; CYC is 27 if either of the bits is set to1.

Note 2. When the SS2FR bit in software standby control register 1 (SSCR1) is set to 1 (fast return function is enabled), CYC is 162 if the LDOSTP bits in both of the PLLn-LDO control registers (PLLnLDOCR, n = 1, 2) are set to 1 (LDO is stopped) or the SKEEP bits in both registers are set to 1 (the PLLn-LDO state before software standby mode 2 is retained); otherwise, CYC is 327.

Table 67.88 RIICHS Timing (1) (2/2)

Conditions: VCC = 1.62 to 1.98 V or VCC = 2.70 to 3.63 V,
Evaluation was with either of the following driving ability settings for the target pins, depending on the VCC voltage.
When VCC = 1.62 to 1.98 V: The driving ability select bits (PmnPFS.DSCR[3:0]) corresponding to the target pins are set for DRV3.
When VCC = 2.70 to 3.63 V: The driving ability select bits (PmnPFS.DSCR[3:0]) corresponding to the target pins are set for DRV2.

Item		Wakeup Function	Symbol	Min.*1	Max.*1	Unit	Test Conditions
RIICHS (Fast-mode Plus) *3 ICFER.FMPE = 1	SCLHS input cycle time		t_{SCL}	$6(12) \times t_{IICcyc} + 240$	—	ns	Figure 67.75
	SCLHS input high pulse width		t_{SCLH}	$3(6) \times t_{IICcyc} + 120$	—	ns	
	SCLHS input low pulse width		t_{SCLL}	$3(6) \times t_{IICcyc} + 120$	—	ns	
	SCLHS, SDAHS input rise time		t_{Sr}	—	120	ns	
	SCLHS, SDAHS input fall time		t_{Sf}	—	120	ns	
	SCLHS, SDAHS input spike pulse removal time		t_{SP}	0	$1(4) \times t_{IICcyc}$	ns	
	SDAHS input bus free time	Enabled	t_{BUF}	$3(6) \times t_{IICcyc} + 120$	—	ns	
		Disabled		$3(6) \times t_{IICcyc} + 4 \times t_{PAcyc} + 120$	—		
	Start condition input hold time	Enabled	t_{STAH}	$t_{IICcyc} + 120$	—	ns	
		Disabled		$1(5) \times t_{IICcyc} + t_{PAcyc} + 120$	—		
	Restart condition input setup time		t_{STAS}	120	—	ns	
	Stop condition input setup time		t_{STOS}	120	—	ns	
	Data input setup time		t_{SDAS}	$t_{IICcyc} + 30$	—	ns	
	Data input hold time		t_{SDAH}	0	—	ns	
	SCLHS, SDAHS capacitive load		C_b*2	—	550	pF	

Note: The pin names include either -A or -B as a suffix to indicate the group to which the given pin belongs. Make sure that pins to be used for a given RIICHS interface are from the same group.
Note: t_{IICcyc}: RIICHS internal reference clock (IICφ) cycle; t_{PAcyc}: PCLKA cycle
Note 1. Numbers enclosed in parentheses are for the case where the ICFER.NFE bit is set to 1, enabling the digital filter, and the ICMR3.NF[1:0] bits are set to 11b.
Note 2. C_b is the total capacitance of the bus lines.
Note 3. These electrical characteristics are only guaranteed when pins with the suffix -A, indicating the group name, as part of the pin name are in use.

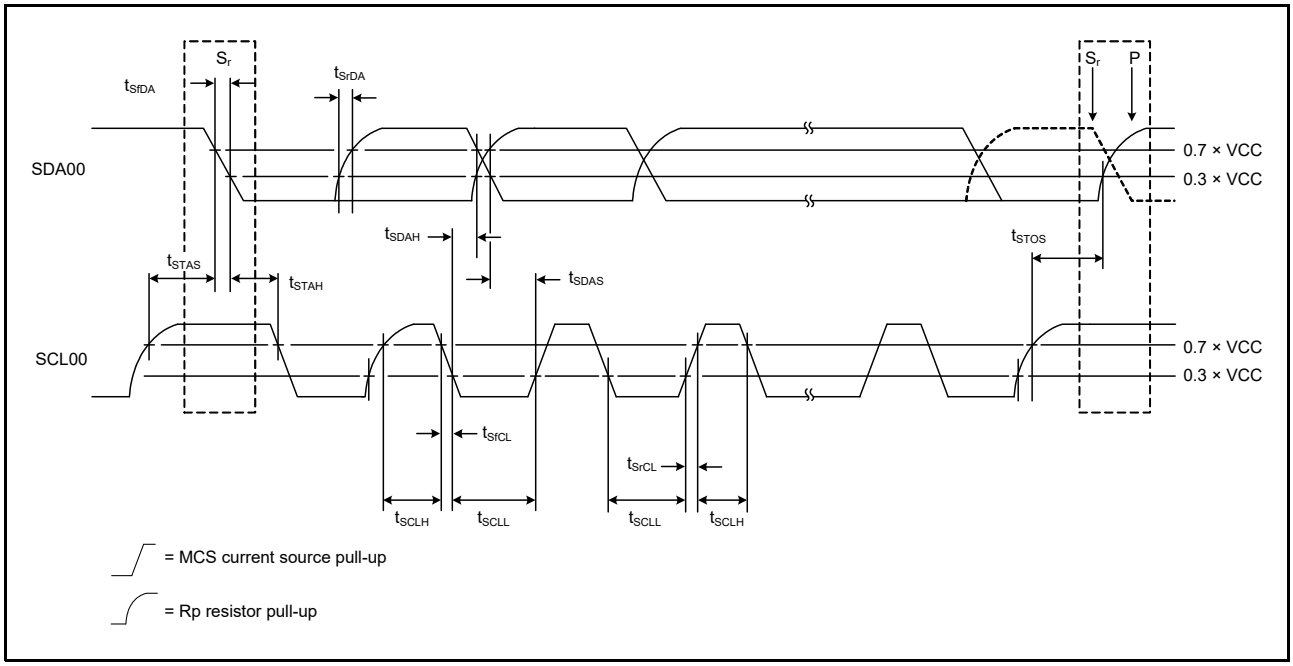

Figure 67.78 I^2C Bus Interface Input/Output Timing (Hs-mode)

Table 67.92 RI3C Timing (Open-Drain Timing Parameters)

Conditions: VCC = 1.65 to 1.95 V, or VCC = 2.97 to 3.63 V

Item	Item	VCC	Symbol	Min.	Max.	Unit	Test Conditions
I3C mode (Open-drain timing parameter)	SCL clock low period		t_{LOW_OD}	200*1, *2	—	ns	Figure 67.80
			$t_{DIG_OD_L}$	t_{LOW_ODmin} + t_{fDA_ODmin}	—		
	SCL clock high period		t_{HIGH}	—	41*3, *4	ns	Figure 67.79
			t_{DIG_H}	—	t_{HIGH} + t_{CF}		
	SDA signal fall time		t_{fDA_OD}	t_{CF}	12	ns	Figure 67.80
	SDA data setup time open drain mode	3.00 V or higher	t_{SU_OD}	12	—	ns	Figure 67.80, Figure 67.81
		1.65 to 1.95 V		18	—		
	Clock after START (S) condition		t_{CAS}	38.4 ns*5	ENAS0: 1 µs	—	Figure 67.80
					ENAS1: 100 µs		
					ENAS2: 2 ms		
					ENAS3: 50 ms*6		
	Clock before STOP (P) condition		t_{CBP}	t_{CASmin}/2	—	s	Figure 67.82
	Current controller to secondary controller overlap time during handoff		$t_{CRHPOverlap}$	$t_{DIG_OD_Lmin}$	—	ns	Figure 67.83
	Bus available condition		t_{AVAL}	1*7	—	µs	—
	Bus idle condition		t_{IDLE}	1	—	ms	—
	Time internal where new controller not driving SDA low		$t_{NEWCRLock}$	$t_{AVALmin}$	—	µs	Figure 67.83

Note: This table only applies when pins with the suffix -A, indicating the group name, as part of the pin name are in use.
Note 1. This is approximately equal to t_{LOWmin} + t_{DS_ODmin} + t_{rDA_ODtyp} + t_{SU_ODmin}.
Note 2. The controller may use a shorter low period if it knows that this is safe, i.e., that SDA is already above V_{IH}.
Note 3. This value is based on t_{SPIKE}, rise and fall times, and interconnects.
Note 4. This maximum high period may be exceeded if the signal can be safely verified by legacy I^2C devices or if interconnect limitations are taken into consideration (such as short bus lengths). If this maximum value cannot be guaranteed by the product specifications, change this value and specify that it cannot be used on mixed buses.
Note 5. On a legacy bus where I^2C devices need to see start, the t_{CAS} Min value is further constrained.
Note 6. Targets that do not support the optional ENTASx CCCs shall use the t_{CAS} Max value shown for ENTAS3
Note 7. On a mixed bus with Fm legacy I^2C devices, t_{AVAL} is 300 ns shorter than the Fm bus free condition time (t_{BUF})

		1.65 to 1.95 V		24	—		
		3.00 V or higher	t_{DIG_L} *2, *4	32	—		
		1.65 to 1.95 V		32	—		
	SCL clock high period for mixed bus*3	3.00 V or higher	t_{HIGH_MIXED}	24	—	ns	Figure 67.80
		1.65 to 1.95 V		24	—		
		3.00 V or higher	$t_{DIG_H_MIXED}$	32	45		
		1.65 to 1.95 V		32	45		
	SCL clock high period	3.00 V or higher	t_{HIGH}	24	—	ns	Figure 67.80
		1.65 to 1.95 V		24	—		
		3.00 V or higher	t_{DIG_H}*2	32	—		
		1.65 to 1.95 V		32	—		
	Clock in to data out for target		t_{SCO}	—	12	ns	Figure 67.84
	SCL clock rise time		t_{CR}	—	150 × 1 /f_{SCL}*5	ns	Figure 67.80
	SCL clock fall time		t_{CF}	—	150 × 1 /f_{SCL}*5	ns	
	SDA signal data hold in push-pull mode (Controller)		t_{HD_PP}*6	t_{CR} + 3*4, t_{CF} + 3*4	—	ns	Figure 67.84
	SDA signal data hold in push-pull mode (Target)			0	—		Figure 67.85
	SDA signal data setup in push-pull mode	3.00 V or higher	t_{SU_PP}	12	N/A	ns	Figure 67.86
		1.65 to 1.95 V		18	N/A		
	Clock after repeated start (Sr)		t_{CASr}	t_{CASmin}	N/A	ns	Figure 67.87
	Clock before repeated start (Sr)		t_{CBSr}	t_{CASmin}/2	N/A	ns	
	Capacitive load per bus line (SDA/SCL)		C_b*7	—	50	pF	—

Note: This table only applies when pins with the suffix -A, indicating the group name, as part of the pin name are in use.
Note 1. $f_{SCL} = 1 / (t_{DIG_L} + t_{DIG_H})$
Note 2. t_{DIG_L} and t_{DIG_H} are the clock low and high periods as seen at the receiver end of the I3C bus using V_{IL} and V_{IH}.
Note 3. In communication with an I3C device on a mixed bus, the $t_{DIG_H_MIXED}$ period must be constrained to ensure that I^2C devices do not interpret I3C signals as valid I^2C signals.
Note 4. As both edges are used, the hold time must be satisfied for the respective edges, for example, t_{CF} + 3 for falling edge clocks, and t_{CR} + 3 for rising edge clocks.
Note 5. The upper limit is 60 ns.
Note 6. The hold time parameter is referred to as t_{HD_SDR} in SDR mode.
Note 7. C_b is the total capacitance of the bus lines.

	Output delay time from when an SSILRCK0 signal is changed*1	Slave	2.70 V or higher	t_{DTRW}	—	20	ns	Figure 67.92
			1.65 V or higher		—	25		

n = 0, 1

Note 1. The SSIE has a single path for transmission in slave mode. To generate the data for transmission, the signals input through the SSILRCKn pin through the abovementioned path are used. After that, the data for transmission proceed to be used as the logical outputs to the SSITXDn pin.

67.5.7.12 SD/MMC Host Interface

Table 67.95 SD/MMC Host Interface Timing

Conditions: VCC = 1.70 to 1.95 V, or VCC = 2.70 to 3.63 V
Evaluation was with either of the following driving ability settings for the target pins, depending on the VCC voltage.
When VCC = 1.70 to 1.95 V: The driving ability select bits (PmnPFS.DSCR[3:0]) are set for DRV6.
When VCC = 2.70 to 3.63 V: The driving ability select bits (PmnPFS.DSCR[3:0]) are set for DRV3.

Item		VCC/VCC2	Symbol	Min.	Max.	Unit	Test Conditions
SDHI	SDCLK clock cycle		t_{SDcyc}	20	—	ns	Figure 67.93
	SDCLK clock high level width		t_{SDWH}	6.5	—	ns	
	SDCLK clock low level width		t_{SDWL}	6.5	—	ns	
	SDCLK clock rising time	2.70 V or higher	t_{SDLH}	—	3	ns	
		1.70 V to 1.95 V		—	4		
	SDCLK clock falling time	2.70 V or higher	t_{SDHL}	—	3	ns	
		1.70 V to 1.95 V		—	4		
	SDCMD/SDDAT output data delay	2.70 V or higher	t_{SDODLY}	–7	4	ns	
		1.70 V to 1.95 V		–7	7		
	SDCMD/SDDAT input data setup time		t_{SDIS}	4.5	—	ns	
	SDCMD/SDDAT input data hold time		t_{SDIH}	1.5	—	ns	

Note: The pin names include either -A or -B as a suffix to indicate the group to which the given pin belongs. Make sure that pins to be used for the SD/MMC host interface are from the same group.
Note: If SD0_DAT4-B to SD0_DAT7-B are used, characteristics above is guaranteed only when VCC = VCC2.

Table 67.101 ESWM Timing (GMII)

Conditions: The driving ability select bits (PmnPFS.DSCR[3:0]) corresponding to the ET0_MDC and ET0_MDIO pins are set for DRV2.
The driving ability select bits (PmnPFS.DSCR[3:0]) corresponding to pins other than ET0_MDC and ET0_MDIO are set as follows.
When VCC = 2.3 to 2.7 V: The driving ability select bits (PmnPFS.DSCR[3:0]) are set for DRV7.
When VCC = 3.0 to 3.6 V: The driving ability select bits (PmnPFS.DSCR[3:0]) are set for DRV6.

Item		Symbol	Min.	Max.	Unit	Test Conditions
ESWM (GMII)	ET0_GTX_CLK frequency	t_{FREQ}	125 – 100ppm	125 + 100ppm	MHz	Figure 67.102, Figure 67.103
	ET0_GTX_CLK cycle	t_{PERIOD}	7.5	8.5	ns	
	ET0_RX_CLK cycle	t_{PERIOD}	7.5	—	ns	
	ET0_GTX_CLK, ET0_RX_CLK high pulse width	t_{HIGH}	2.5	—	ns	
	ET0_GTX_CLK, ET0_RX_CLK low pulse width	t_{LOW}	2.5	—	ns	
	ET0_GTX_CLK, ET0_RX_CLK rising time	t_R	—	1	ns	
	ET0_GTX_CLK, ET0_RX_CLK falling time	t_F	—	1	ns	
	Slew rate of ET0_GTX_CLK and ET0_RX_CLK (during rising)*1	—	0.6	—	V/ns	
	Slew rate of ET0_GTX_CLK and ET0_RX_CLK (during falling)*1	—	0.6	—	V/ns	
	Setup time of ET0_TXD, ET0_TX_EN, and ET0_TX_ER relative to ET0_GTX_CLK	t_{SETUP}	2.5	—	ns	
	Hold time of ET0_TXD, ET0_TX_EN, and ET0_TX_ER relative to ET0_GTX_CLK	t_{HOLD}	0.5	—	ns	
	Setup time of ET0_RXD, ET0_RX_DV, and ET0_RX_ER relative to ET0_RX_CLK	t_{SETUP}	2	—	ns	
	Hold time of ET0_RXD, ET0_RX_DV, and ET0_RX_ER relative to ET0_RX_CLK	t_{HOLD}	0	—	ns	

Note: The above characteristics are only guaranteed for products with part numbers of the form R5K574Nxx4yy (yy = BG, BD, AE).
Note: The pin names include either -A or -B as a suffix to indicate the group to which the given pin belongs. Make sure that pins to be used for the ESWM are from the same group.
Note 1. Clock slew rate is the instantaneous rate of change of the clock potential with respect to time (dV/dt), not an average value over the entire rise or fall time interval.

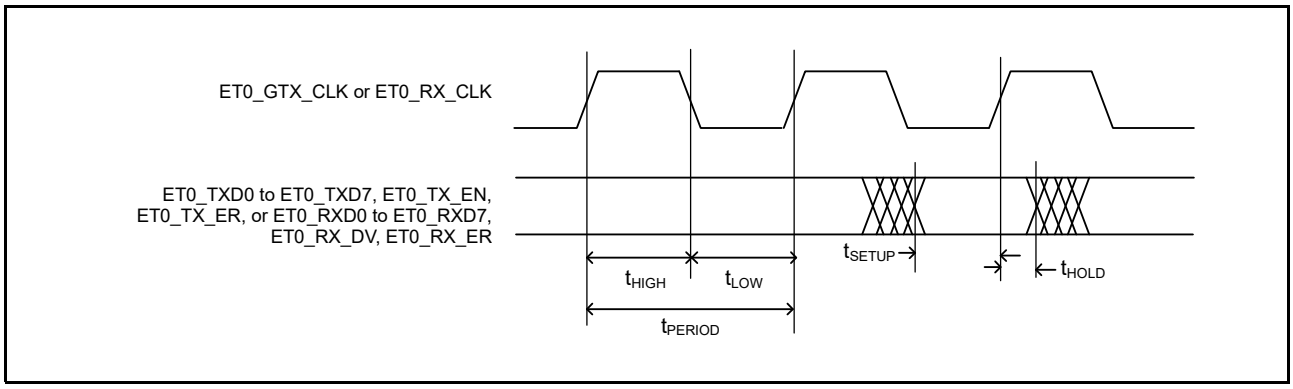

Figure 67.102 GMII Timing

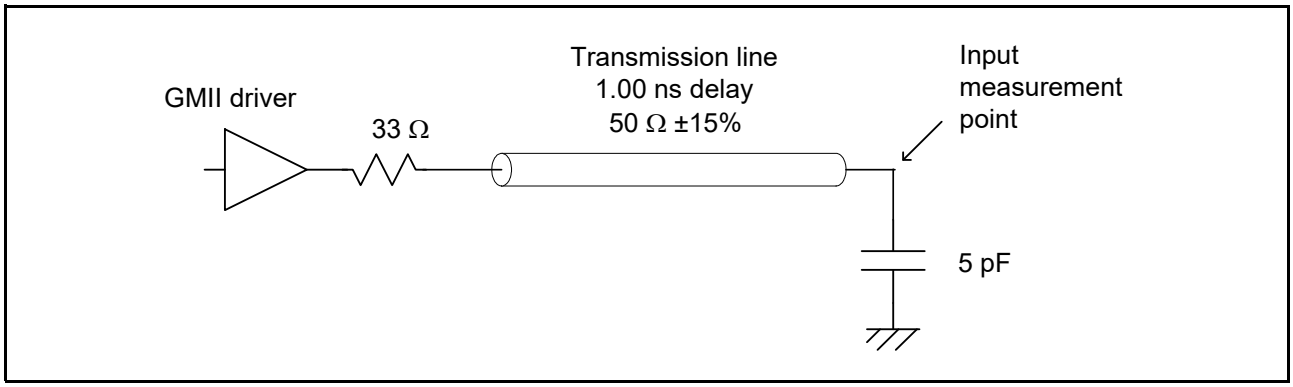

Figure 67.103 GMII Output Timing Measurement Conditions

Table 67.102 ESWM Timing (RGMII)

Conditions: The driving ability select bits (PmnPFS.DSCR[3:0]) corresponding to the ET0_MDC and ET0_MDIO pins are set for DRV2.
The driving ability select bits (PmnPFS.DSCR[3:0]) corresponding to pins other than ET0_MDC and ET0_MDIO are set as follows.
When VCC = 2.3 to 2.7 V: The driving ability select bits (PmnPFS.DSCR[3:0]) are set for DRV7.
When VCC = 3.0 to 3.6 V: The driving ability select bits (PmnPFS.DSCR[3:0]) are set for DRV6.

Item			Symbol	Min.	Max.	Unit	Test Conditions
ESWM (RGMII)	Output data skew relative to RGMII0_TXC*1		T_{skewT}	–500	500	ps	Figure 67.104, Figure 67.106
	Input data skew relative to RGMII0_RXC*1		T_{skewR}	1.0	2.6	ns	
	Output data setup time relative to RGMII0_TXC (integrated delay)		T_{setupT}	1.2	—	ns	Figure 67.105, Figure 67.106
	Output data hold time relative to RGMII0_TXC (integrated delay)		T_{holdT}	1.2	—	ns	
	Input data setup time relative to RGMII0_RXC (integrated delay)		T_{setupR}	1.0	—	ns	
	Input data hold time relative to RGMII0_RXC (integrated delay)		T_{holdR}	1.0	—	ns	
	Clock cycle time	1000 Mbps	—	7.2	8.8	ns	—
		100 Mbps	—	36	44	ns	
		10 Mbps	—	360	440	ns	
	Duty cycle for gigabit*2		—	45	55	ns	
	Duty cycle for 10/100T*2		—	40	60	%	
	Rise/fall time (20 to 80%)		—	—	0.75	%	

Note: The above characteristics are only guaranteed for products with part numbers of the form R5K574Nxx4yy (yy = BG, BD, AE).
Note: The pin names include either -A or -B as a suffix to indicate the group to which the given pin belongs. Make sure that pins to be used for the ESWM are from the same group.
Note 1. This indicates that the clock signals require routing in PC board design so that the trace delay adds a value longer than 1.5 ns and shorter than 2.0 ns to the corresponding clock signal.
Note 2. The duty cycle can be stretched or reduced during speed changes or transitions to the clock domain for received packets as long as the minimum duty cycle is ensured and the length of the stretching does not exceed three cycles of Tcyc, the minimum transition speed.

Differential input (high-accuracy)	AN000P to AN014P, AN000N to AN014N	Conversion time	1.00	—	—	µs	• Sampling time: 40 ADCLK cycles
		Offset error	—	±1.0	±2.5	LSB	—
		Full-scale error	—	±1.0	±2.5		
		Absolute accuracy	—	±3.5	±4.5		
		DNL differential nonlinearity error	—	±0.75	±1.0		
		INL integral nonlinearity error	—	±1.5	±4.0		

Note: Since the DNL values were measured by using the histogram method, the lower limit is –1.

67.7.4 Common Characteristics of Oversampling Mode and Hybrid Mode

Table 67.122 A/D Conversion Characteristics (Common Characteristics of Oversampling Mode and Hybrid Mode) (1)

Conditions: ADCLK: 50 MHz, Successive approximation time: 5 ADCLK cycles, Disconnection detection assistance is not in use, Signal source impedance: 50 Ω or less

Item			Min.	Typ.	Max.	Unit*1	Test Conditions
Resolution			—	—	16	Bit	
Oversampling period	Oversampling mode		0.16	—	—	µs	• Sampling time: 3 ADCLK cycles
	Hybrid mode*2		0.18	—	—		• Sampling time: 8 ADCLK cycles
Digital filter characteristics*3	Sinc filter	Initial delay	—	22	—	/Fos	
		Group delay	—	11	—		
		Normalized cutoff frequency	—	0.033	—	Fin/Fos	

Note 1. Fos is oversampling frequency.
Fin is input frequency.
In the hybrid mode, Fos is obtained by 1/ (the sum of the oversampling cycles in each analog channel assigned to the scan group).
Note 2. The listed value applies per channel.
Note 3. See Figure 67.132, Digital Filter Characteristics (Sinc Filter).

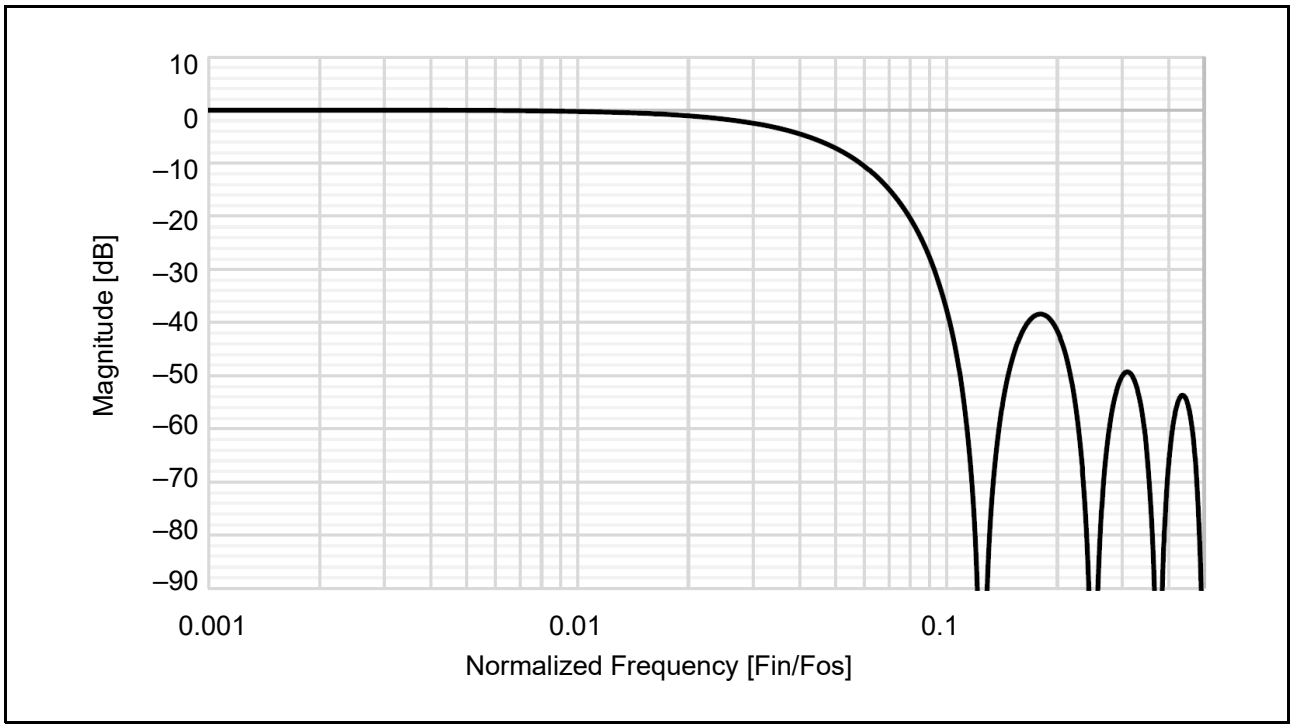

Figure 67.132 Digital Filter Characteristics (Sinc Filter)

Table 67.123 A/D Conversion Characteristics (Common Characteristics of Oversampling Mode and Hybrid Mode) (2)

Conditions: AVCC0 = VCC = VCC2 = 2.70 V to 3.63 V, VREFH0 = VREFH00 = VREFH01 = VREFH02 = 2.70 V to AVCC0
ADCLK: 50 MHz, Successive approximation time: 5 ADCLK cycles, Signal source impedance: 50 Ω or less,
Input frequency: 5 kHz

Item			Min.	Typ.	Max.	Unit	Test Conditions
Sinc filter	Single-ended input	SNDR: Signal-to-noise distortion ratio	—	80	—	dB	—
		ENOB: Effective number of bits	—	13	—	Bit	
	Differential input	SNDR: Signal-to-noise distortion ratio	—	86	—	dB	
		ENOB: Effective number of bits	—	14	—	Bit	

Note: The sampling time depends on the mode and input channel number.
- Oversampling mode (AN000 to AN015): 3 ADCLK cycles
- Hybrid mode (AN000 to AN015): 8 ADCLK cycles

Table 67.124 A/D Conversion Characteristics (Common Characteristics of Oversampling Mode and Hybrid Mode) (3)

Conditions: AVCC0 = VCC = VCC2 = 1.62 V to 2.70 V, VREFH0 = VREFH00 = VREFH01 = VREFH02 = 1.62 V to AVCC0
ADCLK: 50 MHz, Successive approximation time: 10 ADCLK cycles, Signal source impedance: 50 Ω or less,
Input frequency: 5 kHz

Item			Min.	Typ.	Max.	Unit	Test Conditions
Sinc filter	Single-ended input	SNDR: Signal-to-noise distortion ratio	—	74	—	dB	—
		ENOB: Effective number of bits	—	12	—	Bit	
	Differential input	SNDR: Signal-to-noise distortion ratio	—	80	—	dB	
		ENOB: Effective number of bits	—	13	—	Bit	

Note: The sampling time depends on the mode and input channel number.
- Oversampling mode (AN000 to AN015): 3 ADCLK cycles
- Hybrid mode (AN000 to AN015): 8 ADCLK cycles

67.7.5 Oversampling Mode Characteristics

Table 67.125 A/D Conversion Characteristics (Oversampling Mode) (1)

Conditions: AVCC0 = VCC = VCC2 = 2.70 V to 3.63 V, VREFH0 = VREFH00 = VREFH01 = VREFH02 = 2.70 V to AVCC0
ADCLK: 50 MHz, Successive approximation time: 5 ADCLK cycles, Signal source impedance: 50 Ω or less

Item			Min.	Typ.	Max.	Unit	Test Conditions
Single-ended input	AN000 to AN015*1	Offset error*3	—	±0.5	±4.0	LSB	—
		Gain error*3	—	±1.0	±4.0		Single or continuous scan mode
			—	±1.0	±5.0		One-channel continuous scan mode
		DNL differential nonlinearity error*4, *5	—	–1.0 to +1.5	–1.0 to +2.5		—
		INL integral nonlinearity error*4	—	±4.0	±8.0		
	AN016 to AN035*2	Offset error*3	—	±0.5	±4.0	LSB	—
		Gain error*3	—	±1.0	±4.0		
		DNL differential nonlinearity error*4, *5	—	–1.0 to +2.0	–1.0 to +4.0		
		INL integral nonlinearity error*4	—	±4.0	±12		
Differential input	AN000 to AN015*1	Offset error*3	—	±0.25	±2.0	LSB	—
		Gain error*3	—	±0.5	±2.0		Single or continuous scan mode
			—	±0.5	±2.5		One-channel continuous scan mode
		DNL differential nonlinearity error*4, *5	—	–1.0 to +1.5	–1.0 to +2.0		—
		INL integral nonlinearity error*4	—	±3.0	±6.0		

Note: These specifications apply when only one 16-bit A/D converter is operating, the 12-bit D/A converter is not operating, and there is no access to the external bus during A/D conversion.
If another 16-bit A/D converter or 12-bit D/A converter is also in operation or if bus access occurs during A/D conversion, the actual values may not fall within the stated ranges.
When using a 16-bit A/D converter, do not use any pin of port 4 as a digital output.
The above characteristics were observed when AVCC0, AVSS0, VREFH0, VREFH00, VREFH01, VREFH02, VREFL0, VREFL00, VREFL01, VREFL02, and the voltages input to the 16-bit A/D converter had become stable.

Note 1. Sampling time: 3 ADCLK cycles
Note 2. Sampling time: 20 ADCLK cycles
Note 3. This value is for conversion with 12-bit resolution.
Note 4. Test condition: 0.2% to 99.8% of the analog input voltage range
Note 5. Since the DNL values were measured by using the histogram method, the lower limit is –1.

Table 67.126 A/D Conversion Characteristics (Oversampling Mode) (2)

Conditions: AVCC0 = VCC = VCC2 = 1.62 V to 2.70 V, VREFH0 = VREFH00 = VREFH01 = VREFH02 = 1.62 V to AVCC0
ADCLK: 50 MHz, Successive approximation time: 10 ADCLK cycles, Signal source impedance: 50 Ω or less

Item			Min.	Typ.	Max.	Unit	Test Conditions
Single-ended input	AN000 to AN015*1	Offset error*3	—	±0.5	±4.0	LSB	—
		Gain error*3	—	±1.0	±4.0		Single or continuous scan mode
			—	±1.0	±5.0		One-channel continuous scan mode
		DNL differential nonlinearity error*4, *5	—	–1.0 to +2.0	–1.0 to +2.5		—
		INL integral nonlinearity error*4	—	±4.0	±8.0		
	AN016 to AN035*2	Offset error*3	—	±0.5	±4.0	LSB	—
		Gain error*3	—	±1.0	±4.0		
		DNL differential nonlinearity error*4, *5	—	–1.0 to +2.0	–1.0 to +4.0		
		INL integral nonlinearity error*4	—	±4.0	±12		
Differential input	AN000 to AN015*1	Offset error*3	—	±0.25	±2.0	LSB	—
		Gain error*3	—	±0.5	±2.0		Single or continuous scan mode
			—	±0.5	±2.5		One-channel continuous scan mode
		DNL differential nonlinearity error*4, *5	—	–1.0 to +2.0	–1.0 to +2.0		—
		INL integral nonlinearity error*4	—	±3.0	±6.0		

Note: These specifications apply when only one 16-bit A/D converter is operating, the 12-bit D/A converter is not operating, and there is no access to the external bus during A/D conversion.
If another 16-bit A/D converter or 12-bit D/A converter is also in operation or if bus access occurs during A/D conversion, the actual values may not fall within the stated ranges.
When using a 16-bit A/D converter, do not use any pin of port 4 as a digital output.
The above characteristics were observed when AVCC0, AVSS0, VREFH0, VREFH00, VREFH01, VREFH02, VREFL0, VREFL00, VREFL01, VREFL02, and the voltages input to the 16-bit A/D converter had become stable.

Note 1. Sampling time: 22 ADCLK cycles
Note 2. Sampling time: 40 ADCLK cycles
Note 3. This value is for conversion with 12-bit resolution.
Note 4. Test condition: 0.2% to 99.8% of the analog input voltage range
Note 5. Since the DNL values were measured by using the histogram method, the lower limit is –1.

67.7.6 Hybrid Mode Characteristics

Table 67.127 A/D Conversion Characteristics (Hybrid Mode) (1)

Conditions: AVCC0 = VCC = VCC2 = 2.70 V to 3.63 V, VREFH0 = VREFH00 = VREFH01 = VREFH02 = 2.70 V to AVCC0
ADCLK: 50 MHz, Successive approximation time: 5 ADCLK cycles, Signal source impedance: 50 Ω or less

Item			Min.	Typ.	Max.	Unit	Test Conditions
Single-ended input	AN000 to AN015*1 (S&H circuits not in use)	Offset error*3	—	±0.5	±4.0	LSB	—

		INL integral nonlinearity error*4	—	±3.0	±6.0		

S&H: Channel-dedicated sample-and-hold circuits

Note: These specifications apply when only one 16-bit A/D converter is operating, the 12-bit D/A converter is not operating, and there is no access to the external bus during A/D conversion.
If another 16-bit A/D converter or 12-bit D/A converter is also in operation or if bus access occurs during A/D conversion, the actual values may not fall within the stated ranges.
When using a 16-bit A/D converter, do not use any pin of port 4 as a digital output.
The above characteristics were observed when AVCC0, AVSS0, VREFH0, VREFH00, VREFH01, VREFH02, VREFL0, VREFL00, VREFL01, VREFL02, and the voltages input to the 16-bit A/D converter had become stable.

Note 1. Sampling time: 40 ADCLK cycles
Note 2. Sampling time: 84 ADCLK cycles
Note 3. This value is for conversion with 12-bit resolution.
Note 4. Test condition: 0.2% to 99.8% of the analog input voltage range
Note 5. Since the DNL values were measured by using the histogram method, the lower limit is –1.

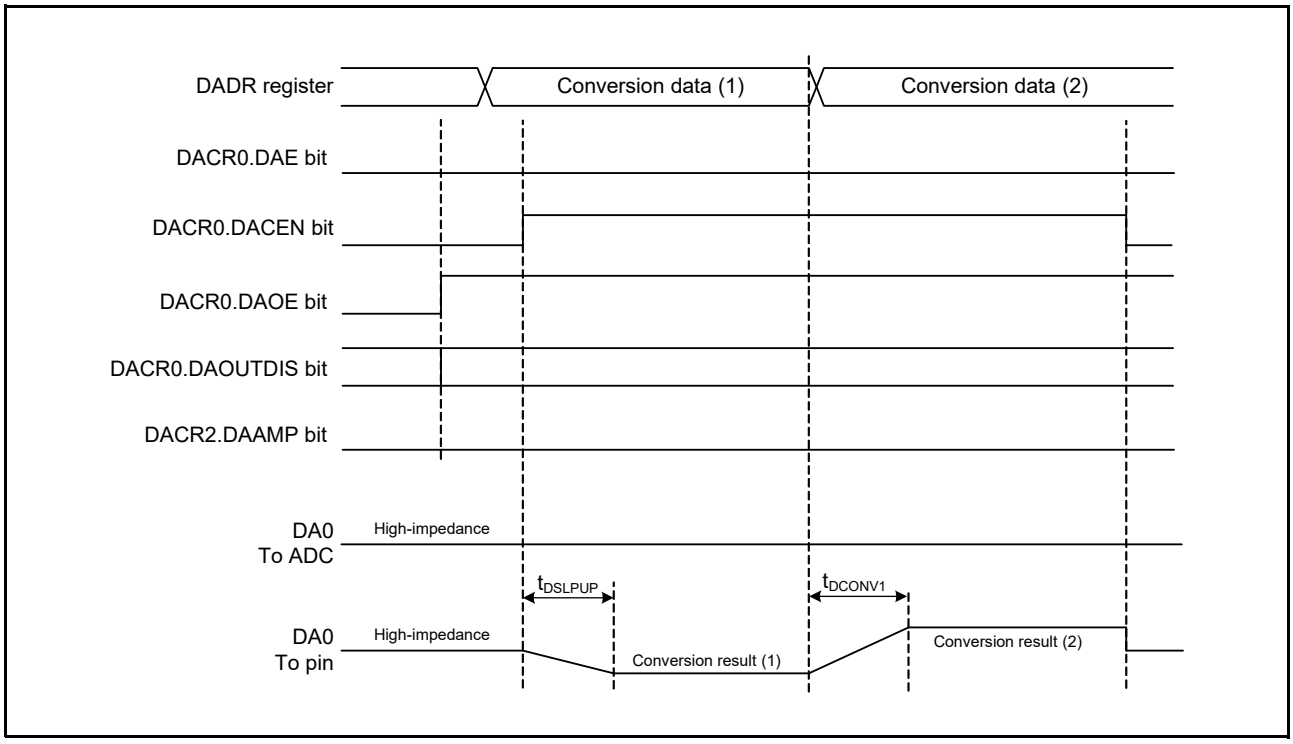
67.8 D/A Conversion Characteristics

Table 67.129 D/A Conversion Characteristics

Item			Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Resolution			—	12	12	12	Bit	—
Unbuffered output	Absolute accuracy	AVCC0 ≥ 2.7 V	—	—	—	±24	LSB	2-MΩ resistive load
				—	—	±6.0		No load
		AVCC0 < 2.7 V		—	—	±36		2-MΩ resistive load
				—	—	±6.0		No load
	Differential nonlinearity error	AVCC0 ≥ 2.7 V	DNL	—	—	±1.0	LSB	—
		AVCC0 < 2.7 V		—	—	±2.0		
	Output resistance		R_O	—	7.8	—	kΩ	—
	Recovery time	AVCC0 ≥ 2.7 V	$t_{DSPLUP1}$	—	—	3	μs	—
		AVCC0 < 2.7 V		—	—	6		
	Conversion time	AVCC0 ≥ 2.7 V	t_{DCONV1}	—	—	3	μs	2-MΩ resistive load, 20-pF capacitive load
			t_{DCONV3}	—	—	3		No load
		AVCC0 < 2.7 V	t_{DCONV1}	—	—	6		2-MΩ resistive load, 20-pF capacitive load
			t_{DCONV3}	—	—	6		No load
Buffered output	Integral nonlinearity error	AVCC0 ≥ 2.7 V	INL	—	—	±4.0	LSB	—
		AVCC0 < 2.7 V		—	—	±8.0		
	Differential nonlinearity error	AVCC0 ≥ 2.7 V	DNL	—	—	±1.0	LSB	
		AVCC0 < 2.7 V		—	—	±2.0		
	Start time	AVCC0 ≥ 2.7 V	t_{DISOUT}	3	—	—	μs	
		AVCC0 < 2.7 V		6	—	—		
	Recovery time	AVCC0 ≥ 2.7 V	$t_{DSPLUP2}$	—	—	3.5	μs	
		AVCC0 < 2.7 V		—	—	6		
	Conversion time	AVCC0 ≥ 2.7 V	t_{DCONV2}	—	—	3.5	μs	
		AVCC0 < 2.7 V		—	—	6		
	Load resistance		R_L	5	—	—	kΩ	
	Load capacitance		C_L	—	—	50	pF	
	Output voltage	AVCC0 ≥ 2.7 V	V_O	0.2	—	AVCC0 – 0.2	V	
		AVCC0 < 2.7 V		0.34	—	AVCC0 – 0.34		

Note: Values in the table above are for the case where the D/A converter is in stand-alone operation (that is, the A/D converters are stopped).

Note: When using the converter with AVCC0 < 2.7 V, set the OFSSEL bit in D/A control register 2 (DACR2) to 1. When using it with AVCC0 at or above 2.7 V, set the OFSSEL bit to 0 (the default value).



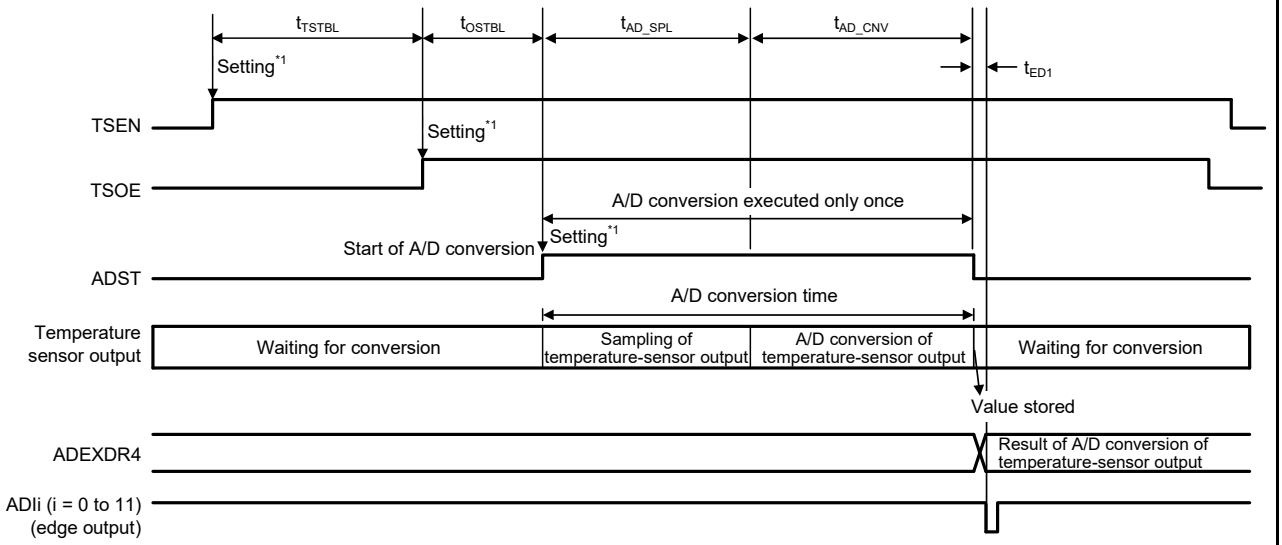


Figure 67.133 12-bit D/A Converter Operation Example (Mode for Outputting to the D/A Pin)

67.9 Temperature Sensor Characteristics

Table 67.130 Temperature Sensor Characteristics

Item		Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Relative accuracy		—	—	±1	—	°C	—
Temperature slope		—	—	2.7	—	mV/°C	—
Output voltage		—	—	0.83	—	V	T_a = 25°C
Temperature sensor start time		t_{TSBL}	—	—	30	µs	Figure 67.134, Figure 67.135, Figure 67.136
Temperature sensor output stabilization wait time		t_{OSBL}	—	—	0	µs	
Stabilization wait time of the abnormal temperature detection circuit in the temperature sensor		t_{RSTBL}	—	—	30	µs	Figure 67.135, Figure 67.136
Sampling time*1		—	4.15	—	—	µs	—
Abnormal detection temperatures	High temperature threshold	T_{jdetH}	105	125	—	°C	Figure 67.137
	Low temperature threshold	T_{jdetL}	—	–40	–20		

Note 1. Set the ADSSTRn register such that the sampling time of the A/D converter satisfies this electrical characteristic.

Note 1. ↓ indicates the time of instruction execution by software.

		$V_{detn_15_rise}$	1.66	1.72	1.77		
		$V_{detn_15_fall}$	1.62	1.68	1.73		
Internal reset time	Power-on reset time	t_{POR1}	—	—	6.7	ms	Figure 67.138
		t_{POR2}	—	—	1.6		
	PVD0 reset time	t_{PVD0}	—	—	*1		Figure 67.139
	PVD1 reset time	t_{PVD1}	—	—	*1		
	PVD2 reset time	t_{PVD2}	—	—	*1		
	PVD4 reset time	t_{PVD4}	—	—	*1		
	PVD5 reset time	t_{PVD5}	—	—	*1		
Minimum VCC drop time (POR)*2	50 mV < VD	t_{VOFFP}	900	—	—	µs	Figure 67.138
	VD ≤ 50 mV		2000	—	—		

Table 67.131 Power-on Reset Circuit and Voltage Detection Circuit Characteristics (2/2)

Item		Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Minimum VCC drop time (PVD)*2	PVD0	t_{VOFF}	25	—	—	µs	Figure 67.139
	PVD1, PVD2, PVD4, PVD5		25	—	—		
Response delay time (POR)	50 mV < VD	t_{detp}	—	—	900	µs	Figure 67.138
	VD ≤ 50 mV		—	—	2000		
Response delay time (PVD)	PVD0	t_{det}	—	—	25	µs	Figure 67.139, Figure 67.140
	PVD1, PVD2, PVD4, PVD5		—	—	25		
PVDn operation stabilization time (after PVD is enabled) (n = 1, 2, 4, 5)		$t_{d(E-A)}$	—	—	20	µs	Figure 67.140

Note 1. On recovering from the deep software standby mode, the internal reset time reaches its maximum, so the maximum value of PVDn (n = 0, 1, 2, 4, 5) becomes equal to the value of t_{DSBY}.

Note 2. The minimum VCC drop time indicates the duration of VCC falling below the minimum voltage detection level of POR or PVD.

Note 1. t_{POR} is determined by the earlier point in time when the t_{POR1} has passed after crossing V_{POR1} or when the t_{POR2} has passed after crossing V_{POR2}.

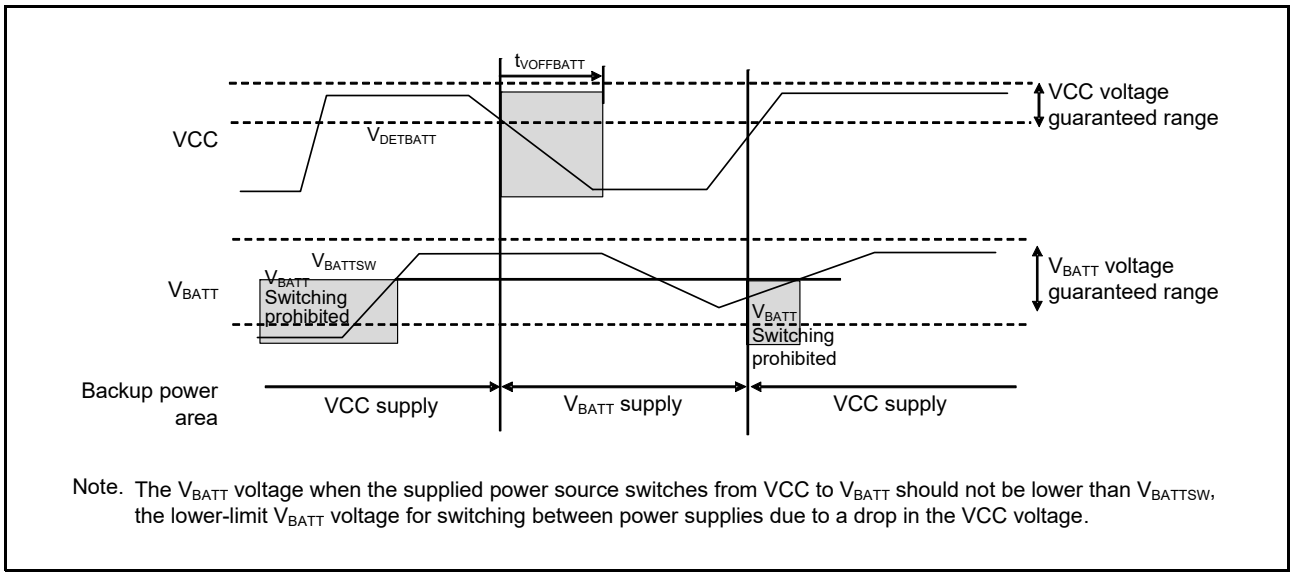
67.14 Battery Backup Function Characteristics

Table 67.136 Battery Backup Function Characteristics

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Voltage level for switching to battery backup*1	$V_{DETBATT_0}$	2.71	2.80	2.89	V	Figure 67.147
	$V_{DETBATT_1}$	2.45	2.53	2.61		
	$V_{DETBATT_2}$	2.03	2.10	2.17		
	$V_{DETBATT_3}$	1.89	1.95	2.01		
	$V_{DETBATT_4}$	1.79	1.85	1.91		
	$V_{DETBATT_5}$	1.69	1.75	1.81		
VCC voltage drop detection stabilization waiting time*2	V_{DETWT}	—	—	20	µs	—
Lower-limit V_{BATT} voltage for power supply switching due to VCC voltage drop	V_{BATTSW}	1.8	—	—	V	Figure 67.147
VCC-off period for starting power supply switching*1, *3	$t_{VOFFBATT}$	25	—	—	µs	
Detection level for backup domain power-down	$V_{PDR(BKP)}$	1.43	1.47	1.52	V	Figure 67.148
Backup domain reset signal assertion delay time*4	$t_{P(PDRL)}$	—	—	2000	µs	
Backup domain reset signal negation delay time	$t_{P(PDRH)}$	—	—	3000	µs	
VBATT voltage measurement stabilization time*5	t_{MONWT}	—	—	4.2	µs	—



Note 1. In deep software standby modes 1 and 2, if the OFS1.PVDAS bit is 0 (voltage monitoring 0 reset is enabled after a reset) and the OFS1.DSBYLPSEL bit is 0 (PVD0 is selected, low power function is enabled, operation depends on VDSEL[2:0] bit setting), the battery backup switching voltage level is V_{det0}.

Note 2. This indicates the time the voltage detection circuit requires to become stable after the value of the VBATTCR2.VDETSEL[2:0] bits has been changed or the value of the VBATTCR1.PSWDIS bit is changed from 1 to 0.

Note 3. This indicates the time over which VCC is below the minimum level of the battery backup switching voltage ($V_{DETBATT_n}$).

Note 4. If the V_{BKP} voltage recovers, that is, exceeds the $V_{POR(BKP)}$ voltage, within this period, the backup domain reset signal may not be generated.

Note 5. This indicates the time that the output voltage required to become stable after the VBATTMCR.VBATTME bit is set to 1.

Note. The V_{BATT} voltage when the supplied power source switches from VCC to V_{BATT} should not be lower than V_{BATTSW}, the lower-limit V_{BATT} voltage for switching between power supplies due to a drop in the VCC voltage.

Figure 67.147 Battery Backup Function Characteristics

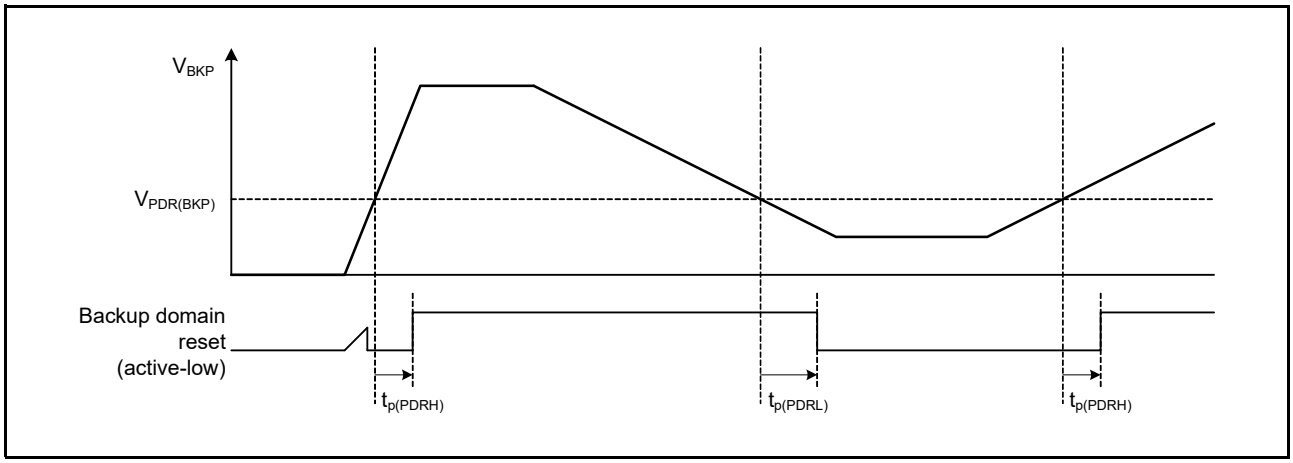


Figure 67.148 Backup Domain Reset Characteristics

67.15 MRAM Characteristics

67.15.1 Code MRAM Characteristics

Table 67.137 Code MRAM Characteristics

Item		Symbol	MRICLK = 300 MHz			MRICLK = 240 MHz			Unit
			Min.	Typ.	Max.	Min.	Typ.	Max.	
Time for programming 32 bytes*1, *2	Normal program mode*3	t_{PMC}	—	6.53	81.3	—	6.72	83.5	µs
	High speed program mode*3		—	4.53	79.3	—	4.72	81.5	
Number of programming operations*4		N_{PC}	100 k	—	—	100 k	—	—	Cycle
Data retention time*5		t_{DRP}	10	—	—	10	—	—	Year

Note 1. When MRPCLK < 125 MHz, add one MRPCLK cycle in units of µs to the time for programming.
Note 2. Use the following approximation formulae to calculate the time for programming at other frequencies:
- Normal program mode
  t_{PMC} (Typ) = 137.8 / f_{MRICLK} + 6.452 [µs], t_{PMC} (Max) = 1879 / f_{MRICLK} + 78.75 [µs]
- High speed program mode
  t_{PMC} (Typ) = 137.8 / f_{MRICLK} + 4.452 [µs], t_{PMC} (Max) = 1879 / f_{MRICLK} + 76.75 [µs]
  (f_{MRICLK}: MRICLK frequency [MHz])

Note 3. The programming mode is selected by the setting of the MHSPEN bit in the MRPSC register.
0: Normal program mode; 1: High speed program mode
Note 4. This indicates the number of programming operations that can be performed per 32-byte code MRAM address range. Programming a given address with the same data also increases the number of programming operations.
Note 5. Test condition: Tj = 125°C

67.15.2 Option-Setting Memory (MRAM Area) Characteristics

Table 67.138 Option-Setting Memory (MRAM Area) Characteristics

Item		Symbol	MRPCLK = 150 MHz			MRPCLK = 120 MHz			Unit
			Min.	Typ.	Max.	Min.	Typ.	Max.	
Time to process a configuration set command*1	Normal program mode*2	t_{PCFG}	—	0.343	7.8	—	0.352	8.08	ms
	High speed program mode*2		—	0.0596	7.46	—	0.0683	7.74	
Number of programming operations*3		N_{CUPC}	100 k	—	—	100 k	—	—	Cycle
Data retention time*4		t_{DRP}	10	—	—	10	—	—	Year

Note 1. Use the following approximation formulae to calculate the times for processing at other frequencies:
- Normal program mode
  t_{PCFG} (Typ) = 6.146 / f_{MRPCLK} + 0.3133 [ms], t_{PCFG} (Max) = 266.5 / f_{MRPCLK} + 6.331 [ms]
- High speed program mode
  t_{PCFG} (Typ) = 5.184 / f_{MRPCLK} + 0.02754 [ms], t_{PCFG} (Max) = 267.5 / f_{MRPCLK} + 6.025 [ms]
  (f_{MRPCLK}: MRPCLK frequency [MHz])

Note 2. The programming mode is selected by the setting of the MHSPEN bit in the MRPSC register.
0: Normal program mode; 1: High speed program mode
Note 3. This indicates the number of configuration set commands that can be issued for the MRAM area. Programming a given address with the same data also increases the number of programming operations.
Note 4. Test condition: Tj = 125°C

67.15.3 Option-Setting Memory (OTP Area with ECC) Characteristics

Table 67.139 Option-Setting Memory (OTP Area with ECC) Characteristics

Item		Symbol	MRPCLK = 150 MHz			MRPCLK = 120 MHz			Unit
			Min.	Typ.	Max.	Min.	Typ.	Max.	
Time for programming 16 bytes*1	MRAM-OTP normal speed write mode*2	t_{OTPE}	—	8.05	113	—	8.05	113	ms
	MRAM-OTP high speed write mode 0*2		—	4.03	56.7	—	4.03	56.7	
	MRAM-OTP high speed write mode 1*2		—	0.229	3.14	—	0.229	3.14	

Note 1. Use the following approximation formulae to calculate the time for programming at other frequencies:
- MRAM-OTP normal speed write mode
  t_{OPTE} (Typ) = 0.5065 / f_{MRPCLK} + 8.123 [ms], t_{OPTE} (Max) = 4.433 / f_{MRPCLK} + 114.1 [ms]
- MRAM-OTP high speed write mode 0
  t_{OPTE} (Typ) = 0.3389 / f_{MRPCLK} + 4.067 [ms], t_{OPTE} (Max) = 2.428 / f_{MRPCLK} + 57.08 [ms]
- MRAM-OTP high speed write mode 1
  t_{OPTE} (Typ) = 0.1458 / f_{MRPCLK} + 0.2312 [ms], t_{OPTE} (Max) = 0.3904 / f_{MRPCLK} + 3.166 [ms]
  (f_{MRPCLK}: MRPCLK frequency [MHz])

Note 2. The MRAM-OTP write mode is selected by the setting of the MWM[1:0] bits in the MWMCR register.
00b: Normal-speed write mode; 01b: High-speed write mode 0; 10b: High-speed write mode 1

67.15.4 Option-Setting Memory (OTP Area without ECC) Characteristics

Table 67.140 Option-Setting Memory (OTP Area without ECC) Characteristics

Item		Symbol	MRPCLK = 150 MHz			MRPCLK = 120 MHz			Unit
			Min.	Typ.	Max.	Min.	Typ.	Max.	
Time for programming 16 bytes*1	MRAM-OTP normal speed write mode*2	t_{OTPENE}	—	14.1	200	—	14.1	200	ms
	MRAM-OTP high speed write mode 0*2		—	7.07	100	—	7.07	100	
	MRAM-OTP high speed write mode 1*2		—	0.458	6.28	—	0.458	6.28	

Note 1. Use the following approximation formulae to calculate the time for programming at other frequencies:
- MRAM-OTP normal speed write mode
  t_{OPTENE} (Typ) = 0.8486 / f_{MRPCLK} + 14.25 [ms], t_{OPTENE} (Max) = 7.711 / f_{MRPCLK} + 201.5 [ms]
- MRAM-OTP high speed write mode 0
  t_{OPTENE} (Typ) = 0.5479 / f_{MRPCLK} + 7.133 [ms], t_{OPTENE} (Max) = 4.148 / f_{MRPCLK} + 100.8 [ms]
- MRAM-OTP high speed write mode 1
  t_{OPTENE} (Typ) = 0.2571 / f_{MRPCLK} + 0.4627 [ms], t_{OPTENE} (Max) = 0.7401 / f_{MRPCLK} + 6.333 [ms]
  (f_{MRPCLK}: MRPCLK frequency [MHz])

Note 2. The MRAM-OTP write mode is selected by the setting of the MWM[1:0] bits in the MWMCR register.
00b: Normal-speed write mode; 01b: High-speed write mode 0; 10b: High-speed write mode 1

67.15.5 MACI Command Characteristics

Table 67.141 MACI Command Characteristics

Item	Symbol	MRPCLK = 150 MHz			MRPCLK = 120 MHz			Unit
		Min.	Typ.	Max.	Min.	Typ.	Max.	
Time to execute a forced-stop command	t_{FS}	—	—	3.31	—	—	3.36	µs
Time to execute an increment counter command	t_{INCC}	—	0.252	1.61	—	0.252	1.61	ms
Time to execute a read counter command	t_{RDC}	—	—	0.13	—	—	0.163	µs

Note: Use the following approximation formulae to calculate the times to execute the commands at other frequencies:
$t_{FS} = 38.62 / f_{MRPCLK} + 3.155$ [µs]
t_{INCC} (Typ) $= 0.3348 / f_{MRPCLK} + 0.2533$ [ms], t_{INCC} (Max) $= 0.8698 / f_{MRPCLK} + 1.62$ [ms]
$t_{RDC} = 19.13 / f_{MRPCLK} + 0.004099$ [µs]
(f_{MRPCLK}: MRPCLK frequency [MHz])

67.15.6 W-HUK Zeroization Characteristics

Table 67.142 W-HUK Zeroization Characteristics

Item	Symbol	MRPCLK = 150 MHz			MRPCLK = 120 MHz			Unit
		Min.	Typ.	Max.	Min.	Typ.	Max.	
Time for W-HUK zeroization operation	t_{ZWH}	—	—	793	—	—	793	ms

Note: Use the following approximation formula to calculate the times for operation at other frequencies:
$t_{ZWH} = 34.59 / f_{MRPCLK} + 799$ [ms]
(f_{MRPCLK}: MRPCLK frequency [MHz])

67.15.7 MRAM Magnetic Field Resistance Characteristics

Table 67.143 MRAM Magnetic Field Resistance Characteristics

Item		Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Operation	Writing	G_{max_wr}	—	—	200	Gauss	—
	Reading	G_{max_rd}	—	—	200		
	No access in progress	G_{max_noac}	—	—	500		
Storage		G_{max_stg}	—	—	500		

67.15.8 Data MRAM Characteristics

Table 67.144 Data MRAM Characteristics

Item		Symbol	MRPCLK = 150 MHz			MRRCLK = 120 MHz			Unit
			Min.	Typ.	Max.	Min.	Typ.	Max.	
16-byte programming time*1	Normal program mode*2	t_{PME}	—	6.63	72.8	—	6.87	74.9	µs
	High speed program mode*2		—	4.63	70.8	—	4.87	72.9	
Number of programming operations*3		N_{PC}	100 k	—	—	100 k	—	—	Cycle
Data retention time*4		t_{DRP}	10	—	—	10	—	—	Year

Note 1. Use the following approximation formulae to calculate the time for programming at other frequencies:
- Normal program mode
  t_{PME} (Typ) = 179.2 / f_{MRPCLK} + 5.725 [µs], t_{PME} (Max) = 1988 / f_{MRPCLK} + 61.9 [µs]
- High speed program mode
  t_{PME} (Typ) = 179.2 / f_{MRPCLK} + 3.725 [µs], t_{PME} (Max) = 1988 / f_{MRPCLK} + 59.9 [µs]
  (f_{MRPCLK}: MRPCLK frequency [MHz])

Note 2. The programming mode is selected by the setting of the MHSPEN bit in the MRPSC register.
0: Normal program mode; 1: High speed program mode

Note 3. This indicates the number of programming operations that can be performed per 16-byte data MRAM address range. Programming a given address with the same data also increases the number of programming operations.

Note 4. Test condition: Tj = 125°C

67.16 Boundary Scan

Table 67.145 Boundary Scan Characteristics

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
TCK clock cycle time	t_{TCKcyc}	100	—	—	ns	Figure 67.149
TCK clock high pulse width	t_{TCKH}	45	—	—	ns	
TCK clock low pulse width	t_{TCKL}	45	—	—	ns	
TCK clock rise time	t_{TCKr}	—	—	5	ns	
TCK clock fall time	t_{TCKf}	—	—	5	ns	
TMS setup time	t_{TMSS}	20	—	—	ns	Figure 67.150
TMS hold time	t_{TMSH}	20	—	—	ns	
TDI setup time	t_{TDIS}	20	—	—	ns	
TDI hold time	t_{TDIH}	20	—	—	ns

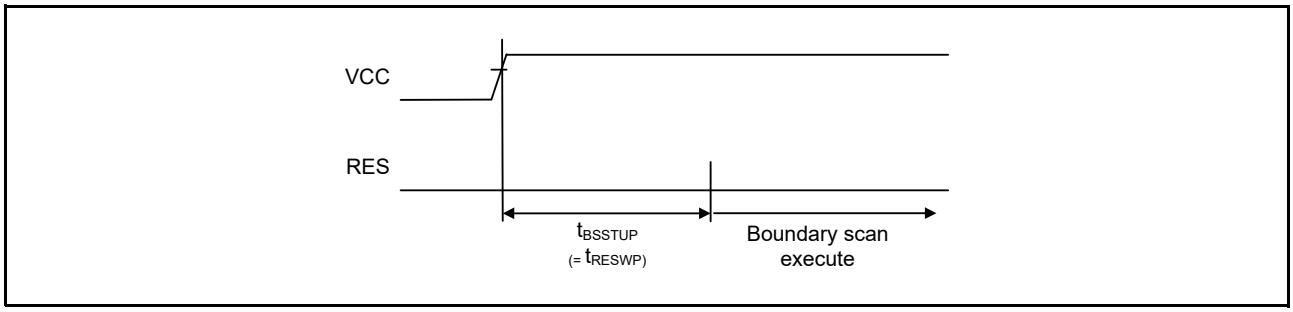

Figure 67.151 Boundary Scan Circuit Activation Time

67.17 Usage Note

67.17.1 Connecting VCL Capacitor and Bypass Capacitors

This MCU integrates an internal voltage-down circuit, which is used for lowering the power supply voltage in the internal MCU to adjust automatically to the optimum level. The number of internal step-down power supplies (VCL pins) differs with the type of package. Connect a capacitor for stabilizing the internal voltage between each VCL pin and a VSS pin. For details on the values of capacitors for each type of package, see Table 67.3, Recommended Operating Conditions (2). Place an external capacitor close to the pins. Do not apply the power supply voltage to the VCL pin.
In addition, place a multilayer ceramic capacitor as a bypass capacitor between each VCC or VCC2 pin and a nearby VSS pin. Implement a bypass capacitor to the MCU power supply pins as close as possible. Use a recommended value of 0.1 µF as the capacitance of the capacitors. For the capacitors related to crystal oscillation, see section 9, Clock Generation Circuit. For the capacitors related to analog modules, also see section 60, 16-Bit A/D Converter (ADC16H).
For notes on designing the printed circuit board, see the descriptions of the application note “Hardware Design Guide” (R01AN1411EJ). The latest version can be downloaded from Renesas Electronics Website.

Appendix 1. Port States in Each Processing Mode

Table 1.1 Port States in Each Processing State (1/2)

Functions	Pin Function	Resets	Software Standby Mode 1, 2 (SSTBY1, 2)		Deep Software Standby Mode 1, 2, 3 (DSTBY1, 2, 3) IOKEEP = 1/0		After Deep Software Standby Mode is Canceled (Return to Start-up Mode)

Table 1.1 Port States in Each Processing State (2/2)

Functions	Pin Function	Resets	Software Standby Mode 1, 2 (SSTBY1, 2)		Deep Software Standby Mode 1, 2, 3 (DSTBY1, 2, 3) IOKEEP = 1/0		After Deep Software Standby Mode is Canceled (Return to Start-up Mode)	
			OPE = 0	OPE = 1	DSTBY1	DSTBY2/ DSTBY3	IOKEEP = 0	IOKEEP = 1*1
External bus (CS area controller, SDRAM area controller)	CKE/SDCS#/RAS#/ CAS#	Hi-Z	Hi-Z	SDSELF. SFEN = 0: High output SDSELF. SFEN = 1: Low output	Keep		Hi-Z	Keep
Pulse-Density Modulation Interface (PDMIF)	PDMCLK0	Hi-Z	PDMCLK output		Keep		Hi-Z	Keep
	PDMDAT0	Hi-Z	Keep-O*2		Keep		Hi-Z	Keep
Other	—	Hi-Z	Keep-O		Keep		Hi-Z	Keep

Hi-Z: High-impedance

Keep-O: Output pins retain their previous values, and input pins become high-impedance.

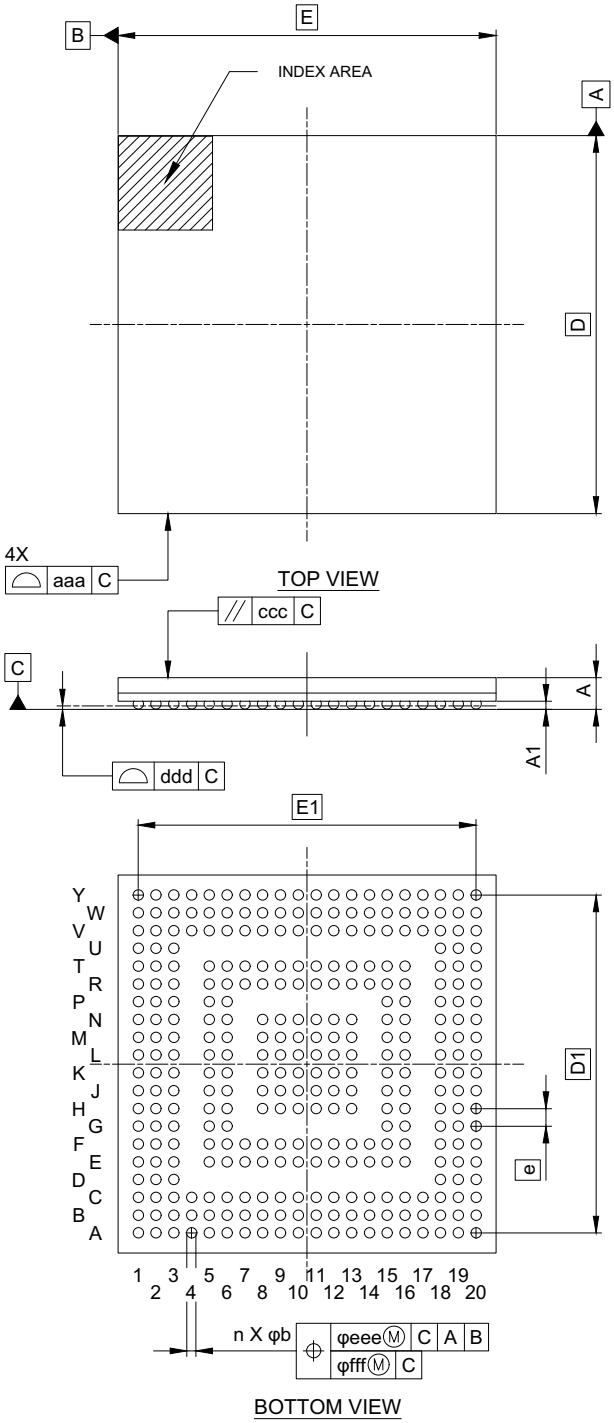
Keep-I: Pin states are retained the same as during periods in Normal mode, Sleep mode, or Deep sleep mode.

Keep: Pin states are retained during periods on software standby.

Note 1. The I/O port state is retained until the DPSBYCR.IOKEEP bit is cleared to 0.

Note 2. Input is enabled while the pin is used as an external interrupt pin.

Note 3. Input is enabled if the pin is specified as the deep software standby cancelling source.



Note 4. Input is enabled while the pin is used as an input pin.

Note 5. For host operation, set the USBHS.SYSCFG.DRPD bit to 1 to enable the USBHS_DP and USBHS_DM pull-down resistors. For device operation, set the USBHS.SYSCFG.DPRPU bit to 1 to enable the DP pull-up resistor.

Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings has been displayed in “Packages” on Renesas Electronics Corporation website.

Appendix 3. Cycles for Access

This appendix gives information on the numbers of clock cycles for access to I/O registers described in this manual.

- Numbers of cycles for access are given per module symbol.
- Numbers of cycles for access are of the stated reference clocks.
- The internal I/O register areas include reserved areas, the addresses of which are not given in the descriptions of registers in the corresponding section. Access to the reserved areas is prohibited. Operation in response to attempted access to these registers and subsequent operation cannot be guaranteed.
- The number of cycles for access to an I/O register depends on the number of clock cycles in bus cycles for on-chip peripherals, cycles for synchronization with a frequency-divided clock, and cycles of waiting for each module.

  The number of cycles for synchronization with a frequency-divided clock depends on the ratio between the frequencies of ICLK and PCLK.
- When the frequencies of ICLK and PCLK are the same, the number of cycles for synchronization with a frequency-divided clock is always fixed.
- When the frequency of ICLK is higher than that of PCLK, at least one cycle of PCLK is added to the number of cycles for synchronization with a frequency-divided clock.
- The listed numbers of cycles for write access are for non-buffered writing.

Note: The numbers of cycles for access given here are for cases where access to registers by the CPU is not in contention with the fetching of instructions to an external memory or with bus access by any other bus master such as the DMAC or DTC.

Table 3.1 List of Cycles for Access (1/4)

Secure Module Symbol	Address (Secure)	Address (Non-secure)	Number of Cycles for Access				Unit	Related Function
			CPUCLK0 = ICLK = PCLK		CPUCLK0 = ICLK > PCLK*1			
			Read	Write	Read	Write		
CPU_CTRL	8100 0000h to 8100 03FFh	0100 0000h to 0100 03FFh	1	1	1	1	CPUCLK0	CPU

Table 3.1 List of Cycles for Access (4/4)

Secure Module Symbol	Address (Secure)	Address (Non-secure)	Number of Cycles for Access				Unit	Related Function
			CPUCLK0 = ICLK = PCLK		CPUCLK0 = ICLK > PCLK*1			
			Read	Write	Read	Write		
PSCU	8780 4000h to 8780 407Fh	0780 4000h to 0780 407Fh	4	3	2 to 4	1 to 3	PCLKB	Peripheral Module Security Attribution Control
PIO	8780 6000h to 8780 60FFh	0780 6000h to 0780 60FFh	4	3	2 to 4	1 to 3	PCLKB	Software Configurable 32-Bit Programmable I/O Port (PIO)
GPTW11, GPTW13, RSCI2, RSCI3	8780 7000h to 8780 703Fh	0780 7000h to 0780 703Fh	4	3	2 to 4	1 to 3	PCLKB	General PWM Timer 11 (GPTW11), General PWM Timer 13 (GPTW13), Serial Communications Interface 2 (RSCI2), Serial Communications Interface 3 (RSCI3)
TMR0, TMR01, TMR1	8782 5000h to 8782 500Fh	0782 5000h to 0782 500Fh	4	3	2 to 4	1 to 3	PCLKB	8-Bit Timer 0 (TMR0), 8-Bit Timer 0 (TMR0) + 8-Bit Timer 1 (TMR1), 8-Bit Timer 1 (TMR1)
TMR2, TMR23, TMR3	8782 5010h to 8782 501Fh	0782 5010h to 0782 501Fh	4	3	2 to 4	1 to 3	PCLKB	8-Bit Timer 2 (TMR2), 8-Bit Timer 2 (TMR2) + 8-Bit Timer 3 (TMR3), 8-Bit Timer 3 (TMR3)
CMT, CMT0, CMT1, CMT2, CMT3	8782 6000h to 8782 601Fh	0782 6000h to 0782 601Fh	4	3	2 to 4	1 to 3	PCLKB	Compare Match Timer (CMT), Compare Match Timer 0 (CMT0), Compare Match Timer 1 (CMT1), Compare Match Timer 2 (CMT2), Compare Match Timer 3 (CMT3)
CMTW0	8782 6100h to 8782 613Fh	0782 6100h to 0782 613Fh	4	3	2 to 4	1 to 3	PCLKB	Compare Match Timer W 0 (CMTW0)
CMTW1	8782 6140h to 8782 617Fh	0782 6140h to 0782 617Fh	4	3	2 to 4	1 to 3	PCLKB	Compare Match Timer W 1 (CMTW1)
PCIF0	8782 7000h to 8782 707Fh	0782 7000h to 0782 707Fh	4	3	2 to 4	1 to 3	PCLKB	Phase-Counting Interface 0 (PCIF0)
PCIF1	8782 7080h to 8782 70FFh	0782 7080h to 0782 70FFh	4	3	2 to 4	1 to 3	PCLKB	Phase-Counting Interface 1 (PCIF1)
DAC12R0	8783 3000h to 8783 307Fh	0783 3000h to 0783 307Fh	4	3	2 to 4	1 to 3	PCLKB	12-Bit D/A Converter 0 (DAC12R0)
DAC12R1	8783 3100h to 8783 317Fh	0783 3100h to 0783 317Fh	4	3	2 to 4	1 to 3	PCLKB	12-Bit D/A Converter 1 (DAC12R1)
TEMPS	8783 5000h to 8783 507Fh	0783 5000h to 0783 507Fh	4	3	2 to 4	1 to 3	PCLKB	Temperature Sensor (TEMPS)
PDC	8784 1000h to 8784 103Fh	0784 1000h to 0784 103Fh	4	3	2 to 4	1 to 3	PCLKB	Parallel Data Capture Unit (PDC)
USB0	8785 0000h to 8785 00FFh	0785 0000h to 0785 00FFh	5	4	3 to 5	2 to 4	PCLKB	USB 2.0 Full-Speed Host/Function Module 0 (USB0)
USB0	8785 0400h to 8785 040Fh	0785 0400h to 0785 040Fh	4	65	2 to 4	63 to 65	PCLKB	USB 2.0 Full-Speed Host/Function Module 0 (USB0)
SDHI	8785 2000h to 8785 23FFh	0785 2000h to 0785 23FFh	4	3	2 to 4	1 to 3	PCLKB	SD/MMC Host Interface (SDHI)
PDMIF	8785 6000h to 8785 63FFh	0785 6000h to 0785 63FFh	4	3	2 to 4	1 to 3	PCLKB	Pulse-Density Modulation Interface (PDM-IF)
SSIE0	8785 D000h to 8785 D03Fh	0785 D000h to 0785 D03Fh	4	3	2 to 4	1 to 3	PCLKB	Serial Sound Interface 0 (SSIE0)
SSIE1	8785 D100h to 8785 D13Fh	0785 D100h to 0785 D13Fh	4	3	2 to 4	1 to 3	PCLKB	Serial Sound Interface 1 (SSIE1)
XSPI0	8786 7000h to 8786 73FFh	0786 7000h to 0786 73FFh	14	13	7 to 11	6 to 10	PCLKB	Expanded Serial Peripheral Interface 0 (XSPI0)
XSPI1	8786 7400h to 8786 77FFh	0786 7400h to 0786 77FFh	14	13	7 to 11	6 to 10	PCLKB	Expanded Serial Peripheral Interface 1 (XSPI1)
XSPI0	8786 8000h to 8786 83FFh	0786 8000h to 0786 83FFh	4	3	2 to 4	1 to 3	PCLKB	Expanded Serial Peripheral Interface 0 (XSPI0)
XSPI1	8786 8400h to 8786 87FFh	0786 8400h to 0786 87FFh	4	3	2 to 4	1 to 3	PCLKB	Expanded Serial Peripheral Interface 1 (XSPI1)
DOTF0	8786 8800h to 8786 88FFh	0786 8800h to 0786 88FFh	4	3	2 to 4	1 to 3	PCLKB	Decryption On The Fly 0 (DOTF0)
DOTF1	8786 8900h to 8786 89FFh	0786 8900h to 0786 89FFh	4	3	2 to 4	1 to 3	PCLKB	Decryption On The Fly 1 (DOTF1)
PORT0 to 9, PORTA to G	87C0 0000h to 87C0 021Fh	07C0 0000h to 07C0 021Fh	4	2	4	2	ICLK	Port Control (n = 0 to 9, A to G)
PFS	87C0 0800h to 87C0 0FFFh	07C0 0800h to 07C0 0FFFh	10	2	10	2	ICLK	Pmn Pin Function Selection (m = 0 to 9, A to G; n = 00 to 15)

Note 1. When the number of cycles of PCLK or MRPCLK is a non-integer value such as 1.5, the minimum and maximum values are expressed as the results of rounding down and up to the nearest integer, respectively. For example, 1.5 to 2.5 is expressed as 1 to 3.

Note 2. “BWAIT” is the number of cycles of waiting specified by USBHS.BUSWAIT.

Note 3. When the ESWM is to be used, do not set ICLK and PCLKA to run at the same frequency. Regarding the operating clock for the ESWM, refer to section 33.3.1, Operating Clocks.

REVISION HISTORY	RX74N Group User's Manual: Hardware

Classifications

- Items with Technical Update document number: Changes according to the corresponding issued Technical Update
- Items without Technical Update document number: Minor changes that do not require Technical Update to be issued
