| 7.5 M | | | | | | | | | | | | | | | | | | | 0 | 1 | 0 | 1 |

Space: Setting prohibited.

—: Can be set, but an error will occur.

Note 1. Continuous transmission or reception is impossible. After transmitting/receiving one frame of data, there is an interval of a 1-bit period before starting transmitting/receiving the next frame of data. The output of the synchronization clock is stopped for a 1-bit period. For this reason, it takes 9 bits worth of time to transfer one frame (8 bits) of data, and the average transfer rate is 8/9 times the bit rate.

Table 18.13 Maximum Bit Rate with External Clock Input (Clock Synchronous Mode)

| P1φ (MHz) | External Input Clock (MHz) | Maximum Bit Rate (Mbps) |

18.2.12 Modulation Duty Register (MDDR)

MDDR corrects the bit rate adjusted by the BRR register.

When the BRME bit in SEMR is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of MDDR (M/256). The relationship between the MDDR setting (M) and the bit rate (B) is given in Table 18.17.

The initial value of MDDR is FFh. Bit 7 in this register is fixed to 1.

The CPU can read the MDDR register, but this register is only writable when the TE and RE bits in SCR are 0.

Table 18.17 Relationship between MDDR Setting (M) and Bit Rate (B)
When Bit Rate Modulation Function is Used

| Mode | SEMR BGDM Bit | Settings ABCS Bit | BRR Setting | Error |
|---|------------------|----------------------|---|--|
| Asynchronous or multi-processor communication | 0 | 0 | $N = \frac{P1\phi \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$ | $\text{Error (\%)} = \left\{ \frac{P1\phi \times 10^6}{B \times 64 \times 2^{2n-1} \times (256/M) \times (N + 1)} - 1 \right\} \times 100$ |
| | 0 | 1 | $N = \frac{P1\phi \times 10^6}{32 \times 2^{2n-1} \times (256/M) \times B} - 1$ | $\text{Error (\%)} = \left\{ \frac{P1\phi \times 10^6}{B \times 32 \times 2^{2n-1} \times (256/M) \times (N + 1)} - 1 \right\} \times 100$ |
| | 1 | 0 | | |
| | 1 | 1 | $N = \frac{P1\phi \times 10^6}{16 \times 2^{2n-1} \times (256/M) \times B} - 1$ | $\text{Error (\%)} = \left\{ \frac{P1\phi \times 10^6}{B \times 16 \times 2^{2n-1} \times (256/M) \times (N + 1)} - 1 \right\} \times 100$ |
| Clock synchronous*1 | | | $N = \frac{P1\phi \times 10^6}{8 \times 2^{2n-1} \times (256/M) \times B} - 1$ | |
| Smart card interface | | | $N = \frac{P1\phi \times 10^6}{S \times 2^{2n+1} \times (256/M) \times B} - 1$ | $\text{Error (\%)} = \left\{ \frac{P1\phi \times 10^6}{B \times S \times 2^{2n+1} \times (256/M) \times (N + 1)} - 1 \right\} \times 100$ |

B: Bit rate (bps)

M: MDDR setting ($128 \leq \text{MDDR} \leq 256$)

N: BRR setting for baud rate generator ($0 \leq N \leq 255$)

P1φ: Operating frequency (MHz)

n and S: Determined by the settings of the SMR and SCMR registers as listed in Table 18.7 and Table 18.8, section 18, Bit Rate Register (BRR).

Only in smart card interface mode, the denominator is 2^{2n+1} . Note that the denominator is 2^{2n-1} in other modes.

Note 1. Do not use this function in clock synchronous mode with the highest speed setting (SMR.CKS[1:0] = 00b, SCR.CKE[1] = 0, and BRR = 0).

18.2.13 Serial Extended Mode Register (SEMR)

| b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|------|------|------|----|------|----|------|
| RXDE SEL | BGDM | NFEN | ABCS | — | BRME | — | ACS0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----|---------|--|--|-------|
| b0 | ACS0 | Asynchronous Mode Clock Source Select | (Valid only in asynchronous mode) 0: External clock input 1: Reserved bit | R/W*1 |
| b1 | — | Reserved | This bit is read as 0. The write value should be 0. | R/W |
| b2 | BRME | Bit Rate Modulation Enable | 0: Bit rate modulation function is disabled. 1: Bit rate modulation function is enabled. | R/W |
| b3 | — | Reserved | This bit is read as 0. The write value should be 0. | R/W |
| b4 | ABCS | Asynchronous Mode Base Clock Select | (Valid only in asynchronous mode) 0: Selects 16 base clock cycles for 1-bit period. 1: Selects 8 base clock cycles for 1-bit period. | R/W*1 |
| b5 | NFEN | Digital Noise Filter Function Enable | (In asynchronous mode) 0: Noise cancellation function for the RXDn input signal is disabled. 1: Noise cancellation function for the RXDn input signal is enabled. | R/W*1 |
| b6 | BGDM | Baud Rate Generator Double-Speed Mode Select | (Only valid the CKE[1] bit in SCR is 0 in asynchronous mode). 0: Baud rate generator outputs the clock with normal frequency. 1: Baud rate generator outputs the clock with doubled frequency. | R/W |
| b7 | RXDESEL | Asynchronous Start Bit Edge Detection Select | (Valid only in asynchronous mode) 0: The low level on the RXDn pin is detected as the start bit. 1: A falling edge on the RXDn pin is detected as the start bit. | R/W*1 |

Note 1. Writable only when TE in SCR = 0 and RE in SCR = 0 (both serial transmission and reception are disabled).

SEMR selects the clock source for 1-bit period in asynchronous mode.

ACS0 Bit (Asynchronous Mode Clock Source Select)

Selects the clock source in the asynchronous mode.

The ACS0 bit is valid in asynchronous mode (CM bit in SMR = 0) and when an external clock input is selected (CKE[1:0] bits in SCR = 10b or 11b).

Set the ACS0 bit to 0 in other than asynchronous mode.

BRME bit (Bit Rate Modulation Enable)

Enables and disables the bit rate modulation function. The bit rate generated by on-chip baud rate generator is evenly corrected when this function is enabled.

NFEN Bit (Digital Noise Filter Function Enable)

This bit enables or disables the digital noise filter function.

When the function is enabled, noise cancellation is applied to the RXDn input signal in asynchronous mode.

In any mode other than above, set the NFEN bit to 0 to disable the digital noise filter function.

When the function is disabled, input signals are transferred as is, as internal signals.

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

Selects the cycle of output clock for the baud rate generator.

This bit is valid when the on-chip baud rate generator is selected as the clock source (SCR.CKE[1] = 0) in asynchronous mode (SMR.CM = 0). For the clock output from the baud rate generator, either normal or doubled frequency can be selected. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1,

the base clock cycle is halved and the bit rate is doubled.
Set this bit to 0 in modes other than asynchronous mode.

RXDESEL Bit (Asynchronous Start Bit Edge Detection Select)

Selects the detection method of the start bit for reception in asynchronous mode. When a break occurs, data receiving operation depends on the settings of this bit. Set this bit to 1 when reception should be stopped while a break occurs or when reception should be started without retaining the RXDn pin input at high level for the period of one data frame or longer after completion of the break.
Set this bit to 0 in modes other than asynchronous mode.

18.2.14 Noise Filter Setting Register (SNFR)

| Bit | Symbol | Bit Name | Description | R/W |
|----------|-----------|---------------------------|---|-------|
| b2 to b0 | NFCS[2:0] | Noise Filter Clock Select | In asynchronous mode, the standard setting for the base clock is as follows. b2 b0 0 0 0: The clock signal divided by 1 is used with the noise filter. Settings other than above are prohibited. | R/W*1 |
| b7 to b3 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |

Note 1. Writing to these bits is only possible when the RE and TE bits in the SCR are 0 (serial reception and transmission disabled).

NFCS[2:0] Bits (Noise Filter Clock Select)

These bits select the sampling clock for the digital noise filter. To use the noise filter in asynchronous mode, set these bits to 000b.

18.2.15 Extended function control register (SECR)

| b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|----|----|----|----|----|------|----|
| — | — | — | — | — | — | CTSE | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|----------|--------|------------|--|-------|
| b0 | — | Reserved | This bit is read as 0. The write value should be 0. | R/W |
| b1 | CTSE | CTS Enable | 0: CTS function is disabled (RTS output function is enabled). 1: CTS function is enabled. | R/W*1 |
| b2 to b7 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |

Note 1. Writing to the bit is only possible when the SCR.RE and SCR.TE bits are 0.

SECR is used to select the extension settings in asynchronous and clock synchronous modes.

CTSE Bit (CTS Enable)

Set this bit to 1 to enable the CTS function. The RTS signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode. Do not set both the CTSE and SSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

18.3 Operation in Asynchronous Mode

Figure 18.2 shows the general format for asynchronous serial communications.

One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level).

In asynchronous serial communications, the communications line is usually held in the mark state (high level).

The SCI monitors the communications line. When the SCI detects a low, it regards that as a start bit and starts serial communication.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and the receiver also have a double-buffered structure, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

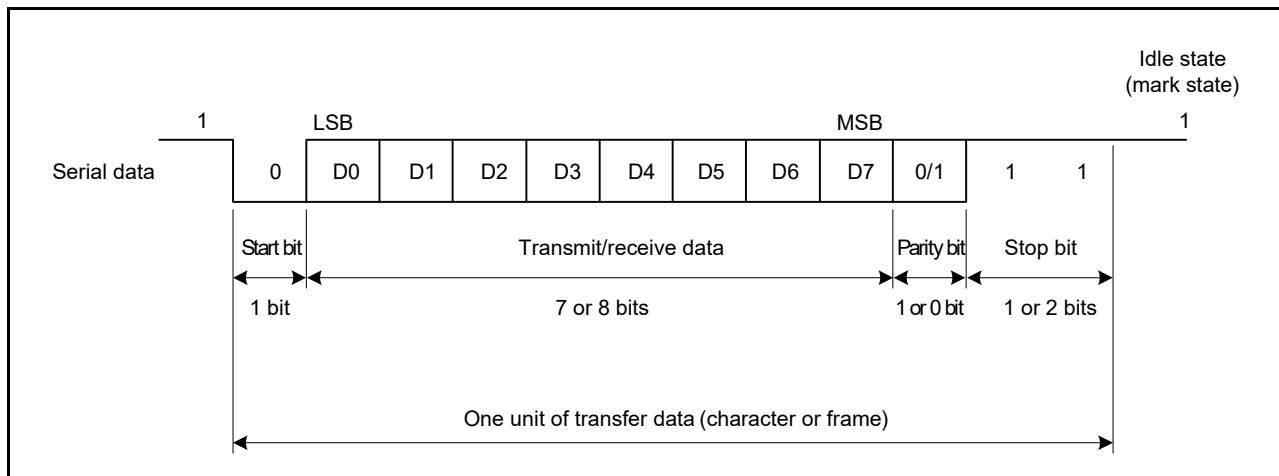

Figure 18.2 Data Format in Asynchronous Serial Communications
(Example with 8-Bit Data, Parity, 2 Stop Bits)

18.3.1 Serial Data Transfer Format

Table 18.18 lists the serial data transfer formats that can be used in asynchronous mode.

Any of 18 transfer formats can be selected according to the SMR and SCMR setting. For details of multi-processor function, refer to section 18.4, Multi-Processor Communications Function.

Table 18.18 Serial Transfer Formats (Asynchronous Mode)

| SCMR Setting | | SMR Setting | | Serial Transfer Format and Frame Length | | | | | | | | | | | | | |
|--------------|-----|-------------|----|---|---|------------|---|---|---|---|---|---|------|------|------|------|------|
| CHR1 | CHR | PE | MP | STOP | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 |
| 0 | 0 | 0 | 0 | 0 | S | 9-bit data | | | | | | | | | STOP | | |
| 0 | 0 | 0 | 0 | 1 | S | 9-bit data | | | | | | | | | STOP | STOP | |
| 0 | 0 | 1 | 0 | 0 | S | 9-bit data | | | | | | | | | P | STOP | |
| 0 | 0 | 1 | 0 | 1 | S | 9-bit data | | | | | | | | | P | STOP | STOP |
| 1 | 0 | 0 | 0 | 0 | S | 8-bit data | | | | | | | | STOP | | | |
| 1 | 0 | 0 | 0 | 1 | S | 8-bit data | | | | | | | | STOP | STOP | | |
| 1 | 0 | 1 | 0 | 0 | S | 8-bit data | | | | | | | | P | STOP | | |
| 1 | 0 | 1 | 0 | 1 | S | 8-bit data | | | | | | | | P | STOP | STOP | |
| 1 | 1 | 0 | 0 | 0 | S | 7-bit data | | | | | | | STOP | | | | |
| 1 | 1 | 0 | 0 | 1 | S | 7-bit data | | | | | | | STOP | STOP | | | |
| 1 | 1 | 1 | 0 | 0 | S | 7-bit data | | | | | | | P | STOP | | | |
| 1 | 1 | 1 | 0 | 1 | S | 7-bit data | | | | | | | P | STOP | STOP | | |
| 0 | 0 | — | 1 | 0 | S | 9-bit data | | | | | | | | | MPB | STOP | |
| 0 | 0 | — | 1 | 1 | S | 9-bit data | | | | | | | | | MPB | STOP | STOP |
| 1 | 0 | — | 1 | 0 | S | 8-bit data | | | | | | | | MPB | STOP | | |
| 1 | 0 | — | 1 | 1 | S | 8-bit data | | | | | | | | MPB | STOP | STOP | |
| 1 | 1 | — | 1 | 0 | S | 7-bit data | | | | | | | MPB | STOP | | | |
| 1 | 1 | — | 1 | 1 | S | 7-bit data | | | | | | | MPB | STOP | STOP | | |

S: Start bit

STOP: Stop bit

P: Parity bit

MPB: Multi-processor bit

18.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a base clock with a frequency of 16 times*1 the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization. Since receive data is sampled at the rising edge of the 8th pulse*1 of the base clock, data is latched at the middle of each bit, as shown in Figure 18.3. Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100 [\%] \cdots \text{Formula (1)}$$

M: Reception margin

N: Ratio of bit rate to clock (N = 16 when ABCS in SEMR = 0, N = 8 when ABCS in SEMR = 1)

D: Duty cycle of clock (D = 0.5 to 1.0)

L: Frame length (L = 9 to 13)

F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined by the formula below.

$$M = \{0.5 - 1/(2 \times 16)\} \times 100 (\%) = 46.875\%$$

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

Note 1. This is an example when the ABCS bit in SEMR is 0. When the ABCS bit is 1, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock.

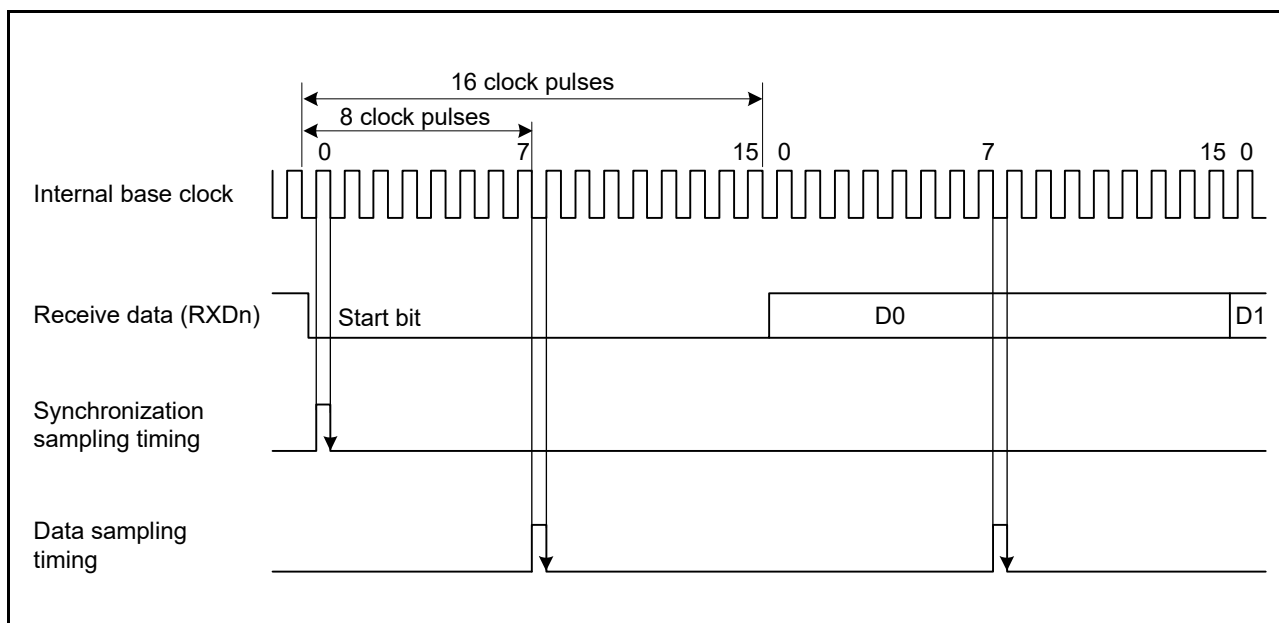

Figure 18.3 Receive Data Sampling Timing in Asynchronous Mode

18.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the SCI's transfer clock, according to the setting of the CM bit in SMR and the CKE[1:0] bits in SCR.

When an external clock is input to the SCKn pin, the clock frequency should be 16 times the bit rate (when ABCS in SEMR = 0) and 8 times the bit rate (when ABCS in SEMR = 1).

When the SCI is operated on an internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 18.4. When the clock output is selected, the clock is output after setting SCR.TE = 1 or SCR.RE = 1.

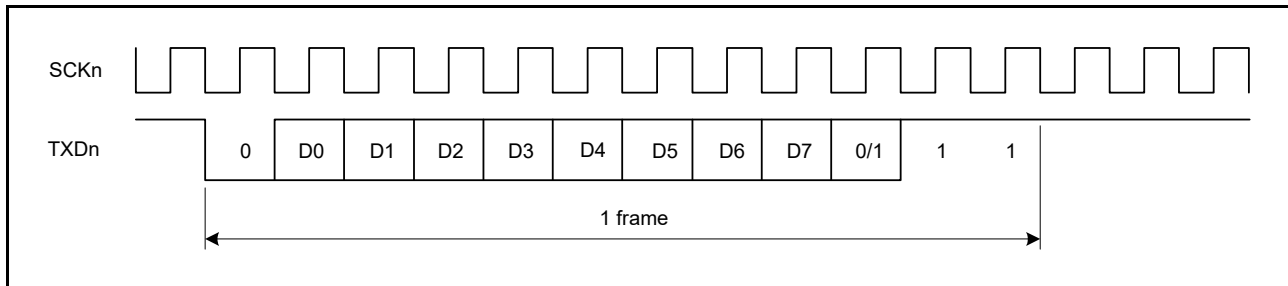

Figure 18.4 Phase Relationship between Output Clock and Transmit Data
(Asynchronous Mode: SEMR.CHR = 0, PE = 1, MP = 0, STOP = 1)

18.3.4 Double-Speed Mode

The output clock frequency of the on-chip baud rate generator is doubled by setting the SEMR.BGDM bit to 1, enabling high-speed communication at a doubled bit rate. If the SEMR.ABCS bit is set to 1 under the above condition, the number of base clock cycles changes from 16 to 8, so the bit rate becomes four times faster than the initial state.

As shown by Formula (1) in section 18.3.2, Receive Data Sampling Timing and Reception Margin in Asynchronous Mode, setting the SEMR.ABCS bit to 1 changes the number of cycles to 8, and the sampling interval becomes longer. This causes the reception margin to decrease. Therefore, setting the SEMR.BGDM bit to 1 and the SEMR.ABCS bit to 0 is recommended instead of setting the SEMR.BGDM bit to 0 and the SEMR.ABCS bit to 1 for high-speed operation at a doubled bit rate.

18.3.5 CTS and RTS Functions

The CTS function controls transmission with the use of input on the CTSn# pin. Setting the SECR.CTSE bit to 1 enables the CTS function. When the CTS function is enabled, transmission starts only while the input on the CTSn# pin is at the low level.

Even when the CTSn# pin is set to the high level after transmission has started, the frame being transmitted is not affected and transmission continues.

The RTS function makes a request for transmission with the use of output on the RTSn# pin. It outputs a low level when reception can be started. Conditions for output of the low and high levels are shown below.

[Conditions for low-level output]

Satisfaction of all conditions listed below

- The value of the RE bit in the SCR is 1
- Reception is not in progress
- There are no received data yet to be read
- The ORER, FER, and PER flags in the SSR are all 0

[Condition for high-level output]

- The conditions for low-level output are not satisfied.

18.3.6 SCI Initialization (Asynchronous Mode)

Before transmitting and receiving data, start by writing the initial value 00h to SCR and then continue through the procedure for SCI given in Figure 18.5. Whenever the operating mode or transfer format is changed, SCR must be initialized before the change is made.

When the external clock is used in asynchronous mode, ensure that the clock signal is supplied even during initialization. Note that setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in SSR nor RDR, RDRH, and RDRL.

Moreover, note that switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of a TXI interrupt request.

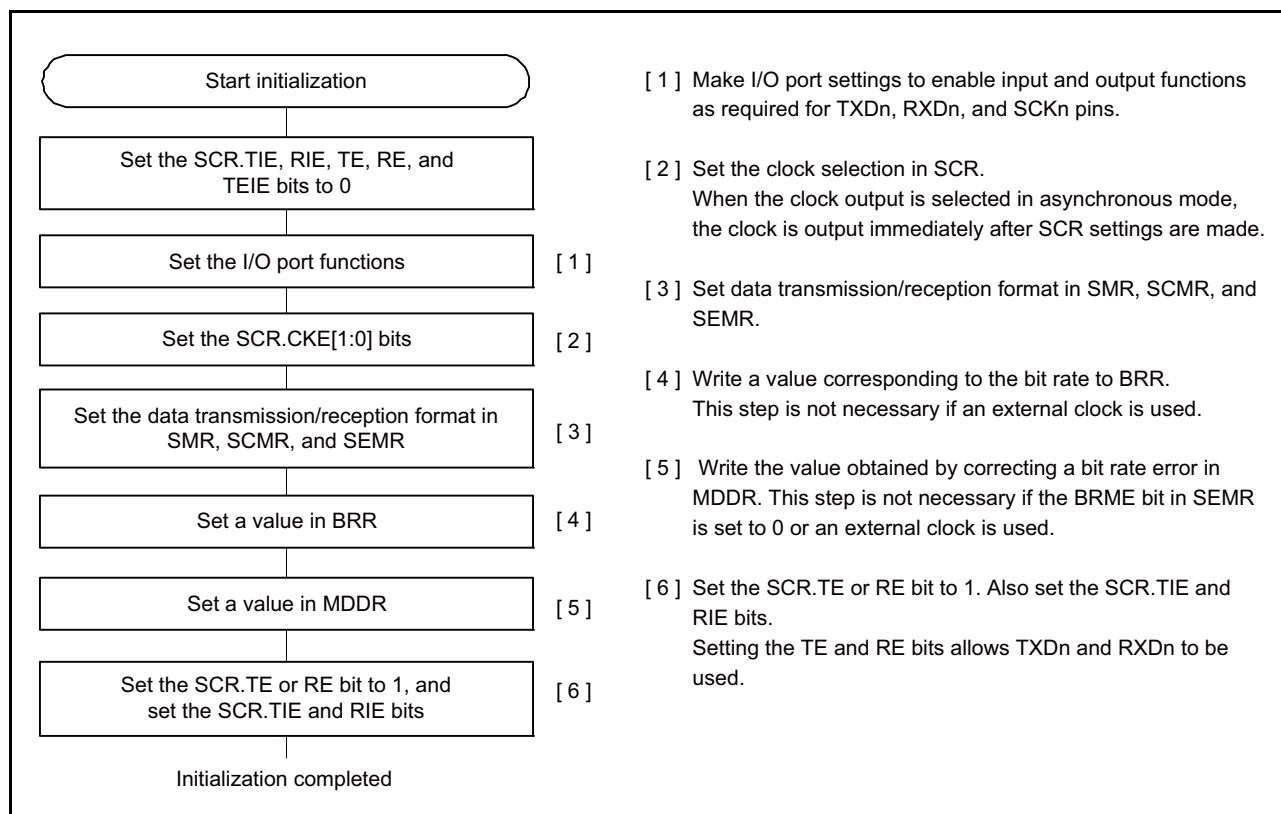

Figure 18.5 Sample SCI Initialization Flowchart (Asynchronous Mode)

18.3.7 Serial Data Transmission (Asynchronous Mode)

Figure 18.6 to Figure 18.8 show an example of the operation for serial transmission in asynchronous mode.

In serial transmission, the SCI operates as described below.

1. The SCI transfers data from TDR*¹ to TSR when data is written to TDR*¹ in the TXI interrupt handling routine. The TXI interrupt request at the beginning of transmission is generated when the TE bit in SCR is set to 1 after the TIE bit in SCR is set to 1 or when these 2 bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the CTSE bit in SECR is set to 0 (CTS function is disabled) and a low level on the CTSn# pin causes data transfer from TDR*¹ to TSR. If the TIE bit in SCR is 1 at this time, a TXI interrupt request is generated. Continuous transmission is obtainable by writing the next transmit data to TDR*¹ in the TXI interrupt handling routine before transmission of the current transmit data is completed. When TEI interrupt requests are in use, set the SCR.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR.TEIE bit to 1 (a TEI interrupt request is enabled) after the last of the data to be transmitted are written to the TDR*¹*² from the handling routine for TXI requests.
3. Data is sent from the TXDn pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The SCI checks for updating of (writing to) TDR*³ at the time of stop bit output.
5. When TDR*³ is updated, setting of the CTSE bit in SECR to 0 (CTS function is disabled) or a low level input on the CTSn# pin cause the next transfer of the next transmit data from TDR*¹ to TSR and sending of the stop bit, after which serial transmission of the next frame starts.
6. If TDR*³ is not updated, the TEND flag in SSR is set to 1, the stop bit is sent, and then the mark state is entered in which 1 is output. If the TEIE bit in SCR is 1 at this time, the TEND flag in SSR is set to 1 and a TEI interrupt request is generated.

Note 1. Write data not to TDR but to the TDRH and TDRL registers when 9-bit data length is selected.

Note 2. Write data in the order from TDRH to TDRL when 9-bit data length is selected.

Note 3. The SCI checks for updating of the TDRL register only and does not check for updating of the TDRH register when 9-bit data length is selected.

Figure 18.9 shows a sample flowchart for serial transmission in asynchronous mode.

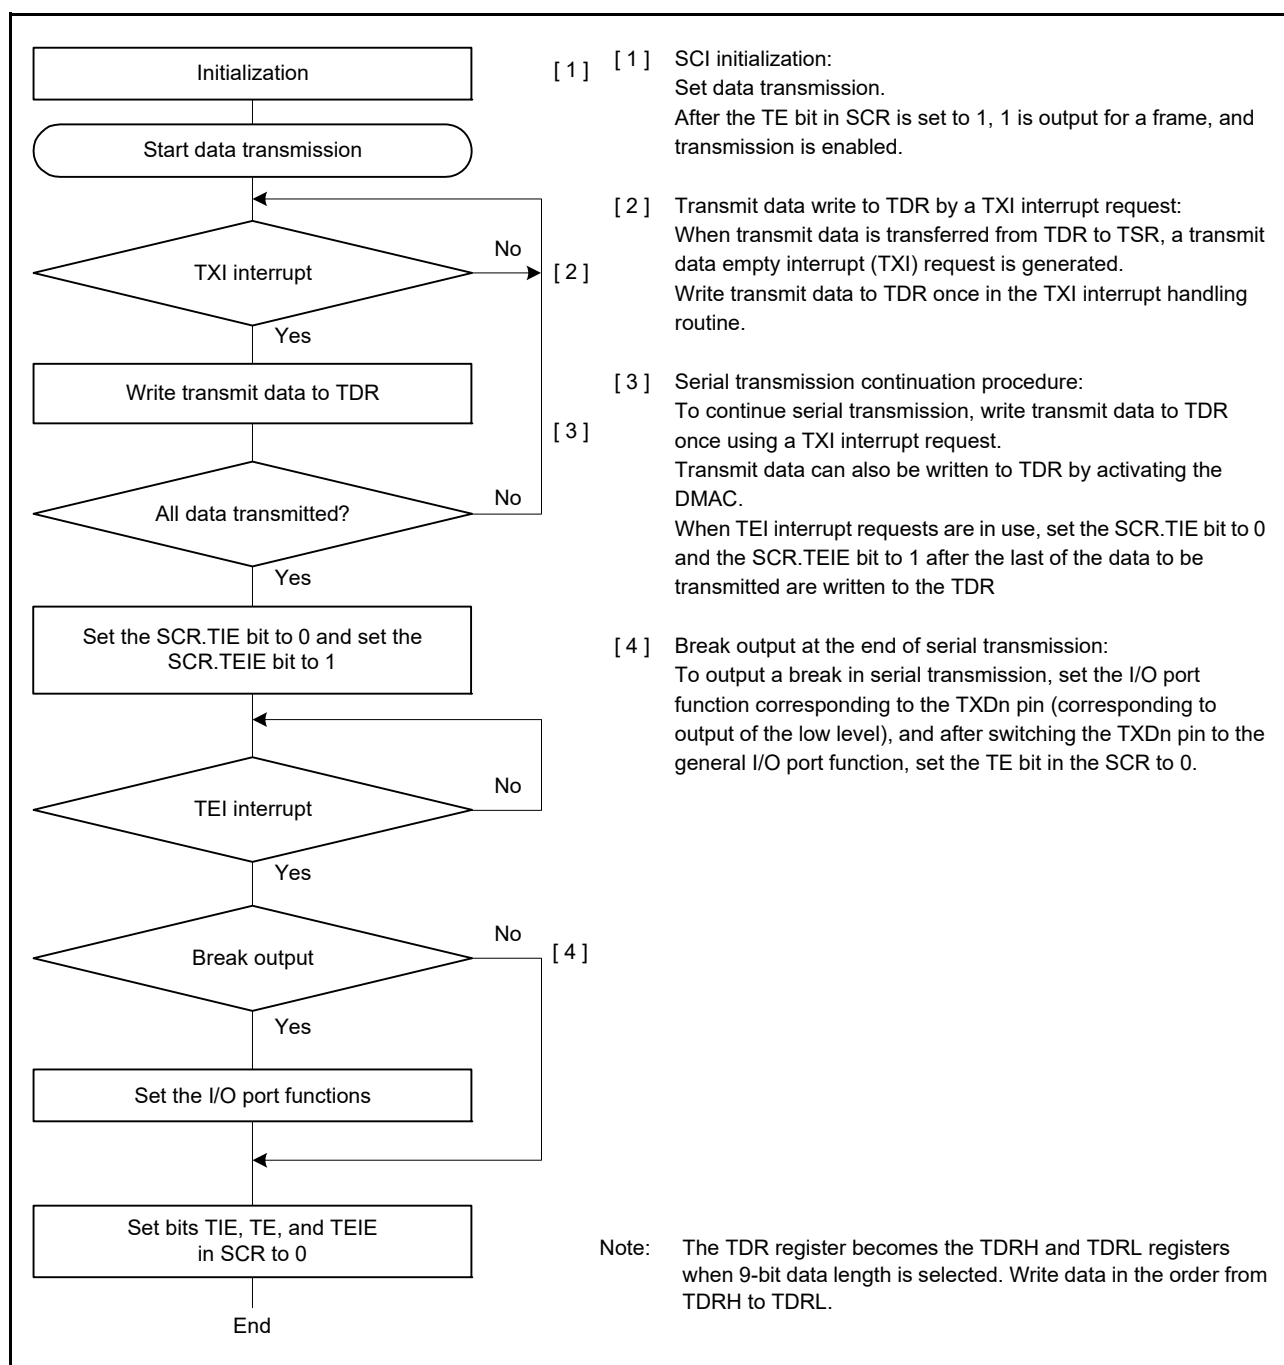

Figure 18.9 Example of Serial Transmission Flowchart in Asynchronous Mode

18.3.8 Serial Data Reception (Asynchronous Mode)

Figure 18.10 and Figure 18.11 show an example of the operation for serial data reception in asynchronous mode. In serial data reception, the SCI operates as described below.

1. When the value of the RE bit in SCR becomes 1, the output signal on the RTSn# pin goes to the low level.
 2. When the SCI monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
 3. If an overrun error occurs, the ORER flag in SSR is set to 1. If the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR*¹.
 4. If a parity error is detected, the PER bit in SSR is set to 1 and receive data is transferred to RDR*¹. If the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated.
 5. If a framing error (when the stop bit is 0) is detected, the FER bit in SSR is set to 1 and receive data is transferred to RDR*¹. If the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated.
 6. When reception finishes successfully, receive data is transferred to RDR*¹. If the RIE bit in SCR is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to RDR*¹ in this RXI interrupt handling routine before reception of the next receive data is completed. When the received data that have been transferred to RDR*² are read, the RTSn# pin output is set to the low level.
- If you do not want the RTSn# pin output to be set to the low level following the reception of the last data, set the SCR.RE bit to 0 and dummy read SCR before reading RDR, and then read RDR.

Note 1. Read data not in RDR but in the RDRH and RDRL registers when 9-bit data length is selected.

Note 2. The SCI checks for reading of the RDRL register only and does not check for reading of the RDRH register when 9-bit data length is selected.

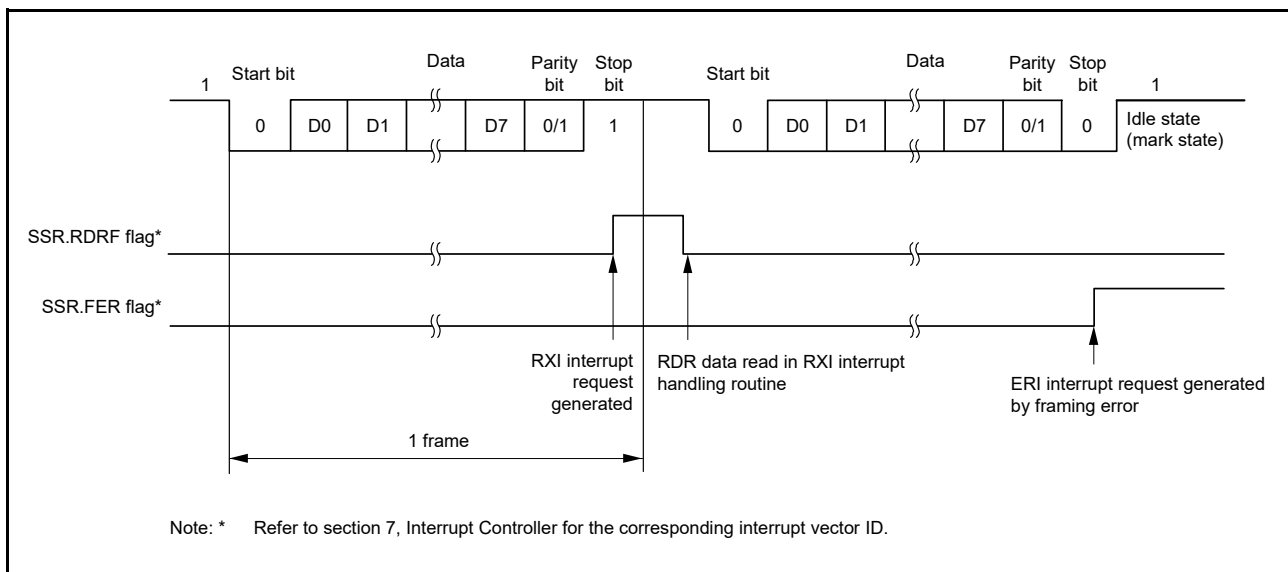

Figure 18.10 Example of SCI Operation for Serial Reception in Asynchronous Mode (1)
(When RTS Function is Not Used) (Example with 8-Bit Data, Parity, 1 Stop Bit)

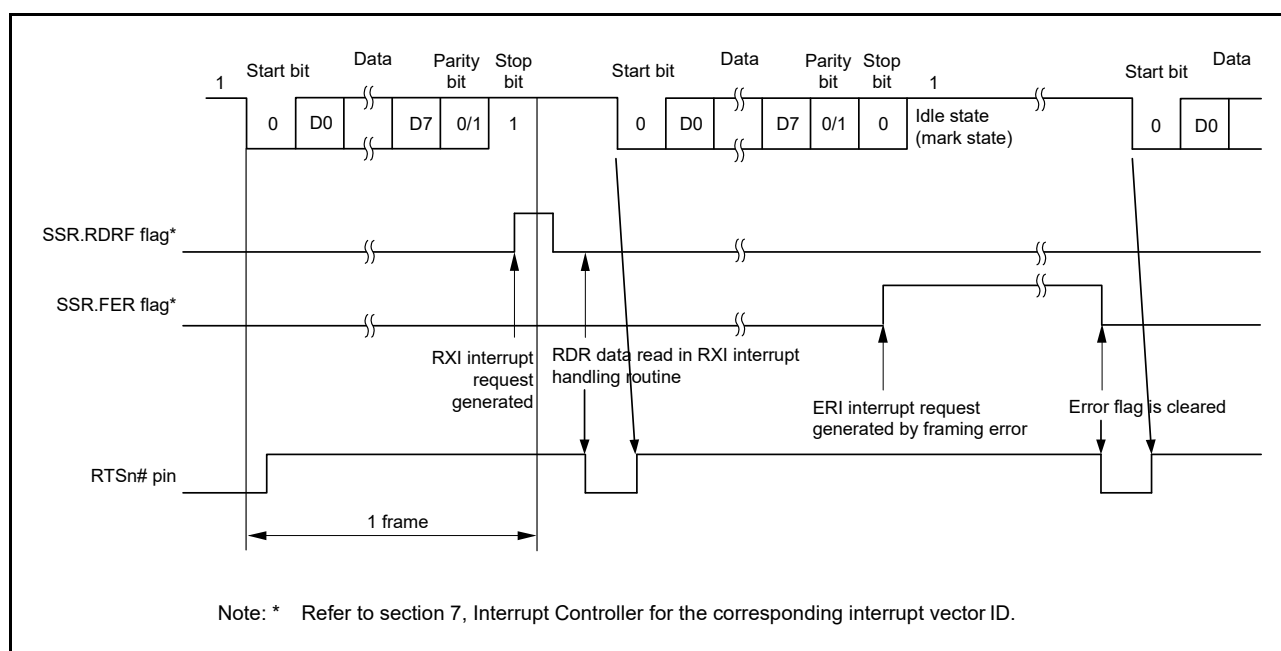

Figure 18.11 Example of SCI Operation for Serial Reception in Asynchronous Mode (2)
(When RTS Function is Used) (Example with 8-Bit Data, Parity, 1 Stop Bit)

Table 18.19 lists the states of the flags in the SSR status register and receive data handling when a receive error is detected.

If a receive error is detected, an ERI interrupt request is generated but an RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, and PER bits to 0 before resuming reception. Moreover, be sure to read the RDR (or the RDRL) during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read the RDR (or the RDRL) register because received data which has not yet been read may be left in RDR (or the RDRL).

Figure 18.12 and Figure 18.13 show samples of flowcharts for serial data reception.

Table 18.19 Flags in the SSR Status Register and Receive Data Handling

| Flags in the SSR Status Register | | | Receive Data | Receive Error Type |
|----------------------------------|-----|-----|----------------------------------|--|
| ORER | FER | PER | | |
| 1 | 0 | 0 | Lost | Overrun error |
| 0 | 1 | 0 | Transferred to RDR* ¹ | Framing error |
| 0 | 0 | 1 | Transferred to RDR* ¹ | Parity error |
| 1 | 1 | 0 | Lost | Overrun error + framing error |
| 1 | 0 | 1 | Lost | Overrun error + parity error |
| 0 | 1 | 1 | Transferred to RDR* ¹ | Framing error + parity error |
| 1 | 1 | 1 | Lost | Overrun error + framing error + parity error |

Note 1. Read data not in RDR but in the RDRH and RDRL registers when 9-bit data length is selected.

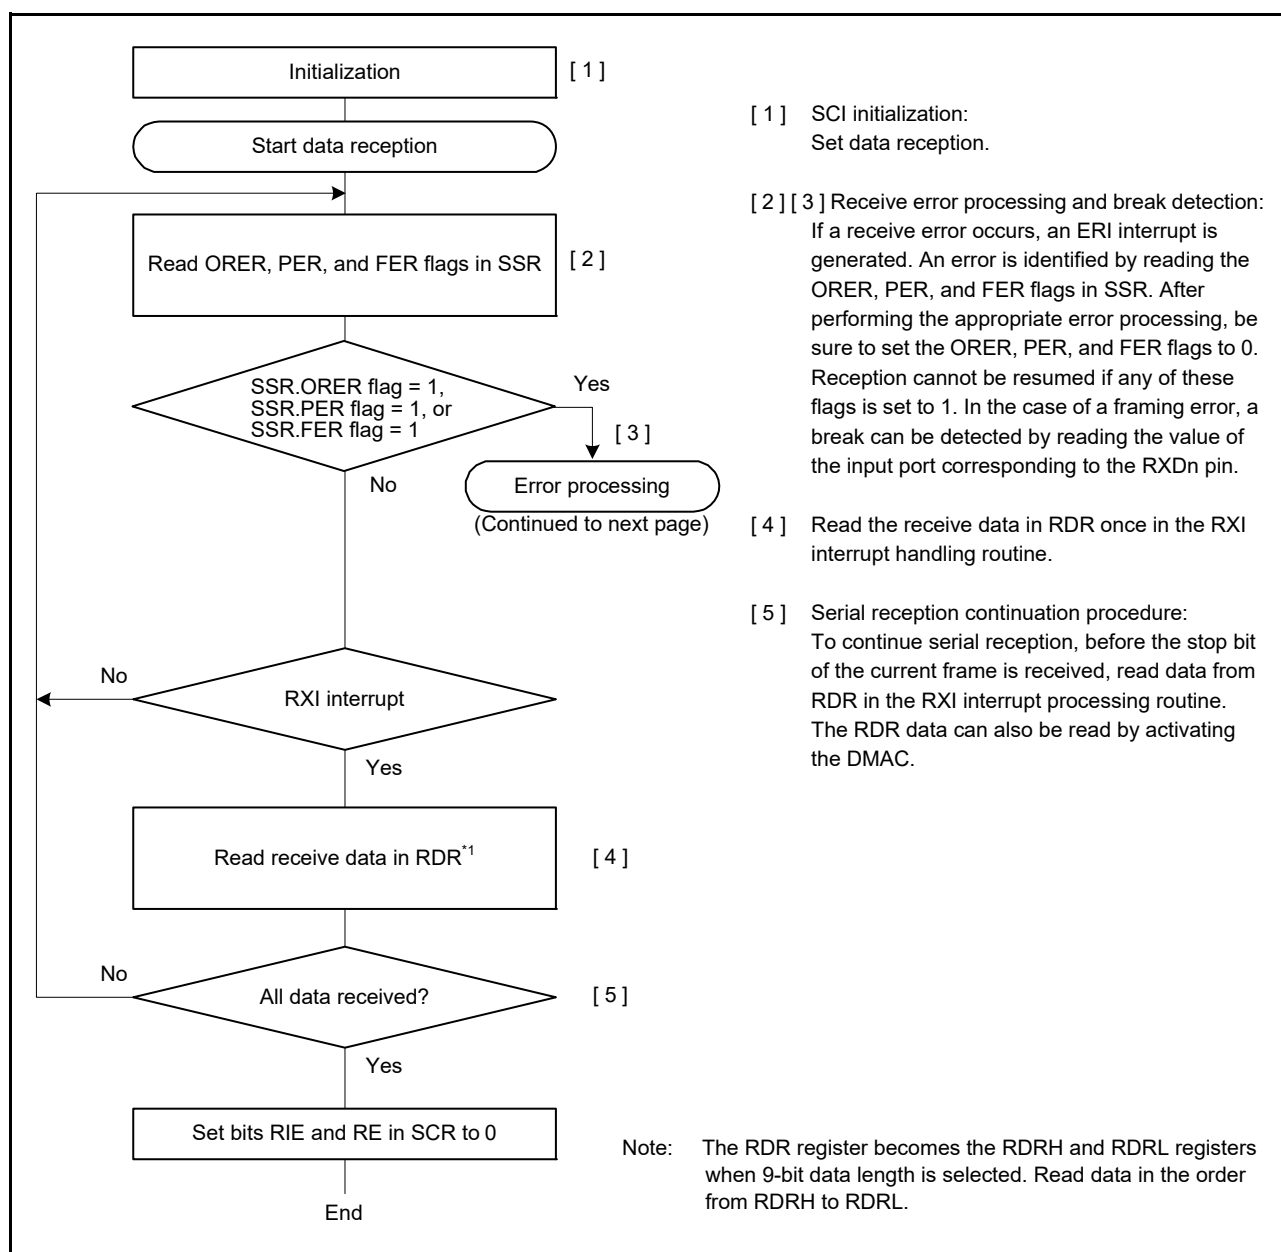

Figure 18.12 Example Flowchart of Serial Reception in Asynchronous Mode (1)

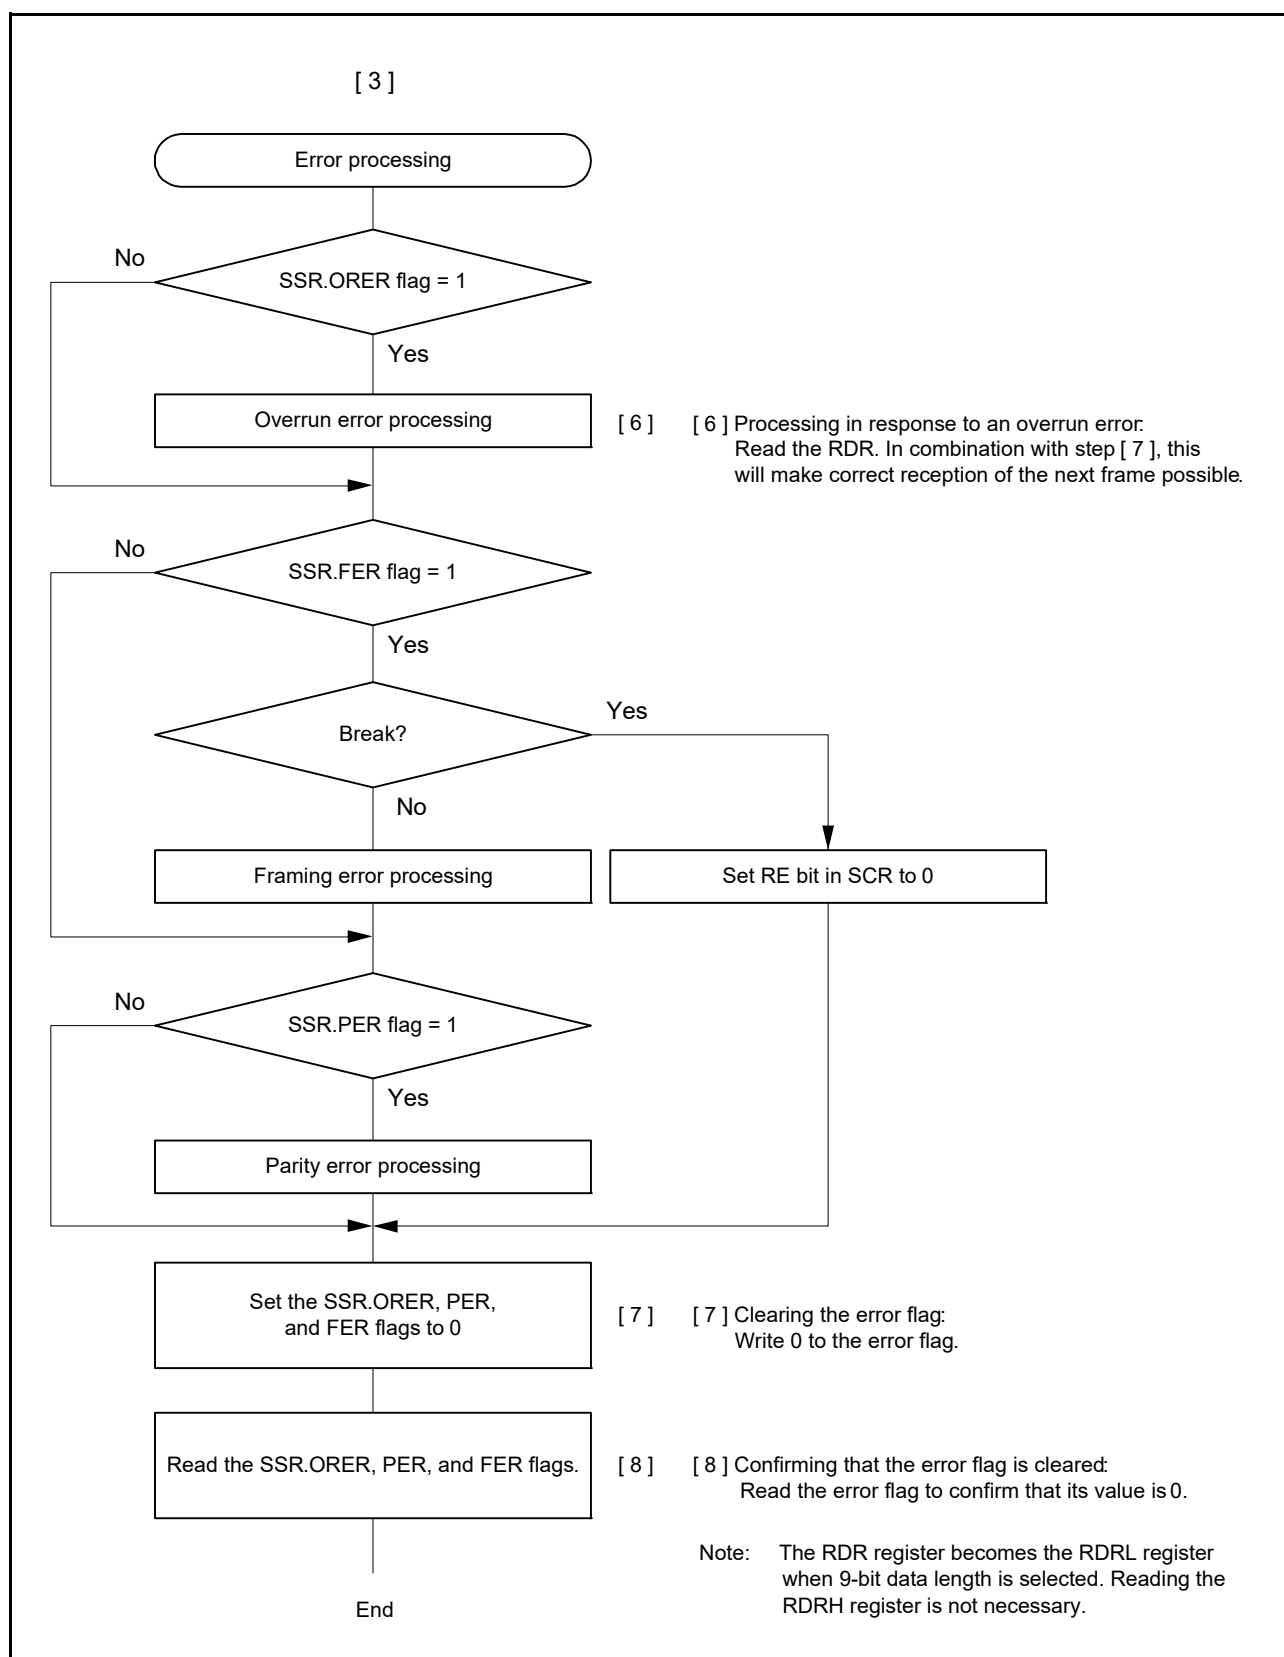

Figure 18.13 Example Flowchart of Serial Reception in Asynchronous Mode (2)

18.4 Multi-Processor Communications Function

Using the multi-processor communication functions enables to transmit and receive data by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle and when the multi-processor bit is set to 0, it indicates the data transmission cycle. Figure 18.14 shows an example of communication between processors by using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits the communication data in which the multi-processor bit set to 0 is added to the transmit data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself and if the two match, receives the communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until again receiving the communication data in which the multi-processor bit is set to 1. For supporting this function, the SCI provides the MPiE bit in SCR. When the MPiE bit is set to 1, transfer of receive data from the RSR to the RDR (the RDRH and RDRL registers when 9-bit data length is selected), detection of a receive error, and setting the respective status flags ORER and FER in SSR are disabled until reception of data in which the multi-processor bit is set to 1. Upon receiving a reception character in which the multi-processor bit is set to 1, the MPBT bit in SSR is set to 1 and the MPiE bit in SCR is automatically cleared, thus returning to a normal reception operation. During this time, an RXI interrupt is generated if the RIE bit in SCR is set. When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the normal asynchronous mode. A clock which is used for the multi-processor communication is also the same as the clock used in the normal asynchronous mode.

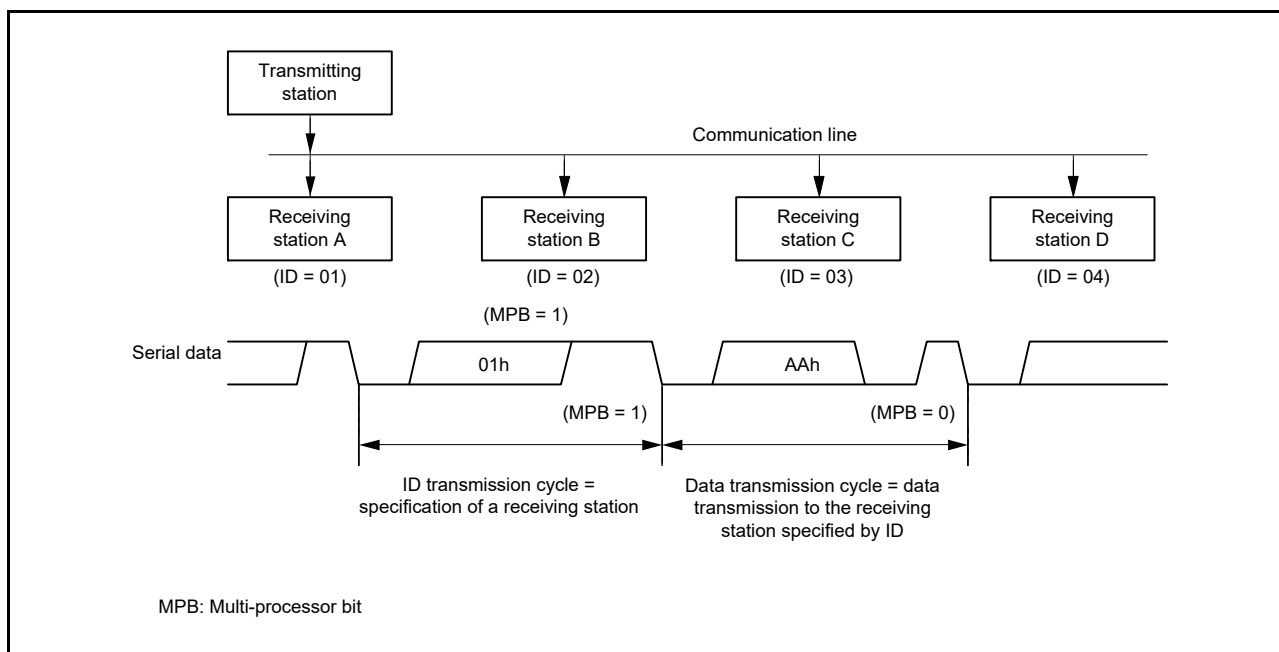

Figure 18.14 An Example of Communication using the Multi-Processor Format
(Example of Transmission of Data AAh to Receiving Station A)

18.4.1 Multi-Processor Serial Data Transmission

Figure 18.15 is a sample flowchart of multi-processor data transmission. In the ID transmission cycle, the ID should be transmitted with the MPBT bit in SSR set to 1. In the data transmission cycle, the data should be transmitted with the MPBT bit set to 0. The other operations are the same as the operations in asynchronous mode.

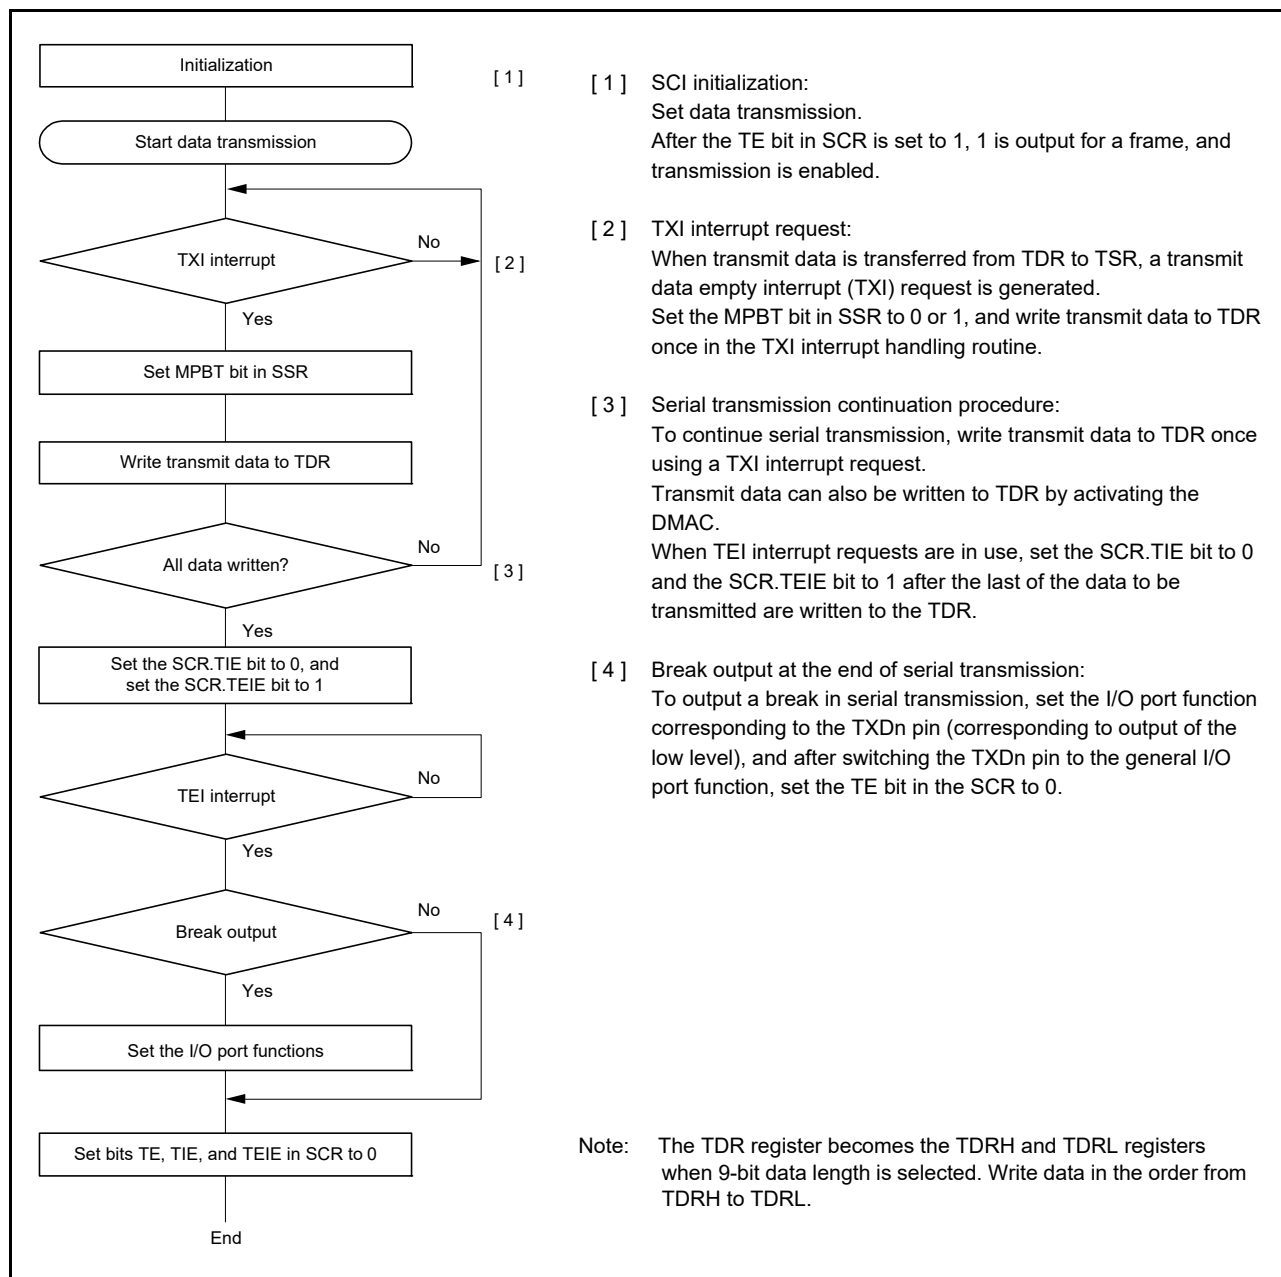

Figure 18.15 Example of Multi-Processor Serial Transmission Flowchart

18.4.2 Multi-Processor Serial Data Reception

Figure 18.17 and Figure 18.18 are sample flowcharts of multi-processor data reception. When the MPiE bit in SCR is set to 1, reading the communication data is skipped until reception of the communication data in which the multi-processor bit is set to 1. When the communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to RDR (the RDRH and RDRL registers when 9-bit data length is selected). During this time, the RXI interrupt request is generated. The other operations are the same as the operations in asynchronous mode. Figure 18.16 is the example of operation for reception.

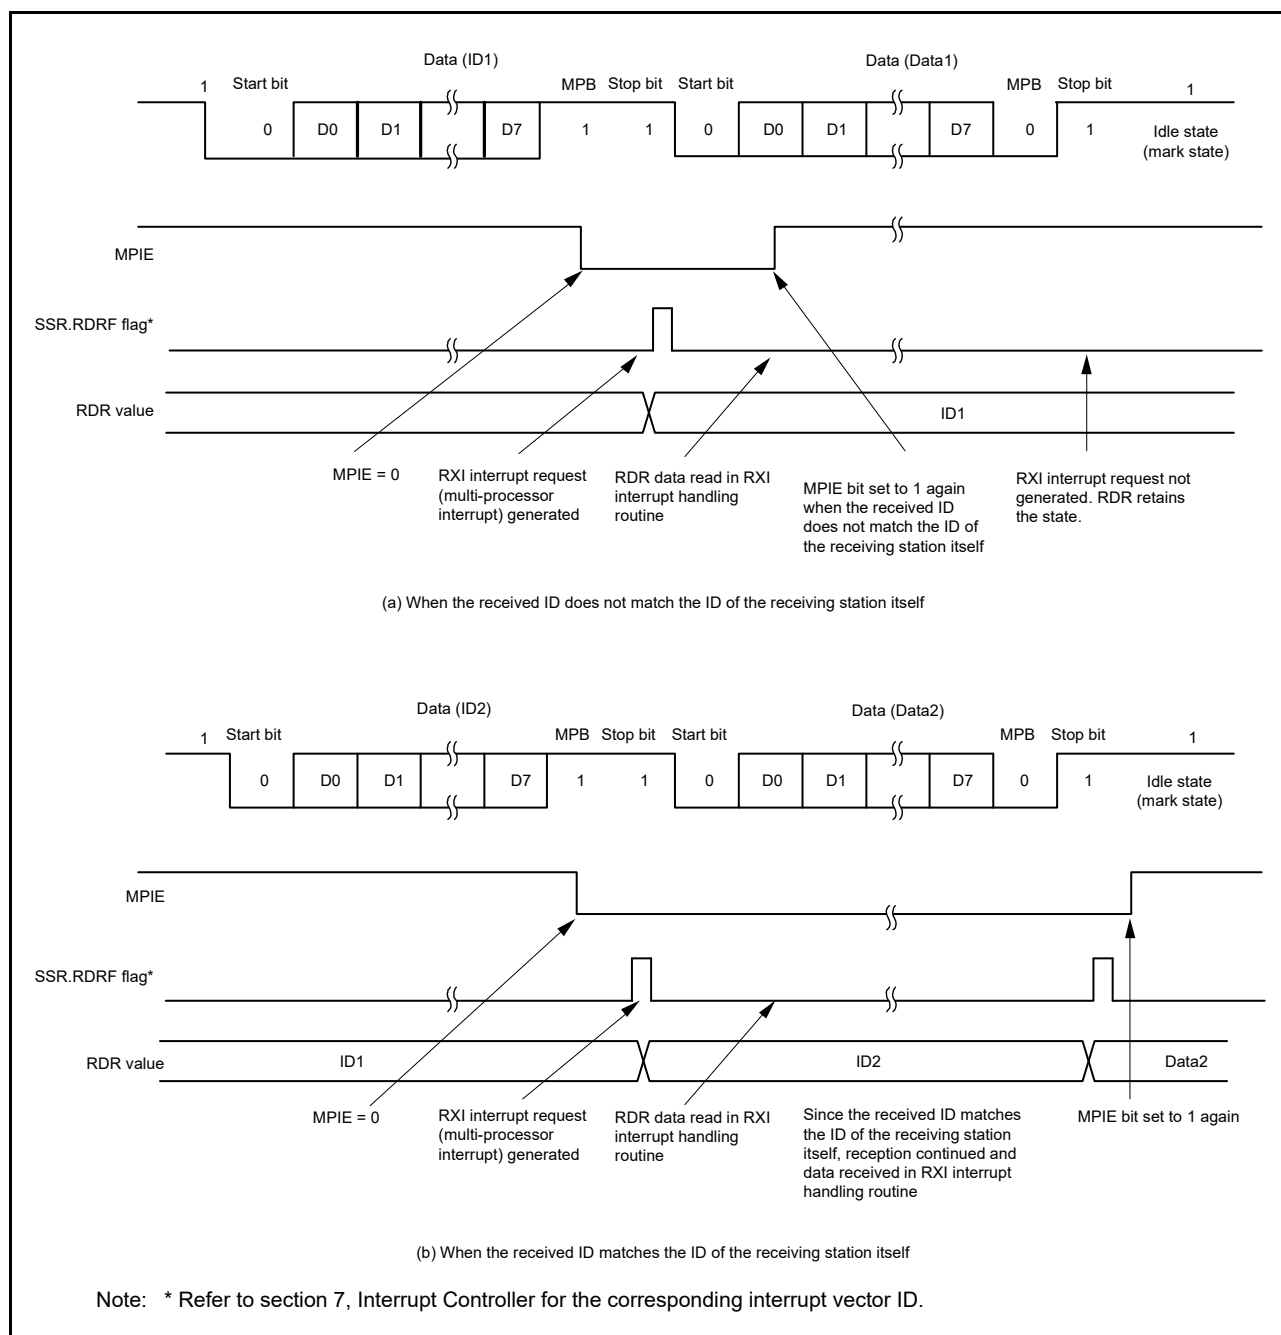

Figure 18.16 Example of SCI Reception (8-Bit Data/Multi-Processor Bit/1 Stop Bit)

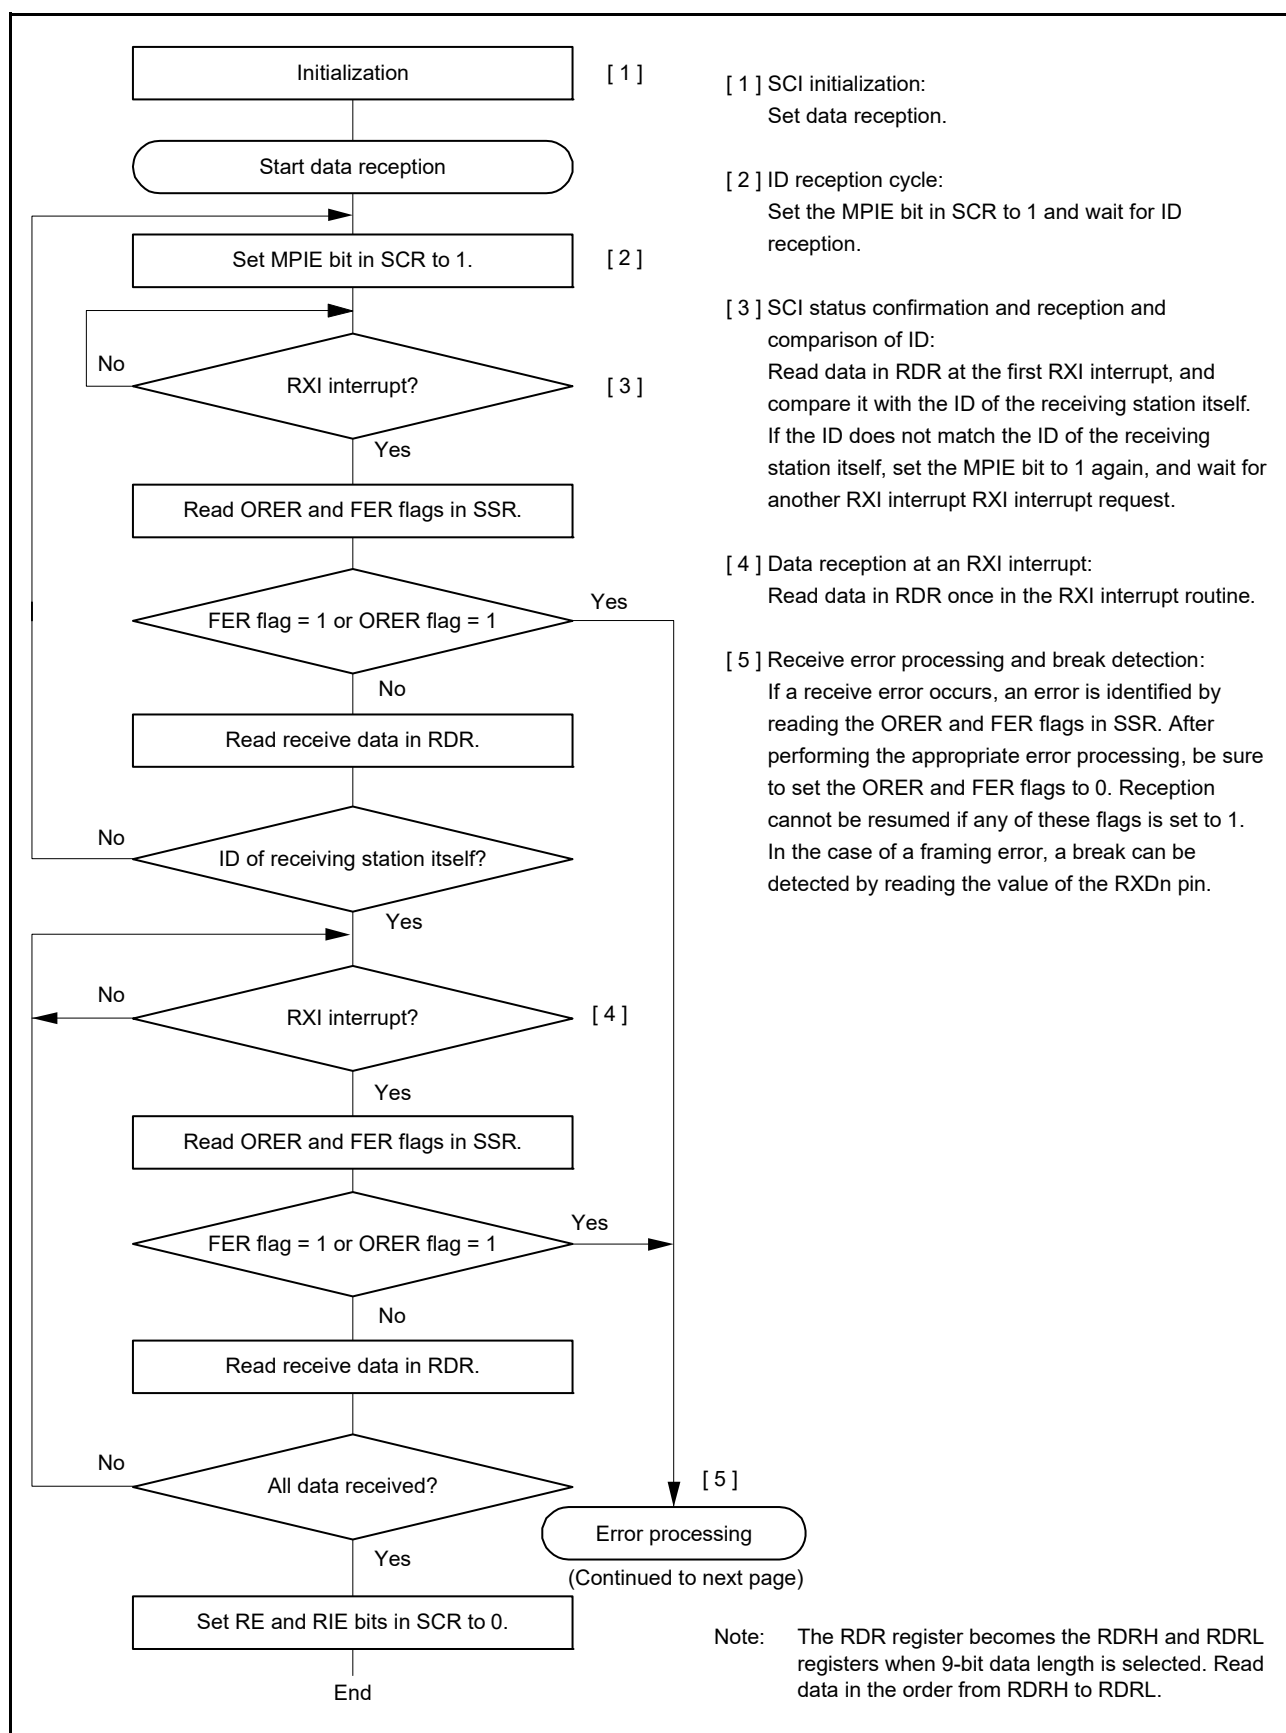

Figure 18.17 Example of Multi-Processor Serial Reception Flowchart (1)

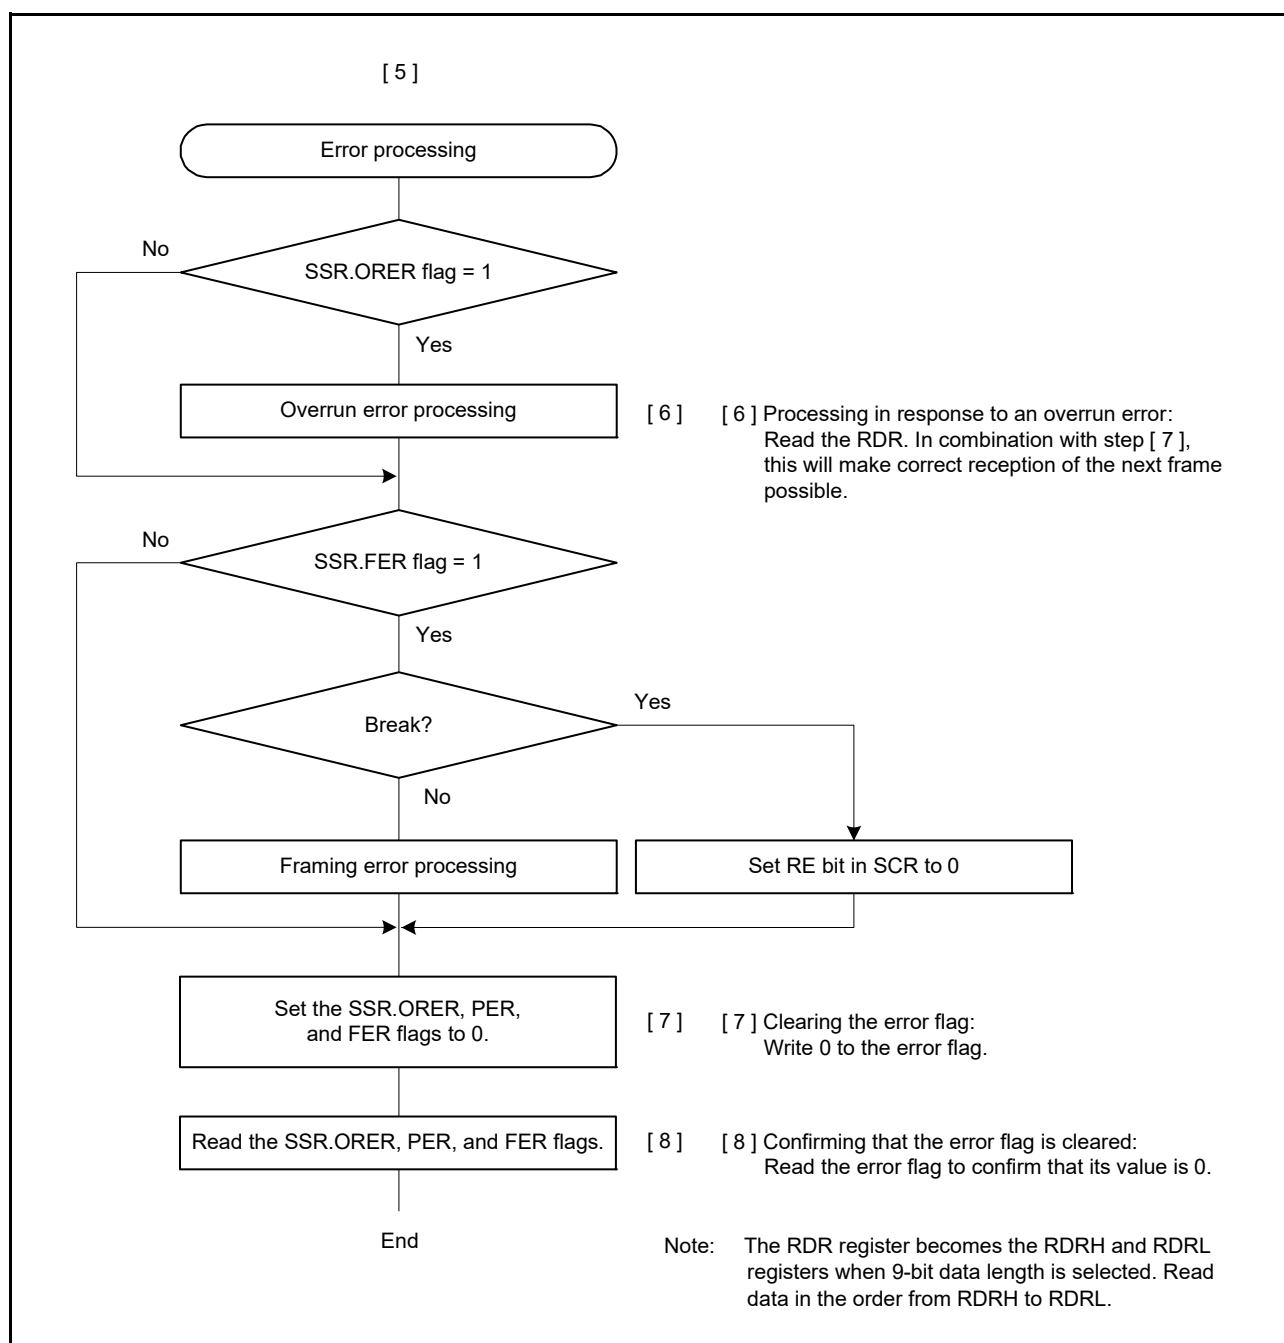

Figure 18.18 Example of Multi-Processor Serial Reception Flowchart (2)

18.5 Operation in Clock Synchronous Mode

Figure 18.19 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In clock synchronous mode, no parity bit can be added.

In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the communication line holds the last bit output state.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by use of a common clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

Figure 18.19 Data Format in Clock Synchronous Serial Communications (LSB First)

18.5.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCKn pin can be selected, according to the setting of the SCR.CKE[1:0] bits.

When the SCI is operated on an internal clock, the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output in the transfer of one character, and when no transfer is performed the clock is held high. However, when only data reception is performed while the CTS function is disabled, the synchronization clock output is started at the same time when the SCR.RE bit is set to 1. The synchronization clock is stopped at the high level when an overrun error occurs or the SCR.RE bit is set to 0.

When only data reception is performed and the CTS function is enabled, the clock output is not started even when the SCR.RE bit is set to 1 if the CTSn# pin input is high when the SCR.RE bit is 0. The synchronization clock output is started when the SCR.RE bit is set to 1 and the CTSn# pin input is low. After that, if the CTSn# pin input is high on completion of the frame reception, the synchronization clock output is stopped at the high level. If the CTSn# pin input continues to be low, the synchronization clock is stopped at the high level when an overrun error occurs or the SCR.RE bit is set to 0.

18.5.2 CTS and RTS Functions

The CTS function handles transmission/reception and transmission start control with the use of input on the CTSn# pin when the clock source is the internal clock. Setting the SECR.CTSE bit to 1 enables the CTS function.

When the CTS function is enabled, transmission/reception or transmission starts only while the input on the CTSn# pin is at the low level.

Even when the CTSn# pin input is set to the high level after transmission/reception or transmission has started, the frame being received/transmitted or being transmitted is not affected and transmission/reception or transmission continues.

The RTS function makes a request to start transmission/reception, reception, or transmission with the use of output on the RTSn# pin when the clock source is an external synchronizing clock. It outputs a low level when serial communications can be started. Conditions for output of the low and high levels are shown below.

[Conditions for low-level output]

Satisfaction of all conditions listed below

- The value of the RE or TE bit in the SCR is 1
- Neither transmission nor reception is in progress
- There are no received data yet to be read (when the SCR.RE bit is 1)
- Transmit data has been written (when the SCR.TE bit is 1)
- ORER flag in SSR is 0

[Condition for high-level output]

The conditions for low-level output are not satisfied.

18.5.3 SCI Initialization (Clock Synchronous Mode)

Before transmitting and receiving data, start by writing the initial value 00h to the SCR and then continue through the procedure for SCI given in Figure 18.20. Whenever the operating mode or transfer format is changed, the SCR must be initialized before the change is made.

Note that setting the SCR.RE bit to 0 initializes neither the ORER, FER, and PER flags in SSR nor RDR.

Moreover, note that switching the value of the SCR.TE bit from 1 to 0 or 0 to 1 while the SCR.TIE bit is 1 leads to the generation of a TXI interrupt request.

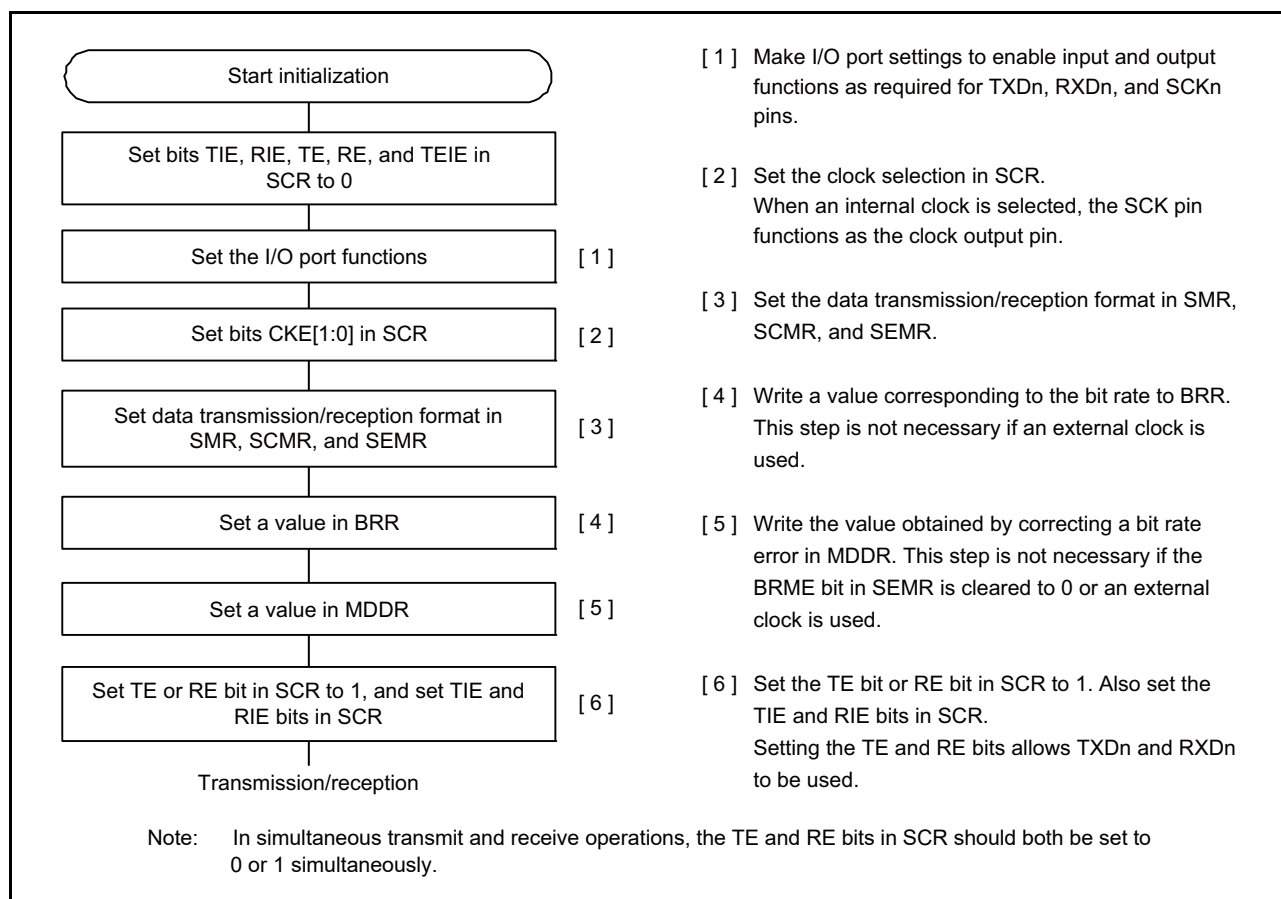

Figure 18.20 Example of SCI Initialization Flowchart (Clock Synchronous Mode)

18.5.4 Serial Data Transmission (Clock Synchronous Mode)

Figure 18.20, Figure 18.21, and Figure 18.22 show an example of the operation for serial transmission in clock synchronous mode.

In serial data transmission, the SCI operates as described below.

1. The SCI transfers data from TDR to TSR when data is written to TDR in the TXI interrupt handling routine. The TXI interrupt request at the beginning of transmission is generated when the TE bit in SCR is set to 1 after the TIE bit in SCR is set to 1 or when these 2 bits are set to 1 simultaneously by a single instruction.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the SCR.TIE bit is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in this TXI interrupt handling routine before transmission of the current transmit data has finished. When TEI interrupt requests are in use, set the SCR.TIE bit to 0 (a TXI interrupt request is disabled) and the SCR.TEIE bit to 1 (a TEI interrupt request is enabled) after the last of the data to be transmitted are written to the TDR from the handling routine for TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when clock output mode has been specified and in synchronization with the input clock when use of an external clock has been specified. Output of the clock signal is suspended until the input CTS signal is at the low level while the CTSE bit in SECR is 1 (CTS function is enabled).
4. The SCI checks for updating of (writing to) the TDR at the time of the last bit output.
5. When TDR is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame is started.
6. If TDR is not updated, set the SSR.TEND flag to 1 and the TXDn pin retains the output state of the last bit. If the TEIE bit in SCR is 1 at this time, a TEI interrupt request is generated. The SCKn pin is held high.

Figure 18.24 shows a sample flowchart of serial data transmission.

Transmission will not start while a receive error flag (ORER, FER, or PER in SSR) is set to 1. Be sure to set the receive error flags to 0 before starting transmission. Note that setting the RE bit in SCR to 0 does not clear the receive error flags.

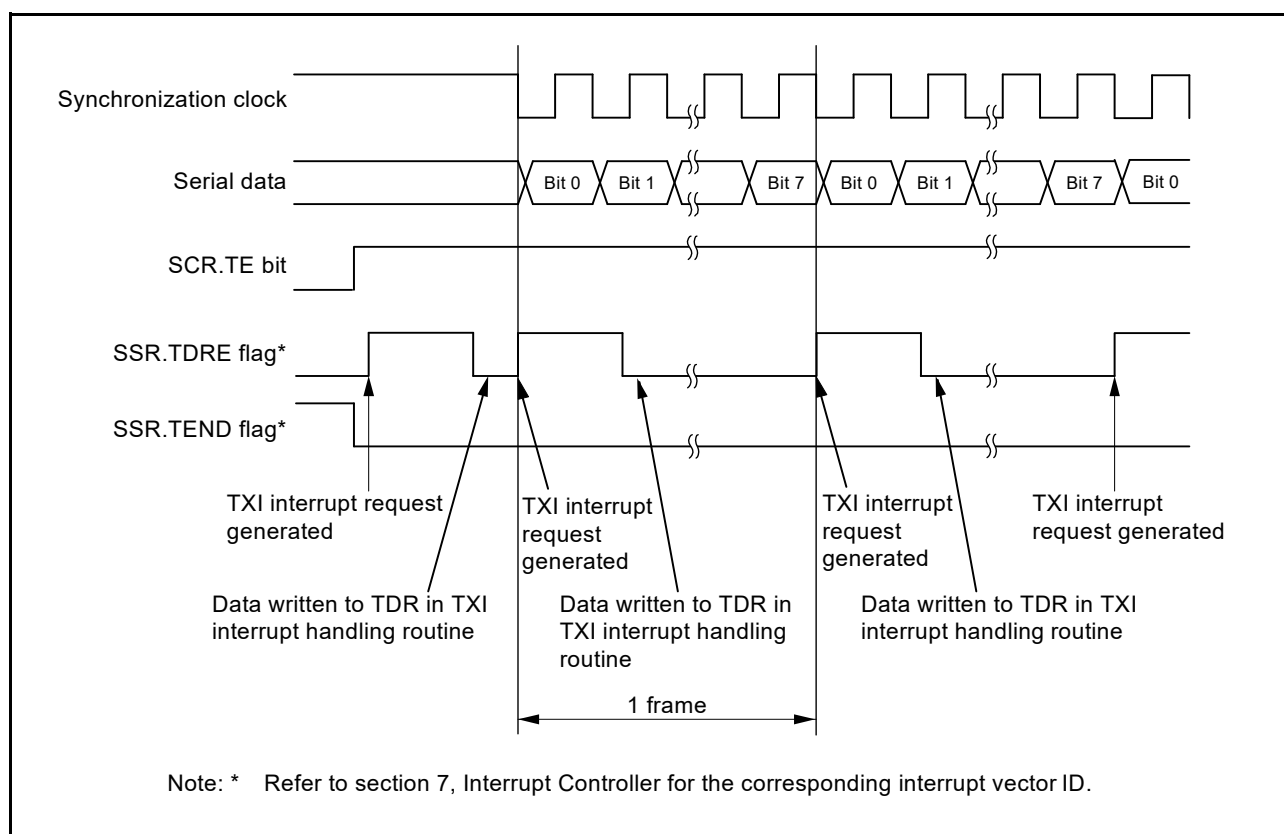

Figure 18.21 Example of Serial Data Transmission in Clock Synchronous Mode (1)
(When the CTS Function is Not Used at the Beginning of Transmission)

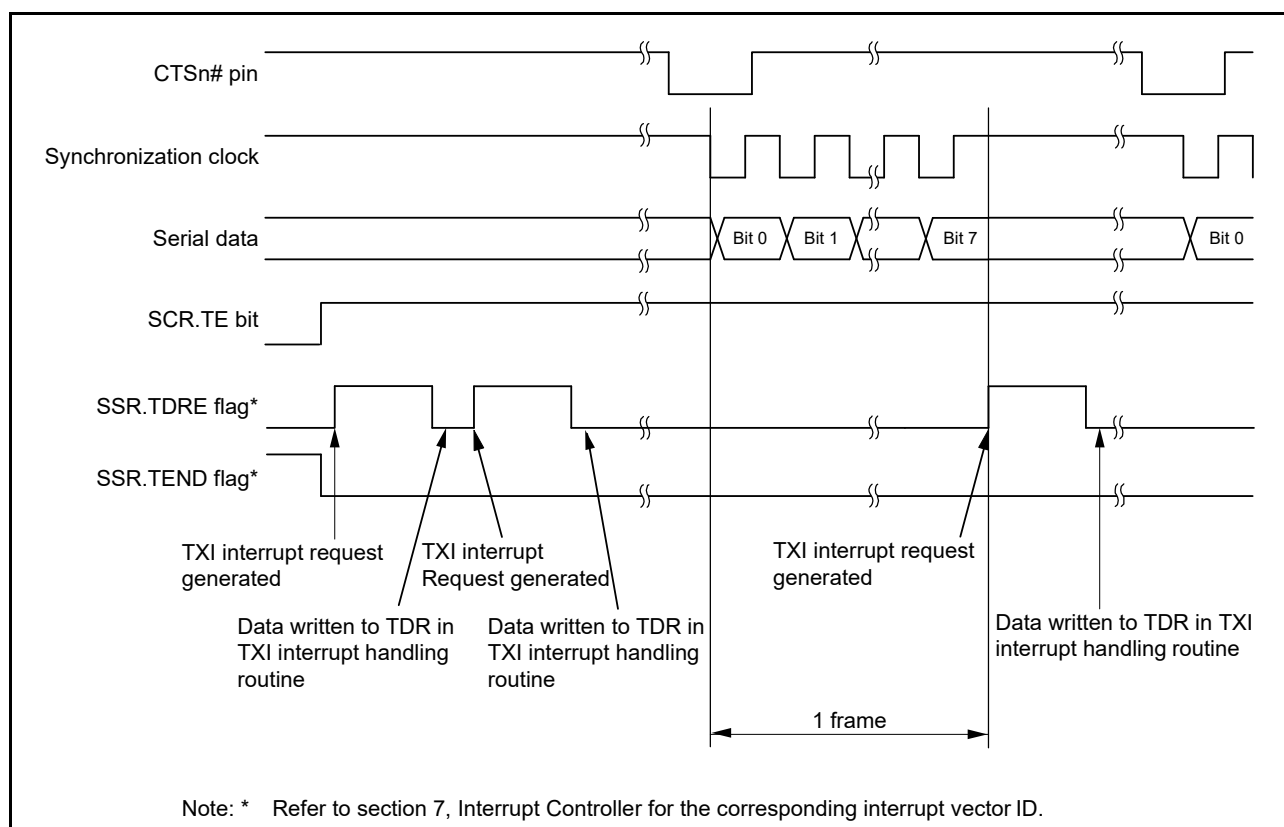

Figure 18.22 Example of Serial Data Transmission in Clock Synchronous Mode (2)
(When the CTS Function is Used at the Beginning of Transmission)

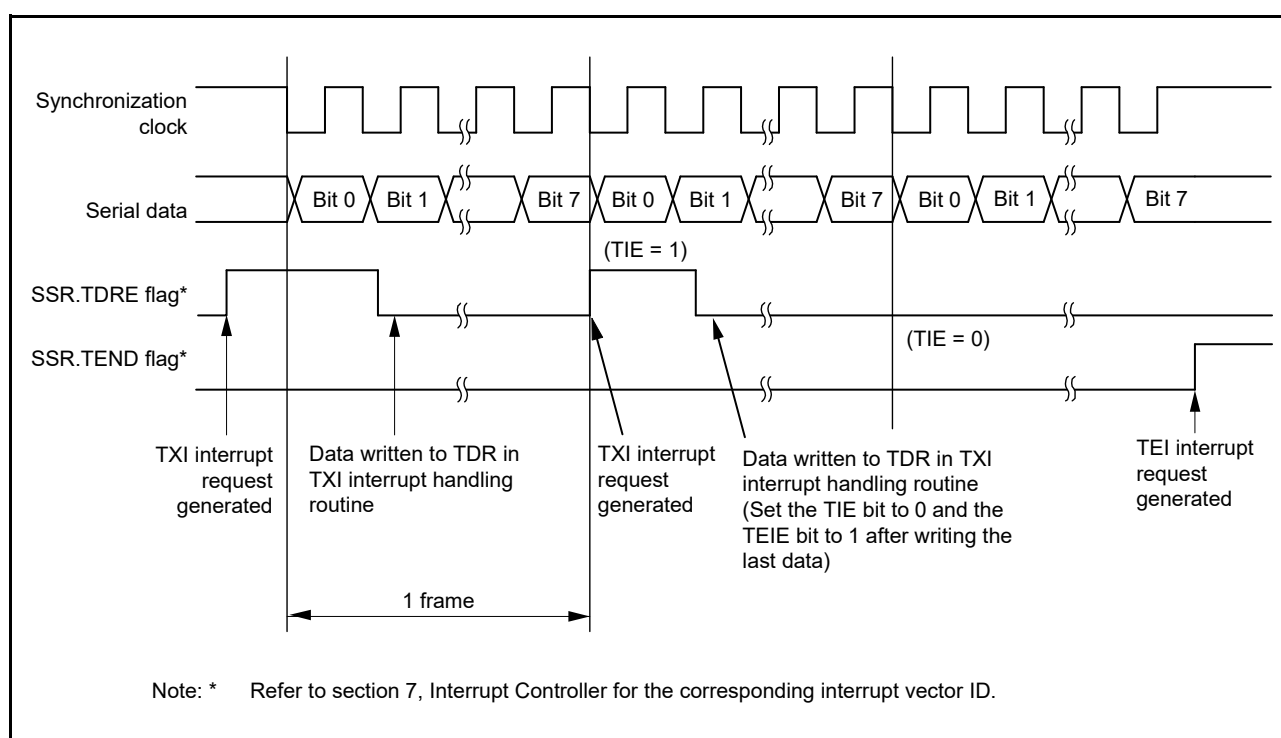

Figure 18.23 Example of Serial Data Transmission in Clock Synchronous Mode (3)
(From the Middle of Transmission until Transmission Completion)

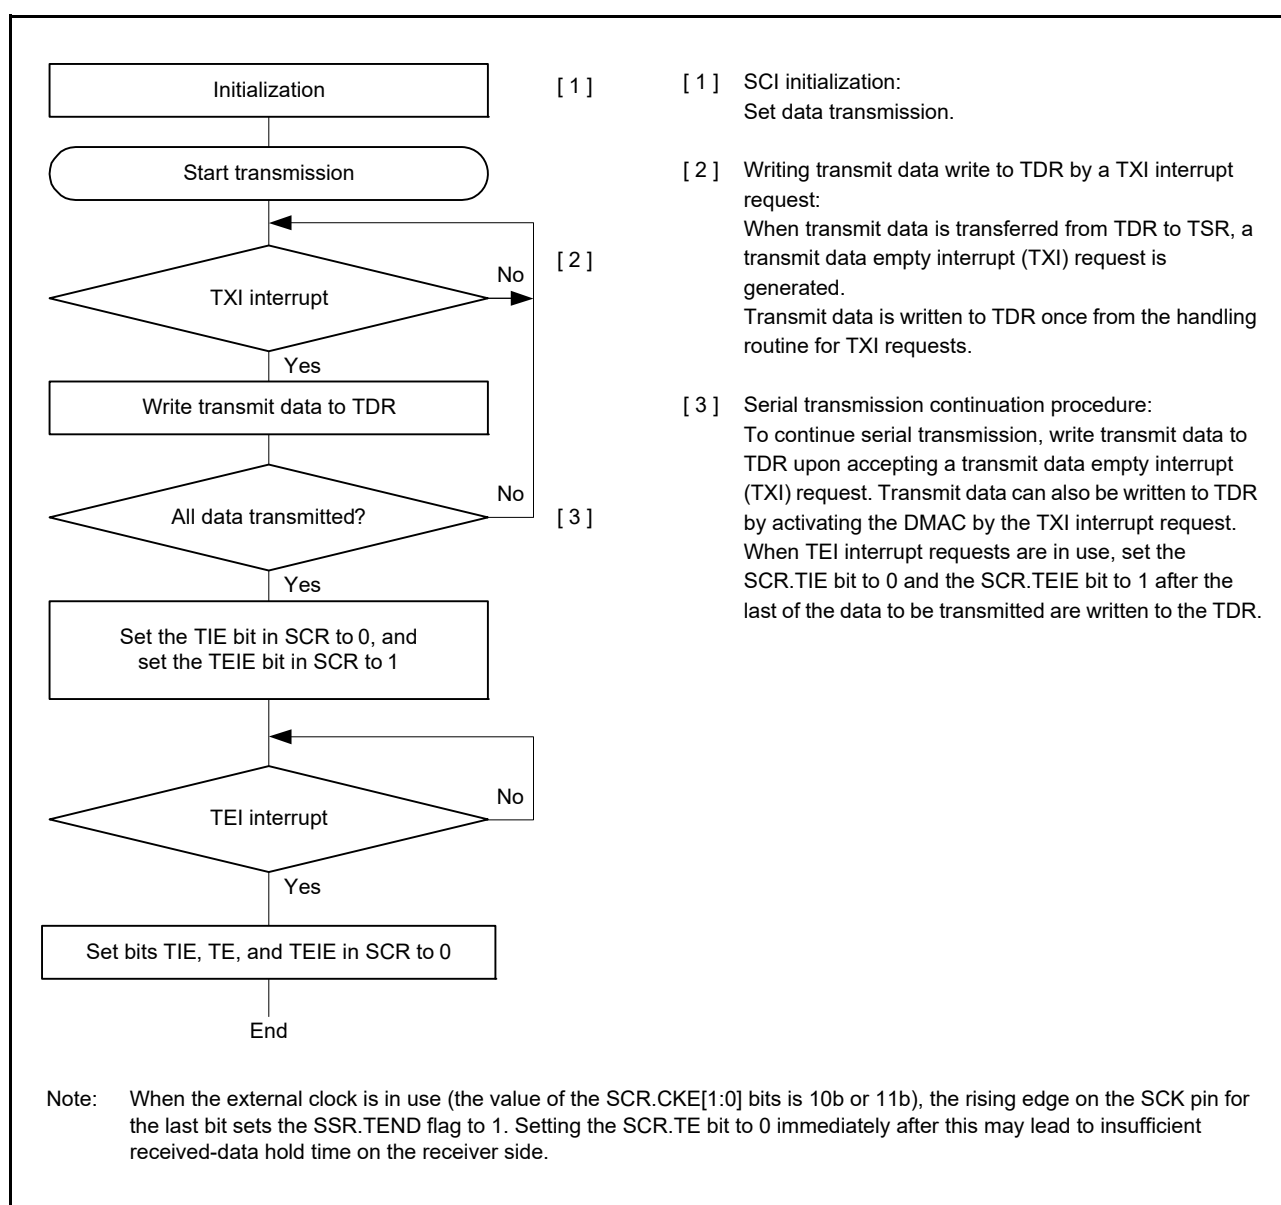

Figure 18.24 Example Flowchart of Serial Transmission in Clock Synchronous Mode

18.5.5 Serial Data Reception (Clock Synchronous Mode)

Figure 18.25 and Figure 18.26 show an example of SCI operation for serial reception in clock synchronous mode. In serial data reception, the SCI operates as described below.

1. The value of the RE bit in SCR becoming 1 places the signal output on the RTSn# pin at the low level (when the RTS function is in use).
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in RSR.
3. If an overrun error occurs, the ORER bit in SSR is set to 1. If the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR.
4. When reception finishes successfully, receive data is transferred to RDR. If the RIE bit in SCR is 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to RDR in this RXI interrupt handling routine before reception of the next receive data is completed. When the received data that have been transferred to RDR are read, the RTSn# pin output is set to the low level (when the RTS function is in use).

If you do not want the RTSn# pin output to be set to the low level following the reception of the last data, set the SCR.RE bit to 0 and dummy read SCR before reading RDR, and then read RDR.

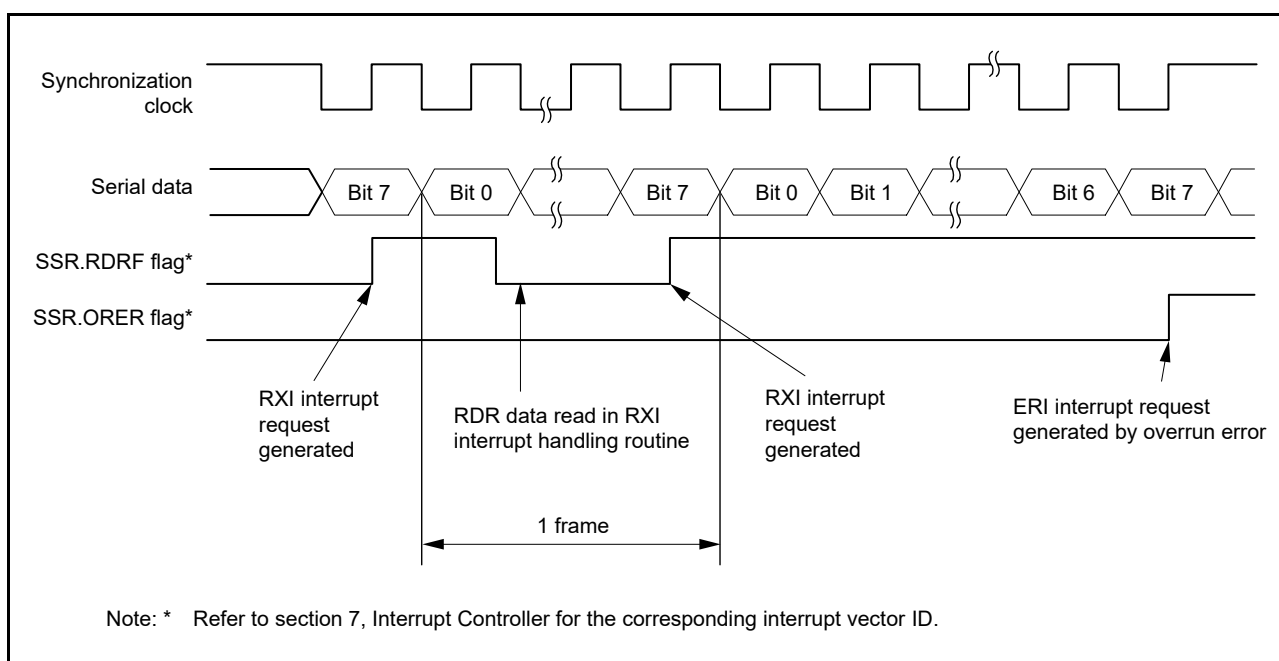

Figure 18.25 Example of Operation for Serial Reception in Clock Synchronous Mode (1)
(When RTS Function is Not Used)

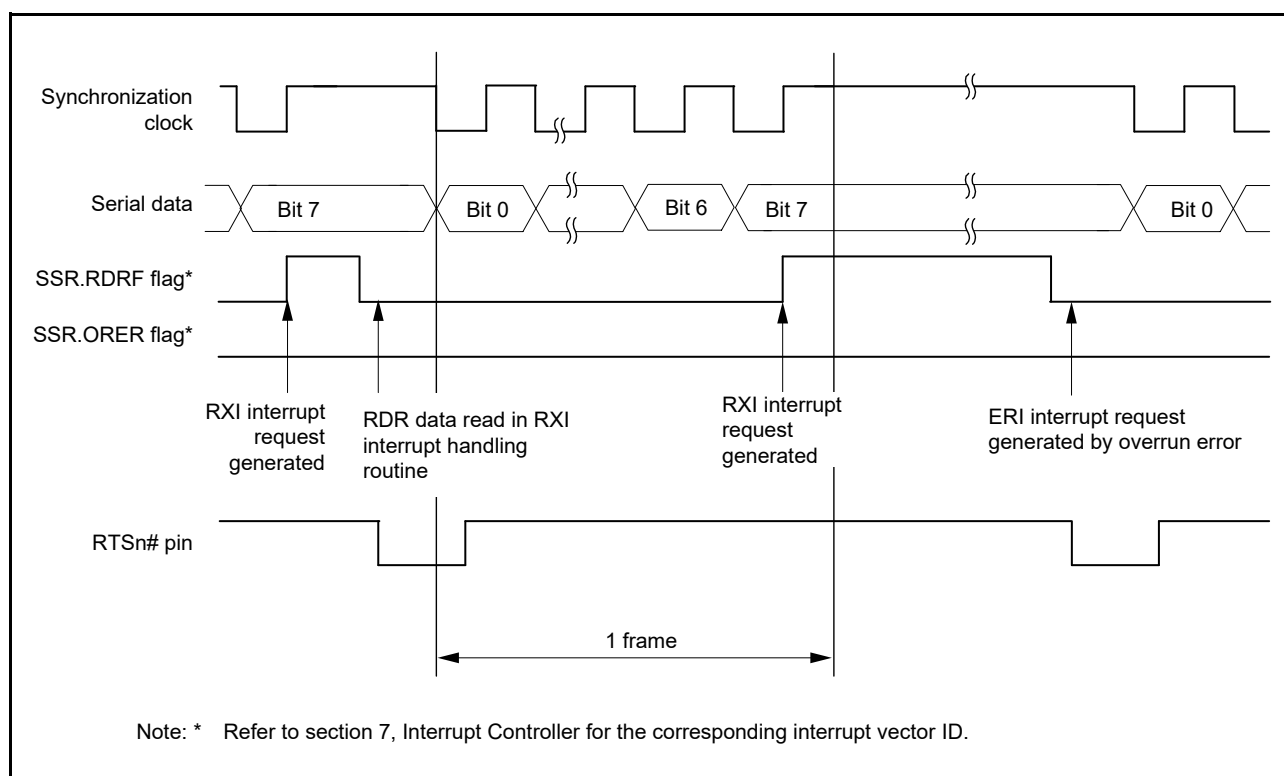

Figure 18.26 Example of Operation for Serial Reception in Clock Synchronous Mode (2)
(When RTS Function is Used)

Data transfer cannot be resumed while a receive error flag is 1. Accordingly, clear the ORER, FER, and PER bits in SSR to 0 before resuming reception. Moreover, be sure to read the RDR during overrun error processing. When a reception is forcibly terminated by setting the SCR.RE bit to 0 during operation, read RDR because received data which has not yet been read may be left in RDR.

Figure 18.27 shows a sample flowchart for serial data reception.

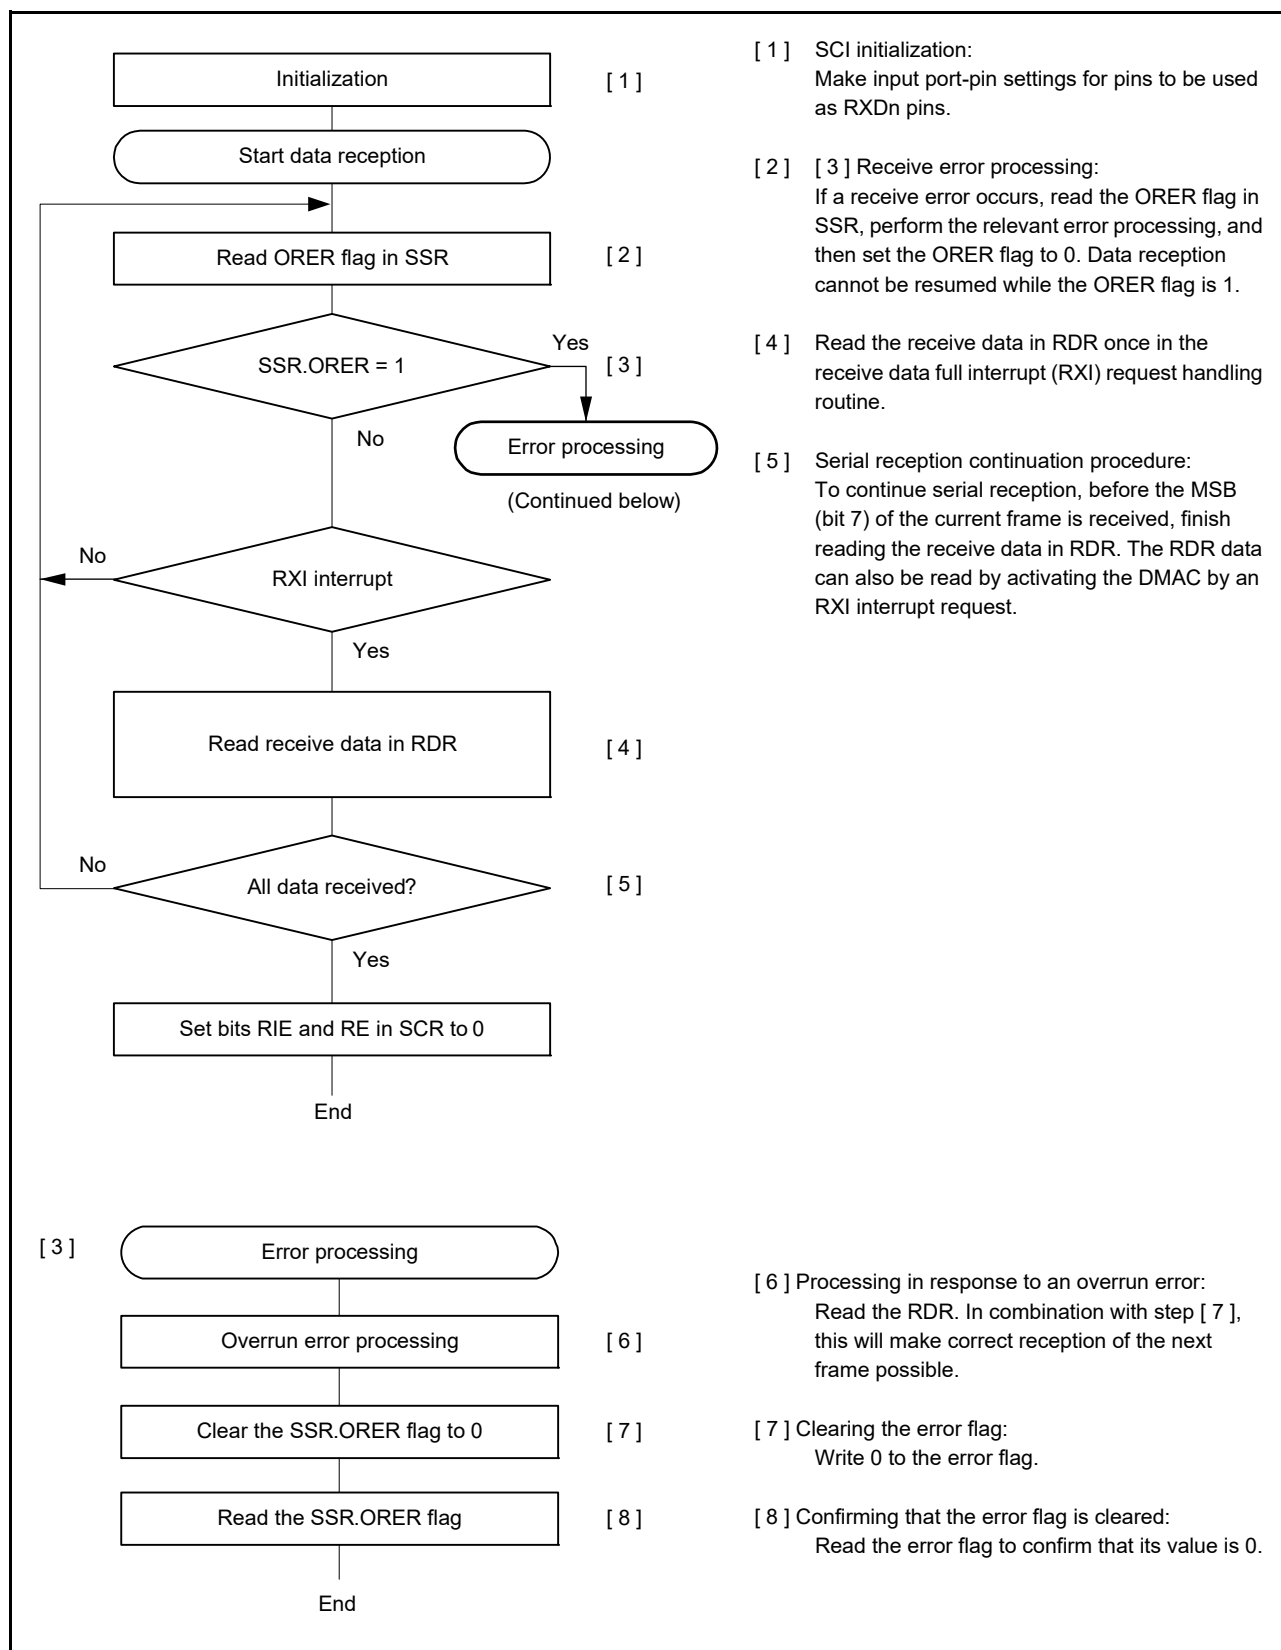

Figure 18.27 Example Flowchart of Serial Reception in Clock Synchronous Mode

18.5.6 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

Figure 18.28 shows a sample flowchart for simultaneous serial transmit and receive operations in clock synchronous mode.

After initializing the SCI, the following procedure should be used for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode, check that the SCI has finished transmission by reading that the TEND flag in SSR is 1, and then initialize the SCR register. Then set the TIE, RIE, TE, and RE bits in SCR to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode, check that the SCI has finished reception, and then set the RIE and RE bits to 0. Then check that the receive error flags (ORER, FER, and PER in SSR) are 0, and then set the TIE, RIE, TE, and RE bits in SCR to 1 simultaneously by a single instruction.

When the RTS function is in use in simultaneous transmit and receive operations, if you do not want the RTSn# pin output to be set to the low level following the reception of the last data as in the case of reception, set the SCR.RE and TE bits to 0 at the same time and dummy read SCR before reading RDR, and then read RDR.

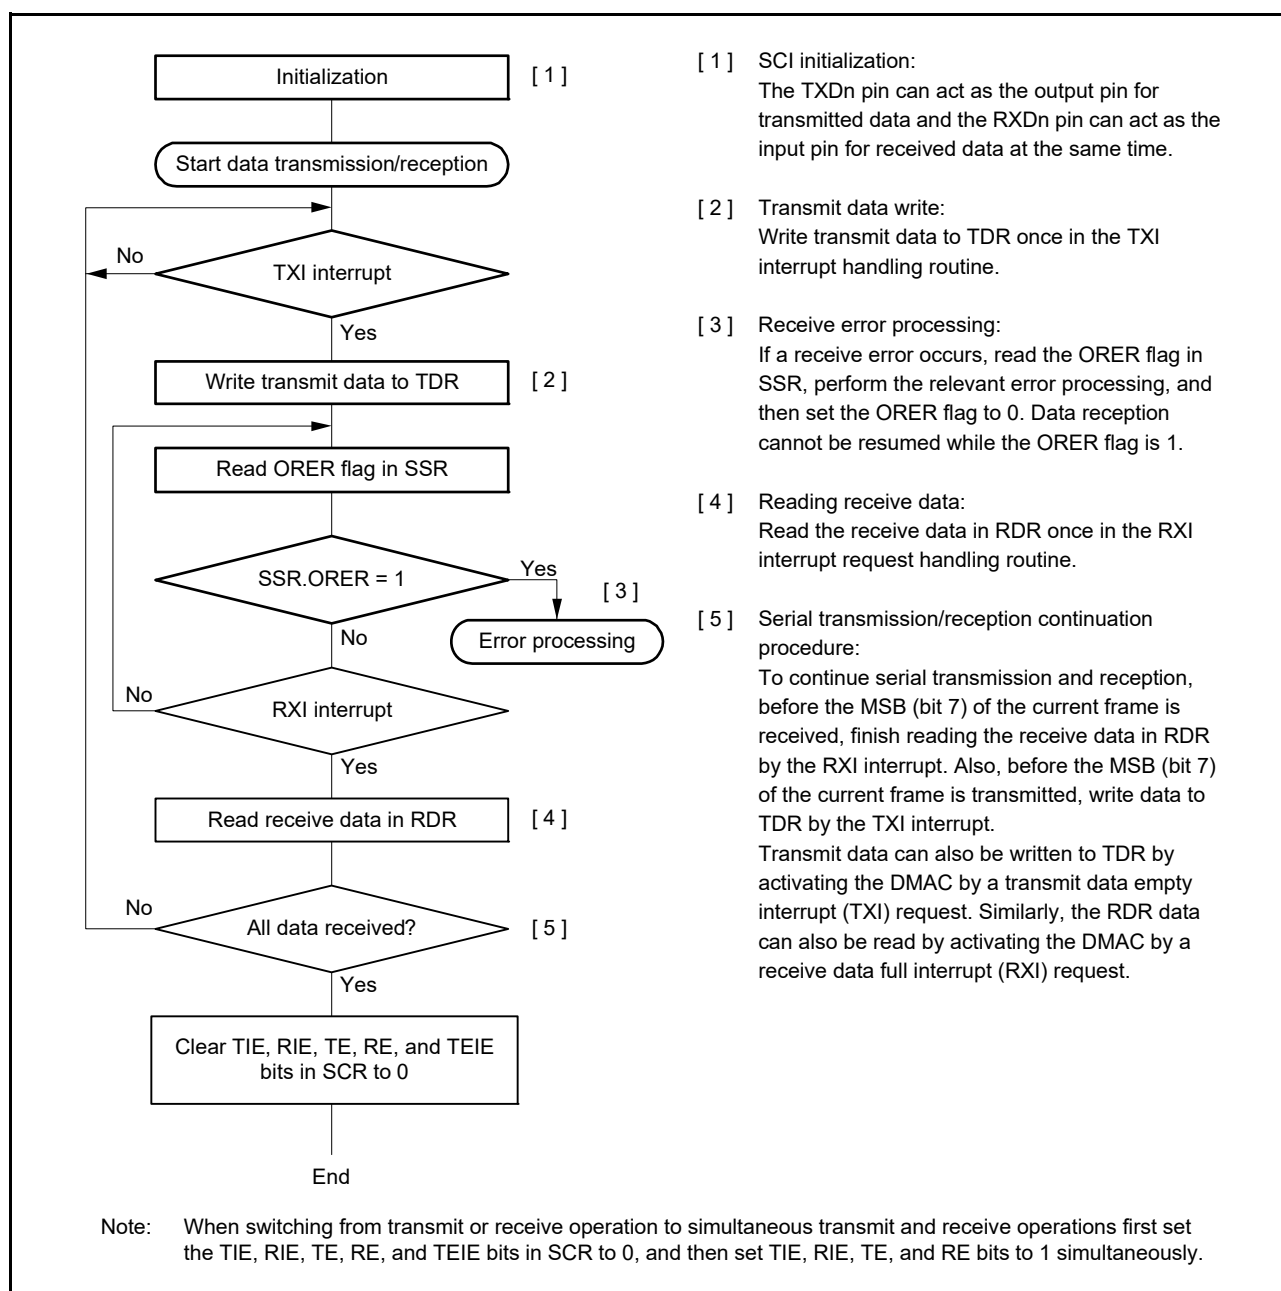

Figure 18.28 Example Flowchart of Simultaneous Serial Transmission and Reception in Clock Synchronous Mode

18.6 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

18.6.1 Sample Connection

Figure 18.29 shows a sample connection between a smart card (IC card) and this MCU.

As in the figure, since this MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the TE and RE bits in SCR to 1 with an IC card disconnected enables closed transmission/reception allowing self-diagnosis.

To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card. The output port of the this MCU can be used to output a reset signal.

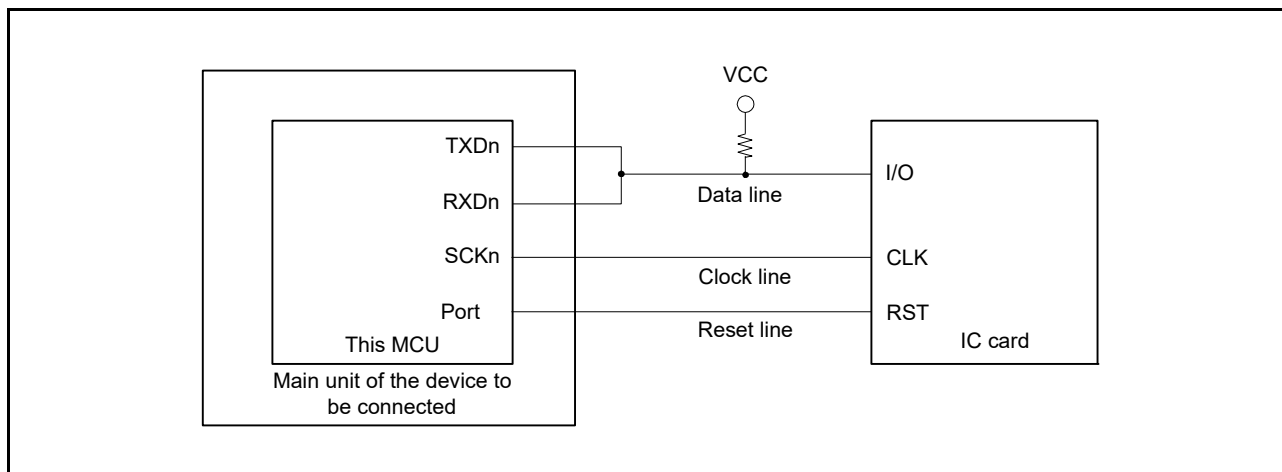

Figure 18.29 Sample Connection with a Smart Card (IC Card)

18.6.2 Data Format (Except in Block Transfer Mode)

Figure 18.30 shows the data transfer formats in smart card interface mode.

- One frame consists of 8-bit data and a parity bit in asynchronous mode.
- During transmission, at least 2 etu (elementary time unit: time required for transferring 1 bit) is secured as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low-level error signal is output for 1 etu after 10.5 etu has passed from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etu.

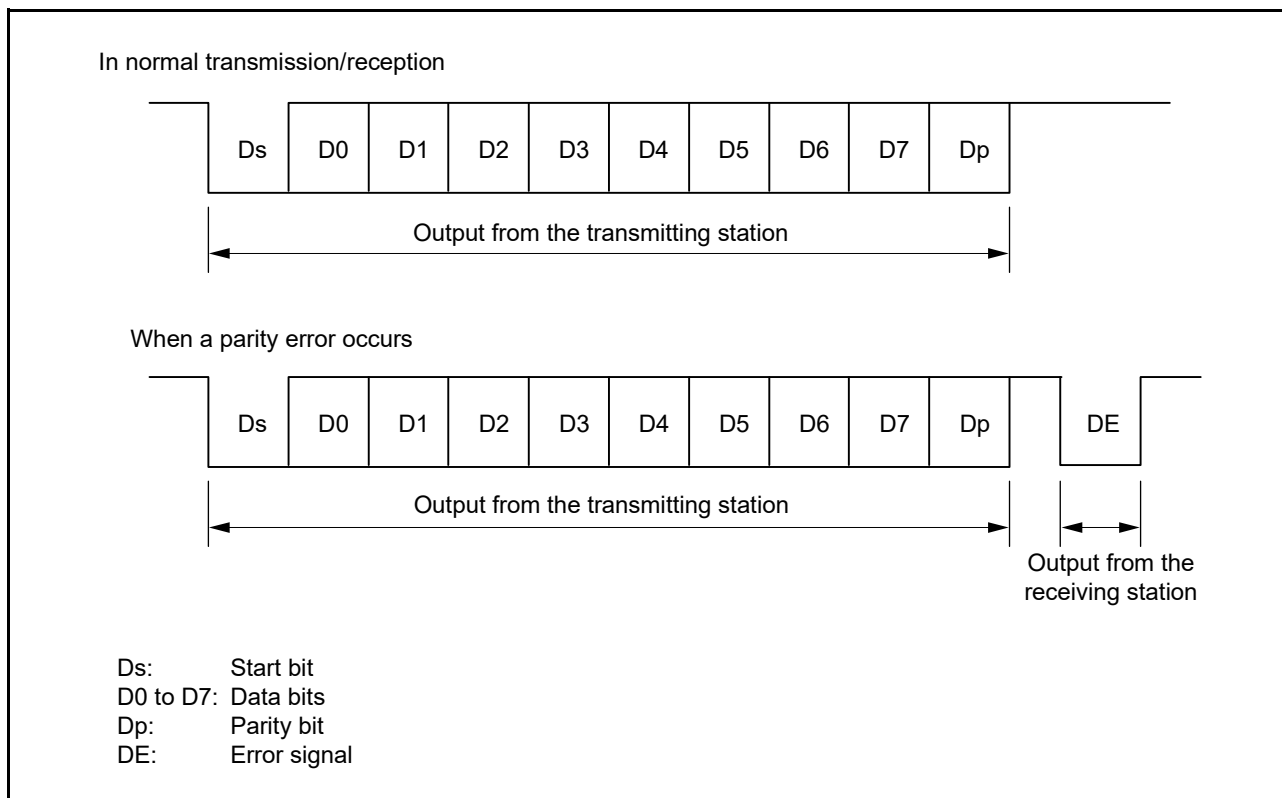

Figure 18.30 Data Formats in Smart Card Interface Mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedure below.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 correspond to states Z and A, respectively, and data is transferred with LSB first as the start character, as shown in Figure 18.31. Therefore, data in the start character in the figure is 3Bh.

When using the direct convention type, write 0 to both the SDIR and SINV bits in SCMR. Write 0 to the PM bit in SMR in order to use even parity, which is prescribed by the smart card standard.

Figure 18.31 Direct Convention (SDIR in SCMR = 0, SINV in SCMR = 0, PM in SMR = 0)

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 correspond to states A and Z, respectively and data is transferred with MSB first as the start character, as shown in Figure 18.32. Therefore, data in the start character in the figure is 3Fh. When using the inverse convention type, write 1 to both the SDIR and SINV bits in SCMR. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to state Z. Since the SINV bit of the this MCU only inverts data bits D7 to D0, write 1 to the PM bit in SMR to invert the parity bit for both transmission and reception.

Figure 18.32 Inverse Convention (SDIR in SCMR = 1, SINV in SCMR = 1, PM in SMR = 1)

18.6.3 Block Transfer Mode

Block transfer mode is different from normal smart card interface mode in the following respects.

- Even if a parity error is detected during reception, no error signal is output. Since the PER bit in SSR is set by error detection, clear the PER bit before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is secured as a guard time from the end of the parity bit until the start of the next frame.
- Since the same data is not retransmitted during transmission, the TEND flag in SSR is set 11.5 etu after transmission start.
- In block transfer mode, the ERS flag in SSR indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred.

18.6.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate according to the settings of the BCP2 bit in SCMR and the BCP[1:0] bits in SMR (the frequency is always 16 times the bit rate in normal asynchronous mode).

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization. Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 18.33. The reception margin here is determined by the following formula.

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100 [\%]$$

M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, 256)

D: Duty cycle of clock (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the above formula, the reception margin is determined by the formula below.

$$M = \{0.5 - 1/(2 \times 372)\} \times 100 [\%] = 49.866\%$$

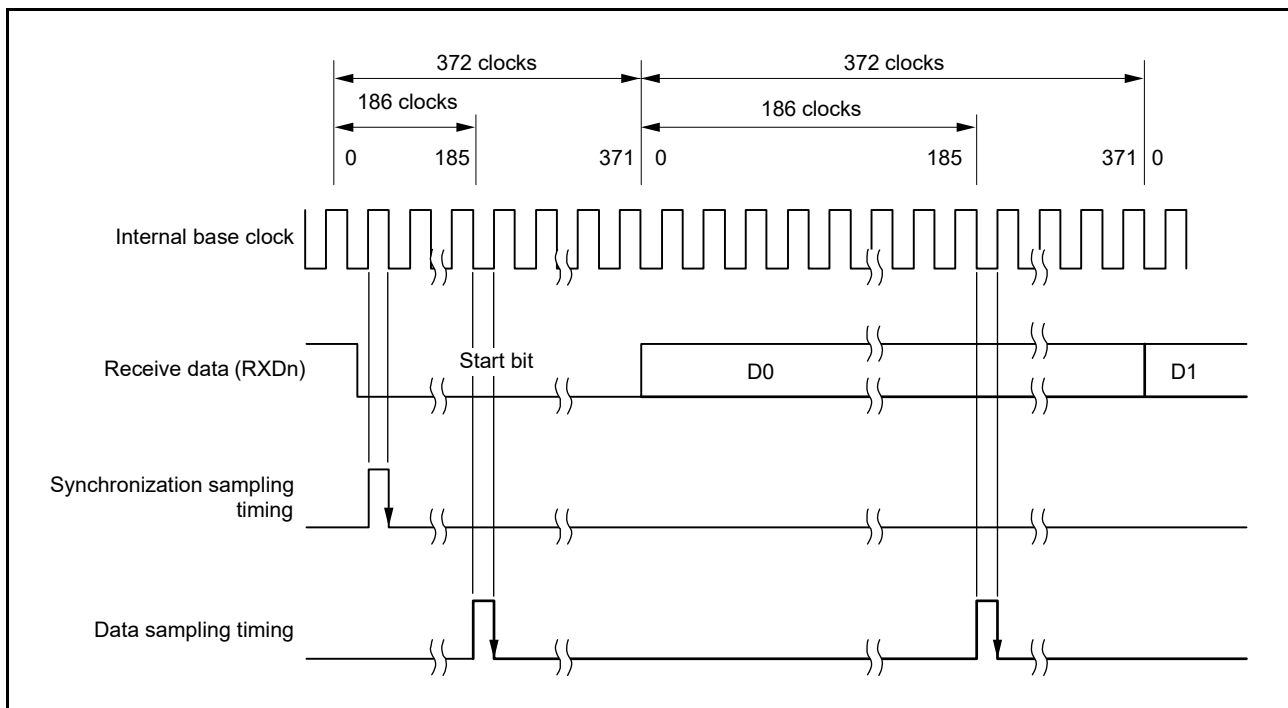

Figure 18.33 Receive Data Sampling Timing in Smart Card Interface Mode
(When Clock Frequency is 372 Times the Bit Rate)

18.6.5 SCI Initialization (Smart Card Interface Mode)

Initialize the SCI following the example of flowchart shown in Figure 18.34.

Be sure to initialize the SCI before switching from transmission mode to reception mode and vice versa. Even if the RE bit is set to 0, the RDR register is not initialized.

To change reception mode to transmission mode, first check that reception has completed, and then initialize the SCI. At the end of initialization, set TE = 1 and RE = 0. Reception completion can be verified by reading the RXI request, ORER, or PER flag in SSR.

To change transmission mode to reception mode, first check that transmission has completed, and then initialize the SCI. At the end of initialization, set TE = 0 and RE = 1. Transmission completion can be verified by reading the TEND flag in SSR.

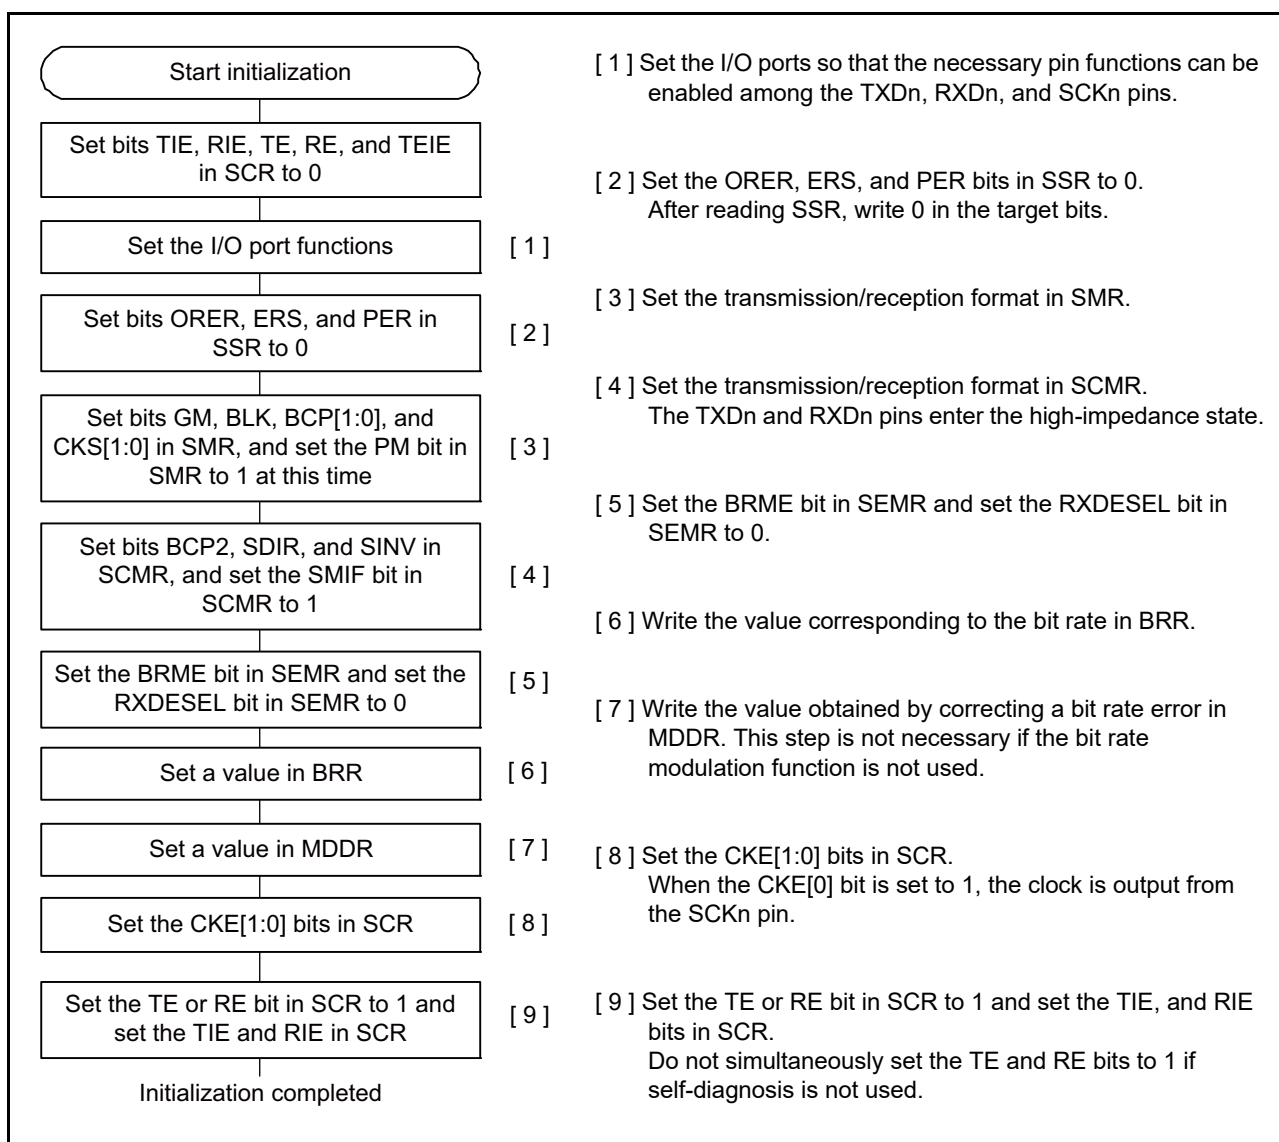

Figure 18.34 Example of SCI Initialization Flowchart (Smart Card Interface Mode)

18.6.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode), in that an error signal is sampled and data can be retransmitted, is different from that in non-smart card interface mode. Figure 18.35 shows the data retransfer operation during transmission.

1. When an error signal from the receiver end is sampled after one-frame data has been transmitted, the ERS flag in SSR is set to 1. If the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.
2. For a frame in which an error signal is received, the TEND flag in SSR is not set. Data is retransferred from TDR to TSR allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI judges that transmission of one-frame data (including retransfer) has been completed, and the TEND flag is set. If the TIE bit in SCR is 1 at this time, a TXI interrupt request is generated. Writing transmit data to TDR starts transmission of the next data.

Figure 18.37 shows a sample flowchart of serial transmission. All the processing steps are automatically performed using a TXI interrupt request to activate the DMAC.

When the TEND flag in SSR is set to 1 in transmission, if the TIE bit in SCR is 1, a TXI interrupt request is generated. The DMAC is activated by a TXI interrupt request if the TXI interrupt request is specified as a source of DMAC activation beforehand, allowing transfer of transmit data. The TEND flag is automatically set to 0 when the DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept to 0 and the DMAC is not activated. Therefore, the SCI and DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, since the ERS flag is not automatically cleared, set the RIE bit to 1 beforehand to enable an ERI interrupt request to be generated at error occurrence, and clear the ERS flag to 0. When transmitting/receiving data using the DMAC, be sure to make settings to enable the DMAC before making SCI settings.

For DMAC settings, refer to section 9, Direct Memory Access Controller.

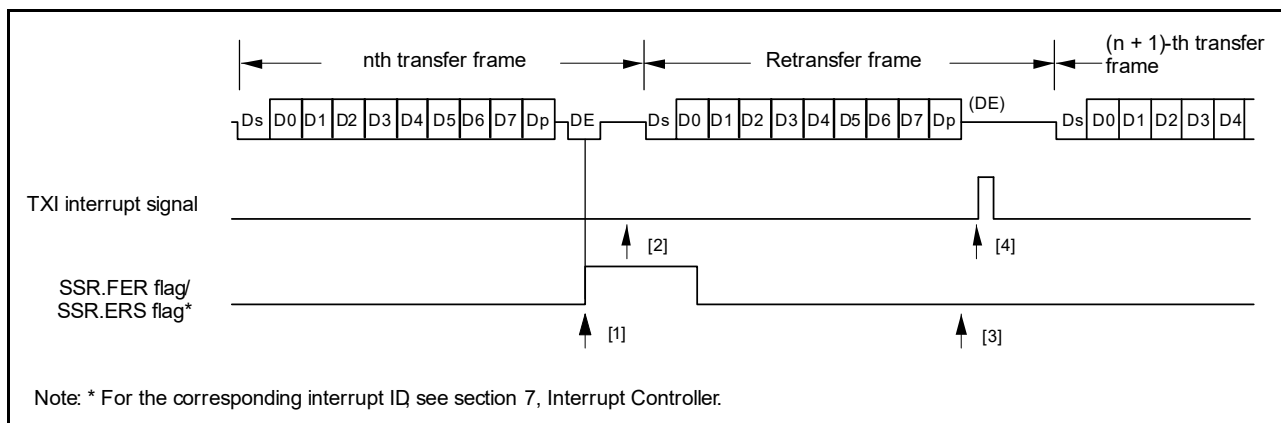

Figure 18.35 Data Retransfer Operation in SCI Transmission Mode

Note that the SSR.TEND flag is set in different timings depending on the GM bit setting in SMR. Figure 18.36 shows the TEND flag generation timing.

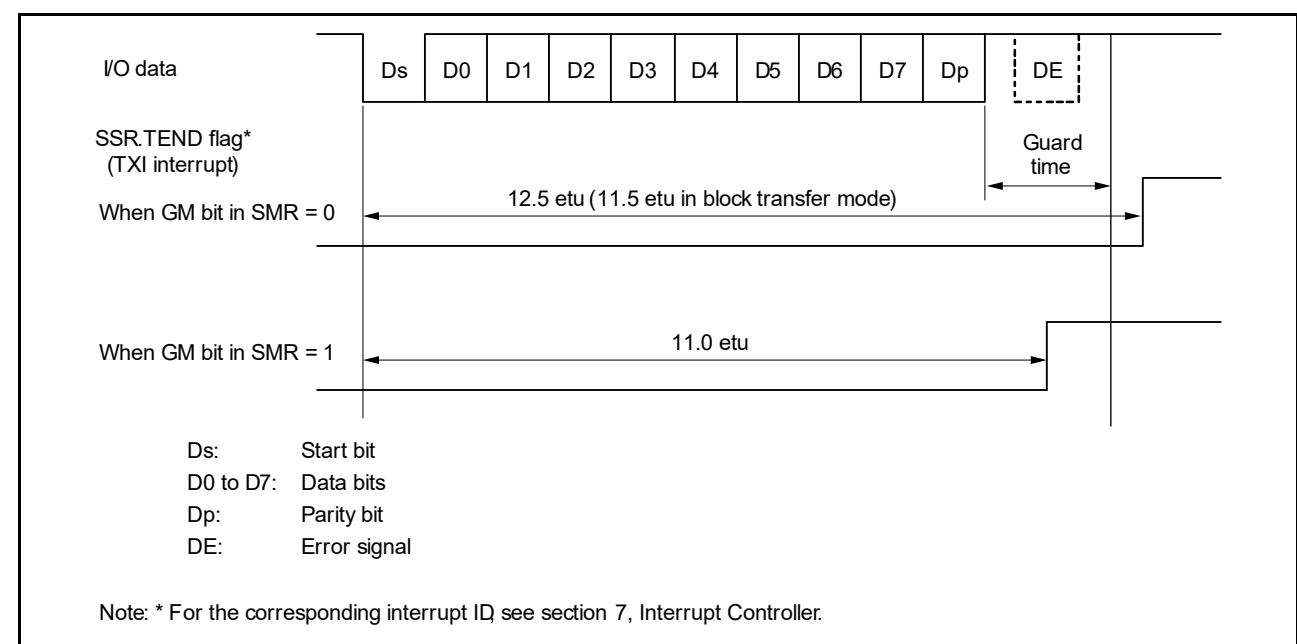

Figure 18.36 SSR.TEND Flag Generation Timing during Transmission

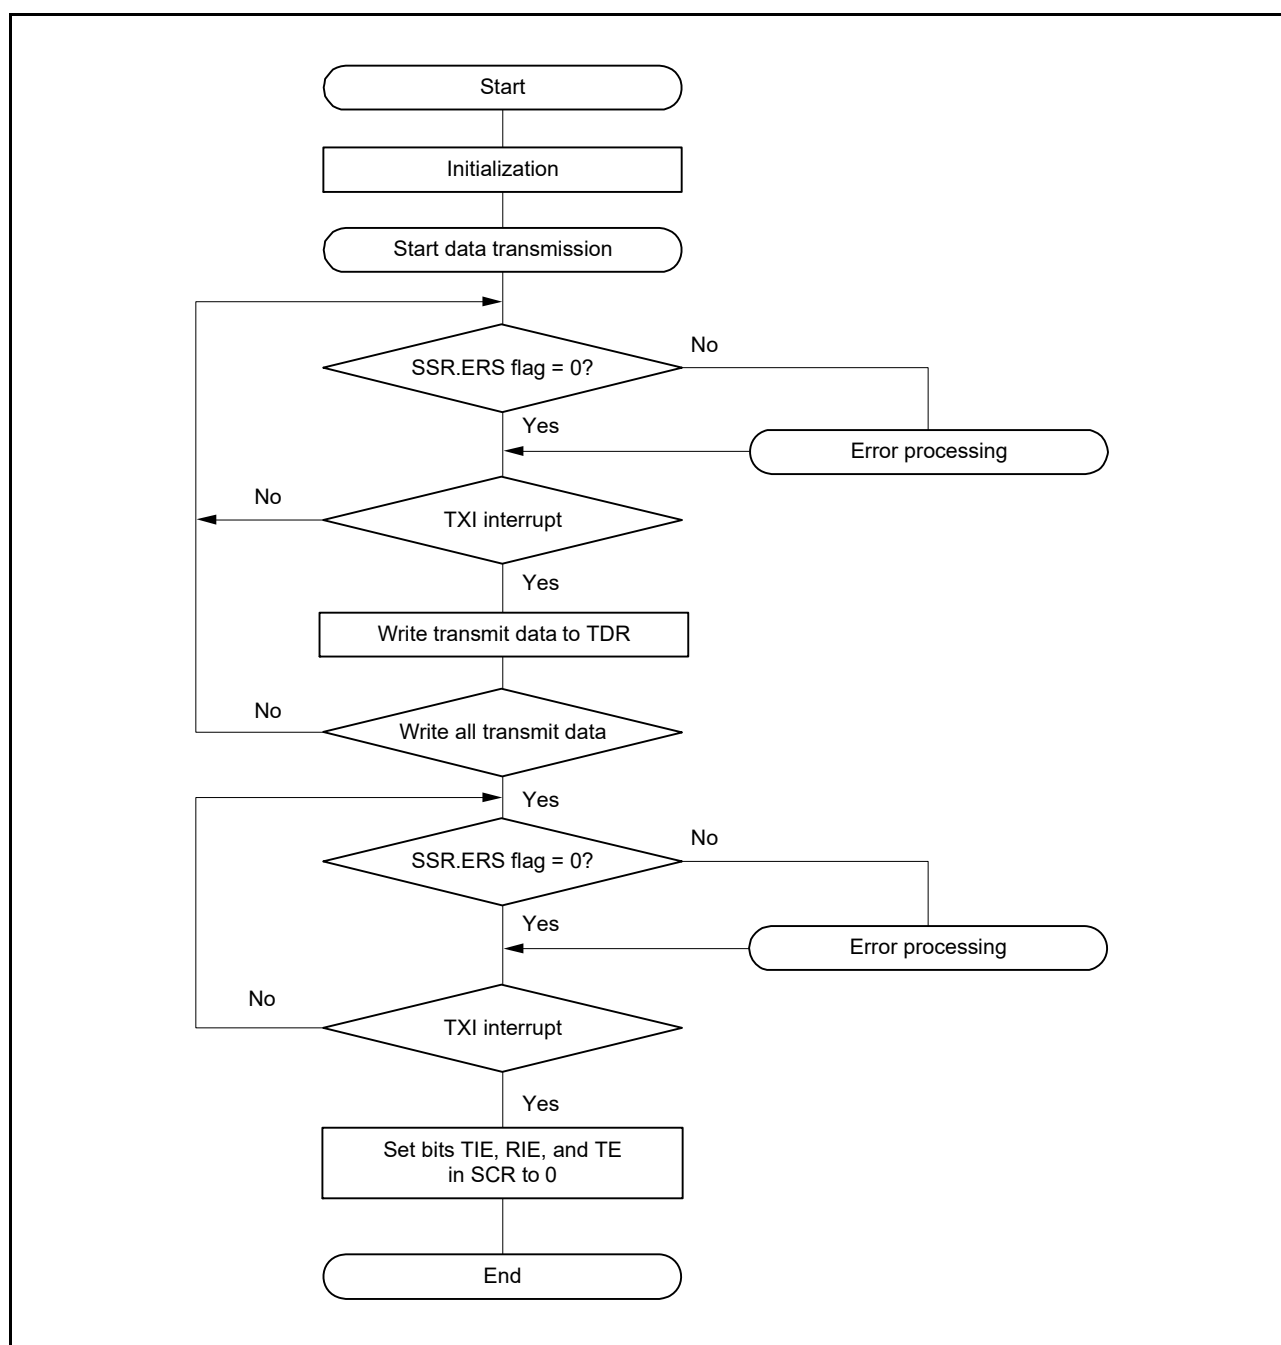

Figure 18.37 Sample Smart Card Interface Transmission Flowchart

18.6.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. Figure 18.38 shows the data retransfer operation in reception mode.

1. If a parity error is detected in receive data, the PER flag in SSR is set to 1. When the RIE bit in SCR is 1 at this time, an ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no RXI interrupt is generated.
3. When no parity error is detected, the PER flag in SSR is not set to 1.
4. In this case, data is determined to have been received successfully. When the RIE bit in SCR is 1, an RXI interrupt request is generated.

Figure 18.39 shows a sample flowchart for serial data reception. All the processing steps are automatically performed using an RXI interrupt request to activate the DMAC.

In reception, setting the RIE bit to 1 allows an RXI interrupt request to be generated. The DMAC is activated by an RXI interrupt request if the RXI interrupt request is specified as a source of DMAC activation beforehand, allowing transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in SSR is set to 1, a receive error interrupt (ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DMAC is transferred.

Even if a parity error occurs and the PER flag is set to 1 during reception, receive data is transferred to RDR, thus allowing the data to be read.

When a reception is forcibly terminated by setting the RE bit in SCR to 0 during operation, read the RDR register because the received data which has not yet been read may be left in RDR.

Note 1. For operations in block transfer mode, refer to section 18.3, Operation in Asynchronous Mode.

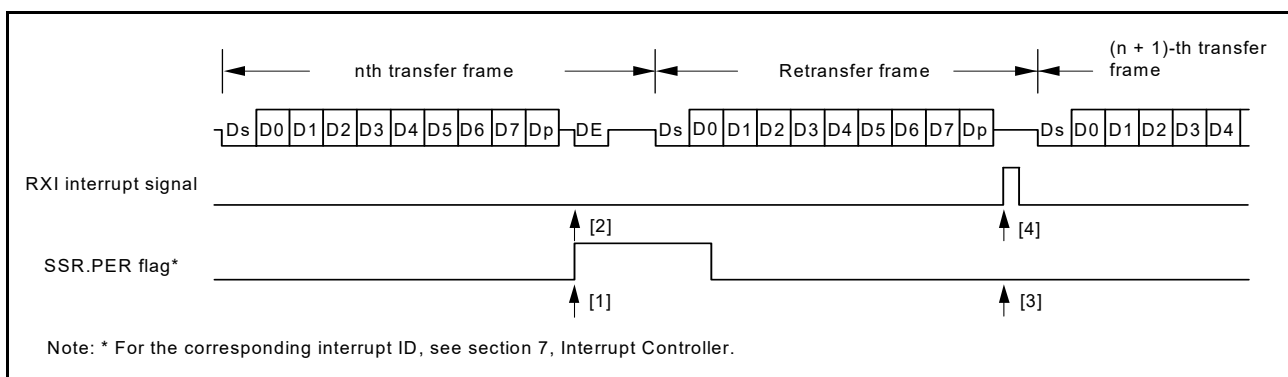

Figure 18.38 Data Retransfer Operation in SCI Reception Mode (Data Retransfer Operation during Reception)

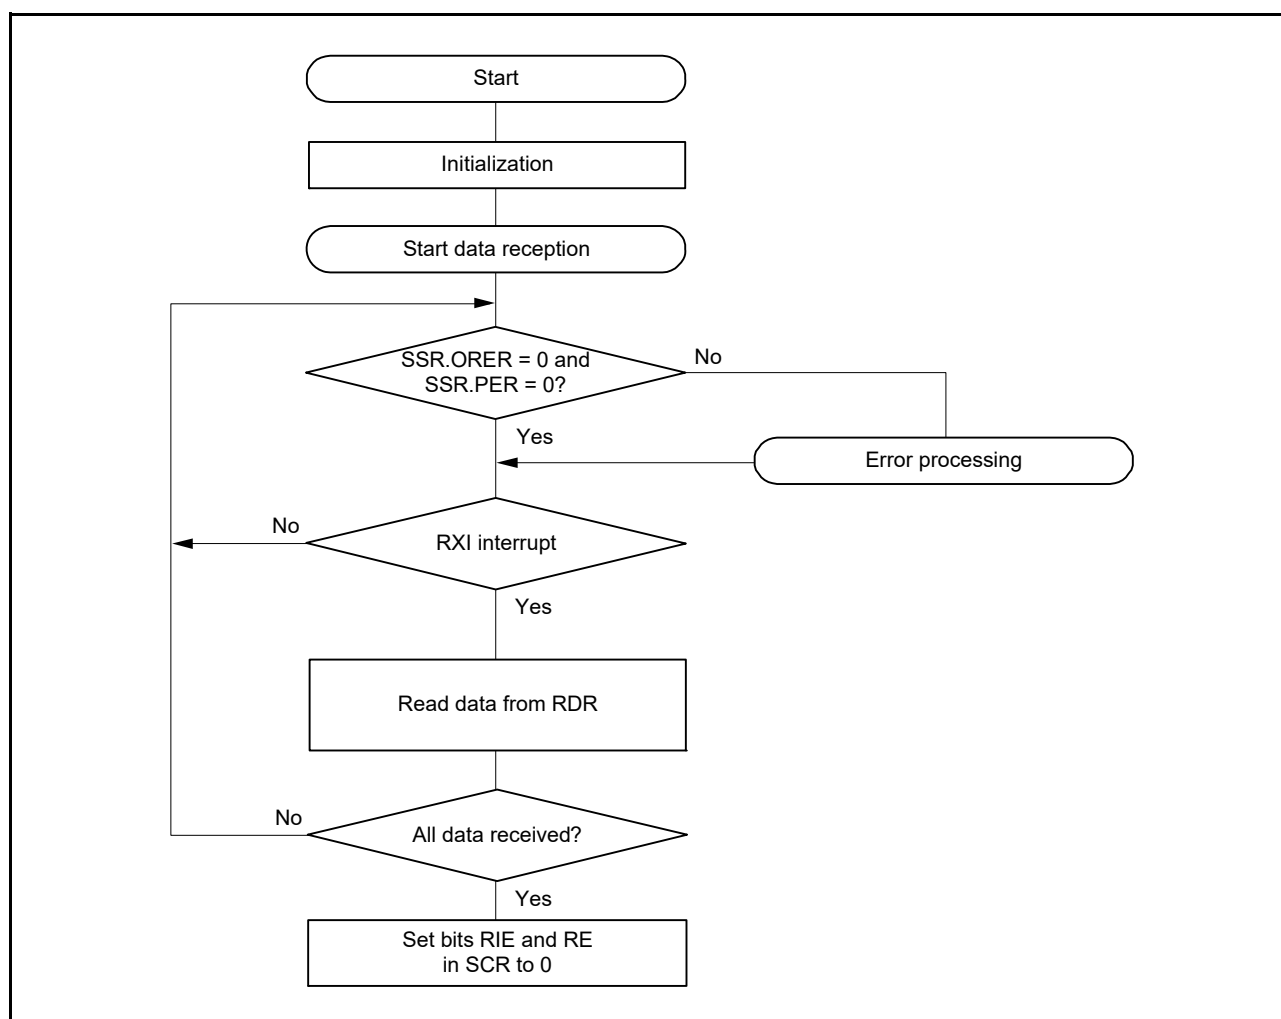

Figure 18.39 Sample Smart Card Interface Reception Flowchart

18.6.8 Clock Output Control

Clock output can be fixed using the CKE[1:0] bits in SCR when the GM bit in SMR is 1. Specifically, the minimum width of a clock pulse can be specified.

Figure 18.40 shows an example of clock output fixing timing when the CKE[0] bit is controlled with GM = 1 and CKE[1] = 0.

Figure 18.40 Clock Output Fixing Timing

At power-on, use the following procedure to secure the appropriate clock duty cycle.

(1) At Power-On

To secure the appropriate clock duty cycle simultaneously with power-on, use the following procedure.

1. Initially, port input is enabled in the high-impedance state. To fix the potential level, use a pull-up or pull-down resistor.
2. Fix the SCKn pin to the specified output by setting the SCR.CKE[1] bit and I/O port functions.
3. Set SMR and SCMR to enable smart card interface mode.
4. Set the SCR.CKE[0] bit to 1 to start clock output.

18.7 Noise Cancellation Function

Figure 18.41 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of two stages of flip-flop circuits and a match-detection circuit. When the level on the pin matches in three consecutive samples taken at the set sampling interval, the matching level continues to be conveyed internally until the level on the pin again matches in three consecutive samples.

In asynchronous mode, the noise cancellation function can be applied on the RXDn input signal. The period of the base clock (1/16th of a bit-period when SEMR.ABCS = 0 and 1/8th of a bit-period when SEMR.ABCS = 1) is the sampling interval.

If the base clock is stopped with the noise filter enabled and then the clock input is started again, the noise filter operation resumes from where the clock was stopped. If SCR.TE and SCR.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, it is determined that a level match is detected and is conveyed to the internal signal. When the level being input corresponds to 0, the initial output of the noise filter is retained until the level matches in three consecutive samples.

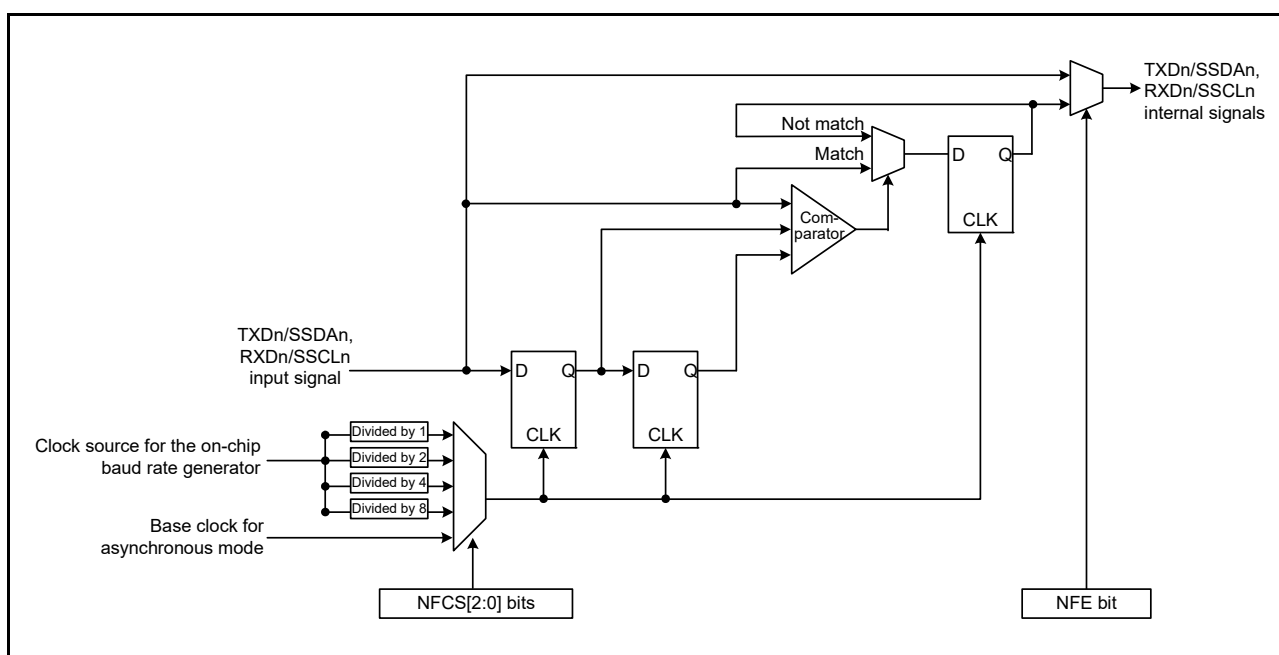

Figure 18.41 Block Diagram of Digital Noise Filter Circuit

18.8 Interrupt Sources

18.8.1 Interrupts in Asynchronous Mode and Clock Synchronous Mode

Table 18.20 lists interrupt sources in asynchronous mode and clock synchronous mode. A different interrupt vector is assigned to each interrupt source, and individual interrupt sources can be enabled or disabled with the enable bits in SCR. If the SCR.TIE bit is 1, a TXI interrupt request is generated when transmit data is transferred from the TDR or TDRL register*¹ to the TSR. A TXI interrupt request can also be generated by setting the SCR.TE bit to 1 after setting the SCR.TIE bit to 1 or by using a single instruction to set the SCR.TE and SCR.TIE bit to 1 at the same time. A TXI interrupt request can activate the DMAC to handle data transfer.

A TXI interrupt request is not generated by setting the SCR.TE bit to 1 while the setting of the SCR.TIE bit is 0 or by setting the SCR.TIE bit to 1 while the setting of the SCR.TE bit is 1.*¹

When new data is not written by the time of transmission of the last bit of the current transmit data and the setting of the SCR.TEIE bit is 1, the SSR.TEND flag becomes 1 and a TEI interrupt request is generated. Furthermore, when the setting of the SCR.TE bit is 1, the SSR.TEND flag retains the value 1 until further transmit data are written to the TDR or TDRL register*¹, and setting the SCR.TEIE bit to 1 leads to the generation of a TEI interrupt request.

Writing data to the TDR or TDRL register*¹ leads to clearing of the SSR.TEND flag and, after a certain time, discarding of the TEI interrupt request.

If the SCR.RIE bit is 1, an RXI interrupt request is generated when received data is stored in the RDR. An RXI interrupt request can activate the DMAC to handle data transfer.

Setting of any from among the ORER, FER, and PER flags in the SSR to 1 while the SCR.RIE bit is 1 leads to the generation of an ERI interrupt request. An RXI interrupt request is not generated at this time. Clearing all three flags (ORER, FER, and PER) leads to discarding of the ERI interrupt request.

Note 1. In the case where asynchronous mode and 9-bit data length are selected

Note 2. To temporarily prohibit TXI interrupts at the time of transmission of the last of the data and so on when you wish a new round of transmission to start after handling of the transmission-completed interrupt, control prohibiting and permitting of the interrupt by using the interrupt request enable bit in the interrupt controller rather than using the SCR.TIE bit. This can prevent the suppression of TXI interrupt requests in the transfer of new data.

Table 18.20 Interrupt Sources

| Name | Interrupt Source | Interrupt Flag | DMAC Activation | Priority |
|------|---------------------|-------------------|-----------------|----------|
| ERI | Receive error | ORER, FER, or PER | Not possible | High |
| RXI | Receive data full | — | Possible | ↑ Low |
| TXI | Transmit data empty | — | Possible | |
| TEI | Transmit end | TEND | Not possible | |

18.8.2 Interrupts in Smart Card Interface Mode

Table 18.21 lists interrupt sources in smart card interface mode. A transmit end interrupt (TEI) request cannot be used in this mode.

Table 18.21 SCI Interrupt Sources

| Name | Interrupt Source | Interrupt Flag | DMAC Activation | Priority |
|------|---|-------------------|-----------------|----------|
| ERI | Receive error or error signal detection | ORER, PER, or ERS | Not possible | High |
| RXI | Receive data full | — | Possible | ↑ Low |
| TXI | Transmit data empty | TEND | Possible | |

Data transmission/reception using the DMAC is also possible in smart card interface mode, similar to in the normal SCI mode. In transmission, when the TEND flag in SSR is set to 1, a TXI interrupt request is generated. This TXI interrupt request activates the DMAC allowing transfer of transmit data if the TXI request is specified beforehand as a source of DMAC activation. The TEND flag is automatically set to 0 when the DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept to 0 and the DMAC is not activated. Therefore, the SCI and DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, the ERS flag in SSR is not automatically cleared to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the RIE bit in SCR to 1 to enable an ERI interrupt request to be generated at error occurrence.

When transmitting/receiving data using the DMAC, be sure to make settings to enable the DMAC before making SCI settings. For DMAC settings, refer to [section 9, Direct Memory Access Controller](#).

In reception, an RXI interrupt request is generated when receive data is set to RDR. This RXI interrupt request activates the DMAC allowing transfer of receive data if the RXI request is specified beforehand as a source of DMAC activation. If an error occurs, the error flag is set. Therefore, the DMAC is not activated and an ERI interrupt request is issued to the CPU instead; the error flag must be cleared.

18.9 Usage Notes

18.9.1 Setting the Module Stop Function

Standby control register 4 (STBCR4) is used to stop and start SCI operations. With the value after a reset, SCI operations are stopped. Register access is enabled by releasing the module stop state. For details, refer to [section 52, Power-Down Modes](#).

18.9.2 Break Detection and Processing

When a framing error is detected, a break can be detected by reading the RXDn pin value directly. In a break, the input from the RXDn pin becomes all 0s, and so the FER flag in SSR is set to 1 (framing error has occurred), and the PER flag in SSR may also be set to 1 (parity error has occurred). The SCI continues the receive operation even after a break is received. Therefore, note that even if the FER flag is set to 0 (no framing error occurred), it will be set to 1 again. When the SEMR.RXDESEL bit is 1, the SCI sets the SSR.FER flag to 1 and stops receiving operation until a start bit of the next data frame is detected. If the SSR.FER flag is set to 0 at this time, the SSR.FER flag retains 0 during the break. When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit at the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

18.9.3 Mark State and Production of Breaks

When the SCR.TE bit is 0 (serial transmission is disabled), setting the I/O port function makes selection of the level and direction (input or output) of the TXDn pin possible. If this is done, the TXDn pin can be placed in the mark state to send a break at the time of data transmission. Until the SCR.TE bit is set to 1 (serial transmission is enabled), the I/O port function is used to set the TXDn pin to output 1 and set the pin mode to a general I/O port pin, and thus place the communication line in the mark state (state of having the value 1). On the other hand, to output a break at the time of data transmission, set the TXDn pin to output 0 and make the pin mode settings for a general I/O port pin. When the SCR.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

18.9.4 Receive Error Flags and Transmit Operations (Clock Synchronous Mode)

Transmission cannot be started when a receive error flag (ORER) in SSR is set to 1, even if data is written to TDR. Be sure to set the receive error flags to 0 before starting transmission. Note also that the receive error flags cannot be set to 0 even if the RE bit in SCR is set to 0 (serial reception is disabled).

18.9.5 Writing Data to TDR

Data can be written to TDR, TDRH, TDRL, and TDRHL. However, if new data is written to TDR, TDRH, TDRL, and TDRHL when transmit data is remaining in TDR, TDRH, TDRL, and TDRHL, the previous data in TDR, TDRH, TDRL, and TDRHL is lost because it has not been transferred to TSR yet. Be sure to write transmit data to TDR, TDRH, TDRL, and TDRHL in the TXI interrupt request handling routine.

18.9.6 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

Update TDR by the CPU or DMAC and wait for at least five P1 ϕ cycles before allowing the transmit clock to be input (see Figure 18.42).

(2) Continuous transmission

- Write the next transmit data to TDR or TDRL before the falling edge of the transmit clock (bit 7) (see Figure 18.42).
- When updating TDR after bit 7 has started to transmit, update TDR while the synchronization clock is in the low-level period, and set the high-level width of the transmit clock (bit 7) to four P1 ϕ cycles or longer (see Figure 18.42).

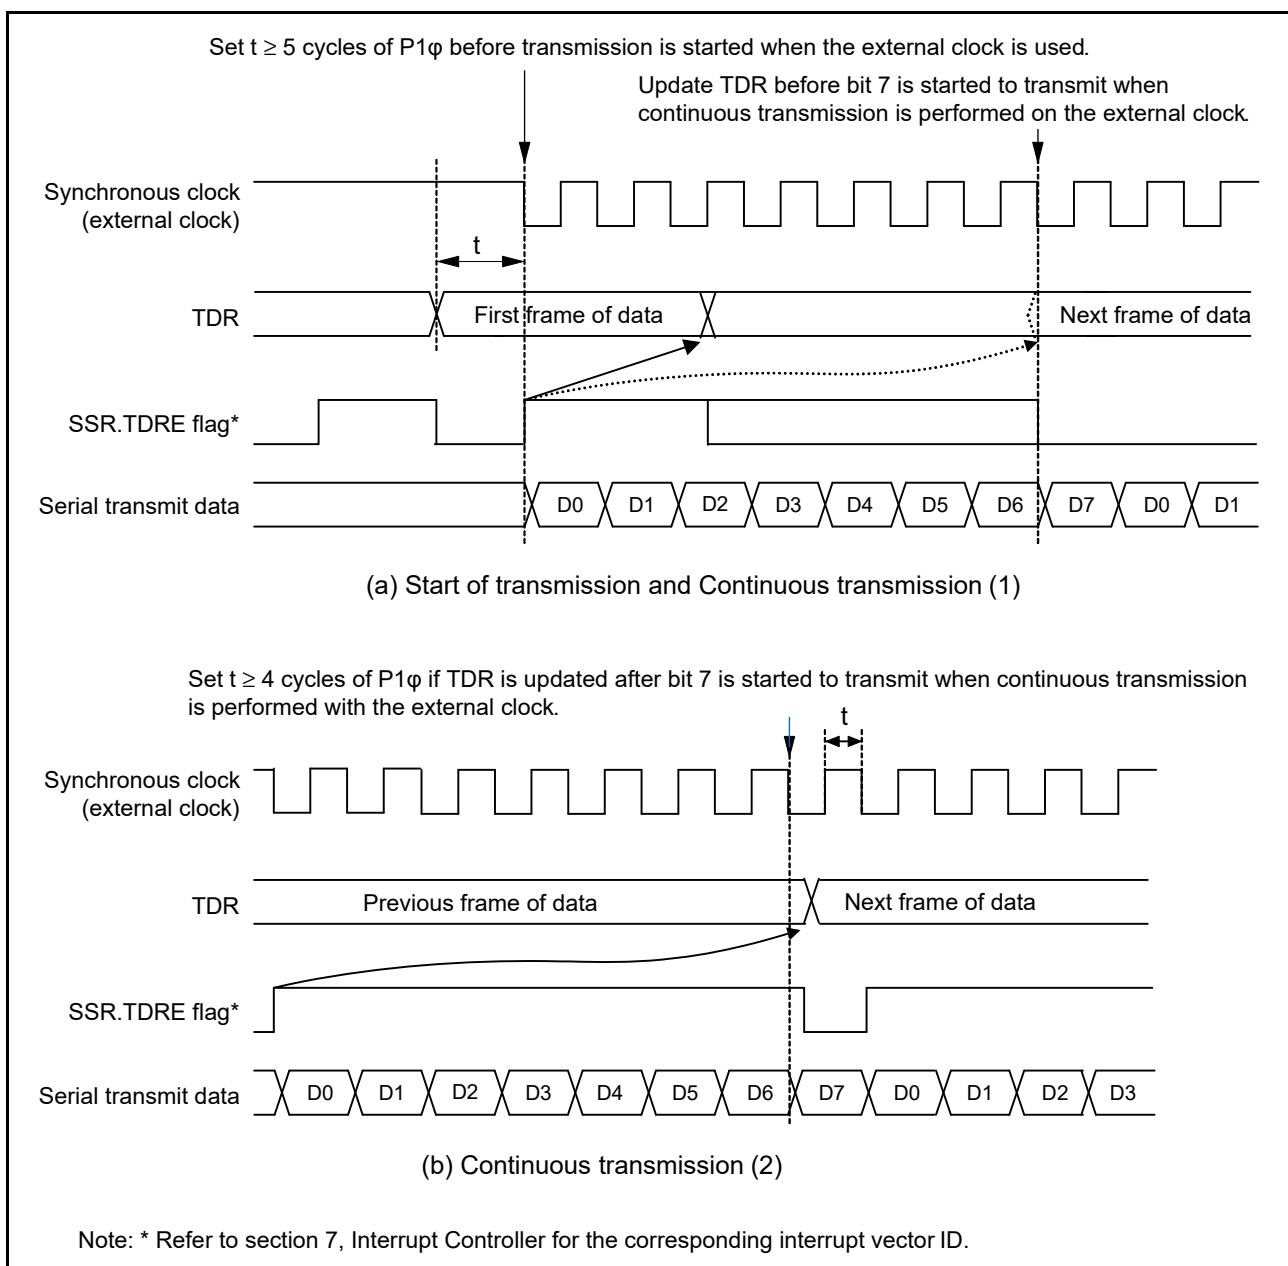

Figure 18.42 Restrictions on Use of External Clock in Clock Synchronous Transmission

18.9.7 Restrictions on Using DMAC

When using the DMAC to read RDR, RDRH, RDRL, and RDRHL, be sure to set the receive data full interrupt (RXI) as the activation source of the relevant SCI.

18.9.8 SCI Operations during Low Power Consumption State

(1) Transmission

When making settings for the module stopped state or in transitions to software standby, stop operations (by setting the TIE, TE, and TEIE bits in the SCR to 0) after switching the TXDn pin to the general I/O port pin function. Setting the TE bit to 0 resets the TSR register and the TEND bit in the SSR. Depending on the port settings, output pins may output the level before a transition to the low power consumption state is made after release from the module stopped state or software standby mode. When transitions to these states are made during transmission, the data being transmitted become indeterminate.

To transmit data in the same transmission mode after cancellation of the low power consumption state, set the TE bit to 1, read SSR, and write data to TDR sequentially to start data transmission. To transmit data with a different transmission mode, initialize the SCI first.

Figure 18.43 shows a sample flowchart for transition to software standby mode during transmission. Figure 18.44 and Figure 18.45 show the port pin states during transition to software standby mode.

(2) Reception

Before specifying the module stop state or making a transition to software standby mode, stop the receive operations (RE = 0 in SCR). If transition is made during data reception, the data being received will be invalid.

To receive data in the same reception mode after cancellation of the low power consumption state, set the RE bit to 1, and then start reception. To receive data in a different reception mode, initialize the SCI first.

Figure 18.46 shows a sample flowchart for transition to software standby mode during reception.

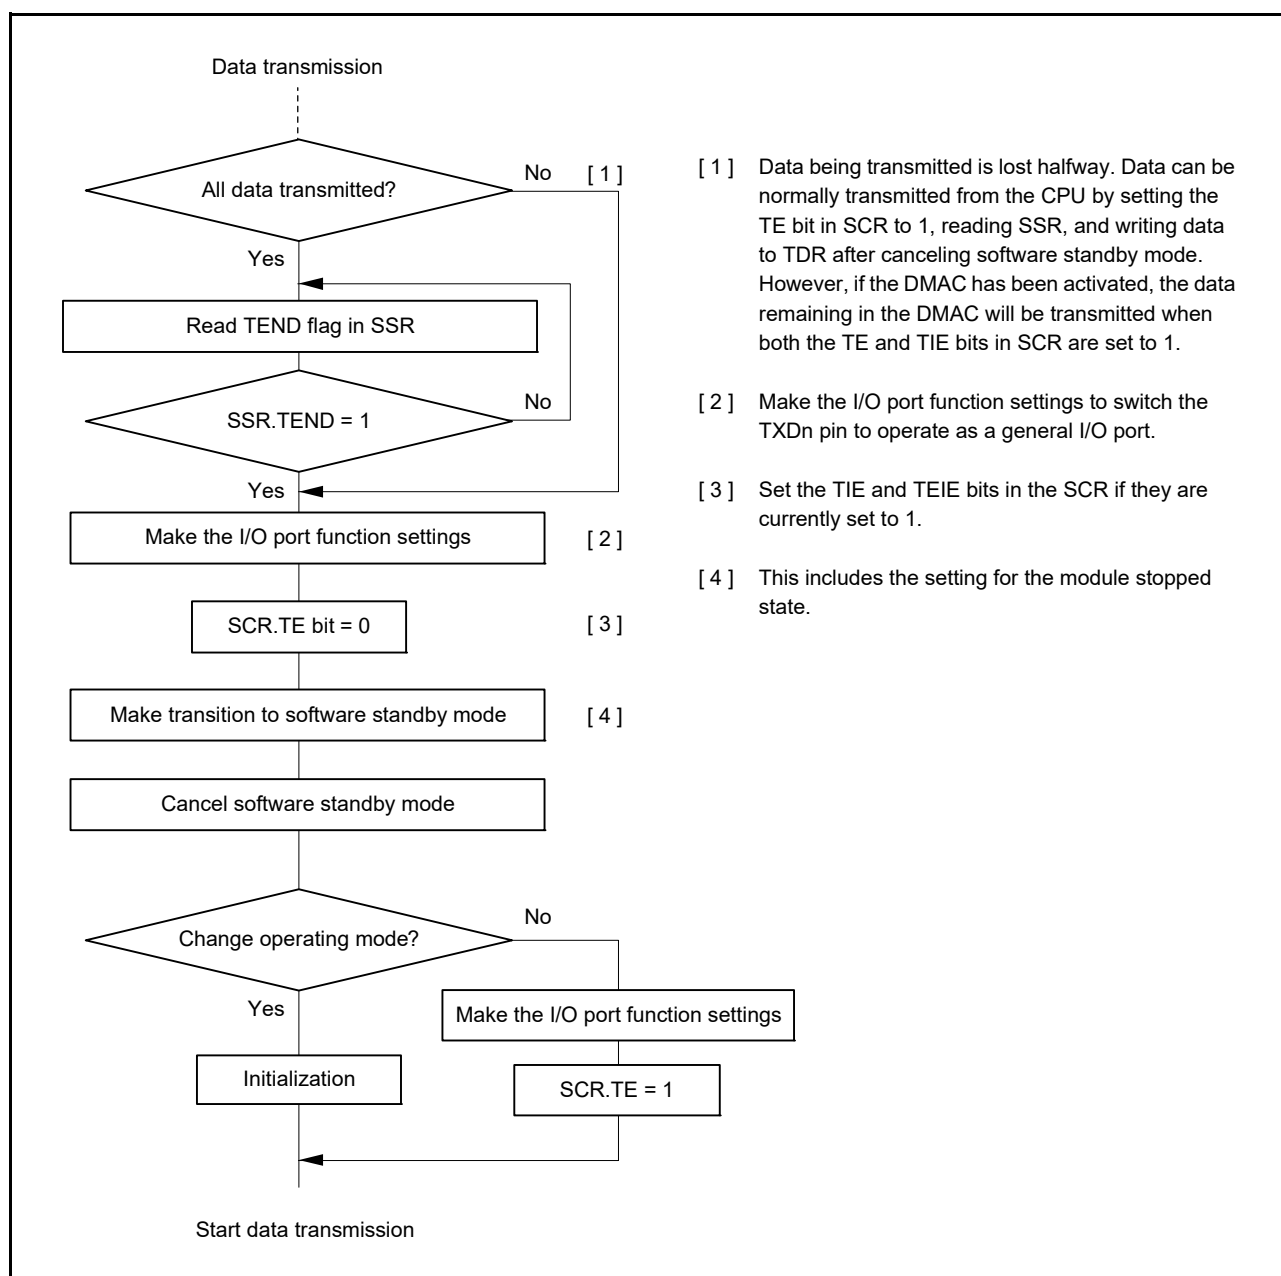

Figure 18.43 Example of Flowchart for Transition to Software Standby Mode during Transmission

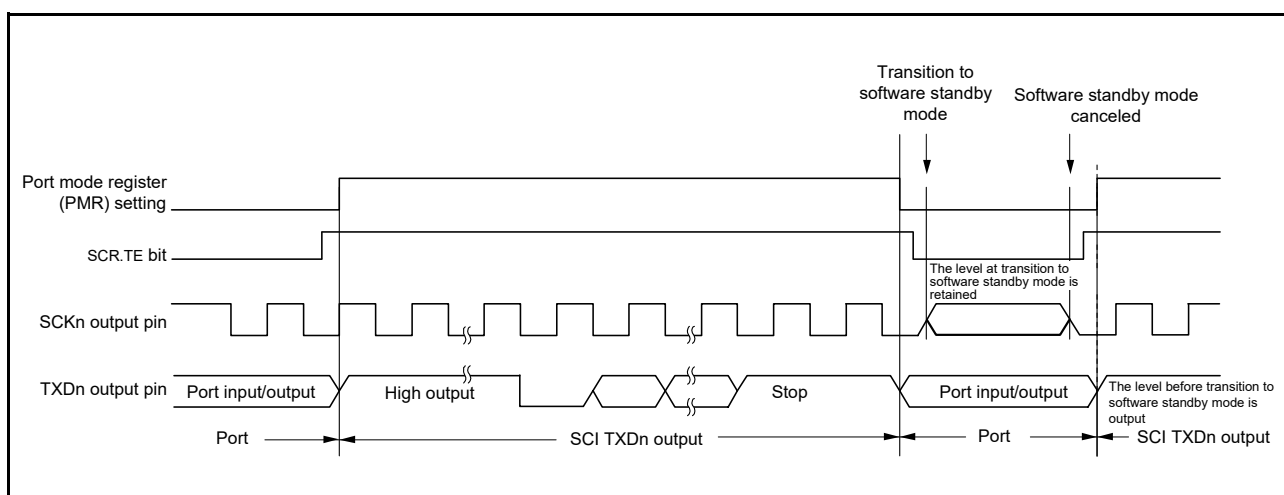

Figure 18.44 Port Pin States during Transition to Software Standby Mode
(Internal Clock, Asynchronous Transmission)

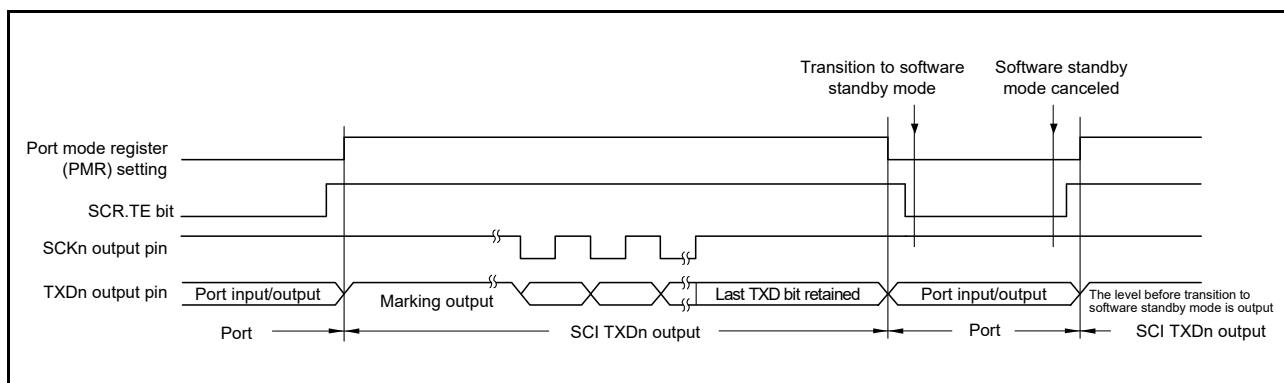

Figure 18.45 Port Pin States during Transition to Software Standby Mode
(Internal Clock, Clock Synchronous Transmission)

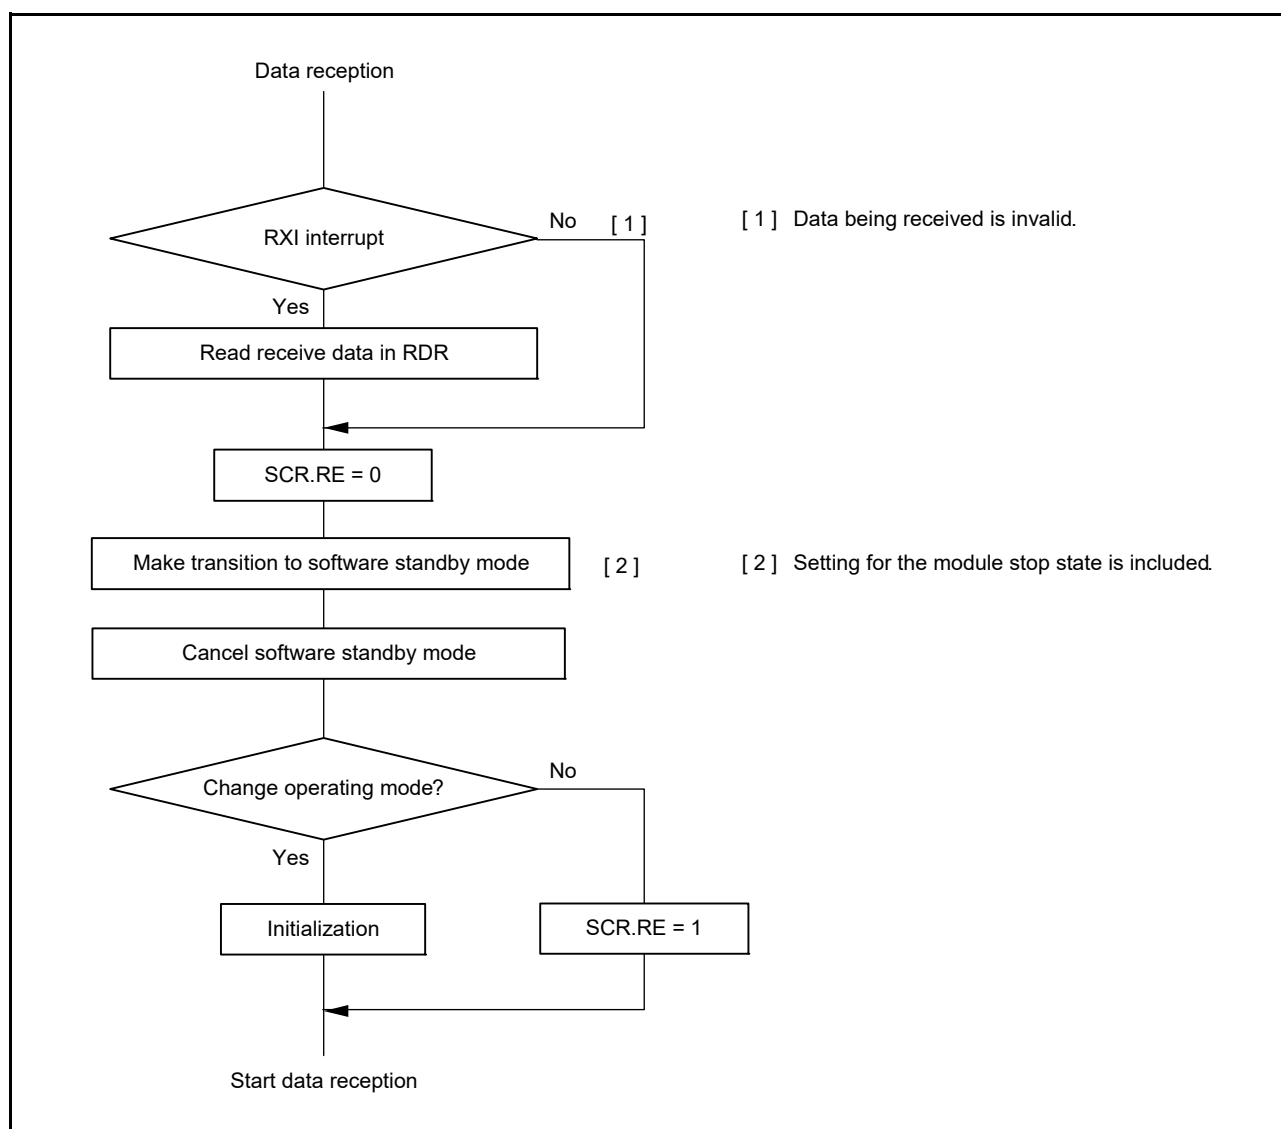

Figure 18.46 Example of Flowchart for Transition to Software Standby Mode during Reception

18.9.9 External Clock Input in Clock Synchronous Mode

In clock synchronous mode, the external clock SCKn must be input as follows:

High-pulse period, low-pulse period = 2 P1φ cycles or more, period = 6 P1φ cycles or more

18.9.10 Note on Transmit Enable Bit (TE bit)

When setting the SCR.TE bit to 0 (serial transmission is disabled) while the pin function is “TXDn”, output of the pin becomes high impedance.

Prevent the TXDn line from becoming high impedance by any of the following ways:

- (1) Connect a pull-up resistor to the TXDn line.
- (2) Change the pin function to “general-purpose I/O port, output” before setting the SCR.TE bit to 0.
Set the SCR.TE bit to 1 before changing the pin function to “TXDn”.

18.10 IrDA Communications

The channel 0 serial communications interface (SCI) is capable of working with the Infrared Data Association (IrDA) module to handle transfer through IrDA communications in conformance with version 1.0 of the IrDA protocol. Using the IRE bit in IRCR to enable the IrDA function leads to encoding and decoding of the SCI_TXD0 and SCI_RXD0 signals of the channel 0 serial communications interface, respectively, to convert them to and from waveforms in conformance with version 1.0 of the IrDA protocol. Infrared transfer in conformance with version 1.0 of the IrDA protocol can be handled by connecting a transceiver for use in infrared communications. In version 1.0 of the IrDA protocol, IrDA transfer starts at a transfer rate of 9600 bps. The transfer rate is changeable during transfer as required. The IrDA module itself does not have a function for automatically changing the transfer rate. Accordingly, change the transfer rate by changing that for the serial communications interface.

A block diagram and pin configuration for IrDA transfer are shown in Figure 18.47 and Table 18.22, respectively.

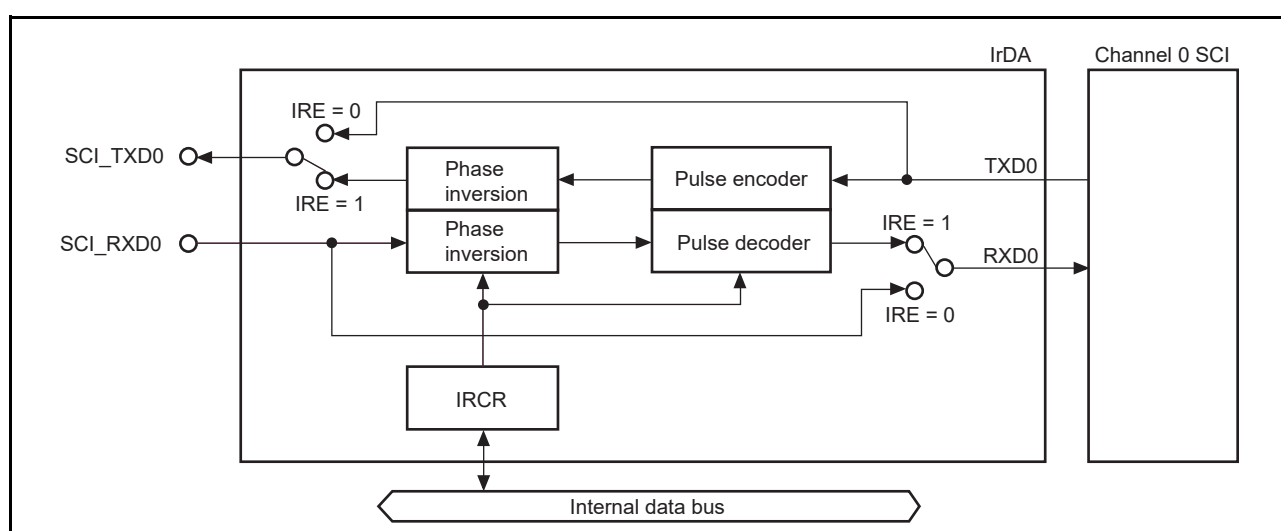

Figure 18.47 Block Diagram

Table 18.22 Pin Configuration

| Pin Name | Symbol | I/O | Function |
|----------------------------|----------|--------|-------------------------------|
| IrDA data transmission pin | SCI_TXD0 | Output | IrDA data transmission output |
| IrDA data reception pin | SCI_RXD0 | Input | IrDA data reception input |

18.11 Description of the IrDA Register

Table 18.23 shows the register configuration.

Table 18.23 Register Configuration

| Register Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|-----------------------|--------------|-----|---------------|------------|-------------|
| IrDA Control Register | IRCR | R/W | H'00 | H'E8014000 | 8 |

18.11.1 IrDA Control Register (IRCR)

IRCR sets the operation of the IrDA module.

| b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|---------------------|------------|----|----|----------|----------|----|----|
| IRE | IRCKS[2:0] | | | IRTX INV | IRRX INV | — | — |
| Value after reset:: | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|----------|------------|-------------------------------|---|-----|
| b1, b0 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b2 | IRRXINV | SCI_RXD0 Data Level Switching | Sets inversion of the logic level of inputs on SCI_RXD0. 0: The input on SCI_RXD0 is used without change as the received data. 1: The input on SCI_RXD0 is inverted before it is treated as the received data. | R/W |
| b3 | IRTXINV | SCI_TXD0 Data Level Switching | Sets inversion of the logic level of outputs on SCI_TXD0. 0: Data for transmission is output without change to SCI_TXD0. The pulse-width setting in the IRCKS bits determines the period over which the pulses are at the high level. 1: Data for transmission is inverted before being output to SCI_TXD0. The pulse-width setting in the IRCKS bits determines the period over which the pulses are at the low level. | R/W |
| b6 to b4 | IRCKS[2:0] | IrDA Clock Select | Selects the pulse width for use in encoding output pulses from SCI_TXD0 when the setting of the IRE bit is 1. 000: Bit rate × 3/16 001: P1φ/2 010: P1φ/4 011: P1φ/8 100: P1φ/16 101: P1φ/32 110: P1φ/64 111: P1φ/128 | R/W |
| b7 | IRE | IrDA Enable | Sets the function for use with the SCI_TXD0 and SCI_RXD0 pins as normal serial or IrDA. 0: Disables the IrDA function. Data from the TXD pin of the channel 0 serial communications interface is output without change to SCI_TXD0. Data on SCI_RXD0 is output without change to the RXD pin of the channel 0 serial communications interface. 1: Enables the IrDA function. Data from the TXD pin of the channel 0 serial communications interface is encoded before being output through SCI_TXD0. Data on SCI_RXD0 is decoded before being output to the RXD pin of the channel 0 serial communications interface. | R/W |

18.12 IrDA Operation

18.12.1 Flow of Settings for IrDA Operation

Set up IrDA operation by following the procedure listed below.

1. Make the general-purpose I/O port-pin settings.
2. Set the IRCR register.
3. Set the registers related to the serial communications interface.

18.12.2 Transmission

In transmission with the IrDA function enabled, serial data (UART frames of data) from the TXD pin of the serial communications interface are converted to IR frames (see Figure 18.48). If the IRTXINV bit is set to 0, when the value of the serial data is 0, a high-level pulse with the width equivalent to three sixteenths of the bit period is output to the SCI_TXD0 pin by default. Note that the high-level pulse width is selectable by using IRCKS[2:0] bits in the IRCR register. In the IrDA protocol, the specifiable high-level pulse widths are from a minimum of 1.41 μ s to a maximum of $(3/16 + 2.5\%) \times \text{bit period}$ or $(3/16 \times \text{bit period}) + 1.08 \mu$ s. When the frequency of P1 ϕ is 66 MHz, the specifiable high-level pulse widths are from a minimum of 1.41 μ s to a maximum of 1.94 μ s. On the other hand, if the value of the serial data is 1, no high-level pulse is output.

Figure 18.48 Example of the Operation in IrDA Transfer

18.12.3 Reception

In reception with the IrDA function enabled, IR frames of data from the SCI_RXD0 pin are converted to serial data and output to the RXD pin of the serial communications interface. If the setting of the IRRXINV bit is 0, the value 0 is output when a high-level pulse is detected and the value 1 is output when no high-level pulse is detected during each bit period. Note that pulses with a width shorter than the minimum pulse width of 1.41 μ s cannot be recognized.

18.12.4 Selecting the High-Level Pulse Width

The correspondences between the specifiable value in the IRCKS[2:0] bits (the minimum pulse width), operating frequency of P1 ϕ , and the bit rate for use in making the pulse width shorter than the bit period $\times 3/16$ in transmission are given in Table 18.24.

Table 18.24 Settings of the IRCKS[2:0] Bits

| P1 ϕ (MHz) | Upper Row: Bit Rate (bps); Lower Row: Bit Period $\times 3/16$ (μ s) | | | | | |
|-----------------|---|-------|-------|-------|-------|--------|
| | 2400 | 9600 | 19200 | 38400 | 57600 | 115200 |
| 78.13 | 78.13 | 19.53 | 9.77 | 4.88 | 3.26 | 1.63 |
| 50 | 111 | 111 | 111 | 111 | 111 | — *1 |
| 60 | 111 | 111 | 111 | 111 | 111 | — *2 |
| 66 | 111 | 111 | 111 | 111 | 111 | — *2 |

Note 1. This bit rate is not specifiable for the serial communications interface.

Note 2. No pulse width shorter than the bit period $\times 3/16$ is specifiable.

18.13 Note on IrDA Usage

18.13.1 Minimum Pulse Width in Reception

Pulses with a width shorter than the minimum pulse width of 1.41 μ s cannot be recognized.

18.13.2 Base Clock in Asynchronous Mode for the Serial Communications Interface

The IrDA module works with the serial communications interface by receiving the base clock with a frequency 16 times the bit rate for communications from the interface. For the serial communications interface, either 16 or 8 cycles of the base clock are selectable as the bit period. On the other hand, the IrDA module is only capable of operation when the setting for the bit period of the serial communications interface is 16 cycles of the base clock.

19. Renesas Serial Peripheral Interface

This LSI circuit includes three independent Renesas serial peripheral interfaces.

This module is capable of full-duplex synchronous serial communication.

19.1 Features

This module has the following features.

- SPI transfer functions
 - Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (SPI clock) signals allows for serial communications through SPI operation (four-wire method).
 - Capable of serial communications in master/slave mode
 - Supports mode fault error detection (only in SPI slave mode)
 - Supports overrun error detection (only in SPI slave mode)
 - Switching of the polarity of the serial transfer clock
 - Switching of the clock phase of serial transfer
- Data format
 - MSB-first/LSB-first selectable
 - Transfer bit-length is selectable as 8, 16, or 32 bits.
- Bit rate
 - RSPCK can be divided by a maximum of 4096 in master mode
 - RSPCK can be generated by dividing P1 ϕ by the on-chip baud rate generator.
 - An externally input clock can be used as a serial clock.
- Buffer configuration
 - 8 bytes for transmission and 32 bytes for reception
- SSL control function
 - One SSL signal for each channel
 - In master mode, outputs SSL signal.
 - In slave mode, inputs SSL signal.
 - Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay)
Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units)
 - Controllable delay from RSPCK stoppage to SSL output negation (SSL negation delay)
Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units)
 - Controllable wait for next-access SSL output assertion (next-access delay)
Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units)
 - Function for changing SSL polarity
- Control in master transfer
 - A transfer of up to four commands can be executed sequentially in looped execution.
 - For each command, the following can be set:
SSL signal value, bit rate, RSPCK polarity/phase, transfer data length, LSB/MSB first, burst, RSPCK delay, SSL negation delay, and next-access delay.
 - A transfer can be initiated by writing to the transmit buffer.
 - A transfer can be initiated by clearing the SPTEF bit.
 - MOSI signal value specifiable in SSL negation
- Interrupt sources
 - Maskable interrupt sources:
 - Receive interrupt (receive buffer full)
 - Transmit interrupt (transmit buffer empty)
 - Error interrupt (mode fault, overrun)

- Others
 - Provides loop back mode
 - Provides a function for disabling (initializing) this module

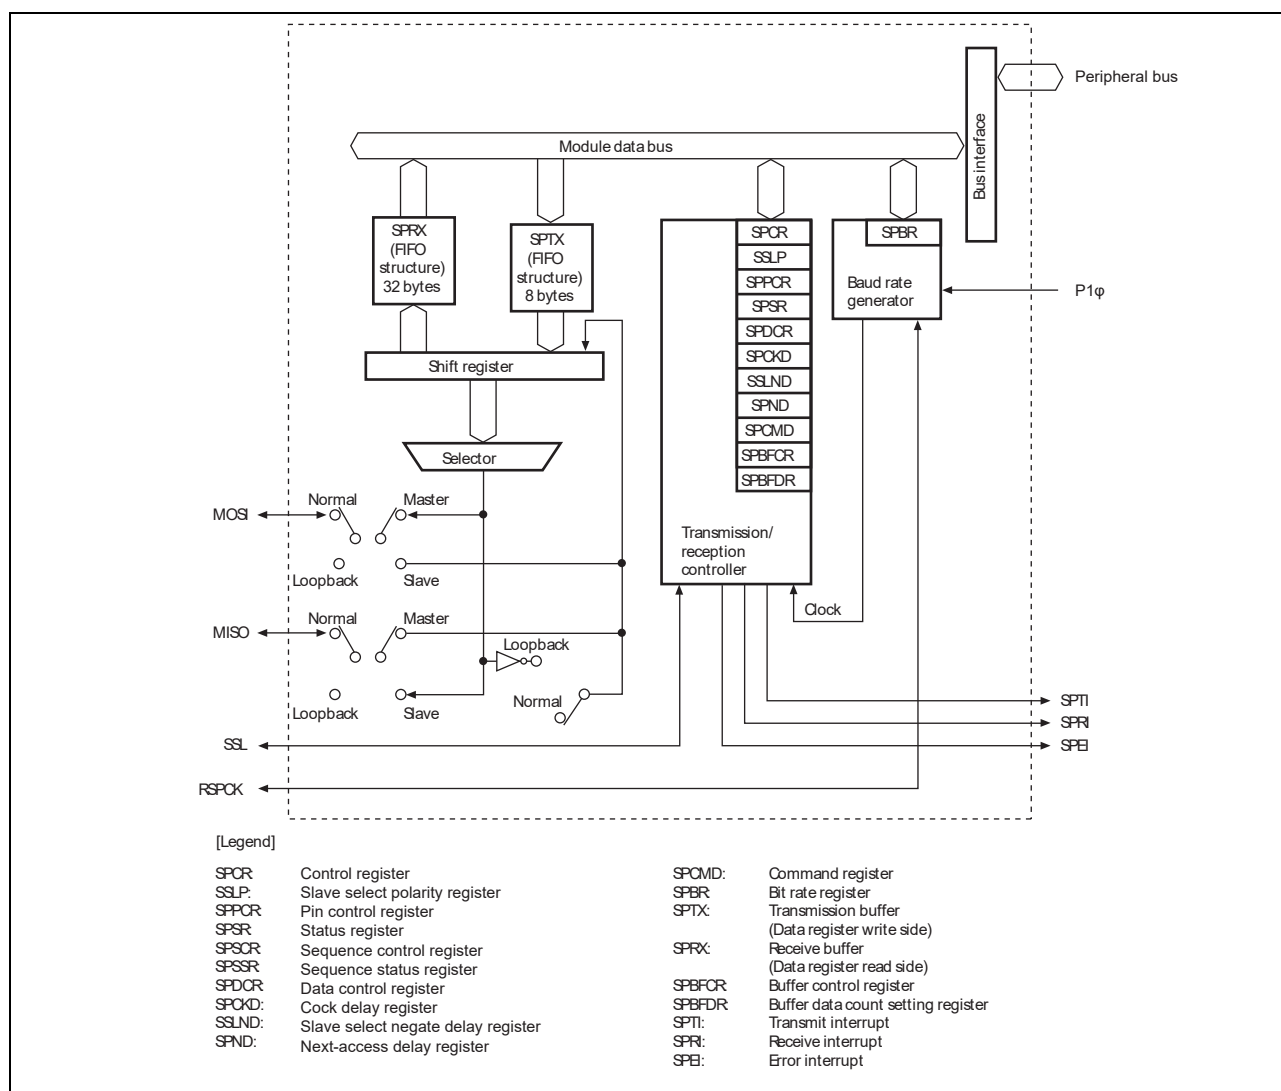

Figure 19.1 Block Diagram (for One Channel)

19.2 Input/Output Pins

Table 19.1 shows the pin configuration. This module automatically switches the input/output direction of the SSL pin. SSL is set as an output in master mode and as an input in slave mode. Pins RSPCK, MOSI, and MISO are automatically set as inputs or outputs according to the setting of master or slave and the level input on SSL (see section 19.4.2, Pin Control).

Table 19.1 Pin Configuration

| Channel | Pin Name | Pin Name | I/O | Function |
|---------|--------------------------|----------|-----|----------------------|
| 0 | Clock pin | RSPCK0 | I/O | Clock input/output |
| | Master transmit data pin | MOSI0 | I/O | Master transmit data |
| | Slave transmit data pin | MISO0 | I/O | Slave transmit data |
| | Slave select 0 pin | SSL00 | I/O | Slave selection |
| 1 | Clock pin | RSPCK1 | I/O | Clock input/output |
| | Master transmit data pin | MOSI1 | I/O | Master transmit data |
| | Slave transmit data pin | MISO1 | I/O | Slave transmit data |
| | Slave select 0 pin | SSL10 | I/O | Slave selection |
| 2 | Clock pin | RSPCK2 | I/O | Clock input/output |
| | Master transmit data pin | MOSI2 | I/O | Master transmit data |
| | Slave transmit data pin | MISO2 | I/O | Slave transmit data |
| | Slave select 0 pin | SSL20 | I/O | Slave selection |

Note: In the description of the pins, the channel is omitted and pin names are described as RSPCK, MOSI, MISO, and SSL.

19.3 Register Descriptions

Table 19.2 shows the register configuration. These registers enable this module to perform the following controls: specifying master/slave modes, specifying a transfer format, and controlling the transmitter and receiver.

Table 19.2 Register Configuration

| Channel | Register Name | Abbreviation*1 | R/W | Initial Value | Address | Access Size |
|---------|--|----------------|---------|---------------|------------|-------------|
| 0 | Control register_0 | SPCR_0 | R/W | H'00 | H'E800C800 | 8 |

Note 1. In the description of the register names, the channel is omitted.

Note 2. Only 0 can be written to clear the flag.

19.3.1 Control Register (SPCR)

SPCR sets the operating mode. If the MSTR and MODFEN bits are changed while the function of this module is enabled by setting the SPE bit to 1, subsequent operations cannot be guaranteed.

| | | | | | | | | |
|----------------|-------|-----|-------|-------|------|--------|---|---|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | SPRIE | SPE | SPTIE | SPEIE | MSTR | MODFEN | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R | R |

| Bit | Bit Name | Initial Value | R/W | Function |
|------|----------|---------------|-----|---|
| 7 | SPRIE | 0 | R/W | <p>Receive Interrupt Enable</p> <p>Enables or disables generation of receive interrupt requests (SPRI) when the number of receive data units in the receive buffer (SPRX) is equal to or greater than the specified receive buffer data triggering number and the SPRF flag in SPSR is set to 1.</p> <p>0: Disables the generation of receive interrupt requests.</p> <p>1: Enables the generation of receive interrupt requests.</p> |
| 6 | SPE | 0 | R/W | <p>Function Enable</p> <p>Setting this bit to 1 enables the module function. When the MODF bit in the status register (SPSR) is 1, the SPE bit cannot be set to 1 (see 19.4.6 Error Detection). Setting the SPE bit to 0 disables the module function, and initializes a part of the module function (see 19.4.7 Initialization).</p> <p>0: Disables the module function.</p> <p>1: Enables the module function.</p> |
| 5 | SPTIE | 0 | R/W | <p>Transmit Interrupt Enable</p> <p>Enables or disables generation of transmit interrupt requests (SPTI) when the number of transmit data units in the transmit buffer (SPTX) is equal to or less than the specified transmit buffer data triggering number and the SPTEF flag in SPSR is set to 1.</p> <p>0: Disables the generation of transmit interrupt requests.</p> <p>1: Enables the generation of transmit interrupt requests.</p> |
| 4 | SPEIE | 0 | R/W | <p>Error Interrupt Enable</p> <p>Enables or disables the generation of error interrupt requests when this module detects a mode fault error and sets the MODF bit in the status register (SPSR) to 1, or when this module detects an overrun error and sets the OVRF bit in SPSR to 1 (see 19.4.6 Error Detection).</p> <p>0: Disables the generation of error interrupt requests.</p> <p>1: Enables the generation of error interrupt requests.</p> <p>Note: This bit is valid only in SPI slave mode.</p> |
| 3 | MSTR | 0 | R/W | <p>Master/Slave Mode Select</p> <p>Selects master/slave mode. According to MSTR bit settings, this module determines the direction of the RSPCK, MOSI, MISO, and SSL pins.</p> <p>0: Slave mode</p> <p>1: Master mode</p> |
| 2 | MODFEN | 0 | R/W | <p>Mode Fault Error Detection Enable</p> <p>Enables or disables the detection of a mode fault error (see 19.4.6 Error Detection).</p> <p>0: Disables the detection of a mode fault error.</p> <p>1: Enables the detection of a mode fault error.</p> <p>Note: This bit is valid only in SPI slave mode. When master mode is specified with the MSTR bit, this bit should always be cleared to 0.</p> |
| 1, 0 | — | All 0 | R | <p>Reserved</p> <p>The write value should always be 0. Otherwise, operation cannot be guaranteed.</p> |

19.3.2 Slave Select Polarity Register (SSLP)

SSLP sets the polarity of the SSL signal. If the contents of SSL0P are changed while the function of this module is enabled by setting the SPE bit in the control register (SPCR) to 1, subsequent operations cannot be guaranteed.

| | | | | | | | | |
|----------------|---|---|---|---|---|---|---|-------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | SSL0P |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R/W |

| Bit | Bit Name | Initial Value | R/W | Function |
|--------|----------|---------------|-----|---|
| 7 to 1 | — | All 0 | R | Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed. |
| 0 | SSL0P | 0 | R/W | SSL Signal Polarity Setting Sets the polarity of the SSL signal. The value of SSL0P indicates the active polarity of the SSL signal. 0: SSL signal 0-active 1: SSL signal 1-active |

19.3.3 Pin Control Register (SPPCR)

SPPCR sets the modes of the pins. If the contents of this register are changed while the function of this module is enabled by setting the SPE bit in the control register (SPCR) to 1, subsequent operations cannot be guaranteed.

| | | | | | | | | |
|----------------|---|---|-------|-------|---|---|---|------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | MOIFE | MOIFV | — | — | — | SPLP |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R/W | R/W | R | R | R | R/W |

| Bit | Bit Name | Initial Value | R/W | Function |
|--------|----------|---------------|-----|---|
| 7, 6 | — | All 0 | R | Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed. |
| 5 | MOIFE | 0 | R/W | MOSI Idle Value Fixing Enable Fixes the MOSI output value when this module in master mode is in an SSL negation period (including the SSL retention period during a burst transfer). When MOIFE is 0, this module outputs the last output value from the previous serial transfer during the SSL negation period to the MOSI pin. (The value is undefined when CPHA is 0). When MOIFE is 1, this module outputs the fixed value set in the MOIFV bit to the MOSI pin. 0: MOSI output value equals the last output value from previous transfer. (The value is undefined when CPHA is 0). 1: MOSI output value equals the value set in the MOIFV bit. |
| 4 | MOIFV | 0 | R/W | MOSI Idle Fixed Value If the MOIFE bit is 1 in master mode, this module, according to MOIFV bit settings, determines the MOSI signal value during the SSL negation period (including the SSL retention period during a burst transfer). 0: MOSI Idle fixed value equals 0. 1: MOSI Idle fixed value equals 1. |
| 3 to 1 | — | All 0 | R | Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed. |
| 0 | SPLP | 0 | R/W | Loopback When the SPLP bit is set to 1, this module shuts off the path between the MISO pin and the shift register, and between the MOSI pin and the shift register, and connects (reverses) the input path and the output path for the shift register. 0: Normal mode 1: Loopback mode |

19.3.4 Status Register (SPSR)

SPSR indicates the operating status.

| | | | | | | | | |
|----------------|------|------|-------|---|---|--------|---|--------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | SPRF | TEND | SPTEF | — | — | MODF | — | OVRF |
| Initial value: | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R/(W)* | R | R/(W)* |

Note: *Only 0 can be written to clear the flag after reading 1.

| Bit | Bit Name | Initial Value | R/W | Function |
|------|----------|---------------|-----|--|
| 7 | SPRF | 0 | R | <p>Receive Buffer Full Flag</p> <p>Indicates that the number of receive data units in the receive buffer (SPRX) is equal to or greater than the receive buffer data triggering number specified in the buffer control register (SPBFCR).</p> <p>0: The number of receive data units in the receive buffer is less than the receive buffer data triggering number.</p> <p>1: The number of receive data units in the receive buffer is equal to or greater than the receive buffer data triggering number.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> The receive buffer data is read until the number of data units in the receive buffer becomes less than the specified receive buffer data triggering number. Receive buffer data reset is enabled. Power-on reset <p>[Setting condition]</p> <ul style="list-style-type: none"> The number of data units in the receive buffer is equal to or greater than the specified receive buffer data triggering number. |
| 6 | TEND | 1 | R | <p>Transmit End</p> <p>This bit is set to 1 when transmission is completed, and this bit is 0 when transmission is not completed.</p> <p>[Clearing condition]</p> <ul style="list-style-type: none"> When transmit data are transferred from the transmit register to the shift register. <p>[Setting condition]</p> <ul style="list-style-type: none"> When the number of data units in the transmit buffer (SPTX) is zero when a serial transfer is completed. <p>Note: This bit is valid only in SPI master mode.</p> |
| 5 | SPTEF | 1 | R | <p>Transmit Buffer Empty Flag</p> <p>Indicates that the number of transmit data units in the transmit buffer (SPTX) is equal to or less than the transmit buffer data triggering number specified in the buffer control register (SPBFCR).</p> <p>0: The number of transmit data units in the transmit buffer is equal to or greater than the specified transmit buffer data triggering number.</p> <p>1: The number of transmit data units in the transmit buffer is less than the specified transmit buffer data triggering number.</p> <p>[Clearing condition]</p> <ul style="list-style-type: none"> When data is written to the transmit buffer until the number of transmit data units in the transmit buffer exceeds the specified transmit buffer data triggering number. <p>[Setting conditions]</p> <ul style="list-style-type: none"> When the number of transmit data units in the transmit buffer is less than the specified transmit buffer data triggering number. When transmit buffer data reset is enabled. Power-on reset |
| 4, 3 | — | All 0 | R | <p>Reserved</p> <p>The write value should always be 0. Otherwise, operation cannot be guaranteed.</p> |

| Bit | Bit Name | Initial Value | R/W | Function |
|-----|----------|---------------|--------|---|
| 2 | MODF | 0 | R/(W)* | <p>Mode Fault Error Flag</p> <p>Indicates the occurrence of a mode fault error. If the MODFEN bit is set to 1 when this module is in slave mode and the SSL pin is negated before the RSPCK cycle necessary for data transfer ends, this module detects a mode fault error. The active level of the SSL signal is determined by the SSL0P bit in the slave select polarity register (SSLP).</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> • SPSR is read when the MODF bit is 1, and then 0 is written to the MODF bit. • Power-on reset <p>0: No mode fault error occurred 1: A mode fault error occurred</p> <p>Note: This bit is valid only in SPI slave mode.</p> |
| 1 | — | 0 | R | <p>Reserved</p> <p>The write value should always be 0. Otherwise, operation cannot be guaranteed.</p> |
| 0 | OVRF | 0 | R/(W)* | <p>Overflow Error Flag</p> <p>Indicates the occurrence of an overflow error. If a serial transfer ends when there is not enough space for receiving the specified length of data in the receive buffer (SPRX), this module detects an overflow error, and sets the OVRF bit to 1.</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> • SPSR is read when the OVRF bit is 1, and then 0 is written to the OVRF bit. • Power-on reset <p>0: No overflow error occurred 1: An overflow error occurred</p> <p>Note: This bit is valid only in SPI slave mode.</p> |

Note: * Only 0 can be written to clear the flag after reading 1.

19.3.5 Data Register (SPDR)

SPDR is a buffer that holds data for transmission and reception.

The transmit buffer (SPTX) and receive buffer (SPRX) are independent and are mapped to SPDR.

SPDR should be read or written to in byte, word, or longword units according to the access width specification bit (SPLW) in the data control register (SPDCR).

The bit length to be used is determined by the data length specification bits (SPB3 to SPB0) in the command register (SPCMD).

The access width set by SPDCR must agree with the data length set by SPCMD.

When data is written to SPDR, the data will be written to the transmit buffer from SPDR if the transmit buffer has a space equal to or more than the SPDR access width. If there is not enough space, data will not be written to the transmit buffer. Even if an attempt is made to write data to the buffer, the data is ignored.

When data is read from SPDR, receive data in the receive buffer will be read. If SPDR is read when there is no receive data in the receive buffer, the read value is undefined.

When SPDR is written to with the longword-, word-, or byte-access width, the transmit data should be written to address 0 irrespective of the access width. If data is written to the other addresses, the data is not guaranteed.

When SPDR is read with the longword-, word-, or byte-access width, the receive data should be read from address 0. If data is read from the other addresses, the data is not guaranteed.

| | | | | | | | | | | | | | | | | |
|----------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

19.3.6 Sequence Control Register (SPSCR)

SPSCR sets the sequence control method when this module operates in master mode. If the contents of SPSCR are changed while the MSTR and SPE bits in the control register (SPCR) are 1 with the function of this module enabled in master mode, the subsequent operation cannot be guaranteed.

| | | | | | | | | |
|----------------|---|---|---|---|---|---|--------|--------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | SPSLN1 | SPSLN0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Function |
|--------|----------|---------------|-----|--|
| 7 to 2 | — | All 0 | R | Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed. |
| 1 | SPSLN1 | 0 | R/W | Sequence Length Specification |
| 0 | SPSLN0 | 0 | R/W | These bits specify a sequence length when this module in master mode performs sequential operations. This module in master mode changes command registers 0 to 3 (SPCMD0 to SPCMD3) to be referenced and the order in which they are referenced according to the sequence length that is set in the SPSLN1 and SPSLN0 bits. The relationship among the setting of bits SPSLN1 and SPSLN0, sequence length, and SPCMD0 to SPCMD3 referenced by this module is shown below. In slave mode, SPCMD0 is always referenced. |
| | | | | Sequence Length Referenced SPCMD # |
| | | | | 00: 1 0 → 0 → ... |
| | | | | 01: 2 0 → 1 → 0 → ... |
| | | | | 10: 3 0 → 1 → 2 → 0 → ... |
| | | | | 11: 4 0 → 1 → 2 → 3 → 0 → ... |

19.3.7 Sequence Status Register (SPSSR)

SPSSR indicates the sequence control status when this module operates in master mode.

| | | | | | | | | |
|----------------|---|---|---|---|---|---|-------|-------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | SPCP1 | SPCP0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Function |
|--------|----------|---------------|-----|---|
| 7 to 2 | — | All 0 | R | Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed. |
| 1 | SPCP1 | 0 | R | Command Pointer |
| 0 | SPCP0 | 0 | R | During sequence control, these bits indicate one of the command registers 0 to 3 (SPCMD0 to SPCMD3) that is currently pointed to by the pointer. The relationship between the setting of SPCP1 and SPCP0 and SPCMD0 to SPCMD3 is shown below. For the sequence control, see section 19.4.8, (1), (c) Sequence Control. |
| | | | | 00: SPCMD0 |
| | | | | 01: SPCMD1 |
| | | | | 10: SPCMD2 |
| | | | | 11: SPCMD3 |

19.3.8 Bit Rate Register (SPBR)

SPBR sets the bit rate in master mode. If the contents of SPBR are changed while the MSTR and SPE bits in the control register (SPCR) are 1 with the function of this module enabled in master mode, the subsequent operation cannot be guaranteed.

| | | | | | | | | |
|----------------|------|------|------|------|------|------|------|------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | SPR7 | SPR6 | SPR5 | SPR4 | SPR3 | SPR2 | SPR1 | SPR0 |
| Initial value: | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

When this module is used in slave mode, the bit rate depends on the bit rate of the input clock regardless of the settings of SPBR and BRDV.

The bit rate is determined by combinations of SPBR settings and the bit settings in the BRDV1 and BRDV0 bits in the command registers (SPCMD0 to SPCMD3). The equation for calculating the bit rate is given below. In the equation, n denotes an SPBR setting (0, 1, 2, ..., 255), and N denotes a BRDV1 and BRDV0 bit setting (0, 1, 2, 3).

$$\text{Bit rate} = \frac{f(P1\phi)}{2 \times (n + 1) \times 2^N}$$

Table 19.3 shows examples of the relationship between the SPBR register and BRDV1 and BRDV0 bit settings.

Table 19.3 Relationship between SPBR and BRDV1 and BRDV0 Settings

| SPBR (n) | BRDV[1:0] (N) | Division Ratio | Bit Rate |
|----------|---------------|----------------|-------------|
| | | | P1φ = 66MHz |
| 0 | 0 | 2* | 33.00 Mbps |
| 1 | 0 | 4 | 16.50 Mbps |
| 2 | 0 | 6 | 11.00 Mbps |
| 3 | 0 | 8 | 8.25 Mbps |
| 4 | 0 | 10 | 6.60 Mbps |
| 5 | 0 | 12 | 5.50 Mbps |
| 5 | 1 | 24 | 2.75 Mbps |
| 5 | 2 | 48 | 1.38 Mbps |
| 5 | 3 | 96 | 687.50 Kbps |
| 255 | 3 | 4096 | 16.11 Kbps |

Note: * Decide the bit rate to be actually used in the system considering timing specifications.

19.3.9 Data Control Register (SPDCR)

SPDCR selects the width to access SPDR from longword-, word-, and byte-width, and enables or disables dummy data transmission for the master mode operation.

If the contents of SPDCR are changed while bit TEND in the status register (SPSR) indicates that transmission is not completed, the subsequent operation cannot be guaranteed.

| | | | | | | | | |
|----------------|-------|-------|-------|---|---|---|---|---|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | TXDMY | SPLW1 | SPLW0 | — | — | — | — | — |
| Initial value: | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Function |
|--------|----------|---------------|-----|--|
| 7 | TXDMY | 0 | R/W | <p>Dummy Data Transmission Enable</p> <p>Enables or disables dummy data transmission.</p> <p>When communication is performed with this bit set to 1, dummy data is transmitted from the MOSI pin and a serial communication can be performed even if there is no transmit data in the transmit buffer.</p> <p>Specifically, if there is no transmit data in the transmit buffer and this bit is set to 1, dummy data is transferred to the shift register. Data previously transmitted from the pin is used as dummy data. If this bit is set to 1 after the initialization and a transfer is performed, the transmitted dummy data is undefined.</p> <p>0: Disables dummy data transmission.</p> <p>1: Enables dummy data transmission.</p> <p>Note: This bit is valid only in the master mode.</p> |
| 6 | SPLW1 | 0 | R/W | <p>Access Width Specification</p> <p>Specifies the width for accessing the data register (SPDR). If the length of data transferred to SPDR does not agree with these bit settings, operation is not guaranteed.*</p> <p>00: Setting prohibited</p> <p>01: SPDR is accessed in bytes (8 bits).</p> <p>10: SPDR is accessed in words (16 bits).</p> <p>11: SPDR is accessed in longwords (32 bits).</p> |
| 5 | SPLW0 | 1 | R/W | |
| 4 to 0 | — | All 0 | R | <p>Reserved</p> <p>The write value should always be 0. Otherwise, operation cannot be guaranteed.</p> |

Note: * The data length is specified by the SPB3 to SPB0 bits in the command register (SPCMD).
See section 19.3.5, Data Register (SPDR).

19.3.10 Clock Delay Register (SPCKD)

SPCKD sets a period from the beginning of SSL signal assertion to RSPCK oscillation (RSPCK delay) when the SCKDEN bit in the command register (SPCMD) is 1. If the contents of SPCKD are changed while the MSTR and SPE bits in the control register (SPCR) are 1 with the function of this module enabled in master mode, the subsequent operation cannot be guaranteed.

When using this module in slave mode, set B'000 to SCKDL2 to SCKDL0.

| | | | | | | | | |
|----------------|---|---|---|---|---|------------|------------|------------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | SCK DL2 | SCK DL1 | SCK DL0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Function |

19.3.11 Slave Select Negation Delay Register (SSLND)

SSLND sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the SSL signal during a serial transfer by this module in master mode. If the contents of SSLND are changed while the MSTR and SPE bits in the control register (SPCR) are 1 with the function of this module enabled in master mode, the subsequent operation cannot be guaranteed.

When using this module in slave mode, set B'000 to SLNDL2 to SLNDL0.

| | | | | | | | | |
|----------------|---|---|---|---|---|------------|------------|------------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | SLN DL2 | SLN DL1 | SLN DL0 |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| 2 | SLNDL2 | 0 | R/W | SSL Negation Delay Setting |
| 1 | SLNDL1 | 0 | R/W | These bits set an SSL negation delay when the SLNDEN bit in SPCMD is 1. |
| 0 | SLNDL0 | 0 | R/W | The relationship between the setting of SLNDL2 to SLNDL0 and the SSL negation delay value is shown below. 000: 1 RSPCK 001: 2 RSPCK 010: 3 RSPCK 011: 4 RSPCK 100: 5 RSPCK 101: 6 RSPCK 110: 7 RSPCK 111: 8 RSPCK |

19.3.12 Next-Access Delay Register (SPND)

SPND sets a non-active period (next-access delay) after termination of a serial transfer when the SPNDEN bit in the command register (SPCMD) is 1. If the contents of SPND are changed while the MSTR and SPE bits in the control register (SPCR) are 1 with the function of this module enabled in master mode, the subsequent operation cannot be guaranteed.

When using this module in slave mode, set B'000 to SPNDL2 to SPNDL0.

19.3.13 Command Register (SPCMD)

Each channel has four command registers (SPCMD0 to SPCMD3). SPCMD0 to SPCMD3 are used to set a transfer format for master mode operation. Some of the bits in SPCMD0 are used to set a transfer mode for slave mode operation. In master mode, this module sequentially references SPCMD0 to SPCMD3 according to the settings in bits SPSTN1 and SPSTN0 in the sequence control register (SPSCR), and executes the serial transfer that is set in the referenced SPCMD. While bit TEND in the status register (SPSR) indicates that transmission is not completed, correct operation of this module cannot be guaranteed if SPCMD is changed that is referred by this module. SPCMD referenced by this module in master mode can be checked by means of bits SPCP1 and SPCP0 in the sequence status register (SPSSR). When the function of this module in slave mode is enabled, operation cannot be guaranteed if the value set in SPCMD0 is changed.

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------------|--------|--------|--------|------|------|------|------|------|-------|---|---|---|-------|-------|------|------|
| | SCKDEN | SLNDEN | SPNDEN | LSBF | SPB3 | SPB2 | SPB1 | SPB0 | SSLKP | — | — | — | BRDV1 | BRDV0 | CPOL | CPHA |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 1 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | R | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Function |
|-----|----------|---------------|-----|--|
| 15 | SCKDEN | 0 | R/W | RSPCK Delay Setting Enable Sets the period from the point this module in master mode activates the SSL signal until the RSPCK starts oscillation (RSPCK delay). If the SCKDEN bit is 0, this module sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, this module starts the oscillation of RSPCK at an RSPCK delay in compliance with the clock delay register (SPCKD) settings. To use this module in slave mode, the SCKDEN bit should be set to 0. 0: An RSPCK delay of 1 RSPCK 1: An RSPCK delay equal to SPCKD settings. |
| 14 | SLNDEN | 0 | R/W | SSL Negation Delay Setting Enable Sets the period from the point this module in master mode stops RSPCK oscillation until this module sets the SSL signal inactive (SSL negation delay). If the SLNDEN bit is 0, this module sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, this module negates the SSL signal at an SSL negation delay in compliance with the slave select negation delay register (SSLND) settings. To use this module in slave mode, the SLNDEN bit should be set to 0. 0: An SSL negation delay of 1 RSPCK 1: An SSL negation delay equal to SSLND settings. |
| 13 | SPNDEN | 0 | R/W | Next-Access Delay Enable Sets the period from the point this module in master mode terminates a serial transfer and sets the SSL signal inactive until this module enables the SSL signal assertion for the next access (next-access delay). If the SPNDEN bit is 0, this module sets the next-access delay to 1 RSPCK + 2P1φ. If the SPNDEN bit is 1, this module inserts a next-access delay in compliance with the next-access delay register (SPND) settings. To use this module in slave mode, the SPNDEN bit should be set to 0. 0: A next-access delay of 1 RSPCK + 2 P1φ 1: A next-access delay equal to SPND settings. |
| 12 | LSBF | 0 | R/W | LSB First Sets the data format in master mode or slave mode to MSB first or LSB first. 0: MSB first 1: LSB first |
| 11 | SPB3 | 0 | R/W | Data Length Setting |
| 10 | SPB2 | 1 | R/W | These bits set a transfer data length in master mode or slave mode. |
| 9 | SPB1 | 1 | R/W | 0100 to 0111: 8 bits |
| 8 | SPB0 | 1 | R/W | 1111: 16 bits 0010, 0011: 32 bits Others: Setting prohibited |

| Bit | Bit Name | Initial Value | R/W | Function |
|--------|----------|---------------|-----|---|
| 7 | SSLKP | 0 | R/W | <p>SSL Signal Level Keeping</p> <p>When this module in master mode performs a serial transfer, this bit specifies whether the SSL signal level for the current command is to be kept or negated between the SSL negation timing associated with the current command and the SSL assertion timing associated with the next command.</p> <p>To use this module in slave mode, the SSLKP bit should be set to 0.</p> <p>0: Negates the SSL signal upon completion of transfer.</p> <p>1: Keeps the SSL signal level from the end of the transfer until the beginning of the next access.</p> |
| 6 to 4 | — | All 0 | R | <p>Reserved</p> <p>The write value should always be 0. Otherwise, operation cannot be guaranteed.</p> |
| 3 | BRDV1 | 1 | R/W | <p>Bit Rate Division Setting</p> <p>These bits are used to determine the bit rate. A bit rate is determined by combinations of bits BRDV1 and BRDV 0 and the settings in the bit rate register (SPBR) (see section 19.3.8, Bit Rate Register (SPBR)). The settings in SPBR determine the base bit rate. The settings in bits BRDV1 and BRDV0 are used to select a bit rate which is obtained by dividing the base bit rate by 1, 2, 4, or 8. In the bits SPCMD0 to SPCMD3, different BRDV1 and BRDV0 settings can be specified. This permits the execution of serial transfers at a different bit rate for each command.</p> <p>00: Select the base bit rate.</p> <p>01: Select the base bit rate divided by 2.</p> <p>10: Select the base bit rate divided by 4.</p> <p>11: Select the base bit rate divided by 8.</p> |
| 2 | BRDV0 | 1 | R/W | |
| 1 | CPOL | 0 | R/W | <p>RSPCK Polarity Setting</p> <p>Sets an RSPCK polarity in master or slave mode. When data communication is performed between the Renesas serial peripheral interface module and the other modules, the same RSPCK polarity should be set for both modules.</p> <p>0: RSPCK = 0 when idle</p> <p>1: RSPCK = 1 when idle</p> |
| 0 | CPHA | 1 | R/W | <p>RSPCK Phase Setting</p> <p>Sets an RSPCK phase in master or slave mode. When data communication is performed between the Renesas serial peripheral interface module and the other modules, the same RSPCK phase should be set for both modules.</p> <p>0: Data sampling on odd edge, data variation on even edge</p> <p>1: Data variation on odd edge, data sampling on even edge</p> |

19.3.14 Buffer Control Register (SPBFCR)

SPBFCR resets the number of data units in the transmit buffer (SPTX) or receive buffer (SPRX) and sets the number of triggering data units.

| | | | | | | | | |
|----------------|-------|-------|------------|-----|---|------------|-----|-----|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | TXRST | RXRST | TXTRG[1:0] | | — | RXTRG[2:0] | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Function |
|--------|------------|---------------|-----|--|
| 7 | TXRST | 0 | R/W | Transmit Buffer Data Reset Resets the transmit buffer to an empty state. Transmit data in the transmit buffer becomes invalid when this bit is set to 1. 0: Disables the reset operation.* 1: Enables the reset operation Note: * The reset operation is performed after a power-on reset. |
| 6 | RXRST | 0 | R/W | Receive Buffer Data Reset Resets the receive buffer to an empty state. Receive data in the receive buffer becomes invalid when this bit is set to 1. 0: Disables the reset operation.* 1: Enables the reset operation Note: * The reset operation is performed after a power-on reset. |
| 5, 4 | TXTRG[1:0] | 00 | R/W | Transmit Buffer Data Triggering Number Specifies the timing at which the transmit buffer empty state is determined, that is when the SPTEF flag in the status register is set. When the number of bytes of data in the transmit buffer (SPTX) is equal to or less than the specified triggering number, the SPTEF flag is set to 1. 00: 7 bytes (1)* 01: 6 bytes (2)* 10: 4 bytes (4)* 11: 0 bytes (8)* Note: * The value in the parenthesis shows the number of available bytes in the transmit buffer (SPTX). |
| 3 | — | 0 | R | Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed. |
| 2 to 0 | RXTRG[2:0] | 000 | R/W | Receive Buffer Data Triggering Number Specifies the timing at which the receive buffer full state is determined, that is when the SPRF flag in the status register is set. When the number of bytes of data in the receive buffer (SPRX) is equal to or greater than the specified triggering number, the SPRF flag is set to 1. 000: 1 byte (31)* 001: 2 bytes (30)* 010: 4 bytes (28)* 011: 8 bytes (24)* 100: 16 bytes (16)* 101: 24 bytes (8)* 110: 32 bytes (0)* 111: 5 bytes (27)* Note: * The value in the parenthesis shows the number of available bytes in the receive buffer (SPRX). |

19.3.15 Buffer Data Count Setting Register (SPBFDR)

SPBFDR indicates the number of data units stored in the transmit buffer (SPTX) and receive buffer (SPRX). The upper eight bits indicate the number of transmit data units in SPTX and the lower eight bits indicate the number of receive data units in SPRX.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|--------|----|---|---|---|---|--------|---|---|---|---|---|

| | — | — | — | — | T[3:0] | | | | — | — | R[5:0] | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Function |
|----------|----------|---------------|-----|---|
| 15 to 12 | — | All 0 | R | Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed. |
| 11 to 8 | T[3:0] | 0000 | R | Indicates the number of bytes of data to be transmitted in SPTX. B'0000 indicates that SPTX is empty. B'1000 indicates that SPTX is full. |
| 7, 6 | — | All 0 | R | Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed. |
| 5 to 0 | R[5:0] | 000000 | R | Shows the number of bytes of received data in SPRX. B'000000 indicates that SPRX is empty. B'100000 indicates that SPRX is full. |

19.4 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data.

19.4.1 Overview of Operations

This module is capable of serial transfers in slave mode and master mode. A particular mode of this module can be selected by using the MSTR bit in the control register (SPCR). Table 19.4 gives the relationship between the modes and SPCR settings, and a description of each mode.

Table 19.4 Relationship between Modes and SPCR and Description of Each Mode

| Mode | Slave (SPI Operation) | Master (SPI Operation) |
|------------------------------------|---------------------------------------|---|
| MSTR bit setting | 0 | 1 |
| MODFEN bit setting | 0 or 1 | 0 |
| RSPCK signal | Input | Output |
| MOSI signal | Input | Output |
| MISO signal | Output/Hi-Z | Input |
| SSL signal | Input | Output |
| SSL polarity modification function | Supported | Supported |
| Transfer rate | Up to $P1\phi/8$ | Up to $P1\phi/2$ |
| Clock source | RSPCK input | On-chip baud rate generator |
| Clock polarity | Two | Two |
| Clock phase | Two | Two |
| First transfer bit | MSB/LSB | MSB/LSB |
| Transfer data length | 8, 16, or 32 bits | 8, 16, or 32 bits |
| Burst transfer | Possible (CPHA = 1) | Possible (CPHA = 0,1) |
| RSPCK delay control | Not supported | Supported |
| SSL negation delay control | Not supported | Supported |
| Next-access delay control | Not supported | Supported |
| Transfer activation method | SSL input active or RSPCK oscillation | Transmit buffer is written when SPE = 1 |
| Sequence control | Not supported | Supported |
| Transmit buffer empty detection | Supported | Supported |
| Receive buffer full detection | Supported | Supported |
| Overrun error detection | Supported | Not Supported |
| Mode fault error detection | Supported (MODFEN = 1) | Not supported |

19.4.2 Pin Control

According to the MSTR bit in the control register (SPCR), this module can automatically switch pin directions and output modes. Table 19.5 shows the relationship between pin states and bit settings.

Table 19.5 Relationship between Pin States and Bit Settings

| Mode | Pin | Pin State* |
|--|-------|------------------|
| Master mode (SPI operation) (MSTR = 1) | RSPCK | CMOS output |
| | SSL | CMOS output |
| | MOSI | CMOS output |
| | MISO | Input |
| Slave mode (SPI operation) (MSTR = 0) | RSPCK | Input |
| | SSL | Input |
| | MOSI | Input |
| | MISO* | CMOS output/Hi-Z |

Note: * When SSL is at the non-active level or the SPE bit in SPCR is cleared to 0, the pin state is Hi-Z.

This module in master mode (SPI operation) determines MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) according to MOIFE and MOIFV bit settings in SPPCR, as shown in Table 19.6.

Table 19.6 MOSI Signal Value Determination during SSL Negation Period

| MOIFE | MOIFV | MOSI Signal Value during SSL Negation Period |
|-------|-------|--|
| 0 | 0, 1 | Last output value from previous transfer (The value is undefined when CPHA is 0) |
| 1 | 0 | Always 0 |
| 1 | 1 | Always 1 |

19.4.3 System Configuration Example

(1) Master/Slave (with This LSI Acting as Master)

Figure 19.2 shows a master/slave system configuration example when this LSI is used as a master. In master/slave configuration, the SSL output of this LSI (master) is not used. The SSL input of the slave is fixed to the low level, and the slave is always maintained in a selected state. In the transfer format corresponding to the case where the CPHA bit in the control register (SPCR) is 0, there are slave devices for which the SSL signal cannot be fixed to the active level. In situations where the SSL signal cannot be fixed, the SSL output of this LSI should be connected to the SSL input of the slave device.

This LSI (master) always drives the RSPCK and MOSI. The slave always drives the MISO.

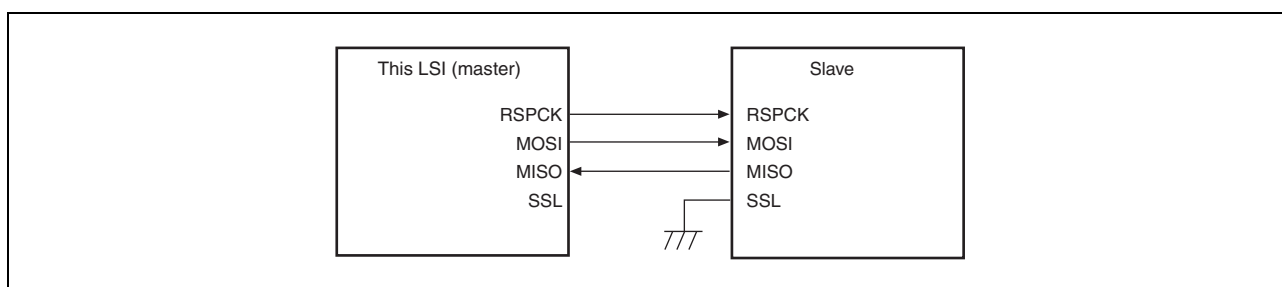

Figure 19.2 Master/Slave Configuration Example (This LSI = Master)

(2) Master/Slave (with This LSI Acting as Slave)

Figure 19.3 shows a master/slave system configuration example when this LSI is used as a slave. When this LSI is to operate as a slave, the SSL pin is used as SSL input. The master always drives the RSPCK and MOSI. This LSI (slave) always drives the MISO. When SSL is at the non-active level, the pin state is Hi-Z.

In the slave configuration in which the CPHA bit in the command register (SPCMD) is set to 1, the SSL input of this LSI (slave) is fixed to the 0 level, this LSI (slave) is always maintained in a selected state, and in this manner it is possible to execute serial transfer (Figure 19.4).

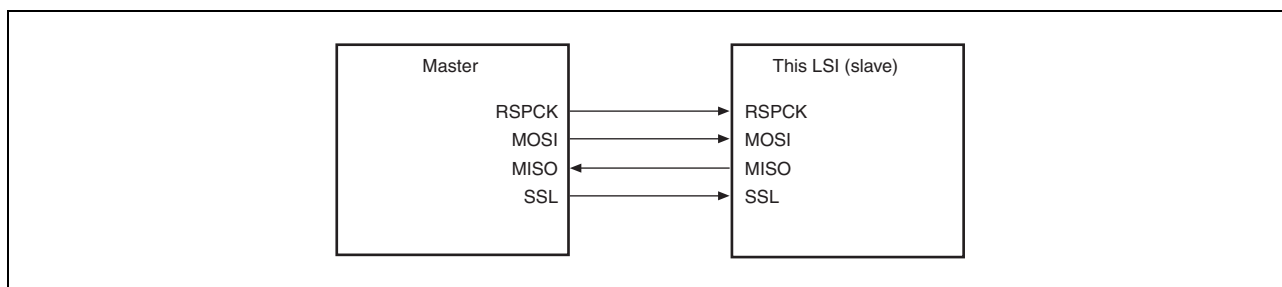

Figure 19.3 Master/Slave Configuration Example (This LSI = Slave)

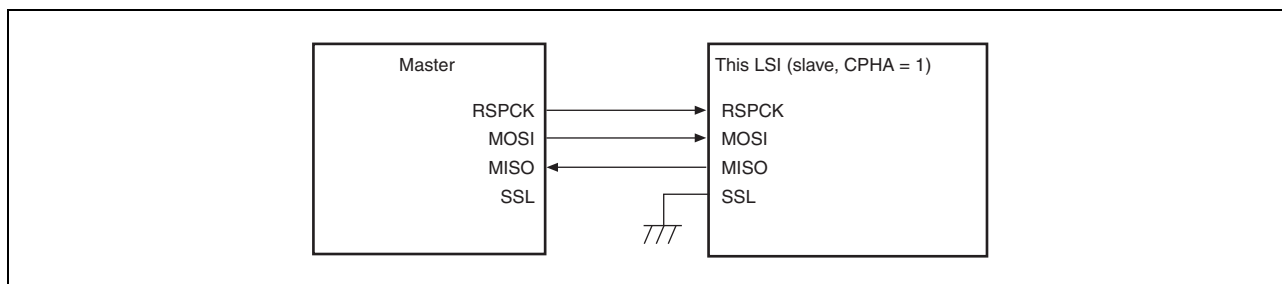

Figure 19.4 Master/Slave Configuration Example (This LSI = Slave, CPHA = 1)

(3) Master/Multi-Slave (with This LSI Acting as Slave)

Figure 19.5 shows a master/multi-slave system configuration example when this LSI is used as a slave. In the example of Figure 19.5, the system is comprised of a master and two LSIs (slave X and slave Y).

The RSPCK and MOSI outputs of the master are connected to the RSPCK and MOSI inputs of the LSIs (slave X and slave Y). The MISO outputs of the LSIs (slave X and slave Y) are all connected to the MISO input of the master. SSLX and SSLY outputs of the master are connected to the SSL inputs of the LSIs (slave X and slave Y), respectively.

The master always drives RSPCK, MOSI, SSLX, and SSLY. Of the LSIs (slave X and slave Y), the slave that receives low level input into the SSL0 input drives MISO.

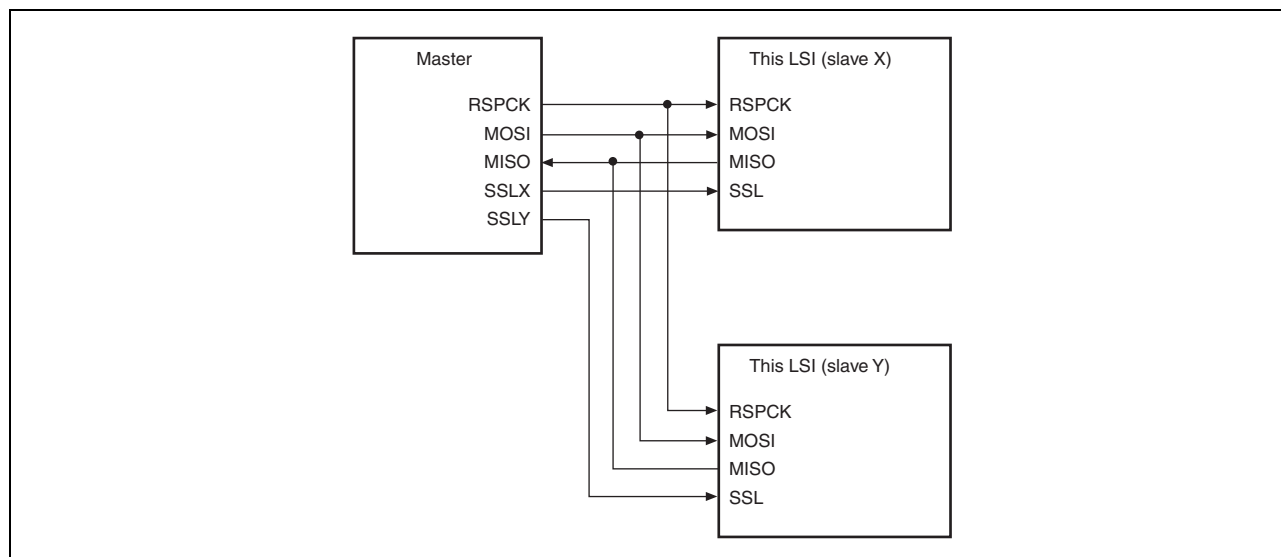

Figure 19.5 Master/Multi-Slave Configuration Example (This LSI = Slave)

19.4.4 Transfer Format

(1) CPHA = 0

Figure 19.6 shows a sample transfer format for the serial transfer of 8-bit data when the CPHA bit in the command register (SPCMD) is 0. In Figure 19.6, RSPCK (CPOL = 0) indicates the RSPCK signal waveform when the CPOL bit in SPCMD is 0; RSPCK (CPOL = 1) indicates the RSPCK signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which this module fetches serial transfer data into the shift register. The input/output directions of the signals depend on the settings of this module. For details, see section 19.4.2, Pin Control.

When the CPHA bit is 0, the driving of valid data to the MOSI and MISO signals commences at an SSL signal assertion timing. The first RSPCK signal change timing that occurs after the SSL signal assertion becomes the first transfer data fetching timing. After this timing, data is sampled at every 1 RSPCK cycle. The change timing for MOSI and MISO signals is always 1/2 RSPCK cycle after the transfer data fetch timing. The settings in the CPOL bit do not affect the RSPCK signal operation timing; they only affect the signal polarity.

t1 denotes a period from an SSL signal assertion to RSPCK oscillation (RSPCK delay). t2 denotes a period from the cessation of RSPCK oscillation to an SSL signal negation (SSL negation delay). t3 denotes a period in which SSL signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the system. For a description of t1, t2, and t3 when this module is in master mode, see section 19.4.3, (1) Master/Slave (with This LSI Acting as Master).

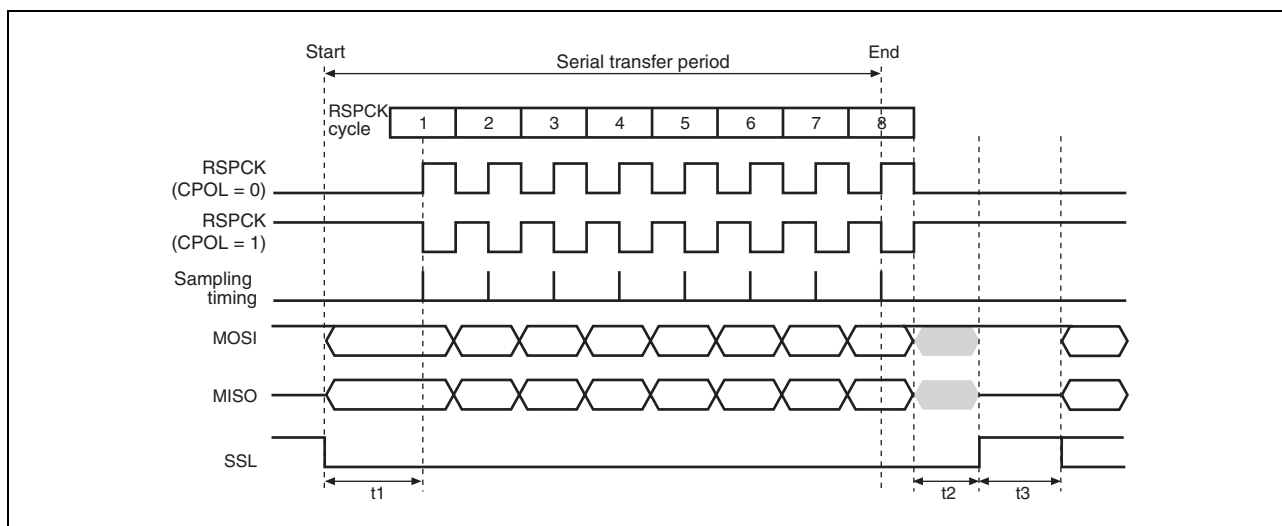

Figure 19.6 Transfer Format (CPHA = 0)

(2) CPHA = 1

Figure 19.7 shows a sample transfer format for the serial transfer of 8-bit data when the CPHA bit in the command register (SPCMD) is 1. In Figure 19.7, RSPCK (CPOL = 0) indicates the RSPCK signal waveform when the CPOL bit in SPCMD is 0; RSPCK (CPOL = 1) indicates the RSPCK signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which this module fetches serial transfer data into the shift register. The input/output directions of the signals depend on the modes (master or slave). For details, see 19.4.2 Pin Control.

When the CPHA bit is 1, the driving of invalid data to the MOSI and MISO signals commences at an SSL signal assertion timing. The driving of valid data to the MOSI and MISO signals commences at the first RSPCK signal change timing that occurs after the SSL signal assertion. After this timing, data is updated at every 1 RSPCK cycle. The transfer data fetch timing is always 1/2 RSPCK cycle after the data update timing. The settings in the CPOL bit do not affect the RSPCK signal operation timing; they only affect the signal polarity.

t1, t2, and t3 are the same as those in the case of CPHA = 0. For a description of t1, t2, and t3 when this module is in master mode, see section 19.4.3, (1) Master/Slave (with This LSI Acting as Master).

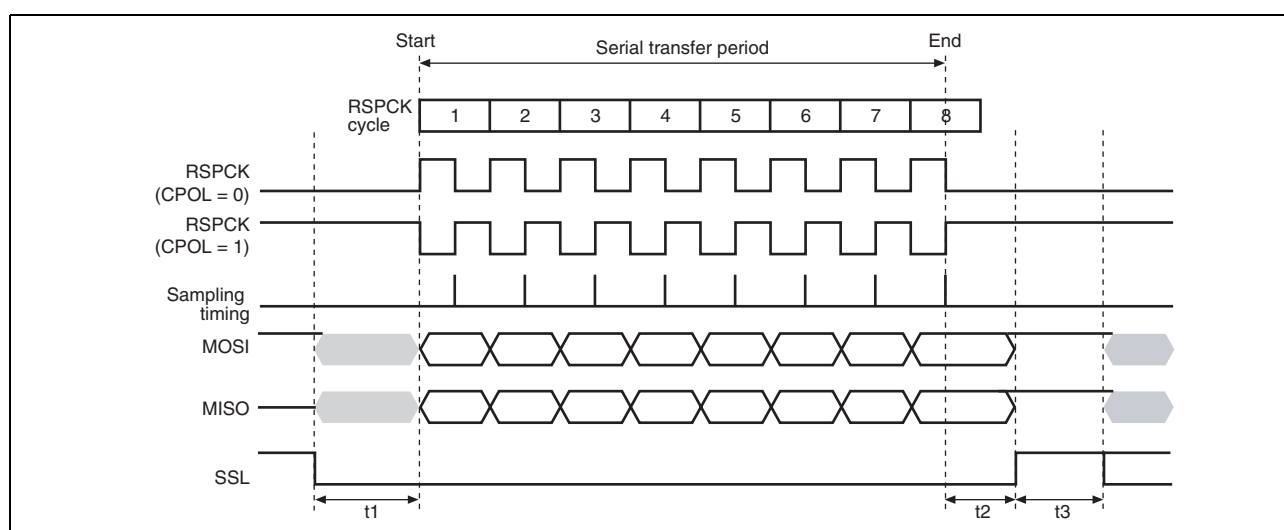

Figure 19.7 Transfer Format (CPHA = 1)

19.4.5 Data Format

The data format depends on the settings in the command register (SPCMD). Irrespective of MSB/LSB first, this module treats the range from the LSB of the data register (SPDR) to the assigned data length as transfer data.

(1) MSB First Transfer (32-Bit Data)

Figure 19.8 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs a 32-bit data length MSB-first data transfer.

The CPU or direct memory access controller writes T31 to T00 to the transmit buffer of SPDR. If the shift register is empty, this module copies the data in the transmit buffer to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from the MSB (bit 31) in the shift register, and shifts in the data from the LSB (bit 0) in the shift register. When the RSPCK cycle required for the serial transfer of 32 bits has passed, data R31 to R00 is stored in the shift register. In this state, this module copies the data from the shift register to the receive buffer, and empties the shift register. If the receive buffer does not have a space for the receive data length after the receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary space in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer, received data R31 to R00 is shifted out from the shift register.

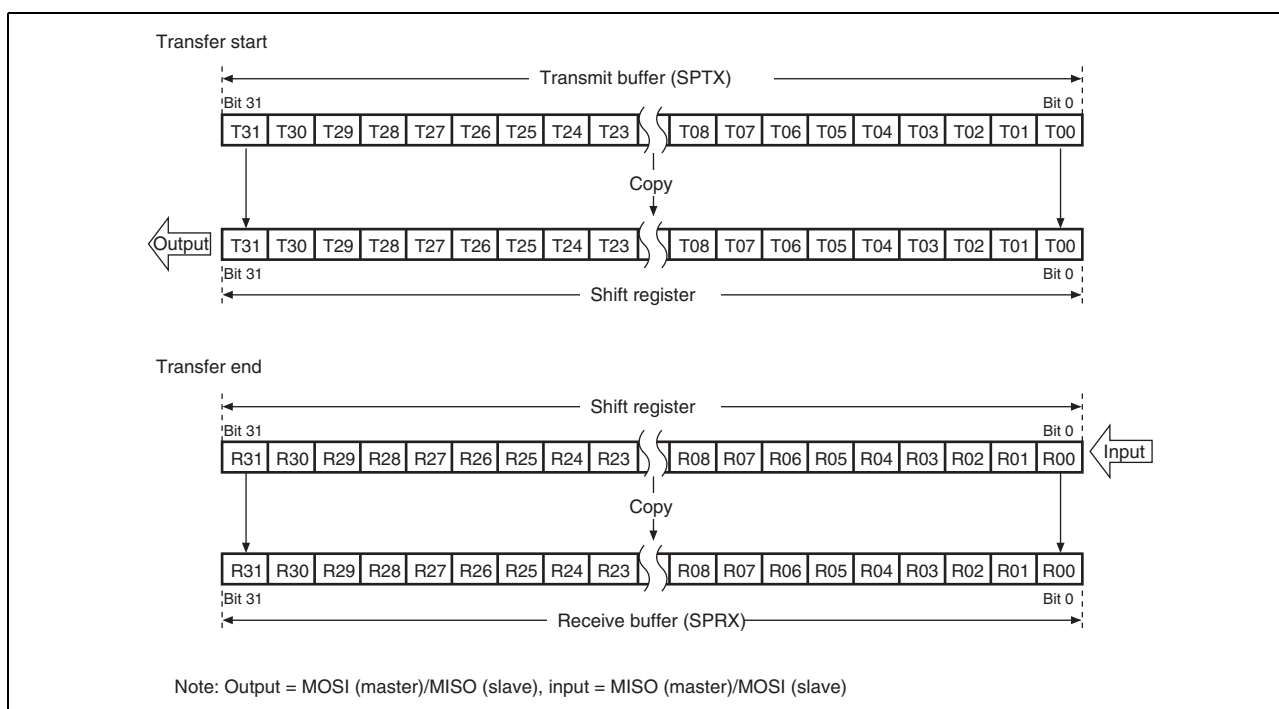

Figure 19.8 MSB First Transfer (32-Bit Data)

(2) MSB First Transfer (16-Bit Data)

Figure 19.9 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs a 16-bit data length MSB-first data transfer.

The CPU or direct memory access controller writes T15 to T00 to the transmit buffer. If the shift register is empty, this module copies the data in the transmit buffer to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from bit 15 in the shift register, and shifts in the data from the LSB (bit 0) in the shift register. When the RSPCK cycle required for the serial transfer of 16 bits has passed, received data R15 to R00 is stored in bits 15 to 0 in the shift register. After completion of the serial transfer, data that existed before the transfer is retained in bits 31 to 16 in the shift register. In this state, this module copies the data from the shift register to the receive buffer, and empties the shift register. If the receive buffer does not have a space for the receive data length after receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary space in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer, received data R15 to R00 is shifted out from the shift register.

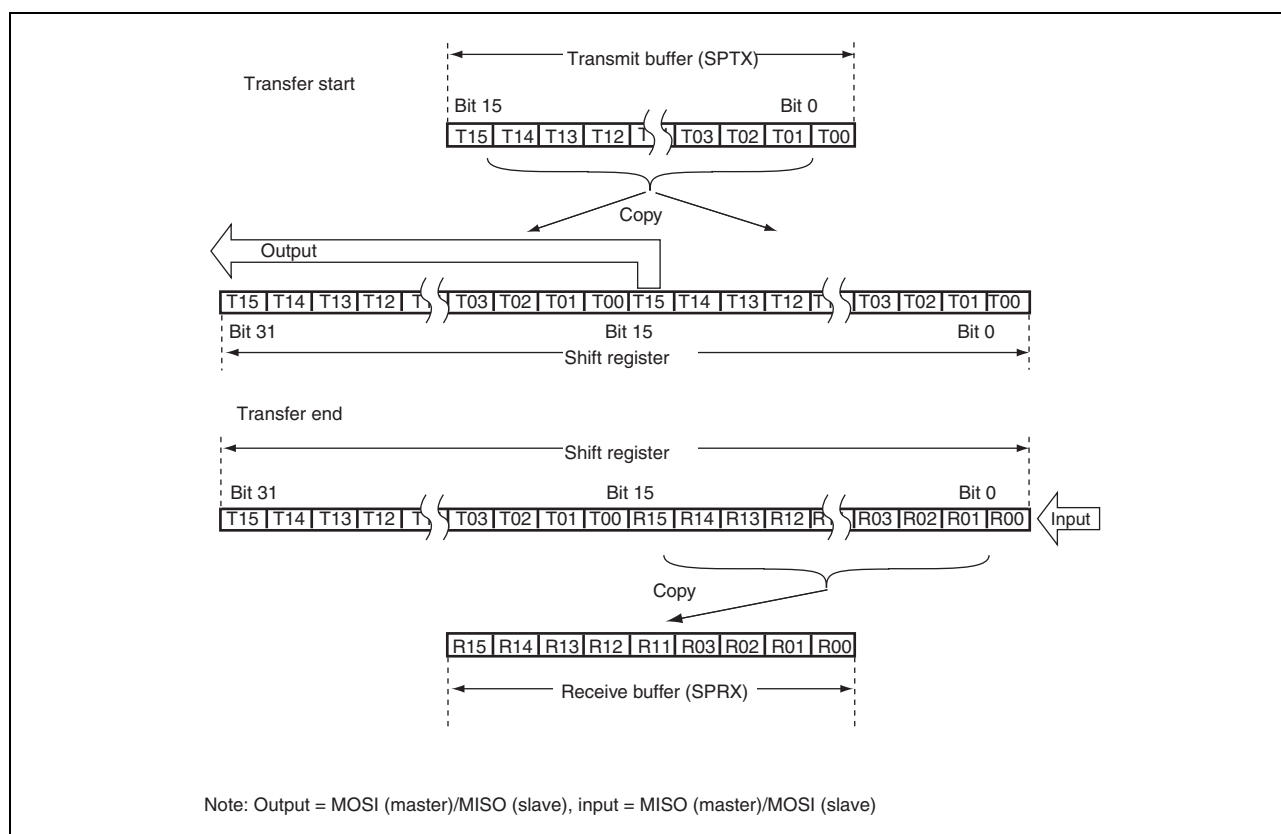

Figure 19.9 MSB First Transfer (16-Bit Data)

(3) MSB First Transfer (8-Bit Data)

Figure 19.10 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs an 8-bit data transfer.

The CPU or direct memory access controller writes T07 to T00 to the transmit buffer. If the shift register is empty, this module copies the data in the transmit buffer to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from bit 7 in the shift register, and shifts in the data from the LSB (bit 0) in the shift register. When the RSPCK cycle required for the serial transfer of 8 bits has passed, received data R07 to R00 is stored in bits 7 to 0 in the shift register. After completion of the serial transfer, data that existed before the transfer is retained in bits 31 to 8 in the shift register. In this state, this module copies the data from the shift register to the receive buffer, and empties the shift register. If the receive buffer does not have a space for the receive data length after receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary area in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer, received data R07 to R00 is shifted out from the shift register.

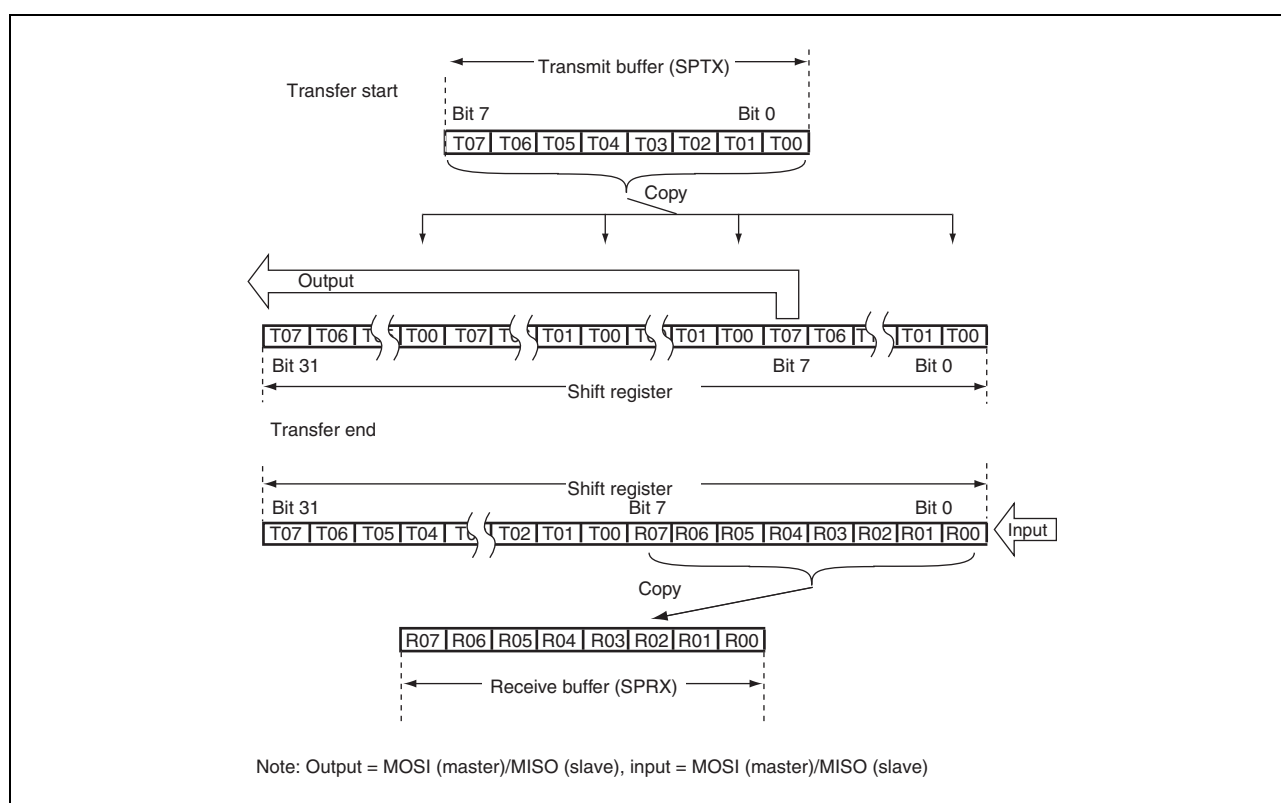

Figure 19.10 MSB First Transfer (8-Bit Data)

(4) LSB First Transfer (32-Bit Data)

Figure 19.11 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs a 32-bit data length LSB-first data transfer.

The CPU or direct memory access controller writes T31 to T00 to the transmit buffer. If the shift register is empty, this module reverses the order of the bits of the data in the transmit buffer, copies it to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from the MSB (bit 31) in the shift register, and shifts in the data from the LSB (bit 0) in the shift register. When the RSPCK cycle required for the serial transfer of 32 bits has passed, data R00 to R31 is stored in the shift register. In this state, this module copies the data, in which the order of the bits is reversed, from the shift register to the receive buffer, and empties the shift register. If the receive buffer does not have a space for the receive data length after receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary space in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer of the SPDR, received data R00 to R31 is shifted out from the shift register.

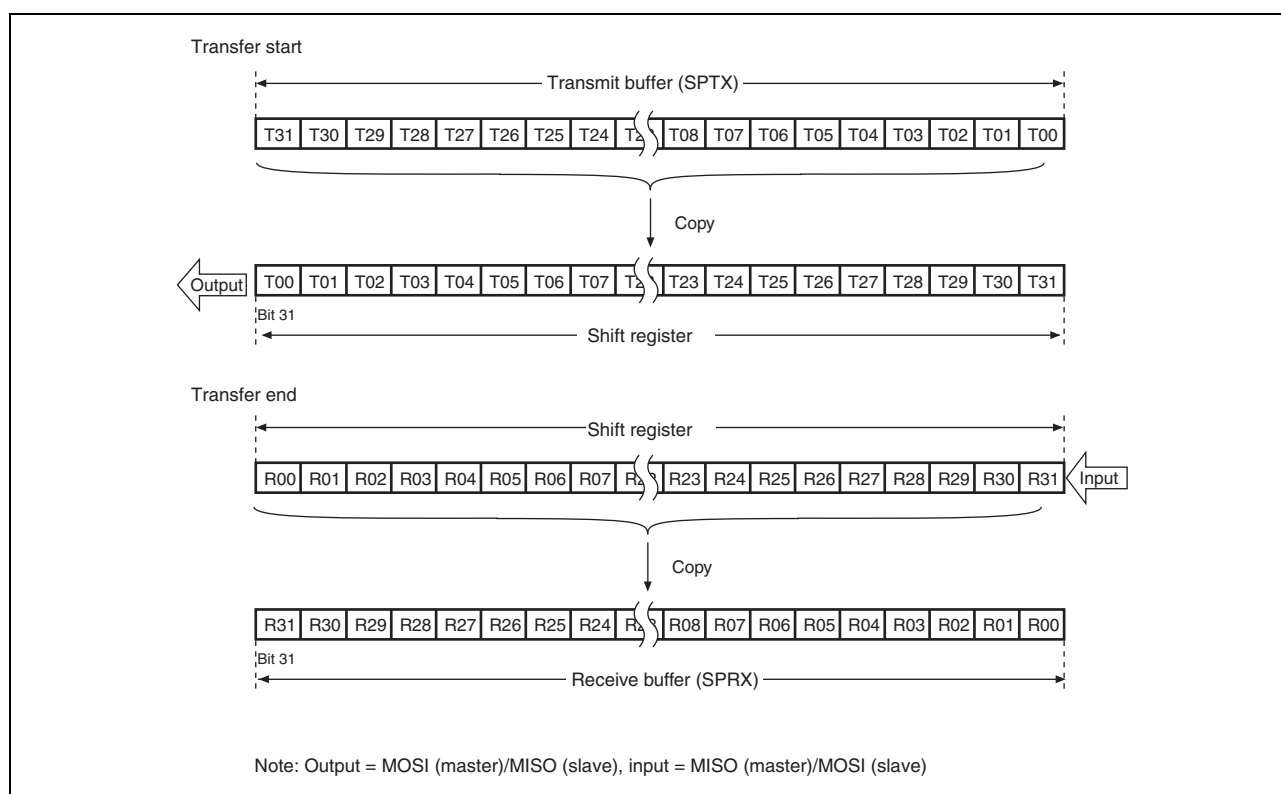

Figure 19.11 LSB First Transfer (32-Bit Data)

(5) LSB First Transfer (16-Bit Data)

Figure 19.12 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs a 16-bit data length LSB-first data transfer.

The CPU or direct memory access controller writes T15 to T00 to the transmit buffer. If the shift register is empty, this module reverses the order of the bits of the data in the transmit buffer, copies it to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from the MSB (bit 31) in the shift register, and shifts in the data from bit 16 in the shift register. When the RSPCK cycle required for the serial transfer of 16 bits has passed, received data R00 to R15 is stored in bits 31 to 16 in the shift register. After completion of the serial transfer, data that existed before the transfer is retained in bits 15 to 0 in the shift register. In this state, this module copies the data, in which the order of the bits is reversed, from the shift register to the receive buffer of SPDR, and empties the shift register.

If the receive buffer does not have a space for the receive data length after receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary space in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer of SPDR, received data R00 to R15 is shifted out from the shift register.

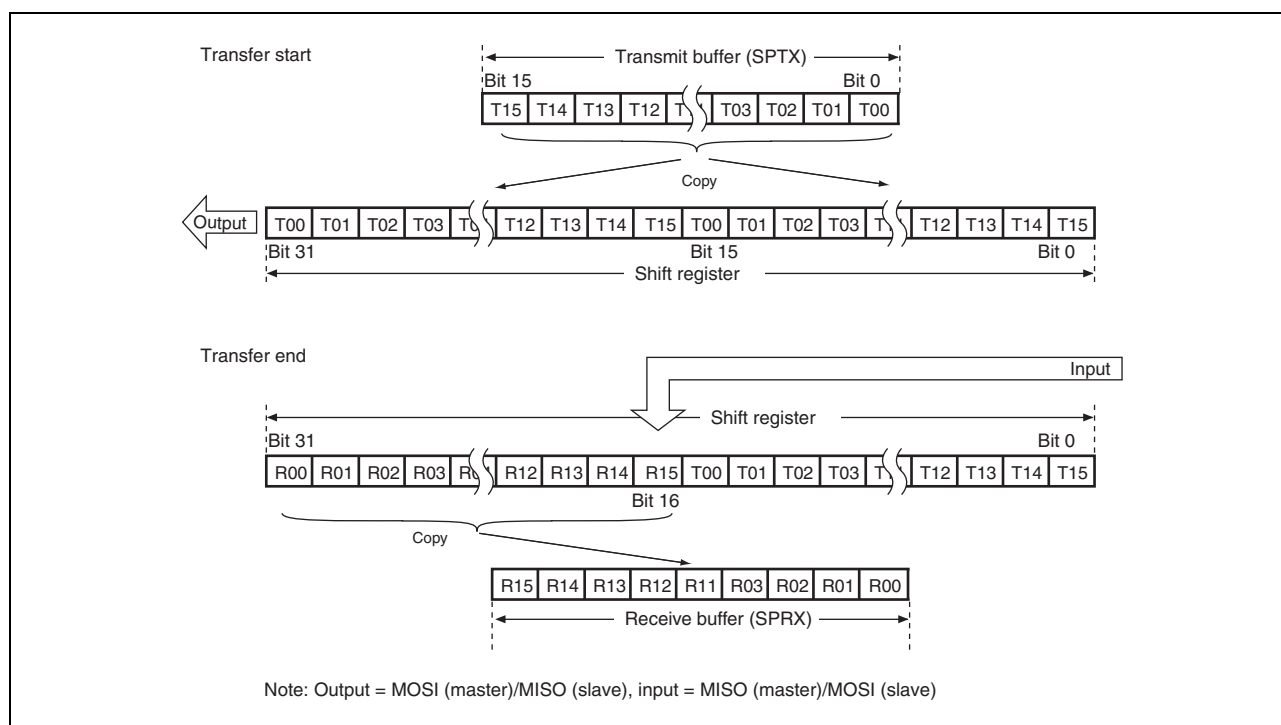

Figure 19.12 LSB First Transfer (16-Bit Data)

(6) LSB First Transfer (8-Bit Data)

Figure 19.13 shows the operation of the transmit buffer (SPTX) and the shift register when this module performs an 8-bit data length LSB-first data transfer.

The CPU or direct memory access controller writes T07 to T00 to the transmit buffer. If the shift register is empty, this module reverses the order of the bits of the data in the transmit buffer, copies it to the shift register, and fully populates the shift register. When serial transfer starts, this module outputs data from the MSB (bit 31) in the shift register, and shifts in the data from bit 24 in the shift register. When the RSPCK cycle required for the serial transfer of 8 bits has passed, received data R00 to R07 is stored in bits 31 to 24 of the shift register. After completion of the serial transfer, data that existed before the transfer is retained in bits 23 to 0 in the shift register. In this state, this module copies the data, in which the order of the bits is reversed, from the shift register to the receive buffer of SPDR, and empties the shift register.

If the receive buffer does not have a space for the receive data length after the receive data has been copied from the shift register to the receive buffer, another serial transfer will not be started. In order to start another serial transfer, data for the receive data length should be read from the receive buffer to secure the necessary space in the receive buffer.

If another serial transfer is started before the CPU or direct memory access controller writes to the transmit buffer of SPDR, received data R00 to R07 is shifted out from the shift register.

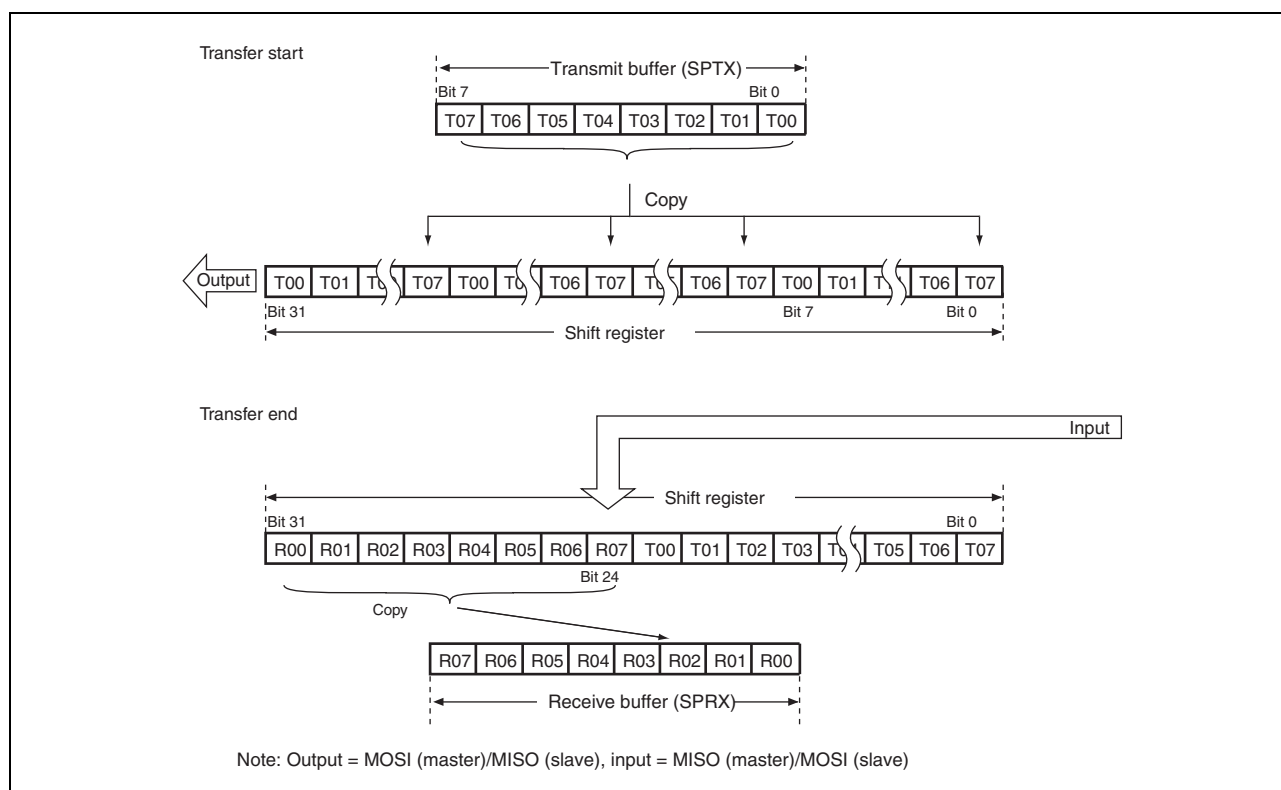

Figure 19.13 LSB First Transfer (8-Bit Data)

19.4.6 Error Detection

In the normal serial transfer, the data written to the transmit buffer of the data register (SPDR) is serially transmitted, and the serially received data can be read from the receive buffer of SPDR. If access is made to SPDR, depending on the status of the transmit buffer/receive buffer or the status at the beginning or end of serial transfer, in some cases non-normal transfers can be executed.

If a non-normal transfer operation occurs, this module detects the event as an overrun error or a mode fault error. Table 19.7 shows the relationship between non-normal transfer operations and the error detection function.

Table 19.7 Relationship between Non-Normal Transfer Operations and Error Detection Function

| | Occurrence Condition | Operation | Error Detection |
|---|--|---|------------------------------------|
| A | SPDR is written when the transmit buffer is full. | Missing write data. | None |
| B | Serial transfer is started in slave mode when transmit data is still not loaded on the shift register. | Data received in previous serial transfer is serially transmitted. | None |
| C | SPDR is read when the receive buffer is empty. | The output data is undefined. | None |
| D | Serial transfer terminates when the receive buffer is full. | Missing serial receive data. | Overrun error (only in slave mode) |
| E | The SSL input signal is negated during serial transfer in slave mode. | Serial transfer suspended. Missing send/receive data. Operation disabled. | Mode fault error |

On operation A shown in Table 19.7, this module does not detect an error. Whether SPDR can be written to or not can be checked using the T[3:0] bits in the buffer data count setting register (SPBFDR).

Likewise, this module does not detect an error on operation B. In a serial transfer that was started before the shift register was updated, this module sends the data that was received in the previous serial transfer, and does not treat the operation indicated in B as an error. Note that the received data from the previous serial transfer is retained in the receive buffer of SPDR, thus it can be correctly read.

Similarly, this module does not detect an error on operation C. To prevent extraneous data from being read, the number of receive data units stored in the receive buffer should be read from the R[5:0] bits in the buffer data count setting register (SPBFDR).

An overrun error shown in D is described in section 19.4.6, (1) Overrun Errors. A mode fault error shown in E is described in section 19.4.6, (2) Mode Fault Error.

(1) Overrun Error

If serial transfer ends when the receive buffer of the data register (SPDR) is full, this module detects an overrun error, and sets the OVRF bit in SPSR to 1. When the OVRF bit is 1, this module does not copy data from the shift register to the receive buffer so that the data prior to the occurrence of the error is retained in the receive buffer. To reset the OVRF bit in SPSR to 0, either perform a power-on reset, or write a 0 to the OVRF bit after SPSR has been read with the OVRF bit set to 1.

Figure 19.14 shows an example of operation of the SPRF and OVRF bits in SPSR. The SPSR and SPDR accesses shown in Figure 19.14 indicate the condition of accesses to SPSR and SPDR, respectively, where I denotes an idle cycle, W a write cycle, and R a read cycle. In the example of Figure 19.14, this module performs an 8-bit serial transfer in which the CPHA bit in the command register (SPCMD) is 1, and CPOL is 0. The numbers given under the RSPCK waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

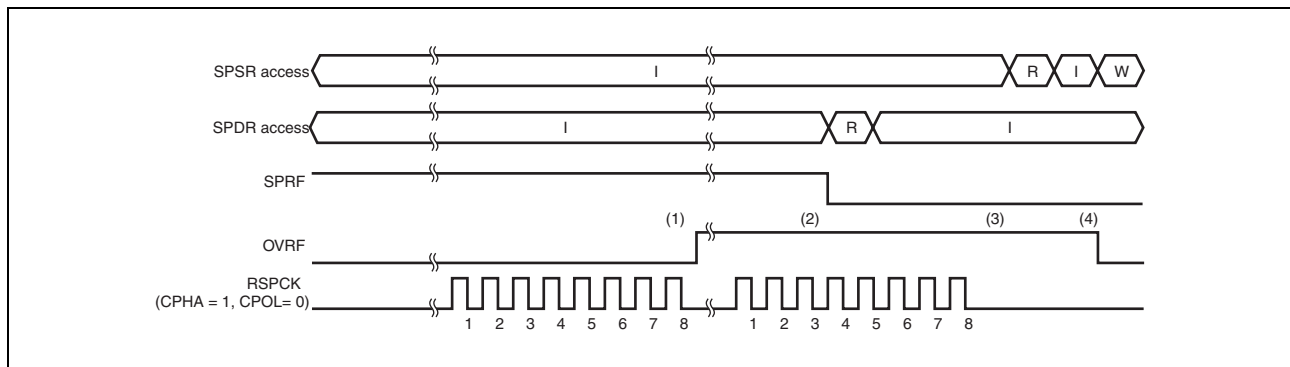

Figure 19.14 SPRF and OVRF Bit Operation Example

The operation of the flags at the timing shown in steps (1) to (4) in the figure is described below.

1. If a serial transfer terminates when the receive buffer does not have a space for the receive data length, this module detects an overrun error, and sets the OVRF bit to 1. This module does not copy the data in the shift register to the receive buffer.
2. The OVRF bit is not cleared even when SPDR is read and thus the number of data bytes in the receive buffer becomes less than the number of the receive buffer data triggering number specified by the RXTRG bits.
3. If the serial transfer terminates in an overrun error state, this module determines that the shift register is empty; in this manner, data transfer is enabled from the transmit buffer to the shift register.
4. If 0 is written to the OVRF bit after SPSR is read with OVRF = 1, this module clears the OVRF bit.

The occurrence of an overrun can be checked either by reading SPSR or by using an error interrupt and reading SPSR. When using an error interrupt, set the SPEIE bit in the control register (SPCR) to 1. When executing a serial transfer without using an error interrupt, measures should be taken to ensure the early detection of overrun errors, such as reading SPSR immediately after SPDR is read.

The OVRF bit is cleared to 0 under the following conditions:

- After SPSR is read in a condition in which the OVRF bit is set to 1, 0 is written to the OVRF bit.
- Power-on reset

Note: When the receive buffer has area enough to store receive data with an overrun error, this module receives receive data.

(2) Mode Fault Error

When the MSTR bit is 0, this module operates in slave mode. This module detects a mode fault error if the SSL input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched) when the MODFEN bit is 1 in slave mode.

Upon detecting a mode fault error, this module stops driving of the output signals and clears the SPE bit in SPCR to 0. When the SPE bit is cleared to 0, the function of this module is disabled and this module stops driving external signals. For details of disabling the function of this module by clearing the SPE bit to 0, see 19.4.7 Initialization.

The occurrence of a mode fault error can be checked either by reading SPSR or by using an error interrupt and reading SPSR. When using an error interrupt, set the SPEIE bit in the control register (SPCR) to 1. To detect a mode fault error without using an error interrupt, it is necessary to poll SPSR.

When the MODF bit is 1, writing 1 to the SPE bit is ignored. To enable the function of this module after the detection of a mode fault error, the MODF bit must be set to 0. The MODF bit is cleared to 0 under the following conditions:

- After SPSR is read in a condition where the MODF bit has turned 1, 0 is written to the MODF bit.
- Power-on reset

19.4.7 Initialization

If 0 is written to the SPE bit in the control register (SPCR) or this module clears the SPE bit to 0 because of the detection of a mode fault error, this module disables the module function, and initializes a part of the module function. When a power-on reset is generated, this module initializes all of the module function. An explanation follows of initialization by the clearing of the SPE bit.

(1) Initialization by Clearing SPE Bit

When the SPE bit in SPCR is cleared, this module performs the following initialization:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state
- Initializing the TEND bit in SPSR

Initialization by the clearing of the SPE bit does not initialize the control bits of this module. For this reason, this module can be started in the same transfer mode as prior to the initialization if the SPE bit is re-set to 1.

19.4.8 SPI Operation

(1) Multi-Master Mode Operation

This section explains the operation in multi-master mode.

(a) Starting Serial Transfer

A serial transfer is started when transmit data is copied from the transmit buffer to the shift register, the shift register becomes full, and the receive buffer has a space for the receive data length. If transmit data has already been written to the shift register, data is not copied from the transmit buffer to the shift register.

For details of the transfer format, see [section 19.4.4, Transfer Format](#).

(b) Terminating Serial Transfer

Irrespective of the CPHA bit in the command register (SPCMD), this module terminates the serial transfer after transmitting an RSPCK edge corresponding to the final sampling timing. After the serial transfer is completed, receive data is copied from the shift register to the receive buffer. If the receive buffer does not have a space for the receive data length after receive data is copied from the shift register to the receive buffer, another serial transfer will not be performed. In order to perform another serial transfer, data for the receive data length should be read from the receive buffer to secure the space for the receive data.

It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the data length depends on the settings in bits SPB3 to SPB0 in SPCMD. For details on the transfer format, see [section 19.4.4, Transfer Format](#).

(c) Sequence Control

The transfer format that is employed in master mode is determined by the sequence control register (SPSCR), command registers 0 to 3 (SPCMD0 to SPCMD3), the bit rate register (SPBR), the clock delay register (SPCKD), the slave select negation delay register (SSLND), and the next-access delay register (SPND).

SPSCR is a register used to determine the sequence configuration for serial transfers that are executed by this module in master mode. The following items are set in command registers SPCMD0 to SPCMD3: SSL output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. SPBR holds some of the bit rate settings; SPCKD, a clock delay value; SSLND, an SSL negation delay; and SPND, a next-access delay value.

According to the sequence length that is assigned to SPSCR, this module makes up a sequence comprised of a part or all of SPCMD0 to SPCMD3. This module contains a pointer to the SPCMD that makes up the sequence. The value of this pointer can be checked by reading bits SPCP1 and SPCP0 in the sequence status register (SPSSR). When the SPE bit in the control register (SPCR) is set to 1 and the function of this module is enabled, this module loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. This module increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, this module sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

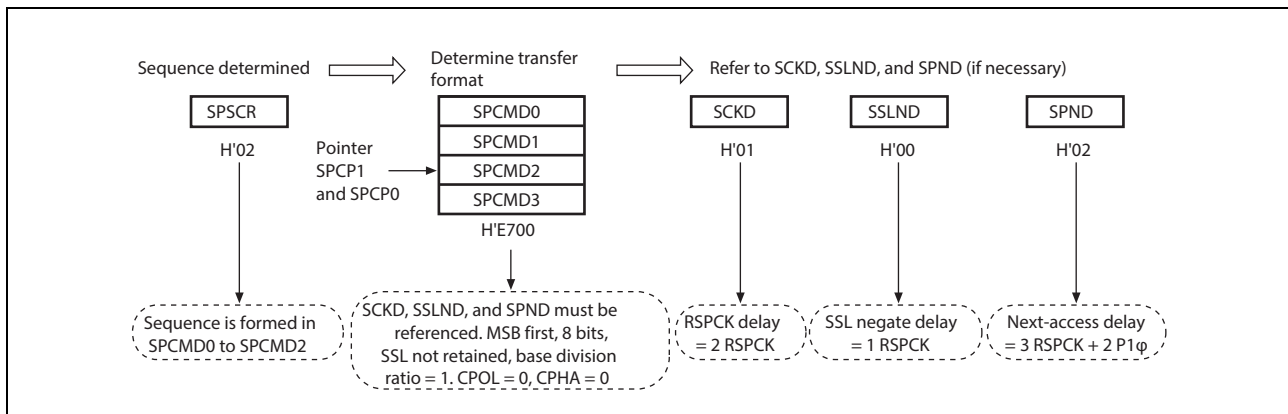

Figure 19.15 Determination Procedure of Serial Transfer Mode in Master Mode

(d) Burst Transfer

If the SSLKP bit in the command register (SPCMD) that this module references during the current serial transfer is 1, this module keeps the SSL signal level during the serial transfer until the beginning of the SSL signal assertion for the next serial transfer. If the SSL signal level for the next serial transfer is the same as the SSL signal level for the current serial transfer, this module can execute continuous serial transfers while keeping the SSL signal assertion status (burst transfer).

Figure 19.16 shows an example of an SSL signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 settings. The text below explains operations (1) to (7) as depicted in Figure 19.16. It should be noted that the polarity of the SSL output signal depends on the settings in the slave select polarity register (SSLP).

1. Based on SPCMD0, this module asserts the SSL signal and inserts RSPCK delays.
2. Serial transfers are executed according to SPCMD0.
3. SSL negation delays are inserted.
4. Because the SSLKP bit in SPCMD0 is 1, this module keeps the SSL signal value on SPCMD0. This period is sustained, at the shortest, for a period equal to the next-access delay of SPCMD0. If the shift register is empty after the passage of a minimum period, this period is sustained until such time as the transmit data is stored in the shift register for another transfer.
5. Based on SPCMD1, this module asserts the SSL signal and inserts RSPCK delays.
6. Serial transfers are executed according to SPCMD1.
7. Because the SSLKP bit in SPCMD1 is 0, this module negates the SSL signal. In addition, a next-access delay is inserted according to SPCMD1.

Figure 19.16 Example of Burst Transfer Operation using SSLKP Bit

If the SSL signal settings in the SPCMD in which 1 is assigned to the SSLKP bit are different from the SSL signal output settings in the SPCMD to be used in the next transfer, this module switches the SSL signal status to SSL signal assertion ((5) in Figure 19.16) corresponding to the command for the next transfer. Notice that if such an SSL signal switching occurs, the slaves that drive the MISO signal compete, and the possibility arises of the collision of signal levels.

This module in master mode references within the module the SSL signal operation for the case where the SSLKP bit is

not used. Even when the CPHA bit in SPCMD is 0, this module can accurately start serial transfers by asserting the SSL signal for the next transfer. For this reason, burst transfers in master mode can be executed irrespective of CPHA bit settings (see section 19.4.8, (2) Slave Mode Operation).

(e) RSPCK Delay (t_1)

The RSPCK delay value in master mode depends on SCKDEN bit settings in the command register (SPCMD) and on clock delay register (SPCKD) settings. This module determines the SPCMD to be referenced during serial transfer by pointer control, and determines an RSPCK delay value during serial transfer by using the SCKDEN bit in the selected SPCMD and SPCKD, as shown in Table 19.8. For a definition of RSPCK delay, see section 19.4.4, Transfer Format.

Table 19.8 Relationship among SCKDEN and SPCKD Settings and RSPCK Delay Values

| SCKDEN | SPCKD | RSPCK Delay Value |
|--------|------------|-------------------|
| 0 | 000 to 111 | 1 RSPCK |
| 1 | 000 | 1 RSPCK |
| | 001 | 2 RSPCK |
| | 010 | 3 RSPCK |
| | 011 | 4 RSPCK |
| | 100 | 5 RSPCK |
| | 101 | 6 RSPCK |
| | 110 | 7 RSPCK |
| | 111 | 8 RSPCK |

(f) SSL Negation Delay (t_2)

The SSL negation delay value in master mode depends on SLNDEN bit settings in the command register (SPCMD) and on SSL negation delay register (SSLND) settings. This module determines the SPCMD to be referenced during serial transfer by pointer control, and determines an SSL negation delay value during serial transfer by using the SLNDEN bit in the selected SPCMD and SSLND, as shown in Table 19.9. For a definition of SSL negation delay, see section 19.4.4, Transfer Format.

Table 19.9 Relationship among SLNDEN and SSLND Settings and SSL Negation Delay Values

| SLNDEN | SSLND | SSL Negation Delay Value |
|--------|------------|--------------------------|
| 0 | 000 to 111 | 1 RSPCK |
| 1 | 000 | 1 RSPCK |
| | 001 | 2 RSPCK |
| | 010 | 3 RSPCK |
| | 011 | 4 RSPCK |
| | 100 | 5 RSPCK |
| | 101 | 6 RSPCK |
| | 110 | 7 RSPCK |
| | 111 | 8 RSPCK |

(g) Next-Access Delay (t_3)

The next-access delay value in master mode depends on SPNDEN bit settings in the command register (SPCMD) and on next-access delay register (SPND) settings. This module determines the SPCMD to be referenced during serial transfer by pointer control, and determines a next-access delay value during serial transfer by using the SPNDEN bit in the selected SPCMD and SPND, as shown in Table 19.10. For a definition of next-access delay, see section 19.4.4, Transfer Format.

Table 19.10 Relationship among SPNDEN and SPND Settings and Next-Access Delay Values

| SPNDEN | SPND | Next-Access Delay Value |
|--------|------------|-------------------------|
| 0 | 000 to 111 | 1 RSPCK + 2 P1 ϕ |
| 1 | 000 | 1 RSPCK + 2 P1 ϕ |
| | 001 | 2 RSPCK + 2 P1 ϕ |
| | 010 | 3 RSPCK + 2 P1 ϕ |
| | 011 | 4 RSPCK + 2 P1 ϕ |
| | 100 | 5 RSPCK + 2 P1 ϕ |
| | 101 | 6 RSPCK + 2 P1 ϕ |
| | 110 | 7 RSPCK + 2 P1 ϕ |
| | 111 | 8 RSPCK + 2 P1 ϕ |

(h) Initialization Flowchart

Figure 19.17 is a flowchart illustrating an example of initialization in SPI operation when this module is used in master mode. For a description of how to set up the interrupt controller, direct memory access controller, and input/output ports, see the descriptions given in the individual blocks.

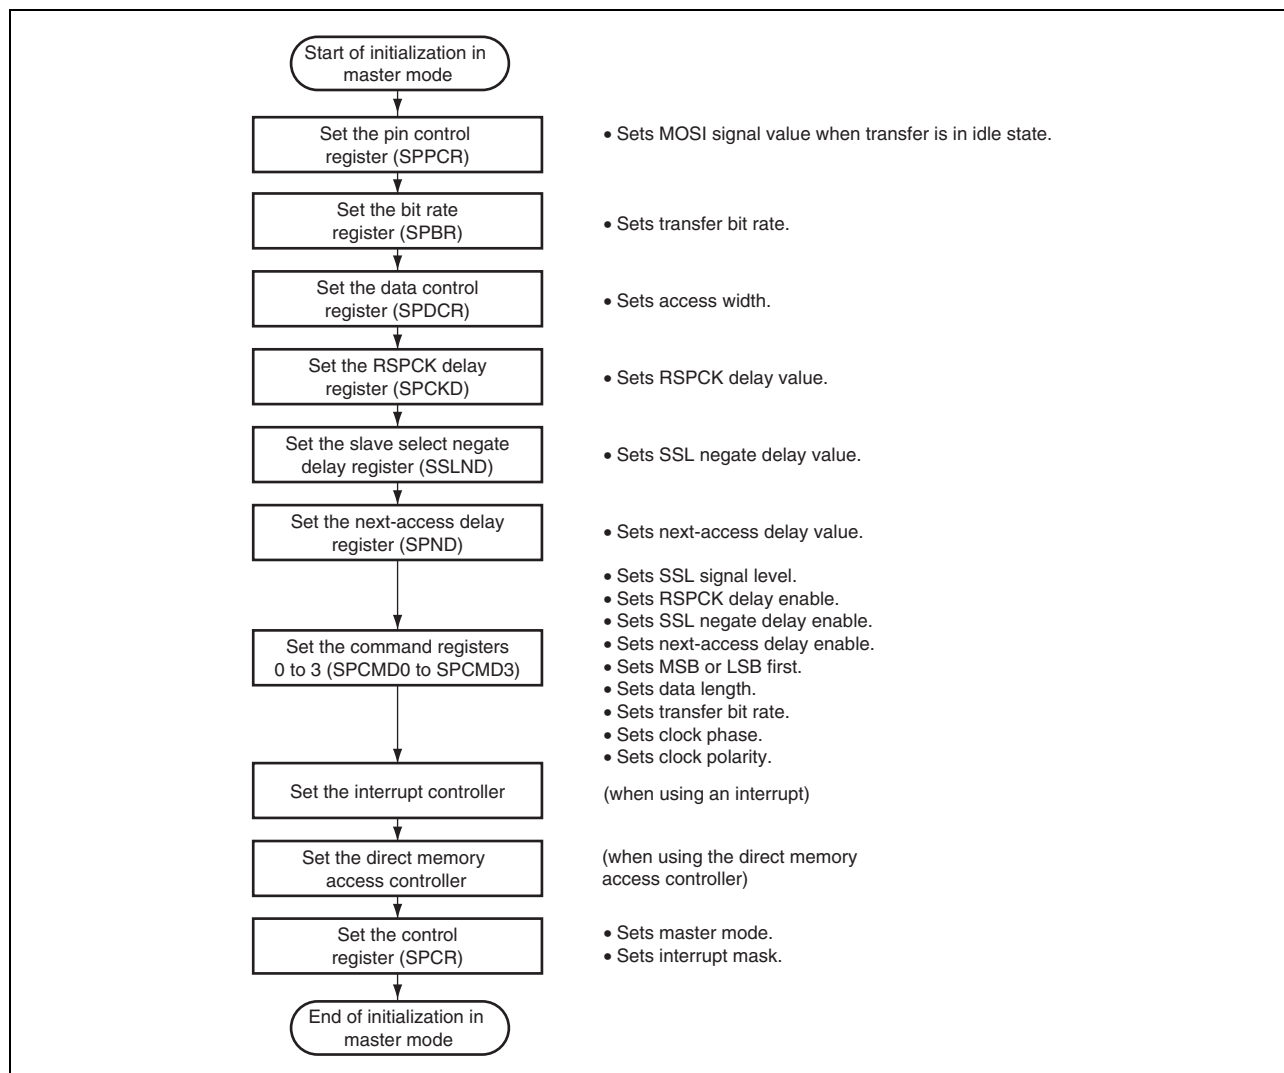

Figure 19.17 Example of Initialization Flowchart in Master Mode

(i) Transfer Operation Flowchart

Figure 19.18 is a flowchart illustrating a transfer in SPI operation when this module is used in master mode.

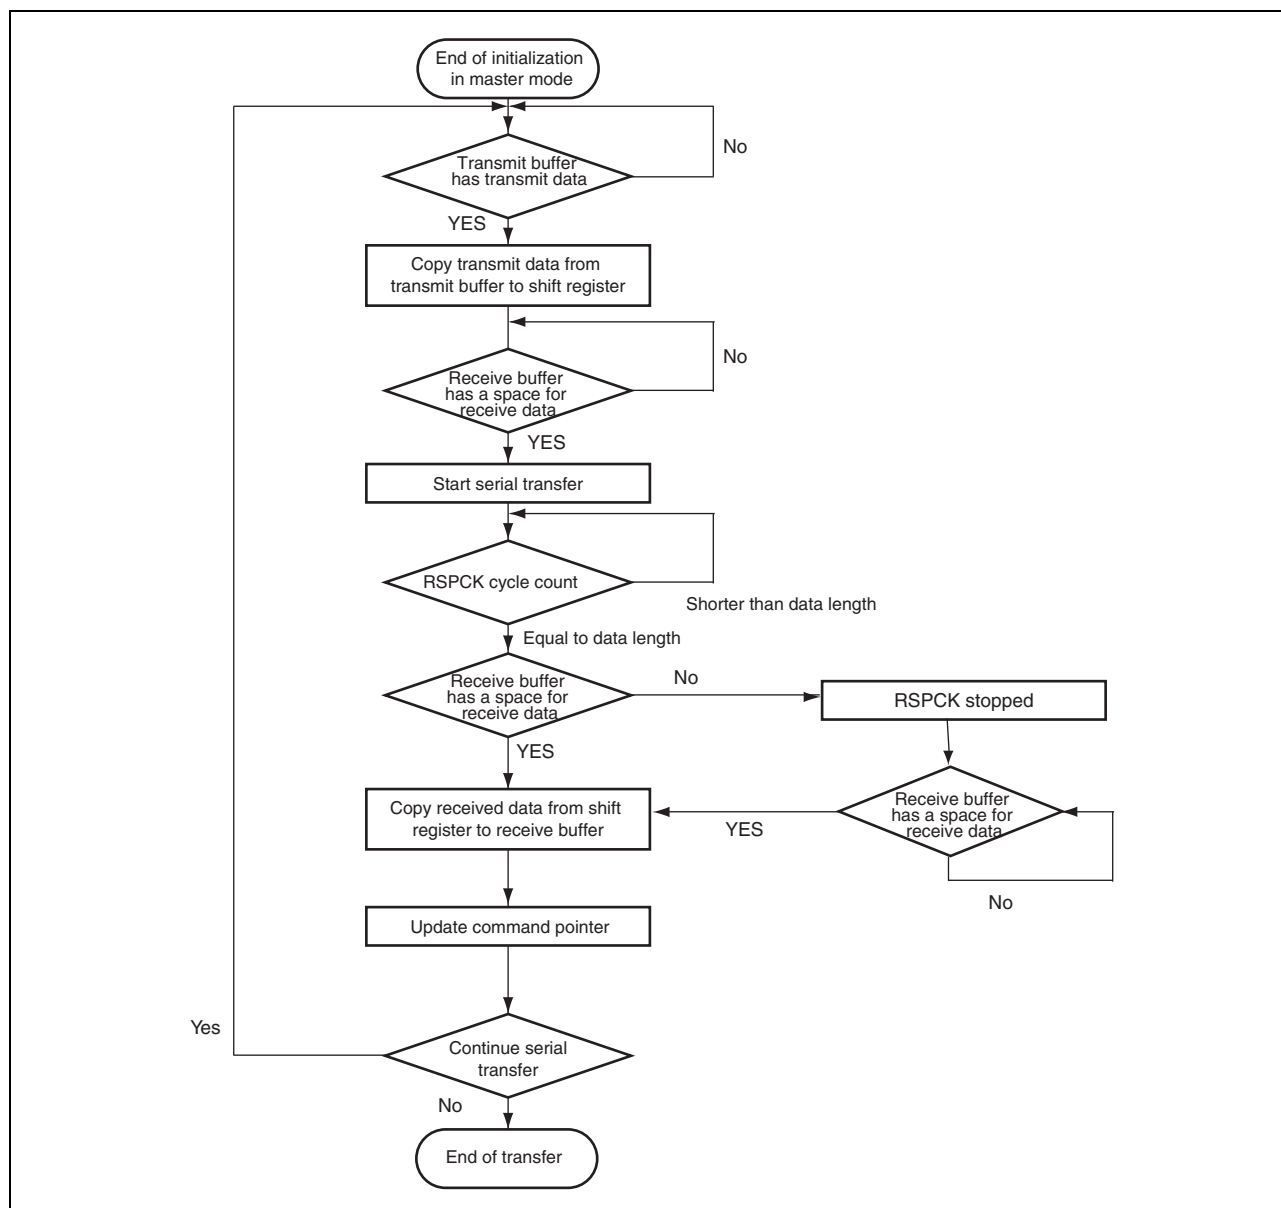

Figure 19.18 Transfer Operation Flowchart in Master Mode

(2) Slave Mode Operation

(a) Starting Serial Transfer

If this module detects an SSL input signal assertion when the CPHA bit in the command register 0 (SPCMD0) is 0, this module is required to start driving valid data to the MISO output signal. For this reason, when the CPHA bit is 0, the asserting of the SSL input signal triggers the start of a serial transfer.

If this module detects the first RSPCK edge in an SSL signal asserted condition when the CPHA bit is 1, this module is required to start driving valid data to the MISO output signal. For this reason, when the CPHA bit is 1, the first RSPCK edge in an SSL signal asserted condition triggers the start of a serial transfer.

When detecting the start of a serial transfer in a condition in which the shift register is empty, this module changes the status of the shift register to "full", so that data cannot be copied from the transmit buffer to the shift register when serial transfer is in progress. If the shift register was full before the serial transfer started, this module leaves the status of the shift register intact, in the full state.

Irrespective of CPHA bit settings, this module starts driving MISO output signals at the SSL signal assertion timing. Whether the data output from this module is valid or invalid differs depending on CPHA bit settings.

For details on the transfer format, see [section 19.4.4, Transfer Format](#). The polarity of the SSL input signal depends on the setting of the SSL0P bit in the slave select polarity register (SSLP).

(b) Terminating Serial Transfer

Irrespective of the CPHA bit in the command register 0 (SPCMD0), this module terminates the serial transfer after detecting an RSPCK edge corresponding to the final sampling timing. When the receive buffer has an enough space for receive data, this module copies received data from the shift register to the receive buffer of the data register (SPDR) upon termination of the serial transfer. Irrespective of the value of the SPRF bit, this module changes the status of the shift register to "empty" upon termination of the serial transfer. If this module detects an SSL input signal negation from the beginning of serial transfer to the end of serial transfer, a mode fault error occurs (see [section 19.4.6, Error Detection](#)).

The final sampling timing changes depending on the bit length of the transfer data. In slave mode, the data length depends on the settings in bits SPB3 to SPB0 bits in SPCMD0. The polarity of the SSL input signal depends on the setting in the SSL0P bit in the slave select polarity register (SSLP). For details on the transfer format, see [section 19.4.4, Transfer Format](#).

(c) Notes on Slave Operations

If the CPHA bit in the command register 0 (SPCMD0) is 0, this module starts serial transfers when it detects the assertion edge for an SSL input signal. In the type of configuration shown in [Figure 19.4](#) as an example, if this module is used in single-slave mode, the SSL signal is always fixed at active state. Therefore, when the CPHA bit is set to 0, this module cannot correctly start a serial transfer. To correctly execute send/receive operation in a configuration in which the SSL input signal is fixed at active state, the CPHA bit should be set to 1. When it is necessary to set the CPHA bit to 0, the SSL input signal should not be fixed.

(d) Burst Transfer

If the CPHA bit in the command register 0 (SPCMD0) is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSL input signal. If the CPHA bit is 1, the period from the first RSPCK edge to the sampling timing for the reception of the final bit in an SSL signal active state corresponds to a serial transfer period. Even when the SSL input signal remains at the active level, this module can accommodate burst transfers because it can detect the start of access.

If the CPHA bit is 0, for the reason given in [section 19.4.8, \(2\), \(c\) Notes on Slave Operations](#), second and subsequent serial transfers during the burst transfer cannot be executed correctly.

(e) Initialization Flowchart

Figure 19.19 is a flowchart illustrating an example of initialization in SPI operation when this module is used in slave mode. For a description of how to set up the interrupt controller, direct memory access controller, and input/output ports, see the descriptions given in the individual blocks.

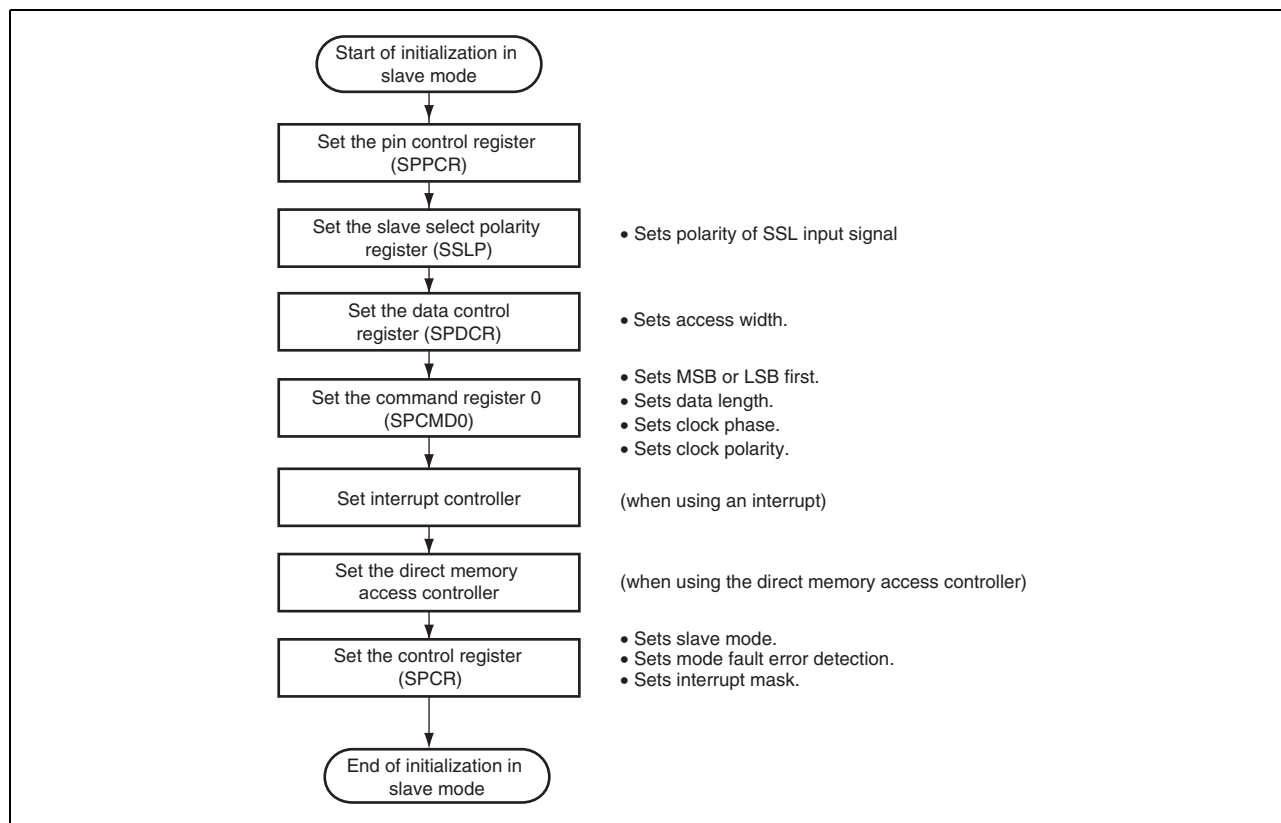

Figure 19.19 Example of Initialization Flowchart in Slave Mode

(f) Transfer Operation Flowchart (CPHA = 0)

Figure 19.20 is a flowchart illustrating a transfer in SPI operation when this module is used in slave mode with the CPHA bit in the command register 0 (SPCMD0) set to 0.

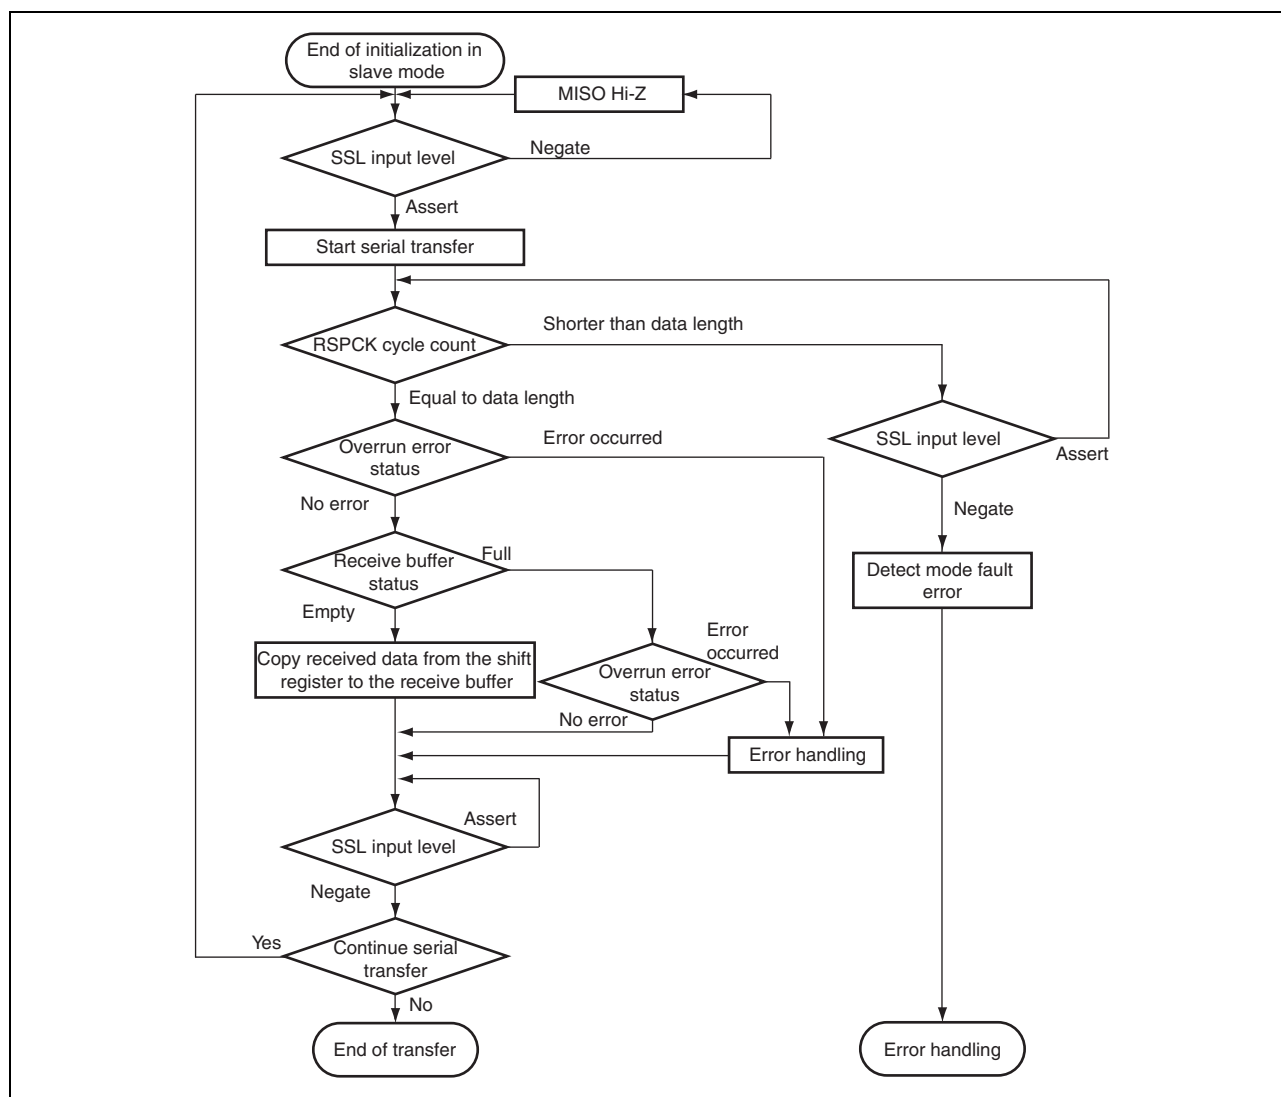

Figure 19.20 Transfer Operation Flowchart in Slave (CPHA = 0)

(g) Transfer Operation Flowchart (CPHA = 1)

Figure 19.21 is a flowchart illustrating a transfer in SPI operation when this module is used in slave mode with the CPHA bit in the command register 0 (SPCMD0) and the MODFEN bit in the control register (SPCR) set to 1, respectively. The subsequent operation is not guaranteed when the serial transfer is started with the MODFEN bit set to 0 and the SSL input level is negated with the number of RSPCK cycles shorter than the data length.

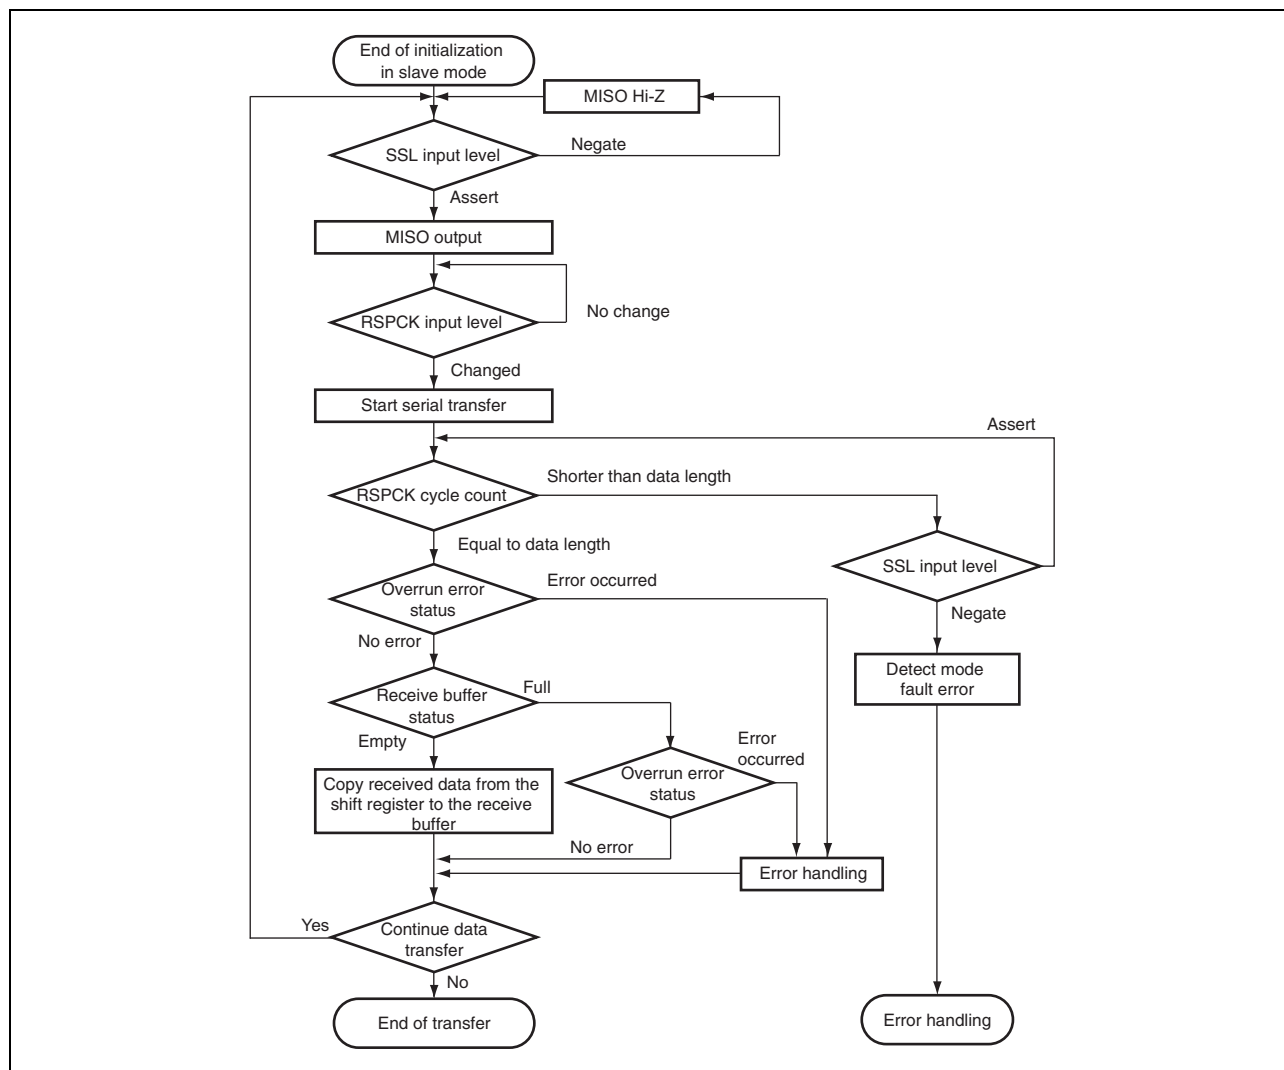

Figure 19.21 Transfer Operation Flowchart in Slave Mode (CPHA = 1)

19.4.9 Error Handling

Figure 19.22 and Figure 19.23 show the error handling. The following error handling is used to return from the error state after an error in master or slave mode.

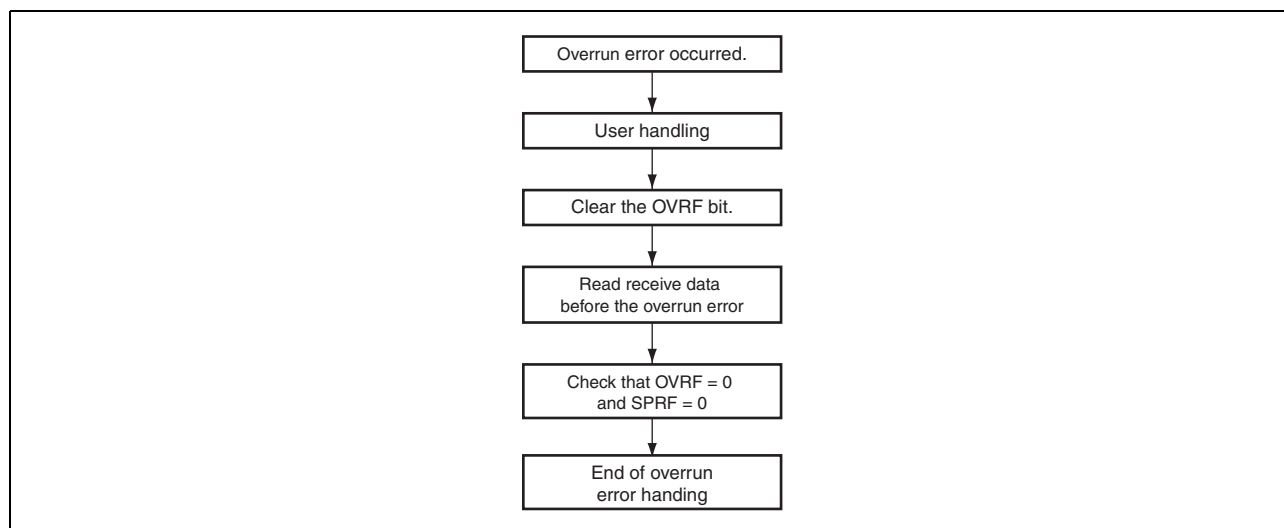

Figure 19.22 Error Handling (Overrun Error)

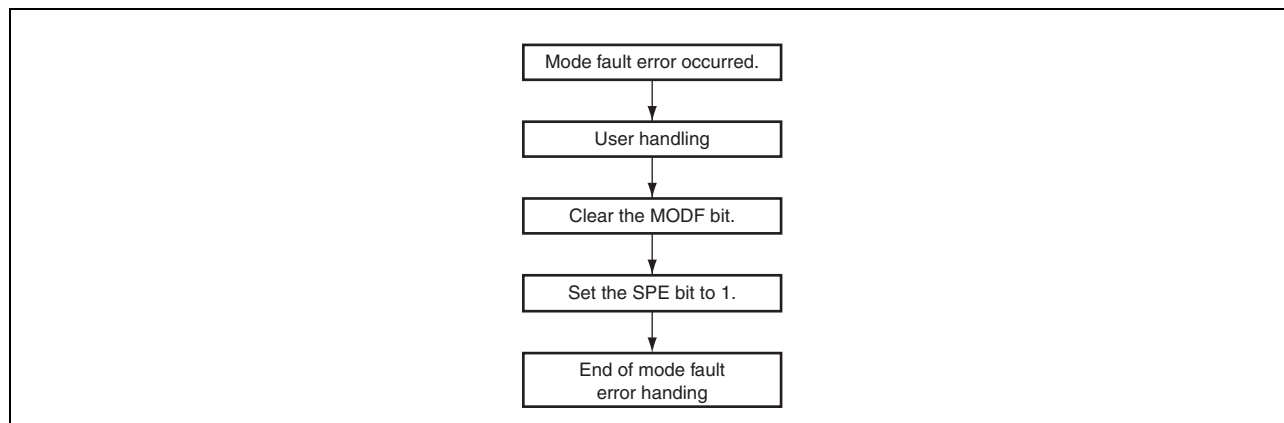

Figure 19.23 Error Handling (Mode Fault Error)

19.4.10 Loopback Mode

When 1 is written to the SPLP bit in the pin control register (SPPCR), this module shuts off the path between the MISO pin and the shift register, and between the MOSI pin and the shift register, and connects the input path and the output path (reversed) of the shift register. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data becomes the received data. Figure 19.24 shows the configuration of the shift register input/output paths for the case where this module in master mode is set in loopback mode.

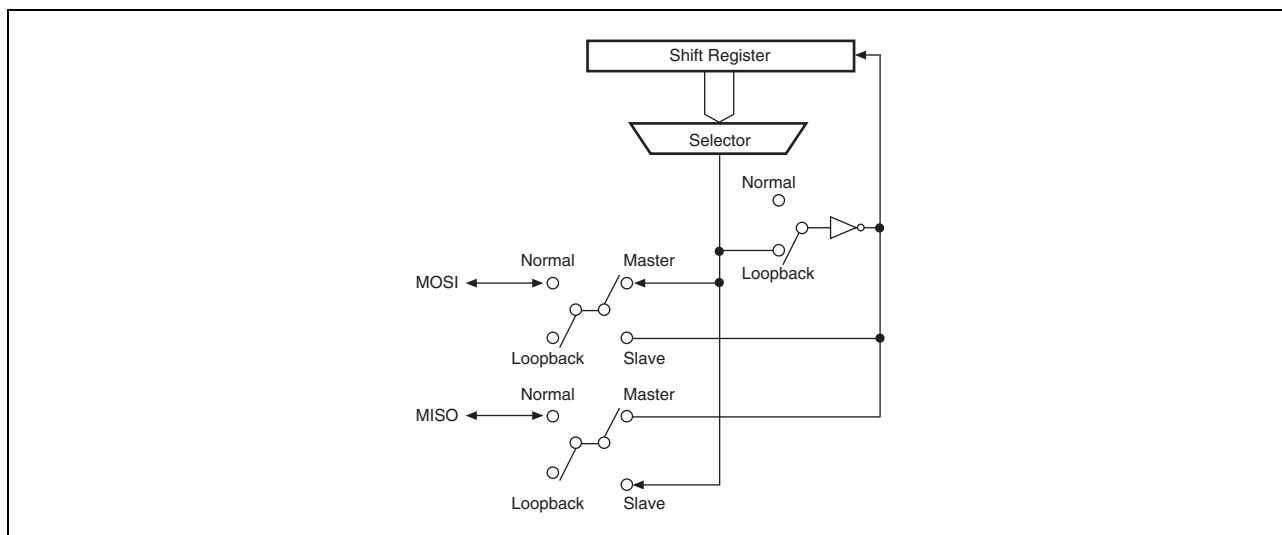

Figure 19.24 Configuration of Shift Register Input/Output Paths in Loopback Mode (Master Mode)

19.4.11 Interrupt Sources

This module has interrupt sources of receive buffer full, transmit buffer empty, mode fault, and overrun. In addition, the direct memory access controller can be activated by the receive buffer full or transmit buffer empty interrupt for data transfer.

Table 19.11 shows the interrupt sources.

When any of the interrupt conditions in Table 19.11 is met, an interrupt is generated. The interrupt sources should be cleared with data transfer by the CPU or direct memory access controller.

Table 19.11 Interrupt Sources

| Name | Interrupt Source | Abbreviation | Interrupt Condition | Activation of Direct Memory Access Controller |
|------|-----------------------|--------------|---------------------------|---|
| SPRI | Receive buffer full | RXI | (SPRIE = 1) • (SPRF = 1) | Possible |
| SPTI | Transmit buffer empty | TXI | (SPTIE = 1) • (SPTEF = 1) | Possible |
| SPEI | Mode fault | MOI | (SPEIE = 1) • (MODF = 1) | — |
| | Overrun | OVI | (SPEIE = 1) • (OVRF = 1) | — |

20. SPI Multi I/O Bus Controller

The SPI multi I/O bus controller enables the direct connection of serial flash, OctaFlash™, Xccela™ flash, or HyperFlash™ memory devices to this LSI chip.

20.1 Features

This module allows the connected serial flash, OctaFlash™, Xccela™ flash, or HyperFlash™ memory devices to be accessed by reading the external address space, or using Manual mode to transmit and receive data.

20.1.1 Serial Flash Memory Interface

- PVcc_SPI: 3.3V
- QSPI0_SPCLK: 66MHz
- Up to two serial flash memory devices are connectable per channel.
Note: Two serial flash memory devices are connected in parallel to implement an 8-bit bus interface.
- A data bus size of 1 bit or 4 bits can be selected for one serial flash memory device.
- Both single data rate (SDR) and double data rate (DDR) transfers are supported.
- Supports master operation. (Slave operation is not supported.)

20.1.2 OctaFlash™, Xccela™ Flash Memory Interface

- PVcc_SPI: 1.8V
- QSPI0_SPCLK: 132MHz
- One Octal-SPI flash memory device is connectable.

Note: OctaFlash™ is a trademark of Macronix International Co., Ltd.

Note: Xccela™ flash memory is a trademark of Micron Technology, Inc.

Note: In this manual, an 8-bit SPI flash memory with 1 chip select, 1 clock source, and 1 data strobe configuration is called "Octal-SPI flash memory".

Note: In this manual, transfer with an 8-bit data bus width is referred to as Octal-SPI flash memory protocol mode. Transfer with a 1-bit data bus width is handled in the same way as for standard serial flash memory.

20.1.3 HyperFlash™ Interface

- PVcc_SPI: 1.8V
- QSPI0_SPCLK/QSPI1_SPCLK: 132MHz
- One HyperFlash memory device is connectable.
- The data bus is fixed to 8-bit width.
- Wrapped burst operation is not supported.

Note: HyperFlash is a trademark of Cypress Semiconductor Corporation.

20.1.4 External Address Space Read Mode

- Read access from the bus master to the SPI multi I/O space is automatically converted to a read command, and the read data is returned to the bus master.
- Normal read operation and burst read operation
- Efficient data reception due to built-in read cache (64-bit line × 32 entries)

20.1.5 Manual Mode

- Read and write commands are available for serial flash memory, Octal-SPI flash memory, or HyperFlash memory.
- A write buffer is provided to improve the efficiency of data write operations.
- The cache is not usable for reading.

20.2 Block Diagram

Figure 20.1 shows a block diagram of this module.

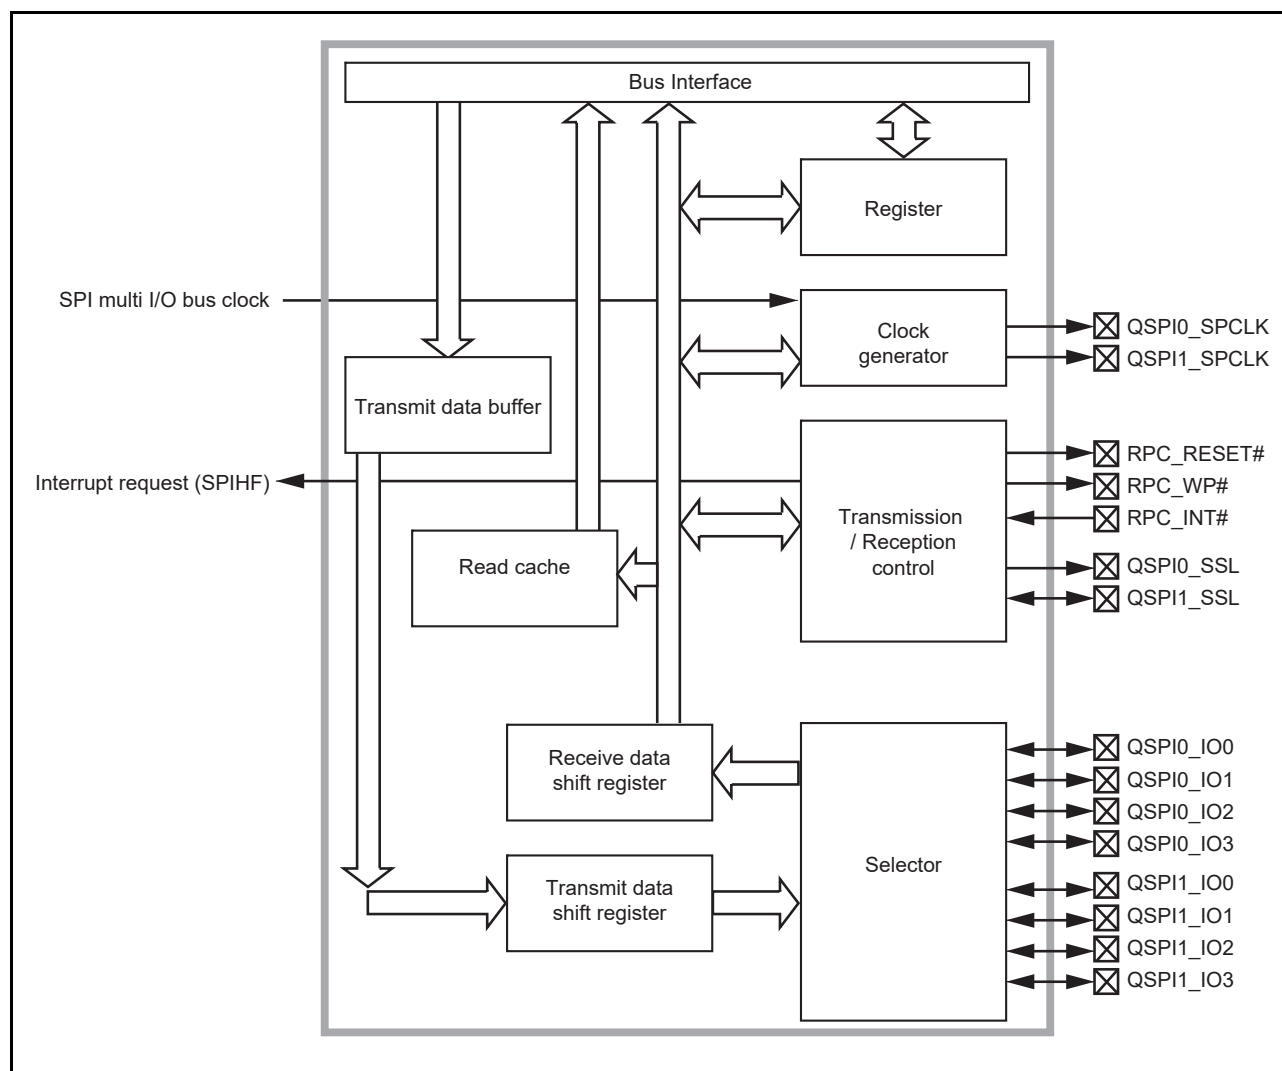

Figure 20.1 Block Diagram

20.3 Input/Output Pins

Table 20.1 shows the pin configuration for one channel.

The operating voltage on pins of the SPI multi I/O bus controller is 3.3 V or 1.8 V.

Before using the pins of the SPI multi I/O bus controller, be sure to set up the dedicated pin POC control register (PPOC) and SPI multi I/O bus controller dedicated pin driving ability control register (PSPIBSC).

For details, see section 51.3.30, Dedicated Pin POC Control Register (PPOC) and section 51.3.34, SPI Multi I/O Bus Controller Dedicated Pin Driving Ability Control Register (PSPIBSC).

Table 20.1 Pin Configuration

| Pin Name | Symbol | I/O | One 4-bit Serial Flash connected. CMNCR.BSZ = 00 | Two 4-bit Serial Flash connected. CMNCR.BSZ = 01 | Connection in Octal-SPI flash memory protocol mode CMNCR.BSZ = 01 | HyperFlash connected. CMNCR.BSZ = 01 |
|-----------------------------|-------------|--------|--|--|---|--|
| Clock* ¹ | QSPI0_SPCLK | Output | SCK | SCK | SCLK | CK |
| Data 0* ¹ | QSPI0_IO0 | I/O | SI/IO0 | SI/IO0 | SI/SIO0 | DQ0 |

| Data 7 | QSPI1_IO3 | I/O | - | HOLD#/IO3 | SIO7 | DQ7 |
| Slave select | QSPI1_SSL | I/O | - | CS# | DQS (Data Strobe) | RWDS (Read Data Strobe) |
| Reset* ² | RPC_RESET# | Output | RESET# | RESET# | RESET# | RESET# |
| Write protect* ² | RPC_WP# | Output | For one 1-bit serial flash memory: WP#/IO2 | - | - | - |
| Interrupt* ² | RPC_INT# | Input | - | - | - | INT# |

Note 1. When connecting a serial flash memory device with the BSZ[1:0] bits set to 00, connect the serial flash memory to the QSPI0 pin group of this LSI.

Note 2. These pin connections must meet to the flash specifications.

20.4 Register Descriptions

Table 20.2 shows the register configuration.

Table 20.2 Register Configuration

| Register Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|---|--------------|-----|---------------|------------|-------------|
| Common control register | CMNCR | R/W | H'01557301 | H'1F800000 | 32 |

| PHY adjustment register 2 | PHYADJ2 | R/W | H'00000000 | H'1F800074 | 32 |

Note: Do not write to any address those listed in the table. Otherwise, correct operation cannot be guaranteed. Reading from a non-listed address returns an undefined value.

20.4.1 Common Control Register (CMNCR)

CMNCR is a 32-bit register that controls the SPI multi I/O bus controller. The settings of this register are reflected both in external address space read mode and manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Note: The settings of the MOIIIO3, MOIIIO2, MOIIIO1, and MOIIIO0 bits for control over fixing the output values are reflected at the time QSPIn_SSL is negated on completion of data transfer.

20.4.2 SSL Delay Register (SSLDL)

SSLDL is a 32-bit register that adjusts the timing between the QSPIn_SSL signal and the QSPIn_SPCLK signal.

The settings of this register are reflected both in external address space read mode and manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

20.4.3 Data Read Control Register (DRCR)

DRCR is a 32-bit register that sets the operation in external address space read mode.

The bits except the SSLN bit should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|-----|------|----|----|----|-------------|-----|-----|-----|------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | SSLN | — | — | — | RBURST[4:0] | | | | |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R | R | R | R | R | R | R | W | R | R | R | R/W | R/W | R/W | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | RCF | RBE | — | — | — | — | — | — | — | SSLE |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | W | R/W | R | R | R | R | R | R | R | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|--------------|---------------|-----|--|
| 31 to 25 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 24 | SSLN | 0 | W | QSPIn_SSL Negation Asserted QSPIn_SSL can be negated by writing 1 to this bit when both the RBE and SSLE bits are 1. This bit is always read as 0. Note: To start next access after QSPIn_SSL negation using this bit, read SSLE in CMNSR = 0 to confirm that the QSPIn_SSL has been negated. |
| 23 to 21 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 20 to 16 | RBURST [4:0] | 11111 | R/W | Read Data Burst Length Sets the burst length (data unit count) when reading. This bit field is enabled when the RBE bit is set to 1. 00000: 1 data unit 00001: 2 continuous data units : 11110: 31 continuous data units 11111: 32 continuous data units One data unit is 64 bits long. |
| 15 to 10 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 9 | RCF | 0 | W | Read Cache Flush When 1 is written to this bit, all the entries in the read cache are cleared. This bit is always read as 0. After using the cache area as the write buffer, the cache area must be cleared by writing 1 to the RCF bit. Note: After flushing the read cache by writing 1 to the RCF bit, read the DRCR register before proceeding to read from the external address space. |
| 8 | RBE | 1 | R/W | Read Burst Turns burst ON or OFF when reading. 0: Data is read according to the access size. 1: Read cache is enabled, and as many data units as the burst count specified in RBURST[4:0] bits is read. Note: When the cache is enabled and read access reaches the last address of the flash memory, the access address does not match the address held in the cache. Control the read address and access size so that read access does not reach the last address of the flash memory. |
| 7 to 1 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | R/W | Description |
|-----|----------|---------------|-----|---|
| 0 | SSLE | 0 | R/W | <p>QSPIn_SSL Negation</p> <p>Sets the conditions for QSPIn_SSL negation during read burst.</p> <p>QSPIn_SSL is negated for each access during normal read.</p> <p>0: QSPIn_SSL is negated after transfer of data set in burst length.</p> <p>1: QSPIn_SSL is negated when the accessed address is not continuous with the previously transferred address.</p> <p>Note 1. Set up this bit when a serial flash memory device is connected.</p> <p>Note 2. When this bit is set to 1, setting the RBURST[4:0] bits to 5'h01 is prohibited.</p> |

20.4.4 Data Read Command Setting Register (DRCMR)

DRCMR is a 32-bit register that sets the commands issued in external address space read mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|----|-----------|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-----------|---------------|-----|--|
| 31 to 24 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | CMD[7:0] | H'A0 | R/W | Command Sets the command. |
| 15 to 8 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | OCMD[7:0] | 'H00 | R/W | Optional Command Sets the optional command. |

20.4.5 Data Read Extended Address Setting Register (DREAR)

DREAR is a 32-bit register that is set when addresses for serial flash memory or according to the Octal-SPI flash memory protocol are to be output in 32-bit mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|----|----------|-----|-----|-----|-----|----------|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | EAV[7:0] | | | | | | | |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | EAC[2:0] | | |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|----------|---------------|-----|--|
| 31 to 24 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | EAV[7:0] | H'00 | R/W | 32-Bit Extended Upper Address Fixed Value Sets the higher-order address bit values for external addresses as specified by the EAC[2:0] bits when addresses for serial flash memory or according to the Octal-SPI flash memory protocol are to be output in 32-bit mode. Bit 0 corresponds to address bit 25 of the serial flash memory or Octal-SPI flash memory, and bit 7 corresponds to bit 32. This setting is valid when the ADE[3] bit in DRENr is 1. When EAC[2:0] are 000, set a fixed value for address bits 32 to 25 of the serial flash memory or Octal-SPI flash memory in EAV[7:0]. When EAC[2:0] are 001, set a fixed value for address bits 32 to 26 of the serial flash memory or Octal-SPI flash memory in EAV[7:1]. When EAC[2:0] are 010, set a fixed value for address bits 32 to 27 of the serial flash memory or Octal-SPI flash memory in EAV[7:2]. When EAC[2:0] are 011, set a fixed value for address bits 32 to 28 of the serial flash memory or Octal-SPI flash memory in EAV[7:3]. (1) When a single serial flash memory device is connected or the Octal-SPI flash memory protocol is in use Address bits 31 to 0 of the serial flash memory are used in access. (2) When two serial flash memory devices are connected Address bits 32 to 1 of the serial flash memory are used in access. |
| 15 to 3 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 2 to 0 | EAC[2:0] | 000 | R/W | 32-Bit Extended External Address Valid Range Sets the range of external addresses to be used as addresses of the serial flash memory or Octal-SPI flash memory when addresses for serial flash memory or according to the Octal-SPI flash memory protocol are to be output in 32-bit mode. This setting is valid when the ADE[3] bit in DRENr is 1. 000: External address bits [24:0] enabled 001: External address bits [25:0] enabled 010: External address bits [26:0] enabled 011: External address bits [27:0] enabled Other than above: Setting prohibited |

20.4.6 Data Read Option Setting Register (DROPR)

DROPR is a 32-bit register that sets the option data in external address space read mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-----------|---------------|-----|--|
| 31 to 24 | OPD3[7:0] | H'00 | R/W | Option Data 3 Sets the option data 3. |
| 23 to 16 | OPD2[7:0] | H'00 | R/W | Option Data 2 Sets the option data 2. |
| 15 to 8 | OPD1[7:0] | H'00 | R/W | Option Data 1 Sets the option data 1. |
| 7 to 0 | OPD0[7:0] | H'00 | R/W | Option Data 0 Sets the option data 0. |

Note: OPD3, OPD2, OPD1, and OPD0 are output in this order.

20.4.7 Data Read Enable Setting Register (DRENr)

DRENr is a 32-bit register that sets the bit size of the command, optional command, address, option data, and read data in external address space read mode and enables outputting them other than read data.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

When HyperFlash memory is connected or a connection is made in Octal-SPI flash memory protocol mode, refer to Table 20.6, Enable Register (HyperFlash), or Table 20.7, Enable Register (Octal-SPI Flash Memory Protocol Mode).

| | | | | | | | | | | | | | | | | |
|----------------|----------|-----|-----------|------|----------|-----|----------|-----|-----------|-----|-----------|-----|----|----|-----------|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| R/W: | R/W | R/W | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|--------|-----------|---------------|-----|--|
| 31, 30 | CDB[1:0] | 10 | R/W | Command Bit Size Sets the command size in bit units. 00: 1 bit 10: 4 bits Other than above: Setting prohibited |
| 29, 28 | OCDB[1:0] | 10 | R/W | Optional Command Bit Size Sets the optional command size in bit units. 00: 1 bit 10: 4 bits Other than above: Setting prohibited |
| 27, 26 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 25, 24 | ADB[1:0] | 10 | R/W | Address Bit Size Sets the address size in bit units. 00: 1 bit 10: 4 bits Other than above: Setting prohibited |
| 23, 22 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 21, 20 | OPDB[1:0] | 10 | R/W | Option Data Bit Size Sets the option data size in bit units. 00: 1 bit 10: 4 bits Other than above: Setting prohibited |
| 19, 18 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 17, 16 | DRDB[1:0] | 10 | R/W | Data Read Bit Size Sets the data read size in bit units. 00: 1 bit 10: 4 bits Other than above: Setting prohibited |

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|-----------|---------------|-----|--|
| 15 | DME | 1 | R/W | Dummy Cycle Enable Enables insertion of the dummy cycle before the read data. Note: A setting is prohibited for a transfer starting with a dummy cycle. 0: Dummy cycle insertion disabled 1: Dummy cycle insertion enabled |
| 14 | CDE | 1 | R/W | Command Enable Sets whether or not the command is to be output. 0: Command output disabled 1: Command output enabled Note: When an Octal-SPI flash memory device is connected and this bit set to 1, set the CDE bit in SMENR register to 0. |
| 13 | — | 0 | R | Reserved This bit is always read as 0. The write value should always be 0. |
| 12 | OCDE | 1 | R/W | Optional Command Enable Sets whether or not the optional command is to be output. 0: Optional command output disabled 1: Optional command output enabled Note: When an Octal-SPI flash memory device is connected, set this bit to 0. |
| 11 to 8 | ADE[3:0] | 0100 | R/W | Address Enable Sets the address to be output. Be sure to use the following setting; otherwise, the operation is not guaranteed. (1) When a serial flash memory device is connected 0000: Output disabled 0111: Address[23:0] 1111: Address[31:0] Other than above: Setting prohibited (2) When two serial flash memory devices are connected or a connection is made in Octal-SPI flash memory protocol mode 0000: Output disabled 0111: Address[24:1] 1111: Address[32:1] 1100: Addresses in Octal-SPI flash memory protocol mode (operation is in accord with the 8-8-8 protocol in Table 20.15) Other than above: Setting prohibited (3) When a HyperFlash memory device is connected 0100: HyperFlash addresses Other than above: Setting prohibited |
| 7 to 4 | OPDE[3:0] | 0000 | R/W | Option Data Enable Sets the option data to be output. Use only the settings given below. Otherwise, the operation cannot be guaranteed. 0000: Output disabled 1000: OPD3 1100: OPD3, OPD2 1110: OPD3, OPD2, OPD1 1111: OPD3, OPD2, OPD1, OPD0 Other than above: Setting prohibited |
| 3 to 0 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |

20.4.8 Manual Mode Control Register (SMCR)

SMCR is a 32-bit register that sets the operation in Manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|-------|----|----|----|----|----|-------|-------|------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | SSLKP | — | — | — | — | — | SPIRE | SPIWE | SPIE |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R/W | R | R | R | R | R | R/W | R/W | W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|----------|---------------|-----|--|
| 31 to 9 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 8 | SSLKP | 0 | R/W | QSPIn_SSL Signal Level Determines the QSPIn_SSL status after the end of transfer. 0: QSPIn_SSL signal is negated at the end of transfer. 1: QSPIn_SSL signal level is maintained from the end of transfer to the start of next access. Note: The setting to start data transfer for reading is prohibited while the setting of SSLKP is 1. |
| 7 to 3 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 2 | SPIRE | 0 | R/W | Data Read Enable Enables reading in manual mode. 0: Data reading disabled 1: Data reading enabled Note: When the transfer data bit size is set to 4 bits with the SPIDB[1:0] bits, the SPIRE and SPIWE bits should not be set to 1 at the same time. |
| 1 | SPIWE | 0 | R/W | Data Write Enable Enables writing in manual mode. 0: Data writing disabled 1: Data writing enabled Note: When the transfer data bit size is set to 4 bits with the SPIDB[1:0] bits, the SPIRE and SPIWE bits should not be set to 1 at the same time. |
| 0 | SPIE | 0 | W | SPI Data Transfer Enable Data is transferred by setting this bit to 1. This bit is enabled only when the TEND bit in CMNSR is set to 1. The operation cannot be guaranteed when this bit is set to 1 with the TEND bit set to 0. This bit is always read as 0. Note: When the QSPIn_SSL pin is de-asserted, the command, optional command, address, and option data that are output enabled are output even if the SPIRE and SPIWE bits are set to 0. When the QSPIn_SSL pin is asserted, follow the notes described in section 20.6.2, Notes on Starting Transfer from the QSPIn_SSL Retained State in Manual Mode. |

20.4.9 Manual Mode Command Setting Register (SMCMR)

SMCMR is a 32-bit register that sets the commands issued in Manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|----|-----------|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | CMD[7:0] | | | | | | | |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | OCMD[7:0] | | | | | | | |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-----------|---------------|-----|--|
| 31 to 24 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 23 to 16 | CMD[7:0] | H'00 | R/W | Command Sets the command. |
| 15 to 8 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 7 to 0 | OCMD[7:0] | H'00 | R/W | Optional Command Sets the optional command. |

20.4.10 Manual Mode Address Setting Register (SMADR)

SMADR is a 32-bit register that sets the addresses in Manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |
|----------------|------------|-----|-----|-----|-----|-----|-----|-----|------------|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | ADR[31:24] | | | | | | | | ADR[23:16] | | | | | | | |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | ADR[15:0] | | | | | | | | | | | | | | | |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|------------|---------------|-----|---|
| 31 to 24 | ADR[31:24] | H'00 | R/W | Address Sets the value of bits 31 to 24 when the serial flash address is output in 32-bit units. If a serial flash memory or Octal-SPI flash memory is connected, the setting of these bits is only valid when the ADE[3] bit in the SMENR register is 1. If HyperFlash memory is connected, the setting of these bits is valid regardless of the setting of the ADE[3] bit. |
| 23 to 0 | ADR[23:0] | H'000000 | R/W | Address Sets the address. |

20.4.11 Manual Mode Option Setting Register (SMOPR)

SMOPR is a 32-bit register that sets the option data in Manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-----------|---------------|-----|--|
| 31 to 24 | OPD3[7:0] | H'00 | R/W | Option Data 3 Sets the option data 3. |
| 23 to 16 | OPD2[7:0] | H'00 | R/W | Option Data 2 Sets the option data 2. |
| 15 to 8 | OPD1[7:0] | H'00 | R/W | Option Data 1 Sets the option data 1. |
| 7 to 0 | OPD0[7:0] | H'00 | R/W | Option Data 0 Sets the option data 0. |

Note: OPD3, OPD2, OPD1, and OPD0 are output in this order.

20.4.12 Manual Mode Enable Setting Register (SMENR)

SMENR is a 32-bit register that sets the bit size of the command, optional command, address, option data, and transfer data in Manual mode and enables their output. SMENR also enables dummy cycle insertion. Disabling all of the command, optional command, address, option data, dummy cycle, and transfer data is prohibited. At least one of them except dummy cycle must be enabled.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

When HyperFlash memory is connected or a connection is made in Octal-SPI flash memory protocol mode, refer to Table 20.6, Enable Register (HyperFlash), or Table 20.7, Enable Register (Octal-SPI Flash Memory Protocol Mode).

| | | | | | | | | | | | | | | | | |

20.4.13 Manual Mode Read Data Register 0 (SMRDR0)

SMRDR0 is a 32-bit register that stores the read data in Manual mode.

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the Manual mode enable setting register (SMENR). Be sure to access from LSB.

The settings of this register should be read when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Note: The contents of this register and SMRDR1 are modified upon completion of reception in manual mode. Be sure to read data when reception in manual mode is completed.

20.4.14 Manual Mode Read Data Register 1 (SMRDR1)

SMRDR1 is a 32-bit register that stores the read data in Manual mode.

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the Manual mode enable setting register (SMENR). Be sure to access from LSB.

The settings of this register should be read when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

20.4.15 Manual Mode Write Data Register 0 (SMWDR0)

SMWDR0 is a 32-bit register that sets the write data in Manual mode.

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the Manual mode enable setting register (SMENR). Be sure to access from address 0.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|---------------|---------------|-----|---|
| 31 to 0 | WDATA0 [31:0] | All 0 | R/W | <p>Write Data</p> <p>Holds the data to be written in Manual mode.</p> <p>Data bits differ depending on the BSZ[1:0] bit setting in CMNCR.</p> <p>BSZ[1:0] = 00: Write data[31:0].</p> <p>BSZ[1:0] = 01: Write data[63:32].</p> <p>Note: In Octal-SPI flash memory protocol mode (OPI), the write data should be arranged and written as follows.</p> <ul style="list-style-type: none"> To write data D[31:0] in the STR mode WDATA0[31:0] = {D[23:20], D[31:28], D[19:16], D[27:24], D[7:4], D[15:12], D[3:0], D[11:8]} To write data D[31:0] in the DTR mode WDATA0[31:0] = {D[31:28], D[23:20], D[27:24], D[19:16], D[15:12], D[7:4], D[11:8], D[3:0]} |

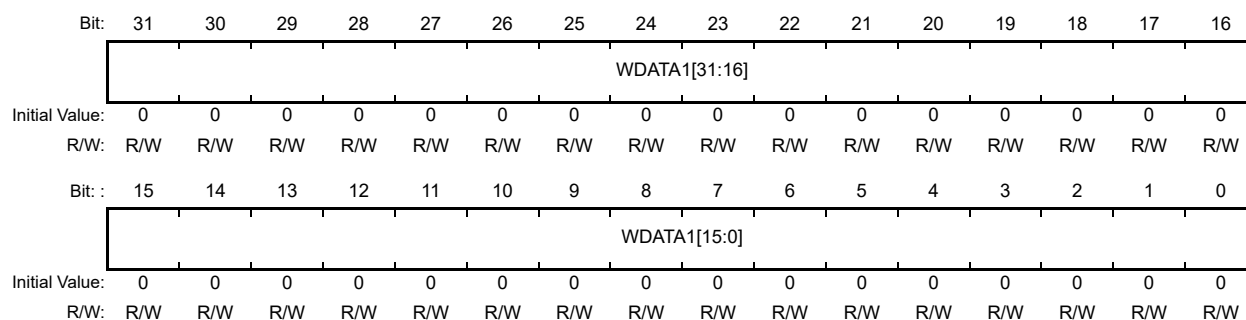

20.4.16 Manual Mode Write Data Register 1 (SMWDR1)

SMWDR1 is a 32-bit register that sets the write data in Manual mode.

This register is enabled when the BSZ[1:0] bits in CMNCR are set to 01 and disabled when the BSZ[1:0] bits in CMNCR are set to 00.

Access to this register should be performed in the same size as the transfer size specified in the SPIDE[3:0] bits in the Manual mode enable setting register (SMENR). Be sure to access from address 0.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|---------------|---------------|-----|--|
| 31 to 0 | WDATA1 [31:0] | All 0 | R/W | <p>Write Data Holds the data to be written in Manual mode. Data bits differ depending on the BSZ[1:0] bit setting in CMNCR. BSZ[1:0] = 00: Bits in this register are disabled. BSZ[1:0] = 01: Write data[31:0].</p> <p>Note: In Octal-SPI flash memory protocol mode (OPI), the write data should be arranged and written as follows.</p> <ul style="list-style-type: none"> •To write data D[31:0] in the STR mode WDATA1[31:0]={D[23:20], D[31:28], D[19:16], D[27:24], D[7:4], D[15:12], D[3:0], D[11:8]} •To write data D[31:0] in the DTR mode WDATA1[31:0]={D[31:28], D[23:20], D[27:24], D[19:16], D[15:12], D[7:4], D[11:8], D[3:0]} |

20.4.17 Common Status Register (CMNSR)

CMNSR is a 32-bit register that holds flags indicating the operating state.

The settings of this register are reflected both in external address space read mode and Manual mode.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial Value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|----------|---------------|-----|--|
| 31 to 2 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 1 | SSLF | 0 | R | QSPIn_SSL Pin Monitor 0: QSPIn_SSL pin is negated 1: QSPIn_SSL pin is asserted |
| 0 | TEND | 1 | R | Transfer End Flag Indicates whether the data transfer has ended. 0: Indicates that data transfer is in progress 1: Indicates that data transfer has ended |

20.4.18 Data Read Dummy Cycle Setting Register (DRDMCR)

DRDMCR is a 32-bit register that sets the number of dummy cycles to be inserted in external address space read mode. The settings of this register are enabled when the DME bit in the data read enable setting register (DRENr) is 1.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |

|---------|------------|---------------|-----|---|
| 31 to 5 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 4 to 0 | DMCYC[4:0] | H'0B | R/W | Number of Dummy Cycles Sets the number of dummy cycles to be inserted when the DME bit in the data read enable setting register (DRENr) is 1. 00001: 2 cycles 00010: 3 cycles ... 10010: 19 cycles 10011: 20 cycles Other than above: Setting prohibited |

20.4.19 Data Read DDR Enable Register (DRDRENr)

DRDRENr is a 32-bit register that sets SDR or DDR transfer of the address, option data, and read data in external address space read mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|----------|---------------|-----|--|
| 31 to 15 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 14 to 12 | HYPE | 101 | R/W | HyperFlash, Octal-SPI flash memory DDR mode enable 101: When HyperFlash memory is connected, not only commands but also addresses and data are transferred according to the Octal-SPI flash memory protocol for DDR mode. 100: Only commands are transferred according to the Octal-SPI flash memory protocol for DDR mode. 000: SPI flash mode Other than above: Setting prohibited |
| 11 to 9 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 8 | ADDRE | 1 | R/W | Address DDR Enable Sets SDR or DDR transfer of the address. 0: SDR transfer 1: DDR transfer Note: Set this bit to 1 when the HyperFlash memory is connected. |
| 7 to 5 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 4 | OPDRE | 0 | R/W | Option Data DDR Enable Sets SDR or DDR transfer of the option data. 0: SDR transfer 1: DDR transfer |
| 3 to 1 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 0 | DRDRE | 1 | R/W | Data Read DDR Enable Sets SDR or DDR transfer of the read data. 0: SDR transfer 1: DDR transfer |

20.4.20 Manual Mode Dummy Cycle Setting Register (SMDMCR)

SMDMCR is a 32-bit register that sets the number of dummy cycles to be inserted in Manual mode.

The settings of this register are enabled when the DME bit in the Manual mode enable setting register (SMENR) is 1.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |

| 31 to 5 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 4 to 0 | DMCYC[4:0] | 00000 | R/W | Number of Dummy Cycles Sets the number of dummy cycles to be inserted when the DME bit in the Manual mode enable setting register (SMENR) is 1. 00001: 2 cycles 00010: 3 cycles 10010: 19 cycles 10011: 20 cycles Other than above: Setting prohibited |

20.4.21 Manual Mode DDR Enable Register (SMDRENr)

SMDRENr is a 32-bit register that sets SDR or DDR transfer of the address, option data, and transfer data in Manual mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |

| 3 to 1 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 0 | SPIDRE | 0 | R/W | Transfer Data DDR Enable Sets SDR or DDR transfer of the transfer data. 0: SDR transfer 1: DDR transfer Note: Set this bit to 1 when the HyperFlash memory is connected. |

20.4.22 PHY Control Register (PHYCNT)

PHYCNT is a 32-bit register that sets the PHY operation mode.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |

20.4.23 PHY Offset Register 1 (PHYOFFSET1)

PHYOFFSET1 is a 32-bit register with two effective bits. These are for selecting DDR or SDR operation.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

| | | | | | | | | | | | | | | | | |

Note: Write the setting values described in the order indicated for the flow of adjustment. |

20.5 Operation

20.5.1 System Configuration

This module can connect one or two serial flash memory devices, an Octal-SPI flash memory device, or a HyperFlash memory device. The number of connected memories can be selected using the BSZ[1:0] bits in CMNCR.

Examples of system configuration are shown in Figure 20.2, Figure 20.3, Figure 20.4, and Figure 20.5 respectively.

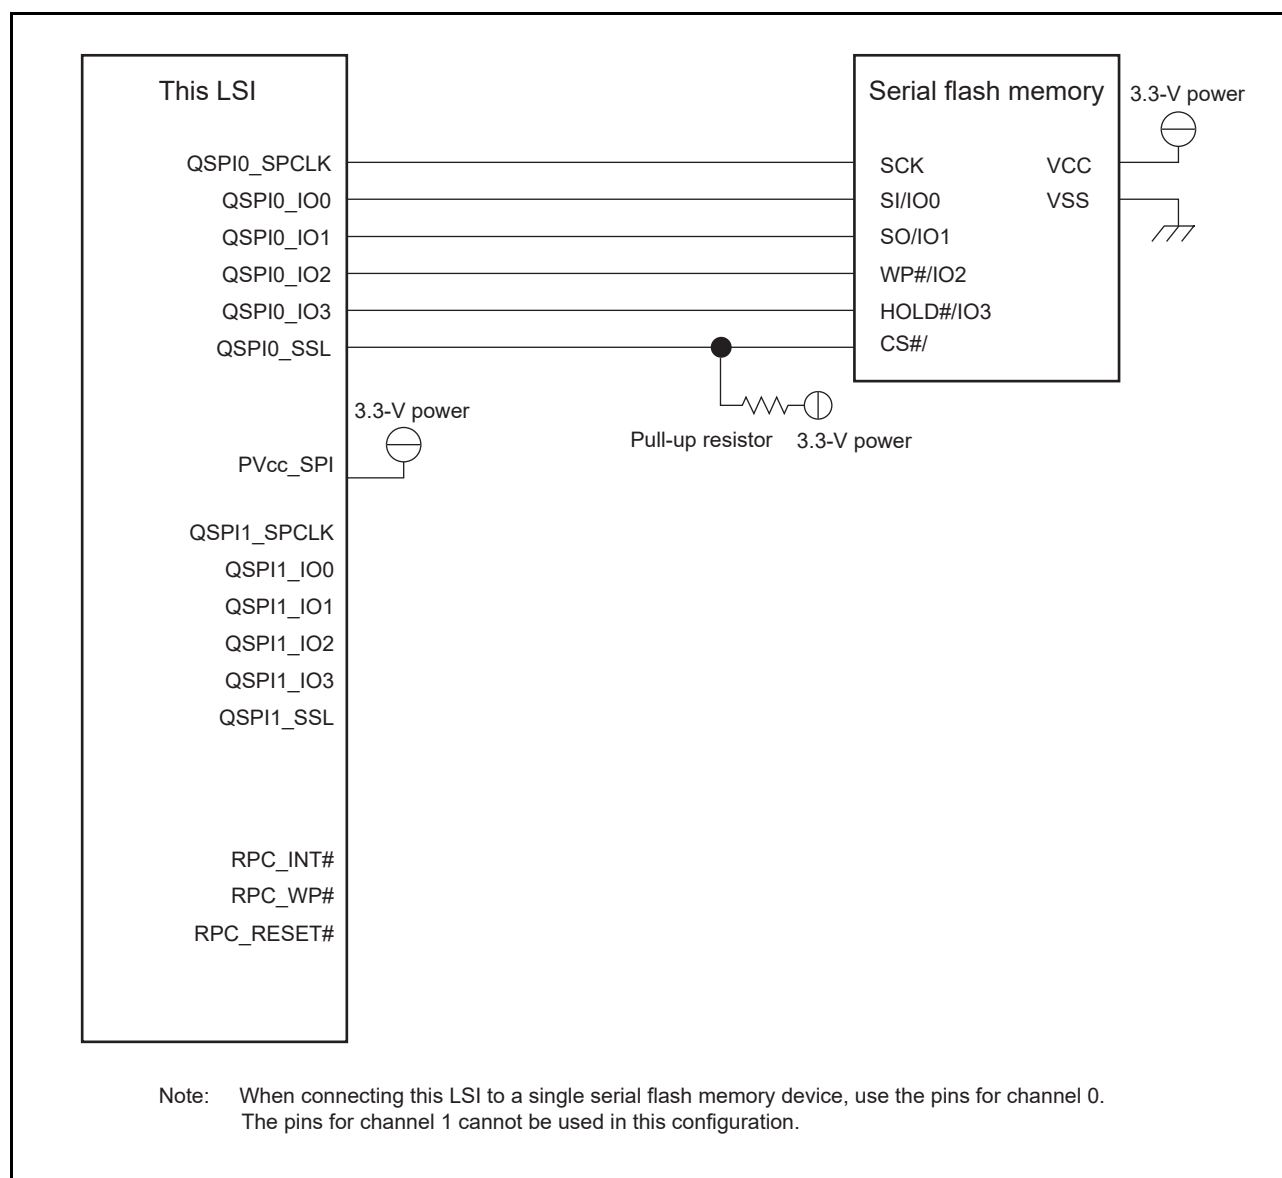

Figure 20.2 System Configuration Example with 4-Bit Data Size and One Serial Flash Memory Connected

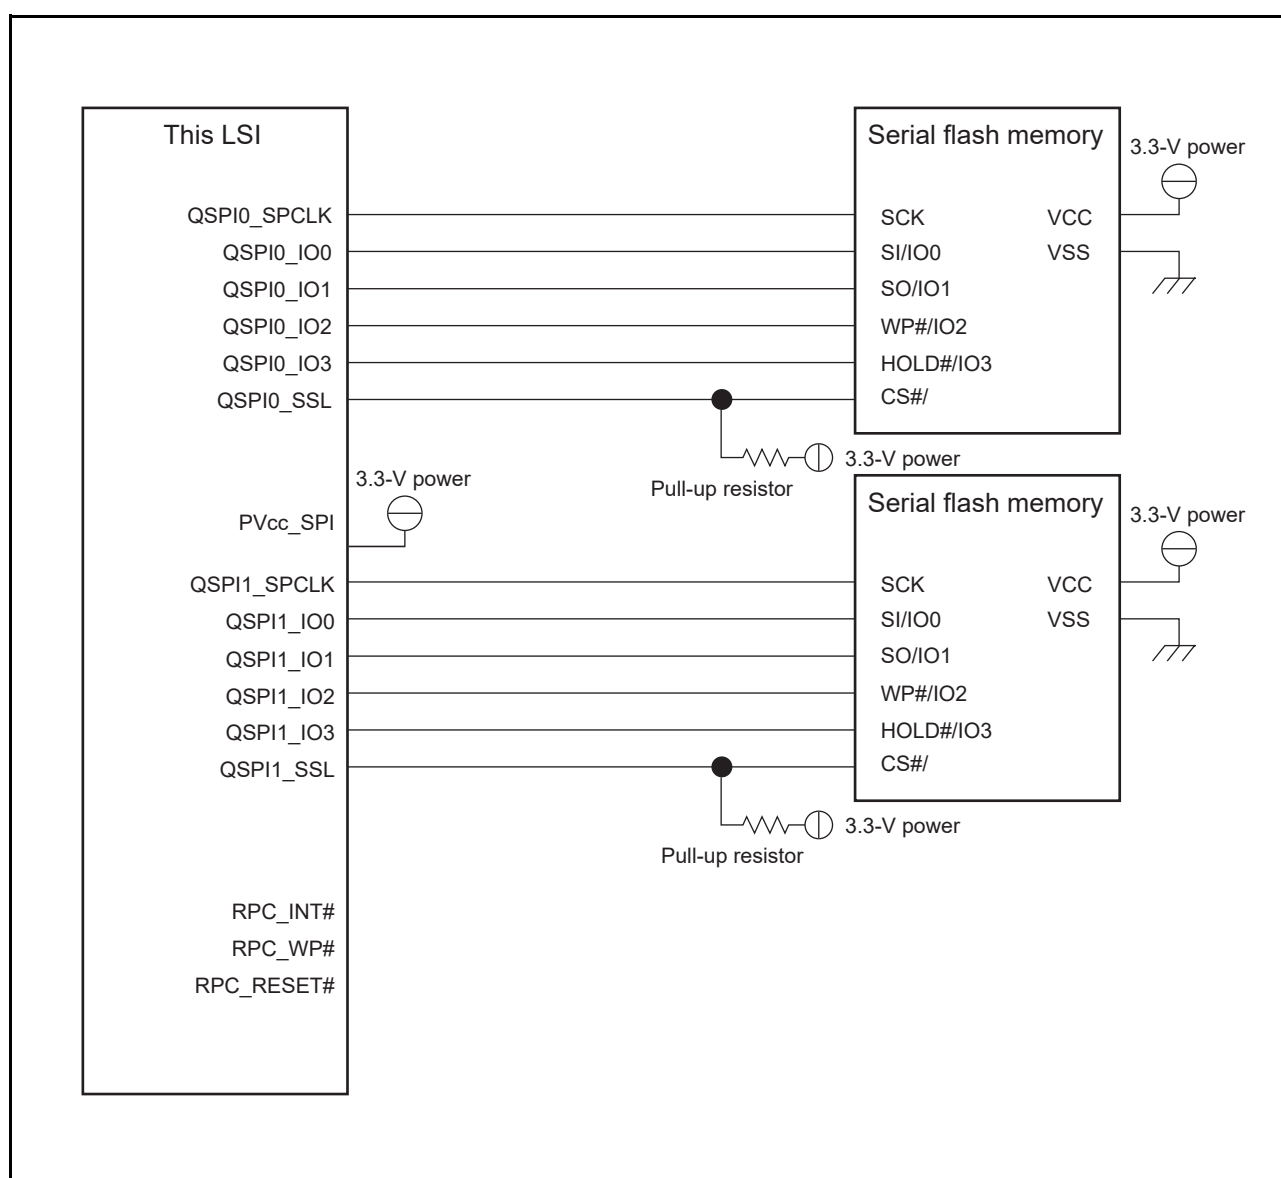

Figure 20.3 System Configuration Example with 4-Bit Data Size and Two Serial Flash Memories Connected (BSZ[1:0] Bits in CMNCR = 01)

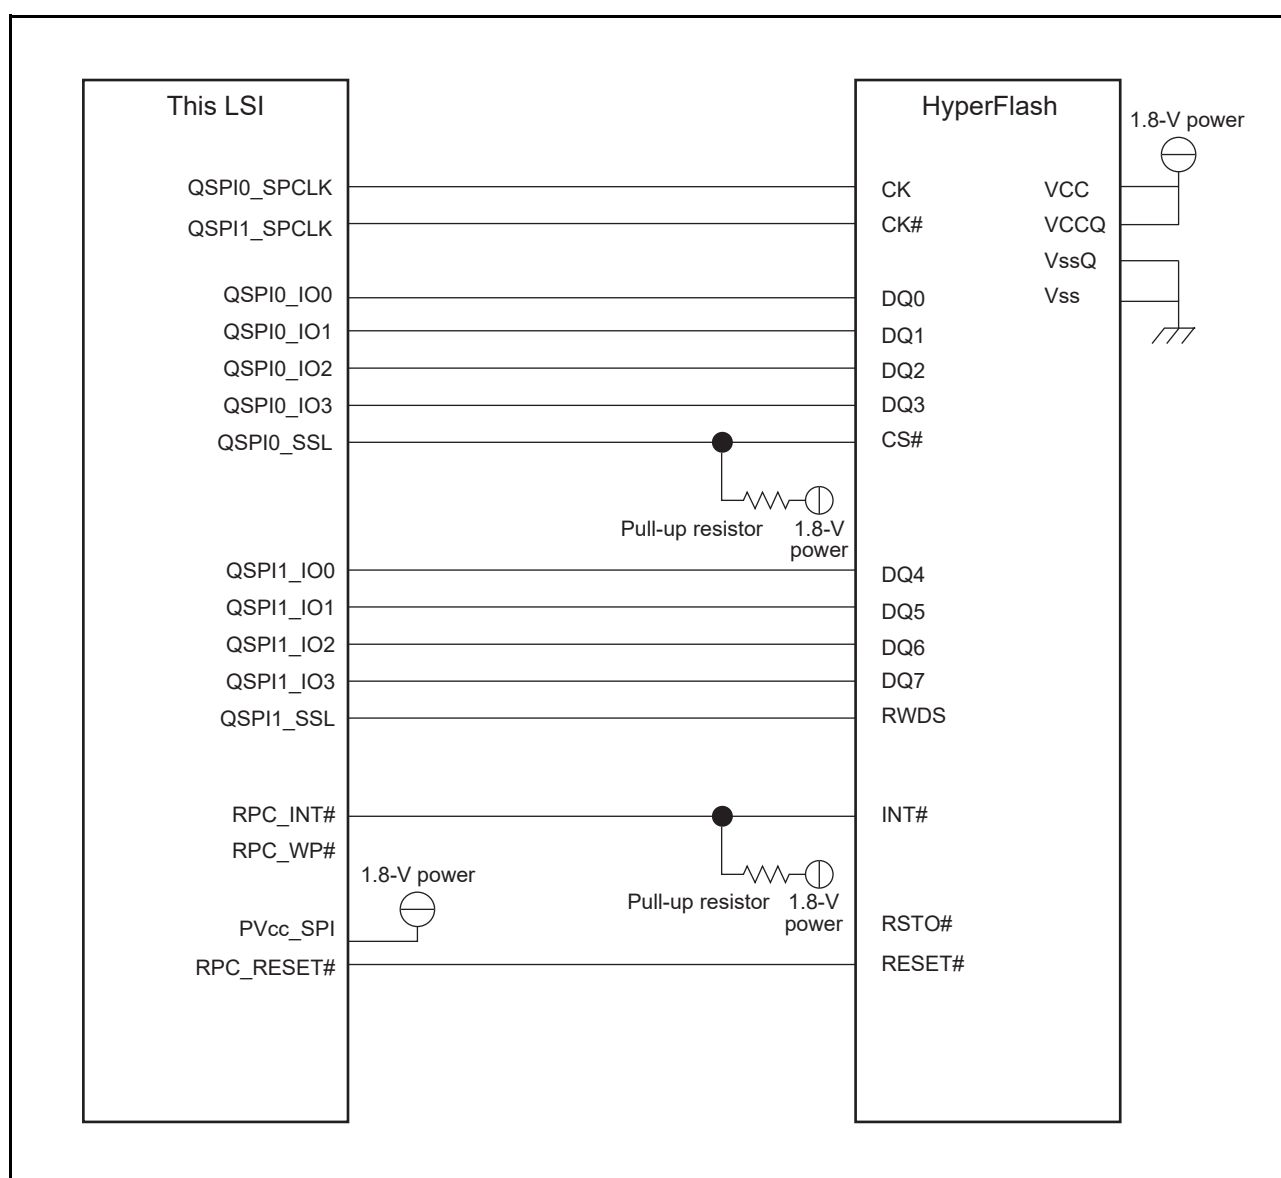

Figure 20.4 System Configuration Example with HyperFlash Connected

Figure 20.5 System Configuration Example with OctaFlash Connected

20.5.2 Address Map

In external address space read mode, the serial, HyperFlash, or Octal-SPI flash memory to be connected are allocated to the SPI multi I/O bus space. The internal address space is 256 Mbytes. However, specifying offset addresses in the DREAR register allows access to a maximum of 4 Gbytes when a single serial flash memory or Octal-SPI flash memory device is connected, and to a maximum of 8 Gbytes when two serial flash memory devices are connected or a single HyperFlash memory device is connected. When HyperFlash memory is connected, address expansion cannot be performed in the external address space read mode.

Use manual mode when HyperFlash memory is connected and an address range greater than 256 Mbytes is to be used.

Table 20.3 Address Map

| Internal Address | Max. Access Area |
|--------------------------|---|
| H'20000000 to H'2FFFFFFF | A serial flash memory or Octal-SPI flash memory device is connected: 4 Gbytes Two serial flash memory devices are connected or a single HyperFlash memory device is connected in manual mode: 8 Gbytes |

Note: When access protection is set, not only this address space, but also the register area is protected.

20.5.3 32-bit Serial Flash Addresses

Since the SPI multi I/O bus space is 256 Mbytes, only a part of the 32-bit serial flash address area can be directly accessed. Here, the fixed value set in the pertinent register is used as the upper bit value of a 32-bit address.

To output serial flash addresses in 32 bits, set the ADE[3] bit in DRENr to 1, set the range of the external addresses used as the serial flash addresses to the EAC[2:0] bits in DREAR, and set the upper bit value of the 32-bit address as the fixed value to the EAV[7:0] bits in DREAR.

Figure 20.6 32-Bit Address Setting

Setting the ADE[3] bit in DRENr to 1 allows the serial flash address to be output using [31:0] bits.

When EAC[2:0] = 000, external address bits [24:0] are valid; set the value for [32:25] bits to EAV[7:0].

When EAC[2:0] = 001, external address bits [25:0] are valid; set the value for [32:26] bits to EAV[7:1].

When EAC[2:0] = 010, external address bits [26:0] are valid; set the value for [32:27] bits to EAV[7:2].

When EAC[2:0] = 011, external address bits [27:0] are valid; set the value for [32:28] bits to EAV[7:3].

The address bits actually used for access depend on the number of serial flash memories connected.

When a single serial flash memory device is connected or the Octal-SPI flash memory protocol is in use, address bits [31:0] are used. When two serial flash memory devices are connected, address bits [32:1] are used.

20.5.4 Operating Modes

This module has two operating modes: external address space read mode and Manual mode.

In external address space read mode, a read access to the SPI multi I/O bus space is converted into Data read protocol and data is received. After data acquisition, data is returned to the bus master that is the issuing source. For details, see section 20.5.5, External Address Space Read Mode.

In Manual mode, arbitrary protocol is carried out using register settings. For details, see section 20.5.7, Manual mode.

20.5.5 External Address Space Read Mode

A read access to the SPI multi I/O bus space can be converted into Data read protocol in external address space read mode. Further, the commands, optional commands, option data, and dummy cycle issued for reading can be modified using registers.

In external address space read mode, either normal read operation or burst read operation can be selected. The transfer format is determined based on the common control register (CMNCR), SSL delay register (SSLDR), data read control register (DRCR), data read command setting register (DRCMR), data read extended address setting register (DREAR), data read option setting register (DROPR), data read enable setting register (DRENr), data read dummy cycle setting register (DRDMCR), and data read DDR enable register (DRDRENr).

(1) Normal Read Operation

When the RBE bit in the DRCR register is set to 0, normal read operation is performed. In the normal read operation, data is read from the external device when the bus master executes read access. After data is read, the QSPIn_SSL pins are negated.

The timing of normal read operation for the serial flash memory is shown in Figure 20.7.

t1 is the time period from QSPIn_SSL pin assertion to QSPIn_SPCLK oscillation (clock delay), t2 is the time period from transmission of the last QSPIn_CLK edge of a transfer to QSPIn_SSL pin negation (QSPIn_SSL negation delay), and t3 is the time period from one transfer end to the next transfer start (next access).

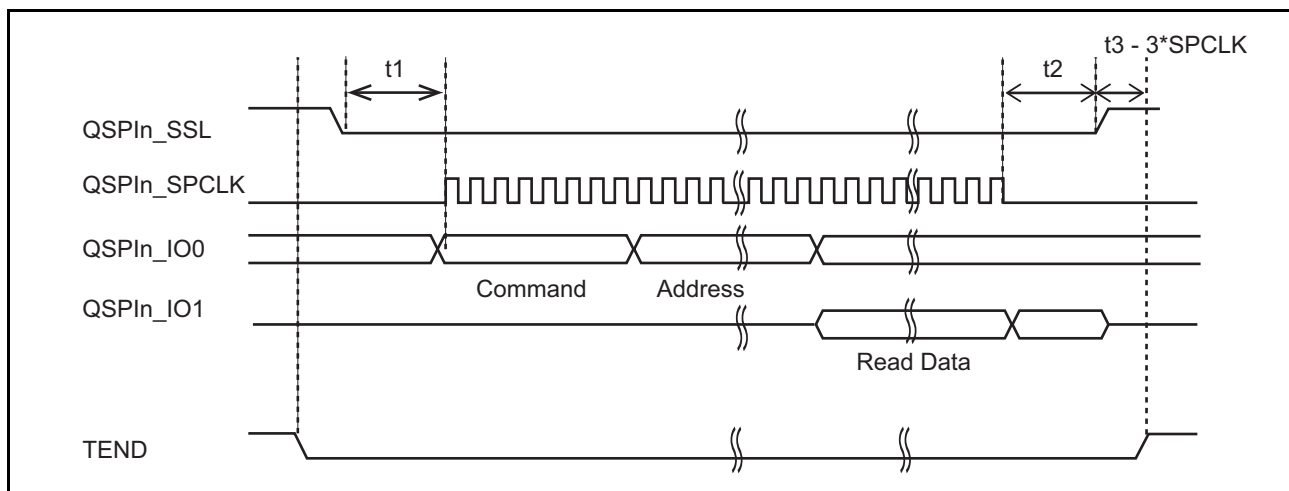

Figure 20.7 Normal Read Operation Timing

Note 1. T1 to T3 are specified with SSLDR.SCKDL, SSLDR.SLNDL and SSLDR.SPNDL bits, respectively.

(2) Burst Read Operation

When the RBE bit in DRCR is set to 1, burst read operation is performed.

Read cache is enabled in the burst read operation. For read cache operation, see section 20.5.6, Read Cache.

When the bus master executes read access, the read cache is first searched for the target data. When the read cache contains the data, it is read from the cache instead of accessing the external device. When the read cache does not contain the data, the external device is read in the burst mode and the read data is stored in the read cache and returned to the bus master. In this operation, the data transfer length is 64 bits \times the value in the RBURST[4:0] bits, and data is always read from a 64-bit boundary address.

The QSPIn_SSL pin status after data transfer can be selected by using the SSLE bit in DRCR. When the SSLE bit is set to 0, the QSPIn_SSL pin is negated after data transfer. For an operation performed when the SSLE bit is set to 1, see section 20.5.5, (3), Burst Read Operation with Automatic QSPIn_SSL Negation, just below.

A pattern diagram of this operation and a burst read operation timing diagram when SSLE bit is set to 0 are shown in Figure 20.8 and Figure 20.9.

Figure 20.8 Burst Read Operation

Note: When connecting this LSI to a single serial flash memory device, use the pins for channel 0.
The pins for channel 1 cannot be used in this configuration.

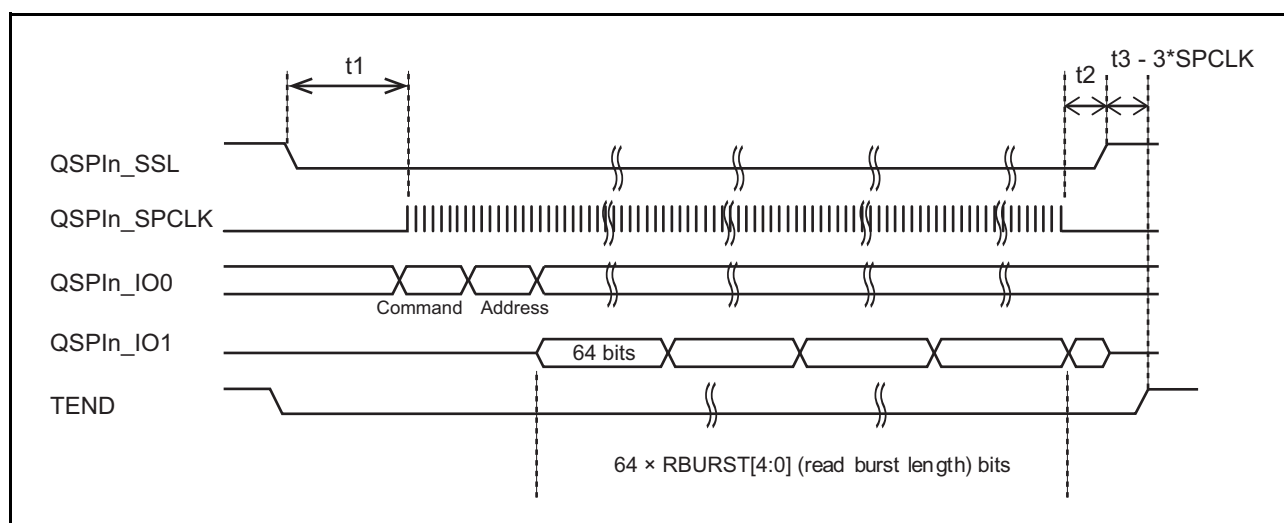

Figure 20.9 Burst Read Operation Timing

Note: T_1 to T_3 are specified with SSLDR.SCKDL, SSLDR.SLNDL and SSLDR.SPNDL bits, respectively.

(3) Burst Read Operation with Automatic QSPIn_SSL Negation

When SSLE bit in DRCR is set to 1, this module does not negate the QSPIn_SSL pin after the burst read transfer. When accessing the next time, if the address is continuous with the previous read address, the burst read operation is performed without issuing the command, optional command, address, option data, or dummy cycle. If the address is not continuous with the previous read address, the QSPIn_SSL pin is once negated and the burst read operation is performed after issuing the command, optional command, address, option data, or dummy cycle.

Burst read timing diagrams for continuous address and non-continuous address are shown in Figure 20.10 and Figure 20.11.

For the next access after negation of the QSPIn_SSL with the SSLN bit in DRCR with this operation, read SSLF = 0 in CMNSR to confirm that the QSPIn_SSL has been negated.

This function is available when serial flash memory is connected.

Figure 20.10 Burst Read Timing for Continuous Address (SSLE Bit = 1)

Figure 20.11 Burst Read Timing for Non-Continuous Address (SSLE Bit = 1)

(4) Initial Setting Flow

An example of an initial setting flow in external address space read mode is shown in Figure 20.12.

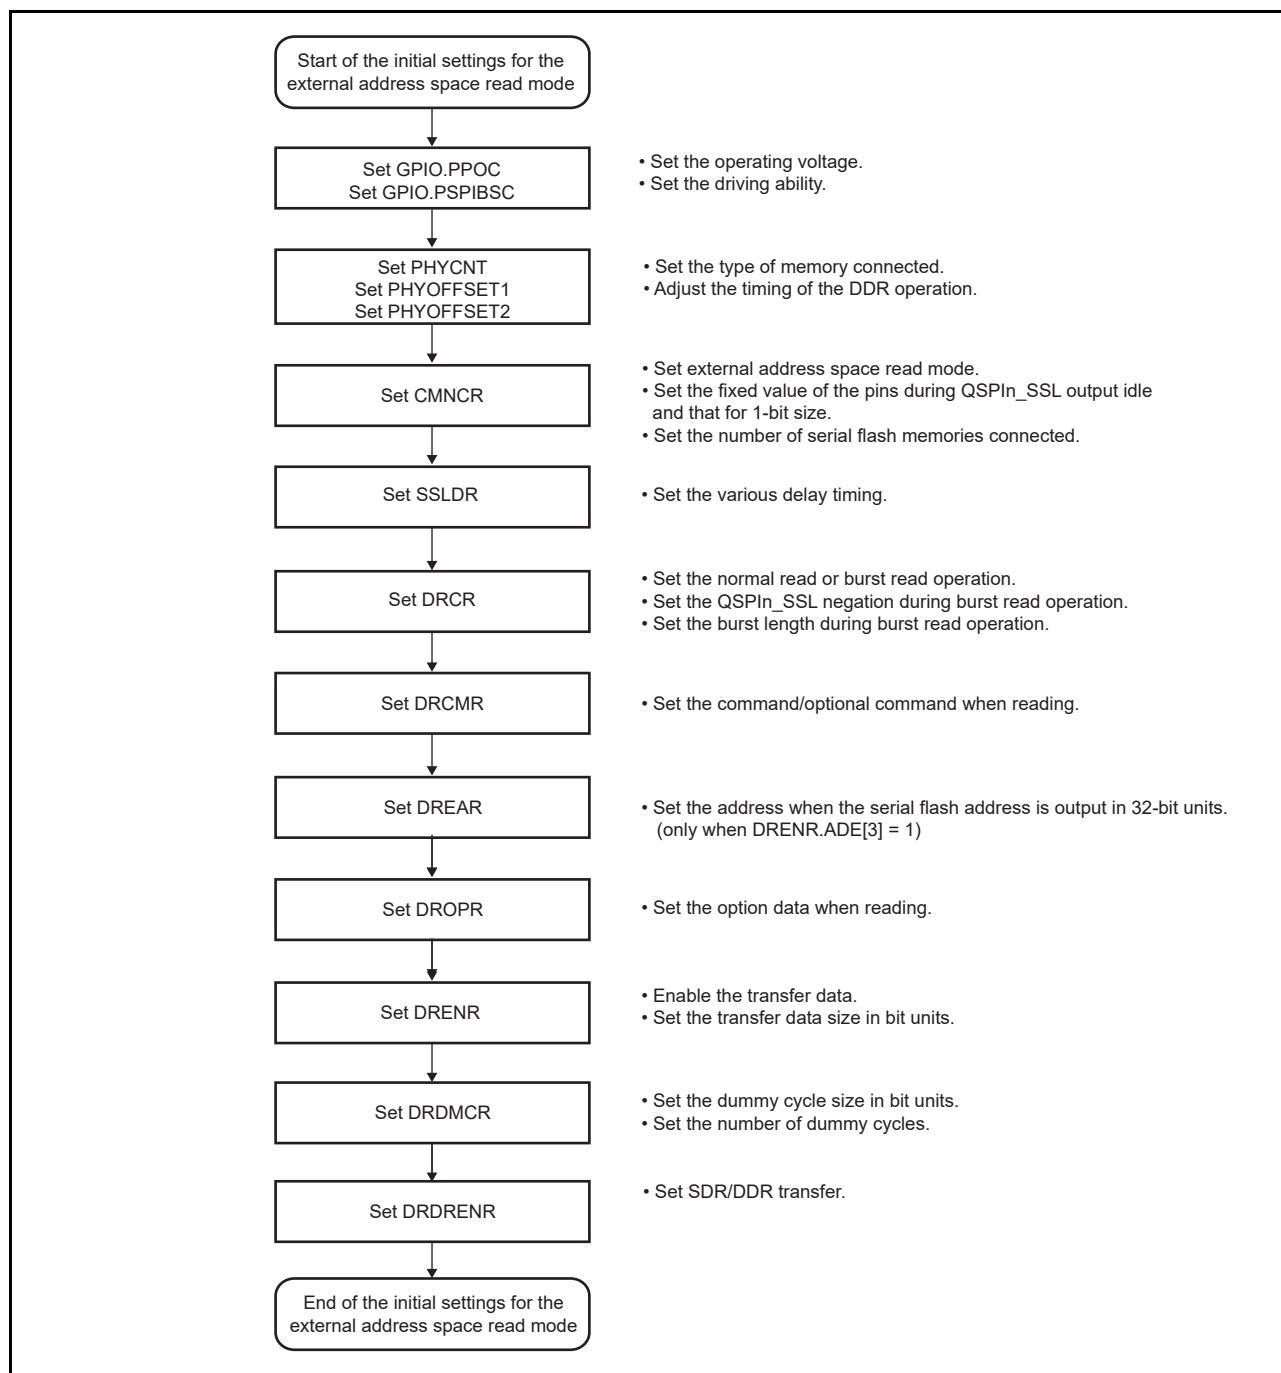

Figure 20.12 Example of Initial Setting Flow in External Address Space Read Mode

20.5.6 Read Cache

This module has a simple built-in read cache. The read cache can be used during external address space read mode and burst read operation. The read cache is configured with a line size of 64 bits and 32 entries.

Read cache configuration is shown in Figure 20.13.

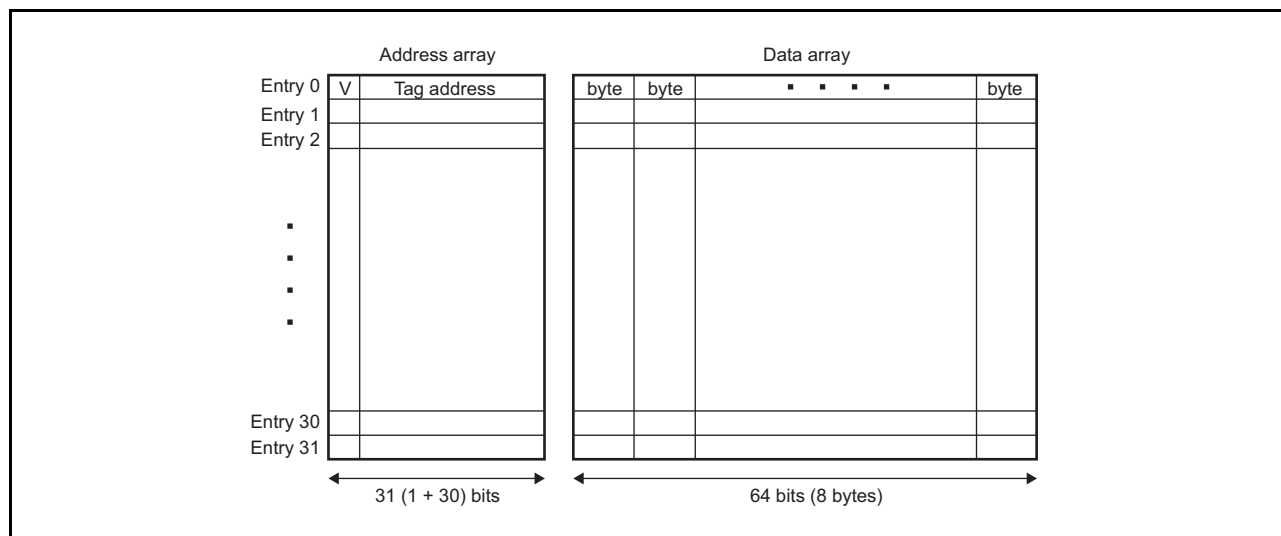

Figure 20.13 Read Cache Configuration

(1) Address Array

The V bit indicates whether the entry data is valid. When the V bit is 1, the data is valid and when V bit is 0, the data is invalid.

The tag address bits hold the address used for the serial flash memory. Address bits 32 to 3 are used for the purpose.

Address bits 23 to 3 are enabled when address output is 24 bits and one serial flash memory is connected; and address bits 24 to 3 are enabled when two serial flash memories are connected.

Address bits 31 to 3 are enabled when address output is 32 bits and one serial flash memory is connected; and address bits 32 to 3 are enabled when two serial flash memories are connected.

(2) Data Array

It retains the 64-bit read data. Registration in the read cache is performed in line units.

(3) Read Operation

In case of read-hit, data is read from the read cache. In case of read-miss, after the $64 \times \text{RBURST}$ (read burst length) data is read from the serial flash memory and the read cache is updated, the data is returned to the bus master.

(4) Data Replacement

The write pointer is used to update data. In case of read-miss, the RBURST (read burst length) portion data is replaced starting at the entry specified by the write pointer. In other words, the data is replaced in the storage order of the data.

Whether data is referred to or not will not affect the replacement order of data.

20.5.7 Manual mode

This module can carry out an arbitrary serial transmission operation by using the register settings.

The transfer format is determined based on the common control register (CMNCR), SSL delay register (SSLDR), Manual mode control register (SMCR), Manual mode command setting register (SMCMR), Manual mode address setting register (SMADR), Manual mode option setting register (SMOPR), and Manual mode enable setting register (SMENR), Manual mode read data register (SMRDR), Manual mode write data register (SMWDR), Manual mode dummy cycle setting register (SMDMCR), and Manual mode DDR enable register (SMDRENDR).

Manual mode can be used for reading the status of the serial flash memory and writing to the serial flash memory.

In this mode, one transfer refers to the operation from when the SPIE bit in SMCR is set to 1 to when the TEND bit is set to 1.

(1) Transfer Start

The transfer of data is started in the set transfer format by setting the SPIE bit in SMCR to 1. When write operation is enabled, the Manual mode write data register is transmitted to the serial flash memory. When read operation is enabled, data read from the serial flash memory is stored into the Manual mode read data register.

The Manual operation timing is shown in Figure 20.14.

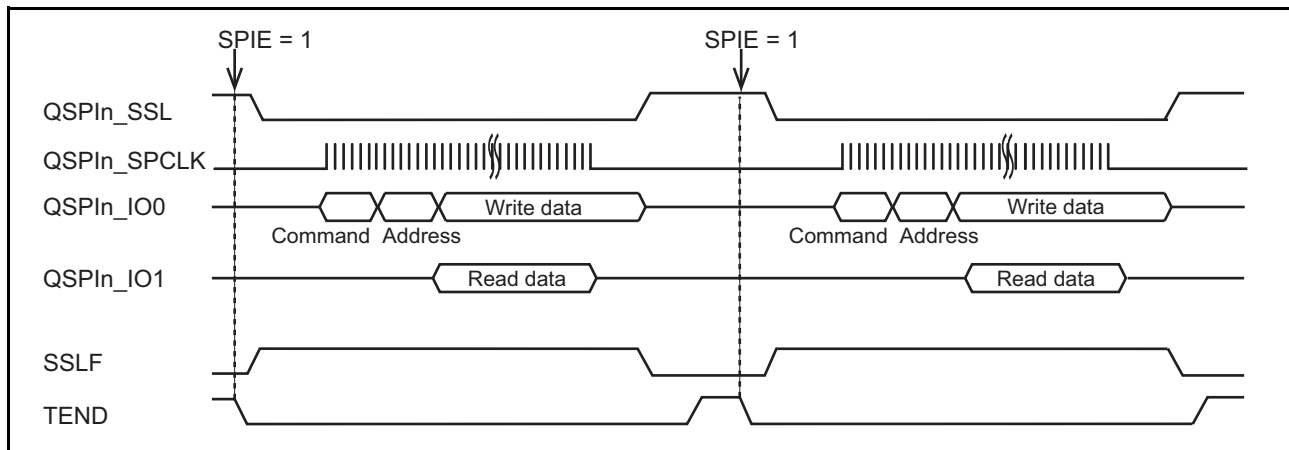

Figure 20.14 Serial transmission operation timing

(2) Read/Write Enable

- Read operation: Data can be read by setting the SPIRE bit in SMCR to 1. The read data is stored into SMRDR.
- Write operation: Data can be written by setting the SPIWE bit in SMCR to 1. The data stored in SMWDR is output.

When the data size is set to 1 bit using the SPIDB[1:0] bits in SMENR, data can be transmitted and received by setting the SPIRE and SPIWE bits to 1. However, when the data size is set to 4 bits by using the SPIDB[1:0] bits, only one of the SPIRE and SPIWE bits should be enabled. The operation is not guaranteed if the both bits are enabled.

(3) Retention of QSPIn_SSL Pin Assertion

By setting the SSLKP bit in SMCR to 1, assertion of the QSPIn_SSL pin can be continued till the next transfer. With this function, the transfer can be carried out continuously with the QSPIn_SSL kept in the asserted state.

The data transfer timing using the SSLKP bit is shown in Figure 20.15.

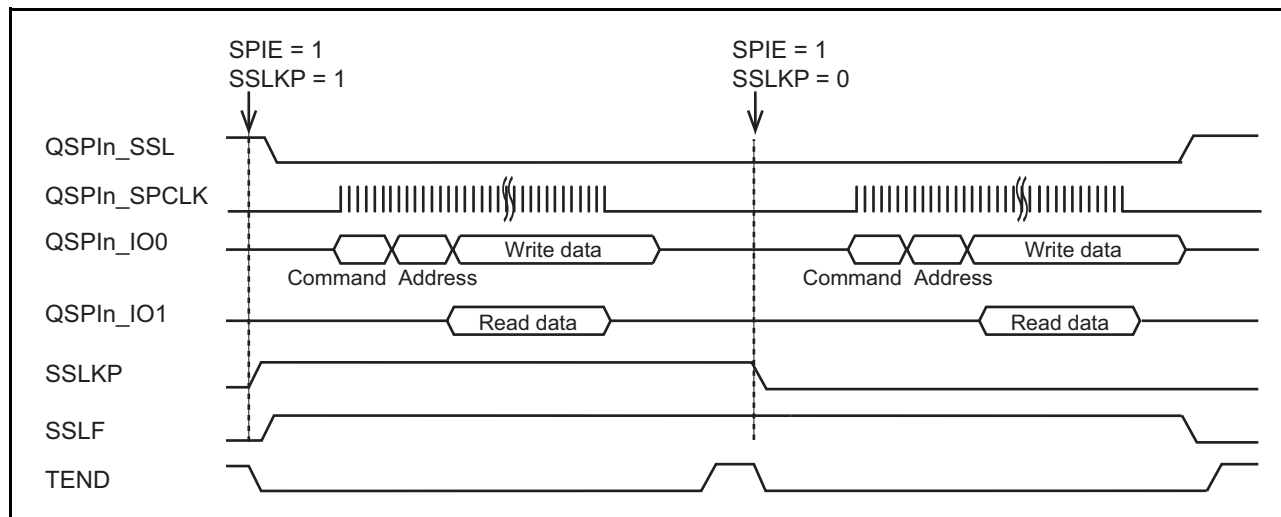

Figure 20.15 Data Transfer Timing using the SSLKP Bit

(4) Initial Setting Flow

An example of an initial setting flow in Manual mode is shown in Figure 20.16.

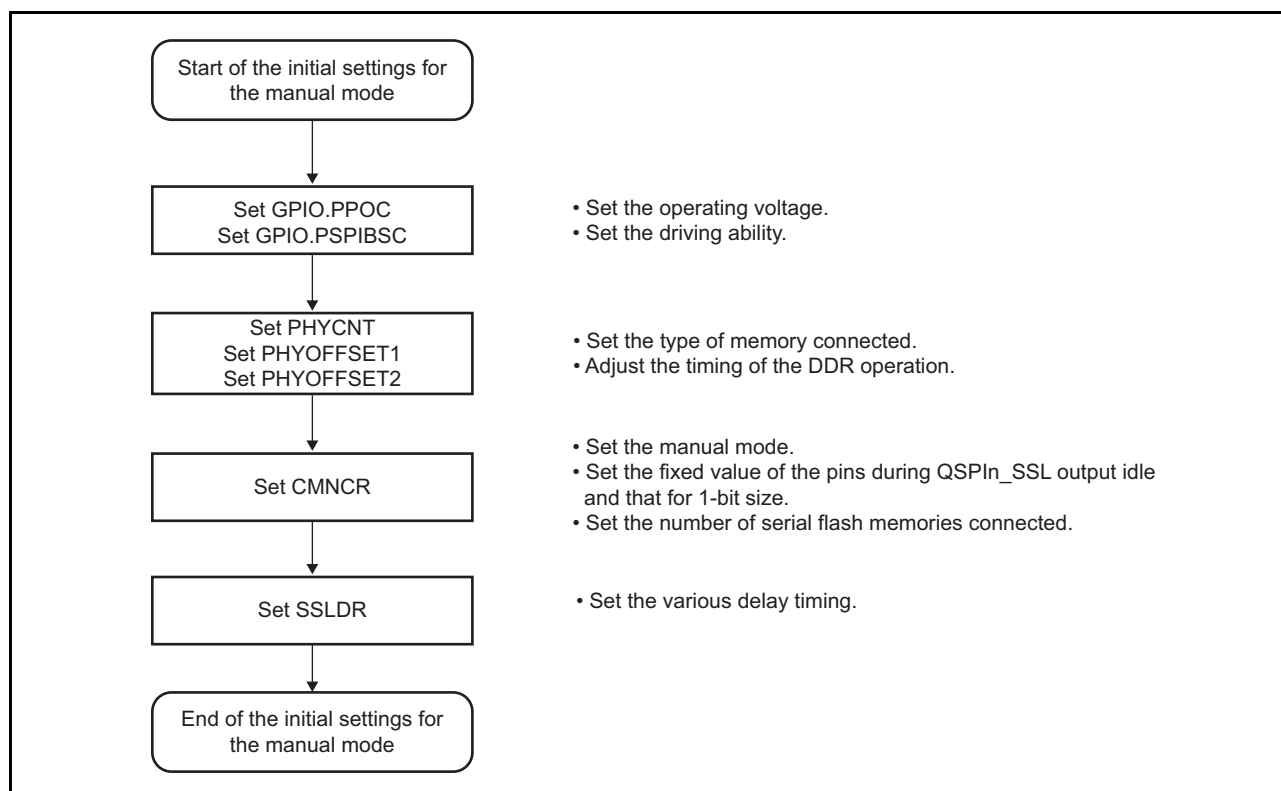

Figure 20.16 Example of Initial Setting Flow in Manual mode

(5) Data Transfer Setting Flow

An example of a data transfer setting flow in manual mode is shown in Figure 20.17.

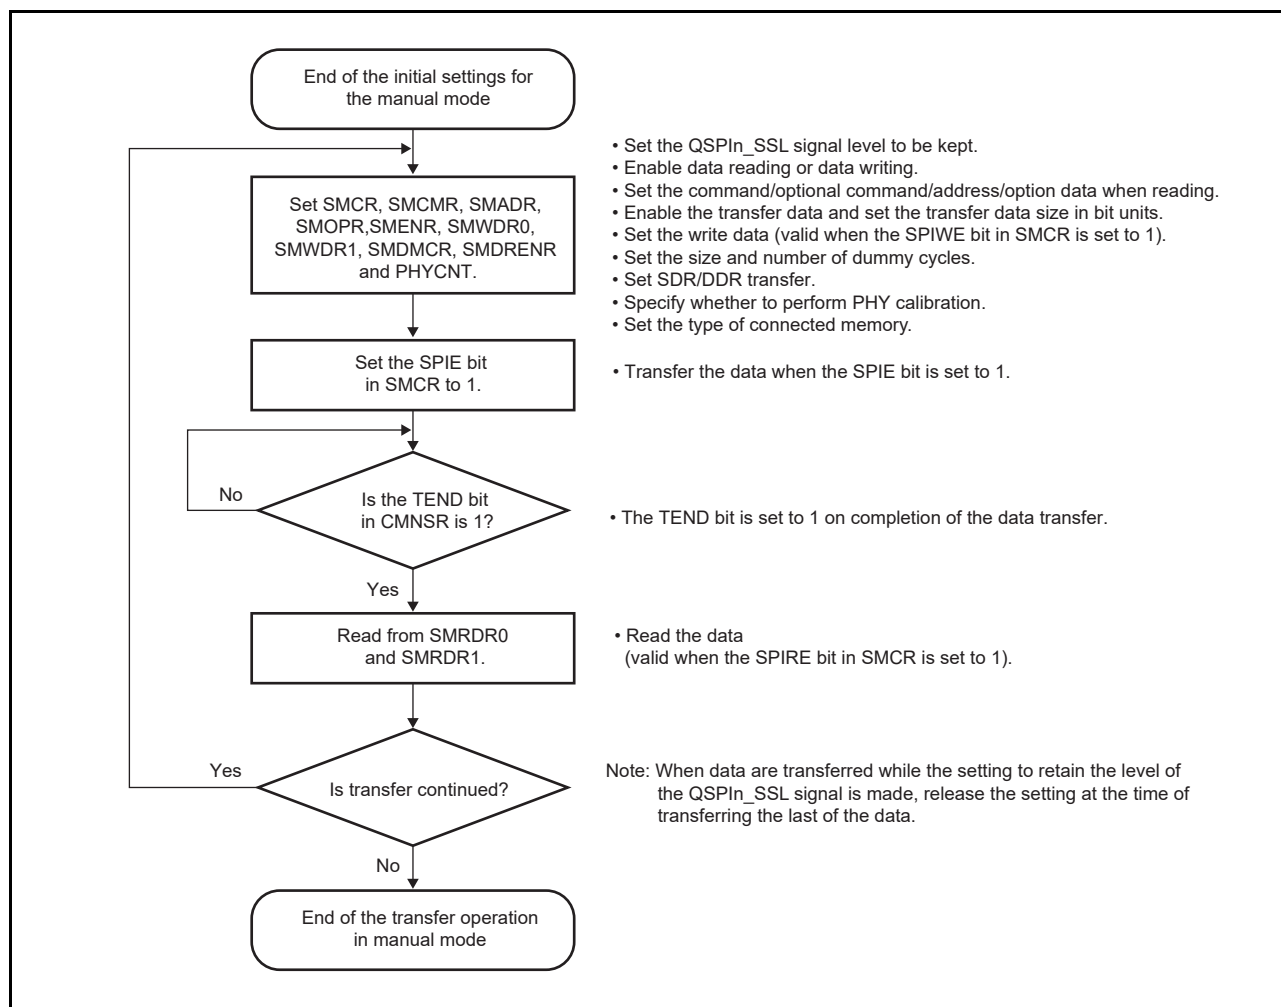

Figure 20.17 Example of a Data Transfer Setting Flow in Manual Mode

20.5.8 Command Sequence

This module can input and output data in the order of command, optional command, address, option data, dummy cycle, and data.

(1) Data Registers

Table 20.4 shows the input and output data.

Table 20.4 Data Registers

| Data | | External Address Space Read Mode | Manual Mode |
|------------------------------|---|--|--|
| Command (8 bits) | | CMD[7:0] bits in DRCMR | CMD[7:0] bits in SMCMR |
| Optional command (8 bits) | | OCMD[7:0] bits in DRCMR | OCMD[7:0] bits in SMCMR |
| Address (32/24 bits) | BSZ[1:0] = 00 (one flash memory connected) | 32 bits: DREAR.EAV[6:3 to 0] bits + lower [27 to 24:0] bits of the read address. 24 bits: Lower [23:0] bits of the read address. | 32 bits: ADR[31:0] bits in SMADR 24 bits: ADR[23:0] bits in SMADR |
| | BSZ[1:0] = 01 (two flash memories connected) | 32 bits: DREAR.EAV[7:3 to 0] bits + lower [27 to 24:1] bits of the read address. 24 bits: Lower [24:1] bits of the read address. | |
| Option data (8 bits × 4) | | DROPR | SMOPR |
| Dummy cycle (2 to 20 cycles) | | DRDMCR | SMDMCR (only when read) |
| Transfer data | | Normal read: 8, 16, and 32 bits Burst read: 64 × RBURST bits | Read: SMRDR0, SMRDR1 Write: SMWDR0, SMWDR1 |

Table 20.5 Data Registers (HyperFlash)

| Data | | External Address Space Read Mode | Manual Mode |
|------------------------------|--|---|---|
| CA0 (47 to 40) | | DRCMR.CMD[7:5] bits + [31:27] bits of the read address. | SMCMR.CMD[7:5] + SMADR.ADR[31:27] |
| CA0 (39 to 32) | | [26:19] bits of the read address. | ADR[26:19] bits in SMADR |
| CA1 (31 to 24) | | [18:11] bits of the read address. | ADR[18:11] bits in SMADR |
| CA1 (23 to 16) | | [10:3] bits of the read address. | ADR[10:3] bits in SMADR |
| CA2 (15 to 8) | | [15:8] bits in DROPR | [15:8] bits in SMOPR |
| CA2 (7 to 0) | | DROPR [7:3] bits + [2:0] bits of the read address. | SMOPR [7:3] bits + SMADR.ADR[2:0] bits |
| Dummy cycle (2 to 20 cycles) | | DRDMCR | SMDMCR |
| Transfer data | | Normal read: 8, 16, and 32 bits Burst read: 64 × RBURST bits | Read: SMRDR0, SMRDR1 Write: SMWDR0, SMWDR1 |

(2) Data Enable

In external address space read mode, enabling or disabling transfer of the command, optional command, address, option data, and dummy cycle can be controlled with the CDE, OCDE, ADE[3:0], OPDE[3:0], and DME bits in DRENr, respectively. The number of dummy cycles can be controlled with the data read dummy cycle setting register (DRDMCR).

Similarly, in manual mode, enabling or disabling the command, optional command, address, option data, dummy cycle, and transfer data can be controlled with the CDE, OCDE, ADE[3:0], OPDE[3:0], DME, and SPIDE[3:0] bits in SMENr, respectively. However, disabling all the above parameters is prohibited in manual mode. At least one of them except dummy cycle must be enabled. The number of dummy cycles can be controlled with the Manual mode dummy cycle setting register (SMDMCR).

For the address and option data in external address space read mode and the address, option data, and transfer data in manual mode, the enable bit setting allowed is determined according to the transfer data size. For the allowed setting combinations of the enable bits and transfer data size, refer to the description of the pertinent register.

If data is disabled, that data is skipped, and input and output of the next data is carried out. The command, optional command, address, and option data are always output. During dummy cycles, the state of the used pins is Hi-Z. In external address space read mode, data is always input; and in manual mode, input and output of data is determined based on the settings of the SPIRE and SPIWE bits in SMCR.

There are some restrictions on dummy cycle insertion; refer to the description of the DME bits in DRENr and SMENr for details.

| | Command | Optional command | Address | | | | Option data | | | | Dummy cycle | Transfer data |
|-------------------------------------|---------|------------------|--------------------------|-------------|------------|-----------|--------------|---------|---------|---------|----------------|---|
| Data | | | | | | | | | | | | |
| In external address space read mode | CMD | OCMD | (EAV[7:0]+) read address | | | | OPD3 | OPD2 | OPD1 | OPD0 | DMCYC | Data read length |
| In manual mode | CMD | OCMD | ADR [31:24] | ADR [23:16] | ADR [15:8] | ADR [7:0] | OPD3 | OPD2 | OPD1 | OPD0 | DMCYC | DATA[3] DATA[2] DATA[1] DATA[0] |
| Enable | | | | | | | | | | | | |
| In external address space read mode | CDE | OCDE | ADE[3] | ADE[2] | ADE[1] | ADE[0] | OPDE[3] | OPDE[2] | OPDE[1] | OPDE[0] | DME | Always enabled |
| In manual mode | CDE | OCDE | ADE[3] | ADE[2] | ADE[1] | ADE[0] | OPDE[3] | OPDE[2] | OPDE[1] | OPDE[0] | DME | SPIDE [3] SPIDE [2] SPIDE [1] SPIDE [0] |
| DDR Enable | | | | | | | | | | | | |
| In external address space read mode | - | - | ADDRE | | | | OPDRE | | | | - | DRDRE |
| In manual mode | - | - | ADDRE | | | | OPDRE | | | | - | SPIDRE |
| | 8 bits | | 32/24 bits | | | | 8/16/32 bits | | | | 2 to 20 cycles | Data length |

Figure 20.18 Data and Enable (Serial Flash)

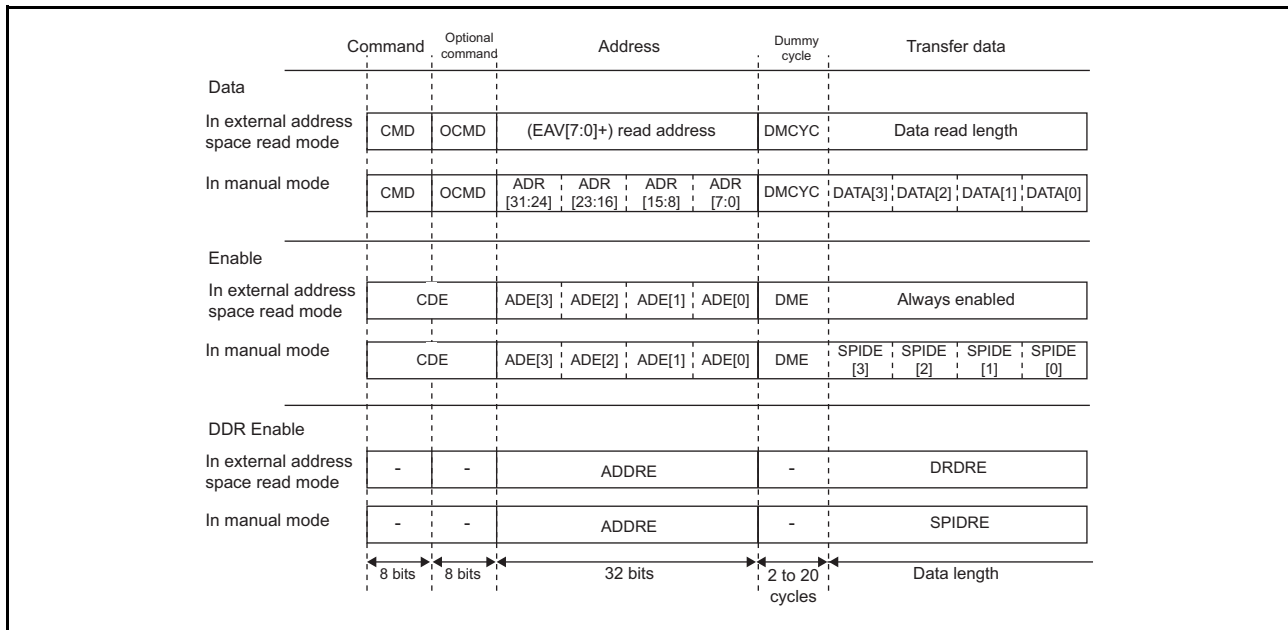

Figure 20.19 Data and Enable (Octal-SPI Flash Memory Protocol Mode)

When the HyperFlash memory is connected to this LSI, the CDE, OCDE, ADE[3:0], OPDE[3:0], and DME bits in the DRENr register and the HYPE[2:0], ADDRE, and OPDRE bits in the DRDRENr register should be set to "enabled" in external address space read mode. In Manual mode, the CDE, OCDE, ADE[3:0], OPDE[3:0], and DME bits in the SMENr register and the HYPE[2:0], ADDRE, OPDRE, and DRDRE bits in the SMDRENr should be set to "enabled".

Table 20.6 Enable Register (HyperFlash)

| External Address Space Read Mode | | | Manual Mode | | |
|----------------------------------|-----------|---------------|-------------|-----------|---------------------|
| Register | Bit | Setting Value | Register | Bit | Setting Value |
| DRENr | CDE | 1 | SMENr | CDE | 1 |
| | OCDE | 1 | | OCDE | 1 |
| | ADE[3:0] | 0100 | | ADE[3:0] | 0100 |
| | OPDE[3:0] | 0000 | | OPDE[3:0] | 0000 |
| | DME | 1 | | DME | Read: 1 Write: 0 |
| | | | SPIDE[3:0] | | |
| | | | 16 bits | | |
| | | | 32 bits | | |
| | | | 64 bits | | |
| | | | 1000 | | |
| | | | 1100 | | |
| | | | 1111 | | |
| DRDRENr | HYPE[2:0] | 101 | SMDRENr | HYPE[2:0] | 101 |
| | ADDRE | 1 | | ADDRE | 1 |
| | OPDRE | 0 | | OPDRE | 0 |
| | DRDRE | 1 | | SPIDRE | 1 |

Table 20.7 Enable Register (Octal-SPI Flash Memory Protocol Mode)

| External Address Space Read Mode | | | Manual Mode | | |
|----------------------------------|-----------|---------------|-------------|------------|---------------------|
| Register | Bit | Setting Value | Register | Bit | Setting Value |
| DRENr | CDE | 1 | SMENr | CDE | 1 |
| | OCDE | 0 | | OCDE | 0 |
| | ADE[3:0] | 1100 | | ADE[3:0] | 1100 |
| | OPDE[3:0] | 0000 | | OPDE[3:0] | 0000 |
| | DME | 1 | | DME | Read: 1 Write: 0 |
| SMENr | CDE | 0 | | SPIDE[3:0] | |
| | | | | 16 bits | 1000 |
| | | | | 32 bits | 1100 |
| | | | | 64 bits | 1111 |
| DRDRENr | HYPE[2:0] | 100, 101 | SMDRENr | HYPE[2:0] | 100, 101 |
| | ADDRE | 1 | | ADDRE | 1 |
| | OPDRE | 0 | | OPDRE | 0 |
| | DRDRE | 1 | | SPIDRE | 1 |

Note: When only commands are to be transferred, set DRDRENr.HYPE or SMDRENr.HYPE to 100.

(3) Bit Size

In external address space read mode, the size of the command, optional command, address, option data, and the read data in bit units is respectively controlled with the CDB[1:0], OCDB[1:0], ADB[1:0], OPDB[1:0], and DRDB[1:0] bits in DRENr.

Similarly, in manual mode, the size of the command, optional command, address, option data, and read write data in bit units is controlled with the CDB[1:0], OCDB[1:0], ADB[1:0], OPDB[1:0], and SPIDB[1:0] bits in SMENr.

(a) 1-bit Size

When the size is set to 1 bit, QSPI0_IO1 and QSPI1_IO1 pins will be the input pins and QSPI0_IO0 and QSPI1_IO0 pins will be the output pins. QSPI0_IO2, QSPI1_IO2, QSPI0_IO3, and QSPI1_IO3 pins are not used.

Figure 20.20 and Figure 20.21 show the transfer format examples.

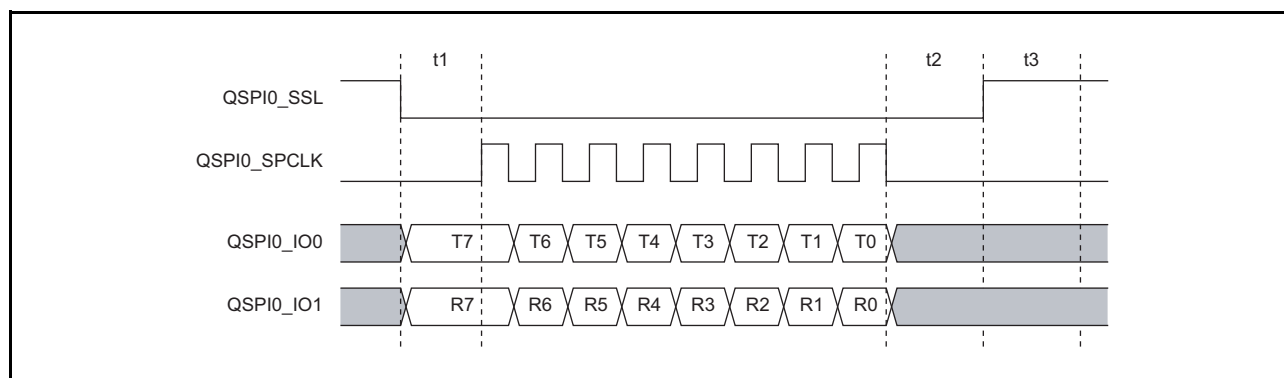

Figure 20.20 Transfer Format Example with 1-Bit Data Size and One Serial Flash Memory Connected

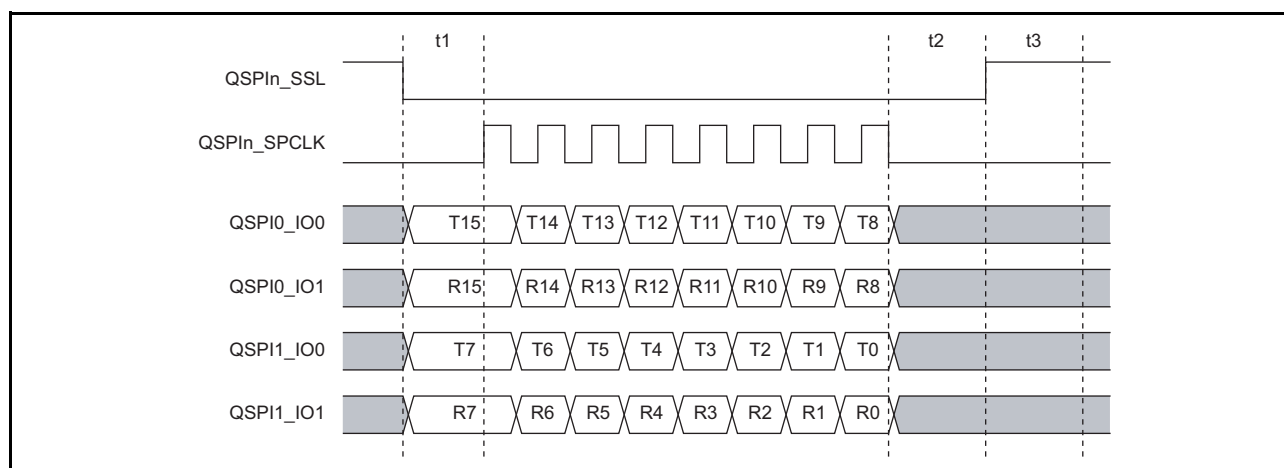

Figure 20.21 Transfer Format Example with 1-Bit Data Size and Two Serial Flash Memories Connected

(b) 4-bit Size (Serial Flash)

When the size is set to 4 bits, QSPI0_IO0, QSPI1_IO0, QSPI0_IO1, QSPI1_IO1, QSPI0_IO2, QSPI1_IO2, QSPI0_IO3, and QSPI1_IO3 pins will be either the input pins or the output pins.

Figure 20.22 and Figure 20.23 show the transfer format examples.

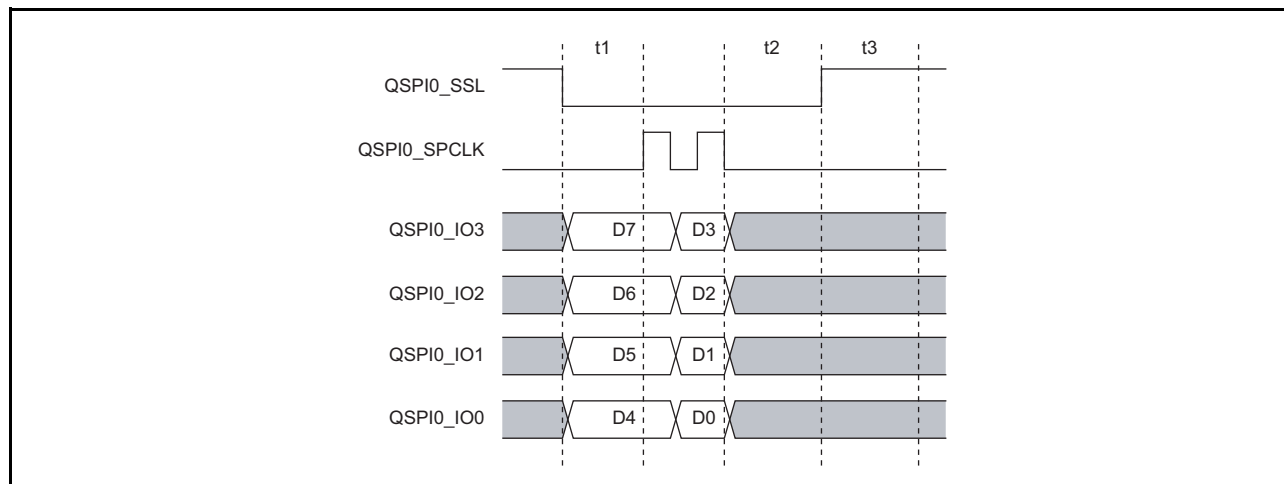

Figure 20.22 Transfer Format Example with 4-Bit Data Size and One Serial Flash Memory Connected

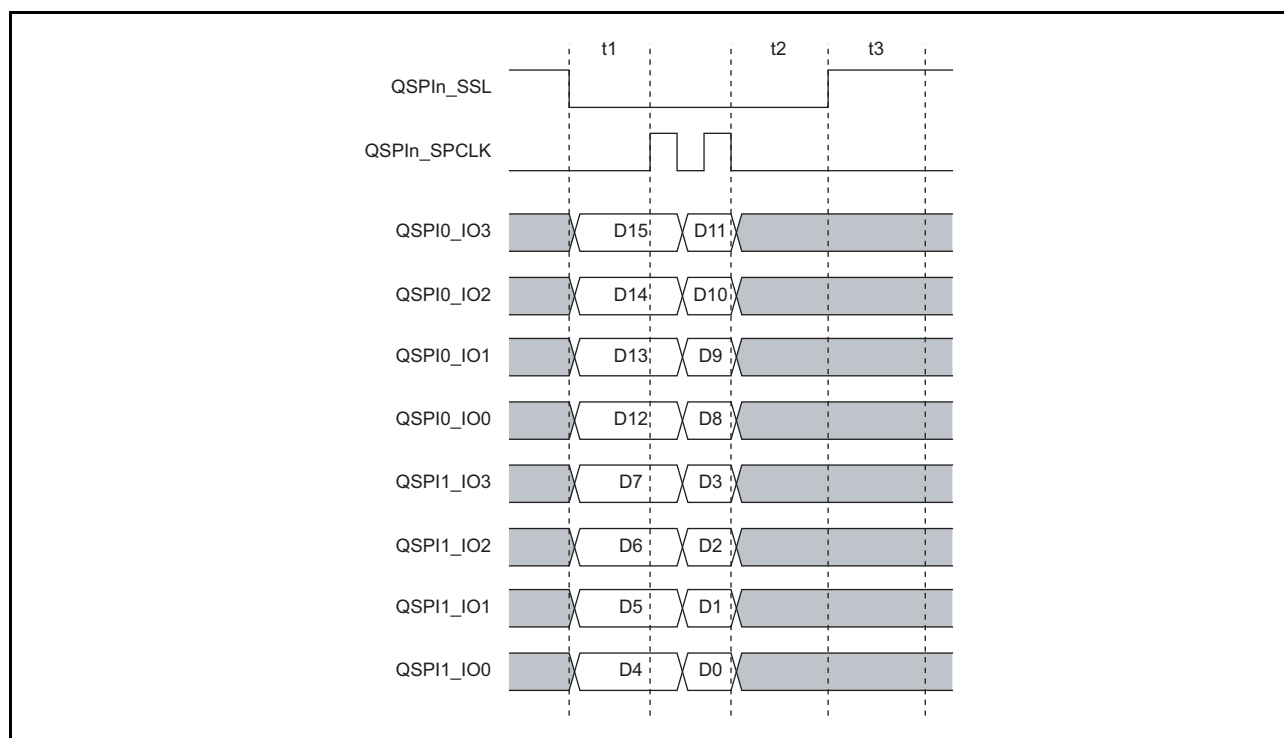

Figure 20.23 Transfer Format Example with 4-Bit Data Size and Two Serial Flash Memories Connected

(c) 8-bit Size (HyperFlash)

When the HyperFlash memory is connected to this LSI, QSPI0_SPCLK and QSPI1_SPCLK work as differential clock pins, QSPI1_SSL works as the read data strobe (RDS) input pin, and QSPI0_IO0, QSPI1_IO0, QSPI0_IO1, QSPI1_IO1, QSPI0_IO2, QSPI1_IO2, QSPI0_IO3, and QSPI1_IO3 work as either input pins or output pins.

Figure 20.24 and Figure 20.25 show the transfer format examples.

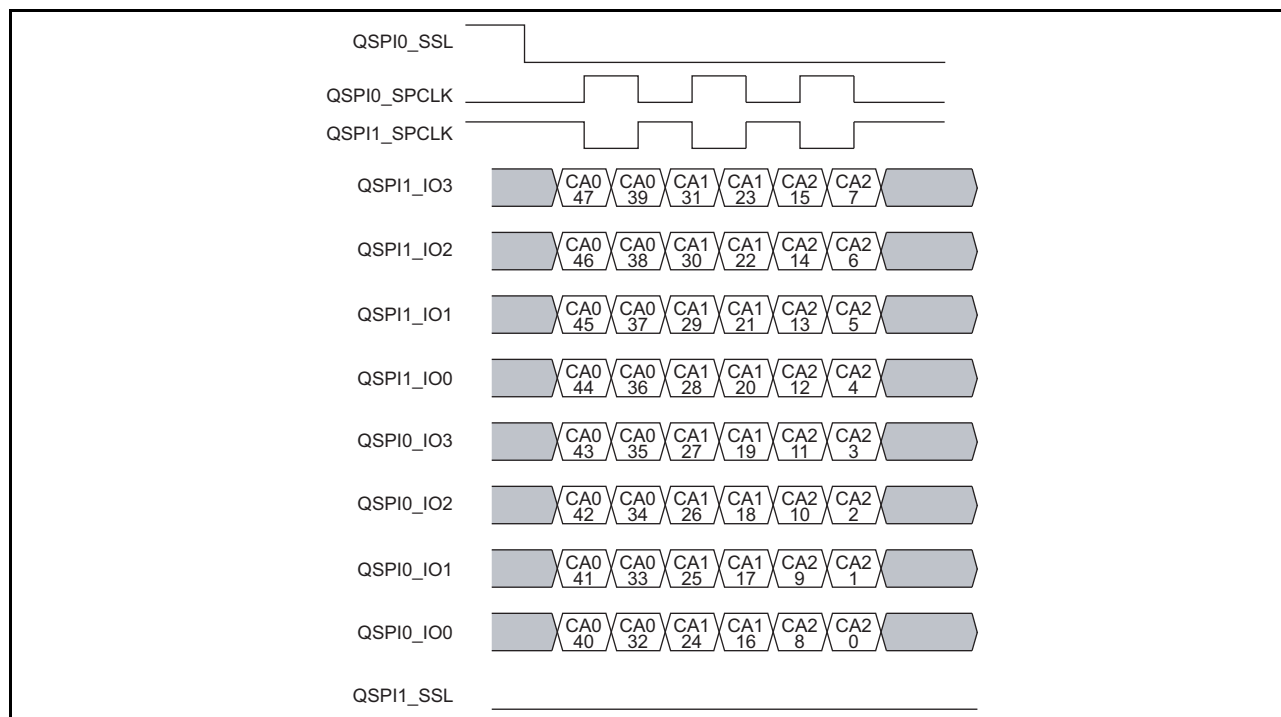

Figure 20.24 Transfer Format Example in the HyperFlash Command and Address Phase

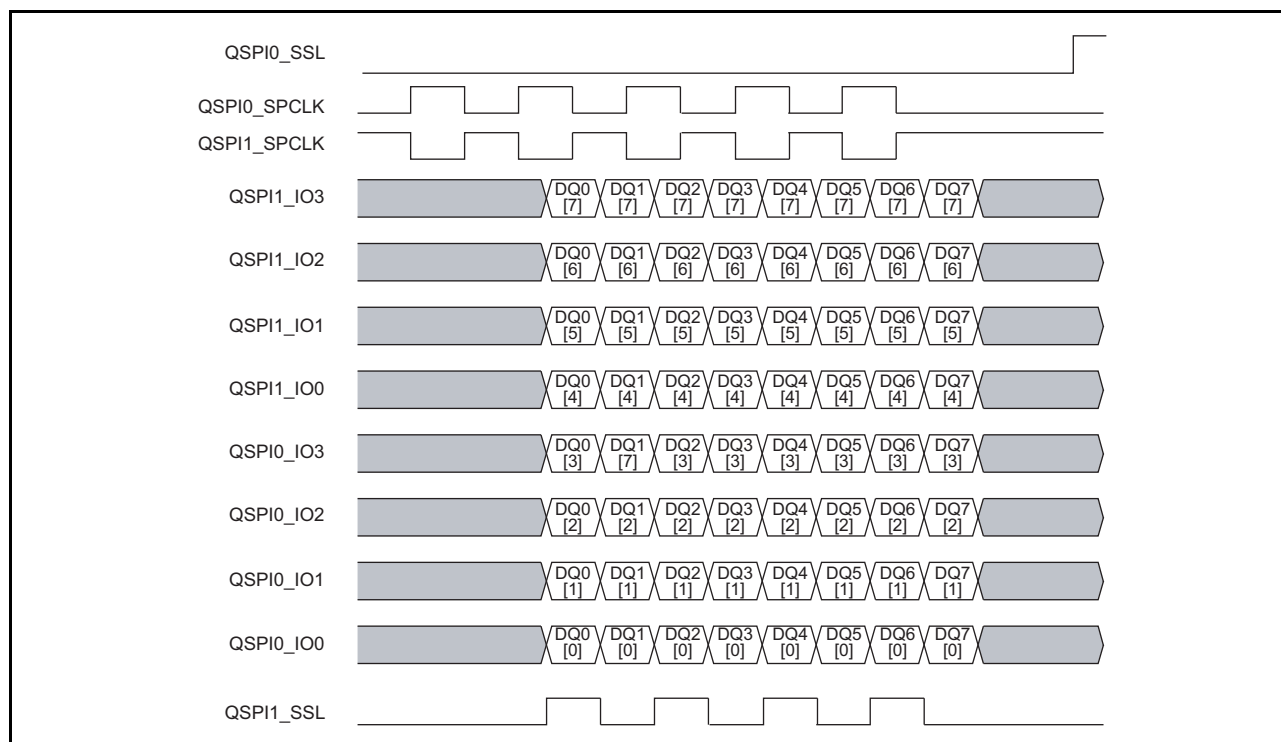

Figure 20.25 Transfer Format Example in the HyperFlash Read Phase

20.5.9 Data Pin Control

With this module, the status of pins can be automatically changed based on the data size to be used and the read/write settings. The pin status during the QSPIn_SSL negation can be set with the MOIIIO3, MOIIIO2, MOIIIO1, and MOIIIO0 bits in CMNCR. The QSPIn_SSL and QSPIn_SPCLK pins are always output pins.

The status of respective pins is specified in Table 20.8 to Table 20.11.

When using only a single serial flash memory device, note that connecting the pins for channel 1 to the serial flash memory is prohibited.

Table 20.8 Pin Status (1)

| Pin | QSPIn_SSL Negation | QSPIn_SSL Assertion | |
|----------------------|--------------------|---|------------|
| | | Command, Optional Command, Address, Option Data | |
| | | 1-bit Size | 4-bit Size |
| QSPI0_IO0, QSPI1_IO0 | MOIIIO0 bit value | Output | Output |
| QSPI0_IO1, QSPI1_IO1 | MOIIIO1 bit value | Hi-Z | Output |
| QSPI0_IO2, QSPI1_IO2 | MOIIIO2 bit value | IO2FV bit value | Output |
| QSPI0_IO3, QSPI1_IO3 | MOIIIO3 bit value | IO3FV bit value | Output |

Table 20.9 Pin Status (2)

| Pin | Transfer Data | | | |
|----------------------|----------------------------------|------------|------------------------------|------------|
| | External Address Space Read Mode | | SPI Operation | |
| | | | SPIRE Bit = 1, SPIWE Bit = 0 | |
| | 1-bit Size | 4-bit Size | 1-bit Size | 4-bit Size |
| QSPI0_IO0, QSPI1_IO0 | IO0FV bit value | Input | IO0FV bit value | Input |
| QSPI0_IO1, QSPI1_IO1 | Input | Input | Input | Input |
| QSPI0_IO2, QSPI1_IO2 | Hi-Z | Input | Hi-Z | Input |
| QSPI0_IO3, QSPI1_IO3 | Hi-Z | Input | Hi-Z | Input |

Table 20.10 Pin Status (3)

| Pin | Transfer Data | | | |
|----------------------|------------------------------|------------|------------------------------|--------------------|
| | SPI Operation | | | |
| | SPIRE Bit = 0, SPIWE Bit = 1 | | SPIRE Bit = 1, SPIWE Bit = 1 | |
| | 1-bit Size | 4-bit Size | 1-bit Size | 4-bit Size |
| QSPI0_IO0, QSPI1_IO0 | Output | Output | Output | Setting prohibited |
| QSPI0_IO1, QSPI1_IO1 | Hi-Z | Output | Input | Setting prohibited |
| QSPI0_IO2, QSPI1_IO2 | IO2FV bit value | Output | IO2FV bit value | Setting prohibited |
| QSPI0_IO3, QSPI1_IO3 | IO3FV bit value | Output | IO3FV bit value | Setting prohibited |

Table 20.11 Pin Status (4)

| Pin | Dummy Cycle |
|----------------------|-----------------|
| QSPI0_IO0, QSPI1_IO0 | IO0FV bit value |
| QSPI0_IO1, QSPI1_IO1 | Hi-Z |
| QSPI0_IO2, QSPI1_IO2 | Hi-Z |
| QSPI0_IO3, QSPI1_IO3 | Hi-Z |

20.5.10 QSPIn_SSL Pin Control

Negation conditions of the QSPIn_SSL pin are as follows.

(1) External Address Space Read Mode

(a) Normal read operation (RBE bit in DRCR = 0)

QSPIn_SSL negated after completing the data transfer and t2 cycle.

(b) Burst read without automatic QSPIn_SSL negation (RBE bit in DRCR = 1, SSLE bit in DRCR = 0)

QSPIn_SSL negated after completing the data transfer and t2 cycle.

(c) Burst read with automatic QSPIn_SSL negation (RBE bit in DRCR = 1, SSLE bit in DRCR = 1)

- QSPIn_SSL negated after t2 cycle when the read address is not continuous with the previously read address
- QSPIn_SSL negated after the SSLN bit in DRCR is set to 1

(2) Manual Mode

(a) QSPIn_SSL pin assertion not retained (SSLKP bit in SMCR = 0)

QSPIn_SSL negated after completing the data transfer and t2 cycle.

(b) QSPIn_SSL pin assertion retained (SSLKP bit in SMCR = 1)

QSPIn_SSL not negated.

When to be negated, data should be transferred after setting the SSLKP bit to 0.

Note: When HyperFlash memory is connected or a connection is made in Octal-SPI flash memory protocol mode, the QSPIn_SSL pin is used as an input terminal for data strobe.

20.5.11 QSPIn_SPCLK Pin Control

QSPI0_SPCLK and QSPI1_SPCLK are output according to the following settings.

Table 20.12 QSPIn_SPCLK Output

| Pin | HyperFlash connected. (CMNCR.BSZ = 01, PHYCNT.PHYMEM = 11) | One serial flash memory connected. (CMNCR.BSZ = 00, PHYCNT.PHYMEM = 00, 01) | Two serial flash memories connected. (CMNCR.BSZ = 01, PHYCNT.PHYMEM = 00, 01) |
|-------------|--|---|---|
| QSPI0_SPCLK | Output | Output | Output |
| QSPI1_SPCLK | Output (Complementary output of QSPI0_SPCLK) | Hi-Z | Output |

20.5.12 Flags

This module has two flag bits SSLF and TEND in CMNSR. These bits are read-only bits.

(1) SSLF Bit

This bit indicates the QSPIn_SSL pin status. The status is 1 when the QSPIn_SSL is asserted, and the status is 0 when the QSPIn_SSL is negated.

(2) TEND Bit

This bit indicates whether transfer of data is in progress or the transfer of data has ended.

During t1 time period, data transfer, t2 time period, t3 time period, and waiting for read access by burst read and QSPIn_SSL automatic negation, the TEND bit is read as 0 to indicate that the transfer of data is in progress. Otherwise, the TEND bit is read as 1 to indicate that transfer of data has ended.

(3) Register Re-writing Timing

The status of the TEND bit determines the rewritable registers.

The registers which can be written to, except the SSLN bit in DRCR, should be modified when TEND = 1. Read SMRDR0 and SMRDR1 when TEND = 1. CMNSR can always be read.

20.5.13 Write Buffer Operation

This module uses the read cache space also as the write buffer space during write operation.

The write buffer improves the performance of write access.

Table 20.13 Write Buffer Space

| Address | Access Size |
|----------------------------|---------------------------|
| H'1F80_8000 to H'1F80_80FF | 4, 8, 16, 32, or 64 bytes |

Note: Be sure to sequentially access this space beginning from its start address with the transfer size set to eight bytes.
If access is non-sequential or random, correct operation is not guaranteed.
When the cache area is used as the write buffer, clearing of this cache area by writing 1 to the RCF bit is required.

Figure 20.26 shows the procedure for using the write buffer. For the initial settings in Manual mode, see Figure 20.16.

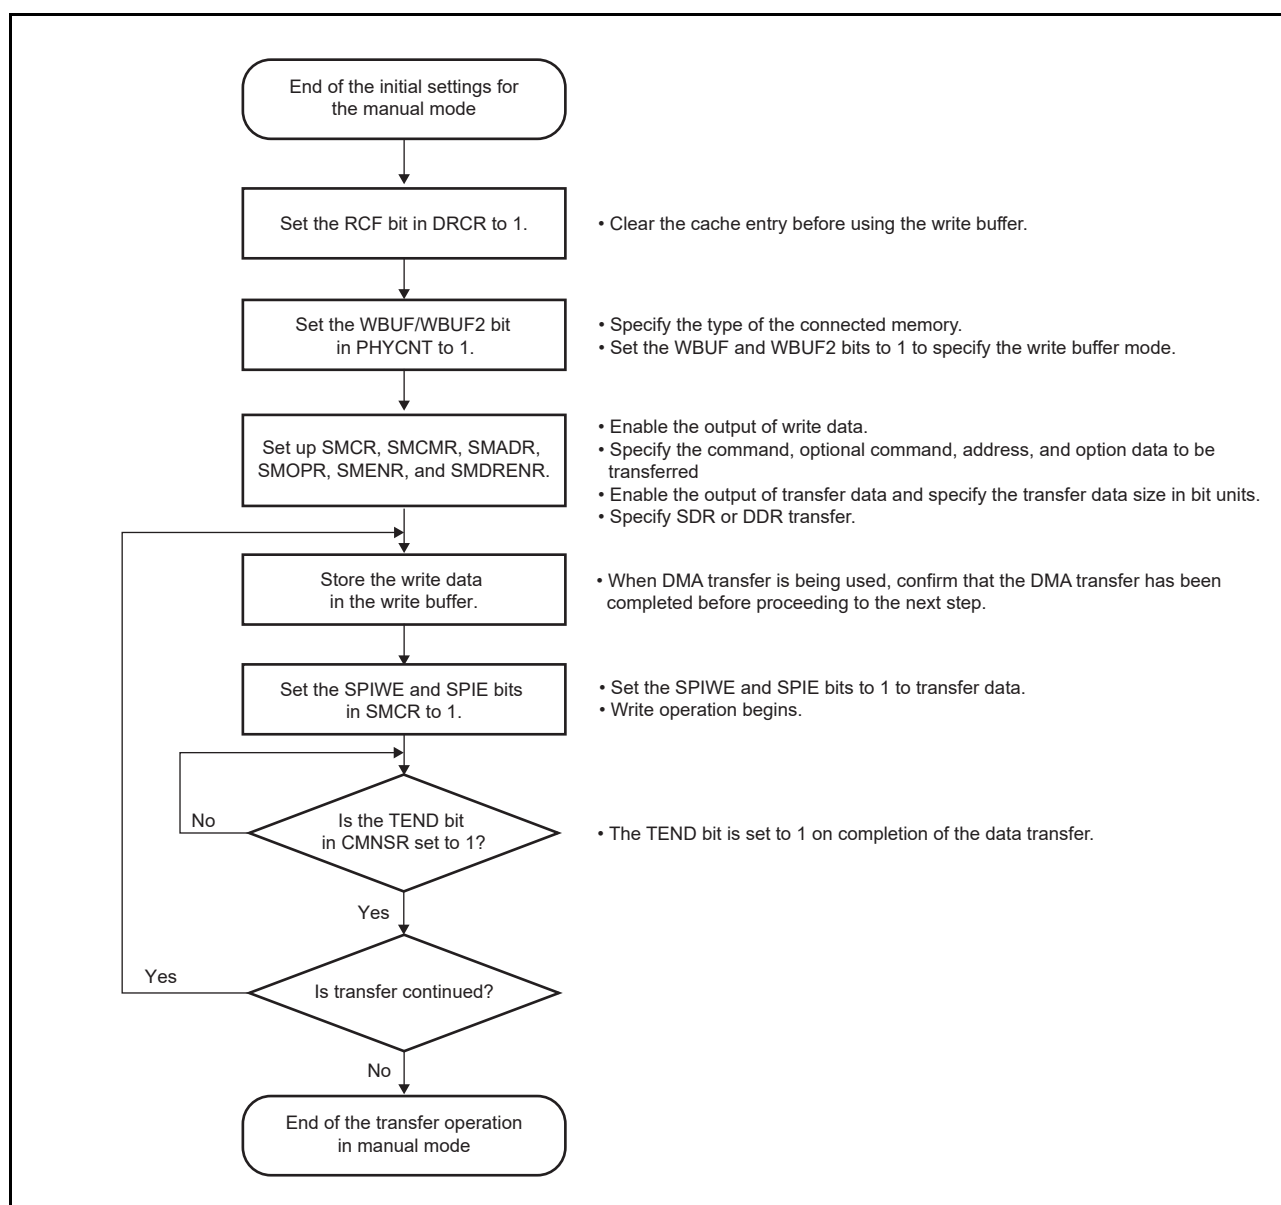

Figure 20.26 Procedure for Using the Write Buffer

20.5.14 Data Alignment in Octal-SPI Flash Memory Protocol Mode

When this LSI chip is connected in Octal-SPI flash memory protocol mode, two data alignment types are available in this module.

Figure 20.27 shows the sequential alignment type and Figure 20.28 shows the alternative alignment type.

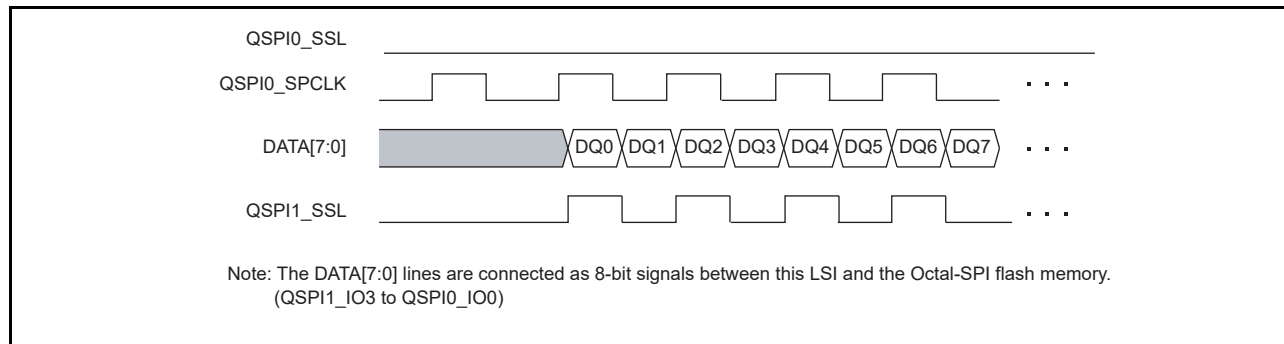

Figure 20.27 Sequential Alignment in Octal-SPI Flash Memory Protocol Mode (PHYCNT.OCTA = 10)

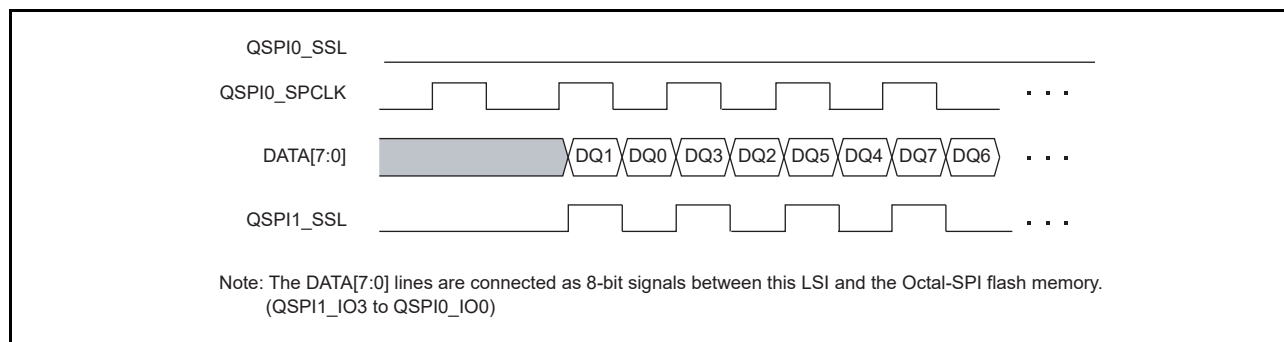

Figure 20.28 Alternative Alignment in Octal-SPI Flash Memory Protocol Mode (PHYCNT.OCTA = 01)

20.5.15 Supported Protocol for Serial Flash Memory

The protocol for serial flash memory that this LSI supports is indicated in Table 20.14.

Table 20.14 Supported Protocol for Serial Flash Memory

| Bit Width (Command-Address-Data) | Command | Address | Data |
|-------------------------------------|---------|---------|------|
| 1-0-0 | SDR | NA | NA |
| 1-0-1 | SDR | NA | SDR |
| 1-1-0 | SDR | SDR | NA |
| 1-1-1 | SDR | SDR | SDR |
| | SDR | DDR | DDR |
| 1-1-4 | SDR | SDR | SDR |
| 1-4-4 | SDR | SDR | SDR |
| | SDR | DDR | DDR |

20.5.16 Supported Protocol for Octal-SPI Flash Memory

The protocol for Octal-SPI flash memory that this LSI supports is indicated in Table 20.15.

Table 20.15 Supported Protocol for Octal-SPI Flash Memory

| Bit Width (Command-Address-Data) | Command | Address | Data |
|-------------------------------------|---------|---------|------|
| 1-0-0 | SDR | NA | NA |
| 1-0-1 | SDR | NA | SDR |
| 1-1-0 | SDR | SDR | NA |
| 1-1-1 | SDR | SDR | SDR |
| 8-0-0 | SDR | NA | NA |
| | DDR | NA | NA |
| 8-0-8 | DDR | NA | DDR |
| 8-8-0 | DDR | DDR | NA |
| 8-8-8 | DDR | DDR | DDR |

20.5.17 Timing Adjustment

When data is transferred with serial flash memory connected, adjustment of the timing between the clock operation and the acquisition of input data is required. When a connection is made in Octal-SPI flash memory protocol mode with the data strobe to be used or HyperFlash memory is connected, the timing of the acquisition of input data is automatically adjusted.

Figure 20.29 (1) shows the flow for timing adjustment when a serial flash memory (SDR mode except in the case of Octal-SPI flash memory) is connected.

Execute this flow before changing the setting of SCLKSEL.SPICR[1:0] from its initial value when the serial flash memory is connected (SDR mode). Execution of this flow at regular intervals is not required.

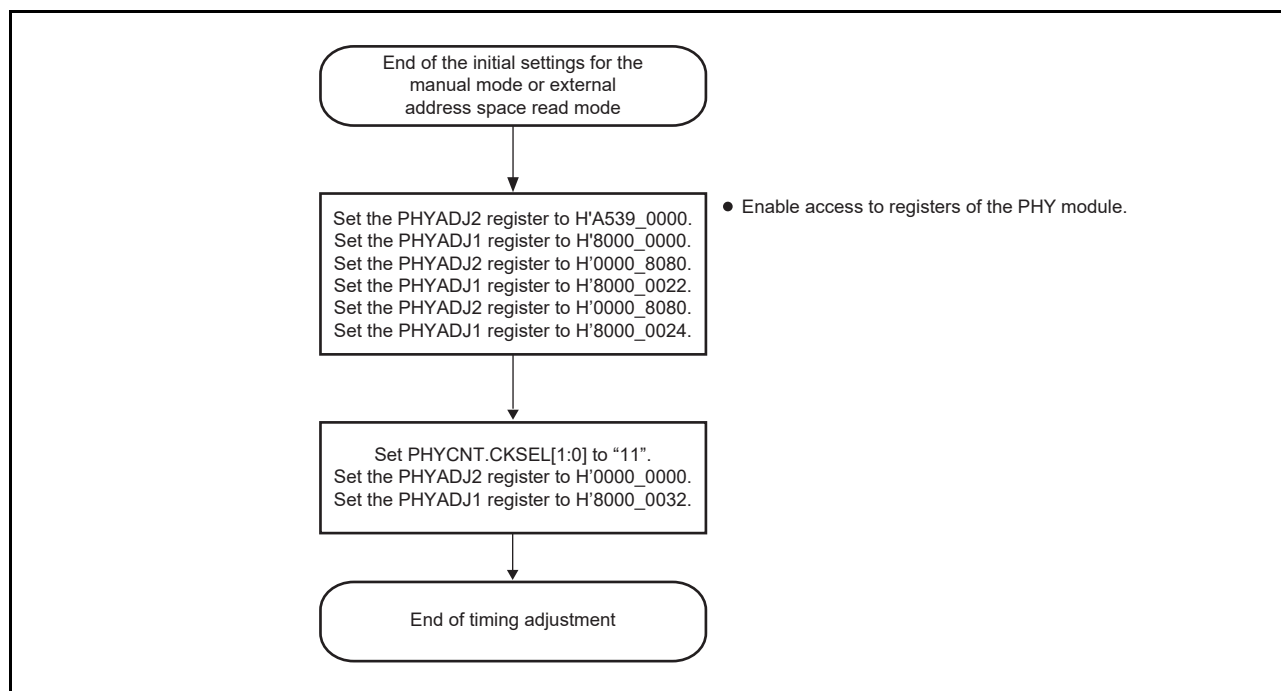

Figure 20.29 (1) Flow of Timing Adjustment when the Serial Flash Memory is Connected (SDR Mode Except in the Case of Octal-SPI Flash Memory)

Figure 20.29 (2) shows the timing adjustment flow for serial flash (DDR mode) connection.

Since the set value acquired in this timing adjustment flow is affected by voltage and temperature variation, this flow should be performed periodically.

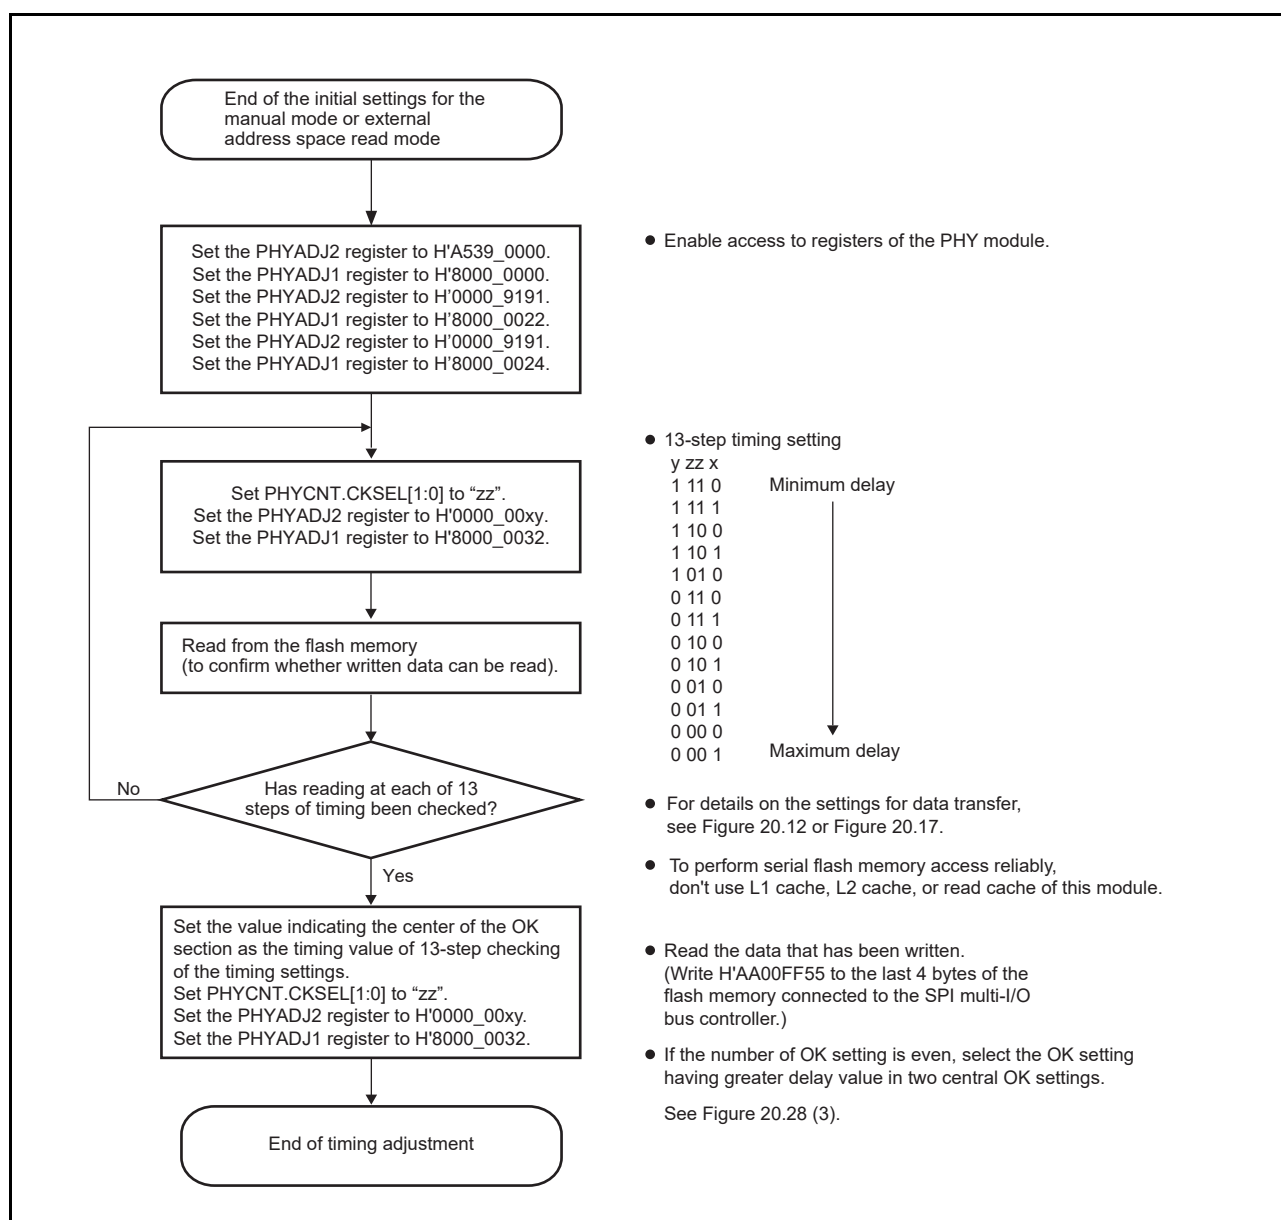

Figure 20.29 (2) Flow of Timing Adjustment when the Serial Flash Memory is Connected (DDR Mode)

Figure 20.29 (3) shows an example of timing setting for serial flash (DDR mode) connection.

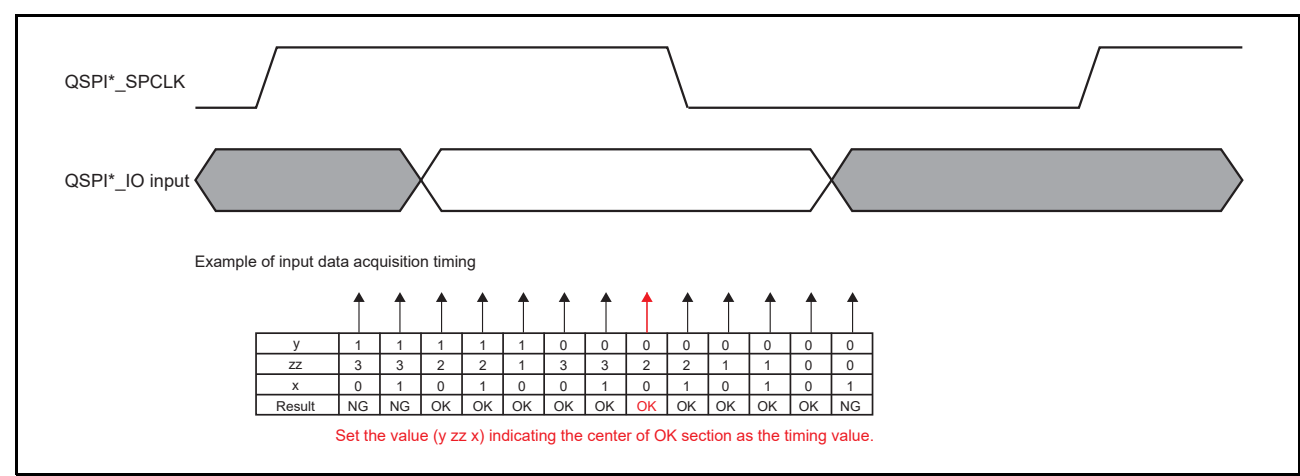

Figure 20.29 (3) Example of Timing Adjustment when the Serial Flash Memory is Connected (DDR Mode)

20.5.18 Data Alignment

Data alignments in external address space read mode and Manual mode are shown in Figure 20.30 and Figure 20.31, respectively. When two serial flash memory devices are connected, the addresses of one device connected to pins QSPI0_IO0 to QSPI0_IO3 are treated as $2n$ and those of the other device connected to pins QSPI1_IO0 to QSPI1_IO3 are treated as $2n + 1$. Be sure that access is in at least word units. Access in byte units is not supported.

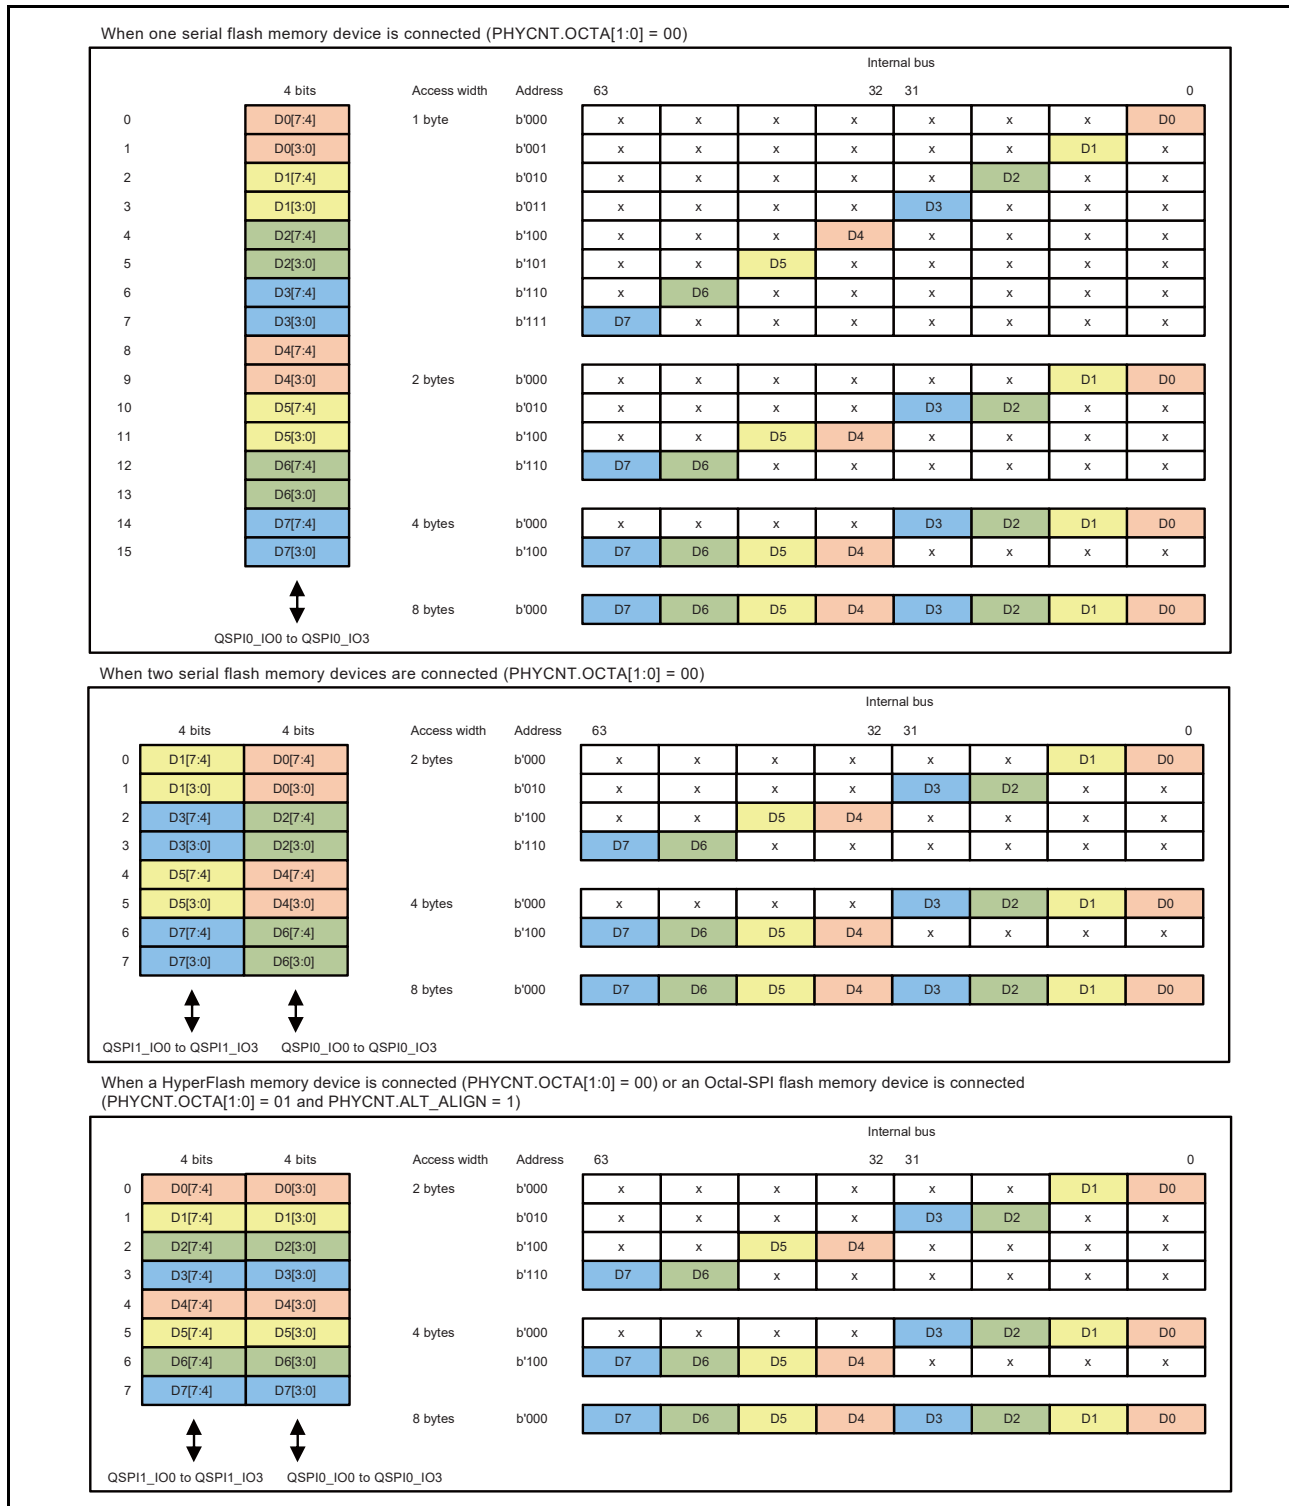

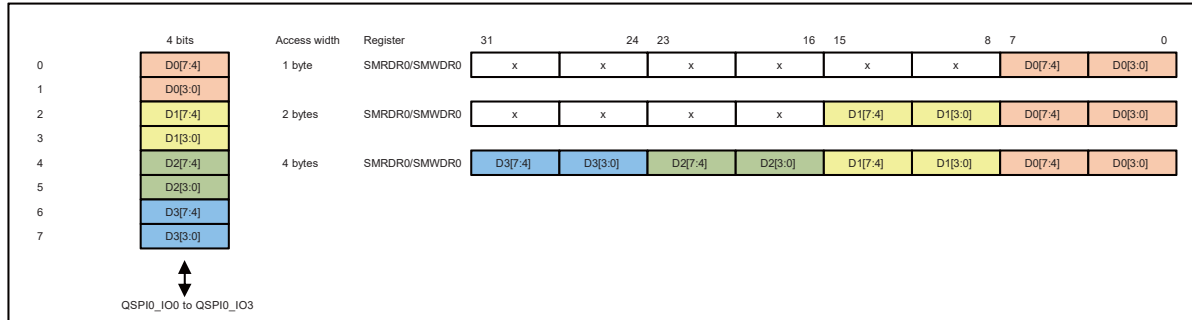

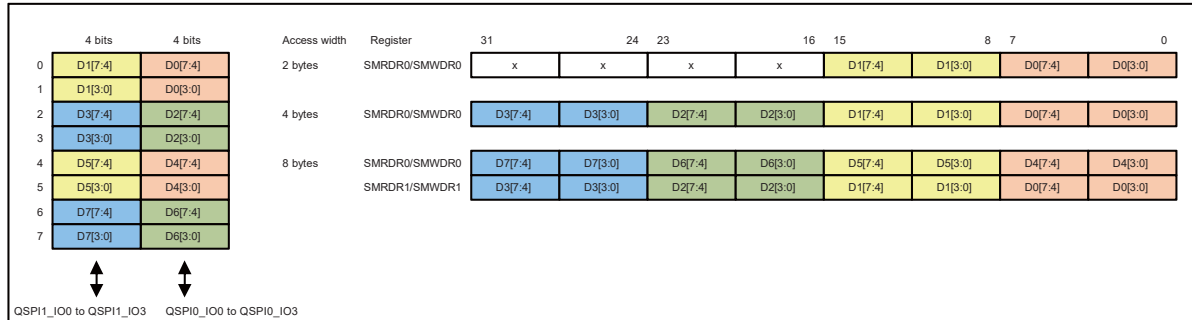

Figure 20.30 Data Alignment in External Address Space Read Mode

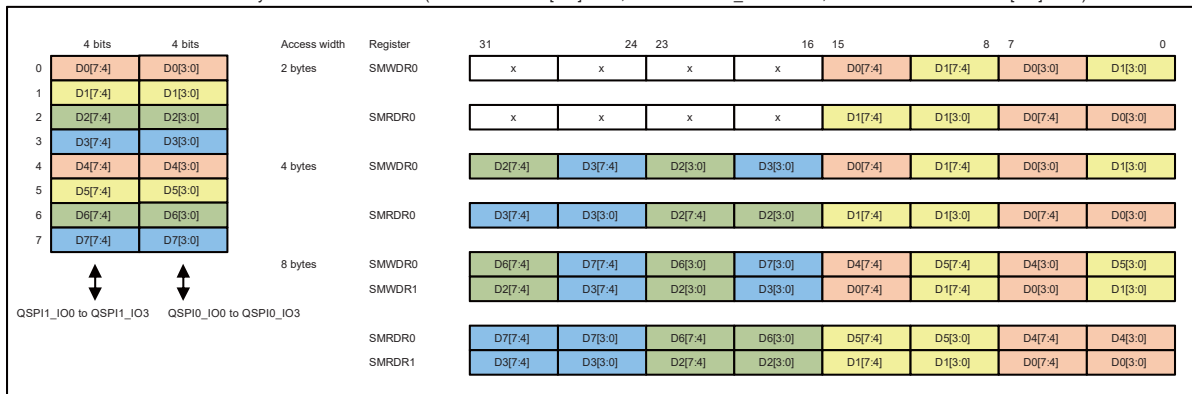

When one serial flash memory device is connected (PHYCNT.OCTA[1:0] = 00)

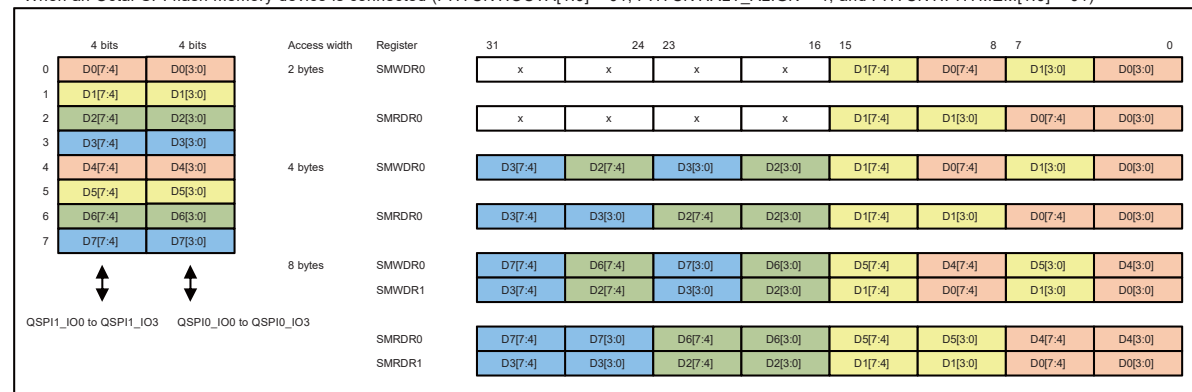

When two serial flash memory devices are connected (PHYCNT.OCTA[1:0] = 00)

When an Octal-SPI flash memory device is connected (PHYCNT.OCTA[1:0] = 01, PHYCNT.ALT_ALIGN = 0, and PHYCNT.PHYMEM[1:0] = 00)

When an Octal-SPI flash memory device is connected (PHYCNT.OCTA[1:0] = 01, PHYCNT.ALT_ALIGN = 1, and PHYCNT.PHYMEM[1:0] = 01)

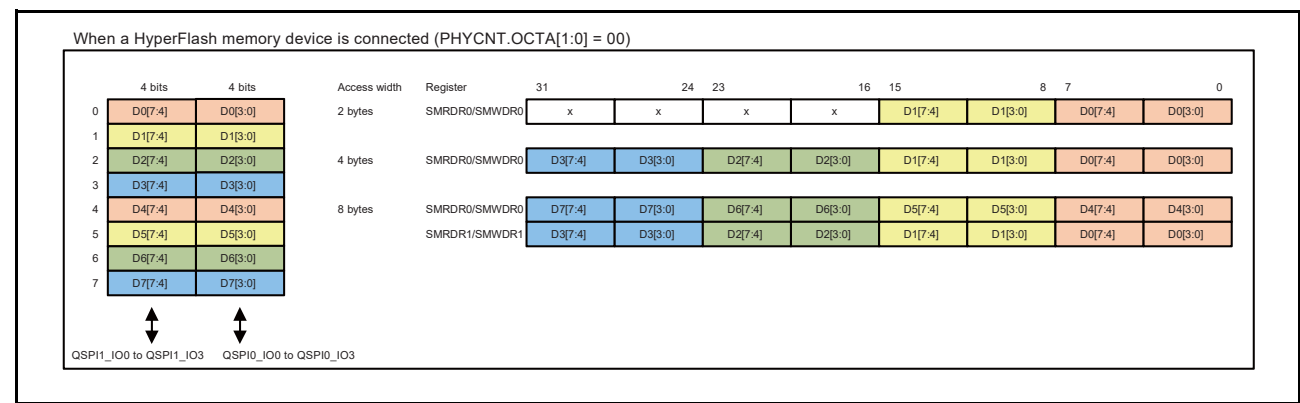

Figure 20.31 Data Alignment in Manual Mode

20.6 Usage Notes

20.6.1 Transfer to read data while the signal on the QSPIn_SSL pin is de-asserted

Set the SMENR.SPIDE[3:0] bits to 1100 or 1111 when transfer only for reading data is to proceed.

Transfer will not proceed normally if the setting of the SMENR.SPIDE[3:0] bits is 1000.

20.6.2 Notes on Starting Transfer from the QSPIn_SSL Retained State in Manual Mode

Be sure to set the SPIWE bit in the SMCR register to 1 when the transfer of a command, optional command, address, or option data is started while the QSPIn_SSL pin is being asserted in Manual mode.

In addition, while the QSPIn_SSL signal is being asserted in Manual mode, the setting to start data transfer for reading is prohibited.

20.6.3 Handling of RPC_RESET#

The state of the RPC_RESET# pin can be changed in the following two ways.

1. Use the RSTEN and RSTVAL bits in the PHYINT register.

The state of the RPC_RESET# pin depends on the value of the RETVAL bits in the PHYINT register.

2. Activate the reset to this module.

While a power-on reset or a software reset is applied to this LSI, the signal on the RPC_RESET# pin goes low.

When the reset is deactivated, the signal on the RPC_RESET# pin goes high.

20.6.4 Software Reset after Release from the Module Stop State

Continue applying a software reset to this module even after the module is released from the module stop state. Note that the signal on the RPC_RESET# pin is low while a software reset is active. Be sure to satisfy the necessary reset period and accessible period for the connected device after a reset.

20.6.5 Writing Data in Octal-SPI Flash Memory Protocol Mode

When writing data in Octal-SPI flash memory protocol mode, the data to be written must be correctly aligned.

For details, refer to section 20.4.15, Manual Mode Write Data Register 0 (SMWDR0), and section 20.4.16, Manual Mode Write Data Register 1 (SMWDR1).

21. HyperBus™ Controller

The HyperBus™ controller enables the connection of HyperFlash™ and HyperRAM™ memory to this LSI chip.

Note: HyperBus™, HyperFlash™ and HyperRAM™ are trademarks of Cypress Semiconductor Corporation.

21.1 Features

- The controller supports a HyperBus interface.
- One each of a HyperFlash device and a HyperRAM device compliant with the HyperBus interface specifications are connectable.
- A chip select signal is assigned to each memory device (HM_CS0#: HyperFlash; HM_CS1#: HyperRAM).
Note: Only one of the memory devices can operate (be read or written to) at a time.

- HM_CK and HM_CK#: 132 MHz
- PVcc_HO: 1.8 V

21.2 Block Diagram

Figure 21.1 shows a block diagram of this module.

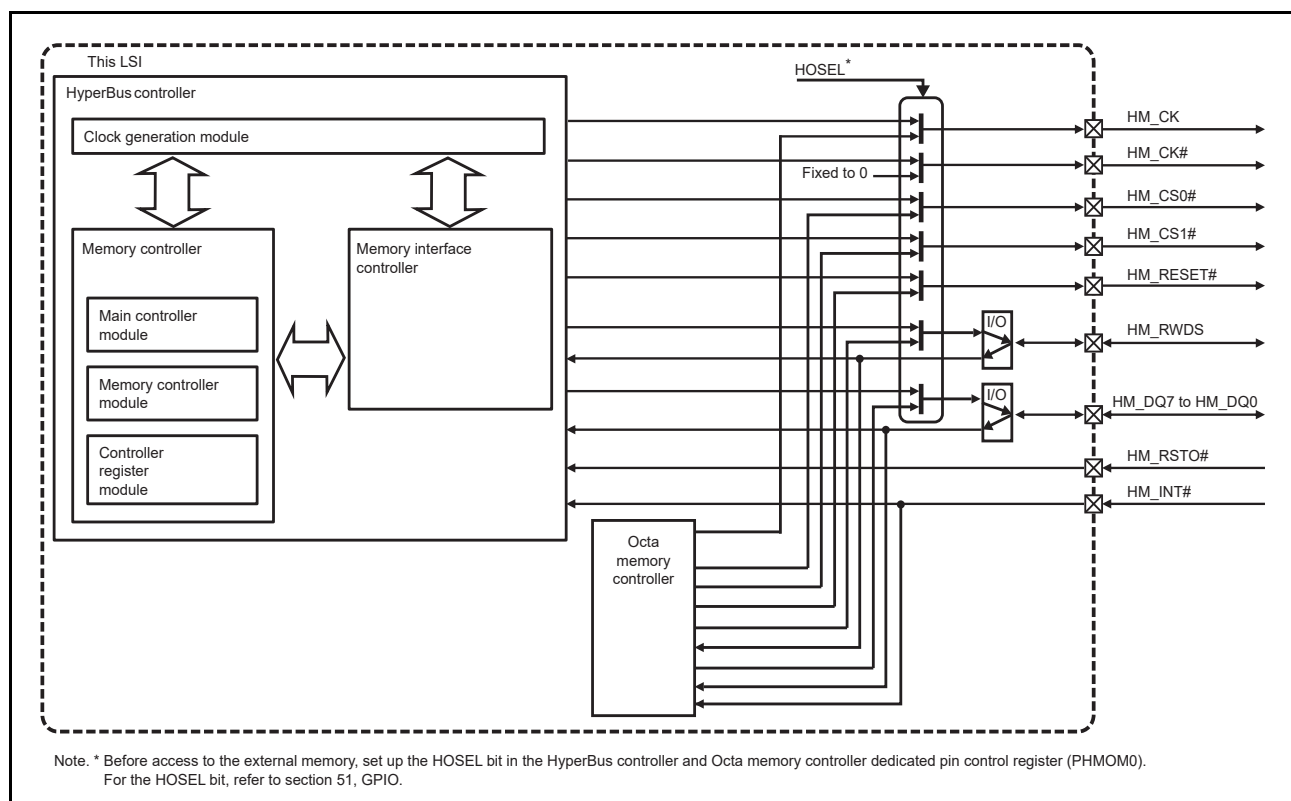

Figure 21.1 Block Diagram

21.3 System Configuration of the HyperBus

Figure 21.2 shows an example of connections between the HyperBus in this LSI and HyperFlash and HyperRAM devices.

CS0# and CS1# should respectively be connected to the HyperFlash and HyperRAM devices.

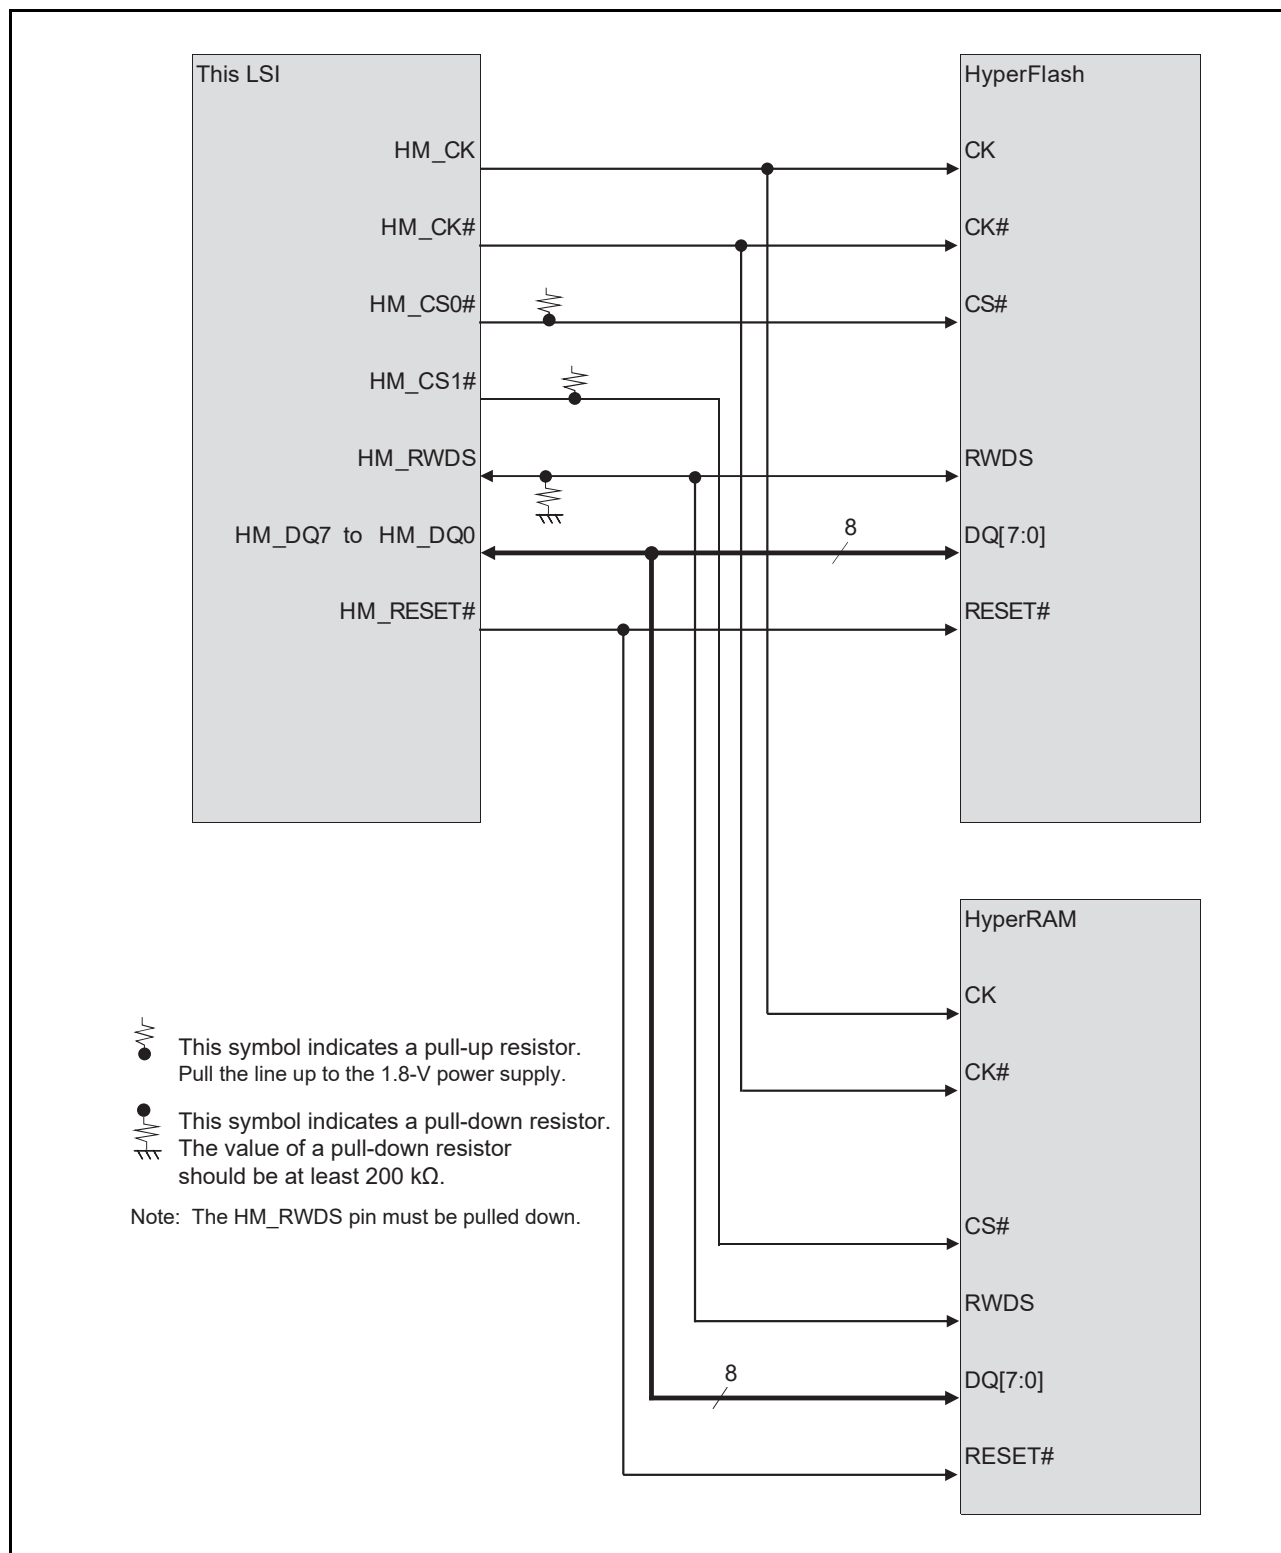

Figure 21.2 Example of Connections between this LSI and Hyper and HyperRAM Devices

21.4 Input/Output Pins

Table 21.1 lists the pins of this module.

Table 21.1 List of Input/Output Pins

| Terminal | I/O | Name | Function |
|------------------|--------------|------------------------|---|
| HM_CK | Output | Clock | Differential clock output |
| HM_CK# | Output | Clock | Differential clock output |
| HM_CS0# | Output | Chip Select 0 | Chip-select signal for a HyperFlash device |
| HM_CS1# | Output | Chip Select 1 | Chip-select signal for a HyperRAM device |
| HM_RWDS | Input/output | Read Write Data strobe | Read data strobe/write data mask |
| HM_DQ7 to HM_DQ0 | Input/output | Data | Data in/out |
| HM_RESET# | output | Reset Output | Reset signal for both HyperFlash and HyperRAM devices |
| HM_RSTO# | Input | Reset Input | Reset signal from a HyperFlash device |
| HM_INT# | Input | Interrupt Input | Interrupt signal from a HyperFlash device |

Note: HM_RSTO# and HM_INT# are input pins that are multiplexed with alternative pin functions that are driven by the 3.3-V power supply. The other pins are solely used for functions that are driven by the 1.8-V power supply.

21.5 Description of Registers

Table 21.2 lists the registers of this module.

Access to these registers is only possible in 32-bit units.

Do not attempt to access addresses other than those listed below.

Table 21.2 List of the HyperBus Controller Registers

| Name | Symbol | R/W | Initial Value | Address | Access Size |
|-----------------------------------|--------|-----|---------------|------------|-------------|
| Controller status register | CSR | R | 0x00000000 | 0x1F400000 | 32 |
| Interrupt enable register | IEN | R/W | 0x00000000 | 0x1F400004 | 32 |
| Interrupt status register | ISR | R | 0x00000000 | 0x1F400008 | 32 |
| CS0 memory configuration register | MCR0 | R/W | 0x00000003 | 0x1F400020 | 32 |
| CS1 memory configuration register | MCR1 | R/W | 0x00000003 | 0x1F400024 | 32 |
| CS0 memory timing register | MTR0 | R/W | 0x00000001 | 0x1F400030 | 32 |
| CS1 memory timing register | MTR1 | R/W | 0x00000001 | 0x1F400034 | 32 |

21.5.1 Controller Status Register (CSR)

CSR indicates the internal state of the HyperBus controller.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|--------------|--------------|-------------|-------------|----|----|----|----|----|----|----|------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | WRSTO ERR | WTRS ERR | WDEC ERR | — | — | — | — | — | — | — | WACT |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | RDS STALL | RRSTO ERR | RTRS ERR | RDEC ERR | — | — | — | — | — | — | — | RACT |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|----------|---------------|-----|---|
| 31 to 27 | — | All 0 | R | Reserved These bits are always read as 0. |
| 26 | WRSTOERR | 0 | R | Write RSTO Error This bit indicates if the memory was in the reset state during attempted writing. The bit is set to 1 if the HyperBus memory was in the reset state during attempted writing. 0: No error 1: The device was in the reset state and the AXI slave error signal was output. |
| 25 | WTRSERR | 0 | R | Write Transaction Error This bit indicates whether the attempted writing conformed to AXI protocol. This bit is set to 1 if the attempted writing did not conform to AXI protocol. 0: No error 1: The attempted writing did not conform to the AXI protocol and the AXI slave error signal was output. |
| 24 | WDECERR | 0 | R | Write Decode Error This bit indicates whether the destination address for writing was acceptable or not. This bit is set to 1 if there is a problem with a destination address. 0: No error 1: The destination address was not acceptable and the AXI slave error signal was output. |
| 23 to 17 | — | All 0 | R | Reserved These bits are always read as 0. |
| 16 | WACT | 0 | R | Write State This bit indicates the state of the write transaction. This bit is set to 1 when a write command is received and set to 0 at the end of the write transaction. 0: Write transaction is idle. 1: Write transaction is in progress. |
| 15 to 12 | — | All 0 | R | Reserved These bits are always read as 0. |
| 11 | RDSSTALL | 0 | R | RDS Timeout This bit indicates whether the read transaction timed out. This bit is set to 1 when the RWDS signal of the HyperBus memory remains low for the specified time in the read transaction. 0: No error 1: The RWDS signal of the HyperBus memory remains low for the specified time and the AXI slave error signal was output. |

| Bit | Bit Name | Initial Value | R/W | Description |
|--------|----------|---------------|-----|--|
| 10 | RRSTOERR | 0 | R | <p>Read RSTO Error</p> <p>This bit indicates if the memory was in the reset state during attempted reading.</p> <p>The bit is set to 1 if the HyperBus memory was in the reset state during attempted reading.</p> <p>0: No error</p> <p>1: The device was in the reset state and the AXI slave error signal was output.</p> |
| 9 | RTRSERR | 0 | R | <p>Read Transaction Error</p> <p>This bit indicates whether the attempted reading conformed to the AXI protocol.</p> <p>This bit is set to 1 when the attempted reading did not conform to the AXI protocol.</p> <p>0: No error</p> <p>1: The attempted reading did not conform to the AXI protocol and the AXI slave error signal was output.</p> |
| 8 | RDECERR | 0 | R | <p>Read Decode Error</p> <p>This bit indicates whether the destination address for reading was acceptable or not.</p> <p>This bit is set to 1 if there is a problem with a destination address.</p> <p>0: No error</p> <p>1: The destination address was not acceptable and the AXI slave error signal was output.</p> |
| 7 to 1 | — | All 0 | R | <p>Reserved</p> <p>These bits are always read as 0.</p> |
| 0 | RACT | 0 | R | <p>Read State</p> <p>This bit indicates the state of the read transaction.</p> <p>This bit is set to 1 when a read command is received and set to 0 at the end of the read transaction.</p> <p>0: Read transaction idle state</p> <p>1: Read transaction is in progress.</p> |

21.5.2 Interrupt enable register (IEN)

IEN sets the interrupt signal.

| | | | | | | | | | | | | | | | | |
|----------------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | INTP | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RPC INTE |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|----------|---------------|-----|---|
| 31 | INTP | 0 | R/W | Interrupt polarity control 0: The IENOn signal is active low. 1: The IENOn signal is active high. |
| 30 to 1 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 0 | RPCINTE | 0 | R/W | Interrupt enable 0: Disable interrupt 1: Enable interrupt by HM_INT# signal of HyperBus memory |

21.5.3 Interrupt status register (ISR)

ISR indicates the state of the interrupt signal.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RPC INTS |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|----------|---------------|-----|---|
| 31 to 1 | — | All 0 | R | Reserved These bits are always read as 0. |
| 0 | RPCINTS | 0 | R | HyperBus memory interrupt state This bit indicates the state of the interrupt signal input to this controller from the HyperBus memory. 0: No interrupt 1: Interrupt |

21.5.4 CS0 Memory configuration register (MCR0)

MCR0 specifies the operations of the HyperBus controller during access to the HyperFlash device.

| | | | | | | | | | | | | | | | | | |
|----------------|-------|----|----|----|----|-------------|-----|-----|-----|-----|-----|-----|-----|-----|----|----|---|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | |
| | MAXEN | — | — | — | — | MAXLEN[8:0] | | | | | | | | | | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | |
| R/W: | R/W | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-------------|---------------|-----|--|
| 31 | MAXEN | 0 | R/W | Maximum time setting enable This bit sets whether the time at low level of the HM_CS0# signal is to be controlled by MAXLEN[8:0]. 0: Time at low level of HM_CS0# is not configurable. 1: Time at low level of HM_CS0# is configured by MAXLEN[8:0]. |
| 30 to 27 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 26 to 18 | MAXLEN[8:0] | All 0 | R/W | Maximum time setting Sets the maximum read/write transaction time (the time at low level of the HM_CS0# signal). 000000000: 1 clock cycle (sufficient for 2 bytes) 000000001: 2 clock cycles (sufficient for 4 bytes) 000000010: 3 clock cycles (sufficient for 6 bytes) ... 111111111: 512 clock cycles (sufficient for 1024 bytes) When MAXEN is 0, this setting has no effect. Clock cycles above refers to cycles of the HM_CK and HM_CK# signals. |
| 17 to 2 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 1, 0 | — | 11 | R | Reserved These bits are always read as 1. The write value should always be 1 |

21.5.5 CS1 Memory configuration register (MCR1)

MCR1 specifies the operations of the HyperBus controller during access to the HyperRAM device.

| | | | | | | | | | | | | | | | | | |
|----------------|-------|----|----|----|----|-------------|-----|-----|-----|-----|-----|----------|-----|-----|----|----|---|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | |
| | MAXEN | — | — | — | — | MAXLEN[8:0] | | | | | | | | | | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | |
| R/W: | R/W | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| | — | — | — | — | — | — | — | — | — | — | CRT | DEV TYPE | — | — | — | — | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | |
| R/W: | R | R | R | R | R | R | R | R | R | R | R/W | R/W | R | R | R | R | |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-------------|---------------|-----|--|
| 31 | MAXEN | 0 | R/W | Maximum time setting enable This bit sets whether the time at low level of the HM_CS1# signal is to be controlled by MAXLEN[8:0]. 0: Time at low level of HM_CS1# is not configurable. 1: Time at low level of HM_CS1# is configured by MAXLEN[8:0]. |
| 30 to 27 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 26 to 18 | MAXLEN[8:0] | All 0 | R/W | Maximum time setting Sets the maximum read/write transaction time (the time at low level of the HM_CS1# signal). 000000000: 1 clock cycle (sufficient for 2 bytes) 000000001: 2 clock cycles (sufficient for 4 bytes) 000000010: 3 clock cycles (sufficient for 6 bytes) ... 111111111: 512 clock cycles (sufficient for 1024 bytes) When MAXEN is 0, this setting has no effect. Clock cycles above refers to cycles of the HM_CK and HM_CK# signals. |
| 17 to 6 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 5 | CRT | 0 | R/W | Access target This bit sets the access target of read/write operation. 0: Memory space 1: Register space |
| 4 | DEVTYPE | 0 | R/W | Device Type Set the value to 1. |
| 3, 2 | — | 00 | R/W | Reserved These bits are always read as 0. The write value should always be 0. |
| 1, 0 | — | 11 | R | Reserved These bits are always read as 1. The write value should always be 1. |

21.5.6 CS0 Memory Timing Register (MTR0)

MTR0 sets access timings of the HM_CS0# signal.

For each timing parameter specified in this register, refer to section 21.6.4, MTR0 and MTR1 Timing Parameters.

| | | | | | | | | | | | | | | | | |
|----------------|-----------|-----|-----|-----|-----------|-----|-----|-----|-----------|-----|-----|-----|-----------|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | RCSH[3:0] | | | | WCSH[3:0] | | | | RCSS[3:0] | | | | WCSS[3:0] | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | RCSH[3:0] | | | | WCSH[3:0] | | | | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-----------|---------------|-----|---|
| 31 to 28 | RCSH[3:0] | 0000 | R/W | Setting Read Chip Select timing Minimum wait time between negating the HM_CS0# pin and starting the next read access 0000: 1.5 clock cycles ... 1111: 16.5 clock cycles |
| 27 to 24 | WCSH[3:0] | 0000 | R/W | Setting Write Chip Select timing Minimum wait time between negating the HM_CS0# pin and starting the next write access 0000: 1.5 clock cycles ... 1111: 16.5 clock cycles |
| 23 to 20 | RCSS[3:0] | 0000 | R/W | Setting Read Chip Select Setup timing Sets setup time of the HM_CS0# signal for reading, after the HM_CS0# signal is asserted. 0000: 1 clock cycle ... 1111: 16 clock cycles |
| 19 to 16 | WCSS[3:0] | 0000 | R/W | Setting Write Chip Select Setup timing Sets setup time of the HM_CS0# signal for writing, after the HM_CS0# signal is asserted. 0000: 1 clock cycle ... 1111: 16 clock cycles |
| 15 to 12 | RCSH[3:0] | 0000 | R/W | Setting Read Chip Select Hold timing Set time from the end of the reading processing until the HM_CS0# signal is negated. 0000: 1 clock cycle ... 1111: 16 clock cycles |
| 11 to 8 | WCSH[3:0] | 0000 | R/W | Setting Write Chip Select Hold timing Set time from the end of the writing processing until the HM_CS0# signal is negated. 0000: 1 clock cycle ... 1111: 16 clock cycles |
| 7 to 1 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 0 | — | 1 | R | Reserved This bit is always read as 1. The write value should always be 1. |

21.5.7 CS1 Memory Timing Register (MTR1)

MTR1 sets access timings of the HM_CS1# signal.

For each timing parameter specified in this register, refer to section 21.6.4, MTR0 and MTR1 Timing Parameters.

| | | | | | | | | | | | | | | | | |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|------------|---------------|-----|--|
| 31 to 28 | RCSHI[3:0] | 0000 | R/W | Setting Read Chip Select timing Minimum wait time between negating the HM_CS1# pin and starting the next read access 0000: 1.5 clock cycles ... 1111: 16.5 clock cycles |
| 27 to 24 | WCSHI[3:0] | 0000 | R/W | Setting Write Chip Select timing Minimum wait time between negating the HM_CS1# pin and starting the next write access 0000: 1.5 clock cycles ... 1111: 16.5 clock cycles |
| 23 to 20 | RCSS[3:0] | 0000 | R/W | Setting Read Chip Select Setup timing Sets setup time of the HM_CS1# signal for reading, after the HM_CS1# signal is asserted. 0000: 1 clock cycles ... 1111: 16 clock cycles |
| 19 to 16 | WCSS[3:0] | 0000 | R/W | Setting Write Chip Select Setup timing Sets setup time of the HM_CS1# signal for writing, after the HM_CS1# signal is asserted. 0000: 1 clock cycles ... 1111: 16 clock cycles |
| 15 to 12 | RCSH[3:0] | 0000 | R/W | Setting Read Chip Select Hold timing Set time from the end of the reading processing until the HM_CS1# signal is negated. 0000: 1 clock cycles ... 1111: 16 clock cycles |
| 11 to 8 | WCSH[3:0] | 0000 | R/W | Setting Write Chip Select Hold timing Set time from the end of the writing processing until the HM_CS1# signal is negated. 0000: 1 clock cycles ... 1111: 16 clock cycles |
| 7 to 4 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |

| Bit | Bit Name | Initial Value | R/W | Description |
|--------|-----------|---------------|-----|--|
| 3 to 0 | LTCY[3:0] | 0001 | R/W | Setting Latency Cycle These bits specify the read and write latency. These bits should only be used in a HyperRAM device. These bits have no effect when the setting of MCR1.DEVTYPE is 0 (HyperFlash is specified). 0000: 5 clock cycles of latency 0001: 6 clock cycles of latency ... 0010 to 1111: Setting prohibited |

21.6 Operation

21.6.1 Address Map

For read access in the memory-map mode, HyperFlash is allocated to the HyperFlash space (0x30000000 to 0x3FFFFFFF), and HyperRAM is allocated to the HyperRAM space (0x40000000 to 0x4FFFFFFF).

One each of a HyperFlash device and a HyperRAM device can be connected to this LSI chip, with up to 256 Mbytes being accessible in each of the devices.

| | Internal Address | Maximum Accessible Area |
|------------|--------------------------|-------------------------|
| HyperFlash | 0x30000000 to 0x3FFFFFFF | Up to 256 Mbytes |
| HyperRAM | 0x40000000 to 0x4FFFFFFF | Up to 256 Mbytes |

21.6.2 HyperBus Memory Interface

This section describes the HyperBus memory interface.

21.6.2.1 Write Operation

This section describes the write operation of HyperBus controller.

HyperBus controller asserts HM_CS0# (HM_CS1#), HM_CK, HM_CK#, HM_DQ7 to HM_DQ0. Then, it outputs 3 words command/address, and writes 1 or more data. The cycle of writing to the HyperRAM device includes the initial clock latency before writing of the data.

Figure 21.3 shows the write waveform of HyperFlash interface Figure 21.4 shows the write waveform of HyperRAM interface.

Figure 21.3 Write Waveform of HyperFlash Interface

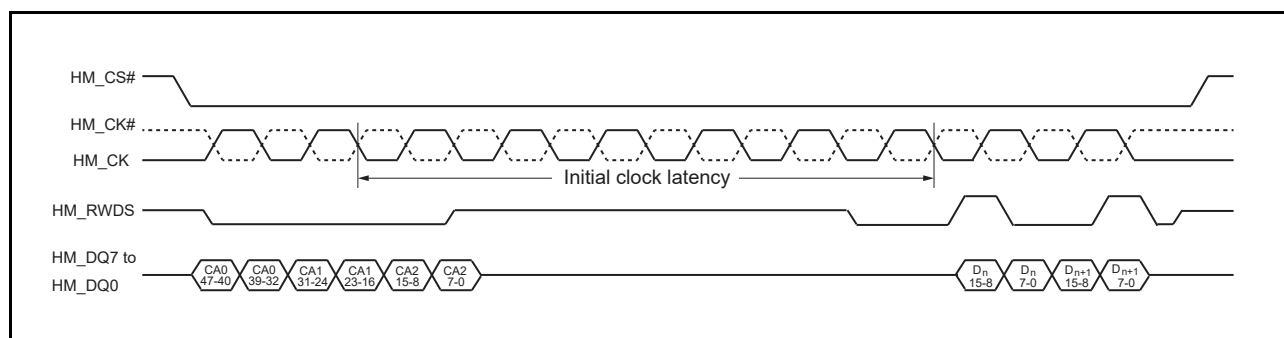

Figure 21.4 Write waveform of HyperRAM interface

21.6.2.2 Read Operation

This section describes the read operation of HyperBus memory interface controller.

HyperBus controller asserts HM_CS0# (HM_CS1#), HM_CK, HM_CK#, and HM_DQ7 to HM_DQ0. Then, it outputs 3 words command/address, and reads 1 or more data by timing of HM_RWDS.

Figure 21.5 shows the read waveform of HyperBus memory interface.

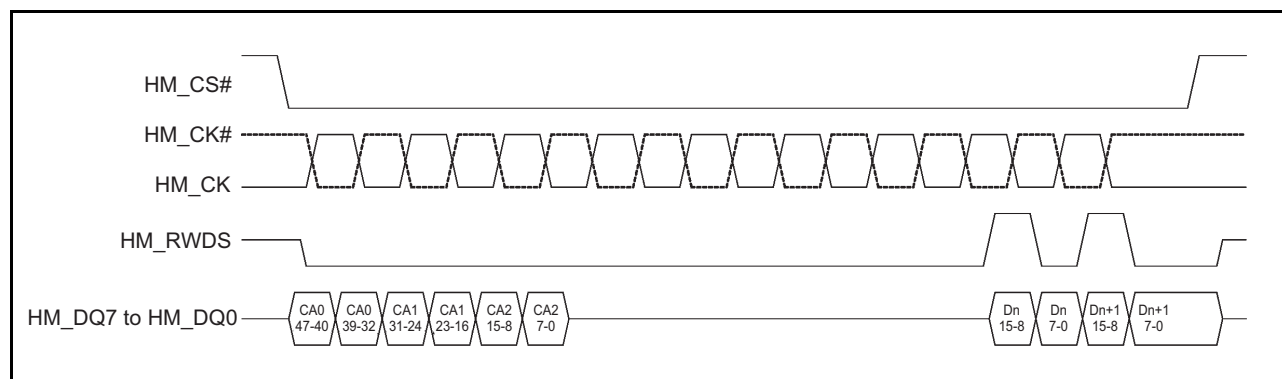

Figure 21.5 Read waveform of HyperBus memory interface

21.6.2.3 One-Byte Write Access

This section describes one-byte write access.

The HyperBus controller outputs three words of command and address data, followed after a cycle for latency by the data to be written in units of two bytes.

When the target device is HyperRAM, the output RWDS signal of the HyperBus interface can be used to mask bytes by driving it to the high level during the operation of writing. This allows the masking of invalid write data.

When the target device is HyperFlash, one-byte write access must not be attempted since HyperFlash only supports two-byte access.

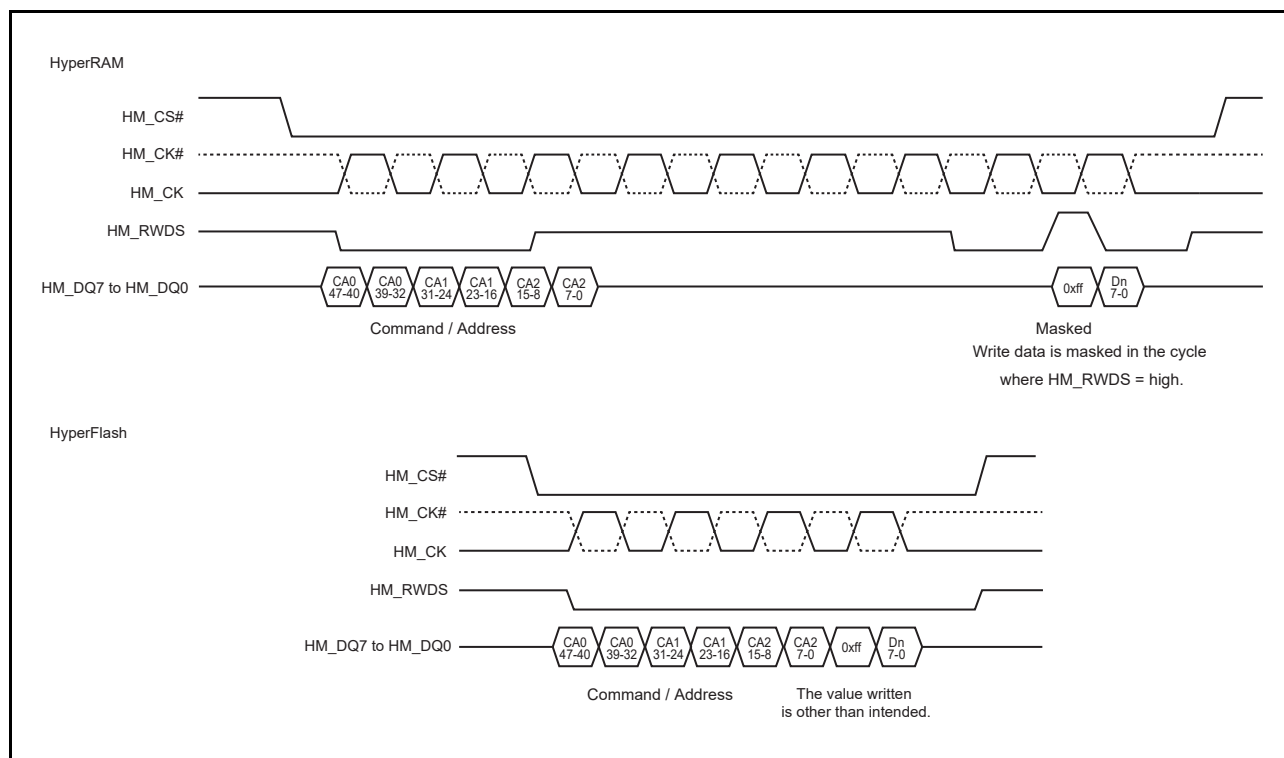

Figure 21.6 Waveforms of One-Byte Writing

21.6.2.4 Command/Address Bit Assignments

HyperBus memory device uses 6 bytes of command/address information to define the transactions characteristics. Table 21.3 shows the assignments of command/address bit in the HyperBus controller.

Table 21.3 Command/Address Bit Assignments

| Bit | Bit Name | Description |
|-----|---------------|---|
| 47 | R/W# | 0: Write, 1: Read |
| 46 | Access target | 0: Memory access, 1: Register access |
| 45 | Burst type | 0: Wrapped burst, 1: Linear burst Note: The output of data must be in accord with the burst type of the AXI bus. The HyperBus controller only supports the transfer of 32-byte and 64-byte bursts. When the secondary cache is used, the burst-access setting of the secondary cache must match the burst-length settings for HyperFlash and HyperRAM so that the wrap boundaries of the burst addresses for the AXI bus match the address boundaries of the wrapped bursts for HyperFlash and HyperRAM. |

| Burst-Length Settings for HyperFlash and HyperRAM | Setting in the Prefetch Control Register for the Secondary Cache | | |
|---|--|--------|--------|
| | Bit 30 | Bit 27 | Bit 23 |
| 32 bytes | 0 | 0 | 0 |
| 64 bytes | 1 | 0 | 1 |
| Other than above: Setting prohibited | — | | |

| | | |
|----------|--------------------|---------------------------------|
| 44 | Reserved | 0 |
| 43 to 16 | High-order address | System word address bits [30:3] |
| 15 | Reserved | 0 |
| 14, 13 | Reserved | 11 |
| 12 to 3 | Reserved | All 0 |
| 2 to 0 | Low-order address | System word address bits [2:0] |

21.6.2.5 Configuration Register Data Alignment in the HyperRAM Space

Figure 21.7 shows the data alignment when the configuration register in the HyperRAM space is accessed.

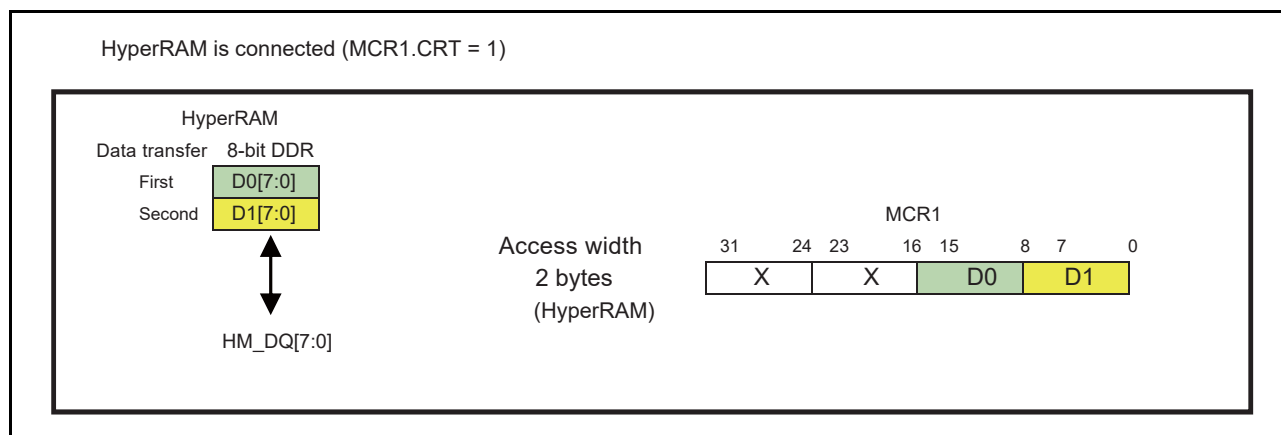

Figure 21.7 Configuration Register Data Alignment in the HyperRAM Space

21.6.3 Operation Flows

This section shows examples of flows of operation of the HyperBus controller.

Before access to the external memory, set up the HOSEL bit in the HyperBus controller and Octa memory controller dedicated pin control register (PHMOM0) and the HYMCR bit field in the SCLK select register (SCLKSEL) in the initial setting steps.

For the HOSEL bit, refer to section 51, GPIO.

For the HYMCR bit field, refer to section 6, Clock Pulse Generator.

21.6.3.1 Write Operation Flow

Figure 21.8 shows the procedure for the writing of N bytes to a HyperFlash device in 2-byte units (Word Program) as an example of the operation flow of writing.

Note: When writing four or more bytes, use a clock frequency that is compliant with the specifications of the HyperBus memory interface.

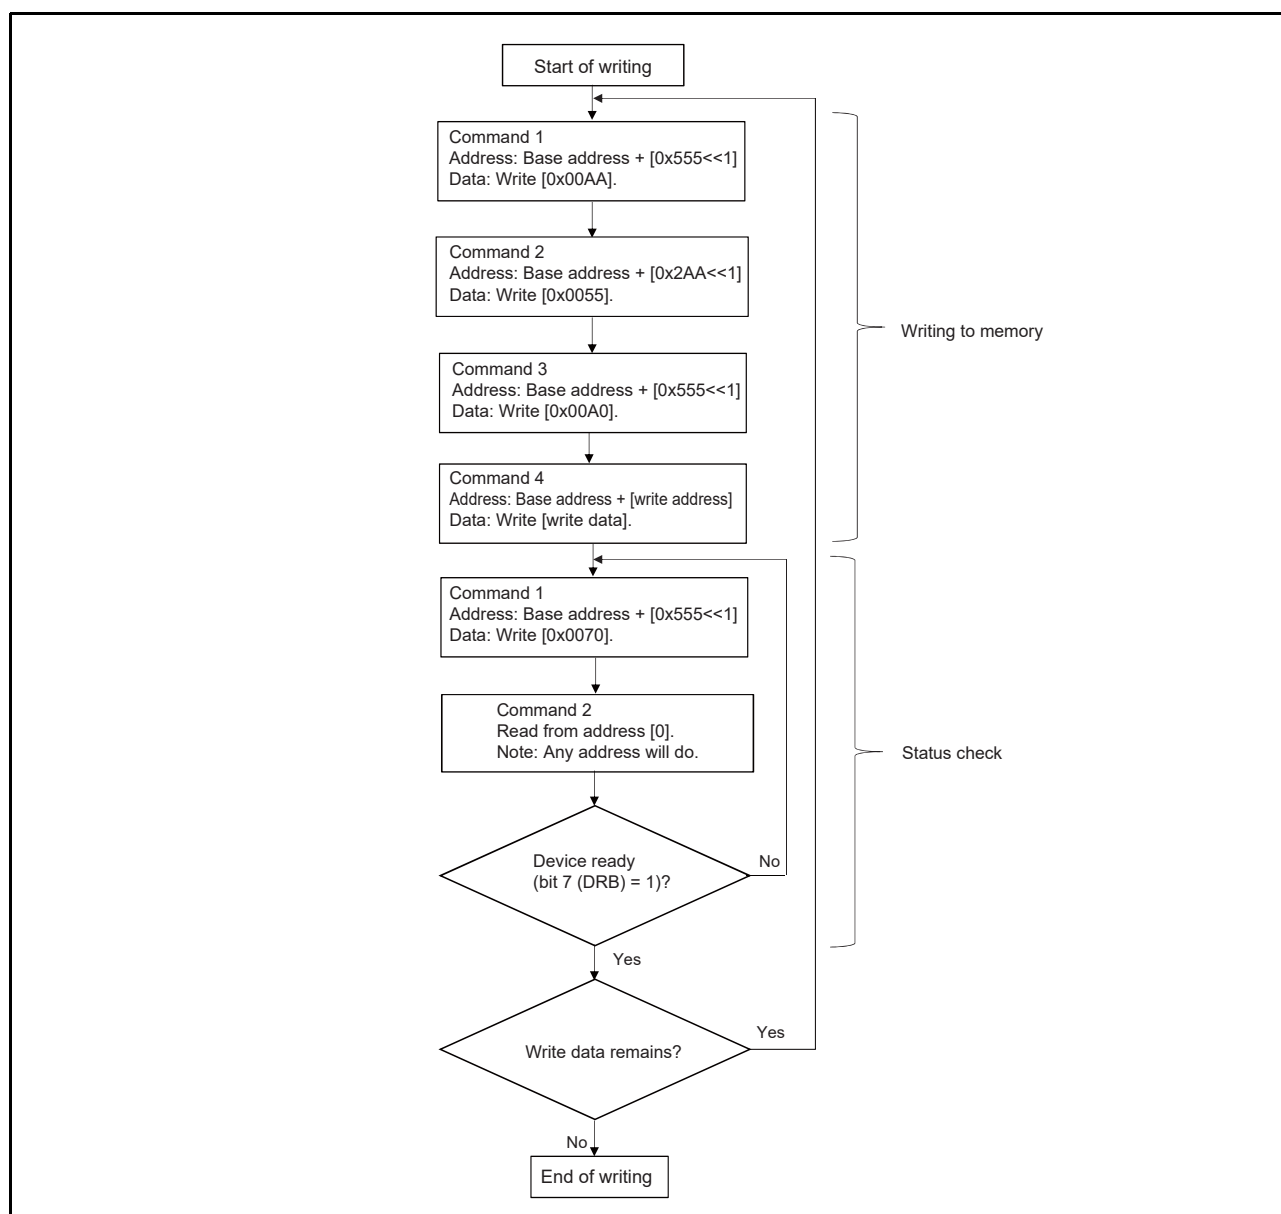

Figure 21.8 Flow of Write Operation for HyperFlash

21.6.3.2 Erase Operation Flow

Figure 21.9 shows an example of the procedure for sector erase.

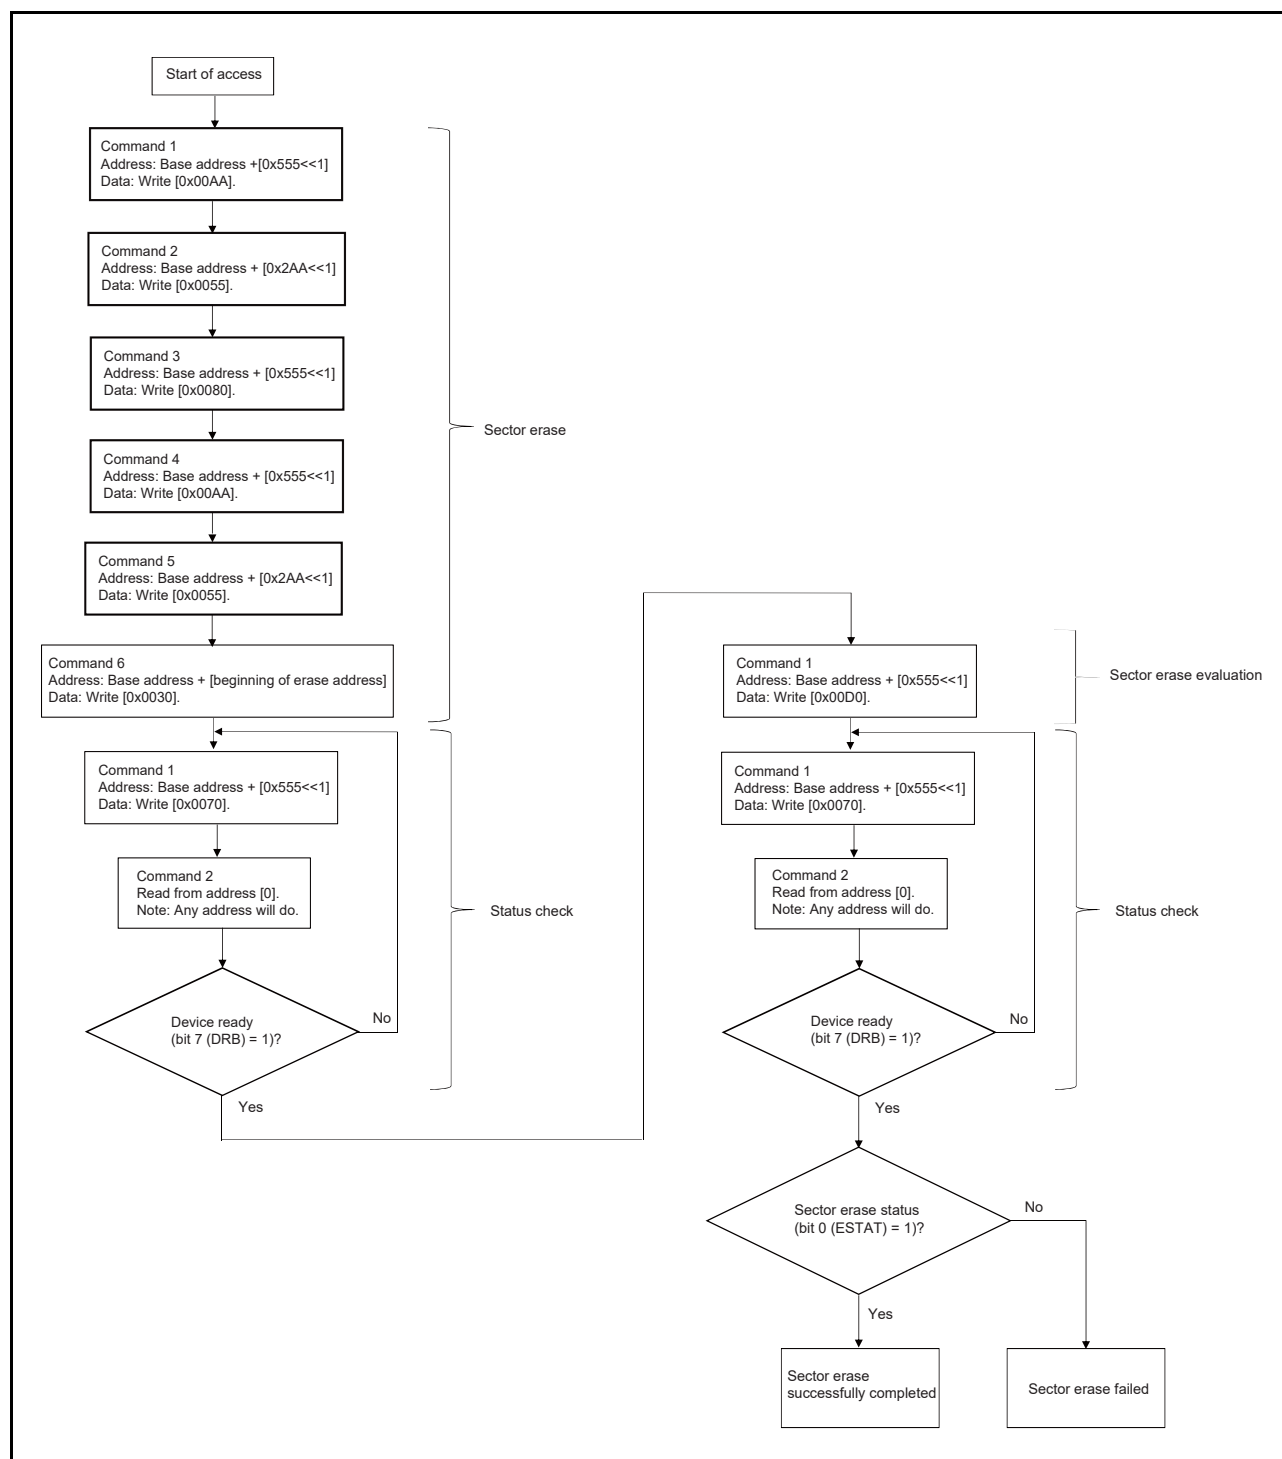

Figure 21.9 Flow of Sector Erase Operation for HyperFlash

21.6.3.3 Flow of Write and Read Operations for the Configuration Register

Figure 21.10 shows an example of writing and reading operations for the volatile configuration registers in a HyperFlash device.

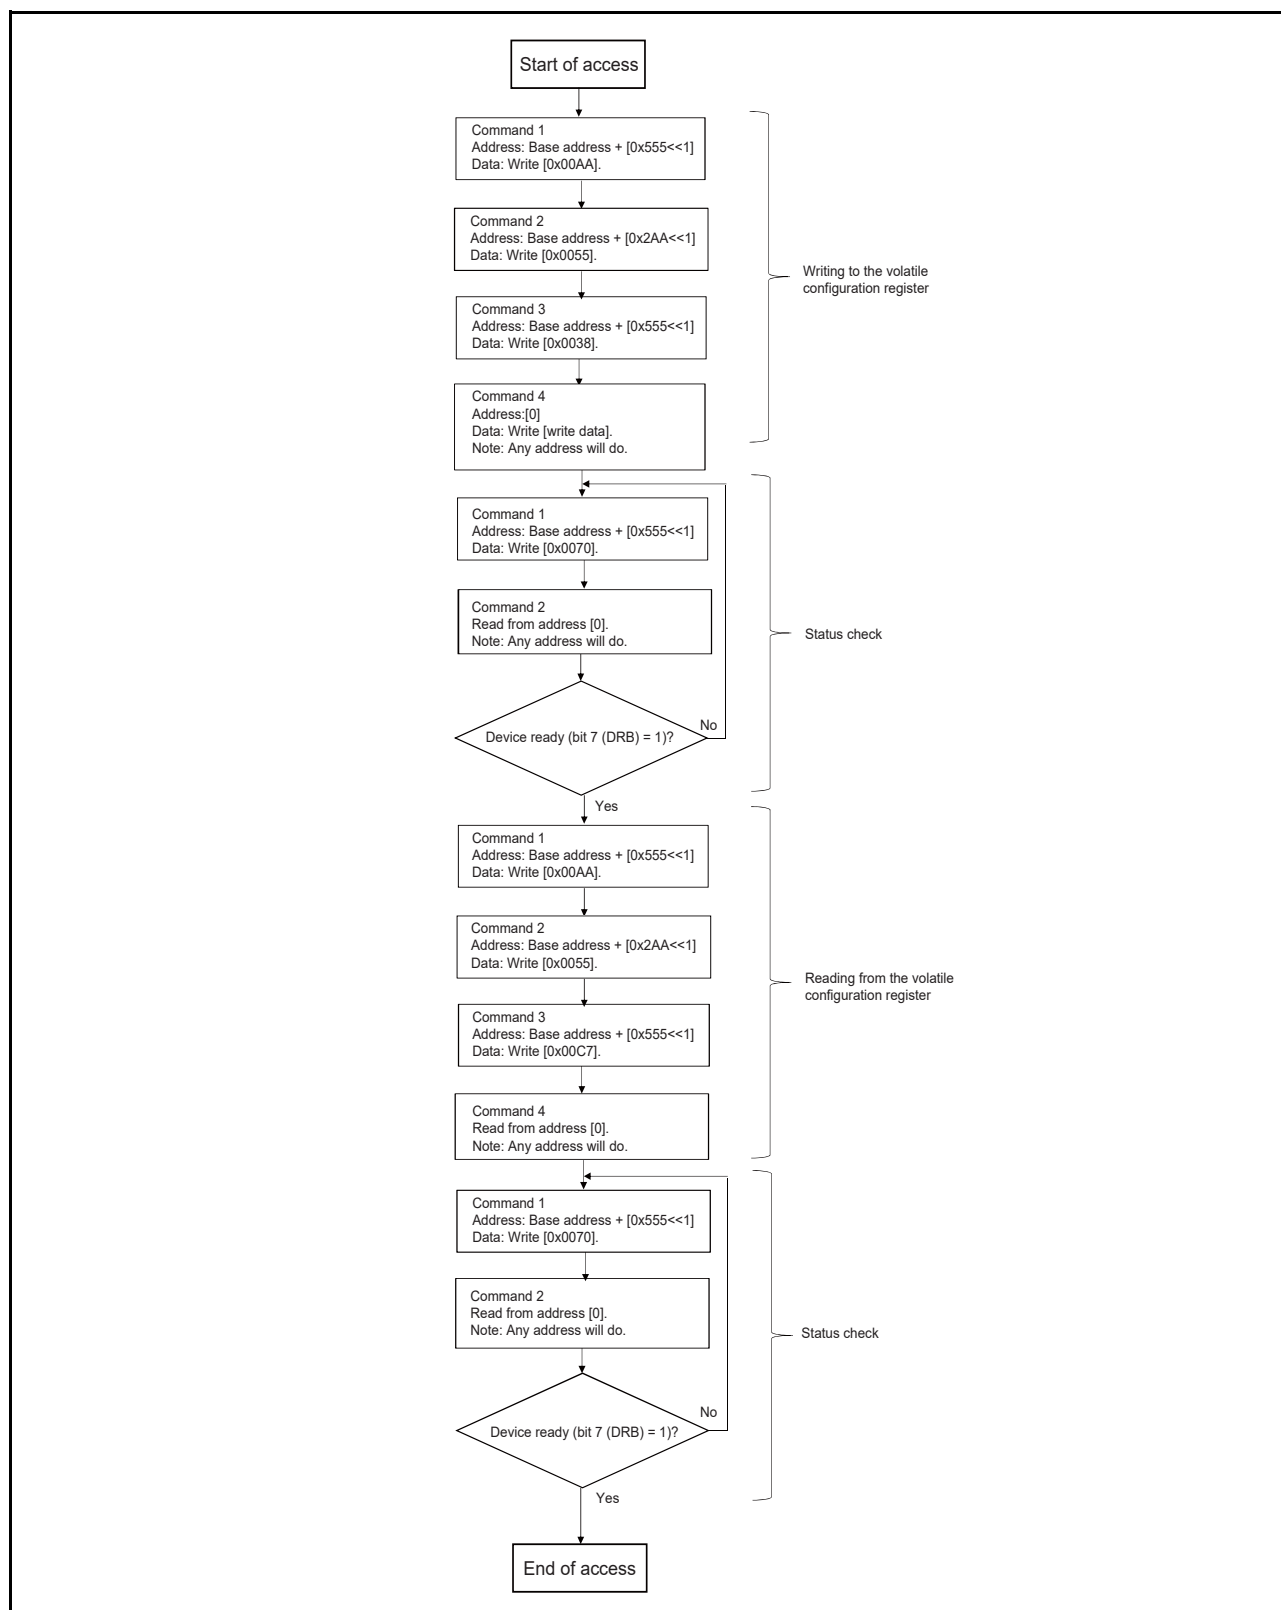

Figure 21.10 Flow of Write and Read Operations for the Volatile Configuration Register

21.6.4 MTR0 and MTR1 Timing Parameters

The timing parameters specified in the CS0 memory timing register (MTR0) and CS1 memory timing register (MTR1) described in section 21.5.6 and section 21.5.7 are shown in the following timing chart.

The chart shows the timings of read and write access by the HyperBus controller to memory (HyperFlash or HyperRAM).

- (1) WCSS/RCSS is the period between assertion of the HM_CS0#/HM_CS1# signal and the first edge of the HM_CK/HM_CK# signal.
- (2) WCSH/RCSH is the period between the last edge of the HM_CK/HM_CK# signal for the current data transfer and negation of the HM_CS0#/HM_CS1# signal.
- (3) WCSHI/RCSHI is the period between the end of a current transfer and the beginning of the next.
- (4) LTCY should only be specified in MTR1. Specifying this timing is only required for a HyperRAM device; it is not required for a HyperFlash device.

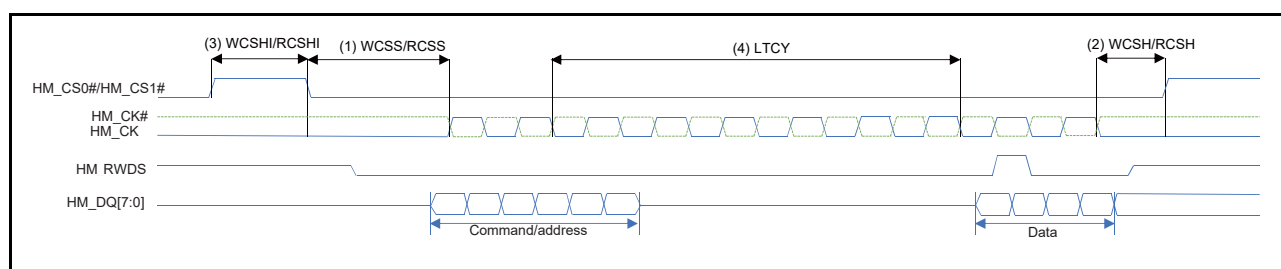

Figure 21.11 Timing Chart of Read and Write Operations

22. Octa Memory Controller

The Octa memory controller enables the connection of OctaFlash™ and OctaRAM™ to this LSI chip.

Note: OctaFlash™ and OctaRAM™ are trademarks of Macronix International Co., Ltd.

22.1 Features

- Macronix Serial Multi I/O (MXSMIO®) Octa Peripheral Interface (OPI) for high-end consumer applications is supported.
- One each of an OctaFlash device and an OctaRAM device compliant with the OPI specifications are connectable.
- A chip select signal is assigned to each memory device (OM_CS0#: OctaFlash; OM_CS1#: OctaRAM).
Note: Only one of the memory devices can operate (be read or written to) at a time.
- Supported device interfaces
 - SPI: Serial peripheral interface (OctaFlash, SPI mode)
 - SOPI: Single Octa I/O (8 bits) (OctaFlash, single data rate)
 - DOPI: Double Octa I/O (8 bits) (OctaFlash and OctaRAM, double data rate)
- 3-byte and 4-byte OctaFlash address commands are supported.
- 4-byte OctaRAM address commands are supported.
- The read-while-write (RWW) operation is supported.
- 1LC and 2LC (latency count) OctaRAM devices are supported.
- The error corrected signal (ECS#) is available, and ECC errors can be detected (for OctaFlash only).
- Fastboot mode is not supported.
- Direct access (memory-mapped reading and writing) by the CPU to memory devices in separate flash and RAM address spaces is supported.
- OM_CK: 132 MHz
- PVcc_HO: 1.8 V

22.2 Block Diagram

Figure 22.1 shows a block diagram of this module.

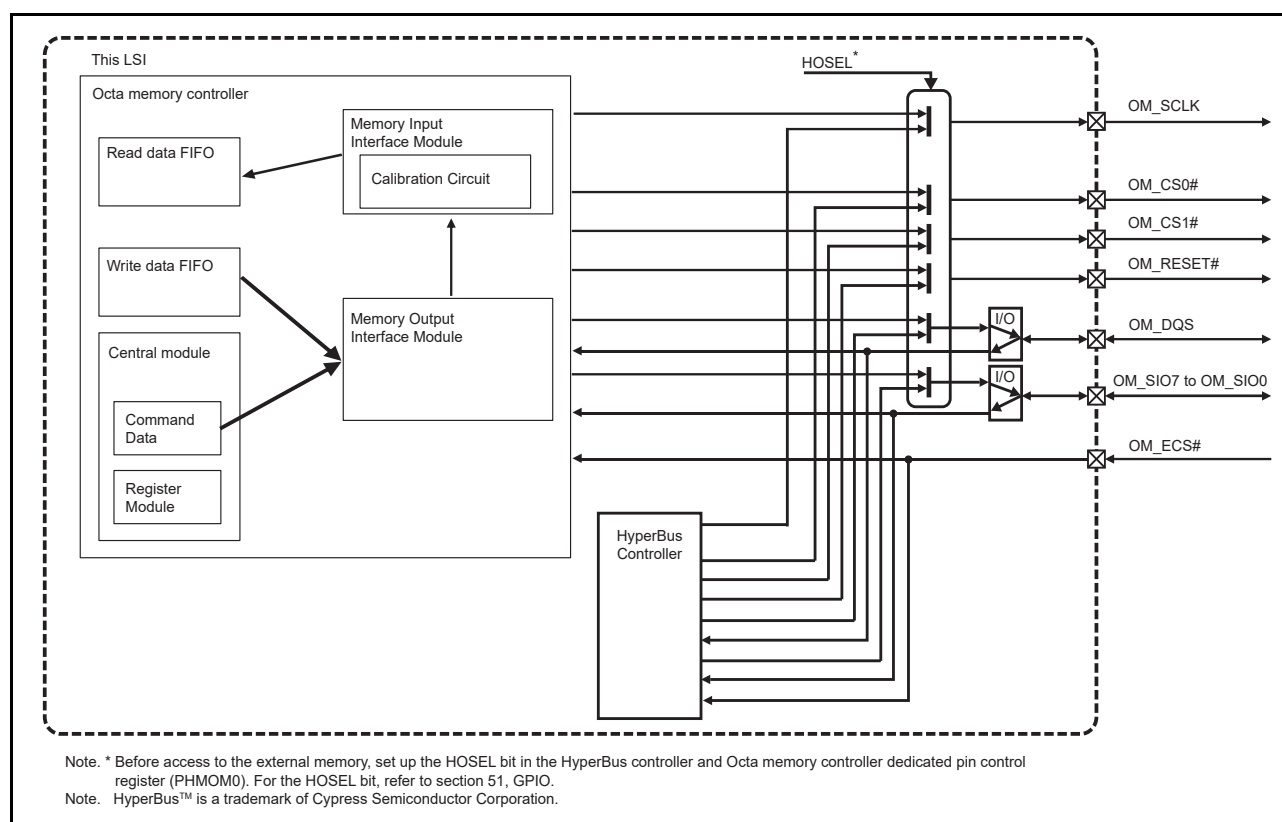

Figure 22.1 Block Diagram

22.3 Input/Output Pins

Table 22.1 shows the pin configuration.

Table 22.1 Configuration of Hyper Memory Controller Pins

| Pin | I/O | Name | Function |
|--------------------|--------------|------------------------|---|
| OM_SCLK | Output | Clock | Clock output |
| OM_CS0# | Output | Chip select 0 | Chip select signal for an OctaFlash device |
| OM_CS1# | Output | Chip select 1 | Chip select signal for an OctaRAM device |
| OM_DQS | Input/Output | Read/write data strobe | Read data strobe/write data mask signal |
| OM_SIO7 to OM_SIO0 | Input/Output | Data | Data input/output |
| OM_RESET# | Output | Reset output | Reset signal for both OctaFlash and OctaRAM devices |
| OM_ECS# | Input | ECC error detection | ECC error detection signal from the external memory |

Note: OM_ECS# is an input pin that is multiplexed with alternative pin functions that are driven by the 3.3-V power supply. The other pins are solely used for functions that are driven by the 1.8-V power supply.

22.3.1 Device Interface

The device interface is compatible with OctaFlash/OctaRAM interface.

When reading data from the memory or programming the memory with data, the bit order changes with the I/O mode.

The bit order is shown below:

Table 22.2 Bit order in accordance with I/O mode

| I/O mode | Bit order (MSB) |
|------------------------------|---|
| Read data from device | |
| 1 I/O (SPI) | OM_SIO1 input |
| 8 I/O (SOPI) | OM_SIO7 to OM_SIO0 input |
| 8 I/O (DOPI) | OM_SIO7 to OM_SIO0 input. Order of data: {D1, D0}, {D3, D2}, ... |
| Program/Write data to device | |
| 1 I/O (SPI) | OM_SIO0 output |
| 8 I/O (SOPI) | OM_SIO7 to OM_SIO0 output |
| 8 I/O (DOPI) | OM_SIO7 to OM_SIO0 output. Order of data: {D1, D0}, {D3, D2}, ... |

22.4 Register Descriptions

Table 22.3 shows the register configuration.

Access to the flash memory or RAM is allowed in either of the following modes.

Memory-map mode

- Reading from and writing to the memory array areas of OctaFlash memory or RAM is possible.

Configuration mode

- Transfer of any commands and data is possible.

Table 22.3 Octa memory controller register configuration

| Register Name | Abbreviation | R/W | Initial Value | Address | Access Size |
|---|--------------|-----|---------------|------------|-------------|
| Device command register | DCR | R/W | H'00000000 | H'1F401000 | 32 |
| Device address register | DAR | R/W | H'00000000 | H'1F401004 | 32 |
| Device command setting register | DCSR | R/W | H'00000000 | H'1F401008 | 32 |
| Device size register 0 | DSR0 | R/W | H'00000000 | H'1F40100C | 32 |
| Device size register 1 | DSR1 | R/W | H'00000000 | H'1F401010 | 32 |
| Memory delay trim register | MDTR | R/W | H'06009400 | H'1F401014 | 32 |

| Configure read register | CRR | R | H'00000000 | H'1F401060 | 32 |

22.4.1 Device Command Register (DCR)

DCR sets the device commands for controller operation.

| | | | | | | | | | | | | | | | | |
|----------------|-------------|-----|-----|-----|-----|-----|-----|-----|-------------|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | DVCMD1[7:0] | | | | | | | | DVCMD0[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-------------|---------------|-----|--|
| 31 to 16 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 15 to 8 | DVCMD1[7:0] | All 0 | R/W | Device Command data Sets the data to be transferred as a command to the device. If DCSR.CMDLEN[2:0] = 2, the controller will send DCR[15:8] as the 1st byte to memory. |
| 7 to 0 | DVCMD0[7:0] | All 0 | R/W | Device Command data Sets the data to be transferred as a command to the device. If DCSR.CMDLEN[2:0] = 1, the controller will send DCR[7:0] as the 1st byte to memory. If DCSR.CMDLEN[2:0] = 2, the controller will send DCR[7:0] as the 2nd byte to memory. |

22.4.2 Device Address Register (DAR)

DAR sets the device address for controller operation.

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|------------|---------------|-----|--|
| 31 to 24 | DVAD3[7:0] | All 0 | R/W | Device Address data 3 Set the device address data. When DCSR.ADLLEN[2:0] = 4 only, set as the first byte. |
| 23 to 16 | DVAD2[7:0] | All 0 | R/W | Device Address data 2 Set the device address data. When DCSR.ADLLEN[2:0] = 3, set as the first byte. When DCSR.ADLLEN[2:0] = 4, set as the second byte. |
| 15 to 8 | DVAD1[7:0] | All 0 | R/W | Device Address data 1 Set the device address data. When DCSR.ADLLEN[2:0] = 3, set as the second byte. When DCSR.ADLLEN[2:0] = 4, set as the third byte. |
| 7 to 0 | DVAD0[7:0] | All 0 | R/W | Device Address data 0 Set the device address data. When DCSR.ADLLEN[2:0] = 3, set as the third byte. When DCSR.ADLLEN[2:0] = 4, set as the fourth byte. |

22.4.3 Device Command Setting Register (DCSR)

DCSR sets device commands.

| | | | | | | | | | | | | | | | | |
|----------------|-------------|-----|-----|------|------|------------|-----|-----|------------|-------------|-----|-----|------|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | ACDA | DOPI | ADLEN[2:0] | | | DAOR | CMDLEN[2:0] | | | ACDV | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | DMLLEN[7:0] | | | | | | | | DALEN[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-------------|---------------|-----|---|
| 31 to 29 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 28 | ACDA | 0 | R/W | Data Access Control Set data access or register access 0: Register access Do not arrange the transfer data. 1: Data access (1) the address bit0 will be forced to 0 in DOPI mode. (2) If DAR[0] of the lead type command is 1, byte 0 from the device will be dropped in DOPI mode. (3) The AXI read data will be arranged according to the DAR. For example: When DAR[1:0] = 1, the first valid data is stored in RDATA[15:8]. (4) The AXI write data is used according to the DAR in DOPI mode. For example: If the target device is Flash Memory and DAR[1:0] = 1, the first byte sent to the flash memory is forced to 0xff. If the target device is RAM and DAR[1:0] = 1, the first byte sent to RAM is masked by DQSM. (5) When the target device is RAM, the address sent to the memory changes according to RAM specification. |
| 27 | DOPI | 0 | R/W | DOPI single byte setting Even in DOPI mode, set this bit to 1 when the read data has only one byte in each cycle. For example: OctaFlash RDID, RDSR command 0: Each cycle has two bytes data. (normal DOPI mode) 1: Each cycle has one byte data. (The byte data changes at the rising edge of the clock and does not change at the falling edge of the clock.) |
| 26 to 24 | ADLEN[2:0] | 000 | R/W | Transfer address length setting Sets the length of the address to be transferred in bytes. |
| 23 | DAOR | 0 | R/W | Data order setting Sets the byte order of data during read and write operations. 0: byte0, byte1, byte2, byte3 1: byte1, byte0, byte3, byte2 |
| 22 to 20 | CMDLEN[2:0] | 000 | R/W | Transfer command length setting Sets the length of the command to be transferred in bytes. |
| 19 | ACDV | 0 | R/W | Access Device setting Sets the device to be accessed. 0: Send commands to device 0. 1: Send commands to device 1. |
| 18 to 16 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 15 to 8 | DMLLEN[7:0] | All 0 | R/W | Dummy cycle (latency) setting Sets the length of dummy cycle (latency) in OM_SCLK units. |
| 7 to 0 | DALEN[7:0] | All 0 | R/W | Transfer data length setting Sets the length of data to be transferred in bytes. When [7:0] is 0, there are no transmission data to memory and reception data from memory. |

22.4.4 Device Size Register 0 (DSR0)

DSR0 specifies the type of memory to be accessed as device 0 and the size of the flash memory.

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|-------------|---------------|-----|--|
| 31, 30 | DV0TYP[1:0] | 00 | R/W | Device 0 type setting Set to 00. |
| 29 to 0 | DV0SZ[29:0] | All 0 | R/W | Device 0 size setting Set a 30-bit value for the size of memory connected as device 0. Examples: H'10000000: 256-Mbyte flash memory H'08000000: 128-Mbyte flash memory |

22.4.5 Device Size Register 1 (DSR1)

DSR1 specifies the type of memory to be accessed as device 1 and the size of the RAM.

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|-------------|---------------|-----|--|
| 31, 30 | DV1TYP[1:0] | 00 | R/W | Device 1 type setting Set to 01. |
| 29 to 0 | DV1SZ[29:0] | All 0 | R/W | Device 1 size setting Set a 30-bit value for the size of memory connected as device 1. Examples: H'00800000: 8-Mbyte RAM Note: Set a value less than or equal to H'00800000. |

22.4.6 Memory Delay Trim Register (MDTR)

MDTR sets the timing adjustment of memory access.

| | | | | | | | | | | | | | | | | |
|----------------|---------------|-----|-----|-----|---------------|-----|-----|-----|-------------|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | DQSEDOPI[3:0] | | | | DV1DEL[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| | DQSESOPI[3:0] | | | | DQSERAM[3:0] | | | | DV0DEL[7:0] | | | | | | | |
| Initial value: | 1 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|---------------|---------------|-----|--|
| 31 to 28 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 27 to 24 | DQSEDOPI[3:0] | H'6 | R/W | OM_DQS enable counter Setting for the DOPI mode (flash memory) For the OM_DQS enable counter, see section 22.7, OM_DQS Enable Counter. |
| 23 to 16 | DV1DEL[7:0] | All 0 | R/W | Device 1 delay setting These bits specify the number of cycles of delay to be inserted in the input strobe signal (OM_DQS) to adjust the timing for latching data during read access to device 1 in the DOPI mode (RAM). For the delay setting of OM_DQS, see section 22.6.1, Delaying OM_DQS. |
| 15 to 12 | DQSESOPI[3:0] | H'9 | R/W | OM_DQS enable counter Setting for the SOPI mode (flash memory) For the OM_DQS enable counter, see section 22.7, OM_DQS Enable Counter. |
| 11 to 8 | DQSERAM[3:0] | H'4 | R/W | OM_DQS enable counter Setting for the DOPI mode (RAM) For the OM_DQS enable counter, see section 22.7, OM_DQS Enable Counter. |
| 7 to 0 | DV0DEL[7:0] | All 0 | R/W | Device 0 delay setting These bits specify the delay cycles to be inserted on the input strobe signal (OM_DQS) to adjust the timing for latching data during read access to device 0 in the SOPI or DOPI mode (flash memory). For the delay setting of OM_DQS, see section 22.6.1, Delaying OM_DQS. |

During a read operation with the OM_DQS clock input (in the SOPI or DOPI mode), the OM_DQS clock transitions from the high-impedance state to the input state (for receiving a value of 0 from the external device) after the command and address phases are completed. To obtain valid data, adjust the DQS enable counter and delay cycles.

OM_DQS enable counter setting (OM_SCLK units)

0000: 1 clock cycle

0001: 2 clock cycles

0010: 3 clock cycles

0010: 4 clock cycles

...

1111: 16 clock cycles

OM_DQS enable counter setting examples

Table 22.4 Examples of Setting the OM_DQS Enable Counter for OctaRAM

| Number of dummy cycles (latency) | RAM | |
|-------------------------------------|--------------|---------------|
| | Pre-cycle On | Pre-cycle Off |
| 3 | 4 | 4 to 5 |
| 4 | 4 to 5 | 4 to 6 |
| 5 | 4 to 6 | 4 to 7 |
| 6 | 4 to 7 | 4 to 8 |
| 7 | 4 to 8 | 4 to 9 |
| 8 | 4 to 9 | 4 to 10 |

Table 22.5 Examples of Setting the OM_DQS Enable Counter for OctaFlash Memory

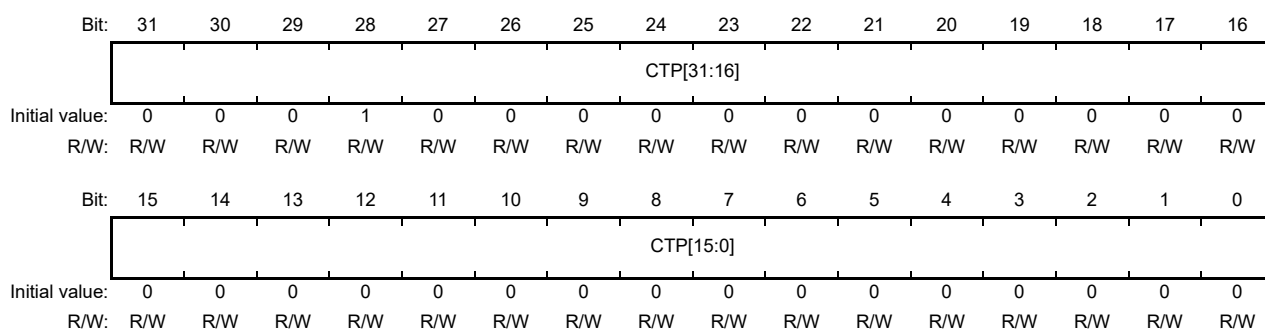

| Number of dummy cycles (latency) | SOPI | DOPI | |
|-------------------------------------|--------------|--------------|---------------|
| | Pre-cycle On | Pre-cycle On | Pre-cycle Off |
| 4 | 8 to 9 | 5 to 6 | 5 to 7 |
| 6 | 8 to 11 | 5 to 8 | 5 to 9 |
| 8 | 8 to 13 | 5 to 10 | 5 to 11 |
| 10 | 8 to 15 | 5 to 12 | 5 to 13 |
| 12 | 8 to 15 | 5 to 14 | 5 to 15 |
| 14 | 8 to 15 | 5 to 15 | 5 to 15 |
| 16 | 8 to 15 | 5 to 15 | 5 to 15 |
| 18 | 8 to 15 | 5 to 15 | 5 to 15 |
| 20 | 8 to 15 | 5 to 15 | 5 to 15 |

These two tables list cases of DQS delay.

If DQS delay cycle is not within this range, refer to section 22.7, OM_DQS Enable Counter, and recalculate the correct range.

22.4.7 Auto-Calibration Timer Register (ACTR)

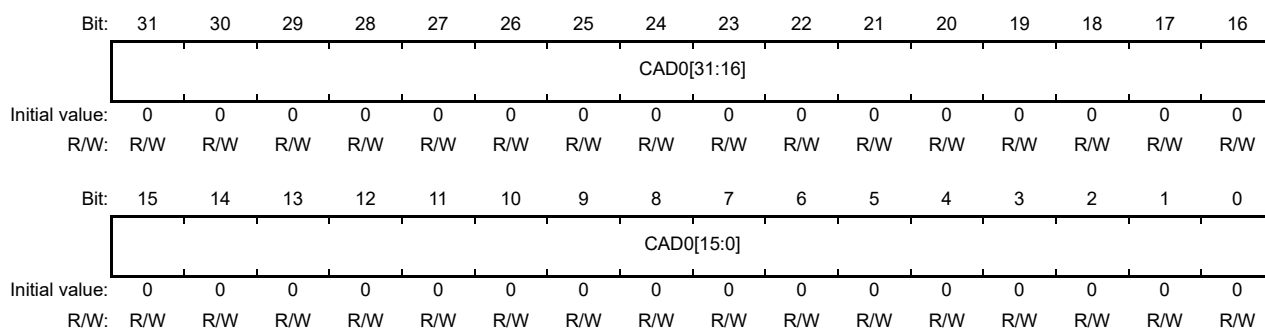

ACTR sets the cycle at which automatic calibration is executed.

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|-----------|---------------|-----|--|
| 31 to 0 | CTP[31:0] | H'10000000 | R/W | Automatic calibration cycle time setting Sets performing cycle for the automatic calibration with 32 bits. Automatic calibration cycle time (ns) = CTP[31:0] × Bp When automatic calibration is enabled (CDSR.ACMODE[1:0] = H'1) and the value of the internal timer is equal to that of this register, automatic calibration will start. |

22.4.8 Auto-Calibration Address Register 0 (ACAR0)

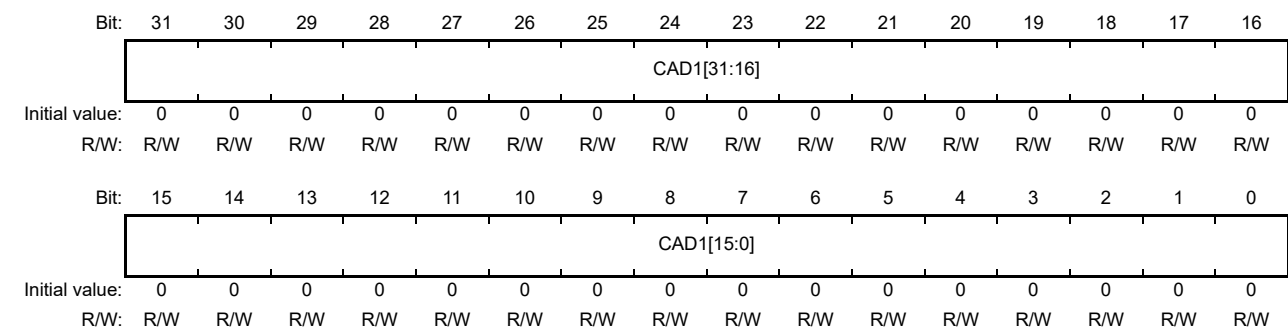

ACAR0 sets the address in OctaFlash memory for writing to and reading from in auto-calibration of device 0.

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|------------|---------------|-----|---|
| 31 to 0 | CAD0[31:0] | All 0 | R/W | Automatic calibration address These bits set the address in OctaFlash memory for writing to and reading from in auto-calibration of device 0. Note: Set an address in terms of the memory space of the OctaFlash device, not in the OctaFlash space within this LSI chip. |

22.4.9 Auto-Calibration Address Register 1 (ACAR1)

ACAR1 sets the address in OctaRAM for writing to and reading from in auto-calibration of device 1.

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|------------|---------------|-----|--|
| 31 to 0 | CAD1[31:0] | All 0 | R/W | Automatic calibration address These bits set the address in OctaRAM for writing to and reading from in auto-calibration of device 1. Note: Set an address in terms of the memory space of the OctaRAM device, not in the OctaRAM space within this LSI chip. |

22.4.10 Device Memory Map Read Chip Select Timing Setting Register (DRCSTR)

DRCSTR sets the timing of memory-mapped reading for each device.

| | | | | | | | | | | | | | | | | |
|----------------|--------------|-----|--------------|-----|-----|---------------|-----|-----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | DVRDLO1[1:0] | | DVRDHI1[2:0] | | | DVRDCMD1[2:0] | | | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | R | R | R | R | R | R |

| | | | | | | | | | | | | | | | | |
|----------------|--------------|-----|--------------|-----|-----|---------------|-----|-----|------|------------|-----|-----|-----|-----|-----|-----|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | DVRDLO0[1:0] | | DVRDHI0[2:0] | | | DVRDCMD0[2:0] | | | CTR0 | CTRW0[6:0] | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|--------------|---------------|-----|---|
| 31, 30 | DVRDLO1[1:0] | 00 | R/W | Device 1 select signal pull-down timing setting* Indicates the timing between the select signal pull-down to the read operation for the device 1. Timing definition from OM_CS1# low to the first OM_SCLK high DOPI mode 00: 1.5 clock cycles 01: 2.5 clock cycles 10: 3.5 clock cycles 11: 4.5 clock cycles Other mode 00: 2 clock cycles 01: 3 clock cycles 10: 4 clock cycles 11: 5 clock cycles |
| 29 to 27 | DVRDHI1[2:0] | 000 | R/W | Device 1 select signal High timing setting* Indicates the timing, from the end of read operation to the select signal is pulled up. Timing definition from the last OM_SCLK low to OM_CS1# high DOPI or (SOP) mode 000: Setting prohibited 001: Setting prohibited 010: Setting prohibited 011: Setting prohibited 100: Setting prohibited 101: 6.5 (7) clock cycles 110: 7.5 (8) clock cycles 111: 8.5 (9) clock cycles Note: The values in parentheses apply to SOP mode. Other mode 000: 2 clock cycles 001: 3 clock cycles 010: 4 clock cycles 011: 5 clock cycles 100: 6 clock cycles 101: 7 clock cycles 110: 8 clock cycles 111: 9 clock cycles |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|---------------|---------------|-----|--|
| 26 to 24 | DVRDCMD1[2:0] | 000 | R/W | Device 1 Command execution interval* Indicates the timing, between command and command for device 1. Timing, until the OM_CS1# signal goes from High to the next Low 000: 2 clock cycles 001: 5 clock cycles 010: 7 clock cycles 011: 9 clock cycles 100: 11 clock cycles 101: 13 clock cycles 110: 15 clock cycles 111: 17 clock cycles |
| 23 to 16 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 15, 14 | DVRDLO0[1:0] | 00 | R/W | Device 0 select signal pull-down timing setting* Indicates the timing between the select signal pull-down to the read operation for the device 0. Timing definition from OM_CS0# low to the first OM_SCLK high DQPI mode 00: 1.5 clock cycles 01: 2.5 clock cycles 10: 3.5 clock cycles 11: 4.5 clock cycles Other mode 00: 2 clock cycles 01: 3 clock cycles 10: 4 clock cycles 11: 5 clock cycles |
| 13 to 11 | DVRDHI0[2:0] | 000 | R/W | Device 0 select signal pull-up timing setting* Indicates the timing, from the end of read operation to the select signal is pulled up. Timing definition from the last OM_SCLK low to OM_CS0# high DQPI or (SQPI) mode 000: Setting prohibited 001: Setting prohibited 010: Setting prohibited 011: Setting prohibited 100: Setting prohibited 101: 6.5 (7) clock cycles 110: 7.5 (8) clock cycles 111: 8.5 (9) clock cycles Note: The values in parentheses apply to SQPI mode. Other mode 000: 2 clock cycles 001: 3 clock cycles 010: 4 clock cycles 011: 5 clock cycles 100: 6 clock cycles 101: 7 clock cycles 110: 8 clock cycles 111: 9 clock cycles |
| 10 to 8 | DVRDCMD0[2:0] | 000 | R/W | Device 0 Command execution interval setting* Indicates the timing between command to command for the device 0. Timing definition from OM_CS0# high to the next OM_CS0# low 000: 2 clock cycles 001: 5 clock cycles 010: 7 clock cycles 011: 9 clock cycles 100: 11 clock cycles 101: 13 clock cycles 110: 15 clock cycles 111: 17 clock cycles |

| Bit | Bit Name | Initial Value | R/W | Description |
|--------|------------|---------------|-----|---|
| 7 | CTR0 | 0 | R/W | Device 0 Continuous read setting When the continuous read is enabled, wait for the continuous read operation to be performed using the value set in CTRW0[6:0]. Do not set this bit to 1 except for OctaFlash DQPI mode. 0: Continuous read disabled for device 0 1: Continuous read enabled for device 0 |
| 6 to 0 | CTRW0[6:0] | All 0 | R/W | Device 0 continuous read cycle setting When continuous read of Device 0 is enabled, the selection signal is fixed to Low for the set clock cycle, after the read operation is performed. If the number of clock cycles exceeds twice the value set in these bits before the next read operation is performed, the select signal is returned to High. |

Note: These clock cycles are values in internal clock units. In OM_SCLK units, the clock cycle is 1/2 of the above table.

22.4.11 Device Memory Map Write Chip Select Timing Setting Register (DWCSTR)

DWCSTR sets the timing of memory-mapped writing for each device.

| | | | | | | | | | | | | | | | | |
|----------------|-------------|-----|-------------|-----|-----|--------------|-----|-----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | DVWLO1[1:0] | | DVWHI1[2:0] | | | DVWCMD1[2:0] | | | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | R | R | R | R | R | R |

| | | | | | | | | | | | | | | | | |
|----------------|-------------|-----|-------------|-----|-----|--------------|-----|-----|---|---|---|---|---|---|---|---|

| | DVWLO0[1:0] | | DVWHI0[2:0] | | | DVWCMD0[2:0] | | | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-------------|---------------|-----|--|
| 31, 30 | DVWLO1[1:0] | 00 | R/W | Device 1 select signal pull-down timing setting* Indicates the timing between the device 1 select signal pull-down to the write operation. Timing definition from OM_CS1# low to the first OM_SCLK high DOP1 mode 00: 1.5 clock cycles 01: 2.5 clock cycles 10: 3.5 clock cycles 11: 4.5 clock cycles Other mode 00: 2 clock cycles 01: 3 clock cycles 10: 4 clock cycles 11: 5 clock cycles |
| 29 to 27 | DVWHI1[2:0] | 000 | R/W | Device 1 select signal pull-up timing setting* Indicates the timing, from the end of write operation to the select signal is pulled up. Timing definition from the last OM_SCLK low to OM_CS1# high DOP1 mode 000: 1.5 clock cycles 001: 2.5 clock cycles 010: 3.5 clock cycles 011: 4.5 clock cycles 100: 5.5 clock cycles 101: 6.5 clock cycles 110: 7.5 clock cycles 111: 8.5 clock cycles Other mode 000: 2 clock cycles 001: 3 clock cycles 010: 4 clock cycles 011: 5 clock cycles 100: 6 clock cycles 101: 7 clock cycles 110: 8 clock cycles 111: 9 clock cycles |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|--------------|---------------|-----|---|
| 26 to 24 | DVWCMD1[2:0] | 000 | R/W | Device 1 Command execution interval setting* Indicates the timing between command to command for the device 1. Timing definition from OM_CS1# high to the next OM_CS1# low 000: 2 clock cycles 001: 5 clock cycles 010: 7 clock cycles 011: 9 clock cycles 100: 11 clock cycles 101: 13 clock cycles 110: 15 clock cycles 111: 17 clock cycles |
| 23 to 16 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 15, 14 | DVWLO0[1:0] | 00 | R/W | Device 0 select signal pull-down timing setting* Indicates the timing between the select signal pull-down to the write operation for the device 0. Timing definition from OM_CS0# low to the first OM_SCLK high DOP mode 00: 1.5 clock cycles 01: 2.5 clock cycles 10: 3.5 clock cycles 11: 4.5 clock cycles Other mode 00: 2 clock cycles 01: 3 clock cycles 10: 4 clock cycles 11: 5 clock cycles |
| 13 to 11 | DVWHI0[2:0] | 000 | R/W | Device 0 select signal pull-up timing setting* Indicates the timing, from the end of write operation to the select signal is pulled up. Timing definition from the last OM_SCLK low to OM_CS0# high DOP mode 000: 1.5 clock cycles 001: 2.5 clock cycles 010: 3.5 clock cycles 011: 4.5 clock cycles 100: 5.5 clock cycles 101: 6.5 clock cycles 110: 7.5 clock cycles 111: 8.5 clock cycles Other mode 000: 2 clock cycles 001: 3 clock cycles 010: 4 clock cycles 011: 5 clock cycles 100: 6 clock cycles 101: 7 clock cycles 110: 8 clock cycles 111: 9 clock cycles |
| 10 to 8 | DVWCMD0[2:0] | 000 | R/W | Device 0 Command execution interval setting* Indicates the timing between command to command for the device 0. Timing definition from OM_CS0# high to the next OM_CS0# low 000: 2 clock cycles 001: 5 clock cycles 010: 7 clock cycles 011: 9 clock cycles 100: 11 clock cycles 101: 13 clock cycles 110: 15 clock cycles 111: 17 clock cycles |
| 7 to 0 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |

Note: These clock cycles are values in internal clock units. In OM_SCLK units, the clock cycle is 1/2 of the above table.

22.4.12 Device Chip Select Timing Setting Register (DCSTR)

DCSTR sets the timing of operations in configuration mode.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| | | | | | | | | | | | | | | | | |
|----------------|--------------|-----|--------------|-----|-----|---------------|-----|-----|---|---|---|---|---|---|---|---|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | DVSELLO[1:0] | | DVSELHI[2:0] | | | DVSELCMD[2:0] | | | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|--------------|---------------|-----|---|
| 31 to 16 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 15, 14 | DVSELLO[1:0] | All 0 | R/W | Device select signal pull-down timing setting* Indicates the timing, from the device selection signal is pulled-down to the command execution. Timing definition from OM_CS# low to the first OM_SCLK high DOPI mode 00: 1.5 clock cycles 01: 2.5 clock cycles 10: 3.5 clock cycles 11: 4.5 clock cycles Other mode 00: 2 clock cycles 01: 3 clock cycles 10: 4 clock cycles 11: 5 clock cycles |
| 13 to 11 | DVSELHI[2:0] | 000 | R/W | Device select signal pull-up timing setting* Indicates the timing when the select signal is pulled up from the end of the command execution. Timing definition from the last OM_SCLK low to OM_CS# high DOPI or (SOP) mode 000: Setting prohibited 001: Setting prohibited 010: Setting prohibited 011: Setting prohibited 100: Setting prohibited 101: 6.5 (7) clock cycles 110: 7.5 (8) clock cycles 111: 8.5 (9) clock cycles Note: The values in parentheses apply to SOP mode. Other mode 000: 2 clock cycles 001: 3 clock cycles 010: 4 clock cycles 011: 5 clock cycles 100: 6 clock cycles 101: 7 clock cycles 110: 8 clock cycles 111: 9 clock cycles |

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|---------------|---------------|-----|---|
| 10 to 8 | DVSELCMD[2:0] | 000 | R/W | Device Command execution interval setting* Indicates the timing between command to command. Timing definition from OM_CS# high to the next OM_CS# low 000: 2 clock cycles 001: 5 clock cycles 010: 7 clock cycles 011: 9 clock cycles 100: 11 clock cycles 101: 13 clock cycles 110: 15 clock cycles 111: 17 clock cycles |
| 7 to 0 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |

Note: These clock cycles are values in internal clock units. In OM_SCLK units, the clock cycle is 1/2 of the above table.

22.4.13 Controller and Device Setting Register (CDSR)

CDSR controls the automatic calibration, pre-cycle setting, and device transfer type of the controller and each of the devices.

| | | | | | | | | | | | | | | | | |
|----------------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | DLFT | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| | | | | | | | | | | | | | | | | |
|----------------|----|----|-----------------|-----------------|-----|-----|---|---|---|-------|-------|--------------|--------------|-----|-----|-----|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | ACMODE [1:0] | ACMEME [1:0] | — | — | — | — | — | DV1PC | DV0PC | DV1TTYP[1:0] | DV0TTYP[1:0] | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R/W | R/W | R/W | R/W | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|--------------|---------------|-----|--|
| 31 | DLFT | 0 | R/W | Deadlock Free Timer Enable Enable the timer to prevent the occurrence of controller deadlock. The timeout status is reset only by a system reset. 0: Enable timer 1: Disable timer Note: This function is available only when OM_SCLK is 132 MHz. Otherwise, disable the timer. |
| 30 to 14 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 13, 12 | ACMODE[1:0] | 00 | R/W | Automatic calibration mode 00: Automatic calibration is disabled.* 01: Automatic calibration is enabled. 10: Setting prohibited. 11: Setting prohibited. The ACMODE bits should be set to disabled during read access to the OctaFlash device. Automatic calibration is only available in the DOPI mode. |
| 11, 10 | ACMEME[1:0] | 00 | R/W | Automatic calibration memory enable setting Automatic calibration supports only DOPI mode. To end DOPI mode, disable automatic calibration. [1]: Enable for device 1 1: Enable 0: Disable [0]: Enable for device 0 1: Enable 0: Disable |
| 9 to 6 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. |
| 5 | DV1PC | 0 | R/W | Device1_memory precycle setting 0: Disable 1: Enable |
| 4 | DV0PC | 0 | R/W | Device0_memory precycle setting 0: Disable 1: Enable |
| 3, 2 | DV1TTYP[1:0] | 00 | R/W | Device1_transfer_type setting 00: SPI mode 01: SOPI mode 10: DOPI mode 11: Setting prohibited |

| Bit | Bit Name | Initial Value | R/W | Description |
|------|--------------|---------------|-----|---|
| 1, 0 | DV0TTYP[1:0] | 00 | R/W | Device0_transfer_type setting 00: SPI mode 01: SOPI mode 10: DOPI mode 11: Setting prohibited |

Note: When automatic calibration is disabled, the device 0 delay (OctaFlash) and device 1 delay (OctaRAM) should be manually specified in the memory delay trim register (MDTR) (see section 22.4.6). Set this register with reference to "initial setting MDTR (OctaFlash memory)" and "initial setting MDTR (OctaRAM)" in Figure 22.16.

22.4.14 Memory Map Dummy Length Register (MDLR)

MDLR sets the number of dummy cycles (latency) for writing and reading the memory map.

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-------------|---------------|-----|--|
| 31 to 24 | DV1WDL[7:0] | All 0 | R/W | Device 1 Write dummy cycles (latency) setting Set the dummy length when writing to device 1 in OM_SCLK cycles unit. |
| 23 to 16 | DV1RDL[7:0] | All 0 | R/W | Device 1 Read dummy cycles (latency) setting Set the dummy length when reading to device 1 in OM_SCLK cycles unit. |
| 15 to 8 | DV0WDL[7:0] | All 0 | R/W | Device 0 Write dummy cycles (latency) setting Set the dummy length when writing to device 0 in OM_SCLK cycles unit. |
| 7 to 0 | DV0RDL[7:0] | All 0 | R/W | Device 0 Read dummy cycles (latency) setting Set the dummy length when reading to device 0 in OM_SCLK cycles unit. |

Note: When changing the dummy cycles (latency) for the OctaFlash device, modify the setting on the memory and then modify the setting in the DMLen[7:0] bits in the device command setting register (DCSR) so that the dummy length becomes the same between the memory and this Octa memory controller. After that, execute the status read command to confirm the memory status.

22.4.15 Memory Map Read/Write Command Register 0 (MRWCR0)

MRWCR0 sets the read/write commands for the device 0.

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|---------------|---------------|-----|--|
| 31 to 24 | D0MWCMD1[7:0] | All 0 | R/W | Memory map write command 1 setting, Set the memory map write command. According to the flash memory spec, there are SPI, SOPI, and DOPI mode. In SPI mode, the controller will not send command 1. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 0 is specified by CDSR.DV0TTY[1:0]. |
| 23 to 16 | D0MWCMD0[7:0] | All 0 | R/W | Memory map write command 0 setting, Set the memory map write command. According to the flash memory spec, there are SPI, SOPI, and DOPI mode. In SPI mode, the controller will send only command 0. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 0 is specified by CDSR.DV0TTY[1:0]. |
| 15 to 8 | D0MRCMD1[7:0] | All 0 | R/W | Memory map read command 1 setting Set the memory map read command. According to the flash memory spec, there are SPI, SOPI, and DOPI mode. In SPI mode, the controller will not send command 1. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 0 is specified by CDSR.DV0TTY[1:0]. |
| 7 to 0 | D0MRCMD0[7:0] | All 0 | R/W | Memory map read command 0 setting, Set the memory map read command. According to the flash memory spec, there are SPI, SOPI, and DOPI mode. In SPI mode, the controller will send only command 0. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 0 is specified by CDSR.DV0TTY[1:0]. |

22.4.16 Memory Map Read/Write Command Register 1 (MRWCR1)

MRWCR1 sets the read/write commands for the device 1.

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|---------------|---------------|-----|---|
| 31 to 24 | D1MWCMD1[7:0] | All 0 | R/W | Memory map write command 1 setting Set the memory map write command. According to the RAM spec, there are SPI, SOPI, and DOPI mode. In SPI mode, the controller will not send command 1. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 1 is specified by CDSR.DV1TTYP[1:0]. |
| 23 to 16 | D1MWCMD0[7:0] | All 0 | R/W | Memory map write command 0 setting Set the memory map write command. According to the RAM spec, there are SPI, SOPI, and DOPI mode. In SPI mode, the controller will send only command 0. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 1 is specified by CDSR.DV1TTYP[1:0]. |
| 15 to 8 | D1MRCMD1[7:0] | All 0 | R/W | Memory map read command 1 setting Set the memory map read command. According to the RAM spec, there are SPI, SOPI, and DOPI mode. In SPI mode, the controller will not send command 1. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 1 is specified by CDSR.DV1TTYP[1:0]. |
| 7 to 0 | D1MRCMD0[7:0] | All 0 | R/W | Memory map read command 0 setting Set the memory map read command. According to the RAM spec, there are SPI, SOPI, and DOPI mode. In SPI mode, the controller will send only command 0. In SOPI and DOPI mode, the controller will send command 1 first and then send command 0. The mode of device 1 is specified by CDSR.DV1TTYP[1:0]. |

22.4.17 Memory Map Read/Write Setting Register (MRWCSR)

MRWCSR sets the memory map read/write operations.

| | | | | | | | | | | | | | | | | |
|----------------|----|------|------------|-----|-----|------------|-----|-----|----|------|------------|-----|-----|------------|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | MWO1 | MWCL1[2:0] | | | MWAL1[2:0] | | | — | MRO1 | MRCL1[2:0] | | | MRAL1[2:0] | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | MWO0 | MWCL0[2:0] | | | MWAL0[2:0] | | | — | MRO0 | MRCL0[2:0] | | | MRAL0[2:0] | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|------------|---------------|-----|---|
| 31 | — | 0 | R | Reserved This bit is always read as 0. The write value should always be 0. |
| 30 | MWO1 | 0 | R/W | Device 1 write order setting 0: Write order is byte0, byte1, byte2, byte3. 1: Write order is byte1, byte0, byte3, byte2. |
| 29 to 27 | MWCL1[2:0] | 000 | R/W | Device 1 write command length setting Set the number of bytes in the write command for device 1. |
| 26 to 24 | MWAL1[2:0] | 000 | R/W | Device 1 write address length setting Set the memory map write address byte length for device 1. |
| 23 | — | 0 | R | Reserved This bit is always read as 0. The write value should always be 0. |
| 22 | MRO1 | 0 | R/W | Device 1 read order setting 0: Read order is byte0, byte1, byte2, byte3. 1: Read order is byte1, byte0, byte3, byte2. Note: This setting is only valid in the DOPI mode. It has no effect in the SOPI or SPI mode. |
| 21 to 19 | MRCL1[2:0] | 000 | R/W | Device 1 read command length setting Set the read command byte length for device 1. |
| 18 to 16 | MRAL1[2:0] | 000 | R/W | Device 1 read address length setting Set the memory map read address byte length for device 1. |
| 15 | — | 0 | R | Reserved This bit is always read as 0. The write value should always be 0. |
| 14 | MWO0 | 0 | R/W | Device 0 write order setting 0: Write order is byte0, byte1, byte2, byte3. 1: Write order is byte1, byte0, byte3, byte2. |
| 13 to 11 | MWCL0[2:0] | 000 | R/W | Device 0 write command length setting Set the write command byte length for device 0. |
| 10 to 8 | MWAL0[2:0] | 000 | R/W | Device 0 write address length setting Set the memory map write address byte length for device 0. |
| 7 | — | 0 | R | Reserved This bit is always read as 0. The write value should always be 0. |
| 6 | MRO0 | 0 | R/W | Device 0 read order setting 0: Read order is byte0, byte1, byte2, byte3. 1: Read order is byte1, byte0, byte3, byte2. Note: This setting is only valid in the DOPI mode. It has no effect in the SOPI or SPI mode. |
| 5 to 3 | MRCL0[2:0] | 000 | R/W | Device 0 read command length setting Set the write command byte length for device 0. |
| 2 to 0 | MRAL0[2:0] | 000 | R/W | Device 0 read address length setting Set the memory map read address byte length for device 0. |

22.4.18 Error Status Register (ESR)

ESR indicates the error status when performing memory map read and write commands.

| | | | | | | | | | | | | | | | | |
|----------------|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | MWESR[7:0] | | | | | | | | MRESR[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|------------|---------------|-----|---|
| 31 to 16 | — | 0 | R | Reserved These bits are always read as 0. |
| 15 to 8 | MWESR[7:0] | All 0 | R | Memory map write error status H'80 = invalid command, H'01 = write data length error |
| 7 to 0 | MRESR[7:0] | All 0 | R | Memory map read error status H'80 = invalid command, H'01 = ECC error, H'02 = preamble error, H'03 = wait OM_DQS timeout |

22.4.19 Configure Write without Data Register (CWNDR)

CWNDR is used to execute a write command without data in the configuration mode. Writing 0 to this register makes this module issue a write command without actually writing data to memory.

Specify an address in DAR, a command in DCSR, and command data in DCR.

Set the DCSR.DALEN bit field to 0 before writing to this register.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W |

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|----------|---------------|-----|-------------------------------------|
| 31 to 0 | — | All 0 | W | The write value should always be 0. |

22.4.20 Configure Write Data Register (CWDR)

CWDR is used to set the data for writing when a write command is to be executed in the configuration mode. Writing to this register makes the controller to issue a write command and transfer the data to be written. The byte order of data transferred by the controller to the memory is in accord with the setting of the DAOR bit in DCSR. Specify an address in DAR, a command in DCSR, and command data in DCR.

Set the DCSR.DALEN bit field to a non-zero value before writing to this register.

| | | | | | | | | | | | | | | | | |
|----------------|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | WD3[7:0] | | | | | | | | WD2[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | WD1[7:0] | | | | | | | | WD0[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|----------|---------------|-----|--|
| 31 to 24 | WD3[7:0] | All 0 | W | Write data 3 Set the third byte of the write data. |
| 23 to 16 | WD2[7:0] | All 0 | W | Write data 2 Set the second byte of the write data. |
| 15 to 8 | WD1[7:0] | All 0 | W | Write data 1 Set the first byte of the write data. |
| 7 to 0 | WD0[7:0] | All 0 | W | Write data 0 Set the zeroth byte of the write data. |

22.4.21 Configure Read Register (CRR)

CRR is used to execute a read command in the configuration mode and holds the data that are read. Reading from this register makes the controller issue a read command and the data that are read are stored in this register. Specify an address in DAR, a command in DCSR, and command data in DCR.

| | | | | | | | | | | | | | | | | |
|----------------|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | RD3[7:0] | | | | | | | | RD2[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | RD1[7:0] | | | | | | | | RD0[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|----------|---------------|-----|--|
| 31 to 24 | RD3[7:0] | All 0 | R | Read data 3 Store the third byte of the read data. |
| 23 to 16 | RD2[7:0] | All 0 | R | Read data 2 Store the second byte of the read data. |
| 15 to 8 | RD1[7:0] | All 0 | R | Read data 1 Store the first byte of the read data. |

| Bit | Bit Name | Initial Value | R/W | Description |
|--------|----------|---------------|-----|--|
| 7 to 0 | RD0[7:0] | All 0 | R | Read data 0 Store the zeroth byte of the read data. |

22.5 Operation

22.5.1 Octa Memory Controller System Configuration

Figure 22.2 shows an example of connections between the Octa memory controller in this LSI and OctaFlash and OctaRAM devices.

CS0# should be connected to the OctaFlash device and CS1# should be connected to the OctaRAM device.

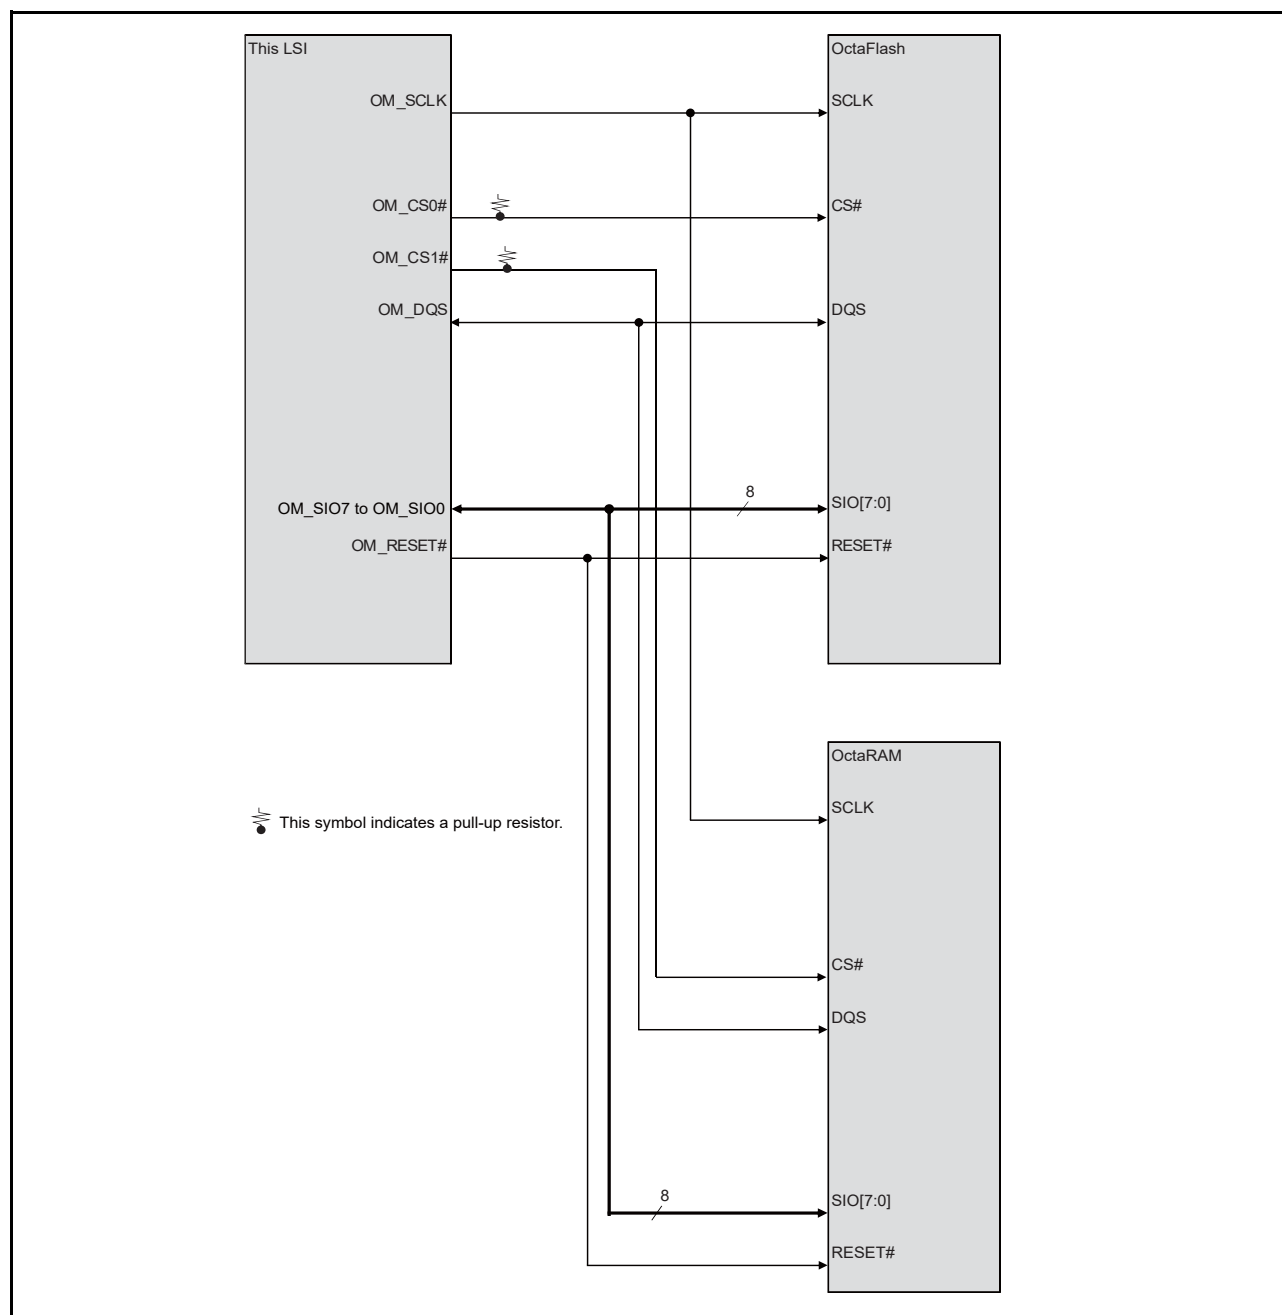

Figure 22.2 Example of Connections between this LSI and OctaFlash and OctaRAM Devices

22.5.2 Address Map

In the memory-map mode, OctaFlash is allocated to the OctaFlash space (H'50000000 to H'5FFFFFFF), and OctaRAM is allocated to the OctaRAM space (H'60000000 to H'607FFFFF).

One OctaFlash device and one OctaRAM device can be connected to this LSI.

| | Internal Address | Maximum Accessible Area |
|-----------|--------------------------|-------------------------|
| OctaFlash | H'50000000 to H'5FFFFFFF | Up to 256 Mbytes |
| OctaRAM | H'60000000 to H'607FFFFF | Up to 8 Mbytes |

22.5.3 Octa Memory Interface

This section describes the Octa memory interface.

22.5.3.1 Write Operation

The Octa memory controller outputs a command and an address and writes one or more data bytes by using lines OM_CS0# (OM_CS1#), OM_SCLK, and OM_SIO7 to OM_SIO0.

The write operation for OctaRAM has latency cycles before data is written to memory.

Figure 22.3 to Figure 22.5 show waveforms of the write operation in the OctaFlash interface, and Figure 22.6 shows a waveform of the write operation in the OctaRAM interface.

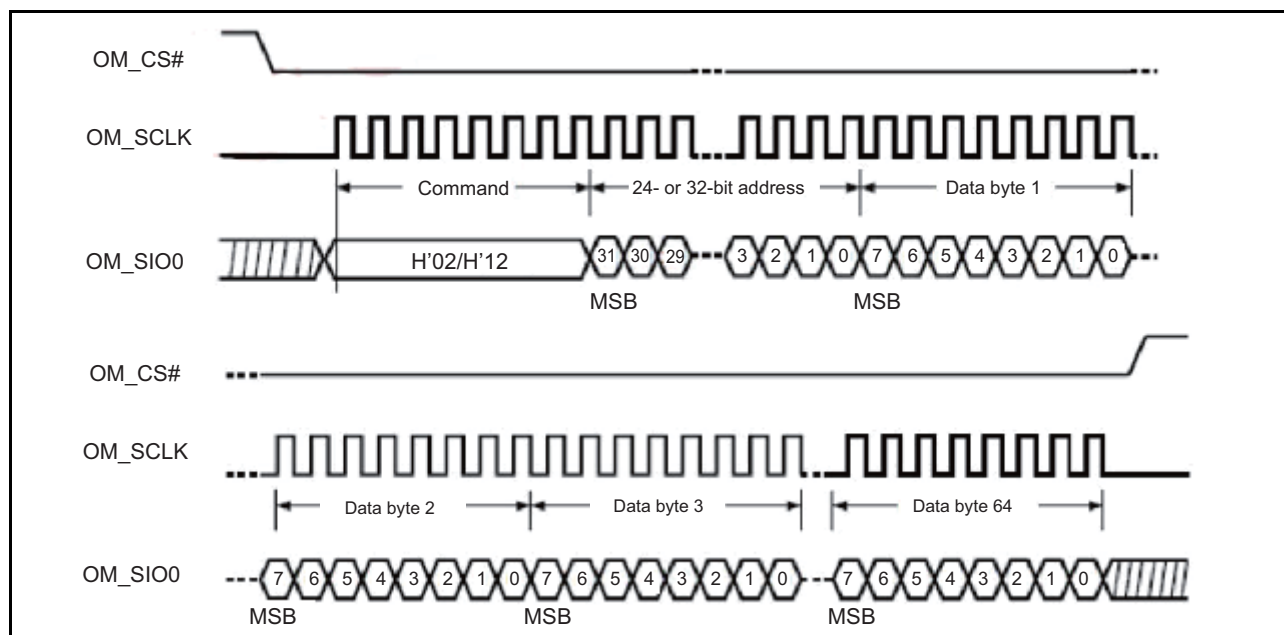

Figure 22.3 Waveform of Write Operation in OctaFlash Interface (SPI Mode)

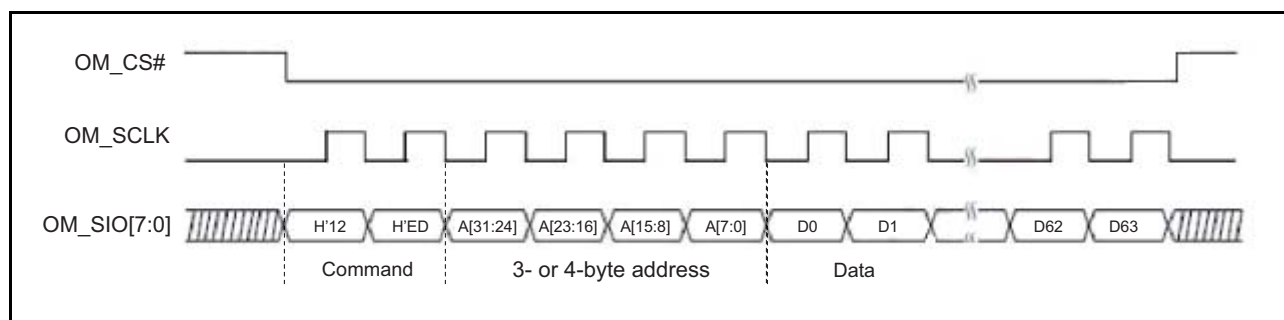

Figure 22.4 Waveform of Write Operation in OctaFlash Interface (SOPI Mode)

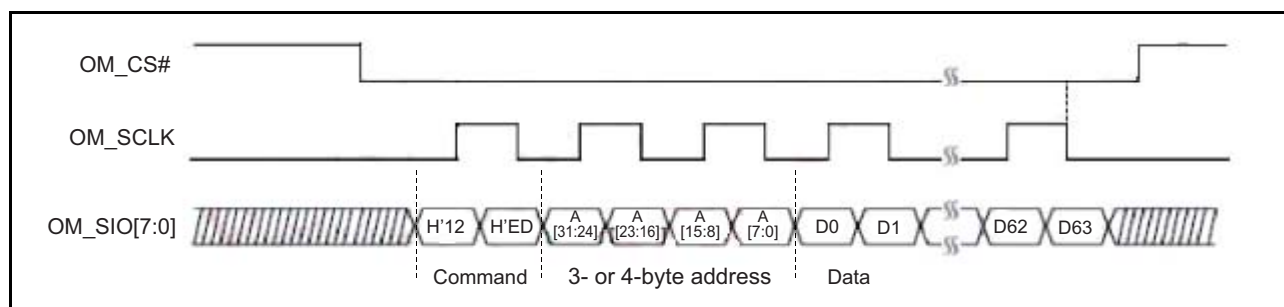

Figure 22.5 Waveform of Write Operation in OctaFlash Interface (DOPI Mode)

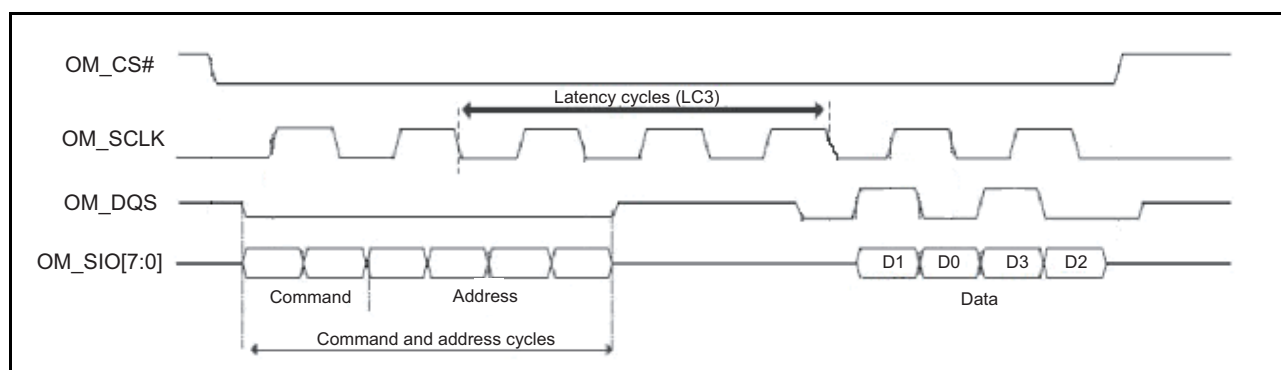

Figure 22.6 Waveform of Write Operation in OctaRAM Interface

22.5.3.2 Read Operation

The Octa memory controller outputs a command and an address and reads one or more data bytes by using lines OM_CS0# (OM_CS1#), OM_SCLK, and OM_SIO7 to OM_SIO0.

The read operation for OctaFlash and OctaRAM has latency cycles before data is read from memory.

The number of latency cycles should be specified in the memory map dummy length setting register (MDLR) (see section 22.4.14) in accordance with the setting in the memory device.

Figure 22.7 to Figure 22.9 show waveforms of the read operation in the OctaFlash interface, and Figure 22.10 shows a waveform of the read operation in the OctaRAM interface.

Figure 22.7 Waveform of Read Operation in OctaFlash Interface (SPI Mode)

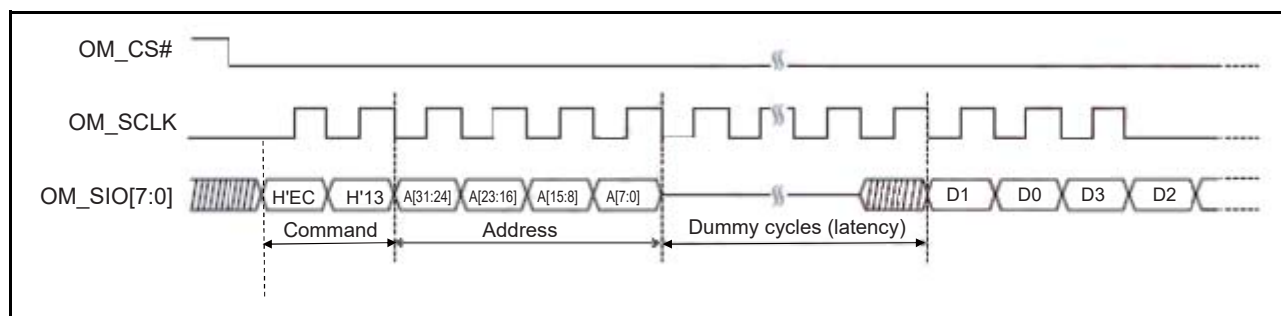

Figure 22.8 Waveform of Read Operation in OctaFlash Interface (SOPI Mode)

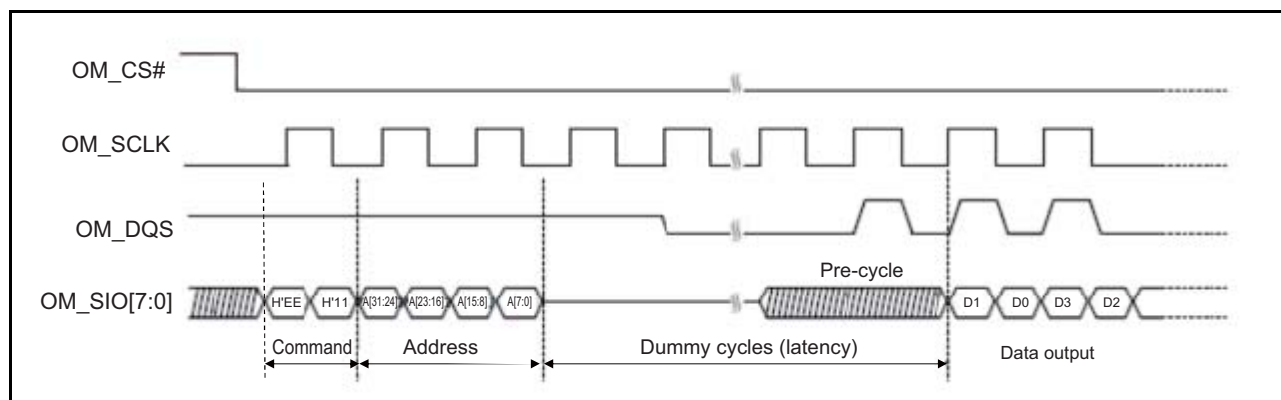

Figure 22.9 Waveform of Read Operation in OctaFlash Interface (DOPI Mode with Pre-cycle Enabled)

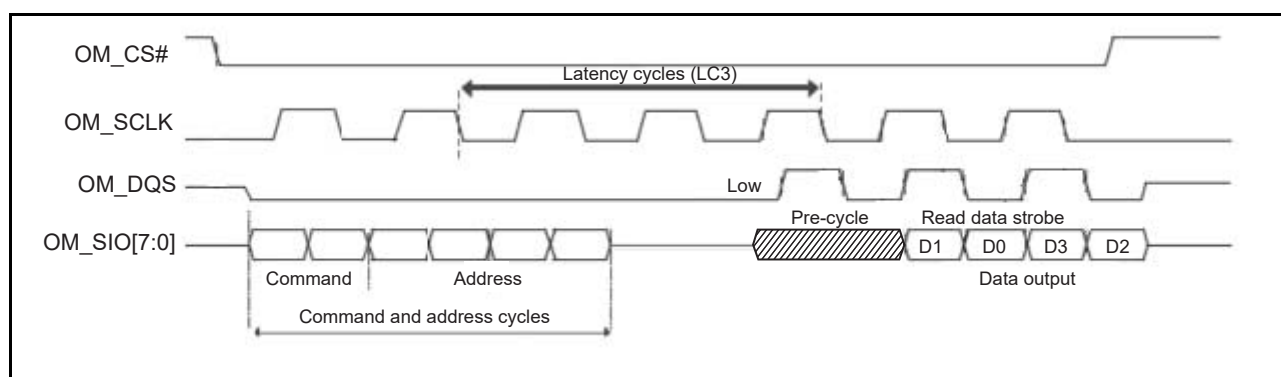

Figure 22.10 Waveform of Read Operation in OctaRAM Interface (with Pre-cycle Enabled)

22.5.4 Data Alignment in the OctaFlash and OctaRAM Spaces

Figure 22.11 shows the memory data alignment in the OctaFlash and OctaRAM spaces.

Figure 22.12 shows the data alignment when the configuration register in OctaFlash or OctaRAM is accessed.

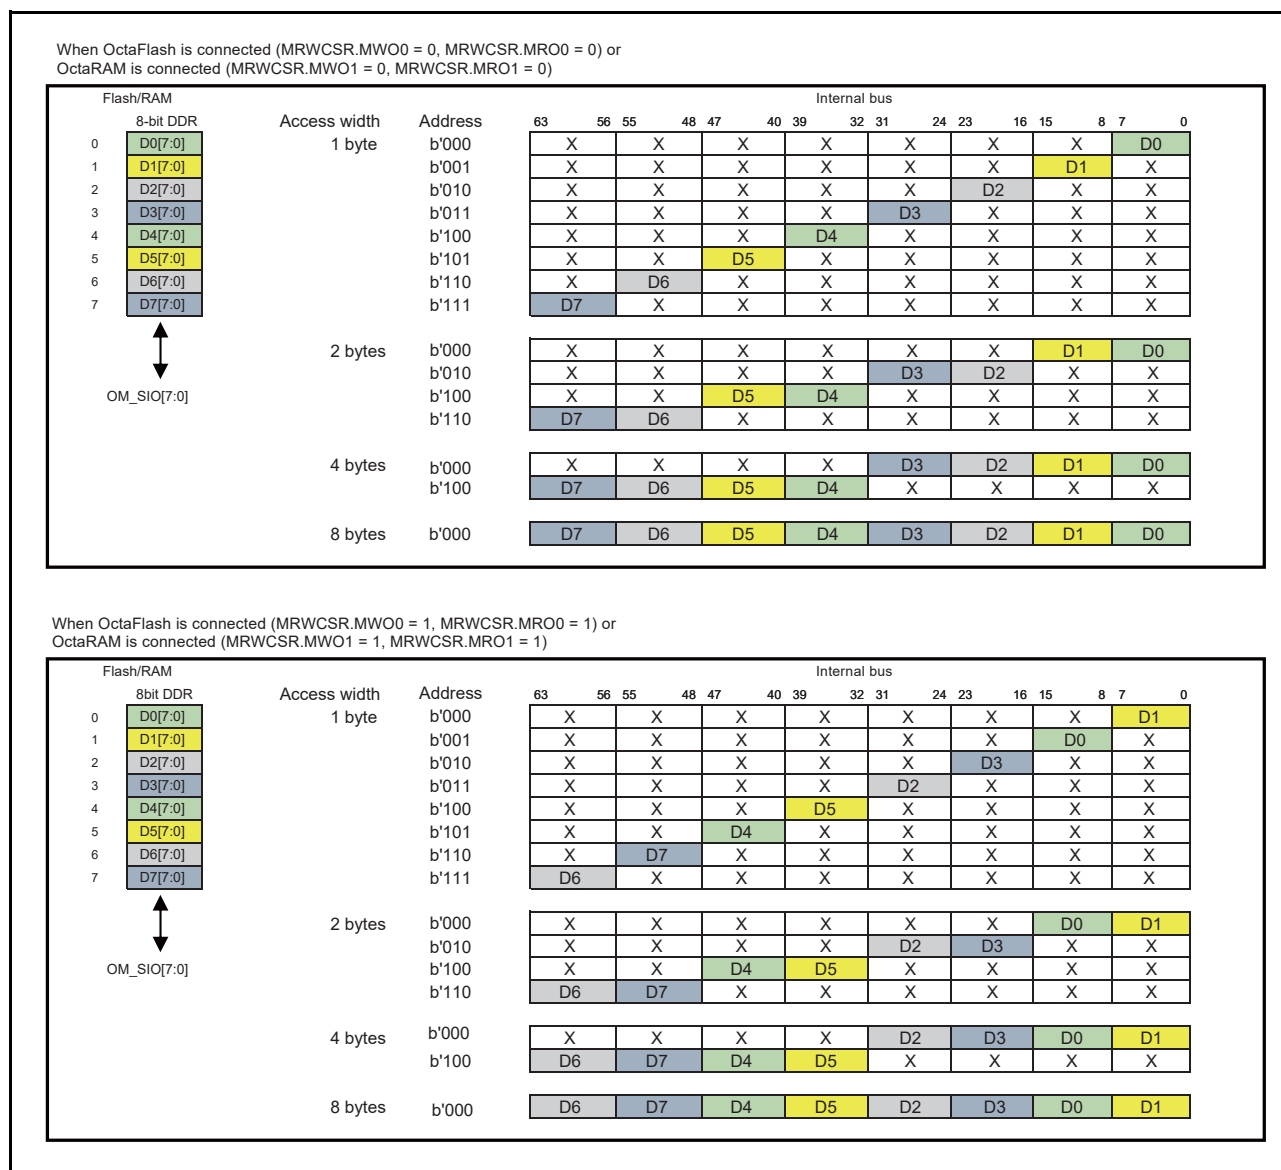

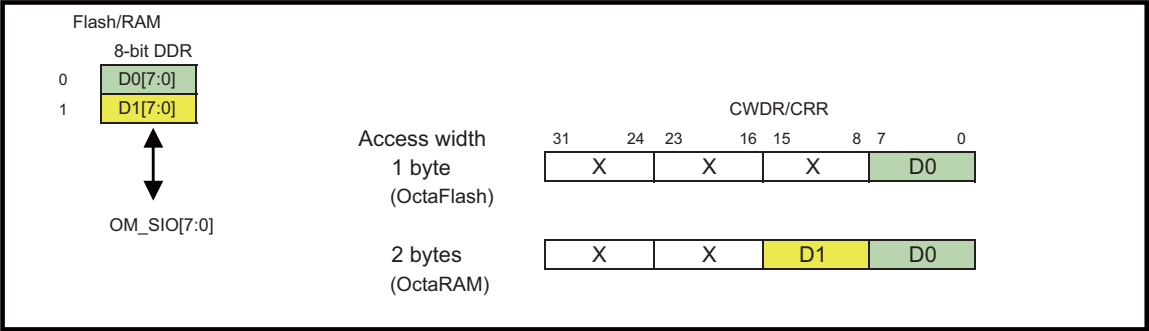

Figure 22.11 Memory Data Alignment in the OctaFlash and OctaRAM Spaces

When OctaFlash is connected (DCSR.DAOR = 0),
OctaRAM is connected (DCSR.DAOR = 0), or
OctaFlash/OctaRAM is connected

When OctaFlash is connected (DCSR.DAOR = 1),
OctaRAM is connected (DCSR.DAOR = 1), or
OctaFlash/OctaRAM is connected

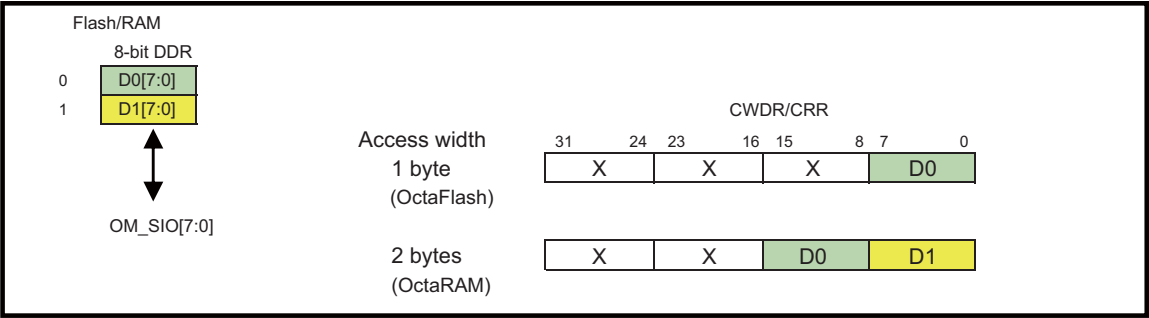

Figure 22.12 Configuration Register Data Alignment in the OctaFlash and OctaRAM Spaces

22.5.5 One-Byte Write Access to an Octa Memory Device in the DOPI Mode

This section describes one-byte write access in the DOPI mode.

Writing to the Octa memory device in the DOPI mode is handled in 2-byte units.

When the target device is OctaRAM, the output OM_DQS signal of the controller can be used to mask bytes by driving it to the high level during the operation of writing. This allows the masking of invalid write data.

When the target device is OctaFlash, one-byte write access must not be attempted since HyperFlash only supports two-byte access.

Figure 22.13 shows the waveforms in one-byte write access in the DOPI mode.

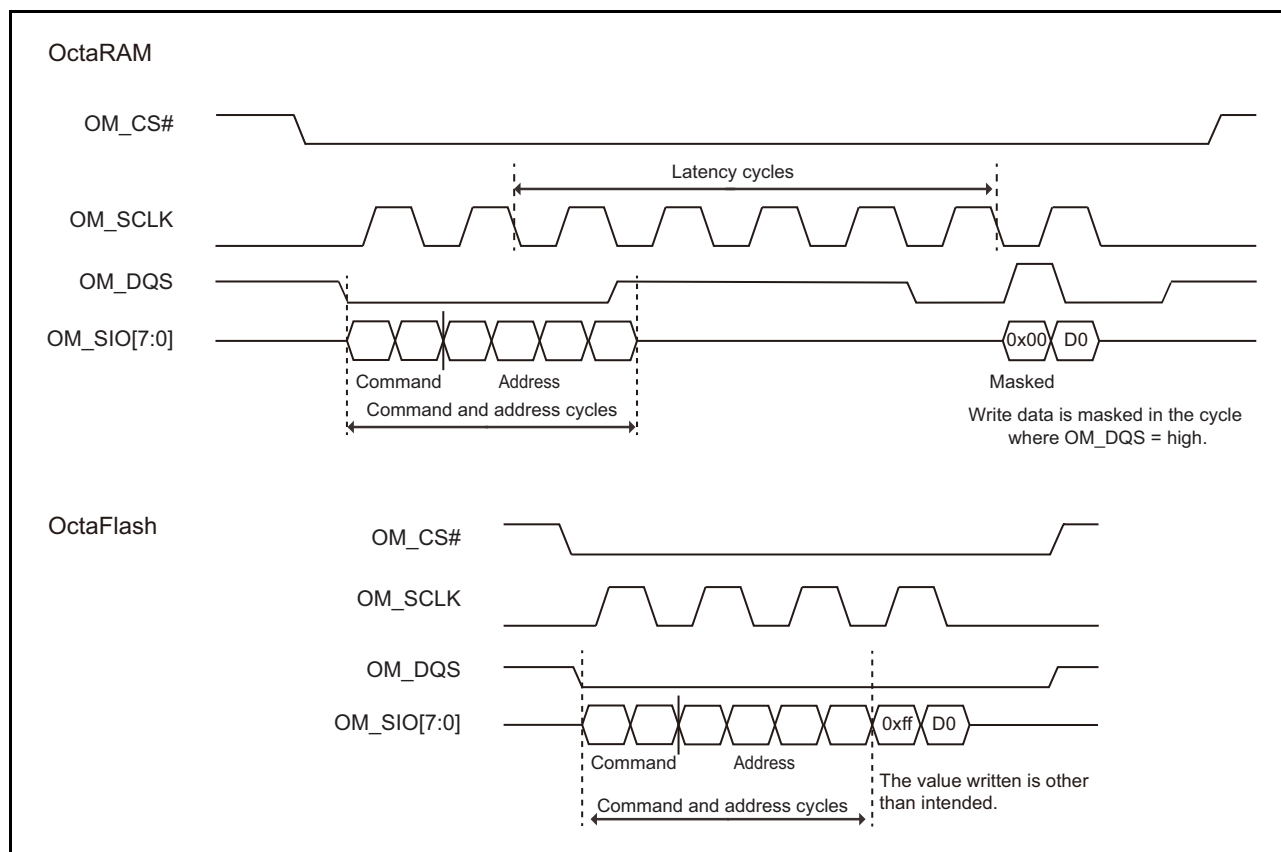

Figure 22.13 Waveforms in One-Byte Write Access in the DOPI Mode

22.5.6 Operation Flows

This section describes the flows of Octa memory controller operations for various purposes.

The following only shows sample settings, and appropriate commands and data should be specified in accordance with the specifications of the target memory device.

The sample settings assume the following environment.

- (1) Memory connections: CS0 (device 0) to OctaFlash and CS1 (device 1) to OctaRAM
- (2) OM_SCLK (Octa memory clock) frequency: 132 MHz

22.5.6.1 Initial Settings

The following shows an example of initial settings of the Octa memory controller.

Before access to the external memory, set up the HOSEL bit in the HyperBus controller and Octa memory controller dedicated pin control register (PHMOM0) in the initial setting steps.

For the HOSEL bit, refer to section 51, GPIO.

Table 22.6 Example of Initial Settings of the Octa Memory Controller

| Step | Read/Write | Address (Register) | Data | Data Length (Bytes) | Description |
|------|------------|-----------------------|------------|---------------------------|---|
| 1 | Write | DSR0 | H'08000000 | 4 | Specifies the type and size of device 0. |
| 2 | Write | DSR1 | H'40800000 | 4 | Specifies the type and size of device 1. |
| 3 | Write | MDTR | H'0740A640 | 4 | Adjusts the memory access timings. |
| 4 | Write | DRCSTR | H'29002900 | 4 | Specifies the read timing for each device. |
| 5 | Write | DWCSTR | H'1A001A00 | 4 | Specifies the write timing for each device. |
| 6 | Write | DCSTR | H'00002900 | 4 | Specifies the timings of the chip select signals. |
| 7 | Write | CDSR | H'0000000A | 4 | Sets up the controller functions. (1) Memory pre-cycle is enabled or disabled. (2) Transfer type is specified (SPI, SOPI, or DOPI). |
| 8 | Write | MDLR | H'05050E0E | 4 | Specifies number of dummy cycles (latency). |
| 9 | Write | MRWCR0 | H'12EDEE11 | 4 | Specifies the read and write commands for device 0. |
| 10 | Write | MRWCR1 | H'2000A000 | 4 | Specifies the read and write commands for device 1. |
| 11 | Write | MRWCSR | H'54545454 | 4 | Sets up the memory-mapped reading and writing. (1) The length (bytes) of a command is specified. (2) The length (bytes) of an address is specified. (3) The order of bytes to be written is specified. |

Note: Set up the HOSEL bit in the HyperBus controller and Octa memory controller dedicated pin control register (PHMOM0).
For the HOSEL bit, refer to section 51, GPIO.

22.5.6.2 Basic Operation Settings

This section describes the basic operations of OctaFlash and OctaRAM.

The following only shows sample settings, and appropriate commands and data should be specified in accordance with the specifications of the target memory device.

(1) OctaFlash Operation Settings

1. Write Enable Settings

| Step | Read/ Write | Register | SPI Mode | | OPI Mode | | Description |
|------|----------------|----------|------------|------------------------|------------|------------------------|-------------|
| | | | Data | Data Length (Bytes) | Data | Data Length (Bytes) | |
| 1 | Write | DCR | H'00000006 | 4 | H'000006F9 | 4 | |
| 2 | Write | DCSR | H'00100000 | 4 | H'00200000 | 4 | |
| 3 | Write | CWNR | Any value | 4 | Any value | 4 | |

2. Read Status Register

| Step | Read/ Write | Register | SPI Mode | | OPI Mode | | Description |
|------|----------------|----------|------------|------------------------|------------|------------------------|--|
| | | | Data | Data Length (Bytes) | Data | Data Length (Bytes) | |
| 1 | Write | DCR | H'00000005 | 4 | H'000005FA | 4 | |
| 2 | Write | DAR | — | — | H'00000000 | 4 | |
| 3 | Write | DCSR | H'00100001 | 4 | H'0C200401 | 4 | |
| 4 | Read | CRR | H'000000xx | 1 | H'000000xx | 1 | The high-order 24 bits are all set to 0s, and the read data is stored in the low-order eight bits. |

3. Read Configuration Register

| Step | Read/ Write | Register | SPI Mode | | OPI Mode | | Description |
|------|----------------|----------|------------|------------------------|------------|------------------------|--|
| | | | Data | Data Length (Bytes) | Data | Data Length (Bytes) | |
| 1 | Write | DCR | H'00000015 | 4 | H'000015EA | 4 | |
| 2 | Write | DAR | — | — | H'00000001 | 4 | |
| 3 | Write | DCSR | H'00100001 | 4 | H'0C200401 | 4 | |
| 4 | Read | CRR | H'000000xx | 1 | H'000000xx | 1 | The high-order 24 bits are all set to 0s, and the read data is stored in the low-order eight bits. |

4. Write Configuration Register

| Step | Read/ Write | Register | SPI Mode | | OPI Mode | | Description |
|------|----------------|----------|----------|------------------------|------------|------------------------|---|
| | | | Data | Data Length (Bytes) | Data | Data Length (Bytes) | |
| 1 | Write | DCR | - | - | H'000001FE | 4 | |
| 2 | Write | DAR | - | - | H'00000001 | 4 | |
| 3 | Write | DCSR | - | - | H'04200001 | 4 | |
| 4 | Write | CWDR | - | - | H'000000xx | 1 | Set all the high-order 24 bits to 0s, and specify the write data in the low-order eight bits. |

5. Read Configuration Register 2

| Step | Read/ Write | Register | SPI Mode | | OPI Mode | | Description |
|------|----------------|----------|------------|------------------------|------------|------------------------|--|
| | | | Data | Data Length (Bytes) | Data | Data Length (Bytes) | |
| 1 | Write | DCR | H'00000071 | 4 | H'0000718E | 4 | |
| 2 | Write | DAR | Address | 4 | Address | 4 | |
| 3 | Write | DCSR | H'04100001 | 4 | H'0C200401 | 4 | |
| 4 | Read | CRR | H'000000xx | 1 | H'000000xx | 1 | The high-order 24 bits are all set to 0s, and the read data is stored in the low-order eight bits. |

6. Write Configuration Register 2

| Step | Read/ Write | Register | SPI Mode | | OPI Mode | | Description |
|------|----------------|----------|------------|------------------------|------------|------------------------|---|
| | | | Data | Data Length (Bytes) | Data | Data Length (Bytes) | |
| 1 | Write | DCR | H'00000072 | 4 | H'0000728D | 4 | |
| 2 | Write | DAR | Address | 4 | Address | 4 | |
| 3 | Write | DCSR | H'04100001 | 4 | H'04200001 | 4 | |
| 4 | Write | CWDR | H'000000xx | 1 | H'000000xx | 1 | Set all the high-order 24 bits to 0s, and specify the write data in the low-order eight bits. |

7. Memory-Map Write and Read Command Settings

| Step | Read/ Write | Register | SPI Mode | | OPI Mode | | Description |
|------|----------------|----------|------------|------------------------|------------|------------------------|-------------|
| | | | Data | Data Length (Bytes) | Data | Data Length (Bytes) | |
| 1 | Write | MRWCR0 | H'00120013 | 4 | H'12EDEE11 | 4 | |
| 2 | Write | MRWCSR | H'00000C0C | 4 | H'00005454 | 4 | |

8. Erase Sector

| Step | Read/ Write | Register | SPI Mode | | OPI Mode | | Description |
|------|----------------|----------|----------------------|------------------------|----------------------|------------------------|-------------|
| | | | Data | Data Length (Bytes) | Data | Data Length (Bytes) | |
| 1 | Write | DCR | H'00000021 | 4 | H'000021DE | 4 | |
| 2 | Write | DAR | Address to be erased | 4 | Address to be erased | 4 | |
| 3 | Write | DCSR | H'04100000 | 4 | H'04200000 | 4 | |
| 4 | Write | CWNR | Any value | 4 | Any value | 4 | |

(2) OctaRAM Operation Settings

1. Read Configuration Register

| Step | Read/ Write | Register | Data | Data Length (Bytes) | Description |
|------|----------------|----------|------------|---------------------|---|
| 1 | Write | DCR | H'0000C000 | 4 | |
| 2 | Write | DAR | H'00040000 | 4 | |
| 3 | Write | DCSR | H'04A80502 | 4 | |
| 4 | Read | CRR | H'0000xxxx | 2 | The high-order 16 bits are all set to 0s, and the read data is stored in the low-order 16 bits. |

2. Write Configuration Register

| Step | Read/ Write | Register | Data | Data Length (Bytes) | Description |
|------|----------------|----------|------------|---------------------|--|
| 1 | Write | DCR | H'00004000 | 4 | |
| 2 | Write | DAR | H'00040000 | 4 | |
| 3 | Write | DCSR | H'04A80002 | 4 | |
| 4 | Write | CWDR | H'0000xxxx | 2 | Set all the high-order 16 bits to 0s, and specify the write data in the low-order 16 bits. |

22.6 Delaying OM_DQS and Auto-Calibration

22.6.1 Delaying OM_DQS

Depending on the characteristics of the DOPI mode, the controller might not be able to latch data on the rising and falling edges of the OM_DQS clock signal. OM_DQS will then require a delay to allow the latching of data with sufficient margins for the setup and hold times. The DV1DEL[7:0] and DV0DEL[7:0] bits in the memory delay trimming register (MDTR) can be used to specify the amount of delay.

Figure 22.14 shows how a delayed OM_DQS becomes asserted at a good time for latching of the data.

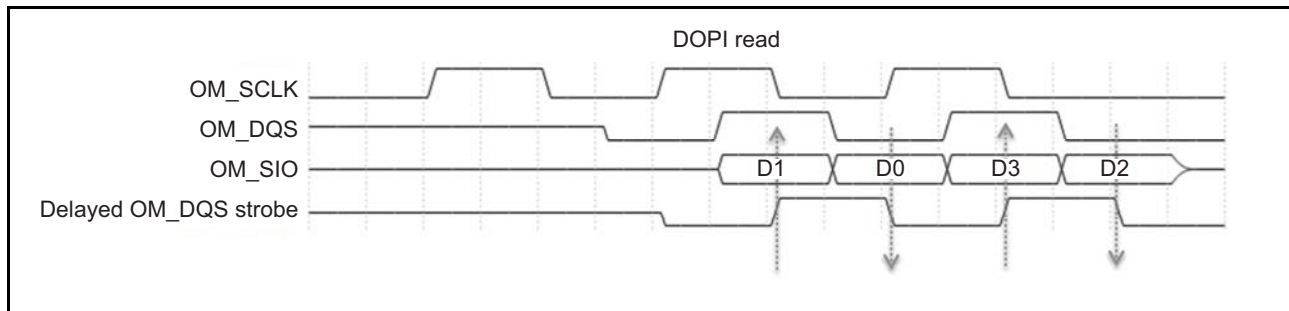

Figure 22.14 Example of Securing the Latching of Data by Delaying OM_DQS

22.6.2 OM_DQS Auto-Calibration

This LSI has an automatic calibration to prevent acquisition of wrong data due to the variation of voltage and temperature. When using the automatic calibration, set the following registers.

- Controller and device setting register (CDSR)
 - Automatic calibration mode ACMODE[1:0] bits setting
- Auto-calibration timer register (ACTR)
 - Automatic calibration cycle time setting
- Auto-calibration address registers 0 and 1 (ACAR0/ACAR1)
 - Preamble pattern store address setting

Automatic calibration requires 16 bytes user area to store the preamble pattern. Store the preamble pattern to the setting address of ACAR0 and ACAR1.

Preamble pattern: H'00F708F7 FF0000F7 0800FF00 FFFF0000

When MRWCSR.MRO1 or MRWCSR.MRO0 is 0,

H'00F708F7 FF0000F7 0800FF00 FFFF0000

When MRWCSR.MRO1 or MRWCSR.MRO0 is 1,

H'F700F708 00FFF700 000800FF FFFF0000

store in the flash memory or RAM device.

The operation proceeds as follows when auto-calibration is enabled.

Once the time specified in ACTR has elapsed, the Octa memory controller varies the delay time for OM_DQS and checks whether the preamble pattern can correctly be read from the address specified in ACAR0 or ACAR1.

The preamble pattern is read 48 times per auto-calibration.

The controller seeks the most appropriate timing of latching in this sequence of reading and updates the DV0DEL or DV1DEL bits in MDTR with the result. This re-starts the timer for auto-calibration.

Note that access to the OctaFlash memory or OctaRAM area by the CPU or other bus masters is held pending until reading of the preamble data for auto-calibration is completed.

Figure 22.15 describes the flow of automatic calibration settings for OctaFlash and OctaRAM devices.

Before starting settings, check that the Octa memory controller is selected in the HOSEL bit in the HyperBus controller and Octa memory controller dedicated pin control register (PHMOM0).

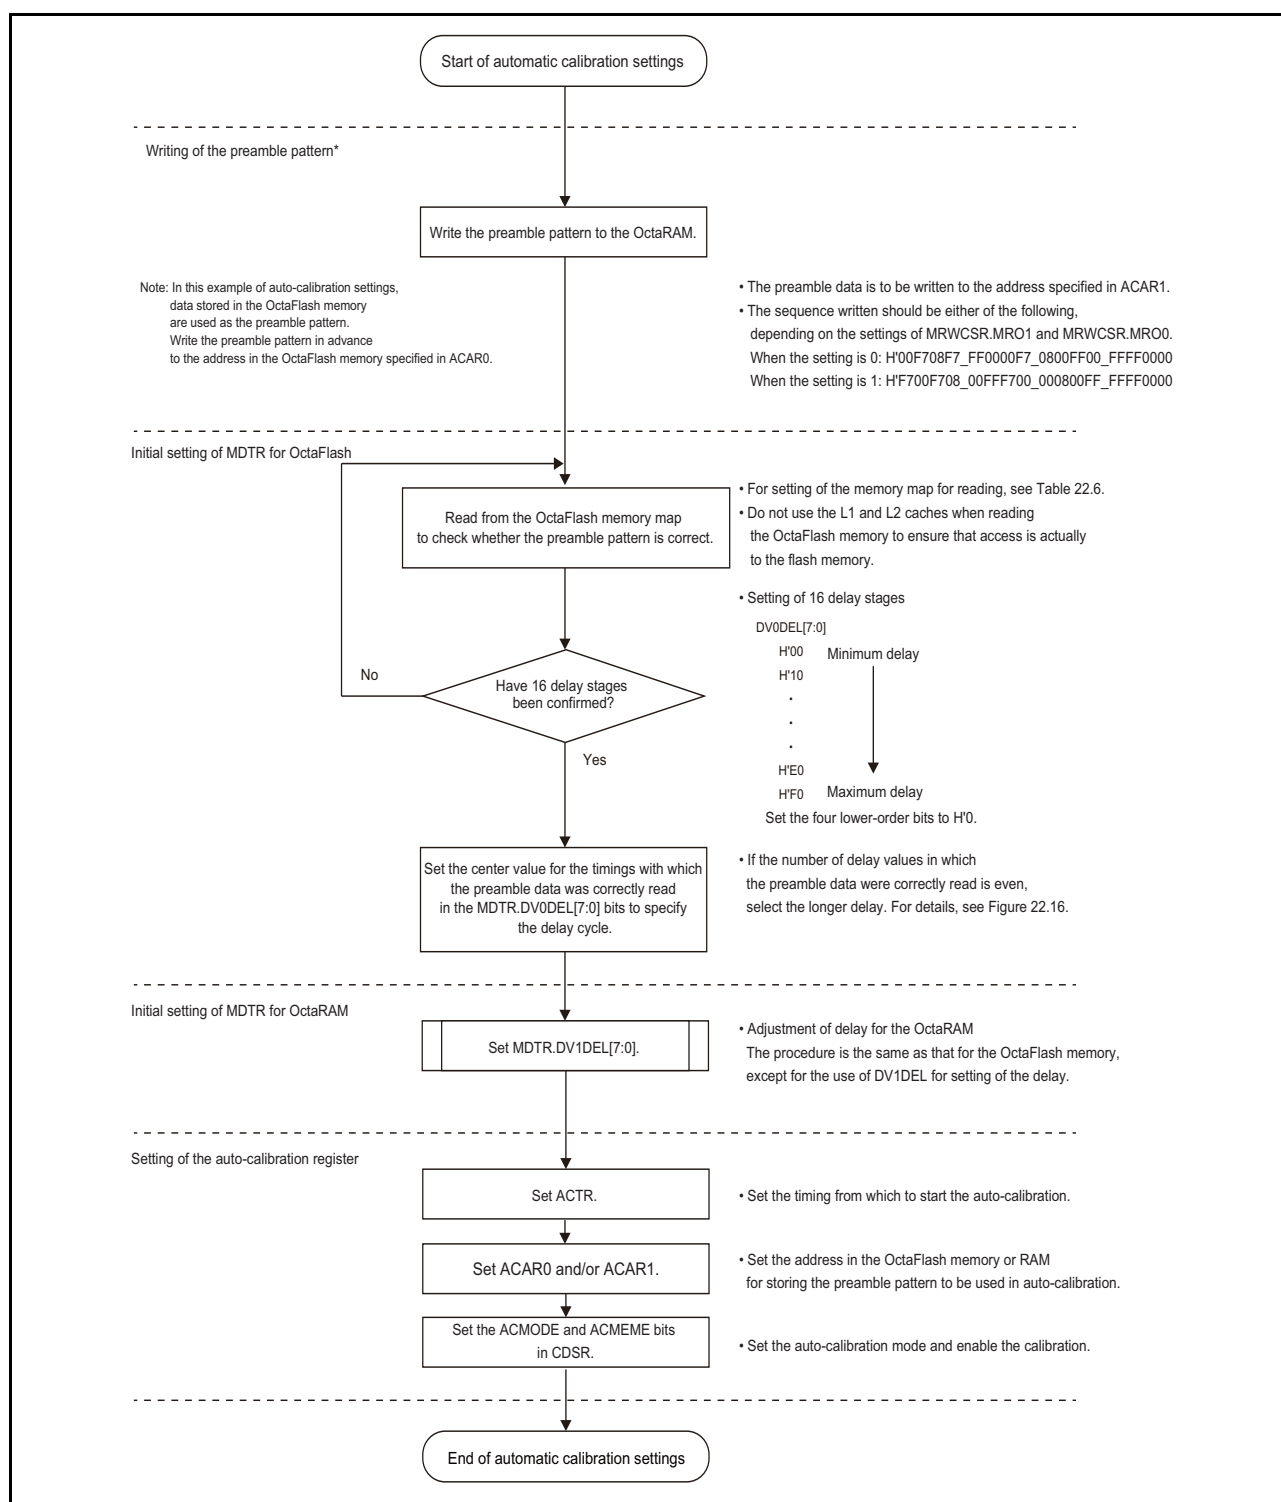

Figure 22.15 Flow of Settings for the Auto-Calibration Mode

Figure 22.16 shows an example of the initial setting of the DV0DEL or DV1DEL Bits in MDTR.

Figure 22.16 Example of the Initial Setting of the DV0DEL or DV1DEL Bits in MDTR

22.7 OM_DQS Enable Counter

During read command operation, the OM_DQS signal is used as the data latch clock by the controller. When the memory device is in the idle state, OM_DQS maintains a high impedance (Hi-Z) state, and asserts low before data is output. This Hi-Z to low transition may latch wrong data by driving the OM_DQS data latch logic of the controller.

Figure 22.15 shows the waveform when OM_DQS maintains a high-impedance (Hi-Z) state and asserts low before data is output.

Avoiding such Hi-Z to low transitions, this controller can bypass wrong data with memory delay trim register (MDTR). (MDTR.DQSEDOPI[3:0] for Flash DOPI mode, MDTR.DQSESOPI[3:0] for Flash SOPI mode, and MDTR.DQSERAM[3:0] for RAM mode)

Each of the bit fields can be set within the range from 0 to 15.

OM_DQS enable counter (MDTR) minimum value \geq Number of the command cycles + number of the address cycles*¹ + number of the stable OM_DQS cycles*² + number of the OM_DQS delay cycles*³
 OM_DQS enable counter (MDTR) maximum value \leq Number of the command cycles + number of the address cycles*¹ + number of the memory dummy cycles (latency) + number of the OM_DQS delay cycles*³ + pre-cycle setting*⁴

- Note 1. Flash SOPI: Number of the command cycles + number of the address cycles = 2 + 4 = 6
 Flash DOPI: Number of the command cycles + number of the address cycles = 1 + 2 = 3
 RAM DOPI: number of command cycles + number of address cycles = 1 + 2 - 1 = 2 (start dummy (latency) calculation from the second cycle)
- Note 2. Number of stable OM_DQS cycles: Maximum value is 2 cycles of OM_SCLK (Reference specification of OctaFlash / OctaRAM)
- Note 3. Number of the OM_DQS delay cycles: OM_DQS clock delay due to external causes
 When OM_DQS delay \leq 0.25 OM_SCLK: OM_DQS delay cycles = -1
 When 0.25 OM_SCLK < OM_DQS delay \leq 1.25 OM_SCLK: OM_DQS delay cycles = 0
 When 1.25 OM_SCLK < OM_DQS delay \leq 2.25 OM_SCLK: OM_DQS delay cycles = 1
 In the flash SOPI mode, read 0.25 as 0.5, 1.25 as 1.5, and 2.25 as 2.5 in the above expressions.
- Note 4. Pre-cycle setting: OM_DQS pre-cycle on/off
 OM_DQS pre-cycle off: Pre-cycle setting = 0
 OM_DQS pre-cycle on: Pre-cycle setting = -1

Setting example: Flash DOPI mode, dummy cycles (latency) = 4, pre-cycle is off

Minimum value of OM_DQS enable counter (MDTR) $\geq 1 + 2 + 2 + 0 = 5$

Maximum value of OM_DQS enable counter (MDTR) $\leq 1 + 2 + 4 + 0 = 7$

From the above, setting MDTR.DQSEDOPI[3:0] from 5 to 7 can latch the correct data. If MDTR is too small, wrong data may be latched due to a transition from Hi-Z to Low. If MDTR is too large, no data is latched.

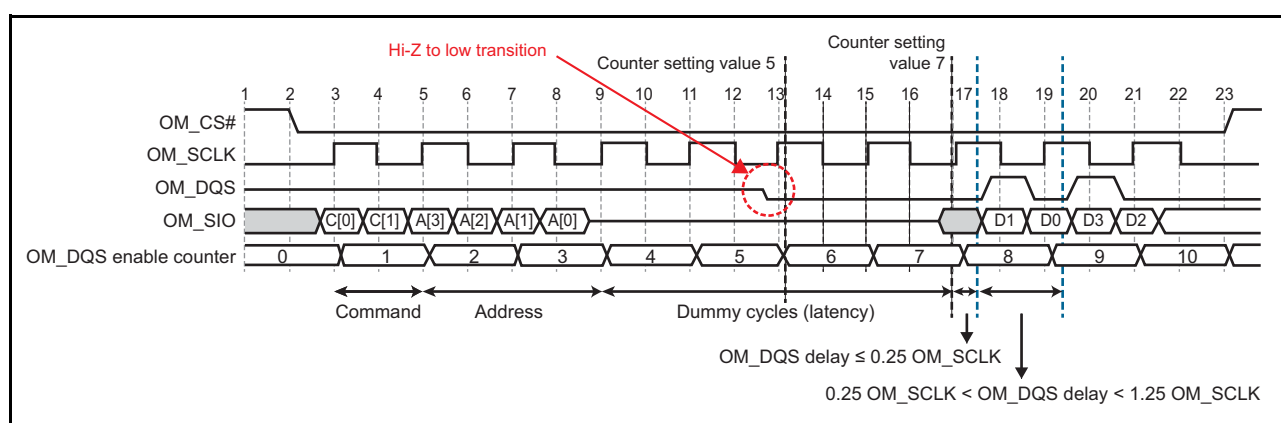

Figure 22.17 Timing of the OM_DQS Enable Counter in DOPI Mode for the Flash Memory with 4 as the Number of Dummy Cycles (Latency), and OM_DQS Pre-Cycle Off

23. I²C Bus Interface

This section gives an overall description of the I²C bus interface (RIIC).

The first section describes the features specific to this LSI, including the number of units and the register base addresses.

The subsequent sections describe the RIIC's functions and registers.

23.1 Features

23.1.1 Channels

This LSI has the following number of channels of the I²C bus interface (RIIC).

Table 23.1 Channels of RIIC

| Item | Description |
|--------------------|--------------------|
| Number of channels | 4 |
| Name | RIICn (n = 0 to 3) |

Table 23.2 Index

| Index | Description |
|-------|---|
| n | Throughout this section, the individual channels of the I ² C bus interface are identified by the index "n" (n = 0 to 3); for example, RIICnCR1 for the I ² C bus control register 1. |

23.1.2 Register Base Addresses

The base address <RIICn_base> of each RIICn is listed in the following table.

All RIICn register addresses are given as values obtained by adding offsets to the register base address <RIICn_base> for each channel.

Table 23.3 Register Base Address

| Channel | Base Address Name | Base Address |
|---------|-------------------|------------------------|
| RIIC0 | <RIIC0_base> | E803_A000 _H |
| RIIC1 | <RIIC1_base> | E803_A400 _H |
| RIIC2 | <RIIC2_base> | E803_A800 _H |
| RIIC3 | <RIIC3_base> | E803_AC00 _H |

23.1.3 External I/O Signals

The following table shows the external I/O signals of the RIIC.

Table 23.4 RIICn Pin Configuration

| Channel | Alternative Port Pin Name | Function |
|---------|---------------------------|----------------------------|
| RIIC0 | RIIC0SCL | RIIC0 serial clock I/O pin |
| | RIIC0SDA | RIIC0 serial data I/O pin |
| RIIC1 | RIIC1SCL | RIIC1 serial clock I/O pin |
| | RIIC1SDA | RIIC1 serial data I/O pin |
| RIIC2 | RIIC2SCL | RIIC2 serial clock I/O pin |
| | RIIC2SDA | RIIC2 serial data I/O pin |
| RIIC3 | RIIC3SCL | RIIC3 serial clock I/O pin |
| | RIIC3SDA | RIIC3 serial data I/O pin |

23.2 Overview

23.2.1 Functional Overview

Communications format

- I²C bus format or SMBus format
- Master mode or slave mode selectable
- Automatic securing of the various set-up times, hold times, and bus-free times for the transfer rate

Transfer rate

Up to 1 Mbps

SCL clock

For master operation, the duty cycle of the SCL clock is selectable in the following range.

0% < Duty cycle < 100%.

Issuing and detecting conditions

- Start, restart, and stop conditions are automatically generated.
- Start conditions (including restart conditions) and stop conditions are detected.

Slave address

- Up to three slave-address settings can be made.
- Seven- and ten-bit address formats are supported (along with the use of both at once).
- General call addresses, device ID addresses, and SMBus host addresses are detected.

Acknowledgement

- For transmission, the acknowledge bit is automatically loaded
 - Transfer of the next data for transmission can be automatically suspended on detection of a not-acknowledge bit.
- For reception, the acknowledge bit is automatically transmitted
 - If a wait between the eighth and ninth clock cycles has been selected, software control of the value in the acknowledge field in response to the received value is possible.

Wait function

- In reception, the following periods of waiting can be obtained by holding the clock signal (SCL) at the low level:
 - Waiting between the eighth and ninth clock cycles
 - Waiting between the ninth clock cycle and the first clock cycle of the next transfer (WAIT function)

SDA output delay function

Timing of the output of transmitted data, including the acknowledge bit, can be delayed.

Arbitration

- For multi-master operation
 - Operation to synchronize the SCL (clock) signal in cases of conflict with the SCL signal from another master is possible.
 - When issuing the start condition would create conflict on the bus, loss of arbitration is detected by testing for non-matching between the internal signal for the SDA line and the level on the SDA line.
 - In master operation, loss of arbitration is detected by testing for non-matching between the signal on the SDA line and the internal signal for the SDA line.
- Loss of arbitration due to detection of the start condition while the bus is busy is detectable (to prevent the issuing of double start conditions).
- Loss of arbitration in transfer of a not-acknowledge bit due to the internal signal for the SDA line and the level on the SDA line not matching is detectable.
- Loss of arbitration due to non-matching of internal and line levels for data is detectable in slave transmission.

Timeout function

The internal time-out function is capable of detecting long-interval stop of the SCL (clock signal).

Noise removal

The interface incorporates analog noise filters and digital noise filters for input on the RIICnSCL and RIICnSDA pins, and the width for noise cancellation by the digital noise filters is adjustable by software.

Interrupt sources

- Eight sources:
 - Transmission complete
 - Receive-data-full
 - Transmit-data-empty
 - Detection of a stop condition
 - Detection of a start condition
 - Reception of a NACK
 - Arbitration lost
 - Timeout

Low power consumption function

Module-stop state can be set.

23.2.2 Block Diagram

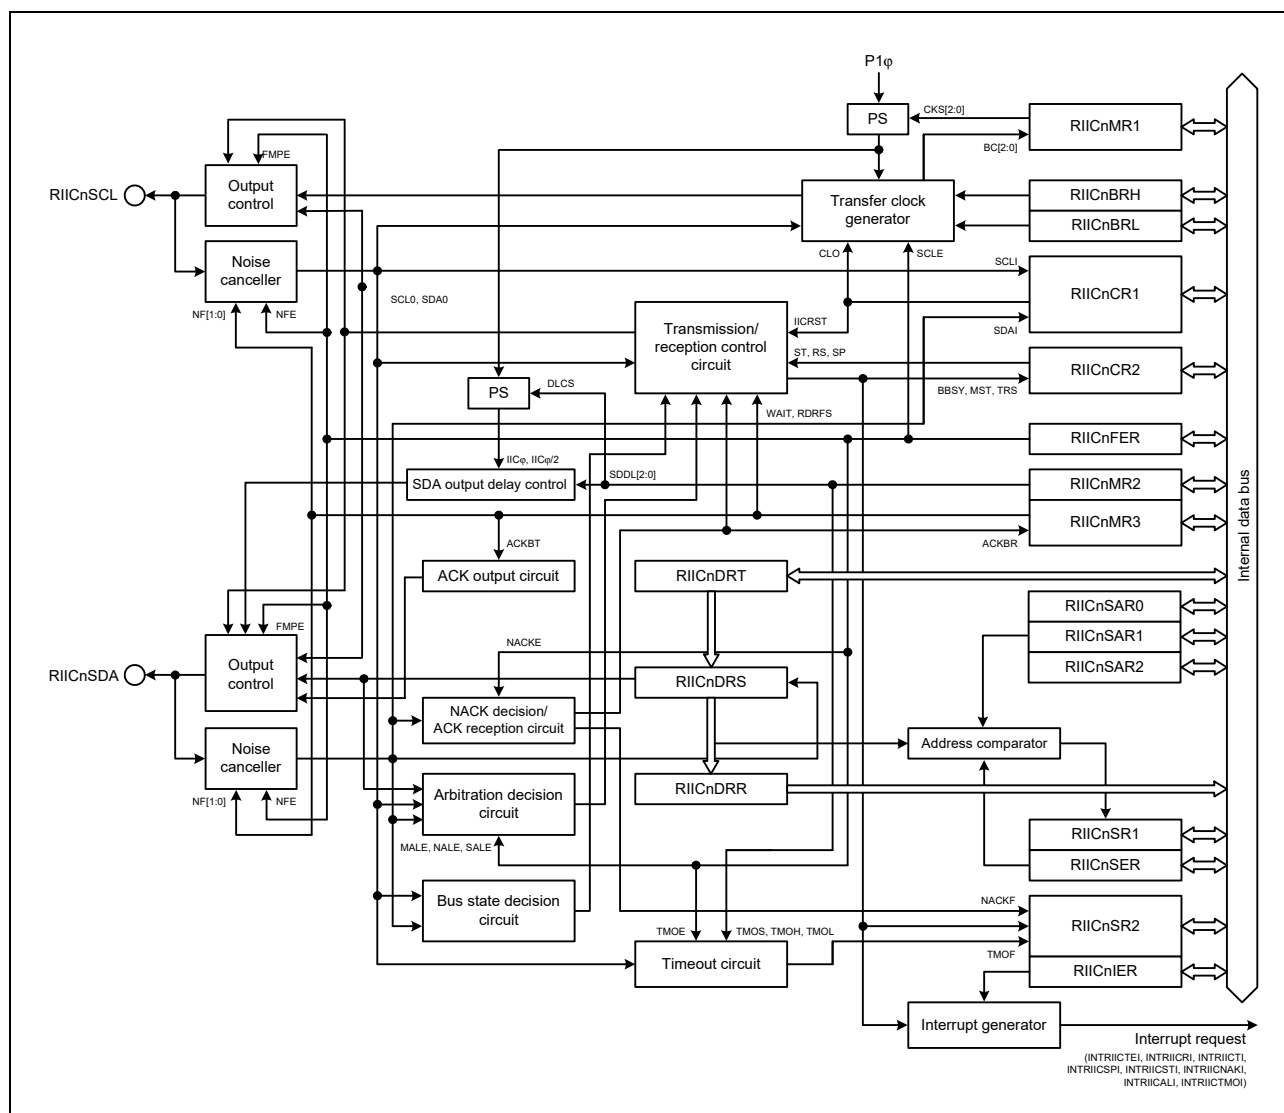

Figure 23.1 Block Diagram of RIIC

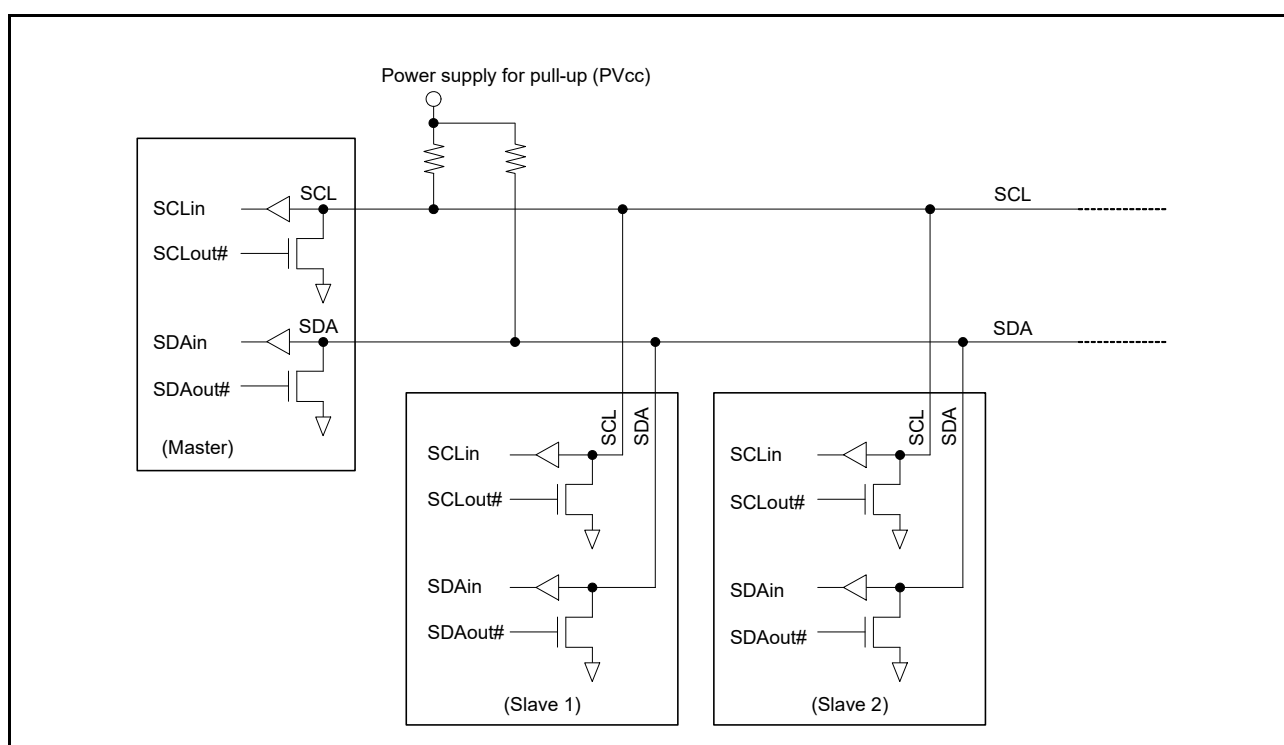

Figure 23.2 Connections to the External Circuit by the I/O Pins (I²C Bus Configuration Example)

RIICnSCL and RIICnSDA are Schmitt input/open-drain output pins for both master and slave operations. Because the output is open drain, an external pull-up resistor is required.

23.3 Registers

| Channel | Register Name | Abbreviation | Address | Access Size |
|---------|---|--------------|------------|-------------|
| RIIC0 | I ² C bus control register 1 | ICCR1 | E803 A000h | 8, 16, 32 |
| | I ² C bus control register 2 | ICCR2 | E803 A004h | 8, 16, 32 |

23.3.1 RIICnCR1 — I²C Bus Control Register 1

Access: RIICnCR1 is a 32-bit readable/writable register.
 RIICnCR1L and RIICnCR1H are 16-bit readable/writable registers.
 RIICnCR1LL, RIICnCR1LH, RIICnCR1HL, and RIICnCR1HH are 8-bit readable/writable registers.

Address: RIICnCR1: <RIICn_base> + 0000_H
 RIICnCR1L: <RIICn_base> + 0000_H, RIICnCR1H: <RIICn_base> + 0002_H
 RIICnCR1LL: <RIICn_base> + 0000_H, RIICnCR1LH: <RIICn_base> + 0001_H, RIICnCR1HL: <RIICn_base> + 0002_H,
 RIICnCR1HH: <RIICn_base> + 0003_H

Initial Value: 0000 001F_H. This register is initialized by any reset.

Table 23.5 RIICnCR1 register contents (1/2)

| Bit Position | Bit Name | Function |
|--------------|----------------------|--|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 | ICE | I ² C Bus Interface Enable 0: Output to the RIICnSCL and RIICnSDA pins is disabled. (Input to the RIICnSCL and RIICnSDA pins is enabled.) 1: Enabled (RIICnSCL and RIICnSDA pins are in the driving state) (An RIIC reset or an internal reset is selected according to the combination of this bit and IICRST bit settings.) |
| 6 | IICRST | I ² C Bus Interface Internal Reset 0: Clears the RIIC reset or internal reset. 1: Initiates the RIIC reset or internal reset. (Clears the bit counter and the SCL/SDA output latch) |
| 5 | CLO | Extra SCL Clock Cycle Output 0: Does not output an extra SCL clock cycle (default). 1: Outputs an extra SCL clock cycle. (The CLO bit is cleared automatically after one clock cycle is output.) |
| 4 | SOWP ^{*2} | SCLO/SDAO Write Protect 0: Allows the SCLO and SDAO bits to be rewritten. (This bit is read as 1.) |
| 3 | SCLO ^{*1,2} | SDA Output Control <ul style="list-style-type: none"> Read: <ul style="list-style-type: none"> 0: RIICnSCL pin output is at a low level. 1: RIICnSCL pin is in a high-impedance state. Write: <ul style="list-style-type: none"> 0: Changes the RIICnSCL pin output to a low level. 1: Changes the RIICnSCL pin in a high-impedance state. (High level output is achieved through an external pull-up resistor.) |

Table 23.5 RIICnCR1 register contents (2/2)

| Bit Position | Bit Name | Function |
|--------------|-----------|--|
| 2 | SDAO*1,*2 | SDA Output Control <ul style="list-style-type: none"> • Read: <ul style="list-style-type: none"> 0: RIICnSDA pin output is at a low level. 1: RIICnSDA pin is in a high-impedance state. • Write: <ul style="list-style-type: none"> 0: Changes the RIICnSDA pin output to a low level. 1: Changes the RIICnSDA pin in a high-impedance state. (High level output is achieved through an external pull-up resistor.) |
| 1 | SCLI | SCL Bus Input Monitor <ul style="list-style-type: none"> 0: RIICnSCL pin input is at a low level. 1: RIICnSCL pin input is at a high level. |
| 0 | SDAI | SDA Bus Input Monitor <ul style="list-style-type: none"> 0: RIICnSDA pin input is at a low level. 1: RIICnSDA pin input is at a high level. |

Note 1. Do not write to these bits during communication. Changing a value during communication may cause a transmission or reception failure or an AL error.

Note 2. To change the SDAO and SCLO bits, set the SOWP bit to 0 at the same timing to set the SDAO and SCLO bits to 0.

CLO Bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, see section 23.13.2, Extra SCL Clock Cycle Output Function.

IICRST Bit (I²C Bus Interface Internal Reset)

This bit is used to reset the internal states of the RIIC.

Setting this bit to 1 initiates an RIIC reset or internal reset.

Whether an RIIC reset or internal reset is initiated is determined according to the combination with the ICE bit. Table 23.6 lists the resets of the RIIC.

The RIIC reset resets all registers including the RIICnCR2.BBSY flag (except ICE and IICRST) and internal states of the RIIC, and the internal reset resets the bit counter (RIICnMR1.BC[2:0] bits), the I²C bus shift register (RIICnDRS), and the I²C bus status registers (RIICnSR1 and RIICnSR2) as well as the internal states of the RIIC. For the reset conditions for each register, see section 23.15, Reset Function of RIIC.

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the RIIC without initializing the port settings and the control and setting registers of the RIIC when the bus or RIIC hangs up due to a communication error.

If the RIIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the RIICnSCL pin and RIICnSDA pin at a high impedance.

Caution: If an internal reset is initiated using the IICRST bit for a bus hang-up occurred during communication with the master device in slave mode, the states may become different between the slave device and the master device (due to the difference in the bit counter information). For this reason, do not initiate an internal reset in slave mode, but initiate restoration processing from the master device. If an internal reset is necessary because the RIIC hangs up with the SCL line in a low level output state in slave mode, initiate an internal reset and then issue a restart condition from the master device or resume communication from the start condition issuance after issuing a stop condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start condition or restart condition from the master device, synchronization will be lost because the master and slave devices operate asynchronously.

Table 23.6 RIIC Resets

| IICRST | ICE | State | Specifications |
|--------|-----|----------------|--|
| 1 | 0 | RIIC reset | Resets all registers (except ICE and IICRST) and internal states of the RIIC. |
| | 1 | Internal reset | Reset the RIICnMR1.BC[2:0] bits, and the RIICnSR1, RIICnSR2, RIICnDRS registers and the internal states of the RIIC. |

ICE Bit (I²C Bus Interface Enable)

The ICE bit selects driving or non-driving of the RIICnSCL and RIICnSDA pins. Moreover, this bit can perform two types of reset in combination with the IICRST bit. For the types of reset, see **Table 23.6**.

Set the ICE bit to 1 when using RIIC. Setting the ICE bit to 1 selects driving of the RIICnSCL and RIICnSDA pins.

Set the ICE bit to 0 when RIIC is not to be used. Clearing the ICE bit to 0 disables output from the RIICnSCL and RIICnSDA pins.

23.3.2 RIICnCR2 — I²C Bus Control Register 2

Access: RIICnCR2 is a 32-bit readable/writable register.
 RIICnCR2L and RIICnCR2H are 16-bit readable/writable registers.
 RIICnCR2LL, RIICnCR2LH, RIICnCR2HL, and RIICnCR2HH are 8-bit readable/writable registers.

Address: RIICnCR2: <RIICn_base> + 0004_H
 RIICnCR2L: <RIICn_base> + 0004_H, RIICnCR2H: <RIICn_base> + 0006_H
 RIICnCR2LL: <RIICn_base> + 0004_H, RIICnCR2LH: <RIICn_base> + 0005_H, RIICnCR2HL: <RIICn_base> + 0006_H,
 RIICnCR2HH: <RIICn_base> + 0007_H

Initial Value: 0000 0000_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Table 23.7 RIICnCR2 register contents

| Bit Position | Bit Name | Function |
|--------------|----------|--|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 | BBSY | Bus Busy Detection Flag 0: The I ² C bus is released (bus free state). 1: The I ² C bus is occupied (bus busy state or in the bus free state). |
| 6 | MST | Master/Slave Mode 0: Slave mode 1: Transmit mode |
| 5 | TRS | Transmit/Receive Mode 0: Receive mode 1: Transmit mode |
| 4 | — | Reserved These bits are read as 0. The write value should be 0. |
| 3 | SP | Stop Condition Issuance Request 0: Does not request to issue a stop condition. 1: Requests to issue a stop condition. |
| 2 | RS | Restart Condition Issuance Request 0: Does not request to issue a restart condition. 1: Requests to issue a restart condition. |
| 1 | ST | Start Condition Issuance Request 0: Does not request to issue a start condition. 1: Requests to issue a start condition. |
| 0 | — | Reserved These bits are read as 0. The write value should be 0. |

ST Bit (Start Condition Issuance Request)

This bit is used to request transition to master mode and issuance of a start condition.

When this bit is set to 1 to request to issue a start condition, a start condition is issued when the BBSY flag is set to 0 (bus free).

For details on the start condition issuance, see [section 23.12, Start Condition/Restart Condition/Stop Condition Issuing Function](#).

[Setting condition]

When 1 is written to the ST bit

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition has been issued
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Caution: Set the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 0 (bus free).

Note that arbitration may be lost if the ST bit is set to 1 (start condition issuance request) when the BBSY flag is set to 1 (bus busy).

RS Bit (Restart Condition Issuance Request)

This bit is used to request that a restart condition be issued in master mode.

When this bit is set to 1 to request to issue a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy) and the MST bit is set to 1 (master mode).

For details on the restart condition issuance, see [section 23.12, Start Condition/Restart Condition/Stop Condition Issuing Function](#).

[Setting condition]

When 1 is written to the RS bit with the RIICnCR2.BBSY flag set to 1

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition has been issued or a start condition is detected
- When a stop condition is detected
- When the RIICnCR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Caution:1. Do not set the RS bit to 1 while issuing a stop condition.

Caution:2. It is commended to issue a restart condition in master transmit mode. If the RS bit is set to 1 (restart condition issuance request) in mode other than master mode, the restart condition is not issued in this mode but the restart condition issuance request bit remains set. If the operating mode changes to master mode with the bit not being cleared, the restart condition may be issued.

SP Bit (Stop Condition Issuance Request)

This bit is used to request that a stop condition be issued in master mode.

When this bit is set to 1 to request to issue a stop condition, a stop condition is issued when the BBSY flag is set to 1 (bus busy) and the MST bit is set to 1 (master mode).

For details on the stop condition issuance, see [section 23.12, Start Condition/Restart Condition/Stop Condition Issuing Function](#).

[Setting condition]

When 1 is written to the SP bit with both the RIICnCR2.BBSY flag and the RIICnCR2.MST bit set to 1

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition has been issued or a stop condition is detected
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Caution:1. Writing to the SP bit is not possible while the setting of the BBSY flag is 0 (bus free).

Caution:2. Do not set the SP bit to 1 while a restart condition is being issued.

TRS Bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.

The RIIC is in receive mode when the TRS bit is set to 0 and is in transmit mode when the bit is set to 1. Combination of this bit and the MST bit indicates the operating mode of the RIIC.

The value of the TRS bit is automatically changed to the value for transmission mode or reception mode by detection or issuing of a start condition, setting or clearing of the R/W# bit, etc.

[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)
- When the R/W# bit added to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in RIICnSER, with the R/W# bit set to 1

[Clearing conditions]

- When a stop condition is detected
- The RIICnSR2.AL (arbitration-lost) flag being set to 1
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended
- In slave mode, a match between the received address and the address enabled in RIICnSER when the value of the received R/W# bit is 0 (including cases where the received address is the general call address)
- In slave transmit mode, a restart condition is detected (a restart condition is detected with RIICnCR2.BBSY = 1 and RIICnCR2.MST = 0)
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

MST Bit (Master/Slave Mode)

This bit indicates master or slave mode.

The RIIC is in slave mode when the MST bit is set to 0 and is in master mode when the bit is set to 1. Combination of this bit and the TRS bit indicates the operating mode of the RIIC.

The value of the MST bit is automatically changed to the value for master mode or slave mode by detection or issuing of a start condition, etc.

[Setting conditions]

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the ST bit set to 1)

[Clearing conditions]

- When a stop condition is detected
- When the RIICnSR2.AL (arbitration-lost) flag is set to 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

BBSY Flag (Bus Busy Detection)

The BBSY flag indicates whether the I²C bus is occupied (bus busy) or released (bus free).

This bit is set to 1 when the SDA line changes from high to low under the condition of SCL = high, assuming that a start condition has been issued.

When the SDA line changes from low to high under the condition of SCL = high, this bit is cleared to 0 after the bus free time (specified in RIICnBRL) start condition is not detected, assuming that a stop condition has been issued.

[Setting condition]

- When a start condition is detected

[Clearing conditions]

- When the bus free time (specified in RIICnBRL) start condition is not detected after detecting a stop condition
- When 1 is written to the RIICnCR1.IICRST bit with the RIICnCR1.ICE bit set to 0 (RIIC reset)

23.3.3 RIICnMR1 — I²C Bus Mode Register 1

Access: RIICnMR1 is a 32-bit readable/writable register.
 RIICnMR1L and RIICnMR1H are 16-bit readable/writable registers.
 RIICnMR1LL, RIICnMR1LH, RIICnMR1HL, and RIICnMR1HH are 8-bit readable/writable registers.

Address: RIICnMR1: <RIICn_base> + 0008_H
 RIICnMR1L: <RIICn_base> + 0008_H, RIICnMR1H: <RIICn_base> + 000A_H
 RIICnMR1LL: <RIICn_base> + 0008_H, RIICnMR1LH: <RIICn_base> + 0009_H, RIICnMR1HL: <RIICn_base> + 000A_H,
 RIICnMR1HH: <RIICn_base> + 000B_H

Initial Value: 0000 0008_H This register is initialized by any reset.

| | | | | | | | | | | | | | | | | |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

| Initial value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| R/W | R | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Table 23.8 RIICnMR1 register contents

| Bit Position | Bit Name | Function |
|--------------|----------|--|
| 31 to 7 | — | Reserved These bits are read as 0. The write value should be 0. |
| 6 to 4 | CKS[2:0] | Internal Reference Clock (IIC ϕ) Selection $b_6 \ b_4$ 0 0 0: IIC ϕ = P1 ϕ /1 0 0 1: IIC ϕ = P1 ϕ /2 0 1 0: IIC ϕ = P1 ϕ /4 0 1 1: IIC ϕ = P1 ϕ /8 1 0 0: IIC ϕ = P1 ϕ /16 1 0 1: IIC ϕ = P1 ϕ /32 1 1 0: IIC ϕ = P1 ϕ /64 1 1 1: IIC ϕ = P1 ϕ /128 |
| 3 | BCWP*1 | BC Write Protect 0: Enables a value to be written in the BC[2:0] bits. (This bit is read as 1.) |
| 2 to 0 | BC[2:0] | Bit Counter $b_2 \ b_0$ 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits |

Note 1. When rewriting the BC[2:0] bits, write 0 to the BCWP bit simultaneously.

BC[2:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCL line. Although these bits are writable and readable, it is not necessary to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one (data is transferred with an additional acknowledge bit) between transferred frames when the SCL line is at a low level.

The values of the BC[2:0] bits return to 000_B at the end of a data transfer including the acknowledge bit or when a start condition including a restart condition is detected.

23.3.4 RIICnMR2 — I²C Bus Mode Register 2

Access: RIICnMR2 is a 32-bit readable/writable register.
 RIICnMR2L and RIICnMR2H are 16-bit readable/writable registers.
 RIICnMR2LL, RIICnMR2LH, RIICnMR2HL, and RIICnMR2HH are 8-bit readable/writable registers.

Address: RIICnMR2: <RIICn_base> + 000C_H
 RIICnMR2L: <RIICn_base> + 000C_H, RIICnMR2H: <RIICn_base> + 000E_H
 RIICnMR2LL: <RIICn_base> + 000C_H, RIICnMR2LH: <RIICn_base> + 000D_H, RIICnMR2HL: <RIICn_base> + 000E_H,
 RIICnMR2HH: <RIICn_base> + 000F_H

Initial Value: 0000 0006_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Table 23.9 RIICnMR2 register contents

| Bit Position | Bit Name | Function |
|--------------|-----------|---|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 | DLCS | SDA Output Delay Clock Source Selection 0: The internal reference clock (IICφ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (IICφ/2) is selected as the clock source of the SDA output delay counter.*1 |
| 6 to 4 | SDDL[2:0] | SDA Output Delay Counter • When RIICnMR2.DLCS = 0 (IICφ) b6 b4 0 0 0: No output delay 0 0 1: 1 IICφ cycle 0 1 0: 2 IICφ cycles 0 1 1: 3 IICφ cycles 1 0 0: 4 IICφ cycles 1 0 1: 5 IICφ cycles 1 1 0: 6 IICφ cycles 1 1 1: 7 IICφ cycles • When RIICnMR2.DLCS = 1 (IICφ/2) b6 b4 0 0 0: No output delay 0 0 1: 1 or 2 IICφ cycles 0 1 0: 3 or 4 IICφ cycles 0 1 1: 5 or 6 IICφ cycles 1 0 0: 7 or 8 IICφ cycles 1 0 1: 9 or 10 IICφ cycles 1 1 0: 11 or 12 IICφ cycles 1 1 1: 13 or 14 IICφ cycles |
| 3 | — | Reserved These bits are read as 0. The write value should be 0. |
| 2 | TMOH | Timeout H Count Control 0: Count is disabled while the SCL line is at a high level. 1: Count is enabled while the SCL line is at a high level. |

Table 23.9 RIICnMR2 register contents

| Bit Position | Bit Name | Function |
|--------------|----------|--|
| 1 | TMOL | Timeout L Count Control 0: Count is disabled while the SCL line is at a low level. 1: Count is enabled while the SCL line is at a low level. |
| 0 | TMOS | Timeout Detection Time Selection 0: Long mode is selected. 1: Short mode is selected. |

Note 1. The setting DLCS = 1 (IIC ϕ /2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting DLCS = 1 becomes invalid and the clock source becomes the internal reference clock (IIC ϕ).

TMOS Bit (Timeout Detection Time Selection)

This bit is used to select long mode or short mode for the timeout detection time when the timeout function is enabled (RIICnFER.TMOE bit = 1). When this bit is set to 0, long mode is selected. When this bit is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14 bit-counter. While the SCL line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IIC ϕ) as a count source.

For details on the timeout function, see section 23, Timeout Function.

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held low when the timeout function is enabled (RIICnFER.TMOE bit = 1).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held high when the timeout function is enabled (RIICnFER.TMOE bit = 1).

SDDL[2:0] Bits (SDA Output Delay Setup Counter)

The SDA output can be delayed by the SDDL[2:0] setting. This counter works with the clock source selected by the DLCS bit. The setting of this function can be used for all types of SDA output, including the transmission of the acknowledge bit.

For details on this function, see section 23.7, Facility for Delaying SDA Output.

Caution: Set the SDA output delay time to meet the I²C bus standard (within the data enable time/acknowledge enable time*1) or the SMBus standard (within the data hold time: 300 [ns] or more, and SCL-clock low-level period - the data setup time: 250 [ns]). Note that, if a value outside the standard is set, communication with communication devices may malfunction or it may seemingly become a start condition or stop condition depending on the bus state.

Note 1. Data enable time/acknowledge enable time
 3,450 [ns] (0 to 100 [kbps]: standard mode (Sm))
 900 [ns] (0 to 400 [kbps]: fast mode (Fm))
 450 [ns] (0 to 1 [Mbps]: fast mode plus (Fm+))

23.3.5 RIICnMR3 — I²C Bus Mode Register 3

Access: RIICnMR3 is a 32-bit readable/writable register.
 RIICnMR3L and RIICnMR3H are 16-bit readable/writable registers.
 RIICnMR3LL, RIICnMR3LH, RIICnMR3HL, and RIICnMR3HH are 8-bit readable/writable registers.

Address: RIICnMR3: <RIICn_base> + 0010_H
 RIICnMR3L: <RIICn_base> + 0010_H, RIICnMR3H: <RIICn_base> + 0012_H
 RIICnMR3LL: <RIICn_base> + 0010_H, RIICnMR3LH: <RIICn_base> + 0011_H, RIICnMR3HL: <RIICn_base> + 0012_H,
 RIICnMR3HH: <RIICn_base> + 0013_H

Initial Value: 0000 0000_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Table 23.10 RIICnMR3 register contents

| Bit Position | Bit Name | Function |
|--------------|----------|---|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 | SMBE | SMBus/I ² C Bus Selection 0: I ² C bus is selected. 1: SMBus is selected. |
| 6 | WAIT*2 | WAIT 0: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.) 1: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low-hold is released by reading RIICnDRR. |
| 5 | RDRFS*2 | RDRF Flag Set Timing Selection 0: The RDRF flag is set at the rising edge of the ninth SCL clock cycle. (The SCL line is not held low at the falling edge of the eighth clock cycle.) 1: The RDRF flag is set at the rising edge of the eighth SCL clock cycle. (The SCL line is held low at the falling edge of the eighth clock cycle.) Low-hold is released by writing a value to the ACKBT bit. |
| 4 | ACKWP*1 | ACKBT Write Protect 0: Modification of the ACKBT bit is disabled. 1: Modification of the ACKBT bit is enabled. |
| 3 | ACKBT*1 | Transmit Acknowledge 0: A 0 is sent as the acknowledge bit (ACK transmission). 1: A 1 is sent as the acknowledge bit (NACK transmission). |
| 2 | ACKBR | Receive Acknowledge 0: A 0 is received as the acknowledge bit (ACK reception). 1: A 1 is received as the acknowledge bit (NACK reception). |
| 1, 0 | NF[1:0] | Noise Filter Stage Selection b1 b0 0 0: Noise of up to one IICφ cycle is filtered out (single-stage filter). 0 1: Noise of up to two IICφ cycles is filtered out (2-stage filter). 1 0: Noise of up to three IICφ cycles is filtered out (3-stage filter). 1 1: Noise of up to four IICφ cycles is filtered out (4-stage filter). |

Note 1. If it is attempted to write 1 to both ACKWP and ACKBT bits, the ACKBT bit cannot be set to 1.

Note 1. The WAIT and RDRFS bits are valid only in receive mode (invalid in transmit mode).

NF[1:0] Bits (Noise Filter Stage Selection)

These bits are used to select the width of noise that can be removed from the signals input to RIICnSCL or RIICnSDA pin.

ACKBR Bit (Receive Acknowledge)

This bit is used to store the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

When 1 is received as the acknowledge bit with the RIICnCR2.TRS bit set to 1

[Clearing conditions]

- When 0 is received as the acknowledge bit with the RIICnCR2.TRS bit set to 1
- When 1 is written to the RIICnCR1.IICRST bit while the RIICnCR1.ICE bit is 0 (RIIC reset)

ACKBT Bit (Transmit Acknowledge)

This bit is used to set the bit to be sent at the acknowledge timing in receive mode.

[Setting condition]

When 1 is written to this bit with the ACKWP bit set to 1

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition issuance is detected
- When 1 is written to the RIICnCR1.IICRST bit while the RIICnCR1.ICE bit is 0 (RIIC reset)

Caution: The ACKBT bit must be written to while the ACKWP bit is 1. If the ACKBT bit is written to with the ACKWP bit cleared to 0, writing to the ACKBT bit is disabled.

ACKWP Bit (ACKBT Write Protect)

This bit is used to control the modification of the ACKBT bit.

RDRFS Bit (RDRF Flag Set Timing Selection)

This bit is used to select the RDRF flag set timing in receive mode and also to select whether to hold the SCL line low at the falling edge of the eighth SCL clock cycle.

When the RDRFS bit is 0, the SCL line is not held low at the falling edge of the eighth SCL clock cycle, and the RDRF flag is set to 1 at the rising edge of the ninth SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 at the rising edge of the eighth SCL clock cycle and the SCL line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the SCL line is released by writing a value to the ACKBT bit.

After data is received with this setting, the SCL line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1) according to receive data.

WAIT Bit (WAIT)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (RIICnDRR) is completely read each time single-byte data is received in receive mode. When the WAIT bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCL line is held low from the falling edge of the ninth clock cycle until the RIICnDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Caution: When the value of the WAIT bit is to be read, be sure to read the RIICnDRR beforehand.

SMBE Bit (SMBus Select)

Setting this bit to 1 enables the RIICnSER.HOAE bit.

23.3.6 RIICnFER — I²C Bus Function Enable Register

Access: RIICnFER is a 32-bit readable/writable register.
 RIICnFERL and RIICnFERH are 16-bit readable/writable registers.
 RIICnFERLL, RIICnFERLH, RIICnFERHL, and RIICnFERHH are 8-bit readable/writable registers.

Address: RIICnFER: <RIICn_base> + 0014_H
 RIICnFERL: <RIICn_base> + 0014_H, RIICnFERH: <RIICn_base> + 0016_H
 RIICnFERLL: <RIICn_base> + 0014_H, RIICnFERLH: <RIICn_base> + 0015_H, RIICnFERHL: <RIICn_base> + 0016_H,
 RIICnFERHH: <RIICn_base> + 0017_H

Initial Value: 0000 0072_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Table 23.11 RIICnFER register contents

| Bit Position | Bit Name | Function |
|--------------|----------|--|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 | FMPE | Fast-mode Plus Enable 0: No fm+ slope control circuit is used for the SCLn pin and SDAn pin 1: An fm+ slope control circuit is used for the SCLn pin and SDAn pin |
| 6 | SCLE | SCL Synchronous Circuit Enable 0: No SCL synchronous circuit is used. 1: An SCL synchronous circuit is used. |
| 5 | NFE | Digital Noise Filter Circuit Enable 0: No digital noise filter circuit is used. 1: A digital noise filter circuit is used. |
| 4 | NACKE | NACK Reception Transfer Suspension Enable 0: Transfer operation is not suspended during NACK reception (transfer suspension disabled). 1: Transfer operation is suspended during NACK reception (transfer suspension enabled). |
| 3 | SALE | Slave Arbitration-Lost Detection Enable 0: Slave arbitration-lost detection is disabled. 1: Slave arbitration-lost detection is enabled. |
| 2 | NALE | NACK Transmission Arbitration-Lost Detection Enable 0: NACK transmission arbitration-lost detection is disabled. 1: NACK transmission arbitration-lost detection is enabled. |
| 1 | MALE | Master Arbitration-Lost Detection Enable 0: Master arbitration-lost detection is disabled. (Disables the arbitration-lost detection function and does not clear the RIICnCR2.MST and TRS bits automatically when arbitration is lost.) 1: Master arbitration-lost detection is enabled. (Enables the arbitration-lost detection function and clears the RIICnCR2.MST and TRS bits automatically when arbitration is lost.) |
| 0 | TMOE | Timeout Function Enable 0: The timeout function is disabled. 1: The timeout function is enabled. |

TMOE Bit (Timeout Function Enable)

This bit is used to enable or disable the timeout function.

For details on the timeout function, see [section 23.13.1, Timeout Function](#).

MALE Bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

NACKE Bit (NACK Reception Transfer Suspension Enable)

This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended.

When the NACKE bit is 0, the next transfer operation is continued regardless of the received acknowledge content.

SCLE Bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1. When the SCLE bit is cleared to 0 (SCL synchronous circuit not used), the RIIC does not synchronize the SCL clock with the SCL input clock. In this setting, the RIIC outputs the SCL clock with the transfer rate set in RIICnBRH and RIICnBRL regardless of the SCL line state. For this reason, if the bus load of the I²C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit is used, it also affects the issuance of a start condition, restart condition, and stop condition, and the continuous output of extra SCL clock cycles.

This bit must not be cleared to 0 except for checking the output of the transfer rate.

FMPE Bit (Fast-mode Plus Enable)

This bit is used to specify whether to use a slope control circuit for Fast-mode Plus [fm+].

When this bit is set to 1, a slope control circuit conforming to the Fast-mode Plus [fm+] slope control standard (tof) of the I²C bus is selected. When this bit is cleared to 0, a slope control circuit conforming to the Standard-mode [Sm] and Fast-mode [fm] slope control standard (tof) of the I²C bus is selected.

Set this bit to 1 when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus[fm+]) of the I²C bus standard. Clear this bit to 0 when using the transmission rate at other rates (up to 100 kbps[Sm], up to 400 kbps[fm]) or for SMBus (10 to 100 kbps).

23.3.7 RIICnSER — I²C Bus Status Enable Register

Access: RIICnSER is a 32-bit readable/writable register.
 RIICnSERL and RIICnSERH are 16-bit readable/writable registers.
 RIICnSERLL, RIICnSERLH, RRIICnSERHL, and RIICnSERHH are 8-bit readable/writable registers.

Address: RIICnSER: <RIICn_base> + 0018_H
 RIICnSERL: <RIICn_base> + 0018_H, RIICnSERH: <RIICn_base> + 001A_H
 RIICnSERLL: <RIICn_base> + 0018_H, RIICnSERLH: <RIICn_base> + 0019_H, RIICnSERHL: <RIICn_base> + 001A_H,
 RIICnSERHH: <RIICn_base> + 001B_H

Initial Value: 0000 0009_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Initial value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 |
| R/W | R | R | R | R | R | R | R | R | R/W | R | R/W | R | R/W | R/W | R/W | R/W |

Table 23.12 RIICnSER register contents

| Bit Position | Bit Name | Function |
|--------------|----------|---|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 | HOAE | Host Address Enable 0: Host address detection is disabled. 1: Host address detection is enabled. |
| 6 | — | Reserved This bit is read as 0. The write value should be 0. |
| 5 | DIDE | Device-ID Address Detection Enable 0: Device-ID address detection is disabled. 1: Device-ID address detection is enabled. |
| 4 | — | Reserved This bit is read as 0. The write value should be 0. |
| 3 | GCE | General Call Address Enable 0: General call address detection is disabled. 1: General call address detection is enabled. |
| 2 | SAR2 | Slave Address Register 2 Enable 0: Slave address in RIICnSAR2 is disabled. 1: Slave address in RIICnSAR2 is enabled. |
| 1 | SAR1 | Slave Address Register 1 Enable 0: Slave address in RIICnSAR1 is disabled. 1: Slave address in RIICnSAR1 is enabled. |
| 0 | SAR0 | Slave Address Register 0 Enable 0: Slave address in RIICnSAR0 is disabled. 1: Slave address in RIICnSAR0 is enabled. |

SARy Bit (Slave Address Register y Enable) (y = 0 to 2)

This bit is used to enable or disable the received slave address and the slave address set in RIICnSARy.

When this bit is set to 1, the slave address set in RIICnSARy is enabled and is compared with the received slave address.

When this bit is cleared to 0, the slave address set in RIICnSARy is disabled and is ignored even if it matches the received slave address.

GCE Bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000 000_B + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RIIC recognizes the received slave address as the general call address independently of the slave addresses set in RIICnSARy (y = 0 to 2) and performs data receive operation.

When this bit is cleared to 0, the received slave address is ignored even if it matches the general call address.

DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID (1111 100_B) is received in the first frame after a start condition or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the RIIC recognizes that the Device-ID address has been received. When the following R/W# bit is 0 [W], the RIIC recognizes the second and the following frames as slave addresses and continues the receive operation.

When this bit is cleared to 0, the RIIC ignores the received first frame even if it matches the device ID address and recognizes the first frame as a normal slave address.

For details on the device-ID address detection, see section 23.9.3, Device-ID Address Detection.

HOAE Bit (Host Address Enable)

This bit is used to specify whether to ignore received host address (0001 000_B) when the RIICnMR3.SMBS bit is 1.

When this bit is set to 1 while the RIICnMR3.SMBS bit is 1, if the received slave address matches the host address, the RIIC recognizes the received slave address as the host address independently of the slave addresses set in RIICnSARy (y = 0 to 2) and performs the receive operation.

When the RIICnMR3.SMBS bit or the HOAE bit is cleared to 0, the received slave address is ignored even if it matches the host address.

23.3.8 RIICnIER — I²C Bus Interrupt Enable Register

Access: RIICnIER is a 32-bit readable/writable register.
 RIICnIERL and RIICnIERH are 16-bit readable/writable registers.
 RIICnIERLL, RIICnIERLH, RIICnIERHL, and RIICnIERHH are 8-bit readable/writable registers.

Address: RIICnIER: <RIICn_base> + 001C_H
 RIICnIERL: <RIICn_base> + 001C_H, RIICnIERH: <RIICn_base> + 001E_H
 RIICnIERLL: <RIICn_base> + 001C_H, RIICnIERLH: <RIICn_base> + 001D_H, RIICnIERHL: <RIICn_base> + 001E_H,
 RIICnIERHH: <RIICn_base> + 001F_H

Initial Value: 0000 0000_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

Table 23.13 RIICnIER register contents

| Bit Position | Bit Name | Function |
|--------------|----------|---|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 | TIE | Transmit Data Empty Interrupt Enable 0: Transmit data empty interrupt request (INTRIICTI) is disabled. 1: Transmit data empty interrupt request (INTRIICTI) is enabled. |
| 6 | TEIE | Transmit End Interrupt Enable 0: Transmit end interrupt request (INTRIICTEI) is disabled. 1: Transmit end interrupt request (INTRIICTEI) is enabled. |
| 5 | RIE | Receive Data Full Interrupt Enable 0: Receive data full interrupt request (INTRIICRI) is disabled. 1: Receive data full interrupt request (INTRIICRI) is enabled. |
| 4 | NAKIE | NACK Reception Interrupt Enable 0: NACK reception interrupt request (INTRIICNAKI) is disabled. 1: NACK reception interrupt request (INTRIICNAKI) is enabled. |
| 3 | SPIE | Stop Condition Detection Interrupt Enable 0: Stop condition detection interrupt request (INTRIICSPI) is disabled. 1: Stop condition detection interrupt request (INTRIICSPI) is enabled. |
| 2 | STIE | Start Condition Detection Interrupt Enable 0: Start condition detection interrupt request (INTRIICSTI) is disabled. 1: Start condition detection interrupt request (INTRIICSTI) is enabled. |
| 1 | ALIE | Arbitration-Lost Interrupt Enable 0: Arbitration-lost interrupt request (INTRIICALI) is disabled. 1: Arbitration-lost interrupt request (INTRIICALI) is enabled. |
| 0 | TMOIE | Timeout Interrupt Enable 0: Timeout interrupt request (INTRIICTMOI) is disabled. 1: Timeout interrupt request (INTRIICTMOI) is enabled. |

TMOIE Bit (Timeout Interrupt Enable)

This bit is used to enable or disable timeout interrupt requests (INTRIICTMOI) when the RIICnSR2.TMOF flag is set to 1. An INTRIICTMOI interrupt request is canceled by clearing the TMOF flag or the TMOIE bit to 0.

ALIE Bit (Arbitration-Lost Interrupt Enable)

This bit is used to enable or disable arbitration-lost interrupt requests (INTRIICALII) when the RIICnSR2.AL flag is set to 1. An INTRIICALII interrupt request is canceled by clearing the AL flag or the ALIE bit to 0.

STIE Bit (Start Condition Detection Interrupt Enable)

This bit is used to enable or disable start condition detection interrupt requests (INTRIICSTI) when the RIICnSR2.START flag is set to 1. An INTRIICSTI interrupt request is canceled by clearing the START flag or the STIE bit to 0.

SPIE Bit (Stop Condition Detection Interrupt Enable)

This bit is used to enable or disable stop condition detection interrupt requests (INTRIICSPI) when the RIICnSR2.STOP flag is set to 1. An INTRIICSPI interrupt request is canceled by clearing the STOP flag or the SPIE bit to 0.

NAKIE Bit (NACK Reception Interrupt Enable)

This bit is used to enable or disable NACK reception interrupt requests (INTRIICNAKI) when the RIICnSR2.NACKF flag is set to 1. An INTRIICNAKI interrupt request is canceled by clearing the NACKF flag or the NAKIE bit to 0.

RIE Bit (Receive Data Full Interrupt Enable)

This bit is used to enable or disable receive data full interrupt requests (INTRIICRI) when the RIICnSR2.RDRF flag in ICSR2 is set to 1. An INTRIICRI interrupt request is canceled by clearing the RDRF flag or the RIE bit to 0.

TEIE Bit (Transmit End Interrupt Enable)

This bit is used to enable or disable transmit end interrupts (INTRIICTEI) when the RIICnSR2.TEND flag is set to 1. An INTRIICTEI interrupt request is canceled by clearing the TEND flag or the TEIE bit to 0.

TIE Bit (Transmit Data Empty Interrupt Enable)

This bit is used to enable or disable transmit data empty interrupts (INTRIICTI) when the RIICnSR2.TDRE flag is set to 1.

23.3.9 RIICnSR1 — I²C Bus Status Register 1

Access: RIICnSR1 is a 32-bit readable/writable register.
 RIICnSR1L and RIICnSR1H are 16-bit readable/writable registers.
 RIICnSR1LL, RIICnSR1LH, RIICnSR1HL, and RIICnSR1HH are 8/1-bit readable/writable registers.

Address: RIICnSR1: <RIICn_base> + 0020_H
 RIICnSR1L: <RIICn_base> + 0020_H, RIICnSR1H: <RIICn_base> + 0022_H
 RIICnSR1LL: <RIICn_base> + 0020_H, RIICnSR1LH: <RIICn_base> + 0021_H, RIICnSR1HL: <RIICn_base> + 0022_H,
 RIICnSR1HH: <RIICn_base> + 0023_H

Initial Value: 0000 0000_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| | — | — | — | — | — | — | — | — | HOA | — | DID | — | GCA | AAS2 | AAS1 | AAS0 |
| Initial value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W | R | R | R | R | R | R | R | R | R/(W) _{*1} | R | R/(W) _{*1} | R | R/(W) _{*1} | R/(W) _{*1} | R/(W) _{*1} | R/(W) _{*1} |

Note 1. Only 0 can be written to this bit.

Table 23.14 RIICnSR1 register contents

| Bit Position | Bit Name | Function |
|--------------|----------|---|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 | HOA | Host Address Detection Flag 0: Host address is not detected. 1: Host address is detected. |
| 6 | — | Reserved This bit is read as 0. The write value should be 0. |
| 5 | DID | Device-ID Address Detection Flag 0: Device-ID command is not detected. 1: Device-ID command is detected. |
| 4 | — | Reserved This bit is read as 0. The write value should be 0. |
| 3 | GCA | General Call Address Detection Flag 0: General call address is not detected. 1: General call address is detected. |
| 2 | AAS2 | Slave Address 2 Detection Flag 0: Slave address 2 is not detected. 1: Slave address 2 is detected. |
| 1 | AAS1 | Slave Address 1 Detection Flag 0: Slave address 1 is not detected. 1: Slave address 1 is detected. |
| 0 | AAS0 | Slave Address 0 Detection Flag 0: Slave address 0 is not detected. 1: Slave address 0 is detected. |

AASy Flag (Slave Address y Detection) (y = 0 to 2)**[Setting conditions]**

<For 7-bit address format: RIICnSARy.FSy = 0>

When the received slave address matches the RIICnSARy.SVA[7:1] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)

This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

<For 10-bit address format: RIICnSARy.FSy = 1>

When the received slave address matches a value of $(1111\ 0_B + \text{RIICnSARy.SVA}[9:8])$ and the following address matches the RIICnSARy.SVA[7:0] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)

This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy bit after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

<For 7-bit address format: RIICnSARy.FSy = 0>

- When the received slave address does not match the RIICnSARy.SVA[7:1] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)

This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

<For 10-bit address format: RIICnSARy.FSy = 1>

- When the received slave address does not match a value of $(1111\ 0_B + \text{RIICnSARy.SVA}[9:8])$ with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)
This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of $(1111\ 0_B + \text{RIICnSARy.SVA}[9:8])$ and the following address does not match the RIICnSARy.SVA[7:0] value with the RIICnSER.SARy bit set to 1 (slave address y detection enabled)

This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

GCA Flag (General Call Address Detection)**[Setting condition]**

When the received slave address matches the general call address $(0000\ 000_B + 0\ [W])$ with the RIICnSER.GCE bit set to 1 (general call address detection enabled)

This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA bit after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address $(0000\ 000_B + 0\ [W])$ with the RIICnSER.GCE bit set to 1 (general call address detection enabled)
This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

DID Flag (Device-ID Address Detection)**[Setting condition]**

- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID $(1111\ 100_B) + 0\ [W])$ with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)

This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

- When a restart condition is detected after a match with the device ID address and the device ID address $(1111\ 100_B) + 1\ [R]$ has matched with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)

This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID bit after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start condition or restart condition is detected does not match a value of (device ID (1111 100_B)) with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)

This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID (1111 100_B) + 0 [W]) and the second frame does not match any of slave addresses 0 to 2 with the RIICnSER.DIDE bit set to 1 (Device-ID address detection enabled)

This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

HOA Flag (Host Address Detection)

[Setting condition]

When the received slave address matches the host address (0001 000_B) while the RIICnMR3.SMBE bit and RIICnSER.HOAE bit are set to 1 (host address detection enabled)

This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA bit after reading HOA = 1
- When a stop condition is detected
- When 0 is written to the RIICnMR3.SMBS bit in ICMR3 or the RIICnSER.HOAE bit
- When the received slave address does not match the host address (0001 000_B) with the RIICnSER.HOAE bit set to 1 (host address detection enabled)

This flag is cleared to 0 at the rising edge of the ninth SCL clock cycle in the frame.

- When 1 is written to the RIICnCR1.IICRST bit 1 to apply an RIIC reset or an internal reset

23.3.10 RIICnSR2 — I²C Bus Status Register 2

Access: RIICnSR2 is a 32-bit readable/writable register.
 RIICnSR2L and RIICnSR2H are 16-bit readable/writable registers.
 RIICnSR2LL, RIICnSR2LH, RIICnSR2HL, and RIICnSR2HH are 8/1-bit readable/writable registers.

Address: RIICnSR2: <RIICn_base> + 0024_H
 RIICnSR2L: <RIICn_base> + 0024_H, RIICnSR2H: <RIICn_base> + 0026_H
 RIICnSR2LL: <RIICn_base> + 0024_H, RIICnSR2LH: <RIICn_base> + 0025_H, RIICnSR2HL: <RIICn_base> + 0026_H,
 RIICnSR2HH: <RIICn_base> + 0027_H

Initial Value: 0000 0000_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

| R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---------------|----|----|----|----|----|----|---|---|------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| | — | — | — | — | — | — | — | — | TDRE | TEND | RDRF | NACKF | STOP | START | AL | TMOF |
| Initial value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W | R | R | R | R | R | R | R | R | R | R(/W) *1 | R(/W) *1 | R(/W) *1 | R(/W) *1 | R(/W) *1 | R(/W) *1 | R(/W) *1 |

Note 1. Only 0 can be written to this bit.

Table 23.15 RIICnSR2 register contents

| Bit Position | Bit Name | Function |
|--------------|----------|---|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 | TDRE | Transmit Data Empty Flag 0: RIICnDRT contains transmit data. 1: RIICnDRT contains no transmit data. |
| 6 | TEND | Transmit End Flag 0: Data is being transmitted. 1: Data has been transmitted. |
| 5 | RDRF | Receive Data Full Flag 0: RIICnDRR contains no receive data. 1: RIICnDRR contains receive data. |
| 4 | NACKF | NACK Reception Flag 0: NACK is not received. 1: NACK is received. |
| 3 | STOP | Stop Condition Detection Flag 0: Stop condition is not detected. 1: Stop condition is detected. |
| 2 | START | Start Condition Detection Flag 0: Start condition is not detected. 1: Start condition is detected. |
| 1 | AL | Arbitration-Lost Flag 0: Arbitration is not lost. 1: Arbitration is lost. |
| 0 | TMOF | Timeout Flag 0: No timeout has occurred. 1: Timeout has occurred. |

TMOF Flag (Timeout)

This flag is set to 1 when the RIIC recognizes timeout after the SCL line state remains unchanged for a certain period.

[Setting condition]

The timeout function is enabled when the RIICnFER.TMOE bit is 1. It detects an abnormal bus state that the SCL line is held low or high during the following conditions:

- The bus is busy (RIICnCR2.BBSY = 1) in master mode (RIICnCR2.MST = 1).
- The slave address matches that of this module (RIICnSR1 register is not 00_H) and the bus is busy (RIICnCR2.BBSY = 1) in slave mode (RIICnCR2.MST = 0).
- Issuing of a start condition is being requested (RIICnCR2.ST = 1) and the bus is free (RIICnCR2.BBSY = 0).

[Clearing conditions]

- When 0 is written to the TMOF bit after reading TMOF = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

AL Flag (Arbitration-Lost)

This flag shows that bus mastership has been lost (loss in arbitration) due to a bus conflict or some other reason when a start condition is issued or an address and data are transmitted. The RIIC monitors the level on the SDA line during transmission and, if the level on the line does not match the value of the bit being output, sets the value of the AL bit to 1 to indicate that the bus is occupied by another device.

The RIIC can also set the flag to indicate the detection of loss of arbitration during NACK transmission in receive mode or during data transmission in slave mode.

[Setting conditions]

<When master arbitration-lost detection is enabled: RIICnFER.MALE = 1>

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDA line is driven low while the internal SDA output is at a high level (the SDA pin is in the high-impedance state))
- When a start condition is detected while the RIICnCR2.ST bit is 1 (start condition issuance request) or the internal SDA output state does not match the SDA line level
- When the RIICnCR2.ST bit is set to 1 (start condition issuance request) with the RIICnCR2.BBSY flag set to 1.

<When NACK arbitration-lost detection is enabled: RIICnFER.NALE = 1>

When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock in the ACK period during NACK transmission in receive mode

<When slave arbitration-lost detection is enabled: RIICnFER.SALE = 1>

When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data transmission in slave transmit mode

[Clearing conditions]

- When 0 is written to the AL bit after reading AL = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Table 23.16 Relationship between Arbitration-Lost Generation Sources and Arbitration-Lost Enable Functions

| RIICnFER | | | RIICnS R2 | | Arbitration-Lost Generation Source |
|----------|------|------|--------------|--------------------------------|--|
| MALE | NALE | SALE | AL | Error | |
| 1 | x | x | 1 | Start condition issuance error | When internal SDA output state does not match SDA line level when a start condition is detected while the RIICnCR2.ST bit is 1 When RIICnCR2.ST is set to 1 with RIICnCR2.BBSY set to 1 |
| | | | 1 | Transmit data mismatch | When transmit data (including slave address) does not match the bus state in master transmit mode |
| x | 1 | x | 1 | NACK transmission mismatch | When ACK is detected during transmission of NACK in master receive mode or slave receive mode |
| x | x | 1 | 1 | Transmit data mismatch | When transmit data does not match the bus state in slave transmit mode |

x: Don't care

START Flag (Start Condition Detection)

[Setting condition]

When a start condition (or a restart condition) is detected

[Clearing conditions]

- When 0 is written to the START bit after reading START = 1
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

STOP Flag (Stop Condition Detection)

[Setting condition]

When a stop condition is detected

[Clearing conditions]

- When 0 is written to the STOP bit after reading STOP = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

NACKF Flag (NACK Reception)

[Setting condition]

When acknowledge is not received (NACK is received) from the receive device in transmit mode with the RIICnFER.NACKF bit set to 1 (transfer suspension enabled)

[Clearing conditions]

- When 0 is written to the NACKF bit after reading NACKF = 1
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Caution: When the NACKF flag is set to 1, the RIIC suspends data transmission/reception. Writing to RIICnDRT in transmit mode or reading from RIICnDRR in receive mode with the NACKF flag set to 1 does not enable data transmit/receive operation. To restart data transmission/reception, clear the NACKF flag to 0.

RDRF Flag (Receive Data Full)**[Setting conditions]**

- Slave receive mode
 - When the received slave address matches and the RIICnCR2.TRS bit is cleared to 0 after a start condition (or a restart condition) is detected
 - At the rising edge of the eighth or ninth SCL clock cycle (selected by the RIICnMR3.RDRFS bit) after receive data is transferred from RIICnDRS to RIICnDRR
- Master receive mode
 - When the slave address and the data direction are transmitted and the receive mode is entered (the RIICnCR2.TRS bit is set to 0) after a start condition (or a restart condition) is issued
 - At the rising edge of the eighth or ninth SCL clock cycle (selected by the RIICnMR3.RDRFS bit) after receive data is transferred from RIICnDRS to RIICnDRR

[Clearing conditions]

- When 0 is written to the RDRF bit after reading RDRF = 1
- When data is read from RIICnDRR
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

TEND Flag (Transmit End)**[Setting condition]**

At the rising edge of the ninth SCL clock cycle while the TDRE flag is 1

[Clearing conditions]

- When 0 is written to the TEND bit after reading TEND = 1
- When data is written to RIICnDRT
- When a stop condition is detected
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

TDRE Flag (Transmit Data Empty)**[Setting conditions]**

- When data has been transferred from RIICnDRT to RIICnDRS and RIICnDRT becomes empty
- When the RIICnCR2.TRS bit is set to 1
 - When the RIICnCR2.MST bit is set to 1 after a start condition (or a restart condition) is detected
 - When the RIIC enters transmit mode from receive mode
- When the received slave address matches while the TRS bit is 1

[Clearing conditions]

- When data is written to RIICnDRT
- When the RIICnCR2.TRS bit is cleared to 0
 - When a stop condition is detected
 - When the RIIC enters receive mode from transmit mode
- When 1 is written to the RIICnCR1.IICRST bit to apply an RIIC reset or an internal reset

Caution: When the NACKF flag is set to 1 while the RIICnFER.NACKF bit is 1, the RIIC suspends data transmission/reception. Here, if the TDRE flag is 0 (next transmit data has been written), data is transferred to the RIICnDRS register and the RIICnDRT register becomes empty at the rising edge of the ninth clock cycle, but the TDRE flag is not set to 1.

23.3.11 RIICnSARy — I²C Slave Address Register y (y = 0 to 2)

Access: RIICnSARy is a 32-bit readable/writable register.
 RIICnSARyL and RIICnSARyH are 16-bit readable/writable registers.
 RIICnSARyLL, RIICnSARyLH, RIICnSARyHL, and RIICnSARyHH are 8-bit readable/writable registers.

Address: RIICnSAR0: <RIICn_base> + 0028_H
 RIICnSAR0L: <RIICn_base> + 0028_H, RIICnSAR0H: <RIICn_base> + 002A_H
 RIICnSAR0LL: <RIICn_base> + 0028_H, RIICnSAR0LH: <RIICn_base> + 0029_H, RIICnSAR0HL: <RIICn_base> + 002A_H,
 RIICnSAR0HH: <RIICn_base> + 002B_H
 RIICnSAR1: <RIICn_base> + 002C_H
 RIICnSAR1L: <RIICn_base> + 002C_H, RIICnSAR1H: <RIICn_base> + 002E_H
 RIICnSAR1LL: <RIICn_base> + 002C_H, RIICnSAR1LH: <RIICn_base> + 002D_H, RIICnSAR1HL: <RIICn_base> + 002E_H,
 RIICnSAR1HH: <RIICn_base> + 002F_H
 RIICnSAR2: <RIICn_base> + 0030_H
 RIICnSAR2L: <RIICn_base> + 0030_H, RIICnSAR2H: <RIICn_base> + 0032_H
 RIICnSAR2LL: <RIICn_base> + 0030_H, RIICnSAR2LH: <RIICn_base> + 0031_H, RIICnSAR2HL: <RIICn_base> + 0032_H,
 RIICnSAR2HH: <RIICn_base> + 0033_H

Initial Value: 0000 0000_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

| R/W | R/W | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Table 23.17 RIICnSARy register contents

| Bit Position | Bit Name | Function |
|--------------|----------|--|
| 31 to 16 | — | Reserved These bits are read as 0. The write value should be 0. |
| 15 | FSy | 7-Bit/10-Bit Address Format Selection 0: The 7-bit address format is selected. 1: The 10-bit address format is selected. |
| 14 to 10 | — | Reserved These bits are read as 0. The write value should be 0. |
| 9 to 1 | SVA[9:1] | 7-Bit Address/10-Bit Address Upper Bits A slave address is set. <ul style="list-style-type: none"> When the FSy bit is 0 (7-bit address format), the SVA[7:1] bits are Valid and form a 7-bit slave address. When the FSy bit is 1 (10-bit address format), SVA[9:1] bits form a 10-bit slave address (combined with the SVA0 bit). |
| 0 | SVA0 | 10-Bit Address LSB The least significant bit (LSB) of a 10-bit slave address is set. <ul style="list-style-type: none"> When the FSy bit is 0 (7-bit address format), this bit is invalid. When the FSy bit is 1 (10-bit address format), this bit is a 10-bit slave address (combined with the SVA[9:1] bits). |

SVA0 Bit (10-Bit Address LSB)

When the 10-bit address format is selected (RIICnSARy.FSy = 1), this bit functions as the LSB of a 10-bit address and forms a 10-bit address in combination with the SVA[9:1] bits.

When the RIICnSER.SARy bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 1, this bit is valid. While the RIICnSARy.FSy bit or SARy bit is 0, the setting of this bit is ignored.

SVA[9:1] Bits (7-Bit Address/10-Bit Address Upper Bits)

When the 7-bit address format is selected (RIICnSARy.FSy = 0), these bits function as a 7-bit address. When the 10-bit address format is selected (RIICnSARy.FSy = 1), these bits function as a 10-bit address in combination with the SVA0 bit.

While the RIICnSER.SARy bit is 0, the setting of these bits is ignored.

FSy Bit (7-Bit/10-Bit Address Format Selection)

This bit is used to select 7-bit address or 10-bit address for slave address y (in RIICnSARy).

When the RIICnSER.SARy bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 0, the 7-bit address format is selected for slave address y, the RIICnSARy.SVA[7:1] setting is valid, and the settings of the SVA[9:8] bits and the RIICnSARy.SVA0 bit are ignored.

When the RIICnSER.SARy bit is set to 1 (RIICnSARy enabled) and the RIICnSARy.FSy bit is 1, the 10-bit address format is selected for slave address y and the settings of the SVA[9:1] bits and the SVA0 bit are valid.

While the RIICnSER.SARy bit is 0 (RIICnSARy disabled), the setting of the RIICnSARy.FSy bit is invalid.

23.3.12 RIICnBRL — I²C Bus Bit Rate Low-Level Register

Access: RIICnBRL is a 32-bit readable/writable register.
 RIICnBRL and RIICnBRLH are 16-bit readable/writable registers.
 RIICnBRLLL, RIICnBRLH, RIICnBRLHL, and RIICnBRLHH are 8-bit readable/writable registers.

Address: RIICnBRL: <RIICn_base> + 0034_H
 RIICnBRL: <RIICn_base> + 0034_H, RIICnBRLH: <RIICn_base> + 0036_H
 RIICnBRLLL: <RIICn_base> + 0034_H, RIICnBRLH: <RIICn_base> + 0035_H, RIICnBRLHL: <RIICn_base> + 0036_H,
 RIICnBRLHH: <RIICn_base> + 0037_H

Initial Value: 0000 00FF_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Table 23.18 RIICnBRL register contents

| Bit Position | Bit Name | Function |
|--------------|----------|--|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 to 5 | — | Reserved These bits are read as 1. The write value should be 1. |
| 4 to 0 | BRL[4:0] | Bit Rate Low-Level Period Low-level period of SCL clock |

The RIICnBRL register is a 5-bit register that is used to set the width at low level for the SCL clock.

It also works to generate the data setup time for automatic SCL low-hold operation (see section 23.10, Automatically Low-Hold Function for SCL); when the RIIC is used only in slave mode, this register needs to be set to a value at least the same as the data setup time*¹.

RIICnBRL counts the low-level period with the internal reference clock source (IIC ϕ) specified by the RIICnMR1.CKS[2:0] bits.

Note 1. Data setup time ($t_{\text{SU: DAT}}$)
 250 [ns] (0 to 100 [kbps]: standard mode (Sm))
 100 [ns] (0 to 400 [kbps]: fast mode (Fm))
 50 [ns] (0 to 1 [Mbps]: fast mode plus (Fm+))

23.3.13 RIICnBRH — I²C Bus Bit Rate High-Level Register

Access: RIICnBRH is a 32-bit readable/writable register.
 RIICnBRHL and RIICnBRHH are 16-bit readable/writable registers.
 RIICnBRHLL, RIICnBRHLH, RIICnBRHHL, and RIICnBRHHH are 8-bit readable/writable registers.

Address: RIICnBRH: <RIICn_base> + 0038_H
 RIICnBRHL: <RIICn_base> + 0038_H, RIICnBRHH: <RIICn_base> + 003A_H
 RIICnBRHLL: <RIICn_base> + 0038_H, RIICnBRHLH: <RIICn_base> + 0039_H, RIICnBRHHL: <RIICn_base> + 003A_H, RIICnBRHHH: <RIICn_base> + 003B_H

Initial Value: 0000 00FF_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Table 23.19 RIICnBRH register contents

| Bit Position | Bit Name | Function |
|--------------|----------|--|
| 31 to 8 | — | Reserved These bits are read as 0. The write value should be 0. |
| 7 to 5 | — | Reserved These bits are read as 1. The write value should be 1. |
| 4 to 0 | BRH[4:0] | Bit Rate High-Level Period High-level period of SCL clock |

RIICnBRH is a 5-bit register to set the high-level period of SCL clock. RIICnBRH is valid in master mode. If the RIIC is used only in slave mode, this register need not to set the high-level period.

RIICnBRH counts the high-level period with the internal reference clock source (IICφ) specified by the RIICnMR1.CKS[2:0] bits in ICMR1.

The frequency and duty cycle are calculated using one of the following expressions (1) to (5) according to the register settings.

Caution: The minimum value that can be specified in RIICnBRL and RIICnBRH is determined according to the values of the SCLE and NFE bits in RIICnFER and the NF bit in RIICnMR3. For details of the minimum specifiable value, see Table 23.20.

(1) When SCLE = 0

$$\text{Frequency} = 1 / \{ [(BRH + 1) + (BRL + 1)] / IIC\phi + tr + tf \}$$

$$\text{Duty cycle} = \{ tr + (BRH + 1) / IIC\phi \} / \{ tr + tf + [(BRH + 1) + (BRL + 1)] / IIC\phi \}$$

(2) When SCLE = 1, NFE = 0, CKS = 000 (IICφ = P1φ)

$$\text{Frequency} = 1 / \{ [(BRH + 3) + (BRL + 3)] / IIC\phi + tr + tf \}$$

$$\text{Duty cycle} = \{ tr + (BRH + 3) / IIC\phi \} / \{ tr + tf + [(BRH + 3) + (BRL + 3)] / IIC\phi \}$$

- (3) When SCLE = 1, NFE = 1, CKS = 000 ($IIC\phi = P1\phi$)
 Frequency = $1 / \{[(BRH + 3 + nf) + (BRL + 3 + nf)] / IIC\phi + tr + tf\}$
 Duty cycle = $\{tr + (BRH + 3 + nf) / IIC\phi\} / \{tr + tf + [(BRH + 3 + nf) + (BRL + 3 + nf)] / IIC\phi\}$
- (4) When SCLE = 1, NFE = 0, CKS = 000 ($IIC\phi < P1\phi$)
 Frequency = $1 / \{[(BRH + 2) + (BRL + 2)] / IIC\phi + tr + tf\}$
 Duty cycle = $\{tr + (BRH + 2) / IIC\phi\} / \{tr + tf + [(BRH + 2) + (BRL + 2)] / IIC\phi\}$
- (5) When SCLE = 1, NFE = 1, CKS = 000 ($IIC\phi < P1\phi$)
 Frequency = $1 / \{[(BRH + 2 + nf) + (BRL + 2 + nf)] / IIC\phi + tr + tf\}$
 Duty cycle = $\{tr + (BRH + 2 + nf) / IIC\phi\} / \{tr + tf + [(BRH + 2 + nf) + (BRL + 2 + nf)] / IIC\phi\}$

Symbols in the expressions

SCLE: RIICnFER.SCLE bit

BRH: RIICnBRH.BRH[4:0] bits

BRL: RIICnBRL.BRL[4:0] bits

CKS: RIICnMR1.CKS bits

NFE: RIICnFER.NFE bit

$IIC\phi$: Internal reference clock selected by the CKS bits

tf: SCL signal falling time [s]*1

tr: SCL signal rising time [s]*1

nf: Number of digital noise filter stages specified in the RIICnMR3.NF[1:0] bits

Note 1. The rising time (tr) and falling time (tf) of the SCL signal depend on the total capacitance of the bus line (Cb) and pull-up resistor (Rp). For details, see I²C Bus Standard from NXP Semiconductors.

Table 23.20 Minimum Specifiable Value for RIICnBRL and RIICnBRH

| SCLE | NFE | nf | Minimum Pulse Width that Passes through Digital Filter | Minimum Specifiable Value for BRH and BRL | Pulse Width when Minimum Value is Specified |
|---|-----|----|--|---|---|
| 0 | 0 | — | $1 \times IIC\phi$ | 1 | $2 \times IIC\phi$ |
| 0 | 1 | 1 | $2 \times IIC\phi$ | 2 | $3 \times IIC\phi$ |
| 0 | 1 | 2 | $3 \times IIC\phi$ | 3 | $4 \times IIC\phi$ |
| 0 | 1 | 3 | $4 \times IIC\phi$ | 4 | $5 \times IIC\phi$ |
| 0 | 1 | 4 | $5 \times IIC\phi$ | 5 | $6 \times IIC\phi$ |
| IIC ϕ cycle > P1 ϕ cycle (CKS \neq 000) | | | | | |
| 1 | 0 | — | $1 \times IIC\phi$ | 0 | $2 \times IIC\phi$ |
| 1 | 1 | 1 | $2 \times IIC\phi$ | 1 | $4 \times IIC\phi$ |
| 1 | 1 | 2 | $3 \times IIC\phi$ | 2 | $6 \times IIC\phi$ |
| 1 | 1 | 3 | $4 \times IIC\phi$ | 3 | $8 \times IIC\phi$ |
| 1 | 1 | 4 | $5 \times IIC\phi$ | 4 | $10 \times IIC\phi$ |
| IIC ϕ cycle = P1 ϕ cycle (CKS = 000) | | | | | |
| 1 | 0 | — | $2 \times P1\phi$ | 0 | $3 \times IIC\phi$ |
| 1 | 1 | 1 | $3 \times P1\phi$ | 1 | $5 \times IIC\phi$ |
| 1 | 1 | 2 | $4 \times P1\phi$ | 2 | $7 \times IIC\phi$ |
| 1 | 1 | 3 | $5 \times P1\phi$ | 3 | $9 \times IIC\phi$ |
| 1 | 1 | 4 | $6 \times P1\phi$ | 4 | $11 \times IIC\phi$ |

Table 23.21 and Table 23.22 list examples of RIICnBRH/RIICnBRL settings.

Table 23.21 Examples of RIICnBRH/RIICnBRL Settings for Transfer Rate (when RIICnFER.SCLE = 1 and RIICnFER.NFE= 0)

23.3.14 RIICnDRT — I²C Bus Transmit Data Register

Access: RIICnDRT is a 32-bit readable/writable register.
 RIICnDRTL and RIICnDRTH are 16-bit readable/writable registers.
 RIICnDRTLL, RIICnDRTLH, RIICnDRTHL, and RIICnDRTHH are 8-bit readable/writable registers.

Address: RIICnDRT: <RIICn_base> + 003C_H
 RIICnDRTL: <RIICn_base> + 003C_H, RIICnDRTH: <RIICn_base> + 003E_H
 RIICnDRTLL: <RIICn_base> + 003C_H, RIICnDRTLH: <RIICn_base> + 003D_H, RIICnDRTHL: <RIICn_base> + 003E_H,
 RIICnDRTHH: <RIICn_base> + 003F_H

Initial Value: 0000 00FF_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|---------------|----|----|----|----|----|----|----|----|----------|-----|-----|-----|-----|-----|-----|-----|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | DRT[7:0] | | | | | | | |
| Initial value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| R/W | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

When RIICnDRT detects a space in the I²C bus shift register (RIICnDRS), it transfers the transmit data that has been written to RIICnDRT to RIICnDRS and starts transmitting data in transmit mode.

The double-buffer structure of RIICnDRT and RIICnDRS allows continuous transmit operation if the next transmit data has been written to RIICnDRT while the RIICnDRS data is being transmitted.

RIICnDRT can always be read and written. Write transmit data to RIICnDRT once when a transmit data empty interrupt (INTRIICTI) request is generated. When writing to bits 8 to 15, be sure to write 0 to these bits.

23.3.15 RIICnDRR — I²C Bus Receive Data Register

Access: RIICnDRR is a 32-bit readable/writable register.
 RIICnDRRL and RIICnDRRH are 16-bit readable/writable registers.
 RIICnDRRL, RIICnDRRLH, RIICnDRRH, and RIICnDRRH are 8-bit readable/writable registers.

Address: RIICnDRR: <RIICn_base> + 0040_H
 RIICnDRRL: <RIICn_base> + 0040_H, RIICnDRRH: <RIICn_base> + 0042_H
 RIICnDRRL: <RIICn_base> + 0040_H, RIICnDRRLH: <RIICn_base> + 0041_H, RIICnDRRH: <RIICn_base> + 0042_H,
 RIICnDRRH: <RIICn_base> + 0043_H

Initial Value: 0000 0000_H This register is initialized by any reset.

| Bit | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| Initial value | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

When 1 byte of data has been received, the received data is transferred from the I²C bus shift register (RIICnDRS) to RIICnDRR to enable the next data to be received.

The double-buffer structure of RIICnDRS and RIICnDRR allows continuous receive operation if the received data has been read from RIICnDRR while RIICnDRS is receiving data.

RIICnDRR cannot be written. Read data from RIICnDRR once when a receive data full interrupt (INTRIICRI) request is generated.

If DRR receives the next receive data before the current data is read from RIICnDRR (while the RIICnSR2.RDRF flag is 1), the RIIC automatically holds the SCL clock low one cycle before the RDRF flag is set to 1 next.

23.3.16 RIICnDRS — I²C Bus Shift Register

Access: This register is not accessible.

Address: —

Initial Value: 0000 00FF_H

| | | | | | | | | | | | | | | | | |

| R/W | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

RIICnDRS is an 8-bit shift register to transmit and receive data.

During transmission, transmit data is transferred from RIICnDRT to RIICnDRS and is sent from the SDA pin. During reception, data is transferred from RIICnDRS to RIICnDRR after 1 byte of data has been received.

RIICnDRS cannot be accessed directly.

23.4 Interrupt Sources

The RIIC issues eight types of interrupt request: transmit end, receive data full, transmit data empty, stop condition detection, start condition detection, NACK reception, arbitration-lost, and timeout.

Table 23.23 lists details of the several interrupt requests. The receive data full and transmit data empty sources are both capable of launching data transfer by the DMAC.

Table 23.23 Interrupt Sources

| Symbol | Interrupt Source | Interrupt Flag | DMAC Launching | Priority*1 | Interrupt Condition |
|-------------|--------------------------------|----------------|----------------|------------------|-----------------------------|
| INTRIICTEI | Transmission complete | TEND | Not possible | High ↑ Low | $TEND = 1 \cdot TEIE = 1$ |
| INTRIICRI | Receive-data-full | RDRF | Possible | | $RDRF = 1 \cdot RIE = 1$ |
| INTRIICTI | Transmit-data-empty | TDRE | Possible | | $TDRE = 1 \cdot TIE = 1$ |
| INTRIICSPI | Detection of a stop condition | STOP | Not possible | | $STOP = 1 \cdot SPIE = 1$ |
| INTRIICSTI | Detection of a start condition | START | Not possible | | $START = 1 \cdot STIE = 1$ |
| INTRIICNAKI | Reception of a NACK | NACKF | Not possible | | $NACKF = 1 \cdot NAKIE = 1$ |
| INTRIICALI | Arbitration lost | AL | Not possible | | $AL = 1 \cdot ALIE = 1$ |
| INTRIICTMOI | Timeout | TMOF | Not possible | Low | $TMOF = 1 \cdot TMOIE = 1$ |

Note 1. When the interrupt priority register (ICDIPRn) setting is the same

Clear or mask the each flag during interrupt handling.

Caution:1. There is a latency (delay) between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt processing. Returning from interrupt processing without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

Caution:2. Since INTRIICRI and INTRIICTI are edge-detected interrupts, they do not require clearing.

Caution:3. When using the INTRIICTEI interrupt, clear the RIICnSR2.TEND flag in the INTRIICTEI interrupt processing.

Caution:4. When using the INTRIICSPI interrupt, clear the RIICnSR2.STOP flag in the INTRIICSPI interrupt processing.

Caution:5. When using the INTRIICSTI interrupt, clear the RIICnSR2.START flag in the INTRIICSTI interrupt processing.

Caution:6. When using the INTRIICNAKI interrupt, clear the RIICnSR2.NACKF flag in the INTRIICNAKI interrupt processing.

Caution:7. When using the INTRIICALI interrupt, clear the RIICnSR2.AL flag in the INTRIICALI interrupt processing.

Caution:8. When using the INTRIICTMOI interrupt, clear the RIICnSR2.TMOF flag in the INTRIICTMOI interrupt processing.

23.5 Operation

23.5.1 Communication Data Format

The I²C bus format consists of 8-bit data and 1-bit acknowledge (one frame). After a start condition or restart condition is issued, the master device sends the slave address and data direction in the first frame. The specified slave is valid until a stop condition is issued or a new slave is specified by a restart condition.

Figure 23.3 shows the I²C bus format, and Figure 23.4 shows the I²C bus timing.

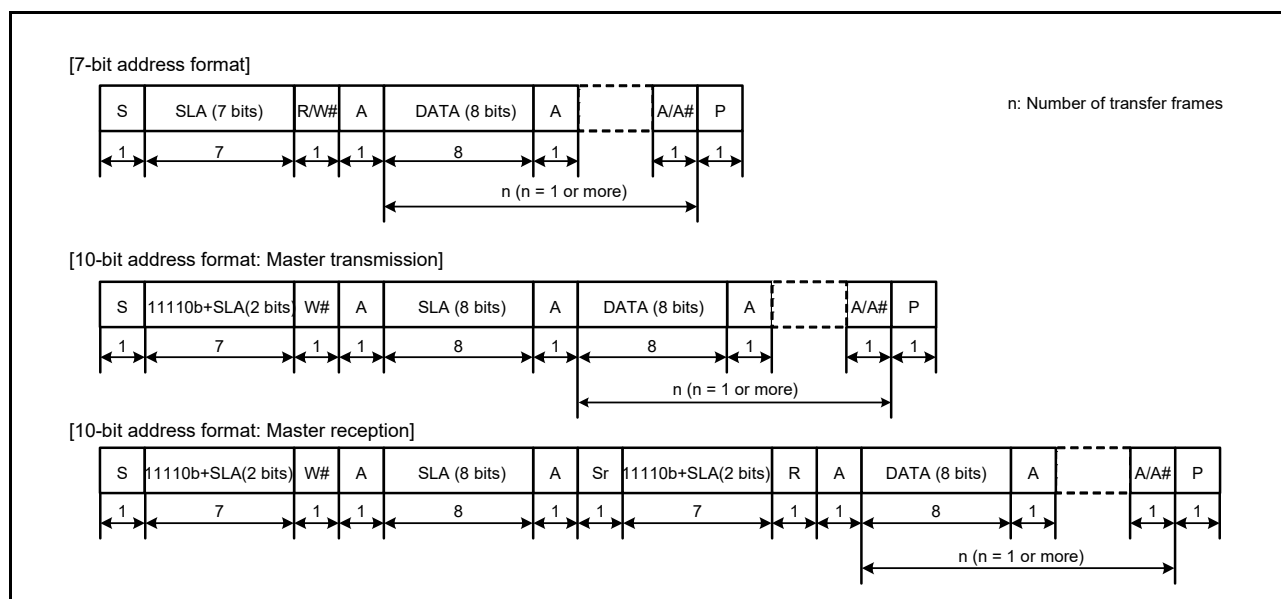

Figure 23.3 I²C Bus Format

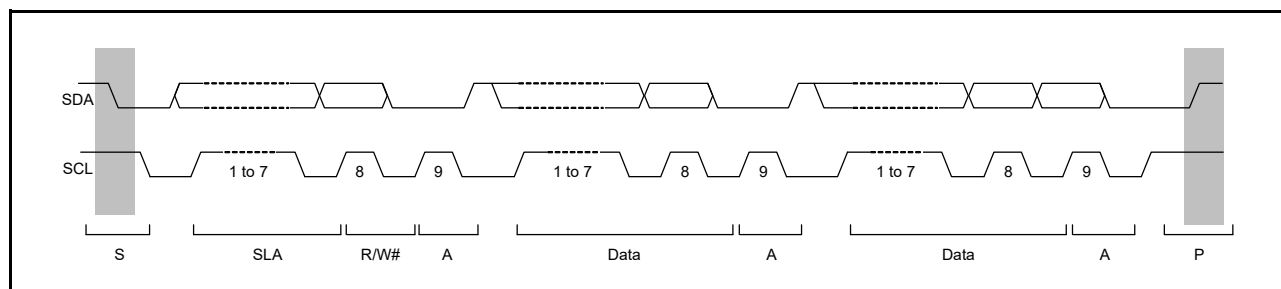

Figure 23.4 I²C Bus Timing (SLA = 7 Bits)

- S: Start condition. The master device drives the SDA line low from high level while the SCL line is at a high level.
- SLA: Slave address, by which the master device selects a slave device.
- R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.
- A: Acknowledge. The receive device drives the SDA line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)
- A#: Not-acknowledge. The receiving device has not returned a response or is not present so the SDA line has remained at the high level.
- Sr: Restart condition. The master device drives the SDA line low from the high level after the setup time has elapsed with the SCL line at the high level.
- DATA: Transmitted or received data
- P: Stop condition. The master device drives the SDA line high from low level while the SCL line is at a high level.

23.5.2 Initial Settings

Before starting data transmission and reception, initialize the RIIC according to the procedure in Figure 23.5.

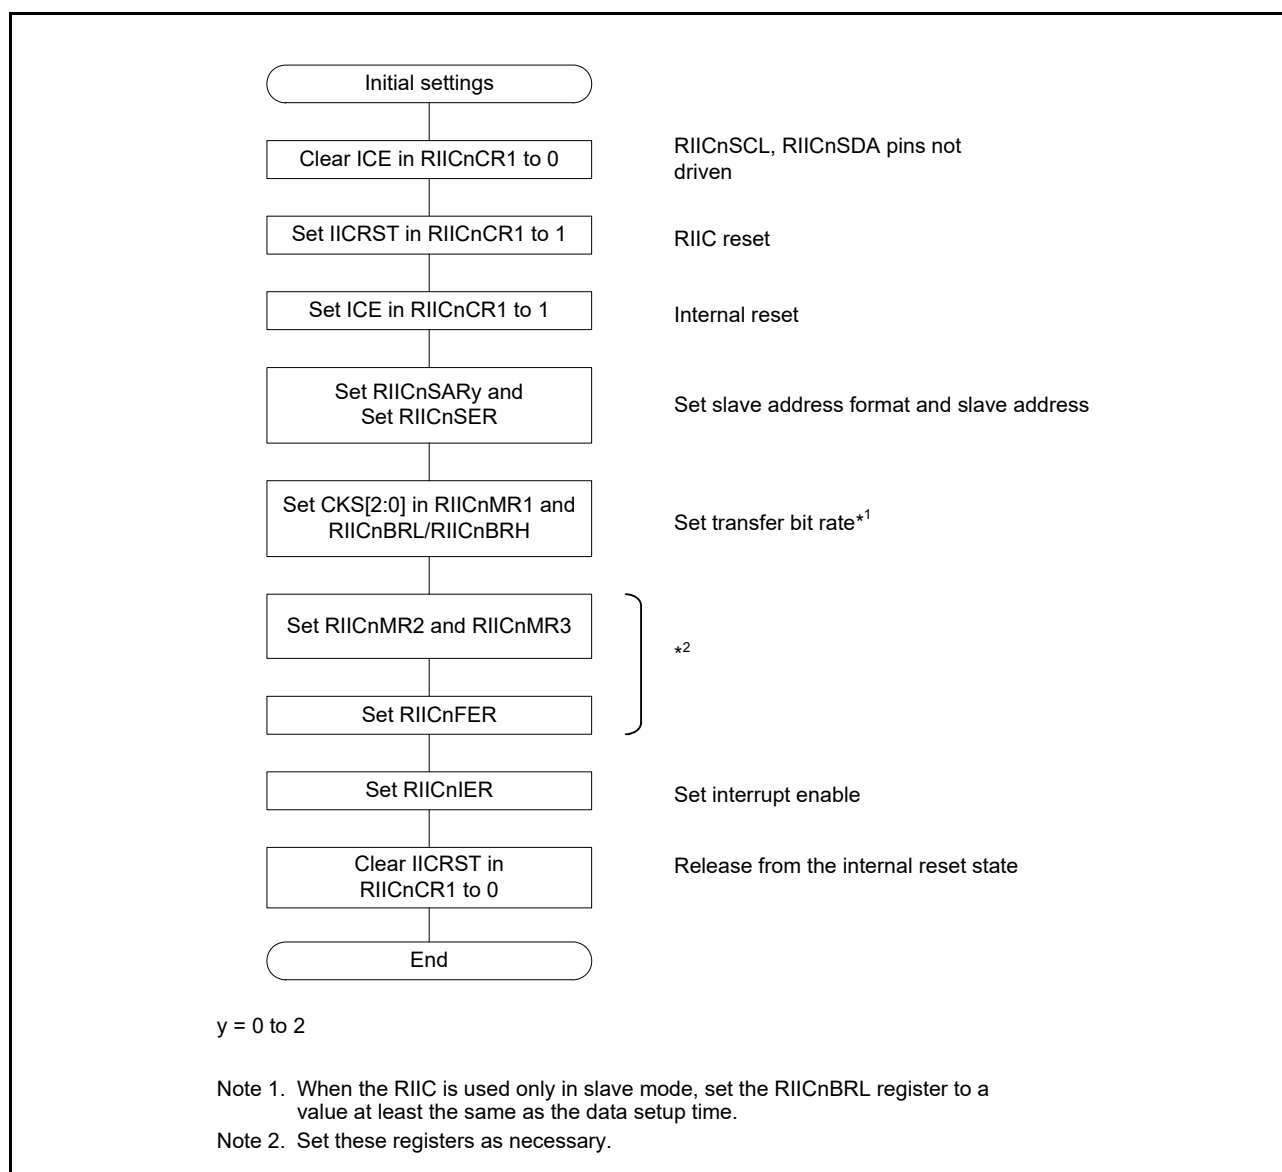

Figure 23.5 Example of RIIC Initialization Flowchart

23.5.3 Master Transmit Operation

In master transmit operation, the RIIC outputs the SCL (clock) and transmitted data signals as the master device, and the slave device returns acknowledgements. Figure 23.6 shows an example of usage of master transmission and Figure 23.7 to Figure 23.9 show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

- (1) Set the RIICnCR1.IICRST bit 1 to 1 (RIIC reset) and then set the RIICnCR1.ICE bit to 1 (internal reset) with the RIICnCR1.ICE bit cleared to 0 (RIICnSCL and RIICnSDA pins not driven). This initializes the internal state and the various flags of RIICnSR1. After that, set registers RIICnSARy, RIICnSER, RIICnMR1, RIICnBRH, and RIICnBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see Figure 23.5). When the necessary register settings have been completed, set the RIICnCR1.IICRST bit to 0 (for release from the reset state). This step is not necessary if initialization of the RIIC has already been completed.
- (2) Read the RIICnCR2.BBSY flag to check that the bus is open, and then set the RIICnCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. At the same time, the BBSY flag and the RIICnSR2.START flag are automatically set to 1 and the ST bit is automatically cleared to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDA line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the RIICnCR2.MST and TRS bits are automatically set to 1, placing the RIIC in master transmit mode. The RIICnSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.
- (3) Check that the RIICnSR2.TDRE flag is 1, and then write the value for transmission (the slave address and the R/W# bit) to RIICnDRT. Once the data for transmission are written to RIICnDRT, the TDRE flag is automatically cleared to 0, the data are transferred from RIICnDRT to RIICnDRS, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIIC continues in master transmit mode.
 Since the RIICnSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the RIICnCR2.SP bit to issue a stop condition.
 For data transmission with an address in the 10-bit format, start by writing 1111 0_B, the two higher-order bits of the slave address, and W# to RIICnDRT as the first address transmission. Then, as the second address transmission, write the eight lower-order bits of the slave address to RIICnDRT.
- (4) After confirming that the RIICnSR2.TDRE flag is 1, write the data for transmission to the RIICnDRT register. The RIIC automatically holds the SCL line low until the data for transmission are ready or a stop condition is issued.
- (5) After the last byte of the data to be transmitted is written to the RIICnDRT register, wait until the value of the RIICnSR2.TEND flag returns to 1, and then set the RIICnCR2.SP bit to 1 (stop condition issuance request). Upon receiving a stop condition issuance request, the RIIC issues the stop condition.
- (6) Upon detecting the stop condition, the RIIC automatically clears the RIICnCR2.MST and TRS bits to 00_B and enters slave receive mode. Furthermore, it automatically clears the RIICnSR2.TDRE and TEND flags to 0, and sets the RIICnSR2.STOP flag in to 1.
- (7) Clear the RIICnSR2.NACKF and STOP flags to 0.

Caution: Operations for transfer start if the RIICnSR2.NACKF flag is cleared to 0 before RIICnSR2.STOP is set to 1. Be sure to confirm that RIICnSR2.STOP is set to 1 before clearing RIICnSR2.NACKF to 0. In particular, when the NACK receive interrupt (INTRIICNAKI) is in use, take care not to clear the NACKF flag to 0 before the STOP flag is set to 1 during interrupt processing.

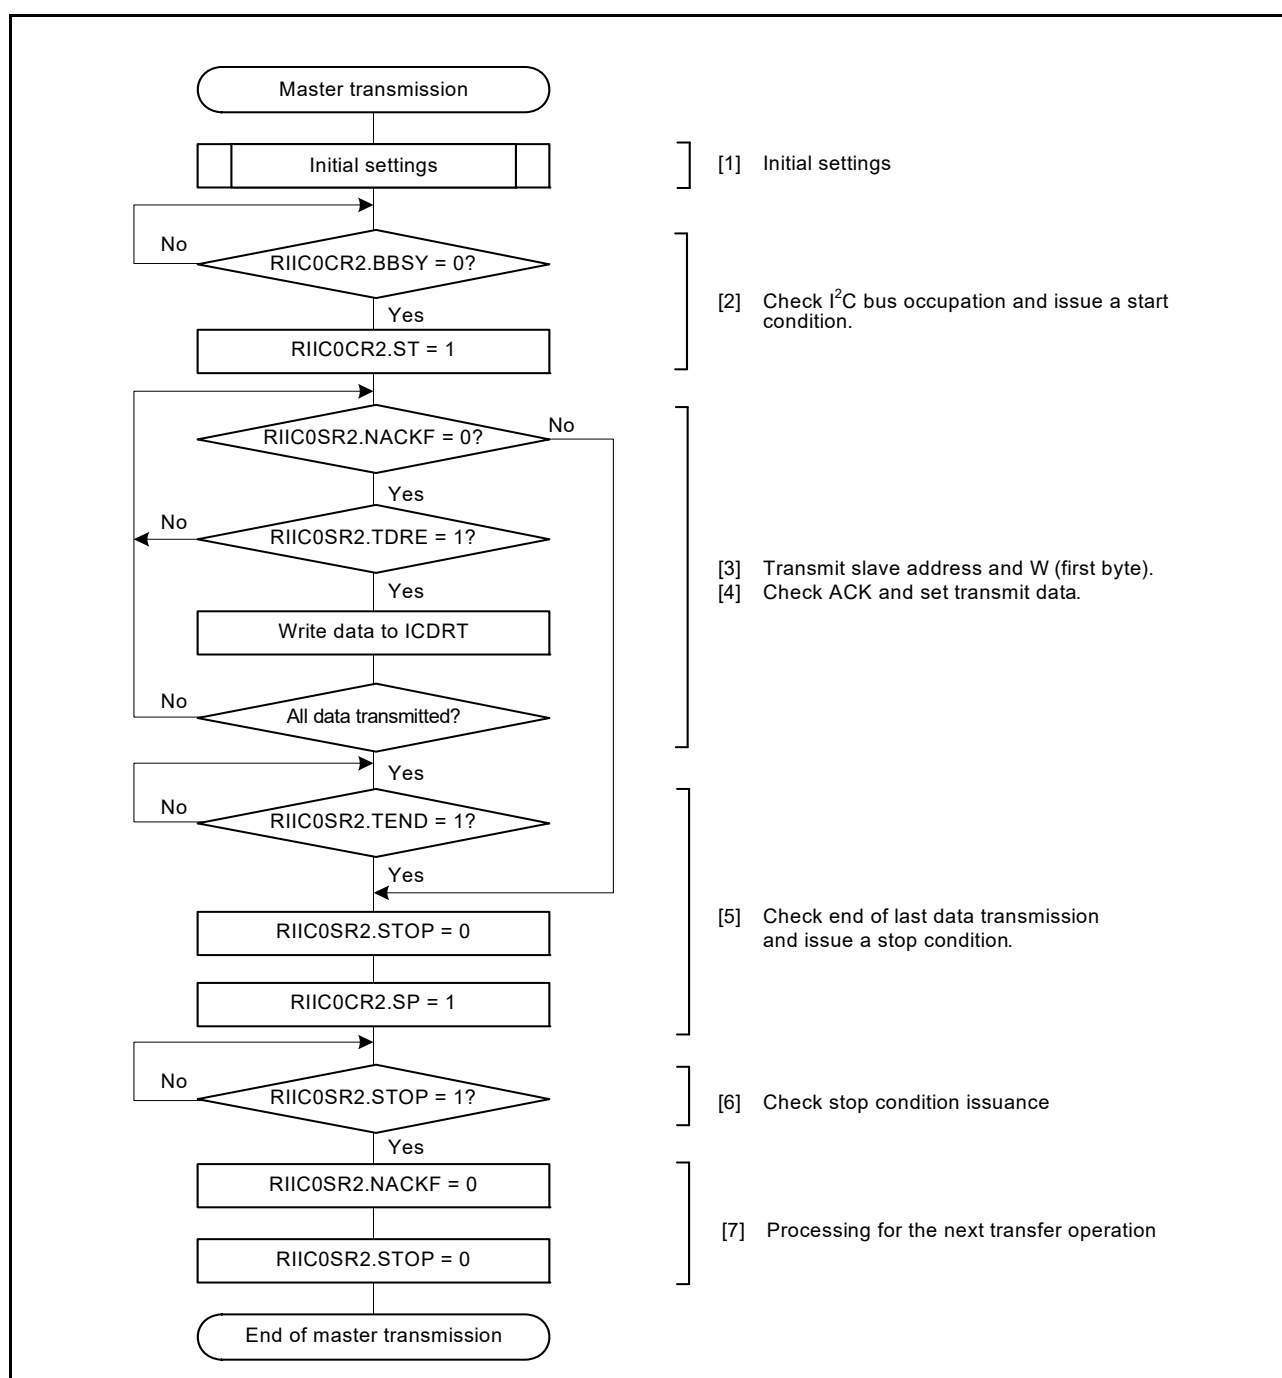

Figure 23.6 Example of Master Transmission Flowchart

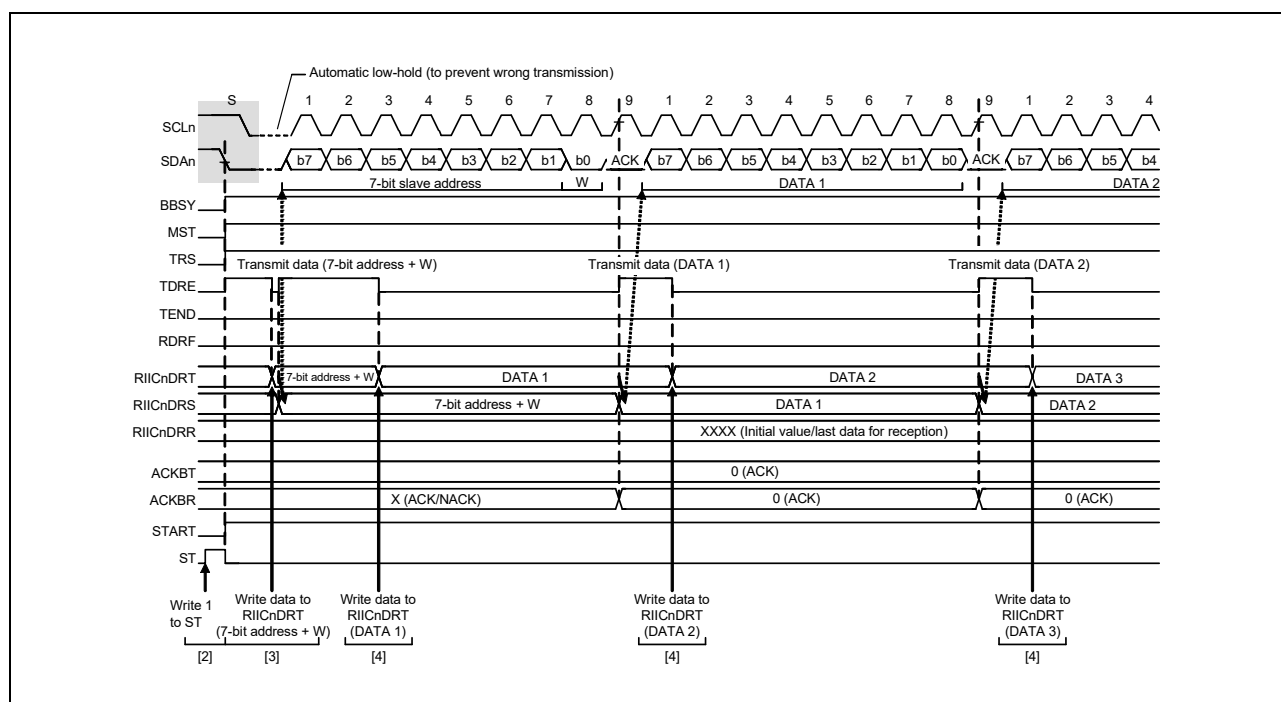

Figure 23.7 Master Transmit Operation Timing (1) (7-Bit Address Format)

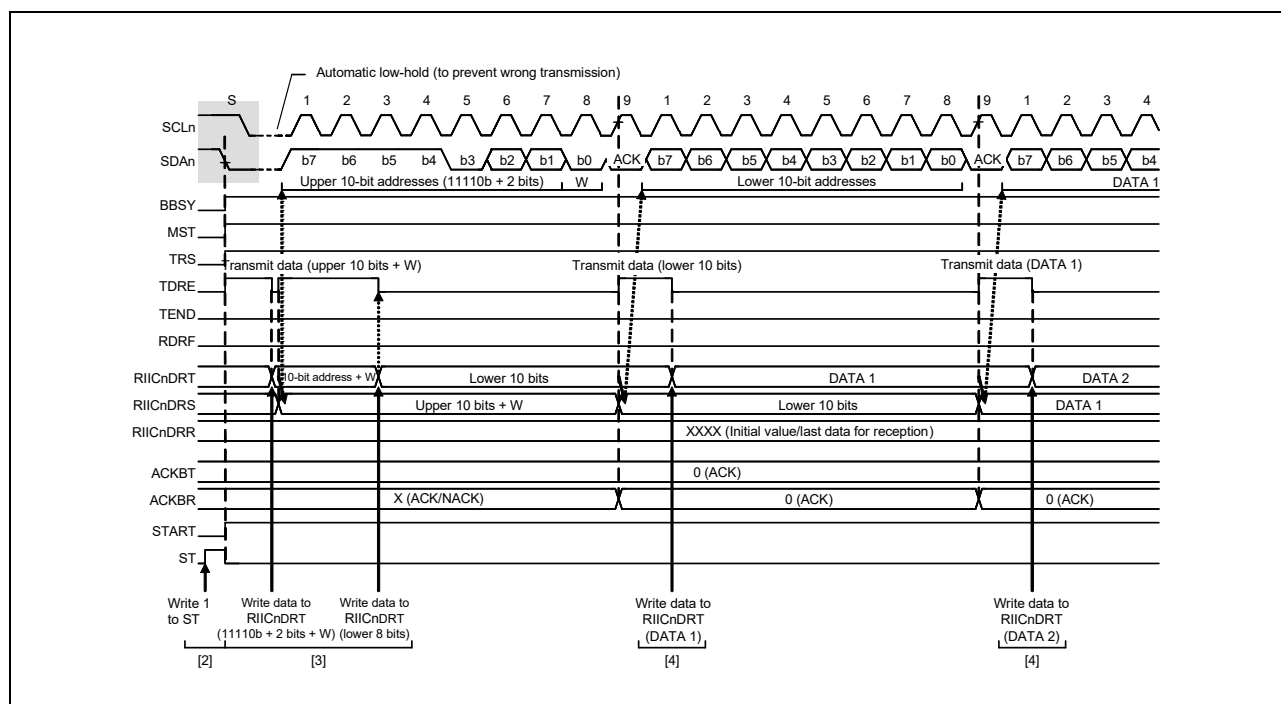

Figure 23.8 Master Transmit Operation Timing (2) (10-Bit Address Format)

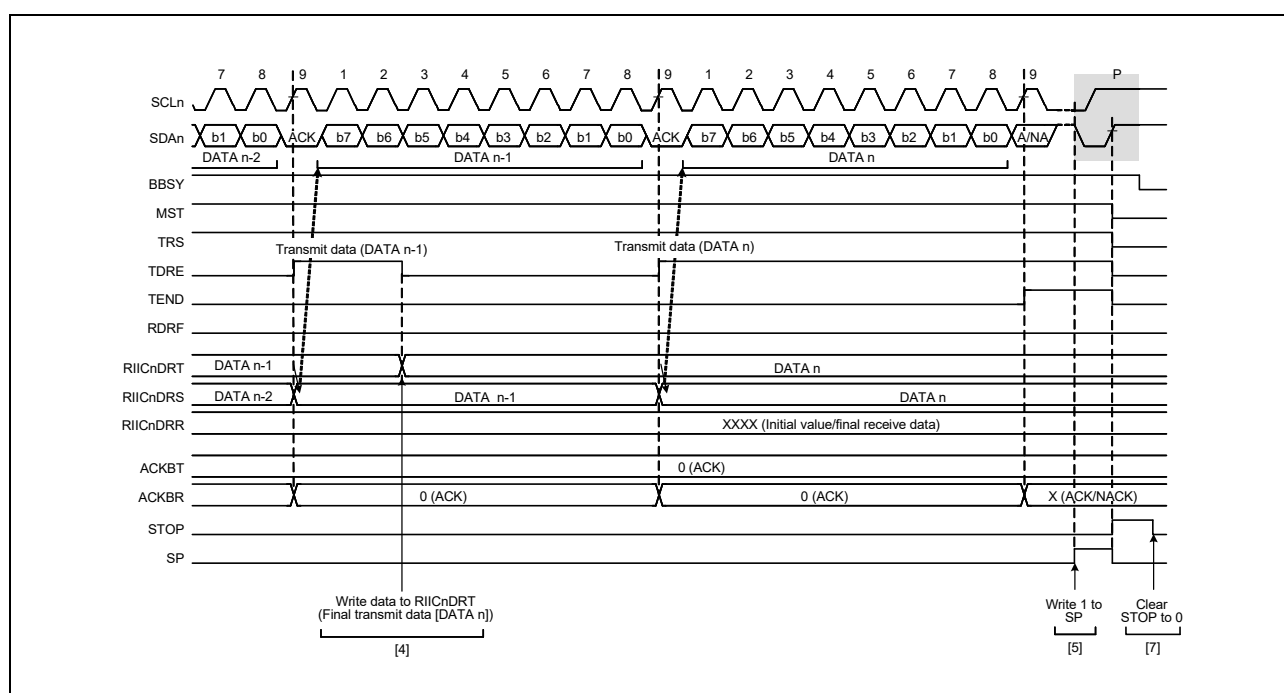

Figure 23.9 Master Transmit Operation Timing (3)

23.5.4 Master Receive Operation

In master receive operation, the RIIC as a master device outputs the SCL (clock) signal, receives data from the slave device, and returns acknowledgements. Since the RIIC must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 23.10 shows an example of usage for the master reception of 3 or more bytes (7-bit address format), Figure 23.14 shows an example of usage for the master reception of 1 or 2 bytes (7-bit address format), and Figure 23.11 to Figure 23.13 show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

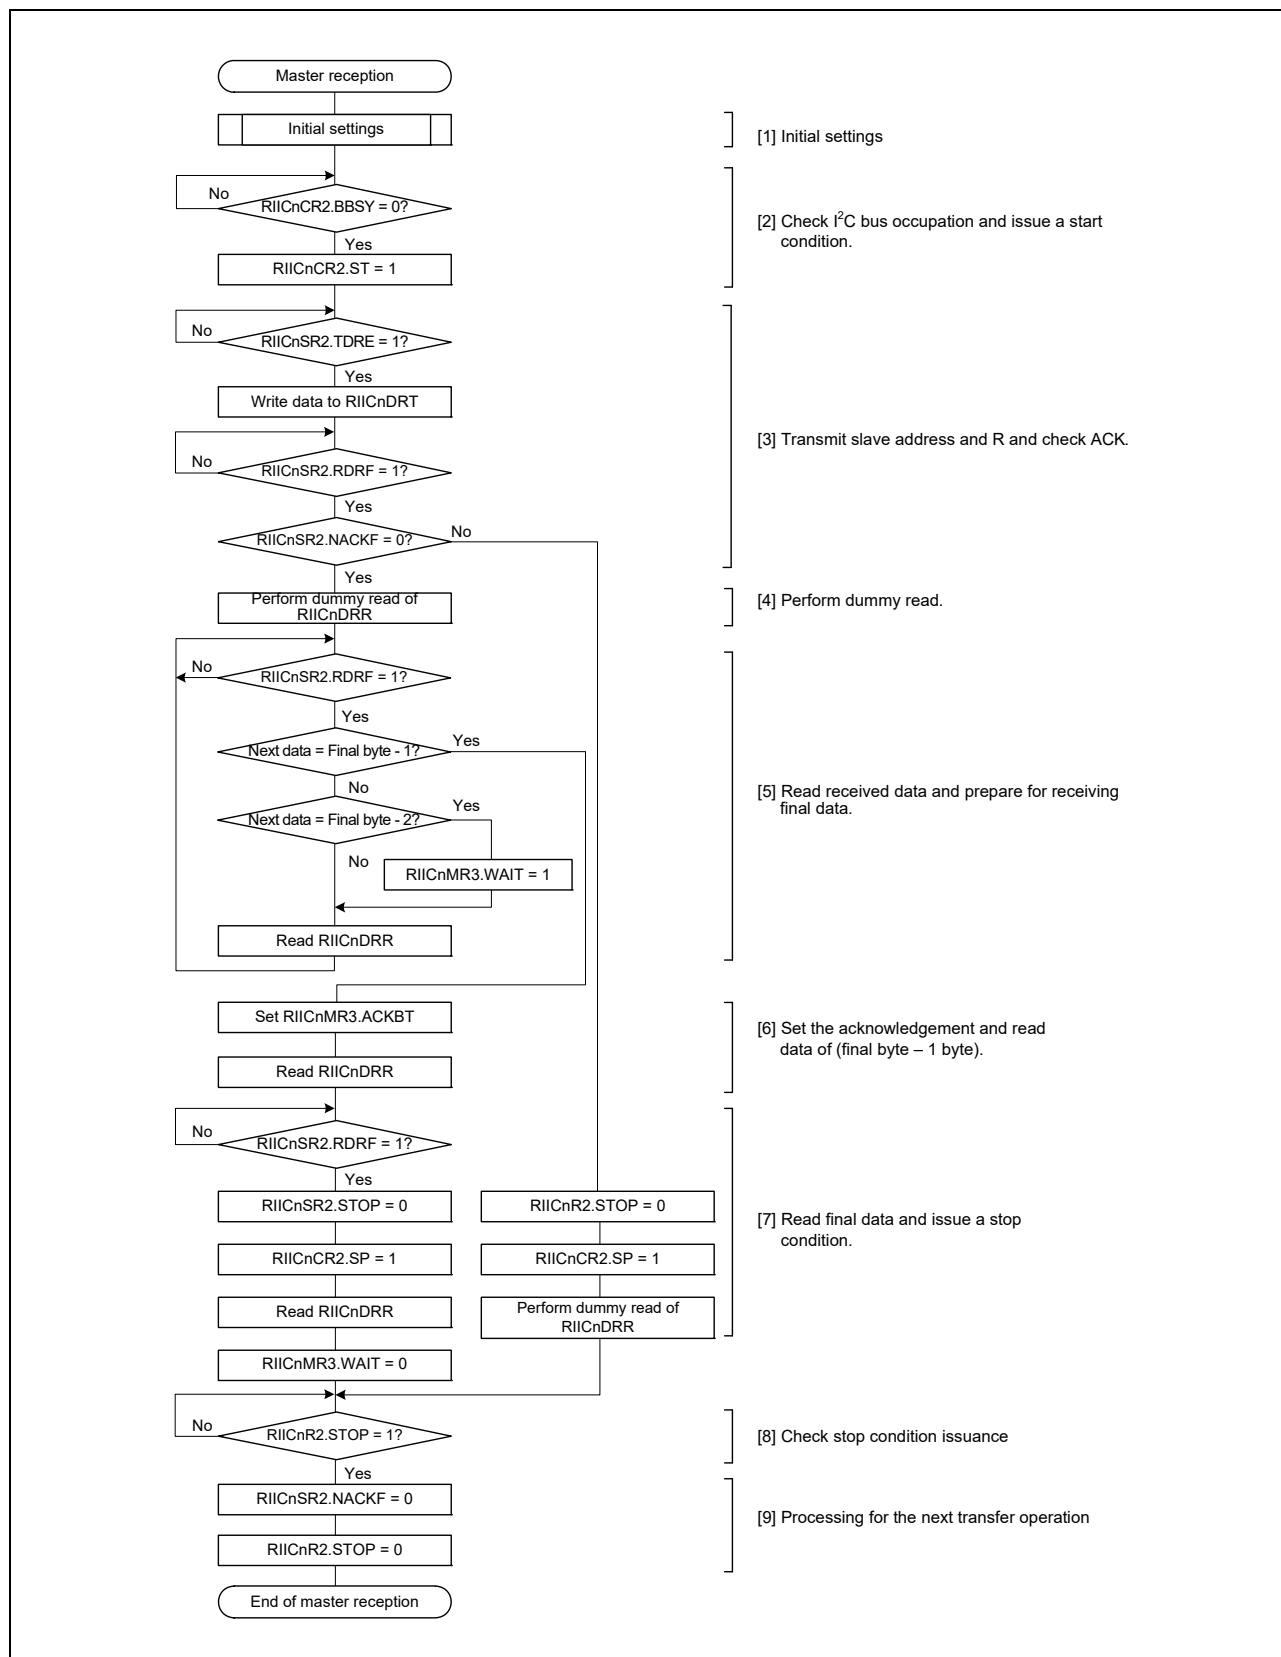

- (1) Set the RIICnCR1.IICRST bit to 1 (RIIC reset) and then set the RIICnCR1.ICE bit to 1 (internal reset) with the RIICnCR1.ICE bit cleared to 0 (RIICnSCL and RIICnSDA pins not driven). This initializes the internal state and the various flags of RIICnSR1. After that, set registers RIICnSARy, RIICnSER, RIICnMR1, RIICnBRH, and RIICnBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see Figure 23.5). When the necessary register settings have been completed, set the RIICnCR1.IICRST bit to 0 (for release from the reset state). This step is not necessary if initialization of the RIIC has already been completed.
- (2) Read the RIICnCR2.BBSY flag to check that the bus is open, and then set the RIICnCR2.ST bit to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. When the RIIC detects the start condition, the BBSY flag and the RIICnSR2.START flag are automatically set to 1 and the ST bit is automatically cleared to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDA line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the RIICnCR2.MST and TRS bits are automatically set to 1, placing the RIIC in master transmit mode. The RIICnSR2.TDRE flag is also automatically set to 1 in response to setting of the TRS bit to 1.
- (3) Check that the RIICnSR2.TDRE flag is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to RIICnDRT. Once the data for transmission are written to RIICnDRT, the TDRE flag is automatically cleared to 0, the data are transferred from RIICnDRT to RIICnDRS, and the TDRE flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the RIICnCR2.TRS bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the RIICnCR2.TRS bit is cleared to 0 on the rising edge of the ninth cycle of SCL (the clock signal), placing the RIIC in master receive mode. At this time, the TDRE flag is automatically cleared to 0 and the RIICnSR2.RDRF flag is automatically set to 1.

Since the RIICnSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the RIICnCR2.SP bit to issue a stop condition.

For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 1111 0B, the two higher-order bits of the slave address, and the R bit places the RIIC in master receive mode.

- (4) Dummy read RIICnDRR after confirming that the RIICnSR2.RDRF flag is 1; this makes the RIIC start output of the SCL (clock) signal and start data reception.
- (5) After 1 byte of data has been received, the RIICnSR2.RDRF flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the RIICnMR3.RDRFS bit. Reading out RIICnDRR at this time will produce the received data, and the RDRF flag is automatically cleared to 0 at the same time. Furthermore, the value of the acknowledgement field received during the ninth cycle of SCL clock is returned as the value set in the RIICnMR3.ACKBT bit. Furthermore, if the next byte to be received is the next to last byte, set the RIICnMR3.WAIT bit to 1 (for wait insertion) before reading the RIICnDRR (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the RIICnMR3.ACKBT bit to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCL line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a stop condition is possible.

- (6) When the RIICnMR3.RDRFS bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the RIICnMR3.ACKBT bit to 1 (NACK).
- (7) After reading out the byte before last from the RIICnDDR register, if the value of the RIICnSR2.RDRF flag is confirmed to be 1, write 1 to the RIICnCR2.SP bit (stop condition issuance request) and then read the last byte from RIICnDDR. When RIICnDDR is read, the RIIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is completed or the SCL line is released from the low-hold state.
- (8) Upon detecting the stop condition, the RIIC automatically clears the RIICnCR2.MST and TRS bits to 00B and enters slave receive mode. Furthermore, detection of the stop condition leads to setting of the RIICnSR2.STOP flag to 1.
- (9) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.NACKF and STOP flags to 0 for the next transfer operation.

Example Flowchart for the Master Reception of 1 or 2 Bytes (7-Bit Address Format)

23.5.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL (clock) signal, the RIIC transmits data as a slave device, and the master device returns acknowledgements.

Figure 23.15 shows an example of usage of slave transmission and Figure 23.16 and Figure 23.17 show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

- (1) Follow the procedure in Figure 23.5 to make initial settings for the RIIC. This step is not necessary if initialization of the RIIC has already been completed. After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.
- (2) After receiving a matching slave address, the RIIC sets one of the corresponding bits RIICnSR1.HOA, GCA, and AAS_y ($y = 0$ to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1, the RIIC automatically places itself in slave transmit mode by setting both the RIICnCR2.TRS bit and the RIICnSR2.TDRE flag to 1.
- (3) After the RIICnSR2.TEND flag is confirmed to be 1, write the data for transmission to the RIICnDRT register. At this time, if the RIIC receives no acknowledge from the master device (receives an NACK signal) while the RIICnFER.NACKF bit is 1, the RIIC suspends transfer of the next data.
- (4) Wait until the RIICnSR2.TEND flag is set to 1 while the RIICnSR2.TDRE flag is 1, after the RIICnSR2.NACKF flag is set to 1 or the last byte for transmission is written to the RIICnDRT register. When the RIICnSR2.NACKF flag or the TEND flag is 1, the RIIC drives the SCL line low on the ninth falling edge of SCL clock.
- (5) When the RIICnSR2.NACKF flag or the RIICnSR2.TEND flag is 1, dummy read RIICnDRR to complete the processing. This releases the SCL line.
- (6) Upon detecting the stop condition, the RIIC automatically clears bits RIICnSR1.HOA, GCA, and AAS_y ($y = 0$ to 2), flags RIICnSR2.TDRE and TEND, and the RIICnCR2.TRS bit to 0, and enters slave receive mode.
- (7) Clear the RIICnSR2.NACKF and STOP flags to 0.

Caution: Operations for transfer start if the RIICnSR2.NACKF flag is cleared to 0 before RIICnSR2.STOP is set to 1. Be sure to confirm that RIICnSR2.STOP is set to 1 before clearing RIICnSR2.NACKF to 0. In particular, when the NACK receive interrupt (INTRIICNAKI) is in use, take care not to clear the NACKF flag to 0 before the STOP flag is set to 1 during interrupt processing.

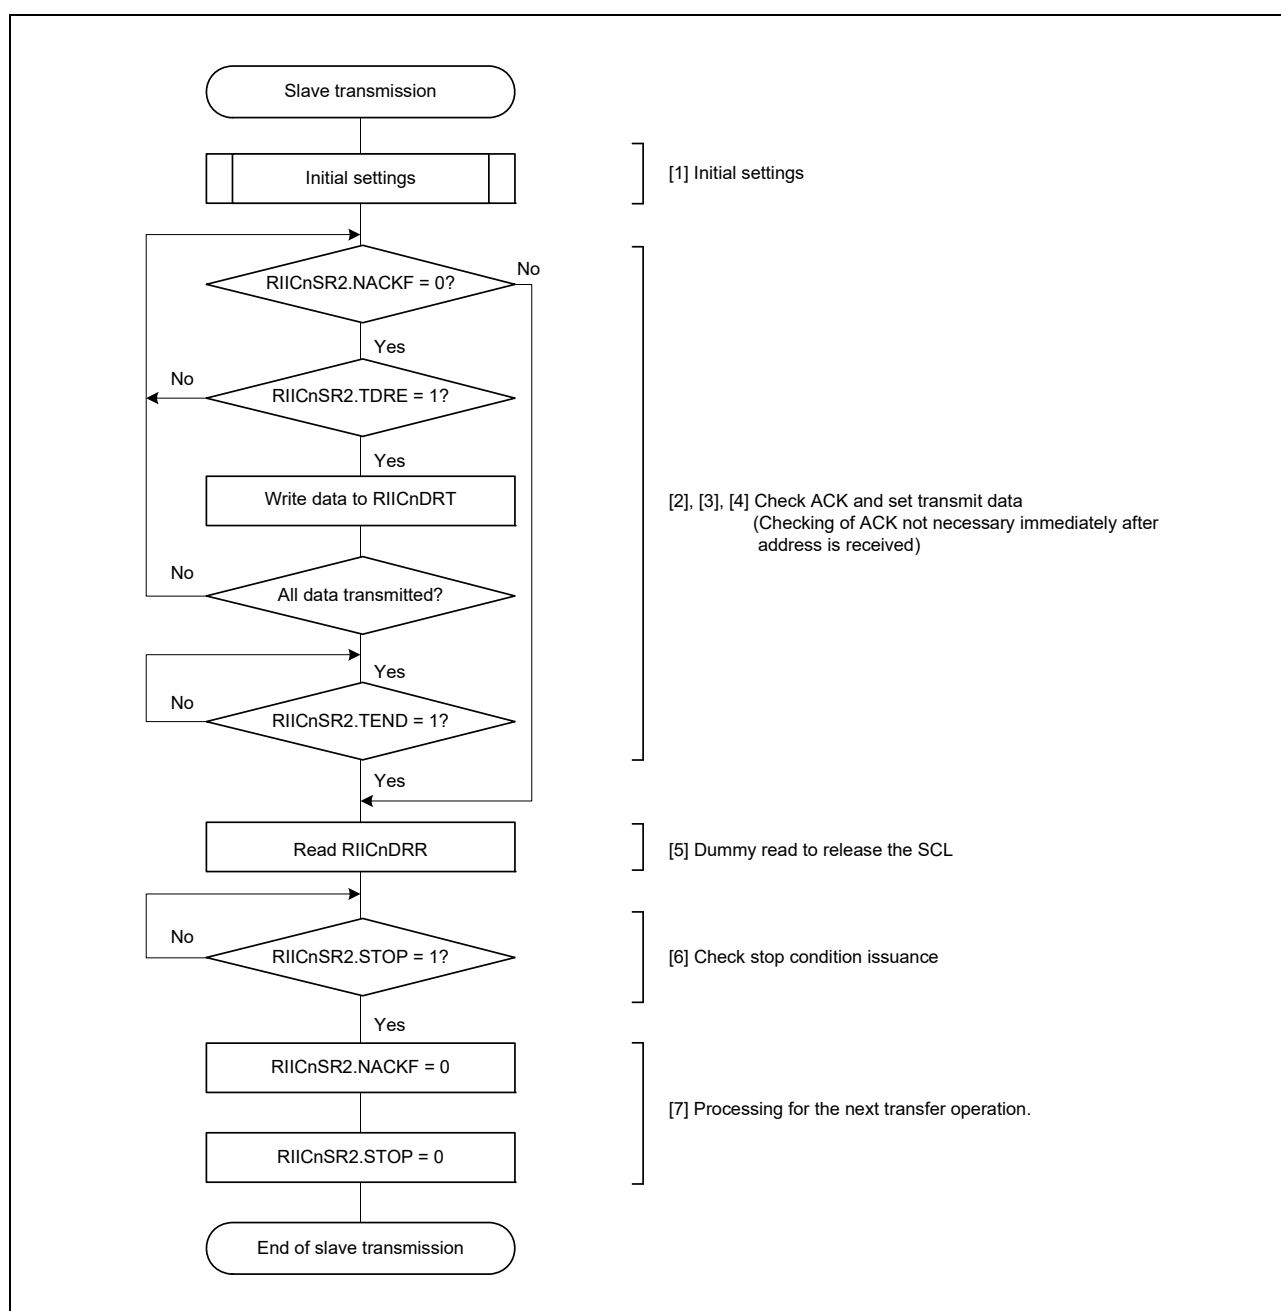

Figure 23.15 Example of Slave Transmission Flowchart

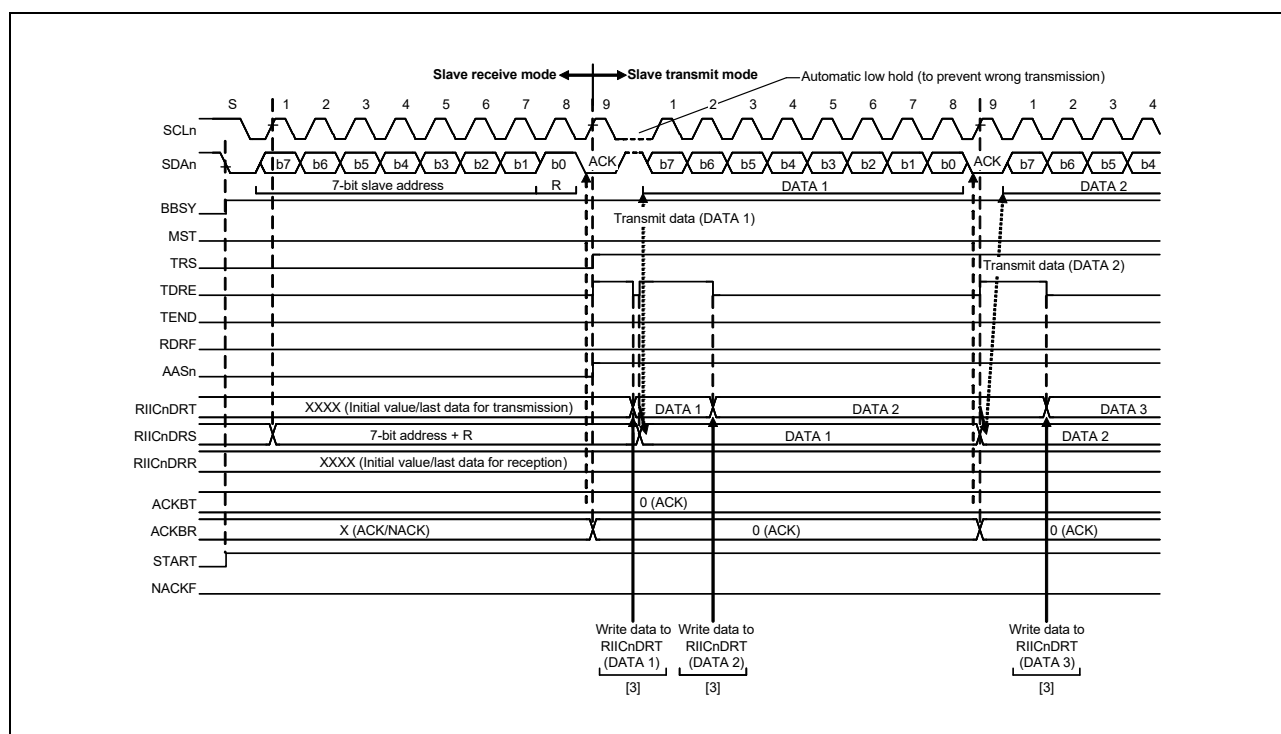

Figure 23.16 Slave Transmit Operation Timing (1) (7-Bit Address Format)

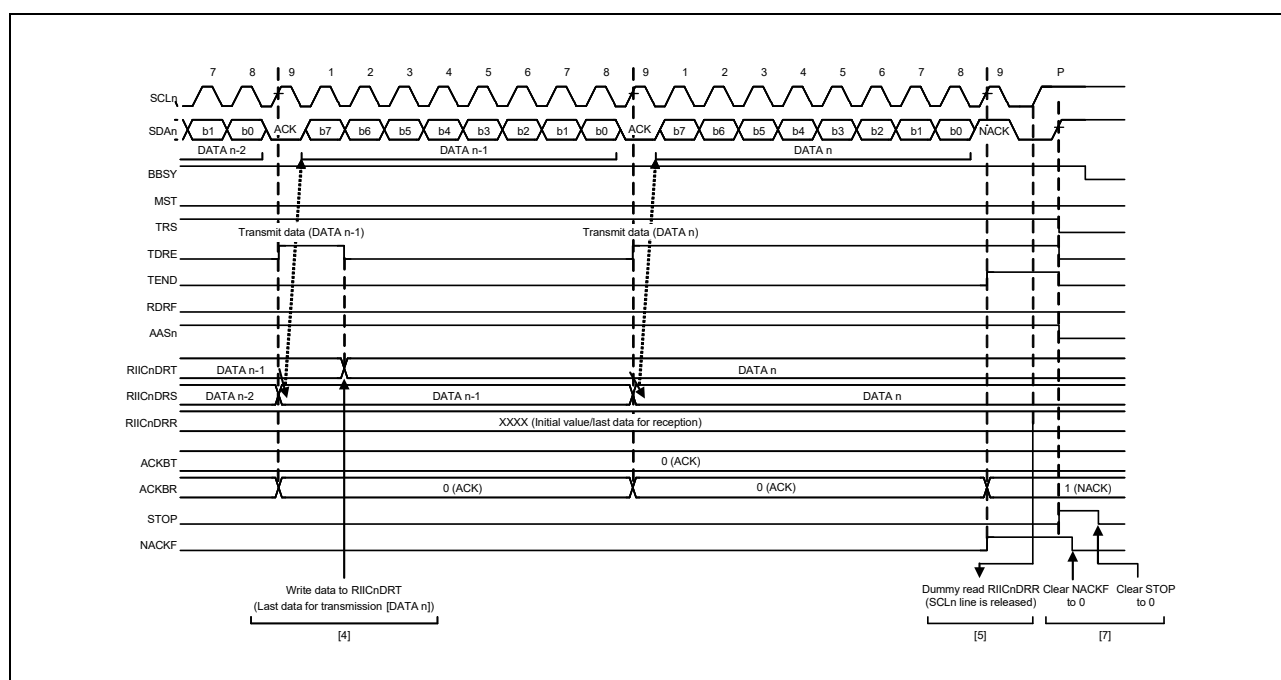

Figure 23.17 Slave Transmit Operation Timing (2)

23.5.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the RIIC returns acknowledgements as a slave device.

Figure 23.18 shows an example of usage of slave reception and Figure 23.19 and Figure 23.20 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

- (1) Follow the procedure in Figure 23.5 to make initial settings for the RIIC. This step is not necessary if initialization of the RIIC has already been completed. After initial settings, the RIIC will stay in the standby state until it receives a slave address that it matches.
- (2) After receiving a matching slave address, the RIIC sets one of the corresponding bits RIICnSR1.HOA, GCA, and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the value set in the RIICnMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, the RIIC continues to place itself in slave receive mode and sets the RIICnSR2.RDRF flag to 1.
- (3) After the RIICnSR2.STOP flag is confirmed to be 0 and the RIICnSR2.RDRF flag to be 1, dummy read RIICnDRR (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower eight bits when the 10-bit address format is selected).
- (4) When RIICnDRR is read, the RIIC automatically clears the RIICnSR2.RDRF flag to 0. If reading of RIICnDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the RIIC holds the SCL line low from one SCL cycle before the timing with which RDRF should be set. In this case, reading RIICnDRR releases the SCL line from being held at the low level.
When the RIICnSR2.STOP flag is 1 and the RIICnSR2.RDRF flag is also 1, read RIICnDRR until all the data is completely received.
- (5) Upon detecting the stop condition, the RIIC automatically clears bits RIICnSR1.HOA, GCA, and AASy (y = 0 to 2) to 0.
- (6) After checking that the RIICnSR2.STOP flag is 1, clear the RIICnSR2.STOP flag to 0 for the next transfer operation.

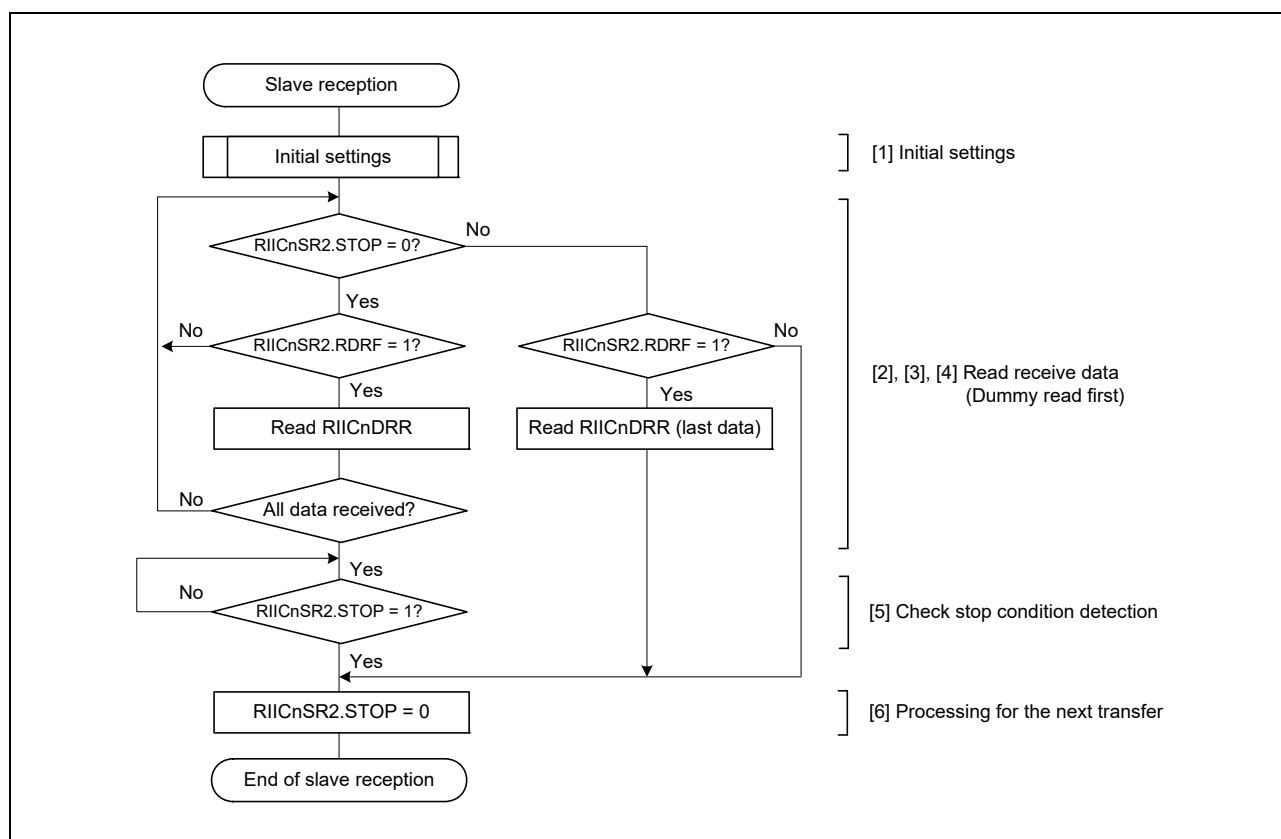

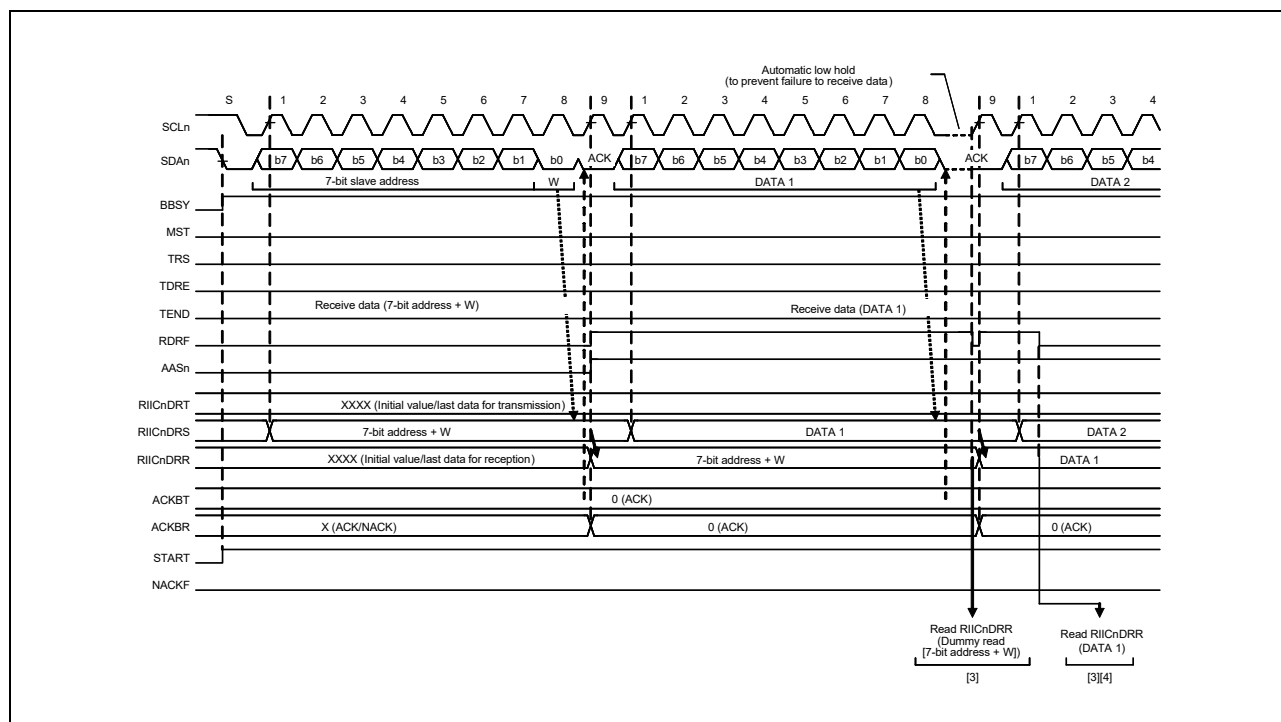

Figure 23.18 Example of Slave Reception Flowchart

Figure 23.19 Slave Receive Operation Timing (1) (7-Bit Address Format, when `RDRFS = 0`)

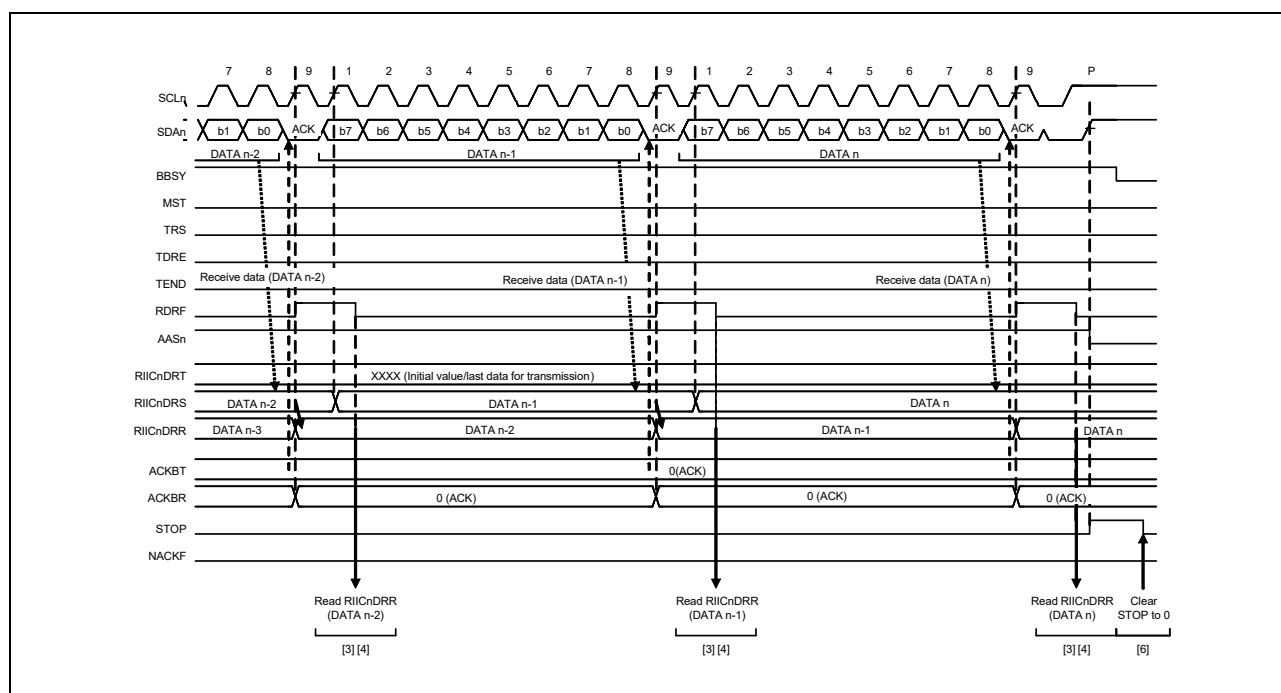

Figure 23.20 Slave Receive Operation Timing (2) (when RDRFS = 0)

23.6 SCL Synchronization Circuit

In generation of the SCL (clock) signal, the RIIC starts counting out the value for width at high level specified in RIICnBRH when it detects a rising edge on the SCL line and drives the SCL line low once counting of the width at high level is complete. When the RIIC detects the falling edge of the SCL line, it starts counting out the width at low level period specified in RIICnBRL, and then stops driving the SCL line (releases the line) once counting of the width at low level is complete. The SCL (clock) signal is thus generated.

If multiple master devices are connected to the I²C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, the RIIC is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCL line during communication.

When the RIIC has detected a rising edge on the SCL line and thus started counting out the width at high level specified in RIICnBRH, and the level on the SCL line falls because an SCL signal is being generated by another master device, the RIIC stops counting when it detects the falling edge, drives the level on the SCL line low, and starts counting out the width at low level specified in RIICnBRL. When the RIIC finishes counting out the width at low level, it stops driving the SCL line to the low level (i.e. releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in the RIIC, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCL line has been released. When the RIIC finishes outputting the low-level period of the SCL clock, the SCL line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the RIICnFER.SCLE bit is set to 1.

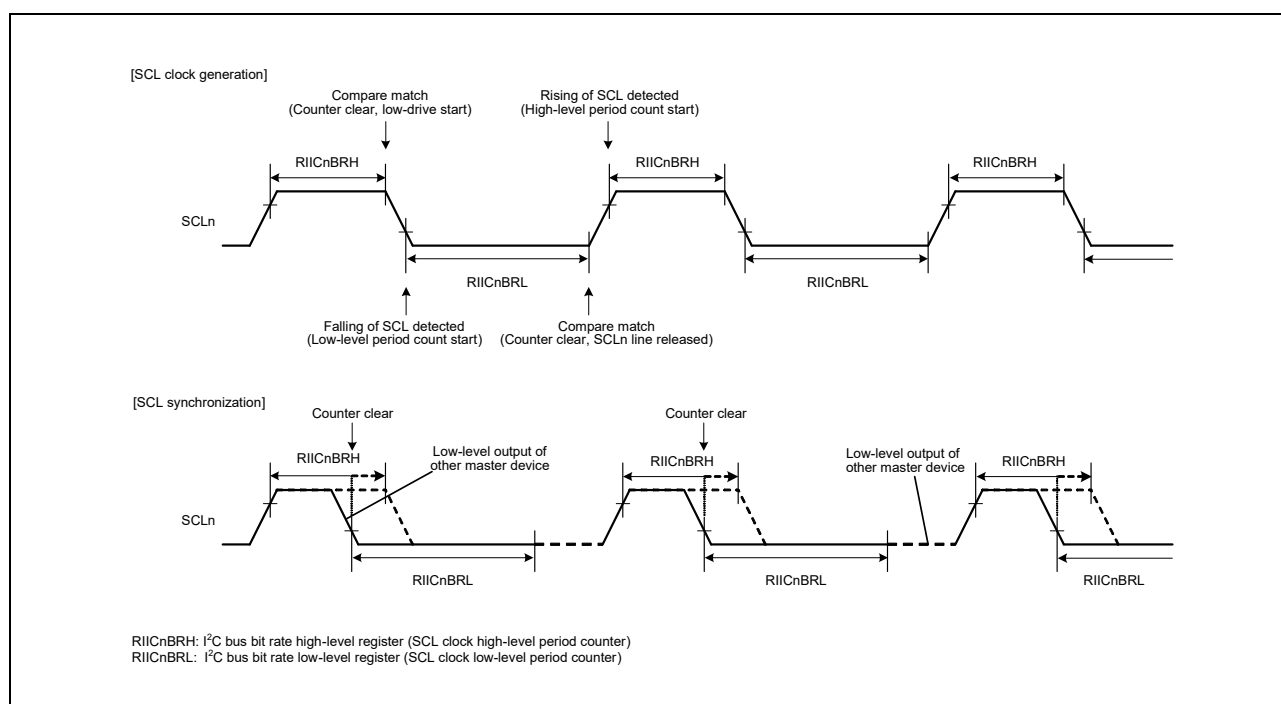

Figure 23.21 Generation and Synchronization of the SCL Signal from the RIIC

23.7 Facility for Delaying SDA Output

The RIIC module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL (clock) signal is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices, with the aim of satisfying the 300-ns (min.) data-hold time requirement of the SMBus specification.

The output delay facility is enabled by setting the RIICnMR2.SDDL[2:0] bits to any value other than 000_B, and disabled by setting the same bits to 000_B.

While the SDA output delay facility is enabled (i.e. while the SDDL[2:0] bits in IMCR2 are set to any value other than 000_B), the RIICnMR2.DLCS bit selects the clock source for counting by the SDA output delay counter as the internal base clock (IIC ϕ) for the RIIC module or as a clock signal derived by dividing the frequency of the internal base clock by two (IIC ϕ /2). The counter counts the number of cycles set in the SDDL[2:0] bits in IMCR2. After counting of the set number of cycles of delay is completed, the RIIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.

Figure 23.22 SDA Output Delay Facility

23.8 Digital Noise-Filter Circuits

Figure 23.23 is a block diagram of the digital noise-filter circuit. When the NFE bit in the RIICnFER register is set to 1, input to the RIICnSCL and RIICnSDA pins are conveyed to the internal circuitry through digital noise-filter circuits. The on-chip digital noise-filter circuit of the RIIC consists of four flip-flop circuit stages connected in series and a match-detection circuit.

The number of effective stages in the digital noise filter is selected by the RIICnMR3.NF[1:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to four IIC ϕ cycles.

The input signal to the RIICnSCL pin (or RIICnSDA pin) is sampled on falling edges of the IIC ϕ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the RIICnMR3.NF[1:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between P1 ϕ and IIC ϕ is small when the RIICnMR1.CKS[2:0] bits are set to 000_B, note that the characteristics of the digital noise filter may lead to the elimination of needed signals as noise.

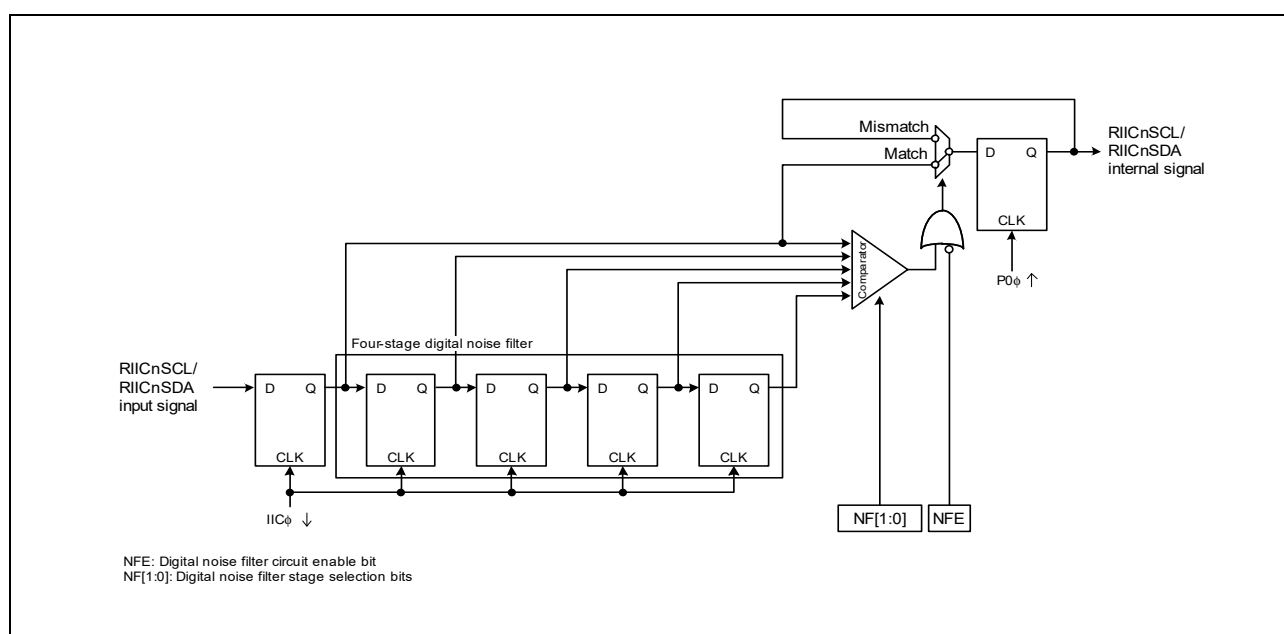

Figure 23.23 Block Diagram of Digital Noise Filter Circuit

23.9 Address Match Detection

The RIIC can set three unique slave addresses in addition to the general call address and host address, and also can set 7-bit or 10-bit slave addresses.

23.9.1 Slave-Address Match Detection

The RIIC can set three unique slave addresses, and has a slave address detection function for each unique slave address. When the RIICnSER.SARy bit (y = 0 to 2) is set to 1, the slave addresses set in RIICnSARy (y = 0 to 2) can be detected. When the RIIC detects a match of the set slave address, the corresponding RIICnSR1.AASy flag (y = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the RIICnSR2.RDRF flag or the RIICnSR2.TDRE flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (INTRIICRI) or transmit data empty interrupt (INTRIICTI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 23.24 to Figure 23.26 show the AASy flag set timing in three cases.

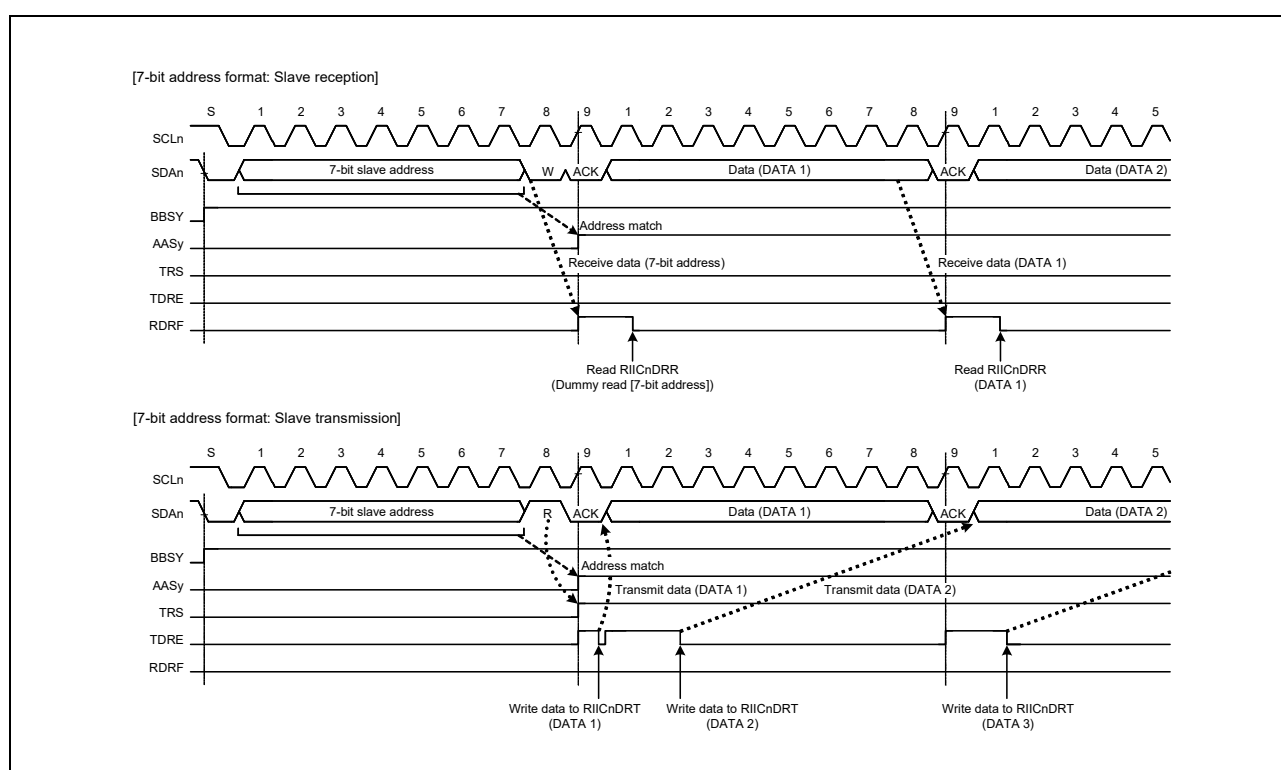

Figure 23.24 AASy Flag Set Timing with 7-Bit Address Format Selected

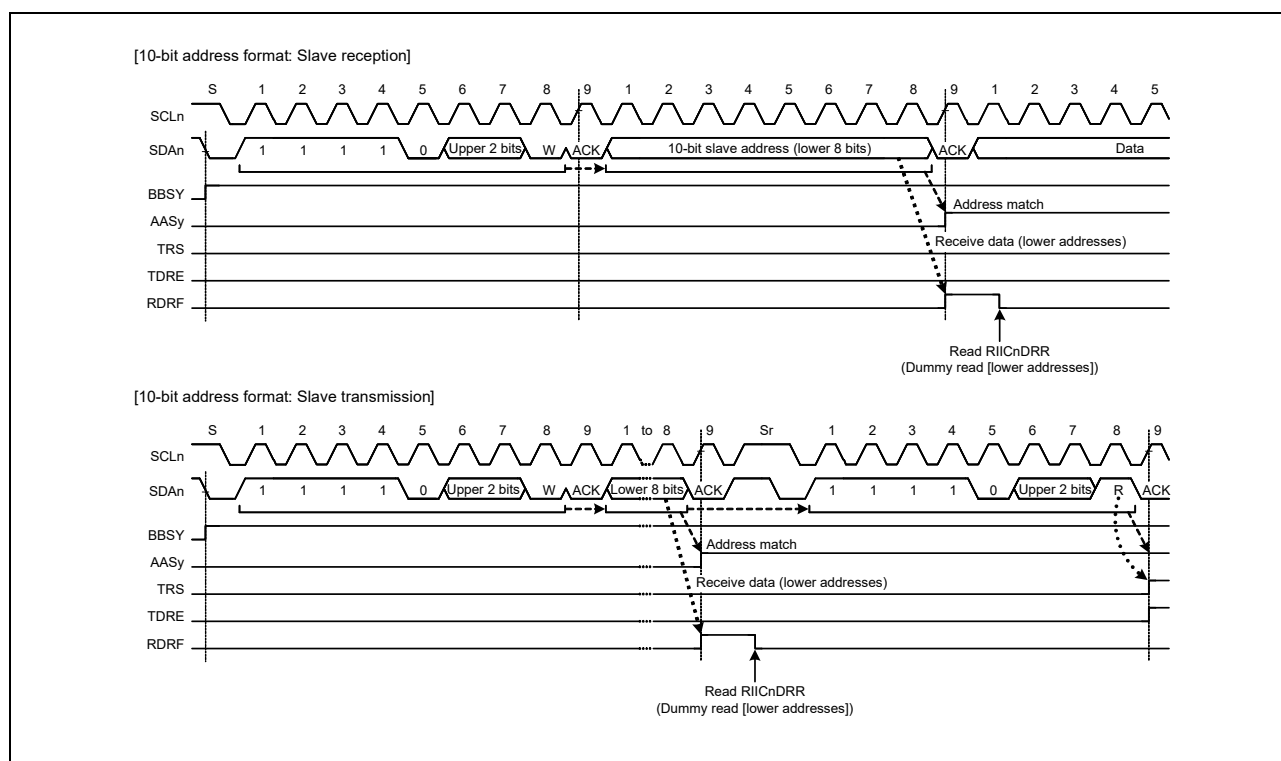

Figure 23.25 AASy Flag Set Timing with 10-Bit Address Format Selected

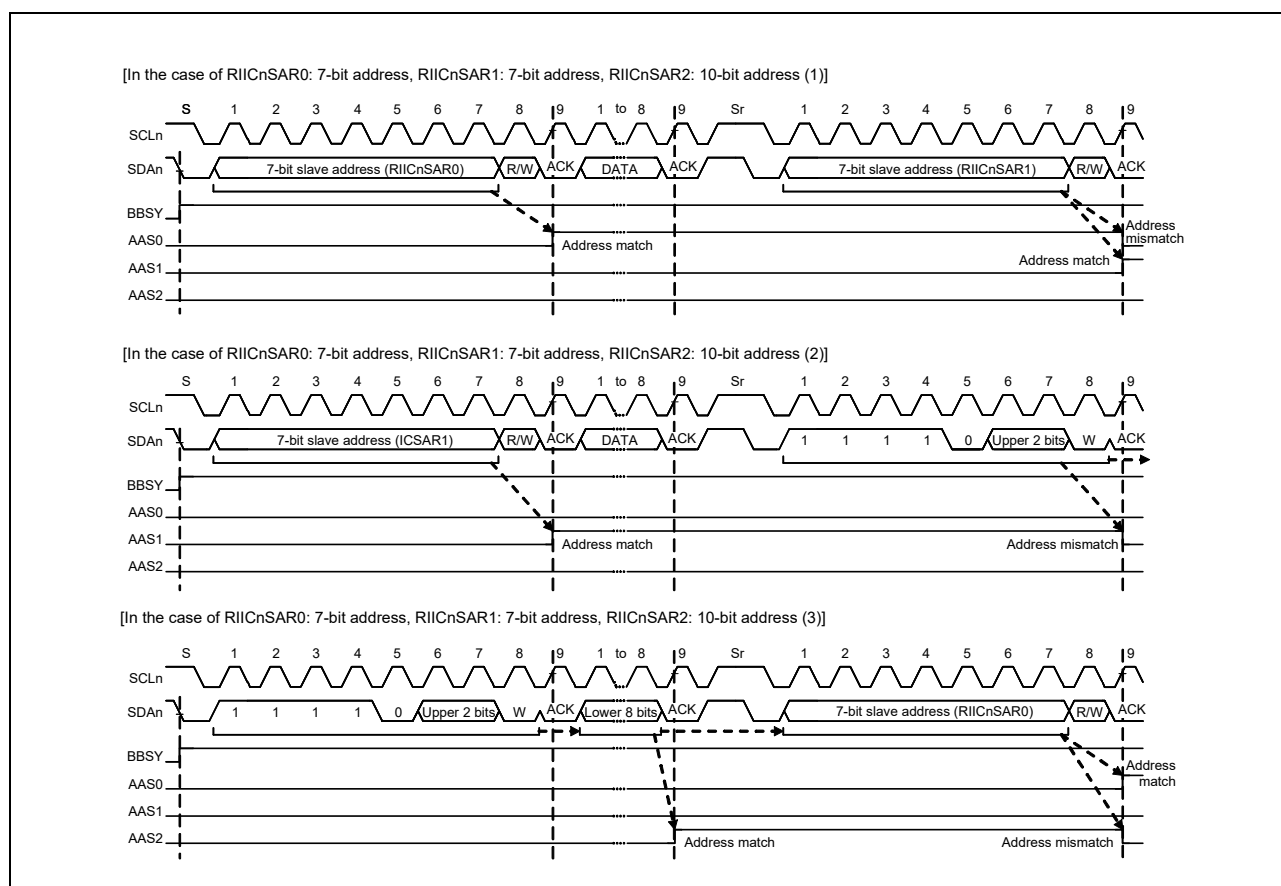

Figure 23.26 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

23.9.2 Detection of the General Call Address

The RIIC has a facility for detecting the general call address ($0000\ 000_B + 0 [W]$). This is enabled by setting the RIICnSER.GCE bit to 1.

If the address received after a start or restart condition is issued is $0000\ 000_B + 1[R]$ (start byte), the RIIC recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RIIC detects the general call address, both the RIICnSR1.GCA flag and the RIICnSR2.RDRF flag are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive data full interrupt (INTRIICRI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

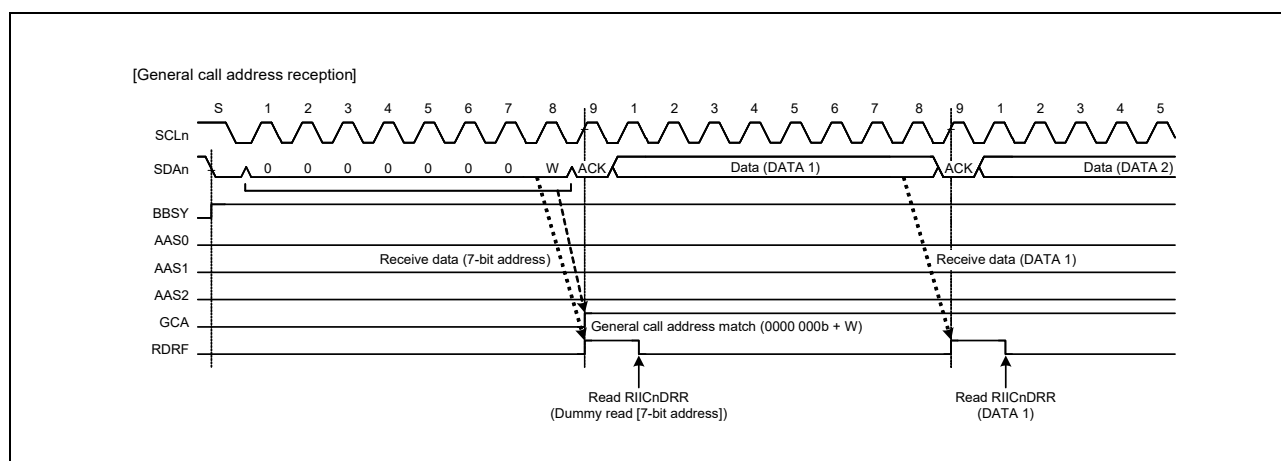

Figure 23.27 Timing of GCA Flag Setting during Reception of General Call Address

23.9.3 Device-ID Address Detection

The RIIC module has a facility for detecting device-ID addresses conformant with the I²C bus specification (Rev. 03). When the RIIC receives 1111 100_B as the first byte after a start condition or restart condition was issued with the RIICnSER.DIDE bit set to 1, the RIIC recognizes the address as a device ID, sets the RIICnSR1.DID flag to 1 on the rising edge of the ninth SCL clock cycle when the following R/W# bit is 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the RIIC sets the corresponding RIICnSR1.AASy flag (y = 0 to 2) to 1.

After that, when the first byte received after a start or restart condition is issued matches the device ID address (1111 100_B) again and the following R/W# bit is 1, the RIIC does not compare the second and subsequent bytes and sets the RIICnSR2.TDRE flag to 1.

In the device-ID address detection function, the RIIC clears the DID flag to 0 if a match with the RIIC's own slave address is not obtained or a match with the device ID address is not obtained after a match with the RIIC's own slave address and the detection of a restart condition. If the first byte after detection of a start or restart condition matches the device ID address (1111 100_B) and the R/W# bit is 0, the RIIC sets the DID flag to 1 and compares the second and subsequent bytes with the RIIC's slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RIIC does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Furthermore, prepare the device-ID fields (three bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details, see I²C Bus Standard from NXP Semiconductors.

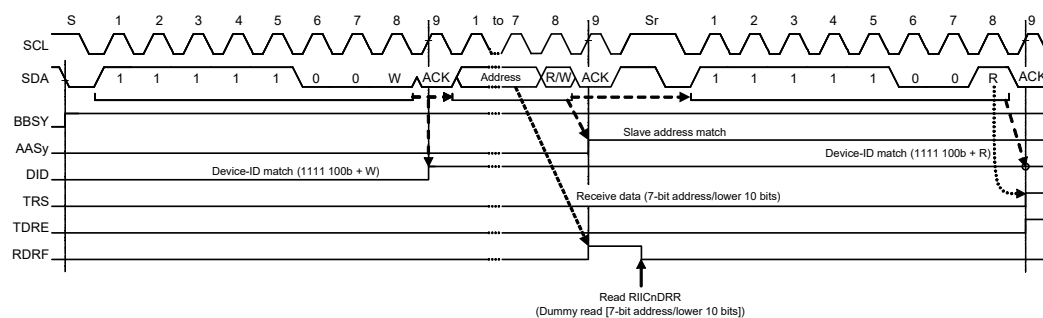

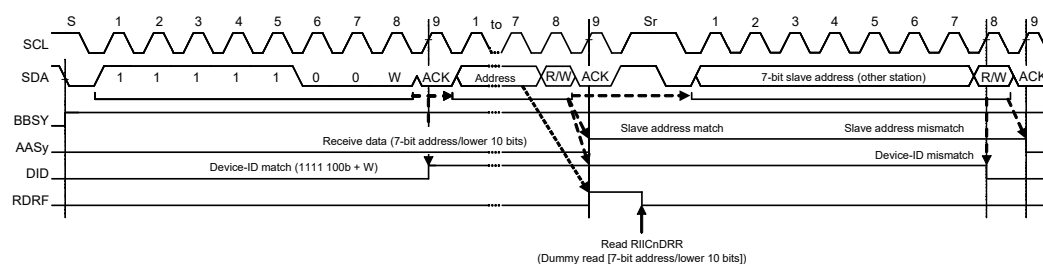

[Device-ID reception]**[When address received after a restart condition is detected does not match the Device-ID]****[When address before the Device-ID + R does not match the slave address]**

Figure 23.28 AASy/DID Flag Set/Clear Timing during Reception of Device-ID

23.9.4 Host Address Detection

The RIIC has a function to detect the host address while the SMBus is operating. When the RIICnSER.HOAE bit is set to 1 while the RIICnMR3.SMBS bit is 1, the RIIC can detect the host address (0001 000_B) in slave receive mode (RIICnCR2.MST and TRS bits = 00_B).

When the RIIC detects the host address, the RIICnSR1.HOA flag is set to 1 at the rising edge of the ninth SCL clock cycle, and at the same time, the RIICnSR2.RDRF flag is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (INTRIICRI) to be generated. The HOA flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001 000_B) is an Rd bit (R/W# bit = 1), the RIIC can also detect the host address. After the host address is detected, the RIIC operates in the same manner as normal slave operation.

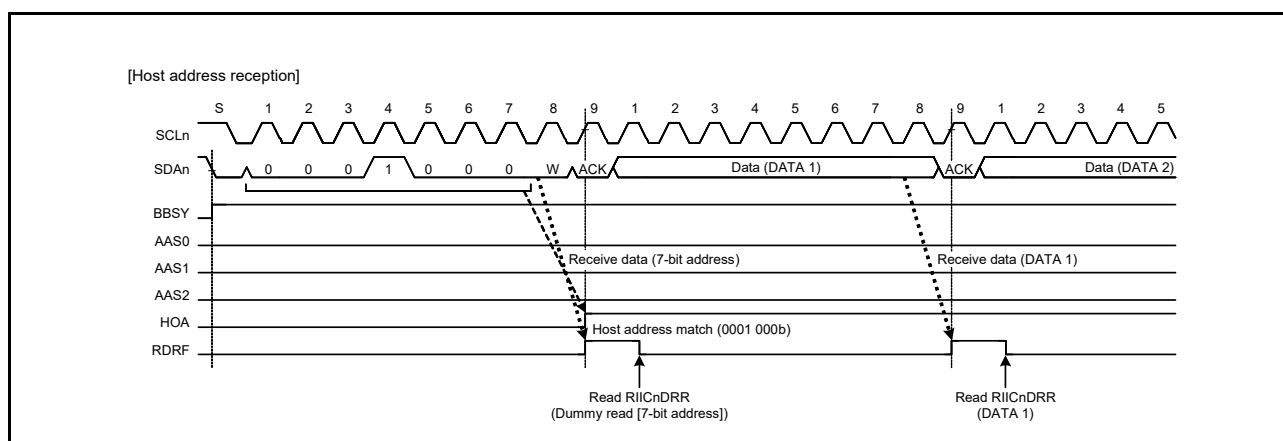

Figure 23.29 HOA Flag Set Timing during Reception of Host Address

23.10 Automatically Low-Hold Function for SCL

23.10.1 Function to Prevent Wrong Transmission of Transmit Data

If the shift register (RIICnDRS) is empty when data have not been written to the transmit data register (RIICnDRT) with the RIIC in transmission mode (RIICnCR2.TRS bit = 1), the SCL signal is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

<Master transmit mode>

- Low-level interval after a start condition or restart condition is issued
- Low-level interval of one clock cycle between the ninth clock cycle of one transfer and the first clock cycle of the next

<Slave transmit mode>

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

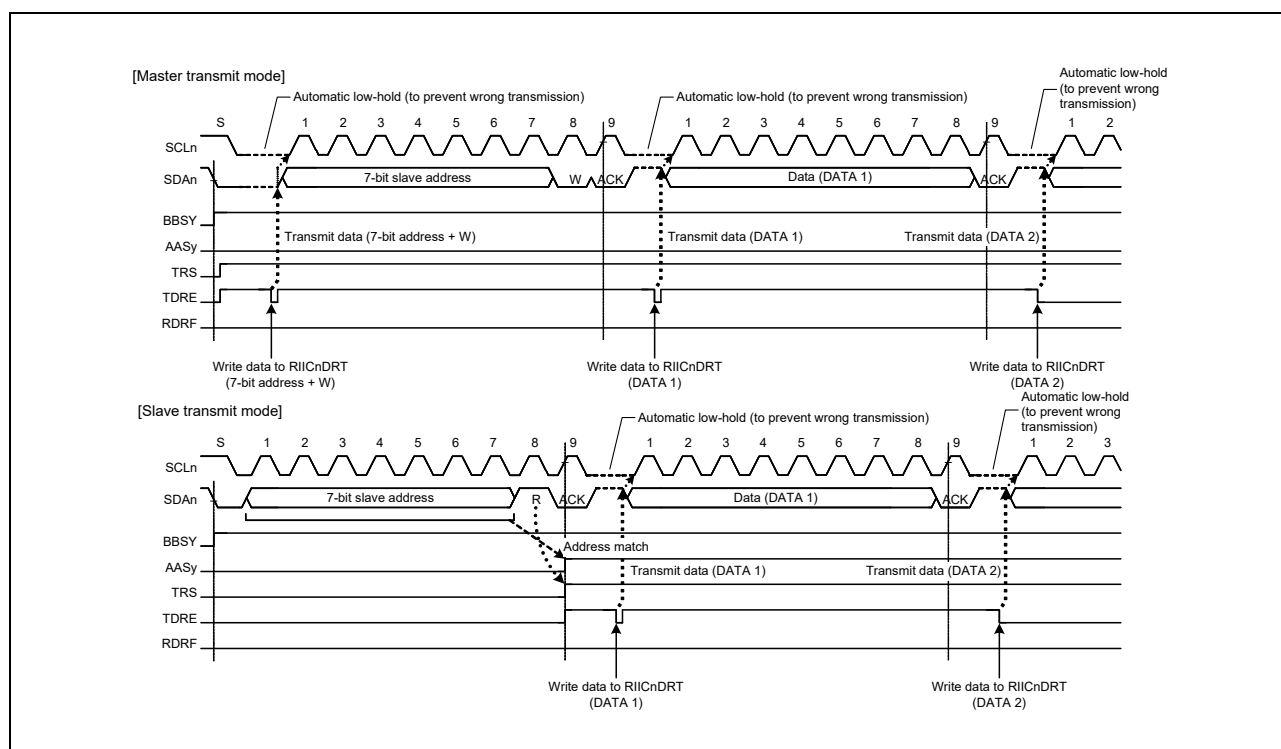

Figure 23.30 Automatic Low-Hold Operation in Transmit Mode

23.10.2 NACK Reception Transfer Suspension Function

The RIIC has a function to suspend transfer operation when NACK is received in transmit mode (RIICnCR2.TRS bit = 1). This function is enabled when the RIICnFER.NACKF bit is set to 1 (transfer suspension enabled). If the next transmit data has already been written (RIICnSR2.TDRE flag = 0) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically suspended. This prevents the SDA line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (RIICnSR2.NACKF flag = 1), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to clear the NACKF flag to 0. In master transmit mode, clear the NACKF flag to 0 after issuing a restart condition or clear the NACKF and STOP flags to 0 after confirming that a stop condition has been issued, and then issue a start condition.

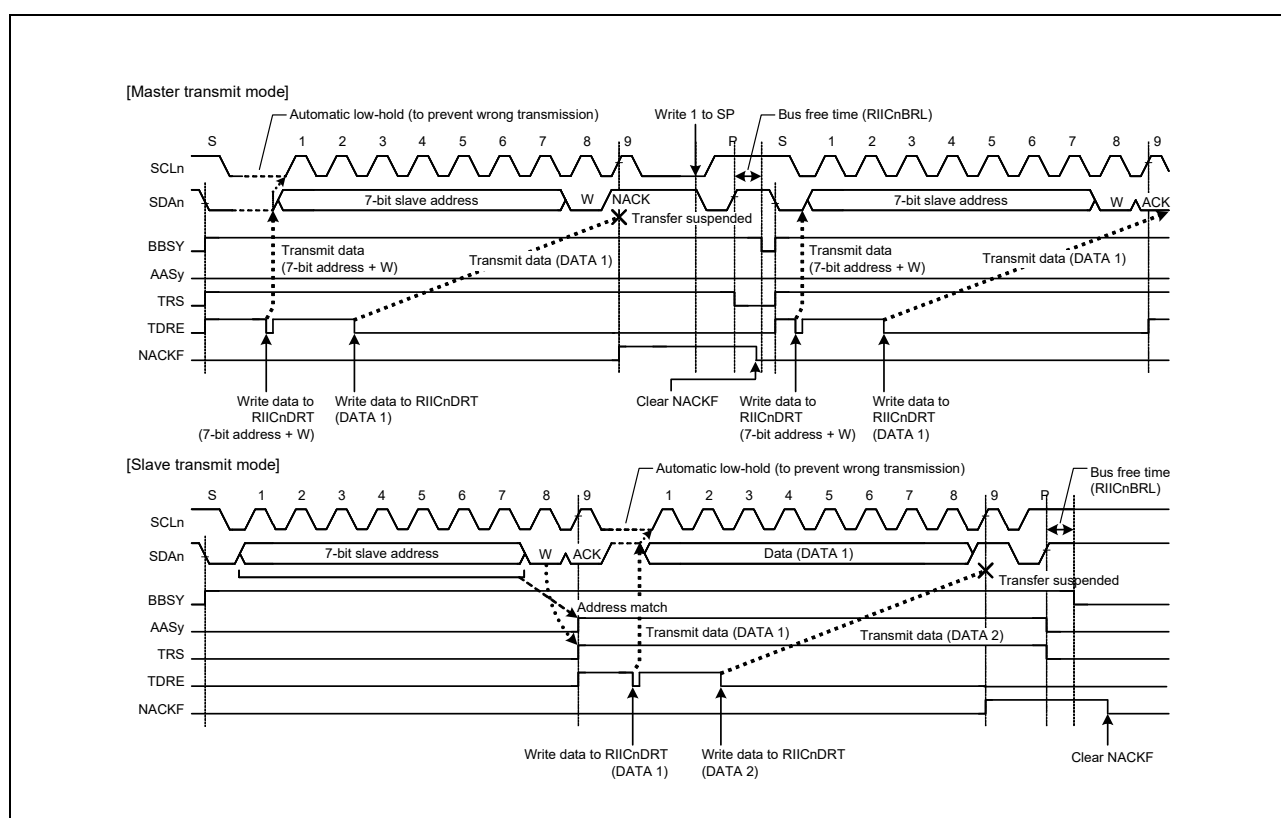

Figure 23.31 Suspension of Data Transfer when NACK is Received (NACKF = 1)

23.10.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (RIICnDRR) read is delayed for a period of one transfer frame or more with receive data full (RIICnSR2.RDRF flag = 1) in receive mode (RIICnCR2.TRS = 0), the RIIC holds the SCL line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIIC's own slave address is designated after a stop condition is issued. This function does not disturb other communication because the RIIC does not hold the SCL line low when a mismatch with its own slave address occurs after a stop condition is issued.

Sections in which the SCL line is held low can be selected with a combination of the RIICnMR3.WAIT and RDRFS bits.

(1) One-Byte Receive Operation and Automatic Low-Hold Function Using the WAIT Bit

When the RIICnMR3.WAIT bit is set to 1, the RIIC performs one-byte receive operation using the WAIT bit function.

Furthermore, when the RIICnMR3.RDRFS bit is 0, the RIIC automatically sends the RIICnMR3.ACKBT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCL line low at the falling edge of the ninth SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from RIICnDRR, which enables bitwise receive operation.

The WAIT bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(2) One-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the RDRFS Bit

When the RIICnMR3.RDRFS bit is set to 1, the RIIC performs one-byte receive operation using the RDRFS bit function.

When the RIICnSR2.RDRFS bit is set to 1, the RDRF flag (receive data full) in RIICnSR2 is set to 1 at the rising edge of the eighth SCL clock cycle, and the SCL line is automatically held low at the falling edge of the eighth SCL clock cycle. This lowhold is released by writing a value to the RIICnMR3.ACKBT bit, but cannot be released by reading data from RIICnDRR, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

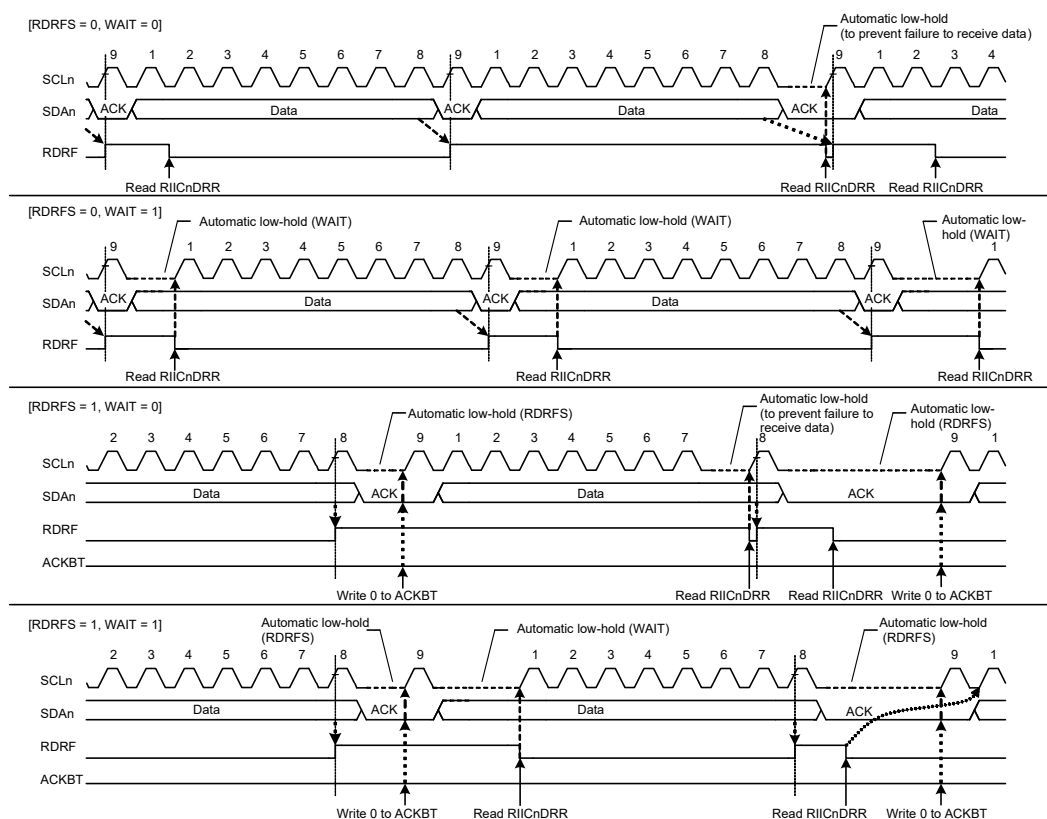

Figure 23.32 Automatic Low-Hold Operation in Receive Mode (Using RDRFS and WAIT Bits)

23.11 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I²C bus standard, the RIIC has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmit mode.

23.11.1 Master Arbitration-Lost Detection (MALE Bit)

The RIIC drives the SDA line low to issue a start condition. However, if the SDA line has already been driven low by another master device issuing a start condition, the RIIC regards its own issuing of a start condition as an error and considers this a loss in arbitration, so priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the RIICnCR2.ST bit to 1 while the bus is busy (RIICnCR2.BBSY flag = 1), the RIIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration, thus preventing a failure of transfer due to issuing of a start condition while transfer is in progress.

When a start condition is issued successfully, if the data for transmission including the address bits (i.e. the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output; i.e. the SDA pin is in the high-impedance state) and the low level is detected on the SDA line, the RIIC loses in arbitration.

After a loss in arbitration of mastership, the RIIC immediately enters slave receive mode. If a slave address (including the general call address) matches its own address at this time, the RIIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the RIICnFER.MALE bit is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Non-matching of the internal level for output on SDA and the level on the SDA line after a start condition was issued by setting the RIICnCR2.ST bit to 1 while the RIICnCR2.BBSY flag was cleared to 0 (erroneous issuing of a start condition)
- Setting of the RIICnCR2.ST bit to 1 (start condition double-issue error) while the RIICnCR2.BBSY flag is set to 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDA line in master transmit mode (RIICnCR2.MST and TRS bits = 11_B)

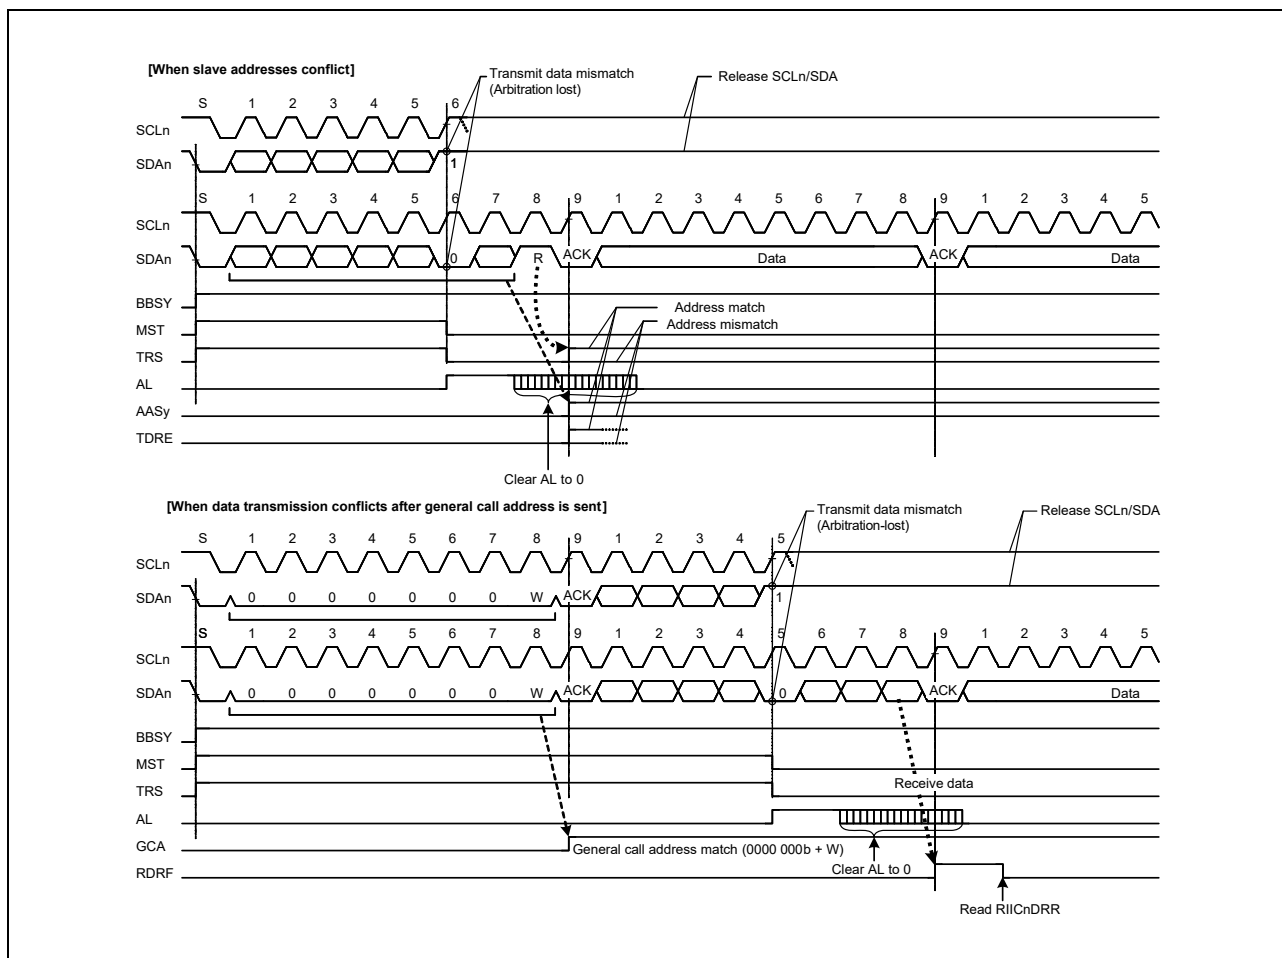

Figure 23.33 Examples of Master Arbitration-Lost Detection (MALE = 1)

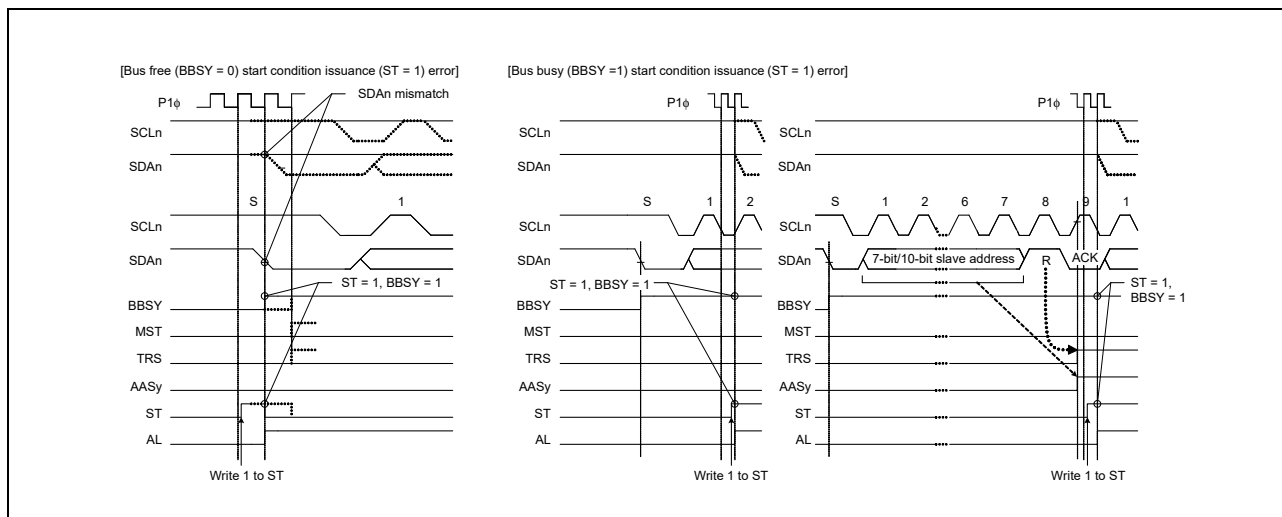

Figure 23.34 Arbitration-Lost when a Start Condition is Issued (MALE = 1)

23.11.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

The RIIC has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDA line (the high output as the internal SDA output; i.e. the SDA pin is in the high-impedance state) and the low level is detected on the SDA line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device. Figure 23.35 shows an example of arbitration-lost detection during transmission of NACK.

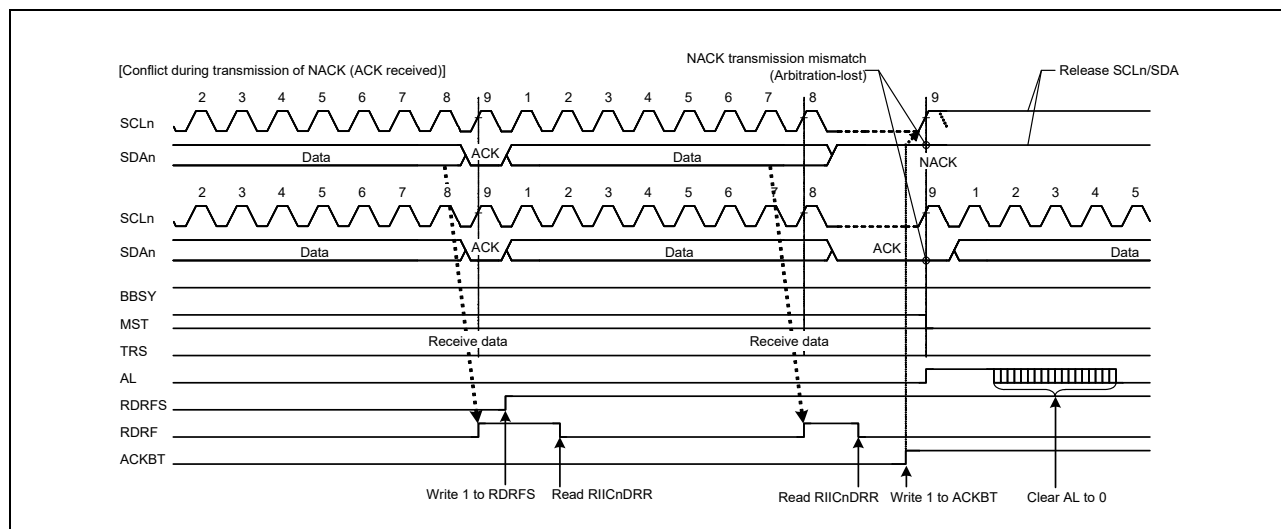

Figure 23.35 Example of Arbitration-Lost Detection during Transmission of NACK (NALE = 1)

The following explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives two bytes of data from the slave device, and master B receives four bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends NACK when it has received two final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received necessary four bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition. Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When the RIIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, the RIIC enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing (such as FF_H transmission processing) necessary if the UDID (Unique Device Identifier) of assign address does not match in the Get UDID (general) processing after the Assign address command.

The RIIC detects arbitration-lost during transmission of NACK when the following condition is met with the RIICnFER.NALE bit set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

When the internal SDA output level does not match the SDA line (ACK is received) during transmission of NACK (RIICnMR3.ACKBT bit = 1).

23.11.3 Slave Arbitration-Lost Detection (SALE Bit)

The RIIC has a function to cause arbitration to be lost if the data for transmission (i.e. the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output; i.e. the SDA pin is in the highimpedance state) and the low level is detected on the SDA line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When it loses slave arbitration, the RIIC enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing (processing for the transmission of FF_H).

The RIIC detects slave arbitration-lost when the following condition is met with the RIICnFER.SALE bit set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

When transmit data excluding acknowledge (internal SDA output level) does not match the SDA line in slave transmit mode (RIICnCR2.MST and TRS bits = 01_B)

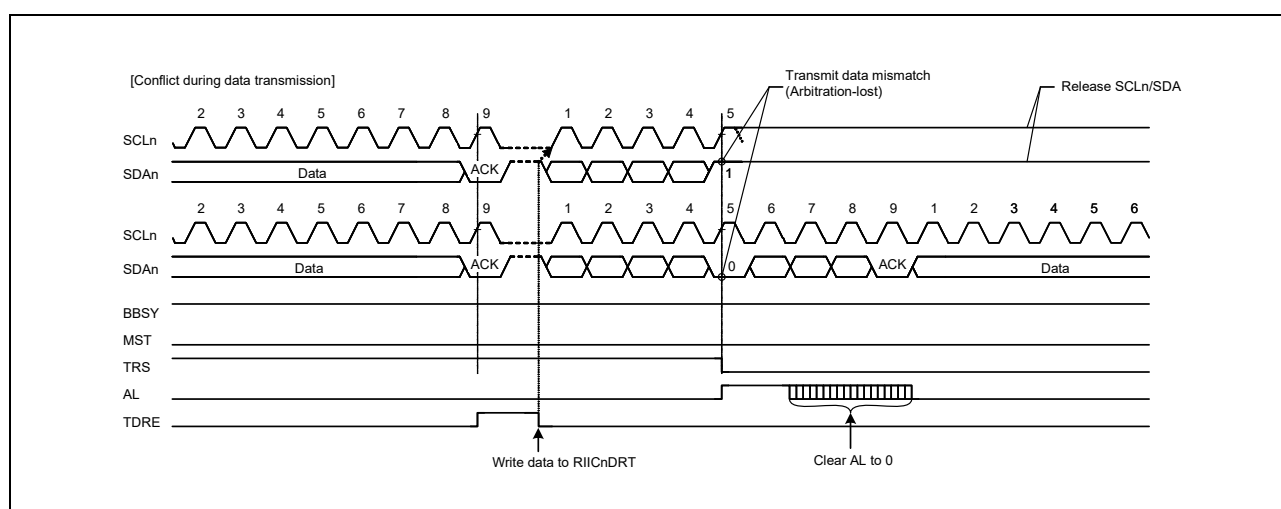

Figure 23.36 Example of Slave Arbitration-Lost Detection (SALE = 1)

23.12 Start Condition/Restart Condition/Stop Condition Issuing Function

23.12.1 Issuing a Start Condition

The RIIC issues a start condition when the RIICnCR2.ST bit is set to 1.

When the ST bit is set to 1, a start condition issuance request is made and the RIIC issues a start condition when the RIICnCR2.BBSY flag is 0 (bus free). When a start condition is issued normally, the RIIC automatically shifts to the master transmit mode.

A start condition is issued in the following sequence.

[Start condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the time set in RIICnBRH and the start condition hold time.
- Drive the SCL line low (high level to low level).
- Detect low level of the SCL line and ensure the low-level period of SCL line set in RIICnBRL.

23.12.2 Issuing a Restart Condition

The RIIC issues a restart condition when the RIICnCR2.RS bit is set to 1.

When the RS bit is set to 1, a restart condition issuance request is made and the RIIC issues a restart condition when the RIICnCR2.BBSY flag is 1 (bus busy) and the RIICnCR2.MST bit is 1 (master mode).

A restart condition is issued in the following sequence.

[Restart condition issuance]

- Release the SDA line.
- Ensure the low-level period of SCL line set in RIICnBRL.
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in RIICnBRL and the restart condition setup time.
- Drive the SDA line low (high level to low level).
- Ensure the time set in RIICnBRH and the restart condition hold time.
- Drive the SCL line low (high level to low level).
- Detect a low level of the SCL line and ensure the low-level period of SCL line set in RIICnBRL.

Caution: To issue a restart condition request, set RIICnSR2.RS to 1 after setting RIICnSR2.START to 0. After checking that RIICnSR2.START is 1, set RIICnSR2.START to 0, and then write the slave address to RIICnDRT.

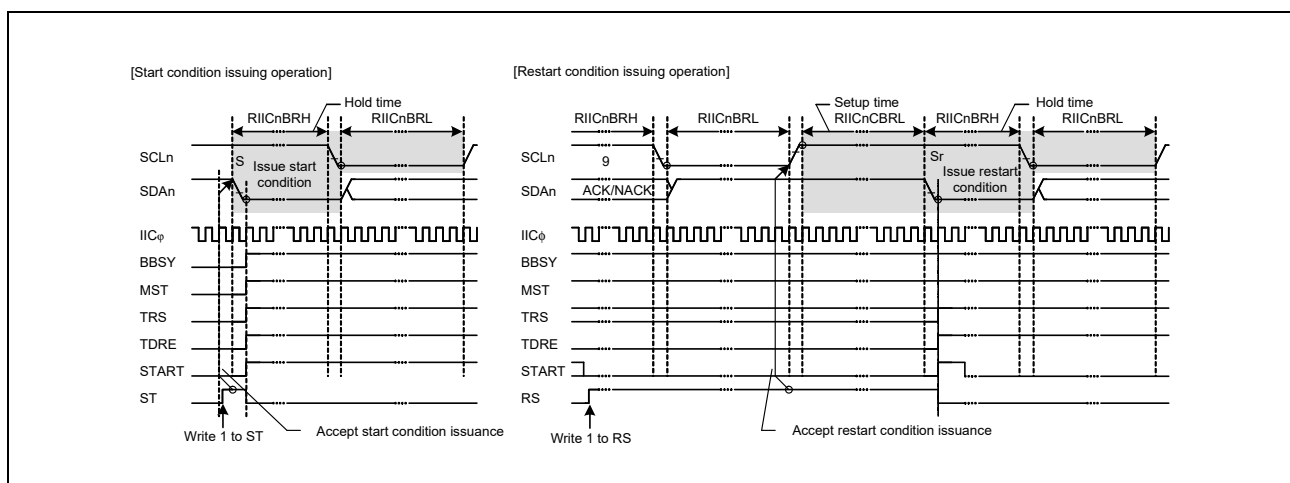

Figure 23.37 Start Condition/Restart Condition Issue Timing (ST and RS Bits)

23.12.3 Issuing a Stop Condition

The RIIC issues a stop condition when the RIICnCR2.SP bit is set to 1.

When the SP bit is set to 1, a stop condition issuance request is made and the RIIC issues a stop condition when the RIICnCR2.BBSY flag is 1 (bus busy) and the RIICnCR2.MST bit is 1 (master mode).

A stop condition is issued in the following sequence.

[Stop condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the low-level period of SCL line set in RIICnBRL.
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in RIICnBRH and the stop condition setup time.
- Release the SDA line (low level to high level).
- Ensure the time set in RIICnBRL and the bus free time.
- Clear the BBSY flag to 0 (to release the bus mastership).

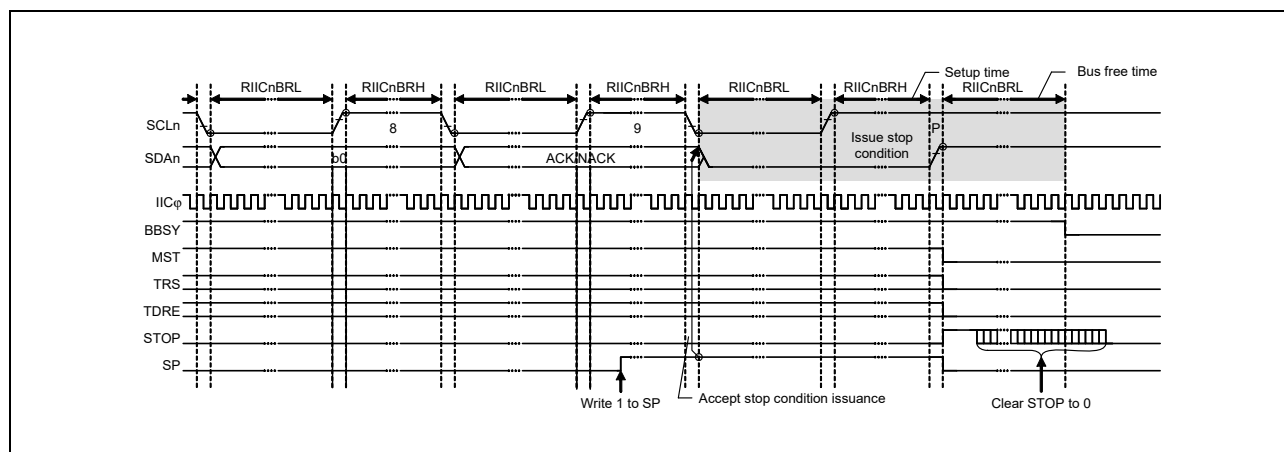

Figure 23.38 Stop Condition Issue Timing (SP Bit)

23.13 Bus Hanging

If the clock signals from the master and slave devices go out of synchronization due to noise or other factors, the I²C bus might hang with a fixed level on the SCL line and/or SDA line.

As measures against the bus hanging, the RIIC has a timeout function to detect hanging by monitoring the SCL line, a function for the output of an extra SCL clock cycle to release the bus from a hung state due to clock signals being out of synchronization, and the RIIC/internal reset function.

By checking the RIICnCR1.SCLO, SDAO, SCLI, and SDAI bits, it is possible to see whether the RIIC or its partner in communications is placing the low level on the SCL or SDA lines.

23.13.1 Timeout Function

The RIIC has the timeout function to detect an abnormality that the SCL line is held for a certain period of time. The RIIC can detect an abnormal bus state by monitoring that the SCL line is held low or high for a predetermined time. The timeout function monitors the SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCL line changes (rising or falling), but continues to count unless the SCL line changes. If the internal counter overflows due to no SCL line change, the RIIC can detect the timeout and report the bus abnormality.

This timeout function is enabled when the RIICnFER.TMOE bit is 1. It detects an abnormal bus state in which the SCL line is held low or high in the following cases.

1. When the bus is busy (RIICnCR2.BBSY = 1) in master mode (RIICnCR2.MST = 1)
2. When the bus is busy (RIICnCR2.BBSY = 1) and the RIIC's own slave address matches (RIICnSR1 is not 00_H) in slave mode (RIICnCR2.MST = 0)
3. While the bus is free (RIICnCR2.BBSY = 0) and issuing of a start condition is being requested (RIICnCR2.ST = 1).

The internal counter of the timeout function works using the internal reference clock (IIC ϕ) set by the RIICnMR1.CKS[2:0] bits as a count source. It functions as a 16-bit counter when long mode is selected (RIICnMR2.TMOS bit = 0) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCL line level (low/high or both levels) during which this counter is activated can be selected by the setting of the RIICnMR2.TMOH and TMOL bits. If both TMOL and TMOH bits are cleared to 0, the internal counter does not work.

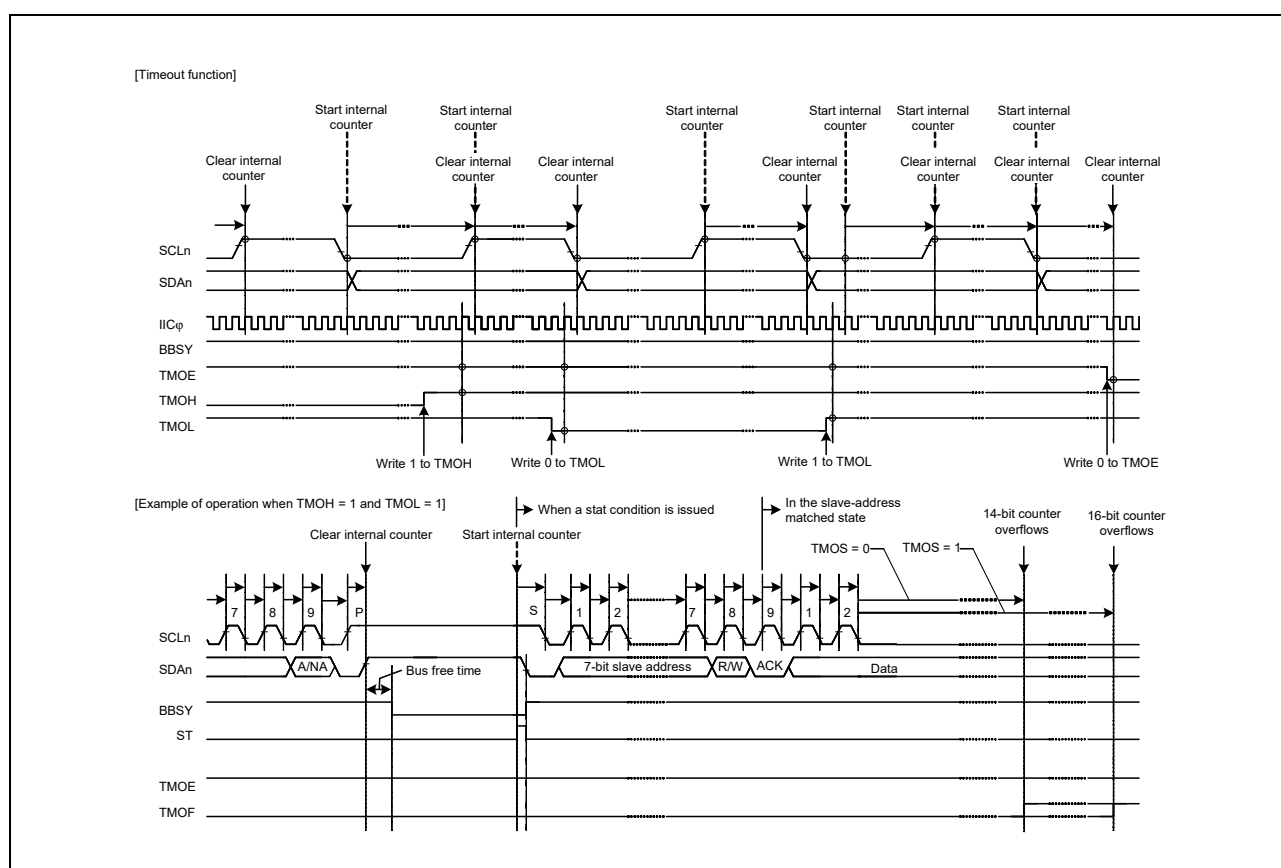

Figure 23.39 Timeout Function (TMOE, TMOS, TMOH, and TMOL Bits)

23.13.2 Extra SCL Clock Cycle Output Function

In master mode, the RIIC module has a facility for the output of extra SCL (clock) cycles to release the SDA line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the SDA line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from the RIIC with single cycles of the SCL (clock) signal as the unit in the case of a bus error where the RIIC cannot issue a stop condition because the slave device is holding the SDA line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the RIICnCR1.CLO bit is set to 1 in master mode, a single cycle of the SCL clock at the frequency corresponding to the transfer rate settings (settings of the RIICnMR1.CKS[2:0] bits, and of the RIICnBRH and RIICnBRL registers) is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit is automatically cleared to 0. At this point, the SCL pin output is held at a low level if the BBSY flag is 1, or the SCL pin outputs at high level if the BBSY flag is 0. Further clock cycles can consecutively be output by writing 1 to the CLO bit after having read CLO is 0 by software.

When the RIIC module is in master mode and the slave device is holding the SDA line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a stop condition is not possible. The facility for output of an extra cycle of the SCL (clock) signal can be used to output extra cycles of SCL one by one to make the slave device release the SDA line from being held at the low level, thus recovering the bus from an unusable state. Release of the SDA line by the slave device can be monitored by reading the RIICnCR1.SDAI bit. After confirming release of the SDA line by the slave device, complete communications by reissuing the stop condition.

[Output conditions for using the RIICnCR1.CLO bit]

- When the bus is free (RIICnCR2.BBSY flag = 0) or in master mode (RIICnCR2.MST bit = 1 and BBSY flag = 1)
- When the communication device does not hold the SCL line low

Figure 23.40 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

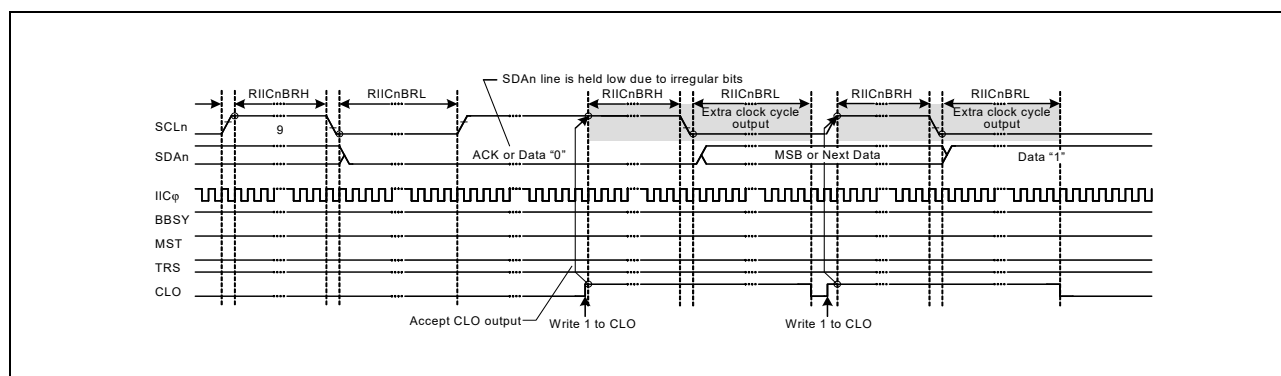

Figure 23.40 Extra SCL Clock Cycle Output Function (CLO Bit)

23.13.3 RIIC Reset and Internal Reset

The RIIC module incorporates a function for resetting itself. There are two types of reset. One is referred to as an RIIC reset; this initializes all registers including the RIICnCR2.BBSY flag. The other is referred to as an internal reset; this releases the RIIC from the slave-address matched state and initializes the internal counter while retaining other settings. After issuing a reset, be sure to clear the RIICnCR1.IICRST bit to 0.

Both types of reset are effective for release from bus-hung states since both restore the output state of the SCL and SDA pins to the high impedance state.

Issuing a reset during slave operation may lead to a loss of synchronization between the master device clock and the slave device clock, so avoided this where possible. Note that monitoring of the bus state, such as for the presence of a start condition, is not possible during an RIIC reset (RIICnCR1.ICE and IICRST bits = 01_B).

For a detailed description of the RIIC and internal resets, see [section 23.15, Reset Function of RIIC](#).

23.14 SMBus Operation

The RIIC is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the RIICnMR3.SMBS bit to 1. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus standard, set the RIICnMR1.CKS[2:0] bits, RIICnCBRH, and RIICnBRL. In addition, determine the values of the RIICnMR2.DLCS bit and the RIICnMR2.SDDL[2:0] bits to meet the data hold time specification of 300 ns or more. If the RIIC is used only as a slave device, the transfer rate setting is not necessary. When the RIIC is used only as a slave device, the transfer rate setting is not necessary, whereas the RIICnBRL needs to be set to a value at least the same as the data setup time (250 ns).

For the SMBus device default address (1100 001_B), use one of the slave address registers L0 to L2 (RIICnSAR0, RIICnSAR1, and RIICnSAR2), and set the corresponding RIICnSARy.FSy bit (7-bit/10-bit address format select) (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the RIICnFER.SALE bit to 1 to enable the slave arbitration lost detection function.

23.14.1 SMBus Timeout Measurement

(1) Measuring timeout of slave device

The following period (timeout interval: $T_{\text{LOW:SEXT}}$) must be measured for slave devices in SMBus communication.

- From start condition to stop condition

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the internal timer using a start condition detection interrupt (INTRIICSTI) and stop condition detection interrupt (INTRIICSPI) of the RIIC. The measured timeout period must be within the total clock low-level period [slave device] $T_{\text{LOW:SEXT}}$: 25 ms (max.) of the SMBus standard.

If the time measured with the internal timer exceeds the clock low-level detection timeout T_{TIMEOUT} : 25 ms (min.) of the SMBus standard, the slave device must release the bus by writing 1 to the RIICnCR1.IICRST bit to issue an internal reset of the RIIC. When an internal reset is issued, the RIIC stops driving the bus for the SCL pin and SDA pin and make the SCL/SDA pin outputs high impedance, which releases the bus.

(2) Measuring timeout of master device

The following periods (timeout interval: $T_{\text{LOW:MEXT}}$) must be measured for master devices in SMBus communication.

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition

To measure timeout for master devices, measure these periods with the internal timer using a start condition detection interrupt (INTRIICSTI), stop condition detection interrupt (INTRIICSPI), and transmit end interrupt (INTRIICTEI) or receive data full interrupt (INTRIICRI) of the RIIC. The measured timeout period must be within the total clock low-level extended period [master device] $T_{\text{LOW:MEXT}}$: 10 ms (max.) of the SMBus standard, and the total of all $T_{\text{LOW:MEXT}}$ from start condition to stop condition must be within $T_{\text{LOW:SEXT}}$: 25 ms (max.).

For the ACK receive timing (rising edge of the ninth SMBCLK clock cycle), monitor the RIICnSR2.TEND flag in master transmit mode (master transmitter) and the RIICnSR2.RDRF flag in master receive mode (master receiver). For this reason, perform bitwise transmit operation in master transmit mode, and hold the RIICnMR3.RDRFS bit 0 until the byte just before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 at the rising edge of the ninth SMBCLK clock cycle.

If the period measured with the internal timer exceeds the total clock low-level extended period [master device] $T_{\text{LOW:MEXT}}$: 10 ms (max.) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout T_{TIMEOUT} : 25 ms (min.) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (writing data to RIICnDRT).

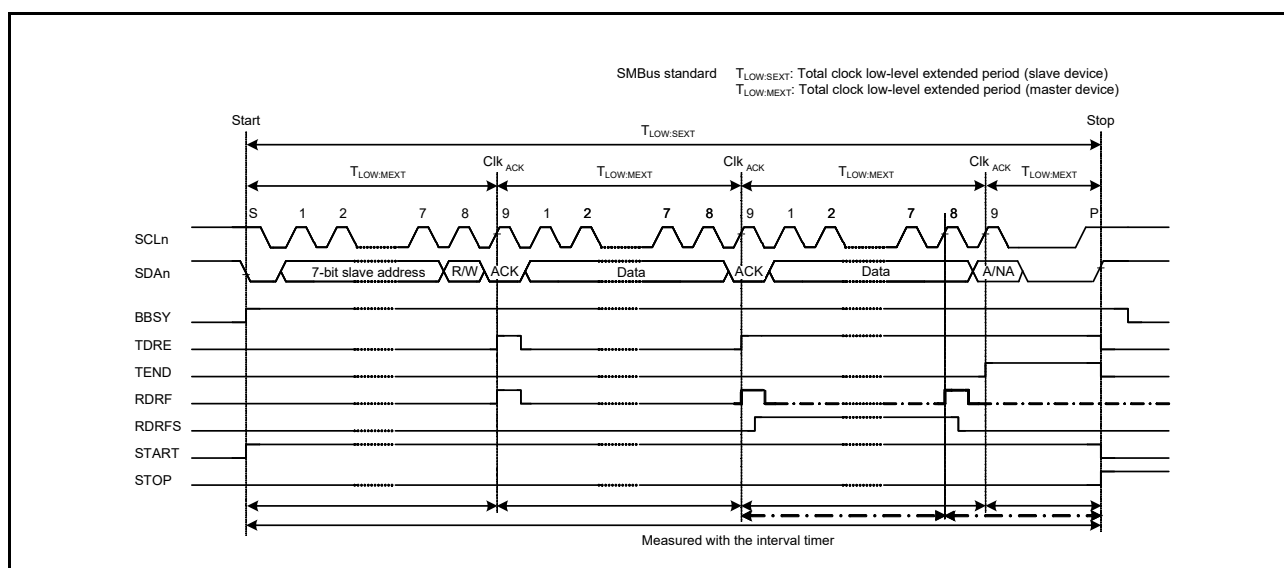

Figure 23.41 SMBus Timeout Measurement

23.14.2 SMBus Host Notification Protocol/Notify ARP Master

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of (or request the SMBus host for) its own slave address or to request its own slave address from the SMBus host.

For this LSI to operate as an SMBus host (or ARP master), the host address (0001 000_B) sent from the slave device must be detected as a slave address, so the RIIC has a function for detecting the host address. To detect the host address as a slave address, set the RIICnMR3.SMBS bit and the RIICnSER.HOAE bit to 1. Operation after the host address has been detected is the same as normal slave operation.

23.15 Reset Function of RIIC

The RIIC has chip reset, RIIC reset, and internal reset functions. Table 23.24 lists the scope of each reset and reset conditions.

Table 23.24 RIIC Reset Functions

| Register | | RIIC Reset (ICE = 0, IICRST = 1) | Internal Reset (ICE = 1, IICRST = 1) | Start Condition/Restart Condition Detection | Stop Condition Detection |

24.4 Function Details

24.4.1 Register Descriptions

24.4.1.1 Control Register (SSICR)

This is a 32-bit readable/writable register. With this register, select an audio clock, control IRQ, select data formats, and set an operation mode.

| | | | | | | | | | | | | | | | | |
|----------------|----|-----|-------|-------|-------|-------|------|-----|----------|-----------|-----|-----|------|----------|-----|-----|

| 10B | | | 6 |
| 11B | | | 8 |

| Bits | Bit Name | R/W | Initial Value | Description |
|----------|----------|-----|---------------|---|
| 21 to 19 | DWL[2:0] | R/W | 000B | Selects data word length*1 000: 8 bits 001: 16 bits 010: 18 bits 011: 20 bits 100: 22 bits 101: 24 bits 110: 32 bits 111: Setting prohibited |
| 18 to 16 | SWL[2:0] | RW | 000B | Selects system word length*1 000: 8 bits 001: 16 bits 010: 24 bits 011: 32 bits 100: 48 bits 101: 64 bits 110: 128 bits 111: 256 bits |
| 15 | — | R | 0 | Reserved. Write 0. The read value is 0. |
| 14 | MST | RW | 0 | Master enable*1 0: Slave-mode communication 1: Master-mode communication |
| 13 | BCKP | RW | 0 | Selects bit clock polarity*1 0: SSILRCK/SSIFS and SSIFTxD/SSIFRxD change at a falling edge (sampling SSILRCK/SSIFS and SSIFRxD at a rising edge of SSIBCK). 1: SSILRCK/SSIFS and SSIFTxD/SSIFRxD change at a rising edge (sampling SSILRCK/SSIFS and SSIFRxD at a falling edge of SSIBCK). |
| 12 | LRCKP | RW | 0 | Selects the initial value and polarity of LRCK/FS*1 0: The initial value is at a high level For SSILRCK/SSIFS, one frame start trigger is falling edge of SSILRCK/SSIFS. 1: The initial value is at a low level For SSILRCK/SSIFS, one frame start trigger is rising edge of SSILRCK/SSIFS. |
| 11 | SPDP | RW | 0 | Selects serial padding polarity*1 0: Padding data is at a low level 1: Padding data is at a high level |
| 10 | SDTA | RW | 0 | Selects serial data alignment*1 0: Transmits and receives serial data first and then padding bits. 1: Transmit and receives padding bits first and then serial data. |
| 9 | PDTA | RW | 0 | Selects placement data alignment*1 0: Left-justifies placement data (SSIFTDR, SSIFRDR) 1: Right-justifies placement data (SSIFTDR, SSIFRDR) |
| 8 | DEL | RW | 0 | Selects serial data delay*1 0: Delay of one cycle of SSIBCK between SSILRCK/SSIFS and SSIFTxD/SSIFRxD. 1: No delay between SSILRCK/SSIFS and SSIFTxD/SSIFRxD. This bit control SSILRCK/SSIFS in monaural format (Refer to section 24.4.2.2, Monaural Format for details). |

| Bits | Bit Name | R/W | Initial Value | Description |
|--------|-----------|-----|---------------|---|
| 7 to 4 | CKDV[3:0] | RW | 0H | Selects bit clock division ratio*1 CKDV[3:0] 0000: AUDIO_MCK 0001: AUDIO_MCK/2 0010: AUDIO_MCK/4 0011: AUDIO_MCK/8 0100: AUDIO_MCK/16 0101: AUDIO_MCK/32 0110: AUDIO_MCK/64 0111: AUDIO_MCK/128 1000: AUDIO_MCK/6 1001: AUDIO_MCK/12 1010: AUDIO_MCK/24 1011: AUDIO_MCK/48 1100: AUDIO_MCK/96 1101: Setting prohibited 1110: Setting prohibited 1111: Setting prohibited |
| 3 | MUEN | RW | 0 | Mute (silent) enable 0: Disables muting on the next frame boundary. 1: Enables muting on the next frame boundary. |
| 2 | — | R | 0 | Reserved. Write 0. The read value is 0. |
| 1 | TEN | RW | 0 | Transmission and reception enable*2 |
| 0 | REN | RW | 0 | (TEN, REN): Operating 00: Disables transmission and reception 01: Enables reception (starts reception) 10: Enables transmission (starts transmission) 11: Enables transmission and reception (starts transmission and reception) |

Note 1. Writing to these bits while SSIF-2 is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Note 2. If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If written, the operation performed immediately after writing is not guaranteed. For example, after enabling operation, make sure that SSISR.IIRQ = 0 and after disabling operation, make sure that SSISR.IIRQ = 1.

- CKS Bit

This bit sets the audio clock in master-mode communication (MST = 1). In slave-mode communication (MST = 0), setting of this bit is invalid.

To write this bit, do so when AUDIO_MCK is not supplied. Refer to the AUCKE bit details explanation in **section 24.4.1.3, FIFO Control Register (SSIFCR)** for detailed timing.

- TUIEN Bit

This bit enables/disables output of transmit underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TUIRQ = 1.

- TOIEN Bit

This bit enables/disables output of transmit overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TOIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TOIRQ = 1.

- RUIEN Bit

This bit enables/disables output of receive underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.RUIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.RUIRQ = 1.

- ROIEN Bit

This bit enables/disables output of receive overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.ROI_{RQ} = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.ROI_{RQ} = 1.

- IIEN Bit

This bit enables/disables output of idle mode interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.IIR_Q = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.IIR_Q = 1.

- FRM[1:0] Bits

These bits set system word number in one frame of the communication formats.

Rewrite these bits when the LR clock supply to the terminal SSILRCK stops. Refer to the LRCONT bit details explanation in section 24.4.1.7, Audio Format Register (SSIOFR) for the output operation of the LR clock.

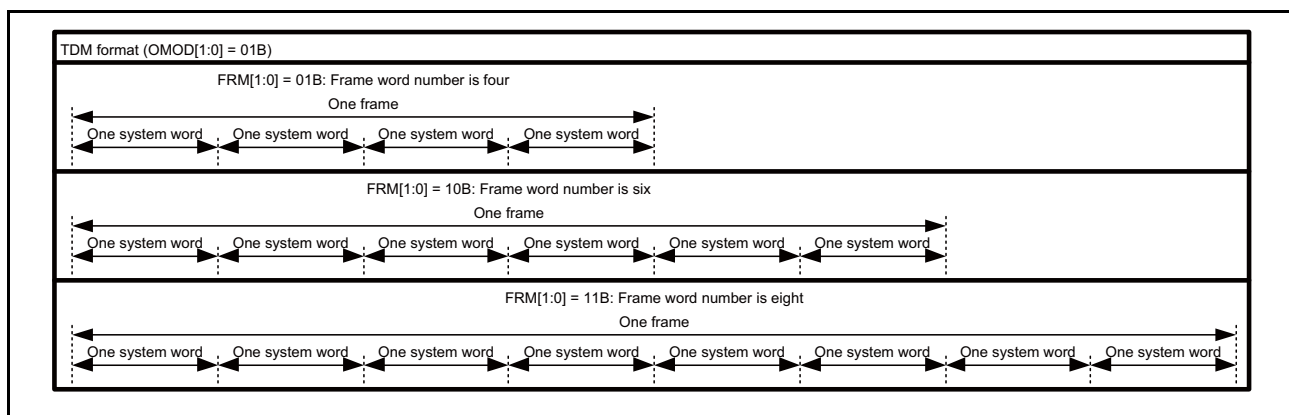

Figure 24.4 Frame word number

- DWL[2:0] Bits

These bits set the number of bits in one data word. The setting whose number of data of system word lengths is shorter than that of the data word length is a prohibition. Refer to Figure 24.13 in section 24.4.2, Communication Formats for details.

- SWL[2:0] Bits

These bits set the number of bits in one system word. Padding bits are sent and received in relation with one data word set with DWL[2:0]. See Table 24.13 in section 24.4.2, Communication Formats for details.

Rewrite these bits when the LR clock supply to the terminal SSILRCK stops. Refer to the LRCONT bit details explanation in section 24.4.1.7, Audio Format Register (SSIOFR) for the output operation of the LR clock.

- MST Bit

This bit sets master-/slave-mode communication.

To write this bit, do so when AUDIO_MCK is not supplied. Refer to the AUCKE bit details explanation in section 24.4.1.3, FIFO Control Register (SSIFCR) for detailed timing.

- BCKP Bit

This bit sets the bit clock polarity (Table 24.5).

To write this bit, do so when AUDIO_MCK is not supplied. Refer to the AUCKE bit details explanation in section 24.4.1.3, FIFO Control Register (SSIFCR) for detailed timing.

Table 24.5 Bit Clock Polarity

| Communication | Master/Slave | Timing | BCKP = 0 | BCKP = 1 |
|---------------|--------------|-----------------------------------|---------------------|---------------------|
| Reception | Slave | At SSILRCK/SSIFS sampling | SSIBCK rising edge | SSIBCK falling edge |
| | Master/slave | At SSIFRxD sampling | SSIBCK rising edge | SSIBCK falling edge |
| Transmission | Master | At change of SSILRCK/SSIFS output | SSIBCK falling edge | SSIBCK rising edge |
| | Master/slave | At change of SSIFTxD output | SSIBCK falling edge | SSIBCK rising edge |

- LRCKP Bit

This bit sets the initial value and polarity of SSILRCK/SSIFS. Set this bit according to the communication format to be used in SSIF-2 (Table 24.6). Only the start trigger is used at slave communication (MST=0).

Rewrite this bit when the LR clock supply to the terminal SSILRCK stops. Refer to the LRCONT bit details explanation in section 24.4.1.7, Audio Format Register (SSIOFR) for the output operation of the LR clock.

Table 24.6 Initial Output Value and Polarity of SSILRCK/SSIFS Pin

| Communication Format | Expected Initial State | Setting Value of LRCKP |
|----------------------|------------------------|------------------------|
| I ² S | H | 0 |
| Monaural | L | 1 |
| TDM | L | 1 |

Note: Do the setting that can be communicated respectively to I²S, monaural, and TDM at the compatible format.

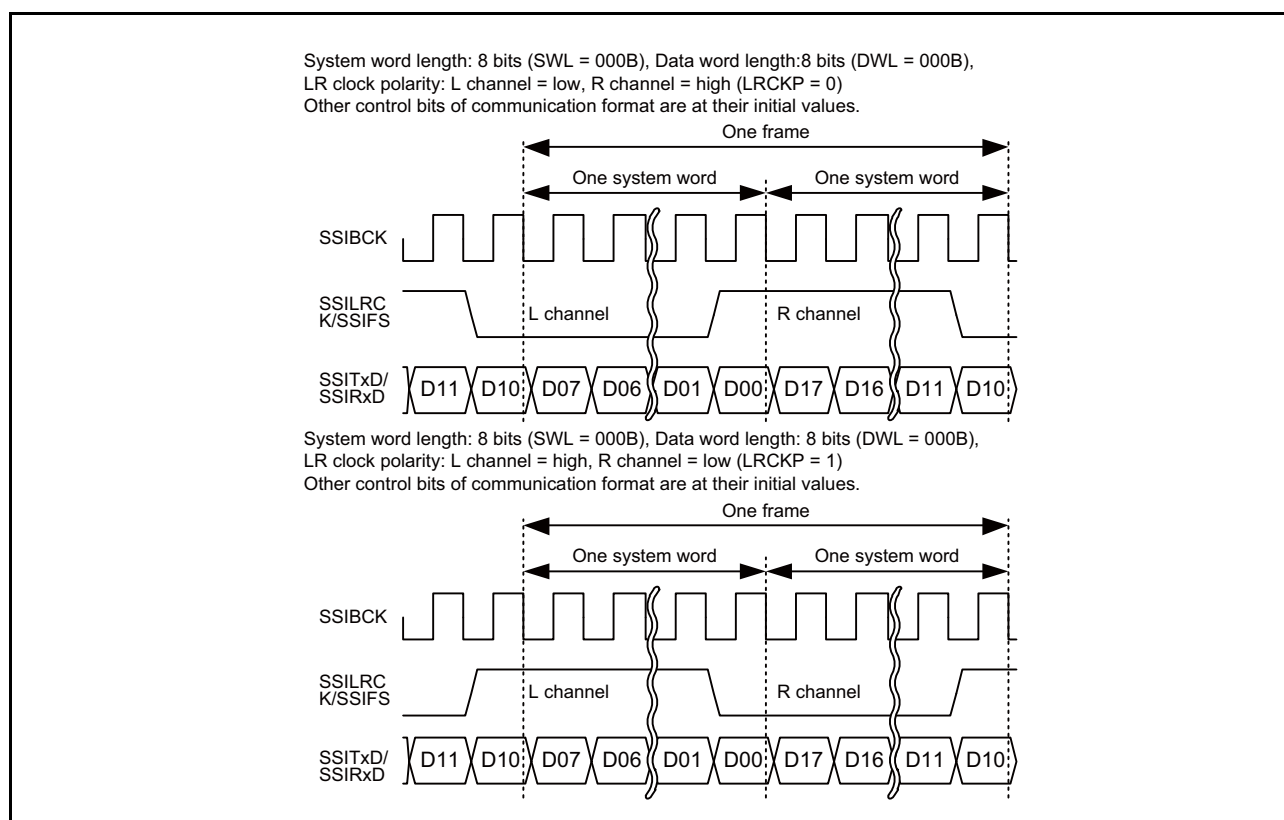

Figure 24.5 LRCK/FS Polarity Setting

- SPDP Bit

This bit sets polarity of padding bits.

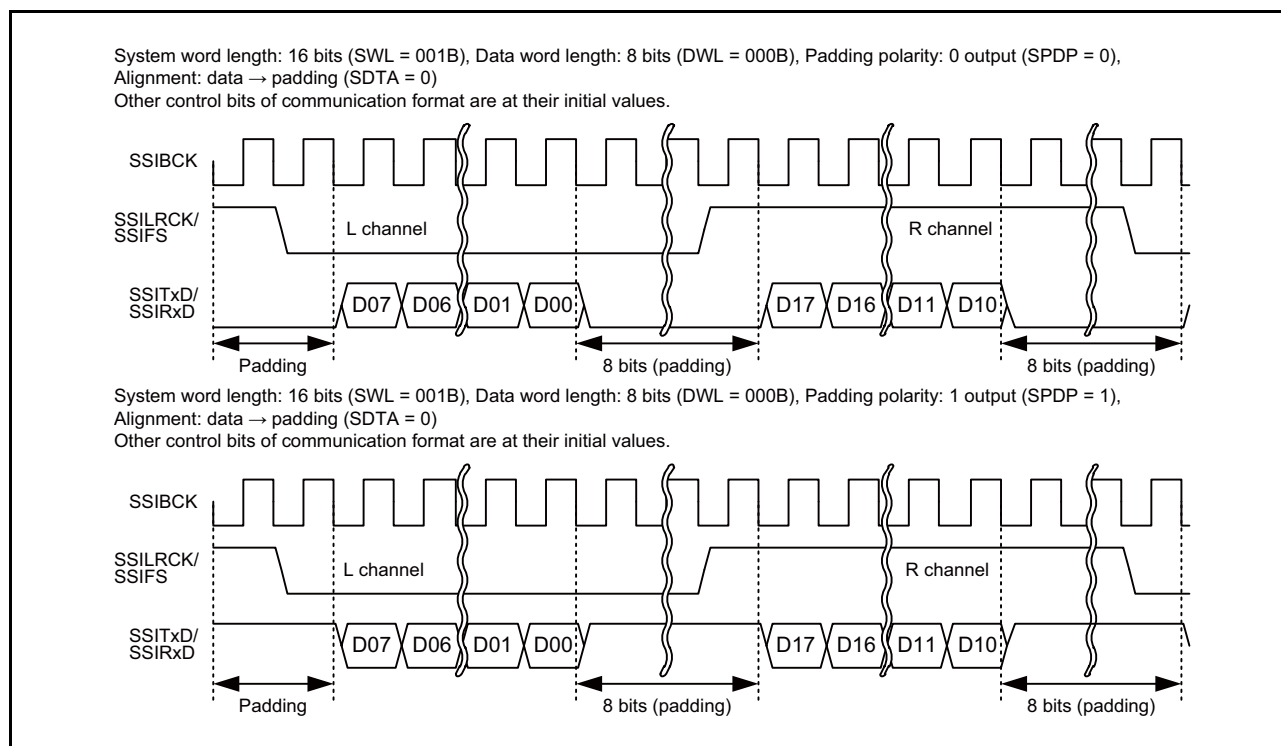

Figure 24.6 Padding Bit Polarity

- SDTA Bit

This bit sets alignment of serial data (data bits and padding bits). For communication without padding bits, this bit is invalid.

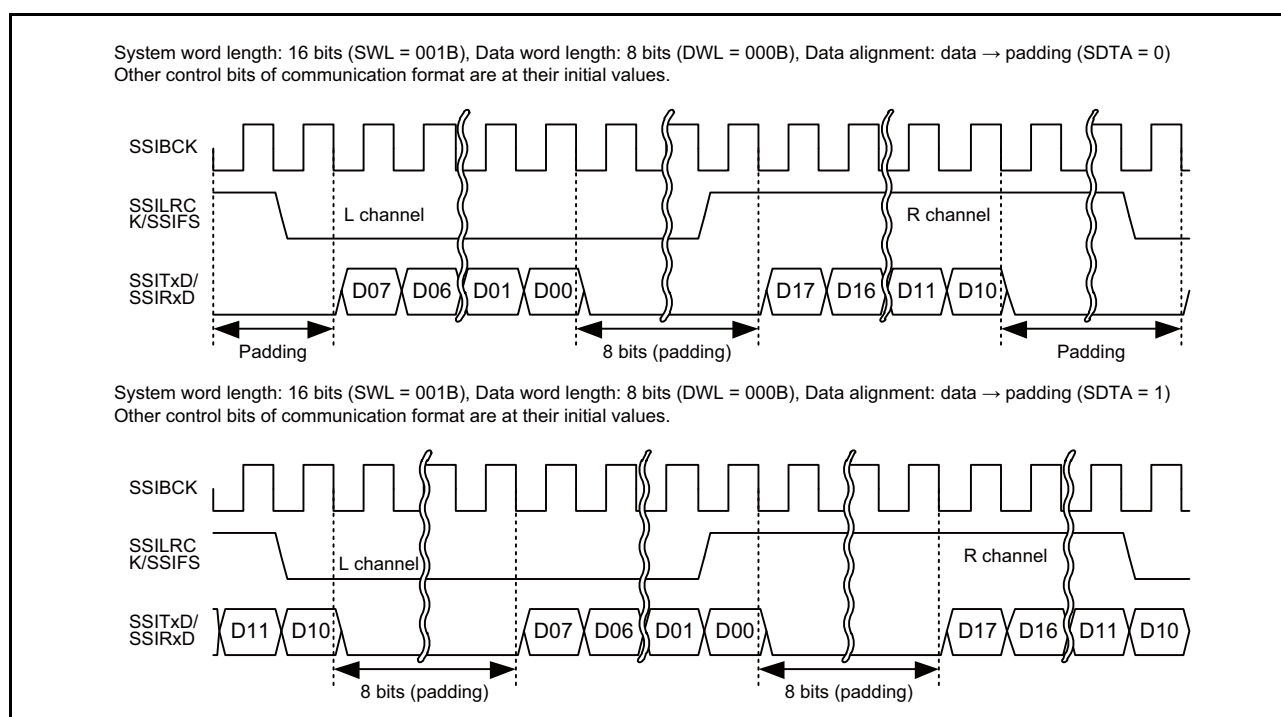

Figure 24.7 Alignment Setting of Serial Data with Padding Bits

- PDTA Bit

This bit sets alignment of placement data. With the setting of data word length as 32 bits (DWL[2:0] = 110B), this bit is invalid.

At transmission:

| First Transfer Data | | Second Transfer Data | | Third Transfer Data | | Fourth Transfer Data | | | |
|--|-----------------------|----------------------|---------|------------------------|---|----------------------|-----------------------------|---|---------|

Figure 24.9 Alignment Setting of Placement Data in Reception

- DEL Bit

This bit sets whether or not there will be a delay between SSILRCK/SSIFS and SSITxD/SSIRxD.

With the I²S format and TDM format, set 0 to DEL (Figure 24.10). With the monaural format, this bit changes the high period width. Refer to section 24.4.2.2, Monaural Format for details. Do the setting that can be communicated at the compatible communication format.

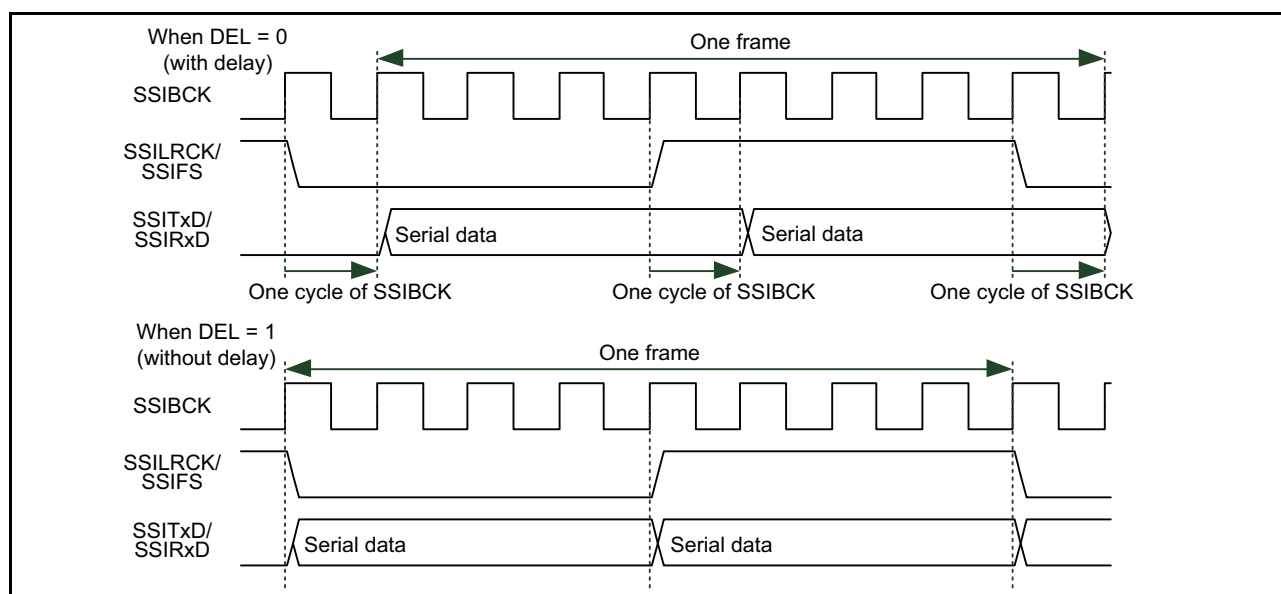

Figure 24.10 Setting of Delay in Serial Data

- CKDV[3:0] Bits

These bits set the division ratio of the bit clock based on AUDIO_MCK in master-mode communication (MST = 1) (Figure 24.11). In slave-mode communication (MST = 0), setting of these bits are invalid.

To write this bit, do so when AUDIO_MCK is not supplied. Refer to the AUCKE bit details explanation in section 24.4.1.3, FIFO Control Register (SSIFCR) for detailed timing.

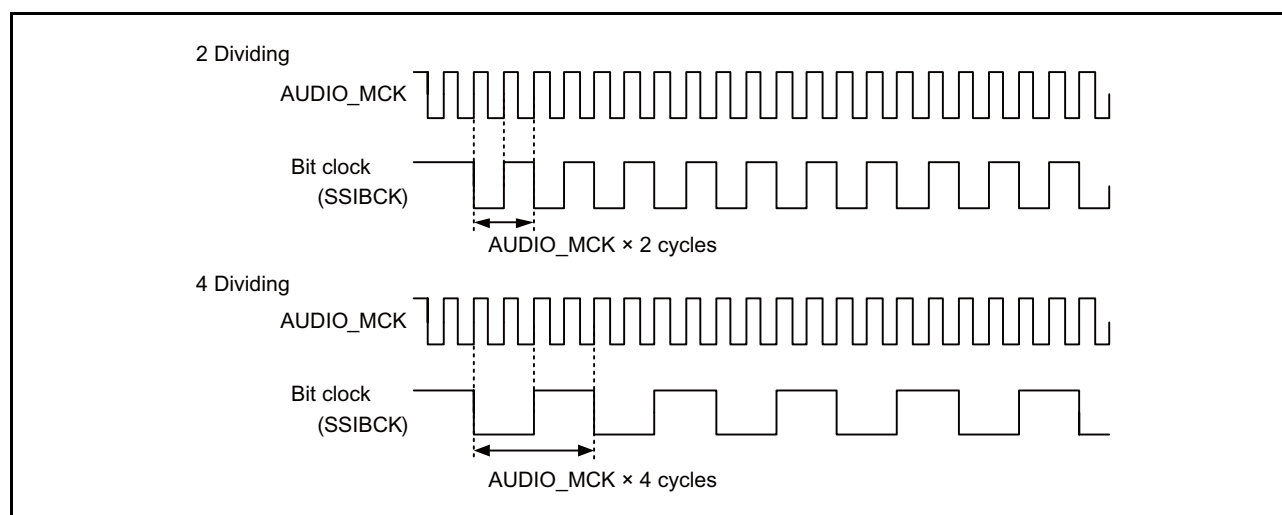

Figure 24.11 Sampling Frequencies in Master-mode Communication

- MUEN Bit

This bit sets/clears the mute function for the data output from the terminal SSITxD. When you set this bit to 1, the output value of SSITxD becomes 0 from the next frame boundary. When you set this bit to 0, the output value of SSITxD can be made the data of the FIFO transmission data register from the following frame boundary.

Note that this bit controls data only. Status flags and interrupt signals are normally generated.

Set this bit after setting completing the communication format.

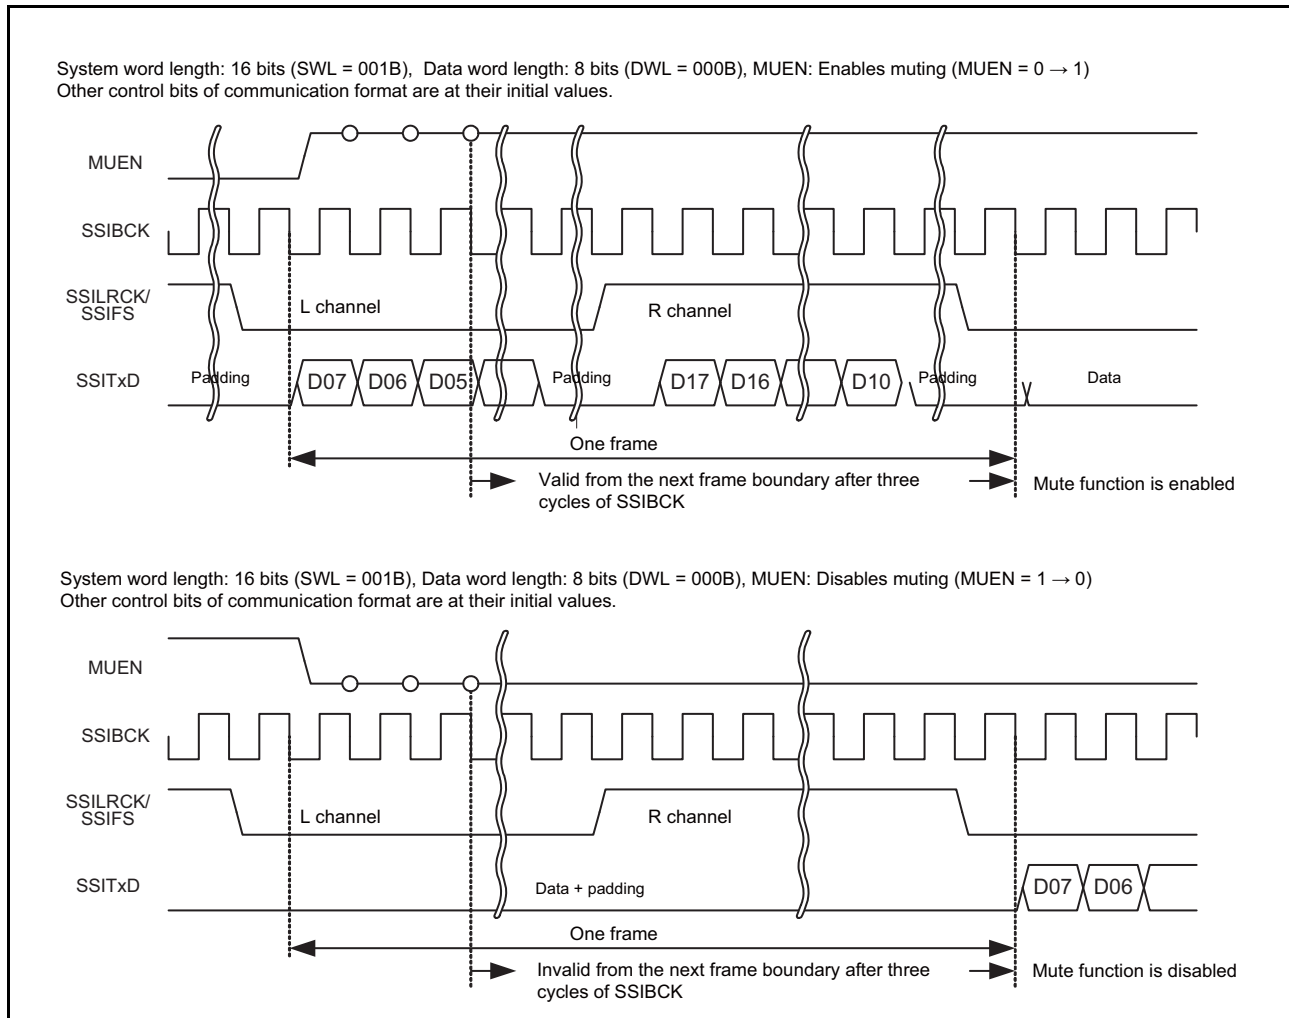

Figure 24.12 Transmit Data with the Mute Function Set

- TEN and REN Bits

These bits enable/disable transmission and reception. Writing 1 to these bits, transmission starts in synchronization with start trigger. Refer to section 24.5.2.2, Transmission, section 24.5.2.3, Reception, and section 24.5.2.4, Transmission and Reception for details. Writing 0 to these bits, transmission stops in synchronization with next frame boundary. Set 1 at the same time when you use SSIF-2 as transmission and reception. To stop communication, make sure to stop transmission and reception (TEN = 0 and REN = 0).

To stop communication without waiting for the frame boundary, follow the software reset procedure.

24.4.1.2 Status Register (SSISR)

This is a readable/writable 32-bit register. It is configured with status flags that indicate SSIF-2 operational state.

| 24 to 0 | — | R | 0000000H | Reserved. Write 0. The read value is 0. |

- TUIRQ Bit

This is a status flag that indicates a transmit underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that writing serial data necessary for one frame to SSIFTDR was slower than one frame of the transmission operation. Even if this flag is cleared after this flag becomes '1', the output value of SSIFTxD is 0. Follow the communication stop procedure (Figure 24.55) and the error procedure (Figure 24.56) to output the data written in transmission FIFO data register (SSIFTDR) to the terminal SSIFTxD. See section 24.5.2.6, Error Handling for the error recovery procedure. This flag is not cleared by transmission FIFO data register reset (SSIFCR.TFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either the following is approved.

- (1) Writing 0 to this flag after reading this flag as 1.*2
- (2) When you do the communication permission (SSICR.TEN is changed from 0 to 1)

[Clearing timing]

Timing according to the above-mentioned clear condition.

- (1) At completion of writing 0 to this flag after reading this flag as 1 (Figure 24.13).
- (2) Write 1 in SSICR.TEN, complete, and after one cycle of P1φ (Figure 24.13).

Figure 24.13 TUIRQ Clearing Timing

- Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.
- Note 2. The state of reading this bit as one is cleared by any of the following three conditions being met:
- Software reset (SSIFCR.SSIRST=1).
 - Completion of writing 0 to this flag after having read it as 1.
 - One cycle of P1φ elapsing after the completion of writing 1 to SSICR.TEN.
- Note 3. After the communication is permitted (SSICR.TEN is written and '1' is written from '0'), the transmission error flag (TOIRQ and TUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the transmission error flag might not be able to be read.

[Setting condition]

When data to be transmitted in the next frame is not fully written to SSIFTDR at the frame boundary of continuance communication.

[Setting timing]

After three cycles of P1 ϕ from frame boundary (Figure 24.14).

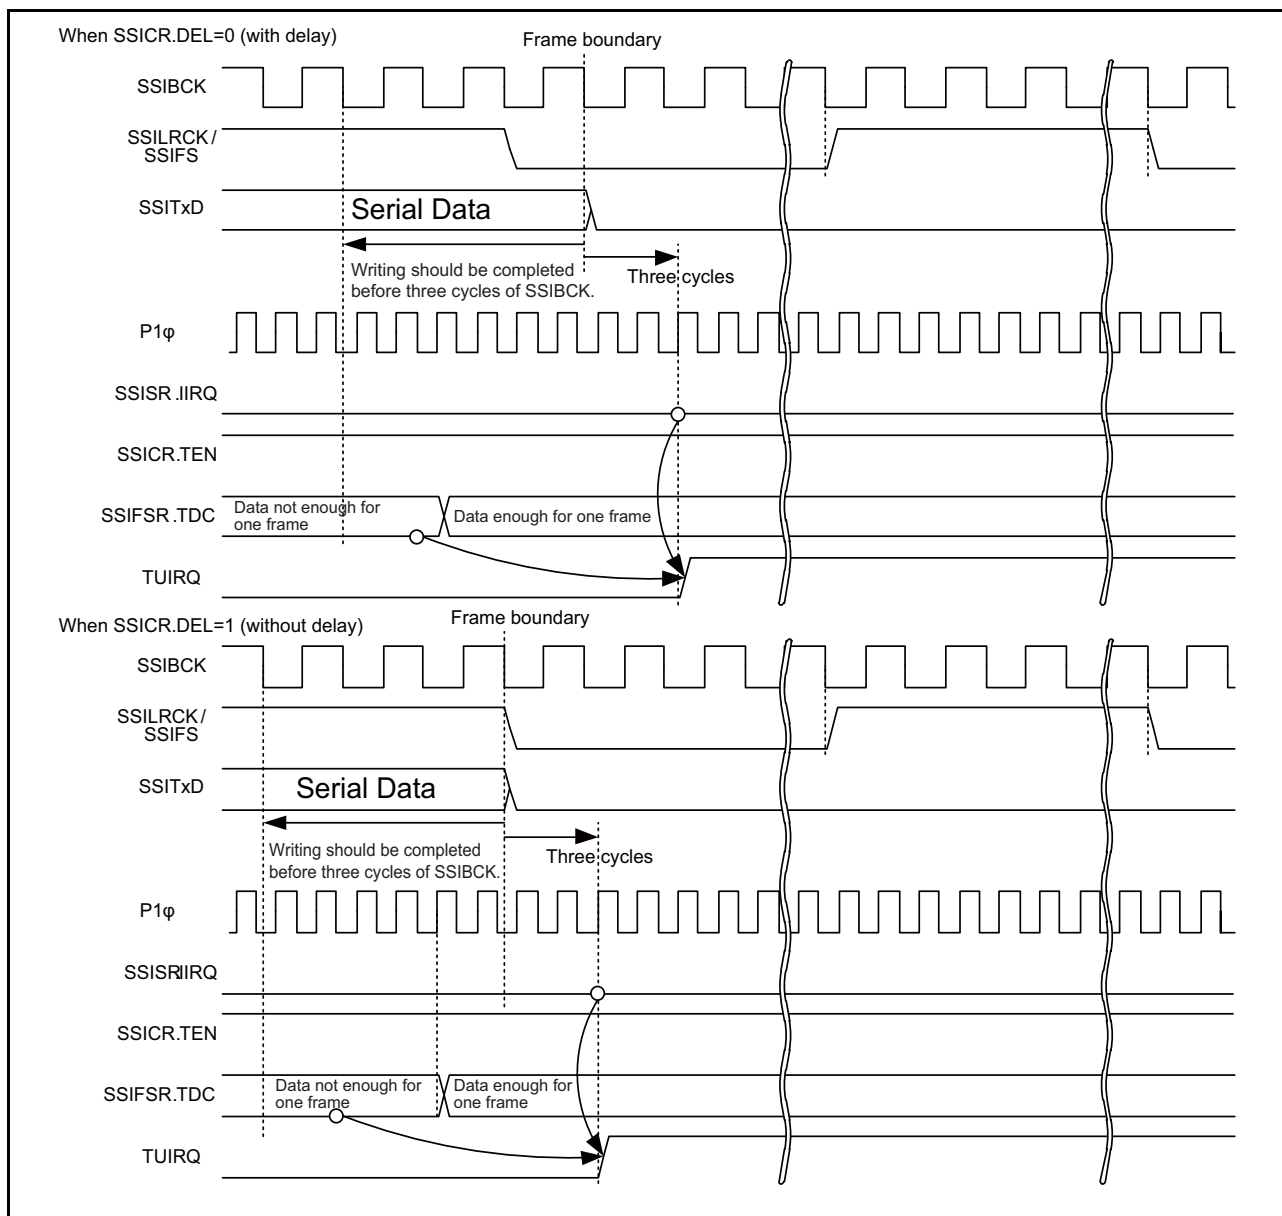

Figure 24.14 TUIRQ Setting Timing (When you continue communicating)

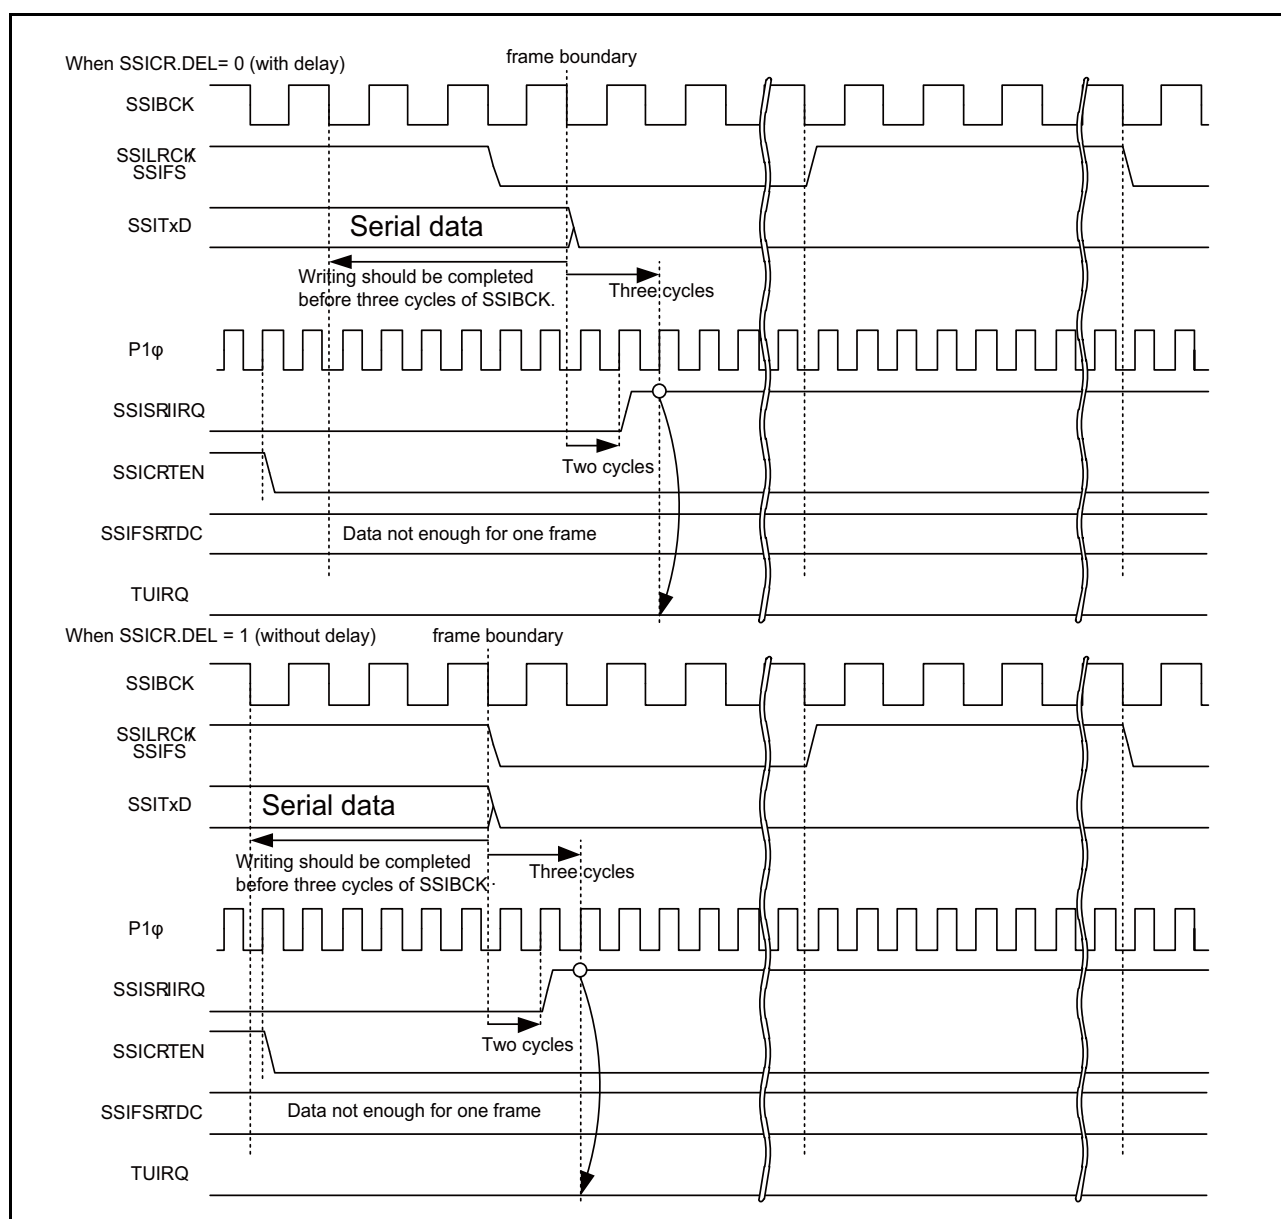

Figure 24.15 TUIRQ Setting Timing (When you stop communicating)

- TOIRQ Bit

This is a status flag that indicates a transmit overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that serial data is written to SSIFTDR when it is full during transmission (SSICR.TEN=1). Data is not written to SSIFTDR where a transmit overflow error is generated. See section 24.5.2.6, Error Handling for the error recovery procedure. This flag is not cleared by transmission FIFO data register reset (SSIFCR.TFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either the following is approved.

- (1) Writing 0 to this flag after reading this flag as 1.*2
- (2) When you do the communication permission (SSICR.TEN is changed from 0 to 1)

[Clearing timing]

Timing according to the above-mentioned clear condition.

- (1) At completion of writing 0 to this flag after reading this flag as 1 (same as Figure 24.13).
- (2) Write 1 in SSICR.TEN, complete, and after one cycle of P1φ (same as Figure 24.13).

Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. The state of reading this bit as one is cleared by any of the following three conditions being met:

- Software reset (SSIFCR.SSIRST=1).
- Completion of writing 0 to this flag after having read it as 1.
- One cycle of P1φ elapsing after the completion of writing 1 to SSICR.TEN.

Note 3. After the communication is permitted (SSICR.TEN is written and '1' is written from '0'), the transmission error flag (TOIRQ and TUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the transmission error flag might not be able to be read.

[Setting condition]

During transmission operation (SSICR.TEN = 1), data is written to SSIFTDR while it is full.

[Setting timing]

At completion of writing to SSIFTDR (Figure 24.16)

Figure 24.16 TOIRQ Setting Timing

• RUIRQ Bit

This is a status flag that indicates a receive underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that SSIFRDR is read while it is empty. Data read from SSIFRDR where a receive underflow error is generated is invalid. See section 24.5.2.6, Error Handling for the error recovery procedure. This flag is not cleared by reception FIFO data register reset (SSIFCR.RFRST). Even if SSIFRDR is read to (SSIFCR.RFRST=1) while resetting reception FIFO data register, it doesn't set 1.

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either the following is approved.

(1) Writing 0 to this flag after reading this flag as 1.*2

(2) When you do the communication permission (SSICR.REN is changed from 0 to 1)

[Clearing timing]

Timing according to the above-mentioned clear condition.

(1) At completion of writing 0 to this flag after reading this flag as 1 (same as Figure 24.13).

(2) Write 1 in SSICR.REN, complete, and after one cycle of P1φ (same as Figure 24.13).

Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. The state of reading this bit as one is cleared by any of the following three conditions being met:

- Software reset (SSIFCR.SSIRST=1).
- Completion of writing 0 to this flag after having read it as 1.
- One cycle of P1φ elapsing after the completion of writing 1 to SSICR.TEN.

Note 3. After the communication is permitted (SSICR.REN is written and '1' is written from '0'), the transmission error flag (ROIRQ and RUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the reception error flag might not be able to be read.

[Setting condition]

Reading from SSIFRDR while it is empty.

[Setting timing]

At completion of reading from SSIFRDR (Figure 24.17).

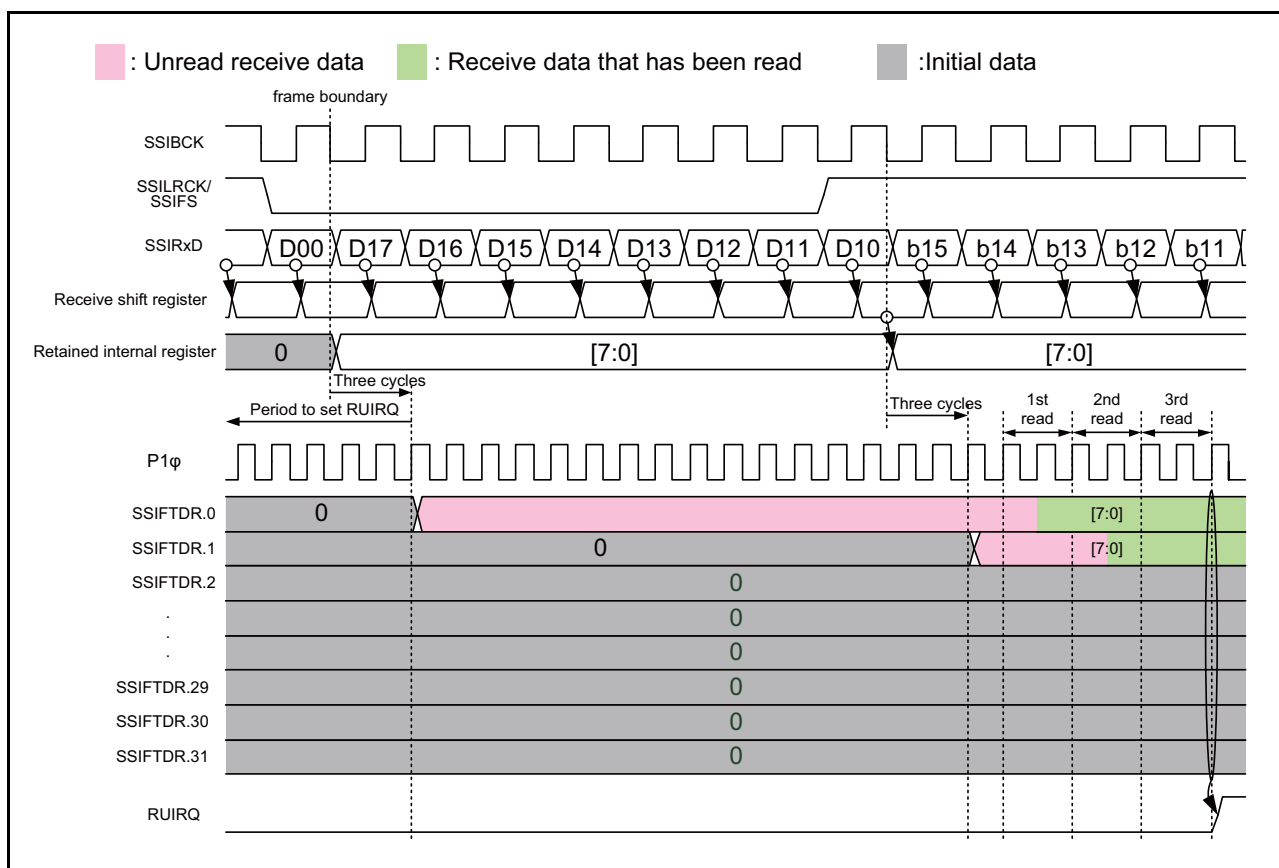

Figure 24.17 RUIRQ Setting Timing

- ROIRQ Bit

This is a status flag that indicates a receive overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that received data is supplied at a higher rate than requested. Data is not transferred from the receive shift register to SSIFRDR where a receive overflow error is generated. See section 24.5.2.6, Error Handling for the error recovery procedure. This flag is not cleared by reception FIFO data register reset (SSIFCR.RFRST).

[Priority order for setting and clearing]

Setting is prioritized.

[Clearing condition]

Writing 0 to this flag after reading this flag as 1.

[Clearing timing]

At completion of writing 0 after reading 1 from an SFR (same as Figure 24.13).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either the following is approved.

(1) Writing 0 to this flag after reading this flag as 1.*2

(2) When you do the communication permission (SSICR.REN is changed from 0 to 1)

[Clearing timing]

Timing according to the above-mentioned clear condition.

(1) At completion of writing 0 to this flag after reading this flag as 1 (same as Figure 24.13).

(2) Write 1 in SSICR.REN, complete, and after one cycle of P1φ (same as Figure 24.13).

Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. The state of reading this bit as one is cleared by any of the following three conditions being met:

- Software reset (SSIFCR.SSIRST=1).
- Completion of writing 0 to this flag after having read it as 1.
- One cycle of P1φ elapsing after the completion of writing 1 to SSICR.TEN.

Note 3. After the communication is permitted (SSICR.REN is written and '1' is written from '0'), the transmission error flag (ROIRQ and RUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the reception error flag might not be able to be read.

[Setting condition]

At completion of receiving new data while SSIFRDR is full.

[Setting timing]

Three cycles of P1φ after reception is completed (Figure 24.18).

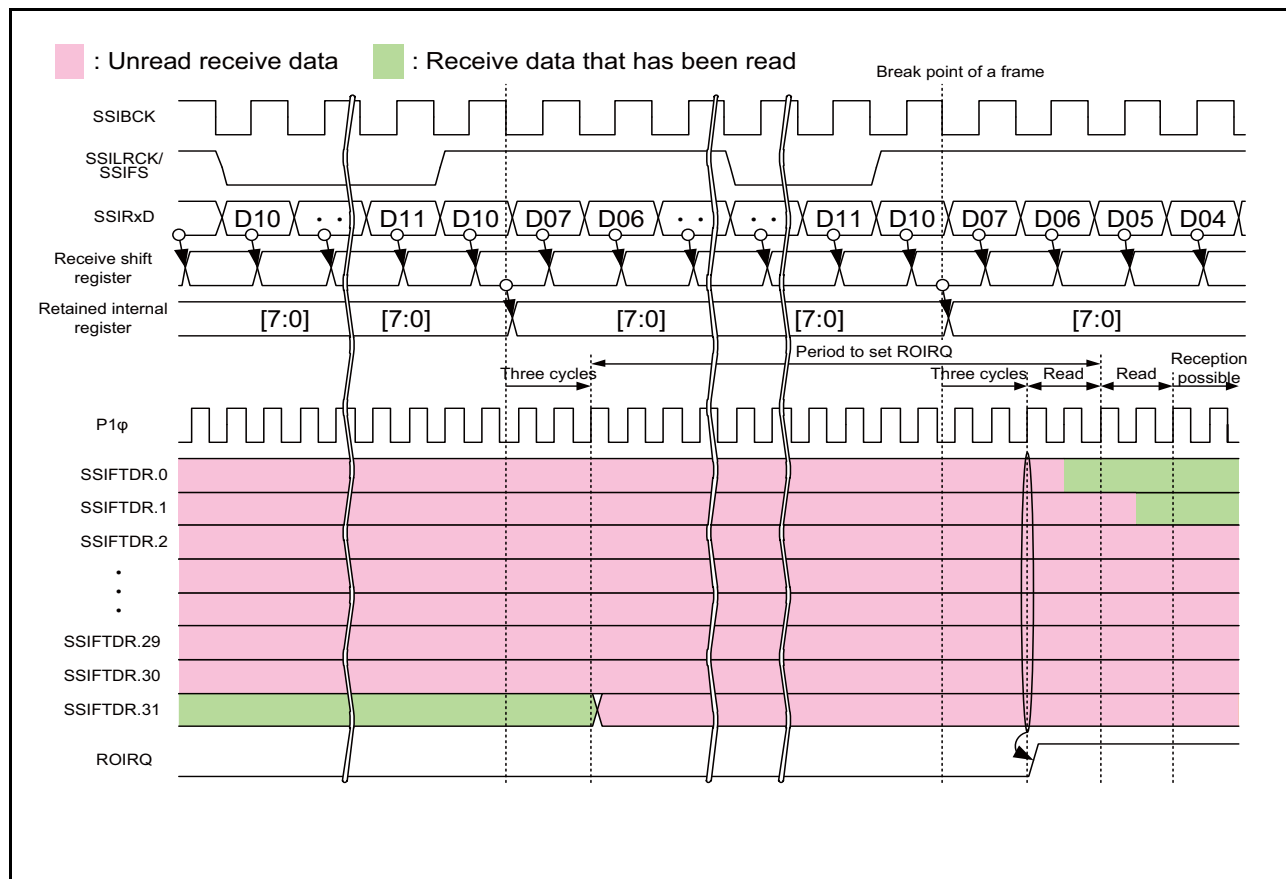

Figure 24.18 ROIRQ Setting Timing

- IIRQ Bit

This is a status flag that indicates the idle state. It indicates whether SSIF-2 is in the idle state or communication state (Figure 24.19 and Figure 24.20).

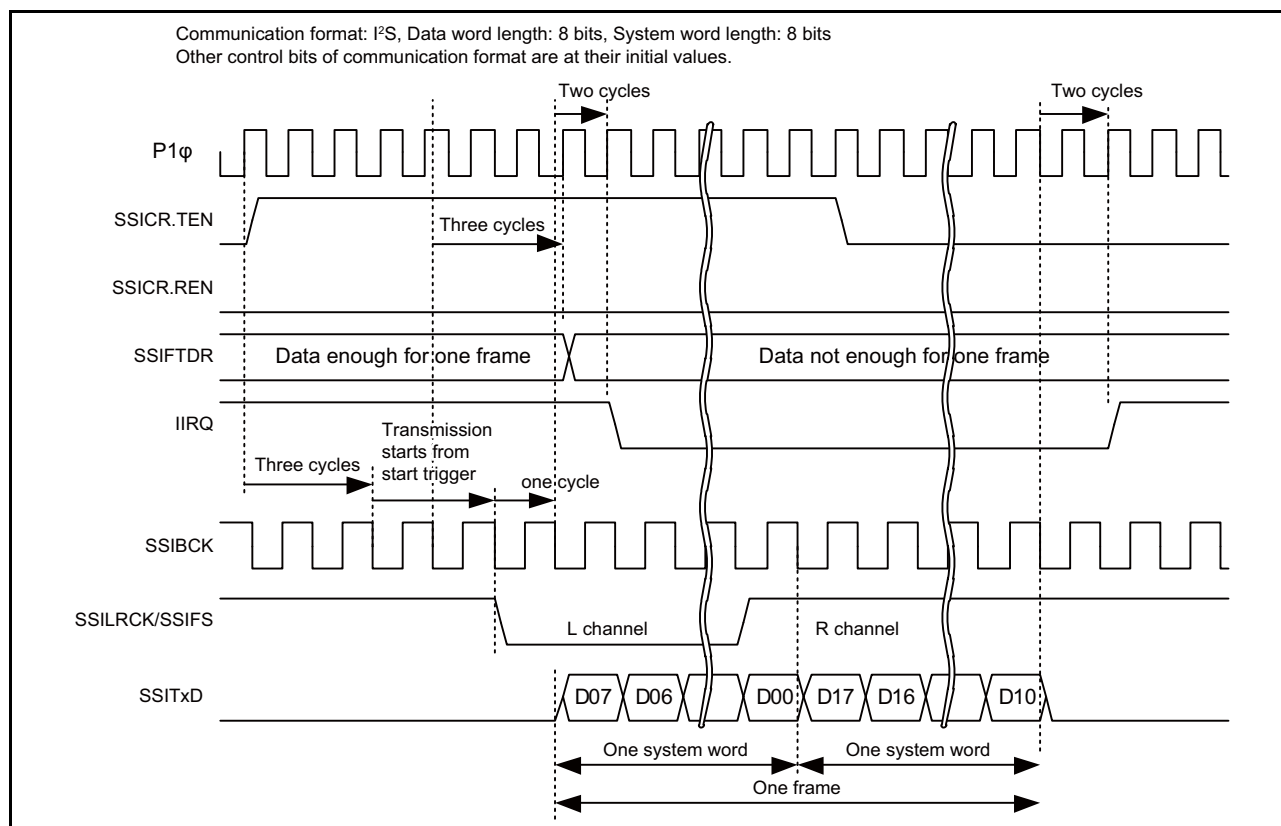

Figure 24.19 IIRQ Setting Timing (Transmission)

- Transmitter (dedicated to transmission)

[Clearing condition]

While transmission is enabled (SSICR.TEN = 1 and SSICR.REN = 0), one frame of data to be transmitted has been written to SSIFTDR, and a start trigger is generated in SSILRCK/SSIFS.

[Clearing timing]

Two cycles of P1φ after one cycle of SSIBCK where a start trigger is generated.

[Setting condition]

One frame of data has been transmitted while transmission and reception are disabled (SSICR.TEN = 0 and SSICR.REN = 0).

[Setting timing]

Two cycles of P1φ after transmission is complete according to the setting condition (frame boundary).

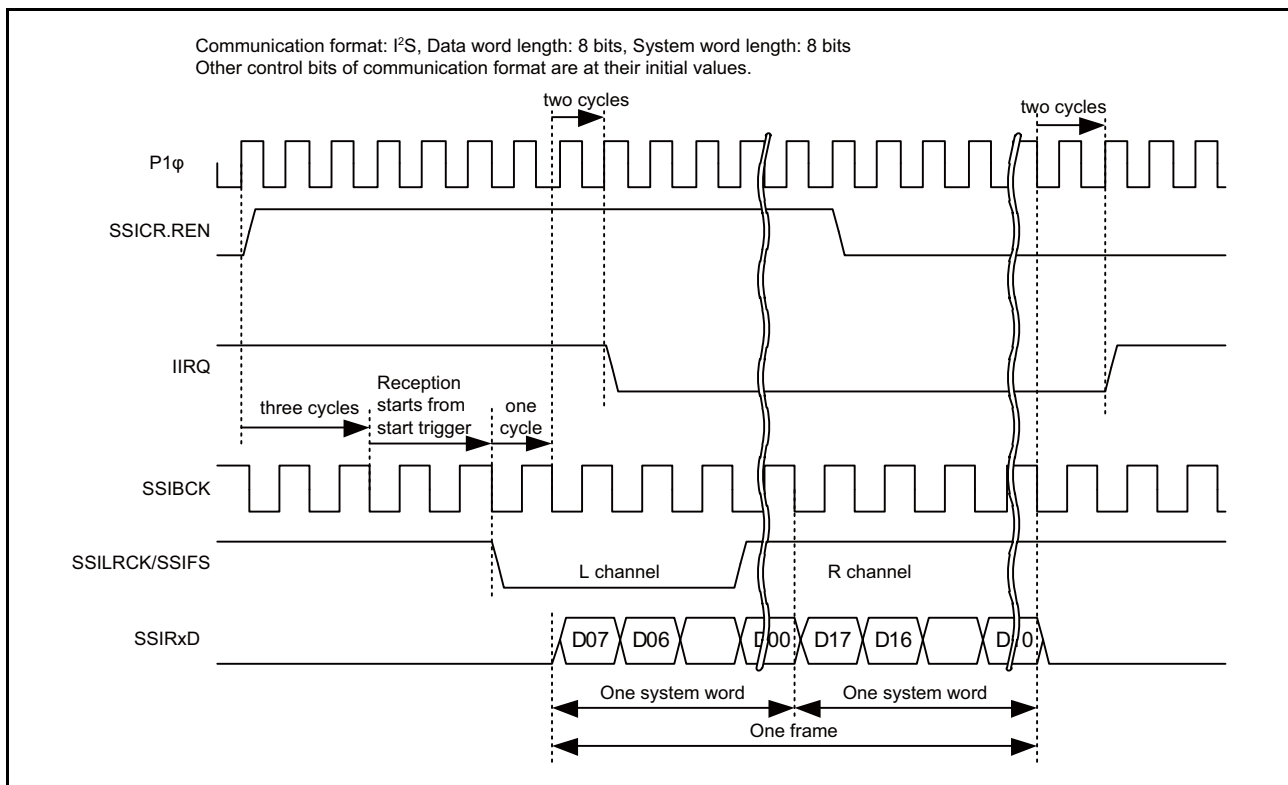

Figure 24.20 IIRQ Setting Timing (Reception)

- Receiver (dedicated to reception)

[Clearing condition]

While reception is enabled (SSICR.TEN = 0 and SSICR.REN = 1), and a start trigger is generated in SSILRCK/SSIFS.

[Clearing timing]

Two cycles of P1φ after one cycle of SSIBCK when a start trigger of the clearing condition is generated.

[Setting condition]

One frame of data has been received while transmission and reception are disabled (SSICR.TEN = 0 and SSICR.REN = 0).

[Setting timing]

Two cycles of P1φ after reception of the setting condition is completed (frame boundary).

- Transceiver (transmission and reception)

[Clearing condition]

While transmission and reception are enabled (SSICR.TEN = 1 and SSICR.REN = 1), one frame of data to be transmitted has been written to SSIFTDR, and a start trigger is generated in SSILRCK/SSIFS.

[Clearing timing]

Two cycles of P1φ after one cycle of SSIBCK when a start trigger of the clearing condition is generated.

[Setting condition]

One frame of data has been transmitted while transmission and reception are disabled (SSICR.TEN = 0 and SSICR.REN = 0).

[Setting timing]

Two cycles of P1φ after transmission is completed according to the setting condition (frame boundary).

24.4.1.3 FIFO Control Register (SSIFCR)

This is a readable/writable 32-bit register. It sets a software reset, byte swap, noise canceller, and enable/disable of interrupt requests.

Note 1. Writing to these bits while SSIF-2 is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Note 2. This bit can only be set to 1 in slave-mode communication (SSICR.MST = '0') except in the case of transmission (SSICR.TEN = '1') while SSICR.DEL = '1'. Be sure to clear this bit to 0 in master-mode communication (SSICR.MST = '1') or during transmission in slave mode (SSICR.MST = '0', SSICR.TEN = '1') while SSICR.DEL = '1'. Set the BCKNCE, LRCKNCE, and RxDNCE bits to the same value.

- AUCKE Bit

This bit enables/disables supply to AUDIO_MCK while in master-mode communication (MST = 1). Select AUDIO_MCK (SSICR.CKS bit) before writing 1 to this bit.

Rewrite this bit after completing the setting (CKS, MST, BCKP, and CKDV of the SSICR register) that relates to AUDIO_MCK.

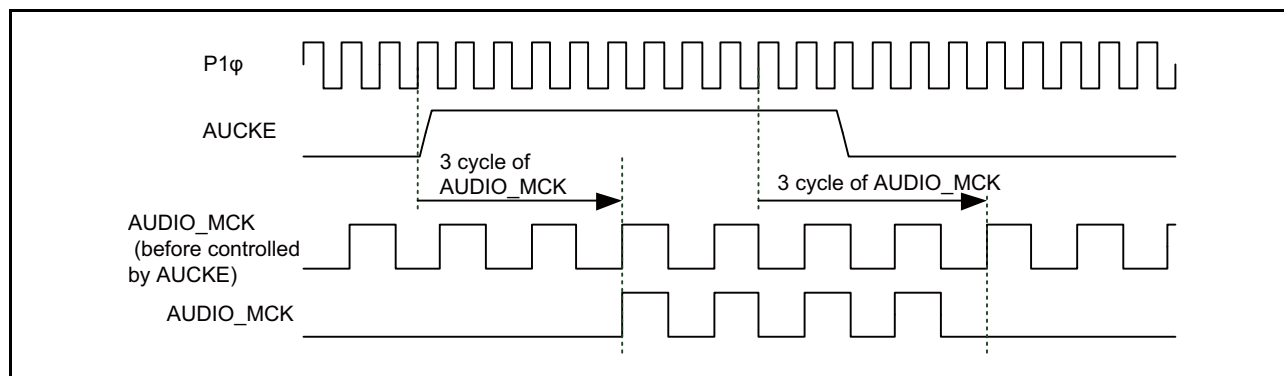

Figure 24.21 Stop/Resume of AUDIO_MCK

Caution: In slave-mode communication (SSICR.MST = 0), SSIF-2 needs supply of SSIBCK. To stop BCK on the master side, make sure that SSIF-2 is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIF-2 becomes idle, take the procedure to start communication (Figure 24.52) or wait for an idle state by taking the procedure to resume communication (Figure 24.57).

Caution: In master-mode communication (SSICR.MST = 1), SSIF-2 operates with the audio clock (AUDIO_MCK). To stop SSIF-2 completely, make sure that SSIF-2 is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.ADCKE. If 0 is written to SSIFCR.ADCKE before SSIF-2 becomes idle, take the procedure to start communication (Figure 24.52) or wait for the idle state by taking the procedure to resume communication (Figure 24.57).

Figure 24.22 and Figure 24.23 show timing until outputting it to the terminal SSIBCK after this bit is set to '1'.

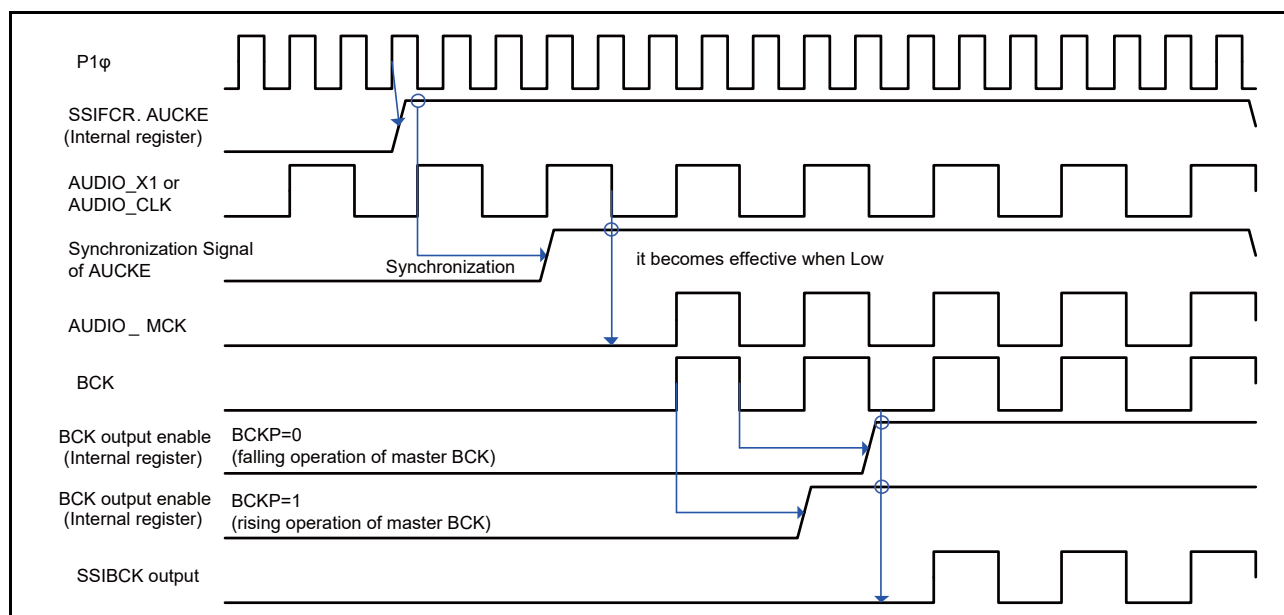

Figure 24.22 Timing chart when it begins to communicate master from system reset

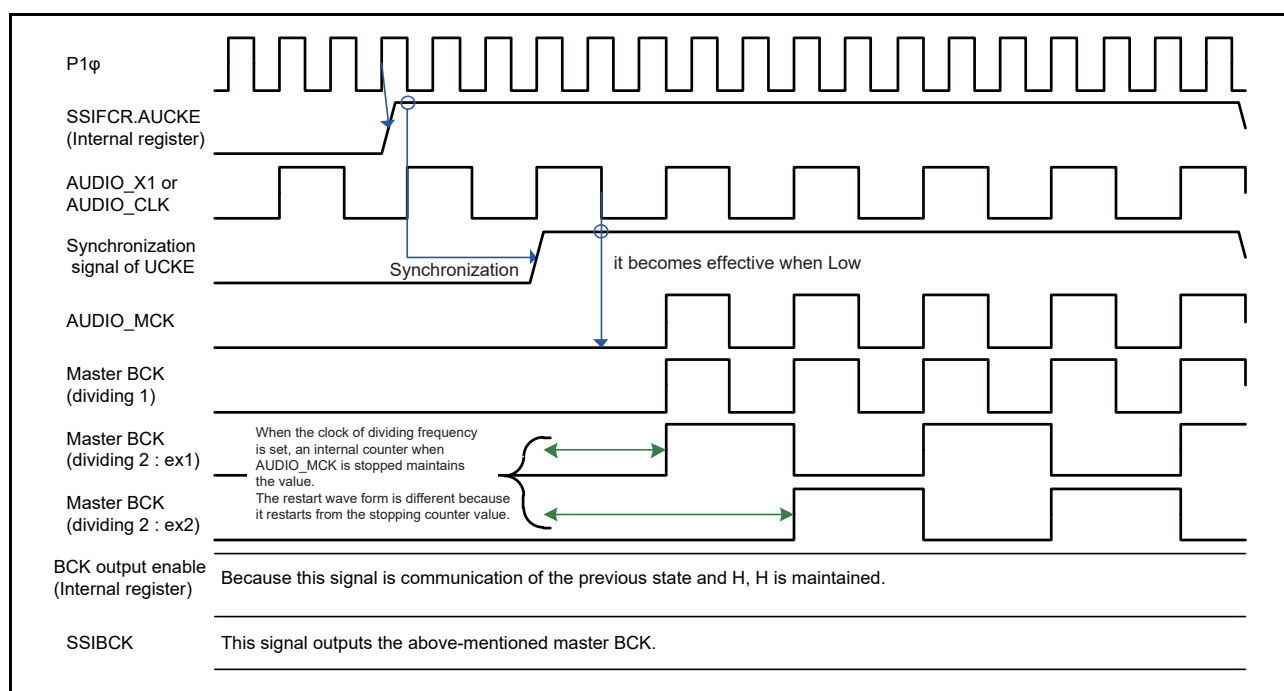

Figure 24.23 Timing chart when it begins to communicate master from communication stop

Note: When the supply of AUDIO_MCK is stopped, the terminal SSIBCK maintains the value. The terminal SSIBCK might stop in the state of "H".

- SSIRST Bit

This bit sets a software reset of SSIF-2. Writing 1 to this bit initializes the internal state of SSIF-2. After a reset by writing 1, write 0 to release the reset because this bit is not automatically cleared to 0. After writing 0 to this bit, make sure that the bit becomes 0 before the next procedure.

To stop communication of SSIF-2 immediately, after turning off the peripheral functions, write 1 to this bit. Initialization by a software reset is performed without any relation with the bit clock.

Table 24.7 Bits Initialized by Software Reset of the SSIFCR.SSIRST Bit

| Symbol | Address (Base+) | | +0 | | | | | | | | +1 | | | | | | | |

- BSW Bit

This bit enables/disables byte swap of register access for the transmit FIFO data register (SSIFTDR) and the receive FIFO data register (SSIFRDR). This bit is valid only with 16-bit access or 32-bit access to SSIFTDR and SSIFRDR (Figure 24.24).

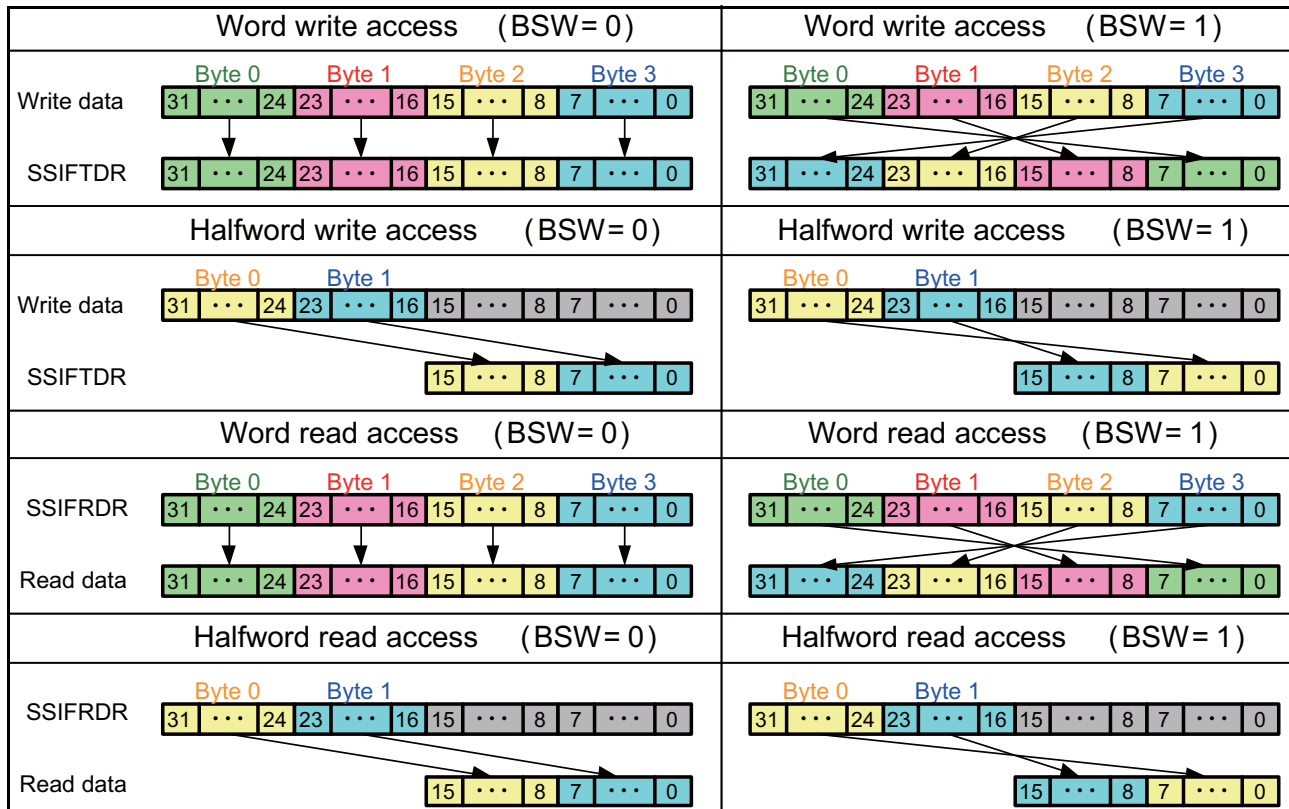

Figure 24.24 Operation Example of Byte Swap

- BCKNCE Bit

This bit enables or disables the noise cancellation function supporting the suppression of transients 15-ns in length (typ.) in input signals on the SSIBCK pin in slave-mode communication (SSICR.MST = '0') except in the case of transmission (SSICR.TEN = '1') while SSICR.DEL = '1'. The setting of this bit in master-mode communication (SSICR.MST = '1') is disabled.

Be sure to clear this bit to 0 in master-mode communication or during transmission in slave mode (SSICR.MST = '0', SSICR.TEN = '1') while SSICR.DEL = '1'. Set the BCKNCE, LRCKNCE, and RXDNCE bits to the same value.

- LRCKNCE Bit

This bit enables or disables the noise cancellation function supporting the suppression of transients 15-ns in length (typ.) in input signals on the SSILRCK and SSIFS pins in slave-mode communication (SSICR.MST = '0') except in the case of transmission (SSICR.TEN = '1') while SSICR.DEL = '1'. The setting of this bit in master-mode communication (SSICR.MST = '1') is disabled.

Be sure to clear this bit to 0 in master-mode communication or during transmission in slave mode (SSICR.MST = '0', SSICR.TEN = '1') while SSICR.DEL = '1'. Set the BCKNCE, LRCKNCE, and RXDNCE bits to the same value.

- RXDNCE Bit

This bit enables or disables the noise cancellation function supporting the suppression of transients 15-ns in length (typ.) in input signals on the SSIRxD pin in slave-mode communication (SSICR.MST = '0') except in the case of transmission (SSICR.TEN = '1') while SSICR.DEL = '1' and while reception is enabled (SSICR.REN = '1').

The setting of this bit in master-mode communication (SSICR.MST = '1') or while reception is disabled (SSICR.REN = '0') is disabled.

Be sure to clear this bit to 0 in master-mode communication or during transmission in slave mode (SSICR.MST = '0', SSICR.TEN = '1') while SSICR.DEL = '1'. Set the BCKNCE, LRCKNCE, and RXDNCE bits to the same value.

- TIE Bit

This bit enables/disables output of transmit data empty interrupts. Transmission data empty interrupt is used as an interrupt factor written in the FIFO transmission data register. Set this bit to 1 after setting set condition (SSISCR.TDES) of transmission data empty interrupt. See Figure 24.25 for the generation timing of a transmit data empty interrupt.

Figure 24.25 Generation timing of transmit data empty interrupt

- RIE Bit

This bit enables/disables output of receive data full interrupts. Receive data empty interrupt is used as an interrupt factor to read the FIFO receive data register. Set this bit to 1 after setting set condition (SSISCR.RDFS) of Receive data empty interrupt. See Figure 24.26 for the generation timing of a receive data full interrupt.

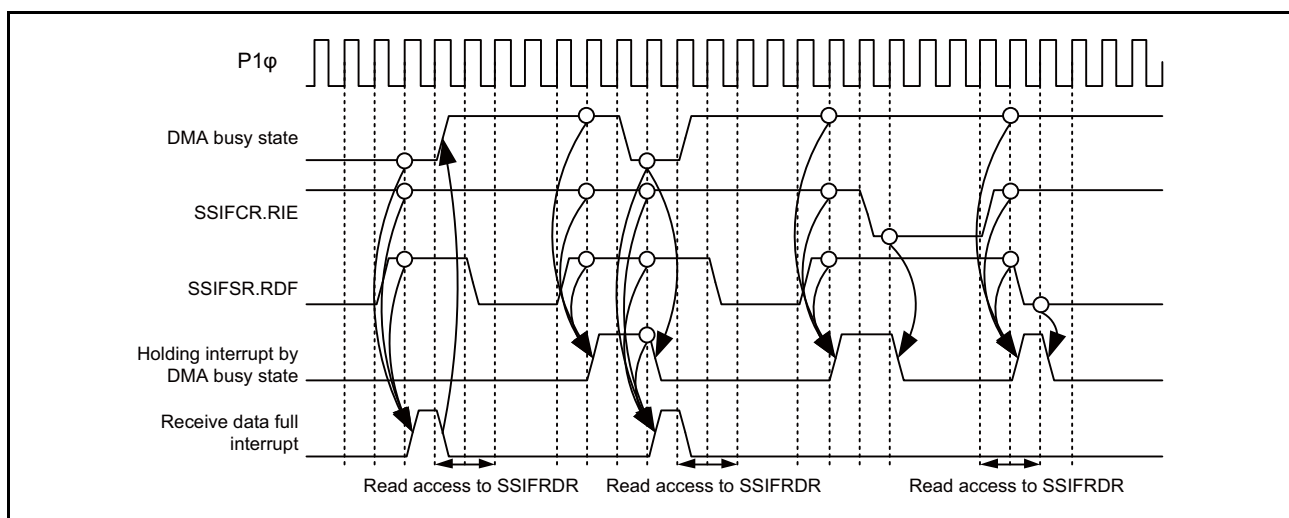

Figure 24.26 Generation timing of receive data empty interrupt

- TFRST Bit

This bit sets a software reset of the transmit FIFO data register (SSIFTDR). Writing 1 to this bit initializes the internal state related to SSIFTDR. See Table 24.8 for the registers to which this software reset is applied. After a reset by writing 1, write 0 to clear the reset condition because this bit is not automatically cleared to 0. After writing 0 to this bit, make sure that the bit becomes 0 before the next procedure.

This bit is a bit of SSIRST for reset. Software reset by SSIRST becomes and writing this bit becomes invalid because of priority.

Table 24.8 Bits Initialized by Software Reset of the SSIFCR.TFRST Bit

| Symbol | Address (Base+) | +0 | | | | | | | | +1 | | | | | | | |

- RFRST Bit

This bit sets a software reset of the receive FIFO data register (SSIFRDR). Writing 1 to this bit initializes the internal state related to SSIFRDR. After a reset by writing 1, write 0 to clear the reset condition because this bit is not automatically cleared to 0. After writing 0 to this bit, make sure that the bit becomes 0 before the next procedure.

This bit is a bit of SSIRST for reset. Software reset by SSIRST becomes and writing this bit becomes invalid because of priority.

Table 24.9 Bits Initialized by Software Reset of the SSIFCR.TFRST Bit

| Symbol | Address (Base+) | +0 | | | | | | | | +1 | | | | | | | |
|---------|--------------------|----|-------------|-----|----------|-----------|-------|------------|-------------|------------|-----------|----|----------|-----------|----------|-----|-----------|

24.4.1.4 FIFO Status Register (SSIFSR)

This register is configured with status flags that indicate the status of the transmit FIFO data register and the receive FIFO data register.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----------|----|----|----|----|----|----|----|----|----|----|----|----|------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | TDC[5:0] | | | | | — | — | — | — | — | — | — | — | TDE |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W0 |

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----------|----|----|----|---|---|---|---|---|---|---|---|---|------|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | RDC[5:0] | | | | | — | — | — | — | — | — | — | — | RDF |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W0 |

| Bit | Bit Name | R/W | Initial Value | Description |
|----------|----------|-----|---------------|--|
| 31, 30 | — | R | 0H | Reserved. Write 0. The read value is 0. |
| 29 to 24 | TDC[5:0] | R | 00H | Number of Transmit FIFO Data Indication Flag |
| 23 to 17 | — | R | 00H | Reserved. Write 0. The read value is 0. |
| 16 | TDE | RW0 | 1 | Transmit Data Empty Flag 0: The free space of SSIFTDR is not more than the value of SSISCR.TDES 1: The free space of SSIFTDR is not less than the value of SSISCR.TDES plus one. |
| 15, 14 | — | R | 0H | Reserved. Write 0. The read value is 0. |
| 13 to 8 | RDC[4:0] | R | 00H | Number of Receive FIFO Data Indication Flag |
| 7 to 1 | — | R | 00H | Reserved. Write 0. The read value is 0. |
| 0 | RDF | RW0 | 0 | Receive Data Full Flag 0: The size of received data in SSIFRDR is not more than the value of SSISCR.RDFS 1: The size of received data in SSIFRDR is not less than the value of SSISCR.RDFS plus one. |

- TDC[5:0] Bits

These bits indicate the number of valid data that are stored in the transmit FIFO data register (SSIFTDR). With this flag as 0H, there is no data to be transmitted. With 10H, there is no space to write data.

- TDE Bit

This bit indicates that the transmit FIFO data register (SSIFTDR) has free space not less than the amount set with the SSIFCR.TTRG bit plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.*¹

[Clearing condition]

Either of the following two:

(1) Writing 0 to this bit after reading this bit as 1. (CPU operation)*²

(2) Last access when SSIFTDR is written by using DMA in one interrupt routine (DMA operation).

[Clearing timing]

Timing according to the above-mentioned clear condition.

(1) At completion of writing 0 to this bit after reading this bit as 1 (Figure 24.13).

(2) At completion of last access when SSIFTDR is written by using DMA in one interrupt routine.

- Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1) and transmit FIFO data register reset (SSIFCR.TFRST = 1). The software reset and transmit FIFO data register reset have priority over all the clearing conditions described above.
- Note 2. The state of reading this bit as one is cleared by any of the following four conditions being met:
- Software reset (SSIFCR.SSIRST = 1)
 - Resetting of the transmit FIFO data register (SSIFCR.TFRST = 1)
 - Completion of writing 0 to this flag after having read it as 1.
 - Last access is performed to write data to SSIFTDR by an interrupt routine using DMA.

[Setting condition]

SSIFTDR has free space not less than the amount set with the SSIFCR.TTRG bit plus one.

[Setting timing]

While operating on P1φ, SSIFTDR is found to have free space not less than “size set in the SSISCR.TDES bits + 1.”

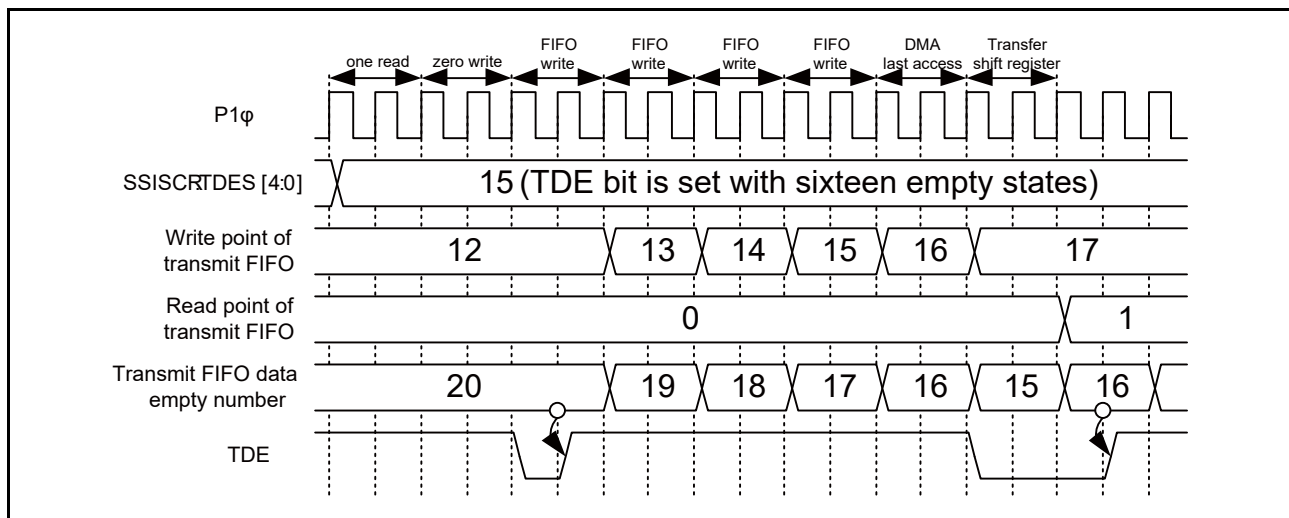

Figure 24.27 Set timing and clear timing of TDE

- RDC[5:0] Bits

These bits indicate the number of valid data that are stored in the receive FIFO data register (SSIFRDR). With this flag as 0H, there is no received data. With 20H, the register is filled with received data and there is no free space.

- RDF Bit

This bit indicates that the receive FIFO data register (SSIFRDR) has unread received data not less than the amount set with the SSISCR.RDFS bit plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.*1

[Clearing condition]

Either of the following two:

- (1) Writing 0 to this bit after reading this bit as 1. (CPU operation)*2
- (2) Last access when SSIFRDR is read by using DMA in one interrupt routine (DMA operation).

[Clearing timing]

Timing according to the above-mentioned clear condition.

- (1) At completion of writing 0 to this bit after reading this bit as 1 (Figure 24.13).
- (2) One cycle of P1φ after the last read access to SSIFRDR by using DMA in one interrupt routine.

- Note 1. This bit is also cleared by a software reset (SSIFCR.SSIRST = 1) and receive FIFO data register reset (SSIFCR.RFRST = 1). Clearing conditions available for these bits are the software reset and receive FIFO data register reset as well as the clearing conditions described above.
- Note 2. The state of reading this bit as one is cleared by any of the following four conditions being met:
- Software reset (SSIFCR.SSIRST = 1)
 - Receive FIFO data register reset (SSIFCR.RFRST = 1)
 - Completion of writing 0 to this flag after having read it as 1.
 - Last access is performed to read data from SSIFRDR by an interrupt routine using DMA.

[Setting condition]

SSIFRDR has data not less than the amount set with the SSISCR.RDFS bit plus one.

[Setting timing]

At completion of transfer from the shift register that results in SSIFRDR having data not less than the amount set with the SSISCR.RDFS bit plus one.

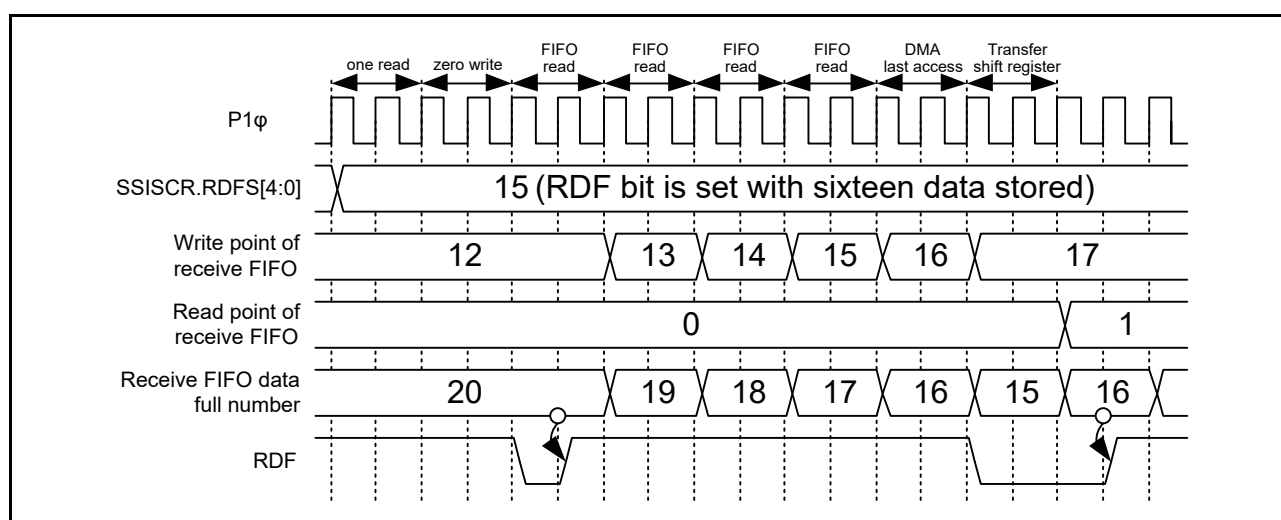

Figure 24.28 Set timing and clear timing of RDF

24.4.1.5 Transmit FIFO Data Register (SSIFTDR)

This is a 32-bit writable register. 0 is returned when this register is read. This register stores data to be serially transmitted.

| Bit | Bit Name | R/W | Initial Value | Description |
|---------|---------------|-----|---------------|--------------------|
| 31 to 0 | SSIFTDR[31:0] | W | 00000000H | Transmit FIFO data |

To use this register for transmission, set DMA operation handling of a transmit data empty interrupt as writing to this register. Determine the access size to this register according to the data word length to be communicated (Table 24.10).

Table 24.10 Register Access Restriction to FIFOs

| Access Size | | | | | |
|----------------|--------------------|------|----------|------|--|
| SSICR.DWL[2:0] | Data Word Length | Byte | Halfword | Word | |
| 000B | 8 | √ | — | — | |
| 001B | 16 | — | √ | — | |
| 010B | 18 | — | — | √ | |
| 011B | 20 | — | — | √ | |
| 100B | 22 | — | — | √ | |
| 101B | 24 | — | — | √ | |
| 110B | 32 | — | — | √ | |
| 111B | Setting prohibited | — | — | — | |

Figure 24.29 shows register access to the transmit FIFO data register.

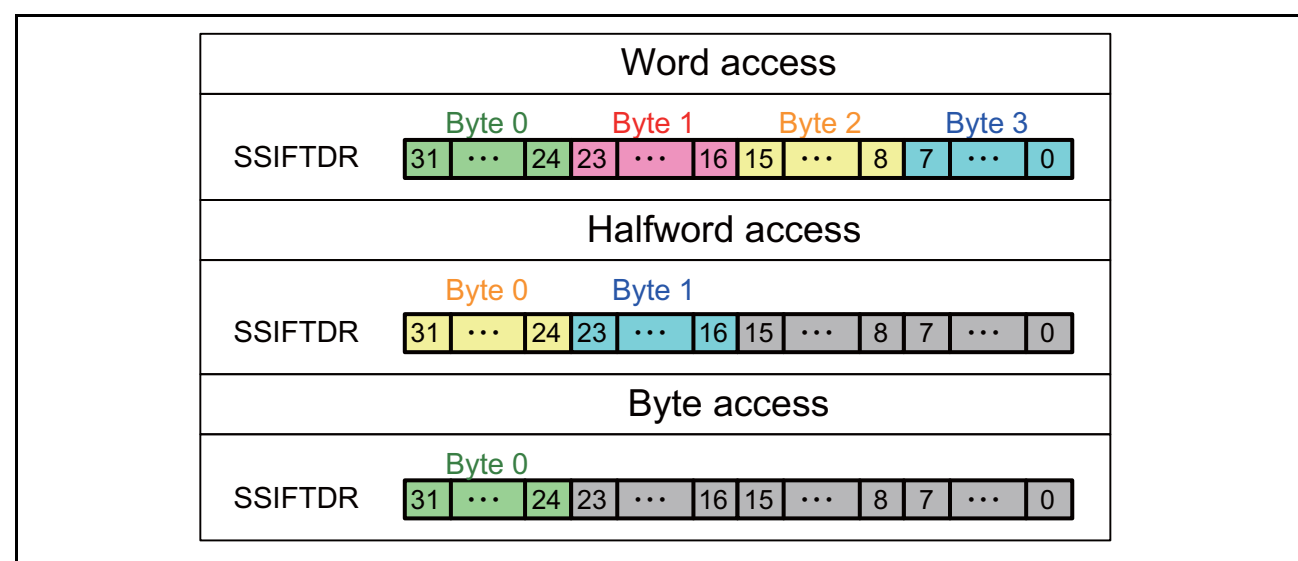

Figure 24.29 Example of Register Access to the Transmit FIFO Data Register

Figure 24.30 shows the configurations and operation examples of the transmit FIFO data register and transmit shift register. The configurations are for storing data to FIFO and not related with communication.

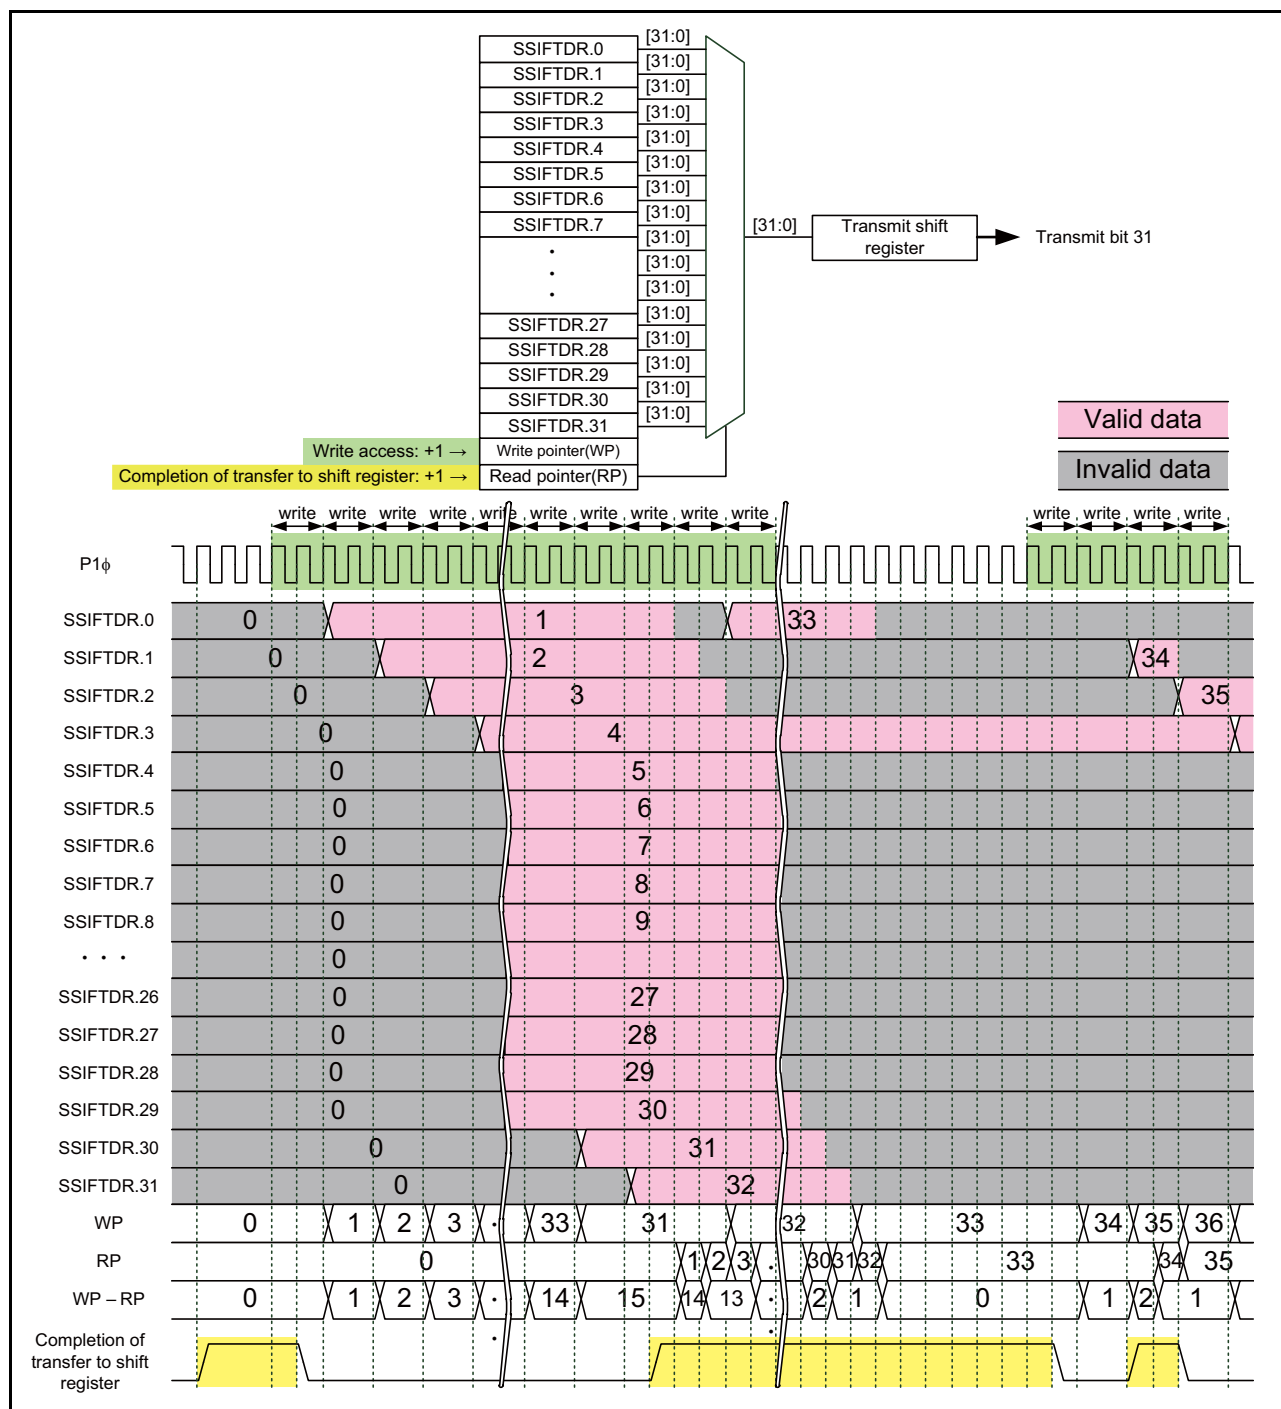

Figure 24.30 Configuration of the Transmit FIFO Data Register and Transmit Shift Register, and FIFO Operation Example

24.4.1.6 Receive FIFO Data Register (SSIFRDR)

This is a readable 32-bit register. This register stores received serial data.

| | | | | |
|---------|---------------|-----|---------------|-------------------|
| Bit | Bit Name | R/W | Initial Value | Description |
| 31 to 0 | SSIFRDR[31:0] | R | 00000000H | Receive FIFO data |

To use this register for reception, set DMA operation handling of a receive data full interrupt as reading from this register. Determine the access size to this register according to the data word length to be communicated (Table 24.10). Register access to the receive FIFO data register is same as for the transmit FIFO data register (Figure 24.29). Figure 24.31 shows the configurations and operation examples of the receive FIFO data register and receive shift register.

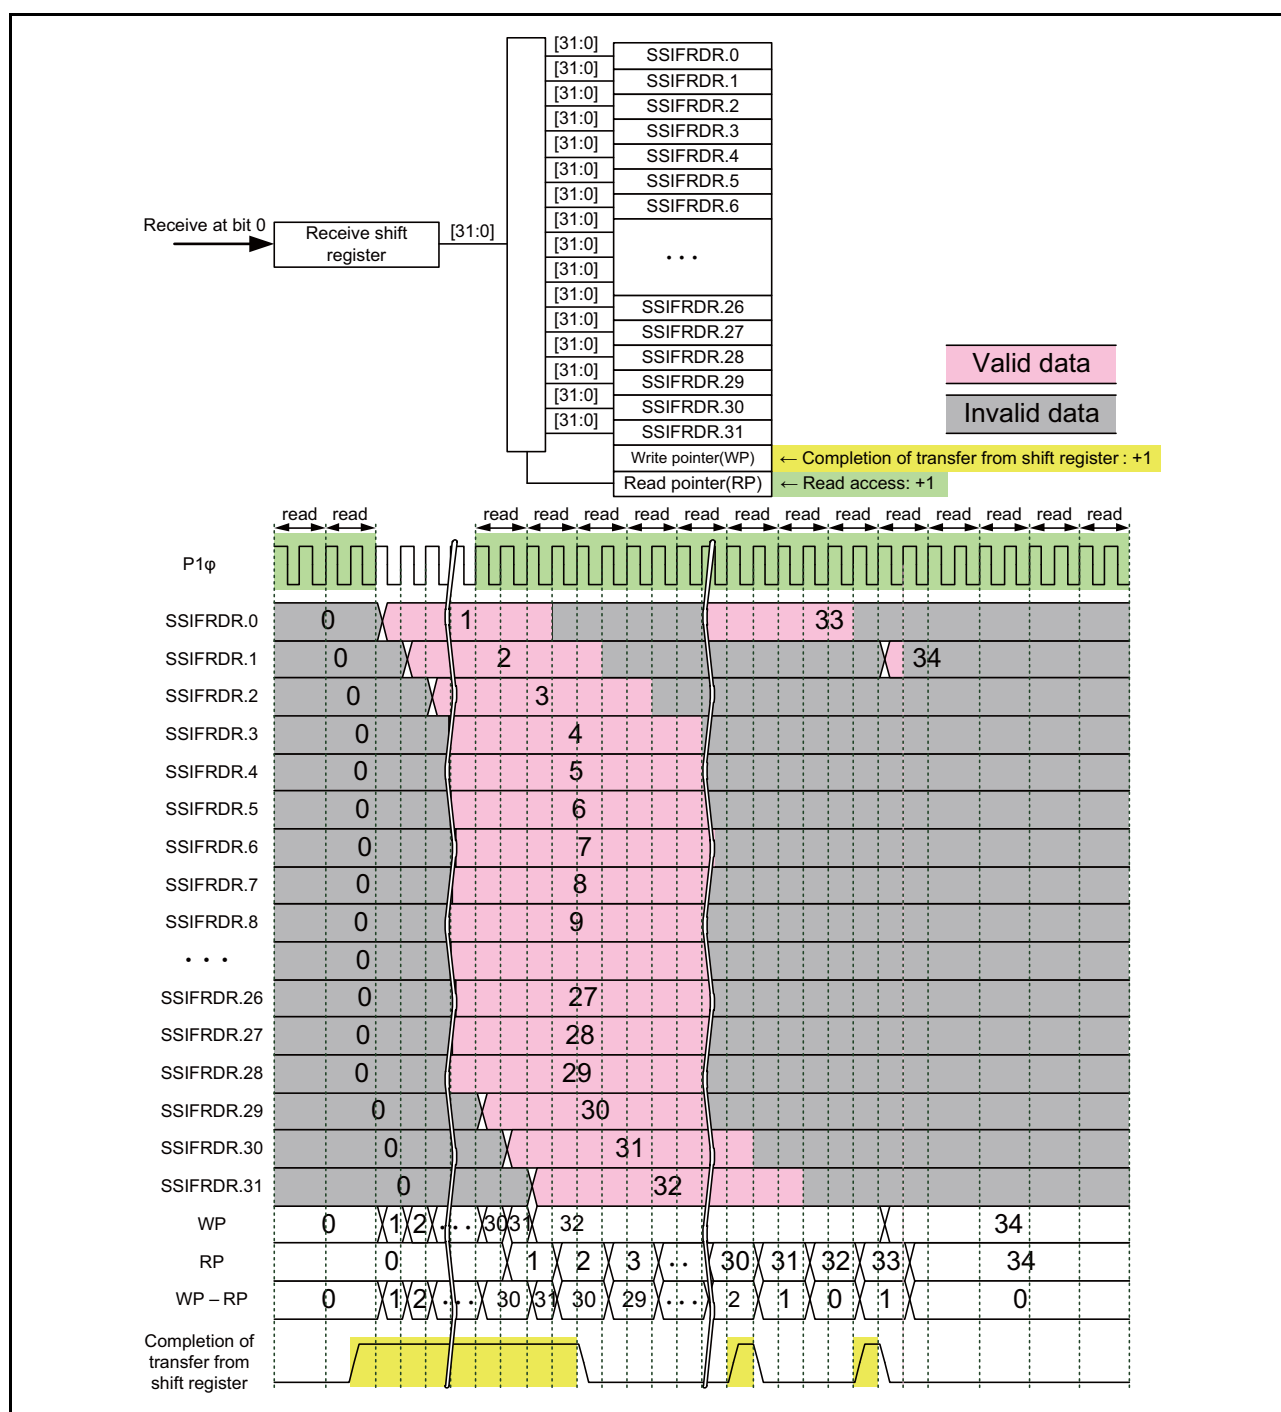

Figure 24.31 Configuration of the Receive FIFO Data Register and Receive Shift Register, and FIFO Operation Example

24.4.1.7 Audio Format Register (SSIOFR)

This is a readable/writable 32-bit register. It sets an audio format including the communication format, LRCK/FS continuation mode, and BCK output stop.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|---------|---------|---|---|---|---|---|---|-----------|-----|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | BCK STP | LR CONT | — | — | — | — | — | — | OMOD[1:0] | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R/W | R/W | R | R | R | R | R | R | R/W | R/W |

| Bit | Bit Name | R/W | Initial Value | Description |
|----------|-----------|-----|---------------|--|
| 31 to 10 | — | R | 000000H | Reserved. Write 0. The read value is 0. |
| 9 | BCKASTP | RW | 0 | BCK Output Stop Enable*1*2 0: Enables output of BCK 1: Disables output of BCK |
| 8 | LRCONT | RW | 0 | LRCK/FS Continuation Enable*1*2 0: Disables LRCK continuation 1: Enables LRCK continuation |
| 7 to 2 | — | R | 00H | Reserved. Write 0. The read value is 0. |
| 1,0 | OMOD[1:0] | RW | 0 | Audio Format Select*3*4 OMOD[1:0]: Format 00: I ² S format 01: TDM format 10: Monaural format 11: Setting prohibited |

Note 1. This bit is valid only in master-mode communication (SSICR.MST = 1). The setting is invalid in slave-mode communication (SSICR.MST = 0).

Note 2. BCKASTP=1 and LRCONT=1 is prohibitions.

Note 3. Writing in this bit is a prohibition when SSIF-2 is communication state (SSISR.IIRQ=0). Operation is not guaranteed when rewriting it.

Note 4. Use the communication format setting that can be communicated when the format of the communication of the opposing device is compatible format of SSIF-2.

- BCKASTP Bit

This bit turns on or off the function to output BCK to the SSIBCK pin according to the communication shown in Figure 24.32 and Figure 24.33 in master-mode communication (SSICR.MST = 1).

Set this bit after setting completing the communication format.

This bit must defend the following usage. Start communication with BCKASTP = 0, and set 1 to BCKASTP while communicating. As a result, the bit clock output to the terminal SSIBCK stops by the automatic operation when the communication stop is done. When you will restart the communication, set 0 to BCKASTP with idle state (SSICR.IIRQ=1) and the AUDIO_MCK supply state (SSIFCR.AUCKE = 1)

When master communication (SSICR.MST=1) and idle state (SSICR.IIRQ=1).

Table 24.11 BCKASTP state, and Output state of SSIBCK pin.

| BCKASTP bit | output state of SSIBCK pin |
|-------------|----------------------------|
| 0 | Enable |
| 1 | Disable |

Note: When the opposing device who is the slave needs the clock of the terminal SSIBCK before the communication operates, it is not possible to use it. Use it to stop clocking after the communication ends (Figure 24.33). Refer to Figure 24.32 for timing that the function becomes effective.

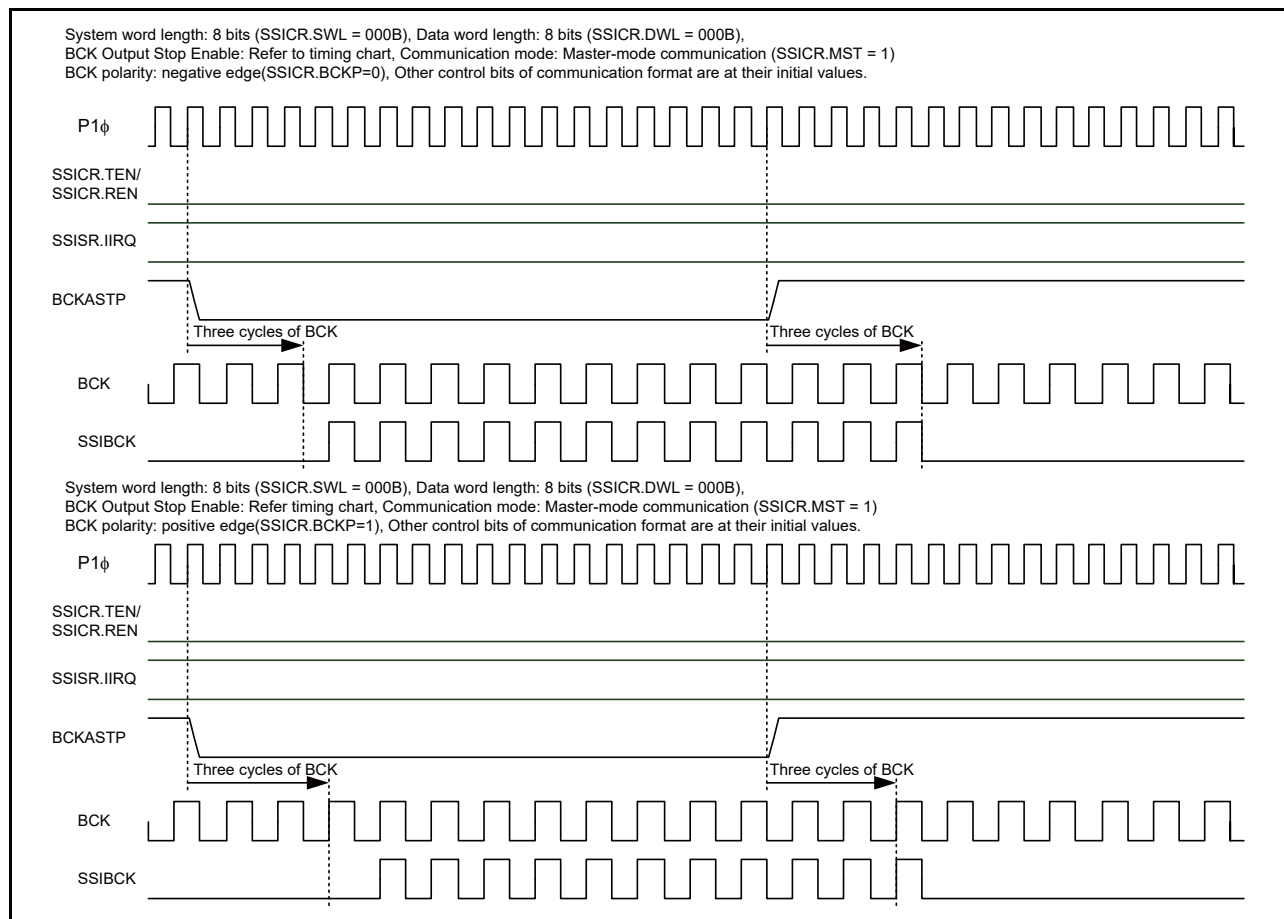

Figure 24.32 Example Operation of the BCKASTP Bit (in idle state)

When master communication (SSICR.MST=1) and the BCK output automatic operation stop function (BCKASTP = 1) (Figure 24.33).

Details of the BCK output to SSIBCK pin are as follows.

- Output start timing: To generate an effective edge in timing that LRCK/FS is changed into the valid value, BCK is output.
- Output stop timing: Frame boundary from 1 to 1.5 clock

Refer to the timing chart of Figure 24.33 for detailed timing.

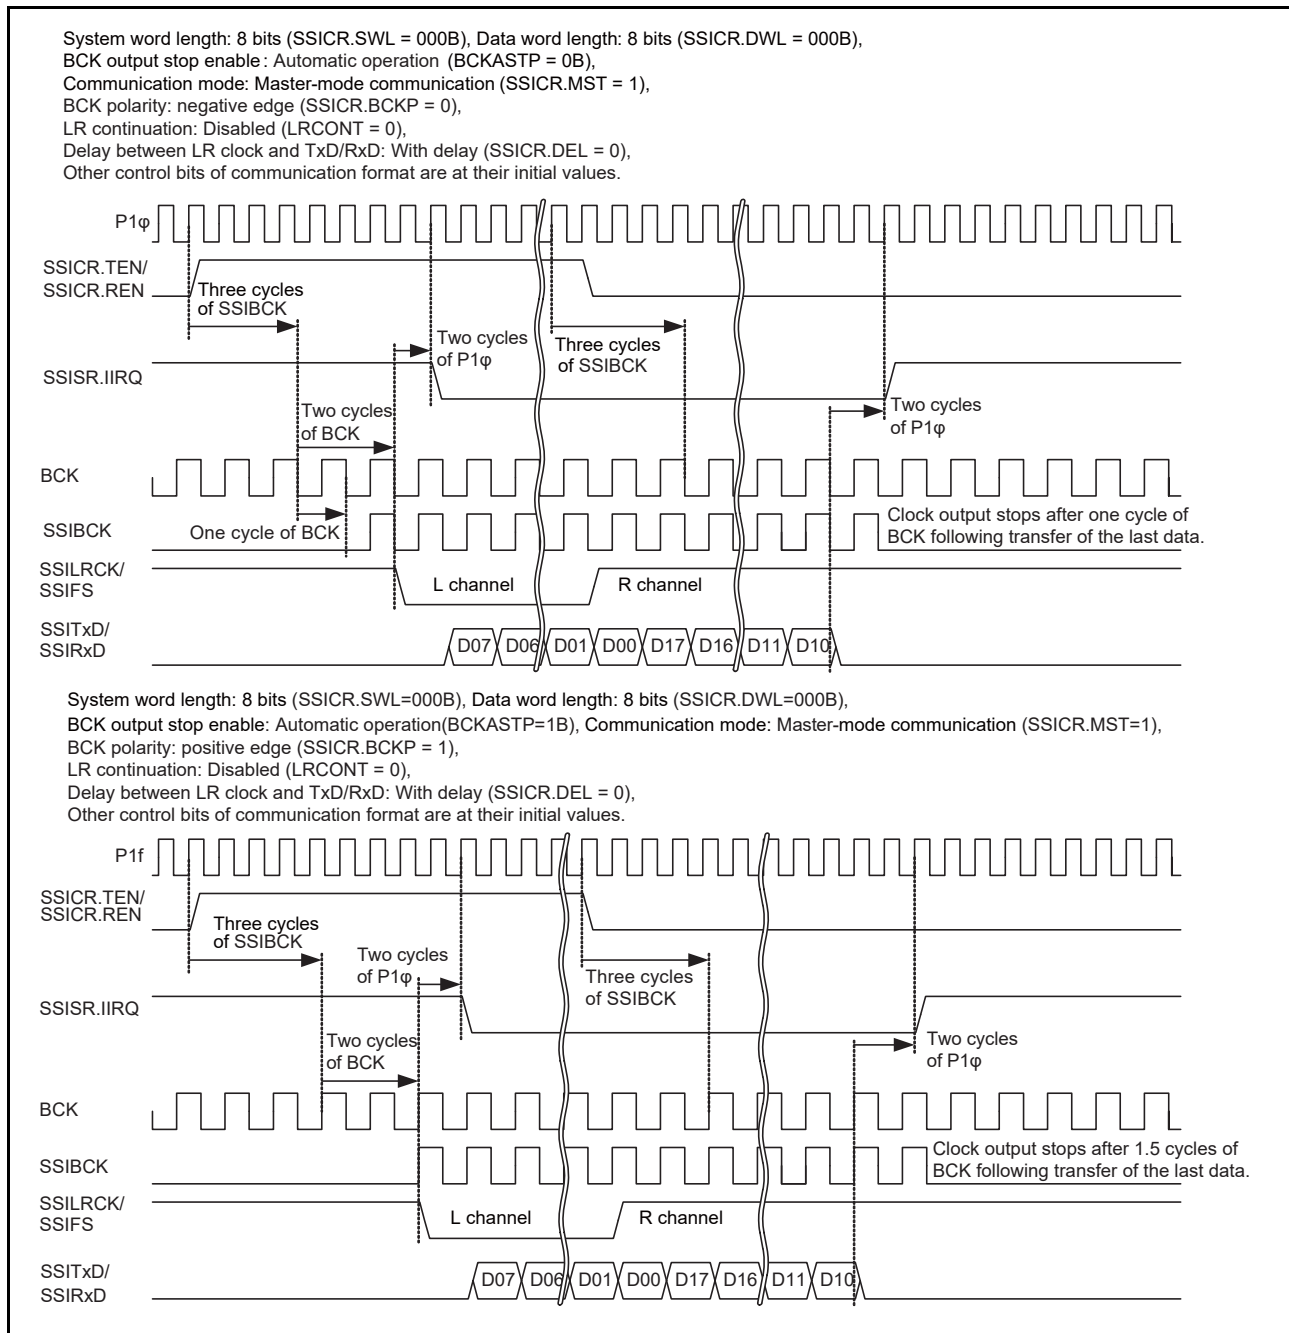

Figure 24.33 Example Operation of the BCKASTP Bit (Communication behavior in BCKASTP=1)

- LRCONT Bit

This bit enables/disables the output from the SSILRCK/SSIFS pin when SSIF-2 is master communication (SSICR.MST=1) and idle state (SSISR.IIRQ=1). Writing 1 to this bit (enables LRCK/FS continuation) in master mode (SSICR.MST = 1) enables continuation of the output from the SSILRCK/SSIFS pins even when idle state.

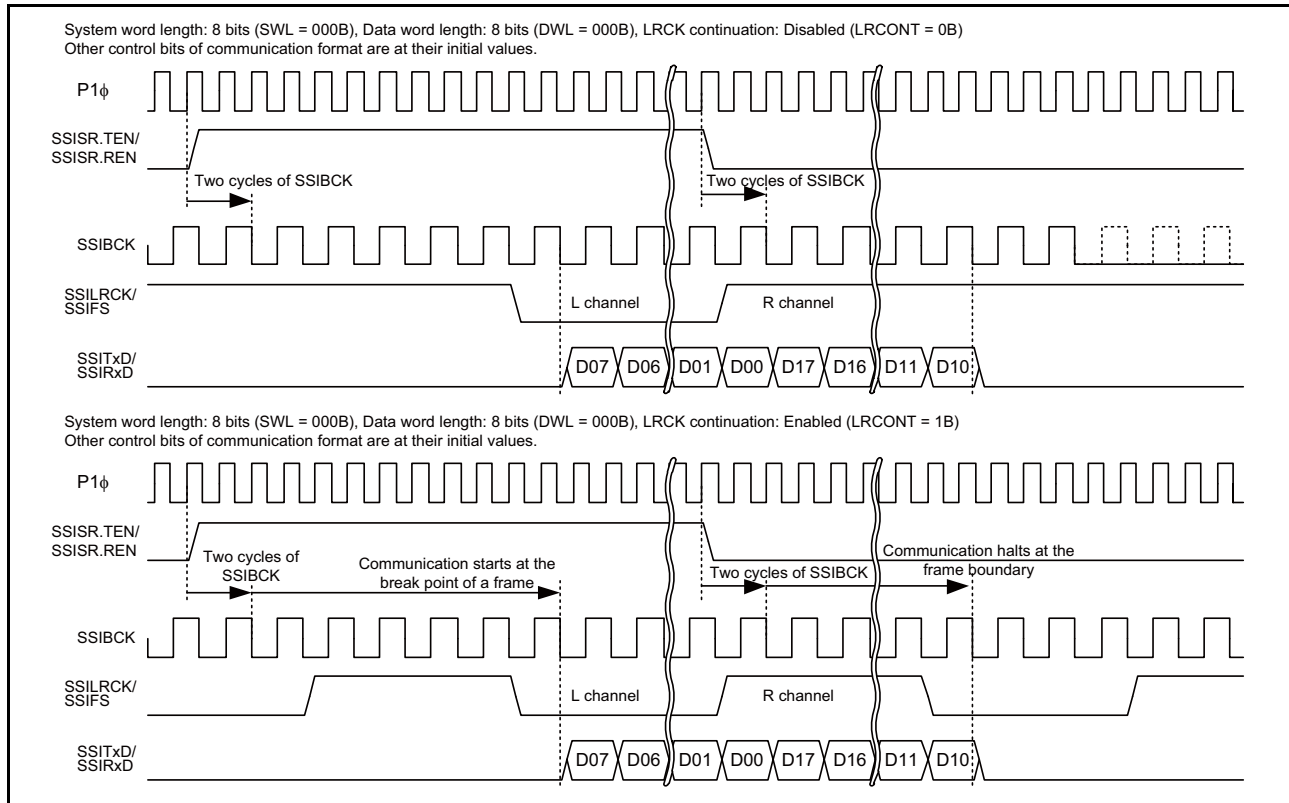

Figure 24.34 Operation Example of LRCK/FS Continuation (in idle state)

- OMOD[1:0] Bits

These bits set an audio format.

Rewrite this bit when the LR clock supply to the terminal SSILRCK stops. Refer to the LRCONT bit details explanation in section 24.4.1.7, Audio Format Register (SSIOFR) for the output operation of the LR clock.

24.4.1.8 Status Control Register (SSISCR)

This is a readable/writable 32-bit register. It sets the operation of the TDE and RDF flags.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|-----------|-----|-----|-----|-----|---|---|-----------|-----|-----|-----|-----|-----|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | TDES[4:0] | | | | — | — | — | RDFS[4:0] | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R/W | R/W | R/W | R/W | R/W | R | R | R | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | R/W | Initial Value | Description |
|----------|-----------|-----|---------------|--|
| 31 to 13 | — | R | 00000H | Reserved. Write 0. The read value is 0. |
| 12 to 8 | TDES[4:0] | RW | 0H | TDE Setting Condition Select*1 TDES[4:0]: Operation 00000B: SSIFTDR has one stage or more free space 00001B: SSIFTDR has two stages or more free space (snip) 11110B: SSIFTDR has thirty-one stages or more free space 11111B: SSIFTDR has thirty-two stages or more free space |
| 7 to 5 | — | R | 0H | Reserved. Write 0. The read value is 0. |
| 4 to 0 | RDFS[4:0] | RW | 0H | RDF Setting Condition Select*1 RDFS[4:0]: Operation 00000B: SSIFRDR has one stage or more data size 00001B: SSIFRDR has two stages or more data size (snip) 01110B: SSIFRDR has thirty-one or more data size 01111B: SSIFRDR has thirty-two stages or more data size |

Note 1. Writing to these bits while SSIF-2 is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

- TDES[4:0] Bits

These bits set the setting condition of the transmit data empty flag (TDE). Set these bits in byte units.

- RDFS[4:0] Bits

These bits set the setting condition of the receive data full flag (RDF). Set these bits in byte units.

24.4.2 Communication Formats

SSIF-2 supports three communication formats (Table 24.12).

Table 24.12 Supported Communication Formats

| Communication Format | SSIOFR.OMOD[1:0] |
|-------------------------|------------------|
| I ² S format | 00 |
| TDM format | 01 |
| Monaural format | 10 |

The following figure shows the serial data configuration common to communication formats. Serial data is determined according to the system word length (SSICR.SWL[2:0]) and the data word length (SSICR.DWL[2:0]). When the system word length is longer than the data word length, padding bits are transferred (Figure 24.35).

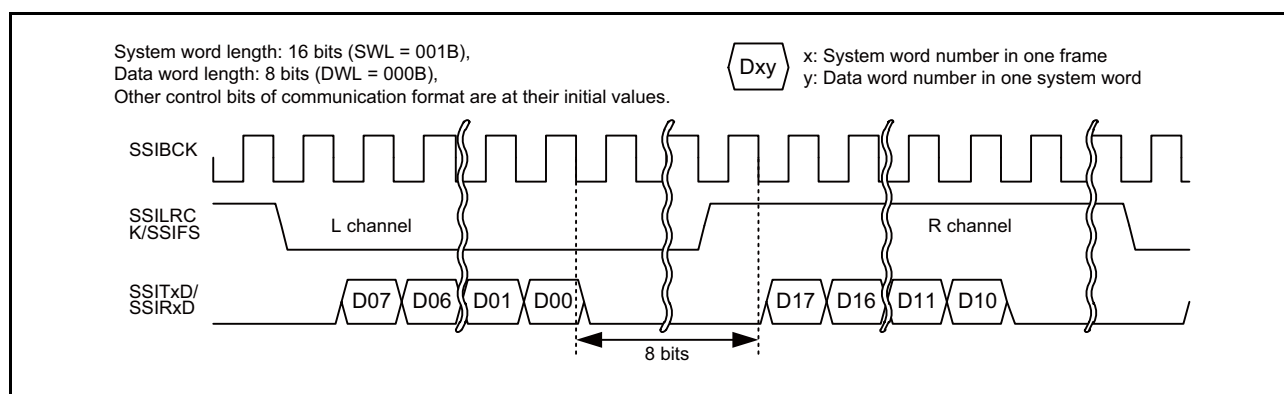

Figure 24.35 Example of Padding Bit Transfer (I²S Format: System Word Length > Data Word Length)

Table 24.13 lists the number of padding bits to be transferred with each combination of system word length (SSICR.SWL[2:0]) and data word length (SSICR.DWL[2:0]). “-” indicates that the setting is prohibited.

Table 24.13 Number of Padding Bits

| | SSICR.DWL[2:0] | 000B | 001B | 010B | 011B | 100B | 101B | 110B | 111B |
|----------------|--------------------|------|------|------|------|------|------|------|-----------------|
| SSICR.SWL[2:0] | System Word Length | 8 | 16 | 18 | 20 | 22 | 24 | 32 | Set prohibition |
| 000B | 8 | 0 | — | — | — | — | — | — | — |
| 001B | 16 | 8 | 0 | — | — | — | — | — | — |
| 010B | 24 | 16 | 8 | 6 | 4 | 2 | 0 | — | — |
| 011B | 32 | 24 | 16 | 14 | 12 | 10 | 8 | 0 | — |
| 100B | 48 | 40 | 32 | 30 | 28 | 26 | 24 | 16 | — |
| 101B | 64 | 56 | 48 | 46 | 44 | 42 | 40 | 32 | — |
| 110B | 128 | 120 | 112 | 110 | 108 | 106 | 104 | 96 | — |
| 111B | 256 | 248 | 240 | 238 | 236 | 234 | 232 | 224 | — |

24.4.2.1 I²S Format

The I²S format is a communication format used for connection with I²S-compatible serial devices. With this format setting (SSIOFR.OMOD[1:0] = 00B), one frame is configured with two system words, one for the channel L and the other for channel R. The SSILRCK/SSIFS signals are at a low level for the channel L and at a high level for the channel R. Set the polarity of the signals with the SSICR.LRCKP bit. Figure 24.36 shows the I²S format without padding. See Figure 24.35 for the format with padding.

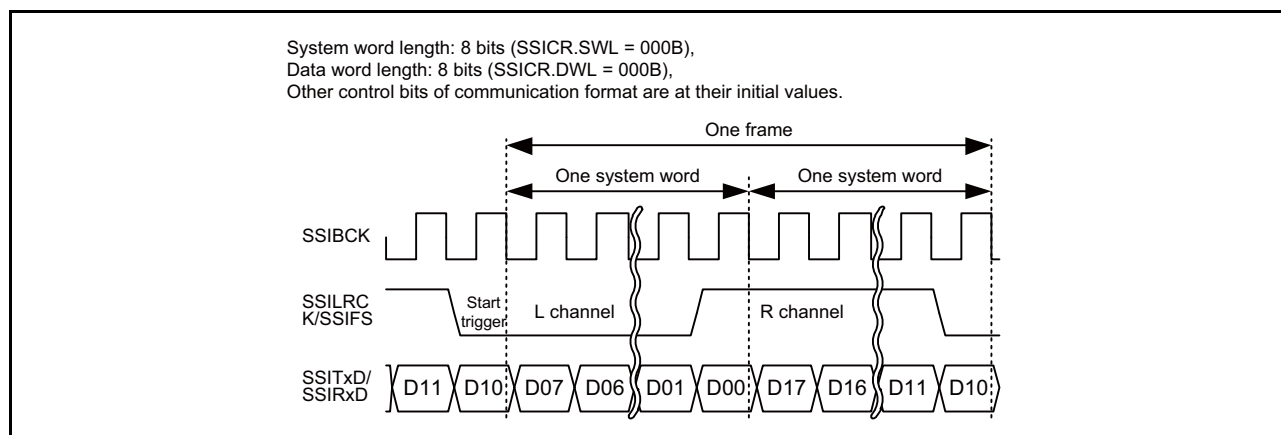

Figure 24.36 I²S Format (Without Padding: System Word Length = Data Word Length)

For the state of external pins when SSIF-2 is in the idle state, see section 24.5.1.1, Idle State.

Note: SSIF-2 has the terminal SSILRCK/SSIFS that shows the synchronization of the communication. Match communication format of the opposing device and SSIF-2 when SSIF-2 is slave communication (SSICR.MST=0). SSIF-2 uses the signal of SSILRCK/SSIFS only as a communication start trigger.

24.4.2.2 Monaural Format

The monaural format is a communication format used for connection with monaural-compatible serial devices. With this format setting (SSIOFR.OMOD[1:0] = 10B), one frame is configured with the number of system words set with the SSICR.FRM[1:0] bits (Figure 24.37). A rising of the SSILRCK/SSIFS signal means a start trigger. Figure 24.37 and Figure 24.38 respectively show the monaural formats without and with padding.

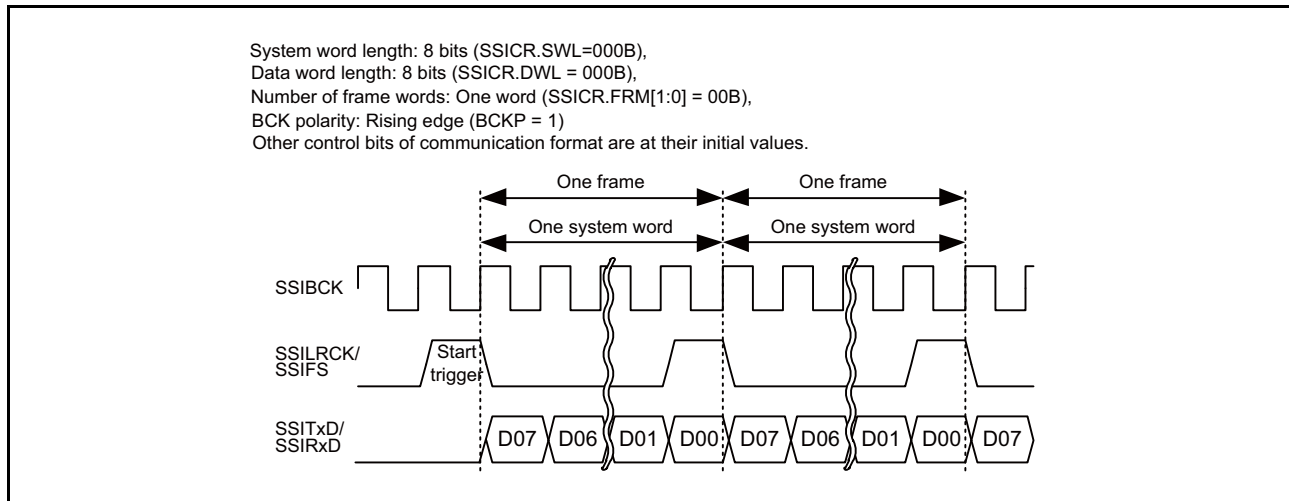

Figure 24.37 Short Frame in Monaural Format (Without Padding: System Word Length = Data Word Length)

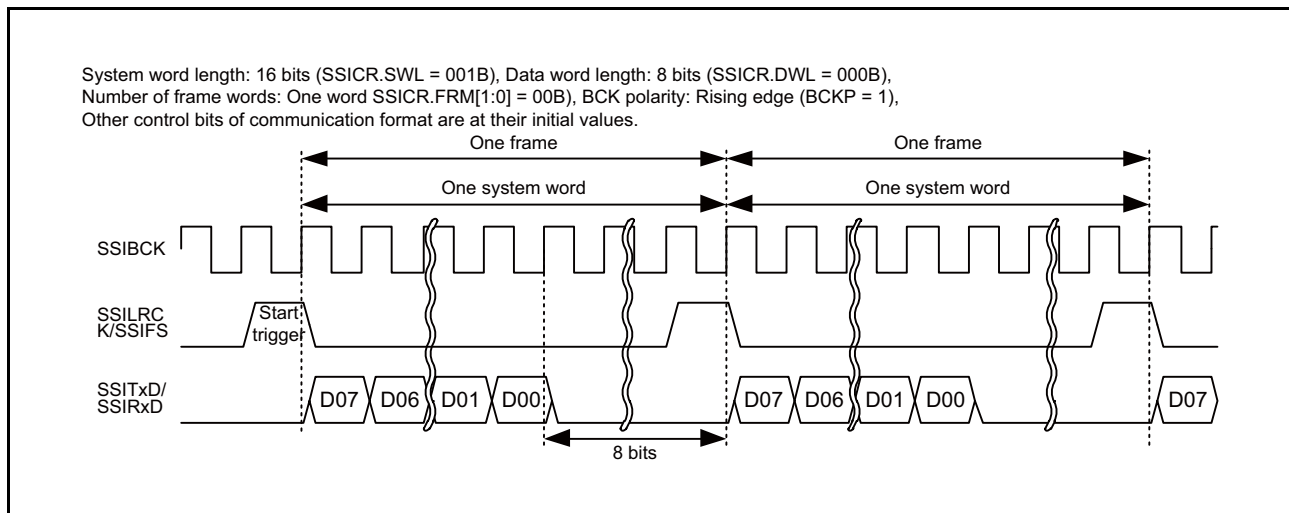

Figure 24.38 Short Frame in Monaural Format (With Padding: System Word Length > Data Word Length)

The monaural formats supported by SSIF-2 consist of short frames and long frames. See section 24.4.2.2, (1), Short Frame and (2), Long Frame for the difference between these two frames.

For the state of external pins state when SSIF-2 is in the idle state, see section 24.5.1.1, Idle State.

Note: SSIF-2 has the terminal SSILRCK/SSIFS that shows the synchronization of the communication. Match communication format of the opposing device and SSIF-2 when SSIF-2 is slave communication (SSICR.MST=0). SSIF-2 uses the signal of SSILRCK/SSIFS only as a communication start trigger.

(1) Short Frame

With the short frame (SSICR.DEL = 0), the SSILRCK/SSIFS signal that indicates a start of serial data is at a high level for one cycle of SSIBCK. Data transfer starts at the falling edge of the signal (Figure 24.37 and Figure 24.38).

(2) Long Frame

With the long frame (SSICR.DEL = 1), the SSILRCK/SSIFS signal that indicates a start of serial data is at a high level for two cycles of SSIBCK. Data transfer starts at the rising edge of the signal (Figure 24.39).

Figure 24.39 Long Frame in Monaural Format (Without Padding)

24.4.2.3 TDM Format

The TDM format is a communication format used for connection with TDM-compatible multi-channel devices. With this format setting (SSIOFR.OMOD[1:0] = 01B), one frame is configured with four to eight system words set with the SSICR.FRM[1:0] bits. With this format, the SSILRCK/SSIFS signal is at a high level for the first one system word and at a low level for the rest. The pulse generated on the SSILRCK/SSIFS signal is defined as the SYNC pulse and its rising edge means a start of one frame. Figure 24.40 and Figure 24.41 respectively show the TDM formats with and without padding.

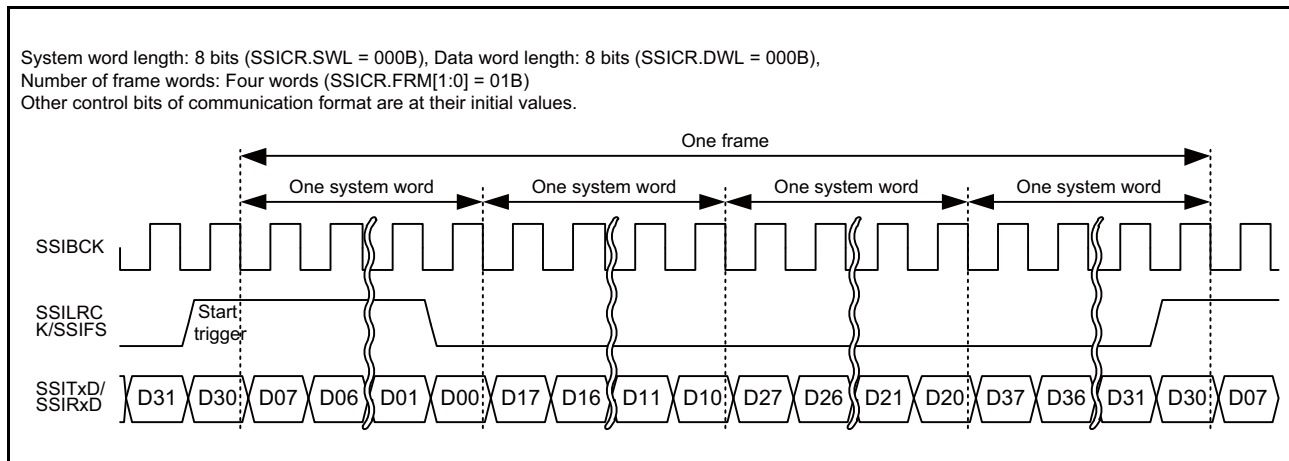

Figure 24.40 TDM Format (Without Padding: System Word Length = Data Word Length)

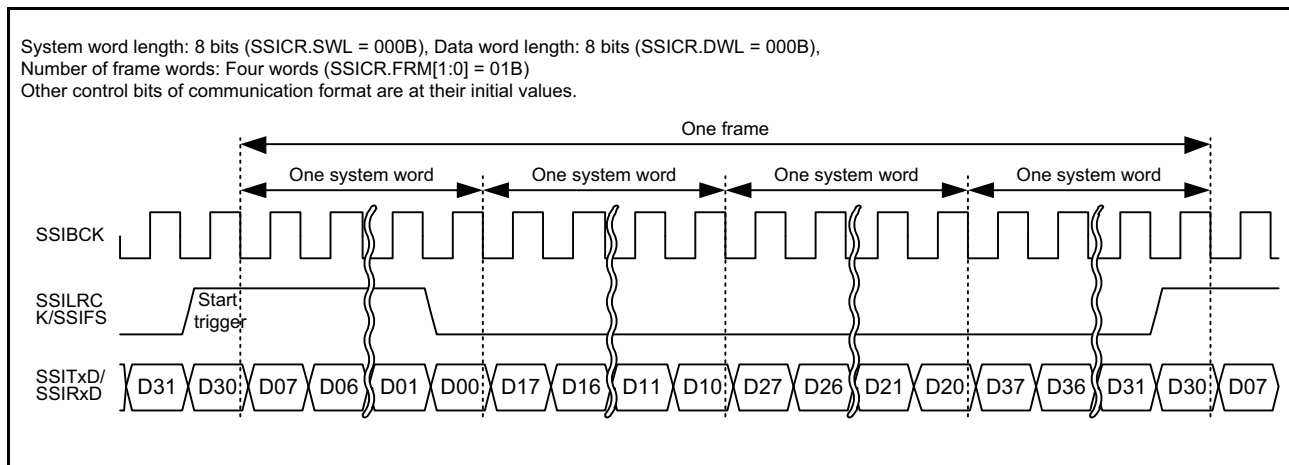

Figure 24.41 TDM Format (With Padding: System Word Length > Data Word Length)

For the state of external pins when SSIF-2 is in the idle state, see section 24.5.1.1, Idle State.

Note: SSIF-2 has the terminal SSILRCK/SSIFS that shows the synchronization of the communication. Match communication format of the opposing device and SSIF-2 when SSIF-2 is slave communication (SSICR.MST=0). SSIF-2 uses the signal of SSILRCK/SSIFS only as a communication start trigger.

24.4.3 Communication Modes

SSIF-2 supports the following communication modes. Table 24.15 lists the control bits that are not available with each communication mode. See section 24.4.3.1 to section 24.4.3.5 for details of these communication modes.

Table 24.14 Communication Modes

| Communication Mode | SSICR.MST Bit | SSICR.REN Bit | SSICR.TEN Bit |
|--|---------------|---------------|---------------|
| Slave-mode transmission | 0 | 0 | 1 |
| Slave-mode reception | 0 | 1 | 0 |
| Slave-mode transmission and reception | 0 | 1 | 1 |
| Master-mode transmission | 1 | 0 | 1 |
| Master-mode reception | 1 | 1 | 0 |

Note 2. Disabled during transmission (SSICR.TEN = '1') when SSICR.DEL = '1'

24.4.3.1 Slave-mode Communication

SSIF-2 operates in slave mode with SSICR.MST = 0. Supply the SSIBCK signal and the SSILRCK/SSIFS signal used for the serial data communication from external devices. If these signals do not match the communication format set for SSIF-2, operation is not guaranteed.

24.4.3.2 Master-mode Communication

SSIF-2 operates in master mode with SSICR.MST = 1. The SSIBCK signal and SSILRCK/SSIFS signal used for the serial data communication are internally generated from the audio clock. These signals use the format according to the setting of SSIF-2. If the communication format of another device working as the slave device does not match the communication format set for SSIF-2, operation is not guaranteed.

24.4.3.3 Transmission

SSIF-2 transmits serial data to opposing device when SSICR.TEN = 1 and SSICR.REN = 0. If the communication format of the opposing device does not match the communication format set for SSIF-2, operation is not guaranteed.

24.4.3.4 Reception

SSIF-2 receives serial data from opposing device when SSICR.TEN = 0 and SSICR.REN = 1. If the communication format of the opposing device does not match the communication format set for SSIF-2, operation is not guaranteed.

24.4.3.5 Transmission and Reception

SSIF-2 transmits and receives serial data to and from opposing device when SSICR.TEN = 1, SSICR.REN = 1. If the communication format of opposing device does not match the communication format set for SSIF-2, operation is not guaranteed.

24.5 Operation

24.5.1 Operational State

SSIF-2 has the following two main operation states (Figure 24.42).

- Idle state (SSISR.IIRQ = 1)
- Communication state (SSISR.IIRQ = 0)

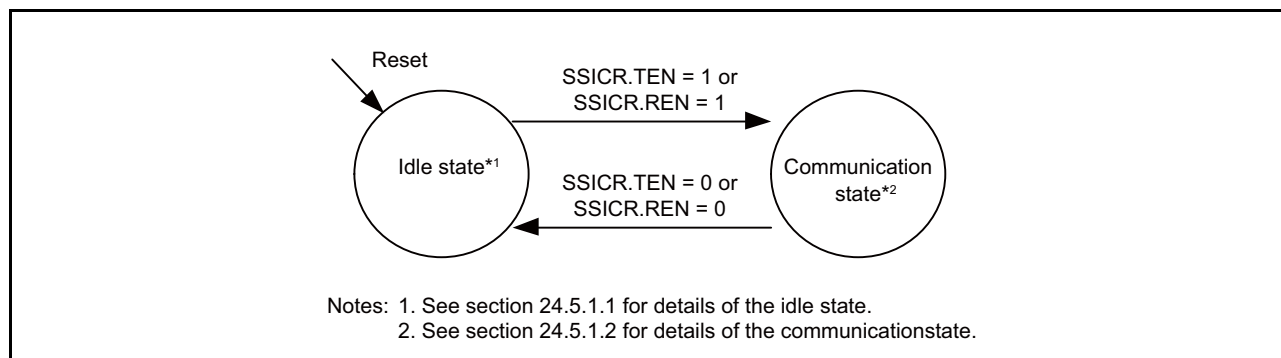

Figure 24.42 SSIF-2 State Transition

24.5.1.1 Idle State

In this state, communication of SSIF-2 is halted. However, when SSICR.MST = 1, output of BCK and LRCK/FS to external pins is enabled depending on the settings in the SSIOFR.BCKASTP bit and the SSIOFR.LRCONT bit (Table 24.16). This function is common to all formats.

Table 24.16 Output from External Pins in the Idle State

| SSICR.MST | SSIOFR.BCKASTP | SSIOFR.LRCONT | Output from Pins | | |
|-----------|----------------|---------------|------------------|---------------|--------|
| | | | SSIBCK | SSILRCK/SSIFS | SSITxD |
| 0 | — | — | Stop | Stop | Stop |
| 1 | 0 | 0 | Supply | Stop | Stop |
| 1 | 0 | 1 | Supply | Supply | Stop |
| 1 | 1 | 0 | Stop | Stop | Stop |
| 1 | 1 | 1 | Stop | Supply | Stop |

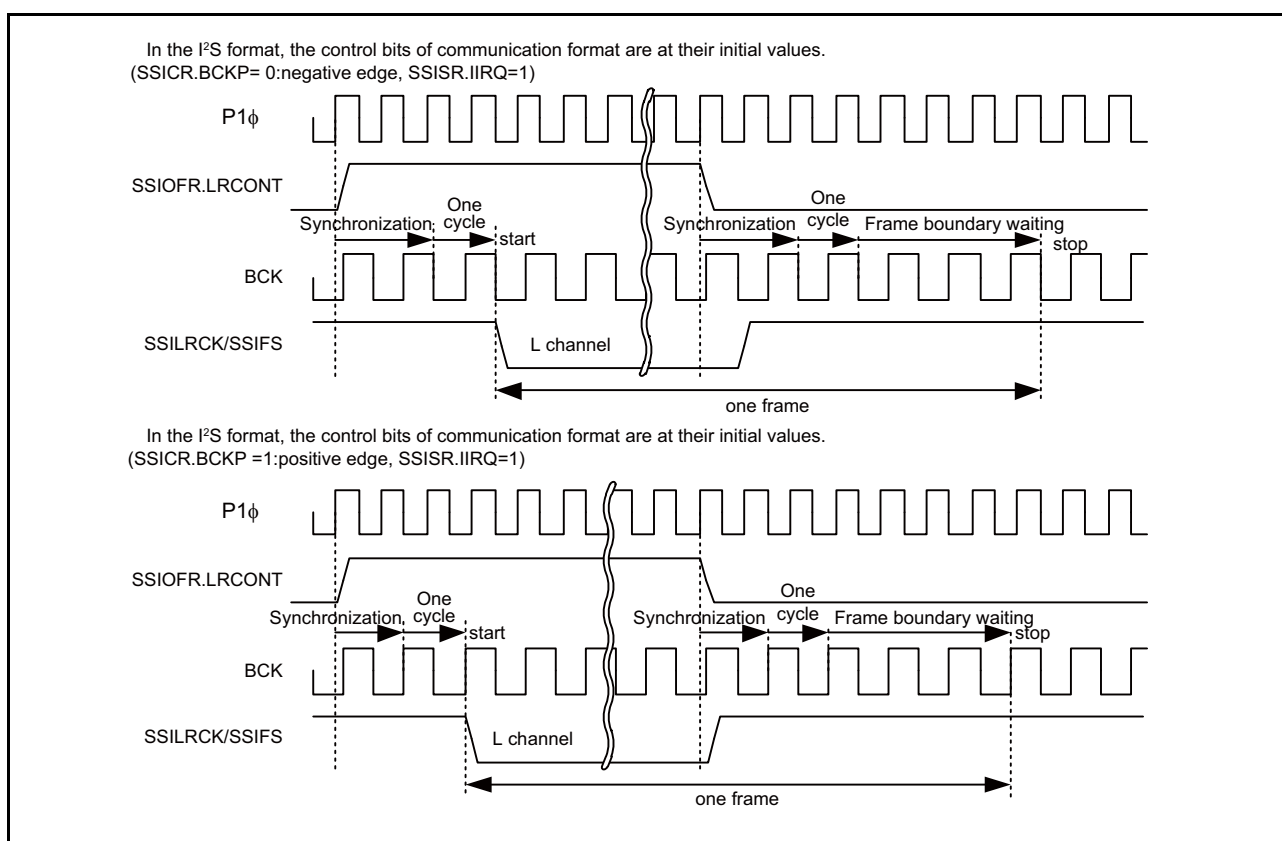

Figure 24.43 Example of LRCK/FS Continuation Release with SSIOFR.LRCONT

Note: To stop the output to the SSILRCK/SSIFS pin with SSIOFR.LRCONT when SSIF-2 is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when 0 is written from 1 to SSIOFR.LRCONT. (Figure 24.43). Make sure that the remote device is not affected.

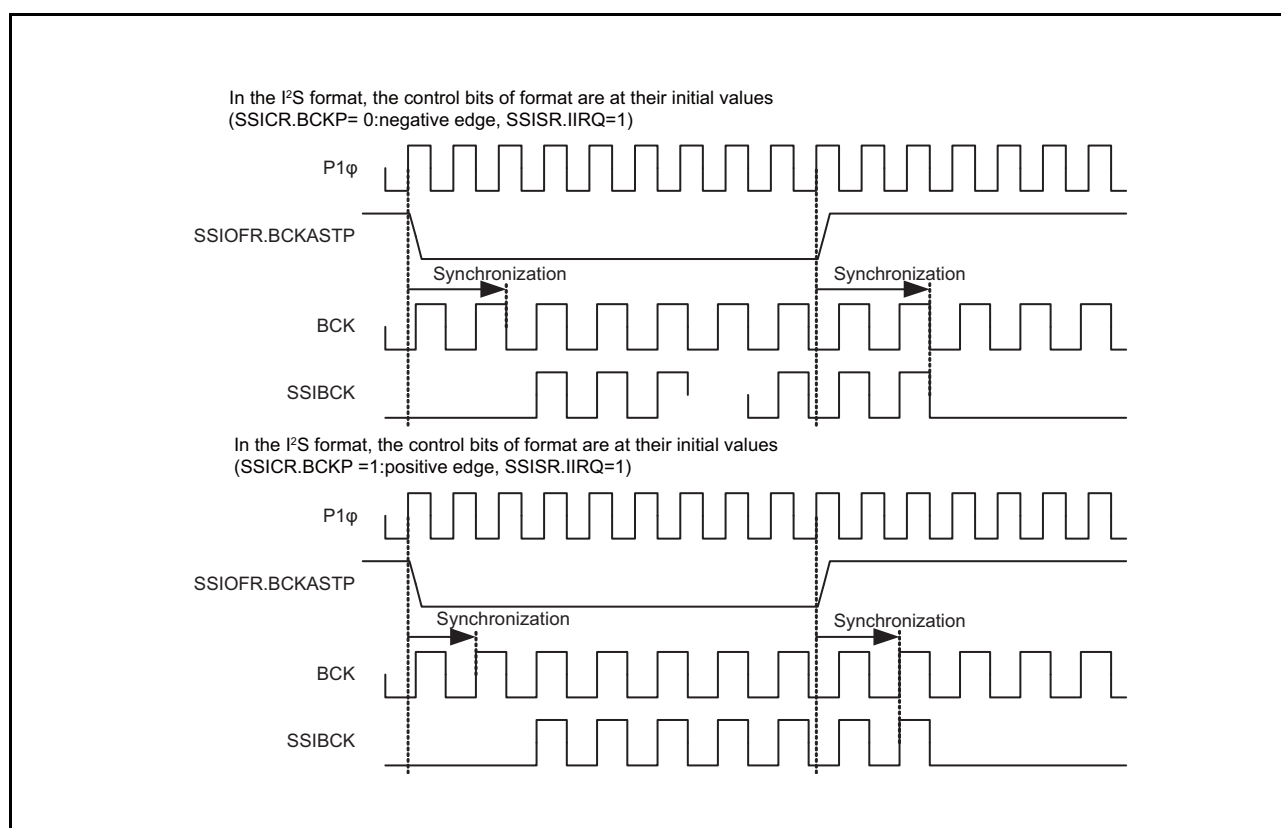

Figure 24.44 Example of Stopping SSIBCK with SSIOFR.BCKASTP

Note: To stop the output to the SSIBCK pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIF-2 is in the idle state, note the following; By writing 0 to SSIOFR.BCKASTP while it is 1, the output stops immediately (Figure 24.44). So, make sure that the remote device is not affected.

24.5.1.2 Communication States

In this state, SSIF-2 is during communication. Figure 24.45 shows transitions of communication states and Table 24.17 lists the conditions for transition. If the transition condition is not satisfied, the state does not transit.

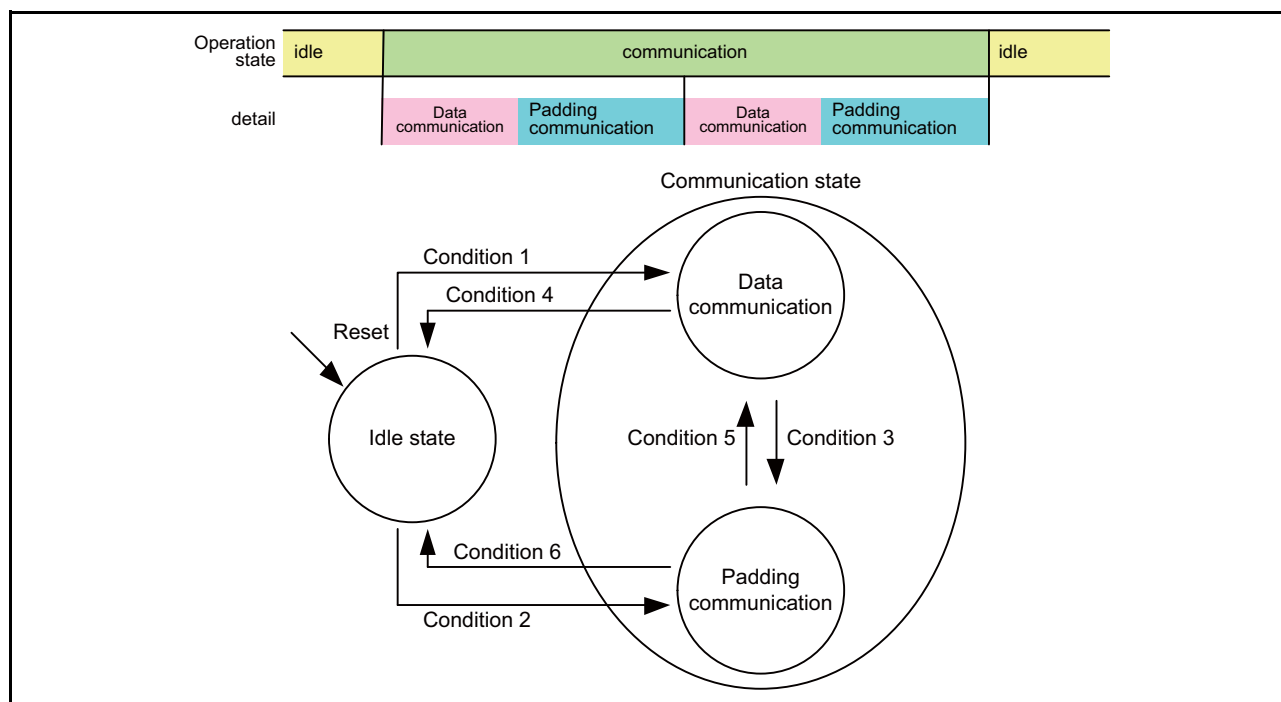

Figure 24.45 Communication State Transition

Table 24.17 Condition for Communication State Transition

| Condition No. | Condition for Transition |
|---------------|---|
| 1 | Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 0 or in the setting without padding bits. |
| 2 | Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 1 and in the setting with padding bits. |
| 3 | The following all of three conditions are satisfied: <ul style="list-style-type: none"> • SSICR.TEN = 1 or SSICR.REN = 1 • In the setting without padding bits • Transfer data words of the last data bit is completed. |
| 4 | The following all of two conditions are satisfied: <ul style="list-style-type: none"> • SSICR.SDTA = 1 or without padding bits • Transfer data words of the last data bit of one frame is completed while SSICR.TEN = 0 and SSICR.REN = 0 |
| 5 | Transfer of the last padding bit is completed while SSICR.TEN = 1 or SSICR.REN = 1 |
| 6 | The following all of two conditions are satisfied: <ul style="list-style-type: none"> • SSICR.SDTA = 0 and with padding bits • Transfer of the last data bit of one frame is completed while SSICR.TEN = 0 and SSICR.REN = 0. |

See Table 24.13 for the setting with/without padding bits.

(1) Data Communication State

In this state, SSIF-2 is during communication. Data of the data word length set with the SSICR.DWL[2:0] bits is transmitted, received, or transmitted and received.

- State Transition in the Setting without Padding Bits

During communication (SSISR.IIRQ = 0), SSIF-2 is during data communication for all the time (Figure 24.46). By disabling transmission and reception (SSICR.TEN = 0 and SSICR.REN = 0), SSIF-2 transits to the idle state (Figure 24.47).

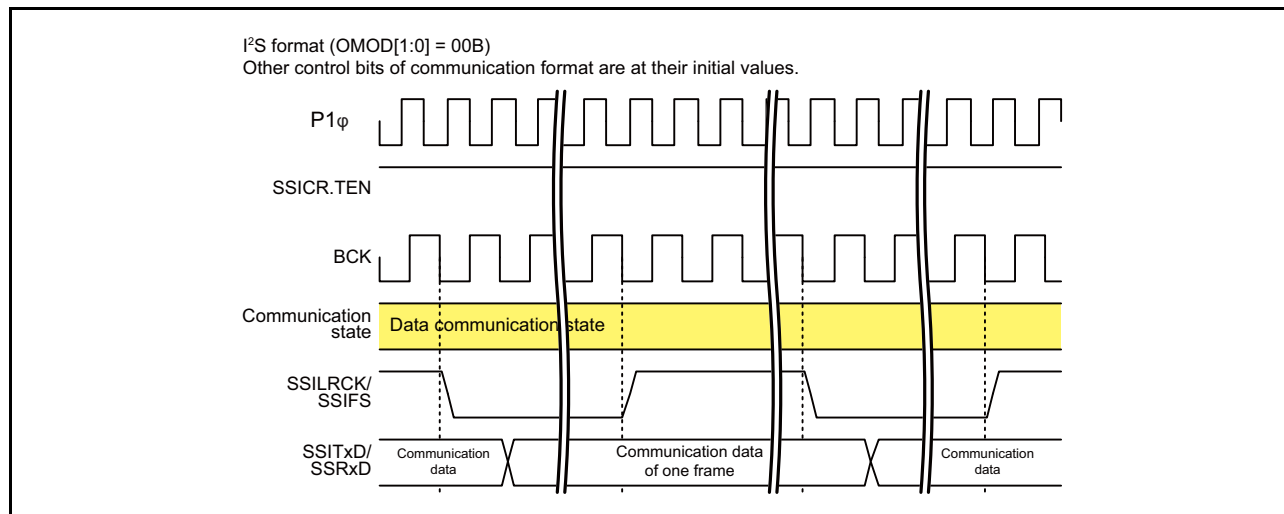

Figure 24.46 Continuation of the Data Communication State

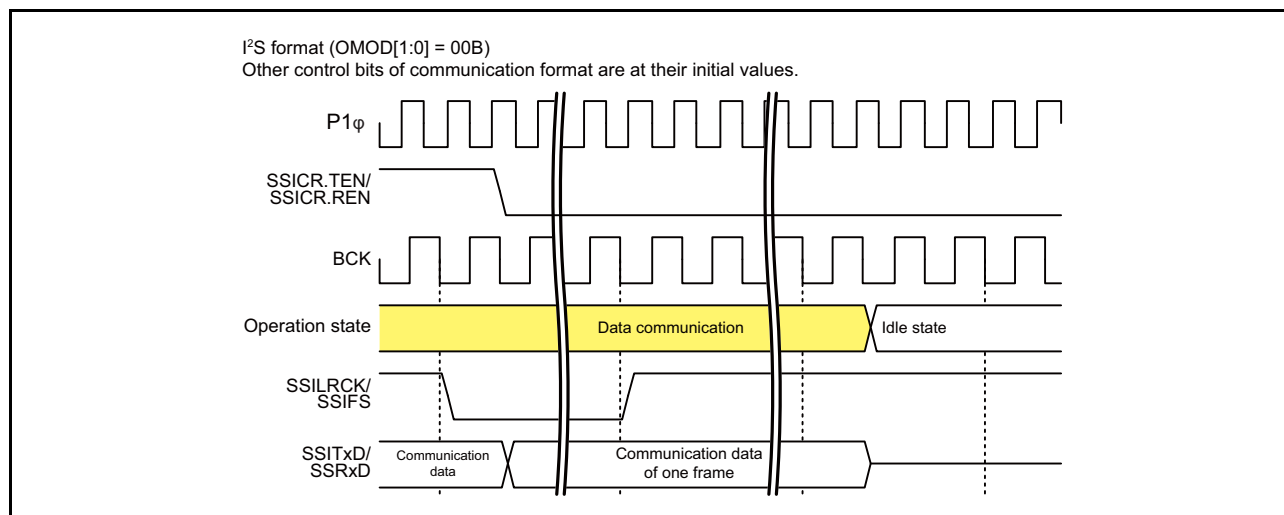

Figure 24.47 Halt from the Data Communication State (without Padding Bits)

- State Transition in the Setting with Padding Bits

During communication (SSISR.IIRQ = 0), after completing transfer of the last bit of a data word, SSIF-2 transits to the padding communication state from data communication state (Figure 24.48). By disabling transmission and reception (SSICR.TEN = 0 and SSICR.REN = 0) while SSICR.SDTA = 1, SSIF-2 transits to the idle state from data communication state when the communication stop is done. (Figure 24.50).

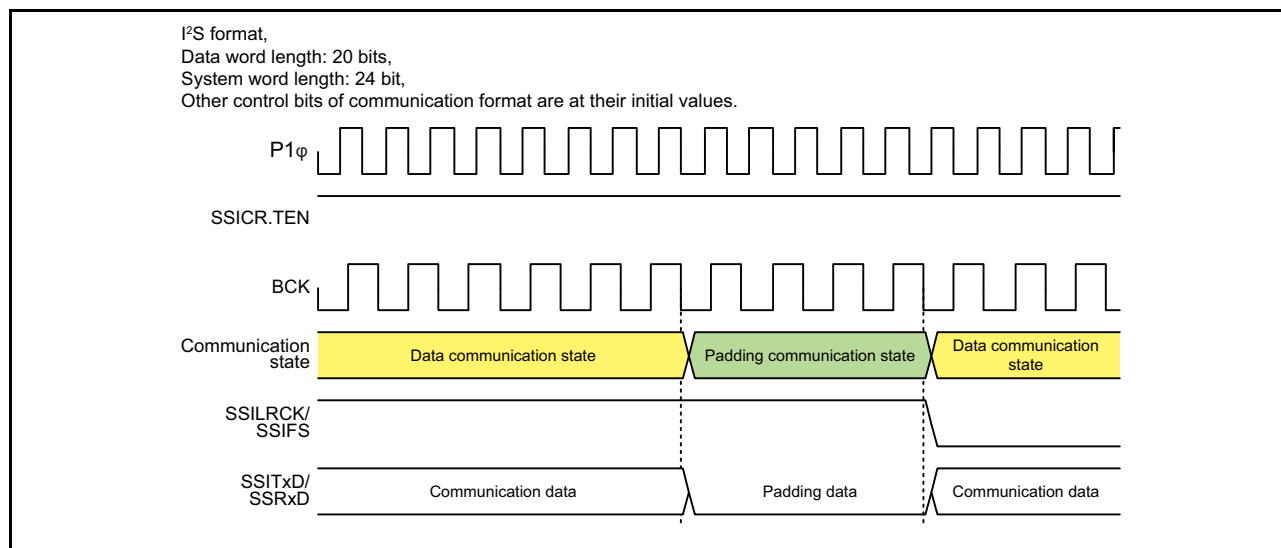

Figure 24.48 Transition from Data Communication to Padding Communication

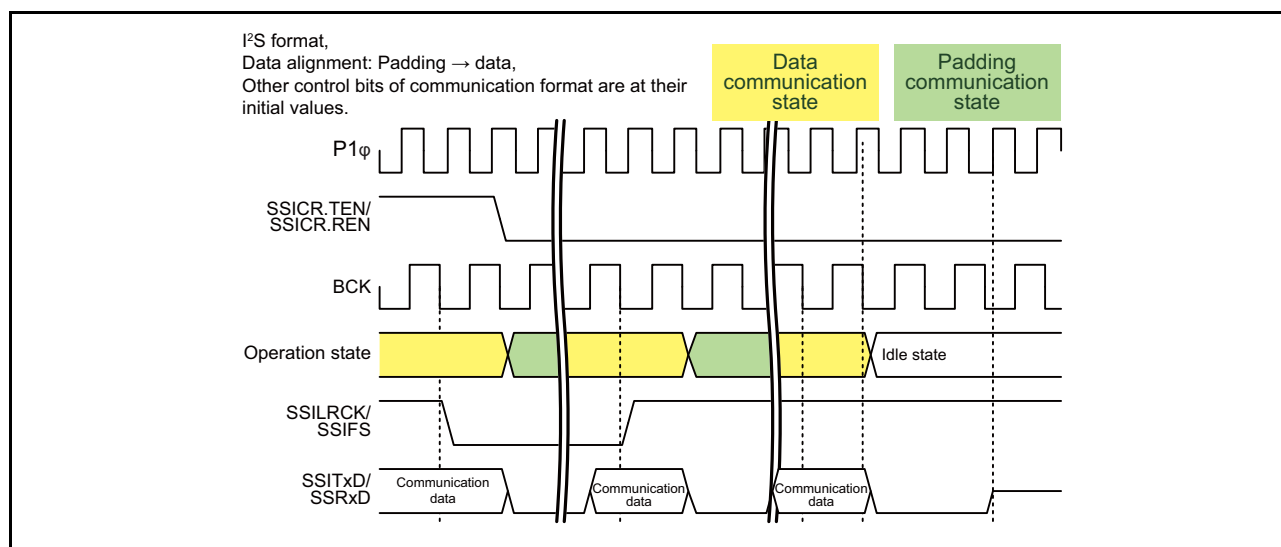

Figure 24.49 Halt from Data Communication (with Padding Bits)

(2) Padding Communication State

In this state, SSIF-2 is during communication. The padding bits set with the SSICR.SWL[2:0] bits and SSICR.DWL[2:0] bits are transmitted, received, or transmitted and received.

- State Transition in the Setting with Padding Bits

During communication (SSISR.IIRQ = 0), after completing transfer of the last padding bit, SSIF-2 transits to data communication state (Figure 24.48). By disabling transmission and reception (SSICR.TEN = 0 and SSICR.REN = 0) while SSICR.SDTA = 0, SSIF-2 transits to the idle state from padding communication when the communication stop is done. (Figure 24.50).

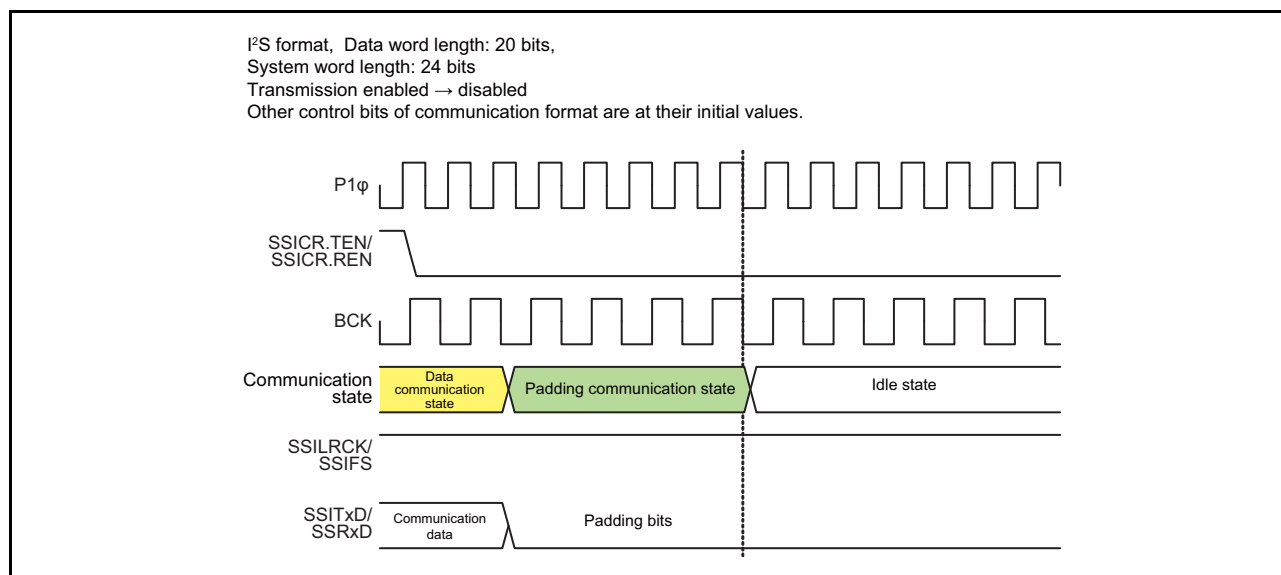

Figure 24.50 Halt from the Padding Communication State

24.5.2 Communication Operation

Figure 24.51 shows the communication flow of SSIF-2.

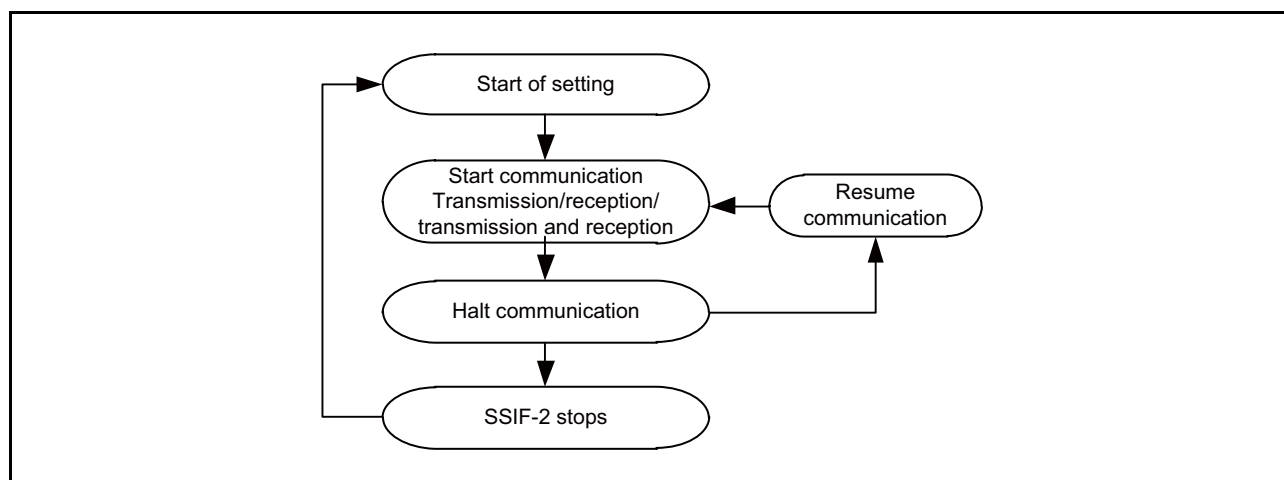

Figure 24.51 SSIF-2 Communication Operation

The procedure of each operation is described in section 24.5.2.1, Start Communication to section 24.5.2.7, Resume Communication.

24.5.2.1 Start Communication

This section describes how to start communication of SSIF-2. Figure 24.52 shows the procedure to start communication. Be sure to follow the procedure. See section 24.5.2.2 for transmission operation and section 24.5.2.3 for reception operation.

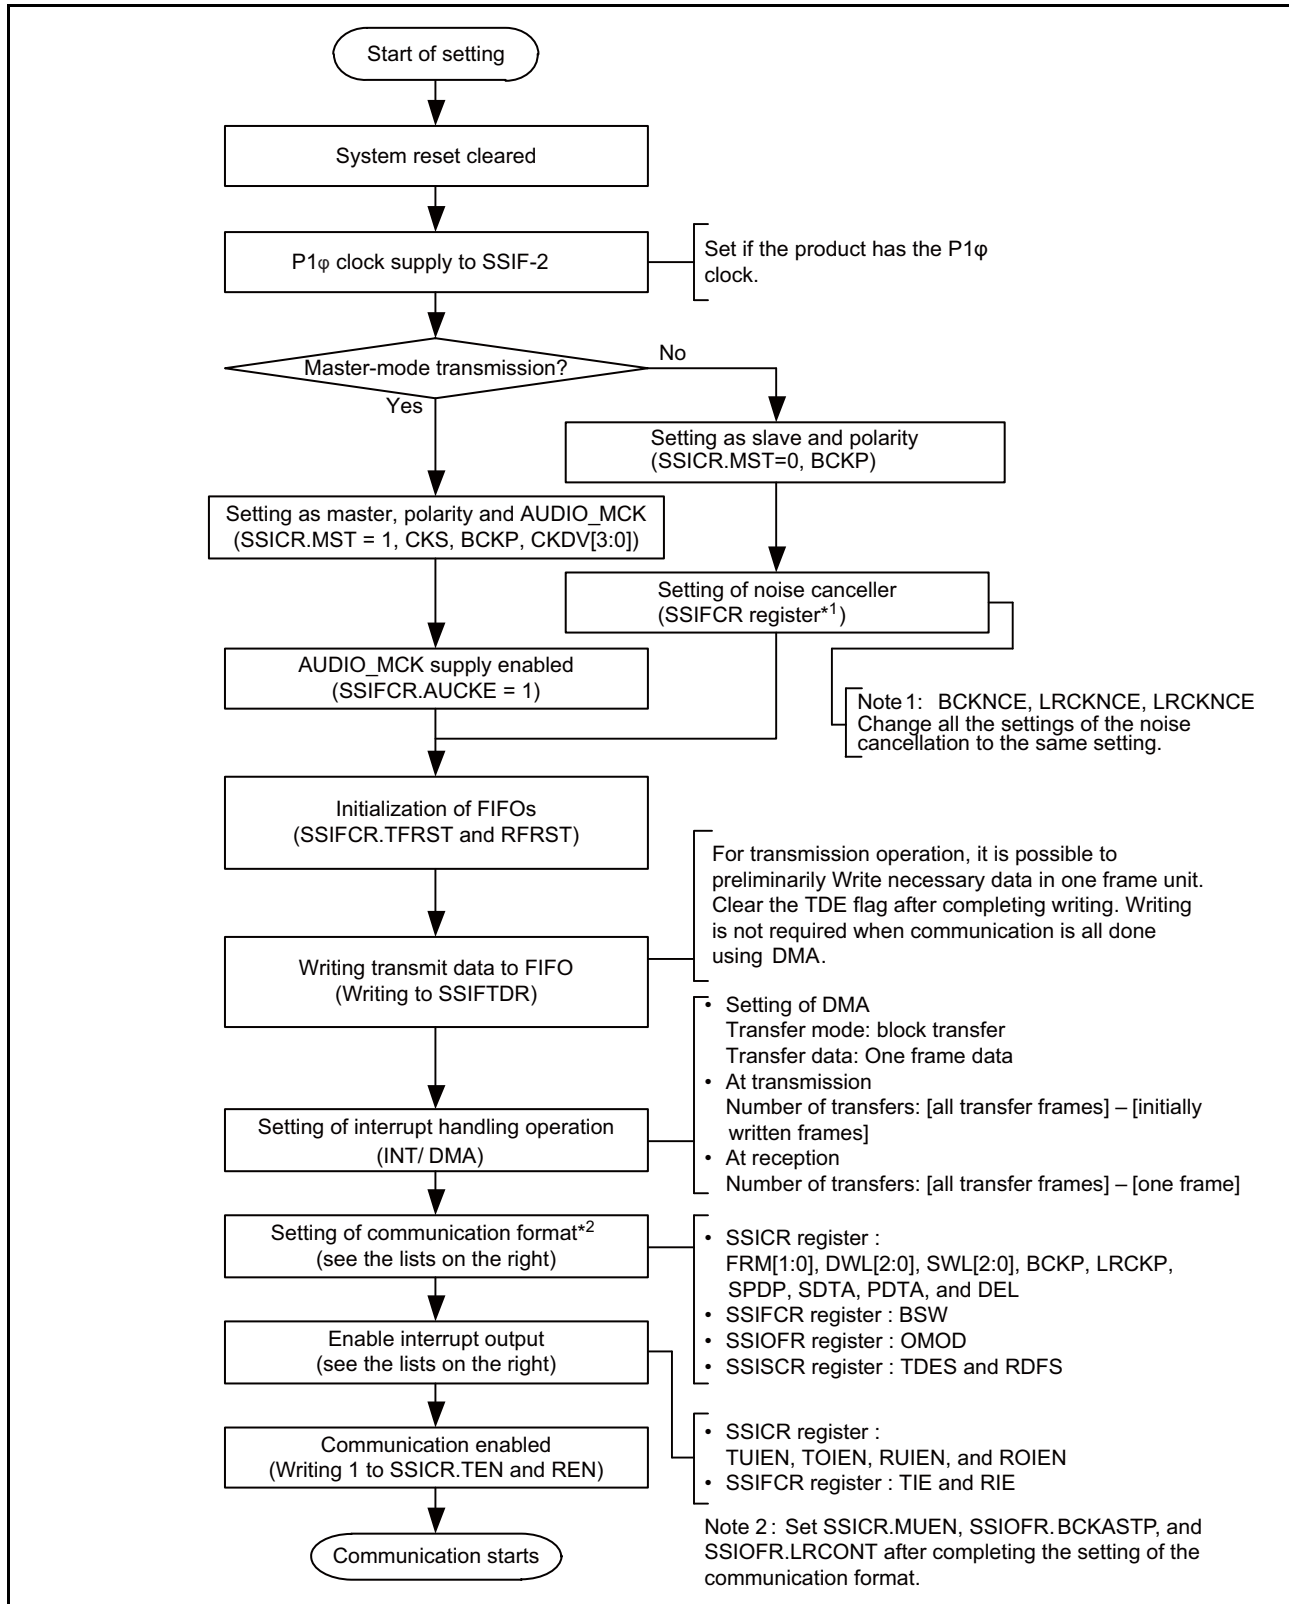

Figure 24.52 Procedure to Start Communication (CPU Procedure)

For SSIF-2 communication, continuous communication is possible with DMA interrupt handling. For transmission, write 1 to SSIFCR.TIE, SSICR.TUIEN, and SSICR.TOIEN. For reception, write 1 to SSIFCR.RIE, SSICR.RUIEN, and SSICR.ROIEN.

24.5.2.2 Transmission

Follow the transmission operation procedure (Figure 24.53) while the transmission is operating.

Transmission starts in synchronization with the start trigger of the SSILRCK/SSIFS signal while transmission is enabled (SSICR.TEN = 1 and SSICR.REN = 0) and while there is one or more frame of serial data in the transmit FIFO data register (SSIFTDR).

SSIF-2 outputs a transmit data empty interrupt to DMA according to the setting condition of TDE (SSISCR.TDES) and transmit data empty interrupt (SSIFCR.TIE) being enabled.

This interrupt requests writing to the transmit FIFO data register (SSIFTDR). By writing to SSIFTDR at each generation of an interrupt, serial data transmission is realized.

In the procedure to start communication, set DMA handling for transmit data empty interrupts as writing to the transmit FIFO data register (SSIFTDR). As a result, SSIF-2 is able not to mediate CPU and to transmit continuous data. When it becomes empty capacity of transmission FIFO data register set with SSISCR.TDES, transmission data empty interrupt is generated. Set the writing number of times according to empty capacity of transmission FIFO data register that transmission data empty interrupt shows. In a case of an error, stop receive procedure (section 24.5.2.5) and then take the error procedure (section 24.5.2.6).

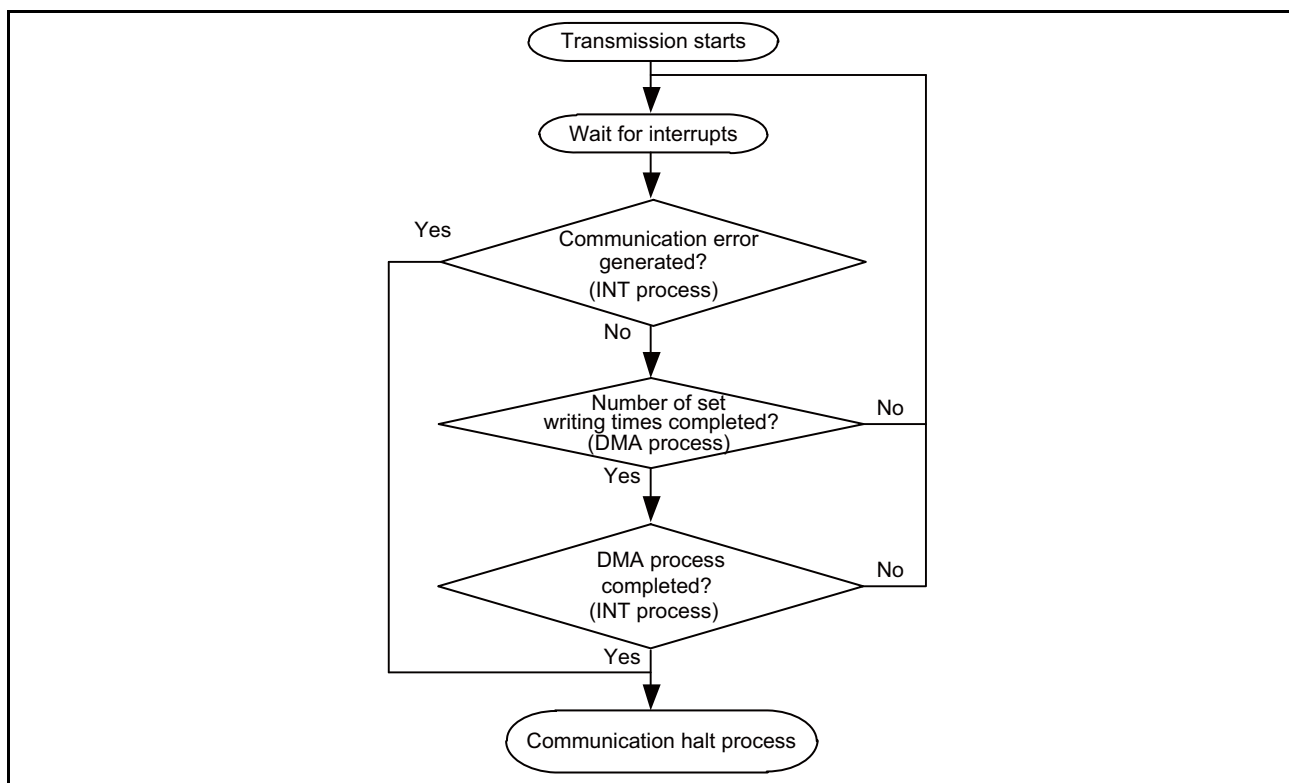

Figure 24.53 Transmission Procedure

Note: The communication flow defined in SSIF-2 uses the DMA. In the case the DMA is not used, observe one of SSIFSR.TDE, and write it in SSIFTDR. Follow empty capacity of transmission FIFO data register set with SSISCR.TDES about the number of times written in SSIFTDR detecting 1 of SSIFSR.TDE. Clear the transmission data that corresponds to empty capacity and clear the SSIFSR.TDE flag to SSIFTDR after writing. Transmission operation consecutive by the repeated thing is possible. SSIFSR.TDE is not cleared when not clearing.

24.5.2.3 Reception

Follow the reception operation procedure (Figure 24.54) while the reception is operating.

Reception starts in synchronization with the start trigger of the SSILRCK/SSIFS signal while reception is enabled (SSICR.TEN = 0 and SSICR.REN = 1). SSIF-2 outputs a receive data full interrupt to DMA according to the setting of RDF (SSISCR.RDFS) and receive data empty interrupt (SSIFCR.RIE) being enabled. This interrupt requests reading from the receive FIFO data register (SSIFRDR). By reading from SSIFRDR at each generation of an interrupt, serial data reception is realized.

In the procedure to start communication, set DMA handling for receive data full interrupts as reading from receive FIFO data register (DDIFRDR). As a result, SSIF-2 is able not to mediate CPU and to receive continuous data. If the data capacity of reception FIFO data register set with SSISCR.RDFS is stored, receive data full interrupt is generated. Set the writing number of times according to the data capacity of reception FIFO data register that receive data full interrupt shows.

In the case of an error, stop the receive operation (section 24.5.2.6) and then take the error procedure (section 24.5.2.6).

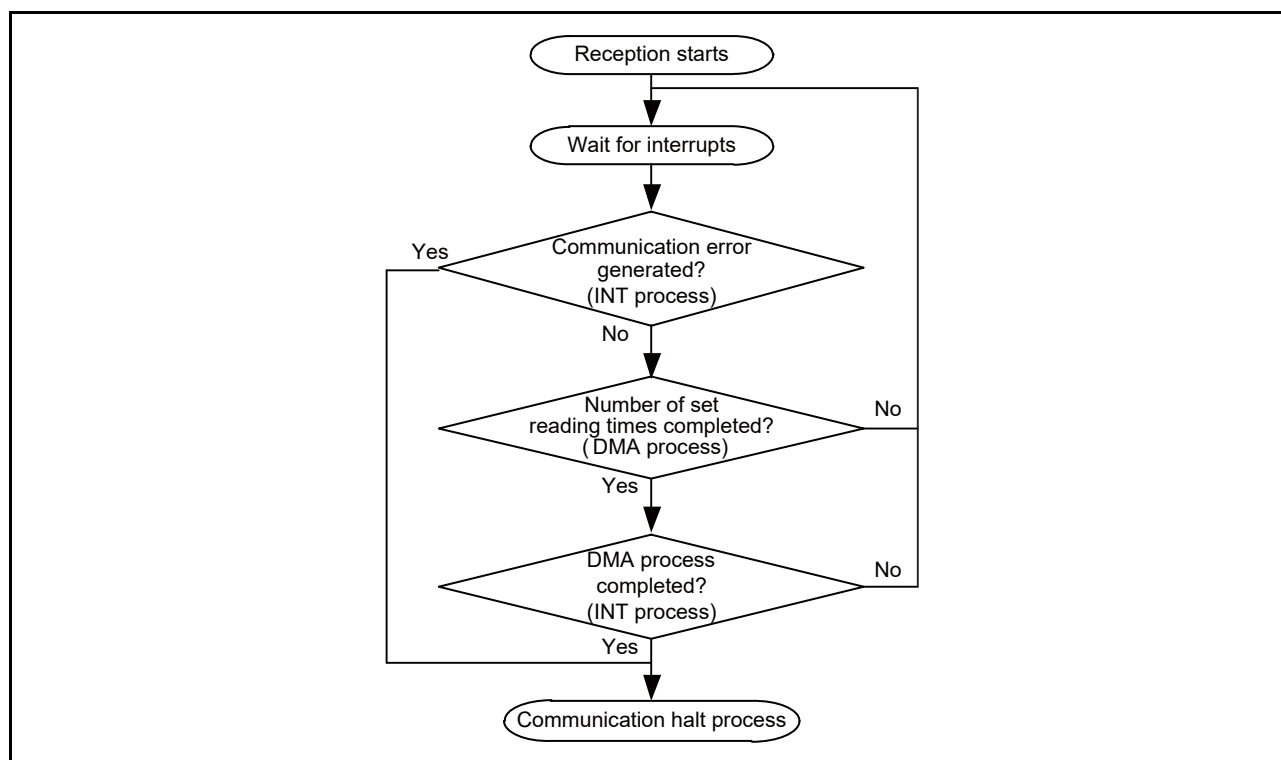

Figure 24.54 Reception Procedure

Note: The communication flow defined in SSIF-2 uses the DMA. In the case the DMA is not used, observe 1 of SSIFSR.RDF, and read SSIFRDR. Follow the receive data capacity of reception FIFO data register set with SSISCR.RDFS about the number of times in which SSIFRDR is read detecting 1 of SSIFSR.RDF. Clear data that does the reception completion and clear the SSIFSR.RDF flag from SSIFRDR after reading. Reception operation consecutive by the repeated thing is possible. SSIFSR.RDF is not cleared when not clearing.

24.5.2.4 Transmission and Reception

Transmission and reception starts in synchronization with the start trigger of the SSILRCK/SSIFS signal while transmission and reception are enabled (SSICR.TEN = 1 and SSICR.REN = 1) and while there is one or more frames of serial data in the transmit FIFO data register (SSIFTDR). The transmission and reception operation of SSIF-2 can be transmitted and received continuously by each doing the procedure for showing in the transmission operation (section 24.5.2.2) and the reception operation (section 24.5.2.3). As transmission and reception are independent in SSIF-2, see sections of transmission and reception respectively. See section 24.5.2.5, Halt Communication to halt communication.

24.5.2.5 Halt Communication

This section describes how to halt communication of SSIF-2. Figure 24.55 shows the procedure to halt communication. Be sure to follow the procedure.

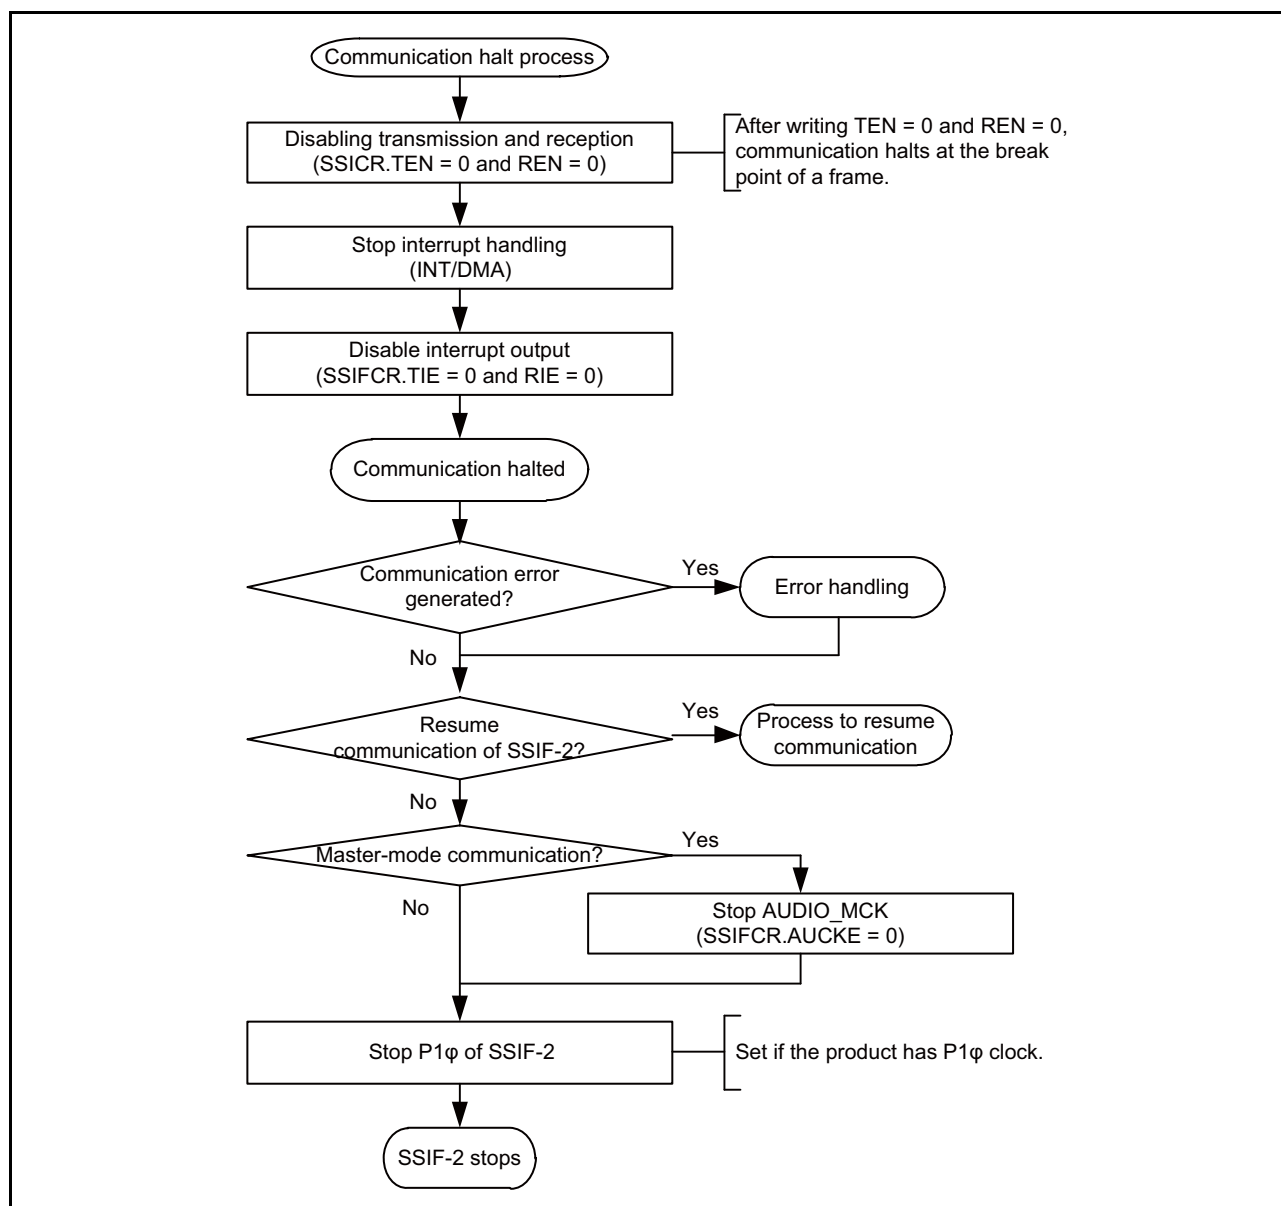

Figure 24.55 Procedure to Halt Communication (CPU Procedure)

To halt the communication of SSIF-2, supply of the following clocks are required until the SSISR.IIRQ bit indicates an idle state.

- Input clock from the SSIBCK pin when SSICR.MST = 0
- AUDIO_MCK when SSICR.MST = 1

To resume communication of SSIF-2 in the previous setting, see section 24.5.2.7, Resume Communication.

Note: When communication of SSIF-2 is halted according to the procedure to halt communication in Figure 24.55, resume communication according to the procedure to start communication in Figure 24.52.

24.5.2.6 Error Handling

SSIF-2 has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error
- Receive overflow error

When an underflow error or overflow error is generated, SSIF-2 need to be restarted. Take the error procedure (Figure 24.56) according to the procedure to halt communication (Figure 24.55).

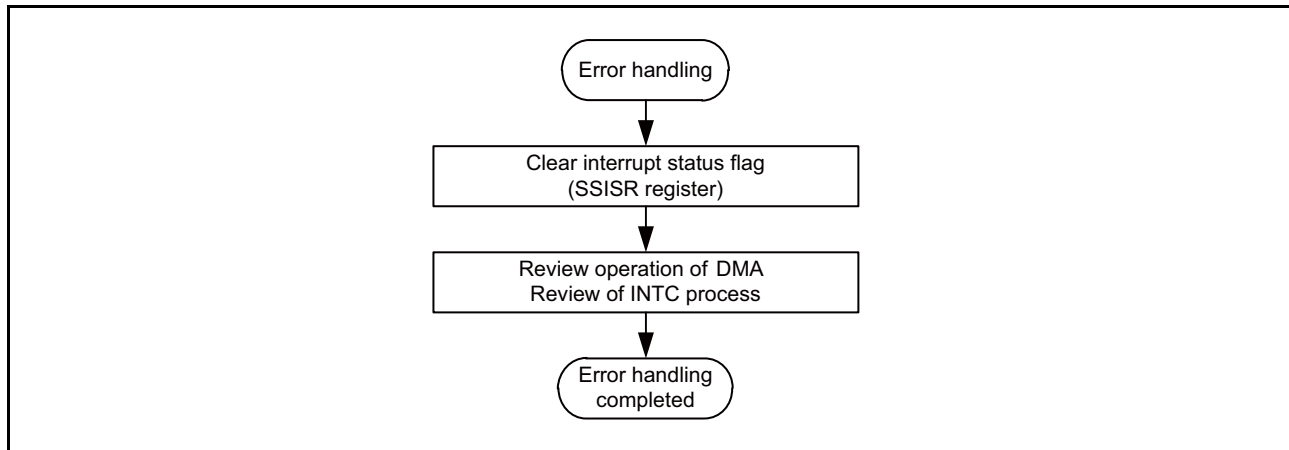

Figure 24.56 Error Handling Procedure

Four error operations are described as follows. When the interrupt output enable bit of the SSICR register is enabled and error flags are set, an error interrupt is generated. See descriptions of flags in section 24.4.1.2, Status Register (SSISR) for the setting conditions of error flags.

(1) Transmit Underflow Error

In the case a transmit underflow error is generated during transmission (SSICR.TEN = 1, SSISR.IIRQ = 0), review the number of write operations to the transmit FIFO data register (SSIFTDR) according to serial data empty interrupts. After generation of a transmit underflow error, data to be transmitted from SSIF-2 are 0 output. To transmit data written to SSIFTxD pin normally, run the procedure to halt communication (Figure 24.55) and then take the error procedure (Figure 24.56). When this error is generated, serial data is consumed as usual. To resume transmission of SSIF-2, write data from the beginning of one frame.

(2) Transmit Overflow Error

In the case a transmit overflow error is generated, review the number of write operations to the transmit FIFO data register (SSIFTDR) according to transmit data empty interrupts. Data is not written to SSIFTDR where a transmit overflow error is generated. This error is generated regardless of while the transmission is operating. To resume transmission of SSIF-2, take the procedure to halt communication (Figure 24.55) and then take the error procedure (Figure 24.56). When communication is resumed, consider the lost serial data.

(3) Receive Underflow Error

In the case a receive underflow error is generated, review the number of reading operations from the receive FIFO data register (SSIFRDR) according to receive data full interrupts. The value read from SSIFRDR is undefined where a receive underflow error is generated. This error is generated regardless of while the reception is operating. To resume reception

of SSIF-2, take the procedure to halt communication (Figure 24.55) and then take the error procedure (Figure 24.56).

(4) Receive Overflow Error

In the case a receive overflow error is generated during reception (SSICR.REN = 1, SSISR.IIRQ = 0), review the number of reading operations from the receive FIFO data register (SSIFRDR) according to receive data full interrupts. Data is not stored in SSIFRDR when a receive overflow error is generated. To resume reception of SSIF-2, take the procedure to halt communication (Figure 24.55) and then take the error handling procedure (Figure 24.56).

24.5.2.7 Resume Communication

To resume communication of SSIF-2, follow the procedure shown in Figure 24.57. After communication is halted, the same setting is applied when it is resumed. To change the settings of clocks and slave/master mode, follow the procedure to start communication (Figure 24.52). For communication after resume, see section 24.5.2.2 and section 24.5.2.3.

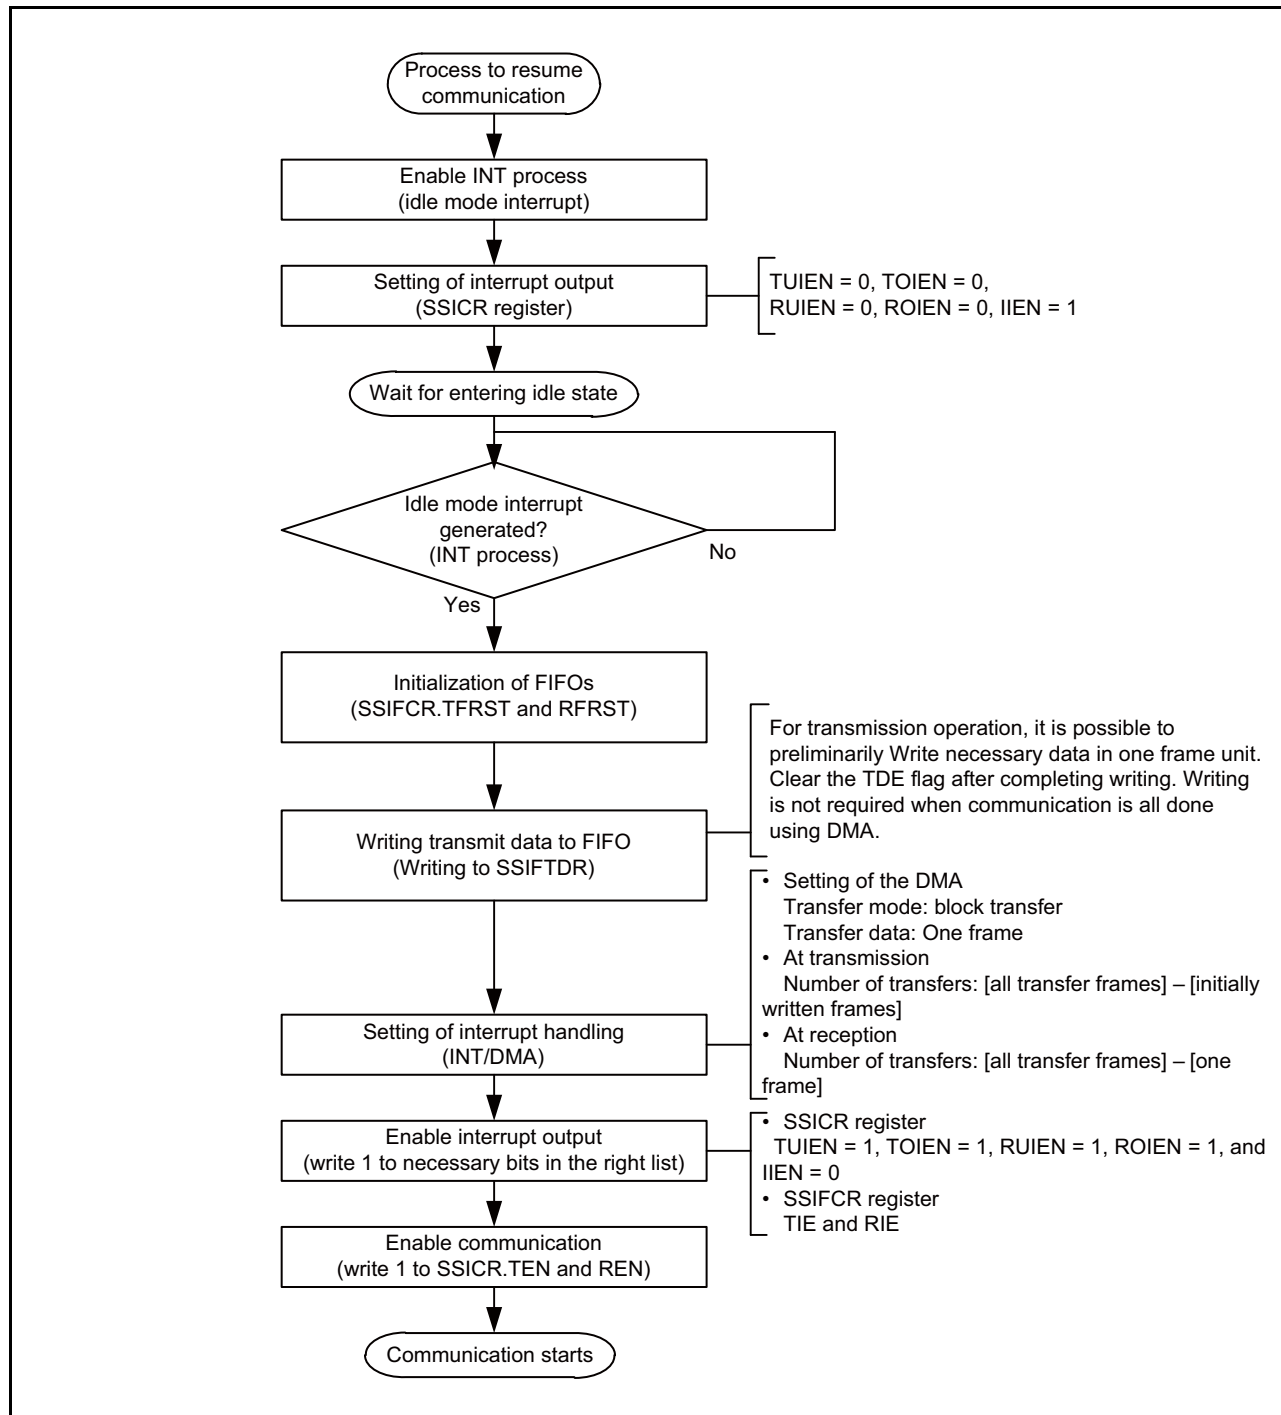

Figure 24.57 Procedure to Resume Communication (CPU Procedure)

24.5.3 Interrupt Sources

Table 24.18 lists the interrupt sources. Set enable/disable of interrupt output of each source with the TUIEN, TOIEN, RUIEN, ROIEN, and I IEN bits in the SSICR register and the TIE and RIE bits in the SSIFCR register.

Table 24.18 Interrupt Sources

| Interrupt Source | Interrupt | Interrupt Flag | Interrupt Sense | DMA Activation |
|------------------|---|---|-----------------|----------------|
| INT_ssif_int_req | Transmit underflow interrupt/ Transmit overflow interrupt/ Receive underflow interrupt/ Receive overflow interrupt/ Idle mode interrupt | SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIIRQ SSISR.IIRQ | Level | Not available |
| INT_ssif_dma_tx | Transmit data empty interrupt | SSIFSR.TDE | Edge | Available |
| INT_ssif_dma_rx | Receive data full interrupt | SSIFSR.RDF | Edge | Available |
| INT_ssif_dma_rt | Receive data full interrupt/ Transmit data empty interrupt | SSIFSR.TDE/SSIFSR.RDF | Edge | Available |

24.5.3.1 INT_ssif_int_req Interrupt

This interrupt source combines five interrupts. Enable output of necessary interrupts before using SSIF-2. This interrupt moves from the flag and the output enable permission that five factors have respectively (Figure 24.58). To clear an interrupt, set the interrupt enable to 0 or clear the interrupt flag to 0.

Figure 24.58 Timing Chart of the Common Interrupt Source, INT_ssif_int_req

(1) Transmit underflow interrupt

As the transmit underflow interrupt, SSISR.TUIRQ is output while SSICR.TUIEN = 1. To restart transmission (SSICR.TEN = 1), enable the output of this interrupt (SSICR.TUIRQ = 1). In the case this interrupt is generated, take the procedure to halt communication (Figure 24.55) and then take the error procedure (Figure 24.56).

(2) Transmit overflow interrupt

As the transmit overflow interrupt, SSISR.TOIRQ is output while SSICR.TOIRQ = 1. To restart transmission (SSICR.TEN = 1), enable the output of this interrupt (SSICR.TOIRQ = 1). In the case this interrupt is generated, take the procedure to halt communication (Figure 24.55) and then take the error procedure (Figure 24.56).

(3) Receive underflow interrupt

As the receive underflow interrupt, SSISR.RUIRQ is output while SSICR.RUIRQ = 1. To restart reception (SSICR.REN = 1), enable the output of this interrupt (SSICR.RUIRQ = 1). In the case this interrupt is generated, take the procedure to halt communication (Figure 24.55) and then take the error procedure (Figure 24.56).

(4) Receive overflow interrupt

As the receive overflow interrupt, SSISR.ROIRQ is output while SSICR.ROIRQ = 1. To restart reception (SSICR.REN = 1), enable the output of this interrupt (SSICR. ROIRQ = 1). In the case this interrupt is generated, take the procedure to halt communication (Figure 24.55) and then take the error procedure (Figure 24.56).

(5) Idle mode interrupt

As the idle mode interrupt, SSISR.IIRQ is output while SSICR.IIEN = 1. When the thing that the communication has stopped completely is confirmed, this interrupt is used. Figure 24.57).

24.5.3.2 INT_ssif_dma_tx Interrupt [full-duplex communication]

As the transmit data empty interrupt, a pulse interrupt is output by the following condition.

- SSIFSR.TDE and SSIFCR.TIE becomes 1.
 SSIF-2 operation: SSIFSR.TDE becomes 1 from 0 while SSIFCR.TIE = 1
 CPU operation: SSIFCR.TIE is changed to 1 from 0 while SSIFSR.TDE = 1

An interrupt suppression function is available for this interrupt to prevent the thing that cannot be taken. When the DMA is busy state (Interrupt cannot be accepted), and the interruption condition occurs, output of this interrupt is held. This interrupt is output after the DMA becomes acceptable (Figure 24.59).

Figure 24.59 INT_ssif_dma_tx Interrupt Timing Chart

24.5.3.3 INT_ssif_dma_rx Interrupt [full-duplex communication]

As the receive data full interrupt, a pulse interrupt is output by the following condition.

- SSIFSR.RDF and SSIFCR.RIE becomes 1.
 SSIF-2 operation: SSIFSR.RDF becomes 1 from 0 while SSIFCR.RIE = 1.
 CPU operation: SSIFCR.RIE is changed to 1 from 0 while SSIFSR.RDF = 1.

An interrupt suppression function is available for this interrupt to prevent the thing that cannot be taken. When the DMA is busy state (Interrupt cannot be accepted), and the interruption condition occurs, output of this interrupt is held. This interrupt is output after the DMA becomes acceptable. It operates in the same way as in Figure 24.59.

24.5.3.4 INT_ssif_dma_rt Interrupt [half-duplex communication]

This interrupt is output by two sources, transmit data empty interrupt and receive data full interrupt. When this interrupt is generated, read the interrupt flag and specify the interrupt source.

An interrupt suppression function is available for this interrupt to prevent the thing that cannot be taken. When the DMA is busy state (Interrupt cannot be accepted), and the interruption condition occurs, output of this interrupt is held. This interrupt is output after the DMA becomes acceptable (Figure 24.59).

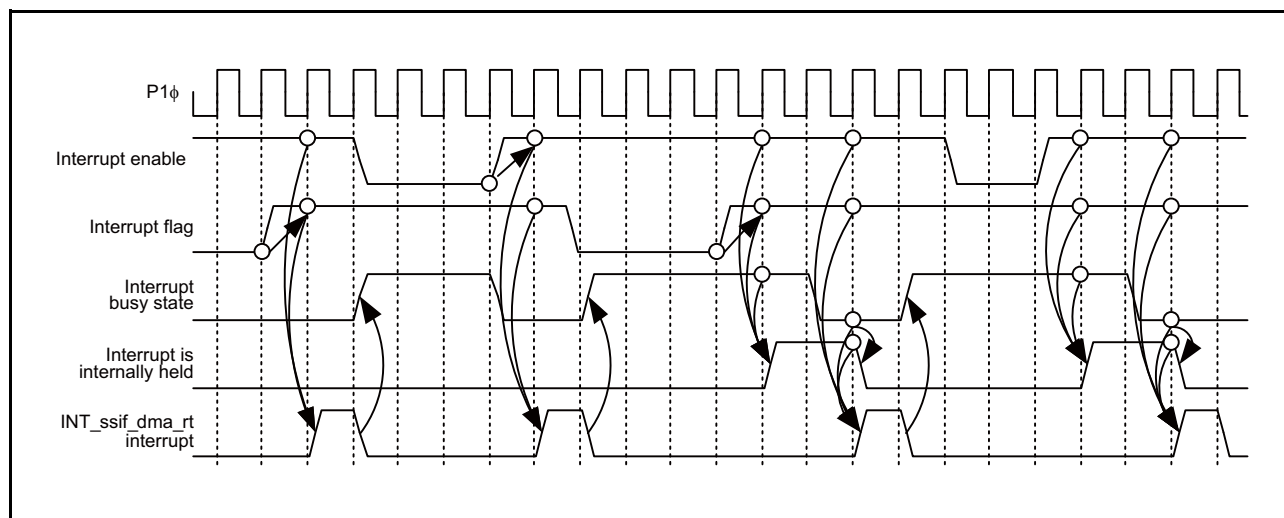

Figure 24.60 INT_ssif_dma_tx Interrupt Timing Chart

24.5.4 Software Resets

SSIF-2 has three software reset bits to reset its states.

- SSIF-2 software reset (SSIFCR.SSIRST)
- Transmit FIFO data register reset (SSICR.TFRST)
- Receive FIFO data register reset (SSIFCR.RFRST)

It explains the procedure of three software reset.

24.5.4.1 Software Reset Procedure

(1) SSIF-2 Software Reset

For the SSIF-2 software reset bit (SSIFCR.SSIRST), follow the procedure shown in Figure 24.61. After a reset, the same setting is applied when it is resumed. To change the settings of clocks and slave/master mode, follow the procedure to start communication (Figure 24.52). See section 24.5.2.2, Transmission and section 24.5.2.3, Reception respectively for transmission and reception after communication is resumed.

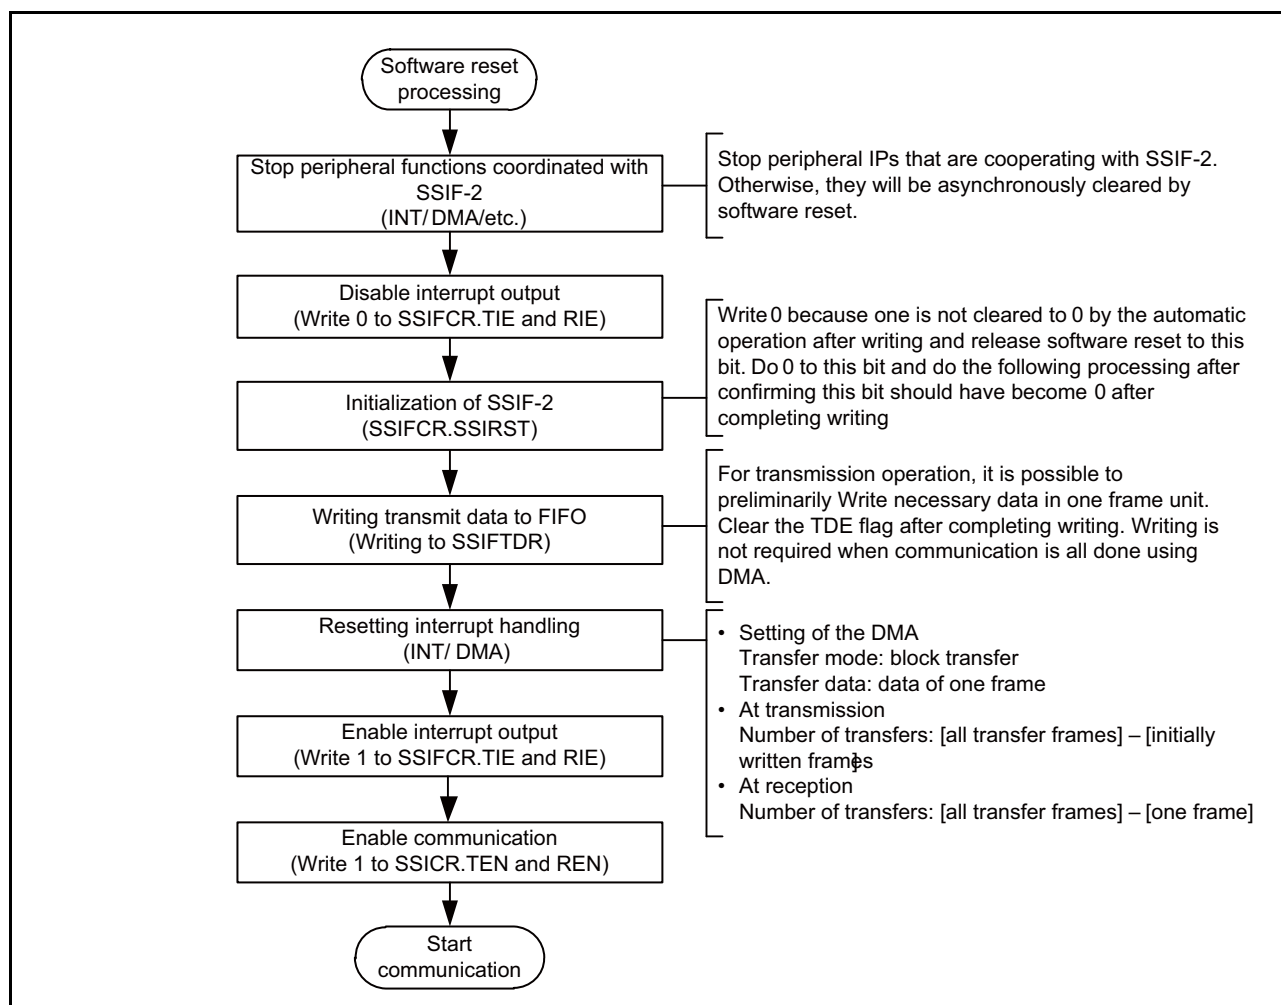

Figure 24.61 Software Reset Procedure (CPU Procedure)

(2) Transmit FIFO Data Register Reset

To initiate a transmit FIFO data register reset, follow the procedure to start communication (Figure 24.52) and resume communication (Figure 24.57).

(3) Receive FIFO Data Register Reset

To initiate a receive FIFO data register reset, follow the procedure to start communication (Figure 24.52) and resume communication (Figure 24.57).

24.6 Notes

24.6.1 Notes

24.6.1.1 Attention by communication using DMA

SSIF-2 assumes the DMA access as follows.

Table 24.19 Interrupt to expect DMA access

| Communication operation | Interrupt | DMA access | LSI specification | Remarks |
|----------------------------|-----------------|------------------|--------------------------|---------|
| Transmission | INT_ssif_dma_tx | Write to SSIFTDR | Full duplex transmission | |
| | INT_ssif_dma_rt | | Half duplex transmission | |
| Reception | INT_ssif_dma_rx | Read SSIFRDR | Full duplex transmission | |
| | INT_ssif_dma_rt | | Half duplex transmission | |
| Transmission and Reception | INT_ssif_dma_tx | Write to SSIFTDR | Full duplex transmission | |
| | INT_ssif_dma_rx | Read SSIFRDR | Half duplex transmission | |

Defend the following when communicating without using DMA.

- Clear SSIFSR.TDE when you access finality when it is writing in SSIFTDR with CPU. There is a possibility that the transmission overflow not intended occurs when not clearing.
- Clear SSIFSR.RDE when you access finality when you read SSIFRDR with CPU. There is a possibility that the reception overflow not intended occurs when not clearing.

24.6.1.2 Notes for Slave-mode Communication

(1) ADCKE Control

In slave-mode communication (SSICR.MST = 0), SSIF-2 needs supply of SSIBCK. To stop BCK on the master side, make sure that SSIF-2 is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIF-2 becomes idle, take the procedure to start communication (Figure 24.52) or wait for an idle state by taking the procedure to resume communication (Figure 24.57).

(2) SSILRCK/SSIFS

SSIF-2 has the terminal SSILRCK/SSIFS that shows the synchronization of the communication. Match communication format of the opposing device and SSIF-2 when SSIF-2 is slave communication (SSICR.MST=0). SSIF-2 uses the signal of SSILRCK/SSIFS only as a communication start trigger.

24.6.1.3 Notes for Master-mode Communication

(1) ADCKE Control

In master-mode communication (SSICR.MST = 1), SSIF-2 operates with the audio clock (AUDIO_MCK). To stop SSIF-2 completely, make sure that SSIF-2 is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.ADCKE. If 0 is written to SSIFCR.ADCKE before SSIF-2 becomes idle, take the procedure to start communication (Figure 24.52).

(2) LRCONT Control

To stop the output to the SSILRCK/SSIFS pin with SSIOFR.LRCONT when SSIF-2 is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when 0 is written from 1 to SSIOFR.LRCONT. (Figure 24.43). Make sure that the remote device is not affected.

(3) BCKASTP Control

To stop the output to the SSIBCK pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIF-2 is in the idle state, note the following; By writing 0 to SSIOFR.BCKASTP while it is 1, the output stops immediately (Figure 24.44). So, make sure that the remote device is not affected.

Note: When the opposing device who is the slave needs the clock of the terminal SSIBCK before the communication operates, it is not possible to use it.

24.6.1.4 Notes for Communication Flow

(1) When an Error Interrupt is Generated

SSIF-2 has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error
- Receive overflow error

When an underflow error or overflow error is generated, SSIF-2 need to be restarted. Take the error procedure (Figure 24.56) according to the procedure to halt communication (Figure 24.55).

(a) Transmit Underflow Error

In the case a transmit underflow error is generated during transmission (SSICR.TEN = 1, SSISR.IIRQ = 0), review the number of write operations to the transmit FIFO data register (SSIFTDR) according to serial data empty interrupts. After generation of a transmit underflow error, data to be transmitted from SSIF-2 are 0 output. To transmit data written to SSIFTxD pin normally, run the procedure to halt communication (Figure 24.55) and then take the error procedure (Figure 24.56). When this error is generated, serial data is consumed as usual. To resume transmission of SSIF-2, write data from the beginning of one frame.

(b) Transmit Overflow Error

In the case a transmit overflow error is generated, review the number of write operations to the transmit FIFO data register (SSIFTDR) according to transmit data empty interrupts. Data is not written to SSIFTDR where a transmit overflow error is generated. This error is generated regardless of while the transmission is operating. To resume transmission of SSIF-2, take the procedure to halt communication (Figure 24.55) and then take the error procedure (Figure 24.56). When communication is resumed, consider the lost serial data.

(c) Receive Underflow Error

In the case a receive underflow error is generated, review the number of reading operations from the receive FIFO data register (SSIFRDR) according to receive data full interrupts. The value read from SSIFRDR is undefined where a receive underflow error is generated. This error is generated regardless of while the reception is operating. To resume reception

of SSIF-2, take the procedure to halt communication (Figure 24.55) and then take the error procedure (Figure 24.56).

(d) Receive Overflow Error

In the case a receive overflow error is generated during reception (SSICR.REN = 1, SSISR.IIRQ = 0), review the number of reading operations from the receive FIFO data register (SSIFRDR) according to receive data full interrupts. Data is not stored in SSIFRDR when a receive overflow error is generated. To resume reception of SSIF-2, take the procedure to halt communication (Figure 24.55) and then take the error handling procedure (Figure 24.56).

(2) Transmit Data Empty Interrupt

The communication flow defined in SSIF-2 uses the DMA. In the case the DMA is not used, observe one of SSIFSR.TDE, and write it in SSIFTDR. Follow empty capacity of transmission FIFO data register set with SSISCR.TDES about the number of times written in SSIFTDR detecting 1 of SSIFSR.TDE. Clear the transmission data that corresponds to empty capacity and clear the SSIFSR.TDE flag to SSIFTDR after writing. Transmission operation consecutive by the repeated thing is possible. SSIFSR.TDE is not cleared when not clearing.

(3) Receive Data Full Interrupt

The communication flow defined in SSIF-2 uses the DMA. In the case the DMA is not used, observe 1 of SSIFSR.RDF, and read SSIFRDR. Follow the receive data capacity of reception FIFO data register set with SSISCR.RDFS about the number of times in which SSIFRDR is read detecting 1 of SSIFSR.RDF. Clear data that does the reception completion and clear the SSIFSR.RDF flag from SSIFRDR after reading. Reception operation consecutive by the repeated thing is possible. SSIFSR.RDF is not cleared when not clearing.

(4) Switching Transfer Modes

1. For state transition from transmission, reception, and transmission and reception, disable transmission and reception (SSICR.TEN = 0, SSICR.REN = 0).
2. Confirm it is in the idle state (SSISR.IIRQ = 1).
3. In the idle state, set the SSICR.TEN bit and the SSICR.REN bit again and resume transfer.

(5) Resume Communication after Halting SSIF-2

When communication of SSIF-2 is halted according to the procedure to halt communication in Figure 24.55, resume communication according to the procedure to resume communication in Figure 24.52.

24.6.1.5 Write Access Restriction

(1) SSICR Register

If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If written, the operation performed immediately after writing is not guaranteed. For example, after enabling operation, make sure that SSISR.IIRQ = 0 and after disabling operation, make sure that SSISR.IIRQ = 1.

(a) TEN Bit and REN Bit

Writing 1 to these bits, transmission starts in synchronization with start trigger. Refer to section 24.5.2.2, Transmission, section 24.5.2.3, Reception, and section 24.5.2.4, Transmission and Reception for details. Writing 0 to these bits, transmission stops in synchronization with next frame boundary. Set 1 at the same time when you use SSIF-2 as transmission and reception. To stop communication, make sure to stop transmission and reception (TEN = 0 and REN = 0).

(2) SSICR Register

(a) Clear operation of TUIRQ and TOIRQ

After the communication is permitted (SSICR.TEN is written and '1' is written from '0'), the transmission error flag (TOIRQ and TUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the transmission error flag might not be able to be read.

(b) Clear operation of RUIRQ and ROIRQ

After the communication is permitted (SSICR.REN is written and '1' is written from '0'), the transmission error flag (ROIRQ and RUIRQ of the SSISR register) is cleared. However, when the SSISR register is continuously read, the clearness of the reception error flag might not be able to be read.

(3) Communication State

Writing to the bits with shaded area in Table 24.20 is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Table 24.20 Bits Protected from Writing during Communication

| Symbol | Address (Base+) | +0 | | | | | | | | +1 | | | | | | | |

25. CANFD Interface (RS-CANFD)

This section contains a generic description of the CANFD interface (RS-CANFD).

The first part of this section describes all this LSI specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of RS-CANFD.

25.1 Features of RS-CANFD

25.1.1 Number of Units and Channels

This product has the following number of RS-CANFD units.

Table 25.1 Number of Units

| RS-CANFD | |
|-----------------|--------|
| Number of Units | 1 |
| Name | RSCFD0 |

This product has the CANFD interface channel listed below.

Table 25.2 Unit Configurations and Channels

| RS-CANFD | |
|--------------------|------------|
| Number of Channels | 2 |
| Name | CAN0, CAN1 |

The RS-CANFD has two interface modes (classical CAN mode and CANFD mode) and uses different registers for each mode. There are two types of register names RSCANnXXX and RSCFDnCFDXXX (XXX: arbitrary) depending on interface modes. When explaining specifications common to two registers, register names are described as RSCFDn(CFD)XXX.

Table 25.3 Index

| Index | Meaning |
|-------|---|
| n | Throughout this section, the individual RS-CANFD units are generically indicated by the index “n” (n = 0); for example, RSCFDn(CFD)GCTR is the global control register of the RSCFDn unit. |
| m | Throughout this section, the individual channels of RS-CANFD units are generically indicated by the index “m” (m = 0, 1); for example, RSCFDn(CFD)CmSTS is the channel m status register. |
| j | The individual registers associated with receive rule table are generically indicated by the index “j” (j = 0 to 15); for example, RSCFDn(CFD)GAFLIDj is the receive rule ID register. |
| k | The individual transmit/receive FIFO buffers are generically indicated by the index “k” (k = 0 to 5); for example, RSCFDn(CFD)CFCK is the transmit/receive FIFO buffer configuration/control register. |
| x | The individual receive FIFO buffers are generically identified by the index “x” (x = 0 to 7); for example, RSCFDn(CFD)RFSTx is the receive FIFO buffer status register. |
| d | Data field registers of transmit/receive FIFO buffers and receive FIFO buffers are identified by “d” (classical CAN mode: d = 0, 1, CANFD mode: d = 0 to 15). For example, the transmit/receive FIFO buffer data field register is described as RSCFDn(CFD)CFDFd_k. |
| q | The individual receive buffers are generically indicated by the index “q” (q = 0 to 31); for example, RSCFDn(CFD)RMIDq is the receive buffer ID register. |
| p | The individual transmit buffers are generically indicated by the index “p” (p = 0 to 31); for example, RSCFDn(CFD)TMCP is the transmit buffer control register. |
| b | Data field registers of receive buffers and transmit buffers are identified by “b” (classical CAN mode: b = 0, 1, CANFD mode: b = 0 to 4). For example, the receive buffer data field register is described as RSCFDn(CFD)RMDFb_q. |
| r | The individual RAM tests for CAN are generically indicated by the index “r” (r = 0 to 63); for example, RSCFDn(CFD)RPGACCr is the RAM test page access register. |
| y | The registers not covered above are indicated by the letter “y” (y = 0); for example, RSCFDn(CFD)RMNDy is a receive buffer new data register. |

Note: The functions and descriptions of registers in this section are for the RS-CANFDs that has 2 channels (m = 0, 1). When referring to information with indexes, regard the index values as the ones corresponding to your target product. Also, note that, if the value of an index exceeds the range described in this section due to your target product, write the value after reset when writing to bits outside the index range.

25.1.2 Register Base Address

RSCFDn base addresses are listed in the following table.

RSCFDn register addresses are given as offsets from the base addresses in general.

Table 25.4 Register Base Address

| Base Address Name | Base Address |
|-------------------|--------------|
| <RSCFD0_base> | E802 0000 |

25.1.3 Clock Supply

The RSCFDn clock supply is shown in the following table.

Table 25.5 Clock Supply

| Unit Name | Clock for the Unit | Supply Clock Name |
|-----------|--------------------|-------------------|
| RSCFDn | clk_xincan | CAN_CLK |
| | clkc | P1φ/2 |
| | pclk | P1φ |

The operating frequency of the RSCFDn depends on the transfer rate and the number of channels in use. Table 25.6 shows the range of the frequency.

Table 25.6 Range of Operating Frequency Depending on the Transfer Rate and the Number of Channels in Use in this LSI

| Condition | | | Range of Operating Frequency | | |
|-----------|---------------|------------------------|------------------------------|------------------------------|------------------------|
| Mode | Transfer Rate | No. of Channels in Use | pclk | clk_xincan* ¹ | clkc* ^{1,2} |
| CANFD | 4.125 Mbps | 2ch | pclk ≥ 64 MHz | 32 MHz ≤ clk_xincan ≤ pclk/2 | 32 MHz ≤ clkc ≤ pclk/2 |
| | | 1ch | | | |
| | 2 Mbps | 2ch | pclk ≥ 32 MHz | 16 MHz ≤ clk_xincan ≤ pclk/2 | 16 MHz ≤ clkc ≤ pclk/2 |
| | | 1ch | | | |
| CAN/CANFD | 1 Mbps | 2ch | pclk ≥ 30.6 MHz | 8 MHz ≤ clk_xincan ≤ pclk/2 | 8 MHz ≤ clkc ≤ pclk/2 |
| | | 1ch | pclk ≥ 27.5 MHz | | |
| | 500 kbps | 2ch | pclk ≥ 27.5 MHz | 4 MHz ≤ clk_xincan ≤ pclk/2 | 4 MHz ≤ clkc ≤ pclk/2 |
| | | 1ch | | | |
| | 125 kbps | 2ch | pclk ≥ 27.5 MHz | 1 MHz ≤ clk_xincan ≤ pclk/2 | 1 MHz ≤ clkc ≤ pclk/2 |
| | | 1ch | | | |

Note 1. Setting the DCS bit in the RSCFDn(CFD)GCFG register enables to select either clk_xincan or clkc. Set clocks less than or equal to pclk/2.

Note 2. When pclk < 25 MHz, select clk_xincan.

25.1.4 Interrupt Request

RSCFDn interrupt requests are listed in the following table.

Table 25.7 Interrupt Requests

| Unit Interrupt Signal | | Outline |
|-----------------------|-------------|---|
| INTRCANGERR | | CAN global error interrupt |
| INTRCANGRECC | | CAN receive FIFO interrupt |
| CAN0 | INTRCAN0ERR | CAN0 error interrupt |
| | INTRCAN0REC | CAN0 transmit/receive FIFO receive completion interrupt |
| | INTRCAN0TRX | CAN0 transmit interrupt |
| CAN1 | INTRCAN1ERR | CAN1 error interrupt |
| | INTRCAN1REC | CAN1 transmit/receive FIFO receive completion interrupt |
| | INTRCAN1TRX | CAN1 transmit interrupt |

25.1.5 External Input/Output Signals

External input/output signals of RSCFDn are listed below.

Table 25.8 External Input/Output Signals

| Unit Signal Name | Outline | Alternative Port Pin Signal |
|-------------------------------|------------------------------------|-------------------------------|
| CANmRX (m = 0, 1) | CANm receive data input | CANmRX (m = 0, 1) |
| CANmTX (m = 0, 1) | CANm transmit data output | CANmTX (m = 0, 1) |
| CANmRX_DATARATE_EN (m = 0, 1) | CANm receive data phase output | CANmRX_DATARATE_EN (m = 0, 1) |
| CANmTX_DATARATE_EN (m = 0, 1) | CANm transmit data phase output | CANmTX_DATARATE_EN (m = 0, 1) |
| CAN_CLK | Clock source for CAN communication | CAN_CLK |

25.2 Overview

25.2.1 Functional Overview

Table 25.9 shows the RS-CANFD module specifications. Figure 25.1 shows the RS-CANFD module block diagram.

Table 25.9 RS-CANFD Module Specifications

| Item | Specification |
|---------------------------|---|
| Number of channels | 2 |
| Protocol | ISO11898-1 compliant Using CANFD frames is selectable by switching interface modes. |
| Communication speed | <p>Classical CAN mode:</p> <ul style="list-style-type: none"> Maximum 1 Mbps $\text{Communication speed (CANm bit time clock)} = \frac{1}{\text{CANm bit time}}$ $\text{CANm bit time} = \text{CANmTq} \times \text{Tq count per bit}$ $\text{CANmTq} = \frac{(\text{BRP}[9:0] \text{ bits in the RSCANnCmCFG register} + 1)}{\text{fCAN}}$ <p>fCAN: Frequency of CAN clock (selected by the DCS bit in the RSCANnGCFG register)</p> <p>CANFD mode:</p> <ul style="list-style-type: none"> Nominal bit rate: max. 1 Mbps, data bit rate: max. 4.125 Mbps $\text{Transmission rate (CANm nominal bit time clock)} = \frac{1}{\text{CANm nominal bit time}}$ $\text{Transmission rate (CANm data bit time clock)} = \frac{1}{\text{CANm data bit time}}$ $\text{CANm nominal bit time} = \text{CANmTq(N)} \times \text{Tq count per nominal bit}$ $\text{CANm data bit time} = \text{CANmTq(D)} \times \text{Tq count per data bit}$ $\text{CANmTq(N)} = \frac{(\text{NBRP}[9:0] \text{ bits in the RSCFDnCFDCmNCFG register} + 1)}{\text{fCAN}}$ $\text{CANmTq(D)} = \frac{(\text{DBRP}[7:0] \text{ bits in the RSCFDnCFDCmDCFG register} + 1)}{\text{fCAN}}$ <p>fCAN: Frequency of CAN clock (selected by the DCS bit in the RSCFDnCFDGCFG register)</p> <p>m = 0, 1 Tq: Time quantum</p> |
| Buffer | <p>160 buffers in total</p> <ul style="list-style-type: none"> Individual buffers: 32 buffers (16 buffers × 2 channels) <ul style="list-style-type: none"> Transmit buffer: 16 buffers per channel Transmit queue: Single queue per channel (shared with the transmit buffer; up to 16 buffers allocatable) Shared buffers: 128 buffers for all channels <ul style="list-style-type: none"> Receive buffer: 0 to 32 buffers Receive FIFO buffer: 8 FIFO buffers (up to 128 buffers allocatable to each) Transmit/receive FIFO buffer: 3 FIFO buffers per channel (up to 128 buffers allocatable to each) |
| Reception function | <ul style="list-style-type: none"> Receives data frames and remote frames. Selects ID format (standard ID, extended ID, or both IDs) to be received. Sets interrupt enable/disable for each FIFO. Mirror function (reception of messages transmitted from the own CAN node) Timestamp function (to record message reception time as a 16-bit timer value) |
| Reception filter function | <ul style="list-style-type: none"> Selects receive messages according to 128 receive rules. Sets the number of receive rules (0 to 128) for each channel. Acceptance filter processing: Sets ID and mask for each receive rule. DLC filter processing: Enables DLC filter check for each acceptance rule. |

| Item | Specification |
|-----------------------------------|--|
| Receive message transfer function | <ul style="list-style-type: none"> • Routing function Transfers receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, and/or transmit/receive FIFO buffer • Label addition function Stores label information together with a message in a receive buffer and FIFO buffer. |
| Transmission function | <ul style="list-style-type: none"> • Transmits data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted. • Sets interrupt enable/disable for each transmit buffer and transmit/receive FIFO buffer. • Selects ID priority transmission or transmit buffer number priority transmission. • Transmit request can be aborted (possible to confirm with a flag) • One-shot transmission function |
| Interval transmission function | Transmit messages at configurable intervals (transmit mode or gateway mode of transmit/receive FIFO buffers) |
| Transmit queue function | Transmits all stored messages according to the ID priority. |
| Transmit history function | Stores the history information of transmission-completed messages Adds timestamp (recording message transmission time as a 16-bit timer value) to the history information. |
| Gateway function | Transmits a received message automatically. |
| Bus off recovery mode selection | Selects the method for returning from bus off state. <ul style="list-style-type: none"> • ISO11898-1 compliant • Automatic entry to channel halt mode at bus-off entry • Automatic entry to channel halt mode at bus-off end • Transition to channel halt mode by program request • Transition to the error-active state by program request (forcible return from the bus off state) |
| Error status monitoring | <ul style="list-style-type: none"> • Monitors CAN protocol errors (stuff error, form error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock). • Detects error status transitions (error warning, error passive, bus off entry, and bus off recovery) • Reads the error counter. • Monitors DLC errors. |
| Interrupt source | 8 sources <ul style="list-style-type: none"> • Global Interrupts (2 sources) <ul style="list-style-type: none"> Receive FIFO interrupt Global error interrupt • Channel interrupts (3 sources/channel) <ul style="list-style-type: none"> CANm transmit interrupt (m = 0, 1) <ul style="list-style-type: none"> - CANm transmit complete interrupt - CANm transmit abort interrupt - CANm transmit/receive FIFO transmit complete interrupt (in transmit mode, gateway mode) - CANm transmit history interrupt - CANm transmit queue interrupt CANm transmit/receive FIFO receive complete interrupt (in receive mode, gateway mode) CANm error interrupt |
| CAN stop mode | Reduces power consumption by stopping clock supply to the RS-CANFD module. |
| CAN clock source | Selects the clk _c or the clk _{xincan} . As for the range of operating frequency, see Table 25.6 |
| Test function | Test function for user evaluation <ul style="list-style-type: none"> • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • Restricted operation mode • RAM test (read/write test) • Inter-channel communication test [CRC error test enabled] |

25.2.2 Interface Modes

The RS-CANFD has two interface modes.

- Classical CAN mode: Handles only classical CAN frames.
- CANFD mode: Handles classical CAN frames and CANFD frames.

These two modes use different register maps with the same base address. Register maps change by switching interface modes.

Interface modes are switched by the RCMC bit in the RSCFDn(CFD)GRMCFG register.

25.2.3 Block Diagram

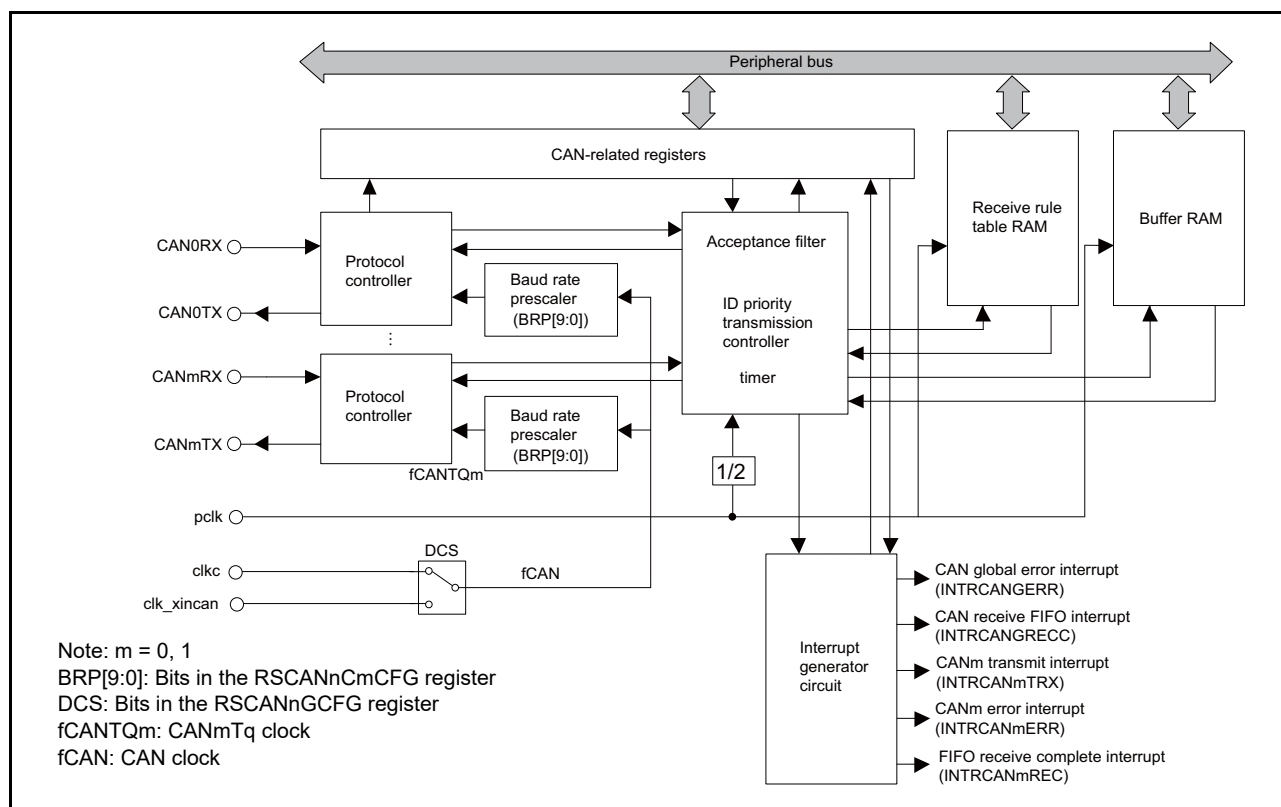

Figure 25.1 RS-CANFD Module Block Diagram (Classical CAN Mode)

In CANFD mode, different clock signals are input to the baud rate prescaler and the protocol controller respectively. See section 25.11.1.3, Communication Speed Setting.

25.3 Registers (Classical CAN Mode)

25.3.1 List of Registers

The following tables list RS-CANFD registers to be used in classical CAN mode.

For details about <RSCFDn_base>, see section 25.1.2, Register Base Address.

For registers initialized in global reset mode and channel reset mode, refer to the following.

- Table 25.176, Registers Initialized in Global Reset Mode or Channel Reset Mode
- Table 25.177, Registers Initialized Only in Global Reset Mode

Table 25.10 Registers

| Module | Register | Symbol | Address |
|---------------------------------------|--|---------------------------|---|
| Interface mode-related registers | | | |
| RSCANn | Global interface mode select register | RSCANnGRMCFG | <RSCFDn_base> + 04FC _H |
| Channel-related registers | | | |
| RSCANn | Channel m Configuration Register | RSCANnCmCFG | <RSCFDn_base> + 0000 _H + (10 _H × m) |
| RSCANn | Channel m control register | RSCANnCmCTR | <RSCFDn_base> + 0004 _H + (10 _H × m) |
| RSCANn | Channel m status register | RSCANnCmSTS | <RSCFDn_base> + 0008 _H + (10 _H × m) |
| RSCANn | Channel m error flag register | RSCANnCmERFL | <RSCFDn_base> + 000C _H + (10 _H × m) |
| Global-related registers | | | |
| RSCANn | Global configuration register | RSCANnGCFG | <RSCFDn_base> + 0084 _H |
| RSCANn | Global control register | RSCANnGCTR | <RSCFDn_base> + 0088 _H |
| RSCANn | Global status register | RSCANnGSTS | <RSCFDn_base> + 008C _H |
| RSCANn | Global error flag register | RSCANnGERFL | <RSCFDn_base> + 0090 _H |
| RSCANn | Global timestamp counter register | RSCANnGTSC | <RSCFDn_base> + 0094 _H |
| RSCANn | Global TX Interrupt Status Register 0 | RSCANnGTINTSTS0 | <RSCFDn_base> + 0460 _H |
| RSCANn | Global FD Configuration Register | RSCANnGFDCFG | <RSCFDn_base> + 0474 _H |
| Receive rule-related registers | | | |
| RSCANn | Receive Rule Entry Control Register | RSCANnGAFLECTR | <RSCFDn_base> + 0098 _H |
| RSCANn | Receive Rule Configuration Register 0 | RSCANnGAFLCFG0 | <RSCFDn_base> + 009C _H |
| RSCANn | Receive Rule ID Register j | RSCANnGAFLIDj | <RSCFDn_base> + 0500 _H + (10 _H × j) |
| RSCANn | Receive Rule Mask Register j | RSCANnGAFLMj | <RSCFDn_base> + 0504 _H + (10 _H × j) |
| RSCANn | Receive Rule Pointer 0 Register j | RSCANnGAFLP0_j | <RSCFDn_base> + 0508 _H + (10 _H × j) |
| RSCANn | Receive Rule Pointer 1 Register j | RSCANnGAFLP1_j | <RSCFDn_base> + 050C _H + (10 _H × j) |
| Receive buffer-related registers | | | |
| RSCANn | Receive Buffer Number Register | RSCANnRMNB | <RSCFDn_base> + 00A4 _H |
| RSCANn | Receive Buffer New Data Register y | RSCANnRMNDy | <RSCFDn_base> + 00A8 _H + (04 _H × y) |
| RSCANn | Receive Buffer ID Register q | RSCANnRMIDq | <RSCFDn_base> + 0600 _H + (10 _H × q) |
| RSCANn | Receive Buffer Pointer Register q | RSCANnRMPTRq | <RSCFDn_base> + 0604 _H + (10 _H × q) |
| RSCANn | Receive Buffer Data Field 0 Register q | RSCANnRMDf0_q | <RSCFDn_base> + 0608 _H + (10 _H × q) |
| RSCANn | Receive Buffer Data Field 1 Register q | RSCANnRMDf1_q | <RSCFDn_base> + 060C _H + (10 _H × q) |
| Receive FIFO buffer-related registers | | | |
| RSCANn | Receive FIFO Buffer Configuration and Control Register x | RSCANnRFCCx | <RSCFDn_base> + 00B8 _H + (04 _H × x) |
| RSCANn | Receive FIFO Buffer Status Register x | RSCANnRFSTSx | <RSCFDn_base> + 00D8 _H + (04 _H × x) |
| RSCANn | Receive FIFO Buffer Pointer Control Register x | RSCANnRFPCTR _x | <RSCFDn_base> + 00F8 _H + (04 _H × x) |
| RSCANn | Receive FIFO Buffer Access ID Register x | RSCANnRFID _x | <RSCFDn_base> + 0E00 _H + (10 _H × x) |
| RSCANn | Receive FIFO Buffer Access Pointer Register x | RSCANnRFPTR _x | <RSCFDn_base> + 0E04 _H + (10 _H × x) |

| Module | Register | Symbol | Address |
|--|--|-----------------|---|
| RSCANn | Receive FIFO Buffer Access Data Field 0 Register x | RSCANnRFDF0_x | <RSCFDn_base> + 0E08 _H + (10 _H × x) |
| RSCANn | Receive FIFO Buffer Access Data Field 1 Register x | RSCANnRFDF1_x | <RSCFDn_base> + 0E0C _H + (10 _H × x) |
| Transmit/Receive FIFO buffer related registers | | | |

25.3.2 Details of Interface Mode-related Registers

25.3.2.1 RSCANnGRMCFG — Global Interface Mode Select Register

Access: RSCANnGRMCFG register can be read/written in 32-bit units
 RSCANnGRMCFG_L, RSCANnGRMCFG_H registers can be read/written in 16-bit units
 RSCANnGRMCFG_LL, RSCANnGRMCFG_LH, RSCANnGRMCFG_HL, RSCANnGRMCFG_HH registers can be read/written in 8-bit units

Address: RSCANnGRMCFG: <RSCFDn_base> + 04FC_H,
 RSCANnGRMCFG_L: <RSCFDn_base> + 04FC_H,
 RSCANnGRMCFG_H: <RSCFDn_base> + 04FE_H,
 RSCANnGRMCFG_LL: <RSCFDn_base> + 04FC_H,
 RSCANnGRMCFG_LH: <RSCFDn_base> + 04FD_H,
 RSCANnGRMCFG_HL: <RSCFDn_base> + 04FE_H,
 RSCANnGRMCFG_HH: <RSCFDn_base> + 04FF_H

Value after reset: 0000 0000_H

Table 25.15 RSCANnGRMCFG Register Contents

| Bit | Bit Name | Function |
|---------|----------|--|
| 31 to 1 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 0 | RCMC | Interface Mode Select 0: Classical CAN mode 1: CANFD mode |

Note 1. The RSCANnGRMCFG register and the RSCFDnCFDGRMCFG register are the same register. Therefore, set either one of the registers.

Modify the RSCANnGRMCFG register only in global reset mode. Before setting other RS-CANFD registers, set this register.

RCMC Bit

Setting this bit to 0 places the RS-CANFD module in classical CAN mode.

Setting this bit to 1 places the RS-CANFD module in CANFD mode. To switch CANFD mode to classical CAN mode, set the value after reset in all registers and bits allocated to the register map of CANFD mode and then modify the RSCANnGRMCFG register.

25.3.3 Details of Channel-related Registers

25.3.3.1 RSCANnCmCFG — Channel Configuration Register (m = 0, 1)

Access: RSCANnCmCFG register can be read/written in 32-bit units
 RSCANnCmCFGL, RSCANnCmCFGH registers can be read/written in 16-bit units
 RSCANnCmCFGLL, RSCANnCmCFGLH, RSCANnCmCFGHL, RSCANnCmCFGHH registers can be read/written in 8-bit units

Address: RSCANnCmCFG: <RSCFDn_base> + 0000_H + (10_H × m)
 RSCANnCmCFGL: <RSCFDn_base> + 0000_H + (10_H × m),
 RSCANnCmCFGH: <RSCFDn_base> + 0002_H + (10_H × m)
 RSCANnCmCFGLL: <RSCFDn_base> + 0000_H + (10_H × m),
 RSCANnCmCFGLH: <RSCFDn_base> + 0001_H + (10_H × m),
 RSCANnCmCFGHL: <RSCFDn_base> + 0002_H + (10_H × m),
 RSCANnCmCFGHH: <RSCFDn_base> + 0003_H + (10_H × m)

| 15 to 10 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 9 to 0 | BRP[9:0] | Prescaler Division Ratio Set When these bits are set to P (0 to 1023), the baud rate prescaler divides fCAN by P + 1. |

Modify the RSCANnCMCFG register in channel reset mode or channel halt mode. Set this register in channel reset mode before shifting to channel communication mode or channel halt mode. For a description of the bit timing parameters and settings, see section 25.11.1, Initial Settings.

SJW[1:0] Bits

These bits are used to specify a Tq value for the resynchronization jump width. Allowed values are 1 Tq to 4 Tq, inclusive.

Set a value less than or equal to the value of the TSEG2 bits.

TSEG2[2:0] Bits

These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2).

Allowed values are 2 Tq to 8 Tq, inclusive.

Set a value smaller than the value of the TSEG1 bits.

TSEG1[3:0] Bits

These bits are used to specify a Tq value for the total length of the propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1).

Allowed values are 4 Tq to 16 Tq, inclusive.

BRP[9:0] Bits

The CANmTq clock (fCANTQm) is calculated by dividing the CAN clock (fCAN) by the baud rate prescaler, ((BRP[9:0]) + 1). One clock cycle of the CANmTq clock is 1 Time Quantum (Tq).

25.3.3.2 RSCANnCmCTR — Channel Control Register (m = 0, 1)

Access: RSCANnCmCTR register can be read/written in 32-bit units
 RSCANnCmCTRL, RSCANnCmCTRH registers can be read/written in 16-bit units
 RSCANnCmCTRLH, RSCANnCmCTRLH, RSCANnCmCTRHL, RSCANnCmCTRHH registers can be read/written in 8-bit units

Address: RSCANnCmCTR: <RSCFDn_base> + 0004_H + (10_H × m)
 RSCANnCmCTRL: <RSCFDn_base> + 0004_H + (10_H × m),
 RSCANnCmCTRH: <RSCFDn_base> + 0006_H + (10_H × m)
 RSCANnCmCTRLH: <RSCFDn_base> + 0004_H + (10_H × m),
 RSCANnCmCTRLH: <RSCFDn_base> + 0005_H + (10_H × m),
 RSCANnCmCTRHL: <RSCFDn_base> + 0006_H + (10_H × m),
 RSCANnCmCTRHH: <RSCFDn_base> + 0007_H + (10_H × m)

Value after reset: 0000 0005_H

| 7 to 4 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 3 | RTBO | Forcible Return from Bus-off When this bit is set to 1, forcible return from the bus off state is made. This bit is always read as 0. |
| 2 | CSLPR | Channel Stop Mode 0: Other than channel stop mode 1: Channel stop mode |
| 1, 0 | CHMDC[1:0] | Mode Select b1 b0 0 0: Channel communication mode 0 1: Channel reset mode 1 0: Channel halt mode 1 1: Setting prohibited |

CRCT Bit

This bit is used to test the CRC generation circuit in the RS-CANFD module. Setting this bit to 1 inverts the first bit of the ID field when a message is received. With this inversion of bit, the CRC calculation result does not match the normal CRC value of the received frame, which can detect a CRC error (the CERR bit in the RSCANnCMERFL register is 1). When using this function, note the following.

- This function is available while the CTME bit in the RSCANnCMCTR register is 1 (communication test mode enabled).
- This function cannot communicate with other CAN nodes. Use this function for inter-channel communication test (the CmICBCE bit in the RSCANnGTSTCFG register is 1).
- Bit inversion in the ID field may cause bit stuffing rule violation. In that case, no CRC error is detected but a stuff error is detected.

Modify this bit only in channel halt mode. This bit is always 0 in channel reset mode.

CTMS[1:0] Bit

These bits are used to select a communication test mode. Modify these bits in channel halt mode only. These bits are set to 0 in channel reset mode.

CTME Bit

Setting this bit to 1 enables communication test mode. Modify this bit in channel halt mode. This bit is set to 0 in channel reset mode.

ERRD Bit

This bit is used to control the display mode of bits 14 to 8 in the RSCANnCMERFL register.

When this bit is clear to 0, if any error is detected while the flags of bits 14-8 in the RSCANnCMERFL register are all 0, only the flags of the first error event are set to 1. If two or more errors occur in the first error event, all the flags of the detected errors are set to 1.

When this bit is set to 1, all the flags of errors that have occurred are set to 1 regardless of the error occurrence order. Modify this bit only in channel reset mode or channel halt mode.

BOM[1:0] Bit

These bits are used to select the bus off recovery mode of the RS-CANFD module.

When the BOM[1:0] bits are set to 00B, return from the bus off state to the error active state is compliant with the CAN specifications. That is, the RS-CANFD module reenters the CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. A bus off recovery interrupt request is generated at the time of return from the bus off state. Even if the CHMDC[1:0] bits are set to 10B (channel halt mode) before recessive bits are detected 128 times, the RS-CANFD module does not transition to channel halt mode until recessive bits are detected 128 times.

When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to 01B, the CHMDC[1:0] bits in the RSCFDnCMCTRRSCANnCMCTR register (m = 0, 1) are set to 10B and the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated and the TEC[7:0] and REC[7:0] bits in the RSCFDnCMSTRRSCANnCMSTS register are cleared to 00H.

When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to 10B, the CHMDC[1:0] bits are set to 10B and the RS-CANFD module transitions to channel halt mode after return from the bus off state (11 consecutive recessive bits are detected 128 times). A bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00H.

When the BOM[1:0] bits are set to 11B and the CHMDC[1:0] bits are set to 10B while the RS-CANFD module is in the bus off state, the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00H. However, if 11 consecutive recessive bits are detected 128 times and the RS-CANFD module has recovered to the error active state from the bus off state before the CHMDC[1:0] bits are set to 10B, a bus off recovery interrupt request is generated.

If a program writes to the CHMDC[1:0] bit at the same time as the RS-CANFD module transition to channel halt mode (at bus off entry when the BOM[1:0] bits are 01B or at bus off end when the BOM[1:0] bits are 10B), the program's writing takes precedence. Modify the BOM[1:0] bits only in channel reset mode.

TAIE Bit

When transmit abort of the transmit buffer is completed with the TAIE bit set to 1, an interrupt request is generated. Modify this bit only in channel reset mode.

ALIE Bit

When the ALF flag in the RSCANnCMERFL register is set to 1 with the ALIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BLIE Bit

When the BLF flag in the RSCANnCMERFL register is set to 1 with the BLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

OLIE Bit

When the OVLF flag in the RSCANnCMERFL register is set to 1 with the OLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BORIE Bit

When the BORF flag in the RSCANnCMERFL register is set to 1 with the BORIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BOEIE Bit

When the BOEF flag in the RSCANnCMERFL register is set to 1 with the BOEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

EPIE Bit

When the EPF flag in the RSCANnCMERFL register is set to 1 with the EPIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

EWIE Bit

When the EWF flag in the RSCANnCMERFL register is set to 1 with the EWIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BEIE Bit

When the BEF flag in the RSCANnCMERFL register is set to 1 with the BEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

RTBO Bit

Setting this bit to 1 in the bus off state forcibly returns the state from the bus off state to the error active state. This bit is automatically cleared to 0. Setting this bit to 1 clears the TEC[7:0] and REC[7:0] bits in the RSCANnCMSTS register to 00H and also clears the BOSTS flag in the RSCANnCMSTS register to 0 (not in bus off state). The other registers remain unchanged. No bus off recovery interrupt request is generated upon return from the bus off state in this case. Use this bit only when the BOM[1:0] bits in the RSCANnCMCTR register are 00B (ISO11898-1 compliant).

A delay of up to 1 CAN bit time occurs after the RTBO bit is set to 1 until the RSCAN module transitions to the error active state. Set this bit to 1 in channel communication mode.

CSLPR Bit

Setting this bit to 1 places the channel into channel stop mode.

Clearing this bit to 0 makes the channel exit channel stop mode.

This bit should not be modified in channel communication mode or channel halt mode.

CHMDC[1:0] Bit

These bits are used to select a channel mode (channel communication mode, channel reset mode, or channel halt mode). For details, see [section 25.6.2, Channel Modes](#). Setting the CSLPR bit to 1 in channel reset mode allows transition to channel stop mode. Do not set the CHMDC[1:0] bits to 11B. When the CAN module has automatically transitioned to channel halt mode based on the setting of the BOM[1:0] bits, the CHMDC[1:0] bits automatically become 10_B.

25.3.3.3 RSCANnCmSTS — Channel Status Register (m = 0, 1)

Access: RSCANnCmSTS register can be read only in 32-bit units
 RSCANnCmSTSL, RSCANnCmSTSH registers can be read only in 16-bit units
 RSCANnCmSTSLL, RSCANnCmSTSLH, RSCANnCmSTSHL, RSCANnCmSTSHH registers can be read only in 8-bit units

Address: RSCANnCmSTS: <RSCFDn_base> + 0008_H + (10_H × m)
 RSCANnCmSTSL: <RSCFDn_base> + 0008_H + (10_H × m),
 RSCANnCmSTSH: <RSCFDn_base> + 000A_H + (10_H × m)
 RSCANnCmSTSLL: <RSCFDn_base> + 0008_H + (10_H × m),
 RSCANnCmSTSLH: <RSCFDn_base> + 0009_H + (10_H × m),
 RSCANnCmSTSHL: <RSCFDn_base> + 000A_H + (10_H × m),
 RSCANnCmSTSHH: <RSCFDn_base> + 000B_H + (10_H × m)

Value after reset: 0000 0005_H

Table 25.18 RSCANnCmSTS Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 24 | TEC[7:0] | The transmit error counter (TEC) can be read. |
| 23 to 16 | REC[7:0] | The receive error counter (REC) can be read. |
| 15 to 8 | Reserved | These bits are read as the value after reset. |
| 7 | COMSTS | Communication Status Flag 0: Communication is not ready. 1: Communication is ready. |
| 6 | RECSTS | Receive Status Flag 0: Bus idle, in transmission or bus off state 1: In reception |
| 5 | TRMSTS | Transmit Status Flag 0: Bus idle or in reception 1: In transmission or bus off state |
| 4 | BOSTS | Bus Off Status Flag 0: Not in bus off state 1: In bus off state |
| 3 | EPSTS | Error Passive Status Flag 0: Not in error passive state 1: In error passive state |
| 2 | CSLPSTS | Channel Stop Status Flag 0: Not in channel stop mode 1: In channel stop mode |
| 1 | CHLTSTS | Channel Halt Status Flag 0: Not in channel halt mode 1: In channel halt mode |
| 0 | CRSTSTS | Channel Reset Status Flag 0: Not in channel reset mode 1: In channel reset mode |

TEC[7:0] Bits

These bits contain the transmit error counter value. For transmit error counter increment/decrement conditions, see the CAN specification (ISO11898-1).

These bits are cleared to 0 in channel reset mode.

REC[7:0] Bits

These bits contain the receive error counter value. For receive error counter increment/decrement conditions, see the CAN specifications (ISO11898-1).

These bits are cleared to 0 in channel reset mode.

COMSTS Flag

This bit indicates that communication is ready.

This flag becomes 1 when the CAN module has detected 11 consecutive recessive bits after it has transitioned from channel reset mode or channel halt mode to channel communication mode. This flag is cleared to 0 in channel reset mode or channel halt mode.

RECSTS Flag

This flag is set to 1 when reception has started, and is cleared to 0 when the bus has become idle or transmission has started.

TRMSTS Flag

This flag is set to 1 when transmission has started, and is cleared to 0 when the bus has become idle or reception has started. This flag remains 1 in the bus off state.

BOSTS Flag

This flag is set to 1 when the bus off state ($TEC[7:0] > 255$) is entered. It is cleared to 0 when the CAN module has exited the bus off state.

EPSTS Flag

This flag is set to 1 when the RS-CANFD module has entered the error passive state ($(128 \leq TEC[7:0] \leq 255)$ or $(128 \leq REC[7:0])$), It is cleared to 0 when the RS-CANFD module has exited the error passive state or has entered channel reset mode.

CSLPSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel stop mode, and is cleared to 0 when the CAN module has returned from channel stop mode.

CHLTSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel halt mode, and is cleared to 0 when the CAN module has returned from channel halt mode.

CRSTSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel reset mode, and is cleared to 0 when the CAN module has transitioned to channel communication mode or channel halt mode. This flag remains 1 when the CAN module transitions from channel reset mode to channel stop mode.

25.3.3.4 RSCANnCmERFL — Channel Error Flag Register (m = 0, 1)

Access: RSCANnCmERFL register can be read/written in 32-bit units
 RSCANnCmERFLL, RSCANnCmERFLH registers can be read/written in 16-bit units
 RSCANnCmERFLLL, RSCANnCmERFLLH, RSCANnCmERFLHL, RSCANnCmERFLHH registers can be read/written in 8-bit units

Address: RSCANnCmERFL: <RSCFDn_base> + 000C_H + (10_H × m)
 RSCANnCmERFLL: <RSCFDn_base> + 000C_H + (10_H × m),
 RSCANnCmERFLH: <RSCFDn_base> + 000E_H + (10_H × m)
 RSCANnCmERFLLL: <RSCFDn_base> + 000C_H + (10_H × m),
 RSCANnCmERFLLH: <RSCFDn_base> + 000D_H + (10_H × m),
 RSCANnCmERFLHL: <RSCFDn_base> + 000E_H + (10_H × m),
 RSCANnCmERFLHH: <RSCFDn_base> + 000F_H + (10_H × m)

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|--------------|-------|-------|------|------|------|------|------|------|------|------|------|------|------|------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | CRCREG[14:0] | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | ADERR | B0ERR | B1ERR | CERR | AERR | FERR | SERR | ALF | BLF | OVLf | BORF | BOEF | EPF | EWf | BEF |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* |

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.19 RSCANnCmERFL Register Contents

| Bit | Bit Name | Function |
|----------|---------------|---|
| 31 | Reserved | When read, the value after reset is returned. When writing to this bit, write the value after reset. |
| 30 to 16 | CRCREG [14:0] | CRC Calculation Data A CRC value calculated based on the transmit message or receive message is indicated. |
| 15 | Reserved | When read, the value after reset is returned. When writing to this bit, write the value after reset. |
| 14 | ADERR | ACK Delimiter Error Flag 0: No ACK delimiter error is detected. 1: ACK delimiter error is detected. |
| 13 | B0ERR | Dominant Bit Error Flag 0: No dominant bit error is detected. 1: Dominant bit error is detected. |
| 12 | B1ERR | Recessive Bit Error Flag 0: No recessive bit error is detected. 1: Recessive bit error is detected. |
| 11 | CERR | CRC Error Flag 0: No CRC error is detected. 1: CRC error is detected. |
| 10 | AERR | ACK Error Flag 0: No ACK error is detected. 1: ACK error is detected. |
| 9 | FERR | Form Error Flag 0: No form error is detected. 1: Form error is detected. |
| 8 | SERR | Stuff Error Flag 0: No stuff error is detected. 1: Stuff error is detected. |
| 7 | ALF | Arbitration-lost Flag 0: No arbitration-lost is detected. 1: Arbitration-lost is detected. |

| Bit | Bit Name | Function |
|-----|----------|--|
| 6 | BLF | Bus Lock Flag 0: No channel bus is detected. 1: Channel bus is detected. |
| 5 | OVLf | Overload Flag 0: No overload is detected. 1: Overload is detected. |
| 4 | BORF | Bus Off Recovery Flag 0: No bus off recovery is detected. 1: Bus off recovery is detected. |
| 3 | BOEF | Bus Off Entry Flag 0: No bus off entry is detected. 1: Bus off entry is detected. |
| 2 | EPF | Error Passive Flag 0: No error passive is detected. 1: Error passive is detected. |
| 1 | EWf | Error Warning Flag 0: No error warning is detected. 1: Error warning is detected. |
| 0 | BEF | Bus Error Flag 0: No channel bus error is detected. 1: Channel bus error is detected. |

See the CAN specification (ISO11898-1) for a description of error occurrence conditions. To clear each flag of this register, the program must write a 0 to the corresponding bit. These flags cannot be set to 1 by the program. If any of these flags is set to 0 at the same time that the program writes 0 to the flag, the flag is still set to 1. The channel reset mode transition clears all of these flags to 0.

If the ERRD bit in the RSCANnCMCTR register is set to 0 (ie, only the flags for the first error event are displayed) and an error related to bits 14 to 8 of RSCANnCMERFL is detected, the flag bits are only set by the error event if bits 14 to 8 were all 0 at the when time the error occurred.

CRCREG[14:0] Flag

When the CTME bit in the RSCANnCMCTR register is set to 1 (communication test mode is enabled), the CRC value calculated based on the transmit or receive message can be read. When the CTME bit is set to 0 (communication test mode is disabled), these bits are always read as 0. This bit is always 0 in channel reset mode.

ADERR Flag

This flag is set to 1 when a form error has been detected in the ACK delimiter during transmission.

B0ERR Flag

This flag is set to 1 when a recessive bit has been detected though a dominant bit was transmitted.

B1ERR Flag

This flag is set to 1 when a dominant bit has been detected though a recessive bit was transmitted.

CERR Flag

This flag is set to 1 when a CRC error has been detected.

AERR Flag

This flag is set to 1 when an ACK error has been detected.

FERR Flag

This flag is set to 1 when a form error has been detected.

SERR Flag

This flag is set to 1 when a stuff error has been detected.

ALF Flag

This flag is set to 1 when an arbitration-lost has been detected.

BLF Flag

This flag is set to 1 when 32 consecutive dominant bits have been detected on the CAN bus in channel communication mode. After that, detection of a dominant lock is restarted when either of the following conditions is met.

- A recessive bit is detected after the BLF bit has been cleared from 1 to 0.
- The CAN module transitions to channel reset mode and returns to channel communication mode after the BLF bit has been cleared from 1 to 0

OVLf Flag

This flag is set to 1 when the overload frame transmit condition has been detected when performing reception or transmission.

BORF Flag

This flag is set to 1 when 11 consecutive recessive bits have been detected 128 times and the CAN module returns from the bus off state. However, this flag is not set to 1 if the CAN module returns from the bus off state in any of the following ways before 11 consecutive recessive bits are detected 128 times.

- The CHMDC[1:0] bits in the RSCANnCMCTR register are set to 01B (channel reset mode).
- The RTBO bit in the RSCANnCMCTR register is set to 1 (forcible return from the bus off state is made).
- The BOM[1:0] bits in the RSCANnCMCTR register are set to 01B (transition to channel halt mode at bus off entry).
- The CHMDC[1:0] bits in the RSCANnCMCTR register are set to 10B (channel halt mode) before 11 consecutive recessive bits are detected 128 times with the BOM[1:0] bits set to 11B (transition to channel halt mode upon a request from the program during bus off).

BOEF Flag

This flag is set to 1 when the bus off state is reached (TEC[7:0] value > 255). This flag is also set to 1 if the bus off state is reached when the BOM[1:0] bits in the RSCANnCMCTR register (m = 0, 1) set to 01B (transition to channel halt mode at bus off entry).

EPF Flag

This flag becomes 1 when the error passive state is reached (REC[7:0] or TEC[7:0] value > 127).

This flag becomes 1 only when the REC[7:0] or TEC[7:0] value first exceeds 127. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 127, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 127 or less and then the REC[7:0] or TEC[7:0] value exceeds 127 again.

EWf Flag

This flag is set to 1 only when the REC[7:0] or TEC[7:0] value first exceeds 95. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 95, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 95 or less and then the REC[7:0] or TEC[7:0] value exceeds 95 again.

BEF Flag

This flag is set to 1 when any one of the ADERR, B0ERR, B1ERR, CERR, AERR, FERR, and SERR flags in the RSCANnCmERFL register is set to 1.

Note: To clear the flag of this register to 0, use a store instruction to write “0” to the given flag and “1” to the other flags.

25.3.4 Details of Global-related Registers

25.3.4.1 RSCANnGCFG — Global Configuration Register

Access: RSCANnGCFG register can be read/written in 32-bit units
 RSCANnGCFGL, RSCANnGCFGH registers can be read/written in 16-bit units
 RSCANnGCFGLL, RSCANnGCFGLH, RSCANnGCFGHL, RSCANnGCFGHH registers can be read/written in 8-bit units

Address: RSCANnGCFG: <RSCFDn_base> + 0084_H
 RSCANnGCFGL: <RSCFDn_base> + 0084_H, RSCANnGCFGH: <RSCFDn_base> + 0086_H
 RSCANnGCFGLL: <RSCFDn_base> + 0084_H, RSCANnGCFGLH: <RSCFDn_base> + 0085_H,
 RSCANnGCFGHL: <RSCFDn_base> + 0086_H, RSCANnGCFGHH: <RSCFDn_base> + 0087_H

Value after reset: 0000 0000_H

| Bit | Bit Name | Function |
|------|----------|--|
| 7 | TMTSCE | Transmission Timestamp Enable 0: Transmission timestamp is disabled. 1: Transmission timestamp is enabled. |
| 6, 5 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 4 | DCS | CAN Clock Source Select*2 0: clk _c 1: clk _{xincan} |
| 3 | MME | Mirror Function Enable 0: Mirror function is disabled. 1: Mirror function is enabled. |
| 2 | DRE | DLC Replacement Enable 0: DLC replacement is disabled. 1: DLC replacement is enabled. |
| 1 | DCE | DLC Check Enable 0: DLC check is disabled. 1: DLC check is enabled. |
| 0 | TPRI | Transmit Priority Select 0: ID priority 1: Transmit buffer number priority |

Note 1. When specifying pclk/2 as the timestamp counter count source, set bits TSBTCS[2:0] to 000B.

Note 2. For the CAN clock frequency settings, see section 25.1.3, Clock Supply.

Modify the RSCANnGCFG register only in global reset mode.

ITRCP[15:0] Bits

These bits are used to set a clock source division value of the interval timer for FIFO buffers. See section 25.8.3.1, Interval Transmission Function.

TSBTCS[2:0] Bits

When the TSSS bit is 1, these bits are used to select the channel of the bit time clock that will be the clock source of the timestamp counter.

TSSS Bits

This bit is used to select a clock source of the timestamp counter.

TSP[3:0] Bits

A clock obtained by dividing the clock source selected with the TSBTCS[2:0] bits and TSSS bit according to the TSP[3:0] bits is used as the timestamp counter count source.

TMTSCE Bits

Setting this bit to 1 makes it possible to store the timestamp of a transmitted message in the transmit history buffer. The timestamp is stored in TMTS[15:0] bits in the RSCANnTHLACCm register.

DCS Bits

When this bit is set to 0, clk_c is used as the clock source of the CAN clock (fCAN).

When this bit is set to 1, clk_{xincan} is used as the clock source of the CAN clock (fCAN).

For the CAN clock frequency settings, see Table 25.6.

MME Bits

Setting this bit to 1 makes the mirror function available.

DRE Bits

When the DRE bit is set to 1, the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message after the DLC value has passed through the DLC filter. In this case, a value of 00H is stored in each data byte beyond the DLC value of the receive rule.

The DLC replacement function is only available when the DCE bit is set to 1 (DLC check is enabled).

DCE Bits

Setting this bit to 1 makes the DLC check function available. When disabling the DLC check function, set the GAFLDLC[3:0] bits in the RSCANnGAFLP0_j register to 0000B before clearing the DCE bit in the RSCANnGCFG register to 0.

TPRI Bits

This bit is used to set the transmit priority.

When this bit is set to 0, ID priority is selected and the transmit priority complies with the CAN bus arbitration rule (ISO11898-1 specifications). When this bit is set to 1, transmit buffer number priority is selected and the lowest transmit buffer number of those has the highest priority.

While the transmit queue is in use, this bit should be set to 0.

25.3.4.2 RSCANnGCTR — Global Control Register

Access: RSCANnGCTR register can be read/written in 32-bit units
 RSCANnGCTRL, RSCANnGCTRH registers can be read/written in 16-bit units
 RSCANnGCTRL, RSCANnGCTRLH, RSCANnGCTRLH, RSCANnGCTRLH registers can be read/written in 8-bit units

Address: RSCANnGCTR: <RSCFDn_base> + 0088_H
 RSCANnGCTRL: <RSCFDn_base> + 0088_H, RSCANnGCTRH: <RSCFDn_base> + 008A_H
 RSCANnGCTRL: <RSCFDn_base> + 0088_H, RSCANnGCTRLH: <RSCFDn_base> + 0089_H,
 RSCANnGCTRLH: <RSCFDn_base> + 008A_H, RSCANnGCTRLH: <RSCFDn_base> + 008B_H

Value after reset: 0000 0005_H

| | | | | | | | | | | | | | | | | |

Table 25.21 RSCANnGCTR Register Contents

| Bit | Bit Name | Function |
|----------|-----------|--|
| 31 to 17 | Reserved | When read, the value after reset is returned. When writing to these bits, write the value after reset. |
| 16 | TSRST | Timestamp Counter Reset Setting the TSRST bit to 1 resets the timestamp counter. This bit is always read as 0. |
| 15 to 11 | Reserved | When read, the value after reset is returned. When writing to these bits, write the value after reset. |
| 10 | THLEIE | Transmit History Buffer Overflow Interrupt Enable 0: Transmit history buffer overflow interrupt is disabled. 1: Transmit history buffer overflow interrupt is enabled. |
| 9 | MEIE | FIFO Message Lost Interrupt Enable 0: FIFO message lost interrupt is disabled. 1: FIFO message lost interrupt is enabled. |
| 8 | DEIE | DLC Error Interrupt Enable 0: DLC error interrupt is disabled. 1: DLC error interrupt is enabled. |
| 7 to 3 | Reserved | When read, the value after reset is returned. When writing to these bits, write the value after reset. |
| 2 | GSLPR | Global Stop Mode 0: Other than global stop mode 1: Global stop mode |
| 1, 0 | GMDC[1:0] | Global Mode Select b1 b0 0 0: Global operating mode 0 1: Global reset mode 1 0: Global test mode 1 1: Setting prohibited |

TSRST Bit

This bit is used to reset the timestamp counter. When this bit is set to 1, the RSCANnGTSCregister is cleared to 0000H.

THLEIE Bit

When the THLEIE bit is set to 1 and the THLES flag in the RSCANnGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

MEIE Bit

When the MEIE bit is set to 1 and the MES flag in the RSCANnGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

DEIE Bit

When the DEIE bit is set to 1 and the DEF flag in the RSCANnGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

GSLPR Bit

Setting this bit to 1 places the RSCAN module into global stop mode.

Clearing this bit to 0 makes the RSCAN module leave from global stop mode.

This bit should not be modified in global operating mode or global test mode.

GMDC[1:0] Bit

These bits are used to select the mode of entire RS-CANFD module (global operating mode, global reset mode, or global test mode). For details, see section 25.6.1, Global Modes. Setting the GSLPR bit to 1 when in global reset mode places the RS-CANFD module into global stop mode.

25.3.4.3 RSCANnGSTS — Global Status Register

Access: RSCANnGSTS register can be read only in 32-bit units
 RSCANnGSTSL, RSCANnGSTSH registers can be read only in 16-bit units
 RSCANnGSTSL, RSCANnGSTSLH, RSCANnGSTSHL, RSCANnGSTSHH registers can be read only in 8-bit units

Address: RSCANnGSTS: <RSCFDn_base> + 008C_H
 RSCANnGSTSL: <RSCFDn_base> + 008C_H, RSCANnGSTSH: <RSCFDn_base> + 008E_H
 RSCANnGSTSL: <RSCFDn_base> + 008C_H, RSCANnGSTSLH: <RSCFDn_base> + 008D_H,
 RSCANnGSTSHL: <RSCFDn_base> + 008E_H, RSCANnGSTSHH: <RSCFDn_base> + 008F_H

Value after reset: 0000 000D_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|--------------|-------------|-------------|-------------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.22 RSCANnGSTS Register Contents

| Bit | Bit Name | Function |
|---------|----------|--|
| 31 to 4 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 3 | GRAMINIT | CAN RAM Initialization Status Flag 0: CAN RAM initialization is completed. 1: CAN RAM initialization is ongoing. |
| 2 | GSLPSTS | Global Stop Status Flag 0: Not in global stop mode 1: In global stop mode |
| 1 | GHLTSTS | Global Test Status Flag 0: Not in global test mode 1: In global test mode |
| 0 | GRSTSTS | Global Reset Status Flag 0: Not in global reset mode 1: In global reset mode |

GRAMINIT Flag

This flag indicates the initialization status of the CAN RAM.

This flag is set to 1 after the MCU has been reset, and is cleared to 0 when CAN RAM initialization is completed.

GSLPSTS Flag

This flag is set to 1 when the CAN module has transitioned to global stop mode, and is cleared to 0 when the CAN module has returned from global stop mode.

GHLTSTS Flag

This flag is set to 1 when the CAN module has transitioned to global test mode, and is cleared to 0 when the CAN module has exited global test mode.

GRSTSTS Flag

This flag is set to 1 when the CAN module has transitioned to global reset mode, and is cleared to 0 when the CAN module has exited global reset mode. This flag remains 1 even when the CAN module has transitioned from global reset mode to global stop mode.

25.3.4.4 RSCANnGERFL — Global Error Flag Register

Access: RSCANnGERFL register can be read/written in 32-bit units
 RSCANnGERFLL, RSCANnGERFLH registers can be read/written in 16-bit units
 RSCANnGERFLLL, RSCANnGERFLLH, RSCANnGERFLHL, RSCANnGERFLHH registers can be read/written in 8-bit units

Address: RSCANnGERFL: <RSCFDn_base> + 0090_H
 RSCANnGERFLL: <RSCFDn_base> + 0090_H, RSCANnGERFLH: <RSCFDn_base> + 0092_H
 RSCANnGERFLLL: <RSCFDn_base> + 0090_H, RSCANnGERFLLH: <RSCFDn_base> + 0091_H,
 RSCANnGERFLHL: <RSCFDn_base> + 0092_H, RSCANnGERFLHH: <RSCFDn_base> + 0093_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|---|---|---|---|---|---|---|-------|-----|------|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | THLES | MES | DEF |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W* |

Note: The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.23 RSCANnGERFL Register Contents

| Bit | Bit Name | Function |
|----------------------|----------|---|
| 31 to 14, 7, 6, 4, 3 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 13 to 8, 5 | Reserved | When read, an undefined value is returned. The write value should be the value after reset. |
| 2 | THLES | Transmit History Buffer Overflow Status Flag 0: No transmit history buffer overflow has occurred. 1: A transmit history buffer overflow has occurred. |
| 1 | MES | FIFO Message Lost Status Flag 0: No FIFO message lost error has occurred. 1: A FIFO message lost error has occurred. |
| 0 | DEF | DLC Error Flag 0: No DLC error has occurred. 1: A DLC error has occurred. |

All flags in the RSCANnGERFL register are cleared to 0 in global reset mode.

THLES Flag

The THLES flag is set to 1 when any one of the THLELT flags in the RSCANnTHLSTSm register (m = 0, 1) is set to 1. This flag is cleared to 0 when the THLELT flags of all channels are set to 0.

MES Flag

The MES flag is set to 1 when any one of the RFMLT flags in the RSCANnRFSTStx register (x = 0 to 7) or the CFMLT flags in the RSCANnCFSTSk register (k = 0 to 5) is set to 1.

This flag is cleared to 0 when all RFMLT flags and CFMLT flags are set to 0.

DEF Flag

The DEF flag is set to 1 when an error has been detected during the DLC check. The program can clear this flag by writing 0 to this bit.

Note: To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to "0" to "0", and the bits not to be set to "0" to "1"

25.3.4.5 RSCANnGTSC — Global Timestamp Counter Register

Access: RSCANnGTSC register can be read only in 32-bit units.
RSCANnGTSC_L, RSCANnGTSC_H registers can be read only in 16-bit units.

Address: RSCANnGTSC: <RSCFDn_base> + 0094_H
RSCANnGTSC_L: <RSCFDn_base> + 0094_H, RSCANnGTSC_H: <RSCFDn_base> + 0096_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | TS[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.24 RSCANnGTSC Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 16 | Reserved | These bits are read as the value after reset. |
| 15 to 0 | TS[15:0] | Timestamp Value The timestamp counter value can be read. Counter Value: 0000 _H to FFFF _H |

TS[15:0] Bits

When the TS[15:0] bits are read, the read value shows the timestamp counter (16-bit free-running counter) value at that time. When the SOF is detected, the TS[15:0] value is captured and later stored in the receive buffer or the FIFO buffer. Furthermore, while the TMTSCE bit in the RSCANnGCFG register is 1, the TS[15:0] value is stored in the transmit history buffer. The timestamp counter is initialized in global reset mode.

The timestamp counter start timing and stop timing depend on the count source.

- When the TSSS bit in the GRSCANnGCFG register is 0 (pclk):
The timestamp counter starts counting when the RSCAN module has transitioned to global operating mode.
This counter stops counting when the RSCAN module has transitioned to global stop mode or global test mode.
- When the TSSS bit is 1 (CANm bit time clock):
The timestamp counter starts counting when the corresponding channel has transitioned to channel communication mode.
This counter stops counting when the corresponding channel has transitioned to channel reset mode or channel halt mode.

25.3.4.6 RSCANnGTINTSTS0 — Global TX Interrupt Status Register 0

Access: RSCANnGTINTSTS0 register can be read only in 32-bit units
 RSCANnGTINTSTS0L, RSCANnGTINTSTS0H registers can be read only in 16-bit units
 RSCANnGTINTSTS0LL, RSCANnGTINTSTS0LH, RSCANnGTINTSTS0HL, RSCANnGTINTSTS0HH registers can be read only in 8-bit units

Address: RSCANnGTINTSTS0: <RSCFDn_base> + 0460_H
 RSCANnGTINTSTS0L: <RSCFDn_base> + 0460_H, RSCANnGTINTSTS0H: <RSCFDn_base> + 0462_H
 RSCANnGTINTSTS0LL: <RSCFDn_base> + 0460_H, RSCANnGTINTSTS0LH: <RSCFDn_base> + 0461_H,
 RSCANnGTINTSTS0HL: <RSCFDn_base> + 0462_H, RSCANnGTINTSTS0HH: <RSCFDn_base> + 0463_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|-------|--------|-------|-------|-------|----|----|----|-------|--------|-------|-------|-------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | THIF1 | CFTIF1 | TQIF1 | TAIF1 | TSIF1 | — | — | — | THIF0 | CFTIF0 | TQIF0 | TAIF0 | TSIF0 |

| R/W: | R | R | R | R* | R* | R* | R* | R* | R | R | R | R* | R* | R* | R* | R* |

Note 1. This bit is automatically cleared in the global reset or channel reset mode.

Table 25.25 RSCANnGTINTSTS0 Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 13 | Reserved | These bits are read as the value after reset. |
| 12 | THIF1 | Channel 1 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested. |
| 11 | CFTIF1 | Channel 1 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested. |
| 10 | TQIF1 | Channel 1 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested. |
| 9 | TAIF1 | Channel 1 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested. |
| 8 | TSIF1 | Channel 1 Transmit Buffer Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested. |
| 7 to 5 | Reserved | These bits are read as the value after reset. |
| 4 | THIF0 | Channel 0 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested. |
| 3 | CFTIF0 | Channel 0 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested. |
| 2 | TQIF0 | Channel 0 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested. |
| 1 | TAIF0 | Channel 0 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested. |

| Bit | Bit Name | Function |
|-----|----------|---|
| 0 | TSIF0 | Channel 0 Transmit Buffer Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested. |

TSIFm Bits

The TSIFm bit is set to 1 when the TMIEp bit in the RSCANnTMIECy register is set to 1 (transmit buffer interrupt enabled) and the TMTRF[1:0] flags in the RSCANnTMSTSp register are set to 10B (transmit completed without abort request) or 11B (transmit completed with abort request).

When the TMTRF[1:0] flags are cleared to 00B under the condition that the TSIFm bit can be set to 1, this flag is cleared to 0. In addition, clearing the TMIEp bit to 0 also clears this flag to 0.

TAIFm Bits

The TAIFm bit is set to 1 when the TAIE bit in the RSCANnCmCTR register is 1 (transmit abort interrupt enabled) and the TMTRF[1:0] flags in the RSCANnTMSTSp register are set to 01B (transmit abort completed).

This flag is cleared to 0 when the TMTRF[1:0] flags are cleared to 00B after the transmit abort is completed.

TQIFm Bits

When the TXQIE bit in the RSCANnTXQCCm register is set to 1 (transmit queue interrupt enabled) and the TXQIF bit in the RSCANnTXQSTSm register is set to 1 (transmit queue interrupt request), the TQIFm bit is set to 1.

When the TXQIF bit (transmit queue interrupt request) in the RSCANnTXQSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the TXQIE bit is cleared to 0.

CFTIFm Bits

When the CFTXIE bit in the RSCANnCFCCk register is set to 1 (transmit/receive FIFO transmit interrupt enabled) and the CFTXIF bit in the RSCANnCFSTSk register is set to 1 (transmit/receive FIFO transmit interrupt request), the CFTIFm bit is set to 1.

When the CFTXIF bit is cleared to 0 under the conditions that the CFTIFm bit can be set to 1, this bit is cleared to 0. This flag is also cleared to 0 when the CFTXIE bit is cleared to 0.

THIFm Bits

When the THLIE bit in the RSCANnTHLCCm register is set to 1 (transmit history interrupt enabled) and the THLIF bit in the RSCANnTHLSTSm register is set to 1 (transmit history interrupt request), the THIFm bit is set to 1.

When the THLIF bit in the RSCANnTHLSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the THLIE bit is cleared to 0.

25.3.4.7 RSCANnGFDCFG — Global FD configuration register

Access: RSCANnGFDCFG register can be read/written in 32-bit unit
 RSCANnGFDCFG L and RSCANnGFDCFG H registers can be read/written in 16-bit unit
 RSCANnGFDCFG LL, RSCANnGFDCFG LH, RSCANnGFDCFG HL, RSCANnGFDCFG HH registers can be read/written in 8-bit unit

Address: RSCANnGFDCFG: <RSCFDn_base> + 0474_H
 RSCANnGFDCFG L: <RSCFDn_base> + 0474_H, RSCANnGFDCFG H: <RSCFDn_base> + 0476_H
 RSCANnGFDCFG LL: <RSCFDn_base> + 0474_H, RSCANnGFDCFG LH: <RSCFDn_base> + 0475_H,
 RSCANnGFDCFG HL: <RSCFDn_base> + 0476_H, RSCANnGFDCFG HH: <RSCFDn_base> + 0477_H

Value after reset: 0000 0000_H

Table 25.26 RSCANnGFDCFG Register Contents

| Bit | Bit Name | Function |
|----------|-------------|---|
| 31 to 10 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 9, 8 | TSCCFG[1:0] | Time-stamp capture setting bit <div style="margin-left: 20px;"> b9 b8 0 0: Captured at a sample point in the SOF bit. 0 1: Captured when a valid frame has been transmitted/received. 1 0: Setting prohibited 1 1: Setting prohibited </div> |
| 7 to 1 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 0 | Reserved | When read, an undefined value is returned. The write value should be the value after reset. |

TSCCFG bit

Select a point where a time-stamp value is captured. Modify this bit only in global reset mode.

25.3.5 Details of Receive Rule-related Registers

25.3.5.1 RSCANnGAFLECTR — Receive Rule Entry Control Register

Access: RSCANnGAFLECTR register can be read/written in 32-bit units
 RSCANnGAFLECTRL, RSCANnGAFLECTRH registers can be read/written in 16-bit units
 RSCANnGAFLECTRL, RSCANnGAFLECTRLH, RSCANnGAFLECTRHL, RSCANnGAFLECTRHH registers can be read/written in 8-bit units

Address: RSCANnGAFLECTR: <RSCFDn_base> + 0098_H
 RSCANnGAFLECTRL: <RSCFDn_base> + 0098_H, RSCANnGAFLECTRH: <RSCFDn_base> + 009A_H
 RSCANnGAFLECTRL: <RSCFDn_base> + 0098_H, RSCANnGAFLECTRLH: <RSCFDn_base> + 0099_H,
 RSCANnGAFLECTRHL: <RSCFDn_base> + 009A_H, RSCANnGAFLECTRHH: <RSCFDn_base> + 009B_H

Value after reset: 0000 0000_H

Table 25.27 RSCANnGAFLECTR Register Contents

| Bit | Bit Name | Function |
|---------|------------|---|
| 31 to 9 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 8 | AFLDAE | Receive Rule Table Write Enable 0: Receive rule table write is disabled. 1: Receive rule table write is enabled. |
| 7 to 5 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 4 to 0 | AFLPN[4:0] | Receive Rule Table Page Number Configuration A page number can be selected from a range of page 0 (00000 _B) to page 7 (00111 _B). |

AFLDAE Bit

Setting this bit to 0 disables the write to the receive rule table. After writes to the receive rule table are completed, set this bit to 0 to disable the write to the table. The receive rule table can be read regardless of the value of this bit.

Set the AFLDAE bit to 1 only in global reset mode.

AFLPN[4:0] Bits

These bits are used to set the page number of the receive rule table. Sixteen receive rules can be set per page.

Set these bits to a value within the range of 00000_B to 00111_B.

25.3.5.2 RSCANnGAFLCFG0 — Receive Rule Configuration Register 0

Access: RSCANnGAFLCFG0 register can be read/written in 32-bit units
 RSCANnGAFLCFG0L, RSCANnGAFLCFG0H registers can be read/written in 16-bit units
 RSCANnGAFLCFG0LL, RSCANnGAFLCFG0LH, RSCANnGAFLCFG0HL, RSCANnGAFLCFG0HH registers can be read/written in 8-bit units

Address: RSCANnGAFLCFG0: <RSCFDn_base> + 009C_H
 RSCANnGAFLCFG0L: <RSCFDn_base> + 009C_H, RSCANnGAFLCFG0H: <RSCFDn_base> + 009E_H
 RSCANnGAFLCFG0LL: <RSCFDn_base> + 009C_H, RSCANnGAFLCFG0LH: <RSCFDn_base> + 009D_H,
 RSCANnGAFLCFG0HL: <RSCFDn_base> + 009E_H, RSCANnGAFLCFG0HH: <RSCFDn_base> + 009F_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |

Table 25.28 RSCANnGAFLCFG0 Register Contents

| Bit | Bit Name | Function |
|----------|-----------|--|
| 31 to 24 | RNC0[7:0] | Number of Rules for Channel 0 Set the number of receive rules exclusively used for channel 0. |
| 23 to 16 | RNC1[7:0] | Number of Rules for Channel 1 Set the number of receive rules exclusively used for channel 1. |
| 15 to 0 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |

Modify the RSCANnGAFLCFG0 register only in global reset mode.

Up to $64 \times$ (number of channels) rules can be registered in the receive rule table as the entire unit. The number of receive rules per channel should meet the following conditions.

- The maximum number of rules per channel is 128.
- The total of the number of rules allocated to each channel is not larger than the number of rules that can be registered in the entire unit.

RNC0[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 0 receive rule table.

Set these bits to a value within the range of 00_H to 80_H.

RNC1[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 1 receive rule table.

Set these bits to a value within the range of 00_H to 80_H.

25.3.5.3 RSCANnGAFLIDj — Receive Rule ID Register (j = 0 to 15)

Access: RSCANnGAFLIDj register can be read/written in 32-bit units
 RSCANnGAFLIDjL, RSCANnGAFLIDjH registers can be read/written in 16-bit units
 RSCANnGAFLIDjLL, RSCANnGAFLIDjLH, RSCANnGAFLIDjHL, RSCANnGAFLIDjHH registers can be read/written in 8-bit units

Address: RSCANnGAFLIDj: <RSCFDn_base> + 0500_H + (10_H × j)
 RSCANnGAFLIDjL: <RSCFDn_base> + 0500_H + (10_H × j),
 RSCANnGAFLIDjH: <RSCFDn_base> + 0502_H + (10_H × j)
 RSCANnGAFLIDjLL: <RSCFDn_base> + 0500_H + (10_H × j),
 RSCANnGAFLIDjLH: <RSCFDn_base> + 0501_H + (10_H × j),
 RSCANnGAFLIDjHL: <RSCFDn_base> + 0502_H + (10_H × j),
 RSCANnGAFLIDjHH: <RSCFDn_base> + 0503_H + (10_H × j)

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|--------------|---------|--------|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | GAFLIDE | GAFLRTR | GAFLLB | GAFLID[28:16] | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Table 25.29 RSCANnGAFLIDj Register Contents

| Bit | Bit Name | Function |
|---------|---------------|--|
| 31 | GAFLIDE | IDE Select 0: Standard ID 1: Extended ID |
| 30 | GAFLRTR | RTR Select 0: Data frame 1: Remote frame |
| 29 | GAFLLB | Receive Rule Target Message Select 0: When a message transmitted from another CAN node is received 1: When the own transmitted message is received |
| 28 to 0 | GAFLID [28:0] | ID Set the ID of the receive rule. For the standard ID, set the ID in bits b10 to b0 and set bits b28 to b11 to 0. |

Modify the RSCANnGAFLIDj register when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLIDE Bit

This bit is used to select the ID format (standard ID or extended ID) of the receive rule. This bit is compared with the IDE bit in the received message during the acceptance filter processing.

GAFLRTR Bit

This bit is used to select the frame format (data frame or remote frame) of the receive rule. This bit is compared with the RTR bit in the received message during the acceptance filter processing.

GAFLLB Bit

When this bit is set to 0, data processing using the receive rule is performed when receiving messages transmitted from another CAN node.

When this bit is set to 1 when the mirror function is used, data processing using the receive rule is performed when the CAN node is receiving its own transmitted messages.

GAFLID[28:0] Bits

These bits are used to set the ID field of the receive rule. The ID value set by these bits is compared with the ID of the received message during the acceptance filter processing.

25.3.5.4 RSCANnGAFLMj — Receive Rule Mask Register (j = 0 to 15)

Access: RSCANnGAFLMj register can be read/written in 32-bit units
 RSCANnGAFLMjL, RSCANnGAFLMjH registers can be read/written in 16-bit units
 RSCANnGAFLMjLL, RSCANnGAFLMjLH, RSCANnGAFLMjHL, RSCANnGAFLMjHH registers can be read/written in 8-bit units

Address: RSCANnGAFLMj: <RSCFDn_base> + 0504_H + (10_H × j)
 RSCANnGAFLMjL: <RSCFDn_base> + 0504_H + (10_H × j),
 RSCANnGAFLMjH: <RSCFDn_base> + 0506_H + (10_H × j)
 RSCANnGAFLMjLL: <RSCFDn_base> + 0504_H + (10_H × j),
 RSCANnGAFLMjLH: <RSCFDn_base> + 0505_H + (10_H × j),
 RSCANnGAFLMjHL: <RSCFDn_base> + 0506_H + (10_H × j),
 RSCANnGAFLMjHH: <RSCFDn_base> + 0507_H + (10_H × j)

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|---------------|--------------|-----|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | GAFL IDEM | GAFL RTRM | — | GAFLIDM[28:16] | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Table 25.30 RSCANnGAFLMj Register Contents

| Bit | Bit Name | Function |
|---------|-------------------|---|
| 31 | GAFLIDEM | IDE Mask 0: The IDE bit is not compared. 1: The IDE bit is compared. |
| 30 | GAFLRTRM | RTR Mask 0: The RTR bit is not compared. 1: The RTR bit is compared |
| 29 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 28 to 0 | GAFLIDM [28:0] | ID Mask 0: The corresponding ID bit is not compared. 1: The corresponding ID bit is compared. |

Modify the RSCANnGAFLMj register when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLIDEM Bit

When this bit is set to 1, filter processing is performed only for messages of the ID format specified by the GAFLIDE bit in the RSCANnGAFLIDj register.

When this bit is cleared to 0, the IDs of all the receive messages and the specified IDs are regarded as matched. To set the GAFLIDEM bit to 0, set the GAFLIDM[28:0] bits to all 0 at the same time.

GAFLRTRM Bit

This bit is used to mask the RTR bit of the receive rule.

GAFLIDM[28:0] Bits

These bits are used to mask the corresponding ID bit of the receive rule.

25.3.5.5 RSCANnGAFLP0_j — Receive Rule Pointer 0 Register (j = 0 to 15)

Access: RSCANnGAFLP0_j register can be read/written in 32-bit units
 RSCANnGAFLP0_jL, RSCANnGAFLP0_jH registers can be read/written in 16-bit units
 RSCANnGAFLP0_jLL, RSCANnGAFLP0_jLH, RSCANnGAFLP0_jHL, RSCANnGAFLP0_jHH registers can be read/written in 8-bit units

Address: RSCANnGAFLP0_j: <RSCFDn_base> + 0508_H + (10_H × j)
 RSCANnGAFLP0_jL: <RSCFDn_base> + 0508_H + (10_H × j),
 RSCANnGAFLP0_jH: <RSCFDn_base> + 050A_H + (10_H × j)
 RSCANnGAFLP0_jLL: <RSCFDn_base> + 0508_H + (10_H × j),
 RSCANnGAFLP0_jLH: <RSCFDn_base> + 0509_H + (10_H × j),
 RSCANnGAFLP0_jHL: <RSCFDn_base> + 050A_H + (10_H × j),
 RSCANnGAFLP0_jHH: <RSCFDn_base> + 050B_H + (10_H × j)

Value after reset: 0000 0000_H

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Table 25.31 RSCANnGAFLP0_j Register Contents

| Bit | Bit Name | Function |
|----------|-------------------|---|
| 31 to 28 | GAFLDLC [3:0] | Receive Rule DLC b31 b30 b29 b28 0 0 0 0: DLC check is disabled. 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes |
| 27 to 16 | GAFLPTR [11:0] | Receive Rule Label Set the 12-bit label information. |
| 15 | GAFLRMV | Receive Buffer Enable 0: No receive buffer is used. 1: A receive buffer is used. |
| 14 to 8 | GAFLRMDP [6:0] | Receive Buffer Number Select Set the receive buffer number to store receive messages. |
| 7 to 0 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |

Modify the RSCANnGAFLP0_j register when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLDLC[3:0] Bits

These bits are used to set the minimum data length necessary for receiving messages. If the data length of a message that is being filtered is equal to or larger than the value set by the GAFLDLC[3:0] bits, the message passes the DLC check. Setting these bits to 0000_b disables the DLC check function allowing messages with any data length to pass the DLC check.

GAFLPTR[11:0] Bits

These bits are used to set a 12-bit label to be attached to messages that have passed through the filter. A label is attached when a message is stored in the receive buffer or the FIFO buffer.

GAFLRMV Bit

When this bit is set to 1, receive messages that have passed through the filter are stored in the receive buffer selected by the GAFLRMDP[6:0] bits.

GAFLRMDP[6:0] Bits

These bits are used to select the number of the receive buffer that stores receive messages that have passed through the filter when the GAFLRMV bit is set to 1. Set these bits to a value smaller than the value set by the NRXMB[7:0] bits in the RSCANnRMNB register.

25.3.5.6 RSCANnGAFLP1_j — Receive Rule Pointer 0 Register (j = 0 to 15)

Access: RSCANnGAFLP1_j register can be read/written in 32-bit units
 RSCANnGAFLP1_jL, RSCANnGAFLP1_jH registers can be read/written in 16-bit units
 RSCANnGAFLP1_jLL, RSCANnGAFLP1_jLH, RSCANnGAFLP1_jHL, RSCANnGAFLP1_jHH registers can be read/written in 8-bit units

Address: RSCANnGAFLP1_j: <RSCFDn_base> + 050CH + (10_H × j)
 RSCANnGAFLP1_jL: <RSCFDn_base> + 050CH + (10_H × j),
 RSCANnGAFLP1_jH: <RSCFDn_base> + 050EH + (10_H × j)
 RSCANnGAFLP1_jLL: <RSCFDn_base> + 050CH + (10_H × j),
 RSCANnGAFLP1_jLH: <RSCFDn_base> + 050DH + (10_H × j),
 RSCANnGAFLP1_jHL: <RSCFDn_base> + 050EH + (10_H × j),
 RSCANnGAFLP1_jHH: <RSCFDn_base> + 050FH + (10_H × j)

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| | — | — | GAFLFDP[13:0] | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Table 25.32 RSCANnGAFLP1_j Register Contents

| Bit | Bit Name | Function |
|----------|-------------------|---|
| 31 to 14 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 13 to 8 | GAFLFDP [13:8] | Transmit/Receive FIFO Buffer k Select (Bit position –8 = target transmit/receive FIFO buffer number k) 0: Transmit/receive FIFO buffer is not selected. 1: Transmit/receive FIFO buffer is selected. |
| 7 to 0 | GAFLFDP [7:0] | Receive FIFO Buffer x Select (Bit position = target receive FIFO buffer number x) 0: Receive FIFO buffer is not selected. 1: Receive FIFO buffer is selected. |

Modify the RSCANnGAFLP1_j register when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLFDP[13:0] Bits

These bits are used to specify FIFO buffers that store receive messages that have passed through the filter. Up to eight FIFO buffers are selectable. However, when the GAFLRMV bit in the RSCANnGAFLP0_j register is set to 1 (a message is stored in the receive buffer), up to seven FIFO buffers can be selected. Only receive FIFO buffers and the transmit/receive FIFO buffer for which the CFM[1:0] bits in the RSCANnCFCCk register are set to 00B (receive mode) or 10B (gateway mode) are selectable.

25.3.6 Details of Receive Buffer-related Registers

25.3.6.1 RSCANnRMNB — Receive Buffer Number Register

Access: RSCANnRMNB register can be read/written in 32-bit units
 RSCANnRMNBL, RSCANnRMNBH registers can be read/written in 16-bit units
 RSCANnRMNBLL, RSCANnRMNBHL, RSCANnRMNBHL, RSCANnRMNBHH registers can be read/written in 8-bit units

Address: RSCANnRMNB: <RSCFDn_base> + 00A4_H
 RSCANnRMNBL: <RSCFDn_base> + 00A4_H, RSCANnRMNBH: <RSCFDn_base> + 00A6_H
 RSCANnRMNBLL: <RSCFDn_base> + 00A4_H, RSCANnRMNBHL: <RSCFDn_base> + 00A5_H,
 RSCANnRMNBHL: <RSCFDn_base> + 00A6_H, RSCANnRMNBHH: <RSCFDn_base> + 00A7_H

Value after reset: 0000 0000_H

Table 25.33 RSCANnRMNB Register Contents

| Bit | Bit Name | Function |
|---------|------------|--|
| 31 to 8 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 7 to 0 | NRXMB[7:0] | Receive Buffer Number Configuration Set the number of receive buffers. Set a value of 0 to 32. |

Modify the RSCANnRMNB register only in global reset mode.

NRXMB[7:0] Bits

These bits are used to set the total number of receive buffers of the RS-CANFD module. The maximum value is 16 × (number of channels).

Setting these bits all to 0 makes receive buffers unavailable.

25.3.6.2 RSCANnRMNDy — Receive Buffer New Data Register (y = 0)

Access: RSCANnRMNDy register can be read/written in 32-bit units
 RSCANnRMNDyL, RSCANnRMNDyH registers can be read/written in 16-bit units
 RSCANnRMNDyLL, RSCANnRMNDyLH, RSCANnRMNDyHL, RSCANnRMNDyHH registers can be read/written in 8-bit units

Address: RSCANnRMNDy: <RSCFDn_base> + 00A8_H + (04_H × y)
 RSCANnRMNDyL: <RSCFDn_base> + 00A8_H + (04_H × y),
 RSCANnRMNDyH: <RSCFDn_base> + 00AA_H + (04_H × y)
 RSCANnRMNDyLL: <RSCFDn_base> + 00A8_H + (04_H × y),
 RSCANnRMNDyLH: <RSCFDn_base> + 00A9_H + (04_H × y),
 RSCANnRMNDyHL: <RSCFDn_base> + 00AA_H + (04_H × y),
 RSCANnRMNDyHH: <RSCFDn_base> + 00AB_H + (04_H × y)

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |

Table 25.34 RSCANnRMNDy Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 16 | RMNSq | Receive Buffer Receive Complete Flag q (q = y × 32 + 31 to y × 32 + 16) 0: There is no new message in receive buffer q. 1: There is a new message in receive buffer q. |
| 15 to 0 | RMNSq | Receive Buffer Receive Complete Flag q (q = y × 32 + 15 to y × 32 + 0) 0: There is no new message in receive buffer q. 1: There is a new message in receive buffer q. |

Write 0 to the RSCANnRMNDy register in global operating mode or global test mode.

RMNSq Flags (q = 0 to 31)

Each RMNSq flag is set to 1 when the processing for storing a message in the corresponding receive buffer starts.

To clear a flag to 0, the program must write 0 to the flag. Use a store instruction to write “0” to the flag and “1” to other flags. These bits cannot be set to 0 while a message is being stored. It takes ten clock cycles of pclk to store a message. These flags are cleared to 0 in global reset mode.

25.3.6.3 RSCANnRMIDq — Receive Buffer ID Register (q = 0 to 31)

Access: RSCANnRMIDq register can be read only in 32-bit units
 RSCFDnRMIDqRSCANnRMIDqL, RSCFDnRMIDqRSCANnRMIDqH registers can be read only in 16-bit units
 RSCFDnRMIDqRSCANnRMIDqLL, RSCFDnRMIDqRSCANnRMIDqLH, RSCFDnRMIDqRSCANnRMIDqHL, RSCFDnRMIDqRSCANnRMIDqHH registers can be read only in 8-bit units

Address: RSCANnRMIDq: <RSCFDn_base> + 0600_H + (10_H × q)
 RSCANnRMIDqL: <RSCFDn_base> + 0600_H + (10_H × q),
 RSCANnRMIDqH: <RSCFDn_base> + 0602_H + (10_H × q)
 RSCANnRMIDqLL: <RSCFDn_base> + 0600_H + (10_H × q),
 RSCANnRMIDqLH: <RSCFDn_base> + 0601_H + (10_H × q),
 RSCANnRMIDqHL: <RSCFDn_base> + 0602_H + (10_H × q),
 RSCANnRMIDqHH: <RSCFDn_base> + 0603_H + (10_H × q)

Value after reset: 0000 0000_H

Table 25.35 RSCANnRMIDq Register Contents

| Bit | Bit Name | Function |
|---------|------------|---|
| 31 | RMIDE | Receive Buffer IDE 0: Standard ID 1: Extended ID |
| 30 | RMRT R | Receive Buffer RTR 0: Data frame 1: Remote frame |
| 29 | Reserved | This bit is read as the value after reset. |
| 28 to 0 | RMID[28:0] | Receive Buffer ID Data These bits contain the standard ID or extended ID of the received message. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0. |

RMIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive buffer

RMRT R Bit

This bit indicates the frame format (data frame or remote frame) of the message stored in the receive buffer.

RMID[28:0] Bits

These bits contain the ID of the message stored in the receive buffer.

25.3.6.4 RSCANnRMPTRq — Receive Buffer Pointer Register (q = 0 to 31)

Access: RSCANnRMPTRq register can be read only in 32-bit units
 RSCFDnRMPTRqRSCANnRMPTRqL, RSCFDnRMPTRqRSCANnRMPTRqH registers can be read only in 16-bit units
 RSCFDnRMPTRqRSCANnRMPTRqLL, RSCFDnRMPTRqRSCANnRMPTRqLH, RSCFDnRMPTRqRSCANnRMPTRqHL, RSCFDnRMPTRqRSCANnRMPTRqHH registers can be read only in 8-bit units

Address: RSCANnRMPTRq: <RSCFDn_base> + 0604_H + (10_H × q)
 RSCANnRMPTRqL: <RSCFDn_base> + 0604_H + (10_H × q),
 RSCANnRMPTRqH: <RSCFDn_base> + 0606_H + (10_H × q)
 RSCANnRMPTRqLL: <RSCFDn_base> + 0604_H + (10_H × q),
 RSCANnRMPTRqLH: <RSCFDn_base> + 0605_H + (10_H × q),
 RSCANnRMPTRqHL: <RSCFDn_base> + 0606_H + (10_H × q),
 RSCANnRMPTRqHH: <RSCFDn_base> + 0607_H + (10_H × q)

Value after reset: 0000 0000_H

Table 25.36 RSCANnRMPTRq Register Contents

| Bit | Bit Name | Function |
|----------|-------------|--|
| 31 to 28 | RMDLC[3:0] | Receive Buffer DLC Data b31 b30 b29 b28 0 0 0 0: No data byte 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes |
| 27 to 16 | RMPTR[11:0] | Receive Buffer Label Data Label information of the received message. |
| 15 to 0 | RMTS[15:0] | Receive Buffer Timestamp Data Timestamp value of the received message. |

RMDLC[3:0] Bits

These bits indicate the data length of the message stored in the receive buffer.

RMPTR[11:0] Bits

These bits indicate the label information of the message stored in the receive buffer.

RMTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the receive buffer.

25.3.6.5 RSCANnRMDF0_q — Receive Buffer Data Field 0 Register (q = 0 to 31)

Access: RSCANnRMDF0_q register can be read only in 32-bit units
 RSCANnRMDF0_qL, RSCANnRMDF0_qH registers can be read only in 16-bit units
 RSCANnRMDF0_qLL, RSCANnRMDF0_qLH, RSCANnRMDF0_qHL, RSCANnRMDF0_qHH registers can be read only in 8-bit units

Address:
 RSCANnRMDF0_q: <RSCFDn_base> + 0608_H + (10_H × q)
 RSCANnRMDF0_qL: <RSCFDn_base> + 0608_H + (10_H × q),
 RSCANnRMDF0_qH: <RSCFDn_base> + 060A_H + (10_H × q)
 RSCANnRMDF0_qLL: <RSCFDn_base> + 0608_H + (10_H × q),
 RSCANnRMDF0_qLH: <RSCFDn_base> + 0609_H + (10_H × q),
 RSCANnRMDF0_qHL: <RSCFDn_base> + 060A_H + (10_H × q),
 RSCANnRMDF0_qHH: <RSCFDn_base> + 060B_H + (10_H × q)

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | RMDB3[7:0] | | | | | | | | RMDB2[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.37 RSCANnRMDF0_q Register Contents

| Bit | Bit Name | Function |
|--|------------|----------------------------|
| 31 to 24 | RMDB3[7:0] | Receive Buffer Data Byte 3 |
| 23 to 16 | RMDB2[7:0] | Receive Buffer Data Byte 2 |
| 15 to 8 | RMDB1[7:0] | Receive Buffer Data Byte 1 |
| 7 to 0 | RMDB0[7:0] | Receive Buffer Data Byte 0 |
| Data for a message stored in the receive buffer can be read. | | |

When the RMDLC[3:0] value in the RSCANnRMPTRq register is smaller than 1000_B, data bytes for which no data is set are read as 00_H.

25.3.6.6 RSCANnRMDF1_q — Receive Buffer Data Field 1 Register (q = 0 to 31)

Access: RSCANnRMDF1_q register can be read only in 32-bit units
 RSCANnRMDF1_qL, RSCANnRMDF1_qH registers can be read only in 16-bit units
 RSCANnRMDF1_qLL, RSCANnRMDF1_qLH, RSCANnRMDF1_qHL, RSCANnRMDF1_qHH registers can be read only in 8-bit units

Address: RSCANnRMDF1_q: <RSCFDn_base> + 060C_H + (10_H × q)
 RSCANnRMDF1_qL: <RSCFDn_base> + 060C_H + (10_H × q),
 RSCANnRMDF1_qH: <RSCFDn_base> + 060E_H + (10_H × q)
 RSCANnRMDF1_qLL: <RSCFDn_base> + 060C_H + (10_H × q),
 RSCANnRMDF1_qLH: <RSCFDn_base> + 060D_H + (10_H × q),
 RSCANnRMDF1_qHL: <RSCFDn_base> + 060E_H + (10_H × q),
 RSCANnRMDF1_qHH: <RSCFDn_base> + 060F_H + (10_H × q)

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|------------|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | RMDB7[7:0] | | | | | | | | RMDB6[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| | RMDB5[7:0] | | | | | | | | RMDB4[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.38 RSCANnRMDF1_q Register Contents

| Bit | Bit Name | Function |
|--|------------|----------------------------|
| 31 to 24 | RMDB7[7:0] | Receive Buffer Data Byte 7 |
| 23 to 16 | RMDB6[7:0] | Receive Buffer Data Byte 6 |
| 15 to 8 | RMDB5[7:0] | Receive Buffer Data Byte 5 |
| 7 to 0 | RMDB4[7:0] | Receive Buffer Data Byte 4 |
| Data for a message stored in the receive buffer can be read. | | |

When the RMDLC[3:0] value in the RSCANnRMPTRq register is smaller than 1000_B, data bytes for which no data is set are read as 00_H.

25.3.7 Details of Receive FIFO Buffer-related Registers

25.3.7.1 RSCANnRFCCx — Receive FIFO Buffer Configuration and Control Register (x = 0 to 7)

Access: RSCANnRFCCx register can be read/written in 32-bit units
 RSCANnRFCCxL, RSCANnRFCCxH registers can be read/written in 16-bit units
 RSCANnRFCCxLL, RSCANnRFCCxLH, RSCANnRFCCxHL, RSCANnRFCCxHH registers can be read/written in 8-bit units

Address: RSCANnRFCCx: <RSCFDn_base> + 00B8_H + (04_H × x)
 RSCANnRFCCxL: <RSCFDn_base> + 00B8_H + (04_H × x),
 RSCANnRFCCxH: <RSCFDn_base> + 00BA_H + (04_H × x)
 RSCANnRFCCxLL: <RSCFDn_base> + 00B8_H + (04_H × x),
 RSCANnRFCCxLH: <RSCFDn_base> + 00B9_H + (04_H × x),
 RSCANnRFCCxHL: <RSCFDn_base> + 00BA_H + (04_H × x),
 RSCANnRFCCxHH: <RSCFDn_base> + 00BB_H + (04_H × x)

Value after reset: 0000 0000_H

Table 25.39 RSCANnRFCCx Register Contents

| Bit | Bit Name | Function |
|----------|-------------|---|
| 31 to 16 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 15 to 13 | RFIGCV[2:0] | Receive FIFO Interrupt Request Timing Select b15 b14 b13 0 0 0: When FIFO is 1/8 full. 0 0 1: When FIFO is 2/8 full. 0 1 0: When FIFO is 3/8 full. 0 1 1: When FIFO is 4/8 full. 1 0 0: When FIFO is 5/8 full. 1 0 1: When FIFO is 6/8 full. 1 1 0: When FIFO is 7/8 full. 1 1 1: When FIFO is full. |
| 12 | RFIM | Receive FIFO Interrupt Source Select 0: An interrupt occurs when the condition set by the RFIGCV[2:0] bits is met. 1: An interrupt occurs each time a message has been received. |
| 11 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 10 to 8 | RFDC[2:0] | Receive FIFO Buffer Depth Configuration b10 b9 b8 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages 1 1 0: 64 messages 1 1 1: 128 messages |
| 7 to 2 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 1 | RFIE | Receive FIFO Interrupt Enable 0: Receive FIFO interrupt is disabled. 1: Receive FIFO interrupt is enabled. |

| Bit | Bit Name | Function |
|-----|----------|---|
| 0 | RFE | Receive FIFO Buffer Enable 0: No receive FIFO buffer is used. 1: Receive FIFO buffers are used. |

RFIGCV[2:0] Bits

These bits are used to specify the number of received messages for generating a receive FIFO interrupt request when the RFIM bit is set to 0 with a fraction for the total number of buffers (the setting of RFDC[2:0]).

When the RFDC[2:0] bits are set to 001_B (4 messages), set the RFIGCV[2:0] bits to 001_B, 011_B, 101_B, or 111_B. Modify these bits only in global reset mode.

RFIM Bit

This bit is used to select a FIFO interrupt source. Modify this bit only in global reset mode.

RFDC[2:0] Bits

These bits are used to select the number of messages that can be stored in a single receive FIFO buffer. When these bits are set to 000_B, no receive FIFO buffer should be used. Modify these bits only in global reset mode.

RFIE Bit

Setting the RFIE bit to 1 enables receive FIFO interrupts. Modify this bit when the RFE bit set to 0 (no receive FIFO buffer is used).

RFE Bit

Setting the RFE bit to 1 makes receive FIFO buffers available. Clearing this bit to 0 sets the RFEMP flag in the RSCFDnRFSTSxRSCANnRFSTSx register to 1 (buffer empty). Modify this bit in global operating mode or global test mode.

Set this bit to 1 with another instruction after the settings to all bits in the RSCANnRFCCx register have been done.

This bit is cleared to 0 in global reset mode.

25.3.7.2 RSCANnRFSTs_x — Receive FIFO Buffer Status Register (x = 0 to 7)

Access: RSCANnRFSTs_x register can be read/written in 32-bit units
 RSCANnRFSTs_xL, RSCANnRFSTs_xH registers can be read/written in 16-bit units
 RSCANnRFSTs_xLL, RSCANnRFSTs_xLH, RSCANnRFSTs_xHL, RSCANnRFSTs_xHH registers can be read/written in 8-bit units

Address: RSCANnRFSTs_x: <RSCFDn_base> + 00D8_H + (04_H × x)
 RSCANnRFSTs_xL: <RSCFDn_base> + 00D8_H + (04_H × x),
 RSCANnRFSTs_xH: <RSCFDn_base> + 00DA_H + (04_H × x)
 RSCANnRFSTs_xLL: <RSCFDn_base> + 00D8_H + (04_H × x),

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.40 RSCANnRFSTs_x Register Contents

| Bit | Bit Name | Function |
|----------|-----------|---|
| 31 to 16 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 15 to 8 | RFMC[7:0] | Receive FIFO Unread Message Counter The number of unread messages stored in the receive FIFO buffer is displayed. |
| 7 to 4 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 3 | RFIF | Receive FIFO Interrupt Request Flag 0: No receive FIFO interrupt request is present. 1: A receive FIFO interrupt request is present. |
| 2 | RFMLT | Receive FIFO Message Lost Flag 0: No receive FIFO message is lost. 1: A receive FIFO message is lost. |
| 1 | RFFLL | Receive FIFO Buffer Full Status Flag 0: The receive FIFO buffer is not full. 1: The receive FIFO buffer is full. |
| 0 | RFEMP | Receive FIFO Buffer Empty Status Flag 0: The receive FIFO buffer contains unread message. 1: The receive FIFO buffer contains no unread message (buffer empty). |

RFMC[7:0] Flag

This flag indicates the number of unread messages in the receive FIFO buffer. This flag becomes 00_H when the RFE bit in the RSCANnRFCC_x register is set to 0.

RFIF Flag

This flag is set to 1 when the receive FIFO interrupt request generation conditions set by the RFIGCV[2:0] bits and the RFIM bit in the RSCANnRFCC_x register are met. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0,

using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

RFMLT Flag

This flag is set to 1 when an attempt is made to store a new message while the receive FIFO buffer is full. In this case, the new message is discarded.

This flag is cleared to 0 in global reset mode or by writing 0 to this flag.

Modify this bit in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

RFFLL Flag

This flag is set to 1 when the number of messages stored in the receive FIFO buffer matches the FIFO buffer depth set by the RFDC[2:0] bits in the RSCANnRFCCx register.

If the number of messages stored in the receive FIFO buffer becomes smaller than the FIFO buffer depth set by the RFDC[2:0] bits, this flag is cleared to 0. This flag is also cleared to 0 when the RFE bit in the RSCANnRFCCx register is set to 0 (no receive FIFO buffer is used) or in global reset mode.

RFEMP Flag

This flag is set to 1 when all messages in the receive FIFO buffer have been read. This flag is also set to 1 when the RFE bit in the RSCANnRFCCx register is 0 or in global reset mode.

This flag is cleared to 0 when even a single received message has been stored in the receive FIFO buffer.

Note: To clear the RFMLT or RFIF flag to 0, use a store instruction to write “0” to the given flag and “1” to the other flags.

25.3.7.3 RSCANnRFPCTR_x — Receive FIFO Buffer Pointer Control Register ($x = 0$ to 7)

Access: RSCANnRFPCTR_x register can only be written in 32-bit units
 RSCANnRFPCTR_{xL}, RSCANnRFPCTR_{xH} registers can only be written in 16-bit units
 RSCANnRFPCTR_{xLL}, RSCANnRFPCTR_{xLH}, RSCANnRFPCTR_{xHL}, RSCANnRFPCTR_{xHH} registers can only be written in 8-bit units

Address: RSCANnRFPCTR_x: <RSCFDn_base> + 00F8_H + (04_H × x)
 RSCANnRFPCTR_{xL}: <RSCFDn_base> + 00F8_H + (04_H × x),
 RSCANnRFPCTR_{xH}: <RSCFDn_base> + 00FA_H + (04_H × x)
 RSCANnRFPCTR_{xLL}: <RSCFDn_base> + 00F8_H + (04_H × x),
 RSCANnRFPCTR_{xLH}: <RSCFDn_base> + 00F9_H + (04_H × x),
 RSCANnRFPCTR_{xHL}: <RSCFDn_base> + 00FA_H + (04_H × x),
 RSCANnRFPCTR_{xHH}: <RSCFDn_base> + 00FB_H + (04_H × x)

Value after reset: 0000 0000_H

Table 25.41 RSCANnRFPCTR_x Register Contents

| Bit | Bit Name | Function |
|---------|-----------|--|
| 31 to 8 | Reserved | The write value should be the value after reset. |
| 7 to 0 | RFPC[7:0] | Receive FIFO Pointer Control When these bits are set to FF _H , the read pointer moves to the next unread message in the receive FIFO buffer. |

RFPC[7:0] Bits

When the RFPC[7:0] bits are set to FF_H, the read pointer moves to the next unread message in the receive FIFO buffer. At this time, the RFMC[7:0] (receive FIFO unread message counter) value in the RSCANnRFSTS_x register is decremented. Read the RSCANnRFID_x, RSCANnRFPTR_x, RSCANnRFDF0_x, and RSCANnRFDF1_x registers to read messages in the receive FIFO buffer, and then write FF_H to the RFPC[7:0] bits.

When writing FF_H to these bits, make sure that the RFE bit in the RSCANnRFCC_x register is set to 1 (receive FIFO buffers are used) and the RFEMP flag in the RSCANnRFSTS_x register is 0 (the receive FIFO buffer contains unread messages).

25.3.7.4 RSCANnRFIDx — Receive FIFO Buffer Access ID Register (x = 0 to 7)

Access: RSCANnRFIDx register can be read only in 32-bit units
 RSCANnRFIDxL, RSCANnRFIDxH registers can be read only in 16-bit units
 RSCANnRFIDxLL, RSCANnRFIDxLH, RSCANnRFIDxHL, RSCANnRFIDxHH registers can be read only in 8-bit units

Address: RSCANnRFIDx: <RSCFDn_base> + 0E00_H + (10_H × x)
 RSCANnRFIDxL: <RSCFDn_base> + 0E00_H + (10_H × x),
 RSCANnRFIDxH: <RSCFDn_base> + 0E02_H + (10_H × x)
 RSCANnRFIDxLL: <RSCFDn_base> + 0E00_H + (10_H × x),
 RSCANnRFIDxLH: <RSCFDn_base> + 0E01_H + (10_H × x),
 RSCANnRFIDxHL: <RSCFDn_base> + 0E02_H + (10_H × x),

Table 25.42 RSCANnRFIDx Register Contents

| Bit | Bit Name | Function |
|---------|------------|---|
| 31 | RFIDE | Receive FIFO Buffer IDE 0: Standard ID 1: Extended ID |
| 30 | RFRTTR | Receive FIFO Buffer RTR 0: Data frame 1: Remote frame |
| 29 | Reserved | This bit is read as the value after reset. |
| 28 to 0 | RFID[28:0] | Receive FIFO Buffer ID Data The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0. |

RFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive FIFO buffer.

RFRTTR Bit

This bit indicates the frame format (data frame or remote frame) of the message stored in the receive FIFO buffer.

RFID[28:0] Bits

These bits indicate the ID of the message stored in the receive FIFO buffer.

25.3.7.5 RSCANnRFPTRx — Receive FIFO Buffer Access Pointer Register (x = 0 to 7)

Access: RSCANnRFPTRx register can be read only in 32-bit units
 RSCANnRFPTRxL, RSCANnRFPTRxH registers can be read only in 16-bit units
 RSCANnRFPTRxLL, RSCANnRFPTRxLH, RSCANnRFPTRxHL, RSCANnRFPTRxHH registers can be read only in 8-bit units

Address: RSCANnRFPTRx: $\langle \text{RSCFDn_base} \rangle + 0\text{E}04_{\text{H}} + (10_{\text{H}} \times x)$
 RSCANnRFPTRxL: $\langle \text{RSCFDn_base} \rangle + 0\text{E}04_{\text{H}} + (10_{\text{H}} \times x)$,

Table 25.43 RSCANnRFPTRx Register Contents

| Bit | Bit Name | Function |
|----------|-------------|---|
| 31 to 28 | RFDLC[3:0] | Receive FIFO Buffer DLC Data b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes |
| 27 to 16 | RFPTR[11:0] | Receive FIFO Buffer Label Data Label information of the received message can be read. |
| 15 to 0 | RFTS[15:0] | Receive FIFO Buffer Timestamp Data Timestamp value of the received message can be read. |

RFDLC[3:0] Bits

These bits contain the data length of the message stored in the receive FIFO buffer.

RFPTR[11:0] Bits

These bits contain the label information of the message stored in the receive FIFO buffer.

RFTS[15:0] Bits

These bits contain the timestamp value of the message stored in the receive FIFO buffer.

25.3.7.6 RSCANnRDFD0_x — Receive FIFO Buffer Access Data Field 0 Register (x = 0 to 7)

Access: RSCANnRDFD0_x register can be read only in 32-bit units
 RSCANnRDFD0_xL, RSCANnRDFD0_xH registers can be read only in 16-bit units
 RSCANnRDFD0_xLL, RSCANnRDFD0_xLH, RSCANnRDFD0_xHL, RSCANnRDFD0_xHH registers can be read only in 8-bit units

Address: RSCANnRDFD0_x: <RSCFDn_base> + 0E08_H + (10_H × x)
 RSCANnRDFD0_xL: <RSCFDn_base> + 0E08_H + (10_H × x),

Table 25.45 RSCANnRFDF1_x Register Contents

| Bit | Bit Name | Function |
|---|------------|---------------------------------|
| 31 to 24 | RFDB7[7:0] | Receive FIFO Buffer Data Byte 7 |
| 23 to 16 | RFDB6[7:0] | Receive FIFO Buffer Data Byte 6 |
| 15 to 8 | RFDB5[7:0] | Receive FIFO Buffer Data Byte 5 |
| 7 to 0 | RFDB4[7:0] | Receive FIFO Buffer Data Byte 4 |
| Data for a message stored in the receive FIFO buffer can be read. | | |

When the RFDLC[3:0] value in the RSCANnRFPTRx register is smaller than 1000_B, data bytes for which no data is set are read as 00_H.

25.3.8 Details of Transmit/Receive FIFO Buffer-related Registers

25.3.8.1 RSCANnCFCK — Transmit/receive FIFO Buffer Configuration and Control Register k (k = 0 to 5)

Access: RSCANnCFCK register can be read/written in 32-bit units
 RSCANnCFCKL, RSCANnCFCKH registers can be read/written in 16-bit units
 RSCANnCFCKLL, RSCANnCFCKLH, RSCANnCFCKHL, RSCANnCFCKHH registers can be read/written in 8-bit units

Address: RSCANnCFCK: <RSCFDn_base> + 0118_H + (04_H × k)
 RSCANnCFCKL: <RSCFDn_base> + 0118_H + (04_H × k),
 RSCANnCFCKH: <RSCFDn_base> + 011A_H + (04_H × k)
 RSCANnCFCKLL: <RSCFDn_base> + 0118_H + (04_H × k),
 RSCANnCFCKLH: <RSCFDn_base> + 0119_H + (04_H × k),
 RSCANnCFCKHL: <RSCFDn_base> + 011A_H + (04_H × k),
 RSCANnCFCKHH: <RSCFDn_base> + 011B_H + (04_H × k)

Value after reset: 0000 0000_H

| 1 | CFRXIE | Transmit/Receive FIFO Receive Interrupt Enable 0: Transmit/receive FIFO receive interrupt is disabled. 1: Transmit/receive FIFO receive interrupt is enabled. |
| 0 | CFE | Transmit/Receive FIFO Buffer Enable 0: No transmit/receive FIFO buffer is used. 1: Transmit/receive FIFO buffers are used. |

CFITT[7:0] Bits

These bits are used to set a message transmission interval when transmitting messages continuously from a transmit/receive FIFO buffer whose CFM[1:0] bits are set to 01_B (transmit mode) or 10_B (gateway mode).

Clear the CFE bit to 0 (no transmit/receive FIFO buffer is used) before modifying the CFITT[7:0] bits.

CFTML[3:0] Bits

These bits are used to set the number of transmit buffer on the channel which will be linked to transmit/receive FIFO buffer k when the CFM[1:0] bits are set to 01_B (transmit mode) or 10_B (gateway mode). There are three transmit/receive FIFO buffers per channel, so channel number m of FIFO buffer k is calculated as $m = k/3$ (integer division). The actual assigned transmit buffer number p linked to FIFO buffer k will be $((16 \times m) + CFTML[3:0])$.

See Table 25.11 and Table 25.12, as for the relationship between transmit/receive FIFO buffer k and transmit buffer p. Setting the CFDC[2:0] bits to 001_B or more enables the setting of the CFTML[3:0] bits.

Do not link to any transmit buffer which is already allocated to a transmit queue on the identical channel or to another transmit/receive FIFO buffer. Modify these bits only in global reset mode.

CFITR Bit

This bit is enabled when the CFITSS bit is 0.

When this bit is 0, the interval timer clock source is the pclk/2 clock divided by the value of the ITRCP[15:0] bits in the RSCANnGCFG register.

When this bit is 1, the interval timer clock source is the pclk/2 clock divided by (the value of the ITRCP[15:0] bits in the RSCANnGCFG register × 10).

Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

CFITSS Bit

When this bit is 0, the clock selected by the CFITR bit is the count source of the interval timer.

When this bit is 1, the bit time clock of the channel to which the FIFO is linked is the count source of the interval timer.

Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

CFM[1:0] Bits

These bits are used to select transmit/receive FIFO mode. Modify these bits only in global reset mode.

CFIGCV[2:0] Bits

These bits are used to specify the number of received messages for generating a transmit/receive FIFO receive interrupt request when the CFM[1:0] bits are set to 00_B (receive mode) or 10_B (gateway mode) and the CFIM bit is set to 0 with a fraction for the total number of buffers (the setting of CFDC[2:0]).

When the CFDC[2:0] bits are set to 001_B (4 messages), set the CFIGCV[2:0] bits to 001_B, 011_B, 101_B, or 111_B.

Modify these bits only in global reset mode.

CFIM Bit

This bit is used to select a transmit/receive FIFO interrupt source. Modify this bit only in global reset mode.

CFDC[2:0] Bits

These bits are used to set the number of messages that can be stored in a single transmit/receive FIFO buffer. When these bits are set to 000_B, do not use a transmit/receive FIFO buffer. Modify these bits only in global reset mode.

CFTXIE Bit

When this bit is set to 1 and the CFTXIF flag in the RSCANnCFSTSk register is set to 1, a transmit/receive FIFO transmit interrupt request is generated.

Modify this bit with the CFE bit set to 0 (no transmit/receive FIFO buffer is used).

CFRXIE Bit

When this bit is set to 1 and the CFRXIF flag in the RSCANnCFSTSk register is set to 1, a transmit/receive FIFO receive interrupt request is generated.

Modify this bit with the CFE bit set to 0.

CFE Bit

Setting this bit to 1 makes transmit/receive FIFO buffers available.

When this bit is set to 0 in transmit mode or gateway mode, if a message in the transmit/receive FIFO buffer is being transmitted or will be transmitted next, the transmit/receive FIFO buffer becomes empty after completion of transmission of that message, or upon detection of a CAN bus error, or arbitration-lost. In other cases or in receive mode, the transmit/receive FIFO buffer becomes empty immediately.

This bit is cleared to 0 when the following conditions are met.

- Receive mode: Global reset mode
- Transmit mode or gateway mode: Channel reset mode

Modify this bit in the following mode.

- Receive mode: Global operating mode or global test mode
- Transmit mode or gateway mode: Channel communication mode or channel halt mode

After all other bits in the RSCANnCFCCk register have been set, set this bit to 1 by using another instruction.

25.3.8.2 RSCANnCFSTSk — Transmit/receive FIFO Buffer Status Register (k = 0 to 5)

Access: RSCANnCFSTSk register can be read/written in 32-bit units
 RSCANnCFSTSkL, RSCANnCFSTSkH registers can be read/written in 16-bit units
 RSCANnCFSTSkLL, RSCANnCFSTSkLH, RSCANnCFSTSkHL, RSCANnCFSTSkHH registers can be read/written in 8-bit units

Address: RSCANnCFSTSk: <RSCFDn_base> + 0178_H + (04_H × k)
 RSCANnCFSTSkL: <RSCFDn_base> + 0178_H + (04_H × k),
 RSCANnCFSTSkH: <RSCFDn_base> + 017A_H + (04_H × k)
 RSCANnCFSTSkLL: <RSCFDn_base> + 0178_H + (04_H × k),
 RSCANnCFSTSkLH: <RSCFDn_base> + 0179_H + (04_H × k),
 RSCANnCFSTSkHL: <RSCFDn_base> + 017A_H + (04_H × k),
 RSCANnCFSTSkHH: <RSCFDn_base> + 017B_H + (04_H × k)

Value after reset: 0000 0001_H

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R/W*1 | R/W*1 | R/W*1 | R | R |

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.47 RSCANnCFSTSk Register Contents

| Bit | Bit Name | Function |
|----------|-----------|--|
| 31 to 16 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 15 to 8 | CFMC[7:0] | Transmit/Receive FIFO Message Counter The number of messages stored in the transmit/receive FIFO buffer. |
| 7 to 5 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 4 | CFTXIF | Transmit/Receive FIFO Transmit Interrupt Request Flag 0: No transmit/receive FIFO transmit interrupt request is present. 1: A transmit/receive FIFO transmit interrupt request is present. |
| 3 | CFRXIF | Transmit/Receive FIFO Receive Interrupt Request Flag 0: No transmit/receive FIFO receive interrupt request is present. 1: A transmit/receive FIFO receive interrupt request is present. |
| 2 | CFMLT | Transmit/Receive FIFO Message Lost Flag 0: No transmit/receive FIFO message is lost. 1: A transmit/receive FIFO message is lost. |
| 1 | CFLL | Transmit/Receive FIFO Buffer Full Status Flag 0: The transmit/receive FIFO buffer is not full. 1: The transmit/receive FIFO buffer is full. |
| 0 | CFEMP | Transmit/Receive FIFO Buffer Empty Status Flag 0: The transmit/receive FIFO buffer contains messages. 1: The transmit/receive FIFO buffer contains no message (buffer empty). |

CFMC[7:0] Bits

The CFMC[7:0] bits indicate the following values that depend on the setting of the CFM[1:0] bits in the RSCANnCFCCk register.

- When CFM[1:0] value is 01_B (transmit mode): Number of untransmitted messages in the buffer
- When CFM[1:0] value is 00_B (receive mode): Number of unread received messages in the buffer
- When CFM[1:0] value is 10_B (gateway mode): Number of untransmitted received messages in the buffer

These bits are cleared to 0 when any of the following conditions is met.

- When CFM[1:0] value is 00_B: In global reset mode
- When CFM[1:0] value is 01_B or 10_B: In channel reset mode
- When the CFE bit in the RSCANnCFCCk register is cleared to 0.

CFTXIF Flag

The CFTXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 01_B or 10_B, and the factor selected by the CFIM bit in the RSCANnCFCCk register occurs

The CFTXIF flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFTXIF flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFRXIF Flag

The CFRXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B or 10_B, and the factor selected by the CFIM bit in the RSCANnCFCCk register occurs

The CFRXIF flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFRXIF flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.

When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFMLT Flag

The CFMLT flag is set to 1 when any of the following conditions is met.

- When an attempt is made to store a new message while the transmit/receive FIFO buffer is full. In this case, the new message is discarded.

The CFMLT flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFMLT flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFFLL Flag

The CFFLL flag is set to 1 when any of the following conditions is met.

- When the number of messages stored in the transmit/receive FIFO buffer matches the FIFO buffer depth set by the CFDC[2:0] bits in the RSCANnCFCCk register.

The CFMLT flag is cleared to 0 when any of the following conditions is met.

- When the number of messages stored in the transmit/receive FIFO buffer becomes smaller than the FIFO buffer depth set by the CFDC[2:0] bits.
- When the CFE bit in the RSCANnCFCCk register is 0 (no transmit/receive FIFO buffer is used): When not in the transmit abort
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

CFEMP Flag

The CFEMP flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B: All messages have been read, or in global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: All messages have been transmitted, or in channel reset mode
- When the CFE bit is 0 (no transmit/receive FIFO buffer is used): Not in the transmit abort

The CFEMP flag is cleared to 0 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B or 10_B: At least one received message has been stored in the transmit/receive FIFO buffer.
- When the CFM[1:0] bits are set to 01_B: A value of FFH has been written to the RSCANnCFPCTRk register after data was written to the RSCANnCFIDk, RSCANnCFPTRk, RSCANnCFDF0_k, and RSCANnCFDF1_k registers.

Note: To clear CFTXIF, CFRXIF, or CFMLT flag to 0, the program must write 0. When writing, use a store instruction to write "0" to the given flag and "1" to other flags.

25.3.8.3 RSCANnCFPCTRk — Transmit/receive FIFO Buffer Pointer Control Register (k = 0 to 5)

Access: RSCANnCFPCTRk register can only be written in 32-bit units
 RSCANnCFPCTRkL, RSCANnCFPCTRkH registers can only be written in 16-bit units
 RSCANnCFPCTRkLL, RSCANnCFPCTRkLH, RSCANnCFPCTRkHL, RSCANnCFPCTRkHH registers can only be written in 8-bit units

Address: RSCANnCFPCTRk: <RSCFDn_base> + 01D8_H + (04_H × k)
 RSCANnCFPCTRkL: <RSCFDn_base> + 01D8_H + (04_H × k),
 RSCANnCFPCTRkH: <RSCFDn_base> + 01DA_H + (04_H × k)
 RSCANnCFPCTRkLL: <RSCFDn_base> + 01D8_H + (04_H × k),
 RSCANnCFPCTRkLH: <RSCFDn_base> + 01D9_H + (04_H × k),
 RSCANnCFPCTRkHL: <RSCFDn_base> + 01DA_H + (04_H × k),
 RSCANnCFPCTRkHH: <RSCFDn_base> + 01DB_H + (04_H × k)

Table 25.48 RSCANnCFPCTRk Register Contents

| Bit | Bit Name | Function |
|---------|-----------|---|
| 31 to 8 | Reserved | The write value should be the value after reset. |
| 7 to 0 | CFPC[7:0] | Transmit/Receive FIFO Pointer Control <ul style="list-style-type: none"> • Receive mode: Writing FFH to these bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. • Transmit mode: Writing FFH to these bits moves the write pointer to the next stage of the transmit/receive FIFO buffer. • Gateway mode: Setting prohibited |

CFPC[7:0] Bits

- Receive mode (CFM[1:0] value in the RSCANnCFCCk register is 00B):
 Writing FFH to the CFPC[7:0] bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value (transmit/receive FIFO message counter) in the RSCANnCFSTSk register is decremented. Read the RSCANnCFIDk, RSCANnCFPTRk, RSCANnCFDF0_k, and RSCANnCFDF1_k registers to read messages from the transmit/receive FIFO buffer, and then write FFH to the CFPC[7:0] bits.
 When writing FFH to these bits, make sure that the CFE bit in the RSCANnCFCCk register is set to 1 (transmit/receive FIFO buffers are used) and the CFEMP flag in the RSCANnCFSTSk register is 0 (the transmit/receive FIFO buffer contains messages).
- Transmit mode (CFM[1:0] value in the RSCANnCFCCk register is 01B):
 Writing FFH to the CFPC[7:0] bits stores the data written to the RSCANnCFIDk, RSCANnCFPTRk, RSCANnCFDF0_k, and RSCANnCFDF1_k registers in the transmit/receive FIFO buffer and moves the write pointer to the next stage of the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value is incremented. Write transmit messages to the RSCANnCFIDk, RSCANnCFPTRk, RSCANnCFDF0_k, and RSCANnCFDF1_k registers before writing FFH to the CFPC[7:0] bits.
 When writing FFH to these bits, make sure that the CFE bit in the RSCANnCFCCk register is set to 1 and the

CFFLL flag in the RSCANnCFSTSk register is 0 (the transmit/receive FIFO buffer is not full).

- Gateway mode (CFM[1:0] value in the RSCANnCFCCk register is 10_B):
Setting prohibited

25.3.8.4 RSCANnCFIDk — Transmit/receive FIFO Buffer Access ID Register (k = 0 to 5)

Access: RSCANnCFIDk register can be read/written in 32-bit units
 RSCANnCFIDkL, RSCANnCFIDkH registers can be read/written in 16-bit units
 RSCANnCFIDkLL, RSCANnCFIDkLH, RSCANnCFIDkHL, RSCANnCFIDkHH registers can be read/written in 8-bit units

Table 25.49 RSCANnCFIDk Register Contents

| Bit | Bit Name | Function |
|---------|------------|---|
| 31 | CFIDE | Transmit/Receive FIFO Buffer IDE 0: Standard ID 1: Extended ID |
| 30 | CFRTR | Transmit/Receive FIFO Buffer RTR 0: Data frame 1: Remote frame |
| 29 | THLEN | Transmit History Data Store Enable This bit is valid only when the CFM[1:0] value is 01 _B (transmit mode). 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer. |
| 28 to 0 | CFID[28:0] | Transmit/Receive FIFO Buffer ID Data <ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11. When CFM[1:0] value is 00_B (receive mode): Standard ID or extended ID in the received message can be read. For standard ID, read bits 10 to 0. Bits 28 to 11 are read as 0. |

This register is writable only when the CFM[1:0] value in the RSCANnCFCCk register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This RSCFDnCFIDk register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, these bits are used to set the ID format of the message to be transmitted from the transmit/receive FIFO buffer.

CFRTR Bit

This bit indicates the data format (data frame or remote frame) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, this bit is used to set the data format of the message to be transmitted from the transmit/receive FIFO buffer.

THLEN Bit

When this bit is set to 1, the transmit history data (label information, buffer number, and buffer type) of transmit messages is stored in the transmit history buffer after transmission is completed.

This bit is enabled when the CFM[1:0] value is 01_B (transmit mode).

CFID[28:0] Bits

These bits contain the ID of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B.

When the CFM[1:0] value is 01_B, this bit is used to set the ID of the message to be transmitted from the transmit/receive FIFO buffer.

25.3.8.5 RSCANnCFPTRk — Transmit/receive FIFO Buffer Access Pointer Register (k = 0 to 5)

Access: RSCANnCFPTRk register can be read/written in 32-bit units
 RSCANnCFPTRkL, RSCANnCFPTRkH registers can be read/written in 16-bit units
 RSCANnCFPTRkLL, RSCANnCFPTRkLH, RSCANnCFPTRkHL, RSCANnCFPTRkHH registers can be read/written in 8-bit units

Address: RSCANnCFPTRk: <RSCFDn_base> + 0E84_H + (10_H × k)
 RSCANnCFPTRkL: <RSCFDn_base> + 0E84_H + (10_H × k),
 RSCANnCFPTRkH: <RSCFDn_base> + 0E86_H + (10_H × k)
 RSCANnCFPTRkLL: <RSCFDn_base> + 0E84_H + (10_H × k),
 RSCANnCFPTRkLH: <RSCFDn_base> + 0E85_H + (10_H × k),
 RSCANnCFPTRkHL: <RSCFDn_base> + 0E86_H + (10_H × k),
 RSCANnCFPTRkHH: <RSCFDn_base> + 0E87_H + (10_H × k)

Value after reset: 0000 0000_H

Table 25.50 RSCANnCFPTRk Register Contents

| Bit | Bit Name | Function |
|----------|-------------|---|
| 31 to 28 | CFDLC[3:0] | Transmit/Receive FIFO Buffer DLC Data b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes |
| 27 to 16 | CFPTR[11:0] | Transmit/Receive FIFO Buffer Label Data <ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set the label information to be stored in the transmit history buffer. Only bits CFPTR[7:0] are valid. When CFM[1:0] value is 00_B (receive mode): The label information of the received message can be read. |
| 15 to 0 | CFTS[15:0] | Transmit/Receive FIFO Buffer Timestamp Data These bits are valid only when the CFM[1:0] value is 00 _B (receive mode). The timestamp value of the received message can be read. |

This register is writable only when the CFM[1:0] value in the RSCANnCFCCk register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFDLC[3:0] Bits

These bits indicate the data length of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, these bits are used to set the data length of the message to be transmitted from the transmit/receive FIFO buffer. If the data length is set to 1001_B or more, the actual transmit data defaults to 8 bytes.

CFPTR[11:0] Bits

These bits indicate the label information attached to the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, the CFPTR[7:0] value is stored in the transmit history buffer when message transmission has been completed.

CFTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the transmit/receive FIFO buffer.

These bits are valid when the CFM[1:0] value is 00_B.

25.3.8.6 RSCANnCFDF0_k — Transmit/receive FIFO Buffer Access Data Field 0 Register (k = 0 to 5)

Access: RSCANnCFDF0_k register can be read/written in 32-bit units
 RSCANnCFDF0_kL, RSCANnCFDF0_kH registers can be read/written in 16-bit units
 RSCANnCFDF0_kLL, RSCANnCFDF0_kLH, RSCANnCFDF0_kHL, RSCANnCFDF0_kHH registers can be read/written in 8-bit units

Address: RSCANnCFDF0_k: <RSCFDn_base> + 0E88_H + (10_H × k)
 RSCANnCFDF0_kL: <RSCFDn_base> + 0E88_H + (10_H × k),
 RSCANnCFDF0_kH: <RSCFDn_base> + 0E8A_H + (10_H × k)
 RSCANnCFDF0_kLL: <RSCFDn_base> + 0E88_H + (10_H × k),
 RSCANnCFDF0_kLH: <RSCFDn_base> + 0E89_H + (10_H × k),
 RSCANnCFDF0_kHL: <RSCFDn_base> + 0E8A_H + (10_H × k),
 RSCANnCFDF0_kHH: <RSCFDn_base> + 0E8B_H + (10_H × k)

Value after reset: 0000 0000_H

Table 25.51 RSCANnCFDF0_k Register Contents

| Bit | Bit Name | Function |
|----------|------------|--|
| 31 to 24 | CFDB3[7:0] | Transmit/Receive FIFO Buffer Data Byte 3 |
| 23 to 16 | CFDB2[7:0] | Transmit/Receive FIFO Buffer Data Byte 2 |
| 15 to 8 | CFDB1[7:0] | Transmit/Receive FIFO Buffer Data Byte 1 |
| 7 to 0 | CFDB0[7:0] | Transmit/Receive FIFO Buffer Data Byte 0 <ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set the transmit/receive FIFO buffer data. When CFM[1:0] value is 00_B (receive mode): The message data stored in the transmit/receive FIFO buffer can be read. |

This register is writable only when the CFM[1:0] value in the RSCANnCFCCk register is 01_B (transmit mode).

This register is readable only when the CFM[1:0] value is 00_B (receive mode). When the CFDLC[3:0] value in the RSCANnCFPTRk register is smaller than 1000_B, data bytes for which no data is set are read as 00_H.

This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

25.3.8.7 RSCANnCFDF1_k — Transmit/receive FIFO Buffer Access Data Field 1 Register (k = 0 to 5)

Access: RSCANnCFDF1_k register can be read/written in 32-bit units
 RSCANnCFDF1_kL, RSCANnCFDF1_kH registers can be read/written in 16-bit units
 RSCANnCFDF1_kLL, RSCANnCFDF1_kLH, RSCANnCFDF1_kHL, RSCANnCFDF1_kHH registers can be read/written in 8-bit units

Address: RSCANnCFDF1_k: <RSCFDn_base> + 0E8C_H + (10_H × k)
 RSCANnCFDF1_kL: <RSCFDn_base> + 0E8C_H + (10_H × k),
 RSCANnCFDF1_kH: <RSCFDn_base> + 0E8E_H + (10_H × k)
 RSCANnCFDF1_kLL: <RSCFDn_base> + 0E8C_H + (10_H × k),
 RSCANnCFDF1_kLH: <RSCFDn_base> + 0E8D_H + (10_H × k),
 RSCANnCFDF1_kHL: <RSCFDn_base> + 0E8E_H + (10_H × k),
 RSCANnCFDF1_kHH: <RSCFDn_base> + 0E8F_H + (10_H × k)

Value after reset: 0000 0000_H

Table 25.52 RSCANnCFDF1_k Register Contents

| Bit | Bit Name | Function |
|----------|------------|---|
| 31 to 24 | CFDB7[7:0] | Transmit/Receive FIFO Buffer Data Byte 7 |
| 23 to 16 | CFDB6[7:0] | Transmit/Receive FIFO Buffer Data Byte 6 |
| 15 to 8 | CFDB5[7:0] | Transmit/Receive FIFO Buffer Data Byte 5 |
| 7 to 0 | CFDB4[7:0] | Transmit/Receive FIFO Buffer Data Byte 4 |
| | | <ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set the transmit/receive FIFO buffer data. When CFM[1:0] value is 00_B (receive mode): The message data stored in the transmit/receive FIFO buffer can be read. |

This register is writable only when the CFM[1:0] value in the RSCANnCFCCk register is 01_B (transmit mode).

This register is readable only when the CFM[1:0] value is 00_B (receive mode). When the CFDL[3:0] value in the RSCANnCFPTRk register is smaller than 1000_B, data bytes for which no data is set are read as 00_H.

This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

25.3.9 Details of FIFO Status-related Registers

25.3.9.1 RSCANnFESTS — FIFO Empty Status Register

Access: RSCANnFESTS register can be read only in 32-bit units
 RSCANnFESTSL, RSCANnFESTSH registers can be read only in 16-bit units
 RSCANnFESTSLL, RSCANnFESTSLH, RSCANnFESTSHL, RSCANnFESTSHH registers can be read only in 8-bit units

Address: RSCANnFESTS: <RSCFDn_base> + 0238_H
 RSCANnFESTSL: <RSCFDn_base> + 0238_H, RSCANnFESTSH: <RSCFDn_base> + 023A_H
 RSCANnFESTSLL: <RSCFDn_base> + 0238_H, RSCANnFESTSLH: <RSCFDn_base> + 0239_H,
 RSCANnFESTSHL: <RSCFDn_base> + 023A_H, RSCANnFESTSHH: <RSCFDn_base> + 023B_H

Value after reset: 03FF FFFF_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

Table 25.53 RSCANnFESTS Register Contents

| Bit | Bit Name | Function |
|----------|----------|---|
| 31 to 14 | Reserved | These bits are read as the value after reset. |
| 13 | CF5EMP | Transmit/Receive FIFO Buffer Empty Status Flag 0: Transmit/receive FIFO buffer k contains a message. 1: Transmit/receive FIFO buffer k contains no message. (k = 0 to 5) |
| 12 | CF4EMP | |
| 11 | CF3EMP | |
| 10 | CF2EMP | |
| 9 | CF1EMP | |
| 8 | CF0EMP | Receive FIFO Buffer Empty Status Flag 0: Receive FIFO buffer x contains a unread messages. 1: Receive FIFO buffer x contains no unread message. (x = 0 to 7) |
| 7 | RF7EMP | |
| 6 | RF6EMP | |
| 5 | RF5EMP | |
| 4 | RF4EMP | |
| 3 | RF3EMP | |
| 2 | RF2EMP | |
| 1 | RF1EMP | |
| 0 | RF0EMP | |

The RSCANnFESTS register is set to 03FF FFFF_H in global reset mode.

CFkEMP Flag (k = 0 to 5)

The CFkEMP flag is set to 1 when the CFEMP flag in the RSCANnCFSTSk register is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)). When the CFEMP flag is cleared to 0 (the transmit/receive FIFO buffer contains messages), the CFkEMP flag is cleared to 0.

RFxEMP Flag (x = 0 to 7)

The RFxEMP flag is set to 1 when the RFEMP flag in the RSCANnRFSTs register is set to 1 (the receive FIFO buffer

contains no unread message). When the RFEMP flag is cleared to 0 (the receive FIFO buffer contains unread messages), the RFxEMP flag is cleared to 0.

25.3.9.2 RSCANnFFSTS — FIFO Full Status Register

Access: RSCANnFFSTS register can be read only in 32-bit units
 RSCANnFFSTSL, RSCANnFFSTSH registers can be read only in 16-bit units
 RSCANnFFSTSLL, RSCANnFFSTSLH, RSCANnFFSTSHL, RSCANnFFSTSHH registers can be read only in 8-bit units

Address: RSCANnFFSTS: <RSCFDn_base> + 023C_H
 RSCANnFFSTSL: <RSCFDn_base> + 023C_H, RSCANnFFSTSH: <RSCFDn_base> + 023E_H
 RSCANnFFSTSLL: <RSCFDn_base> + 023C_H, RSCANnFFSTSLH: <RSCFDn_base> + 023D_H,
 RSCANnFFSTSHL: <RSCFDn_base> + 023E_H, RSCANnFFSTSHH: <RSCFDn_base> + 023F_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | — | — | CF5 FLL | CF4 FLL | CF3 FLL | CF2 FLL | CF1 FLL | CF0 FLL | RF7 FLL | RF6 FLL | RF5 FLL | RF4 FLL | RF3 FLL | RF2 FLL | RF1 FLL | RF0 FLL |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.54 RSCANnFFSTS Register Contents

| Bit | Bit Name | Function |
|----------|----------|---|
| 31 to 14 | Reserved | These bits are read as the value after reset. |
| 13 | CF5FLL | Transmit/Receive FIFO Buffer Full Status Flag 0: Transmit/receive buffer k is not full. 1: Transmit/receive buffer k is full. (k = 0 to 5) |
| 12 | CF4FLL | |
| 11 | CF3FLL | |
| 10 | CF2FLL | |
| 9 | CF1FLL | |
| 8 | CF0FLL | Receive FIFO Buffer Full Status Flag 0: Receive FIFO buffer x is not full. 1: Receive FIFO buffer x is full. (x = 0 to 7) |
| 7 | RF7FLL | |
| 6 | RF6FLL | |
| 5 | RF5FLL | |
| 4 | RF4FLL | |
| 3 | RF3FLL | |
| 2 | RF2FLL | |
| 1 | RF1FLL | |
| 0 | RF0FLL | |

The RSCANnFFSTS register is cleared to 0000 0000_H in global reset mode.

CFkFLL Flag (k = 0 to 5)

The CFkFLL flag is set to 1 when the CFFLL flag in the RSCANnCFSTSk register is set to 1 (the transmit/receive FIFO buffer is full).

When the CFFLL flag is cleared to 0 (the transmit/receive FIFO buffer is not full), the CFkFLL flag is cleared to 0.

RFxFLL Flag (x = 0 to 7)

The RFxFLL flag is set to 1 when the RFFLL flag in the RSCANnRFSTSh register is set to 1 (the receive FIFO buffer is full). When the RFFLL flag is cleared to 0 (the receive FIFO buffer is not full), the RFxFLL flag is cleared to 0.

25.3.9.3 RSCANnFMSTS — FIFO Message Lost Status Register

Access: RSCANnFMSTS register can be read only in 32-bit units
 RSCANnFMSTSL, RSCANnFMSTSH registers can be read only in 16-bit units
 RSCANnFMSTSLH, RSCANnFMSTSLH, RSCANnFMSTSHL, RSCANnFMSTSHH registers can be read only in 8-bit units

Address: RSCANnFMSTS: <RSCFDn_base> + 0240_H
 RSCANnFMSTSL: <RSCFDn_base> + 0240_H, RSCANnFMSTSH: <RSCFDn_base> + 0242_H
 RSCANnFMSTSLH: <RSCFDn_base> + 0240_H, RSCANnFMSTSLH: <RSCFDn_base> + 0241_H,
 RSCANnFMSTSHL: <RSCFDn_base> + 0242_H, RSCANnFMSTSHH: <RSCFDn_base> + 0243_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.55 RSCANnFMSTS Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 14 | Reserved | These bits are read as the value after reset. |
| 13 | CF5MLT | Transmit/Receive FIFO Buffer Message Lost Status Flag 0: No transmit/receive FIFO buffer k message is lost. 1: A transmit/receive FIFO buffer k message is lost. (k = 0 to 5) |
| 12 | CF4MLT | |
| 11 | CF3MLT | |
| 10 | CF2MLT | |
| 9 | CF1MLT | |
| 8 | CF0MLT | |
| 7 | RF7MLT | Receive FIFO Buffer Message Lost Status Flag 0: No receive FIFO buffer x message is lost. 1: A receive FIFO buffer x message is lost. (x = 0 to 7) |
| 6 | RF6MLT | |
| 5 | RF5MLT | |
| 4 | RF4MLT | |
| 3 | RF3MLT | |
| 2 | RF2MLT | |
| 1 | RF1MLT | |
| 0 | RF0MLT | |

The RSCANnFMSTS register is cleared to 0000 0000H in global reset mode.

CFkMLT Flag (k = 0 to 5)

The CFkMLT flag is set to 1 when the CFMLT flag in the RSCANnCFSTSk register is set to 1 (a transmit/receive FIFO message is lost). When the CFMLT flag is cleared to 0, the CFkMLT flag is cleared to 0.

RFxMLT Flag (x = 0 to 7)

The RFxMLT flag is set to 1 when the RFMLT flag in the RSCANnRFSTSh register is set to 1 (a receive FIFO message is lost). When the RFMLT flag is cleared to 0, the RFxMLT flag is cleared to 0.

25.3.9.4 RSCANnRFISTS — Receive FIFO Buffer Interrupt Flag Status Register

Access: RSCANnRFISTS register can be read only in 32-bit units
 RSCANnRFISTSL, RSCANnRFISTSH registers can be read only in 16-bit units
 RSCANnRFISTSLL, RSCANnRFISTSLH, RSCANnRFISTSHL, RSCANnRFISTSHH registers can be read only in 8-bit units

Address: RSCANnRFISTS: <RSCFDn_base> + 0244_H
 RSCANnRFISTSL: <RSCFDn_base> + 0244_H, RSCANnRFISTSH: <RSCFDn_base> + 0246_H
 RSCANnRFISTSLL: <RSCFDn_base> + 0244_H, RSCANnRFISTSLH: <RSCFDn_base> + 0245_H,
 RSCANnRFISTSHL: <RSCFDn_base> + 0246_H, RSCANnRFISTSHH: <RSCFDn_base> + 0247_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|-------|-------|-------|-------|-------|-------|-------|-------|

Table 25.56 RSCANnRFISTS Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 8 | Reserved | These bits are read as the value after reset. |
| 7 | RF7IF | Receive FIFO Buffer Interrupt Request Status Flag |
| 6 | RF6IF | 0: No receive FIFO buffer x interrupt request is present. |
| 5 | RF5IF | 1: A receive FIFO buffer x interrupt request is present. |
| 4 | RF4IF | (x = 0 to 7) |
| 3 | RF3IF | |
| 2 | RF2IF | |
| 1 | RF1IF | |
| 0 | RF0IF | |

The RSCANnRFISTS register is cleared to 0000 0000_H in global reset mode.

RFxIF Flag (x = 0 to 7)

The RFxIF flag is set to 1 when the RFIF flag in the RSCANnRFISTSx register is set to 1 (a receive FIFO interrupt request is present). When the RFIF flag is cleared to 0, the RFxIF is cleared to 0.

25.3.9.5 RSCANnCFRISTS — Transmit/receive FIFO Buffer Receive Interrupt Flag Status Register

Access: RSCANnCFRISTS register can be read only in 32-bit units
 RSCANnCFRISTSLL, RSCANnCFRISTSH registers can be read only in 16-bit units
 RSCANnCFRISTSLL, RSCANnCFRISTSLH, RSCANnCFRISTSHL, RSCANnCFRISTSHH registers can be read only in 8-bit units

Address: RSCANnCFRISTS: <RSCFDn_base> + 0248_H
 RSCANnCFRISTSLL: <RSCFDn_base> + 0248_H, RSCANnCFRISTSH: <RSCFDn_base> + 024A_H
 RSCANnCFRISTSLL: <RSCFDn_base> + 0248_H, RSCANnCFRISTSLH: <RSCFDn_base> + 0249_H,
 RSCANnCFRISTSHL: <RSCFDn_base> + 024A_H, RSCANnCFRISTSHH: <RSCFDn_base> + 024B_H

Value after reset: 0000 0000_H

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.57 RSCANnCFRISTS Register Contents

| Bit | Bit Name | Function |
|---------|----------|--|
| 31 to 6 | Reserved | These bits are read as the value after reset. |
| 5 | CF5RXIF | Transmit/Receive FIFO Buffer Receive Interrupt Request Status Flag |
| 4 | CF4RXIF | 0: No transmit/receive FIFO buffer k receive interrupt request is present. |
| 3 | CF3RXIF | 1: A transmit/receive FIFO buffer k receive interrupt request is present. |
| 2 | CF2RXIF | (k = 0 to 5) |
| 1 | CF1RXIF | |
| 0 | CF0RXIF | |

The RSCANnCFRISTS register is cleared to 0000 0000H in global reset mode.

CFkRXIF Flag (k = 0 to 5)

The CFkRXIF flag is set to 1 when the CFRXIF flag in the RSCANnCFSTSk register is set to 1 (a transmit/receive FIFO receive interrupt request is present). When the CFRXIF flag is cleared to 0, the CFkRXIF flag is cleared to 0.

25.3.9.6 RSCANnCFSTIS — Transmit/receive FIFO Buffer Transmit Interrupt Flag Status Register

Access: RSCANnCFSTIS register can be read only in 32-bit units
 RSCANnCFSTISL, RSCANnCFSTISH registers can be read only in 16-bit units
 RSCANnCFSTISLL, RSCANnCFSTISLH, RSCANnCFSTISHL, RSCANnCFSTISHH registers can be read only in 8-bit units

Address: RSCANnCFSTIS: <RSCFDn_base> + 024C_H
 RSCANnCFSTISL: <RSCFDn_base> + 024C_H, RSCANnCFSTISH: <RSCFDn_base> + 024E_H
 RSCANnCFSTISLL: <RSCFDn_base> + 024C_H, RSCANnCFSTISLH: <RSCFDn_base> + 024D_H,
 RSCANnCFSTISHL: <RSCFDn_base> + 024E_H, RSCANnCFSTISHH: <RSCFDn_base> + 024F_H

Value after reset: 0000 0000_H

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

Table 25.58 RSCANnCFSTIS Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 6 | Reserved | These bits are read as the value after reset. |
| 5 | CF5TXIF | Transmit/Receive FIFO Buffer Transmit Interrupt Request Status Flag |
| 4 | CF4TXIF | 0: No transmit/receive FIFO buffer k transmit interrupt request is present. |
| 3 | CF3TXIF | 1: A transmit/receive FIFO buffer k transmit interrupt request is present. |
| 2 | CF2TXIF | (k = 0 to 5) |
| 1 | CF1TXIF | |
| 0 | CF0TXIF | |

The RSCANnCFSTIS register is cleared to 0000 0000H in global reset mode.

CFkTXIF Flag (k = 0 to 5)

The CFkTXIF flag is set to 1 when the CFTXIF flag in the RSCANnCFSTSk register is set to 1 (a transmit/receive FIFO transmit interrupt request is present). When the CFTXIF flag is cleared to 0, the CFkTXIF flag is cleared to 0.

25.3.10 Details of Transmit Buffer-related Registers

25.3.10.1 RSCANnTMCp — Transmit Buffer Control Register (p = 0 to 31)

Access: RSCANnTMCp registers can be read/written in 8-bit units

Address: RSCANnTMCp: <RSCFDn_base> + 0250_H + (01_H × p)

Value after reset: 00_H

| | | | | | | | | |
|--------------------|---|---|---|---|---|------|-------------------|-------------------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | TMOM | TMTAR | TMTR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R/W | R/W ^{*1} | R/W ^{*1} |

Note 1. The only effective value for writing to this bit is 1, which sets the bit. Otherwise writing to the bit results in retention of its state.

Table 25.59 RSCANnTMCp Register Contents

| Bit | Bit Name | Function |
|--------|----------|---|
| 7 to 3 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 2 | TMOM | One-Shot Transmission Enable 0: One-shot transmission is disabled. 1: One-shot transmission is enabled. |
| 1 | TMTAR | Transmit Abort Request 0: Transmit abort is not requested. 1: Transmit abort is requested. |
| 0 | TMTR | Transmit Request 0: Transmission is not requested. 1: Transmission is requested. |

When the RSCANnTMCp register meets any of the following conditions, set it to 00_H.

- The RSCANnTMCp register corresponds to the transmit buffer number selected by the CFTML[3:0] bits in the RSCANnCFCCk register ($p = m \times 16 + \text{the value of CFTML}[3:0] \text{ bits}$).
- The RSCANnTMCp register corresponds to the transmit buffer allocated to the transmit queue by the TXQDC[3:0] bits in the RSCANnTXQCCm ($m = 0, 1$) register ($p = (m \times 16 + 15) \text{ to } (m \times 16 + 15 - \text{the value of TXQDC}[3:0] \text{ bits})$).

Bits in the RSCANnTMCp register are all cleared to 0 in channel reset mode. Modify the RSCANnTMCp register in channel communication mode or channel halt mode.

TMOM Bit

Setting this bit to 1 enables one-shot transmission. When transmission fails, retransmission defined in the CAN protocol is not performed.

Modify the TMOM bit when the TMTRM flag in the RSCANnTMSTSp register is set to 0. Set the TMOM bit to 1 together with the TMTR bit.

TMTAR Bit

Setting this bit to 1 generates a transmit abort request for the message stored in the transmit buffer. However, a message that is being transmitted or one that will be transmitted next cannot be aborted.

The TMTAR bit can be set to 1 when TMTR bit is 1.

The TMTAR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit.

- Transmission has been completed.
- Transmit abort has been completed.
- An error or arbitration loss has been detected.

If this bit becomes 0 at the same time as the program writes 1 to this bit, this bit becomes 0.

TMTR Bit

Setting this bit to 1 transmits the message stored in the transmit buffer.

The TMTR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit.

- Transmission has been completed.
- Transmit abort has been completed after the TMTAR bit was set to 1.
- An error or arbitration-lost has been detected with the TMOM bit set to 1.

Set the TMTR bit to 1 when the value of TMTRF[1:0] in the RSCANnTMSTSp register is 00_B.

25.3.10.2 RSCANnTMSTSp — Transmit Buffer Status Register (p = 0 to 31)

Access: RSCANnTMSTSp registers can be read/written in 8-bit units

Address: RSCANnTMSTSp: <RSCFDn_base> + 02D0_H + (01_H × p)

Value after reset: 00_H

| | | | | | | | | |
|--------------------|---|---|---|------------|-----------|------------|-----|------------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | TMTAR M | TMTR M | TMTRF[1:0] | | TMTST S |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R/W | R/W | R |

Table 25.60 RSCANnTMSTSp Register Contents

| Bit | Bit Name | Function |
|--------|------------|---|
| 7 to 5 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 4 | TMTARM | Transmit Buffer Transmit Abort Request Status Flag 0: No transmit abort request is present. 1: A transmit abort request is present. |
| 3 | TMTRM | Transmit Buffer Transmit Request Status Flag 0: No transmit request is present. 1: A transmit request is present. |
| 2, 1 | TMTRF[1:0] | Transmit Buffer Transmit Result Status Flag b2 b1 0 0: Transmission is in progress or no transmit request is present. 0 1: Transmit abort has been completed. 1 0: Transmission has been completed (without transmit abort request). 1 1: Transmission has been completed (with transmit abort request). |
| 0 | TMTSTS | Transmit Buffer Transmit Status Flag 0: Transmission is not in progress. 1: Transmission is in progress. |

The RSCANnTMSTSp register is cleared to all 0 in channel reset mode.

TMTARM Flag

The TMTARM flag is set to 1 when the TMTAR bit in the RSCANnTMCp register is set to 1.
The TMTARM flag is set to 0 when the TMTAR bit in the RSCANnTMCp register is set to 0.

TMTRM Flag

The TMTRM flag is set to 1 when the TMTR bit in the RSCANnTMCp register is set to 1.
The TMTRM flag is set to 0 when the TMTR bit in the RSCANnTMCp register is set to 0.

TMTRF[1:0] Flag

This flag indicates the result of transmission from the transmit buffer.

00B: Transmission is in progress or no transmit request is present.

01B: Transmission from the transmit buffer was aborted.

10B: Transmission has been completed with the TMTAR bit in the RSCANnTMCp register set to 0 (transmit abort is not requested).

11B: Transmission has been completed with the TMTAR bit in the RSCANnTMCp register set to 1 (transmit abort is requested).

Write 00B to the TMTRF[1:0] flag in channel communication mode or channel halt mode. Do not write any value other than 00B to this flag.

TMTSTS Flag

This flag is set to 1 when transmission from the transmit buffer starts, and is cleared to 0 when transmission from the transmit buffer has been completed or terminated due to a bus error or arbitration lost.

25.3.10.3 RSCANnTMIDp — Transmit Buffer ID Register (p = 0 to 31)

Access: RSCANnTMIDp register can be read/written in 32-bit units
 RSCANnTMIDpL, RSCANnTMIDpH registers can be read/written in 16-bit units
 RSCANnTMIDpLL, RSCANnTMIDpLH, RSCANnTMIDpHL, RSCANnTMIDpHH registers can be read/written in 8-bit units

Address: RSCANnTMIDp: $\langle \text{RSCFDn_base} \rangle + 1000_{\text{H}} + (10_{\text{H}} \times p)$
 RSCANnTMIDpL: $\langle \text{RSCFDn_base} \rangle + 1000_{\text{H}} + (10_{\text{H}} \times p)$,
 RSCANnTMIDpH: $\langle \text{RSCFDn_base} \rangle + 1002_{\text{H}} + (10_{\text{H}} \times p)$
 RSCANnTMIDpLL: $\langle \text{RSCFDn_base} \rangle + 1000_{\text{H}} + (10_{\text{H}} \times p)$,
 RSCANnTMIDpLH: $\langle \text{RSCFDn_base} \rangle + 1001_{\text{H}} + (10_{\text{H}} \times p)$,
 RSCANnTMIDpHL: $\langle \text{RSCFDn_base} \rangle + 1002_{\text{H}} + (10_{\text{H}} \times p)$,
 RSCANnTMIDpHH: $\langle \text{RSCFDn_base} \rangle + 1003_{\text{H}} + (10_{\text{H}} \times p)$

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|------------|-------|-------|-------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

Table 25.61 RSCANnTMIDp Register Contents

| Bit | Bit Name | Function |
|---------|------------|--|
| 31 | TMIDE | Transmit Buffer IDE 0: Standard ID 1: Extended ID |
| 30 | TMRTR | Transmit Buffer RTR 0: Data frame 1: Remote frame |
| 29 | THLEN | Transmit History Data Store Enable 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer. |
| 28 to 0 | TMID[28:0] | Transmit Buffer ID Data Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11. |

Modify this register when the TMTRM bit in the corresponding RSCANnTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write data to this register. If this register is allocated to the transmit queue, only write data to a transmit buffer p ($p = m \times 16 + 15$) for the corresponding channel.

TMIDE Bit

This bit is used to set the ID format of the message to be transmitted from the transmit buffer.

TMRTR Bit

This bit is used to set the data format of the message to be transmitted from the transmit buffer.

THLEN Bit

When this bit is set to 1, the transmit history data (label information, buffer number, buffer type, and timestamp (timestamp is included if the TMTSCE bit in the RSCANnGCFG register is 1)) of transmit messages is stored in the

transmit history buffer after transmission is completed.

TMID[28:0] Bits

These bits are used to set the ID of the message to be transmitted from the transmit buffer.

25.3.10.4 RSCANnTMPTRp — Transmit Buffer Pointer Register (p = 0 to 31)

Access: RSCANnTMPTRp register can be read/written in 32-bit units
 RSCANnTMPTRpL, RSCANnTMPTRpH registers can be read/written in 16-bit units
 RSCANnTMPTRpLL, RSCANnTMPTRpLH, RSCANnTMPTRpHL, RSCANnTMPTRpHH registers can be read/written in 8-bit units

Address: RSCANnTMPTRp: <RSCFDn_base> + 1004_H + (10_H × p)
 RSCANnTMPTRpL: <RSCFDn_base> + 1004_H + (10_H × p),
 RSCANnTMPTRpH: <RSCFDn_base> + 1006_H + (10_H × p)
 RSCANnTMPTRpLL: <RSCFDn_base> + 1004_H + (10_H × p),
 RSCANnTMPTRpLH: <RSCFDn_base> + 1005_H + (10_H × p),
 RSCANnTMPTRpHL: <RSCFDn_base> + 1006_H + (10_H × p),
 RSCANnTMPTRpHH: <RSCFDn_base> + 1007_H + (10_H × p)

Value after reset: 0000 0000_H

| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.62 RSCANnTMPTRp Register Contents

| Bit | Bit Name | Function |
|----------|------------|---|
| 31 to 28 | TMDLC[3:0] | Transmit Buffer DLC Data b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes |
| 27 to 24 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 23 to 16 | TMPTR[7:0] | Transmit Buffer Label Data Set the label information to be stored in the transmit history buffer. |
| 15 to 0 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |

Modify this register when the TMTRM bit in the corresponding RSCANnTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p ($p = m \times 16 + 15$) for the corresponding channel.

TMDLC[3:0] Bits

These bits are used to set the data length of the message to be transmitted from the transmit buffer when the TMRTR bit in the RSCANnTMIDp register is set to 0 (data frame). If the data length is set to 1001B or more, the transmit data is 8 bytes long.

When the TMRTR bit is set to 1 (remote frame), set the data length of messages to be requested.

TMPTR[7:0] Bits

When message transmission has been completed, the TMPTR[7:0] value is stored in the transmit history buffer.

25.3.10.5 RSCANnTMDF0_p — Transmit Buffer Data Field 0 Register (p = 0 to 31)

Access: RSCANnTMDF0_p register can be read/written in 32-bit units
 RSCANnTMDF0_pL, RSCANnTMDF0_pH registers can be read/written in 16-bit units
 RSCANnTMDF0_pLL, RSCANnTMDF0_pLH, RSCANnTMDF0_pHL, RSCANnTMDF0_pHH registers can be read/written in 8-bit units

Address: RSCANnTMDF0_p: $\langle \text{RSCFDn_base} \rangle + 1008_{\text{H}} + (10_{\text{H}} \times p)$
 RSCANnTMDF0_pL: $\langle \text{RSCFDn_base} \rangle + 1008_{\text{H}} + (10_{\text{H}} \times p)$,
 RSCANnTMDF0_pH: $\langle \text{RSCFDn_base} \rangle + 100A_{\text{H}} + (10_{\text{H}} \times p)$
 RSCANnTMDF0_pLL: $\langle \text{RSCFDn_base} \rangle + 1008_{\text{H}} + (10_{\text{H}} \times p)$,
 RSCANnTMDF0_pLH: $\langle \text{RSCFDn_base} \rangle + 1009_{\text{H}} + (10_{\text{H}} \times p)$,
 RSCANnTMDF0_pHL: $\langle \text{RSCFDn_base} \rangle + 100A_{\text{H}} + (10_{\text{H}} \times p)$,
 RSCANnTMDF0_pHH: $\langle \text{RSCFDn_base} \rangle + 100B_{\text{H}} + (10_{\text{H}} \times p)$

Value after reset: 0000 0000_H

Table 25.63 RSCANnTMDF0_p Register Contents

| Bit | Bit Name | Function |
|----------|------------|-------------------------------|
| 31 to 24 | TMDB3[7:0] | Transmit Buffer Data Byte 3 |
| 23 to 16 | TMDB2[7:0] | Transmit Buffer Data Byte 2 |
| 15 to 8 | TMDB1[7:0] | Transmit Buffer Data Byte 1 |
| 7 to 0 | TMDB0[7:0] | Transmit Buffer Data Byte 0 |
| | | Set the transmit buffer data. |

Modify this register when the TMTRM bit in the corresponding RSCANnTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p ($p = m \times 16 + 15$) for the corresponding channel.

25.3.10.6 RSCANnTMDF1_p — Transmit Buffer Data Field 1 Register (p = 0 to 31)

Access: RSCANnTMDF1_p register can be read/written in 32-bit units
 RSCANnTMDF1_pL, RSCANnTMDF1_pH registers can be read/written in 16-bit units
 RSCANnTMDF1_pLL, RSCANnTMDF1_pLH, RSCANnTMDF1_pHL, RSCANnTMDF1_pHH registers can be read/written in 8-bit units

Address: RSCANnTMDF1_p: $\langle \text{RSCFDn_base} \rangle + 100\text{C}_\text{H} + (10_\text{H} \times p)$
 RSCANnTMDF1_pL: $\langle \text{RSCFDn_base} \rangle + 100\text{C}_\text{H} + (10_\text{H} \times p)$,
 RSCANnTMDF1_pH: $\langle \text{RSCFDn_base} \rangle + 100\text{E}_\text{H} + (10_\text{H} \times p)$
 RSCANnTMDF1_pLL: $\langle \text{RSCFDn_base} \rangle + 100\text{C}_\text{H} + (10_\text{H} \times p)$,
 RSCANnTMDF1_pLH: $\langle \text{RSCFDn_base} \rangle + 100\text{D}_\text{H} + (10_\text{H} \times p)$,
 RSCANnTMDF1_pHL: $\langle \text{RSCFDn_base} \rangle + 100\text{E}_\text{H} + (10_\text{H} \times p)$,

Table 25.64 RSCANnTMDF1_p Register Contents

| Bit | Bit Name | Function |
|----------|------------|-------------------------------|
| 31 to 24 | TMDB7[7:0] | Transmit Buffer Data Byte 7 |
| 23 to 16 | TMDB6[7:0] | Transmit Buffer Data Byte 6 |
| 15 to 8 | TMDB5[7:0] | Transmit Buffer Data Byte 5 |
| 7 to 0 | TMDB4[7:0] | Transmit Buffer Data Byte 4 |
| | | Set the transmit buffer data. |

Modify this register when the TMTRM bit in the corresponding RSCANnTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p ($p = m \times 16 + 15$) for the corresponding channel.

25.3.10.7 RSCANnTMIECy — Transmit Buffer Interrupt Enable Configuration Register (y = 0)

Access: RSCANnTMIECy register can be read/written in 32-bit units
 RSCANnTMIECyL, RSCANnTMIECyH registers can be read/written in 16-bit units
 RSCANnTMIECyLL, RSCANnTMIECyLH, RSCANnTMIECyHL, RSCANnTMIECyHH registers can be read/written in 8-bit units

Address: RSCANnTMIECy: <RSCFDn_base> + 0390_H + (04_H × y)
 RSCANnTMIECyL: <RSCFDn_base> + 0390_H + (04_H × y),
 RSCANnTMIECyH: <RSCFDn_base> + 0392_H + (04_H × y)
 RSCANnTMIECyLL: <RSCFDn_base> + 0390_H + (04_H × y),
 RSCANnTMIECyLH: <RSCFDn_base> + 0391_H + (04_H × y),
 RSCANnTMIECyHL: <RSCFDn_base> + 0392_H + (04_H × y),
 RSCANnTMIECyHH: <RSCFDn_base> + 0393_H + (04_H × y)

Table 25.65 RSCANnTMIECy Register Contents

| Bit | Bit Name | Function |
|----------|----------|---|
| 31 to 16 | TMIEp | Transmit Buffer Interrupt Enable p (p = y × 32 + 31 to y × 32 + 16) 0: Transmit buffer interrupt is disabled 1: Transmit buffer interrupt is enabled |
| 15 to 0 | TMIEp | Transmit Buffer Interrupt Enable p (p = y × 32 + 15 to y × 32 + 0) 0: Transmit buffer interrupt is disabled. 1: Transmit buffer interrupt is enabled. |

TMIEp Bits (p = 0 to 31)

When any of these bits is set to 1 and the corresponding transmission has been completed, a transmit buffer interrupt request is generated.

Modify these bits when the TMTRM flag in the corresponding RSCANnTMSTSp register is 0 (no transmit request is present).

Write 0 to bits corresponding to transmit buffers linked to transmit/receive FIFO buffers or transmit buffers allocated to the transmit queue.

Table 25.66 shows the bit assignment.

Table 25.75 RSCANnTXQCCm Register Contents

| Bit | Bit Name | Function |
|----------|------------|--|
| 31 to 14 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 13 | TXQIM | Transmit Queue Interrupt Source Select 0: When the transmit queue becomes empty upon completion of message transmission, a transmit queue interrupt request is generated. 1: A transmit queue interrupt request is generated each time a message has been transmitted. |
| 12 | TXQIE | Transmit Queue Interrupt Enable 0: Transmit queue interrupt is disabled. 1: Transmit queue interrupt is enabled. |
| 11 to 8 | TXQDC[3:0] | Transmit Queue Depth Configuration Setting these bits to g (g = 2 to 15) makes the (g + 1)-buffer transmit queue available. Setting these bits to 0 disables the transmit queue. Setting these bits to 1 is prohibited. |
| 7 to 1 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 0 | TXQE | Transmit Queue Enable 0: The transmit queue is not used. 1: The transmit queue is used. |

TXQIM Bit

This bit is used to select a transmit queue interrupt source. Modify this bit in channel reset mode.

TXQIE Bit

When the TXQIE bit is set to 1 and the source selected by the TXQIM bit occurs, an interrupt request is generated.
 Set the TXQE bit to 0 before modifying the TXQIE bit.

TXQDC[3:0] Bits

These bits are used to specify the number of transmit buffers to be allocated to the transmit queues. Transmit buffers are allocated to transmit queues in descending order of buffer number, that is, from $(m \times 16 + 15)$ to $(m \times 16 + 0)$. For examples of how buffer allocation is done, see Figure 25.9. Modify these bits only in channel reset mode.

TXQE Bit

Setting this bit to 1 makes the transmit queue available. Modify this bit in channel communication mode or channel halt mode. This bit is cleared to 0 in channel reset mode.

Before setting the TXQE bit to 1, set the TXQDC[3:0] bits to 0010_B or more.

25.3.12.2 RSCANnTXQSTSm — Transmit Queue Status Register (m = 0, 1)

Access: RSCANnTXQSTSm register can be read/written in 32-bit units
 RSCANnTXQSTSmL, RSCANnTXQSTSmH registers can be read/written in 16-bit units
 RSCANnTXQSTSmLL, RSCANnTXQSTSmLH, RSCANnTXQSTSmHL, RSCANnTXQSTSmHH registers can be read/written in 8-bit units

Address: RSCANnTXQSTSm: <RSCFDn_base> + 03C0_H + (04_H × m)
 RSCANnTXQSTSmL: <RSCFDn_base> + 03C0_H + (04_H × m),
 RSCANnTXQSTSmH: <RSCFDn_base> + 03C2_H + (04_H × m)
 RSCANnTXQSTSmLL: <RSCFDn_base> + 03C0_H + (04_H × m),
 RSCANnTXQSTSmLH: <RSCFDn_base> + 03C1_H + (04_H × m),
 RSCANnTXQSTSmHL: <RSCFDn_base> + 03C2_H + (04_H × m),
 RSCANnTXQSTSmHH: <RSCFDn_base> + 03C3_H + (04_H × m)

Value after reset: 0000 0001_H

| | — | — | — | — | — | — | — | — | — | — | — | — | — | TXQIF | TXQFL L | TXQE MP |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W *1 | R | R |

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.76 RSCANnTXQSTSm Register Contents

| Bit | Bit Name | Function |
|----------|----------|---|
| 31 to 13 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 12 to 8 | Reserved | When read, an undefined value is returned. The write value should be the value after reset. |
| 7 to 3 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 2 | TXQIF | Transmit Queue Interrupt Request Flag 0: No transmit queue interrupt request is present. 1: A transmit queue interrupt request is present. |
| 1 | TXQFLL | Transmit Queue Full Status Flag 0: The transmit queue is not full. 1: The transmit queue is full. |
| 0 | TXQEMP | Transmit Queue Empty Status Flag 0: The transmit queue contains messages. 1: The transmit queue contains no message (transmit queue empty). |

TXQIF Flag

The TXQIF flag is set to 1 when the event specified by the TXQIM bit in the RSCANnTXQCCm register has occurred. The TXQIF flag is cleared to 0 in channel reset mode or by writing 0 to this flag. This flag is not cleared to 0 by setting the TXQE bit in the RSCANnTXQCCm register to 0 (the transmit queue is not used).

TXQFLL Flag

The TXQFLL flag is set to 1 when the number of messages set for the transmit queue matches the transmit queue depth set by the TXQDC[3:0] bits in the RSCANnTXQCCm register.

This flag is cleared to 0 in any of the following cases.

- The number of messages set for the transmit queue is smaller than the transmit queue depth set by the TXQDC[3:0] bits.
- In channel reset mode

TXQEMP Flag

The TXQEMP flag is cleared to 0 when even a single message is set for the transmit queue.

This flag is set to 1 in any of the following cases.

- The TXQE bit is set to 0 (the transmit queue is not used).
- The transmit queue becomes empty.
- In channel reset mode

25.3.12.3 RSCANnTXQPCTRM — Transmit Queue Pointer Control Register (m = 0, 1)

Access: RSCANnTXQPCTRM register can only be written in 32-bit units
 RSCANnTXQPCTRM_L, RSCANnTXQPCTRM_H registers can only be written in 16-bit units
 RSCANnTXQPCTRM_{LL}, RSCANnTXQPCTRM_{LH}, RSCANnTXQPCTRM_{HL}, RSCANnTXQPCTRM_{HH} registers can only be written in 8-bit units

Address: RSCANnTXQPCTRM: <RSCFDn_base> + 03E0_H + (04_H × m)
 RSCANnTXQPCTRM_L: <RSCFDn_base> + 03E0_H + (04_H × m),
 RSCANnTXQPCTRM_H: <RSCFDn_base> + 03E2_H + (04_H × m)
 RSCANnTXQPCTRM_{LL}: <RSCFDn_base> + 03E0_H + (04_H × m),
 RSCANnTXQPCTRM_{LH}: <RSCFDn_base> + 03E1_H + (04_H × m),
 RSCANnTXQPCTRM_{HL}: <RSCFDn_base> + 03E2_H + (04_H × m),
 RSCANnTXQPCTRM_{HH}: <RSCFDn_base> + 03E3_H + (04_H × m)

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|------------|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

| R/W: | R | R | R | R | R | R | R | R | W | W | W | W | W | W | W | W |

Table 25.77 RSCANnTXQPCTRM Register Contents

| Bit | Bit Name | Function |
|---------|------------|---|
| 31 to 8 | Reserved | The write value should be the value after reset. |
| 7 to 0 | TXQPC[7:0] | Transmit Queue Pointer Control Writing FFH to these bits moves the write pointer of the transmit queue to the next queue buffer. |

TXQPC[7:0] Bits

Writing FFH to the TXQPC[7:0] bits moves the write pointer to the next transmit queue buffer and generates a transmit request of the message. Write transmit messages to the RSCANnTMID_p, RSCANnTMPTR_p, RSCANnTMDF0_p, and RSCANnTMDF1_p registers (p = 15, 31) before writing FFH to the TXQPC[7:0] bits.

When writing FFH to these bits, make sure that the TXQE bit in the RSCANnTXQCC_m register is set to 1 (the transmit queue is used) and the TXQFLL flag in the RSCANnTXQST_m register is 0 (the transmit queue is not full).

25.3.13 Details of Transmit history-related Registers

25.3.13.1 RSCANnTHLCCm — Transmit History Configuration and Control Register (m = 0, 1)

Access: RSCANnTHLCCm register can be read/written in 32-bit units
 RSCANnTHLCCmL, RSCANnTHLCCmH registers can be read/written in 16-bit units
 RSCANnTHLCCmLL, RSCANnTHLCCmLH, RSCANnTHLCCmHL, RSCANnTHLCCmHH registers can be read/written in 8-bit units

Address: RSCANnTHLCCm: <RSCFDn_base> + 0400_H + (04_H × m)
 RSCANnTHLCCmL: <RSCFDn_base> + 0400_H + (04_H × m),
 RSCANnTHLCCmH: <RSCFDn_base> + 0402_H + (04_H × m)
 RSCANnTHLCCmLL: <RSCFDn_base> + 0400_H + (04_H × m),
 RSCANnTHLCCmLH: <RSCFDn_base> + 0401_H + (04_H × m),
 RSCANnTHLCCmHL: <RSCFDn_base> + 0402_H + (04_H × m),
 RSCANnTHLCCmHH: <RSCFDn_base> + 0403_H + (04_H × m)

Value after reset: 0000 0000_H

Table 25.78 RSCANnTHLCCm Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 11 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 10 | THLDTE | Transmit History Target Buffer Select 0: Entry from transmit/receive FIFO buffers and transmit queue 1: Entry from transmit buffers, transmit/receive FIFO buffers, and transmit queue |
| 9 | THLIM | Transmit History Interrupt Source Select 0: When 12 sets of data have been stored in the transmit history buffer 1: When a single set of transmit history data has been stored |
| 8 | THLIE | Transmit History Interrupt Enable 0: Transmit history interrupt is disabled. 1: Transmit history interrupt is enabled. |
| 7 to 1 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 0 | THLE | Transmit History Buffer Enable 0: Transmit history buffer is not used. 1: Transmit history buffer is used. |

THLDTE Bit

When this bit is set to 0, the transmit history data of messages transmitted from transmit/receive FIFO buffers and the transmit queue is stored in the transmit history buffer. When this bit is set to 1, the transmit history data of messages transmitted from transmit buffers, transmit/receive FIFO buffers, and the transmit queue is stored in the transmit history buffer.

Modify this bit only in channel reset mode.

THLIM Bit

This bit is used to select a transmit history interrupt source.

Modify this bit only in channel reset mode.

THLIE Bit

When the THLIE bit is set to 1 and the source selected by the THLIM bit has occurred, a transmit history interrupt request is generated. Modify the THLIE bit only when the THLE bit set to 0.

THLE Bit

Setting this bit to 1 makes the transmit history buffer available. When data transmission from the buffer selected by the THLDTE bit has been completed, the transmit history data of transmit messages is stored in the transmit history buffer.

Modify this bit in channel communication mode or channel halt mode.

This bit is cleared to 0 in channel reset mode.

25.3.13.2 RSCANnTHLSTSm — Transmit History Status Register (m = 0, 1)

Access: RSCANnTHLSTSm register can be read/written in 32-bit units
 RSCANnTHLSTSmL, RSCANnTHLSTSmH registers can be read/written in 16-bit units
 RSCANnTHLSTSmLL, RSCANnTHLSTSmLH, RSCANnTHLSTSmHL, RSCANnTHLSTSmHH registers can be read/written in 8-bit units

Address: RSCANnTHLSTSm: $\langle \text{RSCFDn_base} \rangle + 0420_{\text{H}} + (04_{\text{H}} \times m)$
 RSCANnTHLSTSmL: $\langle \text{RSCFDn_base} \rangle + 0420_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLSTSmH: $\langle \text{RSCFDn_base} \rangle + 0422_{\text{H}} + (04_{\text{H}} \times m)$
 RSCANnTHLSTSmLL: $\langle \text{RSCFDn_base} \rangle + 0420_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLSTSmLH: $\langle \text{RSCFDn_base} \rangle + 0421_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLSTSmHL: $\langle \text{RSCFDn_base} \rangle + 0422_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLSTSmHH: $\langle \text{RSCFDn_base} \rangle + 0423_{\text{H}} + (04_{\text{H}} \times m)$

Value after reset: 0000 0001_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|------------|----|----|----|----|----|----|----|----|-----------|-----------|-------|--------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| | — | — | — | THLMC[4:0] | | | | — | — | — | — | — | THLIF | THLELT | THLFL | THLEMP |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R/W *1 | R/W *1 | R | R |

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.79 RSCANnTHLSTSm Register Contents

| Bit | Bit Name | Function |
|----------|------------|---|
| 31 to 13 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 12 to 8 | THLMC[4:0] | Transmit History Buffer Unread Data Counter These bits indicate the number of unread data sets stored in the transmit history buffer. |
| 7 to 4 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 3 | THLIF | Transmit History Interrupt Request Flag 0: No transmit history interrupt request is present. 1: A transmit history interrupt request is present. |
| 2 | THLELT | Transmit History Buffer Overflow Flag 0: Transmit history buffer overflow has not occurred. 1: Transmit history buffer overflow has occurred. |
| 1 | THLFL | Transmit history Buffer Full Status Flag 0: Transmit history buffer is not full. 1: Transmit history buffer is full. |
| 0 | THLEMP | Transmit History Buffer Empty Status Flag 0: Transmit history buffer contains unread data. 1: Transmit history buffer contains no unread data (buffer empty). |

THLMC[4:0] Bits

These bits indicate the number of unread data sets stored in the transmit history buffer.

These bits are cleared to 0 in channel reset mode.

THLIF Flag

The THLIF flag is set to 1 when the interrupt source specified with the THLIM bit in the RSCANnTHLCCm register occurs.

This flag is cleared to 0 in channel reset mode or by the program writing 0 to this flag.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.
When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

THLELT Flag

The THLELT flag is set to 1 when an attempt is made to store new transmit history data while the transmit history buffer is full. In this case, the new data is discarded. This flag becomes 0 in channel reset mode or by the program writing 0 to this flag.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.
When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

THLFLL Flag

The THLFLL flag is set to 1 when 16 data sets have been stored in the transmit history buffer, and is cleared to 0 when the number of data sets stored in the transmit history buffer has decreased to less than 16. This bit is also cleared to 0 in channel reset mode or when the THLE bit in the RSCANnTHLCCm register is set to 0 (transmit history buffer is not used).

THLEMP Flag

The THLEMP flag is cleared to 0 when even a single set of transmit history data has been stored in the transmit history buffer.

This flag is set to 1 when all the data in the transmit history buffer has been read. This flag is also set to 1 in channel reset mode or when the THLE bit in the RSCANnTHLCCm register is set to 0 (transmit history buffer is not used).

Note: To clear THLIF or THLELT flag to 0, the program must write 0. When writing, use a store instruction to write “0” to the given flag and “1” to other flags.

25.3.13.3 RSCANnTHLPCTRm — Transmit History Pointer Control Register (m = 0, 1)

Access: RSCANnTHLPCTRm register can only be written in 32-bit units
 RSCANnTHLPCTRmL, RSCANnTHLPCTRmH registers can only be written in 16-bit units
 RSCANnTHLPCTRmLL, RSCANnTHLPCTRmLH, RSCANnTHLPCTRmHL, RSCANnTHLPCTRmHH registers can only be written in 8-bit units

Address: RSCANnTHLPCTRm: $\langle \text{RSCFDn_base} \rangle + 0440_{\text{H}} + (04_{\text{H}} \times m)$
 RSCANnTHLPCTRmL: $\langle \text{RSCFDn_base} \rangle + 0440_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLPCTRmH: $\langle \text{RSCFDn_base} \rangle + 0442_{\text{H}} + (04_{\text{H}} \times m)$
 RSCANnTHLPCTRmLL: $\langle \text{RSCFDn_base} \rangle + 0440_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLPCTRmLH: $\langle \text{RSCFDn_base} \rangle + 0441_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLPCTRmHL: $\langle \text{RSCFDn_base} \rangle + 0442_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLPCTRmHH: $\langle \text{RSCFDn_base} \rangle + 0443_{\text{H}} + (04_{\text{H}} \times m)$

Value after reset: 0000 0000_H

Table 25.80 RSCANnTHLPCTRm Register Contents

| Bit | Bit Name | Function |
|---------|------------|---|
| 31 to 8 | Reserved | When writing to these bits, write the value after reset. |
| 7 to 0 | THLPC[7:0] | Transmit History List Pointer Control Writing FFH to these bits moves the read pointer to the next unread data in the transmit history buffer. |

HLPC[7:0] Bits

When the THLPC[7:0] bits are set to FFH, the read pointer moves to the next data in the transmit history buffer. At this time, the THLMC[4:0] (transmit history buffer unread data counter) value in the RSCANnTHLSTSm register is decremented. Write FFH to the THLPC[7:0] bits after reading from the RSCANnTHLACCm register.

When writing FFH to these bits, make sure that the THLE bit in the RSCANnTHLCCm register is set to 1 (transmit history buffer is used) and the THLEMP flag in the RSCANnTHLSTSm register is 0.

25.3.13.4 RSCANnTHLACCm — Transmit History Access Register (m = 0, 1)

Access: RSCANnTHLACCm register can be read only in 32-bit units
 RSCANnTHLACCmL, RSCANnTHLACCmH registers can be read only in 16-bit units
 RSCANnTHLACCmLL, RSCANnTHLACCmLH, RSCANnTHLACCmHL, RSCANnTHLACCmHH registers can be read only in 8-bit units

Address: RSCANnTHLACCm: $\langle \text{RSCFDn_base} \rangle + 1800_{\text{H}} + (04_{\text{H}} \times m)$
 RSCANnTHLACCmL: $\langle \text{RSCFDn_base} \rangle + 1800_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLACCmH: $\langle \text{RSCFDn_base} \rangle + 1802_{\text{H}} + (04_{\text{H}} \times m)$
 RSCANnTHLACCmLL: $\langle \text{RSCFDn_base} \rangle + 1800_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLACCmLH: $\langle \text{RSCFDn_base} \rangle + 1801_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLACCmHL: $\langle \text{RSCFDn_base} \rangle + 1802_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCANnTHLACCmHH: $\langle \text{RSCFDn_base} \rangle + 1803_{\text{H}} + (04_{\text{H}} \times m)$

Value after reset: 0000 0000_H

Table 25.81 RSCANnTHLACCm Register Contents

| Bit | Bit Name | Function |
|----------|------------|--|
| 31 to 16 | TMTS[15:0] | Timestamp Data The timestamp data of stored data can be read. |
| 15 to 8 | TID[7:0] | Label Data The label information of stored data can be read. |
| 7 | Reserved | This bit is read as the value after reset. |
| 6 to 3 | BN[3:0] | Buffer Number Data The buffer number of transmit source (transmit buffer, transmit/receive FIFO or transmit queue) can be read. |
| 2 to 0 | BT[2:0] | Buffer Type Data b2 b1 b0 0 0 1: Transmit buffer 0 1 0: Transmit/receive FIFO buffer 1 0 0: Transmit queue |

TMTS[15:0] Bits

When the TMTSCE bit in the RSCANnGCFG register is 1, timestamp values in transmit history data stored in the transmit history buffer are displayed. When the TMTSCE bit is 0, these bits are always read as 0.

TID[7:0] Bits

These bits indicate the label information of transmit history data stored in the transmit history buffer.

BN[3:0] Bits

These bits indicate the transmit source buffer number in the transmit history data stored in the transmit history buffer.

BT[2:0] Bits

These bits indicate the type of the transmit source buffer in the transmit history data stored in the transmit history buffer.

25.3.14 Details of Test-related Registers

25.3.14.1 RSCANnGTSTCFG — Global Test Configuration Register

Access: RSCANnGTSTCFG register can be read/written in 32-bit units
 RSCANnGTSTCFG, RSCANnGTSTCFGH registers can be read/written in 16-bit units
 RSCANnGTSTCFGLL, RSCANnGTSTCFGHL, RSCANnGTSTCFGH registers can be read/written in 8-bit units

Address: RSCANnGTSTCFG: <RSCFDn_base> + 0468_H
 RSCANnGTSTCFG: <RSCFDn_base> + 0468_H, RSCANnGTSTCFGH: <RSCFDn_base> + 046A_H
 RSCANnGTSTCFGLL: <RSCFDn_base> + 0468_H, RSCANnGTSTCFGHL: <RSCFDn_base> + 0469_H,
 RSCANnGTSTCFGHL: <RSCFDn_base> + 046A_H, RSCANnGTSTCFGHH: <RSCFDn_base> + 046B_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |

Table 25.82 RSCANnGTSTCFG Register Contents

| Bit | Bit Name | Function |
|----------|------------|---|
| 31 to 23 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 22 to 16 | RTMPS[6:0] | RAM Test Page Configuration Set a value within a range of page 0 (00 _H) to page 19 (13 _H). |
| 15 to 2 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 1 | C1ICBCE | CAN1 Inter-Channel Communication Test Enable 0: CAN1 inter-channel communication test is disabled. 1: CAN1 inter-channel communication test is enabled. |
| 0 | C0ICBCE | CAN0 Inter-Channel Communication Test Enable 0: CAN0 inter-channel communication test is disabled. 1: CAN0 inter-channel communication test is enabled. |

Modify the RSCANnGTSTCFG register only in global test mode.

RTMPS[6:0] Bits

These bits are used to set the RAM test target page number for RAM test. Set a value in the range of 00_H to 13_H, inclusive.

C1ICBCE Bit

Setting this bit to 1 enables the channel 1 inter-channel communication test.
 This bit is cleared to 0 in global reset mode.

C0ICBCE Bit

Setting this bit to 1 enables the channel 0 inter-channel communication test.
 This bit is cleared to 0 in global reset mode.

25.3.14.2 RSCANnGTSTCTR — Global Test Control Register

Access: RSCANnGTSTCTR register can be read/written in 32-bit units
 RSCANnGTSTCTRL, RSCANnGTSTCTRH registers can be read/written in 16-bit units
 RSCANnGTSTCTRLL, RSCANnGTSTCTRLH, RSCANnGTSTCTRHL, RSCANnGTSTCTRHH registers can be read/written in 8-bit units

Address: RSCANnGTSTCTR: <RSCFDn_base> + 046C_H
 RSCANnGTSTCTRL: <RSCFDn_base> + 046C_H, RSCANnGTSTCTRH: <RSCFDn_base> + 046E_H
 RSCANnGTSTCTRLL: <RSCFDn_base> + 046C_H, RSCANnGTSTCTRLH: <RSCFDn_base> + 046D_H,
 RSCANnGTSTCTRHL: <RSCFDn_base> + 046E_H, RSCANnGTSTCTRHH: <RSCFDn_base> + 046F_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|------|----|---------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | RTME | — | ICBCTME |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R | R/W |

Table 25.83 RSCANnGTSTCTR Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 3 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 2 | RTME | RAM Test Enable 0: RAM test is disabled. 1: RAM test is enabled. |
| 1 | Reserved | This bit is read as the value after reset. The write value should be the value after reset. |
| 0 | ICBCTME | Communication Test between Channels Enable 0: Communication test between channels disabled 1: Communication test between channels enabled |

RTME Bit

Setting this bit to 1 enables the RAM test. Modify this bit only in global test mode.

This bit is cleared to 0 in global reset mode.

1. Set the GMDC[1:0] bits in the RSCANnGCTR register to 10B (Global test mode).
2. Set the RTME bit to 1.
3. Check that the RTME bit is set to 1.

ICBCTME Bit

When this bit is set to 1, a communication test is enabled between the channels for which the CmICBCE bit (m = 0, 1) in the RSCANnGTSTCFG register has been set to 1. Modify the ICBCTME bit only in global test mode.

This bit is cleared to 0 in global reset mode.

25.3.14.3 RSCANnGLOCKK — Global Lock Key Register

Access: RSCANnGLOCKK register can only be written in 32-bit units
RSCANnGLOCKKL, RSCANnGLOCKKH registers can only be written in 16-bit units

Address: RSCANnGLOCKK: <RSCFDn_base> + 047C_H
RSCANnGLOCKKL: <RSCFDn_base> + 047C_H, RSCANnGLOCKKH: <RSCFDn_base> + 047E_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | LOCK[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 |

Note 1. Writing to these bits is effective only when the RS-CANFD module is in global test mode.

Table 25.84 RSCANnGLOCKK Register Contents

| Bit | Bit Name | Function |
|----------|------------|---|
| 31 to 16 | Reserved | When writing these bits, write the value after reset. |
| 15 to 0 | LOCK[15:0] | Lock Key These bits are key bits to release protection of test mode. |

The RSCANnGLOCKK register releases protection of special test bits and is write only.

For the protection release data, see section 25.11.4.2, Procedure for Releasing the Protection.

LOCK[15:0] Bits

Writing the protection release data to the LOCK[15:0] bits in succession enables writing 1 to the RTME bit in the RSCANnGTSTCTR register.

After the protection has been released, writing to the I/O register area (<RSCFDn_base> + 0000H to <RSCFDn_base> + 04FFH) of the CAN (except the RAM) enables the protection again.

Reading from the I/O register area of the CAN or reading from/writing to other areas does not enable the protection.

25.3.14.4 RSCANnRPGACCr — RAM Test Page Access Register (r = 0 to 63)

Access: RSCANnRPGACCr register can be read/written in 32-bit units
 RSCANnRPGACCrL, RSCANnRPGACCrH registers can be read/written in 16-bit units
 RSCANnRPGACCrLL, RSCANnRPGACCrLH, RSCANnRPGACCrHL, RSCANnRPGACCrHH registers can be read/written in 8-bit units

Address: RSCANnRPGACCr: $\langle \text{RSCFDn_base} \rangle + 1900_{\text{H}} + (04_{\text{H}} \times r)$
 RSCANnRPGACCrL: $\langle \text{RSCFDn_base} \rangle + 1900_{\text{H}} + (04_{\text{H}} \times r)$,
 RSCANnRPGACCrH: $\langle \text{RSCFDn_base} \rangle + 1902_{\text{H}} + (04_{\text{H}} \times r)$
 RSCANnRPGACCrLL: $\langle \text{RSCFDn_base} \rangle + 1900_{\text{H}} + (04_{\text{H}} \times r)$,
 RSCANnRPGACCrLH: $\langle \text{RSCFDn_base} \rangle + 1901_{\text{H}} + (04_{\text{H}} \times r)$,
 RSCANnRPGACCrHL: $\langle \text{RSCFDn_base} \rangle + 1902_{\text{H}} + (04_{\text{H}} \times r)$,
 RSCANnRPGACCrHH: $\langle \text{RSCFDn_base} \rangle + 1903_{\text{H}} + (04_{\text{H}} \times r)$

Value after reset: 0000 0000_H

Table 25.85 RSCANnRPGACCr Register Contents

| Bit | Bit Name | Function |
|---------|------------|--|
| 31 to 0 | RDTA[31:0] | RAM Data Test Access Data can be read and written in RSCAN RAM. |

Modify the RSCANnRPGACCr register in global test mode with the RTME bit in the RSCANnGTSTCTR register set to 1 (RAM test is enabled).

The RSCANnRPGACCr register is readable and writable when the RTME bit is set to 1.

25.4 Registers (CANFD Mode)

This section describes all registers to be used when the RS-CANFD is used in CANFD mode.

25.4.1 List of Registers

The following tables list RS-CANFD registers to be used in CANFD mode.

For details about $\langle \text{RSCFDn_base} \rangle$, see section 25.1.2, Register Base Address.

- Table 25.176, Registers Initialized in Global Reset Mode or Channel Reset Mode
- Table 25.177, Registers Initialized Only in Global Reset Mode

Table 25.86 Registers

| Module | Register | Symbol | Address |
|----------------------------------|---|--------------------|--|
| Interface mode-related register | | | |
| RSCFDn | Global interface mode select register | RSCFDnCFDGRMCFG | $\langle \text{RSCFDn_base} \rangle + 04\text{FC}_\text{H}$ |
| Channel-related registers | | | |
| RSCFDn | Channel m nominal bit rate configuration register | RSCFDnCFDCmNCFG | $\langle \text{RSCFDn_base} \rangle + 0000_\text{H} + (10_\text{H} \times m)$ |
| RSCFDn | Channel m control register | RSCFDnCFDCmCTR | $\langle \text{RSCFDn_base} \rangle + 0004_\text{H} + (10_\text{H} \times m)$ |
| RSCFDn | Channel m status register | RSCFDnCFDCmSTS | $\langle \text{RSCFDn_base} \rangle + 0008_\text{H} + (10_\text{H} \times m)$ |
| RSCFDn | Channel m error flag register | RSCFDnCFDCmERFL | $\langle \text{RSCFDn_base} \rangle + 000\text{C}_\text{H} + (10_\text{H} \times m)$ |
| RSCFDn | Channel m data bit rate configuration register | RSCFDnCFDCmDCFG | $\langle \text{RSCFDn_base} \rangle + 0500_\text{H} + (20_\text{H} \times m)$ |
| RSCFDn | Channel m CANFD configuration register | RSCFDnCFDCmFDCFG | $\langle \text{RSCFDn_base} \rangle + 0504_\text{H} + (20_\text{H} \times m)$ |
| RSCFDn | Channel m CANFD control register | RSCFDnCFDCmFDCTR | $\langle \text{RSCFDn_base} \rangle + 0508_\text{H} + (20_\text{H} \times m)$ |
| RSCFDn | Channel m CANFD status register | RSCFDnCFDCmFDSTS | $\langle \text{RSCFDn_base} \rangle + 050\text{C}_\text{H} + (20_\text{H} \times m)$ |
| RSCFDn | Channel m CANFD CRC register | RSCFDnCFDCmFDCRC | $\langle \text{RSCFDn_base} \rangle + 0510_\text{H} + (20_\text{H} \times m)$ |
| Global-related registers | | | |
| RSCFDn | Global configuration register | RSCFDnCFDGCFG | $\langle \text{RSCFDn_base} \rangle + 0084_\text{H}$ |
| RSCFDn | Global control register | RSCFDnCFDGCTR | $\langle \text{RSCFDn_base} \rangle + 0088_\text{H}$ |
| RSCFDn | Global status register | RSCFDnCFDGSTS | $\langle \text{RSCFDn_base} \rangle + 008\text{C}_\text{H}$ |
| RSCFDn | Global error flag register | RSCFDnCFDGERFL | $\langle \text{RSCFDn_base} \rangle + 0090_\text{H}$ |
| RSCFDn | Global timestamp counter register | RSCFDnCFDGTSC | $\langle \text{RSCFDn_base} \rangle + 0094_\text{H}$ |
| RSCFDn | Global TX Interrupt Status Register 0 | RSCFDnCFDGTINTSTS0 | $\langle \text{RSCFDn_base} \rangle + 0460_\text{H}$ |
| RSCFDn | Global FD configuration register | RSCFDnCFDGFDCFG | $\langle \text{RSCFDn_base} \rangle + 0474_\text{H}$ |
| Receive rule-related registers | | | |
| RSCFDn | Receive Rule Entry Control Register | RSCFDnCFDGAFLCTR | $\langle \text{RSCFDn_base} \rangle + 0098_\text{H}$ |
| RSCFDn | Receive Rule Configuration Register 0 | RSCFDnCFDGAFLCFG0 | $\langle \text{RSCFDn_base} \rangle + 009\text{C}_\text{H}$ |
| RSCFDn | Receive Rule ID Register j | RSCFDnCFDGAFLIDj | $\langle \text{RSCFDn_base} \rangle + 1000_\text{H} + (10_\text{H} \times j)$ |
| RSCFDn | Receive Rule Mask Register j | RSCFDnCFDGAFLMj | $\langle \text{RSCFDn_base} \rangle + 1004_\text{H} + (10_\text{H} \times j)$ |
| RSCFDn | Receive Rule Pointer 0 Register j | RSCFDnCFDGAFLP0_j | $\langle \text{RSCFDn_base} \rangle + 1008_\text{H} + (10_\text{H} \times j)$ |
| RSCFDn | Receive Rule Pointer 1 Register j | RSCFDnCFDGAFLP1_j | $\langle \text{RSCFDn_base} \rangle + 100\text{C}_\text{H} + (10_\text{H} \times j)$ |
| Receive buffer-related registers | | | |
| RSCFDn | Receive Buffer Number Register | RSCFDnCFDRMNB | $\langle \text{RSCFDn_base} \rangle + 00\text{A4}_\text{H}$ |
| RSCFDn | Receive Buffer New Data Register y | RSCFDnCFDRMNDy | $\langle \text{RSCFDn_base} \rangle + 00\text{A8}_\text{H} + (04_\text{H} \times y)$ |
| RSCFDn | Receive Buffer ID Register q | RSCFDnCFDRMIDq | $\langle \text{RSCFDn_base} \rangle + 2000_\text{H} + (20_\text{H} \times q)$ |
| RSCFDn | Receive Buffer Pointer Register q | RSCFDnCFDRMPTRq | $\langle \text{RSCFDn_base} \rangle + 2004_\text{H} + (20_\text{H} \times q)$ |
| RSCFDn | Receive Buffer CANFD status register q | RSCFDnCFDRMFDSTSq | $\langle \text{RSCFDn_base} \rangle + 2008_\text{H} + (20_\text{H} \times q)$ |
| RSCFDn | Receive Buffer Data Field b Register q | RSCFDnCFDRMDfb_q | $\langle \text{RSCFDn_base} \rangle + 200\text{C}_\text{H} + (04_\text{H} \times b) + (20_\text{H} \times q)$ |

| Module | Register | Symbol | Address |
|--|--|--------------------|---|
| Receive FIFO buffer-related registers | | | |

25.4.2 Details of Interface Mode-related Registers

25.4.2.1 RSCFDnCFDGRMCFG — Global Interface Mode Select Register

Access: RSCFDnCFDGRMCFG register can be read/written in 32-bit units
 RSCFDnCFDGRMCFG_L, RSCFDnCFDGRMCFG_H registers can be read/written in 16-bit units
 RSCFDnCFDGRMCFG_LL, RSCFDnCFDGRMCFG_LH, RSCFDnCFDGRMCFG_HL, RSCFDnCFDGRMCFG_HH registers can be read/written in 8-bit units

Address: RSCFDnCFDGRMCFG: <RSCFDn_base> + 04FC_H
 RSCFDnCFDGRMCFG_L: <RSCFDn_base> + 04FC_H,
 RSCFDnCFDGRMCFG_H: <RSCFDn_base> + 04FE_H
 RSCFDnCFDGRMCFG_LL: <RSCFDn_base> + 04FC_H,
 RSCFDnCFDGRMCFG_LH: <RSCFDn_base> + 04FD_H,
 RSCFDnCFDGRMCFG_HL: <RSCFDn_base> + 04FE_H,
 RSCFDnCFDGRMCFG_HH: <RSCFDn_base> + 04FF_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |

Table 25.91 RSCFDnCFDGRMCFG Register Contents

| Bit | Bit Name | Function |
|---------|----------|--|
| 31 to 1 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 0 | RCMC | Interface Mode Select 0: Classical CAN mode 1: CANFD mode |

Note 1. The RSCANnGRMCFG register and the RSCFDnCFDGRMCFG register are the same register. Therefore, set either one of the registers.

Modify the RSCFDnCFDGRMCFG register only in global reset mode. Before setting other RS-CANFD registers, set this register.

RCMC Bit

Setting this bit to 0 places the RS-CANFD module in classical CAN mode. Setting this bit to 1 places the RS-CANFD module in CANFD mode. To switch classical CAN mode to CANFD mode, set the value after reset in all registers and bits allocated to the register map of classical CAN mode and then modify the RSCFDnCFDGRMCFG register.

25.4.3 Details of Channel-related Registers

25.4.3.1 RSCFDnCFDCmNCFG — Channel Nominal Bit Rate Configuration Register (m = 0, 1)

Access: RSCFDnCFDCmNCFG register can be read/written in 32-bit units
 RSCFDnCFDCmNCFG_L, RSCFDnCFDCmNCFG_H registers can be read/written in 16-bit units
 RSCFDnCFDCmNCFG_LL, RSCFDnCFDCmNCFG_LH, RSCFDnCFDCmNCFG_HL, RSCFDnCFDCmNCFG_HH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmNCFG: <RSCFDn_base> + 0000_H + (10_H × m)
 RSCFDnCFDCmNCFG_L: <RSCFDn_base> + 0000_H + (10_H × m),
 RSCFDnCFDCmNCFG_H: <RSCFDn_base> + 0002_H + (10_H × m)
 RSCFDnCFDCmNCFG_LL: <RSCFDn_base> + 0000_H + (10_H × m),
 RSCFDnCFDCmNCFG_LH: <RSCFDn_base> + 0001_H + (10_H × m),
 RSCFDnCFDCmNCFG_HL: <RSCFDn_base> + 0002_H + (10_H × m),

| 15 to 11 | NSJW[4:0] | Nominal Bit Rate Resynchronization Jump Width Control b15 b14 b13 b12 b11 0 0 0 0 0: 1 T _q 0 0 0 0 1: 2 T _q 0 0 0 1 0: 3 T _q : : 1 1 1 1 0: 31 T _q 1 1 1 1 1: 32 T _q |
| 10 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |

| Bit | Bit Name | Function |
|--------|-----------|--|
| 9 to 0 | NBRP[9:0] | Nominal Bit Rate Prescaler Division Ratio Setting When the set value = P (0 to 1023), the nominal bit rate prescaler divides fCAN by (P + 1). |

Modify the RSCFDnCFDCmNCFG register in channel reset mode or channel halt mode. Set this register in channel reset mode, and then transition to channel communication mode or channel halt mode. For the description and settings of bit timing parameters, see **section 25.11.1, Initial Settings**.

NTSEG2[4:0] Bits

These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2) of nominal bit rate.

Allowed values are 2 Tq to 32 Tq, inclusive.

Set a value smaller than the value of the NTSEG1[6:0] bits.

NTSEG1[6:0] Bits

These bits specify the total length of propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1) of nominal bit rate as a Tq value.

A value of 4 to 128 Tq is settable.

NSJW[4:0] Bits

These bits specify the resynchronization jump width of nominal bit rate as a Tq value. A value of 1 to 32 Tq is settable.

Specify a value equal to or smaller than the NTSEG2[4:0] value.

NBRP[9:0] Bits

The clock obtained by dividing the CAN clock (fCAN) by the nominal bit rate prescaler ((NBRP[9:0]) + 1) becomes CANmTq(N) clock (fCANTQ(N)m). One clock of the CANmTq(N) clock becomes one Time Quantum (Tq).

25.4.3.2 RSCFDnCFDCmCTR — Channel Control Register (m = 0, 1)

Access: RSCFDnCFDCmCTR register can be read/written in 32-bit units
 RSCFDnCFDCmCTRL, RSCFDnCFDCmCTRH registers can be read/written in 16-bit units
 RSCFDnCFDCmCTRLL, RSCFDnCFDCmCTRLLH, RSCFDnCFDCmCTRHL, RSCFDnCFDCmCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmCTR: <RSCFDn_base> + 0004_H + (10_H × m)
 RSCFDnCFDCmCTRL: <RSCFDn_base> + 0004_H + (10_H × m),
 RSCFDnCFDCmCTRH: <RSCFDn_base> + 0006_H + (10_H × m)
 RSCFDnCFDCmCTRLL: <RSCFDn_base> + 0004_H + (10_H × m),
 RSCFDnCFDCmCTRLLH: <RSCFDn_base> + 0005_H + (10_H × m),

| 7 to 4 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 3 | RTBO | Forcible Return from Bus-off When this bit is set to 1, forcible return from the bus off state is made. This bit is always read as 0. |
| 2 | CSLPR | Channel Stop Mode 0: Other than channel stop mode 1: Channel stop mode |
| 1, 0 | CHMDC[1:0] | Mode Select b1 b0 0 0: Channel communication mode 0 1: Channel reset mode 1 0: Channel halt mode 1 1: Setting prohibited |

ROM Bit

When the ROM bit and the CTME bit in the RSCFDnCFDCmCTR register are set to 1, restricted operation mode is enabled. Use the restricted operation mode only when the CTMS[1:0] value in the RSCFDnCFDCmCTR register is 00_B (standard test mode). Modify this bit only in channel halt mode. This bit is always 0 in channel reset mode.

CRCT Bit

This bit is used to test the CRC generation circuit in the RS-CANFD module. Setting this bit to 1 inverts the first bit of the ID field when a message is received. With this inversion of bit, the CRC calculation result does not match the normal CRC value of the received frame, which can detect a CRC error (the CERR bit in the RSCFDnCFDCmERFL register is 1). When using this function, note the following.

- This function is available while the CTME bit in the RSCFDnCFDCmCTR register is 1 (communication test mode enabled).
- This function cannot communicate with other CAN nodes. Use this function for inter-channel communication test (the CmICBCE bit in the RSCFDnCFDGTSTCFG register is 1).
- Bit inversion in the ID field may cause bit stuffing rule violation. In that case, no CRC error is detected but a stuff error is detected.

Modify this bit only in channel halt mode. This bit is always 0 in channel reset mode.

CTMS[1:0] Bits

These bits are used to select a communication test mode. Modify these bits in channel halt mode only. These bits are set to 0 in channel reset mode.

CTME Bit

Setting this bit to 1 enables communication test mode. Modify these bits in channel halt mode. This bit is set to 0 in channel reset mode.

ERRD Bit

This bit is used to control the display mode of bits 14 to 8 in the RSCFDnCFDCmERFL register.

When this bit is clear to 0, if any error is detected while the flags of bits 14-8 in the RSCFDnCFDCmERFL register are all 0, only the flags of the first error event are set to 1. If two or more errors occur in the first error event, all the flags of the detected errors are set to 1.

When this bit is set to 1, all the flags of errors that have occurred are set to 1 regardless of the error occurrence order.

Modify this bit only in channel reset mode or channel halt mode.

BOM[1:0] Bits

These bits are used to select the bus off recovery mode of the RS-CANFD module.

When the BOM[1:0] bits are set to 00_B, return from the bus off state to the error active state is compliant with the CAN specifications. That is, the RS-CANFD module reenters the CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. A bus off recovery interrupt request is generated at the time of return from the bus off state. Even if the CHMDC[1:0] bits are set to 10_B (channel halt mode) before recessive bits are detected 128 times, the RS-CANFD module does not transition to channel halt mode until recessive bits are detected 128 times.

When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to 01_B, the CHMDC[1:0] bits in the RSCFDnCFDCmCTR register (m = 0, 1) are set to 10_B and the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated and the TEC[7:0] and REC[7:0] bits in the RSCFDnCFDCmSTS register are cleared to 00_H.

When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to 10_B, the CHMDC[1:0] bits are set to 10_B and the RS-CANFD module transitions to channel halt mode after return from the bus off state (11 consecutive recessive bits are detected 128 times). A bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H.

When the BOM[1:0] bits are set to 11_B and the CHMDC[1:0] bits are set to 10_B while the RS-CANFD module is in the bus off state, the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H. However, if 11 consecutive recessive bits are detected 128 times and the RS-CANFD module has recovered to the error active state from the bus off state before the CHMDC[1:0] bits are set to 10_B, a bus off recovery interrupt request is generated.

If a program writes to the CHMDC[1:0] bit at the same time as the RS-CANFD module transition to channel halt mode (at bus off entry when the BOM[1:0] bits are 01_B or at bus off end when the BOM[1:0] bits are 10_B), the program's writing takes precedence. Modify the BOM[1:0] bits only in channel reset mode.

TDCVFIE Bit

When the TDCVF flag in the RSCFDnCFDCmFDSTS register is set to 1 after the TDCVFIE bit is set to 1, an interrupt request occurs. Modify this bit only in channel reset mode.

SOCOIE Bit

When the SOCO flag in the RSCFDnCFDCmFDSTS register is set to 1 after the SOCOIE bit is set to 1, an interrupt request occurs. Modify this bit only in channel reset mode.

EOCOIE Bit

When the EOCO flag in the RSCFDnCFDCmFDSTS register is set to 1 after the EOCOIE bit is set to 1, an interrupt request occurs. Modify this bit only in channel reset mode.

TAIE Bit

When transmit abort of the transmit buffer is completed with the TAIE bit set to 1, an interrupt request is generated. Modify this bit only in channel reset mode.

ALIE Bit

When the ALF flag in the RSCFDnCFDCmERFL register is set to 1 with the ALIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BLIE Bit

When the BLF flag in the RSCFDnCFDCmERFL register is set to 1 with the BLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

OLIE Bit

When the OVLF flag in the RSCFDnCFDCmERFL register is set to 1 with the OLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BORIE Bit

When the BORF flag in the RSCFDnCFDCmERFL register is set to 1 with the BORIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BOEIE Bit

When the BOEF flag in the RSCFDnCFDCmERFL register is set to 1 with the BOEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

EPIE Bit

When the EPF flag in the RSCFDnCFDCmERFL register is set to 1 with the EPIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

EWIE Bit

When the EWF flag in the RSCFDnCFDCmERFL register is set to 1 with the EWIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BEIE Bit

When the BEF flag in the RSCFDnCFDCmERFL register is set to 1 with the BEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

RTBO Bit

Setting this bit to 1 in the bus off state forcibly returns the state from the bus off state to the error active state. This bit is automatically cleared to 0. Setting this bit to 1 clears the TEC[7:0] and REC[7:0] bits in the RSCFDnCFDCmSTS register to 00_H and also clears the BOSTS flag in the RSCFDnCFDCmSTS register to 0 (not in bus off state). The other registers remain unchanged. No bus off recovery interrupt request is generated upon return from the bus off state in this case. Use this bit only when the BOM[1:0] bits in the RSCFDnCFDCmCTR register are 00_B (ISO11898-1 compliant). A delay of up to 1 CAN bit time occurs after the RTBO bit is set to 1 until the RSCAN module transitions to the error active state. Set this bit to 1 in channel communication mode.

CSLPR Bit

Setting this bit to 1 places the channel into channel stop mode.

Clearing this bit to 0 makes the channel exit channel stop mode.

This bit should not be modified in channel communication mode or channel halt mode.

CHMDC[1:0] Bits

These bits are used to select a channel mode (channel communication mode, channel reset mode, or channel halt mode). For details, see Figure 25.5. Setting the CSLPR bit to 1 in channel reset mode allows transition to channel stop mode. Do not set the CHMDC[1:0] bits to 11_B. When the CAN module has automatically transitioned to channel halt mode based on the setting of the BOM[1:0] bits, the CHMDC[1:0] bits automatically become 10_B.

25.4.3.3 RSCFDnCFDCmSTS — Channel Status Register (m = 0, 1)

Access: RSCFDnCFDCmSTS register can be read/written in 32-bit units
 RSCFDnCFDCmSTSL, RSCFDnCFDCmSTSH registers can be read/written in 16-bit units
 RSCFDnCFDCmSTSL, RSCFDnCFDCmSTSLH, RSCFDnCFDCmSTSHL, RSCFDnCFDCmSTSHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmSTS: <RSCFDn_base> + 0008_H + (10_H × m)
 RSCFDnCFDCmSTSL: <RSCFDn_base> + 0008_H + (10_H × m),
 RSCFDnCFDCmSTSH: <RSCFDn_base> + 000A_H + (10_H × m)
 RSCFDnCFDCmSTSL: <RSCFDn_base> + 0008_H + (10_H × m),
 RSCFDnCFDCmSTSLH: <RSCFDn_base> + 0009_H + (10_H × m),
 RSCFDnCFDCmSTSHL: <RSCFDn_base> + 000A_H + (10_H × m),
 RSCFDnCFDCmSTSHH: <RSCFDn_base> + 000B_H + (10_H × m)

Value after reset: 0000 0005_H

| | | | | | | | | | | | | | | | | |
|--------------------|----------|----|----|----|----|----|----|-------|----------|--------|--------|-------|-------|---------|---------|-------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | TEC[7:0] | | | | | | | | REC[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | ESIF | COMSTS | RECSTS | TRMSTS | BOSTS | EPSTS | CSLPSTS | CHLTSTS | CRSTS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 1 |
| R/W: | R | R | R | R | R | R | R | R/W*1 | R | R | R | R | R | R | R | R |

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.94 RSCFDnCFDCmSTS Register Contents

| Bit | Bit Name | Function |
|----------|----------|---|
| 31 to 24 | TEC[7:0] | The transmit error counter (TEC) can be read. |
| 23 to 16 | REC[7:0] | The receive error counter (REC) can be read. |
| 15 to 9 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 8 | ESIF | Error State Indication Flag 0: No CANFD message whose ESI bit is recessive has been received. 1: At least one CANFD message whose ESI bit is recessive has been received. |
| 7 | COMSTS | Communication Status Flag 0: Communication is not ready. 1: Communication is ready. |
| 6 | RECSTS | Receive Status Flag 0: Bus idle, in transmission or bus off state 1: In reception |
| 5 | TRMSTS | Transmit Status Flag 0: Bus idle or in reception 1: In transmission or bus off state |
| 4 | BOSTS | Bus Off Status Flag 0: Not in bus off state 1: In bus off state |
| 3 | EPSTS | Error Passive Status Flag 0: Not in error passive state 1: In error passive state |
| 2 | CSLPSTS | Channel Stop Status Flag 0: Not in channel stop mode 1: In channel stop mode |
| 1 | CHLTSTS | Channel Halt Status Flag 0: Not in channel halt mode 1: In channel halt mode |

| Bit | Bit Name | Function |
|-----|----------|---|
| 0 | CRSTSTS | Channel Reset Status Flag 0: Not in channel reset mode 1: In channel reset mode |

TEC[7:0] Bits

These bits contain the transmit error counter value. For transmit error counter increment/decrement conditions, see the CAN specification (ISO11898-1).

These bits are cleared to 0 in channel reset mode.

REC[7:0] Bits

These bits contain the receive error counter value. For receive error counter increment/decrement conditions, see the CAN specifications (ISO11898-1).

These bits are cleared to 0 in channel reset mode.

ESIF Flag

When the recessive ESI bit is detected in a successfully received message, this flag is set to 1. In loopback mode or mirror mode, the own transmission message is regarded as a received message. To clear this flag to 0, write 0 to this bit by the program. This bit cannot be set to 1 by the program. If the flag setting (to 1) timing matches the writing 0 (by the program) timing, this flag is set to 1.

This flag is 0 in channel reset mode.

COMSTS Flag

This bit indicates that communication is ready.

This flag becomes 1 when the CAN module has detected 11 consecutive recessive bits after it has transitioned from channel reset mode or channel halt mode to channel communication mode. This flag is cleared to 0 in channel reset mode or channel halt mode.

RECSTS Flag

This flag is set to 1 when reception has started, and is cleared to 0 when the bus has become idle or transmission has started.

TRMSTS Flag

This flag is set to 1 when transmission has started, and is cleared to 0 when the bus has become idle or reception has started. This flag remains 1 in the bus off state.

BOSTS Flag

This flag is set to 1 when the bus off state ($TEC[7:0] > 255$) is entered. It is cleared to 0 when the CAN module has exited the bus off state.

EPSTS Flag

This flag is set to 1 when the RS-CANFD module has entered the error passive state ($(128 \leq TEC[7:0] \leq 255)$ or $(128 \leq REC[7:0])$), It is cleared to 0 when the RS-CANFD module has exited the error passive state or has entered channel reset mode.

CSLPSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel stop mode, and is cleared to 0 when the CAN module has returned from channel stop mode.

CHLTSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel halt mode, and is cleared to 0 when the CAN module has returned from channel halt mode.

CRSTSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel reset mode, and is cleared to 0 when the CAN module has transitioned to channel communication mode or channel halt mode. This flag remains 1 when the CAN module transitions from channel reset mode to channel stop mode.

25.4.3.4 RSCFDnCFDCmERFL — Channel Error Flag Register (m = 0, 1)

Access: RSCFDnCFDCmERFL register can be read/written in 32-bit units
 RSCFDnCFDCmERFL, RSCFDnCFDCmERFLH registers can be read/written in 16-bit units
 RSCFDnCFDCmERFL, RSCFDnCFDCmERFLH, RSCFDnCFDCmERFLH, RSCFDnCFDCmERFLH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmERFL: <RSCFDn_base> + 000C_H + (10_H × m)
 RSCFDnCFDCmERFL: <RSCFDn_base> + 000C_H + (10_H × m),
 RSCFDnCFDCmERFLH: <RSCFDn_base> + 000E_H + (10_H × m)
 RSCFDnCFDCmERFLH: <RSCFDn_base> + 000C_H + (10_H × m),
 RSCFDnCFDCmERFLH: <RSCFDn_base> + 000D_H + (10_H × m),
 RSCFDnCFDCmERFLH: <RSCFDn_base> + 000E_H + (10_H × m),
 RSCFDnCFDCmERFLH: <RSCFDn_base> + 000F_H + (10_H × m)

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|--------------|-------|-------|------|------|------|------|-----|-----|-----|------|------|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | CRCREG[14:0] | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.95 RSCFDnCFDCmERFL Register Contents

| Bit | Bit Name | Function |
|----------|---------------|--|
| 31 | Reserved | This bit is read as the value after reset. The write value should be the value after reset. |
| 30 to 16 | CRCREG [14:0] | CRC Calculation Data (CRC length:15 bits) A CRC value calculated based on the transmit message or receive message is indicated. |
| 15 | Reserved | This bit is read as the value after reset. The write value should be the value after reset. |
| 14 | ADERR | ACK Delimiter Error Flag 0: No ACK delimiter error is detected. 1: ACK delimiter error is detected. |
| 13 | B0ERR | Dominant Bit Error Flag 0: No dominant bit error is detected. 1: Dominant bit error is detected. |
| 12 | B1ERR | Recessive Bit Error Flag 0: No recessive bit error is detected. 1: Recessive bit error is detected. |
| 11 | CERR | CRC Error Flag 0: No CRC error is detected. 1: CRC error is detected. |
| 10 | AERR | ACK Error Flag 0: No ACK error is detected. 1: ACK error is detected. |
| 9 | FERR | Form Error Flag 0: No form error is detected. 1: Form error is detected. |
| 8 | SERR | Stuff Error Flag 0: No stuff error is detected. 1: Stuff error is detected. |
| 7 | ALF | Arbitration-lost Flag 0: No arbitration-lost is detected. 1: Arbitration-lost is detected. |

| Bit | Bit Name | Function |
|-----|----------|--|
| 6 | BLF | Bus Lock Flag 0: No channel bus is detected. 1: Channel bus is detected. |
| 5 | OVLf | Overload Flag 0: No overload is detected. 1: Overload is detected. |
| 4 | BORF | Bus Off Recovery Flag 0: No bus off recovery is detected. 1: Bus off recovery is detected. |
| 3 | BOEF | Bus Off Entry Flag 0: No bus off entry is detected. 1: Bus off entry is detected. |
| 2 | EPF | Error Passive Flag 0: No error passive is detected. 1: Error passive is detected. |
| 1 | EWf | Error Warning Flag 0: No error warning is detected. 1: Error warning is detected. |
| 0 | BEF | Bus Error Flag 0: No channel bus error is detected. 1: Channel bus error is detected. |

See the CAN specification (ISO11898-1) for a description of error occurrence conditions. To clear each flag of this register, the program must write a 0 to the corresponding bit. These flags cannot be set to 1 by the program. If any of these flags is set to 0 at the same time that the program writes 0 to the flag, the flag is still set to 1. The channel reset mode transition clears all of these flags to 0.

If the ERRD bit in the RSCFDnCFDCmCTR register is set to 0 (ie, only the flags for the first error event are displayed) and an error related to bits 14 to 8 of RSCFDnCFDCmERFL is detected, the flag bits are only set by the error event if bits 14 to 8 were all 0 at the when time the error occurred.

CRCREG[14:0] Flag

When the CTME bit in the RSCFDnCFDCmCTR register is set to 1 (communication test mode is enabled), if transmit or receive message is a classical CAN frame (CRC length = 15 bits), this flag is updated and the CRC value calculated based on the message can be read. When a CANFD frame is sent or received, the value of CRCREG[20:0] bits in the RSCFDnCFDCmFDCRC register is updated. When the CTME bit is set to 0 (communication test mode is disabled), these bits are always read as 0.

ADERR Flag

This flag is set to 1 when a form error has been detected in the ACK delimiter during transmission.

B0ERR Flag

This flag is set to 1 when a recessive bit has been detected though a dominant bit was transmitted.

B1ERR Flag

This flag is set to 1 when a dominant bit has been detected though a recessive bit was transmitted.

CERR Flag

This flag is set to 1 when a CRC error has been detected.

AERR Flag

This flag is set to 1 when an ACK error has been detected.

FERR Flag

This flag is set to 1 when a form error has been detected.

SERR Flag

This flag is set to 1 when a stuff error has been detected.

ALF Flag

This flag is set to 1 when an arbitration-lost has been detected.

BLF Flag

This flag is set to 1 when 32 consecutive dominant bits have been detected on the CAN bus in channel communication mode. After that, detection of a dominant lock is restarted when either of the following conditions is met.

- A recessive bit is detected after the BLF bit has been cleared from 1 to 0.
- The CAN module transitions to channel reset mode and returns to channel communication mode after the BLF bit has been cleared from 1 to 0.

OVLf Flag

This flag is set to 1 when the overload frame transmit condition has been detected when performing reception or transmission.

BORF Flag

This flag is set to 1 when 11 consecutive recessive bits have been detected 128 times and the CAN module returns from the bus off state. However, this flag is not set to 1 if the CAN module returns from the bus off state in any of the following ways before 11 consecutive recessive bits are detected 128 times.

- The CHMDC[1:0] bits in the RSCFDnCFDCmCTR register are set to 01_B (channel reset mode).
- The RTBO bit in the RSCFDnCFDCmCTR register is set to 1 (forcible return from the bus off state is made).
- The BOM[1:0] bits in the RSCFDnCFDCmCTR register are set to 01_B (transition to channel halt mode at bus off entry).
- The CHMDC[1:0] bits in the RSCFDnCFDCmCTR register are set to 10_B (channel halt mode) before 11 consecutive recessive bits are detected 128 times with the BOM[1:0] bits set to 11_B (transition to channel halt mode upon a request from the program during bus off).

BOEF Flag

This flag is set to 1 when the bus off state is reached (TEC[7:0] value > 255). This flag is also set to 1 if the bus off state is reached when the BOM[1:0] bits in the RSCFDnCFDCmCTR register (m = 0, 1) set to 01_B (transition to channel halt mode at bus off entry).

EPF Flag

This flag becomes 1 when the error passive state is reached (REC[7:0] or TEC[7:0] value > 127).

This flag becomes 1 only when the REC[7:0] or TEC[7:0] value first exceeds 127. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 127, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 127 or less and then the REC[7:0] or TEC[7:0] value exceeds 127 again.

EWf Flag

This flag is set to 1 only when the REC[7:0] or TEC[7:0] value first exceeds 95. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 95, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 95 or less and then the REC[7:0] or TEC[7:0] value exceeds 95 again.

BEF Flag

This flag is set to 1 when any one of the ADERR, B0ERR, B1ERR, CERR, AERR, FERR, and SERR flags in the RSCFDnCFDCmERFL register is set to 1.

Note: To clear the flag of this register to 0, use a store instruction to write “0” to the given flag and “1” to the other flags.

25.4.3.5 RSCFDnCFDCmDCFG — Channel Data Bit Rate Configuration Register (m = 0, 1)

Access: RSCFDnCFDCmDCFG register can be read/written in 32-bit units
 RSCFDnCFDCmDCFGL, RSCFDnCFDCmDCFGLH registers can be read/written in 16-bit units
 RSCFDnCFDCmDCFGLL, RSCFDnCFDCmDCFGLH, RSCFDnCFDCmDCFGLH, RSCFDnCFDCmDCFGLH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmDCFG: <RSCFDn_base> + 0500_H + (20_H × m)
 RSCFDnCFDCmDCFGL: <RSCFDn_base> + 0500_H + (20_H × m),

| Bit | Bit Name | Function |
|----------|-------------|--|
| 19 to 16 | DTSEG1[3:0] | Data Bit Rate Time Segment 1 Control <div> <div>b19 b18 b17 b16</div> <div>0 0 0 0: Setting prohibited</div> <div>0 0 0 1: 2 Tq</div> <div>0 0 1 0: 3 Tq</div> <div>0 0 1 1: 4 Tq</div> <div>0 1 0 0: 5 Tq</div> <div>0 1 0 1: 6 Tq</div> <div>0 1 1 0: 7 Tq</div> <div>0 1 1 1: 8 Tq</div> <div>1 0 0 0: 9 Tq</div> <div>1 0 0 1: 10 Tq</div> <div>1 0 1 0: 11 Tq</div> <div>1 0 1 1: 12 Tq</div> <div>1 1 0 0: 13 Tq</div> <div>1 1 0 1: 14 Tq</div> <div>1 1 1 0: 15 Tq</div> <div>1 1 1 1: 16 Tq</div> </div> |
| 15 to 8 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 7 to 0 | DBRP[7:0] | Data Bit Rate Prescaler Division Ratio Setting When the set value = P (0 to 255), the data bit rate prescaler divides fCAN by (P + 1). |

Modify the RSCFDnCFDCmDCFG register in channel reset mode or channel halt mode. Set this register in channel reset mode, and then transition to channel communication mode or channel halt mode. When only classical CAN frames are used in CANFD mode, set the RSCFDnCFDCmDCFG register to the value equal to the set RSCFDnCFDCmNCFG register value. For the description and settings of bit timing parameters, see section 25.11.1, Initial Settings.

DSJW[2:0] Bits

These bits specify the resynchronization jump width of data bit rate as a Tq value. A value of 1 to 8 Tq is settable. Specify a value equal to or smaller than the DTSEG2[2:0] bits value.

DTSEG2[2:0] Bits

These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2) of nominal bit rate. Allowed values are 2 Tq to 8 Tq, inclusive. Set a value smaller than the value of the DTSEG1[3:0] bits.

DTSEG1[3:0] Bits

These bits specify the total length of propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1) of data bit rate as a Tq value. A value of 2 to 16 Tq is settable.

DBRP[7:0] Bits

The clock obtained by dividing the CAN clock (fCAN) by the data bit rate prescaler ((DBRP[7:0]) + 1) becomes CANmTq(D) clock (fCANTQ(D)m). One clock of the CANmTq(D) clock becomes one Time Quantum (Tq). Make sure to set the same value in the NBRP[9:0] bits and the DBRP[7:0] bits. To set the nominal bit rate and data bit rate of different values, change the NTSEG 1 bit and NTSEG 2 bit in the RSCFDnCFDCmNCFG register and the DTSEG 1 bit and DTSEG 2 bit in the RSCFDnCFDCmDCFG register to the desired bit rate values respectively. When the TDCE bit of the RSCFDnCFDCmDCFG register is 1 (transmission delay correction enabled), set the same value of 1 or less to the NBRP [9:0] and DBRP [7:0] bits.

25.4.3.6 RSCFDnCFDCmFDCFG — Channel CANFD Configuration Register (m = 0, 1)

Access: RSCFDnCFDCmFDCFG register can be read/written in 32-bit units
 RSCFDnCFDCmFDCFGL, RSCFDnCFDCmFDCFGH registers can be read/written in 16-bit units
 RSCFDnCFDCmFDCFGLL, RSCFDnCFDCmFDCFGLH, RSCFDnCFDCmFDCFGHL, RSCFDnCFDCmFDCFGHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmFDCFG: <RSCFDn_base> + 0504_H + (20_H × m)
 RSCFDnCFDCmFDCFGL: <RSCFDn_base> + 0504_H + (20_H × m),
 RSCFDnCFDCmFDCFGH: <RSCFDn_base> + 0506_H + (20_H × m)
 RSCFDnCFDCmFDCFGLL: <RSCFDn_base> + 0504_H + (20_H × m),
 RSCFDnCFDCmFDCFGLH: <RSCFDn_base> + 0505_H + (20_H × m),
 RSCFDnCFDCmFDCFGHL: <RSCFDn_base> + 0506_H + (20_H × m),
 RSCFDnCFDCmFDCFGHH: <RSCFDn_base> + 0507_H + (20_H × m)

Value after reset: 0000 0000_H

Table 25.97 RSCFDnCFDCmFDCFG Register Contents

| Bit | Bit Name | Function |
|----------|-----------|--|
| 31, 30 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 29 | REFE | Reception data edge filter enable bit 0: Reception data edge filter disabled 1: Reception data edge filter enabled |
| 28 | FDOE | FD-only mode enable bit 0: FD-only mode disabled 1: FD-only mode enabled |
| 27 | TMME | Transmit Buffer Merge Mode Enable 0: Transmit buffer merge mode is disabled. 1: Transmit buffer merge mode is enabled. |
| 26 | GWBR S | Gateway BRS 0: A frame is transmitted with the BRS bit in the received frame set to 0. 1: A frame is transmitted with the BRS bit in the received frame set to 1. |
| 25 | GWFD F | Gateway FDF 0: A frame is transmitted regarding the received frame as a classical CAN frame. 1: A frame is transmitted regarding the received frame as a CANFD frame. |
| 24 | GWEN | CAN-CANFD Gateway Enable 0: The CAN-CANFD gateway is disabled. 1: The CAN-CANFD gateway is enabled. |
| 23 | Reserved | This bit is read as the value after reset. The write value should be the value after reset. |
| 22 to 16 | TDCO[6:0] | Transmitter Delay Compensation Offset These bits are set to the transmitter delay compensation offset value. |
| 15 to 11 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 10 | ESIC | Error State Display Mode Select 0: Always displays the node error state. 1: When the node is not in the error passive state: Displays the message buffer error state. When the node is in the error passive state: Displays the node error state. |

| Bit | Bit Name | Function |
|--------|-----------------|---|
| 9 | TDCE | Transmitter Delay Compensation Enable 0: Transmitter delay compensation is disabled. 1: Transmitter delay compensation is enabled. |
| 8 | TDCOC | Transmitter Delay Compensation Measurement Select 0: Measurement and offset 1: Only offset |
| 7 to 3 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 2 to 0 | EOCCFG [2:0] | Error Occurrence Counting Method Select b2 b1 b0 0 0 0: All transmit messages and receive messages 0 0 1: All transmit messages 0 1 0: All receive messages 0 1 1: Setting prohibited 1 0 0: Only data phase of transmitted or received CANFD message 1 0 1: Only data phase of transmitted CANFD message 1 1 0: Only data phase of received CANFD message 1 1 1: Setting prohibited |

REFE bit

Setting this bit to 1 enables reception data edge filtering when the idle condition is detected, and a dominant level with less than 2 time quanta is ignored. A dominant level with more than or equal to 2 time quanta is detected as an edge. Modify this bit only in channel reset mode.

FDOE bit

Setting this bit to 1 enables FD-only mode. When data is transmitted, a CANFD frame will be sent regardless of the settings to the CFFDF bit in the RSCFDnCFDCFFDCSTSk register or the TMFDF bit in the RSCFDnCFDTMFDCSTRp register. When a Classical CAN frame is received, a form error is detected. Modify this bit only in channel reset mode.

TMME Bit

Setting this bit to 1 enables transmit buffer merge mode. Modify this bit only in channel reset mode or channel halt mode.

GWBRs Bit

When the GWEN bit is 1, the BRS bit in a CANFD frame to be transmitted by the gateway function is set. Write 0 to this bit to clear the GWBRs bit to 0. Modify this bit only in channel reset mode.

GWFDf Bit

When the GWEN bit is 1, the FDF bit in a CANFD frame to be transmitted by the gateway function is set. Modify this bit only in channel reset mode.

GWEN Bit

This bit is used to control the operation of the transmit/receive FIFO buffer with the CFM[1:0] bits in the RSCFDnCFDCFCCK register set to 10_B (gateway mode).

Setting this bit to 1 enables the CAN-CANFD gateway, enabling transmission in a format different from that of frames received by the gateway function. Received frames are replaced in accordance with the settings of the GWFDf bit and the GWBRs bit. When the DLC value in the received classical CAN frame is 1001_B or more and the GWFDf bit is 1 (CANFD frame), the DLC value is replaced with 1000_B.

While this bit is 1, do not perform routing the following frames by using the gateway function.

- CANFD frames with a payload length of more than 8 bytes
- Remote frames

While this bit is 1, the following frame should be transmitted in the channel by setting of GWFDf.

- When GWFDf bit is set to 0, only classical CAN frames should be transmitted.

- When GWFDF bit is set to 1, only CANFD frames should be transmitted.

Table 25.98 shows the settings and formats of transmit frame and receive frame while the CAN-CANFD gateway is enabled.

Table 25.98 Operation when the CAN-CANFD Gateway is Enabled

| Receive Frame | | | GWDFD Bit | Transmit Frame | | |
|---------------|-----------|--------------------|-----------|----------------|--------------------------------|---------------------------------|
| Format | BRS Bit | Received DLC Value | | Format | BRS Bit | DLC Value to be Transmitted |
| Classical CAN | None | $DLC \leq 1000_B$ | 0 | Classical CAN | None | Not replaced |
| | | $DLC > 1000_B$ | | | | |
| CANFD | Arbitrary | $DLC \leq 1000_B$ | 1 | CANFD | According to GWBRS bit setting | Not replaced |
| Classical CAN | None | $DLC \leq 1000_B$ | | | | Replaced with 1000 _B |
| | | $DLC > 1000_B$ | | | | Not replaced |
| CANFD | Arbitrary | $DLC \leq 1000_B$ | | | | Not replaced |

TDCO[6:0] Bits

These bits are set to the SSP offset value. How to use this value depends on the TDCOC bit in the RSCFDnCFDCmFDCFG register.

When the TDCOC bit is 0, the transmitter delay compensation result equals to the total value of the measured delay value and the TDCO[6:0] value (rounded to the nearest integer T_q).

When the TDCOC bit is 1, the transmitter delay compensation result equals to the TDCO[6:0] value.

The SSP offset value = (set value of TDCO[6:0] bits + 1).

Modify these bits only in channel reset mode or channel halt mode.

ESIC Bit

When the ESIC bit is set to 1, if the channel is in the error active state, the ESI bit value (CFESI bit in the RSCFDnCFDCFFDCSTSk register or TMESI bit in the RSCFDnCFDTMFDCTRp register) set in the transmit/receive FIFO buffer or transmit buffer is transmitted as an ESI bit value of the transmit message. When the channel is in the error passive state or the ESIC bit is 0, the channel status is transmitted as an ESI bit value. Modify this bit only in channel reset mode or channel halt mode.

Table 25.99 ESI Value to Be Transmitted

| ESIC Bit | Channel Status | ESI Value to be Transmitted |
|----------|----------------|---|
| 0 | Error active | 0 (error active node) |
| | Error passive | 1 (error passive node) |
| 1 | Error active | ESI value set in the transmit/receive FIFO buffer or transmit buffer CFESI bit in the RSCFDnCFDCFFDCSTSk register or TMESI bit in the RSCFDnCFDTMFDCTRp register) |
| | Error passive | 1 (error passive node) |

TDCE Bit

Setting this bit to 1 enables transmitter delay compensation. Modify this bit only in channel reset mode or channel halt mode.

TDCOC Bit

When this bit is 0, the SSP position is defined by the total of the measured delay value and the SSP offset value (fixed value).

When this bit is 1, the SSP position is defined only by the SSP offset value.

Modify this bit only in channel reset mode or channel halt mode.

EOCCFG[2:0] Bits

These bits are used to select a frame format and a transmission/reception direction when the error occurrence counter counts CAN bus errors.

Modify these bits only in channel reset mode or channel halt mode.

25.4.3.7 RSCFDnCFDCmFDCTR — Channel CANFD Control Register (m = 0, 1)

Access: RSCFDnCFDCmFDCTR register can be read/written in 32-bit units
 RSCFDnCFDCmFDCTRL, RSCFDnCFDCmFDCTRH registers can be read/written in 16-bit units
 RSCFDnCFDCmFDCTRLL, RSCFDnCFDCmFDCTRLH, RSCFDnCFDCmFDCTRLH, RSCFDnCFDCmFDCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmFDCTR: <RSCFDn_base> + 0508_H + (20_H × m)

Table 25.100 RSCFDnCFDCmFDCTR Register Contents

| Bit | Bit Name | Function |
|---------|----------|--|
| 31 to 2 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 1 | SOCCLR | Successful Occurrence Counter Clear Setting the SOCCLR bit to 1 clears the successful occurrence counter. This bit is always read as 0. |
| 0 | EOCCLR | Error Occurrence Counter Clear Setting the EOCCLR bit to 1 clears the error occurrence counter. This bit is always read as 0. |

SOCCLR Bit

Setting this bit to 1 clears the successful occurrence counter (SOC[7:0] bits in the RSCFDnCFDCmFDSTS register). This bit is automatically cleared to 0.

EOCCLR Bit

Setting this bit to 1 clears the error occurrence counter (EOC[7:0] bits in the RSCFDnCFDCmFDSTS register). This bit is automatically cleared to 0.

25.4.3.8 RSCFDnCFDCmFDSTS — Channel CANFD Status Register (m = 0, 1)

Access: RSCFDnCFDCmFDSTS register can be read/written in 32-bit units
 RSCFDnCFDCmFDSTSL, RSCFDnCFDCmFDSTSH registers can be read/written in 16-bit units
 RSCFDnCFDCmFDSTSL, RSCFDnCFDCmFDSTSLH, RSCFDnCFDCmFDSTSHL, RSCFDnCFDCmFDSTSHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmFDSTS: <RSCFDn_base> + 050C_H + (20_H × m)

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.101 RSCFDnCFDCmFDSTS Register Contents

| Bit | Bit Name | Function |
|----------|-----------|--|
| 31 to 24 | SOC[7:0] | Successful Occurrence Counter The successful occurrence counter value can be read. |
| 23 to 16 | EOC[7:0] | Error Occurrence Counter The error occurrence counter value can be read. |
| 15 to 10 | Reserved | When read, the value after reset is returned. When writing to these bits, write the value after reset. |
| 9 | SOCO | Successful Occurrence Counter Overflow Flag 0: The successful occurrence counter does not overflow. 1: The successful occurrence counter has overflowed. |
| 8 | EOCO | Error Occurrence Counter Overflow Flag 0: The error occurrence counter does not overflow. 1: The error occurrence counter has overflowed. |
| 7 | TDCVF | Transmitter Delay Compensation Violation Flag 0: No transmitter delay compensation violation is present. 1: A transmitter delay compensation violation is present. |
| 6 to 0 | TDCR[6:0] | Transmitter Delay Compensation Result Status The transmitter delay compensation result can be read. |

SOC[7:0] Bits

These bits show the successful occurrence counter value. The successful occurrence counter is incremented upon completion of message reception or transmission without an error. This counter stops counting when it reaches FFH. In loopback mode, this counter is incremented twice.

These bits are cleared to 0 by writing 1 to the SOCCLR bit in the RSCFDnCFDCmCTR register. These bits are 0 in channel reset mode.

EOC[7:0] Bits

These bits show the error occurrence counter value. The error occurrence counter is incremented each time an error occurs according to the condition specified by the EOCCFG[2:0] bits in the RSCFDnCFDCmFDCFG register. This counter stops counting when it reaches FF_H.

These bits are cleared to 0 by writing 1 to the EOCCLR bit in the RSCFDnCFDCmCTR register. These bits are 0 in channel reset mode.

SOCO Flag

This bit indicates that successful occurrence counter overflow has occurred.

This flag is set to 1 when message reception or transmission is completed while the SOC[7:0] value has reached FF_H.

This flag is 0 in channel reset mode.

EOCO Flag

This bit indicates that error occurrence counter overflow has occurred.

This flag is set to 1 when a CAN bus error is detected under the condition specified by the EOCCFG[2:0] bits in the RSCFDnCFDCmFDCFG register when the EOC[7:0] value has reached FF_H. This flag is 0 in channel reset mode.

TDCVF Flag

This bit indicates violation of transmitter delay compensation.

The transmit data is compared with the reception CAN bus level delayed due to the transceiver's loop delay. This delay changes due to physical factors such as temperature. Because the TDCR[6:0] flags are updated for each message, temporary maximum delay cannot be confirmed.

This bit is set to 1 when the transmitter delay compensation exceeds the maximum compensation 3 CAN_m bit times - 2 T_q (CAN_m bit time and T_q are the values of data bit rate).

This flag is 0 in channel reset mode.

TDCR[6:0] Flags

These bits indicate the transmitter delay compensation result as a multiple of CAN clock frequency (f_{CAN}).

This result depends on the settings of the TDCOC bit and TDCO[6:0] bits in the RSCFDnCFDCmFDCFG register.

This flag is updated at a falling edge between the FDF bit and res bit when the TDCE bit (transmitter delay compensation enable) in the RSCFDnCFDCmFDCFG register is set to 1 and also the TDCOC bit (transmitter delay compensation measurement select) in the RSCFDnCFDCmFDCFG register is set to 0.

This flag is 0 in channel reset mode.

25.4.3.9 RSCFDnCFDCmFDCRC — Channel CANFD CRC Register (m = 0, 1)

Access: RSCFDnCFDCmFDCRC register can be read only in 32-bit units
 RSCFDnCFDCmFDCRCL, RSCFDnCFDCmFDCRCH registers can be read only in 16-bit units
 RSCFDnCFDCmFDCRCLL, RSCFDnCFDCmFDCRCLH, RSCFDnCFDCmFDCRCHL, RSCFDnCFDCmFDCRCHH registers can be read only in 8-bit units

Address: RSCFDnCFDCmFDCRC: <RSCFDn_base> + 0510_H + (20_H × m)
 RSCFDnCFDCmFDCRCL: <RSCFDn_base> + 0510_H + (20_H × m),
 RSCFDnCFDCmFDCRCH: <RSCFDn_base> + 0512_H + (20_H × m)

Table 25.102 RSCFDnCFDCmFDCRC Register Contents

| Bit | Bit Name | Function |
|----------|---------------|--|
| 31 to 28 | Reserved | These bits are read as the value after reset. |
| 27 to 24 | SCNT[3:0] | Stuff count Indicate a value of the stuff count in a CANFD frame. Bits 25 to 27 indicate the Gray-coded value of the stuff bit count modulo 8 in the transmitted/received frames. Bit 24 indicates an even parity value of bits 25 to 27. |
| 23 to 21 | Reserved | These bits are read as the value after reset. |
| 20 to 0 | CRCREG [20:0] | CRC Calculation Data (CRC Length: 17 Bits or 21 Bits) These bits show the CRC value calculated based on the transmit message or receive message. When the CRC length is 17 bits, bits b20 to b17 are read as 0. |

SCNT[3:0] Flag

When the CTME bit in the RSCFDnCFDCmCTR register is set to 1 (communication test mode enabled), a stuff count bit value of the CANFD frame can be read if a message transmitted/received is a CANFD frame. When the CTME bit is 0 (communication test mode disabled), this flag is always read as 0. This flag is updated at the first bit in the CRC field of the CANFD frame. These bits are cleared to 0 in channel reset mode.

CRCREG[20:0] Flag

When the CTME bit in the RSCFDnCFDCmCTR register is 1 (communication test mode enabled), if transmit or receive message is a CANFD frame (CRC length = 17 or 21 bits), this flag is updated and the CRC value calculated based on the message can be read. When the CRC length of the message is 17 bits, bits b20 to b17 are always read as 0. When a classical CAN frame is transmitted or received, the CRCREG[14:0] value in the RSCFDnCFDCmERFL register is updated. When the CTME bit is 0 (communication test mode disabled), these bits are always read as 0.

25.4.4 Details of Global-related Registers

25.4.4.1 SCFDnCFDGCFCFG — Global Configuration Register

Access: RSCFDnCFDGCFCFG register can be read/written in 32-bit units
 RSCFDnCFDGCFCFGL, RSCFDnCFDGCFCFGH registers can be read/written in 16-bit units
 RSCFDnCFDGCFCFGLL, RSCFDnCFDGCFCFGLH, RSCFDnCFDGCFCFGLH, RSCFDnCFDGCFCFGLH registers can be read/written in 8-bit units

Address: RSCFDnCFDGCFCFG: <RSCFDn_base> + 0084_H
 RSCFDnCFDGCFCFGL: <RSCFDn_base> + 0084_H, RSCFDnCFDGCFCFGH: <RSCFDn_base> + 0086_H
 RSCFDnCFDGCFCFGLL: <RSCFDn_base> + 0084_H, RSCFDnCFDGCFCFGLH: <RSCFDn_base> + 0085_H,
 RSCFDnCFDGCFCFGLH: <RSCFDn_base> + 0086_H, RSCFDnCFDGCFCFGLH: <RSCFDn_base> + 0087_H

Value after reset: 0000 0000_H

| Bit | Bit Name | Function |
|------|----------|--|
| 7, 6 | Reserved | When read, the value after reset is returned. When writing to these bits, write the value after reset. |
| 5 | CMPOC | Payload Overflow Mode Select 0: No message is stored. 1: Messages are stored and payloads exceeding the buffer size are discarded. |
| 4 | DCS | CAN Clock Source Select*2 0: clkc 1: clk_xincan |
| 3 | MME | Mirror Function Enable 0: Mirror function is disabled. 1: Mirror function is enabled. |
| 2 | DRE | DLC Replacement Enable 0: DLC replacement is disabled. 1: DLC replacement is enabled. |
| 1 | DCE | DLC Check Enable 0: DLC check is disabled. 1: DLC check is enabled. |
| 0 | TPRI | Transmit Priority Select 0: ID priority 1: Transmit buffer number priority |

Note 1. When specifying pclk/2 as the timestamp counter count source, set bits TSBTCS[2:0] to 000_B.

Note 2. For the CAN clock frequency settings, see section 25, Clock Supply.

Modify the RSCFDnCFDGCFCFG register only in global reset mode.

ITRCP[15:0] Bits

These bits are used to set a clock source division value of the interval timer for FIFO buffers. See section 25.8.3.1, Interval Transmission Function.

TSBTCS[2:0] Bits

When the TSSS bit is 1, these bits are used to select the channel of the nominal bit time clock that will be the clock source of the timestamp counter. However, do not select the channel that handles the CANFD frames.

TSSS Bit

This bit is used to select a clock source of the timestamp counter. Select pclk if there is no channel that handles only classical CAN frames.

TSP[3:0] Bits

A clock obtained by dividing the clock source selected with the TSBTCS[2:0] bits and TSSS bit according to the TSP[3:0] bits is used as the timestamp counter count source.

CMPOC Bit

This bit is used to select operation in case the payload length of received message exceeds the payload storage size of the storage buffer.

When this bit is 0, the received message in which the payload overflows is not stored in the buffer.

When this bit is 1, the received message in which the payload overflows is stored in the buffer. At this time, payloads exceeding the buffer's payload storage size are discarded.

The buffer's payload storage size is set by the following bits.

- Receive buffer: RMPLS[1:0] bits in the RSCFDnCFDRMNB register
- Receive FIFO buffer: RFPLS[2:0] bits in the RSCFDnCFDRFCCx register
- Transmit/receive FIFO buffer: CFPLS[2:0] bits in the RSCFDnCFDCFCCk register

DCS Bit

When this bit is set to 0, `clk_c` is used as the clock source of the CAN clock (`fCAN`).

When this bit is set to 1, `clk_xincan` is used as the clock source of the CAN clock (`fCAN`).

For the CAN clock frequency settings, see Table 25.6, Range of Operating Frequency Depending on the Transfer Rate and the Number of Channels in Use in this LSI.

MME Bit

Setting this bit to 1 makes the mirror function available.

DRE Bit

When the DRE bit is set to 1, the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message after the DLC value has passed through the DLC filter. In this case, a value of `00H` is stored in each data byte beyond the DLC value of the receive rule.

The DLC replacement function is only available when the DCE bit is set to 1 (DLC check is enabled).

DCE Bit

Setting this bit to 1 makes the DLC check function available. When disabling the DLC check function, set the `GAFLDLC[3:0]` bits in the `RSCFDnCFDGAFLP0_j` register to `0000B` before clearing the DCE bit in the `RSCFDnCFDGCFCG` register to 0.

TPRI Bit

This bit is used to set the transmit priority.

When this bit is set to 0, ID priority is selected and the transmit priority complies with the CAN bus arbitration rule (ISO11898-1 specifications). When this bit is set to 1, transmit buffer number priority is selected and the lowest transmit buffer number of those has the highest priority.

While the transmit queue is in use, this bit should be set to 0.

25.4.4.2 RSCFDnCFDGCTR — Global Control Register

Access: RSCFDnCFDGCTR register can be read/written in 32-bit units
 RSCFDnCFDGCTRL, RSCFDnCFDGCTRH registers can be read/written in 16-bit units
 RSCFDnCFDGCTRLL, RSCFDnCFDGCTRLH, RSCFDnCFDGCTRHL, RSCFDnCFDGCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGCTR: <RSCFDn_base> + 0088_H
 RSCFDnCFDGCTRL: <RSCFDn_base> + 0088_H, RSCFDnCFDGCTRH: <RSCFDn_base> + 008A_H
 RSCFDnCFDGCTRLL: <RSCFDn_base> + 0088_H, RSCFDnCFDGCTRLH: <RSCFDn_base> + 0089_H,
 RSCFDnCFDGCTRHL: <RSCFDn_base> + 008A_H, RSCFDnCFDGCTRHH: <RSCFDn_base> + 008B_H

Value after reset: 0000 0005_H

Table 25.104 RSCFDnCFDGCTR Register Contents

| Bit | Bit Name | Function |
|----------|-----------|--|
| 31 to 17 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 16 | TSRST | Timestamp Counter Reset Setting the TSRST bit to 1 resets the timestamp counter. This bit is always read as 0. |
| 15 to 12 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 11 | CMPOFIE | Payload Overflow Interrupt Enable 0: A payload overflow interrupt is disabled. 1: A payload overflow interrupt is enabled. |
| 10 | THLEIE | Transmit History Buffer Overflow Interrupt Enable 0: Transmit history buffer overflow interrupt is disabled. 1: Transmit history buffer overflow interrupt is enabled. |
| 9 | MEIE | FIFO Message Lost Interrupt Enable 0: FIFO message lost interrupt is disabled. 1: FIFO message lost interrupt is enabled. |
| 8 | DEIE | DLC Error Interrupt Enable 0: DLC error interrupt is disabled. 1: DLC error interrupt is enabled. |
| 7 to 3 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 2 | GSLPR | Global Stop Mode 0: Other than global stop mode 1: Global stop mode |
| 1, 0 | GMDC[1:0] | Global Mode Select b1 b0 0 0: Global operating mode 0 1: Global reset mode 1 0: Global test mode 1 1: Setting prohibited |

TSRST Bit

This bit is used to reset the timestamp counter. When this bit is set to 1, the RSCFDnCFDGTSC register is cleared to 0000_H.

CMPOFIE Bit

When the CMPOF flag in the RSCFDnCFDGERFL register is set to 1 after the CMPOFIE bit is set to 1, an interrupt request occurs. Modify this bit only in global reset mode.

THLEIE Bit

When the THLEIE bit is set to 1 and the THLES flag in the RSCFDnCFDGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

MEIE Bit

When the MEIE bit is set to 1 and the MES flag in the RSCFDnCFDGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

DEIE Bit

When the DEIE bit is set to 1 and the DEF flag in the RSCFDnCFDGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

GSLPR Bit

Setting this bit to 1 places the RSCAN module into global stop mode.

Clearing this bit to 0 makes the RSCAN module leave from global stop mode.

This bit should not be modified in global operating mode or global test mode.

GMDC[1:0] Bits

These bits are used to select the mode of entire RS-CANFD module (global operating mode, global reset mode, or global test mode). For details, see section 25.6.1, **Global Modes**. Setting the GSLPR bit to 1 when in global reset mode places the RS-CANFD module into global stop mode.

25.4.4.3 RSCFDnCFDGSTS — Global Status Register

Access: RSCFDnCFDGSTS register can be read only in 32-bit units
 RSCFDnCFDGSTSL, RSCFDnCFDGSTSH registers can be read only in 16-bit units
 RSCFDnCFDGSTSL, RSCFDnCFDGSTSLH, RSCFDnCFDGSTSHL, RSCFDnCFDGSTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDGSTS: <RSCFDn_base> + 008C_H
 RSCFDnCFDGSTSL: <RSCFDn_base> + 008C_H, RSCFDnCFDGSTSH: <RSCFDn_base> + 008E_H
 RSCFDnCFDGSTSL: <RSCFDn_base> + 008C_H, RSCFDnCFDGSTSLH: <RSCFDn_base> + 008D_H,
 RSCFDnCFDGSTSHL: <RSCFDn_base> + 008E_H, RSCFDnCFDGSTSHH: <RSCFDn_base> + 008F_H

Value after reset: 0000 000D_H

| | | | | | | | | | | | | | | | | |

| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.105 RSCFDnCFDGSTS Register Contents

| Bit | Bit Name | Function |
|---------|----------|--|
| 31 to 4 | Reserved | These bits are read as the value after reset. |
| 3 | GRAMINIT | CAN RAM Initialization Status Flag 0: CAN RAM initialization is completed. 1: CAN RAM initialization is ongoing. |
| 2 | GSLPSTS | Global Stop Status Flag 0: Not in global stop mode 1: In global stop mode |
| 1 | GHLTSTS | Global Test Status Flag 0: Not in global test mode 1: In global test mode |
| 0 | GRSTSTS | Global Reset Status Flag 0: Not in global reset mode 1: In global reset mode |

GRAMINIT Flag

This flag indicates the initialization status of the CAN RAM.

This flag is set to 1 after the MCU has been reset, and is cleared to 0 when CAN RAM initialization is completed.

GSLPSTS Flag

This flag is set to 1 when the CAN module has transitioned to global stop mode, and is cleared to 0 when the CAN module has returned from global stop mode.

GHLTSTS Flag

This flag is set to 1 when the CAN module has transitioned to global test mode, and is cleared to 0 when the CAN module has exited global test mode.

GRSTSTS Flag

This flag is set to 1 when the CAN module has transitioned to global reset mode, and is cleared to 0 when the CAN module has exited global reset mode. This flag remains 1 even when the CAN module has transitioned from global reset mode to global stop mode.

25.4.4.4 RSCFDnCFDGERFL — Global Error Flag Register

Access: RSCFDnCFDGERFL register can be read/written in 32-bit units
 RSCFDnCFDGERFLL, RSCFDnCFDGERFLH registers can be read/written in 16-bit units
 RSCFDnCFDGERFLLL, RSCFDnCFDGERFLLH, RSCFDnCFDGERFLHL, RSCFDnCFDGERFLHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGERFL: <RSCFDn_base> + 0090_H
 RSCFDnCFDGERFLL: <RSCFDn_base> + 0090_H, RSCFDnCFDGERFLH: <RSCFDn_base> + 0092_H
 RSCFDnCFDGERFLLL: <RSCFDn_base> + 0090_H, RSCFDnCFDGERFLLH: <RSCFDn_base> + 0091_H,
 RSCFDnCFDGERFLHL: <RSCFDn_base> + 0092_H, RSCFDnCFDGERFLHH: <RSCFDn_base> + 0093_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|-------|-------|-----|-------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | CMPOF | THLES | MES | DEF |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 1 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R/W*1 | R | R | R/W*1 |

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.106 RSCFDnCFDGERFL Register Contents

| Bit | Bit Name | Function |
|-------------------|----------|---|
| 31 to 14, 7, 6, 4 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 13 to 8, 5 | Reserved | When read, an undefined value is returned. The write value should be the value after reset. |
| 3 | CMPOF | Payload Overflow Flag 0: No payload overflow has occurred. 1: A payload overflow has occurred. |
| 2 | THLES | Transmit History Buffer Overflow Status Flag 0: No transmit history buffer overflow has occurred. 1: A transmit history buffer overflow has occurred. |
| 1 | MES | FIFO Message Lost Status Flag 0: No FIFO message lost error has occurred. 1: A FIFO message lost error has occurred. |
| 0 | DEF | DLC Error Flag 0: No DLC error has occurred. 1: A DLC error has occurred. |

All flags in the RSCFDnCFDGERFL register are cleared to 0 in global reset mode.

CMPOF Flag

When a payload overflow occurs in any of channel m (m = 0, 1), the CMPOF flag is set to 1. This flag can be cleared to 0 by writing 0 to this bit by the program.

THLES Flag

The THLES flag is set to 1 when any one of the THLELT flags in the RSCFDnCFDTHLSTSm register (m = 0, 1) is set to 1.

This flag is cleared to 0 when the THLELT flags of all channels are set to 0.

MES Flag

The MES flag is set to 1 when any one of the RFMLT flags in the RSCFDnCFDRFSTSx register (x = 0 to 7) or the CFMLT flags in the RSCFDnCFDCFSTSk register (k = 0 to 5) is set to 1.

This flag is cleared to 0 when all RFMLT flags and CFMLT flags are set to 0.

DEF Flag

The DEF flag is set to 1 when an error has been detected during the DLC check. The program can clear this flag by writing 0 to this bit.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

Note: To clear the flag of this register to 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

25.4.4.5 RSCFDnCFDGTSC — Global Timestamp Counter Register

Access: RSCFDnCFDGTSC register can be read only in 32-bit units
RSCFDnCFDGTSC_L, RSCFDnCFDGTSC_H registers can be read only in 16-bit units

Address: RSCFDnCFDGTSC: <RSCFDn_base> + 0094_H
RSCFDnCFDGTSC_L: <RSCFDn_base> + 0094_H, RSCFDnCFDGTSC_H: <RSCFDn_base> + 0096_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| | | | | | | | | | | | | | | | | |
|--------------------|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | TS[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.107 RSCFDnCFDGTSC Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 16 | Reserved | These bits are read as the value after reset. |
| 15 to 0 | TS[15:0] | Timestamp Value The timestamp counter value can be read. Counter Value: 0000 _H to FFFF _H |

TS[15:0] Bits

When the TS[15:0] bits are read, the read value shows the timestamp counter (16-bit free-running counter) value at that time. When the SOF is detected, the TS[15:0] value is captured and later stored in the receive buffer or the FIFO buffer. Furthermore, the TS[15:0] value is stored in the transmit history buffer. The timestamp counter is initialized in global reset mode.

The timestamp counter starts and stops counting differently, depending on the count source.

- When the TSSS bit in the RSCFDnCFDGC_CFG register is 0 (pclk):
The timestamp counter starts counting when the RSCAN module has transitioned to global operating mode.
This counter stops counting when the RSCAN module has transitioned to global stop mode or global test mode.
- When the TSSS bit is 1 (CANm nominal bit time clock):
The timestamp counter starts counting when the corresponding channel has transitioned to channel communication mode.
This counter stops counting when the corresponding channel has transitioned to channel reset mode or channel halt mode.

25.4.4.6 RSCFDnCFDGTINTSTS0 — Global TX Interrupt Status Register 0

Access: RSCFDnCFDGTINTSTS0 register can be read only in 32-bit units
 RSCFDnCFDGTINTSTS0L, RSCFDnCFDGTINTSTS0H registers can be read only in 16-bit units
 RSCFDnCFDGTINTSTS0LL, RSCFDnCFDGTINTSTS0LH, RSCFDnCFDGTINTSTS0HL, RSCFDnCFDGTINTSTS0HH registers can be read only in 8-bit units

Address: RSCFDnCFDGTINTSTS0: <RSCFDn_base> + 0460_H
 RSCFDnCFDGTINTSTS0L: <RSCFDn_base> + 0460_H, RSCFDnCFDGTINTSTS0H: <RSCFDn_base> + 0462_H
 RSCFDnCFDGTINTSTS0LL: <RSCFDn_base> + 0460_H, RSCFDnCFDGTINTSTS0LH: <RSCFDn_base> + 0461_H,
 RSCFDnCFDGTINTSTS0HL: <RSCFDn_base> + 0462_H, RSCFDnCFDGTINTSTS0HH: <RSCFDn_base> + 0463_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |

Note 1. This bit is automatically cleared in the global reset or channel reset mode.

Table 25.108 RSCFDnCFDGTINTSTS0 Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 13 | Reserved | These bits are read as the value after reset. |
| 12 | THIF1 | Channel 1 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested. |
| 11 | CFTIF1 | Channel 1 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested. |
| 10 | TQIF1 | Channel 1 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested. |
| 9 | TAIF1 | Channel 1 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested. |
| 8 | TSIF1 | Channel 1 Transmit Buffer Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested. |
| 7 to 5 | Reserved | These bits are read as the value after reset. |
| 4 | THIF0 | Channel 0 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested. |
| 3 | CFTIF0 | Channel 0 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested. |
| 2 | TQIF0 | Channel 0 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested. |
| 1 | TAIF0 | Channel 0 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested. |

| Bit | Bit Name | Function |
|-----|----------|---|
| 0 | TSIF0 | Channel 0 Transmit Buffer Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested. |

TSIFm Bits

The TSIFm bit is set to 1 when the TMIEp bit in the RSCFDnCFDTMIECy register is set to 1 (transmit buffer interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnCFDTMSTSp register are set to 10_B (transmit completed without abort request) or 11_B (transmit completed with abort request).

When the TMTRF[1:0] flags are cleared to 00_B under the condition that the TSIFm bit can be set to 1, this flag is cleared to 0. In addition, clearing the TMIEp bit to 0 also clears this flag to 0.

TAIFm Bits

The TAIFm bit is set to 1 when the TAIE bit in the RSCFDnCFDCmCTR register is 1 (transmit abort interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnCFDTMSTSp register are set to 01_B (transmit abort completed).

This flag is cleared to 0 when the TMTRF[1:0] flags are cleared to 00_B after the transmit abort is completed.

TQIFm Bits

When the TXQIE bit in the RSCFDnCFDTXQCCm register is set to 1 (transmit queue interrupt enabled) and the TXQIF bit in the RSCFDnCFDTXQSTSm register is set to 1 (transmit queue interrupt request), the TQIFm bit is set to 1.

When the TXQIF bit (transmit queue interrupt request) in the RSCFDnCFDTXQSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the TXQIE bit is cleared to 0.

CFTIFm Bits

When the CFTXIE bit in the RSCFDnCFDCFCCk register is set to 1 (transmit/receive FIFO transmit interrupt enabled) and the CFTXIF bit in the RSCFDnCFDCFSTSk register is set to 1 (transmit/receive FIFO transmit interrupt request), the CFTIFm bit is set to 1.

When the CFTXIF bit is cleared to 0 under the conditions that the CFTIFm bit can be set to 1, this bit is cleared to 0. This flag is also cleared to 0 when the CFTXIE bit is cleared to 0.

THIFm Bits

When the THLIE bit in the RSCFDnCFDTHLCCm register is set to 1 (transmit history interrupt enabled) and the THLIF bit in the RSCFDnCFDTHLSTSm register is set to 1 (transmit history interrupt request), the THIFm bit is set to 1.

When the THLIF bit in the RSCFDnCFDTHLSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the THLIE bit is cleared to 0.

25.4.4.7 RSCFDnCFDGFDCFG — Global FD Configuration Register

Access: RSCFDnCFDGFDCFG register can be read/written in 32-bit units
 RSCFDnCFDGFDCFG L, RSCFDnCFDGFDCFG H registers can be read/written in 16-bit units
 RSCFDnCFDGFDCFG LL, RSCFDnCFDGFDCFG LH, RSCFDnCFDGFDCFG HL, RSCFDnCFDGFDCFG HH registers can be read/written in 8-bit units

Address: RSCFDnCFDGFDCFG: <RSCFDn_base> + 0474_H
 RSCFDnCFDGFDCFG L: <RSCFDn_base> + 0474_H, RSCFDnCFDGFDCFG H: <RSCFDn_base> + 0476_H
 RSCFDnCFDGFDCFG LL: <RSCFDn_base> + 0474_H, RSCFDnCFDGFDCFG LH: <RSCFDn_base> + 0475_H,
 RSCFDnCFDGFDCFG HL: <RSCFDn_base> + 0476_H, RSCFDnCFDGFDCFG HH: <RSCFDn_base> + 0477_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |

| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Table 25.109 RSCFDnCFDGFDCFG Register Contents

| Bit | Bit Name | Function |
|----------|-------------|---|
| 31 to 10 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 9, 8 | TSCCFG[1:0] | Time-stamp capture setting bit b9 b8 0 0: Captured at a sample point in the SOF bit. 0 1: Captured when a valid frame has been transmitted/received. 1 0: Captured at a sample point of the res bit. *1 1 1: Setting prohibited. |
| 7 to 1 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 0 | RPED | Protocol exception event detection disabled bit 0: Protocol exception event detection enabled 1: Protocol exception event detection disabled |

Note 1. When a Classical CAN frame is transmitted/received, a time-stamp value will be captured at the sample point in the SOF bit.

TSCCFG[1:0] Bits

Select a point where a time-stamp value is captured. Modify this bit only in global reset mode.

RPED Bit

Setting this bit to 1 disables the protocol exception event detection. When a protocol exception event is detected while this bit is set to 1, the event is regarded as a form error and an error frame is output. Modify this bit only in global reset mode.

25.4.5 Details of Receive Rule-related Registers

25.4.5.1 RSCFDnCFDGAFLECTR — Receive Rule Entry Control Register

Access: RSCFDnCFDGAFLECTR register can be read/written in 32-bit units
 RSCFDnCFDGAFLECTRL, RSCFDnCFDGAFLECTRH registers can be read/written in 16-bit units
 RSCFDnCFDGAFLECTRLL, RSCFDnCFDGAFLECTRLH, RSCFDnCFDGAFLECTRHL, RSCFDnCFDGAFLECTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLECTR: <RSCFDn_base> + 0098_H
 RSCFDnCFDGAFLECTRL: <RSCFDn_base> + 0098_H, RSCFDnCFDGAFLECTRH: <RSCFDn_base> + 009A_H
 RSCFDnCFDGAFLECTRLL: <RSCFDn_base> + 0098_H, RSCFDnCFDGAFLECTRLH: <RSCFDn_base> + 0099_H,
 RSCFDnCFDGAFLECTRHL: <RSCFDn_base> + 009A_H, RSCFDnCFDGAFLECTRHH: <RSCFDn_base> + 009B_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

Table 25.110 RSCFDnCFDGAFLECTR Register Contents

| Bit | Bit Name | Function |
|---------|------------|---|
| 31 to 9 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 8 | AFLDAE | Receive Rule Table Write Enable 0: Receive rule table write is disabled. 1: Receive rule table write is enabled. |
| 7 to 5 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 4 to 0 | AFLPN[4:0] | Receive Rule Table Page Number Configuration A page number can be selected from a range of page 0 (00000 _B) to page 7 (00111 _B). |

AFLDAE Bit

Setting this bit to 0 disables the write to the receive rule table. After writes to the receive rule table are completed, set this bit to 0 to disable the write to the table. The receive rule table can be read regardless of the value of this bit.

Set the AFLDAE bit to 1 only in global reset mode.

AFLPN[4:0] Bits

These bits are used to set the page number of the receive rule table. Sixteen receive rules can be set per page.

Set these bits to a value within the range of 00000_B to 00111_B.

25.4.5.2 RSCFDnCFDGAFLCFG0 — Receive Rule Configuration Register 0

Access: RSCFDnCFDGAFLCFG0 register can be read/written in 32-bit units
 RSCFDnCFDGAFLCFG0L, RSCFDnCFDGAFLCFG0H registers can be read/written in 16-bit units
 RSCFDnCFDGAFLCFG0LL, RSCFDnCFDGAFLCFG0LH, RSCFDnCFDGAFLCFG0HL, RSCFDnCFDGAFLCFG0HH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLCFG0: <RSCFDn_base> + 009C_H
 RSCFDnCFDGAFLCFG0L: <RSCFDn_base> + 009C_H, RSCFDnCFDGAFLCFG0H: <RSCFDn_base> + 009E_H
 RSCFDnCFDGAFLCFG0LL: <RSCFDn_base> + 009C_H, RSCFDnCFDGAFLCFG0LH: <RSCFDn_base> + 009D_H,
 RSCFDnCFDGAFLCFG0HL: <RSCFDn_base> + 009E_H, RSCFDnCFDGAFLCFG0HH: <RSCFDn_base> + 009F_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|-----------|-----|-----|-----|-----|-----|-----|-----|-----------|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | RNC0[7:0] | | | | | | | | RNC1[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.111 RSCFDnCFDGAFLCFG0 Register Contents

| Bit | Bit Name | Function |
|----------|-----------|--|
| 31 to 24 | RNC0[7:0] | Number of Rules for Channel 0 Set the number of receive rules exclusively used for channel 0. |
| 23 to 16 | RNC1[7:0] | Number of Rules for Channel 1 Set the number of receive rules exclusively used for channel 1. |
| 15 to 0 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |

Modify the RSCFDnCFDGAFLCFG0 register only in global reset mode.

Up to $64 \times$ (number of channels) rules can be registered in the receive rule table as the entire unit. The number of receive rules per channel should meet the following conditions.

- The maximum number of rules per channel is 128.
- The total of the number of rules allocated to each channel is not larger than the number of rules that can be registered in the entire unit.

RNC0[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 0 receive rule table.

Set these bits to a value within the range of 00_H to 80_H.

RNC1[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 1 receive rule table.

Set these bits to a value within the range of 00_H to 80_H.

25.4.5.3 RSCFDnCFDGAFLIDj — Receive Rule ID Register (j = 0 to 15)

Access: RSCFDnCFDGAFLIDj register can be read/written in 32-bit units
 RSCFDnCFDGAFLIDjL, RSCFDnCFDGAFLIDjH registers can be read/written in 16-bit units
 RSCFDnCFDGAFLIDjLL, RSCFDnCFDGAFLIDjLH, RSCFDnCFDGAFLIDjHL, RSCFDnCFDGAFLIDjHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLIDj: $\langle \text{RSCFDn_base} \rangle + 1000_{\text{H}} + (10_{\text{H}} \times j)$
 RSCFDnCFDGAFLIDjL: $\langle \text{RSCFDn_base} \rangle + 1000_{\text{H}} + (10_{\text{H}} \times j)$,
 RSCFDnCFDGAFLIDjH: $\langle \text{RSCFDn_base} \rangle + 1002_{\text{H}} + (10_{\text{H}} \times j)$
 RSCFDnCFDGAFLIDjLL: $\langle \text{RSCFDn_base} \rangle + 1000_{\text{H}} + (10_{\text{H}} \times j)$,
 RSCFDnCFDGAFLIDjLH: $\langle \text{RSCFDn_base} \rangle + 1001_{\text{H}} + (10_{\text{H}} \times j)$,
 RSCFDnCFDGAFLIDjHL: $\langle \text{RSCFDn_base} \rangle + 1002_{\text{H}} + (10_{\text{H}} \times j)$,
 RSCFDnCFDGAFLIDjHH: $\langle \text{RSCFDn_base} \rangle + 1003_{\text{H}} + (10_{\text{H}} \times j)$

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|--------------|-------------|------------|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | GAFL IDE | GAFL RTR | GAFL LB | GAFLID[28:16] | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| | GAFLID[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Table 25.112 RSCFDnCFDGAFLIDj Register Contents

| Bit | Bit Name | Function |
|---------|------------------|--|
| 31 | GAFLIDE | ID Select 0: Standard ID 1: Extended ID |
| 30 | GAFLRTR | RTR Select 0: Data frame 1: Remote frame |
| 29 | GAFLLB | Receive Rule Target Message Select 0: When a message transmitted from another CAN node is received 1: When the own transmitted message is received |
| 28 to 0 | GAFLID [28:0] | ID Set Set the ID of the receive rule. For the standard ID, set the ID in bits b10 to b0 and set bits b28 to b11 to 0. |

Modify the RSCFDnCFDGAFLIDj register when the AFLDAE bit in the RSCFDnCFDGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLIDE Bit

This bit is used to select the ID format (standard ID or extended ID) of the receive rule. This bit is compared with the IDE bit in the received message during the acceptance filter processing.

GAFLRTR Bit

This bit is used to select the frame format (data frame or remote frame) of the receive rule. This bit is compared with the RTR bit in the received message during the acceptance filter processing.

GAFLLB Bit

When this bit is set to 0, data processing using the receive rule is performed when receiving messages transmitted from another CAN node.

When this bit is set to 1 when the mirror function is used, data processing using the receive rule is performed when the CAN node is receiving its own transmitted messages.

GAFLID[28:0] Bits

These bits are used to set the ID field of the receive rule. The ID value set by these bits is compared with the ID of the received message during the acceptance filter processing.

25.4.5.4 RSCFDnCFDGAFLMj — Receive Rule Mask Register (j = 0 to 15)

Access: RSCFDnCFDGAFLMj register can be read/written in 32-bit units
 RSCFDnCFDGAFLMjL, RSCFDnCFDGAFLMjH registers can be read/written in 16-bit units
 RSCFDnCFDGAFLMjLL, RSCFDnCFDGAFLMjLH, RSCFDnCFDGAFLMjHL, RSCFDnCFDGAFLMjHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLMj: <RSCFDn_base> + 1004_H + (10_H × j)
 RSCFDnCFDGAFLMjL: <RSCFDn_base> + 1004_H + (10_H × j),
 RSCFDnCFDGAFLMjH: <RSCFDn_base> + 1006_H + (10_H × j)
 RSCFDnCFDGAFLMjLL: <RSCFDn_base> + 1004_H + (10_H × j),
 RSCFDnCFDGAFLMjLH: <RSCFDn_base> + 1005_H + (10_H × j),
 RSCFDnCFDGAFLMjHL: <RSCFDn_base> + 1006_H + (10_H × j),
 RSCFDnCFDGAFLMjHH: <RSCFDn_base> + 1007_H + (10_H × j)

Value after reset: 0000 0000_H

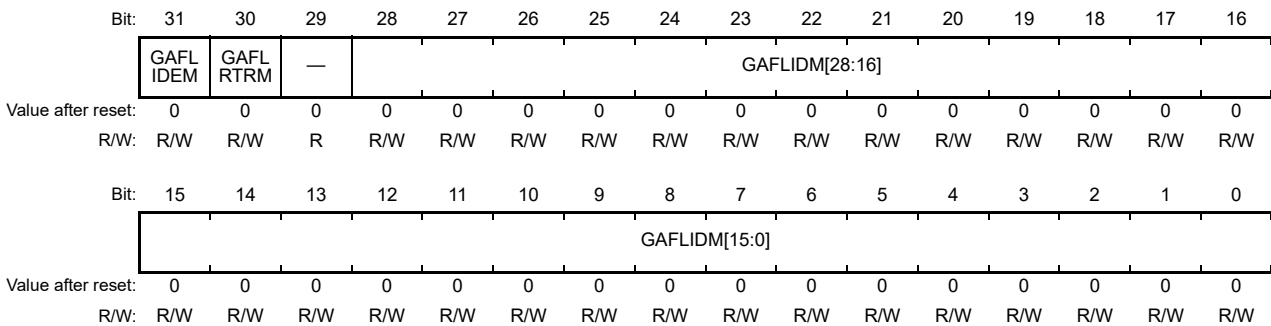

Table 25.113 RSCFDnCFDGAFLMj Register Contents

| Bit | Bit Name | Function |
|---------|---------------|---|
| 31 | GAFLIDEM | IDE Mask 0: The IDE bit is not compared. 1: The IDE bit is compared. |
| 30 | GAFLRTRM | RTR Mask 0: The RTR bit is not compared. 1: The RTR bit is compared |
| 29 | Reserved | This bit is read as the value after reset. The write value should be the value after reset. |
| 28 to 0 | GAFLIDM[28:0] | ID Mask 0: The corresponding ID bit is not compared. 1: The corresponding ID bit is compared. |

Modify the RSCFDnCFDGAFLMj register when the AFLDAE bit in the RSCFDnCFDGAFLMj register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLIDEM Bit

When this bit is set to 1, filter processing is performed only for messages of the ID format specified by the GAFLIDE bit in the RSCFDnCFDGAFLMj register.

When this bit is cleared to 0, the IDs of all the receive messages and the specified IDs are regarded as matched. To set the GAFLIDEM bit to 0, set the GAFLIDM[28:0] bits to all 0 at the same time.

GAFLRTRM Bit

This bit is used to mask the RTR bit of the receive rule.

GAFLIDM[28:0] Bits

These bits are used to mask the corresponding ID bit of the receive rule.

25.4.5.5 RSCFDnCFDGAFLP0_j — Receive Rule Pointer 0 Register (j = 0 to 15)

Access: RSCFDnCFDGAFLP0_j register can be read/written in 32-bit units
 RSCFDnCFDGAFLP0_jL, RSCFDnCFDGAFLP0_jH registers can be read/written in 16-bit units
 RSCFDnCFDGAFLP0jLL, RSCFDnCFDGAFLP0jLH, RSCFDnCFDGAFLP0jHL, RSCFDnCFDGAFLP0jHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLP0_j: <RSCFDn_base> + 1008_H + (10_H × j)
 RSCFDnCFDGAFLP0_jL: <RSCFDn_base> + 1008_H + (10_H × j),
 RSCFDnCFDGAFLP0_jH: <RSCFDn_base> + 100A_H + (10_H × j)
 RSCFDnCFDGAFLP0_jLL: <RSCFDn_base> + 1008_H + (10_H × j),
 RSCFDnCFDGAFLP0_jLH: <RSCFDn_base> + 1009_H + (10_H × j),
 RSCFDnCFDGAFLP0_jHL: <RSCFDn_base> + 100A_H + (10_H × j),
 RSCFDnCFDGAFLP0_jHH: <RSCFDn_base> + 100B_H + (10_H × j)

Value after reset: 0000 0000_H

| 27 to 16 | GAFLPTR [11:0] | Receive Rule Label Set the 12-bit label information. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bit | Bit Name | Function |
|---------|-------------------|--|
| 15 | GAFLRMV | Receive Buffer Enable 0: No receive buffer is used. 1: A receive buffer is used. |
| 14 to 8 | GAFLRMDP [6:0] | Receive Buffer Number Select Set the receive buffer number to store receive messages. |
| 7 to 0 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |

Modify the RSCFDnCFDGAFLP0_j register when the AFLDAE bit in the RSCFDnCFDGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLDLC[3:0] Bits

These bits are used to set the minimum data length necessary for receiving messages. If the data length of a message that is being filtered is equal to or larger than the value set by the GAFLDLC[3:0] bits, the message passes the DLC check. Setting these bits to 0000_B disables the DLC check function allowing messages with any data length to pass the DLC check.

GAFLPTR[11:0] Bits

These bits are used to set a 12-bit label to be attached to messages that have passed through the filter. A label is attached when a message is stored in the receive buffer or the FIFO buffer.

GAFLRMV Bit

When this bit is set to 1, receive messages that have passed through the filter are stored in the receive buffer selected by the GAFLRMDP[6:0] bits.

GAFLRMDP[6:0] Bits

These bits are used to select the number of the receive buffer that stores receive messages that have passed through the filter when the GAFLRMV bit is set to 1. Set these bits to a value smaller than the value set by the NRXMB[7:0] bits in the RSCFDnCFDRMNB register.

25.4.5.6 RSCFDnCFDGAFLP1_j — Receive Rule Pointer 1 Register (j = 0 to 15)

Access: RSCFDnCFDGAFLP1_j register can be read/written in 32-bit units
 RSCFDnCFDGAFLP1_jL, RSCFDnCFDGAFLP1_jH registers can be read/written in 16-bit units
 RSCFDnCFDGAFLP1_jLL, RSCFDnCFDGAFLP1_jLH, RSCFDnCFDGAFLP1_jHL, RSCFDnCFDGAFLP1_jHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLP1_j: <RSCFDn_base> + 100C_H + (10_H × j)
 RSCFDnCFDGAFLP1_jL: <RSCFDn_base> + 100C_H + (10_H × j),
 RSCFDnCFDGAFLP1_jH: <RSCFDn_base> + 100E_H + (10_H × j)
 RSCFDnCFDGAFLP1_jLL: <RSCFDn_base> + 100C_H + (10_H × j),
 RSCFDnCFDGAFLP1_jLH: <RSCFDn_base> + 100D_H + (10_H × j),
 RSCFDnCFDGAFLP1_jHL: <RSCFDn_base> + 100E_H + (10_H × j),
 RSCFDnCFDGAFLP1_jHH: <RSCFDn_base> + 100F_H + (10_H × j)

Value after reset: 0000 0000_H

Table 25.115 RSCFDnCFDGAFLP1_j Register Contents

| Bit | Bit Name | Function |
|----------|----------------|--|
| 31 to 14 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 13 to 8 | GAFLFDP [13:8] | Transmit/Receive FIFO Buffer k Select (Bit position – 8 = target transmit/receive FIFO buffer number k) 0: Transmit/receive FIFO buffer is not selected. 1: Transmit/receive FIFO buffer is selected. |
| 7 to 0 | GAFLFDP [7:0] | Receive FIFO Buffer x Select (Bit position = target receive FIFO buffer number x) 0: Receive FIFO buffer is not selected. 1: Receive FIFO buffer is selected. |

Modify the RSCFDnCFDGAFLP1_j register when the AFLDAE bit in the RSCFDnCFDGAFLP0_j register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLFDP[13:0] Bits

These bits are used to specify FIFO buffers that store receive messages that have passed through the filter. Up to eight FIFO buffers are selectable. However, when the GAFLRMV bit in the RSCFDnCFDGAFLP0_j register is set to 1 (a message is stored in the receive buffer), up to seven FIFO buffers can be selected. Only receive FIFO buffers and the transmit/receive FIFO buffer for which the CFM[1:0] bits in the RSCFDnCFDCFCCK register are set to 00_B (receive mode) or 10_B (gateway mode) are selectable.

25.4.6 Details of Receive Buffer-related Registers

25.4.6.1 RSCFDnCFDRMNB — Receive Buffer Number Register

Access: RSCFDnCFDRMNB register can be read/written in 32-bit units
 RSCFDnCFDRMNB, RSCFDnCFDRMNBH registers can be read/written in 16-bit units
 RSCFDnCFDRMNBLL, RSCFDnCFDRMNBHL, RSCFDnCFDRMNBHL, RSCFDnCFDRMNBHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRMNB: <RSCFDn_base> + 00A4_H
 RSCFDnCFDRMNB: <RSCFDn_base> + 00A4_H, RSCFDnCFDRMNBH: <RSCFDn_base> + 00A6_H
 RSCFDnCFDRMNBLL: <RSCFDn_base> + 00A4_H, RSCFDnCFDRMNBHL: <RSCFDn_base> + 00A5_H,
 RSCFDnCFDRMNBHL: <RSCFDn_base> + 00A6_H, RSCFDnCFDRMNBHH: <RSCFDn_base> + 00A7_H

Value after reset: 0000 0000_H

Table 25.116 RSCFDnCFDRMNB Register Contents

| Bit | Bit Name | Function |
|----------|------------|--|
| 31 to 10 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 9, 8 | RMPLS[1:0] | Receive Buffer Payload Storage Size Select b9 b8 0 0: 8 bytes 0 1: 12 bytes 1 0: 16 bytes 1 1: 20 bytes |
| 7 to 0 | NRXMB[7:0] | Receive Buffer Number Configuration Set the number of receive buffers. Set a value of 0 to 32. |

Modify the RSCFDnCFDRMNB register only in global reset mode.

RMPLS[1:0] Bits

These bits are used to select the maximum payload size that can be stored in the receive buffer.

NRXMB[7:0] Bits

These bits are used to set the total number of receive buffers of the RS-CANFD module. The maximum value is 16 × (number of channels).

Setting these bits all to 0 makes receive buffers unavailable.

25.4.6.2 RSCFDnCFDRMNDy — Receive Buffer New Data Register (y = 0)

Access: RSCFDnCFDRMNDy register can be read/written in 32-bit units
 RSCFDnCFDRMNDyL, RSCFDnCFDRMNDyH registers can be read/written in 16-bit units
 RSCFDnCFDRMNDyLL, RSCFDnCFDRMNDyLH, RSCFDnCFDRMNDyHL, RSCFDnCFDRMNDyHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRMNDy: <RSCFDn_base> + 00A8_H + (04_H × y)
 RSCFDnCFDRMNDyL: <RSCFDn_base> + 00A8_H + (04_H × y),
 RSCFDnCFDRMNDyH: <RSCFDn_base> + 00AA_H + (04_H × y)
 RSCFDnCFDRMNDyLL: <RSCFDn_base> + 00A8_H + (04_H × y),
 RSCFDnCFDRMNDyLH: <RSCFDn_base> + 00A9_H + (04_H × y),
 RSCFDnCFDRMNDyHL: <RSCFDn_base> + 00AA_H + (04_H × y),
 RSCFDnCFDRMNDyHH: <RSCFDn_base> + 00AB_H + (04_H × y)

Value after reset: 0000 0000_H

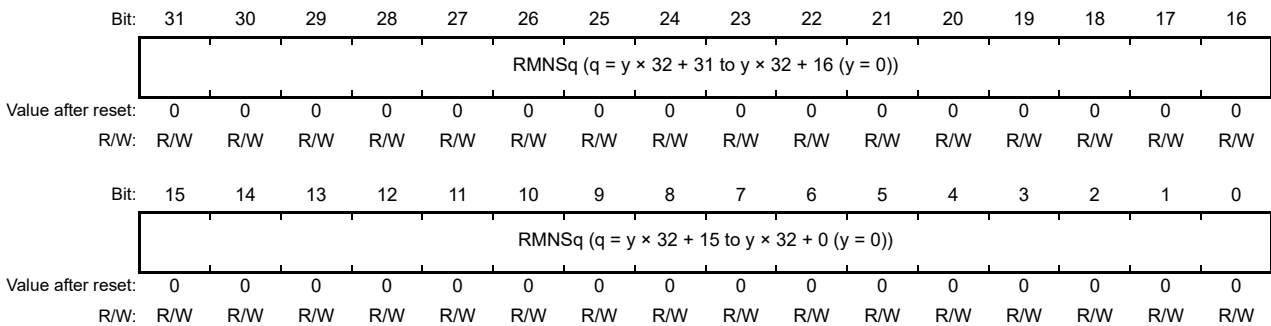

Table 25.117 RSCFDnCFDRMNDy Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 16 | RMNSq | Receive Buffer Receive Complete Flag q (q = y × 32 + 31 to y × 32 + 16) 0: There is no new message in receive buffer q. 1: There is a new message in receive buffer q. |
| 15 to 0 | RMNSq | Receive Buffer Receive Complete Flag q (q = y × 32 + 15 to y × 32 + 0) 0: There is no new message in receive buffer q. 1: There is a new message in receive buffer q. |

Write 0 to the RSCFDnCFDRMNDy register in global operating mode or global test mode.

RMNSq Flags (q = 0 to 31)

Each RMNSq flag is set to 1 when the processing for storing a message in the corresponding receive buffer starts.

To clear a flag to 0, the program must write 0 to the flag. Use a store instruction to write “0” to the flag and “1” to other flags. These bits cannot be set to 0 while a message is being stored. The message storing time depends on the storage payload size of the receive buffer. When the RMPLS[1:0] value in the RSCFDnCFDRMNB register is 00_B (8 bytes), the message storing time is 12 pclk clock cycles. When the RMPLS[1:0] value is 11_B (20 bytes), the message storing time is 18 pclk clock cycles. (2 pclk clock cycles per 4 bytes of storage payload size).

These flags are cleared to 0 in global reset mode.

25.4.6.3 RSCFDnCFDRMIDq — Receive Buffer ID Register (q = 0 to 31)

Access: RSCFDnCFDRMIDq register can be read only in 32-bit units
 RSCFDnCFDRMIDqL, RSCFDnCFDRMIDqH registers can be read only in 16-bit units
 RSCFDnCFDRMIDqLL, RSCFDnCFDRMIDqLH, RSCFDnCFDRMIDqHL, RSCFDnCFDRMIDqHH registers can be read only in 8-bit units

Address: RSCFDnCFDRMIDq: <RSCFDn_base> + 2000_H + (20_H × q)
 RSCFDnCFDRMIDqL: <RSCFDn_base> + 2000_H + (20_H × q),
 RSCFDnCFDRMIDqH: <RSCFDn_base> + 2002_H + (20_H × q)
 RSCFDnCFDRMIDqLL: <RSCFDn_base> + 2000_H + (20_H × q),
 RSCFDnCFDRMIDqLH: <RSCFDn_base> + 2001_H + (20_H × q),
 RSCFDnCFDRMIDqHL: <RSCFDn_base> + 2002_H + (20_H × q),
 RSCFDnCFDRMIDqHH: <RSCFDn_base> + 2003_H + (20_H × q)

Value after reset: 0000 0000_H

Table 25.118 RSCFDnCFDRMIDq Register Contents

| Bit | Bit Name | Function |
|---------|------------|--|
| 31 | RMIDE | Receive Buffer IDE 0: Standard ID 1: Extended ID |
| 30 | RMRT R | Receive Buffer RTR/RRS <ul style="list-style-type: none"> When the received message is a classical CAN frame 0: Data frame 1: Remote frame <ul style="list-style-type: none"> When the received message is a CANFD frame The RRS bit value of the received message can be read. |
| 29 | Reserved | This bit is read as the value after reset. |
| 28 to 0 | RMID[28:0] | Receive Buffer ID Data These bits contain the standard ID or extended ID of the received message. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0. |

RMIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive buffer.

RMRT R Bit

When the received message is a classical CAN frame, this bit indicates the frame format (data frame or remote frame) of the message stored in the receive buffer. When the received message is a CANFD frame, this bit indicates the RRS bit value in the message.

RMID[28:0] Bits

These bits contain the ID of the message stored in the receive buffer.

25.4.6.4 RSCFDnCFDRMPTRq — Receive Buffer Pointer Register (q = 0 to 31)

Access: RSCFDnCFDRMPTRq register can be read only in 32-bit units
 RSCFDnCFDRMPTRqL, RSCFDnCFDRMPTRqH registers can be read only in 16-bit units
 RSCFDnCFDRMPTRqLL, RSCFDnCFDRMPTRqLH, RSCFDnCFDRMPTRqHL, RSCFDnCFDRMPTRqHH registers can be read only in 8-bit units

Address: RSCFDnCFDRMPTRq: $\langle \text{RSCFDn_base} \rangle + 2004_{\text{H}} + (20_{\text{H}} \times q)$
 RSCFDnCFDRMPTRqL: $\langle \text{RSCFDn_base} \rangle + 2004_{\text{H}} + (20_{\text{H}} \times q)$,

| 27 to 16 | RMPTR [11:0] | Receive Buffer Label Data Label information of the received message. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bit | Bit Name | Function |
|---------|----------------|---|
| 15 to 0 | RMTS [15:0] | Receive Buffer Timestamp Data Timestamp value of the received message. |

RMDLC[3:0] Bits

These bits indicate the data length of the message stored in the receive buffer. The number of bytes of the payload to be stored in the receive buffer is determined by the RMPLS[1:0] bits in the RSCFDnCFDRMNB register.

RMPTR[11:0] Bits

These bits indicate the label information of the message stored in the receive buffer.

RMTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the receive buffer.

25.4.6.5 RSCFDnCFDRMFDSTSq — Receive Buffer CANFD Status Register (q = 0 to 31)

Access: RSCFDnCFDRMFDSTSq register can be read only in 32-bit units
 RSCFDnCFDRMFDSTSqL, RSCFDnCFDRMFDSTSqH registers can be read only in 16-bit units
 RSCFDnCFDRMFDSTSqLL, RSCFDnCFDRMFDSTSqLH, RSCFDnCFDRMFDSTSqHL, RSCFDnCFDRMFDSTSqHH registers can be read only in 8-bit units

Address: RSCFDnCFDRMFDSTSq: <RSCFDn_base> + 2008_H + (20_H × q)
 RSCFDnCFDRMFDSTSqL: <RSCFDn_base> + 2008_H + (20_H × q),

Table 25.120 RSCFDnCFDRMFDSTSq Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 3 | Reserved | These bits are read as the value after reset. |
| 2 | RMFDF | FDF 0: Classical CAN frame 1: CANFD frame |
| 1 | RMBRS | BRS 0: The bit rate in the data area does not change. 1: The bit rate in the data area changes. |
| 0 | RMESI | ESI 0: Error active node 1: Error passive node |

RMFDF Bit

This bit indicates the FD format (classical CAN frame or CANFD frame) of the message stored in the receive buffer.

RMBRS Bit

When the RMFDF bit is 1, this bit indicates the BRS bit value of the message stored in the receive buffer. When the RMFDF bit is 0, this bit is always read as 0.

RMESI Bit

When the RMFDF bit is 1, this bit indicates the ESI bit value of the message stored in the receive buffer. When the RMFDF bit is 0, this bit is always read as 0.

25.4.6.6 RSCFDnCFDRMDFb_q — Receive Buffer Data Field b Register (b = 0 to 4, q = 0 to 31)

Access: RSCFDnCFDRMDFb_q register can be read only in 32-bit units
 RSCFDnCFDRMDFb_qL, RSCFDnCFDRMDFb_qH registers can be read only in 16-bit units
 RSCFDnCFDRMDFb_qLL, RSCFDnCFDRMDFb_qLH, RSCFDnCFDRMDFb_qHL, RSCFDnCFDRMDFb_qHH registers can be read only in 8-bit units

Address: RSCFDnCFDRMDFb_q: $\langle \text{RSCFDn_base} \rangle + 200C_H + (04_H \times b) + (20_H \times q)$
 RSCFDnCFDRMDFb_qL: $\langle \text{RSCFDn_base} \rangle + 200C_H + (04_H \times b) + (20_H \times q)$,
 RSCFDnCFDRMDFb_qH: $\langle \text{RSCFDn_base} \rangle + 200E_H + (04_H \times b) + (20_H \times q)$
 RSCFDnCFDRMDFb_qLL: $\langle \text{RSCFDn_base} \rangle + 200C_H + (04_H \times b) + (20_H \times q)$,
 RSCFDnCFDRMDFb_qLH: $\langle \text{RSCFDn_base} \rangle + 200D_H + (04_H \times b) + (20_H \times q)$,
 RSCFDnCFDRMDFb_qHL: $\langle \text{RSCFDn_base} \rangle + 200E_H + (04_H \times b) + (20_H \times q)$,
 RSCFDnCFDRMDFb_qHH: $\langle \text{RSCFDn_base} \rangle + 200F_H + (04_H \times b) + (20_H \times q)$

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |

Table 25.121 RSCFDnCFDRMDFb_q Register Contents

| Bit | Bit Name | Function |
|--|---------------------|------------------------------------|
| 31 to 24 | RMDB4 × b + 3 [7:0] | Receive Buffer Data Byte 4 × b + 3 |
| 23 to 16 | RMDB4 × b + 2 [7:0] | Receive Buffer Data Byte 4 × b + 2 |
| 15 to 8 | RMDB4 × b + 1 [7:0] | Receive Buffer Data Byte 4 × b + 1 |
| 7 to 0 | RMDB4 × b + 0 [7:0] | Receive Buffer Data Byte 4 × b + 0 |
| Data for a message stored in the receive buffer can be read. | | |

When the RMDLC[3:0] value in the RSCFDnCFDRMPTRq register is smaller than the payload storage size of the receive buffer, data bytes for which no data is set are read as 00_H.

Specify the payload storage size of the receive buffer by the RMPLS[1:0] bits in the RSCFDnCFDRMNB register. Do not read or write the RSCFDnCFDRMDFb_q register corresponding to an area larger than the specified size.

25.4.7 Details of Receive FIFO Buffer-related Registers

25.4.7.1 RSCFDnCFDRFCCx — Receive FIFO Buffer Configuration and Control Register (x = 0 to 7)

Access: RSCFDnCFDRFCCx register can be read/written in 32-bit units
 RSCFDnCFDRFCCxL, RSCFDnCFDRFCCxH registers can be read/written in 16-bit units
 RSCFDnCFDRFCCxLL, RSCFDnCFDRFCCxLH, RSCFDnCFDRFCCxHL, RSCFDnCFDRFCCxHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRFCCx: <RSCFDn_base> + 00B8_H + (04_H × x)
 RSCFDnCFDRFCCxL: <RSCFDn_base> + 00B8_H + (04_H × x),
 RSCFDnCFDRFCCxH: <RSCFDn_base> + 00BA_H + (04_H × x),
 RSCFDnCFDRFCCxLL: <RSCFDn_base> + 00B8_H + (04_H × x),
 RSCFDnCFDRFCCxLH: <RSCFDn_base> + 00B9_H + (04_H × x),
 RSCFDnCFDRFCCxHL: <RSCFDn_base> + 00BA_H + (04_H × x),
 RSCFDnCFDRFCCxHH: <RSCFDn_base> + 00BB_H + (04_H × x)

Table 25.122 RSCFDnCFDRFCCx Register Contents

| Bit | Bit Name | Function |
|----------|-------------|---|
| 31 to 16 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 15 to 13 | RFIGCV[2:0] | Receive FIFO Interrupt Request Timing Select b15 b14 b13 0 0 0: When FIFO is 1/8 full. 0 0 1: When FIFO is 2/8 full. 0 1 0: When FIFO is 3/8 full. 0 1 1: When FIFO is 4/8 full. 1 0 0: When FIFO is 5/8 full. 1 0 1: When FIFO is 6/8 full. 1 1 0: When FIFO is 7/8 full. 1 1 1: When FIFO is full. |
| 12 | RFIM | Receive FIFO Interrupt Source Select 0: An interrupt occurs when the condition set by the RFIGCV[2:0] bits is met. 1: An interrupt occurs each time a message has been received. |
| 11 | Reserved | This bit is read as the value after reset. The write value should be the value after reset. |
| 10 to 8 | RFDC[2:0] | Receive FIFO Buffer Depth Configuration b10 b9 b8 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages 1 1 0: 64 messages 1 1 1: 128 messages |
| 7 | Reserved | This bit is read as the value after reset. The write value should be the value after reset. |

| Bit | Bit Name | Function |
|--------|------------|--|
| 6 to 4 | RFPLS[2:0] | Receive FIFO Buffer Payload Storage Size Select b6 b5 b4 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes |
| 3, 2 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 1 | RFIE | Receive FIFO Interrupt Enable 0: Receive FIFO interrupt is disabled. 1: Receive FIFO interrupt is enabled. |
| 0 | RFE | Receive FIFO Buffer Enable 0: No receive FIFO buffer is used. 1: Receive FIFO buffers are used. |

RFICV[2:0] Bits

These bits are used to specify the number of received messages for generating a receive FIFO interrupt request when the RFIM bit is set to 0 with a fraction for the total number of buffers (the setting of RFDC[2:0]).

When the RFDC[2:0] bits are set to 001_B (4 messages), set the RFICV[2:0] bits to 001_B, 011_B, 101_B, or 111_B. Modify these bits only in global reset mode.

RFIM Bit

This bit is used to select a FIFO interrupt source. Modify this bit only in global reset mode.

RFDC[2:0] Bits

These bits are used to select the number of messages that can be stored in a single receive FIFO buffer. When these bits are set to 000_B, no receive FIFO buffer should be used. Modify these bits only in global reset mode.

RFPLS[2:0] Bits

These bits are used to select the maximum payload size that can be stored in the receive FIFO buffer. Modify these bits only in global reset mode.

RFIE Bit

Setting the RFIE bit to 1 enables receive FIFO interrupts. Modify this bit when the RFE bit set to 0 (no receive FIFO buffer is used).

RFE Bit

Setting the RFE bit to 1 makes receive FIFO buffers available. Clearing this bit to 0 sets the RFEMP flag in the RSCFDnCFDRFSTSx register to 1 (buffer empty). Modify this bit in global operating mode or global test mode. Set this bit to 1 with another instruction after the settings to all bits in the RSCFDnCFDRFCCx register have been done. This bit is cleared to 0 in global reset mode.

25.4.7.2 RSCFDnCFDRFSTSx — Receive FIFO Buffer Status Register (x = 0 to 7)

Access: RSCFDnCFDRFSTSx register can be read/written in 32-bit units
 RSCFDnCFDRFSTSxL, RSCFDnCFDRFSTSxH registers can be read/written in 16-bit units
 RSCFDnCFDRFSTSxLL, RSCFDnCFDRFSTSxLH, RSCFDnCFDRFSTSxHL, RSCFDnCFDRFSTSxHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRFSTSx: <RSCFDn_base> + 00D8_H + (04_H × x)
 RSCFDnCFDRFSTSxL: <RSCFDn_base> + 00D8_H + (04_H × x),
 RSCFDnCFDRFSTSxH: <RSCFDn_base> + 00DA_H + (04_H × x)
 RSCFDnCFDRFSTSxLL: <RSCFDn_base> + 00D8_H + (04_H × x),
 RSCFDnCFDRFSTSxLH: <RSCFDn_base> + 00D9_H + (04_H × x),
 RSCFDnCFDRFSTSxHL: <RSCFDn_base> + 00DA_H + (04_H × x),

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.123 RSCFDnCFDRFSTSx Register Contents

| Bit | Bit Name | Function |
|----------|-----------|---|
| 31 to 16 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 15 to 8 | RFMC[7:0] | Receive FIFO Unread Message Counter The number of unread messages stored in the receive FIFO buffer is displayed. |
| 7 to 4 | Reserved | These bits are read as the value after reset. When writing to these bits, write the value after reset. |
| 3 | RFIF | Receive FIFO Interrupt Request Flag 0: No receive FIFO interrupt request is present. 1: A receive FIFO interrupt request is present. |
| 2 | RFMLT | Receive FIFO Message Lost Flag 0: No receive FIFO message is lost. 1: A receive FIFO message is lost. |
| 1 | RFFLL | Receive FIFO Buffer Full Status Flag 0: The receive FIFO buffer is not full. 1: The receive FIFO buffer is full. |
| 0 | RFEMP | Receive FIFO Buffer Empty Status Flag 0: The receive FIFO buffer contains unread message. 1: The receive FIFO buffer contains no unread message (buffer empty). |

RFMC[7:0] Flag

This flag indicates the number of unread messages in the receive FIFO buffer. This flag becomes 00_H when the RFE bit in the RSCFDnCFDRFCCx register is set to 0.

This flag is 00_H in global reset mode.

RFIF Flag

This flag is set to 1 when the receive FIFO interrupt request generation conditions set by the RFIGCV[2:0] bits and the RFIM bit in the RSCFDnCFDRFCCx register are met. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

RFMLT Flag

This flag is set to 1 when an attempt is made to store a new message while the receive FIFO buffer is full. In this case, the new message is discarded.

This flag is cleared to 0 in global reset mode or by writing 0 to this flag.

Modify this bit in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

RFFLL Flag

This flag is set to 1 when the number of messages stored in the receive FIFO buffer matches the FIFO buffer depth set by the RFDC[2:0] bits in the RSCFDnCFDRFCCx register.

If the number of messages stored in the receive FIFO buffer becomes smaller than the FIFO buffer depth set by the RFDC[2:0] bits, this flag is cleared to 0. This flag is also cleared to 0 when the RFE bit in the RSCFDnCFDRFCCx register is set to 0 (no receive FIFO buffer is used) or in global reset mode.

RFEMP Flag

This flag is set to 1 when all messages in the receive FIFO buffer have been read. This flag is also set to 1 when the RFE bit in the RSCFDnCFDRFCCx register is 0 or in global reset mode.

This flag is cleared to 0 when even a single received message has been stored in the receive FIFO buffer.

Note: To clear the RFMLT or RFIF flag to 0, use a store instruction to write “0” to the given flag and “1” to the other flags.

25.4.7.3 RSCFDnCFDRFPCTR_x — Receive FIFO Buffer Pointer Control Register ($x = 0$ to 7)

Access: RSCFDnCFDRFPCTR_x register can only be written in 32-bit units
 RSCFDnCFDRFPCTR_{xL}, RSCFDnCFDRFPCTR_{xH} registers can only be written in 16-bit units
 RSCFDnCFDRFPCTR_{xLL}, RSCFDnCFDRFPCTR_{xLH}, RSCFDnCFDRFPCTR_{xHL}, RSCFDnCFDRFPCTR_{xHH} registers can only be written in 8-bit units

Address: RSCFDnCFDRFPCTR_x: <RSCFDn_base> + 00F8_H + (04_H × x)
 RSCFDnCFDRFPCTR_{xL}: <RSCFDn_base> + 00F8_H + (04_H × x),
 RSCFDnCFDRFPCTR_{xH}: <RSCFDn_base> + 00FA_H + (04_H × x)
 RSCFDnCFDRFPCTR_{xLL}: <RSCFDn_base> + 00F8_H + (04_H × x),
 RSCFDnCFDRFPCTR_{xLH}: <RSCFDn_base> + 00F9_H + (04_H × x),
 RSCFDnCFDRFPCTR_{xHL}: <RSCFDn_base> + 00FA_H + (04_H × x),
 RSCFDnCFDRFPCTR_{xHH}: <RSCFDn_base> + 00FB_H + (04_H × x)

Table 25.124 RSCFDnCFDRFPCTR_x Register Contents

| Bit | Bit Name | Function |
|---------|-----------|--|
| 31 to 8 | Reserved | The write value should be the value after reset. |
| 7 to 0 | RFPC[7:0] | Receive FIFO Pointer Control When these bits are set to FF _H , the read pointer moves to the next unread message in the receive FIFO buffer. |

When the RFDMAEx value in the RSCFDnCFDCDTCT register is 1 (DMA transfer request enabled), do not write a value to this register.

RFPC[7:0] Bits

When the RFPC[7:0] bits are set to FF_H, the read pointer moves to the next unread message in the receive FIFO buffer. At this time, the RFMC[7:0] (receive FIFO unread message counter) value in the RSCFDnCFDRFSTS_x register is decremented. Read the RSCFDnCFDRFID_x, RSCFDnCFDRFPTR_x, RSCFDnCFDRFDSTS_x, and RSCFDnCFDRFDFd_x registers to read messages in the receive FIFO buffer, and then write FF_H to the RFPC[7:0] bits. When writing FF_H to these bits, make sure that the RFE bit in the RSCFDnCFDRFCC_x register is set to 1 (receive FIFO buffers are used) and the RFEMP flag in the RSCFDnCFDRFSTS_x register is 0 (the receive FIFO buffer contains unread messages).

25.4.7.4 RSCFDnCFDRFIDx — Receive FIFO Buffer Access ID Register (x = 0 to 7)

Access: RSCFDnCFDRFIDx register can be read only in 32-bit units
 RSCFDnCFDRFIDxL, RSCFDnCFDRFIDxH registers can be read only in 16-bit units
 RSCFDnCFDRFIDxLL, RSCFDnCFDRFIDxLH, RSCFDnCFDRFIDxHL, RSCFDnCFDRFIDxHH registers can be read only in 8-bit units

Address: RSCFDnCFDRFIDx: $\langle \text{RSCFDn_base} \rangle + 3000_{\text{H}} + (80_{\text{H}} \times x)$
 RSCFDnCFDRFIDxL: $\langle \text{RSCFDn_base} \rangle + 3000_{\text{H}} + (80_{\text{H}} \times x)$,

Table 25.125 RSCFDnCFDRFPCTRx Register Contents

| Bit | Bit Name | Function |
|---------|------------|---|
| 31 | RFIDE | Receive FIFO Buffer IDE 0: Standard ID 1: Extended ID |
| 30 | RFRTR | Receive FIFO Buffer RTR/RRS • When the received message is a classical CAN frame 0: Data frame 1: Remote frame • When the received message is a CANFD frame The RRS bit value of the received message can be read. |
| 29 | Reserved | This bit is read as the value after reset. |
| 28 to 0 | RFID[28:0] | Receive FIFO Buffer ID Data The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0. |

RFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive FIFO buffer.

RFRTR Bit

When the received message is a classical CAN frame, this bit indicates the frame format (data frame or remote frame) of the message stored in the receive FIFO buffer. When the received message is a CANFD frame, this bit indicates the RRS bit value in the message.

RFID[28:0] Bits

These bits indicate the ID of the message stored in the receive FIFO buffer.

25.4.7.5 RSCFDnCFDRFPTRx — Receive FIFO Buffer Access Pointer Register (x = 0 to 7)

Access: RSCFDnCFDRFPTRx register can be read only in 32-bit units
 RSCFDnCFDRFPTRxL, RSCFDnCFDRFPTRxH registers can be read only in 16-bit units
 RSCFDnCFDRFPTRxLL, RSCFDnCFDRFPTRxLH, RSCFDnCFDRFPTRxHL, RSCFDnCFDRFPTRxHH registers can be read only in 8-bit units

Table 25.127 RSCFDnCFDRFFDSTSx Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 3 | Reserved | These bits are read as the value after reset. |
| 2 | RFFDF | FDF 0: Classical CAN frame 1: CANFD frame |
| 1 | RFBRs | BRS 0: The bit rate in the data area does not change. 1: The bit rate in the data area changes. |
| 0 | RFESI | ESI 0: Error active node 1: Error passive node |

RFFDF Bit

This bit indicates the FD format (classical CAN frame or CANFD frame) of the message stored in the receive FIFO buffer.

RFBRs Bit

When the RFFDF bit is 1, this bit indicates the BRS bit value of the message stored in the receive FIFO buffer. When the RFFDF bit is 0, this bit is always read as 0.

RFESI Bit

When the RFFDF bit is 1, this bit indicates the ESI bit value of the message stored in the receive FIFO buffer. When the RFFDF bit is 0, this bit is always read as 0.

25.4.7.7 RSCFDnCFDRFDFd_x — Receive FIFO Buffer Access Data Field d Register (d = 0 to 15, x = 0 to 7)

Access: RSCFDnCFDRFDFd_x register can be read only in 32-bit units
 RSCFDnCFDRFDFd_xL, RSCFDnCFDRFDFd_xH registers can be read only in 16-bit units
 RSCFDnCFDRFDFd_xLL, RSCFDnCFDRFDFd_xLH, RSCFDnCFDRFDFd_xHL, RSCFDnCFDRFDFd_xHH registers can be read only in 8-bit units

Address: RSCFDnCFDRFDFd_x: $\langle \text{RSCFDn_base} \rangle + 300C_H + (04_H \times d) + (80_H \times x)$
 RSCFDnCFDRFDFd_xL: $\langle \text{RSCFDn_base} \rangle + 300C_H + (04_H \times d) + (80_H \times x)$,
 RSCFDnCFDRFDFd_xH: $\langle \text{RSCFDn_base} \rangle + 300E_H + (04_H \times d) + (80_H \times x)$

Table 25.128 RSCFDnCFDRFDFd_x Register Contents

| Bit | Bit Name | Function |
|--|---------------------|------------------------------------|
| 31 to 24 | RFDB4 × d + 3 [7:0] | Receive Buffer Data Byte 4 × d + 3 |
| 23 to 16 | RFDB4 × d + 2 [7:0] | Receive Buffer Data Byte 4 × d + 2 |
| 15 to 8 | RFDB4 × d + 1 [7:0] | Receive Buffer Data Byte 4 × d + 1 |
| 7 to 0 | RFDB4 × d + 0 [7:0] | Receive Buffer Data Byte 4 × d + 0 |
| Data for a message stored in the receive buffer can be read. | | |

When the RFDLC[3:0] value in the RSCFDnCFDRFPTRx register is smaller than the payload storage size of the receive FIFO buffer, data bytes for which no data is set are read as 00_H.

Specify the payload storage size of the receive FIFO buffer by the RFPLS[2:0] bits in the RSCFDnCFDRFCCx register.

Do not read or write the RSCFDnCFDRFDFd_x register corresponding to an area larger than the specified size.

25.4.8 Transmit/Receive FIFO Buffer-related Registers

25.4.8.1 RSCFDnCFDCFCCK — Transmit/receive FIFO Buffer Configuration and Control Register k (k = 0 to 5)

Access: RSCFDnCFDCFCCK register can be read/written in 32-bit units
 RSCFDnCFDCFCCKL, RSCFDnCFDCFCCKH registers can be read/written in 16-bit units
 RSCFDnCFDCFCCKLL, RSCFDnCFDCFCCKLH, RSCFDnCFDCFCCKHL, RSCFDnCFDCFCCKHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCFCCK: <RSCFDn_base> + 0118_H + (04_H × k)
 RSCFDnCFDCFCCKL: <RSCFDn_base> + 0118_H + (04_H × k),
 RSCFDnCFDCFCCKH: <RSCFDn_base> + 011A_H + (04_H × k)
 RSCFDnCFDCFCCKLL: <RSCFDn_base> + 0118_H + (04_H × k),
 RSCFDnCFDCFCCKLH: <RSCFDn_base> + 0119_H + (04_H × k),
 RSCFDnCFDCFCCKHL: <RSCFDn_base> + 011A_H + (04_H × k),
 RSCFDnCFDCFCCKHH: <RSCFDn_base> + 011B_H + (04_H × k)

| 0 | CFE | Transmit/Receive FIFO Buffer Enable 0: No transmit/receive FIFO buffer is used. 1: Transmit/receive FIFO buffers are used. |

CFITT[7:0] Bits

These bits are used to set a message transmission interval when transmitting messages continuously from a transmit/receive FIFO buffer whose CFM[1:0] bits are set to 01_B (transmit mode) or 10_B (gateway mode).

Clear the CFE bit to 0 (no transmit/receive FIFO buffer is used) before modifying the CFITT[7:0] bits.

CFTML[3:0] Bits

These bits are used to set the number of transmit buffer on the channel which will be linked to transmit/receive FIFO buffer k when the CFM[1:0] bits are set to 01_B (transmit mode) or 10_B (gateway mode). There are three transmit/receive FIFO buffers per channel, so channel number m of FIFO buffer k is calculated as $m = k/3$ (integer division). The actual assigned transmit buffer number p linked to FIFO buffer k will be $((16 \times m) + CFTML[3:0])$.

See Table 25.11 and Table 25.12, as for the relationship between transmit/receive FIFO buffer k and transmit buffer p. Setting the CFDC[2:0] bits to 001_B or more enables the setting of the CFTML[3:0] bits. Do not link to any transmit buffer which is already allocated to a transmit queue on the identical channel or to another transmit/receive FIFO buffer. Modify these bits only in global reset mode.

CFITR Bit

This bit is enabled when the CFITSS bit is 0.

When this bit is 0, the interval timer clock source is the pclk/2 clock divided by the value of the ITRCP[15:0] bits in the RSCFDnCFDGCFCFG register.

When this bit is 1, the interval timer clock source is the pclk/2 clock divided by (the value of the ITRCP[15:0] bits in the RSCFDnCFDGCFCFG register × 10).

Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

CFITSS Bit

When this bit is 0, the clock selected by the CFITR bit is the count source of the interval timer.

When this bit is 1, the nominal bit time clock of the channel to which the FIFO is linked is the count source of the interval timer. Use this count source only for the channel that does not handle the CANFD frames.

Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

CFM[1:0] Bits

These bits are used to select transmit/receive FIFO mode. Modify these bits only in global reset mode.

CFIGCV[2:0] Bits

These bits are used to specify the number of received messages for generating a transmit/receive FIFO receive interrupt request when the CFM[1:0] bits are set to 00_B (receive mode) or 10_B (gateway mode) and the CFIM bit is set to 0 with a fraction for the total number of buffers (the setting of CFDC[2:0]).

When the CFDC[2:0] bits are set to 001_B (4 messages), set the CFIGCV[2:0] bits to 001_B, 011_B, 101_B, or 111_B.

Modify these bits only in global reset mode.

CFIM Bit

This bit is used to select a transmit/receive FIFO interrupt source. Modify this bit only in global reset mode.

CFDC[2:0] Bits

These bits are used to set the number of messages that can be stored in a single transmit/receive FIFO buffer. When these bits are set to 000_B, do not use a transmit/receive FIFO buffer. Modify these bits only in global reset mode.

CFPLS[2:0] Bits

These bits are used to select the maximum payload size that can be stored in the transmit/receive FIFO buffer. Modify these bits only in global reset mode.

CFTXIE Bit

When this bit is set to 1 and the CFTXIF flag in the RSCFDnCFDCFSTSk register is set to 1, a transmit/receive FIFO transmit interrupt request is generated.

Modify this bit with the CFE bit set to 0 (no transmit/receive FIFO buffer is used).

CFRXIE Bit

When this bit is set to 1 and the CFRXIF flag in the RSCFDnCFDCFSTSk register is set to 1, a transmit/receive FIFO receive interrupt request is generated.

Modify this bit with the CFE bit set to 0.

CFE Bit

Setting this bit to 1 makes transmit/receive FIFO buffers available.

When this bit is set to 0 in transmit mode or gateway mode, if a message in the transmit/receive FIFO buffer is being transmitted or will be transmitted next, the transmit/receive FIFO buffer becomes empty after completion of transmission of that message, or upon detection of a CAN bus error, or arbitration-lost. In other cases or in receive mode, the transmit/receive FIFO buffer becomes empty immediately.

This bit is cleared to 0 when the following conditions are met.

- Receive mode: Global reset mode
- Transmit mode or gateway mode: Channel reset mode

Modify this bit in the following mode.

- Receive mode: Global operating mode or global test mode
- Transmit mode or gateway mode: Channel communication mode or channel halt mode

After all other bits in the RSCFDnCFDCFCCk register have been set, set this bit to 1 by using another instruction.

25.4.8.2 RSCFDnCFDCFSTSk — Transmit/receive FIFO Buffer Status Register (k = 0 to 5)

Access: RSCFDnCFDCFSTSk register can be read/written in 32-bit units
 RSCFDnCFDCFSTSkL, RSCFDnCFDCFSTSkH registers can be read/written in 16-bit units
 RSCFDnCFDCFSTSkLL, RSCFDnCFDCFSTSkLH, RSCFDnCFDCFSTSkHL, RSCFDnCFDCFSTSkHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCFSTSk: <RSCFDn_base> + 0178_H + (04_H × k)
 RSCFDnCFDCFSTSkL: <RSCFDn_base> + 0178_H + (04_H × k),
 RSCFDnCFDCFSTSkH: <RSCFDn_base> + 017A_H + (04_H × k),
 RSCFDnCFDCFSTSkLL: <RSCFDn_base> + 0178_H + (04_H × k),
 RSCFDnCFDCFSTSkLH: <RSCFDn_base> + 0179_H + (04_H × k),
 RSCFDnCFDCFSTSkHL: <RSCFDn_base> + 017A_H + (04_H × k),
 RSCFDnCFDCFSTSkHH: <RSCFDn_base> + 017B_H + (04_H × k)

Value after reset: 0000 0001_H

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.130 RSCFDnCFDCFSTSk Register Contents

| Bit | Bit Name | Function |
|----------|-----------|--|
| 31 to 16 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 15 to 8 | CFMC[7:0] | Transmit/Receive FIFO Message Counter The number of messages stored in the transmit/receive FIFO buffer. |
| 7 to 5 | Reserved | These bits are read as the value after reset. When writing to these bits, write the value after reset. |
| 4 | CCTXIF | Transmit/Receive FIFO Transmit Interrupt Request Flag 0: No transmit/receive FIFO transmit interrupt request is present. 1: A transmit/receive FIFO transmit interrupt request is present. |
| 3 | CFRXIF | Transmit/Receive FIFO Receive Interrupt Request Flag 0: No transmit/receive FIFO receive interrupt request is present. 1: A transmit/receive FIFO receive interrupt request is present. |
| 2 | CFMLT | Transmit/Receive FIFO Message Lost Flag 0: No transmit/receive FIFO message is lost. 1: A transmit/receive FIFO message is lost. |
| 1 | CFLL | Transmit/Receive FIFO Buffer Full Status Flag 0: The transmit/receive FIFO buffer is not full. 1: The transmit/receive FIFO buffer is full. |
| 0 | CFEMP | Transmit/Receive FIFO Buffer Empty Status Flag 0: The transmit/receive FIFO buffer contains messages. 1: The transmit/receive FIFO buffer contains no message (buffer empty). |

CFMC[7:0] Bits

The CFMC[7:0] bits indicate the following values that depend on the setting of the CFM[1:0] bits in the RSCFDnCFDCFCCK register.

- When CFM[1:0] value is 01_B (transmit mode): Number of untransmitted messages in the buffer
- When CFM[1:0] value is 00_B (receive mode): Number of unread received messages in the buffer
- When CFM[1:0] value is 10_B (gateway mode): Number of untransmitted received messages in the buffer

These bits are cleared to 0 when any of the following conditions is met.

- When CFM[1:0] value is 00_B: In global reset mode
- When CFM[1:0] value is 01_B or 10_B: In channel reset mode
- When the CFE bit in the RSCFDnCFDCFCCK register is cleared to 0.

CFTXIF Flag

The CFTXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 01_B or 10_B, and the factor selected by the CFIM bit in the RSCFDnCFDCFCCK register occurs

The CFTXIF flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFTXIF flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFRXIF Flag

The CFRXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B or 10_B, and the factor selected by the CFIM bit in the RSCFDnCFDCFCCK register occurs

The CFRXIF flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFRXIF flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFMLT Flag

The CFMLT flag is set to 1 when any of the following conditions is met.

- When an attempt is made to store a new message while the transmit/receive FIFO buffer is full. In this case, the new message is discarded.

The CFMLT flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFMLT flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFFLL Flag

The CFFLL flag is set to 1 when any of the following conditions is met.

- When the number of messages stored in the transmit/receive FIFO buffer matches the FIFO buffer depth set by the CFDC[2:0] bits in the RSCFDnCFDCFCCK register.

The CFMLT flag is cleared to 0 when any of the following conditions is met.

- When the number of messages stored in the transmit/receive FIFO buffer becomes smaller than the FIFO buffer depth set by the CFDC[2:0] bits.
- When the CFE bit in the RSCFDnCFDCFCCK register is 0 (no transmit/receive FIFO buffer is used): When not in the transmit abort
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

CFEMP Flag

The CFEMP flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B: All messages have been read, or in global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: All messages have been transmitted, or in channel reset mode
- When the CFE bit is 0 (no transmit/receive FIFO buffer is used): Not in the transmit abort

The CFEMP flag is cleared to 0 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B or 10_B: At least one received message has been stored in the transmit/receive FIFO buffer.
- When the CFM[1:0] bits are set to 01_B: A value of FF_H has been written to the RSCFDnCFDCFPCTRk register after data was written to the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDf_k registers.

Note: To clear CFTXIF, CFRXIF, or CFMLT flag to 0, the program must write 0. When writing, use a store instruction to write “0” to the given flag and “1” to other flags.

25.4.8.3 RSCFDnCFDCFPCTRk — Transmit/receive FIFO Buffer Pointer Control Register (k = 0 to 5)

Access: RSCFDnCFDCFPCTRk register can only be written in 32-bit units
 RSCFDnCFDCFPCTRkL, RSCFDnCFDCFPCTRkH registers can only be written in 16-bit units
 RSCFDnCFDCFPCTRkLL, RSCFDnCFDCFPCTRkLH, RSCFDnCFDCFPCTRkHL, RSCFDnCFDCFPCTRkHH registers can only be written in 8-bit units

Table 25.131 RSCFDnCFDCFPCTRk Register Contents

| Bit | Bit Name | Function |
|---------|-----------|---|
| 31 to 8 | Reserved | The write value should be the value after reset. |
| 7 to 0 | CFPC[7:0] | Transmit/Receive FIFO Pointer Control <ul style="list-style-type: none"> • Receive mode: Writing FF_H to these bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. • Transmit mode: Writing FF_H to these bits moves the write pointer to the next stage of the transmit/receive FIFO buffer. • Gateway mode: Setting prohibited |

When the corresponding transmit/receive FIFO buffer is the first transmit/receive FIFO buffer ($k = 3 \times m$) allocated to channel m and when the CFDMAEm bit in the RSCFDnCFDCDTCT register is 1 (DMA transfer request enabled), do not write a value to this register.

CFPC[7:0] Bits

- Receive mode (CFM[1:0] value in the RSCFDnCFDCFCCK register is 00_B):

Writing FF_H to the CFPC[7:0] bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value (transmit/receive FIFO message counter) in the RSCFDnCFDCFSTSk register is decremented. Read the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDf_k registers to read messages from the transmit/receive FIFO buffer, and then write FF_H to the CFPC[7:0] bits.

When writing FF_H to these bits, make sure that the CFE bit in the RSCFDnCFDCFCCK register is set to 1 (transmit/receive FIFO buffers are used) and the CFEMP flag in the RSCFDnCFDCFSTSk register is 0 (the transmit/receive FIFO buffer contains messages).

- Transmit mode (CFM[1:0] value in the RSCFDnCFDCFCCK register is 01_B):

Writing FF_H to the CFPC[7:0] bits stores the data written to the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDf_k registers in the transmit/receive FIFO buffer and moves the write pointer to the next stage of the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value is incremented. Write transmit messages to the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDf_k registers before writing FF_H to the CFPC[7:0] bits.

When writing FF_H to these bits, make sure that the CFE bit in the RSCFDnCFDCFCCK register is set to 1 and the CFFLL flag in the RSCFDnCFDCFSTSk register is 0 (the transmit/receive FIFO buffer is not full).

- Gateway mode (CFM[1:0] value in the RSCFDnCFDCFCCK register is 10_B):

Setting prohibited

25.4.8.4 RSCFDnCFDCFIDk — Transmit/receive FIFO Buffer Access ID Register (k = 0 to 5)

Access: RSCFDnCFDCFIDk register can be read/written in 32-bit units

Table 25.132 RSCFDnCFDCFIDk Register Contents

| Bit | Bit Name | Function |
|---------|------------|--|
| 31 | CFIDE | Transmit/Receive FIFO Buffer IDE 0: Standard ID 1: Extended ID |
| 30 | CFRTR | Transmit/Receive FIFO Buffer RTR/RRS <ul style="list-style-type: none"> When the CFM[1:0] value is 01_B (transmit mode) <ul style="list-style-type: none"> When the transmit message is a classical CAN frame 0: Data frame 1: Remote frame When the transmit message is a CANFD frame Write 0 to this bit. When the CFM[1:0] value is 00_B (receive mode) <ul style="list-style-type: none"> When the received message is a classical CAN frame 0: Data frame 1: Remote frame When the received message is a CANFD frame The RRS bit value of the received message can be read. |
| 29 | THLEN | Transmit History Data Store Enable This bit is valid only when the CFM[1:0] value is 01 _B (transmit mode). 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer. |
| 28 to 0 | CFID[28:0] | Transmit/Receive FIFO Buffer ID Data <ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11. When CFM[1:0] value is 00_B (receive mode): Standard ID or extended ID in the received message can be read. For standard ID, read bits 10 to 0. Bits 28 to 11 are read as 0. |

This register is writable only when the CFM[1:0] value in the RSCFDnCFDCFCCK register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This RSCFDnCFDCFIDk register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, this bit is used to set the ID format of the message to be transmitted from the transmit/receive FIFO buffer.

CFRTR Bit

If the received message is a classical CAN frame, this bit indicates the data format (data frame or remote frame) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. If the received message is a CANFD frame, this bit indicates the RRS bit value of the received message.

When the CFM[1:0] value is 01_B, this bit is used to set the data format of the message to be transmitted from the transmit/receive FIFO buffer.

When the CFFDF bit in the RSCFDnCFDCFFDCSTSk register is 1 (CANFD frame), set this bit to 0.

THLEN Bit

When this bit is set to 1, the transmit history data (label information, buffer number, buffer type, and timestamp) of transmit messages is stored in the transmit history buffer after transmission is completed.

This bit is enabled when the CFM[1:0] value is 01_B (transmit mode).

CFID[28:0] Bits

These bits contain the ID of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B.

When the CFM[1:0] value is 01_B, this bit is used to set the ID of the message to be transmitted from the transmit/receive FIFO buffer.

25.4.8.5 RSCFDnCFDCFPTRk — Transmit/receive FIFO Buffer Access Pointer Register (k = 0 to 5)

Access: RSCFDnCFDCFPTRk register can be read/written in 32-bit units
 RSCFDnCFDCFPTRkL, RSCFDnCFDCFPTRkH registers can be read/written in 16-bit units
 RSCFDnCFDCFPTRkLL, RSCFDnCFDCFPTRkLH, RSCFDnCFDCFPTRkHL, RSCFDnCFDCFPTRkHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCFPTRk: $\langle \text{RSCFDn_base} \rangle + 3404_{\text{H}} + (80_{\text{H}} \times k)$
 RSCFDnCFDCFPTRkL: $\langle \text{RSCFDn_base} \rangle + 3404_{\text{H}} + (80_{\text{H}} \times k)$,
 RSCFDnCFDCFPTRkH: $\langle \text{RSCFDn_base} \rangle + 3406_{\text{H}} + (80_{\text{H}} \times k)$,
 RSCFDnCFDCFPTRkLL: $\langle \text{RSCFDn_base} \rangle + 3404_{\text{H}} + (80_{\text{H}} \times k)$,
 RSCFDnCFDCFPTRkLH: $\langle \text{RSCFDn_base} \rangle + 3405_{\text{H}} + (80_{\text{H}} \times k)$,
 RSCFDnCFDCFPTRkHL: $\langle \text{RSCFDn_base} \rangle + 3406_{\text{H}} + (80_{\text{H}} \times k)$,
 RSCFDnCFDCFPTRkHH: $\langle \text{RSCFDn_base} \rangle + 3407_{\text{H}} + (80_{\text{H}} \times k)$

Value after reset: 0000 0000_H

Table 25.133 RSCFDnCFDCFPTRk Register Contents

| Bit | Bit Name | Function |
|----------|------------|---------------------------------------|
| 31 to 28 | CFDLC[3:0] | Transmit/Receive FIFO Buffer DLC Data |

| b31 b30 b29 b28 | Classical CAN Frame | CANFD Frame |

| 1 1 1 0 | | 48 data bytes |
| 1 1 1 1 | | 64 data bytes |

| Bit | Bit Name | Function |
|----------|-------------|--|
| 27 to 16 | CFPTR[11:0] | Transmit/Receive FIFO Buffer Label Data <ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): <ul style="list-style-type: none"> Set the label information to be stored in the transmit history buffer. Only bits CFPTR[7:0] are valid. When CFM[1:0] value is 00_B (receive mode): <ul style="list-style-type: none"> The label information of the received message can be read. |
| 15 to 0 | CFTS[15:0] | Transmit/Receive FIFO Buffer Timestamp Data <ul style="list-style-type: none"> These bits are valid only when the CFM[1:0] value is 00_B (receive mode). The timestamp value of the received message can be read. |

This register is writable only when the CFM[1:0] value in the RSCFDnCFDCFCCK register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFDLC[3:0] Bits

These bits indicate the data length of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B.

When the CFM[1:0] value is 01_B, these bits are used to set the data length of the message to be transmitted from the transmit/receive FIFO buffer.

When the CFDLC[3:0] bits are set to 1001_B or more while the CFFDF bit in the RSCFDnCFDCFFDCSTSk register is 0 (CAN frame), 8-byte data is transmitted actually. When the CFFDF bit is 1 (CANFD frame), the settable value range varies depending on the settings of the TMME bit in the RSCFDnCFDCmFDCFG register and the CFPLS[2:0] bits in the RSCFDnCFDCFCCK register.

- When TMME bit = 0 (transmit buffer merge mode disabled):
A value of 0000_B to 1111_B is settable. If the specified data length exceeds the payload storage size specified by the CFPLS[2:0] bits, excessive payloads are padded by CCH.
- When TMME bit = 1 (transmit buffer merge mode enabled):
Set the data length within the payload storage size specified by the CFPLS[2:0] bits.

CFPTR[11:0] Bits

These bits indicate the label information attached to the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, the CFPTR[7:0] value is stored in the transmit history buffer when message transmission has been completed.

CFTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the transmit/receive FIFO buffer.

These bits are valid when the CFM[1:0] value is 00_B.

25.4.8.6 RSCFDnCFDCFFDCSTSk — Transmit/Receive FIFO CANFD Configuration/Status Register (k = 0 to 5)

Access: RSCFDnCFDCFFDCSTSk register can be read/written in 32-bit units
 RSCFDnCFDCFFDCSTSkL, RSCFDnCFDCFFDCSTSkH registers can be read/written in 16-bit units
 RSCFDnCFDCFFDCSTSkLL, RSCFDnCFDCFFDCSTSkLH, RSCFDnCFDCFFDCSTSkHL, RSCFDnCFDCFFDCSTSkHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCFFDCSTSk: $\langle \text{RSCFDn_base} \rangle + 3408_{\text{H}} + (80_{\text{H}} \times k)$
 RSCFDnCFDCFFDCSTSkL: $\langle \text{RSCFDn_base} \rangle + 3408_{\text{H}} + (80_{\text{H}} \times k)$,
 RSCFDnCFDCFFDCSTSkH: $\langle \text{RSCFDn_base} \rangle + 340A_{\text{H}} + (80_{\text{H}} \times k)$,
 RSCFDnCFDCFFDCSTSkLL: $\langle \text{RSCFDn_base} \rangle + 3408_{\text{H}} + (80_{\text{H}} \times k)$,
 RSCFDnCFDCFFDCSTSkLH: $\langle \text{RSCFDn_base} \rangle + 3409_{\text{H}} + (80_{\text{H}} \times k)$,
 RSCFDnCFDCFFDCSTSkHL: $\langle \text{RSCFDn_base} \rangle + 340A_{\text{H}} + (80_{\text{H}} \times k)$,

Table 25.134 RSCFDnCFDCFFDCSTSk Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 3 | Reserved | These bits are read as the value after reset. |
| 2 | CFFDF | FDF 0: Classical CAN frame 1: CANFD frame |
| 1 | CFBRS | BRS 0: The bit rate in the data area does not change. 1: The bit rate in the data area changes. |
| 0 | CFESI | ESI 0: Error active node 1: Error passive node |

This register is writable only when the CFM[1:0] value in the RSCFDnCFDCFCCK register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). Do not read or write this register when the CFM[1:0] value is 10_B (gateway mode).

CFFDF Bit

When the CFM[1:0] value is 00_B, this bit indicates the FD format (classical CAN frame or CANFD frame) of the message stored in the transmit/receive FIFO buffer. When the CFM[1:0] value is 01_B, this bit is used to set the FD format of the message to be transmitted from the transmit/receive FIFO buffer.

CFBRS Bit

When the CFM[1:0] value is 00_B, if the CFFDF bit is 1, this bit indicates the BRS bit value of the message stored in the transmit/receive FIFO buffer. If the CFFDF bit is 0, this bit is always read as 0.

When the CFM[1:0] value is 01_B, if the CFFDF bit is 1, this bit is used to set the BRS bit value of the message to be transmitted from the transmit/receive FIFO buffer. If the CFFDF bit is 0, write 0 to this bit.

CFESI Bit

When the CFM[1:0] value is 00_B, if the CFFDF bit is 1, this bit indicates the ESI bit value of the message stored in the transmit/receive FIFO buffer. If the CFFDF bit is 0, this bit is always read as 0.

When the CFM[1:0] value is 01_B, if the CFFDF bit is 1, this bit is used to set the ESI bit value of the message to be transmitted from the transmit/receive FIFO buffer. The set value is transmitted when the ESIC bit in the RSCFDnCFDCmFDCFG register is 1 and the channel is in the error active state. When the channel is in the error passive state, the ESI bit value that shows an error passive node is transmitted regardless of this bit value. When the CFFDF bit is 0, write 0 to this bit.

25.4.8.7 RSCFDnCFDCFDf_d_k — Transmit/receive FIFO Buffer Access Data Field d Register (d = 0 to 15, k = 0 to 5)

Access: RSCFDnCFDCFDf_d_k register can be read/written in 32-bit units
 RSCFDnCFDCFDf_d_kL, RSCFDnCFDCFDf_d_kH registers can be read/written in 16-bit units
 RSCFDnCFDCFDf_d_kLL, RSCFDnCFDCFDf_d_kLH, RSCFDnCFDCFDf_d_kHL, RSCFDnCFDCFDf_d_kHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCFDf_d_k: $\langle \text{RSCFDn_base} \rangle + 340C_H + (04_H \times d) + (80_H \times k)$
 RSCFDnCFDCFDf_d_kL: $\langle \text{RSCFDn_base} \rangle + 340C_H + (04_H \times d) + (80_H \times k)$,
 RSCFDnCFDCFDf_d_kH: $\langle \text{RSCFDn_base} \rangle + 340E_H + (04_H \times d) + (80_H \times k)$
 RSCFDnCFDCFDf_d_kLL: $\langle \text{RSCFDn_base} \rangle + 340C_H + (04_H \times d) + (80_H \times k)$,
 RSCFDnCFDCFDf_d_kLH: $\langle \text{RSCFDn_base} \rangle + 340D_H + (04_H \times d) + (80_H \times k)$,
 RSCFDnCFDCFDf_d_kHL: $\langle \text{RSCFDn_base} \rangle + 340E_H + (04_H \times d) + (80_H \times k)$,
 RSCFDnCFDCFDf_d_kHH: $\langle \text{RSCFDn_base} \rangle + 340F_H + (04_H \times d) + (80_H \times k)$

Value after reset: 0000 0000_H

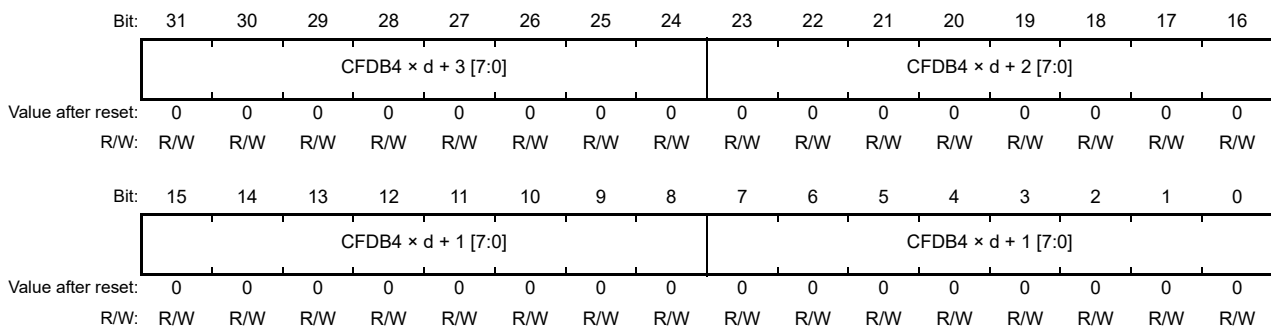

Table 25.135 RSCFDnCFDCFDf_d_k Register Contents

| Bit | Bit Name | Function |
|----------|---------------------|---|
| 31 to 24 | CFDB4 × d + 3 [7:0] | Transmit/Receive FIFO Buffer Data Byte 4 × d + 3 |
| | | Transmit/Receive FIFO Buffer Data Byte 4 × d + 2 |
| 23 to 16 | CFDB4 × d + 2 [7:0] | Transmit/Receive FIFO Buffer Data Byte 4 × d + 1 |
| | | Transmit/Receive FIFO Buffer Data Byte 4 × d + 0 |
| 15 to 8 | CFDB4 × d + 1 [7:0] | <ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set the transmit/receive FIFO buffer data. When CFM[1:0] value is 00_B (receive mode): The message data stored in the transmit/receive FIFO buffer can be read. |
| 7 to 0 | CFDB4 × d + 0 [7:0] | |

This register is writable only when the CFM[1:0] value in the RSCFDnCFDCFCCK register is 01_B (transmit mode).

This register is readable only when the CFM[1:0] value is 00_B (receive mode). When the CFDLC[3:0] value in the RSCFDnCFDCFPTRk register is smaller than the payload storage size of the transmit/receive FIFO buffer, data bytes for which no data is set are read as 00_H.

Specify the payload storage size of the transmit/receive FIFO buffer by the CFPLS[2:0] bits in the RSCFDnCFDCFCCK register. Do not read or write the RSCFDnCFDCFDf_d_k register corresponding to an area larger than the specified size. This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

25.4.9 Details of FIFO Status-related Registers

25.4.9.1 RSCFDnCFDFESTS — FIFO Empty Status Register

Access: RSCFDnCFDFESTS register can be read only in 32-bit units
 RSCFDnCFDFESTSL, RSCFDnCFDFESTSH registers can be read only in 16-bit units
 RSCFDnCFDFESTSL, RSCFDnCFDFESTSLH, RSCFDnCFDFESTSHL, RSCFDnCFDFESTSHH registers can be read only in 8-bit units

Table 25.136 RSCFDnCFDFESTS Register Contents

| Bit | Bit Name | Function |
|----------|----------|---|
| 31 to 14 | Reserved | These bits are read as the value after reset. |
| 13 | CF5EMP | Transmit/Receive FIFO Buffer Empty Status Flag |
| 12 | CF4EMP | 0: Transmit/receive FIFO buffer k contains a message. 1: Transmit/receive FIFO buffer k contains no message. |
| 11 | CF3EMP | (k = 0 to 5) |
| 10 | CF2EMP | |
| 9 | CF1EMP | |
| 8 | CF0EMP | |
| 7 | RF7EMP | Receive FIFO Buffer Empty Status Flag |
| 6 | RF6EMP | 0: Receive FIFO buffer x contains an unread message. 1: Receive FIFO buffer x contains no unread message (buffer empty). |
| 5 | RF5EMP | (x = 0 to 7) |
| 4 | RF4EMP | |
| 3 | RF3EMP | |
| 2 | RF2EMP | |
| 1 | RF1EMP | |
| 0 | RF0EMP | |

This RSCFDnCFDFESTS register is set to 03FF FFFF_H in global reset mode.

CFkEMP Flag (k = 0 to 5)

The CFkEMP flag is set to 1 when the CFEMP flag in the RSCFDnCFDCFSTSk register is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)). When the CFEMP flag is cleared to 0 (the transmit/receive FIFO buffer contains messages), the CFkEMP flag is cleared to 0.

RFxEMP Flag (x = 0 to 7)

The RFxEMP flag is set to 1 when the RFEMP flag in the RSCFDnCFDRFSTSx register is set to 1 (the receive FIFO buffer contains no unread message). When the RFEMP flag is cleared to 0 (the receive FIFO buffer contains unread messages), the RFxEMP flag is cleared to 0.

25.4.9.2 RSCFDnCFDFFSTS — FIFO Full Status Register

Access: RSCFDnCFDFFSTS register can be read only in 32-bit units
 RSCFDnCFDFFSTSL, RSCFDnCFDFFSTSH registers can be read only in 16-bit units
 RSCFDnCFDFFSTSL, RSCFDnCFDFFSTSLH, RSCFDnCFDFFSTSHL, RSCFDnCFDFFSTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDFFSTS: <RSCFDn_base> + 023C_H
 RSCFDnCFDFFSTSL: <RSCFDn_base> + 023C_H, RSCFDnCFDFFSTSH: <RSCFDn_base> + 023E_H
 RSCFDnCFDFFSTSL: <RSCFDn_base> + 023C_H, RSCFDnCFDFFSTSLH: <RSCFDn_base> + 023D_H,
 RSCFDnCFDFFSTSHL: <RSCFDn_base> + 023E_H, RSCFDnCFDFFSTSHH: <RSCFDn_base> + 023F_H

Value after reset: 0000 0000_H

Table 25.137 RSCFDnCFDFFSTS Register Contents

| Bit | Bit Name | Function |
|----------|----------|---|
| 31 to 14 | Reserved | These bits are read as the value after reset. |
| 13 | CF5FLL | Transmit/Receive FIFO Buffer Full Status Flag 0: Transmit/receive buffer k is not full. 1: Transmit/receive buffer k is full. (k = 0 to 5) |
| 12 | CF4FLL | |
| 11 | CF3FLL | |
| 10 | CF2FLL | |
| 9 | CF1FLL | |
| 8 | CF0FLL | |
| 7 | RF7FLL | Receive FIFO Buffer Full Status Flag 0: Receive FIFO buffer x is not full. 1: Receive FIFO buffer x is full. (x = 0 to 7) |
| 6 | RF6FLL | |
| 5 | RF5FLL | |
| 4 | RF4FLL | |
| 3 | RF3FLL | |
| 2 | RF2FLL | |
| 1 | RF1FLL | |
| 0 | RF0FLL | |

The RSCFDnCFDFFSTS register is cleared to 0000 0000_H in global reset mode.

CFkFLL Flag (k = 0 to 5)

The CFkFLL flag is set to 1 when the CFFLL flag in the RSCFDnCFDCFSTSk register is set to 1 (the transmit/receive FIFO buffer is full).

When the CFFLL flag is cleared to 0 (the transmit/receive FIFO buffer is not full), the CFkFLL flag is cleared to 0.

RFxFLL Flag (x = 0 to 7)

The RFxFLL flag is set to 1 when the RFFLL flag in the RSCFDnCFDRFSTSk register is set to 1 (the receive FIFO buffer is full). When the RFFLL flag is cleared to 0 (the receive FIFO buffer is not full), the RFxFLL flag is cleared to 0.

25.4.9.3 RSCFDnCFDFMSTS — FIFO Message Lost Status Register

Access: RSCFDnCFDFMSTS register can be read only in 32-bit units
 RSCFDnCFDFMSTSL, RSCFDnCFDFMSTSH registers can be read only in 16-bit units
 RSCFDnCFDFMSTSL, RSCFDnCFDFMSTSLH, RSCFDnCFDFMSTSHL, RSCFDnCFDFMSTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDFMSTS: <RSCFDn_base> + 0240_H
 RSCFDnCFDFMSTSL: <RSCFDn_base> + 0240_H, RSCFDnCFDFMSTSH: <RSCFDn_base> + 0242_H
 RSCFDnCFDFMSTSL: <RSCFDn_base> + 0240_H, RSCFDnCFDFMSTSLH: <RSCFDn_base> + 0241_H,
 RSCFDnCFDFMSTSHL: <RSCFDn_base> + 0242_H, RSCFDnCFDFMSTSHH: <RSCFDn_base> + 0243_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | CF5 MLT | CF4 MLT | CF3 MLT | CF2 MLT | CF1 MLT | CF0 MLT | RF7 MLT | RF6 MLT | RF5 MLT | RF4 MLT | RF3 MLT | RF2 MLT | RF1 MLT | RF0 MLT |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.138 RSCFDnCFDFMSTS Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 14 | Reserved | These bits are read as the value after reset. |
| 13 | CF5MLT | Transmit/Receive FIFO Buffer Message Lost Status Flag 0: No transmit/receive FIFO buffer k message is lost. 1: A transmit/receive FIFO buffer k message is lost. (k = 0 to 5) |
| 12 | CF4MLT | |
| 11 | CF3MLT | |
| 10 | CF2MLT | |
| 9 | CF1MLT | |
| 8 | CF0MLT | Receive FIFO Buffer Message Lost Status Flag 0: No receive FIFO buffer x message is lost. 1: A receive FIFO buffer x message is lost. (x = 0 to 7) |
| 7 | RF7MLT | |
| 6 | RF6MLT | |
| 5 | RF5MLT | |
| 4 | RF4MLT | |
| 3 | RF3MLT | |
| 2 | RF2MLT | |
| 1 | RF1MLT | |
| 0 | RF0MLT | |

The RSCFDnCFDFMSTS register is cleared to 0000 0000_H in global reset mode.

CFkMLT Flag (k = 0 to 5)

The CFkMLT flag is set to 1 when the CFMLT flag in the RSCFDnCFDFMSTSL register is set to 1 (a transmit/receive FIFO message is lost). When the CFMLT flag is cleared to 0, the CFkMLT flag is cleared to 0.

RFxMLT Flag (x = 0 to 7)

The RFxMLT flag is set to 1 when the RFMLT flag in the RSCFDnCFDFMSTSH register is set to 1 (a receive FIFO message is lost). When the RFMLT flag is cleared to 0, the RFxMLT flag is cleared to 0.

25.4.9.4 RSCFDnCFDRFISTS — Receive FIFO Buffer Interrupt Flag Status Register

Access: RSCFDnCFDRFISTS register can be read only in 32-bit units
 RSCFDnCFDRFISTSL, RSCFDnCFDRFISTSH registers can be read only in 16-bit units
 RSCFDnCFDRFISTSL, RSCFDnCFDRFISTSLH, RSCFDnCFDRFISTSHL, RSCFDnCFDRFISTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDRFISTS: <RSCFDn_base> + 0244_H
 RSCFDnCFDRFISTSL: <RSCFDn_base> + 0244_H, RSCFDnCFDRFISTSH: <RSCFDn_base> + 0246_H
 RSCFDnCFDRFISTSL: <RSCFDn_base> + 0244_H, RSCFDnCFDRFISTSLH: <RSCFDn_base> + 0245_H,
 RSCFDnCFDRFISTSHL: <RSCFDn_base> + 0246_H, RSCFDnCFDRFISTSHH: <RSCFDn_base> + 0247_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|---|---|-------|-------|-------|-------|-------|-------|-------|-------|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | — | — | — | RF7IF | RF6IF | RF5IF | RF4IF | RF3IF | RF2IF | RF1IF | RF0IF |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.139 RSCFDnCFDRFISTS Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 8 | Reserved | These bits are read as the value after reset. |
| 7 | RF7IF | Receive FIFO Buffer Interrupt Request Status Flag |
| 6 | RF6IF | 0: No receive FIFO buffer x interrupt request is present. |
| 5 | RF5IF | 1: A receive FIFO buffer x interrupt request is present. |
| 4 | RF4IF | (x = 0 to 7) |
| 3 | RF3IF | |
| 2 | RF2IF | |
| 1 | RF1IF | |
| 0 | RF0IF | |

The RSCFDnCFDRFISTS register is cleared to 0000 0000_H in global reset mode.

RFxIF Flag (x = 0 to 7)

The RFxIF flag is set to 1 when the RFIF flag in the RSCFDnCFDRFISTSx register is set to 1 (a receive FIFO interrupt request is present). When the RFIF flag is cleared to 0, the RFxIF flag is cleared to 0.

25.4.9.5 RSCFDnCFDCFRISTS — Transmit/receive FIFO Buffer Receive Interrupt Flag Status Register

Access: RSCFDnCFDCFRISTS register can be read only in 32-bit units
 RSCFDnCFDCFRISTS_{SL}, RSCFDnCFDCFRISTS_{SH} registers can be read only in 16-bit units
 RSCFDnCFDCFRISTS_{SL}_L, RSCFDnCFDCFRISTS_{SL}_H, RSCFDnCFDCFRISTS_{SH}_L, RSCFDnCFDCFRISTS_{SH}_H registers can be read only in 8-bit units

Address: RSCFDnCFDCFRISTS: <RSCFDn_base> + 0248_H
 RSCFDnCFDCFRISTS_{SL}: <RSCFDn_base> + 0248_H, RSCFDnCFDCFRISTS_{SH}: <RSCFDn_base> + 024A_H
 RSCFDnCFDCFRISTS_{SL}_L: <RSCFDn_base> + 0248_H, RSCFDnCFDCFRISTS_{SL}_H: <RSCFDn_base> + 0249_H,
 RSCFDnCFDCFRISTS_{SH}_L: <RSCFDn_base> + 024A_H, RSCFDnCFDCFRISTS_{SH}_H: <RSCFDn_base> + 024B_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |

Table 25.140 RSCFDnCFDCFRISTS Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 6 | Reserved | These bits are read as the value after reset. |
| 5 | CF5RXIF | Transmit/Receive FIFO Buffer Receive Interrupt Request Status Flag |
| 4 | CF4RXIF | 0: No transmit/receive FIFO buffer k receive interrupt request is present. 1: A transmit/receive FIFO buffer k receive interrupt request is present. |
| 3 | CF3RXIF | (k = 0 to 5) |
| 2 | CF2RXIF | |
| 1 | CF1RXIF | |
| 0 | CF0RXIF | |

The RSCFDnCFDCFRISTS register is cleared to 0000 0000_H in global reset mode.

CFkRXIF Flag (k = 0 to 5)

The CFkRXIF flag is set to 1 when the CFRXIF flag in the RSCFDnCFDCFRISTS_k register is set to 1 (a transmit/receive FIFO receive interrupt request is present). When the CFRXIF flag is cleared to 0, the CFkRXIF flag is cleared to 0.

25.4.9.6 RSCFDnCFDCFTISTS — Transmit/receive FIFO Buffer Transmit Interrupt Flag Status Register

Access: RSCFDnCFDCFTISTS register can be read only in 32-bit units
 RSCFDnCFDCFTISTSL, RSCFDnCFDCFTISTSH registers can be read only in 16-bit units
 RSCFDnCFDCFTISTSSL, RSCFDnCFDCFTISTSLH, RSCFDnCFDCFTISTSHL, RSCFDnCFDCFTISTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDCFTISTS: <RSCFDn_base> + 024C_H
 RSCFDnCFDCFTISTSL: <RSCFDn_base> + 024C_H, RSCFDnCFDCFTISTSH: <RSCFDn_base> + 024E_H
 RSCFDnCFDCFTISTSSL: <RSCFDn_base> + 024C_H, RSCFDnCFDCFTISTSLH: <RSCFDn_base> + 024D_H,
 RSCFDnCFDCFTISTSHL: <RSCFDn_base> + 024E_H, RSCFDnCFDCFTISTSHH: <RSCFDn_base> + 024F_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

Table 25.141 RSCFDnCFDCFTISTS Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 6 | Reserved | These bits are read as the value after reset. |
| 5 | CF5TXIF | Transmit/Receive FIFO Buffer Transmit Interrupt Request Status Flag |
| 4 | CF4TXIF | 0: No transmit/receive FIFO buffer k transmit interrupt request is present. |
| 3 | CF3TXIF | 1: A transmit/receive FIFO buffer k transmit interrupt request is present. |
| 2 | CF2TXIF | (k = 0 to 5) |
| 1 | CF1TXIF | |
| 0 | CF0TXIF | |

The RSCFDnCFDCFTISTS register is cleared to 0000 0000_H in global reset mode.

CFkTXIF Flag (k = 0 to 5)

The CFkTXIF flag is set to 1 when the CFTXIF flag in the RSCFDnCFDCFSTSk register is set to 1 (a transmit/receive FIFO transmit interrupt request is present). When the CFTXIF flag is cleared to 0, the CFkTXIF flag is cleared to 0.

25.4.10 Details of FIFO DMA-related Registers

25.4.10.1 RSCFDnCFDCDTCT — DMA Enable Register

Access: RSCFDnCFDCDTCT register can be read/written in 32-bit units
 RSCFDnCFDCDTCTL, RSCFDnCFDCDTCTH registers can be read/written in 16-bit units
 RSCFDnCFDCDTCTL, RSCFDnCFDCDTCTLH, RSCFDnCFDCDTCTHL, RSCFDnCFDCDTCTHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCDTCT: <RSCFDn_base> + 0490_H
 RSCFDnCFDCDTCTL: <RSCFDn_base> + 0490_H
 RSCFDnCFDCDTCTH: <RSCFDn_base> + 0492_H
 RSCFDnCFDCDTCTL: <RSCFDn_base> + 0490_H
 RSCFDnCFDCDTCTLH: <RSCFDn_base> + 0491_H
 RSCFDnCFDCDTCTHL: <RSCFDn_base> + 0492_H
 RSCFDnCFDCDTCTHH: <RSCFDn_base> + 0493_H

Value after reset: 0000 0000_H

Table 25.142 RSCFDnCFDCDTCT Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 10 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 9 | CFDMAE1 | Transmit/Receive FIFO Buffer 3 DMA Enable 0: A DMA transfer request of transmit/receive FIFO buffer 3 is disabled. 1: A DMA transfer request of transmit/receive FIFO buffer 3 is enabled. |
| 8 | CFDMAE0 | Transmit/Receive FIFO Buffer 0 DMA Enable 0: A DMA transfer request of transmit/receive FIFO buffer 0 is disabled. 1: A DMA transfer request of transmit/receive FIFO buffer 0 is enabled. |
| 7 | RFDMAE7 | Receive FIFO Buffer x DMA Enable |
| 6 | RFDMAE6 | 0: A DMA transfer request of receive FIFO buffer x is disabled. 1: A DMA transfer request of receive FIFO buffer x is enabled. |
| 5 | RFDMAE5 | (x = 0 to 7) |
| 4 | RFDMAE4 | |
| 3 | RFDMAE3 | |
| 2 | RFDMAE2 | |
| 1 | RFDMAE1 | |
| 0 | RFDMAE0 | |

Modify the RSCFDnCFDCDTCT register in global operating mode or global test mode.

CFDMAEm Bit

This bit is used to enable DMA transfer for transmit/receive FIFO buffer $3 \times m$ (the first transmit/receive FIFO buffer allocated to channel m). DMA transfer is enabled only for transmit/receive FIFO buffers for which the CFM[1:0] bits in the RSCFDnCFDCFCCK register is set to 00_B (receive mode). Set this bit to 0 when the CFM[1:0] value is 01_B (transmit mode) or 10_B (gateway mode).

RFDMAEx Bit

This bit is used to enable DMA transfer for receive FIFO buffer x .

25.4.10.2 RSCFDnCFDCDTSTS — DMA Status Register

Access: RSCFDnCFDCDTSTS register can be read only in 32-bit units
 RSCFDnCFDCDTSTSL, RSCFDnCFDCDTSTSH registers can be read only in 16-bit units
 RSCFDnCFDCDTSTSL, RSCFDnCFDCDTSTSLH, RSCFDnCFDCDTSTSHL, RSCFDnCFDCDTSTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDCDTSTS: <RSCFDn_base> + 0494_H
 RSCFDnCFDCDTSTSL: <RSCFDn_base> + 0494_H
 RSCFDnCFDCDTSTSH: <RSCFDn_base> + 0496_H
 RSCFDnCFDCDTSTSL: <RSCFDn_base> + 0494_H,
 RSCFDnCFDCDTSTSLH: <RSCFDn_base> + 0495_H,
 RSCFDnCFDCDTSTSHL: <RSCFDn_base> + 0496_H,
 RSCFDnCFDCDTSTSHH: <RSCFDn_base> + 0497_H

Value after reset: 0000 0000_H

Table 25.143 RSCFDnCFDCDTSTS Register Contents

| Bit | Bit Name | Function |
|----------|-----------|---|
| 31 to 10 | Reserved | These bits are read as the value after reset. |
| 9 | CFDMASTS1 | Transmit/Receive FIFO Buffer 3 DMA Status 0: DMA transfer of transmit/receive FIFO buffer 3 is not in progress. 1: DMA transfer of transmit/receive FIFO buffer 3 is in progress. |
| 8 | CFDMASTS0 | Transmit/Receive FIFO Buffer 0 DMA Status 0: DMA transfer of transmit/receive FIFO buffer 0 is not in progress. 1: DMA transfer of transmit/receive FIFO buffer 0 is in progress. |
| 7 | RFDMASTS7 | Receive FIFO Buffer x DMA Status 0: DMA transfer of receive FIFO buffer x is not in progress. 1: DMA transfer of receive FIFO buffer x is in progress. (x = 0 to 7) |
| 6 | RFDMASTS6 | |
| 5 | RFDMASTS5 | |
| 4 | RFDMASTS4 | |
| 3 | RFDMASTS3 | |
| 2 | RFDMASTS2 | |
| 1 | RFDMASTS1 | |
| 0 | RFDMASTS0 | |

CFDMASTS_m Bit

When DMA transfer is enabled (CFDMAEm bit in the RSCFDnCFDCDTCT register is 1) for the transmit/receive FIFO buffer 3 × m (the first transmit/receive FIFO buffer allocated to channel m) while the transmit/receive FIFO buffer contains one of more messages, the CFDMASTS_m bit is set to 1 indicating that DMA transfer is in progress.

When all messages in the transmit/receive FIFO buffer have been transferred or DMA transfer is disabled (CFDMAEm bit is 0), the CFDMASTS_m bit is cleared to 0 indicating that DMA transfer has been completed. If the CFDMAEm bit is set to 0 during DMA transfer, the CFDMASTS_m bit is cleared to 0 after the ongoing DMA transfer has been completed (when the message that is being transferred has been transferred to the last byte in the payload storage area).

These bits are cleared to 0 in global reset mode.

RFDMASTSx Bit

When DMA transfer is enabled (corresponding RFDMAEx bit in the RSCFDnCFDCDTCT register is 1) for the receive FIFO buffer x and the receive FIFO buffer contains one or more messages, the RFDMAEx bit is set to 1 indicating that DMA transfer is in progress.

When all messages in the receive FIFO buffer x have been transferred or DMA transfer is disabled (RFDMAEx bit = 0), the RFDMASTSx bit is cleared to 0 indicating that DMA transfer has been completed. If the RFDMAEx bit is set to 0 during DMA transfer, the RFDMASTSx bit is cleared to 0 after the ongoing DMA transfer has been completed (when the message that is being transferred has been transferred to the last byte in the payload storage area)

These bits are cleared to 0 in global reset mode.

25.4.11 Details of Transmit Buffer-related Registers

25.4.11.1 RSCFDnCFDTMCp — Transmit Buffer Control Register (p = 0 to 31)

Access: RSCFDnCFDTMCp registers can be read/written in 8-bit units

Address: RSCFDnCFDTMCp: <RSCFDn_base> + 0250_H + (01_H × p)

Value after reset: 00H

| | | | | | | | | |
|--------------------|---|---|---|---|---|------|------------------|------------------|
| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | TMOM | TMTAR | TMTR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R/W | R/W ¹ | R/W ¹ |

Note 1. The only effective value for writing to this bit is 1, which sets the bit. Otherwise writing to the bit results in retention of its state.

Table 25.144 RSCFDnCFDTMCp Register Contents

| Bit | Bit Name | Function |
|--------|----------|---|
| 7 to 3 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 2 | TMOM | One-Shot Transmission Enable 0: One-shot transmission is disabled. 1: One-shot transmission is enabled. |
| 1 | TMTAR | Transmit Abort Request 0: Transmit abort is not requested. 1: Transmit abort is requested. |
| 0 | TMTR | Transmit Request 0: Transmission is not requested. 1: Transmission is requested. |

When the RSCFDnCFDTMCp register meets any of the following conditions, set it to 00_H.

- The RSCFDnCFDTMCp register corresponds to the transmit buffer number selected by the CFTML[3:0] bits in the RSCFDnCFDCFCCK register ($p = m \times 16 + \text{the value of CFTML}[3:0] \text{ bits}$).
- The RSCFDnCFDTMCp register corresponds to the transmit buffer allocated to the transmit queue by the TXQDC[3:0] bits in the RSCFDnCFDCTXQCCm ($m = 0, 1$) register ($p = (m \times 16 + 15) \text{ to } (m \times 16 + 15 + \text{the value of TXQDC}[3:0] \text{ bits})$).
- RSCFDnCFDTMCp register ($p = (m \times 16) + 1, (m \times 16) + 2, (m \times 16) + 4, \text{ or } (m \times 16) + 5$) corresponding to the transmit buffer allocated as a payload storage area when the TMME bit in the RSCFDnCFDCmFDCFG register is 1 (transmit buffer merge mode)

Bits in the RSCFDnCFDTMCp register are all cleared to 0 in channel reset mode. Modify the RSCFDnCFDTMCp register in channel communication mode or channel halt mode.

TMOM Bit

Setting this bit to 1 enables one-shot transmission. When transmission fails, retransmission defined in the CAN protocol is not performed.

Modify the TMOM bit when the TMTRM flag in the RSCFDnCFDTMSTSp register is set to 0. Set the TMOM bit to 1 together with the TMTR bit.

TMTAR Bit

Setting this bit to 1 generates a transmit abort request for the message stored in the transmit buffer. However, a message that is being transmitted or one that will be transmitted next cannot be aborted.

The TMTAR bit can be set to 1 when TMTR bit is 1.

The TMTAR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit.

- Transmission has been completed.
- Transmit abort has been completed.
- An error or arbitration loss has been detected.

If this bit becomes 0 at the same time as the program writes 1 to this bit, this bit becomes 0.

TMTR Bit

Setting this bit to 1 transmits the message stored in the transmit buffer.

The TMTR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit.

- Transmission has been completed.
- Transmit abort has been completed after the TMTAR bit was set to 1.
- An error or arbitration-lost has been detected with the TMOM bit set to 1.

Set the TMTR bit to 1 when the value of TMTRF[1:0] in the RSCFDnCFDTMSTSp register is 00_B.

25.4.11.2 RSCFDnCFDTMSTSp — Transmit Buffer Status Register (p = 0 to 31)

Access: RSCFDnCFDTMSTSp registers can be read/written in 8-bit units

Address: RSCFDnCFDTMSTSp: <RSCFDn_base> + 02D0_H + (01_H × p)

Value after reset: 00_H

| Bit: | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------------------|---|---|---|------------|-----------|------------|-----|------------|
| | — | — | — | TMTAR M | TMTR M | TMTRF[1:0] | | TMTST S |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R/W | R/W | R |

Table 25.145 RSCFDnCFDTMSTSp Register Contents

| Bit | Bit Name | Function |
|--------|------------|---|
| 7 to 5 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 4 | TMTARM | Transmit Buffer Transmit Abort Request Status Flag 0: No transmit abort request is present. 1: A transmit abort request is present. |
| 3 | TMTRM | Transmit Buffer Transmit Request Status Flag 0: No transmit request is present. 1: A transmit request is present. |
| 2, 1 | TMTRF[1:0] | Transmit Buffer Transmit Result Status Flag b2 b1 0 0: Transmission is in progress or no transmit request is present. 0 1: Transmit abort has been completed. 1 0: Transmission has been completed (without transmit abort request). 1 1: Transmission has been completed (with transmit abort request). |
| 0 | TMTSTS | Transmit Buffer Transmit Status Flag 0: Transmission is not in progress. 1: Transmission is in progress. |

The RSCFDnCFDTMSTSp register is cleared to all 0 in channel reset mode.

TMTARM Flag

The TMTARM flag is set to 1 when the TMTAR bit in the RSCFDnCFDTMCp register is set to 1.

The TMTARM flag is set to 0 when the TMTAR bit in the RSCFDnCFDTMCp register is set to 0.

TMTRM Flag

The TMTRM flag is set to 1 when the TMTR bit in the RSCFDnCFDTMCp register is set to 1.

The TMTRM flag is set to 0 when the TMTR bit in the RSCFDnCFDTMCp register is set to 0.

TMTRF[1:0] Flag

This flag indicates the result of transmission from the transmit buffer.

00_B: Transmission is in progress or no transmit request is present.

01_B: Transmission from the transmit buffer was aborted.

10_B: Transmission has been completed with the TMTAR bit in the RSCFDnCFDTMCp register set to 0 (transmit abort is not requested).

11_B: Transmission has been completed with the TMTAR bit in the RSCFDnCFDTMCp register set to 1 (transmit abort is requested).

Write 00_B to the TMTRF[1:0] flag in channel communication mode or channel halt mode. Do not write any value other than 00_B to this flag.

TMTSTS Flag

This flag is set to 1 when transmission from the transmit buffer starts, and is cleared to 0 when transmission from the transmit buffer has been completed or terminated due to a bus error or arbitration lost.

25.4.11.3 RSCFDnCFDTMIDp — Transmit Buffer ID Register (p = 0 to 31)

Access: RSCFDnCFDTMIDp register can be read/written in 32-bit units
 RSCFDnCFDTMIDpL, RSCFDnCFDTMIDpH registers can be read/written in 16-bit units
 RSCFDnCFDTMIDpLL, RSCFDnCFDTMIDpLH, RSCFDnCFDTMIDpHL, RSCFDnCFDTMIDpHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTMIDp: <RSCFDn_base> + 4000_H + (20_H × p)
 RSCFDnCFDTMIDpL: <RSCFDn_base> + 4000_H + (20_H × p),
 RSCFDnCFDTMIDpH: <RSCFDn_base> + 4002_H + (20_H × p)
 RSCFDnCFDTMIDpLL: <RSCFDn_base> + 4000_H + (20_H × p),
 RSCFDnCFDTMIDpLH: <RSCFDn_base> + 4001_H + (20_H × p),
 RSCFDnCFDTMIDpHL: <RSCFDn_base> + 4002_H + (20_H × p),
 RSCFDnCFDTMIDpHH: <RSCFDn_base> + 4003_H + (20_H × p)

Value after reset: 0000 0000_H

Table 25.146 RSCFDnCFDTMIDp Register Contents

| Bit | Bit Name | Function |
|---------|------------|--|
| 31 | TMIDE | Transmit Buffer IDE 0: Standard ID 1: Extended ID |
| 30 | TMRTR | Transmit Buffer RTR/RRS <ul style="list-style-type: none"> When the transmit message is a classical CAN frame 0: Data frame 1: Remote frame When the transmit message is a CANFD frame Write 0 to this bit. |
| 29 | THLEN | Transmit History Data Store Enable 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer. |
| 28 to 0 | TMID[28:0] | Transmit Buffer ID Data Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11. |

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write data to this register. If this register is allocated to the transmit queue, only write data to a transmit buffer p ($p = m \times 16 + 15$) for the corresponding channel.

TMIDE Bit

This bit is used to set the ID format of the message to be transmitted from the transmit buffer.

TMRTR Bit

This bit is used to set the data format of the message to be transmitted from the transmit buffer.

Set this bit to 0 when the TMFDF bit in the RSCFDnCFDTMFDCTRp register is 1 (CANFD frame).

THLEN Bit

When this bit is set to 1, the transmit history data (label information, buffer number, buffer type, and timestamp) of transmit messages is stored in the transmit history buffer after transmission is completed.

TMID[28:0] Bits

These bits are used to set the ID of the message to be transmitted from the transmit buffer.

25.4.11.4 RSCFDnCFDTMPTRp — Transmit Buffer Pointer Register (p = 0 to 31)

Access: RSCFDnCFDTMPTRp register can be read/written in 32-bit units
 RSCFDnCFDTMPTRpL, RSCFDnCFDTMPTRpH registers can be read/written in 16-bit units
 RSCFDnCFDTMPTRpLL, RSCFDnCFDTMPTRpLH, RSCFDnCFDTMPTRpHL, RSCFDnCFDTMPTRpHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTMPTRp: $\langle \text{RSCFDn_base} \rangle + 4004_{\text{H}} + (20_{\text{H}} \times p)$
 RSCFDnCFDTMPTRpL: $\langle \text{RSCFDn_base} \rangle + 4004_{\text{H}} + (20_{\text{H}} \times p)$,
 RSCFDnCFDTMPTRpH: $\langle \text{RSCFDn_base} \rangle + 4006_{\text{H}} + (20_{\text{H}} \times p)$
 RSCFDnCFDTMPTRpLL: $\langle \text{RSCFDn_base} \rangle + 4004_{\text{H}} + (20_{\text{H}} \times p)$,
 RSCFDnCFDTMPTRpLH: $\langle \text{RSCFDn_base} \rangle + 4005_{\text{H}} + (20_{\text{H}} \times p)$,
 RSCFDnCFDTMPTRpHL: $\langle \text{RSCFDn_base} \rangle + 4006_{\text{H}} + (20_{\text{H}} \times p)$,
 RSCFDnCFDTMPTRpHH: $\langle \text{RSCFDn_base} \rangle + 4007_{\text{H}} + (20_{\text{H}} \times p)$

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |

Table 25.147 RSCFDnCFDTMPTRp Register Contents

| Bit | Bit Name | Function |
|----------|-----------------|--|
| 31 to 28 | TMDLC[3:0] | Transmit Buffer DLC Data |
| | b31 b30 b29 b28 | Classical CAN Frame CANFD Frame |
| | 0 0 0 0 | 0 data bytes |
| | 0 0 0 1 | 1 data byte |
| | 0 0 1 0 | 2 data bytes |
| | 0 0 1 1 | 3 data bytes |
| | 0 1 0 0 | 4 data bytes |
| | 0 1 0 1 | 5 data bytes |
| | 0 1 1 0 | 6 data bytes |
| | 0 1 1 1 | 7 data bytes |
| | 1 0 0 0 | 8 data bytes |
| | 1 0 0 1 | 8 data bytes 12 data bytes |
| | 1 0 1 0 | 16 data bytes |
| | 1 0 1 1 | 20 data bytes |
| | 1 1 0 0 | 24 data bytes |
| | 1 1 0 1 | 32 data bytes |
| | 1 1 1 0 | 48 data bytes |
| | 1 1 1 1 | 64 data bytes |
| 27 to 24 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 23 to 16 | TMPTR[7:0] | Transmit Buffer Label Data Set the label information to be stored in the transmit history buffer. |
| 15 to 0 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p ($p = m \times 16 + 15$) for the corresponding channel.

TMDLC[3:0] Bits

These bits are used to set the data length of the message to be transmitted from the transmit buffer when the TMRTR bit in the RSCFDnCFDTMIDp register is set to 0 (data frame).

When the TMDLC[3:0] bits are set to 1001_B or more while the TMFDF bit in the RSCFDnCFDTMFDCTRp register is 0 (classical CAN frame), 8-byte data is transmitted actually. When the MFDF bit is 1 (CANFD frame), the settable value range varies depending on the setting of the TMME bit in the RSCFDnCFDCmFDCFG register.

- When the TMME bit = 0 (transmit buffer merge mode disabled):
A value of 0000_B to 1111_B is settable. If a value larger than 1100_B is set, payloads exceeding 20 bytes are padded by CCH.
- When the TMME bit = 1 (transmit buffer merge mode enabled):
When the corresponding transmit buffer number $p = (m \times 16) + 0$ or $(m \times 16) + 3$, a value of 0000_B to 1111_B is settable. In other cases, set a value of 0000_B to 1011_B (20 data bytes).

When the TMRTR bit is 1 (remote frame), set the data length of a message to be requested.

TMPTR[7:0] Bits

When message transmission has been completed, the TMPTR[7:0] value is stored in the transmit history buffer.

25.4.11.5 RSCFDnCFDTMFDCTR_p — Transmit Buffer CANFD Configuration Register (p = 0 to 31)

Access: RSCFDnCFDTMFDCTR_p register can be read/written in 32-bit units
 RSCFDnCFDTMFDCTR_{pL}, RSCFDnCFDTMFDCTR_{pH} registers can be read/written in 16-bit units
 RSCFDnCFDTMFDCTR_{pLL}, RSCFDnCFDTMFDCTR_{pLH}, RSCFDnCFDTMFDCTR_{pHL}, RSCFDnCFDTMFDCTR_{pHH} registers can be read/written in 8-bit units

Address: RSCFDnCFDTMFDCTR_p: <RSCFDn_base> + 4008_H + (20_H × p)
 RSCFDnCFDTMFDCTR_{pL}: <RSCFDn_base> + 4008_H + (20_H × p),
 RSCFDnCFDTMFDCTR_{pH}: <RSCFDn_base> + 400A_H + (20_H × p)
 RSCFDnCFDTMFDCTR_{pLL}: <RSCFDn_base> + 4008_H + (20_H × p),

Table 25.148 RSCFDnCFDTMFDCTR_p Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 3 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 2 | TMFDF | FDF 0: Classical CAN frame 1: CANFD frame |
| 1 | TMBRS | BRS 0: The bit rate in the data area does not change. 1: The bit rate in the data area changes. |
| 0 | TMESI | ESI 0: Error active node 1: Error passive node |

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is 0 (transmission not requested). When this register is linked to the transmit/receive FIFO buffer, do not write data to this register. When this register is allocated to the transmit queue, write data only to transmit buffer p (p = m × 16 + 15) of the corresponding channel.

TMFDF Bit

This bit is used to set the FD format of the message to be transmitted from the transmit buffer.

TMBRS Bit

When this bit is set to 1 while the TMFDF bit is 1, the data area of a transmit message is transmitted at the data bit rate. When the TMFDF bit is 0, write 0 to this bit.

TMESI Bit

This bit is used to set the ESI bit value of the message to be transmitted from the transmit buffer when the TMFDF bit is 1. The set value is transmitted when the ESIC bit in the RSCFDnCFDCmFDCFG register is 1 and the channel is in the error active state. When the channel is in the error passive state, the ESI bit value that shows an error passive node is transmitted regardless of this bit value. When the TMFDF bit is 0, write 0 to this bit.

25.4.11.6 RSCFDnCFDTMDFb_p — Transmit Buffer Data Field b Register (b = 0 to 4, p = 0 to 31)

Access: RSCFDnCFDTMDFb_p register can be read/written in 32-bit units
 RSCFDnCFDTMDFb_pL, RSCFDnCFDTMDFb_pH registers can be read/written in 16-bit units
 RSCFDnCFDTMDFb_pLL, RSCFDnCFDTMDFb_pLH, RSCFDnCFDTMDFb_pHL, RSCFDnCFDTMDFb_pHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTMDFb_p: $\langle \text{RSCFDn_base} \rangle + 400C_H + (04_H \times b) + (20_H \times p)$
 RSCFDnCFDTMDFb_pL: $\langle \text{RSCFDn_base} \rangle + 400C_H + (04_H \times b) + (20_H \times p)$,
 RSCFDnCFDTMDFb_pH: $\langle \text{RSCFDn_base} \rangle + 400E_H + (04_H \times b) + (20_H \times p)$
 RSCFDnCFDTMDFb_pLL: $\langle \text{RSCFDn_base} \rangle + 400C_H + (04_H \times b) + (20_H \times p)$,
 RSCFDnCFDTMDFb_pLH: $\langle \text{RSCFDn_base} \rangle + 400D_H + (04_H \times b) + (20_H \times p)$,
 RSCFDnCFDTMDFb_pHL: $\langle \text{RSCFDn_base} \rangle + 400E_H + (04_H \times b) + (20_H \times p)$,
 RSCFDnCFDTMDFb_pHH: $\langle \text{RSCFDn_base} \rangle + 400F_H + (04_H \times b) + (20_H \times p)$

Table 25.149 RSCFDnCFDTMDFb_p Register Contents

| Bit | Bit Name | Function |
|-------------------------------|---------------------|-------------------------------------|
| 31 to 24 | TMDB4 × b + 3 [7:0] | Transmit Buffer Data Byte 4 × b + 3 |
| 23 to 16 | TMDB4 × b + 2 [7:0] | Transmit Buffer Data Byte 4 × b + 2 |
| 15 to 8 | TMDB4 × b + 1 [7:0] | Transmit Buffer Data Byte 4 × b + 1 |
| 7 to 0 | TMDB4 × b + 0 [7:0] | Transmit Buffer Data Byte 4 × b + 0 |
| Set the transmit buffer data. | | |

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p ($p = m \times 16 + 15$) for the corresponding channel.

25.4.11.7 RSCFDnCFDTMIECy — Transmit Buffer Interrupt Enable Configuration Register (y = 0)

Access: RSCFDnCFDTMIECy register can be read/written in 32-bit units
 RSCFDnCFDTMIECyL, RSCFDnCFDTMIECyH registers can be read/written in 16-bit units
 RSCFDnCFDTMIECyLL, RSCFDnCFDTMIECyLH, RSCFDnCFDTMIECyHL, RSCFDnCFDTMIECyHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTMIECy: <RSCFDn_base> + 0390_H + (04_H × y)
 RSCFDnCFDTMIECyL: <RSCFDn_base> + 0390_H + (04_H × y),
 RSCFDnCFDTMIECyH: <RSCFDn_base> + 0392_H + (04_H × y)
 RSCFDnCFDTMIECyLL: <RSCFDn_base> + 0390_H + (04_H × y),

Table 25.150 RSCFDnCFDTMIECy Register Contents

| Bit | Bit Name | Function |
|----------|----------|---|
| 31 to 16 | TMIEp | Transmit Buffer Interrupt Enable p (p = y × 32 + 31 to y × 32 + 16) 0: Transmit buffer interrupt is disabled 1: Transmit buffer interrupt is enabled |
| 15 to 0 | TMIEp | Transmit Buffer Interrupt Enable p (p = y × 32 + 15 to y × 32 + 0) 0: Transmit buffer interrupt is disabled. 1: Transmit buffer interrupt is enabled. |

TMIEp Bits (p = 0 to 31)

When any of these bits is set to 1 and the corresponding transmission has been completed, a transmit buffer interrupt request is generated.

Modify these bits when the TMTRM flag in the corresponding RSCFDnCFDTMSTSp register is 0 (no transmit request is present).

Write 0 to bits corresponding to transmit buffers linked to transmit/receive FIFO buffers or transmit buffers allocated to the transmit queue.

When the TMME bit in the RSCFDnCFDCmFDCFG register is 1 (transmit buffer merge mode enable), set the bit corresponding to the transmit buffer allocated as a payload storage area to 0.

Table 25.151 shows the bit assignment.

Table 25.151 TMIEp Bit Assignment

| Bit | Channel | Transmit Buffer Number |

Table 25.152 RSCFDnCFDTMTRSTSy Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 16 | TMTRSTSp | Transmit Buffer Transmit Request Status Flag p ($p = y \times 32 + 31$ to $y \times 32 + 16$) 0: No transmit request is present. 1: A transmit request is present. |
| 15 to 0 | TMTRSTSp | Transmit Buffer Transmit Request Status Flag p ($p = y \times 32 + 15$ to $y \times 32 + 0$) 0: No transmit request is present. 1: A transmit request is present. |

TMTRSTSp Flags (p = 0 to 31)

These flags indicate the status of the TMTR bit in the RSCFDnCFDTMCp register.

When the TMTR bit is set to 1 (transmission is requested), the corresponding TMTRSTSp flag is set to 1.

The corresponding TMTRSTSp flag is cleared to 0 when the TMTR bit is set to 0 (transmission is not requested) or in channel reset mode.

Table 25.153 shows the bit assignment.

Table 25.153 TMTRSTSp Bit Assignment

| Bit | Channel | Transmit Buffer Number |
|-----|---------|------------------------|

Table 25.158 RSCFDnCFDnTMTASTSy Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 16 | TMTASTSp | Transmit Buffer Transmit Abort Status Flag p (p = y × 32 + 31 to y × 32 + 16) 0: Transmission is not aborted 1: Transmission is aborted |
| 15 to 0 | TMTASTSp | Transmit Buffer Transmit Abort Status Flag p (p = y × 32 + 15 to y × 32 + 0) 0: Transmission is not aborted. 1: Transmission is aborted. |

TMTASTSp Flags (p = 0 to 31)

When the TMTRF[1:0] flag in the RSCFDnCFDnTMTASTSp register is set to 01_B (transmit abort has been completed), the corresponding TMTASTSp flag is set to 1.

A TMTASTSp flag is cleared to 0 when the corresponding TMTRF[1:0] flag is set to 00_B or in channel reset mode.

Table 25.159 shows the bit assignment.

Table 25.159 TMTASTSp Bit Assignment

Table 25.160 RSCFDnCFDTXQCCm Register Contents

| Bit | Bit Name | Function |
|----------|------------|--|
| 31 to 14 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 13 | TXQIM | Transmit Queue Interrupt Source Select 0: When the transmit queue becomes empty upon completion of message transmission, a transmit queue interrupt request is generated. 1: A transmit queue interrupt request is generated each time a message has been transmitted. |
| 12 | TXQIE | Transmit Queue Interrupt Enable 0: Transmit queue interrupt is disabled. 1: Transmit queue interrupt is enabled. |
| 11 to 8 | TXQDC[3:0] | Transmit Queue Depth Configuration Setting these bits to g (g = 2 to 15) makes the (g + 1)-buffer transmit queue available. Setting these bits to 0 disables the transmit queue. Setting these bits to 1 is prohibited. For transmit buffer merge mode, set g to 2 to 9. |
| 7 to 1 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 0 | TXQE | Transmit Queue Enable 0: The transmit queue is not used. 1: The transmit queue is used. |

TXQIM Bit

This bit is used to select a transmit queue interrupt source. Modify this bit in channel reset mode.

TXQIE Bit

When the TXQIE bit is set to 1 and the source selected by the TXQIM bit occurs, an interrupt request is generated.
 Set the TXQE bit to 0 before modifying the TXQIE bit.

TXQDC[3:0] Bits

These bits are used to specify the number of transmit buffers to be allocated to the transmit queues. Transmit buffers are allocated to transmit queues in descending order of buffer number, that is, from $(m \times 16 + 15)$ to $(m \times 16 + 0)$. For examples of how buffer allocation is done, see Figure 25.9.

When the TMME bit in the RSCFDnCFDCmFDCFG register is 1 (transmit buffer merge mode), transmit buffers $(m \times 16 + 5)$ to $(m \times 16 + 0)$ are merged and cannot be allocated to the transmit queue. Therefore, do not set TXQDC[3:0] bits to 10 to 15.

Modify these bits only in channel reset mode.

TXQE Bit

Setting this bit to 1 makes the transmit queue available. Modify this bit in channel communication mode or channel halt mode. This bit is cleared to 0 in channel reset mode.

Before setting the TXQE bit to 1, set the TXQDC[3:0] bits to 0010_B or more.

25.4.13.2 RSCFDnCFDTXQSTSm — Transmit Queue Status Register (m = 0, 1)

Access: RSCFDnCFDTXQSTSm register can be read/written in 32-bit units
 RSCFDnCFDTXQSTSmL, RSCFDnCFDTXQSTSmH registers can be read/written in 16-bit units
 RSCFDnCFDTXQSTSmLL, RSCFDnCFDTXQSTSmLH, RSCFDnCFDTXQSTSmHL, RSCFDnCFDTXQSTSmHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTXQSTSm: <RSCFDn_base> + 03C0_H + (04_H × m)
 RSCFDnCFDTXQSTSmL: <RSCFDn_base> + 03C0_H + (04_H × m),
 RSCFDnCFDTXQSTSmH: <RSCFDn_base> + 03C2_H + (04_H × m)
 RSCFDnCFDTXQSTSmLL: <RSCFDn_base> + 03C0_H + (04_H × m),
 RSCFDnCFDTXQSTSmLH: <RSCFDn_base> + 03C1_H + (04_H × m),
 RSCFDnCFDTXQSTSmHL: <RSCFDn_base> + 03C2_H + (04_H × m),
 RSCFDnCFDTXQSTSmHH: <RSCFDn_base> + 03C3_H + (04_H × m)

Value after reset: 0000 0001_H

| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W *1 | R | R |

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 25.161 RSCFDnCFDTXQSTSm Register Contents

| Bit | Bit Name | Function |
|----------|----------|---|
| 31 to 13 | Reserved | When read, the value after reset is returned. When writing to these bits, write the value after reset. |
| 12 to 8 | Reserved | When read, the undefined value is returned. When writing to these bits, write the value after reset. |
| 7 to 3 | Reserved | When read, the value after reset is returned. When writing to these bits, write the value after reset. |
| 2 | TXQIF | Transmit Queue Interrupt Request Flag 0: No transmit queue interrupt request is present. 1: A transmit queue interrupt request is present. |
| 1 | TXQFL | Transmit Queue Full Status Flag 0: The transmit queue is not full. 1: The transmit queue is full. |
| 0 | TXQEMP | Transmit Queue Empty Status Flag 0: The transmit queue contains messages. 1: The transmit queue contains no message (transmit queue empty). |

TXQIF Flag

The TXQIF flag is set to 1 when the event specified by the TXQIM bit in the RSCFDnCFDTXQCCm register has occurred.

The TXQIF flag is cleared to 0 in channel reset mode or by writing 0 to this flag. This flag is not cleared to 0 by setting the TXQE bit in the RSCFDnCFDTXQCCm register to 0 (the transmit queue is not used).

TXQFLL Flag

The TXQFLL flag is set to 1 when the number of messages set for the transmit queue matches the transmit queue depth set by the TXQDC[3:0] bits in the RSCFDnCFDTXQCCm register.

This flag is cleared to 0 in any of the following cases.

- The number of messages set for the transmit queue is smaller than the transmit queue depth set by the TXQDC[3:0] bits.
- In channel reset mode

TXQEMP Flag

The TXQEMP flag is cleared to 0 when even a single message is set for the transmit queue.

This flag is set to 1 in any of the following cases.

- The TXQE bit is set to 0 (the transmit queue is not used).
- The transmit queue becomes empty.
- In channel reset mode

25.4.13.3 RSCFDnCFDTXQPCTRM — Transmit Queue Pointer Control Register (m = 0, 1)

Access: RSCFDnCFDTXQPCTRM register can only be written in 32-bit units
 RSCFDnCFDTXQPCTRM_L, RSCFDnCFDTXQPCTRM_H registers can only be written in 16-bit units
 RSCFDnCFDTXQPCTRM_{LL}, RSCFDnCFDTXQPCTRM_{LH}, RSCFDnCFDTXQPCTRM_{HL}, RSCFDnCFDTXQPCTRM_{HH} registers can only be written in 8-bit units

Address: RSCFDnCFDTXQPCTRM: <RSCFDn_base> + 03E0_H + (04_H × m)
 RSCFDnCFDTXQPCTRM_L: <RSCFDn_base> + 03E0_H + (04_H × m),
 RSCFDnCFDTXQPCTRM_H: <RSCFDn_base> + 03E2_H + (04_H × m)
 RSCFDnCFDTXQPCTRM_{LL}: <RSCFDn_base> + 03E0_H + (04_H × m),
 RSCFDnCFDTXQPCTRM_{LH}: <RSCFDn_base> + 03E1_H + (04_H × m),
 RSCFDnCFDTXQPCTRM_{HL}: <RSCFDn_base> + 03E2_H + (04_H × m),
 RSCFDnCFDTXQPCTRM_{HH}: <RSCFDn_base> + 03E3_H + (04_H × m)

Value after reset: 0000 0000_H

| R/W: | R | R | R | R | R | R | R | R | W | W | W | W | W | W | W | W |

Table 25.162 RSCFDnCFDTXQPCTRM Register Contents

| Bit | Bit Name | Function |
|---------|------------|---|
| 31 to 8 | Reserved | The write value should be the value after reset. |
| 7 to 0 | TXQPC[7:0] | Transmit Queue Pointer Control Writing FF _H to these bits moves the write pointer of the transmit queue to the next queue buffer. |

TXQPC[7:0] Bits

Writing FF_H to the TXQPC[7:0] bits moves the write pointer to the next transmit queue buffer and generates a transmit request of the message. Write transmit messages to the RSCFDnCFDTMID_p, RSCFDnCFDTMPTR_p, RSCFDnCFDTMFDCTR_p, and RSCFDnCFDTMDFb_p registers (p = 15 and 31) before writing FF_H to the TXQPC[7:0] bits.

When writing FF_H to these bits, make sure that the TXQE bit in the RSCFDnCFDTXQCC_m register is set to 1 (the transmit queue is used) and the TXQFLL flag in the RSCFDnCFDTXQST_m register is 0 (the transmit queue is not full).

25.4.14 Details of Transmit History-related Registers

25.4.14.1 RSCFDnCFDTHLCCm — Transmit History Configuration and Control Register (m = 0, 1)

Access: RSCFDnCFDTHLCCm register can be read/written in 32-bit units
 RSCFDnCFDTHLCCmL, RSCFDnCFDTHLCCmH registers can be read/written in 16-bit units
 RSCFDnCFDTHLCCmLL, RSCFDnCFDTHLCCmLH, RSCFDnCFDTHLCCmHL, RSCFDnCFDTHLCCmHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTHLCCm: $\langle \text{RSCFDn_base} \rangle + 0400_{\text{H}} + (04_{\text{H}} \times m)$
 RSCFDnCFDTHLCCmL: $\langle \text{RSCFDn_base} \rangle + 0400_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCFDnCFDTHLCCmH: $\langle \text{RSCFDn_base} \rangle + 0402_{\text{H}} + (04_{\text{H}} \times m)$

Table 25.163 RSCFDnCFDTHLCCm Register Contents

| Bit | Bit Name | Function |
|----------|----------|--|
| 31 to 11 | Reserved | When read, the value after reset is returned. When writing to these bits, write the value after reset. |
| 10 | THLDTE | Transmit History Target Buffer Select 0: Entry from transmit/receive FIFO buffers and transmit queue 1: Entry from transmit buffers, transmit/receive FIFO buffers, and transmit queue |
| 9 | THLIM | Transmit History Interrupt Source Select 0: When 12 sets of data have been stored in the transmit history buffer 1: When a single set of transmit history data has been stored |
| 8 | THLIE | Transmit History Interrupt Enable 0: Transmit history interrupt is disabled. 1: Transmit history interrupt is enabled. |
| 7 to 1 | Reserved | When read, the value after reset is returned. When writing to these bits, write the value after reset. |
| 0 | THLE | Transmit History Buffer Enable 0: Transmit history buffer is not used. 1: Transmit history buffer is used. |

THLDTE Bit

When this bit is set to 0, the transmit history data of messages transmitted from transmit/receive FIFO buffers and the transmit queue is stored in the transmit history buffer. When this bit is set to 1, the transmit history data of messages transmitted from transmit buffers, transmit/receive FIFO buffers, and the transmit queue is stored in the transmit history buffer.

Modify this bit only in channel reset mode.

THLIM Bit

This bit is used to select a transmit history interrupt source.

Modify this bit only in channel reset mode.

THLIE Bit

When the THLIE bit is set to 1 and the source selected by the THLIM bit has occurred, a transmit history interrupt request is generated. Modify the THLIE bit only when the THLE bit set to 0.

THLE Bit

Setting this bit to 1 makes the transmit history buffer available. When data transmission from the buffer selected by the THLDTE bit has been completed, the transmit history data of transmit messages is stored in the transmit history buffer.

Modify this bit in channel communication mode or channel halt mode.

This bit is cleared to 0 in channel reset mode.

25.4.14.2 RSCFDnCFDTHLSTSm — Transmit History Status Register (m = 0, 1)

Access: RSCFDnCFDTHLSTSm register can be read/written in 32-bit units
 RSCFDnCFDTHLSTSmL, RSCFDnCFDTHLSTSmH registers can be read/written in 16-bit units
 RSCFDnCFDTHLSTSmLL, RSCFDnCFDTHLSTSmLH, RSCFDnCFDTHLSTSmHL, RSCFDnCFDTHLSTSmHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTHLSTSm: <RSCFDn_base> + 0420_H + (04_H × m)
 RSCFDnCFDTHLSTSmL: <RSCFDn_base> + 0420_H + (04_H × m),

| Bit | Bit Name | Function |
|----------|------------|---|
| 31 to 13 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 12 to 8 | THLMC[4:0] | Transmit History Buffer Unread Data Counter These bits indicate the number of unread data sets stored in the transmit history buffer. |
| 7 to 4 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 3 | THLIF | Transmit History Interrupt Request Flag 0: No transmit history interrupt request is present. 1: A transmit history interrupt request is present. |
| 2 | THLELT | Transmit History Buffer Overflow Flag 0: Transmit history buffer overflow has not occurred. 1: Transmit history buffer overflow has occurred. |
| 1 | THLFL | Transmit history Buffer Full Status Flag 0: Transmit history buffer is not full. 1: Transmit history buffer is full. |
| 0 | THLEMP | Transmit History Buffer Empty Status Flag 0: Transmit history buffer contains unread data. 1: Transmit history buffer contains no unread data (buffer empty). |

THLMC[4:0] Bits

These bits indicate the number of unread data sets stored in the transmit history buffer. These bits are cleared to 0 in channel reset mode.

THLIF Flag

The THLIF flag is set to 1 when the interrupt source specified with the THLIM bit in the RSCFDnCFDTHLCCm register occurs.

This flag is cleared to 0 in channel reset mode or by the program writing 0 to this flag.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.

When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

THLELT Flag

The THLELT flag is set to 1 when an attempt is made to store new transmit history data while the transmit history buffer is full. In this case, the new data is discarded. This flag becomes 0 in channel reset mode or by the program writing 0 to this flag.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.

When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

THLFLL Flag

The THLFLL flag is set to 1 when 16 data sets have been stored in the transmit history buffer, and is cleared to 0 when the number of data sets stored in the transmit history buffer has decreased to less than 16. This bit is also cleared to 0 in channel reset mode or when the THLE bit in the RSCFDnCFDTHLCCm register is set to 0 (transmit history buffer is not used).

THLEMP Flag

The THLEMP flag is cleared to 0 when even a single set of transmit history data has been stored in the transmit history buffer.

This flag is set to 1 when all the data in the transmit history buffer has been read. This flag is also set to 1 in channel reset mode or when the THLE bit in the RSCFDnCFDTHLCCm register is set to 0 (transmit history buffer is not used).

Note: To clear THLIF or THLELT flag to 0, the program must write 0. When writing, use a store instruction to write “0” to the given flag and “1” to other flags.

25.4.14.3 RSCFDnCFDTHLPCTRm — Transmit History Pointer Control Register (m = 0, 1)

Access: RSCFDnCFDTHLPCTRm register can only be written in 32-bit units
 RSCFDnCFDTHLPCTRmL, RSCFDnCFDTHLPCTRmH registers can only be written in 16-bit units
 RSCFDnCFDTHLPCTRmLL, RSCFDnCFDTHLPCTRmLH, RSCFDnCFDTHLPCTRmHL, RSCFDnCFDTHLPCTRmHH registers can only be written in 8-bit units

Address: RSCFDnCFDTHLPCTRm: $\langle \text{RSCFDn_base} \rangle + 0440_{\text{H}} + (04_{\text{H}} \times m)$
 RSCFDnCFDTHLPCTRmL: $\langle \text{RSCFDn_base} \rangle + 0440_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCFDnCFDTHLPCTRmH: $\langle \text{RSCFDn_base} \rangle + 0442_{\text{H}} + (04_{\text{H}} \times m)$
 RSCFDnCFDTHLPCTRmLL: $\langle \text{RSCFDn_base} \rangle + 0440_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCFDnCFDTHLPCTRmLH: $\langle \text{RSCFDn_base} \rangle + 0441_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCFDnCFDTHLPCTRmHL: $\langle \text{RSCFDn_base} \rangle + 0442_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCFDnCFDTHLPCTRmHH: $\langle \text{RSCFDn_base} \rangle + 0443_{\text{H}} + (04_{\text{H}} \times m)$

Value after reset: 0000 0000_H

Table 25.165 RSCFDnCFDTHLPCTRm Register Contents

| Bit | Bit Name | Function |
|---------|------------|---|
| 31 to 8 | Reserved | When writing to these bits, write the value after reset. |
| 7 to 0 | THLPC[7:0] | Transmit History List Pointer Control Writing FF _H to these bits moves the read pointer to the next unread data in the transmit history buffer. |

THLPC[7:0] Bits

When the THLPC[7:0] bits are set to FF_H, the read pointer moves to the next data in the transmit history buffer. At this time, the THLMC[4:0] (transmit history buffer unread data counter) value in the RSCFDnCFDTHLSTSm register is decremented. Write FF_H to the THLPC[7:0] bits after reading from the RSCFDnCFDTHLACCm register.

When writing FF_H to these bits, make sure that the THLE bit in the RSCFDnCFDTHLCCm register is set to 1 (transmit history buffer is used) and the THLEMP flag in the RSCFDnCFDTHLSTSm register is 0.

25.4.14.4 RSCFDnCFDTHLACCm — Transmit History Access Register (m = 0, 1)

Access: RSCFDnCFDTHLACCm register can be read only in 32-bit units

RSCFDnCFDTHLACCmL, RSCFDnCFDTHLACCmH registers can be read only in 16-bit units

RSCFDnCFDTHLACCmLL, RSCFDnCFDTHLACCmLH, RSCFDnCFDTHLACCmHL, RSCFDnCFDTHLACCmHH registers can be read only in 8-bit units

Address: RSCFDnCFDTHLACCm: <RSCFDn_base> + 6000_H + (04_H × m)
 RSCFDnCFDTHLACCmL: <RSCFDn_base> + 6000_H + (04_H × m),
 RSCFDnCFDTHLACCmH: <RSCFDn_base> + 6002_H + (04_H × m)
 RSCFDnCFDTHLACCmLL: <RSCFDn_base> + 6000_H + (04_H × m),
 RSCFDnCFDTHLACCmLH: <RSCFDn_base> + 6001_H + (04_H × m),
 RSCFDnCFDTHLACCmHL: <RSCFDn_base> + 6002_H + (04_H × m),

Table 25.166 RSCFDnCFDTHLACCm Register Contents

| Bit | Bit Name | Function |
|----------|------------|--|
| 31 to 16 | TMTS[15:0] | Timestamp Data The timestamp data of stored data can be read. |
| 15 to 8 | TID[7:0] | Label Data The label information of stored data can be read. |
| 7 | Reserved | This bit is read as the value after reset. |
| 6 to 3 | BN[3:0] | Buffer Number Data The buffer number of transmit source (transmit buffer, transmit/receive FIFO or transmit queue) can be read. |
| 2 to 0 | BT[2:0] | Buffer Type Data b2 b1 b0 0 0 1: Transmit buffer 0 1 0: Transmit/receive FIFO buffer 1 0 0: Transmit queue |

TMTS[15:0] Bits

Timestamp values in transmit history data stored in the transmit history buffer are displayed.

TID[7:0] Bits

These bits indicate the label information of transmit history data stored in the transmit history buffer.

BN[3:0] Bits

These bits indicate the transmit source buffer number in the transmit history data stored in the transmit history buffer.

BT[2:0] Bits

These bits indicate the type of the transmit source buffer in the transmit history data stored in the transmit history buffer.

25.4.15 Details of Test-related Registers

25.4.15.1 RSCFDnCFDGTSTCFG — Global Test Configuration Register

Access: RSCFDnCFDGTSTCFG register can be read/written in 32-bit units
 RSCFDnCFDGTSTCFG_L, RSCFDnCFDGTSTCFG_H registers can be read/written in 16-bit units
 RSCFDnCFDGTSTCFG_LL, RSCFDnCFDGTSTCFG_LH, RSCFDnCFDGTSTCFG_HL, RSCFDnCFDGTSTCFG_HH registers can be read/written in 8-bit units

Address: RSCFDnCFDGTSTCFG: <RSCFDn_base> + 0468_H
 RSCFDnCFDGTSTCFG_L: <RSCFDn_base> + 0468_H, RSCFDnCFDGTSTCFG_H: <RSCFDn_base> + 046A_H
 RSCFDnCFDGTSTCFG_LL: <RSCFDn_base> + 0468_H, RSCFDnCFDGTSTCFG_LH: <RSCFDn_base> + 0469_H,
 RSCFDnCFDGTSTCFG_HL: <RSCFDn_base> + 046A_H, RSCFDnCFDGTSTCFG_HH: <RSCFDn_base> + 046B_H

Value after reset: 0000 0000_H

Table 25.167 RSCFDnCFDGTSTCFG Register Contents

| Bit | Bit Name | Function |
|----------|------------|---|
| 31 to 23 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 22 to 16 | RTMPS[6:0] | RAM Test Page Configuration Set a value within a range of page 0 (00 _H) to page 27 (1B _H). |
| 15 to 2 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 1 | C1ICBCE | CAN1 Inter-Channel Communication Test Enable 0: CAN1 inter-channel communication test is disabled. 1: CAN1 inter-channel communication test is enabled. |
| 0 | C0ICBCE | CAN0 Inter-Channel Communication Test Enable 0: CAN0 inter-channel communication test is disabled. 1: CAN0 inter-channel communication test is enabled. |

Modify the RSCFDnCFDGTSTCFG register only in global test mode.

RTMPS[6:0] Bits

These bits are used to set the RAM test target page number for RAM test. Set a value in the range of 00_H to 1B_H, inclusive. Do not access the RAM area higher than the 192th byte on the last page (the setting of the RTMPS bit is 1B_H).

C1ICBCE Bit

Setting this bit to 1 enables the channel 1 inter-channel communication test.
 This bit is cleared to 0 in global reset mode.

C0ICBCE Bit

Setting this bit to 1 enables the channel 0 inter-channel communication test.
 This bit is cleared to 0 in global reset mode.

25.4.15.2 RSCFDnCFDGTSTCTR — Global Test Control Register

Access: RSCFDnCFDGTSTCTR register can be read/written in 32-bit units
 RSCFDnCFDGTSTCTRL, RSCFDnCFDGTSTCTRH registers can be read/written in 16-bit units
 RSCFDnCFDGTSTCTRLL, RSCFDnCFDGTSTCTRLH, RSCFDnCFDGTSTCTRHL, RSCFDnCFDGTSTCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGTSTCTR: <RSCFDn_base> + 046C_H
 RSCFDnCFDGTSTCTRL: <RSCFDn_base> + 046C_H, RSCFDnCFDGTSTCTRH: <RSCFDn_base> + 046E_H
 RSCFDnCFDGTSTCTRLL: <RSCFDn_base> + 046C_H, RSCFDnCFDGTSTCTRLH: <RSCFDn_base> + 046D_H,
 RSCFDnCFDGTSTCTRHL: <RSCFDn_base> + 046E_H, RSCFDnCFDGTSTCTRHH: <RSCFDn_base> + 046F_H

Value after reset: 0000 0000_H

| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R/W | R | R/W |

Table 25.168 RSCFDnCFDGTSTCTR Register Contents

| Bit | Bit Name | Function |
|---------|----------|---|
| 31 to 3 | Reserved | These bits are read as the value after reset. The write value should be the value after reset. |
| 2 | RTME | RAM Test Enable 0: RAM test is disabled. 1: RAM test is enabled. |
| 1 | Reserved | This bit is read as the value after reset. The write value should be the value after reset. |
| 0 | ICBCTME | Communication Test between Channels Enable 0: Communication test between channels disabled 1: Communication test between channels enabled |

RTME Bit

Setting this bit to 1 enables the RAM test. Modify this bit only in global test mode.

This bit is cleared to 0 in global reset mode.

1. Set the GMDC[1:0] bits in the RSCFDnCFDGCTR register to 10_B (Global test mode).
2. Set the RTME bit to 1.
3. Check that the RTME bit is set to 1.

ICBCTME Bit

When this bit is set to 1, a communication test is enabled between the channels for which the CmICBCE bit (m = 0, 1) in the RSCFDnCFDGTSTCFG register has been set to 1. Modify the ICBCTME bit only in global test mode.

This bit is cleared to 0 in global reset mode.

25.4.15.3 RSCFDnCFDGLOCKK — Global Lock Key Register

Access: RSCFDnCFDGLOCKK register can only be written in 32-bit units
RSCFDnCFDGLOCKKL, RSCFDnCFDGLOCKKH registers can only be written in 16-bit units

Address: RSCFDnCFDGLOCKK: <RSCFDn_base> + 047C_H
RSCFDnCFDGLOCKKL: <RSCFDn_base> + 047C_H, RSCFDnCFDGLOCKKH: <RSCFDn_base> + 047E_H

Value after reset: 0000 0000_H

| | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| | | | | | | | | | | | | | | | | |
|--------------------|------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | LOCK[15:0] | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 | W*1 |

Note 1. Writing to these bits is effective only when the RS-CANFD module is in global test mode.

Table 25.169 RSCFDnCFDGLOCKK Register Contents

| Bit | Bit Name | Function |
|----------|------------|---|
| 31 to 16 | Reserved | When writing these bits, write the value after reset. |
| 15 to 0 | LOCK[15:0] | Lock Key These bits are key bits to release protection of test mode. |

The RSCFDnCFDGLOCKK register releases protection of special test bits and is write only.

For the protection release data, see section 25.11.4.2, Procedure for Releasing the Protection.

LOCK[15:0] Bits

Writing the protection release data to the LOCK[15:0] bits in succession enables writing 1 to the RTME bit in the RSCFDnCFDGTSTCTR register.

After the protection has been released, writing to the I/O register area (<RSCFDn_base> + 0000_H to <RSCFDn_base> + 05FF_H) of the CAN (except the RAM) enables the protection again.

Reading from the I/O register area of the CAN or reading from/writing to other areas does not enable the protection.

25.4.15.4 RSCFDnCFDRPGACCr — RAM Test Page Access Register (r = 0 to 63)

Access: RSCFDnCFDRPGACCr register can be read/written in 32-bit units
 RSCFDnCFDRPGACCrL, RSCFDnCFDRPGACCrH registers can be read/written in 16-bit units
 RSCFDnCFDRPGACCrLL, RSCFDnCFDRPGACCrLH, RSCFDnCFDRPGACCrHL, RSCFDnCFDRPGACCrHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRPGACCr: $\langle \text{RSCFDn_base} \rangle + 6400_{\text{H}} + (04_{\text{H}} \times r)$
 RSCFDnCFDRPGACCrL: $\langle \text{RSCFDn_base} \rangle + 6400_{\text{H}} + (04_{\text{H}} \times r)$,
 RSCFDnCFDRPGACCrH: $\langle \text{RSCFDn_base} \rangle + 6402_{\text{H}} + (04_{\text{H}} \times r)$
 RSCFDnCFDRPGACCrLL: $\langle \text{RSCFDn_base} \rangle + 6400_{\text{H}} + (04_{\text{H}} \times r)$,
 RSCFDnCFDRPGACCrLH: $\langle \text{RSCFDn_base} \rangle + 6401_{\text{H}} + (04_{\text{H}} \times r)$,
 RSCFDnCFDRPGACCrHL: $\langle \text{RSCFDn_base} \rangle + 6402_{\text{H}} + (04_{\text{H}} \times r)$,
 RSCFDnCFDRPGACCrHH: $\langle \text{RSCFDn_base} \rangle + 6403_{\text{H}} + (04_{\text{H}} \times r)$

Value after reset: 0000 0000_H

Table 25.170 RSCFDnCFDRPGACCr Register Contents

| Bit | Bit Name | Function |
|---------|------------|--|
| 31 to 0 | RDTA[31:0] | RAM Data Test Access Data can be read and written in RSCAN RAM. |

Modify the RSCFDnCFDRPGACCr register in global test mode with the RTME bit in the RSCFDnCFDGTSTCTR register set to 1 (RAM test is enabled).

The RSCFDnCFDRPGACCr register is readable and writable when the RTME bit is set to 1.

25.5 Interrupt Sources and DMA Trigger

25.5.1 Interrupt Sources

The RS-CANFD module has 8 interrupts that are grouped into global interrupts and channel interrupts.

- Global interrupts (2 sources):
 - Receive FIFO interrupt
 - Global error interrupt
- Channel interrupts (3 sources/channel):
 - CANm transmit interrupt (m = 0, 1)
 - CANm transmit complete interrupt
 - CANm transmit abort interrupt
 - CANm transmit/receive FIFO transmit complete interrupt (in transmit mode, gateway mode)
 - CANm transmit history interrupt
 - CANm transmit queue Interrupt
 - CANm transmit/receive FIFO receive complete interrupt (in receive mode, gateway mode)
 - CANm error interrupt

When an interrupt request is generated, the corresponding interrupt request flag is set to 1 (interrupt request present). In that case, when the interrupt enable bit is set to 1 (enabling interrupts), an interrupt request is output from the RS-CANFD module. (Generation of interrupts also depends on the interrupt control register settings of the interrupt controller.)

Setting the interrupt request flag to 0 (no interrupt request present) or setting the interrupt enable bit to 0 (disabling interrupts) clears the current interrupt request. The current interrupt request is still output until the interrupt request flag is cleared.

Table 25.171 lists the CAN interrupt sources. Figure 25.2 shows the CAN global interrupt block diagram. Figure 25.3 shows the CAN channel interrupt block diagram.

Table 25.171 List of CAN Interrupt Sources

| RCAN | | | | | INTC | DMA |
|----------------------|---|-------------------|---|--|---------------------------|-------------------------------|
| | Interrupt Source (Unit Interrupt Signal) | | Corresponding Interrupt Request Flag | Corresponding Interrupt Enable Bit | Request Source Name | Transfer Request Signal |
| Global interrupts | Receive FIFO (INTRCAN GRECC) | Receive FIFO 0 | RFIF in the RSCFDn(CFD)RFSTS0 register | RFIE in the RSCFDn(CFD)RFCC0 register | RFI | RXF_DMA0 |
| | | Receive FIFO 1 | RFIF in the RSCFDn(CFD)RFSTS1 register | RFIE in the RSCFDn(CFD)RFCC1 register | | RXF_DMA1 |
| | | Receive FIFO 2 | RFIF in the RSCFDn(CFD)RFSTS2 register | RFIE in the RSCFDn(CFD)RFCC2 register | | RXF_DMA2 |
| | | Receive FIFO 3 | RFIF in the RSCFDn(CFD)RFSTS3 register | RFIE in the RSCFDn(CFD)RFCC3 register | | RXF_DMA3 |
| | | Receive FIFO 4 | RFIF in the RSCFDn(CFD)RFSTS4 register | RFIE in the RSCFDn(CFD)RFCC4 register | | RXF_DMA4 |
| | | Receive FIFO 5 | RFIF in the RSCFDn(CFD)RFSTS5 register | RFIE in the RSCFDn(CFD)RFCC5 register | | RXF_DMA5 |
| | | Receive FIFO 6 | RFIF in the RSCFDn(CFD)RFSTS6 register | RFIE in the RSCFDn(CFD)RFCC6 register | | RXF_DMA6 |
| | | Receive FIFO 7 | RFIF in the RSCFDn(CFD)RFSTS7 register | RFIE in the RSCFDn(CFD)RFCC7 register | | RXF_DMA7 |

Table 25.171 List of CAN Interrupt Sources

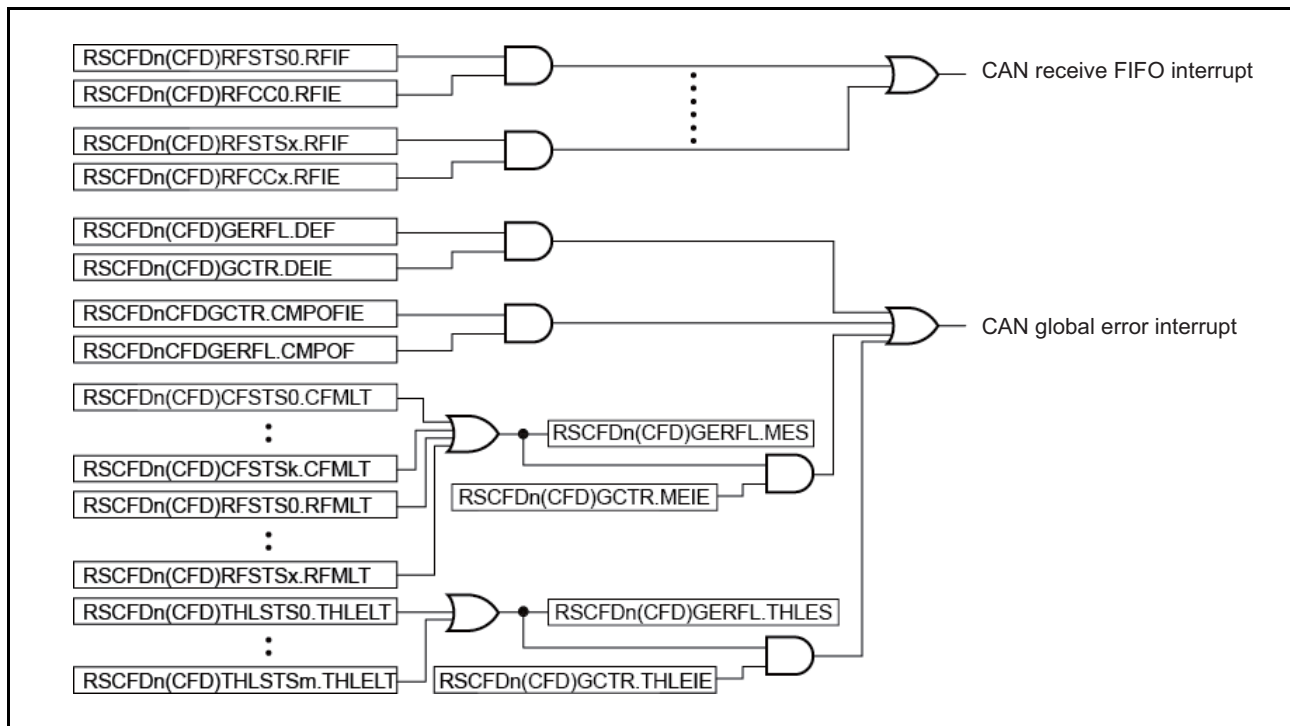

Figure 25.2 CAN Global Interrupt Block Diagram

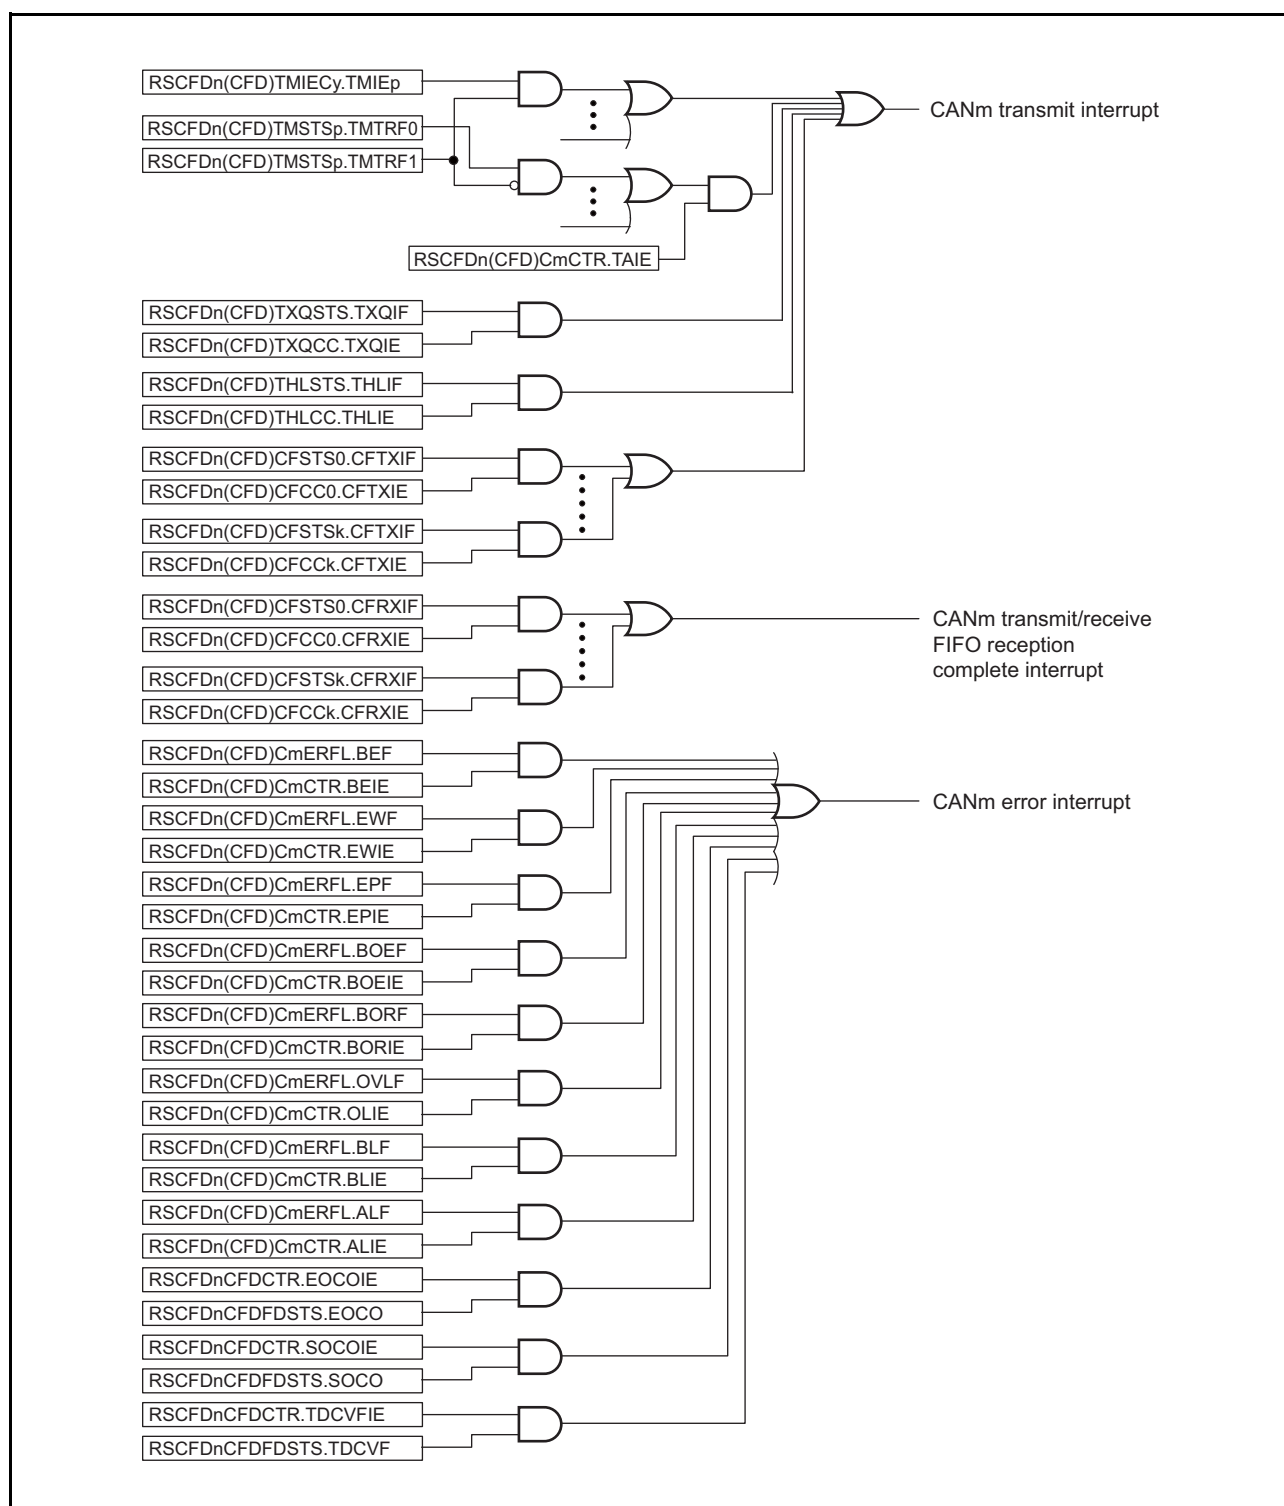

Figure 25.3 CAN Channel Interrupt Block Diagram

25.5.2 DMA Trigger (Only in CANFD Mode)

In CANFD mode, receive FIFO buffers can be related to DMA channels. The following 10 FIFO buffers can be related.

- All receive FIFO buffers x ($x = 0$ to 7)
- The first transmit/receive FIFO buffer k ($k = 3 \times m$, $m = 0, 1$) allocated to channel m

When the DMA enable bit (RFDMAEx or CFDMAEm bit in the RSCFDnCFDCDTCT register) is set to 1 and an unread message is remaining in the related FIFO, a DMA transfer request trigger is generated.

25.6 CAN Modes

The RS-CANFD module has four global modes to control the entire RS-CANFD module status and four channel modes to control individual channel status. Details of global modes are described in section 25.6.1, Global Modes, and details of channel modes are described in section 25.6.2, Table 25.5, Channel Mode State Transition Chart.

- Global stop mode: Stops the clocks of the entire module to achieve low power consumption.
- Global reset mode: Performs initial settings for the entire module.
- Global test mode: Performs test settings and performs the RAM test.
- Global operating mode: Makes the entire module operable.
- Channel stop mode: Stops the channel clock.
- Channel reset mode: Performs initial settings for the channels.
- Channel halt mode: Stops CAN communication and allows channel testing.
- Channel communication mode: Performs CAN communication.

25.6.1 Global Modes

Figure 25.4 shows the transitions of global modes.

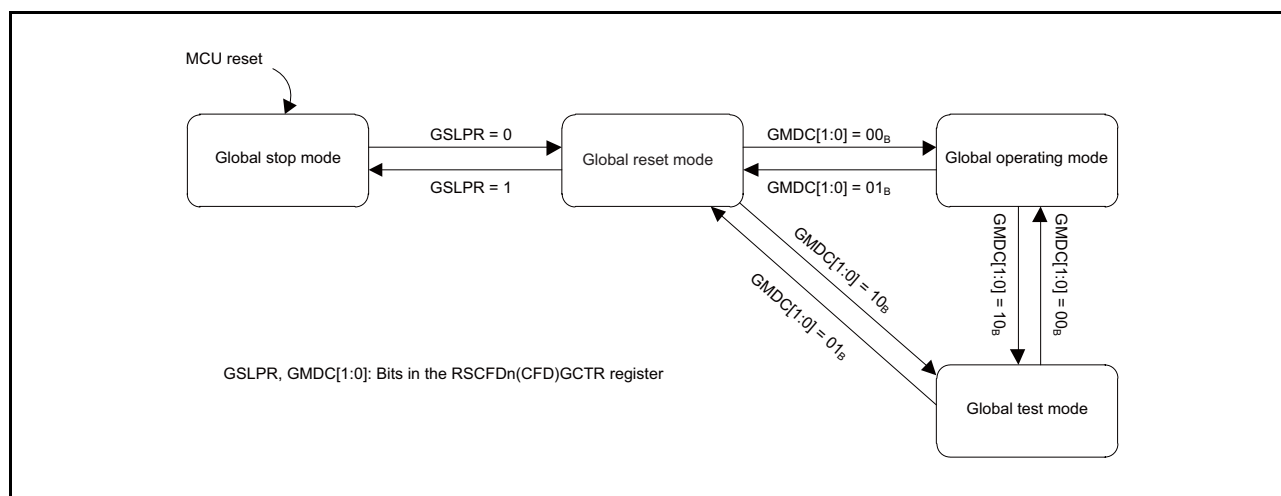

Figure 25.4 Transitions of Global Modes

In some cases, global mode transitions also force channel mode transitions. Table 25.172 shows the channel mode transitions depending on the global mode setting dictated by the GMDC[1:0] bits and the GSLPR bit.

Table 25.172 Transitions of Channel Modes Depending on Global Mode Setting (GMDC[1:0] and GSLPR Bits)

| Channel Mode before Setting | Channel Mode after Setting | | | |
|-----------------------------|--|---|--|---|
| | GMDC[1:0] = 00 _B GSLPR = 0 (Global Operation) | GMDC[1:0] = 10 _B GSLPR = 0 (Global Test) | GMDC[1:0] = 01 _B GSLPR = 0 (Global Reset) | GMDC[1:0] = 01 _B GSLPR = 1 (Global Stop) |
| Channel communication | Channel communication | Channel halt | Channel reset | Transition prohibited |
| Channel halt | Channel halt | Channel halt | Channel reset | Transition prohibited |
| Channel reset | Channel reset | Channel reset | Channel reset | Channel stop |
| Channel stop | Channel stop | Channel stop | Channel stop | Channel stop |

Note 1. GMDC[1:0], GSLPR: Bits in the RSCFDn(CFD)GCTR register

Table 25.173 shows the global mode transition time.

Table 25.173 Global Mode Transition Time

| Mode before Transition | Mode after Transition | Maximum Transition Time |
|------------------------|-----------------------|--------------------------|
| Global stop | Global reset | Three pclk cycles |
| Global reset | Global stop | Three pclk cycles |
| Global reset | Global test | Ten pclk cycles |
| Global reset | Global operating | Ten pclk cycles |
| Global test | Global reset | Two CAN bit times,*1, *2 |
| Global test | Global operating | Three pclk cycles |
| Global operating | Global reset | Two CAN bit times,*1, *2 |
| Global operating | Global test | Two CAN frames,*1 |

Note 1. CAN frame time and CAN bit time of the lowest communication speed of the channels in use

Note 2. In CANFD mode, this time value is the CAN bit time of the nominal bit rate.

25.6.1.1 Global Stop Mode

In global stop mode, clocks of the CAN do not run and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained. Only the clock used by the CPU for writing to the GSLPR bit runs in this mode.

After the MCU is reset, the CAN module transitions to global stop mode. Setting the GSLPR bit in the RSCFDn(CFD)GCTR register to 1 (in global stop mode) in global reset mode sets the CSLPR bit in each of the RSCFDn(CFD)CmCTR register to 1 (channel stop mode). Afterwards, if all channels are forced to transition to channel stop mode, the CAN module transitions to global stop mode. The GSLPR bit should not be modified in global operating mode or global test mode.

25.6.1.2 Global Reset Mode

In global reset mode, RS-CANFD module settings are performed. When the RS-CANFD module transitions to global reset mode, some registers are initialized. For registers to be initialized, see Table 25.176, Registers Initialized in Global Reset Mode or Channel Reset Mode and Table 25.177, Registers Initialized Only in Global Reset Mode.

Setting the GMDC[1:0] bits in the RSCFDn(CFD)GCTR register to 01_B sets the CHMDC[1:0] bits in each of the RSCFDn(CFD)CmCTR registers (m = 0, 1) to 01_B (channel reset mode). If all channels are forced to transition to channel reset mode, the CAN module transitions to global reset mode. Channels that are already in channel reset mode or channel stop mode do not transition (because the CHMDC[1:0] bits have already been set to 01_B).

25.6.1.3 Global Test Mode

In global test mode, settings for test-related registers are performed. When the CAN module transitions to global test mode, all CAN communications are disabled.

Setting the GMDC[1:0] bits in the RSCFDn(CFD)GCTR register to 10_B sets the CHMDC[1:0] bits in each of the RSCFDn(CFD)CmCTR register to 10_B (channel halt mode). If all channels are forced to transition to channel halt mode, the CAN module transitions to global test mode. Channels that are in channel stop mode, channel reset mode, or channel halt mode do not transition.

25.6.1.4 Global Operating Mode

The RS-CANFD module operates in global operating mode.

When the GMDC[1:0] bits in the RSCFDn(CFD)GCTR register are set to 00_B, the RS-CANFD module transitions to global operating mode.

25.6.2 Channel Modes

Figure 25.5 shows a channel mode state transition chart. Table 25.174 shows the channel mode transition time.

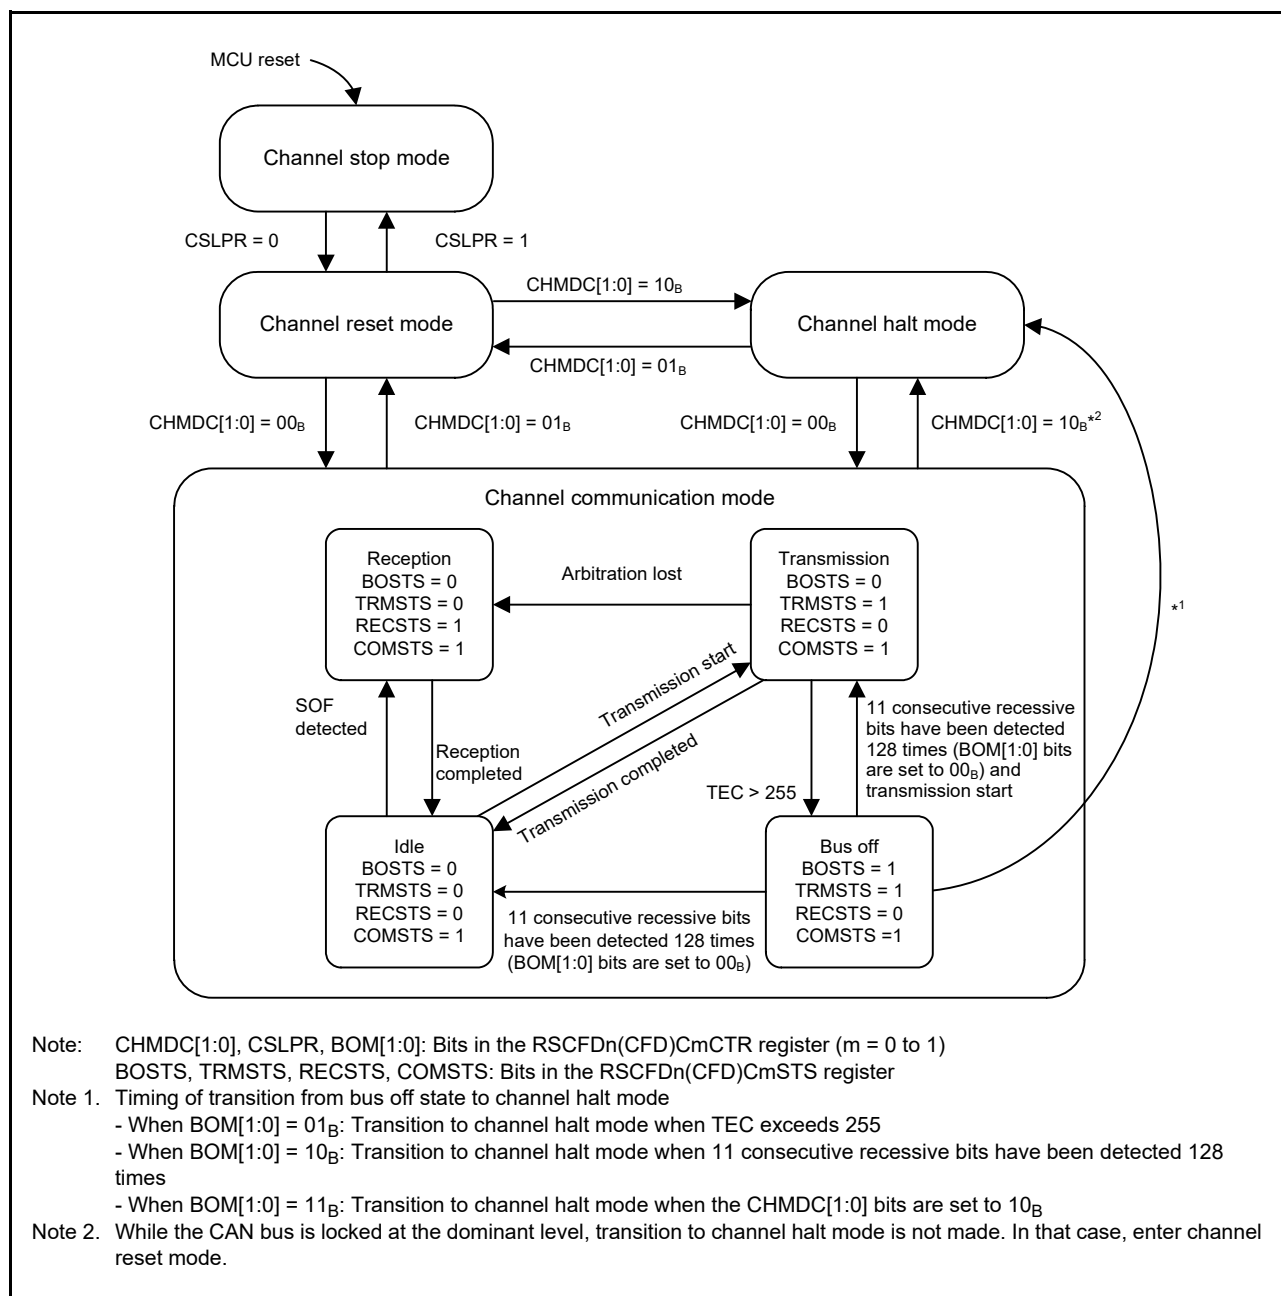

Figure 25.5 Channel Mode State Transition Chart

Table 25.174 Channel Mode Transition Time

| Mode before Transition | Mode after Transition | Maximum Transition Time |
|------------------------|-----------------------|-------------------------|
| Channel stop | Channel reset | Three pclk cycles |
| Channel reset | Channel stop | Three pclk cycles |
| Channel reset | Channel halt | Three CANm bit times*1 |
| Channel reset | Channel communication | Four CANm bit times*1 |
| Channel halt | Channel reset | Two CANm bit times*1 |
| Channel halt | Channel communication | Four CANm bit times*1 |
| Channel communication | Channel reset | Two CANm bit times*1 |
| Channel communication | Channel halt | Two CANm frames |

Note 1. In CANFD mode, this time value is the CANm bit time of the nominal bit rate.

25.6.2.1 Channel Stop Mode

In channel stop mode, clocks are not supplied to channels and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained.

Each channel enters channel stop mode after the MCU is reset. Channels also transition to channel stop mode when the GSLPR bit in the RSCFDn(CFD)CmCTR register (m = 0, 1) is set to 1 (channel stop mode) in channel reset mode. The GSLPR bit should not be modified in channel communication mode and channel halt mode.

25.6.2.2 Channel Reset Mode

In channel reset mode, channel settings are performed. When a channel transitions to channel reset mode, some channel-related registers are initialized. For registers to be initialized, see Table 25.176, Registers Initialized in Global Reset Mode or Channel Reset Mode.

When the CHMDC[1:0] bits in the RSCFDn(CFD)CmCTR register are set to 01_B (channel reset mode) during CAN communication, communication is terminated before it is completed and the channel transitions to channel reset mode. Table 25.175 shows the operation when the CHMDC[1:0] bits are set to 01_B (channel reset mode) during CAN communication.

25.6.2.3 Channel Halt Mode

In channel halt mode, settings for test-related registers of channels are performed. When a channel transitions to channel halt mode, CAN communication of the channel stops.

Table 25.175 shows operation when the CHMDC[1:0] bits are set to 10_B (channel halt mode) during CAN communication.

Table 25.175 Operation in Transitions to Channel Reset Mode/Channel Halt Mode

| Mode | During Reception | During Transmission | Bus Off State |
|---|--|---|--|
| Channel reset (CHMDC[1:0] = 01 _B) | Transitions to channel reset mode before reception is completed.*1 | Transitions to channel reset mode before transmission is completed.*1 | Transitions to channel reset mode before bus off recovery. |
| Channel halt*3 (CHMDC[1:0] = 10 _B) | Transitions to channel halt mode after reception is completed.*2 | Transitions to channel halt mode after transmission is completed. | [When BOM[1:0] = 00 _B] Transitions to channel halt mode (CHMDC[1:0] = 10 _B) only after bus off recovery. [When BOM[1:0] = 01 _B] Transitions to channel halt mode automatically when the condition for transition to bus off state is met. [When BOM[1:0] = 10 _B] Transitions to channel halt mode automatically after bus off recovery. [When BOM[1:0] = 11 _B] Transitions to channel halt mode immediately after the CHMDC[1:0] bits are set to 10 _B before bus off recovery. |

Note 1. To allow transition to channel reset mode after communication is completed, set the CHMDC[1:0] bits to 10_B and confirm that communication has been completed and transition to channel halt mode has been made, and then set the CHMDC[1:0] bits to 01_B.

Note 2. While the CAN bus is locked at the dominant level, transition to channel halt mode is not made. In that case, enter channel reset mode. The CAN bus status can be confirmed with the BLF flag of the RSCFDn(CFD)CmERFL register that becomes 1 when dominant lock is detected.

Note 3. In classical CAN mode, when the transition from channel reset mode to channel halt mode is to be made, set the RSCANnCMCFG register in channel reset mode and then shift to channel halt mode. In CANFD mode, set the RSCFDnCFDCmNCFG register and the RSCFDnCFDCmDCFG register, and then make a transition.

25.6.2.4 Channel Communication Mode

In channel communication mode, CAN communication is performed. Each channel has the following communication states during CAN communication.

- Idle: Neither reception nor transmission is in progress.
- Reception: Receiving a message sent from another node.
- Transmission: Transmitting a message.
- Bus off: Isolated from CAN communication.

When the CHMDC[1:0] bits in the RSCFDn(CFD)CmCTR register are set to 00_B, the channel transitions to channel communication mode. After that, once 11 consecutive recessive bits have been detected, the COMSTS flag in the RSCFDn(CFD)CmSTS register (m = 0, 1) is set to 1 (communication is ready) and transmission and reception are enabled on the CAN network as an active node. At this time, transmission and reception of messages can be started.

25.6.2.5 Bus Off State

A channel transitions to the bus off state according to the transmit/receive error counter increment/decrement rules of the CAN specifications.

The conditions for returning from the bus off state are determined by the BOM[1:0] bits in the RSCFDn(CFD)CmCTR register.

- When BOM[1:0] = 00_B:
Bus off recovery is compliant with the CAN specifications. After 11 consecutive recessive bits have been detected 128 times, a channel returns from the bus off state to the CAN communication ready state (error active state). At that time, the TEC[7:0] and REC[7:0] bits in the RSCFDn(CFD)CmSTS register are initialized to 00_H, the BORF flag in the RSCFDn(CFD)CmERFL register is set to 1 (bus off recovery is detected), and a bus off recovery interrupt request is generated. When the CHMDC[1:0] bits in the RSCFDn(CFD)CmCTR register are set to 10_B (channel halt mode) in the bus off state, the channel transitions to channel halt mode after bus off recovery has been completed (11 consecutive recessive bits have been detected 128 times).
- When BOM[1:0] = 01_B:
When a channel transitions to the bus off state, the CHMDC[1:0] bits are set to 10_B and the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H. The BORF flag is not set to 1, and bus off recovery interrupt request is not generated.
- When BOM[1:0] = 10_B:
When a channel has transitioned to the bus off state, the CHMDC[1:0] bits are set to 10_B. After bus off recovery has been completed (11 consecutive recessive bits have been detected 128 times), the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H, the BORF flag is set to 1, and a bus off recovery interrupt request is generated.
- When BOM[1:0] = 11_B:
When the CHMDC[1:0] bits are set to 10_B in the bus off state, the channel transitions to channel halt mode before bus off recovery is completed. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H, but the BORF flag is not set to 1. Also, a bus off recovery interrupt is not generated.
However, the BORF flag becomes 1 and a bus off recovery interrupt request is generated if a CAN module transitions to error active state (by detecting 128 times of 11 consecutive recessive bits) before CHMDC[1:0] bits are set to 10_B.

If the RS-CANFD module causes the channel to transition to channel halt mode simultaneously with a program write to the CHMDC[1:0] bits, the program write takes precedence. An automatic transition to channel halt mode when the BOM[1:0] bits are set to 01_B or 10_B is made only when the CHMDC[1:0] bits are 00_B (channel communication mode). Furthermore, setting the RTBO bit in the RSCFDn(CFD)CmCTR register to 1 allows a forced return from the bus off state. As soon as the RTBO bit is set to 1, the state changes to the error active state. After 11 consecutive recessive bits have been detected, the CAN module becomes ready for communication. In this case, the BORF flag is not set to 1 and the TEC[7:0] and REC[7:0] bits are initialized to 00_H. Write 1 to the RTBO bit only when the BOM[1:0] value is 00_B. Writing the RTBO bit to 1 in a state other than the bus off state is ignored, and the RTBO bit is immediately set to 0.

25.6.3 Initializing Registers by Transition to CAN Mode

Table 25.176 lists bits and flags to be initialized by a transition to channel reset mode. These bits and flags are also initialized by a transition to global reset mode. Furthermore, Table 25.177 lists bits and flags to be initialized only by a transition to global reset mode.

Table 25.176 Registers Initialized in Global Reset Mode or Channel Reset Mode

| Register | Bit/Flag |
|-------------------------------|---|
| RSCFDn(CFD)CmCTR register | (ROM), CRCT, CTMS[1:0], CTME, CHMDC[1:0] |
| RSCFDn(CFD)CmSTS register | CHLTSTS, EPSTS, BOSTS, TRMSTS, RECSTS, COMSTS, (ESIF), REC[7:0], TEC[7:0] |

| RSCFDn(CFD)CmFDCTR register | EOCCLR, SOCCLR |
| RSCFDn(CFD)CmFDSTS register | SOC[7:0], EOC[7:0], SOCO, EOCO, TDCVF, TDCR[6:0] |
| RSCFDn(CFD)CmFDCRC register | CRCREG[20:0], SCNT[3:0] |
| RSCFDn(CFD)CFCK register | When transmit/receive FIFO buffer is in transmit mode or gateway mode: CFE |
| RSCFDn(CFD)CFSTSk register | When transmit/receive FIFO buffer is in transmit mode or gateway mode: CFMC[7:0], CFFLL, CFEMP, CFMLT, CFRXIF, CFTXIF |
| RSCFDn(CFD)CFTISTS register | CFkTXIF |
| RSCFDn(CFD)TMCP register | TMOM, TMTAR, TMTR |
| RSCFDn(CFD)TMSTSp register | TMTARM, TMTRM, TMTRF[1:0], TMTSTS |
| RSCFDn(CFD)TMTRSTSy register | TMTRSTSp (Bits of corresponding channel are initialized in channel reset mode.) |
| RSCFDn(CFD)TMTARSTSy register | TMTARSTSp (Bits of corresponding channel are initialized in channel reset mode.) |
| RSCFDn(CFD)TMTCASTSy register | TMTCASTSp (Bits of corresponding channel are initialized in channel reset mode.) |
| RSCFDn(CFD)TMTASTSy register | TMTASTSp (Bits of corresponding channel are initialized in channel reset mode.) |
| RSCFDn(CFD)TXQCCm register | TXQE |
| RSCFDn(CFD)TXQSTSm register | TXQIF, TXQFLL, TXQEMP |
| RSCFDn(CFD)THLCCm register | THLE |
| RSCFDn(CFD)THLSTSm register | THLMC[4:0], THLIF, THLELT, THLFLL, THLEMP |
| RSCFDn(CFD)GTINTSTS0 register | TSIFm, TAIFm, TQIFm, CFTIFm, THIFm (m = 0, 1) |

Note: Bits and flags in parentheses exist only in registers for use in CANFD mode.

Table 25.177 Registers Initialized Only in Global Reset Mode

| Register | Bit/Flag |
|-------------------------------|--|
| RSCFDn(CFD)GSTS register | GHLTSTS |
| RSCFDn(CFD)GERFL register | EEF0, EEF1, (CMPOF), THLES, MES, DEF |
| RSCFDn(CFD)GTSC register | TS[15:0] |
| RSCFDn(CFD)RMNDy register | RMNSq |
| RSCFDn(CFD)RFCCx register | RFE |
| RSCFDn(CFD)RFSTs register | RFMC[7:0], RFIF, RFMLT, RFFLL, RFEMP |
| RSCFDn(CFD)CFCCk register | When transmit/receive FIFO buffer is in receive mode: CFE |
| RSCFDn(CFD)CFSTSk register | When transmit/receive FIFO buffer is in receive mode: CFMC[7:0], CFFLL, CFEMP, CFTXIF, CFRXIF, CFMLT |
| RSCFDn(CFD)FESTS register | CFkEMP, RFxEMP |
| RSCFDn(CFD)FFSTS register | CFkFLL, RFxFLL |
| RSCFDn(CFD)FMSTS register | CFkMLT, RFxMLT |
| RSCFDn(CFD)RFISTS register | RFxIF |
| RSCFDn(CFD)CFRISTS register | CFkRXIF |
| RSCFDn(CFD)CFDCDTCT register | CFDMAEm, RFDMAEx |
| RSCFDn(CFD)CFDCDTSTS register | CFDMASTSm, RFDMASTs |
| RSCFDn(CFD)GTSTCFG register | RTMPS[6:0], C0ICBCE, C1ICBCE |
| RSCFDn(CFD)GTSTCTR register | RTME, ICBCTME |

Note: Bits and flags in parentheses exist only in registers for use in CANFD mode.

25.7 Reception Function

There are two reception types.

- Reception by receive buffers:
Zero to 32 receive buffers can be shared by all channels. Since messages stored in receive buffers are overwritten at each reception, the latest receive data can always be read.
- Reception by receive FIFO buffers and transmit/receive FIFO buffers (receive mode):
Eight receive FIFO buffers can be shared by all channels and three dedicated transmit/receive FIFO buffers are provided for each channel. Messages of up to the number of buffer stages specified with the RFDC[2:0] and CFDC[2:0] bits can be stored in FIFO buffers and can be read sequentially from the oldest.

25.7.1 Data Processing Using the Receive Rule Table

Data processing using the receive rule table allows dispatching of selected messages to the specified buffer. Data processing includes acceptance filter processing, DLC filter processing, routing processing, label addition processing, and mirror function processing.

Up to 128 receive rules can be registered per channel and up to $(64 \times \text{number of channels})$ total receive rules can be registered in the entire module. (Up to 128 receive rules can be registered in this module that has two channels.) Set receive rules for each channel. Receive rules cannot be shared with other channels. If receive rules are not set, no messages can be received. Figure 25.6 illustrates how receive rules are registered.

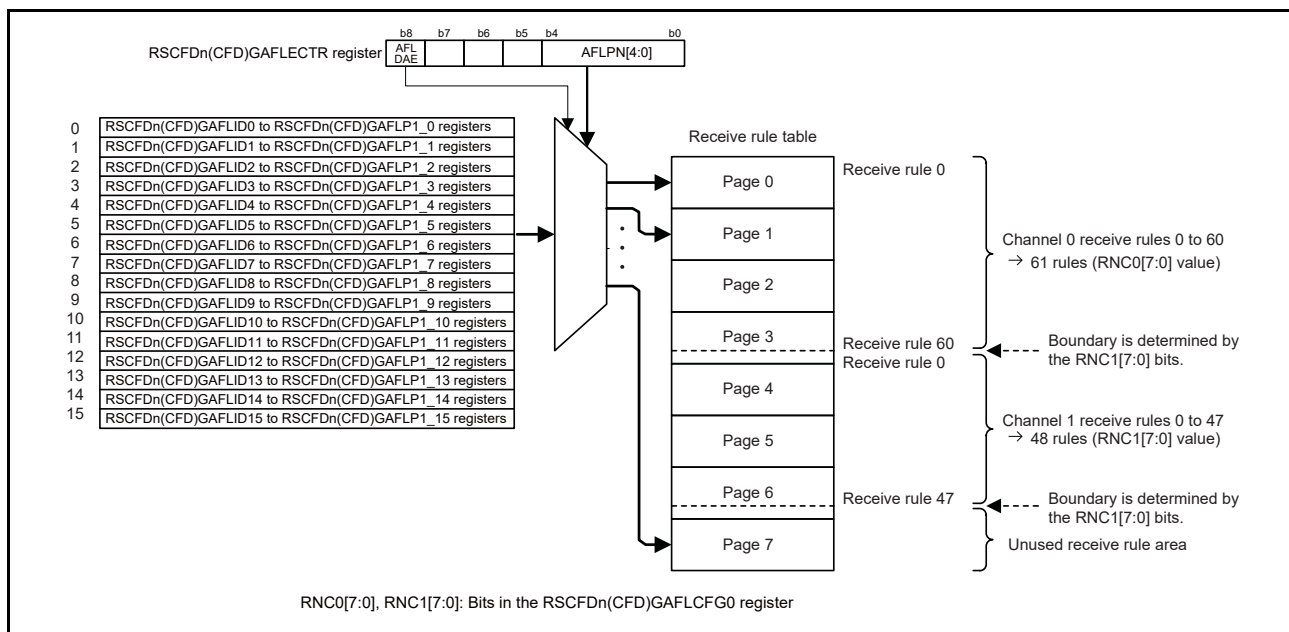

Figure 25.6 Entry of Receive Rules (for Setting Channels 0 and 1)

Note: Receive rules for each channel must be set in contiguous blocks.
Channel 1 rules and channel 0 rules must be set separately.

Each receive rule consists of 16 bytes in the RSCFDn(CFD)GAFLIDj, RSCFDn(CFD)GAFLMj, RSCFDn(CFD)GAFLP0_j, and RSCFDn(CFD)GAFLP1_j registers (j = 0 to 15). The RSCFDn(CFD)GAFLIDj register is used to set GAFLID, GAFLIDE bit, GAFLRTR bit, and the mirror function, the RSCFDn(CFD)GAFLMj register is used to set mask, the RSCFDn(CFD)GAFLP0_j register is used to set label information to be added, DLC value, and storage receive buffer, and the RSCFDn(CFD)GAFLP1_j register is used to set storage FIFO buffer. Up to 16 receive rules can be set per page.

25.7.1.1 Acceptance Filter Processing

In the acceptance filter processing, the ID data, IDE bit, and RTR bit in a received message are compared with the ID data, IDE bit, and RTR bit set in the receive rule of the corresponding channel. When all these bits match, the message passes through the acceptance filter processing. The ID data, IDE bit, and RTR bit in the received message which correspond to the bits set to 0 (bits are not compared) in the RSCFDn(CFD)GAFLMj register are not compared and are regarded as matched.

Check begins with the receive rule of the minimum number for the corresponding channel. When all the bits to be compared in a received message match the bits set in the receive rule or when all the receive rules are compared without any match, filter processing stops. If there is no matching receive rule, the received message is not stored in the receive buffer or FIFO buffer.

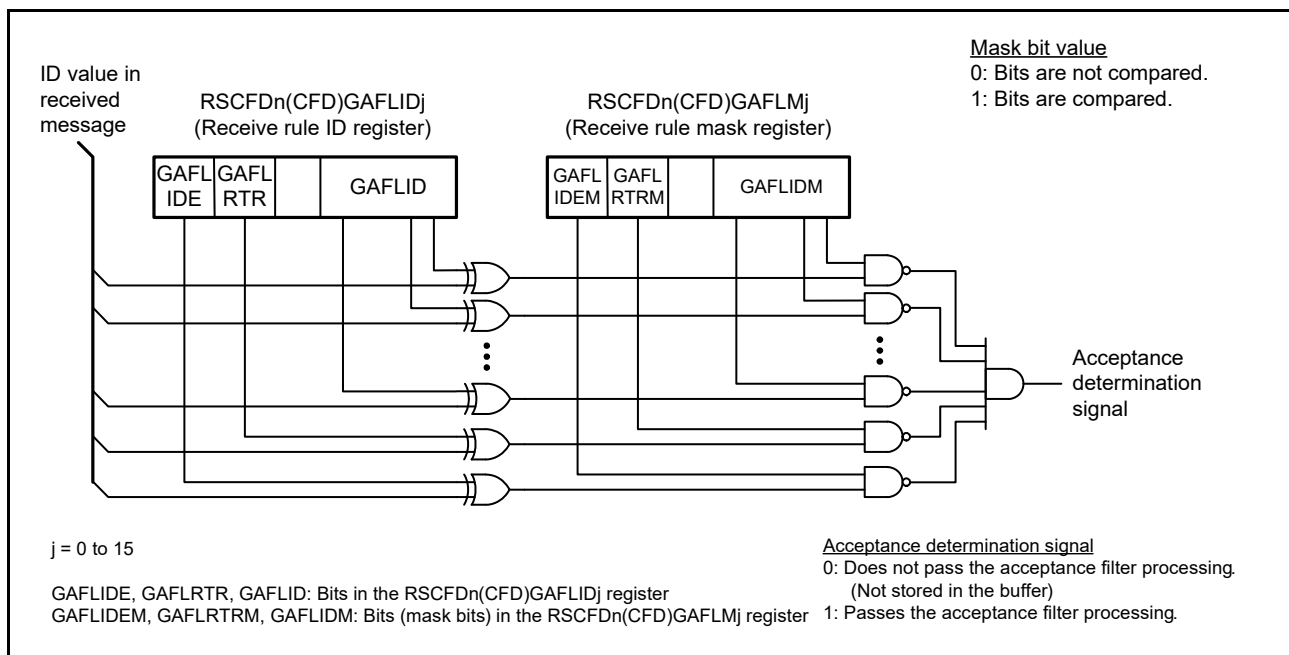

Figure 25.7 Acceptance Filter Function

25.7.1.2 DLC Filter Processing

When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), DLC filter processing is added to messages that passed through the acceptance filter processing. When the DLC value in a message is equal to or larger than the DLC value set in the receive rule, the message passes through the DLC filter processing.

When a message has passed through the DLC filter processing with the DRE bit in the RSCFDn(CFD)GCFG register set to 0 (DLC replacement is disabled), the DLC value in the received message is stored in the buffer. In this case, all the data bytes in the received message are stored in the buffer.

When a message has passed through the DLC filter processing with the DRE bit in the RSCFDn(CFD)GCFG register set to 1 (DLC replacement is enabled), the DLC value in the receive rule is stored in the buffer instead of the DLC value in the received message. In this case, a value of 00_H is stored in each data byte beyond the number of bytes which is indicated by the DLC value in the receive rule.

When the DLC value in the received message is smaller than that in the receive rule, the message does not pass through the DLC filter processing. In this case, the message is not stored in the receive buffer or the FIFO buffer and the DEF flag in the RSCFDn(CFD)GERFL register is set to 1 (a DLC error is present).

25.7.1.3 Routing Processing

Messages that passed through the acceptance filter processing and the DLC filter processing are stored in receive buffers, receive FIFO buffers, or transmit/receive FIFO buffers (set to receive mode or gateway mode). Message storage destination is set by the GAFLRMV and GAFLRMDP[6:0] bits in the RSCFDn(CFD)GAFLP0_j register (j = 0 to 15) and by the RSCFDn(CFD)GAFLP1_j register. Messages that passed through the acceptance filter processing and the DLC filter processing can be stored in up to eight buffers.

In CANFD mode, if the payload length of the received message exceeds the payload storage size of the storage buffer, the CMPOF flag in the RSCFDnCFDGERFL register is set to 1 (payload overflow) and the processing is handled according to the CMPOC bit in the RSCFDnCFDGCFCFG register. When the CMPOC bit is 0, the received message which exceeds the payload storage size is not stored in the buffer. When the CMPOC bit is 1, the received message is stored in the buffer with payloads exceeding the storage size being discarded.

25.7.1.4 Label Addition Processing

It is possible to add 12-bit label information to messages that passed through the filter processing and store them in buffers. This label information is set in the GAFLPTR[11:0] bits in the RSCFDn(CFD)GAFLP0_j register.

25.7.1.5 Mirror Function Processing

The mirror function allows the CAN node to receive its own transmitted messages. The mirror function is made available by setting the MME bit in the RSCFDn(CFD)GCFCFG register to 1 (mirror function is enabled).

When the mirror function is in use, receive rules for which the GAFLLB bit in the RSCFDn(CFD)GAFLIDj register is set to 0 are used for data processing when receiving messages transmitted from other CAN nodes. When the CAN node is receiving its own transmitted messages, receive rules for which the GAFLLB bit is set to 1 are used for data processing.

25.7.1.6 Timestamp

The timestamp counter is a 16-bit free-running counter used for recording message receive time and transmission time. The timestamp counter value is fetched at the timing set with the TSCCFG[1:0] bits in the RSCFDn(CFD)GCFCFG register and is then stored in a receive buffer or a FIFO buffer together with the message ID and data during data reception. The clock source of the timestamp counter is selected by the TSBTCS[2:0] and TSSS bits in the RSCFDn(CFD)GCFCFG register. In classical CAN mode, either pclk/2 or the CANm bit time clock (m = 0, 1). In CANFD mode, the clock source is selectable from pclk/2 or nominal CANm bit time clock. However, do not select the nominal CANm bit time clock of channels that handle CANFD frames. The timestamp counter count source is obtained by dividing the selected clock source by the TSP[3:0] value in the RSCFDn(CFD)GCFCFG register.

When the CANm bit time clock or nominal CANm bit time clock is used as a clock source, the timestamp counter stops when the corresponding channel transitions to channel reset mode or channel halt mode. When the pclk/2 is used as a clock source, the timestamp function is not affected by channel mode.

The timestamp counter value is reset to 0000_H by setting the TSRST bit in the RSCFDn(CFD)GCTR register to 1.

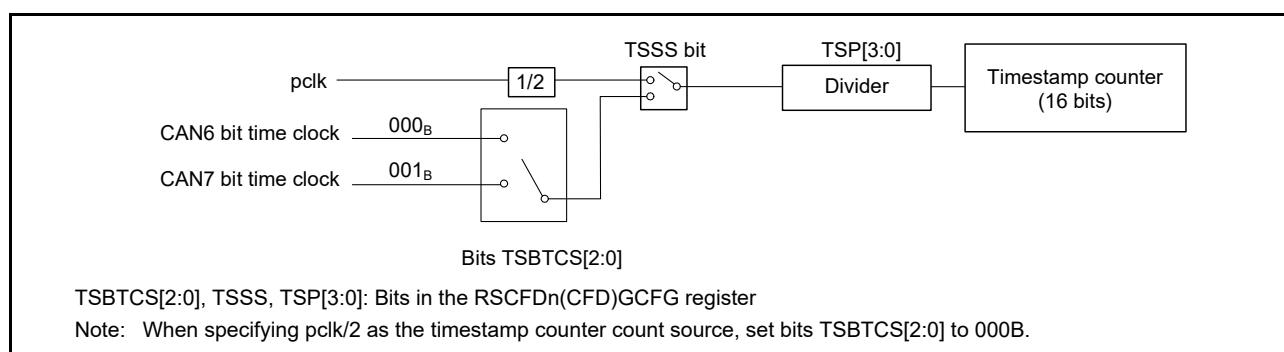

Figure 25.8 Timestamp Function Block Diagram

25.8 Transmission Functions

There are three types of transmission. In classical CAN mode, transmittable payload length is 8 bytes in every transmission type. In CANFD mode, transmittable payload length varies with transmission types.

- Transmission using transmit buffers:

Each channel has 16 buffers. Transmittable payload length in CANFD mode is 20 bytes. However, when transmit buffer merge mode is used, four buffers out of 16 buffers are allocated as a payload-only storage area and two buffers are able to transmit payloads with a length of more than 20 bytes.

- Transmission using transmit/receive FIFO buffers (transmit mode):

Each channel has three FIFO buffers. Up to 128 messages can be contained in a single FIFO buffer. Transmittable payload length in CANFD mode is 64 bytes. Each FIFO buffer is used with a link to a transmit buffer. Only the message to be transmitted next in a FIFO buffer becomes the target of transmit priority determination. Messages are transmitted sequentially on a first-in, first-out basis.

- Transmission using transmit queues:

Up to 16 transmit buffers per channel can be allocated to the transmit queues. Transmittable payload length in CANFD mode is 20 bytes. Transmit buffer $((16 \times m) + 15)$ is used as an access window of a corresponding channel. Transmit buffers are allocated to transmit queues in descending order of buffer number. All messages in transmit queues, which are targets of priority determination, are transmitted in the order of ID number.

Figure 25.9 shows the allocation of transmit queues and transmit/receive FIFO buffer link.

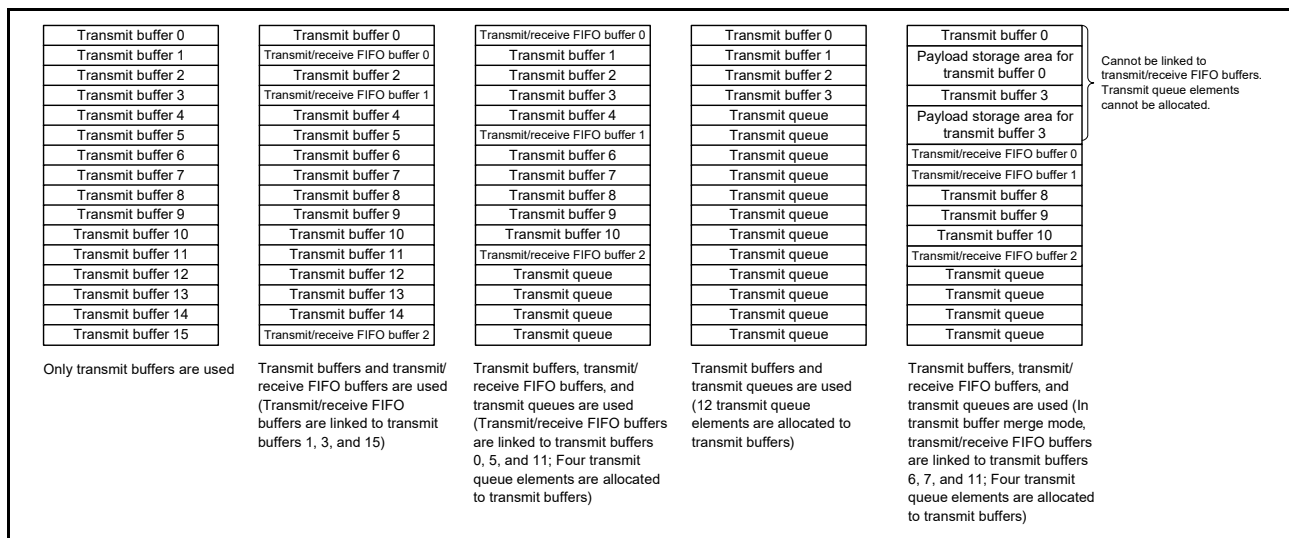

Figure 25.9 Allocation of Transmit Queues and Transmit/Receive FIFO Buffer Links

25.8.1 Transmit Priority Determination

If transmit requests are issued from multiple buffers or from the queue on the same channel, transmit priority is determined using one of the following methods.

The priority is determined by using one of the following methods.

- ID priority (TPRI bit = 0)
- Transmit buffer number priority (TPRI bit = 1)

All CAN channels use the setting of the TPRI bit in the RSCFDn(CFD)GCFG register.

When the TPRI bit is set to 0, messages are transmitted according to the priority of stored message IDs. ID priority conforms to the CAN bus arbitration specification defined in the CAN specifications. All IDs of pending transmit messages are targets of priority determination, regardless of whether they are stored in transmit buffers, transmit/receive FIFO buffers (set to transmit mode or gateway mode), or the transmit queue. If even a single transmit queue is used, select ID priority. When transmit/receive FIFO buffers are used, the oldest message in a FIFO buffer becomes the target of priority determination. When a message is being transmitted from a transmit/receive FIFO buffer, the next message in the FIFO buffer becomes the target of priority determination. When a transmit queue is used, all messages in the transmit queue are targets of priority determination. If the same ID is set for two or more buffers, the buffer with the smaller buffer number takes precedence.

When the TPRI bit is set to 1, the message in the transmit buffer with the minimum buffer number among all buffers with a transmit request is transmitted first. When transmit/receive FIFO buffers are linked to transmit buffers, transmit priority is determined according to linked transmit buffer numbers.

When messages are retransmitted due to an arbitration-lost or an error, transmit priority determination is made again regardless of the TPRI bit.

25.8.2 Transmission Using Transmit Buffers

Setting the transmit request bit (TMTR bit in the RSCFDn(CFD)TMCp register) in a transmit buffer to 1 (transmission is requested) allows transmission of data frames or remote frames.

The transmit result is shown by the TMTRF[1:0] flag in the corresponding RSCFDn(CFD)TMSTSp register (p = 0 to 31). When transmit completes successfully, the TMTRF[1:0] flag is set to 10_B (transmission has been completed (without transmit abort request)) or 11_B (transmission has been completed (with transmit abort request)).

25.8.2.1 Transmit Abort Function

With respect to transmit buffers for which the TMTRM bit in the RSCFDn(CFD)TMSTSp register is set to 1 (a transmit request is present), when the TMTAR bit in the RSCFDn(CFD)TMCp register is set to 1 (transmit abort is requested), the transmit request is canceled. When transmit abort is completed, the TMTRF[1:0] flag in the RSCFDn(CFD)TMSTSp register is set to 01_B (transmit abort has been completed) and the transmit request is canceled (clearing the TMTRM bit to 0).

A message that is being transmitted or a message to be transmitted next according to the transmit priority determination cannot be aborted. However, when an arbitration-lost or an error occurs during transmission of a message for which the TMTAR bit is set to 1, retransmission is not performed.

25.8.2.2 One-Shot Transmission Function (Retransmission Disabling Function)

When the TMOM bit in the RSCFDn(CFD)TMCp register is set to 1 (one-shot transmission is enabled), transmission is performed only once. Even if an arbitration-lost or an error occurs, retransmission is not performed.

The one-shot transmit result is shown by the TMTRF[1:0] flag in the corresponding RSCFDn(CFD)TMSTSp register. When one-shot transmission completes successfully, the TMTRF[1:0] flag is set to 10_B or 11_B. When an arbitration-lost or an error occurs, the TMTRF[1:0] flag is set to 01_B (transmit abort has been completed).

25.8.2.3 Transmit Buffer Merge Mode (Only in CANFD Mode)

Transmit buffers can transmit messages with a payload length of 20 bytes, but can transmit messages with a payload length of up to 64 bytes by merging three transmit buffers in transmit buffer merge mode.

Setting the TMME bit to 1 in the RSCFDnCFDCmFDCFG register enables transmit buffer merge mode. In this mode, six buffers per channel become a merge area and two sets of transmit buffers $(16 \times m) + 0$ to $(16 \times m) + 2$ and transmit buffers $(16 \times m) + 3$ to $(16 \times m) + 5$ are merged. A transmission request is made by the first transmit buffer, and subsequent two buffers are used as a payload storage area. Do not set the transmission request bit (TMTR bit in the RSCFDnCFDTMCp register) and the transmission abort request bit (TMTAR bit in the RSCFDnCFDTMCp register) to 1 for transmit buffers except for the first buffer.

While transmit buffer merge mode is enabled, do not link the transmit/receive FIFO buffer to the merged buffers or allocate it to the transmit queue.

25.8.3 Transmission Using FIFO Buffers

Multiple messages can be stored in a single transmit/receive FIFO buffers, up to the number specified by the FIFO buffer depth, which is set by the CFDC[2:0] bits in the RSCFDn(CFD)CFCCk register (k = 0 to 5). Messages are transmitted sequentially on a first-in, first-out basis.

Each transmit/receive FIFO buffer is linked to a transmit buffer selected by the CFTML[3:0] bits in the RSCFDn(CFD)CFCCk register. When the CFE bit in the RSCFDn(CFD)CFCCk register is set to 1 (transmit/receive FIFO buffers are used), transmit/receive FIFO buffers become targets of transmit priority determination. Priority of only the next transmit message is determined in the FIFO buffer.

When the CFE bit is set to 0 (no transmit/receive FIFO buffer is used), the CFEMP flag is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)) at the timing below.

- The transmit/receive FIFO buffer becomes empty immediately if the message in it is not being transmitted or is not to be transmitted next.
- The transmit/receive FIFO buffer becomes empty after transmission completion, CAN bus error detection, arbitration-lost or the transition to channel halt mode in the case that a message in it is being transmitted or to be transmitted next.

When the CFE bit is cleared to 0, all messages in transmit/receive FIFO buffers are lost and messages cannot be stored in FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

25.8.3.1 Interval Transmission Function

A message transmission interval time can be set to space the transmission of messages from the same FIFO buffer when using a transmit/receive FIFO buffer set to transmit mode or gateway mode.

Immediately after the first message has been transmitted successfully from the FIFO buffer with the CFE bit in the RSCFDn(CFD)CFCCk register set to 1, the interval timer starts counting (after EOF7 of the CAN protocol). After that, when the interval time has passed, the next message is transmitted. The interval timer stops in channel reset mode or by clearing the CFE bit to 0.

The interval time is set by the CFITT[7:0] bits in the RSCFDn(CFD)CFCCk register. When the interval timer is not used, set the CFITT[7:0] bits to 00_H.

Select an interval timer count source using the CFITR and CFITSS bits in the RSCFDn(CFD)CFCCk register. When the CFITR and CFITSS bits are set to 00_B, the count source is obtained by dividing pclk/2 by the value of the ITRCP[15:0] bits. When the CFITR and CFITSS bits are set to 10_B, the count source is obtained by dividing pclk/2 by (the value of the ITRCP[15:0] bits in the RSCFDn(CFD)GCFG register × 10). When the CFITR and CFITSS bits are set to x1_B, the CANm bit time clock becomes a count source in classical CAN mode and the nominal CANm bit time clock becomes a count source in CANFD mode. Use this count source only for the channel that does not handle the CANFD frames.

The interval time is calculated by the following equations where M is the value of ITRCP[15:0] and N is the value of CFITT[7:0].

- When CFITR and CFITSS = 00_B:

$$\frac{1}{\text{pclk frequency}} \times 2 \times M \times N$$

- When CFITR and CFITSS = 10_B:

$$\frac{1}{\text{pclk frequency}} \times 2 \times M \times 10 \times N$$

- When CFITR and CFITSS = x1_B:

$$\text{Classical CAN mode: } \frac{1}{\text{CANm bit time clock frequency}} \times N$$

$$\text{CANFD mode: } \frac{1}{\text{Nominal CANm bit time clock frequency}} \times N$$

Figure 25.10 shows the interval timer block diagram.

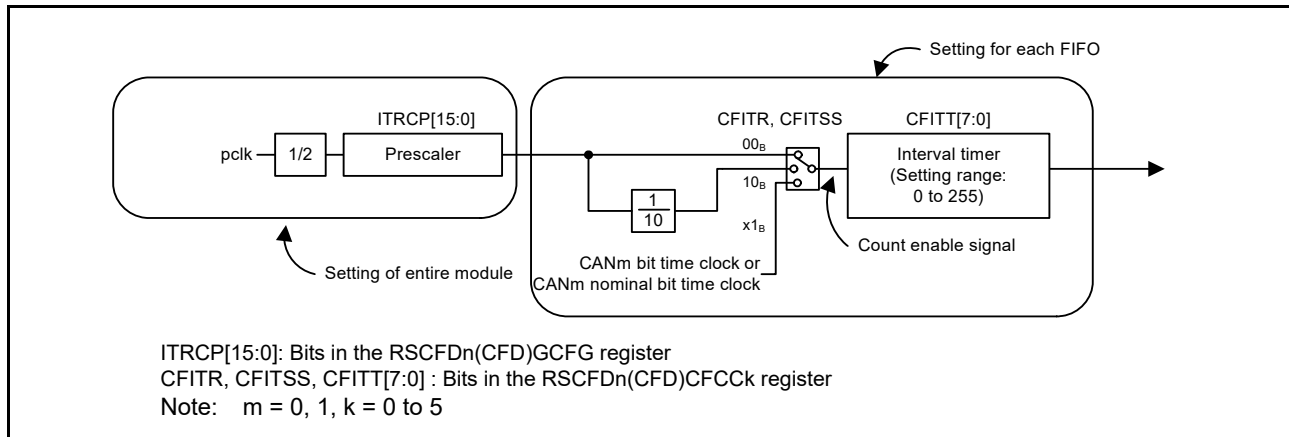

Figure 25.10 Interval Timer Block Diagram

Figure 25.11 shows the interval timer timing diagram.

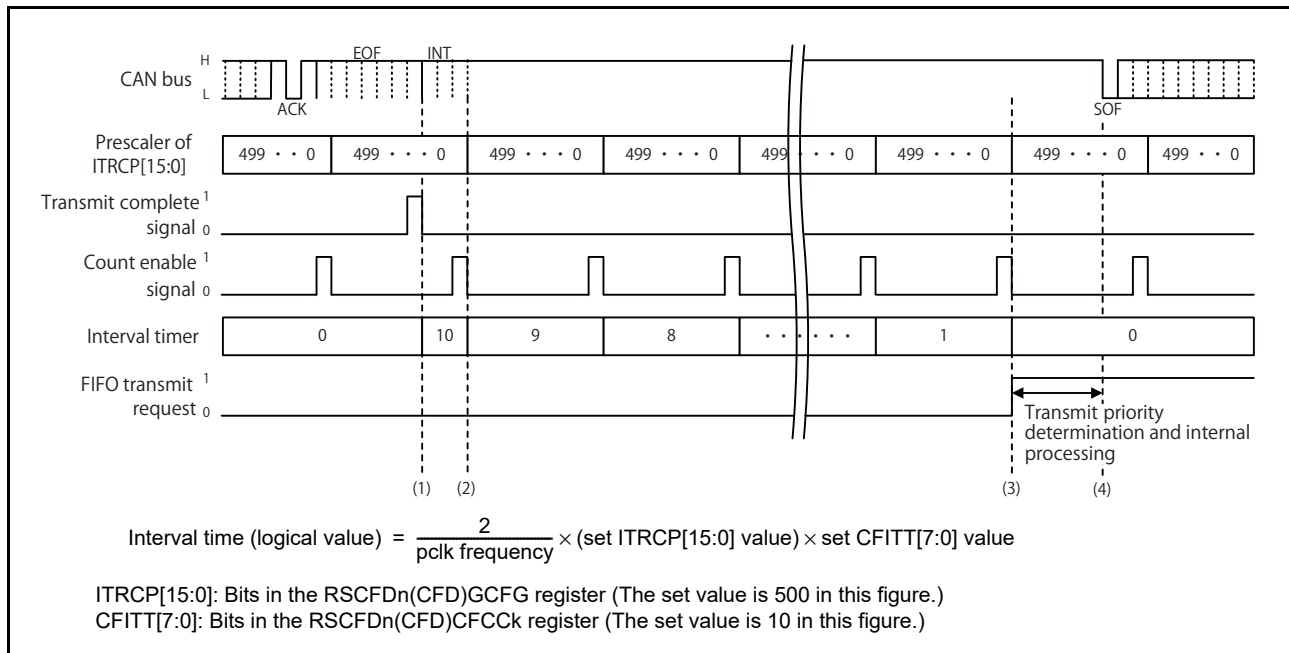

Figure 25.11 Interval Timer Timing Chart

- (1) The interval timer starts counting upon completion of transmission. Since the prescaler is not initialized at the time of transmission completion, the first interval time contains an error of up to one count of the interval timer.
- (2) The interval timer is decremented by the next count enable signal.
- (3) When the interval timer has decreased to 0, the transmit/receive FIFO buffer issues a transmit request.
- (4) The transmit/receive FIFO buffer is determined for the next transmission by the priority determination, it starts transmitting data. Transmission starts usually with a delay of three CANm bit time clock cycles or less from the issue of transmit request. If multiple internal processes (such as receive filter processing, message routing, and transmit priority determination) take place in all channels, a delay of up to 644 cycles of the pclk may be generated.

25.8.4 Transmission Using Transmit Queues

Three to sixteen buffers (up to 10 buffers in transmit buffer merge mode) are allocated to a transmit queue for each channel, and transmit buffer $((16 \times m) + 15)$ is used as an access window of a corresponding channel.

All messages in a transmit queue are targets of transmit priority determination and are transmitted in the ID priority order regardless of storage sequence. If two messages having the same ID are stored in a transmit queue, these messages are not always transmitted in the order of their storage in the transmit queue.

Setting the TXQE bit in the RSCFDn(CFD)TXQCCm register to 0 disables transmit queues. When the TXQE bit is set to 0, the TXQEMP flag in the RSCFDn(CFD)TXQSTSm register is set to 1 (the transmit queue contains no messages (transmit queue empty)) at the timing below.

- The transmit queue becomes empty immediately when no message in it is being transmitted or will be transmitted next.
- The transmit queue becomes empty after transmission completion, CAN bus error detection, arbitration-lost, or the transition to channel halt mode when a message in it is being transmitted or will be transmitted next.

When the TXQE bit is cleared to 0, all messages in transmit queues are lost and messages cannot be stored in transmit queues. Confirm that the TXQEMP flag is set to 1 before setting the TXQE bit to 1 again.

25.8.5 Transmit Data Padding (Only in CANFD Mode)

When the payload length indicated by the set DLC value in a transmit message exceeds the payload storage area size of a buffer to be used for transmission, excessive payloads are padded by CC_H .

This processing is performed in the following cases when the transmit buffer merge mode is disabled (TMME bit in the RSCFDnCFDCmFDCFG register is 0).

- Transmit/receive FIFO set to transmission or gateway mode:
When the payload length of the transmit DLC exceeds the transmit/receive FIFO payload storage area size set by the CFPLS[2:0] bits in the RSCFDnCFDCFCCK register
- Transmit buffer (including transmit queue):
When the payload length of the transmit DLC exceeds 20 bytes

When the transmit buffer merge mode is enabled, no transmit data is padded in any transmission using a transmit buffer, transmit/receive FIFO buffer, or transmit queue. At this time, do not set a payload length more than the payload storage size of the buffer for transmitting as the DLC value in the transmit message.

25.8.6 Transmit History Function

Information about transmission-completed messages can be stored in the transmit history buffer. Each channel has a single transmit history buffer that can contain 16 sets of transmit history data.

A message transmit source buffer type can be selected by the THLDTE bit in the RSCFDn(CFD)THLCCm register. The THLEN bit in the RSCFDn(CFD)CFIDk register (k = 0 to 5) determines whether transmit history data is stored for each message.

In classical CAN mode, the TMTSCE bit in the RSCANnGCFG register can be used to set whether to include a timestamp value in the transmit history data. In CANFD mode, a timestamp value is always included.

The following information on a transmitted message will be stored in the transmit history buffer after the successful completion of transmission.

Storage of the transmit history data after the successful completion of transmission may take up to 128 cycles of pclk in classical CAN mode or 396 cycles of pclk in CANFD mode.

- Buffer type 001_B: Transmit buffer
- 010_B: Transmit/receive FIFO buffer
- 100_B: Transmit queue
- Buffer number: Number of source transmit buffer, transmit queue, or transmit/receive FIFO buffer.
This number depends on buffer types. See Table 25.178.
- Label data: Label information of the transmit message
- Timestamp: Timestamp value of the transmit message
(When the TMTSCE bit is 1 in classical CAN mode)

Table 25.178 Transmit History Data Buffer Numbers

| Buffer Type Buffer No. | 001 _B | 010 _B | 100 _B |
|---------------------------|-----------------------------|---|---|
| 0000 _B | Transmit buffer 16 × m + 0 | Buffer numbers of the transmit buffer linked to the transmit/receive FIFO buffer by the CFTML[3:0] bits in the RSCFDn(CFD)CFCCk register (k = 0 to 5) | Buffer numbers of the transmit buffer allocated to the transmit queue that performed transmission |
| 0001 _B | Transmit buffer 16 × m + 1 | | |
| 0010 _B | Transmit buffer 16 × m + 2 | | |
| 0011 _B | Transmit buffer 16 × m + 3 | | |
| 0100 _B | Transmit buffer 16 × m + 4 | | |
| 0101 _B | Transmit buffer 16 × m + 5 | | |
| 0110 _B | Transmit buffer 16 × m + 6 | | |
| 0111 _B | Transmit buffer 16 × m + 7 | | |
| 1000 _B | Transmit buffer 16 × m + 8 | | |
| 1001 _B | Transmit buffer 16 × m + 9 | | |
| 1010 _B | Transmit buffer 16 × m + 10 | | |
| 1011 _B | Transmit buffer 16 × m + 11 | | |
| 1100 _B | Transmit buffer 16 × m + 12 | | |
| 1101 _B | Transmit buffer 16 × m + 13 | | |
| 1110 _B | Transmit buffer 16 × m + 14 | | |
| 1111 _B | Transmit buffer 16 × m + 15 | | |

Label data is used to identify each message. Unique label data can be added to each message transmitted from a transmit buffer, transmit queue, or transmit/receive FIFO buffer.

The timestamp value is fetched from the timestamp counter at the SOF (start of frame) timing of the message. For details about the timestamp counter, see section 25.7.1.6, Timestamp.

Transmit history data can be read from the RSCFDn(CFD)THLACCm register. If an attempt is made to store new transmit history data while the buffer is full, the buffer overflows and the new data is discarded.

25.9 Gateway Function

When a transmit/receive FIFO buffer is set to gateway mode, receive messages can be transmitted from an arbitrary channel without CPU intervention.

When the CFM[1:0] bits in the RSCFDn(CFD)CFCCk register are set to 10_B (gateway mode) for the transmit/receive FIFO buffer selected by the RSCFDn(CFD)GAFLP1_j register of a channel being used for transmission, messages that pass through filter processing according to the receive rule are stored in the specified transmit/receive FIFO buffer and are automatically transmitted from the buffer.

Messages stored in a transmit/receive FIFO buffer are transmitted sequentially on a first-in, first-out basis. Only the message to be transmitted next becomes the target of transmit priority determination.

Transmit/receive FIFO buffers in the gateway mode are disabled by setting the CFE bit in the RSCFDn(CFD)CFCCk register to 0 and the CFEMP flag becomes 1 according to the timing below.

- The transmit/receive FIFO buffer becomes empty immediately when the message in it is not being transmitted and will not to be transmitted next.
- The transmit/receive FIFO buffer becomes empty after transmission completion, CAN bus error detection, or arbitration-lost when the message in it is being transmitted or will be transmitted next.

When the CFE bit is cleared to 0, all messages in transmit/receive FIFO buffers are lost and messages can no longer be stored in transmit/receive FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

25.9.1 CAN-CANFD Gateway (Only in CANFD Mode)

When the gateway function is used in CANFD mode, a frame to be transmitted can be replaced with a classical CAN frame or a CANFD frame.

Setting the GWEN bit in the RSCFDnCFDCmFDCFG register to 1 enables the CAN-CANFD gateway. The FDF and BRS bits in the transmit frame can be selected by the GWFDF and GWBRS bits in the RSCFDnCFDCmFDCFG register. When the DLC value of the received CAN frame is 1001_B or more and the GWFDF bit is 1 (CANFD frame), the DLC value is replaced with 1000_B.

When the CAN-CANFD gateway is enabled, do not perform routing for the following frames.

- CANFD frames with a payload length of more than 8 bytes
- Remote frames

When the CAN-CANFD gateway is enabled, the following frame should be transmitted in the channel by setting of GWFDF.

- When GWFDF bit is set to 0, only classical CAN frames should be transmitted.
- When GWFDF bit is set to 1, only CANFD frames should be transmitted.

25.10 Test Function

The test function is classified into communication tests and global tests.

- Communication tests: Performed for each channel.
 - Standard test mode
 - Listen-only mode
 - Self-test mode 0 (external loopback mode)
 - Self-test mode 1 (internal loopback mode)
 - Restricted operation mode (only in CANFD mode)
- Global tests: Performed for the entire module
 - RAM test (read/write test)
 - Inter-channel communication test [CRC error test enabled]

25.10.1 Standard Test Mode

CRC tests are enabled in standard test mode. The CRC value calculated by the RS-CANFD module based on the transmit message or receive message is stored in the register. This CRC value is stored in the CRCREG[14:0] bits in the RSCFDn(CFD)CmERFL register when the message is a classical CAN frame (CRC length = 15 bits) or in the CRCREG[20:0] bits in the RSCFDnCFDCmFDCRC register when the message is a CANFD frame (CRC length = 17 or 21 bits). Use the inter-channel communication test function for CRC error tests. For details, see section 25.10.6.1, CRC Error Test.

25.10.2 Listen-Only Mode

Listen-only mode allows reception of data frames and remote frames. Only recessive bits are transmitted on the CAN bus, and the ACK bit, overload flag, and active error flag are not transmitted.

Listen-only mode is available for detecting the communication speed.

Do not make a transmit request from any buffer or queue in listen-only mode.

Figure 25.12 shows the connection when listen-only mode is selected.

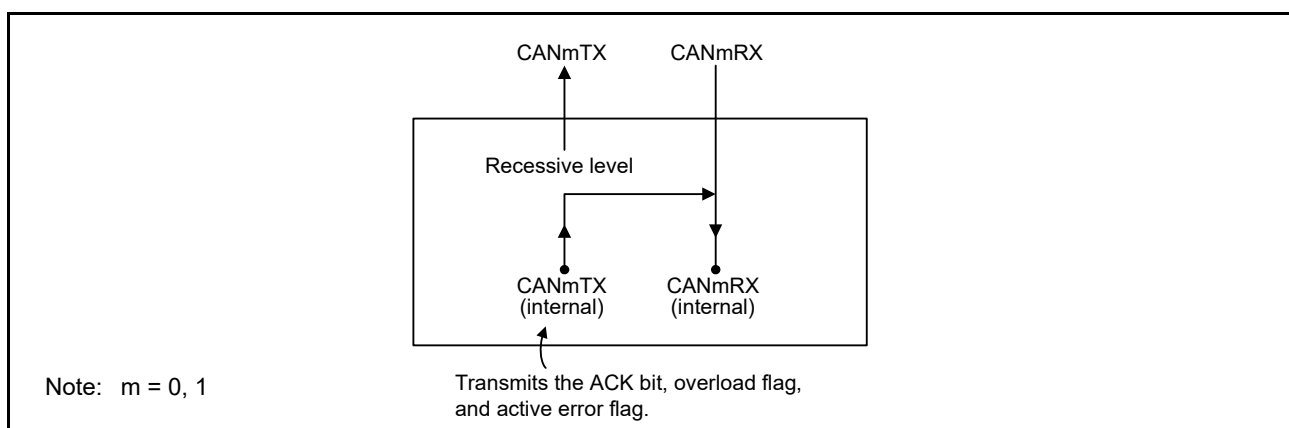

Figure 25.12 Connection when Listen-Only Mode is Selected

25.10.3 Self-Test Mode (Loopback Mode)

In self-test mode, transmitted messages are compared with the receive rule of the own channel and the messages are stored in a buffer if they have passed through the filter processing. Messages transmitted from other CAN nodes are compared only with the receive rule for which the GAFLLB bit in the RSCFDn(CFD)GAFLIDj register ($j = 0$ to 15) is set to 0 (when a message transmitted from another CAN node is received).

If the mirror function and self-test mode are both enabled, the self-test mode setting takes precedence.

25.10.3.1 Self-Test Mode 0 (External Loopback Mode)

Self-test mode 0 is used to perform a loopback test within a channel including the CAN transceiver.

In self-test mode 0, transmitted messages are handled as messages received through the CAN transceiver and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.

Figure 25.13 shows the connection when self-test mode 0 is selected.

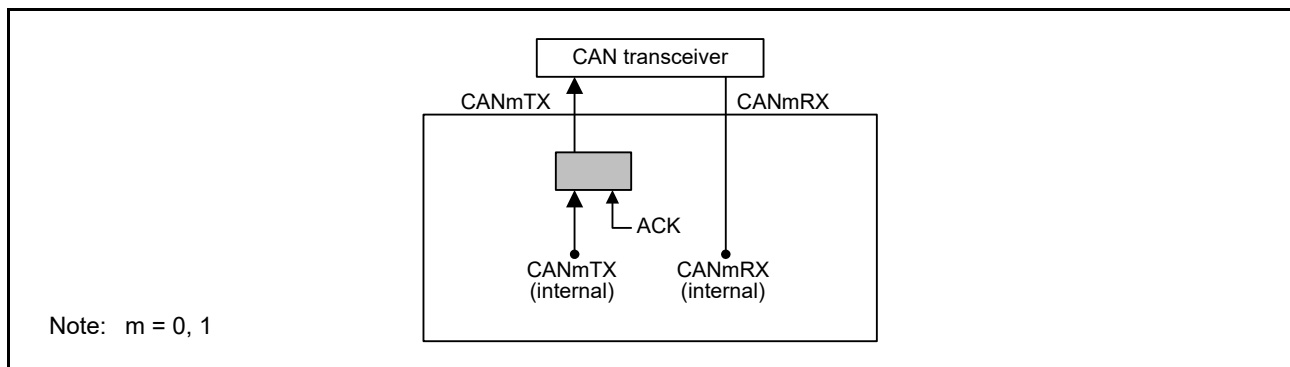

Figure 25.13 Connection when Self-Test Mode 0 is Selected

25.10.3.2 Self-Test Mode 1 (Internal Loopback Mode)

In self-test mode 1, transmitted messages are handled as received messages and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.

In self-test mode 1, internal feedback from the internal CANmTX pin ($m = 0, 1$) to the internal CANmRX pin is performed. The external CANmRX pin input is isolated. The external CANmTX pin outputs only recessive bits.

Figure 25.14 shows the connection when self-test mode 1 is selected.

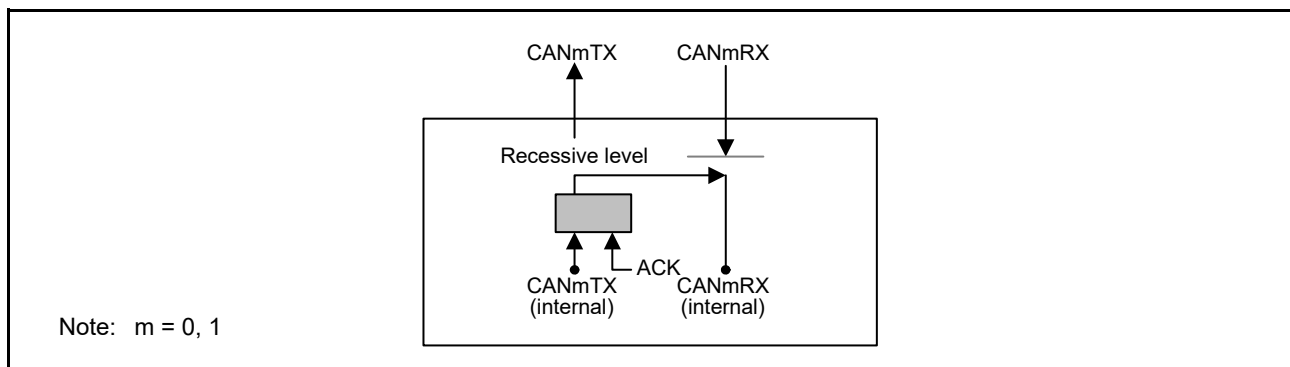

Figure 25.14 Connection when Self-Test Mode 1 is Selected

25.10.4 Restricted Operation Mode (Only in CANFD Mode)

In restricted operation mode, an ACK bit is generated when a valid data frame and a remote frame have been received, but these frames are not transmitted even if an error frame or an overload frame transmit condition is detected. When a condition is detected, operation is suspended until the bus idle state comes for resynchronization with the CAN communication. The receive error counter (REC) and the transmit error counter (TEC) do not change due to an error. A desired transmission request can be made for transmission without restrictions.

25.10.5 RAM Test

The RAM test function allows accesses to all CAN RAM addresses.

When the RAM test function is used, the RAM is divided into pages of 256 bytes each. RAM test page is set by the RTMPS[6:0] bits in the RSCFDn(CFD)GTSTCFG register. Data in the set page can be read from and written to the RSCFDn(CFD)RPGACCr register (r = 0 to 63). The available total RAM size is 5120 bytes (1400_H) in classical CAN mode or 7104 bytes (1BC0_H) in CANFD mode. Do not access the RAM area higher than the 192th byte on the last page (the setting of the RTMPS bit is 1B_H) in CANFD mode.

25.10.6 Inter-Channel Communication Test

The inter-channel communication test function allows communication test by internally connecting CAN channels to each other. During this test, channels are isolated from the external CAN bus.

Before starting data transmission/reception in channel communication mode, make transmission/reception settings for each channel.

Figure 25.15 shows the connection for inter-channel communication test.

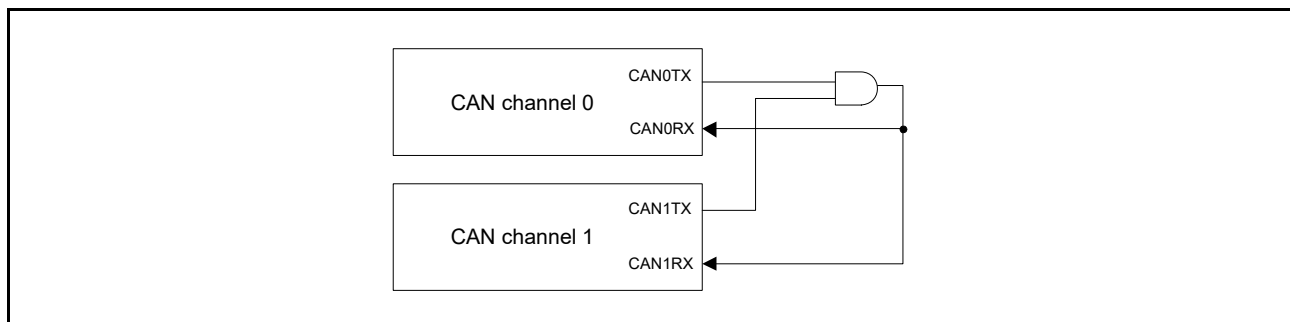

Figure 25.15 Connection for Inter-Channel Communication Test

25.10.6.1 CRC Error Test

A CRC error test is enabled during an inter-channel communication test. The following shows an example of channel 0 CRC error test procedure during a communication test between channel 0 and channel 1.

Preconditions

- Inter-channel communication test is enabled.
- Channel 0 and channel 1 are in standard test mode.

Procedure

1. Make a setting to send a message from the transmit buffer p of channel 1.
2. Set the CRCT bit in the RSCFDn(CFD)C0CTR register to 1 (to enable inversion of the first bit in the received ID field).
3. Set the TMTR bit in the RSCFDn(CFD)TMCp register to 1 (to issue a transmission request to the transmit buffer p of channel 1).
4. Wait for occurrence of a CAN0 error interrupt due to a channel bus error.
5. Read the CRCREG[14:0] bits in the RSCFDn(CFD)CmERFL register or the CRCREG[20:0] bits in the RSCFDnCFDCmFDCRC register of channel 0 and channel 1, and confirm that the CRC values are different on the transmission and the reception side.
6. Confirm that the CERR bit in RSCFDm(CFD)C0ERFL is 1 (CRC error detected).

The CRC error test function generates an incorrect CRC value by inverting the first bit in the received ID field.

Therefore, note that not a CRC error but a stuff error (continuous 6-bit data of the same level) is detected when a message in which ID's upper 5-bit value is 10000B or ID's upper 6-bit value is 011111B is received.

The CRC generation circuit of the RS-CANFD module is contained in the protocol controller of each channel. Another CRC calculation test is not necessary during transmission because the same circuit is used for both transmission and reception.

25.11 RS-CANFD Setting Procedure

25.11.1 Initial Settings

The RS-CANFD module initializes the CAN RAM after the MCU is reset. The RAM initialization time is 2530 cycles of the pclk. The GRAMINIT flag in the RSCFDn(CFD)GSTS register is set to 1 (CAN RAM initialization is ongoing) during the RAM initialization and is cleared to 0 (CAN RAM initialization is finished) when the initialization is completed. Make CAN settings after the GRAMINIT flag is cleared to 0. Figure 25.16 shows the CAN setting procedure after the MCU is reset.

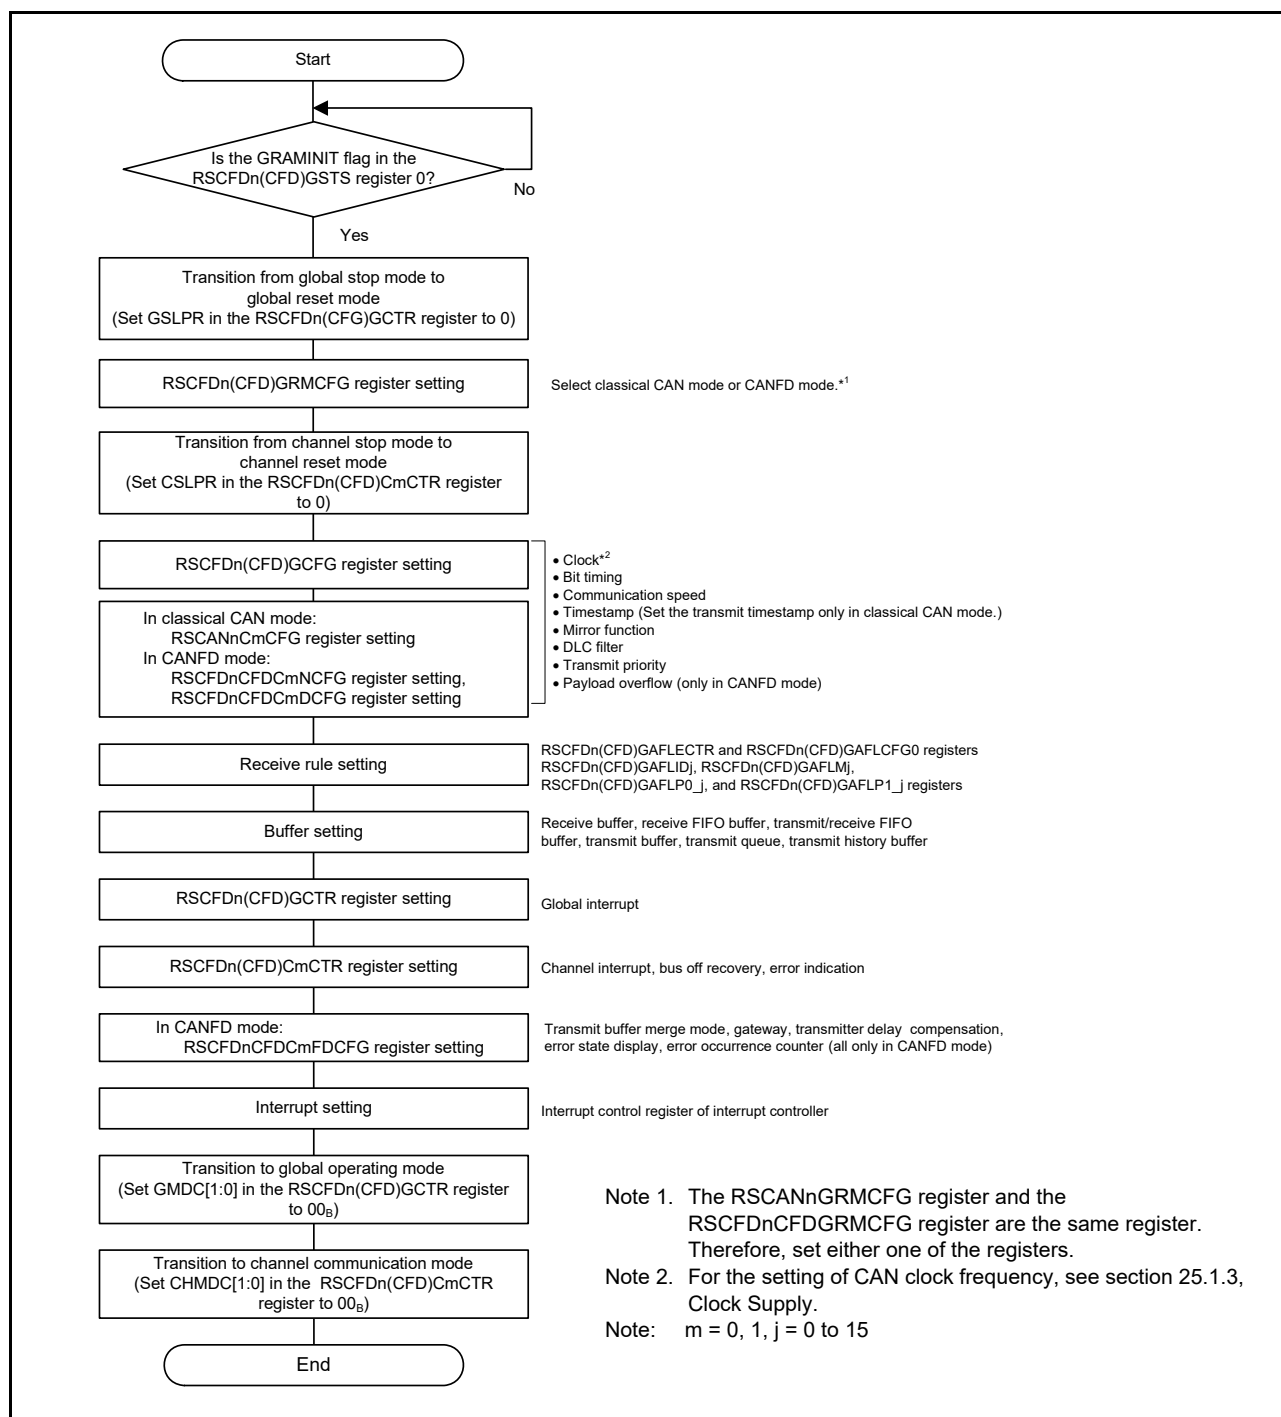

Figure 25.16 CAN Setting Procedure after the MCU is Reset

25.11.1.1 Clock Setting

Set the CAN clock (fCAN) as a clock source of the RS-CANFD module. Select the clk_xincan or clk_c using the DCS bit in the RSCFDn(CFD)GCFG register.

25.11.1.2 Bit Timing Setting

In the CAN protocol, one bit of a communication frame consists of three segments SS, TSEG1, and TSEG2, of which two segments TSEG1 and TSEG2 can be set by the corresponding registers for each channel. In classical CAN mode, set these two segments in the RSCANnCMCFG register. Two bit rates (nominal bit rate and data bit rate) are provided for CANFD mode. Set the nominal bit rate in the RSCFDnCFDCmNCFG register and set the data bit rate in the RSCFDnCFDCmDCFG register. Sample point timing can be determined by setting these two segments. This timing can be adjusted in units of 1 Time Quantum (hereafter referred to as Tq). A single Tq is the cycle of clock obtained by dividing the clock selected by the DCS bit in the RSCFDn(CFD)GCFG register. Set a division ratio by the BRP[9:0] bits in the RSCANnCMCFG register in classical CAN mode (CANmTq clock), and by the NBRP[9:0] bits in the RSCFDnCFDCmNCFG register and the DBRP[7:0] bits in the RSCFDnCFDCmDCFG register in CANFD mode (CANmTq(N) clock and CANmTq(D) clock). Be sure to specify the same values for both NBRP[9:0] and DBRP[7:0]. To specify different values for the nominal bit rate and the data bit rate, change the values of the RSCFDnCFDCmNCFG.NTSEG1 and NTSEG2 bits and RSCFDnCFDCmDCFG.DTSEG1 and DTSEG2 bits, respectively.

When the TDCE bit is set to 1 (Transmitter delay compensation is enabled) in the RSCFDnCFDCmFDCFG register, set the equal value of 1 or less to the bits NBRP[9:0] and DBRP[7:0].

Figure 25.17 shows the bit timing chart. Table 25.179 shows an example of bit timing setting.

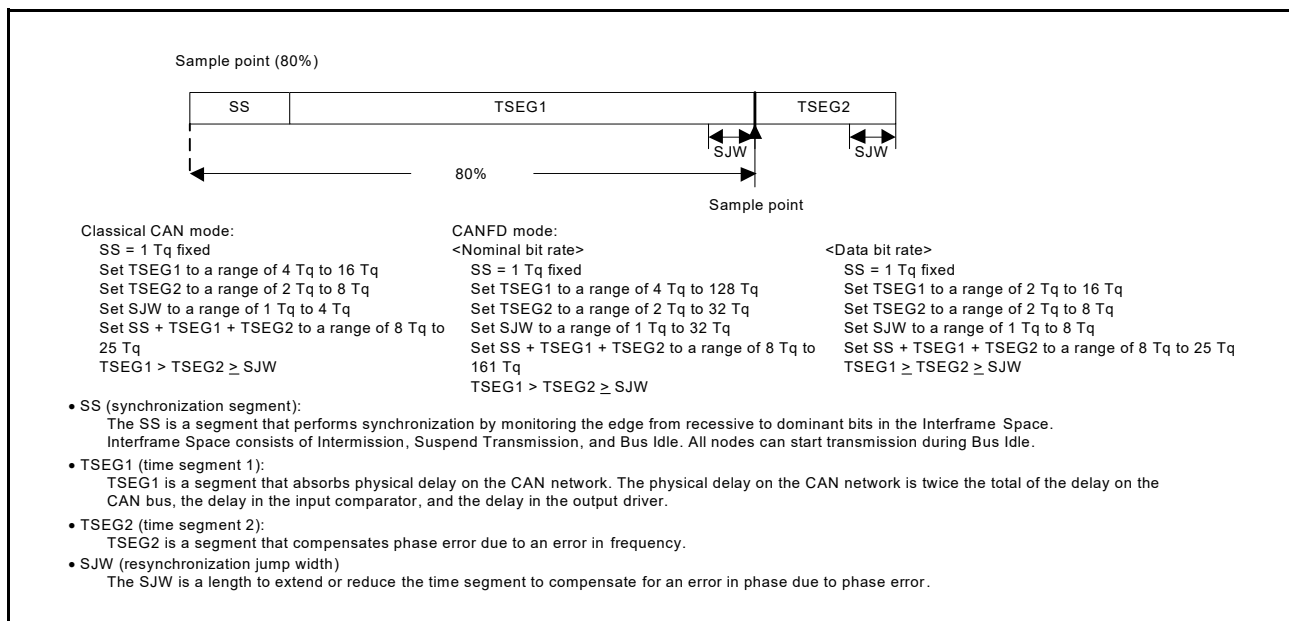

Figure 25.17 Bit Timing Chart

Table 25.179 Example of Bit Timing Setting

| 1 Bit | Set Value (Tq) | | | | Sample Point (%) Note: See Figure 25.17. |
|---------|----------------|-------|-------|-----|---|
| | SS | TSEG1 | TSEG2 | SJW | |
| | 1 | 4 | 3 | 1 | 62.50 |
| 8 Tq | 1 | 5 | 2 | 1 | 75.00 |
| | 1 | 6 | 3 | 1 | 70.00 |
| 10 Tq | 1 | 7 | 2 | 1 | 80.00 |
| | 1 | 10 | 5 | 1 | 68.75 |
| 16 Tq | 1 | 11 | 4 | 1 | 75.00 |
| | 1 | 12 | 7 | 1 | 65.00 |
| 20 Tq | 1 | 13 | 6 | 1 | 70.00 |
| 50 Tq*1 | 1 | 39 | 10 | 4 | 80.00 |

Note 1. Only in CANFD mode

25.11.1.3 Communication Speed Setting

Set the CAN communication speed for each channel using the fCAN, baud rate prescaler division value, and Tq count per bit time. For CANFD mode, set two types of transmission rate (arbitration phase and data phase) for each channel. Figure 25.18 shows the CAN clock control block diagram, and Table 25.180 and Table 25.181 show examples of the communication speed setting.

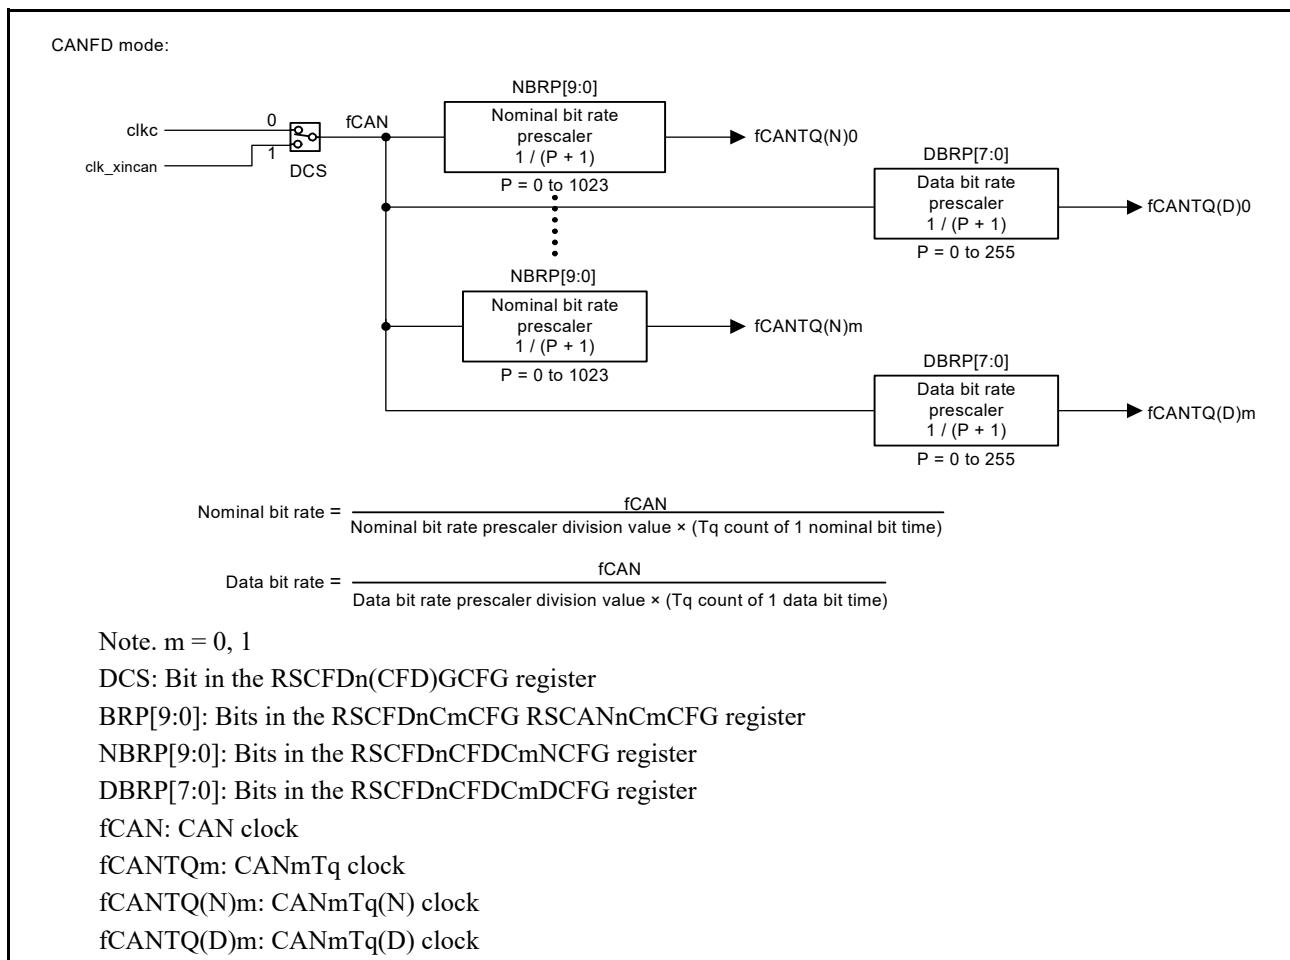

Figure 25.18 CAN Clock Control Block Diagram

Table 25.180 Example of Communication Speed Setting (Classical CAN Mode)

| Communication Speed | fCAN | | |
|---------------------|-------------------------|------------------------|-----------------------|
| | 32 MHz | 16 MHz | 8 MHz |
| 1 Mbps | 8 Tq (4) 16 Tq (2) | 8 Tq (2) 16 Tq (1) | 8 Tq (1) |
| 500 Kbps | 8 Tq (8) 16 Tq (4) | 8 Tq (4) 16 Tq (2) | 8 Tq (2) 16 Tq (1) |
| 250 Kbps | 8 Tq (16) 16 Tq (8) | 8 Tq (8) 16 Tq (4) | 8 Tq (4) 16 Tq (2) |
| 125 Kbps | 8 Tq (32) 16 Tq (16) | 8 Tq (16) 16 Tq (8) | 8 Tq (8) 16 Tq (4) |

Table 25.181 Example of Transmission Rate Setting (Nominal Bit Rate and Data Bit Rate in CANFD Mode)

| Communication Speed | fCAN | |
|---------------------------|----------------------------|----------------------------|
| | 32 MHz | 16 MHz |
| Nominal bit rate 1 Mbps | Nominal bit rate 32 Tq (1) | None |
| Data bit rate 4 Mbps | Data bit rate 8 Tq (1) | |
| Nominal bit rate 500 Kbps | Nominal bit rate 64 Tq (1) | Nominal bit rate 32 Tq (1) |
| Data bit rate 2 Mbps | Data bit rate 16 Tq (1) | Data bit rate 8 Tq (1) |

Note: Values in () are baud rate prescaler division values.

25.11.1.4 Receive Rule Setting

Receive rules can be set using receive rule-related registers.

Up to 16 receive rules can be registered per page. Specify pages 0 to 23 (for 6-channel unit) by the AFLPN[4:0] bits in the RSCFDn(CFD)GAFLECTR register. Set receive rule table write enable/disable using the AFLDAE bit.

Figure 25.19 shows the receive rule setting procedure.

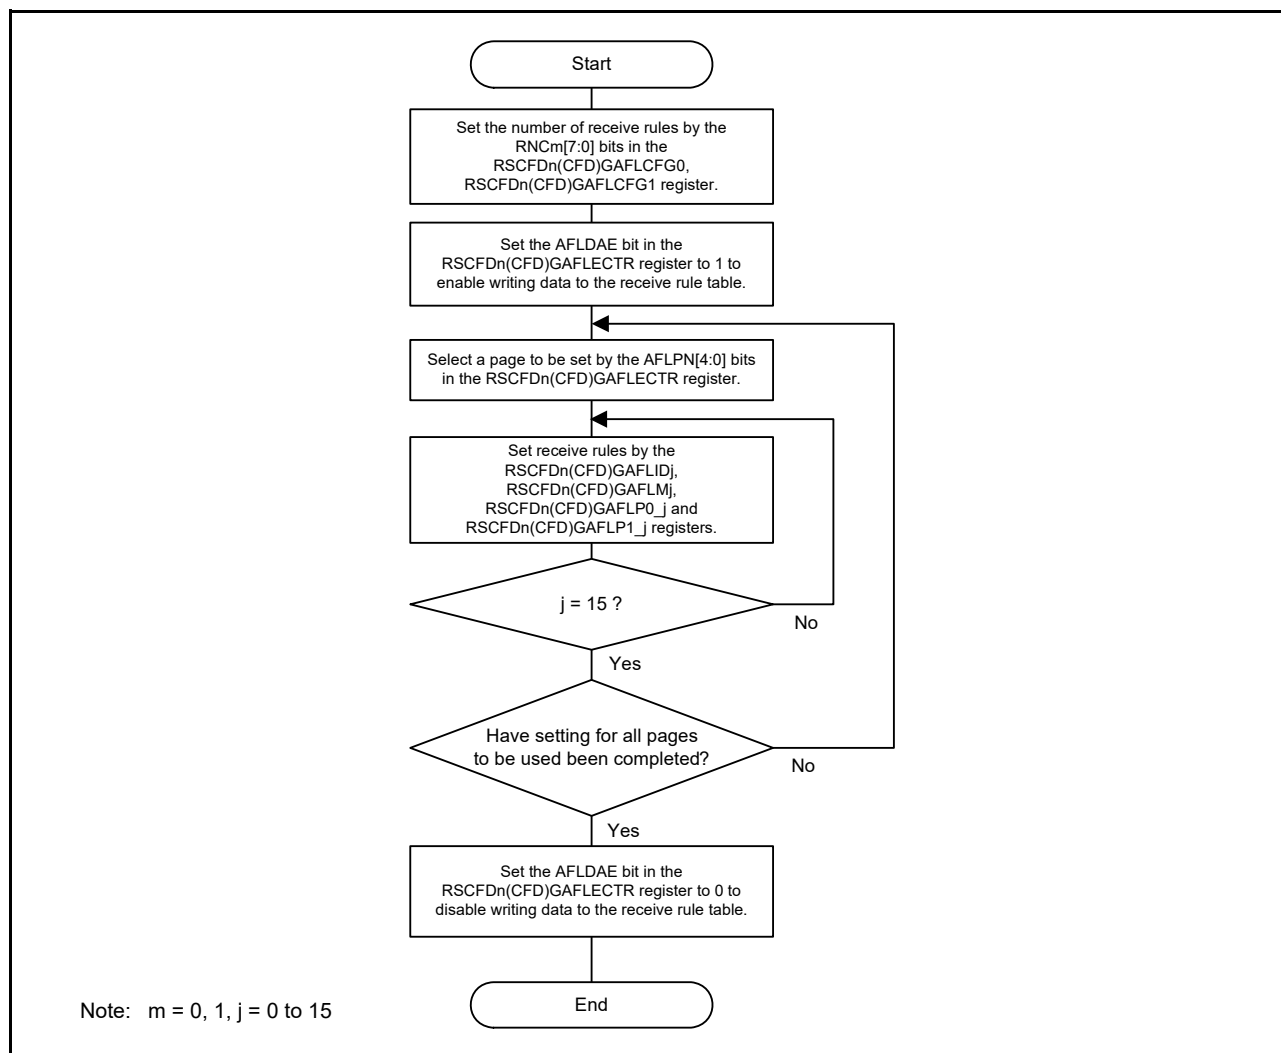

Figure 25.19 Receive Rule Setting Procedure

25.11.1.5 Buffer Setting

Set the number of buffers to be used (number of messages to be stored) and interrupt sources. Also set the payload storage size for CANFD mode. For transmit/receive FIFO buffers that are set to transmit mode, set transmit buffers to be linked.

In classical CAN mode, up to 2048 bytes of the RAM can be used in receive buffers and FIFO buffers. Up to 128 buffers are available, and 16 bytes are used per buffer. Configure the buffers so that the following conditions are met.

Number of receive buffers + total number of depth of receive FIFO buffers \times +
total number of depth of transmit/receive FIFO buffers $k \leq 128$ buffers

In CANFD mode, up to 3584 bytes of the RAM can be used in receive buffers and FIFO buffers. Configure the buffers so that the following conditions are met.

Number of receive buffers \times (12 + payload storage size) + total of (number of depth \times (12 + payload storage size))
of receive FIFO buffers \times + total of (number of depth \times (12 + payload storage size)) of transmit/receive FIFO
buffers $k \leq 3584$ bytes

Figure 25.20 shows the buffer configuration. Figure 25.21 shows the buffer setting procedure.

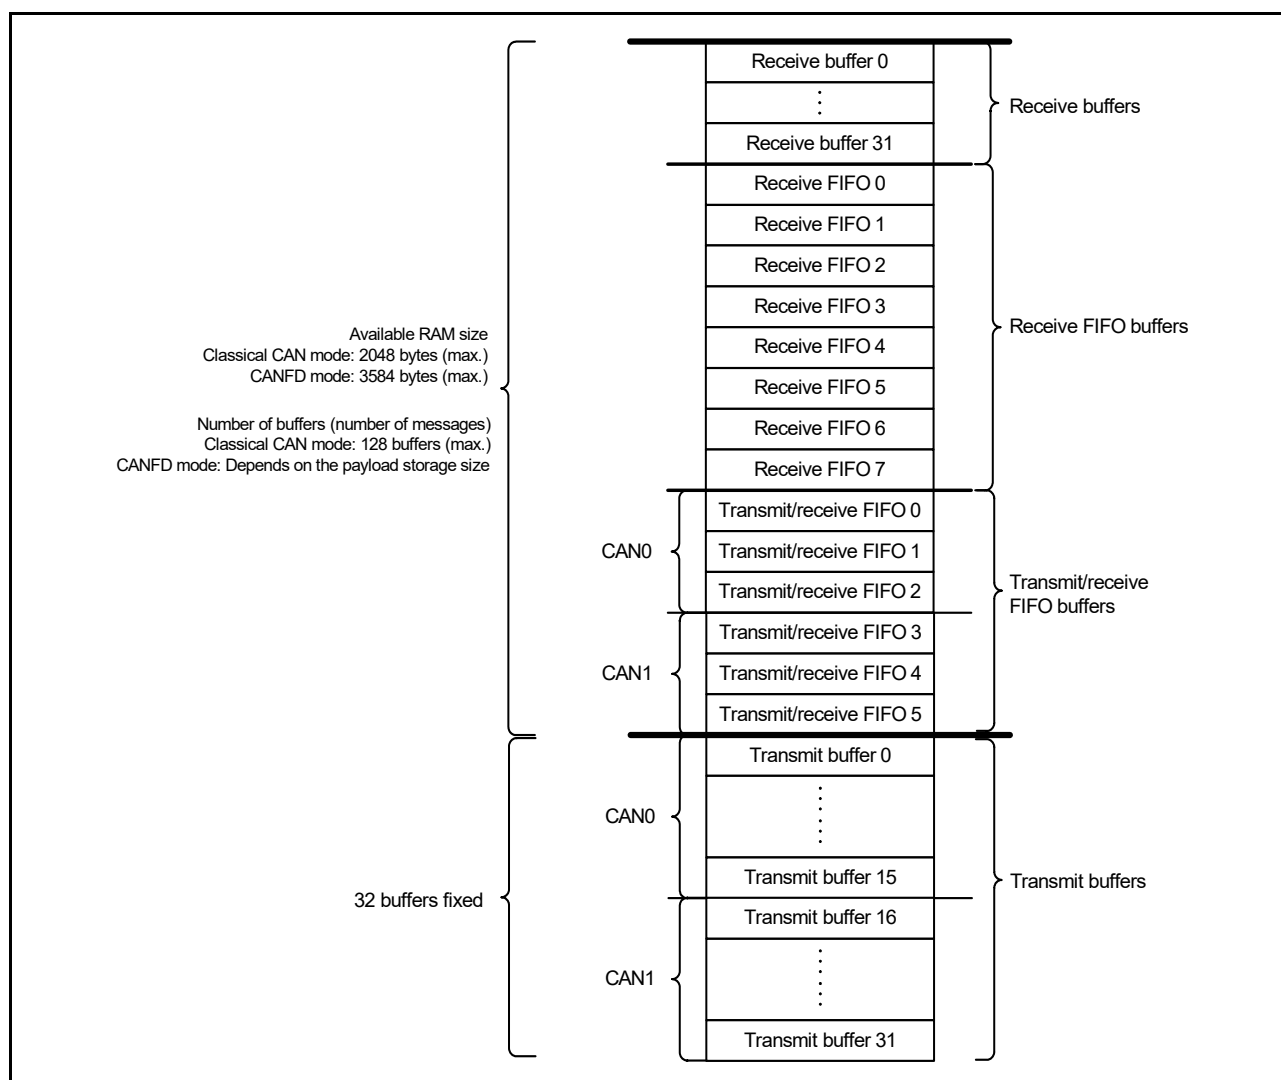

Figure 25.20 Buffer Configuration

Note: Receive buffers, receive FIFO buffers, transmit/receive FIFO buffers, and transmit buffers are located in succession.

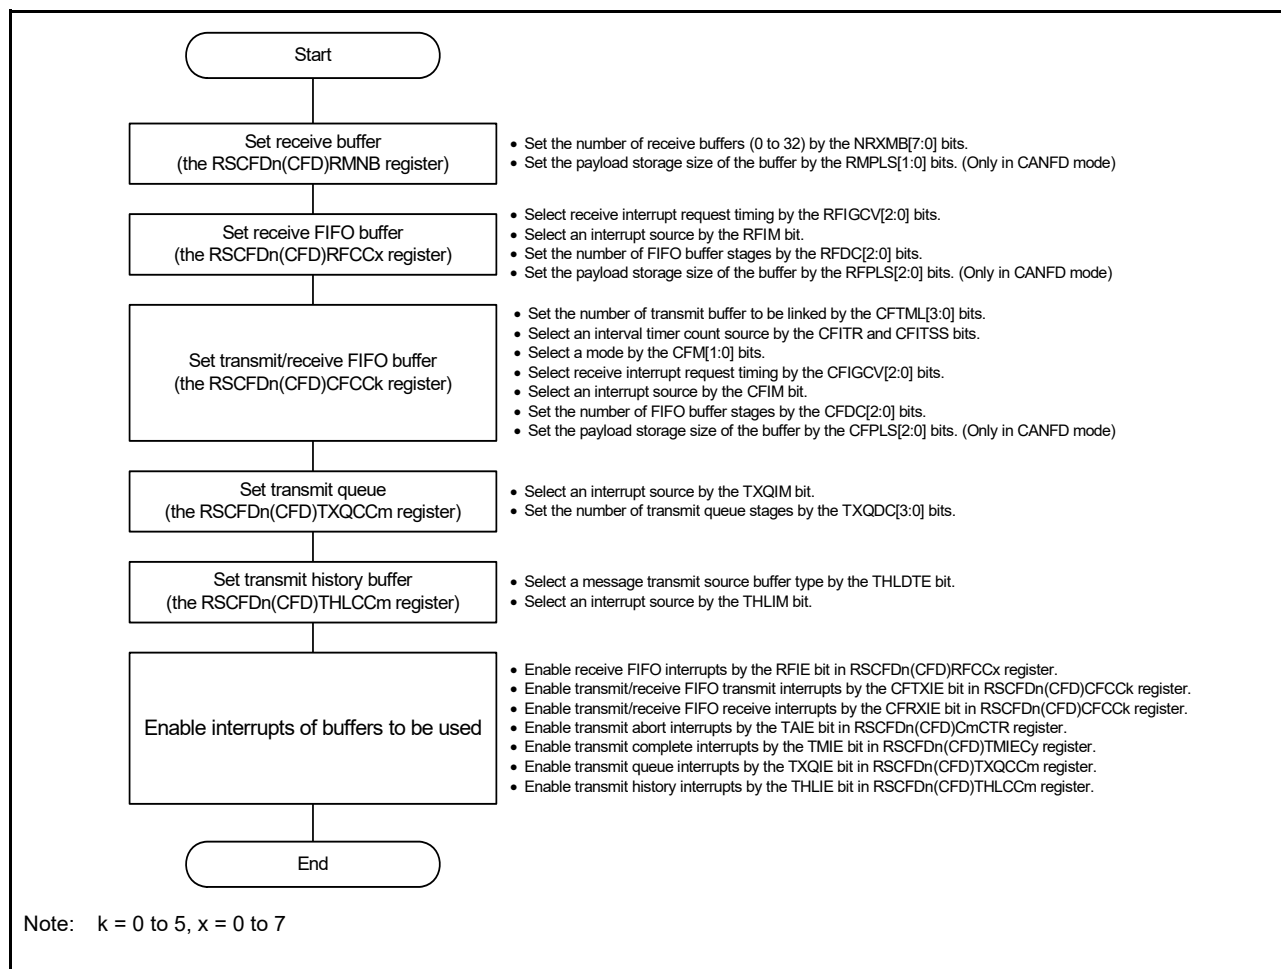

Figure 25.21 Buffer Setting Procedure

25.11.1.6 Transmitter Delay Compensation (Only in CANFD Mode)

A high baud rate is used in CANFD mode. Transmitter delay compensation is provided as a function to accept propagation delay in this case.

To use this function, set the TDCE bit in the RSCFDnCFDCmFDCFG register to 1. Also set the secondary sample point (SSP) timing used in the data phase by the TDCOC bit and TDCO[6:0] bits in the RSCFDnCFDCmFDCFG register. When the TDCOC bit is 0, the SSP timing equals the total value of the delay measured by the RS-CANFD module and the TDCO[6:0] value. (This value is rounded off to the nearest integer of T_q .) Usually, the TDCO[6:0] value must be equal to $SS + TSEG1$, the sample point timing.

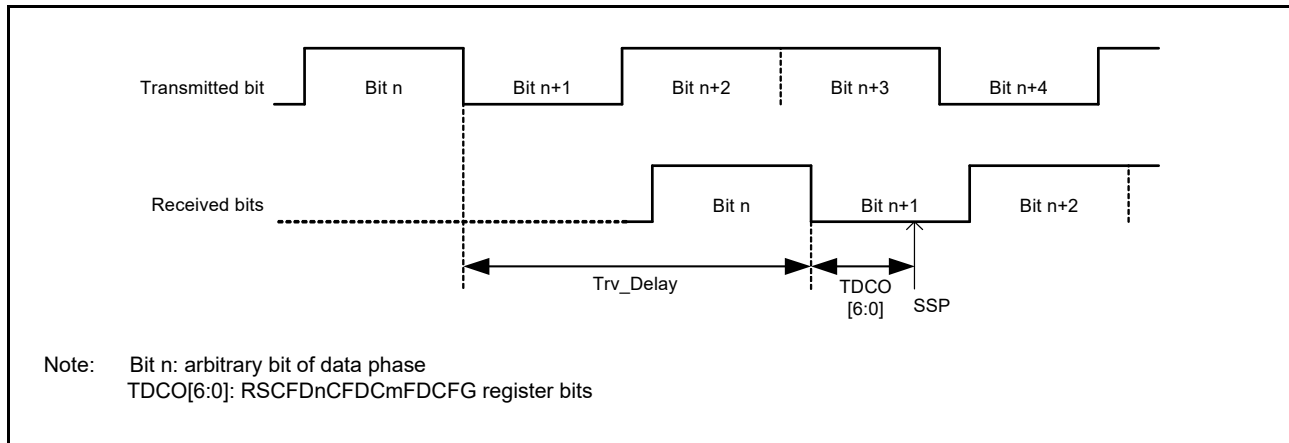

Figure 25.22 SSP Timing

When the TDCOC bit is 1, the SSP timing is determined only by the TDCO[6:0] value. (When the DBRP[7:0] value in the RSCFDnCFDCmDCFG register is larger than 0, the TDCO[6:0] value is also rounded off to the nearest integer of T_q .)

The RS-CANFD module compensates a delay up to $(3 \text{ CANm bit time} - 2 T_q)$. (Both CANm bit time and T_q are data bit rate values.)

When the TDCE bit in RSCFDnCFDCmFDCFG register is 1 (transmitter delay compensation is enabled), set bits NBRP[9:0] and DBRP[7:0] to the same value that is less than 1.

25.11.2 Reception Procedure

25.11.2.1 Receive Buffer Reading Procedure

When the processing to store received messages in a receive buffer starts, the RMNSq flag in the RSCFDn(CFD)RMNDy register ($y = 0$, $q = 0$ to 31) is set to 1 (receive buffer q contains a new message). Messages can be read from registers RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDnCFDRMFDSTSq (only in CANFD mode), and RSCFDn(CFD)RMDFb_q ($b = 0$ or 1 in classical CAN mode, $b = 0$ to 4 in CANFD mode). Figure 25.23 shows the receive buffer reading procedure. This procedure ensures the consistency of messages read from registers RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDnCFDRMFDSTSq, and RSCFDn(CFD)RMDFb_q.

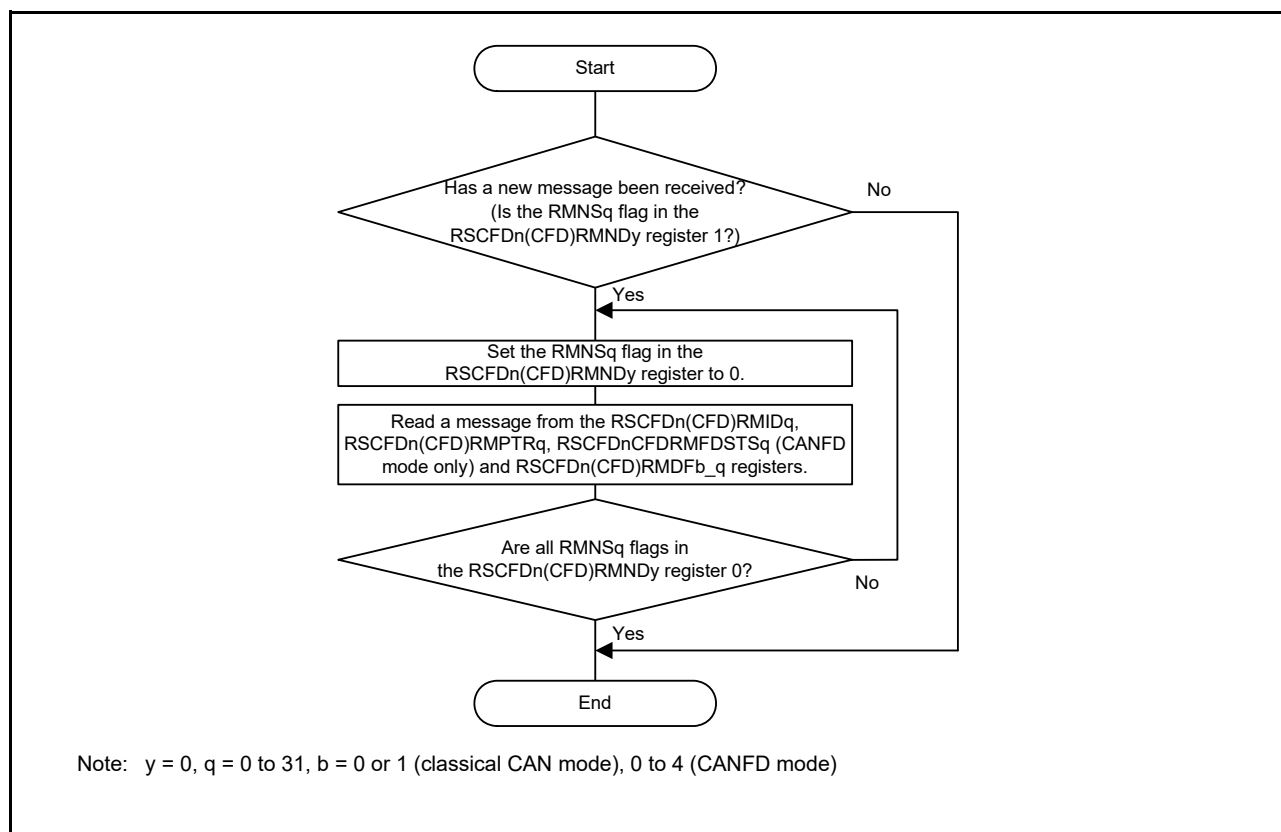

Figure 25.23 Receive Buffer Reading Procedure

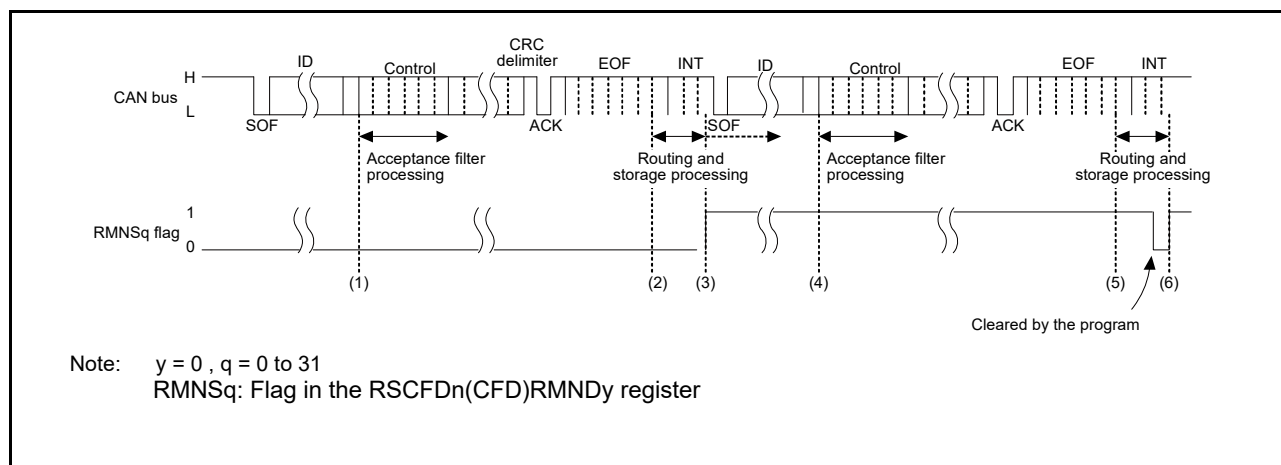

Figure 25.24 Receive Buffer Reception Timing Chart

- (1) When the ID field in a message has been received, the acceptance filter processing starts.
- (2) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.
- (3) When the message has passed through the DLC filter processing, the processing to store the message in the specified receive buffer starts.

When the message storage processing starts, the RMNSq flag in the corresponding RSCFDn(CFD)RMNDy register is set to 1 (the receive buffer contains a new message). If other channels are performing filter processing or transmit priority determination processing, the routing processing and the storage processing may be delayed.
- (4) When the ID field of the next message has been received, the acceptance filter processing starts.
- (5) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.
- (6) When the corresponding RMNSq flag is cleared to 0 (the receive buffer contains no new message), this flag is set to 1 again when the message storage processing starts. Even if the RMNSq flag remains 1, a new message is overwritten to the receive buffer. The RMNSq flag should not be cleared to 0 during storage of messages.

25.11.2.2 FIFO Buffer Reading Procedure

When received messages have been stored in one or more receive FIFO buffers or a transmit/receive FIFO buffer that is set to receive mode or gateway mode, the corresponding message count display counter (RFMC[7:0] bits in the RSCFDn(CFD)RFSTSx register (x = 0 to 7) or CFMC[7:0] bits in the RSCFDn(CFD)CFSTSk register (k = 0 to 17)) is incremented. At this time, when the RFIE bit (receive FIFO interrupt is enabled) in the RSCFDn(CFD)RFCCx register or the CFRXIE bit (transmit/receive FIFO receive interrupt is enabled) in the RSCFDn(CFD)CFCCk register is set to 1, an interrupt request is generated. Received messages can be read from the RSCFDn(CFD)RFIDx, RSCFDn(CFD)RFPTRx, RSCFDn(CFD)RFFDSTSx (only in CANFD mode), and RSCFDn(CFD)RFDFd_x (d = 0 or 1 in classical CAN mode, d = 0 to 15 in CANFD mode) registers for receive FIFO buffers, or from the RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, RSCFDn(CFD)CFDCFFDCSTSk (only in CANFD mode), and RSCFDn(CFD)CFDFd_k registers for transmit/receive FIFO buffers. Messages in FIFO buffers can be read sequentially on a first-in, first-out basis.

When the message count display counter value matches the FIFO buffer depth (a value set by the RFDC[2:0] bits in the RSCFDn(CFD)RFCCx register or the CFDC[2:0] bits in the RSCFDn(CFD)CFCCk register), the RFFLL or CFFLL flag is set to 1 (the receive FIFO buffer is full).

When all messages have been read out of the FIFO buffer, the RFEMP flag in the RSCFDn(CFD)RFSTSx register or the CFEMP flag in the RSCFDn(CFD)CFSTSk register is set to 1 (the receive FIFO buffer contains no unread message (buffer empty)).

If the RFE bit or the CFE bit is cleared to 0 (no receive FIFO buffer is used) with the interrupt request flag (RFIF flag in the RSCFDn(CFD)RFSTSx register or CFRXIF flag in the RSCFDn(CFD)CFSTSk register) set to 1 (a receive FIFO interrupt request is present), the interrupt request flag is not automatically cleared to 0. The program must clear the interrupt request flag to 0.

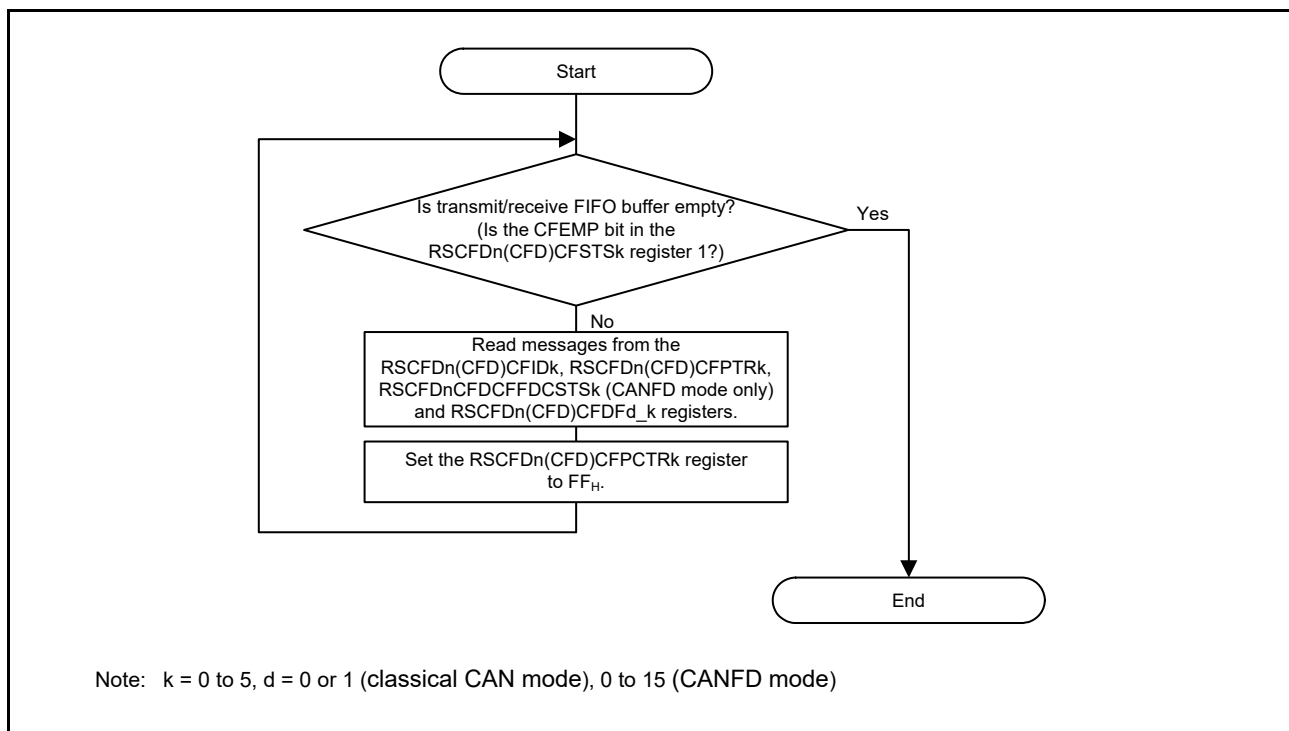

Figure 25.25 Transmit/Receive FIFO Buffer Reading Procedure

When reading a message in CANFD mode, do not read the RSCFDnCFDRFDFd_x or RSCFDnCFDCFDFd_k register corresponding to the area exceeding the payload storage size specified by the RFPLS[2:0] bits in the RSCFDnCFDRFCCx register or the CFPLS[2:0] bits in the RSCFDnCFDCFCCk register.

Table 25.182 Payload Storage Area of Receive FIFO Buffer

| Set RFPLS[2:0] Value | Payload Storage Size | Corresponding Data Field Registers |
|----------------------|----------------------|---------------------------------------|
| 000 _B | 8 bytes | RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF1_x |
| 001 _B | 12 bytes | RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF2_x |
| 010 _B | 16 bytes | RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF3_x |
| 011 _B | 20 bytes | RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF4_x |
| 100 _B | 24 bytes | RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF5_x |
| 101 _B | 32 bytes | RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF7_x |
| 110 _B | 48 bytes | RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF11_x |
| 111 _B | 64 bytes | RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF15_x |

Table 25.183 Payload Storage Area of Transmit/Receive FIFO Buffer

| Set CFPLS[2:0] Value | Payload Storage Size | Corresponding Data Field Registers |
|----------------------|----------------------|---------------------------------------|
| 000 _B | 8 bytes | RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF1_k |
| 001 _B | 12 bytes | RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF2_k |
| 010 _B | 16 bytes | RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF3_k |
| 011 _B | 20 bytes | RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF4_k |
| 100 _B | 24 bytes | RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF5_k |
| 101 _B | 32 bytes | RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF7_k |
| 110 _B | 48 bytes | RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF11_k |
| 111 _B | 64 bytes | RSCFDnCFDCFDF0_k to RSCFDnCFDCFDF15_k |

Figure 25.26 FIFO Buffer Reception Timing Chart

- (1) When the ID field in a message has been received, the acceptance filter processing starts.
- (2) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFCG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.
- (3) When the message has passed through the DLC filter processing and the CFE bit in the RSCFDn(CFD)CFCCk register is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCFDn(CFD)CFCCk register is 001_B or more, the message is stored in the transmit/receive FIFO buffer that is set to receive mode. The CFMC[7:0] value in the RSCFDn(CFD)CFSTSk register is incremented and becomes 01_H. When the CFIM bit in the RSCFDn(CFD)CFCCk register is set to 1 (a FIFO receive interrupt request is generated each time a message has been received), the CFRXIF flag in the RSCFDn(CFD)CFSTSk register is set to 1 (a transmit/receive FIFO receive interrupt request is present). The CFRXIF flag can be reset to 0 by the program.
- (4) When the ID field of the next message has been received, the acceptance filter processing starts.

- (5) Read received messages from the RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, and RSCFDn(CFD)CFDFd_k registers and write FF_H to the RSCFDn(CFD)CFPCTRk register. This causes the CFMC[7:0] bits in the RSCFDn(CFD)CFSTSk register to be decremented. When CFMC[7:0] becomes 00_H, the CFEMP flag in the RSCFDn(CFD)CFSTSk register becomes 1 (the transmit/receive FIFO buffer contains no message (buffer empty)).
- (6) When the message matches the receive rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.
- (7) The message is stored in the transmit/receive FIFO buffer set in receive mode when the message has passed through the DLC filter process if the CFE bit is set to 1 (transmit/receive FIFO buffers are used), and the CFDC[2:0] bits are set to 001_B or more. The CFMC[7:0] bit value is incremented by 1 to be 01_H. When the CFIM bit is set to 1 (an interrupt occurs each time a message has been received), the CFRXIF flag is set to 1 (a transmit/receive FIFO receive interrupt request is present).

The message is stored in the receive FIFO buffer if the RFE bit in the RSCFDn(CFD)RFCCx register is set to 1 (receive FIFO buffers are used), and the RFDC[2:0] bits in the RSCFDn(CFD)RFCCx register are set to 001_B or more. The RFMC[7:0] bits in the RSCFDn(CFD)RFSTSx register are set to 01_H by being incremented by 1. When the RFIM bit in the RSCFDn(CFD)RFCCx register is set to 1 (an interrupt occurs each time a message has been received), the RFIF flag in the RSCFDn(CFD)RFSTSx register is set to 1 (a receive FIFO interrupt request is present).

25.11.2.3 FIFO Buffer Reading Procedure by DMA Transfer

In CANFD mode, the following FIFO buffers can be read by DMA transfer.

- All receive FIFO buffers x ($x = 0$ to 7)
- The first transmit/receive FIFO buffer k allocated to channel m ($k = 3 \times m$, $m = 0, 1$)

The DMA enable bit (RFDMAEx or CFDMAEm bit in the RSCFDnCFDCDTC register) can be set at any time.

However, before setting the DMA enable bit to 1 (to enable DMA transfer requests), set the receive interrupt enable bit (RFIE bit in the RSCFDnCFDRFCCx register or CFRXIE bit in the RSCFDnCFDCFCCK register) of related FIFO buffers to 0 (to disable interrupts). When DMA transfer requests are enabled, do not write a value to the FIFO control register (RSCFDnCFDRFCCx register or RSCFDnCFDCFCCK register).

When an unread message is remaining in a DMA transfer-enabled FIFO buffer, a DMA transfer request trigger is generated. Specify the FIFO access register address for the transfer source address, and adjust the transfer size so that data can be read to the end of the payload storage area with a single trigger. The end of the payload storage area depends on the payload storage size specified by the RFPLS[2:0] bits in the RSCFDnCFDRFCCx register or the CFPLS[2:0] bits in the RSCFDnCFDCFCCK register.

After the end of the payload stored in the FIFO buffer has been read, the RFMC[7:0] value in the RSCFDnCFDRFSTSx register or the CFMC[7:0] value in the RSCFDnCFDCFSTSx register is automatically decremented. After that, if an unread message is remaining in the FIFO buffer, a trigger is generated again.

When the RFDMAEx or CFDMAEm bit is set to 0 (to disable DMA transfer requests) during DMA transfer, wait until the DMA transfer status (RFDMASTSx or CFDMASTSx bit in the RSCFDnCFDCDTSTS register) is cleared to 0 (DMA transfer disabled), and then start the next processing (enabling DMA transfer again etc.). When disabling DMA transfer, examine how to process a message remaining in the FIFO buffer and a newly arriving message. When the FIFO buffer is enabled, it continues to receive messages.

25.11.3 Transmission Procedure

25.11.3.1 Procedure for Transmission from Transmit Buffers

Figure 25.27 shows the procedure for transmission from transmit buffers.

Figure 25.28 shows a timing chart where messages are transmitted from two transmit buffers in the same channel and transmission has been successfully completed. Figure 25.29 shows a timing chart where messages are transmitted from two transmit buffers in the same channel and transmit abort has been completed.

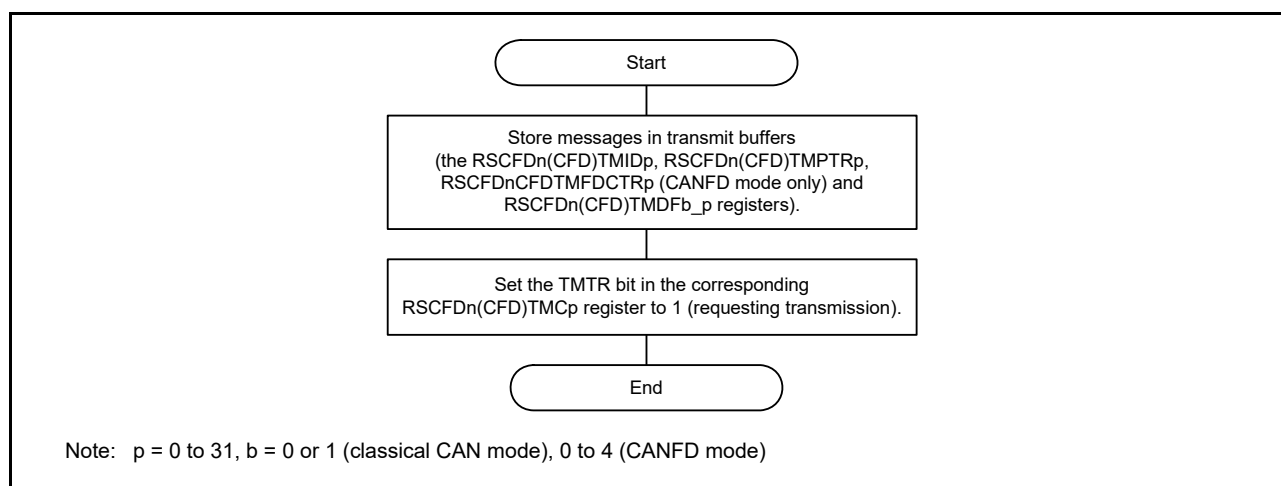

Figure 25.27 Procedure for Transmission from Transmit Buffers

In CANFD mode and transmit buffer merge mode, messages with a payload size of more than 20 bytes can be transmitted from transmit buffers $(16 \times m) + 0$ and transmit buffers $(16 \times m) + 3$. At this time, transmit buffers $(16 \times m) + 1$ to $(16 \times m) + 2$ and transmit buffers $(16 \times m) + 4$ to $(16 \times m) + 5$ are allocated as a payload storage area. Registers RSCFDnCFD(TM)IDp, RSCFDnCFD(TM)PTRp, and RSCFDnCFD(TM)FDCTRp corresponding to these buffers can be used as data field registers that can store 4-byte data bytes (payload) like the RSCFDnCFD(TM)DFb_p register. Table 25.184 shows message storage registers when transmitting a message with a payload size of more than 20 bytes from transmit buffer 0.

Table 25.184 Message Storage Registers in Transmit Buffer Merge Mode (Example of Transmit Buffer 0)

| Transmit Buffer | Offset from Base Address | Symbol | Register Function in Transmit Buffer Merge Mode |
|-------------------|--|--------------------------------------|--|
| Transmit buffer 0 | 4000 _H | RSCFDnCFDTMID0 | Transmit buffer 0 ID data, transmit history data store enable bit, RTR bit, and IDE bit |
| | 4004 _H | RSCFDnCFDTMPTR0 | Transmit buffer 0 label data and DLC data |
| | 4008 _H | RSCFDnCFDTMFDCTR0 | Transmit buffer 0 ESI bit, BRS bit, and FDF bit |
| | 400C _H to 401C _H | RSCFDnCFDTMDF0_0 to RSCFDnCFDTMDF4_0 | Transmit buffer 0 data bytes 0, 1, 2, and 3 to transmit buffer 0 data bytes 16, 17, 18, and 19 |
| Transmit buffer 1 | 4020 _H | RSCFDnCFDTMID1 | Transmit buffer 0 data bytes 20, 21, 22, and 23 |
| | 4024 _H | RSCFDnCFDTMPTR1 | Transmit buffer 0 data bytes 24, 25, 26, and 27 |
| | 4028 _H | RSCFDnCFDTMFDCTR1 | Transmit buffer 0 data bytes 28, 29, 30, and 31 |
| | 402C _H to 403C _H | RSCFDnCFDTMDF0_1 to RSCFDnCFDTMDF4_1 | Transmit buffer 0 data bytes 32, 33, 34, and 35 to transmit buffer 0 data bytes 48, 49, 50, and 51 |
| Transmit buffer 2 | 4040 _H | RSCFDnCFDTMID2 | Transmit buffer 0 data bytes 52, 53, 54, and 55 |
| | 4044 _H | RSCFDnCFDTMPTR2 | Transmit buffer 0 data bytes 56, 57, 58, and 59 |
| | 4048 _H | RSCFDnCFDTMFDCTR2 | Transmit buffer 0 data bytes 60, 61, 62, and 63 |
| | 404C _H to 405C _H | RSCFDnCFDTMDF0_2 to RSCFDnCFDTMDF4_2 | Not used |

Figure 25.28 Transmit Buffer Transmission Timing Chart (Transmission Completed Successfully)

- (1) When the TMTR bit in the RSCFDn(CFD)TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmit buffer. If transmit buffer a is determined to be the highest-priority transmit buffer, the TMTSTS flag in the corresponding RSCFDn(CFD)TMSTSa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.
- (2) When a transmit request from a buffer is present, the priority determination starts at the first bit of CRC field for the next transmission. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.
- (3) When transmission completes successfully, the TMTRF[1:0] flag in the RSCFDn(CFD)TMSTSa register is set to 10_B (transmission has been completed (without transmit abort request)) and the TMTSTS flag and the TMTR bit in the RSCFDn(CFD)TMCa register are cleared to 0. When the TMIEa bit in the RSCFDn(CFD)TMIEC0 register is 1 (transmit buffer interrupt is enabled), a CAN0 transmit complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B (transmission is in progress or no transmit request is present).
- (4) Before starting the next transmission, set the TMTRF[1:0] flag to 00_B. Write the next message to the transmit buffer, and then set the TMTR bit to 1 (transmission is requested). The TMTR bit can be set to 1 only when the TMTRF[1:0] flag value is 00_B.

If an arbitration-lost has occurred after transmission is started, the TMTSTS flag is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC field to search the highest-priority transmit buffer. If an error has occurred during transmission or after arbitration loss, the priority determination processing is reexecuted during transmission of an error frame.

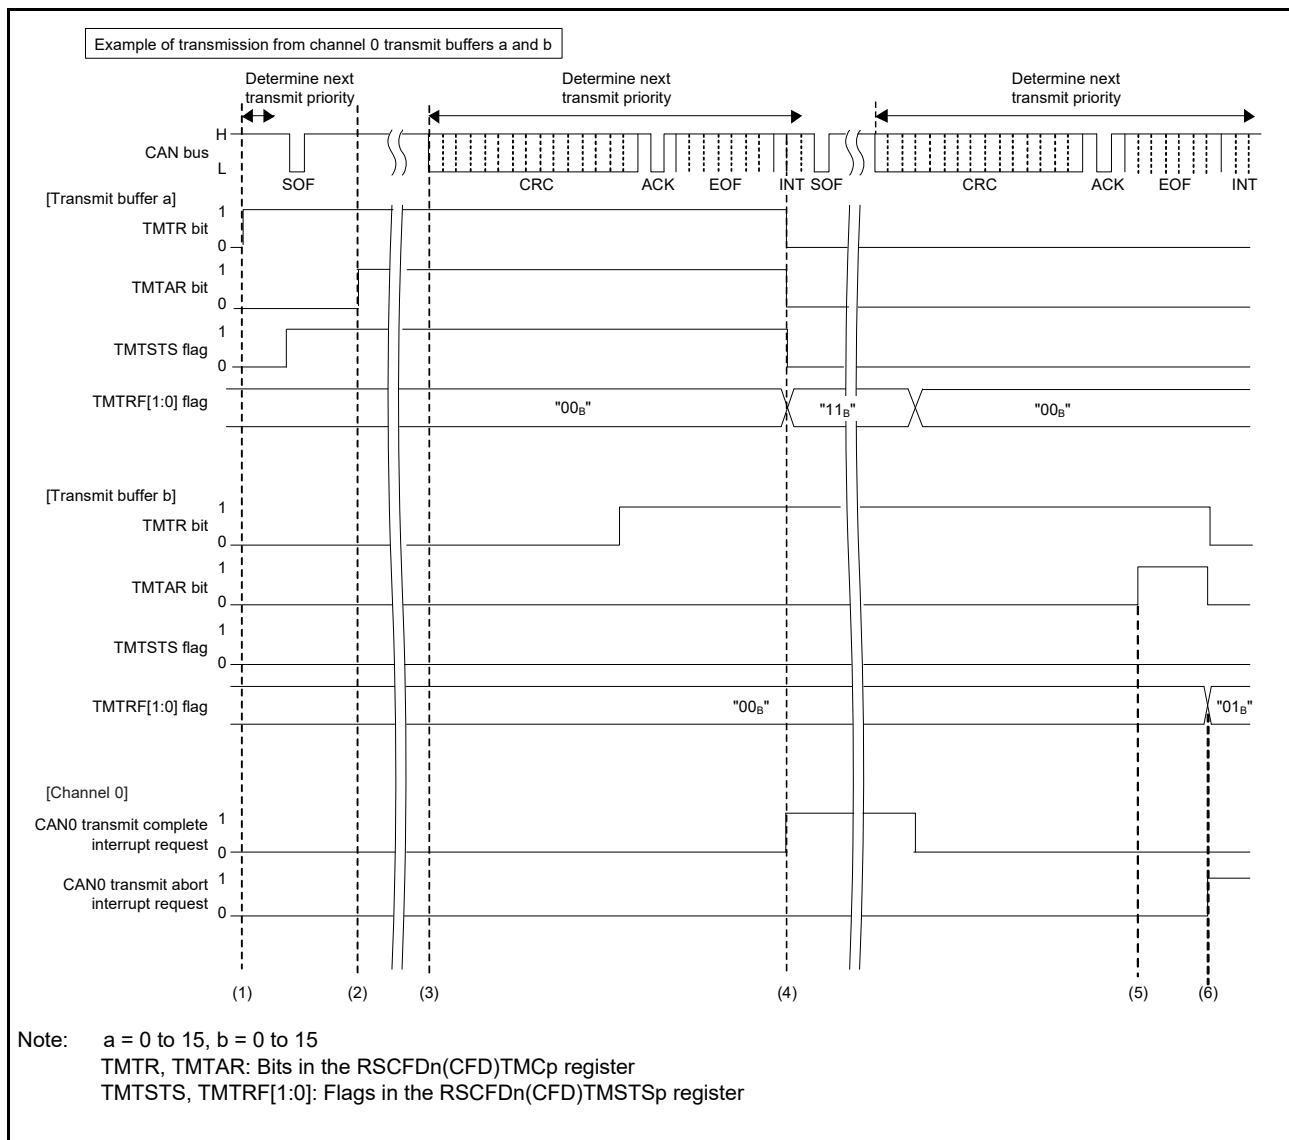

Figure 25.29 Transmit Buffer Transmission Timing Chart (Transmit Abort Completed)

- (1) When the TMTR bit in the RSCFDn(CFD)TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmit buffer. If transmit buffer a is determined to be the highest-priority transmit buffer, the TMTSTS flag in the corresponding RSCFDn(CFD)TMSTSa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.
- (2) When it is determined that the transmit buffer is used for the next transmission or transmission is in progress, message transmission is not aborted unless an error or arbitration loss occurs even if the TMTAR bit is set to 1 (transmit abort is requested).
- (3) The priority determination starts at the first bit of the CRC field for the next transmission. In this timing chart, buffer b is not selected as the next transmit buffer. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.
- (4) When transmission completes successfully, the TMRF[1:0] flag in the RSCFDn(CFD)TMSTSa register is set to 11_B (transmission has been completed (with transmit abort request)) and the TMTSTS flag and the TMTR bit in the RSCFDn(CFD)TMCa register are cleared to 0. When the TMIEa value in the RSCFDn(CFD)TMIEC0 register is 1

(transmit buffer interrupt is enabled), a CAN0 transmit complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B (transmission is in progress or no transmit request is present).

- (5) While another CAN node is transmitting data on the CAN bus (TMTSTS flag = 0), if the TMTAR bit is set to 1 while the corresponding channel is determining transmit priority, the TMTR bit cannot be cleared to 0.
- (6) After the internal processing time has passed, the transmission is terminated and the TMTRF[1:0] flag is set to 01_B. When the transmit buffer is not transmitting data and is not selected as the next transmit buffer and priority determination is not being made, an abort request is immediately accepted and the TMTRF[1:0] flag is set to 01_B. At this time, the TMTR and TMTAR bits are cleared to 0. When transmit abort is completed with the TAIE bit in the RSCFDn(CFD)CmCTR register set to 1 (transmit abort interrupt is enabled), an interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B.

If an arbitration loss has occurred after the CAN channel started transmission, the TMTSTS bit is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC field to find the highest-priority transmit buffer. If an error has occurred during transmission or after arbitration loss, the priority determination processing is reexecuted during transmission of an error frame.

25.11.3.2 Procedure for Transmission from Transmit/Receive FIFO Buffers

Figure 25.30 shows the procedure for transmission from transmit/receive FIFO buffers.

Figure 25.31 shows a timing chart where messages are transmitted from two transmit/receive FIFO buffers in the same channel and transmission has been successfully completed. Figure 25.32 shows a timing chart where messages are transmitted from two transmit/receive FIFO buffers in the same channel and transmit abort has been completed.

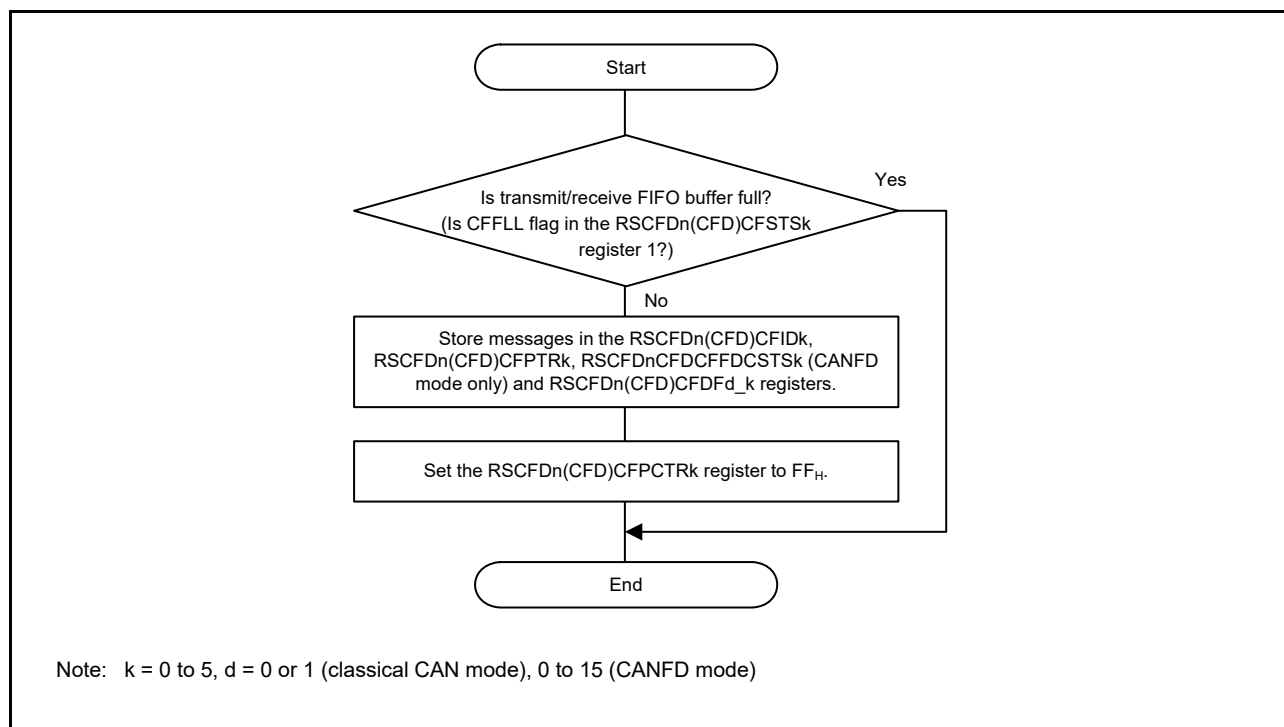

Figure 25.30 Procedure for Transmission from Transmit/Receive FIFO Buffers

When storing a message, do not write a value to the RSCFDnCFDCFDf_d_k register corresponding to the area exceeding the payload storage size specified by the CFPLS[2:0] bits in the RSCFDnCFDCFCCK register.

Table 25.185 Payload Storage Area of Transmit/Receive FIFO Buffer

| Set CFPLS[2:0] Value | Payload Storage Size | Corresponding Data Field Registers |
|----------------------|----------------------|---|
| 000 _B | 8 bytes | RSCFDnCFDCCFDF0_k to RSCFDnCFDCCFDF1_k |
| 001 _B | 12 bytes | RSCFDnCFDCCFDF0_k to RSCFDnCFDCCFDF2_k |
| 010 _B | 16 bytes | RSCFDnCFDCCFDF0_k to RSCFDnCFDCCFDF3_k |
| 011 _B | 20 bytes | RSCFDnCFDCCFDF0_k to RSCFDnCFDCCFDF4_k |
| 100 _B | 24 bytes | RSCFDnCFDCCFDF0_k to RSCFDnCFDCCFDF5_k |
| 101 _B | 32 bytes | RSCFDnCFDCCFDF0_k to RSCFDnCFDCCFDF7_k |
| 110 _B | 48 bytes | RSCFDnCFDCCFDF0_k to RSCFDnCFDCCFDF11_k |
| 111 _B | 64 bytes | RSCFDnCFDCCFDF0_k to RSCFDnCFDCCFDF15_k |

Figure 25.31 Transmit/Receive FIFO Buffer Transmission Timing Chart (Transmission Completed Successfully)

- (1) While the CAN bus is idle, when the CFE bit in the RSCFDn(CFD)CFCCa register is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCFDn(CFD)CFCCa register is 001_B (4 messages) or more and the CFMC[7:0] value in the RSCFDn(CFD)CFSTSa register is 01_H or more, the priority determination processing starts to determine the highest-priority transmit message. When the highest-priority transmit message has been determined, transmission of the message starts. In this figure, the message is transmitted from transmit/receive FIFO buffer a of channel 0.
- (2) When a transmit request from a buffer is present, the priority determination starts at the first bit of the CRC field for the next transmission. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.
- (3) When transmission completes successfully, the CFMC[7:0] value in the RSCFDn(CFD)CFSTSa register is decremented. Setting the CFIM bit in the RSCFDn(CFD)CFCCa register to 1 (a FIFO transmit interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCFDn(CFD)CFSTSk register to 1 (a transmit/receive FIFO transmit interrupt request is present).

- (4) The program can clear the CFTXIF flag.
- (5) Message transmission from transmit/receive FIFO buffer b of channel 0 has been completed and the CFMC[7:0] value in the RSCFDn(CFD)CFSTSb register is decremented. The CFMC[7:0] bits are cleared to 00_H and therefore the CFEMP flag in the RSCFDn(CFD)CFSTSb register is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)).

Transmission is continued until the CFEMP flag is set to 1. It is possible to continuously store transmit messages in FIFO buffers until the CFFLL flag in the RSCFDn(CFD)CFSTSa and RSCFDn(CFD)CFSTSb register is set to 1 (the transmit/receive FIFO buffer is full).

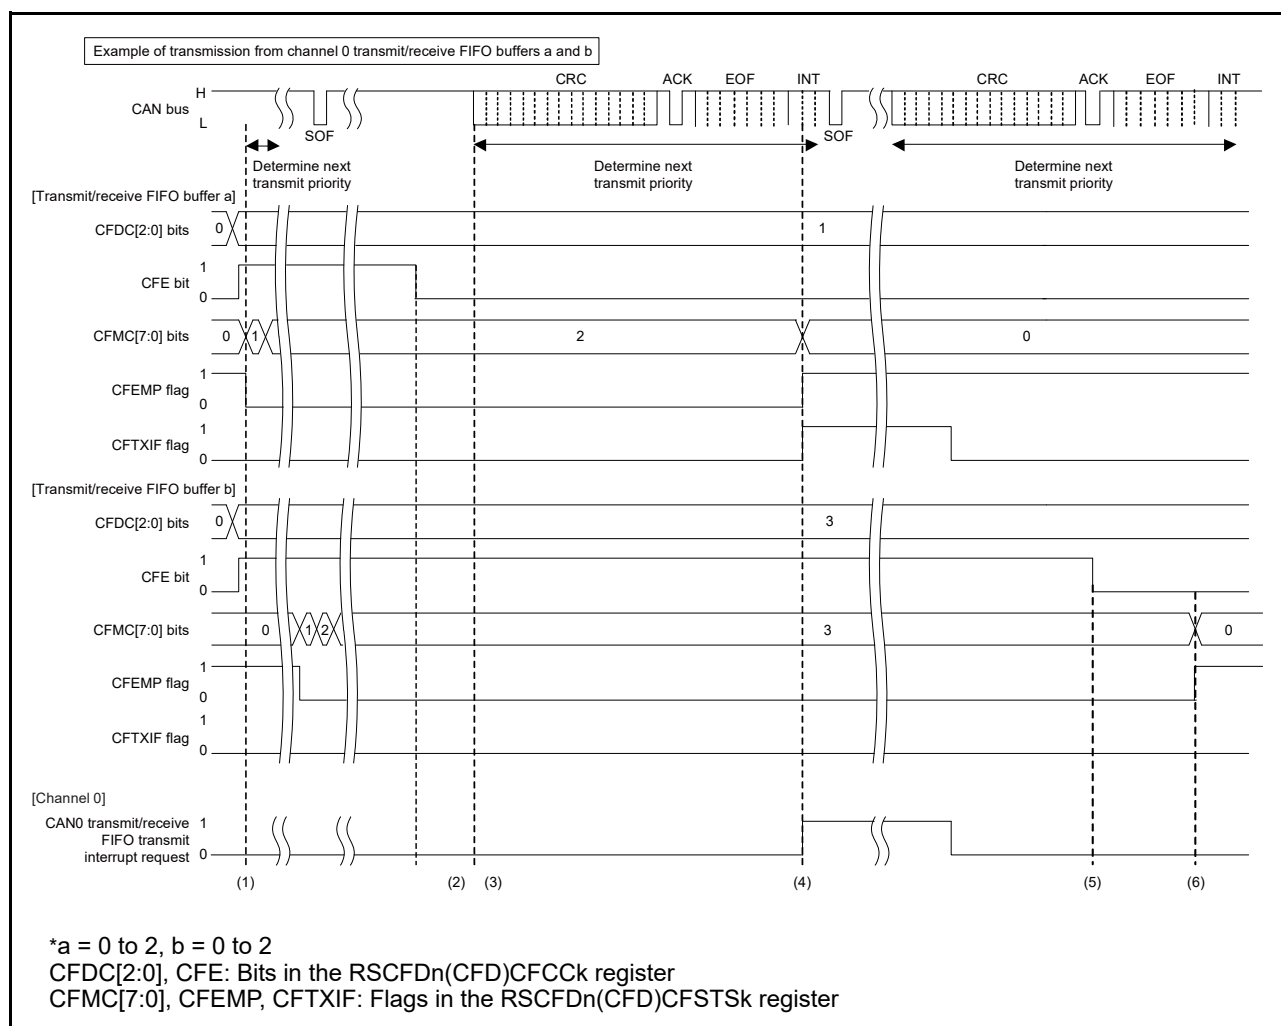

Figure 25.32 Transmit/Receive FIFO Buffer Transmission Timing Chart (Transmit Abort Completed)

- (1) While the CAN bus is idle, when the CFE bit in the RSCFDn(CFD)CFCCa register is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCFDn(CFD)CFCCa register is 001_B (4 messages) or more and the CFMC[7:0] value in the RSCFDn(CFD)CFSTSa register is 01_H or more, the priority determination processing starts to determine the highest-priority transmit message. When the highest-priority transmit message has been determined, transmission of the message starts. In this figure, the message is transmitted from transmit/receive FIFO buffer a of channel 0.
- (2) When transmission is in progress or it is determined that the transmit/receive FIFO buffer is used for the next transmission, message transmission is not aborted unless an error or arbitration loss occurs even if the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).
- (3) When a transmit request from a buffer is present, the priority determination starts at the first bit of the CRC field for the next transmission. In this figure, transmit/receive FIFO buffer b is not selected as a buffer for the next transmission. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.
- (4) When transmit completes successfully, the CFMC[7:0] value is cleared to 00_H. Setting the CFIM bit to 1 (a FIFO transmit interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCFDn(CFD)CFSTSa register to 1 (a transmit/receive FIFO transmit interrupt request is present). The program can clear the CFTXIF flag.
- (5) If another CAN node on the CAN bus is transmitting data (not from transmit/receive FIFO buffer b), transmit/receive FIFO buffers cannot be disabled immediately even if the CFE bit in the RSCFDn(CFD)CFCCb register is cleared to 0 (no transmit/receive FIFO buffer is used) during transmit priority determination. (The CFEMP flag in the RSCFDn(CFD)CFSTSb register is not set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)) immediately.)
- (6) After the internal processing time has passed, transmit/receive FIFO buffers are disabled and the CFMC[7:0] bits in the RSCFDn(CFD)CFSTSb register are cleared to 00_H and the CFEMP flag is set to 1. When the transmit/receive FIFO buffer is not transmitting data and is not selected as the next transmit buffer and priority determination is not in progress, the transmit/receive FIFO buffer is immediately disabled. (The CFMC[7:0] bits are cleared to 00_H and the CFEMP flag is set to 1.)

25.11.3.3 Procedure for Transmission from the Transmit Queue

Figure 25.33 shows the procedure for transmission from the transmit queue.

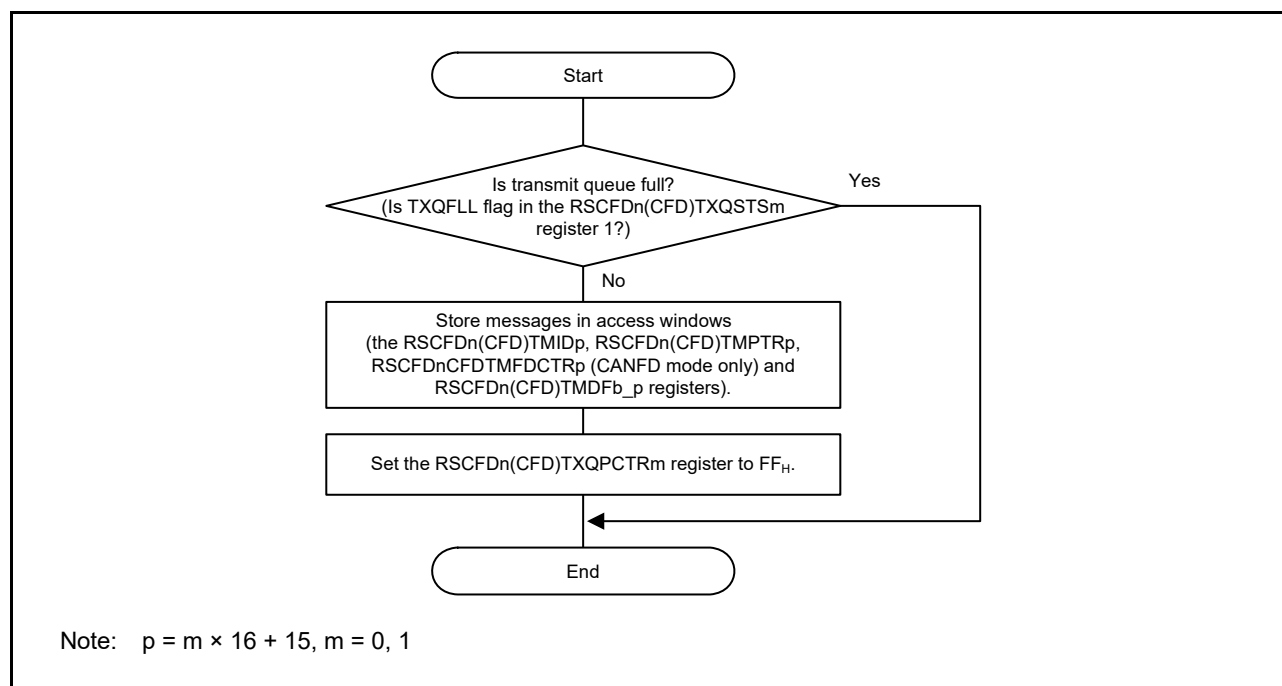

Figure 25.33 Procedure for Transmission from the Transmit Queue

25.11.3.4 Transmit History Buffer Reading Procedure

Transmit history data can be read from the RSCFDn(CFD)THLACCm register. The next data can be accessed by writing FF_H to the corresponding RSCFDn(CFD)THLPCTRm register (m = 0, 1) after reading a set of data. Figure 25.34 shows the transmit history buffer reading procedure.

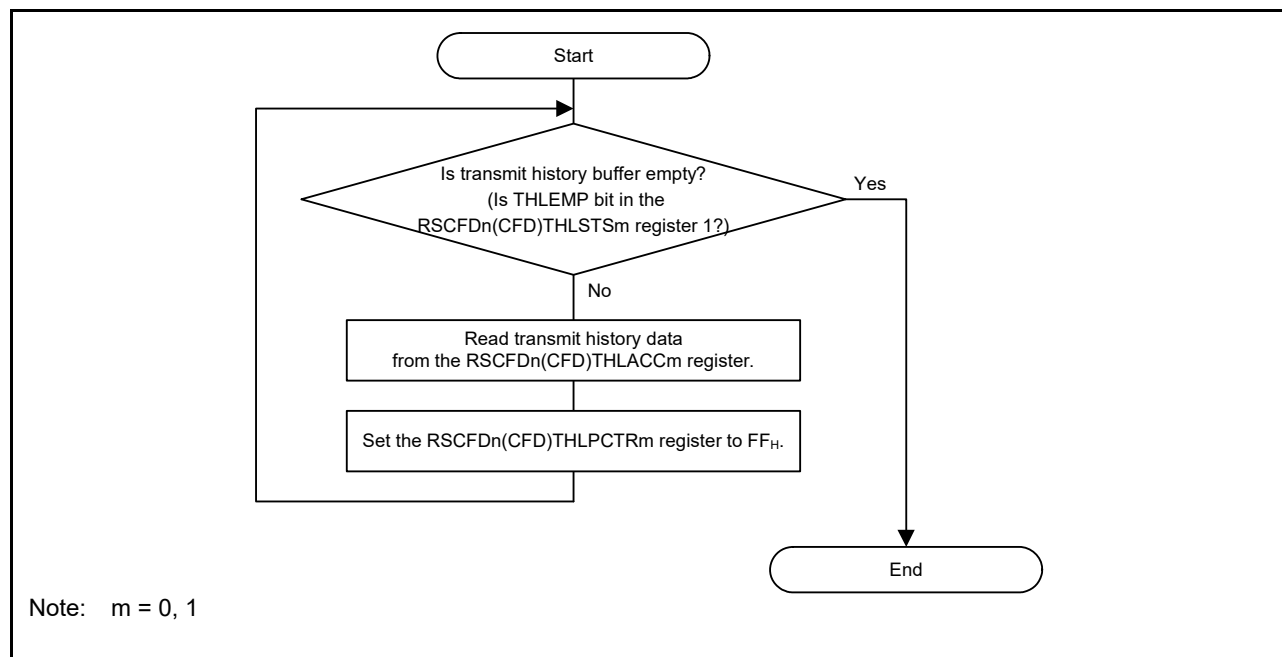

Figure 25.34 Transmit History Buffer Reading Procedure

25.11.4 Test Settings

25.11.4.1 Self-Test Mode Setting Procedure

Self-test mode allows communication test on a channel basis by enabling a CAN node to receive its own transmitted messages.

Figure 25.35 shows the self-test mode setting procedure.

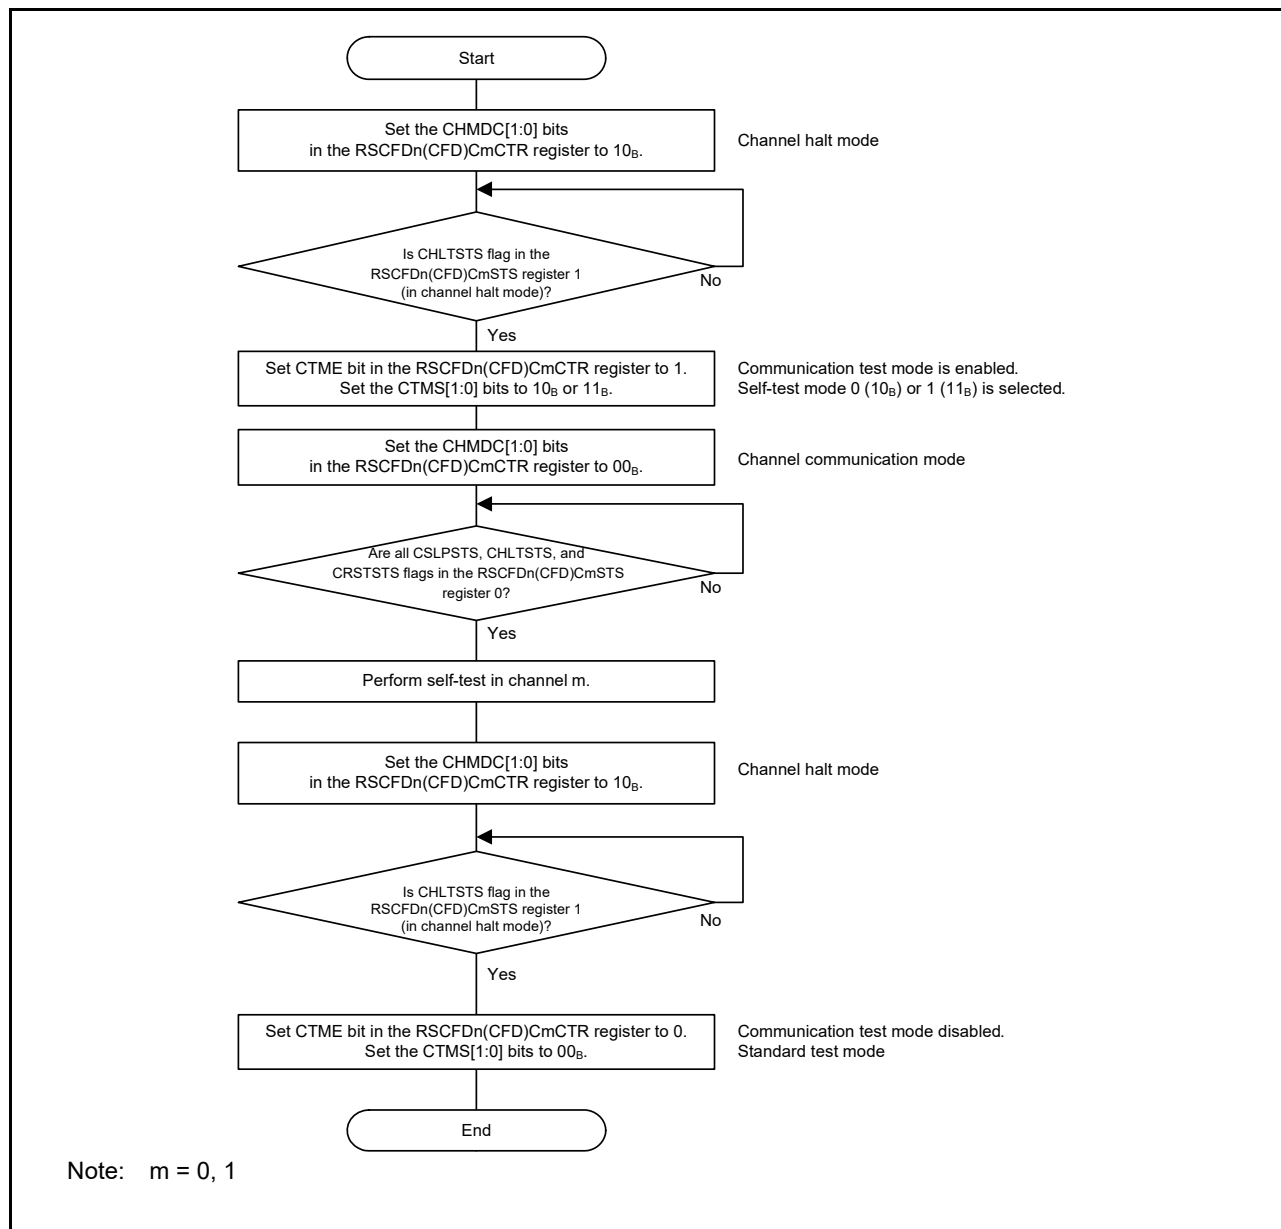

Figure 25.35 Self-Test Mode Setting Procedure

25.11.4.2 Procedure for Releasing the Protection

Since the global test function in Table 25.186 is protected, write the protection release data 1 and release data 2 in succession to the LOCK[15:0] bits in the RSCFDn(CFD)GLOCKK register, then set the target test bit to 1.

Table 25.186 Protection Release Data for Test Function

| Test Function | Protection Release Data 1 | Protection Release Data 2 | Target Bit |
|---------------|---------------------------|---------------------------|---|
| RAM test | 7575 _H | 8A8A _H | RTME bit in the RSCFDn(CFD)GTSTCTR register |

If an incorrect value is written to the LOCK[15:0] bits, restart from writing the protection release data 1. Figure 25.36 shows the procedure for releasing the protection.

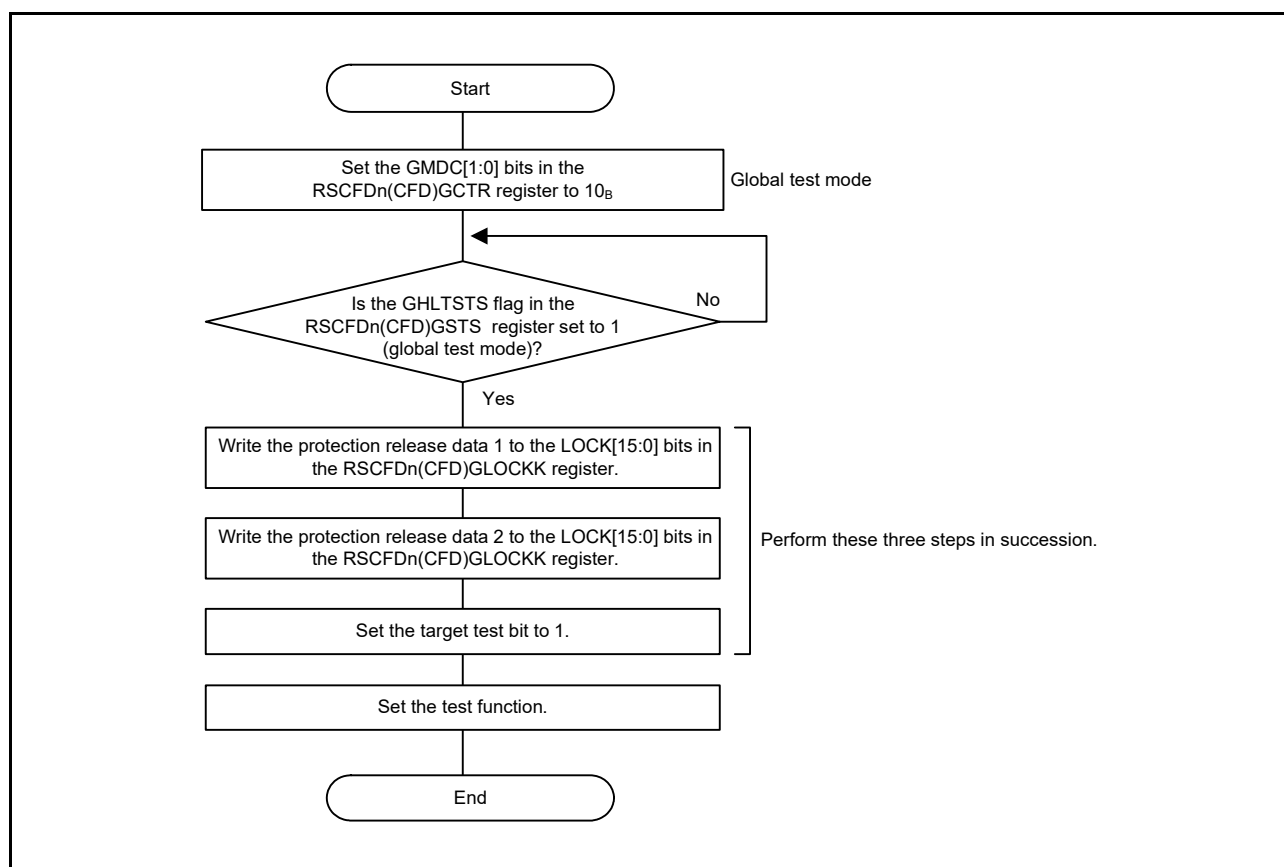

Figure 25.36 Protection Release Procedure

25.11.4.3 RAM Test Setting Procedure

RAM tests include CAN RAM read/write test. The read/write test verifies that data written to the RAM is read correctly. Before closing the RAM test, write 0000 0000_H to all pages of the CAN RAM.

Figure 25.37 shows the RAM test setting procedure.

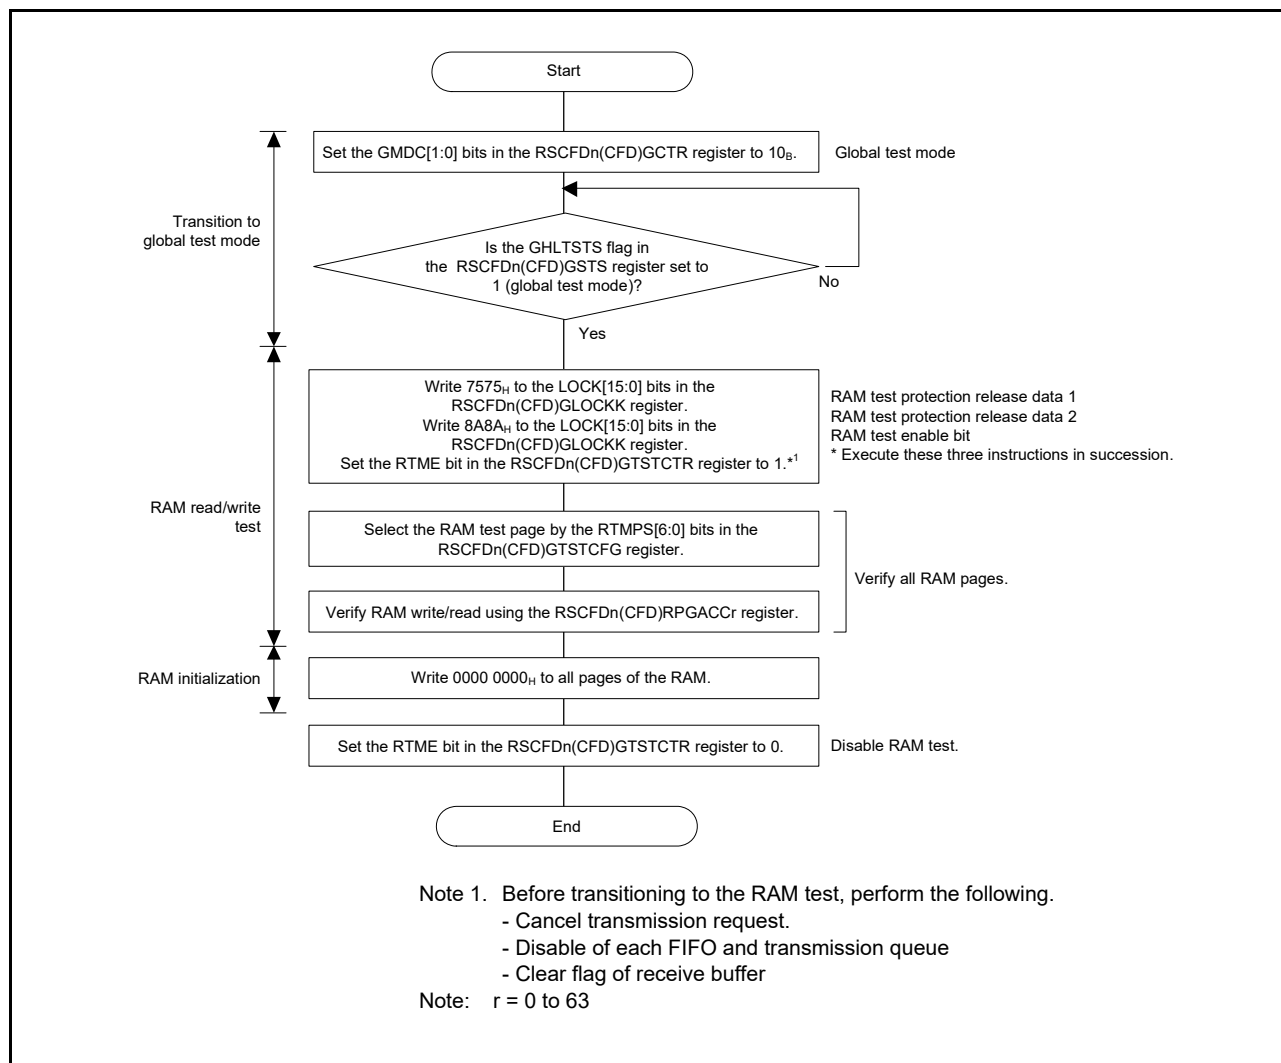

Figure 25.37 RAM Test Setting Procedure

25.11.4.4 Inter-Channel Communication Test Setting Procedure

Communication testing can be performed by transmitting and receiving data between different channels.

Figure 25.38 shows the inter-channel communication test setting procedure.

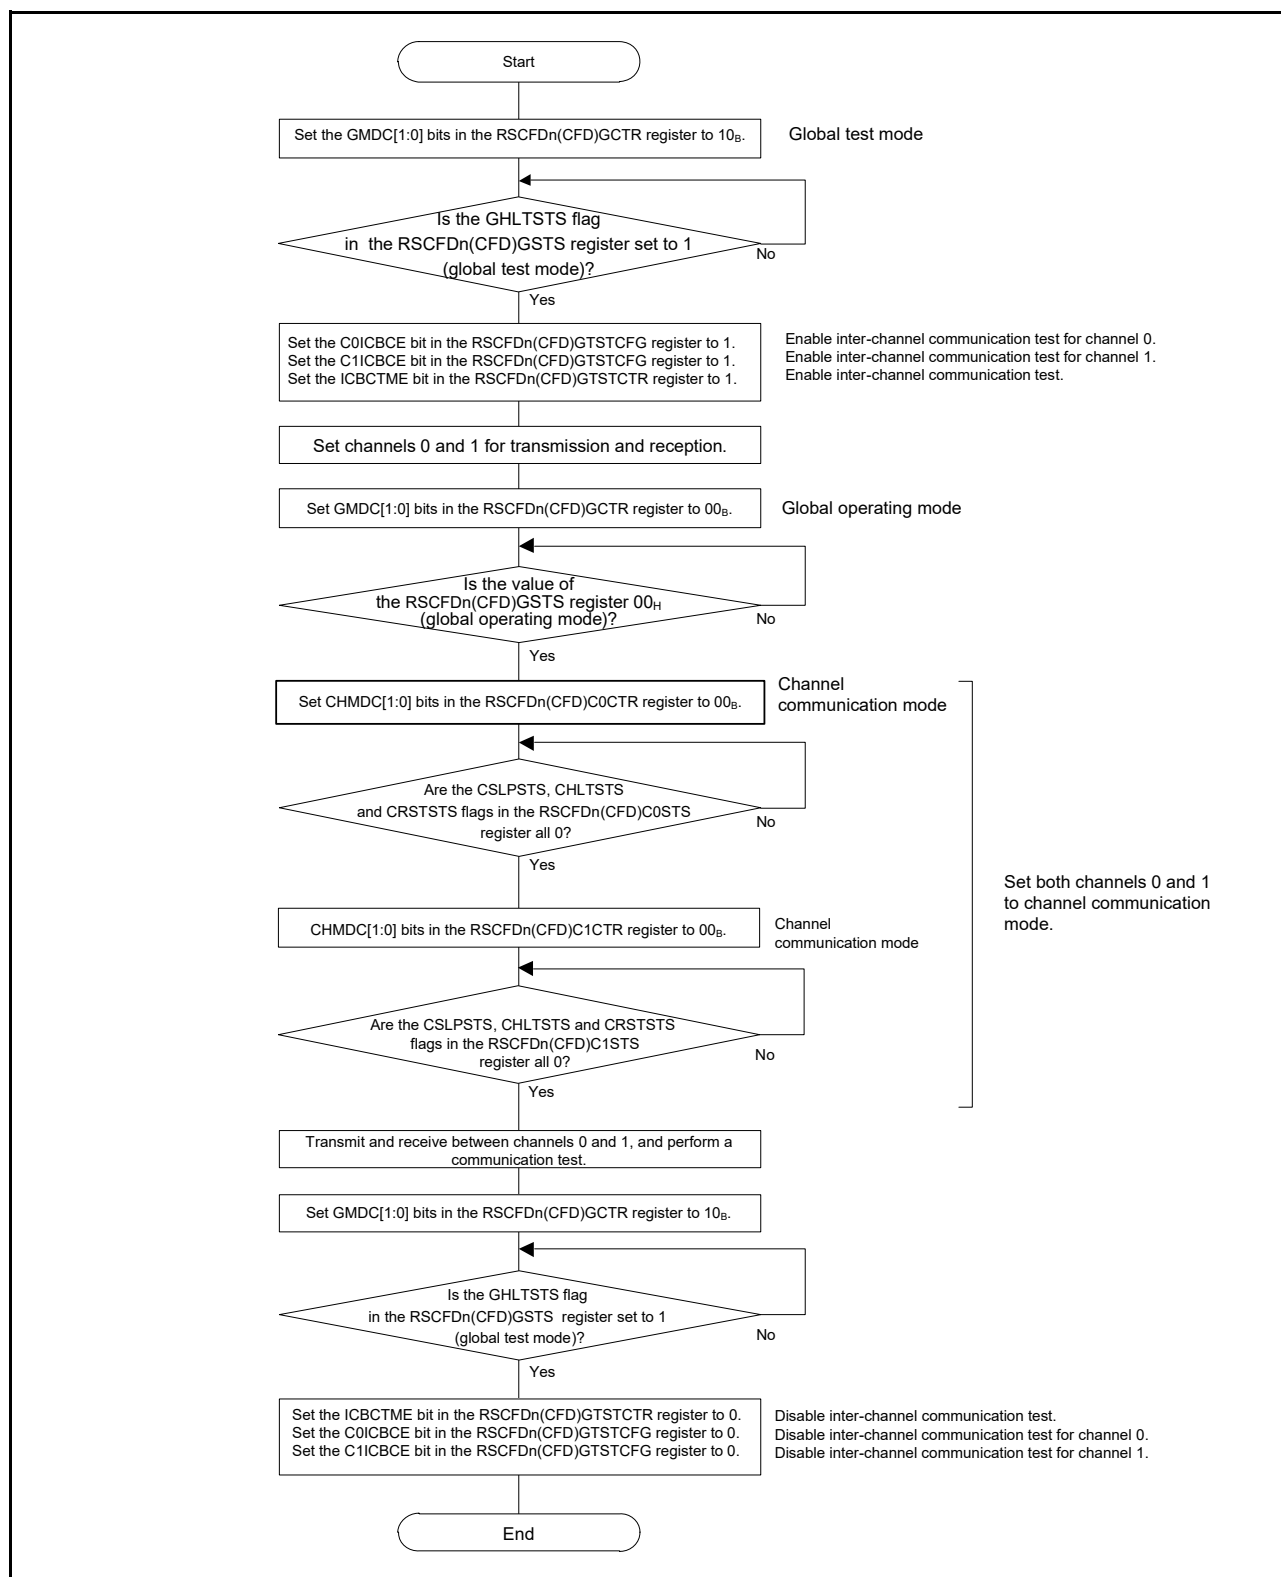

Figure 25.38 Inter-Channel Communication Test Setting Procedure (Example of Communication Test between Channel 0 and Channel 1)

25.12 Notes on the RS-CANFD Module

- When changing the interface mode without applying a power-on reset, write the value after reset to all registers and bits that are not allocated to the register map after change and then modify the RSCFDnCFDGRMCFG register.
- When changing a global mode, check the GSLPSTS, GHLTSTS, and GRSTSTS flags in the RSCFDn(CFD)GSTS register for transitions. When changing a channel mode, check the CSLPSTS, CHLTSTS, and CRSTSTS flags in the RSCFDn(CFD)CmSTS register ($m = 0, 1$) for transitions.
- When only classical CAN frames are used in CANFD mode, set the RSCFDnCFDCmDCFG register to the value equal to the set RSCFDnCFDCmNCFG register value.
- The acceptance filter processing checks receive rules sequentially in ascending order from the minimum rule number. If the same ID, IDE bit, or RTR bit value is set for multiple receive rules, the minimum number of receive rule is used for the acceptance filter processing. If the message does not pass through the subsequent DLC filter processing, the data processing is terminated without returning to the acceptance filter processing and the message is not stored in the buffer.
- When linking transmit buffers to transmit/receive FIFO buffers or allocating transmit buffers to transmit queues, set the control register (RSCFDn(CFD)TMCp) of the corresponding transmit buffer to 00_H. The status register (RSCFDn(CFD)TMSTSp) of the corresponding transmit buffer should not be used. Flags in other status registers (registers RSCFDn(CFD)TMTRSTS0 to RSCFDn(CFD)TMTRSTS2, RSCFDn(CFD)TMTARSTS0 to RSCFDn(CFD)TMTARSTS2, RSCFDn(CFD)TMTCASTS0 to RSCFDn(CFD)TMTCASTS2, and RSCFDn(CFD)TMTASTS0 to RSCFDn(CFD)TMTASTS2), which correspond to transmit buffers linked to transmit/receive FIFO buffers or allocated to transmit queues remain unchanged. Set the enable bit in the corresponding interrupt enable register (registers RSCFDn(CFD)TMIEC0 to RSCFDn(CFD)TMIEC2) to 0 (transmit buffer interrupt is disabled).
- When using transmit buffer merge mode (in CANFD mode), write 00_H to the control register (RSCFDn(CFD)TMCp) of the transmit buffer corresponding to the transmit buffer allocated as a payload storage area. Set the enable bit of corresponding interrupt enable registers (RSCFDn(CFD)TMIEC0 to RSCFDn(CFD)TMIEC2) to 0 (to disable interrupts).
- Transmit buffers that are linked to transmit/receive FIFO buffers must not be allocated to transmit queues. Do not allocate a transmit buffer allocated as a payload storage area in transmit buffer merge mode (in CANFD mode) to the transmit queue either.
- Only a single transmit/receive FIFO buffer can be linked to a transmit buffer. Do not link two or more transmit/receive FIFO buffers to transmit buffers of the same number.
- When the CANm bit time clock is selected as a timestamp counter clock source, the timestamp counter stops when the corresponding channel has transitioned to channel reset mode or channel halt mode.
- In case of an attempt to store a new received message when the receive FIFO buffer and the transmit/receive FIFO buffer are full, the new message is discarded. If you wish to store a new transmit message in the transmit/receive FIFO buffer or the transmit queue, check that the transmit/receive FIFO buffer or the transmit queue is not full.
- In the case of registers that access the RAM, the value after reset shown in **section 25.3, Registers (Classical CAN Mode)** and **section 25.4, Registers (CANFD Mode)** indicate the values cleared by initialization of the CAN RAM. Values before clear are undefined. The following registers apply.
 - Receive rule (RSCFDn(CFD)GAFLIDj, RSCFDn(CFD)GAFLMj, RSCFDn(CFD)GAFLP0_j, RSCFDn(CFD)GAFLP1_j registers)
 - Receive buffers (RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDnCFDRMFDSTSq, RSCFDn(CFD)RMDfB_q registers)
 - Receive FIFO buffer access registers (RSCFDn(CFD)RFIDx, RSCFDn(CFD)RFPTRx, RSCFDnCFDRFFDSTSx, and RSCFDn(CFD)RFDFd_x registers)
 - Transmit/receive FIFO buffer access registers (RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDn(CFD)CFDFd_k registers)

- Transmit buffers (RSCFDn(CFD)TMIDp, RSCFDn(CFD)TMPTRp, RSCFDnCFDTMFDCTRp, and RSCFDn(CFD)TMDfb_p registers)
- Transmit history access register (RSCFDn(CFD)THLACCM registers)
- RAM test page access register (RSCFDn(CFD)RPGACCr registers)
- The values of unused receive buffers (RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDnCFDRMFDSTSq, and RSCFDn(CFD)RMDfb_q registers), receive FIFO buffer access registers (RSCFDn(CFD)RFIDx, RSCFDn(CFD)RFPTRx, RSCFDnCFDRFFDSTSx, and RSCFDn(CFD)RFDFd_x registers) and transmit/receive FIFO buffer access registers (RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDn(CFD)CFDFd_k registers) are undefined when the RS-CANFD module transitions to global operation mode or global test mode after exiting from global reset mode.

26. Renesas SPDIF Interface

26.1 Overview

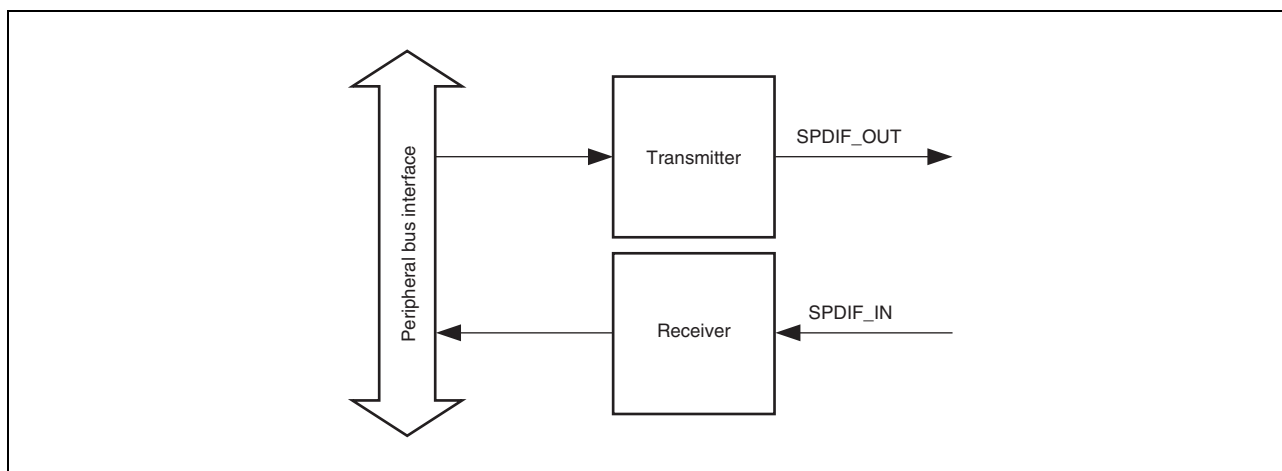

Figure 26.1 Overview Block Diagram

26.2 Features

- Supports the IEC 60958 standard (stereo and consumer use modes only).
- Supports sampling frequencies of 32 kHz, 44.1 kHz, and 48 kHz.
- Supports audio word sizes of 16 to 24 bits per sample.
- Biphase mark encoding.
- Double buffered data.
- Parity encoded serial data.
- Simultaneous transmit and receive
- Receiver autodetects IEC 61937 compressed mode data

26.3 Functional Block Diagram

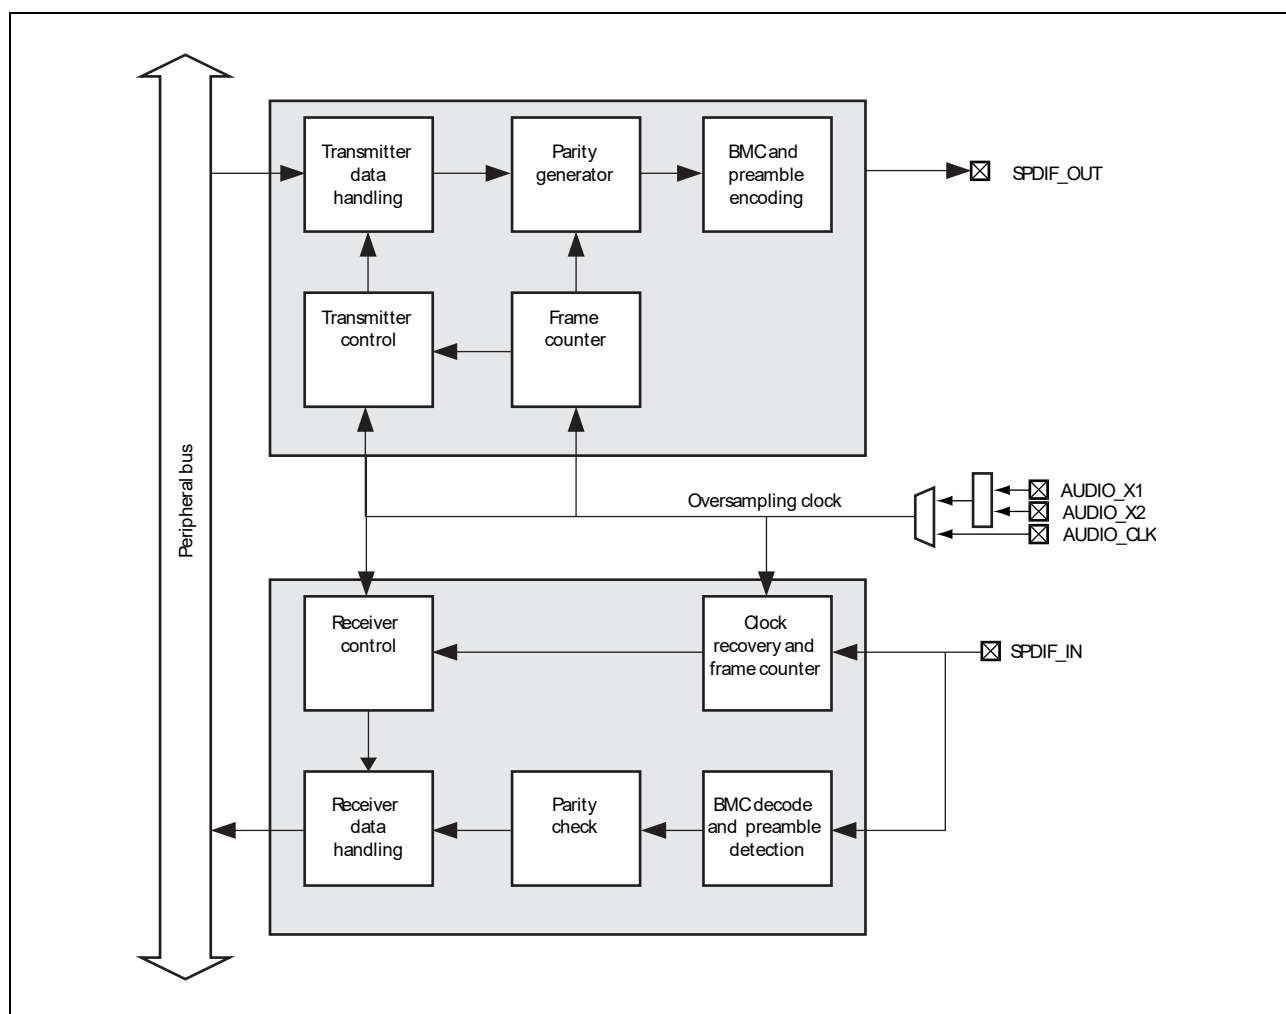

Figure 26.2 Functional Block Diagram

26.4 Input/Output Pins

Table 26.1 shows the pin configuration.

Table 26.1 Pin Configuration

| Channel | Pin Name | I/O | Description |
|------------------|-----------|--------|---|
| 0 | SPDIF_OUT | Output | Transmitter biphasemark encoded SPDIF bitstream |
| 1 | SPDIF_IN | Input | Receiver biphasemark encoded SPDIF bitstream |
| 0, 1 (Common) | AUDIO_CLK | Input | External clock for audio |
| | AUDIO_X1 | Input | Crystal resonator/external clock for audio |
| | AUDIO_X2 | Output | |

26.5 Renesas SPDIF (IEC60958) Frame Format

The Renesas SPDIF frame consists of two subframes (for channels 1 and 2), each of which contains a 4-bit preamble, audio data of up to 24 bits, a V flag, a user bit, a channel status bit, and an even parity bit. Figure 26.3 shows the subframe format. According to this format, the Renesas SPDIF performs biphasemark modulation (channel coding) that will make the transmission line's DC component a minimum value.

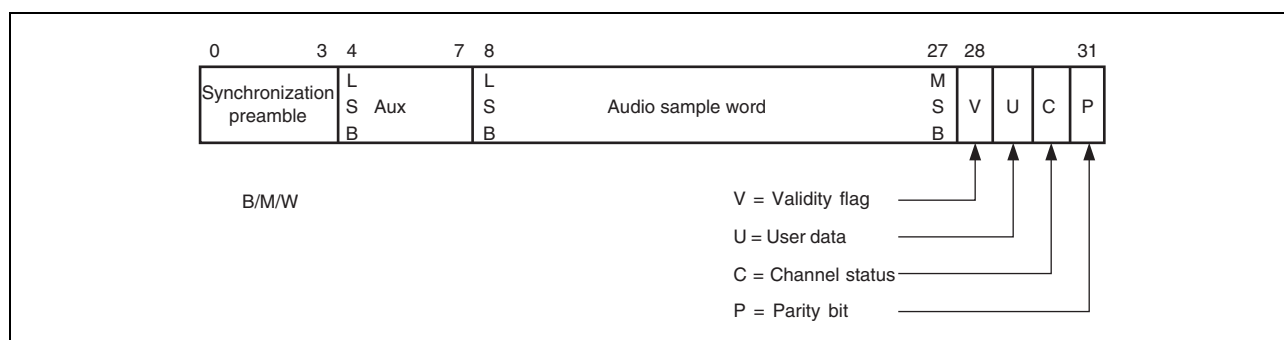

Figure 26.3 Subframe Format

Figure 26.4 shows the block format, which consists of 192 continuous frames. One block begins at the starting frame (preamble B) and ends at the 192nd frame (frame 191), and the preamble is used to identify all subframes. Each block has a total of 384 subframes, which are classified into three categories: subframe 0 indicating the beginning of a new block, subframe 1 (usually the channel 1), and subframe 2 (usually the channel 2). Usually, the music data sent and received by the SPDIF is continuous so that continuous blocks appear.

Figure 26.4 Block Format

Table 26.2 shows the binary values of the Renesas SPDIF preambles. The polarity of these preambles differs depending on the status of the preceding symbol (parity bit).

Table 26.2 Binary Preamble Values

| Preamble | Preceding Symbol's Status = 0 | Preceding Symbol's Status = 1 |
|----------|-------------------------------|-------------------------------|
| B | 11101000 | 00010111 |
| M | 11100010 | 00011101 |
| W | 11100100 | 00011011 |

Note: As shown in Figure 26.3, the even parity bit at time slot 31 of a subframe determines the type of a preamble for one cycle of transmission. Usually, therefore, any one is selected from the set states that are sent through the Renesas SPDIF. However, IEC60958 requires decoding both types in view of connection with the preamble polarity reversed; the Renesas SPDIF has preambles decoded according to Table 26.2.

Channel status information is encoded at the rate of one bit per subframe, making the channel status information per block have a total of 192 bits for each of subframes 1 and 2. For the format of the channel status, refer to the IEC 60958 standard.

26.6 Register

Table 26.3 shows the register configuration.

Table 26.3 Register Configuration

| Channel | Register Name | Abbreviation | Address | Access Size |
|-----------------|---------------------------------------|--------------|-------------|-------------|
| 0 (Transmit) | Transmitter channel 1 audio register | TLCA | H'E804 F000 | 32 |
| | Transmitter channel 2 audio register | TRCA | H'E804 F004 | 32 |
| | Transmitter channel 1 status register | TLCS | H'E804 F008 | 32 |
| | Transmitter channel 2 status register | TRCS | H'E804 F00C | 32 |
| | Transmitter user data register | TUI | H'E804 F010 | 32 |
| 1 (Receive) | Receiver channel 1 audio register | RLCA | H'E804 F014 | 32 |
| | Receiver channel 2 audio register | RRCA | H'E804 F018 | 32 |
| | Receiver channel 1 status register | RLCS | H'E804 F01C | 32 |
| | Receiver channel 2 status register | RRCS | H'E804 F020 | 32 |
| | Receiver user data register | RUI | H'E804 F024 | 32 |
| 0, 1 (Common) | Control register | CTRL | H'E804 F028 | 32 |
| | Status register | STAT | H'E804 F02C | 32 |
| 0, 1 (Common) | Transmitter DMA audio data register | TDAD | H'E804 F030 | 32 |
| | Receiver DMA audio data register | RDAD | H'E804 F034 | 32 |

Note: All registers are longword registers and must be accessed as such.

A register diagram containing a 0 indicates that the write value should always be 0 (if the register is writable) and that the read value should always be 0 (if readable).

26.7 Register Descriptions

Legend:

Initial Value: Register value after reset

—: Undefined value

R/W: Readable/writable register. The write value can be read.

R: Read only register. The write value should always be 0.

R/WC0: Readable/writable register. Writing 0 initializes the bit, but writing 1 is ignored.

R/WC1: Readable/writable register. Writing 1 initializes the bit, but writing 0 is ignored.

W: Write only register. Reading is prohibited. If this bit is reserved, the write value should always be 0.

—/W: Write only, Read value undefined

26.7.1 Control Register (CTRL)

| | | | | | | | | | | | | | | | | |
|----------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|

| Initial value: | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R/WC0 | R/WC0 | R/WC0 | R/WC0 | R/WC0 | R/WC0 | R/WC0 | R/WC0 | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|----------|---------------|-------|---|
| 31 to 17 | — | All 0 | R | Reserved |
| 16 | CMD | 0 | R | Compressed Mode Data Sets if the data being received is compressed mode data (When bit 1 = 1 in the V flag and channel status). 0: Data is not in compressed mode 1: Data is in compressed mode |
| 15 | RIS | 1 | R | Receiver Idle State Sets if the receiver is in the idle state. 0: Receiver is not in idle state 1: Receiver in idle state |
| 14 | TIS | 1 | R | Transmitter Idle State Sets if the transmitter is in the idle state. 0: Transmitter is not in idle state 1: Transmitter is in idle state |
| 13 | UBO | 0 | R/WC0 | User Buffer Overrun* Sets if the receiver user buffer overruns. This bit is cleared by writing 0 to the register. If bit REIE and bit UBOI in the control register are set this causes an interrupt. 0: User buffer has not overrun 1: User buffer has overrun |
| 12 | UBU | 0 | R/WC0 | User Buffer Underrun* Sets if the transmitter user buffer underrun. This bit is cleared by writing 0. If bits TEIE and UBUI in the control register are set this causes an interrupt. 0: User buffer has not underrun 1: User buffer has underrun |
| 11 | CE | 0 | R/WC0 | Clock Error* Sets when the clock recovery falls out of synchronization. This bit is cleared by writing 0. If bits REIE and CREI in the control register are set this causes an interrupt. 0: Clock recovery stable 1: Clock recovery error |
| 10 | PARE | 0 | R/WC0 | Parity Error* Sets when the parity checker produces a fail result. This bit is cleared by writing 0. If bits REIE and PAEI in the control register are set this causes an interrupt. 0: Parity check correct 1: Parity error |
| 9 | PREE | 0 | R/WC0 | Preamble Error* Sets when the start of word preamble fails to appear in the correct place. This bit is cleared by writing 0. If bits REIE and PREI in the control register are set this causes an interrupt. Note: Only set after a start of block preamble has occurred. 0: Preamble is in the correct place 1: Preamble error |

| Bit | Bit Name | Initial Value | R/W | Description |
|-----|----------|---------------|-------|---|
| 8 | CSE | 0 | R/WC0 | Channel Status Error*1 Sets when the channel status information is written before the 32nd frame of the current block. This bit is cleared by writing 0. If bits TEIE and CSEI in the control register are set this causes an interrupt. 0: Channel status correct 1: Channel status error |
| 7 | ABO | 0 | R/WC0 | Audio Buffer Overrun*1 Indicates that the receiver audio buffer is full in both the first and second stages and that data has been overwritten. This bit is cleared by writing 0. If bits REIE and ABOI in the control register are set then this causes an interrupt. 0: Receiver audio buffer has not overrun 1: Receiver audio buffer has overrun |
| 6 | ABU | 0 | R/WC0 | Audio Buffer Underrun*1 Indicates that the transmitter audio buffer is empty in both the first and second stages and that the last data transmission has been repeated. This bit is cleared by writing 0. If bits TEIE and ABUI in the control register are set then this causes an interrupt. 0: Transmitter audio buffer has not underrun 1: Transmitter audio buffer has underrun |
| 5 | RUIR | 0 | R | Receiver User Information Register Status Indicates the status of the receiver user information register. This bit is cleared by reading from the receiver user register. If bit RUUI in the control register is set then this causes an interrupt. 0: Receiver user information register is empty 1: Receiver user information register is full |
| 4 | TUIR | 0 | R | Transmitter User Information Register Status Indicates the status of the transmitter user information register. This bit is cleared by writing to the transmitter user register. If bit TUUI in the control register is set then this causes an interrupt. 0: Transmitter user information register is full 1: Transmitter user information register is empty |
| 3 | CSRX | 0 | R | Channel 1 and Channel 2 Status for Receiver Indicates the status of the receiver channel status registers. This bit is cleared by reading from the receiver channel status registers. If bit RCSI in the control register is set this causes an interrupt. 0: Receiver channel status registers are empty 1: Receiver channel status registers are full |
| 2 | CBRX | 0 | R | Channel 1 and Channel 2 Buffers for Receiver Indicates the status of the receiver audio channel registers. This bit is cleared by reading from the receiver audio channel registers. If bit RCBI in the control register is set this causes an interrupt. 0: Receiver audio channel registers are empty 1: Receiver audio channel registers are full |
| 1 | CSTX | 0 | R | Channel 1 and Channel 2 Status for Transmitter Indicates the status of the transmitter channel status registers. This bit is cleared by writing to the transmitter channel status registers. If bit TCSI in the control register is set this causes an interrupt. 0: Transmitter channel status register is full 1: Transmitter channel status register is empty |
| 0 | CBTX | 0 | R | Channel 1 and Channel 2 Buffers for Transmitter Indicates the status of the transmitter audio channel registers. This bit is cleared by writing to the transmitter audio channel registers. If bit TCBI in the control register is set this causes an interrupt. 0: Transmitter audio channel registers are full 1: Transmitter audio channel registers are empty |

Note 1. When an error bit is detected during DMA transfer, DMA transfer settings must be made again. In this case, the Renesas SPDIF's module enable bit (either the RME or TME bit) and the DMA enable bit (either the RDE or TDE bit) must be disabled and the error status must be cleared before making DMA transfer settings again. Then the module enable bit should be set and DMA transfer can be started again.

| 23 to 0 | Audio PCM Data | All 0 | W | Audio PCM Data LSB aligned PCM encoded audio data. |

26.7.6 Transmitter User Data Register (TUI)

U-bit data in subframes is written in to this register. Because U-bit data is transmitted in a sequence of subframes 1 and 2, you need to update the data on a 16-frame basis. For the contents of the user bytes refer to the appropriate standard for the device in use. The user bits to be transmitted are set in sequence starting at the LSB.

| | | | | | | | | | | | | | | | | |
|----------------|-------------|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 15 to 8 | User Byte 2 | All 0 | W | |
| 7 to 0 | User Byte 1 | All 0 | W | |

26.7.7 Transmitter Channel 1 Status Register (TLCS)

The 30-bit register stores the channel status information to be transmitted. For each channel, channel status information per frame consists of 192 bits. Because necessary data covers only the 30 bits that are set in the following register, zeros continue to be sent after the transmission of the first 30 bits.

| | | | | | | | | | | | | | | | | |
|----------------|------------|----|-----------|----|---------|----|----|----|-----------|----|----------|----|------------|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

26.8 Functional Description—Transmitter

26.8.1 Transmitter Module

The transmitter module transmits PCM data and auxiliary information after encoding it according to the method of biphase-mark modulation that complies with the IEC60958 standard (SPDIF).

The clock for the transmitter module is an oversampling clock supplied from the outside. This clock usually selects a value that serves as an oversample at a frequency eight times larger than the clock frequency required for biphase-mark encoding. In this case, the clock frequency required to transmit 32 time slots in a subframe is 512 times as large as the sample frequency for audio data.

Audio data and channel status information are first written into the module's channel 1 and then into channel 2.

Generally, the channel status need to be written only when the information changes. The SPDIF module requests that the channel status be written in 30 frames -- when all the current channel status data have been transmitted. You need to write somewhere between frame 31 and the beginning of the next block of 192 frames.

The audio data is stored in a double buffer arrangement. To make sure that the first stage buffer is empty, you can send an interrupt request or poll the status register. DMA transfers send channel 1 audio data on the first request and channel 2 data on the second.

The channel status information is stored in the 30-bit registers of channels 1 and 2. For each channel, the channel status information per frame consists of 192 bits. Because necessary data covers only 30 bits, zeros continue to be sent after the transmission of the first 30 bits until the block is completed.

User data forms a 32-bit double buffer arrangement. You can make sure that the first stage buffer is empty by either sending an interrupt request or polling the status register. Usually, information about the user data will become insufficient with the length of data between blocks. Transmission takes place in a sequence of channels 1 and 2. For the user data within a block, 384 bits are transmitted before the next block is continuously transmitted.

The audio data handled by the Renesas SPDIF module is a linear PCM, making it possible to set up to 24 bits. For this reason, the V flag indicating that audio data is a linear PCM remains to be 0. The V flag involves no register-based setting. An even parity is created for each 32 bits of serial output data (excluding the preamble).

Note: When transmitter user buffer underrun occurs, the current data in the buffer data of SPDIF is transmitted until the next data is filled.

26.8.2 Transmitter Module Initialization

The device defaults to an idle state when it comes out of reset, or can be put into an idle state when 0 is written to the TME bit in the CTRL register. When the transmitter module is idle, it has the following settings:

- The transmitter idle status bit (TIS) is set to 1, all other status bits are cleared to 0.
- Preamble generation is invalid.
- Synchronization between channels 1 and 2 is set to 0 (0 for channel 1, 1 for channel 2).
- Both word_count and frame_count are set to 0.
- The output from the biphasemark encoder is set to 0.

Channel status, user and audio data registers will retain its value prior to putting the module into idle. To exit the idle state the user must write 1 to the TME bit in the CTRL register.

26.8.3 Initial Settings for Transmitter Module

When the TME bit is set to 1, the TUIR and CSTX bits are set to 1. After that, if data is written in the order of 1) TUI and 2) TLCS and TRCS, a channel status error will occur. To avoid this, be sure to write data in the order of 1) TLCS and TRCS and 2) TUI.

Before writing the first audio data (write access to TLCA or TRCA by the CPU or write access to TDAD by the DMA transfer) after setting the TME bit to 1, be sure to check that the CSTX and TUIR bits are cleared by writing to TLCS, TRCS, and TUI.

26.8.4 Transmitter Module Data Transfer

Once the transmitter module has left the idle state, it is ready for data transfer. Data transfer timing can be achieved in three ways. Either the transfer is done by interrupts, DMA requests or by polling the status register. There is a shared interrupt line (for both transmit and receive) and a single transmitter DMA request line.

Figure 26.5 shows a data transfer with an interrupt for the transmitter.

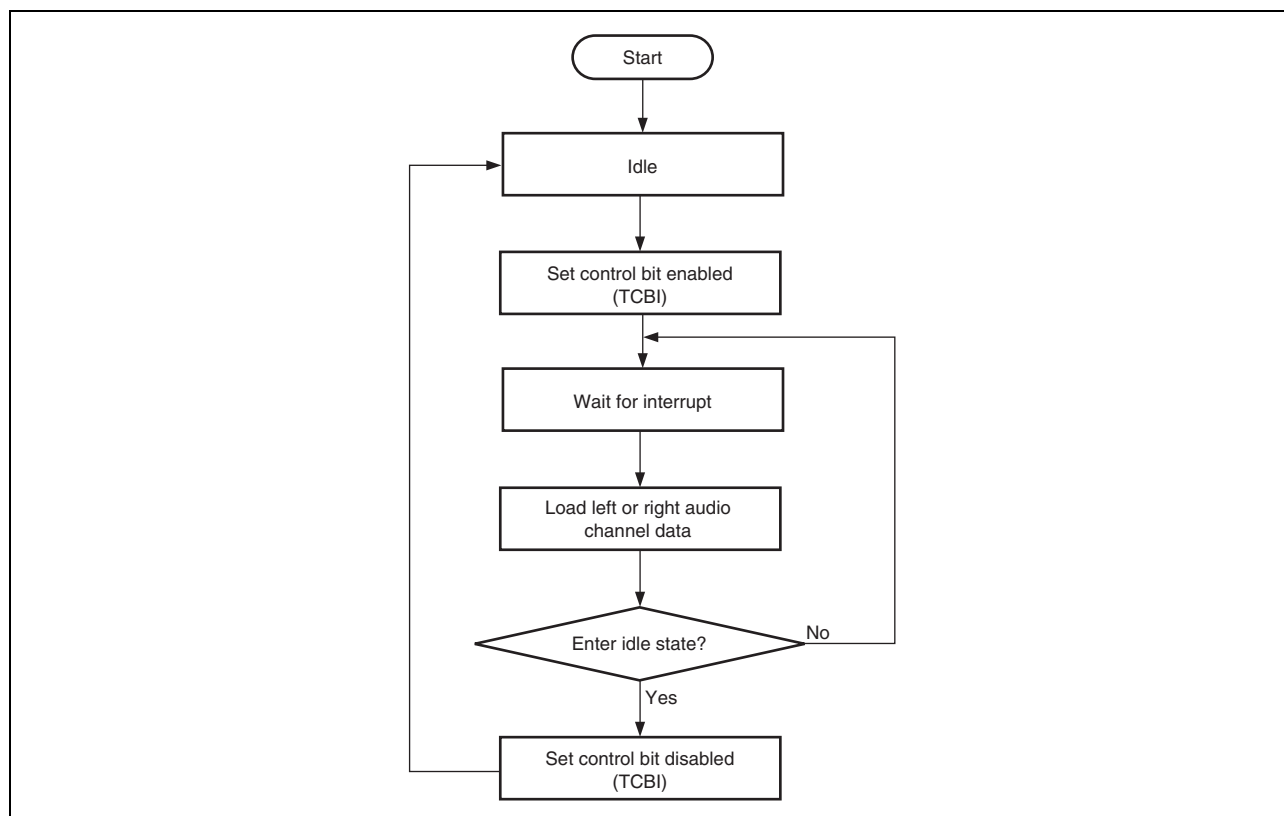

Figure 26.5 Transmitter Data Transfer Flow Diagram - Interrupt Driven

Figure 26.6 shows a data transfer with a DMA transfer for the transmitter.

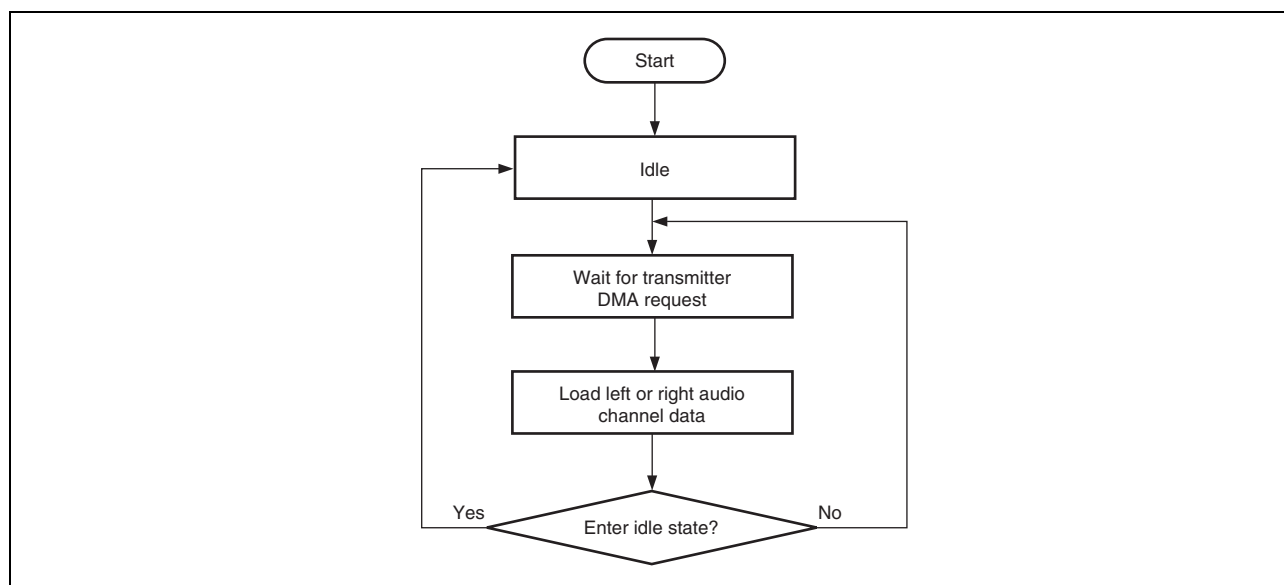

Figure 26.6 Transmitter Data Transfer Flow Diagram—DMA Request Driven

Channel status information is required to be updated when the information has changed. Because the updating needs to be done before the transmission of the next block, the channel status to be updated should be written after 30 frames have been sent; this is indicated either by an interrupt or by polling the status bit. If channel status is written before 30 frames have been sent (while current information is being sent) then an interrupt indicates that the channel status error bit (CSE) in the status register has been set.

Note: 30 frames contains all the valid information in a single channel status block.

26.9 Functional Description—Receiver

26.9.1 Receiver Module

The receiver module demodulates data and clock signals from the input encoded according to the IEC60958 standard. The encoded data, shown in linear PCM format, is stored into the audio data register. The register also stores the channel status and user information being received simultaneously as auxiliary information.

The main clock for the receiver module is an oversampling clock supplied from the outside. The module operates at a frequency four times as large as the oversampling clock.

Note: The oversampling clock is the same for the transmitter and receiver.

Clock recovery is performed using a pulse width counter and averaging filters to produce a sampling pulse in the middle of each bit in the datastream. A clock error status bit indicates clock synchronization loss. Synchronization is achieved when a preamble occurs on the data stream for the first time. Continuous adjustment prevents jitter and/or clock drift from affecting clock recovery, provided that they fall within the clock recovery specifications.

Once the clock recovery is successful the biphase-mark decoder initiates its preamble detection. The decoder searches for the start of block preamble (see [Table 26.2](#)). A preamble error status bit indicates that following preambles have not appeared at the correct time, such failures are most likely caused by transmission loss or interference.

Even parity checking is performed on the decoded data. A discrepancy will result in the parity error status bit being set. The SPDIF module acquires user data and channel status information in addition to audio data. The audio is stored in a double buffer arrangement. Either an interrupt request because of a full buffer or polling of the status bit will indicate when the data is ready to be read. DMA transfers receive channel 1 audio data on the first request and channel 2 data on the second.

Channel status is stored in a 30-bit register. Channel status information is received at 1-bit per subframe. Therefore the registers will not be full until a total of 30 frames for each channel have been received. New channel status is compared with the current data to see if it has changed and is only read by the processor if it has. User data, which is also received at the same time, is stored into the register on a subframe basis, so that the reception is completed when 16 frames are reached.

Note 1. Channel status data requests do not support DMA.

Note 2. When receiver user buffer overrun occurs, the current data in the buffer data of SPDIF is overwritten by the next incoming data from SPDIF interface.

26.9.2 Receiver Module Initialization

The device defaults to an idle state when it comes out of reset, or can be put into an idle state by writing 0 to bit RME in the CTRL register. Whilst idle the module has the following settings:

- The receiver idle status bit is set to 1, all other status bits are cleared to 0.
- Synchronization between channels 1 and 2 is set to 0 (0 for channel 1, 1 for channel 2).
- Both Word_count and frame_count are set to 0.

Channel status registers, user data registers and audio data registers will retain its value prior to putting the module into idle. To exit the idle state the user must write 1 to the bit RME in the CTRL register.

26.9.3 Receiver Module Data Transfer

Once the module has left the idle state it is ready for data transfer. Data transfer timing can be achieved in three ways. The transfer can be done by interrupts, or by polling the status register, or by DMA. There is a shared interrupt line (transmit and receive) and a single receiver DMA request line. Data transfer for the receiver can be interrupted by error signals caused by:

1. Clock recovery failure.
2. Transmission loss or interference – indicated by a preamble error.
3. Parity check failure.

Transmission loss or interference can cause the start of subframe or start of block preamble to be misplaced or not present.

Parity check failure occurs when the parity bit is incorrect, this can be caused by any of the above.

- Clock Recovery Deviation

The receive margin for clock recovery is based on the following equation:

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

where M = receive margin

N = oversampling rate

L = frame length = 33

D = duty cycle = 0.6

F = oversampling clock deviation = Level II accuracy = 1000 in $10e^{-6}$

Figure 26.7 indicates what the receive margin M represents

Figure 26.7 Receive Margin

Introducing jitter into the equation gives the following inequality.

$$j \leq \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\%$$

J = clock jitter

Eight times oversampling produces a receive margin = 39.25%

Four times oversampling produces a receive margin = 31.75%

Two times oversampling produces a receive margin = 16.75%

The fastest sample frequency is 48 kHz. This requires a clock speed of $128 \times 48 \text{ kHz} = 6.144 \text{ MHz}$. The worst case jitter in one cycle is specified at 40 ns = 24.5% of the period. This means that an oversampling rate of 4 or more will satisfy the inequality and therefore be sufficient for clock recovery.

Figure 26.8 illustrates the receiver data transfer using interrupts.

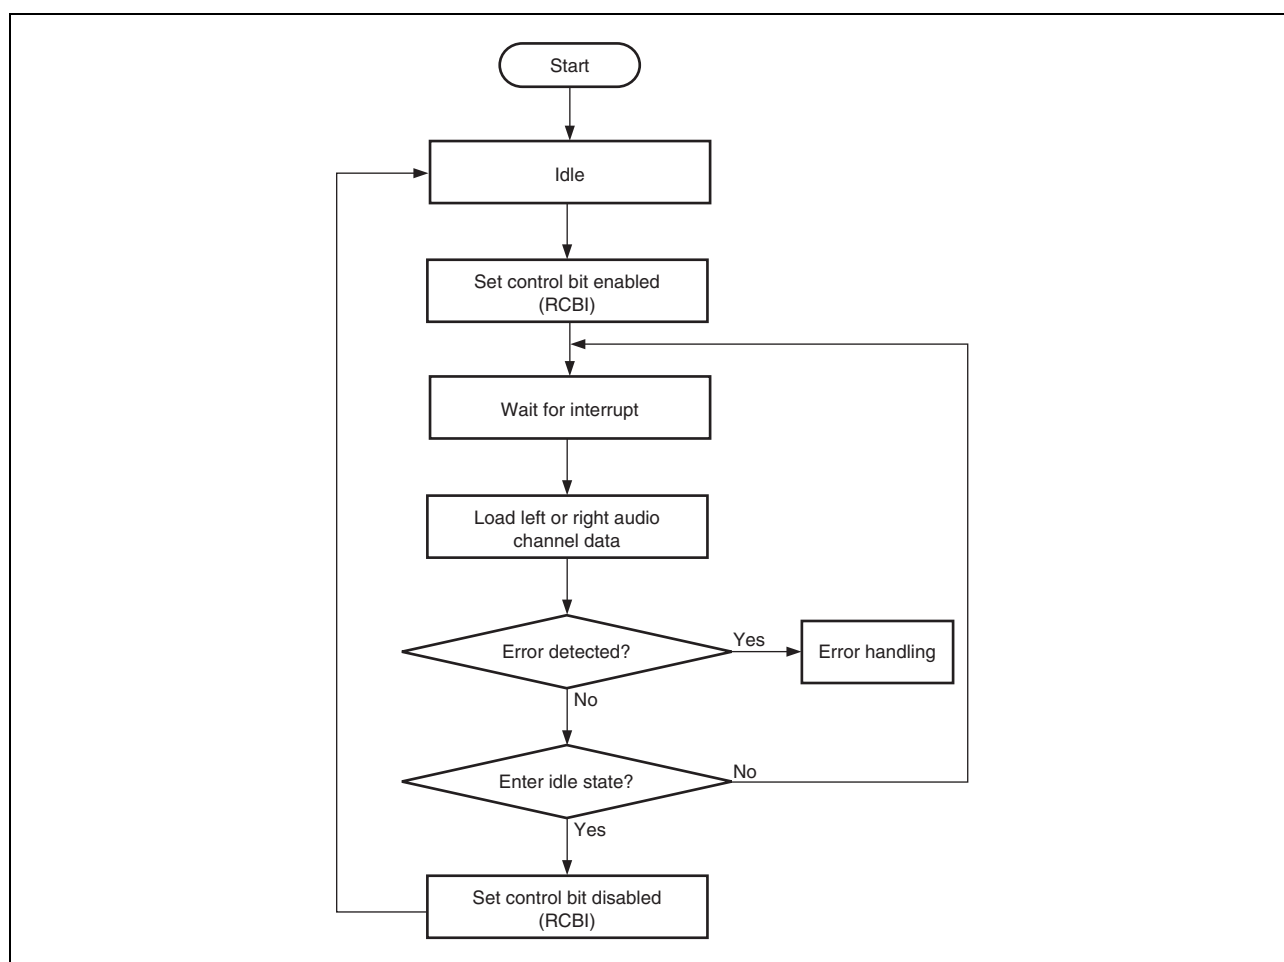

Figure 26.8 Receiver Data Transfer Flow Diagram - Interrupt Driven

Interrupts to indicate that the channel status information register is full occur after frame 30 has been received and only if the information has changed. When the first four bytes have been stored an interrupt occurs.

26.10 Disabling the Module

26.10.1 Transmitter and Receiver Idle

The transmitter or receiver modules can be disabled by writing 0 to the idle bit in the control register (TME for the transmitter and RME for the receiver). The idle state can be detected by polling the idle bit in the status register (TIS and RIS).

26.11 Compressed Mode Data

Compressed mode data is defined in the IEC 61937 specification. This module only detects compressed mode data. This is done by checking the parity flag (V flag) and bit 1 in the channel status data. If both are one then the data is in compressed mode. This is indicated by the setting of the CMD bit in the status register.

Note: Only the receiver detects compressed mode data since the information is not relevant to the transmitter.

IEC61937 Compressed Mode Digital Audio Interface

26.13 Usage Notes

26.13.1 Clearing TUIR

After TUI is written to, the TUIR bit is cleared only after transmission of a maximum of one frame is completed. When using a transmitter user information interrupt to write data to TUI, check that the TUIR bit is cleared before terminating the interrupt handling routine so that the interrupt is not unexpectedly accepted again.

26.13.2 Frequency of Clock Input for Audio

The frequency of the clock input to the AUDIO_X1 and AUDIO_X2 or AUDIO_CLK must be lower than the $P1\phi$ frequency.

27. Ethernet Controller (ETHERC)

27.1 Overview

This MCU has a two-channel Ethernet controller (ETHERC) compliant with the Ethernet or IEEE802.3 Media Access Control (MAC) layer protocol. Each ETHERC channel has one channel of the MAC layer interface, and connecting the MCU to the physical layer LSI (PHY-LSI) allows transmission and reception of frames compliant with the Ethernet/IEEE802.3 standard. The ETHERC is connected to the Ethernet controller direct memory access controller (EDMAC), so data can be transferred without using the CPU.

Table 27.1 lists the ETHERC specifications. Figure 27.1 shows the ETHERC configuration. Table 27.2 lists the ETHERC I/O pins.

Figure 27.2 and Figure 27.3 show examples of connecting the MCU to the PHY-LSI.

Table 27.1 ETHERC Specifications

| Item | Description |
|-----------------------------|---|
| Number of channels | Two channels |
| Protocol | Flow control compliant with IEEE802.3x |
| Data transmission/reception | Frames compliant with the Ethernet/IEEE802.3 standard can be transmitted and received. |
| Bit rate | Supports 10 Mbps and 100 Mbps |
| Operation modes | Supports full-duplex and half-duplex modes |
| Interfaces | Media Independent Interface (MII), Reduced Media Independent Interface (RMII), compliant with the IEEE802.3u standard |
| Functions | Magic Packet™ *1 detection, Wake-On-LAN (WOL) signal output |

Note 1. Magic Packet is a trademark of Advanced Micro Devices, Inc.

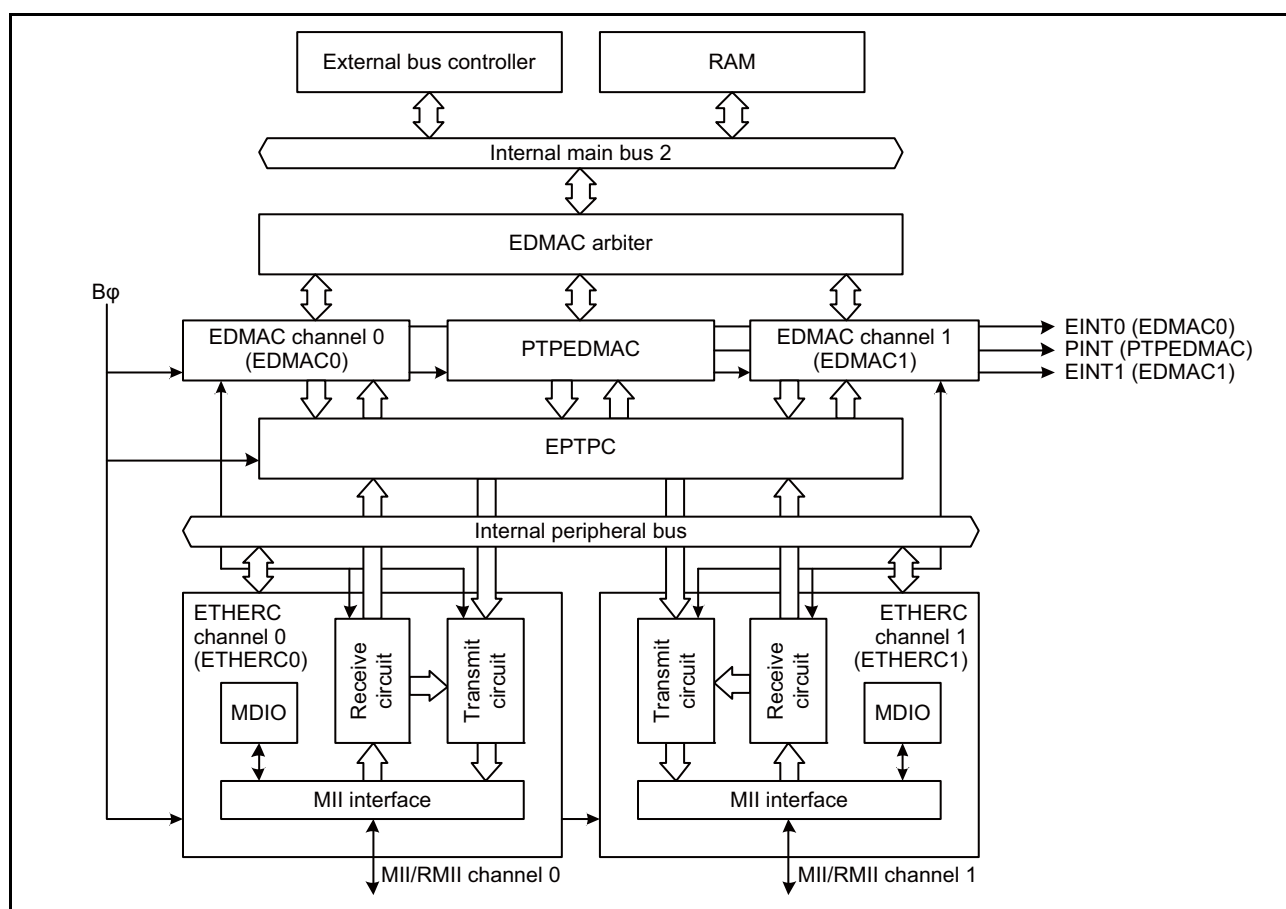

Figure 27.1 ETHERC Configuration

Table 27.2 ETHERC I/O Pins (n = 0, 1)

| Operating Mode | Pin Name | I/O | Description |
|----------------|---------------------------|------------------|--|
| MII | ETn_TX_CLK *1 | Input | Transmit clock Timing reference signal for outputting the ETn_TX_EN, ETn_ETXD3 to ETn_ETXD0, and ETn_TX_ER signals. |
| | ETn_RX_CLK *1 | Input | Receive clock Timing reference signal for inputting the ETn_RX_DV, ETn_ERXD3 to ETn_ERXD0, and ETn_RX_ER signals |
| | ETn_TX_EN *1 | Output | Transmit data valid This signal indicates that valid transmit data has been output on pins ETn_ETXD3 to ETn_ETXD0. |
| | ETn_ETXD3 to ETn_ETXD0 *1 | Output | 4-bit transmit data |
| | ETn_TX_ER *1 | Output | This signal notifies the PHY-LSI that an error occurred during transmission. |
| | ETn_RX_DV *1 | Input | Receive data valid This signal indicates that valid receive data is on pins ETn_ERXD3 to ETn_ERXD0. |
| | ETn_ERXD3 to ETn_ERXD0 *1 | Input | 4-bit receive data |
| | ETn_RX_ER *1 | Input | Receive error This signal indicates that there is an error in a frame that is being transferred from the PHY-LSI to the ETHERC. |
| | ETn_CRS *1 | Input | Carrier sense |
| | ETn_COL *1 | Input | Collision detection signal |
| | ETn_MDC *1 | Output | Management data clock Reference clock signal for transfer of information on the ETn_MDIO pin. |
| | ETn_MDIO *1 | I/O | Management data I/O Bidirectional data signal for exchanging management data with the PHY-LSI. |
| | ETn_LINKSTA | Input | Link status input from the PHY-LSI |

The ECMR register controls the ETHERC operation.

Set bits in the ECMR register, excluding bits TE and RE, during initialization after a reset. When rewriting this register outside the initialization process, set the EDMACn.EDMR.SWR bit to 1 to reset the EDMAC and ETHERC, and then set this register again.

PRM Bit (Promiscuous Mode)

When the PRM bit is set to 1, the ETHERC operates in promiscuous mode where all Ethernet frames are received. In promiscuous mode, the ETHERC receives all valid frames regardless of whether or not the address matches the destination address or broadcast address and regardless of the multicast bit setting.

RTM Bit (Bit Rate)

The RTM bit sets the bit rate when the RMII is selected.

ILB Bit (Internal Loopback Mode)

When the ILB bit is set to 1, transmit frames can be looped back in the MCU. Set the DM bit to 1 (full-duplex mode) to perform a loopback test.

TE Bit (Transmission Enable)

When the TE bit is set to 1, the ETHERC transmit function is enabled.

When the TE bit is set to 0, the transmit function is disabled after the frame being processed is completely transmitted.

RE Bit (Reception Enable)

When the RE bit is set to 1, the ETHERC receive function is enabled.

When the RE bit is set to 0, the receive function is disabled after the frame being processed is completely received.

PRCEF Bit (CRC Error Frame Receive Mode)

When the PRCEF bit is set to 1, the EDMAC is not notified that a CRC error has occurred even when the error is detected in a receive frame. Accordingly, the EDMACn.EESR.CERF flag and RFS0 bit in receive descriptor 0 (RD0) do not become 1.

ZPF Bit (0 Time PAUSE Frame Enable)

When the ZPF bit is 1, a PAUSE frame that contains the pause_time parameter of 0 is transmitted when the PAUSE frame transmit request is canceled before the PAUSE time of the previously transmitted PAUSE frame has not elapsed. After the PAUSE frame that contains the pause_time parameter of 0 is received, the ETHERC is ready for transmission. When the ZPF bit is 0, even if the PAUSE frame transmit request from the receive FIFO is canceled, the next PAUSE frame is not transmitted until the PAUSE time of the previously transmitted PAUSE frame has elapsed. When a PAUSE frame that contains the pause_time parameter of 0 is received, the PAUSE frame is discarded.

27.2.2 Receive Frame Maximum Length Register (RFLR)

Address: ETHERC0.RFLR E820 4108h, ETHERC1.RFLR E820 4308h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----------|-----|----|----|----|----|----|----|----|----|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | RFL[11:0] | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|------------------------------|--|-----|
| b11 to b0 | RFL[11:0] | Receive Frame Maximum Length | The set value becomes the maximum frame length. Values that are less than 1,518 bytes are regarded as 1,518 bytes, and values larger than 2,048 bytes are regarded as 2,048 bytes. | R/W |
| b31 to b12 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The RFLR register sets the maximum frame length that can be received by the MCU. Set the length in bytes.
Do not rewrite this register while the ECMR.RE bit is 1 (receive function is enabled).

RFL[11:0] Bits (Receive Frame Maximum Length)

The RFL[11:0] bits set a frame length to be checked. When the number of bytes for fields from the destination address to the frame check sequence (FCS) of the received frame exceeds the RFL[11:0] bit value, the EDMAC is notified of a frame-too-long error.

When the received frame length exceeds the RFL[11:0] bit value, the excess data is discarded.

27.2.3 ETHERC Status Register (ECSR)

Address: ETHERC0.ECSR E820 4110h, ETHERC1.ECSR E820 4310h

| | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|----|----|----|----|-----|-------|----|-------|-----|-----|
| b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| — | — | — | — | — | — | — | — | — | — | BFR | PSRTO | — | LCHNG | MPD | ICD |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|---|--|--------|
| b0 | ICD | False Carrier Detect Flag | 0: PHY-LSI has not detected a false carrier on the line. 1: PHY-LSI has detected a false carrier on the line. | R/W *1 |
| b1 | MPD | Magic Packet Detect Flag | 0: Magic Packet has not been detected. 1: Magic Packet has been detected. | R/W *1 |
| b2 | LCHNG | Link Signal Change Flag | 0: Change in the ETn_LINKSTA signal has not been detected. 1: Change in the ETn_LINKSTA signal has been detected (high to low, or low to high). | R/W *1 |
| b3 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b4 | PSRTO | PAUSE Frame Retransmit Over Flag | 0: PAUSE frame retransmit count has not reached the upper limit. 1: PAUSE frame retransmit count has reached the upper limit. | R/W *1 |
| b5 | BFR | Continuous Broadcast Frame Reception Flag | 0: Continuous reception of broadcast frames has not been detected. 1: Continuous reception of broadcast frames has been detected. | R/W *1 |
| b31 to b6 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

Note 1. Write 1 to clear the flag.

The ECSR register indicates the status of the ETHERC.

When any flag in the ECSR register becomes 1 while the corresponding bit in the ECSIPR register is 1 (interrupt is notified), the EDMACn.EESR.ECI flag becomes 1.

ICD Flag (False Carrier Detect Flag)

The ICD flag indicates that the PHY-LSI has detected a false carrier on the line.

The ICD flag becomes 1 when a receive error signal shown in Figure 1.11 is received from the PHY-LSI. Note that the information may not be correct when signals input from the PHY-LSI change faster than software recognizes the change. Check the timing of the PHY-LSI.

LCHNG Flag (Link Signal Change Flag)

The LCHNG flag indicates that ETn_LINKSTA signal input from the PHY-LSI has changed from high to low, or from low to high.

Refer to the PSR.LMON flag for the current link status.

PSRTO Flag (PAUSE Frame Retransmit Over Flag)

The PSRTO flag indicates that the number of retransmissions reaches the value set in the TPAUSER register when retransmitting a PAUSE frame while automatic PAUSE frame transmission is enabled.

27.2.4 ETHERC Interrupt Enable Register (ECSIPR)

Address: ETHERC0.ECSIPR E820 4118h, ETHERC1.ECSIPR E820 4318h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|------------|-------------|----|-------------|-------|-------|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | BFSIP R | PSRTO IP | — | LCHN GIP | MPDIP | ICDIP |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|---------|---|---|-----|
| b0 | ICDIP | False Carrier Detect Interrupt Enable | 0: Notification of the false carrier detect interrupt is disabled. 1: Notification of the false carrier detect interrupt is enabled. | R/W |
| b1 | MPDIP | Magic Packet Detect Interrupt Enable | 0: Notification of the Magic Packet detect interrupt is disabled. 1: Notification of the Magic Packet detect interrupt is enabled. | R/W |
| b2 | LCHNGIP | LINK Signal Change Interrupt Enable | 0: Notification of ETn_LINKSTA signal change interrupt is disabled. 1: Notification of ETn_LINKSTA signal change interrupt is enabled. | R/W |
| b3 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b4 | PSRTOIP | PAUSE Frame Retransmit Over Interrupt Enable | 0: Notification of PAUSE frame retransmit over interrupt is disabled. 1: Notification of PAUSE frame retransmit over interrupt is enabled. | R/W |
| b5 | BFSIPR | Continuous Broadcast Frame Reception Interrupt Enable | 0: Notification of continuous broadcast frame reception interrupt is disabled. 1: Notification of continuous broadcast frame reception interrupt is enabled. | R/W |
| b31 to b6 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The ECSIPR register selects whether or not to notify the EDMAC of the status indicated by the ECSR register. Each bit corresponds to the flag in the ECSR register that has the same bit number.

27.2.5 PHY Interface Register (PIR)

Address: ETHERC0.PIR E820 4120h, ETHERC1.PIR E820 4320h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|-----|-----|-----|-----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | MDI | MDO | MMD | MDC |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|--------------------------------|--|-----|
| b0 | MDC | MII/RMII Management Data Clock | The MDC bit value is output from the ETn_MDC pin to supply the management data clock to the MII or RMII. | R/W |
| b1 | MMD | MII/RMII Management Mode | 0: Read 1: Write | R/W |
| b2 | MDO | MII/RMII Management Data-Out | The MDO bit value is output from the ETn_MDIO pin when the MMD bit is 1 (write). The value is not output when the MMD bit is 0 (read). | R/W |
| b3 | MDI | MII/RMII Management Data-In | This bit indicates the level of the ETn_MDIO pin. The write value should be 0. | R/W |
| b31 to b4 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The PIR register is used to access registers in the PHY-LSI via the MII or RMII. The management clock and management data are controlled by software.

Refer to section 27.3.4, Accessing MII/RMII Registers for details on accessing MII and RMII registers.

27.2.6 PHY Status Register (PSR)

Address: ETHERC0.PSR E820 4128h, ETHERC1.PSR E820 4328h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|------|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | LMON |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|-----------------------------|--|-----|
| b0 | LMON | ETn_LINKSTA Pin Status Flag | The link status can be read by connecting the link signal output from the PHY-LSI to the ETn_LINKSTA pin. For details on the polarity, refer to the specifications of the connected PHY-LSI. | R |
| b31 to b1 | — | Reserved | The read value is 0. The write value should be 0. | R |

The PSR register is used to monitor interface signals from the PHY-LSI.

27.2.7 Random Number Generation Counter Limit Setting Register (RDMLR)

Address: ETHERC0.RDMLR E820 4140h, ETHERC1.RDMLR E820 4340h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|----------------------------------|---|-----|
| b19 to b0 | RMD[19:0] | Random Number Generation Counter | 00000h: Normal operation 00001h to FFFFh: Setting prohibited | R/W |
| b31 to b20 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The RDMLR register sets the maximum value for the counter used in the random number generator.

Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled) or while the ECMR.RE bit is 1 (receive function is enabled).

27.2.8 Interpacket Gap Register (IPGR)

Address: ETHERC0.IPGR E820 4150h, ETHERC1.IPGR E820 4350h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|----------|-----------------|---|-----|
| b4 to b0 | IPG[4:0] | Interpacket Gap | 00h: 16 bit time 01h: 20 bit time : : 14h: 96 bit time (initial value) : : 1Fh: 140 bit time | R/W |
| b31 to b5 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The IPGR register sets the interpacket gap (IPG) value.

Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled) or while the ECMR.RE bit is 1 (receive function is enabled).

Refer to section 27.3.6, Adjusting Transmission Efficiency by Changing the IPG.

27.2.9 Automatic PAUSE Frame Register (APR)

Address: ETHERC0.APR E820 4154h, ETHERC1.APR E820 4354h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|----------|------------------------------|---|-----|
| b15 to b0 | AP[15:0] | Automatic PAUSE Time Setting | These bits set the value of the pause_time parameter for a PAUSE frame that is automatically transmitted. Transmission is not performed until the set value multiplied by 512 bit time has elapsed. | R/W |
| b31 to b16 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The APR register sets the PAUSE time of the PAUSE frame that is automatically transmitted. The value set in the APR register is used for the pause_time parameter of the PAUSE frame.

Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled) or while the ECMR.RE bit is 1 (receive function is enabled).

27.2.10 Manual PAUSE Frame Register (MPR)

Address: ETHERC0.MPR E820 4158h, ETHERC1.MPR E820 4358h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|----------|---------------------------|---|-----|
| b15 to b0 | MP[15:0] | Manual PAUSE Time Setting | These bits set the value of the pause_time parameter for a PAUSE frame that is manually transmitted. Transmission is not performed until the set value multiplied by 512 bit time has elapsed. The read value is undefined. | R/W |
| b31 to b16 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The MPR register sets the PAUSE time of the PAUSE frame that is manually transmitted. The value set in the MPR register is used for the pause_time parameter of the PAUSE frame.

When a value is set to this register, a PAUSE frame is transmitted. Rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled).

27.2.11 Received PAUSE Frame Counter (RFCF)

Address: ETHERC0.RFCF E820 4160h, ETHERC1.RFCF E820 4360h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------------|---------------------------|---|-----|
| b7 to b0 | RPAUSE [7:0] | Manual PAUSE Time Setting | Received PAUSE Frame CountNumber of received PAUSE frames | R |
| b31 to b8 | — | Reserved | The read value is 0. | R |

The RFCF register is a counter indicating the number of received PAUSE frames. The counter is reset after this register is read.

27.2.12 PAUSE Frame Retransmit Count Setting Register (TPAUSER)

Address: ETHERC0.TPAUSER E820 4164h, ETHERC1.TPAUSER E820 4364h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|---------------|--|--|-----|
| b15 to b0 | TPAUSE [15:0] | Automatic PAUSE Frame Retransmit Setting | 0000h: Number of retransmissions is unlimited 0001h: Maximum number of retransmissions is 1 : : FFFFh: Maximum number of retransmissions is 65,535 | R/W |
| b31 to b16 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The TPAUSER register selects the maximum number of times a PAUSE frame is automatically transmitted. Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled).

27.2.13 PAUSE Frame Retransmit Counter (TPAUSEECR)

Address: ETHERC0.TPAUSEECR E820 4168h, ETHERC1.TPAUSEECR E820 4368h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|----------|------------------------------|---|-----|
| b7 to b0 | TXP[7:0] | PAUSE Frame Retransmit Count | Number of times a PAUSE frame was retransmitted | R |
| b31 to b8 | — | Reserved | The read value is 0. | R |

The TPAUSEECR register is a counter indicating the number of times a PAUSE frame was automatically retransmitted. The counter is reset after this register is read.

27.2.14 Broadcast Frame Receive Count Setting Register (BCFRR)

Address: ETHERC0.BCFRR E820 416Ch, ETHERC1.BCFRR E820 436Ch

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|--|---|-----|
| b15 to b0 | BCF[15:0] | Broadcast Frame Continuous Receive Count Setting | 0000h: Number of receptions is unlimited. 0001h: Receive 1 frame. : : FFFFh: Receive 65,535 frames. | R/W |
| b31 to b16 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The BCFRR register sets the number of times broadcast frames can be received continuously. When the number of received frames exceeds the BCF[15:0] bit value, the ECSR.BFR flag is set to 1 and the subsequent broadcast frames are discarded. Note that the internal counter that counts the continuous reception of broadcast frames is reset if it receives the frames other than broadcast frames.

Do not rewrite this register while the ECMR.RE bit is 1 (receive function is enabled).

27.2.15 MAC Address Upper Bit Register (MAHR)

Address: ETHERC0.MAHR E820 41C0h, ETHERC1.MAHR E820 43C0h

The MAHR register sets the upper 32 bits (b47 to b16) of the 48-bit MAC address. For example, if the MAC address is 01-23-45-67-89-AB, set the register to 0123 4567h.

Set the MAHR register during initialization after a reset. Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled) or while the ECMR.RE bit is 1 (receive function is enabled). When rewriting this register, set the EDMACn.EDMR.SWR bit to 1 to reset the EDMAC and ETHERC and then set this register again.

27.2.16 MAC Address Lower Bit Register (MALR)

Address: ETHERC0.MALR E820 41C8h, ETHERC1.MALR E820 43C8h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|--|-----|
| b15 to b0 | — | — | These bits set the lower 16 bits of the MAC address. | R/W |
| b31 to b16 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The MALR register sets the lower 16 bits of the 48-bit MAC address. For example, if the MAC address is 01-23-45-67-89-AB, set the register to 0000 89ABh.

Set the MALR register during initialization after a reset. Do not rewrite this register while the ECMR.TE bit is 1 (transmit function is enabled) or while the ECMR.RE bit is 1 (receive function is enabled). When rewriting this register, set the EDMACn.EDMR.SWR bit to 1 to reset the EDMAC and ETHERC and then set this register again.

27.2.17 Transmit Retry Over Counter Register (TROCR)

Address: ETHERC0.TROCR E820 41D0h, ETHERC1.TROCR E820 43D0h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

The TROCR register is a counter indicating the number of frames that fail to be retransmitted.

The TROCR register is incremented by 1 when a frame fails to be retransmitted 15 times. The counter stops when the TROCR register value becomes FFFF FFFFh. The counter value becomes 0 by writing any value to the TROCR register.

27.2.18 Late Collision Detect Counter Register (CDCR)

Address: ETHERC0.CDCR E820 41D4h, ETHERC1.CDCR E820 43D4h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Value after reset: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| Value after reset: | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

The CDCR register is a counter indicating the number of late collisions that have been detected after transmission starts. When the CDCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the CDCR register.

27.2.19 Lost Carrier Counter Register (LCCR)

Address: ETHERC0.LCCR E820 41D8h, ETHERC1.LCCR E820 43D8h

The LCCR register is a counter indicating the number of times a loss of carrier is detected during frame transmission. When the LCCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the LCCR register.

27.2.20 Carrier Not Detect Counter Register (CNDCCR)

Address: ETHERC0.CNDCCR E820 41DCh, ETHERC1.CNDCCR E820 43DCh

The CNDCCR register is a counter indicating the number of times a carrier is not detected during preamble transmission. When the CNDCCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the CNDCCR register.

27.2.21 CRC Error Frame Receive Counter Register (CEFCR)

Address: ETHERC0.CEFCR E820 41E4h, ETHERC1.CEFCR E820 43E4h

The CEFCR register is a counter indicating the number of received frames where a CRC error has been detected. When the CEFCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the CEFCR register.

27.2.22 Frame Receive Error Counter Register (FRECR)

Address: ETHERC0.FRECR E820 41E8h, ETHERC1.FRECR E820 43E8h

The FRECR register is a counter indicating the number of times a frame receive error has occurred. The PHY-LSI notifies the ETHERC of the frame receive error using the ETn_RX_ER pin.

The FRECR register is incremented each time the ETn_RX_ER pin becomes high. When the FRECR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the FRECR register.

The SYSR.INFABT flag of the EPTPC may be set to 1 when a frame receive error occurs, regardless of whether or not the EPTPC is in use. In such cases, reset the EPTPC, PTPEDMAC, and respective channel of the ETHERC and EDMAC. For the procedure of resetting, see section 27, Handling when Control Information Included a Mismatch.

27.2.23 Too-Short Frame Receive Counter Register (TSFRCR)

Address: ETHERC0.TSFRCR E820 41ECh, ETHERC1.TSFRCR E820 43ECh

The TSFRCR register is a counter indicating the number of times a short frame that is shorter than 64 bytes has been received. When the TSFRCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the TSFRCR register.

27.2.24 Too-Long Frame Receive Counter Register (TLFRCR)

Address: ETHERC0.TLFRCR E820 41F0h, ETHERC1.TLFRCR E820 43F0h

The TLFRCR register is a counter indicating the number of times a long frame that is longer than the RFLR register value has been received.

When the TLFRCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the TLFRCR register.

Note that the TLFRCR register is not incremented when a frame is received with the alignment error. In this case, the RFCR register is incremented.

27.2.25 Received Alignment Error Frame Counter Register (RFCR)

Address: ETHERC0.RFCR E820 41F4h, ETHERC1.RFCR E820 43F4h

The RFCR register is a counter indicating the number of times a frame has been received with the alignment error (frame is not an integral number of octets).

When the RFCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the RFCR register.

The SYSR.INFABT flag of the EPTPC may be set to 1 when an alignment error is detected, regardless of whether or not the EPTPC is in use. In such cases, reset the EPTPC, PTPEDMAC, and respective channel of the ETHERC and EDMAC. For the procedure of resetting, see section 27, Handling when Control Information Included a Mismatch.

27.2.26 Multicast Address Frame Receive Counter Register (MAFCR)

Address: ETHERC0.MAFCR E820 41F8h, ETHERC1.MAFCR E820 43F8h

The MAFCR register is a counter indicating the number of times a frame where the multicast address is set has been received.

When the RFCR register value becomes FFFF FFFFh, the counter stops. The counter value becomes 0 by writing any value to the RFCR register.

27.3 Operation

This section is an overview of the ETHERC operations. The ETHERC supports flow control compliant with IEEE802.3x, and can transmit and receive PAUSE frames.

27.3.1 Transmission

The ETHERC transmitter assembles transmit data into a frame and outputs it to the MII/RMII when a transmit request is received from the EDMAC. The frame transmitted via the MII/RMII is transmitted on the line by the PHY-LSI. Figure 27.4 shows the state transitions of the ETHERC transmit-ter.

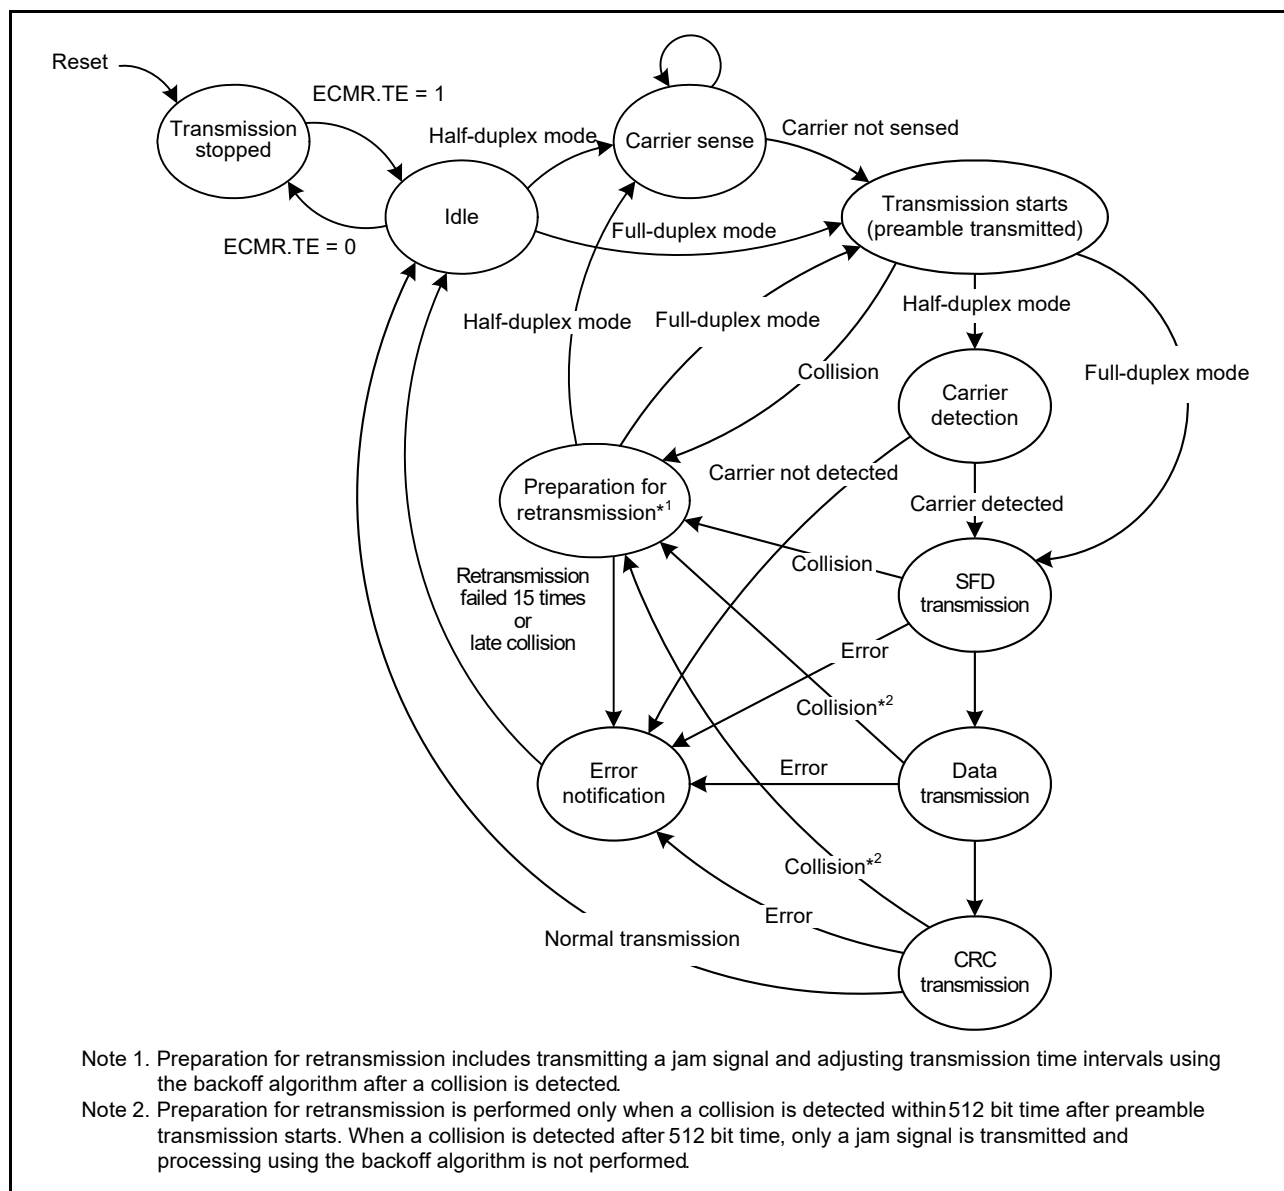

Figure 27.4 ETHERC Transmitter State Transitions

1. When setting the ECMR.TE bit to 1, the ETHERC enters the transmit idle state.
2. When a transmit request is received from the EDMAC, the ETHERC enters the carrier sense state. The ETHERC waits for the interpacket gap and then transmits a preamble to the MII/RMII. When full-duplex mode is selected, it is not required to sense a carrier, so the ETHERC transmits a preamble immediately after receiving a transmit request from the EDMAC.
3. The ETHERC transmits the Start Frame Delimiter (SFD), transmit data, and CRC sequentially. When the transmission is completed successfully, the ETHERC notifies the EDMAC of successful completion, and the EDMAC sets the EDMACn.EESR.TC flag to 1. When a late collision or loss of carrier is detected during data transmission, the ETHERC stops the transmission and notifies the EDMAC of the error.
4. After the time for the interpacket gap has elapsed, the ETHERC enters the idle state and continues transmission when transmit data remains.

27.3.2 Reception

The ETHERC receiver separates the frame input from the MII/RMII into the preamble, SFD, receive data, and CRC, and transmits only receive data (destination address, source address, type/length, data/LLC). Figure 27.5 shows the state transitions of the ETHERC receiver.

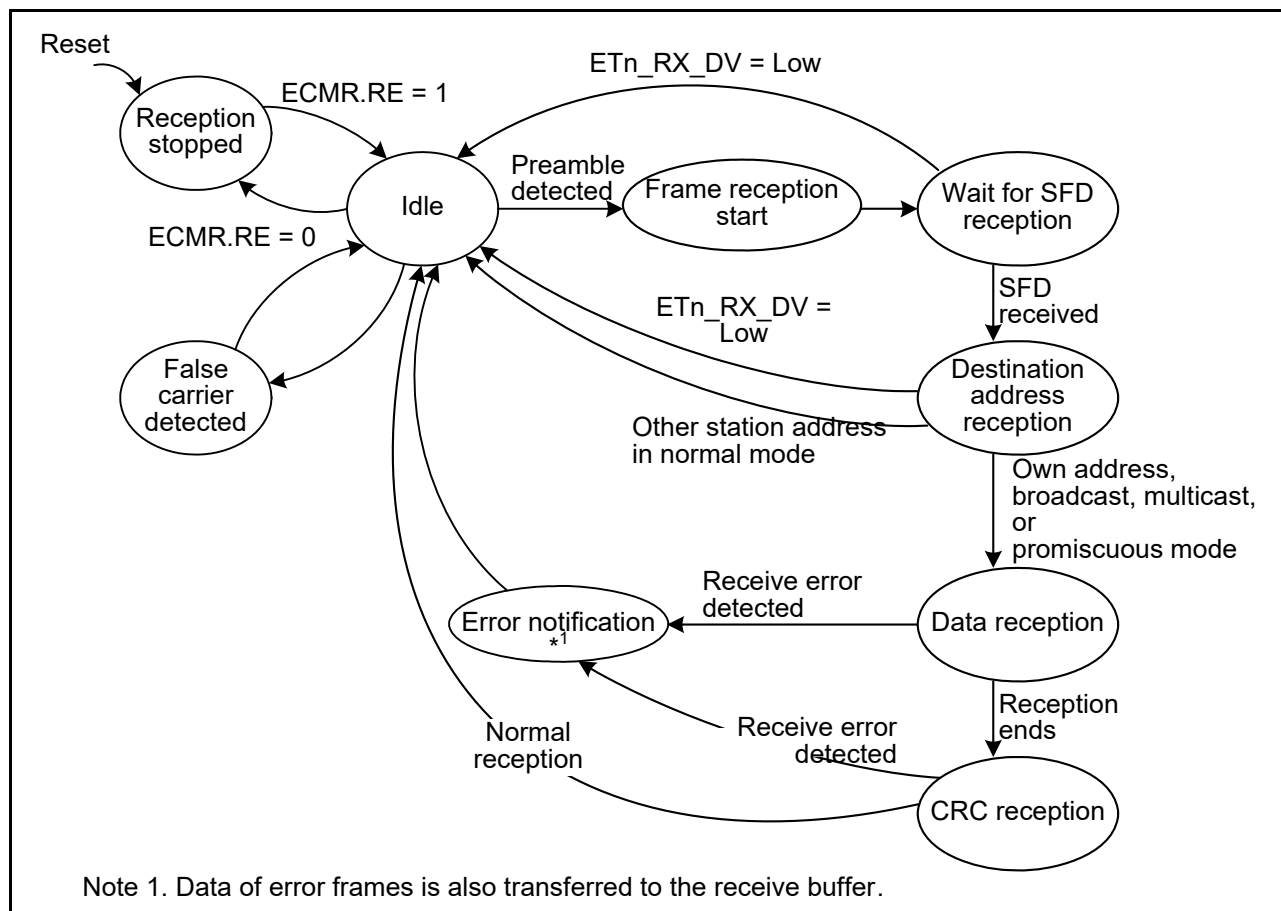

Figure 27.5 ETHERC Receiver State Transitions

1. When setting the ECMR.RE bit to 1, the ETHERC enters the receive idle state.
2. When the SFD following the preamble of the receive packet is detected, the ETHERC starts reception. If the received SFD is invalid, the ETHERC discards the frame.
3. In normal mode, the ETHERC starts data reception when the destination address of the receive frame is the address of the MCU or the receive frame is broadcast frame or multicast frame. In promiscuous mode, the ETHERC starts data reception regardless of the receive frame type.
4. After receiving data from the MII/RMII, the ETHERC performs the CRC check. The ETHERC notifies the EDMAC of the CRC check result. After the received data is transferred to the receive buffer, the CRC check result is written back to the receive descriptor as a status. The result is also reflected in the EDMACn.EESR.CERF flag.
5. When the ECMR.RE bit is 1 after one frame has been received, the ETHERC prepares to receive the next frame.

27.3.3 Frame Timing

27.3.3.1 MII Frame Timing

Figure 27.6 to Figure 27.11 show the MII frame timing.

Figure 27.6 MII Frame Transmit Timing During Normal Transmission

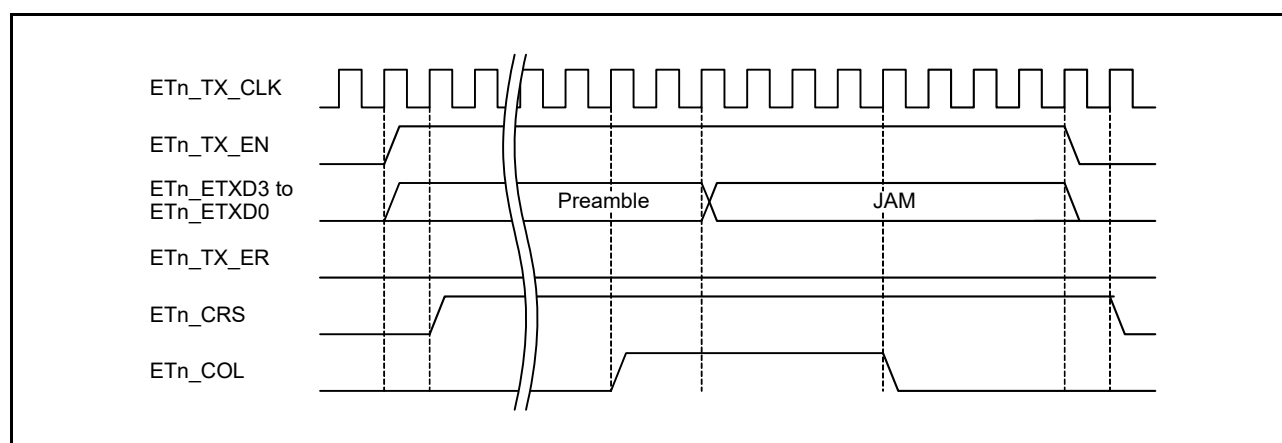

Figure 27.7 MII Frame Transmit Timing When Collision Occurs

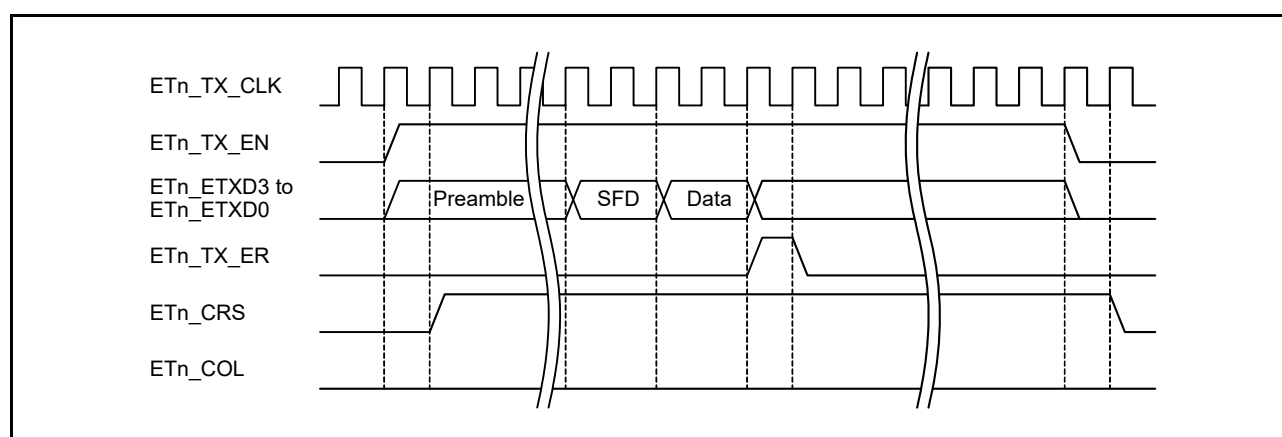

Figure 27.8 MII Frame Transmit Timing When Transmit Error Occurs

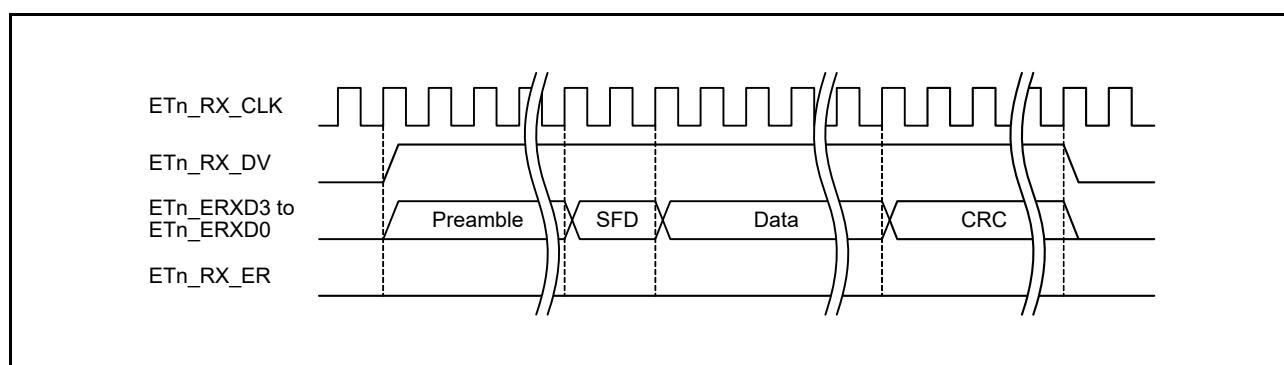

Figure 27.9 MII Frame Receive Timing During Normal Reception

Figure 27.10 MII Frame Receive Timing for Receive Error Notification

Figure 27.11 MII Frame Receive Timing for False Carrier Notification

27.3.3.2 RMII Frame Timing

The RMII frame timing is shown in Figure 27.12 to Figure 27.14.

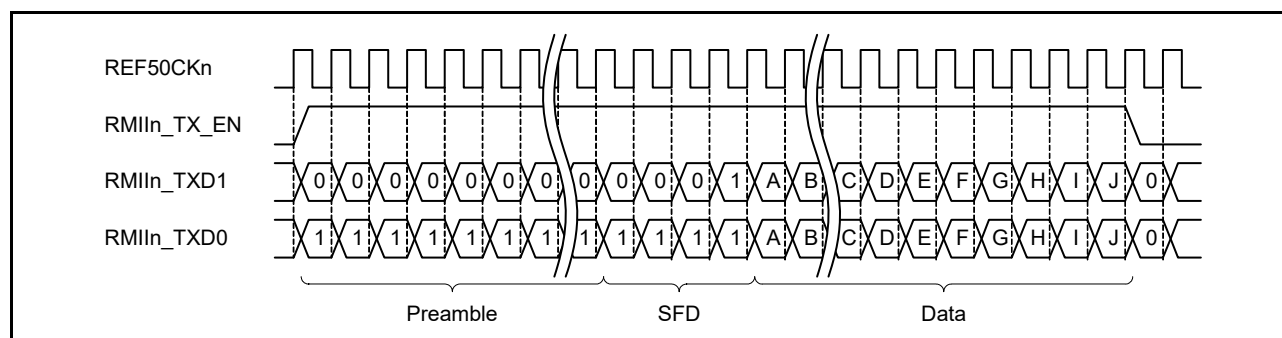

Figure 27.12 RMII Frame Transmit Timing During Normal Transmission

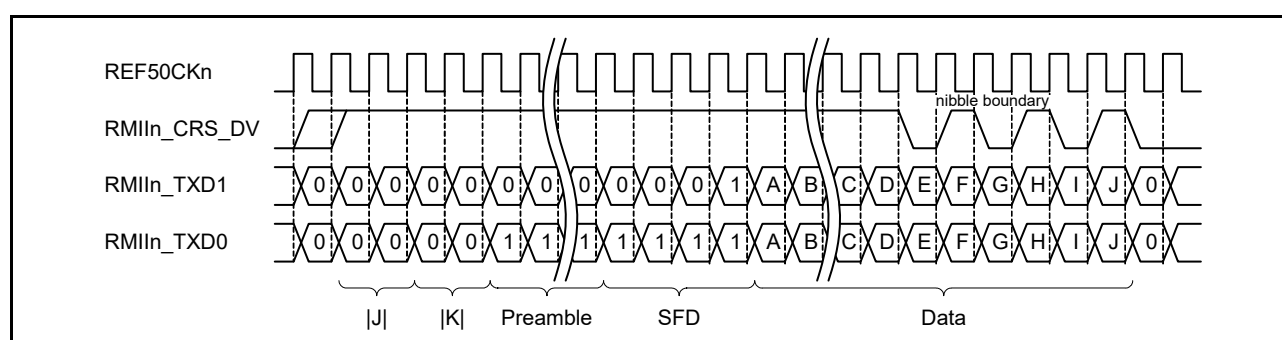

Figure 27.13 RMII Frame Receive Timing During Normal Reception

Figure 27.14 RMII Frame Receive Timing When False Carrier Is Detected

27.3.4 Accessing MII/RMII Registers

Use the PIR register to access the MII/RMII registers in the PHY-LSI. Serial data in the MII/RMII management frame format is transmitted and received via the ETn_MDC and ETn_MDIO pins controlled by software.

27.3.4.1 MII/RMII Management Frame Format

Table 27.4 lists the MII/RMII management frame format.

Table 27.4 MII/RMII Management Frame Format

| Access Type | MII/RMII Management Frame | | | | | | | |
|----------------|---------------------------|----|----|-------|-------|----|--------------------|------|
| Item | PRE | ST | OP | PHYAD | REGAD | TA | DATA | IDLE |
| Number of bits | 32 | 2 | 2 | 5 | 5 | 2 | 16 | 1 |
| Read | 1...1 | 01 | 10 | 00001 | RRRRR | Z0 | DDDDDDDDDDDDDDDDDD | Z |
| Write | 1...1 | 01 | 01 | 00001 | RRRRR | 10 | DDDDDDDDDDDDDDDDDD | Z |

PRE (preamble): Send 32 consecutive 1's.

ST (start of frame): Send 01b.

OP (operation code): Send 10b for read or 01b for write.

PHYAD (PHY address): Up to 32 PHY-LSIs can be connected to one MAC. PHY-LSIs are selected with these 5 bits.

When the PHY-LSI address is 1, send 00001b.

REGAD (register address): One register is selected from up to 32 registers in the PHY-LSI.

When the register address is 1, send 00001b.

TA (turnaround): 2-bit turnaround time to avoid contention between the register address and data during a read operation

(a) Send 10b during a write operation.

(b) Release the bus for 1 bit during a read operation (Z is output)

(indicated as Z0 because 0 is output from the PHY-LSI on the next clock cycle).

DATA (data): 16-bit data. Sequentially send or receive starting from the MSB.

IDLE (IDLE condition): Wait time to input the next MII/RMII management format

(a) Release the bus during a write operation (Z is output).

(b) No control is required since a bus has already been released during a read operation.

27.3.4.2 MII/RMII Register Access Procedure

Access to the MII/RMII registers includes writing data in 1-bit units, reading data in 1-bit units, and releasing the bus.

Figure 27.15 to Figure 27.18 show examples of the MII/RMII register access timing. The access timing differ with the PHY-LSI type.

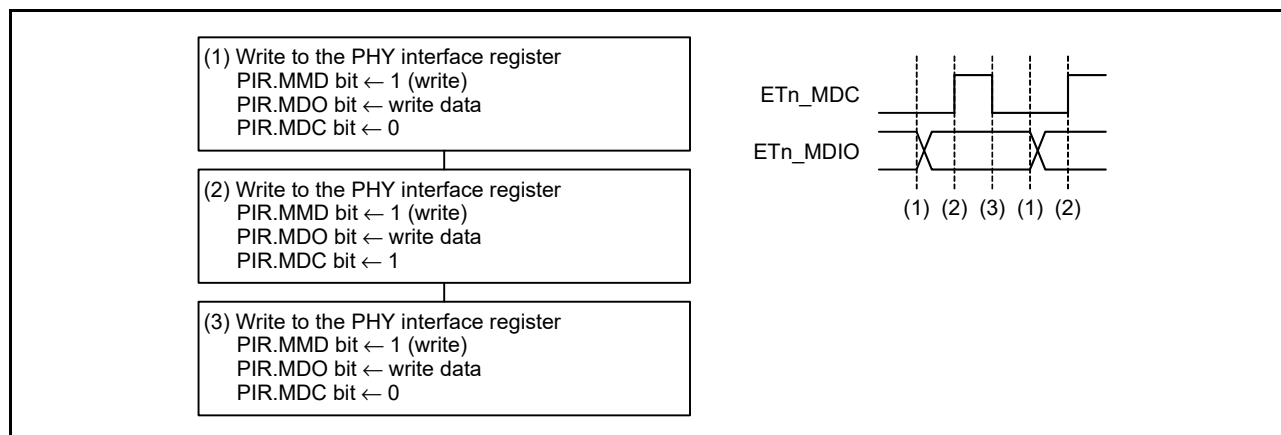

Figure 27.15 1-Bit Data Write Flow

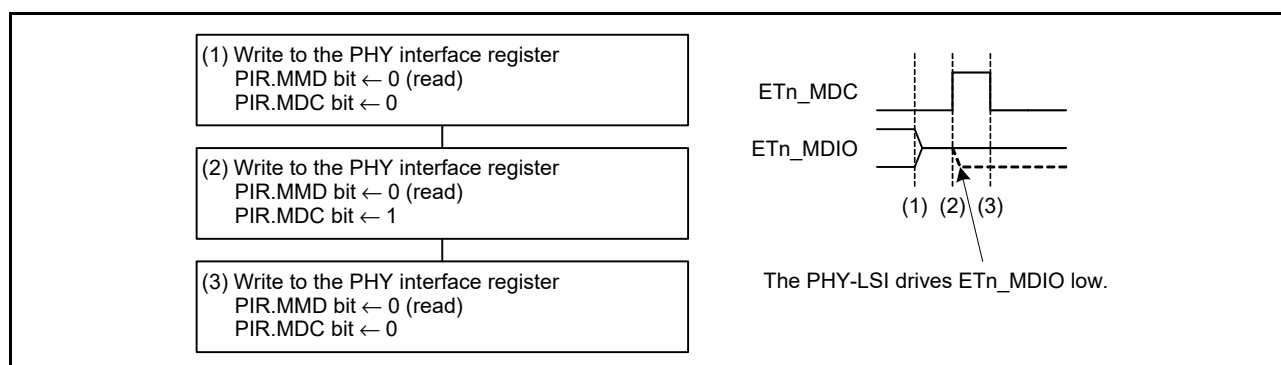

Figure 27.16 Bus Release Flow (TA in Read Operation in Table 1.3)

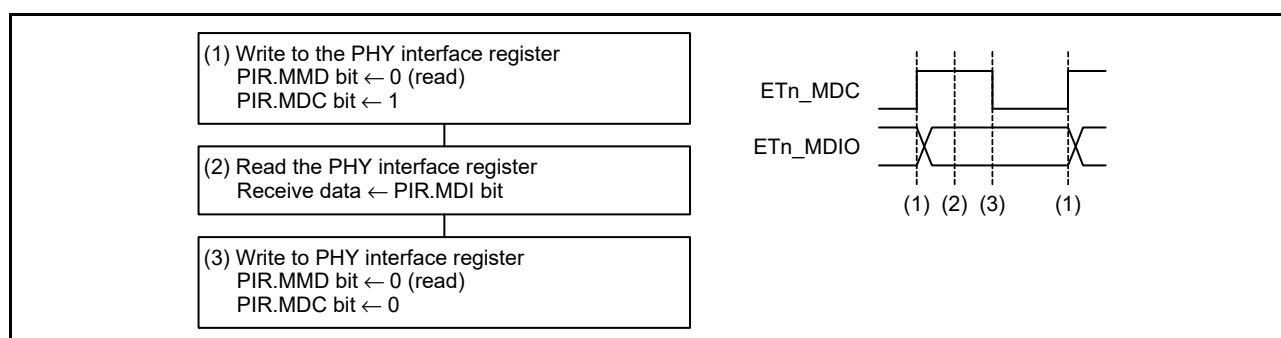

Figure 27.17 1-Bit Data Read Flow

Figure 27.18 Bus Release Flow (IDLE in Write Operation in Table 1.3)

27.3.5 Magic Packet Detection

The ETHERC supports Wake-On-LAN (WOL). WOL is a function to detect a Magic Packet transmitted from a host device or other device and exit a low power consumption state such as sleep mode. When the ETHERC detects a Magic Packet, high is output from the ETn_WOL pin. Write 1 to the EDMACn.EDMR.SWR bit to set the ETn_WOL pin to low.

Since a Magic Packet is transmitted in broadcast mode, the Magic Packet is received regardless of the destination MAC address selected in the format. The ETHERC outputs high from the ETn_WOL pin only when the destination MAC address matches its own MAC address. Refer to the technical documentation provided by Advanced Micro Devices, Inc. for details on the Magic Packet. The following describes an example of the procedure to use WOL in the MCU.

1. Set the interrupt controller to disable the EINTn interrupt request.
2. Set the ECMR.MPDE bit to 1 to enable Magic Packet detection. Set the ECMR.RE bit to 1 to enable reception.
3. Set the ECSIPR.MPDIP bit to 1 to enable notification of the Magic Packet detect interrupt.
4. Set the EDMACn.EESIPR.ECIIP bit to 1 to enable the ETHERC status register source interrupt.
5. Set the interrupt controller to enable the EINTn interrupt request.
6. Change the CPU operating mode to sleep mode or place unused peripherals in the module stop state as needed.
7. When a Magic Packet is detected, an interrupt request is sent to the CPU. High is output from the ETn_WOL pin to notify peripheral devices that the Magic Packet has been detected.

27.3.5.1 Notes on Magic Packet Detection

The ETHERC receives packets, including broadcast packets, even when waiting to receive a Magic Packet. Therefore, receive data may have been stored in the receive FIFO of the EDMAC when a Magic Packet is detected. Also, flags in registers ECSR and EDMACn.EESR may have been changed. When returning to normal operation by detecting a Magic Packet, set the EDMACn.EDMR.SWR bit to 1 to reset the ETHERC and EDMAC.

27.3.6 Adjusting Transmission Efficiency by Changing the IPG

The IPG is a non-transmit period between transmit frames. The ETHERC can change the value of the IPG. Transmission efficiency can be increased or decreased by setting the IPGR register. The typical value of the IPG is specified by the IEEE802.3 standard. When changing the setting, confirm that all devices operate normally in the same network.

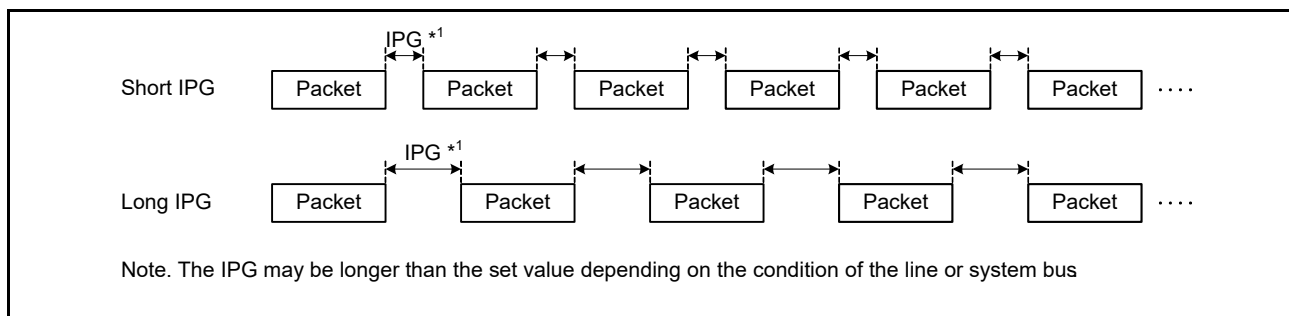

Figure 27.19 Differences in Transmission Efficiency Based on Changes in the IPG

27.3.7 Flow Control

The ETHERC can perform flow control compliant with IEEE802.3x in full-duplex mode, and the receiver and transmitter can be set individually. PAUSE frames can be transmitted automatically or manually.

27.3.7.1 Automatic PAUSE Frame Transmission

When the ECMR.TXF bit is set to 1, automatic PAUSE frame transmission is enabled. A PAUSE frame is automatically transmitted by a PAUSE frame transmit request from the EDMAC. The APR.AP[15:0] bit value is used for the pause_time parameter of the PAUSE frame.

After a PAUSE frame is transmitted, if the EDMAC is still requesting PAUSE frame transmission when the PAUSE time elapses, a PAUSE frame is transmitted again. The maximum number of PAUSE frame retransmissions can be set in the TPAUSER.TPAUSE[15:0] bits. If the maximum number of retransmissions is reached, subsequent PAUSE frames are not transmitted.

Figure 27.20 shows the procedure to set automatic PAUSE frame transmission.

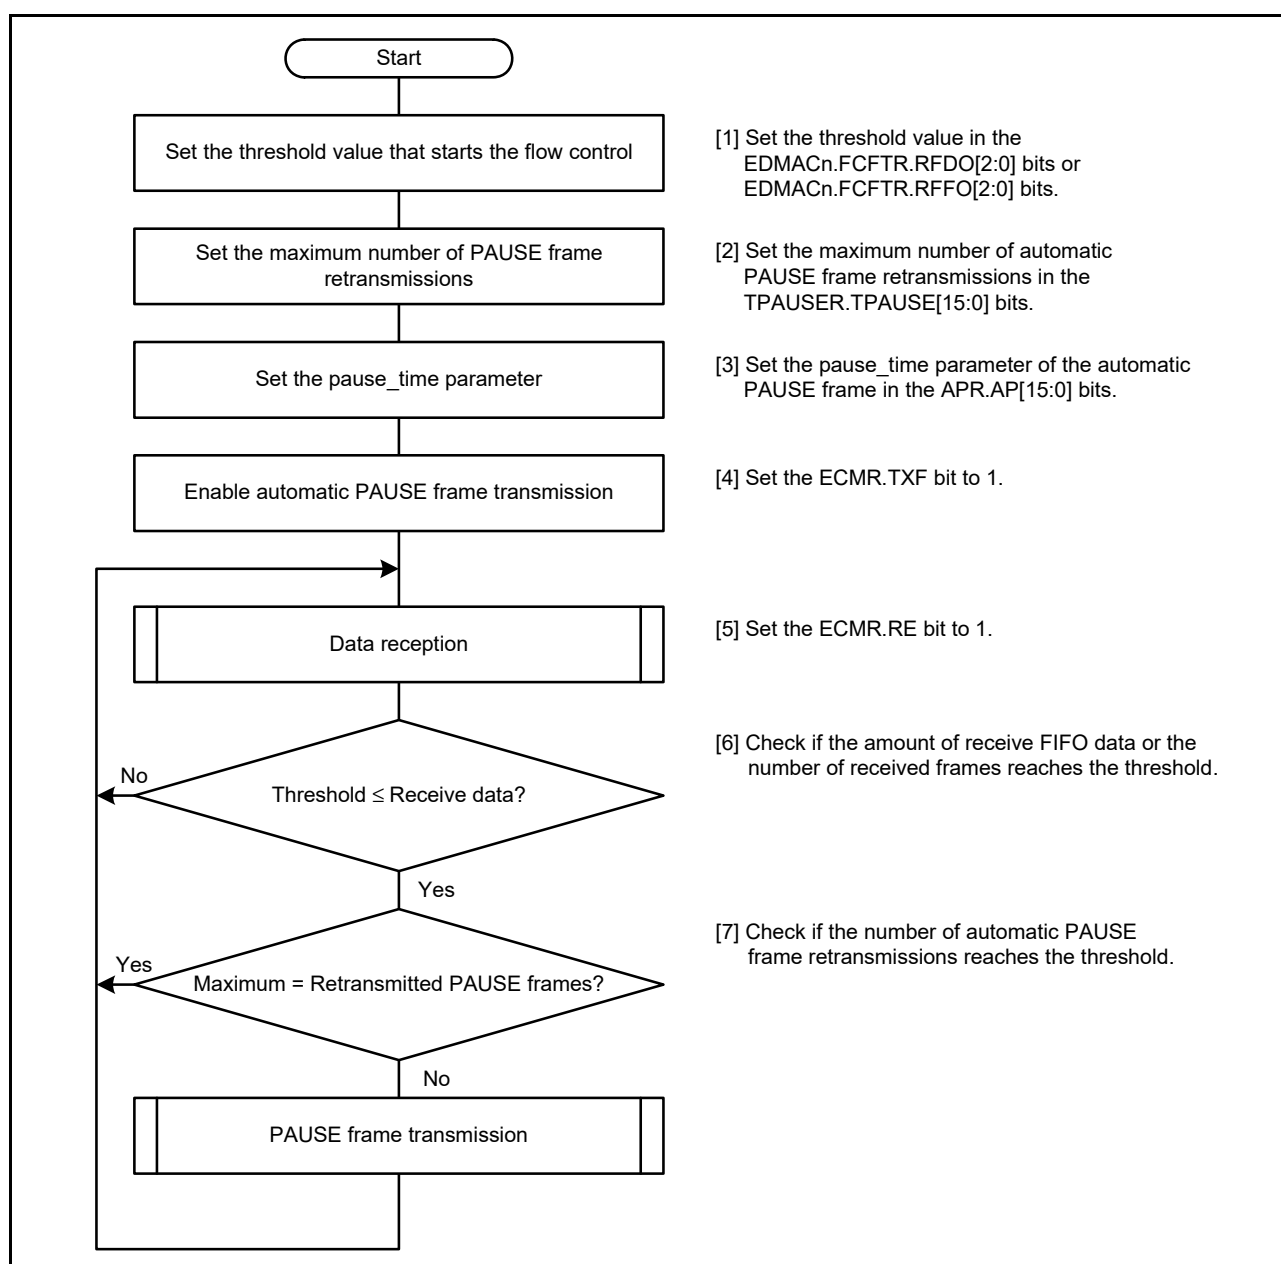

Figure 27.20 Example of Procedure to Set Automatic PAUSE Frame Transmission

27.3.7.2 Manual PAUSE Frame Transmission

A PAUSE frame can be manually transmitted at any time. When writing the `pause_time` parameter of the PAUSE frame to the `MPR.MP[15:0]` bits by software, the ETHERC transmits a PAUSE frame once. When transmitting a PAUSE frame more than once, write to the `MPR.MP[15:0]` bits for each transmission.

27.3.7.3 PAUSE Frame Reception

When setting the `ECMR.RXF` bit to 1, PAUSE frame detection is enabled. After a PAUSE frame is received, the ETHERC completes transmitting the current frame and waits for the PAUSE time of the received PAUSE frame to elapse before the next frame can be transmitted. Also, the ETHERC increments the `RFCF.RPAUSE[7:0]` bit value.

However, while waiting for the PAUSE time to elapse, if a PAUSE frame that contains a `pause_time` parameter of 0 is received and the `ECMR.ZPF` bit is 1, the ETHERC becomes ready to transmit.

27.4 Interrupts

When a flag in the `ECSR` register becomes 1 and the corresponding bit in the `ECSIPR` register is 1, the ETHERC notifies the EDMAC of the status as an interrupt source. After receiving the notification, the EDMAC sets the `EDMACn.EESR.ECI` flag to 1. When the `EDMACn.EESIPR.ECIIP` bit is 1, the EDMAC sends an `EINTn` interrupt request to the CPU. Refer to section 29, DMA Controller for the Ethernet Controller (EDMACa) for details.

27.5 Usage Notes

27.5.1 Conditions for the LCHNG Flag to Become 1

The ECSR.LCHNG flag may become 1 even when the input level of the ETn_LINKSTA pin remains the same. In this case, high is input to the ETn_LINKSTA pin when setting the GPIO.PmnPFS register to assign the ETn_LINKSTA signal to a port or when releasing the ETHERC and EDMAC software reset using the EDMACn.EDMR.SWR bit. The ECSR.LCHNG flag becomes 1 because the ETn_LINKSTA signal in the ETHERC is fixed low regardless of the input level to the external pin while the GPIO does not assign the ETn_LINKSTA signal or during the ETHERC and EDMAC software reset.

To avoid wrongly generating a link signal change interrupt, clear the ECSR.LCHNG flag and then set the ECSIPR.LCHNGIP bit to 1.

27.5.2 Input to the RMII_n_RX_ER Pin While the RMII is Selected

When the width of a reception error signal received from the PHY-LSI is only one cycle of the REF50CK_n clock (50 MHz) while the RMII is selected, the signal is not recognized as an error signal.

27.5.3 Handling when Control Information Included a Mismatch

When the setting of the BYPASS.BYPASS_n bit of the EPTPC is 0, the SYSR.INFABT flag of the EPTPC_n might be set to 1 on reception of an alignment error or a frame error. In such cases, reset the EPTPC, PTPEDMAC, and respective channel of the ETHERC and EDMAC. For the procedure of resetting, see section 27, Procedure of Resetting the Ethernet Controller.

27.5.4 Points to Note when the EPTPC Is not in Use

When the EPTPC is not to be used, set the BYPASS0 and BYPASS1 bits in the BYPASS register of the EPTPC to 1.

27.5.5 Procedure of Resetting the Ethernet Controller

Follow the steps below to reset the ETHERC, EPTPC, and EDMAC.

(a) When the EPTPC is not in use:

- (1) Write 0000 0001h to the EDMR register in the respective channel of the EDMAC (resetting the ETHERC_n and EDMAC_n).
- (2) Wait for 64 cycles of B_φ until initialization is completed.

(b) When the EPTPC is in use:

- (1) Write 0000 0001h to the PTRSTR register of the EPTPC (resetting the EPTPC).
- (2) Write 0000 0001h to the EDMR register of the PTPEDMAC (resetting the PTPEDMAC).
- (3) Write 0000 0001h to the EDMR register of the respective channel of EDMAC (resetting the ETHERC_n and EDMAC_n).
- (4) Wait for 64 cycles of B_φ until initialization is completed.
- (5) Write 0000 0000h to the PTRSTR register of the EPTPC (releasing the EPTPC from the reset state).
- (6) Wait for 256 cycles of B_φ until the EPTPC is released from the reset state.

28. PTP Module for the Ethernet Controller (EPTPCa)

28.1 Overview

This MCU has an on-chip Precision Time Protocol (PTP) module for the Ethernet controller (EPTPC). The module applies the PTP defined in version 2 of the IEEE 1588-2008 standard to handle timing and synchronization between devices. The EPTPC is composed of synchronization frame processing units (SYNFP0 and SYNFP1), a packet relation controller unit (PRC-TC), and a statistical time correction algorithm unit (STCA).

Use the EPTPC in combination with the on-chip Ethernet controller (ETHERC) and the DMA controller for the PTP Ethernet controller (PTPEDMAC).

Table 28.1 lists the EPTPC specifications, and Figure 28.1 shows the EPTPC configuration.

Table 28.1 EPTPC Specifications

| Item | Description |
|--|---|
| Protocol | Compliant with the Precision Time Protocol (PTP) defined in IEEE 1588 |
| Synchronization frame processing units (SYNFP0 and SYNFP1) | <ul style="list-style-type: none"> Transmits and receives PTP messages as a master or slave. The following four clock devices are supported: <ul style="list-style-type: none"> Ordinary clock (OC) Boundary clock (BC) End-to-end transparent clock (E2E TC) Peer-to-peer transparent clock (P2P TC) Calculates the meanPathDelay and offsetFromMaster values defined in IEEE 1588. Capable of generating a master clock. Hardware filtering of received multicast packets with a MAC address Capable of hardware filtering in accord with the type of PTP message Supports PTP message frames in layer 4 (IPv4 and UDP) and layer 2 (Ethernet frames). Can be used as a normal Ethernet port when time synchronization is not in use. |
| Packet relation controller unit (PRC-TC) | <ul style="list-style-type: none"> Relaying of received data between Ethernet ports 0 and 1 Setting the same MAC address for Ethernet ports 0 and 1 allows transmission of data from the two ports or from only one of them. Store-and-forward method or cut-through method selectable for the relaying of packets |
| Statistical time correction algorithm unit (STCA) | <ul style="list-style-type: none"> Frequency of the clock signal supplied to the statistical time correction algorithm unit is selectable as 20, 25, or 50 MHz. The clock source can be selected from the external clock ETn_SCLKIN (20, 25, or 50 MHz), REF50CKn (50 MHz), or ETn_RX_CLK (25 MHz). Note: When ETn_RX_CLK is selected, ETn_RX_CLK must be fixed to 25 MHz (100 Mbps). In slave operation, the synchronized state can be indicated from the offsetFromMaster value staying below a previously specified threshold. Additionally, the threshold can be calculated statistically from collected positive and negative gradient values (worst-10 acquisition). The local clock counter holds corrected time information obtained from a master clock. The STCA clock can be used as the clock source for generating pulse signals from pulse output timer m (m = 0 to 5). |
| Interrupt sources | MINT interrupt <ul style="list-style-type: none"> Requested when the state of the individual modules is changed. Requested on rising edges of the pulse signal generated by the pulse output timer. IPLS interrupt <ul style="list-style-type: none"> Requested on rising or falling edges of the pulse signal generated by the previously selected pulse output timer group. Can be requested on every edge or only once. |

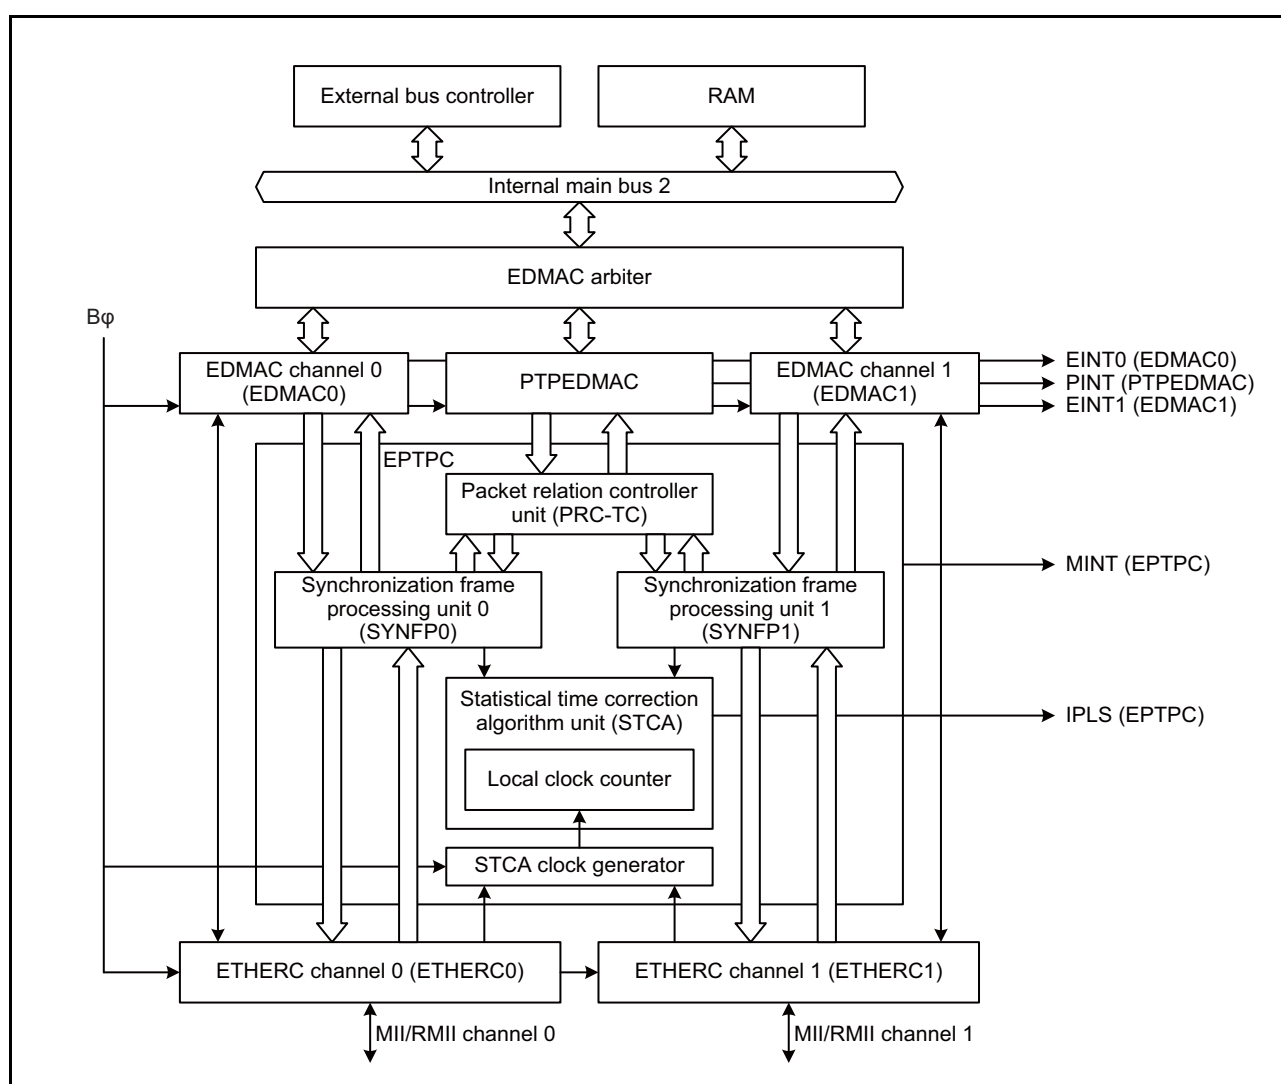

Figure 28.1 EPTPC Configuration

In this section, channels may not be mentioned in overall descriptions of modules that have multiple channels. Examples of the notation are listed in Table 28.2.

Table 28.2 Examples of the Notation

| Module Name | Channel | Meaning |
|----------------------|------------|--|
| SYNFPn module | n = 0, 1 | Synchronization processing units 0 and 1 (SYNFP0 and SYNFP1) |
| Pulse output timer m | m = 0 to 5 | Pulse output timer channels 0 to 5 |

28.1.1 Combination of Clock Device and Ethernet Port

The EPTPC supports operation as three types of clock device: an ordinary clock (OC), boundary clock (BC), or transparent clock (TC). Furthermore, it supports both end-to-end (E2E) and peer-to-peer (P2P) operation for all three clock devices.

Available combinations for usage of Ethernet ports 0 and 1 are listed in Table 28.3.

Table 28.3 Combination of Clock Device and Ethernet Port

| Clock Device | Ethernet Port 0 | | Ethernet Port 1 | |
|---|------------------------------|--------------------|------------------------------|-----|
| EPTPC control disabled | PTP packets are not handled. | | | |
| Only Ethernet port 0 is used for handling PTP packets Ordinary Clock (OC) | Master | End-to-end (E2E) | PTP packets are not handled. | |
| | | Peer-to-peer (P2P) | | |
| | Slave | E2E | | |
| | | P2P | | |
| Only Ethernet port 1 is used for handling PTP packets (OC) | PTP packets are not handled. | | Master | E2E |
| | | | | P2P |
| | | | Slave | E2E |
| | | | | P2P |
| Boundary clock (BC) | Master | E2E | Master | E2E |
| | | E2E | | P2P |
| | | P2P | | E2E |
| | | P2P | | P2P |
| | Master | E2E | Slave | E2E |
| | | E2E | | P2P |
| | | P2P | | E2E |
| | | P2P | | P2P |
| | Slave | E2E | Master | E2E |
| | | E2E | | P2P |
| | | P2P | | E2E |
| | | P2P | | P2P |
| Transparent clock (TC) | E2E TC | | | |
| | P2P TC | | | |

28.1.2 Frame Format of PTP Messages

The frame format of PTP messages can be selected from the four/two types by setting the FORM0 and FORM1 bits in the SYNFP frame format setting register (SYFORMR).

Figure 28.2 shows the PTP message formats for transmission and reception by the EPTPC.

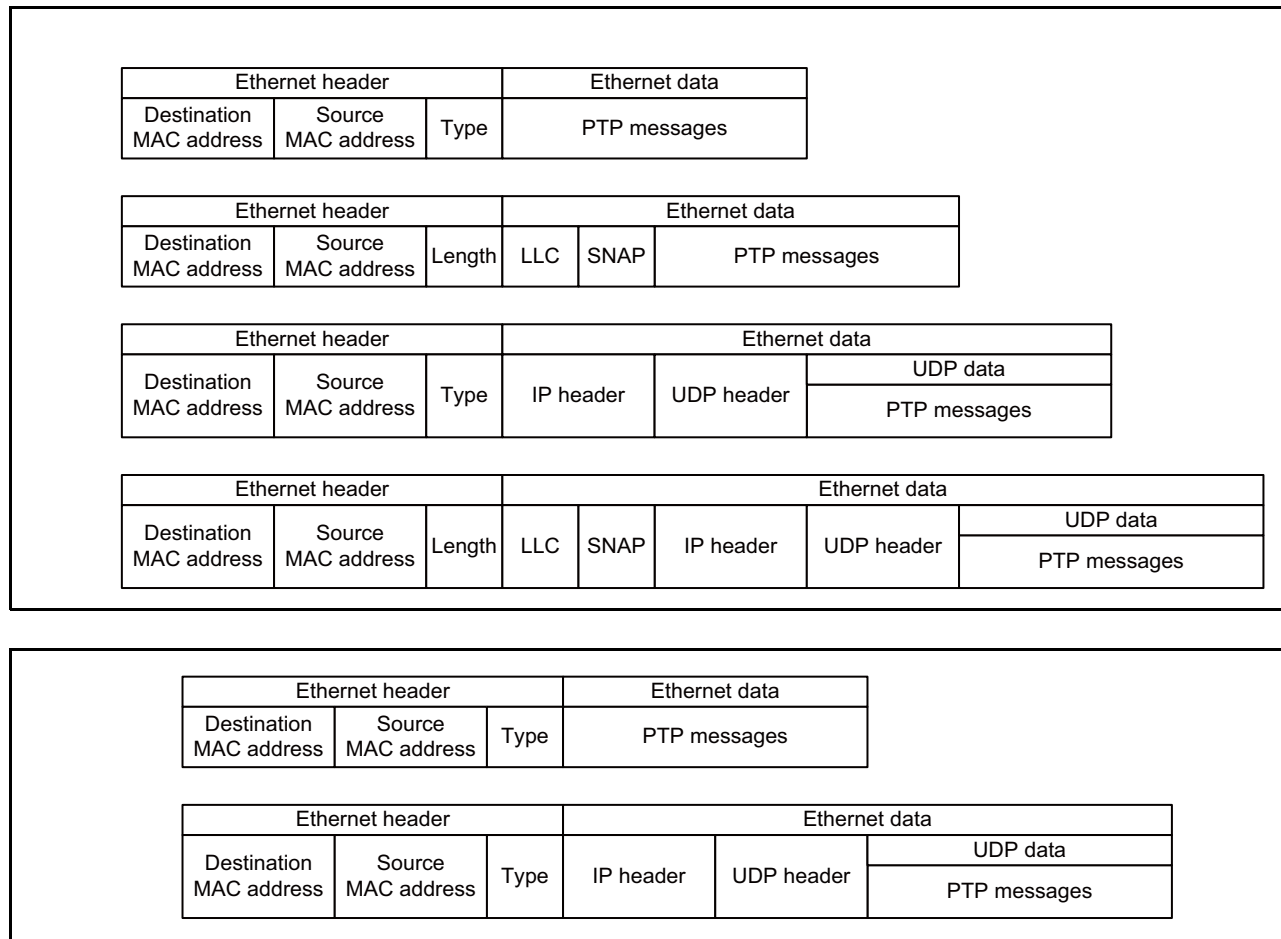

Figure 28.2 Frame Format of PTP Messages

The EPTPC sends PTP messages. The MAC and IP addresses that indicate the destination of each PTP message should usually be multicast addresses defined by IEEE 1588 in accord with the type of the PTP message.

The port number, which must be specified when a PTP message is encapsulated for use with the UDP, is also defined by IEEE 1588 and should be selected in accord with the type of the PTP message.

Table 28.4 lists the types of PTP messages and values that need to be specified for respective Ethernet frame formats.

Table 28.4 Type of PTP Message for Multicast and Information to Specify the Ethernet Frame Format

| Type of PTP Message | | | IEEE802.3 Frame Format (SYFORMR.FORM0 Bit = 1) | | Ethernet II Frame Format (SYFORMR.FORM0 Bit = 0) | | UDP Port No.*1 |
|---------------------|---------------------|---------------------------|---|-------------|---|-----------|-------------------|
| | | | MAC Address | IP Address | MAC Address | Ethertype | |
| PTP- primary | Event messages | Sync | 01-00-5E-00-01-81 | 224.0.1.129 | 01-1B-19-00-00-00 | 88F7h | 319 |
| | | Delay_Req | | | | | |
| PTP- pdelay | | Pdelay_Req | 01-00-5E-00-00-6B | 224.0.0.107 | 01-80-C2-00-00-0E | | 320 |
| | | Pdelay_Resp | | | | | |
| | | Pdelay_Resp_ Follow_Up | | | | | |
| PTP- primary | General messages | Announce | 01-00-5E-00-01-81 | 224.0.1.129 | 01-1B-19-00-00-00 | | |
| | | Follow_Up | | | | | |
| | | Delay_Resp | | | | | |
| | | Signaling | | | | | |
| | | Management | | | | | |

Note 1. The port number must be specified only when a PTP message is encapsulated for use with the UDP (i.e. the SYFORMR.FORM1 bit = 1).

28.1.3 Type of PTP Message and Details of Processing

Table 28.5 and Table 28.6 respectively give details of processing by the EPTPC for receiving and transmitting PTP messages.

Table 28.5 List of PTP Messages for Reception by the EPTPC

| Message Type | Message | Details of Processing |
|--------------|-----------------------|---|
| Event | Sync | Calculates the value of offsetFromMaster if twoStepFlag in flagField is FALSE. |
| | Delay_Req | Responds to Delay_Resp. |
| | Pdelay_Req | Responds to Pdelay_Resp. |
| | Pdelay_Resp | Calculates the value of meanPathDelay if twoStepFlag in flagField is FALSE. |
| General | Announce | — |
| | Follow_Up | Calculates the value of offsetFromMaster if twoStepFlag in flagField of the most recently received Sync message was TRUE and the value of meanPathDelay is fixed. |
| | Delay_Resp | Calculates the value of meanPathDelay. |
| | Pdelay_Resp_Follow_Up | Calculates the value of meanPathDelay if twoStepFlag in flagField of the most recently received Pdelay_Resp message was TRUE. |
| | Management | — |
| | Signaling | — |

Table 28.6 List of PTP Messages for Transmission by the EPTPC

| Message Type | Message | Details of Processing |
|--------------|-----------------------|--|
| Event | Sync | Sync messages are transmitted at the fixed interval specified by the SYTLIR.SYNC[7:0] bits. |
| | Delay_Req | Transmission proceeds with an interval from 0 to twice the interval set by the value of the SYTLIR.DREQ[7:0] bits and determined by a random number. |
| | Pdelay_Req | Pdelay_Req messages are transmitted at the fixed interval specified by the SYTLIR.DREQ[7:0] bits. |
| | Pdelay_Resp | Transmission of responses to Pdelay_Req. |
| General | Announce | Announce messages are transmitted at the fixed interval specified by the SYTLIR.ANCE[7:0] bits. |
| | Follow_Up | — |
| | Delay_Resp | Transmission of responses to Delay_Req |
| | Pdelay_Resp_Follow_Up | — |
| | Management | — |
| | Signaling | — |

28.2 Register Descriptions

Table 28.7 shows the register configuration.

Table 28.7 Register Configuration

| Module | Register Name | Abbreviation | Address | Access size |
|--------|---|--------------|------------|-------------|
| EPTPC | PTP reset register | PTRSTR | E820 4500h | 32 |
| | STCA clock select register | STCSELR | E820 4504h | 32 |

28.2.1 MINT Interrupt Source Status Register (MIESR)

Address: EPTPC.MIESR E820 5000h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|------|------|------|------|------|------|
| | — | — | — | — | — | — | — | — | — | — | CYC5 | CYC4 | CYC3 | CYC2 | CYC1 | CYC0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|-----|-----|-----|----|
| | — | — | — | — | — | — | — | — | — | — | — | — | PRC | SY1 | SY0 | ST |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|---|--|-------|
| b0 | ST | STCA Status Flag | 0: No change in the state of the STCA module 1: A change in the state of the STCA module | R |
| b1 | SY0 | SYNFP0 Status Flag | 0: No change in the state of the SYNFP0 module 1: A change in the state of the SYNFP0 module | R |
| b2 | SY1 | SYNFP1 Status Flag | 0: No change in the state of the SYNFP1 module 1: A change in the state of the SYNFP1 module | R |
| b3 | PRC | PRC-TC Status Flag | 0: No change in the state of the PRC-TC module 1: A change in the state of the PRC-TC module | R |
| b15 to b4 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b16 | CYC0 | Pulse Output Timer 0 Rising Edge Detection Flag | 0: A rising edge in the periodic pulse signal from pulse output timer 0 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 0 is detected. | R/W*1 |
| b17 | CYC1 | Pulse Output Timer 1 Rising Edge Detection Flag | 0: A rising edge in the periodic pulse signal from pulse output timer 1 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 1 is detected. | R/W*1 |
| b18 | CYC2 | Pulse Output Timer 2 Rising Edge Detection Flag | 0: A rising edge in the periodic pulse signal from pulse output timer 2 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 2 is detected. | R/W*1 |
| b19 | CYC3 | Pulse Output Timer 3 Rising Edge Detection Flag | 0: A rising edge in the periodic pulse signal from pulse output timer 3 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 3 is detected. | R/W*1 |
| b20 | CYC4 | Pulse Output Timer 4 Rising Edge Detection Flag | 0: A rising edge in the periodic pulse signal from pulse output timer 4 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 4 is detected. | R/W*1 |
| b21 | CYC5 | Pulse Output Timer 5 Rising Edge Detection Flag | 0: A rising edge in the periodic pulse signal from pulse output timer 5 is not detected. 1: A rising edge in the periodic pulse signal from pulse output timer 5 is detected. | R/W*1 |
| b31 to b22 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The MIESR register indicates changes in the states of the STCA, SYNFPn, and PRC-TC modules which act as sources of MINT interrupts and the detection of rising edges of pulse output timers m.

For the MINT interrupt, see section 28.4, Interrupts.

28.2.2 MINT Interrupt Request Enable Register (MIEIPR)

Address: EPTPC.MIEIPR E820 5004h

| b3 | PR | PRC-TC Status Interrupt Request Enable | 0: Disables the generation of MINT interrupt requests by the PRC-TC status flag. 1: Enables the generation of MINT interrupt requests by the PRC-TC status flag. | R/W |
| b15 to b4 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b16 | CYC0 | Pulse Output Timer 0 Rising Edge Detection Interrupt Request Enable | 0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 0. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 0. | R/W |
| b17 | CYC1 | Pulse Output Timer 1 Rising Edge Detection Interrupt Request Enable | 0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 1. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 1. | R/W |
| b18 | CYC2 | Pulse Output Timer 2 Rising Edge Detection Interrupt Request Enable | 0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 2. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 2. | R/W |
| b19 | CYC3 | Pulse Output Timer 3 Rising Edge Detection Interrupt Request Enable | 0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 3. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 3. | R/W |
| b20 | CYC4 | Pulse Output Timer 4 Rising Edge Detection Interrupt Request Enable | 0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 4. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 4. | R/W |
| b21 | CYC5 | Pulse Output Timer 5 Rising Edge Detection Interrupt Request Enable | 0: Disables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 5. 1: Enables the generation of MINT interrupt requests in response to detection of a rising edge of pulse output timer 5. | R/W |
| b31 to b22 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The MIEIPR register is used to enable or disable the generation of MINT interrupt requests when MINT interrupt source conditions are satisfied.

28.2.3 IPLS Interrupt Request Enable Register (ELIPPR)

Address: EPTPC.ELIPPR E820 5010h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| Value after reset: | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|---|---|-----|
| b5 to b0 | — | Reserved | These bits are always read as 1. The write value should always be 1. | R |
| b7, b6 | — | Reserved | These bits are always read as 0. The write value should always be 0. | R |
| b13 to b8 | — | Reserved | These bits are always read as 1. The write value should always be 1. | R |
| b15, b14 | — | Reserved | These bits are always read as 0. The write value should always be 0. | R |
| b16 | PLSP | Pulse Output Timer Rising Edge Detection IPLS Interrupt Request Enable | 0: Disables IPLS interrupt requests due to rising edges of signals from the selected pulse output timer. 1: Enables IPLS interrupt requests due to rising edges of signals from the selected pulse output timer. | R/W |
| b23 to b17 | — | Reserved | These bits are always read as 0. The write value should always be 0. | R |
| b24 | PLSN | Pulse Output Timer Falling Edge Detection IPLS Interrupt Request Enable | 0: Disables IPLS interrupt requests due to falling edges of signals from the selected pulse output timer. 1: Enables IPLS interrupt requests due to falling edges of signals from the selected pulse output timer. | R/W |
| b31 to b25 | — | Reserved | These bits are always read as 0. The write value should always be 0. | R |

The register also enables and disables IPLS interrupts due to rising or falling edges of signals from the pulse output timer selected in the IPTSELR register.

The ELIPACR register can be used to set up the one-time-only output of IPLS interrupt requests.

For the IPLS interrupt, see section 28.4, Interrupts.

28.2.4 IPLS Interrupt Enable Automatic Clearing Register (ELIPACR)

Address: EPTPC.ELIPACR E820 5014h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| | — | — | — | — | — | — | — | PLSN | — | — | — | — | — | — | — | PLSP |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|------------------------------------|---|-----|
| b15 to b0 | — | Reserved | These bits are always read as 0. The write value should always be 0. | R |
| b16 | PLSP | ELIPPR.PLSP Bit Automatic Clearing | 0: Disables automatic clearing of the enable bit for IPLS interrupt requests in response to detection of rising edges of the pulse output timer. 1: Enables automatic clearing of the enable bit for IPLS interrupt requests in response to detection of rising edges of the pulse output timer. | R/W |
| b23 to b17 | — | Reserved | These bits are always read as 0. The write value should always be 0. | R |
| b24 | PLSN | ELIPPR.PLSN Bit Automatic Clearing | 0: Disables automatic clearing of the enable bit for IPLS interrupt requests in response to detection of falling edges of the pulse output timer. 1: Enables automatic clearing of the enable bit for IPLS interrupt requests in response to detection of falling edges of the pulse output timer. | R/W |
| b31 to b25 | — | Reserved | These bits are always read as 0. The write value should always be 0. | R |

The ELIPACR register is used to enable one-time output of an IPLS interrupt request triggered by detecting edges of the periodic pulses of pulse output timer m.

Normally, an IPLS interrupt request is generated at each edge of the periodic pulses of pulse output timer m while the corresponding bit in the ELIPPR register is 1 (enabled).

When a bit in the ELIPPR register is 1 while the corresponding bit in the ELIPACR register is also 1, the bit in the ELIPPR register automatically becomes 0 when an IPLS interrupt request is generated.

For the IPLS interrupt, see section 28.4, Interrupts.

28.2.5 STCA Status Register (STSR)

Address: EPTPC.STSR E820 5040h

| | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|------|-------------|-----|-------------|------|
| b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| — | — | — | — | — | — | — | — | — | — | — | W10D | SYNTO UT | — | SYNC OUT | SYNC |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|---------|---|--|-------|
| b0 | SYNC | Synchronized State Detection Flag | 0: Synchronization is not detected. 1: Synchronization is detected. | R/W*1 |
| b1 | SYNCOUT | Synchronization Loss Detection Flag | 0: A loss of synchronization is not detected. 1: A loss of synchronization is detected. | R/W*1 |
| b2 | — | Reserved | This bit is read as 0. The write value should be 0. | R |
| b3 | SYNTOUT | Sync Message Reception Timeout Detection Flag | 0: A Sync message reception timeout is not detected. 1: A Sync message reception timeout is detected. | R/W*1 |
| b4 | W10D | Worst 10 Acquisition Completion Flag | 0: The worst 10 values have not been acquired yet. 1: The worst 10 values have been acquired. | R/W*1 |
| b31 to b5 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note: When the SYNSTARTR.STR bit is 0, the value of the corresponding flag remains.

Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The STSR register indicates the state of the STCA module.

SYNC Flag (Synchronized State Detection Flag)

This flag indicates that synchronization has occurred at least the same as the number of times specified by the STMR.SYTH[3:0] bits in succession when the STMR.ALEN0 bit is 1. When the STMR.ALEN0 bit is 0, the SYNC flag is not set to 1 even if synchronization has occurred more than the specified number of times in succession.

SYNCOUT Flag (Synchronization Loss Detection Flag)

This flag indicates that loss of synchronization has occurred at least the same as the number of times specified by the STMR.DVTH[3:0] bits in succession when the STMR.ALEN0 bit is 1.

Since the time is not synchronized immediately after time synchronization is started (SYNSTARTR.STR bit is set to 1), the SYNCOUT becomes 1 regardless of the STMR.ALEN0 bit setting. When using the SYNTOUT flag, set the SYNTOUT flag to 0 immediately after starting time synchronization.

When the STMR.ALEN0 bit is 0, the SYNCOUT flag does not become 1 even if loss of synchronization has occurred at least the same as the specified number of times in succession after time synchronization is started and the SYNTOUT flag is immediately set to 0.

SYNTOUT Flag (Sync Message Reception Timeout Detection Flag)

This flag indicates that a Sync message has not been received during the period specified by the SYNTOR register when the STMR.ALEN1 bit is 1. The SYNTOUT flag becomes 1 immediately if time synchronization is started (SYNSTARTR.STR bit is set to 1) when no Sync message has been received after the EPTPC starts. When using the SYNTOUT flag, set the SYNTOUT flag to 0 immediately after starting time synchronization.

W10D Flag (Worst 10 Acquisition Completion Flag)

This flag indicates that acquisition of the worst 10 has been completed.

28.2.6 STCA Status Notification Enable Register (STIPR)

Address: EPTPC.STIPR E820 5044h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|------|-------------|----|-------------|------|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | W10D | SYNTO UT | — | SYNC OUT | SYNC |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|---------|------------------------------------|---|-----|
| b0 | SYNC | SYNC Status Notification Enable | 0: Disables notification of the state of STSR.SYNC. 1: Enables notification of the state of STSR.SYNC. | R/W |
| b1 | SYNCOUT | SYNCOUT Status Notification Enable | 0: Disables notification of the state of STSR.SYNCOUT. 1: Enables notification of the state of STSR.SYNCOUT. | R/W |
| b2 | — | Reserved | This bit is read as 0. The write value should be 0. | R |
| b3 | SYNTOUT | SYNTOUT Status Notification Enable | 0: Disables notification of the state of STSR.SYNTOUT. 1: Enables notification of the state of STSR.SYNTOUT. | R/W |
| b4 | W10D | W10D Status Notification Enable | 0: Disables notification of the state of STSR.W10D. 1: Enables notification of the state of STSR.W10D. | R/W |
| b31 to b5 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The STIPR register specifies whether the MIESR.ST flag does or does not reflect changes in the state of the STCA module.

28.2.7 STCA Clock Frequency Setting Register (STCFR)

Address: EPTPC.STCFR E820 5050h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|-----------|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | STCF[1:0] | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|-----------|----------------------|---|-----|
| b1, b0 | STCF[1:0] | STCA Clock Frequency | b1 b0 0 0: 20 MHz 0 1: 25 MHz 1 0: 50 MHz 1 1: Setting prohibited | R/W |
| b31 to b2 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note: Set a value in this register before starting the EDMAC, ETHERC, and PTPEDMAC. Do not change the settings during operations.

The STCFR register is used to select the frequency of the clock source for the STCA module (STCA clock).

The setting in the STCFR register must be for the same frequency as that selected by the setting of the STCSELR register.

STCF[1:0] Bits (STCA Clock Frequency)

These bits select the frequency of the STCA clock.

To enable synchronous control in compliance with IEEE 1588, the STCA clock frequency must be selected from 20 MHz, 25 MHz, or 50 MHz. If the frequency selected by these bits differs from the clock frequency actually input to the STCA module, operation is not guaranteed.

28.2.8 STCA Operating Mode Register (STMR)

Address(es): EPTPC.STMR E820 5054h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 | | |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|--|---|-----|
| b7 to b0 | WINT[7:0] | Worst 10 Acquisition Time | 00h: The worst 10 values are not acquired. 01h: Sync message reception: 1 time : FFh: Sync message reception: 255 times | R/W |
| b12 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b13 | CMOD | Time Synchronization Correction Mode | 0: Mode 1 1: Mode 2 | R/W |
| b14 | — | Reserved | This bit is read as 0. The write value should be 0. | R |
| b15 | W10S | Worst 10 Acquisition Control Select | 0: Measurement is started by hardware and the value acquired in the PW10VR or MW10R register is used as the limit for filtering. 1: Measurement is started by the GETW10R.GW10 bit. Also, the value set in the PLIMITR or MLIMITR register is used as the limit for filtering. | R/W |
| b19 to b16 | SYTH[3:0] | Synchronized State Detection Threshold Setting | 0h: None*1 1h: 1 time : Fh: 15 times | R/W |
| b23 to b20 | DVTH[3:0] | Synchronization Loss Detection Threshold Setting | 0h: None*2 | |
| b27 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b28 | ALEN0 | Alarm Detection Enable 0 | 0: The STSR.SYNC or SYNCOUT flag is not set to 1 on detection of synchronization or loss of synchronization. 1: The STSR.SYNC or SYNCOUT flag is set to 1 on detection of synchronization or loss of synchronization. | R/W |
| b29 | ALEN1 | Alarm Detection Enable 1 | 0: The STSR.SYNTOUT flag is not set to 1 on detection of the Sync message reception timeout interrupt. 1: The STSR.SYNTOUT flag is not set to 1 on detection of the Sync message reception timeout interrupt. | R/W |
| b31, b30 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note 1. The STSR.SYNC flag does not become 1 regardless of the ALEN0 bit setting.

Note 2. The STSR.SYNCOUT flag does not become 1 regardless of the ALEN0 bit setting.

The STMR register is used to set the operating mode of the STCA module.

WINT[7:0] Bits (Worst 10 Acquisition Time)

These bits set the time for acquiring the worst 10 gradients (the number of times Sync messages are received). Usually, it is recommended to set the number of times of Sync message receptions to 32 or more.

CMOD Bit (Time Synchronization Correction Mode)

Mode 1 or mode 2 can be selected to correct the local time information when the EPTPC operates as a slave clock. Select the appropriate mode in consideration of system configuration, etc.

Table 28.8 is a summary of the two individual correction modes.

Table 28.8 Types and Features of Correction Mode

| Correction Mode | Function | Features | Notes |
|-----------------|---|---|--|
| Mode 1 | Mode for correcting the counter every Sync message reception by using the current offsetFromMaster (operation is in mode 1 after the start of correction, and then shifts to the specified mode). | The time information of the master clock is set as the local time information at a time. | (e.g. packets are temporarily being discarded due to a failure of communications). |
| Mode 2 | Mode where the gradient value calculated from offsetFromMaster (worst-10 control) is retained and used in correcting the local time information so that it approximates the time information of the master clock. | Even if calculating offsetFromMaster is not possible, a certain level of synchronization can be guaranteed in this mode (the counter is still corrected from the gradient information). | Establishing synchronization takes longer. |

W10S Bit (Worst 10 Acquisition Control Select)

This bit selects the value used for measurement and filtering of worst 10 gradients. When this bit is set to 0, the values acquired in registers PW10VRU, PW10VRM, and PW10VRL and registers MW10RU, MW10RM, and MW10RL are used as the limit for the filter. When the bit is set to 1, the values set in registers PLIMITRU, PLIMITRM, and PLIMITRL and registers MLIMITRU, MLIMITRM, and MLIMITRL are used as the limit for the filter.

SYTH[3:0] Bits (Synchronized State Detection Threshold Setting)

These bits specify a value for the number of consecutive times being below the thresholds will be judged as synchronization. Specifically, the value falling within the thresholds set in registers SYNTDBRU and SYNTDBRL as many times as the value of these bits indicates the synchronized state. When the ALEN0 bit is 1, the STSR.SYNCOUT flag becomes 1.

DVTH[3:0] Bits (Synchronization Loss Detection Threshold Setting)

These bits specify a value for the number of consecutive times exceeding a threshold will be judged as a loss of synchronization. Specifically, synchronization is judged to have been lost when the value in registers SYNTDARU and SYNTDARL is consecutively exceeded as many times as the value of these bits. When the ALEN0 bit is 1, the STSR.SYNCOUT flag becomes 1.

ALEN0 Bit (Alarm Detection Enable 0)

When this bit is 1, the STSR.SYNC or SYNCOUT flag is set to 1 on detection of synchronization or loss of synchronization. When this bit is 0, the SYNC or SYNCOUT flag is not set to 1 even if synchronization or loss of synchronization is detected.

ALEN1 Bit (Alarm Detection Enable 1)

When this bit is 1, the STSR.SYNTOUT flag is set to 1 if a Sync message is not received within the time specified by the SYNTOR register. When this bit is 0, the SYNTOUT flag is not set to 1 even if the reception timeout has occurred.

28.2.9 Sync Message Reception Timeout Register (SYNTOR)

Address(es): EPTPC.SYNTOR E820 5058h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | A Sync message not being received within 1024 × n (ns), where n is the setting, leads to a timeout for reception of Sync messages, leading to the STSR.SYNTOUT flag being set to 1. | R/W |

The SYNTOR register is used to specify the timeout period for reception of Sync messages. The timeout period is 1024 times the setting of these bits, in units of nanoseconds.

A Sync message not being received within the period specified by these bits is judged to represent a timeout.

When the SYNTOR register is 0, the STSR.SYNTOUT flag does not become 1.

28.2.10 IPLS Interrupt Request Timer Select Register (IPTSELR)

Address(es): EPTPC.IPTSELR E820 5060h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|---------|-----------------------------|--|-----|
| b0 | IPTSEL0 | Pulse Output Timer 0 Select | 0: Pulse output timer 0 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 0 is selected as a source of IPLS interrupt requests. | R/W |
| b1 | IPTSEL1 | Pulse Output Timer 1 Select | 0: Pulse output timer 1 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 1 is selected as a source of IPLS interrupt requests. | R/W |
| b2 | IPTSEL2 | Pulse Output Timer 2 Select | 0: Pulse output timer 2 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 2 is selected as a source of IPLS interrupt requests. | R/W |
| b3 | IPTSEL3 | Pulse Output Timer 3 Select | 0: Pulse output timer 3 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 3 is selected as a source of IPLS interrupt requests. | R/W |
| b4 | IPTSEL4 | Pulse Output Timer 4 Select | 0: Pulse output timer 4 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 4 is selected as a source of IPLS interrupt requests. | R/W |
| b5 | IPTSEL5 | Pulse Output Timer 5 Select | 0: Pulse output timer 5 is not selected as a source of IPLS interrupt requests. 1: Pulse output timer 5 is selected as a source of IPLS interrupt requests. | R/W |
| b31 to b6 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The IPTSELR register is used to select the pulse output timer that generates IPLS interrupt requests.

Each pulse output timer *m* takes the clock signal from the STCA as its clock source and produces pulses with a specified period and duty cycle. An IPLS interrupt is requested on rising edges if the ELIPPR.PLSP bit is set to 1 and on falling edges if the PLSN bit in the same register is set to 1. The interrupt request signal becomes the logical OR of the interrupt requests from the given channels when bits for multiple channels in register IPTSELR are set to 1. For the IPLS interrupt, see section 28.4, Interrupts.

28.2.11 MINT Interrupt Request Timer Select Register (MITSELR)

Address(es): EPTPC.MITSELR E820 5064h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|---------|---------|---------|---------|---------|---------|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | MINTEN5 | MINTEN4 | MINTEN3 | MINTEN2 | MINTEN1 | MINTEN0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|---------|---|--|-----|
| b0 | MINTEN0 | Pulse Output Timer 0 MINT Interrupt Output Enable | 0: Output of rising edges by pulse output timer 0 is not reflected by the MIESR.CYC0 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 0 is reflected by the MIESR.CYC0 flag as a MINT interrupt source. | R/W |
| b1 | MINTEN1 | Pulse Output Timer 1 MINT Interrupt Output Enable | 0: Output of rising edges by pulse output timer 1 is not reflected by the MIESR.CYC1 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 1 is reflected by the MIESR.CYC1 flag as a MINT interrupt source. | R/W |
| b2 | MINTEN2 | Pulse Output Timer 2 MINT Interrupt Output Enable | 0: Output of rising edges by pulse output timer 2 is not reflected by the MIESR.CYC2 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 2 is reflected by the MIESR.CYC2 flag as a MINT interrupt source. | R/W |
| b3 | MINTEN3 | Pulse Output Timer 3 MINT Interrupt Output Enable | 0: Output of rising edges by pulse output timer 3 is not reflected by the MIESR.CYC3 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 3 is reflected by the MIESR.CYC3 flag as a MINT interrupt source. | R/W |
| b4 | MINTEN4 | Pulse Output Timer 4 MINT Interrupt Output Enable | 0: Output of rising edges by pulse output timer 4 is not reflected by the MIESR.CYC4 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 4 is reflected by the MIESR.CYC4 flag as a MINT interrupt source. | R/W |
| b5 | MINTEN5 | Pulse Output Timer 5 MINT Interrupt Output Enable | 0: Output of rising edges by pulse output timer 5 is not reflected by the MIESR.CYC5 flag as a MINT interrupt source. 1: Output of rising edges by pulse output timer 5 is reflected by the MIESR.CYC5 flag as a MINT interrupt source. | R/W |
| b31 to b6 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The MITSELR register is used to select pulse output timer m that generates MINT interrupt requests.

Each pulse output timer m takes the clock signal from the STCA as its clock source and produces pulses with a specified period and duty cycle. A MINT interrupt is requested on rising edges of the pulse signal from the corresponding pulse output timer m if the setting of the MIEIPR.CYCm bit is 1.

For the MINT interrupt, see section 28.4, Interrupts.

28.2.12 Time Synchronization Channel Select Register (STCHSELR)

Address(es): EPTPC.STCHSELR E820 506Ch

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |

| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | SYSEL |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|--------------------------------|--|-------|
| b0 | SYSEL | Timer Information Input Select | 0: Time information from the SYNFP0 module is used. 1: Time information from the SYNFP1 module is used. | R/W*1 |
| b31 to b1 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note 1. Do not change the value of this bit while the SYNSTARTR.STR bit is 1.

The STCHSELR register selects the time information input to the STCA module.

28.2.13 Slave Time Synchronization Start Register (SYNSTARTR)

Address(es): EPTPC.SYNSTARTR E820 5080h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|-----|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | STR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|------------------------------------|--|-----|
| b0 | STR | Slave Time Synchronization Control | 0: Slave time synchronization is stopped. 1: Slave time synchronization is started. | R/W |
| b31 to b1 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYNSTARTR register is used to start or stop time synchronization. This register is used when the EPTPC is operating as a slave node.

28.2.14 Local Clock Counter Initial Value Load Directive Register (LCIVLDR)

Address(es): EPTPC.LCIVLDR E820 5084h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|------|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | LOAD |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|--|--|-----|
| b0 | LOAD | Local Clock Counter Initial Value Load Directive | 0: The initial value is not loaded into the local clock counter. 1: The initial value is loaded into the local clock counter. | W*1 |
| b31 to b1 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note 1. Do not change the value of this bit while the SYNSTARTR.STR bit is 1.

The LCIVLDR register is used to set the value of registers LCIVRU, LCIVRM, and LCIVRL as the initial value of the local clock counter.

28.2.15 Synchronization Loss Detection Threshold Registers (SYNTDARU, SYNTDARL)

Address(es): EPTPC.SYNTDARU E820 5090h

| | | | | | | | | | | | | | | | | |
|--------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the higher-order 32 bits of the threshold for detection of loss of synchronization. | R/W |

Address(es): EPTPC.SYNTDARL E820 5094h

| | | | | | | | | | | | | | | | | |
|--------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|----------------------|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits hold the setting for the lower-order 32 bits of the threshold for detection of loss of synchronization. | R/W |

The settings of the SYNTDARU and SYNTDARL registers specify the threshold value for offsetFromMaster to be used in judging loss of synchronization. When setting a threshold value, write the higher-order 32 bits to SYNTDARU and the lower-order 32 bits to SYNTDARL, in that order and in consecutive operations.

If the offsetFromMaster value becomes at least the same as the value specified in SYNTDARU and SYNTDARL, a loss of synchronization is detected. Set a value in SYNTDARU and SYNTDARL in units of nanoseconds.

SYNTDARU and SYNTDARL are not used when the device is operating as a master clock.

28.2.16 Synchronization Detection Threshold Registers (SYNTDBRU, SYNTDBRL)

Address(es): EPTPC.SYNTDBRU E820 5098h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the higher-order 32 bits of the threshold for detection of synchronization. | R/W |

Address(es): EPTPC.SYNTDBRL E820 509Ch

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits hold the setting for the lower-order 32 bits of the threshold for detection of synchronization. | R/W |

The settings of the SYNTDBRU and SYNTDBRL registers specify the threshold value for offsetFromMaster to be used in judging synchronization. When setting a threshold value, write the higher-order 32 bits to SYNTDBRU and the lower-order 32 bits to SYNTDBRL, in that order and in consecutive operations.

If the offsetFromMaster value is less than the value specified in SYNTDBRU and SYNTDBRL, synchronization is detected. Set a value in SYNTDBRU and SYNTDBRL in units of nanoseconds.

SYNTDBRU and SYNTDBRL are not used when the device is operating as a master clock.

If the offsetFromMaster value is less than the value specified in SYNTDBRU and SYNTDBRL, synchronization is detected. Set a value in SYNTDBRU and SYNTDBRL in units of nanoseconds.

SYNTDBRU and SYNTDBRL are not used when the device is operating as a master clock.

28.2.17 Local Clock Counter Initial Value Registers (LCIVRU, LCIVRM, LCIVRL)

Address(es): EPTPC.LCIVRU E820 50B0h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the higher-order 16 bits of the integer portion of the initial value for the local clock counter. | R/W |
| b31 to b16 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |

Address(es): EPTPC.LCIVRM E820 50B4h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits hold the setting for the lower-order 32 bits of the integer portion of the initial value for the clock counter. | R/W |

Address(es): EPTPC.LCIVRL E820 50B8h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits hold the setting for the fractional portion of the initial value of the clock counter in nanoseconds. | R/W |

Registers LCIVRU, LCIVRM, and LCIVRL specify the initial value in seconds of the clock counter. When setting an initial value, write the higher-order 16 bits of the integer portion to LCIVRU, the lower-order 32 bits of the integer portion to LCIVRM, and the fractional portion in nanoseconds to LCIVRL, in that order and in consecutive operations. The value of registers LCIVRU, LCIVRM, and LCIVRL can be used as the initial value of the local clock counter. When setting the value of registers LCIVRU, LCIVRM, and LCIVRL in the local clock counter, set the LCIVLDR.LOAD bit to 1.

Example) When 2.000000025s is to be set as the initial value, write the following values to each of the registers.

LCIVRU: 0000 0000h

LCIVRM: 0000 0002h

LCIVRL: 0000 0019h

28.2.18 Worst 10 Acquisition Directive Register (GETW10R)

Address(es): EPTPC.GETW10R E820 5124h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|------|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | GW10 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|--------------------------------|---|-------|
| b0 | GW10 | Worst 10 Acquisition Directive | 0: The worst-10 values are not acquired. 1: Starts acquisition of the worst-10 values. | R/W*1 |
| b31 to b16 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |

Note 1. Do not set this bit to 1 while the STMR.W10S bit is 0.

The GETW10R register is used in software control to start calculation of gradient values for use in selecting the worst-10 values.

A gradient value is the amount by which the timer counter of a slave is incremented when a given interval elapses. Setting the GW10 bit to 1 while the value of the STMR.W10S bit is 1 selects calculation of a gradient value by the EPTPC each time it receives a Sync message. Gradient values are calculated the number of times specified by the STMR.WINT[7:0] bits. The GW10 bit is cleared to 0 on completion of this number of calculations. The GETW10R register is not used in operation as a master clock.

28.2.19 Positive Gradient Limit Registers (PLIMITRU, PLIMITRM, PLIMITRL)

Address(es): EPTPC.PLIMITRU E820 5128h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b30 to b0 | — | — | These bits hold the setting for the higher-order 31 bits of the limit for the positive gradient. | R/W |
| b31 | — | Reserved | This bit is read as 0. The write value should be 0. | R |

Address(es): EPTPC.PLIMITRM E820 512Ch

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits hold the setting for the middle-order 32 bits of the limit for the positive gradient. | R/W |

Address(es): EPTPC.PLIMITRL E820 5130h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the lower-order 32 bits of the limit for the positive gradient. | R/W |

Registers PLIMITRU, PLIMITRM, and PLIMITRL are used to specify an upper limit on gradient (= positive gradient) for use in time synchronization. When setting an upper limit, write values consecutively to PLIMITRU, PLIMITRM, and PLIMITRL in that order.

The gradients that is at least the same as the value specified in registers PLIMITRU, PLIMITRM, and PLIMITRL are not used in time synchronization. Registers PLIMITRU, PLIMITRM, PLIMITRL are not used when the device is operating as a master clock. Registers PLIMITRU, PLIMITRM, and PLIMITRL are effective while the STMR.CMOD and W10S bits are 1.

The gradient value to be set in the register is calculated by using the following expression.

$$\text{PLIMITRU, PLIMITRM, and PLIMITRL register values} = A \text{ (s)} / T \text{ (s)} \times 232$$

A: The time (s) by which the slave local clock counter advances during the interval between received Sync messages

T: The actual time (s) between received Sync messages

For example, if the interval between Sync messages is 0.5 seconds and the local clock counter advances by 0.7 seconds during that time, and this is to be set as the limit, then the setting for PLIMITR = $0.7/0.5 \times 232 = 6\,012\,954\,214 = 1\,666\,6666\text{h}$, and the settings for the individual registers are as follows: PLIMITRU = 0000 0000h, PLIMITRM = 0000 0001h, and PLIMITRL = 6666 6666h.

The minimum setting depends on the STCA clock frequency as the clock source for counting by the local clock counter. For example, if the STCA clock frequency is 50 MHz, then the minimum allowable setting for registers PLIMITRU, PLIMITRM, and PLIMITRL = $(1/50 \text{ (MHz)}) \text{ (s)} / 0.5 \text{ (s)} \times 232 = 172 = \text{ACh}$, and the settings for the individual registers are as follows: PLIMITRU = 0000 0000h, PLIMITRM = 0000 0000h, and PLIMITRL = 0000 00ACh.

The gradient limit values to be set are valid when time synchronization correction mode is mode 2 (the STMR.CMOD bit is 1) and the gradient is controlled by software (the STMR.W10S bit is 1).

28.2.20 Negative Gradient Limit Registers (MLIMITRU, MLIMITRM, MLIMITRL)

Address(es): EPTPC.MLIMITRU E820 5134h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b30 to b0 | — | — | These bits hold the setting for the higher-order 31 bits of the limit for the negative gradient. | R/W |
| b31 | — | Reserved | This bit is read as 0. The write value should be 0. | R |

Address(es): EPTPC.MLIMITRM E820 5138h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits hold the setting for the middle-order 32 bits of the limit for the negative gradient. | R/W |

Address(es): EPTPC.MLIMITRL E820 513Ch

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the lower-order 32 bits of the limit for the negative gradient. | R/W |

Registers MLIMITRU, MLIMITRM, and MLIMITRL are used to specify a lower limit for the gradient (= negative gradient) for use in time synchronization. Use two's complement to set a lower limit. When setting a lower limit, write values consecutively to MLIMITRU, MLIMITRM, and MLIMITRL in that order.

The gradients that are less than the value specified in registers MLIMITRU, MLIMITRM, and MLIMITRL are not used in time synchronization. Registers MLIMITRU, MLIMITRM, and MLIMITRL are not used when the device is operating as a master clock. Registers MLIMITRU, MLIMITRM, and MLIMITRL are effective while the STMR.CMOD and W10S bits are 1.

The procedure for setting a value and the minimum value that can be set are the same as for registers PLIMITRU, PLIMITRM, and PLIMITRL.

28.2.21 Statistical Information Retention Control Register (GETINFOR)

Address(es): EPTPC.GETINFOR E820 5140h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | INFO |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|-------------------------------|--|-----|
| b0 | INFO | Information Retention Control | [When written] 0: Has no effects. 1: Information is retained. [When read] 0: Information retention is completed. 1: Processing for information retention is in progress. Once information fetching is directed, values of various statistical information read before completion of information fetching are not guaranteed. | R/W |
| b31 to b1 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The GETINFOR register controls retention of the following statistical information.

- Registers LCCVRU, LCCVRM, and LCCVRL
- Registers PW10VRU, PW10VRM, and PW10VRL
- Registers MW10RU, MW10RM, and MW10RL

The only value that is writable to the INFO bit is 1. When setting a value in registers PW10VRU, PW10VRM, and PW10VRL, or registers MW10RU, MW10RM, and MW10RL, set the INFO bit to 1 only while the STMR.W10S bit is 1. If the INFO bit is set to 1 before acquisition of the worst-10 values is completed, whether the information retained in registers PW10VRU, PW10VRM, and PW10VRL and registers MW10RU, MW10RM, MW10RL is correct or not is not guaranteed. Use the GETW10R.GW10 bit to confirm that acquisition has been completed before setting the INFO bit to 1. The INFO bit is automatically returned to 0 on completion of information fetching.

28.2.22 Local Clock Counters (LCCVRU, LCCVRM, LCCVRL)

Address(es): EPTPC.LCCVRU E820 5170h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|--|-----|
| b15 to b0 | — | — | These bits are for reading the higher-order 16 bits of the integer portion of the local clock counter's value. | R |
| b31 to b16 | — | Reserved | These bits are read as 0. | R |

Address(es): EPTPC.LCCVRM E820 5174h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits are for reading the lower-order 32 bits of the integer portion of the local clock counter's value. | R |

Address(es): EPTPC.LCCVRL E820 5178h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits are for reading the fractional portion of the local clock counter's value (in nanoseconds). | R |

Registers LCCVRU, LCCVRM, and LCCVRL indicate the local clock counter's value.

When the GETINFOR.INFO bit is set to 1, the value of the local clock counter at that time is stored in registers LCCVRU, LCCVRM, and LCCVRL. The higher-order 16 bits of the integer portion in seconds are saved in LCCVRU, the lower-order 32 bits of the integer portion in seconds are saved in LCCVRM, and the fractional portion in nanoseconds is saved in LCCVRL.

For example, if the local time information is 14:25, 44 seconds, 10 milliseconds, 23 microseconds, and 39 nanoseconds, registers LCCVRU, LCCVRM, and LCCVRL have $14 \times 3600 + 25 \times 60 + 44 = 51944$ (s) = 0000 0000 CAE8h as the setting of the higher-order 48 bits and $10 \times 106 + 23 \times 103 + 39 = 10023039$ (ns) = 0098 F07Fh as the setting of the lower-order 32 bits.

28.2.23 Positive Gradient Worst 10 Value Registers (PW10VRU, PW10VRM, PW10VRL)

Address(es): EPTPC.PW10VRU E820 5210h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits are for reading the higher-order 32 bits of the positive gradient value. | R |

Address(es): EPTPC.PW10VRM E820 5214h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits are for reading the middle-order 32 bits of the positive gradient value. | R |

Address(es): EPTPC.PW10VRL E820 5218h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits are for reading the lower-order 32 bits of the positive gradient value. | R |

Registers PW10VRU, PW10VRM, and PW10VRL indicate the worst 10 of the positive gradient values.

When the GETINFOR.INFO bit is set to 1, the worst 10 value at that time is stored in registers PW10VRU, PW10VRM, and PW10VRL.

The format of the worst 10 gradients stored in registers PW10VRU, PW10VRM, and PW10VRL are the same as for registers PLIMITRU, PLIMITRM, and PLIMITRL. For details on the format of the values, see the description of the PLIMITR registers.

Registers PW10VRU, PW10VRM, and PW10VRL are not used when the device is used as a master clock.

28.2.24 Negative Gradient Worst 10 Value Registers (MW10RU, MW10RM, MW10RL)

Address(es): EPTPC.MW10RU E820 52D0h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits are for reading the higher-order 32 bits of the negative gradient value. | R |

Address(es): EPTPC.MW10RM E820 52D4h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits are for reading the middle-order 32 bits of the negative gradient value. | R |

Address(es): EPTPC.MW10RL E820 52D8h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits are for reading the lower-order 32 bits of the negative gradient value. | R |

Registers MW10RU, MW10RM, and MW10RL indicate the worst 10 of the negative gradient values.

When the GETINFOR.INFO bit is set to 1, the worst 10 value at that time is stored in registers MW10RU, MW10RM, and MW10RL.

The format of the worst 10 gradients stored in registers MW10RU, MW10RM, and MW10RL are the same as for registers MLIMITRU, MLIMITRM, and MLIMITRL. For details on the format of the values, see the description of the MLIMITR registers.

Registers MW10RU, MW10RM, and MW10RL are not used when the device is used as a master clock.

28.2.25 Timer Start Time Setting Registers (TMSTTRUm, TMSTTRLm) (m = 0 to 5)

Address(es): EPTPC.TMSTTRU0 E820 5300h, EPTPC.TMSTTRU1 E820 5310h, EPTPC.TMSTTRU2 E820 5320h, EPTPC.TMSTTRU3 E820 5330h, EPTPC.TMSTTRU4 E820 5340h, EPTPC.TMSTTRU5 E820 5350h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the higher-order 32 bits of the start time of the pulse output timer in nanoseconds | R/W |

Address(es): EPTPC.TMSTTRL0 E820 5304h, EPTPC.TMSTTRL1 E820 5314h, EPTPC.TMSTTRL2 E820 5324h, EPTPC.TMSTTRL3 E820 5334h, EPTPC.TMSTTRL4 E820 5344h, EPTPC.TMSTTRL5 E820 5354h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the lower-order 32 bits of the start time of the pulse output timer in nanoseconds. | R/W |

Registers TMSTTRUm and TMSTTRLm are used to set the start time of pulse output timer m.

Set the start time of pulse output timer m (64 bits) in units of nanoseconds. Though the setting is in units of nanoseconds, the start time of pulse output timer m depends on the resolution of the STCA clock.

For example, if the STCA clock is running at 50 MHz, one cycle takes 20 ns, so the time at which the timer starts may differ from the time set in registers TMSTTRUm and TMSTTRLm by up to 20 ns.

When writing to registers TMSTTRUm and TMSTTRLm, write values consecutively in order of TMSTTRUm and then TMSTTRLm while the TMSTARTR.ENm bit is 0.

Note, however, that the format for setting times in registers TMSTTRUm and TMSTTRLm differs from that described in section 28.2.22, Local Clock Counters (LCCVRU, LCCVRM, LCCVRL).

28.2.26 Timer Cycle Setting Registers m (TMCYCRm) (m = 0 to 5)

Address(es): EPTPC.TMCYCR0 E820 5308h, EPTPC.TMCYCR1 E820 5318h, EPTPC.TMCYCR2 E820 5328h, EPTPC.TMCYCR3 E820 5338h, EPTPC.TMCYCR4 E820 5348h, EPTPC.TMCYCR5 E820 5358h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|--|-----|
| b29 to b0 | — | — | These bits set the cycle of the pulse output timer in nanoseconds. Set a value that is equivalent to at least four cycles of the STCA clock. | R/W |
| b31 to b30 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

A TMCYCRm register specifies the period of the output signal generated by the corresponding pulse output timer m. Set a value in nanoseconds that is equivalent to at least four cycles of the STCA clock while the value of the TMSTARTR.ENm bit is 0.

Though the settings of TMCYCRm registers are in units of nanoseconds, the period of the output signal generated by pulse output timer m and the time at which the timer starts depend on the period of the STCA clock. For example, one cycle of the STCA clock running at 50 MHz takes 20 ns, so the clock source for counting by pulse output timer m may differ from the period set in the TMCYCRm registers by up to 19 ns. The SYNFP module handles calculations to correct this difference.

For example, if the setting for the timer period is 81 ns and the STCA clock is running at 50 MHz, the only available settings close to the actual timer period are for 80 ns or 100 ns. By setting the timer period in the SYNFP module to 80 ns for 19 and to 100 ns for 1 of every 20 cycles, we are able to adjust the average period to 81 ns.

$$(80 \text{ (ns)} \times 19 + 100 \text{ (ns)} \times 1) / 20 = 81 \text{ (ns)}$$

The minimum value that can be set in a TMCYCRm register is four cycles of the STCA clock. For example, if the STCA clock is running at 50 MHz, the minimum setting corresponds to 80 ns. Timer operation is not guaranteed if a value set in one of these registers is less than this value.

28.2.27 Timer Pulse Width Setting Register m (TMPLSRm) (m = 0 to 5)

Address(es): EPTPC.TMPLSR0 E820 530Ch, EPTPC.TMPLSR1 E820 531Ch, EPTPC.TMPLSR2 E820 532Ch, EPTPC.TMPLSR3 E820 533Ch, EPTPC.TMPLSR4 E820 534Ch, EPTPC.TMPLSR5 E820 535Ch

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|---|-----|
| b28 to b0 | — | — | These bits set the width at high level of the pulse signal from the timer in nanoseconds. Set a value that is equivalent to at least two cycles of the STCA clock. | R/W |
| b31 to b29 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

A TMPLSRm register specifies the width at high level of the output signal generated by the corresponding pulse output timer m.

When the TMSTARTR.ENm bit is 0, set a value corresponding to a time no shorter than two cycles of the STCA clock in units of nanoseconds.

The higher-order 3 bits of the TMPLSRm register are reserved. These bits are read as 000b. When writing, write 000b to these bits.

Though the settings of the TMPLSRm register are in units of nanoseconds, the width at high level of the signal from the timer depends on the period of the STCA clock. The method for correcting the width at high level of the signal from the timer is the same as that for correcting the timer periods set by the TMCYCRm register.

28.2.28 Timer Start Register (TMSTARTR)

Address(es): EPTPC.TMSTARTR E820 537Ch

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------------------------|--|-----|
| b0 | EN0 | Pulse Output Timer 0 Start | 1: Starts pulse output timer 0. 1: Starts pulse output timer 0. | R/W |
| b1 | EN1 | Pulse Output Timer 1 Start | 0: Stops pulse output timer 1. 1: Starts pulse output timer 1. | R/W |
| b2 | EN2 | Pulse Output Timer 2 Start | 0: Stops pulse output timer 2. 1: Starts pulse output timer 2. | R/W |
| b3 | EN3 | Pulse Output Timer 3 Start | 0: Stops pulse output timer 3. 1: Starts pulse output timer 3. | R/W |
| b4 | EN4 | Pulse Output Timer 4 Start | 0: Stops pulse output timer 4. 1: Starts pulse output timer 4. | R/W |
| b5 | EN5 | Pulse Output Timer 5 Start | 0: Stops pulse output timer 5. 1: Starts pulse output timer 5. | R/W |
| b31 to b6 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The TMSTARTR register is used to start and stop pulse output timer m.

28.2.29 PRC-TC Status Register (PRSR)

Address(es): EPTPC.PRSR E820 5400h

| b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
|--------------------|-----|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| — | — | URE1 | URE0 | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|-----|-----|-----|-----|----|------|----|----|----|----|-------|-------|-------|-------|
| — | — | — | — | — | — | — | MACE | — | — | — | — | OVRE3 | OVRE2 | OVRE1 | OVRE0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|--|---|-------|
| b0 | OVRE0 | Relay Packet Overflow Detection Flag 0 | 0: No overflow in transfer of data from SYNFP1 to PTPEDMAC 1: An overflow has been detected in transfer of data from SYNFP1 to PTPEDMAC. | R/W*1 |
| b1 | OVRE1 | Relay Packet Overflow Detection Flag 1 | 0: No overflow in transfer of data from SYNFP0 to PTPEDMAC 1: An overflow has been detected in transfer of data from SYNFP0 to PTPEDMAC. | R/W*1 |
| b2 | OVRE2 | Relay Packet Overflow Detection Flag 2 | 0: No overflow in transfer of data from SYNFP1 to SYNFP0 1: An overflow has been detected in transfer of data from SYNFP1 to SYNFP0. | R/W*1 |
| b3 | OVRE3 | Relay Packet Overflow Detection Flag 3 | 0: No overflow in transfer of data from SYNFP0 to SYNFP1 1: An overflow has been detected in transfer of data from SYNFP0 to SYNFP1. | R/W*1 |
| b7 to b4 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b8 | MACE | Source MAC Address Mismatch Detection Flag | 0: A MAC address mismatch has not been detected. 1: A MAC address mismatch has been detected. | R/W*1 |
| b15 to b9 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b27 to b16 | — | Reserved | These bits are read as undefined. The write value should be 0. | R/W |
| b28 | URE0 | Relay Packet Underflow Detection Flag 0 | 0: No underflow in transfer of data from SYNFP1 to SYNFP0 1: An underflow has been detected in transfer of data from SYNFP1 to SYNFP0. | R/W*1 |
| b29 | URE1 | Relay Packet Underflow Detection Flag 1 | 0: No underflow in transfer of data from SYNFP0 to SYNFP1 1: An underflow has been detected in transfer of data from SYNFP0 to SYNFP1. | R/W*1 |
| b31, b30 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The PRSR register indicates the state of the PRC-TC module.

The PRC-TC module transmits and receives Ethernet packets through Ethernet port 0, Ethernet port 1, and the PTPEDMAC.

The PRSR register indicates the states as overflows, underflows, and non-matching MAC addresses in the transmission and reception of Ethernet packets.

OVRE0 Flag (Relay Packet Overflow Detection Flag 0)

This flag indicates that the FIFO buffer has overflowed while packets were being transferred from the SYNFP1 module to the PTPEDMAC. The data received in the PTPEDMAC may be incorrect if the setting of the OVRE0 flag is 1.

OVRE1 Flag (Relay Packet Overflow Detection Flag 1)

This flag indicates that the FIFO buffer has overflowed while packets were being transferred from the SYNFP0 module to the PTPEDMAC. The data received in the PTPEDMAC may be incorrect if the setting of the OVRE1 flag is 1.

OVRE2 Flag (Relay Packet Overflow Detection Flag 2)

This flag indicates that the FIFO buffer has overflowed while packets were being transferred from the SYNFP1 module to the SYNFP0 module.

OVRE3 Flag (Relay Packet Overflow Detection Flag 3)

This flag indicates that the FIFO buffer has overflowed while packets were being transferred from the SYNFP0 module to the SYNFP1 module.

MACE Flag (Source MAC Address Mismatch Detection Flag)

This flag becomes 1 if the source MAC address of a packet for transmission from the PTPEDMAC matches none of registers PRMACRU0, PRMACRL0, PRMACRU1, and PRMACRL1.

URE0 Flag (Relay Packet Underflow Detection Flag 0)

This flag indicates that the FIFO buffer has underflowed while packets were being transferred from the SYNFP1 module to the SYNFP0 module.

URE1 Flag (Relay Packet Underflow Detection Flag 1)

This flag indicates that the FIFO buffer has underflowed while packets were being transferred from the SYNFP0 module to the SYNFP1 module.

28.2.30 PRC-TC Status Notification Enable Register (PRIPR)

Address(es): EPTPC.PRIPR E820 5404h

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|---|-----|
| b23 to b0 | — | — | These bits hold the setting for the lower-order 24 bits of the local MAC address for Ethernet port 0. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Registers PRMACRU0 and PRMACRL0 are used to set the local MAC address for Ethernet port 0. Set the higher-order 24 bits and the lower-order 24 bits of the MAC address in PRMACRU0 and PRMACRL0, respectively.

These registers are used in transmission from the PTPEDMAC to send frames from transmission sources with MAC addresses matching the value of this register to Ethernet port 0. Set registers PRMACRU0 and PRMACRL0 to the same value as registers SYMACRU and SYMACRL for the EPTPC0 module.

Rewrite registers PRMACRU0 and PRMACRL0 before starting the EDMAC, ETHERC, and PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.32 Channel 1 Local MAC Address Registers (PRMACRU1, PRMACRL1)

Address(es): EPTPC.PRMACRU1 E820 5418h

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|---|-----|
| b23 to b0 | — | — | These bits hold the setting for the lower-order 24 bits of the local MAC address for Ethernet port 1. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Registers PRMACRU1 and PRMACRL1 are used to set the local MAC address for Ethernet port 1. Set the higher-order 24 bits and the lower-order 24 bits of the MAC address in registers PRMACRU1 and PRMACRL1, respectively.

These registers are used in transmission from the PTPEDMAC to send frames from transmission sources with MAC addresses matching the value of this register to Ethernet port 1. Set registers PRMACRU1 and PRMACRL1 to the same value as registers SYMACRU and SYMACRL for the EPTPC1 module.

Rewrite registers PRMACRU1 and PRMACRL1 before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.33 Packet Transmission Control Register (TRNDISR)

Address(es): EPTPC.TRNDISR E820 5420h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|-----------|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | TDIS[1:0] | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|-----------------------------|--|-----|
| b1, b0 | TDIS[1:0] | Packet Transmission Control | b1 b0 0 0: PTP packets are transmitted through both Ethernet port 0 and Ethernet port 1. 0 1: PTP packets are only transmitted through Ethernet port 0. 1 0: PTP packets are only transmitted through Ethernet port 1. 1 1: Setting prohibited | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The TRNDISR register controls transmission of PTP packets when Ethernet port 0 and Ethernet port 1 have the same local MAC address.

When registers PRMACRU0 and PRMACRL0 and registers PRMACRU1 and PRMACRL1 have the same local MAC address setting, the EPTPC can select whether PTP packets with the matching address are transmitted through both ports or are only transmitted through one port or the other.

If Ethernet port 0 and Ethernet port 1 have different local MAC address settings, set the TDIS[1:0] bits to 00b. If the setting is other than 00b, the transmission of frames with an source MAC address matching that of the Ethernet port may be blocked.

Rewrite the TRNDISR register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.34 Relay Mode Register (TRNMR)

Address(es): EPTPC.TRNMR E820 5430h

| b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| — | — | — | — | — | — | FWD1 | FWD0 | — | — | — | — | — | — | — | MOD |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|------------------------|--|-----|
| b0 | MOD | Cut-Through Mode | 0: Store-and-forward 1: Cut-through | R/W |
| b7 to b1 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b8 | FWD0 | Channel 0 Relay Enable | 0: Unicast, multicast (other than PTP packets), and broadcast messages from the other node are not relayed from port 0 to port 1. 1: Unicast, multicast (other than PTP packets), and broadcast messages from the other node are relayed from port 0 to port 1. | R/W |
| b9 | FWD1 | Channel 1 Relay Enable | 0: Unicast, multicast (other than PTP packets), and broadcast messages from the other node are not relayed from port 1 to port 0. 1: Unicast, multicast (other than PTP packets), and broadcast messages from the other node are relayed from port 1 to port 0. | R/W |
| b31 to b10 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The TRNMR register is used to control relaying of packets between Ethernet port 0 and Ethernet port 1 by the PRC-TC module. For example, as Figure 28.3 shows, if the network is in a daisy-chain configuration, packets can be transferred through all three devices by enabling relaying of packets between Ethernet port 0 and Ethernet port 1 in the center of the figure.

For recalculating the CRC value in packet transfer, in the case of cut-through mode, a packet that had an abnormal CRC value may be transferred with a normal CRC value. Use store-and-forward mode when abnormal packets need to be discarded. There is no difference in the latency of transfer in cut-through mode and store-and-forward mode when the length of the packets is shorter than 96 bytes.

Rewrite the TRNMR register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

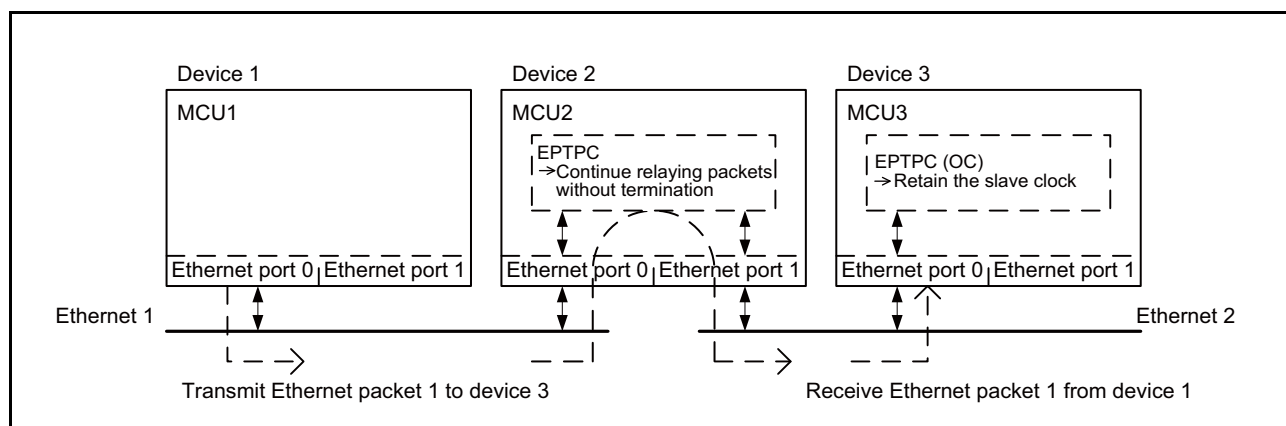

Figure 28.3 Network Configuration Example

28.2.35 Cut-Through Transfer Start Threshold Register (TRNCTTDR)

Address(es): EPTPC.TRNCTTDR E820 5434h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-------------|----|----|----|----|----|----|----|----|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | THVAL[10:0] | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------------|------------------------------|--|-----|
| b1, b0 | THVAL [10:0] | FIFO Read Start Threshold | Threshold for starting to read data from the relay FIFO in cut-through mode (specified as the number of bytes)*1 | R |
| b10 to b2 | | | | R/W |
| b31 to b11 | — | Reserved | These bits are read as 0. The write value should be 0. | |

Note 1. A value cannot be set in the lower-order 2 bits. These bits are fixed to 0.
A value of less than 96 bytes cannot be set.

The TRNCTTDR register is used to set the threshold for the transmitting port starting to read data from the relay FIFO when the cut-through method is selected for relaying between the Ethernet ports.

When the TRNMR.MOD bit is 1, data transfer can start without waiting for all frame data to be stored in the relay FIFO. The setting of the THVAL[10:0] bits is the amount of data, in bytes, that must be stored in the relay FIFO before transmission starts. Set a multiple of four as the threshold value.

Reading from the relay FIFO starts when either of the following conditions is met.

- The relay FIFO holds at least as much data as the number of bytes specified by the THVAL[10:0] bits.
- The relay FIFO holds at least one frame.

Rewrite the TRNCTTDR register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.36 SYNFP Status Register (SYSR)

Address(es): EPTPC0.SYSR E820 5800h, EPTPC1.SYSR E820 5C00h

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|---|--|-------|
| b0 | OFMUD | offsetFromMaster Value Update Flag | 0: The offsetFromMaster value has not been updated. 1: The offsetFromMaster value has been updated. | R/W*1 |
| b1 | INTCHG | Receive logMessageInterval Value Change Detection Flag | 0: No change in the received logMessageInterval value. 1: A change in the received logMessageInterval value. | R/W*1 |
| b2 | MPDUD | meanPathDelay Value Update Flag | 0: The meanPathDelay value has not been updated. 1: The meanPathDelay value has been updated. | R/W*1 |
| b3 | — | Reserved | This bit is read as 0. The write value should be 0. | R |
| b4 | DRPTO | Delay_Resp/Pdelay_Resp Reception Timeout Detection Flag | 0: A Delay_Resp/Pdelay_Resp timeout has not occurred. 1: A Delay_Resp/Pdelay_Resp timeout has occurred. | R/W*1 |
| b5 | INTDEV | Receive logMessageInterval Value Out-of-Range Flag | 0: The received logMessageInterval value is within the range. 1: The received logMessageInterval value is out of the range. | R/W*1 |
| b6 | DRQOVR | Delay_Req Reception FIFO Overflow Detection Flag | 0: The received Delay_Req has not caused the reception FIFO to overflow. 1: The received Delay_Req has caused the reception FIFO to overflow. | R/W*1 |
| b11 to b7 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b12 | RECLP | Loop Reception Detection Flag | 0: A received message has not returned through a loop. 1: A received message has returned through a loop. | R/W*1 |
| b13 | — | Reserved | This bit is read as 0. The write value should be 0. | R/W |
| b14 | INFABT | Control Information Abnormality Detection Flag | 0: No abnormality in control information 1: Abnormality in control information | R/W*1 |
| b15 | — | Reserved | This bit is read as 0. The write value should be 0. | R |
| b16 | RESDN | Response Stop Completion Detection Flag | 0: Stopping responses has not been completed. 1: Stopping responses has been completed. | R/W*1 |
| b17 | GENDN | Generation Stop Completion Detection Flag | 0: Stopping generation has not been completed. 1: Stopping generation has been completed. | R/W*1 |
| b23 to b18 | — | Reserved | These bits are read as undefined. The write value should be 0. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note 1. Writing 1 clears the flag. Writing 0 does not affect the flag value.

The SYSR register indicates the state of the SYNFP module.

OFMUD Flag (offsetFromMaster Value Update Flag)

This flag indicates that the value of offsetFromMaster has been updated.

INTCHG Flag (Receive logMessageInterval Value Change Detection Flag)

This flag indicates that the logMessageInterval value of the Delay_Resp, Sync or Announce message differs from the previously received value.

MPDUD Flag (meanPathDelay Value Update Flag)

This flag indicates that the value of meanPathDelay has been updated.

INTDEV Flag (Receive logMessageInterval Value Out-of-Range Flag)

This flag indicates the reception of a Delay_Resp message with a logMessageInterval value outside the range -7 to 6.

DRQOVR Flag (Delay_Req Reception FIFO Overflow Detection Flag)

This flag indicates that the FIFO buffer for storing information from received Delay_Req messages holds 32 or more entries.

RECLP Flag (Loop Reception Detection Flag)

This flag indicates that the value of the sourcePortIdentity field in a received PTP message matches the local PortIdentity (as set by registers SYCIDRU, SYCIDRL, and SYPNUMR).

INFABT Flag (Control Information Abnormality Detection Flag)

This flag indicates that the control information included a mismatch.

When this bit is set to 1, reset the EPTPC, PTPEDMAC, and respective channel of the ETHERC and EDMAC. Follow the procedure below to reset these functional blocks.

- (1) Write “0000 0001h” to the PTRSTR register of the EPTPC.
- (2) Write “0000 0001h” to the EDMR register of the PTPEDMAC.
- (3) Write “0000 0001h” to the EDMR register of the respective channel of the EDMAC.
- (4) Wait until the initialization is completed (for 64 cycles of Bφ).
- (5) Write “0000 0000h” to the PTRSTR register of the EPTPC.

For details on resetting these functional blocks, see section 28.2.83, PTP Reset Register (PTRSTR) and section 29.2.1, EDMAC Mode Register (EDMR).

RESDN Flag (Response Stop Completion Detection Flag)

This flag indicates the end of processing for transmission of a Delay_Resp or Pdelay_Resp as response messages when the handling of a received Delay_Req or Pdelay_Req by the SYNFP module has been disabled by the setting of the SYRFL1R or SYRVLDR register.

GENDN Flag (Generation Stop Completion Detection Flag)

This flag indicates the end of processing for transmission of messages of a type disabled in the SYTRENr or SYRVLDR register.

28.2.37 SYNFP Status Notification Enable Register (SYIPR)

Address(es): EPTPC0.SYIPR E820 5804h, EPTPC1.SYIPR E820 5C04h

| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYIPR register specifies whether the MIESR.SYn flag does or does not reflect changes in the state of the SYNFPn module.

28.2.38 SYNFP MAC Address Registers (SYMACRU, SYMACRL)

Address(es): EPTPC0.SYMACRU E820 5810h, EPTPC1.SYMACRU E820 5C10h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|--|-----|
| b23 to b0 | — | — | These bits hold the setting for the higher-order 24 bits of the local MAC address. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |

Address(es): EPTPC0.SYMACRL E820 5814h, EPTPC1.SYMACRL E820 5C14h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|---|-----|
| b23 to b0 | — | — | These bits hold the setting for the lower-order 24 bits of the local MAC address. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |

Registers SYMACRU and SYMACRL are used to specify the local MAC address for Ethernet ports 0 and 1. Rewrite registers SYMACRU and SYMACRL before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.39 SYNFP LLC-CTL Value Register (SYLLCCTLR)

Address(es): EPTPC0.SYLLCCTLR E820 5818h, EPTPC1.SYLLCCTLR E820 5C18h

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | CTL[7:0] | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|----------|---------------|--|-----|
| b7 to b0 | CTL[7:0] | LLC-CTL Field | Set a value used for the control field in the LLC sublayer when generating IEEE802.3 frames. | R/W |
| b31 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYLLCCTLR register is used to set the control field (LLC-CTL) value of LCC frames generated by the SYNFP module.

Rewrite the SYLLCCTLR register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.40 SYNFP Local IP Address Register (SYIPADDRR)

Address(es): EPTPC0.SYIPADDRR E820 581Ch, EPTPC1.SYIPADDRR E820 5C1Ch

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | | | | | | | | | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the local IP address. | R/W |

The SYIPADDRR register is used to specify the local IP address for Ethernet ports 0 and 1.

Rewrite the SYIPADDRR register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.41 SYNFP Specification Version Setting Register (SYSPVRR)

Address(es): EPTPC0.SYSPVRR E820 5840h, EPTPC1.SYSPVRR E820 5C40h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|-----------|----|----|----------|----|----|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | TRSP[3:0] | | | VER[3:0] | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|-----------|-------------------------------|--|-----|
| b3 to b0 | VER[3:0] | versionPTP Field Value | These bits are used to set the versionPTP field value of the PTP v2 header. When a message is received, this value is compared with the versionPTP field of the received frame. In generating messages, the value is used for the versionPTP field of the frame for transmission. Set these bits to 0010b (PTP v2). | R/W |
| b7 to b4 | TRSP[3:0] | transportSpecific Field Value | These bits are used to set the transportSpecific field value of the PTP v2 header. When a message is received, this value is compared with the transportSpecific field of the received frame. In generating messages, the value is used for the transportSpecific field of the frame for transmission. Set these bits to 0000b (IEEE 1588). | R/W |
| b31 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYSPVRR register is used to set the transportSpecific and versionPTP field values of the PTP v2 message header. The value should not be modified while reception or transmission of PTP messages is enabled.

28.2.42 SYNFP Domain Number Setting Register (SYDOMR)

Address(es): EPTPC0.SYDOMR E820 5844h, EPTPC1.SYDOMR E820 5C44h

[illegible]

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|-----------|----------------------------------|--|-----|
| b7 to b0 | DNUM[7:0] | domainNumber Field Value Setting | <p>These bits are used to set the domainNumber field value of the PTP v2 header.</p> <p>When a message is received, this value is compared with the domainNumber field of the received frame as a condition for PTP reception processing.</p> <p>In generating messages, the value is used for the domainNumber field of the frame for transmission.</p> | R/W |
| b31 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYDOMR register is used to set the domainNumber field value of the PTP v2 message header. The value should not be modified while reception or transmission of PTP messages is enabled.

28.2.43 Announce Message Flag Field Setting Register (ANFR)

Address(es): EPTPC0.ANFR E820 5850h, EPTPC1.ANFR E820 5C50h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|------------------------|---|-----|
| b0 | FLAG0 | leap61 | This bit is used to set the logical value of the leap61 member of timePropertiesDS. 0: leap61 is set to FALSE. 1: leap61 is set to TRUE. | R/W |
| b1 | FLAG1 | leap59 | This bit is used to set the logical value of the leap59 member of timePropertiesDS. 0: leap59 is set to FALSE. 1: leap59 is set to TRUE. | R/W |
| b2 | FLAG2 | currentUtcOffsetValid | This bit is used to set the logical value of the currentUtcOffsetValid member of timePropertiesDS. 0: currentUtcOffsetValid is set to FALSE. 1: currentUtcOffsetValid is set to TRUE. | R/W |
| b3 | FLAG3 | ptpTimescale | This bit is used to set the logical value of the ptpTimescale member of timePropertiesDS. 0: ptpTimescale is set to FALSE. 1: ptpTimescale is set to TRUE. | R/W |
| b4 | FLAG4 | timeTraceable | This bit is used to set the logical value of the timeTraceable member of timePropertiesDS. 0: timeTraceable is set to FALSE. 1: timeTraceable is set to TRUE. | R/W |
| b5 | FLAG5 | frequencyTraceable | This bit is used to set the logical value of the frequencyTraceable member of timePropertiesDS. 0: frequencyTraceable is set to FALSE. 1: frequencyTraceable is set to TRUE. | R/W |
| b7, b6 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |
| b8 | FLAG8 | alternateMasterFlag | 0: alternateMasterFlag is set to FALSE. 1: alternateMasterFlag is set to TRUE. | R/W |
| b9 | — | Reserved | This bit is read as 0. The write value should be 0. | R/W |
| b10 | FLAG10 | unicastFlag | 0: unicastFlag is set to FALSE. 1: unicastFlag is set to TRUE. | R/W |
| b12, b11 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |
| b13 | FLAG13 | PTP profile Specific 1 | 0: PTP profile Specific 1 is set to FALSE. 1: PTP profile Specific 1 is set to TRUE. | R/W |
| b14 | FLAG14 | PTP profile Specific 2 | 0: PTP profile Specific 2 is set to FALSE. 1: PTP profile Specific 2 is set to TRUE. | R/W |
| b31 to b15 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |

The ANFR register is used to set the flagField section of the header when the SYNFP module is to generate an Announce message.

The value specified by the ANFR register is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

28.2.44 Sync Message Flag Field Setting Register (SYNFR)

Address(es): EPTPC0.SYNFR E820 5854h, EPTPC1.SYNFR E820 5C54h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|------------|------------|-----|-----|------------|-------|-------|----|----|----|----|----|----|----|----|
| | — | FLAG 14 | FLAG 13 | — | — | FLAG 10 | FLAG9 | FLAG8 | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|------------------------|---|-----|
| b7 to b0 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |
| b8 | FLAG8 | alternateMasterFlag | 0: alternateMasterFlag is set to FALSE. 1: alternateMasterFlag is set to TRUE. | R/W |
| b9 | FLAG9 | twoStepFlag | Set this bit to 0 (FALSE). | R/W |
| b10 | FLAG10 | unicastFlag | 0: unicastFlag is set to FALSE. 1: unicastFlag is set to TRUE. | R/W |
| b12, b11 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |
| b13 | FLAG13 | PTP profile Specific 1 | 0: PTP profile Specific 1 is set to FALSE. 1: PTP profile Specific 1 is set to TRUE. | R/W |
| b14 | FLAG14 | PTP profile Specific 2 | 0: PTP profile Specific 2 is set to FALSE. 1: PTP profile Specific 2 is set to TRUE. | R/W |
| b31 to b15 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |

The SYNFR register is used to set the flagField section of the header when the SYNFP module is to generate a Sync message.

The value specified by the SYNFR register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

28.2.45 Delay_Req Message Flag Field Setting Register (DYRQFR)

Address(es): EPTPC0.DYRQFR E820 5858h, EPTPC1.DYRQFR E820 5C58h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|------------|------------|-----|-----|------------|----|----|----|----|----|----|----|----|----|----|
| | — | FLAG1 4 | FLAG1 3 | — | — | FLAG1 0 | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|------------------------|---|-----|
| b9 to b0 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |
| b10 | FLAG10 | unicastFlag | 0: unicastFlag is set to FALSE. 1: unicastFlag is set to TRUE. | R/W |
| b12, b11 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |
| b13 | FLAG13 | PTP profile Specific 1 | 0: PTP profile Specific 1 is set to FALSE. 1: PTP profile Specific 1 is set to TRUE. | R/W |
| b14 | FLAG14 | PTP profile Specific 2 | 0: PTP profile Specific 2 is set to FALSE. 1: PTP profile Specific 2 is set to TRUE. | R/W |
| b31 to b15 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |

Register DYRQFR is used to set the flagField section of the header when the SYNFP module is to generate a Delay_Req or Pdelay_Req message.

The value specified by DYRQFR is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

28.2.46 Delay_Resp Message Flag Field Setting Register (DYRPFR)

Address(es): EPTPC0.DYRPFR E820 585Ch, EPTPC1.DYRPFR E820 5C5Ch

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|--------------------|--------------------|-----|-----|--------------------|-------|-------|----|----|----|----|----|----|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | FLAG1 ₄ | FLAG1 ₃ | — | — | FLAG1 ₀ | FLAG9 | FLAG8 | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|------------------------|---|-----|
| b7 to b0 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |
| b8 | FLAG8 | alternateMasterFlag*1 | 0: alternateMasterFlag is set to FALSE. 1: alternateMasterFlag is set to TRUE. | R/W |
| b9 | FLAG9 | twoStepFlag*2 | Set this bit to 0 (FALSE). | R/W |
| b10 | FLAG10 | unicastFlag | 0: unicastFlag is set to FALSE. 1: unicastFlag is set to TRUE. | R/W |
| b12, b11 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |
| b13 | FLAG13 | PTP profile Specific 1 | 0: PTP profile Specific 1 is set to FALSE. 1: PTP profile Specific 1 is set to TRUE. | R/W |
| b14 | FLAG14 | PTP profile Specific 2 | 0: PTP profile Specific 2 is set to FALSE. 1: PTP profile Specific 2 is set to TRUE. | R/W |
| b31 to b15 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |

Note 1. This bit is reserved for Pdelay_Resp messages. Set the bit to 0.

Note 2. This bit is reserved for Delay_Resp messages.

The DYRPFR register is used to set the flagField section of the header when the SYNFP module is to generate a Delay_Resp or PDelay_Resp message.

The value specified by the DYRPFR register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

Do not change the value of the DYRPFR register while processing for the transmission of Delay_Resp or Pdelay_Resp messages is enabled. Furthermore, after disabling this processing for transmission, do not change the value of the DYRPFR register until the SYSR.RESDN flag becomes 1.

28.2.47 SYNFP Local Clock ID Registers (SYCIDRU, SYCIDRL)

Address(es): EPTPC0.SYCIDRU E820 5860h, EPTPC1.SYCIDRU E820 5C60h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the higher-order 32 bits of the clock-ID of the local port. | R/W |

Address(es): EPTPC0.SYCIDRL E820 5864h, EPTPC0.SYCIDRL E820 5C64h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the higher-order 32 bits of the clock-ID of the local port. | R/W |

The SYCIDR registers are used to set the clock-ID of the local port.

The registers are used for the clockIdentity section in the sourcePortIdentity field of the header when the SYNFP module is to generate a PTP message.

When a PTP message is received, the value of these registers is compared with the clockIdentity section in the sourcePortIdentity field of the PTP message to determine whether the message is one that was transmitted by you.

Usually, the setting should be the same as the value of portDS.portIdentity.clockIdentity.

Do not change the value of these registers while processing for the reception or transmission of PTP messages is enabled.

28.2.48 SYNFP Local Port Number Register (SYPNUMR)

| | | | | |
|------------|------------|---------------------------|--|-----|
| Bit | Symbol | Bit Name | Description | R/W |
| b15 to b0 | PNUM[15:0] | Local Port Number Setting | These bits hold the setting for the port number of the local port. | R/W |
| b31 to b16 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYPNUMR register is used to set the port number of the local port.

This register is used for the portNumber section in the sourcePortIdentity field of the header when the SYNFP module is to generate a PTP message.

When a PTP message is received, the value of this register is compared with the portNumber section in the sourcePortIdentity field of the PTP message to determine whether the message is one that was transmitted by the local device.

Usually, the setting should be the same as the value of portDS.portIdentity.portNumber.

Do not change the value of this register while processing for the reception or transmission of PTP messages is enabled.

28.2.49 SYNFP Register Value Load Directive Register (SYRVLDR)

Address(es): EPTPC0.SYRVLDR E820 5880h, EPTPC1.SYRVLDR E820 5C80h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|------|------|------|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | ANUP | STUP | BMUP |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|--|---|-----|
| b0 | BMUP | BMC Update | When this bit is set to 1, the SYNFP module simultaneously reflects values of registers storing the MasterClock identifying information. | W |
| b1 | STUP | State Update | When this bit is set to 1, the SYNFP module simultaneously reflects register values for PTP message reception and transmission. | W |
| b2 | ANUP | Announce Message Generation Information Update | When this bit is set to 1, the Announce message generation block simultaneously reflects register values required for generating Announce messages. | W |
| b31 to b3 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYRVLDR register is used for simultaneously updating multiple register values in the SYNFP module.

BMUP Bit (BMC Update)

When the BMUP bit is set to 1, the SYNFP module simultaneously reflects the values of registers storing the MasterClock identifying information listed below.

- Registers MTCIDU and MTCIDL
- MTPID register

STUP Bit (State Update)

When the STUP bit is set to 1, the SYNFP module simultaneously reflects the values of registers and bits for PTP message reception and transmission listed below.

- SYNFR register
- DYRQFR register
- SYTLIR.DREQ[7:0] bits
- RSTOUTR register
- SYRFL1R register
- SYRFL2R register
- SYTRENR register

ANUP Bit (Announce Message Generation Information Update)

When the ANUP bit is set to 1, the Announce message generation block simultaneously reflects the values of registers and bits required for generating Announce messages listed below.

- ANFR register
- SYTLIR.ANCE[7:0] bits
- GMPR register
- GMCQR register
- Registers GMIDRU and GMIDRL
- CUOTSR register
- SRR register

28.2.50 SYNFP Reception Filter Register 1 (SYRFL1R)

Address(es): EPTPC0.SYRFL1R E820 5890h, EPTPC1.SYRFL1R E820 5C90h

| b20 | PDRQ[2:0] | Pdelay_Req Message Processing | 0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC. | R/W |
| b21 | | | 0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1. | R/W |
| b22 | — | Reserved | 0: The SYNFP does not process messages. 1: The SYNFP processes messages. | R/W |
| b23 | — | Reserved | This bit is read as 0. The write value should be 0. | R |

| Bit | Symbol | Bit Name | Description | R/W |
|-----|------------|--|--|-----|
| b24 | PDRP[2:0] | Pdelay_Resp Message Processing | 0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC. | R/W |
| b25 | | | 0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1. | R/W |
| b26 | | | 0: The SYNFP does not process messages. 1: The SYNFP processes messages. | R/W |
| b27 | — | Reserved | This bit is read as 0. The write value should be 0. | R |
| b28 | PDFUP[2:0] | Pdelay_Resp_Follow_Up Message Processing | 0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC. | R/W |
| b29 | | | 0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1. | R/W |
| b30 | | | 0: The SYNFP does not process messages. 1: The SYNFP processes messages. | R/W |
| b31 | — | Reserved | This bit is read as 0. The write value should be 0. | R |

The SYRFL1R register is used to set up filtering for the reception of PTP messages.

Multiple bits corresponding to different types of messages can be set to 1. Setting all bits for a type of message to 0 leads to all messages of the given type being discarded.

The value specified by the SYRFL1R register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

28.2.51 SYNFP Reception Filter Register 2 (SYRFL2R)

Address(es): EPTPC0.SYRFL2R E820 5894h, EPTPC0.SYRFL2R E820 5C94h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|----------|-----|-----|-----|-----|-----|-----|-----|----------|-----|-----|-----|----------|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|----------|---------------------------------------|--|-----|
| b0 | MAN[1:0] | Management Message Processing Setting | 0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC. | R/W |
| b1 | | | 0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1. | R/W |
| b3, b2 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b4 | SIG[1:0] | Signaling Message Processing Setting | 0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC. | R/W |
| b5 | | | 0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1. | R/W |
| b27 to b6 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b28 | ILL[1:0] | Illegal Message Processing Setting*1 | 0: Messages are not transferred to the PTPEDMAC. 1: Messages are transferred to the PTPEDMAC. | R/W |
| b29 | | | 0: The PRC-TC does not relay messages between ports 0 and 1. 1: The PRC-TC relays messages between ports 0 and 1. | R/W |
| b31, b30 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note 1. PTP messages other than PTP v2 messages and messages of undefined type are handled as illegal messages.

The SYRFL2R register is used to set up filtering for the reception of PTP messages.

Multiple bits corresponding to different types of messages can be set to 1. Setting all bits for a type of message to 0 leads to all messages of the given type being discarded.

The value specified by the SYRFL2R register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

28.2.52 SYNFP Transmission Enable Register (SYTRENR)

Address(es): EPTPC0.SYTRENRE820 5898h, EPTPC1.SYTRENRE820 5C98h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|-----|-----|------|-----|-----|----|-----|----|----|----|------|----|----|----|------|
| | — | — | — | PDRQ | — | — | — | DRQ | — | — | — | SYNC | — | — | — | ANCE |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|--|--|-----|
| b0 | ANCE | Announce Message Transmission Enable | 0: Announce messages are not transmitted. 1: Announce messages are transmitted. | R/W |
| b3 to b1 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b4 | SYNC | Sync Message Transmission Enable | 0: Sync messages are not transmitted. 1: Sync messages are transmitted. | R/W |
| b7 to b5 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b8 | DRQ | Delay_Req Message Transmission Enable | 0: Delay_Req messages are not transmitted. 1: Delay_Req messages are transmitted. | R/W |
| b11 to b9 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b12 | PDRQ | Pdelay_Req Message Transmission Enable | 0: Pdelay_Req messages are not transmitted. 1: Pdelay_Req messages are transmitted. | R/W |
| b31 to b13 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYTRENR register is used to enable or disable transmission of PTP messages.

The PDRQ and DRQ bits should not be set to 1 at the same time. Operation is not guaranteed when both bits are set to 1. The value specified by the SYTRENR register is only reflected in the SYNFP module after the SYRVLDRE820 STUP bit is set to 1.

28.2.53 Master Clock ID Registers (MTCIDU, MTCIDL)

Address(es): EPTPC0.MTCIDU E820 58A0h, EPTPC1.MTCIDU E820 5CA0h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the higher-order 32 bits of the clock-ID of the master clock. | R/W |

Address(es): EPTPC0.MTCIDL E820 58A4h, EPTPC1.MTCIDL E820 5CA4h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the higher-order 32 bits of the clock-ID of the master clock. | R/W |

Registers MTCIDU and MTCIDL are used to set the clock-ID of the master for synchronization.

The value specified by registers MTCIDU and MTCIDL is only reflected in the SYNFP module after the SYRVLDR.BMUP bit is set to 1.

28.2.54 Master Clock Port Number Register (MTPID)

| Bit | Symbol | Bit Name | Description | R/W |
|------------|----------------|-------------------------------------|--|-----|
| b15 to b0 | PNUM [15:0] | Master Clock Port Number Setting | These bits hold the setting for the port number of the master clock. | R/W |
| b31 to b16 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The MTPID register is used to set the port number of the master for synchronization.

The value specified by the MTPID register is only reflected in the SYNFP module after the SYRVLDR.BMUP bit is set to 1.

In normal usage, set the value of parentDS.parentPortIdentity.portNumber in this register.

28.2.55 SYNFP Transmission Interval Setting Register (SYTLIR)

Address(es): EPTPC0.SYTLIR E820 58C0h, EPTPC1.SYTLIR E820 5CC0h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|--|---|-----|
| b7 to b0 | ANCE[7:0] | Announce Message Transmission Interval Setting | These bits set the interval for the transmission of Announce messages. | R/W |
| b15 to b8 | SYNC[7:0] | Sync Message Transmission Interval Setting | These bits set the interval for the transmission of Sync messages. The setting is also placed in the logMessageInterval field of transmitted Sync messages. | R/W |
| b23 to b16 | DREQ[7:0] | Delay_Req Transmission Interval Average Value/ Pdelay_Req Transmission Interval Setting | The bits set the average interval for the transmission of Delay_Req messages and the interval for the transmission of Pdelay_Req messages. The setting is also placed in the logMessageInterval field of Delay_Resp messages. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYTLIR register is used to set the interval for the transmission of messages generated by the SYNFP module. The setting is an integer logarithm in base 2 ($\log_2(x)$) and determines a value x in seconds.

In other words, the interval for transmission is 2^n (s), where n is the setting. The available settings are from -7 (F9h) to +6 (06h).

Example:

If the setting is 06h, then the interval for transmission is $2^6 = 64$ (s).

If the setting is 00h, then the interval for transmission is $2^0 = 1$ (s).

If the setting is FFh, then the interval for transmission is $2^{-1} = 0.5$ (s) = 500 (ms).

If the setting is F9h, then the interval for transmission is $2^{-7} = 0.0078125$ (s) = 7.8125 (ms).

The value set in the ANCE[7:0] bits is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1. The value set in the DREQ[7:0] and SYNC[7:0] bits is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

28.2.56 SYNFP Received logMessageInterval Value Indication Register (SYRLIR)

Address(es): EPTPC0.SYRLIR E820 58C4h, EPTPC1.SYRLIR E820 5CC4h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|------------|---|--|-----|
| b7 to b0 | ANCE[7:0] | Announce Message logMessageInterval Field Indication Flag | These bits indicate the logMessageInterval field value of a received Announce message. | R |
| b15 to b8 | SYNC[7:0] | Sync Message logMessageInterval Field Indication Flag | These bits indicate the logMessageInterval field value of a received Sync message. | R |
| b23 to b16 | DRESP[7:0] | Delay_Resp Message logMessageInterval Field Indication Flag | These bits indicate the logMessageInterval field value of a received Delay_Resp message. | R |
| b31 to b24 | — | Reserved | These bits are read as 0. | R |

The SYRLIR register indicates the logMessageInterval field values of received PTP messages.

28.2.57 offsetFromMaster Value Registers (OFMRU, OFMRL)

Address(es): EPTPC0.OFMRU E820 58C8h, EPTPC1.OFMRU E820 5CC8h zzz

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits indicate the higher-order 32 bits of the calculated offsetFromMaster value. | R |

Address(es): EPTPC0.OFMRL E820 58CCh, EPTPC1.OFMRL E820 5CCCh

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits indicate the lower-order 32 bits of the calculated offsetFromMaster value. | R |

Registers OFMRU and OFMRL indicate the calculated offsetFromMaster value.

The value is expressed as two's complements in units of nanoseconds. Note that the numeric representation*1 differs from that of the offsetFromMaster member of the current data set (currentDS).

When read, access to the registers should be in order of OFMRU and then OFMRL.

Note 1. The value of currentDS.offsetFromMaster is multiplied by 2^{16} .

Example: 2.5 (ns) = 00000000_00028000h

28.2.58 meanPathDelay Value Registers (MPDRU, MPDRL)

Address(es): EPTPC0.MPDRU E820 58D0h, EPTPC1.MPDRU E820 5CD0h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits indicate the higher-order 32 bits of the calculated meanPathDelay value. | R |

Address(es): EPTPC0.MPDRL E820 58D4h, EPTPC1.MPDRL E820 5CD4h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits indicate the lower-order 32 bits of the calculated meanPathDelay value. | R |

Registers MPDRU and MPDRL indicate the calculated meanPathDelay value.

The value is expressed as two's complements in units of nanoseconds. Note that the numeric representation^{*1} differs from that of the meanPathDelay member of the current data set (currentDS).

When read, access to the registers should be in order of MPDRU and then MPDRL.

Note 1. The value of currentDS.meanPathDelay is multiplied by 2^{16} .

Example: 2.5 (ns) = 00000000_00028000h

28.2.59 grandmasterPriority Field Setting Register (GMPR)

Address(es): EPTPC0.GMPR E820 58E0h, EPTPC1.GMPR E820 5CE0h

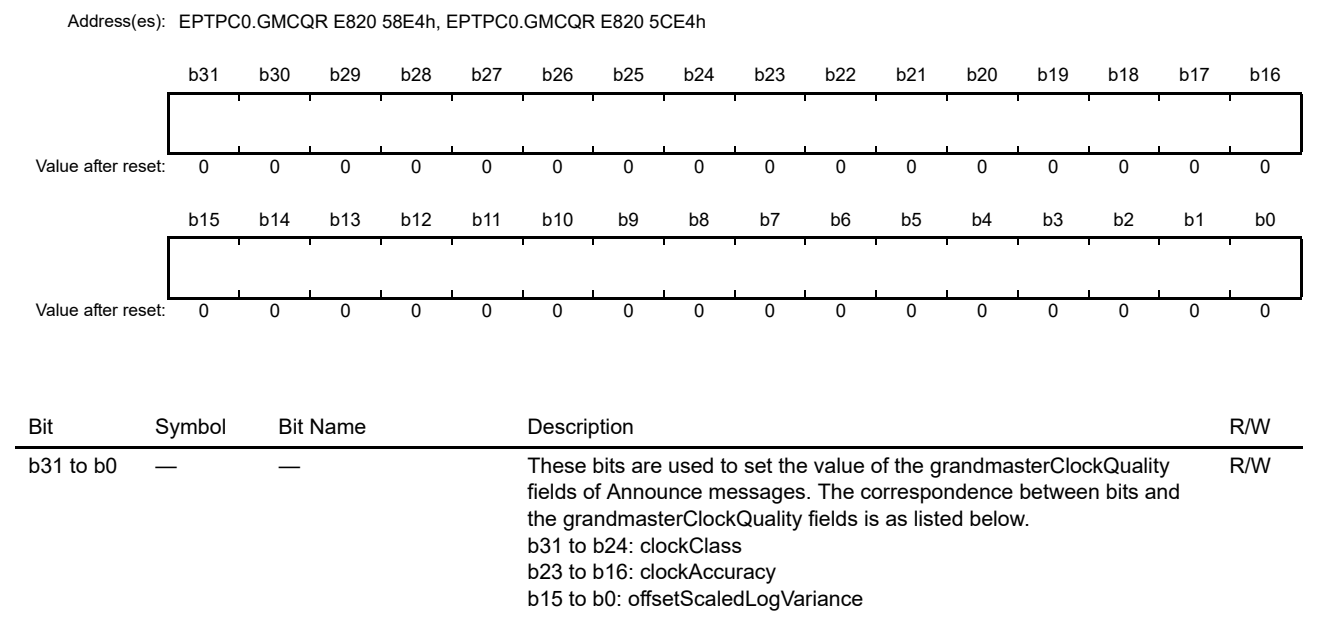

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-------------|--|---|-----|
| b7 to b0 | GMPR2 [7:0] | grandmasterPriority2 Field Value Setting | These bits are used to set the value of the grandmasterPriority2 fields of Announce messages. | R/W |
| b15 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b23 to b16 | GMPR1 [7:0] | grandmasterPriority1 Field Value Setting | These bits are used to set the value of the grandmasterPriority1 fields of Announce messages. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The GMPR register is used to specify the grandmasterPriority1 and grandmasterPriority2 field values of Announce messages generated by the SYNFP module.

The value specified by the GMPR register is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

28.2.60 grandmasterClockQuality Field Setting Register (GMCQR)

The GMCQR register is used to specify the grandmasterClockQuality field value of Announce messages generated by the SYNFP module.

The value specified by the GMCQR register is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

28.2.61 grandmasterIdentity Field Setting Registers (GMIDRU, GMIDRL)

Address(es): EPTPC0.GMIDRU E820 58E8h, EPTPC1.GMIDRU E820 5CE8h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the higher-order 32 bits of the value of the grandmasterIdentity fields of Announce messages. | R/W |

Address(es): EPTPC0.GMIDRL E820 58ECh, EPTPC1.GMIDRL E820 5CECh

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits hold the setting for the lower-order 32 bits of the value of the grandmasterIdentity fields of Announce messages. | R/W |

Registers GMIDRU and GMIDRL are used to specify the grandmasterIdentity field value of Announce messages generated by the SYNFP module.

The value specified by registers GMIDRU and GMIDRL is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

28.2.62 currentUtcOffset/timeSource Field Setting Register (CUOTSR)

Address(es): EPTPC0.CUOTSR E820 58F0h, EPTPC1.CUOTSR E820 5CF0h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|------------|--------------------------------|---|-----|
| b7 to b0 | TSRC[7:0] | timeSource Field Setting | These bits set the value of the timeSource fields of Announce messages. | R/W |
| b15 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b31 to b16 | CUTO[15:0] | currentUtcOffset Field Setting | These bits set the value of the currentUtcOffset fields of Announce messages. | R/W |

The CUOTSR register is used to specify the currentUtcOffset and timeSource field values of Announce messages generated by the SYNFP module.

The value specified by the CUOTSR register is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

28.2.63 stepsRemoved Field Setting Register (SRR)

Address(es): EPTPC0.SRR E820 58F4h, EPTPC1.SRR E820 5CF4h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-------------|----------------------------------|---|-----|
| b15 to b0 | SRMV [15:0] | stepsRemoved Field Value Setting | These bits set the value of the stepsRemoved fields of Announce messages. | R/W |
| b31 to b16 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SRR register is used to specify the stepsRemoved field value of Announce messages generated by the SYNFP module.

The value specified by the SRR register is only reflected in the SYNFP module after the SYRVLDR.ANUP bit is set to 1.

28.2.64 PTP-primary Message Destination MAC Address Setting Registers (PPMACRU, PPMACRL)

Address(es): EPTPC0.PPMACRU E820 5900h, EPTPC1.PPMACRU E820 5D00h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|---|-----|
| b23 to b0 | — | — | These bits hold the setting for the higher-order 24 bits of the destination MAC address for PTP-primary messages. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Address(es): EPTPC0.PPMACRL E820 5904h, EPTPC1.PPMACRL E820 5D04h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|--|-----|
| b23 to b0 | — | — | These bits hold the setting for the lower-order 24 bits of the destination MAC address for PTP-primary messages. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The PPMACR registers are used to specify the destination MAC address for PTP-primary messages. In normal usage, set 01:1B:19:00:00:00 in these registers.

The value is used in the destination MAC address field when generating an Ethernet frame for a PTP-primary message. It is also used as a determining condition for received frames carrying PTP messages.

Set a value in these registers before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.65 PTP-pdelay Message MAC Address Setting Registers (PDMACRU, PDMACRL)

Address(es): EPTPC0.PDMACRU E820 5908h, EPTPC1.PDMACRU E820 5D08h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|--|-----|
| b23 to b0 | — | — | These bits hold the setting for the higher-order 24 bits of the destination MAC address for PTP-pdelay messages. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Address(es): EPTPC0.PDMACRL E820 590Ch, EPTPC1.PDMACRL E820 5D0Ch

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|---|-----|
| b23 to b0 | — | — | These bits hold the setting for the lower-order 24 bits of the destination MAC address for PTP-pdelay messages. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The PDMACR registers are used to specify the destination MAC address for PTP-pdelay messages. In normal usage, set 01:80:C2:00:00:0E in these registers.

The value is used in the destination MAC address field when generating frames carrying PTP-pdelay messages in the Ethernet format. It is also used as a determining condition for received frames carrying PTP messages.

Set a value in these registers before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.66 PTP Message Ethertype Setting Register (PETYPER)

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-------------|-------------------------------------|---|-----|
| b15 to b0 | TYPE [15:0] | PTP Message Ethertype Value Setting | These bits hold the setting for the Ethertype field value for frames in the Ethernet II format. | R/W |
| b31 to b16 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The PETYPER register is used to specify the Ethertype field for frames carrying the PTP messages. In normal usage, set 0000 88F7h in this register.

The value is used in the Ethertype field when generating frames carrying PTP messages in the Ethernet II format. It is also used as a determining condition for received frames carrying PTP messages.

Set a value in these registers before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.67 PTP-primary Message Destination IP Address Setting Register (PPIPR)

The PPIPR register is used to specify the destination IP address for PTP messages. In normal usage, set E000 0181h (224.0.1.129) in this register.

The value is used in the destination IP address field when generating frames carrying PTP-primary messages in the IPv4 format. The lower-order 23 bits are also used in the destination MAC address field for Ethernet frames. The value is also used as a determining condition for received frames carrying PTP messages.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.68 PTP-pdelay Message Destination IP Address Setting Register (PDIPR)

Address(es): EPTPC0.PDIPR E820 5924h, EPTPC1.PDIPR E820 5D24h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 1 | 1 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | These bits hold the setting for the destination IP address for PTP-pdelay messages. | R/W |

The PDIPR register is used to specify the destination IP address for PTP-pdelay messages. In normal usage, set E000 006Bh (224.0.0.107) in this register.

The value is used in the destination IP address field when generating frames carrying PTP-pdelay messages in the IPv4 format. The lower-order 23 bits are also used in the destination MAC address field for Ethernet frames. The value is also used as a determining condition for received frames carrying PTP messages.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.69 PTP Event Message TOS Setting Register (PETOSR)

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|-----------|---|---|-----|
| b7 to b0 | EVTO[7:0] | PTP Event Message TOS Field Value Setting | These bits hold the setting for the value of the TOS field within the IPv4 headers of PTP event messages. | R/W |
| b31 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The PETOSR register is used to set the TOS (type of service) field value within the IPv4 headers of PTP event messages. Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.70 PTP general Message TOS Setting Register (PGTOSR)

Address(es): EPTPC0.PGTOSR E820 592Ch, EPTPC1.PGTOSR E820 5D2Ch

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|-----------|----|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | | | | | GETO[7:0] | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|-----------|---|---|-----|
| b7 to b0 | GETO[7:0] | PTP general Message TOS Field Value Setting | These bits hold the setting for the value of the TOS field within the IPv4 headers of PTP general messages. | R/W |
| b31 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The PGTOSR register is used to set the TOS (type of service) field value within the IPv4 headers of PTP general messages.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.71 PTP-primary Message TTL Setting Register (PPTTLR)

Address(es): EPTPC0.PPTTLR E820 5930h, EPTPC1.PPTTLR E820 5D30h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|-----------|----|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | | | | | PRTL[7:0] | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|-----------|---|---|-----|
| b7 to b0 | PRTL[7:0] | PTP-primary Message TTL Field Value Setting | These bits hold the setting for the value of the TTL field within the IPv4 headers of PTP-primary messages. | R/W |
| b31 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The PPTTLR register is used to set the TTL (time to live) field value within the IPv4 headers of PTP-primary messages. Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.72 PTP-pdelay Message TTL Setting Register (PDTTLR)

Address(es): EPTPC0.PDTTLR E820 5934h, EPTPC1.PDTTLR E820 5D34h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|-----------|------------------------------------|--|-----|
| b7 to b0 | PDTL[7:0] | PTP-pdelay Message TTL Field Value | These bits hold the setting for the value of the TTL field within the IPv4 headers of PTP-pdelay messages. | R/W |
| b31 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The PDTTLR register is used to set the TTL field value within the IPv4 headers of PTP-pdelay messages. Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.73 PTP Event Message UDP Destination Port Number Setting Register (PEUDPR)

Address(es): EPTPC0.PEUDPR E820 5938h, EPTPC1.PEUDPR E820 5D38h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------------|---|--|-----|
| b15 to b0 | EVUPT [15:0] | PTP Event Message Destination Port Number Setting | These bits hold the setting for the value of the destination port number field within the UDP headers of PTP event messages. | R/W |
| b31 to b16 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The PEUDPR register is used to set the destination port number field value within the UDP headers of PTP event messages. In normal usage, set 013Fh (319) in this register.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.74 PTP general Message UDP Destination Port Number Setting Register (PGUDPR)

Address(es): EPTPC0.PGUDPR E820 593Ch, EPTPC1.PGUDPR E820 5D3Ch

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------------|---|--|-----|
| b15 to b0 | GEUPT [15:0] | PTP general Message Destination Port Number | These bits hold the setting for the value of the destination port number field within the UDP headers of PTP general messages. | R/W |
| b31 to b16 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The PGUDPR register is used to set the destination port number field value within the UDP headers of PTP general messages. In normal usage, set 0140h (320) in this register.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.75 Frame Reception Filter Setting Register (FFLTR)

Address(es): EPTPC0.FFLTR E820 5940h, EPTPC1.FFLTR E820 5D40h

| b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|--------|
| — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | EXTPRM |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |

| b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|-----|-----|-----|
| — | — | — | — | — | — | — | — | — | — | — | — | — | ENB | PRT | SEL |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|--|--|-----|
| b0 | SEL | Receive MAC Address Select* ¹ | <p>This bit selects how filtering is handled when multicast frames other than PTP messages are received.</p> <p>b2 b0</p> <p>0 0 0: Filtering is disabled (all multicast frames are received).</p> <p>0 0 1: Filtering is disabled (all multicast frames are received).</p> <p>0 1 0: Filtering is disabled (all multicast frames are received).</p> <p>0 1 1: Filtering is disabled (all multicast frames are received).</p> <p>1 0 0: Do not receive multicast frames.</p> <p>1 0 1: Do not receive multicast frames.</p> <p>1 1 0: Only receive multicast frames matching the MAC address setting in registers FMAC0RU and FMAC0RL.</p> <p>1 1 1: Only receive multicast frames matching the MAC address setting in registers FMAC1RU and FMAC1RL).</p> | R/W |
| b1 | PRT | Frame Reception Enable* ¹ | | R/W |
| b2 | ENB | Reception Filter Enable* ¹ | | R/W |
| b15 to b3 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b16 | EXTPRM | Extended Promiscuous Mode Setting | <p>0: Normal operation (unicast frames addressed to the EPTPC are received, filtering of PTP frames is applied, multicast filtering is applied, and all broadcast frames are received).</p> <p>1: Extended promiscuous mode (all frames are received)</p> | R/W |
| b31 to b17 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note 1. The setting of these bits is only effective when the EXTPRM bit is 0.

The FFLTR register is used to switch extended promiscuous mode on or off and to select how filtering is handled when multicast frames other than PTP messages are received.

The filter for the reception of multicast frames other than PTP messages is enabled by setting the ENB, PRT, and SEL bits to 110b or 111b. Frames passed by the filter are then transferred by EDMACn.

Relaying of multicast frames other than PTP messages is in accord with the TRNMR register and relaying and reception of PTP messages is in accord with the setting of registers SYRFL1R and SYRFL2R.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.76 Frame Reception Filter MAC Address 0 Setting Registers (FMAC0RU, FMAC0RL)

Address(es): EPTPC0.FMAC0RU E820 5960h, EPTPC1.FMAC0RU E820 5D60h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|--|-----|
| b23 to b0 | — | — | These bits hold the setting for the higher-order 24 bits of the destination MAC address for received multicast frames. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Address(es): EPTPC0.FMAC0RL E820 5964h, EPTPC1.FMAC0RL E820 5D64h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|---|-----|
| b23 to b0 | — | — | These bits hold the setting for the lower-order 24 bits of the destination MAC address for received multicast frames. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Registers FMAC0RU and FMAC0RL are used to specify the MAC address for filtering in the reception of multicast frames other than PTP messages.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.77 Frame Reception Filter MAC Address 1 Setting Registers (FMAC1RU, FMAC1RL)

Address(es): EPTPC0.FMAC1RU E820 5968h, EPTPC1.FMAC1RU E820 5D68h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|--|-----|
| b23 to b0 | — | — | These bits hold the setting for the higher-order 24 bits of the destination MAC address for received multicast frames. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Address(es): EPTPC0.FMAC1RL E820 596Ch, EPTPC1.FMAC1RL E820 5D6Ch

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|---|-----|
| b23 to b0 | — | — | These bits hold the setting for the lower-order 24 bits of the destination MAC address for received multicast frames. | R/W |
| b31 to b24 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Registers FMAC1RU and FMAC1RL are used to specify the MAC address for filtering in the reception of multicast frames other than PTP messages.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.78 Asymmetric Delay Setting Registers (DASYMRU, DASYMRL)

Address(es): EPTPC0.DASYMRU E820 59C0h, EPTPC1.DASYMRU E820 5DC0h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|----------|--|-----|
| b15 to b0 | — | — | These bits hold the setting for the higher-order 16 bits of the asymmetric delay value. Set them to 0000h in this MCU. | R/W |
| b31 to b16 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Address(es): EPTPC0.DASYMRL E820 59C4h, EPTPC1.DASYMRL E820 5DC4h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|--|-----|
| b31 to b0 | — | — | These bits hold the setting for the lower-order 32 bits of the asymmetric delay value. Set them to 0000 0000h in this MCU. | R/W |

Registers DASYMRU and DASYMRL are used to set the asymmetric delay value (delayAsymmetry).

Set the registers DASYMRU and DASYMRL to 0000 0000h in this MCU.

28.2.79 Timestamp Latency Setting Register (TSLATR)

Address(es): EPTPC0.TSLATR E820 59C8h, EPTPC1.TSLATR E820 5DC8h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-------------|---------------------------------------|---|-----|
| b15 to b0 | EGP [15:0] | Output Port Timestamp Latency Setting | These bits hold the setting for the time stamp latency (ns) for the output ports. | R/W |
| b31 to b16 | INGP [15:0] | Input Port Timestamp Latency Setting | These bits hold the setting for the time stamp latency (ns) for the input ports. | R/W |

The TSLATR register is used to set the amount of latency in timestamp acquisition in nanoseconds. The value should not be modified while reception or transmission of PTP messages is enabled.

EGP[15:0] Bits (Output Port Timestamp Latency Setting)

Set the corresponding fixed value in Table 28.9. The timestamp latency differs with the link transfer rate (100 Mbps or 10 Mbps) and the frequency of the STCA clock (25 or 50 MHz).

Table 28.9 Settings of the EGP[15:0] Bits (ns)

| Link Transfer Rate | | STCA Clock Frequency | | |
|--------------------|----------|----------------------|--------|--------|
| | | 20 MHz | 25 MHz | 50 MHz |
| MII | 100 Mbps | 590 | 625 | 695 |
| | 10 Mbps | 7430 | 7465 | 7535 |
| RMII | 100 Mbps | 770 | 805 | 875 |
| | 10 Mbps | 9230 | 9265 | 9335 |

INGP[15:0] Bits (Input Port Timestamp Latency Setting)

Set the corresponding fixed value in Table 28.10. The timestamp latency differs with the link transfer rate (100 Mbps or 10 Mbps) and the frequency of the STCA clock (25 or 50 MHz).

Table 28.10 Settings of the INGP[15:0] Bits (ns)

| Link Transfer Rate | | STCA Clock Frequency | | |
|--------------------|----------|----------------------|--------|--------|
| | | 20 MHz | 25 MHz | 50 MHz |
| MII | 100 Mbps | 980 | 945 | 875 |
| | 10 Mbps | 8180 | 8145 | 8075 |
| RMII | 100 Mbps | 1060 | 1025 | 955 |
| | 10 Mbps | 8980 | 8945 | 8875 |

28.2.80 SYNFP Operation Setting Register (SYCONFR)

Address(es): EPTPC0.SYCONFR E820 59CCh, EPTPC1.SYCONFR E820 5DCCh

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-------|-----|-----|-----|--------|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | TCMOD | — | — | — | FILDIS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-------|-----|-----|----|----|-----------|----|----|----|----|----|----|----|--|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 | |
| | — | — | — | SBDIS | — | — | — | — | TCYC[7:0] | | | | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|--|---|-----|
| b7 to b0 | TCYC[7:0] | PTP Message Transmission Interval Setting | These bits are used to set the time from the completion of one transmission to the start of the next in cycles of the transmission clock. A value n in these bits means that a transmission interval of n cycles will be secured. No interval is secured if the setting is 00h. The recommended value is 28h (40 cycles). | R/W |
| b11 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b12 | SBDIS | Sync Message Transmission Bandwidth Securing Disable | 0: Securing of the bandwidth for the transmission of SYNC messages is enabled (transfer by the EDMAC is given lower priority). 1: Securing of the bandwidth for the transmission of SYNC messages is disabled (transfer by the EDMAC is given higher priority). | R/W |
| b15 to b13 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b16 | FILDIS | Receive Message domainNumber Filter Disable | 0: Filtering conditions for the reception of PTP messages include comparison with the domainNumber field. 1: Filtering conditions for the reception of PTP messages do not include comparison with the domainNumber field. | R/W |
| b19 to b17 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b20 | TCMOD | TC Mode Setting | 0: E2E TC 1: P2P TC | R/W |
| b31 to b21 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYCONFR register controls operation of the SYNFP module.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

TCYC[7:0] Bits (PTP Message Transmission Interval Setting)

The TCYC[7:0] bits are used to secure the waiting time between packets to keep a fixed transmission delay time. The setting defines the interval from input of the transmission completed signal from the ETHERC to output of the next transmission request as a number of cycles of the transmission clock (which runs at 2.5 MHz if the link transfer rate is 10 Mbps and at 25 MHz if the rate is 100 Mbps).

SBDIS Bit (Sync Message Transmission Bandwidth Securing Disable)

This bit disables securing of bandwidth to increase accuracy of the interval for the transmission of SYNC messages.

TCMOD Bit (TC Mode Setting)

This bit sets the delay mechanism for operation as a transparent clock (TC). The bit setting changes the method of calculating the values used in the correctionField field during operation as a TC.

28.2.81 SYNFP Frame Format Setting Register (SYFORMR)

Address(es): EPTPC0.SYFORMR E820 59D0h, EPTPC1.SYFORMR E820 5DD0h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|-------|-------|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | FORM1 | FORM0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|-------------------------------|--|-----|
| b0 | FORM0 | Ethernet Frame Format Setting | Set this bit to 0 (Ethernet II frame format). 0: Ethernet II frame format | R/W |
| b1 | FORM1 | Ethernet/UDP Encapsulation | 0: PTP directly over Ethernet 1: PTP over UDP/IPv4 | R/W |
| b31 to b2 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The SYFORMR register is used to set the format for frame generation by the SYNFP module.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

28.2.82 Response Message Reception Timeout Register (RSTOUTR)

| Bit | Symbol | Bit Name | Description | R/W |
|----------|--------|---|--|-----|
| 31 to b0 | — | Response Message Reception Timeout Time Setting | A response message not being received within $n \times 1024$ (ns), where n is the setting, is judged to represent a timeout. | R/W |

The RSTOUTR register is used to set the time for detection of a timeout in the reception of PTP response messages (Delay_Resp and Pdelay_Resp).

If a Delay_Resp or Pdelay_Resp message is not received within the time specified by this register after transmission of a Delay_Req or Pdelay_Req message, the SYSR.DRPTO flag becomes 1.

The value specified by this register is only reflected in the SYNFP module after the SYRVLDR.STUP bit is set to 1.

28.2.83 PTP Reset Register (PTRSTR)

Address(es): EPTPC.PTRSTR E820 4500h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|-------|

| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RESET |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------------------|--|-----|
| b0 | RESET | EPTPC Software Reset | 0: The EPTPC is not reset. 1: The EPTPC is reset.*1 | R/W |
| b31 to b1 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note 1. Do not access the EPTPC-related registers other than this register while a software reset is being issued.

The PTRSTR register is used to reset the EPTPC.

It takes 64 cycles of the peripheral module clock (B ϕ) until initialization of the EPTPC is completed. After the RESET bit is set to 1, wait for 64 cycles of the B ϕ before setting its value back to 0.

28.2.84 STCA Clock Select Register (STCSELR)

Address(es): EPTPC.STCSELR E820 4504h

| | | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|--------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|---|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 | |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | |
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 | |
| | — | — | — | — | — | SCLKSEL[2:0] | | — | — | — | — | — | — | — | — | — | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|------------------|-------------------|---|-----|
| b0 | — | Reserved | This bit is read as 0. The write value should be 0. | R |
| b2, b1 | — | Reserved | These bits are read as 1. The write value should be 1. | R |
| b7 to b3 | — | Reserved | These bits are read as 0. The write value should be 0. | R |
| b10 to b8 | SCLKSEL [2:0] | STCA Clock Select | b10 b8 0 1 0: Input clock from the REF50CK0 pin 0 1 1: Input clock from the REF50CK1 pin 1 0 0: Input clock from the ET0_RX_CLK pin / Input clock from the ET0_SCLKIN pin 1 0 1: Input clock from the ET1_RX_CLK pin / Input clock from the ET1_SCLKIN pin Settings other than above are prohibited. | R/W |
| b31 to b11 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

The STCSELR register selects the STCA clock signal for use in the EPTPC.

Set a value in this register before starting the EDMAC, ETHERC, or PTPEDMAC. Do not change the settings while the EPTPC is operating.

SCLKSEL[2:0] Bits (STCA Clock Select)

These bits select the STCA clock signal for use in the EPTPC.

Switching of ETn_RX_CLK/ETn_SCLKIN is selected with an Etn_EXOUT_SEL bit of section 51.3.36, Peripheral Pin Function Control Register (PMODEPFS). For details, refer to section 51, GPIO.

28.2.85 1588 Module Bypass Register (BYPASS)

Address(es): EPTPC.BYPASS E820 4508h

| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|---------|
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | BYPASS1 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |

| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | BYPASS0 |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|---------|--------------------------------------|---|-----|
| b0 | BYPASS0 | Ether 0ch 1588 module bypass setting | 0: Use the 1588 module of Ethernet channel 0. 1: Bypass the 1588 module of Ethernet channel 0. | R/W |
| b15 to b1 | — | Reserved | These bits are read as 0. The write value should be 0. | |
| b16 | BYPASS1 | Ether 1ch 1588 module bypass setting | 0: Use the 1588 module of Ethernet channel 1. 1: Bypass the 1588 module of Ethernet channel 1. | |
| b31 to b17 | — | Reserved | These bits are read as 0. The write value should be 0. | R |

Note: Do not access the bypass register while the Ethernet is operating. The 1588 module can be bypassed by setting the bypass register if EPTPC is not used.

28.3 Operation

The EPTPC is set not to receive (analyze) and transmit (generate) PTP messages after release from the reset state.

Accordingly, the EPTPC has no effect on the transmission and reception of frames by the ETHERC and EDMAC at that time.

Settings of the EPTPC registers are required for the ETHERC and EDMAC to be able to use packet filtering by MAC address in the SYNFP modules and for relaying between Ethernet ports by the PRC-TC module. That is, the transmission and reception of PTP messages requires setting of the EPTPC.

Figure 28.4 is a block diagram of the modules involved in transferring and relaying frames.

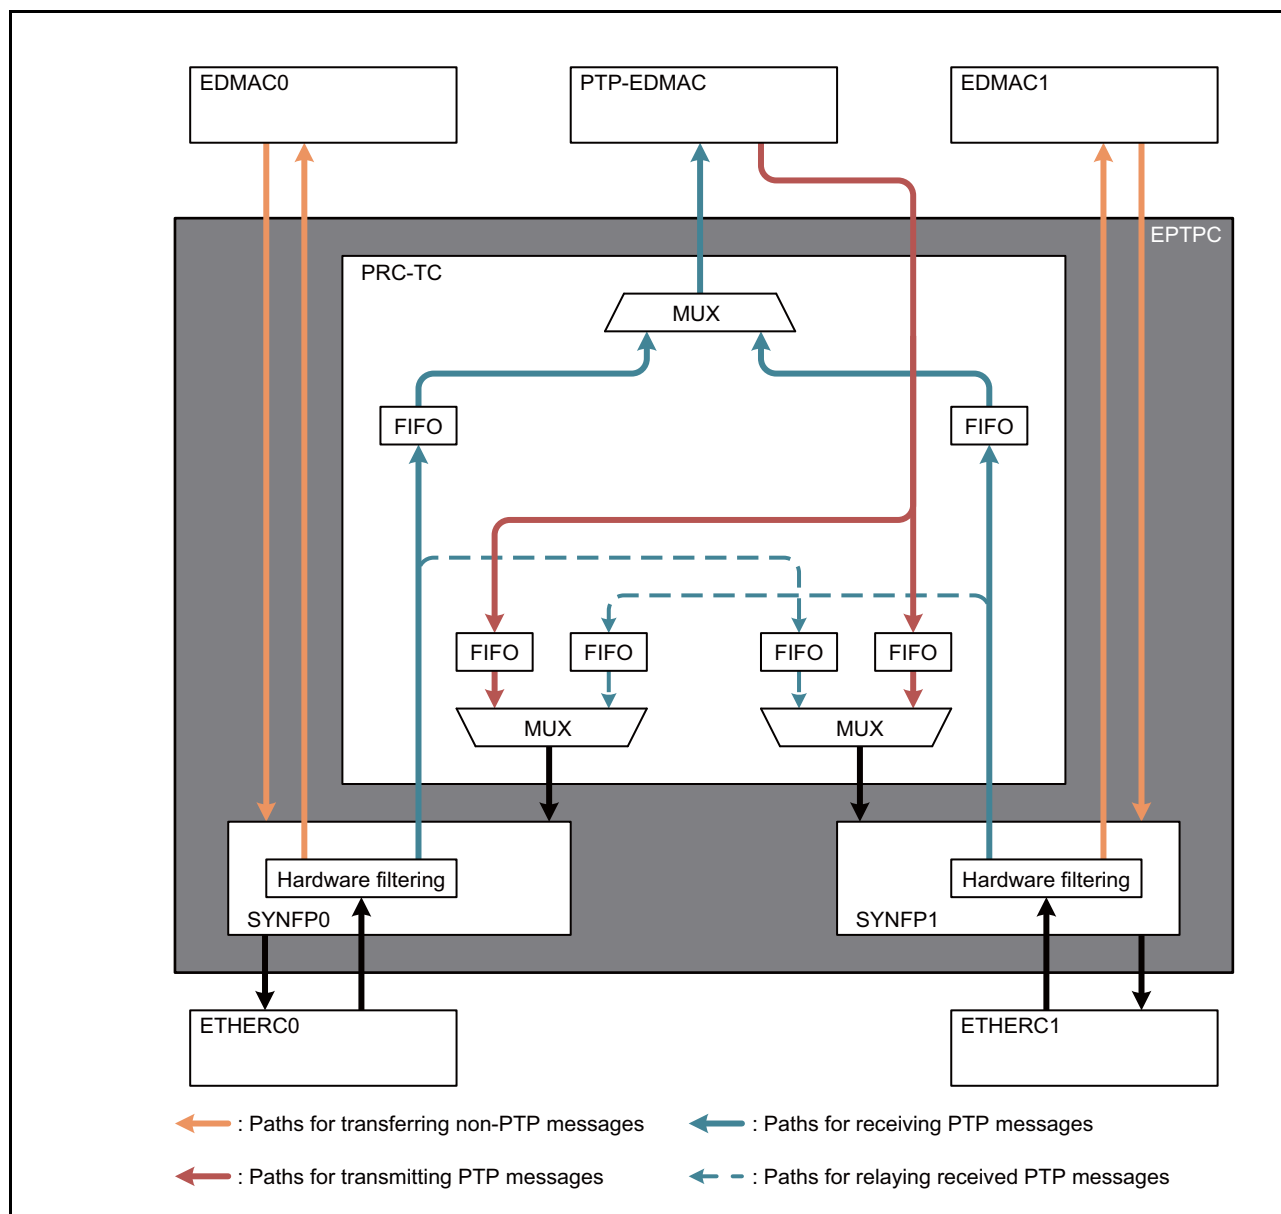

Figure 28.4 Block Diagram of the Modules Involved in Transferring and Relaying Frames

28.3.1 Transmission and Reception and Relaying of Non-PTP Messages

The EPTPC operates in extended promiscuous mode if the setting of the FFLTR.EXTPRM bit is 1 (extended promiscuous mode). In this mode, all frames received by the Ethernet ports are transferred to the EDMAC without filtering.

The EPTPC operates in normal mode if the setting of the FFLTR.EXTPRM bit is 0 (normal operation). In this mode, the SYNFP module applies its hardware filtering function to filter frames received by the Ethernet ports.

Frames for the other node can also be relayed to the Ethernet port on the other side in accord with the settings of the TRNMR.FWD0 and FWD1 bits.

The EPTPC and EDMAC transfer received unicast frames if they are for the given node. When a received frame is for the other node, the EPTPC is able to relay received frames to the other port if relaying between Ethernet ports is enabled. Operation when multicast frames are received can be selected from the following: frames are transferred to the EDMAC, frames are not transferred to the EDMAC, or frames are transferred to the EDMAC only when the address matches the specified MAC address. The EPTPC also relays multicast frames to the other Ethernet port if relaying between Ethernet ports is enabled.

The EPTPC transfers received broadcast frames to the EDMAC for the receiving Ethernet port. The EPTPC also relays broadcast frames to the other Ethernet port if relaying between Ethernet ports is enabled.

The PRC-TC module, which handles the relaying of frames received by one Ethernet port to the other Ethernet port, has a relaying FIFO buffer for use in this process. Either of two methods for reading out from the relaying FIFO is selectable: store and forward or cut-through. With the cut-through method, reading out from the relaying FIFO starts when it holds more than one frame or more data than a specified threshold value, or when both of these conditions are satisfied. The TRNCTTDR.THVAL[10:0] bits specify the threshold value for reading out from the relaying FIFO.

With the cut-through method, when a frame is handled as an error frame due to a fault (such as malformed data being read) after a read operation starts, there is no procedure for notifying the ETHERC module of the error. Accordingly, the ETHERC may send such error frames over the line as if they were normal frames. Avoid situations of this kind by using the store-and-forward method with the relaying FIFO. With the store-and-forward method, the PRC-TC module internally discards error frames.

28.3.2 Paths for the Transfer of Non-PTP Messages

Messages received through the Ethernet port are transferred to the EDMAC. The PRC-TC module is capable of relaying messages between the Ethernet ports.

Figure 28.5 is a diagram of paths for the transmission and reception and relaying of non-PTP messages.

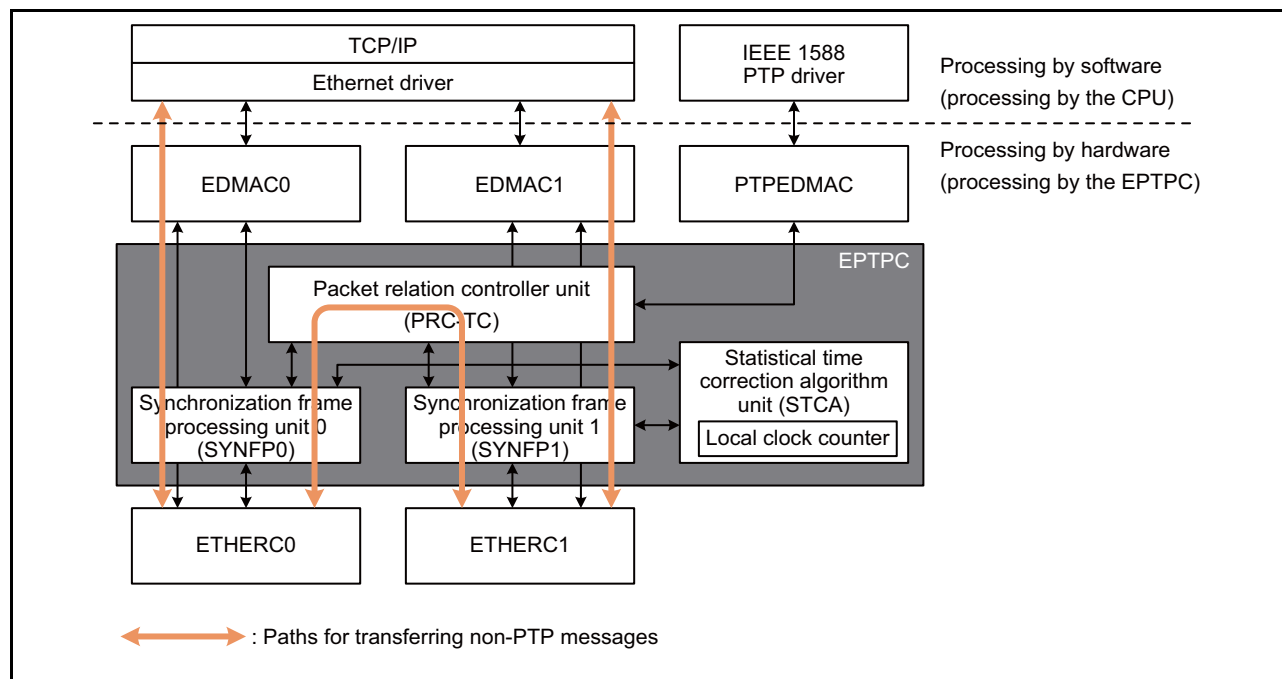

Figure 28.5 Paths for the Transmission and Reception and Relaying of Non-PTP Messages

28.3.3 Transmission and Reception and Relaying of PTP Messages

Hardware of the EPTPC automatically handles analysis of and the extraction of fields from received PTP messages, and generation and transmission of PTP messages. However, software must still handle the transmission of certain PTP messages. Table 28.11 shows the specifications for control over the transmission and reception of the various PTP messages.

Table 28.11 Control over the Transmission and Reception of PTP Messages

| Message Type | Message | OC (Ordinary Clock)/BC (Boundary Clock) | | TC (Transparent Clock) |
|--------------|-----------------------|---|---------------------------------------|--------------------------------------|
| | | Master | Slave | |
| Event | Sync | Generation (automatic) | Reception (automatic) | Relaying (automatic) |
| | Delay_Req | Generation (automatic) | Reception (automatic) | Relaying (automatic) |
| | Pdelay_Req | Generation and reception (automatic) | Generation and reception (automatic) | Generation and reception (automatic) |
| | Pdelay_Resp | Generation and reception (automatic) | Generation and reception (automatic) | Generation and reception (automatic) |
| General | Announce | Generation (automatic) | Reception (software) | Reception (software) |
| | Follow_Up | —*1 | Reception (automatic) | Relaying (automatic) |
| | Delay_Resp | Packet generation | Reception (automatic) | Relaying (automatic) |
| | Pdelay_Resp_Follow_Up | —*1 | Reception (automatic) | Relaying (automatic) |
| | Management | Transmission and reception (software) | Transmission and reception (software) | Relaying (automatic) |
| | Signaling | Transmission and reception (software) | Transmission and reception (software) | Relaying (automatic) |

Note 1. Control is not required as the clock in this case is a one-step clock.

28.3.4 Paths for the Transfer of PTP Messages

Paths for the transfer of PTP messages differ according to whether transfer requires processing by software or is automatically processed by hardware.

28.3.4.1 Paths for the Transfer of PTP Messages Requiring Processing by Software

Paths for the transfer of PTP messages where transfer requires processing by software are shown in Figure 28.6. The figure shows paths for message, clock-type, and process combinations for which “(software)” is indicated in Table 28.11.

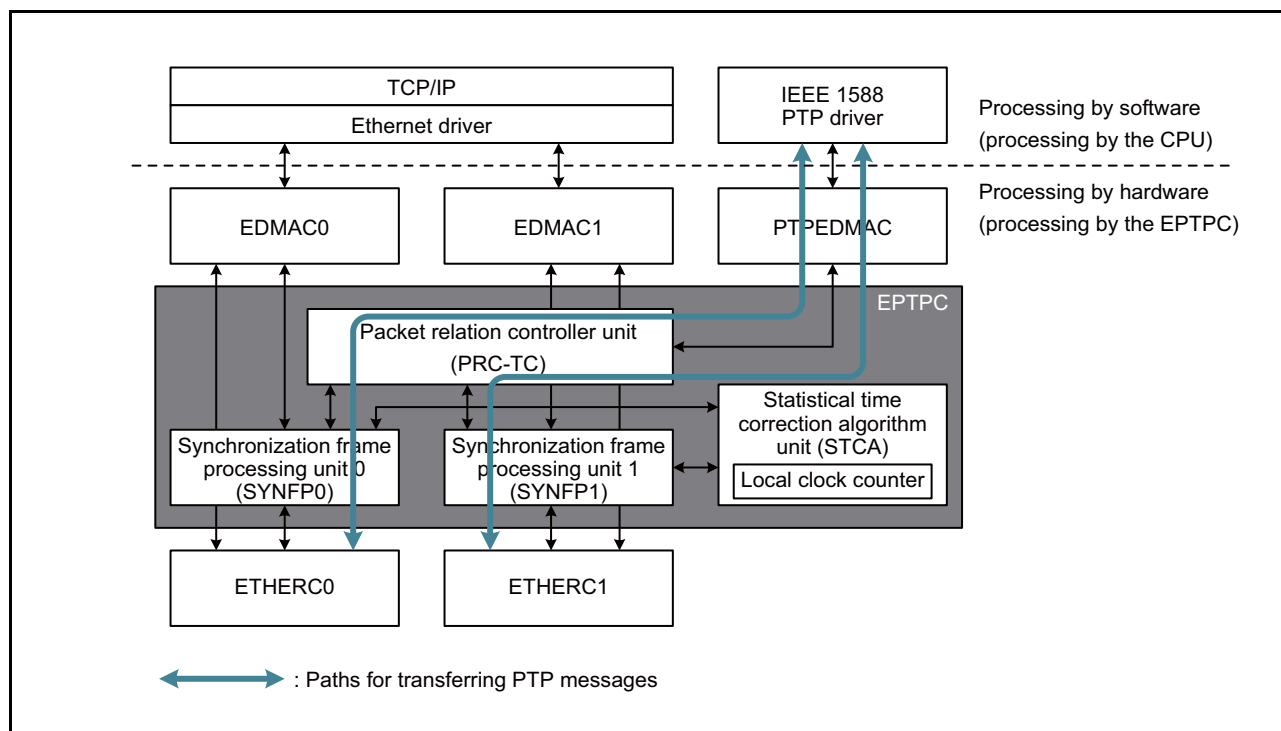

Figure 28.6 Paths for the Transfer of PTP Messages Requiring Processing by Software

28.3.4.2 Paths for the Transfer of PTP Messages Automatically Handled by Hardware

In the case of PTP messages for which hardware automatically handles the processing, the SYNFP modules handle transmission and reception, and the PRC-TC module handles relaying.

(1) Generation of and Response to PTP Messages by Hardware

Paths for transfer in the automatic generation of and response to PTP messages by the SYNFP modules are shown in Figure 28.7. The paths in the figure are used for operations “Generation (automatic)”, “Reception (automatic)”, and “Generation and reception (automatic)” indicated in Table 28.11.

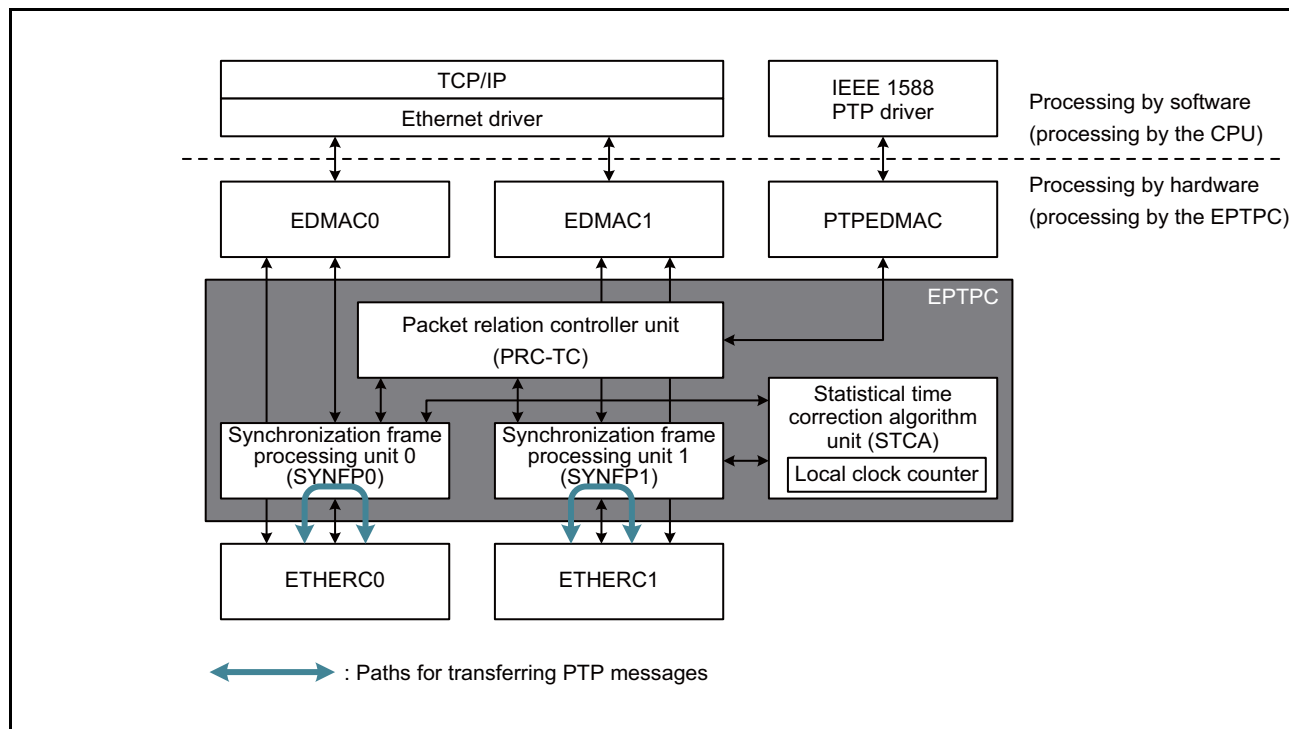

Figure 28.7 Paths for the Generation of and Response to PTP Messages by Hardware

(2) Relaying of PTP Messages by Hardware

Figure 28.8 shows paths for the relaying of PTP messages by the PRC-TC module. The paths in the figure are used for the “Relaying” operation indicated in Table 28.11.

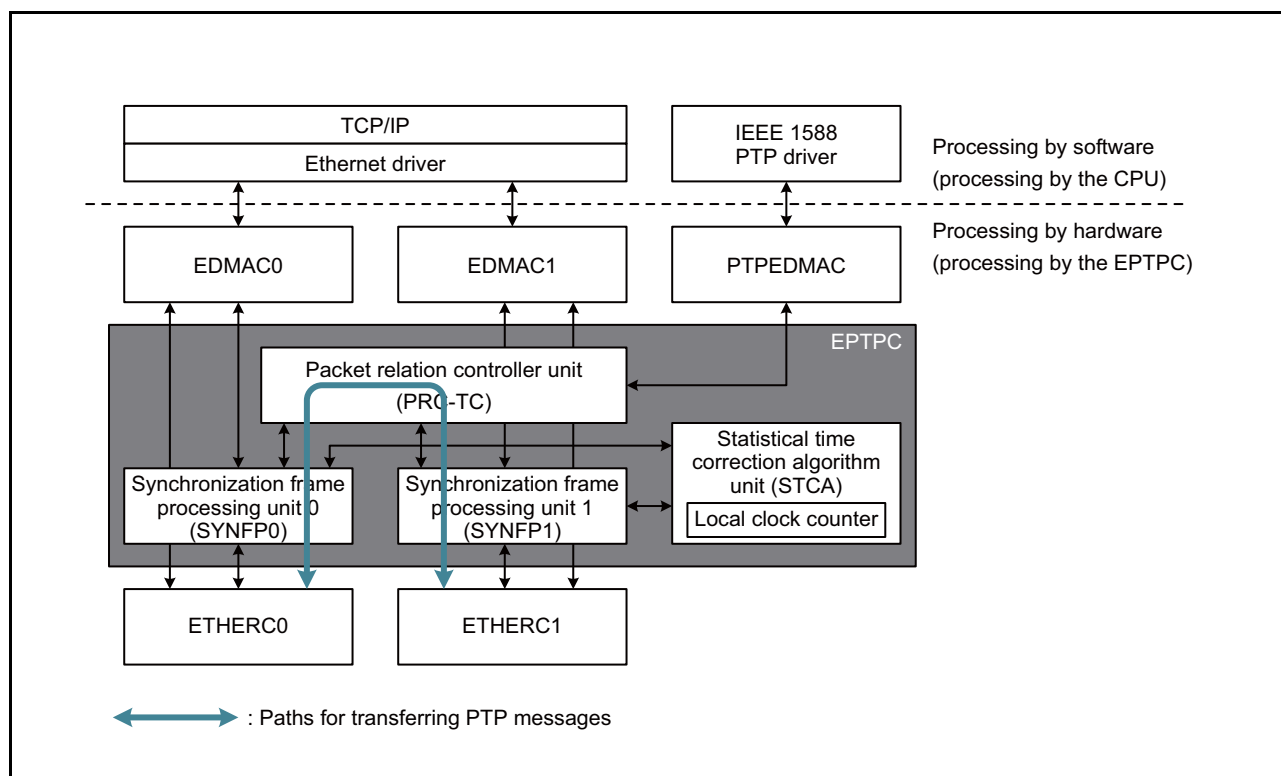

Figure 28.8 Paths for the Relaying of PTP Messages by Hardware

28.3.5 Clock Devices

The EPTPC can operate as the clock device defined in IEEE 1588.

28.3.5.1 End-to-End (E2E)

(1) Master

PTP messages are transmitted and received as listed below in operation as an end-to-end (E2E) master.

Table 28.12 List of PTP Message Processing (by an E2E Master)

| Message Type | Message | Details of Processing |
|--------------|-----------------------|---|
| Event | Sync | Sync messages are transmitted at the fixed interval specified by the SYTLIR.SYNC[7:0] bits. |
| | Delay_Req | When this message is received, a Delay_Resp message is transmitted in response. |
| | Pdelay_Req | — |
| | Pdelay_Resp | — |
| General | Announce | Announce messages are transmitted at the fixed interval specified by the SYTLIR.ANCE[7:0] bits. |
| | Follow_Up | — |
| | Delay_Resp | This is transmitted as the response to a received Delay_Req messages. |
| | Pdelay_Resp_Follow_Up | — |
| | Management | Management messages are transmitted and received by software via the PTPEDMAC. |
| | Signaling | Signaling messages are transmitted and received by software via the PTPEDMAC. |

(2) Slave

PTP messages are transmitted and received as listed below in operation as an E2E slave, and the calculated offsetFromMaster is used to correct the local time information.

Table 28.13 List of PTP Message Processing (by an E2E Slave)

| Message Type | Message | Details of Processing |
|--------------|-----------------------|--|
| Event | Sync | The offsetFromMaster value is calculated when this message is received if twoStepFlag in flagField was FALSE (one-step clock). |
| | Delay_Req | Delay_Req messages are transmitted at random intervals from 0 to the time specified by the SYTLIR.DREQ[7:0] bits × 2. |
| | Pdelay_Req | — |
| | Pdelay_Resp | — |
| General | Announce | Announce messages are transmitted by software via the PTPEDMAC. |
| | Follow_Up | The offsetFromMaster value is calculated when this message is received if twoStepFlag in flagField of the most recently received Sync message was TRUE (two-step clock). |
| | Delay_Resp | The meanPathDelay value is calculated when this message is received. |
| | Pdelay_Resp_Follow_Up | — |
| | Management | Management messages are transmitted and received by software via the PTPEDMAC. |
| | Signaling | Signaling messages are transmitted and received by software via the PTPEDMAC. |

28.3.5.2 Peer-to-Peer (P2P)

(1) Master

PTP messages are transmitted and received as listed below in operation as a peer-to-peer (P2P) master.

Table 28.14 List of PTP Message Processing (by a P2P Master)

| Message Type | Message | Details of Processing |
|--------------|-----------------------|---|
| Event | Sync | Timestamps for transmission are transmitted at the fixed interval specified by the SYTLIR.SYNC[7:0] bits. When this message is received, a Pdelay_Resp message is transmitted in response. |
| | Delay_Req | — |
| | Pdelay_Req | Pdelay_Req messages are transmitted at the fixed interval specified by the SYTLIR.DREQ[7:0] bits. |
| | Pdelay_Resp | This is transmitted as the response to a received Pdelay_Req messages. The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField was FALSE (one-step clock). |
| General | Announce | Announce messages are transmitted at the fixed interval specified by the SYTLIR.ANCE[7:0] bits. |
| | Follow_Up | — |
| | Delay_Resp | — |
| | Pdelay_Resp_Follow_Up | The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField of the most recently received Pdelay_Resp message was TRUE (two-step clock). |
| | Management | Management messages are transmitted by software via the PTPEDMAC. |
| | Signaling | Signaling messages are transmitted by software via the PTPEDMAC. |

(2) Slave

PTP messages are transmitted and received as listed below in operation as a P2P slave, and the calculated offsetFromMaster is used to correct the local time information.

Table 28.15 List of PTP Message Processing (by a P2P Slave)

| Message Type | Message | Details of Processing |
|--------------|-----------------------|---|
| Event | Sync | The offsetFromMaster value is calculated when this message is received if twoStepFlag in flagField was FALSE (one-step clock). |
| | Delay_Req | — |
| | Pdelay_Req | Pdelay_Req messages are transmitted at the fixed interval specified by the SYTLIR.DREQ[7:0] bits. When this message is received, a Pdelay_Resp message is transmitted in response. |
| | Pdelay_Resp | This is transmitted as the response to a received Pdelay_Req messages. The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField was FALSE (one-step clock). |
| General | Announce | Announce messages are transmitted by software via the PTPEDMAC. |
| | Follow_Up | The offsetFromMaster value is calculated when this message is received if twoStepFlag in flagField of the most recently received Sync message was TRUE (two-step clock). |
| | Delay_Resp | — |
| | Pdelay_Resp_Follow_Up | The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField of the most recently received Pdelay_Resp message was TRUE (two-step clock). |
| | Management | Management messages are transmitted and received by software via the PTPEDMAC. |
| | Signaling | Signaling messages are transmitted and received by software via the PTPEDMAC. |

28.3.5.3 Ordinary Clock (OC)

PTP messages are transmitted and received through one Ethernet port in operation as an ordinary clock.

An ordinary clock operates as the grand master clock or as a slave clock in the master-slave hierarchy.

For operation as an E2E master, E2E slave, P2P master, or P2P slave, see [section 28.3.7, Operation as an E2E Master](#), [section 28.3.8, Operation as an E2E Slave](#), [section 28.3.10, Operation as a P2P Master](#), and [section 28.3.11, Operation as a P2P Slave](#).

28.3.5.4 Boundary Clock (BC)

PTP messages are transmitted and received through both ports in operation as a boundary clock.

One port operates as a slave in synchronization with the root master clock and the other operates as the master that delivers time information synchronized with the master clock.

Both ports can also operate as masters.

For operation as an E2E master, E2E slave, P2P master, or P2P slave, see [section 28.3.7, Operation as an E2E Master](#), [section 28.3.8, Operation as an E2E Slave](#), [section 28.3.10, Operation as a P2P Master](#), and [section 28.3.11, Operation as a P2P Slave](#).

28.3.5.5 Transparent Clock (TC)

(1) E2E TC

In operation as an E2E transparent clock, received PTP-primary and PTP-pdelay messages are relayed.

Table 28.16 List of Packet Processing (by an E2E TC)

| Message Type | Message | Details of Processing |
|--------------|-----------------------|---|
| Event | Sync | The packet residence time in the clock device is added when these messages are relayed. |
| | Delay_Req | |
| | Pdelay_Req | |
| | Pdelay_Resp | |
| General | Announce | These messages are relayed. |
| | Follow_Up | |
| | Delay_Resp | |
| | Pdelay_Resp_Follow_Up | |
| | Management | These messages are relayed. |
| | Signaling | Messages are also transmitted and received by software via the PTPEDMAC. |

(2) P2P TC

In operation as a P2P transparent clock, PTP-primary messages other than Delay_Req and Delay_Resp are relayed.

Table 28.17 List of Packet Processing (by a P2P TC)

| Message Type | Message | Details of Processing |
|--------------|-----------------------|---|
| Event | Sync | The packet residence time in the clock device is added when this message is relayed. |
| | Delay_Req | — |
| | Pdelay_Req | Pdelay_Req messages are transmitted at the fixed interval specified by the SYTLIR.DREQ[7:0] bits. When this message is received, a Pdelay_Resp message is transmitted in response. |
| | Pdelay_Resp | This is transmitted as the response to a received Pdelay_Req messages. The meanPathDelay value is calculated when this message is received if twoStepFlag in flagField was FALSE (one-step clock). |
| General | Announce | These messages are relayed. |
| | Follow_Up | |
| | Delay_Resp | |
| | Pdelay_Resp_Follow_Up | |
| | Management | These messages are relayed. |
| | Signaling | Messages are also transmitted and received by software via the PTPEDMAC. |

28.3.6 EPTPC Initialization

Transmitting and receiving PTP messages requires settings in various registers of the EPTPC.

Table 28.18 is a list of the registers for which settings are required. Set the registers corresponding to the Ethernet port used. Also set the registers listed in Table 28.19 if the UDP and IPv4 are used for the frame format of the PTP messages.

Table 28.18 List of the Registers for which Settings are Required

| Register Name | Settings | Description |
|-----------------------|-----------------------------|---|
| STCFR | Example: 0000 0002h | The value for 50 MHz is given as an example. Three other settings are also available. |
| STCSELR | Example: 0000 0206h | The value for the input clock from the REF50CK0 pin is given as an example. |
| PRMACRU0, PRMACRL0 | As desired | This setting is not required if Ethernet port 0 is not used. |
| PRMACRU1, PRMACRL1 | As desired | This setting is not required if Ethernet port 1 is not used. |
| SYCONFR | Example: 0000 0028h | The setting differs with the type of PTP clock operation. |
| SYMACRU, SYMACRL | As desired | |
| SYSVRR | 0000 0002h | transportSpecific and version fields |
| SYDOMR | As desired | |
| SYCIDRU, SYCIDRL | As desired | Set the same value for Ethernet ports 0 and 1. |
| SYPNUMR | 0000 0001h or 0000 0002h | If the PTP clock operates as an OC, the setting is 0000 0001h. If it operates as a BC or TC, set 0000 0001h for one port and 0000 0002h for the other. |
| PPMACRU, PPMACRL | 01:1B:19:00:00:00 | MAC address for PTP-primary messages |
| PDMACRU, PDMACRL | 01:80:C2:00:00:0E | MAC address for PTP-pdelay messages |
| DASYMRU, DASYMRL | 0000 0000h | - |
| TSLATR | As desired | Depends on the link transfer rate and STCA clock frequency. |
| SYFORMR | As desired | Four settings are available. |
| SYLLCCTLR | 0000 0003h | LLC-CTL field value for Ethernet frames |
| PETYPER | 0000 88F7h | Ethertype for PTP messages |

Table 28.19 List of the Registers for which Settings are Required (Additional Settings Required when UDP or IPv4 is to be Used)

| Register Name | Settings | Description |
|---------------|------------|--|
| SYIPADDRR | As desired | Local IP address |
| PRIPR | E000 0181h | IP address for PTP-primary messages |
| PETOSR | As desired | Set the highest allowable traffic class selector codepoint as the value for the differentiated service (DS) field. |
| PGTOSR | As desired | |
| PPTTLR | As desired | TTL field value for PTP-primary messages |
| PEUDPR | 0000 013Fh | UDP port number for event messages |
| PGUDPR | 0000 0140h | UDP port number for general messages |
| PDIPR | E000 006Bh | IP address for PTP-pdelay messages |
| PDTTLR | 0000 0001h | TTL field value for PTP-pdelay messages |

In operation as an OC or BC, set registers as shown below in order to transfer received Announce, Management, and Signaling messages to the PTPEDMAC.

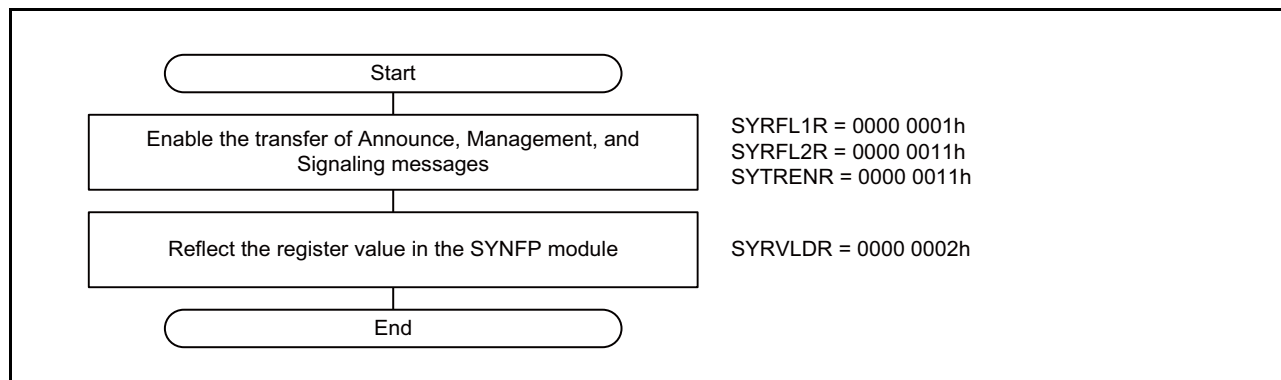

Figure 28.9 Common Settings for PTP Devices

28.3.7 Operation as an E2E Master

28.3.7.1 Preparatory Setting

Table 28.20 lists the registers for use in operation as an E2E master.

If the EPTPC operates as an OC or as a BC with both ports serving as masters, set the initial value of the time information in advance. Refer to section 28.2.17, Local Clock Counter Initial Value Registers (LCIVRU, LCIVRM, LCIVRL) for the initial value of the time information. Reflecting the values set in the registers requires setting the SYRVLDR.STUP or ANUP bit to 1.

Table 28.20 Registers for Use in Operation as an E2E Master

| Register Name | SYRVLDR Register Bits Used for Loading Direction | Settings | Description |
|---------------|--|------------------------|--|
| SYNFR | STUP | 0000 0000h | flagField for Sync messages |
| SYTLIR | STUP ANUP | Example: 0000 0001h | Delay_Resp: 1s Sync: 1s Announce: 2s |
| ANFR | ANUP | 0000 0000h | flagField for Announce messages |
| GMPR | ANUP | As desired | |
| GMCQR | ANUP | As desired | |
| GMIDR | ANUP | As desired | |
| CUOTSR | ANUP | As desired | timeSource: Internal Oscillator |
| SRR | ANUP | As desired | If the EPTPC operates as an OC or as a BC with both ports serving as masters, set this register to 0000 0000h. If the EPTPC operates as a BC in the combination of a slave and master, set this register to the StepsRemoved field value of Announce messages received by the slave plus one. |
| SYRFL1R | STUP | 0000 4001h | This enables the processing of Delay_Req messages by the SYNFP module. |
| SYRFL2R | STUP | 0000 0011h | This enables the transfer of Signaling and Management messages to the PTPEDMAC. |
| SYTRENr | STUP | 0000 0011h | This enables the transmission of Sync and Announce messages. |

28.3.7.2 Procedure for Starting Operations

Figure 28.10 shows the procedure for settings to start operation as an E2E master.

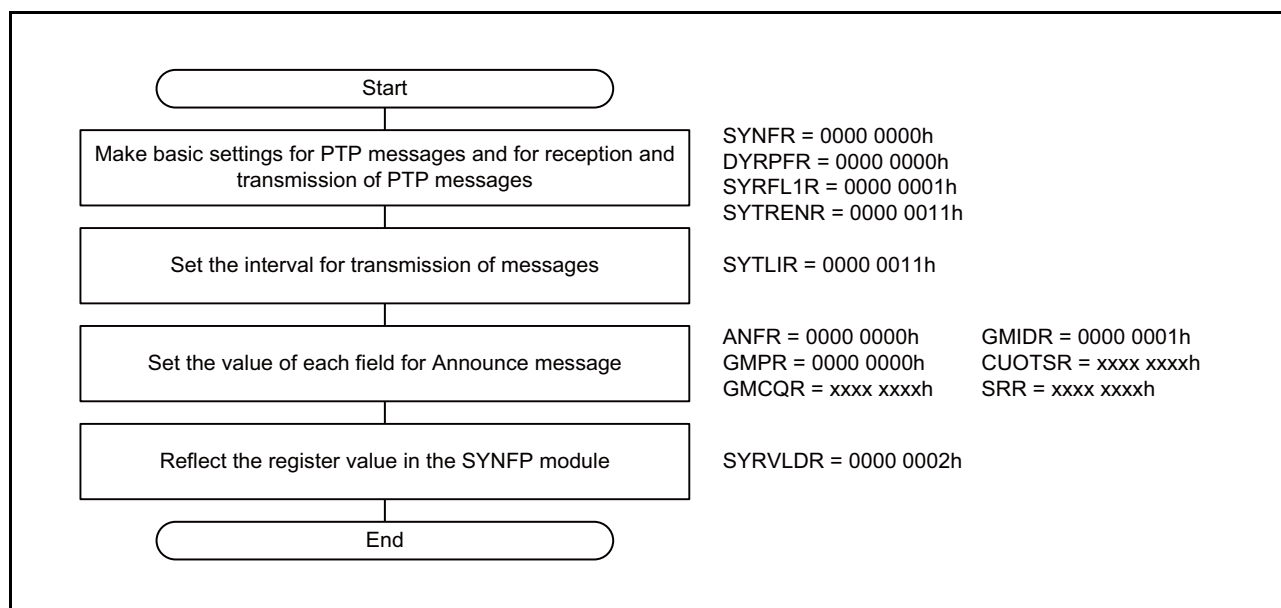

Figure 28.10 Procedure for Starting Operation as an E2E Master

28.3.7.3 Procedure for Changing the Settings

Increases in the frequency of receiving Delay_Req messages due to network conditions may lead to an overflow of the FIFO buffer which is receiving the Delay_Req messages. In such cases, change the value of the logMessageInterval field of Delay_Resp messages so that the slave sending the Delay_Req messages lengthens the interval between the messages. Figure 28.11 shows the procedure for changing the value of the logMessageInterval field.

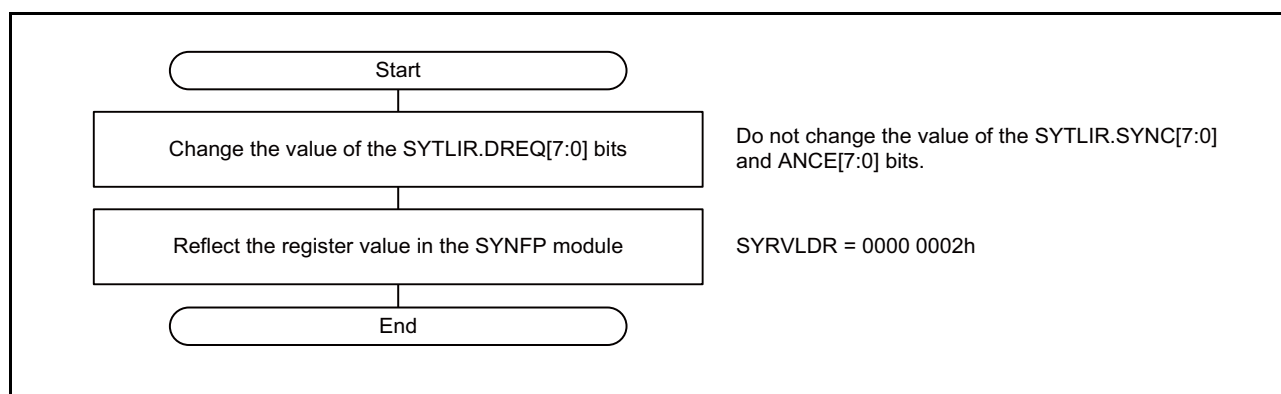

Figure 28.11 Procedure for Changing the Value of the logMessageInterval Field for Delay_Resp Messages

28.3.7.4 Procedure for Stopping Operations

Figure 28.12 shows the procedure for stopping operation as an E2E master. To confirm that the operation as the E2E master is completely stopped, read the SYSR.GENDN flag and RESDN flag to check that generating messages and sending responses are completely stopped.

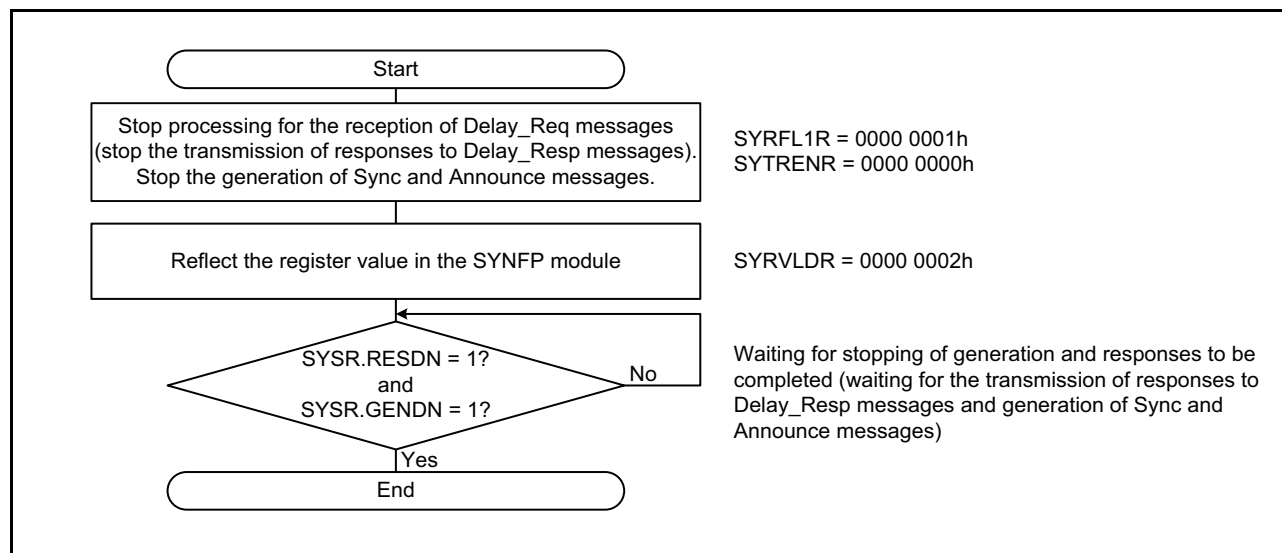

Figure 28.12 Procedure for Stopping Operation as an E2E Master

28.3.8 Operation as an E2E Slave

28.3.8.1 Preparatory Setting

Table 28.21 lists the registers for use in operation as an E2E slave.

Reflecting the value set in the register in SYNFP operations requires setting the SYRVLDR.STUP, ANUP, or BMUP bit to 1.

Table 28.21 Registers for Use in Operation as an E2E Slave

| Register Name | SYRVLDR Register Bits Used for Loading Direction | Settings | Description |
|---------------|--|------------------------|---|
| MTCID | BMUP | As desired | This is the clockIdentity value of the master clock that provides synchronization. |
| MTPID | BMUP | As desired | This is the portNumber value of the master clock that provides synchronization. |
| SYTLIR | ANUP BMUP | Example: 0000 0000h | Delay_Resp: 1 s ^{*1} |
| RSTOUTR | STUP | As desired | |
| SYNTOR | — | As desired | |
| SYRFL1R | STUP | 0004 0441h | This enables the reception of Delay_Resp, Follow_Up, and Sync messages and the transfer of Announce messages to the PTPEDMAC. |
| SYRFL2R | STUP | 0000 0011h | This enables the transfer of Signaling and Management messages to the PTPEDMAC. |
| SYTRENR | STUP | 0000 0100h | This enables the generation of Delay_Req messages. |

Note 1. In the reception of Delay_Resp messages by an E2E slave, the SYTLIR.DREQ[7:0] bits must be adjusted if the value of the SYRLIR.DRESP[7:0] flags is to be altered. The SYTLIR.DREQ[7:0] bits specify a value in the range from -7 to 6. Set the SYTLIR.DREQ[7:0] bits to -7 if the value indicated by the SYRLIR.DRESP[7:0] flags is less than or equal to -8 and to 6 if the value indicated by the SYRLIR.DRESP[7:0] flags is greater than or equal to 7.

28.3.8.2 Procedure for Starting Operations

Figure 28.13 shows the procedure for settings to start operation as an E2E slave.

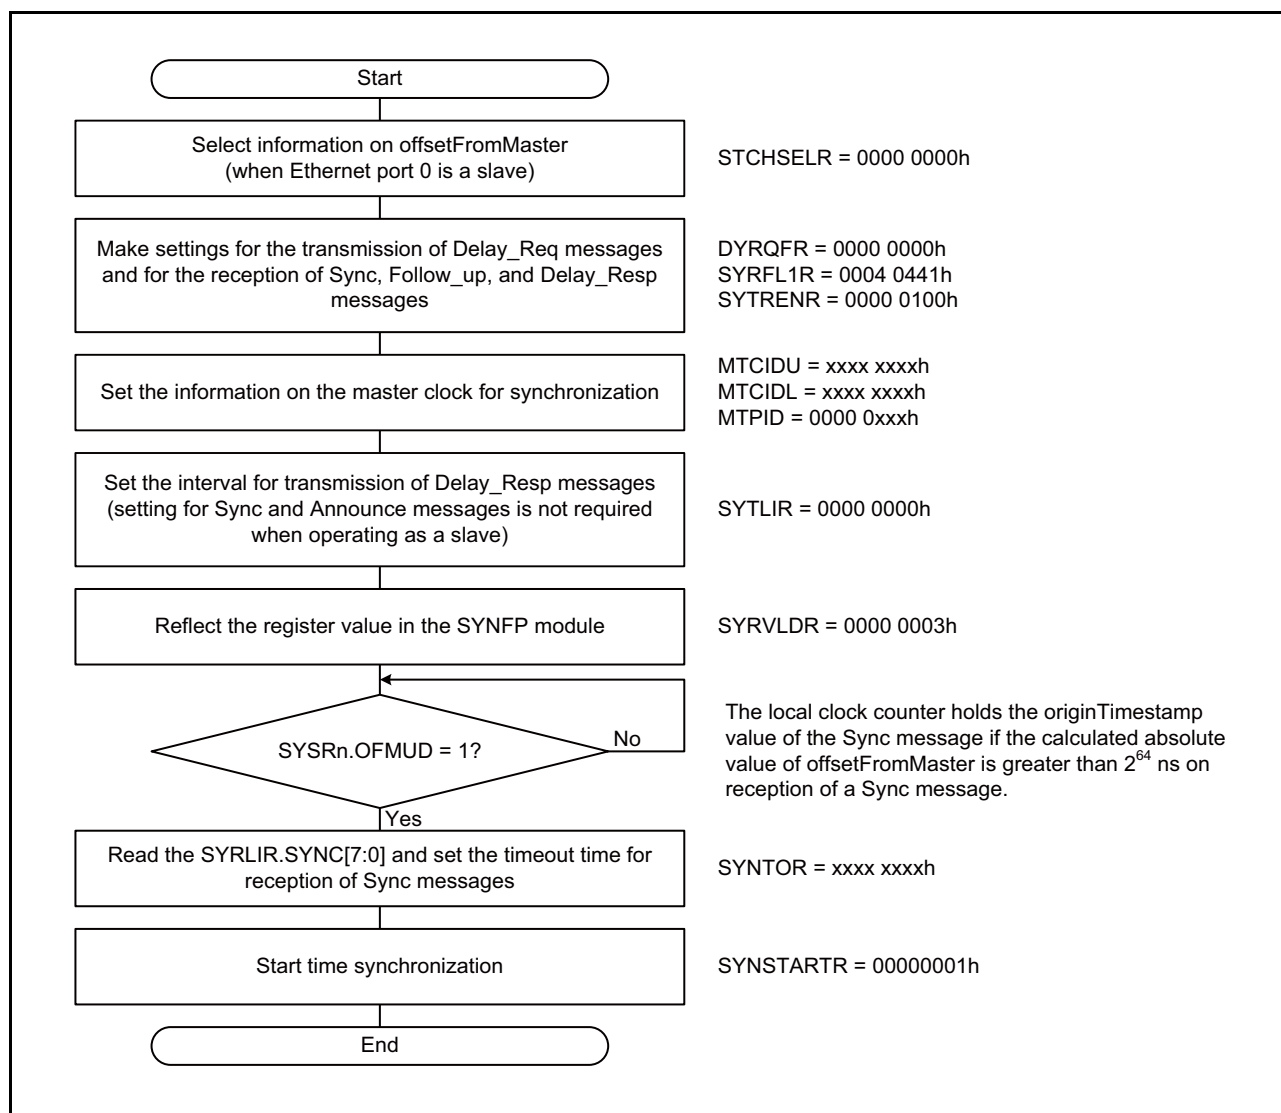

Figure 28.13 Procedure for Starting Operation as an E2E Slave

28.3.8.3 Procedure for Changing the Settings

IEEE 1588 stipulates that the average interval for the transmission of Delay_Req messages must be adjusted in response to changes in the value of the logMessageInterval field of received Delay_Resp messages. The EPTPC sets the SYSR.INTCHG flag to 1 if the logMessageInterval value of a received message differs from that of the previous message.

When this happens, set the SYTLIR.DREQ[7:0] bits to the value of the SYRLIR.DRESP[7:0] bits.

The SYTLIR.DREQ[7:0] bits specify a value in the range from -7 to 6. Set the SYTLIR.DREQ[7:0] bits to -7 if the value indicated by the SYRLIR.DRESP[7:0] flags is less than or equal to -8 and to 6 if the value indicated by the SYRLIR.DRESP[7:0] bits is greater than or equal to 7.

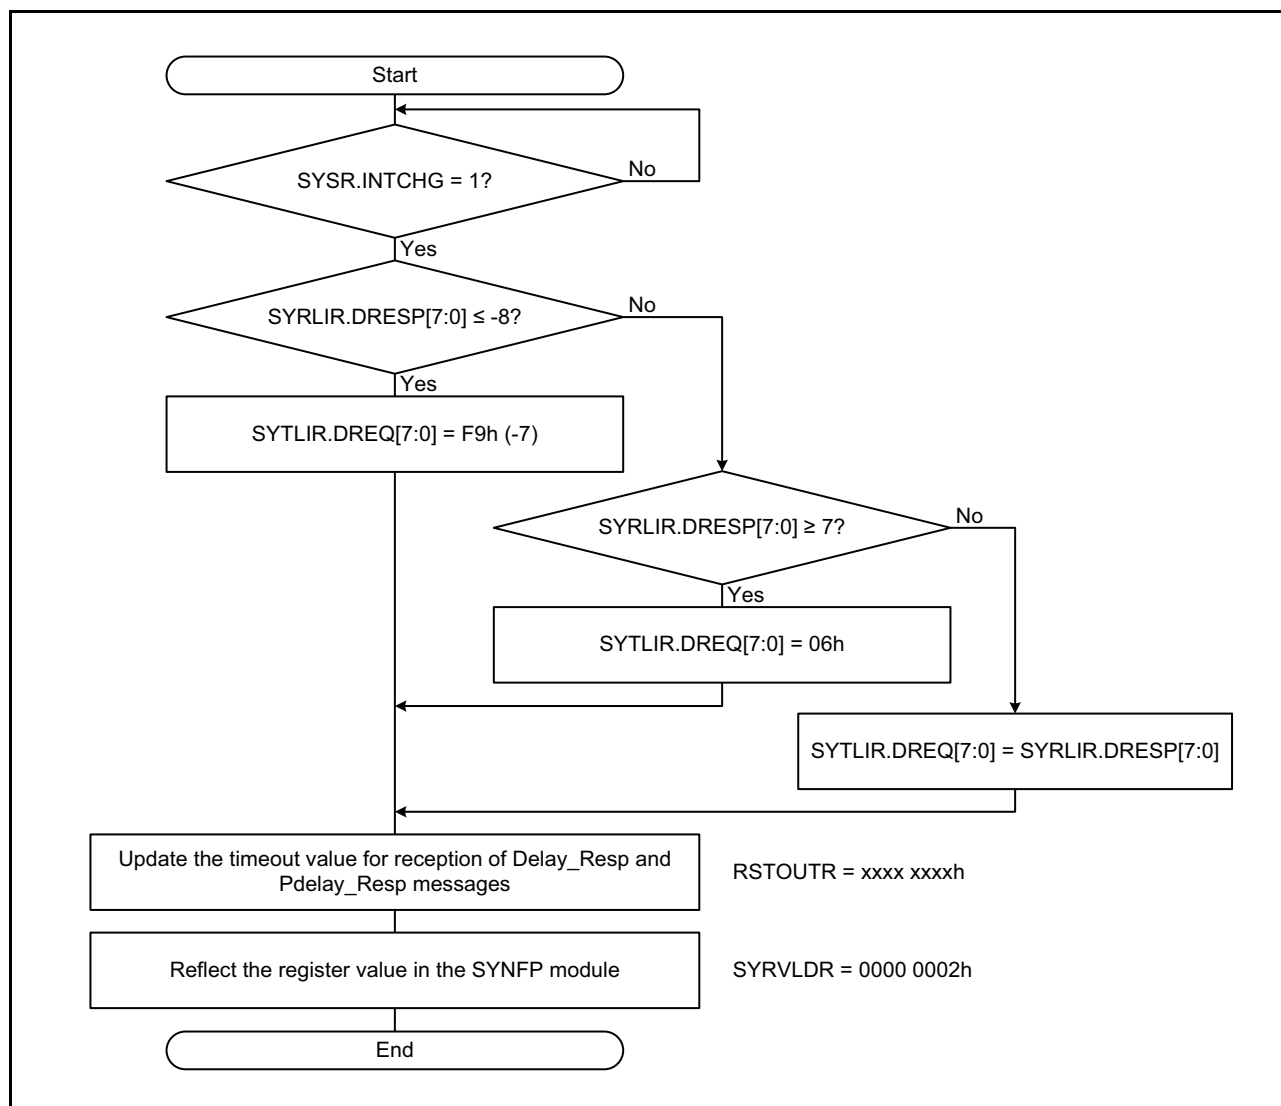

Figure 28.14 Procedure for Changing the Interval for Transmission of Delay_Req Messages

28.3.8.4 Procedure for Stopping Operations

Figure 28.15 shows the procedure for stopping operation as an E2E slave. To confirm that operation as an E2E slave is completely stopped, read the SYSR.GENDN flag to check that generation is completely stopped.

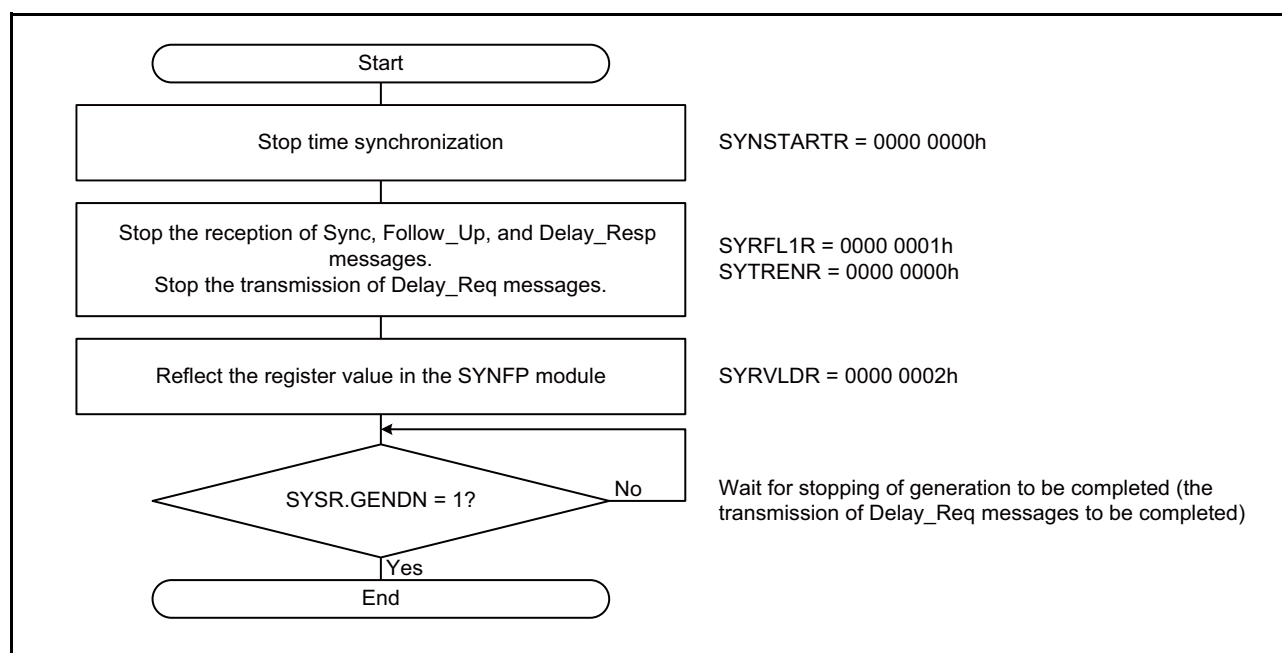

Figure 28.15 Procedure for Stopping Operation as an E2E Slave

28.3.9 P2P Operation (Common to Master and Slave)

If the EPTPC is to be operated as a P2P, the SYNFP module handles the processing of PTP-pdelay messages regardless of whether operation is to be as a master or slave. The interval for Pdelay_Req transmission and the parameters for monitoring of Pdelay_Resp messages must be set at the same time. Registers for use in operation as a P2P are listed in Table 28.22.

Table 28.22 Registers for Use in Operation as a P2P

| Register Name | SYRVLDR Register Bits Used for Loading Direction | Settings | Description |
|---------------|--|------------|--|
| MTCID | BMUP | As desired | This is the clockIdentity value of the synchronized master clock. |
| MTPID | BMUP | As desired | This is the portNumber value of the synchronized master clock. |
| SYTLIR | ANUP STUP | 0000 0000h | Announce: — Sync: — Pdelay_Req: 1 s |
| RSTOUTR | STUP | As desired | |
| SYRFL1R | STUP | 4440 0001h | This enables the reception of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages and the transfer of Announce messages to the PTPEDMAC. |
| SYRFL2R | STUP | 0000 0011h | This enables the transfer of Signaling and Management messages to the PTPEDMAC. |
| SYTRENR | STUP | 0000 1000h | This enables the generation of Pdelay_Req messages. |

28.3.9.1 Procedure for Starting Operations

Figure 28.16 shows the procedure for starting operation as a P2P (sending and receiving PTP-pdelay messages).

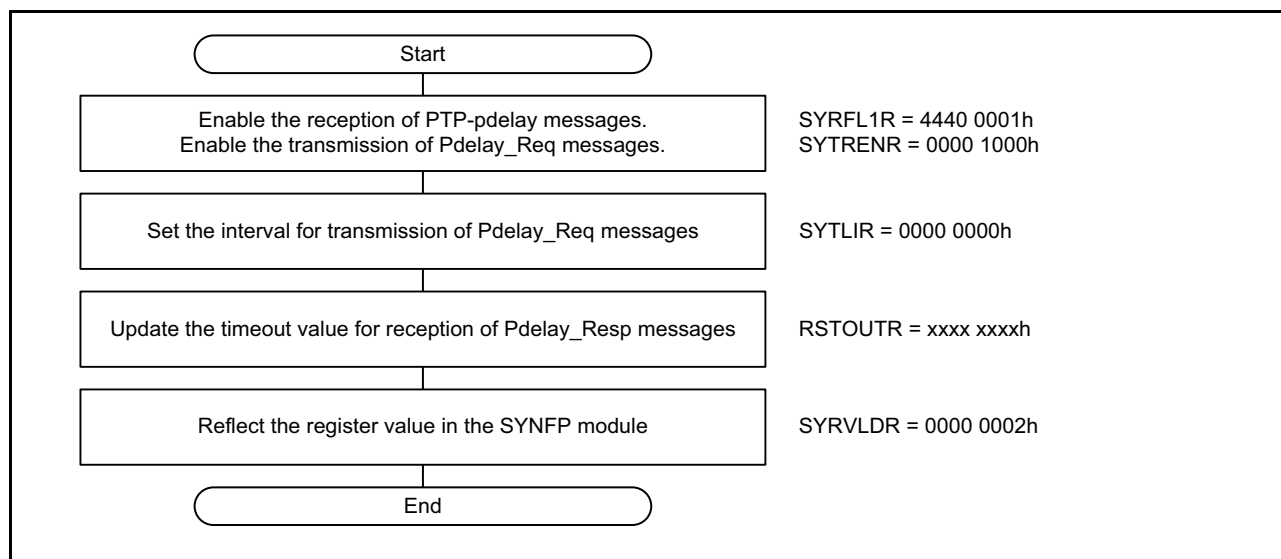

Figure 28.16 Procedure for Starting Operation as a P2P

28.3.9.2 Procedure for Stopping Operations

Figure 28.17 shows the procedure for stopping operation as a P2P (sending and receiving PTP-pdelay messages).

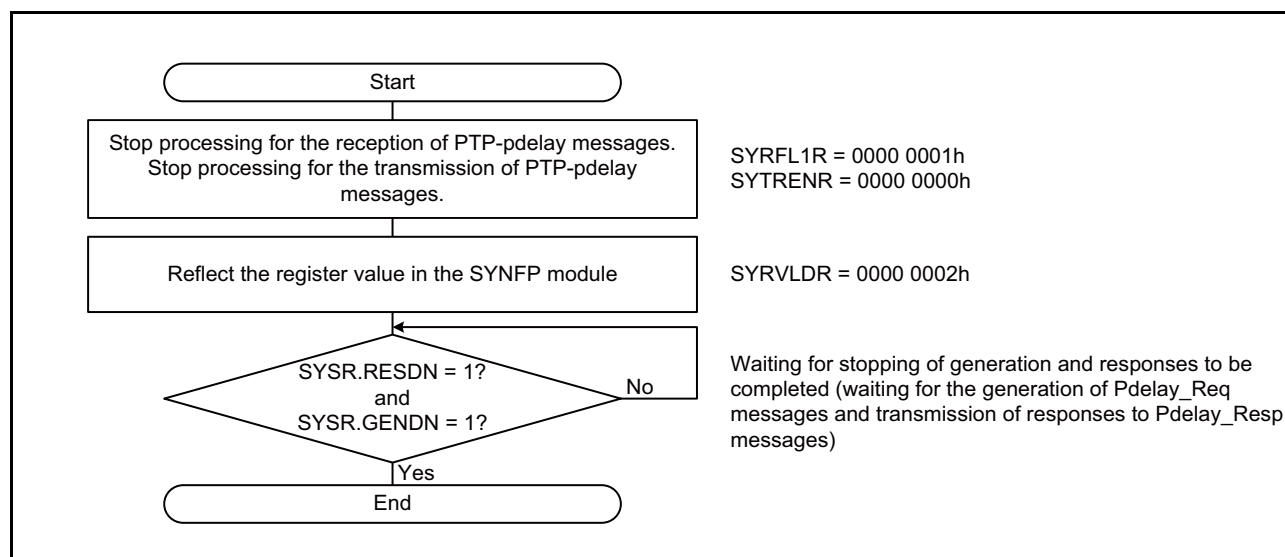

Figure 28.17 Procedure for Stopping Operation as a P2P

28.3.10 Operation as a P2P Master

When the EPTPC operates as OC or BC that uses both ports as the master, set the initial value of time information in advance as required. Refer to section 28.2.17, Local Clock Counter Initial Value Registers (LCIVRU, LCIVRM, LCIVRL) for the initial value of time information. Registers for use in operation as a P2P master are listed in Table 28.23.

Table 28.23 Registers for Use in Operation as a P2P Master

| Register Name | SYRVLDR Register Bits Used for Loading Direction | Settings | Description |
|---------------|--|------------------------|--|
| SYCONFR | — | 0000 0028h | |
| ANFR | ANUP | 0000 0000h | flagField for Announce messages |
| SYNFR | STUP | 0000 0000h | flagField for Sync messages |
| SYTLIR | ANUP STUP | Example: 0000 0001h | Announce: 2 s Sync: 1 s Pdelay_Req: 1 s |
| GMPR | ANUP | As desired | Grandmaster Priority1 and Priority2 |
| GMCQR | ANUP | As desired | Grandmaster Quality |
| GMIDR | ANUP | As desired | Grandmaster Identity |
| CUOTSR | ANUP | As desired | currentUtcOffset, timeSource |
| SRR | ANUP | As desired | StepsRemoved |
| RSTOUTR | STUP | As desired | |
| SYRFL1R | STUP | 4440 0000h | This enables the reception of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages. |
| SYRFL2R | STUP | 0000 0011h | This enables the transfer of Signaling and Management messages to the PTPEDMAC. |
| SYTRENr | STUP | 0000 1011h | This enables the transmission of Pdelay_Req, Sync, and Announce messages. |

28.3.10.1 Procedure for Starting Operations

When transmission of Sync and Announce messages is started during operation as a P2P (sending and receiving PTP-pdelay messages), the EPTPC operates as a P2P master. Figure 28.18 shows the procedure for starting operation as a P2P mas-ter.

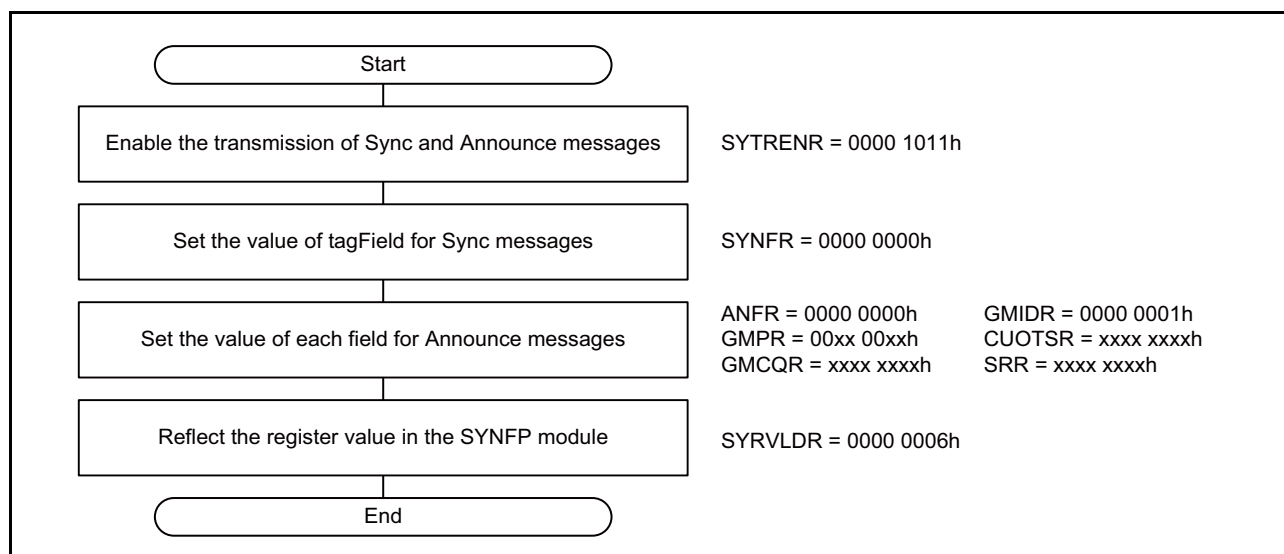

Figure 28.18 Procedure for Starting Operation as a P2P Master

28.3.10.2 Procedure for Stopping Operations

Figure 28.19 shows the procedure for stopping the transmission of Sync and Announce messages to stop operation as a P2P master.

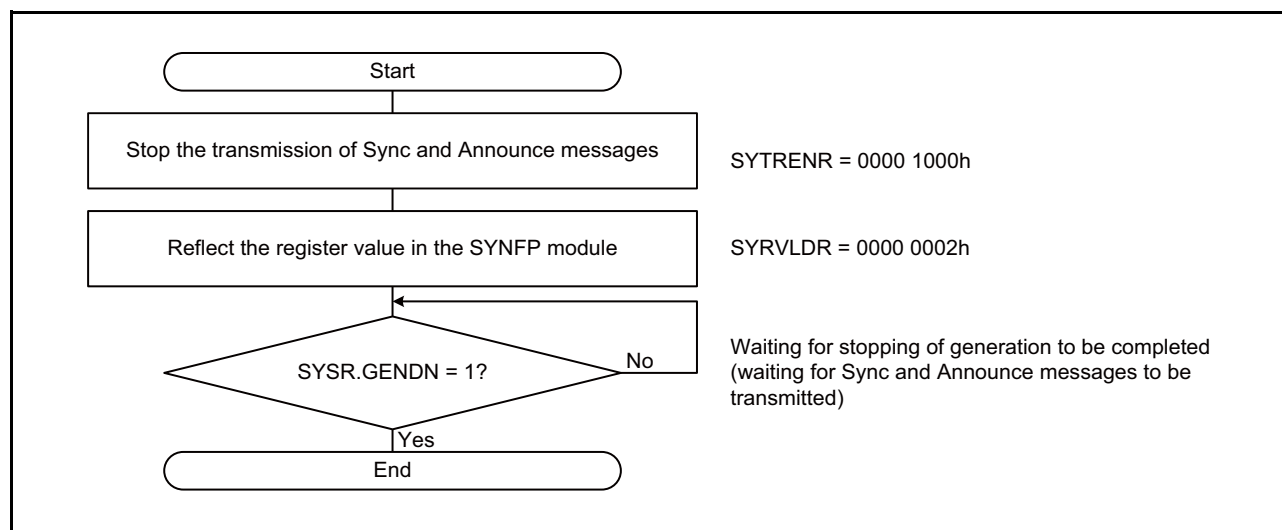

Figure 28.19 Procedure for Stopping Operation as a P2P Master

28.3.11 Operation as a P2P Slave

Setting a SYNFP module to receive Sync messages and Follow_Up messages during P2P operation obtains operation as a P2P slave. Information on the master clock for synchronization must be specified.

Table 28.24 lists the registers for use in operation as a P2P slave.

Table 28.24 Registers for Use in Operation as a P2P Slave

| Register Name | SYRVLDR Register Bits Used for Loading Direction | Settings | Description |
|---------------|--|------------|---|
| MTCID | BMUP | As desired | This is the clockIdentity value of the synchronized master clock. |
| MTPID | BMUP | As desired | This is the portNumber value of the synchronized master clock. |
| RSTOUTR | STUP | As desired | |
| SYRFL1R | STUP | 4440 0441h | This enables the reception of Pdelay_Req, Pdelay_Resp, Pdelay_Resp_Follow_Up, Follow_Up, and Sync messages and the transfer of Announce messages to the PTPEDMAC. |

28.3.11.1 Procedure for Starting Operations

Figure 28.20 shows the procedure for making the additional settings for shifting to operation as a slave during operation as a P2P (sending and receiving PTP-pdelay messages).

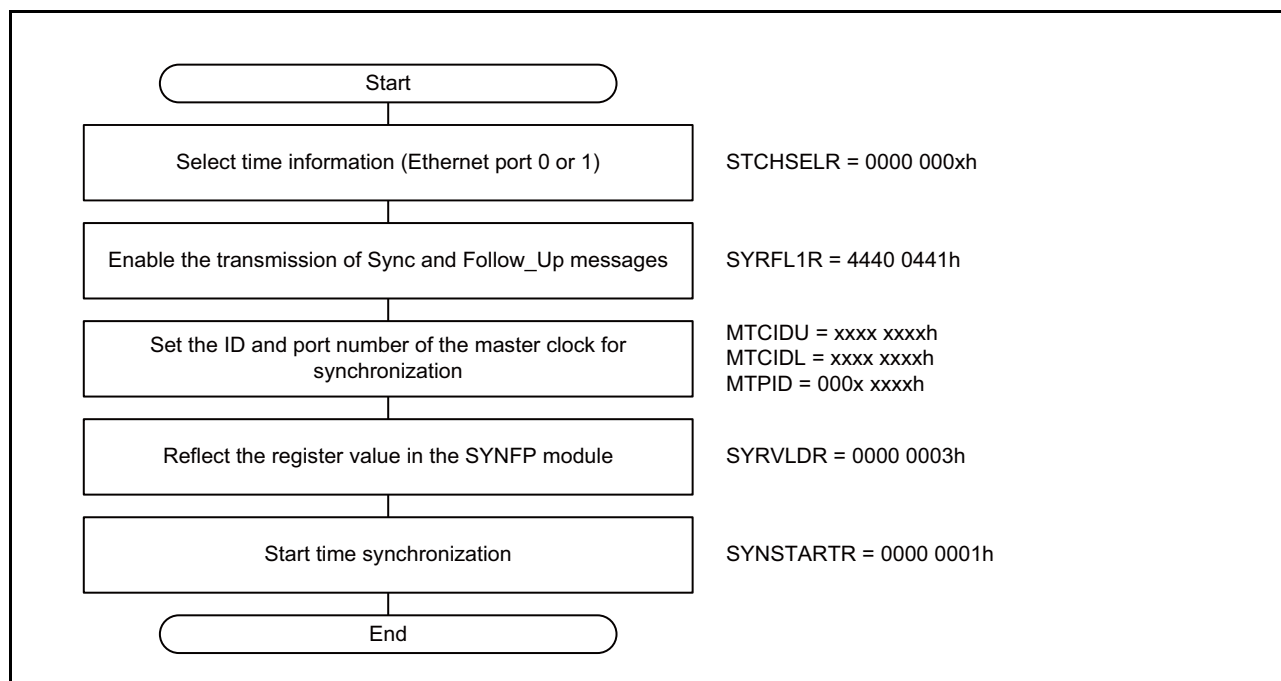

Figure 28.20 Procedure for Starting Operation as a P2P Slave

28.3.11.2 Procedure for Stopping Operations

Figure 28.21 shows the procedure for stopping the reception of Sync and Follow_Up messages to stop operation as a P2P slave.

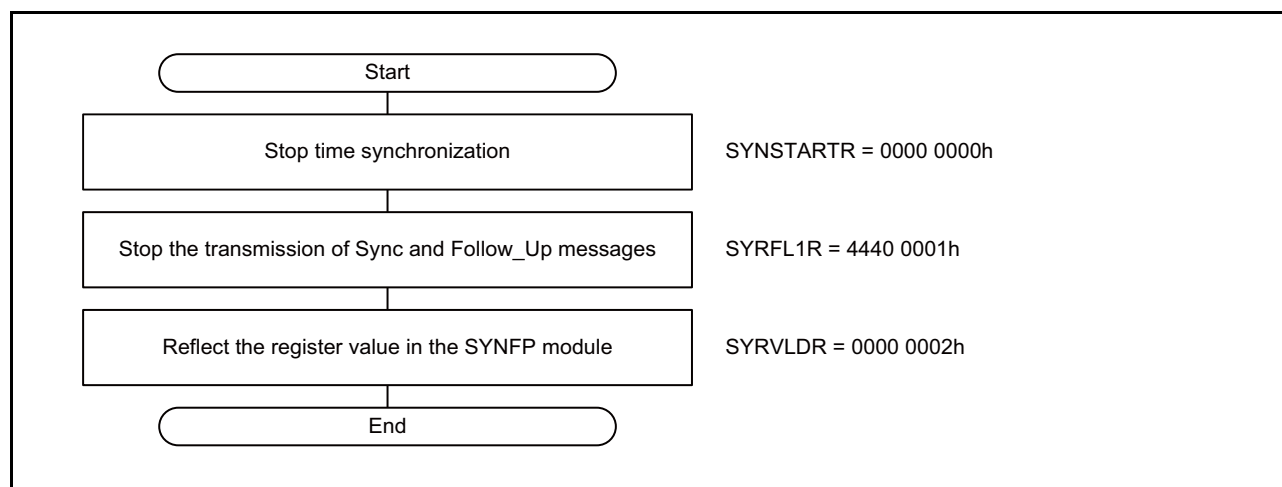

Figure 28.21 Procedure for Stopping Operation as a P2P Slave

28.3.12 Operation as an E2E TC

28.3.12.1 Preparatory Setting

Table 28.25 lists the registers for use in operation as an E2E TC.

Make the settings for both the SYNFP0 and SYNFP1 modules.

Table 28.25 Registers for Use in Operation as an E2E TC

| Register Name | SYRVLDR Register Bits Used for Loading Direction | Settings | Description |
|---------------|--|------------------------|--|
| SYCONFR | — | Example: 0000 0028h | Set the TCMOD bit to 0 as a preparatory setting for the PTP device. |
| SYRFL1R | STUP | 2222 2222h | This enables the relaying of messages by the PRC-TC. |
| SYRFL2R | STUP | 2000 0033h | This enables the transfer of Signaling and Management messages to the PTPEDMAC and the relaying of these messages by the PRC-TC. |
| SYTRENR | STUP | 0000 0000h | No generation of messages |

28.3.12.2 Procedure for Starting Operations

Figure 28.22 shows the procedure for starting operation as an E2E TC.

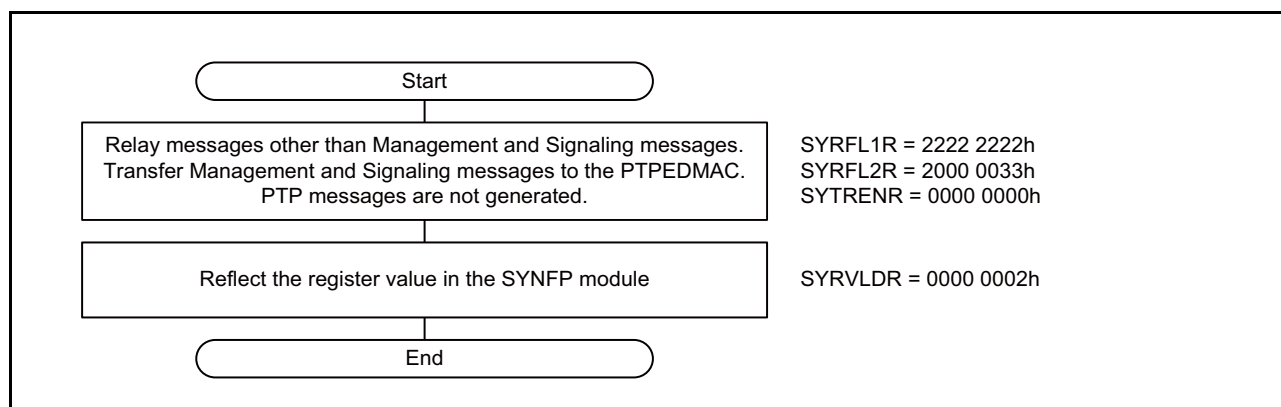

Figure 28.22 Procedure for Starting Operation as an E2E TC

28.3.13 Operation as a P2P TC

Table 28.26 lists the registers for use in operation a P2P TC.
Make the settings for both the SYNFP0 and SYNFP1 modules.

Table 28.26 Registers for Use in Operation as a P2P TC

| Register Name | SYRVLDR Register Bits Used for Loading Direction | Settings | Description |
|---------------|--|------------------------|--|
| SYCONFR | — | Example: 0010 0028h | Set the TCMOD bit to 1 as a preparatory setting for the PTP device. |
| RSTOUTR | STUP | As desired | |
| SYTLIR | STUP | Example: 0000 0000h | Pdelay_Req: 1 s |
| SYRFL1R | STUP | 4440 0222h | This enables the discarding of Delay_Req and Delay_Resp messages and the relaying of Sync, Follow_Up, and Announce messages by the PRC-TC. |
| SYRFL2R | STUP | 2000 0033h | This enables the transfer of Signaling and Management messages to the PTPEDMAC and the relaying of these messages by the PRC-TC |
| SYTRENR | STUP | 0000 1000h | This enables the generation of Pdelay_Req messages. |

28.3.13.1 Procedure for Starting Operations

Figure 28.23 shows the procedure for starting operation as a P2P TC.

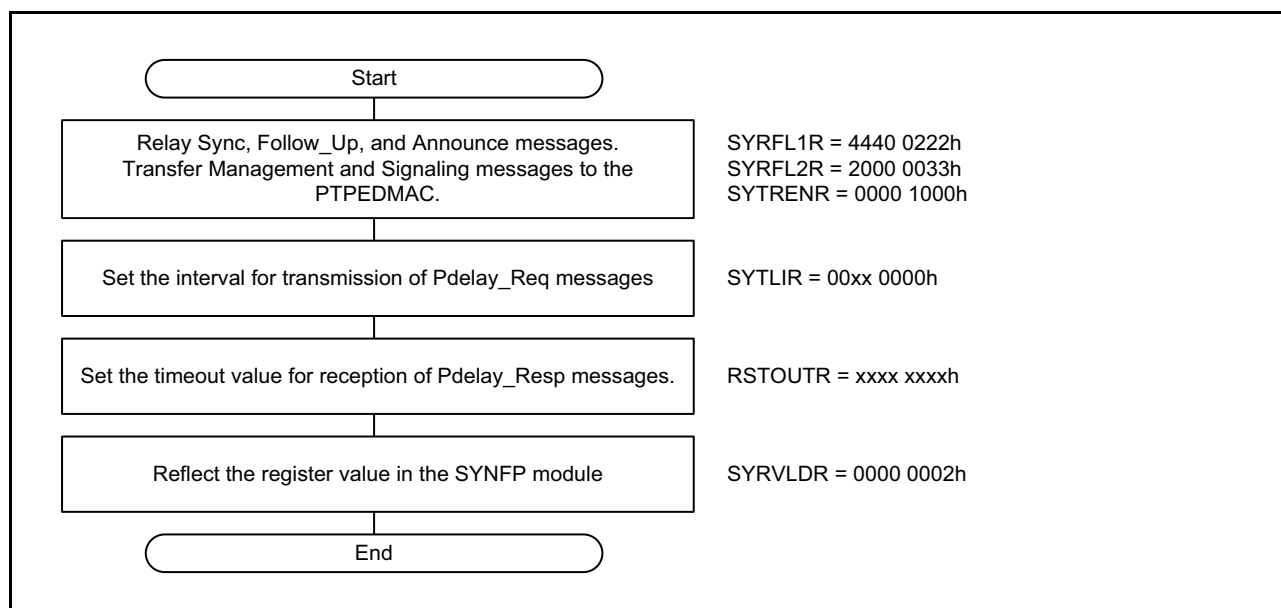

Figure 28.23 Procedure for Starting Operation as a P2P TC

28.3.14 Monitoring of Received Messages

28.3.14.1 Reception of Announce Messages

The EPTPC does not detect timeouts in the reception of Announce messages. To detect timeouts in the reception of these messages, monitor the reception of Announce messages by software.

28.3.14.2 Reception of Sync Messages

The STSR.SYNTOUT flag becomes 1 when a timeout in the reception of a Sync message occurs during the correction of time synchronization.

The SYSR.OFMUD flag becomes 1 when a Sync message is received, regardless of whether time synchronization is being corrected. Accordingly, the reception of Sync messages is detectable by reference to the SYSR.OFMUD flag even if the correction of time synchronization stops due to a timeout in the reception of a Sync message.

28.3.14.3 Reception of Delay_Resp and Pdelay_Resp Messages

The SYSR.DRPTO flag becomes 1 when a timeout in the reception of a Delay_Resp message occurs after the transmission of a Delay_Req message during operation as an E2E slave, or when a timeout in the reception of a Pdelay_Resp message occurs after the transmission of a Pdelay_Req message during operation as a P2P.

The SYSR.MPDUD flag becomes 1 when a Delay_Resp or Pdelay_Resp message is received, so the reception of these messages is still detectable in the case of a timeout in reception.

28.3.15 Correcting Time Synchronization

A slave detects differences in the clock gradient relative to the master clock. The `offsetFromMaster` values calculated by using the standard IEEE 1588 algorithm are used to calculate the clock gradient, so the result includes elements of network fluctuation besides frequency differences. The EPTPC has a “worst 10” function to eliminate fluctuations due to network load, etc. With these functions, the time is corrected from the calculated gradient difference values and results of correction are obtained as shown in Figure 28.25.

Figure 28.24 Configuration of the Time Correction Circuit

Figure 28.25 Overview of Time Correction

28.3.15.1 Judging Synchronization and Loss of Synchronization

The absolute value of `offsetFromMaster` reaching or exceeding the value specified in the `SYNTDARU` or `SYNTDARL` register is considered a loss of synchronization. The absolute value of `offsetFromMaster` being less than the absolute values of the synchronization detection threshold registers (`SYNTDBRU` and `SYNTDBRL`) is considered synchronization.

The values of the `STSR.SYNCOUT` and `SYNC` flags become 1 when synchronization is lost and obtained, respectively. Hysteresis can be obtained by setting the respective threshold registers to appropriate different values. Furthermore, the `STMR.DVTH[3:0]` and `SYTH[3:0]` bits can be used to set the consecutive number of times detection must occur for the judgment of loss of synchronization and of synchronization.

Set registers `SYNTDARU` and `SYNTDARL` to low values and the number of times detection is required to judge loss of synchronization to one in systems where control must be aborted if synchronization is lost due to fluctuations in network conditions. Set registers `SYNTDARU` and `SYNTDARL` and the number of times detection is required to large values in systems where the above condition does not apply.

Figure 28.26 shows an example of a situation where synchronization is being lost and regained. In this example, the number of consecutive times detection is required is three for both synchronization and loss of synchronization.

Note: The setting of the `STSR.SYNCOUT` flag is 1 when time synchronization starts, even though the condition for judging loss of synchronization has not been satisfied at this stage. For this reason, detection of loss of synchronization must be ignored immediately after time synchronization starts.

Figure 28.26 Example of a Situation where Synchronization is being Lost and Regained (the number of consecutive detection times is specified as three by the `STMR.DVTH[3:0]` and `SYTH[3:0]` bits)

28.3.15.2 Worst 10 Function

The worst 10 function is for imposing limits with regard to exceedingly large and small values among the calculated values for differences in clock gradient.

Values for difference in clock gradient are collected by observing the state of transfer over a specified interval and threshold values to impose limits are extracted from the observed values. With regard to differences in gradient, not only errors in the clock but also fluctuations in network conditions must be considered, and differences in both the positive and negative directions as shown in Figure 28.27 are collected

From among the collected values for positive and negative gradient difference, the largest values for gradient, from the first to the tenth place (worst to tenth worst), are acquired and the tenth worst is used as a threshold value. Fluctuations in the time kept by a slave clock can be suppressed by continually overwriting the tenth worst value for gradient difference with new values large enough to exceed the threshold. Furthermore, periodic collections of gradient values can also be made for updating the threshold values during operations or for the method of setting threshold values from previously measured results

However, note that while fluctuations in the time kept by a slave clock can be suppressed by the effective filtering of values for gradient difference (collecting the worst 10 values and using the tenth worst), following of the time kept by a master clock also becomes slower.

Figure 28.27 Overview of Gradient Differences

28.3.15.3 Collecting Differences in Clock Gradient and Extracting the Worst Ten Values

During slave operation, the EPTPC is capable of calculating the offsetFromMaster values from received messages and then calculating gradient differences between the local clock (acting as a slave clock) and master clock from those values. Specifically, the worst ten values are extracted from the sets of collected values for gradient difference. Either automatic filtering by the hardware or software-triggered filtering can be designated for acquisition of the sets of worst-10 values.

Figure 28.28 gives an overview of the collection of values for gradient difference.

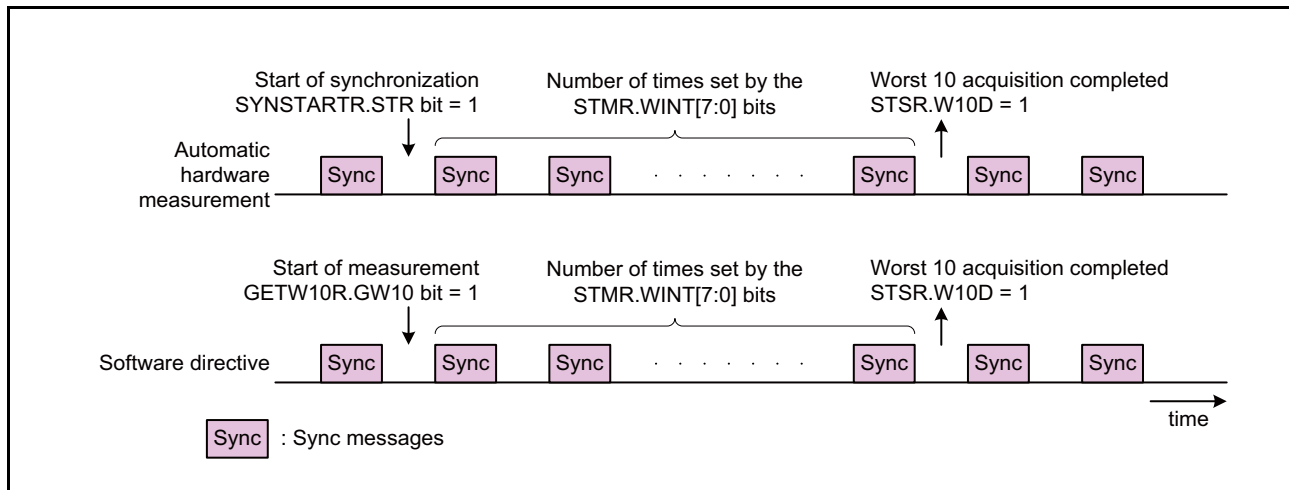

Figure 28.28 Overview of the Collection of Values for Gradient Differences

(1) Collecting Gradient Differences and Extracting the Worst Ten Values by Hardware

The EPTPC automatically collects the values of gradient difference by hardware if the STMR.W10S bit is 0.

When the SYNSTARTR.STR bit is set to 1 (starting slave time synchronization), the EPTPC collects gradient difference values for the number of times set by the STMR.WINT[7:0] bits. When the collection of gradient difference values is finished, the tenth largest values on the positive and negative gradient difference sides are stored as the tenth worst values in registers PW10VRU, PW10VRM, and PW10VRL and registers MW10RU, MW10RM, and MW10RL. When acquisition of the worst 10 values is complete, the STSR.W10D flag becomes 1.

Filtering of gradient difference values by using the stored tenth worst values then proceeds automatically.

Note that if the number of times set by STMR.WINT[7:0] bits are fewer than ten times, the double of the best of the collected values on the positive side is stored in registers PW10VRU, PW10VRM, and PW10VRL, and the half of the best of the collected values on the negative side is stored in registers MW10RU, MW10RM, and MW10RL.

(2) Collecting Gradient Differences and Extracting the Worst Ten Values by Software

The EPTPC collects values of gradient differences by software if the STMR.W10S bit is 1.

When the GETW10R.GW10 bit is set to 1 after time synchronization has started, the EPTPC collects gradient difference values for the number of times set by the STMR.WINT[7:0] bits. When the collection of gradient difference values is finished, the tenth largest values on the positive and negative gradient difference sides are stored as the tenth worst values in registers PW10VRU, PW10VRM, and PW10VRL and registers MW10RU, MW10RM, and MW10RL. When acquisition of the worst 10 values is complete, the STSR.W10D flag becomes 1.

Since filtering of gradient difference values proceeds with the values set in registers PLIMITRU, PLIMITRM, and PLIMITRL and registers MLIMITRU, MLIMITRM, and MLIMITRL as the upper and lower limits for filtering, the values stored in registers PW10VRU, PW10VRM, and PW10VRL and registers MW10RU, MW10RM, and MW10RL must be written to the PLIMITRU, PLIMITRM, and PLIMITRL and registers MLIMITRU, MLIMITRM, and MLIMITRL, respectively.

Note that if the number of times set by the STMR.WINT[7:0] bits is fewer than ten or times, the double of the best of the collected values on the positive is stored in registers PW10VRU, PW10VRM, and PW10VRL, and the half of the best of the collected values on the negative side is stored in registers MW10RU, MW10RM, and MW10RL.

The flowchart in Figure 28.29 shows an example of the procedure for software-triggered acquisition of the worst 10 values.

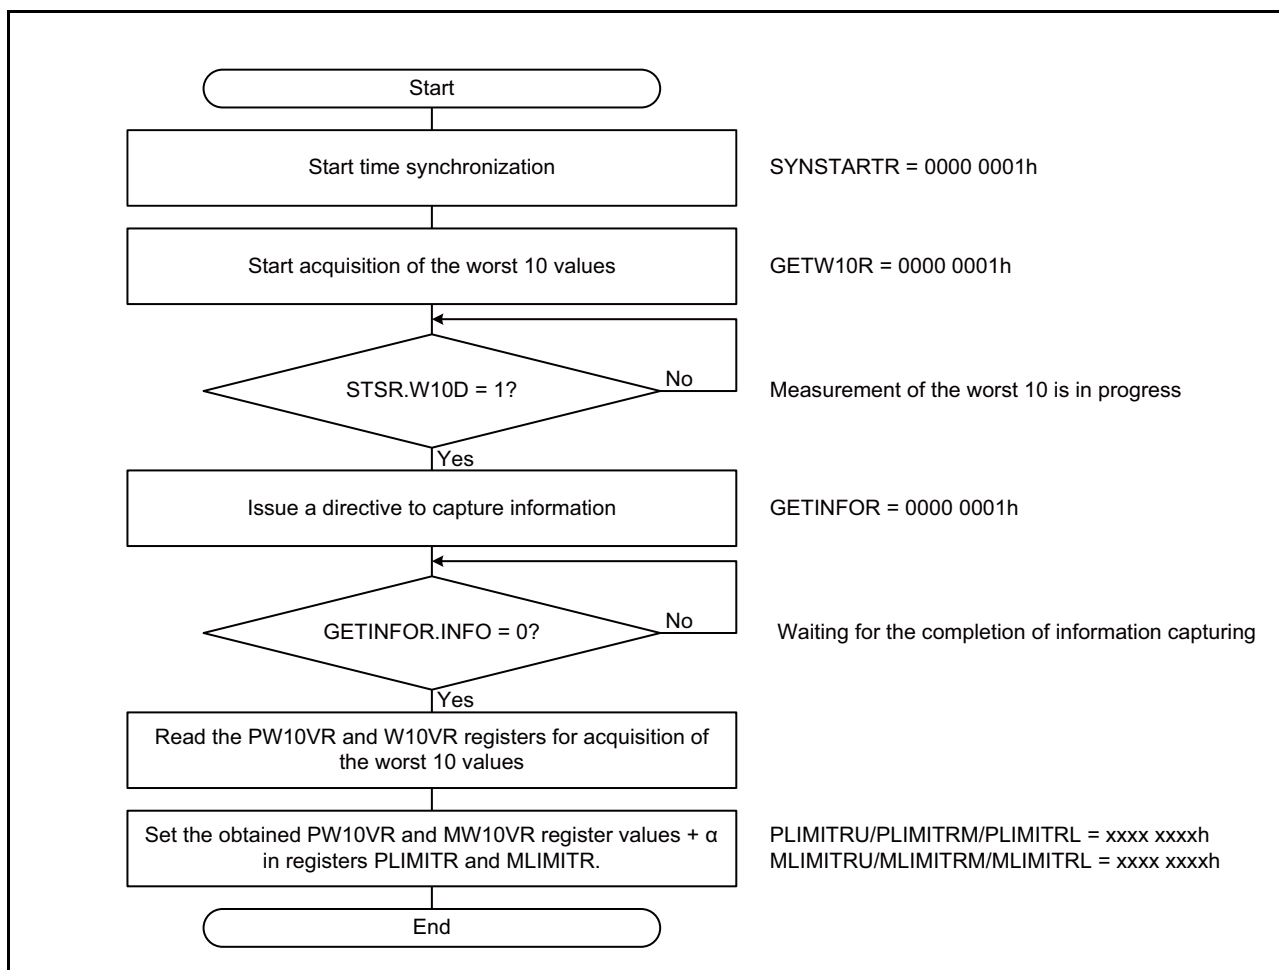

Figure 28.29 Example of the Procedure for Software-Triggered Acquisition of the Worst 10 Values

28.3.16 Local Clock Counter

The local clock counter retains the synchronized time information. The counter starts counting from 0 after the ETHERC is released from the module stop state or the EPTPC is released from the software reset state. The local clock counter can then be set to any desired value. The procedure for setting the initial value in the local clock counter is shown in Figure 28.30.

The time information kept by the local clock counter is also readable. Figure 28.31 shows the procedure for reading the time information kept by the local clock counter.

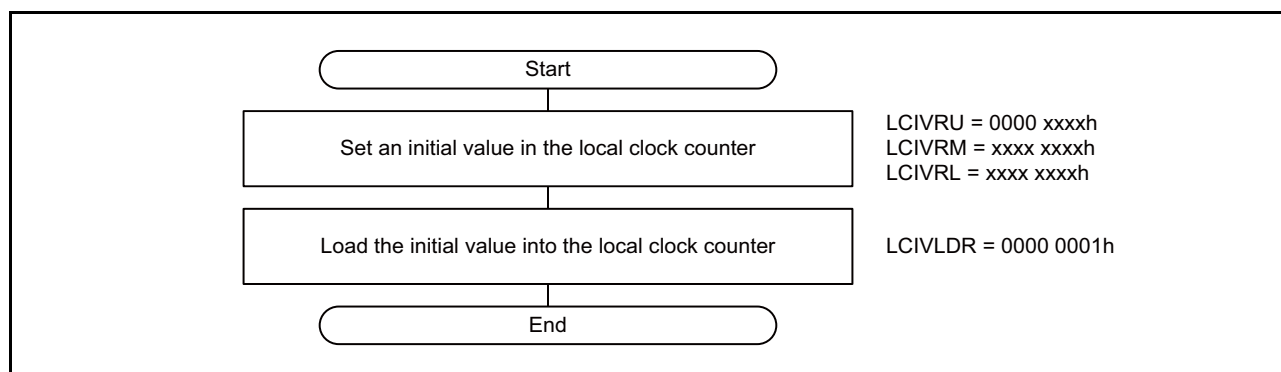

Figure 28.30 Procedure for Setting a New Initial Value in the Local Clock Counter

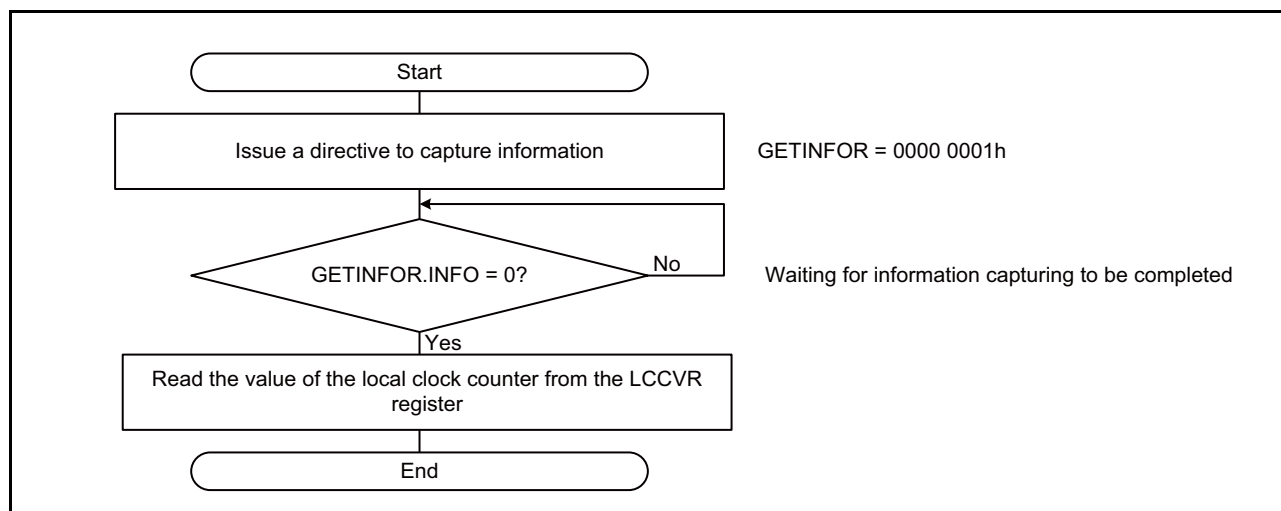

Figure 28.31 Procedure for Reading the Time Kept by the Local Clock Counter

28.3.17 Pulse Output Timer

The STCA module of the EPTPC incorporates six timers (pulse output timers 0 to 5) which operate independently of each other.

The pulse output timers produce periodic pulses, and the rising or falling edges of these pulses can be used as interrupt requests or output to the ELC as event signals. The time at which a pulse output timer starts operating (t_{start}), and the period (t_c) and pulse width (t_w) of the output pulses, can be specified.

The timing of pulse output timer operation is shown in Figure 28.32, and limits on the settings are listed in Table 28.27.

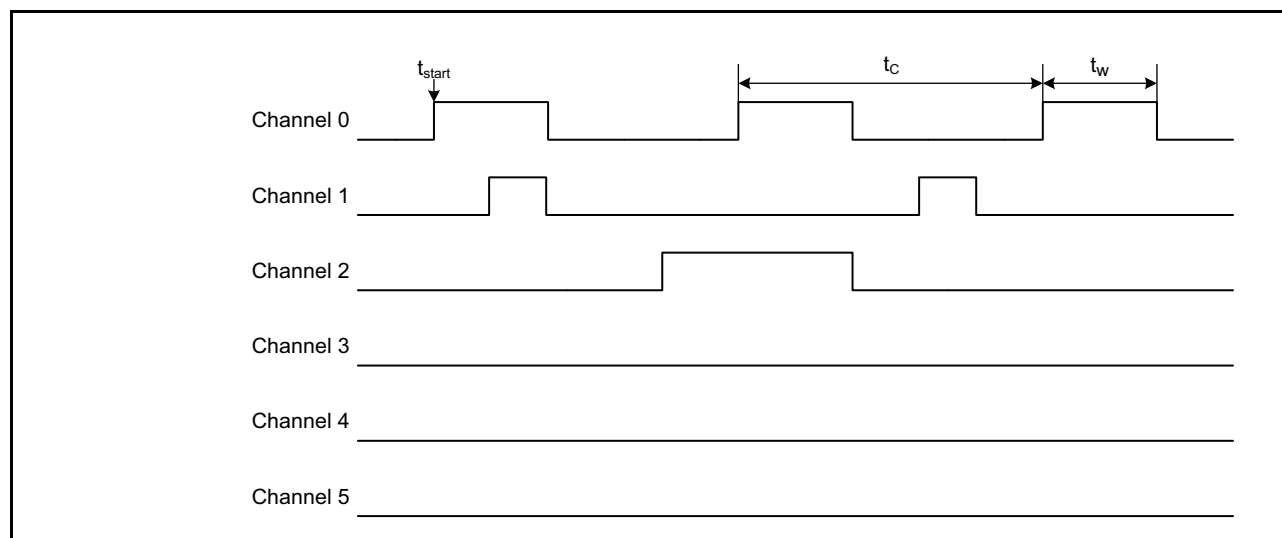

Figure 28.32 Time at which a Pulse Output Timer Starts Operating

Table 28.27 Limits on the Values that can be Specified for a Pulse Output Timer

| Item | Description |
|-------------------------------|---|
| Cycle (t_c) | At least four cycles of the STCA clock and no greater than 1 s |
| Resolution of the cycle | Set in units of nanoseconds. However, the timing of rising edges is rounded by the period of the system clock (50 ns, 40 ns, or 20 ns). |
| Pulse width (t_w) | At least two cycles of the STCA clock and no greater than 500 ms |
| Resolution of the pulse width | Set in units of nanoseconds. However, the timing of falling edges is rounded by the period of the system clock (50 ns, 40 ns, or 20 ns). |

28.3.17.1 Procedure for Setting a Pulse Output Timer

Figure 28.33 shows the procedure for setting a pulse output timer.

Note that a timer does not produce periodic pulses if the time set in registers TMSTTRUm and TMSTTRLm (m = 0 to 5) has already passed. Set the time for a pulse output timer to start to a later time than the time when the timer is being set.

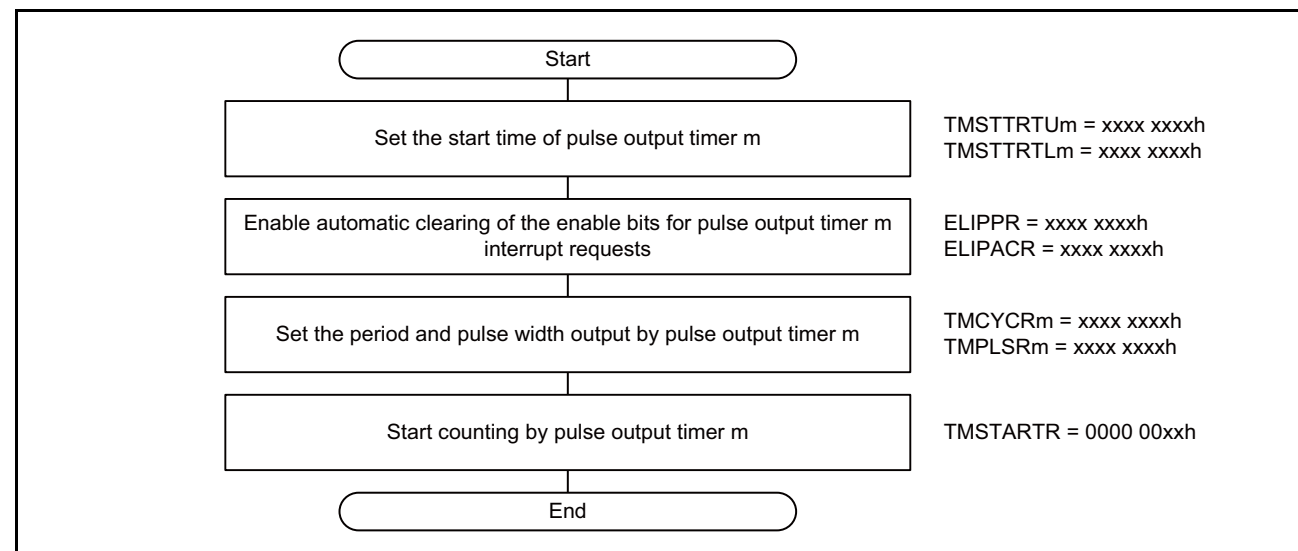

Figure 28.33 Procedure for Setting a Pulse Output Timer

28.3.17.2 Output of periodic pulses as interrupt requests or event signals

MINT interrupt requests, IPLS interrupt requests, or event output signals for the ELC can be generated by detecting rising or falling edges of the periodic pulses from the pulse output timer. The edge for detection and pulse output timer to use can be selected, and automatic clearing of enable bits for the IPLS interrupt or event output can be set. Make the required settings before setting the TMSTARTR.ENm bit to 1 (starting pulse output timer m).

(1) MINT Interrupt Request

Rising edges of the periodic pulses from the pulse output timers can be detected to generate MINT interrupt requests. Falling edges cannot be used in this way. The pulse output timers for use in generating MINT interrupt requests are selected by the MITSELR.MINTENm bits.

Automatic clearing of the enable bits for MINT interrupt requests is not available.

(2) IPLS Interrupt Request

Rising or falling edges of the periodic pulses from the pulse output timers can be detected to generate IPLS interrupt requests. The pulse output timers for use in generating IPLS interrupt requests are selected by the IPTSELR.IPTSELM bits.

Setting the ELIPACR.PLSP or PLSN bit enables automatic clearing of the enable bits for IPLS interrupt requests.

28.3.18 Priority Control in Transmission

28.3.18.1 Arbitration

In cases of contention between a message for transmission from the PTPEDMAC and a request for relaying from another channel, the PRC-TC module gives priority to the request for relaying from the other channel.

Cases of contention between multiple requests for the transmission of messages by the SYNFP module are also arbitrated in the order of priority shown in Table 28.28.

Table 28.28 Priority in Arbitration for Messages for Transmission

| Messages for Transmission | Priority Order | Remark |
|---|--------------------|--|
| Sync | 1 Highest priority | |
| Delay_Req, Pdelay_Req | 2 | There is no device type that simultaneously transmits Delay_Req and Pdelay_Req messages. |
| Delay_Resp, Pdelay_Resp | 3 | There is no device type that simultaneously transmits Delay_Resp and Pdelay_Resp messages. |
| Announce | 4 | |
| Relay messages from another channel | 5 | The PRC-TC module determines the order of priority for these two items. |
| Messages for transmission from the PTPEDMAC | 5 | |
| Messages for transmission from the EDMAC | 6 | |

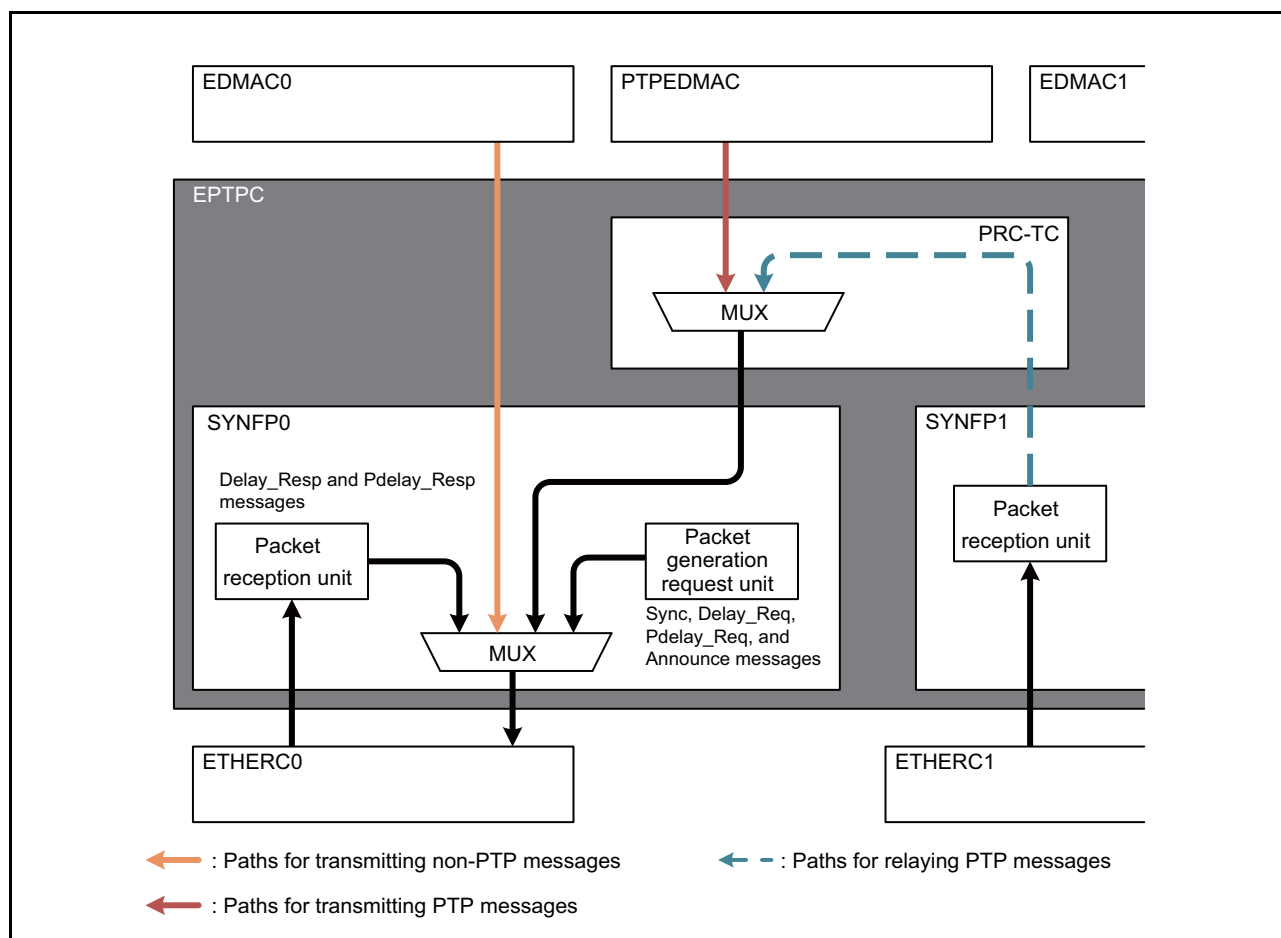

Figure 28.34 Arbitration in Message Transmission

28.3.18.2 Securing of Bandwidth for the Transmission of Sync Messages

The EPTPC secures bandwidth for the transmission of Sync messages, and is capable of handling transmission at very precise intervals.

If the transmission of a Sync message at a fixed interval proceeds at the same time as transmission by the PTPEDMAC or the relaying of messages by another channel is in progress, because transmission of the Sync message proceeds when the other processing is complete, the interval for transmission will no longer be fixed.

By securing bandwidth for the transmission of Sync messages, the transmission of messages from EDMAC0, EDMAC1, and the PTPEDMAC is limited, and the transmission of Sync messages can be handled without fluctuations. Securing of bandwidth for the transmission of Sync messages can be disabled by setting the SYCONFR.SBDIS bit to 1. Figure 28.35 gives a schematic view of securing bandwidth for the transmission of Sync messages.

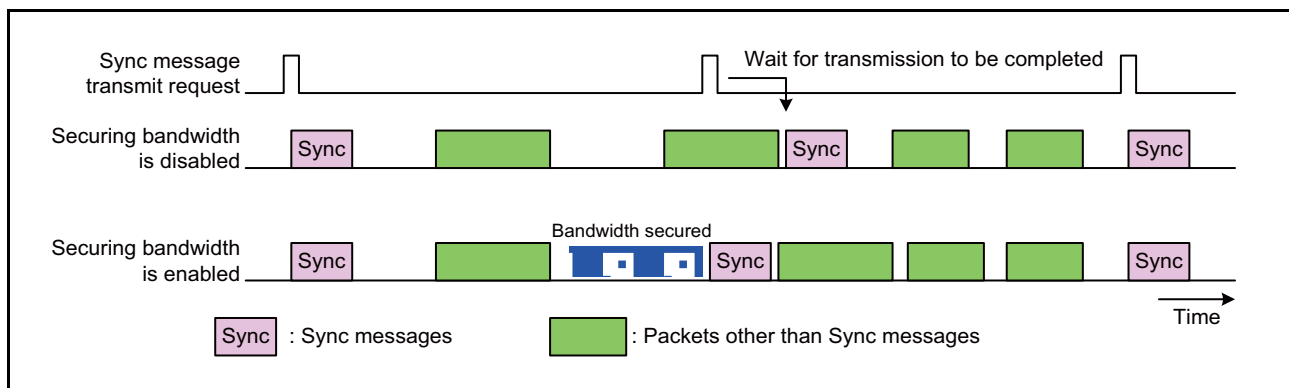

Figure 28.35 Securing of Bandwidth for the Transmission of Sync Messages

28.3.18.3 Securing of Transmission Interval

In the transmission of messages by the ETHERC, if there is a fixed delay from the time of a request for transmission to the time of transmission on the MII of Ethernet port 0 or 1, time stamp values of PTP messages can be used for accurately obtaining the size of the delay during operation as a slave. However, in the case of continuous transfer and so on, in situations where processing of messages to wait for interpacket gap times is required, delay times may fluctuate. Specifying an interval for frame transmission in SYCONFR.TCYC[7:0] bits to control the interval between the completion of transmission and the next request for transmission makes the ETHERC able to secure the reliability of time stamp values, thus avoiding the effects of interpacket gap times and obtaining a fixed delay for transmission.

28.4 Interrupts

The EPTPC has the MINT interrupt request and IPLS interrupt request.

Figure 28.36 shows the relation between the MINT interrupt request and IPLS interrupt request. Figure 28.37 shows the details on interrupt requests of the pulse output timer.

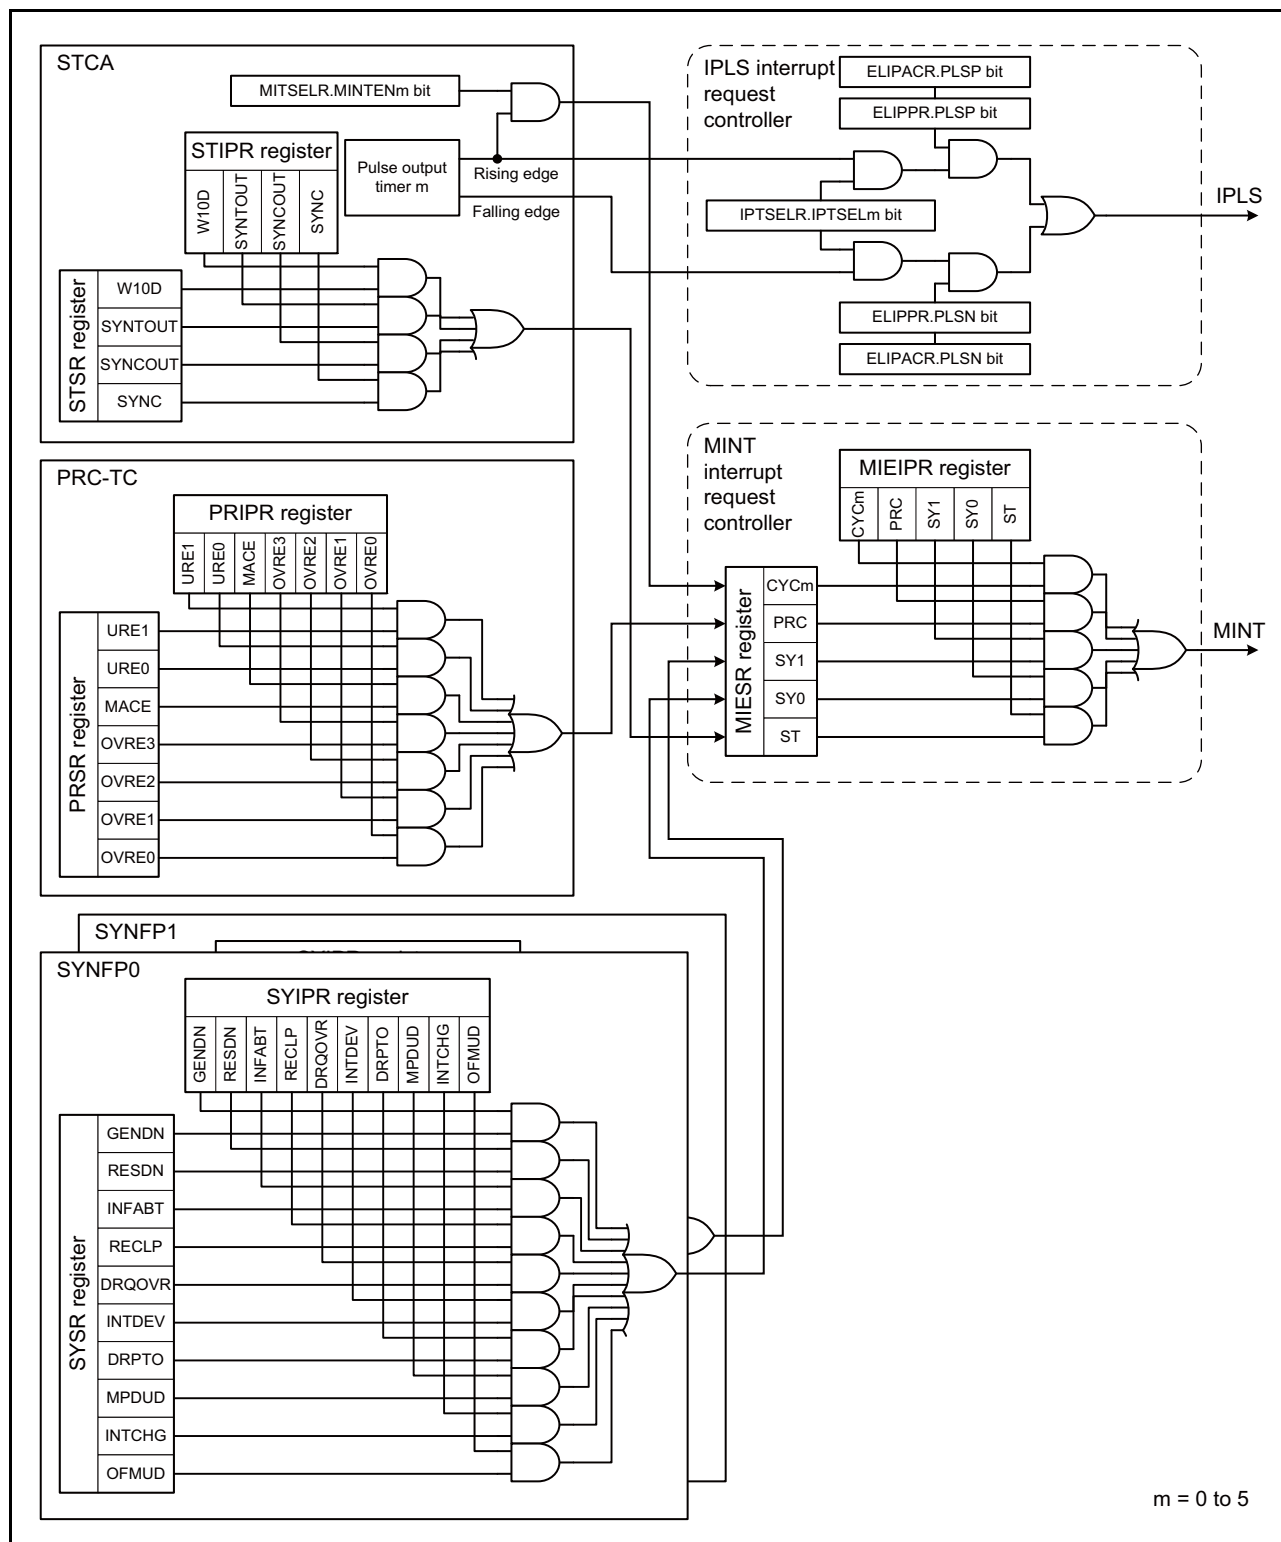

Figure 28.36 MINT Interrupt Request and IPLS Interrupt Request

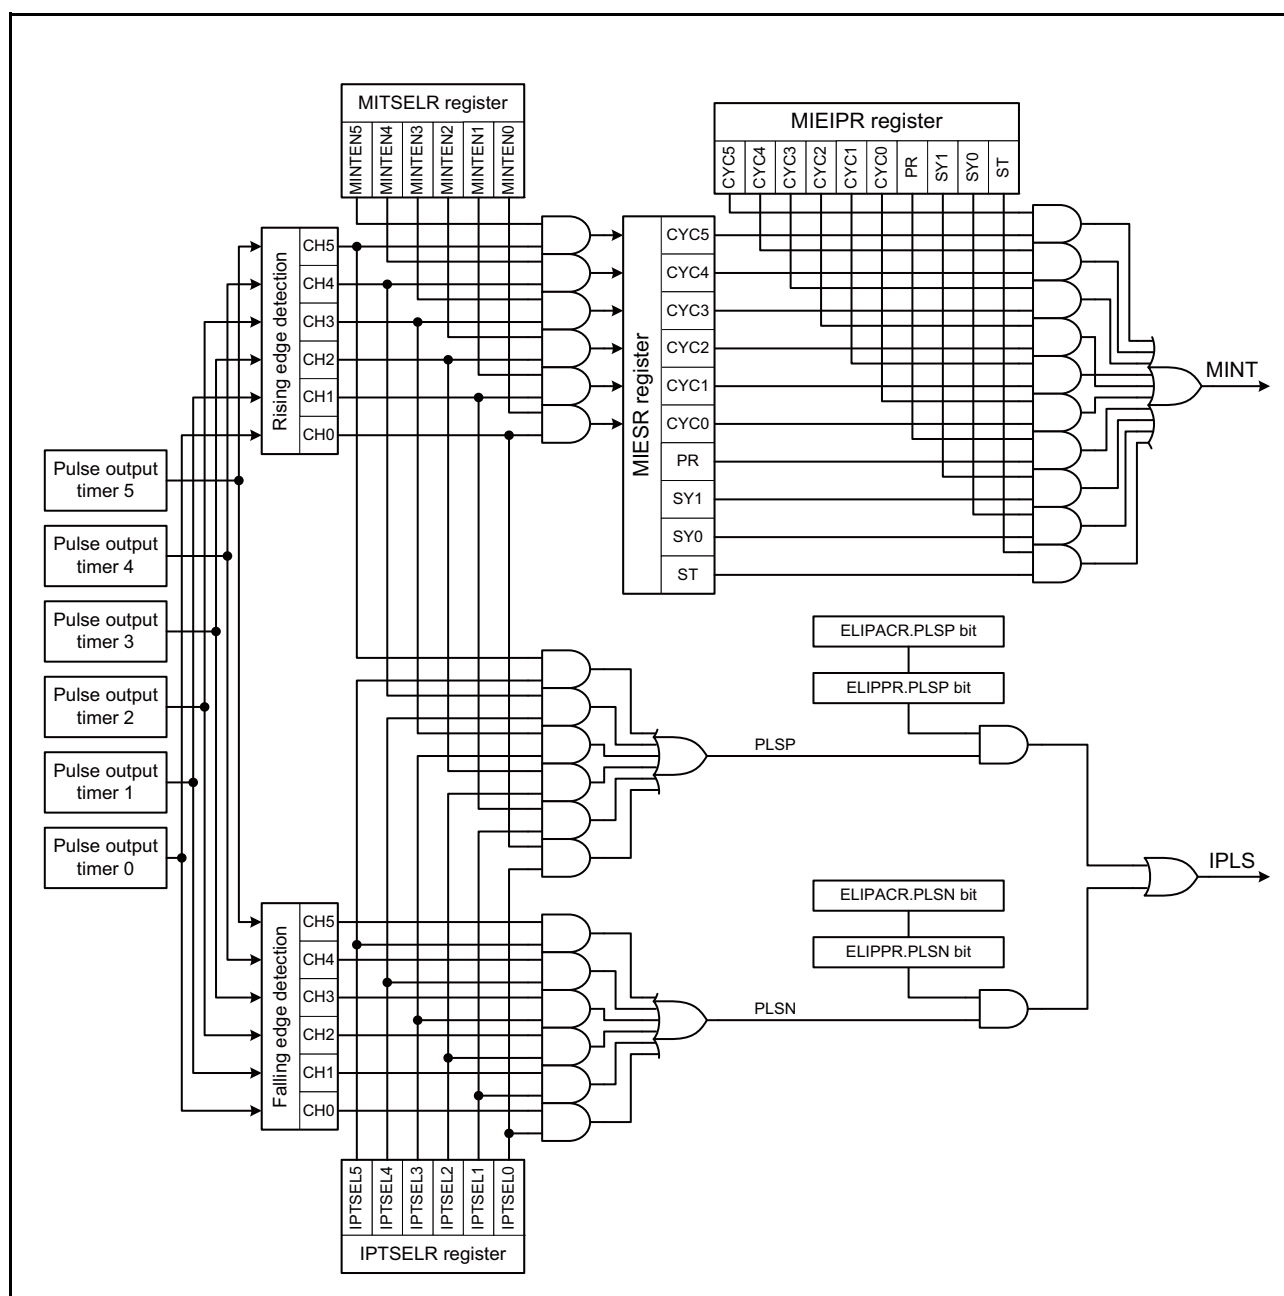

Figure 28.37 Details on Interrupt Requests of the Pulse Output Timer

28.5 Usage Notes

28.5.1 Setting of the Module-Stop Function

Operation of the EPTPC can be disabled or enabled with the standby control register 6 (STBCR6). The value following a reset is for the STBCR6 to stop. The registers of the EPTPC become accessible after 3 μ s have elapsed following its release from the module-stop state and clearing of the BYPASS.BYPASSn bit to 0. For details on the module-stop function, see section 52, Power-Down Modes. Table 28.29 shows the relation between the settings of the respective bits and the accessibility of each of the EPTPC registers.

Access to the STCA and SYNFP units must proceed while the STCA and MII clock signals are being supplied to the respective units.

Table 28.29

| STBCR6 Register | | | | BYPASS Register | | Allocation of Register Addresses for Access | | | | | |
|--------------------------------|--------------------------------|--------------------------------|-------------------------------|-----------------|---------|---|--------------------------------|--|--|--|--|
| MSTP65 (ETHERC0, EDMAC0) | MSTP64 (ETHERC1, EDMAC1) | MSTP63 (EPTPC, PTPEDMAC) | MSTP62 (common circuit) | BYPASS0 | BYPASS1 | E820 4500h to E820 45FFh | E820 5000h to E820 503Fh | E820 5040h to E820 53FFh (STCA) | E820 5400h to E820 57FFh (PRC-TC) | E820 5800h to E820 5BFFh (SYNFP0) | E820 5C00h to E820 5FFFh (SYNFP1) |
| 0 | 0 | 0 | 0 | 0 | 0 | Accessible | Accessible | Accessible | Accessible | Accessible | Accessible |
| 0 | 1 | 0 | 0 | 0 | 1 | Accessible | Accessible | Accessible | Accessible | Accessible | Not accessible |
| 1 | 0 | 0 | 0 | 1 | 0 | Accessible | Accessible | Accessible | Accessible | Not accessible | Accessible |
| 0 | 0 | 1 | 0 | 1 | 1 | Accessible | Not accessible | Not accessible | Not accessible | Not accessible | Not accessible |
| 0 | 1 | 1 | 0 | 1 | 1 | Accessible | Not accessible | Not accessible | Not accessible | Not accessible | Not accessible |
| 1 | 0 | 1 | 0 | 1 | 1 | Accessible | Not accessible | Not accessible | Not accessible | Not accessible | Not accessible |
| 1 | 1 | 1 | 1 | 1 | 1 | Not accessible | Not accessible | Not accessible | Not accessible | Not accessible | Not accessible |

Note: Settings other than those listed above are prohibited.

Writing does not proceed if you attempt access to the non-accessible registers or access while the MII and STCA clock signals are not being supplied. If you attempt reading, 0h is returned.

28.5.1.1 Release from the Module-Stop State

Before using the EPTPC, follow the steps below to release the EPTPC from the module-stop state. Do not proceed with other processing while this procedure is in progress.

- (1) Clear the MSTP62, MSTP63, MSTP64, and MSTP65 bits in the STBCR6 register to 0.
- (2) Clear the BYPASS0 and BYPASS1 bits in the BYPASS register to 0.
- (3) Wait for 3μs.

Note: The procedure above is for cases where all functions are to be enabled. Set the respective bits as required.

28.5.1.2 Transition to the Module-Stop State

Follow the steps below to place the ETHERC, EPTPC, and EDMAC in the module-stop state. Do not proceed with other processing while this procedure is in progress.

- (1) Reset the ETHERC, EPTPC, and EDMAC.*1
- (2) Set the BYPASS0 and BYPASS1 bits in the BYPASS register to 1.
- (3) Clear the MSTP62, MSTP63, MSTP64, and MSTP65 bits in the STBCR6 register to 1.
- (4) Wait for 3 μs.

Note 1. See section 27.5.4, Points to Note when the EPTPC Is not in Use.

28.5.2 Notes on Placing the CPU on Software Standby

When you intend to place the CPU on software standby, start by placing the ETHERC, EPTPC, and EDMAC in the module stop state before executing the WFI instruction.

28.5.3 Wait Cycles for Register Access

Access to registers in the EPTPC involves the arbitration of different clock signals, specifically the peripheral module clock signal (Bφ), the STCA clock signal, and the MII clock signals such as TX_CLK. Accordingly, numbers of wait cycles for register access differ with the combination of the frequency settings of the peripheral module clock signal, of the STCA clock signal, and of the MII clock signals.

Table 28.30 gives examples of numbers of wait cycles for different combinations of clock frequency. Add 1 to 2 cycles to these values to obtain the number of access cycles.

Table 28.30 Wait Cycles for Register Access (when the frequency of the STCA clock is 50 MHz)

| Address Range | STCA Clock = 50MHz | | | | | | | |
|--------------------------------------|--------------------------------------|------------|--------------------------------|-----------------|-------------------------------------|------------|--------------------------------|------------|
| | Peripheral Module Clock Bφ = 132 MHz | | | | Peripheral Module Clock Bφ = 33 MHz | | | |
| | MII Clock 25 MHz (100 Mbps) | | MII Clock 2.5 MHz (10 Mbps) | | MII Clock 25 MHz (100 Mbps) | | MII Clock 2.5 MHz (10 Mbps) | |
| | Read | Write | Read | Write | Read | Write | Read | Write |
| E820 4500h to E820 45FFh | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 |
| E820 5000h to E820 503Fh | 4 | 4 | 4 | 4 | 4 | 4 | 4 | 4 |
| E820 5040h to E820 53FFh (STCA) | 7 | 19 to 25*1 | 7 | 19 to 25*1 | 7 | 15 to 17*1 | 7 | 15 to 17*1 |
| E820 5400h to E820 57FFh (PRC-TC) | 8 | 8 | 8 | 8 | 8 | 8 | 8 | 8 |
| E820 5800h to E820 5BFFh (SYNFP0) | 8 | 25 to 37*2 | 8 | 119 to 225*2 | 8 | 17 to 21*2 | 8 | 41 to 69*2 |
| E820 5C00h to E820 5FFFh (SYNFP1) | 8 | 23 to 33*2 | 8 | 111 to 225*2 | 8 | 17 to 21*2 | 8 | 41 to 69*2 |

Note 1. The number of wait cycles in access to the STCA-related registers (Wstca) can be calculated to be in the following range from the periods of the peripheral module clock (tc(Bφ)) and STCA clock (tc(STCA)).

$$\begin{aligned} \text{The minimum value of Wstca} &= \text{Int}(\text{tc}(\text{STCA})/\text{tc}(\text{B}\phi)) \times 2 + 15 && (\text{tc}(\text{B}\phi) \leq \text{tc}(\text{STCA})) \\ &= 15 && (\text{tc}(\text{B}\phi) > \text{tc}(\text{STCA})) \end{aligned}$$

$$\begin{aligned} \text{The maximum value of Wstca} &= \text{Int}(\text{tc}(\text{STCA})/\text{tc}(\text{B}\phi)) \times 4 + 17 && (\text{tc}(\text{B}\phi) \leq \text{tc}(\text{STCA})) \\ &= 17 && (\text{tc}(\text{B}\phi) > \text{tc}(\text{STCA})) \end{aligned}$$

• Int(A) is the calculation of the largest integer not greater than A.

• This calculation presumes that the CPU clock and peripheral module clock have the same periods.

For example, if the frequency of the peripheral module clock is 132 MHz and that of the STCA clock is 50 MHz, the minimum value of Wstca = Int (50 [ns]/7.58 [ns]) × 2 + 15 = 19, and the maximum value of Wstca = Int (50 [ns]/7.58 [ns]) × 4 + 17 = 25.

Note 2. The number of wait cycles in access to the SYNFP-related registers (Wsynf) can be calculated to be in the following range from the periods of the peripheral module clock (tc(Bφ)) and MII clock (tc(MII)).

$$\begin{aligned} \text{The minimum value of Wsynf} &= \text{Int}(\text{tc}(\text{MII})/\text{tc}(\text{B}\phi)) \times 2 + 15 && (\text{tc}(\text{B}\phi) \leq \text{tc}(\text{MII})) \\ &= 15 && (\text{tc}(\text{B}\phi) > \text{tc}(\text{MII})) \end{aligned}$$

$$\begin{aligned} \text{The maximum value of Wsynf} &= \text{Int}(\text{tc}(\text{MII})/\text{tc}(\text{B}\phi)) \times 4 + 17 && (\text{tc}(\text{B}\phi) \leq \text{tc}(\text{MII})) \\ &= 17 && (\text{tc}(\text{B}\phi) > \text{tc}(\text{MII})) \end{aligned}$$

• Int(A) is the calculation of the largest integer not greater than A.

• This calculation presumes that the CPU clock and peripheral module clock have the same periods.

For example, if the frequency of the peripheral module clock is 132 MHz and the transmission rate is 10 Mbps (so the MII clock is running at 2.5 MHz), the minimum value of Wsynf = Int (400 [ns]/7.58 [ns]) × 2 + 15 = 119, and the maximum value of Wsynf = Int (400 [ns]/7.58 [ns]) × 4 + 17 = 225.

28.5.4 Restriction on the EPTPCa Operation when the MII Interface is in Use

The ETn_RX_CLK signal of the MII can be used for the STCA clock, however, it must be fixed to 25 MHz (100 Mbps) when in use. Use the ETn_SCLKIN signal instead if you may use the ETHERC at 10 Mbps when the MII is in use.

28.5.5 Transfer by PTPEDMAC when the Transparent Clock (TC) is in Use

When the setting of any of the following bits is 1, indicating the processing of a PTP event message, do not use PTPEDMAC to transfer data for transmission. Instead, use EDMACn of a corresponding channel for transfer (n = 0, 1).

- SYRFL1R.PDRP[1], SYRFL1R.PDRQ[1], SYRFL1R.DRP[1], or SYRFL1R.SYNC[1]

29. DMA Controller for the Ethernet Controller (EDMACa)

29.1 Overview

This MCU has three channels for the ethernet controller direct memory access controller (EDMAC): two channels for the ethernet controller (ETHERC) and one channel for the PTP controller (EPTPC). EDMAC0 and EDMAC1 control data transmission and reception for ETHERC0 and ETHERC1, respectively. The PTPEDMAC controls data transmission and reception for ETHERC0 and ETHERC1 according to the EPTPC settings. In this section, channel numbers are indicated as n ($n = 0, 1$).

The EDMAC controls most of the transmit/receive buffer management for communications. This reduces the load on the CPU and allows efficient data transmission and reception. The data transfers are controlled according to the information (referred to as descriptors) on the memory.

Table 29.1 lists the EDMAC specifications. Figure 29.1 shows the EDMAC configuration, and Figure 29.2 shows the configuration of descriptors and transmit/receive buffers on the memory.

Table 29.1 EDMAC Specifications

| Item | Description |
|---------------------------------|---|
| Data transmission and reception | <ul style="list-style-type: none"> Controls data transmission and reception according to descriptors Supports single buffer frame transmission and reception (1 buffer per frame), and multi-buffer frame transmission and reception (multiple buffers per frame) |
| Functions | <ul style="list-style-type: none"> Minimizes system bus occupation time using block transfer (32-byte units) Writes back the transmit/receive frame state to descriptors Inserts padding in receive data |
| Low power consumption function | The EDMAC can be set to the module-stop state to reduce power consumption. |

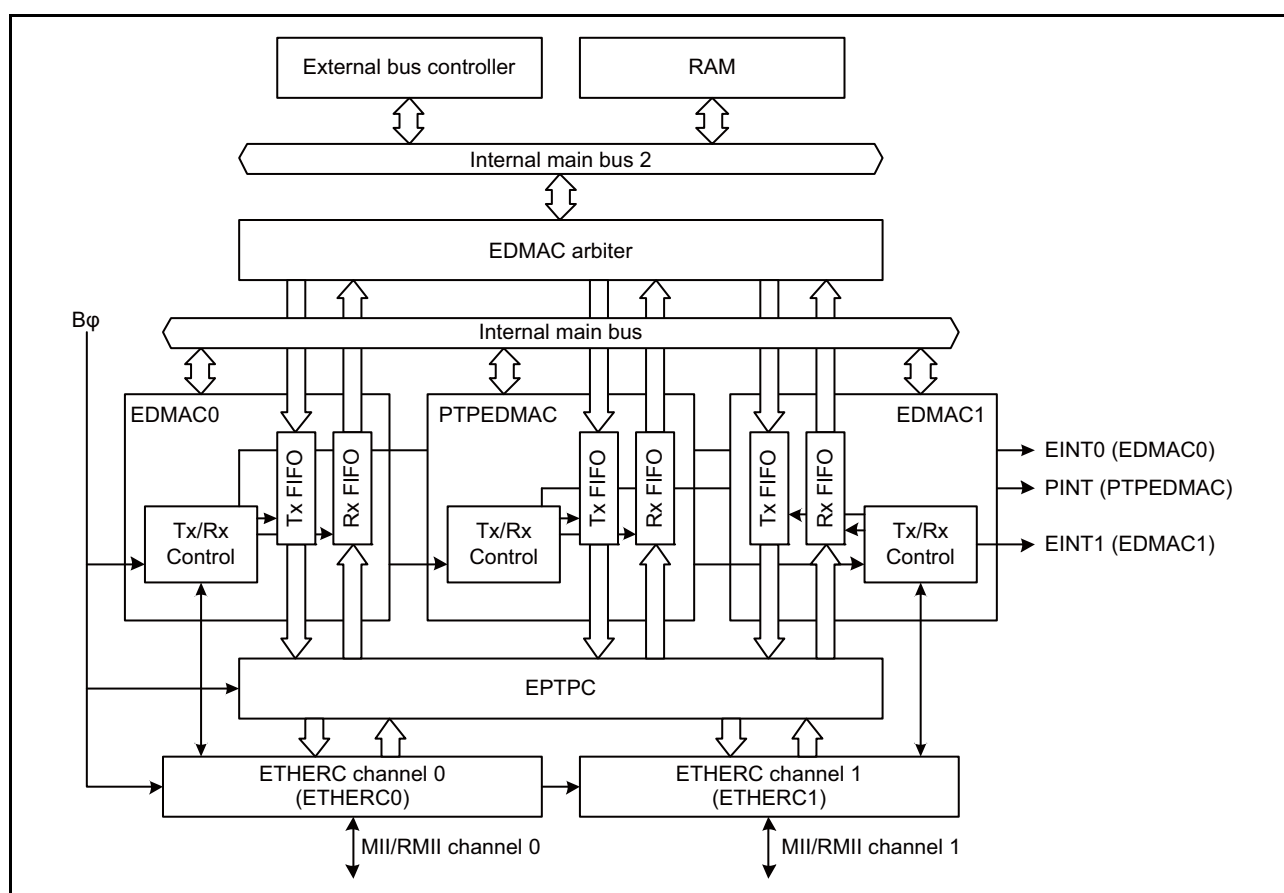

Figure 29.1 EDMAC Configuration

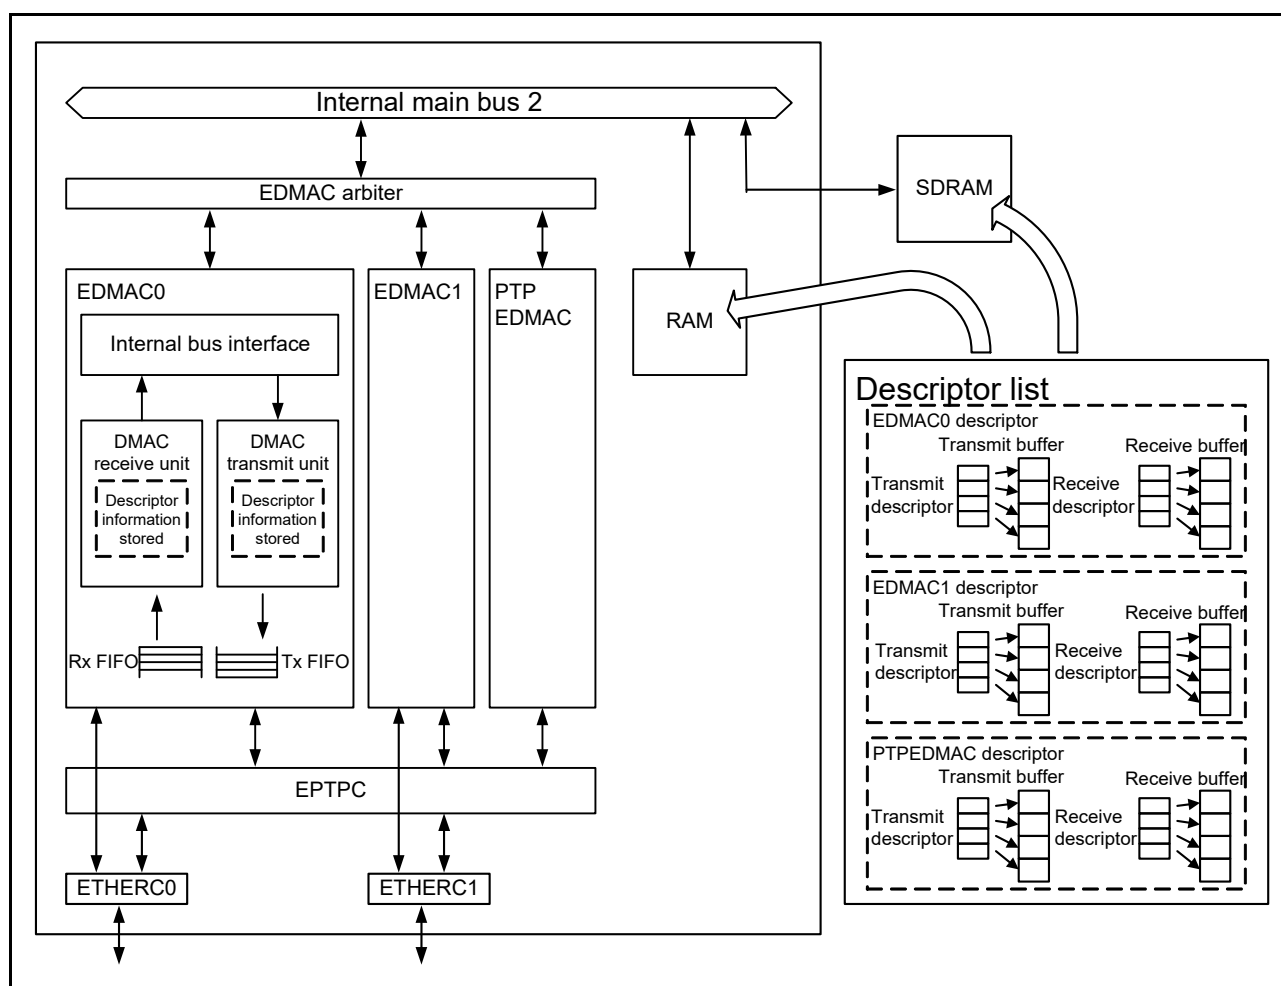

Figure 29.2 Configuration of Descriptors and Transmit/Receive Buffers on the Memory

29.2 Register Descriptions

Table 29.2 shows the register configuration.

Table 29.2 Register Configuration

| Module | Register Name | Abbreviation | Address | Access size |
|--------|---|--------------|------------|-------------|
| EDMAC0 | EDMAC mode register | EDMR | E820 4000h | 32 |

29.2.1 EDMAC Mode Register (EDMR)

Address: EDMAC0.EDMR E820 4000h, EDMAC1.EDMR E820 4200h, PTPEDMAC.EDMR E820 4400h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|---------|----|----|----|----|-----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | DE | DL[1:0] | — | — | — | — | SWR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|---------|---------------------------------------|--|-----|
| b0 | SWR | Software Reset | When 1 is written, the corresponding channels of the EDMAC and ETHERC are reset. Note that for the PTPEDMAC, the ETHERC are not reset. Registers TDLAR, RDLAR, RMFCR, TFUCR, and RFOCR are not reset with this bit. The read value is 0. | R/W |
| b3 to b1 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b5, b4 | DL[1:0] | Transmit/Receive Descriptor Length | b5 b4 0 0: 16 bytes 0 1: 32 bytes 1 0: 64 bytes 1 1: 16 bytes | R/W |
| b6 | DE | Big Endian Mode/Little Endian Mode *1 | 0: Big endian mode 1: Little endian mode | R/W |
| b31 to b7 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

Note 1. This setting applies to data for the transmit/receive buffer. It does not apply to transmit/receive descriptors and registers.

The EDMR register controls EDMAC operation.

Set the EDMR register during the initialization process after a reset. When rewriting this register outside of the initialization process, set the SWR bit to 1 to reset the EDMAC and ETHERC, and then set this register again. If the ETHERC and EDMAC are reset during data transmission or reception, abnormal data may be sent on the line. Do not rewrite this register while the ETHERC transmit or receive function is enabled. It takes 64 cycles of the peripheral module clock (Bφ) to initialize the ETHERC and EDMAC. Complete the initialization process before accessing registers in the ETHERC and EDMAC.

29.2.2 EDMAC Transmit Request Register (EDTTR)

Address: EDMAC0.EDTTR E820 4008h, EDMAC1.EDTTR E820 4208h, PTPEDMAC.EDTTR E820 4408h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | TR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|------------------|---|-----|
| b0 | TR | Transmit Request | When 1 is written, the EDMAC reads the corresponding descriptor and transmits frames where the TD0.TACT bit is 1. The TR bit becomes 0 after all the valid frames are transmitted. Writing 0 to this bit has no effect. | R/W |
| b31 to b1 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The EDTTR register controls EDMAC transmission.

After the EDMAC has transmitted one frame, it reads the next descriptor. When the TD0.TACT bit in the descriptor is 1, the EDMAC continues transmission. When the TD0.TACT bit is 0, the EDMAC sets the TR bit to 0 and stops transmission.

29.2.3 EDMAC Receive Request Register (EDRRR)

Address: EDMAC0.EDRRR E820 4010h, EDMAC1.EDRRR E820 4210h, PTPEDMAC.EDRRR E820 4410h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|-----------------|---|-----|
| b0 | RR | Receive Request | 0: Receive function is disabled.*1 1: Receive descriptor is read, and the receive function is enabled. | R/W |
| b31 to b1 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

Note 1. If the receive function is disabled during frame reception, write-back to the receive descriptor is not performed successfully. Subsequent pointers for reading a receive descriptor become abnormal and the EDMAC cannot operate normally. In this case, to enable the EDMAC receive function again, execute a software reset by setting the EDMR.SWR bit to 1. To disable the EDMAC receive function without resetting the EDMAC, set the ETHERCn.ECMR.RE bit to 0. Next, after the EDMAC has completed reception and write-back to the receive descriptor has been confirmed, set the RR bit to 0.

The EDRRR register controls EDMAC reception.

When the RR bit becomes 1, the EDMAC reads the receive descriptor. When the RD0.RACT bit is 1, the EDMAC waits for a receive request from the ETHERC.

When the EDMAC has received data for the receive buffer size, it reads the next descriptor and waits to receive a frame. If the RD0.RACT bit is 0, the EDMAC sets the RR bit to 0 and stops reception.

29.2.4 Transmit Descriptor List Start Address Register (TDLAR)

Address: EDMAC0.TDLAR E820 4018h, EDMAC1.TDLAR E820 4218h, PTPEDMAC.TDLAR E820 4418h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | The start address of the receive descriptor list is set. Set the start address according to the descriptor length selected by the EDMR.DL[1:0] bits. 16-byte boundary: Lower 4 bits = 0000b 32-byte boundary: Lower 5 bits = 00000b 64-byte boundary: Lower 6 bits = 000000b | R/W |

The TDLAR register sets the start address of the transmit descriptor list.

Align each descriptor on the corresponding boundary to the descriptor length selected by the EDMR.DL[1:0] bits.

Do not rewrite the TDLAR register during transmission. Rewrite the TDLAR register while the EDTRR.TR bit is 0.

29.2.5 Receive Descriptor List Start Address Register (RDLAR)

Address: EDMAC0.RDLAR E820 4020h, EDMAC1.RDLAR E820 4220h, PTPEDMAC.RDLAR E820 4420h

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|----------|---|-----|
| b31 to b0 | — | — | The start address of the receive descriptor list is set. Set the start address according to the descriptor length selected by the EDMR.DL[1:0] bits. 16-byte boundary: Lower 4 bits = 0000b 32-byte boundary: Lower 5 bits = 00000b 64-byte boundary: Lower 6 bits = 000000b | R/W |

The RDLAR register sets the start address of the receive descriptor list.
Allocate each descriptor on the corresponding boundary to the descriptor length selected by the EDMR.DL[1:0] bits.
Do not rewrite the RDLAR register during reception. Rewrite the RDLAR register while the EDRRRR.RR bit is 0.

29.2.6 ETHERC/EDMAC Status Register (EDMACn.EESR)

Address: EDMAC0.EESR E820 4028h, EDMAC1.EESR E820 4228h

| | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|------|------|-------|------|-----|-----|-----|------|------|-----|------|
| b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |

| b20 | TDE | Transmit Descriptor Empty Flag | 0: The EDMAC detects that the transmit descriptor valid bit (TD0.TACT) is 1. 1: The EDMAC detects that the transmit descriptor valid bit (TD0.TACT) is 0. | R/W |
| b21 | TC | Frame Transfer Complete Flag | 0: Transfer have not been completed, or no transfer has been requested. 1: All frames indicated by the transmit descriptor have been completely transferred to the transmit FIFO. | R/W |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|-------------------------------------|--|------|
| b22 | ECI | ETHERC Status Register Source Flag | 0: ETHERC status interrupt source has not been detected. 1: ETHERC status interrupt source has been detected. | R *1 |
| b23 | — | Reserved | The read value is 0. The write value should be 0. | R |
| b24 | RFCOF | Receive Frame Counter Overflow Flag | 0: Receive frame counter has not overflowed. 1: Receive frame counter has overflowed. | R/W |
| b25 | RABT | Receive Abort Detect Flag | 0: Frame reception has not been aborted or no reception has been requested. 1: Frame reception has been aborted. | R/W |
| b26 | TABT | Transmit Abort Detect Flag | 0: Frame transmission has not been aborted or no transmission has been requested. 1: Frame transmission has been aborted. | R/W |
| b29 to b27 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b30 | TWB | Write-Back Complete Flag | 0: Write-back has not been completed, or no transmission has been requested. 1: Write-back to the transmit descriptor has been completed. | R/W |
| b31 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

Note 1. The ECI flag is read-only. When the source in the ETHERCn.ECSR register is cleared, the ECI flag is also cleared.

The EDMACn.EESR register indicates the ETHERC and EDMAC communication status.

Each flag in the EESR register can be output as an interrupt request signal (EINTn) from the EDMAC. Each flag, excluding the ECI flag, becomes 0 by writing 1. The value of each flag is not changed by writing 0. Each interrupt source can be enabled by the corresponding bit in the EDMACn.EESIPR register.

CERF Flag (CRC Error Flag)

The CERF flag becomes 1 when an error is detected in checking the frame check sequence (FCS) field of the receive frame.

PRE Flag (PHY-LSI Receive Error Flag)

The PRE flag indicates the RX_ER signal output from the PHY-LSI is high.

RTSF Flag (Frame-Too-Short Error Flag)

The RTSF flag indicates that a received frame was less than 64 bytes.

RTLFL Flag (Frame-Too-Long Error Flag)

The RTLFL flag indicates that a received frame is greater than the upper limit of the receive frame length set in the ETHERCn.RFLR register. The excess data is discarded.

RRF Flag (Alignment Error Flag)

The RRF flag indicates that a frame is not an integral number of octets. The last word that is not an integral number of octets is not transferred.

RMAF Flag (Multicast Address Frame Receive Flag)

The RMAF flag indicates that a multicast frame has been received.

TRO Flag (Transmit Retry Over Flag)

This flag indicates that a collision occurred again during the 15th retry of frame transmission.

CD Flag (Late Collision Detect Flag)

The CD flag indicates that a late collision has been detected during frame transmission.

DLC Flag (Loss of Carrier Detect Flag)

The DLC flag indicates that a loss of carrier has been detected during frame transmission.

CND Flag (Carrier Not Detect Flag)

The CND flag becomes 1 when a carrier has not been detected during preamble transmission.

RFOF Flag (Receive FIFO Overflow Flag)

The RFOF flag indicates that the receive FIFO has overflowed during frame reception.

RDE Flag (Receive Descriptor Empty Flag)

The RDE flag indicates that the read receive descriptor is invalid.

When this flag becomes 1, set the RD0.RACT bit in the receive descriptor to 1 and set the EDRRR.RR bit to 1 to resume reception.

FR Flag (Frame Receive Flag)

The FR flag indicates that a frame has been received and the receive descriptor has been updated. The FR flag becomes 1 every time a frame is received.

TFUF Flag (Transmit FIFO Underflow Flag)

The TFUF flag indicates that no data remains in the transmit FIFO during frame transmission. Incomplete data is sent on the line.

TDE Flag (Transmit Descriptor Empty Flag)

The TDE flag indicates that the TD0.TACT bit of the transmit descriptor is 0 while the previous transmit descriptor indicates that the frame is not complete (TD0.TFP[1:0] bits are 10b or 00b) in multi-buffer frame transmission. As a result, an incomplete frame may be sent.

When this flag becomes 1, perform a software reset and then set the EDTRR.TR bit to 1 to resume transmission. Transmission starts from the address stored in the TDLAR register.

TC Flag (Frame Transfer Complete Flag)

The TC flag indicates that all the data specified by the transmit descriptor has been transmitted from the ETHERC. This flag becomes 1 when one frame has been transmitted in single-buffer frame transmission or when the last data of a frame is transmitted in multi-buffer frame transmission and the TD0.TACT bit in the next transmit descriptor is 0. After frame transmission is completed, the EDMAC writes the transfer status back to the descriptor.

ECI Flag (ETHERC Status Register Source Flag)

The ECI flag becomes 1 when an interrupt request is generated by the ETHERC.ECSR register.

ADE Flag (Address Error Flag)

The ADE flag indicates that the memory address that the EDMAC tried to transfer is invalid.

RFCOF Flag (Receive Frame Counter Overflow Flag)

The RFCOF flag indicates that the next frame reception starts while the number of frames stored in the receive FIFO reaches the maximum number of frames (16 frames). Note that the received frame is discarded while the RFCOF flag is 1.

RABT Flag (Receive Abort Detect Flag)

The RABT flag indicates that the ETHERC has aborted frame reception due to a CRC error, PHY-LSI receive error, frame-too-short error, frame-too-long error, or other error.

TABT Flag (Transmit Abort Detect Flag)

The TABT flag indicates that the ETHERC has aborted frame transmission due to transmit retry over, loss of carrier, no carrier detection, or other error.

TWB Flag (Write-Back Complete Flag)

The TWB flag indicates the EDMAC has completed writing back to the descriptor after frame transmission. Note that this flag becomes 1 after each frame transmission when the TRIMD.TIM bit is 0. This flag becomes 1 only when the TRIMD.TIS bit is 1.

29.2.7 PTP/EDMAC Status Register (PTPEDMAC.EESR)

Address: PTPEDMAC.EESR E820 4428h

| b29 to b27 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b30 | TWB | Write-Back Complete Flag | 0: Write-back has not been completed, or transmission has not been requested. 1: Write-back to the transmit descriptor has been completed. | R/W |
| b31 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The PTPEDMAC.EESR register indicates the PTPEDMAC communication status.

Each flag in the EESR register can be output as an interrupt request signal (PINT) from the PTPEDMAC. Each flag becomes 0 by writing 1. The value of each flag is not changed by writing 0. Each interrupt source, excluding the TYPE[3:0] flag, can be enabled by setting the corresponding bit in the PTPEDMAC.EESIPR register.

TYPE[3:0] Flags (PTP v2 Message Type Flag)

The TYPE[3:0] flags indicate the type of received PTP message.

PVER Flag (PTP v2 Packet Flag)

The PVER flag indicates whether the received packet is a PTP v2 packet.

RPORT Flag (Receive Port Flag)

The RPORT flag indicates which Ethernet port has been used for receiving PTP messages.

MACE Flag (MAC Address Mismatch Flag)

The MACE flag indicates the source MAC address is different from the set value.

RFOF Flag (Receive FIFO Overflow Flag)

The RFOF flag indicates that the receive FIFO has overflowed during frame reception.

RDE Flag (Receive Descriptor Empty Flag)

The RDE flag indicates that the read receive descriptor is invalid.

When this flag becomes 1, set the RD0.RACT bit in the receive descriptor to 1 and set the EDRRR.RR bit to 1 to resume reception.

FR Flag (Frame Receive Flag)

The FR flag indicates that a frame has been received and the receive descriptor has been updated. The FR flag becomes 1 every time a frame is received.

TFUF Flag (Transmit FIFO Underflow Flag)

The TFUF flag indicates that no data remains in the transmit FIFO during frame transmission. Incomplete data is sent on the line.

TDE Flag (Transmit Descriptor Empty Flag)

The TDE flag indicates that the TD0.TACT bit of the transmit descriptor is 0 while the previous transmit descriptor indicates that the frame is not complete (TD0.TFP[1:0] bits are 10b or 00b) in multi-buffer frame transmission. As a result, an incomplete frame may be sent.

When this flag becomes 1, perform a software reset and then set the EDTRR.TR bit to 1 to resume transmission. Transmission starts from the address stored in the TDLAR register.

TC Flag (Frame Transfer Complete Flag)

The TC flag indicates that all the data specified by the transmit descriptor has been transmitted from the ETHERC. This flag becomes 1 when one frame has been transmitted in single-buffer frame transmission or when the last data of a frame is transmitted in multi-buffer frame transmission and the TD0.TACT bit in the next transmit descriptor is 0. After frame transmission is completed, the PTPEDMAC writes the transfer status back to the descriptor.

ADE Flag (Address Error Flag)

The ADE flag indicates that the memory address that the PTPEDMAC tried to transfer is invalid.

RFCOF Flag (Receive Frame Counter Overflow Flag)

The RFCOF flag indicates that the next frame reception starts while the number of frames stored in the receive FIFO reaches the maximum number of frames (16 frames). Note that the received frame is discarded while the RFCOF flag is 1.

TABT Flag (Transmit Abort Detect Flag)

The TABT flag indicates that the ETHERC has aborted frame transmission due to transmit retry over, loss of carrier, no carrier detection, or other error.

TWB Flag (Write-Back Complete Flag)

The TWB flag indicates the PTPEDMAC has completed writing back to the descriptor after frame transmission. Note that this flag becomes 1 after each frame transmission when the TRIMD.TIM bit is 0. This flag becomes 1 only when the TRIMD.TIS bit is 1.

29.2.8 ETHERC/EDMAC Status Interrupt Enable Register (EDMACn.EESIPR)

Address: EDMAC0.EESIPR E820 4030h, EDMAC1.EESIPR E820 4230h

| b4 | RRFCE | RRF Flag Copy Enable | 0: The EESR.RRF flag status is reflected in the RD0.RFE bit of the receive descriptor. 1: The EESR.RRF flag status is not reflected in the RD0.RFE bit of the receive descriptor. | R/W |
| b6, b5 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b7 | RMAFCE | RMAF Flag Copy Enable | 0: The EESR.RMAF flag status is reflected in the RD0.RFE bit of the receive descriptor. 1: The EESR.RMAF flag status is not reflected in the RD0.RFE bit of the receive descriptor. | R/W |
| b31 to b8 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The EDMACn.TRSCER register selects whether the receive status indicated by flags EDMACn.EESR.RMAF and RRF is reflected in the RFE bit of the receive descriptor as a summary. The bits in the TRSCER register correspond to bits in the EESR register that have the same number. When setting the RMAFCE or RRFCE bit to 0, the corresponding receive status (EESR.RMAF or RRF flag) is reflected in the RFE bit of the receive descriptor. When setting the RMAFCE or RRFCE bit to 1, the corresponding receive status is not reflected in the RFE bit.

29.2.11 Missed-Frame Counter Register (RMFCR)

Address: EDMAC0.RMFCR E820 4040h, EDMAC1.RMFCR E820 4240h, PTPEDMAC.RMFCR E820 4440h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|----------------------|---|-----|
| b15 to b0 | MFC[15:0] | Missed-Frame Counter | These bits indicate the number of frames that are discarded and not transferred to the receive buffer during reception. | R/W |
| b31 to b16 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The RMFCR register indicates that the number of frames that could not be stored in the receive FIFO and were therefore discarded during reception. When the receive FIFO overflows, it stops receiving data, and the remain-ing frames are discarded. At the same time, the RMFCR register value is incremented. When the RMFCR register value reaches FFFFh, incrementing is halted. When any value is written to the RMFCR register, the counter value becomes 0.

For the frame that has not been completely received, after data in the receive FIFO is transferred to the receive buffer, the RACT bit in the receive descriptor 0 (RD0) becomes 0 (descriptor disabled), the RFS9 bit becomes 1 (receive FIFO overflow), and the EDMACn.EESR.RFOF or PTPEDMAC.EESR.RFOF flag becomes 1 (overflow has occurred).

29.2.12 Transmit FIFO Threshold Register (TFTR)

Address: EDMAC0.TFTR E820 4048h, EDMAC1.TFTR E820 4248h, PTPEDMAC.TFTR E820 4448h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|-------------------------|--|-----|
| b10 to b0 | TFT[10:0] | Transmit FIFO Threshold | b10 b0 000h: Store and forward mode 001h to 00Ch: Setting prohibited 00Dh to 200h: The threshold is the set value multiplied by 4. Example: 00Dh: 52 bytes 040h: 256 bytes 100h: 1024 bytes 200h: 2048 bytes 201h to 7FFh: Setting prohibited | R/W |
| b31 to b11 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

Note 1. When starting transmission before one frame data has been completely written, take care to prevent an underflow.

Note 2. To prevent a transmit underflow, using the initial value (store and forward mode) is recommended.

The TFTR register sets the transmit FIFO threshold at which the first transmission starts. The actual threshold is the set value multiplied by 4.

The ETHERC starts transmission when the amount of data in the transmit FIFO exceeds the number of bytes set in the TFTR register, when the transmit FIFO is full, or when one frame data has been completely written. Set the TFTR register while the EDTRR.TR bit is 0.

29.2.13 FIFO Depth Register (FDR)

Address: EDMAC0.FDR E820 4050h, EDMAC1.FDR E820 4250h, PTPEDMAC.FDR E820 4450h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|----------|----|----|----|----|----|----|----|----------|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | | | TFD[4:0] | | | — | — | — | | | RFD[4:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|----------|---------------------|--|-----|
| b4 to b0 | RFD[4:0] | Receive FIFO Depth | b4 b0 01111: 4096 bytes Settings other than above are prohibited. | R/W |
| b7 to b5 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b12 to b8 | TFD[4:0] | Transmit FIFO Depth | b12 b8 00111: 2048 bytes Settings other than above are prohibited. | R/W |
| b31 to b13 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The FDR register sets the transmit and receive FIFO depths.

Set this register to 0000 070Fh before starting transmission and reception.

29.2.14 Receive Method Control Register (RMCR)

Address: EDMAC0.RMCR E820 4058h, EDMAC1.RMCR E820 4258h, PTPEDMAC.RMCR E820 4458h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|-----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | RNR |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|-----------------------|--|-----|
| b0 | RNR | Receive Request Reset | 0: EDRRR.RR bit (receive request bit) is set to 0 when one frame has been received. 1: EDRRR.RR bit (receive request bit) is not set to 0 when one frame has been received. | R/W |
| b31 to b1 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The RMCR register sets how to control the EDRRR.RR bit when receiving a frame.

Since the EDRRR.RR bit becomes 0 when one frame has been received while the RNR bit is 0, the RR bit needs to be set to 1 by software to receive the subsequent frame.

Since the EDRRR.RR bit does not become 0 when one frame has been received while the RNR bit is 1, the EDMAC reads the next receive descriptor and continues receiving frames. It is recommended to set the RNR bit to 1 when receiving data continuously.

Set the RMCR register while the EDRRR.RR bit is 0.

29.2.15 Transmit FIFO Underflow Counter (TFUCR)

Address: EDMAC0.TFUCR E820 4064h, EDMAC1.TFUCR E820 4264h, PTPEDMAC.TFUCR E820 4464h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-------------|-------------------------------|---|-----|
| b15 to b0 | UNDER[15:0] | Transmit FIFO Underflow Count | These bits indicate how many times the transmit FIFO has underflowed. The counter stops when the counter value reaches FFFFh. | R/W |
| b31 to b16 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The TFUCR register indicates how many times the transmit FIFO has underflowed.
When writing any value to the TFUCR register, the counter value becomes 0.

29.2.16 Receive FIFO Overflow Counter (RFOCR)

Address: EDMAC0.RFOCR E820 4068h, EDMAC1.RFOCR E820 4268h, PTPEDMAC.RFOCR E820 4468h

| Bit | Symbol | Bit Name | Description | R/W |
|------------|------------|-----------------------------|---|-----|
| b15 to b0 | OVER[15:0] | Receive FIFO Overflow Count | These bits indicate how many times the receive FIFO has overflowed. The counter stops when the counter value reaches FFFFh. | R/W |
| b31 to b16 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The RFOCR register indicates how many times the receive FIFO has overflowed.
When writing any value to the RFOCR register, the counter value becomes 0.

29.2.17 Independent Output Signal Setting Register (IOSR)

Address: EDMAC0.IOSR E820 406Ch, EDMAC1.IOSR E820 426Ch

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|----|----|-----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | ELB |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|------------------------|---|-----|
| b0 | ELB | External Loopback Mode | 0: The ETn_EXOUT pin outputs low. 1: The ETn_EXOUT pin outputs high. | R/W |
| b31 to b1 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The IOSR register selects the output level of the ETHERC external output pin (ETn_EXOUT) in external loopback mode.

The ELB bit value is output to the ETn_EXOUT pin of the MCU as is, which can be used to set loopback mode for the PHY-LSI. To use the loopback function of the PHY-LSI through this register, the PHY-LSI needs to be provided with the pin to be connected to the ETn_EXOUT pin.

29.2.18 Flow Control Start FIFO Threshold Setting Register (FCFTR)

Address: EDMAC0.FCFTR E820 4070h, EDMAC1.FCFTR E820 4270h, PTPEDMAC.FCFTR E820 4470h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----------|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | RFFO[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|----|----|-----------|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | RFDO[2:0] | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|---|--|-----|
| b2 to b0 | RFDO[2:0] | Receive FIFO Data PAUSE Output Threshold | b2 b0 0 0 0: When 224 (256 - 32) bytes of data is stored in the receive FIFO. 0 0 1: When 480 (512 - 32) bytes of data is stored in the receive FIFO. : 1 1 0: When 1760 (1792 - 32) bytes of data is stored in the receive FIFO. 1 1 1: When 2016 (2048 - 32) bytes of data is stored in the receive FIFO. | R/W |
| b15 to b3 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b18 to b16 | RFFO[2:0] | Receive FIFO Frame PAUSE Output Threshold | b18 b16 0 0 0: When 2 receive frames have been stored in the receive FIFO. 0 0 1: When 4 receive frames have been stored in the receive FIFO. 0 1 0: When 6 receive frames have been stored in the receive FIFO. : 1 1 0: When 14 receive frames have been stored in the receive FIFO. 1 1 1: When 16 receive frames have been stored in the receive FIFO. | R/W |
| b31 to b19 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The FCFTR register sets the ETHERC flow control (sets the threshold for automatically transmitting a PAUSE frame). The threshold can be set using the data size (RFDO[2:0] bits) and the number of frames (RFFO[2:0] bits) stored in the receive FIFO. The flow control starts when the stored data size or number of stored frames reaches its threshold.

29.2.19 Receive Data Padding Insert Register (RPADIR)

Address: EDMAC0.RPADIR E820 4078h, EDMAC1.RPADIR E820 4278h, PTPEDMAC.RPADIR E820 4478h

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----------|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | PADS[1:0] | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|-----------|----|----|----|----|----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | PADR[5:0] | | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|------------|-----------|--------------|---|-----|
| b5 to b0 | PADR[5:0] | Padding Slot | b5 b0 00h: Padding is inserted at the head of received data. 01h: Padding is inserted between the 1st byte and 2nd byte of received data. : 3Eh: Padding is inserted between the 62nd byte and 63rd byte of received data. 3Fh: Padding is inserted between the 63rd byte and 64th byte of received data | R/W |
| b15 to b6 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b17, b16 | PADS[1:0] | Padding Size | b17 b16 0 0: No padding is inserted. 0 1: 1 byte is inserted. 1 0: 2 bytes are inserted. 1 1: 3 bytes are inserted. | R/W |
| b31 to b18 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The RPADIR register sets insertion of padding for received data. The padding value is 00h.

Set the EDMR.SWR bit to 1 to reset before rewriting the RPADIR register.

29.2.20 Transmit Interrupt Setting Register (TRIMD)

Address: EDMAC0.TRIMD E820 407Ch, EDMAC1.TRIMD E820 427Ch, PTPEDMAC.TRIMD E820 447Ch

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | b31 | b30 | b29 | b28 | b27 | b26 | b25 | b24 | b23 | b22 | b21 | b20 | b19 | b18 | b17 | b16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| | | | | | | | | | | | | | | | | |
|--------------------|-----|-----|-----|-----|-----|-----|----|----|----|----|----|-----|----|----|----|-----|
| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
| | — | — | — | — | — | — | — | — | — | — | — | TIM | — | — | — | TIS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|---------------------------|--|-----|
| b0 | TIS | Transmit Interrupt Enable | 0: Transmit Interrupt is disabled. 1: Transmit Interrupt is enabled. Set the EESR.TWB flag to 1 in the mode selected by the TIM bit to notify an interrupt. | R/W |
| b3 to b1 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b4 | TIM | Transmit Interrupt Mode | 0: Transmission complete interrupt mode An interrupt occurs when a frame has been transmitted. 1: Write-back complete interrupt mode An interrupt occurs when write-back to the transmit descriptor has been completed while the TWBI bit is 1. | R/W |
| b31 to b5 | — | Reserved | The read value is 0. The write value should be 0. | R/W |

The TRIMD register sets transmit interrupt mode and enables/disables the transmit interrupt.

When the condition set in this register is satisfied, the EESR.TWB flag becomes 1, and an interrupt request is output when the EESIPR.TWBIP bit is 1.

29.2.21 Receive Buffer Write Address Register (RBWAR)

Address: EDMAC0.RBWAR E820 40C8h, EDMAC1.RBWAR E820 42C8h, PTPEDMAC.RBWAR E820 44C8h

The RBWAR register indicates the last address that the EDMAC has written data to when writing to the receive buffer. Refer to the address indicated by the RBWAR register to recognize which address in the receive buffer the EDMAC is writing data to. Note that the address that the EDMAC is outputting to the receive buffer may not match the read value of the RBWAR register during data reception.

The RBWAR register is read only. Do not write to this register.

29.2.22 Receive Descriptor Fetch Address Register (RDFAR)

Address: EDMAC0.RDFAR E820 40CCh, EDMAC1.RDFAR E820 42CCh, PTPEDMAC.RDFAR E820 44CCh

The RDFAR register indicates the start address of the last fetched receive descriptor when the EDMAC fetches descriptor information from the receive descriptor.

Refer to the address indicated by the RDFAR register to recognize which receive descriptor information the EDMAC is using for the current processing. Note that the address of the receive descriptor that the EDMAC fetches may not match the read value of the RDFAR register during data reception.

The RDFAR is read only. Do not write to this register.

29.2.23 Transmit Buffer Read Address Register (TBRAR)

Address: EDMAC0.TBRAR E820 40D4h, EDMAC1.TBRAR E820 42D4h, PTPEDMAC.TBRAR E820 44D4h

The TBRAR register indicates the last address that the EDMAC has read data from when reading data from the transmit buffer.

Refer to the address indicated by the TBRAR register to recognize which address in the transmit buffer the EDMAC is reading from. Note that the address that the EDMAC is outputting to the transmit buffer may not match the read value of the TBRAR register.

The TBRAR register is read only. Do not write to this register.

29.2.24 Transmit Descriptor Fetch Address Register (TDFAR)

Address: EDMAC0.TDFAR E820 40D8h, EDMAC1.TDFAR E820 42D8h, PTPEDMAC.TDFAR E820 44D8h

The TDFAR register indicates the start address of the last fetched transmit descriptor when the EDMAC fetches descriptor information from the transmit descriptor.

Refer to the address indicated by the TDFAR register to recognize which transmit descriptor information the EDMAC is using for the current processing. Note that the address of the transmit descriptor that the EDMAC fetches may not match the read value of the TDFAR register.

The TDFAR is read only. Do not write to this register.

29.3 Operation

The EDMAC transfers data according to the information written in the descriptor. Two types of descriptors are provided: transmit descriptor and receive descriptor. A descriptor includes the buffer size, address, and transmit/receive status. The EDMAC transmits or receives data continuously using sequentially arranged descriptors (descriptor list).

29.3.1 Descriptor Lists and Data Buffers

To transfer data using the EDMAC, create the transmit and receive descriptor lists on the memory, set the start address of the transmit descriptor list to the TDLAR register, and set the start address of the receive descriptor list to the RDLAR register. Also, transmit and receive buffers corresponding to the each descriptor are required.

Align the descriptor list on the appropriate address boundary according to the descriptor length set by the EDMR.DL[1:0] bits. The transmit buffer can be aligned on a long word boundary, word boundary, or byte boundary. When the valid transmit buffer size is 16 bytes or less, align it on a 32-byte boundary. Align the receive buffer on a 32-byte boundary. Set different addresses for the transmit and receive descriptors and buffers for EDMAC0, EDMAC1, and the PTPEDMAC.

29.3.1.1 Transmit Descriptor

Figure 29.3 shows the relation between a transmit descriptor and transmit buffer. A transmit descriptor consists of TD0 to TD2. The transmit frame and transmit buffer configuration can be selected from one buffer per frame (single-buffer frame transmission) or multiple buffers per frame (multi-buffer frame transmission) by setting the transmit descriptor.

Figure 29.3 Relation between a Transmit Descriptor and Transmit Buffer

(1) Transmit Descriptor 0 (TD0)

| Bit | Symbol | Bit Name | Description | R/W |
|------------------|-------------|--------------------------------------|---|-----|
| <u>b25 to b0</u> | <u>TFS</u> | Transmit Frame Status | Set all bits to 0 when creating a descriptor. After write-back, the bits indicate the following: [for EDMACn] TFS25 to TFS9: Reserved TFS8: Transmit abort is detected (the value is equivalent to the EESR.TABT flag). TFS7 to TFS4: Reserved TFS3: No carrier is detected (the value is equivalent to the EESR.CND flag). TFS2: Loss of carrier is detected (the value is equivalent to the EESR.DLC flag). TFS1: Late collision during transmission is detected (the value is equivalent to the EESR.CD flag). TFS0: Transmit retry over (the value is equivalent to the EESR.TRO flag) When each bit becomes 1, it indicates that the corresponding error has occurred during frame transmission. When any of the TFS bits becomes 1, the TFE bit also becomes 1. When any bit from TFS3 to TFS0 becomes 1, the TFS8 bit also becomes 1. [for the PTPEDMAC] TFS25 to TFS9: Reserved TFS8: Transmit abort is detected (the value is equivalent to the EESR.TABT flag). TFS7 to TFS1: Reserved TFS0: The transmission source MAC address of the transmit frame data does not match the set value (the value is equivalent to the EESR.MACE flag). When each bit becomes 1, it indicates that the corresponding error has occurred during frame transmission. When any of the TFS bits becomes 1, the TFE bit also becomes 1. When TFS0 becomes 1, TFS8 also becomes 1. | R/W |
| b26 | TWBI | Write-Back Complete Interrupt Enable | 0: Interrupt does not occur when write-back to this descriptor has been completed. 1: Interrupt occurs when write-back to this descriptor has been completed. | R/W |
| <u>b27</u> | <u>TFE</u> | Transmit Frame Error | 0: Frame transmission is successfully completed. 1: An error occurs during frame transmission (transmission aborted). | R/W |
| b29, b28 | TFP[1:0] | Transmit Frame Position | b29 b28 0 0: Transmit buffer indicated by this descriptor is the middle of a transmit frame (frame information is incomplete). 0 1: Transmit buffer indicated by this descriptor is the end of a transmit frame (frame information is complete). 1 0: Transmit buffer indicated by this descriptor is the head of a transmit frame (frame information is incomplete.) 1 1: Transmit buffer indicated by this descriptor is all of a transmit frame (one buffer per frame). | R/W |
| b30 | TDLE | Transmit Descriptor List End | When this bit is 1, it indicates that this descriptor is the last descriptor of the descriptor list. | R/W |
| <u>b31</u> | <u>IACI</u> | Transmit Descriptor Valid | This bit indicates that this descriptor is valid. | R/W |

Note: Bits for write-back are underlined.

TD0 indicates the transmit frame settings, and the status after transmission.

TWBI Bit (Write-Back Complete Interrupt Enable)

This bit setting is valid, when the TRIMD.TIM bit is 1.

To generate an interrupt request, the TRIMD.TIS and EESIPR.TWBIP bits must be set to 1.

TFE Bit (Transmit Frame Error)

When the TFE bit is 1, it indicates that one or more of the TFS bits is 1.

TFP[1:0] Bits (Transmit Frame Position)

The TFP[1:0] bits indicate which part of a transmit frame corresponds to the transmit buffer indicated by this descriptor. The TFP[1:0] and TD1.TBL bit settings must be logically consistent in the previous and next descriptors.

TACT Bit (Transmit Descriptor Valid)

The TACT bit indicates that this descriptor is valid. The TACT bit is set to 1 by software. This bit becomes 0 when the transmit frame has been transferred or when the transmission is aborted.

(2) Transmit Descriptor 1 (TD1)

| Bit | Symbol | Bit Name | Description | R/W |
|------------|--------|------------------------|---|-----|
| b15 to b0 | — | Reserved | The read value is 0. The write value should be 0. | R/W |
| b31 to b16 | TBL | Transmit Buffer Length | Set a valid byte length of the corresponding transmit buffer. Set a value equal to or greater than 1. | R/W |

TD1 is used to set a valid byte length of the transmit buffer.

(3) Transmit Descriptor 2 (TD2)

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|-------------------------|--|-----|
| b31 to b0 | TBA | Transmit Buffer Address | Set the start address of the transmit buffer. When the TD1.TBL bit value is 1 to 16 bytes, align it on a 32-byte boundary. | R/W |

TD2 is used to set the start address of the transmit buffer.

29.3.1.2 Receive Descriptor

Figure 29.4 shows the relation between a receive descriptor and receive buffer. The receive frame and receive buffer configuration can be selected from one buffer per frame (single-buffer frame transmission) or multiple buffers per frame (multi-buffer frame transmission) by setting the receive descriptor. If the receive buffer length (RBL) is set to 0, operation indicated by the descriptor is not guaranteed.

Figure 29.4 Relation between Receive Descriptor and Receive Buffer

(1) Receive Descriptor 0 (RD0)

| Bit | Symbol | Bit Name | Description | R/W |
|------------------|-----------------|-----------------------------|--|-----|
| <u>b26 to b0</u> | <u>RFS</u> | Receive Frame Status | <p>Set all bits to 0 when creating a descriptor. After write-back, the bits indicate the following:</p> <p>[for EDMACn]</p> <p>RFS26 to RFS10: Reserved</p> <p>RFS9: Receive FIFO overflow (the value is equivalent to the EESR.RFOF flag)</p> <p>RFS8: Receive abort is detected (the value is equivalent to the EESR.RABT flag).</p> <p>RFS7: Multicast address frame is received (the value is equivalent to the EESR.RMAF flag).</p> <p>RFS6 and RFS5: Reserved</p> <p>RFS4: Alignment error is detected (the value is equivalent to the EESR.RRF flag).</p> <p>RFS3: Frame-too-long error (the value is equivalent to the EESR.RTLF flag)</p> <p>RFS2: Frame-too-short error (the value is equivalent to the EESR.RTSF flag)</p> <p>RFS1: PHY-LSI receive error (the value is equivalent to the EESR.PRE flag)</p> <p>RFS0: CRC error (the value is equivalent to the EESR.CERF flag)</p> <p>When each bit becomes 1, it indicates that the corresponding error has occurred during frame reception. When any of the RFS bits becomes 1, the RFE bit also becomes 1 (set the TRSCER register to select whether bits RFS7 and RFS4 are reflected in the RFE bit). When any bit from RFS3 to RFS0 becomes 1, the RFS8 bit also becomes 1.</p> <p>[for the PTPEDMAC]</p> <p>RFS26 to RFS10: Reserved</p> <p>RFS9: Receive FIFO overflow (the value is equivalent to the EESR.RFOF flag)</p> <p>RFS8: Reserved</p> <p>RFS7: Receive port (the value is equivalent to the EESR.RPORT flag)</p> <p>RFS4: PTPV2 packet is received (the value is equivalent to the EESR.PVER flag).</p> <p>The PTPEDMAC can receive only PTP packets. If a non-PTP packet is received, the packet is not transferred to the PTPEDMAC, and it is discarded.</p> <p>RFS3 to RFS0: Type of the received PTP message (the value is equivalent to the EESR.TYPE[3:0] flags)</p> <p>Each bit indicates the status of the received frame.</p> | R/W |
| <u>b27</u> | <u>RFE</u> | Receive Frame Error | <p>[for EDMACn]</p> <p>0: No error has occurred in the received frame.</p> <p>1: An error has occurred in the received frame.</p> <p>[for the PTPEDMAC]</p> <p>Reserved</p> | R/W |
| <u>b29, b28</u> | <u>RFP[1:0]</u> | Receive Frame Position | <p>b29 b28</p> <p>0 0: Receive buffer indicated by this descriptor is the middle of a receive frame (frame information is incomplete).</p> <p>0 1: Receive buffer indicated by this descriptor is the end of a receive frame (frame information is complete).</p> <p>1 0: Receive buffer indicated by this descriptor is the head of a receive frame (frame information is incomplete).</p> <p>1 1: Receive buffer indicated by this descriptor is all of a receive frame (one buffer per frame).</p> | R/W |
| b30 | RDLE | Receive Descriptor List End | When this bit is 1, it indicates that this descriptor is the last one of the descriptor list. | R/W |
| <u>b31</u> | <u>RACT</u> | Receive Descriptor Valid | Indicates that this descriptor is valid. | R/W |

Note: Bits for write-back are underlined.

RD0 indicates the receive frame status.

RFE Bit (Receive Frame Error)

When the RFE bit is 1, it indicates that one or more of the RFS bits is 1 (set the TRSCER register to select whether bits RFS7 and RFS4 of EDMACn are reflected in the RFE bit).

RFP[1:0] Bits (Receive Frame Position)

The RFP[1:0] bits indicate which part of a receive frame corresponds to the receive buffer indicated by this descriptor.

RACT Bit (Receive Descriptor Valid)

The RACT bit indicates that this descriptor is valid. The RACT bit is set to 1 by software. This bit becomes 0 when all data has been transferred to the receive buffer indicated by RD2 or when the receive buffer becomes full.

(2) Receive Descriptor 1 (RD1)

| Bit | Symbol | Bit Name | Description | R/W |
|------------------|------------|-----------------------|---|-----|
| <u>b15 to b0</u> | <u>RFL</u> | Receive Frame Length | These bits indicate the length (number of bytes) of the receive frame stored in the buffer. The number of bytes for padding set by the RPADIR register is not included. These bits are written back to the descriptor corresponding to the end of a frame. | R/W |
| b31 to b16 | RBL | Receive Buffer Length | These bits indicate the byte length of the corresponding receive buffer. Set an integral multiple of 32 as the buffer length. | R/W |

Note: Bits for write-back are underlined.

RD1 indicates the receive buffer length. When reception is completed, the receive frame length is written back.

(3) Receive Descriptor 2 (RD2)

| Bit | Symbol | Bit Name | Description | R/W |
|-----------|--------|------------------------|--|-----|
| b31 to b0 | RBA | Receive Buffer Address | These bits indicate the start address of the receive buffer. Align the buffer address on a 32-byte boundary. | R/W |

RD2 indicates the start address of the receive buffer.

29.3.2 Transmission

When setting the EDTRR.TR bit to 1 while the ETHERCn.ECMR.TE bit is 1, the EDMAC reads the descriptor following the previously used descriptor in the transmit descriptor list (or the descriptor indicated by the TDLAR register after a reset). When the TACT bit is 1 in the transmit descriptor (TD0), the EDMAC sequentially reads transmit data from the start address of the transmit buffer indicated by transmit descriptor 2 (TD2) and transfers them to the ETHERC via the transmit FIFO. The ETHERC creates a transmit frame and starts transmission to the MII/RMII. When all data indicated by the TD1.TBL bit is transferred, write-back is performed according to the TD0.TFP[1:0] bits as follows:

- When the TD0.TFP[1:0] bits are 00b or 10b (frame information is incomplete), the TD0.TACT bit is written back.
- When the TD0.TFP[1:0] bits are 01b or 11b (frame information is complete), bits TD0.TACT, TD0.TFS, and TD0.TFE are written back.

When the TD0.TACT bit in the read descriptor is 1, the EDMAC continues reading descriptors and transmit frames. When the TD0.TACT bit in the read descriptor is 0, the EDMAC sets the EDTRR.TR bit to 0 and stops transmission.

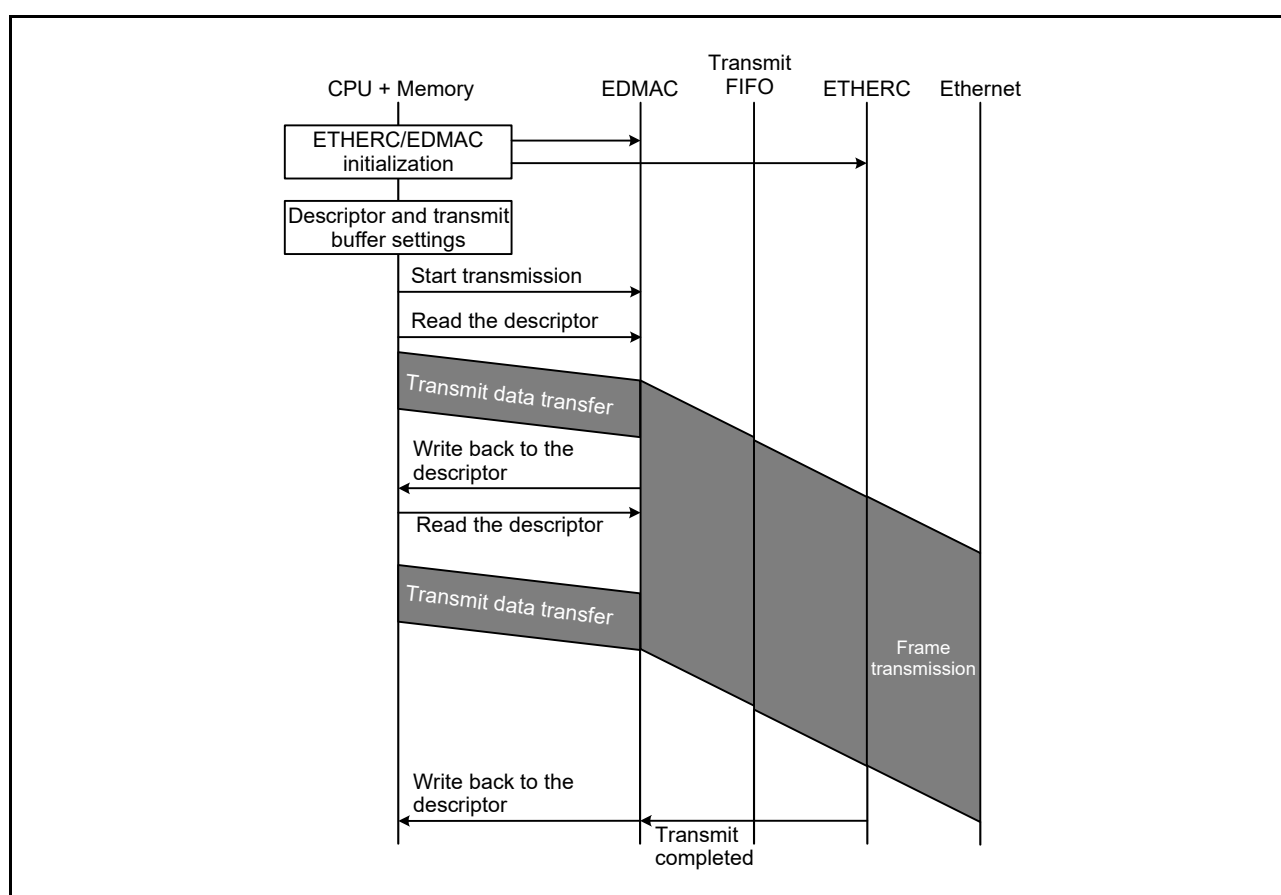

Figure 29.5 Example of Transmission Flow

29.3.3 Reception

When setting the EDRRR.RR bit to 1 while the ETHERCn.ECMR.RE bit is 1, the EDMAC reads the receive descriptor following the previously used descriptor (or descriptor indicated by the RDLAR register after a reset) and then waits for reception. While the RD0.RACT bit is 1, if the data stored to the receive FIFO is 32 bytes or more, or if the end byte of the frame is stored in the receive buffer, the EDMAC transfers data from the receive FIFO to the receive buffer indicated by receive descriptor 2 (RD2). If the data length of the received frame is longer than the buffer length set by the RBL bit in receive descriptor 1 (RD1), the EDMAC writes back 10b or 00b to the RD0.RFP[1:0] bits and 0 to the RD0.RACT bit when the receive buffer becomes full, and then the EDMAC reads the next data. After that, the EDMAC transfers data to another receive buffer. When the frame reception is completed or when the frame reception is aborted by an error, the EDMAC writes back 11b or 01b to the RD0.RFP[1:0] bits, 0 to the RD0.RACT bit, and the receive frame length to the RD1.RFL bit.*¹ When the RMC.RNR bit is 1, the EDMAC reads the next descriptor and waits for reception. When the RNR bit is 0, the EDMAC sets the EDRRR.RR bit to 0 and stops reception.

Note 1. If the reception is interrupted when the data stored in the FIFO is less than 16 times, the data in the FIFO are discarded without being transferred. At this time, the corresponding error flag does not also set to 1.

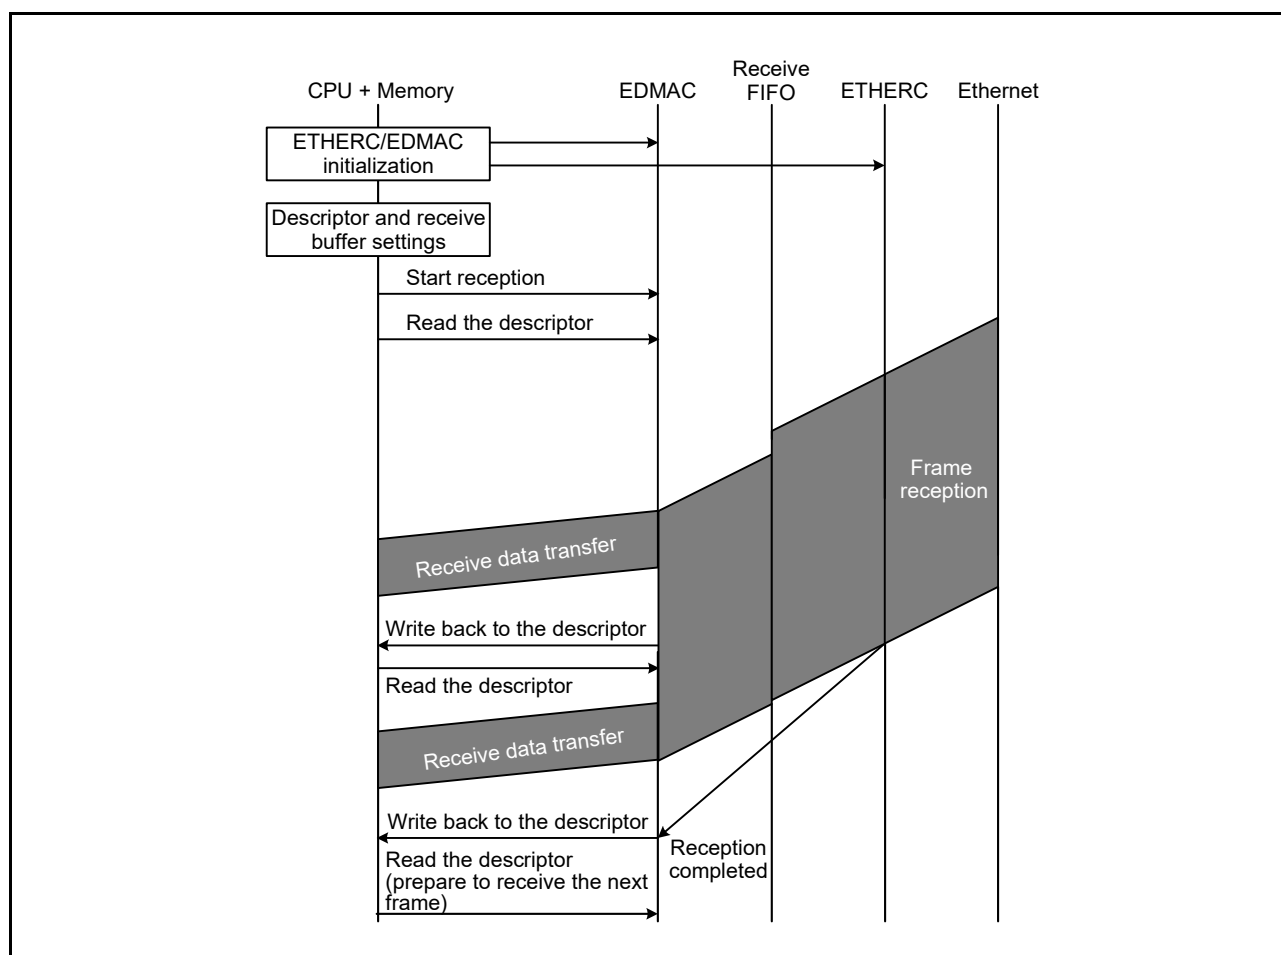

Figure 29.6 Example of Reception Flow

29.3.4 Multi-Buffer Frame Transmission

29.3.4.1 Error Processing While Transmitting a Multi-Buffer Frame

If an error occurs during multi-buffer frame transmission, the EDMAC performs the processing shown in Figure 29.7. In the figure, when the TACT bit of transmit descriptor 0 (TD0) is 0, the descriptor indicates that all data in the buffer has been successfully transmitted. When the TACT bit is 1, the descriptor indicates that data in the buffer has not yet been transmitted. If a frame transmit error ^{*1} occurs in the head or middle of the frame while the TD0.TACT bit is 1, the EDMAC stops data transmission from the transmit FIFO and EDMAC data transfer, and sets the TD0.TACT bit to 0. After that, the EDMAC reads the next descriptor to see if the descriptor indicates the middle of the frame (TD0.TFP[1:0] bits are 00b) or the end of the frame (TD0.TFP[1:0] bits are 01b). When the descriptor indicates the middle of the frame, the EDMAC sets the TD0.TACT bit to 0 and reads the next descriptor. When the descriptor indicates the end of the frame, the EDMAC not only sets the TD0.TACT bit to 0, but also writes back to bits TD0.TFE and TD0.TFS. After an error occurs, data in the buffer is not transmitted until write-back to the descriptor for the end of the frame. When the corresponding transmit error interrupt is enabled in the EESIPR register, an interrupt request is generated immediately after write-back to the descriptor for the end of the frame.

Note 1. For EDMACn, a transmit retry-over condition, late collision, or loss of carrier is detected, or a carrier is not detected. For the PTPEDMAC, the MAC address does not match the set value.

Figure 29.7 EDMAC Operation After a Transmit Error Occurs

29.3.4.2 Error Processing While Receiving a Multi-Buffer Frame

If an error occurs during multi-buffer frame reception, the EDMAC performs the processing shown in Figure 29.8

In the figure, when the RACT bit of receive descriptor 0 (RD0) is 0, the descriptor indicates that data has been successfully received in the buffer. When the RACT bit is 1, the descriptor indicates that data has not yet been received in the buffer. If a frame receive error*¹ occurs, the EDMAC stops receiving data of the frame, but it transfers data that has already been stored in the receive FIFO to the receive buffer.

When the receive buffer becomes full during transfer, the EDMAC sets the RACT bit to 0 and the RFP[1:0] bits to 10b or 00b and reads the next descriptor. After all data in the receive FIFO has been transferred, the EDMAC writes back the status to the descriptor.

When the corresponding receive error interrupt is enabled in the EESIPR register, an interrupt request is generated immediately after write-back to the descriptor. When there is a request to receive a new frame, the EDMAC continues reception using the descriptor following the descriptor where the error occurred.

Note 1. For EDMACn, a CRC error, PHY-LSI receive error, frame-too-short error, frame-too-long error, or alignment error is detected. For the PTPEDMAC, a parity error is detected.

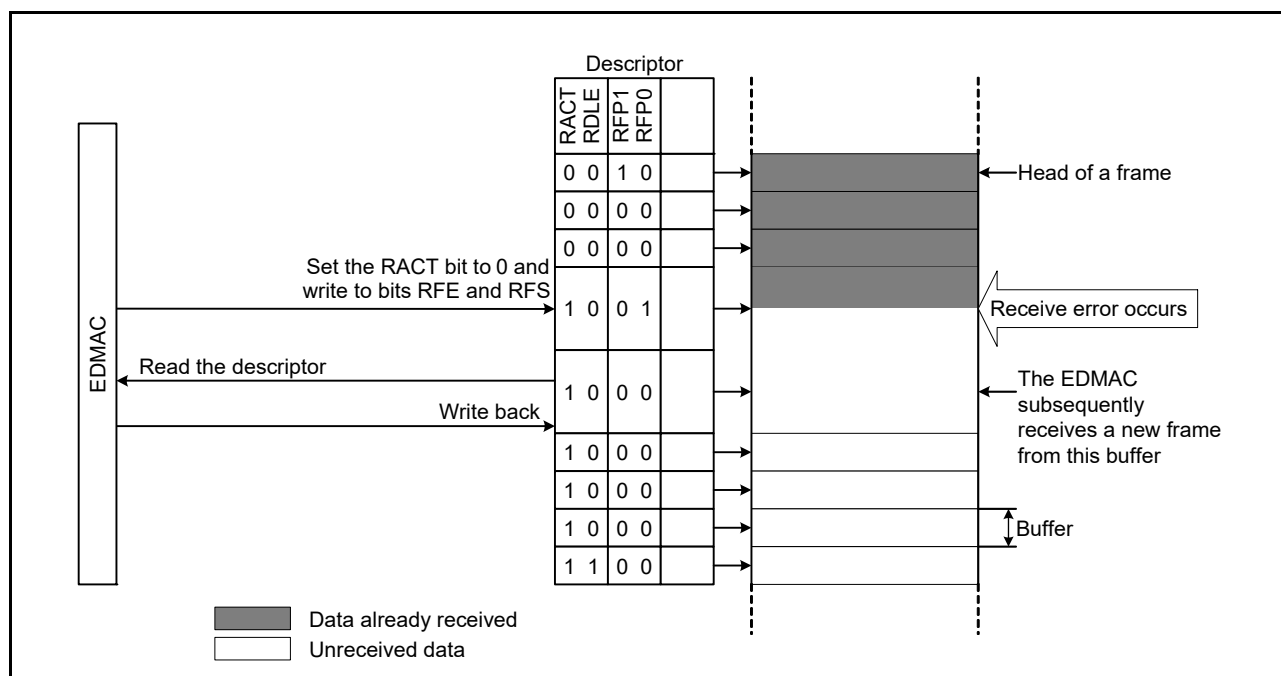

Figure 29.8 EDMAC Operation After a Receive Error Occurs

29.3.5 EDMAC Channel Priority

Priority of the three EDMAC channels (EDMAC0, EDMAC1, PTPEDMAC) is determined in a round-robin fashion. Each time transfer of one channel is completed, the channel becomes the lowest priority. This operation is shown in Figure 29.9. After a reset, the priority is EDMAC0 > EDMAC1 > PTPEDMAC.

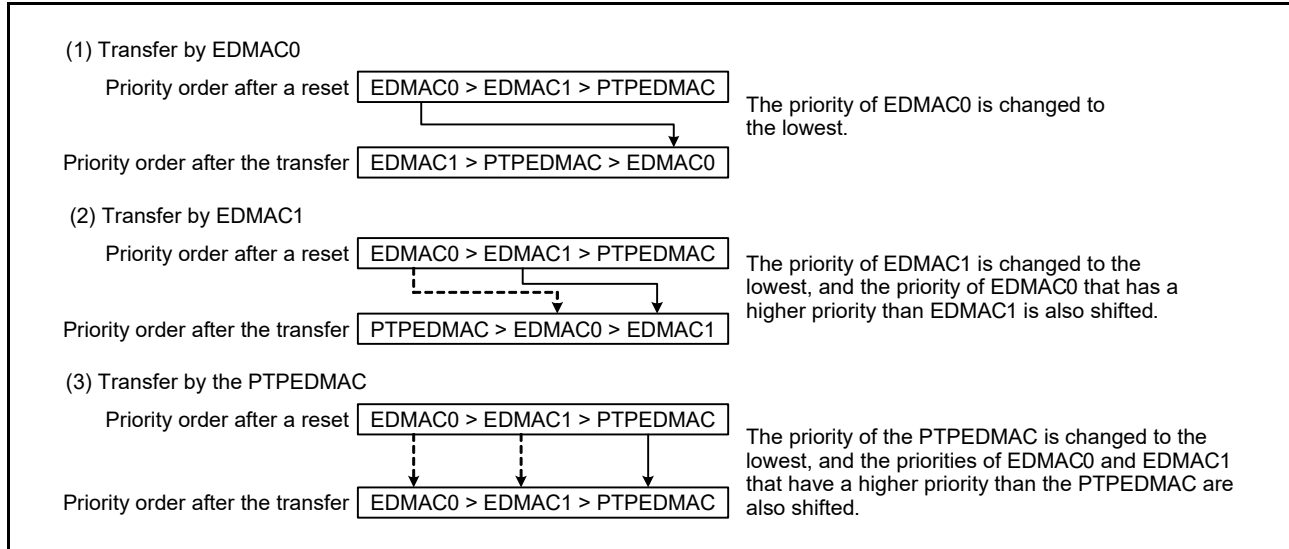

Figure 29.9 Operation in Round-Robin Fashion

Figure 29.10 shows change of the channel priority order when transfer requests are concurrently generated to EDMAC0 and the PTPEDMAC and a transfer request to the EDMAC1 while EDMAC0 is transferring data.

1. Transfer requests are concurrently generated to EDMAC0 and the PTPEDMAC.
2. Since EDMAC0 has a higher priority than the PTPEDMAC, EDMAC0 starts a transfer (PTPEDMAC waits to transfer).
3. A transfer request is generated to EDMAC1 during the transfer by EDMAC0 (EDMAC1 and the PTPEDMAC wait to transfer).
4. After EDMAC0 ends the transfer, the priority of EDMAC0 is changed to the lowest.
5. Since EDMAC1 has higher priority than the PTPEDMAC at this time, EDMAC1 starts a transfer (PTPEDMAC waits to transfer).
6. After EDMAC1 ends the transfer, the priority of EDMAC1 is changed to the lowest.
7. The PTPEDMAC starts a transfer.
8. After the PTPEDMAC ends the transfer, the priority of PTPEDMAC is changed to the lowest.

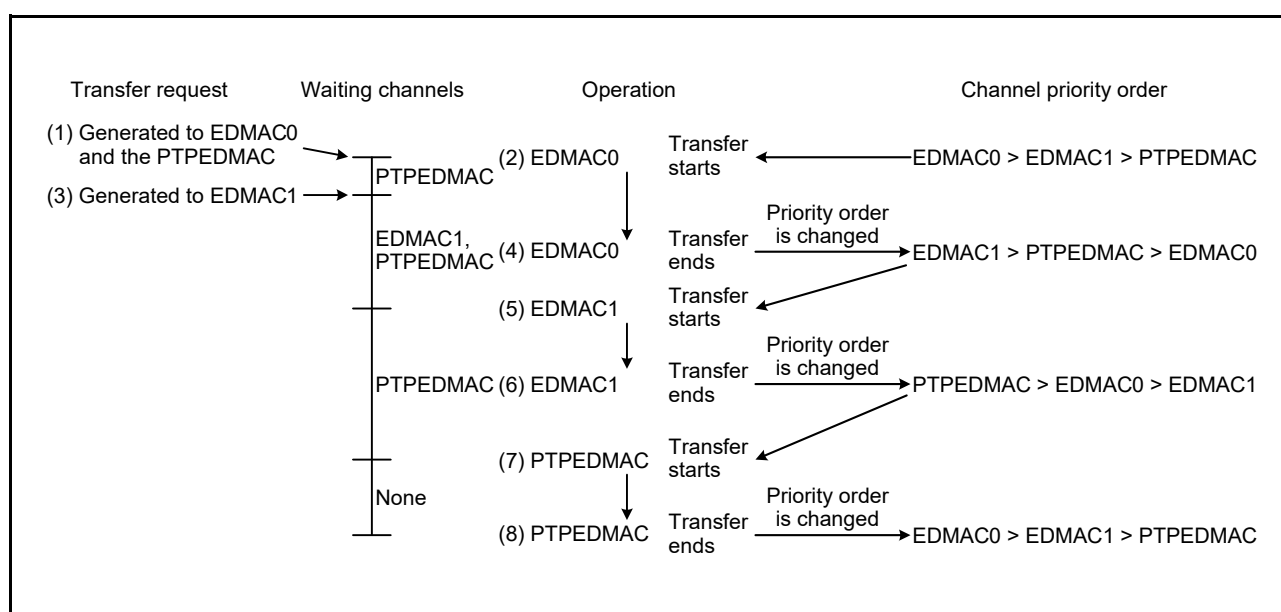

Figure 29.10 Channel Priority in Round-Robin Fashion

29.4 Interrupts

When any of the status flags in the EESR register becomes 1 while the corresponding interrupt request enable bit in the EESIPR register is 1, EDMACn outputs an EINTn interrupt request or the PTPEDMAC outputs a PINT interrupt request to the CPU.

29.5 Usage Notes

29.5.1 Setting the Module-Stop Function

The following bits in Standby Control Register 6 (STBCR6) are used to enable/disable the EDMAC operation.

- MSTP65 bit is used to enable/disable the ETHERC0 and the EDMAC0 operation.
- MSTP64 bit is used to enable/disable the ETHERC1 and the EDMAC1 operation.
- MSTP63 bit is used to enable/disable the EPTPC and the PTPEDMAC operation.

After a reset, the EDMAC is stopped. After exiting the module-stop state, registers can be accessed. Refer to [section 52, Power-Down Modes](#) for details.

29.5.2 Stopping the EDMAC during Operations

When stopping EDMAC operation by using a sleep instruction or module-stop function while the EDMAC is running, confirm that bits EDTRR.TR and EDRRR.RR are 0. If the EDMAC is stopped while the EDTRR.TR or EDRRR.RR bit 1, the data for the frame that is being transmitted or received may not be complete, and EDMAC operation after exiting the sleep mode or module-stop state is not guaranteed.

30. A/D Converter

30.1 Overview

This LSI incorporates one unit of a 12-bit successive approximation A/D converter, up to eight analog input channels are selectable.

The A/D conversion accuracy is selectable from 12-bit conversion, and conversion to a digital value can be performed with the relationship between speed and resolution optimized.

The A/D converter has three operating modes: single scan mode in which the analog inputs of up to 8 channels arbitrarily selected are converted for only once in ascending channel order; continuous scan mode in which the analog inputs of up to 8 channels arbitrarily selected are continuously converted in ascending channel order; and group scan mode in which up to 8 channels of the analog inputs are arbitrarily divided into two groups (group A and group B) or three groups (group A, group B, and group C) and converted in ascending channel order in each group.

In group scan mode, either of two groups (group A, B) and three groups (groups A, B, C) must be selected.

The scan start conditions (trigger) for each group (A, B or A, B, C) can be independently selected, and scan for each group (A, B or A, B, C) can be started at different timing.

In group priority control in group scan mode, along with operation as described above, if a request to start scan for a priority group is accepted during scanning for a low priority group, the scanning for the low priority group is discontinued and scan for the priority group is started.

The priority order of group priority control is group A > group B > group C.

In group priority control, if a request to start group B scan is accepted during group C scanning, the group C scanning is interrupted and the group B scan is started. If a request to start group A scan is accepted during group C scanning, the group C scanning is interrupted and group A scan is started. Similarly, if a request to start group A scan is accepted during group B scanning, the group B scanning is interrupted and group A scan is started.

Additionally, scan for the interrupted group can be restarted after the scan for the priority group has completed.

In double trigger mode, one analog input channel arbitrarily selected is converted in single scan mode or group scan mode (group A), and the resulting data of A/D conversion started by the first and second synchronous triggers are stored into different registers (duplication of A/D conversion data).

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages internally generated in the A/D converter is converted.

The compare function specifies the upper-side reference value for window A and lower-side reference value for window B and outputs an interrupt when the A/D-converted value of the selected channel meets the comparison conditions. Furthermore, the comparator operation to compare the A/D-converted value with the lower-side reference value is also available.

Table 30.1 lists the specifications of the A/D converter and Table 30.2 indicates the functions of the A/D converter.

Table 30.1 Specifications of A/D Converter

| Item | Specifications |
|-------------------------------------|--|
| Input channels | Eight channels |
| A/D conversion method | Successive approximation method |
| Resolution | 12 bits / 10 bits / 8 bits selectable |
| Conversion time | 1 μ s per channel (when A/D conversion clock ADCLK = 33 MHz) |
| A/D conversion clock | Peripheral module clock PCLK (= P1 ϕ) and A/D conversion clock ADCLK (= P0 ϕ) can be set so that the frequency division ratio should be one of the following. PCLK to ADCLK frequency division ratio = 1:1, 1:2 Each clock is set using the clock pulse generator. |
| Data registers | <ul style="list-style-type: none"> 8 registers for analog input, 1 for A/D-converted data duplication in double trigger mode, 2 for A/D-converted data duplication during extended operation in double trigger mode, and 1 register for self-diagnosis. The results of A/D conversion are stored in the A/D data registers. 8-, 10-, and 12-bit accuracy conversion for the results of A/D conversion The value obtained by adding up A/D-converted results is stored as a value in the number of bit for conversion accuracy + 2 bits*³ in the A/D data registers in A/D-converted value addition mode. Double trigger mode (selectable in single scan and group scan modes): The first piece of A/D-converted analog-input data on one selected channel is stored in the data register for the channel, and the second piece is stored in the duplication register. Extended operation in double trigger mode (available for specific triggers): A/D-converted analog-input data on one selected channel is stored in the duplication register that is prepared for each type of trigger. |
| Operating modes | <ul style="list-style-type: none"> Single scan mode: <ul style="list-style-type: none"> - A/D conversion is performed only once on the analog inputs of up to 8 channels arbitrarily selected. Continuous scan mode: <ul style="list-style-type: none"> - A/D conversion is performed repeatedly on the analog inputs of up to 8 channels arbitrarily selected. Group scan mode: <ul style="list-style-type: none"> - Two (group A, B) or three (group A, B, C) can be selected for the number of groups to be used. (When the number of groups is two, only the combination of group A and group B can be selected.) - Analog inputs of up to 8 channels arbitrarily selected are divided into group A and group B, or group A, group B, and group C, and A/D conversion of the analog input selected on a group basis is performed only once. - The conditions for scanning start of group A, group B and group C (trigger) can be independently selected, thus allowing A/D conversion of group A, group B, and group C to be started independently. Group scan mode (when group priority is selected): <ul style="list-style-type: none"> - If a trigger for a priority group occurs during scanning for a low priority group, the scanning for the low priority group is interrupted and scan for the priority group is started. The priority order is group A (high) > group B > group C (low). - Whether to re-execute (rescan) the scan for the low priority group after the scan for the priority group is completed can be set. Additionally, whether to start rescan from the head of the selected channels or from the channel on which A/D conversion has not finished can be selected. |
| Conditions for A/D conversion start | <ul style="list-style-type: none"> Software trigger Synchronous trigger Trigger by the multi-function timer pulse unit 3 (MTU3a) and the general-purpose PWM timer (GPT). Asynchronous trigger A/D conversion can be triggered by the ADTRG# external trigger pin. |

Note 1. To set ADTRG# as the trigger to start A/D conversion, set the general I/O function. See section 51, GPIO for details.

Table 30.3 lists the I/O pins of the A/D converter.

Table 30.3 I/O Pins of A/D Converter

| Pin Name | I/O | Name | Function |
|----------------|-------|--|--|
| AN007 to AN000 | Input | Analog input pins | Analog input pin 0 to 7 |
| ADTRG# | Input | A/D conversion trigger input | External trigger input pin for starting A/D conversion |
| AVcc | Input | Analog power supply / Analog reference voltage | A/D converter power supply and Analog reference voltage supply pin |
| AVss | Input | Analog ground | A/D converter ground pin |

30.2 Register Descriptions

Table 30.4 shows the register list of this module.

Table 30.4 List of registers of this A/D Converter

| Name | Symbol | Value after reset | Address | Access size |
|---|-----------|-------------------|------------|-------------|
| A/D Control Register | ADCSR | 0000h | E800_5800h | 16 |
| A/D Channel Select Register A0 | ADANSA0 | 0000h | E800_5804h | 16 |
| A/D-Converted Value Addition/Average Mode Select Register 0 | ADADS0 | 0000h | E800_5808h | 16 |
| A/D-Converted Value Addition/Average Count Select Register | ADADC | 00h | E800_580Ch | 8 |
| A/D Control Extended Register | ADCER | 0000h | E800_580Eh | 16 |
| A/D Start Trigger Select Register | ADSTRGR | 0000h | E800_5810h | 16 |
| A/D Channel Select Register B0 | ADANSB0 | 0000h | E800_5814h | 16 |
| A/D Data Duplication Register | ADDBLDR | 0000h | E800_5818h | 16 |
| A/D Self-Diagnosis Data Register | ADRD | 0000h | E800_581Eh | 16 |
| A/D Data Register 0 | ADDR0 | 0000h | E800_5820h | 16 |
| A/D Data Register 1 | ADDR1 | 0000h | E800_5822h | 16 |
| A/D Data Register 2 | ADDR2 | 0000h | E800_5824h | 16 |
| A/D Data Register 3 | ADDR3 | 0000h | E800_5826h | 16 |
| A/D Data Register 4 | ADDR4 | 0000h | E800_5828h | 16 |
| A/D Data Register 5 | ADDR5 | 0000h | E800_582Ah | 16 |
| A/D Data Register 6 | ADDR6 | 0000h | E800_582Ch | 16 |
| A/D Data Register 7 | ADDR7 | 0000h | E800_582Eh | 16 |
| A/D Disconnection Detection Control Register | ADDISCR | 00h | E800_587Ah | 8 |
| A/D Group Scan Priority Control Register | ADGSPCR | 0000h | E800_5880h | 16 |
| A/D Data Duplication Register A | ADDBLDRA | 0000h | E800_5884h | 16 |
| A/D Data Duplication Register B | ADDBLDRB | 0000h | E800_5886h | 16 |
| A/D Compare Function AB Status Monitor Register | ADWINMON | 00h | E800_588Ch | 8 |
| A/D Compare Control Register | ADCMPCR | 0000h | E800_5890h | 16 |
| A/D Compare Function Window-A Channel Selection Register 0 | ADCMANSR0 | 0000h | E800_5894h | 16 |
| A/D Compare Function Window-A Comparison Condition Setting Register 0 | ADCMPLR0 | 0000h | E800_5898h | 16 |
| A/D Compare Function Window-A Lower Level Setting Register | ADCMPDR0 | 0000h | E800_589Ch | 16 |
| A/D Compare Function Window-A Upper Level Setting Register | ADCMPDR1 | 0000h | E800_589Eh | 16 |
| A/D Compare Function Window-A Channel Status Register 0 | ADCMPSR0 | 0000h | E800_58A0h | 16 |
| A/D Compare Function Window-B Channel Selection Register | ADCMPBNSR | 00h | E800_58A6h | 8 |
| A/D Compare Function Window-B Lower Level Setting Register | ADWINLLB | 0000h | E800_58A8h | 16 |
| A/D Compare Function Window-B Upper Level Setting Register | ADWINULB | 0000h | E800_58AAh | 16 |
| A/D Compare Function Window-B Status Register | ADCMPBSR | 00h | E800_58ACh | 8 |
| A/D Channel Select Register C0 | ADANSC0 | 0000h | E800_58D4h | 16 |
| A/D Group C Trigger Select Register | ADGCTRGR | 00h | E800_58D9h | 8 |
| A/D Sampling State Register 0 | ADSSTR0 | 0Bh | E800_58E0h | 8 |
| A/D Sampling State Register 1 | ADSSTR1 | 0Bh | E800_58E1h | 8 |
| A/D Sampling State Register 2 | ADSSTR2 | 0Bh | E800_58E2h | 8 |
| A/D Sampling State Register 3 | ADSSTR3 | 0Bh | E800_58E3h | 8 |
| A/D Sampling State Register 4 | ADSSTR4 | 0Bh | E800_58E4h | 8 |
| A/D Sampling State Register 5 | ADSSTR5 | 0Bh | E800_58E5h | 8 |
| A/D Sampling State Register 6 | ADSSTR6 | 0Bh | E800_58E6h | 8 |
| A/D Sampling State Register 7 | ADSSTR7 | 0Bh | E800_58E7h | 8 |

30.2.1 A/D Data Register y (ADDRy: y = 0 to 7), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB)

The ADDRy registers (y = 0 to 7) are 16-bit read-only registers for storing the result of A/D conversion. Register ADDBLDR is a 16-bit read-only register for storing the result of A/D conversion in response to the second trigger in double trigger mode. Registers ADDBLDRA and ADDBLDRB are 16-bit read-only registers for storing the result of A/D conversion during extended operation in double trigger mode.

The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers vary according to the following conditions.

- The setting of the A/D data register format select bit (determining whether the data are flush-left or flush-right in the registers)
- The setting of the A/D conversion-accuracy selection bits (8-, 10-, or 12-bit)
- The setting of the A/D-Converted Value Addition/Average Count Select Register (A/D conversion count, A/D converted value average mode is selected or not selected)

The data formats (section 30.2.23, Data Format, (1) to (9)) for each given condition are shown below.

Table 30.5 Correspondence between the Addition Count and the Setting Condition

| A/D conversion accuracy | Format specification | Addition/ Average deselected | Conversion count when addition is selected (addition count) | | | | | Conversion count when average is selected | |
|-------------------------------|-------------------------|------------------------------------|--|-------------------|-------------------|-------------------|-------------------|--|---------|
| | | | 1 (0) time | 2 (1) times | 3 (2) times | 4 (3) times | 16 (15) times | 2 times | 4 times |
| 8-bit | Right-aligned | (1) | (3)* ¹ | (3)* ¹ | (3)* ¹ | (3)* ¹ | | (1) | (1) |
| | Left-aligned | (2) | (4)* ¹ | (4)* ¹ | (4)* ¹ | (4)* ¹ | | (2) | (2) |
| 10-bit | Right-aligned | (3) | (5)* ¹ | (5)* ¹ | (5)* ¹ | (5)* ¹ | | (3) | (3) |
| | Left-aligned | (4) | (6)* ¹ | (6)* ¹ | (6)* ¹ | (6)* ¹ | | (4) | (4) |
| 12-bit | Right-aligned | (5) | (7)* ¹ | (7)* ¹ | (7)* ¹ | (7)* ¹ | (9)* ² | (5) | (5) |
| | Left-aligned | (6) | (8)* ¹ | (8)* ¹ | (8)* ¹ | (8)* ¹ | (9)* ² | (6) | (6) |

Note 1. Only when 1 (0) to 4 (3) times is specified as the conversion count (addition count) in addition mode, the A/D conversion addition result is 2-bit-extended and stored in the A/D data register.

The explanation about this is also described in "When A/D-converted value addition mode is selected".

Note 2. When addition is selected and 16-time conversion (15-time addition) is specified with 12-bit A/D conversion accuracy, the A/D conversion addition result is 4-bit-extended and stored in the A/D data register.

For details about this register format, see section 30.2.23, Data Format, (1) to (9). In that section, see the description as follows:

- Replace bit symbol "DATA[*:0]" with "AD[*:0]".
- "Function" should be n-bit A/D-converted value. (n = 8, 10, 12, 14 to 16)
- The R/W attribute should be R.

When A/D-converted value average mode is selected

A/D-converted value average mode can be selected only when 2 or 4 times is specified in A/D-converted value addition mode. When A/D-converted value average mode is set, the average of A/D conversion results is retained in the A/D data register. Even if A/D-converted value average mode is selected, the value is stored in the A/D data register according to the settings of the A/D data register format select bit in the same way as normal A/D conversion.

When A/D-converted value addition mode is selected

When the bit accuracy is set to 12-bit accuracy, 1, 2, or 4 times can be specified in A/D-converted value addition mode. Additionally, only when the bit accuracy is set to 12-bit accuracy, 16 times can be specified in A/D-converted value addition mode.

In A/D-converted value addition mode, the value obtained by adding up of A/D conversion results is retained in the A/D data register as a bit-extended value of the conversion accuracy specified.

When 12-bit A/D conversion accuracy is selected and 1 to 4 times is specified in addition mode, 2-bit extension is performed. When 12-bit A/D conversion accuracy is selected and 16 times is specified in addition mode, 4-bit extension is performed.

Even if A/D-converted value addition mode is selected, the value is stored in the A/D data register according to the settings of the A/D data register format select bits.

30.2.2 A/D Self-Diagnosis Data Register (ADRD)

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the A/D converter's self-diagnosis. In addition to the AD bit indicating A/D-converted value, the self-diagnosis status bit (DIAGST) is included in. In the ADRD register, the following different formats are used depending on the conditions below.

- The setting of the A/D data register format select bit (determining whether the data are flush-left or flush-right in the registers)
- The setting of the A/D conversion-accuracy selection bits (ADCER.ADPRC[1:0]) (8-, 10-, or 12-bit)

The A/D-converted value addition mode and A/D-converted value average mode cannot be applied to the A/D self-diagnosis function. For details of self-diagnosis, see section 30.2.9, A/D Control Extended Register (ADCER).

The settings for flush-right data

DIAGST[1:0] is allocated to the upper two bits (b15, b14). The A/D conversion result is allocated to the bit position b13 to b0 depending on the setting of the A/D conversion accuracy specify bits.

A/D Conversion Accuracy Specify Bits = 8-bit accuracy

A/D Conversion Accuracy Specify Bits = 10-bit accuracy

A/D Conversion Accuracy Specify Bits = 12-bit accuracy

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|-------------|-----------------------|---|-----|
| b13 to b0 | AD[11*:0] | — | The data width varies depending on the setting of the A/D conversion accuracy specify bits. 8-bit: AD[7:0] is stored in b7 to b0. 10-bit: AD[9:0] is stored in b9 to b0. 12-bit: AD[11:0] is stored in b11 to b0. | R |
| — | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b15, b14 | DIAGST[1:0] | Self-Diagnosis Status | b15 b14 0 0: Self-diagnosis has never been executed since power-on. 0 1: Self-diagnosis using the voltage of 0 V has been executed. 1 0: Self-diagnosis using the voltage of reference power supply × 1/2 has been executed. 1 1: Self-diagnosis using the voltage of reference power supply has been executed. | R |

The settings for flush-left data

DIAGST[1:0] is allocated to the lower two bits (b1, b0). The A/D conversion result is allocated to the bit position b15 to b2 depending on the setting of the A/D conversion accuracy specify bits.

A/D Conversion Accuracy Specify Bits = 12-bit accuracy

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|-------------|-----------------------|---|-----|
| b1, b0 | DIAGST[1:0] | Self-Diagnosis Status | <div> <div>b1 b0</div> <div>0 0: Self-diagnosis has never been executed since power-on.</div> <div>0 1: Self-diagnosis using the voltage of 0 V has been executed.</div> <div>1 0: Self-diagnosis using the voltage of reference power supply × 1/2 has been executed.</div> <div>1 1: Self-diagnosis using the voltage of reference power supply has been executed.</div> </div> | R |
| b15 to b2 | AD[11** :0] | — | The data width varies depending on the setting of the A/D conversion accuracy specify bits. 8-bit: AD[7:0] is stored in b15 to b8. 10-bit: AD[9:0] is stored in b15 to b6. 12-bit: AD[11:0] is stored in b15 to b4. | R |
| — | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

30.2.3 A/D Control Register (ADCSR)

ADCSR sets A/D conversion control, mode/trigger/interrupt.

| b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----------|-----|------|-----|-----|------|-------|------|--------|----|-------------|----|----|----|----|
| ADST | ADCS[1:0] | | ADIE | — | — | TRGE | EXTRG | DBLE | GBADIE | — | DBLANS[4:0] | | | | |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Function | R/W |
|----------|--------------|---|--|-------|
| b4 to b0 | DBLANS [4:0] | A/D Conversion Data Duplication Channel Select Double Trigger Channel Select | These bits select one analog input channel for which to duplicate A/D conversion data. The setting is only effective while double trigger mode is selected. These bits select one analog input channel for double triggered operation. The setting is only effective while double trigger mode is selected. | R/W |
| b5 | — | Reserved | This bit is read as 0. The write value should be 0. | R0 |
| b6 | GBADIE | Group B Scan End Interrupt Enable | 0: Disables S12GBADIE0 interrupt generation upon group B scan completion. 1: Enables S12GBADIE0 interrupt generation upon group B scan completion. | R/W |
| b7 | DBLE | Double Trigger Mode Select | 0: Deselects double trigger mode. 1: Selects double trigger mode. | R/W |
| b8 | EXTRG | Trigger Select*1 | 0: A/D conversion is started by a synchronous trigger (MTU, GPT). 1: A/D conversion is started by the asynchronous trigger (ADTRG#). | R/W |
| b9 | TRGE | Trigger Start Enable | 0: Disables A/D conversion to be started by the synchronous or asynchronous trigger. 1: Enables A/D conversion to be started by the synchronous or asynchronous trigger. | R/W |
| b11, b10 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b12 | ADIE | Scan End Interrupt Enable | 0: Disables S12ADIE0 interrupt generation upon scan completion. 1: Enables S12ADIE0 interrupt generation upon scan completion. | R/W |
| b14, b13 | ADCS [1:0] | Scan Mode Select | 00: Single scan mode 01: Group scan mode 10: Continuous scan mode 11: Setting prohibited | R/W |
| b15 | ADST | A/D Conversion Start | 0: Stops A/D conversion process 1: Starts A/D conversion process | R/W*2 |

Note 1. Starting A/D conversion using an external pin (asynchronous trigger)

After a high-level signal is input to the external pin (ADTRG#), write 1 to both the TRGE and EXTRG bits in ADCSR and change the signals of ADTRG# to the low level. Thus the falling edge of ADTRG# are detected and the scan conversion process is started. In this case, the pulse width of the low-level input must be at least 1.5 clock cycles of PCLK.

Note 2. See the following description of the ADST bit.

DBLANS[4:0] Bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one of the channels for A/D conversion data duplication in double trigger mode. The A/D conversion results of the analog input of the channel selected by the DBLANS[4:0] bits are stored into the A/D data register y when conversion is started by the first trigger, and into the A/D data duplication register when started by the second trigger. Table 30.6 shows selection of the channel for double triggered operation.

The A/D-converted value addition/average functions with double trigger mode become available by selecting the channel selected in the DBLANS[4:0] bits using the ADADS0 register. When double trigger mode is selected, the channels selected in the ADANSA0 register are invalid, and the channel selected in the DBLANS[4:0] bits is subject to A/D conversion.

When double trigger mode is selected in group scan mode, double trigger mode only operates on group A and does not operate on groups B and C.

Although in double trigger mode, multiple analog input channels cannot be selected for group A, they can be selected for groups B and C.

The DBLANS[4:0] bits should be set while the ADST bit is 0. (They should not be set simultaneously when 1 is written to the ADST bit.)

Table 30.6 Selection of the Channel on which to Duplicate A/D Conversion Data

| DBLANS[4:0] | Duplication channel |
|-------------|---------------------|
| 5'd0 | AN000 |
| 5'd1 | AN001 |
| 5'd2 | AN002 |
| 5'd3 | AN003 |
| 5'd4 | AN004 |
| 5'd5 | AN005 |
| 5'd6 | AN006 |
| 5'd7 | AN007 |

GBADIE Bit (Group B Scan End Interrupt Enable)

The GBADIE bit sets whether to enable or disable group B scan end interrupt (S12GBADI0) in group scan mode.

DBLE Bit (Double Trigger Mode Select)

In double trigger mode, the following operations 1 and 2 are performed on condition that the scan is started by the synchronous trigger (MTU, GPT) selected in ADSTRGR.TRSA[5:0].

If the ADIE bit is set to 1, the scan end interrupt is output not upon completion of the first scan but upon completion of the second scan.

The first piece of A/D conversion data of the analog input selected in the DBLANS[4:0] bits is stored in the A/D data register y, and the second piece is stored in the A/D data duplication register.

When the DBLE bit is set to 1, channels selected in the ADANSA0 register are invalid. Double trigger mode is not selected when the DBLE bit is set to 0. If the DBLE bit is set to 1 again, the preceding operations 1 and 2 are performed with the first scan by the first trigger.

In continuous scan mode, double trigger mode should not be selected.

Software trigger should not be used in double trigger mode.

The DBLE bit should be set when the ADST bit set to 0.

(This bit should not be set simultaneously when 1 is written to the ADST bit.)

EXTRG Bit (Trigger Select)

The EXTRG bit selects the synchronous trigger or the asynchronous trigger as the trigger for starting A/D conversion.

TRGE Bit (Trigger Start Enable)

The TRGE bit sets whether to enable or disable starting of A/D conversion by the synchronous trigger and the asynchronous trigger.

This bit should be set to 1 in group scan mode.

ADIE Bit (Scan End Interrupt Enable)

The ADIE bit sets whether to enable or disable generation of the A/D scan end interrupt (S12ADI0) in group scan mode (except for group B, C scan).

With double trigger mode deselected, the S12ADI0 interrupt is generated after the first scan is completed if the ADIE bit is set to 1.

With double trigger mode selected, the S12ADI0 interrupt is generated after the second scan is completed if the ADIE bit is set to 1 as long as the scan is started by the synchronous trigger (MTU, GPT) selected by the ADSTRGR.TRSA[5:0] bits.

ADCS[1:0] Bits (Scan Mode Select)

The ADCS bit select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs of a maximum of eight channels selected with the ADANSA0 register in the ascending order of the channel number, and when one cycle of A/D conversion is completed for all the selected channels, the scan conversion is stopped.

In continuous scan mode, while the ADST bit in ADCSR is 1, A/D conversion is performed for the analog inputs of a maximum of eight channels selected with the ADANSA0 register in the ascending order of the channel number, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is repeated from the first channel. If the ADST bit in ADCSR is set to 0 during continuous scan, A/D conversion is stopped even if scanning is in progress.

In group scan mode, A/D conversion is performed for the analog inputs (group A) of a maximum of eight channels selected with the ADANSA0 register in the ascending order of the channel number after scanning is started by the synchronous trigger (MTU, GPT) selected by the TRSA[5:0] bits in ADSTRGR, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is stopped.

A/D conversion is also performed for the analog inputs (group B/group C) of a maximum of eight channels selected with the ADANSB0/ADANSC0 register in the ascending order of the channel number after scanning is started by the synchronous trigger (MTU, GPT) selected by the TRSB[5:0]/TRSC[5:0] bits in ADSTRGR, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is stopped.

In group scan mode, different channels and triggers should be selected for group A, group B and group C.

To use two groups when group scan mode is enabled, group A and group B should be used (ADGCTRGR.GRCE = 1'b0). Likewise, to use three groups, group A, group B, and group C should be used (ADGCTRGR.GRCE = 1'b1).

The ADCS[1:0] bits should be set while the ADST bit is 0 (it should not be set simultaneously when 1 is written to the ADST bit.)

ADST Bit (A/D Conversion Start)

The ADST bit starts or stops A/D conversion process.

Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and conversion target analog input.

[Setting conditions]

The ADST bit is set to 1 if one of the following conditions is satisfied:

- 1 is written by software.
- The synchronous trigger (MTU, GPT) selected by the ADSTRGR.TRSA[5:0] bits is detected with ADCSR.EXTRG and ADCSR.TRGE bits being set to 0 and 1, respectively.
- The synchronous trigger (MTU, GPT) selected by the ADSTRGR.TRSB[5:0] bits is detected with the ADCSR.TRGE bit being set to 1 in group scan mode.
- The asynchronous trigger is detected with the ADCSR.TRGE and ADCSR.EXTRG bits being set to 1 and the ADSTRGR.TRSA[5:0] bits being set to 00000b.
- When group priority control operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRP bit is set to 1, and A/D conversion for the lowest-priority group starts.

[Clearing conditions]

The ADST bit is cleared to 0 if one of the following conditions is satisfied:

- 0 is written by software.
- The A/D conversion of all the selected channels is completed in single scan mode.
- Group A scan is completed in group scan mode.
- Group B scan is completed in group scan mode.
- Group C scan is completed in group scan mode.
- When group priority control operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRSCN bit is set to 1, and scan for the lowest-priority group started by trigger completes.

Note 1. When group priority control operation mode has been enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 1.

Note 2. When group priority control operation mode has been enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 0. When forcibly terminating A/D conversion, follow the procedure for clearing the ADST bit.

Note 3. When the single scan succession function is used (ADGSPCR.GBRP = 1) with group priority control operation mode enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADST bit retains 1.

30.2.4 A/D Channel Select Register A0 (ADANSA0)

ADANSA0 selects analog input channels for A/D conversion among AN000 to AN007. In group scan mode, this register selects group A channels.

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|------------|--------------------------------|--|-----|
| b7 to b0 | ANSA0[7:0] | A/D Conversion Channels Select | 0: AN000 to AN007 are not subjected to conversion. 1: AN000 to AN007 are subjected to conversion. | R/W |
| b15 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

ANSA0[7:0] Bits (A/D Conversion Channel Select)

The ANSA0[7:0] bits select analog input channels for A/D conversion among AN000 to AN007. The channels to be selected and the number of channels can be arbitrarily set. The ANSA0[0] bit corresponds to AN000 and the ANSA0[7] bit corresponds to AN007. When double trigger mode is selected, the channel selected by the ANSA0[7:0] bits is invalid, and the channel selected by the ADCSR.DBLANS[4:0] bits is selected in group A instead. The ANSA0[7:0] bits should be set while the ADCSR.ADST bit is 0.

30.2.5 A/D Channel Select Register B0 (ADANSB0)

ADANSB0 selects analog input channels for A/D conversion among AN000 to AN007 in group B when group scan mode is selected. The ADANSB0 register is not used in any scan mode other than group scan mode.

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|------------|--------------------------------|--|-----|
| b7 to b0 | ANSB0[7:0] | A/D Conversion Channels Select | 0: AN000 to AN007 are not subjected to conversion. 1: AN000 to AN007 are subjected to conversion. | R/W |
| b15 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

ANSB0[7:0] Bits (A/D Conversion Channel Select)

The ANSB0[7:0] bits select analog input channels for A/D conversion among AN000 to AN007 in group B when group scan mode is selected. The ANSB0[0] bit corresponds to AN000 and the ANSB0[7] bit corresponds to AN007. The ANSB0[7:0] bits should be set while the ADCSR.ADST bit is 0.

30.2.6 A/D Channel Select Register C0 (ADANSC0)

ADANSC0 selects analog input channels for A/D conversion among AN000 to AN007 in group C when group scan mode is selected. The ADANSC0 register is not used in any scan mode other than group scan mode.

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|------------|--------------------------------|--|-----|
| b7 to b0 | ANSC0[7:0] | A/D Conversion Channels Select | 0: AN000 to AN007 are not subjected to conversion. 1: AN000 to AN007 are subjected to conversion. | R/W |
| b15 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

ANSC0[7:0] Bits (A/D Conversion Channel Select)

The ANSC0[7:0] bits select analog input channels for A/D conversion among AN000 to AN007 in group C when group scan mode is selected. The ANSC0[0] bit corresponds to AN000 and the ANSB0[7] bit corresponds to AN007. The ANSC0[7:0] bits should be set while the ADCSR.ADST bit is 0.

30.2.7 A/D-Converted Value Addition/Average Mode Select Register 0 (ADADS0)

ADADS0 selects the channels AN000 to AN007 on which A/D conversion is performed successively for the specified number of times (The possible addition count depends on the conversion accuracy to be used. See Table 30.5 in section 30.2.1.) and then converted values are added (integrated) or averaged.

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|-----------|---|--|-----|
| b15 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b7 to b0 | ADS0[7:0] | A/D-Converted Value Addition/Average Channel Select | 0: A/D-converted value addition/average mode for AN000 to AN007 is not selected. 1: A/D-converted value addition/average mode for AN000 to AN007 is selected. | R/W |

ADS0[7:0] Bits (A/D-Converted Value Addition/Average Channel Select)

When the ADS0[n] bit of the number that is the same as that of A/D-converted channel selected by the ANSA0[n] bits (n = 0 to 7) in ADANSA0 register or DBLANS[4:0] bits in ADCSR register, ANSB0[n] bits (n = 0 to 7) in ADANSB0 register, and ANSC0[n] bits (n = 0 to 7) in ADANSC0 register is set to 1, A/D conversion of analog input of the selected channels is performed successively (The possible addition count depends on the conversion accuracy to be used. See Table 30.5 in section 30.2.1.) that is set with the ADC[2:0] bits in ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register. As for the channel on which the A/D conversion is performed and addition/average mode is not selected, a normal one-time conversion is executed and the conversion result is stored to the A/D data register.

The ADS0[7:0] bits should be set while the ADCSR.ADST bit is 0.

Figure 30.1 shows the scan sequence when ADS0[2] and ADS0[6] are set to 1.

It is assumed that the scan is operated in continuous scan mode (ADCS = 10b in ADCSR), addition mode is selected (ADADC.AVEE = 0), the number of additions is set to 3 (conversion is performed four times) (ADADC.ADC[2:0] = 011b), and AN000 to AN007 is selected (ADANSA0.ANSA0[7:0] = 00FFh). Conversion is started from AN000. Conversion for AN002 is performed four times, and the value obtained by addition (integration) is stored in the A/D data register 2. Then, conversion for AN003 is started. Conversion for AN006 is performed four times successively, and the value obtained by addition (integration) is stored in the A/D data register 6. After conversion of AN007 is completed, the same sequence repeats from AN000.

Figure 30.1 Scan Conversion Sequence with ADADC.ADC[2:0] = 011b, ADADC.AVEE = 0, ADS[2] = 1, and ADS[6] = 1

30.2.8 A/D-Converted Value Addition/Average Count Select Register (ADADC)

ADADC sets the addition count and average count for A/D conversion of the channel for which A/D-converted value addition/average mode is selected, and selects either addition or average mode.

| Bit | Symbol | Bit Name | Function | R/W |
|--------------------------------|----------|-----------------------|--|-----|
| b2 to b0 | ADC[2:0] | Addition Count Select | b2 b1 b0 0 0 0: 1-time conversion (no addition; same as normal conversion) 0 0 1: 2-time conversion (addition once) 0 1 0: 3-time conversion (addition twice)*1 0 1 1: 4-time conversion (addition three times) 1 0 1: 16-time conversion (addition 15 times) | R/W |
| Other settings are prohibited. | | | | |
| b6 to b3 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b7 | AVEE | Average Mode Enable | 0: Addition mode is selected.*1 1: Average mode is selected.*1 | R/W |

Note 1. The AVEE bit is only effective for 2-time and 4-time conversion. When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to three times. (ADADC.ADC[2:0] = 010b)

ADC[2:0] Bits (Addition Count Select)

The ADC[1:0] bits set the addition count common to the channels for which A/D conversion and A/D-converted value addition/average mode is selected, including the channels selected in double trigger mode (by ADCSR.DBLANS[4:0] bits).

When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to three times (ADADC.ADC[2:0] = 010b).

Additionally, as described in Table 30.5 in section 30.2.1, the combination of a condition in which the addition count is 16 (ADADC.ADC[2:0] = 101b) and a condition in which the A/D conversion accuracy is 8 or 10 bits (ADCER.ADPRC[1:0] = 10b or 01b) is a prohibited setting.

The ADC[2:0] bits should be set while the ADCSR.ADST bit is 0.

AVEE Bit (Average Mode Enable)

The AVEE bit selects addition or average mode for A/D conversion of the channel for which A/D conversion and A/D-converted value addition/average mode is selected, including the channels selected in double trigger mode (by ADCSR.DBLANS[4:0] bits).

When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to three times (ADADC.ADC[2:0] = 010b). The average of 3-time conversion cannot be calculated.

The AVEE bits should be set while the ADCSR.ADST bit is 0.

30.2.9 A/D Control Extended Register (ADCER)

The ADCER register sets the A/D data register, A/D conversion accuracy, and self-diagnosis conversion.

| b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|-----|-----|-----|-------|--------|--------------|----|----|-----|----|----|----|------------|----|----|
| ADR FMT | — | — | — | DIAGM | DIAGLD | DIAGVAL[1:0] | — | — | ACE | — | — | — | ADPRC[1:0] | — | — |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Function | R/W |
|------------|--------------|---|--|-----|
| b0 | — | Reserved | This bit is read as 0. The write value should be 0. | R0 |
| b2, b1 | ADPRC[1:0] | A/D Conversion Accuracy Specify | b2 b1 0 0: A/D conversion is performed with 12-bit accuracy. 0 1: A/D conversion is performed with 10-bit accuracy. 1 0: A/D conversion is performed with 8-bit accuracy. 1 1: Setting is prohibited. | R/W |
| b4, b3 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b5 | ACE | A/D Data Register Automatic Clearing Enable | 0: Disables automatic clearing. 1: Enables automatic clearing. | R/W |
| b7, b6 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b9, b8 | DIAGVAL[1:0] | Self-Diagnosis Conversion Voltage Select | b9 b8 0 0: Setting prohibited when self-diagnosis is enabled 0 1: Uses the voltage of 0 V for self-diagnosis. 1 0: Uses the voltage of reference power supply $\times 1/2$ for self-diagnosis. 1 1: Uses the voltage of reference power supply for self-diagnosis. | R/W |
| b10 | DIAGLD | Self-Diagnosis Mode Select | 0: Rotation mode for self-diagnosis voltage 1: Fixed mode for self-diagnosis voltage | R/W |
| b11 | DIAGM | Self-Diagnosis Enable | 0: Disables self-diagnosis of A/D converter. 1: Enables self-diagnosis of A/D converter. | R/W |
| b14 to b12 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b15 | ADRFMT | A/D Data Register Format Select | 0: Right-alignment is selected for the A/D data register format. 1: Left-alignment is selected for the A/D data register format. | R/W |

ADPRC[1:0] Bits (A/D Conversion Accuracy Specify)

These bits select the A/D conversion accuracy among 8-, 10-, or 12-bit accuracy. When the A/D conversion accuracy is changed, A/D conversion time is also changed.

See section 30.3.6, Analog Input Sampling and Scan Conversion Time for details.

The ADPCR[1:0] bits should be set while the ADCSR.ADST bit is 0.

ACE Bit (Automatic Clearing Enable)

The ACE bit selects enabling or disabling of automatic clearing (all “0”) of the A/D data register (ADDRy, ADDR, ADDBLDR, ADDBLDRA, or ADDBLDRB) when reading any of these registers by the CPU or DMACA. Automatic clearing of the A/D data register enables a failure which has not been updated in the A/D data register to be detected.

DIAGVAL[1:0] Bits (Conversion Voltage Select Self-Diagnosis)

For details, refer to the descriptions of the ADCER.DIAGLD bit.

Self-diagnosis should not be executed by setting the ADCER.DIAGLD bit to 1 when the ADCER.DIAGVAL[1:0] bits are set to 00b.

DIAGLD Bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated or the fixed voltage is used in self-diagnosis. Setting this bit (ADCER.DIAGLD) to 0 allows conversion of the voltages in rotation mode where 0, the reference power supply $\times 1/2$, and the reference power supply are converted in this order. The fixed voltage specified by the ADCER.DIAGVAL[1:0] bits is converted when self-diagnosis voltage fixed mode is selected. In self-diagnosis voltage rotation mode, the self-diagnosis voltage value does not return to 0 when scan conversion is completed. When scan conversion is restarted, therefore, rotation starts at the voltage value following the previous value. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value. The DIAGLD bit should be set while the ADCSR.ADST bit is 0.

DIAGM Bit (Self-Diagnosis Enable)

The DIAGM bit selects execution of self-diagnosis.

Self-diagnosis is used to detect a failure of the A/D converter. It is used to convert the voltage value selected from the internally generated voltage values 0, the reference power supply $\times 1/2$, and the reference power supply. When conversion is completed, information on the converted voltage and the conversion result is stored into the self-diagnosis data register (ADRD). ADRD can then be read out by software to determine whether the conversion result falls within the normal range (normal) or not (abnormal). Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. To use the double trigger function (ADCSR.DBLE = 1), self-diagnosis should be deselected (set the DIAGM bit to 0).

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed in group A, B and C. The DIAGM bit should be set while the ADCSR.ADST bit is 0.

ADRFMT Bit (A/D Data Register Format Select)

The ADRFMT bit specifies right-alignment or left-alignment for the data to be stored in ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADCMPDR0/1, ADWINLLB, or ADWINULB.

The ADRFMT bit should be set while the ADCSR.ADST bit is 0.

see section 30.2.23, Data Format for details.

30.2.10 A/D Start Trigger Select Register (ADSTRGR)

ADSTRGR selects the A/D conversion start trigger.

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|-----------|---|--|-----|
| b5 to b0 | TRSB[5:0] | A/D Conversion Start Trigger Select for Group B | Select the A/D conversion start trigger for group B in group scan mode. | R/W |
| b7, b6 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b13 to b8 | TRSA[5:0] | A/D Conversion Start Trigger Select | Select the A/D conversion start trigger in single scan mode and continuous mode. In group scan mode, the A/D conversion start trigger for group A is selected. | R/W |
| b15, b14 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

TRSB[5:0] Bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits require to be set only in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. Therefore, the TRSB[5:0] bits should be set to the value other than 000000b and the ADCSR.TRGE bit should be set to 1 in group scan mode.

When group is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 3Fh.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by the trigger may have no effect.

Because an A/D conversion start trigger requires synchronization processing, a delay of the period for synchronization processing occurs. See section 30.3.6, Analog Input Sampling and Scan Conversion Time for details.

Table 30.7 lists the A/D conversion startup sources selected by the TRSB[5:0] bits.

TRSA[5:0] Bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode. In group scan mode, the trigger to start scanning of the analog input selected in group A is selected. When scanning is executed in group scan mode or double trigger mode, a software trigger and an asynchronous trigger cannot be used at the same time.

- When using the A/D conversion startup source of a synchronous trigger (MTU, GPT), set the TRGE bit in ADCSR to 1 and set the EXTRG bit in ADCSR to 0.
- When using the asynchronous trigger (ADTRG#), set the TRGE bit in ADCSR to 1 and set the EXTRG bit in ADCSR to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, and the TRSA[5:0] bits.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger may have no effect.

Because an A/D conversion start trigger requires synchronization processing, a delay of the period for synchronization processing occurs.

See section 30.3.6, Analog Input Sampling and Scan Conversion Time for details.

Table 30.8 lists the selection of A/D activation sources selected by the TRSA[5:0] bits.

Table 30.7 Selection of A/D Activation Sources by the TRSB[5:0] Bits (for Group B only)

| Module | Source | Remarks | TRSB[5] | TRSB[4] | TRSB[3] | TRSB[2] | TRSB[1] | TRSB[0] |

30.2.11 A/D Group C Trigger Select Register (ADGCTRGR)

The ADGCTRGR register enables the operation of group C and selects the A/D conversion start trigger. For details about the setting of group priority control, see section 30.3.4.3, Group Priority Control.

| Bit | Symbol | Bit Name | Function | R/W |
|----------|-----------|---|---|-----|
| b5 to b0 | TRSC[5:0] | A/D Conversion Start Trigger Select for Group C | Select the A/D conversion start trigger for group C in group scan mode. | R/W |
| b6 | GCADIE | Group C Scan End Interrupt Enable | 0: Disables S12GCADI0 interrupt generation upon group C scan completion. 1: Enables S12GCADI0 interrupt generation upon group C scan completion. | R/W |
| b7 | GRCE | Group C Dedicated A/D Conversion Operation Enable | Sets whether to enable A/D conversion operation of group C. 0: Do not use group C. 1: Use group C. | R/W |

TRSC[5:0] Bits (A/D Conversion Start Trigger Select for Group C)

The TRSC[5:0] bits select the trigger to start scanning of the analog input selected in group C. The TRSC[5:0] bits require to be set only in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group C, setting a software trigger or an asynchronous trigger is prohibited. Therefore, the TRSC[5:0] bits should be set to the value other than 000000b and the ADCSR.TRGE bit and ADCSR.GRCE bit should be set to 1 in group scan mode.

When group is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group C to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSC[5:0] bits to 3Fh.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by the trigger may have no effect.

Because an A/D conversion start trigger requires synchronization processing, a delay of the period for synchronization processing occurs. See section 30.3.6, Analog Input Sampling and Scan Conversion Time for details.

Table 30.9 lists the A/D conversion startup sources selected by the TRSB[5:0] bits.

GCADIE Bit (Group C Scan End Interrupt Enable)

The GCADIE bit enables or disables generation of the group C scan end interrupt (S12GCADI0) in group scan mode.

GRCE Bit (Group C Dedicated A/D Conversion Operation Enable)

The GRCE bit should be set to 1 to use group C in group scan mode.

When the GRCE bit is set to 0, input of a trigger for group C is invalid. When ADGSPCR.GBRP is set to 1 under group priority control with group C (ADGSPCR.PGS bit = 1), single scan operation is performed continuously on group C. (When the GRCE bit is set to 1, single scan operation is not performed continuously on group B.)

The ADCSR.ADST bit must be 0 when the GRCE bit is set.

Table 30.9 Selection of A/D Activation Sources by the TRSC[5:0] Bits (for Group C only)

| Module | Source | Remarks | TRSC[5] | TRSC[4] | TRSC[3] | TRSC[2] | TRSC[1] | TRSC[0] |
|-----------------------------------|------------------|---|---------|---------|---------|---------|---------|---------|
| Trigger source de-selection state | | | 1 | 1 | 1 | 1 | 1 | 1 |
| MTU | TRGA0N | Compare match with or input capture to MTU0.TGRA | 0 | 0 | 0 | 0 | 0 | 1 |
| | TRGA1N | Compare match with or input capture to MTU1.TGRA | 0 | 0 | 0 | 0 | 1 | 0 |
| | TRGA2N | Compare match with or input capture to MTU2.TGRA | 0 | 0 | 0 | 0 | 1 | 1 |
| | TRGA3N | Compare match with or input capture to MTU3.TGRA | 0 | 0 | 0 | 1 | 0 | 0 |
| | TRGA4N | Compare match with or input capture to MTU4.TGRA, or an underflow of MTU4.TCNT (in the trough) in complementary PWM mode | 0 | 0 | 0 | 1 | 0 | 1 |
| | TRGA6N | Compare match with or input capture to MTU6.TGRA | 0 | 0 | 0 | 1 | 1 | 0 |
| | TRGA7N | Compare match with or input capture to MTU7.TGRA, or an underflow of MTU7.TCNT (in the trough) in complementary PWM mode | 0 | 0 | 0 | 1 | 1 | 1 |
| | TRG0N | Compare match with MTU0.TGRE | 0 | 0 | 1 | 0 | 0 | 0 |
| | TRG4AN | Compare match between MTU4.TADCORA and MTU4.TCNT | 0 | 0 | 1 | 0 | 0 | 1 |
| | TRG4BN | Compare match between MTU4.TADCORB and MTU4.TCNT | 0 | 0 | 1 | 0 | 1 | 0 |
| | TRG4AN or TRG4BN | Compare match between MTU4.TADCORA and MTU4.TCNT, or between MTU4.TADCORB and MTU4.TCNT | 0 | 0 | 1 | 0 | 1 | 1 |
| | TRG4ABN | Compare match between MTU4.TADCORA and MTU4.TCNT, and between MTU4.TADCORB and MTU4.TCNT (when interrupt skipping function 2 is in use) | 0 | 0 | 1 | 1 | 0 | 0 |
| | TRG7AN | Compare match between MTU7.TADCORA and MTU7.TCNT | 0 | 0 | 1 | 1 | 0 | 1 |
| | TRG7BN | Compare match between MTU7.TADCORB and MTU7.TCNT | 0 | 0 | 1 | 1 | 1 | 0 |
| | TRG7AN or TRG7BN | Compare match between MTU7.TADCORA and MTU7.TCNT, or between MTU7.TADCORB and MTU7.TCNT | 0 | 0 | 1 | 1 | 1 | 1 |
| | TRG7ABN | Compare match between MTU7.TADCORA and MTU7.TCNT, and between MTU7.TADCORB and MTU7.TCNT (when interrupt skipping function 2 is in use) | 0 | 1 | 0 | 0 | 0 | 0 |

| Module | Source | Remarks | TRSC[5] | TRSC[4] | TRSC[3] | TRSC[2] | TRSC[1] | TRSC[0] |
|--------|--------------------------|---|---------|---------|---------|---------|---------|---------|
| GPT | ADTRGA0 | Compare match with GPT0.GTADTRA | 0 | 1 | 0 | 0 | 0 | 1 |
| | ADTRGB0 | Compare match with GPT0.GTADTRB | 0 | 1 | 0 | 0 | 1 | 0 |
| | ADTRGA1 | Compare match with GPT1.GTADTRA | 0 | 1 | 0 | 0 | 1 | 1 |
| | ADTRGB1 | Compare match with GPT1.GTADTRB | 0 | 1 | 0 | 1 | 0 | 0 |
| | ADTRGA2 | Compare match with GPT2.GTADTRA | 0 | 1 | 0 | 1 | 0 | 1 |
| | ADTRGB2 | Compare match with GPT2.GTADTRB | 0 | 1 | 0 | 1 | 1 | 0 |
| | ADTRGA3 | Compare match with GPT3.GTADTRA | 0 | 1 | 0 | 1 | 1 | 1 |
| | ADTRGB3 | Compare match with GPT3.GTADTRB | 0 | 1 | 1 | 0 | 0 | 0 |
| | ADTRGA0 or ADTRGB0 | Compare match with GPT0.GTADTRA or with GPT0.GTADTRB | 0 | 1 | 1 | 0 | 0 | 1 |
| | ADTRGA1 or ADTRGB1 | Compare match with GPT1.GTADTRA or with GPT1.GTADTRB | 0 | 1 | 1 | 0 | 1 | 0 |
| | ADTRGA2 or ADTRGB2 | Compare match with GPT2.GTADTRA or with GPT2.GTADTRB | 0 | 1 | 1 | 0 | 1 | 1 |
| | ADTRGA3 or ADTRGB3 | Compare match with GPT3.GTADTRA or with GPT3.GTADTRB | 0 | 1 | 1 | 1 | 0 | 0 |

30.2.12 A/D Sampling State Register n (ADSSTRn) (n = 0 to 7)

The ADSSTRn register sets the sampling time for analog input.

| Bit | Symbol | Bit Name | Function | R/W |
|----------|----------|-----------------------|---|-----|
| b7 to b0 | SST[7:0] | Sampling Time Setting | These bits set the sampling time in the range from 5 to 255 states. | R/W |

If one state is one ADCLK (A/D conversion clock) cycle and the ADCLK clock is 33 MHz, one state is 30.3 ns. The initial value is 11 states. If the impedance of analog input signal source is too high to secure sufficient sampling time or if the ADCLK clock is slow, the sampling time can be adjusted.

These bits should be set while the ADCSR.ADST bit is 0.

The lower limit of the sampling time setting depends on the frequency ratio:

If the frequency ratio of PCLK to ADCLK = 1:1 or 1:2, the sampling time must be set to 5 states or longer.

Table 30.10 shows the relationship between the A/D sampling state register and the relevant channels.

For details, refer to section 30.3.6, Analog Input Sampling and Scan Conversion Time.

Table 30.10 Relationship between A/D Sampling State Register and Relevant Channels

| Bit Name | Corresponding Channel |
|-----------------------|-----------------------|
| ADSSTR0.SST[7:0] bits | AN000, Self-diagnosis |
| ADSSTR1.SST[7:0] bits | AN001 |
| ADSSTR2.SST[7:0] bits | AN002 |
| ADSSTR3.SST[7:0] bits | AN003 |
| ADSSTR4.SST[7:0] bits | AN004 |
| ADSSTR5.SST[7:0] bits | AN005 |
| ADSSTR6.SST[7:0] bits | AN006 |
| ADSSTR7.SST[7:0] bits | AN007 |

30.2.13 A/D Disconnection Detection Control Register (ADDISCR)

ADDISCR sets the disconnection detection assist function.

| Bit | Symbol | Bit Name | Function | R/W |
|----------|-------------|--|--|-----|
| b4 to b0 | ADNDIS[4:0] | Disconnection Detection Assist Setting | Disconnection detection assist function is set. b4 ADNDIS[4]: Setting precharge or discharge 0: discharge 1: precharge b3 to b0 ADNDIS[3:0]: Setting the period of precharge or discharge. | R/W |
| b7 to b5 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

ADNDIS[4:0] Bits (Disconnection Detection Assist Setting)

These bits select either precharge or discharge and the period of precharge/discharge for the A/D disconnection detection assist function. Setting the ADNDIS[4] = 1 allows to select precharge and setting the ADNDIS[4] = 0 allows to select discharge. The period of precharge/discharge can be set with the ADNDIS[3:0] bits. When the ADNDIS[3:0] = 0000b, the disconnection detection assist function is not effective. Setting of the ADNDIS[3:0] bits to 0001b is prohibited. Except for the case of ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge/discharge.

ADNDIS[4:0] bits should be set while the ADCSR.ADST bit is 0.

30.2.14 A/D Group Scan Priority Control Register (ADGSPCR)

The ADGSPCR register sets priority control to interrupt scanning for a low priority group in group scan mode and execute scan for a priority group.

For details about the setting of group priority control, see section 30.3.4.3, Group Priority Control.

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|------|-------|-----|-----|-----|-----|----|----|----|----|----|----|----|----|--------|-----|
| | GBRP | LGRRS | — | — | — | — | — | — | — | — | — | — | — | — | GBRSCN | PGS |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|--------|--|---|-----|
| b0 | PGS | Group Priority Control Setting* ¹ | 0: Operation is without group A priority control 1: Operation is with group A priority control | R/W |
| b1 | GBRSCN | Low Priority Group Restart Setting | (Enabled only when PGS = 1. Reserved when PGS = 0.) 0: Scanning for group is not restarted after having been discontinued due to group priority control. 1: Scanning for group is restarted after having been discontinued due to group priority control. | R/W |
| b8 to b2 | — | Reserved | These bits are read as 0. The write value should be 0. | R/W |
| b13 to b9 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b14 | LGRRS | Restart Channel Select | (Enabled only when PGS = 1 and GBRSCN = 1. Reserved when PGS = 0 or GBRSCN = 0.) 0: Rescan is performed from the first channel of the scan. 1: Rescan is performed from the channel on which A/D conversion has not completed. | R/W |
| b15 | GBRP | Single Scan Continuous Start* ² | (Enabled only when PGS = 1. Reserved when PGS = 0.) 0: Single scan is not continuously activated. 1: Single scan for the lowest priority group is continuously activated. | R/W |

Note 1. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation cannot be guaranteed.

Note 2. When the GBRP bit is set to 1, single scan is performed continuously on the lowest priority group regardless of the setting of the GBRSCN bit.

PGS Bit (Group A Priority Control Setting)

This bit controls priority operation in group scan mode. Set the PGS bit to 1 to enable group priority control. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation cannot be guaranteed.

In group priority control, if a request to start scan for a priority group is accepted during scanning for a low priority group, the scanning for the low priority group is interrupted and scan for the priority group is started.

The priority order is group A > group B > group C. If a request to start group B scan is accepted during group C scanning, the group C scanning is interrupted and group B scan is started.

If a request to start group A scan is accepted during group C scanning, the group C scanning is interrupted and group A scan is started. Likewise, if a request to start group A scan is accepted during group B scanning, the group B scanning is interrupted and group A scan is started.

When the PGS bit has been set to 0, A/D conversion must be cleared by software according to section 30.5.2, Notes on Stopping A/D Conversion.

When the PGS bit has been set to 1, make register settings according to section 30.3.4.3, Group Priority Control.

GBRSCN Bit (Low priority group Restart Setting)

This bit controls the restarting of scan operation when group priority control is enabled. The setting of the GBRSCN bit has an effect when the PGS bit is set to 1.

If a scan operation on a low priority group has been stopped by a priority group trigger input with the GBRSCN bit set to 1, the scan operation is restarted on completion of the A/D conversion on a priority group. Also, if a low priority group

trigger is input during A/D conversion on a priority group, the scan operation on a low priority group is restarted on completion of the A/D conversion on a priority group. If the GBRSCN bit has been set to 0, triggers that are input during A/D conversion are ignored.

GBRSCN bit should be set while the ADCSR.ADST bit is 0.

LGRRS Bit (Restart Channel Select)

This bit sets the rescan start channel when group priority control is enabled. The setting of the LGRRS bit is valid when the PGS and GBRSCN bits are 1.

When the LGRRS bit is 0, scan to be performed after scan for the priority group is re-executed from the first channel for the low priority group whose scan was interrupted due to group priority control.

When the LGRRS bit is 1, scan to be performed after scan for the priority group is re-executed*1 from the channel on which A/D conversion has not completed for the low priority group whose scan was interrupted due to group priority control.

The LGRRS bits should be set while the ADCSR.ADST bit is 0.

Note: If A/D conversion for an addition setting channel has not completed for the specified number of times at the time of interruption, A/D conversion for the addition setting channel is performed again for the specified number of times at the time of re-execution.

GBRP Bit (Single Scan Continuous Start Setting)

Set the GBRP bit to perform single scan operation continuously on the lowest priority group under group priority control. This bit is set when a single scan operation is to be performed continuously on group B.

The setting of the GBRP bit is valid when the PGS bit is 1.

The lowest priority group is group C when groups A, B, C are used, and group B when only groups A and B are used.

Setting the GBRP bit to 1 starts a single scan for the lowest priority group. On completion of a scan, a single scan for the lowest priority group is automatically restarted. If scan has been interrupted due to group priority control, a single scan for the lowest priority group is automatically restarted on completion of the A/D conversion on the priority group.

Disable trigger input for the lowest priority group before setting the GBRP bit to 1. Setting the GBRP bit to 1 performs a rescan only for the lowest priority group even if the GBRSCN bit is 0.

GBRP bit should be set while the ADCSR.ADST bit is 0.

30.2.15 A/D Compare Control Register (ADCMPCR)

ADCMPCR is used to set compare window A/B operation.

| | b15 | b14 | b13 | b12 | b11 | b10 | b9 | b8 | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|--------|-------|--------|-----|-------|-----|-------|----|----|----|----|----|----|----|----|----|

| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Function | R/W |
|----------|--------|-----------------------------------|---|-----|
| b8 to b0 | — | Reserved | These bits are read as 0. The write value should be 0 | R0 |
| b9 | CMPBE | Compare Window B Operation Enable | 0: Compare Window B disabled 1: Compare Window B enabled | R/W |
| b10 | — | Reserved | This bit is read as 0. The write value should be 0 | R0 |
| b11 | CMPAE | Compare Window A Operation Enable | 0: Compare Window A disabled 1: Compare Window A enabled | R/W |
| b12 | — | Reserved | This bit is read as 0. The write value should be 0 | R0 |
| b13 | CMPBIE | Compare B Interrupt Enable | 0: Generation of an S12ADCMPI0 interrupt in response to matches with a condition for comparison (Window B) is disabled. 1: Generation of an S12ADCMPI0 interrupt in response to matches with a condition for comparison (Window B) is enabled. | R/W |
| b14 | WCMPE | Window Function Setting | 0: Window function disabled Window A and B operate as a comparator to compare the single value on the lower side with the A/D conversion result. 1: Window function enabled Window A and B operate as a window comparator to compare the two values on the upper and lower sides with the A/D conversion result. | R/W |
| b15 | CMPAIE | Compare A Interrupt Enable | 0: Generation of an S12ADCMPI0 interrupt in response to matches with a condition for comparison (Window A) is disabled. 1: Generation of an S12ADCMPI0 interrupt in response to matches with a condition for comparison (Window A) is enabled. | R/W |

CMPBE Bit (Compare Window B Operation Enable)

This bit selects enabling or disabling of Window B operation. This bit should be set while the ADCSR.ADST bit is 0. Set this bit to 0 when setting the following registers. This bit sets to “0” when

- A/D Channel Select Register A0/B0 (ADANSA0, ADANSB0)
- The CMPCHB[5:0] bits in the A/D Compare Function Window-B Channel Selection Register (ADCMPBNSR) (ADCMPBNSR.CMPCHB[5:0])

CMPAE Bit (Compare Window A Operation Enable)

Enabling or disabling of Window A operation. This bit should be set while the ADCSR.ADST bit is 0. Set this bit to 0 when setting the following registers.

- A/D Channel Select Register A0/B0 (ADANSA0, ADANSB0)
- Window-A Channel Selection Register 0 (ADCMPANSR0)

CMPBIE Bit (Compare B Interrupt Enable)

This bit selects enables or disables generation of a compare interrupt (S12ADCMPI0) in response to matches with a condition for comparison (Window B).

WCMPE Bit (Window Function Setting)

This bit selects enabling or disabling of Window function. This bit should be set while the ADCSR.ADST bit is 0.

CMPAIE Bit (Compare A Interrupt Enable)

This bit selects enables or disables generation of a compare interrupt (S12ADCMPAI0) in response to matches with a condition for comparison (Window A).

30.2.16 A/D Compare Function Window-A Channel Selection Register 0 (ADCMPANSR0)

ADCMPANSR0 selects analog input channels for comparison from among AN000 to AN007 in the compare window A condition.

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|--------------|---------------------------------|--|-----|
| b7 to b0 | CMPCHA0[7:0] | Compare Window A Channel Select | 0: The corresponding channel from among AN000 to AN007 is not a target for the compare Window A. 1: The corresponding channel from among AN000 to AN007 is a target for the compare Window A. | R/W |
| b15 to b8 | — | Reserved | These bits are read as 0. The write value should be 0 | R0 |

CMPCHA0[7:0] Bits (Compare Channel Select)

Setting the CMPCHA0[n] bit which has the same number as the A/D channel selected by the ADANSA.ANSA[n] (n = 0 to 7), ADANSB.ANSB[n] (n = 0 to 7) or ADANSC.ANSC[n] (n = 0 to 7) bits to 1 enables comparison with that channel. Set the CMPCHA0[7:0] bits while ADCSR.ADST bit is 0.

30.2.17 A/D Compare Function Window-A Comparison Condition Setting Register 0 (ADCMPPLR0)

The ADCMPPLR0 register sets the condition for use in comparing the values of the ADCMPDR0 and ADCMPDR1 registers with results of A/D conversion.

Set the ADCMPPLR0 register while ADCSR.ADST is 0.

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|---------------|---------------------------------------|---|-----|
| b7 to b0 | CMPLCHA0[7:0] | Compare window A Compare Level Select | Set the condition for comparison with the selected channels from among AN000 to AN007 under the compare window A condition. Compare conditions are shown in Table 30.11. When Window function is disabled (ADCMPCR.WCMPE = 0): 0: ADCMPDR0 register value > A/D-converted value 1: ADCMPDR0 register value < A/D-converted value When Window function is enabled (ADCMPCR.WCMPE = 1): 0: AD-converted value < ADCMPDR0 register value or A/D-converted value > ADCMPDR1 register value 1: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value | R/W |
| b15 to b8 | — | Reserved | These bits are read as 0. The write value should be 0 | R0 |

CMPLCHA0[7:0] Bits (Compare Condition Select)

The CMPLCHA0[7:0] bits set the condition for use in comparison with the selected channel from among AN000 to AN007 under the compare window A condition. A condition can be set for individual comparison of each analog input. The CMPLCHA0[0] bit is used for AN000, and the CMPLCHA0[7] bit is used for AN007.

When the result of comparison matches the set condition, ADCMPSR0.CMPSTCHA0n is set to 1 and a compare interrupt (S12ADCMPI0) is generated.

Table 30.11 Compare function description of compare function window A

Compare condition when Window function is disabled

| CMPLCHA0[*] = 1'b0 | | CMPLCHA0[*] = 1'b1 | |
|---|-------------|---|-------------|
| ADCMPDR0 register value ≤ A/D-converted value | Not matched | ADCMPDR0 register value < A/D-converted value | Matched |
| ADCMPDR0 register value > A/D-converted value | Matched | ADCMPDR0 register value ≥ A/D-converted value | Not matched |

Compare condition when Window function is enabled

| CMPLCHA0[*] = 1'b0 | |
|---|-------------|
| ADCMPDR1 register value < A/D-converted value | Matched |
| ADCMPDR0 register value ≤ A/D-converted value ≤ ADCMPDR1 register value | Not matched |
| A/D-converted value < ADCMPDR0 register value | Matched |
| CMPLCHA0[*] = 1'b1 | |
| ADCMPDR1 register value ≤ A/D-converted value | Not matched |
| ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value | Matched |
| A/D-converted value ≤ ADCMPDR0 register value | Not matched |

30.2.18 A/D Compare Function Window-A Lower Level Setting Register (ADCMPDR0), A/D Compare Function Window-A Upper Level Setting Register (ADCMPDR1), A/D Compare Function Window-B Lower Level Setting Register (ADWINLLB), A/D Compare Function Window-B Upper Level Setting Register (ADWINULB)

The ADCMPDR0 register is a readable/writable register to set the reference data when the compare window A function is used. ADCMPDR0 sets the reference data for comparison with the selected channels.

ADCMPDR0 sets the lower-side reference value (CMPLLA[15:0]) for window A, and ADCMPDR1 sets the upper-side reference value (CMPULA[15:0]) for window A.

The ADWINULB and ADWINLLB registers are readable/writable registers to set the reference data when the compare window B function is used.

ADWINLLB sets the lower-side reference value (CMPLLB[15:0]) for window B, and ADWINULB sets the upper-side reference value (CMPULB[15:0]) for window B.

- The ADCMPDRy, ADWINULB, and ADWINLLB registers are writable even during A/D conversion. The reference value can be dynamically*¹ changed by rewriting register values during A/D conversion.
- Specify the settings so that upper-side reference value \geq lower-side reference value ($CMPULA \geq CMPLLA$, $CMPULB \geq CMPLLB$).
- The ADCMPDR1 and ADWINULB registers are not used when Window function is disabled.

Note 1. Each of the upper-side and lower-side reference values are changed when the corresponding register is written. For example, a comparison is made between the upper-side reference value (after rewriting) and the lower-side reference value (before rewriting) as shown below in the time between rewriting of the upper-side reference value and rewriting of the lower-side reference value.

If the comparison during the rewriting of these two reference values is problematic, rewrite these reference values when the ADCSR.ADST bit and the associated window operation enable bit (ADCMPDR.CMPAE or ADCMPDR.CMPBE) are 0.

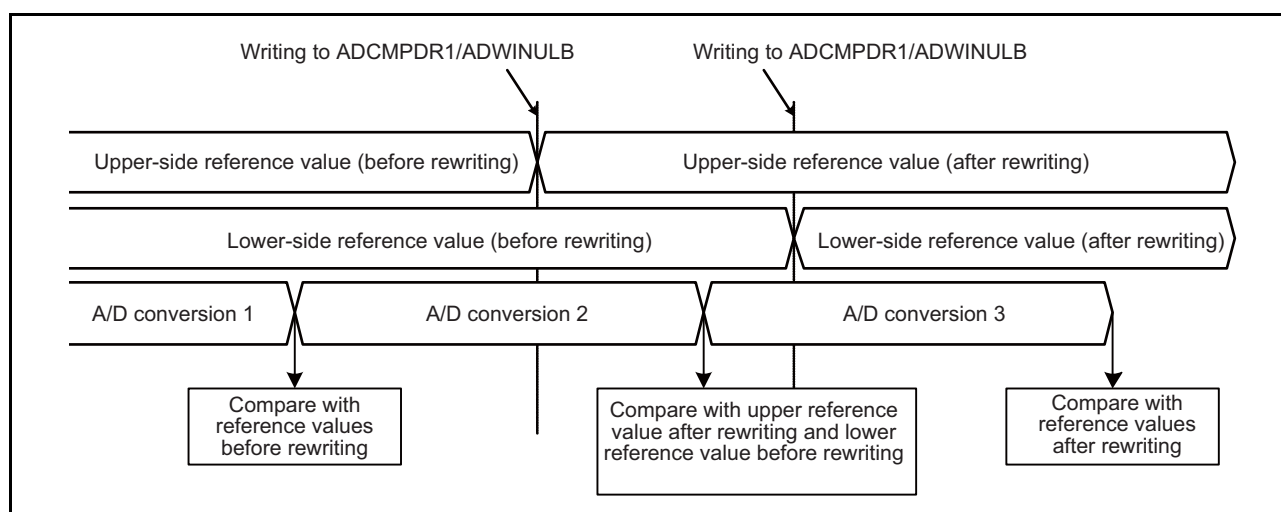

Figure 30.2 Reflection Timing of Reference Values

Note the following settings so that the ADCMPDRy, ADWINULB, and ADWINLLB registers are set according to the A/D data register format shown in section 30.2.1, A/D Data Register y (ADDRy: y = 0 to 7), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB)*2.

For the correspondence between each condition and data format, see section 30.2.1, Table 30.5.

- The value of the A/D data register format select bit (flush-right or flush-left)
- The value of A/D conversion accuracy specify bits (12 bits, 10 bits, 8 bits)
- The value of A/D-converted value addition/average mode select register (A/D conversion value average mode is selected or not selected)

Note 2. If a compare value is set in a format different from the A/D data register format, the correct comparison result cannot be obtained.

For details about this register format, see section 30.2.23, (1) to (9). In that section, see the description as follows:

- For ADCMPDR0, replace bit symbol "DATA[*:0]" with "CMPLLA[*:0]".
"Function" should be n-bit compare level (lower-side reference value for window A) (n = 8, 10, 12, 14, 16).
The R/W attribute of CMPLLA[*:0] should be R/W.
- For ADCMPDR1, replace bit symbol "DATA[*:0]" with "CMPULA[*:0]".
"Function" should be n-bit compare level (upper-side reference value for window A) (n = 8, 10, 12, 14, 16).
The R/W attribute of CMPULA[*:0] should be R/W.
- For ADWINLLB, replace bit symbol "DATA[*:0]" with "CMPLLB[*:0]".
"Function" should be n-bit compare level (lower-side reference value for window B) (n = 8, 10, 12, 14, 16).
The R/W attribute of CMPLLB[*:0] should be R/W.
- For ADWINULB, replace bit symbol "DATA[*:0]" with "CMPULB[*:0]".
"Function" should be n-bit compare level (upper-side reference value for window B) (n = 8, 10, 12, 14, 16).
The R/W attribute of CMPULB[*:0] should be R/W.

30.2.19 A/D Compare Function Window-A Channel Status Register 0 (ADCMPSR0)

The ADCMPSR0 register sets the compare window A function.

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|--------------------|--------------------------|--|-----|
| b7 to b0 | CMPSTCHA0 [7:0] | Compare Window-A Flag | Indicates compare results of CH(AN000 to AN007) when window A is active (ADCMPCR.CMPAE = 1b). 0: Condition for comparison was not met. 1: Condition for comparison was met. | R/W |
| b15 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

CMPSTCHA0[7:0] Bits (Compare Window-A Flag)

These bits are status flags that indicate the comparison result of channels (AN000 to AN007) that are subject to the window A comparison condition.

When the result of comparison on completion of A/D conversion matches the condition set in ADCMPLR0.CMPLCHAN, the corresponding flags are set to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt (S12ADCMPAI0) request is generated when the setting of the flag becomes 1. The CMPSTCHA0[0] bit is used for AN000, and the CMPSTCHA0[7] bit is used for AN007. The value 1 cannot be written to the CMPSTCHA0n bit.

[Setting “1” condition]

When ADCMPCR.CMPAE = 1b, The condition set in ADCMPLR0.CMPLCHAN is met.

[Clearing “0” condition]

0 is written after reading 1.

30.2.20 A/D Compare Function Window-B Channel Selection Register (ADCMPBNSR)

The ADCMPBNSR register sets the compare window B function.

| Bit | Symbol | Bit Name | Function | R/W |
|----------|-----------------|--|--|-----|
| b5 to b0 | CMPCHB [5:0] | Compare Window B Channel Select | Selects a channel to be compared with the compare window B conditions. 6'b000000: AN000 6'b000001: AN001 6'b000010: AN002 to 6'b111111: Not selected Note: Setting any value from 6'b001000 to 6'b111110 is prohibited. | R/W |
| b6 | — | Reserved | This bit is read as 0. The write value should be 0. | R0 |
| b7 | CMPLB | Compare Window B Compare Condition Setting | Sets comparison conditions for channels for window B. Table 30.12 shows the compare conditions. When Window function is disabled (ADCMPPCR.WCMPE bit = 0): 0: CMPLLB register value > A/D-converted value 1: CMPLLB register value < A/D-converted value When Window function is enabled (ADCMPPCR.WCMPE bit = 1): 0: A/D-converted value < CMPLLB register value or CMPULB register value < A/D-converted value 1: CMPLLB register value < A/D-converted value < CMPULB register value | R/W |

CMPCHB[5:0] Bits (Compare Window B Channel Select)

These bits select a channel to be compared with the compare window B conditions from AN000 to AN007.

Specifying the number (hexadecimal) of the A/D conversion channel selected in the ADANSA0.ANSA0[n] (n = 0 to 7) bits and ADANSB0.ANSB0[n] (n = 0 to 7) bits enables the compare window B function.

Set the CMPCHB[5:0] bits while the ADCSR.ADST bit is 0.

CMPLB Bit (Compare Window B Compare Condition Setting)

This bit sets comparison conditions for channels for window B. When the result of comparison of analog input matches the set condition, ADCMPBSR0.CMPSTB is set to 1 and a compare interrupt (S12ADCMPBI0) is generated.

Table 30.12 Explanation of Compare Conditions for Compare Function Window B

Compare condition when Window function is disabled

CMPLB = 1'b0

| | |
|--|-------------|
| ADWINLLB register value \leq A/D-converted value | Not matched |
| ADWINLLB register value | Matched |

CMPLB = 1'b1

| | |
|--|-------------|
| ADWINLLB register value $<$ A/D-converted value | Matched |
| ADWINLLB register value \geq A/D-converted value | Not matched |

Compare condition when Window function is enabled

CMPLB = 1'b0

| | |
|---|-------------|
| A/D-converted value $>$ ADWINULB register value | Matched |
| ADWINLLB register value \leq A/D-converted value \leq ADWINULB register value | Not matched |
| A/D-converted value $<$ ADWINLLB register value | Matched |

CMPLB = 1'b1

| | |
|---|-------------|
| A/D-converted value \geq ADWINULB register value | Not matched |
| ADWINLLB register value $<$ A/D-converted value $<$ ADWINULB register value | Matched |
| A/D-converted value \leq ADWINLLB register value | Not matched |

30.2.21 A/D Compare Function Window-B Status Register (ADCMPBSR)

The ADCMPBSR register stores the result of comparison by the compare window B function.

| b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|----|----|----|----|----|----|------------|
| — | — | — | — | — | — | — | CMP STB |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Function | R/W |
|----------|--------|-----------------------|---|-----|
| b0 | CMPSTB | Compare Window-B Flag | Indicates compare results of CH (AN000 to AN007) when window B is active (ADCMPCR.CMPBE = 1b) 0: Condition for comparison was not met. 1: Condition for comparison was met. | R/W |
| b7 to b1 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

CMPSTB Bits (Compare Window-B Flag)

These bits are status flags that indicate the comparison result of channels (AN000 to AN007) that are subject to the window B comparison condition. When the result of comparison on completion of A/D conversion matches the condition set in ADCMPBSR.CMPLB, the corresponding flags are set to 1. When the ADCMPCR.CMPBIE bit is 1, a compare interrupt (S12ADCMPBI0) request is generated when the setting of the flag becomes 1. The value 1 cannot be written to the CMPSTB bit.

[Setting “1” condition]

When ADCMPCR.CMPBE = 1b, The condition set in ADCMPBSR.CMPLB is met.

[Clearing “0” condition]

0 is written after reading 1.

30.2.22 A/D Compare Function AB Status Monitor Register (ADWINMON)

The ADWINMON register can be used to monitor comparison results and combination results.

| | b7 | b6 | b5 | b4 | b3 | b2 | b1 | b0 |
|--------------------|----|----|-------------|-------------|----|----|----|-------------|
| | — | — | MON CMPB | MON CMPA | — | — | — | MON COMB |
| Value after reset: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| Bit | Symbol | Bit Name | Function | R/W |
|----------|---------|-----------------------------|--|-----|
| b7, b6 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b5 | MONCMPB | Comparison Result Monitor B | 0: Window B comparison conditions are not met. 1: Window B comparison conditions are met. | R |
| b4 | MONCMPA | Comparison Result Monitor A | 0: Window A comparison conditions are not met. 1: Window A comparison conditions are met. | R |
| b3 to b1 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b0 | MONCOMB | Combination Result Monitor | Indicates the combination result. This bit is valid while both window A and B are active. 0: Window A/B composite conditions are not met. 1: Window A/B composite conditions are met. | R |

MONCMPB Bit (Comparison Result Monitor B)

This bit is a read-only bit which is read as 1 when the A/D-converted value of the target channel for window B meets the condition set in the ADCMPBNSR.CMPLB bit, and is read as 0 when it does not meet the condition.

[Setting “1” condition]

Under the condition that ADCMPCR.CMPBE = 1b, the condition set in ADCMPBNSR.CMPLB is met.

[Setting “0” condition]

Under the condition that ADCMPCR.CMPBE = 1b, the condition set in ADCMPBNSR.CMPLB is not met.

When ADCMPCR.CMPBE = 0b (Automatic clearing is performed when the value of ADCMPCR.CMPBE is changed from 1b to 0b.)

MONCMPA Bit (Comparison Result Monitor A)

This bit is a read-only bit which is read as 1 when the A/D-converted value of the target channel for window A meets the condition set in ADCMPLR0 and ADCMPLER, and is read as 0 when it does not meet the condition.

[Setting “1” condition]

Under the condition that ADCMPCR.CMPAE = 1b, the condition set in ADCMPLR0.CMPLCHAn is met.

[Setting “0” condition]

Under the condition that ADCMPCR.CMPAE = 1b, the condition set in ADCMPLR0.CMPLCHAn is not met.

When ADCMPCR.CMPAE = 0b (Automatic clearing is performed when the value of ADCMPCR.CMPAE is changed from 1b to 0b.)

MONCOMB Bit (Combination Result Monitor)

This read-only bit indicates a result of combining comparison condition result A and comparison result condition B with the combination condition set in the ADCMPCR.CMPAB[1:0] bits.

[Setting “1” condition]

Under the condition that ADCMPCR.CMPAE = 1 and ADCMPCR.CMPBE = 1, the combination condition set in the ADCMPCR.CMPAB[1:0] bits is met.

[Setting “0” condition]

The combination condition set in the ADCMPCR.CMPAB[1:0] bits is not met.

When ADCMPCR.CMPAE = 0 or ADCMPCR.CMPBE = 0

30.2.23 Data Format

The data formats in this module are shown below.

Data Format (1)

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|-----------|-----------------------------------|--|-----|
| b7 to b0 | DATA[7:0] | A/D-converted value/compare level | 8-bit A/D-converted value | R |
| | | | 8-bit compare level | R/W |
| b15 to b8 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

Data Format (2)

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|-----------|-----------------------------------|--|-----|
| b7 to b0 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b15 to b8 | DATA[7:0] | A/D-converted value/compare level | 8-bit A/D-converted value | R |
| | | | 8-bit compare level | R/W |

Data Format (3)

| Bit | Symbol | Bit Name | Function | R/W |
|------------|-----------|-----------------------------------|--|-----|
| b9 to b0 | DATA[9:0] | A/D-converted value/compare level | 10-bit A/D-converted value | R |
| | | | 10-bit compare level | R/W |
| b15 to b10 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

Data Format (4)

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|-----------|-----------------------------------|--|-----|
| b5 to b0 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b15 to b6 | DATA[9:0] | A/D-converted value/compare level | 10-bit A/D-converted value | R |
| | | | 10-bit compare level | R/W |

Data Format (5)

| Bit | Symbol | Bit Name | Function | R/W |
|------------|------------|-----------------------------------|--|-----|
| b11 to b0 | DATA[11:0] | A/D-converted value/compare level | 12-bit A/D-converted value | R |
| | | | 12-bit compare level | R/W |
| b15 to b12 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

Data Format (6)

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|------------|-----------------------------------|--|-----|
| b3 to b0 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b15 to b4 | DATA[11:0] | A/D-converted value/compare level | 12-bit A/D-converted value | R |
| | | | 12-bit compare level | R/W |

Data Format (7)

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|------------|-----------------------------------|--|-----|
| b13 to b0 | DATA[13:0] | A/D-converted value/compare level | 14-bit A/D-converted value | R |
| | | | 14-bit compare level | R/W |
| b15, b14 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |

Data Format (8)

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|------------|-----------------------------------|--|-----|
| b1, b0 | — | Reserved | These bits are read as 0. The write value should be 0. | R0 |
| b15 to b2 | DATA[13:0] | A/D-converted value/compare level | 14-bit A/D-converted value | R |
| | | | 14-bit compare level | R/W |

Data Format (9)

| Bit | Symbol | Bit Name | Function | R/W |
|-----------|------------|-----------------------------------|----------------------------|-----|
| b15 to b0 | DATA[15:0] | A/D-converted value/compare level | 16-bit A/D-converted value | R |
| | | | 16-bit compare level | R/W |

30.3 Operation

30.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

A scan conversion is performed in three operating modes: single scan mode, continuous scan mode, and group scan mode. In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until the ADST bit in ADCSR register is cleared to 0 from 1 by software.

In group scan mode, the selected channels of group A, the selected channels of group B, and the selected channels of group C are scanned once after starting to be scanned according to the respective synchronous triggers.

In single scan mode and continuous scan mode, A/D conversion is performed for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for ANn channels of group A selected by the ADANSA0 register first, and then performed for ANn channels of group B selected by the ADANSB0 register, and then performed for ANn channels of group C selected by the ADANSC0 register, respectively, starting from the channel with the smallest number n.

When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three voltages internally generated in the A/D converter is converted.

Double trigger mode is to be used with single scan mode or group scan mode. With double trigger mode being enabled (set ADCSR.DBLE to 1), A/D conversion data of a channel selected by the DBLANS[4:0] bits in ADCSR register is duplicated only if the conversion is started by any of the synchronous triggers selected by the TRSA[5:0] bits in ADSTRGR register.

In group scan mode, the double trigger function can be used only for group A.

Extended double trigger mode means that double trigger mode is enabled, and the following synchronous triggers (two types of synchronous trigger source enabled) are selected as the A/D conversion start trigger in ADSTRGR.TRSA[5:0].

- TRG4AN or TRG4BN (Sets ADSTRGR.TRSA[5:0] to “001011”.)
- TRG7AN or TRG7BN (Sets ADSTRGR.TRSA[5:0] to “001111”.)
- ADTRGA0 or ADTRGB0 (Sets ADSTRGR.TRSA[5:0] to “011001”.)
- ADTRGA1 or ADTRGB1 (Sets ADSTRGR.TRSA[5:0] to “011010”.)
- ADTRGA2 or ADTRGB2 (Sets ADSTRGR.TRSA[5:0] to “011011”.)
- ADTRGA3 or ADTRGB3 (Sets ADSTRGR.TRSA[5:0] to “011100”.)

In extended double trigger mode, in addition to normal double trigger mode operation, A/D conversion data triggered by TRGnAN (n = 4, 7) and ADTRGAm (m = 0 to 3) is stored in A/D data duplication register A (ADDBLDRA), and A/D conversion data triggered by TRGnBN (n = 4, 7) and ADTRGBm (m = 0 to 3) is stored in A/D data duplication register B (ADDBLDRB).

If two types of trigger sources have occurred simultaneously, the A/D conversion data is stored in A/D data duplication register B (ADDBLDRB) without being sorted by the trigger sources. Note that if a new trigger is input during A/D conversion caused by another trigger, the new trigger is ignored.

30.3.2 Single Scan Mode

30.3.2.1 Basic Operation

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as below.

- (1) When the ADST bit in ADCSR register is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (MTU, GPT), or input of an asynchronous trigger. A/D conversion is performed for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.
- (2) Each time A/D conversion of a single channel is completed, the result of A/D conversion is stored in the corresponding A/D data register (ADDRy).
- (3) When A/D conversion of all the selected channels is completed, an S12ADI0 interrupt request is generated if the ADIE bit in ADCSR is 1 (S12ADI0 interrupt upon scanning completion is enabled).
- (4) The ADST bit in ADCSR remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the A/D converter enters a waiting state.

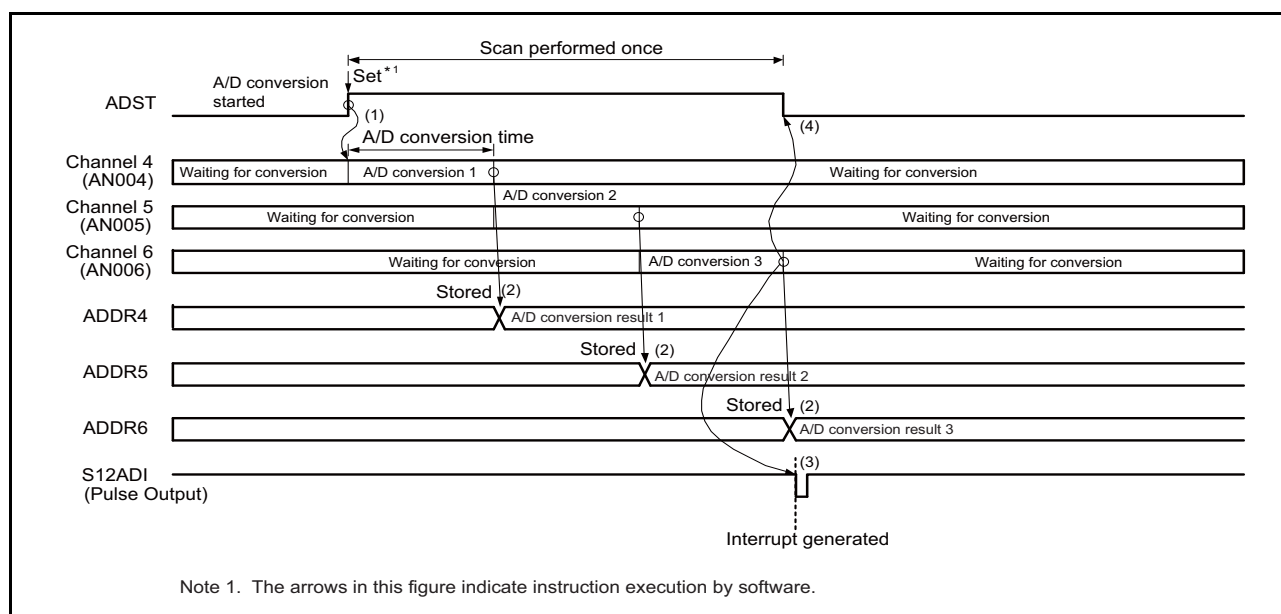

Figure 30.3 Example of Operation in Single Scan Mode (Basic Operation: AN004 to AN006 Selected)

30.3.2.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage AV_{cc} supplied to the A/D converter, and then A/D conversion is performed once on the analog input of the selected channels as below.

- (1) A/D conversion for self-diagnosis is first started when the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU, GPT), or an asynchronous trigger input.
- (2) When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored into the A/D self-diagnosis data register (ADDRD). A/D conversion is then performed for ANn pins selected by the ADANSA0 register, starting from the channel with the smallest number n.
- (3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (4) When A/D conversion of all the selected channels is completed, an S12ADI0 interrupt request is generated if the ADIE bit in ADCSR is 1 (S12ADI0 interrupt upon scanning completion enabled).
- (5) The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the A/D converter enters a waiting state.

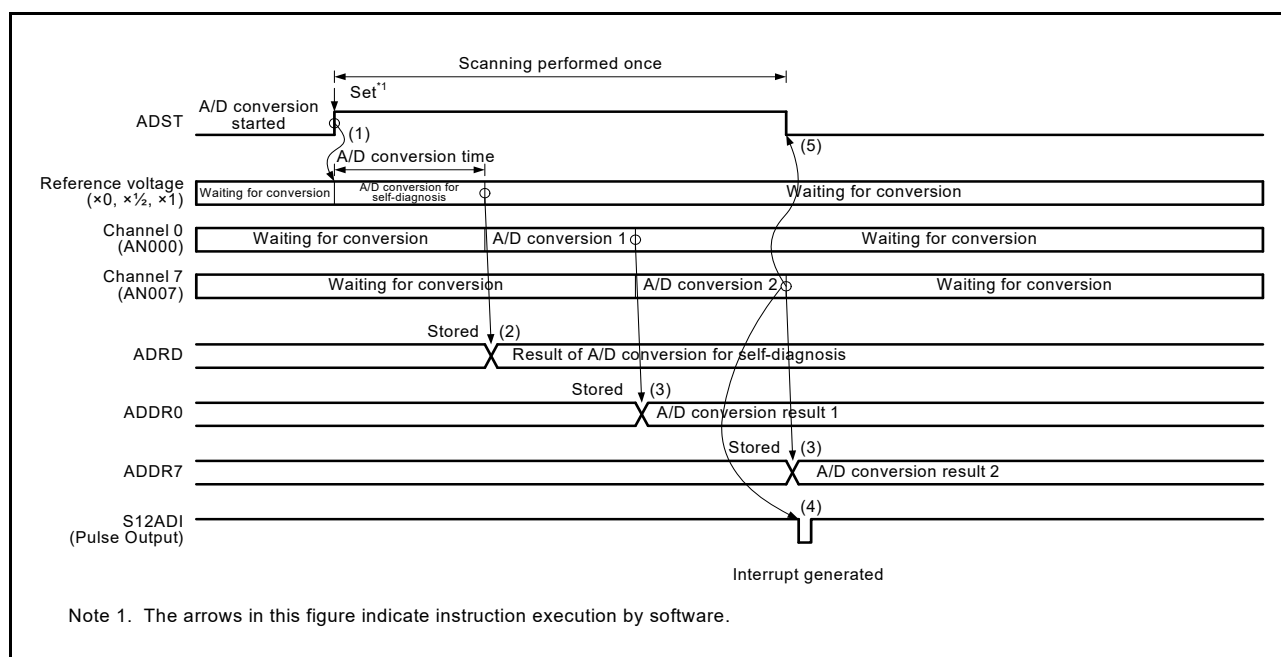

Figure 30.4 Example of Operation in Single Scan Mode
(Basic Operation: AN000 and AN007 Selected + Self-Diagnosis)

30.3.2.3 A/D Conversion in Double Trigger Mode

When double trigger mode is selected in single scan mode, A/D conversion is performed for two rounds of single scan operation started by a synchronous trigger (MTU, GPT) as a sequence as shown below. Self-diagnosis should be deselected.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the DBLANS[4:0] bits in ADCSR and setting the DBLE bit in ADCSR to 1. When the DBLE bit in ADCSR is set to 1, channel selection using the ADANSA0 register is invalid. In double trigger mode, a synchronous trigger (MTU, GPT) should be selected using the TRSA[5:0] bits in ADSTRGR; the EXTRG bit and TRGE bit in ADCSR should be set to 0 and 1, respectively. Software trigger should not be used.

- (1) When the ADST bit in ADCSR is set to 1 (A/D conversion start) by a synchronous trigger input (MTU, GPT), A/D conversion is started on the single channel selected by the DBLANS[4:0] bits in ADCSR.
- (2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (3) The ADST bit in ADCSR is automatically cleared to 0 and the A/D converter enters a waiting state. Here, an S12ADI0 interrupt request is not generated irrespective of the ADIE (S12ADI0 interrupt upon scanning completion enabled) bit setting in ADCSR.
- (4) When the ADST bit in ADCSR is set to 1 (A/D conversion start) by the second synchronous trigger input, A/D conversion is started on the single channel selected by the DBLANS[4:0] bits in ADCSR.
- (5) When A/D conversion is completed, the A/D conversion result is stored into the A/D data duplication register (ADDBLDR), which is exclusively used in double trigger mode.
- (6) If the ADIE bit in ADCSR is 1 (S12ADI0 interrupt upon scanning completion enabled), an S12ADI0 interrupt is generated.
- (7) The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion is completed. Then the A/D converter enters a waiting state.

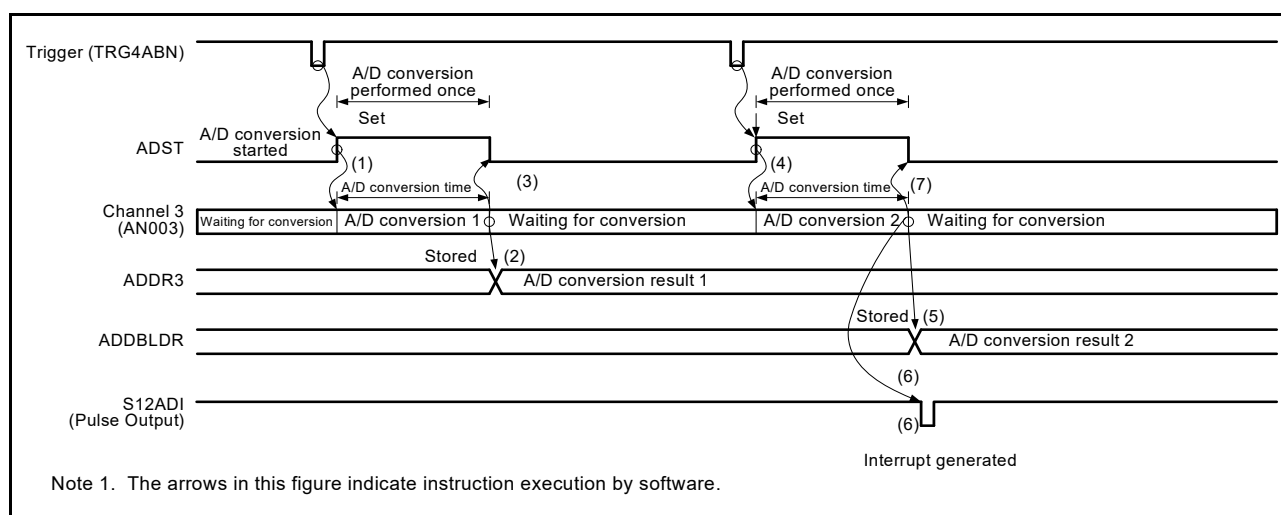

Figure 30.5 Example of Operation in Single Scan Mode
(Double Trigger Mode Selected; AN003 Duplicated; TRG4ABN is selected as the trigger)

30.3.2.4 Extended Operations When Double Trigger Mode is Selected

When double trigger mode is selected in single scan mode, two rounds of single scan operation are performed as shown below.

In double trigger extended mode, should be selected TRG4AN or TRG4BN, TRG7AN or TRG7BN, ADTRGA0 or ADTRGB0, ADTRGA1 or ADTRGB1, ADTRGA2 or ADTRGB2, and ADTRGA3 or ADTRGB3 using the TRSA[5:0] bits in ADSTRGR register; the EXTRG bit and TRGE bit in ADCSR register should be set to 0 and 1, respectively.

Software trigger should not be used.

Self-diagnosis should be deselected.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the DBLANS[4:0] bits in ADCSR register and setting the DBLE bit in ADCSR register to 1. When the DBLE bit in ADCSR register is set to 1, channel selection using the ADANSA0 register is invalid.

- (1) A/D conversion for the single channel selected by the ADCSR.DBLANS[4:0] bits starts when the TRG4AN input sets the ADCSR.ADST bit to 1 (starting A/D conversion).
- (2) The result is stored in the corresponding A/D data register (ADDRy) and in A/D data-duplication register A (ADDBLDRA) on completion of the A/D conversion for the channel.
- (3) The ADST bit is automatically cleared and the A/D converter enters the waiting state. An S12ADI0 interrupt is not generated at this time, regardless of the setting of the ADCSR.ADIE bit (i.e. whether or not this is set to enable S12ADI0 interrupts in response to scan completion).
- (4) When the TRG4BN input sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the single channel selected by the ADCSR.DBLANS[4:0] bits starts.
- (5) The result is stored in the A/D data-duplication register (ADDBLDR) and in A/D data-duplication register B (ADDBLDRB) on completion of A/D conversion.
- (6) An S12ADI0 interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI0 interrupt upon scanning completion enabled).
- (7) The ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is automatically cleared on completion of conversion, after which the A/D converter enters the waiting state.

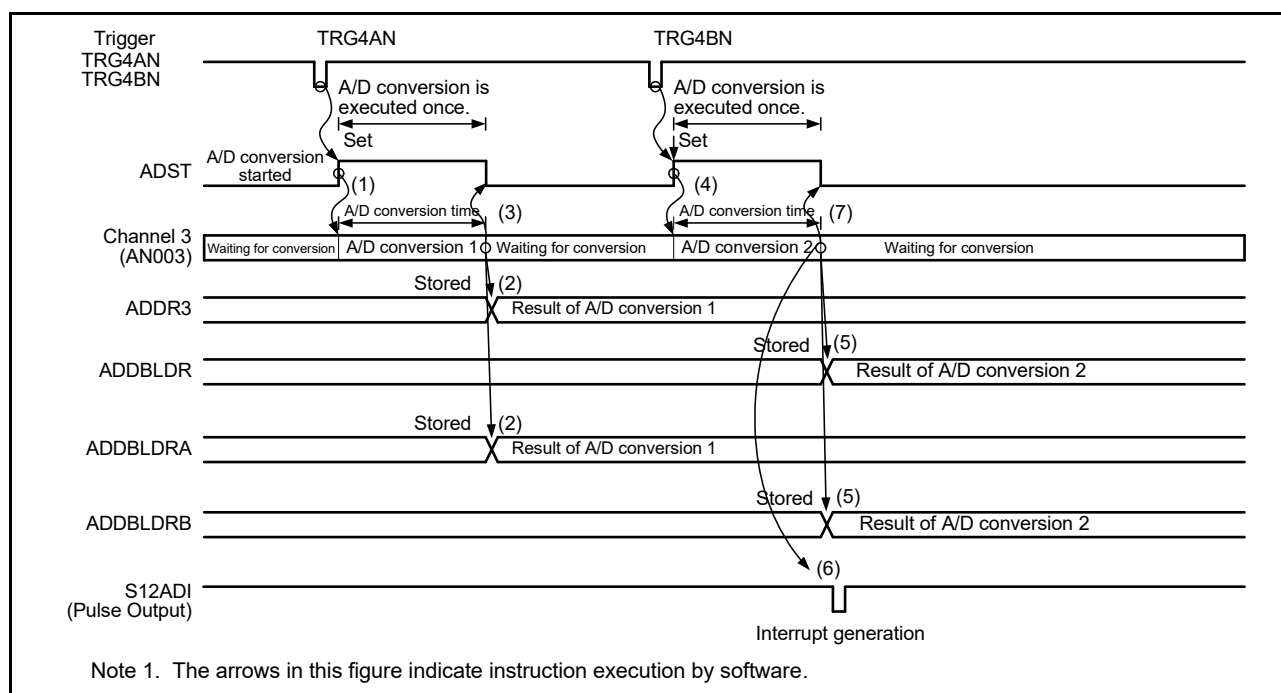

Figure 30.6 Example of Operation in Single Scan Mode
(Duplication Selected for AN003, TRG4AN or TRG4BN Selected)

30.3.3 Continuous Scan Mode

30.3.3.1 Basic Operation

In basic operation of continuous scan mode, A/D conversion is performed repeatedly on the analog input of the channels selected as below.

- (1) When the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU, GPT), or an asynchronous trigger input, A/D conversion is performed for ANn pins selected by the ADANSA0 register, starting from the channel with the smallest number n.
- (2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (3) When A/D conversion of all the selected channels is completed, an S12ADI0 interrupt is generated if the ADCSR.ADIE bit is 1 (S12ADI0 interrupt upon scanning completion enabled). The A/D converter sequentially starts A/D conversion for ANn pins selected by the ADANSA0 register, starting from the channel with the smallest number n.
- (4) The ADST bit in ADCSR is not automatically cleared and steps 2 and 3 are repeated as long as the bit remains 1 (A/D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the A/D converter enters a waiting state.
- (5) When the ADST bit is later set to 1 (A/D conversion start), A/D conversion is started again for ANn pins selected by the ADANSA0 register, starting from the channel with the smallest number n.

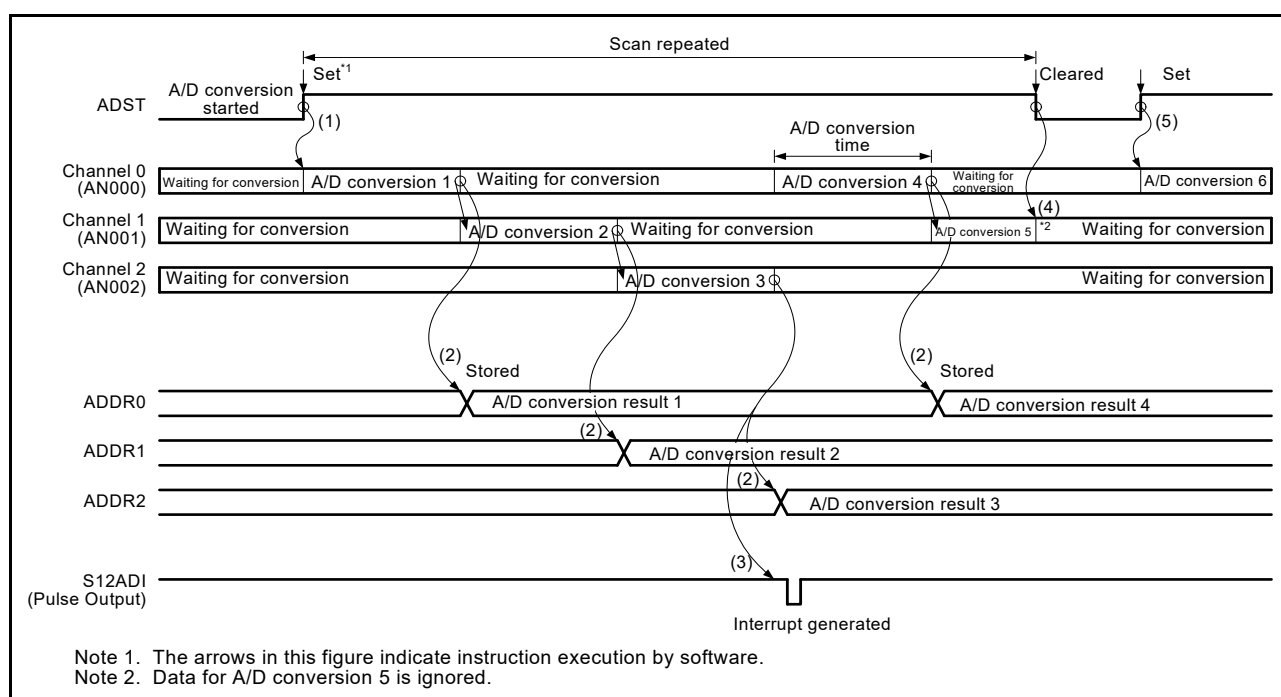

Figure 30.7 Example of Operation in Continuous Scan Mode (Basic Operation: AN000 to AN002 Selected)

30.3.3.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage AV_{CC} supplied to the A/D converter, and then A/D conversion is performed on the analog input of the selected channels, which sequence is repeated as below.

- (1) A/D conversion due to self-diagnosis is first started when the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU, GPT), or an asynchronous trigger input.
- (2) When A/D conversion due to self-diagnosis is completed, the A/D conversion result is stored into the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn pins selected by the ADANSA0 register, starting from the channel with the smallest number n.
- (3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
- (4) When A/D conversion of all the selected channels is completed, an S12ADI0 interrupt is generated if the ADCSR.ADIE bit is 1 (S12ADI0 interrupt upon scanning completion is enabled). At the same time, the A/D converter starts A/D conversion due to self-diagnosis and then starts A/D conversion on ANn pins selected by the ADANSA0 register, starting from the channel with the smallest number n.
- (5) The ADST bit in ADCSR is not automatically cleared and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit in ADCSR is set to 0 (A/D conversion stop), A/D conversion stops and the A/D converter enters a waiting state.
- (6) When the ADST bit is later set to 1 (A/D conversion start), conversion is started again from the A/D conversion due to self-diagnosis.

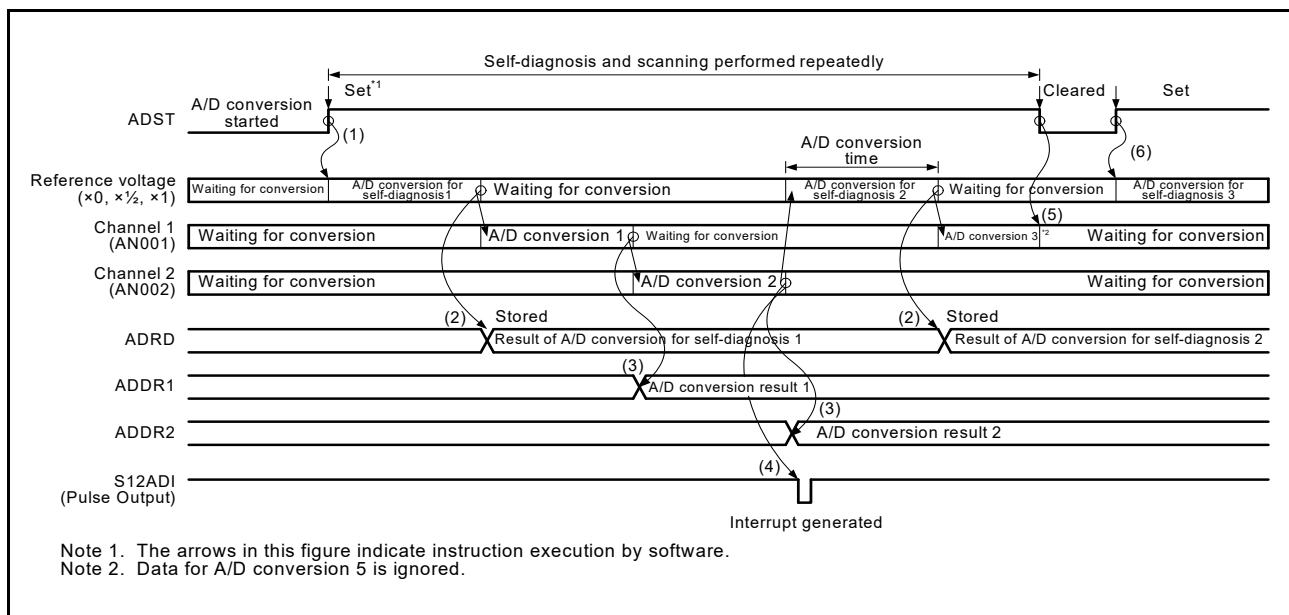

Figure 30.8 Example of Operation in Continuous Scan Mode
(Basic Operation; AN001 and AN002 Selected + Self-Diagnosis)

30.3.4 Group Scan Mode

30.3.4.1 Basic Operation

Either two (group A, B) or three (group A, B, C) can be selected for the number of groups to be used in group scan mode. In basic operation of group scan mode, A/D conversion is performed once on the analog inputs of all the specified channels in group A and group B or group A, group B, and group C after scanning is started by a synchronous trigger as below. Scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers of group A, B, and C can be selected using the TRSA[5:0], TRSB[5:0], and TRSC[5:0] bits in ADSTRGR, respectively. The different triggers should be set for group A, group B, and group C to prevent simultaneous scan operation of group A, group B, and group C. Software trigger should not be used.

The ADANSA0 register is used to select the channels subject to scan operation for group A. The ADANSB0 register is used to select the channels subject to scan operation for group B. The ADANSC0 register is used to select the channels subject to scan operation for group C.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for group A and group B or group A, group B, and group C.

The following describes operation in group scan mode using a trigger of the MTU. Specifically, the TRG4AN, TRG4BN, and TRG4ABN triggers of the MTU are assumed to be used to start conversion of group A, group B, and group C, respectively.

- (1) Scanning of group A is started by the TRG4AN trigger of the MTU.
- (2) When group A scanning is completed, an S12ADI0 interrupt is generated if the ADIE bit in ADCSR is 1 (S12ADI0 interrupt upon scanning completion is enabled).
- (3) Scanning of group B is started by the TRG4BN trigger of the MTU.
- (4) When group B scanning is completed, a S12GBADI0 interrupt is generated if the GBADIE bit in ADCSR is 1 (S12GBADI0 interrupt upon scanning completion is enabled).
- (5) Scanning of group C is started by the TRG4ABN trigger of the MTU.
- (6) When group C scanning is completed, a S12GCADI0 interrupt is generated if the GBADIE bit in ADCSR is 1 (S12GCADI0 interrupt upon scanning completion is enabled).

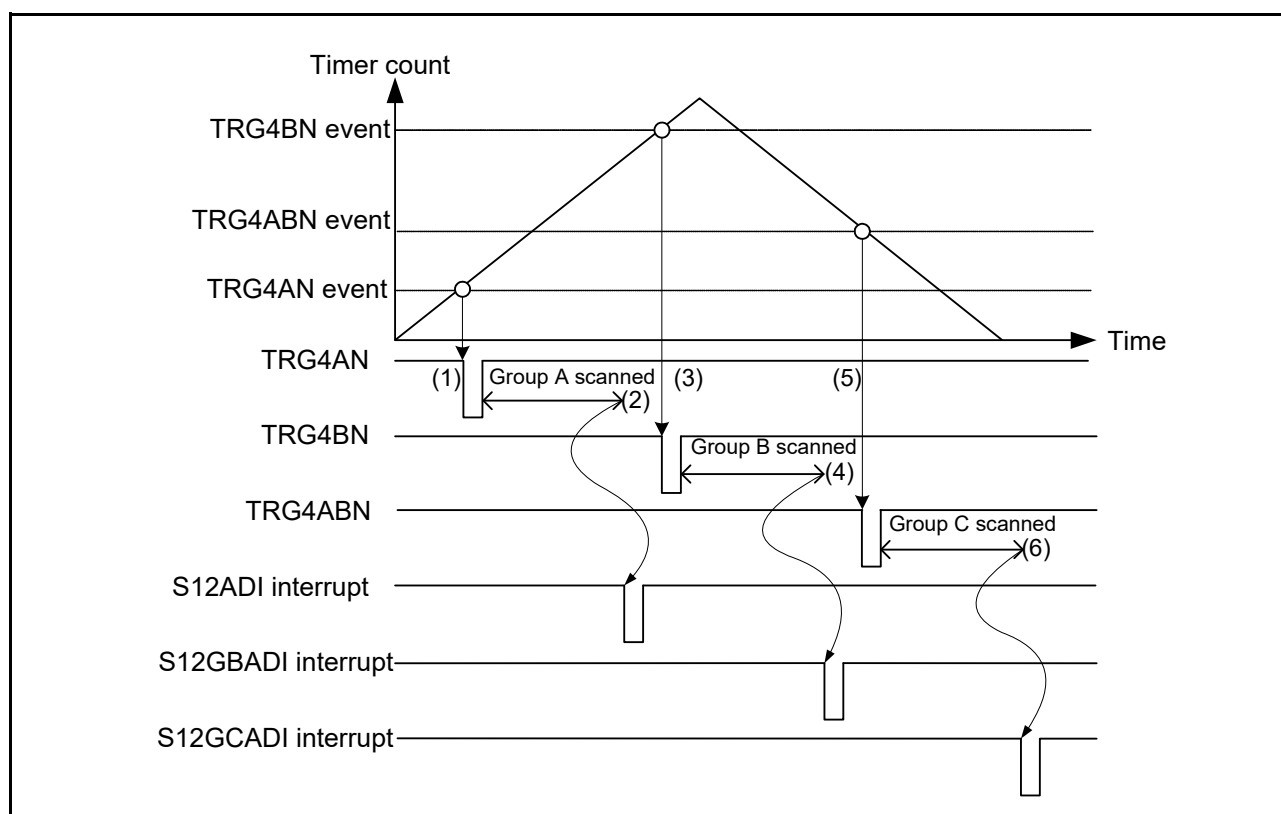

Figure 30.9 Example of Operation in Group Scan Mode (Basic Operation: Triggers from MTU Used)

30.3.4.2 A/D Conversion in Double Trigger Mode

When double trigger mode is selected in group scan mode, A/D conversion is performed for two rounds of single scan operation started by a synchronous trigger (MTU, GPT) as a sequence for group A. For group B and group C, single scan operation started by a synchronous trigger (MTU, GPT) is performed once.

In group scan mode, the synchronous triggers of group A, B, and C can be selected using the TRSA[5:0], TRSB[5:0], and TRSC[5:0] bits in ADSTRGR, respectively. The different triggers should be selected for group A, group B, and group C to prevent simultaneous A/D conversion of group A, group B and group C. Software trigger, or asynchronous trigger (ADTRG#) should not be used.

When TRG4AN or TRG4BN, TRG7AN or TRG7BN, ADTRGA0 or ADTRGB0, ADTRGA1 or ADTRGB1, ADTRGA2 or ADTRGB2, or ADTRGA3 or ADTRGB3 is selected as the synchronous trigger for group A (the ADSTRGR.TRSA[5:0] bits), operation proceeds in extended double trigger mode.

The DBLANS[4:0] bits in the ADCSR register are used to select the channels subject to scan operation for group A. The ADANSB0 register is used to select the channels subject to scan operation for group B. The ADANSC0 register is used to select the channels subject to scan operation for group C.

When double trigger mode is selected in group scan mode, self-diagnosis cannot be selected.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the DBLANS[4:0] bits in ADCSR and setting the DBLE bit in ADCSR to 1.

The following describes operation in group scan mode with double trigger mode using a trigger of the MTU.

Specifically, the TRG4ABN, TRGA0N, and TRGA1N triggers of the MTU are assumed to be used to start conversion of group A, group B, and group C, respectively.

- (1) Scanning of group C is started by the TRGA1N trigger of the MTU.
- (2) When group C scanning is completed, a S12GCADI0 interrupt is generated if the GCADIE bit in ADGCTRGR is 1 (S12GCADI0 interrupt upon scanning completion is enabled).
- (3) Scanning of group B is started by the TRGA0N trigger of the MTU.
- (4) When group B scanning is completed, a S12GBADI0 interrupt is generated if the GBADIE bit in ADCSR is 1 (S12GBADI0 interrupt upon scanning completion is enabled).
- (5) The first scanning of group A is started by the first TRG4ABN trigger of the MTU.
- (6) When the first scanning of group A is completed, the conversion result is stored into the corresponding A/D data register (ADDRy); an S12ADI0 interrupt is not generated irrespective of the ADIE bit setting in ADCSR.
- (7) The second scanning of group A is started by the second TRG4ABN trigger of the MTU.
- (8) When the second scanning of group A is completed, the conversion result is stored into the ADDBLDR register. An S12ADI0 interrupt is generated if the ADIE bit in ADCSR is 1 (S12ADI0 interrupt is enabled).
- (9) The second scanning of group B is started by the second TRGA0N trigger of the MTU.
- (10) When the second scanning of group B is completed, an S12GBADI0 interrupt is generated if the GBADIE bit in ADCSR is 1 (S12GBADI0 interrupt is enabled).
- (11) The second scanning of group C is started by the second TRGA1N trigger of the MTU.
- (12) When the second scanning of group C is completed, an S12GCADI0 interrupt is generated if the GCADIE bit in ADGCTRGR is 1 (S12GCADI0 interrupt is enabled).

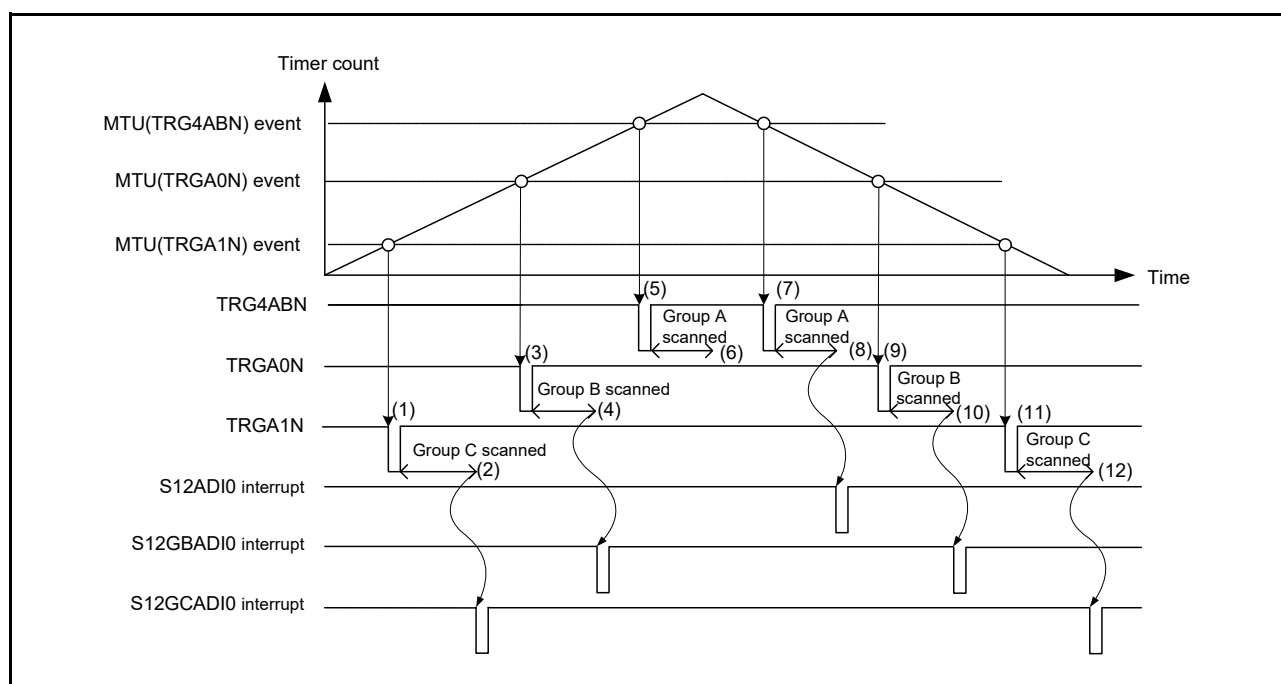

Figure 30.10 Example of Operation in Group Scan Mode with Double Trigger Mode
(Basic Operation: Triggers from MTU Used)

30.3.4.3 Group Priority Control

Setting the ADGSPCR.PGS bit to 1 in group scan mode makes operation proceed under group priority control.

The order of group priority is group A > group B > group C. The number of groups to be used in group scan mode can be selected from either two (group A, B) or three (group A, B, C) by setting ADGCTRGR.GRCE.

When setting the ADGSPCR.PGS bit to 1, follow the procedure described in Figure 30.11. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

In operation in basic group scan mode, input of the trigger for the other group during scan operation in group A, group B, or group C is ignored, and scan operations in group A, group B, or group C are the same in single scan mode.

Under group priority control, if a priority group trigger is input during scan operation for low priority group, scan operation for low priority group is discontinued and scan operation for priority group proceeds.

If the setting of the ADGSPCR.GBRSCN bit is 0, the low priority group enters the waiting state on completion of the scan operation for priority group. Additionally, trigger input for the low priority group that occurs during scanning is ignored.

If the setting of the ADGSPCR.GBRSCN bit is 1, the converter automatically restarts scanning for low priority group after completion of the scan operation for priority group.

Additionally, trigger input for the low priority group that occurs during scanning for the priority group is valid, and on completion of the scan for the priority group, scanning for the low priority group is automatically executed.

If the setting of the ADGSPCR.GBRSCN bit is 1 and ADGSPCR.LGRRS bit is 0, the converter restarts scanning for low priority group from the head of the group.

Additionally, when ADGSPCR.LGRRS is set to 1, scan for the low priority group is re-executed from the interrupted channel. Note that when the self-diagnosis function is used, scan is re-executed from the interrupted channel on completion of self-diagnosis.

Table 30.13 shows the relation between the setting of the ADGSPCR.GBRSCN bit and operation in response to trigger input during scanning.

When the ADGSPCR.GBRP bit is set to 1, single scan is continuously performed as scanning operation for the lowest priority group.

When setting a trigger in group scan mode, select a synchronous trigger for group A using the ADSTRGR.TRSA[5:0] bits, select a synchronous trigger for group B different from that of group A using the ADSTRGR.TRSB[5:0] bits, and select a synchronous trigger for group C different from those of group A and group B using the ADGCTRGR.TRSC[5:0] bits.

When two groups are enabled (the ADGCTRGR.GRCE bit is set to 0) in group scan mode and the ADGSPCR.GBRP bit is set to 1, set the ADSTRGR.TRSB[5:0] bits to 3Fh.

Additionally, when three groups are enabled (the ADGCTRGR.GRCE bit is set to 1) in group scan mode and the ADGSPCR.GBRP bit is set to 1, set the ADGCTRGR.TRSC[5:0] bits to 3Fh.

Furthermore, as targets for scan operation, select channels for group A, group B, and group C using the ADANSA0, ADANSB0, and ADANSC0 registers, respectively.

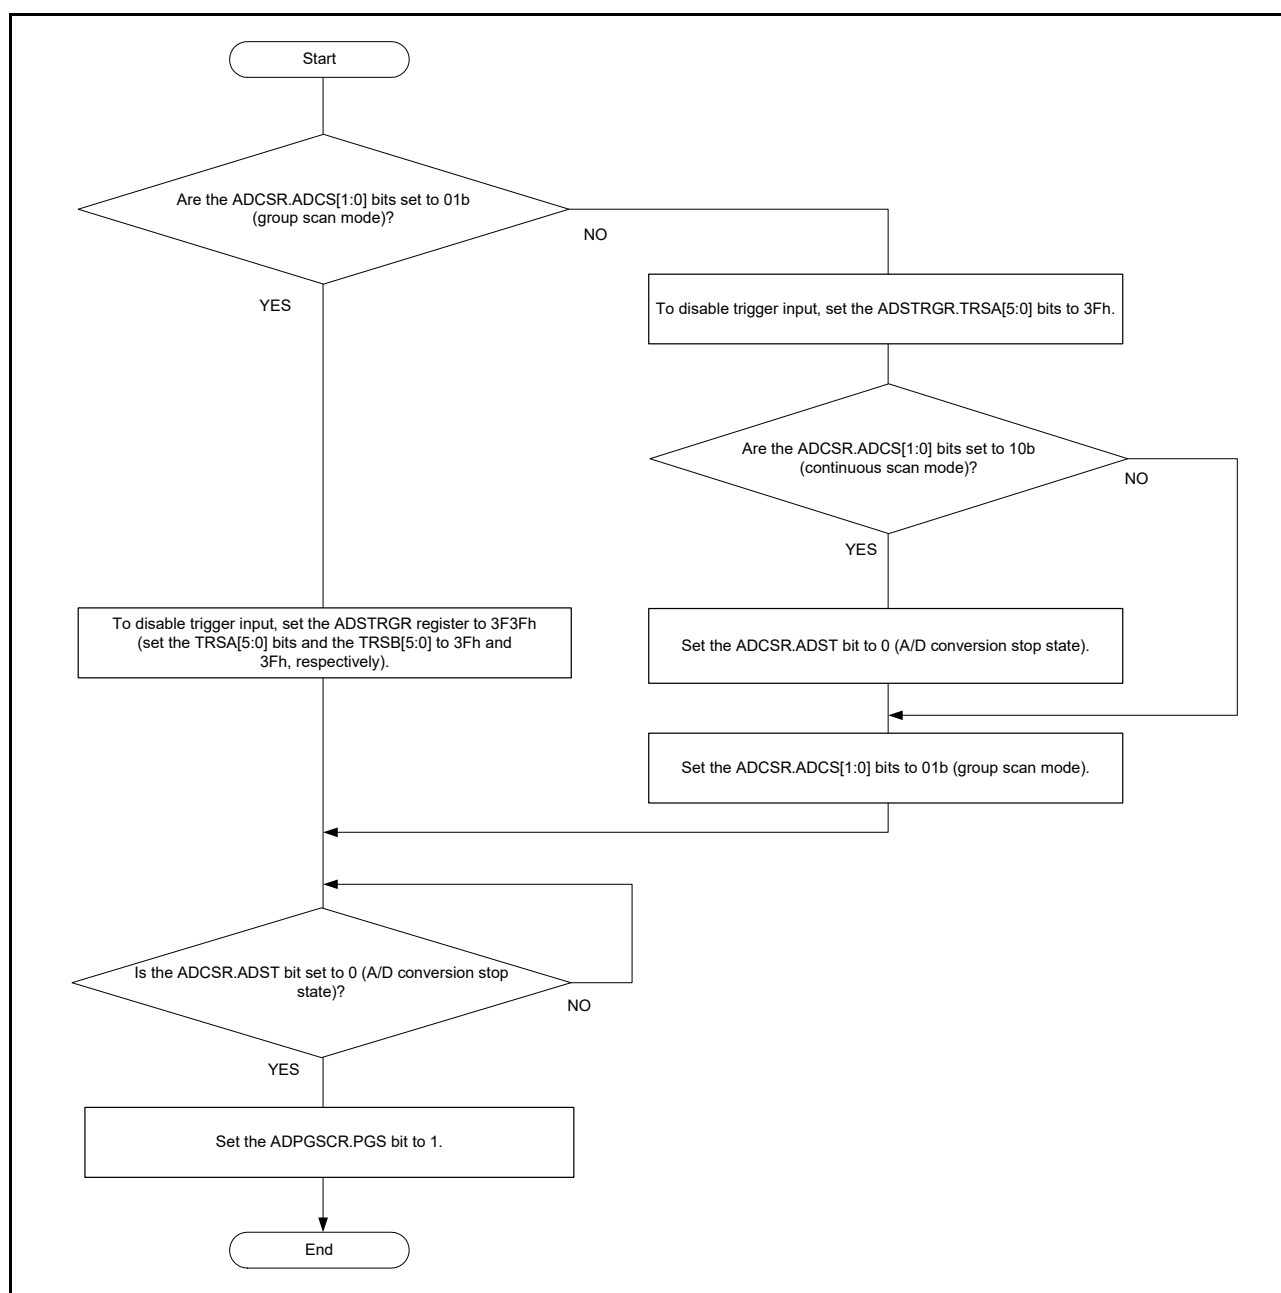

Figure 30.11 Flow of Setting the ADPGSCR.PGS Bit

Table 30.13 Control of Scan Operations According to the Settings of the ADGSPCR.GBRSCN Bit

| A/D Conversion Operation | Trigger Input | ADGSPCR.GBRSCN = 0 | ADGSPCR.GBRSCN = 1 |
|--|------------------------------|---|---|
| When A/D conversion for group A is in progress | Input of trigger for group A | Trigger input is ineffective. | Trigger input is ineffective. |
| | Input of trigger for group B | Trigger input is ineffective. | A/D conversion is performed on group B after A/D conversion on group A is completed. |
| | Input of trigger for group C | Trigger input is ineffective. | A/D conversion is performed on group C after A/D conversion on group A is completed. |
| When A/D conversion for group B is in progress | Input of trigger for group A | Conversion for group B that is in progress is discontinued and conversion for group A starts. | <ul style="list-style-type: none"> Conversion in progress for group B is discontinued and conversion for group A starts. Conversion for group B starts after conversion for group A is completed. |
| | Input of trigger for group B | Trigger input is ineffective. | <ul style="list-style-type: none"> Trigger input is ineffective. |
| | Input of trigger for group C | Trigger input is ineffective. | <ul style="list-style-type: none"> Conversion for group C starts after conversion for group B is completed. |
| When A/D conversion for group C is in progress | Input of trigger for group A | Conversion for group C that is in progress is discontinued and conversion for group A starts. | <ul style="list-style-type: none"> Conversion in progress for group C is discontinued and conversion for group A starts. Conversion for group C starts after conversion for group A is completed. |
| | Input of trigger for group B | Conversion for group C that is in progress is discontinued and conversion for group B starts. | <ul style="list-style-type: none"> Conversion in progress for group C is discontinued and conversion for group B starts. Conversion for group C starts after conversion for group B is completed. |
| | Input of trigger for group C | Trigger input is ineffective. | Trigger input is ineffective. |

When using group priority control operation mode, refer to the following table, and select the desired operation mode and set the register.

Table 30.14 Group Priority Control Settings and Operation Mode for Two Groups
(ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 0)

| ADGSPCR | | | Operation Category |
|---------|-------|------|--|
| GBRSCN | LGRRS | GBRP | |
| 0 | — | 0 | Group priority control for two groups (A, B) When a trigger for group A is input, the group B scanning is ended (no re-execution). |
| 1 | 0 | 0 | Group priority control for two groups (A, B) After the group B scanning is interrupted, the group B scan is restarted from the head of the channels specified in ADANSB0 on completion of the group A scan. |
| 1 | 1 | 0 | Group priority control for two groups (A, B) After the group B scanning is interrupted, the group B scan is restarted from the interrupted channel* ¹ of the channels specified in ADANSB0 on completion of the group A scan. |
| — | 0 | 1 | Group priority control for two groups (A, B) Single scan is continuously performed on group B without any start trigger input. After the group B scanning is interrupted, single scan is restarted from the head of the channels specified in ADANSB0 on completion of the group A scan. |
| 1 | 1 | 1 | Group priority control for two groups (A, B) Single scan is continuously performed on group B without any start trigger input. After the group B scanning is interrupted, single scan is restarted from the interrupted channel* ¹ of the channels specified in ADANSB0 on completion of the group A scan. |

Note: When the self-diagnosis function is enabled (ADCER.DIAGM = 1), A/D conversion for the interrupted channel starts on completion of self-diagnosis.

Table 30.15 Group Priority Control Settings and Operation Mode for Three Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1)

| ADGSPCR | | | |
|---------|-------|------|---|
| GBRSCN | LGRRS | GBRP | Operation Category |
| 0 | — | 0 | Group priority control for three groups (A, B, C) When a trigger for group A is input, the group B scanning is ended (no re-execution). When a trigger for group A or group B is input, the group C scanning is ended (no re-execution). |
| 0 | — | 1 | Group priority control for three groups (A, B, C) When a trigger for group A is input, the group B scanning is ended (no re-execution). Single scan is continuously performed on group C without any start trigger input. After the group C scanning is interrupted, the scan is restarted from the head of the channels specified in ADANSC0 on completion of the group A/B scan. |
| 1 | 0 | 0 | Group priority control for three groups (A, B, C) After the group B scanning is interrupted, the scan is restarted from the head of the channels specified in ADANSB0 on completion of the group A scan. After the group C scanning is interrupted, the scan is restarted from the head of the channels specified in ADANSC0 on completion of the group A/B scan. |
| 1 | 1 | 0 | Group priority control for three groups (A, B, C) After the group B scanning is interrupted, the scan is restarted from the interrupted channel* of the channels specified in ADANSB0 on completion of the group A scan. After the group C scanning is interrupted, the scan is restarted from the interrupted channel* of the channels specified in ADANSC0 on completion of the group A/B scan. |
| 1 | 0 | 1 | Group priority control for three groups (A, B, C) After the group B scanning is interrupted, the scan is restarted from the head of the channels specified in ADANSB0 on completion of the group A scan. Single scan is continuously performed on group C without any start trigger input. After the group C scanning is interrupted, single scan is restarted from the head of the channels specified in ADANSC0 on completion of the group A/B scan. |
| 1 | 1 | 1 | Group priority control for three groups (A, B, C) After A/D conversion on group B is interrupted, the A/D conversion is restarted from the interrupted channel* of the channels specified in ADANSB0 on completion of the group A scan. Single scan is continuously performed on group C without any start trigger input. After the group C scanning is interrupted, single scan is restarted from the interrupted channel* of the channels specified in ADANSC0 on completion of the group A/B scan. |

Note: When the self-diagnosis function is enabled (ADCER.DIAGM = 1), A/D conversion for the interrupted channel starts on completion of self-diagnosis.

(1) Group priority control for two groups (when ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 0)

The following examples 1 to 3 describes the operations in group scan mode under group scan mode group priority operation (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

Example of operation (1) "Trigger input for group A during group B scanning" with rescan enabled

- (1) When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channel pins selected in the ADANSB0 register starts in order from the channel with the lowest number.
- (2) On completion of A/D conversion for a channel, the result is stored in the corresponding A/D data register (ADDRy).
- (3) When a trigger for group A is input during group B scanning, the group B scanning is interrupted while the ADCSR.ADST bit holds 1, and group A scanning for the ANn channels selected in the ADANSA0 register starts in order from the channel with the smallest number n. If A/D conversion is not completed at the time of interruption, the A/D conversion result is not stored in the A/D data register y (ADDRy).
- (4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
- (5) An S12ADI0 interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI0 interrupt upon scanning completion is enabled).
- (6) If the ADGSPCR.GBRSCN bit is set to 1 (rescan is performed on the group interrupted due to group priority control), conversion for the ANn channels of group B selected in the ADANSB0 register starts in order from the channel with the lowest number n while the ADCSR.ADST bit holds 1.
- (7) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
- (8) An S12GBADI0 interrupt is generated if the setting of the ADCSR.GBADIE bit is 1 (S12GBADI0 interrupt upon group B scanning completion enabled).
- (9) The ADCSR.ADST bit is automatically cleared on completion of all scanning, after which the A/D converter enters the waiting state.

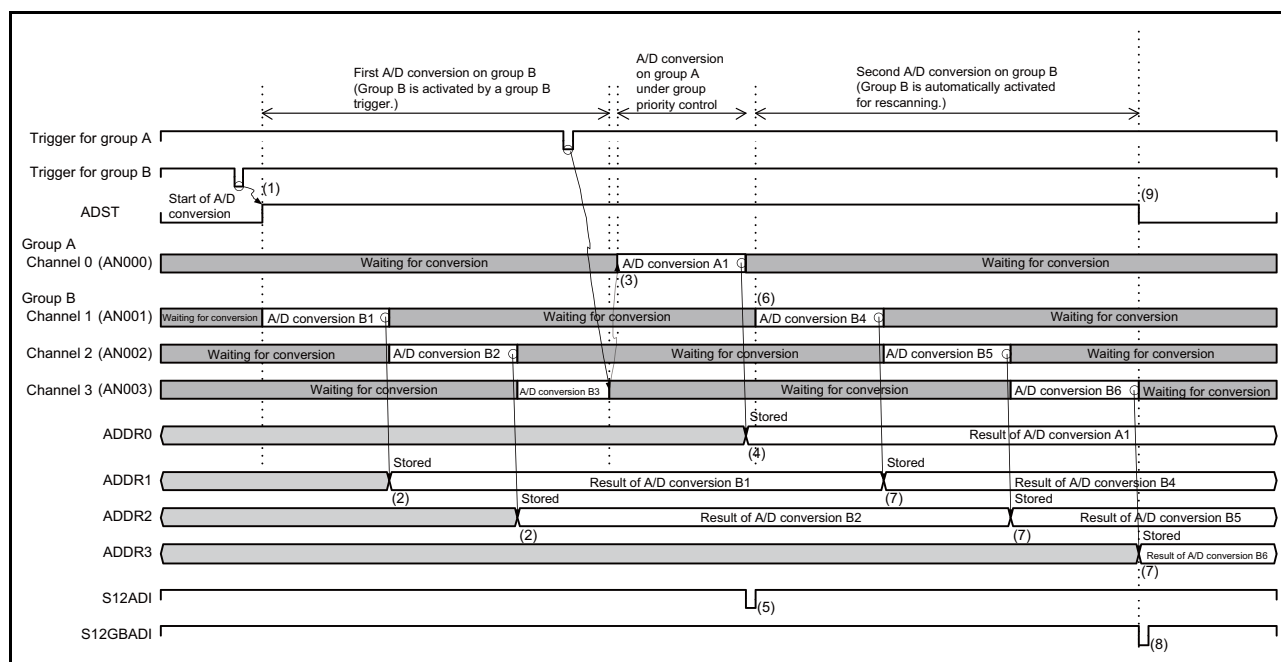

Figure 30.12 Example of Operations under Group Priority Control (1)
 "Trigger Input for Group A during Group B Scanning" with Rescan Enabled
 (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Example of operation (2) "Trigger input for group A during group B rescanning" with rescan enabled

Figure 30.13 shows an example when a group A trigger is input again during rescanning operation on group B. Even during rescanning, if a trigger for group A is input, group A scan starts and on completion of the group A scan, group B scan starts.

Operation related to the ADST bit, storage of the A/D conversion result in the A/D data register y (ADDRy), and interrupt request is the same as that of Example of operation (1).

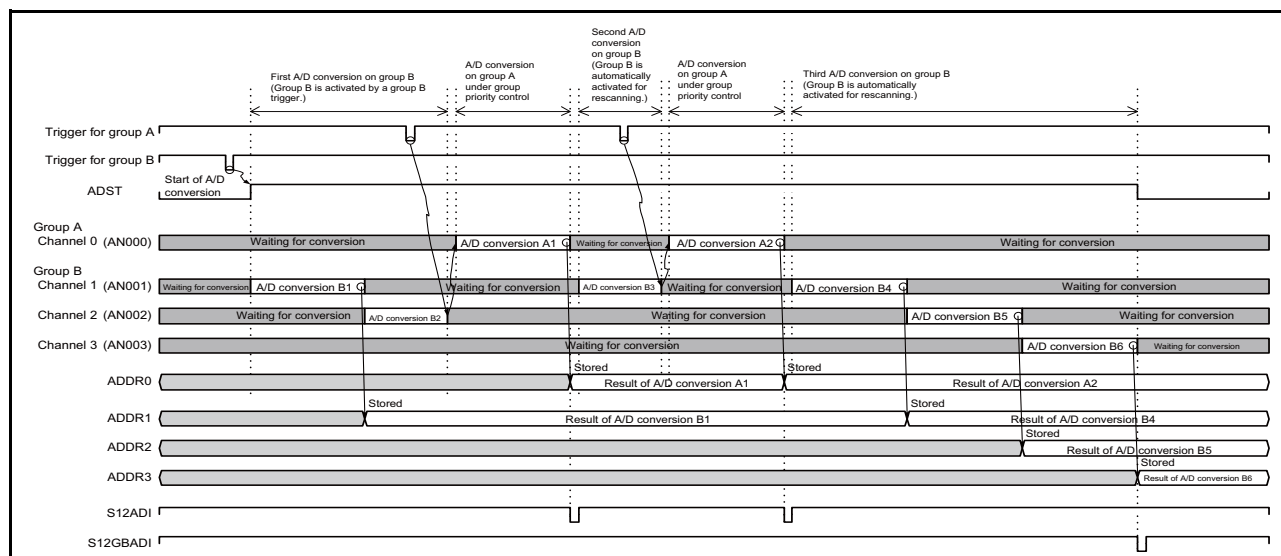

Figure 30.13 Example of Operations under Group Priority Control (2) "Trigger Input for Group A during Group B Rescanning" with Rescan Enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)

Example of operation (3) "Trigger input for group B during group A scanning" with rescan enabled

This section describes operation when the ADGPSCR.GBRSCN bit is set to 1 (rescan is performed on the group interrupted due to group priority control), and a trigger for group B is input during group A scanning.

When the ADGPSCR.GBRSCN bit is set to 0, any trigger for group B that is input during group A scanning is invalid.

- (1) When a group A trigger input sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channel pins of group A selected in the ADANSA0 register starts in order from the channel with the lowest number n.
- (2) When a trigger for group B is input during group A scanning, group B enters the scan-ready state.
- (3) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
- (4) After that, an S12ADI0 interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI0 interrupt upon scanning completion is enabled).
- (5) On completion of the group A scan, scan for the ANn channels of group B selected in the ADANSB0 register is performed in order from the channel with the smallest number n while the ADCSR.ADST bit holds 1.
(If a trigger for group A is input during group B scanning, as in Example of operation (1), group A scan starts and on completion of the group A scan, group B scan starts.)
- (6) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
- (7) After that, an S12GBADI0 interrupt is generated if the setting of the ADCSR.GBADIE bit is 1 (S12GBADI0 interrupt upon group B scanning completion enabled).
- (8) The ADCSR.ADST bit is automatically cleared on completion of all scanning, after which the A/D converter enters the waiting state.

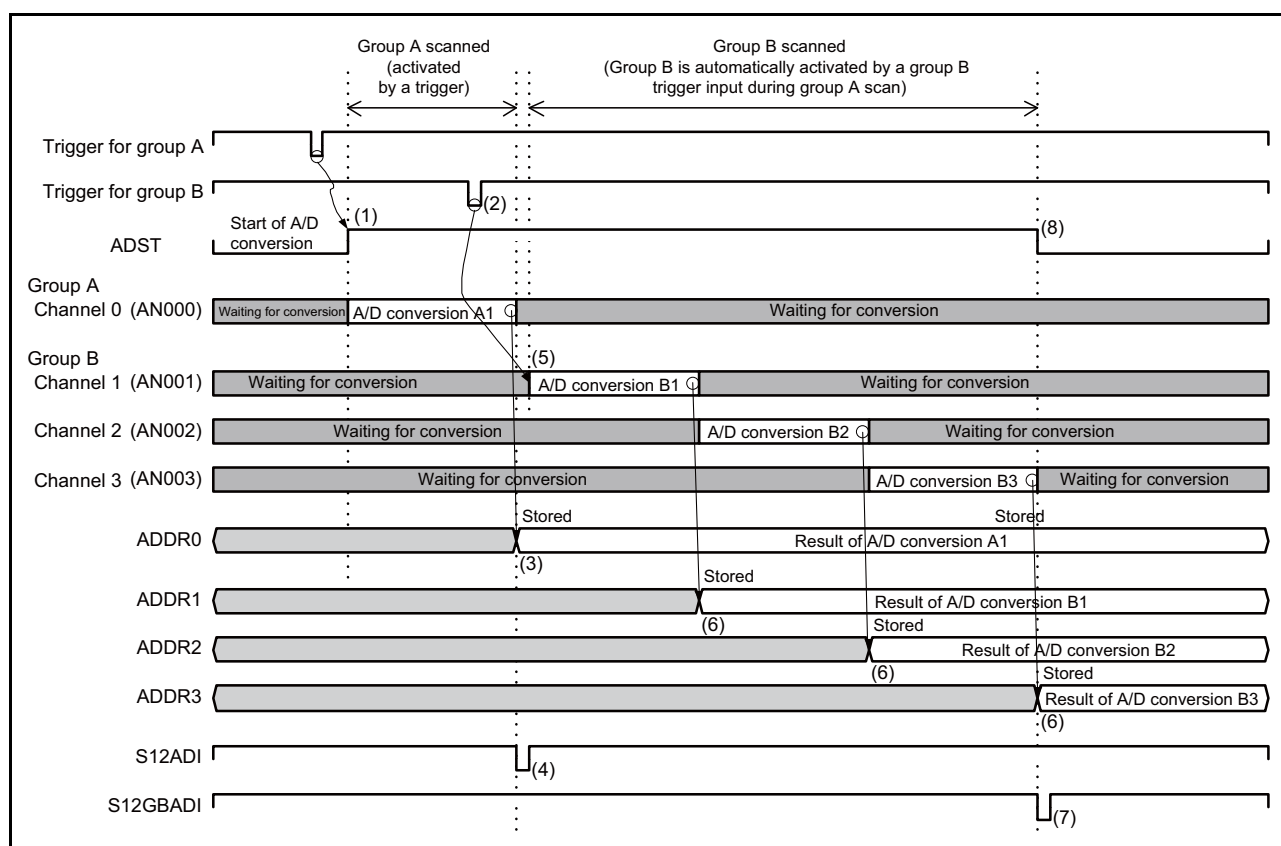

Figure 30.14 Example of Operations under Group Priority Control (3) "Trigger Input for Group B during Group A Scanning" with Rescan Enabled (when $\text{ADGSPCR.GBRSCN} = 1$, $\text{ADGSPCR.GBRP} = 0$, $\text{ADGSPCR.LGRRS} = 0$)

Example of operation (4) describes group priority control in group scan mode ($\text{ADGSPCR.GBRSCN} = 0$, $\text{ADGSPCR.GBRP} = 0$, and $\text{ADGSPCR.LGRRS} = 0$) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

Example of operation (4) "Trigger input for group A during group B scanning" with rescan disabled

- (1) When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), scan for the ANn channels selected in the ADANSB0 register starts in order from the channel with the smallest number n.
- (2) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (3) When a trigger for group A is input during group B scanning, the group B scanning is interrupted while the ADCSR.ADST bit holds 1, and group A scan for the ANn channels selected in the ADANSA0 register starts in order from the channel with the smallest number n. If A/D conversion is not completed at the time of interruption, the A/D conversion result is not stored in the A/D data register y (ADDRy).
- (4) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (5) On completion of the group A scan, an S12ADI0 interrupt request is generated if the ADCSR.ADIE bit is set to 1 (S12ADI0 interrupt upon scanning completion is enabled).
- (6) The ADST bit is automatically cleared on completion of the group A scan and the A/D converter enters the waiting state. Group B scan is not performed until the next input of a trigger for group B.

Figure 30.15 Example of Operations under Group Priority Control (4) "Trigger Input for Group A during Group B Scanning" with Rescan Disabled (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)

Example of operation (5) describes group priority control in group scan mode (ADGSPCR.GBRP = 1 and ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 and 2 are selected for group B. When the ADGCTRGR.GRCE bit is set to 1, single scan is performed continuously on group C and group B scan starts in response to trigger input.

Example of operation (5) "Continuous Operation of Single Scan for Group B"

- (1) When ADGSPCR.GBRP is set to 1, the ADCSR.ADST bit is set to 1 (starting A/D conversion), and scan for the ANn channels selected in the ADANSB0 register starts in order from the channel with the smallest number n.
- (2) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (3) When a trigger for group A is input during group B scanning, the group B scanning is interrupted while the ADCSR.ADST bit holds 1, and group A scan for the ANn channels selected in the ADANSA0 register starts in order from the channel with the smallest number n. If A/D conversion is not completed at the time of interruption, the A/D conversion result is not stored in the A/D data register y (ADDRy).
- (4) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (5) On completion of the group A scan, an S12ADI0 interrupt request is generated if the ADCSR.ADIE bit is set to 1 (S12ADI0 interrupt upon scanning completion is enabled).
- (6) If the ADGSPCR.GBRP bit is set to 1 (performing single scan continuously), group B scan for the ANn channels selected in the ADANSB0 register restarts in order from the channel with the smallest number n while the ADCSR.ADST bit holds 1.
- (7) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (8) An S12GBADI0 interrupt request is generated if the ADCSR.GBADIE bit is set to 1 (S12GBADI0 interrupt upon group B scanning completion is enabled).
- (9) If the ADGSPCR.GBRP bit is set to 1 (performing single scan continuously), group B scan for the ANn channels selected in the ADANSB0 register restarts in order from the channel with the smallest number n while the ADCSR.ADST bit holds 1.

Disable group B trigger input to perform a single scan operation continuously on group B.

Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit is set to 1. Clearing of the ADCSR.ADST bit is prohibited while the ADGSPCR.GBRP bit is set to 1. Follow the procedure for clearing operation by software through the ADCSR.ADST bit, shown in section 30.5.2, Notes on Stopping A/D Conversion, to forcibly stop scanning when ADGSPCR.GBRP = 1.

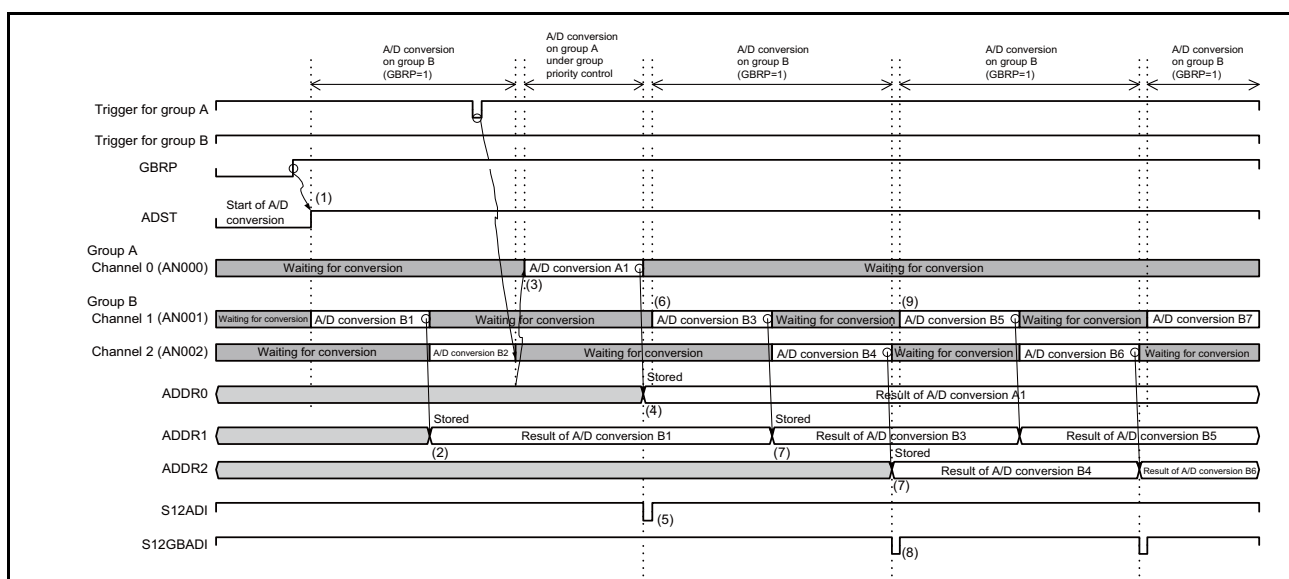

Figure 30.16 Example of Operations under Group Priority Control (5) "Continuous Operation of Single Scan for Group B" (when ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1'b0, ADGCTRGR.GRCE = 0)

(2) Group priority control for three groups (when ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1)

Examples of operation (1) to (3) describe group priority control in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 1) when channel 0 is selected for group A, channels 1, 2 are selected for group B, and channels 3, 4 are selected for group C. The priority group means group A and group B for group C, and group A for group B.

Example of operation (1) "Trigger input for priority group during scanning for low priority group" with rescan enabled

- (1) When input of a trigger for group C sets the ADCSR.ADST bit to 1 (starting A/D conversion), scan for the ANn channels selected in the ADANSC0 register starts in order from the channel with the smallest number n.
- (2) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (3) When a trigger for group B is input during group C scanning, the group C scanning is interrupted while the ADCSR.ADST bit holds 1, and group B scan for the ANn channels selected in the ADANSB0 register starts in order from the channel with the smallest number n. If A/D conversion is not completed at the time of interruption, the A/D conversion result is not stored in the A/D data register y (ADDRy).
- (4) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (5) When a trigger for group A is input during group B scanning, the group B scanning is interrupted while the ADCSR.ADST bit holds 1, and group A scan for the ANn channels selected in the ADANSA0 register starts in order from the channel with the smallest number n. If A/D conversion is not completed at the time of interruption, the A/D conversion result is not stored in the A/D data register y (ADDRy).
- (6) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (7) An S12ADI0 interrupt request is generated if the ADCSR.ADIE bit is set to 1 (S12ADI0 interrupt upon scanning completion is enabled).
- (8) If the ADGSPCR.GBRSCN bit is set to 1 (rescan is performed on the group interrupted due to group priority control), group B scan for the ANn channels selected in the ADANSB0 register restarts in order from the channel with the smallest number n while the ADCSR.ADST bit holds 1. At this time, if the ADGSPCR.LGRRS bit is set to 1, group B scan starts from the channel on which A/D conversion was interrupted.
- (9) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (10) An S12GBADI0 interrupt request is generated if the ADCSR.GBADIE bit is set to 1 (S12GBADI0 interrupt upon group B scanning completion is enabled).
- (11) If the ADGSPCR.GBRSCN bit is set to 1, group C scan for the ANn channels selected in the ADANSC0 register starts in order from the channel with the smallest number n while the ADCSR.ADST bit holds 1. At this time, if the ADGSPCR.LGRRS bit is set to 1, group C scan starts from the channel on which A/D conversion was interrupted.
- (12) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (13) An S12GCADI0 interrupt request is generated if the ADGCTRGR.GCADIE bit is set to 1 (S12GCADI0 interrupt upon group C scanning completion is enabled).
- (14) The ADCSR.ADST bit is automatically cleared on completion of all the scans and the A/D converter enters the waiting state.

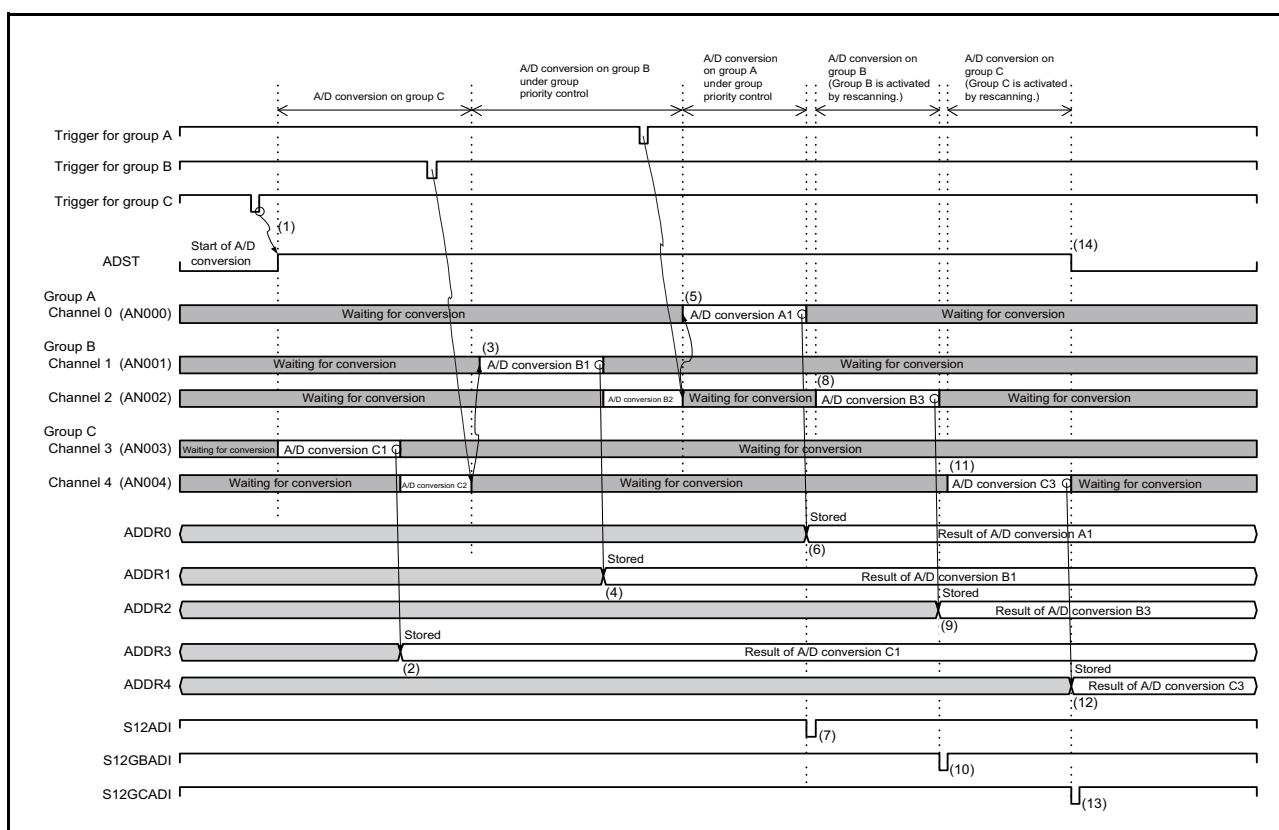

Figure 30.17 Example of Operations under Group Priority Control (1) "Trigger Input for Priority Group during Scanning for Low Priority Group" with Rescan Enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)

Example of operation (2) "Trigger input for priority group during rescanning for low priority group" with rescan enabled

Figure 30.18 describes the case in which a trigger for group A is input during group B rescanning.

Even during rescanning for a low priority group, if a trigger for a priority group (priority group to group C includes group A and group B, and that to group B includes group A) is input, the priority group scan starts and on completion of the priority group scan, scan for the interrupted low priority group starts.

Operation related to the ADST bit, storage of the A/D conversion result in the A/D data register y (ADDRy), and interrupt request is the same as that of Example of operation (1).

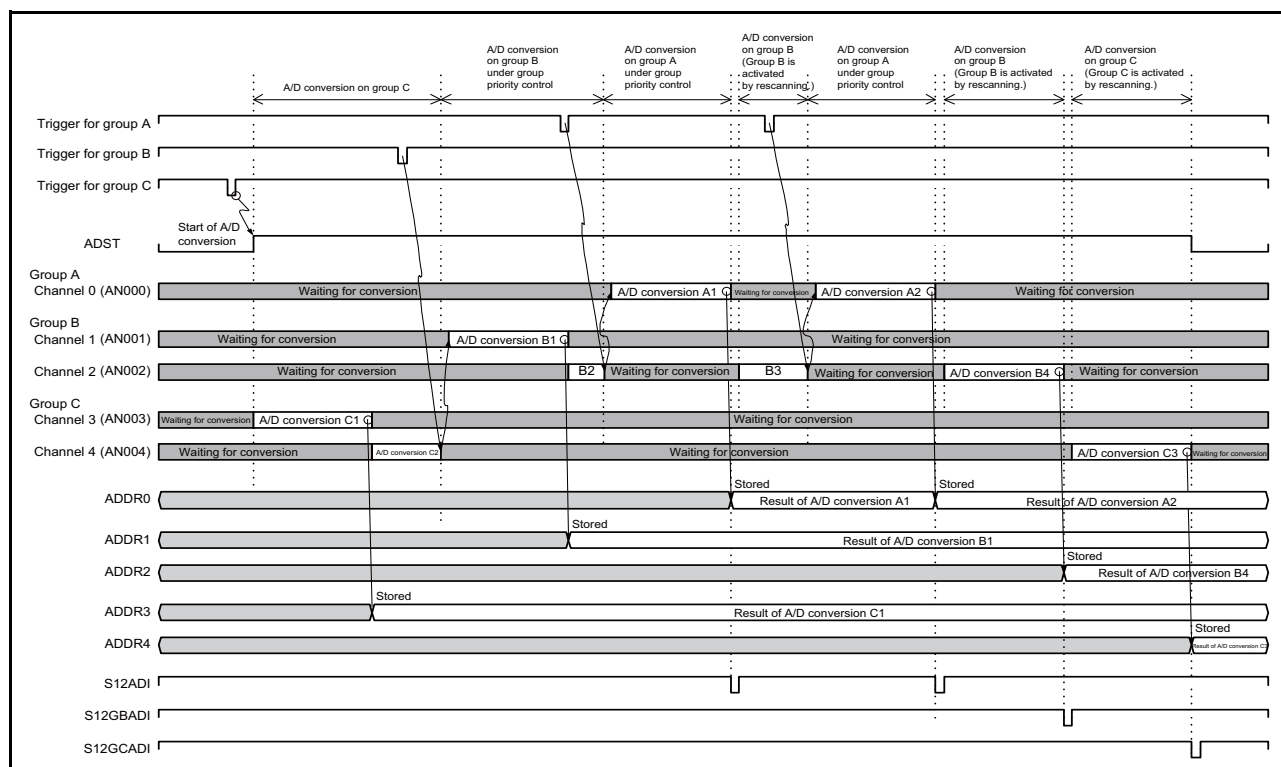

Figure 30.18 Example of Operations under Group Priority Control (2) "Trigger Input for Priority Group during Rescanning for Low Priority Group" with Rescan Enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)

Example of operation (3) "Trigger input for low priority group during scanning for priority group" with rescan enabled

This section describes operation when the ADGPSCR.GBRSCN bit is set to 1 (rescan is performed on the group interrupted due to group priority control), and a trigger for a low priority group is input during scanning for a priority group. When the ADGPSCR.GBRSCN bit is set to 0, any trigger for a low priority group that is input during scanning for a priority group is invalid.

- (1) When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), scan for the ANn channels of group A selected in the ADANSA0 register starts in order from the channel with the smallest number n.
- (2) When a trigger for group B is input during group A scanning, group B enters the scan-ready state.
- (3) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (4) On completion of the group A scan, an S12ADI0 interrupt request is generated if the ADCSR.ADIE bit is set to 1 (S12ADI0 interrupt upon scanning completion is enabled).
- (5) On completion of the group A scan, scan for the ANn channels of group B selected in the ADANSB0 register is performed in order from the channel with the smallest number n while the ADCSR.ADST bit holds 1. At this time, if the ADGPSCR.LGRRS bit is set to 1, group B scan starts from the channel on which A/D conversion was interrupted.
(If a trigger for group A is input during group B scanning, as in Example of operation (1), group A scan starts and on completion of the group A scan, group B scan starts.)
- (6) When a trigger for group C is input during group B scanning, group C enters the scan-ready state.
- (7) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (8) On completion of the group B scan, an S12GBADI0 interrupt request is generated if the ADCSR.GBADIE bit is set to 1 (S12GBADI0 interrupt upon scanning completion is enabled).
- (9) On completion of the group B scan, scan for the ANn channels of group C selected in the ADANSC0 register is performed in order from the channel with the smallest number n while the ADCSR.ADST bit holds 1. At this time, if the ADGPSCR.LGRRS bit is set to 1, group C scan starts from the channel on which A/D conversion was interrupted.
(If a trigger for group A or group B is input during group C scanning, as in Example of operation (1), group A or group B scan starts and on completion of the scan, group C scan starts.)
- (10) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (11) On completion of the group C scan, an S12GCADI0 interrupt request is generated if the ADGCTRGR.GCADIE bit is set to 1 (S12GCADI0 interrupt upon scanning completion is enabled).
- (12) The ADCSR.ADST bit is automatically cleared on completion of all the scans and the A/D converter enters the waiting state.

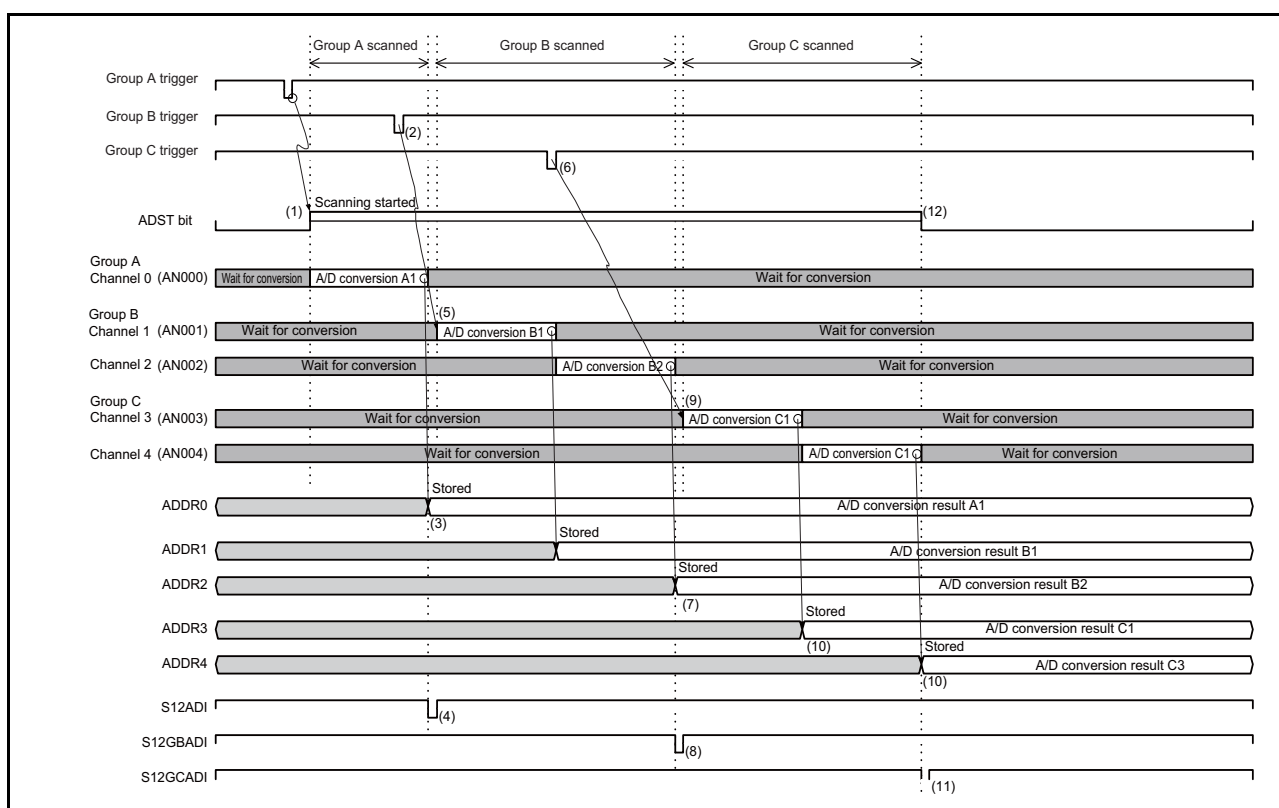

Figure 30.19 Example of Operations under Group Priority Control (3) "Trigger Input for Low Priority Group during Scanning for Priority Group" with Rescan Enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1'b1, ADGCTRGR.GRCE = 1)

Examples of operation (4) describes group priority control in group scan mode (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0) when channel 0 is selected for group A, channels 1, 2 are selected for group B, and channels 3, 4 are selected for group C.

Example of operation (4) "Trigger input for priority group during scanning for low priority group" with rescan disabled

- (1) When input of a trigger for group C sets the ADCSR.ADST bit to 1 (starting A/D conversion), scan for the ANn channels selected in the ADANSC0 register starts in order from the channel with the smallest number n.
- (2) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (3) When a trigger for group B is input during group C scanning, the group C scanning is interrupted while the ADCSR.ADST bit holds 1, and group B scan for the ANn channels selected in the ADANSB0 register starts in order from the channel with the smallest number n. If A/D conversion is not completed at the time of interruption, the A/D conversion result is not stored in the A/D data register y (ADDRy).
- (4) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (5) When a trigger for group A is input during group B scanning, the group B scanning is interrupted while the ADCSR.ADST bit holds 1, and group A scan for the ANn channels selected in the ADANSA0 register starts in order from the channel with the smallest number n. If A/D conversion is not completed at the time of interruption, the A/D conversion result is not stored in the A/D data register y (ADDRy).
- (6) On completion of the group A scan, an S12ADI0 interrupt request is generated if the ADCSR.ADIE bit is set to 1 (S12ADI0 interrupt upon scanning completion is enabled).
- (7) The ADST bit is automatically cleared on completion of the group A scan and the A/D converter enters the waiting state. Scan for group B and group C is not performed until the next input of a trigger for each group.

Figure 30.20 Example of Operations under Group Priority Control (4) "Trigger Input for Priority Group during Scanning for Low Priority Group" with Rescan Disabled (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)

Examples of operation (5) describes group priority control in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 1, and ADGSPCR.LGRRS = 1) when channel 0 is selected for group A, channel 1 is selected for group B, and channels 2, 3 are selected for group C.

When the ADGCTRGR.GRCE bit is set to 0, single scan is performed continuously on group B and input of a trigger for group C is invalid.

Example of operation (5) "Continuous Operation of Single Scan for Group C"

- (1) When ADGSPCR.GBRP is set to 1, the ADCSR.ADST bit is set to 1 (starting A/D conversion), and scan for the ANn channels selected in the ADANSC0 register starts in order from the channel with the smallest number n.
- (2) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (3) When a trigger for group B is input during group C scanning, the group C scanning is interrupted while the ADCSR.ADST bit holds 1, and group B scan for the ANn channels selected in the ADANSB0 register starts in order from the channel with the smallest number n. If A/D conversion is not completed at the time of interruption, the A/D conversion result is not stored in the A/D data register y (ADDRy).
- (4) When a trigger for group A is input during group B scanning, the group B scanning is interrupted while the ADCSR.ADST bit holds 1, and group A scan for the ANn channels selected in the ADANSA0 register starts in order from the channel with the smallest number n. If A/D conversion is not completed at the time of interruption, the A/D conversion result is not stored in the A/D data register y (ADDRy).
- (5) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (6) An S12ADI0 interrupt request is generated if the ADCSR.ADIE bit is set to 1 (S12ADI0 interrupt upon scanning completion is enabled).
- (7) If the ADGSPCR.GBRSCN bit is set to 1 (rescan is performed on the group interrupted due to group priority control), group B scan for the ANn channels selected in the ADANSB0 register restarts in order from the channel with the smallest number n while the ADCSR.ADST bit holds 1. At this time, if the ADGSPCR.LGRRS bit is set to 1, group B scan starts from the channel on which A/D conversion was interrupted.
- (8) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (9) An S12GBADI0 interrupt request is generated if the ADCSR.GBADIE bit is set to 1 (S12GBADI0 interrupt upon group B scanning completion is enabled).
- (10) If the ADGSPCR.GBRSCN bit is set to 1 (rescan is performed on the group interrupted due to group priority control), group C scan for the ANn channels selected in the ADANSC0 register restarts in order from the channel with the smallest number n while the ADCSR.ADST bit holds 1. At this time, if the ADGSPCR.LGRRS bit is set to 1, group C scan starts from the channel on which A/D conversion was interrupted.
- (11) On completion of A/D conversion on a single channel, the A/D conversion result is stored in the corresponding A/D data register y (ADDRy).
- (12) An S12GCADI0 interrupt request is generated if the ADGSPCR.GBCDIE bit is set to 1 (S12GCADI0 interrupt upon group C scanning completion is enabled).
- (13) If the ADGSPCR.GBRP bit is set to 1 (performing single scan continuously), group C scan for the An channels selected in the ADANSC0 register restarts in order from the channel with the smallest number n while the ADCSR.ADST bit holds 1.

Disable group B trigger input to perform a single scan operation continuously on group C.

Steps 13, 11, 12, and then 13 are repeated as long as the ADGSPCR.GBRP bit is set to 1.

Clearing of the ADCSR.ADST bit is prohibited while the ADGSPCR.GBRP bit is set to 1.

Follow the procedure for clearing operation by software through the ADCSR.ADST bit, shown in section 30.5.2,

Notes on Stopping A/D Conversion, to forcibly stop scanning when ADGSPCR.GBRP = 1.

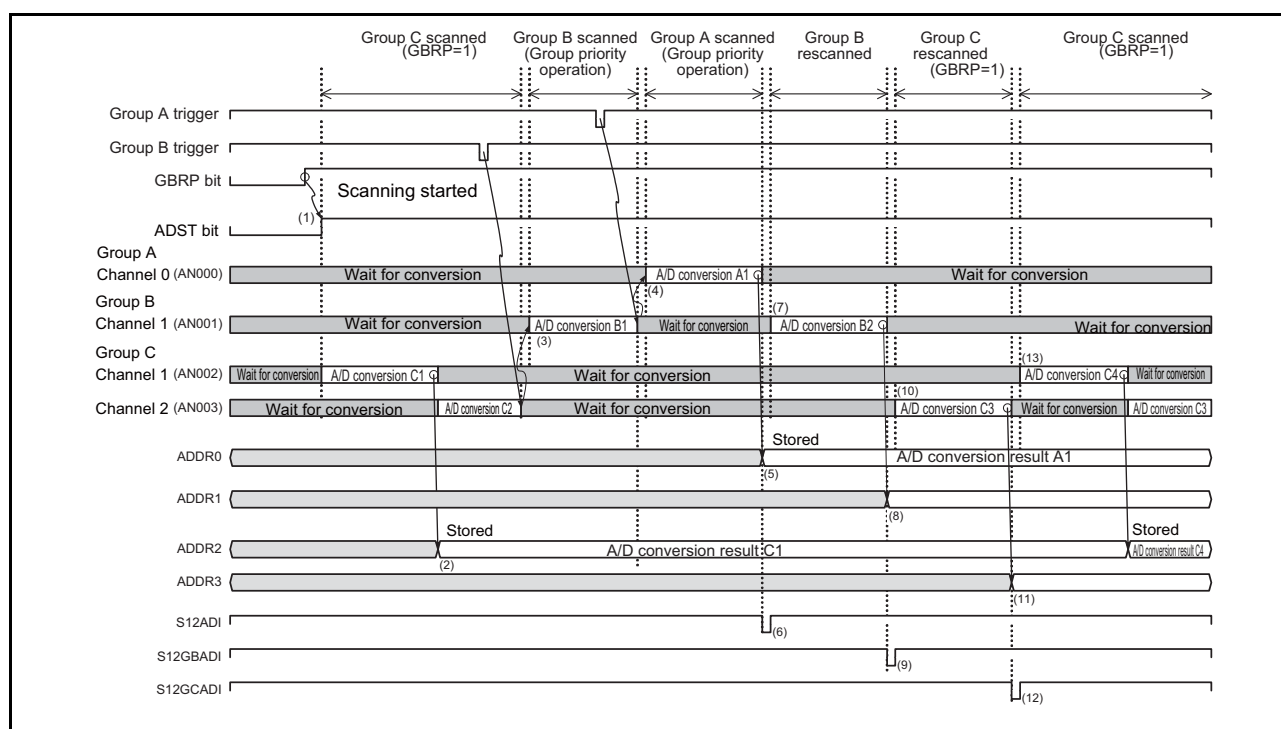

Figure 30.21 Example of Operations under Group Priority Control "Continuous Operation of Single Scan for Group C" (when ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1)

30.3.5 Comparison (Window A, Window B)

30.3.5.1 Compare Function Window A/B

Comparison is of a reference value set in a register with the result of A/D conversion on selected channels.

A reference value can be set for each window (A/B).

Self-diagnosis function and double-triggered mode are not available while comparison is in use.

The main difference between window A and window B is that the number of channels which can be selected in window B is one and the interrupt output signal is different.

Operation using comparison in combination with continuous scan mode is described below.

- (1) A/D conversion is started in the order of the selected channels when ADCSR.ADST is set to 1 (to start A/D conversion) by software, or in response to a synchronous trigger (MTU, GPT) or asynchronous trigger.
- (2) When A/D conversion is completed, the result is stored in the A/D Data Register y (ADDRy).
When ADCMPCR.CMPAE = 1'b1, if the channel is set to a target for window A in the ADCMPANSRy and ADCMPANSER registers, the result is compared with the ADCMPDR0/1 register settings. If ADCMPCR.CMPAE = 1'b1, the register is selected for Window-A by the settings of the ADCMPANSRy and ADCMPANSER registers, its value is then compared with that of the ADCMPDR0 or ADCMPDR1 registers.
When ADCMPCR.CMPBE = 1'b1, if the channel is set to a target for window B in the ADCMPBNSR register, the result is compared with the ADWINULB/ADWINLLB register settings. If ADCMPCR.CMPBE = 1'b1, the register is selected for Window-B by the settings of the ADCMPBNSR register, its value is then compared with that of the ADWINULB or ADWINLLB registers.
- (3) If the result of comparison meets the condition set in the ADCMPLR0 and ADCMPLER registers, the Window-A flag bits ADCMPSR0.CMPSTCHA0n, ADCMPSR1.CMPSTCHA1n, ADCMPSER.CMPSTTSA, and ADCMPSER.CMPSTOCA are set to 1. If the setting of the ADCMPCR.CMPAIE bit is 1 at this time, an S12ADCMPAI0 interrupt request (level) is also generated.
If the result of comparison meets the condition set in the ADCMPBNSR.CMPLB bit, the Window-B flag bit ADCMPBSR.CMPSTB is set to 1. If the setting of the ADCMPCR.CMPBIE bit is 1 at this time, an S12ADCMPBI0 interrupt request (level) is also generated.
- (4) When comparison is completed for all selected A/D conversion, A/D conversion is started again.
- (5) If the setting of the ADCSR.ADST bit is 0 (A/D conversion stop) after the S12ADCMPAI0 or S12ADCMPBI0 interrupt is accepted, processing proceeds for channels that have the compare flag.
- (6) The S12ADCMPAI0 interrupt signal is deasserted when all of the Window-A compare flags have been cleared. The S12ADCMPBI0 interrupt signal is deasserted when all of the Window-B compare flags have been cleared. To start further comparison, start A/D conversion again.

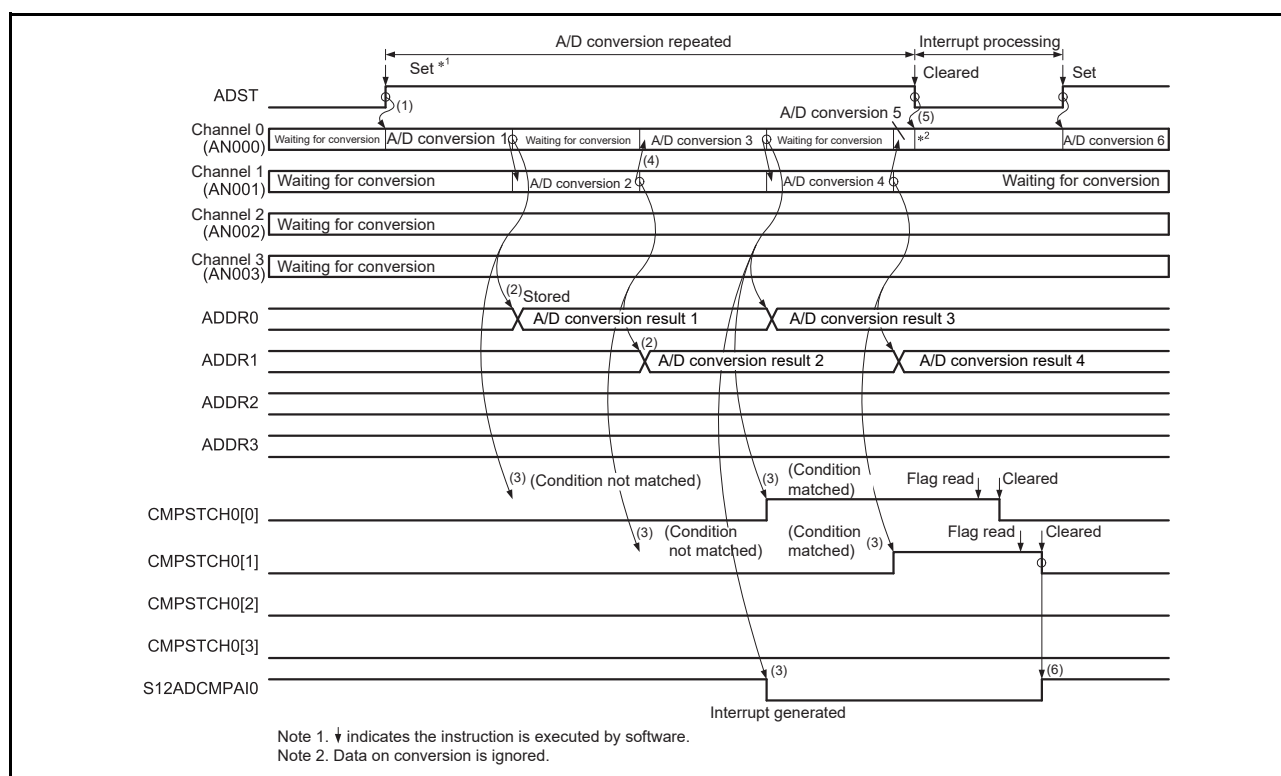

Figure 30.22 Operation Example of Comparison (AN000 to AN003 Comparison Targets)

30.3.5.2 Restrictions on the Compare Function

The following restrictions apply to the compare function:

1. Self-diagnosis function and double-triggered mode are not available while comparison is in use. (ADRD, ADDBLDR, ADDBLDRA, and ADDBLDRB are not subject to the compare function.)
2. An identical channel cannot be set in window A and window B.
3. Specify the settings so that upper-side reference value \geq lower-side reference value.

30.3.6 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger; a synchronous trigger; or ADTRG# (an external trigger). After the start-of-scanning-delay time (tD) has elapsed, processing for disconnection detection assistance, and processing of conversion for self-diagnosis proceed, and this is followed by A/D conversion.

Figure 30.23 shows the scan conversion timing in which scan conversion is activated by a software trigger or a synchronous trigger. Figure 30.24 shows the scan conversion timing in which scan conversion is activated by ADTRG# (an external trigger). The scan conversion time (tSCAN) includes the start-of-scanning-delay time (tD), disconnection detection assistance processing time (tDIS)*2, self-diagnosis A/D conversion processing time (tDIAG)*3, A/D conversion processing time (tCONV), and end-of-scanning-delay time (tED).

The A/D conversion processing time (tCONV) consists of input sampling time (tSPL) and time for conversion by successive approximation (tSAM). The sampling time (tSPL) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTR register.

The time for conversion by successive approximation (tSAM) is at 13 ADCLK states with 12-bit accuracy selected, 11 ADCLK states with 10-bit accuracy selected, and 9 ADCLK states with 8-bit accuracy selected. Table 30.16 shows the scan conversion time.

The scan conversion time (tSCAN) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = tD + (tDIS \times n) + tDIAG + (tCONV \times n)^*3 + tED$$

The scan conversion time for the first cycle in continuous scan mode is tSCAN for single scan minus tED. The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed to (tDIS × n) + tDIAG + tDSD + (tCONV × n)*3.

Note 1. When disconnection detection assistance is not selected, tDIS = 0.

Note 2. When the self-diagnosis function is not used, tDIAG = 0 and tDSD = 0.

Note 3. Although when the sampling time (tSPL) of the selected channels is identical, "tCONV × n" is applied, when it differs according to the channel, the sum of the sampling time (tSPL) and successive approximation (tSAM) of each channel is applied.

Table 30.16 Times for Conversion during Scanning (in Numbers of Cycles of the ADCLK and PCLKH)

| Item | | | Symbol | Type/Conditions | | | Unit |
|---|--|---|------------------|-----------------------|---|------------------|-------|
| | | | | Synchronous Trigger*3 | External (Asynchronous) Trigger | Software Trigger | |
| Scan start processing time*1*2 | A/D conversion on group under group priority control. | Low priority groups are to be interrupted (The priority group is activated after the low priority group is stopped by an A/D conversion source of the priority group) | tD | 2 PCLK + 6 ADCLK | — | — | Cycle |
| | | Low priority groups are not to be interrupted (Activation by an A/D conversion source of the priority group) | | 2 PCLK + 4 ADCLK | — | — | |
| | | A/D conversion when self-diagnosis is enabled | | 2 PCLK + 6 ADCLK | 4 PCLK + 6 ADCLK | 6 ADCLK | |
| | Other than above | | 2 PCLK + 4 ADCLK | 4 PCLK + 4 ADCLK | 4 ADCLK | | |
| | Disconnection detection assistance processing time | | | tDIS | The setting of ADNDIS[3:0] (initial value = 00h) × ADCLK | | |
| Self-diagnosis conversion processing time*1 | Sampling time | | tDIAG | tSPL | The setting of ADSSTR0 (initial value = 0Bh) × ADCLK | | |
| | Time for conversion by successive approximation | 12-bit conversion accuracy | | tSAM | 15 ADCLK | | |
| | | 10-bit conversion accuracy | | | 13 ADCLK | | |
| | | 8-bit conversion accuracy | | | 11 ADCLK | | |
| | After completion of self-diagnosis conversion. Normal A/D conversion is to be started. | | | tDED | 2 ADCLK | | |
| | Self-diagnosis conversion is to be started after completion of conversion for continuous scan on the last channel. | | tDSD | 2 ADCLK | | | |
| A/D conversion processing time*1 | Sampling time | | tCONV | tSPL | The setting of ADSSTRn (n = 0 to 7) (initial value = 0Bh) × ADCLK | | |
| | Time for conversion by successive approximation | 12-bit conversion accuracy | | tSAM | 13 ADCLK | | |
| | | 10-bit conversion accuracy | | | 11 ADCLK | | |
| | | 8-bit conversion accuracy | | | 9 ADCLK | | |
| Scan end processing time*1 | | | tED | 1 PCLK + 3 ADCLK | | | |

Note 1. Refer to Figure 30.23 and Figure 30.24 for illustration of times tD, tDIAG, tCONV, and tED.

Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.

Note 3. This does not include the time consumed in the path from timer output to trigger input.

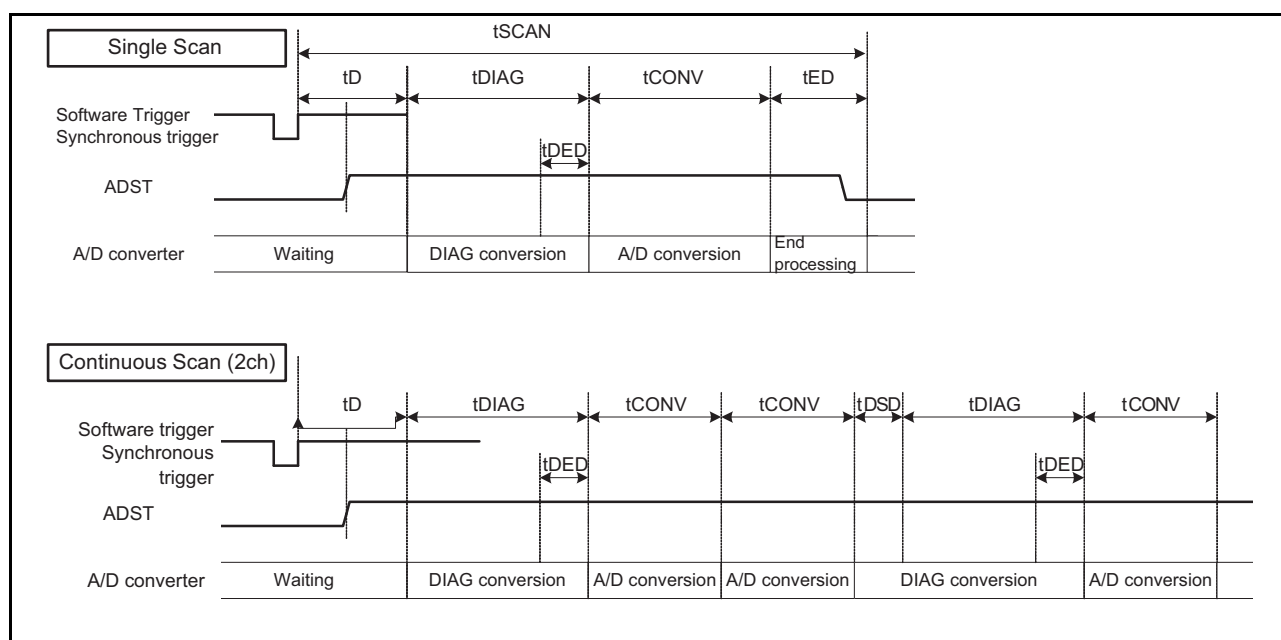

Figure 30.23 Scan Conversion Timing (Activated by Software or Synchronous Trigger Input)

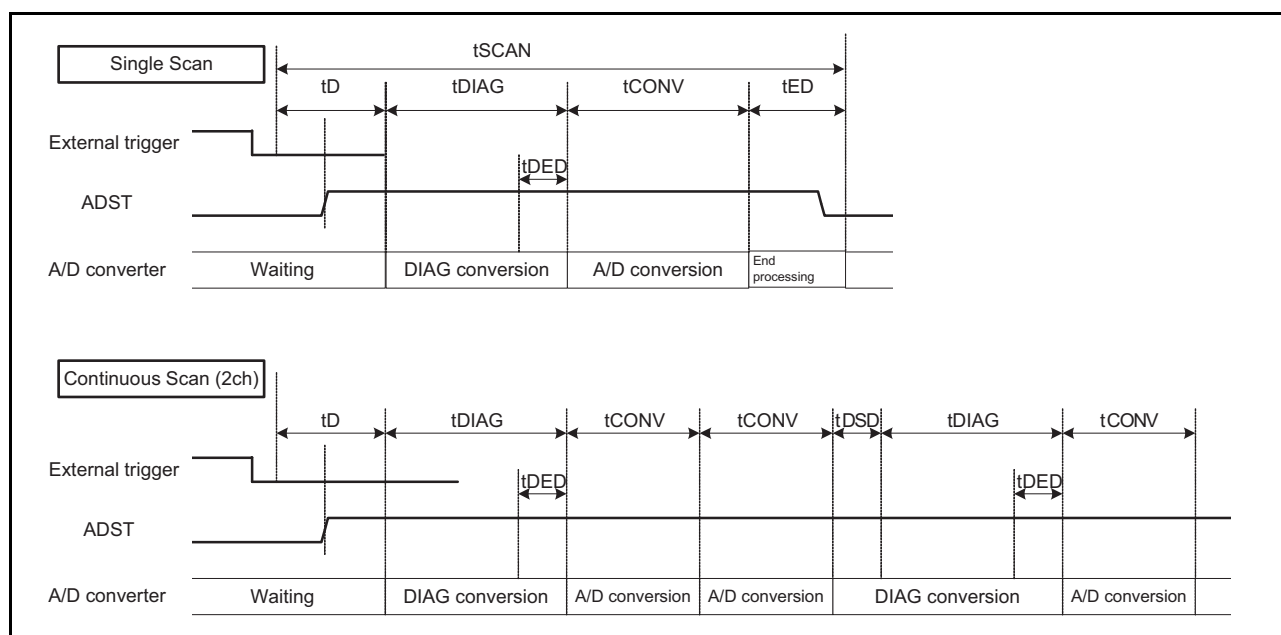

Figure 30.24 Scan Conversion Timing (Activated by Asynchronous Trigger Input (ADTRG#))

30.3.6.1 Timing of Scan Interruption and Start under Group Priority Control

Under group priority control, the timing of scan interruption and start is as follows.

1. Timing of interruption of scanning for the low priority group and start of scan for the priority group
2. Timing of restart of scan for the interrupted low priority group, and timing of start of scan for the low priority group after completion of scan for the high priority group in response to a trigger for the low priority group accepted during scanning for the high priority group
3. Timing of continuous operation of single scan for the low priority group

Figure 30.25 shows these timings, respectively.

The timing of interruption/start of scan for group A and group C or group B and group C is the same as the timing of interruption/start of scan for group A and group B shown in Figure 30.25. The timing of continuous operation of single scan is the same for both group B (using two groups) and group C (using three groups).

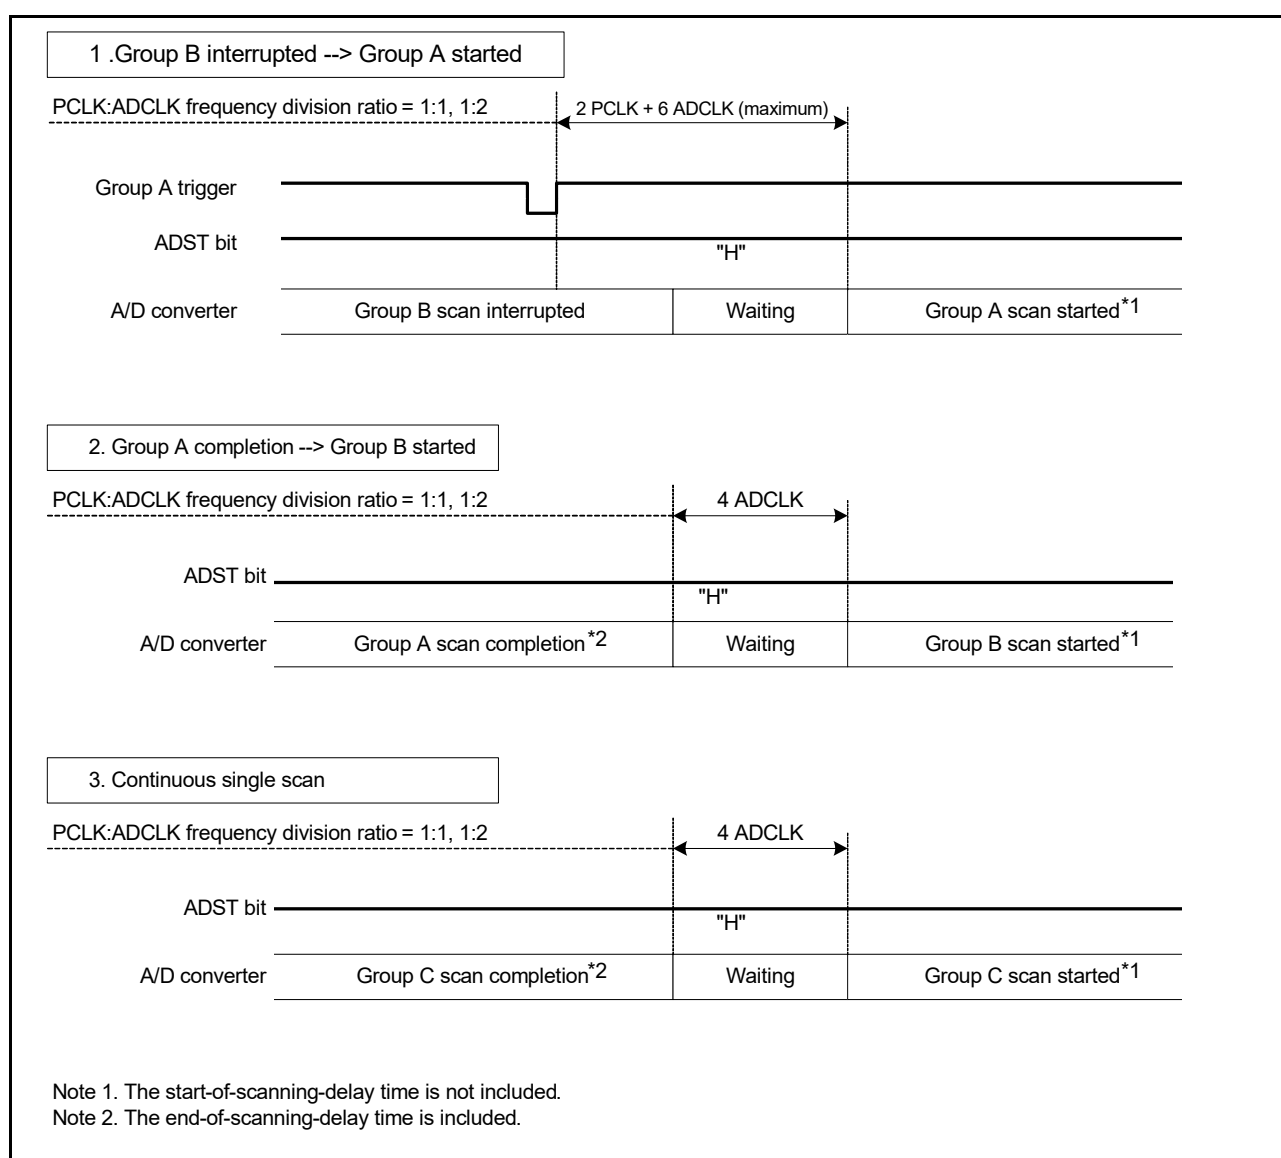

Figure 30.25 Timing of Scan Interruption and Start under Group Priority Control

30.3.7 Usage Example of Register Automatic Clearing Function

Setting the ACE bit in ADCER register to 1 automatically clears the A/D Data Register y (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB) to 0000h when the A/D data registers are read by the CPU or DMAC.

This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB). The following describes the examples in which the function to automatically clear the ADDRy register is enabled and disabled.

In a case where the ACE bit in ADCER register is 0 (automatic clearing is disabled), if the A/D conversion result (0222h) is not written to the ADDRy register for some reason, the old data (0111h) will be the ADDRy value. Furthermore, if this ADDRy value is read into a general register using an A/D scan end interrupt, the old data (0111h) can be saved in the general register. When checking whether there is an update failure, it is necessary to frequently save the old data in the RAM or a general register.

In a case where the ACE bit in ADCER register is 1 (automatic clearing is enabled), when ADDRy = 0111h is read by the CPU or DMAC, ADDRy is automatically cleared to 0000h. After that, if the A/D conversion result 0222h cannot be transferred to ADDRy for some reason, the cleared data (0000h) remains as the ADDRy value. If this ADDRy value is read into a general register using an A/D scan end interrupt at this point, 0000h will be saved in the general register. Occurrence of an ADDRy update failure can be determined by simply checking that the read data value is 0000h.

30.3.8 A/D-Converted Value Addition/Average Function

In A/D-converted value addition function, the same channel is A/D-converted 2, 3, 4, or 16 consecutive times and the sum of the converted values is stored in the data register. In A/D-converted value average function, the same channel is A/D converted 2 or 4 consecutive times and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average function can be specified when A/D conversion of the channel select analog input is selected.

Note 1. The addition count can be set to 16 only when 12-bit conversion accuracy is selected.

30.3.9 Disconnection Detection Assist Function

This converter incorporates the function to fix the charge for sampling capacitance to the specified state before start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

Figure 30.26 illustrates the A/D conversion operation when the disconnection detection assist function is used. Figure 30.27 shows an example of disconnection detection when precharge is selected. Figure 30.28 shows an example of disconnection detection when discharge is selected.

Figure 30.26 Operation of A/D Conversion when the Disconnection Detection Assist Function is Used

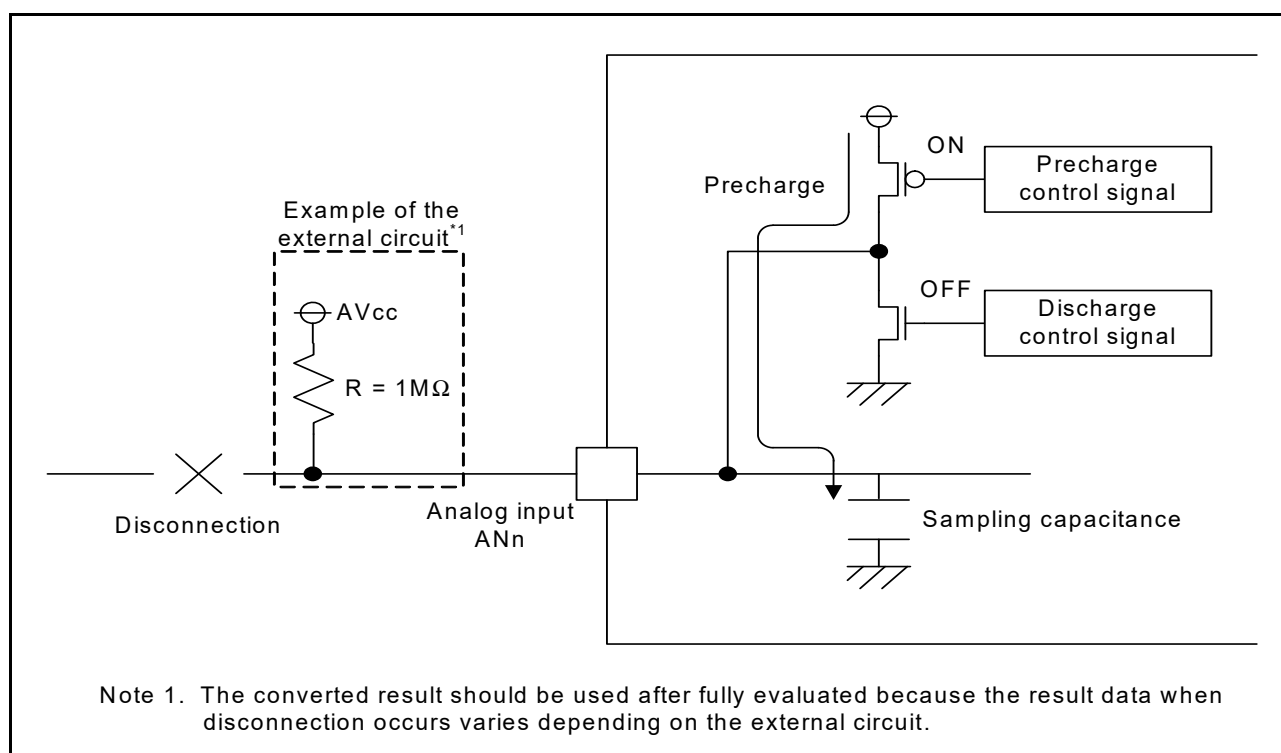

Figure 30.27 Example of Disconnection Detection when Precharge is Selected

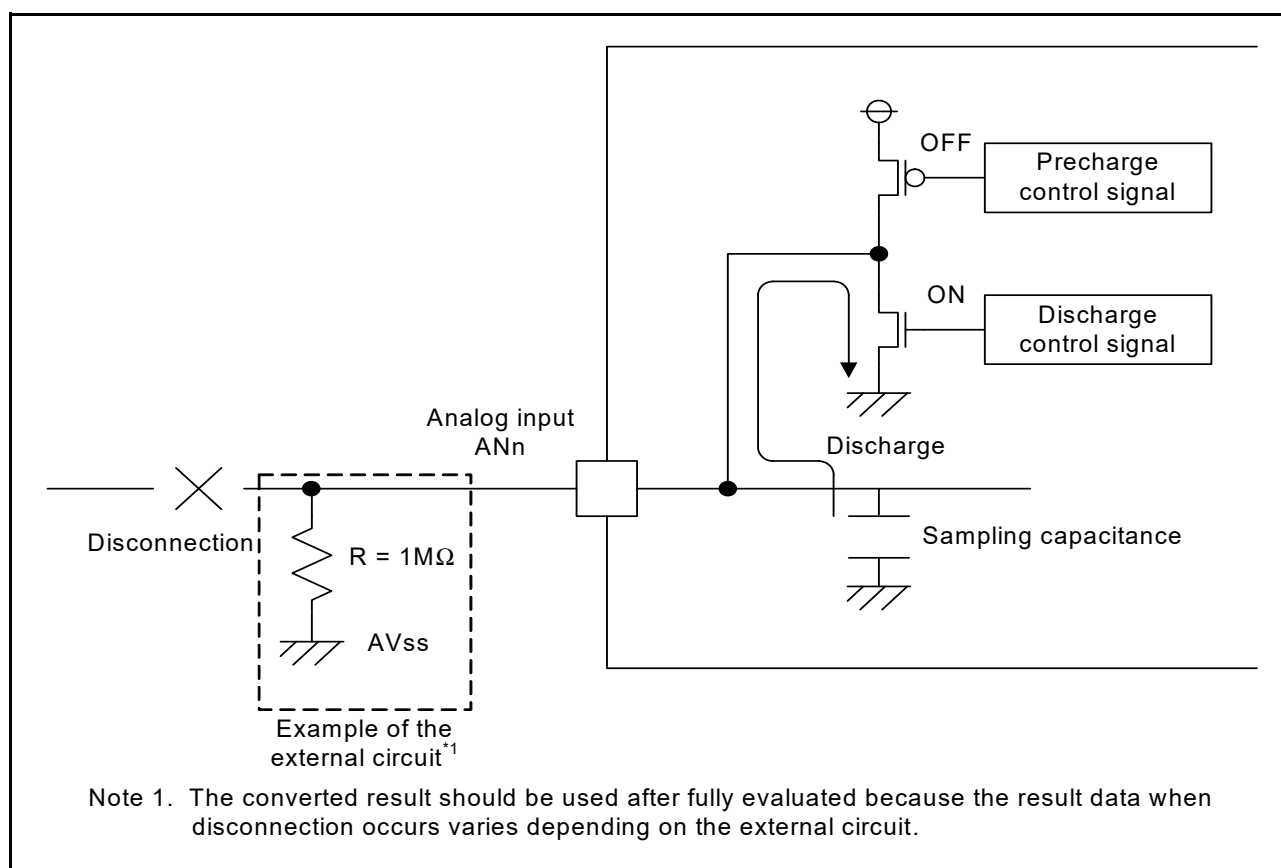

Figure 30.28 Example of Disconnection Detection when Discharge is Selected

30.3.10 Starting A/D Conversion with Asynchronous Trigger

The A/D conversion can be started by the input of an asynchronous trigger.

To start up the A/D converter by an asynchronous trigger, after setting general-purpose I/O pin function, the A/D conversion start trigger select bits (ADSTRGR.TRSA[5:0]) should be set to 0h and a high-level signal should be input to the asynchronous trigger (ADTRG# pin). Both the ADCSR.TRGE and ADCSR.EXTRG bits then should be set to 1.

Figure 30.29 shows a timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected for group B and group C used in group scan mode. For details about the settings of the pin function, see section 51, GPIO.

Figure 30.29 Asynchronous Trigger Input Timing

30.3.11 Starting A/D Conversion with Synchronous Trigger from Peripheral Module

The A/D conversion can be started by a synchronous trigger (one pulse of "L" in PCLK synchronization) from MTU or GPT. To start the A/D conversion by a synchronous trigger, the ADCSR.TRGE bit should be set to 1, the ADCSR.EXTRG bit should be cleared to 0, and the relevant sources should be selected by the ADSTRGR.TRSA[5:0] and ADSTRGR.TRSB[5:0] bits.

30.4 Interrupt Sources and DMAC Transfer Requests

30.4.1 Interrupt Requests

The A/D converter can send scan end interrupt requests S12ADI0, S12GBADI0, and S12GCADI0 to the CPU. The module also generates the S12ADCMPAI0 and S12ADCMPBI0 interrupt for the CPU in response to matches with a condition for comparison.

Setting the ADCSR.ADIE bit to 1 and 0 enables and disables an S12ADI0 interrupt, respectively; similarly, setting the ADCSR.GBADI0 bit to 1 and 0 enables and disables an S12GBADI0 interrupt, respectively.

Setting the ADCMPCR.CMPAIE bit to 1 and 0 enables and disables an S12ADCMPAI0 interrupt, respectively.

Setting the ADCMPCR.CMPBIE bit to 1 and 0 enables and disables an S12ADCMPBI0 interrupt, respectively.

In addition, the DMAC can be started up when an S12ADI0, an S12GBADI0, or an S12GCADI0 interrupt is generated.

Using an S12ADI0, an S12GBADI0, or an S12GCADI0 interrupt to allow the DMAC to read the converted data enables continuous conversion without burden on software.

Set the N0TB_n or N1TB_n register, CHCFG_n register, and other registers for DMA according to the number of A/D data registers to be transferred.

For details, see section 9, Direct Memory Access Controller.

30.5 Usage Notes

30.5.1 Notes on Reading Data Registers

The A/D data registers, A/D data duplication registers, A/D data duplication register A, A/D data duplication register B, and A/D self-diagnosis data register should be read in word units. If a register is read twice in byte units, that is, the upper byte and lower byte are separately read, the A/D-converted value having been read first may disagree with the A/D-converted value having been read for the second time. To prevent this, the data registers should never be read in byte units.

30.5.2 Notes on Stopping A/D Conversion

30.5.2.1 A/D Conversion Stopping Procedure

To stop A/D conversion when an asynchronous trigger or a synchronous trigger has been selected as the condition for starting A/D conversion, follow the procedure in Figure 30.30.

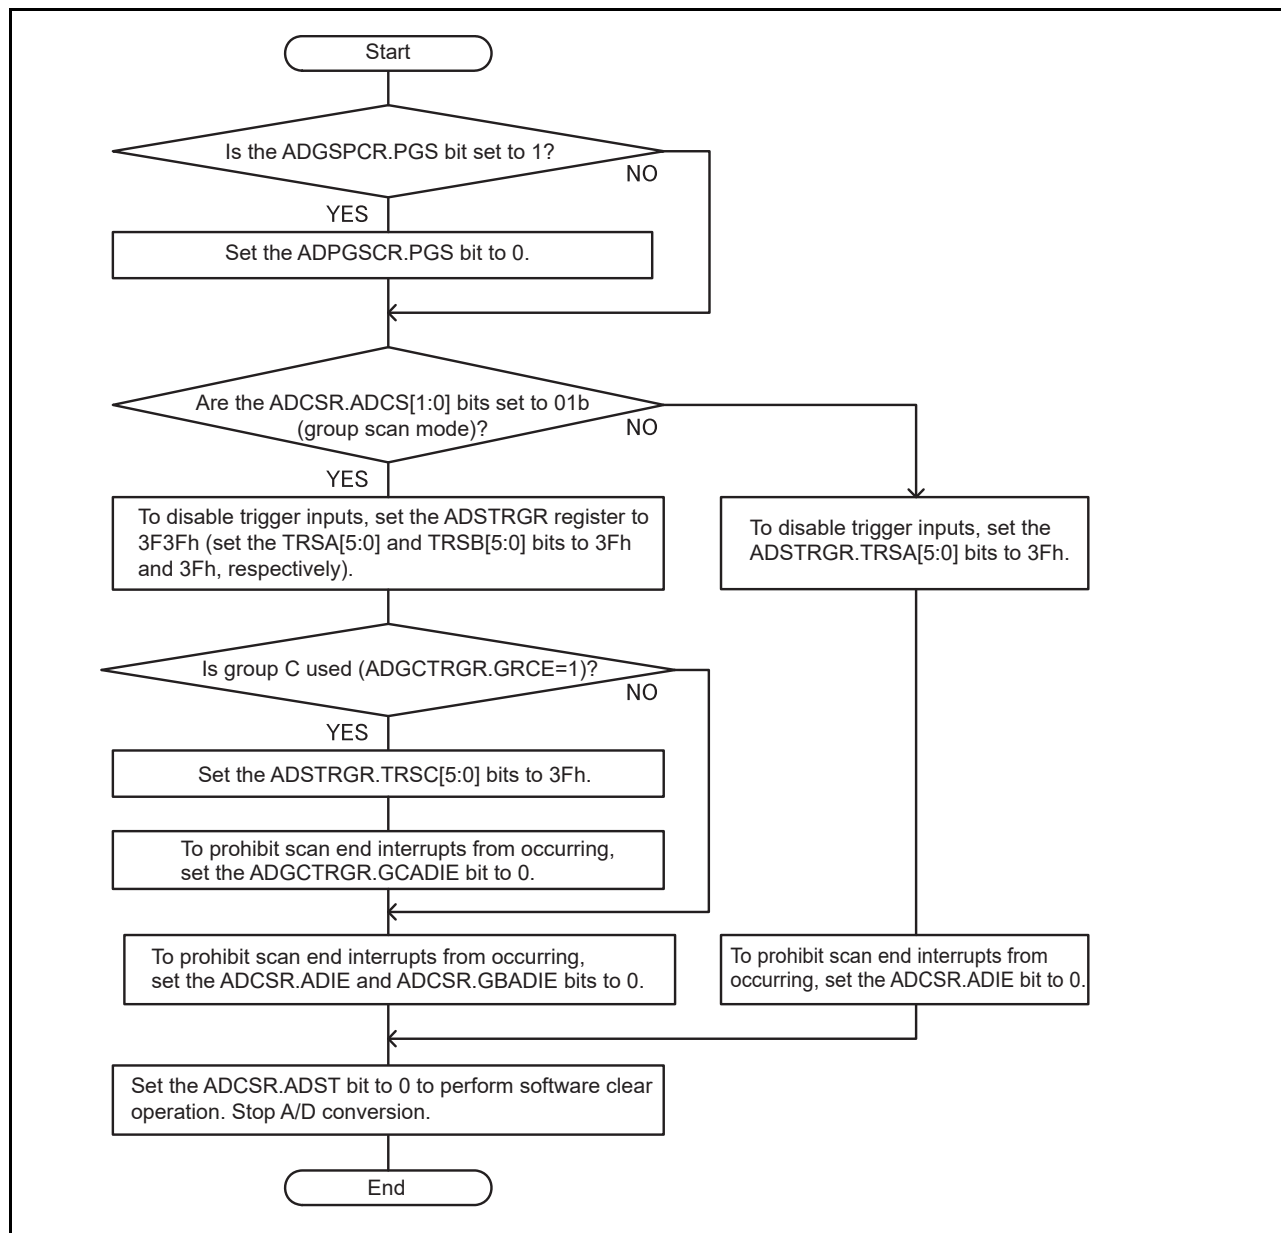

Figure 30.30 Procedures for Clear Operation by Software through the ADCSR.ADST Bit

Note: It takes two ADCLK cycles from software clear operation to the stop of scanning. To set the following operation after executing the software clear operation, a wait of at least two ADCLK cycles should be included.

- Scan end interrupt enable
- A/D conversion start by software
- Trigger input enable setting

30.5.2.2 Notes on Modes and Status Bits

Initialize or reset individually the voltage status in self-diagnosis, odd/even determination in double trigger mode, and the monitor bits in the compare function, if necessary.

- The reset value of voltage status in self-diagnosis can be selected in ADCER.DIAGVAL[1:0] after ADCER.DIAGLD is set to 1.
- Double trigger mode operates from the first scan after ADCSR.DBLE is set to 1 from 0.
- To initialize the monitor bits (MONCMPA, MONCMPB, MONCMPA) in the compare function, set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

30.5.3 A/D Conversion Restarting Timing and Termination Timing

It takes a maximum of six ADCLK cycles for the idle analog unit of the A/D converter to be restarted by setting the ADST bit in ADCSR register to 1. It takes a maximum of two ADCLK cycles for the operating analog unit of the 12-bit A/D converter to be terminated by setting the ADST bit in ADCSR register to 0.

30.5.4 Notes on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data in the case that the CPU does not complete reading out the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

30.5.5 Module Standby Function Setting

Operation of the A/D converter can be disabled or enabled using the standby control register. The initial setting is for operation of the A/D converter to be halted. Releasing the module standby mode enables access to the registers. After canceling module standby mode, wait for at least 1 μ s before starting A/D conversion.

For details, see section 52, Power-Down Modes.

30.5.6 Notes on Entering Low Power Consumption States

Before entering the Power-Down mode, make sure to stop A/D conversion. Here, set the ADST bit in ADCSR register to 0, and secure certain period of time until the analog unit of the A/D converter is stopped.

Follow the procedure given below to secure this time.

Follow the procedure for clear operation by software through the ADCSR.ADST bit, shown in Figure 30.30. After that, wait for two clock cycles of ADCLK before entering the Power-Down mode.

30.5.7 Notes on Canceling Software Standby Mode

After canceling software standby mode, wait for the oscillation stabilization time to elapse and then wait for at least 1 μ s before starting A/D conversion. For details, see section 52, Power-Down Modes.

30.5.8 Error in Absolute Accuracy When Disconnection Detection Assistance is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the A/D converter. This is because an error voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull-down resistor (R_p) and the resistance of the signal source (R_s). This error in absolute accuracy is calculated from the following formula. Only use disconnection detection assistance after thorough evaluation.

Maximum error in absolute accuracy (LSB) = $4095 \times R_s / R_p$

30.5.9 Range of Voltage on the Analog Input Pins

The voltage to be applied on the analog input pin should be in the range $AV_{SS} \leq AN00n$ ($n = 0$ to 7) $\leq AV_{CC}$. Using this LSI chip with a voltage out of the allowed range may adversely affect the reliability of the LSI.

30.5.10 Notes on Board Design

When designing a board, as much as possible make sure that the signal wiring runs for the digital and analog circuits do not overlap or are not placed close to each other in the layout. Otherwise, electromagnetic induction and so on will occur, and this may adversely affect the precision of the values produced by A/D conversion.

The analog signals (AN000 to AN007) and analog power source (AV_{CC}) are separated from the digital circuits by using the analog ground (AV_{SS}). Be sure to connect a $0.1\mu F$ capacitor between the analog power source and analog ground.

The analog ground (AV_{SS}) should be connected to a stable digital ground (V_{SS}) on the board (single-point ground plane connection).

30.5.11 Notes on Noise Prevention

To avoid damage to the analog input pins (AN000 to AN007) due to abnormal voltages such as excessive surges, connect protection circuits to the analog input pins (AN000 to AN007) with reference to that shown in Figure 30.31.

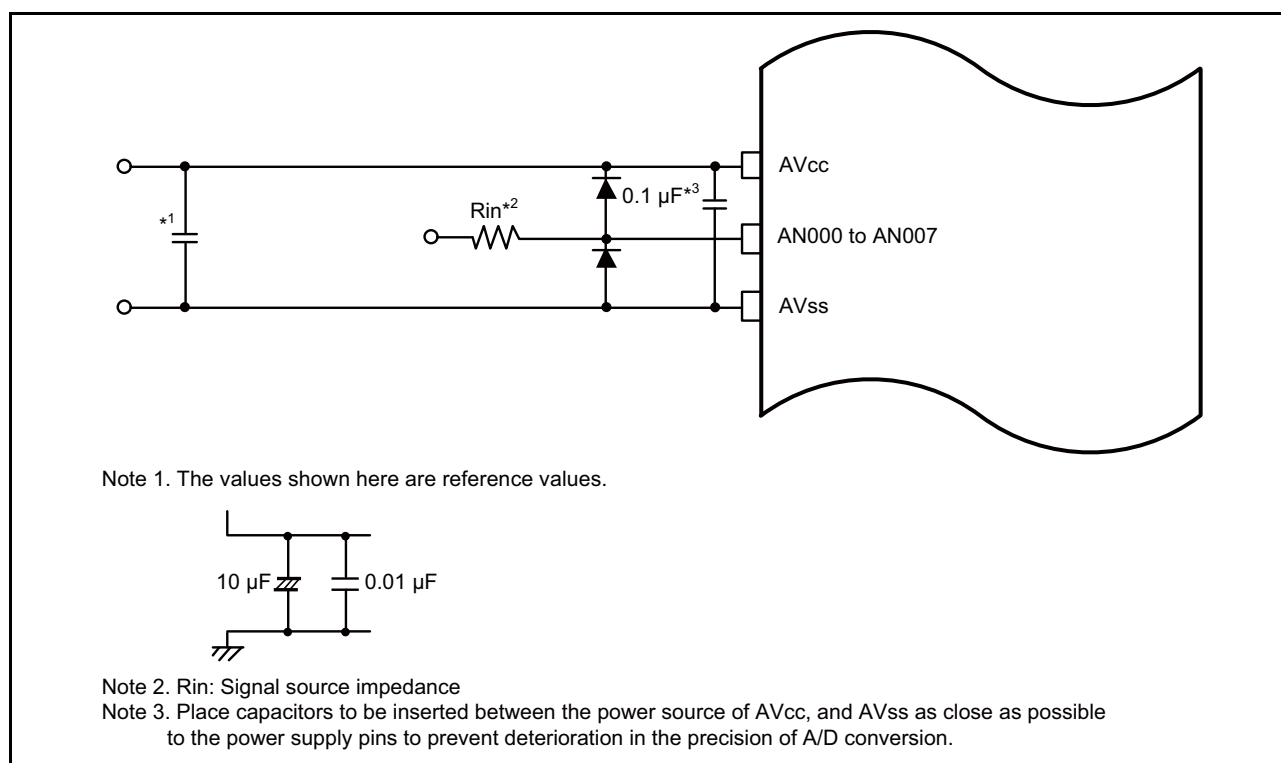

Figure 30.31 Example of a Protection Circuit for the Analog Inputs

31. NAND Flash Controller

31.1 Overview

The NAND flash controller supports the functionality of the high-level interface described in the ONFi 1.0 specifications.

31.1.1 Features

- Compatibility
 - Compatible with the ONFi 1.0 specification. (8 bits)
Note that this does not apply in cases where timing mode 3, 4, or 5 is in use.
 - Support for the Small Block devices
- Note: Only devices that allow to disable CE signal when device is in the busy state are supported.
- Support for the low capacity devices (which use four address bytes) with the help of generic sequence.
- DMA Controller
 - Scatter-gather mode/registers managed mode
 - 32-bit system memory addressing.
 - Programmable FIFO threshold as a trigger for the DMA controller
- Interrupt Controller
 - Each interrupt can be masked.
 - Each interrupt has its own status flag.
 - The status flags are also valid when the given interrupt is masked, and can be checked by the software polling mechanism.
 - Single interrupt signal output
- Data buffering
 - FIFO module based on dual port memory.
- ECC unit
 - The ECC module is based on the BCH algorithms.
 - The syndrome calculation, error detection and error correction phases in the BCH-based modules are pipelined.
 - The ECC unit supports the following options: 256-, 512-, and 1024-byte data blocks. The data block size depends on the selected ECC option.
- Advanced features
 - The page cache read/write sequences are supported.
 - The multiple planes read/write sequences are supported.
 - The multi-LUN work mode is supported.
 - Command queuing mechanism.

Note: A queue is used when a host writes to a register. The queue is used when writing is to registers other than those listed below.

- INT_STATUS
- STATUS
- FIFO_INIT
- ECC_STAT
- FIFO_DATA

Writing to the registers listed above is executed immediately. Writing to the other registers, on the other hand, is executed through command queuing.

- The advanced Bad Blocks Management system
 - Record tables are stored in the system memory.
 - Implementation of hardware with the search algorithm

31.1.2 Block Diagram

Figure 31.1 is a block diagram of this module.

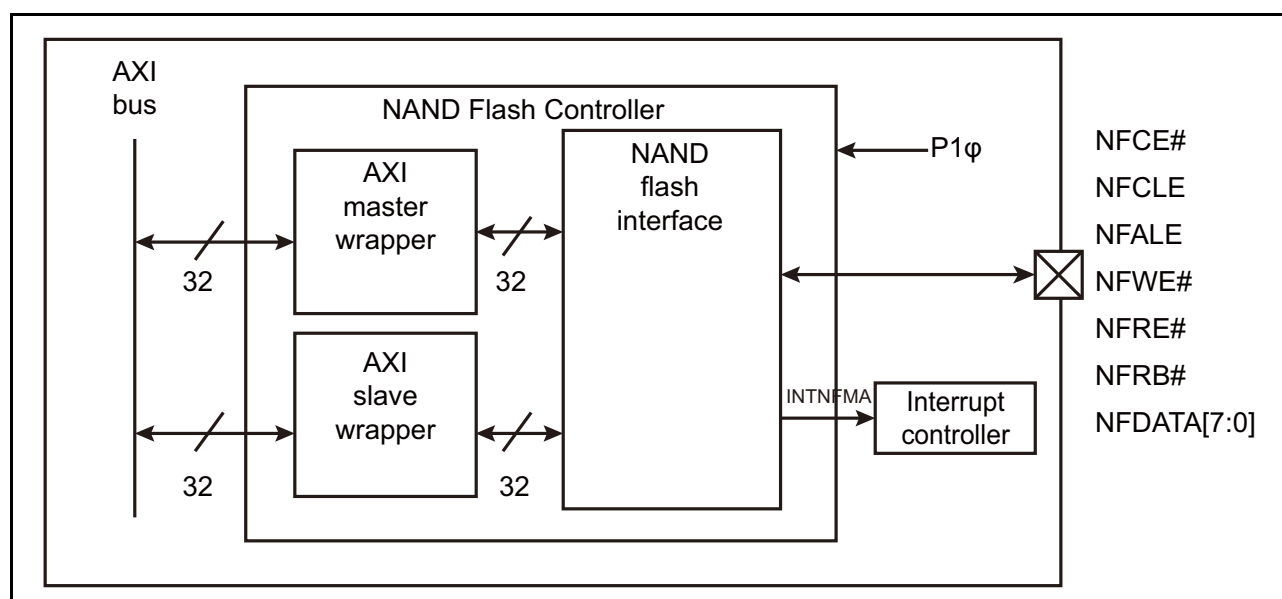

Figure 31.1 Block Diagram

The INTNFMA interrupt signal described in this section corresponds to the NAND interrupt sources of this controller.

31.1.3 External Pins

Table 31.1 lists the pin configuration.

Table 31.1 Pin Configuration

| Name | I/O | Function |
|-------------|-----|----------------------|
| NFRE# | O | Read Enable |
| NFCE# | O | Chip Enable |
| NFCLE | O | Command Latch Enable |
| NFALE | O | Address Latch Enable |
| NFWWE# | O | Write Enable |
| NFDATA[7:0] | I/O | Data |
| NFRB# | I | Ready/busy |

31.1.4 Register Configuration

Table 31.2 shows the register configuration.

Table 31.2 Register Configuration

| Name | Abbreviation | R/W | Address | Initial Value | Access Size |
|--|----------------|-----|------------|---------------|-------------|
| Controller commands register | COMMAND | R/W | H'E822C000 | H'0000 0000 | 32 |
| Main configurations register | CONTROL | R/W | H'E822C004 | H'0000 0000 | 32 |
| Controller status register | STATUS | R | H'E822C008 | H'0000 0001 | 32 |
| Mask register for the READ STATUS commands | STATUS_MASK | R/W | H'E822C00C | H'0000 4040 | 32 |
| Interrupts mask register | INT_MASK | R/W | H'E822C010 | H'0000 0000 | 32 |
| Interrupts status register | INT_STATUS | R/W | H'E822C014 | H'0000 0000 | 32 |
| ECC module control register | ECC_CTRL | R/W | H'E822C018 | H'0000 0000 | 32 |
| ECC offset in the spare area register | ECC_OFFSET | R/W | H'E822C01C | H'0000 0000 | 32 |
| ECC module status register | ECC_STAT | R/W | H'E822C020 | H'0000 0000 | 32 |
| Column address register 0 | ADDR0_COL | R/W | H'E822C024 | H'0000 0000 | 32 |
| Row address register 0 | ADDR0_ROW | R/W | H'E822C028 | H'0000 0000 | 32 |
| Column address register 1 | ADDR1_COL | R/W | H'E822C02C | H'0000 0000 | 32 |
| Row address register 1 | ADDR1_ROW | R/W | H'E822C030 | H'0000 0000 | 32 |
| FIFO module interface register | FIFO_DATA | R/W | H'E822C038 | — | 32 |
| Data register | DATA_REG | R/W | H'E822C03C | H'0000 0000 | 32 |

| MLUN register | MLUN | R/W | H'E822C0BC | H'0000 0000 | 32 |
| Records table size register | DEV0_SIZE | R/W | H'E822C0C0 | H'0000 0000 | 32 |
| DMA trigger level value register | DMA_TRIG_TLVL | R/W | H'E822C114 | H'0000 0000 | 32 |
| CMD ID initial value register | CMD_MARK | W | H'E822C124 | H'0000 0000 | 32 |
| LUN status register | LUN_STATUS_0 | R | H'E822C128 | H'0000 00FF | 32 |
| Generic sequence timing configuration register 3 | TIME_GEN_SEQ_3 | R/W | H'E822C134 | H'0000 0000 | 32 |
| ECC error level counter register | ECC_CNT | R/W | H'E822C14C | H'0000 0000 | 32 |

31.2 Register Description

31.2.1 Controller commands register (COMMAND)

COMMAND specifies the command sequence code and selects data.

The write of the command sequence code to this register triggers the programmed command sequence execution. If the execution cannot be started immediately, the transfer to this register is prolonged by the series of the WAIT responses.

Each command sequence can generate an interrupt when it is completed.

| | | | | | | | | | | | | | | | | |
|----------------|------------|-----|-----|-----|-----|-----|-----|-----|-------------------------|-----------|--------------------------|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | CMD_2[7:0] | | | | | | | | CMD_1[7:0]/CMD_3[7:0]*1 | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | CMD_0[7:0] | | | | | | | | DATA_SEL | INPUT_SEL | CMD_SEQ[5:0] OPC[1:0] | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-----------------------------|---------------|-----|--|
| 31 to 24 | CMD_2[7:0] | H'00 | R/W | Code of the third command in a sequence |
| 23 to 16 | CMD_1[7:0]/ CMD_3[7:0]*1 | H'00 | R/W | Code of the second command in a sequence |
| 15 to 8 | CMD_0[7:0] | H'00 | R/W | Code of the first command in a sequence |
| 7 | DATA_SEL | 0 | R/W | Data/FIFO selection 0: FIFO selected 1: DATA register selected |
| 6 | INPUT_SEL | 0 | R/W | Input module selection 0: select the registers in the Slave I/F Unit (SIU) module as input 1: select the DMA module as input |
| 5 to 0 | CMD_SEQ[5:0] | H'00 | R/W | Command code |

Note 1. Depending on the selected command sequence, this field will store CMD1 or CMD3 code.
In the generic sequence, both commands are used in a single sequence.

31.2.2 Main configurations register (CONTROL)

CONTROL stores the common configuration parameters.

| | | | | | | | | | | | | | | | | |
|----------------|----|---------|--------|----|----|----|----|----|-------------------|---------|----------------|-----|---------------------|-----|-----------------|-----------------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | AUTO_READ_STAT_EN | MLUN_EN | SMALL_BLOCK_EN | — | — | — | ADDR1_AUTO_INCR | ADDR0_AUTO_INCR |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | RW | R | R | R | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | PROT_EN | BBM_EN | — | — | — | — | — | BLOCK_SIZE[1:0] | ECC_EN | INT_EN | — | ECC_BLOCK_SIZE[1:0] | — | — | — |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R/W | R/W | R | R | R | R | R | R/W | R/W | R/W | R/W | R | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-------------------|---------------|-----|--|
| 31 to 24 | — | All 0 | R | Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
| 23 | AUTO_READ_STAT_EN | 0 | R/W | Auto Read Status mode enable If active, the controller reads the status after the PROGRAM PAGE and ERASE BLOCK commands. It can trigger an interrupt. The ERROR_MASK field in the STATUS_MASK register must be configured when this feature is enabled. After executing a PROGRAM PAGE or ERASE BLOCK command, you can use the field to check the state following the operation (in terms of success or failure). 0: Auto Read Status mode disabled 1: Auto Read Status mode enabled |
| 22 | MLUN_EN | 0 | R/W | Multi LUN mode enables If active, it enables controller multi LUN work mode 0: Multi LUN mode disabled 1: Multi LUN mode enabled For more details, see section 31.3.4, Multi LUN Work Mode. |
| 21 | SMALL_BLOCK_EN | 0 | R/W | Enable small block mode In this mode, the controller sends only a single byte as the column address instead of two bytes, as done in the big block NAND Flash devices. 0: big block mode enabled 1: small block mode enabled Note: Only devices that allow to disable CE signal when device is in the busy state are supported. |
| 20 to 18 | — | All 0 | R | Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
| 17 | ADDR1_AUTO_INCR | 0 | R/W | Address auto increment for row address register 1 (ADDR1_ROW) When this bit is set, sending any command sequence using address register 1 causes the increment of address register 1. 0: auto increment disabled 1: auto increment enabled |
| 16 | ADDR0_AUTO_INCR | 0 | R/W | Address auto increment for row address register 0 (ADDR0_ROW) When this bit is set, sending any command sequence using address register 0 causes the increment of address register 0 0: auto increment disabled 1: auto increment enabled |
| 15 | — | 0 | R | Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit. |
| 14 | PROT_EN | 0 | R/W | Protect mechanism enable 0: protect disabled 1: protect enabled |

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|---------------------|---------------|-----|--|
| 13 | BBM_EN | 0 | R/W | Bad Block Management enable flag For more details, see section 31.3.5, Remapping Mechanism. |
| 12 to 8 | — | All 0 | R | Reserved These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
| 7, 6 | BLOCK_SIZE[1:0] | H'0 | R/W | The Block Size 00: 32 pages per block 01: 64 pages per block 10: 128 pages per block 11: 256 pages per block |
| 5 | ECC_EN | 0 | R/W | Hardware ECC support enable 0: ECC disabled 1: ECC enabled Hardware ECC can be used only when $m * (ECC_BLOCK_SIZE) \leq DATA_SIZE \leq m * (ECC_BLOCK_SIZE + 32)$, where m is 1,2,3... |
| 4 | INT_EN | 0 | R/W | Global Interrupt enable 0: Interrupts disabled 1: Interrupts enabled For more details, see section 31.3.6, Interrupts Mechanism. |
| 3 | — | 0 | R | Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit. |
| 2, 1 | ECC_BLOCK_SIZE[1:0] | H'0 | R/W | The ECC Block Size: 00: 256 bytes 01: 512 bytes 10: 1024 bytes 11: not available The ECC block size can be changed only when all memory devices are ready. |
| 0 | READ_STATUS_EN | 0 | R/W | Automatically READ STATUS/check RnB lines The STATUS_MASK field in the STATUS_MASK register must be configured when this feature is enabled. This bit is used to select how the controller detects the ready or busy state of the device. 0: The controller checks RnB lines. 1: The controller sends READ STATUS commands. Note: Automatically sent READ STATUS command is only available in devices compatible with ONFI 1.0. |

31.2.3 GENERIC_SEQ register (GEN_SEQ_CTRL)

GENERIC_SEQ is used to parameterize the generic sequences. For more details, see section 31.3.2, Generic Sequence. For examples, see Table 31.7.

| | | | | | | | | | | | | | | | | |
|----------------|---------|---------------|---------|-------------|-------------|-------------|-------------|---------|------------|---------|---------|-----|-----|-----|-----|-----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | CMD_3[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | IMD_SEQ | DELAY_EN[1:0] | DATA_EN | ROW_A1[1:0] | ROW_A0[1:0] | COL_A1[1:0] | COL_A0[1:0] | CMD3_EN | CMD2_EN | CMD1_EN | CMD0_EN | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|---------------|---------------|-----|--|
| 31 to 24 | — | All 0 | R | Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
| 23 to 16 | CMD_3[7:0] | H'00 | R/W | Command 3 code value |
| 15 | IMD_SEQ | 0 | R/W | Enable immediate command execution This bit allows the command sequence to be executed without checking the selected target state. 0: feature disabled 1: feature enable |
| 14, 13 | DELAY_EN[1:0] | H'0 | R/W | Enable the busy 0 or 1 phase These bits allow enabling or disabling the presence of the “busy” phase in the generic sequence. 00: disable both delays 01: enable delay 0 10: enable delay 1 11: disable both delays |
| 12 | DATA_EN | 0 | R/W | Enable data part sequence This bit allows enabling or disabling the data phase of the generic sequence. 0: disable data phase 1: enable data phase |
| 11, 10 | ROW_A1[1:0] | H'0 | R/W | Row Address Cycles The number of bytes of row addresses to be sent to the NAND Flash device 00: 0 address cycles 01: 1 address cycle 10: 2 address cycles 11: 3 address cycles |
| 9, 8 | ROW_A0[1:0] | H'0 | R/W | Row Address Cycles The number of bytes of row addresses to be sent to the NAND Flash device 00: 0 address cycles 01: 1 address cycle 10: 2 address cycles 11: 3 address cycles |
| 7, 6 | COL_A1[1:0] | H'0 | R/W | Column Address Cycles The number of bytes of column addresses to be sent to the NAND Flash device 00: 0 address cycles 01: 1 address cycle 10: 2 address cycles 11: setting prohibited |

| Bit | Bit Name | Initial Value | R/W | Description |
|------|-------------|---------------|-----|---|
| 5, 4 | COL_A0[1:0] | H'0 | R/W | Column Address Cycles The number of bytes of column addresses to be sent to the NAND Flash device 00: 0 address cycles 01: 1 address cycle 10: 2 address cycles 11: setting prohibited |
| 3 | CMD3_EN | 0 | R/W | Enable Command 3 Phase This bit allows enabling or disabling the presence of the "command 3" phase in the generic sequence. 1: enable 0: disable |
| 2 | CMD2_EN | 0 | R/W | Enable Command 2 phase This bit allows enabling or disabling the presence of the "command 2" phase in the generic sequence. 1: enable 0: disable |
| 1 | CMD1_EN | 0 | R/W | Enable Command 1 phase This bit allows enabling or disabling the presence of the "command 1" phase in the generic sequence. 1: enable 0: disable |
| 0 | CMD0_EN | 0 | R/W | Enable Command 0 phase This bit allows enabling or disabling the presence of the "command 0" phase in the generic sequence. 1: enable 0: disable |

31.2.4 Controller status register (STATUS)

STATUS stores the NAND Flash controller and connected device status flags. These flags can be used to obtain the current controller internal state.

The CTRL_STAT flag is set after the controller starts to execute the requested command for the selected NAND Flash device, and it is active while the command execution is not completed. Command execution can be divided into two phases. In the first phase, the command sequence is executed at the moment when the NAND Flash device goes into the busy state. After that, the controller stores information about the pending operation on the selected device. In the second phase, the controller automatically finishes the pending command execution based on the previously stored data. As long as this flag is set, the controller does not accept any new commands.

The MEM0_ST flag indicates the state of the NAND flash device. The flag has the same function as the NAND Flash device RnB line.

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----------------|----------------------|--------------|-------------|----|----|----|----|----|----|-------------|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | CMD_ID[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |
| Bit: | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | — | — | — | — | — | DATA REG_ST | DATASIZE ERROR_ST | CTRL STAT | — | — | — | — | — | — | — | MEM0 _ST |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|-------------------|---------------|-----|--|
| 31 to 24 | — | All 0 | R | Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
| 23 to 16 | CMD_ID[7:0] | H'00 | R | Command ID The current command under execution identification marker added before command was put in to the command FIFO. |
| 15 to 11 | — | All 0 | R | Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
| 10 | DATA_REG_ST | 0 | R | The DATA_REG: Resetting of this flag is possible only by reading the data from the DATA_REG register. 1: data in DATA_REG is available 0: data in DATA_REG is not available |
| 9 | DATASIZE_ERROR_ST | 0 | R | The Data Size value error This bit indicates that the value written to the DATA_SIZE register is not correct when the ECC is enabled. For details on the values of the correct size of data, see the description of the DATA_SIZE register. 0: correct value 1: incorrect value |
| 8 | CTRL_STAT | 0 | R | The main controller status bit 0: controller ready 1: controller busy |
| 7 to 1 | — | All 0 | R | Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
| 0 | MEM0_ST | 1 | R | Device 0 status flag 1: device ready 0: device busy |

Note: When using the READ PARAMETER PAGE command, the block size for the ECC memory (ECC_BLOCK_SIZE) must be the same as that set in the DATA_SIZE register.
When using the SET FEATURES, GET FEATURES, or READ ID command, disable the ECC function.

31.2.5 LUN status register (LUN_STATUS_0)

LUN_STATUS_0 allows to access the LUN status information. Each bit of the LUN status field contain the status of single LUN of device. The busy state is indicated as "0", and the ready state is indicated as "1".

| | | | | | | | | | | | | | | | | |
|----------------|----|----|----|----|----|----|----|----|---------------|----|----|----|----|----|----|----|
| Bit: | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — | — |

| | — | — | — | — | — | — | — | — | MEM0_LUN[7:0] | | | | | | | |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| R/W: | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R | R |

| Bit | Bit Name | Initial Value | R/W | Description |
|---------|---------------|---------------|-----|--|
| 31 to 8 | — | All 0 | R | Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
| 7 to 0 | MEM0_LUN[7:0] | H'FF | R | Memory 0 LUN-s status field. |

31.2.6 Interrupts mask register (INT_MASK)

INT_MASK allows masking of the selected interrupts source in the NAND Flash controller. The masked interrupts still set the corresponding bits in the status register, but do not assert the interrupt signal.

| Bit | Bit Name | Initial Value | R/W | Description |
|----------|------------------|---------------|-----|--|
| 31 to 25 | — | All 0 | R | Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
| 24 | ECC_INT0_EN | 0 | R/W | Enables the interrupt from the ECC module status for Memory device 0. 0: interrupt disabled 1: interrupt enabled |
| 23 to 17 | — | All 0 | R | Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
| 16 | STAT_ERR_INT0_EN | 0 | R/W | Enables the interrupt when the most recently finished operation on the Memory device 0 failed. This applies to PROGRAM PAGE and ERASE BLOCK operations. It is not valid following a READ-series operation. 0: interrupt disabled 1: interrupt enabled |
| 15 to 9 | — | All 0 | R | Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits. |
