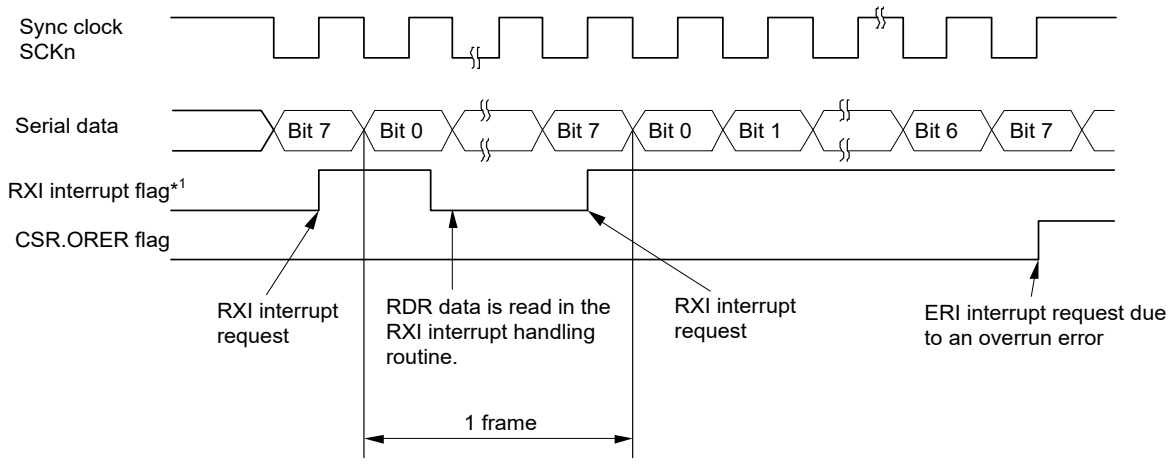
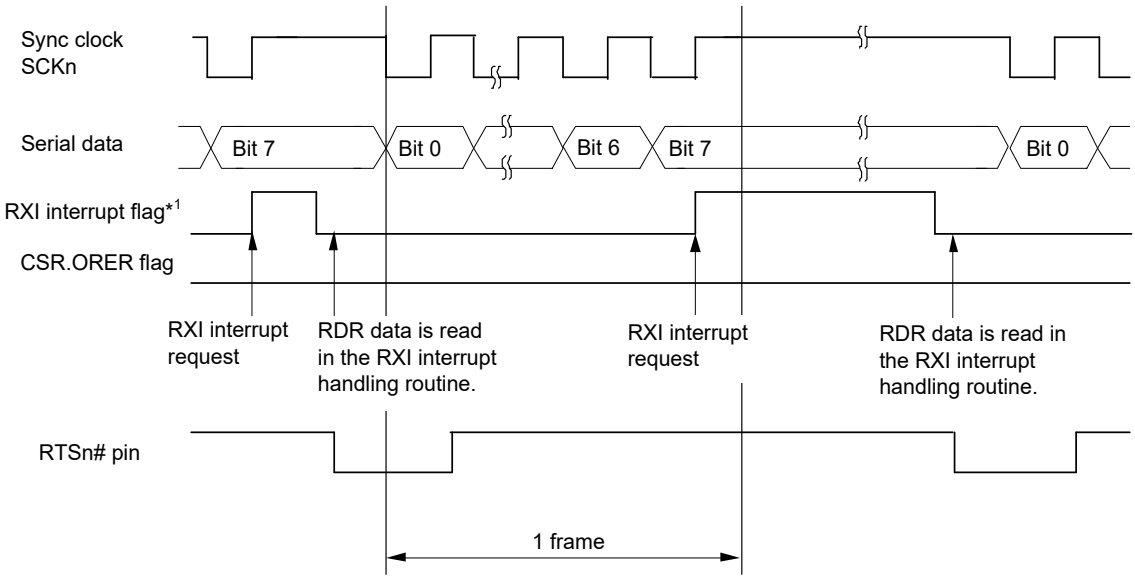
   If you want to prevent the RTSn# pin output from turning low level after the final data is received, clear the CCR0.RE bit to 0b and then read the RDR register.



Note 1. For corresponding interrupt source numbers, see **4.6 Interrupt Controller**.

Figure 7.3-88 Serial Data Reception Example in Clock Synchronous Mode (1) (RTS Function Not Used/CPHA = 1b, CPOL = 1b)

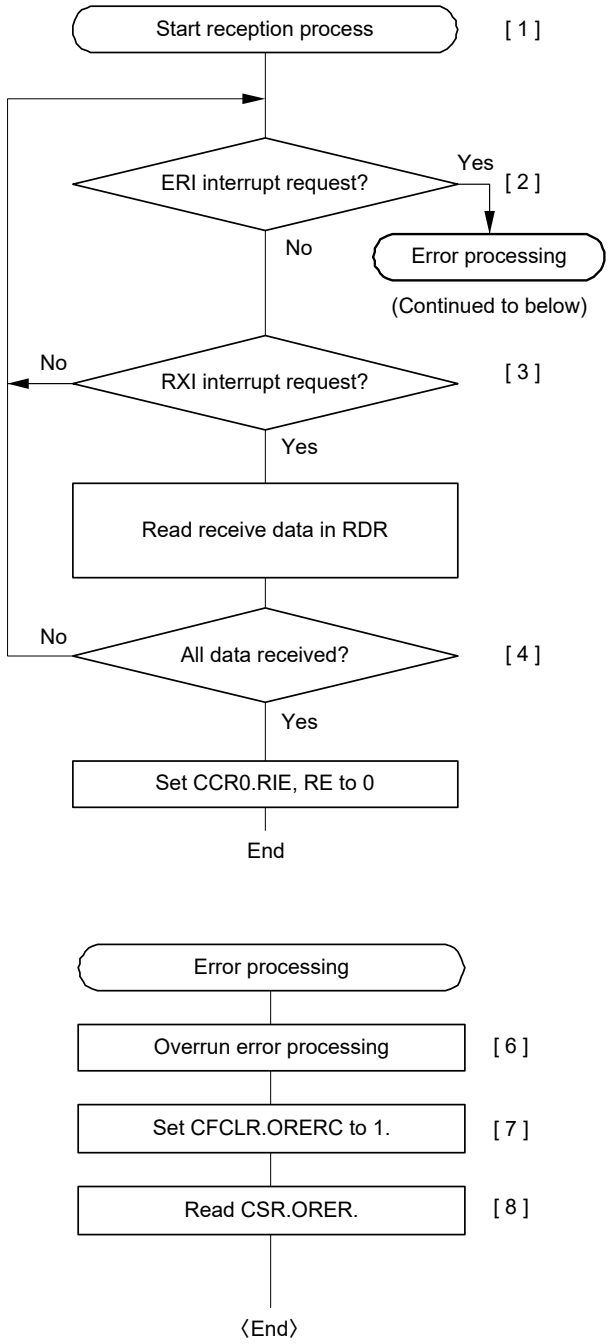


Note 1. For corresponding interrupt source numbers, see **4.6 Interrupt Controller**.

Figure 7.3-89 Serial Data Reception Example in Clock Synchronous Mode (2) (RTS Function Used/CPHA = 1b, CPOL = 1b)

While the reception error flag is set to 1b, subsequent reception is disabled. Therefore, before continuing reception, be sure to clear the ORER flag in CSR to 0b. Also be sure to read the RDR register in the overrun error processing. If the CCR0.RE bit is set to 0b during reception to forcibly terminate the reception operation, unread receive data may be remaining in the RDR register. In this case, read the RDR register.

Figure 7.3-90 shows an example of serial data reception flowchart.



[1] Start reception process

[2] Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to ORER is 0. Reception cannot be resumed if ORER is 1.

[3] Read the receive data in RDR once in the RXI interrupt handling routine.

[4] Serial reception continuation procedure:
To continue serial reception, before the MSB bit (bit 7) of the current frame is received, read data from RDR in the RXI interrupt handling routine. The RDR data can also be read by activating the DMAC.

[6] Overrun error processing:
Read RDR.

[7] Clear the error flag:
Set the flag clear bit corresponding to the reception error to 1. Done this step and step [6], the next frame can be received normally.

[8] Confirming that the error flag is cleared:
Confirm all error flags are cleared.

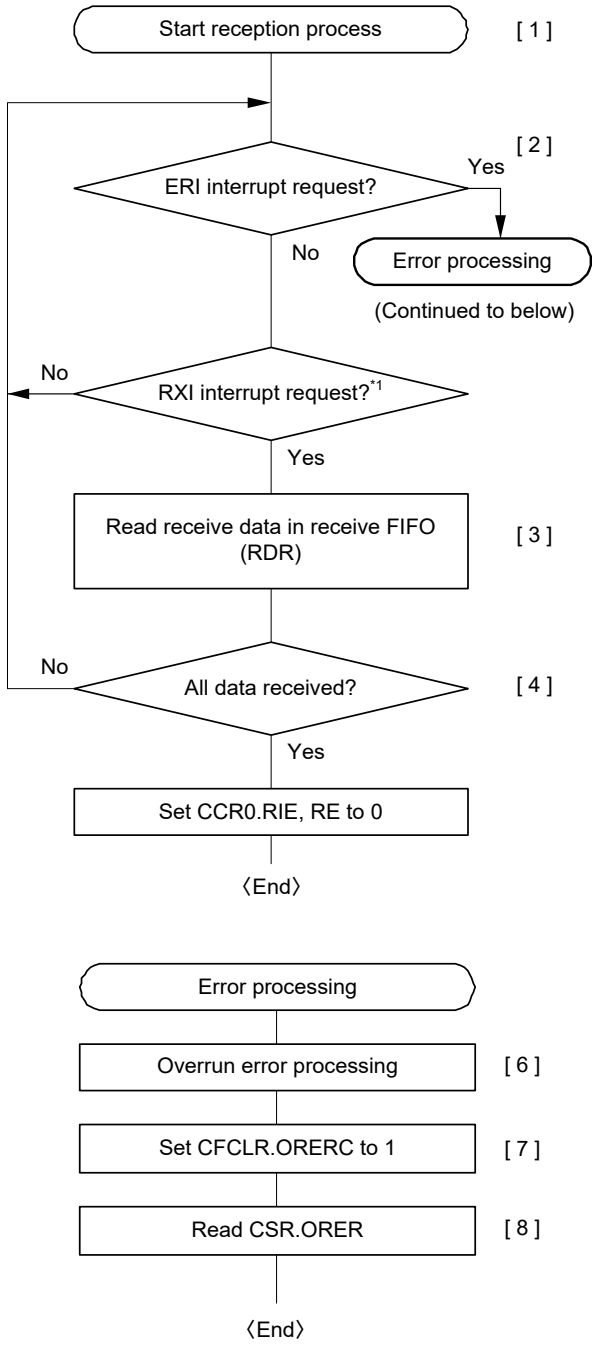
Figure 7.3-90 Sample Flowchart for Serial Reception in Clock Synchronous Mode (Non-FIFO Selected)

(2) FIFO selected

Figure 7.3-91 shows an example of serial data reception flowchart (a FIFO buffer selected) in clock synchronous mode. The SCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

1. When the CCR0.RE bit is set to 1b, the RTSn# pin output turns low level (when the RTS function is used).
2. The SCI starts receiving data in synchronization with input or output of the sync clock and transfers the received data to the receive FIFO (RDR register).
3. When an overrun error occurs, the CSR.ORER flag is set to 1b. When the CCR0.RIE bit = 1b at this time, an ERI interrupt request is generated and the received data is not transferred to the receive FIFO (RDR register)*[1].
4. When data is normally received, the received data is transferred to the receive FIFO (RDR register)*[1]. When the number of receive data stored in the receive FIFO (RDR register) is equal to or more than the threshold value of the receive FIFO, the CSR.RDRF flag is set to 1b. When the RIE bit = 1b at this time, an RXI interrupt request is generated. Reading the received data transferred to the receive FIFO (RDR register) in the RXI interrupt handling routine before an overrun error occurs enables continuous reception. When the received data transferred to the receive FIFO (RDR register) is read and the number of data becomes lower than the RTS# output threshold value, the RTSn# pin output becomes low level (when the RTS function is used).

Note 1. The RDR.RDAT[8] bit is not used.



[1] Start reception process

[2] Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to ORER is 0. Reception cannot be resumed if ORER is 1.

[3] Read the receive data in the receive FIFO (RDR) in the RXI interrupt handling routine. The reception data stored in the receive FIFO (RDR) is read until the number of stored data will be below the FCR.RTRG value at least. You can confirm the number of the reception data in the FIFO by FRSR.R[5:0].

[4] Serial reception continuation procedure:
To continue serial reception, before the overrun error occurs, read data from RDR and clear RDRF flag to 0. The RDR data can also be read by activating the DMAC. In this case, the RDRF flag is cleared automatically, so please do not operate the RDRF flag.

Note 1. Set all received data to an integer multiple of the receive FIFO threshold. If it is not an integral multiple, return to step [2] and it will become an infinite loop, so set a timeout time separately using a timer etc.

[6] Overrun error processing:
Read RDR.

[7] Clear the error flag:
Set the flag clear bit corresponding to the reception error to 1. Done this step and step [6], the next frame can be received normally.

[8] Confirming that the error flag is cleared:
Confirm all error flags are cleared.

Figure 7.3-91 Example of Serial Reception in Clock Synchronous Mode (FIFO Selected)

7.3.8.6 Serial Data Transmission and Reception (Clock Synchronous Mode)

(1) Non-FIFO selected

Figure 7.3-92 shows an example of serial data concurrent transmission/reception flowchart in clock synchronous mode. After the SCI is initialized, perform the following procedure for serial data concurrent transmission/reception. When switching mode from transmission to concurrent transmission/reception, check that the CSR.TEND flag is set to 1b to ensure that the SCI is in the transmission complete state. Then set CCR0.TE = 0b and RE = 0b and then set the TE, RE, TIE, and RIE bits in CCR0 to 1b simultaneously by a single instruction.

When switching mode from reception to concurrent transmission/reception, check that the SCI is in the reception complete state, and then set CCR0.TE = 0b and RE = 0b. After that, check that the error flags (ORER, FER, and PER) in CSR are cleared to 0b, and then set the TE, RE, TIE, and RIE bits in CCR0 to 1b simultaneously by a single instruction.

When the RTS function is used in the concurrent transmission/reception operation, if you want to prevent the RTSn# pin output from turning to low after the final data is received as in the reception operation, clear the RE and TE bits in CCR0 to 0b simultaneously, and then read the RDR register.

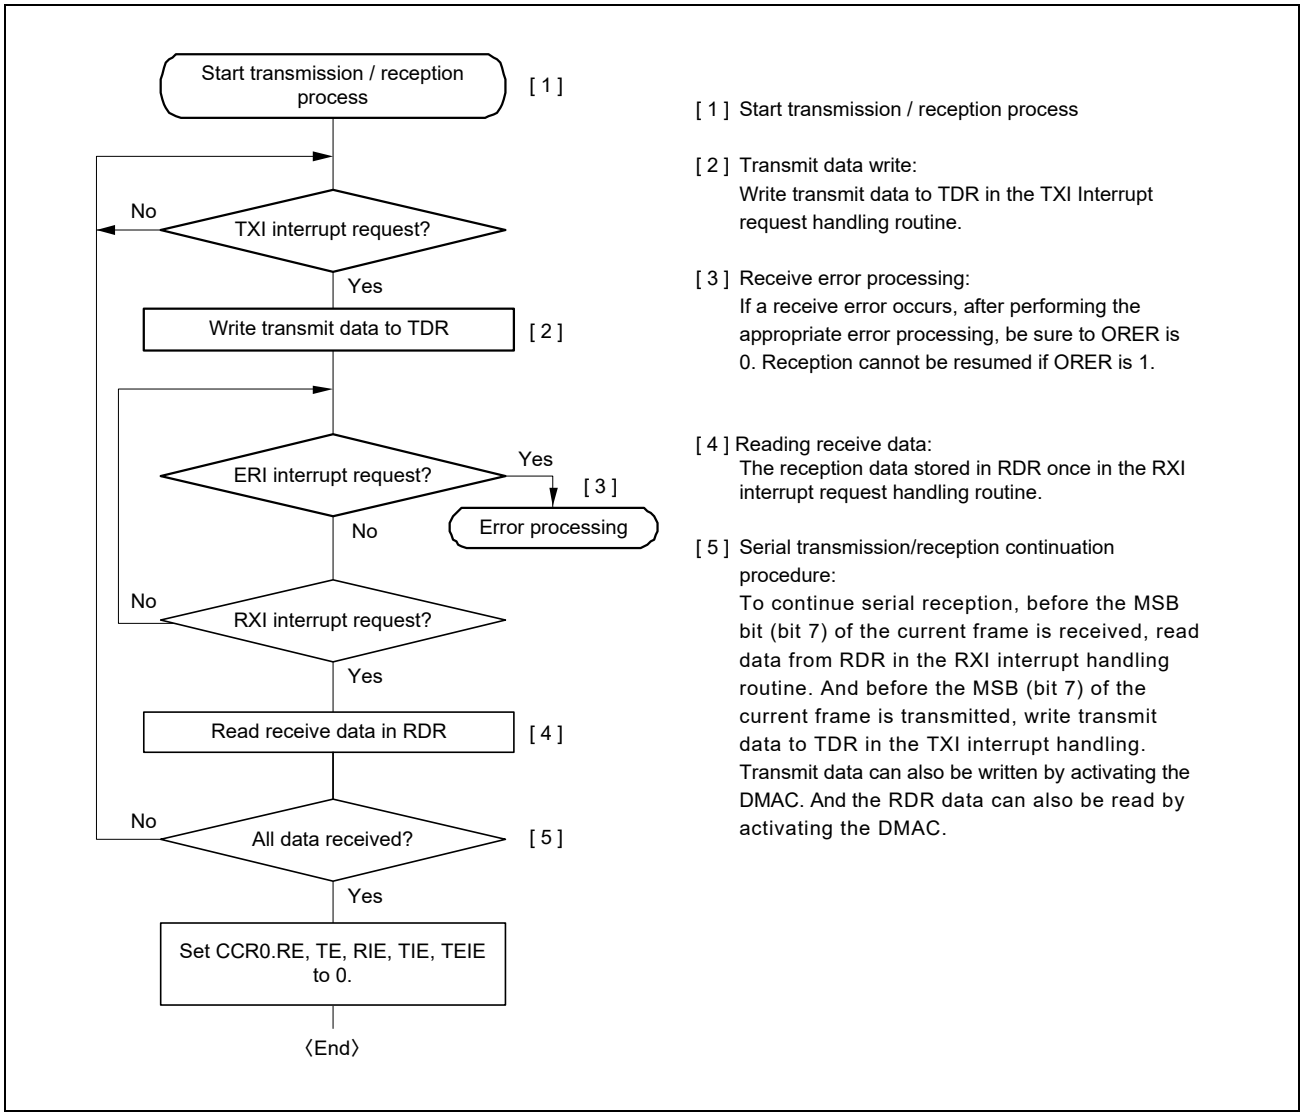


Figure 7.3-92 Serial Data Concurrent Transmission/Reception Flowchart Example in Clock Synchronous Mode (Non-FIFO Selected)

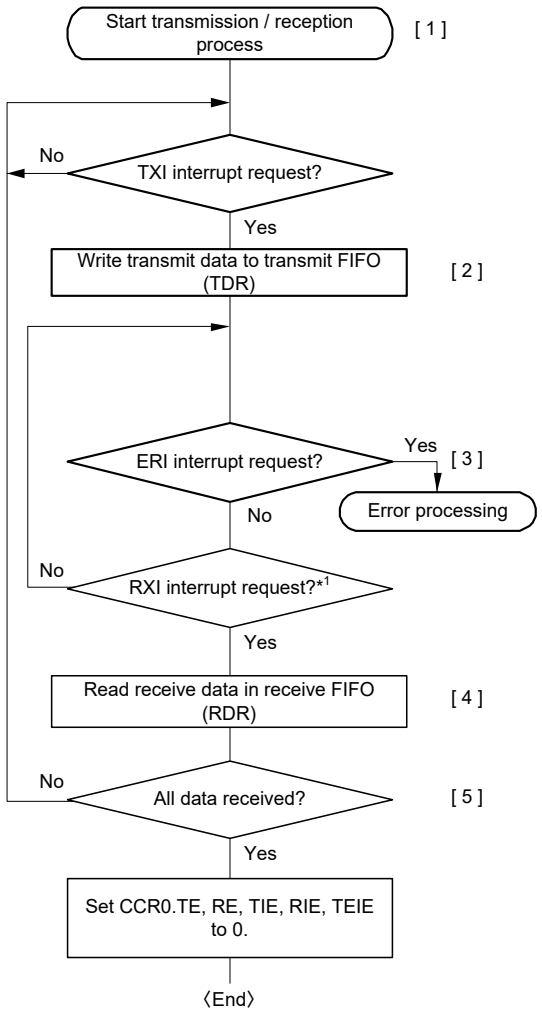
(2) FIFO selected

Figure 7.3-93 shows an example of serial data concurrent transmission/reception flowchart (a FIFO buffer selected) in clock synchronous mode.

After the SCI is initialized, perform the following procedure for serial data concurrent transmission/reception. When switching mode from transmission to concurrent transmission/reception, check that the CSR.TEND flag is set to 1b to ensure that the SCI is in the transmission complete state. Then set CCR0.TE = 0b and RE = 0b and then set the TE, RE, TIE, and RIE bits in CCR0 to 1b simultaneously by a single instruction.

When switching mode from reception to concurrent transmission/reception, check that the SCI is in the reception complete state, and then set CCR0.TE = 0b and RE = 0b. After that, check that the error flags (ORER, FER, and PER) in CSR are cleared to 0b, and then set the TE, RE, TIE, and RIE bits in CCR0 to 1b simultaneously by a single instruction.



[1] Start transmission / reception process

[2] Transmit data write:
Write transmit data to transmit FIFO (TDR) in the TXI Interrupt request handling routine.
The number of transmission data it's possible to write in is N_{FIFO} (= 32) - (the number of stored transmit FIFO data).

[3] Receive error processing:
If a receive error occurs, after performing the appropriate error processing, be sure to ORER is 0. Reception cannot be resumed if ORER is 1.

[4] Read receive data:
Read the receive data in the receive FIFO (RDR) in the RXI interrupt handling routine. The reception data stored in the receive FIFO (RDR) is read until the number of stored data will be below the FCR.RTRG value at least. You can confirm the number of the reception data in the FIFO by FRSR.R[5:0].

[5] Serial transmission/reception continuation procedure:
To continue serial reception, before the overrun error occurs, read data from RDR and clear CSR.RDRF.
To continue serial transmission, write transmit data to the transmit FIFO (TDR) by using a TXI interrupt and clear TDRE flag to 0.
Transmit data can also be written to the transmit FIFO (TDR) by activating the DMAC. And The RDR data can also be read by activating the DMAC. In this case, the TDRE and RDRF are cleared automatically, so please do not operate the TDRE and RDRF.

Note 1. Set all received data to an integer multiple of the receive FIFO threshold. If it is not an integral multiple, return to step [2] and it will become an infinite loop, so set a timeout time separately using a timer etc.

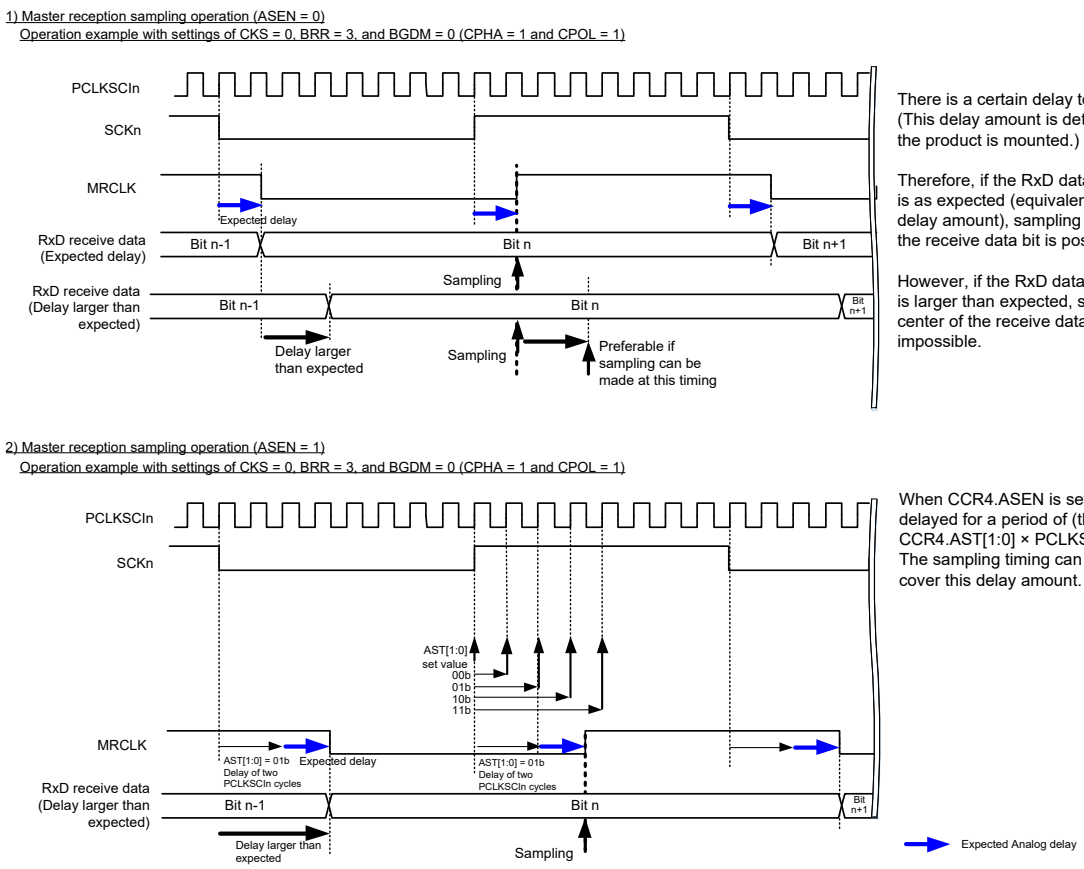
Figure 7.3-93 Serial Data Concurrent Transmission/Reception Flowchart Example in Clock Synchronous Mode (FIFO Selected)

7.3.8.7 Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with Internal Clock Used

When the clock synchronous internal clock is used (master mode), MRCLK is used as a reception sampling clock.

This function adjusts the reception sampling timing by delaying MRCLK by 1 to 4 RSCI_m_TCLK and adding a digital delay.

Setting the CCR4.ASEN bit to 1b enables this function. The delay value is set in CCR4.AST[1:0].



Note: This timing chart illustrates the reception sampling timing adjustment function.

Figure 7.3-94 Reception Sampling Timing Adjustment Operation in Clock Synchronous Mode (Master)

7.3.9 Simple-SPI Mode

As an extended function of the SCI, the SCI supports Simple-SPI (4-wire serial bus) mode that allows communication from one or more master devices to multiple slave devices.

Simple-SPI mode is enabled by the Simple-SPI mode setting (CCR3.MOD[2:0] = 011b) and by setting the CCR0.SSE bit to 1b. When using the 4-wire serial bus in master mode with a single master, the SS pin function on the master side is not required. Therefore, the CCR0.SSE bit is set to 0b.

Figure 7.3-95 shows an example of Simple-SPI connection.

In simple-SPI mode, data is transmitted and received in synchronization with clock pulses in the same way as clock synchronous mode. A character of communication data consists of 8-bit data. No parity bit can be attached.

Because the SCI has an internal transmitter and a receiver independently, the transmitter and the receiver can share a clock to enable full-duplex communication. Furthermore, because both the transmitter and the receiver have a double-buffer structure, continuous transmission and reception are possible by writing the next transmit data during transmission and reading the previous receive data during reception.

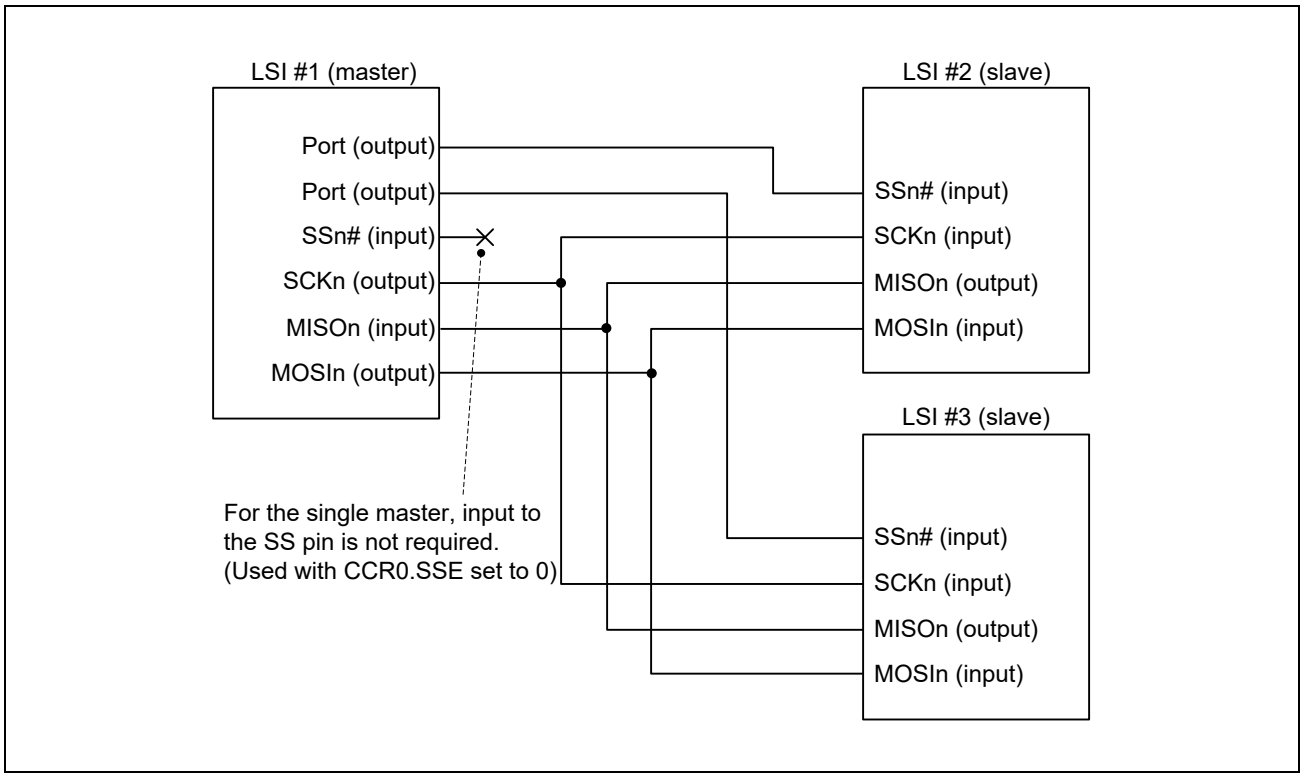


Figure 7.3-95 Simple-SPI Connection Example

7.3.9.1 Pin Status in Master and Slave Mode

In simple-SPI mode, input and output directions of each pin vary depending on master mode (CCR3.CKE[1:0] = 00b or 01b) and slave mode (CCR3.CKE[1:0] = 10b or 11b).

Table 7.3-30 shows the relationship among mode, SSn# pin input, and each pin state.

Table 7.3-30 Relationship among Mode, SSn# Pin Input, and Each Pin State

Mode	SSn# Pin Input	TXDn (MOSIn) Pin State	RXDn (MISOn) Pin State	SCKm Pin State
Master mode*1	High level (Communication enabled)	Transmit data output*2	Receive data input	Clock output*3
	Low level (Communication disabled)	High impedance	Receive data input (disabled)	High impedance
Slave mode	High level (Communication disabled)	Receive data input (disabled)	High impedance	Clock input (disabled)
	Low level (Communication enabled)	Receive data input	Transmit data output*2	Clock input

Note 1. When single master is selected (SSE bit = 0b), communication is enabled (equivalent to the state when the SSn# pin input is high level) regardless of the SSn# pin input level. The SSn# pin is not used and is available for other purposes.

Note 2. High impedance when transmission is disabled (CCR0.TE bit = 0b)

Note 3. High impedance when multi-master (SSE bit = 1b) is selected and transmission/reception is disabled (CCR0.TE, RE bits = 00b)

7.3.9.2 SS Function in Master Mode

Setting the CCR3.CKE[1:0] bits to 00b or 01b enables master mode.

In single master mode (SSE bit = 0b), the SSn# pin is not used and data transmission and reception are enabled regardless of the SSn# pin input level. The SSn# pin is available for other purposes.

When in multi-master mode (SSE bit = 1b) and the SSn# pin input is high, the master outputs a clock from the SCKm pin and performs transmission and reception operations. And outputting clock indicates “There are no other masters” or “Another master is not performing reception or transmission”. When the SSn# pin input level is low in multi-master mode (SSE bit = 1b), this means that another master exists and it is performing data transmission/reception. At this time, the SCI makes the TXDn pin output and the SCKm pin output high impedance and does not start data transmission/reception. In addition, the CSR.MFF bit is set to 1b as a mode fault error. In multi-master mode, read this flag bit to perform the error processing. If a mode fault error occurs during the transmission/reception operation, the SCKm pin and the TXDn pin output are made high impedance while the SSn# pin input level is low. When the SSn# pin input becomes high level, the SCKm pin outputs a clock signal and the TXDn pin outputs data. Even if the SCKm pin and the TXDn pin are in the high impedance state, internal transmission/reception operation continues, but it stops after transmission/reception of a single character is complete. In this case, any of TXI, RXI, and TEI interrupts occurs.

Control the SSn# pin output in master mode with a general-purpose port.

7.3.9.3 SS Function in Slave Mode

Setting the CCR3.CKE[1:0] bits to 10b or 11b enables slave mode.

When the SSn# pin input level is high, the RXDn pin output becomes high impedance and the clock input from the SCKm pin is ignored. When the SSn# pin input level is low, the clock input from the SCKm pin becomes effective, enabling data transmission and reception.

When the SSn# pin input changes from low to high level during the transmission/reception operation, the RXDn pin output is made high impedance and the transmission/reception operation is immediately suspended. If the transmission is in progress, the CSR.TEND flag will not be set, a transmit end interrupt will not be output, and an abnormal stop status will occur. So, do not negate the SSn# pin during slave transmission/reception. If an abnormal stop occurs, set CCR0.RE and CCR0.TE to 0b to stop transmission / reception. To resume transmission/reception, set CCR0.RE and CCR0.TE to 1b after at least RSCI_m_TCLK × 3 cycles + RSCI_m_PCLK × 3 cycles.

7.3.9.4 Relationship between Clock and Transmit/Receive Data

The clock to be used for data transmission/reception is selectable from four types using the CCR3.CPOL and CPHA bits. **Figure 7.3-96** shows the relationship between clock and transmit data/receive data. The same relationship applies to master mode and slave mode.

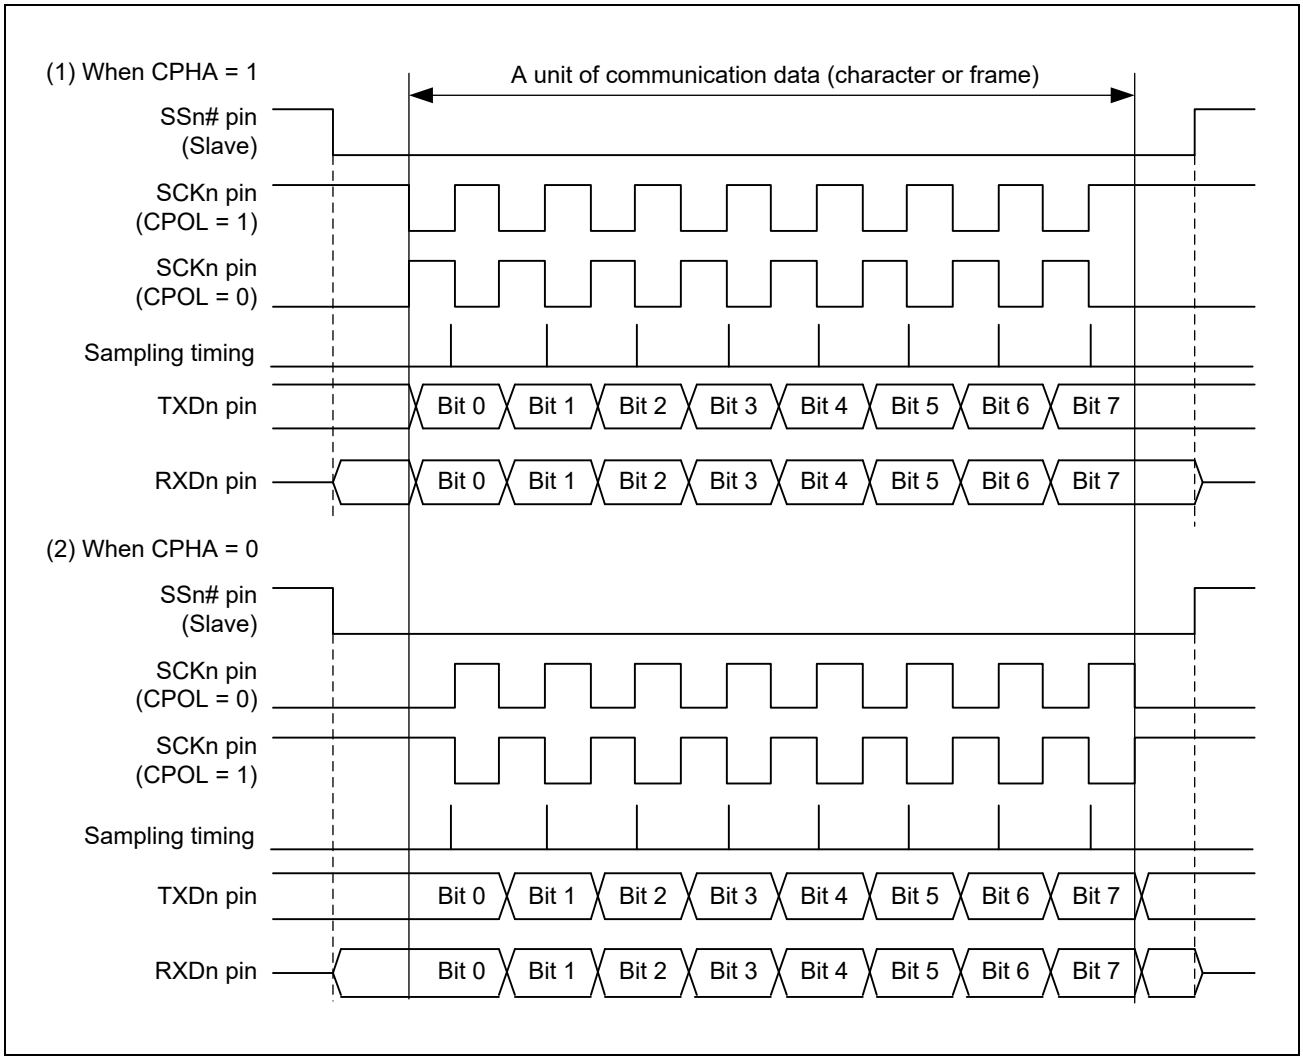

Figure 7.3-96 Relationship between Clock and Transmit Data/Receive Data in Simple-SPI Mode

7.3.9.5 SCI Initialization in Simple-SPI Mode

The SCI can be initialized using the same initialization procedure as for clock synchronous mode (**Figure 7.3-82**). The master devices and slave devices use the same clock type selected by the CCR3.CPOL and CPHA bits.

Before performing initialization or changing operating mode or communication format, be sure to stop communication (CCR0.RE = 0b and CCR0.TE = 0b).

Note that setting the RE bit to 0b does not initialize the ORER, FER, and PER flags in CSR and the RDR register.

Note that, when CCR0.TIE = 1b, setting the TE bit to 1b from 0b generates a TXI interrupt.

7.3.9.6 Serial Data Transmission and Reception in Simple-SPI Mode

In master mode, set the SSn# pin of the destination slave device to low level before starting data transmission/reception and set to high level after the end of data transmission/reception. In multiple master operation with CCR0.SSE = 1b even in master mode, a mode fault error will occur if the SSn# pin goes low. Therefore, make sure that no mode fault error has occurred before starting communication, and start communication, and make sure that no mode fault error has occurred even after communication ends. If a mode fault error has occurred, communication may be incomplete, so measures such as retransmission are required. The other procedures are the same as in clock synchronous mode.

In slave mode, it operates according to the SSn# pin input level. Other steps are the same as those of clock synchronous mode.

7.3.9.7 Reception Sampling Timing Adjustment Function in Simple-SPI Mode with Internal Clock Used

The reception sampling timing adjustment function in simple SPI mode is the same as the reception sampling timing adjustment function in clock synchronous mode. For the description of operation, see **7.3.8.7 Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with Internal Clock Used**.

7.3.10 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be corrected by evenly enabling the clocks of the number specified in the CCR2.MDDR[7:0] bits among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in CCR2.

Figure 7.3-97 shows an example where the RSCI_m_TCLK is selected by the CKS[1:0] bits in CCR2 and the BRR and MDDR are set to 0 and 160 respectively in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256). The enable of internal clock has non-balanced. So, notice the pulse width of the internal base clock is caused bias.

Do not use this function in Clock Synchronous mode, Simple-SPI mode, Smart Card Interface mode and Simple-LIN mode.

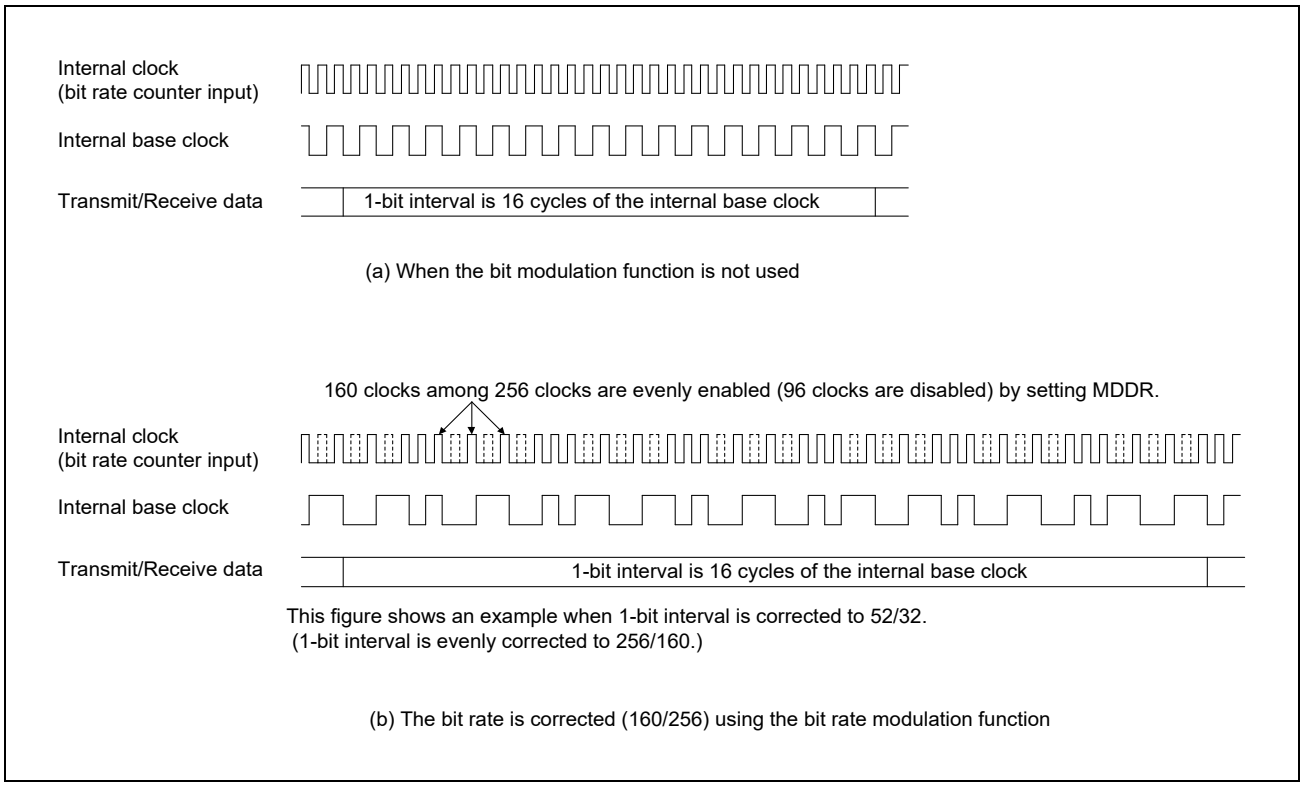

Figure 7.3-97 Example of Internal Base Clock when Bit Rate Modulation Function is Used

7.3.11 Noise Cancellation Function

Figure 7.3-98 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a two-stage flip-flop circuits and a match detection circuit. When the input signals of the noise filter and the output signals of the two- stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. (When the same level is retained for three cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for three cycles or shorter is considered as a noise, not as a receive signal.)

In asynchronous mode and simple-LIN mode, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The sampling period of the noise filter can be selected from the base clock period and the divided clock of the baud rate generator clock source by CCR1.NFCS[2:0].

(When CCR1.NFCS[2:0] = 000b, CCR2.ABCS = 0b and CCR2.ABCSE = 0b, the cycle is 1/16 of a period 1 transfer bit.
When CCR1.NFCS[2:0] = 000b, CCR2.ABCS = 1b and CCR2.ABCSE = 0b, the cycle is 1/8 of a period 1 transfer bit.
When CCR1.NFCS[2:0] = 000b, CCR2.ABCSE = 1b, the cycle is 1/6 of a period 1 transfer bit.)

In simple I2C mode, the noise elimination function can be used for the input pins of SDAn and SCLn. The sampling period of the noise filter can be selected from the divided clock of the baud rate generator clock source by CCR1.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When CCR0.TE and CCR0.RE are set to 0b during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, it is determined that a level match is detected and is conveyed as an internal signal. When the level being input corresponds to 0b, the initial output of the noise filter is retained until the level matches in three consecutive sampling cycles.

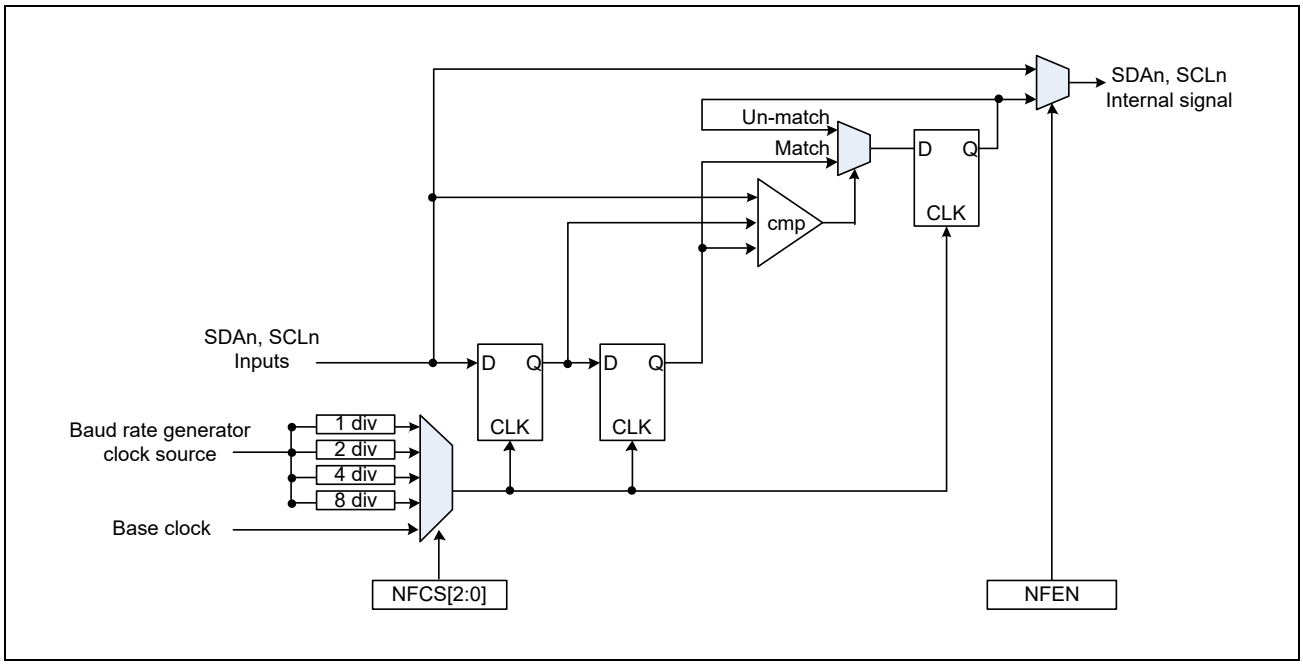

Figure 7.3-98 Block Diagram of Digital Noise Filter Circuit

7.3.12 RS-485 Driver Control Function

Setting the DEN bit in the SCI Common Control Register 3 (CCR3) to 1b enables the RS-485 driver control function and generates a DE (Driver Enable) signal that enables the external transceiver transmission mode. The DE signal outputs a valid level for the period with Driver assertion time and Driver negation time added before and after data transmission. The DE signal valid level is set by the DEPOL bit in the driver control register (DCR).

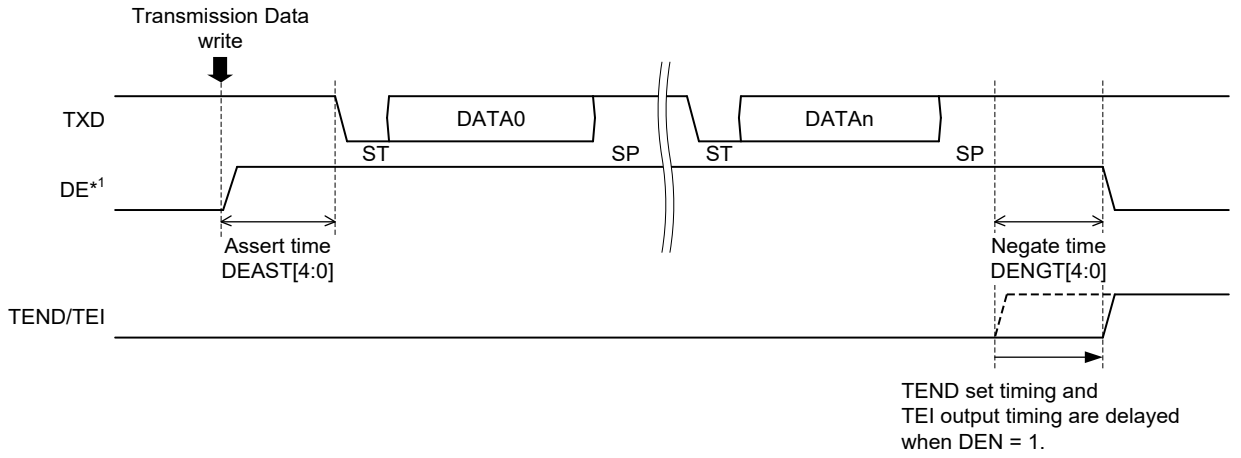
The Driver assertion time is the time from when the DE signal is valid until the start bit starts. Set by DEAST[4:0] of driver control register (DCR).

The Driver negation time is the time from the end of the last stop bit of the transmitted message to the invalidation of the DE signal. Set with DENGT[4:0] of the driver control register (DCR).

DEAST and DENGT are expressed in base clock units. For details, see **7.3.2.2.14 Driver Control Register (RSCIm_DCR)**.

When this function is used (DEN = 1b), the TEND set timing and TEI interrupt output timing are at the end of the driver negation time.

When transmission is completed and the next transmission data is not written before the DE signal is negated, the DE signal is negated once. If the timing for writing the next transmit data is not in time, assert the DE signal after negating it again, insert the Driver assertion time, and transmit the next data. If you want to perform the next transmission with the DE signal asserted, write the next transmission data to the TDR quickly enough in consideration of the synchronization delay time of the register.



Note: ST = Start bit
SP = Stop bit

Note 1. When DCR.DEPOL = 0b

Figure 7.3-99 The Image Waveform for RS-485 Driver Control DE Signal Output

7.3.13 Loopback Function

The loopback function can be used in asynchronous mode with the internal clock, and clock synchronous mode with the internal clock.

When 1b is written to the SPLP bit in the CCR1 register, SCI blocks the external input (RXD) path and connects the output path of the transmit data register and the input path of the receive data register.

When this function is used with TINV = 1b, inversion of transmission data becomes reception data. However, this function can be used with TINV = 1b only when operating in clock synchronous mode internal clock.

Table 7.3-31 shows the relationship between the TINV and SPLP bit settings and the received data.

Table 7.3-31 TINV and SPLP Bit Settings and Received Data

TINV	SPLP	Receive Data	Communication Mode	
			Async Internal Clock	Clock Sync Internal Clock
x	0	Receive Data from RXD pin	Possible	Possible
0	1	Transmit Data	Possible	Possible
1	1	Inverted transmit data	Impossible	Possible

Figure 7.3-100 shows the configuration of the shift register input/output path in loopback mode.

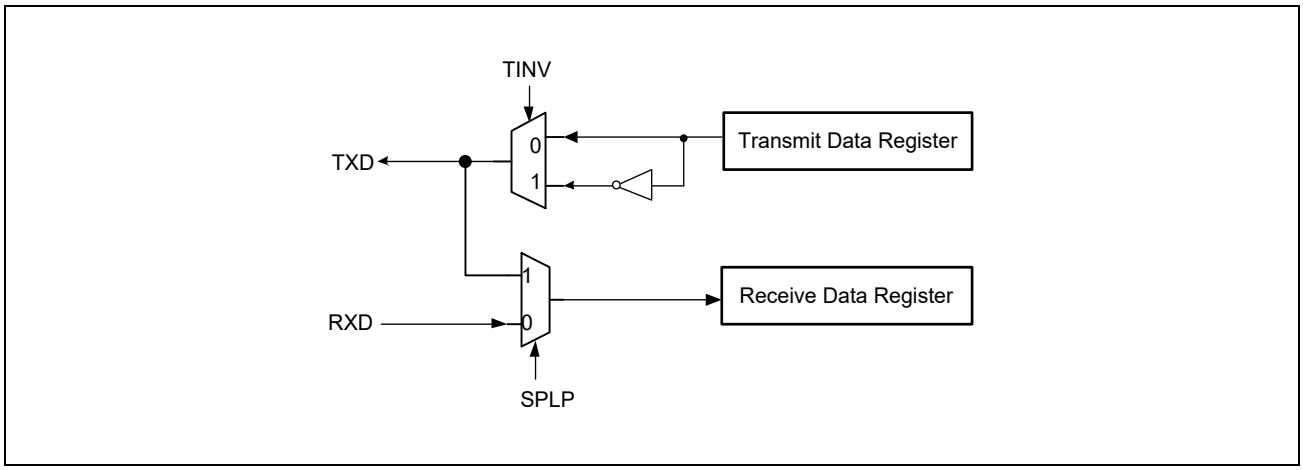


Figure 7.3-100 Shift Register Input/Output Configuration Image in Loopback Mode

7.3.14 Half-Duplex Communication Function

Do not use the half-duplex communication function in Simple-I2C mode, Simple-SPI mode, and Smart Card Interface mode.

In other communication modes, if the CCR1.SHARPS bit is set to 1b, half-duplex communication using the TXD pin is possible. When half-duplex communication is used, transmission and reception must be performed exclusively. Transmission and reception settings (CCR0.TE = 1b and CCR0.RE = 1b) is prohibited.

However, if half-duplex communication is performed as the master in clock synchronous mode, perform transmission/reception settings (CCR0.TE = 1b and CCR0.RE = 1b) and perform dummy transmission. By dummy transmission (arbitrary transmission data is written to TDR), SCKm is output and reception is enabled. The dummy transmission data is discarded inside the module and is not actually transmitted.

During half-duplex communication, the only communication port terminal used is the TXD pin. Output when CCR0.TE = 1b, input when CCR0.TE = 0b.

7.3.15 Synchronizer Bypass Function

This module has a bus clock (RSCI_m_PCLK) and the operation clock (RSCI_m_TCLK). And these have each operating circuit. Therefore, there is a synchronization circuit for signal transfer between different clocks, and synchronization delay time is required for signal propagation between different clocks.

However, the synchronization circuit can be bypassed by the CCR3.BPEN bit only when the same clock is input to the bus clock and the operation clock. In this case, eliminates synchronization delay time and improves responsiveness. **Figure 7.3-101** shows the image waveform of the bypass function.

This module also has a synchronization circuit between the communication clock (SCK) and the operation clock (RSCI_m_TCLK), but this synchronization circuit cannot be bypassed.

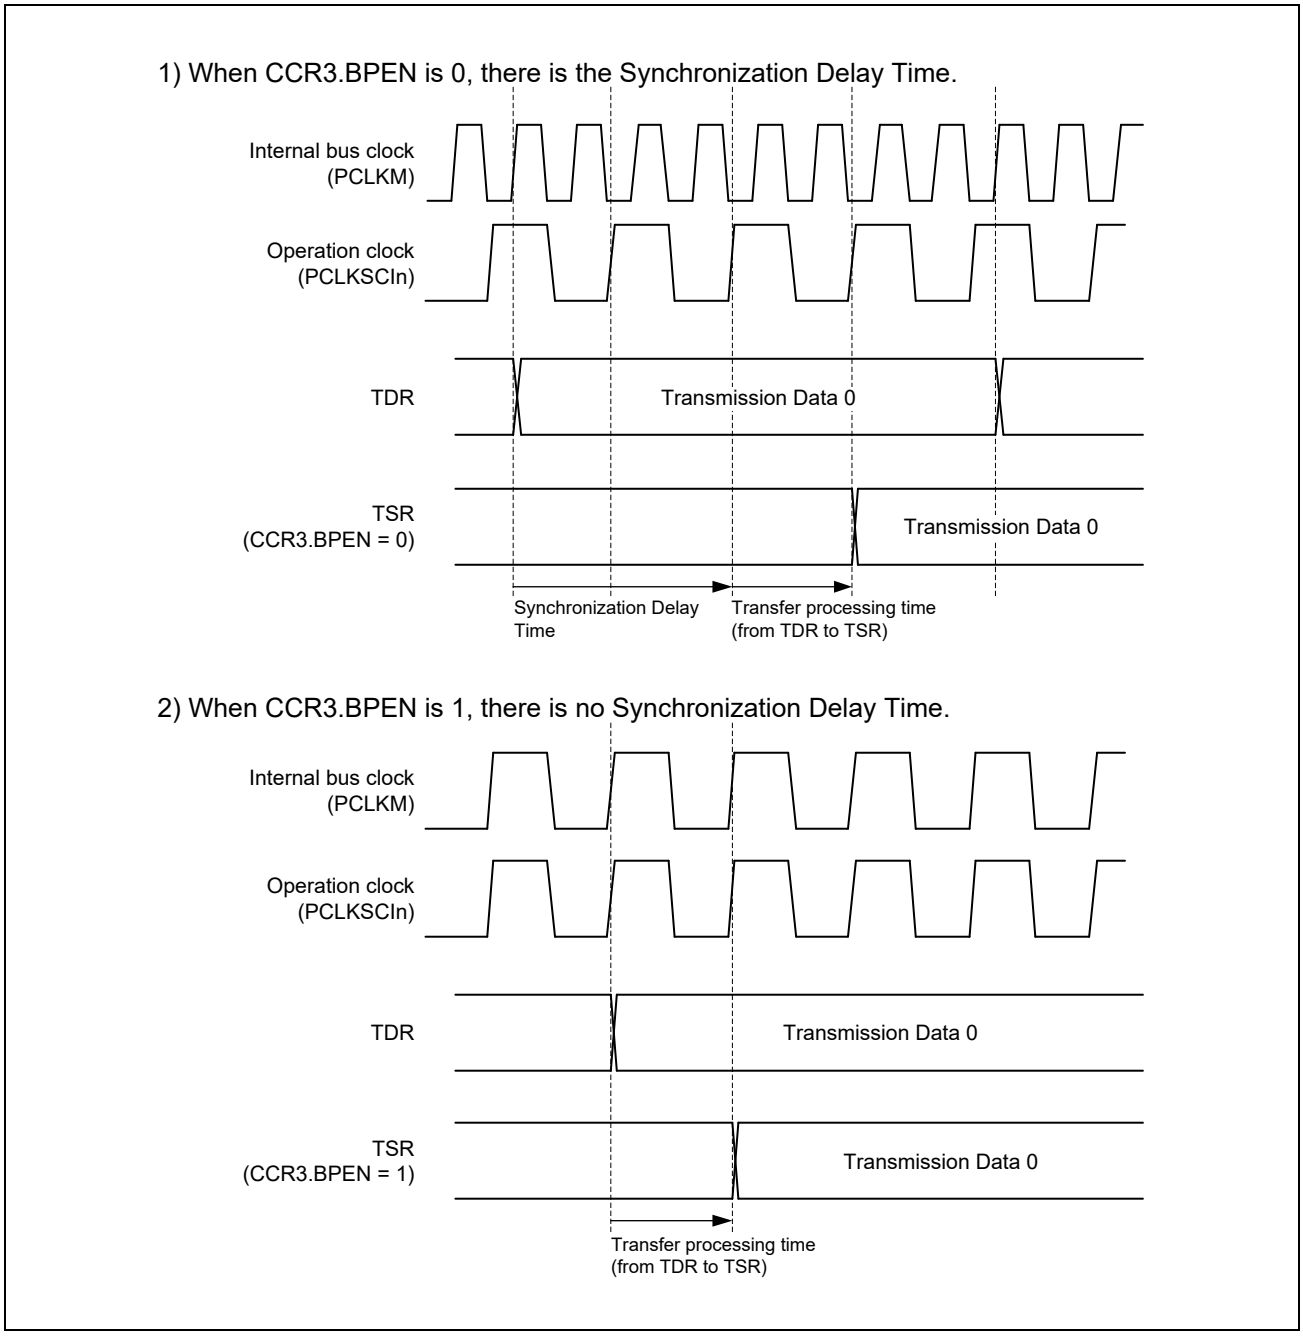

Figure 7.3-101 Image Waveform of Synchronizer Bypass Function

7.3.16 Half Data Communication Function

Setting the HCR.HDEN bit to 1b supports half data communication in which data 0 is pulsed low for the first half of a 1-bit period. Since this function operates only in the asynchronous mode, see the asynchronous mode for the setting, transmission, and reception flow.

7.3.16.1 Reception in Half Data Communication

When receiving during half data communication, the falling edge of the input from the RXDm_MISOm_SCLm pin is detected and the signal after the start bit is recognized is received. One frame is sampled according to the set bit rate, and if the stop bit is correctly received without error, the data value is stored in the receive data register RDR.

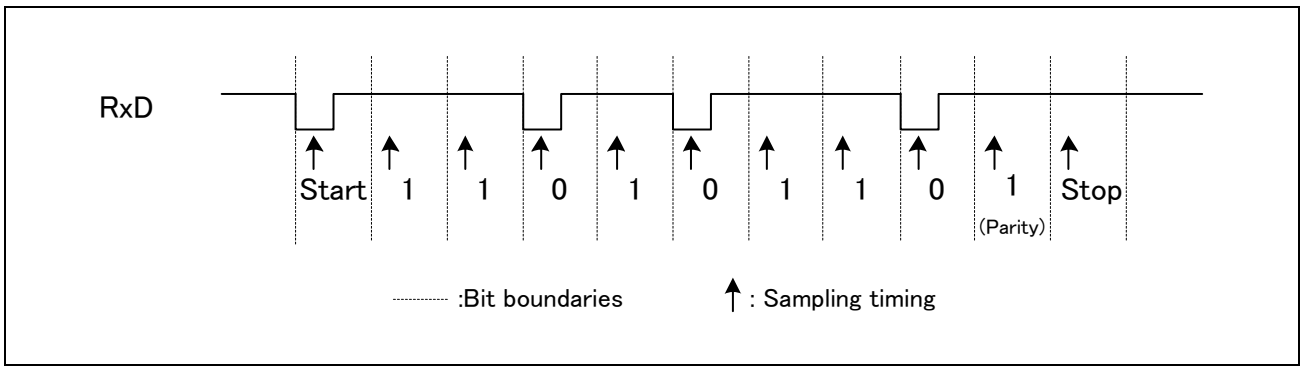

Figure 7.3-102 Half Data Communication Reception Timing Chart

For reception in half data communication, it is necessary to sample at the timing of 1/4 of 1 bit in order to capture the pulse in the first half of the 1 bit period. Sampling operates with a frequency 16 times the bit rate*1 as the base clock as in the asynchronous mode. The start bit is detected by detecting the Low level from the falling edge of RxD four times continuously with the base clock. When High is detected during communication, it is regarded as noise and waits for the next falling edge.

To set the sampling timing to 1/4 of the 1-bit period, enable the reception sampling timing adjustment function with the CCR4.ASEN bit, set the CCR4.AJD bit to 1b and the CCR4.AST bit to 100b, and adjust from the center of the bit, which is the previous sampling timing, four clocks ahead of the base clock.

Since the sampling timing can be adjusted backward and forward using the reception sampling timing adjustment function, this timing can be adjusted according to the reception status. Increasing the CCR4.AST bit value from 100b will move the sampling timing forward, and decreasing it will move it backward. See **7.3.3.10 The Function of Adjust Receive Sampling Timing (Asynchronous Mode)** for the details of adjustment.

After recognizing the start bit, sampling is performed at the timing according to the set bit rate, but the low width and high width of the waveform are not checked. Therefore, it is possible to receive even a normal asynchronous waveform.

Note 1. Half data communication function is supported only when CCR2.ABCS = 0b and CCR2.ABCSE = 0b.

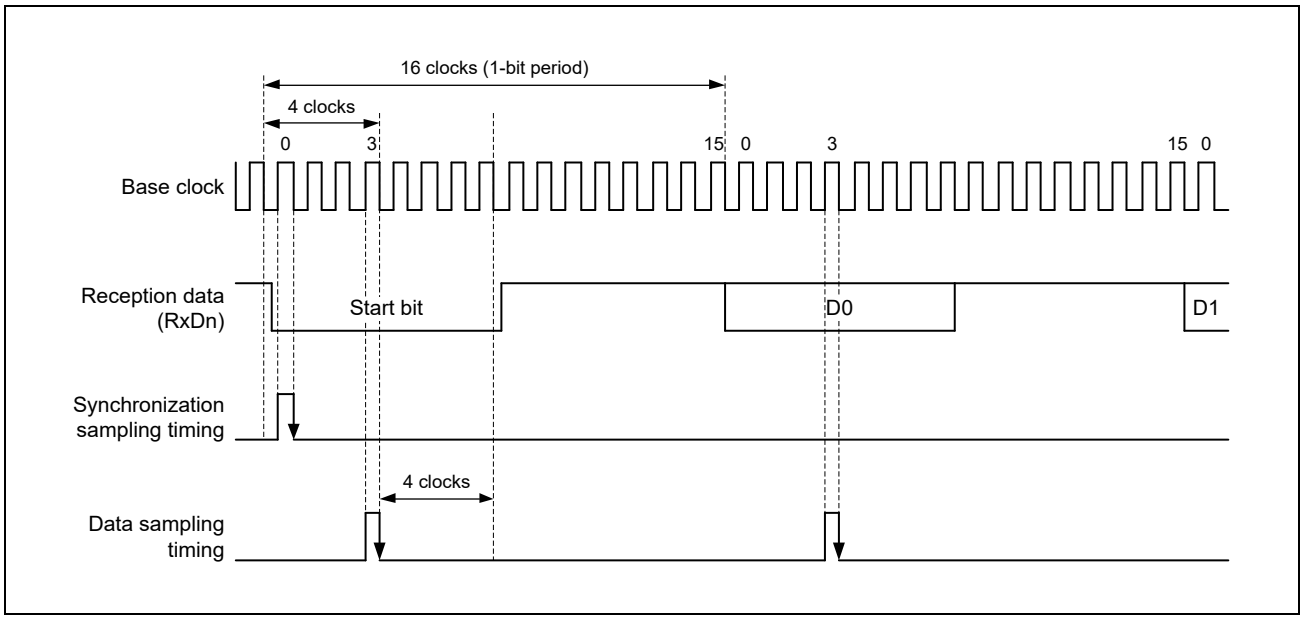

Figure 7.3-103 Details of Reception Sampling Timing during Half Data Communication

7.3.16.2 Transmission in Half Data Communication

In transmission during half data communication, data 0 is output as a low pulse for the first half of the 1-bit period.

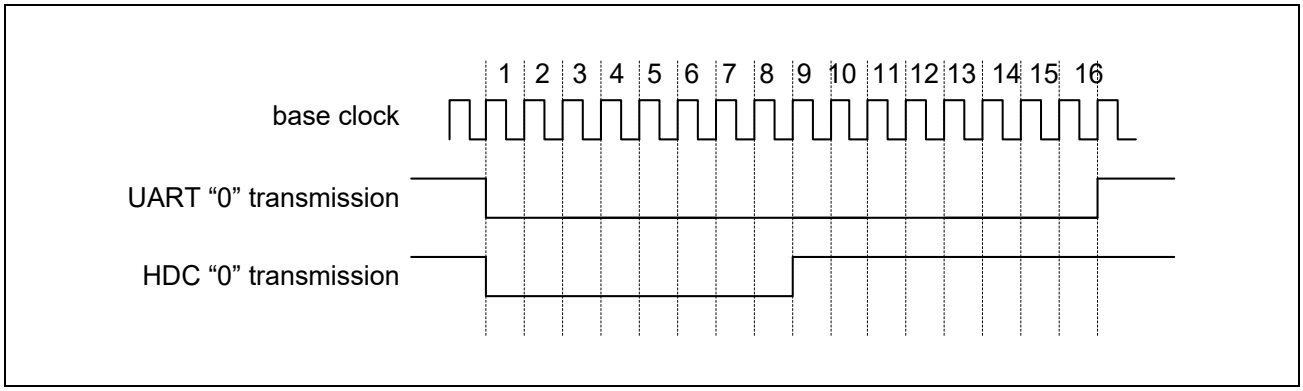

Figure 7.3-104 Transmission Waveform in Half Data Communication

Figure 7.3-105 shows an example of the transmission waveform.

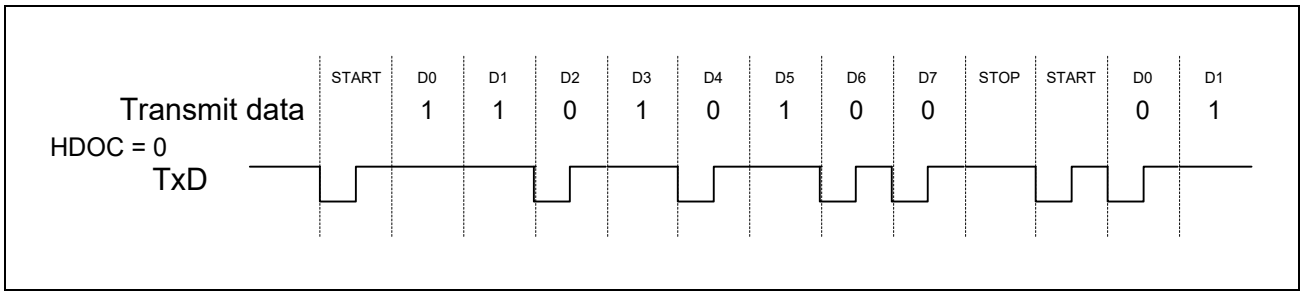

Figure 7.3-105 Difference in Half Data Transmission Waveform (when HDST = 0b, HDOC = 0b)

When CCR0.TE bit = 0b, TxD pins become Hi-Z, but can be controlled by the CCR1.SPB2IO bit and CCR1.SPB2DT bit. At this time, output is applied to the TxD pins.

7.3.16.3 Register Settings for Half Data Communication

The half data communication function is a part of asynchronous mode function, but some settings are not supported when using this function. Set each bit of the common control register as shown in **Table 7.3-32** before use. Register bits not listed can be set in the same way as in the asynchronous mode.

Table 7.3-32 Common Control Register Setting Values for Half Data Communication

Register.Bit Name	Value	Remarks
CCR0.DCME	0b	Use this setting when the address match function is to be disabled.
CCR1.NFCS[2:0]	000b	Use this setting when using the noise filter.
CCR1.SHARPS	0b	Half-duplex communication with the TxD terminal cannot be used.
CCR1.CTSE	0b	Use this setting to disable the CTS function.
CCR2.BRME	0b	Bit rate modulation function cannot be used.
CCR2.ABCSE	0b	Only 1 bit can be set for 16 cycles of base clock.
CCR2.ABCS	0b	Only 1 bit can be set for 16 cycles of base clock.
CCR3.CKE[1:0]	00b	Use this setting to enable internal clock and disable clock output.
CCR3.DEN	0b	Use this setting to disable the RS-485 driver function.
CCR3.FM	0b	Use this setting to disable the FIFO function.
CCR3.MOD[2:0]	000b	Set to asynchronous mode.
CCR3.RxDESEL	1b	Detect the start bit at the falling edge of the RxD pin input.
CCR3.STP	0b	Use this setting to select 1 stop bit.
CCR3.SINV	0b	Use this setting to disable data inversion.
CCR3.LSBF	1b	Use this setting for LSB first.
CCR3.CHR[1:0]	10b	Use this setting for the 8 bit length.
CCR4.AJD	1b	Use this setting when receiving half data communication.
CCR4.AST[2:0]	100b	Use this setting when receiving half data communication.*1
CCR4.ATEN	0b	Use this setting to disable the adjust transmit timing function.
CCR4.ASEN	1b	Use this setting when receiving half data communication.

Note 1. This is the central timing setting for half data. It can be adjusted if needed.

7.3.17 Interrupt Signal

Table 7.3-33 lists SCI interrupt signals.

When performing transmission and reception using DMAC, be sure to set DMAC first, and then set SCI. See **4.7 DMA Controller (DMAC)** for how to set DMAC.

Table 7.3-33 SCI Interrupt Sources

Name	ICU Input Name	Interrupt Sources	CA55 GIC Request	CM33 GIC Request	DMAC Activation
ERI	RSCI_CHm_INT_sc_eri_n	Error interrupt	Possible	Possible	Not possible
RXI	RSCI_CHm_INT_sc_rxi_n	Simple-I2C: Reception end interrupt Other mode: Receive data full interrupt	Possible	Possible	Possible*1
TXI	RSCI_CHm_INT_sc_txi_n	Simple-I2C and Smart Card Interface: Transmit end interrupt Other mode: Transmit data empty interrupt	Possible	Possible	Possible*1
TEI	RSCI_CHm_INT_sc_tei_n	Simple-I2C: Completion of generation of a start, restart, or stop condition (STI) Other mode: Transmit end interrupt	Possible	Possible	Not possible
AED	RSCI_CHm_INT_sc_aed_n	Active edge detection interrupt	Possible	Possible	Possible
BFD	RSCI_CHm_INT_sc_bfd_n	Break Field detection interrupt	Possible	Possible	Not possible

Note: m = 0 to 9

Note 1. Available interrupt sources change dependent on operation mode.

7.3.17.1 Buffer Operations for TXI and RXI Interrupts

The TXI and RXI interrupts have an interrupt buffer function. When the first interrupt request is generated during interrupt handling and the next interrupt request is generated (when the status flag of the Interrupt Controller Unit (ICU) is 1), the module does not output the interrupt request, and the SCI holds it internally. The interrupt that can be held is up to one.

7.3.17.2 Interrupt in Asynchronous Mode, Clock Synchronous Mode, and Simple-SPI Mode

A different interrupt vector is assigned to each interrupt source, and individual interrupt sources can be enabled or disabled with the enable bits in CCR0 register.

(1) Non-FIFO selected

Table 7.3-34 lists interrupt sources in Asynchronous Mode, Clock Synchronous Mode, and Simple-SPI Mode with Non-FIFO selected.

If the CCR0.TIE bit is 1b, a TXI interrupt request is generated when transmit data is transferred from the TDR to the TSR. At the start of transmission, a TXI interrupt request can also be generated by using a single instruction to set the CCR0.TE and CCR0.TIE bit to 1b at the same time. A TXI interrupt request can activate the DMAC to handle data transfer.

A TXI interrupt request is not generated by setting the CCR0.TIE bit to 1b while the setting of the CCR0.TE bit is 1b.*1

When the CCR0.TEIE bit is 1b, the CSR.TEND flag becomes 1b and the TEI interrupt request is generated if the next data is not written to the TDR register by the timing to transmit the last bit of transmission data. In addition, the TEND flag holds 1b during the period from setting the CCR0.TE bit to 1b until writing transmit data to the TDR register, and if the TEIE bit is set to 1b, a TEI interrupt request is generated.

Writing data to the TDR register clears the TEND flag and cancels the TEI interrupt request, but it takes time to cancel it.

If the CCR0.RIE bit is 1b, an RXI interrupt request is generated when received data is stored in the RDR. An RXI interrupt request can activate the DMAC to handle data transfer.

Setting of any from among the ORER, FER, PER flags in the CSR to 1b while the CCR0.RIE bit is 1b leads to the generation of an ERI interrupt request.

An RXI interrupt request is not generated at this time. Clearing all three flags (ORER, FER, PER) leads to discarding of the ERI interrupt request.

Note 1. To temporarily prohibit TXI interrupts at the time of transmission of the last of the data and so on when you wish a new round of transmission to start after handling of the transmit end interrupt, control prohibiting and permitting of the interrupt by using the interrupt request enable bit in the interrupt controller rather than using the TIE bit. This can prevent the suppression of TXI interrupt requests in the transfer of new data.

Table 7.3-34 SCI Interrupt Sources with Non-FIFO Selected

Name	Interrupt Source	Interrupt Flag	Level/Pulse Output	Interrupt Enable	DMAC Activation
ERI	Receive error	ORER, FER, PER, DFER, DPER	Level	RIE	Not possible
RXI	Receive data full	RDRF	Pulse	RIE	Possible
	Address match	DCMF			
TXI	Transmit data empty	TDRE	Pulse	TIE	Possible
	TE = 0 -> 1 detection				
TEI	Transmit end	TEND	Level	TEIE	Not possible

(2) FIFO selected

Table 7.3-35 lists interrupt sources in Asynchronous Mode, Clock Synchronous Mode, and Simple-SPI Mode with FIFO selected.

If the CCR0.TIE bit is 1b, a TXI interrupt request is generated when the stored number of data in transmit FIFO becomes the threshold value indicated in FCR.TTRG or below. A TXI interrupt request can also be generated by using a single instruction to set the CCR0.TE and CCR0.TIE bit to 1b at the same time. A TXI interrupt request is not generated by setting the CCR0.TIE bit to 1b while the setting of the CCR0.TE bit is 1b. If CCR0.TEIE bit is 1b, when the next data is not being written in transmit FIFO by the timing to which the last bit of the transmission data is sent, CSR.TEND flag will be 1b and TEI interrupt request is generated.

If the CCR0.RIE bit is 1b, RXI interrupt request is generated when the stored number of data in receive FIFO becomes the threshold value indicated in FCR.RTRG or above. When FCR.RTRG is set to 0b, RXI interrupt request is occurred if the quantity of data in receive FIFO is greater than or equal to 1.

If the CCR0.RIE bit is 1b, when CSR.ORER flag is set to 1b or the data a framing error or a parity error generated is stored in receive FIFO, ERI interrupt request is generated.

When the number of data stored in a receive FIFO at this time is a threshold value or above, RXI interrupt request is also generated. The ERI interrupt request can be canceled by clearing all flags (CSR.ORER, FER, and PER).

Table 7.3-35 SCI Interrupt Sources with FIFO Selected

Name	Interrupt Source	Interrupt Flag	Level/Pulse Output	Interrupt Enable	DMAC Activation
ERI	Receive error	ORER, FER, PER, DFER, DPER	Level	RIE	Not possible
		DR (FCR.DRES = 1b)			
RXI	Receive FIFO data full	RDRF	Pulse	RIE	Possible
	Receive data ready	DR (FCR.DRES = 0b)			
	Address match	DCMF			
TXI	Transmit FIFO data empty	TDRE	Pulse	TIE	Possible
	TE = 0 -> 1 detection				
TEI	Transmit end	TEND	Level	TEIE	Not possible

7.3.17.3 Interrupt in Smart Card Interface Mode

Table 7.3-36 lists interrupt sources in smart card interface mode. A transmit end interrupt (TEI) request cannot be used in this mode.

Table 7.3-36 SCI Interrupt Sources in Smart Card Interface Mode

Name	Interrupt Source	Interrupt Flag	Level/Pulse Output	Interrupt Enable	DMAC Activation
ERI	Receive error or error signal detection	ORER, PER, ERS	Level	RIE	Not possible
RXI	Receive data full	RDRF	Pulse	RIE	Possible
TXI	Transmit end	TEND	Pulse	TIE	Possible
	When set TE = 0 -> 1				

Data transmission/reception using the DMAC is also possible in smart card interface mode. In transmission operation, when the TEND flag in CSR is set to 1b, a TXI interrupt request is generated. This TXI interrupt request activates the DMAC allowing transfer of transmit data if the TXI request is specified beforehand as a source of DMAC activation. The TEND flag is automatically set to 0b when the DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept to 0b and the DMAC is not activated. Therefore, the SCI and DMAC automatically transmit the specified number of bytes, including retransmission in the case of error occurrence. However, the ERS flag in CSR is not automatically cleared to 0b at error occurrence. Therefore, the ERS flag must be cleared by previously setting the RIE bit in CCR0 to 1b to enable an ERI interrupt request to be generated at error occurrence.

In reception operation, an RXI interrupt request is generated when receive data is set to RDR. This RXI interrupt request activates the DMAC allowing transfer of receive data if the RXI request is specified beforehand as a source of DMAC activation. If an error occurs, the error flag is set. Therefore, the DMAC is not activated and an ERI interrupt request is issued to the CPU instead; the error flag must be cleared.

When transmitting/receiving data using the DMAC, be sure to make settings to enable the DMAC before making SCI settings. For DMAC settings, see **4.7 DMA Controller (DMAC)**.

7.3.17.4 Interrupts in Simple-I2C Mode

Table 7.3-37 lists SCI interrupts in simple-I2C mode.

The STI interrupt is allocated to the transmit end interrupt (TEI) request. The receive error interrupt (ERI) request cannot be used.

The DMAC can also be used to handle transfer in simple I2C mode.

When the value of the IICINTM bit in ICR is 1b, a RXI request will be generated on the falling edge of the SCLn signal for the eighth bit. If the RXI has been set up as an activating request for the DMAC beforehand, the RXI request will activate the DMAC to handle transfer of the received data. Furthermore, a TXI request is generated on the falling edge of the SCLn signal for the ninth bit (acknowledge bit). If the TXI has been set up as an activating request for the DMAC beforehand, the TXI request will activate the DMAC to handle transfer of the transmit data. (In this case, ACK/NACK judging are impossible.)

When the value of the IICINTM bit in ICR is 0b, SCI operates as follows.

RXI request (ACK detection) is generated if the input on the SDAn pin is at the low level on the rising edge of the SCLn signal for the ninth bit (acknowledge bit).

TXI request (NACK detection) is generated if the input on the SDAn pin is at the high level on the rising edge of the SCLn signal for the ninth bit (acknowledge bit).

If the RXI has been set up as an activating request for the DMAC beforehand, the RXI request will activate the DMAC to handle transfer of the received data. Also, if the DMAC is used for data transfer in reception or transmission, be sure to set up and enable the DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in ICR are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 7.3-37 SCI Interrupt Sources in Simple-I2C Mode

Name	Interrupt Source		Interrupt Flag	Level/Pulse Output	Interrupt Enable	DMAC Activation
	IICINTM = 1	IICINTM = 0				
RXI	Reception end	—	—	Pulse	RIE	Possible*1
	—	ACK detection	—			Possible
TXI	Transmit end	—	—	Pulse	TIE	Possible*1
	—	NACK detection	—			Possible
STI	Completion of generation of a start, restart, or stop condition		IICSTIF	Level	TEIE	Not Possible

Note 1. If the DMAC is being used, you cannot confirm whether ACK or NACK.

7.3.17.5 Interrupts in Simple-LIN Mode

Table 7.3-38 lists RSCI interrupts in simple-LIN mode.

Table 7.3-38 RSCI Interrupt Sources in Simple-LIN Mode

Name	Interrupt Sources	Interrupt Flag	Flag that Needs to be Confirmed	Level/Pulse Output	Interrupt Enable	DMAC Activation
ERR	Error	ORER,FER,PER	—	Level	RIE	Not Possible
		BCDF,COF	—		BCDIE,RIE, COFIE	
RXI	Reception Data full flag	RDRF	CF0MF, CF1MF, PIBDF	Pulse	RIE	XSR0.SFSF = 0b :Possible XSR0.SFSF = 1b: Not Possible
AED	Active edge detection	AEDF	—	Pulse	AEDIE	Possible
TXI	Transmit data empty interrupt	TDRE	—	Pulse	TIE	Possible
	When set TE = 0->1					
	Break Field output completion	BFOF	—		TIE, BFOIE	
TEI	Transmit end	TEND	—	Level	TEIE	Not Possible
BFD	Break Field Detection	BFDF	—	Level	BFDIE	Not Possible

In Simple-LIN mode, in addition to reception errors (ORER, FER, PER), an ERI interrupt request is output when a bus conflict is detected during transmission, or when a counter overflow of the Simple-LIN module occurs. At this time, a RXI interrupt request is not output. The ERI interrupt request can be canceled by clearing all the flags.

When transmitting Start Frame, if CCR0.TIE = 1b and XCR0.BFOIE = 1b, a TXI interrupt request is output when Break Field transmission is completed. When Control Field 0 data is written to the TDR register, data transmission starts. Therefore, transmission using DMAC is possible.

Set CCR0.TEIE = 1b after writing the last transmit data to the TDR register and transmission starts.

During Start Frame reception (XSR0.SFSF = 1b), reception using DMAC by RXI interrupt is not possible. Check the CSR register and XSR0 register, check the reception status (see **Figure 7.3-61**), and then clear the flag. Also read the RDR register (if you do not need to check the received data value, clear the RDRF flag without reading the RDR register). When reception of Control Field 1 is completed (XSR0.CF1MF = 1b), Start Frame detection is disabled (XSR0.SFSF = 0b) and reception using DMAC is possible. Be sure to read the RDR register.

When Start Frame / Break Field detection is enabled (XCR1.SDST = 1b), if a Break Field longer than the period set in XCR2.BFLW [15: 0] is received, the BFDF flag is set and a BFD interrupt request is output. Then RSCI becomes the Start Frame reception state. Clear the BFDF flag.

When Start Frame / Break Field detection is enabled (XCR1.SDST = 1b) and the bit rate measurement function is enabled (XCR1.BMEN = 1b), an AED interrupt factor is output when an active edge is detected. Read the timer count capture value (XSR1.TCNT [15: 0]).

7.3.18 Usage Notes

7.3.18.1 Notes on Module Standby Mode

(1) Transmission

Before using the power consumption reduction function to reduce SCI's power consumption, please do the following to confirming transmission end (CSR.TEND = 1b):

- Set the output pin state after transmission operation is stopped by CCR1.SPB2DT, SPB2IO.
- Stop the transmission (CCR0.TIE = 0b, TE = 0b, TEIE = 0b).

When transitions to these states are made during transmission, the data being transmitted become indeterminate.

To transmit data in the same transmission mode after cancellation of the low power consumption state, set the TE bit to 1b, read CSR, and write data to TDR sequentially to start data transmission. To transmit data with a different transmission mode, initialize the SCI first.

To start transmission using the DMAC after cancellation of the low power consumption state, set the TE and TIE bit to 1b. The TXI interrupt flag is set to 1b and transmission starts using the DMAC.

Figure 7.3-106 shows a sample flowchart for transition to the low power consumption state during transmission. **Figure 7.3-107** and **Figure 7.3-108** show the port pin states during transition to the low power consumption state.

(2) Reception

(a) When Address match function is non used as condition of resumption (wake-up)

Before specifying the module stop state or making a transition to the low power consumption state, stop the receive operations (CCR0.RE = 0b). If transition is made during data reception, the data being received will be invalid.

Figure 7.3-109 shows a sample flowchart for reception to software standby mode during reception.

(b) When Address match function is used as condition of resumption (wake-up)

When using the power consumption reduction function to reduce SCI's power consumption, please do the following:

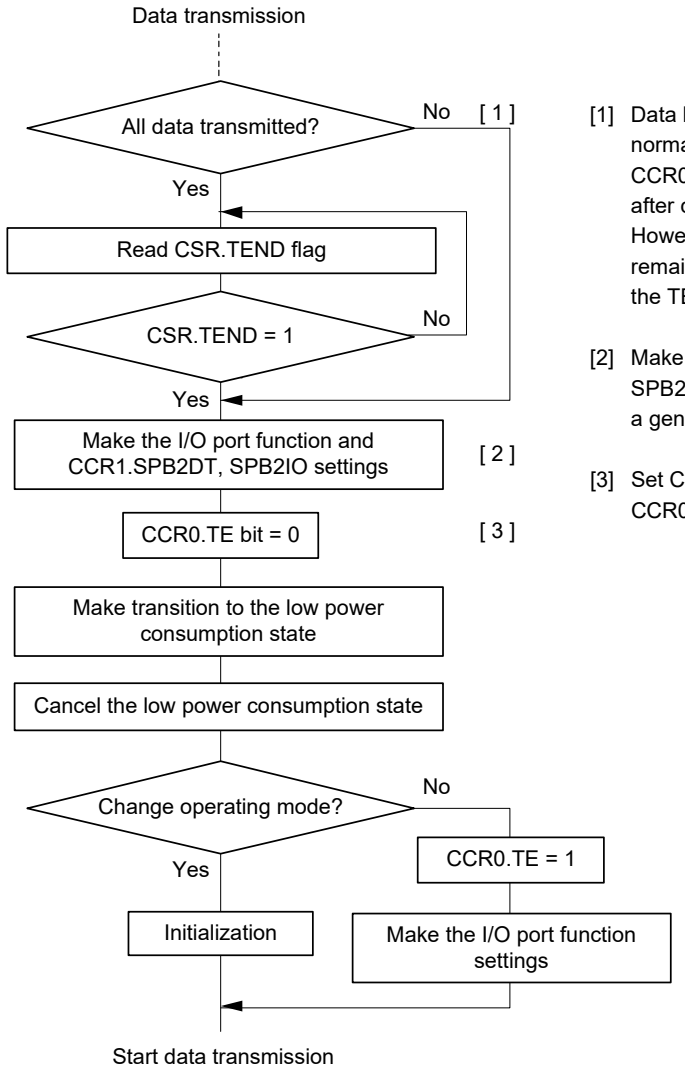
- Set the operation mode of after released.
- Set the compare data to CCR4.CMPD and set 1b to CCR0.DCME.
- Set the receive operation (CCR0.RE = 1b).

Please set CCR3.RXDESEL= 0b. Because there is a possibility that a start bit (falling edge of RXDn pin) cannot be detected at the time of low power consumption mode release.

After detecting the falling edge of the RxD terminal and transitioning from standby mode to snooze mode, the operating clock is supplied to SCI and data is received by RSCI. The address match function determines the received data, and if it matches, it transitions from snooze mode to normal mode, and if it does not match, it transitions to standby mode again. This operation behaves as if the standby mode is continued until the communication data matching the CMPD is received, and after the standby mode is released, the normal reception operation is continued.

When using this function, the reception speed must be slow enough because it is necessary to perform the transition from the falling-edge detection of the RxD terminal to the snooze mode, and from the clock supply to the RSCI to the reception.

Figure 7.3-110 shows a sample flowchart for reception to the low power consumption state during reception.



[1] Data being transmitted is lost halfway. Data can be normally transmitted from the CPU by setting the CCR0.TE to 1, reading CSR, and writing data to TDR after canceling the low power consumption state. However, if the DMAC has been activated, the data remaining in the DMAC will be transmitted when both the TE and TIE bits in CCR0 are set to 1.

[2] Make the I/O port function and CCR1.SPB2DT, SPB2IO settings to switch the TXDn pin to operate as a general I/O port.

[3] Set CCR0.TE bit to 0. Set also 0 to CCR0.TIE and CCR0.TEIE if these bits were 1.

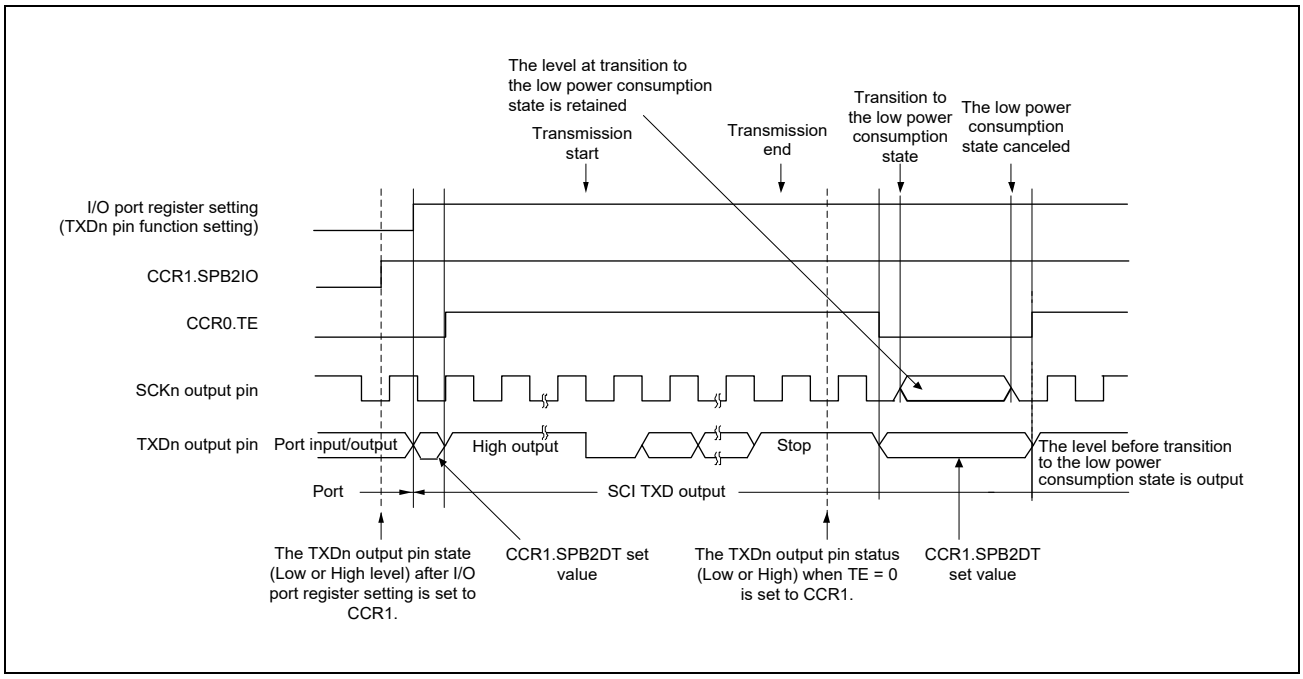

Figure 7.3-107 Port Pin States during Transition to Module Standby Mode (Internal Clock, Asynchronous Transmission)

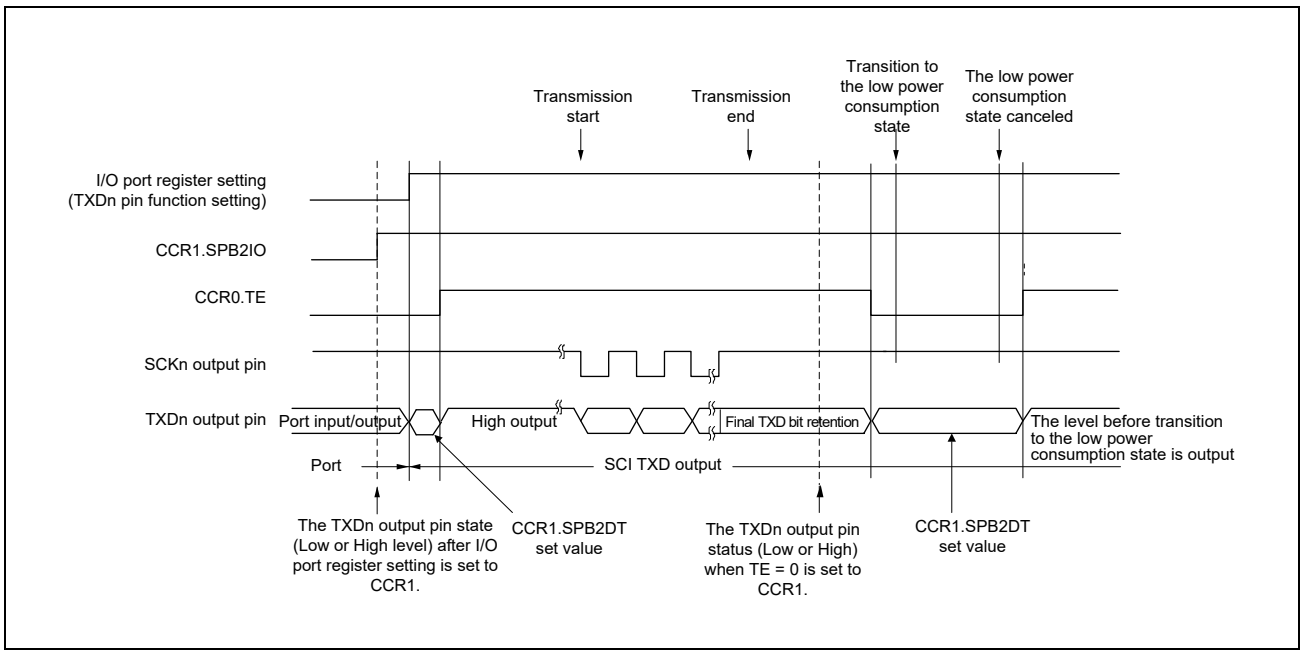

Figure 7.3-108 Port Pin States during Transition to Module Standby Mode (Internal Clock, Clock Synchronous Transmission)

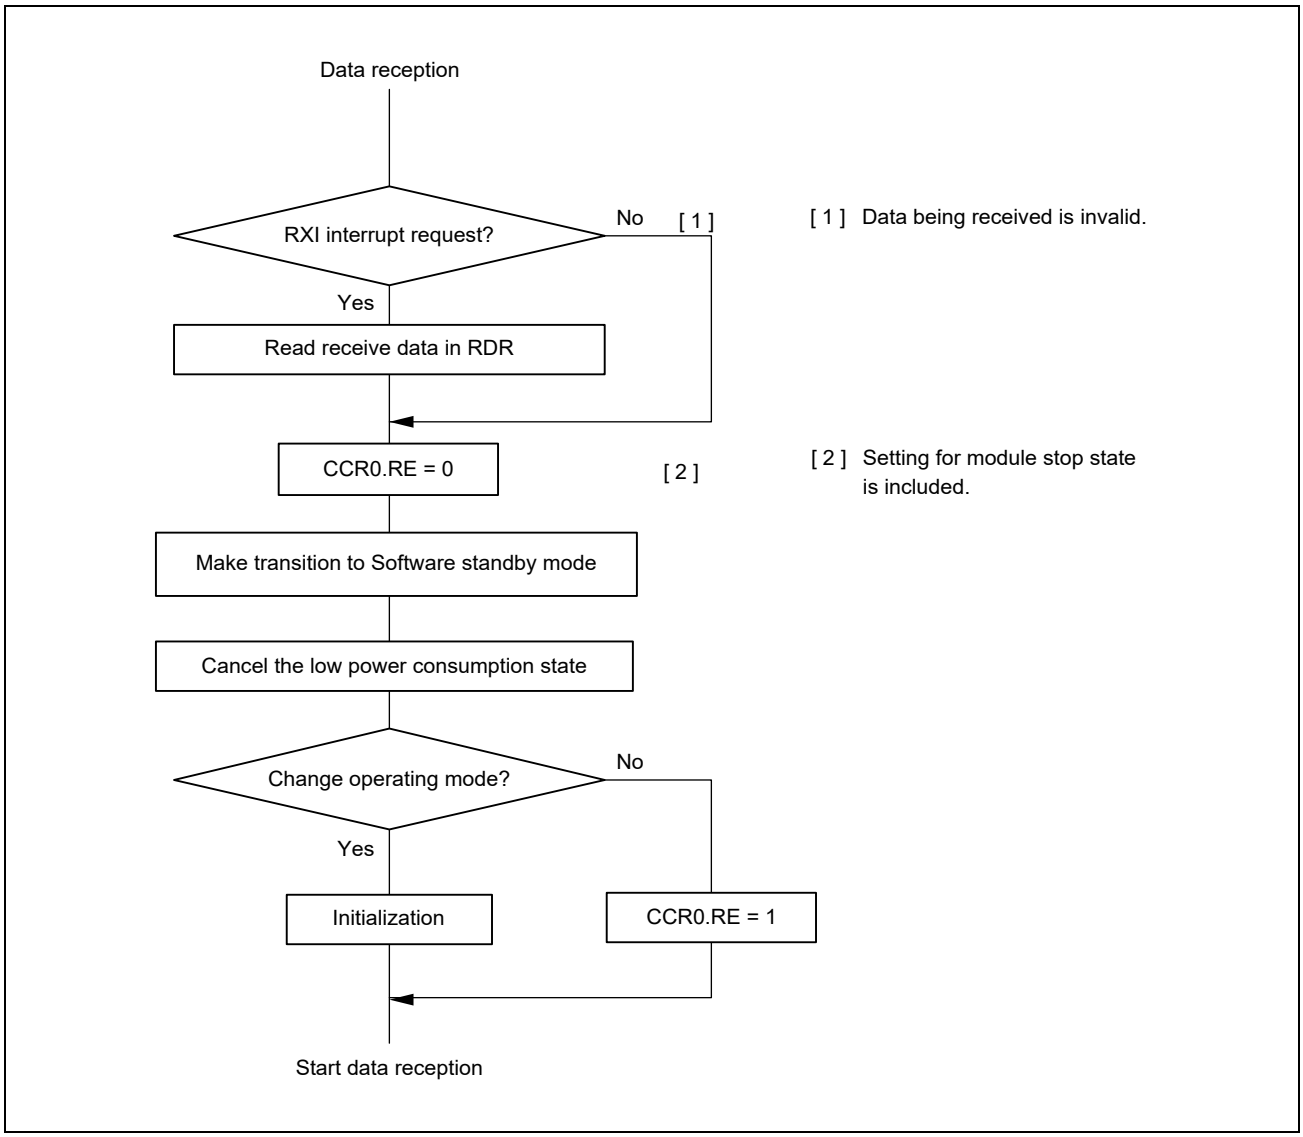

Figure 7.3-109 Example of Flowchart for Reception to Module Standby Mode during Reception

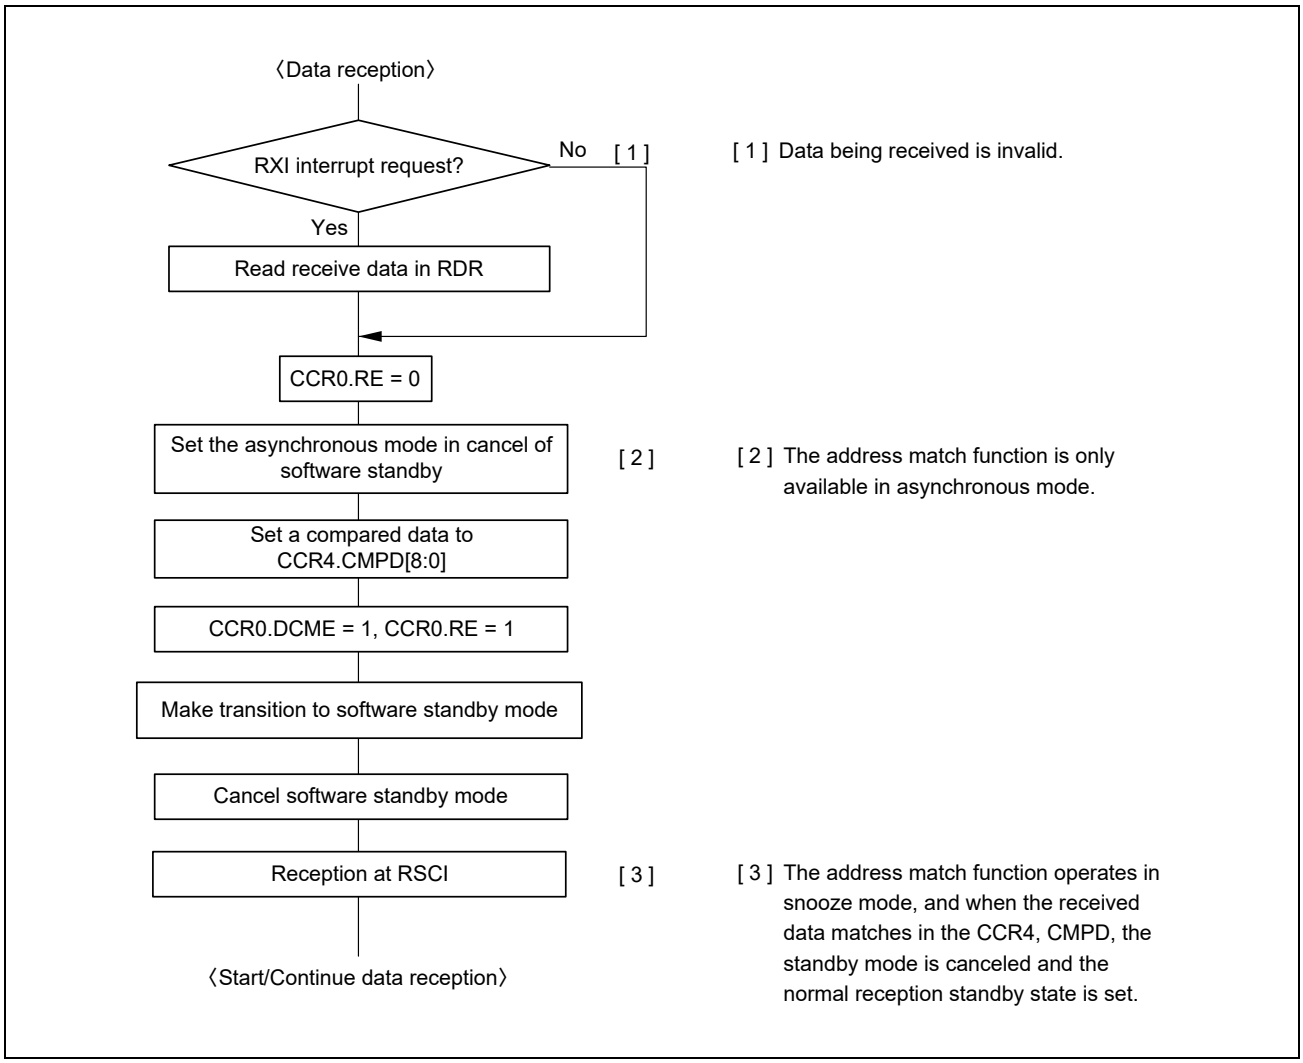

Figure 7.3-110 Example of Flowchart for Reception to Module Standby Mode during Reception With Address Match

7.3.18.2 Break Detection and Processing

(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading CSR.RXDMON bit value. In a break, the input from the RXDn pin becomes all 0s, and so the CSR.FER flag is set to 1b (framing error has occurred), and the CSR.PER flag may also be set to 1b (parity error has occurred). When the CCR3.RXDESEL bit is 0b, the SCI continues the receive operation even after a break is received. Therefore, note that even if the FER flag is set to 0b (no framing error occurred), it will be set to 1b again. When the CCR3.RXDESEL bit is 1b, the SCI sets the CSR.FER flag to 1b and stops receiving operation until a start bit of the next data frame is detected. If the CSR.FER flag is set to 0b at this time, the CSR.FER flag retains 0b during the break. When the RXDn pin is set to 1b and the break ends, detecting the beginning of the start bit at the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected, when SCI detects that continuous receive data is 0b for 1 frame, the data stored into the receive FIFO (RDR) and reception stops. When a framing error is detected, a break can be detected by reading CSR.RXDMON bit value. After the RxD signal is in the mark state and it has finished the break, a stock of reception data to the receive FIFO (RDR) resumes.

7.3.18.3 Mark State and Production of Breaks

When CCR0.TE = 0b (serial transmission is disabled), the state of the TXDn pin can be set by CCR1.SPB2IO bit and CCR1.SPB2DT bit. Using this, it's possible to do a TXDn pin in the mark state and send a breakout. When you want to make a communication-line in the mark state (the state of 1) until the CCR0.TE bit is set to 1b (serial transmission is enabled), execute the following operations. First, set output level High by the CCR1.SPB2IO and CCR1.SPB2DT bits. Next, it's changed to a TXDn pin by I/O port function. On the other hand, if you want to send a break when sending data, set the CCR0.TE bit to 0b after setting the SPB2IO and SPB2DT bits in the CCR1 register to low level output. Setting the TE bit to 0b initializes the transmitter regardless of the current transmission status.

7.3.18.4 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode)

Transmission can be started by writing transmit-data to TDR even if CSR.ORER is 1b. However, reception cannot be started. Note also that the receive error flags cannot be set to 0 even if the CCR0.RE is set to 0b (serial reception is disabled).

7.3.18.5 Writing Data to TDR

(1) Non-FIFO selected

Data can be written to TDR anytime when CCR0.TE = 1b. However, if new data is written to TDR when transmit data is remaining in TDR, the previous data in TDR is lost because it has not been transferred to TSR yet. If you use DMAC, be sure to write transmit data to TDR in the TXI interrupt request handling routine.

(2) FIFO selected

Data can be written to transmit FIFO (TDR) when TE is 1b. Check the number of writable data with the FTSR.T[5:0] bits.

7.3.18.6 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

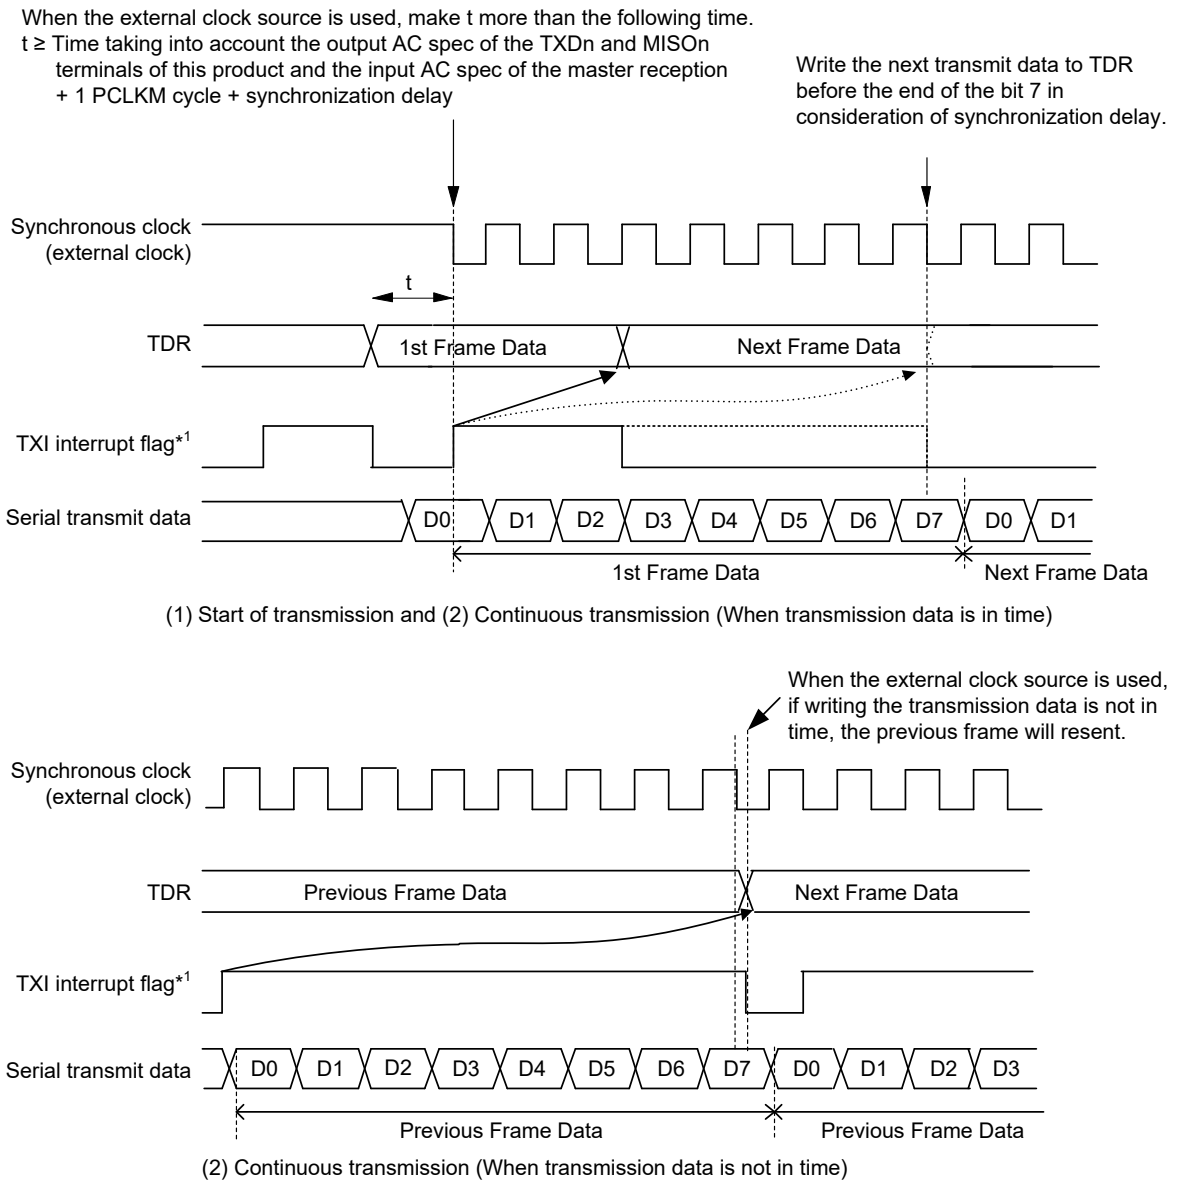
Update TDR by the CPU or DMAC and wait at least the following time until the start of the external clock input: (See **Figure 7.3-111**.)

Time taking into account the output AC specification of the TXDn and MISOn pins of this product and the input AC specification of the master reception + 1 RSCI_m_PCLK cycle + synchronization delay (2 to 3 RSCI_m_TCLK).

(2) Continuous transmission

Write the next transmit data to TDR before the falling edge*[1] of the transmit clock for bit 7. Please write the transmit data to TDR in consideration of synchronization delay [2 to 3 RSCI_m_TCLK]. If the transmit data cannot be written in time, the previous frame data is resent. (See **Figure 7.3-111**.)

Note 1. When CCR3.CPOL = 1b and CCR3.CPHA = 0b, or CCR3.CPOL = 0b and CCR3.CPHA = 1b. In the case of CCR3.CPOL = 0b and CCR3.CPHA = 0b, or CCR3.CPOL = 1b and CCR3.CPHA = 1b, it is the rising edge.



Note 1. See **4.6 Interrupt Controller** for details on the corresponding interrupt vector number.

Figure 7.3-111 Restrictions on Use of External Clock in Clock Synchronous Transmission

7.3.18.7 Notes on Starting Transfer

At the point where transfer starts, when the interrupt status flag in the interrupt controller is 1, follow the procedure below to clear interrupt requests before permitting operations (by setting the CCR0.TE or CCR0.RE bit to 1b).

For details on the interrupt status flag, see section XX, Interrupt Controller (ICU).

- Confirm that transfer has stopped (the setting of the CCR0.TE or CCR0.RE bits is 0b).
- Set the corresponding interrupt enable bit (CCR0.TIE, CCR0.TEIE, or CCR0.RIE) to 0b.
- Read the corresponding interrupt enable bit (CCR0.TIE, CCR0.TEIE, or CCR0.RIE bit) to check that it has actually become 0b.
- Set the interrupt status flag in the interrupt controller to 0b.

7.3.18.8 Limitations on Simple SPI Mode

(1) Master Mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set by the CCR3.CPHA and CPOL bits when CCR0.SSE = 1b. This prevents the clock line from being placed in the high-impedance state when the CCR0.TE bit is set to 0b or unexpected edges from being generated on the clock line when the CCR0.TE bit is changed from 0b to 1b.
  In a single-master mode, pull up or pull down the clock line is not necessary because the clock line does not become high-impedance state when CCR0.SSE = 0b and CCR0.TE = 0b.
- In the case of the setting for clock delay (CCR3.CPHA = 0b), the receive data full interrupt (RXI) is generated before the final clock edge on the SCKm pin as indicated in **Figure 7.3-112**. If the TE and RE bits become 0b at this time before the final edge of the clock signal on the SCKm pin, the SCKm pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Furthermore, an RXI interrupt may lead to the input signal on the SSn# pin of a connected slave going to the high level before the final edge of the clock signal on the SCKm pin, leading to incorrect operation of the slave.
- In a multi-master mode, take care because the SCKm pin output becomes high-impedance while the input on the SSn# pin is at the low level if a mode fault error occurs as the current character is being transferred. And stopping supply of the clock signal to the connected slave. Remake the settings for the connected slave to avoid misaligned bits when transfer is restarted.

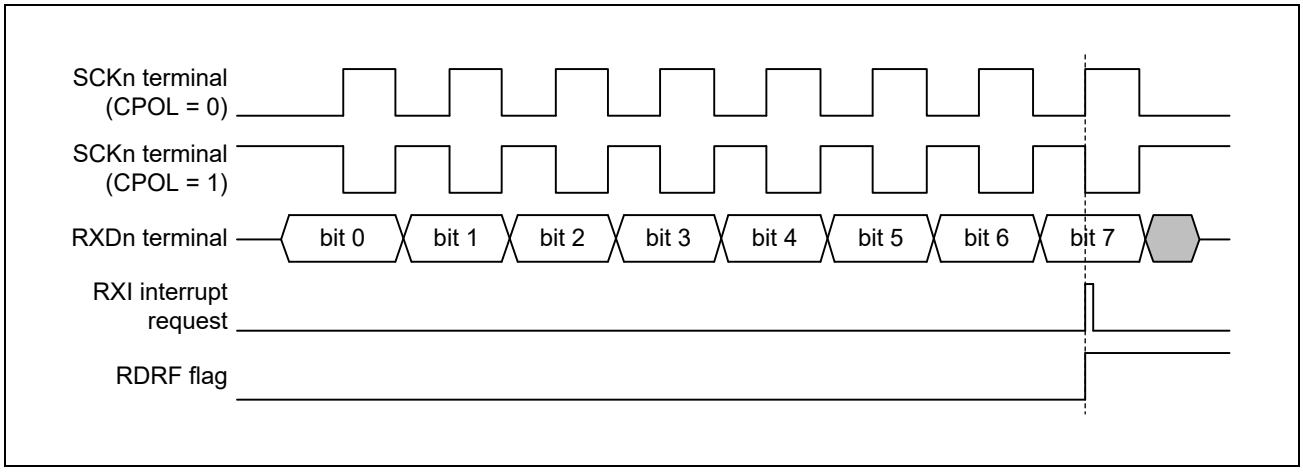


Figure 7.3-112 Timing of the RXI Interrupt in Simple SPI Mode (with Clock Delay)

(2) Slave Mode

- It takes “1 RSCI_m_PCLK + synchronization delay time + data output delay time (AC spec)” from writing the transmit data to the TDR register until the data is output to the MSIOn pin. Take these into account when starting external clock input.
- Provide an external clock signal to the master the same as the data length for transfer.
- Secure the SS input setup time (AC spec) from the SS# low-level input to the start of external clock input.
- Control the input on the SSn# pin before the start and after the end of data transfer.
- When the level being input on the SSn# pin is to be changed from low to high while the current character is being transferred, the transmission and reception are stopped immediately. Set the TE and RE bits in the CCR0 to 0b and, after remaking the settings, restart transfer of the first byte.

7.3.18.9 Notes on Transmit Enable Bit (TE)

In initial register value, when CCR0.TE = 0b, and the terminal function is TXDn, the pin outputs high impedance. So please make sure that the TXDn line will not be high impedance by the following one of ways.

1. The pull-up resistance is connected to the TXDn line.
2. Before CCR0.TE bit is 0b, the function of the terminal is changed to general-purpose input port or output port. And after CCR0.TE bit is 1b, the function of the pin is changed to TXDn.
3. In asynchronous mode, you can set CCR1 and decided level of TXDn pin during TE is 0b.

In the simple SPI mode slave operation, the MSIOn pin operates in the same way as the above TXDn pin, so please deal with 1 or 2 in the same way. (3 cannot be used.)

7.3.18.10 Notes on Simple-LIN mode

In Simple-LIN mode (CCR3.MOD[2:0] = 110b), the following functions cannot be used.

- Multi-processor communication function
- Bit Rate Modulation function
- Loopback function
- FIFO buffer

7.3.18.11 Notes on RS-485 Driver Control Function

- RS-485 Driver control function is valid only in asynchronous mode.
- When RS-485 Driver control function is active (CCR3.DEN = 1b), the TEND set timing/TEI output timing changes as follows. Wait for the TEI interrupt and set the TE bit in CCR0 to 0b.
  When RS-485 Driver control function is inactive: When STOP bit output is completed. When RS-485 Driver control function is active: At the end of DE negation time.

7.3.18.12 Notes on Loopback Function

The Loopback function is valid in asynchronous mode with internal clock and clock synchronous mode with internal clock.

7.3.18.13 Notes Regarding Register Access when Operation Clock (RSCI_m_TCLK) is Slower than Bus Clock (RSCI_m_PCLK)

If the operating clock (RSCI_m_TCLK) is slower than the bus clock (RSCI_m_PCLK), the interval for writing access to the same register should be at least RSCI_m_TCLK × 3 cycles + RSCI_m_PCLK × 3 cycles. Synchronization delay time and signal processing time are required to ensure that the setting value of the first write access is propagated to the subsequent logic circuit and the circuit is controlled correctly.

7.3.18.14 Notes on Interrupting Operation

If 0b is written to CCR0.RE during data reception and the reception operation is interrupted, there is a possibility of an invalid state, so please do not use the received data (RDR register stored value) and the flag value of each status register. To interrupt the reception operation, stop the interrupt or event link reception side and then write 0b to the CCR0.RE bit.

In addition, when 0b is written to each operation enable bit (CCR0.RE, CCR0.TE) and the operation is interrupted, the following time is required to safely stop the internal circuit. During this time, access to this register is prohibited.

RSCI_m_TCLK × 3 cycles + RSCI_m_PCLK × 3 cycles

7.3.18.15 Notes on Communication Mode Transition

When changing the communication mode setting bits CCR3.MOD[2:0] and switching the communication mode, set CCR0.RE = 0b and CCR0.TE = 0b to stop the communication operation. In order to transition the internal circuit state safely, the register access interval should be at least RSCI_m_TCLK × 3 cycles + RSCI_m_PCLK × 3 cycles. During this time, write access to this register is prohibited. As an example, the following describes the transition from Asynchronous mode to Clock- synchronous mode.

1. Confirm stop of reception and transmission at asynchronous mode (CCR3.MOD[2:0] = 000b).
2. Write 0b to CCR0.TE and CCR0.RE, stop communication.
3. Wait “RSCI_m_TCLK × 3 cycles + RSCI_m_PCLK × 3 cycles”. During this time, access to this register is prohibited.
4. Write 010b to CCR3.MOD[2:0].
5. Wait “RSCI_m_TCLK × 3 cycles + RSCI_m_PCLK × 3 cycles”. During this time, access to this register is prohibited.

SECTION 7 LOW-SPEED INTERFACE

7.4 Serial Communications Interface with FIFO (SCIF)

This LSI has one channel of serial communication interface (SCIF) with FIFO that supports asynchronous serial communication. The SCIF has 16-stage FIFO buffers for transmission and reception that enable this LSI to perform efficient high-speed continuous communication.

7.4.1 Overview

Table 7.4-1 lists the specifications of the SCIF.

Table 7.4-1 Specifications of SCIF

Item		Description
Channel		1 channel
Serial communication method		Asynchronous communication
Transfer speed		Selectable bit rate with an on-chip baud rate generator
Full duplex communication		Transmitting section: realizes continuous data transmission using 16-stage FIFO buffer Receiving section: realizes continuous data reception using 16-stage FIFO buffer
Data transmission		Selectable either LSB-first or MSB-first transfer
Interrupt source		The following six sources: • Transmit-end (TEIF) • Transmit-FIFO-data-empty (TXIF) • Receive-FIFO-data-full (RXIF) • Receive-data-ready (DRIF) • Receive-error (ERIF) • Break detection or overrun (BRIF)
Asynchronous communication	Character length	7 or 8 bits
	Transmission stop bit length	1 or 2 bits
	Parity	Even, odd, or none
	Receive error detection	Parity, overrun, and framing errors
	Break detection	Break signal detection function by hardware.
	Noise cancellation	Incorporates a digital noise filter in the RXD pin input path.
Bit rate modulation		Enables errors to be decreased by correcting the output of the on-chip baud rate generator.

Figure 7.4-1 shows a block diagram of the SCIF.

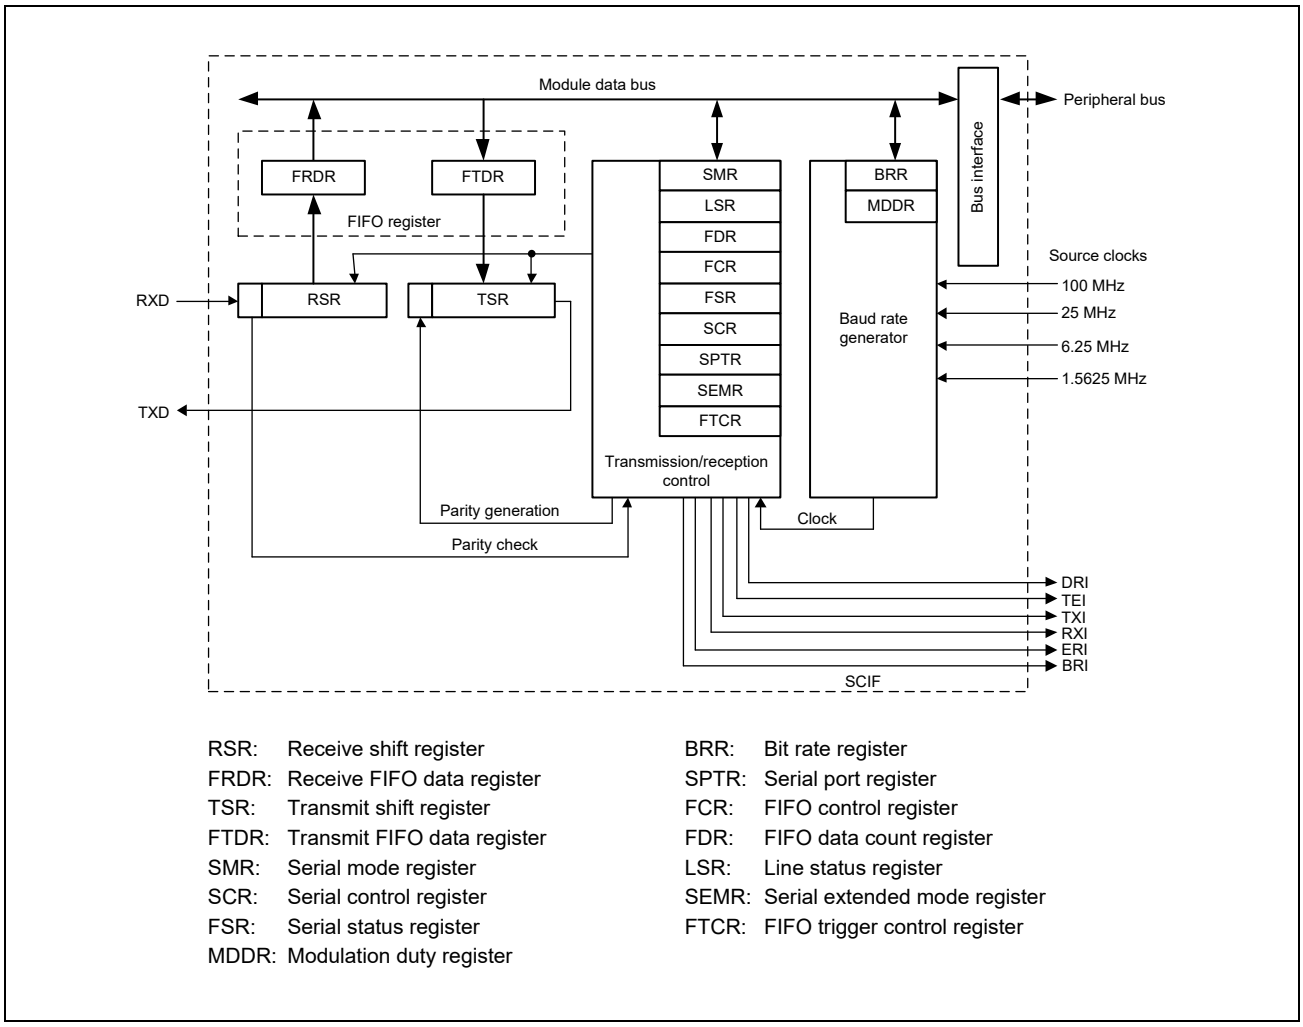

Figure 7.4-1 Block Diagram of SCIF

Table 7.4-2 lists the input/output pins of the SCIF.

Table 7.4-2 Pin Configuration of the SCIF

Channel	Item	Pin Name	Input/ Output	Function
SCIFn (n = 0)	Receive data pin	SCIF_RXD	Input	Receive data input
	Transmit data pin	SCIF_TXD	Output	Transmit data output

Note: In the notation of the pins, the channel is omitted, and pin names are represented as RXD and TXD.

7.4.2 Registers

The base address for the SCIF is as follows.

Table 7.4-3 Register Base Address

Base Register Name	Unit Name	Base Address
<SCIF0_base>	SCIF0	0_11C0_1400h (0_51C0_1400h*1, 0_41C0_1400h*2)

Note 1. CM33 Address Space Non-Secure

Note 2. CM33 Address Space Secure

7.4.2.1 List of Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Receive Shift Register	SCIFm_RSR	xxh	-	-
Transmit Shift Register	SCIFm_TSR	xxh	-	-
Serial Mode Register	SCIFm_SMR	0000h	0000h	16
Bit Rate Register	SCIFm_BRR	FFh	0002h	8
Modulation Duty Register	SCIFm_MDDR	FFh	0002h	8
Serial Control Register	SCIFm_SCR	0000h	0004h	16
Transmit FIFO Data Register	SCIFm_FTDR	FFh	0006h	8
Reserve	-	-	0007h	-
Serial Status Register	SCIFm_FSR	0020h	0008h	16
Receive FIFO Data Register	SCIFm_FRDR	00h	000Ah	8
Reserve	-	-	000Bh	-
FIFO Control Register	SCIFm_FCR	0000h	000Ch	16
FIFO Data Count Register	SCIFm_FDR	0000h	000Eh	16
Serial Port Register	SCIFm_SPTR	000xh	0010h	16
Line Status Register	SCIFm_LSR	0000h	0012h	16
Serial Extended Mode Register	SCIFm_SEMR	00h	0014h	8
Reserve	-	-	0015h	-
FIFO Trigger Control Register	SCIFm_FTCR	1F1Fh	0016h	16

Note: SCIFm_BRR and SCIFm_MDDR are located at the same address. Setting the MDDRS bit of the SEMR register switches these registers.

7.4.2.2 Register Description

The prefix (SCIFm_) of the register names is omitted in this and subsequent sections.

7.4.2.2.1 Receive Shift Register (SCIFm_RSR)

The RSR register receives serial data and temporally stores the data. The SCIF stores the serial data input via the RXD pin into the RSR register and converts the data to the parallel form. When one byte of data has been received, it is automatically transferred to the receive FIFO data register (FRDR).

The CPU cannot read from or write to the RSR register directly.

Access Size : 8 bits
Address : Undefined
Initial Value : xxh

Bit	7	6	5	4	3	2	1	0
	-							
Initial Value	x	x	x	x	x	x	x	x
R/W	-	-	-	-	-	-	-	-

7.4.2.2.2 Transmit Shift Register (SCIFm_TSR)

The SCIF transfers the transmit data from the transmit FIFO data register (FTDR) to the TSR register, and then transmits the data serially to the TXD pin. After transmitting one byte of data, the SCIF automatically transfers the next transmit data from the FTDR register into the TSR register and starts transmission.

The CPU cannot read from or write to the TSR register directly.

Access Size : 8 bits
Address : Undefined
Initial Value : xxh

Bit	7	6	5	4	3	2	1	0
	[7:0]							
Initial Value	x	x	x	x	x	x	x	x
R/W	-	-	-	-	-	-	-	-

x = Undefined

7.4.2.2.3 Serial Mode Register (SCIFm_SMR)

The SMR register specifies the SCIF serial communication format and selects the clock source for the baud rate generator.

The CPU can always read and write to the SMR register.

Access Size : 16 bits
Address : <SCIF0_base> + 0000h
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	CHR	PE	PM	STOP	-	CKS[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
6	CHR	0h	RW	Character Length 0b: 8-bit data 1b: 7-bit data*2
5	PE	0h	RW	Parity Enable 0b: Parity bit addition or check is disabled. 1b: Parity bit addition or check is enabled.
4	PM	0h	RW	Parity Mode 0b: Even parity 1b: Odd parity
3	STOP	0h	RW	Stop Bit Length 0b: One stop bit 1b: Two stop bits
2	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1 to 0	CKS[1:0]	0h	RW	Clock Select 00b: 1 × P0ϕ*1 01b: 1/4 × P0ϕ*1 10b: 1/16 × P0ϕ*1 11b: 1/64 × P0ϕ*1

Note 1. P0ϕ: Peripheral clock (SCIF_0_clk_pck)

Note 2. When 7-bit data is selected, the MSB (bit 7) of the transmit FIFO data register is not transmitted.

CKS[1:0] Bits (Clock Select)

Select an internal clock source for the on-chip baud rate generator. For further information on the clock source, bit rate register settings, and baud rates, see **7.4.2.2.9 Bit Rate Register (SCIFm_**BRR).

STOP Bit (Stop Bit Length)

Selects one bit or two bits as the stop bit length. When receiving, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1b, it is treated as a stop bit, but if the second stop bit is 0b, it is treated as the start bit of the next incoming character.

Note: When transmitting with one stop bit, a single 1 bit (stop bit) is added at the end of each transmission character.

Note: When transmitting with two stop bits, two 1 bits (stop bits) are added at the end of each transmission character.

PM Bit (Parity Mode)

Selects either the even or odd parity check. The setting of this bit is effective only when the parity enable (PE) bit of this register is set to 1b. The setting of this bit is ignored when parity addition/check is disabled.

Note: If even parity is selected, the parity bit is added to data to be transmitted to make the total number of 1s even in the transmission character and parity bit combined. When receiving, the SCIF verifies that the total number of 1s in the received character and parity bit combined is even.

Note: If odd parity is selected, the parity bit is added to data to be transmitted to make the total number of 1s odd in the transmission character and parity bit combined. When receiving, the SCIF verifies that the total number of 1s in the received character and parity bit combined is odd.

PE Bit (Parity Enable)

Selects whether to add a parity bit on data transmission and whether to enable/disable the parity check on data reception.

Note: When this bit is set to 1b, an even or odd parity bit specified in the PM bit is added to data to be transmitted. The SCIF verifies whether the parity bit of the received data is even or odd as specified in the PM bit when receiving.

CHR Bit (Character Length)

Selects 7- or 8-bit data length.

7.4.2.2.4 Bit Rate Register (SCIFm_BRR)

The BRR register is an 8-bit register that, together with the baud rate generator clock source selected by the CKS[1:0] bits in the serial mode register (SMR), determines the serial transmit/receive bit rate.

This register is located at the same address as that of the MDDR register and selected when the MDDRS bit in SEMR is 0b. The CPU can read and write to BRR. Writing to BRR should be executed when TE = RE = 0b in the SCR register.

Access Size : 8 bits
Address : <SCIF0_base> + 0002h
Initial Value : FFh

Bit	7	6	5	4	3	2	1	0
	-							
Initial Value	1	1	1	1	1	1	1	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW

The BRR setting is calculated using the following formulae.

- When the baud rate generator is in normal mode (SEMR.BGDM = 0b):

$$N = \frac{100}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

(When operating on the base clock with a frequency 16 times the bit rate (SMER.ABCS0 = 0b))

$$N = \frac{100}{32 \times 2^{2n-1} \times B} \times 10^6 - 1$$

(When operating on the base clock with a frequency 8 times the bit rate (SMER.ABCS0 = 1b))

- When the baud rate generator is in double-speed mode (SEMR.BGDM = 1b):

$$N = \frac{100}{32 \times 2^{2n-1} \times B} \times 10^6 - 1$$

(When operating on the base clock with a frequency 16 times the bit rate (SMER.ABCS0 = 0b))

$$N = \frac{100}{16 \times 2^{2n-1} \times B} \times 10^6 - 1$$

(When operating on the base clock with a frequency 8 times the bit rate (SMER.ABCS0 = 1b))

B: Bit rate (bit/s)
N: Setting of the BRR register ($0 \leq N \leq 255$) (The setting must satisfy the electrical characteristics).
n: Baud rate generator clock source (n = 0, 1, 2, 3) (For the clock sources and values of n, see **Table 7.4-4**).

NOTE

The MDDR register is used to adjust the bit rate. For details, see **7.4.2.2.6 Modulation Duty Register (SCIFm_**MDDR).

Table 7.4-4 SMR Register Setting

n	Frequency of Baud Rate Generator Clock Source (MHz)	SMR Register Settings	
		CKS1	CKS0
0	100	0	0
1	25	0	1
2	6.25	1	0
3	1.5625	1	1

The bit rate error is calculated using the following formulae.

- When the baud rate generator is in normal mode (SEMR.BGDM = 0b):

$$\text{Error}\ (\%) = \left\{\frac{100 \times 10^6}{(\mathrm{N}+1) \times \mathrm{B} \times 64 \times 2^{2\mathrm{n}-1}} - 1\right\} \times 100$$

(When operating on the base clock with a frequency 16 times the bit rate (SMER.ABCS0 = 0b))

$$\text{Error}\ (\%) = \left\{\frac{100 \times 10^6}{(\mathrm{N}+1) \times \mathrm{B} \times 32 \times 2^{2\mathrm{n}-1}} - 1\right\} \times 100$$

(When operating on the base clock with a frequency 8 times the bit rate (SMER.ABCS0 = 1b))

- When the baud rate generator is in double-speed mode (SEMR.BGDM = 1b):

$$\text{Error}\ (\%) = \left\{\frac{100 \times 10^6}{(\mathrm{N}+1) \times \mathrm{B} \times 32 \times 2^{2\mathrm{n}-1}} - 1\right\} \times 100$$

(When operating on the base clock with a frequency 16 times the bit rate (SMER.ABCS0 = 0b))

$$\text{Error}\ (\%) = \left\{\frac{100 \times 10^6}{(\mathrm{N}+1) \times \mathrm{B} \times 16 \times 2^{2\mathrm{n}-1}} - 1\right\} \times 100$$

(When operating on the base clock with a frequency 8 times the bit rate (SMER.ABCS0 = 1b))

Table 7.4-5 lists the examples of the BRR register setting.

Table 7.4-5 Bit Rates and BRR Register Settings

Bit Rate (bps)	n	N	Error (%)
150	—	—	—
300	3	162	−0.15
600	2	80	0.47
1200	2	162	−0.15
2400	2	80	0.47
4800	1	162	−0.15
9600	1	80	0.47
14400	0	216	0.01
19200	0	162	−0.15
28800	0	108	−0.45
31250	0	99	0.00
38400	0	80	0.47
115200	0	26	0.47
500000	0	5	*1

Note: These values assume bits SEMR.ABCS0 and SEMR.BGDM are both 0b.
When either the SEMR.ABCS0 bit or SEMR.BGDM bit is set to 1b, the bit rate is doubled.
When bits SEMR.ABCS0 and SEMR.BGDM are both 1b, the bit rate is quadrupled.
Configure settings so the range of error is no greater than 1%.

Note 1. Values for the blank cells in the table can be set using the MDDR register.
For details, see **7.4.2.2.6 Modulation Duty Register (SCIFm_**MDDR) and the **Table 7.4-7**.

Table 7.4-6 lists the maximum bit rates for various frequencies when the baud rate generator is used.

Table 7.4-6 Maximum Bit Rates for Various Frequencies with Baud Rate Generator

Frequency of Baud Rate Generator Clock Source (MHz)	Maximum Bit Rate (bit/s)	Settings	
		n	N
100	12500000	0	0

Note: These values assume bits SEMR.ABCS0 and SEMR.BGDM are both 1b. When either the SEMR.ABCS0 bit or SEMR.BGDM bit is set to 1b, the bit rate is 1/2. When bits SEMR.ABCS0 and SEMR.BGDM are both 1b, the bit rate is 1/4.

7.4.2.2.5 Serial Control Register (SCIFm_SCR)

The SCR register enables or disables the SCIF transmission/reception and interrupt requests, and selects the transmit/receive clock source. The CPU can always read from and write to the SCR register.

Access Size : 16 bits
Address : <SCIF0_base> + 0004h
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	TIE	RIE	TE	RE	REIE	TEIE	CKE[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7	TIE	0h	RW	Transmit Interrupt Enable 0b: Transmit-FIFO-data-empty interrupt request (TXI) is disabled. 1b: Transmit-FIFO-data-empty interrupt request (TXI) is enabled.
6	RIE	0h	RW	Receive Interrupt Enable 0b: Receive-FIFO-data-full interrupt (RXI), receive-data ready interrupt (DRI), receive-error interrupt (ERI), and break interrupt (BRI) requests are disabled. 1b: Receive-FIFO-data-full interrupt (RXI), receive-data ready interrupt (DRI), receive-error interrupt (ERI), and break interrupt (BRI) requests are enabled.
5	TE	0h	RW	Transmit Enable 0b: Data transmission is disabled. 1b: Data transmission is enabled.
4	RE	0h	RW	Receive Enable 0b: Data reception is disabled. 1b: Data reception is enabled.
3	REIE	0h	RW	Receive Error Interrupt Enable 0b: Receive-error interrupt (ERI) and break interrupt (BRI) requests are disabled. 1b: Receive-error interrupt (ERI) and break interrupt (BRI) requests are enabled.
2	TEIE*1	0h	RW	Transmit End Interrupt Enable 0b: Transmit end interrupt (TEI) request is disabled. 1b: Transmit end interrupt (TEI) request is enabled.
1 to 0	CKE[1:0]	0h	RW	Clock Enable In asynchronous mode: 0xb: Internal clock is used for clock source. 1xb: Setting prohibited

Note 1. TEI interrupt requests can be cleared by reading 1b from the TEND flag, and then clearing the setting to 0b, or by setting the TEIE bit to 0b.

REIE Bit (Receive Error Interrupt Enable)

Specifies whether to enable or disable a receive-error interrupt (ERI) request and a break interrupt (BRI) request. The setting of this bit is only valid when the RIE bit is set to 0b.

Note: ERI interrupt requests can be cleared by reading 1b from the ER bit in the FSR register, and then clearing the setting to 0b, or by clearing both the RIE and REIE bits in this register to 0b. BRI interrupt requests can be cleared by reading 1b from the BRK bit in the FSR register, or from the ORER flag in the LSR register, and then clearing the setting to 0b, or by clearing both the RIE and REIE bits in this register to 0b.

RE Bit (Receive Enable)

Specifies whether to enable or disable the serial data reception.

Note: Setting this bit to 0b does not affect the receive flags (DR, ER, BRK, RDF, FER, and PER in the FSR register, and ORER in the LSR register). These flags retain their previous values.

Note: Serial reception starts when a start bit is detected. Before setting this bit to 1b, be sure to set the serial mode register (SMR) and the FIFO control register (FCR) to select the receive format and reset the receive FIFO.

TE Bit (Transmit Enable)

Specifies whether to enable or disable the serial data transmission.

Note: Serial transmission starts after writing of data to be transmitted into the FTDR register under this condition. Before setting this bit to 1b, be sure to set the serial mode register (SMR) and the FIFO control register (FCR) to select the transmit format and reset the transmit FIFO.

RIE Bit (Receive Interrupt Enable)

Specifies whether to enable or disable a receive-FIFO-data-full (RXI) interrupt request when the RDF flag in the serial status register (FSR) is set to 1b, a receive-data ready (DRI) interrupt request when the DR flag in the FSR register is set to 1b, a receive-error (ERI) interrupt request when the ER flag in the FSR register is set to 1b, and a break (BRI) interrupt request when the BRK flag in the FSR register or the ORER flag in the line status register (LSR) is set to 1b.

Note: RXI interrupt requests can be cleared by reading 1b from the DR or RDF flag in the FSR register, then clearing the flag to 0b, or by clearing the RIE bit to 0b. DRI interrupt requests can be cleared by reading 1b from the DR flag in the FSR register, and then clearing the setting to 0b, or by clearing the RIE bit in this register to 0b. Receive error interrupt (ERI) requests and break interrupt (BRI) requests can be cleared by clearing both the RIE and REIE bits in this register to 0b.

TIE Bit (Transmit Interrupt Enable)

Specifies whether to enable or disable a transmit-FIFO-data-empty interrupt (TXI) request when the serial transmit data is transferred from the transmit FIFO data register (FTDR) into the transmit shift register (TSR), the quantity of data in the transmit FIFO data register falls below the specified trigger number for transmission, and the TDFE flag in the serial status register (FSR) is set to 1b.

Note: TXI interrupt requests can be cleared either by writing a greater quantity of transmit data than the specified transmission trigger number into the FTDR register, reading 1b from the TDFE flag, and then clearing the TDFE flag to 0b, or by clearing this bit to 0b.

7.4.2.2.6 Modulation Duty Register (SCIFm_MDDR)

The MDDR register corrects the bit rate adjusted by the BRR register. The value after reset of this register is FFh. When the BRME bit in SEMR is set to 1b, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of MDDR (MDDR/256). The relationship between the MDDR register setting and the bit rate (B) is given by the following formula. The MDDR register is located at the same address as that of the BRR register and is selected when the MDDRS bit in SEMR is 1b. This register is only writable when TE = RE = 0b in the SCR register. b7 in this register is fixed to 1b.

Access Size : 8 bits
Address : <SCIF0_base> + 0002h
Initial Value : FFh

Bit	7	6	5	4	3	2	1	0
	-							
Initial Value	1	1	1	1	1	1	1	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW

The formulae below show the relationships between the MDDR setting and the bit rate (B) when the bit rate modulation function is used.

- When the baud rate generator is in normal mode (SEMR.BGDM = 0b):

$$B = \frac{100 \times 10^6}{64 \times 2^{2n-1} \times (256/MDDR) \times (N+1)}$$

(When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0b))

$$B = \frac{100 \times 10^6}{32 \times 2^{2n-1} \times (256/MDDR) \times (N+1)}$$

(When operating on the base clock with a frequency 8 times the bit rate (SEMR.ABCS0 = 1b))

- When the baud rate generator is in double-speed mode (SEMR.BGDM = 1b):

$$B = \frac{100 \times 10^6}{32 \times 2^{2n-1} \times (256/MDDR) \times (N+1)}$$

(When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0b))

$$B = \frac{100 \times 10^6}{64 \times 2^{2n-1} \times (256/MDDR) \times (N+1)}$$

(When operating on the base clock with a frequency 8 times the bit rate (SEMR.ABCS0 = 1b))

B: Bit rate (bits/s)
N: BRR register setting ($0 \leq N \leq 255$)
(The setting must satisfy the electrical characteristics).
MDDR: MDDR setting ($128 \leq MDDR \leq 256$)
n: Baud rate generator clock source (n = 0, 1, 2, 3) (For the clock sources and values of n, see **Table 7.4-7**).

Table 7.4-7 Bit Rates and BRR and MDDR Registers Settings

Bit Rate (bps)	n	N	MDDR	Error (%)
150	3	252	199	0.02
300	3	161	255	0.08
600	3	80	255	0.08
1200	2	161	255	0.08
2400	2	80	255	0.08
4800	1	161	255	0.08
9600	1	80	255	0.08
14400	—	—	—	—
19200	0	161	255	0.08
28800	0	107	254	0.08
31250	—	—	—	—
38400	0	80	253	0.08
115200	0	26	255	0.08
500000	0	5	246	0.10

Note: These values assume bits SEMR.ABCS0 and SEMR.BGDM are both 0b. When either the SEMR.ABCS0 bit or SEMR.BGDM bit is set to 1b, the bit rate is doubled. When bits SEMR.ABCS0 and SEMR.BGDM are both 1b, the bit rate is quadrupled. Configure settings so the range of error is no greater than 1%.

7.4.2.2.7 Transmit FIFO Data Register (SCIFm_FTDR)

The FTDR register is an 8-bit, 16-stage FIFO register that stores serial transmission data. When the SCIF detects that the transmit shift register (TSR) is empty, it transmits data written in the FTDR register to the TSR register and starts serial transmission. Continuous serial transmission is executed until there is no transmit data left in the FTDR register. Writing the transmit data to the FTDR register should be done when a transmit data empty interrupt (TXI) request is generated. When the FTDR register becomes full of transmit data (16 bytes), no more data can be written. Even if new data is written, the data is ignored.

The CPU can read from the FTDR register but cannot write to it.

Access Size : 8 bits
Address : <SCIF0_base> + 0006h
Initial Value : FFh

Bit	7	6	5	4	3	2	1	0
	[7:0]							
Initial Value	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R

7.4.2.2.8 Serial Status Register (SCIFm_FSR)

The FSR register is a 16-bit register. The 8 lower-order bits indicate the status flag representing the SCIF operating state.

The CPU can always read and write to the FSR register, but cannot write 1b to the status flags (ER, TEND, TDFE, BRK, RDF, and DR bits) in this register. These flags can be only cleared to 0 when they have first been read (after being set to 1). b3 (FER) and b2 (PER) are read-only bits that cannot be written.

Access Size : 16 bits
Address : <SCIF0_base> + 0008h
Initial Value : 0020h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial Value	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7	ER	0h	RW*1	Receive Error Flag 0b: Reception is in progress or has normally completed. 1b: A framing error or parity error has occurred during reception.
6	TEND	0h	RW*1	Transmit End Flag 0b: Transmission is in the waiting state or in progress. 1b: Transmission is completed.
5	TDFE	1h	RW*1	Transmit FIFO Data Empty Flag 0b: The quantity of transmit data written in the FTDR register exceeds the specified transmission trigger number. 1b: The quantity of transmit data written in the FTDR register is equal to or less than the specified transmission trigger number.*3
4	BRK	0h	RW*1	Break Detect Flag 0b: No break signal is received. 1b: A break signal is received.*2
3	FER	0h	R	Framing Error Flag*4 0b: No receive framing error occurred in the next data read from the FRDR register. 1b: A receive framing error occurred in the next data read from the FRDR register.
2	PER	0h	R	Parity Error Flag*4 0b: No receive parity error occurred in the next receive data read from the FRDR register. 1b: A receive parity error occurred in the next receive data read from the FRDR register.
1	RDF	0h	RW*1	Receive FIFO Data Full Flag 0b: The quantity of receive data in the FRDR register falls below the specified reception trigger number. 1b: The quantity of receive data written in the FRDR register is equal to or greater than the specified reception trigger number.
0	DR	0h	RW*1	Receive Data Ready Flag 0b: Reception is in progress, or no received data has remained in the FRDR register after normally completed receiving. 1b: Next receive data has not been received.

Note 1. To clear the flag, 0b can only be written after 1b is read.

Note 2. When a break signal is detected, transfer of the receive data (0h) to the FRDR register stops after the detection. When the break ends and the receive signal becomes mark state (high level), the transfer of receive data resumes.

Note 3. Since the FTDR register is a 16-byte FIFO register, the maximum quantity of data that can be written when TDFE is 1 is “16 minus the number of non-transmitted data units”. If additional data is written, the data is ignored. The quantity of data in the FTDR register is indicated by the 8 higher-order bits of the FDR register.

Note 4. When the DMAC is used to read data, the generation of errors cannot be checked by reading this flag.

DR Bit (Receive Data Ready Flag)

Indicates that the quantity of data stored in the receive FIFO data register (FRDR) falls below the specified reception trigger number, and that no next data has been received yet after the elapse of 15 ETUs from the last stop bit.

[Setting condition]

- DR is set to 1b when the FRDR register contains less data than the specified reception trigger number, and no next data has been received yet after the elapse of 15 ETUs*1 from the last stop bit.

[Clearing conditions]

When either of the following is satisfied:

- DR is cleared to 0b when DR = 1b is read and then 0b is written to the DR flag.
- DR is cleared to 0b when all received data in the FRDR register are read.

Note 1. This is equivalent to one and a half (1.5) frames in the 8-bit format with one stop bit (ETU: elementary time unit).

Note: When the RE bit in SCR is cleared to 0, the DR bit is not affected and retains its previous value.

RDF Bit (Receive FIFO Data Full Flag)

Indicates that receive data has been transferred to the receive FIFO data register (FRDR), and the quantity of data in FRDR becomes equal to or greater than the specified reception trigger number.

[Setting condition]

- RDF is set to 1b when the quantity of receive data which is equal to or greater than the specified reception trigger number are stored in the FRDR register*1.

[Clearing conditions]

- RDF is cleared to 0b when RDF = 1b is read and then 0b is written to this bit.
- RDF is cleared to 0b when the FRDR register is read.

Note 1. Since the FRDR register is a 16-byte FIFO register, the maximum quantity of data that can be read when this bit is 1b is equivalent to the specified reception trigger number. If an attempt is made to read after all the data in the FRDR register has been read, the read data is undefined. The quantity of receive data in the FRDR register is indicated by the 8 lower-order bits of the FDR register.

PER Bit (Parity Error Flag)

Indicates whether there is a parity error in the data read from the receive FIFO data register (FRDR).

[Setting condition]

- PER is set to 1b when a parity error is present in the next data read from the FRDR register.

[Clearing condition]

- PER is cleared to 0b when no parity error is present in the next data read from the FRDR register.

FER Bit (Framing Error Flag)

Indicates whether there is a framing error in the data read from the receive FIFO data register (FRDR).

[Setting condition]

- FER is set to 1b when a framing error is present in the next data read from the FRDR register.

[Clearing condition]

- FER is cleared to 0b when no framing error is present in the next data read from the FRDR register.

BRK Bit (Break Detect Flag)

Indicates that a break signal has been detected in receive data.

[Setting condition]

- BRK is set to 1b when data including a framing error is received, and the framing error is followed by at least one frame of data received at the space 0 level (low level).

[Clearing condition]

- BRK is cleared to 0b when software reads BRK after it has been set to 1b and then writes 0b to BRK.

TDFE Bit (Transmit FIFO Data Empty Flag)

Indicates that data has been transferred from the transmit FIFO data register (FTDR) into the transmit shift register (TSR), the quantity of data in the FRDR register becomes equal to or less than the specified transmission trigger number, and writing of transmit data to the FRDR register is enabled.

[Setting conditions]

When either of the following is satisfied:

- TDFE is set to 1b when the TE bit in SCR is 0b.
- TDFE is set to 1b when the quantity of transmit data written in the FRDR register is equal to or less than the specified transmission trigger number.

[Clearing conditions]

- TDFE is cleared to 0b when 0b is written in the TDFE bit after reading TDFE = 1b.
- When transmit data is written to the FTDR register

TEND Bit (Transmit End Flag)

Indicates that the FRDR register contains no more valid data and transmission is completed when transmitting the last bit of the transmit data.

[Setting condition]

When the following is satisfied:

- TEND is set to 1b when the FTDR register does not contain transmit data when the last bit of the serial transmission data is transmitted.

[Clearing conditions]

- When transmit data is written to the FTDR register
- When 0b is written to TEND after it has been read as 1b

ER Bit (Receive Error Flag)

Indicates the occurrence of a framing error, or of a parity error when receiving the parity-added data*[1].

[Setting conditions]

When either of the following is satisfied:

- ER is set to 1b when the stop bit is found to be 0b after checking whether the stop bit of the received data is 1b at the end of one data receive operation*[1].

- ER is set to 1b when the total number of 1s in the received data and parity bit combined does not match the even or odd parity setting specified by the PM bit in the SMR register.

[Clearing condition]

- When 0b is written to ER after it has been read as 1b

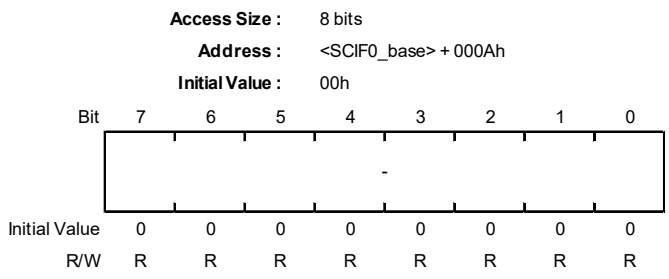
Note 1. Clearing the RE bit to 0b in the SCR register does not affect this bit, which retains its previous value. Even if a receive error occurs, the receive data is transferred to the FRDR register and the receive operation is continued. Whether the data read from the FRDR register includes a receive error can be detected by the FER and PER bits in the FSR register.

Note: In two stop bits mode, only the first stop bit is checked; the second stop bit is not checked.

7.4.2.2.9 Receive FIFO Data Register (SCIFm_FRDR)

The FRDR register is an 8-bit, 16-stage FIFO register that stores the received serial data. When the SCIF receives one byte of serial data, it transfers the received data from the receive shift register (RSR) to the FRDR register and completes the receive operation. Continuous reception is possible until the received 16 bytes of data are stored. If the FRDR register is read when there is no received data in the FRDR register, an undefined value is read.

When the FRDR register is full of received data, subsequently received serial data is lost.



7.4.2.2.10 FIFO Control Register (SCIFm_FCR)

The FCR register resets the quantity of data in the transmit FIFO data register (FTDR) and the receive FIFO data register (FRDR) and specifies the number of triggers. This register also specifies whether to enable the loop-back test.

The CPU can always read and write to the FCR register.

Access Size : 16 bits
Address : <SCIF0_base> + 000Ch
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	RTRG[1:0]		TTRG[1:0]		-	TFRST	RFRST	LOOP
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7 to 6	RTRG[1:0]	0h	RW	Receive FIFO Data Trigger Number Select In asynchronous mode: 00b: 1 01b: 4 10b: 8 11b: 14
5 to 4	TTRG[1:0]	0h	RW	Transmit FIFO Data Trigger Number Select 00b: 8 (8)*1 01b: 4 (12)*1 10b: 2 (14)*1 11b: 0 (16)*1
3	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	TFRST	0h	RW	Transmit FIFO Data Register Reset 0b: Normal operation 1b: Resets the FTDR register.
1	RFRST	0h	RW	Receive FIFO Data Register Reset 0b: Normal operation 1b: Resets the FRDR register.
0	LOOP	0h	RW	Loop-Back Test 0b: Loop back test is disabled. 1b: Loop back test is enabled

Note 1. Values in parentheses are the numbers of empty bytes in the FTDR register when the TDFE flag is set to 1b and a transmit FIFO data empty interrupt (TXI) request is generated.

LOOP Bit (Loop-Back Test)

Internally connects between the transmit output pin (TXD) and the receive input pin (RXD) to perform loop-back testing.

RFRST Bit (Receive FIFO Data Register Reset)

Disables the receive data in the receive FIFO data register (FRDR) and makes the data to the empty state. If you set this bit to 1b, be sure to clear it to 0b afterward.

TFRST Bit (Transmit FIFO Data Register Reset)

Disables the transmit data in the transmit FIFO data register (FTDR) and makes the data to the empty state. If you set this bit to 1b, be sure to clear it to 0b afterward.

TTRG[1:0] Bits (Transmit FIFO Data Trigger Number Select)

Specify the reference quantity of data for transmission (i.e., the threshold number of entries to trigger the writing of further data for transmission) for setting of the TDFE flag in the serial status register (FSR). When the number of entries for transmission in the transmission FIFO, i.e. the number of entries written to the transmit FIFO data register (FTDR) that are yet to be transmitted, falls to or below the specified trigger number for transmission, the TDFE flag is set to 1b and a transmit FIFO data empty interrupt (TXI) request is generated.

The setting in these bits is valid when the TTRGS bit in the FTCR register is 0b. When the TTRGS bit in the FTCR register is 1b, the setting of the TFTC[4:0] bits in the FTCR register is valid.

RTRG[1:0] Bits (Receive FIFO Data Trigger Number Select)

Specify the reference quantity of receive data (i.e., the threshold number of entries to trigger the reading of received data) for setting of the RDF flag in the serial status register (FSR). When the number of entries in the reception FIFO, i.e. the number of entries yet to be read from the receive FIFO data register (FRDR), rises to or above the specified trigger number for reception, the RDF flag is set to 1b and a receive FIFO data full interrupt (RXI) request is generated.

The setting in these bits is valid when the RTRGS bit in the FTCR register is 0b. When the RTRGS bit in the FTCR register is 1b, the setting of the RFTC[4:0] bits in the FTCR register is valid.

7.4.2.2.11 FIFO Data Count Register (SCIFm_FDR)

The FDR register indicates the quantity of data stored in the transmit FIFO data register (FTDR) and the receive FIFO data register (FRDR).

This register indicates the quantity of transmit data in the FTDR register with the 8 higher-order bits, and the quantity of receive data in the FRDR register with the 8 lower-order bits. The CPU can always read the FDR register.

Access Size : 16 bits
Address : <SCIF0_base> + 000Eh
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	T[4:0]					-	-	-	R[4:0]				
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
12 to 8	T[4:0]	0h	R	Non-Transmitted Data Quantity in FTDR Indicate the quantity of non-transmitted data stored in the FTDR register.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4 to 0	R[4:0]	0h	R	Receive Data Quantity in FRDR Indicate the quantity of receive data stored in the FRDR register.

Note: To clear the flag, 0b can only be written after 1b is read.

R[4:0] Bits

Indicate the quantity of receive data stored in the FRDR register.

00h means no received data, and 10h means that all of the received data is stored in the FRDR register.

T[4:0] Bits

Indicate the quantity of non-transmitted data stored in the FTDR register.

00h means no transmit data, and 10h means that all of the data for transmission is stored in the FTDR register.

7.4.2.2.12 Serial Port Register (SCIFm_SPTR)

The SPTR register controls input/output and data of the pins multiplexed to SCIF function. The CPU can always read and write to the SPTR register.

NOTE

b0 of this register indicates the input status of the corresponding pin. See the description of the bit for details.

Access Size : 16 bits
Address : <SCIF0_base> + 0010h
Initial Value : 000xh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SPB2IO	SPB2DT
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 2	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1	SPB2IO	0h	RW	Serial Port Break Input/Output Controls the TXD pin in combination with the TE bit in the SCR register and the SPB2DT bit.
0	SPB2DT	x	RW	Serial Port Break Data Select Controls the TXD pin in combination with the TE bit in the SCR register and the SPB2IO bit. See **Table 7.4-8**.

x = Undefined

SPB2DT Bit (Serial Port Break Data Select)

This bit specifies the output level of the TXD pin when the setting of the SCR.TE bit is 0b. The RXD pin input status can be read from this bit regardless of the SPB2IO bit setting. However, the RXD pin function must have been selected with the general I/O port.

SPB2IO Bit (Serial Port Break Input/Output)

Controls the TXD pin in combination with the TE bit in the SCR register and the SPB2DT bit.

Table 7.4-8 TXD Pin Status

SCR.TE Bit Setting	SPB2IO Bit Setting	SPB2DT Bit Setting	TXD Pin Status
0	0	×	Setting prohibited
0	1	0	Low output
0	1	1	High output
1	×	×	Transmit data output

Remarks: ×: Don't care

7.4.2.2.13 Line Status Register (SCIFm_LSR)

The LSR register is a 16-bit register. The PER and FER bits indicate the number of receive errors in the receive FIFO data register. 1b cannot be written to the OREER status flag. The flag should be read as 1b prior to clearing it to 0b.

Access Size : 16 bits
Address : <SCIF0_base> + 0012h
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	PER[3:0]				-	-	FER[3:0]				-	ORER
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW*1

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 8	PER[3:0]	0h	R	Parity Error Count Indicates the quantity of data with a parity error among the receive data stored in the receive FIFO data register (FRDR).
7 to 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
5 to 2	FER[3:0]	0h	R	Framing Error Count Indicates the quantity of data with a framing error among the receive data stored in the receive FIFO data register (FRDR).
1	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	ORER	0h	RW*1	Overrun Error Flag 0b: Reception is in progress or has normally completed. 1b: An overrun error has occurred during reception.

Note 1. To clear the flag, 0 can only be written after 1b is read.

ORER Bit (Overrun Error Flag)

Indicates that receive operation abnormally stops due to occurrence of an overrun error. This flag is not affected and retains its previous state if the RE bit in the serial control register (SCR) is cleared to 0b. The receive FIFO data register (FRDR) retains the data before an overrun error occurred, and newly received data is lost. When the ORER bit is set to 1b, the SCIF cannot continue subsequent serial reception.

[Setting condition]

- When the next serial reception is completed with the receive FIFO in full state (16-byte data is received)

[Clearing condition]

- When 0b is written to ORER after being read as 1b.

Note: When the internal clock is selected while the SCIF is in clock synchronous mode, the amount of receive data can be controlled, so no overrun occurs.

FER[3:0] Bits (Framing Error Count)

The values of bits 5 to 2 indicate the quantity of data with a framing error after the ER bit in the FSR register is set. Reading 0000b from the FER[3:0] bits means all 16-byte receive data in the FRDR register have a framing error.

PER[3:0] Bits (Parity Error Count)

The values of bits 11 to 8 indicate the quantity of data with a parity error after the ER bit in the FSR register is set. Reading 0000b from the PER[3:0] bits means all 16-byte receive data in the FRDR register have a parity error.

7.4.2.2.14 Serial Extended Mode Register (SCIFm_SEMR)

The SEMR register specifies either LSB or MSB first, enables the noise cancellation, operation in normal or double-speed mode of the baud rate generator, and bit rate modulation, and selects the modulation register and the sampling count (either 8 or 16 times).

Access Size : 8 bits
Address : <SCIF0_base> + 0014h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	BGDM	-	BRME	MDDRS	DIR	NFEN	-	ABCS0
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	BGDM	0h	RW	Baud Rate Generator Double- Speed Mode Select 0b: Baud rate generator normal mode: Baud rate generator operates on the clock signal produced by dividing the clock source by two. 1b: Baud rate generator double-speed mode: Baud rate generator operates on the clock signal produced by the clock source (no frequency division).
6	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5	BRME	0h	RW	Bit Rate Modulation Enable 0b: Bit rate modulation is disabled. 1b: Bit rate modulation is enabled.
4	MDDRS	0h	RW	Modulation Duty Register Select 0b: BRR register is accessible. 1b: MDDR register is accessible.
3	DIR	0h	RW	Data Transfer Direction Select 0b: Transmits the data in the FTDR register by the LSB-first method. The received data is stored in the FRDR register by the LSB-first method. 1b: Transmits the data in the FTDR register by the MSB-first method. The received data is stored in the FRDR register by the MSB-first method.
2	NFEN	0h	RW	Noise Cancellation Enable 0b: Noise cancellation for the RxD pin is disabled. 1b: Noise cancellation for the RxD pin is enabled.
1	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	ABCS0	0h	RW	Asynchronous Base Clock Select 0b: Operates on a frequency 16 times the transfer rate as the base clock. 1b: Operates on a frequency 8 times the transfer rate as the base clock.

ABCS0 Bit (Asynchronous Base Clock Select)

Selects the base clock for 1-bit period.

NFEN Bit (Noise Cancellation Enable)

Reduces noise of the input to the RxD pin. For details, see **7.4.8 Noise Cancellation**.

DIR Bit (Data Transfer Direction Select)

Selects the serial communication format. This bit is valid only when the transmit/receive data length is 8 bits.

MDDRS Bit (Modulation Duty Register Select)

Selects the register to be enabled access to it.

BRME Bit (Bit Rate Modulation Enable)

Specifies whether to enable or disable the bit rate modulation.

BGDM Bit (Baud Rate Generator Double-Speed Mode Select)

Selects operating mode of the baud rate generator. When setting 1b in this bit, the baud rate generator included in the SCIF operates in double-speed mode.

7.4.2.2.15 FIFO Trigger Control Register (SCIFm_FTCR)

The FTCR register is a 16-bit register that specifies FIFO trigger conditions. The CPU can always read from and write to the FTCR register.

Access Size : 16 bits
Address : <SCIF0_base> + 0016h
Initial Value : 1F1Fh

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RTRGS	-	-	RFTC[4:0]					TTRGS	-	-	TFTC[4:0]				
Initial Value	0	0	0	1	1	1	1	1	0	0	0	1	1	1	1	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15	RTRGS	0h	RW	Receive Trigger Select 0b: RTRG[1:0] bits in FCR are valid. 1b: RFTC[4:0] bits in FTCR are valid.
14 to 13	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
12 to 8	RFTC[4:0]	1Fh	RW	Receive FIFO Data Trigger Number 01h: Receive data trigger number is 1. 10h: Receive data trigger number is 16. Do not set 00h and 11h to 1Fh in these bits.
7	TTRGS	0h	RW	Transmit Trigger Select 0b: TTRG[1:0] bits in FCR are valid. 1b: TFTC[4:0] bits in FTCR are valid.
6 to 5	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4 to 0	TFTC[4:0]	1Fh	RW	Transmit FIFO Data Trigger Number 00h: Transmit data trigger number is 0. 0Fh: Transmit data trigger number is 15. Do not set 10h to 1Fh in these bits.

TFTC[4:0] Bits (Transmit FIFO Data Trigger Number)

Specify the reference quantity of data for transmission (i.e., the threshold number of entries to trigger the writing of further data for transmission) for setting of the TDFE flag in the serial status register (FSR).

When the number of entries for transmission in the transmission FIFO, i.e. the number of entries written to the transmit FIFO data register (FTDR) that are yet to be transmitted, falls to or below the specified trigger number for transmission, the TDFE flag is set to 1b and a transmit FIFO data empty interrupt (TXI) request is generated.

RFTC[4:0] Bits (Receive FIFO Data Trigger Number)

Specify the reference quantity of receive data (i.e., the threshold number of entries to trigger the reading of received data) for setting of the RDF flag in the serial status register (FSR).

When the number of entries in the reception FIFO, i.e. the number of entries yet to be read from the receive FIFO data register (FRDR), rises to or above the specified trigger number for reception, the RDF flag is set to 1b and a receive FIFO data full interrupt (RXI) request is generated.

7.4.3 Operation

7.4.3.1 Overview

The SCIF supports asynchronous serial communication in which characters are synchronized individually.

The SCIF has a 16-stage FIFO buffer for both transmission and reception, reducing the overhead of the CPU and enabling continuous high-speed communication. Selection of a transmission/reception format is enabled with the serial mode register (SMR). **Table 7.4-9** shows the transmission format which can be selected in the serial mode register (SMR).

- Data length is selectable as either 7 or 8 bits
- Parity addition and 1- or 2-bit stop bit addition are selectable.
  (The combination of the preceding selections determines the transmission/reception format and character length).
- In reception, it is possible to detect framing errors, parity errors, receive FIFO data full, overrun errors, receive data ready, and breaks.
- The stored data quantities are indicated in the FIFO data count register (FDR), respectively for transmit and receive FIFO data.
- The SCIF operates using the clock of on-chip baud rate generator.

Table 7.4-9 SMR Register Settings and SCIF Communication Formats

SMR Register			SCIF Transmission/Reception Format		
b6	b5	b3			
CHR	PE	STOP	Data Length	Parity Bit	Stop Bit Length
0	0	0	8 bits	Not set	1 bit
		1			2 bits
	1	0		Set	1 bit
		1			2 bits
1	0	0	7 bits	Not set	1 bit
		1			2 bits
	1	0		Set	1 bit
		1			2 bits

7.4.3.2 Asynchronous Serial Communication

In the asynchronous serial communication performed by the SCIF, each transmitted or received character begins with a start bit and ends with a stop bit. Serial communication is synchronized one character at a time.

The transmitting and receiving sections of the SCIF are independent, so full duplex communication is possible. The transmitter and receiver are 16-stage FIFO buffered, so data can be written and read while transmitting and receiving are in progress, enabling continuous transmission and reception.

Figure 7.4-2 shows the general format of asynchronous serial communication.

In asynchronous serial communication, the communication line is normally held in the mark (high) state. The SCIF monitors the line and starts serial communication when the line goes to the space (low) state, considered as a start bit. One serial character consists of a start bit (low), data (LSB first when LSB-first transfer is selected), parity bit (high or low), and stop bit (high), in that order.

When receiving, the SCIF synchronizes at the falling edge of the start bit. The SCIF samples each data bit on the eighth pulse of a clock with a frequency 16 or 8 times the bit rate*[1]. Receive data is latched at the center of each bit.

Note 1. When the SEMR.ABCS0 bit = 0b, data is sampled on the eighth pulse of a clock with a frequency 16 times the bit rate.
When the SEMR.ABCS0 bit = 1b, data is sampled on the fourth pulse of a clock with a frequency 8 times the bit rate.

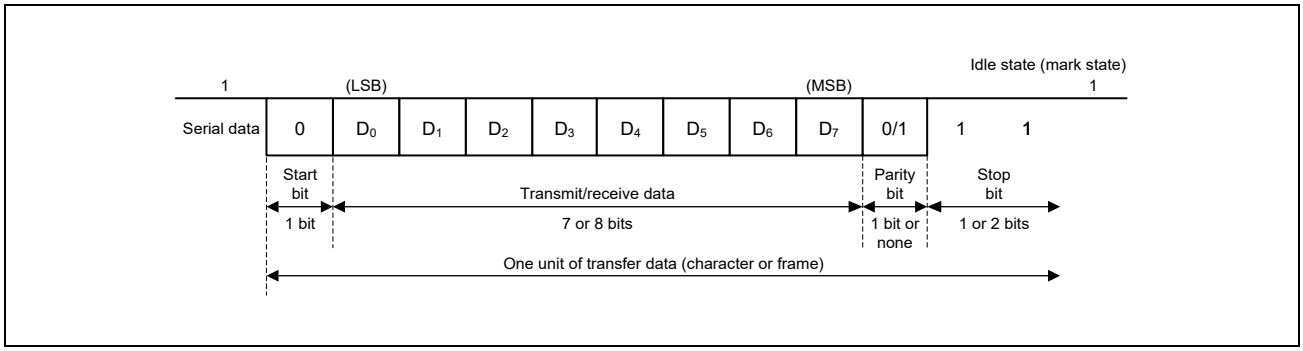


Figure 7.4-2 Data Format in Asynchronous Communication
(8-bit Data with Parity and Two Stop Bits when LSB-First Transfer is Selected)

7.4.3.3 Transmit/Receive Formats

Table 7.4-10 lists the eight communications formats that can be selected. The format is selected by setting in the serial mode register (SMR).

Table 7.4-10 Serial Communications Formats

SMR Setting			Serial Transmit/Receive Format and Frame Length											
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	START	8-bit data								STOP		
		1	START	8-bit data								STOP	STOP	
	1	0	START	8-bit data								P	STOP	
		1	START	8-bit data								P	STOP	STOP
1	0	0	START	7-bit data							STOP			
		1	START	7-bit data							STOP	STOP		
	1	0	START	7-bit data							P	STOP		
		1	START	7-bit data							P	STOP	STOP	

Note: START: Start bit
STOP: Stop bit
P: Parity bit

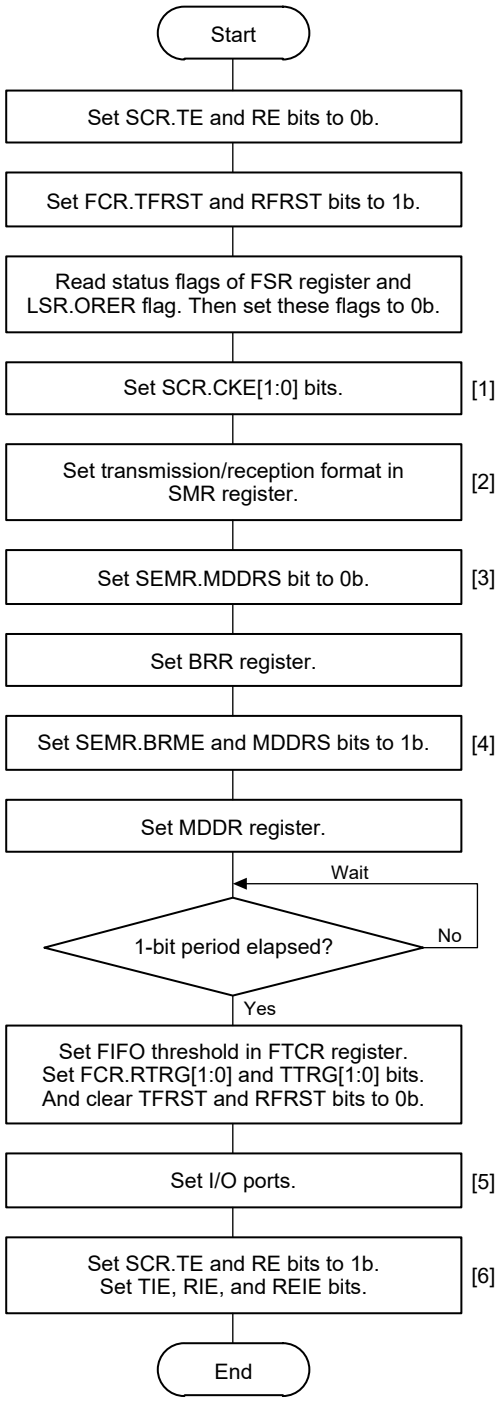
7.4.3.4 Transmitting and Receiving Data

7.4.3.4.1 SCIF initialization

Before transmitting or receiving data, clear the TE and RE bits to 0b in the serial control register (SCR), and then initialize the SCIF as follows.

When changing operating mode or communication format, always clear the TE and RE bits in the SCR register to 0b before following the procedure given below. Clearing TE to 0b initializes the transmit shift register (TSR). Clearing TE and RE to 0b, however, does not initialize the serial status register (FSR), transmit FIFO data register (FTDR), or receive FIFO data register (FRDR), which retain their previous contents. Clear TE to 0b after all transmit data has been transmitted and the TEND flag in the FSR register is set. The TE bit can be cleared to 0b during transmission, but the transmit data (the TXD pin output level) after the TE bit is cleared to 0b depends on the settings of the SPB2IO and SPB2DT bits in the SPTR register. Set the TFRST bit in the FCR register to 1b and reset the FTDR register before TE is set to 1b again to start transmission.

When an external clock is used, the clock should not be stopped during initialization or subsequent operation. SCIF operation becomes unreliable if the clock is stopped. **Figure 7.4-3** shows a sample flowchart for initializing the SCIF.



[1] Set the TIE, RIE, TE, and RE bits in the SCR register to 0b before setting the CKE[1:0] bits.

[2] Set the transmission/reception format in the SMR register.

[3] Clear the SEMR.MDDRS bit to 0b and write a value corresponding to the bit rate in the BRR register. Not necessary if an external clock is used.

[4] Set the SEMR.BRME and MDDRS bits to 1b and write a value corresponding to the bit rate in the MDDR register. Not necessary if an external clock is used. Wait for at least 1-bit period before proceeding to the next step.

[5] Set I/O ports and the MPC register so that they can be used as the SCK, TXD, and RXD pins.

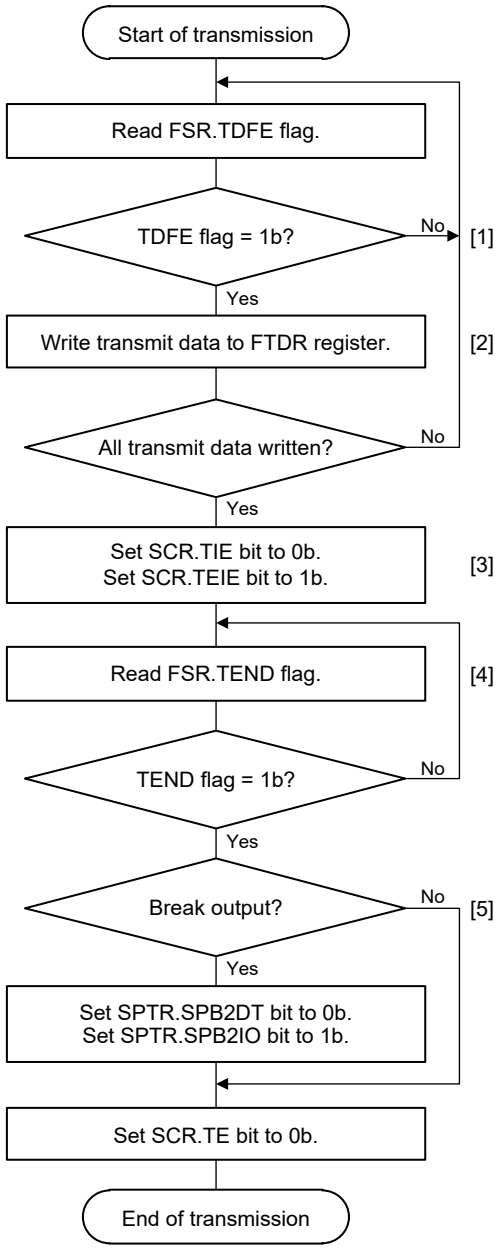
[6] After setting the MDDR register, wait for at least 1-bit period and then write 1b to the SCR.TE or RE bit. To permit interrupt requests, set TIE, RIE and REIE bits to 1b. Setting the TE and RE bits to 1b makes the TXD and RXD pins available to be used. The TXD pin enters the mark state and the RXD pin enters the idle state waiting for a start bit.

Figure 7.4-3 Sample Flowchart for SCIF Initialization

7.4.3.4.2 Transmitting serial data

Figure 7.4-4 shows a sample flowchart for serial transmission.

Follow the procedure given below for serial data transmission after enabling the SCIF for transmission.



[1] Check the SCIFA status and write the transmit data:
Read the FSR register, confirm that the TDFE flag is set to 1b, and then write the transmit data to the FTDR register. The transmit data quantity that can be written is "16 - FDR.T[4:0]". A change of the TDFE flag from 0b to 1b can be known by a TXIF interrupt request.

[2] Serial transmission continuation procedure:
When transmit data is written to the FTDR register, the TDFE flag is automatically cleared to 0b.

[3] Serial transmission end procedure (when TXIF or TEIF interrupt is used):
After the last transmission data is written to the FTDR register, set the TIE bit to 0b and the TEIE bit to 1b in the SCR register. If the DMAC is activated to write the transmit data to the FTDR register, enable the transmit end interrupt. This will generate a CPU interrupt request when the last transmit data is written in the FTDR register. The TIE and TEIE bit settings will be changed by the CPU interrupt process.
This procedure is unnecessary if the TXIF or TEIF interrupt is not used.

[4] Serial transmission end confirmation:
Read the FSR register and confirm that the TEND flag has changed to 1b.
A change of the TEND flag from 0b to 1b can be known by a TEIF interrupt request.

[5] Break output during serial transmission:
To cause a break to be output during serial transmission, set the SPB2DT bit to 0b and the SPB2IO bit to 1b in the SPTR register. Then set the SCR.TE bit to 0b.*1

In Step [1], the number of data bytes that can be written can be checked by the FDR.T[4:0] flag (non-transmitted data quantity in the FTDR register).

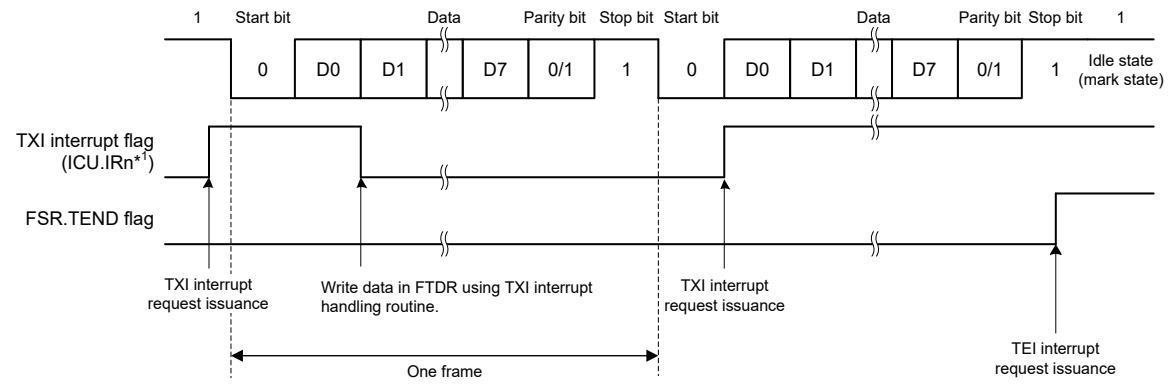
Note 1. The SPB2DT bit of the SPTR register indicates the input status of the RXD pin. Writings to the SPB2DT and SPB2IO bits of this register in 1-bit unit are handled as read-modify-write, which may lead to undesired values to be written to the SPB2DT bit. To avoid this, when modifying the SPB2DT or SPB2IO bit, for example, write the other bit (the bit used in combination) at the same time.

Figure 7.4-4 Sample Flowchart for Transmitting Serial Data

The SCIF performs serial transmission as described below.

1. When data is written into the transmit FIFO data register (FTDR) by the TXI interrupt processing routine, the SCIF transfers the data from the FTDR register to the transmit shift register (TSR) and starts transmission. Confirm that the TDFE flag in the serial status register (FSR) is set to 1b before writing transmit data to the FTDR register. The number of data bytes that can be written is “16 minus the number of non-transmitted data units”.
2. When data is transferred from the FTDR register to the TSR register and transmission is started, consecutive transmit operations are performed until there is no transmit data left in the FTDR register. When the number of transmit data bytes in the FTDR register becomes equal to or less than the transmission trigger number specified in the FIFO control register (FCR) or FIFO trigger control register (FTCR), the TDFE flag is set. If the TIE bit in the serial control register (SR) is set to 1b at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated. The serial transmit data is output from the TXD pin in the following order.
   a) Start bit: One-bit 0 is output.
   b) Transmit data: 8- or 7-bit data is output in LSB-first order (when LSB-first transfer is selected).
   c) Parity bit: One parity bit (even or odd parity) is output. (A format in which a parity bit is not output can also be selected.)
   d) Stop bit(s): One or two 1 bits (stop bits) are output.
   e) Mark state: 1 is output continuously until the start bit that starts the next transmission is output.
3. The SCIF checks the transmit data of the FTDR register at the timing for sending the stop bit. If data is present, the data is transferred from the FTDR register to the TSR register, the stop bit is output, and then serial transmission of the next frame is started. If there is no data to be transmitted, the TEND flag in the FSR register is set to 1b, the stop bit is output, and then the SCIF enters the mark state (high level) in which 1 is output continuously.

Figure 7.4-5 shows an example of the operation for transmission.

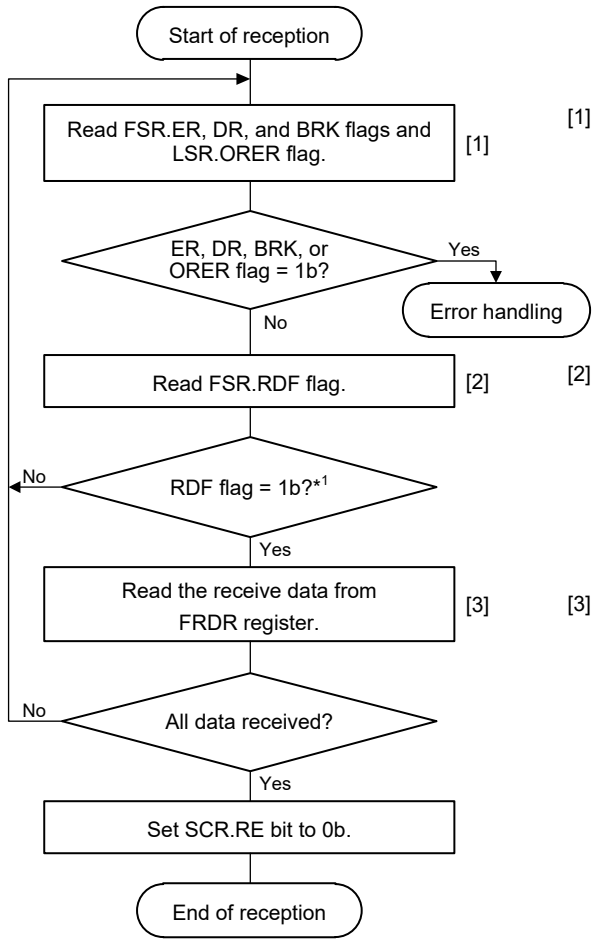


Note 1. For the corresponding interrupt number, see **8 Interrupt Controller**.

Figure 7.4-5 Example of Transmit Operation
(8-bit Data with Parity and One Stop Bit when LSB-First Transfer is Selected)

7.4.3.4.3 Receiving serial data

Figure 7.4-6 and **Figure 7.4-7** show sample flowcharts for serial reception. Follow the procedure given below for serial data reception after enabling the SCIF for reception.



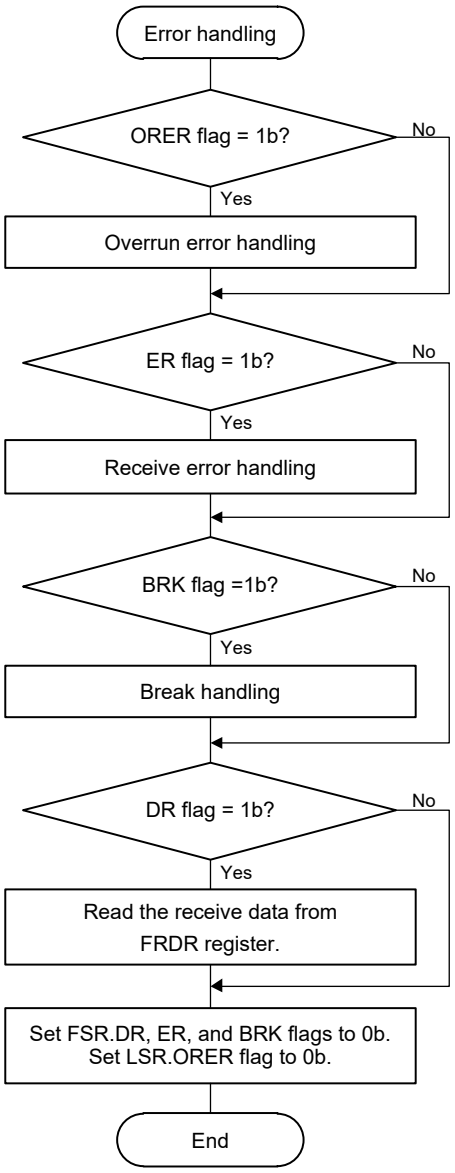
[1] Receive error handling and break detection:
When a receive error occurs, read the ER, DR, and BRK flags in the FSR register and the LSR.ORER flag to identify the error. After handling the error as specified, clear the ER, DR, BRK, and ORER flags to 0b.
In the case where a framing error occurs, a break can be detected by reading the value of the RXD pin.
Error occurrence can be known by a BRIF, ERIF, or DRIF interrupt request.

[2] Check the SCIFA status and read the receive data:
Read the FSR register, confirm that the RDF flag is set to 1b, and then read the receive data at least as much as the amount specified by the receive FIFO threshold from those stored in the FEDR register. The receive data quantity that can be read can be checked by the FDR.R[4:0] flag.
A change of the RDF flag from 0b to 1b can be known by an RXIF interrupt request.

[3] Serial reception continuation procedure:
When receive data is read from the FRDR register, the RDF flag is automatically cleared to 0b.

Note 1. The number of all the received data units should be an integral multiple of the receive FIFO threshold. If not, process returns to Step [1] and enters an infinite loop. In this case, it is necessary to set the timeout processing using a timer.

Figure 7.4-6 Sample Flowchart for Receiving Serial Data (1)



- Whether a framing error or parity error has occurred in the received data that is read from the FRDR register can be checked with the FER and PER flags in the FSR register.
- When a break signal is received, the received data is not transferred to the FRDR register while the BRK flag is set to 1b. However, note that the last data in the FRDR register is 00h and the break data in which a framing error occurred is stored.

Figure 7.4-7 Sample Flowchart for Receiving Serial Data (2)

The SCIF performs serial reception as described below.

1. The SCIF monitors the communication line, and if a 0 start bit is detected, it performs internal synchronization to start reception.
2. The received data is stored into the RSR register in LSB-to-MSB order (when LSB-first transfer is selected).
3. The parity bit and stop bit are received.
   After receiving these bits, the SCIF carries out the following checks.
   a) Stop bit check: The SCIF checks whether the stop bit is 1. If there are two stop bits, only the first is checked.
   b) The SCIF checks whether receive data can be transferred from the receive shift register (RSR) to the receive FIFO data register (FRDR).
   c) Parity bit check: The SCIF checks whether the parity bit is an expected value.
   d) Overrun error check: The SCIF checks whether the ORER flag is 0b, indicating that the overrun error has not occurred.
   e) Break check: The SCIF checks whether the BRK flag is 0b, indicating that the break state is not set.

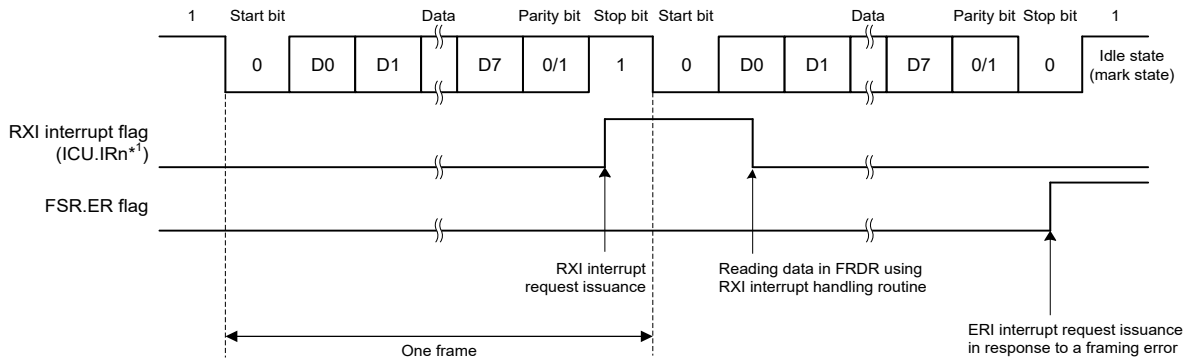
   If all the above checks are passed, the receive data is stored in the FRDR register.

   Note: When a parity error or a framing error occurs, reception is not suspended.

4. When receive data units equaling or exceeding the specified reception trigger number are stored in the receive FIFO data register (FRDR) and the RDF flag is changed to 1b, a receive FIFO data full interrupt (RXI) request is generated while the RIE bit in the SCR register is set to 1b. When the quantity of data in the FRDR register falls below the specified reception trigger number and the RIE bit in the SCR register is set to 1b, a receive data ready interrupt (DRI) request is generated if no next data is received after the elapse of 15 ETUs*[1] from the last stop bit (the DR flag in the FSR register is 1b). When the ER flag in the FSR register is changed to 1b, a receive error interrupt (ERI) request is generated while the RIE or REIE bit in the SCR register is set to 1b. When the BRK or ORER flag is changed to 1b in the FSR register, a break reception interrupt (BRI) request is generated while the RIE or REIE bit in the SCR register is set to 1b.

Note 1. It is equivalent to 1 and half frames of 8-bit format with one stop bit (ETU: Element Time Unit).

Figure 7.4-8 shows an example of the operation for reception.



Note 1. For the corresponding interrupt number, see **4.6 Interrupt control unit (ICU)**.

Figure 7.4-8 Example of SCIF Receive Operation
(8-bit Data with Parity and One Stop Bit when LSB-First Transfer is Selected)

7.4.4 Bit Rate Modulation

Using the bit rate modulation, the bit rate can be corrected by skipping the specified number of clock pulses input to the baud rate generator. To correct the bit rate, only the number of clock pulses specified in the MDDR register are enabled among 256 internal clock pulses specified by the CKS1 and CKS0 bits in the SMR register in a way that forms average intervals.

Figure 7.4-9 shows an example where the baud rate generator clock source is selected by the CKS[1:0] bits in SMR and BRR and MDDR are set to 0 and 160, respectively. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256). Note that skipping an internal clock causes bias and expansion or contraction is generated in the pulse width of the base clock.

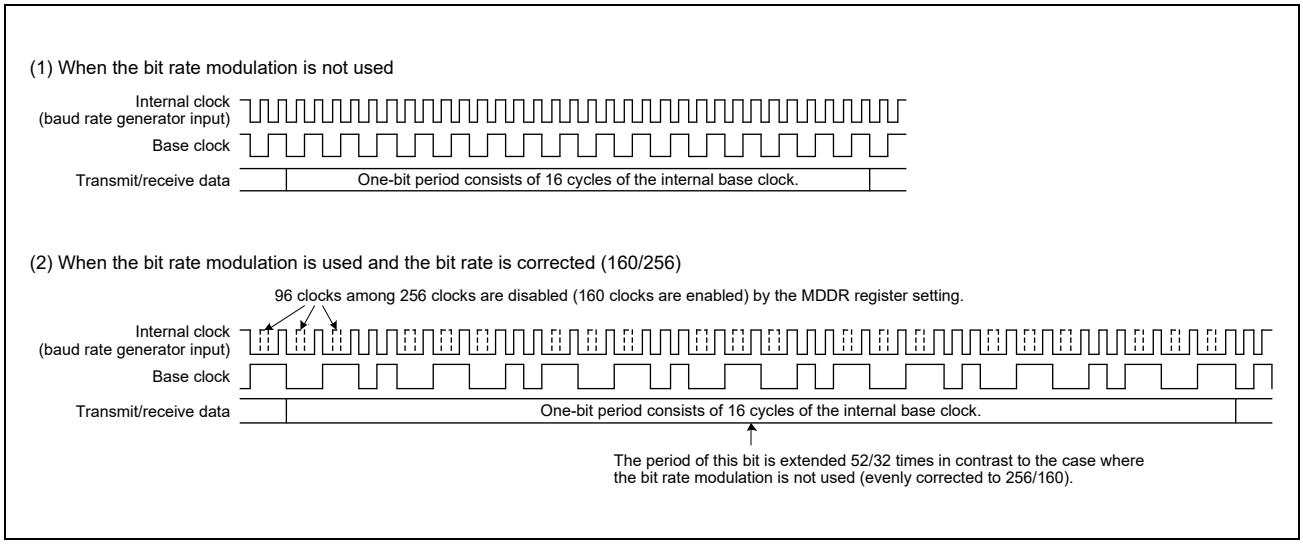


Figure 7.4-9 Example of Internal Base Clock when Bit Modulation is Used

7.4.5 Interrupt Sources

The SCIF has six interrupt sources: transmit-FIFO-data-empty (TXI), receive-error (ERI), receive-FIFO-data-full (RXI), break (BRI), transmit-end (TEI), receive-data-ready (DRI). The TEI, DRI, ERI, and BRI interrupts share the same vector number.

Table 7.4-11 shows the interrupt sources and priority. The interrupt sources can be enabled or disabled using the TIE, RIE, REIE, TEIE bits in the SCR register and are separately input to the interrupt controller.

When the quantity of transmit data written in the FTDR register as a result of transmission is equal to or less than the specified transmission trigger number, the TDFE flag in the serial status register (FSR) is set to 1b and a TXI interrupt request is generated.

When the data units equaling or exceeding the specified transmission trigger number are stored in the receive FIFO register (FRDR) and the RDF flag in the FSR register is set to 1b, a receive data full interrupt (RXI) request is generated. When the quantity of received data in the FRDR register is below the specified reception trigger number and no next data has been received yet even after the period of 15 ETUs elapsed*[1] from the last stop bit, the DR flag in the FSR register is set to 1b and a receive data ready interrupt (DRI) request is generated. In clock synchronous mode, a DRI interrupt request is not generated.

When the BRK flag in the FSR register or the ORER flag in the LSR register is set to 1b, a BRI interrupt request is issued. When the ER flag in the FSR register is set to 1b, an ERI interrupt request is issued.

When the TEND flag in the FSR register is set to 1b, a TEI interrupt request is issued.

When the RIE bit is cleared to 0b and the REIE bit in the SCR register is set to 1b, an ERI and a BRI interrupt requests are issued but an RXI interrupt request is not.

An TXI interrupt indicates that transmit data can be written and an RXI interrupt indicates that receive data is stored in the FRDR register.

Note 1. It is equivalent to 1 and half frames of 8-bit format with one stop bit (ETU: Element Time Unit).

Table 7.4-11 SCIF Interrupt Sources

Name	Level/ Edge	Interrupt Source	Interrupt Enable Bit	DMAC Activation
SCIF_ub1_brk_n	Level	Interrupt caused by break (BRK) or overrun (ORER).	RIE or REIE	Impossible
SCIF_ub1_rerr_n	Level	Interrupt caused by framing or parity (ER).	RIE or REIE	Impossible
SCIF_ub1_rxi_n	Level	Interrupt caused by receive FIFO data full (RDF).	RIE	Possible
SCIF_ub1_txi_n	Level	Interrupt caused by transmit FIFO data empty (TDFE).	TIE	Possible
SCIF_ub1_tei_nl	Level	Interrupt caused by transmit end (TEND).	TEIE	Impossible
SCIF_ub1_dri_n	Level	Interrupt caused by receive data ready (DR).	RIE	Impossible
SCIF_ub1_tei_dri_n	Level	Interrupt caused by transmit end (TEND) and receive data ready (DR)	TEIE and RIE	Impossible

Note: The TEI and DRI interrupts share the same vector number.
The ERI and BRI interrupts share the same vector number.
If CPU processing is used, clear the flag after the block transfer. If the DMAC is activated, access to the flags is prohibited.

7.4.6 Event Link Output

The SCIF handles event output for the event link controller (ELC) corresponding to the following sources.

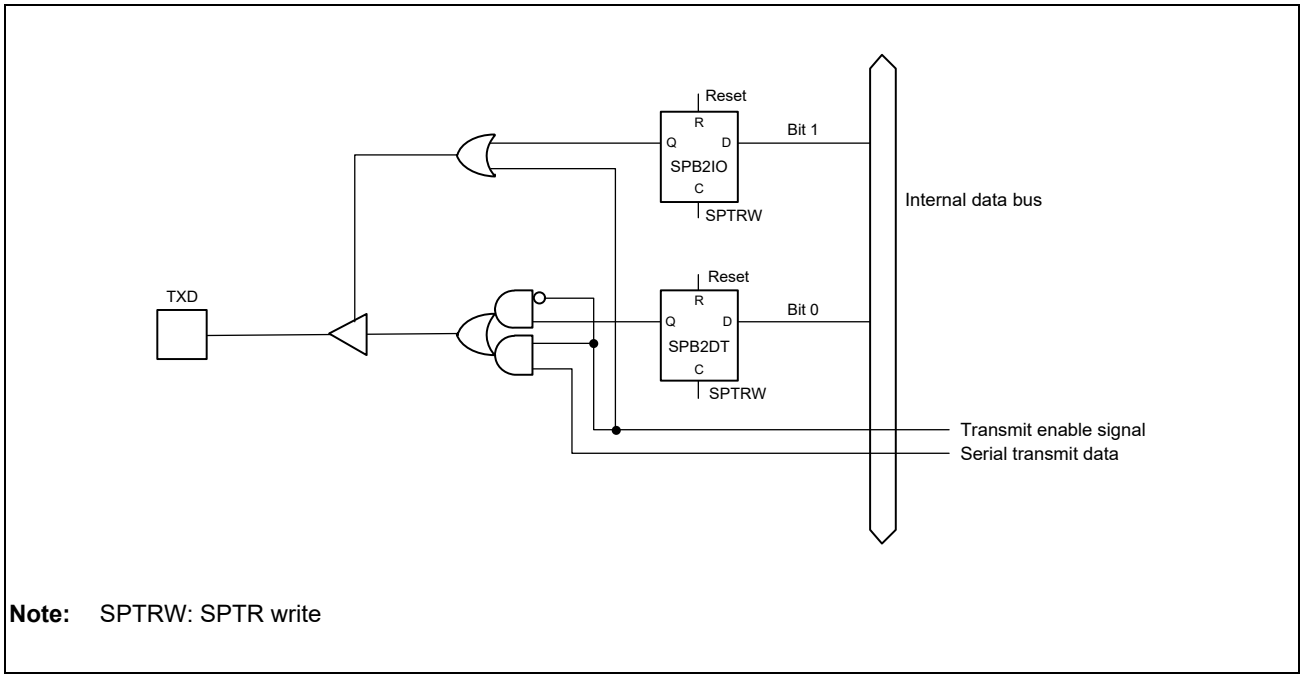
■ **Transmit FIFO data empty**

When a transmit data FIFO becomes empty, the corresponding event signal can be output for another module via the ELC.

■ **Receive FIFO data full**

When a receive data FIFO becomes full, the corresponding event signal can be output for another module via the ELC.

7.4.7 Serial Port Register (SPTR) and SCIF-Related Pins



Note: SPTRW: SPTR write

Figure 7.4-10 SPB2IO Bit and SPB2DT Bit in the SPTR Register, and TXD Pin

7.4.8 Noise Cancellation

Figure 7.4-11 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a two-stage flip-flop circuits and a match detection circuit. When the input signals of the noise filter and the output signals of the two-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. (When the levels sampled on three consecutive cycles of the sampling clock of the noise filter match, the signal is considered valid. If three consecutive sampled values do not match, the signal is considered to be noise rather than a received signal).

The noise cancellation can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn pin is taken in the flip-flop circuit of the noise filter on the base clock (the clock with a frequency 16 or 8 times the transfer rate*[1]).

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.RE is set to 0b during input of the base clock, the noise filter outputs 0 as the internal RxDn signal. The internal match detector continues operating even while operations for reception are stopped, and the result from the last time previous consecutive samples matched is output at the same time as operations for reception are resumed.

Note 1. A frequency 16 times bit rate when the SEMR.ABCS0 bit and the SEMR.BGDM bit are both 0b, and a frequency 8 times bit rate when either the SEMR.ABCS0 bit or the SEMR.BGDM bit is 1b.

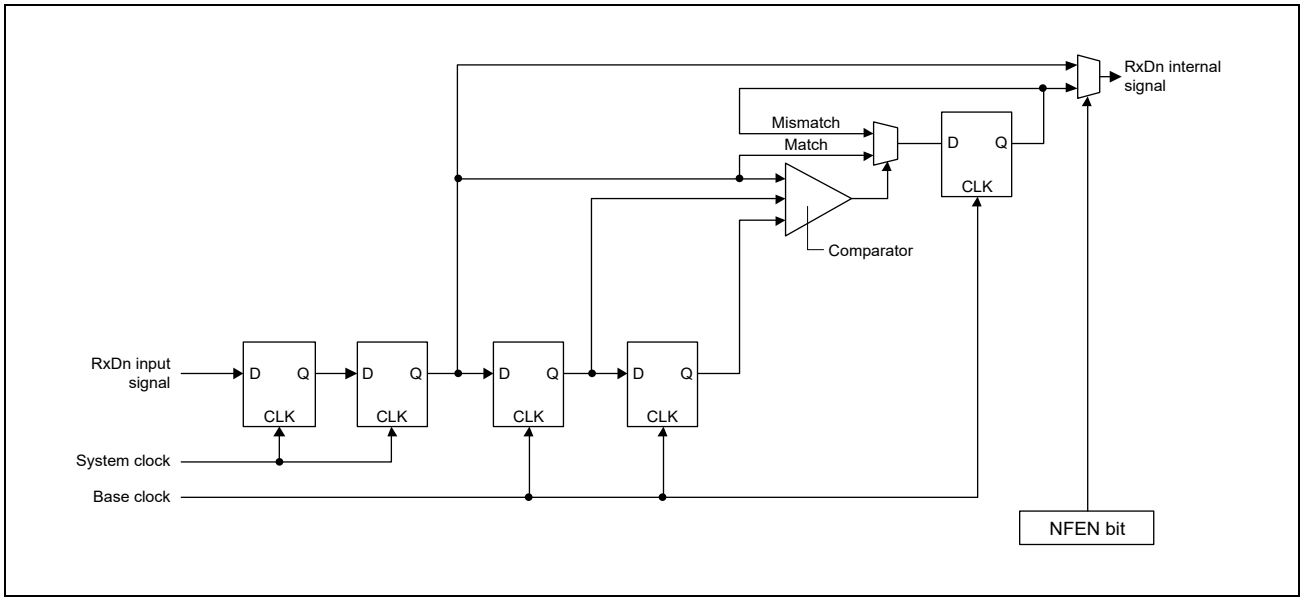


Figure 7.4-11 Block Diagram of Digital Noise Filter Circuit

7.4.9 Usage Notes

The following is the notes on using the SCIF.

7.4.9.1 FTDR Register Writing and TDFE Flag

The TDFE flag in the serial status register (FSR) is set when the number of transmit data bytes written in the transmit FIFO data register (FTDR) has fallen below the transmission trigger number set by bits TTRG[1:0] in the FIFO control register (FCR) or bits TFTC[4:0] in the FIFO trigger control register (FTCR). After the TDFE flag is set, transmit data up to the number of empty bytes in the FTDR register can be written, allowing efficient continuous transmission.

However, if the number of data bytes written in the FTDR register is equal to or less than the specified transmission trigger number, the TDFE flag will be set to 1b again even after being read as 1b and cleared to 0b.

The number of transmit data bytes in the FTDR register can be checked by the 8 higher-order bits of the FIFO data count register (FDR).

7.4.9.2 FRDR Register Reading and RDF Flag

The RDF flag in the serial status register (FSR) is set when the number of receive data bytes in the receive FIFO data register (FRDR) has become equal to or greater than the reception trigger number set by bits RTRG[1:0] in the FIFO control register (FCR) or bits RFTC[4:0] in the FIFO trigger control register (FTCR). After the RDF flag is set, receive data equivalent to the trigger number can be read from the FRDR register, allowing efficient continuous reception.

However, if the number of data bytes in the FRDR register exceeds the reception trigger number, the RDF flag will be set to 1b again even after being read as 1b and cleared to 0b.

The number of receive data bytes in the FRDR register can be checked by the 8 lower-order bits of the FIFO data count register (FDR).

7.4.9.3 Break Detection and Processing

When a framing error (FER) is detected, a break signal can be detected by reading the RXD pin value directly. In a break, the input from the RXD pin becomes all low. Therefore, the FER flag in the serial status register (FSR) is set to 1b and the parity error flag (PER) may also be set to 1b.

Upon detection of a break signal, the SCIF stops the received data transfer to the FRDR register but continues the receive operation.

7.4.9.4 Writing to the SPTR Register

b0 of the SPTR register indicates the input status of the corresponding pin. (See the description of the bit in **7.4.2.2.12 Serial Port Register (SCIFm_**SPTR) for details.)

7.4.9.5 Break Signal Transmission

The output signal from the TXD pin is determined by the SPB2IO bit and the SPB2DT bit in the serial port register (SPTR). The break signal can be sent by using these bits.

The TXD pin does not function as a transmit data output pin during the period from when the SCIF is initialized to when the TE bit in the SCR register is set to 1b (transmission possible). The TXD pin status during this period is replaced by the SPB2DT bit value. Therefore, the SPB2IO and SPB2DT bits in the SPTR register must have been set to 1b (high output) at first (mark (high) status).

To transmit the break signal during serial transmission, set the SPB2IO bit in the SPTR register to 1b, clear the SPB2DT bit to 0b (specify a low level), and then clear the TE bit in the SCR register to 0b (transmission stop). Clearing the TE bit to 0b initializes the transmitter regardless of the current transmission status, and outputs a low level from the TXD pin.

7.4.9.6 Receive Data Sampling Timing and Receive Margin

The SCIF operates on a base clock with a frequency 16 times the transfer rate*[1]. In reception, the SCIF internally latches the received data at the rising edge of the eighth base clock pulse*[1]. The timing is shown in **Figure 7.4-12**.

Note 1. This is an example when the SEMR.ABCS0 bit is 0b. When the ABCS0 bit is 1b, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock. The receive margin can therefore be expressed as shown in equation 1.

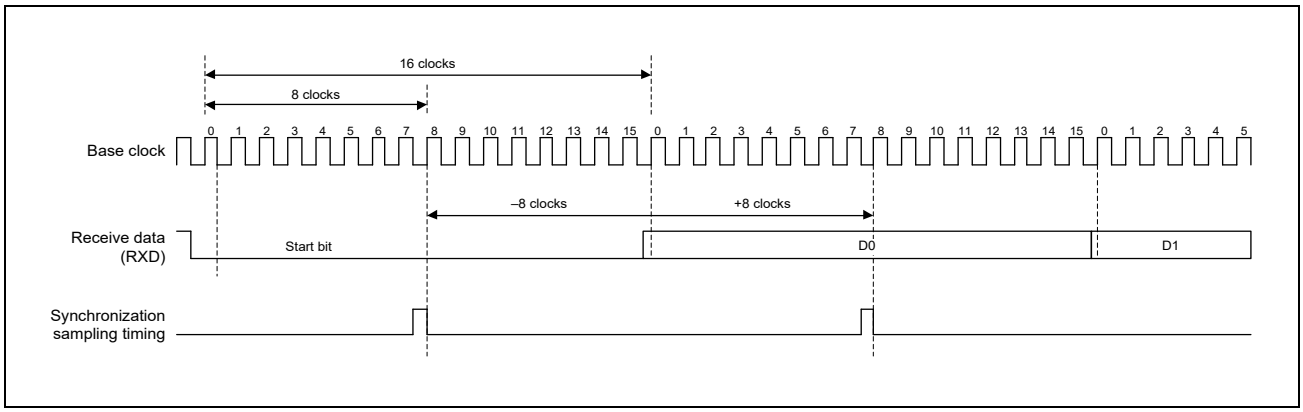

Figure 7.4-12 Receive Data Sampling Timing

The receive margin can therefore be expressed as shown in equation 1.

[Equation 1]

$$M = \{(0.5 - \frac{1}{2N} - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\} \times 100[\%]$$

Where: M: Receive margin (%)
N: Ratio of clock frequency to bit rate (N = 16)
D: Clock duty (D = 0 to 1.0)
L: Frame length (L = 9 to 12)
F: Absolute deviation of clock frequency

From equation 1, if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation 2.

[Equation 2]

When D = 0.5 and F = 0:

$$M = (\frac{0.5 - 1}{(2 \times 16)}) \times 100\% = 46.875\%$$

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

7.4.9.7 Note on FER Flag and PER Flag in Serial Status Register (FSR)

The FER flag and PER flag in the serial status register (FSR) are status flags that apply to next entry to be read from the receive FIFO data register (FRDR). After the CPU or DMAC reads the receive FIFO data register, the flags of framing errors and parity errors in the receive data will be cleared. To check the received data for the states of framing errors and parity errors, only read the receive FIFO data register after reading the serial status register.

SECTION 7 LOW-SPEED INTERFACE

7.5 Serial Peripheral Interface (RSPI)

7.5.1 Overview

The RSPI (hereafter SPI) supports serial communications for transmit-receive, transmit only, and receive only. The SPI is provided with a function for high-speed serial communication with multiple processors and peripheral devices.

7.5.1.1 Features

Table 7.5-1 lists the specifications of the SPI, and **Figure 7.5-1** shows a block diagram of the SPI.

Table 7.5-1 SPI Specifications (1/3)

Item	Description
Number of channels	3 channels
Transfer functions	• SPI serial communication (4-wire) and clock synchronous (3-wire) serial communication are possible by using the MOSI (Master Out Slave In), MISO (Master In Slave Out), SSL (Slave Select), and RSPCK (SPI Clock) signals. • Transmit-only operation is available • Receive-only operation is available • Serial communication is possible in master mode and slave mode • RSPCK polarity switching • RSPCK phase switching
Data format	• MSB first or LSB first selectable. • Transfer bit length selectable from 4 to 32 bits • 32 bit × 16 stage FIFO transmit and receive buffers • Up to four frames transferable in one round of transmission or reception (each frame consisting of up to 32 bits) • Byte swap operating function • Transmit/receive data inversion
Bit rate	• In master mode, the on-chip baud rate generator divides the RSPI_n_TCLK to generate RSPCK. A division ratio of 2 to 4096 is settable. • In slave mode, an external input clock is used as a serial clock. The maximum frequency = RSPI_n_TCLK/2 (High width: 1 RSPI_n_TCLK cycle, low width: 1 RSPI_n_TCLK cycle)
Buffer configuration	• Transmit buffer and receive buffer are configured independently.
Error detection	• Mode fault error detection • Underrun error detection • Overrun error detection • Parity error detection

Table 7.5-1 SPI Specifications (2/3)

Item	Description
SSL control function	**[Motorola SPI mode]** • Four SSL pins (SSLn0 to SSLn3) each channel • In master mode, SSLn0 to SSLn3 pins are output. • In slave mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins unused • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Configurable delay between frames in burst transfer • Function for changing SSL polarity **[TI SSP mode]** • Four SSL pins (SSL0 to SSL3) each channel • In master mode, SSLn0 to SSLn3 pins are output. • In slave mode, SSLn0 pin for input, and SSLn1 to SSLn3 pins unused • Controllable delay from SSL output assertion to SSL output negation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to Output disable (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Configurable delay between frames in burst transfer • Function for changing SSL polarity
Communication Protocol	• Motorola SPI • TI SSP (Synchronous Serial Protocol)
Synchronization bypass function	• Synchronization circuit can be bypassed using bus clock (RSCI_n_PCLK) as operation clock (RSCI_n_TCLK)
Control in master transfer	**[Motorola SPI mode]** • Transfers of up to eight commands each can be executed sequentially in looped execution • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, LSB first/MSB first, burst, RSPCK delay, SSL negation delay, next-access delay • Transfers can be initiated by writing to the transmit buffer • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function **[TI SSP mode]** • Transfers of up to eight commands each can be executed sequentially in looped execution • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, LSB first/MSB first, burst, RSPCK delay, SSL negation delay (Output disable delay), next- access delay • Transfers can be initiated by writing to the transmit buffer • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function
Interrupt sources	• Maskable Interrupt sources SPI receive buffer full / Receive data ready interrupt SPI transmit buffer empty interrupt SPI communication end interrupt SPI error interrupt (mode fault, overrun, parity error, receive data ready) SPI idle interrupt (SPI idle)

Table 7.5-1 SPI Specifications (3/3)

Item	Description
Others	• SPI disable (initialization) function • Loopback mode function
Module-stop function	Module-stop state can be set to reduce power consumption*1

Note 1. Module stop condition: It depends on the setting higher than this module. This module is not reset, and the clock stops on module stop condition. It contributes to low power consumption, because the clock stops.

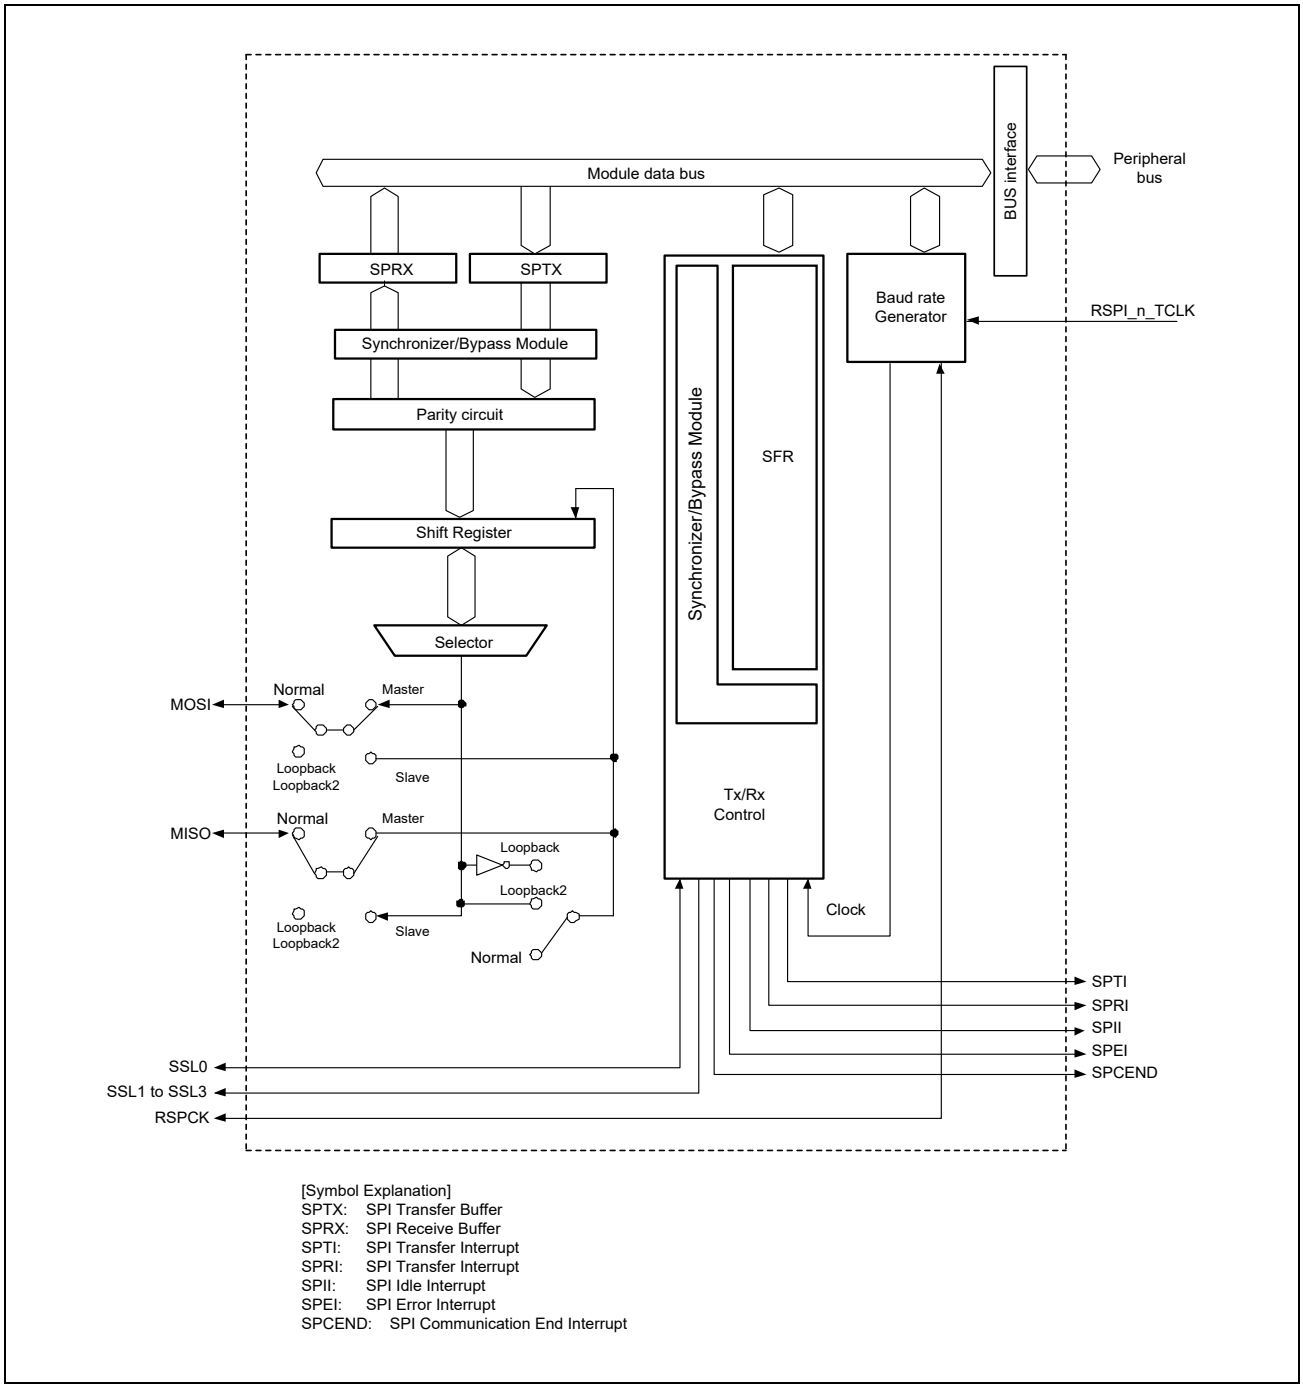

Figure 7.5-1 SPI Block Diagram

The SPI automatically switches the SSL0 pin input and output directions. The SSL0 pin is switched to output when master is set, and it is switched to input when slave is set. Furthermore, the SPI automatically switches the input and output directions of pins RSPCK, MOSI, MISO, SSL1 to SSL3 according to the master/slave setting and SPI operation (4-wire)/clock synchronous operation (3-wire) SSL0 input level. (See **7.5.3.2 SPI Pin Control**.)

Table 7.5-2 lists the I/O pins used in the SPI.

Table 7.5-2 SPI Pin Configuration

Channel	Pin Name	Signal Name	Input/Output	Function
RSPI0	RSPCKA	RSPCK	I/O	Clock I/O
	MOSIA	MOSI	I/O	Master transmit data I/O
	MISOA	MISO	I/O	Slave transmit data I/O
	SSLA0	SSL0	I/O	Slave selection signal I/O
	SSLA1	SSL1	Output	Slave selection signal output
	SSLA2	SSL2	Output	Slave selection signal output
	SSLA3	SSL3	Output	Slave selection signal output
RSPI1	RSPCKB	RSPCK	I/O	Clock I/O
	MOSIB	MOSI	I/O	Master transmit data I/O
	MISOB	MISO	I/O	Slave transmit data I/O
	SSLB0	SSL0	I/O	Slave selection signal I/O
	SSLB1	SSL1	Output	Slave selection signal output
	SSLB2	SSL2	Output	Slave selection signal output
	SSLB3	SSL3	Output	Slave selection signal output
RSPI2	RSPCKC	RSPCK	I/O	Clock I/O
	MOSIC	MOSI	I/O	Master transmit data I/O
	MISOC	MISO	I/O	Slave transmit data I/O
	SSLC0	SSL0	I/O	Slave selection signal I/O
	SSLC1	SSL1	Output	Slave selection signal output
	SSLC2	SSL2	Output	Slave selection signal output
	SSLC3	SSL3	Output	Slave selection signal output

7.5.2 Registers

The base addresses for the respective channels are as follows.

Table 7.5-3 Register Base Addresses

Base Register Name	Channel	Base Address
<RSPI0_base>	RSPI0	0_1280_0000h (5280_0000h*1, 4280_0000h*2)
<RSPI1_base>	RSPI1	0_1280_0400h (5280_0400h*1, 4280_0400h*2)
<RSPI2_base>	RSPI2	0_1280_0800h (5280_0800h*1, 4280_0800h*2)

Note 1. CM33 Address Space Non-Secure

Note 2. CM33 Address Space Secure

7.5.2.1 List of Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]*1
SPI Data Register	RSPIm_SPDR/SPDR_HA/SPDR_BY	0000_0000h	0000h	8, 16, 32
SPI Clock Delay Register	RSPIm_SPCKD	00h	0004h	8
SPI Slave Select Negation Delay Register	RSPIm_SSLND	00h	0005h	8
SPI Next-Access Delay Register	RSPIm_SPND	00h	0006h	8
SPI Clock Digital Control Register for Master Receive	RSPIm_MRCKD	00h	0007h	8
SPI Control Register	RSPIm_SPCR	0000_0000h	0008h	8, 16, 32
SPI Control Register for Master Receive only	RSPIm_SPCRRM	00h	000Ch	8
SPI Control Register for Received Data Ready Detection	RSPIm_SPDRCR	00h	000Dh	8
SPI Pin Control Register	RSPIm_SPPCR	00h	000Eh	8
SPI Control Register 2	RSPIm_SPCR2	00h	000Fh	8
SPI Slave Select Polarity Register	RSPIm_SSLP	00h	0010h	8
SPI Bit Rate Register	RSPIm_SPBR	FFh	0011h	8
Reserve	-	-	0012h to 0012h	-
SPI Sequence Control Register	RSPIm_SPSCR	00h	0013h	8
SPI Command Register 0	RSPIm_SPCMD0	0007_0000h	0014h	8, 16, 32
SPI Command Register 1	RSPIm_SPCMD1	0007_0000h	0018h	8, 16, 32
SPI Command Register 2	RSPIm_SPCMD2	0007_0000h	001Ch	8, 16, 32
SPI Command Register 3	RSPIm_SPCMD3	0007_0000h	0020h	8, 16, 32
SPI Command Register 4	RSPIm_SPCMD4	0007_0000h	0024h	8, 16, 32
SPI Command Register 5	RSPIm_SPCMD5	0007_0000h	0028h	8, 16, 32
SPI Command Register 6	RSPIm_SPCMD6	0007_0000h	002Ch	8, 16, 32
SPI Command Register 7	RSPIm_SPCMD7	0007_0000h	0030h	8, 16, 32
Reserve	-	-	0034h to 003Fh	-
SPI Data Control Register	RSPIm_SPDCR	0000h	0040h	8, 16
Reserve	-	-	0042h to 0043h	-
SPI Data Control Register 2	RSPIm_SPDCR2	0000h	0044h	8, 16
Reserve	-	-	0046h to 0050h	-
SPI Sequence Status Register	RSPIm_SPSSR	00h	0051h	8
SPI Status Register	RSPIm_SPSR	2000h	0052h	8, 16
Reserve	-	-	0054h to 0057h	-
SPI Transfer FIFO Status Register	RSPIm_SPTFSR	04h	0058h	8
Reserve	-	-	0059h to 005Bh	-
SPI Receive FIFO Status Register	RSPIm_SPRFSR	00h	005Ch	8
Reserve	-	-	005Dh to 005Fh	-
SPI Polling Register	RSPIm_SPPSR	0000_0000h	0060h	8, 16, 32
Reserve	-	-	0064h to 0069h	-

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
SPI Status Clear Register	RSPIm_SPSRC	0000h	006Ah	8, 16
SPI FIFO Clear Register	RSPIm_SPFCR	00h	006Ch	8

Note 1. The read access size is fixed at 32 bits.

7.5.2.2 Register Description

The prefix (RSPIm_) of the register names is omitted in this and subsequent sections.

7.5.2.2.1 SPI Data Register (RSPIm_SPDR/SPDR_HA/SPDR_BY)

Access Size : 8, 16, 32 bits
Address : <RSPIm_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SPD[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

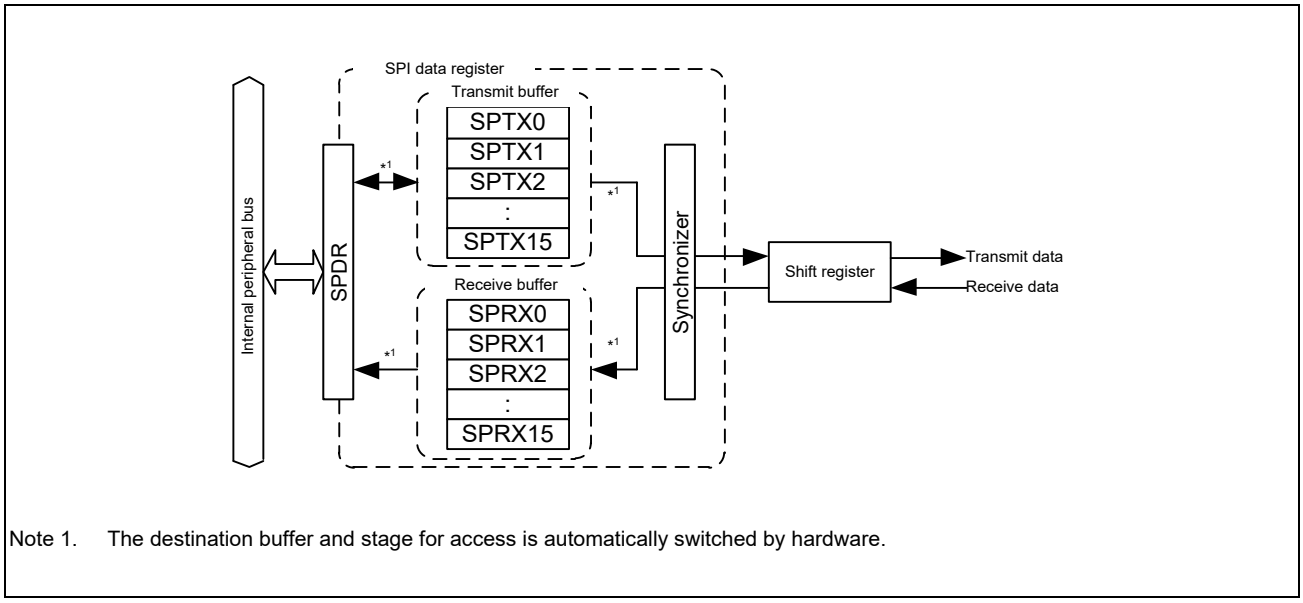
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPD[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SPD[31:0]	0h	RW	The SPI data register (SPDR) is used to store SPI's transmit data and receive data. Transmit buffers and receive buffers independently function.

Note: The read access size is fixed at 32 bits.

SPDR is the interface with the buffers that hold data for transmission and reception by the SPI.

Figure 7.5-2 shows the structure of SPDR.



Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 7.5-2 Structure of SPDR

32 bit × 16 stage transmit FIFO and 32 bit × 16 receive FIFO are provided. These 32 stage FIFO are mapped to one address in the SPDR. Transmit buffers (SPTXn, n = 0 to 15) can be written by writing data to SPDR to transmit written data.

Upon completion of receiving data, receive buffers store received data. When an overrun error occurs, data in the receive buffer is not updated.

Bus Interface

The SPI data register has 32 bit × 16 stage transmit FIFO and 32 bit × 16 receive FIFO (32 bytes in total). These 128 bytes are mapped to the 4-byte space of SPDR. Write transmit data from the LSB. Received data is stored from the LSB.

SPDR register write operation and read operation are described below.

a) Write

A transmit buffer write pointer is provided for transmit buffers. When data is written to SPDR, the pointer automatically switches to the next buffer. The following illustrates the structure of the transmit buffer bus interface (write).

Figure 7.5-3 shows the configuration of the bus interface with the transmission buffer in the case of writing to SPDR.

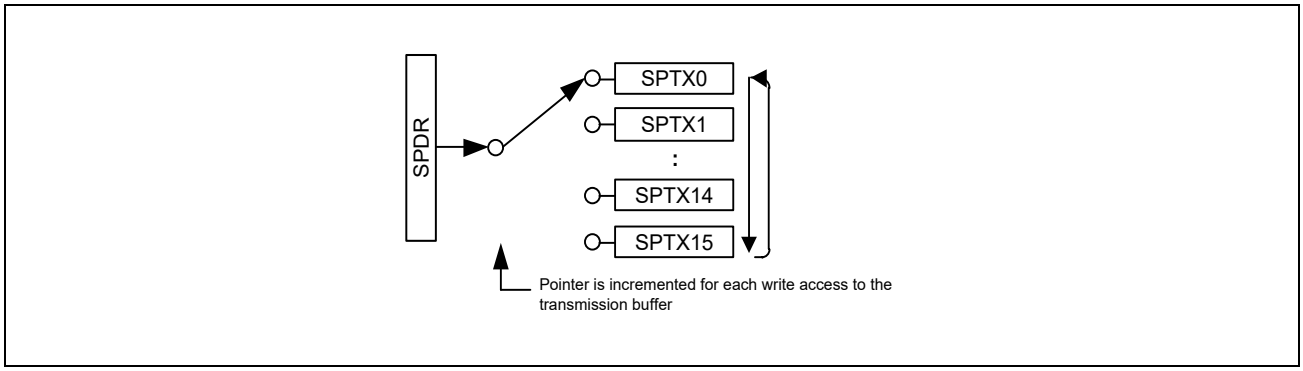


Figure 7.5-3 Structure of SPDR (Write)

The transmit buffer (SPTX0 to SPTX3) switching order:

SPTX0→SPTX1→SPTX2→SPTX3→…→SPTX15→SPTX0→SPTX1→…

When writing transmit data to transmit buffers (SPTXn), write transmit data of frames +1 specified by the Transmission FIFO threshold setting bits of SPI data control register 2 (SPDCR2.TTRG[1:0]) while an SPI transmit buffer empty interrupt is present (SPSR.SPTEF flag = 1b). Writing to the transmit buffer (SPTXn, n = 0 to 15) in the state where there is no empty stage in the transmit FIFO does not update the buffer value.

b) Read

Values can be read from receive buffers (SPRXn, n = 0 to 15) or transmit buffers (SPTXn, n = 0 to 15) by reading the SPDR register. Reading a receive buffer or reading a transmit buffer can be selected by the SPI receive data or transmit data select bit (SPDCR.SPRDTD).

The SPDR register is read according to the independent receive buffer read pointer and the transmit buffer read pointer.

The following illustrates the structure of the receive buffer and transmit buffer bus interface (read).

Figure 7.5-4 shows the configuration of the bus interface with the receive and transmission buffers in the case of reading from SPDR.

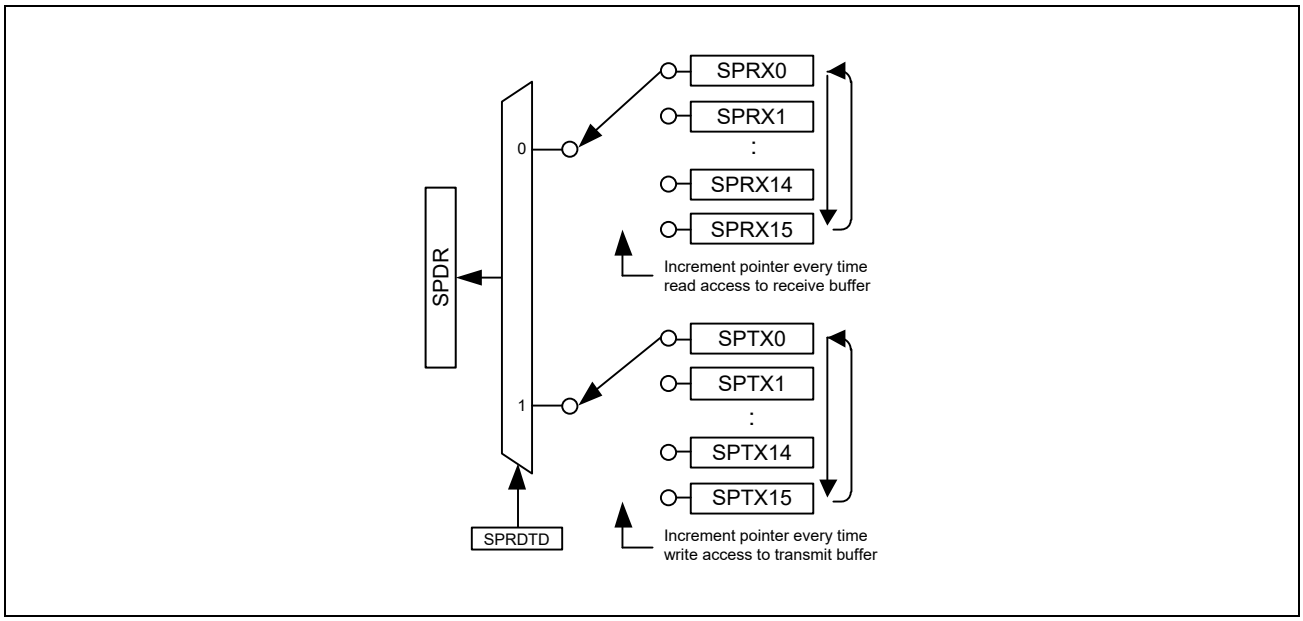

Figure 7.5-4 Structure of SPDR (Read)

When a receive buffer is read, the receive buffer read pointer automatically switches to the next buffer. The receive buffer read pointer switches in the same order as the transmit buffer write pointer.

The transmit buffer read pointer is updated during the SPDR write access, but it is not updated during the transmit buffer read access. When a transmit buffer is read, the value written to SPDR last can be read.

7.5.2.2.2 SPI Clock Delay Register (RSPIm_SPCKD)

Access Size : 8 bits
Address : <RSPIm_base> + 0004h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	SCKDL[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	SCKDL[2:0]	0h	RW	RSPCK Delay Setting 000b: 1 RSPCK 001b: 2 RSPCK 010b: 3 RSPCK 011b: 4 RSPCK 100b: 5 RSPCK 101b: 6 RSPCK 110b: 7 RSPCK 111b: 8 RSPCK

[In the Motorola-SPI case]

The SPCKD register is used to set the period (RSPCK delay) from the start of assertion of the SSL signal to the RSPCK oscillation while SPCMD.SCKDEN = 1b. If SPCKD is modified while SPCR.MSTR = 1b and SPCR.SPE = 1b, subsequent operation is not guaranteed.

[In the TI-SSP case]

The SPCKD register is used to set the period (RSPCK delay) from the start of assertion of the SSL signal to the RSPCK oscillation while SPCMD.SCKDEN = 1b. Also, it is used to set the period until the SSL signal is negated. If SPCKD is modified while SPCR.MSTR = 1b and SPCR.SPE = 1b, subsequent operation is not guaranteed.

SCKDL[2:0] bits (RSPCK Delay Setting)

These bits are used to set the RSPCK delay value when SPCMD.SCKDEN = 1b.

To use the SPI in slave mode, set SCKDL[2:0] bits to 0b.

7.5.2.2.3 SPI Slave Select Negation Delay Register (RSPIm_SSLND)

Access Size : 8 bits
Address : <RSPIm_base> + 0005h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	SLNDL[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	SLNDL[2:0]	0h	RW	SSL Negation Delay Bits This is the synchronization delay for replacing the RSPCK input with RSPI_n_TCLK. RSPCK Delay Setting 000b: 1 RSPCK [Master mode] 1 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 001b: 2 RSPCK [Master mode] 2 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 010b: 3 RSPCK [Master mode] 3 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 011b: 4 RSPCK [Master mode] 4 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 100b: 5 RSPCK [Master mode] 5 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 101b: 6 RSPCK [Master mode] 6 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 110b: 7 RSPCK [Master mode] 7 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode] 111b: 8 RSPCK [Master mode] 8 RSPI_n_TCLK + (2~3 RSPI_n_TCLK (Synchronization delay)) [TI-SSP case in Slave Mode]

[In the Motorola-SPI case]

The SSLND register is used to set the period (SSL negation delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the SSL signal while SPCMD.SCKDEN = 1b. If SSLND is modified while SPCR.MSTR = 1b and SPCR.SPE = 1b, subsequent operation is not guaranteed.

[In the TI-SSP case]

The SSLND register is used to set the period (Output disable delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the Output enable signal while SPCMD.SCKDEN = 1b. Also, that is used to set the period from when the SPI in slave mode detects the last RSPCK edge of serial transfer to when the Output enable signal is negated. If SSLND is modified while the SPE bit in SPCR.SPE = 1b, subsequent operation is not guaranteed.

SLNDL[2:0] bits (SSL Negation Delay Bits)

[In the Motorola-SPI case]

These bits are used to set the SSL negation delay value when SPCMD.SLNDEN = 1b.
To use the SPI in slave mode except TI-SSP, set SLNDL[2:0] bits to 0b.

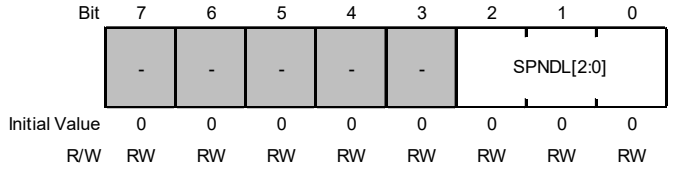
[In the TI-SSP case]

These bits are used to set the Output disable delay value when SPCMD.SLNDEN = 1b.

7.5.2.2.4 SPI Next-Access Delay Register (RSPIm_SPND)

The SPND register is used to set the SSL signal inactive period (next-access delay) after completion of serial transfer while SPCMD.SCKDEN = 1b. If SPND is modified while SPCR.MSTR = 1b and SPCR.SPE = 1b, subsequent operation is not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 0006h
Initial Value : 00h



Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	SPNDL[2:0]	0h	RW	SPI Next-Access Delay Bits RSPCK Delay Setting 000b: 1 RSPCK + 5 RSPI_n_TCLK 001b: 2 RSPCK + 5 RSPI_n_TCLK 010b: 3 RSPCK + 5 RSPI_n_TCLK 011b: 4 RSPCK + 5 RSPI_n_TCLK 100b: 5 RSPCK + 5 RSPI_n_TCLK 101b: 6 RSPCK+ 5 RSPI_n_TCLK 110b: 7 RSPCK + 5 RSPI_n_TCLK 111b: 8 RSPCK + 5 RSPI_n_TCLK

SPNDL[2:0] bits (SPI Next-Access Delay Bits)

These bits are used to set the next-access delay value when SPCMD.SCKDEN = 1b. To use the SPI in slave mode, set SPNDL[2:0] bits to 0b.

7.5.2.2.5 SPI Clock Digital Control Register for Master Receive (RSPIm_MRCKD)

The MRCKD register is a register for adjusting the reception sampling timing in master mode. If the ARST[2:0] bits are rewritten while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 0007h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	ARST[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	ARST[2:0]	0h	RW	Receive Sampling Timing Adjustment Bits The sampling of the serial data (MISO) input in master mode can be adjusted by delaying 0 to 7 RSPI_n_TCLK from the center of the bit. 000b: 0 RSPI_n_TCLK delay 001b: 1 RSPI_n_TCLK delay 010b: 2 RSPI_n_TCLK delay 011b: 3 RSPI_n_TCLK delay 100b: 4 RSPI_n_TCLK delay 101b: 5 RSPI_n_TCLK delay 110b: 6 RSPI_n_TCLK delay 111b: 7 RSPI_n_TCLK delay

ARST[2:0] bits (Receive Sampling Timing Adjustment Bits)

These bits are used to select the amount of reception sampling timing adjustment. The sampling timing can be adjusted by delaying 0 to 7 RSPI_n_TCLK from the center of the bit.

Delay setting exceeding the dividing ratio is prohibited.

This bit setting is valid only when the loopback function is not used (when SPPCR.SPLP = 0b, when MRCLK is selected (SPCR.SPSCKSEL = 1b), and SPPCR.SPLP2 = 0b) and in master mode. For details, see SPSCKSEL bit of **7.5.2.2.6 SPI Control Register (RSPIm_**SPCR).

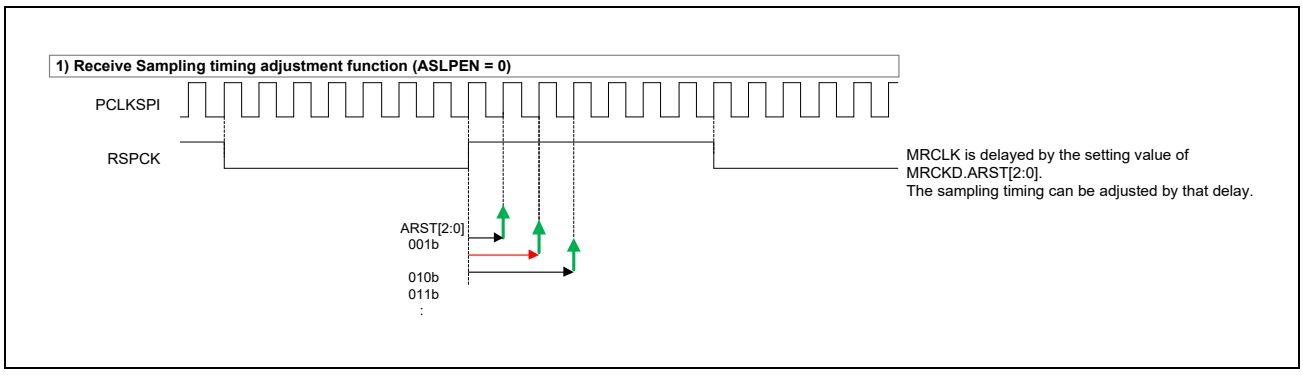


Figure 7.5-5 Description about Receive Sampling Timing Adjustment Function

7.5.2.2.6 SPI Control Register (RSPIm_SPCR)

The SPCR register is used to set operating mode of the SPI. If the set MSTR, TXMD[1:0], SPFRF, SPMS, MODFEN, BFDS, SCKASE, PTE, SPOE, SPPE, SPSCKSEL, and BPEN bit value is modified while SPCR.SPE = 1b, subsequent operation is not guaranteed.

Access Size : 8, 16, 32 bits
Address : <RSPIm_base> + 0008h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BPEN	MSTR	TXMD[1:0]		-	-	SPFRF	SPMS	-	-	CENDIE	SPTIE	SPDRES	SPIIE	SPRIE	SPEIE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	BPEN	0h	RW	Synchronization Circuit Bypass Enable 0b: Non-Bypass 1b: Bypass
30	MSTR	0h	RW	SPI Master/Slave Mode Select 0b: Slave mode 1b: Master mode
29, 28	TXMD[1:0]	0h	RW	Communication Mode Select 00b: Transmit-Receive 01b: Transmit only 1xb: Receive only
27, 26	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
25	SPFRF	0h	RW	SPI Frame Format Select When SPMS = 1 (clock synchronous operation (3-wire)), this bit setting is invalid. 0b: Motorola-SPI 1b: TI-SSP
24	SPMS	0h	RW	SPI Function Enable 0b: SPI operation (4-wire) 1b: Clock synchronous operation (3-wire)
23, 22	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
21	CENDIE	0h	RW	SPI Communication End Interrupt Enable 0b: Communication end interrupt request is disabled. 1b: Communication end interrupt request is enabled.
20	SPTIE	0h	RW	SPI Transmit Buffer Empty Interrupt Enable 0b: SPI transmit buffer empty interrupt request is disabled. 1b: SPI transmit buffer empty interrupt request is enabled.
19	SPDRES	0h	RW	SPI Receive Data Ready Error Select 0b: Receive data full interrupt 1b: Error interrupt
18	SPIIE	0h	RW	SPI Idle Interrupt Enable 0b: Idle interrupt request is disabled. 1b: Idle interrupt request is enabled.
17	SPRIE	0h	RW	SPI Receive Buffer Full Interrupt Enable 0b: SPI receive buffer full interrupt request is disabled. 1b: SPI receive buffer full interrupt request is enabled.
16	SPEIE	0h	RW	SPI Error Interrupt Enable 0b: SPI error interrupt request is disabled. 1b: SPI error interrupt request is enabled.

Bit	Bit Name	Initial Value	R/W	Description
15	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
14	MODFEN	0h	RW	Mode Fault Error Detection Enable 0b: Mode fault error detection is disabled. 1b: Mode fault error detection is enabled.
13	BFDS	0h	RW	Between Burst Transfer Frames Delay Select 0b: Delay (RSPCK delay, SSL negation delay and next-access delay) between frames is inserted in burst transfer. 1b: Delay between frames is not inserted in burst transfer.
12	SCKASE	0h	RW	RSPCK Auto-Stop Function Enable 0b: RSPCK auto-stop function is disabled. 1b: RSPCK auto-stop function is enabled.
11	PTE	0h	RW	Parity Self-Diagnosis Enable 0b: Parity circuit self-diagnosis function is disabled. 1b: Parity circuit self-diagnosis function is enabled.
10	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9	SPOE	0h	RW	Parity Mode 0b: Even parity is used for transmission and reception. 1b: Odd parity is used for transmission and reception.
8	SPPE	0h	RW	Parity Enable 0b: A parity bit is not added to transmit data. Received-data parity check is not performed. 1b: A parity bit is added to transmit data. Received-data parity check is performed.
7	SPSCKSEL	0h	RW	SPI Master Receive Clock Select 0b: MRIOCLK (Adjust with Analog Delay (SPCR2.SPSCKDL)) 1b: MRCLK (Adjust with Digital Delay (MRCKD.ARST))
6 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	SPE	0h	RW	SPI Function Enable 0b: SPI function is disabled. 1b: SPI function is enabled.

Note: The read access size is fixed at 32 bits.

SPE bit (SPI Function Enable)

The SPE bit is used to enable or disable SPI functions. Setting this bit to 1b enables SPI functions. When SPSR.MODF = 1b, the SPCR.SPE bit is cleared to 0b and the SPCR.SPE bit cannot be set to 1b until the MODF flag is cleared to 0b. (See **7.5.3.10 Error Detection**.) Setting the SPE bit to 0b disables SPI functions and initializes a part of module functions. (See **7.5.3.12 SPI Initialization**.)

SPSCKSEL bit (SPI Master Receive Clock Select)

The SPSCKSEL bit selects the clock used to sample the received data in master mode. By setting this bit, the sampling timing of the MISO can be adjusted. This bit setting is valid only when the loopback function is not used (when SPPCR.SPLP = 0b and SPPCR.SPLP2 = 0b) and in master mode.

Figure 7.5-6 shows a Master Receive Clock Delay configuration. By selecting this bit, you can select MRIOCLK (adjust with analog delay (SPCR2.SPSCKDL)) or MRCLK (adjust with digital delay (MRCKD.ARST)).

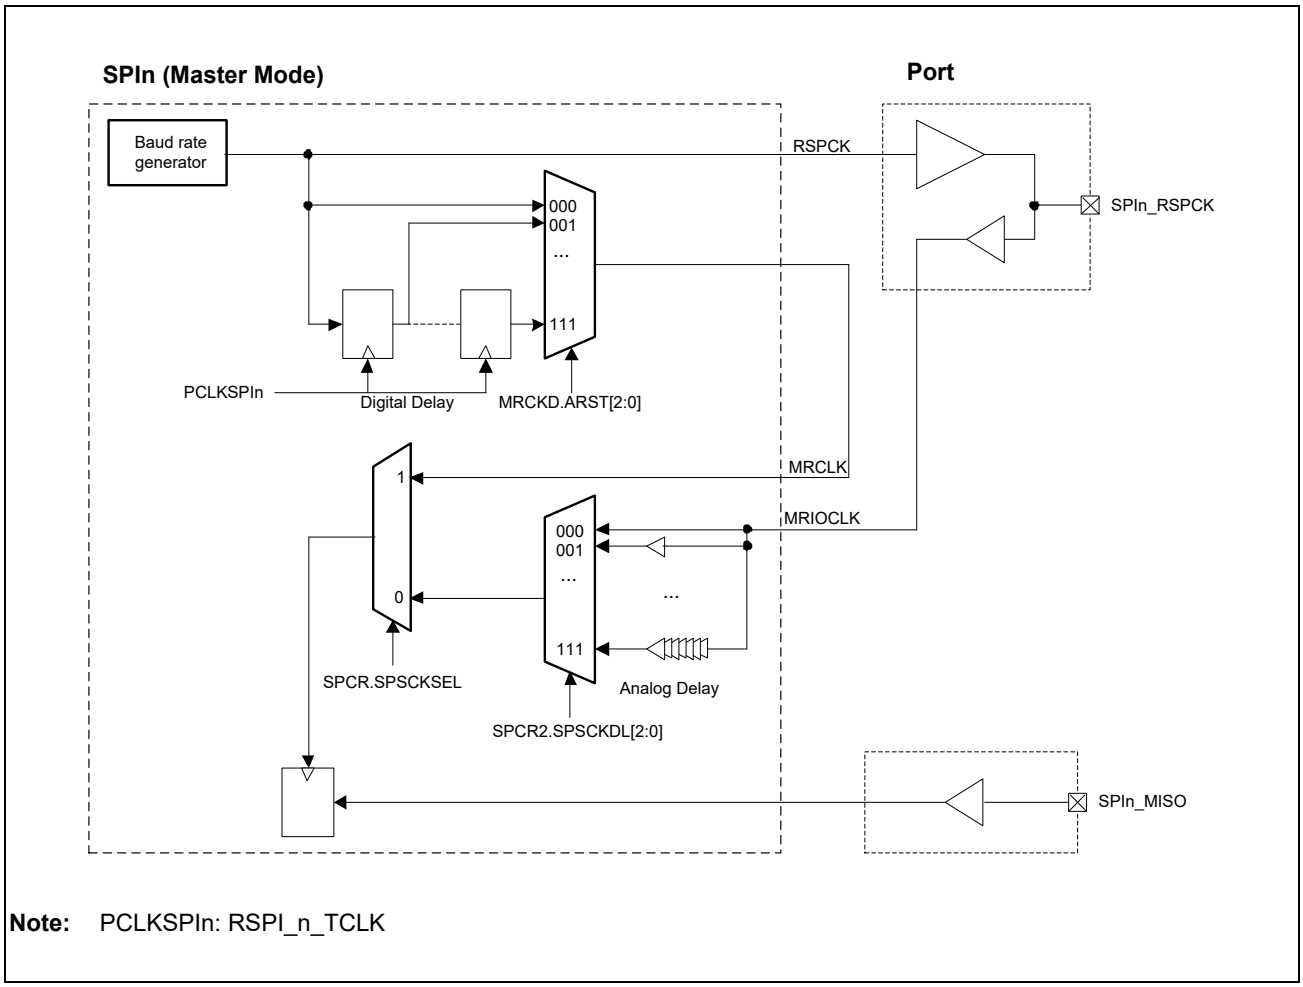

Figure 7.5-6 Master Receive Clock Delay Configuration (Master Mode)

SPPE bit (Parity Enable)

The SPPE bit is used to enable or disable the parity function.

SPOE bit (Parity Mode)

The SPOE bit is used to specify even parity or odd parity.

In even parity mode, the parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an even number. In the same way, in odd parity mode, a parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an odd number. The SPOE bit is valid only when the SPCR.SPPE is set to 1b.

PTE bit (Parity Self-Diagnosis Enable)

The PTE bit is used to enable or disable self-diagnosis of the parity circuit to confirm that the parity function is normal.

SCKASE bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit is used to enable or disable the RSPCK auto-stop function. When this function is enabled, the RSPCK clock stops immediately before an overrun error occurs during data reception in master mode. For details, see **7.5.3.10.1 Overrun error**.

BFDS bit (Between Burst Transfer Frames Delay Select)

The BFDS bit controls whether insert the delay time between the burst transfer frames.

Valid in the master mode (SPCR.MSTR = 1b) for frames with the SPCMDm.SSLKP bit set to 1b.

This bit should be set to 0b in slave mode. The usage of SSL delay control between transfer frames is shown as below.

For details, see **(4) Burst transfer** in **7.5.3.13.2 Slave mode operation**.

(1) Non-burst transmits

(2) Burst transmit with delay between frames
(2-1) From the 1st frame to the last previous frame
(2-2) The last frame

(3) Burst transmit with no delay between frames
(3-1) From the 1st frame to the last previous frame
(3-2) The last frame

Table 7.5-4 Usage of SSL Delay Control between Transfer Frames (Master Mode)

No.	SPCMDm SSLKP Bit	SPCR BFDS Bit	SSL Delay Control Register*1 (RSPCK clock delay, SSL negation delay, next access delay)
(1)	0b	0b	Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay, and next access delay.
(2-1)	1b	0b	
(2-2)	0b	0b	
(3-1)	1b	1b	Any given value. But delay is inserted only below. • RSPCK clock delay of the 1st frame • SSL negation delay and next access delay of the last frame
(3-2)	0b	1b	

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit. (See **7.5.2.2.14 SPI Command Register n (RSPIm_SPCMDn) (n = 0 to** 7).)
The SPCKD.SCKDL[2:0] bits: RSPCK delay
The SSLND.SLNDL[2:0] bits: SSL negate delay
The SPND.SPNDL[2:0] bits: Next access delay

[Setting/Operation Example] (Motorola SPI, BFDS = 1 Case)

SPCMD0.SSLKP = 1b → Burst transfer/no interframe delay between 0 and 1 (SSL keep active)
SPCMD1.SSLKP = 1b → Burst transfer/no interframe delay between 1 and 2 (SSL keep active)
SPCMD2.SSLKP = 1b → Burst transfer/no interframe delay between 2 and 3 (SSL keep active)
SPCMD3.SSLKP = 1b → Burst transfer/no interframe delay between 3 and 4 (SSL keep active)
SPCMD4.SSLKP = 0b → do not Burst Transfer, and once in-activate SSL.

(BFDS setting is invalid because it does not Burst Transfer.)

SPCMD5.SSLKP = 1b → Burst transfer/no interframe delay between 5 and 6 (SSL keep active)
SPCMD6.SSLKP = 1b → Burst transfer/no interframe delay between 6 and 7 (SSL keep active)
SPCMD7.SSLKP = 0b → do not Burst Transfer, and once in-activate SSL.

(BFDS setting is invalid because it does not Burst Transfer.)

MODFEN bit (Mode Fault Error Detection Enable)

The MODFEN bit is used to enable or disable detection of a mode fault error. (See **7.5.3.10 Error Detection**.) The SPI determines SSL0 pin input or output direction according to the combination of the MODFEN and MSTR bits. (See **7.5.3.2 SPI Pin Control**.)

SPEIE bit (SPI Error Interrupt Enable)

The SPEIE bit is used to enable or disable an SPI error interrupt request when the SPI detects a mode fault error or an underrun error and sets the MODF flag in the SPI status register (SPSR) to 1b, when the SPI detects an overrun error and sets the OVRF flag in SPSR to 1b, or when the SPI detects a parity error and sets the PERF flag in SPSR to 1b. (See **7.5.3.10 Error Detection**.)

SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

The SPRIE bit is used to enable or disable a receive buffer full interrupt request of the SPI.

SPIIE bit (SPI Idle Interrupt Enable)

The SPIIE bit is used to enable or disable an idle interrupt request of the SPI after the SPI detects the idle state and sets the IDLNF flag in the SPI status register (SPSR) to 0b.

SPDRES bit (SPI Receive Data Ready Error Select)

When a receive data ready is detected (SPSR.SPDRF = 1b), select whether to use SPRI interrupt request or SPEI interrupt request.

SPTIE bit (SPI Transmit Buffer Empty Interrupt Enable)

The SPTIE bit is used to enable or disable a transmit buffer empty interrupt request of the SPI.

A transmit buffer empty interrupt request at the beginning of transmission is generated by setting the SPE bit to 1b simultaneously when or after the SPTIE bit is set to 1b. Note that a transmit buffer empty interrupt is generated while the SPTIE bit is 1b even though SPI functions are disabled (SPE bit = 0b).

CENDIE bit (SPI Communication End Interrupt Enable)

The CENDIE bit controls generation of a communication end interrupt request.

SPMS bit (SPI Function Enable)

The SPMS bit is used to select SPI operation (4-wire) or clock synchronous operation (3-wire).

For clock synchronous operation, the SSL pin is not used but three pins RSPCK, MOSI, and MISO are used for communication. When SPMS = 1b (clock synchronous operation (3-wire)), the setting of the SPFRF bit is invalid.

To perform clock synchronous operation in master mode (SPCR.MSTR = 1b), the SPCMD.CPHA bit can be set to 0b or 1b. To perform clock synchronous operation in slave mode (SPCR.MSTR = 0b), set the CPHA bit to 1b. If this bit is set to 0b for clock synchronous operation in slave mode (SPCR.MSTR = 0b), subsequent operation is not guaranteed.

The communication status according to the settings of SPCR.MSTR, SPCR.TXMD[1:0], SPCR.SPFRF, and SPCR.SPMS as follows.

Table 7.5-5 SPI Communication Status (1/2)

SPCR MSTR	SPCR TXMD[1]	SPCR TXMD[0]	SPCR SPFRF	SPCR SPMS	Communication Status	Communication Status No.
1	0	0	0	0	Transmit-Receive Master / Motorola SPI / SPI operation (4-wire)	1-(1)
1	0	0	1	0	Transmit-Receive Master / TI-SSP / SPI operation (4-wire)	1-(2)
1	0	0	—	1	Transmit-Receive Master / Clock synchronous operation (3-wire)	1-(3)
1	0	1	0	0	Transmit only Master / Motorola SPI / SPI operation (4-wire)	1-(4)
1	0	1	1	0	Transmit only Master / TI-SSP / SPI operation (4-wire)	1-(5)

Table 7.5-5 SPI Communication Status (2/2)

SPCR MSTR	SPCR TXMD[1]	SPCR TXMD[0]	SPCR SPFRF	SPCR SPMS	Communication Status	Communication Status No.
1	0	1	—	1	Transmit only Master / Clock synchronous operation (3-wire)	1-(6)
1	1	—	0	0	Receive only Master / Motorola SPI / SPI operation (4-wire)	1-(7)
1	1	—	1	0	Receive only Master / TI-SSP / SPI operation (4-wire)	1-(8)
1	1	—	—	1	Receive only Master / Clock synchronous operation (3-wire)	1-(9)
0	0	0	0	0	Transmit-Receive Slave / Motorola SPI / SPI operation (4-wire) (default)	0-(1)
0	0	0	1	0	Transmit-Receive Slave / TI-SSP / SPI operation (4-wire)	0-(2)
0	0	0	—	1	Transmit-Receive Slave / Clock synchronous operation (3-wire)	0-(3)
0	0	1	0	0	Transmit only Slave / Motorola SPI / SPI operation (4-wire)	0-(4)
0	0	1	1	0	Transmit only Slave / TI-SSP / SPI operation (4-wire)	0-(5)
0	0	1	—	1	Transmit only Slave / Clock synchronous operation (3-wire)	0-(6)
0	1	—	0	0	Receive only Slave / Motorola SPI / SPI operation (4-wire)	0-(7)
0	1	—	1	0	Receive only Slave / TI-SSP / SPI operation (4-wire)	0-(8)
0	1	—	—	1	Receive only Slave / Clock synchronous operation (3-wire)	0-(9)

SPFRF bit (SPI Frame Format Select)

The SPFRF bit selects the communication protocol.

The format of the SPI terminal (RSPCK, SSL0 to 3) can be set according to the set communication protocol.

When SPMS = 1b (clock synchronous operation (3-wire)), this bit is invalid because SSL is not used.

TXMD[1:0] bits (Communication Mode Select)

The TXMD[1:0] bits are used to select the transmit-receive, transmit-only, and receive-only serial communication.

TXMD[1:0] = 01b

→ Transmit-only is performed without reception.
→ Receive buffer full interrupt request cannot be used.

TXMD[1] = 1b

→ Receive-only is performed without transmission.
→ Transmit buffer empty interrupt request cannot be used.

For details, see **7.5.3.6 Communications Operating Mode**.

MSTR bit (SPI Master/Slave Mode Select)

The MSTR bit is used to select master mode or slave mode of the SPI. The SPI determines input/output directions of pins RSPCK, MOSI, MISO, and SSL1 to SSL3 according to the MSTR bit setting.

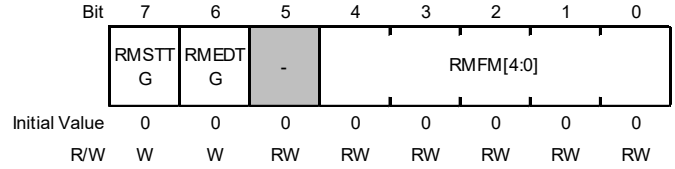
BPEN bit (Synchronization Circuit Bypass Enable)

When BPEN = 1b, bus clock (RSPI_n_PCLK) is used as operation clock (RSPI_n_TCLK) and synchronization circuit is bypassed.

7.5.2.2.7 SPI Control Register for Master Receive Only (RSPIm_SPCRRM)

The SPCRRM register controls the start and completion of communication for master mode reception only operation. If the RMFM[4:0] bits are rewritten while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 000Ch
Initial Value : 00h



Bit	Bit Name	Initial Value	R/W	Description
7	RMSTTG	0h	W	1b: Receive Start (writable only when in Master Receive) Reading value is always 0b.
6	RMEDTG	0h	W	1b: Receive End (writable only when in Master Receive) Reading value is always 0b.
5	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4 to 0	RMFM[4:0]	0h	RW	Frame processing count setting in Master Receive only 00h: This function is not used.*1 01h: Automatically stop communication after processing 1 received frame. : 1Fh: Automatically stop communication after processing 31 received frames.

Note 1. See **(9) Software processing flow**.

RMFM[4:0] bits (Frame processing count setting in Master Receive only)

The number of received frames can be adjusted when operating in master receive only. Valid only when the master mode (SPCR.MSTR = 1b) and the communication operation mode select bits (SPCR.TXMD[1:0]) are 10b.

Only the start bit in master mode reception automatically stops communication after “starts frame processing according to the value set in this bit” after reception starts.

RMEDTG bit (1b: Receive End (writable only when in Master Receive))

This bit is used to end reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1b) and the communication mode select bits (SPCR.TXMD[1:0]) are 10b.

RMSTTG bit (1b: Receive Start (writable only when in Master Receive))

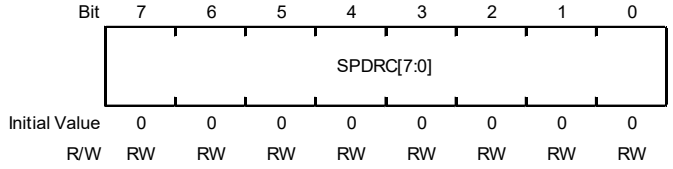
This bit is used to start reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1b) and the communication mode select bits (SPCR.TXMD[1:0]) are 10b.

Writing 1b to this bit during reception is not accepted. Write again after reception is completed.

7.5.2.2.8 SPI Control Register for Received Data Ready Detection (RSPIm_SPDRCR)

The SPDRCR register is used to set the SPI receive data ready detection function. If the set value is changed while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 000Dh
Initial Value : 00h



Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SPDRC[7:0]	0h	RW	SPI Receive Data Ready Detect Adjustment 00h: Disable receive data ready detection function 01h: Performs reception data ready judgment after 1 RSPI_n_TCLK : FFh: Performs reception data ready judgment after 255 RSPI_n_TCLK

SPDRC[7:0] bits (SPI Receive Data Ready Detect Adjustment)

The receive data ready detection function can be disabled or, if used, the period until detection can be set from 1 to 255 RSPI_n_TCLK.

The value set in the SPDRC[7:0] bits is used to 1b set the SPDRF flag. For details, see the description of SPDRF in **7.5.2.2.18 SPI Status Register (RSPIm_**SPSR).

7.5.2.2.9 SPI Pin Control Register (RSPIm_SPPCR)

The SPPCR register is used to set pin mode of the SPI. If SPPCR is modified with the SPCR.SPE bit = 1b, subsequent operation is not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 000Eh
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	MOIFE	MOIFV	-	-	SPLP2	SPLP
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7, 6	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5	MOIFE	0h	RW	MOSI Idle Value Fixing Enable 0b: The MOSI output value is the last data of previous transfer. 1b: The MOSI output value is the set MOIFV bit value.
4	MOIFV	0h	RW	MOSI Idle Fixed Value 0b: The fixed value of MOSI idle = 0. 1b: The fixed value of MOSI idle = 1.
3, 2	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1	SPLP2	0h	RW	SPI Loopback 2 0b: Normal mode 1b: Loopback mode (data is not inverted for transmission)
0	SPLP	0h	RW	SPI Loopback 0b: Normal mode 1b: Loopback mode (data is inverted for transmission)

SPLP bit (SPI Loopback)

When the SPLP bit is set to 1b, the SPI shuts down the route between the MISO pin and the shift register (when SPCR.MSTR = 1b) or shuts down the route between the MOSI pin and the shift register, inverts the input route value in the shift register, and then connects the route to the output route (when SPCR.MSTR = 0b) (loopback mode).

SPLP2 bit (SPI Loopback 2)

When the SPLP2 bit is set to 1b, the SPI shuts down the route between the MISO pin and the shift register (when SPCR.MSTR = 1b) or shuts down the route between MOSI pin and the shift register and then connects the route to the output route without inverting the input route value in the shift register (when SPCR.MSTR = 0b) (loopback mode). If this bit is set to 1b together with the SPLP bit, setting this bit takes precedence.

MOIFV bit (MOSI Idle Fixed Value)

This bit is used to select the MOSI pin output value during the SSL negation period (including SSL retention period in burst transfer) when SPCR.MOIFE = 1b in master mode.

MOIFE bit (MOSI Idle Value Fixing Enable)

This bit is used for the SPI in master mode to fix the MOSI output value during the SSL negation period (including SSL retention period in burst transfer). When SPCR.MOIFE = 0b, the SPI outputs the last data of the previous serial transfer to MOSI during the SSL negation period. When SPCR.MOIFE = 1b, the SPI outputs the fixed MOIFV bit value to MOSI.

7.5.2.2.10 SPI Control Register 2 (RSPIm_SPCR2)

The SPCR2 register is used to set the analog delay of the master receive clock. If the value set in this register is changed while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 000Fh
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	SPSCKDL[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	SPSCKDL[2:0]	0h	RW	SPI Master Receive Clock Analog Delay Valid only in master mode 000b: No delay 001b: 1.1 ns (max) 010b: 2.2 ns (max) 011b: 3.3 ns (max) 100b: 4.4 ns (max) 101b: 5.5 ns (max) 110b: 6.6 ns (max) 111b: 7.7 ns (max)

SPSCKDL[2:0] bits (SPI Master Receive Clock Analog Delay)

These bits set the analog delay for MRIOCLK input to SPI in master mode. By setting these bits, the sampling timing of the received data can be adjusted. For details, see the SPSCKSEL bit of **7.5.2.2.6 SPI Control Register (RSPIm_**SPCR).

7.5.2.2.11 SPI Slave Select Polarity Register (RSPIm_SSLP)

The SSLP register is used to set the polarity of SSL0 to SSL3 signals of the SPI. If any of these SSLP bits is modified with the SPCR.SPE bit = 1b, subsequent operation is not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 0010h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	SSL3P	SSL2P	SSL1P	SSL0P
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3	SSL3P	0h	RW	SSL3 Signal Polarity Setting 0b: In the Motorola-SPI case, the SSL3 signal is active low (0). In the TI-SSP case, the SSL3 signal is active high (1). 1b: In the Motorola-SPI case, the SSL3 signal is active high (1). In the TI-SSP case, the SSL3 signal is active low (0).
2	SSL2P	0h	RW	SSL2 Signal Polarity Setting 0b: In the Motorola-SPI case, the SSL2 signal is active low (0). In the TI-SSP case, the SSL2 signal is active high (1). 1b: In the Motorola-SPI case, the SSL2 signal is active high (1). In the TI-SSP case, the SSL2 signal is active low (0).
1	SSL1P	0h	RW	SSL1 Signal Polarity Setting 0b: In the Motorola-SPI case, the SSL1 signal is active low (0). In the TI-SSP case, the SSL1 signal is active high (1). 1b: In the Motorola-SPI case, the SSL1 signal is active high (1). In the TI-SSP case, the SSL1 signal is active low (0).
0	SSL0P	0h	RW	SSL0 Signal Polarity Setting 0b: In the Motorola-SPI case, the SSL0 signal is active low (0). In the TI-SSP case, the SSL0 signal is active high (1). 1b: In the Motorola-SPI case, the SSL0 signal is active high (1). In the TI-SSP case, the SSL0 signal is active low (0).

SSLnP bits (SSLn Signal Polarity Setting)

These bits are used to specify the polarity of SSL signals. The set SSLnP bit (n = 3 to 0) values indicate the active polarity of SSLn signals.

SSL0 is different from SSL1, SSL2, and SSL3. In slave mode, it functions as an input.

For details, see **7.5.3.3.2 Master/single slave (this LSI = slave)**.

7.5.2.2.12 SPI Bit Rate Register (RSPIm_SPBR)

Access Size : 8 bits
Address : <RSPIm_base> + 0011h
Initial Value : FFh

Bit	7	6	5	4	3	2	1	0
	SPR[7:0]							
Initial Value	1	1	1	1	1	1	1	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	SPR[7:0]	FFh	RW	The SPBR register is used to set the bit rate in master mode. If SPBR is modified while SPCR.MSTR = 1b and SPCR.SPE = 1b, subsequent operation is not guaranteed.

When the SPI is used in slave mode, the bit rate depends on the input clock bit rate regardless of the SPBR.BRDV setting. (Specify a bit rate that meets electrical characteristics.)

The bit rate is determined by a combination of the set SPBR and BRDV[1:0] in the SPCMDm register (SPCMD0 to SPCMD7).

The bit rate is calculated by the following expression, where “n” is the set SPBR value (0 to 255) and “N” is the set BRDV[1:0] bits value (0 to 3).

$$\text{Bit rate} = \frac{\text{f(RSPI\_n\_TCLK)}}{2 \times (\text{n} + 1) \times 2^{\text{N}}}$$

Table 7.5-6 shows an example of correspondence between bit rates and set values of SPBR and BRDV[1:0].

Table 7.5-6 Corresponding between Bit Rates and Set Values (Examples)

SPBR (n)	BRDV[1:0] Bits (N)	Division Ratio	Bit Rate
			RSPI_n_TCLK = 200 MHz
1	0	4	50.0 Mbps
2	0	6	33.4 Mbps
3	0	8	25.0 Mbps
4	0	10	20.0 Mbps
5	0	12	16.66 Mbps
5	1	24	8.34 Mbps
5	2	48	4.16 Mbps
5	3	96	2.08 Mbps
255	3	4096	48.8 kbps

7.5.2.2.13 SPI Sequence Control Register (RSPIm_SPSCR)

The SPSCR register is used to set the sequence length for the SPI to perform master operation.

Before modifying the SPSLN[2:0] bits in SPSCR while SPCR.MSTR = 1b and SPCR.SPE = 1b, confirm that SPSR.IDLNF = 0b.

Access Size : 8 bits
Address : <RSPIm_base> + 0013h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	SPSLN[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	SPSLN[2:0]	0h	RW	SPI Sequence Length Specification The order in which the SPCMD0 to SPCMD07 registers are to be referenced is changed in accordance with the sequence length that is set in these bits. The relationship among the setting of these bits, the sequence length, and the SPCMD0 to SPCMD7 register numbers referenced by SPI is as follows. However, the SPI in slave mode always refers to SPCMD0. 000b: Sequence Length = 1 (0→0→···) 001b: Sequence Length = 2 (0→1→0→···) 010b: Sequence Length = 3 (0→1→2→0→···) 011b: Sequence Length = 4 (0→1→2→3→0→···) 100b: Sequence Length = 5 (0→1→2→3→4→0→···) 101b: Sequence Length = 6 (0→1→2→3→4→5→0→···) 110b: Sequence Length = 7 (0→1→2→3→4→5→6→0→···) 111b: Sequence Length = 8 (0→1→2→3→4→5→6→7→0→···)

Note: The read access size is fixed at 32 bits.

SPSLN[2:0] bits (SPI Sequence Length Specification)

These bits are used to set the sequence length for the SPI in master mode to perform sequence operation.

According to the sequence length specified by SPSLN[2:0] bits, the SPI in master mode changes the SPCMDm registers (SPCMD0 to SPCMD7) to be referenced and the reference sequence. For details, see **7.5.3.14.1(3) Sequence control**.

The SPI in slave mode always references SPCMD0.

7.5.2.2.14 SPI Command Register n (RSPIm_SPCMDn) (n = 0 to 7)

The SPI has eight SPI command registers (SPCMD0 to SPCMD7) that are used to set the transfer format of the SPI in master mode. Furthermore, some bits in SPCMD0 are used to set the transfer format of the SPI in slave mode.

The SPI in master mode sequentially references SPCMD0 to SPCMD7 according to the setting of SPSCR.SPSLN[2:0], and then performs serial transfer specified in the referenced SPCMD.

SPCMD should be set while the transmit buffer is empty (next-transfer data is not set) and data which refers to SPCMD has not been written.

The SPCMD referenced by the SPI in master mode is indicated by SPCP[2:0] in the SPSSR register. If SPCMD0 is modified while the SPI in slave mode is enabled (SPCR.SPE = 1b), subsequent operation is not guaranteed.

Access Size : 8, 16, 32 bits

Address : <RSPIm_base> + 0014h + n x 0004h

Initial Value : 0007_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	SCKDEN	0h	RW	RSPCK Delay Setting Enable 0b: RSPCK delay is 1 RSPCK. [In the Motorola-SPI case] RSPCK delay is 0 RSPCK. [In the TI-SSP case] 1b: RSPCK delay is the set value of the RSPCK delay register (SPCKD).
14	SLNDEN	0h	RW	SSL Negation Delay Setting Enable 0b: [Master] SSL negation delay is 1 RSPCK. [Slave in the TI-SSP] SSL negation delay is 1 RSPI_n_TCLK + 2~3 RSPI_n_TCLK (Synchronization delay) 1b: SSL negation delay is the set value of the slave select negation delay register (SSLND).

Bit	Bit Name	Initial Value	R/W	Description
13	SPNDEN	0h	RW	SPI Next-Access Delay Enable 0b: Next-access delay is 1 RSPCK + 5 RSPI_n_TCLK 1b: Next-access delay is the set value of the SPI next-access delay register (SPND).
12	LSBF	0h	RW	SPI LSB First 0b: MSB first 1b: LSB first
11 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7	SSLKP	0h	RW	SSL Signal Level Hold 0b: All SSL signals are negated at the end of transfer. 1b: SSL signal level is held after the transfer ends until the next access starts.
6 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3, 2	BRDV[1:0]	0h	RW	Bit Rate Division 00b: The base bit rate is selected. 01b: Two-divided base bit rate is selected. 10b: Four-divided base bit rate is selected. 11b: Eight-divided base bit rate is selected.
1	CPOL	0h	RW	RSPCK Polarity 0b: RSPCK in idle state is 0. 1b: RSPCK in idle state is 1.
0	CPHA	0h	RW	RSPCK Phase This register is valid only for Motorola-SPI cases. (In the TI-SSP case, it is fixed at 1). 0b: Data is sampled at an odd edge and changes at an even edge. 1b: Data changes at an odd edge and is sampled at an even edge.

Note: The read access size is fixed at 32 bits.

CPHA bit (RSPCK Phase)

This bit is used to set the RSPCK phase of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK phase must be set for both modules.

When SPCR.SPMS = 0b and SPCR.SPFRF = 1b (in TI SSP mode), setting CPHA = 0b is invalid.

This register is valid only for Motorola-SPI cases.

CPOL bit (RSPCK Polarity)

This bit is used to set the RSPCK polarity of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK polarity must be set for both modules.

BRDV[1:0] bits (Bit Rate Division)

This register is used to determine the bit rate with a combination of the set values of the BRDV[1:0] bits and the SPBR register. The set SPBR value determines the base bit rate. The set BRDV[1:0] bits value is used to select undivided, 2-divided, 4-divided, or 8-divided base bit rate. SPCMD0 to SPCMD7 enable setting of different BRDV[1:0] values. This makes it possible to perform serial transfer with a different bit rate for each command.

SSLKP bit (SSL Signal Level Hold)

This bit is used to set whether to hold or negate the SSL signal level of the current command during a period from the SSL negation timing for the current command to the SSL assertion timing for the next command when the SPI in master mode performs serial transfer. Setting this bit to 1b enables burst transfer in SPI operation master mode. For details, see **(4) Burst transfer** in **7.5.3.13.1 Master mode operation**.

To use the SPI in slave mode, set SSLKP bit to 0b.

LSBF bit (SPI LSB First)

This bit is used to set the data format of the SPI in master mode or slave mode to MSB first or LSB first.

SPNDEN bit (SPI Next-Access Delay Enable)

This bit is used to set the period from SSL negation to SSL assertion in SPI master mode. When SPNDEN = 0b, the SPI sets the next-access delay to 1 RSPCK + 5 RSPI_n_TCLK. When SPNDEN = 1b, the SPI inserts the next-access delay in accordance with the SPND register setting.

To use the SPI in slave mode, set SPNDEN bit to 0b.

SLNDEN bit (SSL Negation Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period from RSPCK oscillation stop to SSL negation in SPI master mode. When SLNDEN = 0b, the SPI sets the SSL negation delay to 1 RSPCK. When SLNDEN = 1b, the SPI negates the SSL signal with the RSPCK delay in accordance with the SSLND register setting.
To use the SPI in slave mode, set SLNDEN bit to 0b.

[In the TI-SSP case]

This bit is used to set the period from RSPCK oscillation stop to output disable in SPI master mode, or last edge of RSPCK to output disable in slave mode. When the SLNDEN bit is 0b, the SSL negate delay is 1 RSPCK in master mode and 1 RSPI_n_TCLK + 2 to 3 RSPI_n_TCLK (Synchronization delay) in slave mode. When SLNDEN = 1b, the SPI negates the SSL signal with the RSPCK delay in accordance with the SSLND register setting.
When using SPI in slave mode except TI SSP setting, set the SLNDEN bit to 0b.

SCKDEN bit (RSPCK Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period (RSPCK delay) after the SPI in master mode activates the SSL signal until it oscillates RSPCK. When SCKDEN = 0b, the SPI sets the RSPCK delay to 1 RSPCK. When SCKDEN = 1b, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the SPCKD register setting.
To use the SPI in slave mode, set SCKDEN bit to 0b.

[In the TI-SSP case]

This bit is used to set the period from the start of assertion of the SSL signal to the RSPCK oscillation (RSPCK delay) and the period of the SSL signal to negation by the SPI in master mode. When SCKDEN = 0b, the SPI does not set the RSPCK delay. When SCKDEN = 1b, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the SPCKD register setting.
To use the SPI in slave mode, set SCKDEN bit to 0b.

SPB[4:0] bits (SPI Data Length)

These bits are used to set the transfer data length of the SPI in master mode or slave mode.

SSLA[1:0] bits (SSL Signal Assertion)

These bits are used to control SSL signal assertion for the SPI in master mode to perform serial transfer. The set SSLA[1:0] bits value controls assertion of the SSL3 to SSL0 signals. The signal polarity when the SSL signal is asserted depends on the set value of the SSLP register.

To use the SPI in slave mode, set SSLA[1:0] bits to 0b.

7.5.2.2.15 SPI Data Control Register (RSPIm_SPDCR)

The SPDCR register controls the data format.

If the value set in this register is changed while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8, 16 bits
Address : <RSPIm_base> + 0040h
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	SPFC[3:0]				-	-	-	SINV	SPRDTD	-	-	BYSW

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
11 to 8	SPFC[3:0]	0h	RW	Frame Count Number of Frames Specification 0000b: 1 frame 0001b: 2 frames 0010b: 3 frames 0011b: 4 frames : 1110b: 15 frames 1111b: 16 frames
7 to 5	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	SINV	0h	RW	Serial data invert 0b: Not invert serial data 1b: Invert serial data
3	SPRDTD	0h	RW	SPI Receive Data or Transmit Data Selection 0b: The SPDR reads the receive buffer 1b: The SPDR reads the transmit buffer
2, 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	BYSW	0h	RW	Byte Swap Operating Mode Select 0b: Byte swap is disabled 1b: Byte swap is enabled

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. A data after byte swap is different by a data length (setting of SPCMD.SPB[4:0]).

When byte swap, A data length (setting of SPB[4:0]) must be set to 32 bits or 16 bits. Other case of data length (for example, 4 to 15, 17 to 31 bit length), byte swap is not guaranteed. For the arrangement of data before and after swapping data lengths of 32 bits and 16 bits, see **7.5.3.4 Data Format** and **7.5.3.4.5 Byte swap reception**.

When the parity function set to valid, the behavior is not guaranteed.

SPRDTD bit (SPI Receive Data or Transmit Data Selection)

The SPRDTD bit is used to select receive buffer or transmit buffer from which the SPI data register (SPDR) value is read.

When the transmit buffer is read, the value written to SPDR the last time is read.

SINV bit (Serial data invert)

The SINV bit is used to invert transmit data and receive data.

When the SINV bit is set to 1b, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/ reception data.

SPFC[1:0] bits (Frame Count)

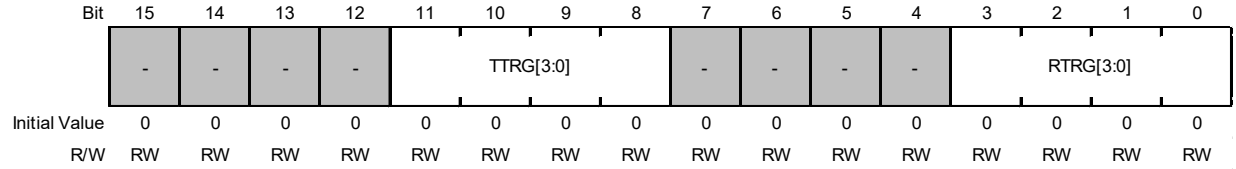
The SPFC[1:0] bits are used for the condition to set the CENDF flag in slave receive only mode. For details on the CENDF flag setting conditions, see **7.5.2.2.18 SPI Status Register (RSPIm_**SPSR).

The SPFC[1:0] bits are invalid except in the slave receive only mode.

7.5.2.2.16 SPI Data Control Register 2 (RSPIm_SPDCR2)

The SPDCR2 register controls the FIFO threshold. If the value set in this register is changed while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8, 16 bits
Address : <RSPIm_base> + 0044h
Initial Value : 0000h



Bit	Bit Name	Initial Value	R/W	Description
15 to 12	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
11 to 8	TTRG[3:0]	0h	RW	Transmission FIFO threshold setting When using DMA, set the threshold to 0 for RTRG and TTRG bits. 0000b: Threshold 0 0001b: Threshold 1 0010b: Threshold 2 0011b: Threshold 3 : 1111b: Threshold 15
7 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3 to 0	RTRG[3:0]	0h	RW	Receive FIFO threshold setting When using DMA, set the threshold to 0 for RTRG and TTRG bits. 0000b: Threshold 0 0001b: Threshold 1 0010b: Threshold 2 0011b: Threshold 3 : 1111b: Threshold 15

Note: The read access size is fixed at 32 bits.

RTRG[3:0] bits (Receive FIFO threshold setting)

Set the receive FIFO threshold.

When the number of data stored in the receive FIFO > the number of frames set by RTRG[3:0], the receive buffer full flag is set.

TTRG[3:0] bits (Transmission FIFO threshold setting)

Set the transmit FIFO threshold.

When the number of empty stages in the transmit FIFO > the number of frames set in TTRG[3:0], the transmit buffer empty flag is set.

7.5.2.2.17 SPI Sequence Status Register (RSPIm_SPSSR)

The SPSSR register indicates the sequence control status when the SPI performs master operation. Write access to SPSSR is ignored.

Access Size : 8 bits
Address : <RSPIm_base> + 0051h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	SPECM[2:0]			-	SPCP[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	-	0h	R	Reserved Whenever it is read, 0b is read.
6 to 4	SPECM[2:0]	0h	R	SPI Error Command 000b: SPCMD0 001b: SPCMD1 010b: SPCMD2 011b: SPCMD3 100b: SPCMD4 101b: SPCMD5 110b: SPCMD6 111b: SPCMD7
3	-	0h	R	Reserved Whenever it is read, 0b is read.
2 to 0	SPCP[2:0]	0h	R	SPI Command Pointer 000b: SPCMD0 001b: SPCMD1 010b: SPCMD2 011b: SPCMD3 100b: SPCMD4 101b: SPCMD5 110b: SPCMD6 111b: SPCMD7

SPCP[2:0] bits (SPI Command Pointer)

These bits show the SPCMDm registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the current pointer in the SPI sequence control. For details about the SPI sequence control, see **7.5.3.13.1 Master mode operation**.

SPECM[2:0] bits (SPI Error Command)

These bits show the SPCMDm registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the command pointer (SPCP[2:0] bits) when an error was detected in the SPI sequence control. The SPI updates the SPECM[2:0] bits value only when an error is detected. When no error is present (SPSR.OVRF = 0b, SPSR.MODF = 0b, SPSR.PERF = 0b), the SPECM[2:0] bits value has no meaning. For the SPI's error detection function, see **7.5.3.10 Error Detection**. For the SPI's sequence control, see **7.5.3.13.1 Master mode operation**.

7.5.2.2.18 SPI Status Register (RSPIm_SPSR)

Access Size : 8, 16 bits
Address : <RSPIm_base> + 0052h
Initial Value : 2000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPRF	CENDF	SPTEF	UDRF	PERF	MODF	IDLNF	OVRF	SPDRF	-	-	-	-	-	-	-
Initial Value	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	SPRF	0h	R	SPI Receive Buffer Full Flag 0b: The number of data stored in the receive FIFO ≤ number of frames set by the SPDCR2.RTRG bit. 1b: The number of data stored in the receive FIFO > number of frames set by the SPDCR2.RTRG bit.
14	CENDF	0h	R	Communication End Flag 0b: The SPI is not communicating or communicating. 1b: The SPI communication completed.
13	SPTEF	1h	R	SPI Transmit Buffer Empty Flag 0b: The number of empty stages in the transmit FIFO ≤ the value set in SPDCR2.TTRG 1b: The number of empty stages in the transmit FIFO > the value set in SPDCR2.TTRG
12	UDRF	0h	R	Underrun Error Flag This bit indicates error status in combination with the MODF flag. The UDRF bit is valid when MODF flag is 1. 0b: Mode fault error occurred (MODF = 1) 1b: Underrun error occurred (MODF = 1)
11	PERF	0h	R	Parity Error Flag 0b: No parity error is present. 1b: A parity error is present.
10	MODF	0h	R	Mode Fault Error Flag 0b: Neither mode fault error nor underrun error is present. 1b: A mode fault error or underrun error is present.
9	IDLNF	0h	R	SPI Idle Flag 0b: The SPI is in the idle state. 1b: The SPI is in the transfer state.
8	OVRF	0h	R	Overrun Error Flag 0b: No overrun error is present. 1b: An overrun error is present.
7	SPDRF	0h	R	SPI Receive Data Ready Flag 0b: Receive data ready not detected 1b: Receive data ready detected
6 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read.

SPDRF bit (SPI Receive Data Ready Flag)

During communication (SPCR.SPE = 1b), a certain period of time has elapsed while the number of data stored in the reception FIFO ≤ the reception FIFO threshold.

This bit is set to 0b when the reception operation is not performed (SPCR.TXMD[1:0] = 01b).

[Setting (to 1b) condition]

All the following two conditions are met:

- SPDRCR.SPDRC[7:0] ≠ 00h
- After the receive FIFO has been written, when the number of data stored in the receive FIFO ≤ the receive FIFO threshold and the value set by SPDRC[7:0] has elapsed

[Clearing (to 0b) condition]

- When 1b is written to the SPSRC.SPDRFC bit

OVRF bit (Overrun Error Flag)

This flag indicates whether an overrun error is present. When the RSPCK clock auto-stop function is enabled (SPCR.SCKASE bit = 1b) in master mode (SPCR.MSTR bit = 1b), no overrun error occurs and, therefore, this flag is not set to 1b. For details, see **7.5.3.10.1 Overrun error**.

[Setting (to 1b) condition]

When serial transfer is completed in one of the following two conditions with data stored in the receive FIFO for the number of FIFO stages.

- The SPCR.TXMD[1:0] bits = 00b. (transmit-receive mode)
- The SPCR.TXMD[1:0] bits = 10b. (receive only)

[Clearing (to 0b) condition]

- When 1b is written to the SPSRC.OVRFC bit

IDLNF bit (SPI Idle Flag)

This flag indicates transfer status of the SPI.

[Setting (to 1b) condition]

[Transmit-Receive, Transmit-only Master mode]

- None of the [Transmit-Receive, Transmit-only Master mode] in [Clearing (to 0b) conditions]

[Receive-only Master mode]

- When 1b is written to SPCRRM.RMSTTG bit

[Slave mode]

- SPCR.SPE = 1b (SPI function enabled)

[Clearing (to 0b) conditions]

Communication status: 1-(1) to (6) For details of communication status, see **Table 7.5-5**.

[Transmit-Receive, Transmit-only Master mode]

Any of the following two conditions is met:

- SPCR.SPE = 0b (SPI initialization)
- All the following three conditions are met:
  - The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 15)
  - SPSSR.SPCP[2:0] = 000b (at the beginning of sequence control)
  - The operation completed until the next access delay (the master main state machine has transitioned to the idle state)

[Receive-only Master mode]

Communication status: 1-(7) to (9)

Any of the following two conditions is met:

- SPCR.SPE = 0b (SPI initialization)
- Any of the following three conditions is met:
  - When RMFM[4:0] = 00h, after writing 1b to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)

- When RMFM[4:0] ≠ 00h, after writing 1b to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 00h, the operation is completed up to the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

[Slave mode]

Communication status: 0-(1) to (9)

- SPCR.SPE = 0b (SPI initialization)

MODF bit (Mode Fault Error Flag)

This flag indicates whether a mode fault error or an underrun error is present. The UDRF flag allows you to see which error (mode fault error or underrun error) has occurred.

[Setting (to 1b) condition]

[Slave, Motorola-SPI mode]

Any of the following two conditions is met:

- The SSL0 pin is negated before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0b (slave mode), SPCR.SPFRF bit = 0b (Motorola-SPI) and the SPCR.MODFEN bit = 1b (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1b (SPI function enabled), and then the SPI has detected an underrun error.

[Slave, TI-SSP mode]

Any of the following two conditions is met:

- The SSL0 pin is asserted before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0b (slave mode), SPCR.SPFRF bit = 1b (TI-SSP) and the SPCR.MODFEN bit = 1b (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1b (SPI function enabled), and then the SPI has detected an underrun error.

The SSL signal active level depends on the SSLP.SSLiP bits (SSL signal polarity bits).

[Clearing (to 0b) condition]

- When 1b is written to the SPSRC.MODFC bit

PERF bit (Parity Error Flag)

This flag indicates whether a parity error is present.

[Setting (to 1b) condition]

When the serial transfer ends and a parity error is detected with the SPCR.SPPE bit set to 1b under any of the following two conditions:

- The SPCR.TXMD[1:0] bits = 00b (transmit-receive)
- The SPCR.TXMD[1:0] bits = 10b (receive-only)

[Clearing (to 0b) condition]

- When 1 is written to the SPSRC.PERFC bit

UDRF bit (Underrun Error Flag)

This flag indicates that a mode fault error or an underrun error is present.

[Setting (to 1) condition]

- Serial transfer is started before transmit data output becomes ready while the SPCR.MSTR bit = 0b (slave mode) and the SPCR.TXMD[1:0] bits = 00b or 01b (transmit-receive or transmit-only) and the SPCR.SPE bit = 1b (SPI function enabled), and then the SPI has detected an underrun error.

[Clearing (to 0b) condition]

- When 1b is written to the SPSRC.UDRFC bit

SPTEF bit (SPI Transmit Buffer Empty Flag)

This flag indicates the transmit buffer (SPTX) status in the SPI data register (SPDR).

[Setting (to 1) condition]

Any of the following three conditions is met:

- The SPCR.SPE bit is set to 0b (SPI initialization)
- When the number of empty transmission FIFO stages > SPDCR2.TTRG[3:0]
- When 1b is written to SPFCR.SPFRST

[Clearing (to 0b) condition]

Any of the following two conditions is met:

- At the time of final access when transmission data is written to SPDR (SPTXn, n = 0 to 15) in one processing routine using DMAC
- When 1b is written to the SPSRC.SPTEFC bit

Writing a value to the SPDR register is enabled only while the SPTEF flag = 1b. If a value is written to the SPDR register while the SPTEF flag = 0b, transmit buffer data is not updated.

CENDF bit (Communication End Flag)

This flag indicates communication end status of SPI. It turns 1 at communication end and turns 0 at starting next communication.

[Setting (to 1b) condition]

- Transmit-Receive/Transmit-only Master mode

  Communication status: 1-(1) to (6). For details of communication status, see **Table 7.5-5**.
  The following three conditions are met:

  - The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 15)
  - The SPSSR.SPCP[2:0] are 000b (it means the head of the sequential control)
  - Operation completed until the next access delay (the master main state machine has transitioned to the idle state)

- Receive-only Master mode

  Communication status: 1-(7) to (9)
  Any of the following three conditions is met:

  - When RMFM[4:0] = 00h, after writing 1b to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)

- When RMFM[4:0] ≠ 00h, after writing 1b to RMEDTG, operation completed until the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 00h, the operation is completed up to the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

- Transmit-receive/transmit-only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0b).

  Communication status: 0-(1), (4)
  The following three conditions are met:
  - The next transfer data is not set in the transmission buffer
  - The transmission shift register is empty (it means SPI does not do serial transfer)
  - SSL0 was negated

- Transmit-receive/transmit-only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0b).

  Communication status: 0-(2), (5)
  The following three conditions are met:
  - The next transfer data is not set in the transmission buffer
  - The transmission shift register is empty (it means SPI does not do serial transfer)
  - When the SSL negate delay is completed

- Transmit-receive/transmit only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1b)

  Communication status: 0-(3), (6)
  The following three conditions are met:
  - The next transfer data is not set in the transmission buffer
  - The transmission shift register is empty (it means SPI does not do serial transfer)
  - The last even edge of RSPCK of the frame was detected (when the SPCMD.CPHA bit is 1b)

- Receive only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0b).

  Communication status: 0-(7)
  The following condition is met:
  - SSL0 input was negated after getting frames for SPDCR.SPFC set value in the receive buffer

- Receive only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0b).

  Communication status: 0-(8)
  The following condition is met:
  - SSL0 negate delay is completed after getting frames for SPDCR.SPFC set value in the receive buffer

- Receive only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1b).

  Communication status: 0-(9)
  The following condition is met:
  - The last even edge of RSPCK of the last frame received for SPFC set value was detected (when the SPCMD.CPHA bit is 1b)

[Clearing (to 0b) condition]

- Transmit-Receive/transmit-only Master mode

  Communication status: 1-(1) to (6)
  Any of the following two conditions is met:

  - The next transmit data was written to the transmit buffer (SPTX)
  - When 1b is written to the SPSRC.CENDFC bit

- Receive-only Master mode

  Communication status: 1-(7) to (9)
  Any of the following two conditions is met:

  - When 1b is written to the SPCRRM.RMSTTG bit with SPCR.SPE = 1b
  - When 1b is written to the SPSRC.CENDFC bit

- Transmit-receive/transmit only slave mode

  Communication status: 0-(1) to (6)
  Satisfy one of following conditions:

  - The next transmit data is written to the transmit buffer (SPTX)
  - When 1b is written to the SPSRC.CENDFC bit

- Receive-only slave mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0b).

  Communication status: 0-(7) to (8)
  Satisfy one of following conditions:

  - SSL0 assertion of next data is detected
  - When 1b is written to the SPSRC.CENDFC bit

- Receive-only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1b).

  Communication status: 0-(9)
  Satisfy one of following conditions:

  - The first edge of RSPCK of the next data is detected
  - When 1b is written to the SPSRC.CENDFC bit

SPRF bit (SPI Receive Buffer Full Flag)

This flag indicates the receive buffer (SPRX) status in the SPDR register.

[Setting (to 1b) condition]

When the number of data stored in the receive FIFO > the number of frames set in the SPDCR2.RTRG[3:0] bits in Transmit-Receive, Receive-only modes. However, the SPRF flag does not change from 0b to 1b while the OVRF flag = 1b. (See **7.5.3.10 Error Detection**.)

[Clearing (to 0b) condition]

Any of the following three conditions is met:

- At the last access when read data is read from SPDR (SPRXn, n = 0 to 15) in one processing routine using DMAC
- When 1b is written to the SPSRC.SPRFC bit
- When 1b is written to the SPFCR.SPFRST bit

7.5.2.2.19 SPI Transfer FIFO Status Register (RSPIm_SPTFSR)

Access Size : 8 bits
Address : <RSPIm_base> + 0058h
Initial Value : 04h

Bit	7	6	5	4	3	2	1	0
	-	-	-	TFDN[4:0]				
Initial Value	0	0	0	0	0	1	0	0
R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read.
4 to 0	TFDN[4:0]	4h	R	Transmit FIFO data empty stage number 0_0000b: Number of empty stages 0 0_0001b: Number of empty stages 1 0_0010b: Number of empty stages 2 0_0011b: Number of empty stages 3 0_0100b: Number of empty stages 4 : 1_0000b: Number of empty stages 16

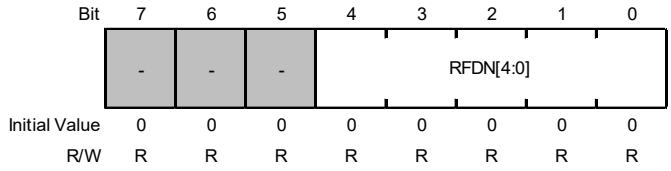
Note: TFDN[4:0] is initialized by SPCR.SPE = 0b.

7.5.2.2.20 SPI Receive FIFO Status Register (RSPIm_SPRFSR)

Access Size : 8 bits

Address : <RSPIm_base> + 005Ch

Initial Value : 00h



Bit	Bit Name	Initial Value	R/W	Description
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read.
4 to 0	RFDN[4:0]	0h	R	Receive FIFO data store stage number 0_0000b: Number of store stages 0 0_0001b: Number of store stages 1 0_0010b: Number of store stages 2 0_0011b: Number of store stages 3 0_0100b: Number of store stages 4 : 1_0000b: Number of empty stages 16

Note: RFDN[4:0] is initialized by SPCR.SPE = 0b.

7.5.2.2.21 SPI Polling Register (RSPIm_SPPSR)

Access Size : 8, 16, 32 bits

Address : <RSPIm_base> + 0060h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	SPEPS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read.
0	SPEPS	0h	R	SPI Polling Status 0b: SPCR.SPE is 0 1b: SPCR SPE is 1

Note: This bit shows a result of SPCR.SPE after synchronization by the operation clock (RSPI_n_TCLK).

Note: The read access size is fixed at 32 bits.

7.5.2.2.22 SPI Status Clear Register (RSPIm_SPSRC)

The SPSRC register clears the status flag (SPSR) that indicates the operating status of SPI.

Access Size : 8, 16 bits

Address : <RSPIm_base> + 006Ah

Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPRFC	CENDFC	SPTEFC	UDRFC	PERFC	MODFC	-	OVRFC	SPDRFC	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	R	W	W	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	SPRFC	0h	W	SPI Receive Buffer Full Flag Clear By writing 1b, the SPI Receive Buffer Full Flag can be cleared. The read value is always 0b.
14	CENDFC	0h	W	Communication End Flag Clear By writing 1b, the Communication End Flag can be cleared. The read value is always 0b.
13	SPTEFC	0h	W	SPI Transmit Buffer Empty Flag Clear By writing 1b, the SPI Transmit Buffer Empty Flag can be cleared. The read value is always 0b.
12	UDRFC	0h	W	Underrun Error Flag Clear By writing 1b, the Underrun Error Flag can be cleared. The read value is always 0b. When clearing the UDRF flag, clear the MODF flag at the same time (MODFC = 1).
11	PERFC	0h	W	Parity Error Flag Clear By writing 1b, the Parity Error Flag can be cleared. The read value is always 0b.
10	MODFC	0h	W	Mode Fault Error Flag Clear By writing 1b, the Mode Fault Error Flag can be cleared. The read value is always 0b. Before setting MODFC and UDRFC, make sure that SPSR.MODF and UDRF are set to 1b.
9	-	0h	R	Reserved Whenever it is read, 0b is read.
8	OVRFC	0h	W	Overrun Error Flag Clear By writing 1b, the Overrun Error Flag can be cleared. The read value is always 0b.
7	SPDRFC	0h	W	SPI Receive Data Ready Flag Clear The SPI receive data ready flag can be cleared by writing 1b. When read, 0b is read.
6 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read.

7.5.2.2.23 SPI FIFO Clear Register (RSPIm_SPFCR)

The SPFCR register is used to clear the FIFO.

If SPFCR is rewritten while SPCR.SPE = 1b, subsequent operations are not guaranteed.

Access Size : 8 bits
Address : <RSPIm_base> + 006Ch
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	SPFRST
Initial Value	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	-	All 0	W	Reserved The written value should always be 0b.
0	SPFRST	0h	W	SPI FIFO clear By writing 1b, the pointer in the FIFO and the stored data are initialized. Reading value is always 0b.

7.5.3 Operation

In this section, a word “serial transfer period” is used as a word that means a period from the start of valid data drive to latching of the final valid data.

7.5.3.1 Overview of SPI Operations

The SPI can transfer data in the following five modes.

- Slave mode (SPI operation)
- Master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

SPI modes can be set by the MSTR, MODFEN, SPMS and SPFRF bits in the SPCR register.

Table 7.5-7 lists the relationship between SPI modes and SPCR settings, and outline of each mode.

Table 7.5-7 Relationship between SPI Modes and SPCR Settings and Description of Each Mode (1/2)

Mode	Slave (SPI Operation)	Master (SPI Operation)	Slave (Clock Synchronous Operation)	Master (Clock Synchronous Operation)
MSTR bit setting	0	1	0	1
MODFEN bit setting	0 or 1	0	0	0
SPMS bit setting	0	0	1	1
SPFRF bit setting	valid	valid	In-valid	In-valid
RSPCK signal	Input	Output	Input	Output
MOSI signal	Input	Output	Input	Output
MISO signal	Output/Hi-Z	Input	Output	Input
SSL0 signal	Input	Output	Hi-Z (not used)	Hi-Z (not used)
SSL1 to SSL3 signals	Hi-Z (not used)	Output	Hi-Z (not used)	Hi-Z (not used)
SSL polarity modification function	Supported	Supported	—	—
Transfer rate	Up to RSPI_n_TCLK/2	Up to RSPI_n_TCLK/2	Up to RSPI_n_TCLK/2	Up to RSPI_n_TCLK/2
Clock source	RSPCK input	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	2 types			
Clock phase	2 types*1	2 types*5	One (CPHA = 1b)	2 types
First transfer bit	MSB/LSB			
Transfer data length	4 to 32 bits			
Burst transfer	Enabled (CPHA = 1b)	Enabled (CPHA = 0b, 1b)	—	—
RSPCK delay control	Not supported	Supported	Not supported	Supported
SSL negation delay control	Not supported*6	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Not supported	Supported
Transfer activation method	SSL input active or RSPCK oscillation	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1b	RSPCK oscillation	Transmit buffer empty interrupt request or transmit buffer write when SPTEF = 1b
Sequence control	Not supported	Supported	Not supported	Supported

Table 7.5-7 Relationship between SPI Modes and SPCR Settings and Description of Each Mode (2/2)

Mode	Slave (SPI Operation)	Master (SPI Operation)	Slave (Clock Synchronous Operation)	Master (Clock Synchronous Operation)
Transmission buffer empty detection	Supported*4	Supported	Supported*4	Supported
Reception buffer full detection	Supported*1			
Overrun error detection	Supported*1	Supported*1,*3	Supported*1	Supported*1,*3
Parity error detection	Supported*1,*2			
Mode fault error detection	Supported (MODFEN = 1b)	Not supported	Not supported	Not supported
Underrun error detection	Supported*4	Not supported	Supported*4	Not supported

Note 1. When SPI is transmit-master mode or transmit-slave mode (see **Table 7.5-5**), none of receive buffer full error, overrun error, and parity error is detected.

Note 2. When the SPCR.SPPE bit is 0b, parity error is not detected.

Note 3. When the SPCR.SCKASE bit is 1b, overrun error is not detected.

Note 4. When SPI is receive only slave mode (see **Table 7.5-5**), none of transmit buffer empty and underrun error is detected.

Note 5. CPHA = 0b is invalid in TI SSP mode. (Even if it is set, the operation is the same as when CPHA = 1b.)

Note 6. Available only in TI SSP mode.

7.5.3.2 SPI Pin Control

The SPI automatically switches pin directions and output modes according to the settings of the SPCR.MSTR, SPCR.MODFEN and SPCR.SPMS bits.

Table 7.5-8 shows the relationship between pin state and set values of each bit.

For details of OE function, see **7.5.3.5 Transfer Format (Frame Format)**.

Table 7.5-8 Relationship between Pin States and Set Control Bit Values

Mode	Pin	Pin State*1
Master mode (SPI operation) (MSTR = 1b, MODFEN = 0b, SPMS = 0b)	RSPCK	Output
	SSL0 to SSL3	Output
	MOSI	Output
	MISO	Input
Slave mode (SPI operation) (MSTR = 0b, SPMS = 0b)	RSPCK	Input
	SSL0	Input
	SSL1 to SSL3*3	Not used
	MOSI	Input
	MISO*2	Output/Hi-Z
Master mode (Clock synchronous operation) (MSTR = 1b, MODFEN = 0b, SPMS = 1b)	RSPCK	Output
	SSL0 to SSL3*3	Not used
	MOSI	Output
	MISO	Input
Slave mode (Clock synchronous operation) (MSTR = 0b, SPMS = 1b)	RSPCK	Input
	SSL0 to SSL3*3	Not used
	MOSI	Input
	MISO	Output

Note 1. The set SPI value is not applied to multi-function pins for which the SPI function is not selected.

Note 2. Motorola-SPI: When SSL0 is inactive level or when SPCR.SPE = 0b, the pin state becomes Hi-Z.
TI-SSP: When SSL0 is except the communication period or when SPCR.SPE = 0b (assertion after SPE = 1b and communication completed), the pin status changes to Hi-Z.

Note 3. These pins are available for use as I/O port pins.

The SPI in master mode (SPI operation) determines the MOSI signal value in the SSL negation period (including the SSL hold period in burst transfer) according to the settings of the SPPCR.MOIFE and SPPCR.MOIFV bits, as listed in **Table 7.5-9**.

Table 7.5-9 Determining the MOSI Signal Value in the SSL Negation Period

MOIFE Bit	MOIFV Bit	MOSI Signal Value during SSL Negation Period
0	0, 1	Final data from previous transfer
1	0	Always low
1	1	Always high

7.5.3.3 SPI System Configuration Examples

This configuration example describes that 0 level of SSL signals is active level. When connecting and using in a multi-slave mode, the transfer format of the connected device should be unified to either Motorola-SPI or TISSP.

7.5.3.3.1 Master/single slave (this LSI = master)

Figure 7.5-7 shows an example of master/single slave SPI system configuration where this LSI is used as a master. In the master/single slave configuration, the SSL0 to SSL3 output signals of this LSI (master) are not used.

SSL input signals of the SPI slave are fixed to 0 level to always select the SPI slave. When SPCMD.CPHA = 0b, some slave devices cannot fix SSL signals to active level in the relevant transfer format. If the SSL signal level cannot be fixed, connect the SSL output of this LSI to the SSL input of the slave device.

This LSI (master) always drives the RSPCK and MOSI pins. The SPI slave always drives the MISO pin.

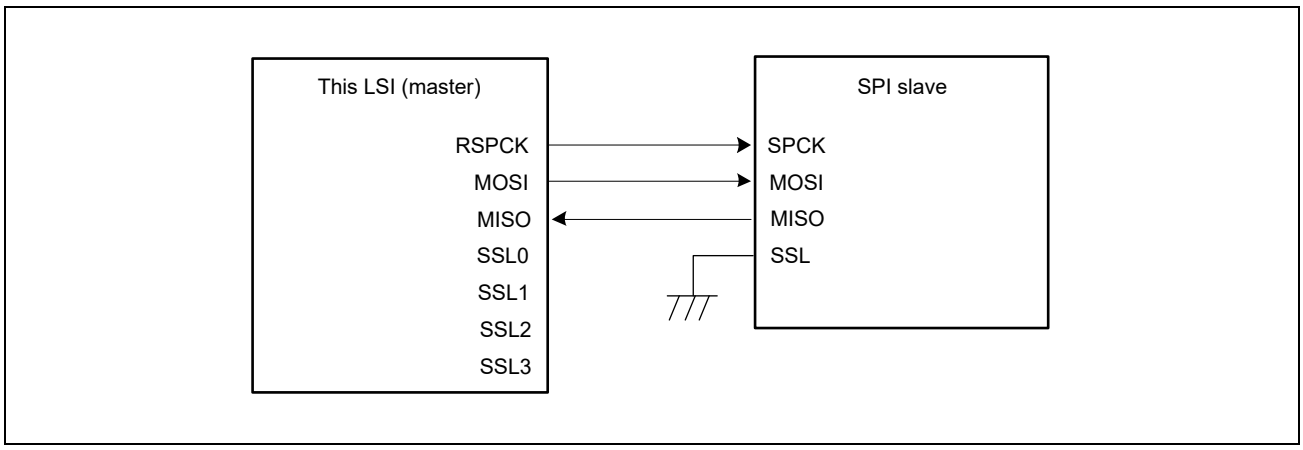


Figure 7.5-7 Master/Single-Slave Configuration Example (This LSI = Master)

7.5.3.3.2 Master/single slave (this LSI = slave)

Figure 7.5-8 shows an example of master/single slave SPI system configuration where this LSI is used as a slave. When this LSI is used as a slave, the SSL0 pin is used as SSL input. The SPI master always drives the RSPCK and MOSI pins. This LSI (slave) always drives the MISO pin. When the SSL0 level is inactive, the pin state becomes Hi-Z.

In the single slave configuration with the SPCMD.CPHA bit set to 1b, set the SPCR.SPFRF bit to 0b, and set the SPMS bit to 0b. There is the SSL0 input level of this LSI (slave) is fixed to 0 so that this LSI (slave) can be always selected and serial transfer can also be performed (**Figure 7.5-9**). However, the communication end interrupt does not output when SSL0 input was fixed as **Figure 7.5-9**.

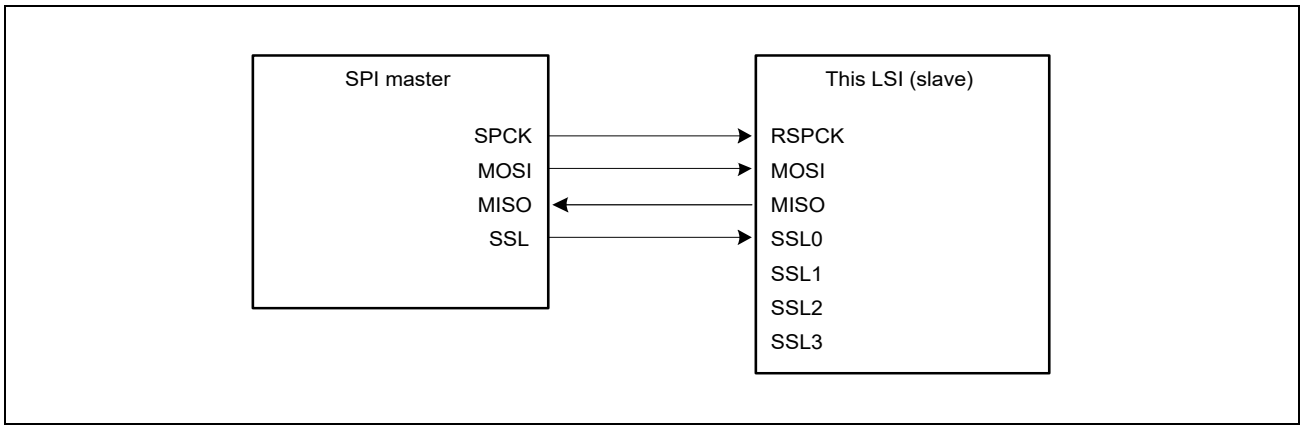

Figure 7.5-8 Master/Single-Slave Configuration Example (This LSI = Slave, CPHA = 0b)

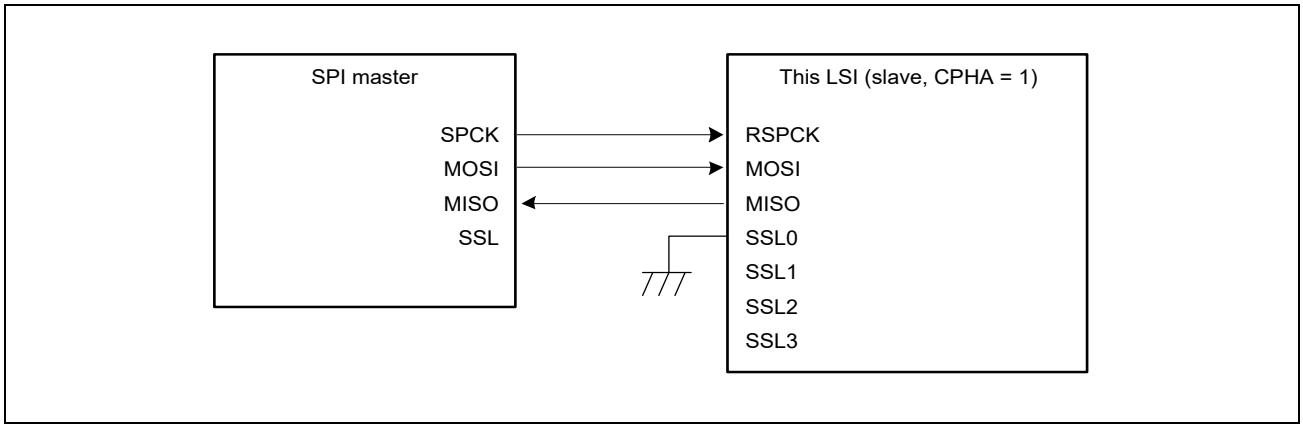

Figure 7.5-9 Master/Single-Slave Configuration Example (This LSI = Slave, CPHA = 1b)

7.5.3.3.3 Master/multi-slave (this LSI = master)

Figure 7.5-10 shows an example of master/multi-slave SPI system configuration where this LSI is used as a master. In the example in **Figure 7.5-10**, the SPI system is comprised of this LSI (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCK output and MOSI output pins of the master are connected to the RSPCK input and MOSI input pins of SPI slave 0 to SPI slave 3. All of the MISO output pins of SPI slave 0 to SPI slave 3 are connected to the MISO input pin of the master. The SSL0 to SSL3 output pins of this LSI (master) are connected to the SSL input pin of SPI slave 0 to SPI slave 3.

The master always drives RSPCK, MOSI, and SSL0 to SSL3 pins. The slave (out of SPI slave 0 to SPI slave 3) where 0 level is input to SSL input pin drives the MISO pin.

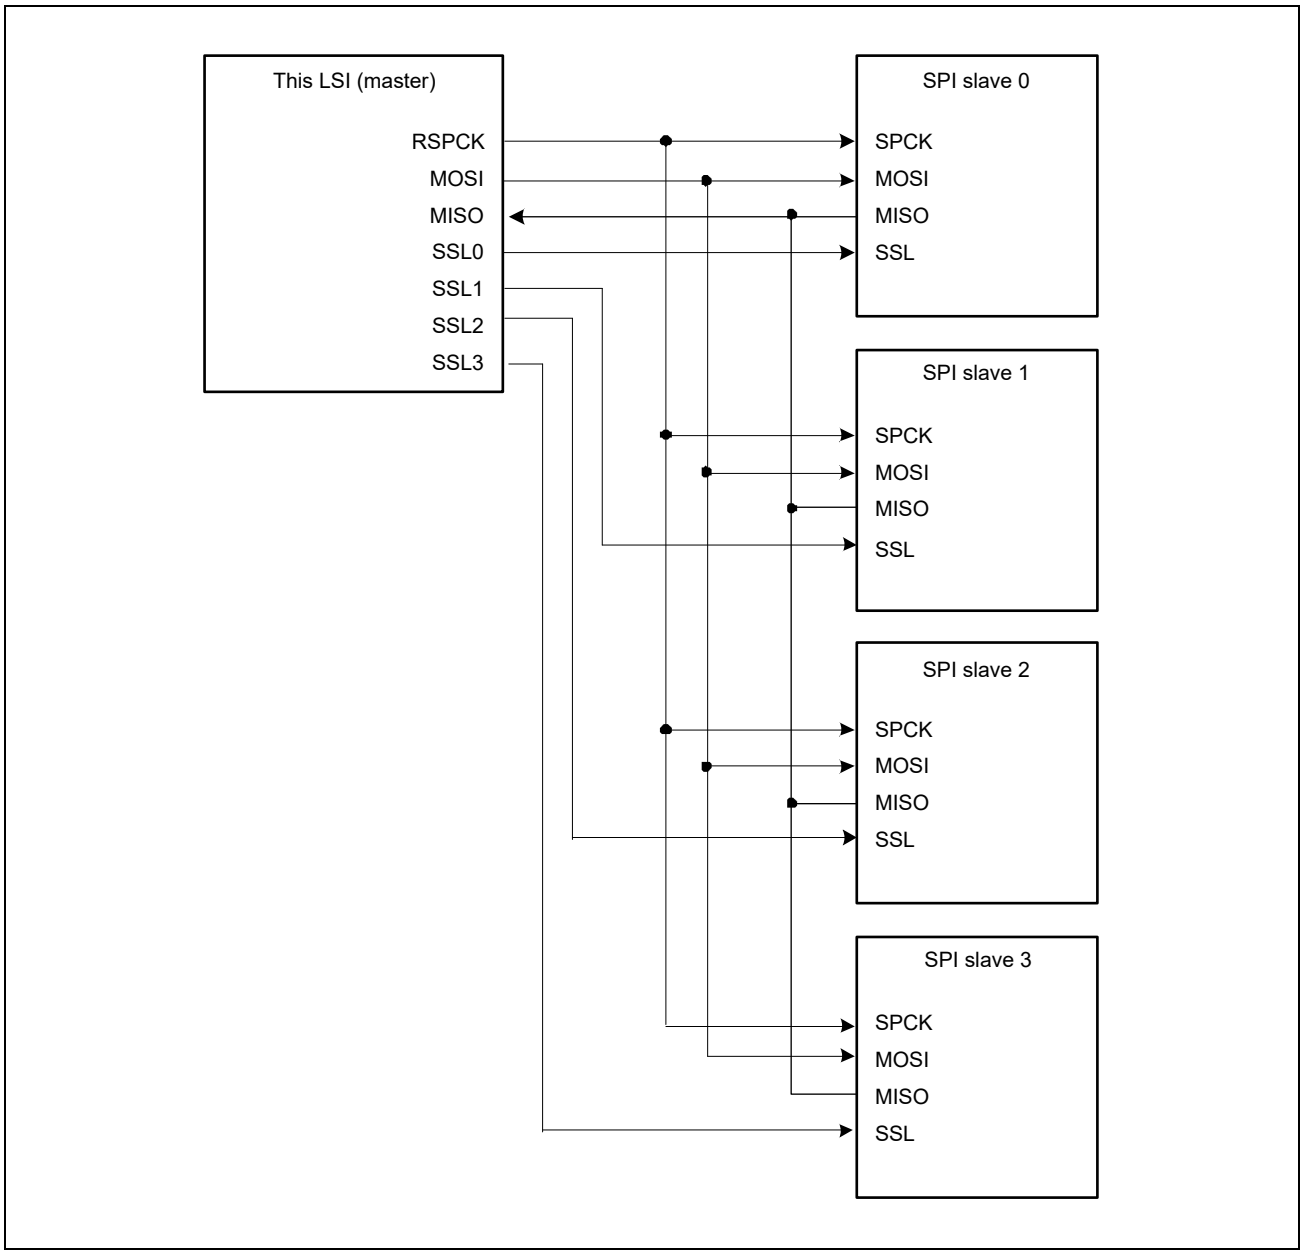

Figure 7.5-10 Master/Multi-Slave Configuration Example (This LSI = Master)

7.5.3.3.4 Master/multi-slave (with this LSI acting as slave)

Figure 7.5-11 shows an example of master/multi-slave SPI system configuration where this LSI is used as a slave. In the example in **Figure 7.5-11**, the SPI system consists of the SPI master and two these LSIs (slave X, slave Y).

The RSPCK output and MOSI output pins of the SPI master are connected to the RSPCK input and MOSI input pins of the LSIs (slave X, slave Y). The MISO output pin of the LSIs (slave X, slave Y) is connected to the MISO input pin of the SPI master. The SSLX output and SSLY output pins of the SPI master are connected to the SSL0 input pin of the LSIs (slave X, slave Y).

The SPI master always drives the RSPCK, MOSI, SSLX, and SSLY pins. The slave X or slave Y (this LSI) where 0 level is input to the SSL0 input pin drives the MISO pin.

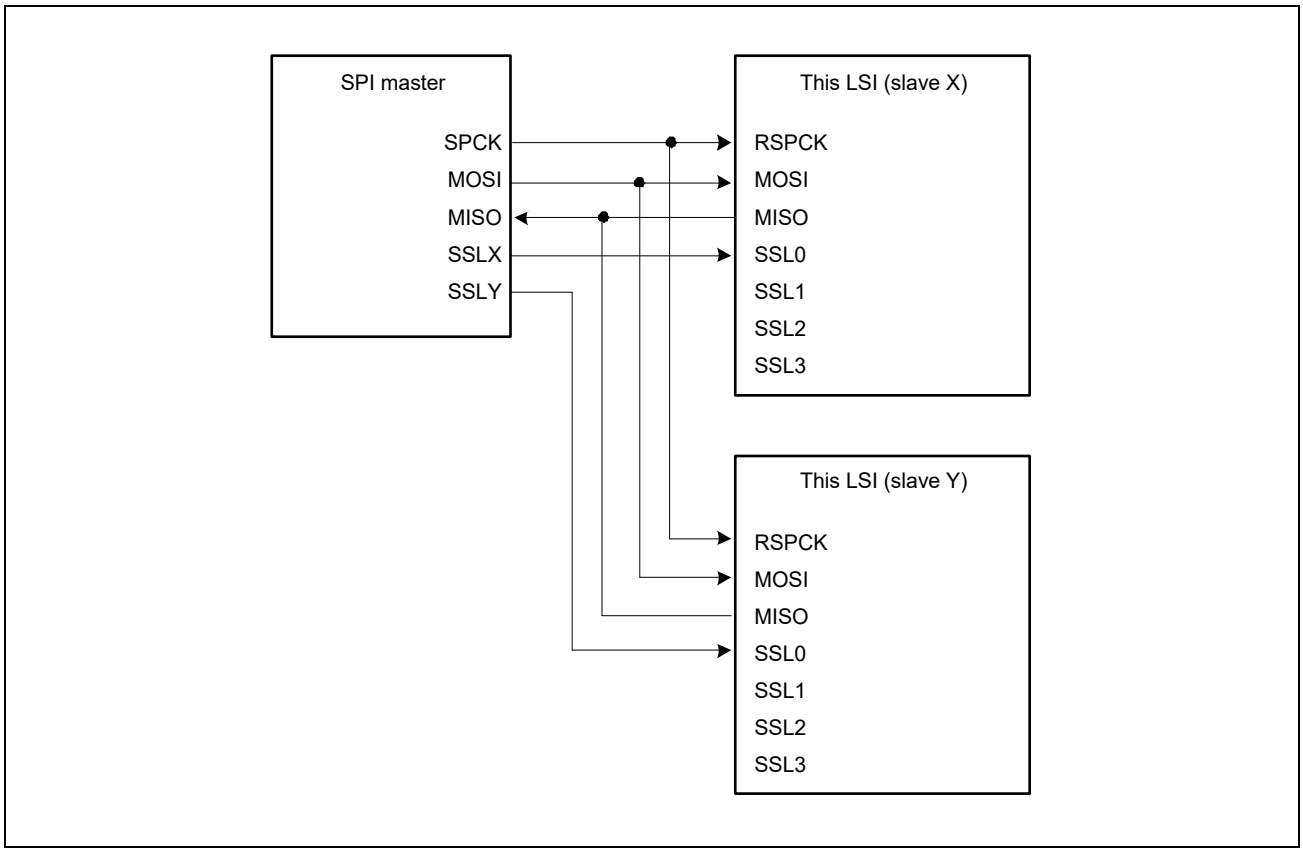

Figure 7.5-11 Master/Multi-Slave Configuration Example (This LSI = Slave)

7.5.3.3.5 Master (clock synchronous operation)/slave (clock synchronous operation) (this LSI = master)

Figure 7.5-12 shows an example of master (clock synchronous operation)/slave (clock synchronous operation) SPI system configuration where this LSI is used as a master. In this configuration, the SSL0 to SSL3 output pins of this LSI (master) are not used.

This LSI (master) always drives the RSPCK and MOSI pins. The SPI slave always drives the MISO pin.

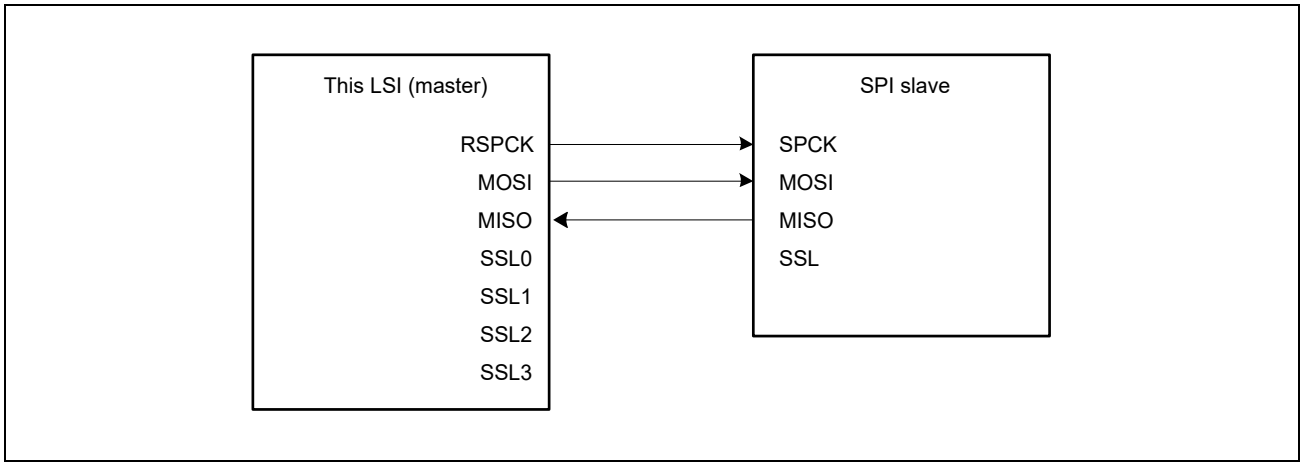

Figure 7.5-12 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This LSI = Master)

7.5.3.3.6 Master (clock synchronous operation)/slave (clock synchronous operation) (this LSI = slave)

Figure 7.5-13 shows an example of master (clock synchronous operation)/slave (clock synchronous operation) SPI system configuration where this LSI is used as a slave. When this LSI is used as a slave (clock synchronous operation), this LSI (slave) always drives the MISO pin and the SPI master always drives the RSPCK and MOSI pins.

Only in the single slave configuration with the SPCMD.CPHA bit set to 1b, this LSI (slave) can perform serial transfer.

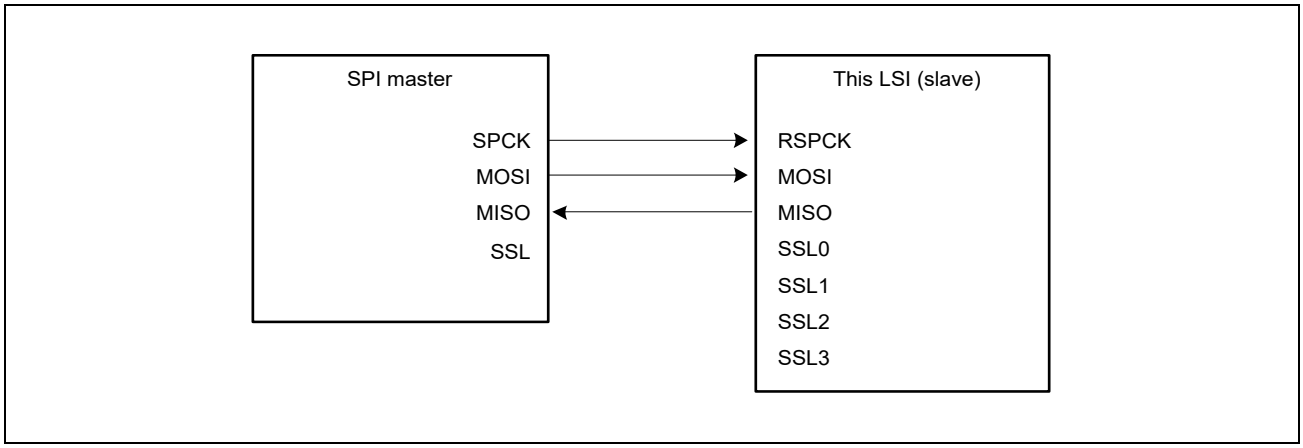

Figure 7.5-13 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This LSI = Slave, CPHA = 1b)

7.5.3.4 Data Format

Data format of the SPI depends on the set values of the SPCMD register and the SPCR.SPPE bit. The SPI handles data of the set data length from the LSB in the SPDR register as transfer data regardless of MSB first or LSB first.

7.5.3.4.1 Data format of one frame

The data format of one frame for transmission and reception is shown below.

(1) With parity disabled (SPPE = 0b)

When the parity function is disabled, data of the bit length specified by SPCMDm.SPB[4:0] is transmitted and received.

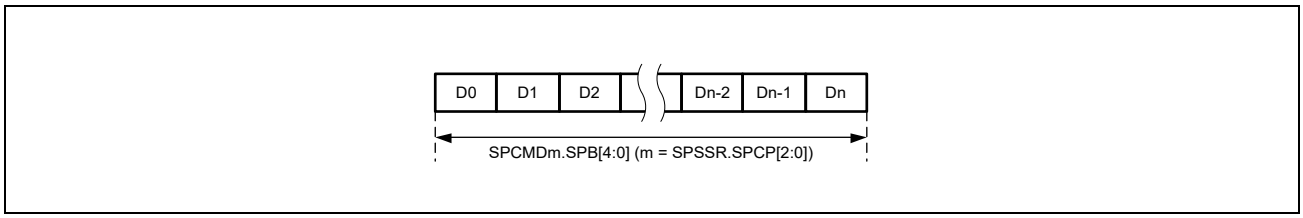

Figure 7.5-14 Outline of Data Format (when Parity Function is Disabled)

(2) With parity enabled (SPPE = 1b)

When the parity function is enabled, data of the bit length specified by SPCMDm.SPB[4:0] is transmitted and received. However, the final bit is used as a parity bit.

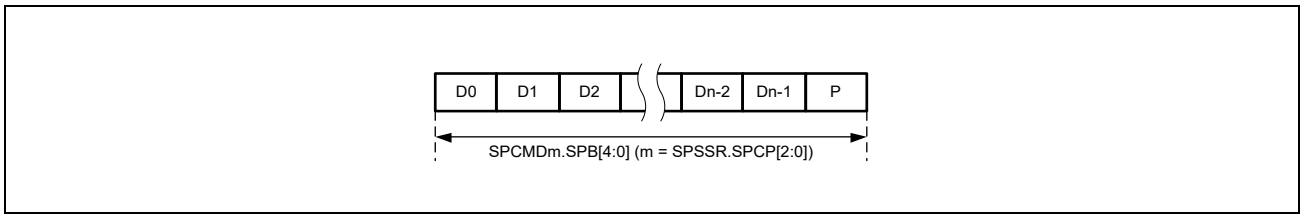

Figure 7.5-15 Outline of Data Format (when Parity Function is Enabled)

7.5.3.4.2 When parity is disabled (SPPE = 0b)

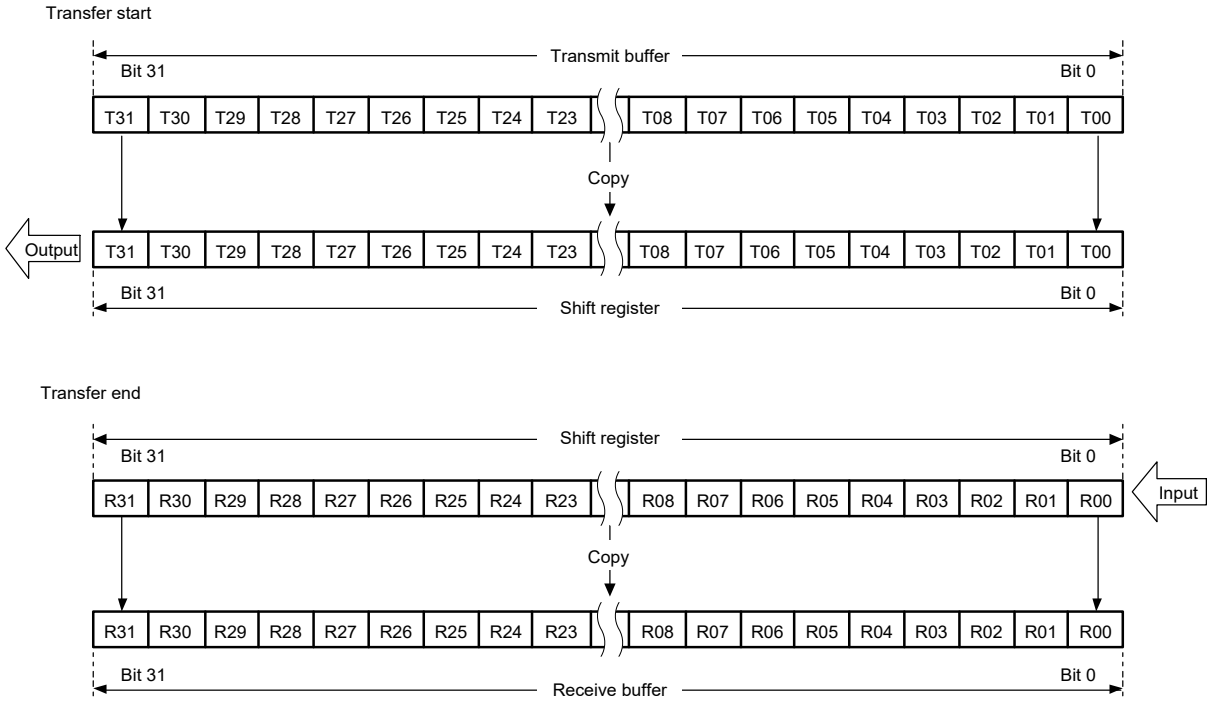
When the parity function is disabled, transmit buffer data is copied to the shift register without processing it. The following describes the relationship between SPDR, and shift register by using a combination of MSB first/LSB first and bit length.

(3) MSB first transfer (32-bit data)

Figure 7.5-16 shows operations of the SPDR register and the shift register when the SPI performs 32-bit MSB-first transfer with the parity function disabled.

In transmission, T31 to T00 in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.

In reception, received data is stored in bit 0 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R31 to R00, the shift register value is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

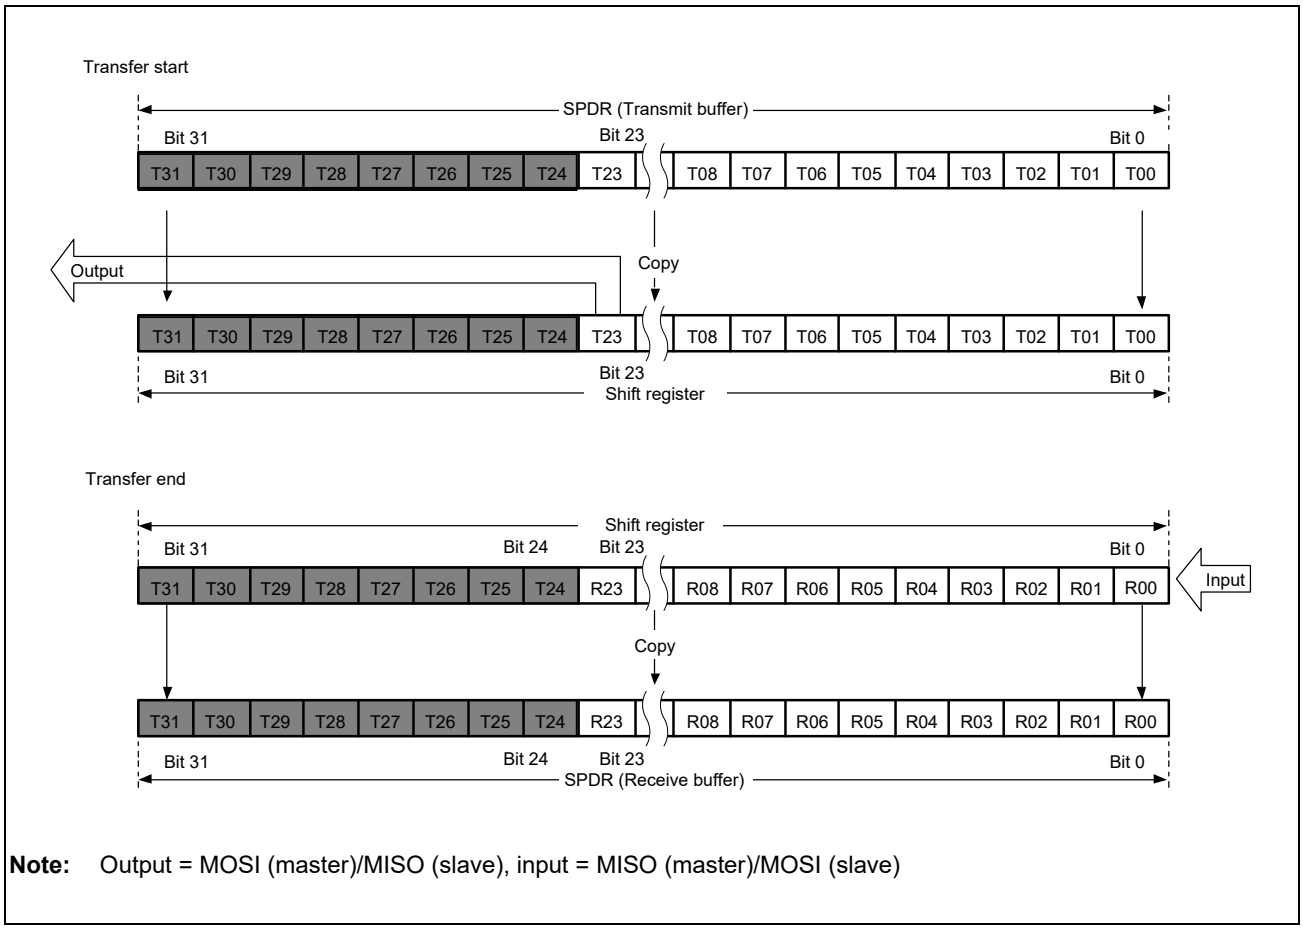
Figure 7.5-16 MSB First Transfer (32-Bit Data, Parity Disabled)

(4) MSB first transfer (24-bit data)

As an example of MSB-first transfer of data other than 32 bits with the parity function disabled, **Figure 7.5-17** shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, lower 24 bits (T23 to T00) in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T23 → T22 → … → T00 as transmit data.

In reception, received data is stored in bit 0 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R23 to R00, the shift register value is copied to the receive buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 7.5-17 MSB First Transfer (24-Bit Data, Parity Disabled)

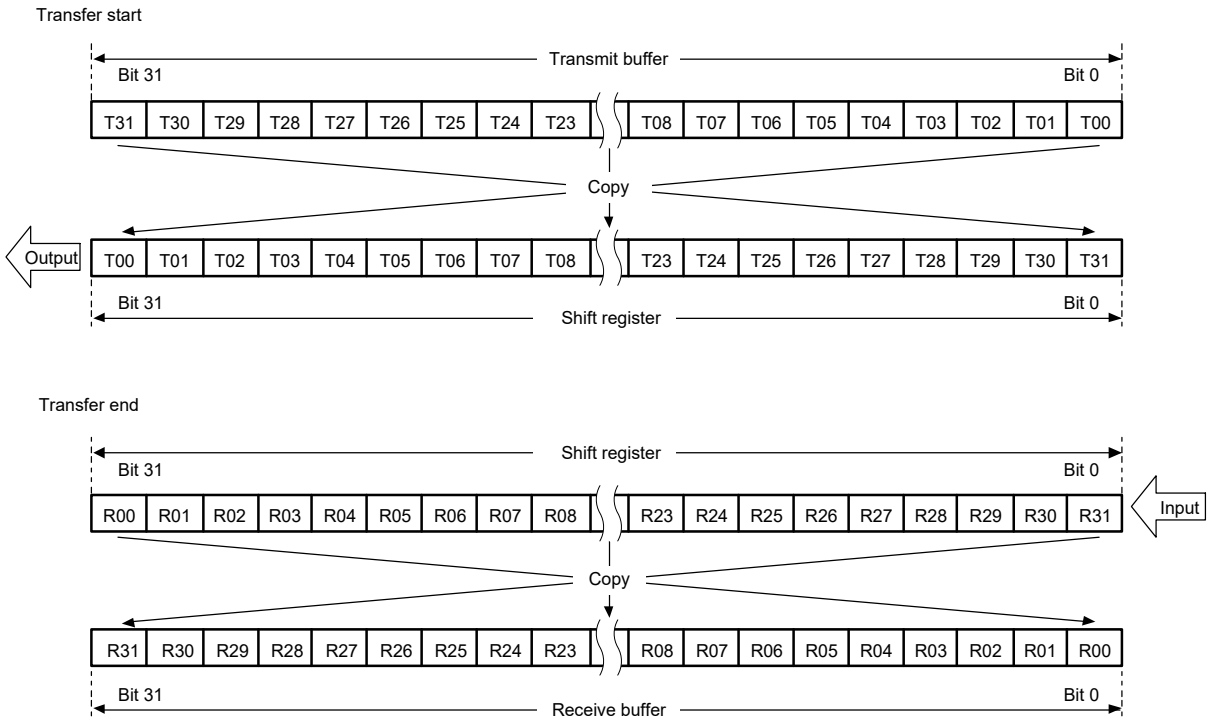
(5) LSB first transfer (32-bit data)

Figure 7.5-18 shows operations of the SPDR register and the shift register when the SPI performs 32-bit LSB-first transfer with the parity function disabled.

In transmission, bit values of the transmit buffer (T31 to T00) are reversed in bit units and are copied to the shift register in the order of T00 to T31. Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.

In reception, the first received data is stored in bit 0 of the shift register, and received data is shifted in units of data.

When necessary RSPCK cycles are input and data is stored from R00 to R31, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of R31 to R00.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

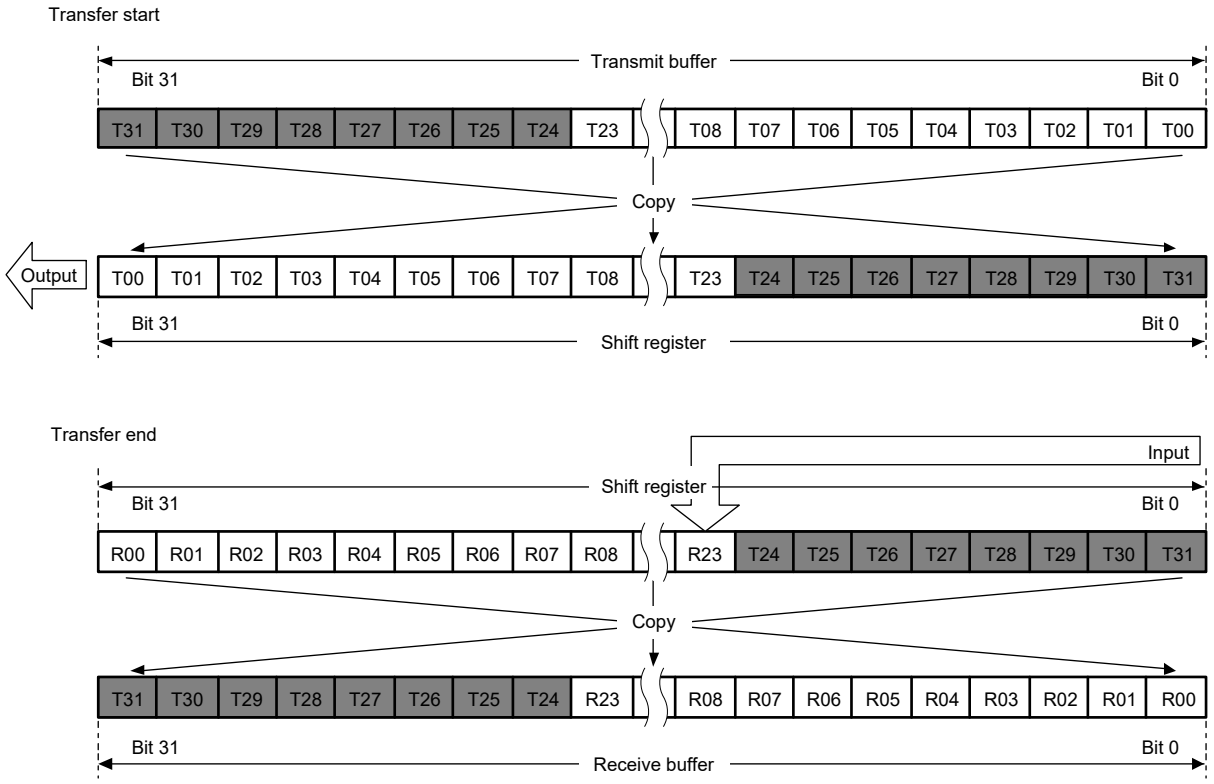
Figure 7.5-18 LSB First Transfer (32-Bit Data, Parity Disabled)

(6) LSB first transfer (24-bit data)

As an example of LSB-first transfer of data other than 32 bits with the parity function disabled, **Figure 7.5-19** shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, lower 24-bit values of the transmit buffer (T23 to T00) are reversed to the order from T00 to T23 in bit units and are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T23 as transmit data.

In reception, received data is stored in bit 8 of the shift register, and received data is shifted in units of data. When necessary RSPCK cycles are input and data is stored from R00 to R23, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of R23 (bit 23) to R00 (bit 0).



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 7.5-19 LSB First Transfer (24-Bit Data, Parity Disabled)

7.5.3.4.3 When parity is enabled (SPPE = 1b)

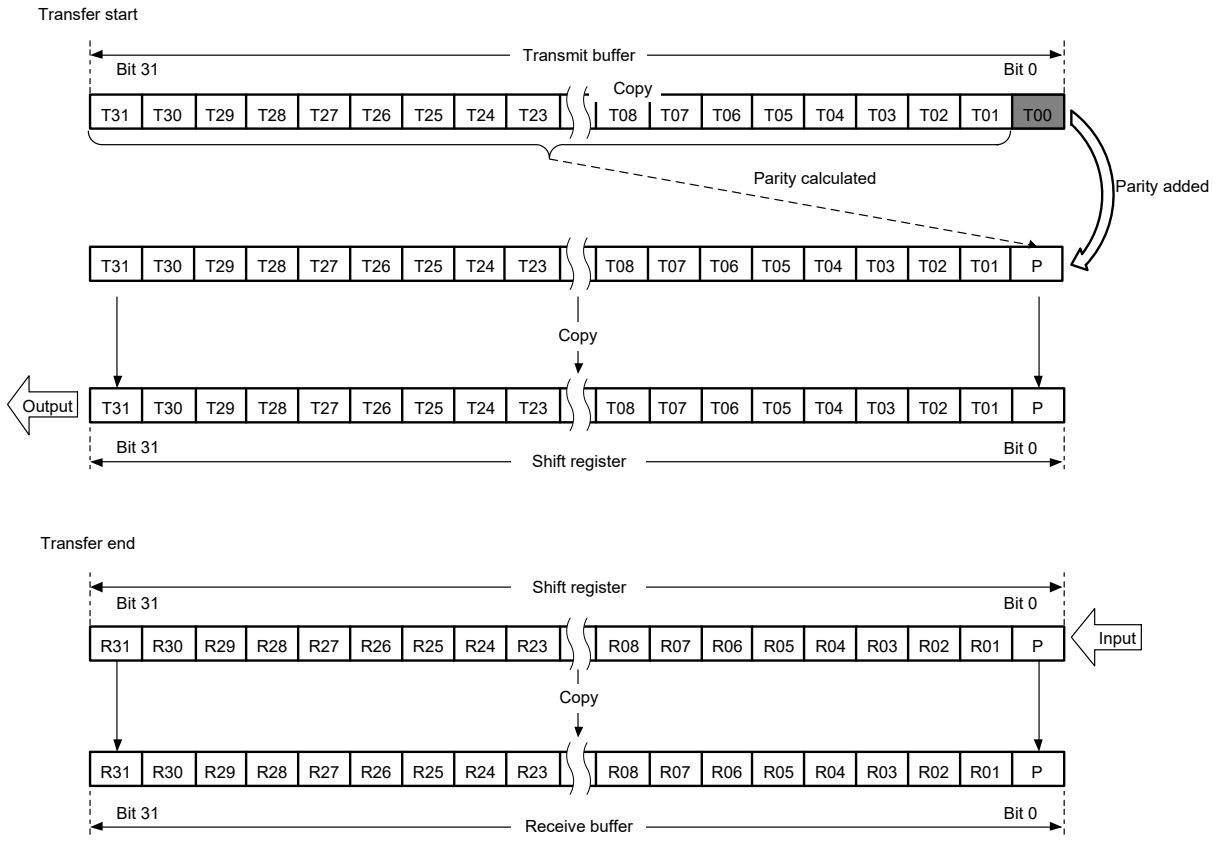
When the parity function is enabled, the LSB of transmit data or received data is converted to a parity bit. The parity bit value is calculated and converted by the hardware.

(1) MSB first transfer (32-bit data)

Figure 7.5-20 shows operations of the SPDR register and the shift register when the SPI performs 32-bit MSB-first transfer with the parity function enabled.

In transmission, the parity bit (P) value is calculated first from the data value T31 to T01, then the final bit T00 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T31 → T30 → … → T01 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R31 to P, the shift register value is copied to the receive buffer, and at the same time, R31 to P data is checked to determine whether a parity error is present.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

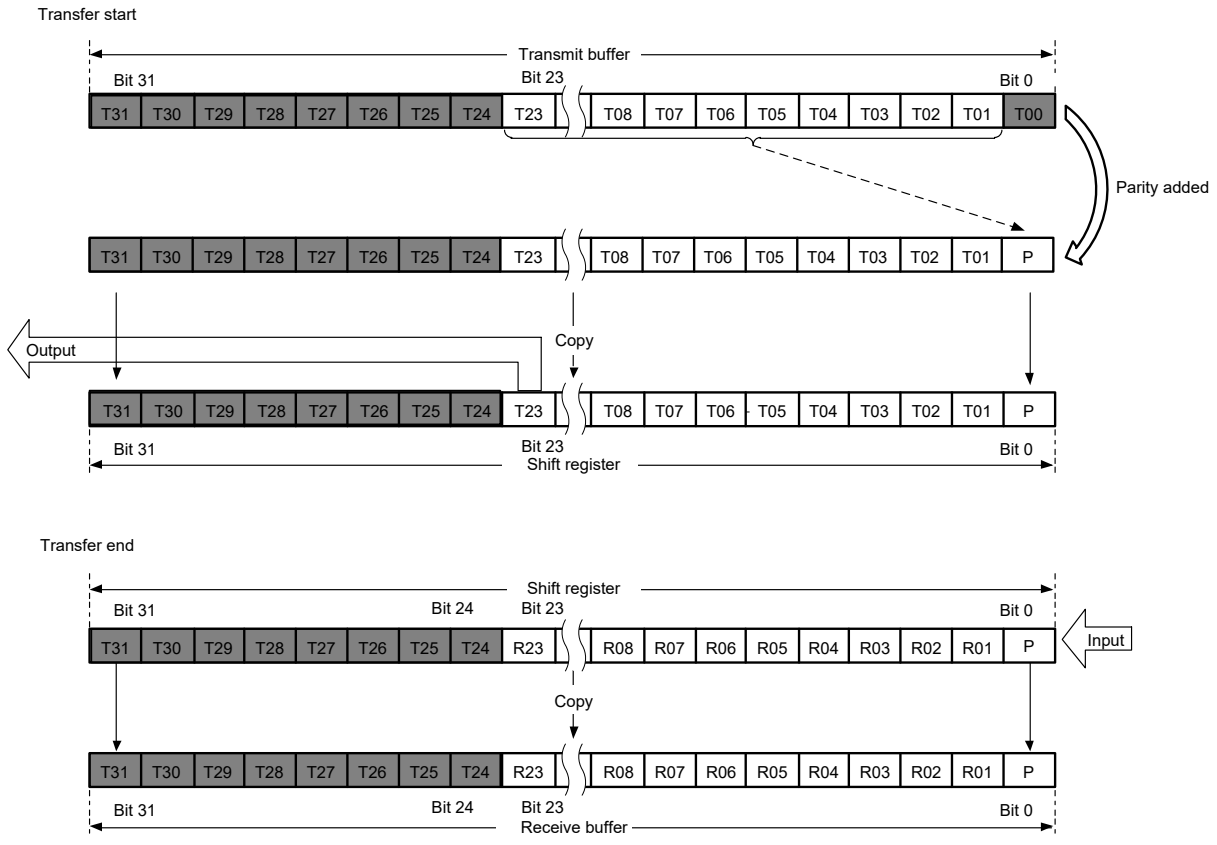
Figure 7.5-20 MSB First Transfer (32-Bit Data, Parity Enabled)

(2) MSB first transfer (24-bit data)

As an example of MSB-first transfer of data other than 32 bits with the parity function enabled, **Figure 7.5-21** shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, the parity bit (P) value is calculated first from the data value T23 to T01, then the final bit T00 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T23 → T22 → … → T01 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R23 to P, the shift register value is copied to the receive buffer, and at the same time, R23 to P data is checked to determine whether a parity error is present.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

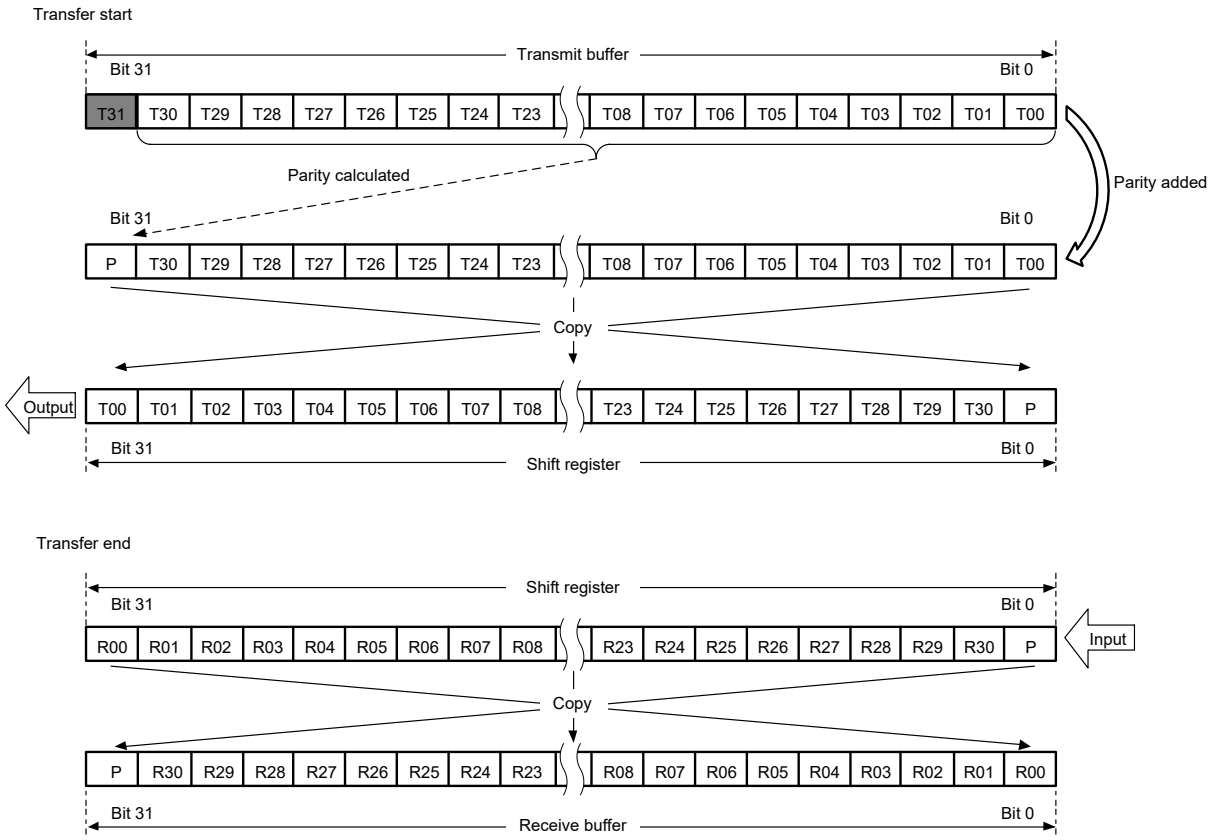
Figure 7.5-21 MSB First Transfer (24-Bit Data, Parity Enabled)

(3) LSB first transfer (32-bit data)

Figure 7.5-22 shows operations of the SPDR register and the shift register when the SPI performs 32-bit LSB-first transfer with the parity function enabled.

In transmission, the parity bit (P) value is calculated first from the data value T30 to T00, then the final bit T31 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T00 → T01 → … → T30 → P.

In reception, received data is stored in bit 0 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R00 to P, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of P to R00, and at the same time, R00 to P data is checked to determine whether a parity error is present.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

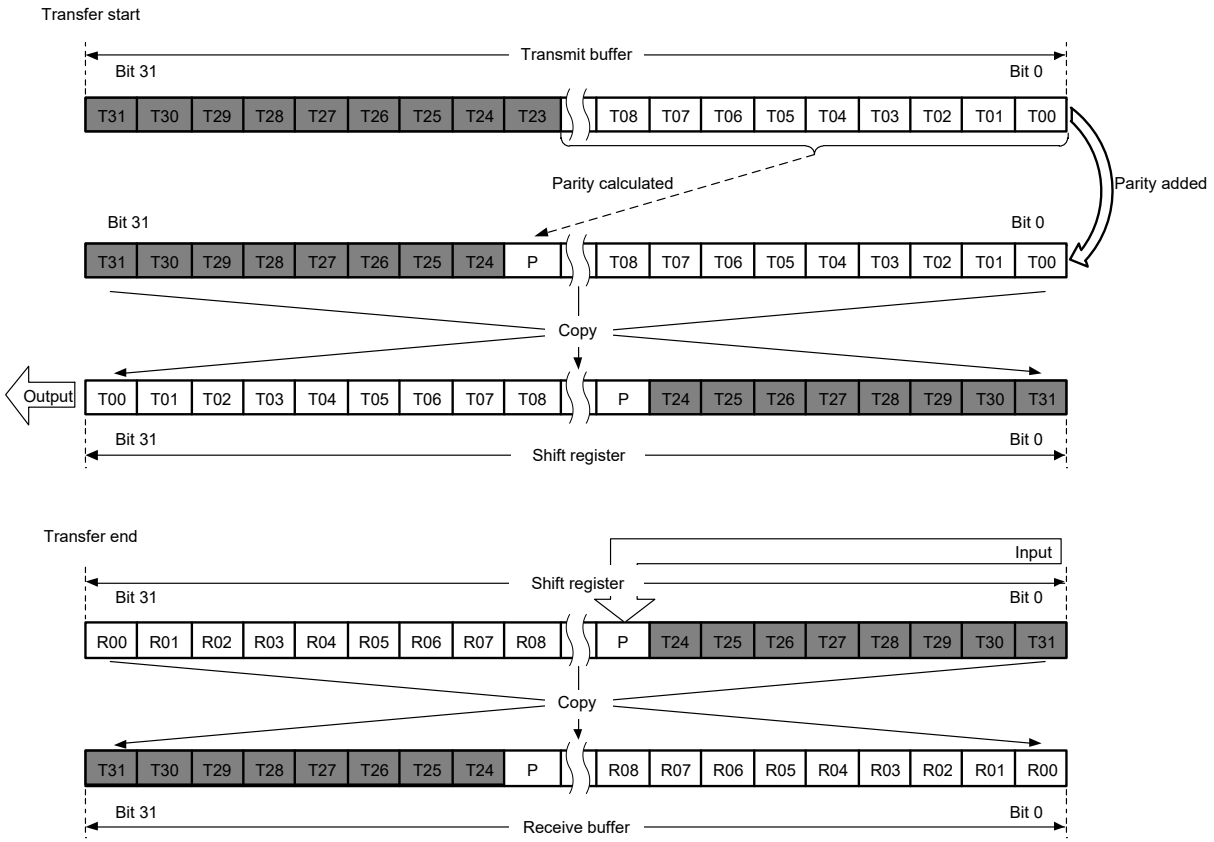
Figure 7.5-22 LSB First Transfer (32-Bit Data, Parity Enabled)

(4) LSB first transfer (24-bit data)

As an example of LSB-first transfer of data other than 32 bits with the parity function enabled, **Figure 7.5-23** shows operations of the SPDR register and the shift register when the SPI performs 24-bit data transfer.

In transmission, the parity bit (P) value is calculated first from the data value T22 to T00, then the final bit T23 is replaced with the calculated P value, and then transmit data is copied to the shift register. Transmit data is transmitted in the order of T00 → T01 → … → T22 → P.

In reception, received data is stored in bit 8 of the shift register, and is then shifted in units of data. When necessary RSPCK cycles are input and received data is stored from R00 to P, bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of P (bit 23) to R00 (bit 0), and at the same time, R00 to P data is checked to determine whether a parity error is present.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 7.5-23 LSB First Transfer (24-Bit Data, Parity Enabled)

7.5.3.4.4 Byte swap transmission

When byte swapping is enabled, the data in the transmission buffer, swapped in 8-bit units, is copied to the shift register.

(1) 32-bit data length

Figure 7.5-24 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 32-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. MSB First Transfer (When the byte swap is disabled.)
   Data (Byte3 [T31 to T24] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register.
   Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → … → T00 as transmit data.
2. MSB First Transfer (When the byte swap is enabled.)
   Byte values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte3 [T07 to T00] to Byte0 [T31 to T24].
   Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14→ … → T08 → T23 → T22 → … → T16 → T31 → T30 → … → T24 as transmit data.
3. LSB-first transfer (When the byte swap is disabled.)
   Bit values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are

copied to the shift register in the order of Byte0 [T00 to T07] to Byte3 [T24 to T31].
Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T31 as transmit data.

4. LSB-first transfer (When the byte swap is enabled.)
Bit values of each byte of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte3 [T24 to T31] to Byte0 [T00 to T07].
Bit values in the shift register are shifted and transmitted in the order of T24 → T25 → … → T31 → T16 → T17 → … → T23 → T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

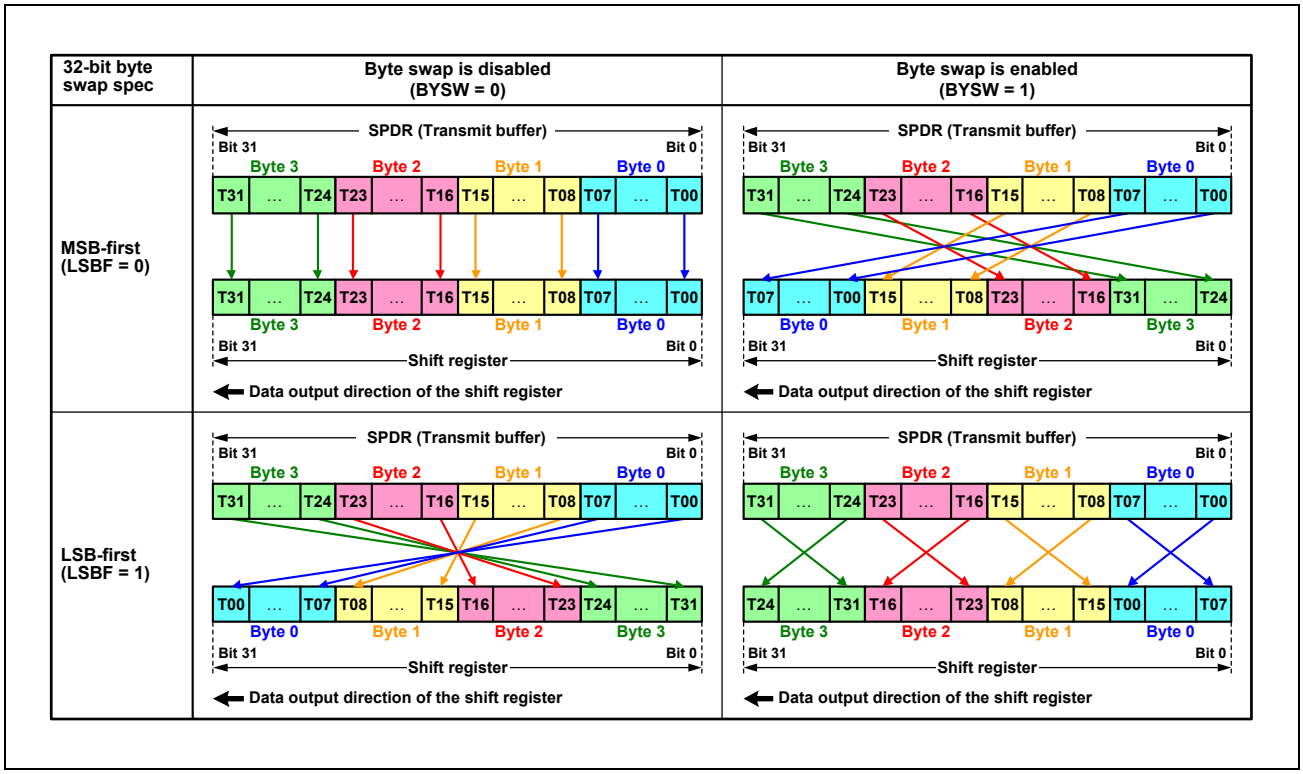


Figure 7.5-24 Byte Swap with MSB/LSB Transfer (32 Bits)

(2) 16-bit data length

Figure 7.5-25 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 16-bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. MSB First Transfer (When the byte swap is disabled.)
Data (Byte1 [T15 to T08] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register.
Bit values in the shift register are shifted and transmitted in the order of T15 → T14 → … → T00 as transmit data.

2. MSB First Transfer (When the byte swap is enabled.)
Byte values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte1 [T07 to T00] to Byte0 [T15 to T08].
Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → … → T00 → T15 → T14→ … → T08 as transmit data.

3. LSB-first transfer (When the byte swap is disabled.)
Bit values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte1 [T08 to T15].
Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → … → T15 as transmit data.

4. LSB-first transfer (When the byte swap is enabled.)
   Bit values of each byte of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte1 [T08 to T15] to Byte0 [T00 to T07].
   Bit values in the shift register are shifted and transmitted in the order of T08 → T09 → … → T15 → T00 → T01 → … → T07 as transmit data.

Figure 7.5-25 Byte Swap with MSB/LSB Transfer (16 Bits)

NOTE

- When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[4:0] setting).
  If setting the other length, the behavior is not guaranteed.
- When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0b).
  If setting the parity function as valid (SPPE bit = 1b), the behavior is not guaranteed.
- Set SPDCR.BYSW bit, when SPCR.SPE bit is 0b. If rewriting BYSW bit, when SPE bit is 1b, the behavior after it is not guaranteed.

7.5.3.4.5 Byte swap reception

When byte swap is enabled, the data in the shift register, swapped in 8-bit units, is copied to the receive buffer.

(1) 32-bit data length

Figure 7.5-26 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 32- bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. MSB First Transfer (When the byte swap is disabled.)
   The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → … → R00.
   When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.
2. MSB First Transfer (When the byte swap is enabled.)
   The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08 → R23 → R22 → … → R16 → R31 → R30 → … → R24.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].
3. LSB-first transfer (When the byte swap is disabled.)
   The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → … → R31.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte3 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].
4. LSB-first transfer (When the byte swap is enabled.)
   The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24 → R25 → … → R31 → R16 → R17 → … → R23 → R08 → R09 → … → R15 → R00 → R01 → … → R07.
   When necessary RSPCK cycles are input and data is stored from Byte3 [R24 to R31] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

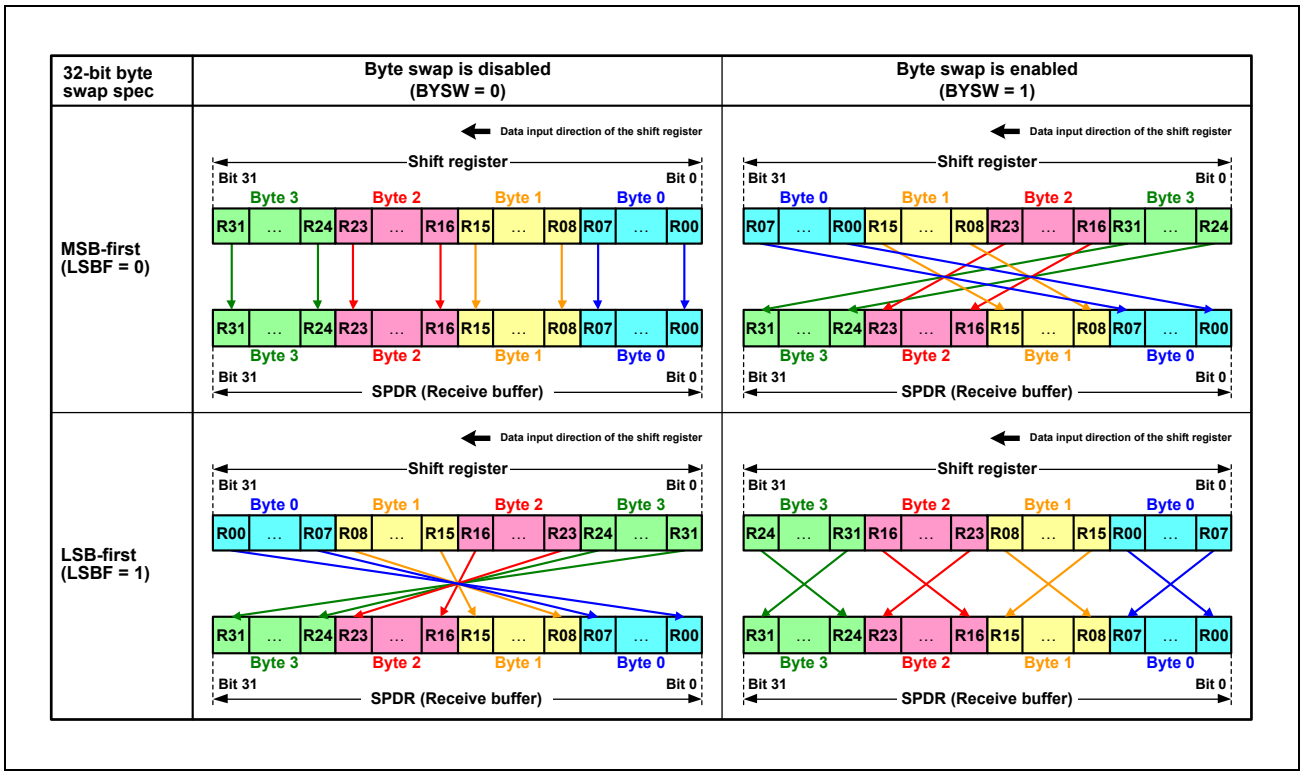

Figure 7.5-26 Byte Swap with MSB/LSB Reception (32 Bits)

(2) 16-bit data length

Figure 7.5-27 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 16- bit data length, using a combination of MSB/LSB first and with/without byte swap.

1. MSB First Transfer (When the byte swap is disabled.)
   The first received data (R15) is stored in bit 0 of the shift register, and received data is shifted in the order of R15 → R14 → … → R00.
   When necessary RSPCK cycles are input and data is stored from Byte1 [R15 to R08] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.
2. MSB First Transfer (When the byte swap is enabled.)
   The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → … → R00 → R15 → R14 → … → R08.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte1 [R15 to R08], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].
3. LSB-first transfer (When the byte swap is disabled.)
   The first received data (R00) is stored in bit 15 of the shift register, and received data is shifted in the order of R00 → R01 → … → R15.
   When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte1 [R08 to R15], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].
4. LSB-first transfer (When the byte swap is enabled.)
   The first received data (R08) is stored in bit 0 of the shift register, and received data is shifted in the order of R08 → R09 → … → R15 → R00 → R01 → … → R07.

When necessary RSPCK cycles are input and data is stored from Byte1 [R08 to R15] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte1 [R15 to R08] to Byte0 [R07 to R00].

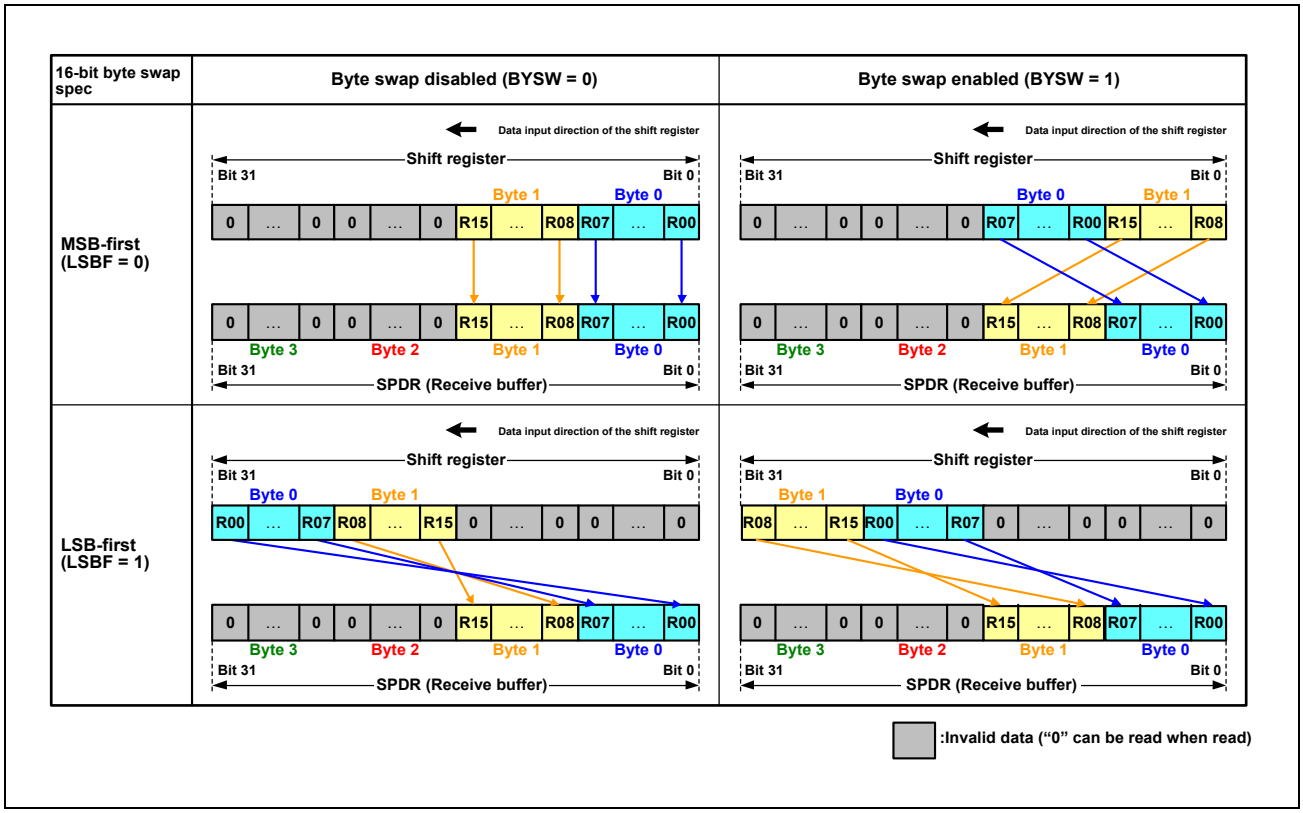

Figure 7.5-27 Byte Swap with MSB/LSB Reception (16 Bits)

NOTE

- When using the byte swap, set 16 bits or 32 bits to the data length (SPCMD.SPB[4:0] setting) .
  If setting the other length, the behavior is not guaranteed.
- When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0b).
  If setting the parity function as valid (SPPE bit = 1b), the behavior is not guaranteed.
- Set SPDCR2.BYSW bit, when SPCR.SPE bit is 0b. If rewriting BYSW bit, when SPE bit is 1b, the behavior after it is not guaranteed.

7.5.3.5 Transfer Format (Frame Format)

7.5.3.5.1 CPHA = 0b

Figure 7.5-28 shows an example of transfer format of 8-bit data serial transfer when SPCMD.CPHA = 0b. However, when the SPI is in slave mode (SPCR.MSTR = 0b) with the CPHA bit set to 0b, clock synchronous operation (SPCR.SPMS = 1b) is not guaranteed. In **Figure 7.5-28**, RSPCK (CPOL = 0b) is the RSPCK signal waveform when SPCMD.CPOL = 0b, and RSPCK (SPCMD.CPOL = 1b) is the RSPCK signal waveform when SPCMD.CPOL = 1b. The sampling timing shows the time when the SPI latches serial transfer data in the shift register. Input and output directions of each signal depend on SPI settings. (See **7.5.3.2 SPI Pin Control**.)

When SPCMD.CPHA = 0b, output of valid data to the MOSI signal and valid data drive to the MISO signal start at the SSL signal assertion timing. The first RSPCK signal change timing after the SSL signal is asserted is the first transfer data latch timing. After this timing, data is sampled in each RSPCK cycle. The MOSI signal and the MISO signal change always after the half RSPCK cycles of the transfer data latch timing. The set CPOL bit value does not affect the RSPCK signal operation timing but affects only the signal polarity.

Period t1 is the period (RSPCK delay) from SSL signal assertion to RSPCK oscillation. Period t2 is the period (SSL negation delay) from RSPCK oscillation stop to SSL signal negation. Period t3 is the period (next-access delay) to inhibit SSL signal assertion for the next transfer after serial transfer is completed. Periods t1, t2, and t3 are controlled by the master device in the SPI system. For t1, t2, and t3 when this LSI (SPI) is in master mode, see **7.5.3.13.1 Master mode operation**.

[In the Motorola-SPI case]

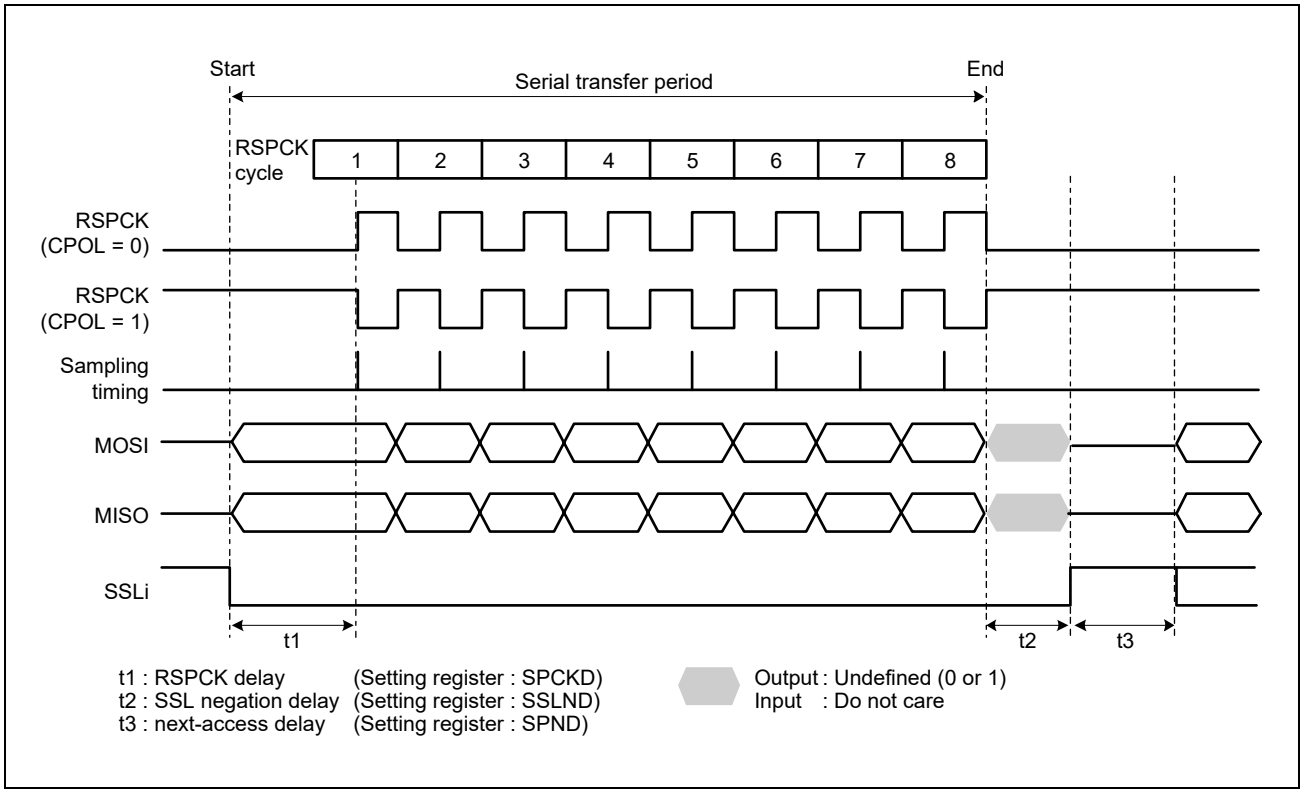

Figure 7.5-28 SPI Transfer Format (CPHA = 0b, SPFRF = 0b)

7.5.3.5.2 CPHA = 1b

Figure 7.5-29 shows an example of transfer format of 8-bit data serial transfer when SPCMD.CPHA = 1b. However, when SPCR.SPMS = 1b, communication is performed by using only RSPCK, MOSI, and MISO signals without using the SSL signal. In **Figure 7.5-29**, RSPCK (CPOL = 0b) is the RSPCK signal waveform when SPCMD.CPOL = 0b, and RSPCK (SPCMD.CPOL = 0b) is the RSPCK signal waveform when SPCMD.CPOL = 0b. The sampling timing shows the time when the SPI latches serial transfer data in the shift register. Input and output directions of each signal depend on SPI mode (master or slave mode). (See **7.5.3.2 SPI Pin Control**.)

When SPCMD.CPHA = 1b, invalid data drive to the MISO signal starts at the SSL signal assertion timing. Output of valid data to the MOSI and MISO signals starts at the first RSPCK signal change timing after the SSL signal is asserted.

After this timing, data is updated in each RSPCK cycle. Transfer data is always latched after 1/2 RSPCK cycle of this timing. The set CPOL bit value does not affect the RSPCK signal operation timing but affects only the signal polarity.

Periods t1, t2, and t3 are the same as when CPHA = 0b. For t1, t2, and t3 when this LSI (SPI) is in master mode, see **7.5.3.13.1 Master mode operation**.

[In the Motorola-SPI case]

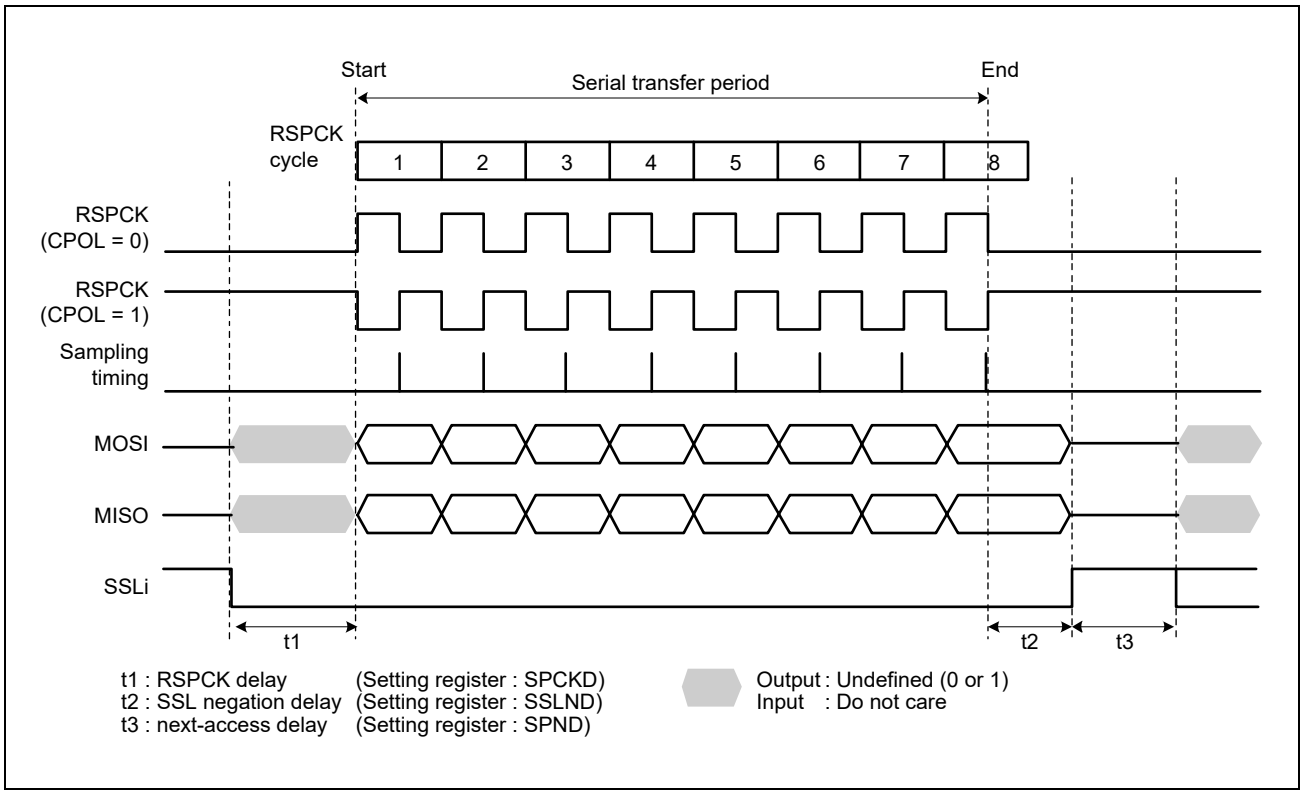

Figure 7.5-29 SPI Transfer Format (CPHA = 1b, SPFRF = 0b)

7.5.3.6 Communications Operating Mode

Transmit-Receive serial communication, transmit-only operation, and Receive-only operation are selected by setting the Communication Mode Select bits (TXMD[1:0]) of the SPCR register.

SPDR access described in **Figure 7.5-30**, **Figure 7.5-31**, and **Figure 7.5-32** shows an access to the SPDR register. W shows a write cycle.

7.5.3.6.1 Transmit-receive serial communication (TXMD[1:0] = 00b)

Figure 7.5-30 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 00b. In the example in **Figure 7.5-30**, the SPI performs 8-bit data serial transfer with the settings of RTRG = FIFO stage - 1, SPDCR2.TTRG = 0b, SPCMD.CPHA = 1b, and SPCMD.CPOL = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

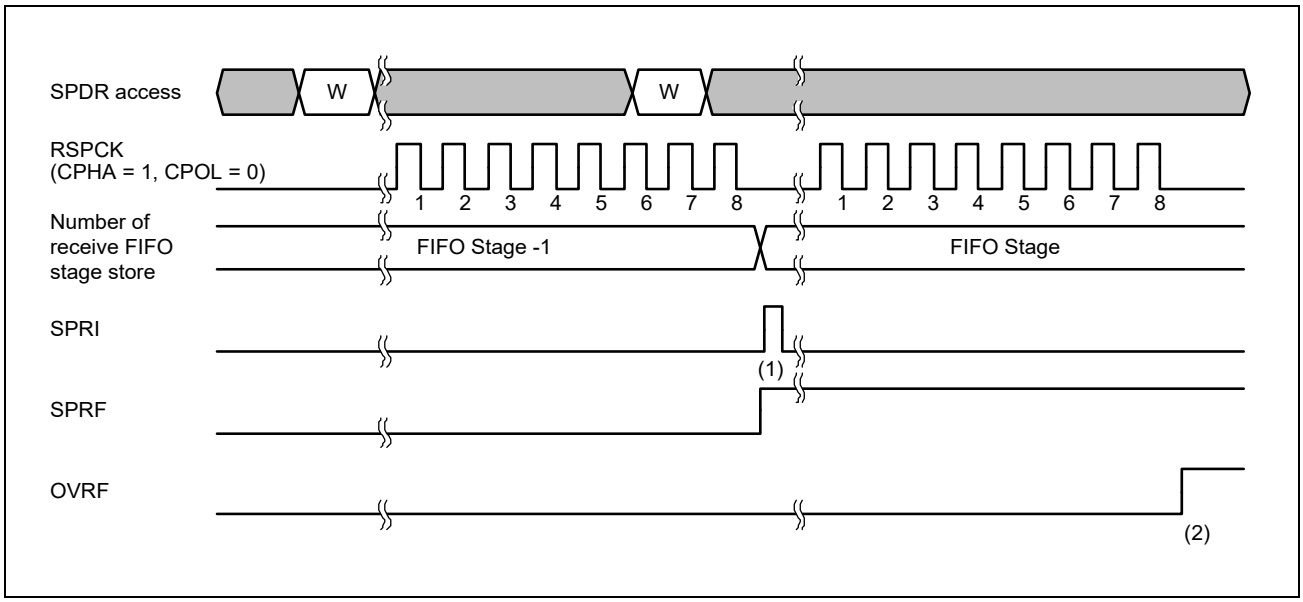

Figure 7.5-30 Operation Example of TXMD[1:0] = 00b

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1b) and copies the received data in the shift register to the receive buffer.

(2) When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the OVRF flag in the SPSR register to 1 and discards the received data in the shift register.

In Transmit-Receive serial communication (TXMD[1:0] = 00b), transmit data is transmitted and receive data is received. Therefore, the SPRF flag and the OVRF flag are set to 1b at timings (1) and (2) respectively.

7.5.3.6.2 Transmit-only serial communication (TXMD[1:0] = 01b)

Figure 7.5-31 shows an example of operation when the communication mode select bits (TXMD[1:0]) in the SPCR register are set to 01b. In the example in **Figure 7.5-31**, the SPI performs 8-bit data serial transfer with the settings of SPDCR2.TTRG[1:0] = 00b, SPDCR2.RTRG[1:0] = 00b, SPCMD.CPHA = 1b, and SPCMD.CPOL = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

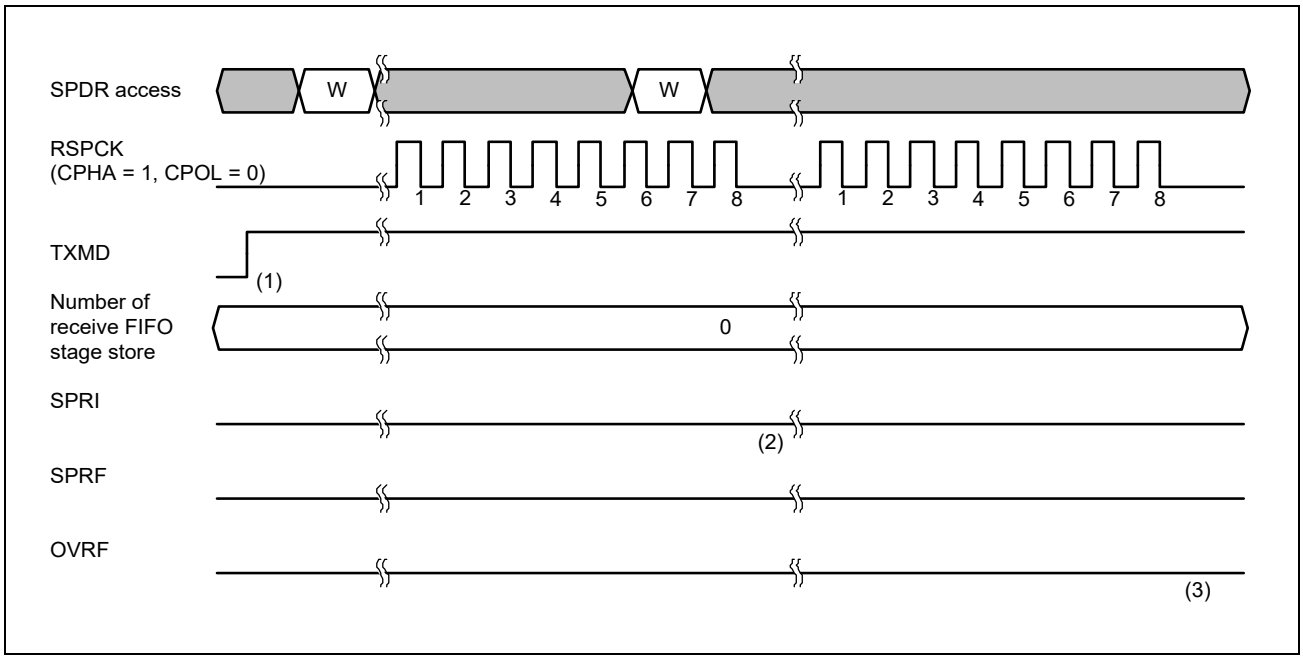

Figure 7.5-31 Operation Example of TXMD[1:0] = 01b

The following describes operation of flags at timings (1) to (3) in the figure above.

(1) Before setting TXMD[1:0] to 01b (transmit-only serial communication), confirm that the receive buffer is empty and that the SPRF and OVRF flags in the SPSR register are 0b.

(2) In transmit-only serial communication (TXMD[1:0] = 01b), when serial transfer ends without receiving data in the receiving FIFO of SPDR, the SPRF flag remains 0 and the shift register data is not copied to the receive buffer.

(3) The OVRF flag remains 0 even after serial transfer ends because previously received data is not remaining in the SPDR's receive buffer, and the shift register data is not copied to the receive buffer.

In transmit-only serial communication (TXMD[1:0] = 01b), transmit data is transmitted but receive data is not received. Therefore, the SPRF flag and the OVRF flag remain 0 at each timing of (1) to (3).

7.5.3.6.3 Receive-only serial communication (TXMD[1:0] = 10b)

Figure 7.5-32 shows an example of operation when the communication mode select bit (TXMD[1]) in the SPI control register (SPCR) is set to 1b. In the example in **Figure 7.5-32**, the SPI performs 8-bit data serial transfer with the settings of SPDCR2.TTRG[1:0] = 0b, SPDCR2.RTRG[1:0] = FIFO stage - 1, SPCMD.CPHA = 1b, and CPOL in SPCMD = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

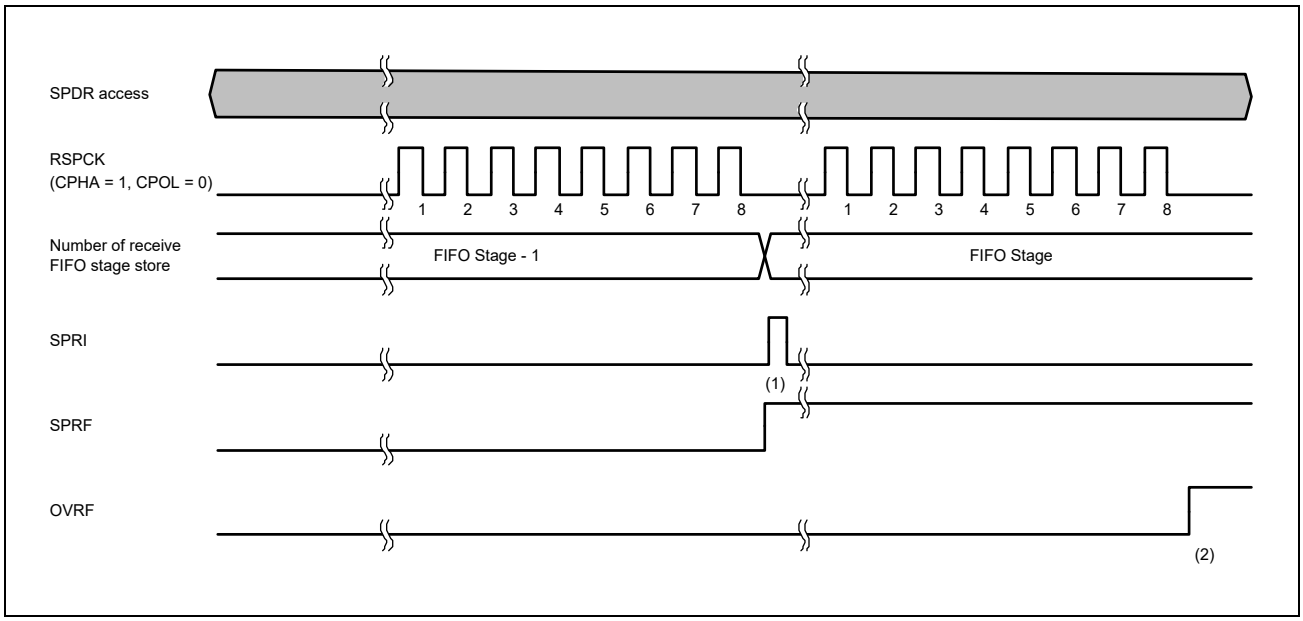

Figure 7.5-32 Operation Example of TXMD[1:0] = 10b

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request SPRI (setting the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the OVRF flag in the SPSR.SPI register to 1b and discards the received data in the shift register.

7.5.3.7 Transmission buffer empty/receive buffer full interrupt

Figure 7.5-33 show an example of operation of SPI transmit buffer empty interrupt (SPTI) and SPI receive buffer full interrupt (SPRI) respectively. “SPDR access” described in **Figure 7.5-33** and shows an access to the SPDR register. W shows a write cycle and R shows a read cycle. In each example of operation, the SPI performs 8-bit data serial transfer with the settings of SPCR.TXMD[1:0] = 00b, SPDCR2.TTRG = 0b, SPDCR2.RTRG = 0b, SPCMD.CPHA = 0b (**Figure 7.5-33**), and SPCMD.CPOL = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

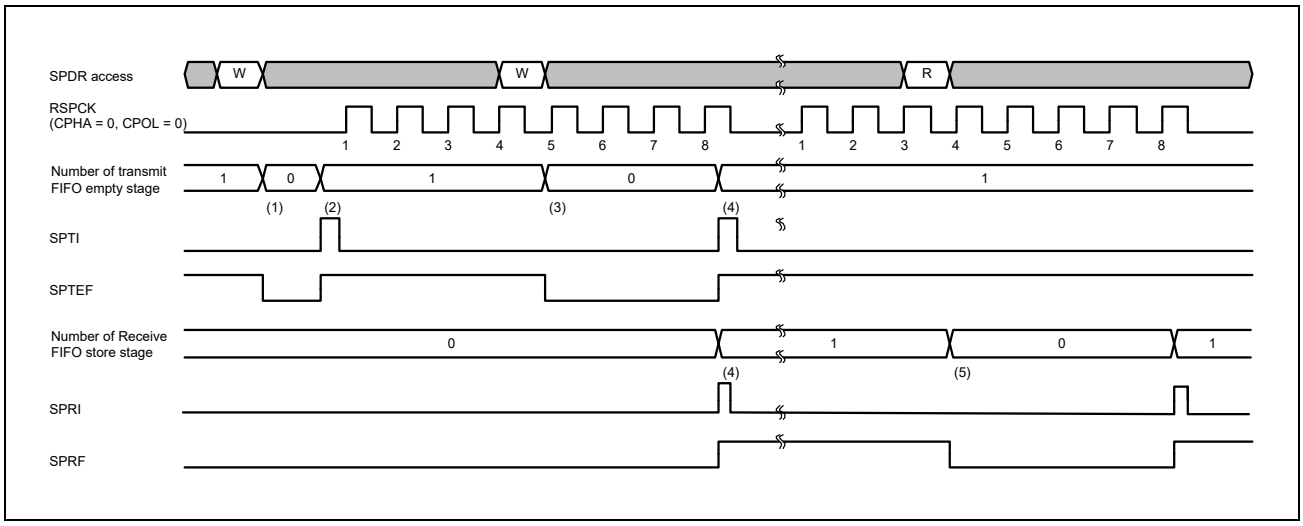

Figure 7.5-33 Example of SPTI Interrupt and SPRI Interrupt Operations

The following describes operation at timings (1) to (5) in the figure above.

(1) When transmit data is written to SPDR before the data for the next transfer is not set to the FIFO of the SPDR, the SPI writes data to the transmission buffer. When transmit data is written to SPDR in one processing routine using DMAC, the SPSR.SPTEF flag is cleared to 0b at the last access.

(2) When the shift register is empty, the SPI copies transmit buffer data to the shift register. At this time, if transmit FIFO empty stage number > TTRG value, then the SPI generates a transmit buffer empty interrupt request (SPTI) and sets the SPTEF flag to 1. How to start serial transfer depends on SPI mode. (See **7.5.3.13 SPI Operation** and **7.5.3.14 Clock Synchronous Operation**.)

(3) When transmit data is written to SPDR upon a transmit buffer empty interrupt request (SPTI) or in the transmit buffer empty determination processing due to the SPTEF flag, the SPI writes data to the transmit buffer. When the transmit data is written to SPDR in one processing routine using DMAC, the SPTEF flag is cleared to 0b at the last access. The SPI does not copy transmit buffer data to the shift register because the shift register contains serial transfer data.

(4) When serial transfer ends (data sampling clock edge in the final bit is detected) while the receive buffer of SPDR > FIFO stage number, the SPI copies the received data in the shift register to the receive buffer. At this time, a receive buffer full interrupt request is generated and the SPRF flag is set to 1b. When serial transfer ends, the shift register becomes empty. If the next transfer data is set in the transmit FIFO before serial transfer ends, the SPI set the SPTEF flag to 1b and copies transmit buffer data to the shift register. Even if received data is not copied from the shift register to the receive buffer while an overrun error is present, the SPI determines that the shift register is empty at the end of serial transfer, enabling data transfer from the transmit buffer to the shift register.

(5) When SPDR is read upon a receive buffer full interrupt request (SPRI) or in the receive buffer full determination processing due to the SPRF flag, received data can be read. If the received data is read from SPDR in one processing routine using DMAC, the SPRF flag is cleared to 0b at the last access.

When transmit data is written to the SPDR register while no empty stages in the transmit FIFO, the SPI does not update transmit buffer data. Write transmit data to the SPDR register upon a transmit buffer empty interrupt request or check the empty or not the transmission buffer by the SPTEF flag.

While SPCR.SPTIE = 1b, when the SPI is disabled (SPCR.SPE = 0b), an SPI transmit buffer empty interrupt is generated. However, SPI transmit buffer empty interrupt is inhibited by disabling SPI transmit buffer empty interrupt (SPCR.SPTIE = 0b) at the same time as SPE bit setting.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the SPI detects an overrun error without copying data from the shift register to the receive buffer (as described in **S7.5.3.10 Error Detection**). To prevent overrun of received data, read received data before the next serial transfer ends.

Transmit buffer state and receive buffer state can be monitored by an SPI transmit buffer empty interrupt and an SPI receive buffer full interrupt or a corresponding interrupt flag or by the SPTEF and SPRF flags.

7.5.3.8 Idle Interrupt

The idle interrupt during master mode operation is when the SPCP[2:0] of the SPSSR register becomes 000b (start of sequence control), the IDLNF flag in the SPSR register is set to 1b and an idle interrupt request is made during master mode operation. An interrupt request is also made by clearing the SPCR.SPE bit to 0b.

7.5.3.8.1 In the Motorola-SPI case

Figure 7.5-34 shows an example of idle interrupt operation during normal operation.

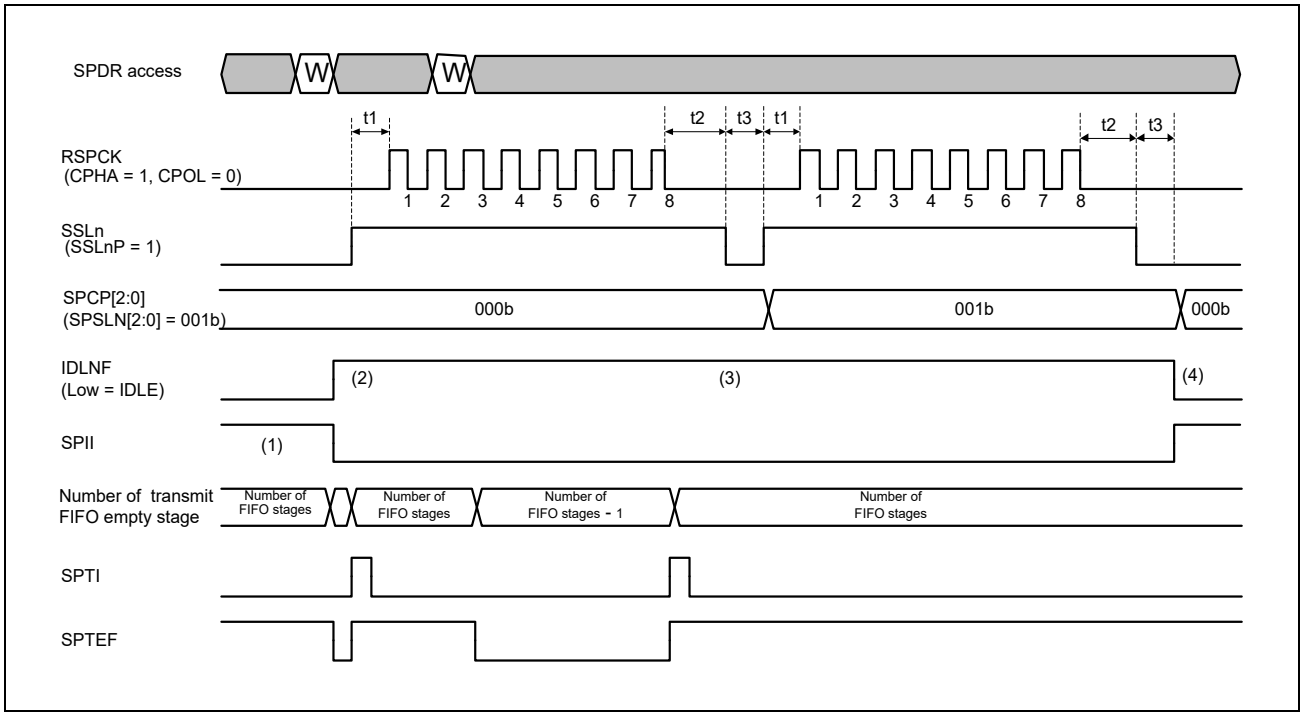

Figure 7.5-34 Example of Idle Interrupt Operation (Master Mode/Motorola-SPI)

(1) At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data makes sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI control register (SPCR) is set to 1b before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0b before starting transmission.

(2) After transmission has started, the IDLNF flag remains 1b (BUSY) regardless of the transmit buffer state.

(3) The SPCP[2:0] bits change the command to the next command the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The IDLNF flag is cleared to 0 (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1b currently, an SPII interrupt is output.

7.5.3.8.2 In the TI-SSP case

Figure 7.5-35 shows an example of idle interrupt operation during normal operation.

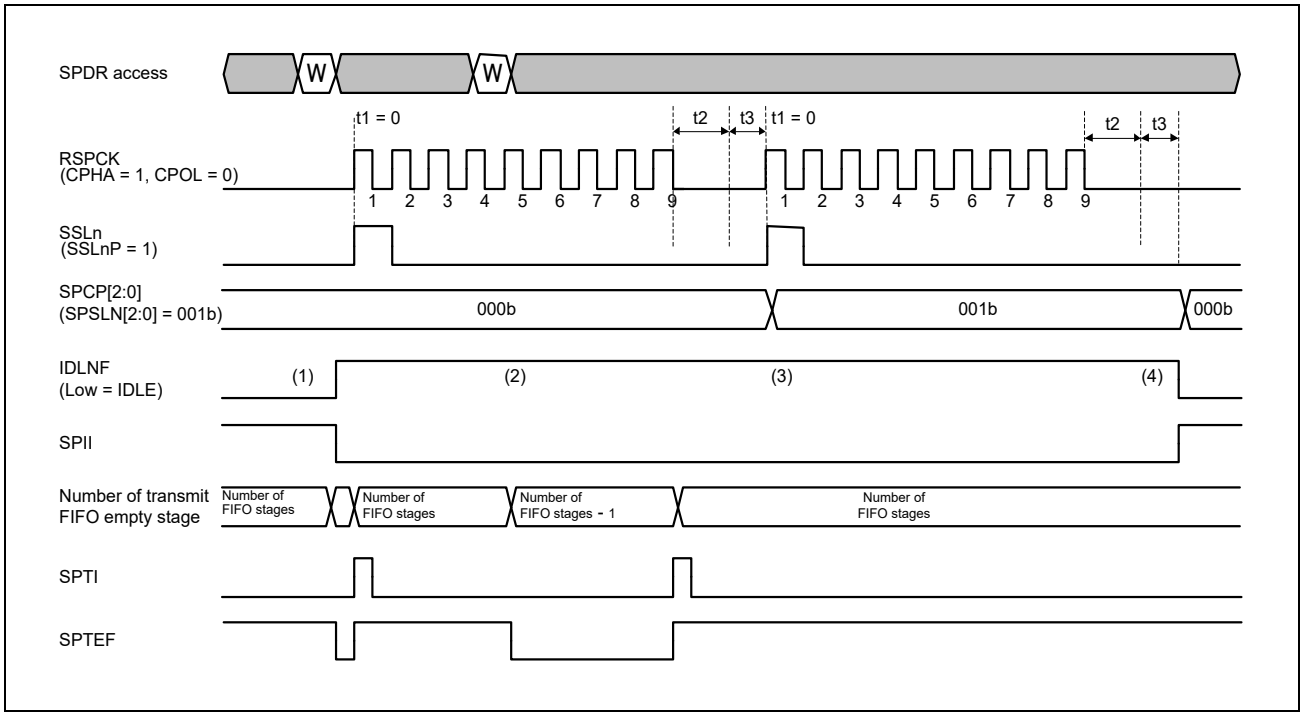

Figure 7.5-35 Example of Idle Interrupt Operation (Master Mode/TI-SSP)

(1) At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0b (IDLE). Writing transmit data makes sets the IDLNF flag to 1b (BUSY). When the SPCR.SPIIE bit is set to 1b before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0b before starting transmission.

(2) After transmission has started, the IDLNF flag remains 1b (BUSY) regardless of the transmit buffer state.

(3) The SPCP[2:0] bits change the command to the next command the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The IDLNF flag is cleared to 0b (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When SPCR.SPIIE = 1b currently, an SPII interrupt is output.

7.5.3.9 Communication End Interrupt

7.5.3.9.1 Transmit-receive/transmit-only in master mode

Refer to the description of the CENDF bit in **7.5.2.2.19 SPI Transfer FIFO Status Register (RSPIm_**SPTFSR) and **7.5.2.2.18 SPI Status Register (RSPIm_**SPSR) for the setting/clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Master Mode.

(1) In the Motorola-SPI case

Figure 7.5-36 shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

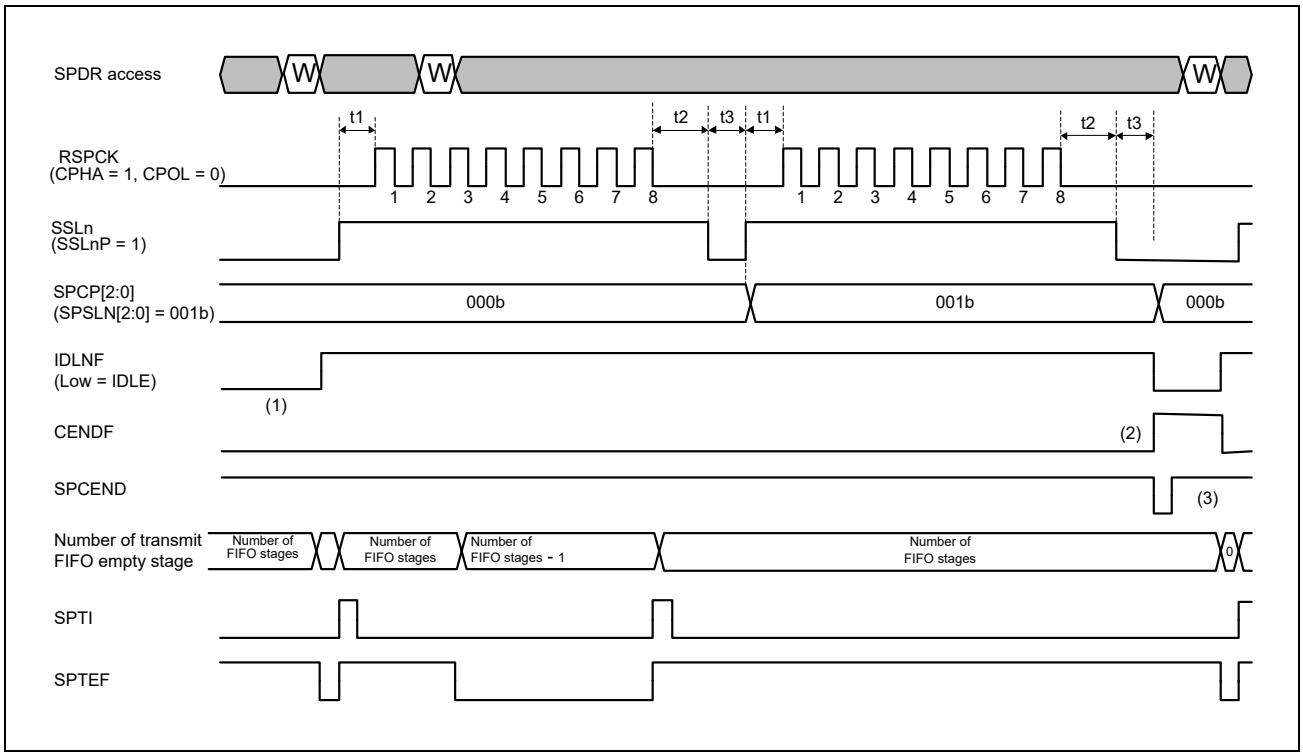

Figure 7.5-36 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-Only Master Mode/Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. The SPCEND interrupt is then output with 1 PCLKM cycle width if the CENDIE bit is 1b.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 7.5-37 shows an example of communication end interrupt operation during transmit-receive/transmit-only master mode.

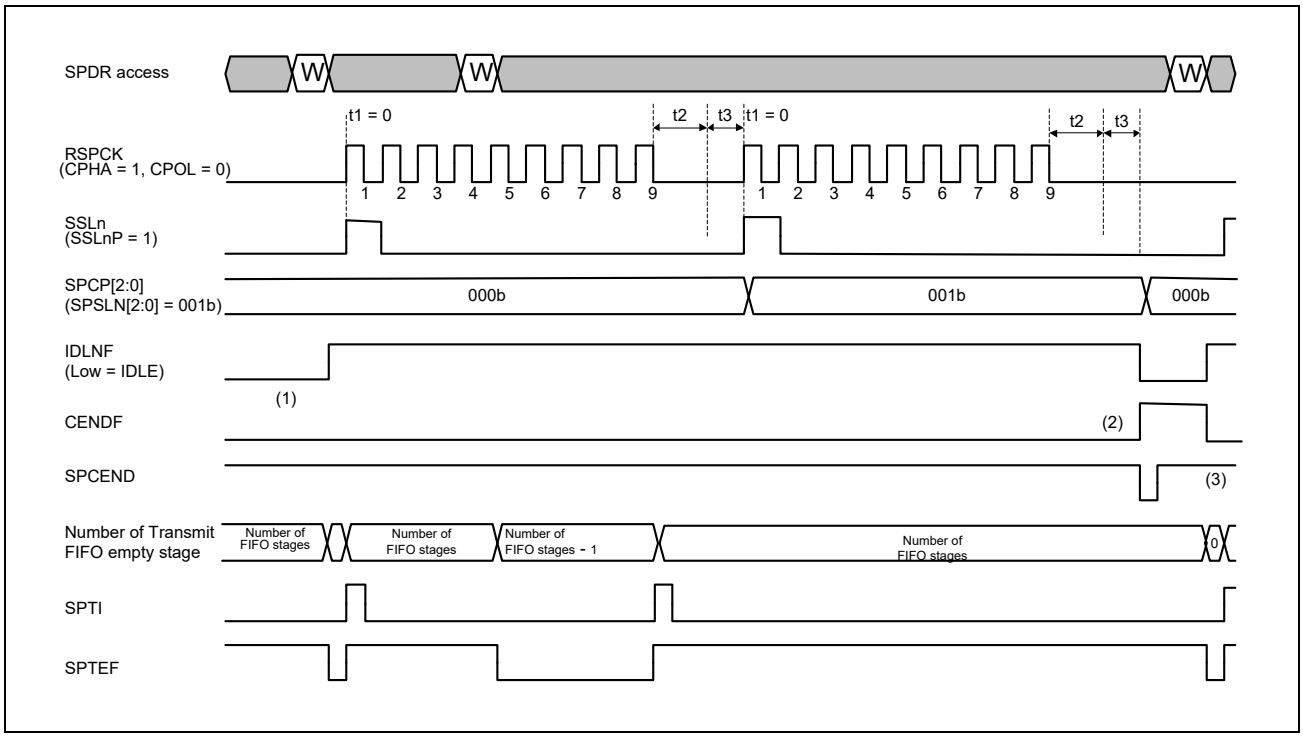

Figure 7.5-37 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-Only Master Mode/TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication starts, and these are kept during communication.

(2) The CENDF flag is 1b (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. The SPCEND interrupt is then output with 1 PCLKM cycle width if the CENDIE bit is 1b.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

7.5.3.9.2 Receive-only in master mode

Refer to the description of the CENDF bit in **7.5.2.2.18 SPI Status Register (RSPIm_**SPSR) for the setting/clearing conditions of the communication completion flag during Receive-only in Master Mode.

Figure 7.5-38 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] = 00h.

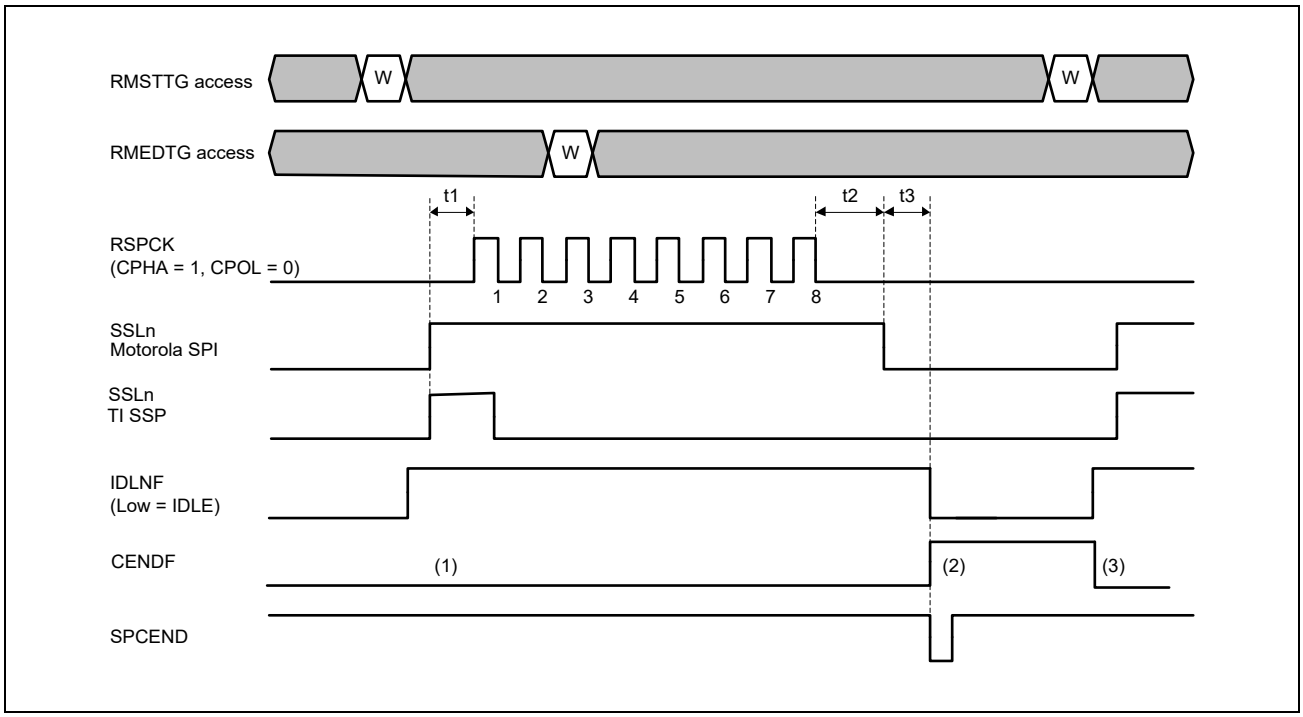

Figure 7.5-38 Example of Communication End Interrupt Operation (Receive-Only Master Mode/Motorola-SPI) at RMFM[4:0] = 00h

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, by writing 1 to RMEDTG during the communication frame. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared when writing 1b to RMSTTG, or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

Figure 7.5-39 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] ≠ 00h.

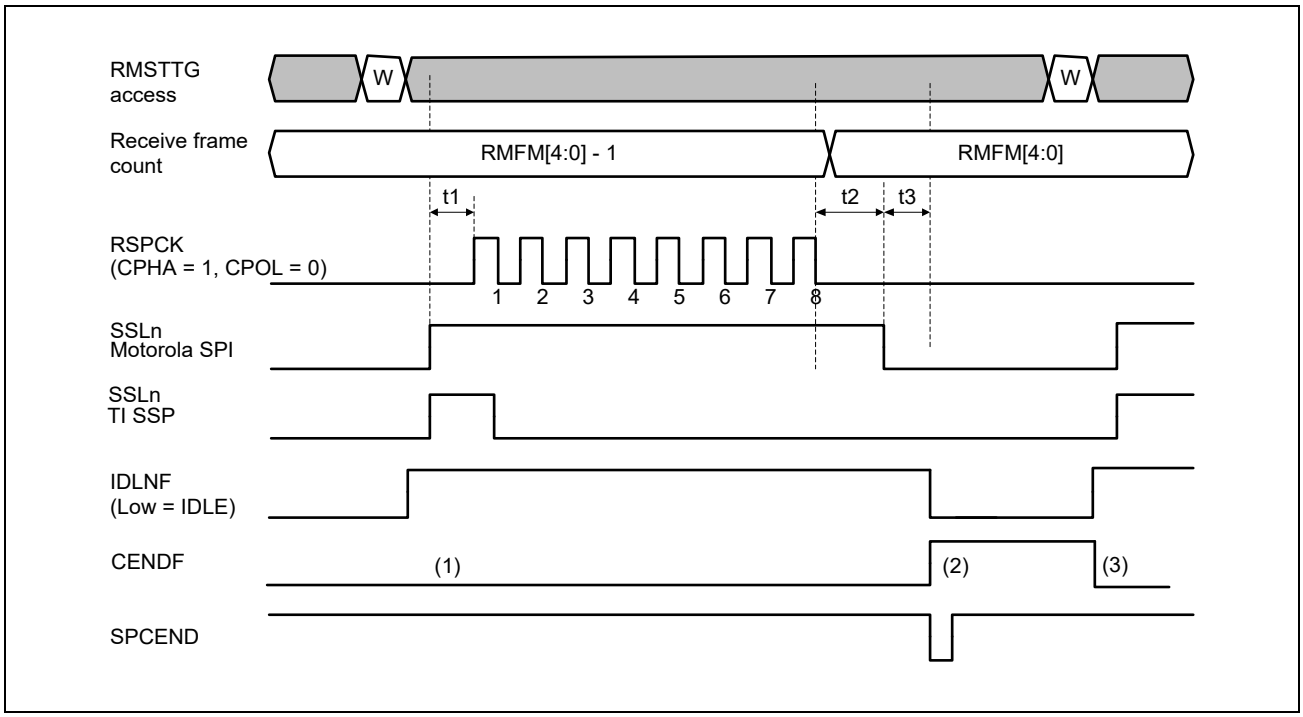

Figure 7.5-39 Example of Communication End Interrupt Operation (Receive-Only Master Mode/Motorola-SPI) at RMFM[4:0] ≠ 00h

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the end of t3 cycle, after receiving the number of frames set by RMFM[4:0]. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1b.

(3) The CENDF flag is cleared when writing 1b to RMSTTG, or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

In slave mode operation, the output timing of the communication end interrupt is dependent on the value of the SPCR.SPMS bit (SPI mode select bit). The clear timing of the communication end interrupt is dependent on the communication mode (transmit-receive or transmit-only or receive-only).

7.5.3.9.3 Transmit-receive/transmit-only in slave mode on SPI operation (4-wire)

See the description for the CENDF bit in **7.5.2.2.18 SPI Status Register (RSPIm_**SPSR) for the setting/clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Slave Mode (4-wire).

(1) In the Motorola-SPI case

Figure 7.5-40 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

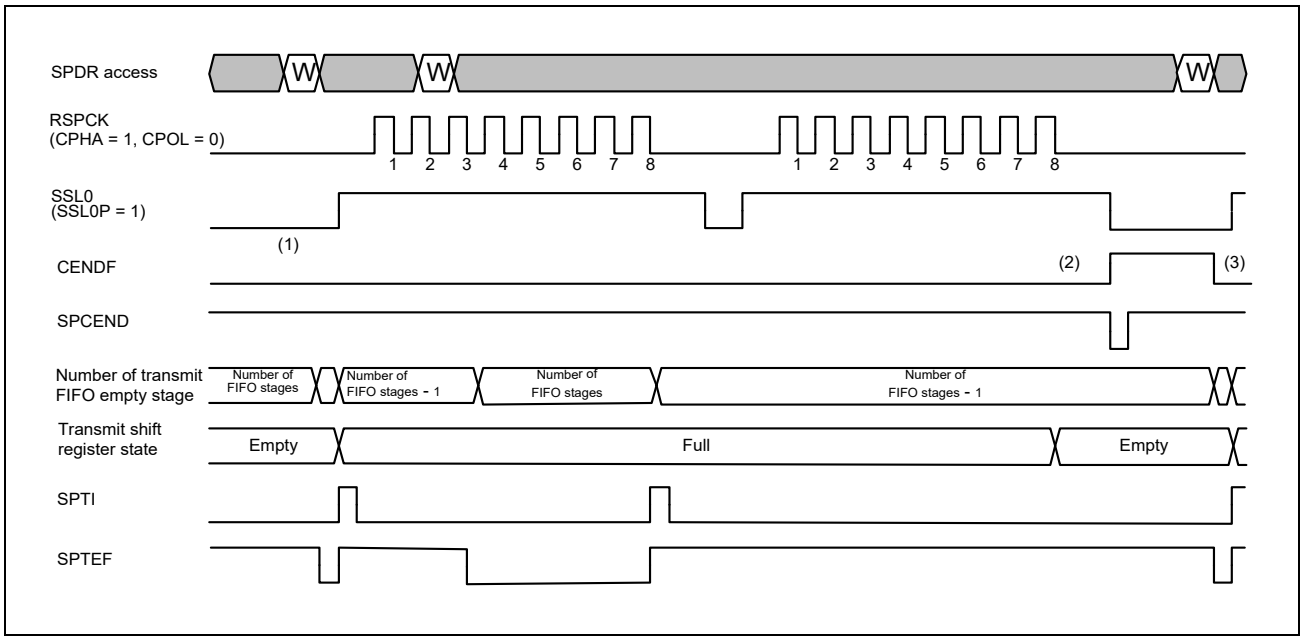

Figure 7.5-40 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-Only Slave Mode on SPI Operation/Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication starts, and these are kept during communication.

(2) The CENDF flag is 1 (communication end) at the timing of SSL0 negate, when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. The SPCEND interrupt is then output with 1 PCLKM cycle width if SPCR.CENDIE = 1b.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 7.5-41 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

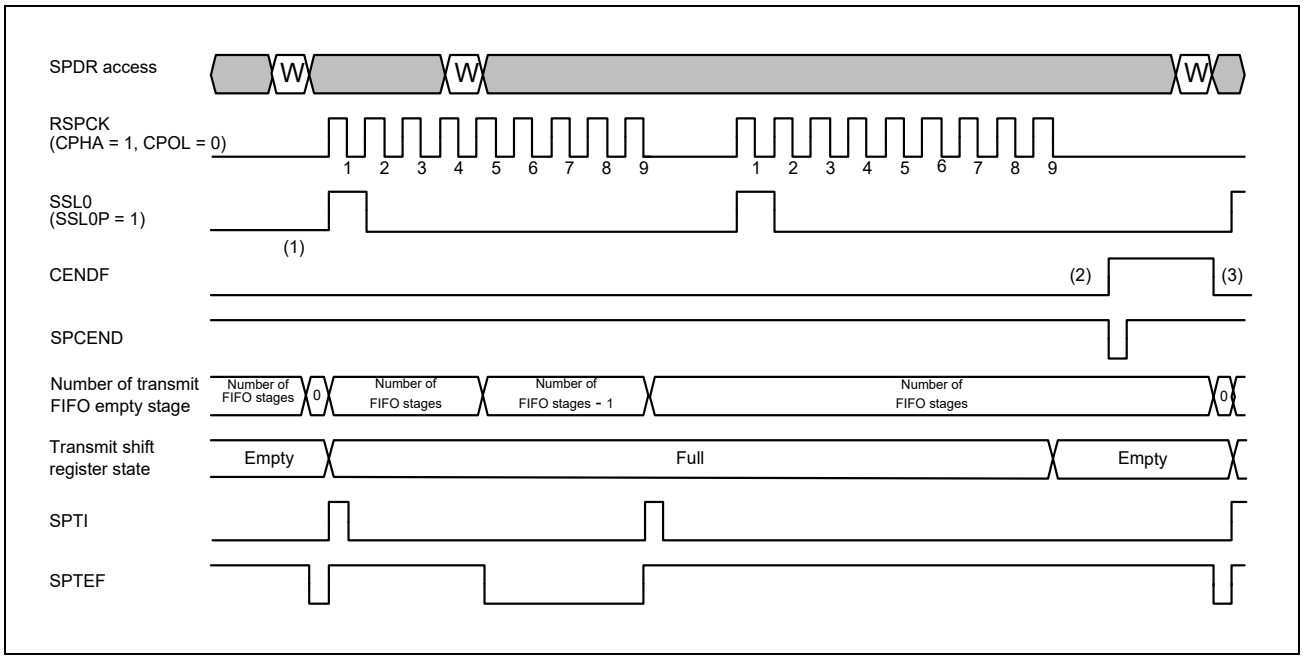

Figure 7.5-41 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-Only Slave Mode on SPI Operation/TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is 1 (communication end) at the RSPCK last data bit sampling, when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if the CENDIE bit is 1.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

7.5.3.9.4 Receive only in slave mode on SPI operation (4-wire)

Refer to the description of the CENDF bit in **7.5.2.2.18 SPI Status Register (RSPIm_**SPSR) for the setting/clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

(1) In the Motorola-SPI case

Figure 7.5-42 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

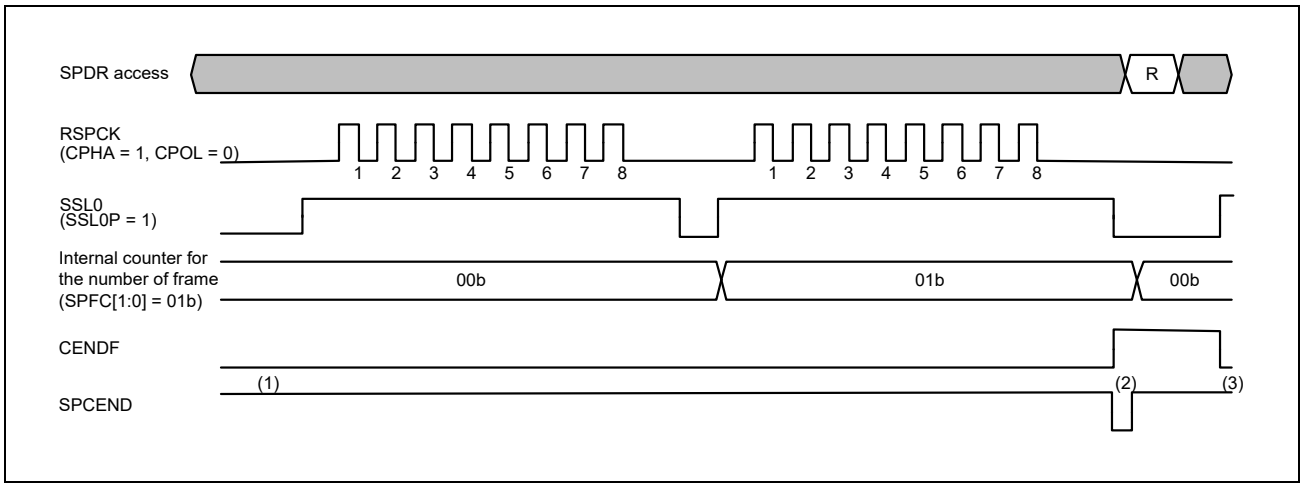

Figure 7.5-42 Example of Communication End Interrupt Operation (Receive-Only Slave Mode on SPI Operation/Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication start, and these have kept during communication.

(2) After store the frames for the SPDCR.SPFC register set value in the receive buffer, the CENDF flag becomes 1b (communication completed) at the timing of SSL0 negation. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1b.

(3) The CENDF flag is cleared at the SSL0 assert when the next transmission start, or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

(2) In the TI-SSP case

Figure 7.5-43 shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

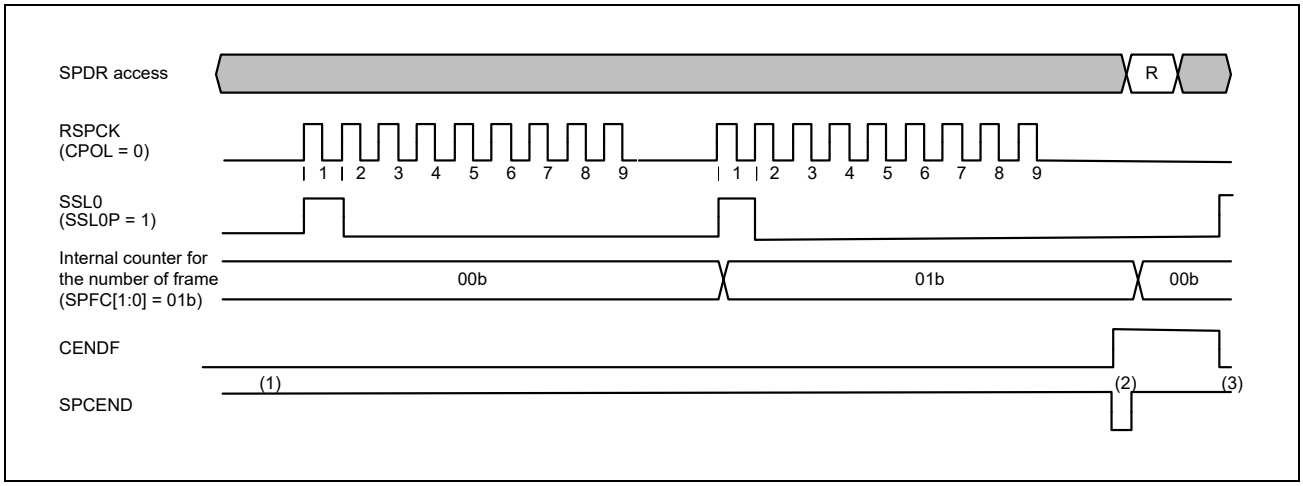

Figure 7.5-43 Example of Communication End Interrupt Operation (Receive-Only Slave Mode on SPI Operation/TI-SSP)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is 1b (communication end) at the RSPCK last data bit sampling, when the last frame transmission ends. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1b.

(3) The CENDF flag is cleared at the SSL0 assert when the next transmission start, or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

7.5.3.9.5 Transmit-receive/transmit-only in slave mode on clock synchronous operation (3-wire)

Refer to the description of the CENDF bit in **7.5.2.2.18 SPI Status Register (RSPIm_**SPSR) for the setting/clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

Figure 7.5-44 shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on clock synchronous operation (3-wire).

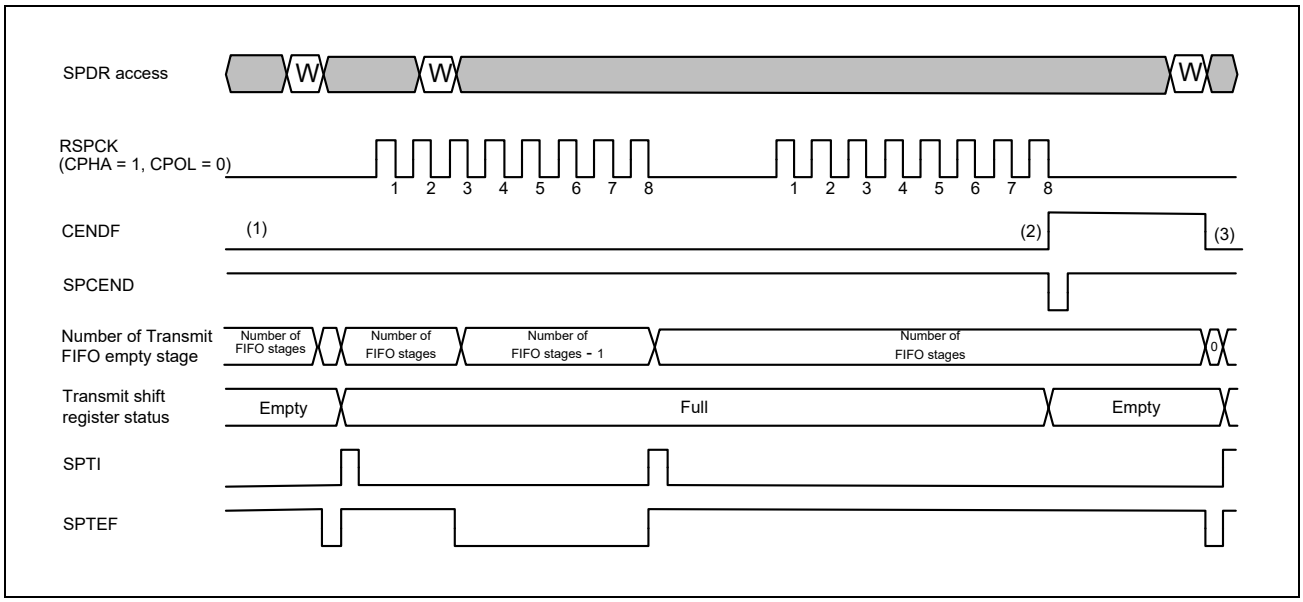

Figure 7.5-44 Example of Communication End Interrupt Operation (Receive-Only Slave Mode on SPI Operation/Motorola-SPI)

(1) The CENDF flag is 0 and the level of SPCEND is 1b before communication start, and these have kept during communication.

(2) When the next transfer data is not set in the transmit FIFO and the transmit shift register is empty, the SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1b.

(3) The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX), or when 1b is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

7.5.3.9.6 Receive only in slave mode on clock synchronous operation (3-wire)

Refer to the description of the CENDF bit in **7.5.2.2.19 SPI Transfer FIFO Status Register (RSPIm_**SPTFSR) and **7.5.2.2.18 SPI Status Register (RSPIm_**SPSR) for the setting/clearing conditions of the communication completion flag during Receive-only in Slave Mode on Clock Synchronous (3-wire).

Figure 7.5-45 shows an example of communication end interrupt operation during receive only slave mode on clock synchronous operation.

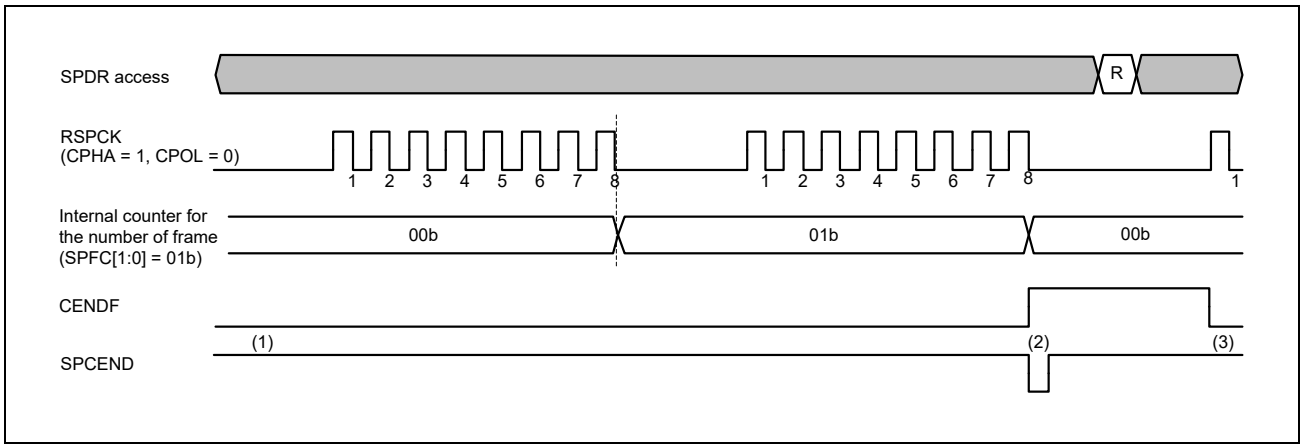

Figure 7.5-45 Example of Communication End Interrupt Operation (Receive-Only Slave Mode on Clock Synchronous Operation)

(1) The CENDF flag is 0 and the level of SPCEND is 1 before communication start, and these have kept during communication.

(2) The CENDF flag is set to 1 (communication completed) at the timing of the last data bit sampling of RSPCK in the last frame communication when the last frame of the SPDCR.SPFC bit set value is received. The SPCEND interrupt is then outputs with PCLKM 1 cycle width if SPCR.CENDIE = 1.

(3) The CENDF flag is cleared at the first edge of RSPCK for the next transmission, or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

7.5.3.9.7 Common operation

In this Section, the operation common to each mode communication in **7.5.3.9.1 Transmit-receive/transmit-only in master mode** to **7.5.3.9.6 Receive only in slave mode on clock synchronous operation (3-wire)** is explained. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, a flag of communication end (CENDF) is set, but no interrupt is output. However, if the enable of communication end interrupt (CENDIE) is set to 1 before clearing the flag of communication end (CENDF) while the enable of SPI function (SPE) is 1, the communication end interrupt is output.

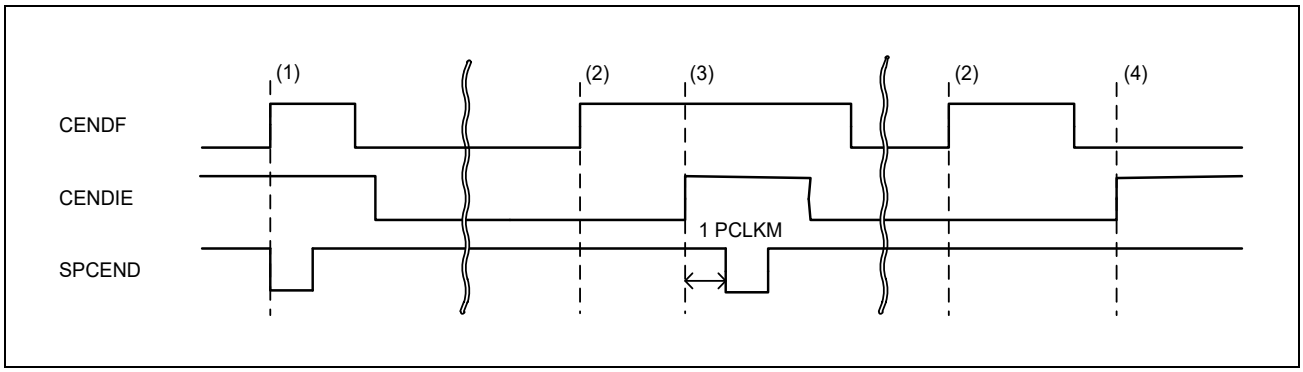

Figure 7.5-46 Example of Communication End Interrupt Operation (Enable Control)

(1) When the enable of SPI communication end interrupt (CENDIE) is 1b, at the time of communication completion, the following two are the same timing

— a flag of communication end (CENDF)
— the communication end interrupt

(2) When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following occurs, but no interrupt.
— a flag of communication end (CENDF)

(3) After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt is output after 1 PCLKM.

(4) After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt is not output.

7.5.3.10 Error Detection

In normal serial transfer of SPI, data written to the transmit buffer in the SPDR register is transmitted in serial and received serial data can be read from the SPDR's receive buffer. Depending on the transmit buffer or receive buffer status when SPDR is accessed and the SPI status at the start or end of serial transfer, abnormal transfer is performed.

When some abnormal transfer operation takes place, the SPI detects it as an underrun error, overrun error, parity error, or mode fault error. **Table 7.5-10** shows the relationship between abnormal transfer operation and the SPI's error detection function.

Table 7.5-10 Abnormal Transfer Occurrence Conditions and Error Detection Function of SPI

	Transfer Occurrence Condition	SPI Operation	Error Detection
1	SPDR is written when while no empty stages in the transmit FIFO.	• Transmit buffer data is retained. • No write data is present.	None
2	SPDR is read while no data stored in receive FIFO.	Received data and previously received serial data are read.	None
3	Serial transfer starts in transmit slave mode or transmit-only slave mode, before transmit data output is ready.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Underrun error
4	Serial transfer ends when data is stored in the receive FIFO for the number of FIFO stages.	• Receive FIFO data is retained. • No serial receive data is present.	Overrun error
5	Incorrect parity bit has been received with the parity function enabled in following mode. • Transmit/receive-only master mode • Transmit/receive slave mode • Receive-only slave mode	The parity error flag is asserted.	Parity error
6	[In the Motorola-SPI case] The SSL0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Mode fault error
7	[In the TI-SSP case] The SSL0 input signal is asserted during serial transfer in slave mode.	• Serial transfer is suspended. • No transmit data or receive data is present. • Driving of the MISO output signal is stopped. • SPI function is disabled.	Mode fault error

The SPI does not detect any error for the operation shown in No.1 in **Table 7.5-10**. To prevent missing of data during SPDR writing, write data to SPDR upon a transmit buffer empty interrupt request or while the SPSR.SPTEF flag is 1b.

The SPI does not detect any error also for the operation shown in No.2 in **Table 7.5-10**. To prevent reading of unnecessary data, read data from SPDR upon a receive buffer full interrupt request or while the SPSR.SPRF flag is 1b.

The underrun error shown in No.3 in **Table 7.5-10** is described in **7.5.3.10.4 Underrun error**.

The overrun error shown in No.4 in **Table 7.5-10** is described in **7.5.3.10.1 Overrun error**.

The parity error shown in No.5 in **Table 7.5-10** is described in **7.5.3.10.2 Parity error**.

The mode fault error shown in No.6 to No.9 in **Table 7.5-10** is described in **7.5.3.10.3 Mode fault error**.

For transmission and reception interrupts, see **7.5.3.7 Transmission buffer empty/receive buffer full interrupt**.

7.5.3.10.1 Overrun error

When serial transfer ends while the receive buffer in the SPDR register is full, the SPI detects an overrun error and sets the OVRF flag in SPSR to 1b. While the OVRF flag is 1b, the SPI does not copy shift register data to the receive buffer. Therefore, data before an error occurs is retained in the receive buffer. To clear the OVRF flag in SPSR to 0b, issue a system reset or 1b is written to the SPSRC.OVRFC bit.

Figure 7.5-47 shows operation of the SPRF flag and the OVRF flag in SPSR. “SPSR access” and “SPDR access” described in **Figure 7.5-47** show an access to SPSR and SPDR respectively. “W” shows a write cycle and “R” shows a read cycle. In the example in **Figure 7.5-47**, the SPI performs 8-bit data serial transfer with the settings of SPCMD.CPHA = 1b and SPCMD.CPOL = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

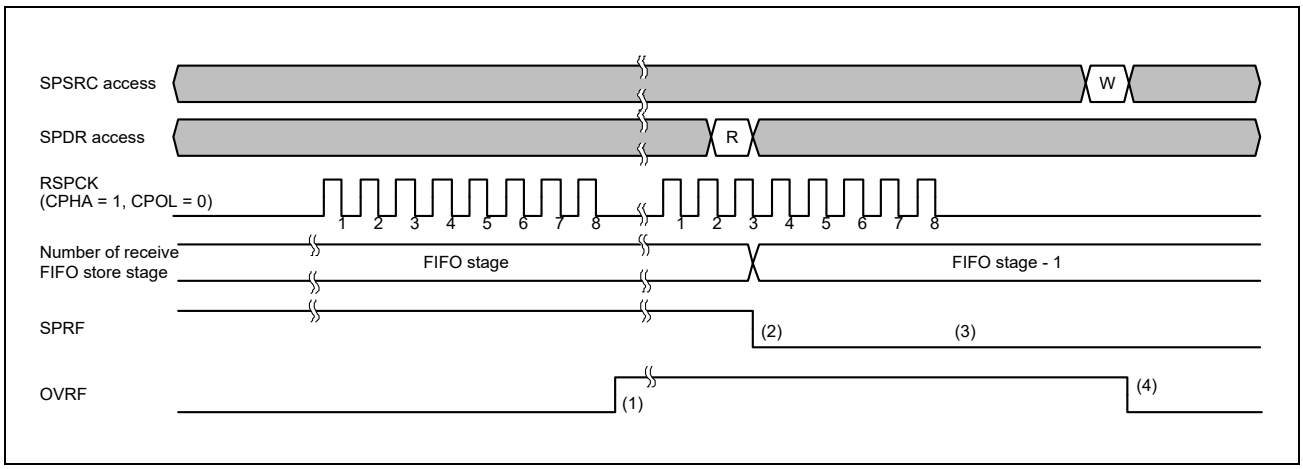

Figure 7.5-47 Example of Operation of SPRF and OVRF Flags

The following describes operation of flags at timings (1) to (4) in the figure above.

(1) When serial transfer ends while data is stored for the number of FIFO stages, the SPI detects an overrun error and sets the OVRF flag to 1b. The SPI does not copy shift register data to the receive buffer. The SPI does not detect a parity error even when SPPE = 1b. In master mode, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPECM[2:0] bits.

(2) The SPI can read receive buffer data by reading SPDR. At this time, the SPRF flag is cleared to 0 at the last access when the received data is read from SPDR in one processing routine using DMAC.

(3) When serial transfer ends while the OVRF flag is 1b (overrun error), the SPI does not copy shift register data to the receive buffer (SPRF flag remains 0) and no SPI receive buffer full interrupt is generated. The SPI does not detect a parity error even when SPPE = 1b. In master mode, the SPI does not update the SPSSR.SPECM[2:0] bits. When the SPI does not copy received data from the shift register to receive buffer while an overrun error is present, the

SPI also determines that the shift register is empty at the end of serial transfer, enabling data transfer from the transmit buffer to the shift register.

(4) When 1 is written to the SPSRC.OVRFC bit.

Whether an overrun error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To perform serial transfer without using an SPI error interrupt, read SPDR and then immediately read SPSR to quickly detect an overrun error. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM bits. When an overrun error occurs and the OVRF flag is set to 1, successful reception is disabled until the OVRF flag is cleared to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. **Figure 7.5-48** and **Figure 7.5-49** show the clock stop waveform when a serial transfer continues while the reception buffer is full in master mode.

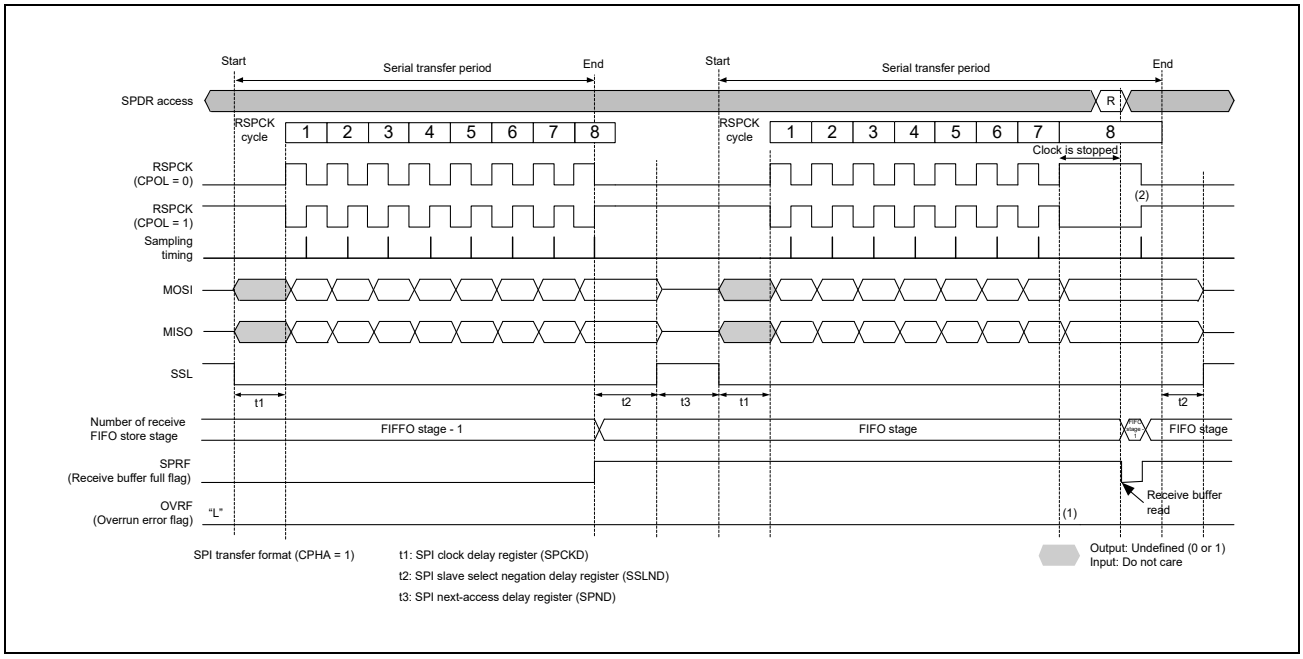

Figure 7.5-48 Clock Stop Waveform when Serial Transfer Continues with Data is Stored for the Number of FIFO Stages in Master Mode (CPHA = 1b)

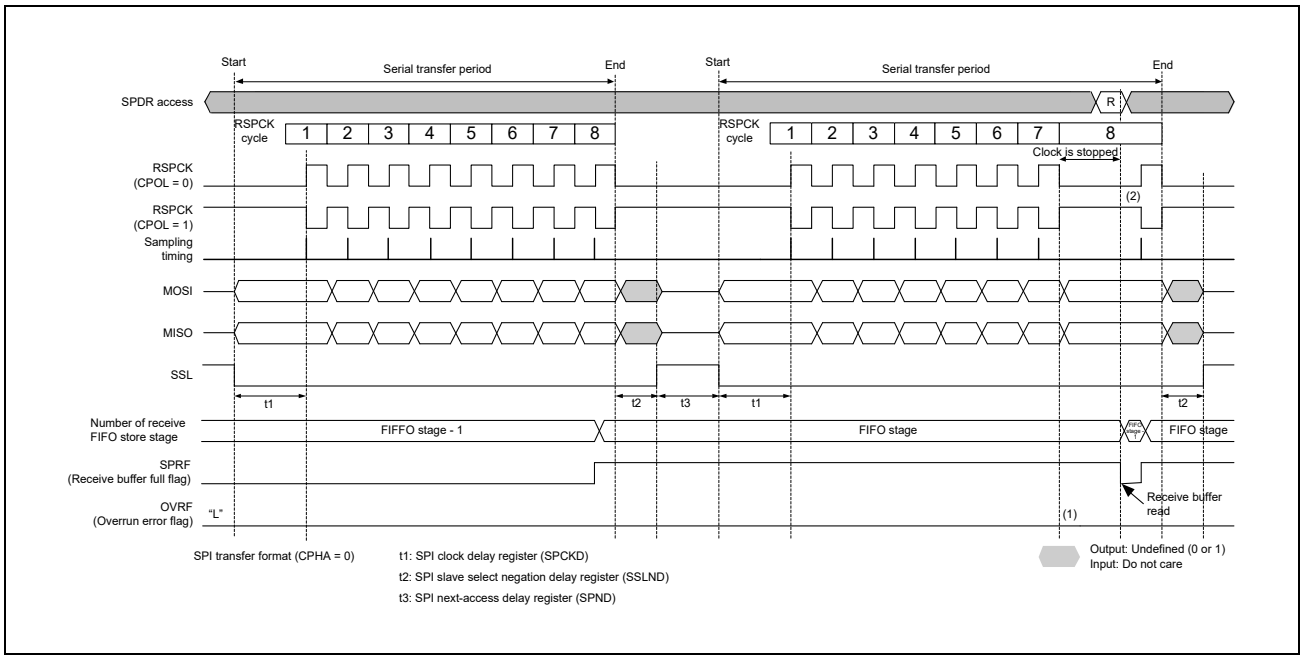

Figure 7.5-49 Clock Stop Waveform when Serial Transfer Continues with Data is Stored for the Number of FIFO Stages in Master Mode (CPHA = 0b)

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) While data is stored in the receive FIFO for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.

(2) Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read, the RSPCK clock restarts.

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. The **Figure 7.5-50** and the **Figure 7.5-51** show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the data is stored in the receive FIFO for the number of FIFO stages.

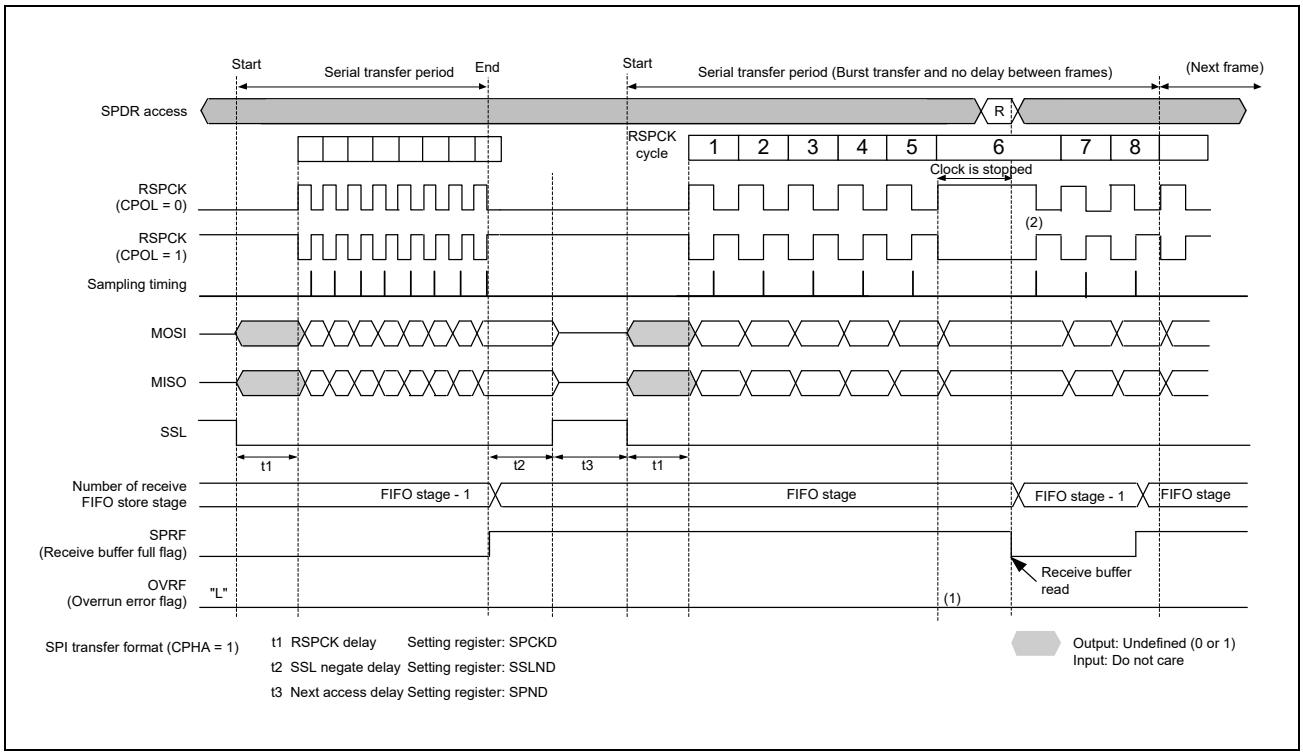

Figure 7.5-50 Clock Stop Waveform when Serial Transfer Continues in the Receive Buffer Full with Data is Stored for the Number of FIFO Stages in Master Mode (at Burst Transfer and No Delay between Frames CPHA = 1b)

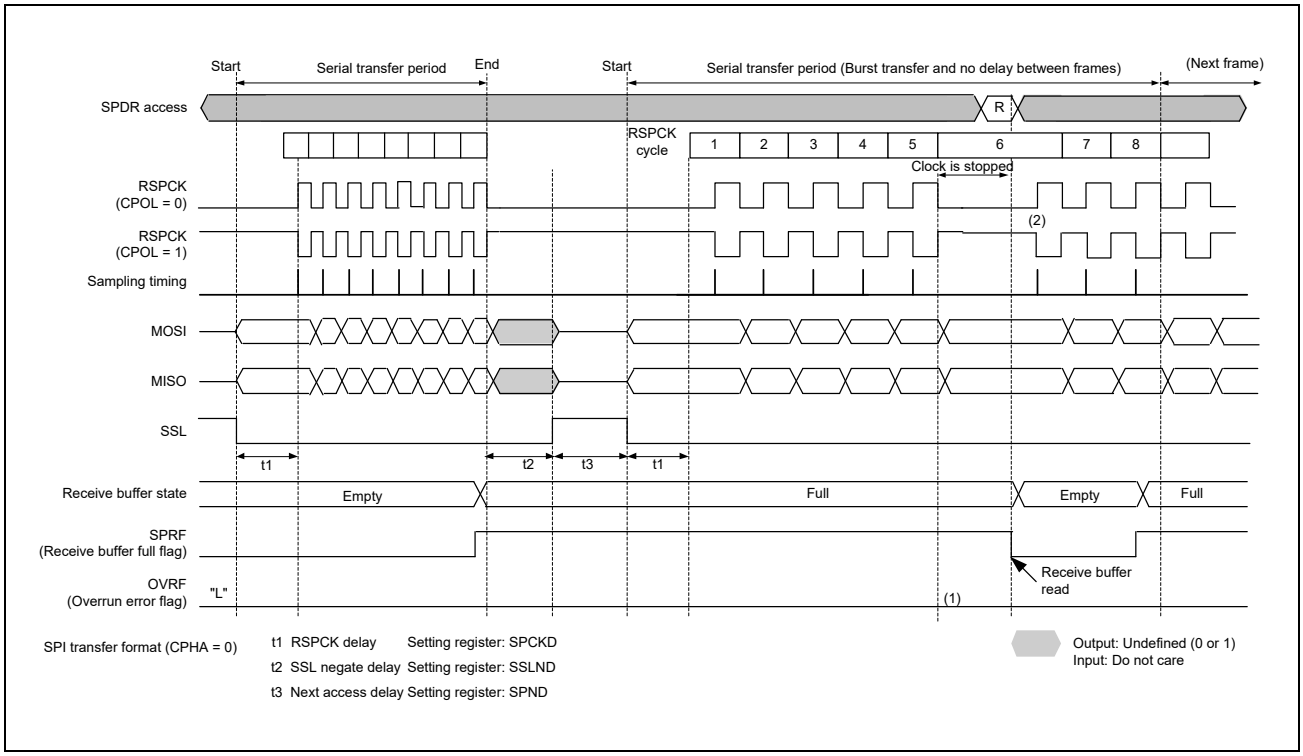

Figure 7.5-51 Clock Stop Waveform when Serial Transfer Continues with Data is Stored for the Number of FIFO Stages in Master Mode (at Burst Transfer and No Delay between Frames CPHA = 0b)

The following describes operation of flags at timings (1) and (2) in the figure above.

(1) While the data is stored for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.

(2) Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read, the RSPCK clock restarts.

7.5.3.10.2 Parity error

After transfer in transmit-receive or receive-only master mode, transmit-receive slave mode or receive only slave mode while the SPCR.SPPE = 1b, the SPI checks occurrence of a parity error. When the SPI detects a parity error in received data, the PERF flag in the SPSR register is set to 1b. While the OVRF flag is 1b, the SPI does not copy shift register data to the receive buffer. Therefore, parity error in received data is not detected. To clear the PERF flag in SPSR to 0b, issue a system reset or write 1b to the SPSRC.PERFC bit.

Figure 7.5-52 shows operation of the OVRF and PERF flags in SPSR. “SPSR access” described in **Figure 7.5-52** shows an access to SPSR. “W” shows a write cycle and “R” shows a read cycle. In the example in **Figure 7.5-52**, the SPI performs transmit-receive serial communication while SPCR.SPPE = 1b. The SPI performs 8-bit data serial transfer with the settings of SPCMD.CPHA = 1b and SPCMD.CPOL = 0b. Numbers under the RSPCK waveform show the number of RSPCK cycles (number of transfer bits).

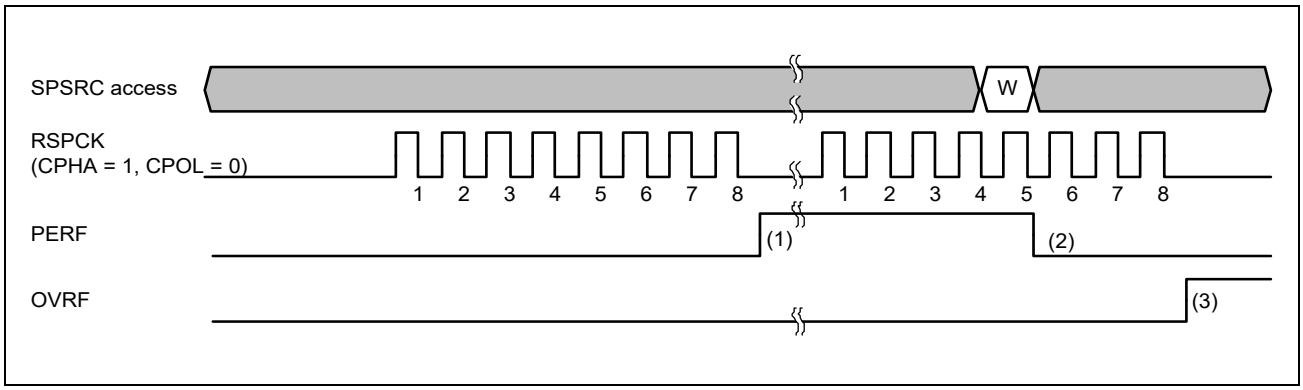

Figure 7.5-52 Example of Operation of OVRF and PERF Flags

The following describes operation of flags at timings (1) to (3) in the figure above.

(1) When the SPI does not detect an overrun error and terminates the serial transfer, the SPI copies shift register data to the receive buffer. When the SPI checks the received data and detects a parity error at this time, the PERF flag is set to 1b. In master mode, the SPI copies the value of pointer to the SPCMD register to the SPSSR.SPCM [2:0] bits.

(2) When 1 is written to the SPSRC.PERFC bit.

(3) When the SPI detects an overrun error and terminates the serial transfer, the SPI does not copy shift register data to the receive buffer and does not detect a parity error.

Whether a parity error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To use an SPI error interrupt, set the SPCR.SPEIE bit to 1b. To perform serial transfer without using an SPI error interrupt, read SPDR to quickly detect a parity error. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPSSR.SPECM[2:0] bits.

7.5.3.10.3 Mode fault error

When the SPCR.MSTR = 0b, the SPI operates in slave mode. When SPCR.SPMS = 0b and SPCR.MODFEN = 1b in slave mode, if the SSL0 input signal is negated during the serial transfer period (from valid data drive start to final valid data latch), the SPI detects a mode fault error while any of the following 2 conditions is met.

(1) In the Motorola-SPI case

When the SSL0 input signal is negated while serial data transfer.

(2) In the TI-SSP case

When the SSL0 input signal is asserted while serial data transfer. However, during burst transfer, no error is detected even if the SSL0 input signal is asserted during the last bit of frame.

When the SPI detects a mode fault error, it stops driving output signals and clears the SPCR.SPE bit.

When the SPE bit is cleared, the SPI function is disabled (as described in **7.5.3.12 SPI Initialization**).

Whether a mode fault error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To detect a mode fault error without using an SPI error interrupt, poll SPSR.

While the MODF flag = 1b, the SPI ignores writing 1b to the SPE bit. To enable the SPI function after a mode fault error is detected, clear the MODF flag to 0b without fail.

7.5.3.10.4 Underrun error

While the SPI is operating in slave mode (SPCR.MSTR = 0b) and the communication mode select SPCR.TXMD[1:0] bits are set to 00b or 01b, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1b (SPI function enabled), the SPI detects an underrun error and sets the MODF and UDRF flags in the SPSR register to 1b.

When the SPI detects an underrun error, it stops driving output signals and clears the SPE bit to 0b. When the SPE bit is cleared, the SPI function is disabled (as described in **7.5.3.12 SPI Initialization**)

Whether an underrun error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To detect an underrun error without using an SPI error interrupt, poll SPSR.

While the MODF flag = 1b, the SPI ignores writing 1b to the SPE bit. To enable the SPI function after an underrun error is detected, clear the MODF flag to 0 without fail.

7.5.3.11 Received Data Ready Detection

When SPCR.TXMD[1:0] = 00b, 01b, or 11b, and SPDRCR.SPDRC[7:0] ≠ 00h, after receiving data in the receive FIFO during communication (SPE = 1), SPDR.SPDRF flag is set to 1 when the received data is not stored even after the number of received FIFOs ≤ the threshold value and the value set in SPDRCR.SPDRC[7:0] has elapsed.

When the receive data ready is detected, the interrupt can be selected as SPRI or SPEI with the SPCR.SPDRES bit. **Figure 7.5-53** shows an example of reception data ready detection operation.

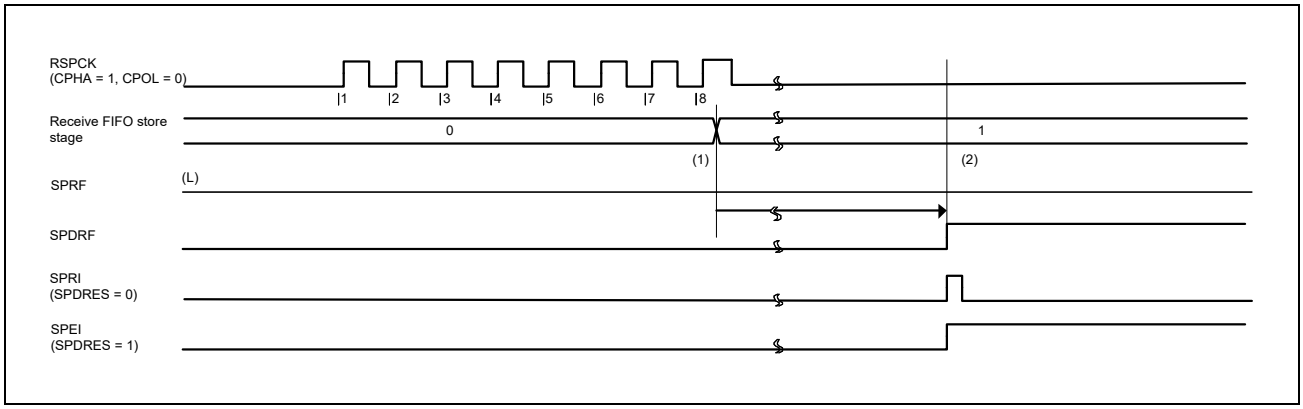

Figure 7.5-53 Received Data Ready

The following describes operation at the timings indicated by (1) and (2) in the figure.

(1) Store the received data in the receive FIFO. SPRF is 0b, because receive FIFO store stage ≤ RTRG.

(2) Set SPDRF and assert SPRI or SPEI because there is no writing to the receive FIFO for the amount of SPDRC[7:0] set from (1).

7.5.3.12 SPI Initialization

When 0b is written to the SPCR.SPE bit or when the SPI clears the SPE bit to 0b after it detects a mode fault error or an underrun error, the SPI disables the SPI function and initializes a part of module functions. Furthermore, the SPI initializes all module functions when a system reset occurs. The following describes initialization by clearing the SPCR.SPE bit and by using a system reset.

7.5.3.12.1 Initialization by clearing the SPE bit

When the SPCR.SPE bit is cleared to 0b, the SPI performs the following initialization:

- Suspends the ongoing serial transfer.
- Stops driving output signals (Hi-Z) in slave mode.
- Resets the internal SPI state.
- SPSR.SPTEF flag = 1b.

In initialization by clearing the SPE bit, control bits in SPI are not initialized. For this reason, re-setting the SPE bit to 1b activates the SPI with the pre-initialization transfer mode.

Values of the CENDF flag, the SPRF flag, OVRF flag, MODF flag, PERF flag, and UDRF flag in SPSR are not initialized. The SPSSR register value is not initialized either. For this reason, it is possible to read receive buffer data and check the communication completion status and the error status during SPI transfer also after the SPI is initialized.

SPSR.SPTEF flag is initialized to 1b. Therefore, if the SPCR.SPTIE bit is set to 1 after the SPI is initialized, an SPI transmit buffer empty interrupt is generated. When the CPU initializes the SPI, write 0b to the SPE bit and the SPTIE bit to disable an SPI transmit buffer empty interrupt.

7.5.3.12.2 System reset

In initialization by using a system reset, all SPI control bits, status bits, and data register are initialized in addition to the initialization described in **7.5.3.12.1 Initialization by clearing the SPE bit** to completely initialize the SPI.

7.5.3.13 SPI Operation

7.5.3.13.1 Master mode operation

(1) Starting a serial transfer

When data is written to the SPDR register while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 15) data in SPDR.

While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**. The SSL output signal polarity depends on the set SSLP register value.

(2) Terminating a serial transfer

[Except Receive-only in Master Mode]

After the SPI detects the RSPCK edge corresponding to the final sampling timing regardless of the SPCMD.CPHA bit value, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPDR register after serial transfer.
The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. The SSL output signal polarity depends on the set SSLP register value. For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**.

[Receive-only in Master Mode]

When any of the following 2 conditions is met, then SPI terminating the serial transfer.

- After the SPI detects the RSPCK edge corresponding to the final sampling timing regardless of the SPCMD.CPHA bit value, the SPI terminates serial transfer.
- When writing SPCRRM.RMEDTG = 1b during the serial transfer period, the SPI terminates the serial transfer.

When the number of data stored in the receive FIFO < the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPDR register after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. The SSL output signal polarity depends on the set SSLP register value. For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**.

(3) Sequence control

The transfer format in master mode is determined as follows.

The transfer format in master mode is determined by the SPSCR register, SPCMDm (m = 0 to 7) register, SPBR register, SPCKD register, SSLND register, and SPND register.

The SPSCR register is used to determine the sequence configuration for serial transfer to be performed by the SPI in master mode. The SSL output signal value, MSB first/LSB first, data length, a part of bit rate settings, RSPCK polarity and phase, SPCKD enable/disable, SSLND enable/disable, and SPND enable/disable are set in SPCMD0 to SPCMD7.

A part of bit rate settings is set in SPBR, the SPI clock delay value is set in SPCKD, the SSL negation delay value is set in SSLND, and the access delay value is set in SPND.

The SPI configures the sequence that structures a part of or whole of SPCMD0 to SPCMD7 according to the sequence length specified in SPSCR. The SPI has a pointer to SPCMD that configures the sequence. This pointer value can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPE bit in the SPCR register is set to 1 to enable the SPI function, the SPI sets the pointer to commands in SPCMD0 and applies the SPCMD0 setting to the transfer format at the start of serial transfer. The SPI increments the pointer the next-access delay period ends in each data transfer. When the serial transfer corresponding to the final command that configures the sequence is completed, the SPI sets the pointer in SPCMD0. Thus sequence is repeatedly executed.

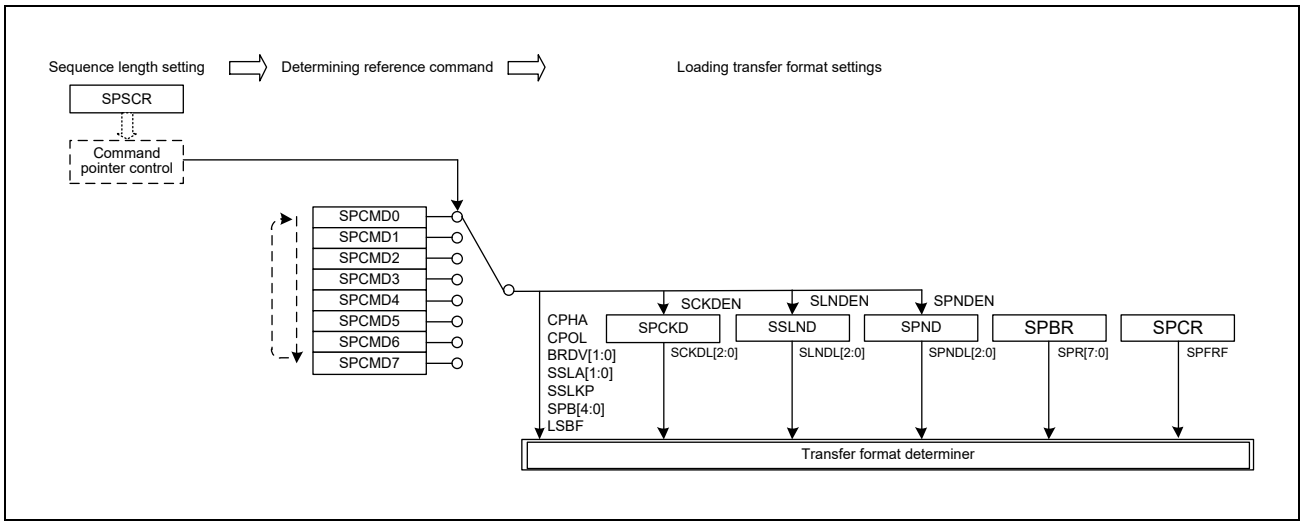

Figure 7.5-54 Determining Serial Transfer Method in Master Mode

In this section, a frame consists of data (SPDR) and configuration (SPCMDm).

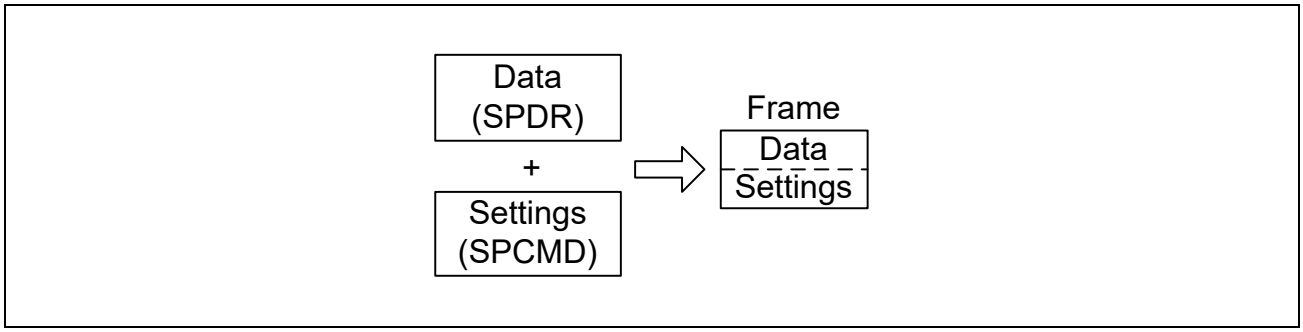

Figure 7.5-55 Conceptual Diagram of Frame

Figure 7.5-56 shows the correspondence between the SPI command register and transmit buffer (SPTXn, n = 0 to 15)/receive buffer (SPRXn, n = 0 to 15) in the sequence operation.

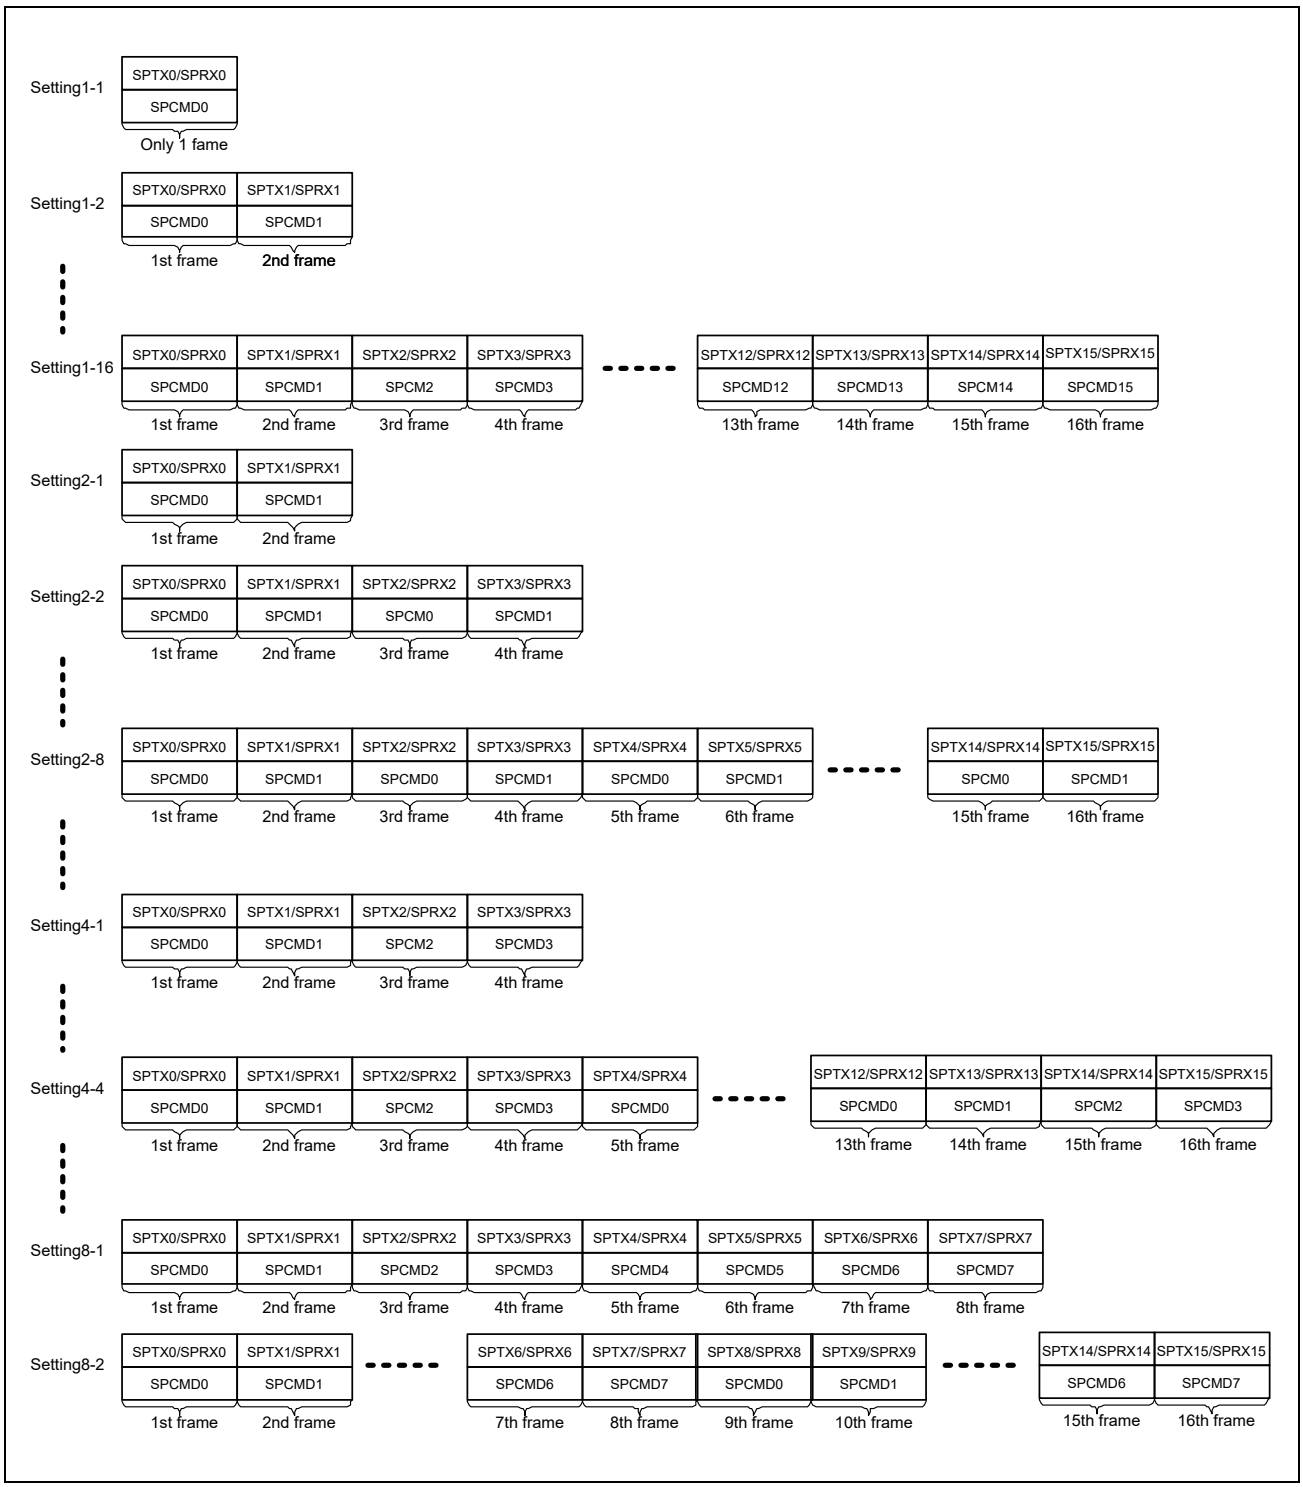

Figure 7.5-56 Correspondence between SPI Command Register and Transmit/Receive Buffers in Sequence Operation

(4) Burst transfer

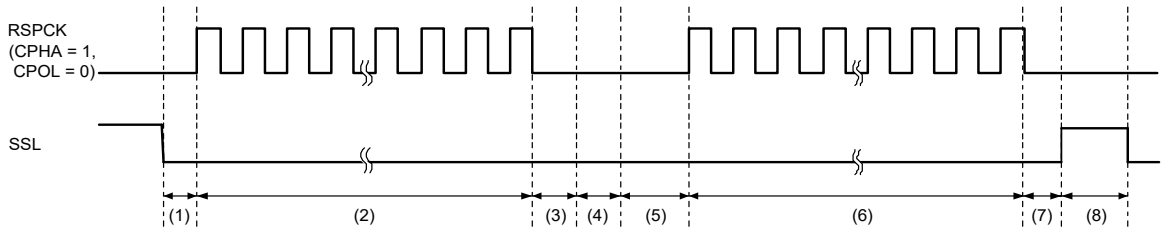
This section describes burst transfer during transmit-receive/transmit-only operation.

[In the Motorola-SPI case]

When the SPCMD.SSLKP bit, which the SPI references in the current serial transfer, is 1b, the SPI retains the SSL signal level during serial transfer until the SSL signal assertion of the next serial transfer starts. When the SSL signal level in the next serial transfer is the same as the SSL signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSL signal assertion status (burst transfer).

(a) SPCR.BFDS = 0b

Figure 7.5-57 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in **Figure 7.5-57**. The SSL output signal polarity depends on the set the SSLP register.



(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0.

(2) Perform serial transfer according to SPCMD0.

(3) Insert an SSL negation delay.

(4) The SSL signal value in SPCMD0 is retained because SPCMD0.SSLKP = 1b. This period additionally continues for 5 RSPI_n_TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0. When the shift register is empty after the minimum period has passed, this period continues until transmit data for the next transfer is stored in the shift register.

(5) Assert the SSL signal and insert an RSPCK delay according to SPCMD1.

(6) Perform serial transfer according to SPCMD1.

(7) Insert SSL negate delay.

(8) The SSL signal is negated because SPCMD1.SSLKP = 0b. Furthermore, the next-access delay is inserted according to SPCMD1.

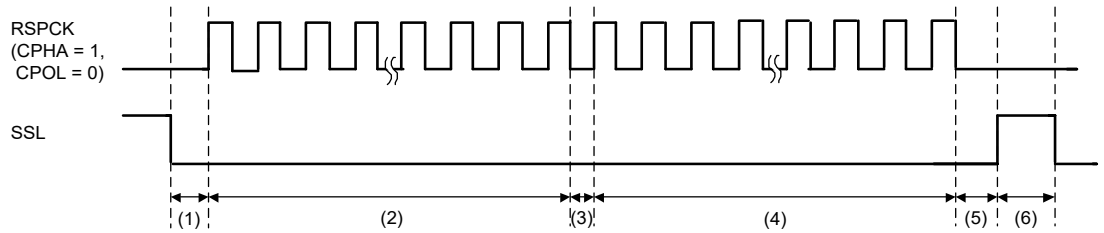
Figure 7.5-57 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 0b, SPFRF = 0b)

If the SSL signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSL signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSL signal state when the SSL signal corresponding to the next-transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSL signal operation in the module when SSLKP is not used. Even when SPCMD.CPHA = 0b, the SPI can accurately start serial transfer by using the next-transfer SSL signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See **7.5.3.13 SPI Operation**.)

(b) SPCR.BFDS = 1

Figure 7.5-58 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in **Figure 7.5-58**. The SSL output signal polarity depends on the set SSSLP register value.



(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.

(2) Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.

(3) The value of SSL signal according to SPCMD0 was hold, because SPCMD0.SSLKP = 1b. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last frame.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0b. Furthermore, the next-access delay is inserted according to SPCMD1.

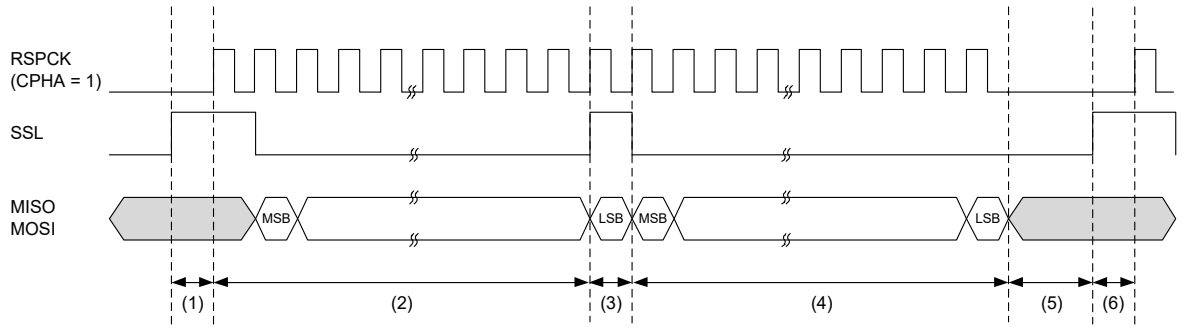
Figure 7.5-58 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1b, SPFRF = 0b)

[In the TI-SSP case]

SPI asserts the SSL signal for one cycle at the start of serial transfer.
Serial transfer can be executed continuously by asserting the SSL signal for one cycle at the start of the next serial transfer (burst transfer).

(c) SPCMD.SSLKP = 1b and SPCR.BFDS = 1b

SPCMD0 to SPCMD1 are shown in **Figure 7.5-59**. The following shows an example of SSL signal operation and serial data MISO/MOSI when burst transfer is realized using the settings. The SSL output signal polarity depends on the set SPI slave select polarity register (SSLP) value.



(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.

(2) Perform serial transfer according to SPCMD0.

(3) Final data transfer and SSL assertion are performed simultaneously. If the shift register is empty during the RSPCK negation period between frames, wait for the output of the last clock until the transmission data for the next transfer is stored in the shift register.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last frame.

(6) The SSL signal is negated because the SPCMD1.SSLKP = 0b.

Figure 7.5-59 Example of Burst Transfer Operation (SPFRF = 1b)

If the SSL signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSL signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSL signal state when the SSL signal corresponding to the next-transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

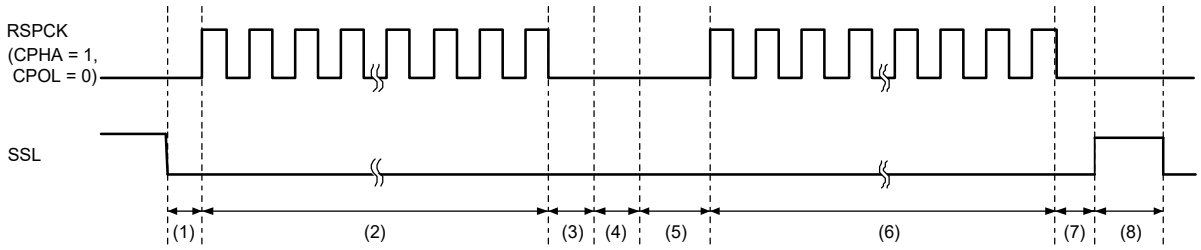
This section describes burst transfer during receive-only operation.

[In the Motorola-SPI case]

When the SPCMD.SSLKP bit, which the SPI references in the current serial transfer, is 1, the SPI retains the SSL signal level during serial transfer until the SSL signal assertion of the next serial transfer starts. When the SSL signal level in the next serial transfer is the same as the SSL signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSL signal assertion status (burst transfer).

(d) SPCR.BFDS = 0b

Figure 7.5-60 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in **Figure 7.5-60**. The SSL output signal polarity depends on the set SSLP register value.



(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0.

(2) Perform serial transfer according to SPCMD0.

(3) Insert an SSL negation delay.

(4) The SSL signal value in SPCMD0 is retained because SPCMD0.SSLKP = 1b. This period additionally continues for 5 RSPI_n_TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0.

(5) Assert the SSL signal and insert an RSPCK delay according to SPCMD1.

(6) Perform serial transfer according to SPCMD1.

(7) Insert SSL negate delay.

(8) The SSL signal is negated because SPCMD1.SSLKP = 0b. Furthermore, the next-access delay is inserted according to SPCMD1.

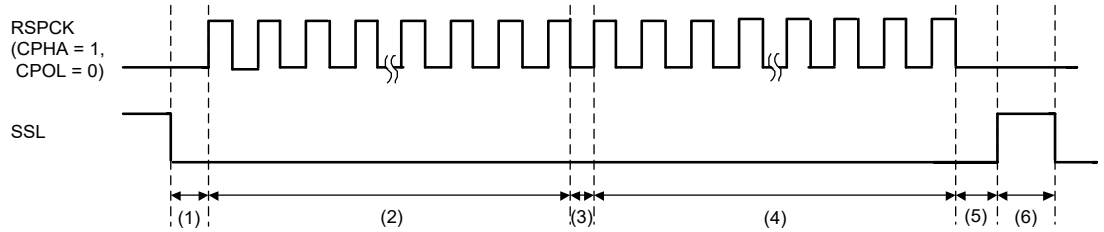
Figure 7.5-60 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 0b, SPFRF = 0b)

If the SSL signal output setting and the SSL signal output setting between SPCMDs used for burst transfer are different, SPI switches the SSL signal state when the SSL signal corresponding to the next transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSL signal operation in the module when SSLKP is not used. Even when SPCMD.CPHA = 0b, the SPI can accurately start serial transfer by using the next-transfer SSL signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See **7.5.3.13, SPI Operation**.)

(e) SPCR.BFDS = 1b

Figure 7.5-61 shows an example of SSL signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in **Figure 7.5-61**. The SSL output signal polarity depends on the set SSLP register value.



(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst.

(2) Perform serial transfer according to SPCMD0.

(3) Since it is not the last frame, the SSL signal value at SPCMD0 is retained. RSPCK negation between frames is 0.5 RSPCK for the next frame.

(4) Perform serial transfer according to SPCMD1.

(5) Insert SSL negate delay for the last time.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0b. Furthermore, the next-access delay is inserted according to SPCMD1.

Note: "Last frame": Frame set by RMFM[4:0] bits when SPCRRM.RMFM[4:0] ≠ 00h
Or, a frame in which SPCRRM.RMEDTG = 1b has been accepted.

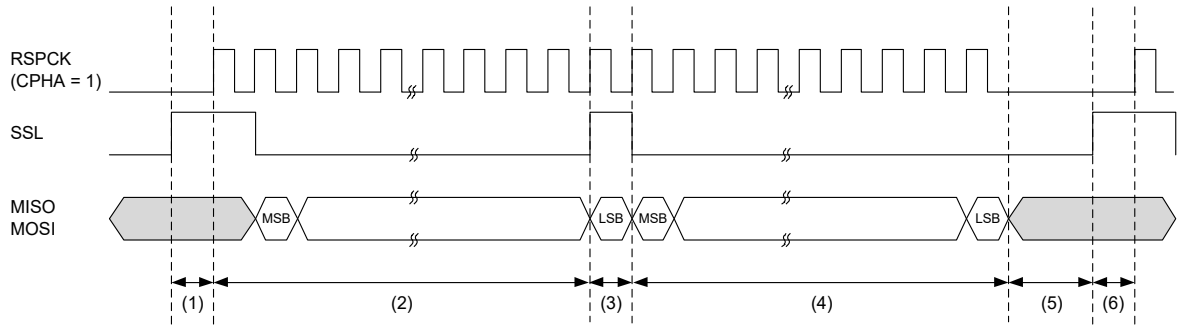
Figure 7.5-61 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1, SPFRF = 0)

[In the TI-SSP case]

SPI asserts the SSL signal for one cycle at the start of serial transfer.
Serial transfer can be executed continuously by asserting the SSL signal for one cycle at the start of the next serial transfer (burst transfer).

(f) SPCMD.SSLKP = 1b and SPCR.BFDS = 1b

SPCMD0 to SPCMD1 are shown in **Figure 7.5-62**. The following shows an example of SSL signal operation and serial data MISO/MOSI when burst transfer is realized using the settings. The SSL output signal polarity depends on the set SSLP register value.



(1) Assert the SSL signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst.

(2) Perform serial transfer according to SPCMD0.

(3) Final data transfer and SSL assertion are performed simultaneously.

(4) Perform serial transfer according to SPCMD1.

(5) Insert Output disable delay for the last frame.

(6) The SSL signal is negated because SPCMD1.SSLKP = 0b.

Note: "Last frame": Frame set by RMFM[4:0] bits when SPCRRM.RMFM[4:0] ≠ 00h
Or, a frame in which SPCRRM.RMEDTG = 1b has been accepted.

Figure 7.5-62 Example of Burst Transfer Operation (SPFRF = 0b)

If the SSL signal output setting between the SPCMDs used for burst transfer differs from the SSL signal output setting, SPI switches the SSL signal state when the SSL signal corresponding to the next transfer command is asserted (5). Note that, if an SSL signal change like this takes place, slaves that drive the MISO signal may conflict with each other, which may cause collision of signal level.

(5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the settings of the SPCMD.SCKDEN and SPCKD.SCKDL[2:0] bits. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the RSPCK delay value for serial transfer by using the selected SPCMD.SCKDEN bit and SPCKD.SCKDL[2:0] bits as shown in **Table 7.5-11**. For the definition of RSPCK delay, see **7.5.3.5 Transfer Format (Frame Format)**.

RSPCK delay insert to only the first frame of burst transmission, when transmit without "Between Burst Transfer Frames Delay" (SPCMD.SSLKP = 1b, SPCR.BFDS = 1b).

Table 7.5-11 Relationship between SCKDEN/SPCKD and RSPCK Delay Value

SPCMDm.SCKDEN Bit	SPCKD.SCKDL[2:0] Bits	RSPCK Delay Value	
		Motorola-SPI	TI-SSP
0	000b to 111b	1 RSPCK	0 RSPCK
1	000b	1 RSPCK	1 RSPCK
	001b	2 RSPCK	2 RSPCK
	010b	3 RSPCK	3 RSPCK
	011b	4 RSPCK	4 RSPCK
	100b	5 RSPCK	5 RSPCK
	101b	6 RSPCK	6 RSPCK
	110b	7 RSPCK	7 RSPCK
	111b	8 RSPCK	8 RSPCK

(6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the settings of the SPCMD.SLNDEN bit and SSLND.SLNDL[2:0]. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the SSL negation delay value for serial transfer by using the selected SPCMD.SLNDEN and SSLND.SLNDL[2:0] as shown in **Table 7.5-12**. For the definition of SSL negation delay, see **7.5.3.5 Transfer Format (Frame Format)**.

SSL negate delay insert to only the last frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay” (SPCMD.SSLKP = 1b, SPCR.BFDS = 1b).

Table 7.5-12 Relationship between SSLND and SSL Negation Delay Value

SLNDEN	SSLND.SLNDL[2:0] Bits	SSL Negation Delay Value
0	000b to 111b	1 RSPCK cycle
1	000b	1 RSPCK cycle
	001b	2 RSPCK cycle
	010b	3 RSPCK cycle
	011b	4 RSPCK cycle
	100b	5 RSPCK cycle
	101b	6 RSPCK cycle
	110b	7 RSPCK cycle
	111b	8 RSPCK cycle

(7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the settings of the SPCMD.SPNDEN bit and SPND.SPNDL[2:0] bits. The SPI determines SPCMD to be referenced in serial transfer by the pointer control, and then determines the RSPCK delay value for serial transfer by using the selected SPCMD.SPNDEN bit and SPND.SPNDL[2:0] bits as shown in **Table 7.5-13**. For the definition of next-access delay, see **7.5.3.5 Transfer Format (Frame Format)**.

Next-Access delay insert to only the last frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay” (SPCMD.SSLKP = 1b, SPCR.BFDS = 1b).

Table 7.5-13 Relationship between SPNDEN Bit, SPND Bits, and Next-Access Delay Value

SPNDEN Bit	SPND.SPNDL[2:0] Bits	Next-Access Delay Value
0	000b to 111b	1 RSPCK + 5 RSPI_n_TCLK cycles
1	000b	1 RSPCK + 5 RSPI_n_TCLK cycles
	001b	2 RSPCK + 5 RSPI_n_TCLK cycles
	010b	3 RSPCK + 5 RSPI_n_TCLK cycles
	011b	4 RSPCK + 5 RSPI_n_TCLK cycles
	100b	5 RSPCK + 5 RSPI_n_TCLK cycles
	101b	6 RSPCK + 5 RSPI_n_TCLK cycles
	110b	7 RSPCK + 5 RSPI_n_TCLK cycles
	111b	8 RSPCK + 5 RSPI_n_TCLK cycles

(8) Initialization flowchart

Figure 7.5-63 shows an example of initialization flow when using the SPI in master-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

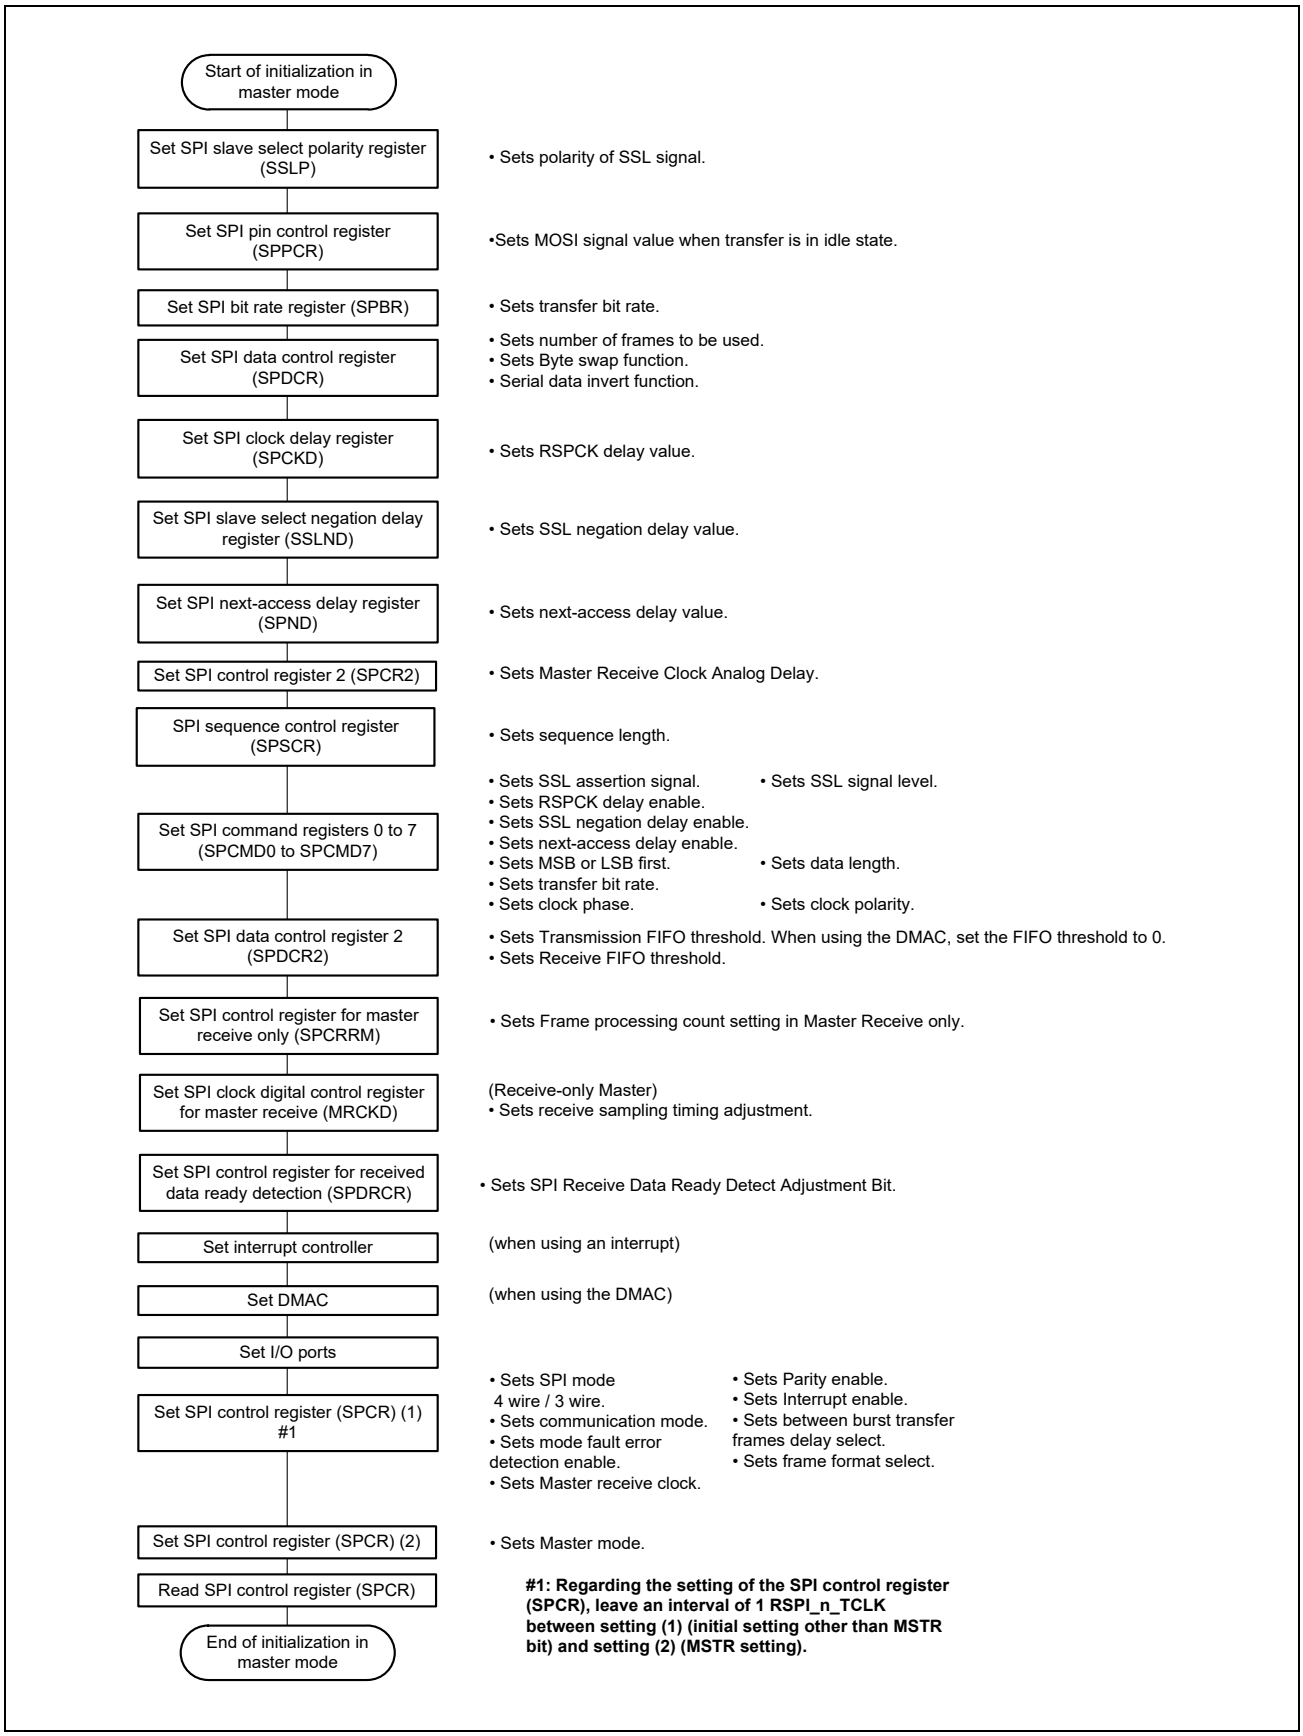


Figure 7.5-63 Example of Initialization Flowchart in Master Mode (SPI Operation)

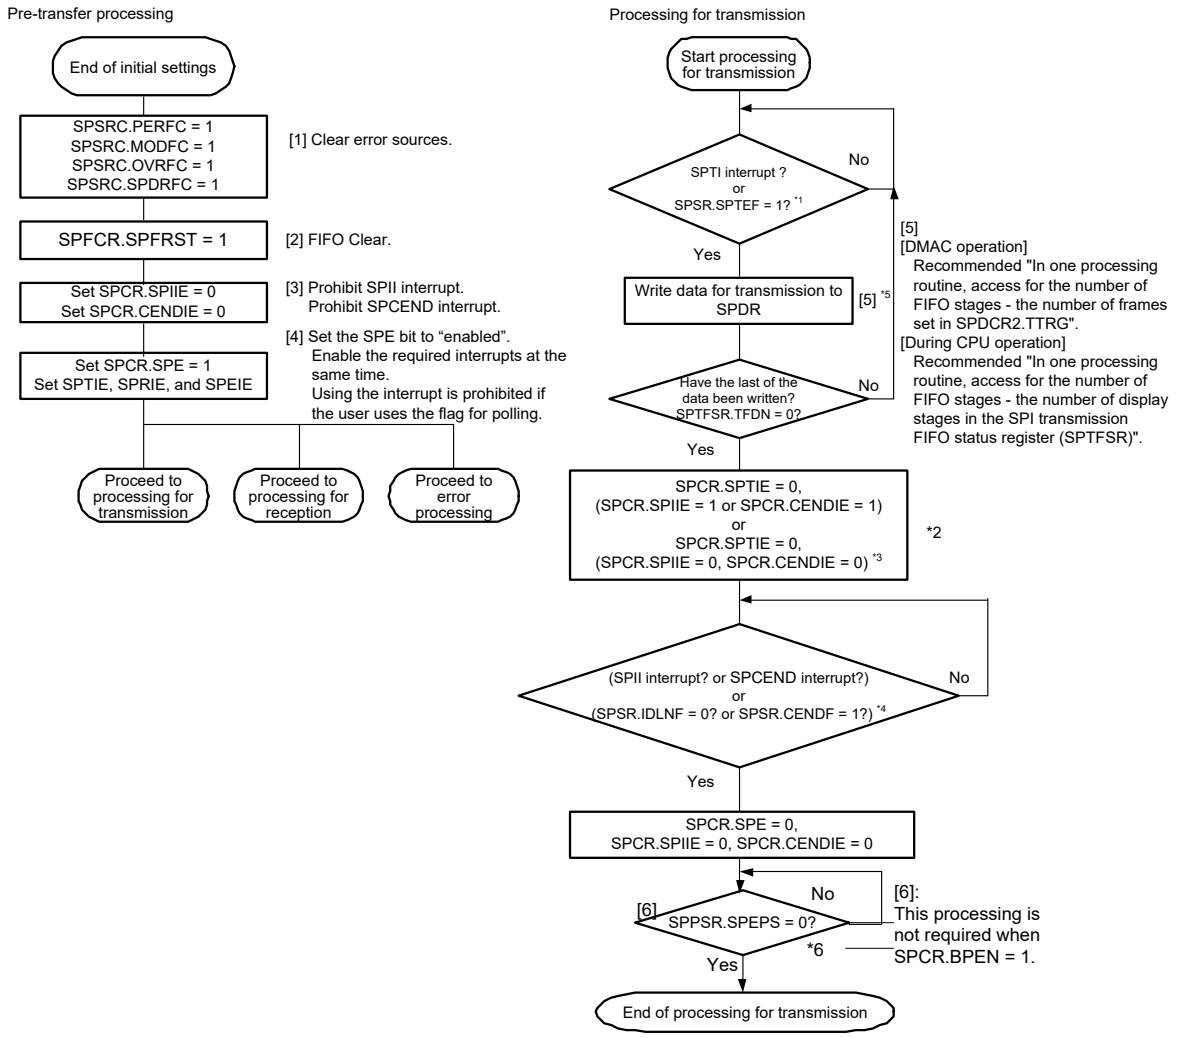
(9) Software processing flow

Figure 7.5-64 to **Figure 7.5-67** show examples of the flow of software processing.

(a) Transmit processing flow

Enabling an SPII or SPCEND interrupt after final transmit data is written makes it possible to notify the CPU that transmission of all data has been completed.



Note: SPII: Idle interrupt
SPTI: Transmission buffer empty interrupt

Note 1. Proceed to process of writing data for transmission after reading SPSR.SPTEF flag is 1b, if the user uses the flag for polling.

Note 2. The user can know the communication end by SPII interrupt (IDLNF flag) or SPCEND interrupt (CENDF flag). Please use either SPII interrupt (IDLNF flag) or SPCEND interrupt (CENDF flag).

Note 3. Set SPII interrupt prohibited (SPCR.SPIIE = 0b) and SPCEND interrupt prohibited (SPCR.CENDIE = 0b), if the user uses the flag for polling.

Note 4. Wait more than 1 PCLKM, after writing data for transmission to SPDR, and before starting polling of SPSR.IDLNF or SPSR.CENDF, if the user uses the flag for polling.

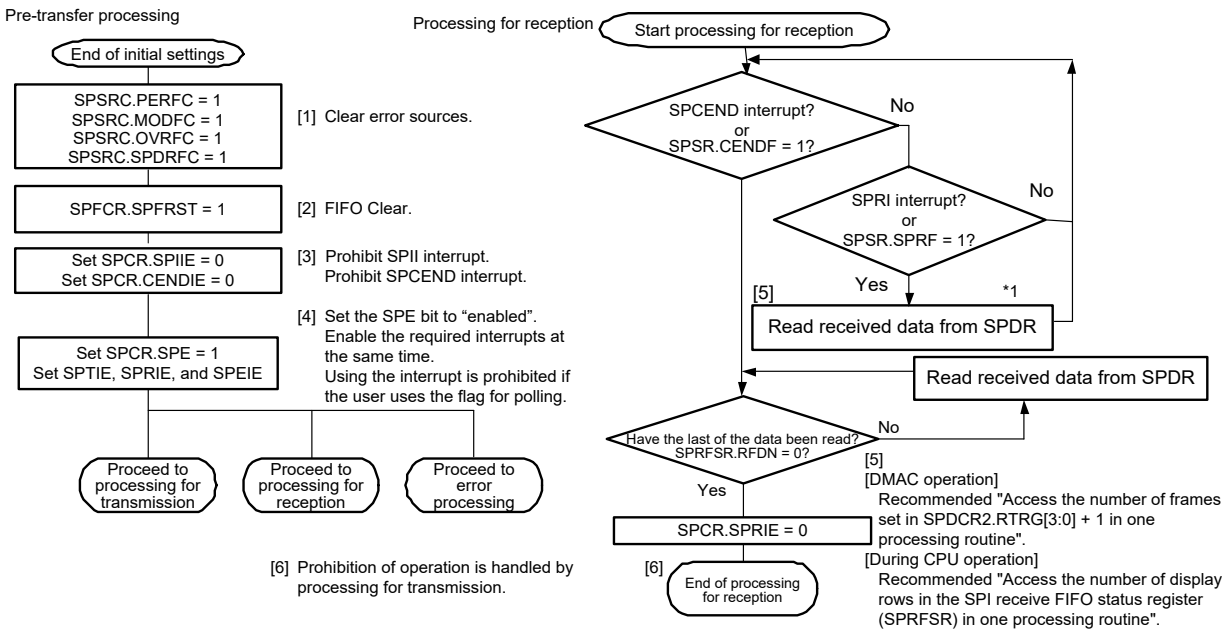
Note 5. During CPU operation, "Write 1b to SPI transmit buffer empty flag clear bit (SPSRC.SPTEFC) after one processing routine."

Note 6. When setting to 0b in slave mode and SPCR.BPEN = 0b, check that SPPSR.SPEPS has become 0b. (Not required when BPEN = 1b.)

Figure 7.5-64 Software Processing Flowchart in Master Mode (Transmission)

(b) Reception processing flow

The SPI always requires transmission because it does not have reception-only operation.

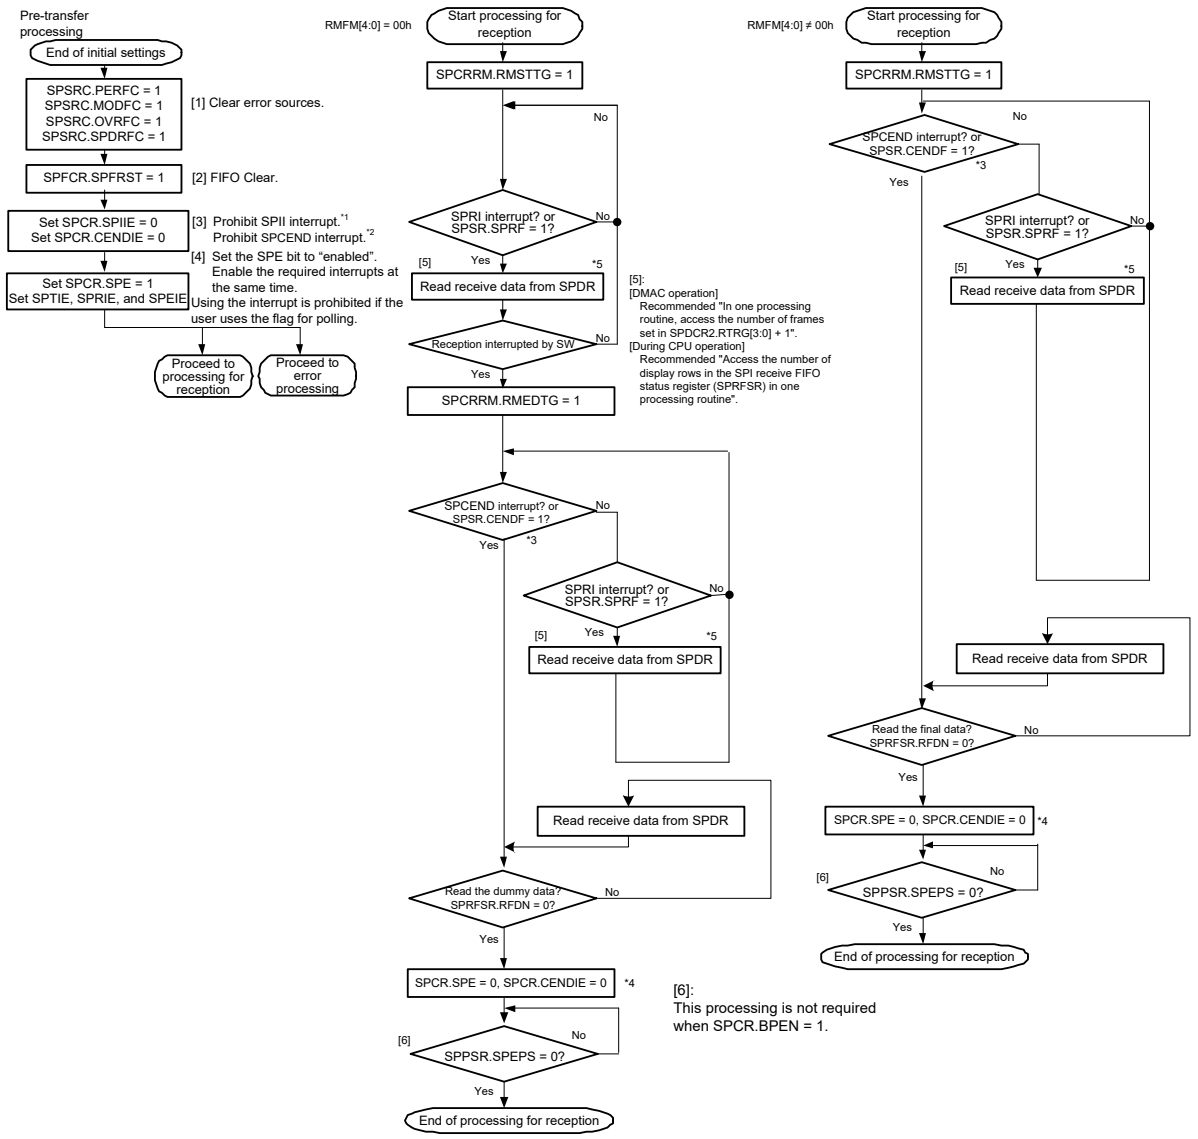


Note: SPII: Idle interrupt
SPRI: Reception buffer full interrupt

Note 1. During CPU operation, write 1 to the SPI receive buffer full flag clear bit (SPSRC.SPRFC) after one processing routine.

Figure 7.5-65 Software Processing Flowchart in Master Mode (Reception)

(c) Master reception-only processing flow



Note 1. The end of communication can be determined by the SPCEND interrupt (CENDF flag). Use the SPCEND interrupt (CENDF flag).

Note 2. Disable SPCEND interrupt (SPCR.CENDIE = 0b) during flag polling.

Note 3. A communication completion interrupt at reception only operation (Master) occurs at a predetermined timing under any of the following conditions.
- Frame number processing set by RMFM completed (RMFM[4:0] ≠ 00h)
- RMEDTG = 1b, when processing of the number of frames set by RMFM is not completed (including RMFM[4:0] = 00h)

Note 4. Internal trigger is also cleared.

Note 5. During CPU operation, write 1b to the SPI receive buffer full flag clear bit (SPSRC.SPRFC) after one processing routine.

Figure 7.5-66 Software Processing Flowchart in Master Mode (Reception-Only)

(d) Error processing flow

When a mode fault error occurs, the SPE bit is automatically cleared to stop transmission and reception operations.

However, other error sources do not clear the SPE bit or stop transmission and reception operations. For this reason, if an error occurs due to another source different from the source of the error occurred first, the SPECM[2:0] value is updated. Therefore, we recommend that you clear the SPE bit to stop the ongoing operation.

When interrupts are used and an error has occurred, clear an Interrupt flag in the error processing because an SPTI interrupt request or an SPRI interrupt request may be remaining in an Interrupt flag. Furthermore, when an SPRI interrupt request is remaining, read the receive buffer to initialize the SPI's internal sequencer.

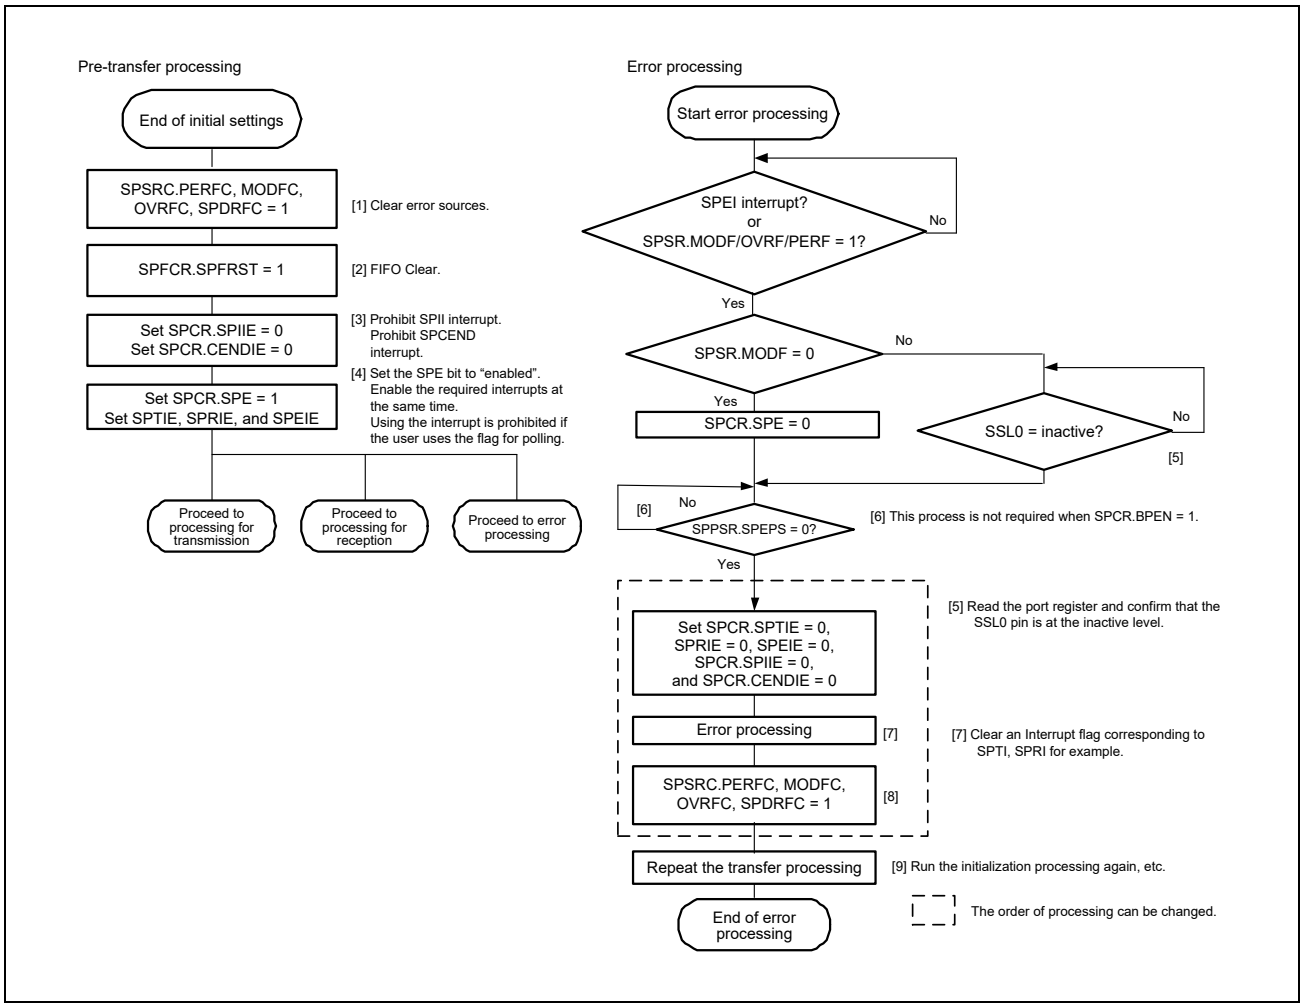


Figure 7.5-67 Flowchart for Master Mode (Error Processing)

7.5.3.13.2 Slave mode operation

(1) Starting a serial transfer

When the SPI detects SSL0 input signal assertion while SPCMD0.CPHA = 0, valid data drive to the MISO output signal must be started. For this reason, the SSL0 input signal assertion becomes a trigger to start serial transfer.

While SPCMD0.CPHA = 1b, when the SPI detects the first RSPCK edge with the SSL0 input signal asserted, valid data drive to the MISO output signal must be started. For this reason, the first RSPCK edge in the SSL0 signal assertion state becomes a trigger to start serial transfer when SPCMD0.CPHA = 1b.

The SPI starts driving the MISO output signal at the SSL0 signal assertion timing independently of the CPHA bit setting. Data that the SPI outputs is enabled or disabled depending on the set CPHA bit value.

For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**. The SSL0 input signal polarity depends on the set SSL0P bit value in the SSLP register.

(2) Terminating a serial transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing regardless of the value of SPCMD0.CPHA bit, the SPI terminates serial transfer. When the number of data stored in the receive FIFO is smaller than the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer. The SPI also changes the shift register status to empty after serial transfer regardless of the receive buffer status. When the SPI detects SSL0 input signal negation during a period from serial transfer start to the end of serial transfer, a mode fault error occurs. (See **7.5.3.10 Error Detection**.)

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in slave mode depends on the set value of the SPCMD0.SPB[4:0] bits. The SSL0 input signal polarity depends on the set value of SSLP.SSL0P bit. For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**.

(3) Notes on single-slave operations

[In the Motorola-SPI case]

Upon detecting the SSL0 input signal assertion edge while SPCMD0.CPHA = 0b, the SPI starts serial transfer. When using the SPI in single slave mode in a configuration as shown in the example in **Figure 7.5-9**, the SPI cannot start serial transfer correctly while CPHA is set to 0b because the SSL0 input signal is always active. To correctly perform transmission and reception of the SPI in slave mode in a configuration where the SSL0 input signal is fixed to active state, set the CPHA bit to 1b. If the CPHA bit needs to be set to 0b, do not fix the SSL0 input signal.

[In the TI-SSP case]

When TI SSP is set, when SPI is used as a single slave in the configuration shown in the example of **Figure 7.5-9**, the SSL0 input signal is always fixed to the inactive state, SPI cannot start serial transfer correctly.

When using a single slave, use the configuration shown in the example in **Figure 7.5-8**.

(4) Burst transfer

[In the Motorola-SPI case]

When SPCMD0.CPHA = 1b, continuous serial transfer (burst transfer) is possible while maintaining the SSL0 input signal assertion state. When SPCMD0.CPHA = 1b, the period (from the first RSPCK edge in the SSL0 input signal active state until the sampling timing for receiving the final bit) corresponds to the serial transfer period. Even if the SSL0 input signal is always at the active level, start of an access can be detected, which allows burst transfer.
When SPCMD0.CPHA = 0b, the second and subsequent serial burst transfers cannot be performed correctly for the same reason as (3).

[In the TI-SSP case]

In serial transfer, data transfer starts after the SSL input signal is asserted for RSPCK 1 cycle. Since frame transfer starts from the SSL input signal, SSL must be asserted between frames.

(5) Initialization flowchart

Figure 7.5-68 shows an example of initialization flow when using the SPI in slave-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

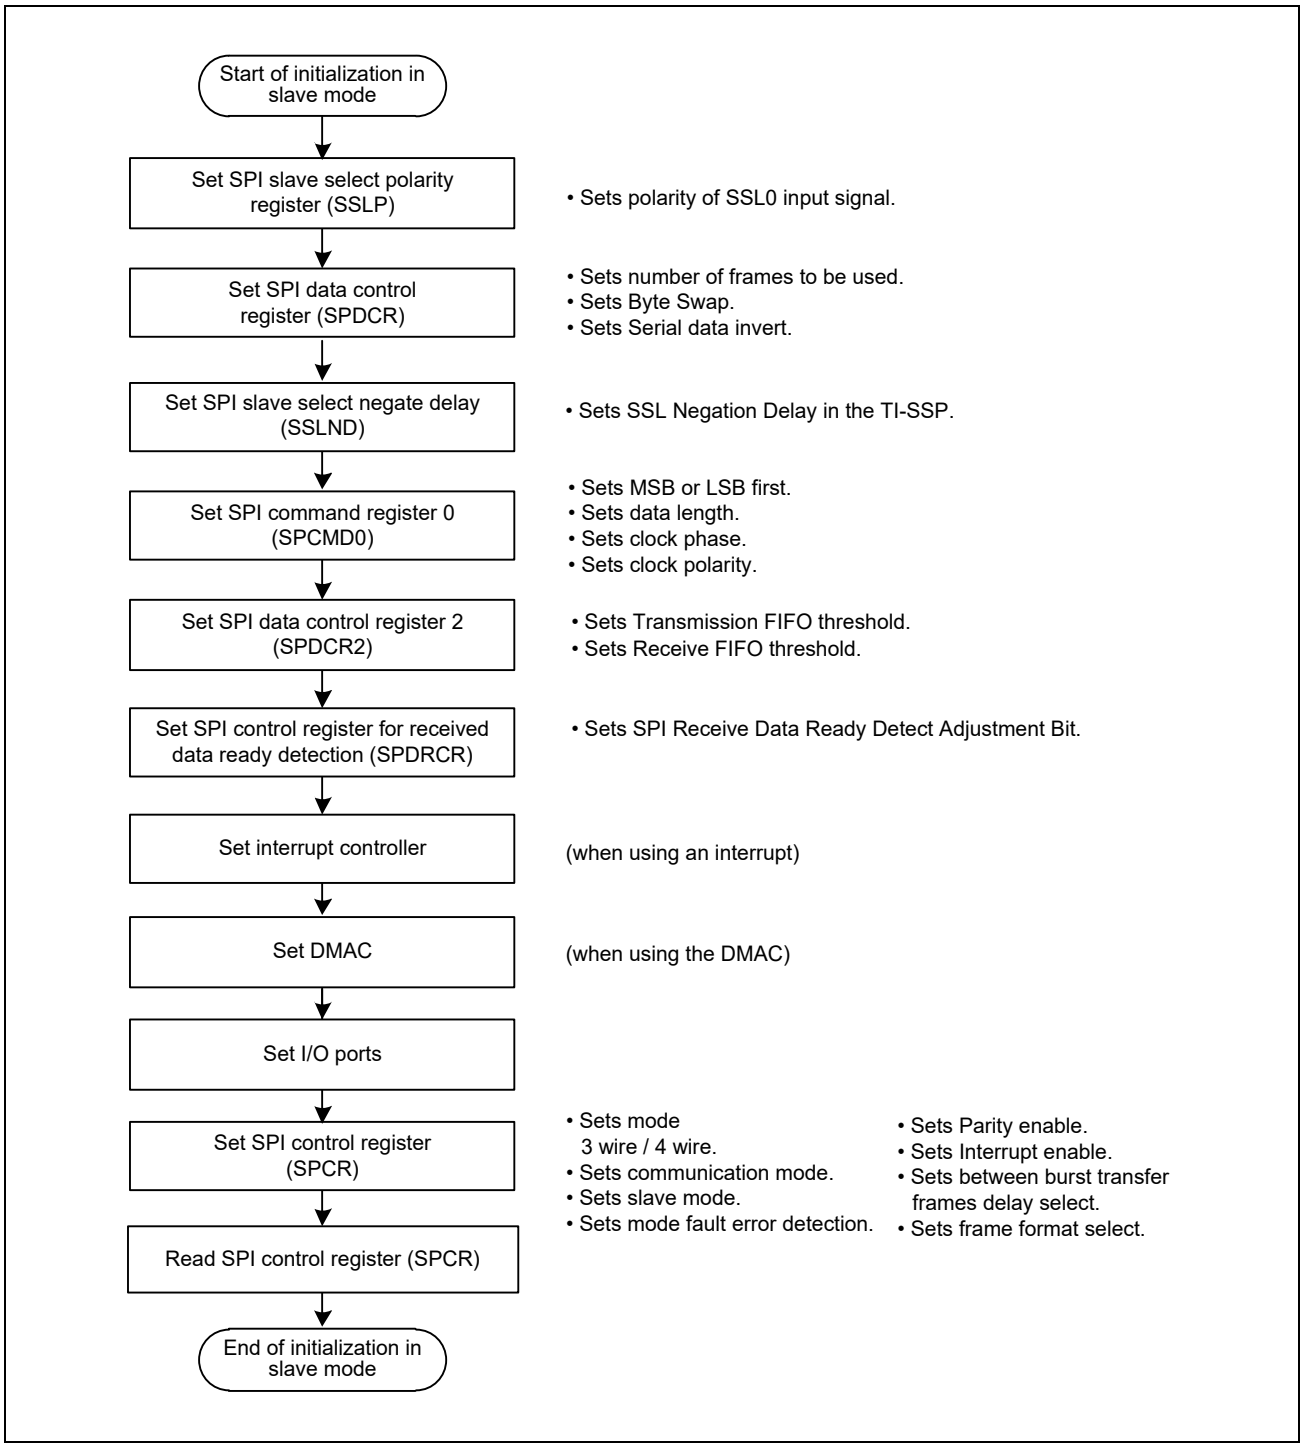

Figure 7.5-68 Example of Initialization Flow in Slave Mode

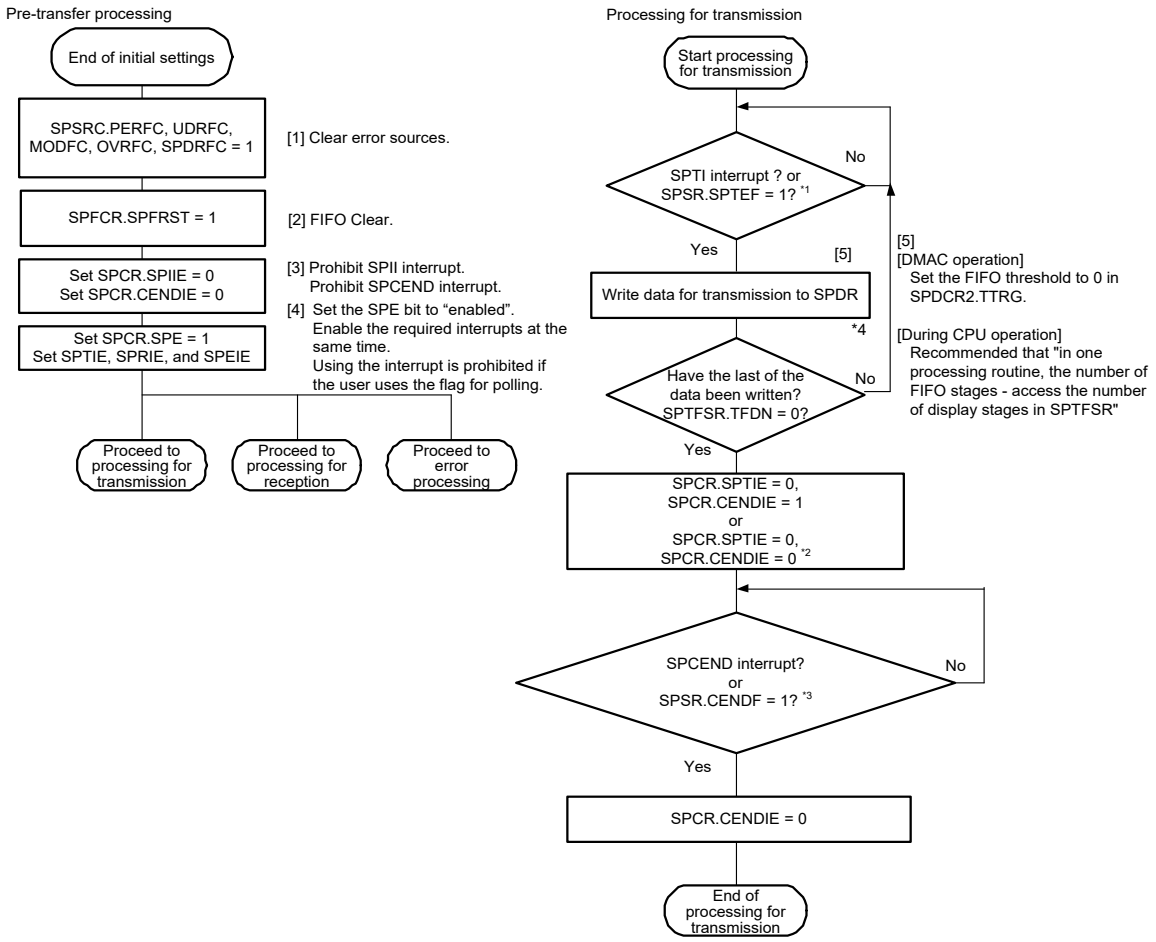
(6) Software processing flow

Figure 7.5-69 to **Figure 7.5-72** show examples of the flow of software processing.

(a) Transmit processing flow



Note: SPII: Idle interrupt

Note 1. Proceed to process of writing data for transmission after reading SPSR.SPTEF flag is 1b, if the user uses the flag for polling.

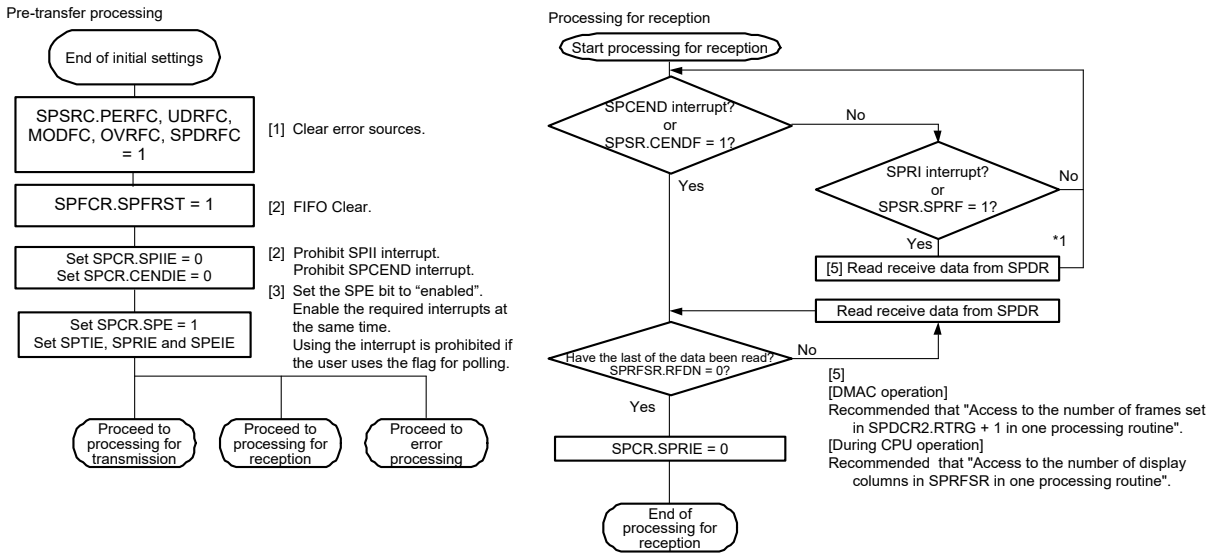
Note 2. Set SPCEND interrupt prohibited (SPCR.CENDIE = 0b), if the user uses the flag for polling.

Note 3. Wait more than 1 PCLKM, after writing data for transmission to SPDR, and before starting polling of SPSR.IDLNF or SPSR.CENDF , if the user uses the flag for polling.

Note 4. During CPU operation, write 1b to the SPI transmit buffer empty flag clear bit (SPSRC.SPTEFC) after one processing routine.

Figure 7.5-69 Software Processing Flowchart in Slave Mode (Transmission)

(b) Reception processing flow

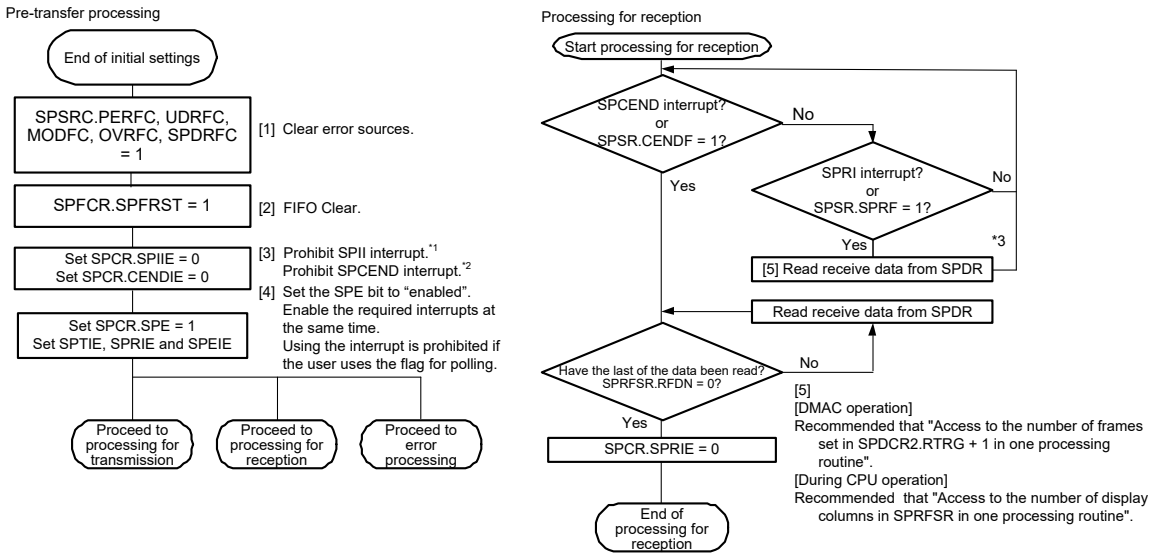


Note: SPII: Idle interrupt

Note 1. During CPU operation, "Write 1b to the SPI receive buffer full flag clear bit (SPSRC.SPTEFC) after one processing routine."

Figure 7.5-70 Flowchart in Slave Mode (Reception)

(c) Master reception-only processing flow



Note: SPII: Idle interrupt

Note 1. The end of communication can be determined by the SPCEND interrupt (CENDF flag). Use the SPCEND interrupt (CENDF flag).

Note 2. Disable the SPCEND interrupt (SPCR.CENDIE = 0b) during flag polling.

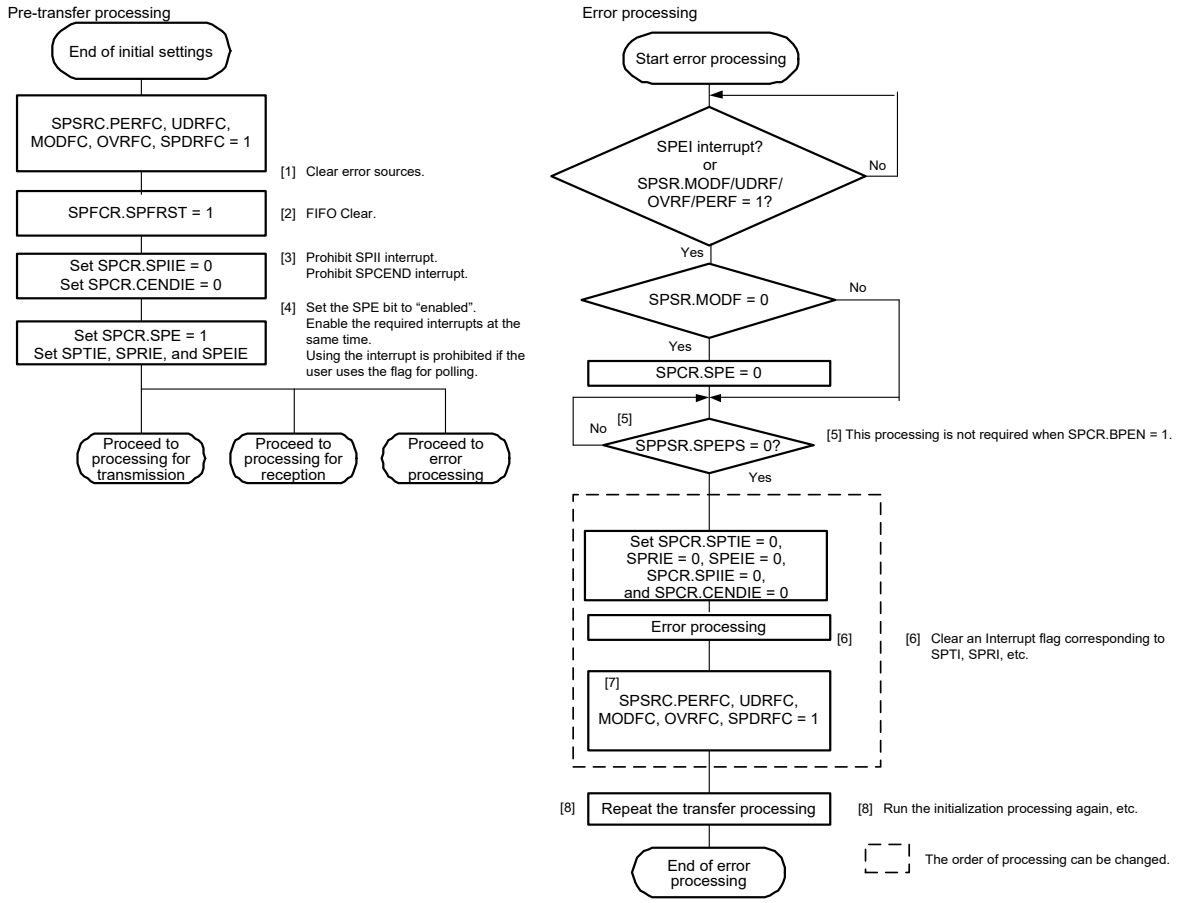
Note 3. During CPU operation, write 1 to the SPI receive buffer full flag clear bit (SPSRC.SPTEFC) after one processing routine.

Figure 7.5-71 Software Processing Flowchart in Slave Mode (Reception-Only)

(d) Error processing flow

In slave mode operation, the MODF flag can be cleared regardless of the SSL0 pin status even when a mode fault error is present.

When interrupts are used and an error has occurred, clear an Interrupt flag in the error processing because an SPTI interrupt request or an SPRI interrupt request may be remaining in an Interrupt flag. Furthermore, when an SPRI interrupt request is remaining, read the receive buffer to initialize the SPI's internal sequencer.



Note: SPEI: SPI error interrupt
SPII: Idle interrupt
SPRI: Reception buffer full interrupt
SPTI: Transmission buffer empty interrupt

Figure 7.5-72 Software Processing Flowchart in Slave Mode (Error Processing)

7.5.3.14 Clock Synchronous Operation

When SPCR.SPMS bit = 1b, the SPI operates in synchronization with clock. Clock synchronous operation enables communication by using three pins RSPCK, MOSI, and MISO without using SSL pins. SSL pins can be used as I/O ports.

Clock synchronous operation does not use SSL pins for communication, but the module operates internally in the similar manner to SPI operation. In master mode operation and slave mode operation, communication is possible according to the flow similar to SPI operation, but no mode fault error is detected because SSL pins are not used.

In clock synchronous operation, if the SPCMD.CPHA bit is set to 0b in slave mode (SPCR.MSTR = 0b), subsequent operation is not guaranteed.

7.5.3.14.1 Master mode operation

(1) Starting a serial transfer

When data is written to the SPDR register while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTXn, n = 0 to 15) data in SPDR. While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**. In clock synchronous operation, however, the SSL0 output signal is not used for communication.

(2) Terminating a serial transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPCMD.SPB[4:0] bits. For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**. In clock synchronous operation, however, the SSL0 output signal is not used for communication.

(3) Sequence control

The transfer format in master mode is determined by the SPSCR, SPCMDm (m = 0 to 7), SPBR, SPCKD, SSLND, and SPND registers. These settings are valid though SSL signals are not output in clock synchronous operation.

The SPSCR register is used to determine the sequence configuration for serial transfer to be performed by the SPI in master mode. MSB first/LSB first, data length, a part of bit rate settings, RSPCK polarity and phase, SPCKD enable/disable, SSLND enable/disable, and SPND enable/disable are set in SPCMD0 to SPCMD7. A part of bit rate settings is set in SPBR, the SPI clock delay value is set in SPCKD, the SSL negation delay value is set in SSLND, and the access delay value is set in SPND.

The SPI configures the sequence that structures a part of or whole of SPCMD0 to SPCMD7 according to the sequence length specified in SPSCR. The SPI has a pointer to SPCMD that configures the sequence. This pointer value can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1b to enable the SPI function, the SPI sets the pointer to commands in SPCMD0 and applies the SPCMD0 setting to the transfer format at the start of serial transfer. The SPI increments the pointer when the next-access delay period ends in each data transfer. When the serial transfer corresponding to the final command that configures the sequence is completed, the SPI sets the pointer in SPCMD0. Thus sequence is repeatedly executed.

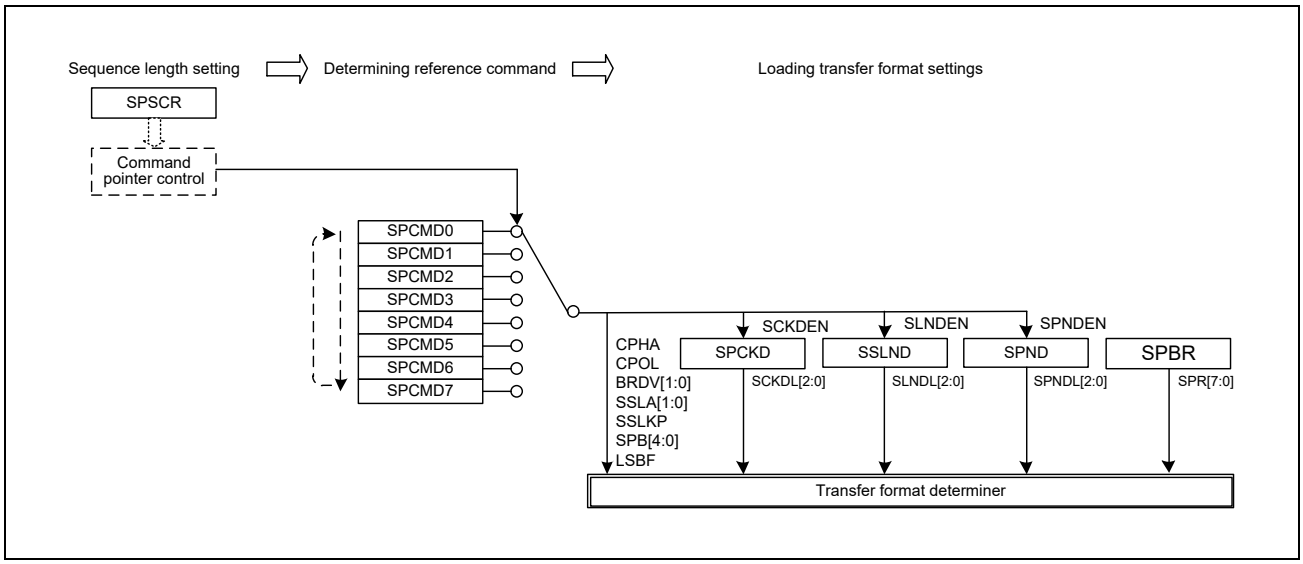


Figure 7.5-73 Determining Serial Transfer Method in Master Mode

In this section, a frame consists of data (SPDR) and configuration (SPCMDm (m = 0 to 7)).

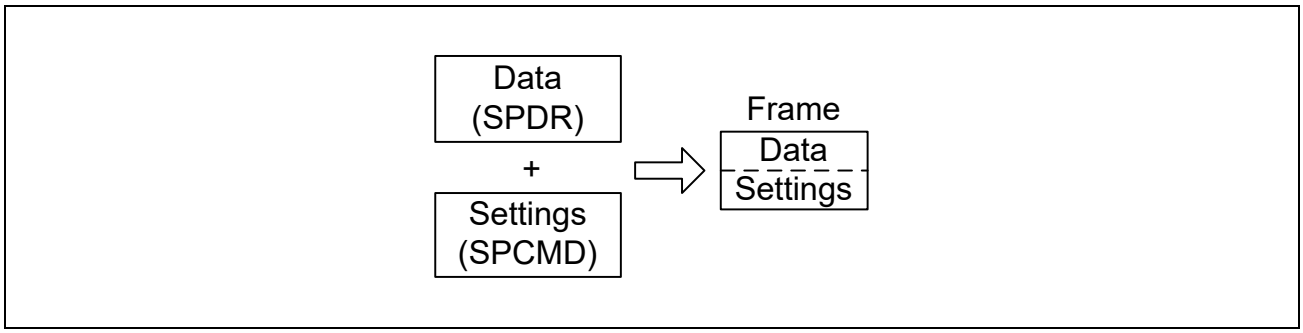

Figure 7.5-74 Conceptual Diagram of Frame

Figure 7.5-75 shows the correspondence between the command in the sequence operation performed and the transmit buffer/receive buffer.

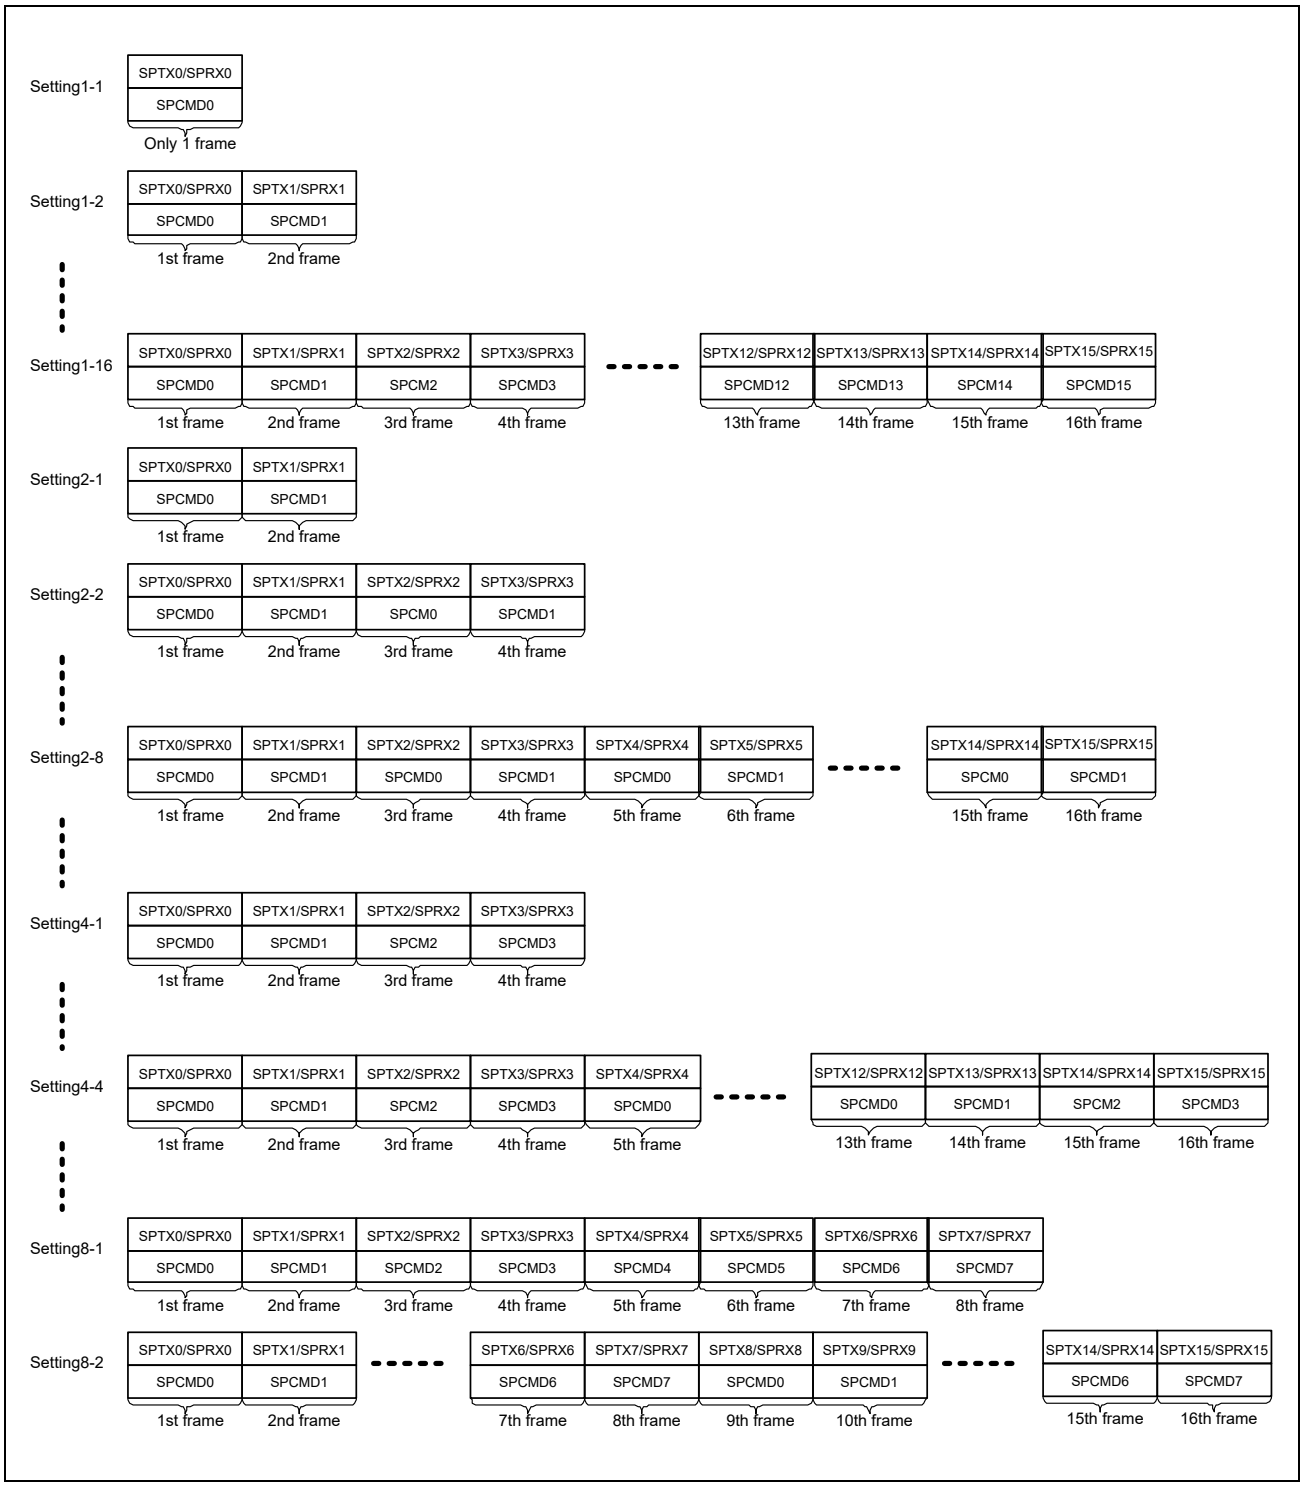

Figure 7.5-75 Correspondence between SPI Command Register and Transmit/Receive Buffers in Sequence Operation

(4) Initialization flow

Figure 7.5-76 shows an example of initialization flow when using the SPI in master-mode clock synchronous operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

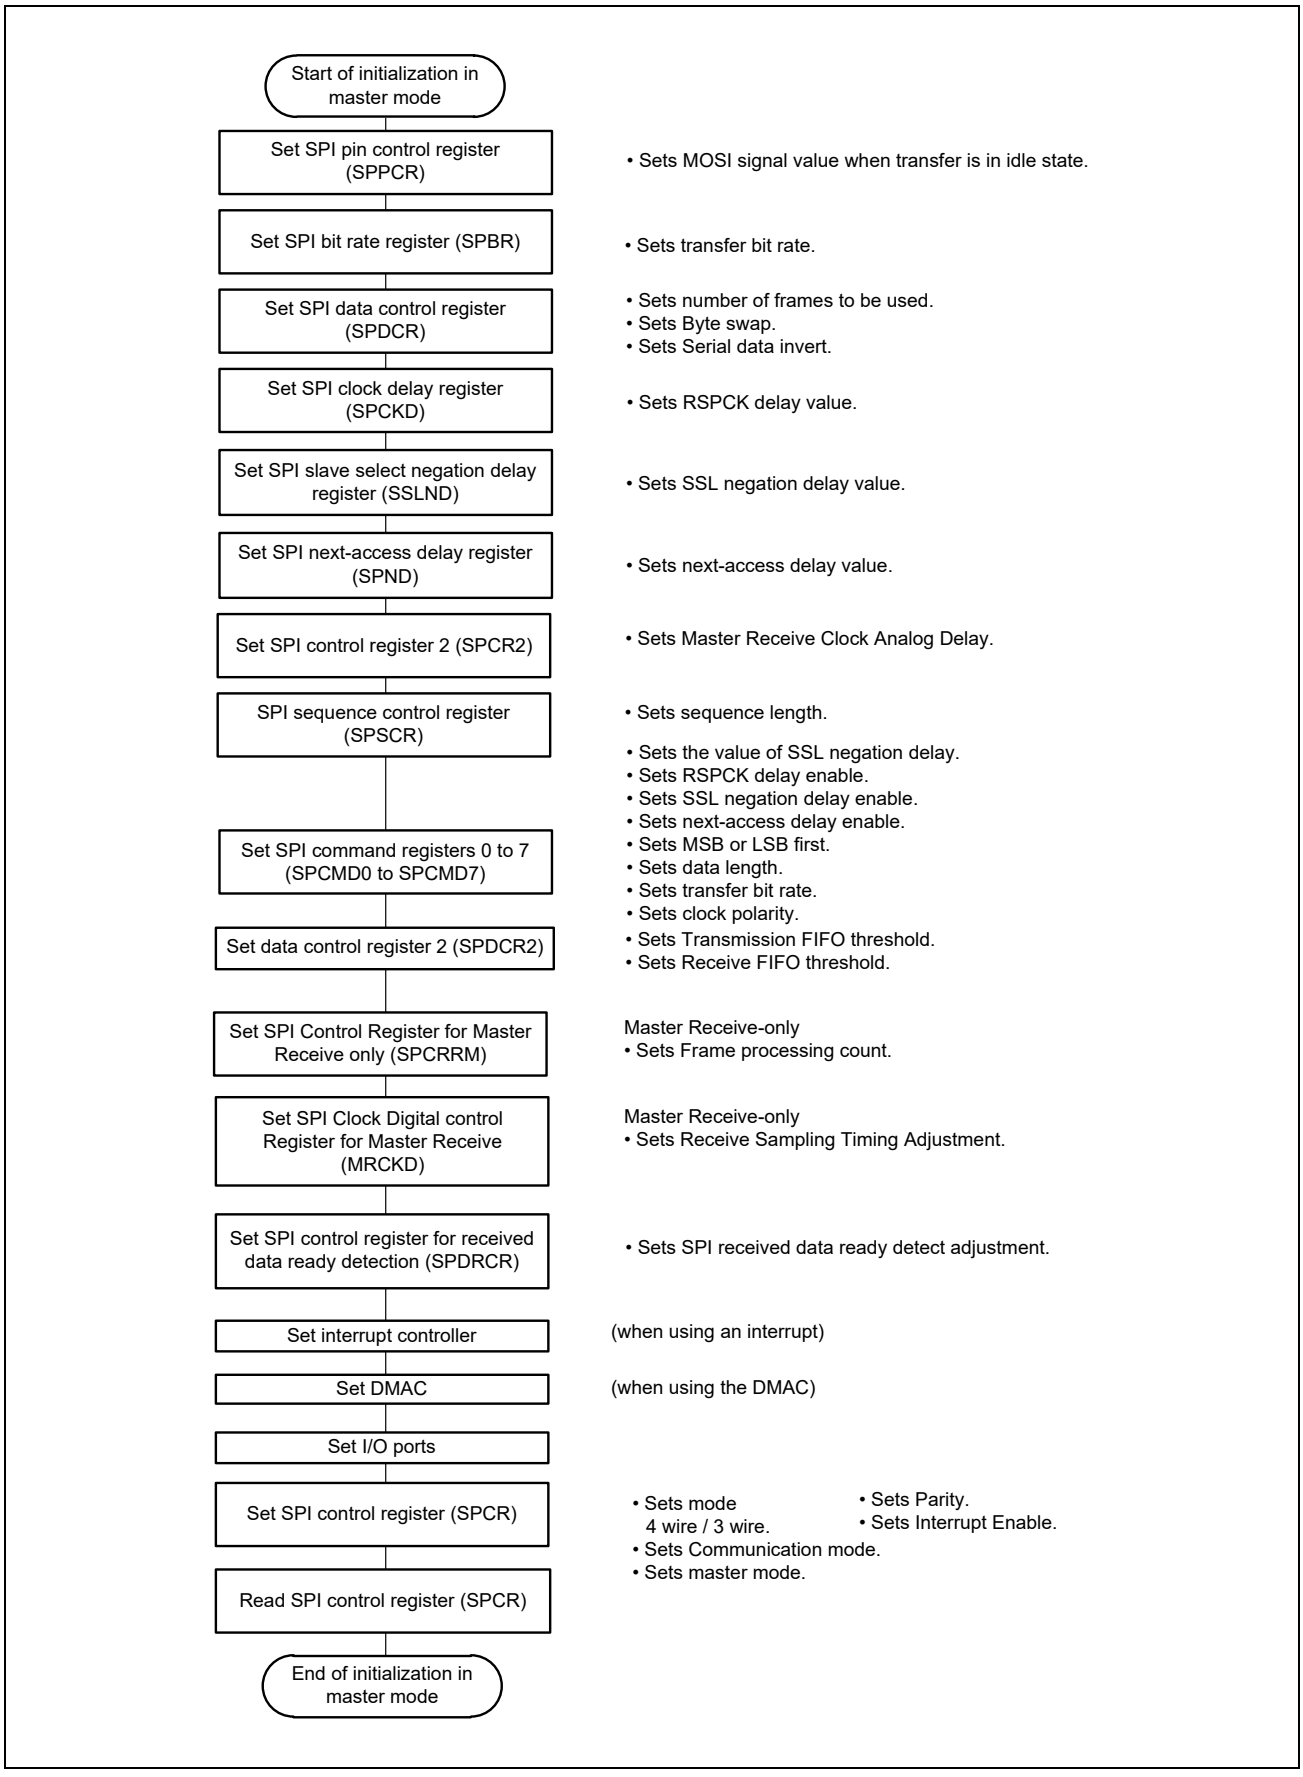

Figure 7.5-76 Example of Initialization Flowchart in Master Mode (Clock Synchronous Operation)

(5) Flow of software processing

The software processing flow is omitted here because it is similar to the flow for SPI operation. However, no mode fault error occurs.

7.5.3.14.2 Slave mode operation

(1) Starting a serial transfer

When SPCR.SPMS = 1b, the first RSPCK edge becomes a trigger to start serial transfer of the SPI.

While SPCR.SPMS = 1b, the SPI always drives the MISO output signal.

For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**. In clock synchronous operation, however, the SSL0 input signal is not used.

(2) Terminating a serial transfer

Upon detecting the RSPCK edge corresponding to the final sampling timing, the SPI terminates serial transfer. When the number of data stored in the receive FIFO < the number of FIFO stages, the SPI copies received data from the shift register to the receive buffer in the SPDR register after serial transfer. The SPI also changes the shift register status to empty after serial transfer regardless of the receive buffer status. The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in slave mode depends on the set value of the SPCMD0.SPB[4:0] bits. For details about the SPI transfer format, see **7.5.3.5 Transfer Format (Frame Format)**.

(3) Initialization flowchart

Figure 7.5-77 shows an example of initialization flow when using the SPI in slave-mode clock synchronous operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

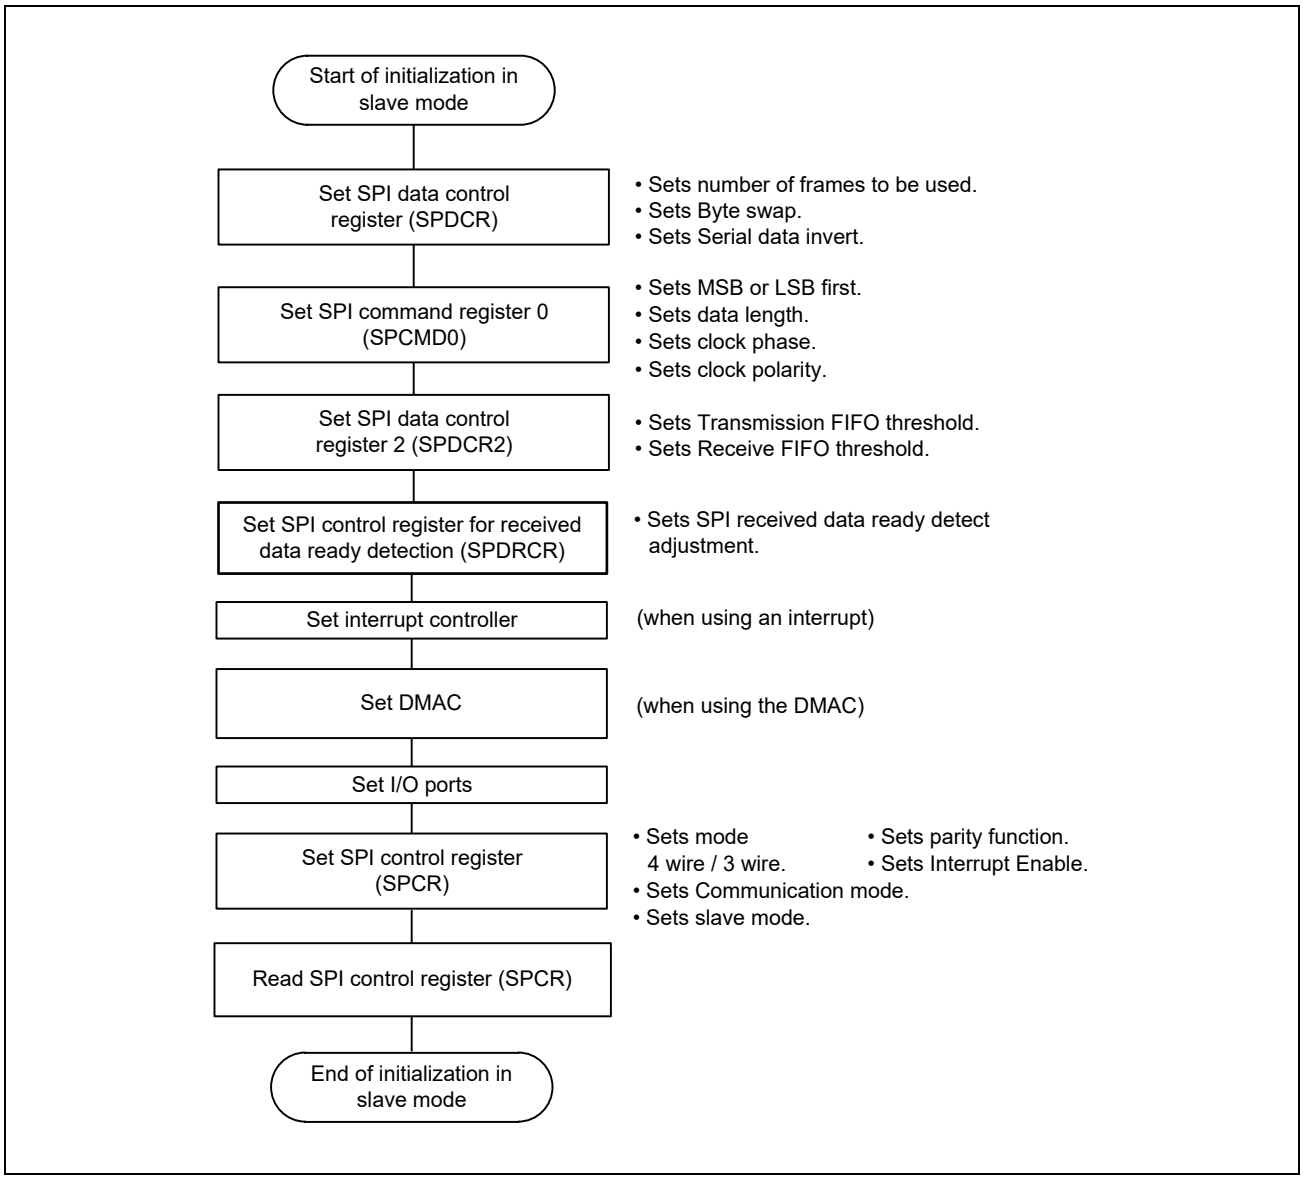

Figure 7.5-77 Example of Initialization Flow in Slave Mode

(4) Flow of software processing

The software processing flow is omitted here because it is similar to the flow for SPI operation. However, no mode fault error occurs.

7.5.3.15 Loopback Mode

When 1b is written to the SPPCR.SPLP bit or SPPCR.SPLP2 bit, the SPI disconnects the path between MISO pin and shift register (when SPCR.MSTR = 1b) or between MOSI pin and shift register (when SPCR.MSTR = 0b), and then connects the shift register input path to the output path. When SPCR.MSTR = 1, the SPI does not disconnect the path between MOSI pin and shift register. When SPCR.MSTR = 0b, the SPI does not disconnect the path between MISO pin and shift register.

When serial transfer is performed in loopback mode, transmit data or inverted transmit data of the SPI becomes received data of the SPI.

Figure 7.5-78 shows the relationship between settings of the SPLP2 and SPLP bits and received data.

Table 7.5-14 SPLP2 and SPLP Bit Settings and Received Data

SPPCR.SPLP2 Bit	SPPCR.SPLP Bit	Received Data
0b	0b	Input data from the MOSI pin or MISO pin
0b	1b	Inversed transmit data
1b	0b	Transmit data
1b	1b	Transmit data

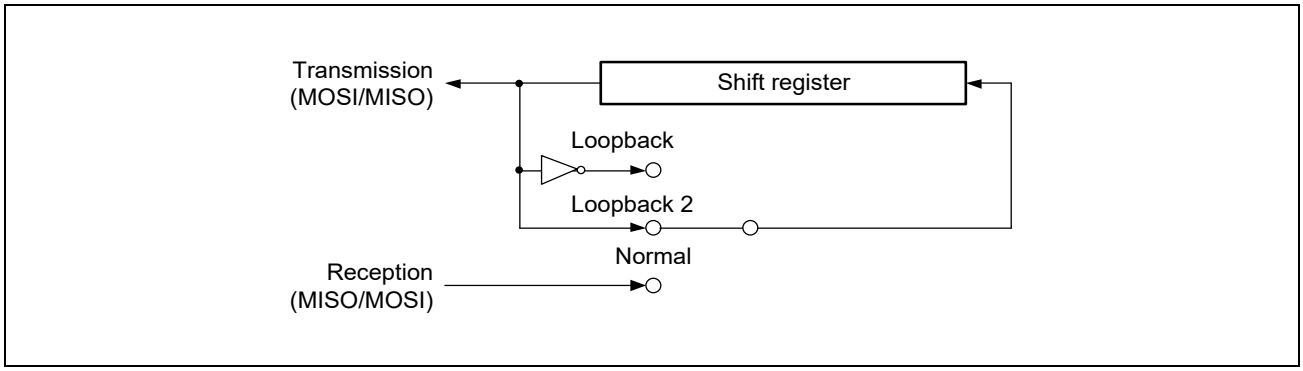

Figure 7.5-78 Configuration of Shift Register I/O Paths in Loopback Mode

7.5.3.16 Self-Diagnosis of Parity Function

The parity circuit consists of a section to add a parity bit to transmit data and a section to detect an error in receive data.

To detect a failure of these sections of the parity circuit, self-diagnosis of the parity circuit is performed according to the flow in **Figure 7.5-79**.

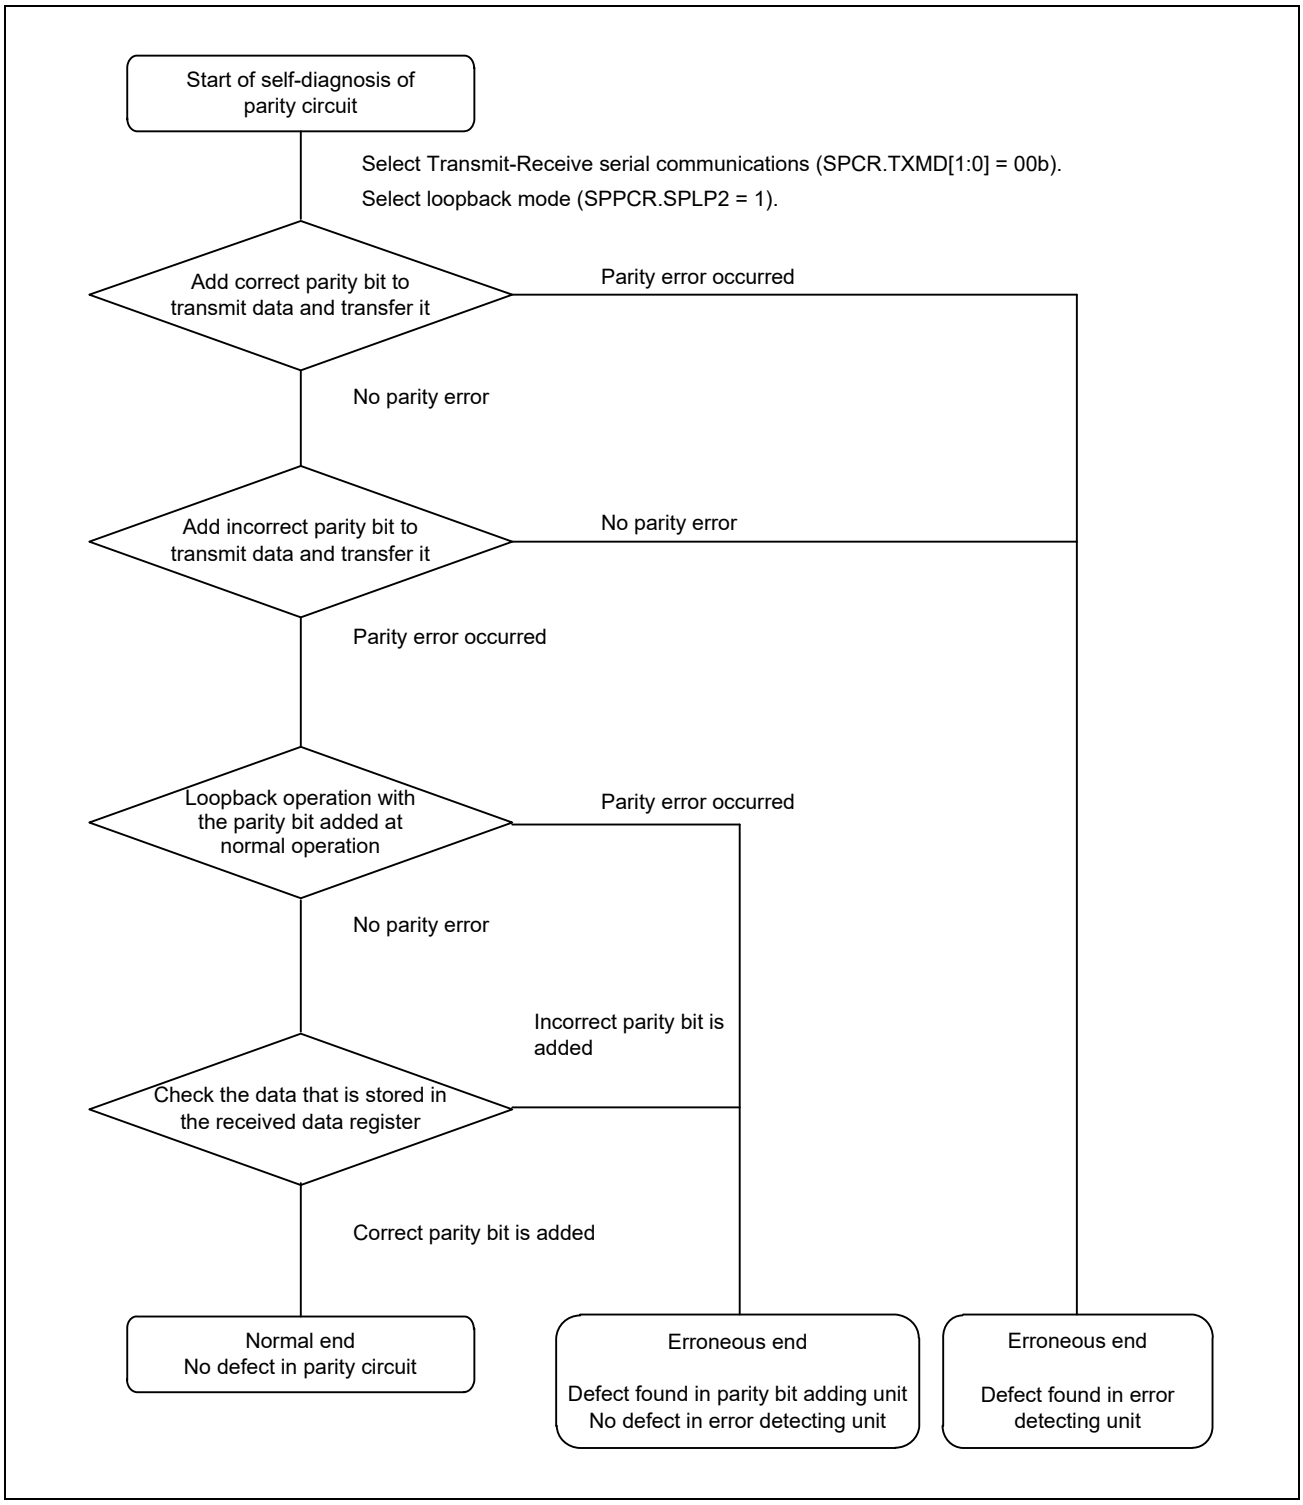

Figure 7.5-79 Parity Circuit Self-Diagnosis Flow

7.5.3.17 Interrupt Requests

The SPI has the following interrupt sources: receive buffer full, transmit buffer empty, mode fault, underrun, overrun, parity error, SPI idle, communication end, and received data ready. Furthermore, the DMAC can be activated by a receive buffer full interrupt request and a transmit buffer empty interrupt request to start data transfer.

Mode fault, underrun, overrun, parity error, and received data ready (SPCR.SPDRES = 1b) interrupt requests are allocated to vector addresses in SPEI. Therefore, identify these interrupt sources by reading respective flags. **Table 7.5-15** lists SPI's interrupt sources. When each interrupt condition in **Table 7.5-15** is met, an interrupt is generated. Clear the receive buffer full and transmit buffer empty interrupt sources by performing data transfer.

When starting transmission or reception by using the DMAC, configure the DMAC to enable it, and then configure the SPI.

Even when the transmit buffer empty interrupt or receive buffer full interrupt condition is met while an Interrupt flag is 1, an interrupt request is not output to ICU but is internally retained. (Only one request per source can be internally retained.) When an Interrupt flag is cleared to 0, the retained interrupt request is output to ICU and then automatically cleared. An internally retained interrupt request can also be cleared by setting the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0b.

Table 7.5-15 Interrupt Sources of SPI

Interrupt Source	Symbol	ICU Input Name	Interrupt Condition	DMAC Activation
Reception buffer full	SPRI	RSPI_CHn_sp_rxintpls_n	SPRIE = 1b and (receive buffer full (SPRF = 1b) | (SPDRES = 0b and Receive data ready (SPDRF = 1b)))	Activated
Transmission buffer empty	SPTI	RSPI_CHn_sp_txintpls_n	SPTIE = 1b and transmit buffer empty (SPTEF = 1b)	Activated
SPI errors (mode fault, underrun, overrun, and parity error, received data ready)	SPEI	RSPI_CHn_sp_errint_n	SPEIE = 1b and (MODF = 1b | UDRF = 1b | OVRF = 1b | PERF = 1b | (SPDRES = 1b and SPDRF = 1b))	—
SPI idle	SPII	RSPI_CHn_sp_idint_n	SPIIE = 1b and IDLNF = 0b	—
Communication end*1	SPCEND	RSPI_CHn_sp_ceintpls_n	CENDIE = 1b and CENDF = 1b	—

Note 1. See **7.5.3.9.7 Common operation** for details on the communication completion interrupt output conditions.

Note: n = 0 to 2

7.5.4 Usage Notes

7.5.4.1 Notes on Communication Start

When an Interrupt flag is 1 at the beginning of communication, perform the following procedure to clear an interrupt request before enabling operation (setting the SPCR.SPE bit to 1b).

1. Confirm that communication is not going (SPCR.SPE = 0b).
2. Set the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0b.
3. Read the corresponding interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that it is 0b.
4. Set the Interrupt flag to 0.

7.5.4.2 Notes on the Module-Stop Function

To stop this module using the power consumption reducing function, be sure to set the SPE bit in SPCR to 0b to terminate communication and then use the power consumption reducing function.

7.5.4.3 Notes on SPRF and SPTEF Flags

When using the SPRF and SPTEF flags in SPSR by polling them, set the SPRIE and SPTIE bits in SPCR to 0b.

7.5.4.4 Notes on Receive Sampling Function

When using the receive sampling function (sampling receive data with MRIOCLK or MRCLK), set the SSLND register considering the delay of the receive data sampling clock (MRIOCLK or MRCLK) from RSPCK. Please see **7.5.2.2.3 SPI Slave Select Negation Delay Register (RSPIm_**SSLND).

7.5.4.5 Notes on Burst Transfer in Master Mode

During burst transfer, changing the following settings between SPCMD with the SSLKP bit set to 1b and SPCMD used in the next transfer is prohibited.

1. SSL Signal Assertion setting (SSLA[1:0] bits)
2. RSPCK output setting (CPHA, CPOL, BRDV[1:0] bits)

7.5.4.6 Notes on TI-SSP in Slave Mode

In the slave TI SSP mode, the delay between frames must observe the following intervals.

Secure the following intervals on the master side.

[Master side: interval from RSPCK edge of last bit to RSPCK edge of next SSL] > [Slave side: Output enable delay time = RSPI_n_TCLK × (1 to 2) + SLNDL[2:0] setting value]

7.5.4.7 Notes at SPE = 1b

(1) When SPCR.SPE = 1b, if the following register bits are rewritten, subsequent operations are not guaranteed.

SPFCR	SPFRST

Note 1. Rewriting prohibited in slave mode. In master mode, this is possible only when there is no next transfer data in the transmit FIFO.

(2) After rewriting from SPE = 1b to 0b when SPCR.BPEN = 0b, or when SPSR.MODF is set to 1b, check that the SPPSR.SPEPS bit is set to 0b, then do the next operation.

SECTION 7 LOW-SPEED INTERFACE

7.6 CRC Operation Unit (CRC)

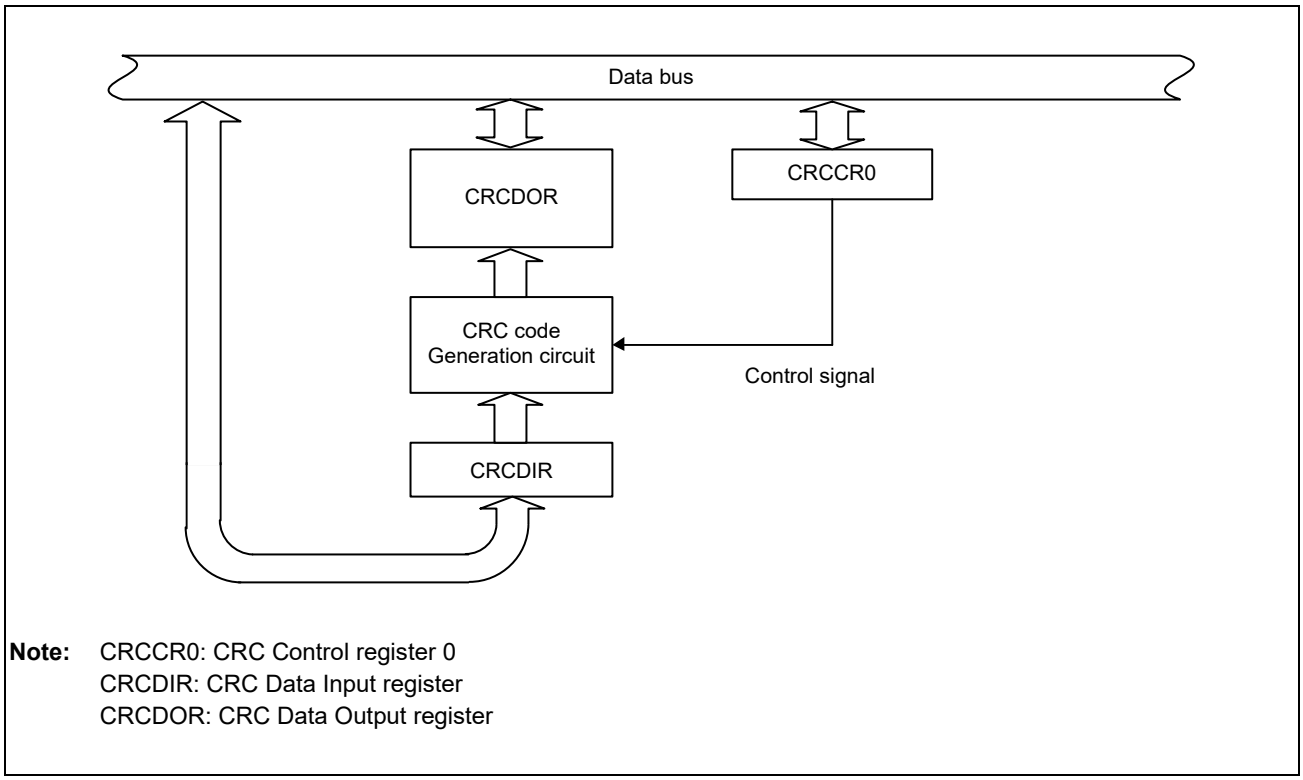
7.6.1 Overview

Cyclic redundancy check (CRC) operation units generate CRC codes. **Table 7.6-1** lists the specifications of the CRC operation unit, and **Figure 7.6-1** shows a block diagram of the CRC operation unit.

Table 7.6-1 CRC Specifications

Parameter	Description	
Number of channels	1 channel	
Data size	8 bits	32 bits
Data for CRC calculation*1	CRC codes are generated for any desired data in 8n-bit units (where n is a natural number)	CRC codes are generated for any desired data in 32n-bit units (where n is a natural number)
CRC processor unit	8-bit parallel processing	32-bit parallel processing
CRC generating polynomial	One of three generating polynomials is selectable • 8-bit CRC $X^8 + X^2 + X + 1$ (CRC-8) • 16-bit CRC $X^{16} + X^{15} + X^2 + 1$ (CRC-16) $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT)	One of two generating polynomials is selectable • 32-bit CRC $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32) $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C)
CRC calculation switching	The order of the bits produced by CRC calculation can be switched for LSB first or MSB first communication	
CRC snoop	Monitoring reads from and writes to a certain register address	

Note 1. The circuit does not have a function to divide data for calculation into CRC calculation units. Write data in 8-bit or 32-bit units.



Note: CRCCR0: CRC Control register 0
CRCDIR: CRC Data Input register
CRCDOR: CRC Data Output register

Figure 7.6-1 CRC Block Diagram

7.6.2 CRC Registers

The base address for the CRC is as follows.

Table 7.6-2 Register Base Address

Base Register Name	Base Address
<CRC_base>	0_1300_0800h (5300_0800h*1, 4300_0800h*2)

Note 1. CM33 Address Space Non-Secure

Note 2. CM33 Address Space Secure

7.6.2.1 List of Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
CRC Control Register 0	CRCCR0	00h	0000h	8
CRC Control Register 1	CRCCR1	00h	0001h	8
Reserve	-	-	0002h to 0003h	-
CRC Data Input Register	CRCDIR	0000_0000h	0004h	32
CRC Data Output Register	CRCDOR	0000_0000h	0008h	32
Snoop Address Register	CRCSAR	0000h	000Ch	16

7.6.2.2 CRC Register Descriptions

7.6.2.2.1 CRC Control Register 0 (CRCCR0)

Access Size : 8 bits
Address : <CRC_base> + 0000h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	DORCLR	LMS	-	-	-	GPS[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	W	RW	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	DORCLR	0h	W	The read value is undefined CRCDOR Register Clear 0b: No effect 1b: Clears the CRCDOR register
6	LMS	0h	RW	CRC Calculation Switching 0b: Generates CRC for LSB first communication. 1b: Generates CRC for MSB first communication.
5 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	GPS[2:0]	0h	RW	CRC Generating Polynomial Switching 000b: No calculation is executed. 001b: 8-bit CRC-8 ($X^8 + X^2 + X + 1$) 010b: 16-bit CRC-16 ($X^{16} + X^{15} + X^2 + 1$) 011b: 16-bit CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) 100b: 32-bit CRC-32 ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 101b: 32-bit CRC-32C ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) Others: No calculation is executed.

GPS[2:0] bits (CRC Generating Polynomial Switching)

Set these bits to select the CRC Generating Polynomial.

LMS bit (CRC Calculation Switching)

The setting this bit selects the order of the bits of generated CRC codes. The bit selects transmission of the lower-order byte of the CRC code first for LSB first communication, or the higher-order byte first for MSB first communication. For details on the transmission and reception of CRC codes, see **7.6.3 Operation**.

DORCLR bit (CRCDOR Register Clear)

Write 1b to this bit so that the CRCDOR register is set to 0000_0000h.

7.6.2.2.2 CRC Control Register 1 (CRCCR1)

Access Size : 8 bits
Address : <CRC_base> + 0001h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	CRCSEN	CRCSWR	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	CRCSEN	0h	RW	0b: Disabled 1b: Enabled
6	CRCSWR	0h	RW	0b: Snoop-on-read 1b: Snoop-on-write
5 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

CRCSEN Bit (Snoop enable bit)

When setting this bit to 1b, CRC snoop operation is valid. When setting this bit to 0b, CRC snoop operation is invalid.

CRCSWR Bit (Snoop-on-write/read switch bit)

This bit selects the direction of the access in the address monitoring function.

When setting this bit to 0b (initial value), CRC snoop operation to reading a certain register address is valid. Similarly, when setting this bit to 1b, CRC snoop operation to writing a certain register address is valid.

7.6.2.2.3 CRC Data Input Register (CRCDIR)

CRCDIR is a readable/writable register. Write data for CRC calculation to this register.

Access Size : 32 bits
Offset Address : <CRC_base> + 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DIR[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DIR[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DIR[31:0]	0h	RW	CRC Data Input

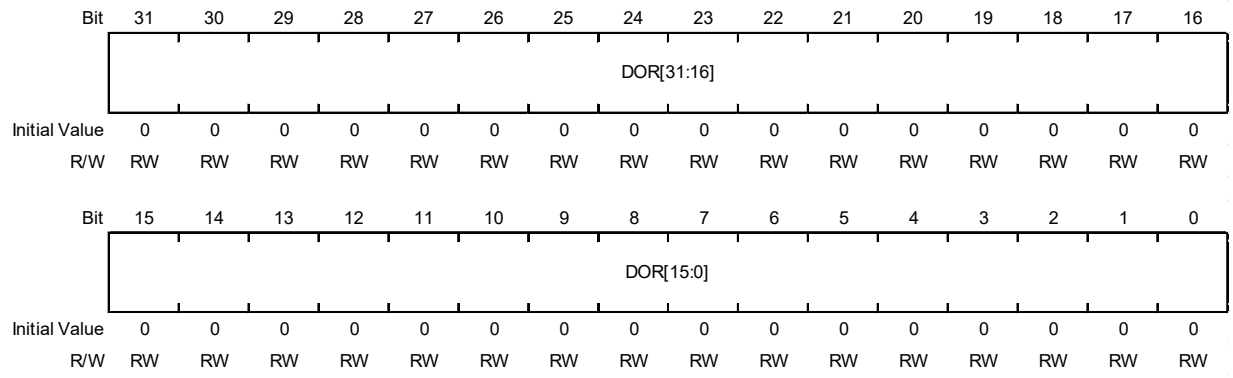
7.6.2.2.4 CRC Data Output Register (CRCDOR)

CRCDOR is a readable/writable register.

Since its initial value is 0000_0000h, rewrite the CRCDOR register to perform calculation using a value other than the initial value.

Data written to the CRCDIR register is CRC calculated and the result is stored in the CRCDOR register. If the CRC code is calculated following the transferred data and the result is 0000_0000h, there is no CRC error.

Access Size : 32 bits
Offset Address : <CRC_base> + 0008h
Initial Value : 0000_0000h



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DOR[31:0]	0h	RW	CRC Data Output

7.6.2.2.5 Snoop Address Register (CRCSAR)

Access Size : 16 bits
Offset Address : <CRC_base> + 000Ch
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CRCSAR[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	CRCSAR[15:0]	0h	RW	Set the I/O register address to snoop

CRCSA Bit (register snoop address bit)

Set these bits to the certain register address for CRC snoop operation.

Only the following address can be set in CRCSA[13:0] (1300_080Ch)

0000h RSPI0.SPDR

0400h RSPI1.SPDR

0800h RSPI2.SPDR

0C00h RSCI0.RDR, 0C04h RSCI0.TDR

1000h RSCI1.RDR, 1004h RSCI1.TDR

1400h RSCI2.RDR, 1404h RSCI2.TDR

1800h RSCI3.RDR, 1804h RSCI3.TDR

1C00h RSCI4.RDR, 1C04h RSCI4.TDR

2000h RSCI5.RDR, 2004h RSCI5.TDR

2400h RSCI6.RDR, 2404h RSCI6.TDR

2800h RSCI7.RDR, 2804h RSCI7.TDR

2C00h RSCI8.RDR, 2C04h RSCI8.TDR

3000h RSCI9.RDR, 3004h RSCI9.TDR

7.6.3 Operation

7.6.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB first or MSB first communication.

The following shows examples of generating the CRC code for input data (F0h) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before the CRC calculation (when a 16-bit CRC is in use, bits [31:16] of CRCDOR are not updated).

When an 8-bit CRC is in use, the valid bits of the CRC code is obtained in the lower-order byte of CRCDOR. When a 32-bit CRC is in use, the valid bits of the CRC code is obtained in bits [31:0] of CRCDOR.

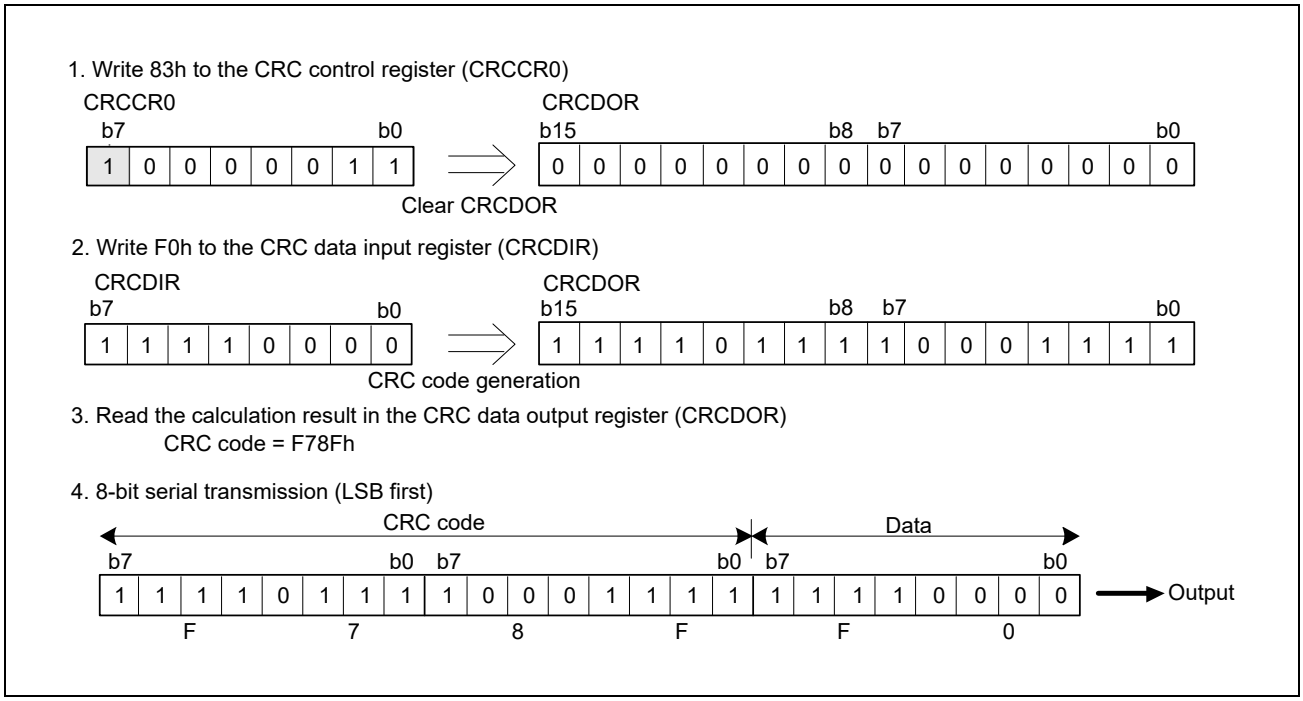


Figure 7.6-2 LSB First Data Transmission

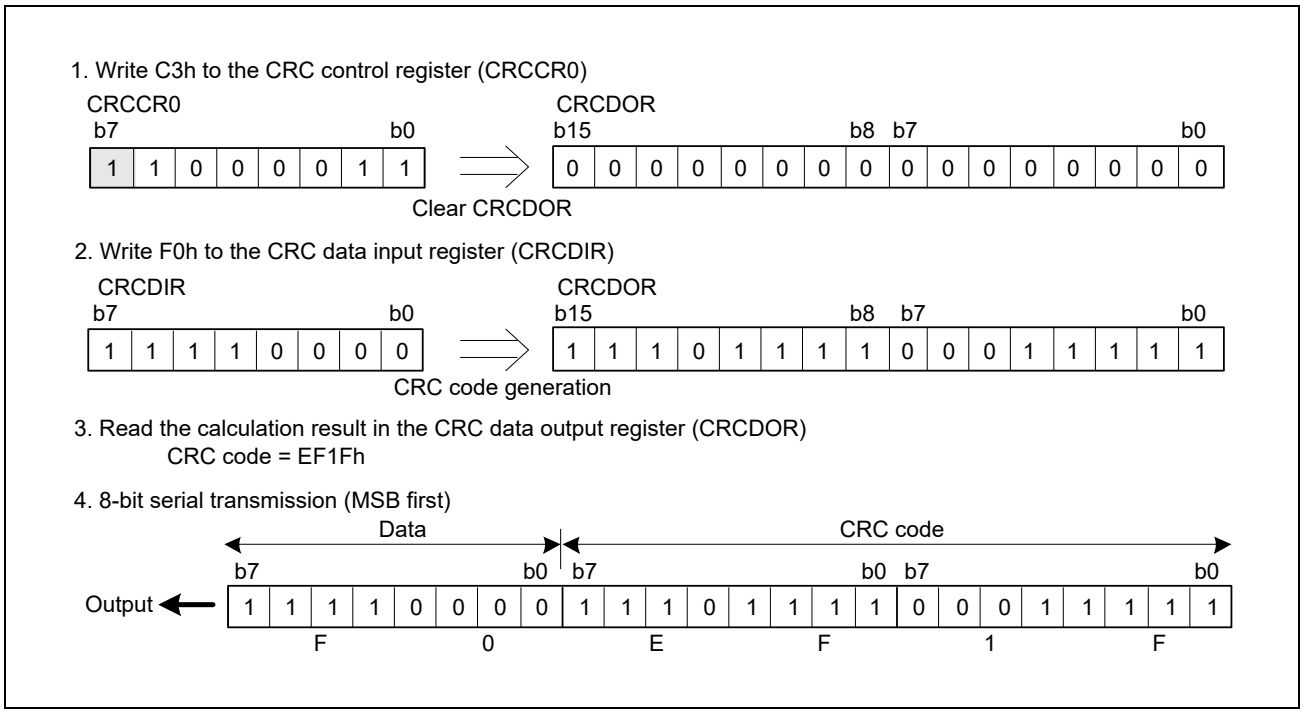

Figure 7.6-3 MSB First Data Transmission

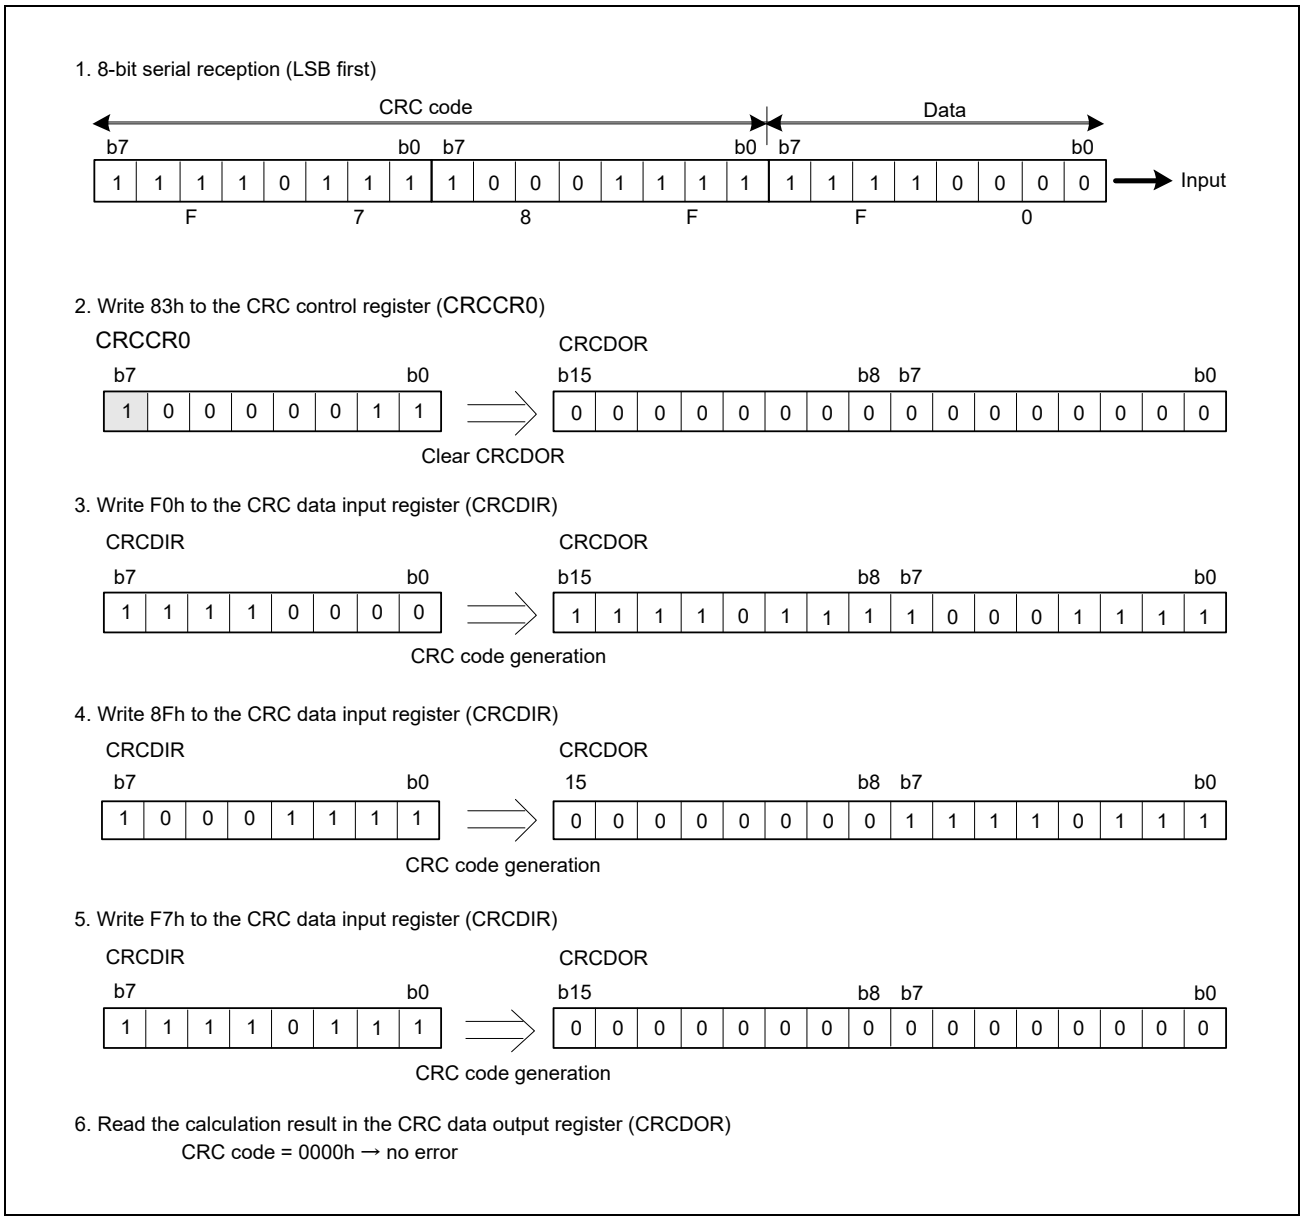

Figure 7.6-4 LSB First Data Reception

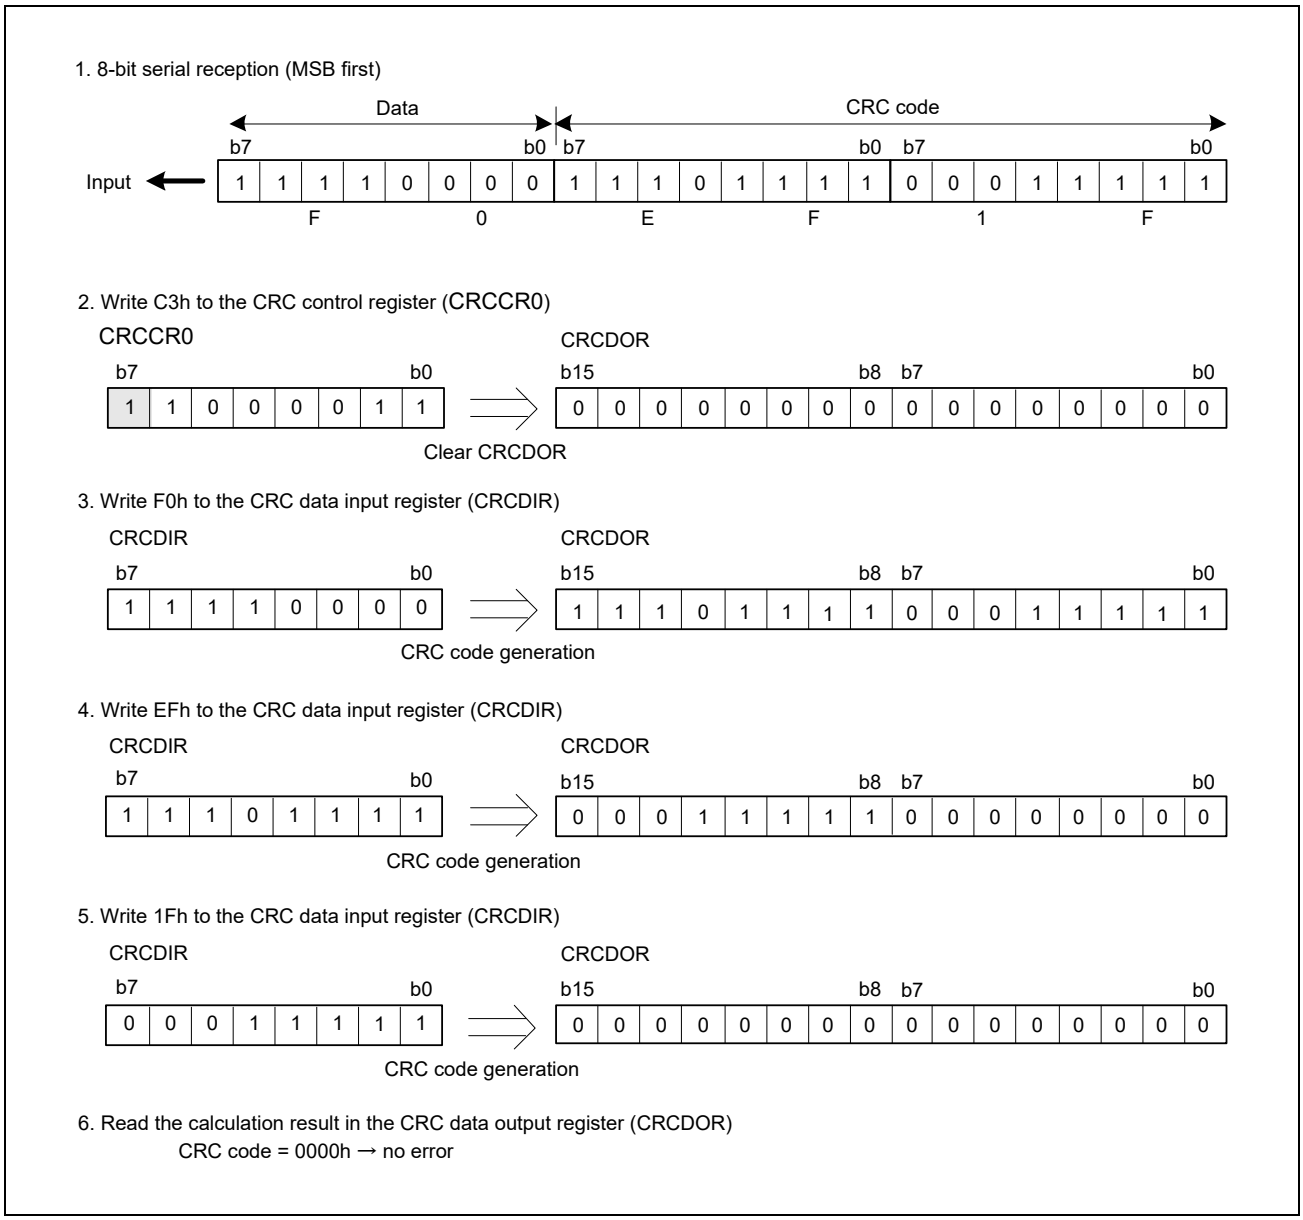

Figure 7.6-5 MSB First Data Reception

7.6.3.2 CRC Snoop

The CRC snoop monitors reads from and writes to a certain register address and performs CRC calculation on the data read from and written to the aforementioned I/O register address automatically. Because the CRC snoop recognizes writes to and reads from a certain register address as a trigger to automatically perform CRC calculation, there is no need to write data to the CRCDIR register. All I/O register addresses from 1280_0000h to 1280_33FFh are subject to the CRC snoop. The CRC snoop is useful in monitoring writes to the Serial transmit buffer, and reads from the Serial receive buffer.

To use this function, write a target I/O register address to bits CRCSA13 to CRCSA0 in the CRCSAR register, and set the CRCSEN bit in the CRCCR1 register to 1b to enable CRC snoop operation. Then, set the CRCSWR bit in the CRCCR1 register to 1b to enable snooping on writes to the target, or set the CRCSWR bit in the CRCCR1 register to 0b to enable snooping on reads from the target.

When setting the CRCSEN bit to 1b and the CRCSWR bit to 1b and writing data to a target I/O register address by the CPU or DMA, the CRC calculator stores the data in the CRCDIR register and performs CRC calculation. Similarly, when setting the CRCSEN bit to 1b and the CRCSWR bit to 0b and reading data in a target I/O register address, the CRC calculator stores the data in the CRCIN register and performs CRC calculation.

When the CRC code is generated using the CRC-8, CRC-16 and CRC-CCITT generator polynomial, the target I/O register address is accessed in bytes (8 bits). Similarly, when the CRC code is generated using the CRC-32 and CRC-32C generator polynomial, the target I/O register address is accessed in long words (32 bits).

7.6.4 Usage Notes

7.6.4.1 Note on Transmission

Note that the sequence of transmission for the CRC code differs according to whether transmission is LSB first or MSB first.

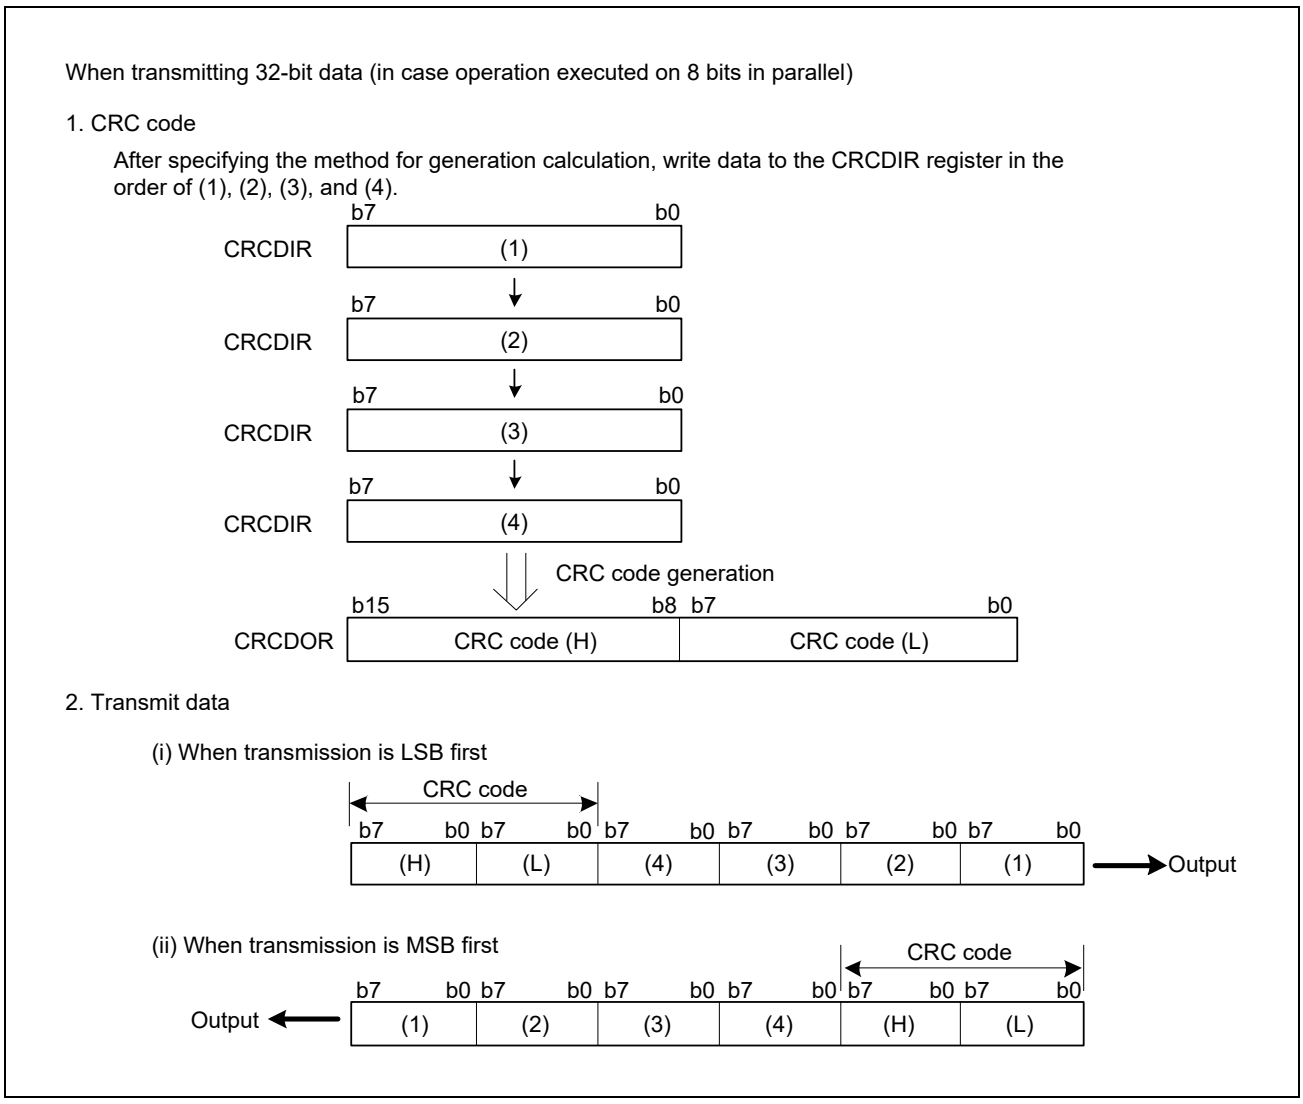

Figure 7.6-6 LSB First and MSB First Data Transmission

SECTION 7 LOW-SPEED INTERFACE

7.7 I²C Bus Interface (RIIC)

This section describes the RIIC functions of this LSI.

7.7.1 Overview

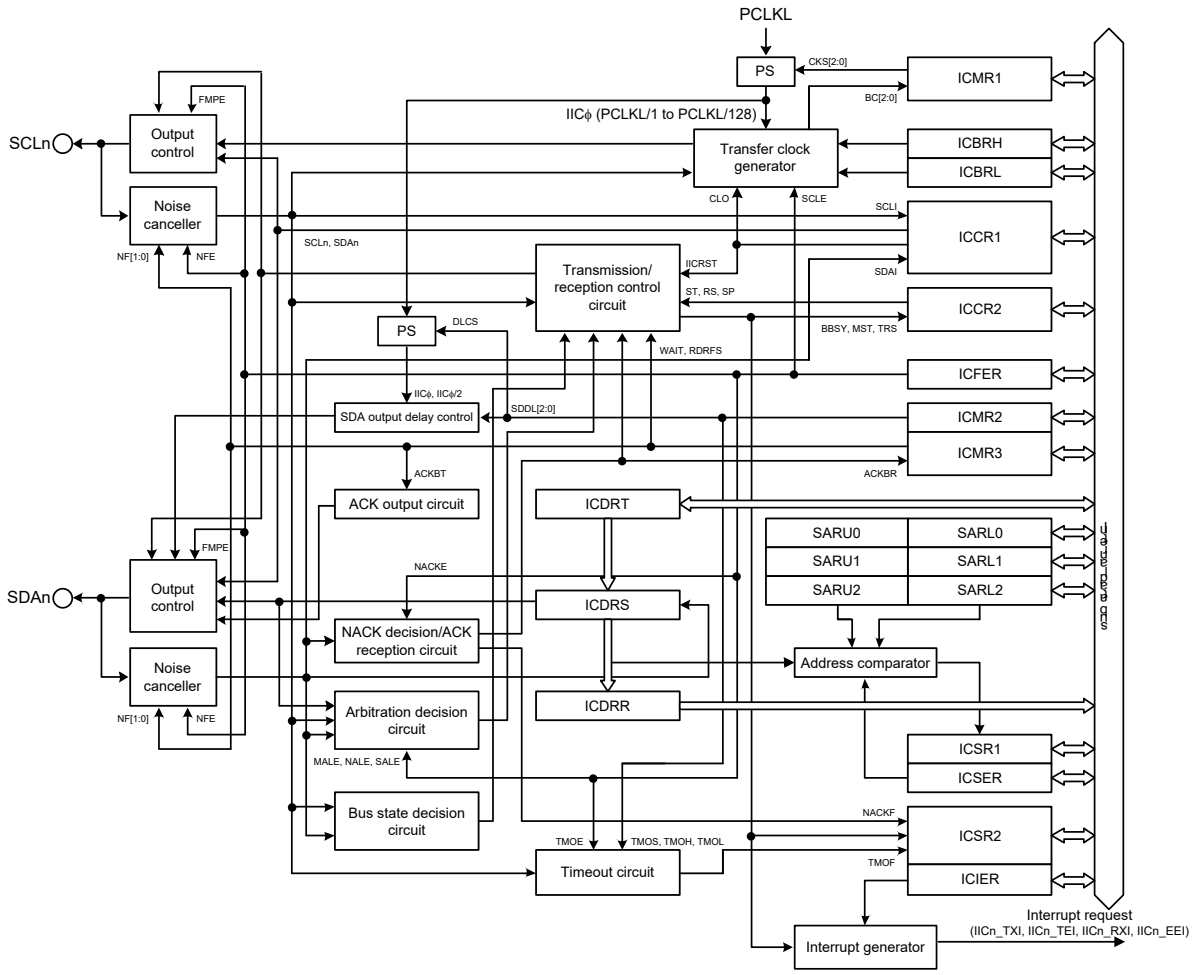
The LSI has a two-channel I²C Bus Interface (RIIC) module that conforms with and provides a subset of the NXP I²C bus (inter-integrated circuit bus) interface functions. **Table 7.7-1** lists the RIIC specifications, **Figure 7.7-1** shows a block diagram, and **Figure 7.7-2** shows an example of I/O pin connections to external circuits, with an I²C bus configuration. **Table 7.7-2** lists the I/O pins.

Table 7.7-1 RIIC Specifications (1/2)

Parameter	Specifications
Number of channels	9 channels (RIIC0-7 in the PD_OTHERS domain, RIIC8 in the PD_AWO domain)
Communications format	• I²C bus format or SMBus format. • Master or slave mode selectable. • Automatic securing of the setup times, hold times, and bus-free times for the transfer rate.
Transfer rate	Fast-mode+ supported, up to 1 Mbps.
SCL clock	For master operation, the duty cycle of the SCL clock is selectable in the range from 4% to 96%.
Issuing and detecting conditions	• Start, restart, and stop conditions are automatically generated. • Start conditions (including restart conditions) and stop conditions are detectable.
Slave address	• Configurable for up to three different slave addresses. • 7-bit and 10-bit address formats supported, including simultaneous use. • General call addresses, device ID addresses, and SMBus host addresses detectable.
Acknowledgment	• For transmission, automatic loading of the acknowledge bit. Transfer of the next transmit data can be automatically suspended on detection of a not-acknowledge bit. • For reception, automatic transmission of the acknowledge bit. If a wait between the 8th and 9th clock cycles is selected, software can control the value in the acknowledge field in response to the received value.
Wait function	During reception, the following wait periods are available by holding the SCL clock low: • Waiting between the 8th and 9th clock cycles. • Waiting between the 9th clock cycle and the 1st clock cycle of the next transfer.
SDA output delay function	Output timing of transmitted data, including the acknowledge bit, can be delayed.

Table 7.7-1 RIIC Specifications (2/2)

Parameter	Specifications
Arbitration	• For multi-master operation: – SCL clock synchronization is possible when conflict occurs with the SCL signal from another master. – When issuing the start condition creates conflict on the bus, loss of arbitration is detected by testing for mismatching between the internal signal for the SDA line and the level on the SDA line. – In master operation, loss of arbitration is detected by testing for mismatching between the signal on the SDA line and the internal signal for the SDA line. • Loss of arbitration because the start condition occurs while the bus is busy is detectable, to prevent the issuing of double start conditions. • Loss of arbitration is detectable on transfer of a not-acknowledge bit because the internal signal for the SDA line and the level on the SDA line do not match. • Loss of arbitration because mismatching of internal and line levels for data is detectable in slave transmission.
Timeout function	Internal detection of long-interval stops of the SCL clock.
Noise cancellation	• Digital noise filters for both the SCL and SDA signals. • Programmable window for noise cancellation by the filters.
Interrupt sources	• Transfer error or event generation: arbitration detection, NACK, timeout, start or restart condition, or stop condition. • Receive data full, including matching with a slave address. • Transmit data empty, including matching with a slave address. • Transmit end.
RIIC operating modes	• Master transmit • Master receive • Slave transmit • Slave receive



Note: PCLKL: RIIC_n_ckm (n = 0 to 8)

Figure 7.7-1 RIIC Block Diagram

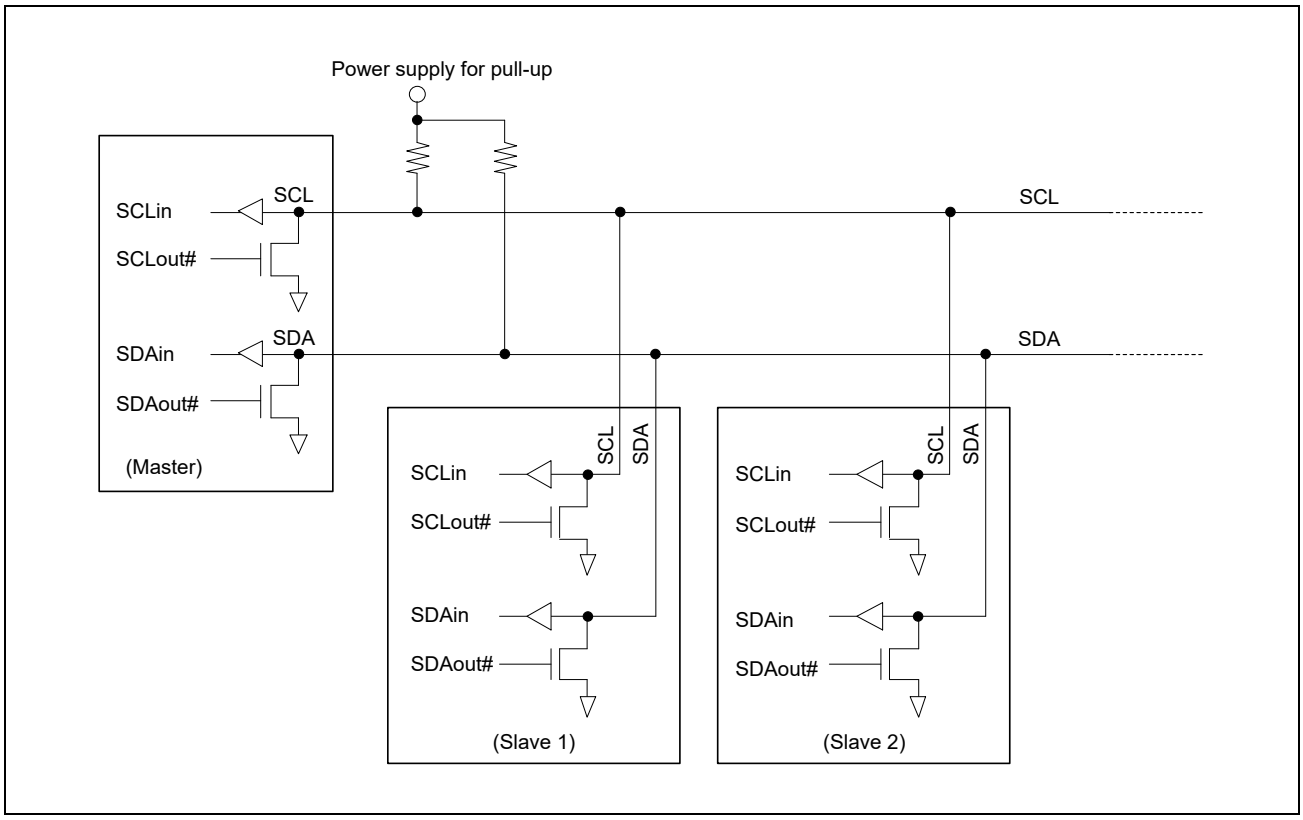


Figure 7.7-2 I/O Pin Connection to an External Circuit (I^2C Bus Configuration Example)

The input level of the signals for RIIC is CMOS. Change to TTL is not supported.

Table 7.7-2 RIIC I/O Pins

Channel	Pin Name	Input/Output	Function
RIIC0	SCL0	I/O	RIIC0 serial clock I/O pin
	SDA0	I/O	RIIC0 serial data I/O pin
RIIC1	SCL1	I/O	RIIC1 serial clock I/O pin
	SDA1	I/O	RIIC1 serial data I/O pin
RIIC2	SCL2	I/O	RIIC2 serial clock I/O pin
	SDA2	I/O	RIIC2 serial data I/O pin
RIIC3	SCL3	I/O	RIIC3 serial clock I/O pin
	SDA3	I/O	RIIC3 serial data I/O pin
RIIC4	SCL4	I/O	RIIC4 serial clock I/O pin
	SDA4	I/O	RIIC4 serial data I/O pin
RIIC5	SCL5	I/O	RIIC5 serial clock I/O pin
	SDA5	I/O	RIIC5 serial data I/O pin
RIIC6	SCL6	I/O	RIIC6 serial clock I/O pin
	SDA6	I/O	RIIC6 serial data I/O pin
RIIC7	SCL7	I/O	RIIC7 serial clock I/O pin
	SDA7	I/O	RIIC7 serial data I/O pin
RIIC8	SCL8	I/O	RIIC8 serial clock I/O pin
	SDA8	I/O	RIIC8 serial data I/O pin

Table 7.7-3 RIIC Interrupt Sources

Name	Interrupt Sources	CA55 GIC Request	CM33 GIC Request	CR8 GIC Request	DMAC Activation
RIIC_CHm_spi_n	Stop condition detection	Possible	Possible	Possible	Not possible
RIIC_CHm_sti_n	Start condition detection	Possible	Possible	Possible	Not possible
RIIC_CHm_naki_n	NACK detection	Possible	Possible	Possible	Not possible
RIIC_CHm_ali_n	Arbitration lost	Possible	Possible	Possible	Not possible
RIIC_CHm_tmoi_n	Timeout detection	Possible	Possible	Possible	Not possible
RIIC_CHm_ri_n	Receive data full	Possible	Possible	Possible	Possible
RIIC_CHm_ti_n	Transmit data empty	Possible	Possible	Possible	Possible
RIIC_CHm_tei_n	Transmit end	Possible	Possible	Possible	Not possible

Note: m = 0 to 8

Table 7.7-4 RIIC Event Signal Output to the ELC

Name	Event Sources
RIIC_CHm_iic_elcerrp	Transfer error or event generation
RIIC_CHm_iic_elcrdrfp	Receive data full
RIIC_CHm_iic_elctdrep	Transmit data empty
RIIC_CHm_iic_elctendp	Transmit end

Note: m = 0 to 8

7.7.2 RIIC Registers

The base addresses for the respective channels are as follows.

Table 7.7-4 Register Base Addresses

Base Register Name	RIIC ch	Base Address
<RIIC0_base>	RIIC0	0_1440_0400h (5440_0400h*1, 4440_0400h*2)
<RIIC1_base>	RIIC1	0_1440_0800h (5440_0800h*1, 4440_0800h*2)
<RIIC2_base>	RIIC2	0_1440_0C00h (5440_0C00h*1, 4440_C400h*2)
<RIIC3_base>	RIIC3	0_1440_1000h (5440_1000h*1, 4440_1000h*2)
<RIIC4_base>	RIIC4	0_1440_1400h (5440_1400h*1, 4440_1400h*2)
<RIIC5_base>	RIIC5	0_1440_1800h (5440_1800h*1, 4440_1800h*2)
<RIIC6_base>	RIIC6	0_1440_1C00h (5440_1C00h*1, 4440_1C00h*2)
<RIIC7_base>	RIIC7	0_1440_2000h (5440_2000h*1, 4440_2000h*2)
<RIIC8_base>	RIIC8	0_11C0_1000h (51C0_1000h*1, 41C0_1000h*2)

Note 1. CM33 Address Space Non-Secure

Note 2. CM33 Address Space Secure

7.7.2.1 List of Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
I2C Bus Control Register 1	RIICm_ICCR1	1Fh	0000h	8
I2C Bus Control Register 2	RIICm_ICCR2	00h	0001h	8
I2C Bus Mode Register 1	RIICm_ICMR1	08h	0002h	8
I2C Bus Mode Register 2	RIICm_ICMR2	06h	0003h	8
I2C Bus Mode Register 3	RIICm_ICMR3	00h	0004h	8
I2C Bus Function Enable Register	RIICm_ICFER	72h	0005h	8
I2C Bus Status Enable Register	RIICm_ICSER	09h	0006h	8
I2C Bus Interrupt Enable Register	RIICm_ICIER	00h	0007h	8
I2C Bus Status Register 1	RIICm_ICSR1	00h	0008h	8
I2C Bus Status Register 2	RIICm_ICSR2	00h	0009h	8
Slave Address Register L 0	RIICm_SARL0	00h	000Ah	8
Slave Address Register U 0	RIICm_SARU0	00h	000Bh	8
Slave Address Register L 1	RIICm_SARL1	00h	000Ch	8
Slave Address Register U 1	RIICm_SARU1	00h	000Dh	8
Slave Address Register L 2	RIICm_SARL2	00h	000Eh	8
Slave Address Register U 2	RIICm_SARU2	00h	000Fh	8
I2C Bus Bit Rate Low-Level Register	RIICm_ICBRL	FFh	0010h	8
I2C Bus Bit Rate High-Level Register	RIICm_ICBRH	FFh	0011h	8
I2C Bus Transmit Data Register	RIICm_ICDRT	FFh	0012h	8
I2C Bus Receive Data Register	RIICm_ICDRR	00h	0013h	8

7.7.2.2 RIIC Register Descriptions

The prefix (RIICm_) of the register names is omitted in this and subsequent sections.

7.7.2.2.1 I²C Bus Control Register 1 (RIICm_ICCR1)

Access Size : 8 bits
Address : <RIICm_base> + 0000h
Initial Value : 1Fh

Bit	7	6	5	4	3	2	1	0
	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Initial Value	0	0	0	1	1	1	1	1
R/W	RW	RW	RW	W	RW	RW	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	ICE	0h	RW	IIC-Bus Interface Enable Used in combination with the IICRST bit to select either RIIC or internal reset. 0b: Disable (SCLn and SDAn pins in inactive state) 1b: Enable (SCLn and SDAn pins in active state)
6	IICRST	0h	RW	IIC-Bus Interface Internal Reset This setting clears the bit counter and the SCLn/SDAn output latch. 0b: Release RIIC reset or internal reset 1b: Initiate RIIC reset or internal reset
5	CLO	0h	RW	Extra SCL Clock Cycle Output This bit is cleared automatically after one clock cycle is output. 0b: Do not output extra SCL clock cycle (default) 1b: Output extra SCL clock cycle
4	SOWP	1h	W	The read value is undefined SCLO/SDAO Write Protect 0b: Write enable SCLO and SDAO bits 1b: Write protect SCLO and SDAO bits
3	SCLO	1h	RW	SCL Output Control/Monitor Use an external pull-up resistor to drive the signal high. 0b: Read: RIIC drives SCLn pin low Write: RIIC drives SCLn pin low 1b: Read: RIIC releases SCLn pin Write: RIIC releases SCLn pin
2	SDAO	1h	RW	SDA Output Control/Monitor Use an external pull-up resistor to drive the signal high. 0b: Read: RIIC drives SDAn pin low Write: RIIC drives SDAn pin low 1b: Read: RIIC releases SDAn pin Write: RIIC releases SDAn pin
1	SCLI	1h	R	SCL Line Monitor 0b: SCLn line is low 1b: SCLn line is high
0	SDAI	1h	R	SDA Line Monitor 0b: SDAn line is low 1b: SDAn line is high

SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO and SCLO bits directly control the SDAn and SCLn signals output from the RIIC.

When writing to these bits, also write 0b to the SOWP bit. Setting these bits results in input to the RIIC by the input buffer.

When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, or during transmission or reception.

Operation after rewriting under the specified conditions is not guaranteed. When reading these bits, the state of signals output from the RIIC can be read.

CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows the output of an extra SCL clock cycle for debugging or error processing. Normally, set this bit to 0b.

Setting this bit to 1 in a normal communication state causes a communication error. For details on this function, see **7.7.11.2 Extra SCL Clock Cycle Output Function**.

IICRST bit (IIC-Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the RIIC. Setting this bit to 1b initiates an RIIC reset or internal reset.

Whether an RIIC reset or internal reset is initiated is determined by setting this bit in combination with the ICE bit.

Table 7.7-5 lists the RIIC resets.

The RIIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits, and internal states of the RIIC. In addition to the internal states of the RIIC, the internal reset initializes the following:

- Bit counter (ICMR1.BC[2:0] bits)
- I^2C Bus Shift Register (ICDRS)
- I^2C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SCLO and ICCR1.SDAO bits)
- I^2C Bus Control Register 2 (except ICCR2.BBSY bit)

For the reset conditions of each register, see **7.7.15 Resets, Registers, and Function States when Issuing Each Condition**.

An internal reset initiated with the IICRST bit set to 1b during operation (with the ICE bit set to 1b) resets the internal states of the RIIC without initializing the port settings and the control and setting registers of the RIIC when the bus or RIIC hangs up because of a communication error. If the RIIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the SCLn pin and SDAn pin at high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is necessary because the RIIC hangs with the SCLn line in a low level output state in slave mode, initiate an internal reset, and then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

Table 7.7-5 RIIC Resets

IICRST	ICE	State	Specifications
1b	0b	IIC reset	Resets all registers except ICCR1.ICE and ICCR1.IICRST bits, and the internal states of the RIIC
	1b	Internal reset	Resets the following: • ICMR1.BC[2:0] bits • ICCR1, ICSR2, ICDRS registers • SDAO and SCLO Output Control/Monitor (ICCR1.SCLO and ICCR1.SDAO bits) • I^2C Bus Control Register 2 (except ICCR2.BBSY bit) • Internal states of the RIIC.

ICE bit (IIC-Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCLn and SDAn pins. It can also be combined with the IICRST bit to initiate two types of resets. See **Table 7.7-5** for the reset types.

Set the ICE bit to 1b when using the RIIC. The SCLn and SDAn pins are placed in the active state when the ICE bit is set to 1b. Set the ICE bit to 0b when the RIIC is not used. The SCLn and SDAn pins are placed in the inactive state when the ICE bit is set to 0b. Do not assign the SCLn or SDAn pin to the RIIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the RIIC.

7.7.2.2.2 I²C Bus Control Register 2 (RIICm_ICCR2)

Access Size : 8 bits
Address : <RIICm_base> + 0001h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	BBSY	MST	TRS	-	SP	RS	ST	-
Initial Value	0	0	0	0	0	0	0	0
R/W	R	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	BBSY	0h	R	Bus Busy Detection Flag 0b: I2C bus released (bus free state) 1b: I2C bus occupied (bus busy state)
6	MST	0h	RW	Master/Slave Mode 0b: Slave mode 1b: Master mode
5	TRS	0h	RW	Transmit/Receive Mode 0b: Receive mode 1b: Transmit mode
4	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3	SP	0h	RW	Stop Condition Issuance Request 0b: Do not issue a stop condition request 1b: Issue a stop condition request
2	RS	0h	RW	Restart Condition Issuance Request 0b: Do not issue a restart condition request 1b: Issue a restart condition request
1	ST	0h	RW	Start Condition Issuance Request 0b: Do not issue a start condition request 1b: Issue a start condition request
0	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition.

When this bit is set to 1b, a start condition is issued when the BBSY flag is set to 0b (bus free state). For details on issuing a start condition, see **7.7.10 Start, Restart, and Stop Condition Issuing Function**.

[Setting condition]

- When 1b is written to the ST bit.

[Clearing conditions]

- When 0b is written to the ST bit.
- When a start condition is issued (a start condition is detected).
- When the AL (arbitration-lost) flag in ICSR2 is set to 1b.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

Note: Set the ST bit to 1b (start condition issuance request) when the BBSY flag is set to 0b (bus free state). Arbitration might be lost if the ST bit is set to 1b (start condition request) when the BBSY flag is 1b (bus busy state).

RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode.

When this bit is set to 1b to request a restart condition, a restart condition is issued when the BBSY flag is set to 1b (bus busy state) and the MST bit is set to 1b (master mode). For details on issuing a restart condition, see **7.7.10 Start, Restart, and Stop Condition Issuing Function**.

[Setting condition]

- When 1b is written to the RS bit with the BBSY flag in ICCR2 set to 1b.

[Clearing conditions]

- When 0b is written to the RS bit.
- When a restart condition is issued (a start condition is detected).
- When the AL (arbitration-lost) flag in ICSR2 is set to 1b.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

Note: Do not set the RS bit to 1b while issuing a stop condition.

Note: If 1b (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1b. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

SP bit (Stop Condition Issuance Request)

The SP bit requests that a stop condition be issued in master mode.

When this bit is set to 1b, a stop condition is issued when the BBSY flag is set to 1b (bus busy state) and the MST bit is set to 1b (master mode). For details on this function, see **7.7.10 Start, Restart, and Stop Condition Issuing Function**.

[Setting condition]

- When 1b is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1b.

[Clearing conditions]

- When 0b is written to the SP bit.
- When a stop condition is issued (a stop condition is detected).
- When the AL (arbitration-lost) flag in ICSR2 is set to 1b.
- When a start condition and a restart condition are detected.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0b (bus free state).

Note: Do not set the SP bit to 1b while a restart condition is being issued.

TRS bit (Transmit/Receive Mode)

The TRS bit indicates transmit or receive mode.

The RIIC is in receive mode when the TRS bit is 0b and in transmit mode when the bit is 1b. The combination of the TRS bit and the MST bit indicates the operating mode of the RIIC.

The value of the TRS bit automatically changes to 1b for transmit mode or 0b for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1b, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1b).
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1b).
- When the R/W# bit added to the slave address is set to 0b in master mode.
- When the address received in slave mode matches the address enabled in ICSER, with the R/W# bit set to 1b.
- When 1b is written to the TRS bit with the MTWP bit in ICMR1 set to 1b.

[Clearing conditions]

- When a stop condition is detected.
- When the AL (arbitration-lost) flag in ICSR2 is set to 1b.
- In master mode, on the reception of a slave address to which a R/W# bit with the value 1b is appended.
- In slave mode, on a match between the received address and the address enabled in ICSER when the value of the received R/W# bit is 0b, including when the received address is the general call address.
- In slave mode, when a restart condition is detected (a start condition is detected with ICCR2.BBSY = 1b and ICCR2.MST = 0b).
- When 0b is written to the TRS bit with the MTWP bit in ICMR1 set to 1b.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

MST bit (Master/Slave Mode)

The MST bit indicates master or slave mode. The RIIC is in slave mode when the MST bit is set to 0b and is in master mode when the bit is set to 1b. The combination of the MST bit and the TRS bit indicates the operating mode of the RIIC.

The value of the MST bit automatically changes to 1b for master mode or 0b for slave mode when a start condition is issued, or when a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1b, writing to this bit is not necessary during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1b).
- When 1b is written to the MST bit with the MTWP bit in ICMR1 set to 1b.

[Clearing conditions]

- When a stop condition is detected.
- When the AL (arbitration-lost) flag in ICSR2 is set to 1b.

- When 0b is written to the MST bit with the MTWP bit in ICMR1 set to 1b.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

BBSY bit (Bus Busy Detection Flag)

The BBSY flag indicates whether the I^2C bus is occupied (bus busy state) or released (bus free state).

The flag is set to 1b when the SDAn line changes from high to low when the SCLn line is high, assuming that a start condition was issued.

The flag is set to 0b when the SDAn line changes from low to high with the SCLn line high, if the bus free time (ICBRL setting) start condition is not detected, assuming that a stop condition was issued.

[Setting condition]

- When a start condition is detected.

[Clearing conditions]

- When the bus free time (ICBRL setting) start condition is not detected after detecting a stop condition.
- When 1b is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0b (RIIC reset).

7.7.2.2.3 I²C Bus Mode Register 1 (RIICm_ICMR1)

Access Size : 8 bits
Address : <RIICm_base> + 0002h
Initial Value : 08h

Bit	7	6	5	4	3	2	1	0
	MTWP	CKS[2:0]			BCWP	BC[2:0]		
Initial Value	0	0	0	0	1	0	0	0
R/W	RW	RW	RW	RW	W	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	MTWP	0h	RW	MST/TRS Write Protect 0b: Write protect MST and TRS bits in ICCR2 1b: Write enable MST and TRS bits in ICCR2
6 to 4	CKS[2:0]	0h	RW	Internal Reference Clock Select Select the internal reference clock source (IICΦ) for the IIC. 000b: PCLKL clock 001b: PCLKL/2 clock 010b: PCLKL/4 clock 011b: PCLKL/8 clock 100b: PCLKL/16 clock 101b: PCLKL/32 clock 110b: PCLKL/64 clock 111b: PCLKL/128 clock
3	BCWP	-	W	The read value is undefined BC Write Protect 0b: Write enable BC[2:0] bits 1b: Write protect BC[2:0] bits
2 to 0	BC[2:0]	0h	RW	Bit Counter 000b: 9 bits 001b: 2 bits 010b: 3 bits 011b: 4 bits 100b: 5 bits 101b: 6 bits 110b: 7 bits 111b: 8 bits

BC[2:0] bits (Bit Counter)

The BC[2:0] bits function as a counter that indicates the number of bits remaining to be transferred on detection of a rising edge on the SCLn line. Although BC[2:0] are read/write bits, it is not required to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCLn line is at a low level.

The value in the BC[2:0] bits return to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

7.7.2.2.4 I²C Bus Mode Register 2 (RIICm_ICMR2)

Access Size : 8 bits
Address : <RIICm_base> + 0003h
Initial Value : 06h

Bit	7	6	5	4	3	2	1	0
	DLCS	SDDL[2:0]			-	TMOH	TMOL	TMOS
Initial Value	0	0	0	0	0	1	1	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	DLCS	0h	RW	SDA Output Delay Clock Source Select 0b: Select internal reference clock (IICΦ) as clock source for SDA output delay counter 1b: Select internal reference clock divided by 2 (IICΦ/2) as clock source for SDA output delay counter*1
6 to 4	SDDL[2:0]	0h	RW	SDA Output Delay Counter 000b: No output delay 001b: 1 IICΦ cycle (When ICMR2.DLCS = 0 (IICΦ)) 1 or 2 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 010b: 2 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 3 or 4 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 011b: 3 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 5 or 6 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 100b: 4 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 7 or 8 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 101b: 5 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 9 or 10 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 110b: 6 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 11 or 12 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2)) 111b: 7 IICΦ cycles (When ICMR2.DLCS = 0 (IICΦ)) 13 or 14 IICΦ cycles (When ICMR2.DLCS = 1 (IICΦ/2))
3	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	TMOH	1h	RW	Timeout H Count Control 0b: Disable count while SCLn line is high 1b: Enable count while SCLn line is high
1	TMOL	1h	RW	Timeout L Count Control 0b: Disable count while SCLn line is low 1b: Enable count while SCLn line is low
0	TMOS	0h	RW	Timeout Detection Time Select 0b: Select long mode 1b: Select short mode

Note 1. The setting DLCS = 1 (IICϕ/2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IICϕ).

TMOS bit (Timeout Detection Time Select)

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1b).

When this bit is set to 0b, long mode is selected. When it is set to 1b, short mode is selected.

In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14 bit counter. While the SCLn line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter counts up in synchronization with the internal reference clock (IICϕ) as a count source.

For details on this function, see **7.7.11.1 Timeout Function**.

TMOL bit (Timeout L Count Control)

The TMOL bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held low and the timeout function is enabled (ICFER.TMOE = 1b).

TMOH bit (Timeout H Count Control)

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held high and the timeout function is enabled (ICFER.TMOE = 1).

SDDL[2:0] bits (SDA Output Delay Counter)

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including the transmission of the acknowledge bit.

Set the SDA output delay to meet the I^2C bus standard for the data enable time/acknowledge enable time,*1 or the SMBus standard, within [data hold time (300 ns or more + the SCL-clock low-level period) - the data setup time (250 ns)]. If a value outside the standard is set, communication between the devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see **7.7.5 SDA Output Delay Function**.

Note 1. Data enable time/acknowledge enable time
3,450 ns for up to 100 kbps: Standard-mode (Sm)
900 ns for up to 400 kbps: Fast-mode (Fm)
450 ns for up to 1 Mbps: Fast-mode plus (Fm+)

7.7.2.2.5 I²C Bus Mode Register 3 (RIICm_ICMR3)

Access Size : 8 bits
Address : <RIICm_base> + 0004h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	SMBS	WAIT	RDRFS	ACKWP	ACKBT	ACKBR	NF[1:0]	
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	SMBS	0h	RW	SMBus/IIC-Bus Select 0b: Select I2C bus 1b: Select SMBus
6	WAIT	0h	RW	WAIT Low-hold is released by reading ICDRR. 0b: No wait. SCLn is not held low during the period between 9th clock cycle and 1st clock cycle. 1b: Wait. SCLn is held low during the period between 9th clock cycle and 1st clock cycle.
5	RDRFS	0h	RW	RDRF Flag Set Timing Select Low-hold is released by writing to ACKBT. 0b: Set the RDRF flag on the rising edge of the 9th SCL clock cycle. The SCLn line is not held low on the falling edge of the 8th clock cycle. 1b: Set the RDRF flag on the rising edge of the 8th SCL clock cycle. The SCLn line is held low on the falling edge of the 8th clock cycle.
4	ACKWP	0h	RW	ACKBT Write Protect 0b: Write protect ACKBT bit 1b: Write enable ACKBT bit
3	ACKBT	0h	RW	Transmit Acknowledge 0b: Send 0 as the acknowledge bit (ACK transmission) 1b: Send 1 as the acknowledge bit (NACK transmission)
2	ACKBR	0h	R	Receive Acknowledge 0b: 0 received as the acknowledge bit (ACK reception) 1b: 1 received as the acknowledge bit (NACK reception)
1, 0	NF[1:0]	0h	RW	Noise Filter Stage Select 00b: Filter out noise of up to 1 IICΦ cycle (single-stage filter) 01b: Filter out noise of up to 2 IICΦ cycles (2-stage filter) 10b: Filter out noise of up to 3 IICΦ cycles (3-stage filter) 11b: Filter out noise of up to 4 IICΦ cycles (4-stage filter)

NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see **7.7.6 Digital Noise Filter Circuits**.

Note: Set the noise range to be filtered out by the noise filter within a range less than the SCLn line high-level period or low-level period. If the noise range is set to a value of [SCL clock width: high-level period or low-level period, whichever is shorter] - [1.5 internal reference clock (IICϕ) cycles] or more, the SCL clock is regarded as noise by the noise filter function of the RIIC, which might prevent the RIIC from operating normally.

ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1b is received as the acknowledge bit with the TRS bit in ICCR2 set to 1b.

[Clearing conditions]

- When 0b is received as the acknowledge bit with the TRS bit in ICCR2 set to 1b.
- When 1b is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0b (IIC reset).

ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode.

[Setting condition]

- When 1b is written to this bit with the ACKWP bit set to 1b.

[Clearing conditions]

- When 0b is written to this bit with the ACKWP bit set to 1b.
- When stop condition issuance is detected with the SP bit in ICCR2 set to 1b.
- When 1b is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0b (IIC reset).

ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCLn line low on the falling edge of the 8th SCL clock cycle.

When the RDRFS bit is 0b, the SCLn line is not held low on the falling edge of the 8th SCL clock cycle, and the RDRF flag is set to 1b on the rising edge of the 9th SCL clock cycle.

When the RDRFS bit is 1b, the RDRF flag is set to 1b on the rising edge of the 8th SCL clock cycle, and the SCLn line is held low on the falling edge of the 8th SCL clock cycle. The low-hold of the SCLn line is released by a write to the ACKBT bit.

After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0b) or NACK (ACKBT = 1b), based on the receive data.

WAIT bit (WAIT)

The WAIT bit controls whether to forcefully hold the period between the 9th SCL clock cycle and the 1st SCL clock cycle low until the receive data buffer (ICDRR) is completely read each time a single-byte data is received in receive mode.

When the WAIT bit is 0b, the receive operation is continued without holding the period between the 9th and the 1st SCL clock cycle low. When both the RDRFS and WAIT bits are 0b, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1b, the SCLn line is held low from the falling edge of the 9th clock cycle until the ICDRR value is read each time a single-byte data is received. This enables the receive operation in byte units.

Note: When the value of the WAIT bit is to be read, be sure to first read the ICDRR.

SMBS bit (SMBus/IIC-Bus Select)

Setting the SMBS bit to 1b selects the SMBus and enables the HOAE bit in ICSER.

7.7.2.2.6 I²C Bus Function Enable Register (RIICm_ICFER)

Access Size : 8 bits
Address : <RIICm_base> + 0005h
Initial Value : 72h

Bit	7	6	5	4	3	2	1	0
	FMPE	SCLE	NFE	NACKE	SALE	NALE	MALE	TMOE
Initial Value	0	1	1	1	0	0	1	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	FMPE	0h	RW	Fast-mode Plus Enable 0b: No Fm+ slope control circuit is used for the SCLn pin and SDAn pin. 1b: An Fm+ slope control circuit is used for the SCLn pin and SDAn pin.
6	SCLE	1h	RW	SCLn Synchronous Circuit Enable 0b: Do not use the SCLn synchronous circuit 1b: Use the SCLn synchronous circuit
5	NFE	1h	RW	Digital Noise Filter Circuit Enable 0b: Do not use the digital noise filter circuit 1b: Use the digital noise filter circuit
4	NACKE	1h	RW	NACK Reception Transfer Suspension Enable 0b: Do not suspend transfer operation during NACK reception (disable transfer suspension) 1b: Suspend transfer operation during NACK reception (enable transfer suspension)
3	SALE	0h	RW	Slave Arbitration-Lost Detection Enable 0b: Disable 1b: Enable
2	NALE	0h	RW	NACK Transmission Arbitration-Lost Detection Enable 0b: Disable 1b: Enable
1	MALE	1h	RW	Master Arbitration-Lost Detection Enable 0b: Disable the arbitration-lost detection function and disable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost 1b: Enable the arbitration-lost detection function and enable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost
0	TMOE	0h	RW	Timeout Function Enable 0b: Disable 1b: Enable

TMOE bit (Timeout Function Enable)

The TMOE bit enables or disables the timeout function. For details on this function, see **7.7.11.1 Timeout Function**.

MALE bit (Master Arbitration-Lost Detection Enable)

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. For normal operation, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

The NALE bit specifies whether to cause loss of arbitration when ACK is detected during the transmission of NACK in receive mode, for example, when slaves with the same address exist on the bus, or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

SALE bit (Slave Arbitration-Lost Detection Enable)

The SALE bit specifies whether to cause loss of arbitration when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example, when slaves with the same address exist on the bus, or when a mismatch with the transmit data occurs because of noise.

NACKE bit (NACK Reception Transfer Suspension Enable)

The NACKE bit specifies whether to continue or discontinue the data transfer when NACK is received in transmit mode. Normally, set this bit to 1b.

When NACK is received with the NACKE bit set to 1b, the next transfer operation is suspended. When the NACKE bit is 0b, the next transfer operation is continued regardless of the received acknowledge content.

For details, see **7.7.8.2 NACK Reception Transfer Suspension Function**.

SCLE bit (SCL Synchronous Circuit Enable)

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. For normal operation, set this bit to 1b.

When the SCLE bit is set to 0b (no SCL synchronous circuit used), the RIIC does not synchronize the SCL clock with the SCL input clock. With this setting, the RIIC outputs the SCL clock with the transfer rate set in ICBRH and ICBRL, regardless of the SCLn line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output. When no SCL synchronous circuit is used, it also affects the issuance of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0b except when checking the output of the set transfer rate.

FMPE Bit (Fast-mode Plus Enable)

The FMPE bit specifies whether to use a slope control circuit for Fast-mode Plus [Fm+].

When the FMPE bit is set to 1b, a slope control circuit conforming to the Fast-mode Plus [Fm+] slope control standard (tof) of the I2C bus is selected. When the FMPE bit is set to 0b, a slope control circuit conforming to the Standard-mode [Sm] and Fast-mode [fm] slope control standard (tof) of the I2C bus is selected.

Set the FMPE bit to 1b when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus [Fm+]) of the I2C bus standard. Set the FMPE bit to 0b when using the transmission rate at other rates (up to 100 kbps [Sm], up to 400 kbps [fm]) or for SMBus (10 to 100 kbps).

7.7.2.2.7 I²C Bus Status Enable Register (RIICm_ICSER)

Access Size : 8 bits
Address : <RIICm_base> + 0006h
Initial Value : 09h

Bit	7	6	5	4	3	2	1	0
	HOAE	-	DIDE	-	GCAE	SAR2E	SAR1E	SAR0E
Initial Value	0	0	0	0	1	0	0	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	HOAE	0h	RW	Host Address Enable 0b: Disable host address detection 1b: Enable host address detection
6	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5	DIDE	0h	RW	Device ID Address Detection Enable 0b: Disable device ID address detection 1b: Enable device ID address detection
4	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3	GCAE	1h	RW	General Call Address Enable 0b: Disable general call address detection 1b: Enable general call address detection
2	SAR2E	0h	RW	Slave Address Register 2 Enable 0b: Disable slave address in SARL2 and SARU2 1b: Enable slave address in SARL2 and SARU2
1	SAR1E	0h	RW	Slave Address Register 1 Enable 0b: Disable slave address in SARL1 and SARU1 1b: Enable slave address in SARL1 and SARU1
0	SAR0E	1h	RW	Slave Address Register 0 Enable 0b: Disable slave address in SARL0 and SARU0 1b: Enable slave address in SARL0 and SARU0

SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1b, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0b, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000_000b + 0b [W]: All 0) when it is received.

When this bit is set to 1b, if the received slave address matches the general call address, the RIIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2), and performs the data receive operation. When this bit is set to 0b, the received slave address is ignored even if it matches the general call address.

DIDE bit (Device ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device ID address when a device ID (1111_100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1b, if the received first frame matches the device ID, the RIIC recognizes that the device ID address was received. When the next R/W# bit is 0b (W), the RIIC recognizes the second and the subsequent frames as

slave addresses and continues the receive operation. When this bit is set to 0b, the RIIC ignores the received first frame even if it matches the device ID address, and recognizes the first frame as a normal slave address.

For details on the device ID function, see **7.7.7.3 Device ID Address Detection**.

HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001_000b) when the SMBS bit in ICMR3 is 1b.

When this bit is set to 1b while the SMBS bit in ICMR3 is 1b, if the received slave address matches the host address, the RIIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2), and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0b, the received slave address is ignored even if it matches the host address.

7.7.2.2.8 I²C Bus Interrupt Enable Register (RIICm_ICIER)

Access Size : 8 bits
Address : <RIICm_base> + 0007h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	TIE	TEIE	RIE	NAKIE	SPIE	STIE	ALIE	TMOIE
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0h	RW	Transmit Data Empty Interrupt Request Enable 0b: Disable transmit data empty interrupt (IICn_TXI) request 1b: Enable transmit data empty interrupt (IICn_TXI) request
6	TEIE	0h	RW	Transmit End Interrupt Request Enable 0b: Disable transmit end interrupt (IICn_TEI) request 1b: Enable transmit end interrupt (IICn_TEI) request
5	RIE	0h	RW	Receive Data Full Interrupt Request Enable 0b: Disable receive data full interrupt (IICn_RXI) request 1b: Enable receive data full interrupt (IICn_RXI) request
4	NAKIE	0h	RW	NACK Reception Interrupt Request Enable 0b: Disable NACK reception interrupt IICn_EEI (NACKF) request 1b: Enable NACK reception interrupt IICn_EEI (NACKF) request
3	SPIE	0h	RW	Stop Condition Detection Interrupt Request Enable 0b: Disable stop condition detection interrupt IICn_EEI (STOP) request 1b: Enable stop condition detection interrupt IICn_EEI (STOP) request
2	STIE	0h	RW	Start Condition Detection Interrupt Request Enable 0b: Disable start condition detection interrupt IICn_EEI (START) request 1b: Enable start condition detection interrupt IICn_EEI (START) request
1	ALIE	0h	RW	Arbitration-Lost Interrupt Request Enable 0b: Disable arbitration-lost interrupt IICn_EEI (AL) request 1b: Enable arbitration-lost interrupt IICn_EEI (AL) request
0	TMOIE	0h	RW	Timeout Interrupt Request Enable 0b: Disable timeout interrupt IICn_EEI (TMOF) request 1b: Enable timeout interrupt IICn_EEI (TMOF) request

TMOIE bit (Timeout Interrupt Request Enable)

The TMOIE bit enables or disables timeout interrupt IICn_EEI (TMOF) requests when the TMOF flag in ICSR2 is 1b. To cancel a IICn_EEI (TMOF) interrupt request, set the TMOF flag or the TMOIE bit to 0b.

ALIE bit (Arbitration-Lost Interrupt Request Enable)

The ALIE bit enables or disables arbitration-lost interrupt IICn_EEI (AL) requests when the AL flag in ICSR2 is 1b. To cancel an IICn_EEI (AL) interrupt request, set the AL flag or the ALIE bit to 0b.

STIE bit (Start Condition Detection Interrupt Request Enable)

The STIE bit enables or disables start condition detection interrupt IICn_EEI (START) requests when the START flag in ICSR2 is 1b. To cancel an IICn_EEI (START) interrupt request, set the START flag or the STIE bit to 0b.

SPIE bit (Stop Condition Detection Interrupt Request Enable)

The SPIE bit enables or disables stop condition detection interrupt IICn_EEI (STOP) requests when the STOP flag in ICSR2 is 1b. To cancel an IICn_EEI (STOP) interrupt request, set the STOP flag or the SPIE bit to 0b.

NAKIE bit (NACK Reception Interrupt Request Enable)

The NAKIE bit enables or disables NACK reception interrupt IICn_EEI (NACKF) requests when the NACKF flag in ICSR2 is 1. To cancel an IICn_EEI (NACKF) interrupt request, set the NACKF flag or the NAKIE bit to 0b.

RIE bit (Receive Data Full Interrupt Request Enable)

The RIE bit enables or disables receive data full interrupt (IICn_RXI) requests when the RDRF flag in ICSR2 is 1b.

TEIE bit (Transmit End Interrupt Request Enable)

The TEIE bit enables or disables transmit end interrupt (IICn_TEI) requests when the TEND flag in ICSR2 is 1b. To cancel an IICn_TEI interrupt request, set the TEND flag or the TEIE bit to 0b.

TIE bit (Transmit Data Empty Interrupt Request Enable)

The TIE bit enables or disables transmit data empty interrupt (IICn_TXI) requests when the TDRE flag in ICSR2 is 1b.

7.7.2.2.9 I²C Bus Status Register 1 (RIICm_ICSR1)

Access Size : 8 bits
Address : <RIICm_base> + 0008h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	HOA	-	DID	-	GCA	AAS2	AAS1	AAS0
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	HOA	0h	RW	Host Address Detection Flag This bit is set to 1b when the received slave address matches the host address (0001_000b). 0b: Host address not detected 1b: Host address detected
6	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5	DID	0h	RW	Device ID Address Detection Flag This bit is set to 1 when the first frame received immediately after a start condition is detected matches a value of (device ID (1111_100b) + 0 [W]). 0b: Device ID command not detected 1b: Device ID command detected
4	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3	GCA	0h	RW	General Call Address Detection Flag 0b: General call address not detected 1b: General call address detected
2	AAS2	0h	RW	Slave Address 2 Detection Flag 0b: Slave address 2 not detected 1b: Slave address 2 detected
1	AAS1	0h	RW	Slave Address 1 Detection Flag 0b: Slave address 1 not detected 1b: Slave address 1 detected
0	AAS0	0h	RW	Slave Address 0 Detection Flag 0b: Slave address 0 not detected 1b: Slave address 0 detected

AASy bit (Slave Address y Detection Flag) (y = 0 to 2)

The AASy flag indicates whether slave address y was detected.

[Setting conditions]

For 7-bit address format (SARUy.FS = 0b):

- When the received slave address matches the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1 (slave address y detection enabled).
  The AASy flag is set to 1b on the rising edge of the 9th SCL clock cycle in the frame.

For 10-bit address format: (SARUy.FS = 1b):

- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address matches the SARLy value, with the SARyE bit in ICSER set to 1b (slave address y detection enabled).
  The AASy flag is set to 1b on the rising edge of the 9th SCL clock cycle in the frame.

[Clearing conditions]

- When 0b is written to the AASy flag after reading AASy = 1b
- When a stop condition is detected.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

For 7-bit address format (SARUy.FS = 0b):

- When the received slave address does not match the SVA[6:0] value in SARLy, with the SARyE bit in ICSER set to 1b (slave address y detection enabled).
  The AASy flag is set to 0b on the rising edge of the 9th SCL clock cycle in the frame.

For 10-bit address format (SARUy.FS = 1b):

- When the received slave address does not match a value of 11110b + SVA[1:0] in SARUy, with the SARyE bit in ICSER set to 1b (slave address y detection enabled).
  The AASy flag is set to 0b on the rising edge of the 9th SCL clock cycle in the frame.
- When the received slave address matches a value of 11110b + SVA[1:0] in SARUy, and the subsequent address does not match the SARLy value, with the SARyE bit in ICSER set to 1b (slave address y detection enabled).
  The AASy flag is set to 0b on the rising edge of the 9th SCL clock cycle in the frame.

GCA bit (General Call Address Detection Flag)

The GCA flag indicates whether the general call address was detected.

[Setting condition]

- When the received slave address matches the general call address (0000_000b + 0b [W]), with the GCAE bit in ICSER set to 1b (general call address detection enabled).
  The GCA flag is set to 1b on the rising edge of the 9th SCL clock cycle in the frame.

[Clearing conditions]

- When 0b is written to the GCA flag after reading GCA = 1b.
- When a stop condition is detected.
- When the received slave address does not match the general call address (0000_000b + 0b [W]), with the GCAE bit in ICSER set to 1b (general call address detection enabled).
  The GCA flag is set to 0b on the rising edge of the 9th SCL clock cycle in the frame.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

DID bit (Device ID Address Detection Flag)

The DID flag indicates whether the device ID address was detected.

[Setting condition]

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111_100b) + 0b [W]), with the DIDE bit in ICSER set to 1b (device ID address detection enabled).
  The DID flag is set to 1b on the rising edge of the 9th SCL clock cycle in the frame.

[Clearing conditions]

- When 0b is written to the DID flag after reading DID = 1b.
- When a stop condition is detected.
- When the first frame received immediately after a start or restart condition is detected does not match a value of the device ID (1111_100b), with the DIDE bit in ICSER set to 1b (device ID address detection enabled).
  The DID flag is set to 0b on the rising edge of the 9th SCL clock cycle in the frame.
- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111_100b) + 0b [W]), and the second frame does not match any slave address from 0 to 2, with the DIDE bit in ICSER set to 1b (device ID address detection enabled).
  The DID flag is set to 0b on the rising edge of the 9th SCL clock cycle in the frame.

- When 1b is written to the IICRST bit in ICCR1 to initiate an RIIC reset or internal reset.

HOA bit (Host Address Detection Flag)

The HOA flag indicates whether the host address was detected.

[Setting condition]

- When the received slave address matches the host address (0001 000b), with the HOAE bit in ICSER set to 1b (host address detection enabled).
  The HOA flag is set to 1b on the rising edge of the 9th SCL clock cycle in the frame.

[Clearing conditions]

- When 0b is written to the HOA flag after reading HOA = 1b.
- When a stop condition is detected.
- When the received slave address does not match the host address (0001 000b), with the HOAE bit in ICSER set to 1b (host address detection enabled).
  The HOA flag is set to 0b on the rising edge of the 9th SCL clock cycle in the frame.
- When 1b is written to the IICRST bit in ICCR1 to initiate an RIIC reset or internal reset.

7.7.2.2.10 I²C Bus Status Register 2 (RIICm_ICSR2)

Access Size : 8 bits
Address : <RIICm_base> + 0009h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	TDRE	TEND	RDRF	NACKF	STOP	START	AL	TMOF
Initial Value	0	0	0	0	0	0	0	0
R/W	R	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	TDRE	0h	R	Transmit Data Empty Flag 0b: ICDRT contains transmit data 1b: ICDRT contains no transmit data
6	TEND	0h	RW	Transmit End Flag 0b: Data being transmitted 1b: Data transmit complete
5	RDRF	0h	RW	Receive Data Full Flag 0b: ICDRR contains no receive data 1b: ICDRR contains receive data
4	NACKF	0h	RW	NACK Detection Flag 0b: NACK not detected 1b: NACK detected
3	STOP	0h	RW	Stop Condition Detection Flag 0b: Stop condition not detected 1b: Stop condition detected
2	START	0h	RW	Start Condition Detection Flag 0b: Start condition not detected 1b: Start condition detected
1	AL	0h	RW	Arbitration-Lost Flag 0b: Arbitration not lost 1b: Arbitration lost
0	TMOF	0h	RW	Timeout Detection Flag 0b: Timeout not detected 1b: Timeout detected.

TMOF bit (Timeout Detection Flag)

The TMOF flag is set to 1 when RIIC detects a timeout because the SCLn line state remains unchanged for the set period.

[Setting condition]

- When the SCLn line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1b (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0b is written to the TMOF flag after reading TMOF = 1b.
- When 1b is written to the IICRST bit in ICCR1 to initiate an RIIC reset or internal reset.

AL bit (Arbitration-Lost Flag)

The AL flag indicates that the bus mastership is lost in arbitration because of a bus conflict or because of some other reason, when a start condition was issued, or an address and data was transmitted.

The RIIC monitors the level on the SDAn line during transmission. If the level on the line does not match the value of the bit being output, the RIIC sets the AL flag to 1b to indicate that the bus is occupied by another device. The RIIC can also detect loss of arbitration during NACK transmission in receive mode or during data transmission in slave mode.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1b):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode.
- When a start condition is detected while the ST bit in ICCR2 is 1b (start condition requested) or the internal SDA output state does not match the SDAn line level.
- When the ST bit in ICCR2 is 1b (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1b):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1b):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

[Clearing conditions]

- When 0b is written to the AL flag after reading AL = 1b.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

Table 7.7-6 Relationship between Arbitration-Lost Generation Sources and Arbitration-Lost Enable Functions

ICFER			ICSR2		
MALE	NALE	SALE	AL	Error	Arbitration-Lost Generation Source
1	×	×	1	Start condition issuance error	When internal SDA output state does not match SDAn line level when a start condition is detected, while the ST bit in ICCR2 is 1.
					When ST in ICCR2 is set to 1 while BBSY in ICCR2 is 1.
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode.
×	1	×	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master or slave receive mode.
×	×	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode.

Note: × = Don't care

START bit (Start Condition Detection Flag)

The START flag indicates whether a start or restart condition is detected.

[Setting condition]

- When a start or restart condition is detected.

[Clearing conditions]

- When 0b is written to the START flag after reading START = 1b.
- When a stop condition is detected.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

STOP bit (Stop Condition Detection Flag)

The STOP flag indicates whether a stop condition is detected.

[Setting condition]

- When a stop condition is detected.

[Clearing conditions]

- When 0b is written to the STOP flag after reading STOP = 1b.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

NACKF bit (NACK Detection Flag)

The NACKF flag indicates whether a NACK was detected.

[Setting condition]

- When acknowledge is not received (NACK received) from the receive device in transmit mode, with the NACKE bit in ICFER set to 1b (transfer suspension enabled).

[Clearing conditions]

- When 0b is written to the NACKF flag after reading NACKF = 1b.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

Note: When the NACKF flag is set to 1b, the RIIC suspends data transmission and reception. Writing to ICDRT in transmit mode or reading from ICDRR in receive mode with the NACKF flag set to 1b does not enable data transmit or receive operation. To restart data transmission or reception, set the NACKF flag to 0b.

RDRF bit (Receive Data Full Flag)

The RDRF flag indicates whether the IDCRR contains receive data.

[Setting conditions]

- When receive data is transferred from ICDRS to ICDRR.
  The RDRF flag is set to 1b on the rising edge of the 8th or 9th SCL clock cycle (selected in the RDRFS bit in ICMR3).
- When the received slave address matches after a start (or restart) condition is detected with the TRS bit in ICCR2 set to 0b.

[Clearing conditions]

- When 0b is written to the RDRF flag after reading RDRF = 1b.
- When data is read from ICDRR.
- When 1b is written to the IICRST bit in ICCR1 to initiate an RIIC reset or internal reset.

TEND bit (Transmit End Flag)

The TEND flag indicates whether data transmission is still being transmitted or is complete.

[Setting condition]

- On the rising edge of the 9th SCL clock cycle while the TDRE flag is 1b.

[Clearing conditions]

- When 0b is written to the TEND flag after reading TEND = 1b.
- When data is written to ICDRT.
- When a stop condition is detected.
- When 1b is written to the IICRST bit in ICCR1 to initiate an RIIC reset or internal reset.

TDRE bit (Transmit Data Empty Flag)

The TDRE flag indicates whether the ICDRT contains transmit data.

[Setting conditions]

- When data is transferred from ICDRT to ICDRS and ICDRT becomes empty.
- When the TRS bit in ICCR2 is set to 1b.
- When the received slave address matches while the TRS bit is 1b.

[Clearing conditions]

- When data is written to ICDRT.
- When the TRS bit in ICCR2 is set to 0b.
- When 1b is written to the IICRST bit in ICCR1 to apply an RIIC reset or internal reset.

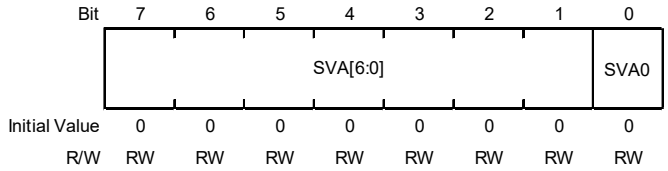
Note: The NACKF flag becoming 1 while the ICFER.NACKE bit is 1 suspends data transmission and reception by the RIIC. Even if the next data for transmission has already been written to the ICDRT register (the TDRE flag is 0b), the data in the ICDRT register is retained but not transferred to the ICDRS register. At this point, the TDRE flag does not become 1.

7.7.2.2.11 Slave Address Register L y (RIICm_SARLy) (y = 0 to 2)

Access Size : 8 bits

Address : <RIICm_base> + 000Ah + 0002h × y

Initial Value : 00h



Bit	Bit Name	Initial Value	R/W	Description
7 to 1	SVA[6:0]	0h	RW	7-bit Address/10-bit Address Lower Bits Slave address setting
0	SVA0	0h	RW	10-bit Address LSB Slave address setting

SVA0 bit (10-bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1b), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSER is set to 1b (SARLy and SARUy enabled) and the SARUy.FS bit is 1b. When the SARUy.FS or SARyE bit is 0b, the setting in this bit is ignored.

SVA[6:0] bits (7-bit Address/10-bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0b), the SVA[6:0] bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS = 1b), these bits combined with the SVA0 bit to form the lower 8 bits of a 10-bit address. When the SARyE bit in ICSER is 0b, the setting in these bits is ignored.

7.7.2.2.12 Slave Address Register U y (RIICm_SARUy) (y = 0 to 2)

Access Size : 8 bits

Address : <RIICm_base> + 000Bh + 0002h × y

Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	SVA[1:0]		FS
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2, 1	SVA[1:0]	0h	RW	10-bit Address Upper Bits Slave address setting
0	FS	0h	RW	7-bit/10-bit Address Format Select 0b: Select 7-bit address format 1b: Select 10-bit address format

FS bit (7-bit/10-bit Address Format Select)

The FS bit selects a 7-bit or 10-bit address format for slave address y (in SARLy and SARUy).

When the SARyE bit in ICSER is set to 1b (SARLy and SARUy enabled) and the SARUy.FS bit is 0b, the 7-bit address format is selected for slave address y, the SVA[6:0] setting in SARLy is valid, and the SVA[1:0] and SVA0 settings in SARLy are ignored.

When the SARyE bit in ICSER is set to 1b (SARLy and SARUy enabled) and the SARUy.FS bit is 1b, the 10-bit address format is selected for slave address y and the SVA[1:0] and SARLy settings are valid.

When the SARyE bit in ICSER is 0b (SARLy and SARUy disabled), the SARUy.FS setting is invalid.

SVA[1:0] bits (10-bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1b), the SVA[1:0] bits function as the upper 2 bits of a 10-bit address.

These bits are valid when the SARyE bit in ICSER is set to 1b (SARLy and SARUy enabled) and the SARUy.FS bit is 1b. When the SARUy.FS or SARyE bit is 0b, the setting in these bits is ignored.

7.7.2.2.13 I²C Bus Bit Rate Low-Level Register (RIICm_ICBRL)

Access Size : 8 bits
Address : <RIICm_base> + 0010h
Initial Value : FFh

Bit	7	6	5	4	3	2	1	0
	-	-	-	BRL[4:0]				
Initial Value	1	1	1	1	1	1	1	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	-	All 1	RW	Reserved Whenever it is read, 1b is read. The written value should always be 1b.
4 to 0	BRL[4:0]	1Fh	RW	Bit Rate Low-Level Period Low-level period setting of SCL clock

ICBRL is a 5-bit register that sets the low-level period of the SCL clock. ICBRL also works to generate the data setup time for the automatic SCL low-hold operation (see **7.7.8 Automatic Low-Hold Function for SCL**). When the RIIC is used only in slave mode, this register must be set to a value longer than the data setup time.*1

ICBRL counts the low-level period with the internal reference clock source (IICϕ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set the ICBRL register to a value at least one greater than the number of stages in the noise filter. For this number, see the description of the ICMR3.NF[1:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns for up to 100 kbps: Standard-mode (Sm)
100 ns for up to 400 kbps: Fast-mode (Fm)
50 ns for up to 1 Mbps: Fast-mode plus (Fm+)

7.7.2.2.14 I²C Bus Bit Rate High-Level Register (RIICm_ICBRH)

Access Size : 8 bits
Address : <RIICm_base> + 0011h
Initial Value : FFh

Bit	7	6	5	4	3	2	1	0
	-	-	-	BRH[4:0]				
Initial Value	1	1	1	1	1	1	1	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	-	All 1	RW	Reserved Whenever it is read, 1b is read. The written value should always be 1b.
4 to 0	BRH[4:0]	1Fh	RW	Bit Rate High-Level Period High-level period setting of SCL clock

ICBRH is a 5-bit register that sets the high-level period of the SCL clock. ICBRH is valid in master mode. If the RIIC is used only in slave mode, no setting is required in this register.

ICBRH counts the high-level period with the internal reference clock source (IICϕ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1b), set the ICBRH register to a value at least one greater than the number of stages in the noise filter. For this number, see the description of the ICMR3.NF[1:0] bits.

The RIIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

(1) ICFER.SCLE = 0b
Transfer rate = 1/{[(BRH + 1) + (BRL + 1)]/IICϕ*[1] + tr*[2] + tf*[2]}
Duty cycle = {tr + [(BRH + 1)/IICϕ]}/{tr + tf + [(BRH + 1) + (BRL + 1)]/IICϕ}

(2) ICFER.SCLE = 1b and ICFER.NFE = 0b and CKS[2:0] = 000b (IICϕ = PCLKL*[4])
Transfer rate = 1/{[(BRH + 3) + (BRL+ 3)]/IICϕ + tr + tf}
Duty cycle = {tr + [(BRH + 3)/IICϕ]}/{tr + tf + [(BRH + 3) + (BRL + 3)]/IICϕ}

(3) ICFER.SCLE = 1b and ICFER.NFE = 1b and CKS[2:0] = 000b (IICϕ = PCLKL)
Transfer rate = 1/{[(BRH + 3 + nf*[3]) + (BRL + 3 + nf)]/IICϕ + tr + tf}
Duty cycle = {tr + [(BRH + 3 + nf)/IICϕ]}/{tr + tf + [(BRH + 3 + nf) + (BRL + 3 + nf)]/IICϕ}

(4) ICFER.SCLE = 1b and ICFER.NFE = 0b and CKS[2:0] ≠ 000b
Transfer rate = 1/{[(BRH + 2) + (BRL + 2)]/IICϕ + tr + tf}
Duty cycle = {tr + [(BRH + 2)/IICϕ]}/{tr + tf + [(BRH + 2) + (BRL + 2)]/IICϕ}

(5) ICFER.SCLE = 1b and ICFER.NFE = 1b and CKS[2:0] ≠ 000b
Transfer rate = 1/{[(BRH + 2 + nf) + (BRL + 2 + nf)]/IICϕ + tr + tf}
Duty cycle = {tr + [(BRH + 2 + nf)/IICϕ]}/{tr + tf + [(BRH + 2 + nf) + (BRL + 2 + nf)]/IICϕ}

Note 1. IICϕ = PCLKL × Division ratio.
Note 2. The SCLn line rise time (tr) and SCLn line fall time (tf) depend on the total bus line capacitance (Cb) and the pull-up resistor (Rp).
For details, see the I²C bus standard from NXP Semiconductors.
Note 3. nf = Number of digital noise filter stages selected in the ICMR3.NF bit.
Note 4. PCLKL: RIIC_n_ckm [n = 0 to 8]

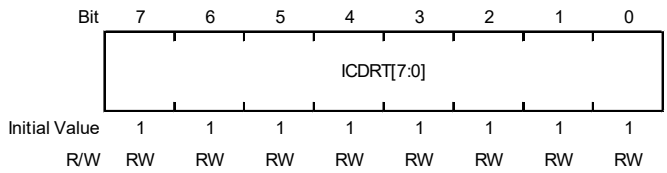
7.7.2.2.15 I²C Bus Transmit Data Register (RIICm_ICDRT)

Access Size : 8 bits
Address : <RIICm_base> + 0012h
Initial Value : FFh



Bit	Bit Name	Initial Value	R/W	Description
7 to 0	ICDRT[7:0]	FFh	RW	Transmit Data

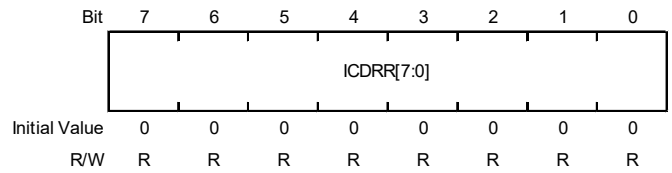
When ICDRT detects a space in the I²C Bus Shift Register (ICDRS), it transfers the transmit data that is written to ICDRT to ICDRS and starts transmitting data in transmit mode.

The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read from and written to. Write transmit data to ICDRT when a transmit data empty interrupt (IICn_TXI) request is generated.

7.7.2.2.16 I²C Bus Receive Data Register (RIICm_ICDRR)

Access Size : 8 bits
Address : <RIICm_base> + 0013h
Initial Value : 00h



Bit	Bit Name	Initial Value	R/W	Description
7 to 0	ICDRR[7:0]	0h	R	Receive Data

When 1 byte of data is received, the received data is transferred from the I²C Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received.

The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR when a receive data full interrupt (IICn_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR while the RDRF flag in ICSR2 is 1b, the RIIC automatically holds the SCL clock low for 1 cycle before the RDRF flag is set to 1b again.

7.7.2.2.17 I²C Bus Shift Register (RIICm_ICDRS)

Access Size : 8 bits
Address : <RIICm_base> + n/a
Initial Value : xxh

Bit	7	6	5	4	3	2	1	0
	[7:0]							
Initial Value	x	x	x	x	x	x	x	x
R/W	-	-	-	-	-	-	-	-

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	[7:0]	x	-	The read value is undefined

ICDRS is an 8-bit shift register to transmit and receive data.

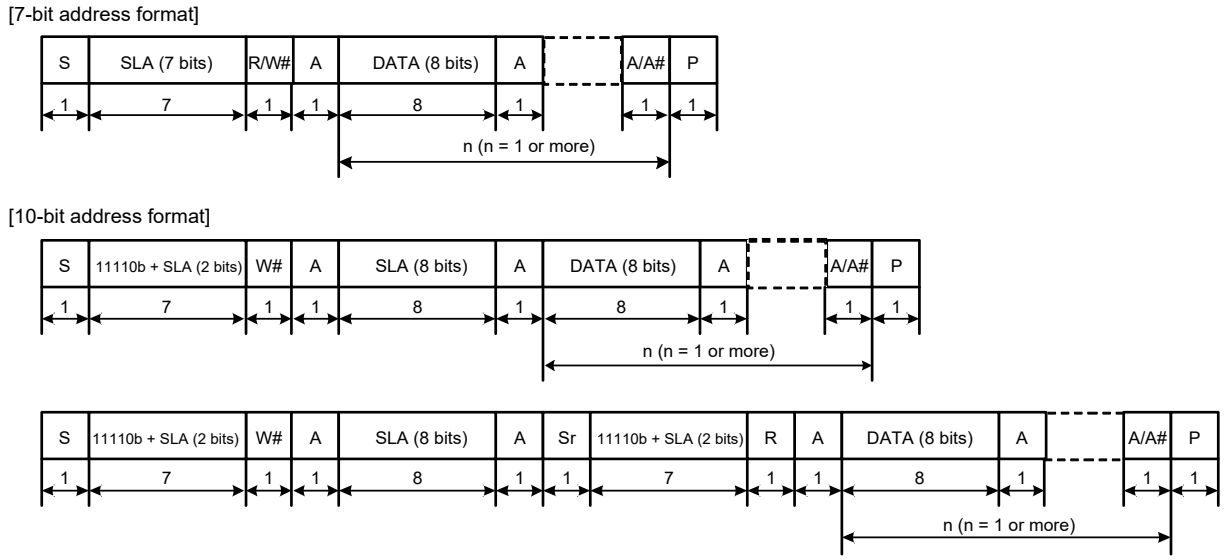
During transmission, transmit data is transferred from ICDRT to ICDRS and is sent from the SDAn pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

7.7.3 Operation

7.7.3.1 Communication Data Format

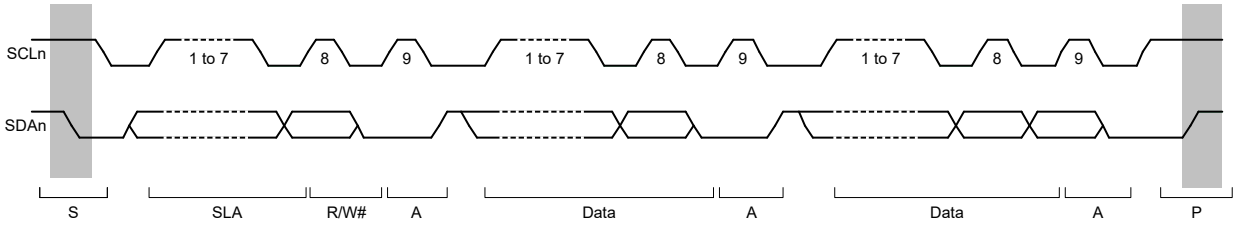
The I²C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 7.7-3 shows the I²C bus format, and **Figure 7.7-4** shows the I²C bus timing.



Note: n: Number of transfer frames

Figure 7.7-3 I²C Bus Format



S: Start condition. The master device drives the SDAn line low from high while the SCLn line is high.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.

A: Acknowledge. The receive device drives the SDAn line low. In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.

A#: Not Acknowledge. The receive device drives the SDAn line high.

Sr: Restart condition. The master device drives the SDAn line low from the high level after the setup time has elapsed with the SCLn line high.

DATA: Transmitted or received data

P: Stop condition. The master device drives the SDAn line high from low while the SCLn line is high.

Figure 7.7-4 I^2C Bus Timing when the SLA Setting = 7 Bits

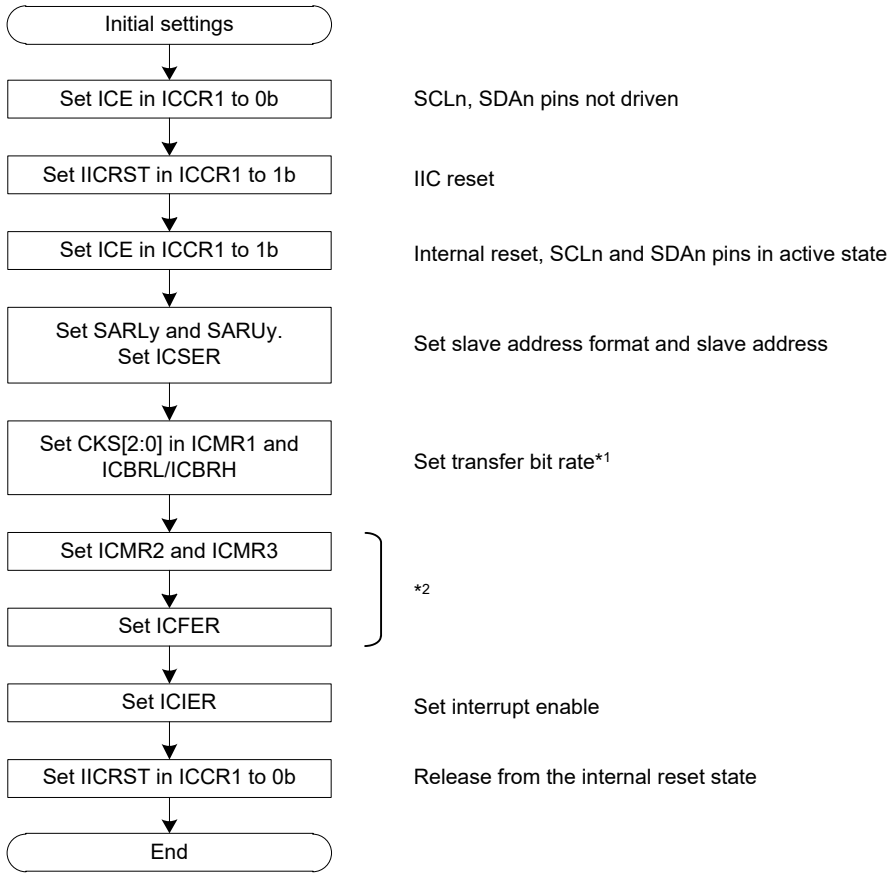
7.7.3.2 Initial Settings

Before starting data transmission and reception, initialize the RIIC using the procedure shown in **Figure 7.7-5**.

1. Set the ICCR1.ICE bit set to 0b to set the SCLn and SDAn pins to the inactive state.
2. Set the ICCR1.IICRST bit to 1b to initiate RIIC reset.
3. Set the ICCR1.ICE bit to 1b to initiate internal reset, which initializes the flags and the internal state of the ICSR1 register.
4. Set the SARLy, SARUy, ICSER, ICMR1, ICBRH, and ICBRL registers (y = 0 to 2), and set the other registers as required. For the initial RIIC settings, see **Figure 7.7-5**.
5. When the required register settings are complete, set the ICCR1.IICRST bit to 0b, to release the RIIC reset.

NOTE

This procedure is not necessary if the RIIC initialization is already complete.



Note: y = 0 to 2

Note 1. When the RIIC is used only in slave mode, set the ICBRL register to a value longer than the data setup time.

Note 2. Set these registers as required.

Figure 7.7-5 Example RIIC Initialization Flow

7.7.3.3 Master Transmit Operation

In master transmit operation, the RIIC outputs the SCL clock and transmit data signals as the master device, and the slave device returns the acknowledgments. **Figure 7.7-6** shows an example of master transmission, and **Figure 7.7-7** to **Figure 7.7-9** show the operation timing in master transmission.

To set up and perform master transmission:

1. To initialize the RIIC, follow the procedure in **7.7.3.2 Initial Settings**.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1b (start condition request). On receiving the request, the RIIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to 1b and the ST bit is automatically set to 0b. If the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1b, the RIIC recognizes that the start condition requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1b, placing the RIIC in master transmit mode. The TDRE flag in ICSR2 also automatically sets to 1b in response to the setting of the TRS bit to 1b.
3. Check that the TDRE flag in ICSR2 is 1b, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag is automatically set to 0b, the data is transferred from ICDRT to ICDRS, and the TDRE flag again sets to 1b. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 0b, the RIIC continues in master transmit mode.
   If the ICSR2.NACKF flag is 1b, indicating that no slave device recognized the address or that there was an error in communications, write 1b to the ICCR2.SP bit to issue a stop condition.
   To transmit data with an address in the 10-bit format, start by writing 11110b, the 2 upper bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower bits of the slave address to ICDRT.
4. After confirming that the TDRE flag in ICSR2 is 1b, write the transmit data to the ICDRT register. The RIIC automatically holds the SCLn line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1b, and then set the SP bit in ICCR2 to 1b (stop condition requested). On receiving a stop condition request, the RIIC issues the stop condition.
6. On detecting the stop condition, the RIIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. In addition, the RIIC automatically sets the TDRE and TEND flags to 0b, and sets the STOP flag in ICSR2 to 1b.
7. After checking that the ICSR2.STOP flag is 1b, set the ICSR2.NACKF and STOP flags to 0b for the next transfer operation.

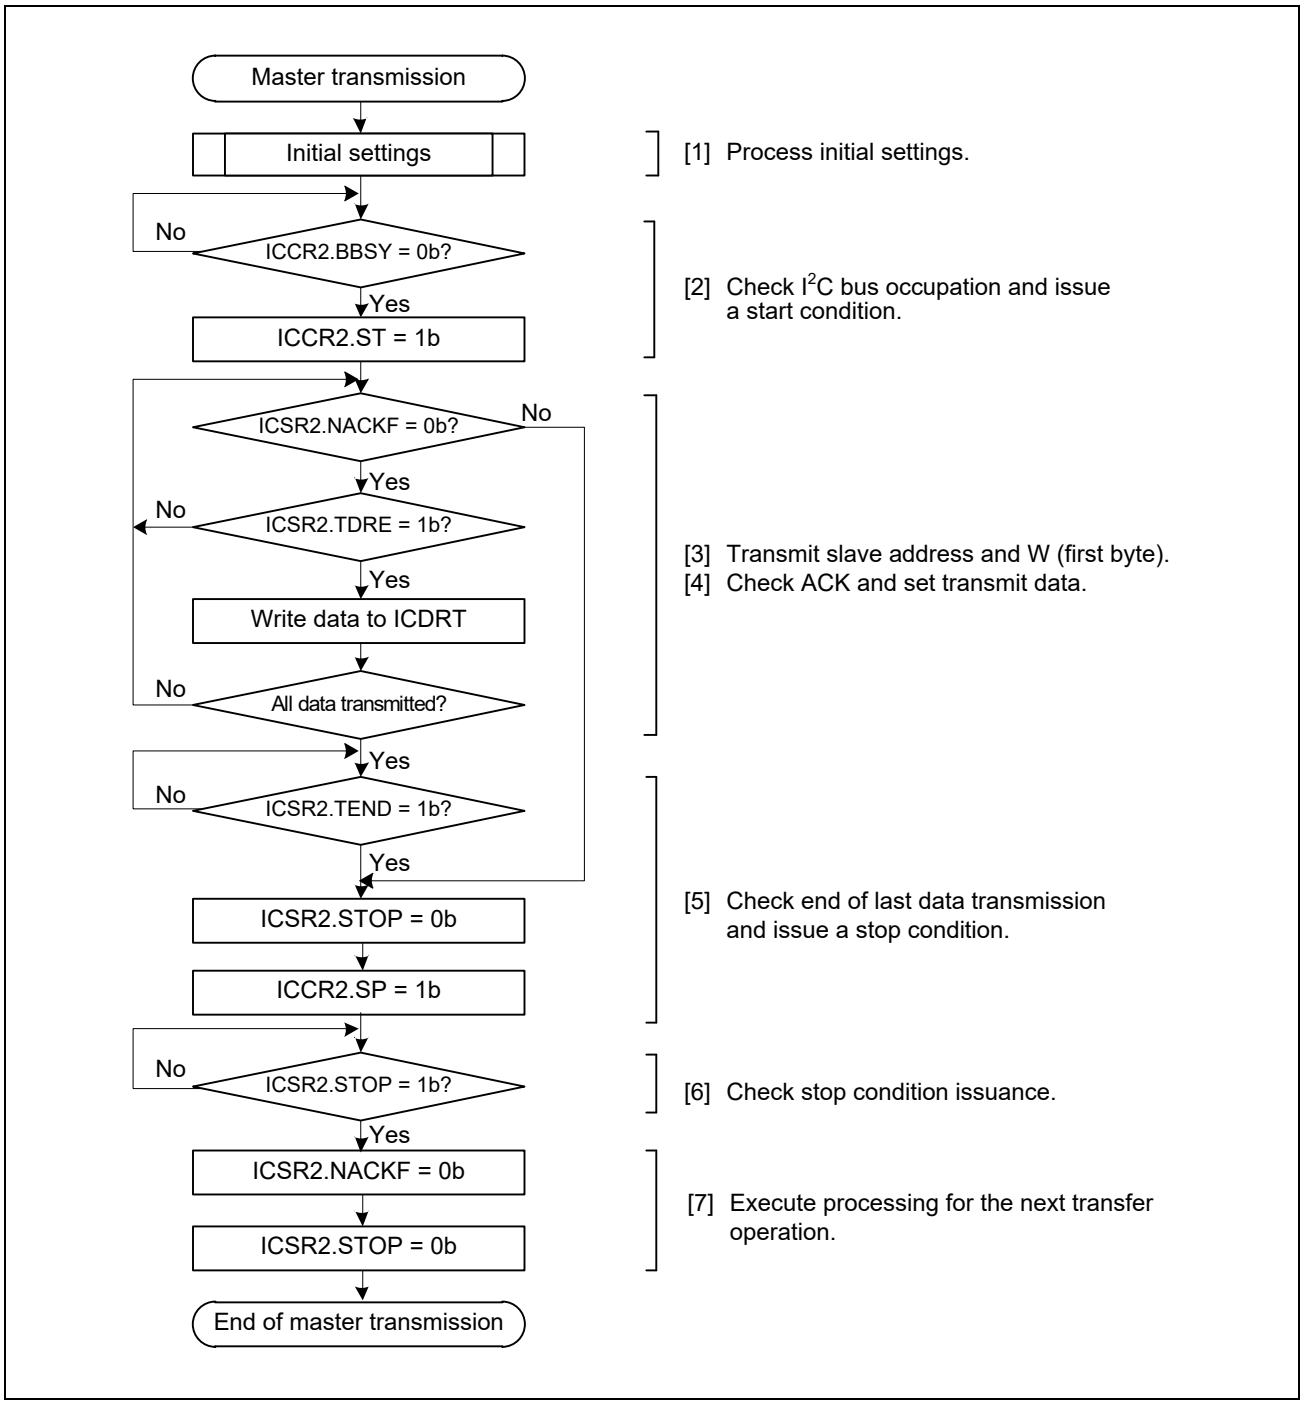


Figure 7.7-6 Example Master Transmission Flow

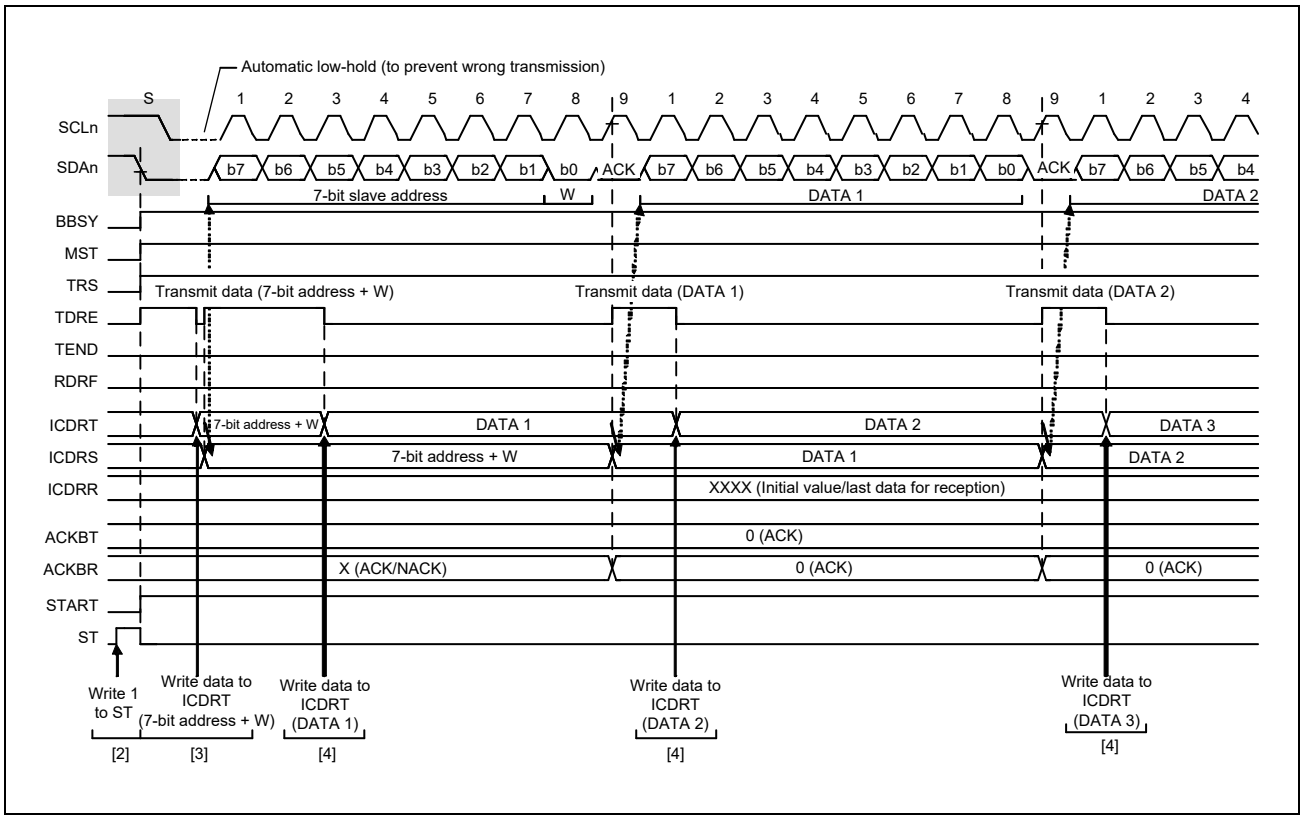

Figure 7.7-7 Master Transmit Operation Timing (1) with 7-Bit Address Format

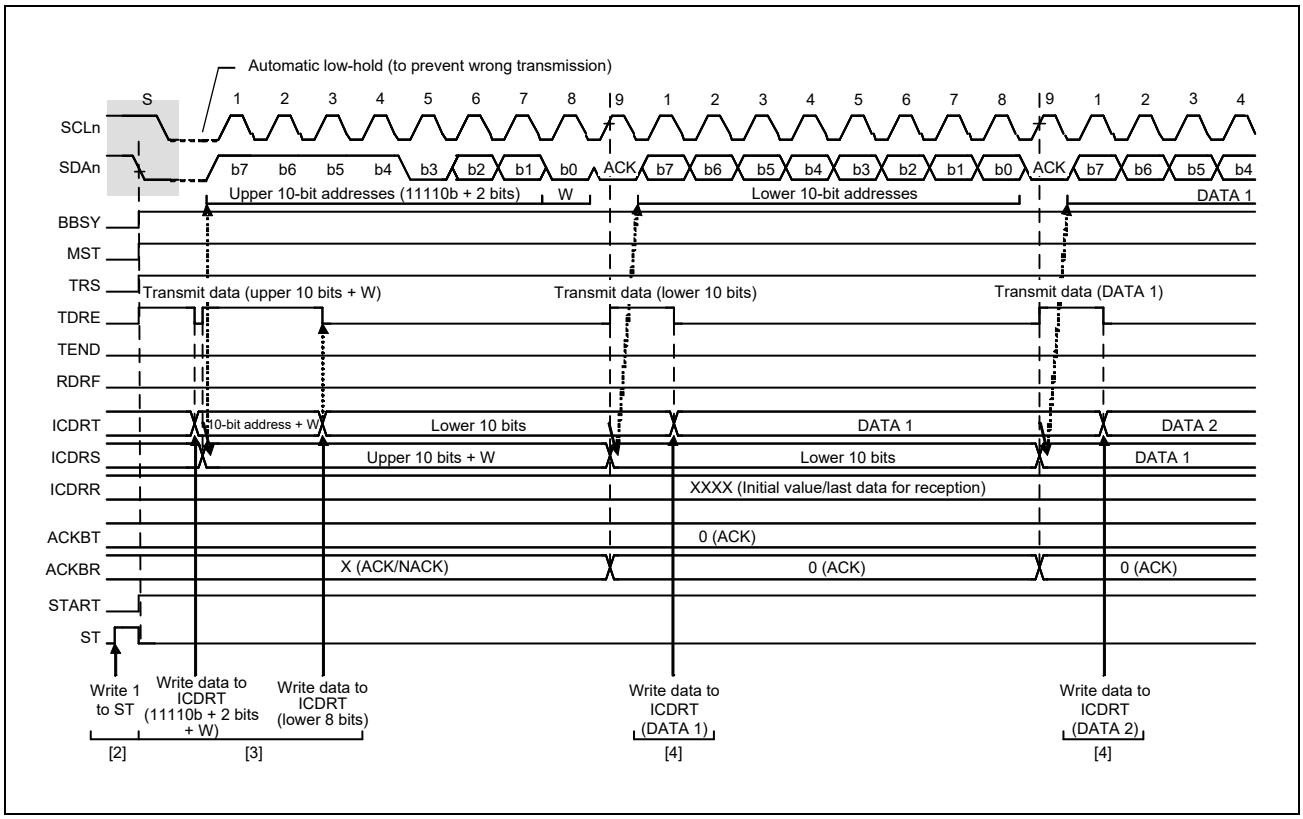

Figure 7.7-8 Master Transmit Operation Timing (2) with 10-Bit Address Format

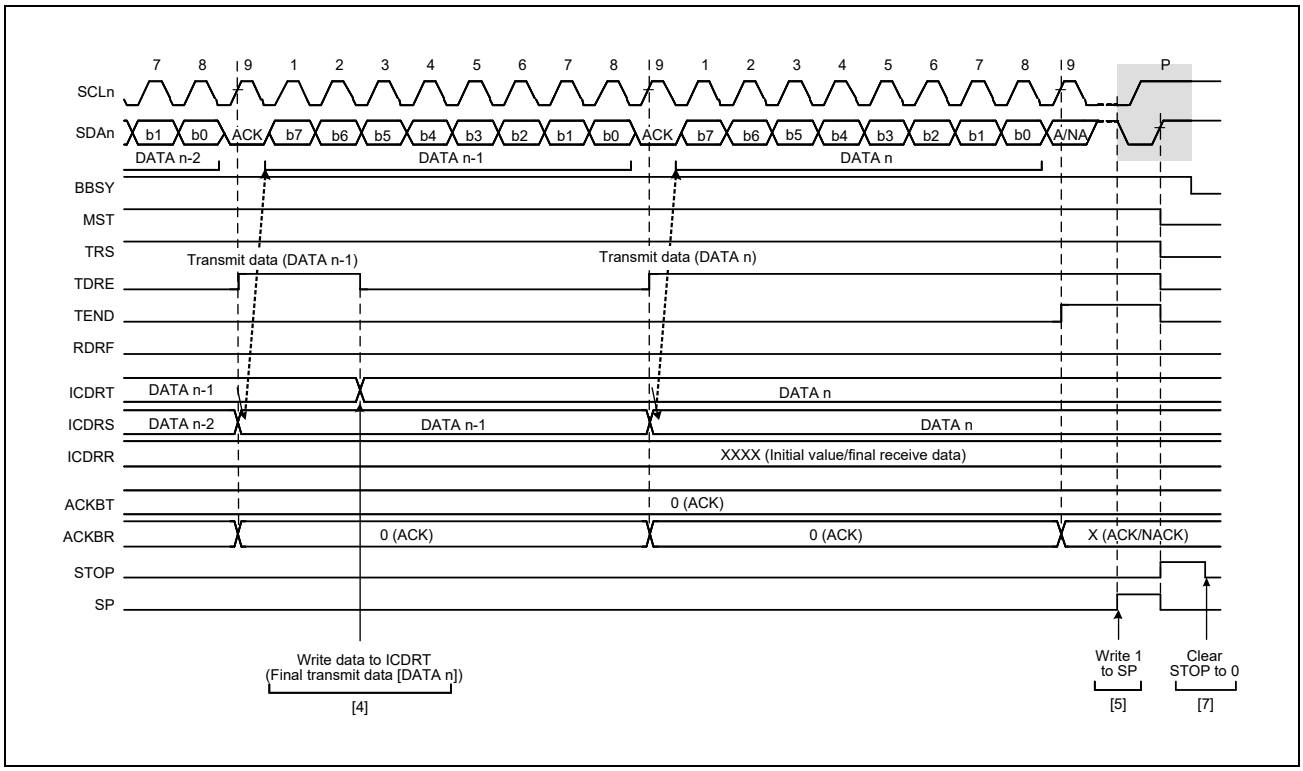

Figure 7.7-9 Master Transmit Operation Timing (3)

7.7.3.4 Master Receive Operation

In master receive operation, the RIIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the RIIC must start by sending a slave address to the associated slave device, the slave address part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 7.7-10 and **Table 7.7-11** show examples of master reception (7-bit address format), and **Figure 7.7-12** to **Figure 7.7-14** show the operation timing in master reception.

To set up and perform master reception:

1. To initialize the RIIC, follow the procedure in **7.7.3.2 Initial Settings**.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1b to request the issue of a start condition. On receiving the request, the RIIC issues a start condition. When the RIIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1b, and the ST bit automatically sets to 0b. If the start condition is detected and the levels for the SDA output and the levels on the SDAn line match while the ST bit is 1b, the RIIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1b, placing the RIIC in master transmit mode. The TDRE flag in ICSR2 also is automatically set to 1b in response to the setting of the TRS bit to 1b.
3. Check that the TDRE flag in ICSR2 is 1b, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag is automatically set to 0b, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1b. When the byte containing the slave address and R/W# bit is transmitted, the value of the ICCR2.TRS bit automatically updates to select transmit or receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 1b, the TRS bit is set to 0b on the rising edge of the 9th cycle of the SCL clock, placing the RIIC in master receive mode. At this time, the TDRE flag is set to 0b and the ICSR2.RDRF flag is automatically set to 1b.
   If the ICSR2.NACKF flag is 1b, indicating that no slave device recognized the address or that there is an error in communications, write 1b to the ICCR2.SP bit to issue a stop condition.
   For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmit 11110b, the two upper bits of the slave address, and the R bit to place the RIIC in master receive mode.
4. Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1b. Doing so causes the RIIC to start output of the SCL clock and start data reception.
5. After 1 byte of data is received, the RDRF flag in ICSR2 is set to 1b on the rising edge of the 8th or 9th cycle of the SCL clock, as selected in the RDRFS bit in ICMR3. Reading ICDRR produces the received data, and automatically sets the RDRF flag to 0b. The value of the acknowledgment field received during the 9th cycle of the SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the second-to-last byte, set the ICMR3.WAIT bit to 1b for wait insertion before reading ICDRR, containing the second-to-last byte. In addition to enabling NACK output, even when interrupts or other operations result in delays in setting the ICMR3.ACKBT bit to 1b (NACK) in step (6), this fixes the SCLn line to the low level on the rising edge of the 9th clock cycle in reception of the last byte, which enables the issuing of a stop condition.
6. When the ICMR3.RDRFS bit is 0b, and the slave device must be notified that it is to end transfer for data reception after transfer of the next and final byte, set the ICMR3.ACKBT bit to 1b (NACK).
7. After reading the second-to-last byte from the ICDRR register, if the value of the ICSR2.RDRF flag is 1b, write 1b to the SP bit in ICCR2 (stop condition requested), and then read the last byte from ICDRR. When ICDRR is read, the RIIC is released from the wait state and issues the stop condition after low-level output in the 9th clock cycle is complete or the SCLn line is released from the low-hold state.

8. On detecting the stop condition, the RIIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, detection of the stop condition sets the ICSR2.STOP flag to 1b.
9. Check that the ICSR2.STOP flag is 1b, and then set the ICSR2.NACKF and ICSR2.STOP flags to 0b for the next transfer operation.

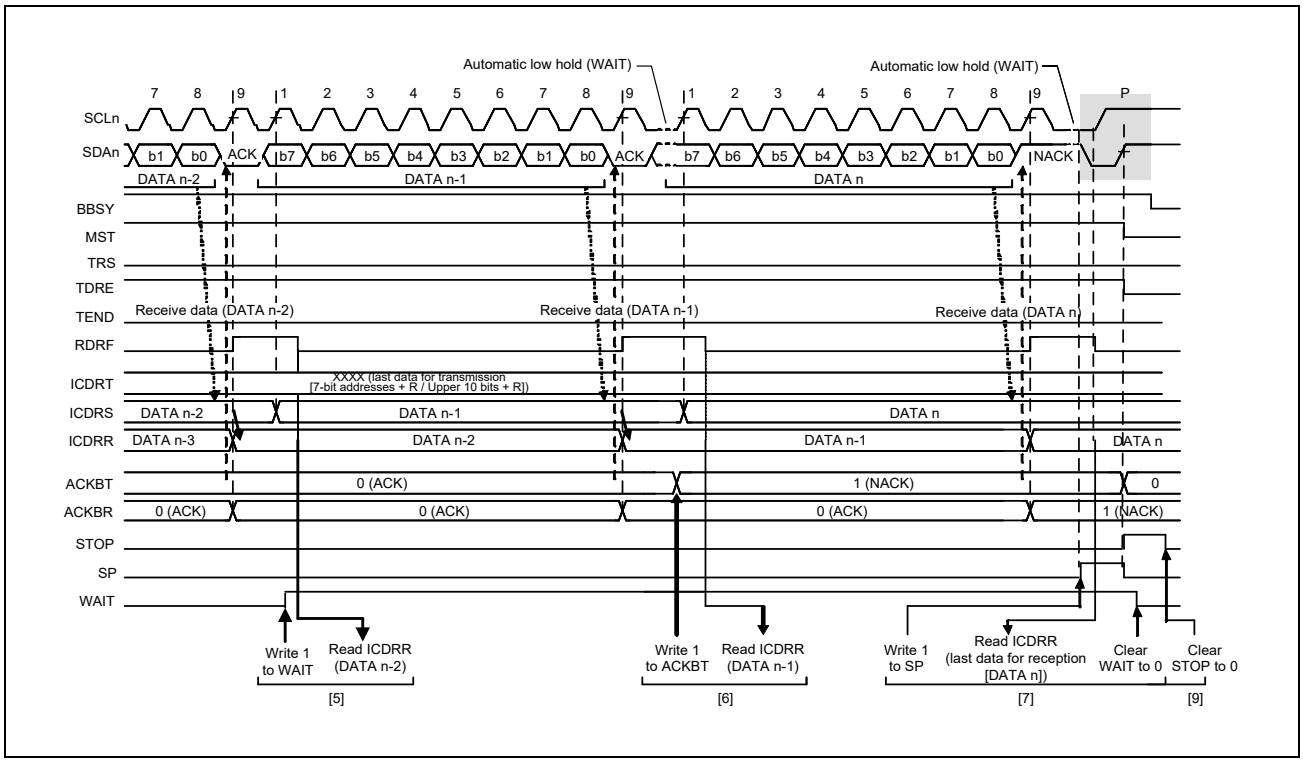

Figure 7.7-14 Master Receive Operation Timing (3) when RDRFS = 0b

7.7.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the RIIC transmits data as a slave device, and the master device returns the acknowledgments.

Figure 7.7-15 shows an example of slave transmission, and **Figure 7.7-16** and **Figure 7.7-17** show the operation timing in slave transmission.

To set up and perform slave transmission:

1. To initialize the RIIC, follow the procedure in **7.7.3.2 Initial Settings**.
   After the initialization, the RIIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the RIIC sets one of the associated bits ICSR1.HOA, GCA, and AASy (y = 0 to 2) flags to 1b on the rising edge of the 9th cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the 9th cycle of the SCL clock. If the value of the received R/W# bit is 1b, the RIIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1b.
3. Check that the ICSR2.TEND flag is 1b, and write the transmit data to the ICDRT register. If the RIIC receives no acknowledge from the master device (receives a NACK signal) while the ICFER.NACKE bit is 1,b the RIIC suspends transfer of the next data.
4. Wait until the ICSR2.TEND flag is set to 1b while the ICSR2.TDRE flag is 1b, after the ICSR2.NACKF flag is set to 1b or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1b, the RIIC drives the SCLn line low on the 9th falling edge of the SCL clock.
5. When the ICSR2.NACKF flag or the ICSR2.TEND flag is 1b, dummy read ICDRR to complete the processing. This releases the SCLn line.
6. On detecting the stop condition, the RIIC automatically sets the ICSR1.HOA, GCA, and AASy (y = 0 to 2) flags, the ICSR2.TDRE and TEND flags, and the ICCR2.TRS bit to 0b, and enters slave receive mode.
7. Check that the ICSR2.STOP flag is 1b, and then set the ICSR2.NACKF and STOP flags to 0b for the next transfer operation.

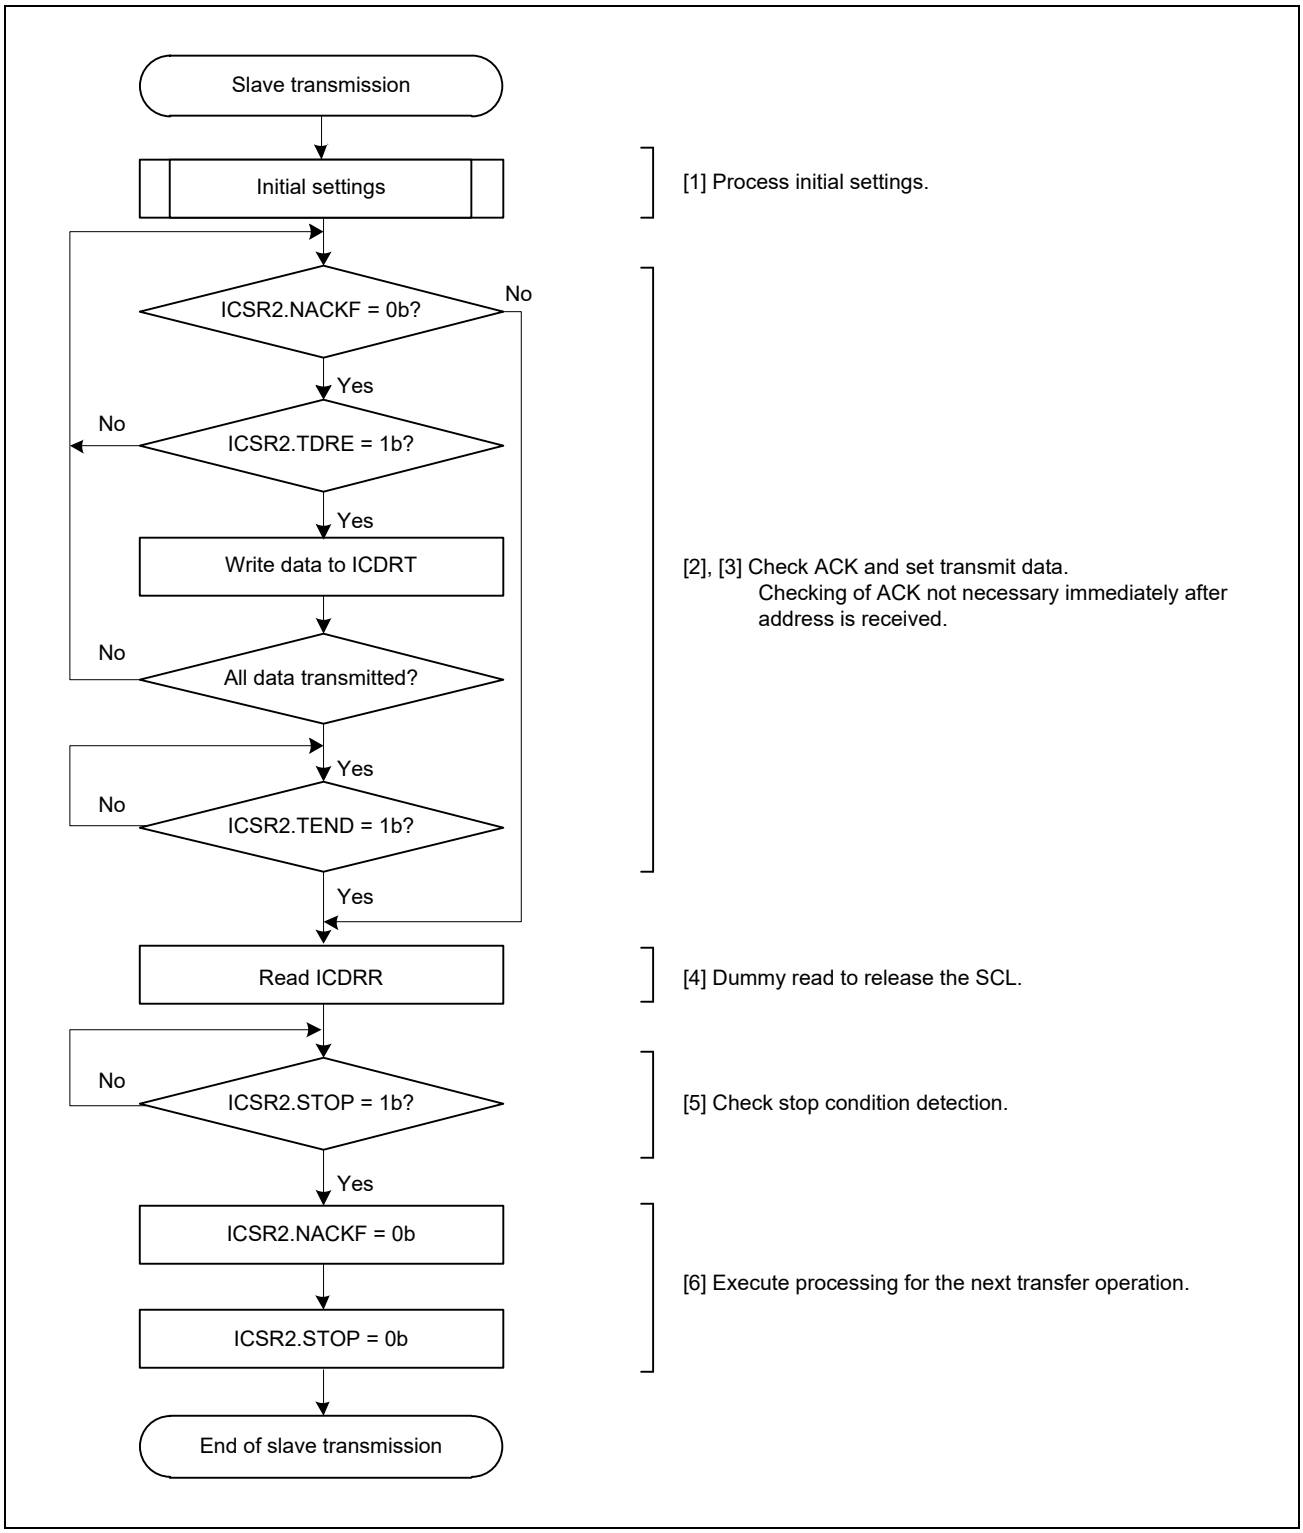

Figure 7.7-15 Example Slave Transmission Flow

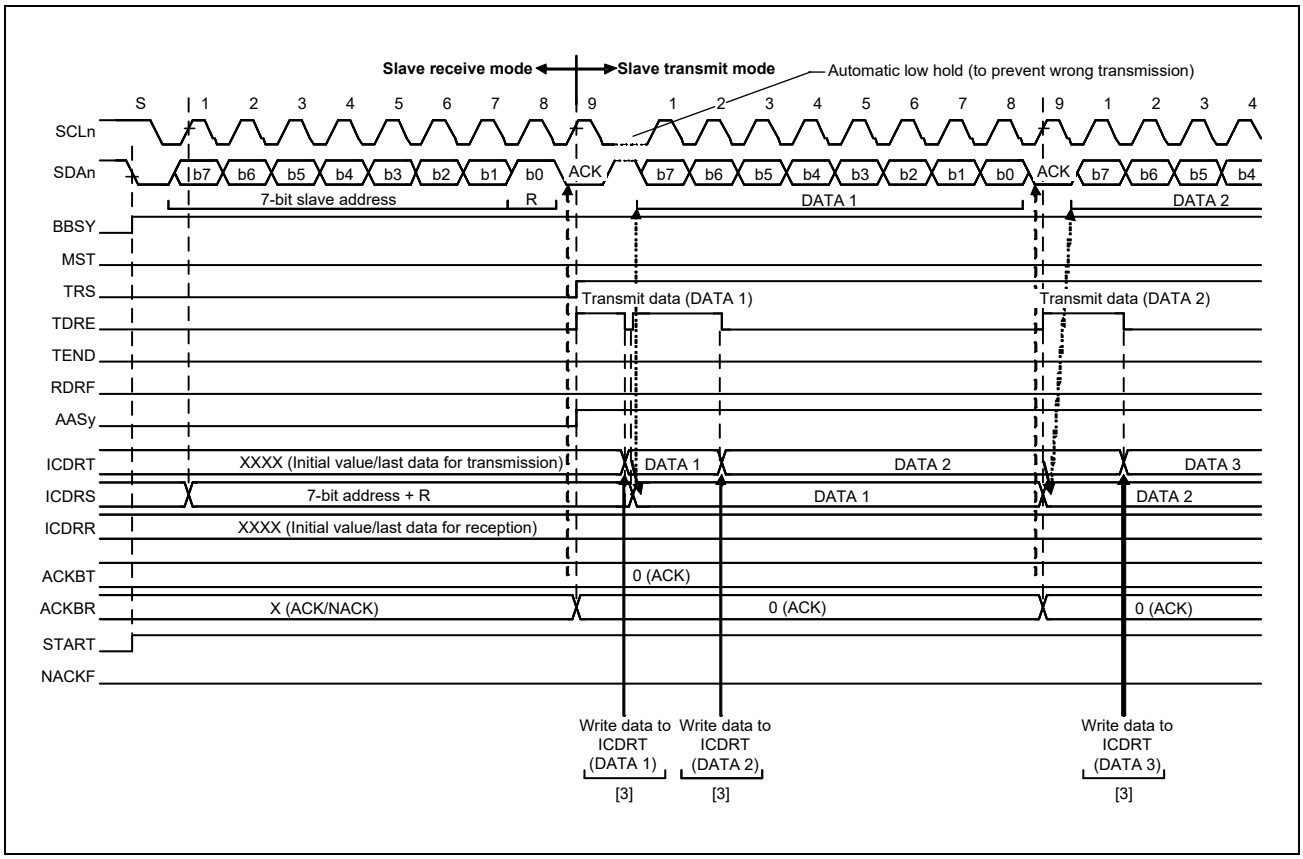

Figure 7.7-16 Slave Transmit Operation Timing (1) with 7-Bit Address Format

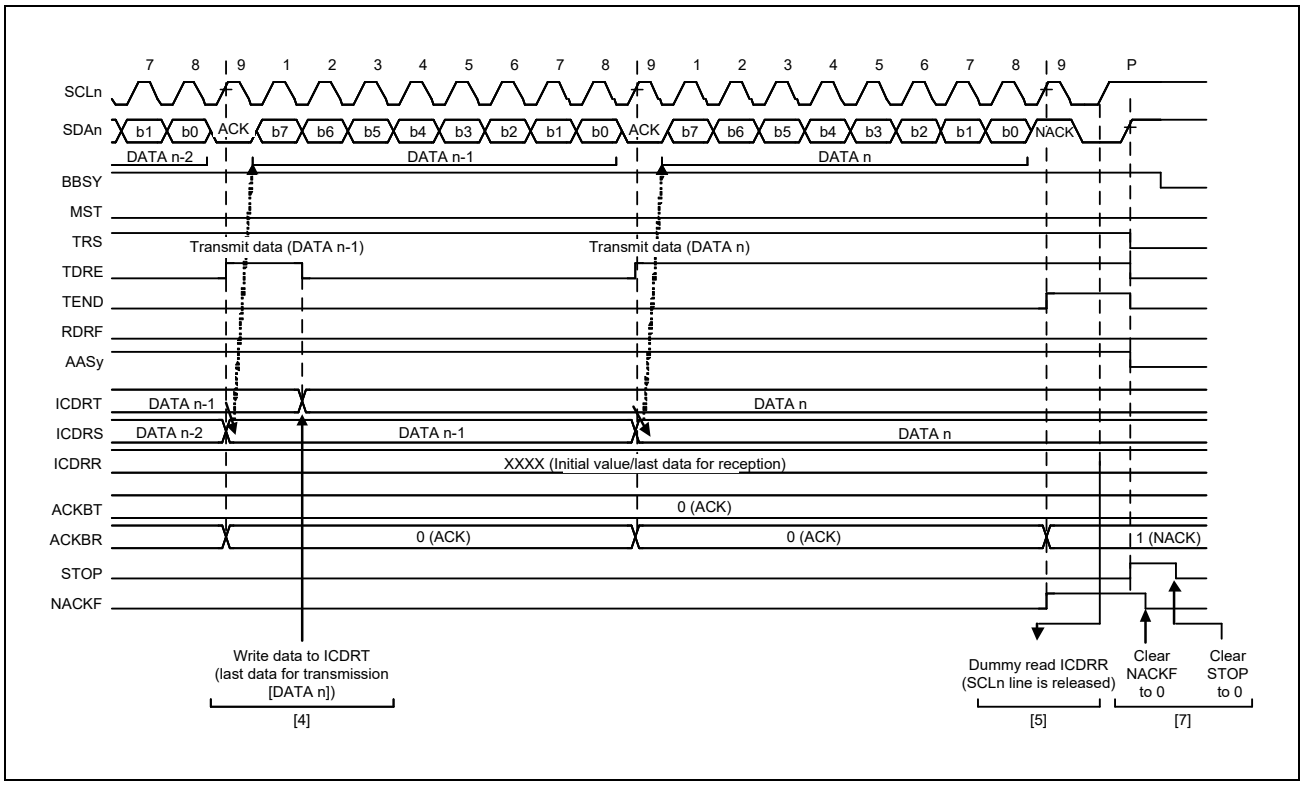

Figure 7.7-17 Slave Transmit Operation Timing (2)

7.7.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the RIIC returns acknowledgments as a slave device.

Figure 7.7-18 shows an example of slave reception, and **Figure 7.7-19** and **Figure 7.7-20** show the operation timing in slave reception.

To set up and perform slave reception:

1. To initialize the RIIC, follow the procedure in **7.7.3.2 Initial Settings**.
   After the initialization, the RIIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the RIIC sets one of the associated ICSR1.HOA, GCA, and AASy (y = 0 to 2) flags to 1b on the rising edge of the 9th cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the 9th cycle of the SCL clock. If the value of the received R/W# bit is 0b, the RIIC continues to place itself in slave receive mode and sets the RDRF flag in ICSR2 to 1b.
3. Check that the ICSR2.STOP flag is 0b and the ICSR2.RDRF flag is 1b, and then dummy read the ICDRR register. The dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected.
4. When ICDRR is read, the RIIC automatically sets the ICSR2.RDRF flag to 0b. If reading of ICDRR is delayed and the next byte is received while the RDRF flag is still set to 1b, the RIIC holds the SCLn line low until 1 SCL cycle before the point where RDRF must be set. In this case, reading ICDRR releases the SCLn line from being held at the low level. When the ICSR2.STOP flag is 1b and the ICSR2.RDRF flag is also 1b, read ICDRR until all the data is completely received.
5. On detecting the stop condition, the RIIC automatically clears the ICSR1.HOA, GCA, and AASy (y = 0 to 2) flags to 0b.
6. Check that the ICSR2.STOP flag is 1b, then set the ICSR2.STOP flag to 0b for the next transfer operation.

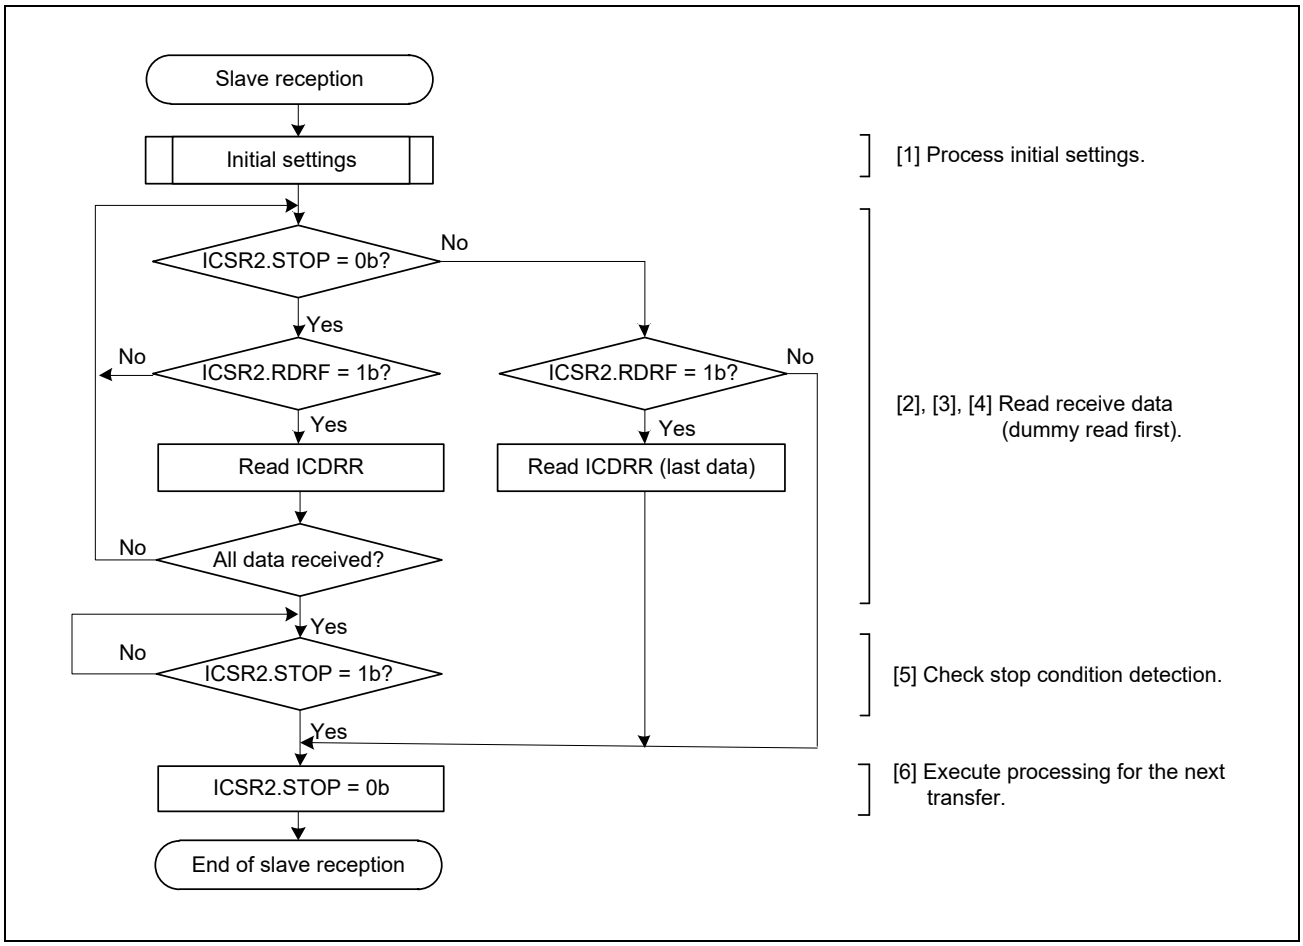

Figure 7.7-18 Example Slave Reception Flow

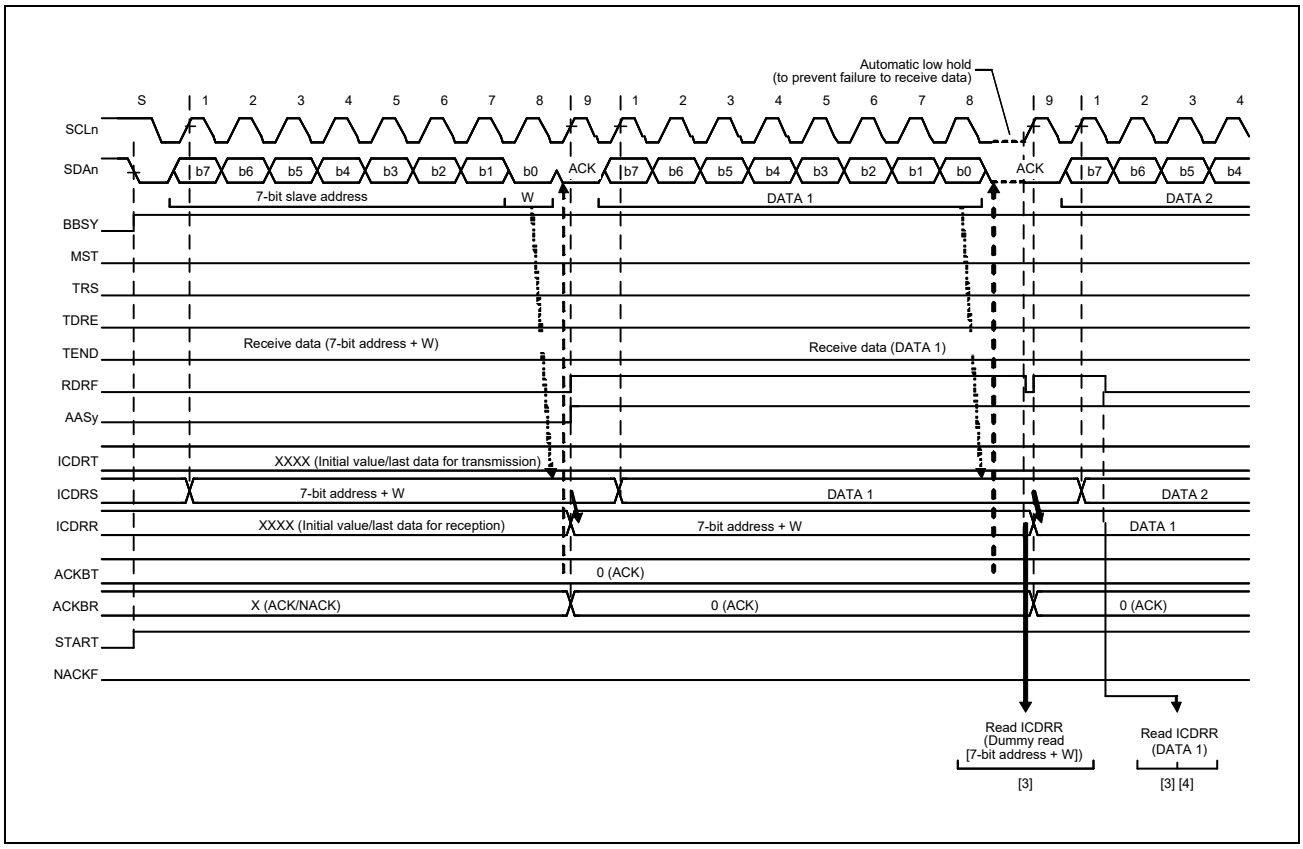

Figure 7.7-19 Slave Receive Operation Timing (1) with 7-Bit Address Format, when RDRFS = 0b

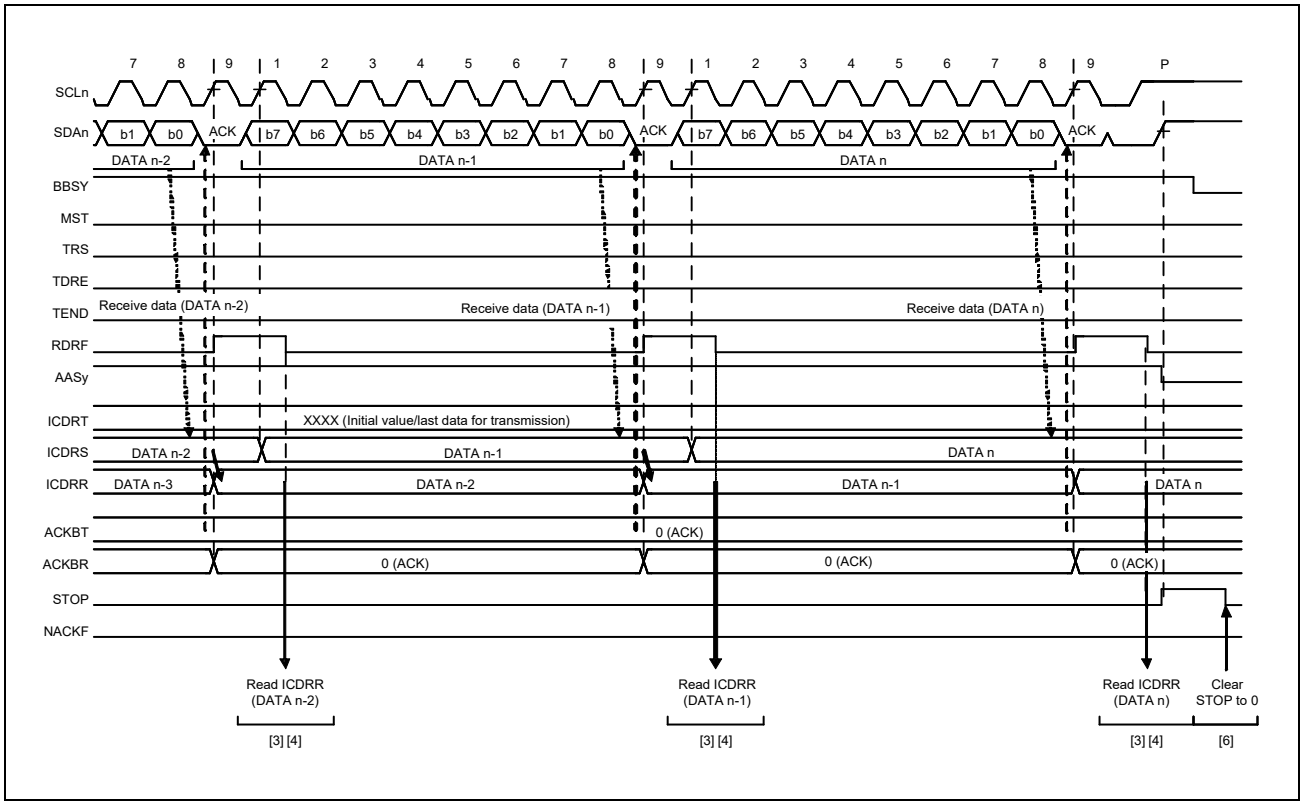

Figure 7.7-20 Slave Receive Operation Timing (2) when RDRFS = 0b

7.7.4 SCL Synchronization Circuit

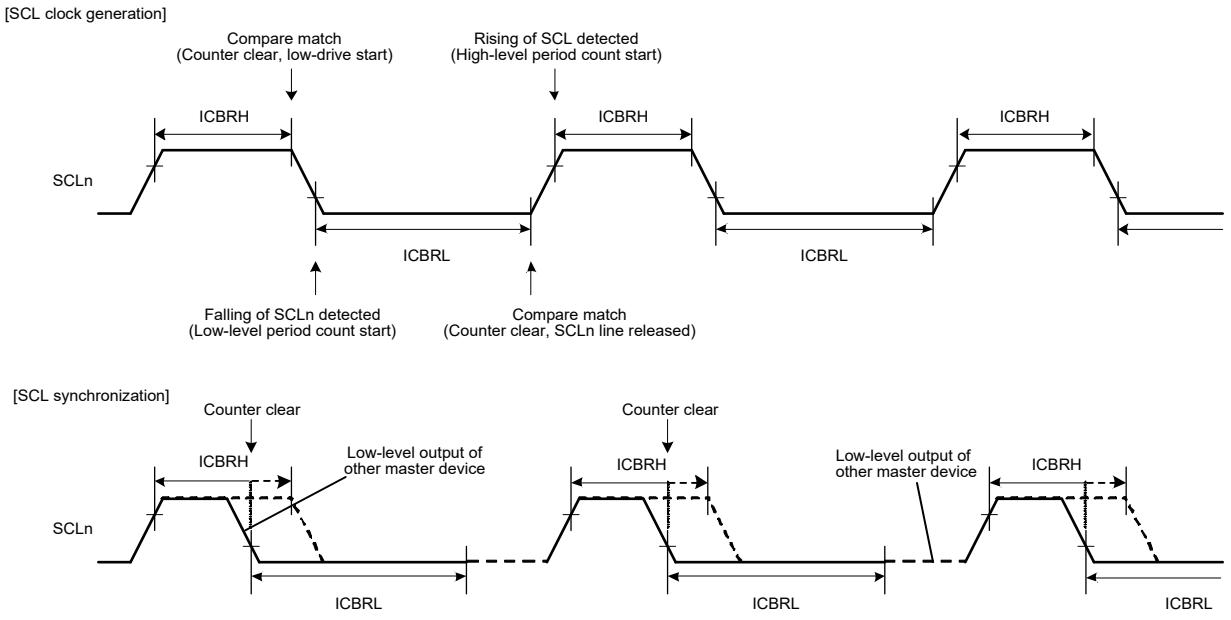
For generation of the SCL clock, RIIC starts counting the value for the high-level period specified in ICBRH when it detects a rising edge on the SCLn line, and drives the SCLn line low when it completes counting. When RIIC detects the falling edge of the SCLn line, it starts counting the value for the low-level period specified in ICBRL, and then stops driving the SCLn line, releasing the line when it completes counting. The RIIC repeats this process to generate the SCL clock.

If multiple master devices are connected to the I^2C bus, a collision of SCL signals might arise because of contention with another master device. In such cases, the master devices must synchronize their SCL signals. Because this synchronization of SCL signals must be bit by bit, RIIC is equipped with an SCL synchronization circuit to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When RIIC detects a rising edge on the SCLn line and starts counting the high-level period specified in ICBRH, and the level on the SCLn line falls because an SCL signal is being generated by another master device, RIIC performs the following:

1. Stops counting when it detects the falling edge.
2. Drives the level on the SCLn line low.
3. Starts counting the low-level period specified in ICBRL.

When the RIIC finishes counting the low-level period, it stops driving the SCLn line low to release the line. If the low-level period of the SCL clock signal from the other master device is longer than the low-level period set in the RIIC, the low-level period of the SCL signal is extended. When the low-level period for the other master device ends, the SCL signal rises because the SCLn line is released. When the RIIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, when SCL signals from more than one master are contending, the high-level period of the SCL signal is synchronized with that of the clock with the narrower period, and the low-level period of the SCL signal is synchronized with that of the clock with the broader period. However, such synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1b.



Note: ICBRH: I²C Bus Bit Rate High-Level Register (SCL clock high-level period counter)
ICBRL: I²C Bus Bit Rate Low-Level Register (SCL clock low-level period counter)

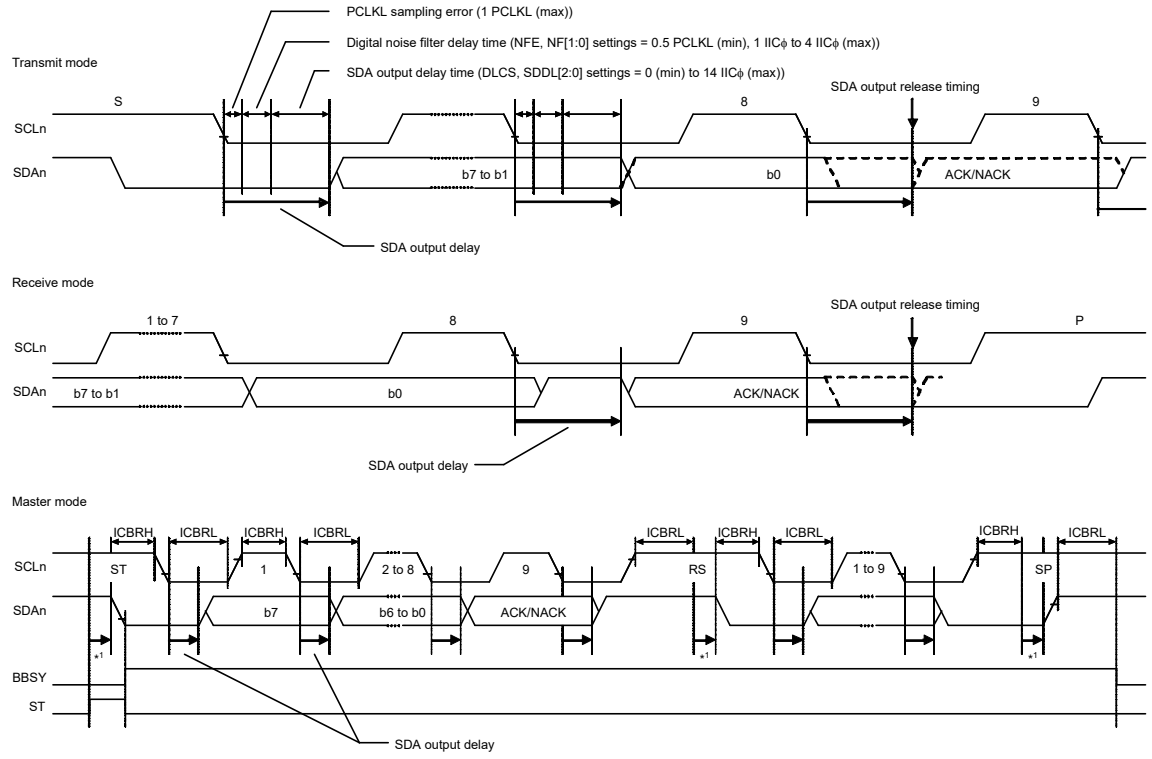
Figure 7.7-21 Generation and Synchronization of SCL Signal from RIIC

7.7.5 SDA Output Delay Function

The RIIC module provides a function for delaying the output on the SDA line. The delay can be applied to all outputs on the SDA line, including the issuing of start, restart, and stop conditions, data, and the ACK and NACK signals.

With this function, SDA output is delayed from the detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval during which the SCL clock is low. This approach helps prevent erroneous operation of communications devices, with the aim of satisfying the 300 ns minimum data-hold time requirement of the SMBus specification. The output delay function is enabled by setting the SDDL[2:0] bits in ICMR2 to any value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled, for example, the DLCS bit in ICMR2 selects the clock source for the SDA output delay counter, either as the internal base clock (IICϕ) for the RIIC module or as the internal base clock divided by two (IICϕ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. When the delay count is reached, the RIIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.



Note 1. The output delay function is set by the DLCS and SDDL[2:0] bits when a start (ST), restart (RS), or stop (SP) condition is issued.

Figure 7.7-22 SDA Output Delay Function

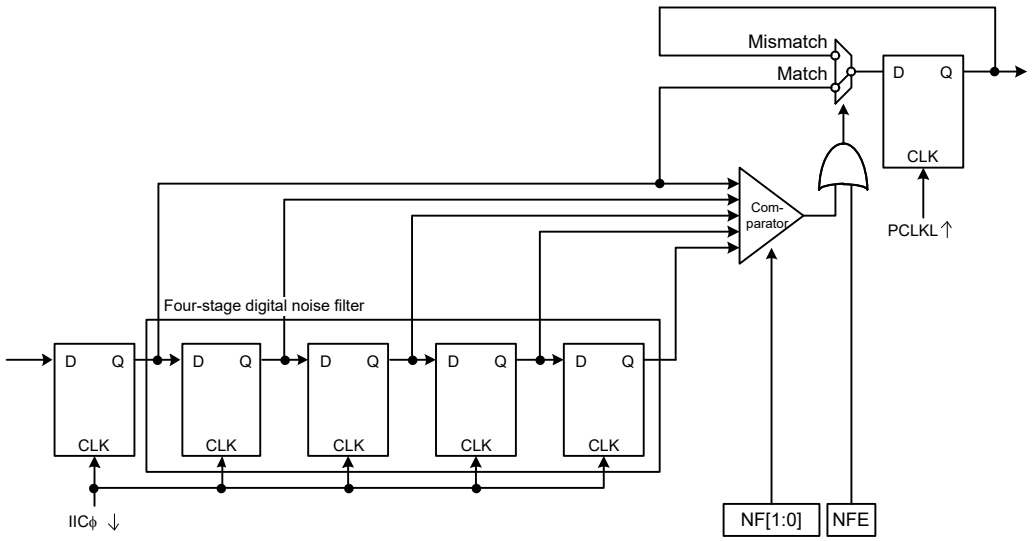
7.7.6 Digital Noise Filter Circuits

The internal circuitry sees the states of the SCLn and SDAn pins through analog and digital noise-filter circuits. **Figure 7.7-23** shows a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the RIIC consists of four flip-flop circuit stages connected in series, and a match- detection circuit.

The number of valid stages in the digital noise filter is selected in the NF[1:0] bits in ICMR3. The selected number of valid stages determines the noise-filtering capability as a period from 1 to 4 IICϕ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the RIICϕ signal. When the input signal level matches the output level of the number of valid flip-flop circuit stages as selected in the NF[1:0] bits in ICMR3, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is saved.



Note: NFE: Digital Noise Filter Circuit Enable bit
NF[1:0]: Noise Filter Stage Select bits

Figure 7.7-23 Digital Noise Filter Circuit Block Diagram

7.7.7 Address Match Detection

IIC can set three unique slave addresses in addition to the general call address and host address. The slave addresses can be 7-bit or 10-bit slave addresses.

7.7.7.1 Slave-Address Match Detection

IIC can set three unique slave addresses and has a slave address detection function for each unique slave address. When the SARyE bit (y = 0 to 2) in ICSER is set to 1b, the slave addresses set in SARUy and SARLy (y = 0 to 2) can be detected.

When the RIIC detects a match of the set slave address, the associated AASy (y = 0 to 2) flag in ICSR1 is set to 1b on the rising edge of the 9th SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1b by the subsequent R/W# bit. This causes a receive data full interrupt (IICn_RXI) or transmit data empty interrupt (IICn_TXI) to be generated. The AASy flag identifies which slave address is specified.

Figure 7.7-24 to **Figure 7.7-26** show the AASy flag set timing in three cases.

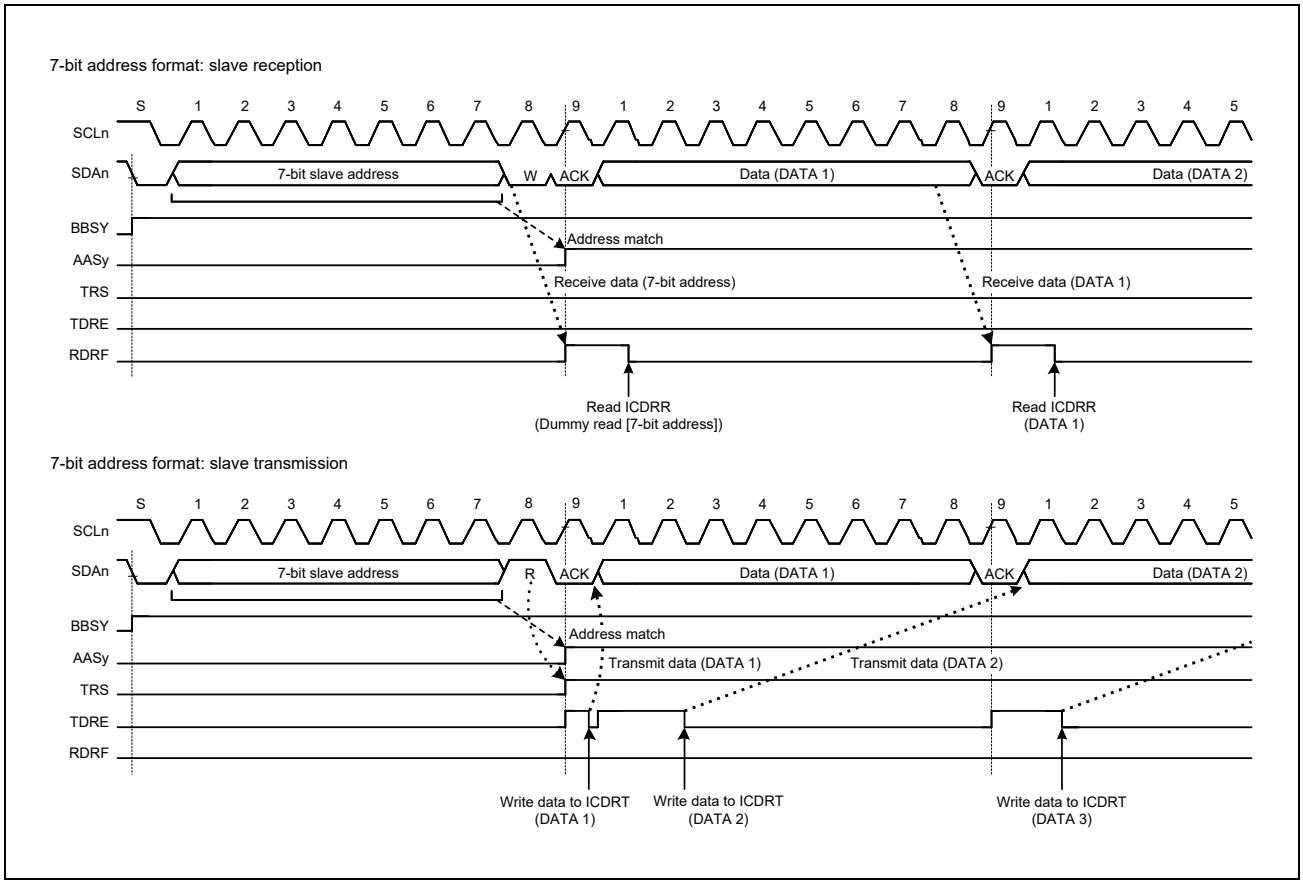


Figure 7.7-24 AASy Flag Set Timing with 7-Bit Address Format

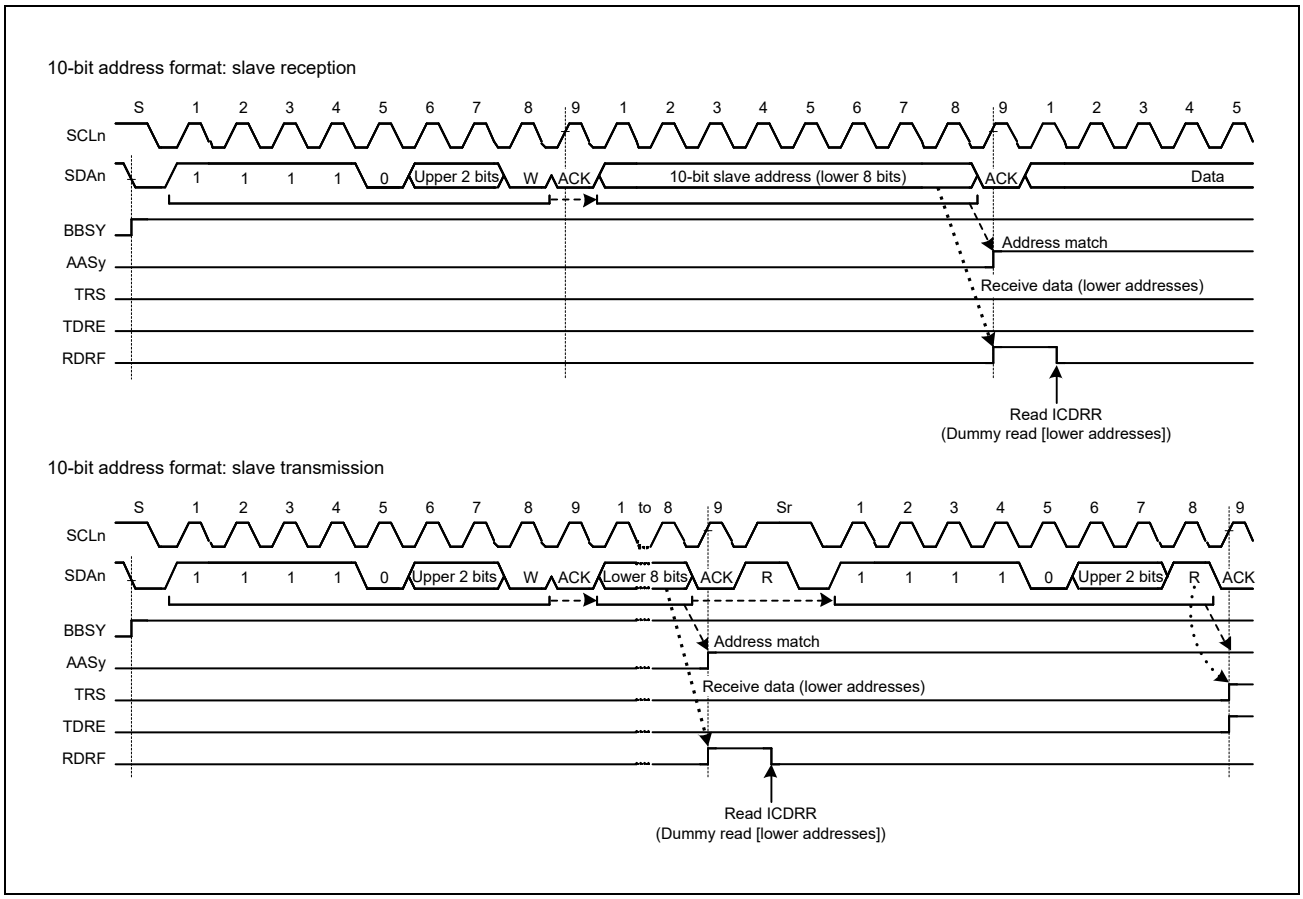

Figure 7.7-25 AASy Flag Set Timing with 10-Bit Address Format

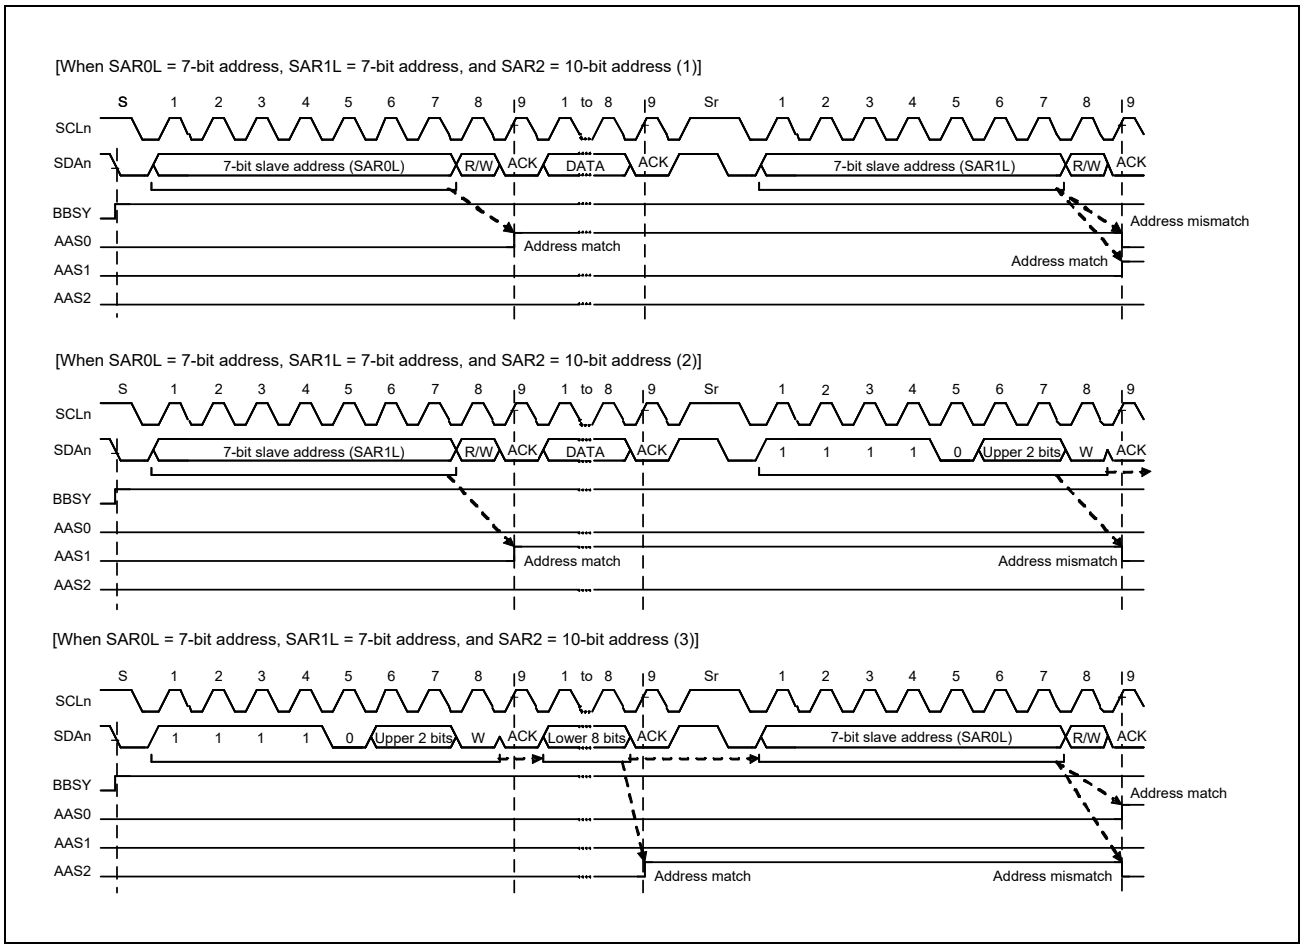

Figure 7.7-26 AASy Flag Set and Clear Timing with 7- and 10-Bit Address Formats Mixed

7.7.7.2 Detection of General Call Address

The RIIC provides detection of the general call address (0000_000b + 0b [W]). General call address detection is enabled by setting the GCAE bit in ICSER to 1b.

If the address received after a start or restart condition is issued is 0000_000b + 1b [R] (start byte), the RIIC recognizes this as the address of a slave device with an all-zero address, but not as the general call address.

When the RIIC detects the general call address, both the GCA flag in ICSR1 and the RDRF flag in ICSR2 set to 1b on the rising edge of the 9th cycle of the SCL clock. This leads to the generation of a receive data full interrupt (IICn_RXI). The value of the GCA flag can be checked to confirm that the general call address is transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

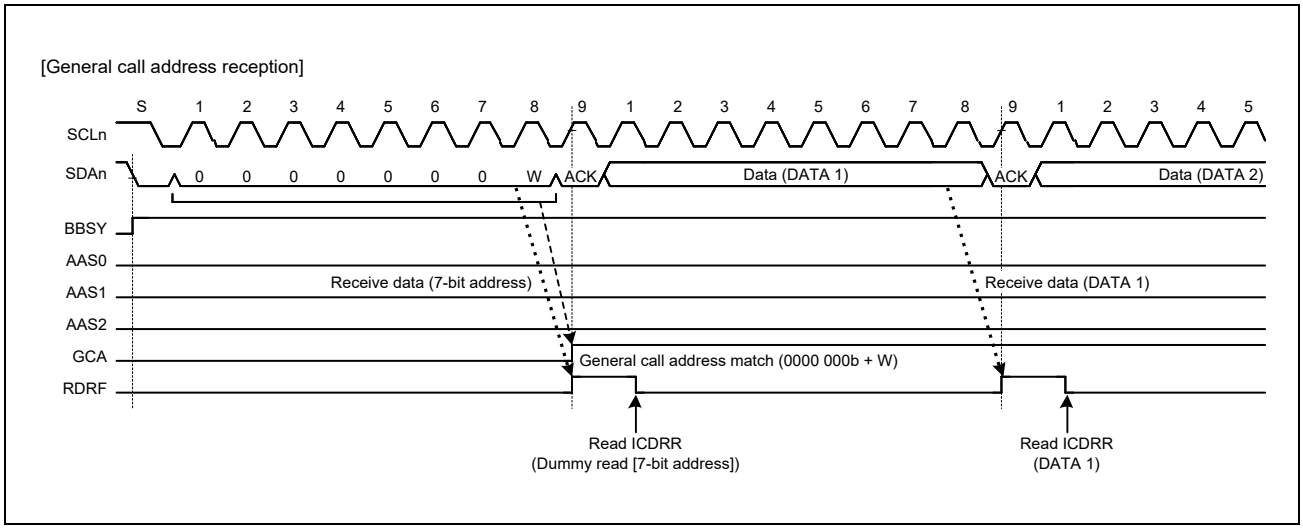

Figure 7.7-27 Timing of GCA Flag Setting during Reception of General Call Address

7.7.7.3 Device ID Address Detection

The RIIC module provides detection of the device ID address in compliance with the I^2C bus specification.

When RIIC receives 111_1100b as the first seven bits of the first byte after a start or restart condition is issued with the DIDE bit in ICSER set to 1b, it recognizes the address as a device ID address, sets the DID flag in ICSR1 to 1b on the rising edge of the 9th SCL clock cycle when the subsequent R/W# bit is 0b, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the RIIC sets the associated AASy (y = 0 to 2) flag in ICSR1 to 1b.

When the first byte received after the issue of a start or restart condition matches the device ID address (1111_100b) again and the subsequent R/W# bit is 1b, RIIC does not compare the second and subsequent bytes, and sets the ICSR2.TDRE flag to 1b.

In the device ID address detection function, RIIC sets the DID flag to 0b if a match with the RIIC slave address is not obtained, or a match with the device ID address is not obtained after a match with the RIIC slave address, and a restart condition is detected. If the first byte after the detection of a start or restart condition matches the device ID address (1111_100b) and the R/W# bit is 0b, RIIC sets the DID flag to 1b and compares the second and subsequent bytes with the slave address of RIIC. If the R/W# bit is 1b, the DID flag holds the previous value and RIIC does not compare the second and subsequent bytes. In this way, reception of a device ID address can be checked by reading the DID flag after confirming that TDRE = 1b.

Additionally, prepare the device ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device ID field as normal transmit data. For details on the information that must be included in device ID fields, contact NXP Semiconductors.

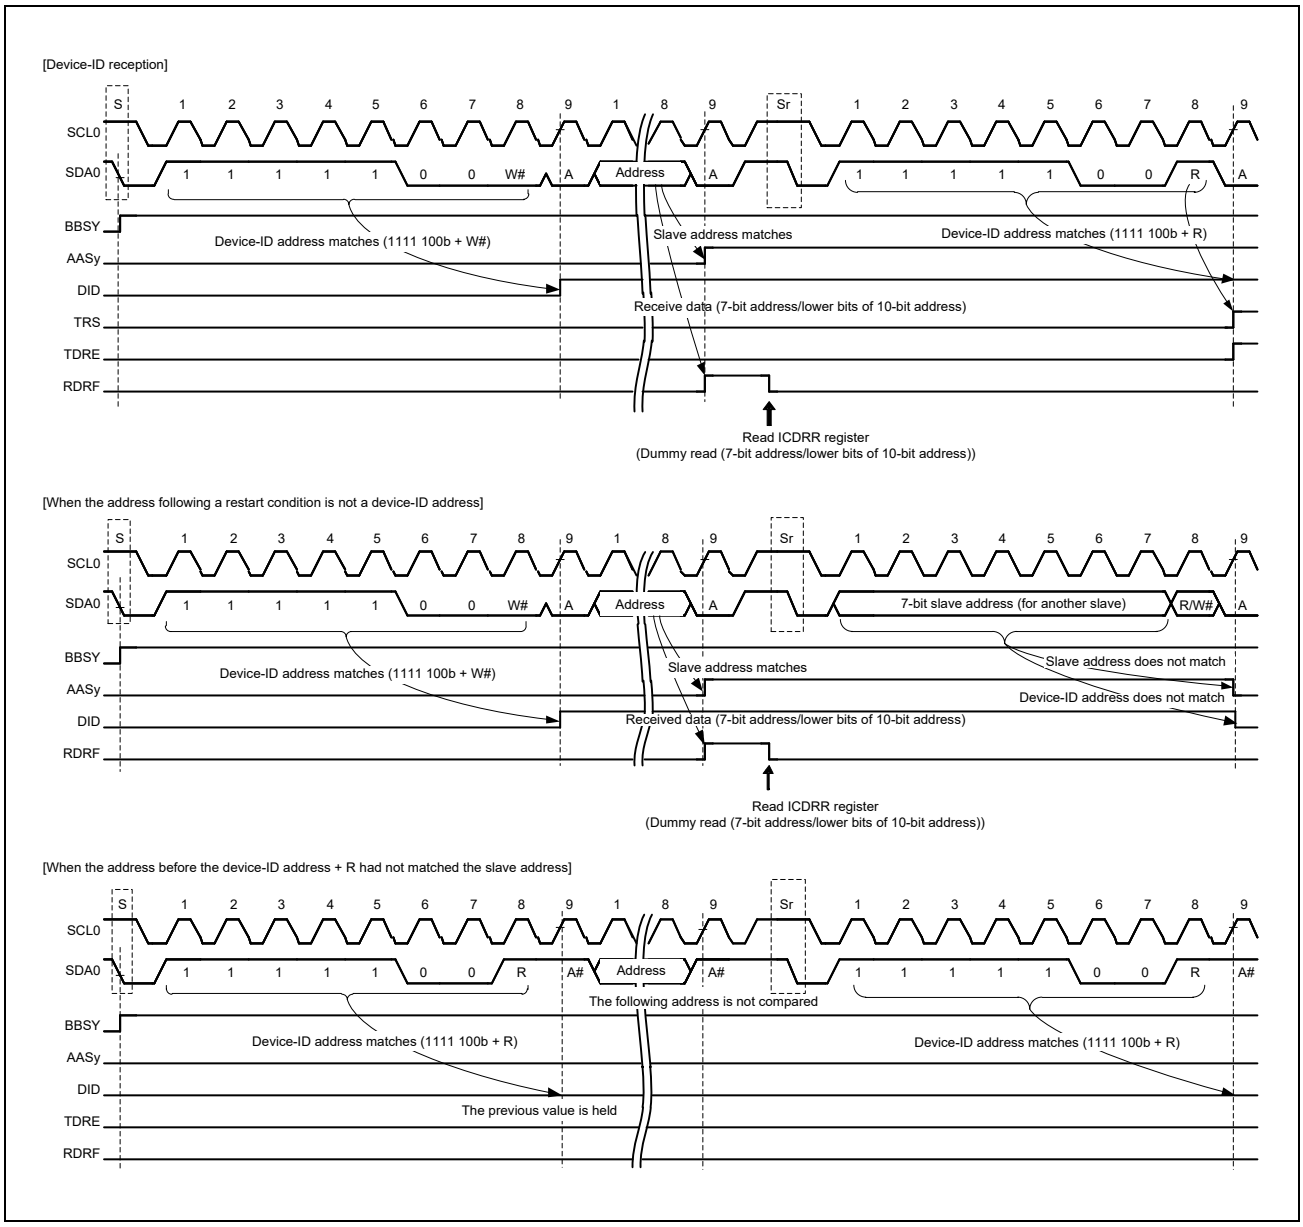

Figure 7.7-28 AASy and DID Flag Set and Clear Timing during Reception of Device ID

7.7.7.4 Host Address Detection

The RIIC provides host address detection while the SMBus is operating. When the HOAE bit in ICSER is set to 1 while the SMBS bit in ICMR3 is 1b, the RIIC can detect the host address (0001 000b) in slave receive mode (MST and TRS bits = 00b in ICCR2).

When the RIIC detects the host address, the HOA flag in ICSR1b is set to 1 on the rising edge of the 9th SCL clock cycle. At the same time, the RDRF flag in ICSR2 is set to 1b when the R/W# bit is 0b. This causes a receive data full interrupt (IICn_RXI) to be generated. The HOA flag indicates that the host address was sent from another device.

If the bit following the host address (0001 000b) is a read bit (R/W# bit = 1b), the RIIC can also detect the host address. After the host address is detected, the RIIC operates in the same manner as in normal slave operation.

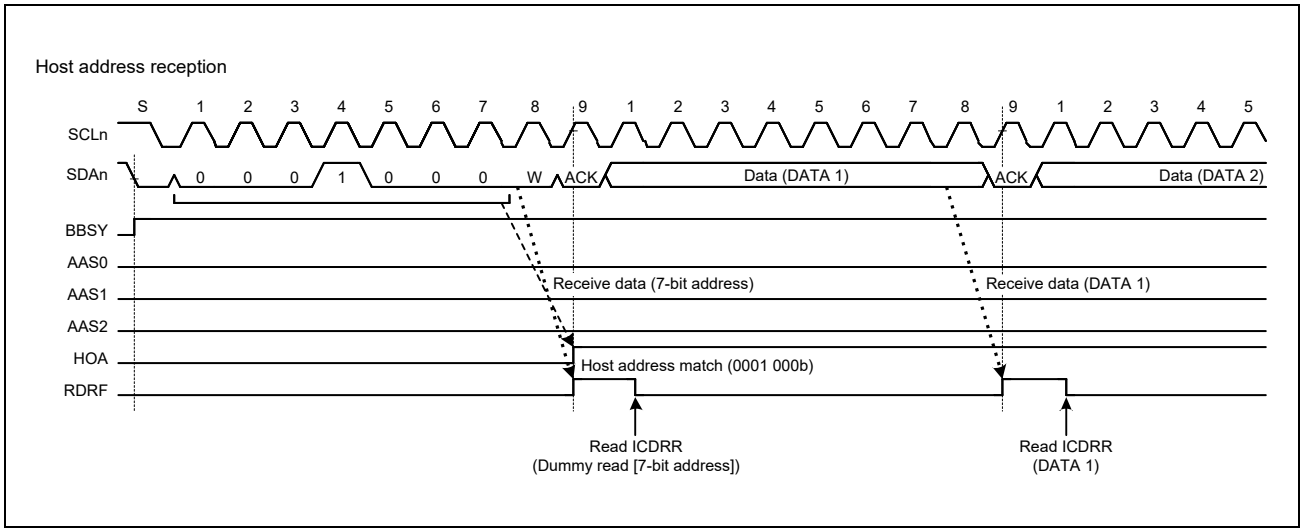

Figure 7.7-29 HOA Flag Set Timing during Reception of Host Address

7.7.8 Automatic Low-Hold Function for SCL

7.7.8.1 Function to Prevent Wrong Transmission of Transmit Data

If the I²C Bus Shift Register (ICDRS) is empty when data has not been written to the I²C Bus Transmit Data Register (ICDRT) with the RIIC in transmission mode (TRS bit = 1b in ICCR2), the SCLn line is automatically held at the low level over subsequent intervals. This low-hold period is extended until the transmit data is written, which prevents the unintended transmission of erroneous data.

- Master transmit mode
  - Low-level interval after a start or restart condition is issued
  - Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.
- Slave transmit mode
  - Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

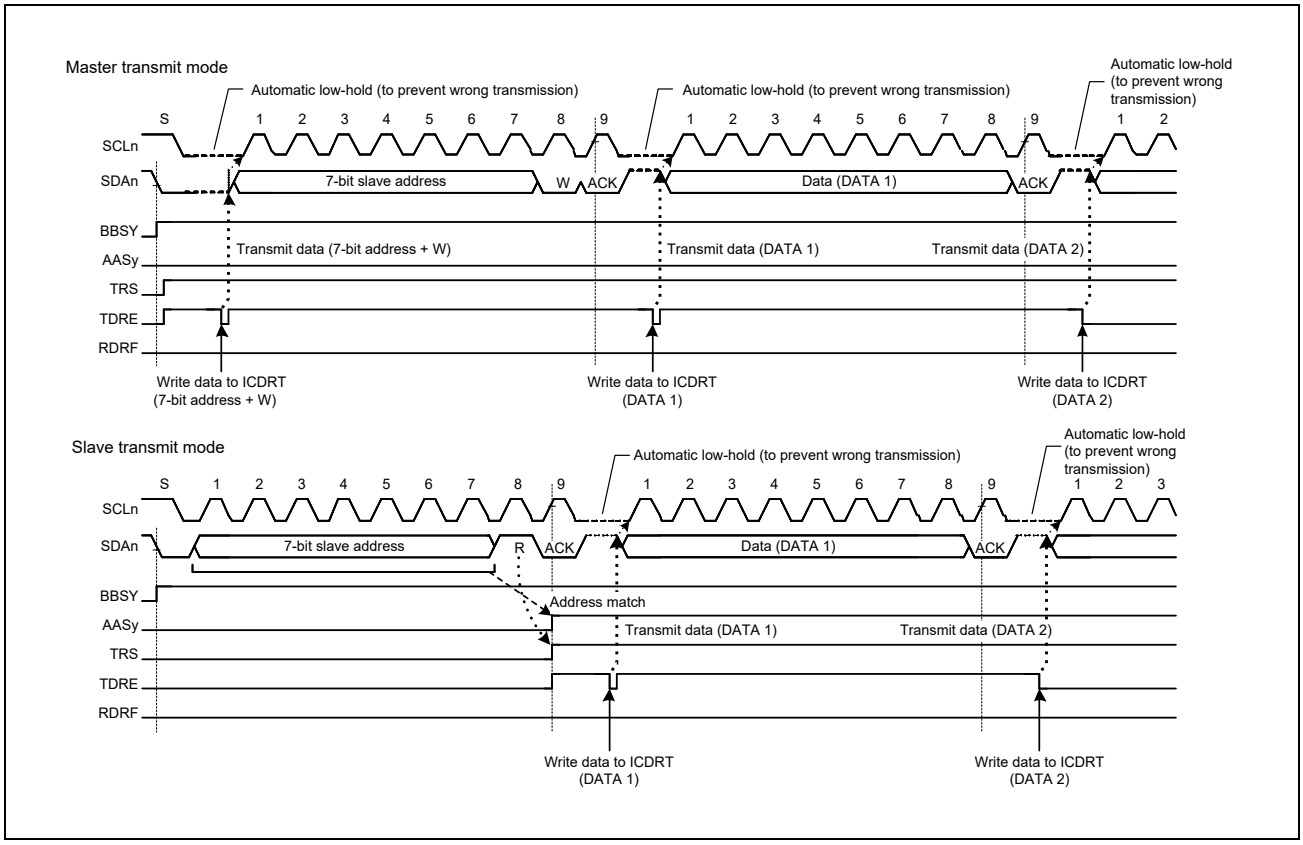

Figure 7.7-30 Automatic Low-Hold Operation in Transmit Mode

7.7.8.2 NACK Reception Transfer Suspension Function

This function suspends transfer operation when NACK is received in transmit mode (TRS bit = 1b in ICCR2). This function is enabled when the NACKE bit in ICFER is set to 1b. If the next transmit data is already written (TDRE flag = 0b in ICSR2) when NACK is received, the next data transmission on the falling edge of the 9th SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the data transmission is suspended by this function (NACKF flag = 1b in ICSR2), the following data transmission and data reception are not started. To resume data transfer, set the NACKF flag to 0b. In master transmit mode, restart data transfer by setting the NACKF flag to 0b after generating a restart condition, or restart data transfer from a start condition after generating a stop condition and setting the NACKF flag to 0b.

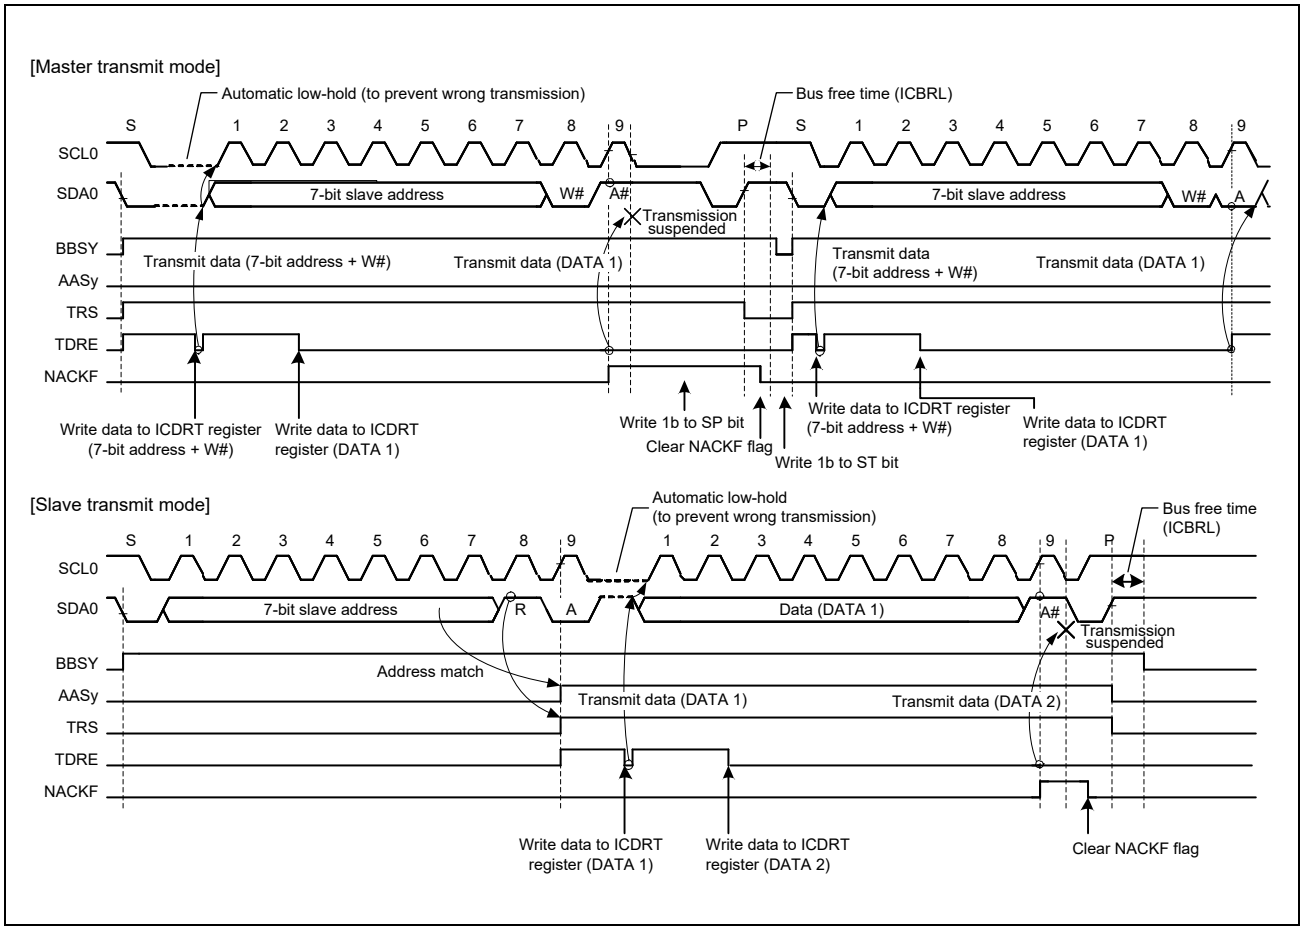

Figure 7.7-31 Suspension of Data Transfer when NACK is Received, when NACKE = 1

7.7.8.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1b in ICSR2) in receive mode (TRS = 0b in ICCR2), the RIIC holds the SCLn line low automatically immediately before the next data is received to prevent failure to receive data.

This function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIIC slave address is designated after a stop condition is issued. This function does not interfere with other communication because the RIIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.

Periods in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

7.7.8.3.1 1-byte receive operation and automatic low-hold function using the WAIT bit

When the WAIT bit in ICMR3 is set to 1b, RIIC performs a 1-byte receive operation using the WAIT bit function. Additionally, when the ICMR3.RDRFS bit is 0b, RIIC automatically sends the ACKBT bit value in ICMR3 for the acknowledge bit in the period from the falling edge of the 8th SCL clock cycle to the falling edge of the 9th SCL clock cycle, and automatically holds the SCLn line low on the falling edge of the 9th SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables byte-wise receive operation.

The WAIT bit function is enabled for receive frames after a match with the RIIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

7.7.8.3.2 1-byte receive operation (ACK/NACK transmission control) and automatic low-hold function using the RDRFS bit

When the RDRFS bit in ICMR3 is set to 1b, the RIIC performs a 1-byte receive operation using the RDRFS bit function.

When the RDRFS bit is set to 1b, the RDRF (receive data full) flag in ICSR2 is set to 1 on the rising edge of the 8th SCL clock cycle, and the SCLn line is automatically held low on the falling edge of the 8th SCL clock cycle. This low-hold is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation through the ACK or NACK transmission control based on the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the RIIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

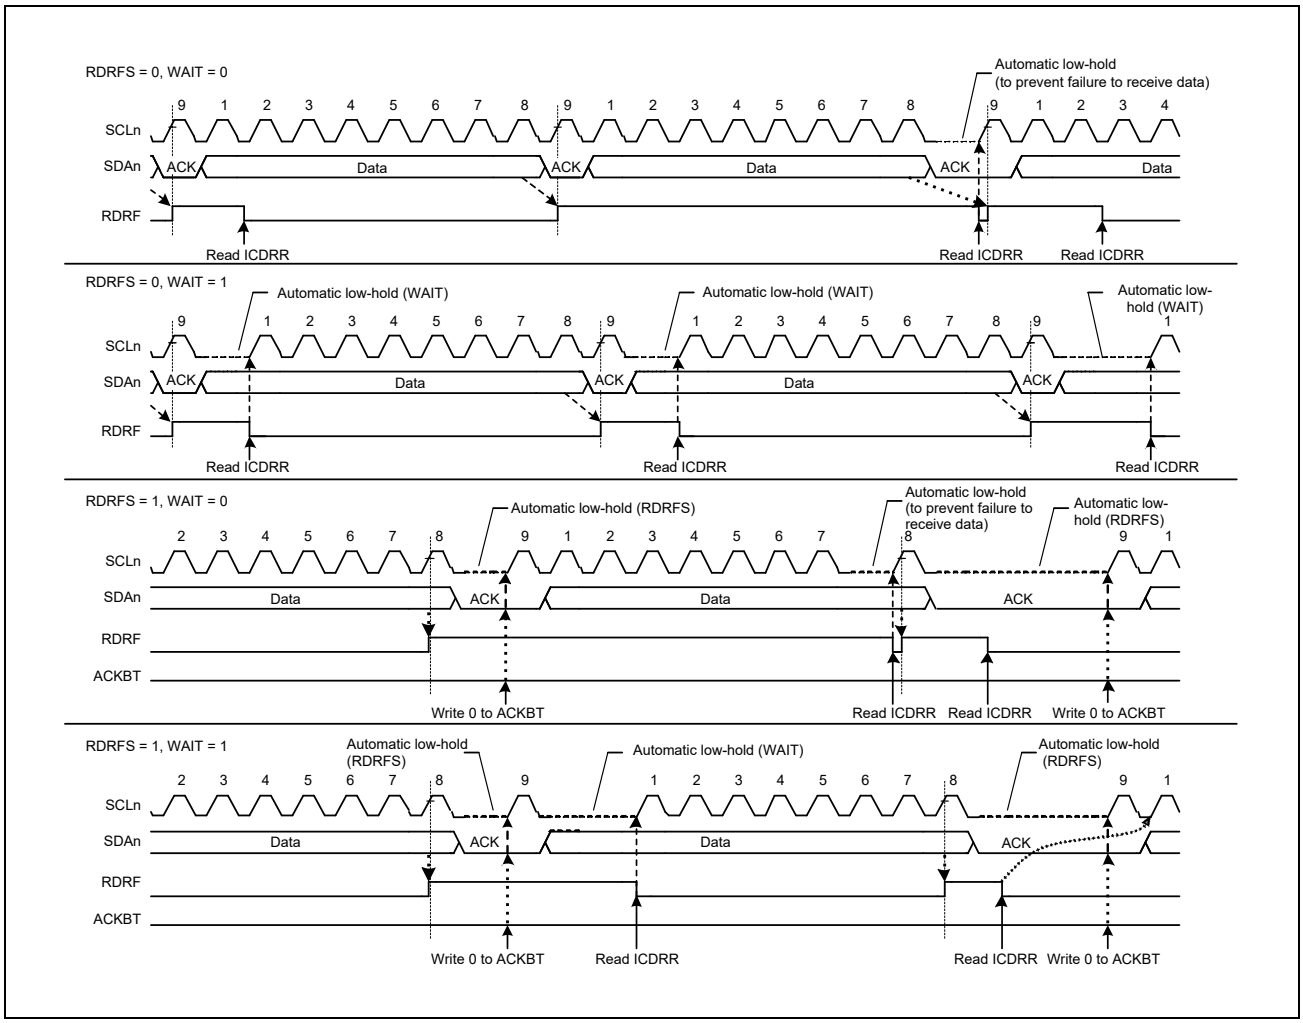

Figure 7.7-32 Automatic Low-Hold Operation in Receive Mode using the RDRFS and WAIT Bits

7.7.9 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I²C bus standard, RIIC provides functions to prevent double-issue of a start condition, detect arbitration-lost during the transmission of NACK, and detect arbitration lost in slave transmit mode.

7.7.9.1 Master Arbitration-Lost Detection (MALE Bit)

RIIC drives the SDAn line low to issue a start condition. However, if the SDAn line was already driven low by another master device issuing a start condition, RIIC regards its own start condition as an error and considers this a loss in arbitration.

Priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1b while the bus is busy (BBSY flag = 1b in ICCR2), RIIC regards this as a double-issuing-of-start- condition error and considers itself to have lost the arbitration. This prevents a failure of transfer resulting from a start condition issued while transfer is in progress.

When a start condition is issued successfully, if the transmit data including the address bits (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high- impedance state) and a low level is detected on the SDAn line, RIIC loses the arbitration.

After a loss in arbitration of mastership, the RIIC immediately enters slave receive mode. If a slave address, including the general call address, matches its own address at this time, the RIIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICFER is 1b (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Mismatching of the internal level for output on SDA and the level on the SDAn line after a start condition was issued by setting the ST bit in ICCR2 to 1b while the BBSY flag in ICCR2 is set to 0b (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1b (start condition double-issue error) while the BBSY flag is 1b
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in master transmit mode (MST and TRS bits = 11b in ICCR2).

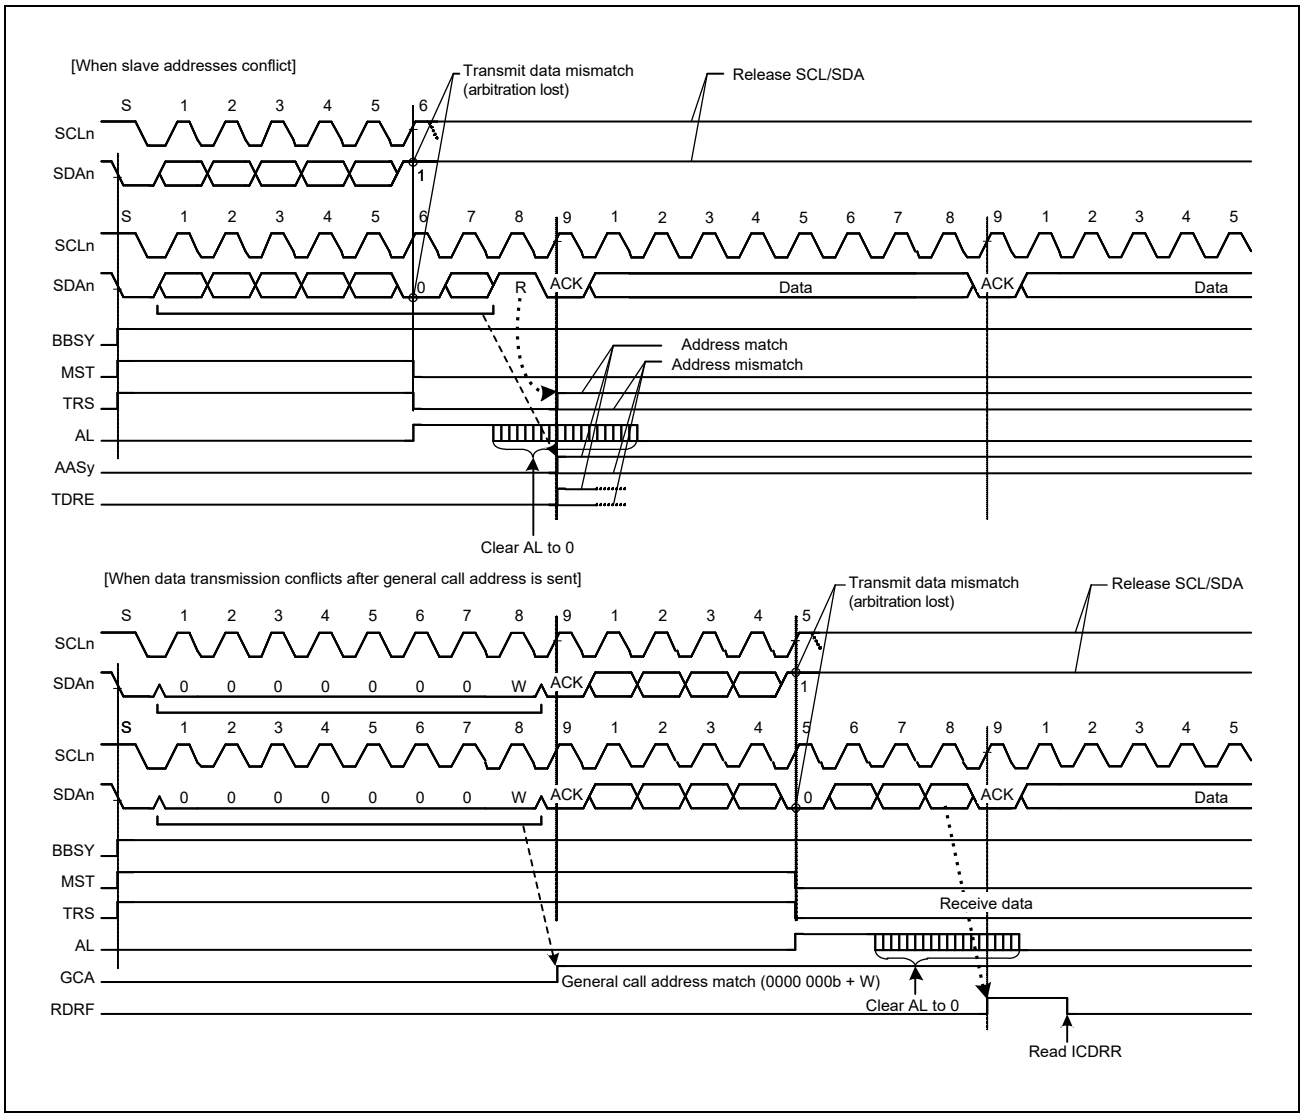

Figure 7.7-33 Examples of Master Arbitration-Lost Detection when MALE = 1

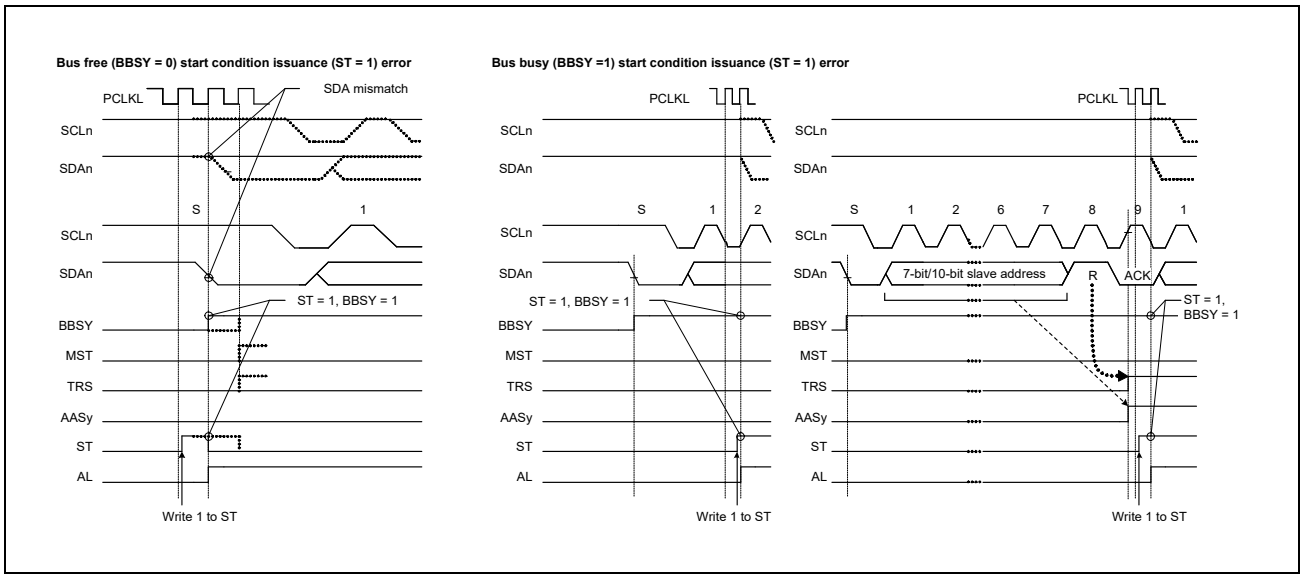

Figure 7.7-34 Arbitration-Lost when Start Condition is issued when MALE = 1

7.7.9.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

This function causes arbitration to be lost if the internal SDA output level does not match the level on the SDAn line during transmission of NACK in receive mode. Arbitration is lost because of a conflict between NACK and ACK transmissions when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send or receive the same information through a single slave device. **Figure 7.7-35** shows an example of arbitration-lost detection during the transmission of NACK.

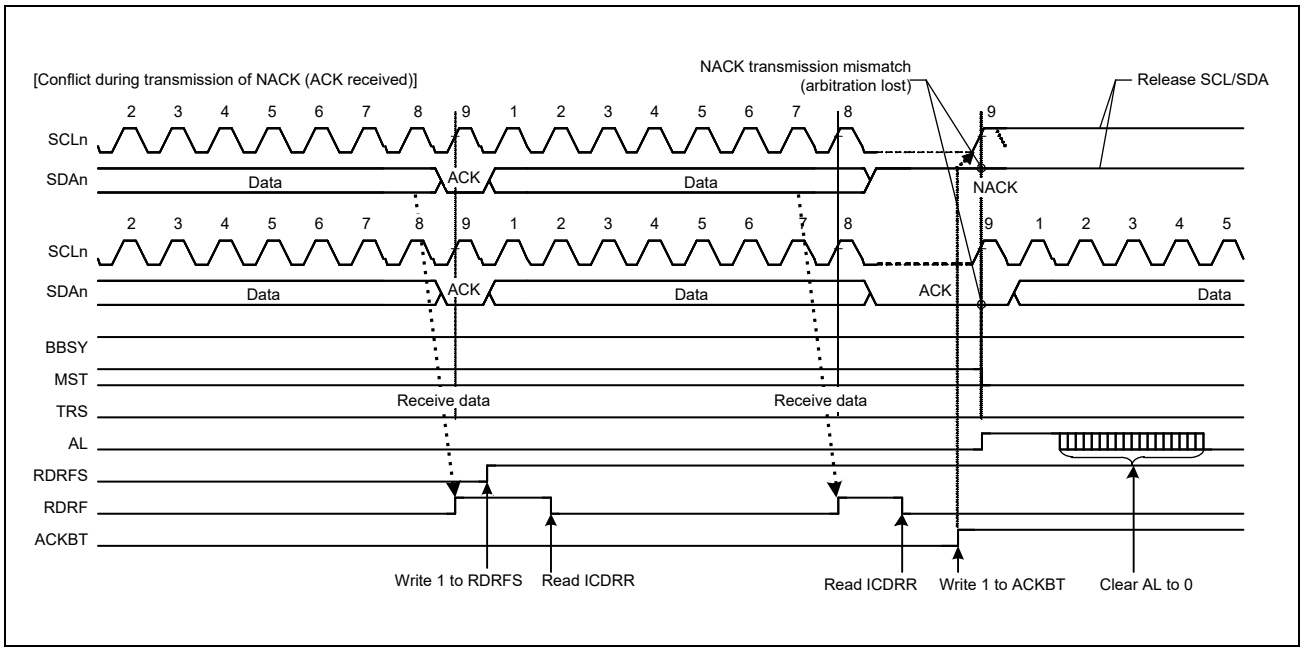

Figure 7.7-35 Example of Arbitration-Lost Detection during Transmission of NACK when NALE = 1

The following description explains arbitration-lost detection using an example in which two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in either master A or B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Master A sends NACK when it has received the 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the required 4 bytes of data.

The NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect the ACK transmitted by master B and issues a stop condition. The stop condition issue conflicts with the SCL clock output of master B, which disrupts communication.

When RIIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost. If arbitration is lost during transmission of NACK, RIIC immediately cancels the slave match condition and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing, such as FFh transmission processing, which is required if the UDID (Unique Device Identifier) of the assigned address does not match in the Get UDID general processing after the Assign Address command.

The RIIC detects arbitration-lost during transmission of NACK when the following condition is met with the NALE bit in ICFER set to 1b (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKBT bit = 1b in ICMR3).

7.7.9.3 Slave Arbitration-Lost Detection (SALE Bit)

This function causes arbitration to be lost if the transmit data (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state), and the low level is detected on the SDAn line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When RIIC loses slave arbitration, RIIC is immediately released from the slave-matched state and enters slave receive mode.

This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing for the transmission of FFh.

IIC detects slave arbitration-lost when the following condition is met with the SALE bit in ICFER set to 1b (slave arbitration- lost detection enabled).

[Condition for slave arbitration-lost]

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDAn line in slave transmit mode (MST and TRS bits = 01b in ICCR2).

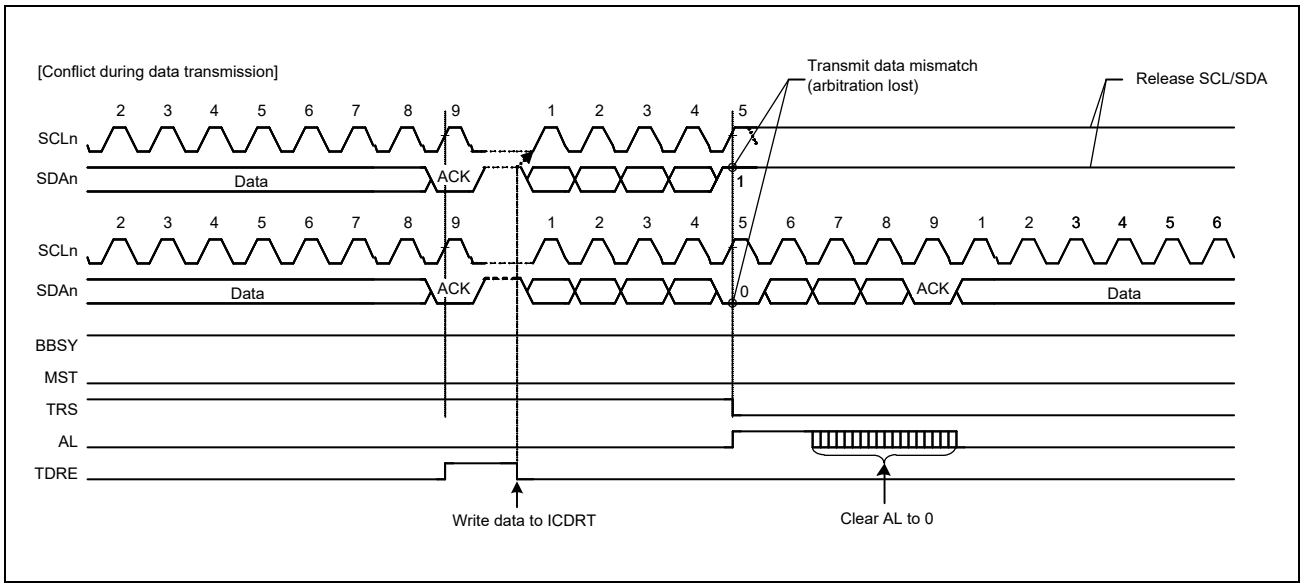

Figure 7.7-36 Example of Slave Arbitration-Lost Detection when SALE = 1

7.7.10 Start, Restart, and Stop Condition Issuing Function

7.7.10.1 Issuing a Start Condition

IIC issues a start condition when the ST bit in ICCR2 is set to 1b. When the ST bit is set to 1b, a start condition request is made, and RIIC issues a start condition when the BBSY flag in ICCR2 is 0b (bus free state). When a start condition is issued normally, RIIC automatically shifts to the master transmit mode.

To issue a start condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure that the time set in ICBRH and the start condition hold time elapse.
3. Drive the SCLn line low (high level to low level).
4. Detect low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

7.7.10.2 Issuing a Restart Condition

IIC issues a restart condition when the RS bit in ICCR2 is set to 1.

When the RS bit is set to 1b, a restart condition request is made, and RIIC issues a restart condition when the BBSY flag in ICCR2 is 1b (bus busy state) and the MST bit in ICCR2 is 1b (master mode).

To issue a restart condition:

1. Release the SDAn line.
2. Ensure that the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRL and the restart condition setup time elapse.
5. Drive the SDAn line low (high level to low level).
6. Ensure the time set in ICBRH and the restart condition hold time elapse.
7. Drive the SCLn line low (high level to low level).
8. Detect a low level on the SCLn line and ensure the low-level period of the SCLn line set in ICBRL elapses.

Note: When issuing restart condition requests, write the slave address to ICDRT after confirming that ICCR2.RS = 0b. Data written while ICCR2.RS = 1b is not forwarded because of the retransmission condition before the occurrence.

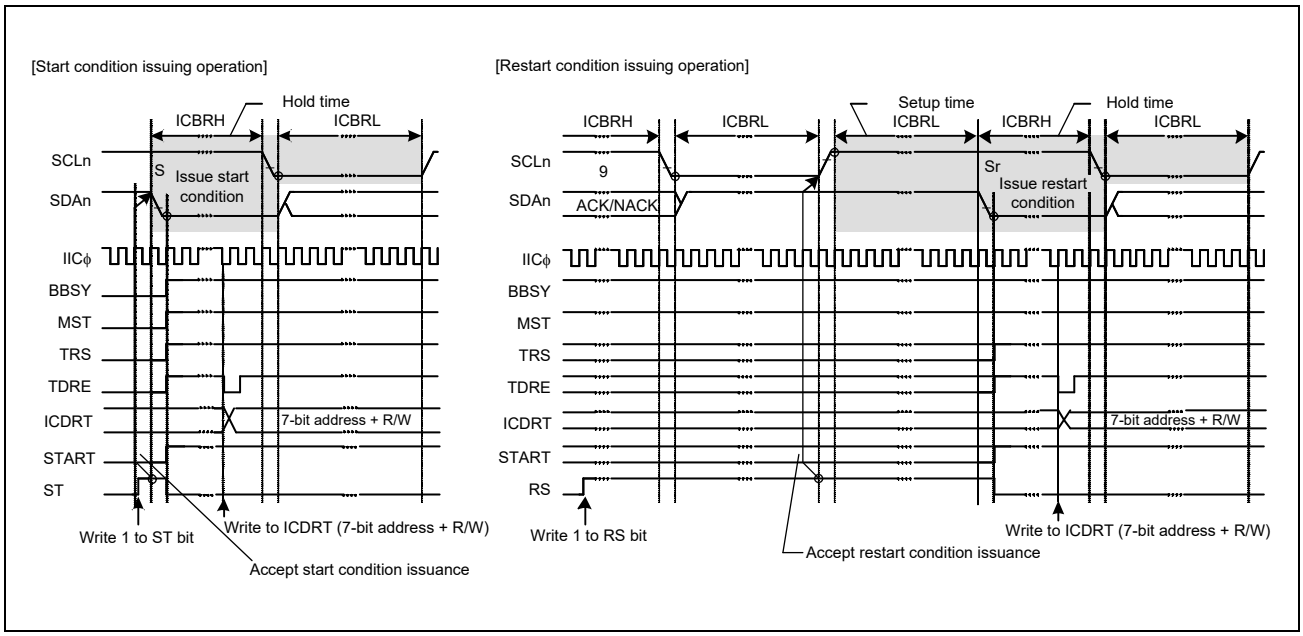

Figure 7.7-37 Start and Restart Condition Issue Timing using the ST and RS Bits

Figure 7.7-38 shows the operation timing when a restart condition is issued after the master transmission.

To issue a restart condition after the master transmission:

1. Initialize the RIIC using the details provided in **7.7.3.2 Initial Settings**.
2. Read the BBSY flag in IICR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1b (start condition issuance request). On receiving the request, the RIIC issues a start condition. At the same time, the BBSY flag and the START flag in ICSR2 are automatically set to 1b and the ST bit is automatically set to 0b. If the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1b, the RIIC recognizes that a start condition is successfully issued as requested by the ST bit. The MST and TRS bits in ICCR2 are automatically set to 1b, placing the RIIC in master transmit mode. The TDRE flag in ICSR2 is also automatically set to 1b when the TRS bit is set to 1b.
3. Check that the TDRE flag in ICSR2 is 1b, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. After the transmit data is written to ICDRT, the TDRE flag is automatically set to 0b, the data is transferred from ICDRT to ICDRS, and the TDRE flag is again set to 1b. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode according to the value of the transmitted R/W# bit. If the value of the R/W# bit is 0b, the RIIC continues in master transmit mode. If the ICSR2.NACKF flag is 1b at this time, indicating that no slave device recognized the address or that there was an error in communications, write 1b to the ICCR2.SP bit to issue a stop condition. To transmit data with an address in the 10-bit format, start by writing 11110b, the 2 upper bits of the slave address, and W to ICDRT as the first address transmission. Then, as the second address transmission, write the 8 lower bits of the slave address to ICDRT.
4. After confirming that the TDRE flag in ICSR2 is 1b, write the data for transmission to the ICDRT register. The RIIC automatically holds the SCLn line low until the data for transmission is ready, and a restart or stop condition is issued.
5. After all bytes of data for transmission are written to the ICDRT register, wait until the value of the TEND flag in ICSR2 returns to 1b. Then, after checking that the START flag in ICSR2 is 1b, set the START flag in ICSR2 to 0b.

6. Set the RS bit in ICCR2 to 1b (restart condition issuance request). Upon receiving the request, the RIIC issues a restart condition.
7. After checking that the START flag in ICSR2 is 1b, write the value for transmission (the slave address and the R/W# bit) to ICDRT.

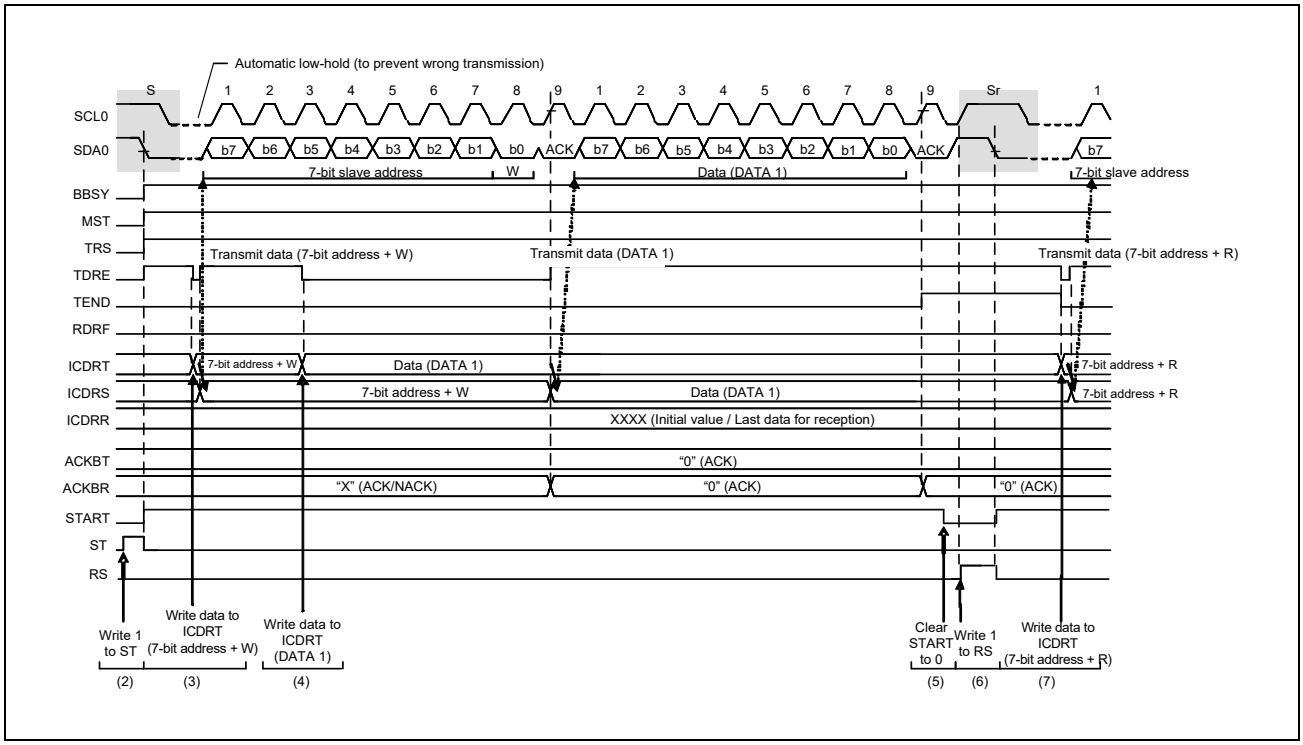

Figure 7.7-38 Restart Condition Issue Timing after Master Transmission

7.7.10.3 Issuing a Stop Condition

IIC issues a stop condition when the SP bit in ICCR2 is set to 1. When the SP bit is set to 1b, a stop condition request is made, and the RIIC issues a stop condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1b (master mode).

To issue a stop condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure that the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure that the time set in ICBRH and the stop condition setup time elapse.
5. Release the SDAn line (low level to high level).
6. Ensure the time set in ICBRL and the bus free time elapse.
7. Clear the BBSY flag to 0b to release the bus mastership.

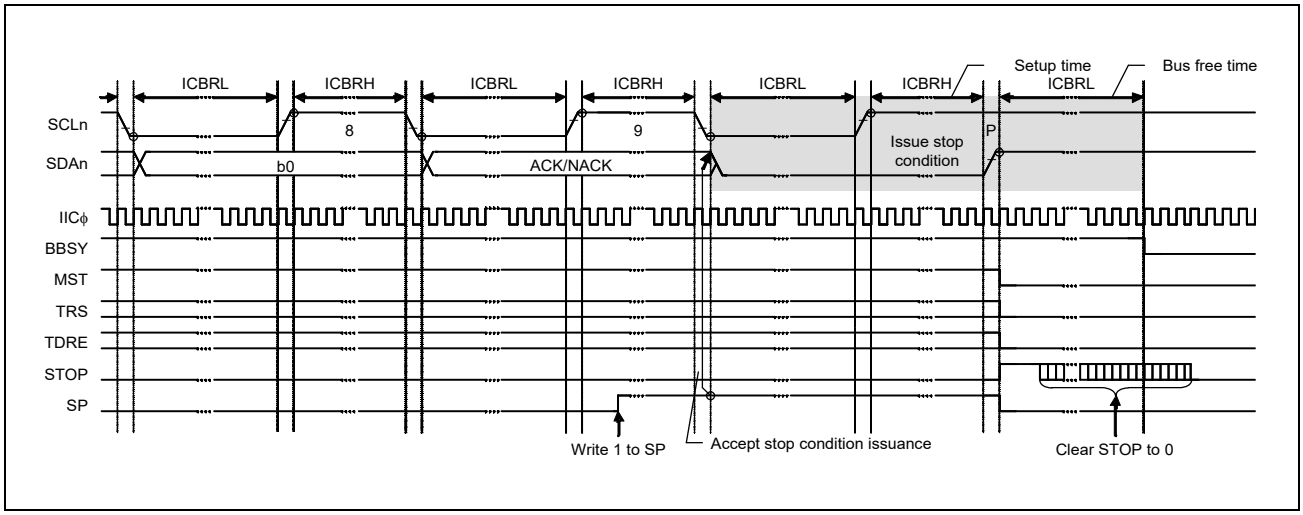

Figure 7.7-39 Stop Condition Issue Timing using the SP Bit

7.7.11 Bus Hanging

If the clock signals from the master and slave devices are out of synchronization because of noise or other factors, the I^2C bus might hang with a fixed level on the SCLn line or SDAn line.

To manage bus hanging, the RIIC has the following:

- A timeout function to detect hanging by monitoring the SCLn line
- A function for the output of an extra SCL clock cycle to release the bus from a hung state because of clock signals being out of synchronization
- An RIIC reset function
- An internal reset function

By checking the SCLO, SDAO, SCLI, and SDAI bits in ICCR1, it is possible to see whether the RIIC or its communicating partner is placing the SCLn or SDAn lines at the low level.

7.7.11.1 Timeout Function

The timeout function can detect when the SCLn line is stuck longer than the predetermined time. The RIIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.

The timeout function monitors the SCLn line state and counts the low-level or high-level period using the internal counter.

The timeout function resets the internal counter each time the SCLn line changes (rises or falls), but continues to count unless the SCLn line changes. If the internal counter overflows because no SCLn line changes, the RIIC can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICFER.TMOE bit is 1b. It detects a hung state when the SCLn line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1b) in master mode (ICCR2.MST bit is 1b)
- IIC slave address is detected (ICSR1 register is not 00h) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0b)
- The bus is free (ICCR2.BBSY flag is 0b) while a start condition is requested (ICCR2.ST bit is 1b)

The internal counter of the timeout function uses the internal reference clock (IICΦ) set in the CKS[2:0] bits in ICMR1 as a count source. It functions as a 16-bit counter when long mode is selected (TMOS bit = 0b in ICMR2) or a 14-bit counter when short mode is selected (TMOS bit = 1b).

The SCLn line level (low, high, or both levels) during which this counter is activated can be selected in the TMOH and TMOL bits in ICMR2. If both TMOL and TMOH bits are set to 0b, the internal counter is disabled.

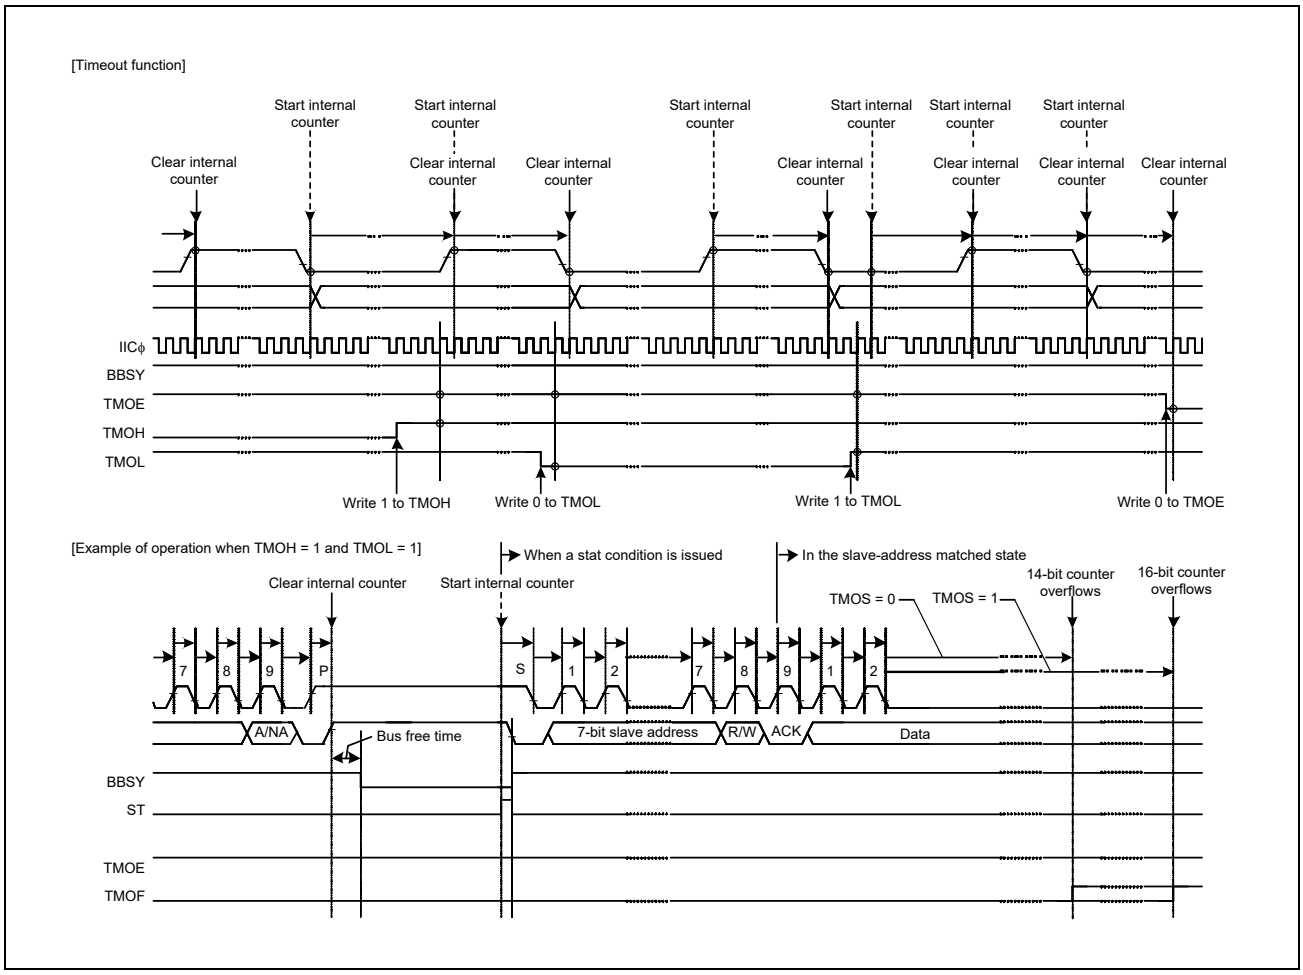

Figure 7.7-40 Timeout Function using the TMOE, TMOS, TMOH, and TMOL Bits

7.7.11.2 Extra SCL Clock Cycle Output Function

In master mode, this function outputs extra SCL clock cycles from the RIIC to release the SDAn line of the slave device from being held at the low level because the master is out of synchronization with the slave device.

It uses single cycles of the SCL clock for a bus error where the RIIC cannot issue a stop condition because the slave device is holding the SDAn line at the low level. Do not use this function in normal situations.

Using it when communications are proceeding correctly leads to malfunctioning.

When the CLO bit in ICCR1 is set to 1b in master mode, an additional clock pulse at the frequency set by the CKS[2:0] bits in ICMR1 and the ICBRH and ICBRL registers is output from the SCL0 pin. After output of this clock pulse, the CLO bit automatically becomes 0b. The SCL0 pin is held low when the BBSY bit in ICCR2 flag is 1b and held high when the BBSY flag is 0b. Consecutive additional clock pulses can be output by writing 1b to the CLO bit after confirming the CLO bit to be 0b.

When the RIIC module is in master mode and the slave device is holding the SDAn line at the low level because synchronization with the slave device is lost because of effects like noise, the output of a stop condition is not possible.

This function can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held at the low level, and recover the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDAI bit in ICCR1. After confirming the release of the SDAn line by the slave device, complete the communication by reissuing the stop condition.

Use this function with the MALE bit in ICFER set to 0b (master arbitration-lost detection disabled).

[Output conditions for using the CLO bit in ICCR1]

- When the bus is free (BBSY flag in ICCR2 = 0b) or in master mode (MST bit = 1b and BBSY flag = 1b in ICCR2)
- When the communication device does not hold the SCLn line low.

Figure 7.7-41 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

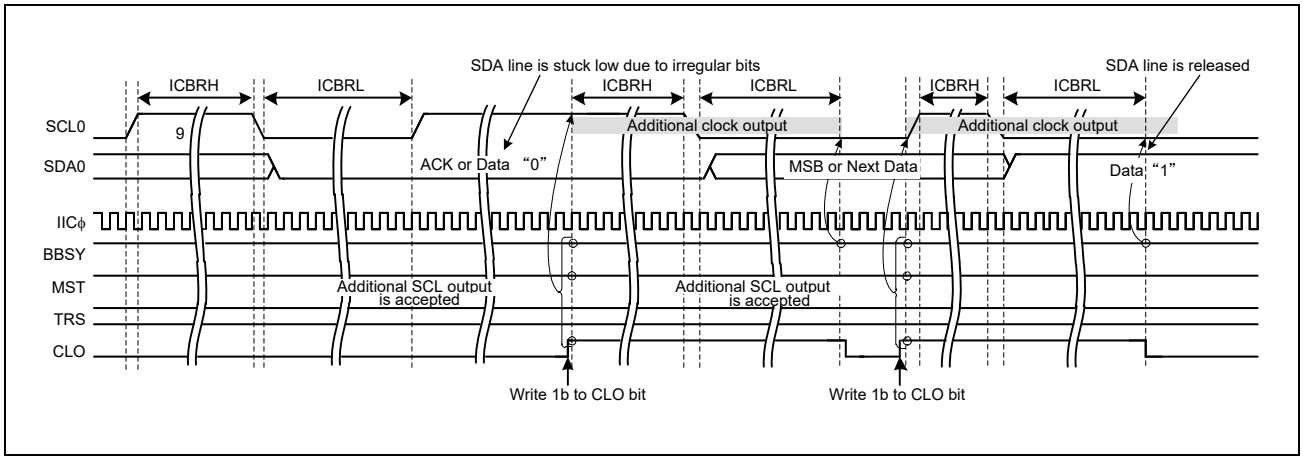

Figure 7.7-41 Extra SCL Clock Cycle Output Function using the CLO Bit

7.7.11.3 IIC Reset and Internal Reset

The RIIC module has two types of resets:

- IIC reset, which initializes all registers, including the BBSY flag in ICCR2
- Internal reset, which releases the RIIC from the slave-address matched state and initializes the internal counter while saving other settings.

After issuing a reset, always set the IICRST bit in ICCR1 to 0b.

Both types of resets are valid for release from bus-hung states, because both restore the output state of the SCLn and SDAn pins to the high-impedance state.

Issuing a reset during slave operation might lead to a loss of synchronization between the master device clock and the slave device clock, so avoid this when possible. In addition, monitoring of the bus state, such as for the presence of a start condition, is not possible during an RIIC reset (ICE and IICRST bits = 01b in ICCR1).

For a detailed description of the RIIC and internal resets, see **7.7.15 Resets, Registers, and Function States when Issuing Each Condition**.

7.7.12 SMBus Operation

IIC supports data communication conforming to the SMBus Specification, version 2.0. To perform SMBus communication, set the SMBS bit in ICMR3 to 1b. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus standard, set the CKS[2:0] bits in ICMR1, ICBRH, and ICBRL. In addition, specify the values in the DLCS bit in ICMR2 and the SDDL[2:0] bits in ICMR2 to meet the data hold time specification of 300 ns or more. When the RIIC is used only as a slave device, the transfer rate setting is not required, but ICBRL must be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100_001b), use one of the slave address registers L0 to L2 (SARL0, SARL1, and SARL2), and set the associated FS bit (7- or 10-bit address format select) in SARUy (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the SALE bit in ICFER to 1b to enable the slave arbitration-lost detection function.

7.7.12.1 SMBus Timeout Measurement

7.7.12.1.1 Measuring slave device timeout

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication:

- From start condition to stop condition

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the internal timer using the RIIC start condition detection interrupt (STIn) and stop condition detection interrupt (SPIn). The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:SEXT}$: 25 ms (maximum) of the SMBus standard.

If the time measured with the internal timer exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the slave device must release the bus by writing 1b to the IICRST bit in ICCR1 to issue an internal reset of the RIIC. When an internal reset is issued, the RIIC stops driving the bus for the SCLn and SDAn pins and makes the SCLn/ SDAn pin output high-impedance, which releases the bus.

7.7.12.1.2 Measuring master device timeout

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication:

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition

To measure timeout for master devices, measure these periods with the internal timer using the RIIC start condition detection interrupt (STIn), stop condition detection interrupt (SPIn), transmit end interrupt (IICn_TEI), or receive data full interrupt (IICn_RXI). The measured timeout period must be within the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (maximum) of the SMBus standard, and the total of all $T_{LOW:MEXT}$ values from the start condition to stop condition must be within $T_{LOW:SEXT}$: 25 ms (maximum).

For the ACK receive timing (rising edge of the 9th SCL clock cycle), monitor the TEND flag in ICSR2 in master transmit mode (master transmitter) and the RDRF flag in ICSR2 in master receive mode (master receiver). Perform byte-wise transmit operations in master transmit mode, and hold the RDRFS bit in ICMR3 at 0b until the byte

immediately before the reception of the final byte in master receive mode. While the RDRFS bit is 0b, the RDRF flag is set to 1b on the rising edge of the 9th SCL clock cycle.

If the period measured with internal timer exceeds the total clock low-level extended period (master device), $T_{LOW:MEXT}$: 10 ms (maximum) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout, $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (stop writing data to ICDRT).

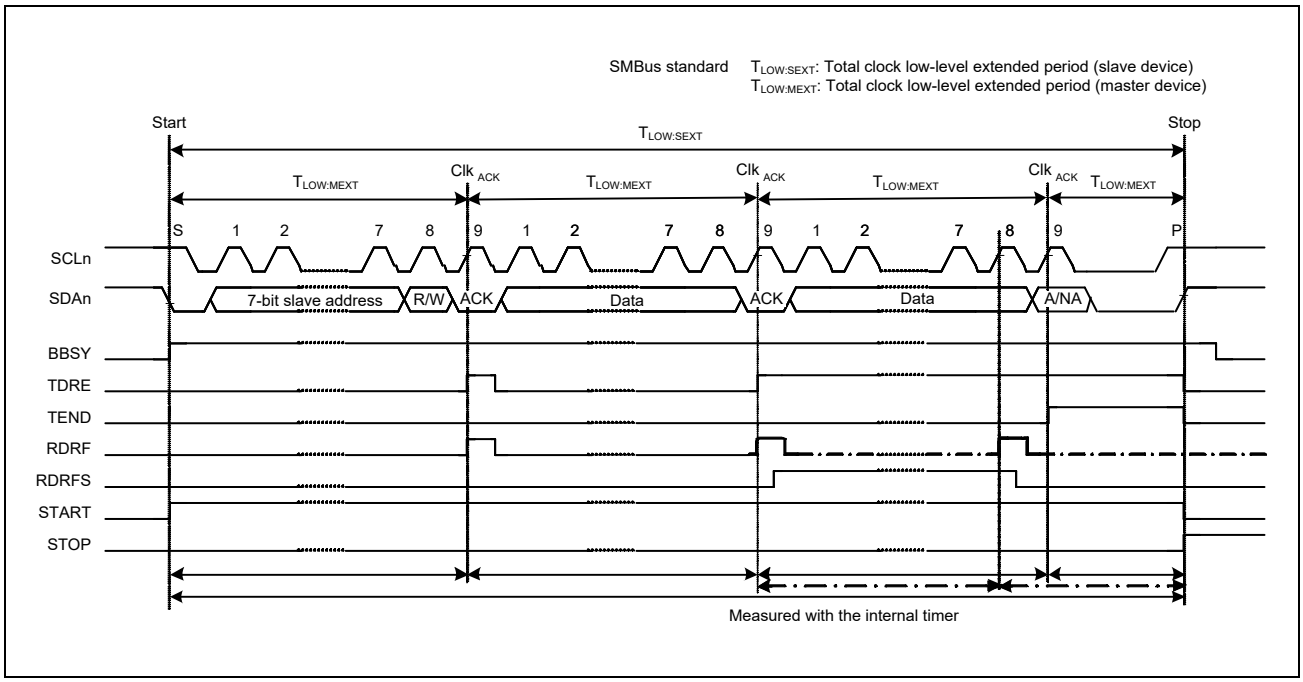

Figure 7.7-42 SMBus Timeout Measurement

7.7.12.2 Packet Error Code (PEC)

The LSI provides a CRC calculator, which enables transmission of a packet error code (PEC) or allows checking the received data in SMBus data communication for the RIIC. For the CRC-generating polynomials of the CRC calculator, see **7.6 CRC Operation Unit (CRC)**.

In master transmit mode, the PEC data can be generated by writing all transmit data to the CRC Data Input register (CRCDIR) in the CRC calculator.

In master receive mode, the PEC data can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC Data Output Register (CRCDOR) with the received PEC data.

To send ACK or NACK based on the match or mismatch result when the final byte is received as a result of the PEC code check, set the RDRFS bit in ICMR3 to 1b before the rising edge of the 8th SCL clock cycle during reception of the final byte, and hold the SCLn line low on the falling edge of the 8th clock cycle.

7.7.12.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address or to request its own slave address from the SMBus host.

For a product using the LSI to operate as an SMBus host or ARP master, the host address (0001 000b) sent from the slave device must be detected as a slave address, and so the RIIC has a function for detecting the host address. To detect the host address as a slave address, set the SMBS bit in ICMR3 and the HOAE bit in ICSER to 1b. Operation after the host address is detected is the same as normal slave operation.

7.7.13 Interrupt Sources

The RIIC issues 9types of interrupt request :transmit end, receive data full, transmit data empty, arbitration-lost, NACK detection, timeout detection, start condition detection, stop condition detection and slave address match during wake up function.

Table 7.7-10 lists details about the interrupt requests. The receive data full and transmit data empty interrupts can activate data transfer by the DMAC.

Table 7.7-10 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	DMAC Activation	Interrupt Condition
RIIC_CHm_ali_n*4	Arbitration lost	AL	Not possible	AL = 1b, ALIE = 1b
RIIC_CHm_naki_n*4	NACK detection	NACKF	Not possible	NACKF = 1b, NAKIE = 1b
RIIC_CHm_tmoi_n*4	Timeout detection	TMOF	Not possible	TMOF = 1b, TMOIE = 1b
RIIC_CHm_sti_n*4	Start condition detection	START	Not possible	START = 1b, STIE = 1b
RIIC_CHm_spi_n*4	Stop condition detection	STOP	Not possible	STOP = 1b, SPIE = 1b
RIIC_CHm_ri_n*2,*4	Receive data full	RDRF	Possible	RDRF = 1b, RIE = 1b
RIIC_CHm_ti_n*1,*4	Transmit data empty	TDRE	Possible	TDRE = 1b, TIE = 1b
RIIC_CHm_tei_n*3,*4	Transmit end	TEND	Not possible	TEND = 1b, TEIE = 1b

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. When an interrupt flag is cleared or masked, read the relevant flag again to check whether clearing or masking is complete, and then return from interrupt handling. Not doing so creates the possibility of repeated processing of the same interrupt.

Note 1. Because IICn_TXI is an edge-detected interrupt, it does not require clearing. Additionally, the TDRE flag in ICSR2 (condition for IICn_TXI) is automatically set to 0b when transmit data is written to ICDRT or a stop condition is detected (STOP flag = 1b in ICSR2).

Note 2. Because IICn_RXI is an edge-detected interrupt, it does not require clearing. Additionally, the RDRF flag in ICSR2 (condition for IICn_RXI) automatically is set to 0b when data is read from ICDRR.

Note 3. When using the IICn_TEI interrupt, clear the TEND flag in ICSR2 in the IICn_TEI interrupt handling. The TEND flag in ICSR2 automatically is set to 0b when transmit data is written to ICDRT or a stop condition is detected (STOP flag = 1b in ICSR2).

Note 4. Channel number (m = 0 to 8).

Clear or mask each flag during interrupt handling.

7.7.14 Even Link Output

The RIIC handles event output for the event link controller (ELC) corresponding to the following sources.

■ Transfer error event

When a transfer error event occurs, the corresponding event signal can be output for another module via the ELC.

■ Receive data full

When a receive data register becomes full, the corresponding event signal can be output for another module via the ELC.

■ Transmit data empty

When a transmit data register becomes empty, the corresponding event signal can be output for another module via the ELC.

■ Transmit end

On completion of transfer, the corresponding event signal can be output for another module via the ELC.

Table 7.7-2 Event Signal Output to the ELC

Name	Sources
RIIC_CHm_iic_elcerrp	Transfer error or event generation
RIIC_CHm_iic_elcrdrfp	Receive data full
RIIC_CHm_iic_elctdrep	Transmit data empty
RIIC_CHm_iic_elctendp	Transmit end

Note: m = 0 to 8

7.7.15 Resets, Registers, and Function States when Issuing Each Condition

The RIIC provides chip reset, RIIC reset, and internal reset functions. **Table 7.7-11** lists the RIIC resets, registers, and function states when issuing each condition.

Table 7.7-11 Resets, Registers, and Function States when Issuing Each Condition

Registers		Chip Reset	RIIC Reset (ICE = 0b, IICRST = 1b)	Internal Reset (ICE = 1b, IICRST = 1b)	Start or Restart Condition Detection	Stop Condition Detection
ICCR1	ICE, IICRST	Reset	Saved	Saved	Saved	Saved
	SCLO, SDAO		Reset	Reset

Note 1. This bit is not reset. This bit becomes 0 or 1 in accordance with the conditions.

SECTION 7 LOW-SPEED INTERFACE

7.8 I3C Bus Interface (I3C)

7.8.1 Overview

7.8.1.1 Functional Overview

The I3C bus interface (I3C) has 1 channel. The I3C module conform with and provide a subset of the NXP I^2C (Inter-Integrated Circuit) bus interface functions and a subset of the MIPI I3C.

Table 7.8-1 lists the I^2C specifications, and **Table 7.8-2** lists the I3C specifications.

Table 7.8-1 I^2C Specifications (1/2)

Item	Description
Operation mode	Master mode and slave mode selectable
Data handler	Single buffer transfer
Communication protocol	• I^2C bus format – Standard-mode (Sm): 0 to 100 kbps – Fast-mode (Fm): 0 to 400 kbps – Fast-mode Plus (Fm+): 0 to 1 Mbps – High-speed mode (Hs-mode): 0 to 3.4 Mbps • SMBus format: 10 to 100 kbps
Address format	• 7-bit address • 10-bit address
Address detection	• Slave address (static address) (max 3 addresses) • General call address • Hs-mode master code • Device ID • Host address • 10-bit slave addressing
Clock stretching	Clock stretching capability
Noise-filter	• Digital noise-filter
Interrupt source	• Receive data buffer full • Transmit data buffer empty • START condition detection • STOP condition detection • Transmit end • NACK detection • Arbitration lost • Timeout detection • Wake-up condition detection
Error detection	• NACK received • Arbitration lost error • Timeout error

Table 7.8-1 I^2C Specifications (2/2)

Item	Description
Event link output	• Communication event • Receive data buffer full event • Transmit data buffer empty event • Transmit end event
Wake-up source	• Address detection of slave address

Table 7.8-2 I3C Specifications (1/2)

Item	Description
Operation mode	Master (main master/secondary master) mode and slave mode selectable
Data handler	• Master: – Normal FIFO buffer transfer • Slave: – Normal FIFO buffer transfer
Communication protocol	• SDR (I3C single data rate) mode – Private message – Broadcast message (common command code) – Direct message (common command code) • Legacy I^2C message – Fast-mode (Fm): 0 to 400 kbps – Fast-mode Plus (Fm+): 0 to 1 Mbps
In-band interrupt	• Slave interrupt request • Master ship request (secondary master only) • Hot-join event
Address format	7-bit address
Address detection	• Slave address (static address or dynamic address) • Broadcast address (7Eh)
Clock stalling	Clock stalling capability
Timing Control	• Synchronous Timing Control – Sync Mode: Synchronous Basic Mode • Asynchronous Timing Control – Async Mode 0: Asynchronous Basic Mode – Async Mode 1: Asynchronous Advanced Mode
Interrupt source	• Non-recoverable internal error • Transfer error • Transfer abort • Response queue full • Command queue empty • IBI status queue full • Receive data buffer full • Transmit data buffer empty • Receive status queue full • START condition detection • STOP condition detection • Timeout detection • Wake-up condition detection

Table 7.8-2 I3C Specifications (2/2)

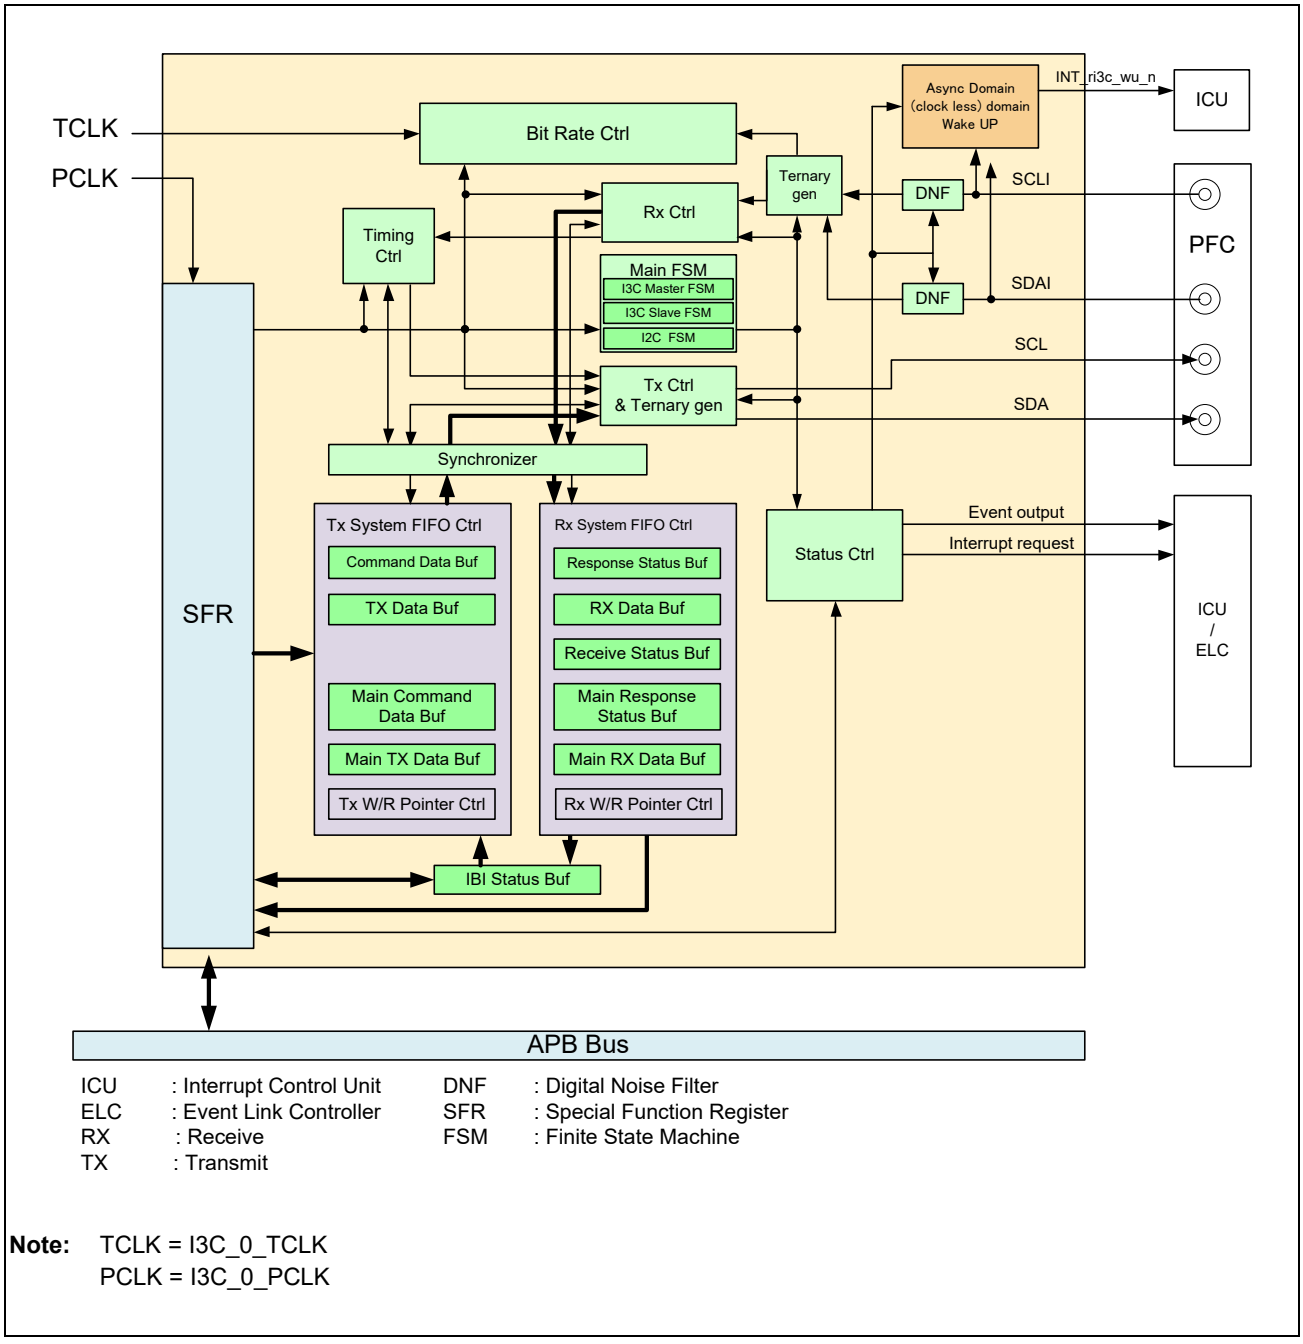
Item	Description
Error detection	• Non-recoverable internal error • CRC error • Parity error • Frame error • Address header error • Address NACKed or dynamic address assignment NACKed • Receive overflow or transfer underflow error • Aborted • NACK received for the I^2C write data transfer • Timeout error
Event link output	• Communication event • Response buffer full event • Command buffer empty event • IBI Status buffer full event • Receive data buffer full event • Transmit data buffer empty event • Receive status buffer full event • Synchronous timing event • MREF counter overflow event • MREF capture event • Additional master-initiated bus event
Wake-up source	• Master: – SDA30 assertion of IBI (START condition detection) • Slave: – Address detection of broadcast address (0x7E) and slave address

Table 7.8-3 I3C I/O Pins

Function	Pin name	Input/ Output	Description
I3C	SCL30	I/O	Input/output pins for clock
	SDA30	I/O	Input/output pins for data

7.8.2 Block Diagram [I²C/I3C common]

Figure 7.8-1 shows the main components of this I3C.



Note: TCLK = I3C_0_TCLK
PCLK = I3C_0_PCLK

Figure 7.8-1 I3C Block Diagram

7.8.3 Registers

This section describes details of the register functions.

Table 7.8-4 shows the base address of I3C.

Table 7.8-4 Register Base Address

Base Register Name	The Base Address
<I3C_base>	0_1240_0000h (5240_0000h*1, 4240_0000h*2)

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

7.8.3.1 List of Registers

I3C registers are listed in the following table. (m = 0)

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Protocol Selection Register	I3Cm_PRTS	0000_0001h	0000h	32
Reserve	-	-	0004h to 0013h	-
Bus Control Register	I3Cm_BCTL	0000_0000h	0014h	32
Master Device Address Register	I3Cm_MSDVAD	0000_0000h	0018h	32
Reserve	-	-	001Ch to 001Fh	-
Reset Control Register	I3Cm_RSTCTL	0000_0000h	0020h	32
Present State Register	I3Cm_PRSST	0000_0000h	0024h	32
Reserve	-	-	0028h to 002Fh	-
Internal Status Register	I3Cm_INST	0000_0000h	0030h	32
Internal Status Enable Register	I3Cm_INSTE	0000_0000h	0034h	32
Internal Interrupt Enable Register	I3Cm_INIE	0000_0000h	0038h	32
Internal Status Force Register	I3Cm_INSTFC	0000_0000h	003Ch	32
Reserve	-	-	0040h to 0043h	-
Device Characteristic Table Register	I3Cm_DVCT	0000_0000h	0044h	32
Reserve	-	-	0048h to 0057h	-
IBI Notify Control Register	I3Cm_IBINCTL	0000_0000h	0058h	32
Reserve	-	-	005Ch to 005Fh	-
Bus Function Control Register	I3Cm_BFCTL	0000_0101h	0060h	32
Slave Control Register	I3Cm_SVCTL	0000_0000h	0064h	32
Reserve	-	-	0068h to 006Fh	-
Reference Clock Control Register	I3Cm_REFCKCTL	0000_0000h	0070h	32
Standard Bit Rate Register	I3Cm_STDBR	3F3F_FFFFh	0074h	32
Extended Bit Rate Register	I3Cm_EXTBR	3F3F_FFFFh	0078h	32
Bus Free Condition Detection Time Register	I3Cm_BFRECDT	0000_0000h	07Ch	32
Bus Available Condition Detection Time Register	I3Cm_BAVLCDT	0000_0000h	0080h	32
Bus Idle Condition Detection Time Register	I3Cm_BIDLCDT	0000_0000h	0084h	32

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Output Control Register	I3Cm_OUTCTL	0000_0003h	0088h	32
Input Control Register	I3Cm_INCTL	0000_00D0h	008Ch	32
Timeout Control Register	I3Cm_TMOCTL	0000_0030h	0090h	32
Reserve	-	-	0094h to 0097h	-
Wake-Up Unit Control Register	I3Cm_WUCTL	0000_0041h	0098h	32
Reserve	-	-	009Ch to 009Fh	-
Acknowledge Control Register	I3Cm_ACKCTL	0000_0000h	00A0h	32
SCL Stretch Control Register	I3Cm_SCSTRCTL	0000_0000h	00A4h	32
Reserve	-	-	00A8h to 00AFh	-
SCL Stalling Control Register	I3Cm_SCSTLCTL	0000_0000h	00B0h	32
Reserve	-	-	00B4h to 00BFh	-
Slave Transfer Data Length Register	I3Cm_SVTDLG0	0000_0000h	00C0h	32
Reserve	-	-	00C4h to 011Fh	-
Synchronous Timing Control Register	I3Cm_STCTL	0000_0000h	0120h	32
Asynchronous Timing Control Register	I3Cm_ATCTL	0000_0000h	0124h	32
Asynchronous Timing Trigger Register	I3Cm_ATTRG	0000_0000h	0128h	32
Asynchronous Timing Control Counter Enable Register	I3Cm_ATCCNTE	0000_0000h	012Ch	32
Reserve	-	-	0130h to 013Fh	-
Condition Control Register	I3Cm_CNDCTL	0000_0000h	0140h	32
Reserve	-	-	0144h to 014Fh	-
Normal Command Queue Port Register	I3Cm_NCMDQP	0000_0000h	0150h	32
Normal Response Queue Port Register	I3Cm_NRSPQP	0000_0000h	0154h	32
Normal Transfer Data Buffer Port Register	I3Cm_NTDTBP0/NTDTBP0_BY	0000_0000h	0158h	32
Reserve	-	-	015Ch to 017Bh	-
Normal IBI Queue Port Register	I3Cm_NIBIQP	0000_0000h	017Ch	32
Normal Receive Status Queue Port Register	I3Cm_NRSQP	0000_0000h	0180h	32
Reserve	-	-	0184h to 018Fh	-
Normal Queue Threshold Control Register	I3Cm_NQTHCTL	0101_0101h	0190h	32
Normal Transfer Data Buffer Threshold Control Register	I3Cm_NTBTHCTL0	0101_0101h	0194h	32
Reserve	-	-	0198h to 01BFh	-
Normal Receive Status Queue Threshold Control Register	I3Cm_NRQTHCTL	0000_0001h	01C0h	32
Reserve	-	-	01C4h to 01CFh	-
Bus Status Register	I3Cm_BST	0000_0000h	01D0h	32
Bus Status Enable Register	I3Cm_BSTE	0000_0000h	01D4h	32
Bus Interrupt Enable Register	I3Cm_BIE	0000_0000h	01D8h	32
Bus Status Force Register	I3Cm_BSTFC	0000_0000h	01DCh	32
Normal Transfer Status Register	I3Cm_NTST	0000_0000h	01E0h	32

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Normal Transfer Status Enable Register	I3Cm_NTSTE	0000_0000h	01E4h	32
Normal Transfer Interrupt Enable Register	I3Cm_NTIE	0000_0000h	01E8h	32
Normal Transfer Status Force Register	I3Cm_NTSTFC	0000_0000h	01ECh	32
Reserve	-	-	01F0h to 020Fh	-
Bus Condition Status Register	I3Cm_BCST	0000_0000h	0210h	32
Slave Status Register	I3Cm_SVST	0000_0000h	0214h	32
Wake-Up Unit Operating Status Register	I3Cm_WUST	0000_0000h	0218h	32
MsyncCNT Counter Capture Register	I3Cm_MRCCPT	0000_0000h	021Ch	32
Reserve	-	-	0220h to 0223h	-
Device Address Table Basic Register 0	I3Cm_DATBAS0	0000_0000h	0224h	32
Device Address Table Basic Register 1	I3Cm_DATBAS1	0000_0000h	0228h	32
Device Address Table Basic Register 2	I3Cm_DATBAS2	0000_0000h	022Ch	32
Device Address Table Basic Register 3	I3Cm_DATBAS3	0000_0000h	0230h	32
Device Address Table Basic Register 4	I3Cm_DATBAS4	0000_0000h	0234h	32
Device Address Table Basic Register 5	I3Cm_DATBAS5	0000_0000h	0238h	32
Device Address Table Basic Register 6	I3Cm_DATBAS6	0000_0000h	023Ch	32
Device Address Table Basic Register 7	I3Cm_DATBAS7	0000_0000h	0240h	32
Reserve	-	-	0244h to 02AFh	-
Slave Device Address Table Basic Register 0	I3Cm_SDATBAS0	0000_0000h	02B0h	32
Slave Device Address Table Basic Register 1	I3Cm_SDATBAS1	0000_0000h	02B4h	32
Slave Device Address Table Basic Register 2	I3Cm_SDATBAS2	0000_0000h	02B8h	32
Reserve	-	-	02BCh to 02CFh	-
Master Device Characteristic Table Register 0	I3Cm_MSDCT0	0000_0000h	02D0h	32
Master Device Characteristic Table Register 1	I3Cm_MSDCT1	0000_0000h	02D4h	32
Master Device Characteristic Table Register 2	I3Cm_MSDCT2	0000_0000h	02D8h	32
Master Device Characteristic Table Register 3	I3Cm_MSDCT3	0000_0000h	02DCh	32
Master Device Characteristic Table Register 4	I3Cm_MSDCT4	0000_0000h	02E0h	32
Master Device Characteristic Table Register 5	I3Cm_MSDCT5	0000_0000h	02E4h	32
Master Device Characteristic Table Register 6	I3Cm_MSDCT6	0000_0000h	02E8h	32
Master Device Characteristic Table Register 7	I3Cm_MSDCT7	0000_0000h	02ECh	32
Reserve	-	-	02F0h to 030Fh	-
Extended Device Address Table Basic Register	I3Cm_EXDATBAS	0000_0000h	0310h	32
Reserve	-	-	0314h to 031Fh	-
Slave Device Characteristic Table Register	I3Cm_SVDCT	0000_0000h	0320h	32
Slave Device Characteristic Table Provisional ID Low Register	I3Cm_SDCTPIDL	0000_0000h	0324h	32
Slave Device Characteristic Table Provisional ID High Register	I3Cm_SDCTPIDH	0000_0000h	0328h	32
Reserve	-	-	032Ch to 032Fh	-

Reserve	-	-	03D4h to 03DFh	-
SC1 Capture monitor Register	I3Cm_SC1CPT	0000_0000h	03E0h	32
SC2 Capture monitor Register	I3Cm_SC2CPT	0000_0000h	03E4h	32

7.8.3.2 Register Description

The prefix (I3Cm_) of the register names is omitted in this and subsequent sections.

7.8.3.2.1 Protocol Selection Register (I3Cm_PRTS)

Access Size : 32 bits
Address : <I3C_base> + 0000h
Initial Value : 0000_0001h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	PRTMD
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	PRTMD	1h	RW	Protocol Mode 0b: I3C protocol mode 1b: I2C protocol mode

PRTMD bit (Protocol Mode)

PRTMD = 0b: I3C FIFO buffer transfer (Equivalent to HCI)

PRTMD = 1b: I^2C single buffer transfer

7.8.3.2.2 Bus Control Register (I3Cm_BCTL)

Access Size : 32 bits
Address : <I3C_base> + 0014h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BUSE	RSM	ABT	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	HJACK CTL	-	-	-	-	-	-	-	INCBA
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	BUSE	0h	RW	Bus Enable*2 0b: I3C bus operation is disabled. 1b: I3C bus operation is enabled.
30	RSM	0h	RW	Resume*2 Values when read: 0b: I3C is running. 1b: I3C is suspended (RW1C).
29	ABT	0h	RW	Abort*1 0b: I3C is running. 1b: I3C has aborted a transfer.
28 to 9	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
8	HJACKCTL	0h	RW	Hot-Join Acknowledge Control*1 0b: ACK the Hot-Join request 1b: NACK and send broadcast CCC to disable Hot-Join
7 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	INCBA	0h	RW	Include I3C Broadcast Address*1 0b: Do not include I3C broadcast address for private transfers 1b: Include I3C broadcast address for private transfers

Note 1. This bit supports I3C master mode and I3C secondary master mode.

Note 2. This bit supports all I3C mode.

INCBA bit (Include I3C Broadcast Address)

This bit controls whether the I3C broadcast address (7Eh) is included for private transfers.

If the I3C broadcast address is not included for private transfers, then IBIs driven from Slaves might not win the arbitration, potentially delaying acceptance of the IBIs.

HJACKCTL bit (Hot-Join Acknowledge Control)

This bit acts as global control to either ACK (0) or NACK (1) all Hot-Join Requests arriving from the Devices on the I3C Bus. If set to NACK (1), then the NACK will be followed by the broadcast CCC to disable Hot-Join.

ABT bit (Abort)

When set to 1b, this bit allows I3C to relinquish control of the I3C Bus before completing the currently issued transfer.

In response to an ABORT request, I3C issues the STOP condition on the I3C Bus after the complete data byte is transferred or received.

The Driver shall clear the ABT bit to allow operation on the Bus.

If BCTL.ABT is set and ABORT processing is performed, please ignore ERR_STATUS of Response Descriptor.

RSM bit (Resume)

This bit is used to resume I3C operation following the Halt state.

I3C enters the Halt state (as indicated in register PRSTDBG) as a result of any type of error occurring in a transfer.

The error type is indicated by the field ERR_STATUS in register NRSPQP, NRSQP and NIBIQP).

After I3C has entered the Halt state, the application must write the value 1 to the RSM bit to resume I3C operation. I3C shall auto-clear the RSM bit once it has resumed making transfers (it has initiated the next Command).

BUSE bit (Bus Enable)

Enables or disables the operation on the I3C Bus by I3C.

Set the BUSE bit to 1b when using I3C. The SCL and SDA pins are placed in the active state when the BUSE bit is set to 1b. Set the BUSE bit to 0b when I3C is not to be used. The SCL and SDA pins are placed in the inactive state when the BUSE bit is set to 0b.

If the software sets this bit, then it also confirms that initialization is done, and that I3C can use the programmed register values (For example, generation of SCL on IBI detection, etc.). If this bit is not set, then I3C shall not generate SCL for incoming IBI.

Software may disable I3C bus operation while it is active, However:

- If a disable request occurs while receiving IBI, the actual disabling will not occur until reception of the IBI is complete.
- When the software reads the value 0 from this field, this indicates that I3C bus operation disable operation has completed.
  If commands remain in the command queue, do not set BUSE = 0b.

7.8.3.2.3 Master Device Address Register (I3Cm_MSDVAD)

Access Size : 32 bits
Address : <I3C_base> + 0018h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MDYADV	-	-	-	-	-	-	-	-	MDYAD[6:0]						
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	MDYADV	0h	RW	Master Dynamic Address Valid 0b: The master dynamic address field is not valid. 1b: The master dynamic address field is valid.
30 to 23	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
22 to 16	MDYAD[6:0]	0h	RW	Master Dynamic Address
15 to 0	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

Note: This register supports I3C master mode.

MDYAD[6:0] bits (Master Dynamic Address)

This field is used to program I3C master dynamic address. I3C uses this address to respond to master transactions in I3C interface mode (slave or secondary master role).

In I3C main master mode, the software shall program the dynamic address as it self-assigns its dynamic address.

MDYADV bit (Master Dynamic Address Valid)

This bit indicates whether or not the value in the MDYAD field is valid.

In I3C main master mode, the user sets this bit to 1b as it self-assigns its dynamic address.

Note: After setting MSDVAD, and setting BCTL. BUSE = 1b, the device will act as main master.
Without setting MSDVAD, setting SVDCT.TBCR[7:6] = 00b (Device Role Slave), and setting BCTL.BUSE = 1b, the device will act as slave.
Without setting MSDVAD, setting MSDCTm.RBCR[7:6] = 01b (Device Role Master), and setting BCTL.BUSE = 1b, the device will act as slave.

7.8.3.2.4 Reset Control Register (I3Cm_RSTCTL)

For details on reset for each register, see **7.8.7 Reset Descriptions**.

Access Size : 32 bits
Address : <I3C_base> + 0020h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	INTLRST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	RSQRST	IBIQRST	RDBRST	TDBRST	RSPQRST	CMDQRST	RI3CRST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
16	INTLRST	0h	RW	Internal Software Reset 0b: Release of some registers and internal state. 1b: Reset of some registers and internal state.
15 to 7	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
6	RSQRST	0h	RW	Receive Status Queue Software Reset*2 0b: The Receive Status Queue in I3C is not flushed. 1b: The Receive Status Queue in I3C is flushed.
5	IBIQRST	0h	RW	IBI Queue Software Reset*1 0b: The IBI Queues in I3C are not flushed. 1b: The IBI Queues in I3C are flushed.
4	RDBRST	0h	RW	Receive Data Buffer Software Reset*1 0b: The Receive Queues in I3C are not flushed. 1b: The Receive Queues in I3C are flushed.
3	TDBRST	0h	RW	Transmit Data Buffer Software Reset*1 0b: The Transmit Queues in I3C are not flushed. 1b: The Transmit Queues in I3C are flushed.
2	RSPQRST	0h	RW	Response Queue Software Reset*1 0b: The Response Queues in I3C are not flushed. 1b: The Response Queues in I3C are flushed.
1	CMDQRST	0h	RW	Command Queue Software Reset*1 0b: The Command Queues in I3C are not flushed. 1b: The Command Queues in I3C are flushed.
0	RI3CRST	0h	RW	I3C Software Reset 0b: Release I3C reset. 1b: Initiate I3C reset.

Note 1. This bit supports all I3C mode.

Note 2. This bit supports I3C secondary master mode and I3C slave mode.

RI3CRST bit (I3C Software Reset)

On Driver setting this bit to 1b, I3C shall be reset and disabled.

All registers shall return to their reset values, and the software shall re-initialize I3C.

This field is cleared automatically upon I3C reset completion. This field also resets all Queues in I3C.

CMDQRST bit (Command Queue Software Reset)

On software setting this bit to 1b, the Command Queues in I3C shall be flushed.

This field shall be cleared automatically upon Command Queue reset completion.

RSPQRST bit (Response Queue Software Reset)

On software setting this bit to 1b, the Response Queues in I3C shall be flushed.

This field shall be cleared automatically upon Response Queue reset completion.

TDBRST bit (Transmit Data Buffer Software Reset)

On software setting this bit to 1b, the Transmit Data Buffers in I3C shall be flushed.

This field shall be cleared automatically upon Transmit Data Buffer reset completion.

RDBRST bit (Receive Data Buffer Software Reset)

On software setting this bit to 1b, the Receive Data Buffers in I3C shall be flushed.

This field shall be cleared automatically upon completion of Receive Data Buffer reset.

IBIQRST bit (IBI Queue Software Reset)

On software setting this bit to 1b, the IBI Queues in I3C shall be flushed.

This field shall be cleared automatically upon completion of IBI Queue reset.

RSQRST bit (Receive Status Queue Software Reset)

On software setting this bit to 1b, the Receive Status Queues in I3C shall be flushed. This field shall be cleared automatically upon Receive Status Queue reset completion.

INTLRST bit (Internal Software Reset)

When set to 1b, some of registers is reset. For details on the registers to be reset, see **7.8.7 Reset Descriptions**.

Note: When setting internal software reset during bus operation enable, use DISEC CCC in advance to disable IBI transmission to I3C Slave in order to avoid conflict with IBI from I3C Slave connected to I3C Bus.

7.8.3.2.5 Present State Register (I3Cm_PRSST)

Access Size : 32 bits
Address : <I3C_base> + 0024h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	PRSSTWP	-	-	TRMD	-	CRMS	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	W	RW	RW	R	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7	PRSSTWP	-	W	The read value is undefined Present State Write Protect*2 0b: CRMS bit is protected. 1b: CRMS bit can be written when writing simultaneously with the value of the target bit.
6 to 5	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	TRMD	0h	R	Transmit/Receive Mode*3 0b: Receive mode 1b: Transmit mode
3	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	CRMS	0h	RW*1	Current Master*2 0b: The Master is not the Current Master, and must request and acquire bus ownership before initiating any transfer. 1b: The Master is the Current Master, and as a result can initiate transfers.
1 to 0	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

Note 1. When the PRSSTWP bit is set to 1b, the CRMS bit can be written to.

Note 2. This bit supports I^2C, I3C master, and I3C secondary master mode.

Note 3. This bit supports I^2C mode.

CRMS bit (Current Master)

Indicates the set condition and reset condition of each operation mode.

- Operation Mode [I^2C/I3C common]

  [Clearing conditions]

  - When 0b written to the PRSST.CRMS by the software.

  [Setting conditions]

  - When 1b written to the PRSST.CRMS by the software.

- Operation Mode [I^2C]

  [Clearing conditions]

  - When STOP is issued.

- When Master arbitration-lost is detected.

[Setting conditions]

- When START is issued.

- Operation Mode [I3C Main Master]

[Clearing conditions]

- When 0b written to the MSDVAD.MDYADV by the software.
- When GETACCMST transmission is successfully completed by issuing STOP, after responding ACK to the Mastership-Request received from the Secondary Master.

[Setting conditions]

- When 1b written to the MSDVAD.MDYADV by the software.
- When GETACCMST reception is successfully completed by issuing STOP, after the ACK is responded to the Mastership-Request transmitted to the Secondary Master.

- Operation Mode [I3C Secondary Master]

[Clearing condition]

- When GETACCMST transmission is successfully completed by issuing STOP, after responding ACK to the Mastership-Request received from the Non-Current Master.

[Setting condition]

- When GETACCMST reception is successfully completed by issuing STOP, after the ACK is responded to the Mastership-Request transmitted to the Current Master.

The PRSST register returns I3C current state.

State has two parts: this register which is mandatory, and an additional optional PRSST_DEBUG register intended for debug purposes (see the Debug Capability registers in the Extended Capabilities list).

TRMD bit (Transmit/Receive Mode)

This bit indicates transmit or receive mode.

I3C is in receive mode when the TRMD bit is set to 0b and is in transmit mode when the bit is set to 1b. Combination of this bit and the CRMS bit indicates the operating mode of I3C.

The value of TRMD bit is automatically changed to 1b for transmit mode or 0b for receive mode by issuing or detection of a START condition and setting of the R/W# bit.

[Setting conditions]

- When a START condition is issued normally according to the START condition issuance request (when a START condition is detected with the CNDCTL.STCND bit set to 1b).
- When a Repeated START condition is issued normally according to the Repeated START condition issuance request (when a Repeated START condition is detected with the CNDCTL.SRCND bit set to 1b).
- When the R/W# bit added to the slave address is set to 0b in master mode.
- When the address received in slave mode matches the address enabled in SVCTL, with the R/W# bit set to 1b.

[Clearing conditions]

- When a STOP condition is detected.
- The ALF (arbitration-lost) flag in BST being set to 1b.

- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended.
- In slave mode, a match between the received address and the address enabled in SVCTL when the value of the received R/W# bit is 0b (including cases where the received address is the general call address).
- In slave mode, a Repeated START condition is detected (a Repeated START condition is detected with BCST.BFREF = 0b and CRMS = 0b).

PRSSTWP bit (Present State Write Protect)

PRSSTWP is always 0b when reading.

When writing to PRSST, writing 1 to this bit at the same time enables writing to CRMS bit.

7.8.3.2.6 Internal Status Register (I3Cm_INST)

The Interrupt Status register reflects the status of outstanding interrupt(s).

Access Size : 32 bits
Address : <I3C_base> + 0030h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	INEF	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
10	INEF	0h	RW*1	Internal Error Flag 0b: I3C Internal Error has not detected. 1b: I3C Internal Error has detected.
9 to 0	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

Note: This register supports all I3C mode.

Note 1. Clearing (to 0) condition: Writing 0b after 1b is read.

INEF bit (Internal Error Flag)

When this bit is 1b, it indicates that I3C Internal Error has detected.

When this bit is 0b, it indicates that I3C Internal Error has not detected.

[Setting conditions]

- The following 1 is satisfied and any of the following 2) to 9) are satisfied.

1) The INSTE.INEE bit = 1b
2) When transmit data is written to the Transmit Data Buffer that is completely full.
3) When received data is read from the Receive Data Buffer that is completely empty.
4) When Command Descriptor is written to the Command Queue that is completely full.
5) When Response Descriptor is read from the Response Status Queue that is completely empty.
6) When Receive Status Descriptor is read from the Receive Status Queue that is completely empty.
7) When IBI Status Descriptor is read from the IBI Queue under the condition that the IBI Queue is completely empty and PRSST.CRMS = 1b.
8) When IBI Data is written to the IBI Queue under the condition that the IBI Queue is completely full and PRSST.CRMS = 0b.
9) When the Response Status Queue, IBI Status Queue or Receive Status Queue overflows.

[Clearing condition]

- When 0b is written to the INEF bit after reading INEF bit = 1b.

7.8.3.2.7 Internal Status Enable Register (I3Cm_INSTE)

Access Size : 32 bits
Address : <I3C_base> + 0034h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	INEE	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
10	INEE	0h	RW	Internal Error Enable 0b: Disable INST.INEF 1b: Enable INST.INEF
9 to 0	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

Note: This register supports all I3C mode.

INEE bit (Internal Error Enable)

When this bit set to 1b, it enables detection of I3C Internal Error.

When this bit set to 0b, it disables detection of I3C Internal Error.

7.8.3.2.8 Internal Interrupt Enable Register (I3Cm_INIE)

Access Size : 32 bits
Address : <I3C_base> + 0038h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	INEIE	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
10	INEIE	0h	RW	Internal Error Interrupt Enable 0b: Disables Non-recoverable Internal Error Interrupt Signal. 1b: Enables Non-recoverable Internal Error Interrupt Signal.
9 to 0	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

Note: This register supports all I3C mode.

INEIE bit (Internal Error Interrupt Enable)

When set to 1b and register INEF is set, the hardware Controller asserts an interrupt to the Host.

7.8.3.2.9 Internal Status Force Register (I3Cm_INSTFC)

Access Size : 32 bits
Address : <I3C_base> + 003Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	INEFC	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	-	All 0	W	Reserved The written value should always be 0b.
10	INEFC	0h	W	Internal Error Force 0b: Not force a specific interrupt 1b: Force a specific interrupt
9 to 0	-	All 0	W	Reserved The written value should always be 0b.

Note: This register supports all I3C mode.

INEFC bit (Internal Error Force)

For debug, helps to force this interrupt.

7.8.3.2.10 Device Characteristic Table Register (I3Cm_DVCT)

Access Size : 32 bits
Address : <I3C_base> + 0044h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	IDX[4:0]					-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read.
23 to 19	IDX[4:0]	0h	R	DCT Table Index Current index of the DCT, which is used as the starting index for the I3C ENTDAA CCC.
18 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read.

Note: This register supports I3C master mode and I3C secondary master mode.

IDX[4:0] bits (DCT Table Index)

Once the complete characteristics of device that won the arbitration are written to the DCT (during ENTDAA using Address Assignment Command) this index is incremented by 1.

7.8.3.2.11 IBI Notify Control Register (I3Cm_IBINCTL)

Access Size : 32 bits
Address : <I3C_base> + 0058h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	NRSIRCTL	-	NRMRCTL	NRHJCTL
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3	NRSIRCTL	0h	RW	Notify Rejected Slave Interrupt Request Control 0b: Do not pass rejected IBI Status to the IBI Queue/Rings, if the incoming SIR is NACKed and is auto-disabled based on DVSIRRJ field in relevant DATBASn register. 1b: Pass rejected IBI Status to the IBI Queue/Rings, if the incoming SIR is NACKed and is auto-disabled based on DVSIRRJ field in relevant DATBASn register.
2	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1	NRMRCTL	0h	RW	Notify Rejected Master Request Control 0b: Do not pass rejected IBI Status to IBI Queue/Ring, if the incoming Master Request is NACKed and is auto-disabled based on DVMRRJ field in relevant DATBASn register. 1b: Pass rejected IBI Status to the IBI Queue, if the incoming Master Request is NACKed and is autodisabled based on DVMRRJ field in relevant DATBASn register.
0	NRHJCTL	0h	RW	Notify Rejected Hot-Join Control 0b: Do not pass rejected IBI Status to IBI Queue, if the incoming Hot-Join request is NACKed and is auto-disabled based on field HJACKCTL of BCTL. 1b: Pass rejected IBI Status to the IBI Queue, if the incoming Hot-Join request is NACKed and is auto-disabled based on field HJACKCTL of BCTL.

Note: This register supports I3C master mode and I3C secondary master mode.

NRHJCTL bit (Notify Rejected Hot-Join Control)

Enables or disables reporting rejection of individual Hot Join requests.

NRMRCTL bit (Notify Rejected Master Request Control)

Enables or disables reporting rejection of individual Master Requests.

NRSIRCTL bit (Notify Rejected Slave Interrupt Request Control)

Enables or disables reporting rejection of individual Slave Interrupt Requests (SIR).

7.8.3.2.12 Bus Function Control Register (I3Cm_BFCTL)

Access Size : 32 bits
Address : <I3C_base> + 0060h
Initial Value : 0000_0101h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HSME	FMPE	-	SMBS	-	-	-	SCSYNE	-	-	-	-	-	SALE	NALE	MALE
Initial Value	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
15	HSME	0h	RW	High Speed Mode Enable*1 0b: Disable High Speed Mode. 1b: Enable High Speed Mode.
14	FMPE	0h	RW	Fast-mode Plus Enable*1 0b: No Fm+ slope control circuit is used for the SCL30 pin and SDA30 pin. 1b: An Fm+ slope control circuit is used for the SCL30 pin and SDA30 pin.
13	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
12	SMBS	0h	RW	SMBus/I2C Bus Selection*1 0b: The I2C bus is selected. 1b: The SMBus is selected.
11 to 9	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
8	SCSYNE	1h	RW	SCL30 Synchronous Circuit Enable*1 0b: No SCL30 synchronous circuit is used. 1b: An SCL30 synchronous circuit is used.
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	SALE	0h	RW	Slave Arbitration-Lost Detection Enable*1 0b: Slave arbitration-lost detection disabled 1b: Slave arbitration-lost detection enabled
1	NALE	0h	RW	NACK Transmission Arbitration-Lost Detection Enable*1 0b: NACK transmission arbitration-lost detection disabled 1b: NACK transmission arbitration-lost detection enabled
0	MALE	1h	RW	Master Arbitration-Lost Detection Enable*1 0b: Master arbitration-lost detection disabled Disables the arbitration-lost detection function and does not clear the CRMS and TRMD bits in PRSST automatically when arbitration is lost. 1b: Master arbitration-lost detection enabled Enables the arbitration-lost detection function and clears the CRMS and TRMD bits in PRSST automatically when arbitration is lost.

Note 1. This bit supports I^2C mode.

MALE bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1b.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

SALE bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

SCSYNE bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1b.

When the SCSYNE bit set to 0b (no SCL synchronous circuit used), I3C does not synchronize the SCL clock with the SCL input clock. In this setting, I3C outputs the SCL clock with the transfer rate set in STDBR and EXTBR regardless of the SCL line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit uses, it also affects the issuance of a START condition, Repeated START condition, and STOP condition, and the continuous output of extra SCL clock cycles.

This bit must not be set to 0b except for checking the output of the set transfer rate.

FMPE bit (Fast-mode Plus Enable)

This bit is used to specify whether to use a slope control circuit for Fast-mode Plus [Fm+].

When this bit is set to 1b, a slope control circuit conforming to the Fast-mode Plus [Fm+] slope control specification (tof) of the I3C-bus is selected. When this bit is set to 0b, a slope control circuit conforming to the Standard-mode [Sm] and Fast- mode [fm] slope control specification (tof) of the I3C-bus is selected.

Set this bit to 1b when using the transmission rate within a range up to 1 Mbps (Fast-mode Plus [Fm+]) of the I3C-bus specification. Set this bit to 0b when using the transmission rate at other rates (up to 100 kbps [Sm], up to 400 kbps [Fm]) or for SMBus (10 to 100 kbps).

Note: When communicating in Hs-mode, set as follows.
- Set FMPE to 0b when sending Hs-mode master code (0000 1XXXb) with Fast-mode.
- Set FMPE to 1b when sending Hs-mode master code (0000 1XXXb) with Fast-mode Plus.

HSME bit (High Speed Mode Enable)

This bit is used for communicating in Hs-mode.

When this bit is set to 1b, the Hs-mode master code is recognized and Hs-mode communication is possible.

After the START condition is detected, if Hs-mode master code (0000 1XXXb) transmission is recognized, Hs-mode communication starts from Repeated START after receiving the NACK response.

It communicates at the bit rate set in STDBR until the NACK response, and automatically switches from Repeated START condition issuance after receiving the NACK response to the bit rate set in EXTBR.

Hs-mode continues until a STOP condition is detected.

When the STOP condition is detected, the bit rate is automatically switched to the bit rate set in STDBR.

Note: When this bit is set to 1b, the BST.NACKDF bit will not be set even if a NACK response is received after sending the Hs-mode master code.

7.8.3.2.13 Slave Control Register (I3Cm_SVCTL)

Access Size : 32 bits
Address : <I3C_base> + 0064h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	HOAE	0h	RW	Host Address Enable*1 0b: Host address detection disabled 1b: Host address detection enabled
14 to 7	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
6	DVIDE	0h	RW	Device-ID Address Enable*1 0b: Device-ID address detection disabled 1b: Device-ID address detection enabled
5	HSMCE	0h	RW	Hs-mode Master Code Enable*1 0b: Hs-mode Master Code Detection disabled 1b: Hs-mode Master Code Detection enabled
4 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	GCAE	0h	RW	General Call Address Enable*1 0b: General call address detection disabled 1b: General call address detection enabled

Note 1. This bit supports I^2C mode.

Note 2. These bits support I^2C, I3C secondary master, and I3C slave mode.

GCAE bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000 000 + 0 (write): All 0) when it is received. When this bit is set to 1b, if the received slave address matches the general call address, I3C recognizes the received slave address as the general call address independently of the slave addresses set in the SVDVADn.SVAD[9:0] bits (n = 0 to 2) and performs data receive operation.

When this bit is set to 0b, the received slave address is ignored even if it matches the general call address.

HSMCE bit (Hs-mode Master Code Enable)

This bit is used to specify whether to recognize and execute the Hs-mode master code (00001xxxb) is received in the first byte after a START condition is detected.

When this bit is set to 1b, if the received first byte matches the Hs-mode master code, IIC recognizes that the Hs-mode master code has been received.

The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVADn.SVAD[9:0].

If the addresses match, the transmission / reception operation continues according to the R/W# bit value.

Hs-mode continues until a STOP condition is detected.

When this bit is set to 0b, I3C will ignore the pattern until a STOP condition is detected, even if it matches the Hs-mode master code.

Note: When this bit is set to 1b, SCSTRCTL.ACKTWE bit must be set to 0b and SCSTRCTL.RWE bit must be set to 1b.

DVIDE bit (Device-ID Address Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID (1111 100) is received in the first byte after a START condition or Repeated START condition is detected.

When this bit is set to 1b, if the received first byte matches the Device-ID, I3C recognizes that the Device-ID address has been received. When the following R/W# bit is 0b (write), I3C recognizes the second and the following bytes as slave addresses and continues the receive operation.

When this bit is set to 0b, I3C ignores the received first byte even if it matches the Device ID address and recognizes the first byte as a normal slave address.

For details on the Device-ID address detection, see **(c) Device-ID Address Detection [I2C mode]**.

HOAE bit (Host Address Enable)

This bit is used to specify whether to ignore received host address (0001 000) when the BFCTL.SMBS bit = 1b.

When this bit is set to 1b while the SMBS bit = 1b, if the received slave address matches the host address, I3C recognizes the received slave address as the host address independently of the slave addresses set in the SVDVADn.SVAD[9:0] bits (n = 0 to 2) and performs the receive operation.

When the SMBS bit or the HOAE bit is set to 0b, the received slave address is ignored even if it matches the host address.

SVAEn bits (Slave Address Enable n) (n = 0 to 2)

This bit is used to enable or disable the slave address set in the SVDVADn.SVAD[9:0] bits.

When this bit is set to 1b, the slave address set in the SVAD[9:0] bits is enabled and is compared with the received slave address.

When this bit is set to 0b, the slave address set in the SVAD[9:0] bits is disabled and is ignored even if it matches the received slave address.

7.8.3.2.14 Reference Clock Control Register (I3Cm_REFCKCTL)

Access Size : 32 bits
Address : <I3C_base> + 0070h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	IREFCKS*1 [2:0]	0h	RW	Internal Reference Clock Selection Selects the internal reference clock source (I3Cϕ) for I3C. 000b: I3C_0_TCLK/1 clock 001b: I3C_0_TCLK/2 clock 010b: I3C_0_TCLK/4 clock 011b: I3C_0_TCLK/8 clock 100b: I3C_0_TCLK/16 clock 101b: I3C_0_TCLK/32 clock 110b: I3C_0_TCLK/64 clock 111b: I3C_0_TCLK/128 clock

Note 1. Set the IREFCKS[2:0] bits to 000b in I3C mode.

7.8.3.2.15 Standard Bit Rate Register (I3Cm_STDBR)

The STDBR register sets the bit rate according to the operating speed.

- I^2C mode: Bit rate setting when communicating with Standard-mode / Fast-mode / Fast-mode plus
- I3C master mode: Bit rate setting selected by mode bit of command descriptor
- I3C slave mode: I3C bit rate setting

Access Size : 32 bits
Address : <I3C_base> + 0074h
Initial Value : 3F3F_FFFFh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DSBRPO	-	SBRHP[5:0]						-	-	SBRLP[5:0]					
Initial Value	0	0	1	1	1	1	1	1	0	0	1	1	1	1	1	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SBRHO[7:0]								SBRLO[7:0]							
Initial Value	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	DSBRPO	0h	RW	Double the Standard Bit Rate Period for Open-Drain*4 0b: The time period set for SBRHO[7:0] and SBRLO[7:0] is not doubled. 1b: The time period set for SBRHO[7:0] and SBRLO[7:0] is doubled.
30	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
29 to 24	SBRHP[5:0]	3Fh	RW	Standard Bit Rate High-Level Period Push-Pull*3 Count value of the high-level period of SCL30 clock
23, 22	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
21 to 16	SBRLP[5:0]	3Fh	RW	Standard Bit Rate Low-level Period Push-Pull*2 Count value of the low-level period of SCL30 clock
15 to 8	SBRHO[7:0]	FFh	RW	Standard Bit Rate High-Level Period Open-Drain*1 Count value of the high-level period of SCL30 clock
7 to 0	SBRLO[7:0]	FFh	RW	Standard Bit Rate Low-Level Period Open-Drain*1 Count value of the low-level period of SCL30 clock

Note 1. These bits support I^2C, I3C master, and I3C secondary master mode.

Note 2. These bits support I3C master mode and I3C secondary master mode.

Note 3. These bits support all I3C mode.

Note 4. This bit supports I^2C, I3C master, and I3C secondary master mode.

The I^2C transfer rate and the SCL clock duty are calculated using the following expression.

$$\text{Transfer rate} = 1/\{[(\text{High} - \text{Level Period} + \alpha^{*1}) + (\text{Low} - \text{Level Period} + \alpha)]/\text{I3C}\phi^{*2} + \text{SCL line rising time [tr]}^{*3} + \text{SCL line falling time [tf]}^{*3}\}$$

$$\text{Duty cycle} = \{\text{SCL line rising time [tr]} + (\text{High} - \text{Level Period} + \alpha)/\text{I3C}\phi\}/\{\text{SCL line falling time [tf]} + (\text{Low} - \text{Level Period} + \alpha)/\text{I3C}\phi\}$$

Note 1. α depend on the number of stages in the noise filter.

Note 2. I3Cϕ = I3C_0_TCLK × Division ratio

Note 3. The SCL line rising time [tr] and SCL line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I²C-bus specification from NXP Semiconductors.

The I3C transfer rate and the SCL clock duty are calculated using the following expression.

$$\text{Transfer rate} = 1/[(\text{High} - \text{Level Period} + \text{Low} - \text{Level Period})/\text{I3C}\phi + \text{SCL line rising time [tr]} + \text{SCL line falling time [tf]}]$$

$$\text{Duty cycle} = [\text{SCL line rising time [tr]} + \text{High} - \text{Level Period}/\text{I3C}\phi]/[\text{SCL line falling time [tf]} + \text{Low} - \text{Level Period}/\text{I3C}\phi]$$

SBRLO[7:0] bits (Count value of the Low-level period of SCL clock)

The SBRLO[7:0] bits are used to set the low-level period of SCL clock in Open-Drain mode.

I3C counts the low-level period with the internal reference clock source (I3Cϕ) specified by the REFCKCTL.IREFCKS[2:0] bits. It also works to generate the data setup time for automatic SCL low-hold operation (see **(6) Clock Stretching [I2C mode]**); when I3C is used in I²C slave mode, these bits need to be set to a value longer than the data setup time*[1].

If the digital noise filter is enabled (INCTL.DNFE = 1b), set the SBRLO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

Note 1. Data setup time (tSU: DAT)
250 ns (up to 100 kbps: Standard-mode [Sm])
100 ns (up to 400 kbps: Fast-mode [Fm])
50 ns (up to 1 Mbps: Fast-mode plus [Fm+])
10 ns (up to 3.4 Mbps: Hs-mode [HS])

SBRHO[7:0] bits (Count value of the High-level period of SCL clock)

The SBRHO[7:0] bits use to set the high-level period of SCL clock in Open-Drain mode. SBRHO[7:0] bits are valid in master mode. If I3C is used only in I²C slave mode, these bits need not to set the high-level period.

I3C counts the high-level period with the internal reference clock source (I3Cϕ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1b), set the SBRHO[7:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

SBRLP[5:0] bits (Standard Bit Rate Low-level Period Push-Pull)

SBRLP[5:0] bits are used to set the low-level period of SCL clock in Push-Pull.

I3C counts the low-level period with the internal reference clock source (I3Cϕ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1b), set the SBRLP[5:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

SBRHP[5:0] bits (Standard Bit Rate High-Level Period Push-Pull)

SBRHP[5:0] bits is used to set the high-level period of SCL clock in Push-Pull mode.

SBRHP[5:0] bits are valid in master mode. If I3C is used only in I^2C slave mode, these bits need not to set the high-level period.

I3C counts the high-level period with the internal reference clock source (I3Cϕ) specified by the REFCKCTL.IREFCKS[2:0] bits.

If the digital noise filter is enabled (the INCTL.DNFE bit = 1b), set the SBRHP[5:0] bits to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the INCTL.DNFS[3:0] bits.

DSBRPO bit (Double the Standard Bit Rate Period for Open-Drain)

When DSBRPO = 1b, double the high-level period that is set in SBRHO[7:0] and double the low-level period that is set in SBRLO[7:0].

Table 7.8-5 Requirement and Usage of Setting in Each Mode

	Device Mode				
Bit Name	I^2C Master	I^2C Slave	I3C Master	I3C Secondary Master	I3C Slave
SBRHP[5:0]	Not used	Do not use	Setting required*3	Setting required*4	Not used
SBRLP[5:0]	Not used	Do not use	Setting required*3	Setting required*5	Not used
SBRHO[7:0]	Setting required*1	Do not use	Setting required*3	Setting required*5	Not used
SBRLO[7:0]	Setting required*1	Setting required*2	Setting required*3	Setting required*5	Not used

Note 1. The setting value is used for the data rate of ST, FM, and FM+ mode.

Note 2. The setting value is used for the data setup time of automatic SCL low-hold operation.

Note 3. The setting value is used for the data rate of each communication.

Note 4. When operating with I3C Master, the setting value is used for the data rate of each communication.
When operating with I3C Slave, the setting value is not used.

Note 5. When operating with I3C Master, the setting value is used for the data rate of each communication.
When operating with I3C Slave, the setting value is not used.

7.8.3.2.16 Extended Bit Rate Register (I3Cm_EXTBR)

The EXTBR register sets the bit rate according to the operating speed.

- I^2C mode: Bit rate setting for communicating in high-speed mode
- I3C master mode: Bit rate setting selected by mode bit of command descriptor
- I3C slave mode: Unused

Access Size : 32 bits
Address : <I3C_base> + 0078h
Initial Value : 3F3F_FFFFh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
29 to 24	EBRHP[5:0]	3Fh	RW	Extended Bit Rate Low-Level Period Push-Pull*2 Count value of the high-level period of SCL30 clock
23, 22	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
21 to 16	EBRLP[5:0]	3Fh	RW	Extended Bit Rate Low-Level Period Push-Pull*2 Count value of the low-level period of SCL30 clock
15 to 8	EBRHO[7:0]	FFh	RW	Extended Bit Rate High-Level Period Open-Drain*1 Count value of the high-level period of SCL30 clock
7 to 0	EBRLO[7:0]	FFh	RW	Extended Bit Rate Low-Level Period Open-Drain*1 Count value of the low-level period of SCL30 clock

Note 1. These bits support I^2C, I3C master, and I3C secondary master mode.

Note 2. These bits support I3C master mode and I3C secondary master mode.

EBRLO[7:0] bits (Extended Bit Rate Low-Level Period Open-Drain)

See SBRLO[7:0] bits of **7.8.3.2.15 Standard Bit Rate Register (I3Cm_STDBR)** for details. Watch SBRHO, SBRLO as EBRHO[7:0], EBRLO[7:0].

EBRHO[7:0] bits (Extended Bit Rate High-Level Period Open-Drain)

See SBRHO[7:0] bits of **7.8.3.2.15 Standard Bit Rate Register (I3Cm_STDBR)** for details. Watch SBRHO, SBRLO as EBRHO[7:0], EBRLO[7:0].

EBRLP[5:0] bits (Extended Bit Rate Low-Level Period Push-Pull)

See SBRLP[5:0] bits of **7.8.3.2.15 Standard Bit Rate Register (I3Cm_STDBR)** for details. Watch SBRHP, SBRLP as EBRHP[5:0], EBRLP[5:0].

EBRHP[5:0] bits (Extended Bit Rate High-Level Period Push-Pull)

See SBRHP[5:0] bits of **7.8.3.2.15 Standard Bit Rate Register (I3Cm_STDBR)** for details. Watch SBRHP, SBRLP as EBRHP[5:0], EBRLP[5:0].

Table 7.8-6 Requirement and Usage of Setting in Each Mode

Bit Name	Device Mode				
	I^2C Master	I^2C Slave	I3C Master	I3C Secondary Master	I3C Slave
EBRHP[5:0]	Not used	Not used	Setting required*3	Setting required*4	Not used
EBRLP[5:0]	Not used	Not used	Setting required*3	Setting required*4	Not used
EBRHO[7:0]	Setting required*1	Not used	Setting required*3	Setting required*4	Not used
EBRLO[7:0]	Setting required*1	Setting required*2	Setting required*3	Setting required*4	Not used

Note 1. The setting value is used for the data rate of High-Speed mode.

Note 2. The setting value is used for the data setup time of automatic SCL low-hold operation in Hs-mode.

Note 3. The setting value is used for the data rate of each communication.

Note 4. When operating with I3C Master, the setting value is used for the data rate of each communication.
When operating with I3C Slave, the setting value is not used.

7.8.3.2.17 Bus Free Condition Detection Time Register (I3Cm_BFRECDT)

Access Size : 32 bits
Address : <I3C_base> + 007Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	FRECYC[8:0]								
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
8 to 0	FRECYC[8:0]	0h	RW	Bus Free Condition Detection Cycle The count value is a period for detecting the Bus free condition.

FRECYC[8:0] bits (Bus Free Condition Detection Cycle)

I3C counts the period for detecting the Bus free condition with the I3Cϕ.

These bits set the Bus Free period. This Bus Free period is counted by the internal reference clock (I3Cϕ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BFREF flag for Bus Free detection behavior.

7.8.3.2.18 Bus Available Condition Detection Time Register (I3Cm_BAVLCDT)

Access Size : 32 bits
Address : <I3C_base> + 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

	-	-	-	-	-	-	-	AVLCYC[8:0]								
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
8 to 0	AVLCYC[8:0]	0h	RW	Bus Available Condition Detection Cycle The count value is a period for detecting the Bus available condition.

Note: This register supports all I3C mode.

AVLCYC[8:0] bits (Bus Available Condition Detection Cycle)

I3C counts the period for detecting the Bus available condition with the I3Cϕ.

These bits set the Bus Available period. This Bus Available period is counted by the internal reference clock (I3Cϕ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BAVLF flag for Bus Available detection behavior.

7.8.3.2.19 Bus Idle Condition Detection Time Register (I3Cm_BIDLCDT)

Access Size : 32 bits
Address : <I3C_base> + 0084h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	IDLCYC[17:16]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IDLCYC[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
17 to 0	IDLCYC[17:0]	0h	RW	Bus Idle Condition Detection Cycle The count value is a period for detecting the Bus idle condition.

Note: This register supports all I3C mode.

IDLCYC[17:0] bits (Bus Idle Condition Detection Cycle)

I3C counts the period for detecting the Bus idle condition with the I3Cϕ.

These bits set the Bus Idle period. This Bus Idle period is counted by the internal reference clock (I3Cϕ) selected by the REFCKCTL.IREFCKS[2:0] bits. See the BCST.BIDLF flag for Bus Available detection behavior.

7.8.3.2.20 Output Control Register (I3Cm_OUTCTL)

Access Size : 32 bits
Address : <I3C_base> + 0088h
Initial Value : 0000_0003h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SDODCS	-	-	-	-	SDOD[2:0]			-	-	-	EXCYC	-	SOCWP	SCOC	SDOC
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	W	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
15	SDODCS	0h	RW	SDA30 Output Delay Clock Source Selection*3 0b: The internal reference clock (I3Cϕ) is selected as the clock source of the SDA30 output delay counter. 1b: The internal reference clock divided by 2 (I3Cϕ/2) is selected as the clock source of the SDA30 output delay counter.*4
14 to 11	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
10 to 8	SDOD[2:0]	0h	RW	SDA30 Output Delay*2 000b: No output delay 001b: 1 I3Cϕ cycle (When OUTCTL.SDODCS = 0b (I3Cϕ)) 1 or 2 I3Cϕ cycles (When OUTCTL.SDODCS = 1b (I3Cϕ/2)) 010b: 2 I3Cϕ cycles (When OUTCTL.SDODCS = 0b (I3Cϕ)) 3 or 4 I3Cϕ cycles (When OUTCTL.SDODCS = 1b (I3Cϕ/2)) 011b: 3 I3Cϕ cycles (When OUTCTL.SDODCS = 0b (I3Cϕ)) 5 or 6 I3Cϕ cycles (When OUTCTL.SDODCS = 1b (I3Cϕ/2)) 100b: 4 I3Cϕ cycles (When OUTCTL.SDODCS = 0b (I3Cϕ)) 7 or 8 I3Cϕ cycles (When OUTCTL.SDODCS = 1b (I3Cϕ/2)) 101b: 5 I3Cφ cycles (When OUTCTL.SDODCS = 0b (I3Cφ)) 9 or 10 I3Cϕ cycles (When OUTCTL.SDODCS = 1b (I3Cϕ/2)) 110b: 6 I3Cφ cycles (When OUTCTL.SDODCS = 0b (I3Cϕ)) 11 or 12 I3Cϕ cycles (When OUTCTL.SDODCS = 1b (I3Cϕ/2)) 111b: 7 I3Cφ cycles (When OUTCTL.SDODCS = 0b (I3Cφ)) 13 or 14 I3Cϕ cycles (When OUTCTL.SDODCS = 1b (I3Cϕ/2))
7 to 5	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	EXCYC	0h	RW	Extra SCL30 Clock Cycle Output*3 The EXCYC bit is cleared automatically after one clock cycle is output. 0b: Does not output an extra SCL30 clock cycle (default). 1b: Outputs an extra SCL30 clock cycle.
3	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	SOCWP	0h	W	SCL30/SDA30 Output Control Write Protect*1 0b: Bits SCOC and SDOC are protected. 1b: Bits SCOC and SDOC can be written (When writing simultaneously with the value of the target bit). This bit is read as 0b.
1	SCOC	1h	RW	SCL30 Output Control*1 High level output is achieved through an external pull-up resistor. 0b: I3C drives the SCL30 pin low. 1b: I3C releases the SCL30 pin.
0	SDOC	1h	RW	SDA30 Output Control*1 0b: I3C drives the SDA30 pin low. 1b: I3C releases the SDA30 pin.

Note 1. This bit supports I^2C, I3C master, and I3C secondary master mode.

Note 2. These bits support I^2C mode.

Note 3. This bit supports I^2C mode.

Note 4. The setting SDODCS = 1b (I3Cϕ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting SDODCS = 1b becomes invalid and the clock source becomes the internal reference clock (I3Cϕ).

SDOC bit (SDA Output Control) and SCOC bit (SCL Output Control)

These bits are used to directly control the SDA and SCL signals output from this module.

When writing to these bits, also write 1b to the SOCWP bit at the same time.

The result of setting these bits is input to I3C via the input buffer. When slave mode is selected, a START condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a START condition, STOP condition, Repeated START condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

EXCYC bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.

Normally, set the bit to 0b. Setting the bit to 1 in a normal communication state causes a communication error.

For details on this function, see **(10) Port Control**, **(a) Extra SCL Clock Cycle Output Function**.

7.8.3.2.21 Input Control Register (I3Cm_INCTL)

Access Size : 32 bits
Address : <I3C_base> + 008Ch
Initial Value : 0000_00D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	DNFE	DNFS[3:0]			
Initial Value	0	0	0	0	0	0	0	0	1	1	0	1	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7 to 6	-	All 1	RW	Reserved Whenever it is read, 1b is read. The written value should always be 1b.
5	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	DNFE	1h	RW	Digital Noise Filter Circuit Enable 0b: No digital noise filter circuit is used. 1b: A digital noise filter circuit is used.
3 to 0	DNFS[3:0]	0h	RW	Digital Noise Filter Stage Selection 0h: Noise of up to one I3Cϕ cycle is filtered out (single-stage filter). 1h: Noise of up to two I3Cϕ cycles is filtered out (2-stage filter). 2h: Noise of up to three I3Cϕ cycles is filtered out (3-stage filter). 3h: Noise of up to four I3Cϕ cycles is filtered out (4-stage filter). 4h: Noise of up to five I3Cϕ cycles is filtered out (5-stage filter). ⋮ Fh: Noise of up to sixteen I3Cϕ cycles is filtered out (16-stage filter).

Note: This register supports I^2C mode.

DNFS[3:0] bits (Digital Noise Filter Stage Selection)

These bits are used to select the number of stages in the digital noise filter.

For details on the digital noise filter function, see **(3) Digital Noise-Filter Circuits [I2C mode]**.

In I^2C High Speed mode, the module changes the number of noise filter stage to a quarter of the number of noise filter stage automatically.

Note: Set the noise range to be filtered out by the noise filter within a range less than the SCL line high-level period or low-level period. If the noise range is set to a value of (SCL clock width: high-level period or low-level period, whichever is shorter) - [1.5 internal reference clock (I3Cϕ) cycles] or more, the SCL clock is regarded as noise by the noise filter function of I3C, which may prevent I3C from operating normally.

Note: In I^2C High Speed mode, the lower 2 bits of the DNFS [3:0] bits are ignored, and the number of filter stages for 1 to 4 stages is selected by the upper 2 bits.

7.8.3.2.22 Timeout Control Register (I3Cm_TMOCTL)

Access Size : 32 bits
Address : <I3C_base> + 0090h
Initial Value : 0000_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7, 6	TOMDS[1:0]	0h	RW	Timeout Operation Mode Selection 00b: Timeout is detected during the following conditions: The bus is busy (BCST.BFREF = 0) in master mode. I3C's own slave address is detected and the bus is busy in slave mode. The bus is free (BCST.BFREF = 1) while generation of a START condition is requested (CNDCTL.STCND = 1). 01b: Timeout is detected while the bus is busy. 10b: Timeout is detected while the bus is free. 11b: Setting prohibited
5	TOHCTL	1h	RW	Timeout H Count Control 0b: Count is disabled while the SCL30 line is at a high level. 1b: Count is enabled while the SCL30 line is at a high level.
4	TOLCTL	1h	RW	Timeout L Count Control 0b: Count is disabled while the SCL30 line is at a low level. 1b: Count is enabled while the SCL30 line is at a low level.
3, 2	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1, 0	TODTS[1:0]	0h	RW	Timeout Detection Time Selection 00b: 16-bit timeout 01b: 14-bit timeout 10b: 8-bit timeout 11b: 6-bit timeout

TODTS[1:0] bits (Timeout Detection Time Selection)

These bits are used to select for the timeout detection time when the timeout function is enabled (BSTE.TODE bit = 1b).

When these bits are set to 00b, the timeout detection internal counter functions as a 16-bit counter.

When these bits are set to 01b, the counter functions as a 14-bit counter.

When these bits are set to 10b, the counter functions as an 8-bit counter.

When these bits are set to 11b, the counter functions as a 6-bit counter.

While the SCL line is in the state that enables this counter as specified by bits TOHCTL and TOLCTL, the counter counts up in synchronization with the internal reference clock (I3Cϕ) as a count source.

For details on the timeout function, see **(3) Timeout Error Detection**.

TOLCTL bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held low when the timeout function is enabled (BSTE.TODE = 1b).

TOHCTL bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCL line is held high when the timeout function is enabled (BSTE.TODE = 1b).

TOMDS[1:0] bits (Timeout Operation Mode Selection)

These bits are used to select the detection condition for timeout when the timeout function is enabled.

7.8.3.2.23 Wake-Up Unit Control Register (I3Cm_WUCTL)

Access Size : 32 bits
Address : <I3C_base> + 0098h
Initial Value : 0000_0041h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	WUFE	WUFSYNE	-	WUANFS	-	-	-	WUACKS
Initial Value	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7	WUFE	0h	RW	Wake-Up Function Enable 0b: Wake-up function disabled 1b: Wake-up function enabled Do not set WUFE = 0 during wake-up operation.
6	WUFSYNE	1h	RW	Wake-Up Function Synchronous Enable 0b: I3C asynchronous circuit enabled 1b: I3C synchronous circuit enabled
5	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	WUANFS	0h	RW	Wake-Up Analog Noise Filter Selection*1 0b: Do not add the Wake-Up analog filter. 1b: Add the Wake-Up analog filter.
3 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	WUACKS	1h	RW	Wake-Up Acknowledge Selection*1 Choice of four response modes with a combination of RSTCTL.INTLRST bit and WUACKS bit. Shown in the **Table 7.8-7**.

Note 1. This bit supports I^2C mode.

Table 7.8-7 Wake-Up Mode

INTLRST	WUACKS	Operation Mode	Description
0	0	Normal Wake-up mode 1	ACK response at 9th SCL and SCL low-hold after at 9th SCL.
0	1	Normal Wake-up mode 2	No ACK response immediately and SCL low-hold between 8th and 9th SCL. Release SCL low-hold and ACK response at 9th SCL.
1	0	Command recovery mode	ACK response at 9th SCL and not SCL low-hold.
1	1	EEP response mode	NACK response at 9th SCL and not SCL low-hold.

Note: In Wake-up mode 2, HS mode cannot be used.

WUFSYNE bit (Wake-Up Function Synchronous Enable)

This bit is used to switch between the I3C_0_PCLK synchronous operation and the I3C_0_PCLK asynchronous operation.

The bit is used in combination with the WUASYNF flag when Wake-up function is effective (WUCTL.WUFE bit =1b).

- When switching from the I3C_0_PCLK synchronous operation to the I3C_0_PCLK asynchronous operation:

- I3C operation changes into the I3C_0_PCLK asynchronous operation while the BCST.BFREF flag = 1, when the WUASYNF flag set to 1 while the WUFSYNE bit = 0b.
- The reception can operate without depending on the state of operation of I3C_0_PCLK (with I3C_0_PCLK stopped) after it switches to the I3C_0_PCLK asynchronous operation (Wake-up event detection operation).

- When switching from the I3C_0_PCLK asynchronous operation to the I3C_0_PCLK synchronous operation:
  - I3C operation changes into the I3C_0_PCLK synchronous operation at the following conditions. (At the same timing when the WUASYNF flag becomes 0)
  - In the case Wake-up event is detected: right after the WUFSYNE bit is set to 1b.
  - In the case Wake-up event is not detected: when STOP condition is detected after the WUFSYNE bit is set to 1b.

[Setting conditions]

- When 1b is written to the WUFSYNE bit.
- WUCTL.WUFE=0b

[Clearing condition]

- When 0b is written to the WUFSYNE bit.

7.8.3.2.24 Acknowledge Control Register (I3Cm_ACKCTL)

Access Size : 32 bits
Address : <I3C_base> + 00A0h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	ACKT WP	ACKT	ACKR
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	W	RW	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	ACKTWP	0h	W	ACKT Write Protect 0b: The ACKT bit are protected. 1b: The ACKT bit can be written (when writing simultaneously with the value of the target bit). This bit is read as 0b.
1	ACKT	0h	RW	Acknowledge Transmission 0b: A 0 is sent as the acknowledge bit (ACK transmission). 1b: A 1 is sent as the acknowledge bit (NACK transmission).
0	ACKR	0h	R	Acknowledge Reception 0b: A 0 is received as the acknowledge bit (ACK reception). 1b: A 1 is received as the acknowledge bit (NACK reception).

Note: This register supports I^2C mode.

ACKR bit (Acknowledge Reception)

This bit is used to store the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1b is received as the acknowledge bit with the PRSST.TRMD bit set to 1b.

[Clearing condition]

- When 0b is received as the acknowledge bit with the PRSST.TRMD bit set to 1b.

ACKT bit (Acknowledge Transmission)

[Setting condition]

- When 1b is written to the ACKT bit and 1b is written to the ACKTWP bit at the same time.

[Clearing conditions]

- When 0b is written to the ACKT bit and 1b is written to the ACKTWP bit at the same time.
- When a STOP condition is detected. (when a STOP condition is detected with the CNDCTL.SPCND bit set to 1b.)

Note: Set the ACKT bit to 0b in I^2C Slave mode.

ACKTWP bit (ACKT Write Protect)

This bit is used to control the modification of the ACKT bit.

When changing the ACKT bit, setting this bit to 1b at the same time can change the ACKT bit.

When this bit is read, 0b is always read.

7.8.3.2.25 SCL Stretch Control Register (I3Cm_SCSTRCTL)

Access Size : 32 bits
Address : <I3C_base> + 00A4h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RWE	ACKTWE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	RW	Reserved Whenever it is read, 0 is read. The written value should always be 0b.
1	RWE	0h	RW	Receive Wait Enable 0b: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.) 1b: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low-hold is released by reading NTDTBP0.
0	ACKTWE	0h	RW	Acknowledge Transmission Wait Enable 0b: NTST.RDBFF0 is set at the rising edge of the ninth SCL30 clock cycle. (The SCL30 line is not held low at the falling edge of the eighth clock cycle.) 1b: NTST.RDBFF0 is set at the rising edge of the eighth SCL30 clock cycle. (The SCL30 line is held low at the falling edge of the eighth clock cycle.) Low-hold is released by writing a value to the ACKCTL.ACKT bit.

Note: This register supports I^2C mode.

ACKTWE bit (Acknowledge Transmission Wait Enable)

This bit is used to select the NTST.RDBFF0 flag set timing in receive mode and also to select whether to hold the SCL line low at the falling edge of the eighth SCL clock cycle.

When ACKTWE = 0b, the SCL line is not held low at the falling edge of the eighth SCL clock cycle, and the NTST.RDBFF0 flag is set to 1 at the rising edge of the ninth SCL clock cycle.

When ACKTWE = 1b, the NTST.RDBFF0 flag is set to 1b at the rising edge of the eighth SCL clock cycle and the SCL line is held low at the falling edge of the eighth SCL clock cycle. The low-hold of the SCL line is released by writing a value to the ACKCTL.ACKT bit.

After data is received with this setting, the SCL line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKCTL.ACKT = 0b) or NACK (ACKCTL.ACKT = 1b) according to receive data.

RWE bit (Receive Wait Enable)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (NTDTBP0) is completely read each time single-byte data is received in receive mode.

When RWE = 0b, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the ACKTWE and RWE bits = 0b, continuous receive operation is enabled with the double buffer.

When RWE = 1b, the SCL line is held low from the falling edge of the ninth clock cycle until the NTDTBP0 value is read each time single-byte data is received.

This enables receive operation in byte units.

Note: When the value of the RWE bit is to be read, be sure to read the NTDTBP0 beforehand.

7.8.3.2.26 SCL Stalling Control Register (I3Cm_SCSTLCTL)

When setting this register, follow Chapter 5.1.2.5 Master Clock Stalling of MIPI I3C Spec V1.0, and use it only when necessary because of its negative impacts on bus performance.

Access Size : 32 bits
Address : <I3C_base> + 00B0h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ACKPE	PARPE	-	AAPE	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	STLCYC[15:0]

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	ACKPE	0h	RW	ACK phase Enable Stall enable bit during ACK/NACK phase 0b: Does not stall the SCL30 clock during the ACK/NACK phase. 1b: Stall the SCL30 clock during the ACK/NACK phase.
30	PARPE	0h	RW	Parity Phase Enable Stall enable bit in parity bit period 0b: Does not stall the SCL30 clock during the parity bit period. 1b: Stall the SCL30 clock during the parity bit period.
29	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
28	AAPE	0h	RW	Assigned Address Phase Enable Enable bit that allows stall by the first bit at address assignment 0b: Does not stall the SCL30 clock during the address assignment phase. 1b: Stall the SCL30 clock during address assignment phase.
27 to 16	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
15 to 0	STLCYC[15:0]	0h	RW	Stalling Cycle Counter setting of stall period (I3Cϕ cycle). Common use for each phase.

Note: This register supports I3C master mode and I3C secondary master mode.

STLCYC[15:0] bits (Stalling Cycle)

These bits set the SCL stall period. The SCL stall period is counted by the internal reference clock (I3Cϕ). This is a counter common to the enable bits of each phase.

AAPE bit (Assigned Address Phase Enable)

The master can stall SCL during the low period of the first bit of the assigned address phase of the Enter Dynamic Address Assignment CCC command. It can gain time in assigning dynamic address to the device based on the BCR and DCR of the slave. However, because the Dynamic Address Assignment procedure sends the dynamic address set in the DATBASm register in sequence, it is not necessary to set this bit and it is prohibited.

PARPE bit (Parity Phase Enable)

The parity bit of the transmission data of I3C write transfer can be used for SCL stalling to avoid underrun of the transmission data FIFO. However, when the transmission data FIFO of the I3C master becomes empty, SCL stalling is

performed regardless of the setting of this bit, it is not necessary to set this bit and it is prohibited. It is necessary to set this bit when the I3C slave requires preparation time to receive data.

ACKPE bit (ACK phase Enable)

Determine the need to perform SCL stalling in the ACK/NACK phase based on the following criteria:

- It is necessary to set this bit when the I3C and I^2C slaves connected to the bus require preparation time to receive or transmit data.
- In legacy I^2C communication, if there is a possibility that the data FIFO of the I3C master might underrun or overflow, it is not necessary to set this bit because SCL Stalling is performed by FIFO Empty or Full regardless of the setting of this bit.
- Other than legacy I^2C communication, the data FIFO of I3C master might underrun or overflow, and if SCL stalling is required in ACK phase, this bit can be set. However, it is necessary to build the software so that the FIFO does not underrun or overflow due to the interrupt generated according to the FIFO threshold setting (NQTHCTL, NTBTHCTL, NRQTHCTL).
- When I3C master responds ACK/NACK to IBI, it is not necessary to set this bit because ACK/NACK response can be set in advance by BCTL.HJACK, DATBASm.DVMRRJ and DATBASm.DVS IRRJ.
- It is necessary to set this bit when the I3C slave connected to the bus requires preparation time to transmit data for Direct GET CCC.

7.8.3.2.27 Slave Transfer Data Length Register (I3Cm_SVTDLG0)

Access Size : 32 bits
Address : <I3C_base> + 00C0h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	STDLG[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	W	Reserved The written value should always be 0b.
0	ATSTRG	0	W	The read value is undefined Asynchronous Timing Software Trigger 0b Write: Do nothing 1b Write: Software trigger (one-shot pulse) output This bit is always read as 0b

Note: This register supports I3C secondary master mode and I3C slave mode.

7.8.3.2.31 Asynchronous Timing Control Counter Enable Register (I3Cm_ATCCNTE)

Access Size : 32 bits

Address : <I3C_base> + 012Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	ATCE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	ATCE	0h	RW	Asynchronous Timing Counter Enable for MREF, MC2, SC1, SC2. 0b: Disable 1b: Enable

Note: This register supports all I3C mode.

7.8.3.2.32 Condition Control Register (I3Cm_CNDCTL)

Access Size : 32 bits
Address : <I3C_base> + 0140h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	SPCND	SRCND	STCND
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	SPCND	0h	RW	STOP (P) Condition Issuance 0b: Does not request to issue a STOP condition. 1b: Requests to issue a STOP condition.
1	SRCND	0h	RW	Repeated START (Sr) Condition Issuance 0b: Does not request to issue a Repeated START condition. 1b: Requests to issue a Repeated START condition.
0	STCND	0h	RW	START (S) Condition Issuance 0b: Does not request to issue a START condition. 1b: Requests to issue a START condition.

Note: This register supports I^2C mode.

STCND bit (START (S) Condition Issuance)

This bit is used to request transition to master mode and issuance of a START condition.

For details on the START condition issuance, see **(3) START Condition / Repeated START Condition / STOP Condition Issuing Function**.

[Setting condition]

- When 1b is written to the STCND bit

[Clearing conditions]

- When 0b is written to the STCND bit
- When a START condition has been issued (A START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1b

Note: Set the STCND bit to 1b (START condition issuance request) when the BCST.BFREF flag is set to 1b (bus free state). Note that arbitration may be lost due to a START condition issuance error if the STCND bit is set to 1b (START condition issuance request) when the BFREF flag is set to 0b (bus busy state).

SRCND bit (Repeated START (Sr) Condition Issuance)

This bit is used to request that a Repeated START condition be issued in master mode.

When this bit is set to 1b to request to issue a Repeated START condition, a Repeated START condition is issued when the BFREF flag is set to 0b (bus busy state) and the PRSST.CRMS bit is set to 1b (master mode).

For details on the Repeated START condition issuance, see **(3) START Condition / Repeated START Condition / STOP Condition Issuing Function**.

[Setting condition]

- When 1b is written to the SRCND bit with the BCST.BFREF flag set to 0b

[Clearing conditions]

- When 0b is written to the SRCND bit
- When a Repeated START condition has been issued (A Repeated START condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1b

Note: Do not set the SRCND bit to 1b while issuing a STOP condition.
If 1b (requests to issue a Repeated START condition) is written to the SRCND bit in slave mode, the Repeated START condition is not issued but the SRCND bit remains set to 1b.
If the operating mode changes to master mode with the bit not being cleared, note that the Repeated START condition may be issued.

SPCND bit (STOP (P) Condition Issuance)

This bit is used to request that a STOP condition be issued in master mode.

When this bit is set to 1b to request to issue a STOP condition, a STOP condition is issued when the BCST.BFREF flag is set to 0b (bus busy state) and the PRSST.CRMS bit is set to 1b (master mode).

For details on the STOP condition issuance, see **(3) START Condition / Repeated START Condition / STOP Condition Issuing Function**.

[Setting condition]

- When 1b is written to the SPCND bit with the BCST.BFREF flag set to 0b and the PRSST.CRMS bit set to 1b

[Clearing conditions]

- When 0b is written to the SPCND bit
- When a STOP condition has been issued (A STOP condition is detected)
- When the BST.ALF (arbitration-lost) flag is set to 1b
- When a START condition and a Repeated START condition are detected

Note: Writing to the SPCND bit is not possible while the setting of the BCST.BFREF flag = 1b (bus free state).
Do not set the SPCND bit to 1b while a Repeated START condition is being issued.

7.8.3.2.33 Normal Command Queue Port Register (I3Cm_NCMDQP)

32-bit mailbox register NCMDQP contains a command descriptor structure that depends on the requested transfer type:

- Address Assignment Command (see **(1) Address Assign Command**)
- Immediate Data Transfer (see **(2) Immediate Transfer Command**)
- Regular Data Transfer (see **(3) Regular Transfer Command**)
- Write + Write/Read Combo Transfer (see **(4) Combo Transfer Command**)
- Internal Control Command (see **(5) Internal Control Command**)

Within the command descriptor, DWORDs appear starting with the Least Significant DWORD, in order until the Most Significant DWORD.

Access Size : 32 bits
Address : <I3C_base> + 0150h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7.8.3.2.35 Normal Transfer Data Buffer Port Register (I3Cm_NTDTBP0/NTDTBP0_BY)

32-bit mailbox register NTDTBP0 is a 32-bit bi-directional data transfer register which is used both to read from the Normal Receive Data Buffer, and to write to the Normal Transmit Data Buffer.

In other words, the Normal Receive Data Buffer and the Normal Transmit Data Buffer have the same offset, forming a single bidirectional port for transmitting or receiving I3C data.

Access Size : 32 bits
Address : <I3C_base> + 0158h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NTDTBP0[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	NTDTBP0[31:0]	0h	RW	Normal Transfer Data Buffer Port NTDTBP0 is a 32-bit read/write register. NTDTBP0_BY (NTDTBP0[7:0]) is a 8-bit read/write register.

Note: NTDTBP0 is for 32-bit access in I3C mode.
NTDTBP0_BY is for 8-bit access in I^2C mode.

Read Operations:

[I3C protocol mode]

Data Read from the Normal Receive Data Buffer. It should be read based on Normal Queue Status Level indications. The Receive data is always aligned to a 4-byte boundary, and stored in the Normal Receive Data Buffer. If the length of the data transfer is not aligned to a 4-byte boundary, then there will be extra (unused) bytes at the end of the transferred data. The valid data must be identified using the DATA_LENGTH field in the Response Descriptor.

[I^2C protocol mode]

When 1 byte of data has been received, the received data is transferred from the internal shift register to NTDTBP0 to enable the next data to be received. The double-buffer structure of the internal shift register and NTDTBP0 allows continuous receive operation if the received data has been read from NTDTBP0 while the internal shift register is receiving data. Read data from NTDTBP0 once when a receive data full interrupt (INT_ri3c_rx_n) request is generated. If NTDTBP0 receives the next receive data before the current data is read from NTDTBP0 (while the RDBFF0 flag in NTST is 1b), this module automatically holds the SCL clock low one cycle before the RDBFF0 flag is set to 1b next. The lower 8 bits of the read 32-bit data are valid as received data.

Write Operations:

[I3C protocol mode]

Data Written to the Normal Transmit Data Buffer. Data DWORDs written to the Normal Transmit Data Buffer are placed onto the I3C bus one byte at a time, with the DWORD LSB first. Within each byte, bits are placed onto the I3C bus in big-endian order, with bit 7 going out first on the bus. The transmit data should always start aligned to a 4-byte

boundary, and written to the NTDTBP0 register. If the length of the transfer is not aligned to a 4-byte boundary, then there will be extra (unused) bytes at the end of the transferred data. I3C shall only send the valid number of bytes indicated in the DATA_LENGTH field of the Command Descriptor.

[I^2C protocol mode]

When NTDTBP0 detects a space in the internal shift register, it transfers the transmit data that has been written to NTDTBP0 to the internal shift register and starts transmitting data in transmit mode. The double-buffer structure of NTDTBP0 and the internal shift register allows continuous transmit operation if the next transmit data has been written to NTDTBP0 while the internal shift register data is being transmitted. Write transmit data to NTDTBP0 once when a transmit data empty interrupt (INT_ri3c_tx_n) request is generated. The lower 8 bits of the written 32-bit data are valid as transmission data.

7.8.3.2.36 Normal IBI Queue Port Register (I3Cm_NIBIQP)

Access Size : 32 bits
Address : <I3C_base> + 017Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NIBIQP[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NIBIQP[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	NIBIQP[31:0]	0h	RW	Normal IBI Queue Port

Note: This register supports all I3C mode.

When receiving an IBI, 32-bit mailbox register NIBIQP is used for both:

- Read the IBI status descriptor (see **7.8.4.1.3 IBI Status Descriptor**)
- Read the IBI data (which is raw/opaque data).

The IBI status descriptor is a read-only structure describing an IBI event received from a Slave device on the I3C bus.

Remark If the I3C HCI auto-read feature is used, then the IBI data includes the data received from the auto-generated private read operation.
Even if LAST_STATUS is set to 0b, the driver software still evaluates the data payload length by examining the CHUNKS field.

7.8.3.2.37 Normal Receive Status Queue Port Register (I3Cm_NRSQP)

32-bit mailbox register NRSQP contains a receive status structure (see **7.8.4.1.4 Receive Status Descriptor**).

Access Size : 32 bits
Address : <I3C_base> + 0180h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NRSQP[31:16]

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	NRSQP[31:0]	0h	R	Normal Receive Status Queue Port

Note: This register supports I3C secondary master mode and I3C slave mode.

7.8.3.2.38 Normal Queue Threshold Control Register (I3Cm_NQTHCTL)

The Queue Threshold Control register controls the interrupt trigger thresholds for the Command Queue, the Response Queue, and the IBI Queue.

Access Size : 32 bits
Address : <I3C_base> + 0190h
Initial Value : 0101_0101h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	IBIQTH[2:0]			IBIDSSZ[7:0]							
Initial Value	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
26 to 24	IBIQTH[2:0]	1h	RW	Normal IBI Queue Threshold*1 000b: I3C Protocol mode (Master): Interrupt is generated when the Outstanding IBI Status count is 1 or more. I3C Protocol mode (Slave): Interrupt is issued when IBI Data Buffer is completely empty. Others: I3C Protocol mode (Master): Interrupt is generated when the Outstanding IBI Status count is N + 1 or more. (N = IBIQTH[2:0]) I3C Protocol mode (Slave): Interrupt is issued when IBI Data Buffer contains N empties. (N = IBIQTH[2:0])
23 to 16	IBIDSSZ[7:0]	1h	RW	Normal IBI Data Segment Size*2 Supported Values: Minimum: 1 (4 bytes) Maximum: 63 (252 bytes), provided that the configured IBI Queue depth is 64 or more. When ATCCNTE.ATCE = 1, restrict to the number of segments is 2 or more.
15 to 10	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9, 8	RSPQTH[1:0]	1h	RW	Normal Response Queue Threshold*1 00b: Interrupt is issued when Response Queue contains 1 entry (DWORD). 01b: Interrupt is issued when Response Queue contains 2 entries (DWORD). 10b: Interrupt is issued when Response Queue contains 3 entries (DWORD). 11b: Interrupt is issued when Response Queue contains 4 entries (DWORD).
7 to 2	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1, 0	CMDQTH[1:0]	1h	RW	Normal Command Ready Queue Threshold*1 00b: Interrupt is issued when Command Queue is completely empty. 01b: Interrupt is issued when Command Queue contains 1 empty. 10b: Interrupt is issued when Command Queue contains 2 empties. 11b: Interrupt is issued when Command Queue contains 3 empties.

Note: This register supports I3C secondary master mode and I3C slave mode.

Note 1. These bits support all I3C mode.

Note 2. These bits support I3C master mode and I3C secondary master mode.

CMDQTH[1:0] bits (Normal Command Ready Queue Threshold)

Controls the minimum number of Command Queue empties needed to trigger the INTCMD interrupt.

RSPQTH[1:0] bits (Normal Response Queue Threshold)

Controls the minimum number of Response Queue entries needed to trigger the INTRESP interrupt.

IBIDSSZ[7:0] bits (Normal IBI Data Segment Size)

This is the IBI data segment size, in DWORDs (4 bytes).

In PIO mode, this field allows the incoming IBI data to be sliced into multiple segments generating status individually, to support cutthrough readout of a long IBI payload data.

When Asynchronous Timing Control mode is supported, this field should be set to a value other than 1 or 3 to allow the single data segment to contain the entire Master time-stamp value (i.e., both MREF and MC2).

IBIQTH[2:0] bits (Normal IBI Queue Threshold)

For I3C protocol mode (Master): PRTS.PRTMD = 0b and PRSST.CRMS = 1b.

Controls generation of the INTIBI interrupt, based on the value of the IBI Queue's Outstanding IBI status count.

Each IBI status entry can represent either the complete IBI payload (if the IBI payload byte size is 4×IBIDSSZ or less), or a segment of the IBI payload (if the IBI payload byte size is more than 4 × IBIDSSZ).

For I3C protocol mode (Slave): PRTS.PRTMD bit = 0b, PRSST.CRMS bit = 0b.

Controls the minimum number of IBI Data Buffer empties needed to trigger the INTIBI interrupt.

7.8.3.2.39 Normal Transfer Data Buffer Threshold Control Register (I3Cm_NTBTHCTL0)

The Data Buffer Control register controls the interrupt trigger thresholds for the Receive Data Buffer Queue and the Transmit Data Buffer Queue.

Access Size : 32 bits
Address : <I3C_base> + 0194h
Initial Value : 0101_0101h

18 to 16	TXSTTH[2:0]	1h	RW	Normal Transmit Start Threshold*2 000b: Wait for 2 entry DWORDs 001b: Wait for 4 entry DWORDs 010b: Wait for 8 entry DWORDs 011b: Wait for 16 entry DWORDs Others: Setting prohibited
15 to 11	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
10 to 8	RXDBTH[2:0]	1h	RW	Normal Receive Data Buffer Threshold*1 000b: Interrupt triggers at 2 Receive Buffer entries, in DWORDs 001b: Interrupt triggers at 4 Receive Buffer entries, in DWORDs 010b: Interrupt triggers at 8 Receive Buffer entries, in DWORDs Others: Setting prohibited
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	TXDBTH[2:0]	1h	RW	Normal Transmit Data Buffer Threshold*1 000b: Interrupt triggers at 2 Transmit Buffer empties, in DWORDs 001b: Interrupt triggers at 4 Transmit Buffer empties, in DWORDs 000b: Interrupt triggers at 8 Transmit Buffer empties, in DWORDs Others: Setting prohibited

Note 1. These bits support all I3C mode.

Note 2. These bits support I3C master mode and I3C secondary master mode.

TXDBTH[2:0] bits (Normal Transmit Data Buffer Threshold)

Minimum number of Transmit FIFO empties, in DWORDs, that will trigger the INT_ri3c_tx_n interrupt.

RXDBTH[2:0] bits (Normal Receive Data Buffer Threshold)

Minimum number of Receive FIFO entries in DWORDs that will trigger the INT_ri3c_rx_n interrupt.

TXSTTH[2:0] bits (Normal Transmit Start Threshold)

When preparing to initiate a Write Transfer on the I3C Bus, I3C shall wait until the Transmit Buffer has at least the indicated number of locations available.

Two optional configurable Modes are available:

(1) Store and Forward Mode
If the TXSTTH[2:0] field is set to the Transmit Buffer size (011b), then I3C shall delay initiation of the Write Command as follows:

- If the data length to be transferred is more than the Transmit Buffer size (16 DWORDs), then this module shall wait until the Transmit FIFO is completely full.
- If the data length to be transferred is less than the Transmit Buffer size (16 DWORDs), then I3C shall wait until enough Transmit FIFO locations are available to store the data to be transferred.

(2) Threshold Mode
If the TXSTTH[2:0] field value is less than the Transmit Buffer size (011b), then I3C shall initiate the Write Command as soon as the indicated number of Transmit FIFO locations are entries.

RXSTTH[2:0] bits (Normal Receive Start Threshold)

When preparing to initiate a Read Transfer on the I3C bus, I3C shall wait until the Receive Buffer has at least the indicated number of empty locations in DWORDs.

Two optional configurable Modes are available:

(1) Store and Forward Mode
If the RXSTTH[2:0] field is set to the Receive Buffer size (011b), then I3C shall delay initiation of the Read Command as follows:

- If the data length to be transferred is more than the Receive Buffer size (16 DWORDs), then this module shall wait until the Receive FIFO is completely empty.
- If the data length to be transferred is less than the Receive Buffer size (16 DWORDs), then I3C shall wait until enough Receive FIFO locations are available to store the data to be transferred.

(2) Threshold Mode
If the RXSTTH[2:0] field value is less than the Receive Buffer size (011b), then I3C shall initiate the Read Command as soon as the indicated number of Receive FIFO locations are empty.

7.8.3.2.40 Normal Receive Status Queue Threshold Control Register (I3Cm_NRQTHCTL)

Access Size : 32 bits

Address : <I3C_base> + 01C0h

Initial Value : 0000_0001h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
24	WUCNDDF	0h	RW*2	Wake-Up Condition Detection Flag 0b: Wake-Up Condition is not detected. 1b: Wake-Up Condition is detected.
23 to 21	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
20	TODF	0h	RW*2	Timeout Detection Flag 0b: Timeout is not detected. 1b: Timeout is detected.
19 to 17	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
16	ALF	0h	RW*2	Arbitration Lost Flag*1 0b: Arbitration is not lost 1b: Arbitration is lost.
15 to 9	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
8	TENDF	0h	RW*2	Transmit End Flag*1 0b: Data is being transmitted. 1b: Data has been transmitted.
7 to 5	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	NACKDF	0h	RW*2	NACK Detection Flag*1 0b: NACK is not detected. 1b: NACK is detected.
3, 2	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1	SPCNDDF	0h	RW*2	STOP Condition Detection Flag 0b: STOP condition is not detected. 1b: STOP condition is detected.
0	STCNDDF	0h	RW*2	START Condition Detection Flag 0b: START condition is not detected. 1b: START condition is detected.

Note 1. This bit supports I^2C mode.

Note 2. Clearing (to 0) condition: Writing 0b after 1b is read.

STCNDDF bit (START Condition Detection Flag)

[Setting conditions]

- All of the followings are satisfied:

1) The BSTE.STCNDDE bit = 1b.
   Thexxx
2) When a START condition (or a Repeated START condition) is detected.

[Clearing conditions]

- When 0b is written to the STCNDDF flag after reading STCNDDF flag = 1b.
- When a STOP condition is detected.

SPCNDDF bit (STOP Condition Detection Flag)

[Setting conditions]

- All of the followings are satisfied:
  1) The BSTE.SPCNDDE bit = 1b.
  2) When a STOP condition is detected.

[Clearing condition]

- When 0b is written to the SPCNDDF flag after reading SPCNDDF flag = 1b.

NACKDF bit (NACK Detection Flag)

[Setting conditions]

- All of the followings are satisfied:
  1) The PRTS.PRTMD bit = 1b (I^2C protocol mode).
  2) The BSTE.NACKDE bit = 1b (Enables NACK detection interrupt status logging).
  3) When acknowledge is not received (NACK is received) from the receive device in transmit mode.

[Clearing condition]

- When 0b is written to the NACKDF flag after reading NACKDF flag = 1b.

TENDF bit (Transmit End Flag)

[Setting conditions]

- All of the followings are satisfied:
  1) The PRTS.PRTMD bit = 1b (I^2C protocol mode).
  2) The BSTE.TENDE bit = 1b (Enables Transmit End Interrupt Status logging).
  3) At the rising edge of the ninth SCL clock cycle while the NTST.TDBEF0 flag = 1b. Excluding when sending an address.

[Clearing conditions]

- When 0b is written to the TENDF flag after reading TENDF flag = 1b.
- When data is written to the NTDTBP0 register.
- When a STOP condition is detected.

ALF bit (Arbitration Lost Flag)

[Setting conditions]

- When master arbitration-lost detection is enabled: BSTE.ALE bit = 1b, BFCTL.MALE = 1b.

- When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data (including slave address) transmission in master transmit mode (when the SDA line is driven low while the internal SDA output is at a high level (the SDA pin is in the high-impedance state)).
- All of the followings are satisfied.
  1) When the START condition is detected while the CNDCTL.STCND bit = 1b.
  2) When the internal SDA output state does not match the SDA line level.
- When the CNDCTL.STCND bit is set to 1 (START condition issuance request) while the BCST.BFREF flag = 0b.

- When NACK arbitration-lost detection is enabled: BSTE.ALE bit = 1b, BFCTL.NALE = 1b.
  - When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock in the ACK period during NACK transmission in receive mode.
- When slave arbitration-lost detection is enabled: BSTE.ALE bit = 1b, BFCTL.SALE = 1b.
  - When the internal SDA output state does not match the SDA line level at the rising edge of SCL clock except for the ACK period during data transmission in slave transmit mode.

[Clearing condition]

- When 0b is written to the ALF flag after reading ALF flag = 1b.

TODF bit (Timeout Detection Flag)

[Setting conditions]

- All of the followings are satisfied.
  1) The BSTE.TODE bit = 1b (Enables Timeout Detection Interrupt Status logging).
  2) When the master mode or the received slave address matches the slave address n in Slave mode.
  3) When the SCL line state remains unchanged for the period specified by TMOCTL register.

[Clearing condition]

- When 0b is written to the TODF flag after reading TODF flag = 1b.

WUCNDDF bit (Wake-Up Condition Detection Flag)

[Setting conditions]

- For I^2C Protocol mode: PRTS.PRTMD bit = 1b.

  When I3C_0_PCLK and I3C_0_TCLK are supplied after all of the following 1) to 4) are satisfied.
  1) The WUCTL.WUFE bit = 1b (Wake-up function is enabled).
  2) The BSTE.WUCNDDE bit = 1b (Enables Wake-up Condition Detection Status logging).
  3) The WUST.WUASYNF flag = 1b.
  4) When the address received in slave mode matches the address of slave enabled in the SVCTL.SVAEn bit (except for the Device-ID address).
- For I3C Protocol mode (Master): PRTS.PRTMD bit = 0b, PRSST.CRMS bit = 1b.

  When I3C_0_PCLK and I3C_0_TCLK are supplied after all of the following 1) to 4) are satisfied.
  1) The WUCTL.WUFE bit = 1b (Wake-up function is enabled).
  2) The BSTE.WUCNDDE bit = 1b (Enables Wake-up Condition Detection Status logging).

3) The WUST.WUASYNF flag = 1b.

4) When low level of the SDA line is detected (When the START condition is detected).

- For I3C Protocol mode (Slave) : PRTS.PRTMD bit = 0b, PRSST.CRMS bit = 0b.

  When I3C_0_PCLK and I3C_0_TCLK are supplied after all of the following 1) to 4) are satisfied.

  1) The WUCTL.WUFE bit = 1b (Wake-up function is enabled).

  2) The BSTE.WUCNDDE bit = 1b (Enables Wake-up Condition Detection Status logging).

  3) The WUST.WUASYNF flag = 1b.

  4) When the Broadcast Address (7Eh) is detected after a START (or Repeated START) condition and the own Dynamic Address is detected after the Repeated START condition following the Broadcast Address.

[Clearing condition]

- When 0b is written to the WUCNDDF flag after reading WUCNDDF flag = 1b while the WUST.WUASYNF flag = 0b.

7.8.3.2.42 Bus Status Enable Register (I3Cm_BSTE)

Access Size : 32 bits

Address : <I3C_base> + 01D4h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
24	WUCNDDE	0h	RW	Wake-Up Condition Detection Enable 0b: Disables Wake-Up Condition Detection Status logging 1b: Enables Wake-Up Condition Detection Status logging
23 to 21	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
20	TODE	0h	RW	Timeout Detection Enable 0b: Disables Timeout Detection Interrupt Status logging. 1b: Enables Timeout Detection Interrupt Status logging.
19 to 17	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
16	ALE	0h	RW	Arbitration Lost Enable*1 0b: Disables Arbitration Lost Interrupt Status logging. 1b: Enables Arbitration Lost Interrupt Status logging.
15 to 9	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
8	TENDE	0h	RW	Transmit End Enable*1 0b: Disables Transmit End Interrupt Status logging. 1b: Enables Transmit End Interrupt Status logging.
7 to 5	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	NACKDE	0h	RW	NACK Detection Enable*1 0b: Disables NACK Detection Interrupt Status logging. 1b: Enables NACK Detection Interrupt Status logging.
3, 2	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1	SPCNDDE	0h	RW	STOP Condition Detection Enable 0b: Disables STOP condition Detection Interrupt Status logging. 1b: Enables STOP condition Detection Interrupt Status logging.
0	STCNDDE	0h	RW	START Condition Detection Enable 0b: Disables START condition Detection Interrupt Status logging. 1b: Enables START condition Detection Interrupt Status logging.

Note 1. This bit supports I^2C mode.

STCNDDE bit (START Condition Detection Enable)

When this bit is 1b, operation of BST.STCNDDF is enabled. For the setting conditions and clearing conditions of the BST.STCNDDF flag, see the details of BST.STCNDDF.

SPCNDDE bit (STOP Condition Detection Enable)

When this bit is 1b, operation of BST.SPCNDDF is enabled. For the setting conditions and clearing conditions of the BST.SPCNDDF flag, see the details of BST.SPCNDDF.

NACKDE bit (NACK Detection Enable)

When this bit is 1b, the operation of BST.NACKDF is enabled. This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received from the slave device in transmit mode. Normally, set this bit to 1b. For the setting conditions and clearing conditions of the BST.NACKDF flag, see the details of BST.NACKDF.

TENDE bit (Transmit End Enable)

When this bit is 1b, the operation of BST.TENDF is enabled. For the setting conditions and clearing conditions of the BST.TENDF flag, see the details of BST.TENDF.

ALE bit (Arbitration Lost Enable)

When this bit is 1b, the operation of BST.ALF is enabled. For the setting conditions and clearing conditions of the BST.ALF flag, see the details of BST.ALF.

TODE bit (Timeout Detection Enable)

When this bit is 1b, the operation of BST.TODF is enabled. For the setting conditions and clearing conditions of the BST.TODF flag, see the details of BST.TODF.

WUCNDDE bit (Wake-Up Condition Detection Enable)

When this bit is 1b, the operation of BST.WUCNDDF is enabled.

For the setting conditions and clearing conditions of the BST.WUCNDDF flag, see the details of BST.WUCNDDF.

7.8.3.2.43 Bus Interrupt Enable Register (I3Cm_BIE)

The BIE register enables signaling of outstanding bus interrupts received by I3C.

Access Size : 32 bits
Address : <I3C_base> + 01D8h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
24	WUCNDDIE	0h	RW	Wake-Up Condition Detection Interrupt Enable 0b: Disables Wake-Up Condition Detection Interrupt Signal. 1b: Enables Wake-Up Condition Detection Interrupt Signal.
23 to 21	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
20	TODIE	0h	RW	Timeout Detection Interrupt Enable 0b: Disables Timeout Detection Interrupt Signal. 1b: Enables Timeout Detection Interrupt Signal.
19 to 17	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
16	ALIE	0h	RW	Arbitration Lost Interrupt Enable*1 0b: Disables Arbitration Lost Interrupt Signal. 1b: Enables Arbitration Lost Interrupt Signal.
15 to 9	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
8	TENDIE	0h	RW	Transmit End Interrupt Enable*1 0b: Disables Transmit End Interrupt Signal. 1b: Enables Transmit End Interrupt Signal.
7 to 5	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	NACKDIE	0h	RW	NACK Detection Interrupt Enable*1 0b: Disables NACK Detection Interrupt Signal. 1b: Enables NACK Detection Interrupt Signal.
3, 2	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1	SPCNDDIE	0h	RW	STOP Condition Detection Interrupt Enable 0b: Disables STOP condition Detection Interrupt Signal. 1b: Enables STOP condition Detection Interrupt Signal.
0	STCNDDIE	0h	RW	START Condition Detection Interrupt Enable 0b: Disables START condition Detection Interrupt Signal. 1b: Enables START condition Detection Interrupt Signal.

Note 1. This bit supports I^2C mode.

STCNDDIE bit (START Condition Detection Interrupt Enable)

This bit enables or disables the START Condition Detection interrupt requests when the BST.STCNDDF flag is set to 1.

SPCNDDIE bit (STOP Condition Detection Interrupt Enable)

This bit enables or disables the STOP Condition Detection interrupt requests when the BST.SPCNDDF flag is set to 1b.

NACKDIE bit (NACK Detection Interrupt Enable)

This bit enables or disables the NACK Detection interrupt requests when the BST.NACKDF flag is set to 1b.

TENDIE bit (Transmit End Interrupt Enable)

This bit enables or disables the Transmit End interrupt (I3C_TEND) requests when the BST.TENDF flag is set to 1b.

ALIE bit (Arbitration Lost Interrupt Enable)

This bit enables or disables the Arbitration Lost interrupt requests when the BST.ALF flag is set to 1b.

TODIE bit (Timeout Detection Interrupt Enable)

This bit enables or disables the Timeout Detection interrupt requests when the BST.TODF flag is set to 1b.

WUCNDDIE bit (Wake-Up Condition Detection Interrupt Enable)

This bit is used to enable or disable the Wake-up condition detection interrupt (INTWU) requests when the BST.WUCNDDF flag is set to 1b.

7.8.3.2.44 Bus Status Force Register (I3Cm_BSTFC)

Access Size : 32 bits

Address : <I3C_base> + 01DCh

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	WUCNDDFC	-	-	-	TODFC	-	-	-	ALFC

R/W	R	R	R	R	R	R	R	W	R	R	R	W	R	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
24	WUCNDDFC	0h	W	Wake-Up Condition Detection Force 0b: Not Force Wake-Up Condition Detection Interrupt for software testing. 1b: Force Wake-Up Condition Detection Interrupt for software testing.
23 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	TODFC	0h	W	The read value is undefined Timeout Detection Force 0b: Not Force Timeout Detection Interrupt for software testing. 1b: Force Timeout Detection Interrupt for software testing.
19 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	ALFC	0h	W	The read value is undefined Arbitration Lost Force*1 0b: Not Force Arbitration Lost Interrupt for software testing. 1b: Force Arbitration Lost Interrupt for software testing.
15 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	TENDFC*2	0h	W	The read value is undefined Transmit End Force*1 0b: Not Force Transmit End Interrupt for software testing. 1b: Force Transmit End Interrupt for software testing.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	NACKDFC	0h	W	The read value is undefined NACK Detection Force*1 0b: Not Force NACK Detection Interrupt for software testing. 1b: Force NACK Detection Interrupt for software testing.
3	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	-	0h	W	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1	SPCNDDFC	0h	W	The read value is undefined STOP condition Detection Force 0b: Not Force STOP condition Detection Interrupt for software testing. 1b: Force STOP condition Detection Interrupt for software testing.
0	STCNDDFC	0h	W	The read value is undefined START condition Detection Force 0b: Not Force START condition Detection Interrupt for software testing. 1b: Force START condition Detection Interrupt for software testing.

Note 1. This bit supports I^2C mode.

Note 2. TENDFC does not work unless TDBEF0 = 1b.

7.8.3.2.45 Normal Transfer Status Register (I3Cm_NTST)

Access Size : 32 bits

Address : <I3C_base> + 01E0h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	RSQFF	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	TEF	-	-	-	TABTF	RSPQFF	CMDQEF	IBIQEFF	RDBFF0	TDBEF0

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
20	RSQFF	0h	RW*3	Normal Receive Status Queue Full Flag*2 0b: The number of Receive Status Queue entries is less than or equal to the NRQTHCTL.RSQTH threshold. 1b: The number of Receive Status Queue entries is more than the NRQTHCTL.RSQTH threshold.
19 to 10	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9	TEF	0h	RW*3	Normal Transfer Error Flag*1 0b: Transfer Error does not occur. 1b: Transfer Error occurs. To clear this bit, write 0 after 1 is read.
8 to 6	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5	TABTF	0h	RW*3	Normal Transfer Abort Flag*1 0b: Transfer Abort does not occur. 1b: Transfer Abort occur. To clear this bit, write 0 after 1 is read.
4	RSPQFF	0h	RW*3	Normal Response Queue Full Flag*1 0b: The number of Response Queue entries is less than or equal to the NQTHCTL.RSPQTH threshold. 1b: The number of Response Queue entries is more than the NQTHCTL.RSPQTH threshold.
3	CMDQEF	0h	RW*3	Normal Command Queue Empty Flag*1 0b: If the NQTHCTL.CMDQTH = 0b: The number of Command Queue empties is less than the Command Queue size. If the NQTHCTL.CMDQTH is other than 0b: The number of Command Queue empties is less than the NQTHCTL.CMDQTH threshold. 1b: If the NQTHCTL.CMDQTH = 0b: The number of Command Queue empties is the Command Queue size. If the NQTHCTL.CMDQTH is other than 0b: The number of Command Queue empties is more than or equal to the NQTHCTL.CMDQTH threshold.

Bit	Bit Name	Initial Value	R/W	Description
2	IBIQEFF	0h	RW*3	Normal IBI Queue Empty/Full Flag*1 0b: For I3C protocol mode (Master): PRTS.PRTMD bit = 0b, PRSST.CRMS bit = 1b. The number of IBI Status Queue entries is less than or equal to the NQTHCTL.IBIQTH threshold. For I3C protocol mode (Slave) : PRTS.PRTMD bit = 0b, PRSST.CRMS bit = 0b. If the NQTHCTL.IBIQTH = 0b: The number of IBI Data Buffer empties is less than the IBI Data Buffer size. If the NQTHCTL.IBIQTH is other than 0b: The number of IBI Data Buffer empties is less than the NQTHCTL.IBIQTH threshold. 1b: For I3C protocol mode (Master): PRTS.PRTMD bit = 0, PRSST.CRMS bit = 1b. The number of IBI Status Queue entries is more than the NQTHCTL.IBIQTH threshold. For I3C protocol mode (Slave) : PRTS.PRTMD bit = 0b, PRSST.CRMS bit = 0b. If the NQTHCTL.IBIQTH = 0b: The number of IBI Data Buffer empties is the IBI Data Buffer size. If the NQTHCTL.IBIQTH is other than 0b: The number of IBI Data Buffer empties is more than or equal to the NQTHCTL.IBIQTH threshold.
1	RDBFF0	0h	RW*3	Normal Receive Data Buffer Full Flag*1 0b: For I2C protocol mode: PRTS.PRTMD bit = 1b. Normal Receive Data Buffer contains no receive data. For I3C Protocol mode: PRTS.PRTMD bit = 0b. The number of entries in the Normal Receive Data Buffer is less than the NTBTHCTL0.RXDBTH[2:0] threshold. 1b: For I2C protocol mode: PRTS.PRTMD bit = 1b. Normal Receive Data Buffer contains receive data. For I3C Protocol mode: PRTS.PRTMD bit = 0b. The number of entries in the Normal Receive Data Buffer is more than or equal to the NTBTHCTL0.RXDBTH[2:0] threshold.
0	TDBEF0	0h	RW*3	Normal Transmit Data Buffer Empty Flag*1 0b: For I2C protocol mode: PRTS.PRTMD bit = 1b. Normal Transmit Data Buffer contains transmit data. For I3C protocol mode: PRTS.PRTMD bit = 0b. The number of empties in the Normal Transmit Data Buffer is less than the NTBTHCTL0.TXDBTH[2:0] threshold. 1b: For I2C protocol mode: PRTS.PRTMD bit = 1b. Normal Transmit Data Buffer contains no transmit data. For I3C protocol mode: PRTS.PRTMD bit = 0b. The number of empties in the Normal Transmit Data Buffer is more than or equal to the NTBTHCTL0.TXDBTH[2:0] threshold.

Note 1. This bit supports all I3C mode.

Note 2. This bit supports I3C secondary master mode and I3C slave mode.

Note 3. Clearing (to 0) condition: Writing 0b after 1b is read.

TDBEF0 bit (Normal Transmit Data Buffer Empty Flag)

[Setting conditions]

- For I^2C Protocol mode: PRTS.PRTMD bit = 1b.

  The following condition 1 is satisfied and any of the following conditions 2) to 4) are satisfied:

  1) The NTSTE.TDBEE0 bit = 1b (enables Transmit Data Buffer Empty Interrupt Status logging).
  2) When data has been transferred from the Normal Transmit Data Buffer to the Shift Register and the Normal Transmit Data Buffer becomes empty*1.
  3) When the PRSST.TRMD bit is set to 1b.
  4) 4When the received slave address matches while the TRMD bit = 1b.

- For I3C Protocol mode: PRTS.PRTMD bit = 0b.

  The following conditions 1) and 2) are satisfied:

  1) The NTSTE.TDBEE0 bit = 1b (enables Transmit Data Buffer Empty Interrupt Status logging).

2) When the number of empties in the Normal Transmit Data Buffer is the NTBTHCTL0.TXDBTH[2:0] threshold or more (see NTBTHCTL0 register).

[Clearing conditions]

- For I^2C Protocol mode: PRTS.PRTMD bit = 1b.
  - When data is written to NTDTBP0.
  - When the TRMD bit in PRSST is set to 0b.
- For I3C protocol mode: PRTS.PRTMD bit = 0b.
  - Write 0b to this bit after 1b is read.
  - On completion of the last write access to Normal Transmit Data by DMAC.
  - When the number of empties in the Normal Transmit Data Buffer is less than the NTBTHCTL0.TXDBTH[2:0] threshold (see NTBTHCTL0 register).

Note 1. When the BST.NACKDF flag is set to 1b while the BSTE.NACKDE bit = 1b, I3C aborts data transmission/reception. If the TDBEF0 flag = 0b (next transmit data has been written), data is transferred to the Shift Register and the Normal Transmit Data Buffer register becomes empty at the rising edge of the 9th clock cycle, but the TDBEF0 flag is not set to 1b.

RDBFF0 bit (Normal Receive Data Buffer Full Flag)

[Setting conditions]

- For I^2C Protocol mode: PRTS.PRTMD bit = 1b.

  The following condition 1 is satisfied and any of the following condition 2) or 3) is satisfied:

  1) The NTSTE.RDBFE0 bit = 1b (enables Receive Data Buffer Full Interrupt Status logging).
  2) When receive data is transferred from Shift Register to Normal Receive Data Buffer.
     The RDBFF0 flag is set to 1b on the rising edge of the 8th or 9th SCL clock cycle (selected in the ACKTWE bit in SCSTRCTL).
  3) When the received slave address matches after a START (or Repeated START) condition is detected with the TRMD bit in PRSST set to 0b.
- For I3C Protocol mode: PRTS.PRTMD bit = 0b. The following conditions 1) and 2) are satisfied:
  1) The NTSTE.RDBFE0 bit = 1b (enables Receive Data Buffer Full Interrupt Status logging).
  2) When the number of Normal Receive Data Buffer entries is the NTBTHCTL0.RXDBTH[2:0] threshold or more (see NTBTHCTL0 register).

[Clearing conditions]

- For I^2C Protocol mode: PRTS.PRTMD bit = 1b.
  - When data is read from NTDTBP0.
- For I3C Protocol mode: PRTS.PRTMD bit = 0b.
  - Write 0b to this bit after 1b is read.
  - On completion of the last read access to Normal Receive Data by DMAC.
  - When the number of Normal Receive Data Buffer entries is less than the NTBTHCTL0.RXDBTH[2:0] threshold (see NTBTHCTL0 register).

IBIQEFF bit (Normal IBI Queue Empty/Full Flag)

[Setting conditions]

- For I3C Protocol mode (Master): PRTS.PRTMD bit = 0b, PRSST.CRMS bit = 1b.

  The following 1) and 2) are satisfied.

  1) The NTSTE.IBIQEFE bit = 1b. (Enables IBI Status Buffer Empty/Full Interrupt Status logging)
  2) When the number of IBI Status Queue entries is more than the NQTHCTL.IBIQTH threshold (see register NQTHCTL).

- For I3C Protocol mode (Slave) : PRTS.PRTMD bit = 0b, PRSST.CRMS bit = 0b.

  If the NQTHCTL.IBIQTH = 0b:

  The following 1) and 2) are satisfied.

  1) The NTSTE.IBIQEFE bit = 1b. (Enables IBI Status Buffer Empty/Full Interrupt Status logging)
  2) When IBI Data Buffer is completely empty

- If the NQTHCTL.IBIQTH is other than 0b:

  The following 1) and 2) are satisfied.

  1) The NTSTE.IBIQEFE bit = 1b. (Enables IBI Status Buffer Empty/Full Interrupt Status logging)
  2) When the number of IBI Data Buffer empties is the NQTHCTL.IBIQTH threshold or more (see register NQTHCTL).

[Clearing conditions]

- For I3C protocol mode (master): PRTS.PRTMD bit = 0b, PRSST.CRMS bit = 1b.
  - Write 0b to this bit after 1b is read.
  - On completion of the last read access to IBI Status by DMAC.
  - When the number of IBI Status Queue entries is the NQTHCTL.IBIQTH threshold or less (see NQTHCTL register).
- For I3C protocol mode (slave): PRTS.PRTMD bit = 0b, PRSST.CRMS bit = 0b.
  - Write 0b to this bit after 1b is read.
  - On completion of the last write access to IBI Status by DMAC.
- If the NQTHCTL.IBIQTH = 0b:
  - When IBI Data Buffer is not completely empty.
- If the NQTHCTL.IBIQTH is other than 0b:
  - When the number of IBI Data Buffer empties is less than the NQTHCTL.IBIQTH threshold (see NQTHCTL register).

CMDQEF bit (Normal Command Queue Empty Flag)

[Setting conditions]

- If the NQTHCTL.CMDQTH = 0b:

  The following 1) and 2) are satisfied.

  1) The NTSTE.CMDQEE bit = 1b. (Enables Command Buffer Empty Interrupt Status logging)
  2) When Command Queue is completely empty

- If the NQTHCTL.CMDQTH is other than 0b:

  The following 1) and 2) are satisfied.

  1) The NTSTE.CMDQEE bit = 1b. (Enables Command Buffer Empty Interrupt Status logging)
  2) When the number of Command Queue empties is the NQTHCTL.CMDQTH threshold or more (see register NQTHCTL).

[Clearing conditions]

- Write 0b to this bit after 1b is read.
- On completion of the last write access to Normal Command by DMAC.

If the NQTHCTL.CMDQTH = 0b:

- When Command Queue is not completely empty.

If the NQTHCTL.CMDQTH is other than 0b:

- When the number of Command Queue empties is less than the NQTHCTL.CMDQTH threshold (see NQTHCTL register).

RSPQFF bit (Normal Response Queue Full Flag)

[Setting conditions]

- The following 2 conditions are satisfied:
  1) The NTSTE.RSPQFE bit = 1b (enables Response Buffer Full Interrupt Status logging).
  2) When the number of Response Queue entries is more than the NQTHCTL.RSPQTH threshold (see NQTHCTL register).

[Clearing conditions]

- Write 0b to this bit after 1b is read.
- On completion of the last read access to Normal Receive Status by DMAC.
- When the number of Response Queue entries is the NQTHCTL.RSPQTH threshold or less (see NQTHCTL register).

TABTF bit (Normal Transfer Abort Flag)

[Setting conditions]

- The following 2 conditions are satisfied:
  1) The NTSTE.TABTE bit = 1b (enables Transfer Abort Interrupt Status logging).
  2) When any transfer is aborted.

[Clearing condition]

- Write 0b to this bit after 1b is read.

TEF bit (Normal Transfer Error Flag)

[Setting conditions]

- The following 2 conditions are satisfied:
  1) The NTSTE.TEE bit = 1b (enables Transfer Error Interrupt Status logging).
  2) When any transfer error occurs on the I3C bus. The Error type for this error is available in the Response or Receive Status structure corresponding to the Transfer command.

[Clearing condition]

- Write 0b to this bit after 1b is read.

RSQFF bit (Normal Receive Status Queue Full Flag)

[Setting conditions]

- The following 2 conditions are satisfied:
  1) The NTSTE.RSQFE bit = 1b (Normal Receive Status Queue Full Enable).
  2) When the number of Receive Status Queue entries is more than the NRQTHCTL.RSQTH threshold (see NRQTHCTL register).

[Clearing conditions]

- Write 0 to this bit after 1 is read.
- On completion of the last read access to Normal Receive Status by DMAC.
- When the number of Receive Status Queue entries is the NRQTHCTL.RSQTH threshold or less (see register NRQTHCTL).

7.8.3.2.46 Normal Transfer Status Enable Register (I3Cm_NTSTE)

Access Size : 32 bits
Address : <I3C_base> + 01E4h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
20	RSQFE	0h	RW	Normal Receive Status Queue Full Enable*2 0b: Disables Receive Status Buffer Full Interrupt Status logging. 1b: Enables Receive Status Buffer Full Interrupt Status logging.
19 to 10	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9	TEE	0h	RW	Normal Transfer Error Enable*1 0b: Disables Transfer Error Interrupt Status logging. 1b: Enables Transfer Error Interrupt Status logging.
8 to 6	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5	TABTE	0h	RW	Normal Transfer Abort Enable*1 0b: Disables Transfer Abort Interrupt Status logging. 1b: Enables Transfer Abort Interrupt Status logging.
4	RSPQFE	0h	RW	Normal Response Queue Full Enable*1 0b: Disables Response Buffer Full Interrupt Status logging. 1b: Enables Response Buffer Full Interrupt Status logging.
3	CMDQEE	0h	RW	Normal Command Queue Empty Enable*1 0b: Disables Command Buffer Empty Interrupt Status logging. 1b: Enables Command Buffer Empty Interrupt Status logging.
2	IBIQEFE	0h	RW	Normal IBI Queue Empty/Full Enable*1 0b: Disables IBI Status Buffer Empty/Full Interrupt Status logging. 1b: Enables IBI Status Buffer Empty/Full Interrupt Status logging.
1	RDBFE0	0h	RW	Normal Receive Data Buffer Full Enable 0b: Disables Receive Data Buffer Full Interrupt Status logging. 1b: Enables Receive Data Buffer Full Interrupt Status logging.
0	TDBEE0	0h	RW	Normal Transmit Data Buffer Empty Enable 0b: Disables Transmit Data Buffer Empty Interrupt Status logging. 1b: Enables Transmit Data Buffer Empty Interrupt Status logging.

Note 1. This bit supports all I3C mode.

Note 2. This bit supports I3C secondary master mode and I3C slave mode.

TDBEE0 bit (Normal Transmit Data Buffer Empty Enable)

When this bit is 1b, the operation of NTST.TDBEF0 is enabled.

For the setting conditions and clearing conditions of the NTST.TDBEF0 flag, see the details of NTST.TDBEF0.

RDBFE0 bit (Normal Receive Data Buffer Full Enable)

When this bit is 1b, the operation of NTST.RDBFF0 is enabled.

For the setting conditions and clearing conditions of the NTST.RDBFF0 flag, see the details of NTST.RDBFF0.

IBIQEFE bit (Normal IBI Queue Empty/Full Enable)

When this bit is 1b, the operation of NTST.IBIQEFF is enabled.

For the setting conditions and clearing conditions of the NTST.IBIQEFF flag, see the details of NTST.IBIQEFF.

CMDQEE bit (Normal Command Queue Empty Enable)

When this bit is 1b, the operation of NTST.CMDQEF is enabled.

For the setting conditions and clearing conditions of the NTST.CMDQEF flag, see the details of NTST.CMDQEF.

RSPQFE bit (Normal Response Queue Full Enable)

When this bit is 1b, the operation of NTST.RSPQFF is enabled.

For the setting conditions and clearing conditions of the NTST.RSPQFF flag, see the details of NTST.RSPQFF.

TABTE bit (Normal Transfer Abort Enable)

When this bit is 1b, the operation of NTST.TABTF is enabled.

For the setting conditions and clearing conditions of the NTST.TABTF flag, see the details of NTST.TABTF.

TEE bit (Normal Transfer Error Enable)

When this bit is 1b, the operation of NTST.TEF is enabled.

For the setting conditions and clearing conditions of the NTST.TEF flag, see the details of NTST.TEF.

RSQFE bit (Normal Receive Status Queue Full Enable)

When this bit is 1b, the operation of NTST.RSQFF is enabled.

For the setting conditions and clearing conditions of the NTST.RSQFF flag, see the details of NTST.RSQFF.

7.8.3.2.47 Normal Transfer Interrupt Enable Register (I3Cm_NTIE)

The PIO Interrupt Signal Enable register enables signaling of outstanding interrupts received by I3C.

Access Size : 32 bits
Address : <I3C_base> + 01E8h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
20	RSQFIE	0h	RW	Normal Receive Status Queue Full Interrupt Enable*2 0b: Disables Receive Status Buffer Full Interrupt Signal. 1b: Enables Receive Status Buffer Full Interrupt Signal.
19 to 10	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9	TEIE	0h	RW	Normal Transfer Error Interrupt Enable*1 0b: Disables Transfer Error Interrupt Signal. 1b: Enables Transfer Error Interrupt Signal.
8 to 6	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5	TABTIE	0h	RW	Normal Transfer Abort Interrupt Enable*1 0b: Disables Transfer Abort Interrupt Signal. 1b: Enables Transfer Abort Interrupt Signal.
4	RSPQFIE	0h	RW	Normal Response Queue Full Interrupt Enable*1 0b: Disables Response Buffer Full Interrupt Signal. 1b: Enables Response Buffer Full Interrupt Signal.
3	CMDQEIE	0h	RW	Normal Command Queue Empty Interrupt Enable*1 0b: Disables Command Buffer Empty Interrupt Signal. 1b: Enables Command Buffer Empty Interrupt Signal.
2	IBIQEFIE	0h	RW	Normal IBI Queue Empty/Full Interrupt Enable*1 0b: Disables IBI Status Buffer Empty/Full Interrupt Signal. 1b: Enables IBI Status Buffer Empty/Full Interrupt Signal.
1	RDBFIE0	0h	RW	Normal Receive Data Buffer Full Interrupt Enable 0b: Disables Receive Data Buffer Full Interrupt Signal. 1b: Enables Receive Data Buffer Full Interrupt Signal.
0	TDBEIE0	0h	RW	Normal Transmit Data Buffer Empty Interrupt Enable 0b: Disables Transmit Data Buffer Empty Interrupt Signal. 1b: Enables Transmit Data Buffer Empty Interrupt Signal.

Note 1. This bit supports all I3C mode.

Note 2. This bit supports I3C secondary master mode and I3C slave mode.

TDBEIE0 bit (Normal Transmit Data Buffer Empty Interrupt Enable)

This bit is used to enable or disable the Normal Transmit Data buffer empty interrupt (INT_ri3c_tx_n) requests when the NTST.TDBEF0 flag is set to 1b.

RDBFIE0 bit (Normal Receive Data Buffer Full Interrupt Enable)

This bit is used to enable or disable the Normal Receive Data buffer full interrupt (INT_ri3c_rx_n) requests when the NTST.RDBFF0 flag is set to 1b.

IBIQEFIE bit (Normal IBI Queue Empty/Full Interrupt Enable)

This bit is used to enable or disable the Normal IBI Status buffer full interrupt (INTIBI) requests when the NTST.IBIQEFF flag is set to 1b.

CMDQEIE bit (Normal Command Queue Empty Interrupt Enable)

This bit is used to enable or disable the Normal Command buffer empty interrupt (INTCMD) requests when the NTST.CMDQEF flag is set to 1b.

RSPQFIE bit (Normal Response Queue Full Interrupt Enable)

This bit is used to enable or disable the Normal Response Status buffer full interrupt (INTRESP) requests when the NTST.RSPQFF flag is set to 1b.

TABTIE bit (Normal Transfer Abort Interrupt Enable)

This bit is used to enable or disable the Normal Transfer Abort interrupt (INTABORT) requests when the NTST.TABTF flag is set to 1b.

TEIE bit (Normal Transfer Error Interrupt Enable)

This bit is used to enable or disable the Normal Transfer Error interrupt (INTTERR) requests when the NTST.TEF flag is set to 1b.

RSQFIE bit (Normal Receive Status Queue Full Interrupt Enable)

This bit is used to enable or disable the Normal Receive Status buffer full interrupt (INTRCV) requests when the NTST.RSQFF flag is set to 1b.

7.8.3.2.48 Normal Transfer Status Force Register (I3Cm_NTSTFC)

The PIO Interrupt Force register is used to force specific interrupt. It can be used for debug purposes.

Access Size : 32 bits
Address : <I3C_base> + 01ECh
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	W	Reserved The written value should always be 0b.
20	RSQFFC	0h	W	Normal Receive Status Queue Full Force*2 0b: Not Force Receive Status Buffer Full Interrupt for software testing. 1b: Force Receive Status Buffer Full Interrupt for software testing.
19 to 10	-	All 0	W	Reserved The written value should always be 0b.
9	TEFC	0h	W	Normal Transfer Error Force*1 0b: Not Force Transfer Error Interrupt for software testing. 1b: Force Transfer Error Interrupt for software testing.
8 to 6	-	All 0	W	Reserved The written value should always be 0b.
5	TABTFC	0h	W	Normal Transfer Abort Force*1 0b: Not Force Transfer Abort Interrupt for software testing. 1b: Force Transfer Abort Interrupt for software testing.
4	RSPQFFC	0h	W	Normal Response Queue Full Force*1 0b: Not Force Response Buffer Full Interrupt for software testing. 1b: Force Response Buffer Full Interrupt for software testing.
3	CMDQEFC	0h	W	Normal Command Queue Empty Force*1 0b: Not Force Command Buffer Empty Interrupt for software testing. 1b: Force Command Buffer Empty Interrupt for software testing.
2	IBIQEFFC	0h	W	Normal IBI Queue Empty/Full Force*1 0b: Not Force IBI Status Buffer Full Interrupt for software testing. 1b: Force IBI Status Buffer Full Interrupt for software testing.
1	RDBFFC0	0h	W	Normal Receive Data Buffer Full Force 0b: Not Force Receive Data Buffer Full Interrupt for software testing. 1b: Force Receive Data Buffer Full Interrupt for software testing.
0	TDBEFC0	0h	W	Normal Transmit Data Buffer Empty Force 0b: Not Force Transmit Data Buffer Empty Interrupt for software testing. 1b: Force Transmit Data Buffer Empty Interrupt for software testing.

Note 1. This bit supports all I3C mode.

Note 2. This bit supports I3C secondary master mode and I3C slave mode.

TDBEFC0 bit (Normal Transmit Data Buffer Empty Force)

For software testing, when set to 1b, forces the corresponding interrupt, subject to TDBEE0 and TDBEIE0 configuration.

RDBFFC0 bit (Normal Receive Data Buffer Full Force)

For software testing, when set to 1b, forces the corresponding interrupt, subject to RDBFE0 and RDBFIE0 configuration.

IBIQEFFC bit (Normal IBI Queue Empty/Full Force)

For software testing, when set to 1b, forces the corresponding interrupt, subject to IBIQEFE and IBIQEFIE configuration.

CMDQEFC bit (Normal Command Queue Empty Force)

For software testing, when set to 1b, forces the corresponding interrupt, subject to CMDQEE and CMDQEIE configuration.

RSPQFFC bit (Normal Response Queue Full Force)

For software testing, when set to 1b, forces the corresponding interrupt, subject to RSPQFE and RSPQFIE configuration.

TABTFC bit (Normal Transfer Abort Force)

For software testing, forces the corresponding interrupt, subject to TABTE and TABTIE configuration.

TEFC bit (Normal Transfer Error Force)

For software testing, when set to 1b, forces the corresponding interrupt, subject to TEE and TEIE configuration.

RSQFFC bit (Normal Receive Status Queue Full Force)

For software testing, when set to 1b, forces the corresponding interrupt, subject to RSQFE and RSQFIE configuration.

7.8.3.2.49 Bus Condition Status Register (I3Cm_BCST)

Access Size : 32 bits
Address : <I3C_base> + 0210h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	BIDLF	BAVLF	BFREF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read.
2	BIDLF	0h	R	Bus Idle Detection Flag*1 0b: Have not Detected Bus Idle 1b: Have Detected Bus Idle
1	BAVLF	0h	R	Bus Available Detection Flag*1 0b: Have not Detected Bus Available 1b: Have Detected Bus Available
0	BFREF	0h	R	Bus Free Detection Flag 0b: Have not Detected Bus Free 1b: Have Detected Bus Free

Note 1. This bit supports all I3C mode.

BFREF bit (Bus Free Detection Flag)

The Bus Free Condition is a period occurring after a STOP and before a START, and with the following duration:

- For Pure Bus: A duration of at least tCAS
- For Mixed Bus (at least one Legacy I^2C is present on the I3C Bus): A duration of at least tBUF

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cϕ) that are set by BFRECDT.FRECYC[8:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cϕ) that are set by BFRECDT.FRECYC[8:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0b.

BAVLF bit (Bus Available Detection Flag)

The Bus Available Condition is a period during which the Bus Free Condition is sustained continuously for a duration of at least tAVAL. A Slave can only issue a START Request (for an In-Band Interrupt, or for a Master Handoff Request) after a Bus Available Condition.

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cϕ) that are set by BAVLCDT.AVLCYC[8:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cϕ) that are set by BAVLCDT.AVLCYC[8:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0b.

BIDLF bit (Bus Idle Detection Flag)

The I3C Bus Idle Condition is in order to help ensure Bus stability during Hot-Join events. The Bus Idle Condition is a period during which the Bus Available Condition is sustained continuously for a duration of at least tIDLE.

If a Hot-Join Device is powered up onto the I3C Bus at the same time as the Main Master, then the Hot-Join Device may pull SDA Low after 1 ms if (1) the Main Master has SCL and SDA pulled up, and (2) the Master does not act on the I3C Bus within the same Idle period.

[Setting conditions]

- After a STOP condition is detected, when the number of cycles (I3Cϕ) that are set by BIDLCDT.IDLCYC[17:0] has passed in the state of SCL = SDA = 1.
- After setting BCTL.BUSE to 1, when the number of cycles (I3Cϕ) that are set by BIDLCDT.IDLCYC[17:0] has passed in the state of SCL = SDA = 1.

[Clearing conditions]

- When SCL and SDA are other than high.
- When the BCTL.BUSE bit is set to 0b.

7.8.3.2.50 Slave Status Register (I3Cm_SVST)

Access Size : 32 bits
Address : <I3C_base> + 0214h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	SVAF2	SVAF1	SVAF0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HOAF	-	-	-	-	-	-	-	-	DVIDF	HSMCF	-	-	-	-	GCAF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
18	SVAF2	0h	RW*1	Slave Address Detection Flag 2 0b: Slave 2 not detected 1b: Slave 2 detected
17	SVAF1	0h	RW*1	Slave Address Detection Flag 1 0b: Slave 1 not detected 1b: Slave 1 detected
16	SVAF0	0h	RW*1	Slave Address Detection Flag 0 0b: Slave 0 not detected 1b: Slave 0 detected
15	HOAF	0h	RW*1	Host Address Detection Flag 0b: Host address not detected 1b: Host address detected This bit set to 1b when the received slave address matches the host address (0001_000b).
14 to 7	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
6	DVIDF	0h	RW*1	Device-ID Address Detection Flag 0b: Device-ID command not detected 1b: Device-ID command detected This bit set to 1b when the first frame received immediately after a START condition is detected matches a value of (device ID (1111_100) + 0[W]).
5	HSMCF	0h	RW*1	Hs-mode Master Code Detection Flag 0b: Hs-mode Master Code not detected 1b: Hs-mode Master Code detected
4 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	GCAF	0h	RW*1	General Call Address Detection Flag 0b: General call address not detected 1b: General call address detected

Note: This register supports I^2C mode.

Note 1. Clearing (to 0) condition: Writing 0b after 1b is read.

GCAF bit (General Call Address Detection Flag)

I^2C Normal Wake-Up Mode1/2 sets GCAF to 1b when switching from asynchronous operation to synchronous unit.

[Setting conditions]

- This flag is set to 1b at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.

1) The SVCTL.GCAE bit = 1b (General call address detection is enabled).
2) When the received slave address matches the general call address (0000 000 + 0 (write)).

[Clearing conditions]

- When 0b is written to the GCAF flag after reading GCAF flag to be 1b.
- When a STOP condition is detected.
- When a Repeated START condition is detected.

HSMCF bit (Hs-mode Master Code Detection Flag)

I^2C Normal Wake-Up Mode1/2 sets HSMCF to 1b when switching from asynchronous operation to synchronous unit.

[Setting conditions]

- This flag is set to 1b at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1) The SVCTL.HSMCE bit = 1b (Hs-mode master code detection is enabled).
  2) When the first byte received immediately after a START condition is detected matches a value of Hs-mode master code (0000 1XXX) + 1 (NACK).

[Clearing conditions]

- When 0b is written to the HSMCF flag after reading HSMCF flag to be 1b.
- When a STOP condition is detected.

DVIDF bit (Device-ID Address Detection Flag)

[Setting conditions]

- This flag is set to 1b at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1) The SVCTL.DVIDE bit = 1b (Device-ID address detection is enabled).
  2) When the first byte received immediately after a START condition or Repeated START condition is detected matches a value of Device ID (1111 100) + 0 (write).

[Clearing conditions]

- When 0b is written to the DVIDF flag after reading DVIDF flag to be 1b.
- When a STOP condition is detected.
- This flag is set to 0b at the rising edge of the ninth SCL clock cycle in the first byte when the following 1 and 2 or 1 and 3 are satisfied.
  1) The SVCTL.DVIDE bit = 1b (Device-ID address detection is enabled).
  2) When the first byte received immediately after a START condition or Repeated START condition is detected does not match a value of Device ID (1111 100).
  3) When the first byte received immediately after a START condition or Repeated START condition is detected matches a value of (device ID (1111 100) + 0 [W]) and the second byte does not match any of slave addresses 0 to 2.

HOAF bit (Host Address Detection Flag)

I²C Normal Wake-Up Mode1/2 sets HOAF to 1 at the time of switching from asynchronous operation to synchronous unit.

[Setting conditions]

- This flag is set to 1b at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1) The SVCTL.HOAE bit = 1b (Host address detection is enabled).
  2) When the received slave address matches the host address (0001 000).

[Clearing conditions]

- When 0b is written to the HOAF flag after reading HOAF flag to be 1b.
- When a STOP condition is detected.
- When a Repeated START condition is detected.

SVAFn bits (Slave Address Detection Flag n) (n = 0 to 2)

I²C Normal Wake-Up Mode1/2 sets SVAF2/1/0 to 1 when switching from asynchronous operation to synchronous unit.

[Setting conditions]

- For 7-bit address format: SVDVADn.SADLG bit = 0b.

  This flag is set to 1b at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.
  1) The SVCTL.SVAEn bit = 1b (Slave n enabled).
  2) When the received slave address matches the SVDVADn.SVAD[6:0] bits value.
- For 10-bit address format: SVDVADn.SADLG bit = 1b.

  This flag is set to 1b at the rising edge of the ninth SCL clock cycle in the second byte when all of the followings are satisfied.
  1) The SVCTL.SVAEn bit = 1b (Slave n enabled).
  2) When the received slave address matches a value of 11110 + SVDVADn.SVAD[9:8] bits and the following address matches the SVDVADn.SVAD[7:0] value.

[Clearing conditions]

- When 0b is written to the SVAFn flag after reading SVAFn flag to be 1b.
- When a STOP condition is detected.

For 7-bit address format: SVDVADn.SADLG bit = 0b.

This flag is set to 0b at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.

1) The SVCTL.SVAEn bit = 1b (Slave n enabled).
2) When the received slave address does not match SVDVADn.SVAD[6:0] bits value.

For 10-bit address format: SVDVADn.SADLG bit = 1b.

This flag is set to 0b at the rising edge of the ninth SCL clock cycle in the first byte when all of the followings are satisfied.

1) The SVCTL.SVAEn bit = 1b (Slave n enabled).

2) When the received slave address does not match a value of 11110 + SVDVADn.SVAD[9:8] bits.

- This flag is set to 0b at the rising edge of the ninth SCL clock cycle in the second byte when all of the followings are satisfied.

1) The SVCTL.SVAEn bit = 1b (Slave n enabled).

2) When the received slave address matches a value of 11110 + SVDVADn.SVAD[9:8] bits and the following address does not match the SVDVADn.SVAD[7:0] value.

7.8.3.2.51 Wake-Up Unit Operating Status Register (I3Cm_WUST)

Access Size : 32 bits
Address : <I3C_base> + 0218h
Initial Value : 0000_0000h

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read.
0	WUASYNF	0h	R	Wake-Up Function Asynchronous Operation Status Flag 0b: I3C synchronous circuit enable condition 1b: I3C asynchronous circuit enable condition

WUASYNF bit (Wake-Up Function Asynchronous Operation Status Flag)

This bit shows whether I3C is in the I3C_0_TCLK asynchronous operation (WUCTL.WUFE bit = 1b).

[Setting conditions]

- The following 1) and 2) are satisfied.
  1) The WUCTL.WUFE bit = 1b (Wake-up function is enabled)
  2) When the BCST.BFREF flag = 1b after 0b is written to the WUCTL.WUFSYNE bit

[Clearing condition: I^2C slave]

- The WUCTL.WUFE bit = 0b (Wake-up function is disabled)
- All of the following 1) to 3) are satisfied.
  1) The WUCTL.WUFE bit = 1b (Wake-up function is enabled)
  2) Wake-up event is detected
  3) When 1b is written to the WUCTL.WUFSYNE bit while the WUASYNF flag = 1b

[Clearing condition: I3C slave]

- The WUCTL.WUFE bit = 0b (Wake-up function is disabled)
- All of the following 1) to 4) are satisfied.
  1) The WUCTL.WUFE bit = 1b (Wake-up function is enabled)
  2) Wake-up event is detected
  3) When 1b is written to the WUCTL.WUFSYNE bit while the WUASYNF flag =1b
  4) When a STOP condition is detected.

[Clearing condition: I^2C/I3C slave]

- All of the following 1) to 5) are satisfied.

1) The WUCTL.WUFE bit = 1b (Wake-up function is enabled)
2) Wake-up event is not detected
3) The WUASYNF flag = 1b
4) The WUCTL.WUFSYNE bit = 1b
5) When a STOP condition is detected.

[Clearing condition: I3C master]

- The WUCTL.WUFE bit = 0b (Wake-up function is disabled)
- All of the following 1) to 4) are satisfied.
  1) The WUCTL.WUFE bit = 1b (Wake-up function is enabled)
  2) Wake-up event is detected
  3) The WUASYNF flag = 1b
  4) The WUCTL.WUFSYNE bit = 1b

7.8.3.2.52 MsyncCNT Counter Capture Register (I3Cm_MRCCPT)

Access Size : 32 bits
Address : <I3C_base> + 021Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MRCCPT[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MRCCPT[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MRCCPT[31:0]	0h	R	MSyncCNT Counter Capture Used in Async Mode 1, not used in Async Mode0.

Note: This register supports I3C master mode and I3C secondary master mode.

MRCCPT[31:0] bits (MSyncCNT Counter Capture)

- Async Mode 1 (Asynchronous Advanced Mode)

When ATCCNTE.ATCE is enabled, the counter starts counting. Its value is captured as MSyncCNT for each aME (SDA falling edge of START condition), and stored in the capture register.

7.8.3.2.53 Device Address Table Basic Register n (I3Cm_DATBASn) (n = 0 to 7)

Access Size : 32 bits
Address : <I3C_base> + 0224h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DVTYP	DVNACK[1:0]		-	-	-	-	-	DVDYAD[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DVIBITS	DVMRRJ	DVSIRRJ	DVIBIPL	-	-	-	-	-	DVSTAD[6:0]						
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	DVTYP	0h	RW	Device Type 0b: I3C Device 1b: I2C Device
30 to 29	DVNACK[1:0]	0h	RW	Device NACK Retry Count Device-specific retry count
28 to 24	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
23 to 16	DVDYAD[7:0]	0h	RW	Device I3C Dynamic Address Bit 23 is the parity bit, per the I3C specification, computed and updated by the software driver.
15	DVIBITS	0h	RW	Device IBI Time-stamp 0b: The Master shall not time-stamp IBIs from this Device with Master Time-stamps. 1b: The Master shall time-stamp IBIs for this Device with Master Time-stamps.
14	DVMRRJ	0h	RW	Device In-Band Master Request Reject 0b: This Device shall ACK Master Requests. 1b: This Device shall NACK Master Requests and send the auto-disable command.
13	DVSIRRJ	0h	RW	Device In-Band Slave Interrupt Request Reject 0b: This Device shall ACK the SIR. 1b: This Device shall NACK the SIR and send the auto-disable CCC.
12	DVIBIPL	0h	RW	Device IBI Payload 0b: IBIs from this Device do not carry a Data Payload. 1b: IBIs from this Device do carry a Data Payload.
11 to 7	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
6 to 0	DVSTAD[6:0]	0h	RW	Device Static Address I3C Static Address

Note: This register supports I3C master mode and I3C secondary master mode.

DVIBIPL bit (Device IBI Payload)

Indicates whether IBIs from this Device have a Data Payload. This field reflects the IBI Payload bit in the Device's Bus Characteristics Register (BCR).

During IBI handling for this Device, the Master shall use this field to determine whether or not to drive reception of the IBI Data Payload. Data continuation is indicated by the T-Bit.

DVSIRRJ bit (Device In-Band Slave Interrupt Request Reject)

Controls whether this Device, when operating in the Master role, will accept vs. reject Slave Interrupt Requests from other Devices.

DVMRRJ bit (Device In-Band Master Request Reject)

Controls whether this Device, when operating in the Master role, will accept vs. reject Master requests from other Devices. This bit is only valid if I3C declares Non-Current Master Capability.

DVIBITS bit (Device IBI Time-stamp)

Enables or disables IBI time-stamping for a specific Device.

Note: The IBI Status Descriptor for each IBI event indicates whether or not the individual IBI event was actually time- stamped. Set to 0 except for Async mode 0 and Async mode 1 of timing control.

DVNACK[1:0] bits (Device NACK Retry Count)

These bits set the number of retries when a NACK response is received from the slave for the transaction set in the Command Descriptor.

Note: When ENTDAA is executed by Address Assign Command, the setting of this bit is ignored and the transaction ends when NACK is received once.

Note: I3C will retry according to the setting of DVNACK[1:0], even if it receives a NACK for the broadcast address.

Note: If DVNACK[1:0] is 00b, I3C will not retry even for Direct CCCs.

7.8.3.2.54 Slave Device Address Table Basic Register n (I3Cm_SDATBASn) (n = 0 to 2)

Access Size : 32 bits
Address : <I3C_base> + 02B0h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	SDDYAD[6:0]						
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	SDIBIPL	-	SDADLS	SDSTAD[9:0]									
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
22 to 16	SDDYAD*1 [6:0]	0h	RW	Slave Device I3C Dynamic Address*5
15 to 13	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
12	SDIBIPL*1	0h	RW	Slave Device IBI Payload*4 This bit is the mirror bit of the SVDCT.TBCR[2]. 0b: IBIs from this device do not carry a data payload. 1b: IBIs from this device carry a data payload.
11	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
10	SDADLS	0h	RW	Slave Device Address Length Selection*3 0b: Slave device address length 7 bits selected. 1b: Slave device address length 10 bits selected. (I2C device only)
9 to 0	SDSTAD[9:0]	0h	RW	Slave Device Static Address*2 I3C / I2C Static Address

Note: SW write to the SDATBAS register of the main master is prohibited.

Note 1. This bit is valid only in SDATBAS0 register.

Note 2. These bits support I^2C, I3C secondary master, and I3C slave mode.

Note 3. This bit supports I^2C mode.

Note 4. This bit supports I3C secondary master mode and I3C slave mode.

Note 5. These bits support I3C secondary master mode and I3C slave mode.

SDSTAD[9:0] bits (Slave Device Static Address)

When the 7-bit address format is selected (SDADLS bit is 0b), the lower 7 bits of SDSTAD[9:0] function as the 7-bit address.

When the 10-bit address format is selected (SDADLS bit is 1b), the SDSTAD[9:0] function as the 10-bit address. While the SVCTL.SVAEn bit is 0b, the setting of this bit is ignored.

SDIBIPL bit (Slave Device IBI Payload)

Indicates whether IBIs from this Device have a Data Payload. This field reflects the IBI Payload bit in the Device's Bus Characteristics Register (BCR).

During IBI handling for this Device, the Master shall use this field to determine whether or not to drive reception of the IBI Data Payload. Data continuation is indicated by the T-Bit.

SDDYAD[6:0] bits (Slave Device I3C Dynamic Address)

[Update conditions]

- When writing Dynamic Address value.
- When Slave Address value is its own Static Address in receiving SETDASA CCC (Direct), these bits are updated to Dynamic Address value.*1
- When Dynamic Address Assignment procedure that starts by receiving ENTDAA CCC (Broadcast) is established.*1
- When receiving RSTDAA CCC (Broadcast), all bits are cleared to 0.*1
- When Slave Address value is its own Dynamic Address in receiving RSTDAA CCC (Direct), all bits are cleared to 0.*1
- When Slave Address value is its own Dynamic Address in receiving SETNEWDA CCC (Direct), these bits are updated to the Dynamic Address value.*1
- When receiving SETAASA CCC (Broadcast), these bits are updated to the value of SDSTAD[6:0] bits*2.

Note 1. See the MIPI I3C Specification v1.0.

Note 2. See the MIPI I3C Basic Specification v1.0.

7.8.3.2.55 Master Device Characteristic Table Register n (I3Cm_MSDCTn) (n = 0 to 7)

Access Size : 32 bits

Address : <I3C_base> + 02D0h + n x 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RBCR76[1:0]		-	-	RBCR3	RBCR2	RBCR1	RBCR0	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
15, 14	RBCR76[1:0]	0h	RW	Device Role 00b: I3C Slave 01b: I3C Master*3 Others: Setting prohibited
13, 12	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
11	RBCR3	0h	RW	Offline Capable*2 0b: Device will always respond to I3C bus commands. 1b: Device will not always respond to I3C bus commands.
10	RBCR2	0h	RW	IBI Payload 0b: No data byte follows the accepted IBI. 1b: Mandatory one or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit.
9	RBCR1	0h	RW	IBI Request Capable 0b: Not Capable 1b: Capable
8	RBCR0	0h	RW	Max Data Speed Limitation*1 0b: No Limitation 1b: Limitation
7 to 0	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

Note: This register supports I3C master mode and I3C secondary master mode.

Note 1. Master shall use the GETMXDS CCC to interrogate the Slave for specific limitation.

Note 2. Offline Capable Devices retain the Dynamic Address.

Note 3. For an I3C Device acting as I3C Main Master, the BCR Device Role bits will contain the value 01.

RBCRn bits (Received Bus Characteristic Register)

Each I3C Device that is connected to the I3C Bus shall have an associated read-only Bus Characteristics Register (BCR). This read-only register describes the I3C compliant Device's role and capabilities for use in Dynamic Address assignment and Common Command Codes.

Note: When RBCR[2] is 0b and when ACK response to Slave Interrupt Request from I3C Slave while DATBASm.DVSIRRJ is set to 0b, STOP Condition is issued after ACK response. When RBCR[2] is 1b and when ACK response to Slave Interrupt Request from I3C Slave while DATBASm.DVSIRRJ is set to 0b, IBI Payload is received after ACK response. STOP Condition is issued after end of IBI Payload.

[Update condition]

When receiving of Bus Characteristics Register (BCR) from Device in the Dynamic Address Assignment procedure starting by receiving ENTDAA CCC (Broadcast).*1

Note 1. See the MIPI I3C Specification v1.0

7.8.3.2.56 Extended Device Address Table Basic Register (I3Cm_EXDATBAS)

Access Size : 32 bits
Address : <I3C_base> + 0310h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

11	TBCR3	0h	RW	Offline Capable*2 0b: Device will always respond to I3C bus commands. 1b: Device will not always respond to I3C bus commands.
10	TBCR2	0h	RW	IBI Payload 0b: No data byte follows the accepted IBI. 1b: Mandatory one or more data bytes follow the accepted IBI. Data byte continuation is indicated by T-Bit.
9	TBCR1	0h	RW	IBI Request Capable 0b: Not Capable 1b: Capable
8	TBCR0	0h	RW	Max Data Speed Limitation*1 0b: No Limitation 1b: Limitation
7 to 0	TDCR[7:0]	0h	RW	Transfer Device Characteristic Register 255 available codes for describing the type of sensor, or device. Examples: Accelerometer, gyroscope, composite devices Default value is 0b: Generic Device

Note: This register supports I3C secondary master mode and I3C slave mode.

Note 1. Master shall use the GETMXDS CCC to interrogate the Slave for specific limitation.

Note 2. Offline Capable Devices retain the Dynamic Address.

Note 3. For an I3C Device acting as I3C Main Master, the BCR Device Role bits will contain the value 01.

TDCR[7:0] bits (Transfer Device Characteristic Register)

Each I3C device that is connected to the I3C bus has an associated Device Characteristics Register (DCR). This register describes the I3C compliant device type such as accelerometer and gyroscope, for use in Dynamic Address assignment and Common Command Codes.

TBCRn bits (Transfer Bus Characteristic Register)

Each I3C device that is connected to the I3C bus has an associated Bus Characteristics Register (BCR). This register describes the role and capabilities of the I3C compliant device for use in Dynamic Address assignment and Common Command Codes.

When I3C Slave issues IBI by Command Descriptor, the setting values of TBCR[7:0] are as follows:

[Slave Interrupt Request : No IBI Payload follow the accepted IBI]

- TBCR1 = 1b
- TBCR2 = 0b

Note: Set DATA_LENGTH[15:0] of Command Descriptor to 0.

[Slave Interrupt Request : IBI Payload follow the accepted IBI]

- TBCR1 = 1b
- TBCR2 = 1b

Note: Set DATA_LENGTH[15:0] of Command Descriptor to any value.

[Mastership Request]

- TBCR1 = 1b
- TBCR76[1:0] = 01b

[Hot-join Event]

- TBCR1 = 1b

When I3C Slave receives CCC from I3C Master, it performs the following operations according to the setting of TBCR[7:0]:

- When TBCR2 = 1b, CMRLG.IBIPSZ[7:0] is sent as the 3rd byte data to GETMRL CCC from I3C Master
- When TBCR0 = 0b, NACK responses to GETMXDS CCC from I3C Master
- When TBCR0 = 1, ACK responses to GETMXDS CCC from I3C Master and sends data from CMDSPW, CMDSPR, and CMDSPT registers

7.8.3.2.58 Slave Device Characteristic Table Provisional ID Low Register (I3Cm_SDCTPIDL)

Access Size : 32 bits

Address : <I3C_base> + 0324h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	SDYADV*4	0h	R	Slave Dynamic Address Valid*3 0b: Dynamic Address is disabled. 1b: Dynamic Address is enabled.
30	SSTADV	0h	R	Slave Static Address Valid*1 0b: Slave address is disabled. 1b: Slave address is enabled.
29, 28	-	All 0	R	Reserved Whenever it is read, 0b is read.
27	SADLG	0h	R	Slave Address Length*2 0b: The 7-bit address format is selected. 1b: The 10-bit address format is selected.
26	-	0h	R	Reserved Whenever it is read, 0b is read.
25 to 16	SVAD[9:0]	0h	R	Slave Address*1 A slave address is set. When rewriting SVAD, change to SVAE = 0b and rewrite.
15 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read.

Note 1. These bits support I^2C, I3C secondary master, and I3C slave mode.

Note 2. This bit supports I^2C mode.

Note 3. This bit supports I3C secondary master mode and I3C slave mode.

Note 4. This bit is valid only in SVDVAD0 register.

SVAD[9:0] bits (Slave Address)

The SVAD[9:0] bits indicate a valid slave address.

[The SVDVAD0.SDYADV bit = 1b]

Note: This condition is only for SVDVAD0.SVAD[9:0].

- The SVAD[9:7] bits = 0b
- The SVAD[6:0] bits = the SDATBAS0.SDDYAD[6:0] bits

[The SVDVADn.SSTADV bit = 1b and the SVDVADn.SADLG bit = 0b]

- The SVAD[9:7] bits = 0b
- The SVAD[6:0] bits = the SDATBASn.SDSTAD[6:0] bits

[The SVDVADn.SSTADV bit = 1b and the SVDVADn.SADLG bit = 1b]

- The SVAD[9:0] bits = the SDATBASn.SDSTAD[9:0] bits

SADLG bit (Slave Address Length)

[Setting conditions]

- All of the followings are satisfied:
  1) The PRTS.PRTMD bit = 1b (I^2C Protocol mode)
  2) The SVCTL.SVAEn bit = 1b (Slave n is enabled)
  3) The SDATBASn.SDADLS bit = 1b (The address length is 10 bits)

[Clearing condition]

- [Setting condition] is not satisfied.

SSTADV bit (Slave Static Address Valid)

[Setting conditions]

- All of the followings are satisfied:
  1) The SVCTL.SVAEn bit = 1b (Slave n is enabled)
  2) The SVDVAD0.SDYADV bit = 0b (Dynamic Address is disabled)

     Note: This condition is only for SVDVAD0.SSTADV.

  3) If the SVDVADn.SADLG bit = 0b, the SDATBASn.SDSTAD[6:0] bits are not all 0
     If the SVDVADn.SADLG bit = 1b, the SDATBASn.SDSTAD[9:0] bits are not all 0

[Clearing condition]

- "[Setting condition]" is not satisfied.

SDYADV bit (Slave Dynamic Address Valid)

[Setting conditions]

- All of the followings are satisfied:
  1) The PRTS.PRTMD bit = 0b (I3C Protocol mode)
  2) The SVCTL.SVAEn bit = 1b (Slave n is enabled)
  3) The SDATBAS0.SDDYAD[6:0] bits are not all 0

     Note: This condition is only for SVDVAD0.SDYADV.

[Clearing condition]

- "[Setting condition]" is not satisfied.

7.8.3.2.61 CCC Slave Events Command Register (I3Cm_CSECMD)

Access Size : 32 bits
Address : <I3C_base> + 0350h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	HJEVE	-	MSRQE	SVIRQE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3	HJEVE	0h	RW	Hot-Join Event Enable 0b: DISABLED: Slave-initiated Hot-Join is Disabled by the Master to control. 1b: ENABLED: Slave-initiated Hot-Join is Enabled by the Master to control.
2	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1	MSRQE	0h	RW	Mastership Requests Enable 0b: DISABLED: Mastership requests from Secondary Masters is Disabled by the Current Master to control. 1b: ENABLED: Mastership requests from Secondary Masters is Enabled by the Current Master to control.
0	SVIRQE	0h	RW	Slave Interrupt Requests Enable 0b: DISABLED: Slave-initiated Interrupts is Disabled by the Master to control. 1b: ENABLED: Slave-initiated Interrupts is Enabled by the Master to control.

Note: This register supports I3C secondary master mode and I3C slave mode.

SVIRQE bit (Slave Interrupt Requests Enable)

This bit allows the Master to control when Slave-initiated Interrupts are allowed on the I3C Bus.

These four Direct (ENEC/DISEC Format 1) or Broadcast (ENEC/DISEC Format 2) CCCs allows the Master to control when Slave- initiated traffic is (Enable) vs. is not (Disable) allowed on the I3C Bus. This control governs a Slave's attempts to request an Interrupt (ENI), to request Mastership (ENMR), or to signify a Hot-Join event (ENHJ).

[Setting conditions]

- When writing 1b
- When receiving ENEC CCC (Broadcast) with ENINT bit = 1b.*1
- When ENINT bit = 1b with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

- When writing 0b.
- When receiving DISEC CCC (Broadcast) with DISINT bit = 1b.*1
- When DISINT bit = 1b with own Slave Address in receiving DISEC CCC (Direct).*1

MSRQE bit (Mastership Requests Enable)

This bit allows the Current Master to control when Mastership requests from Secondary Masters are allowed on the I3C Bus.

[Setting conditions]

- When writing 1b.
- When receiving ENEC CCC (Broadcast) with ENMR bit = 1b.*1
- When ENMR bit = 1b with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

- When writing 0b.
- When receiving DISEC CCC (Broadcast) with DISMR bit = 1b.*1
- When DISMR bit = 1b with own Slave Address in receiving DISEC CCC (Direct).*1

HJEVE bit (Hot-Join Event Enable)

This bit allows the Master to control when Slave-initiated Hot-Join is allowed on the I3C Bus. [Setting conditions]

- When writing 1b.
- When receiving ENEC CCC (Broadcast) with ENHJ bit = 1b.*1
- When ENHJ bit = 1b with own Slave Address in receiving ENEC CCC (Direct).*1

[Clearing conditions]

- When writing 0b.
- When receiving DISEC CCC (Broadcast) with DISHJ bit = 1b.*1
- When DISHJ bit = 1b with own Slave Address in receiving DISEC CCC (Direct)*1

Note 1. See the MIPI I3C Specification v1.0

7.8.3.2.62 CCC Enter Activity State Register (I3Cm_CEACTST)

Access Size : 32 bits
Address : <I3C_base> + 0354h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	ACTST[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3 to 0	ACTST[3:0]	0h	RW	Activity State 1h: ENTAS0 (1 µs: Latency-free operation) 2h: ENTAS1 (100 µs) 4h: ENTAS2 (2 ms) 8h: ENTAS3 (50 ms: Lowest-activity operation) Others: Setting prohibited

Note: This register supports I3C secondary master mode and I3C slave mode.

ACTST[3:0] bits (Activity State)

[Update conditions]

- When writing Activity State value.
- When receiving ENTAS0 CCC (Broadcast), these bits are updated to 1h.*1
- When receiving ENTAS1 CCC (Broadcast), these bits are updated to 2h.*1
- When receiving ENTAS2 CCC (Broadcast), these bits are updated to 4h.*1
- When receiving ENTAS3 CCC (Broadcast), these bits are updated to 8h.*1
- When Slave Address value is its own Slave Address in receiving ENTAS0 CCC (Direct), these bits are updated to 1h.*1
- When Slave Address value is its own Slave Address in receiving ENTAS1 CCC (Direct), these bits are updated to 2h.*1
- When Slave Address value is its own Slave Address in receiving ENTAS2 CCC (Direct), these bits are updated to 4h.*1
- When Slave Address value is its own Slave Address in receiving ENTAS3 CCC (Direct), these bits are updated to 8h.*1

Note 1. See the MIPI I3C Specification v1.0.

7.8.3.2.63 CCC Max Write Length Register (I3Cm_CMWLG)

Access Size : 32 bits
Address : <I3C_base> + 0358h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MWLG[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
15 to 0	MWLG[15:0]	0h	RW	Max Write Length

Note: This register supports I3C secondary master mode and I3C slave mode.

MWLG[15:0] bits (Max Write Length)

These bits use for the I3C Master to set or get a maximum data write length in bytes for one Slave Device.

This Max Write Length does not affect data write lengths for Broadcast CCCs. The Set/Get Max Write Length value is transmitted over two bytes, with the most significant byte (MSB) transmitted first. The minimum value that Max Write Length can be set to is 8.

[Update conditions]

- When writing Max Write Length value.
- When receiving SETMWL CCC (Broadcast), these bits are updated to MWL value.*1
- When Slave Address value is its own Slave Address in receiving SETMWL CCC (Direct), these bits are updated to MWL value.*1

Note 1. See the MIPI I3C Specification v1.0

7.8.3.2.64 CCC Max Read Length Register (I3Cm_CMRLG)

Access Size : 32 bits
Address : <I3C_base> + 035Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	IBIPSZ[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MRLG[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
23 to 16	IBIPSZ[7:0]	0h	RW	IBI Payload Size
15 to 0	MRLG[15:0]	0h	RW	Max Read Length

Note: This register supports I3C secondary master mode and I3C slave mode.

MRLG[15:0] bits (Max Read Length)

These bits use for the I3C Master to set or get a maximum data read length for one Slave Device.

The Set/Get Max Read Length value is transmitted over the first two bytes, with most significant byte (MSB) transmitted first. The minimum value to which Max Read Length can be set is 16.

[Update conditions]

- When writing Max Read Length value.
- When receiving SETMRL CCC (Broadcast), these bits are updated to MRL value.*1
- When Slave Address value is its own Slave Address in receiving SETMRL CCC (Direct), these bits are updated to MRL value.*1

IBIPSZ[7:0] bits (IBI Payload Size)

These bits use for the I3C Master to set or get optionally a maximum IBI payload size.

For devices with BCR bit 2 set to 1b, the Max IBI payload size value is added as a third-byte, where a value of 0 indicates an unlimited payload size. If Timing Control is used, then the minimum IBI payload size is either four bytes or five bytes. If Timing Control is not used, then the minimum IBI payload size is one (one byte).

This CCC is optional for the Slave, with two exceptions:

1. This CCC is required if both (a) any private Read Request Message (s) and/or any extended Read Request CCC (s) implemented by the Slave support a variable limit on the maximum number of data bytes that the Slave may return per Message, and (b) this limit is greater than 16 bytes.
2. This CCC is required if the Slave both (a) supports an IBI Payload (as indicated with BCR bit 1), and (b) will transmit more than one byte of private payload (not counting Timing Control bytes, when Timing Control is used).

[Update conditions]

- When writing Max IBI payload size value.
- When receiving SETMRL CCC (Broadcast), these bits are updated to IBI payload size value.*1
- When Slave Address value is its own Slave Address in receiving SETMRL CCC (Direct), these bits are updated to IBI payload size value.*1

Note 1. See the MIPI I3C Specification v1.0.

7.8.3.2.65 CCC Enter Test Mode Register (I3Cm_CETSTMD)

Access Size : 32 bits
Address : <I3C_base> + 0360h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	TSTMD[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read.
7 to 0	TSTMD[7:0]	0h	R	Test Mode 00h: Exit Test Mode This value removes all I3C devices from Test Mode. 01h: Vendor Test Mode This value indicates that I3C devices shall return a random 32bit value in the provisional ID during the Dynamic Address Assignment procedure. Others: MIPI reserved Reserved for future use by the MIPI Alliance

Note: This register supports I3C secondary master mode and I3C slave mode.

TSTMD[7:0] bits (Test Mode)

When these bits set to 00h, all I3C Devices remove from Test Mode.

When these bits set to 01h, I3C Devices shall return a random 32bit value in the Provisional ID during the Dynamic Address Assignment procedure.

The Broadcast CCC informs all I3C Devices that the Master is entering a specified Test Mode during manufacturing or Device test. The Enter Test Mode command Frame format includes a byte that specifies which Test Mode to enter.

Supporting I3C Devices shall enter the indicated Test Mode upon receipt of the Enter Test Mode CCC.

[Update condition]

- When receiving ENTTM CCC (Broadcast), these bits are updated to Test Mode Byte value.*1

Note 1. See the MIPI I3C Specification v1.0.

7.8.3.2.66 CCC Get Device Status Register (I3Cm_CGDVST)

Access Size : 32 bits
Address : <I3C_base> + 0364h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VDRSV[7:0]								ACTMD[1:0]		PRTE	-	PNDINT[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
15 to 8	VDRSV[7:0]	0h	RW	Vendor Reserved Reserved for vendor-specific meaning
7 to 6	ACTMD[1:0]	0h	RW	Slave Device's current Activity Mode 00b: Activity Mode 0 01b: Activity Mode 1 10b: Activity Mode 2 11b: Activity Mode 3
5	PRTE	0h	RW	Protocol Error 0b: The Slave has not detected a protocol error since the last Status read. 1b: The Slave has detected a protocol error since the last Status read.
4	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3 to 0	PNDINT[3:0]	0h	RW	Pending Interrupt Contains the interrupt number of any pending interrupt, or 0 if no interrupts are pending. This encoding allows for up to 15 numbered interrupts. If more than one interrupt is set, then the highest priority interrupt shall be returned.

Note: This register supports I3C secondary master mode and I3C slave mode.

PRTE bit (Protocol Error)

If this bit set to 1b, then the Slave detects a protocol error since the last Status read.

The Slave checks for such errors. Note that this value self-clears by the hardware upon every successful completion of a Master read of the Slave's Status.

The Direct CCC is a Get request for one I3C Slave Device to return its current Status, in the two-byte format detailed. Note that byte 0 is the LSB, and byte 1 is the MSB.

[Setting condition]

- When the Slave detected a protocol error.*1

[Clearing condition]

- When transmission by own Slave Address is completed without error after receiving GETSTATUS CCC (Direct).*1

ACTMD[1:0] bits (Slave Device's current Activity Mode)

Contains the two-bit ID of the Slave Device's current Activity Mode (readiness to support data read of sensor or related information).

Note 1. See the MIPI I3C Specification v1.0.

7.8.3.2.67 CCC Max Data Speed W (Write) Register (I3Cm_CMDSPW)

Access Size : 32 bits

Address : <I3C_base> + 0368h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
23 to 16	INAC[7:0]	0h	RW	Inaccuracy Byte This byte represents the maximum variation of the Slave's internal oscillator in 1/10th percent (0.1%) increments, up to 25.5%. 00h: 0.0% 0Fh: 1.5% 1Fh: 3.1% 2Fh: 4.7% 3Fh: 6.3% 4Fh: 7.9% 5Fh: 9.5% 6Fh: 11.1% 7Fh: 12.7% 8Fh: 14.3% 9Fh: 15.9% AFh: 17.5% BFh: 19.1% CFh: 20.7% DFh: 22.3% EFh: 23.9% FFh: 25.5%
15 to 8	FREQ[7:0]	0h	RW	Frequency Byte This byte represents the Slave's internal oscillator frequency in increments of 0.5 MHz (500 kHz), up to 127.5 MHz. 00h: 32.0 KHz 0Fh: 7.5 MHz 1Fh: 15.5 MHz 2Fh: 23.5 MHz 3Fh: 31.5 MHz 4Fh: 39.5 MHz 5Fh: 47.5 MHz 6Fh: 55.5 MHz 7Fh: 63.5 MHz Others: Setting prohibited
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	SPTASYN1	0h	RW	Support Async Mode 1 0b: Async Mode 1 is not supported. 1b: Async Mode 1 is supported.
1	SPTASYN0	0h	RW	Support Async Mode 0 0b: Async Mode 0 is not supported. 1b: Async Mode 0 is supported.

Bit	Bit Name	Initial Value	R/W	Description
0	SPTSYN	0h	RW	Supports Sync Mode 0b: Sync Mode is not supported. 1b: Sync Mode is supported.

Note: This register supports I3C secondary master mode and I3C slave mode.

SPTASYN1 bit (Support Async Mode 1)

Bit mask indicating Async Mode 1 of Timing Control Mode(s) the target Slave supports.

If this bit set (has value 1), then that Slave supports Async Mode 1 of Timing Control Mode.

SPTASYN0 bit (Support Async Mode 0)

Bit mask indicating Async Mode 0 of Timing Control Mode(s) the target Slave supports.

If this bit set (has value 1), then that Slave supports Async Mode 0 of Timing Control Mode.

SPTSYN bit (Supports Sync Mode)

Bit mask indicating Sync Mode of Timing Control Mode(s) the target Slave supports.

If this bit set (has value 1), then that Slave supports Sync Mode of Timing Control Mode.

The Directed CCC provides the framework for the Master to query the Exchange Timing capabilities supported by the I3C Slaves. The Get Exchange Timing Support Information CCC causes the addressed Slave to return four data bytes containing key information on supported current state, and internal oscillator/clock frequency and inaccuracy.

7.8.3.2.71 CCC Exchange Timing Support Information S (State) Register (I3Cm_CETSS)

Bit mask indicating which Timing Control Mode (if any) is currently enabled for the target Slave, and whether any counter overflows have occurred since the most recent previous check. If a Timing Control Mode bit is set (has value 1), then that Slave has currently enabled the corresponding Timing Control Mode. If the Overflow bit is set (has value 1), then that Slave experienced a counter overflow since the most recent previous check.

Access Size : 32 bits
Address : <I3C_base> + 0378h
Initial Value : 0000_0000h

31 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7	ICOVF	0h	RW	Internal Counter Overflow 0b: Slave has not experienced a counter overflow since the most recent previous check. 1b: Slave experienced a counter overflow since the most recent previous check.
6 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2, 1	ASYNE[1:0]	0h	RW	Async Mode Enable 00b: All Mode disabled 01b: Async Mode 0 enabled 10b: Async Mode 1 enabled 11b: Setting prohibited
0	SYNE	0h	RW	Sync Mode Enable 0b: Sync Mode disabled 1b: Sync Mode enabled

Note: This register supports I3C secondary master mode and I3C slave mode.

ASYNE[1] bit (Async Mode Enabled 1)

Slave Timing Control Async Mode 1 is enabled.

[Setting condition]

- When writing 1b.
- When CETSM.SPTASYN[1] bit = 1b and either of the following 1) or 2) is satisfied.
  1) When receiving SETXTIME CCC(Broadcast) with Defining byte value EFh.
  2) When Slave Address value is its own Slave Address in receiving SETXTIME CCC(Direct) with Defining byte value EFh.

[Clearing condition]

- When writing 0b.
- When CETSM.SPTASYN[1] bit = 1b and either of the following 1) or 2) is satisfied.

1) When receiving SETXTIME CCC(Broadcast) with Defining byte value DFh.
2) When Slave Address value is its own Slave Address in receiving SETXTIME CCC(Direct) with Defining byte value DFh.

ASYNE[0] bit (Async Mode Enabled 2)

Slave Timing Control Async Mode 0 is enabled.

[Setting condition]

- When writing 1b.
- When CETSM.SPTASYN[0] bit = 1b and either of the following 1) or 2) is satisfied.
  1) When receiving SETXTIME CCC(Broadcast) with Defining byte value DFh.
  2) When Slave Address value is its own Slave Address in receiving SETXTIME CCC(Direct) with Defining byte value DFh.

[Clearing condition]

- When writing 0b.
- When CETSM.SPTASYN[0] bit = 1 and either of the following 1) or 2) is satisfied.
  1) When receiving SETXTIME CCC(Broadcast) with Defining byte value EFh.
  2) When Slave Address value is its own Slave Address in receiving SETXTIME CCC(Direct) with Defining byte value EFh.

7.8.3.2.72 Bit Count Register (I3Cm_BITCNT)

Access Size : 32 bits
Address : <I3C_base> + 0380h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read.
4 to 0	BCNT[4:0]	0h	R	Bit Counter Indicates the number of bits remaining to be transferred. For details on the values, see **Table 7.8-8** and **Table 7.8-9**.

BCNT[4:0] bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a sampling edge on the SCL line.

Table 7.8-8 I^2C transfer / Legacy I^2C transfer

	Master		Slave	
BCNT[4:0]	Address phase	Data phase	Address phase	Data phase
00h	2 to 1 bits	2 to 1 bits	3 to 1 bits	2 to 1 bits
01h	3 bits	3 bits	4 bits	3 bits
02h	4 bits	4 bits	5 bits	4 bits
03h	5 bits	5 bits	6 bits	5 bits
04h	6 bits	6 bits	7 bits	6 bits
05h	7 bits	7 bits	8 bits	7 bits
06h	8 bits	8 bits	9 bits	8 bits
07h	9 bits	9 bits	—	9 bits

Table 7.8-9 I3C transfer

	SDR*1	
BCNT[4:0]	Transmission	Reception
00h	1 bit	2 to 1 bits
01h	2 bits	3 bits
02h	3 bits	4 bits
03h	4 bits	5 bits
04h	5 bits	6 bits

	SDR*1	
BCNT[4:0]	Transmission	Reception
05h	6 bits	7 bits
06h	7 bits	8 bits
07h	8 bits	9 bits
08h	9 bits	—

Note 1. The address phase is the same as in **Table 7.8-8**.

7.8.3.2.73 Normal Queue Status Level Register (I3Cm_NQSTLV)

Access Size : 32 bits
Address : <I3C_base> + 0394h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	IBISCNT[4:0]					IBIQLV[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read.
28 to 24	IBISCNT[4:0]	0h	R	Normal IBI Status Count*2 Number of IBI Status entries currently in the IBI Queue.
23 to 16	IBIQLV[7:0]	0h	R	Normal IBI Queue Level*1 Number of buffer entries currently in the IBI Queue.
15 to 8	RSPQLV[7:0]	0h	R	Normal Response Queue Level*1 Number of buffer entries currently in the Response Queue.
7 to 0	CMDQFLV[7:0]	0h	R	Normal Command Queue Free Level*1 Number of free buffer entries currently in the Command Queue. Reset value is the depth of the Command Queue.

Note 1. These bits support all I3C mode.

Note 2. These bits support I3C master mode and I3C secondary master mode.

7.8.3.2.74 Normal Data Buffer Status Level Register (I3Cm_NDBSTLV0)

Access Size : 32 bits
Address : <I3C_base> + 0398h
Initial Value : 0000_0001h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDBLV[7:0]								TDBFLV[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read.
15 to 8	RDBLV[7:0]	0h	R	Normal Receive Data Buffer Level Indicates the number of Receive Data Buffer entries in the Receive Data Queue.
7 to 0	TDBFLV[7:0]	1h	R	Normal Transmit Data Buffer Free Level Indicates the number of free Transmit Data Buffer entries in the Transmit Data Queue. Reset value is the depth of the Transmit Data Queue.

Note: This register supports all I3C mode.

7.8.3.2.75 Normal Receive Status Queue Status Level Register (I3Cm_NRSQSTLV)

Access Size : 32 bits

Address : <I3C_base> + 03C0h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	RSQLV[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read.
7 to 0	RSQLV[7:0]	0h	R	Normal Receive Status Queue Level

Note: This register supports I3C secondary master mode and I3C slave mode.

7.8.3.2.76 Present State Debug Register (I3Cm_PRSTDBG)

Access Size : 32 bits

Address : <I3C_base> + 03CCh

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	SDOLV	SCOLV	SDILV	SCILV
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read.
3	SDOLV	0h	R	SDA30 Output Level 0b: I3C has driven the SDA30 pin low. 1b: I3C has released the SDA30 pin.
2	SCOLV	0h	R	SCL30 Output Level 0b: I3C has driven the SCL30 pin low. 1b: I3C has released the SCL30 pin.
1	SDILV	0h	R	SDA30 Line Signal Level This bit is used to check the SDA30 Line level, in order to recover from errors and for debugging.
0	SCILV	0h	R	SCL30 Line Signal Level This bit is used to check the SCL30 Line level, in order to recover from errors and for debugging.

SDOLV bit (SDA Output Level) and SCOLV bit (SCL Output Level)

When reading these bits, the state of signals output from I3C can be read.

7.8.3.2.77 Master Error Counters Register (I3Cm_MSERRCNT)

Access Size : 32 bits

Address : <I3C_base> + 03D0h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	M2ECNT[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read.
7 to 0	M2ECNT[7:0]	0h	R	M2 Error Counter Counts I3C Type M2 errors on the I3C Bus. Cleared upon read out.

Note: This register supports I3C secondary master mode and I3C slave mode.

7.8.3.2.78 SC1 Capture monitor Register (I3Cm_SC1CPT)

Access Size : 32 bits
Address : <I3C_base> + 03E0h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SC1CPT[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read.
15 to 0	SC1CPT[15:0]	0h	R	SC1 Capture

Note: This register supports I3C secondary master mode and I3C slave mode.

SC1C[15:0] bits (SC1 Capture)

- Async Mode 0 (Asynchronous Basic Mode)

  After enabling ATCCNTE.ATCE, SC1 Counter counts up from SC1 count trigger*1 to SCL rise edge next to ACK for the IBI, and capture it as SC1.

- Async Mode 1 (Asynchronous Advanced Mode)

  After enabling ATCCNTE.ATCE, SC1 Counter counts up from SC1 count trigger*1 to the first aME, and capture it as SC1.

Note 1. SW or external trigger can be selected by selection bits.

Remark As the timing control specification, the SC1 counter value is included in the IBI frame as IBI data and is sent to I3C Master, therefore it is not necessary for the I3C Slave to read this register. If the I3C Slave needs to read this register, read it after completing the IBI frame.

7.8.3.2.79 SC2 Capture monitor Register (I3Cm_SC2CPT)

Access Size : 32 bits
Address : <I3C_base> + 03E4h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SC2CPT[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read.
15 to 0	SC2CPT[15:0]	0h	R	SC2 Capture

Note: This register supports I3C secondary master mode and I3C slave mode.

SC2C[15:0] bits (SC2 Capture)

- Async Mode 0 (Asynchronous Basic Mode)

  After enabling ATCCNTE.ATCE, SC2 Counter counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as SC2.

- Async Mode 1 (Asynchronous Advanced Mode)

  After enabling ATCCNTE.ATCE, SC2 Counter counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and capture it as SC2.

Remark As the timing control specification, the SC2 counter value is included in the IBI frame as IBI data and is sent to I3C Master, therefore it is not necessary for the I3C Slave to read this register. If the I3C Slave needs to read this register, read it after completing the IBI frame.

7.8.4 Operation

7.8.4.1 Data Structures

7.8.4.1.1 Command Descriptor

The write-only Command Descriptor structure is 64 bits in length. The Command Descriptor is put to the Command Queue with writes to the Command Queue Port.

Write to the Command Queue Port in the following order:

1. First write: The least significant DWORD (Command Descriptor Structure Low).
2. Second write: The most significant DWORD (Command Descriptor Structure High).

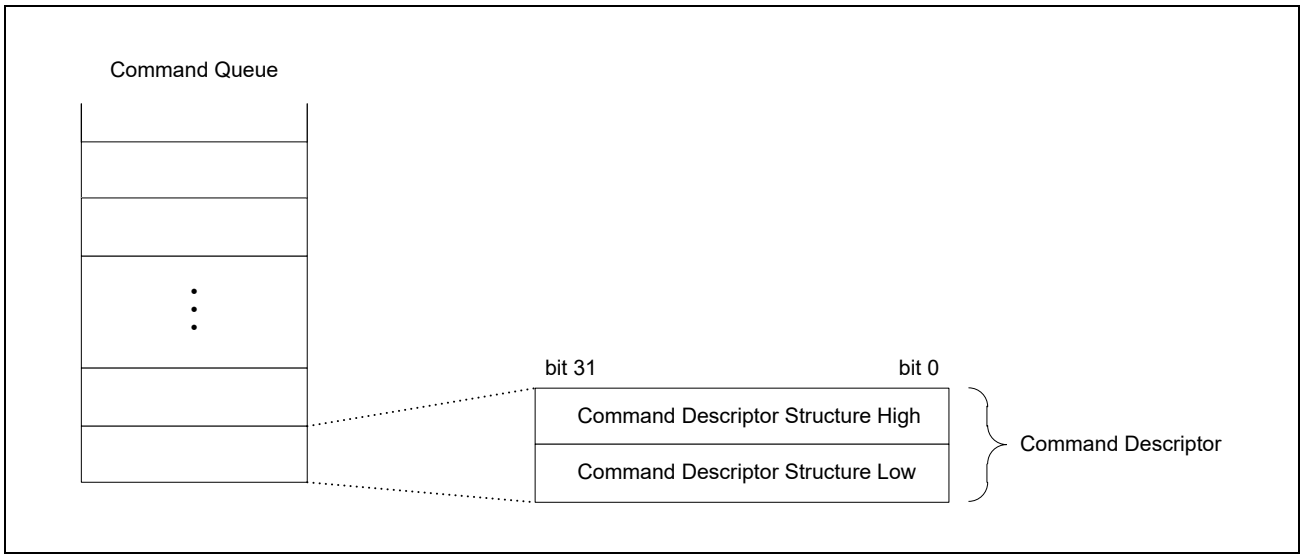

Figure 7.8-2 Command descriptor data structure

I3C provides a Command Descriptor structure for each command type as follows:

- Address Assign Command
- Immediate Transfer Command
- Regular Transfer Command
- Combo Transfer Command
- Internal Control Command

Details are explained in the following sections.

(1) Address Assign Command

This command is used for address assignment (ENTDAA, SETDASA).

Remark When issuing SETAASA CCC, use the Immediate Transfer command.

The I3C provides an address assign command for the following mode:

- I3C Master Mode

Details of the Address Assign command structure are as follows.

Bit position	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field	TOC	ROC	DEV_COUNT[3:0]				—	—	—	—	EXT_DEVICE	DEV_INDEX[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field	—	CMD[7:0]								TID[3:0]				CMD_ATTR[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Command Attributes 0h: XFER: Regular Transfer 1h: IMMED_DATA_XFER: Immediate Data Transfer 2h: ADDR_ASSGN_CMD: Address Assignment Command 3h: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 7h: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Transaction ID	W
14:7	CMD[7:0]	Transfer Command CCC Value	W
15	—	The write value should be 0b.	W
20:16	DEV_INDEX[4:0]	Device Index	W
21	EXT_DEVICE	Extended Device Index 0b: Use the DATBASm table indicated by DEV_INDEX[4:0]. 1b: Use the EXDATBAS table.	W
25:22	—	The write value should be 0b.	W
29:26	DEV_COUNT[3:0]	Device Count	W

Bit	Symbol	Function	R/W
30	ROC	Response on Completion 0b: NOT_REQUIRED: Response Status is not required. 1b: REQUIRED: Response Status is required.	W
31	TOC	Terminate on Completion 0b: RESTART: Issue Repeated START (Sr) at end of transfer 1b: STOP: Issue STOP (P) at end of transfer	W
63:32	—	The write value should be 0b.	W

CMD_ATTR[2:0] bits (Command Attributes)

Command Type, defining the format of the other fields.

TID[3:0] bits (Transaction ID)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

CMD[7:0] bits (Transfer Command CCC Value)

Specifies CCC code indicating whether Address Assignment uses ENTDAA or SETDASA commands. The field comprises the entire command code (ENTDAA or SETDASA).

DEV_INDEX[4:0] bits (Device Index)

Indicates the DATBASm table index for the Slave device being addressed with the transfer. Static and device addressing related information are stored to this index in the DATBASm.

DEV_COUNT[3:0] bits (Device Count)

Indicates the number of devices that a dynamic address is assigned to.

ROC bit (Response on Completion)

Controls whether Response Status is sent after successful completion of the Transfer command. The successful completion is read from register NRSPQP. Upon unsuccessful transfer the Response Status is sent.

TOC bit (Terminate on Completion)

Controls what bus condition to issue after the Transfer command completes.

For ENTDAA, a STOP condition is issued regardless of the setting value of TOC. It is meaningful for SETDASA transfers.

When sending SETDASA CCC by TOC = 0b (RESTART), the next command must be set to SETDASA CCC with the Address Assign Command.

When the next command is not the same SETDASA CCC flame, it must be set to TOC = 1b (STOP).

(2) Immediate Transfer Command

This structure directly contains data (max 4 bytes) to be transferred, and as a result is only useful for Transfers/CCCs that write data. This structure shall not be used for Read operations (for example, to receive data).

When transmitting data of 4 bytes or less, use this Immediate Transfer Command to communicate.

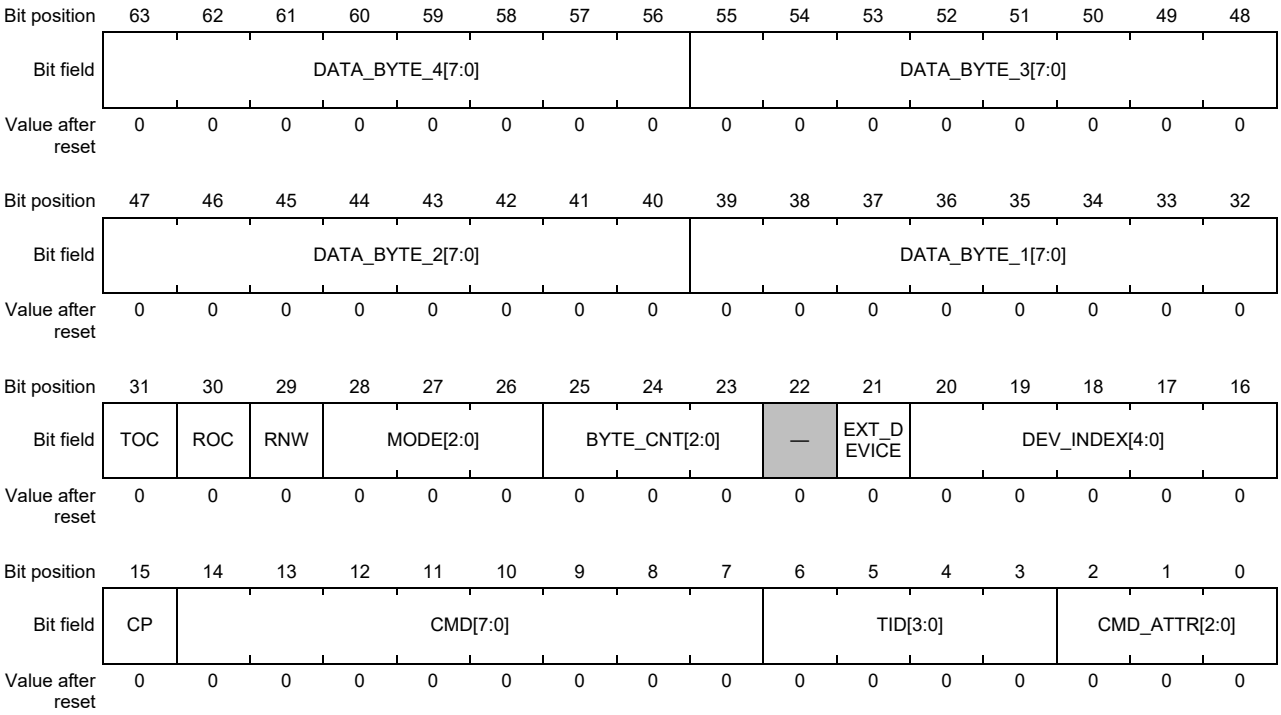
When transmitting data of 5 bytes or more, use the Regular Transfer Command to communicate.

For the Regular Transfer Command, see **(3) Regular Transfer Command**.

I3C provides an Immediate Transfer Command for the following mode:

- I3C Master Mode

Details of the Immediate Transfer Command Structure of each mode are shown in this section.



Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Immediate Data Transfer Command Attribute 0h: XFER: Regular Transfer 1h: IMMED_DATA_XFER: Immediate Data Transfer 2h: ADDR_ASSGN_CMD: Address Assignment Command 3h: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 7h: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Immediate Data Transfer Transaction ID	W
14:7	CMD[7:0]	Immediate Data Transfer CCC Value	W
15	CP	Immediate Data Transfer Command Present 0b: TRANFSER: This structure describes an SDR transfer, so the CMD field is not valid. 1b: CCC: This structure describes a CCC transfer, so the CMD field is valid.	W
20:16	DEV_INDEX[4:0]	Immediate Data Transfer Device Index	W

Bit	Symbol	Function	R/W
21	EXT_DEVICE	Immediate Data Transfer Extended Device Index 0b: Use the DATBASm table indicated by DEV_INDEX[4:0]. 1b: Use the EXDATBAS table.	W
22	—	The write value should be 0b.	W
25:23	BYTE_CNT[2:0]	Immediate Data Transfer Byte Count 0h: No payload 1h: 1 byte is valid. 2h: 2 bytes are valid. 3h: 3 bytes are valid. 4h: 4 bytes are valid. Others: Setting prohibited	W
28:26	MODE[2:0]	Immediate Data Transfer Mode and Speed Values 0h: I3C SDR0/Data rate: STDBR (I3C mode) I2C Message 0/Data rate: STDBR (I2C mode) 1h: I3C SDR1/Data rate: EXTBR (I3C mode) I2C Message 0/Data rate: EXTBR (I2C mode) 2h: I3C SDR2/Data rate: STDBR × 2 (I3C mode) Reserved (I2C mode) 3h: I3C SDR3/Data rate: EXTBR × 2 (I3C mode) Reserved (I2C mode) 4h: I3C SDR4/Data rate: EXTBR × 4 (I3C mode) Reserved (I2C mode) Others: Setting prohibited	W
29	RNW	Immediate Data Transfer R/W 0b: WRITE: Write transfer 1b: READ: Read transfer	W
30	ROC	Immediate Data Transfer Response on Completion 0b: NOT_REQUIRED: Response Status is not required. 1b: REQUIRED: Response Status is required.	W
31	TOC	Immediate Data Transfer Terminate on Completion 0b: RESTART: Issue Repeated START (Sr) at end of data transfer 1b: STOP: Issue STOP (P) at end of data transfer	W
39:32	DATA_BYTE_1[7:0]	Immediate Data Transfer Data Byte 1 Direct argument	W
47:40	DATA_BYTE_2[7:0]	Immediate Data Transfer Data Byte 2 Direct argument	W
55:48	DATA_BYTE_3[7:0]	Immediate Data Transfer Data Byte 3 Direct argument	W
63:56	DATA_BYTE_4[7:0]	Immediate Data Transfer Data Byte 4 Direct argument	W

CMD_ATTR[2:0] bits (Immediate Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Immediate Data Transfer Transaction ID)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

CP bit (Immediate Data Transfer Command Present)

Indicates whether CMD field is valid for CCC Transfer.

DEV_INDEX[4:0] bits (Immediate Data Transfer Device Index)

Indicates the DATBASm Table index for the Slave Device being addressed with the transfer. Static and Device addressing related information will be stored to this index in the DATBASm.

BYTE_CNT[2:0] bits (Immediate Data Transfer Byte Count)

Number of valid data bytes to use in this Immediate Data Transfer Descriptor.

This field must be set to non-zero value, except for CCCs that does not have payload defined.

MODE[2:0] bits (Immediate Data Transfer Mode and Speed Values)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C Mode vs. I^2C Mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

RNW bit (Immediate Data Transfer R/W)

Identifies direction of the transfer.

This field shall always be set to 0b, because Immediate transfers are valid for Write transactions only.

ROC bit (Immediate Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the data transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Immediate Data Transfer Terminate on Completion)

Controls what Bus condition is issued after completion of the data transfer.

When sending Direct CCC by TOC = 0b (RESTART), next command must be set to same Direct CCC.

When the next command is not the same Direct CCC, must be set to TOC = 1b (STOP).

(3) Regular Transfer Command

This structure does not contain data to be transferred.

For Master Mode, the data buffer is available through Transfer Data Queue Port (Receive Data Queue Port and Transmit Data Queue Port).

When transmitting data of 5 bytes or more, use this Regular Transfer Command to communicate.

When transmitting data of 4 bytes or less, use the Immediate Transfer Command to communicate.

For the Regular Transfer Command, see **(2) Immediate Transfer Command**.

For I3C Slave Mode, the IBI Payload buffer is available through IBI Status Queue Port.

I3C provides a Regular Transfer Command for each mode below.

- I3C Master Mode
- I3C Slave Mode

Details of the regular transfer command structure of each mode are shown below.

(1) I3C Master Mode

Bit position	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field	DATA_LENGTH[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Data Transfer Command Attribute Command Type, defining the format of the other fields. Values: 0h: XFER: Regular Transfer 1h: IMMED_DATA_XFER: Immediate Data Transfer 2h: ADDR_ASSGN_CMD: Address Assignment Command 3h: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 7h: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Data Transfer Transaction ID Identification tag for this command	W

Bit	Symbol	Function	R/W
14:7	CMD[7:0]	Data Transfer CCC Code Value Specifies the I3C Command code	W
15	CP	Data Transfer Command Present 0b: TRANFSER: This structure describes an SDR transfer, so the CMD field is not valid. 1b: CCC: This structure describes a CCC transfer, so the CMD field is valid.	W
20:16	DEV_INDEX[4:0]	Data Transfer Device Index	W
21	EXT_DEVICE	Data Transfer Extended Device Index 0b: Use the DATBASm Table indicated by DEV_INDEX[4:0]. 1b: Use the EXDATBAS table.	W
25:22	—	The write value should be 0b.	W
28:26	MODE[2:0]	Data Transfer Speed and Mode 0h: I3C SDR0/Data rate: STDBR (I3C mode) I²C Message 0/Data rate: STDBR (I²C mode) 1h: I3C SDR1/Data rate: EXTBR (I3C mode) I²C Message 0/Data rate: EXTBR (I²C mode) 2h: I3C SDR2/Data rate: STDBR × 2 (I3C mode) Reserved (I²C mode) 3h: I3C SDR3/Data rate: EXTBR × 2 (I3C mode) Reserved (I²C mode) 4h: I3C SDR4/Data rate: EXTBR × 4 (I3C mode) Reserved (I²C mode) Others: Setting prohibited	W
29	RNW	Data Transfer R/W 0b: WRITE: Write transfer 1b: READ: Read transfer	W
30	ROC	Data Transfer Response on Completion 0b: NOT_REQUIRED: Response Status is not required. 1b: REQUIRED: Response Status is required.	W
31	TOC	Data Transfer Terminate on Completion 0b: RESTART: Issue Repeated START (Sr) at end of transfer 1b: STOP: Issue STOP (P) at end of transfer	W
47:32	—	The write value should be 0.	W
63:48	DATA_LENGTH [15:0]	Data Transfer Data Length Indicates the number of bytes to be transferred. This field must be set to non-zero value, except for CCCs that does not have payload defined.	W

CMD_ATTR[2:0] bits (Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Data Transfer Transaction ID Identification tag for this command)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

CP bit (Data Transfer Command Present)

Indicates whether he contents of the CMD field is valid for a CCC Transfer.

DEV_INDEX[4:0] bits (Data Transfer Device Index)

Indicates the DATBASm Table index for the Slave Device being addressed with the transfer. Static and Device addressing related information will be stored to this index in the DATBASm.

MODE[2:0] bits (Data Transfer Speed and Mode)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C Mode vs. I^2C Mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

RNW bit (Data Transfer R/W)

Identifies direction of the transfer.

ROC bit (Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Data Transfer Terminate on Completion)

Controls what Bus condition will be issued after completion of the transfer.

When sending Direct CCC by TOC = 0b (RESTART), next command must be set to same Direct CCC.

When the next command is not the same Direct CCC, must be set to TOC = 1b (STOP).

DATA_LENGTH[15:0] bits (Data Transfer Data Length)

Number of valid data bytes to use in this Regular Transfer Descriptor.

This field must be set to non-zero value, except for CCCs that does not have payload defined.

Length setting of GETMXDS command should be fixed to 5.

(2) I3C Slave Mode

Bit position	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

Bit field	HJ	—	—	—	—	—	—	—	—	TID[3:0]				CMD_ATTR[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Data Transfer Command Attribute Command Type, defining the format of the other fields. Values: 0h: XFER: Regular Transfer 1h: IMMED_DATA_XFER: Immediate Data Transfer 2h: ADDR_ASSGN_CMD: Address Assignment Command 3h: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 7h: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Data Transfer Transaction ID Identification tag for this command	W
14:7	—	The write value should be 0b.	W
15	HJ	Data Transfer Hot-Join Event 0b: Slave Interrupt Request or Mastership Request, so the RNW field is valid. 1b: Hot-Join Event, so the RNW field is not valid.	W
21:16	—	The write value should be 0b.	W
22	ITS	Include timestamp for Async Mode 0b: Do not include timestamp. 1b: Include timestamp.	W
28:23	—	The write value should be 0b.	W
29	RNW	Data Transfer R/W 0b: WRITE: Write transfer (Mastership Request) 1b: READ: Read transfer (Slave Interrupt Request)	W
30	ROC	Data Transfer Response on Completion 0b: NOT_REQUIRED: Response Status is not required. 1b: REQUIRED: Response Status is required.	W
47:31	—	The write value should be 0b.	W
63:48	DATA_LENGTH [15:0]	Data Transfer Data Length Indicates the number of bytes to be transferred. This field must be set to non-zero value, except for CCCs that does not have payload defined.	W

CMD_ATTR[2:0] bits (Data Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Data Transfer Transaction ID Identification tag for this command)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

HJ bit (Data Transfer Hot-Join Event)

Indicates whether Hot-Join Event is valid in this IBI Data transfer.

RNW bit (Data Transfer R/W)

Identifies direction of the transfer.

ROC bit (Data Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

(4) Combo Transfer Command

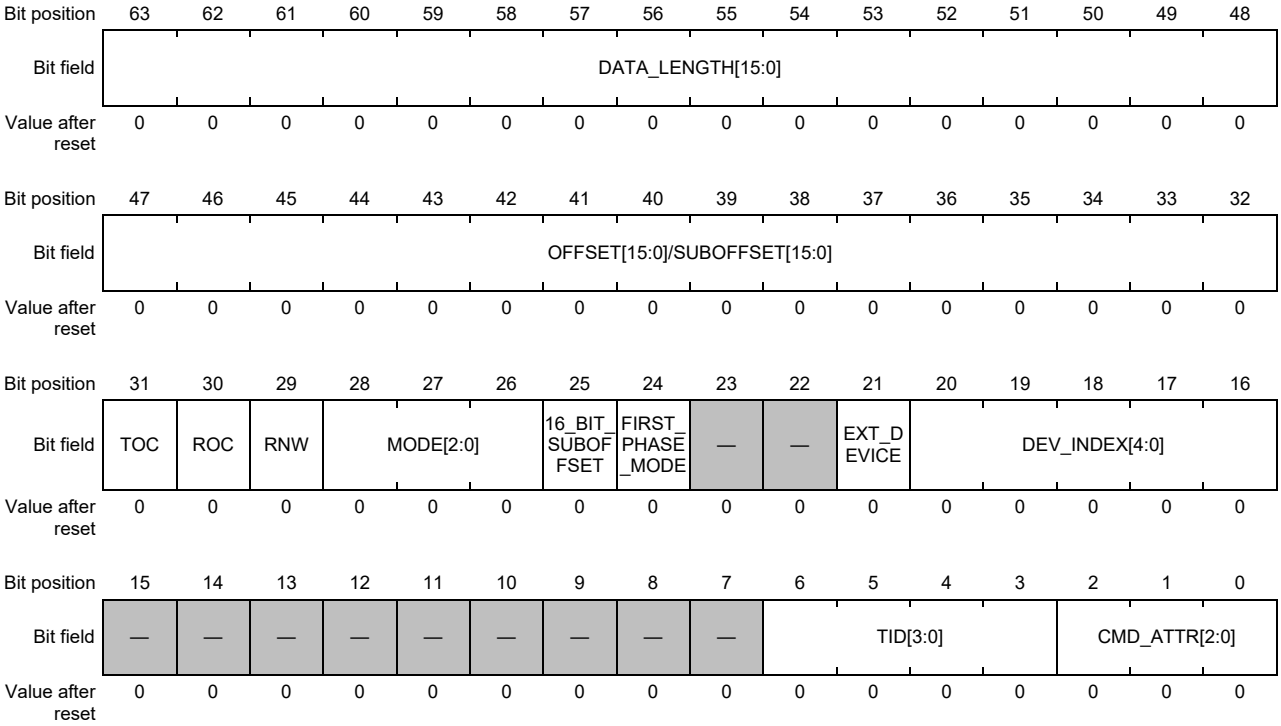
This structure contains a combined Write + Read/Write operation.

The data buffer is available through Transfer Data Queue Port (Receive Data Queue Port and Transmit Data Queue Port).

I3C provides a Combo Transfer Command for the following mode:

- I3C Master Mode

Details of the Combo Transfer Command Structure of each mode are as follows.



Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Combo Transfer Command Attribute Command Type, defining the format of the other fields. 0h: XFER: Regular Transfer 1h: IMMED_DATA_XFER: Immediate Data Transfer 2h: ADDR_ASSGN_CMD: Address Assignment Command 3h: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 7h: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Combo Transfer Transaction ID Identification tag for the command	W
15:7	—	The write value should be 0b.	W
20:16	DEV_INDEX[4:0]	Combo Transfer Device Index	W
21	EXT_DEVICE	Combo Transfer Extended Device Index 0b: Use the DATBASm table indicated by DEV_INDEX[4:0]. 1b: Use the EXDATBAS table.	W
23:22	—	The write value should be 0b.	W

Bit	Symbol	Function	R/W
24	FIRST_PHASE_MODE	Combo Transfer First Phase Mode 0b: SDR: First phase is executed in SDR mode. 1b: MODE: First phase is executed in the mode indicated by the MODE field.	W
25	16_BIT_SUBOFFSET	Combo Transfer Sub Offset Size 0b: 8_BIT_SUBOFFSET: Sub-offset is 8-bits long. Value is encoded in Lower Byte of OFFSET/SUBOFFSET field. 1b: 16_BIT_SUBOFFSET: Sub-offset is 16-bits long.	W
28:26	MODE[2:0]	Combo Transfer Speed and Mode Values for I3C Mode 0h: I3C SDR0/Data rate: STDBR 1h: I3C SDR1/Data rate: EXTBR 2h: I3C SDR2/Data rate: STDBR × 2 3h: I3C SDR3/Data rate: EXTBR × 2 4h: I3C SDR4/Data rate: EXTBR × 4 Others: Setting prohibited	W
29	RNW	Combo Transfer R/W Identifies direction of the transfer 0b: WRITE: Write transfer 1b: READ: Read transfer	W
30	ROC	Combo Transfer Response on Completion 0b: NOT_REQUIRED: Response Status is not required. 1b: REQUIRED: Response Status is required.	W
31	TOC	Combo Transfer Terminate on Completion 0b: RESTART: Issue Repeated START (Sr) at end of transfer 1b: STOP: Issue STOP (P) at end of transfer	W
47:32	OFFSET[15:0]/SUBOFFSET[15:0]	Combo Transfer Offset/Sub-Offset Offset of the target operation	W
63:48	DATA_LENGTH[15:0]	Combo Transfer Data Length Number of bytes to be transferred. This field must be set to non-zero value.	W

CMD_ATTR[2:0] bits (Combo Transfer Command Attribute)

Command Type, defining the format of the other fields.

TID[3:0] bits (Combo Transfer Transaction ID Identification tag for the command)

Used as an identification tag for this command. This field shall be populated by the software Driver, and the same value shall be reflected in the Response Descriptor.

DEV_INDEX[4:0] bits (Combo Transfer Device Index)

Indicates the DATBASm table index for the Slave Device being addressed with the transfer. Static and Device addressing related information will be stored to this index in the DATBASm.

FIRST_PHASE_MODE bits (Combo Transfer First Phase Mode)

Indicates whether the first phase of the Combo Transfer is executed in SDR Mode, vs. the Mode indicated by the MODE field.

MODE[2:0] bits (Combo Transfer Speed and Mode Values for I3C Mode)

Sets the mode and speed for the I3C or I^2C transfer.

Interpretation of this field depends on whether the Device is in I3C Mode vs. I^2C Mode (see the DEVICE field in the DATBASm Table entry indexed by field DEV_INDEX).

RNW bit (Combo Transfer R/W Identifies direction of the transfer)

Identifies direction of the transfer.

ROC bit (Combo Transfer Response on Completion)

Controls whether Response Status is required after successful completion of the data transfer command. The successful completion shall be read from NRSPQP register. Upon unsuccessful transfer the Response Status shall always be sent.

TOC bit (Combo Transfer Terminate on Completion)

Controls what Bus condition is issued after completion of the data transfer.

DATA_LENGTH[15:0] bit (Combo Transfer Data Length Number of bytes to be transferred. This field must be set to non-zero value.)

Number of valid data bytes to use in this Combo Transfer Descriptor.

This field must be set to non-zero value.

(5) Internal Control Command

This structure is used for controlling I3C itself (not for transfer commands).

I3C provides an Internal Control Command for the following mode:

- I3C Master Mode

Details of the Internal Control Command Structure are as follows:

Bit position	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Bit field	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Bit field	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field	—	—	—	ON_OFF	MIPI_CMD[3:0]				—	TID[3:0]				CMD_ATTR[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CMD_ATTR[2:0]	Command Attribute*2 Command Type, defining the format of the other fields. 0h: XFER: Regular Transfer 1h: IMMED_DATA_XFER: Immediate Data Transfer 2h: ADDR_ASSGN_CMD: Address Assignment Command 3h: WWR_COMBO_XFER: Write + Write/Read Combo Transfer 7h: INTERNAL_CONTROL: Internal Control command Others: Setting prohibited	W
6:3	TID[3:0]	Transaction ID Identification tag for the command	W
7	—	The write value should be 0b.	W
11:8	MIPI_CMD[3:0]	MIPI Alliance Command 00h: NoOp, so the ON_OFF field is not valid. 02h: Include 7E (IBA), so the ON_OFF field is valid. Others: Setting prohibited	W
12	ON_OFF	Bus Instance 7E On/Off*1 Enables or disables automatic transmission of the I3C Broadcast Header after every START condition on this I3C Bus instance. 0b: IBA_INCLUDE off 1b: IBA_INCLUDE on	W
63:13	—	The write value should be 0b.	W

Note 1. The IBA_INCLUDE on state set by MIPI_CMD [3:0] = 2h and ON_OFF = 1 is cleared by setting RSTCTL.INTLRST to 1b.

Note 2. The Response descriptor is not stored when the Internal Control Command is executed.

7.8.4.1.2 Response Descriptor

The Response Descriptor is a read-only structure describing the success or failure of a command, and the amount of data transferred.

The Response Descriptor is read from Response Queue with reads from Response Queue Port.

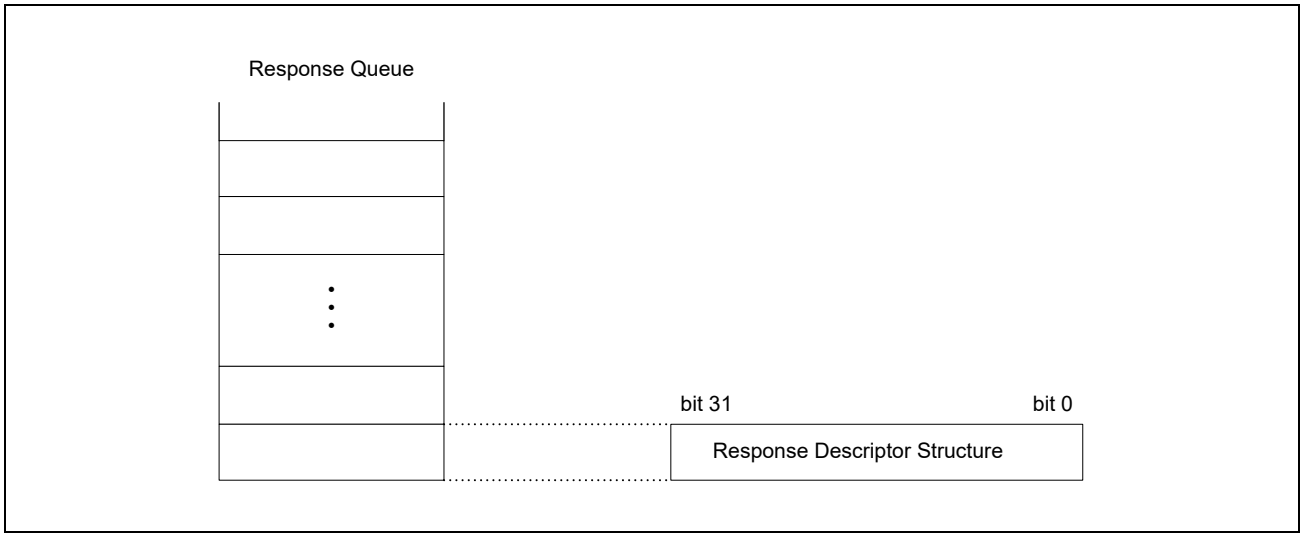


Figure 7.8-3 Response descriptor data structure

I3C provides a Response Descriptor for the following modes:

- I3C Master Mode
- I3C Slave Mode

Details of the Response Descriptor structure of each mode are shown in the following sections.

(1) I3C Master Mode

Bit position	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field	ERR_STATUS[3:0]				TID[3:0]				—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31:28	ERR_STATUS[3:0]	Response Error Status 0h: SUCCESS: Transfer successful, no error. 3h: FRAME: Frame Error 4h: ADDR_HEADER: Address Header Error 5h: NACK: Address NACK'ed or Dynamic Address Assignment NACK'ed 6h: OVL: Receive Overflow or Transfer Underflow Error 8h: ABORTED: Aborted Ah: NOT_SUPPORTED: Command with specific parameters not supported by I3C implementation (for example, specific Internal Control codes may not be supported) Others: Setting prohibited	R

Note: In I3C Slave mode, it is indicated as NOT_SUPPORTED (Ah) in ERR_STATUS[3:0] in the following cases:

- When an abnormal command with a specific parameter that is not supported is stored in the Command Descriptor.
- When the IBI to be transmitted is disabled in the CSECMD register.
- After the normal command for IBI transmission is prepared in the Command Queue, when that IBI is disabled in the CSECMD register by the DISEC CCC frame from the I3C Master.

7.8.4.1.3 IBI Status Descriptor

The IBI Status Descriptor is a read-only structure describing an IBI event received from a Slave device on the I3C Bus.

The IBI Status Descriptor is read from IBI Status Queue with reads from IBI Status Queue Port.

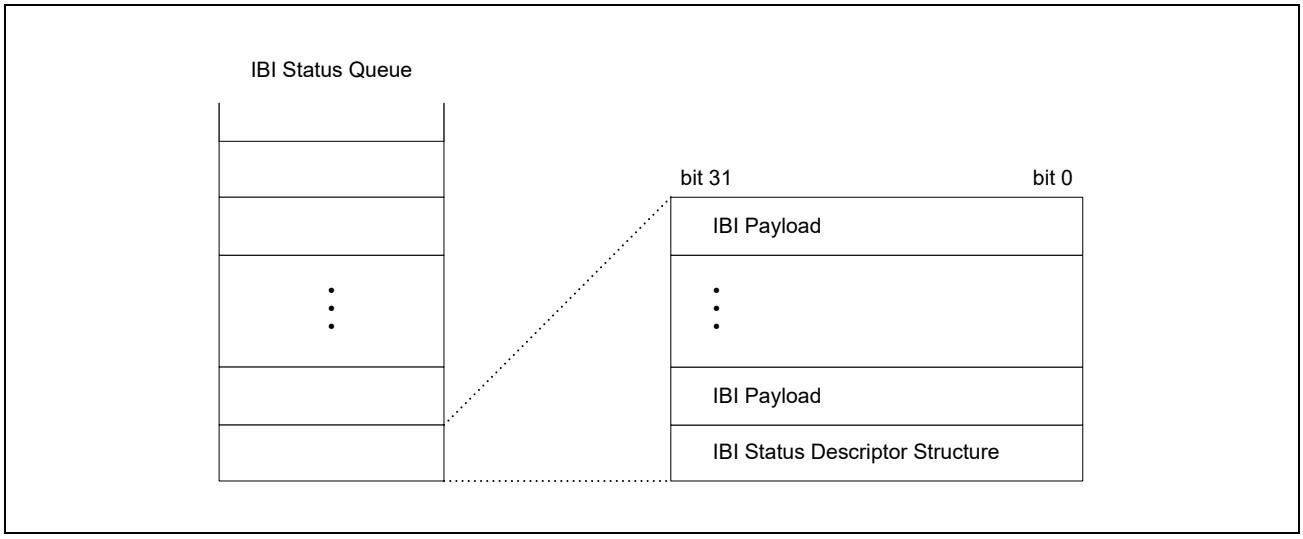

Figure 7.8-4 IBI status descriptor data structure

I3C provides a IBI Status Descriptor for the following mode:

- I3C Master Mode

Details of the IBI Status Descriptor Structure are as follows.

Bit position	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field	IBI_ST	—	—	ERR_STATUS[2:0]			TS	LAST_STATUS	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit position	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field	IBI_ID[7:0]								DATA_LENGTH[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	DATA_LENGTH [7:0]	IBI Data Length Number of data bytes in IBI Data.	R
15:8	IBI_ID[7:0]	IBI Received ID The meaning of this field depends on the context: For Slave Interrupt or Master Request: Bits 15:9 contain the Slave's Device Address, and bit 8 contains the R/W bit. For Hot-Join IBI: Bits 15:8 contain the Hot-Join ID for the IBI.	R
23:16	—	These bits are read as 0b. The write value should be 0b.	R
24	LAST_STATUS	Last IBI Status Last IBI status for the IBI transaction.	R

Bit	Symbol	Function	R/W
25	TS	IBI Time-stamp Present Indicates whether a time-stamp is available for the IBI. 0b: OFF: IBI is not time-stamped. 1b: ON: IBI is time-stamped.	R
28:26	ERR_STATUS[2:0]	IBI Error Status 0h: SUCCESS 3h: ERROR: FRAME (Frame Error) 4h: ERROR: ADDR_HEADER (Address Header Error) 5h: NACK: Address NACKed 7h: ERROR: ABORT (Aborted to Master) Others: Setting prohibited	R
30:29	—	These bits are read as 0b.	R
31	IBI_ST	IBI Received Status Indicates how the received IBI was handled. 0b: The IBI was handled with ACK. 1b: NACK: The IBI was handled with NACK, and then Auto-Disabled.	R

LAST_STATUS bits (Last IBI Status)

Even if LAST_STATUS is set to 0b, the software driver still evaluates the data payload length by examining the CHUNKS field.

7.8.4.1.4 Receive Status Descriptor

The Receive Status Descriptor is a read-only structure describing the success or failure of read/write operation from the master, and the amount of data transferred.

The Receive Status Descriptor is read from Receive Status Queue with reads from Receive Status Queue Port.

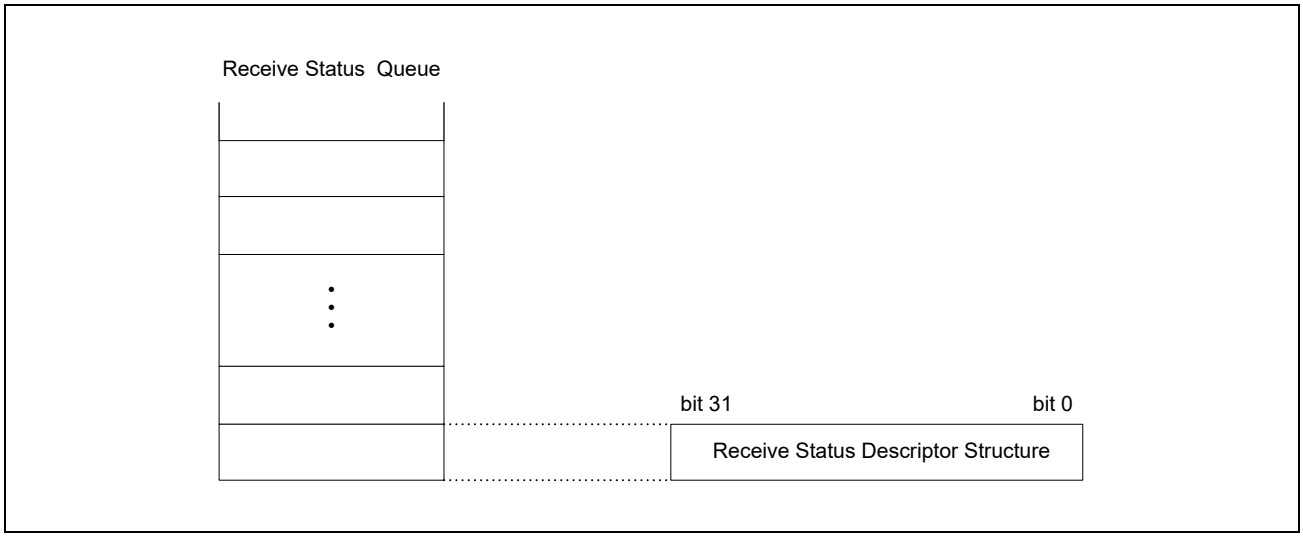

Figure 7.8-5 Receive status descriptor data structure

I3C provides a Receive Status Descriptor for the following mode:

- I3C Slave Mode

Details of the Receive Status Descriptor structure of each mode are as follows.

Bit position	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field	DEV_INDEX[2:0]			TRANSFER_TYPE[1:0]		ERR_STATUS[2:0]			CMD[7:0]

7.8.4.2 Details of Function

7.8.4.2.1 Operation Mode

The support relationship between the mode select (I3C mode / I²C mode) and operation mode (Master / Slave) on the I3C bus or the I²C bus is shown in **Table 7.8-10**.

Table 7.8-10 Support of operating mode

I3C/I²C Bus	I3C mode		I²C mode	
	Master	Slave	Master	Slave
I3C Bus	✓	✓	—	✓
I²C Bus	—	—	✓	✓

Note: ✓: Supported
—: Un-Supported

(1) Master Mode Operation

(a) I²C Master Operation

(a-1) Data Write Transfer (Single Buffer transfer)

In master transmit operation, I3C outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. **Figure 7.8-114** shows an example of usage of master transmission and **Figure 7.8-6** to **Figure 7.8-8** show the timing of operations in master transmission.

The following describes the procedure and operations for master transmission.

1. Initial settings. For details, see **7.8.4.3.1 Initial Setting Flow**.
2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1b (START condition issuance request). Upon receiving the request, I3C issues a START condition. At the same time, the BFREF flag bit is automatically set to 0b, the BST.STCNDDF flag is automatically set to 1b and the STCND bit is automatically set to 0b. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the SDA line have matched while the STCND bit = 1b, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1b, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1b in response to setting of the TRMD bit to 1b.
3. Check that the NTST.TDBEF0 flag = 1b, and then write the value for transmission (the slave address and the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0b, the data are transferred from the Normal Transmit Data Buffer to the Shift Register, and the TDBEF0 flag is again set to 1b. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, I3C continues in master transmit mode. Because the BST.NACKDF flag being 1b at this time indicates that no slave device recognized the address or there was an error in communications, write 1b to the CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0, the 2 higher-order bits of the slave address, and W to the NTDTBP0 register as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to the NTDTBP0 register.

4. After confirming that the NTST.TDBEF0 flag = 1b, write the data for transmission to the NTDTBP0 register. I3C automatically holds the SCL line low until the data for transmission are ready or a STOP condition is issued.
5. After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1, and then set the CNDCTL.SPCND bit to 1b (STOP condition issuance request). Upon receiving a STOP condition issuance request, I3C issues the STOP condition.
6. Upon detecting the STOP condition, I3C automatically sets bits CRMS and TRMD in the PRSST register to 00b and enters slave receive mode. Furthermore, it automatically sets the TDBEF0 and TENDF flags to 0b, and sets the BST.SPCNDDF flag to 1b.
7. After checking that the BST.SPCNDDF flag = 1b, set the BST.NACKDF and SPCNDDF flags to 0b for the next transfer operation.

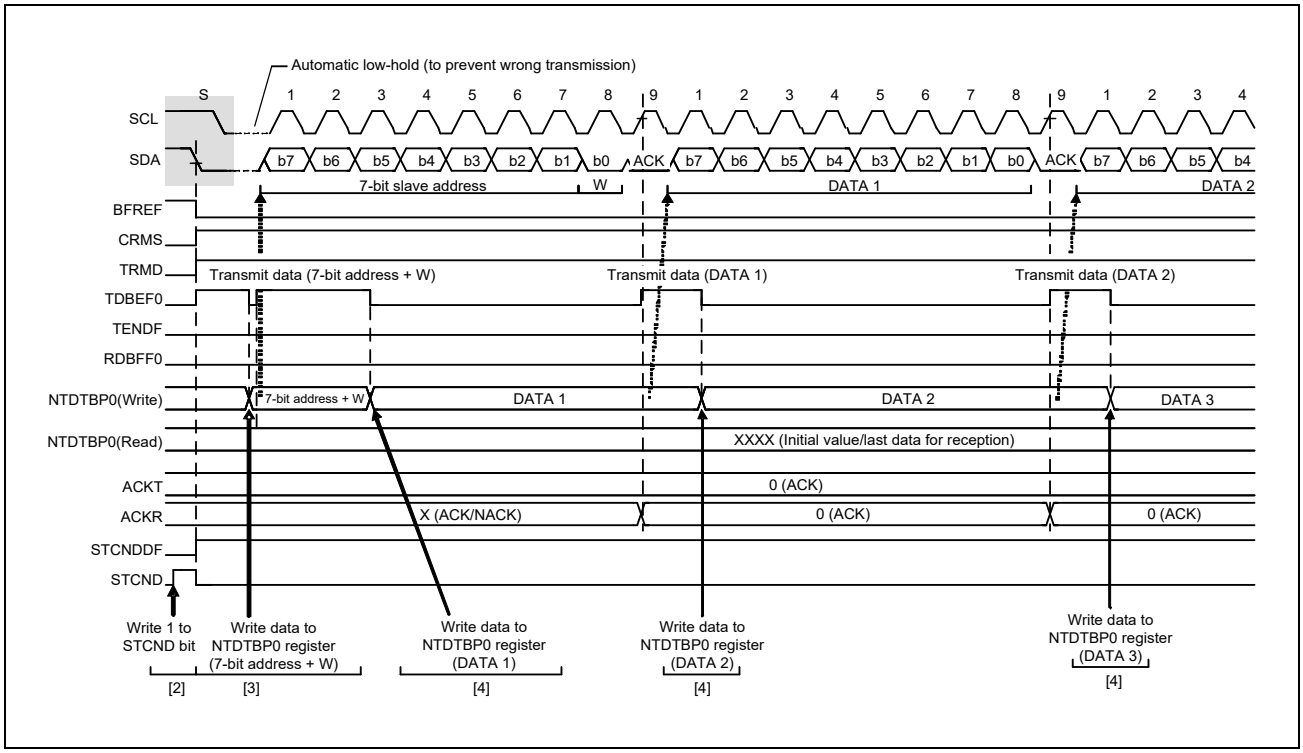

Figure 7.8-6 Master transmit operation timing (1) (7-bit address format)

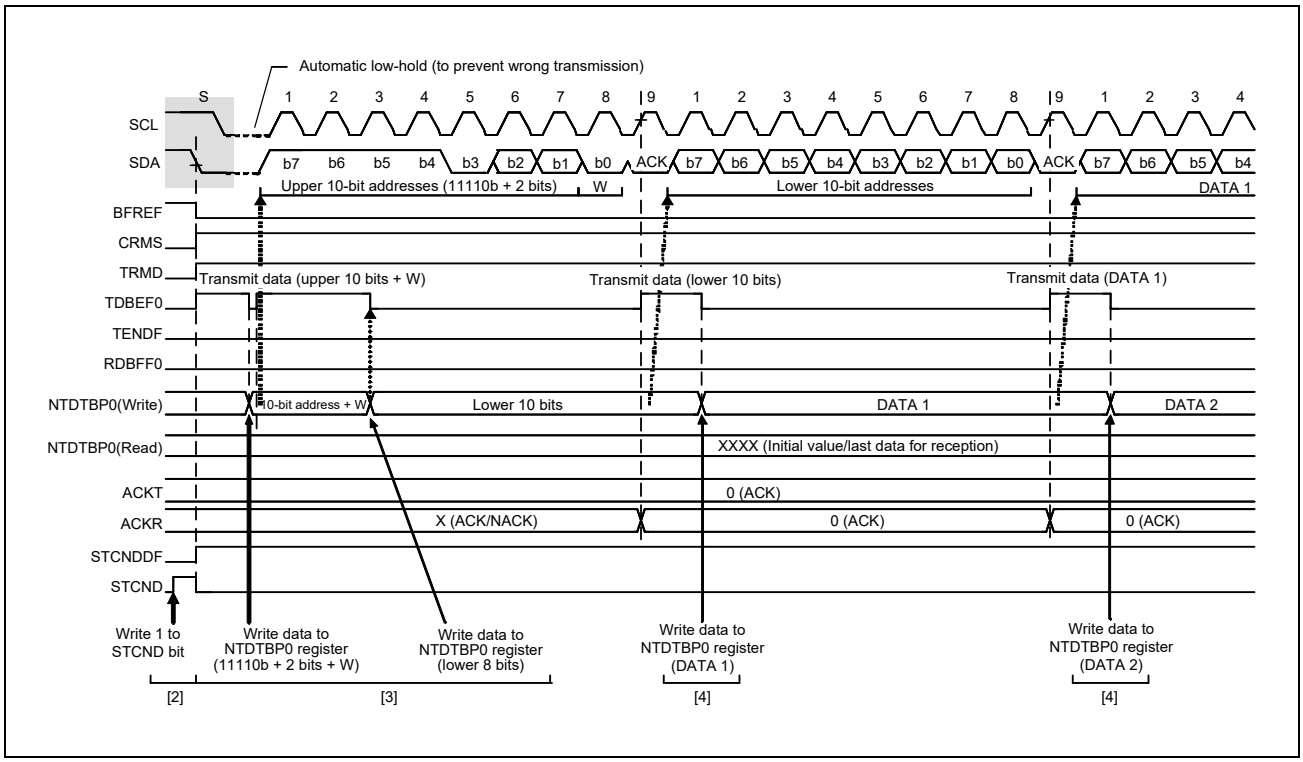

Figure 7.8-7 Master transmit operation timing (2) (10-bit address format)

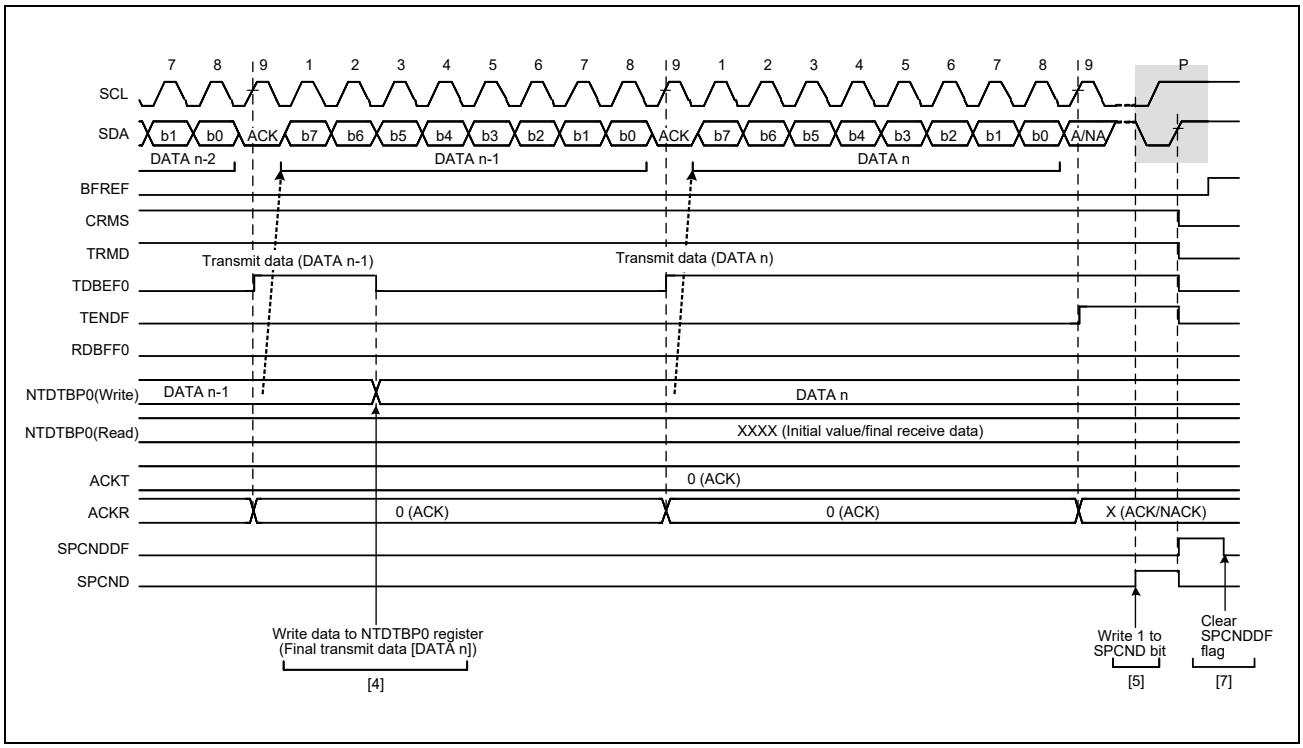

Figure 7.8-8 Master transmit operation timing (3)

(a-2) Data Read Transfer (Single Buffer transfer)

In master receive operation, I3C as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because I3C must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 7.8-115 and **Figure 7.8-116** show examples of usage of master reception (7-bit address format) and **Figure 7.8-9** to **Figure 7.8-11** show the timing of operations in master reception.

The following describes the procedure and operations for master reception.

1. Initial settings. For details, see **7.8.4.3.1 Initial Setting Flow**.
2. Read the BCST.BFREF flag to check that the bus is open, and then set the CNDCTL.STCND bit to 1b (START condition issuance request). Upon receiving the request, I3C issues a START condition. When I3C detects the START condition, the BFREF flag is automatically set to 0b and the BST.STCNDDF flag is automatically set to 1b and the STCND bit is automatically set to 0b. At this time, if the START condition is detected and the levels for the SDA output and the levels on the SDA line have matched while the STCND bit = 1b, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and bits CRMS and TRMD in the PRSST register are automatically set to 1b, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1b in response to setting of the TRMD bit to 1b.
3. Check that the NTST.TDBEF0 flag = 1b, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to the NTDTBP0 register. Once the data for transmission are written to the NTDTBP0 register, the TDBEF0 flag is automatically set to 0b, the data are transferred from the Normal Transmit Data Buffer to the Shift Register, and the TDBEF0 flag is again set to 1b. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the PRSST.TRMD bit is automatically updated to select transmit or receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRMD bit is set to 0b on the rising edge of the ninth cycle of SCL clock, placing I3C in master receive mode. At this time, the TDBEF0 flag is set to 0b. The NTST.RDBFF0 flag is automatically set to 1b when ACK response is received from the slave device. If the slave device is not recognized or a communication failure occurs, the BST.NACKDF flag will be set to 1b. At this time, set 1b to the CNDCTL.SPCND bit to issue a STOP condition. For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a Repeated START condition. After that, transmitting 1111 0, the two higher-order bits of the slave address, and the R bit places I3C in master receive mode.
4. Dummy read the NTDTBP0 register after confirming that the NTST.RDBFF0 flag = 1b; this makes I3C start output of the SCL clock and start data reception.
5. After 1 byte of data has been received, the NTST.RDBFF0 flag is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the SCSTRCTL.ACKTWE bit. Reading the NTDTBP0 register at this time will produce the received data, and the RDBFF0 flag is automatically set to 0b at the same time. Furthermore, the value of the acknowledgment field received during the ninth cycle of SCL clock is returned as the value set in the ACKCTL.ACKT bit. Furthermore, if the next byte to be received is the next to last byte, set the SCSTRCTL.RWE bit to 1b (for wait insertion) before reading the NTDTBP0 register (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ACKCTL.ACKT bit to 1b (NACK) in step 6, due to other interrupts, etc., this fixes the SCL line to the low level on the falling edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a STOP condition is possible.
6. When the SCSTRCTL.ACKTWE bit = 0b and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ACKCTL.ACKT bit to 1b (NACK).

7. After reading the byte before last from the NTDTBP0 register, if the value of the NTST.RDBFF0 flag is confirmed to be 1b, write 1 to the CNDCTL.SPCND bit (STOP condition issuance request) and then read the last byte from the NTDTBP0 register. When 1b is written to the CNDCTL.SPCND bit, I3C is released from the wait state and issues the STOP condition after low-level output in the ninth clock cycle is completed or the SCL line is released from the low- hold state.
8. Upon detecting the STOP condition, I3C automatically sets bits CRMS and TRMD in the PRSST register to 00b and enters slave receive mode. Furthermore, detection of the STOP condition leads to setting of the BST.SPCNDDF flag to 1b.
9. After checking that the BST.SPCNDDF flag = 1b, set the BST.NACKDF and SPCNDDF flags to 0 for the next transfer operation.

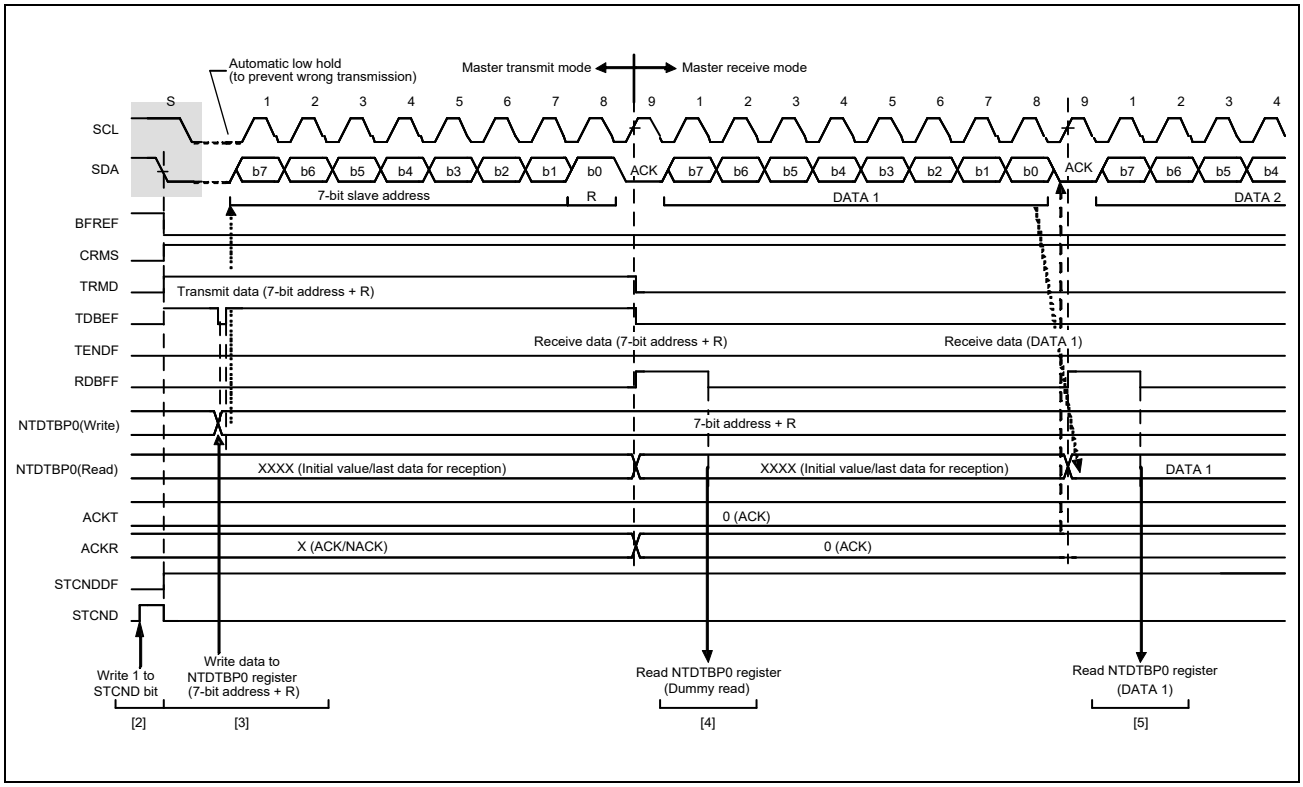

Figure 7.8-9 Master receive operation timing (1) (7-bit address format, when ACKTWE = 0)

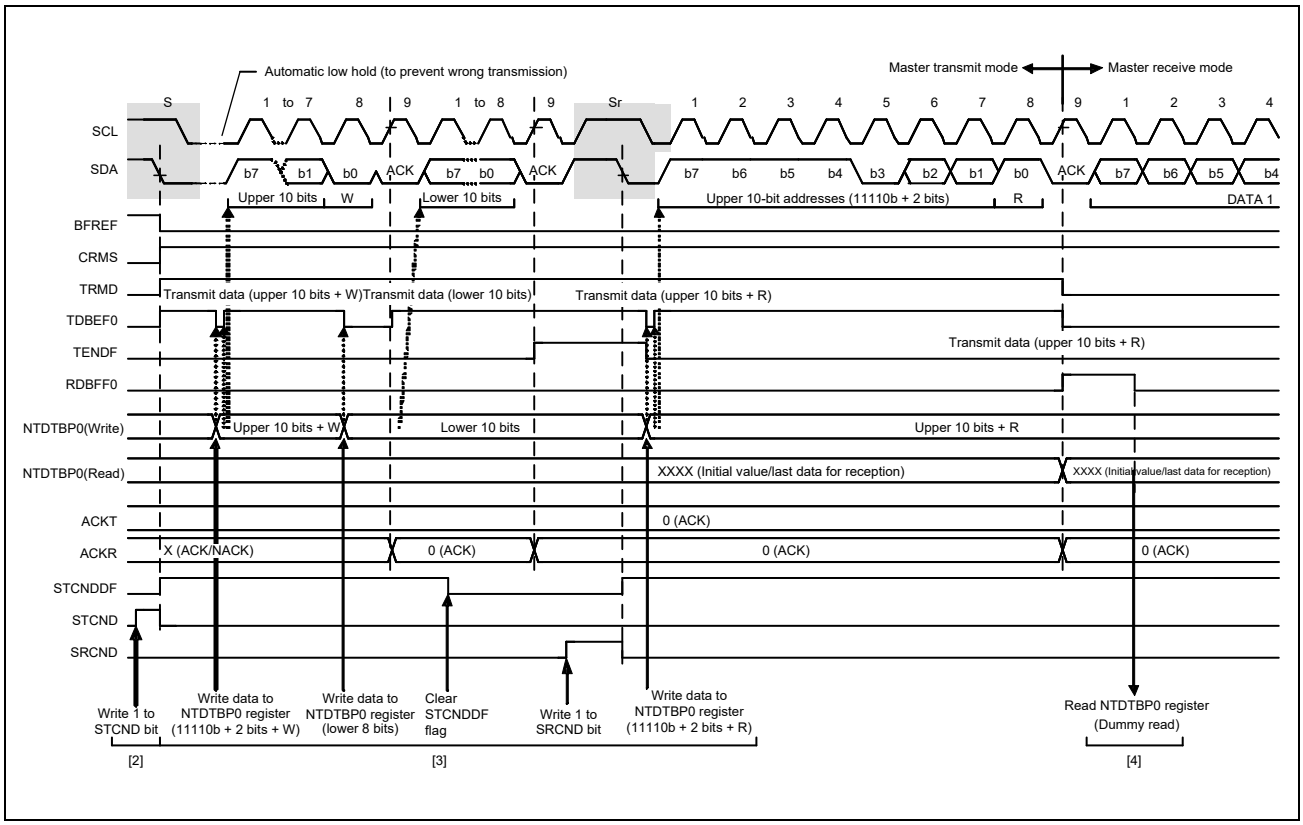

Figure 7.8-10 Master receive operation timing (2) (10-bit address format, when ACKTWE = 0)

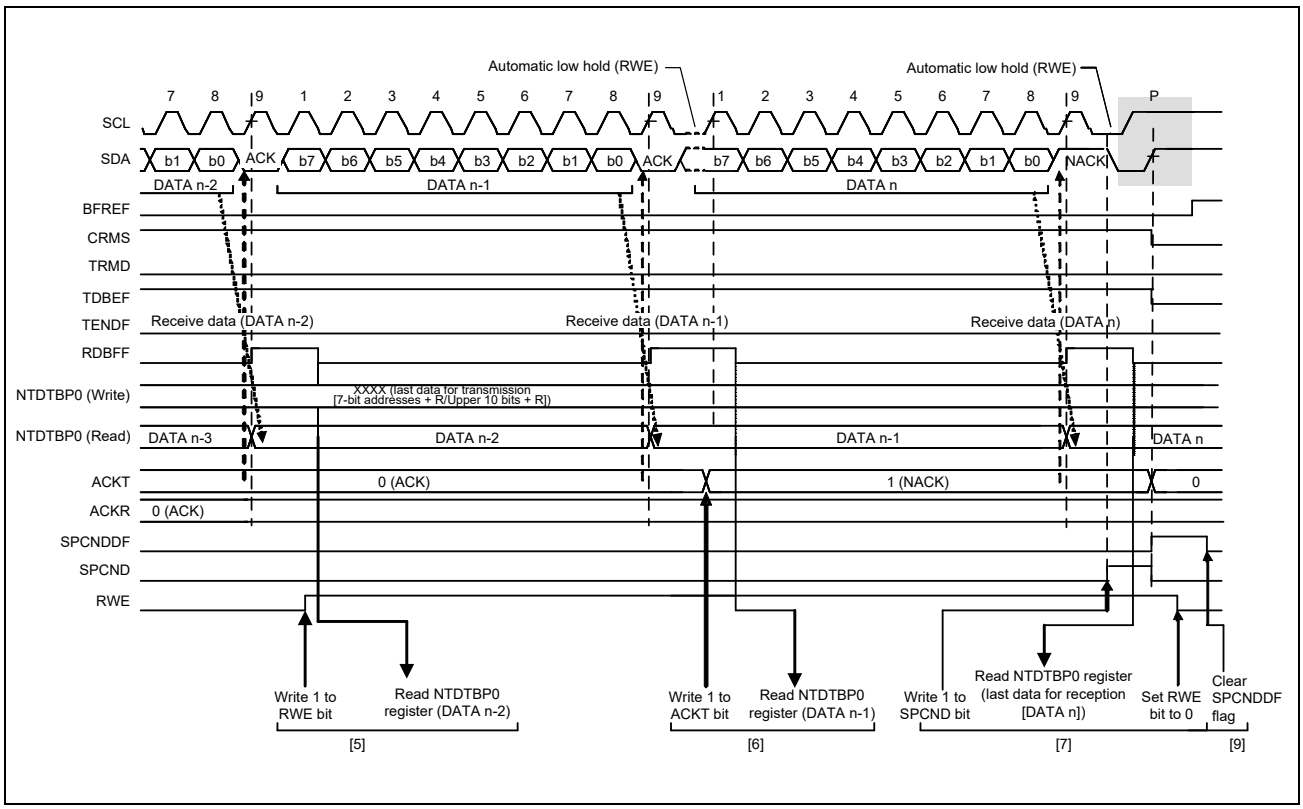

Figure 7.8-11 Master receive operation timing (3) (when ACKTWE = 0)

(b) I3C Master Operation

(b-1) Dynamic Address Assign Procedure

After initializing I3C, first execute Dynamic Address Assign Procedure for I3C Slave connected on the I3C Bus. The following describes the procedure.

1. Initial setting (see **(2) I3C Initial Setting Flow** for details)
2. Execute Dynamic Address Assign with ENTDAA or SETDASA Common Command Code (CCC) for I3C Slave set in DAT (DATBASm register).
3. Write Command Descriptor (Address Assign Command) to Command Buffer via the NCMDQP register.
   When Command Descriptor is written to Command Buffer, Transaction is issued on I3C Bus.
4. When ENTDAA is specified for CMD[7:0] of Address Assign Command:
   Execute Dynamic Address Assign for I3C Slave for the number of DATs specified by DEV_COUNT[3:0] starting with DAT specified by DEV_INDEX[4:0] of Address Assign Command.
   When SETDASA is specified for CMD[7:0] of Address Assign Command:
   Execute Dynamic Address Assign for I3C Slave indicated by DAT specified by DEV_INDEX[4:0] of Address Assign Command.
5. In case of ENTDAA, the Provisional ID, BCR, DCR transmitted from I3C Slave is stored in Receive Data Buffer (BCR is also automatically stored in the MSDCTm register).
   Read the Provisional ID, BCR, and DCR from the Receive Data Buffer via the NTDTBP0 register with an interrupt by RDBFF0 = 1b.
6. When execution of Dynamic Address Assign is completed, issue STOP condition and store the Response Descriptor into the Response Buffer.
7. Read the Response Descriptor via the NRSPQP register and check the status.
8. Check whether the value of the DATA_LENGTH[15:0] bits of the Response Descriptor matches the value of DEV_COUNT[3:0] of the Address Assign Command.

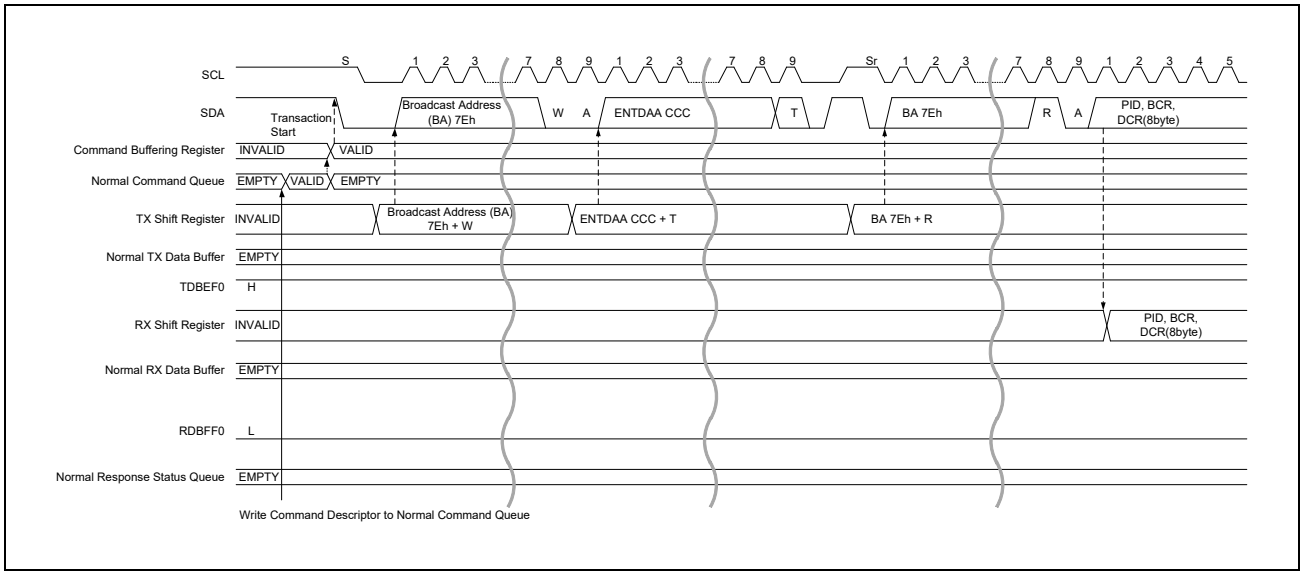

Figure 7.8-12 Dynamic address assign procedure (ENTDAA CCC) timing (1/3)

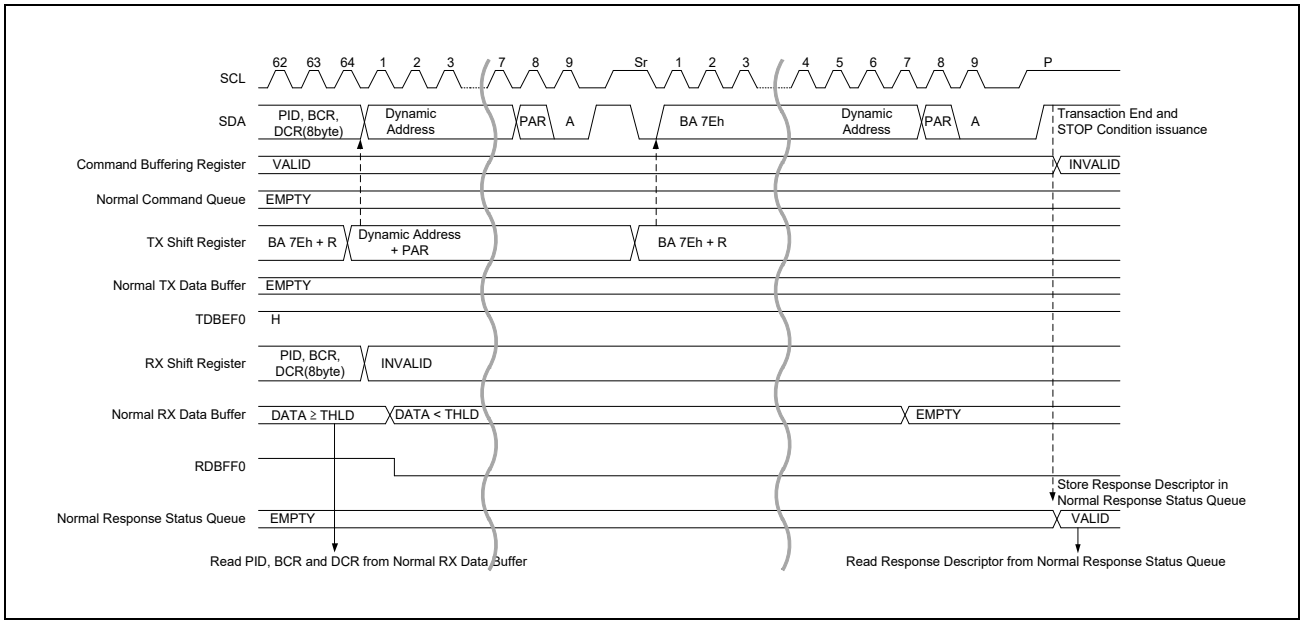

Figure 7.8-14 Dynamic address assign procedure (ENTDAA CCC) timing (3/3)

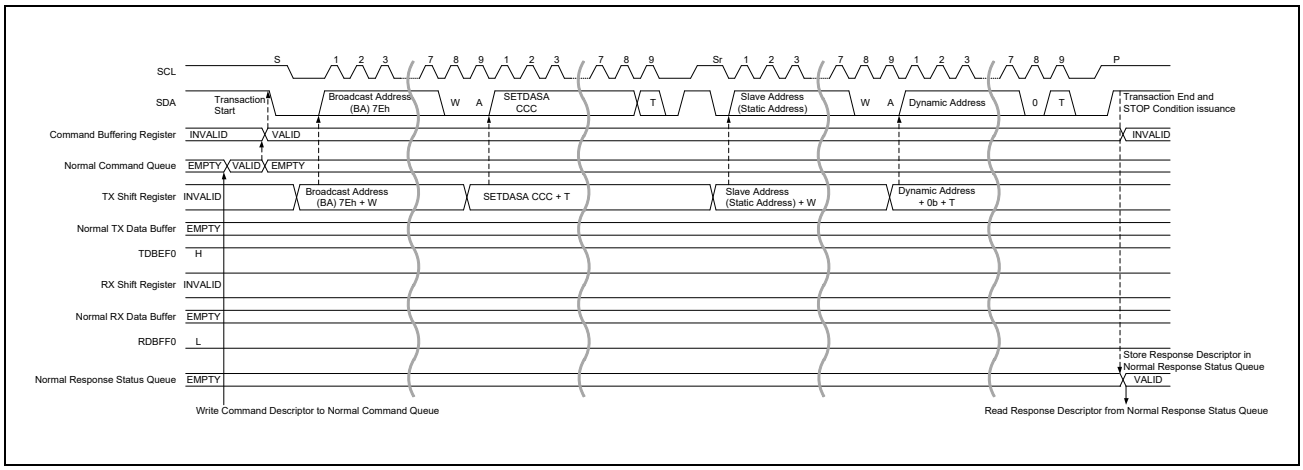

Figure 7.8-15 Dynamic address assign procedure (SETDASA CCC) timing

(b-2) SDR Data Write Transfer

1. Write data for transmission to the Transmit Data Buffer via the NTDTBP0 register.
2. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK).
4. If data for transmission still remain, write data for transmission by an interrupt with TDBEF0 = 1b to the Transmit Data Buffer via the NTDTBP0 register.
5. When data transmission for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, the Repeated START condition or STOP condition is issued and the Response Descriptor is stored in the Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.
7. Check that the value of the DATA_LENGTH[15:0] bits of the Response Descriptor is 0.

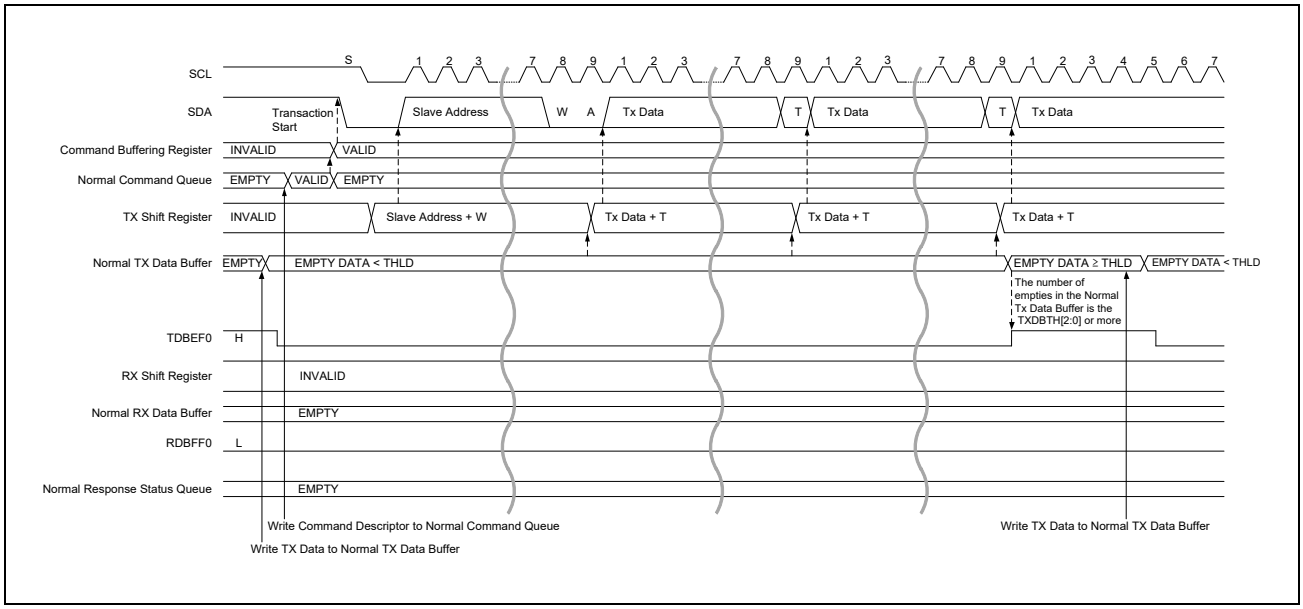

Figure 7.8-16 SDR data write transfer timing (1/2)

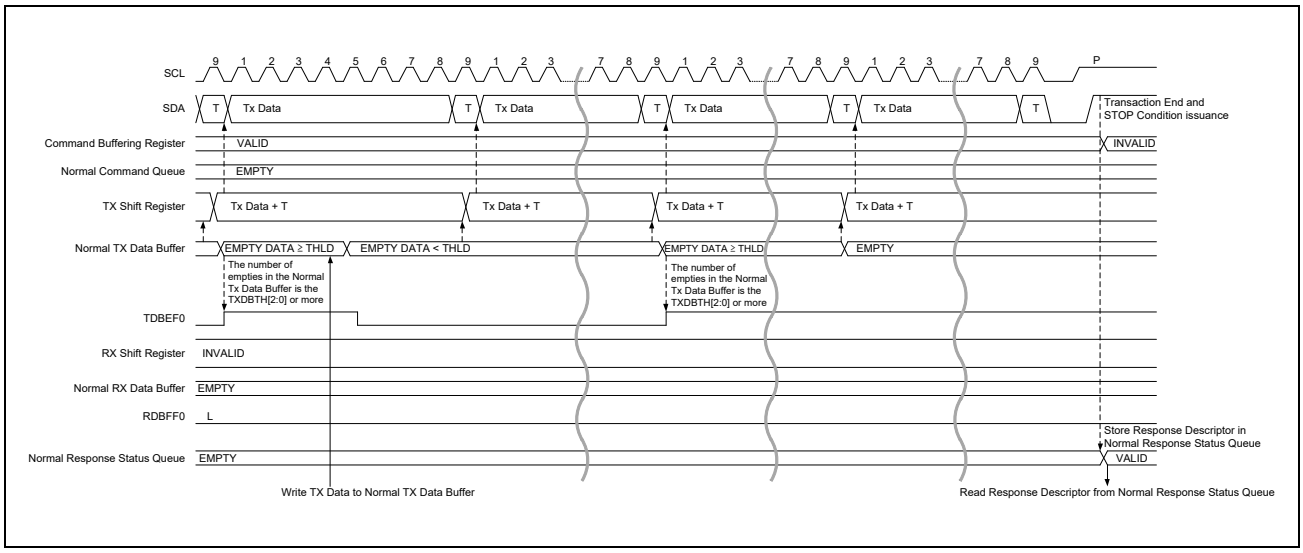

Figure 7.8-17 SDR data write transfer timing (2/2)

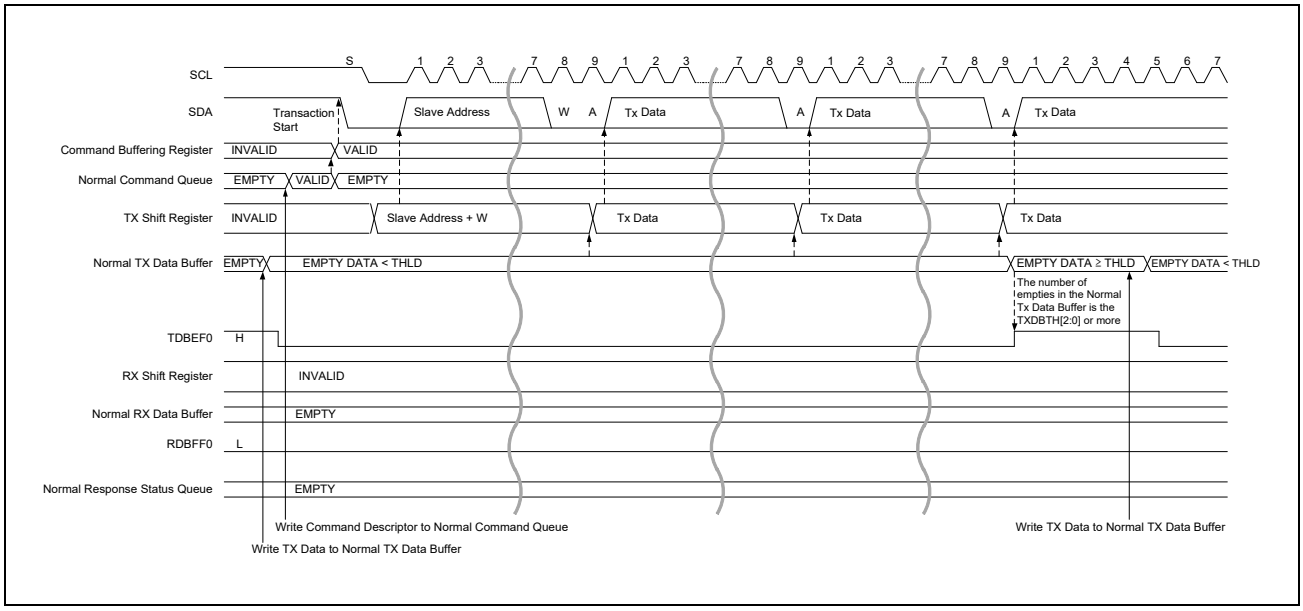

Figure 7.8-18 Legacy I²C message data write timing (1/2)

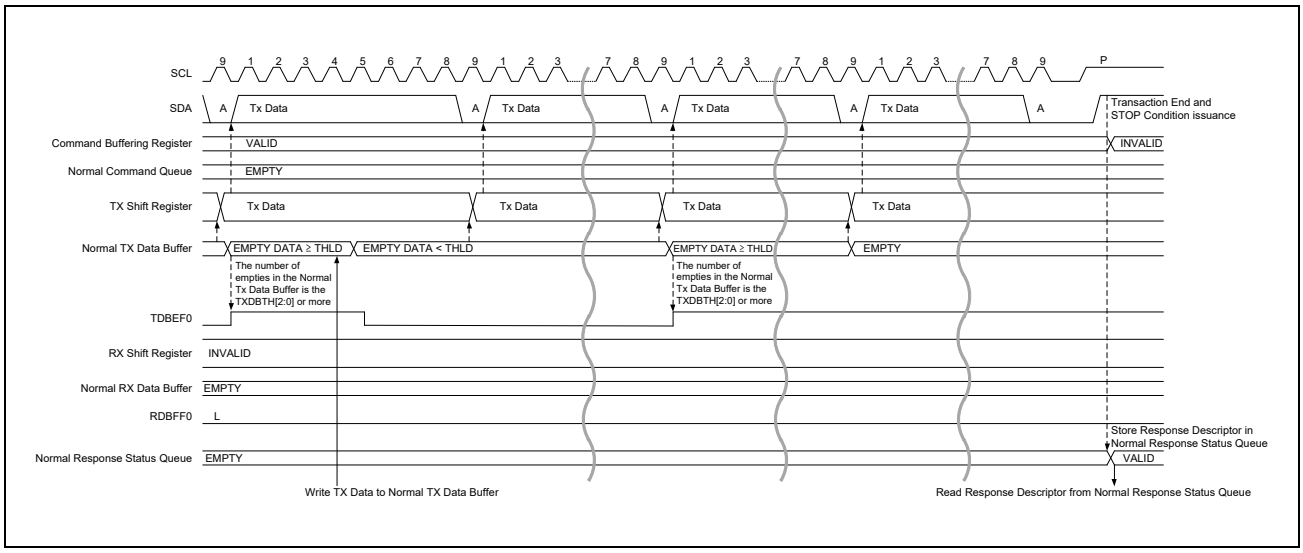

Figure 7.8-19 Legacy I²C message data write timing (2/2)

(b-3) SDR Data Read Transfer

1. Write a Command Descriptor (Immediate Transfer Command or Regular Transfer Command or Combo Transfer Command) for Data Transfer to the Command Buffer via the NCMDQP register.
2. When Command Descriptor is written to Command Buffer, transaction is issued on I3C Bus.
   When NACK is received with the Address Header, transaction of the same command is automatically issued according to the NACK Retry Count value (DATBASm.DVNACK).
3. Data received from the I3C Slave is stored in the Receive Data Buffer.
4. With the RDBFF0 = 1b interrupt, the received data is read from the Receive Data Buffer via the NTDTBP0 register.
5. SDR:
   Detecting Low in T-bit or receiving Data for the number of Data Length specified by the DATA_LENGTH[15:0] bits of Command Descriptor is completed, issue Repeated START condition or STOP condition and store the Response Descriptor into the Response Buffer.
   Legacy I^2C Message:
   When data reception for the number of Data Length specified by the DATA_LENGTH[15:0] bits of Command Descriptor is completed, NACK is issued. After that, issue a Repeated START condition or STOP condition and store the Response Descriptor into the Response Buffer.
6. Read the Response Descriptor via the NRSPQP register and check the status.
7. Check whether the value of the DATA_LENGTH[15:0] bits of the Response Descriptor matches the data length setting value of the Command Descriptor.

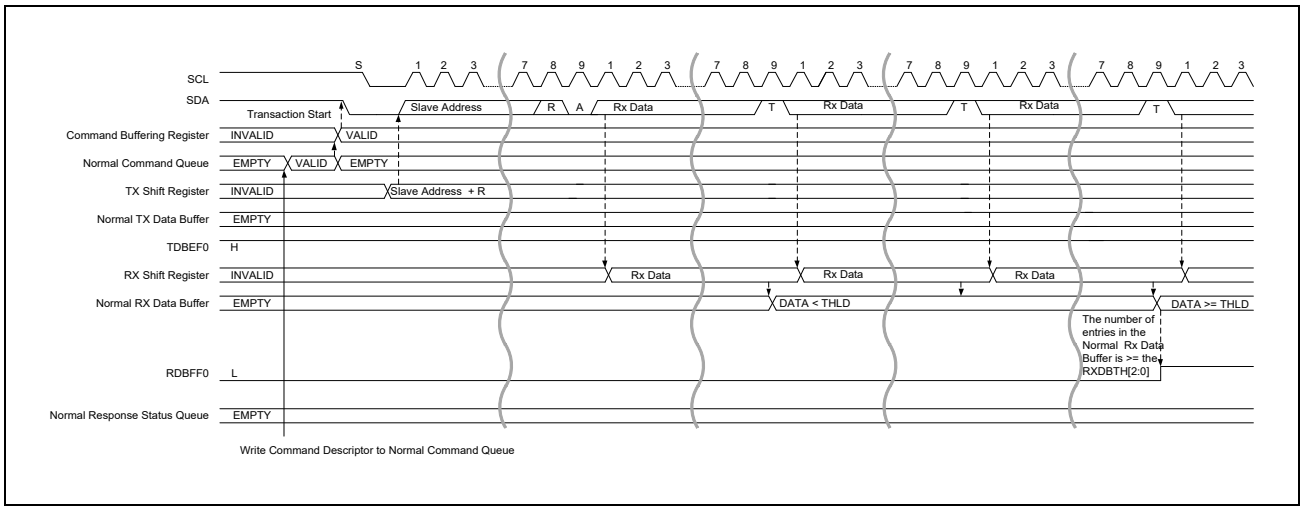

Figure 7.8-20 SDR data read transfer timing (1/2)

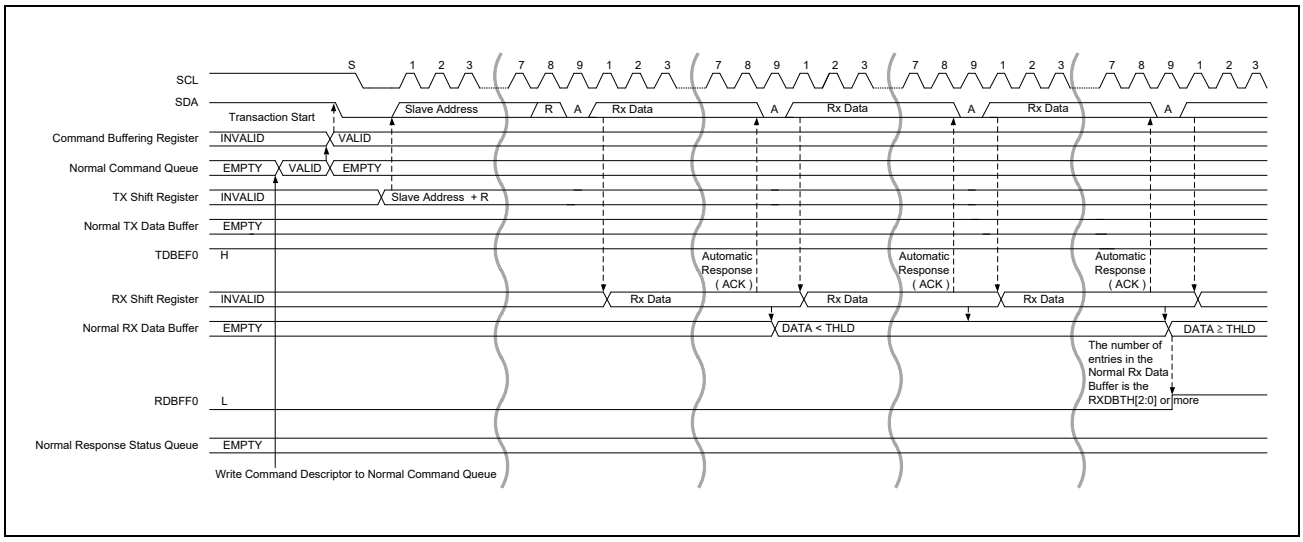

Figure 7.8-22 Legacy I²C message data read transfer timing (1/2)

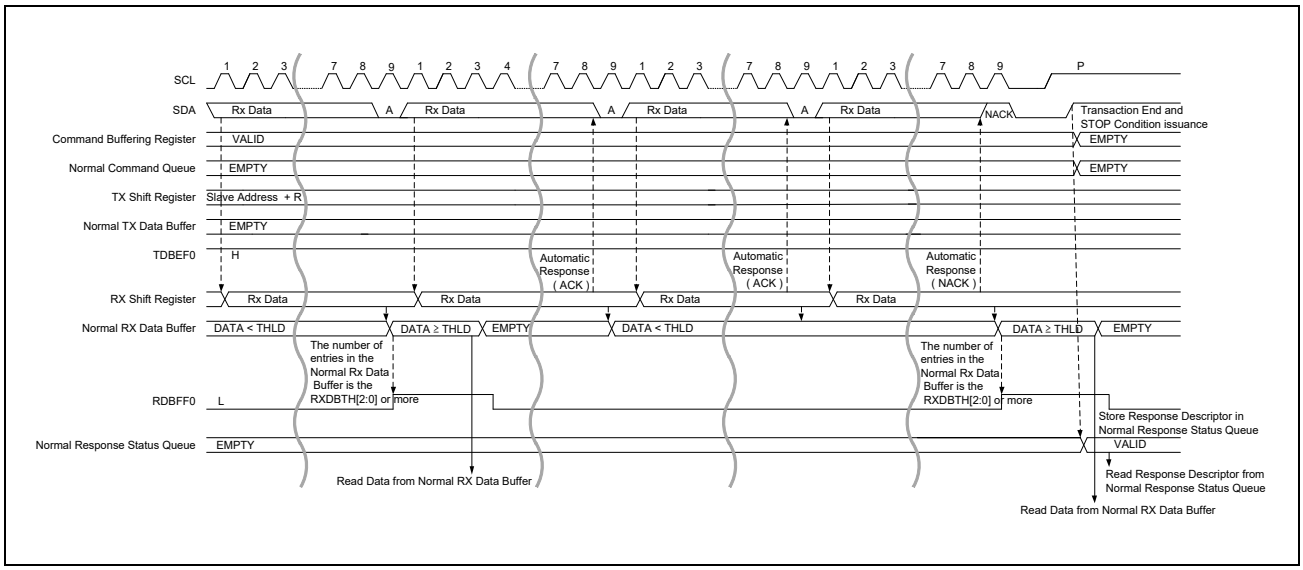

Figure 7.8-23 Legacy I²C message data read transfer timing (2/2)

(b-4) IBI Transfer

1. Write Command Descriptor to the Command Buffer and issue Transaction on I3C Bus.
   If START Request (SDA Low Drive) is issued from the slave device, I3C drives SCL to Low and completes START condition.
   Thereafter, the SCL is supplied and In-Band Interrupt Request is received.
2. In Slave Address with RnW of the Address Header, if losing Arbitration by issuing In-Band Interrupt from I3C Slave, stop issuing Transaction.
3. According to **(8) In-Band Interrupt [I3C mode]**, detect In-Band Interrupt and process.
4. In the interrupt with IBIQEFF = 1b, read the IBI Status Descriptor from the IBI Status Buffer via the NIBIQP register and check the status.
   When detected a Slave Interrupt Request and responded with ACK, Read the IBI Data for the Data Length indicated by the DATA_LENGTH[15:0] bits of the IBI Status Descriptor from the IBI Data Buffer via the NIBIQP register.
5. Restart issuing Transaction of Command of Step1.

An example of the processing procedure after detection of In-Band Interrupt is shown below.

Processing procedure for detecting Mastership Request and transferring master right to Secondary Master

1. If the I3C Secondary Master wins the Arbitration, issue a DEFSLVS CCC and notify Slave information to Secondary Master.
2. Issue a GETACCMST CCC and complete CCC by a STOP condition.

Remark After transferring master right to Secondary Master, to get master right again, issue a Mastership Request according to (f) IBI Transfer of **(b) I3C Slave Operation**.
After Mastership Request is accepted by the Current Master, to get master right again at receiving the GETACCMST CCC and complete CCC by a STOP condition.

Processing procedure when Hot-Join Event is detected

1. Issue a Broadcast Command Code Enter Dynamic Address Assignment (ENTDAA) to start the Dynamic Address Assignment process.
2. Issue a DEFSLVS CCC and notify Slave information to Secondary Master.

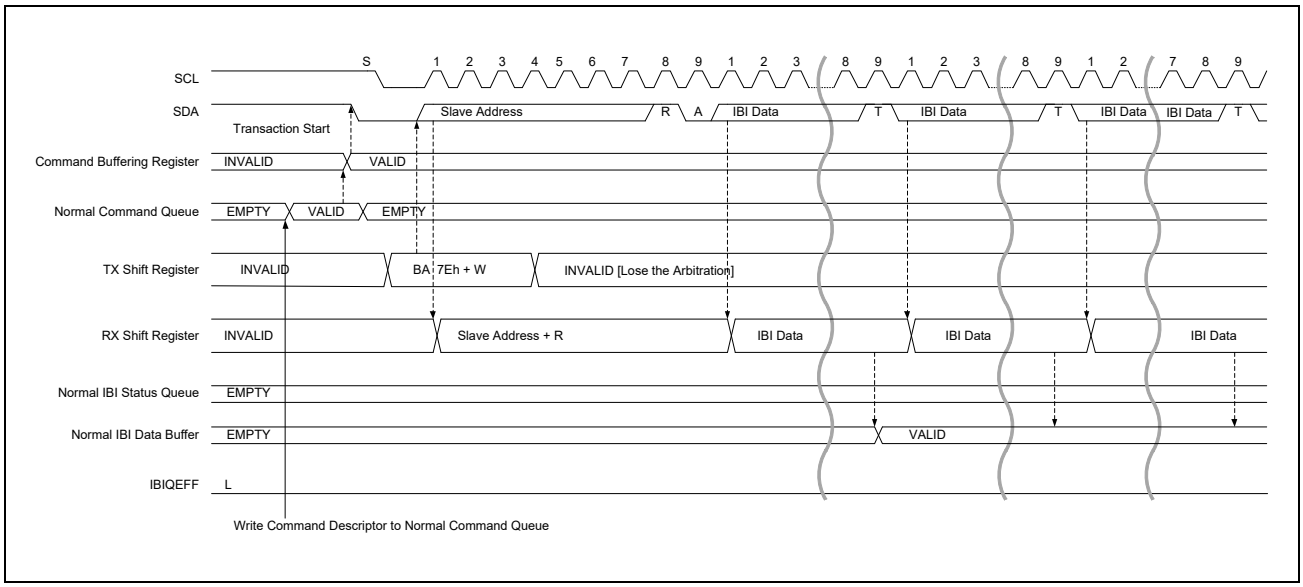

Figure 7.8-24 I3C master IBI transfer timing (1/2)

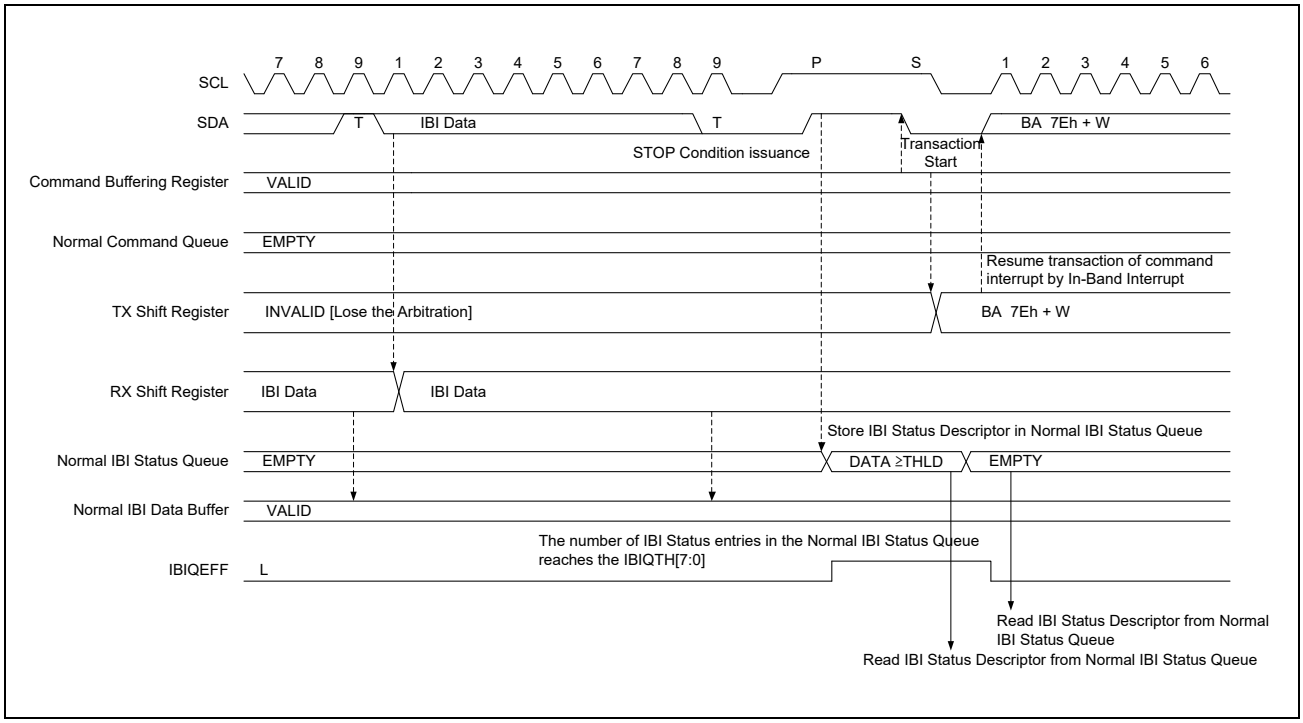

Figure 7.8-25 I3C master IBI transfer timing (2/2)

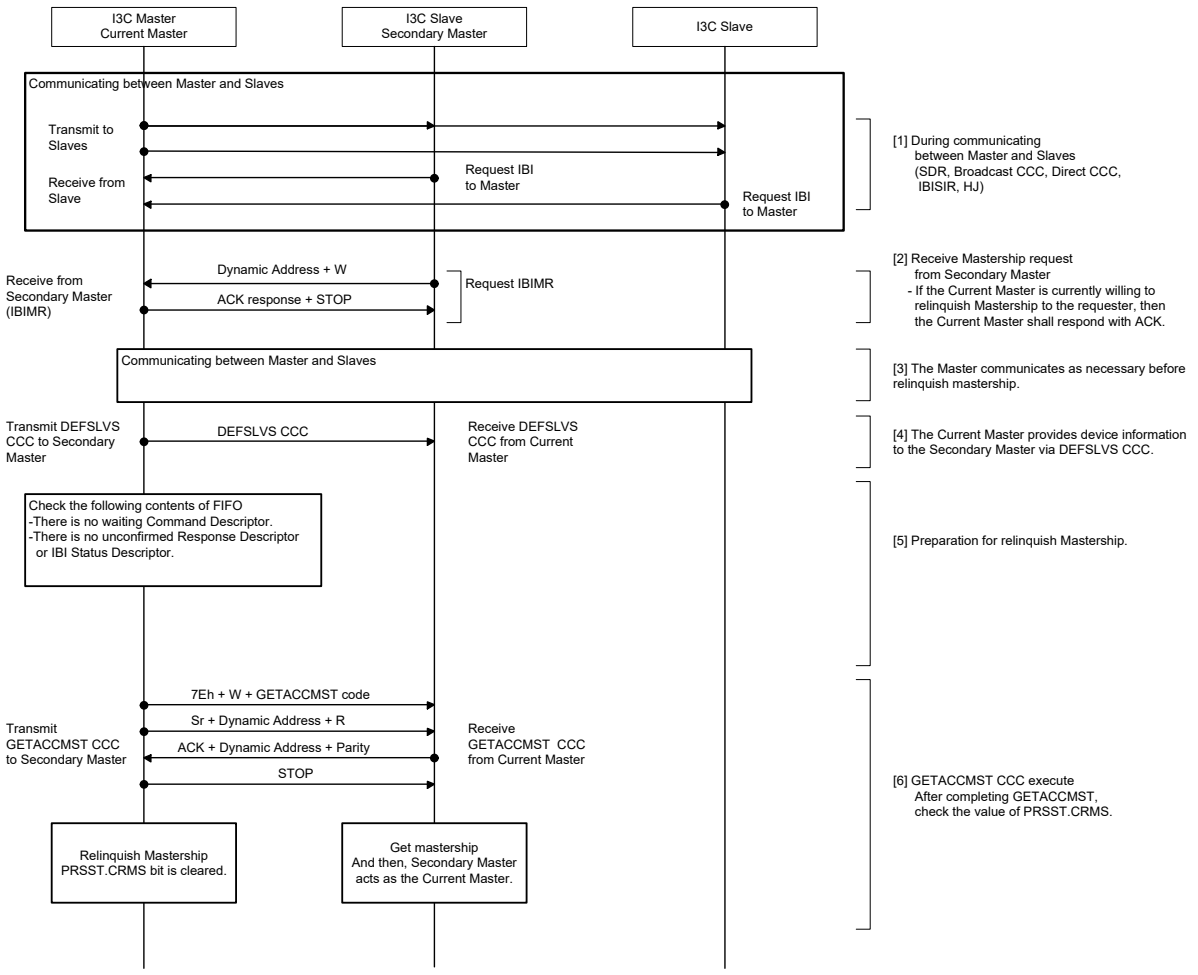

Note: The Abort request during GETACCMST by BCTL.ABT setting is prohibited due to the transfer of Mastership.

Figure 7.8-26 I3C Master Mastership processing flow

(2) Slave Mode Operation

(a) I^2C Slave Operation

(a-1) Data Write Transfer (Single Buffer transfer)

In slave receive operation, the master device outputs the SCL clock and transmit data, and I3C returns acknowledgments as a slave device.

Figure 7.8-122 shows an example of usage of slave reception and **Figure 7.8-27** and **Figure 7.8-28** show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

1. Initial settings. For details, see **7.8.4.3.1 Initial Setting Flow**. After initial settings, I3C will stay in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, I3C sets one of the corresponding bits SVST.HOAF, GCAF, and SVAFn (n = 0 to 2) to 1b on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0b, I3C continues to place itself in slave receive mode and sets the NTST.RDBFF0 flag to 1b.
3. After the BST.SPCNDDF flag is confirmed to be 0b and the NTST.RDBFF0 flag to be 1b, dummy read the NTDTBP0 register (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected).
4. When the NTDTBP0 register is read, I3C automatically sets the NTST.RDBFF0 flag to 0b. If reading of the NTDTBP0 register is delayed and a next byte is received while the RDBFF0 flag is still set to 1b, I3C holds the SCL line low from one SCL cycle before the timing with which RDBFF0 should be set. In this case, reading the NTDTBP0 register releases the SCL line from being held at the low level. When the BST.SPCNDDF flag = 1b and the NTST.RDBFF0 flag is also 1b, read the NTDTBP0 register until all the data is completely received.
5. Upon detecting the STOP condition, I3C automatically clears bits SVST.HOAF, GCAF, and SVAFn (n = 0 to 2) to 0b.
6. After checking that the BST.SPCNDDF flag = 1b, set the BST.SPCNDDF flag to 0b for the next transfer operation.

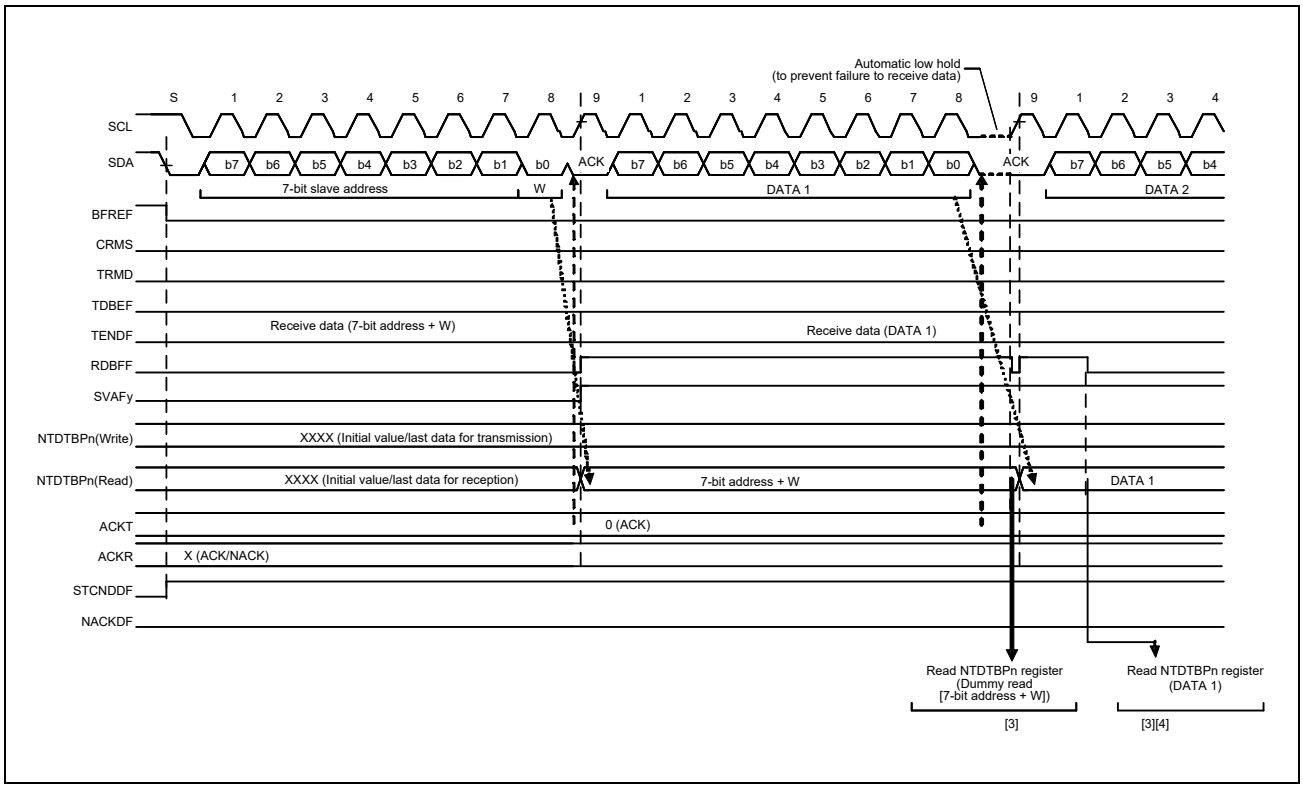

Figure 7.8-27 Slave receive operation timing (1) (7-bit address format, when ACKTWE = 0)

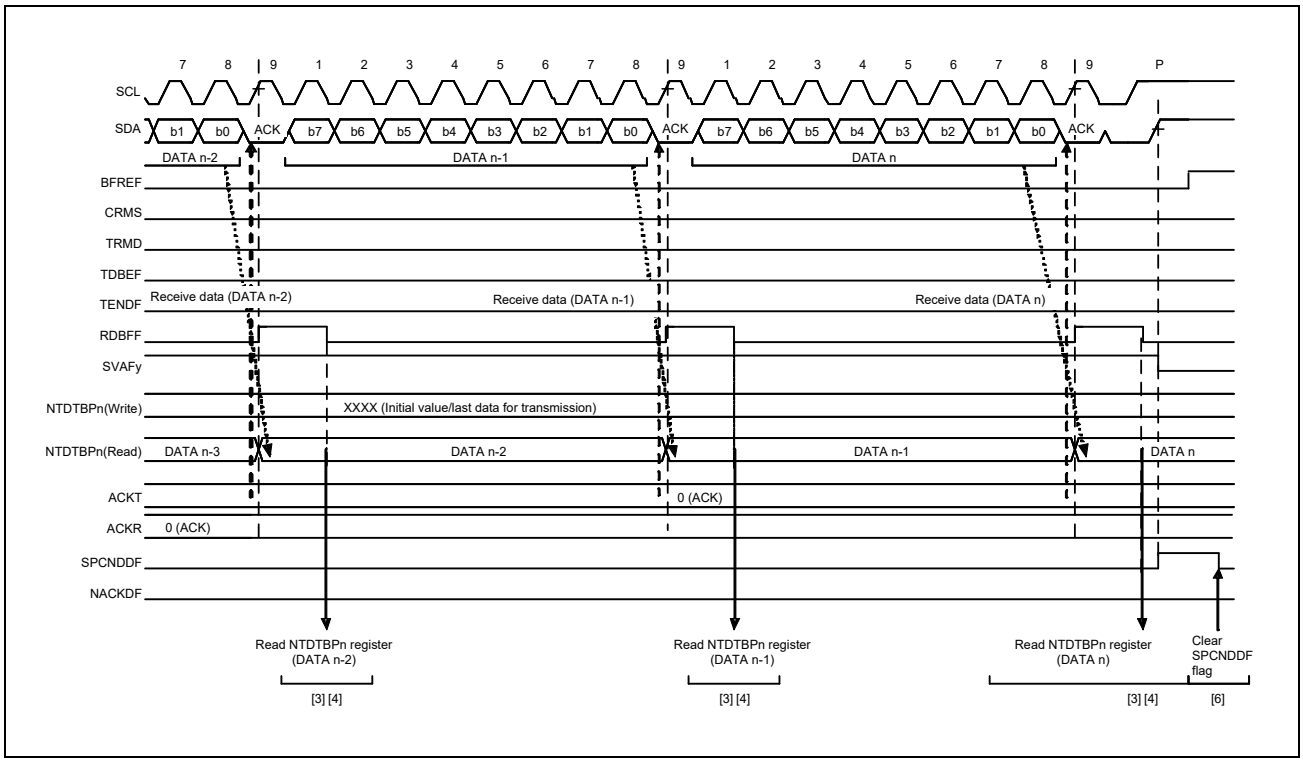

Figure 7.8-28 Slave receive operation timing (2) (when ACKTWE = 0)

(a-2) Data Read Transfer (Single Buffer transfer)

In slave transmit operation, the master device outputs the SCL clock, I3C transmits data as a slave device, and the master device returns acknowledgments.

Figure 7.8-121 shows an example of usage of slave transmission and **Figure 7.8-29** and **Figure 7.8-30** show the timing of operations in slave transmission.

The following describes the procedure and operations for slave transmission.

1. Initial settings. For details, see **7.8.4.3.1 Initial Setting Flow**.
   After initial settings, I3C will stay in the standby state until it receives a slave address that it matches.
2. After receiving a matching slave address, I3C sets one of the corresponding bits SVST.HOAF, GCAF, and SVAFn (n = 0 to 2) to 1b on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the acknowledge bit (ACK) on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 1b, I3C automatically places itself in slave transmit mode by setting both the PRSST.TRMD bit and the NTST.TDBEF0 flag to 1b.
3. After the NTST.TDBEF0 flag is confirmed to be 1b, write the data for transmission to the NTDTBP0 register. At this time, if I3C does not receive acknowledge from the master device (receives a NACK signal) while the BSTE.NACKDE bit = 1b, I3C aborts transfer of the next data.
4. Wait until the following (a) or (b) condition.
   (a) The BST.NACKDF flag is set to 1b.
   (b) The BST.TENDF flag is set to 1b while the NTST.TDBEF0 flag = 1b, after the last byte for transmission is written to the NTDTBP0 register.
5. When the BST.NACKDF flag or the BST.TENDF flag = 1b, dummy read the NTDTBP0 register to complete the processing.
6. Upon detecting the STOP condition, I3C automatically sets bits SVST.HOAF, GCAF, and SVAFn (n = 0 to 2), flags NTST.TDBEF0 and BST.TENDF, and the PRSST.TRMD bit to 0b, and enters slave receive mode.
7. After checking that the BST.SPCNDDF flag = 1b, set the BST.NACKDF and SPCNDDF flags to 0b for the next transfer operation.

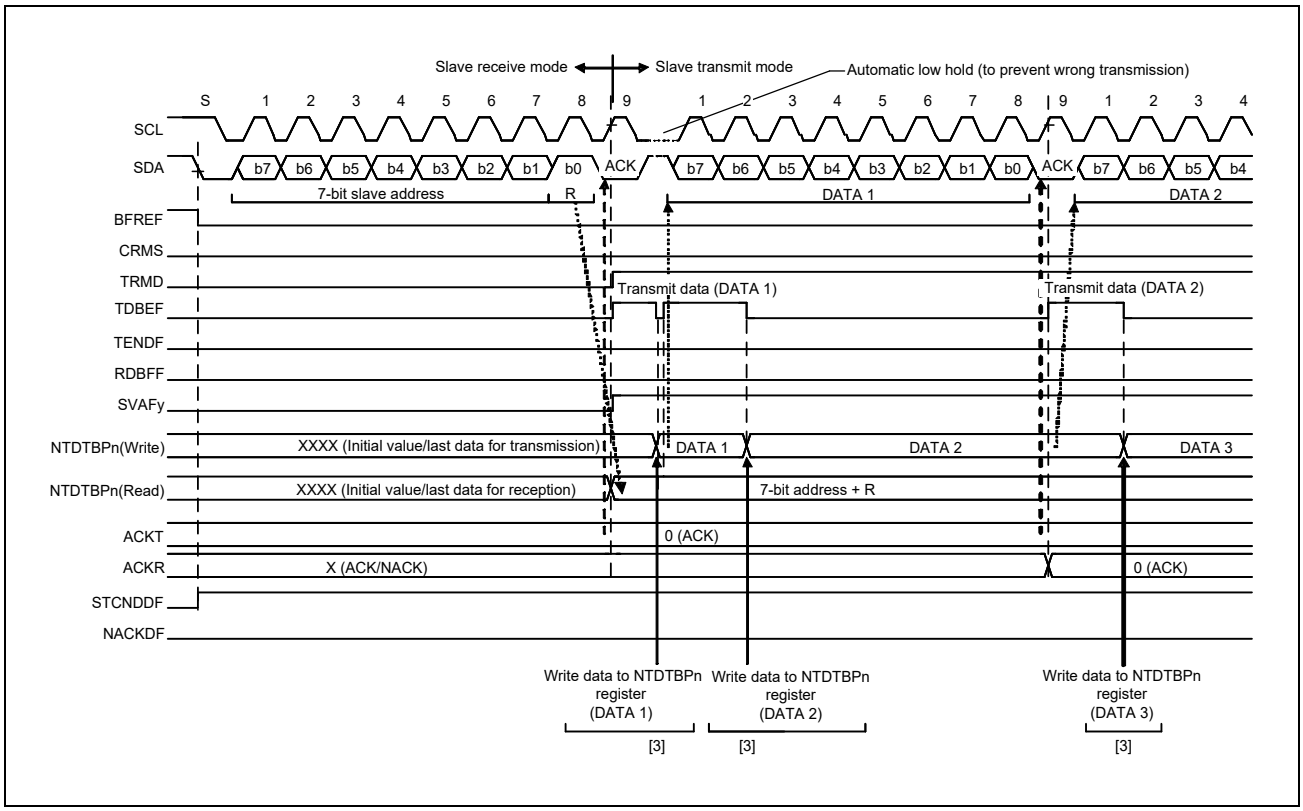

Figure 7.8-29 Slave transmit operation timing (1) (7-bit address format)

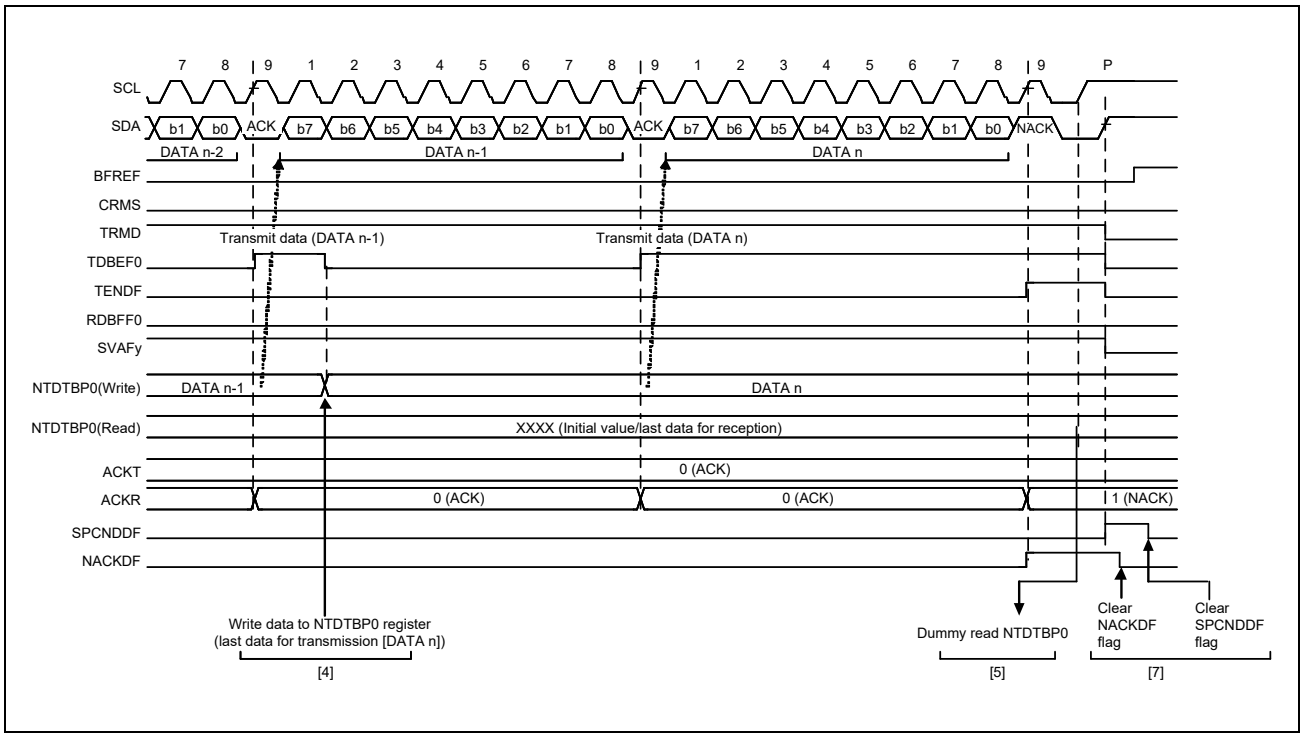

Figure 7.8-30 Slave transmit operation timing (2)

(b) I3C Slave Operation

(b-1) Dynamic Address Assign Procedure

After initializing I3C, the I3C master first performs Dynamic Address Assign Procedure.

The operation of R-I3 during the Dynamic Address Assign Procedure by ENTDAA CCC is described below.

1. Initial setting (For details, see **(2) I3C Initial Setting Flow**)
2. When ENTDAA CCC is received, I3C transmits Provisional ID (SDCTPIDH[31:0], SDCTPIDL[15:0]), BCR (SVDCT.TBCR[7:0]), DCR (SVDCT.TDCR[7:0]) until a dynamic address is assigned. (For details, see "In case of Broadcast CCC (ENTDAA)" of **(f) CCC detection function [I3C mode]**.)
3. When ENTDAA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in Receive Status Buffer.
4. Read Receive Status Descriptor via NRSQP register and check the status.
5. Read the data for the Data Length indicated by the DATA_LENGTH[15:0] bits of the Receive Status Descriptor from the Receive Data Buffer via the NTDTBP0 register.

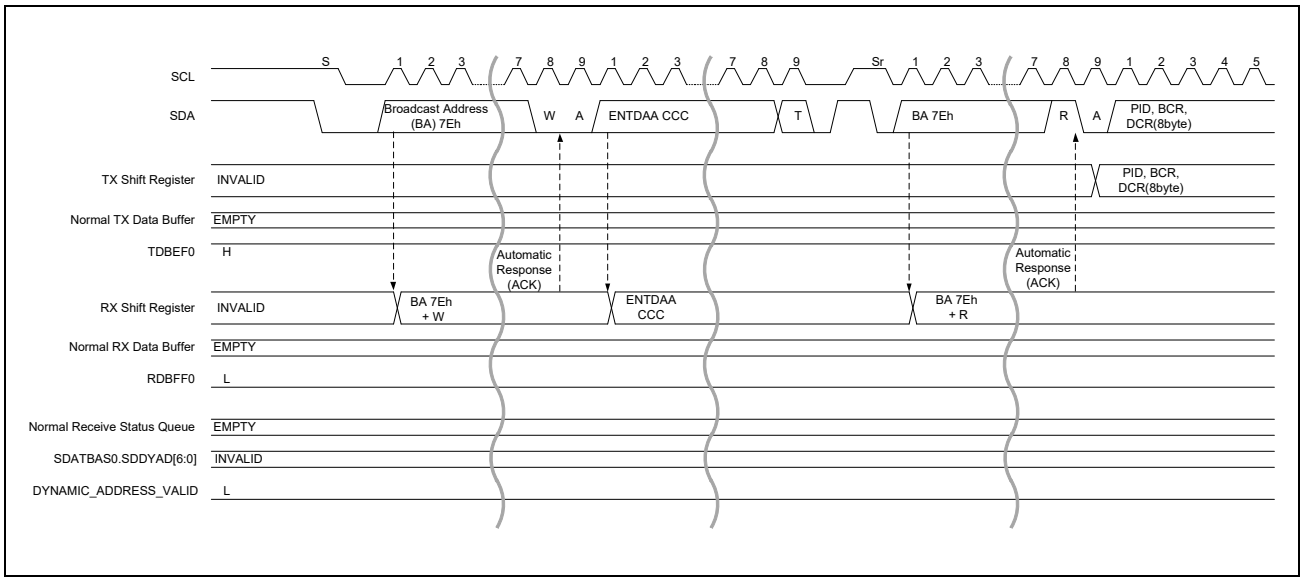

Figure 7.8-31 Dynamic address assign procedure (ENTDAA CCC) timing (1/3)

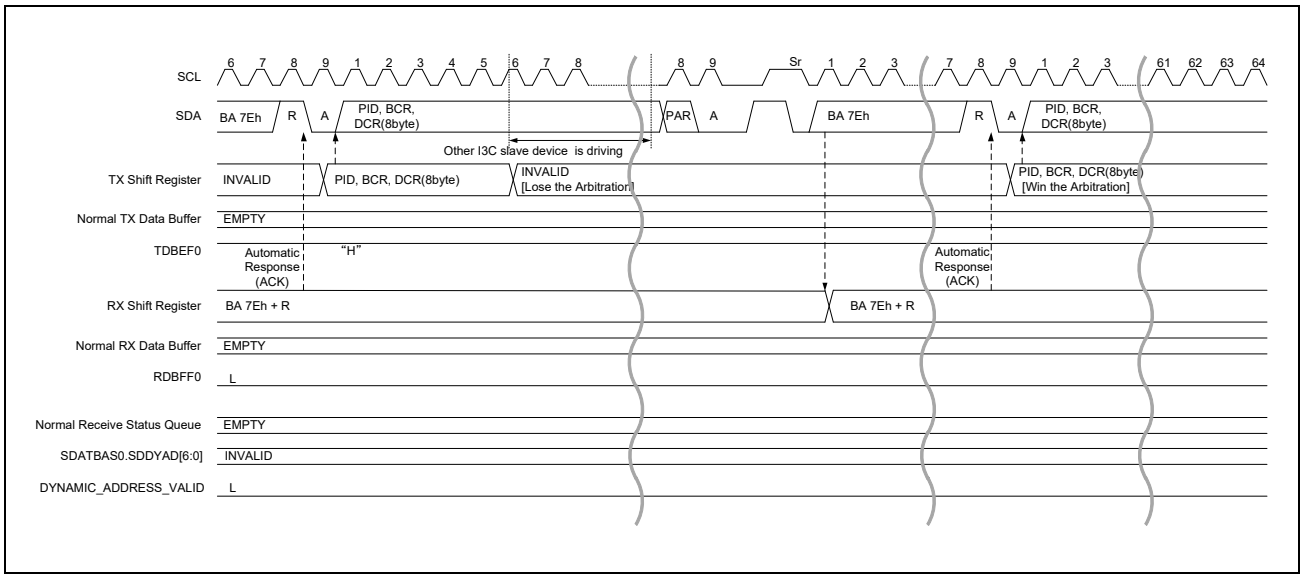

Figure 7.8-32 Dynamic address assign procedure (ENTDAA CCC) timing (2/3)

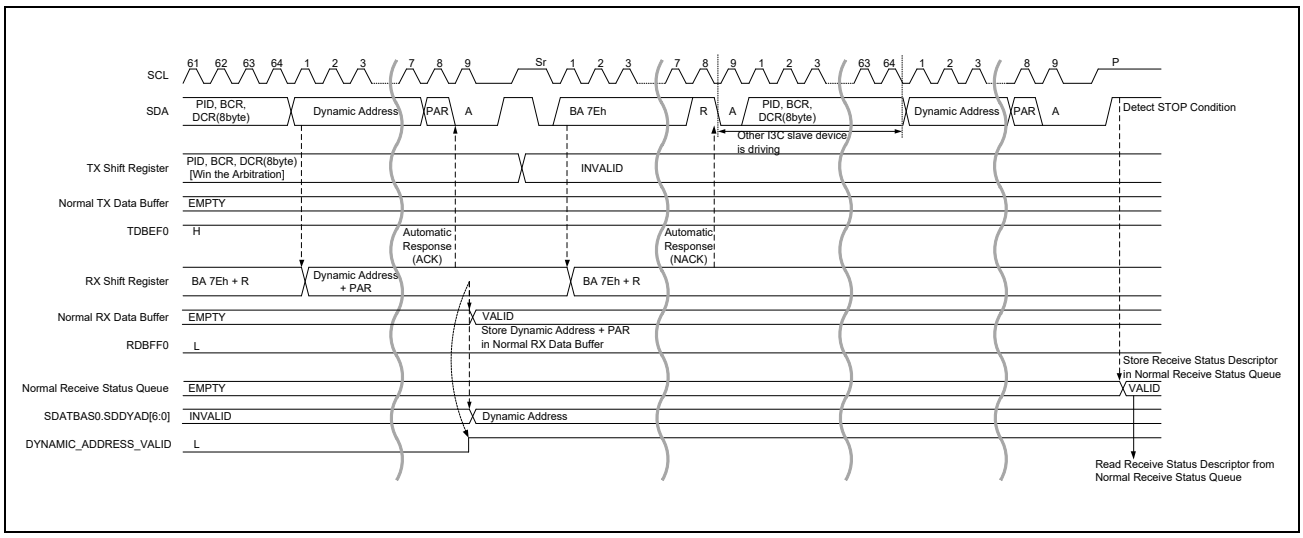

Figure 7.8-33 Dynamic address assign procedure (ENTDAA CCC) timing (3/3)

When communicating with a Static Address until the Dynamic Address is assigned from the I3C Master, by setting to the SDSTAD[6:0] bit of DAT (SDATBASn register), the SSTADV bit of the SVDVADn register is set to 1b and the Static Address Will be effective.

If the I3C Slave has a Static Address and the I3C Master executes the Dynamic Address Assign Procedure, it is possible to assign a Dynamic Address with SETDASA CCC.

The operation of I3C during SETDASA CCC Dynamic Address Assign Procedure is described below.

1. Initial setting (For details, see **(2) I3C Initial Setting Flow**)
2. When SETDASA CCC which agrees with its own Static Address is received, the SDDYAD [6:0] bit of DAT (SDATBAS0 register) is renewed and SDYADV bit of SVDVAD0 register is set in 1b. (For details, see "In case of Direct Write CCC" of **(f) CCC detection function [I3C mode]**.)

3. When SETDASA CCC is completed and a STOP condition is detected, Receive Status Descriptor is stored in Receive Status Buffer.
4. Read Receive Status Descriptor via NRSQP register and check the status.

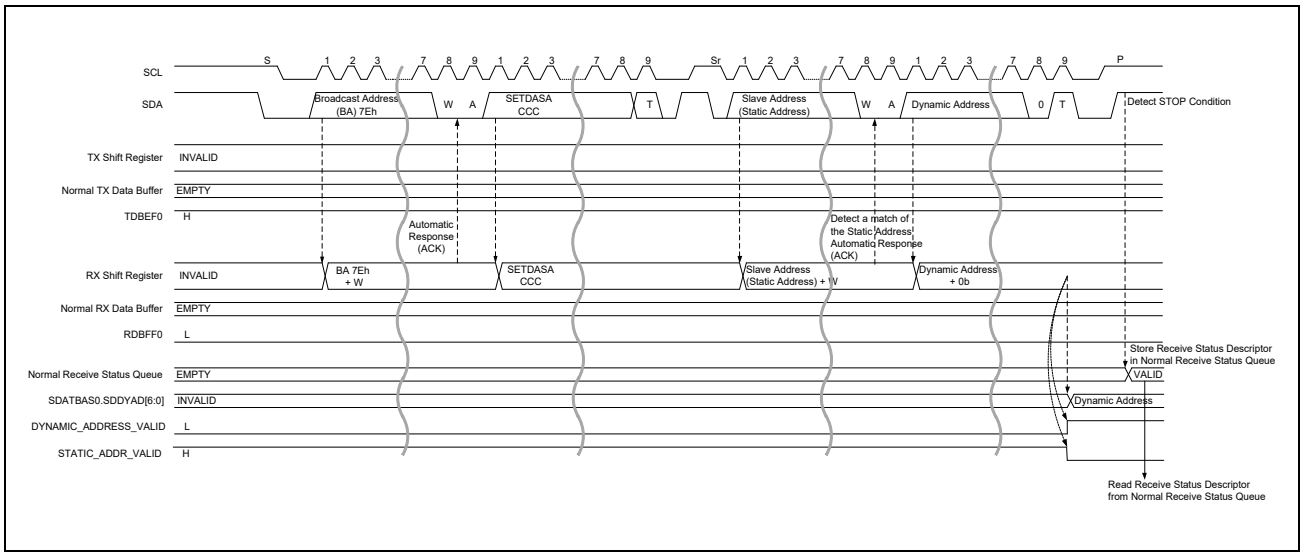

Figure 7.8-34 Dynamic address assign procedure (SETDASA CCC) timing

(b-2) SDR Data Write Transfer

1. When Transaction is issued from the I3C Master, it compares the Slave Address of Address Header with its own Slave Address, and if it matches, I3C responds with ACK.
   When a Transaction is received, if the Receive Data Buffer is full, the I3C Slave will respond with NACK in the Address Header.
   In preparation for retrying the I3C Master, read the data from the Receive Data Buffer via the NTDTBP0 register, and empty the Receive Data Buffer.
2. Data received from I3C Master is stored in the Receive Data Buffer.
3. With the RDBFF0 = 1b interrupt, the received data is read from the Receive Data Buffer via the NTDTBP0 register.
4. When Repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the Receive Status Buffer.
5. Read Receive Status Descriptor via NRSQP register and check the status.

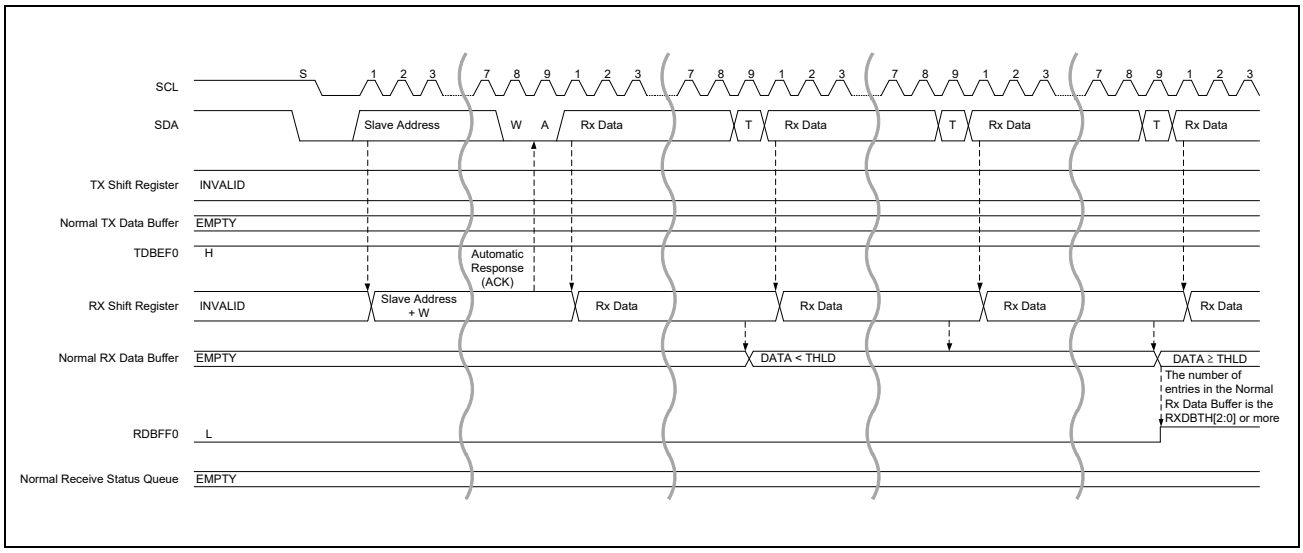

Figure 7.8-35 SDR data write transfer timing (1/2)

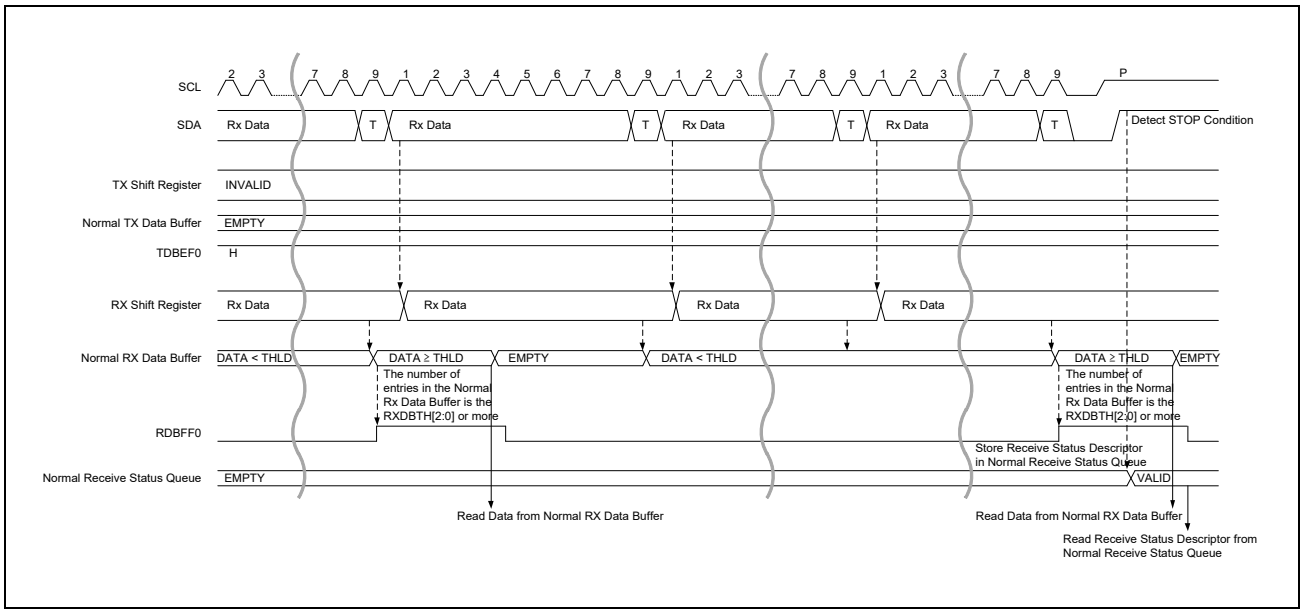

Figure 7.8-36 SDR data write transfer timing (2/2)

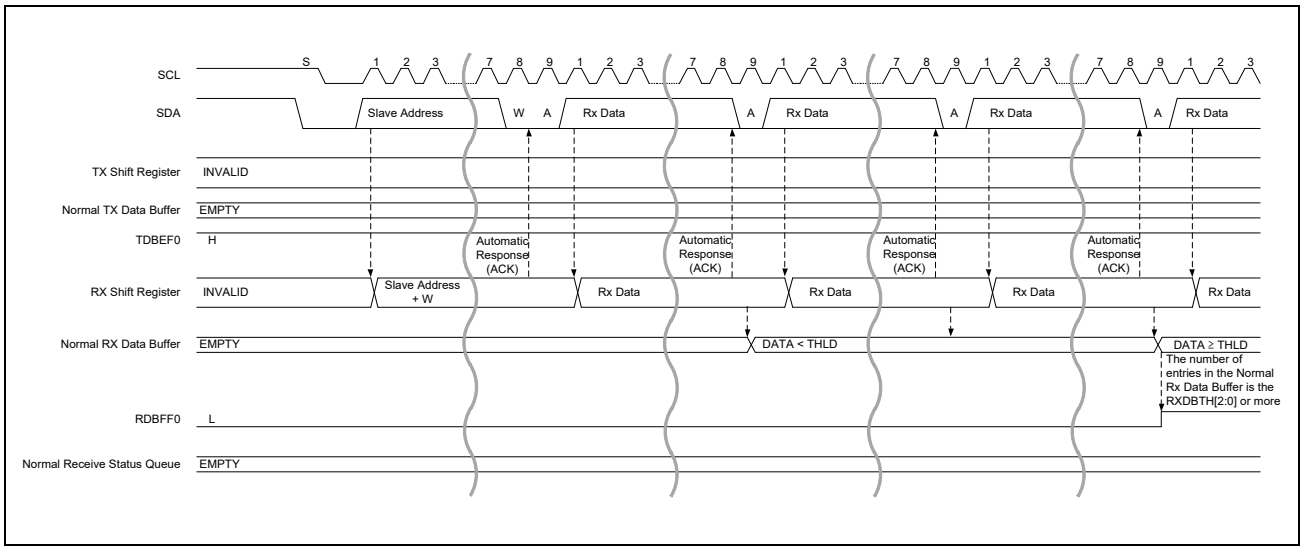

Figure 7.8-37 Legacy I²C message data write transfer timing (1/2)

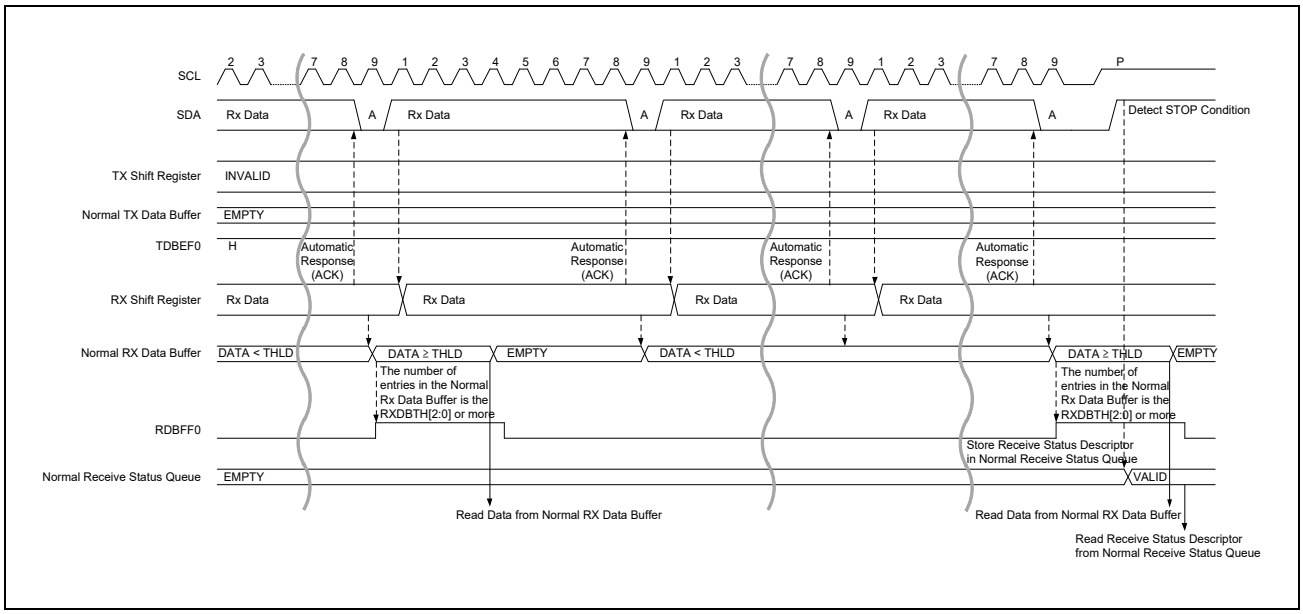

Figure 7.8-38 Legacy I²C message data write transfer timing (2/2)

(b-3) SDR Data Read Transfer

1. Write the data requested from the I3C Master to the Transmit Data Buffer via the NTDTBP0 register.
2. When Transaction is issued from the I3C Master, it compares the Slave Address of Address Header with its own Slave Address, and if it matches, I3C responds with ACK.
   When a Transaction is received, if the Transmit Data Buffer is EMPTY, I3C Slave responds with NACK with the Address Header.
   In preparation for retrying the I3C Master, write data to the Transmit Data Buffer via the NTDTBP0 register.
3. Transmit the data stored in the Transmit Data Buffer.
4. If data to be transmitted still remains, write the data to be transmitted with an interrupt by TDBEF0 = 1b to the Transmit Data Buffer via the NTDTBP0 register.
5. SDR:
   When the transmission of the data stored in the Transmit Data Buffer is completed, Low is output to the T-bit following Data, and it is notified to the I3C Master that it is the final data.
   Legacy I^2C Message:
   When NACK is detected, data transmission is terminated.
6. When a Repeated START condition or STOP condition is detected, the Receive Status Descriptor is stored in the Receive Status Buffer.
7. Read the Receive Status Descriptor via NRSQP and check the status.

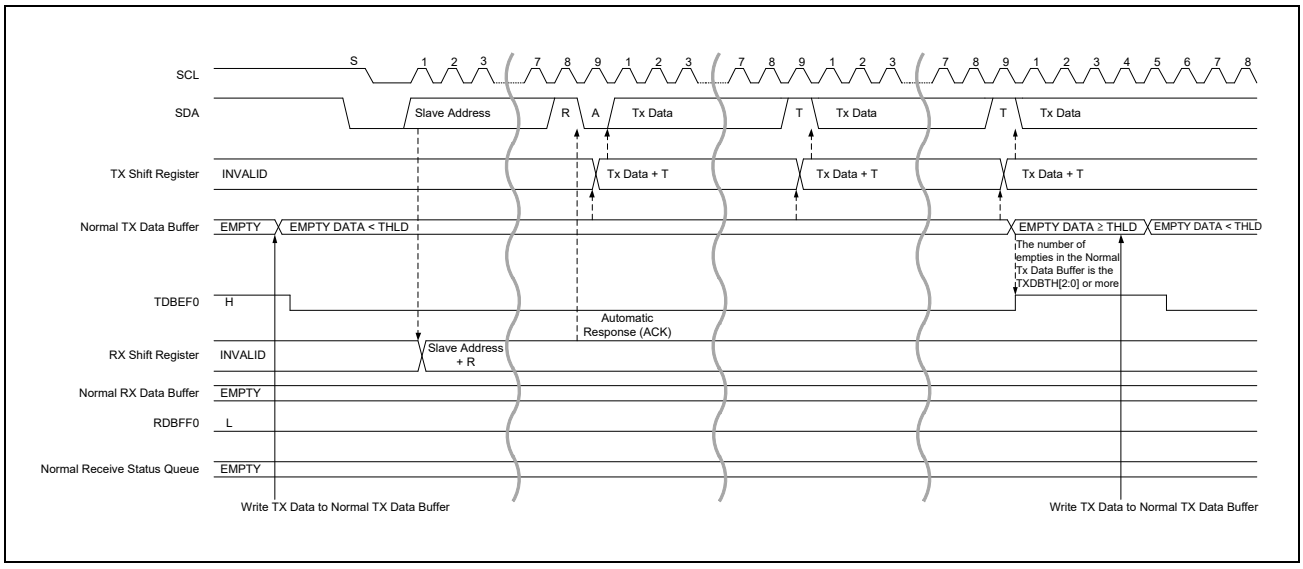

Figure 7.8-39 SDR data read transfer timing (1/2)

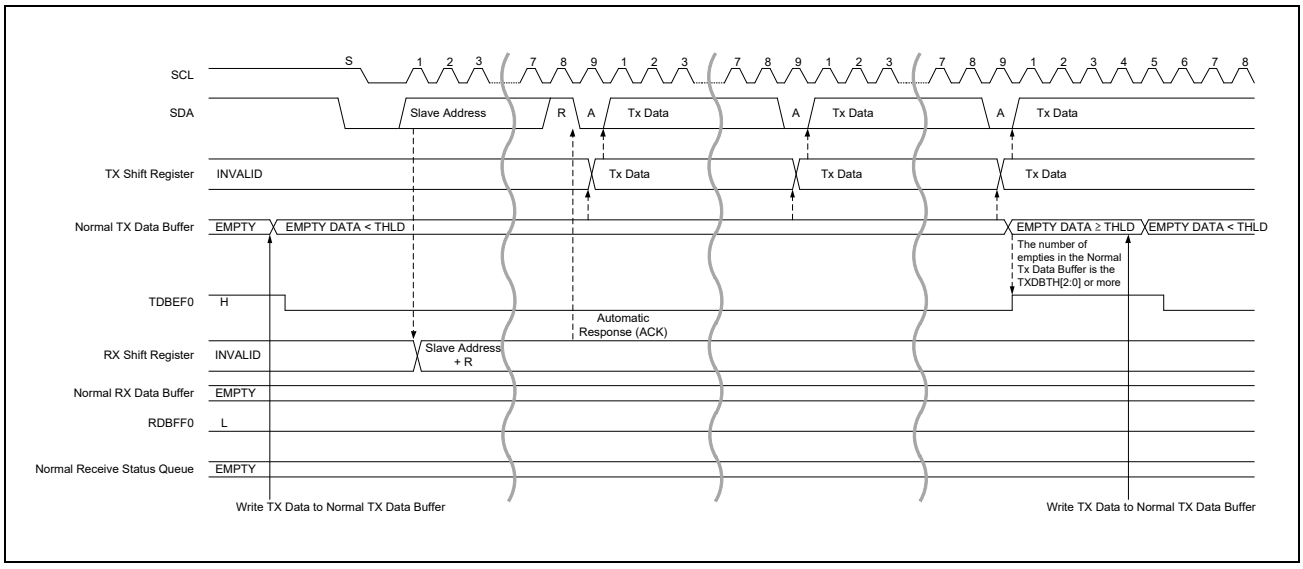

Figure 7.8-41 Legacy I²C message data read transfer timing (1/2)

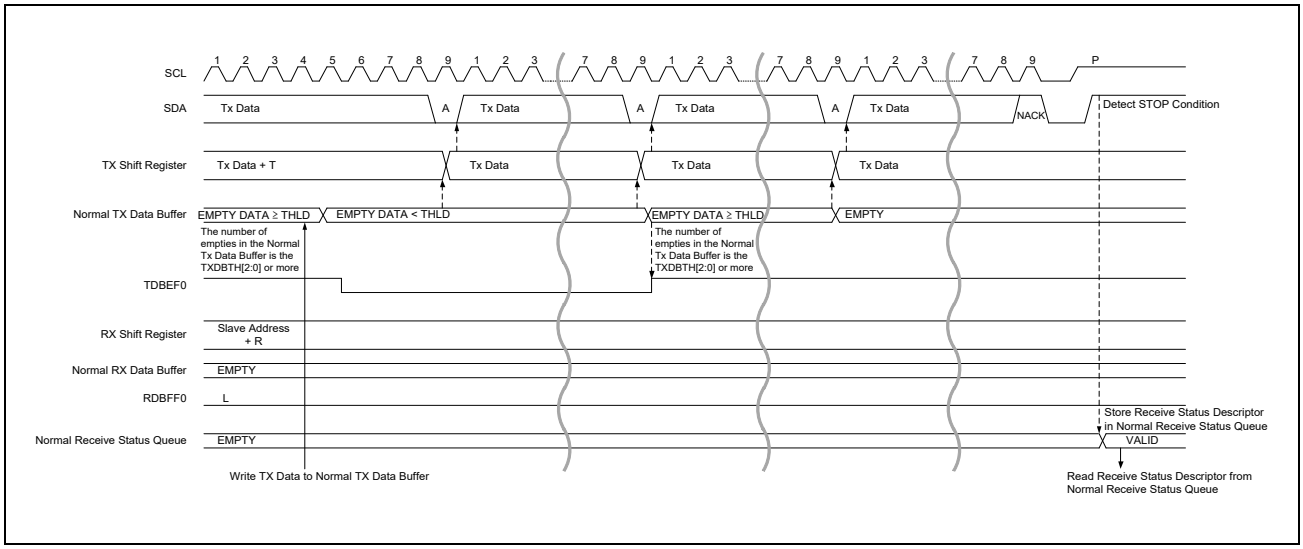

Figure 7.8-42 Legacy I²C message data read transfer timing (2/2)

(b-4) IBI Transfer

1. When sending Slave Interrupt Request.
   When transmitting IBI Data, write IBI Data to the IBI Data Buffer via the NIBIQP register.
2. Write Command Descriptor (Immediate Transfer Command or Regular Transfer Command) to the Command Buffer for IBI Transfer via the NCMDQP register.
3. When Command Descriptor is written to Command Buffer, IBI Transaction is issued under the following conditions.
   - When START condition is detected in Slave Interrupt Request or Mastership Request. (Does not apply a Repeated START condition)
   - If no START is forthcoming within the following Bus Condition, then this module issue a START Request by pulling the SDA line Low.
     a) Slave Interrupt Request, Mastership Request: Bus Available
     b) Hot-Join Event: Bus Idle
4. In Slave Address with RnW of the Address Header, if losing Arbitration by issuing a Transaction from I3C Master, stop issuing Transaction.
   When detecting Repeated START condition or STOP condition, store the Response Descriptor into the Response Buffer.
5. When sending Slave Interrupt Request:
   - When IBI data for transmission still remain, write IBI data with an interrupt by IBIQEFF = 1b to the IBI Data Buffer via the NIBIQP register.
   - When the transmission of IBI Data for the number of Data Length specified by the DATA_LENGTH[15:0] bits of the Command Descriptor is completed, output Low to the T-bit following IBI Data and notify the I3C Master that it is the final IBI Data.
6. When detecting Repeated START condition or STOP condition, store the Response Descriptor into the Response Buffer.
7. Read the Response Descriptor form the Response Buffer with the NRSPQP register and check the status. If NACK is responded, repeat steps 1 to 7.
8. When sending Slave Interrupt Request:
   Check that the value of the DATA_LENGTH[15:0] bit of the Response Descriptor is 0b.

The Mastership processing flow is shown in **Figure 7.8-45**. When joining the I3C Bus by Hot-Join after the I3C Bus has already been configured, issue the Hot-Join according to the flow shown in **Figure 7.8-126**.

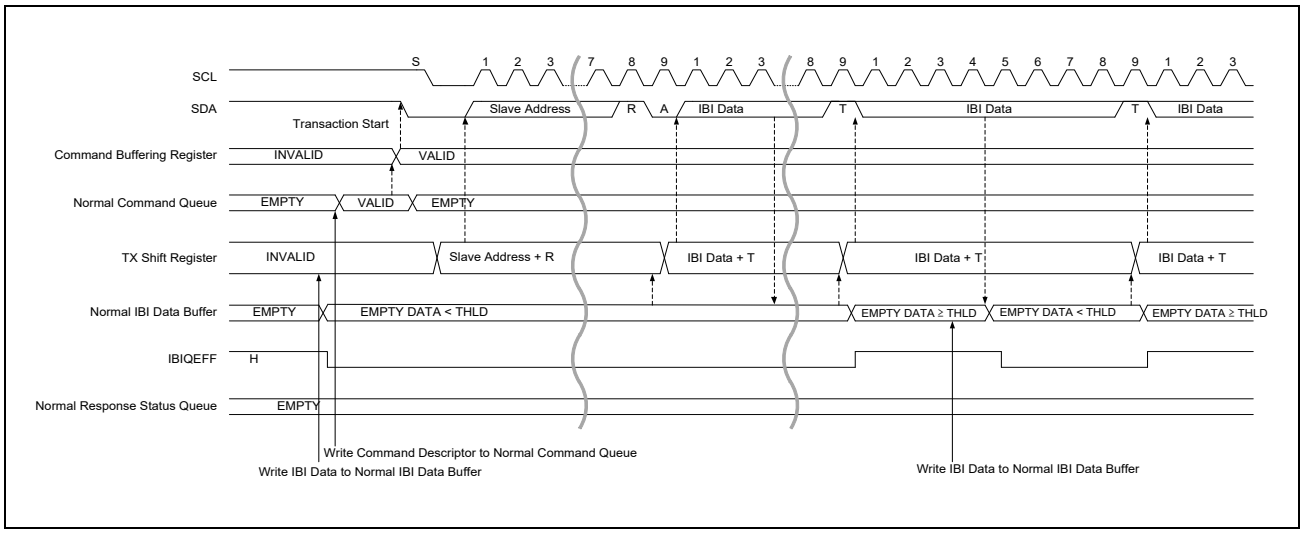

Figure 7.8-43 I3C slave IBI transfer timing (1/2)

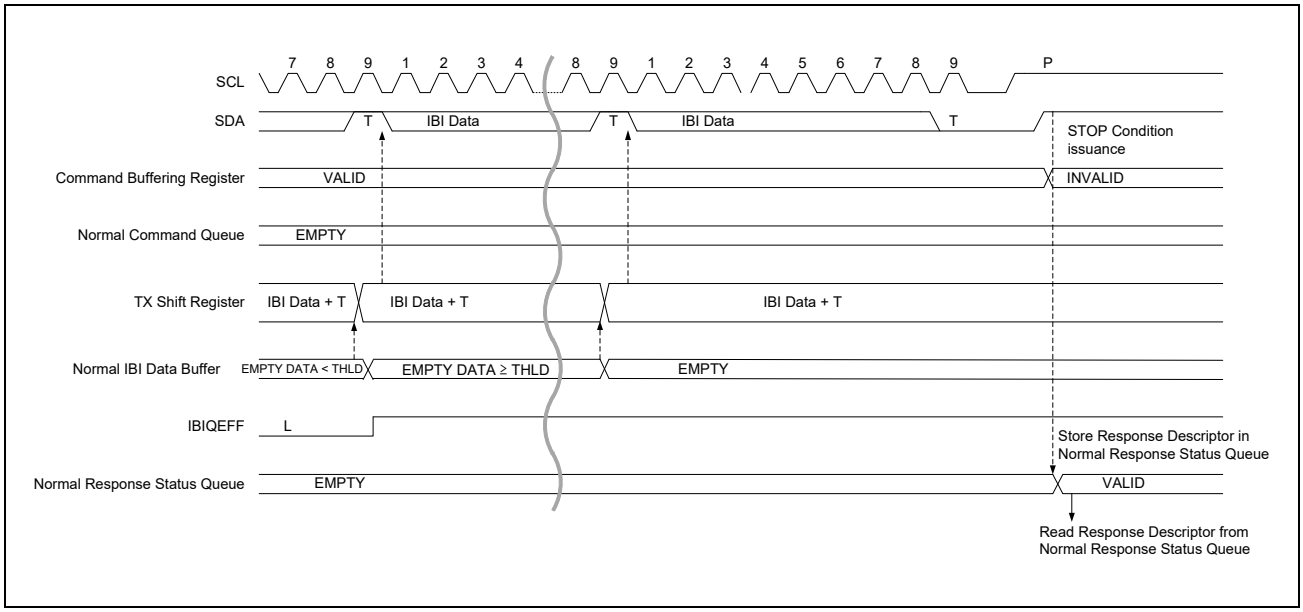

Figure 7.8-44 I3C slave IBI transfer timing (2/2)

7.8.4.2.2 Data Handler

The relationship between the transfer method and the queue is shown in **Table 7.8-11**.

Table 7.8-11 Transfer method and queue

Protocol	Transfer method	Queue/Buffer	size	Master	Slave	Secondary Master
I^2C Mode	Single buffer transfer	Normal Transmit Data	1 byte	✓	✓	—
		Normal Receive Data	1 byte	✓	✓	—
I3C Mode	Normal FIFO buffer transfer	Normal Command	4 QUEUEs	✓	✓	✓
		Normal Response Status	4 QUEUEs	✓	✓	✓
		Normal Transmit Data	16 DWORDs	✓	✓	✓
		Normal Receive Data	16 DWORDs	✓	✓	✓
		Normal Receive Status	2 QUEUEs	—	✓	✓
		Normal IBI Status	2 QUEUEs	✓	—	✓
		Normal IBI Data	8 DWORDs	✓	✓	✓

(1) Transfer Method in I²C Mode

(a) Single Buffer transfer

Each process (condition issue, data transfer, ACK/NACK response) is controlled by software.

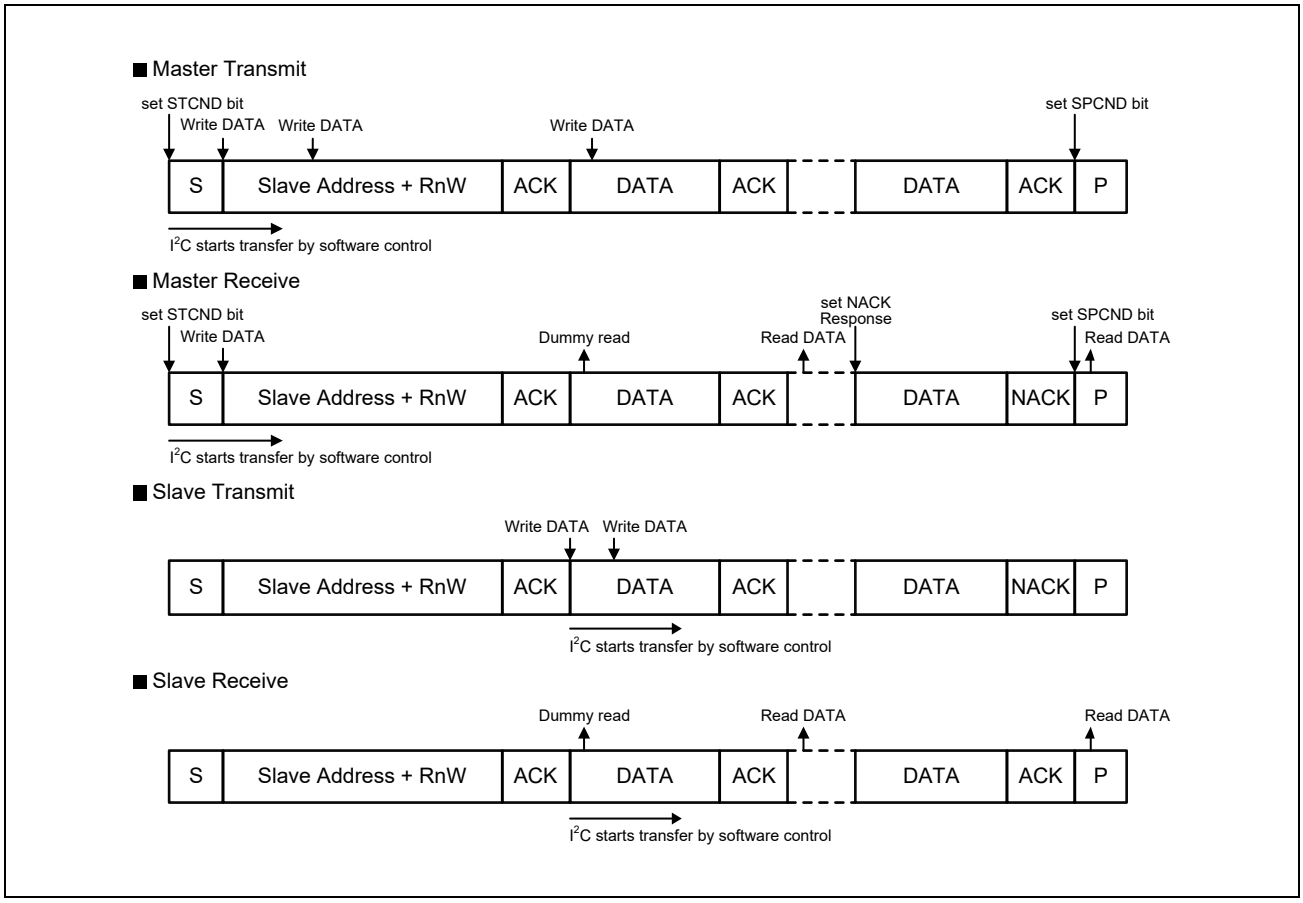

Figure 7.8-46 Data handler with single buffer transfer

(2) Transfer Method in I3C Mode

(a) Normal FIFO Buffer Transfer

I3C autonomously starts transfer when data and command are written.

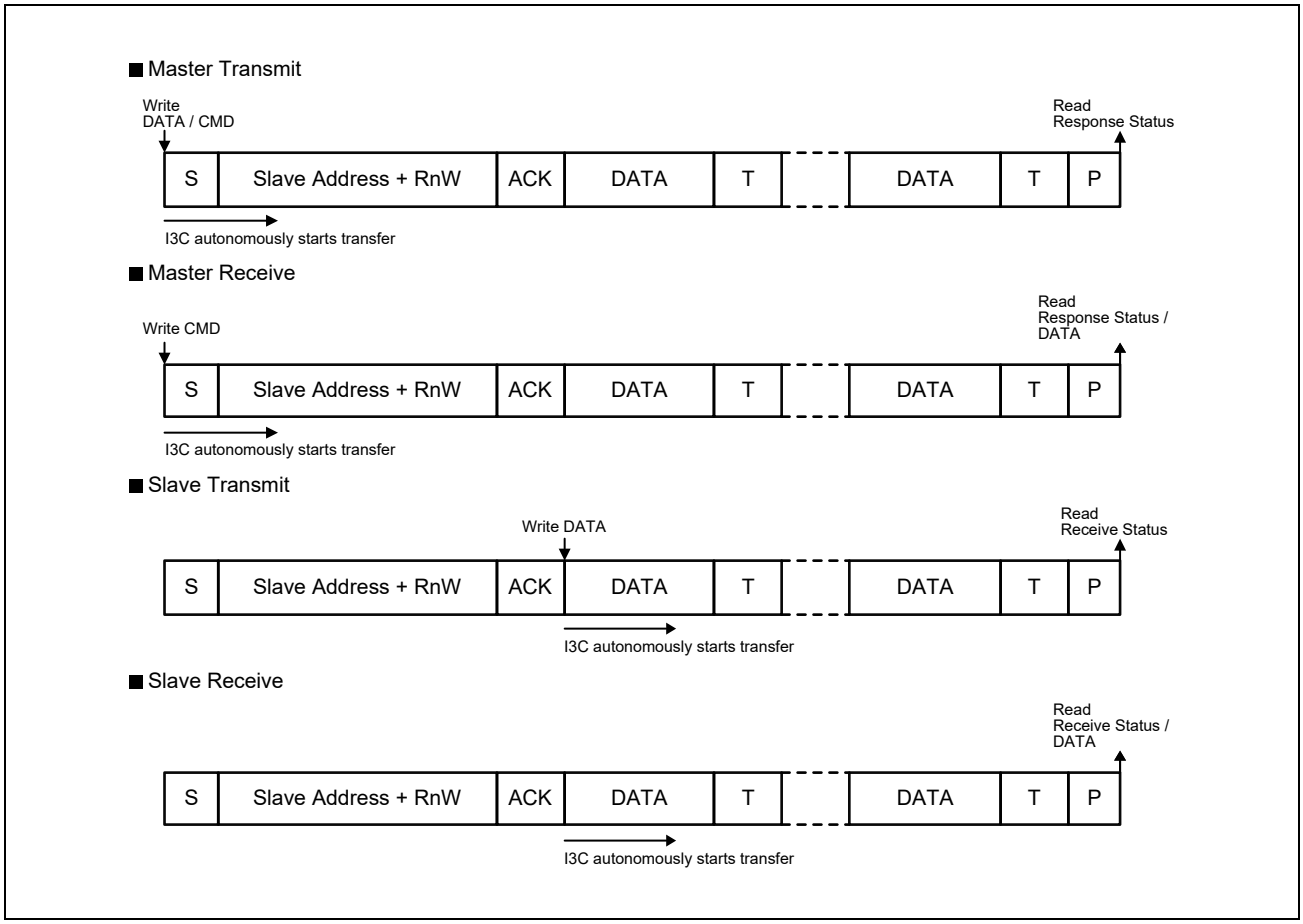

Figure 7.8-47 Data handler with normal FIFO buffer transfer

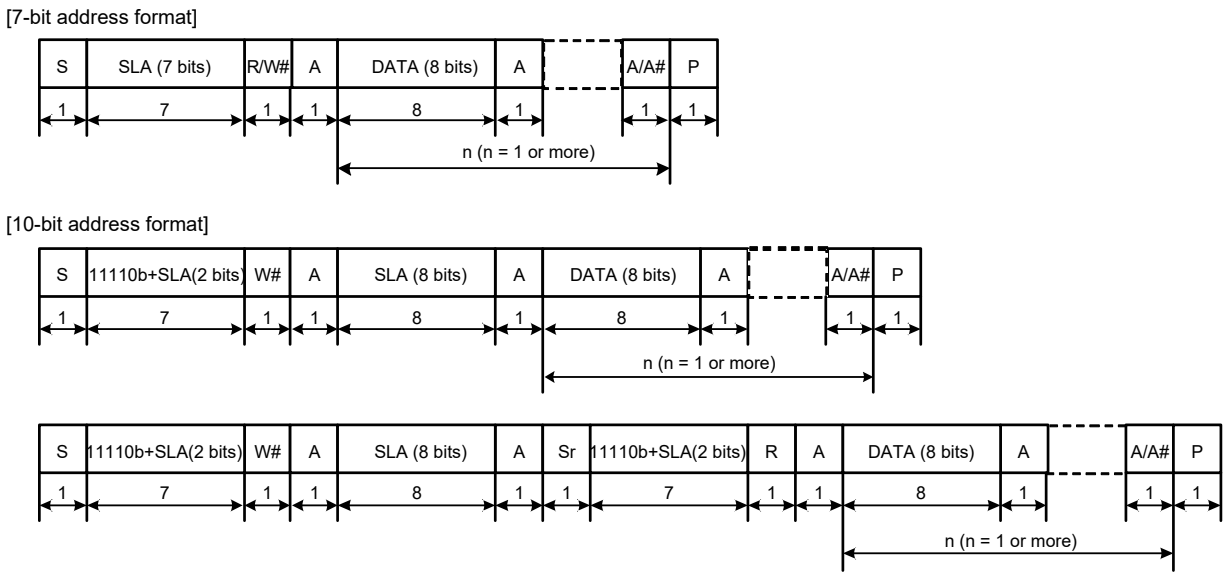
7.8.4.2.3 I²C/I3C Protocol

(1) Communication Protocol

(a) I²C Communication Data Format

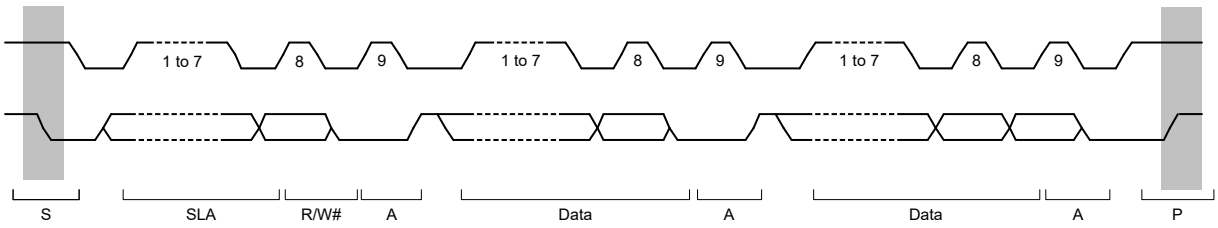
The I²C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a START condition or Repeated START condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a STOP condition is issued.

Figure 7.8-48 shows the I²C bus format, and **Figure 7.8-49** shows the I²C bus timing.



Note: n: Number of transmit DATA bytes

Figure 7.8-48 I²C bus format



S: START condition. The master device drives the SDA line low from high level while the SCL line is at a high level.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W = 1, or from the master device to the slave device when R/W = 0.

A: Acknowledge. The receive device drives the SDA line low. (In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.)

A#: Not Acknowledge. The receive device drives the SDA line high.

Sr: Repeated START condition. The master device drives the SDA line low from the high level after the setup time has elapsed with the SCL line at the high level.

DATA: Transmitted or received data

P: STOP condition. The master device drives the SDA line high from low level while the SCL line is at a high level.

Figure 7.8-49 I^2C bus timing (SLA = 7 bits)

(b) I3C Communication Data Format

Figure 7.8-50 through **Figure 7.8-53** illustrate a typical communication for each of the four I3C Protocols. While these diagrams do not exhaustively illustrate all possible I3C communications, they do serve as useful introductions to the signaling and transmission formatting used in each I3C Protocol.

Figure 7.8-50 illustrates example communication using I3C Single Data Rate (SDR) coding with Broadcast (7Eh). It shows the Master reading a byte of data from the Slave at Address 2Bh in SDR Mode. From the Bus Free Condition, the Master issues a START by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (7Eh) followed by RnW (0 for Write). Then the Master turns on a pull-up resistor and goes to Open Drain.

All Slaves ACK by pulling the SDA line Low (in the Figure, pink fill means the Slave is in control of the SDA line at this time). The Master then issues a Repeated START, then the Address of the Slave (2Bh) it wants to read followed by RnW (1 for Read). The Master then turns on a pull-up resistor and goes to Open Drain, allowing the Slave to acknowledge by pulling the SDA line Low. At this point, the Master continues to toggle the SCL line and release the SDA line, allowing the Slave to drive SDA to send one byte of data (4Ah) followed by T. T = 1b informs the Master that there is additional data, whereas T = 0b signals the end. Here there is additional data, so the Slave drives SDA High until SCL goes High, at which time it releases SDA. The Master has the option of holding SDA High with a weak pullup, which signals to the Slave that the Master allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a Repeated START), which would signal to the Slave that the Master has terminated the Read and is taking over.

SDR Mode is backwards compatible with Legacy I^2C Devices, because the High time of an SCL pulse is always less than 50ns and therefore SCL will always appear to be Low because of the I^2C 50ns Spike Filter.

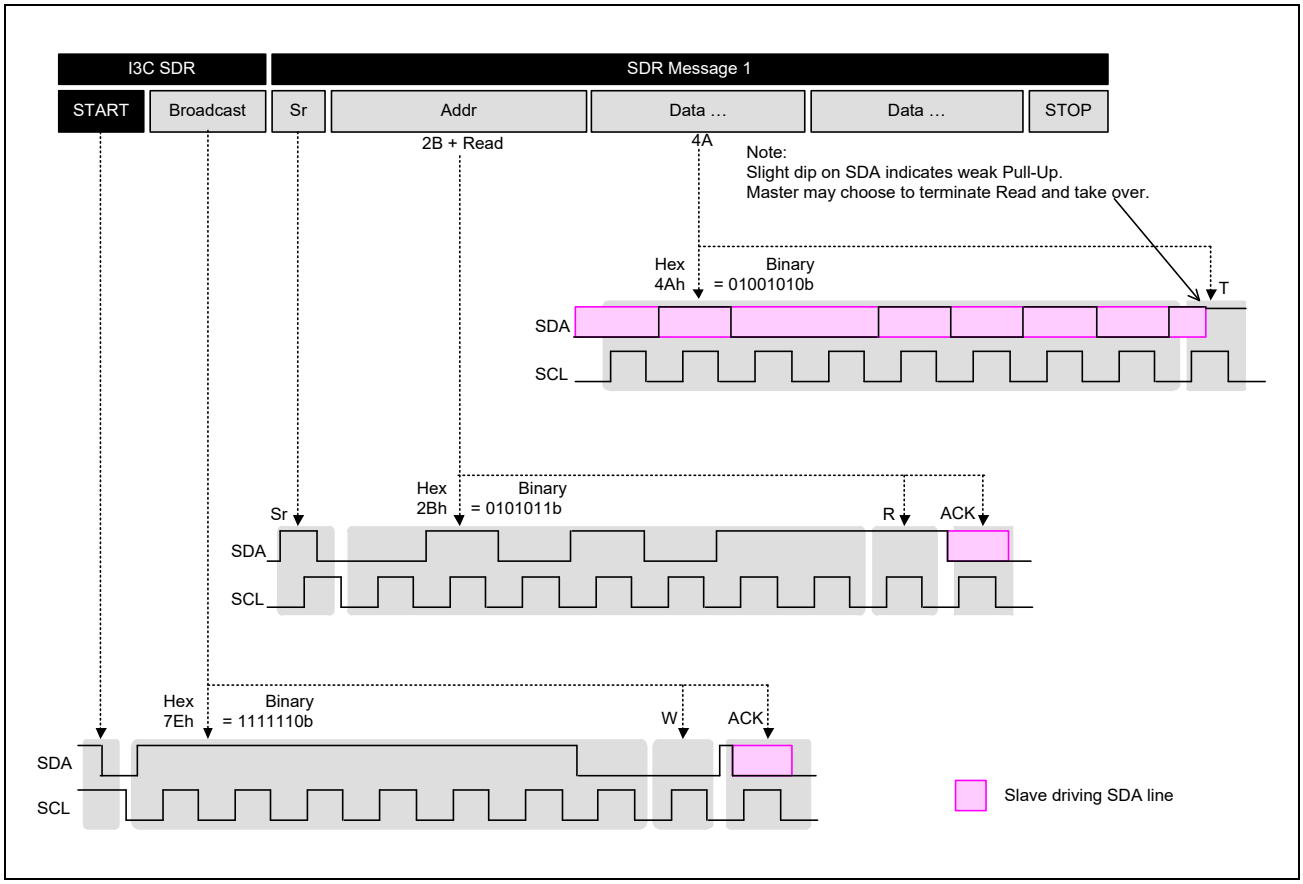


Figure 7.8-50 Example communication using I3C coding SDR with broadcast (7Eh)

Figure 7.8-51 illustrates example communication using I3C Single Data Rate (SDR) coding without Broadcast (7Eh). It shows the Master reading a byte of data from the Slave at Address 2Bh in SDR Mode. From the Bus Free Condition, The Master then issues a START, then the Address of the Slave (2Bh) it wants to read followed by RnW (1 for Read).

The Master then turns on a pull-up resistor and goes to Open Drain, allowing the Slave to acknowledge by pulling the SDA line Low. At this point, the Master continues to toggle the SCL line and release the SDA line, allowing the Slave to drive SDA to send one byte of data (4Ah) followed by T. T = 1b informs the Master that there is additional data, whereas T = 0b signals the end. Here there is additional data, so the Slave drives SDA High until SCL goes High, at which time it releases SDA. The Master has the option of holding SDA High with a weak pull-up, which signals to the Slave that the Master allows another byte to be transmitted, or to pull SDA Low (while SCL is High – hence a Repeated START), which would signal to the Slave that the Master has terminated the Read and is taking over.

SDR Mode is backwards compatible with Legacy I^2C Devices, because the High time of an SCL pulse is always less than 50ns and therefore SCL will always appear to be Low because of the I^2C 50ns Spike Filter.

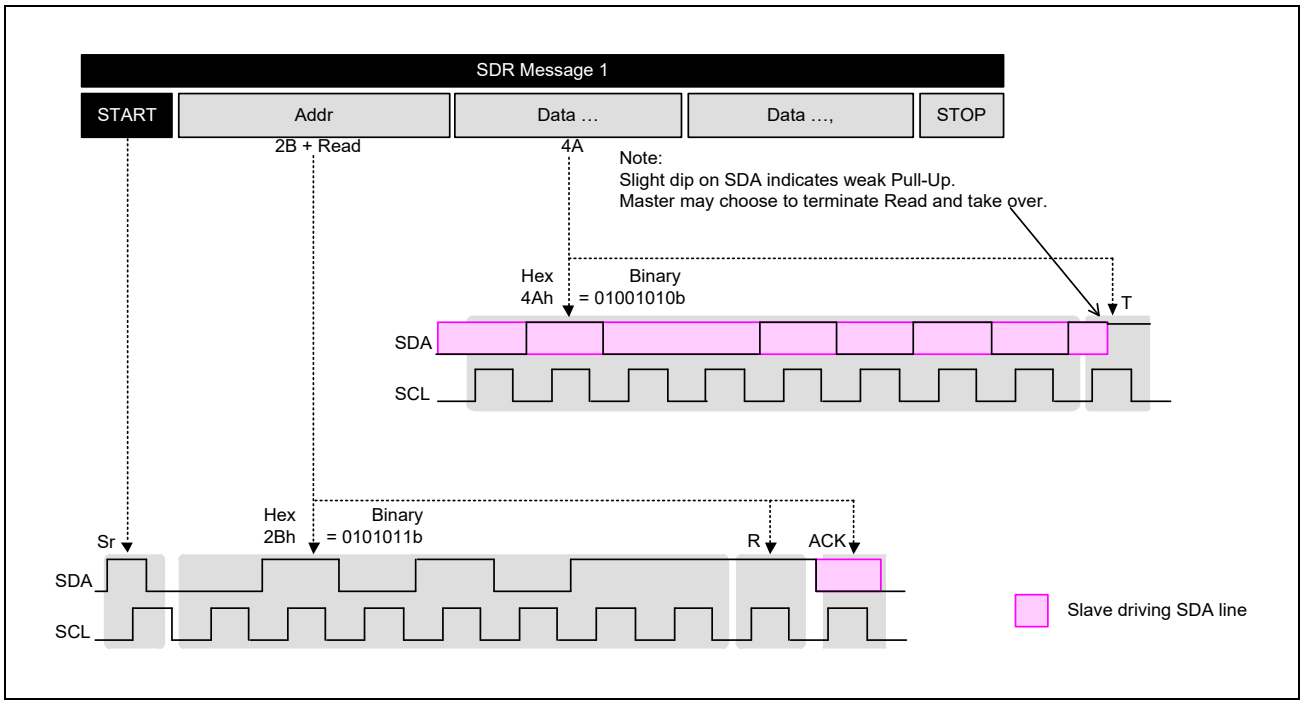

Figure 7.8-51 Example communication using I3C coding SDR without broadcast (7Eh)

Figure 7.8-52 shows the Master issuing a CCC Direct Command to a single Slave. This particular command (GETPID) reads the Provisional ID of a Slave.

From the Bus Free Condition, the Master issues a START by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (7Eh) followed by RnW (0h for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Direct Common Command Code for GETPID (8Ch) followed by parity bit T (odd parity = 0 for 8Ch) then the 7-bit Dynamic Address of the Slave (chosen arbitrarily here to be 2Bh) followed by a RnW bit (1 for Read). Then the Master turns on a pull-up resistor and goes to Open Drain, allowing the Slave at Address 2Bh to ACK by pulling SDA Low, which tells the Master that the Slave Acknowledges the command and will comply. (Alternatively, the Slave may NACK by not pulling SDA Low, which would inform the Master that the Slave will not comply – in this case, that an error occurred.) Following the ACK the Slave outputs its 48-bit PID one byte at a time, and then the Master issues a Repeated START (this part of the waveform sequence is not shown in the Figure).

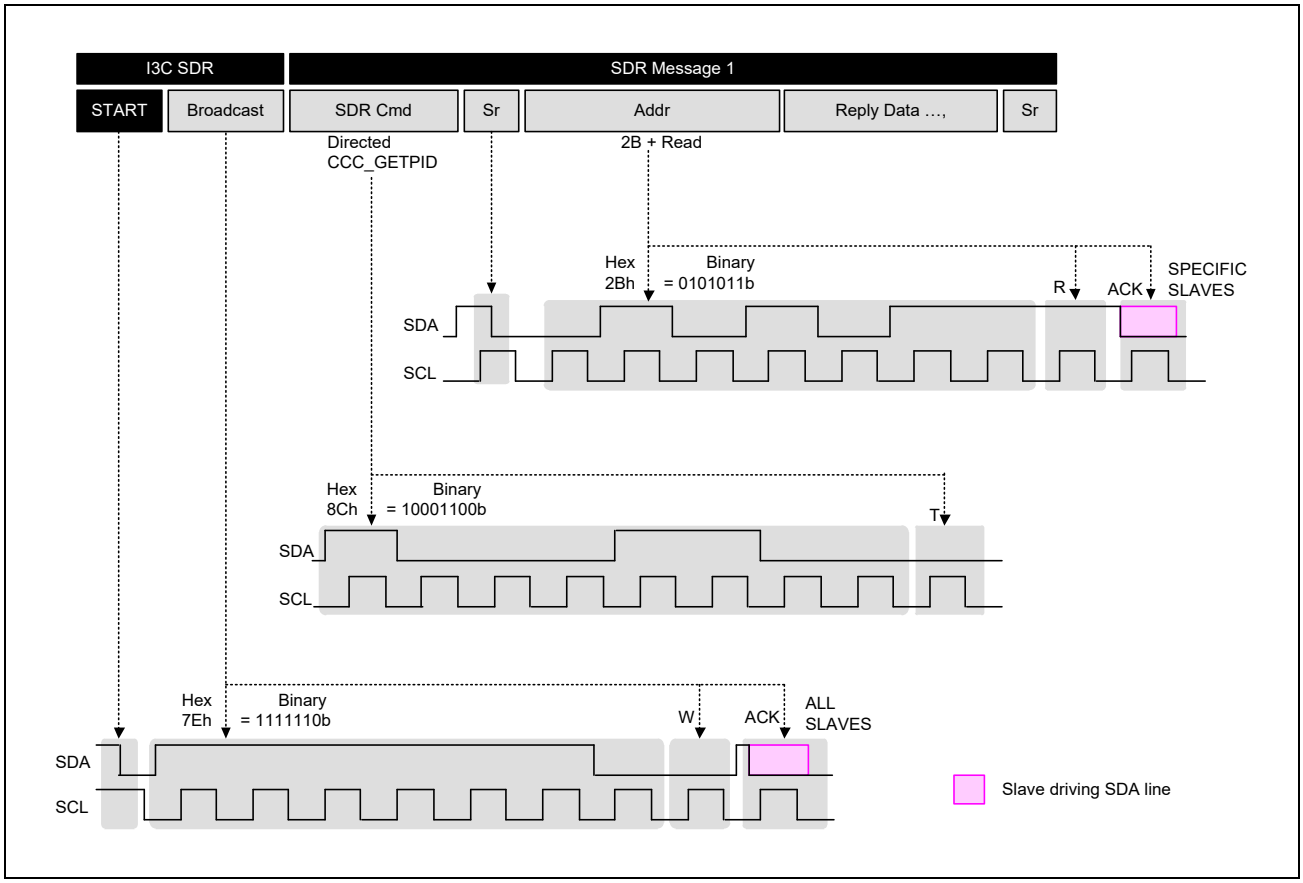

Figure 7.8-52 Example communication using I3C coding SDR with CCC direct addressing

Figure 7.8-53 illustrates example SDR communication with a CCC Broadcast command. The command used in this example sets the Maximum Read Length of all Slaves to 43 bytes (002Bh).

From the Bus Free Condition, the Master issues a START by driving the SDA line Low while keeping the SCL line High. It then issues the Broadcast Address (7Eh) followed by RnW (0h for Write). Then the Master turns on a pull-up resistor and goes to Open Drain. All Slaves ACK by pulling SDA Low (in the Figure, pink fill means the Slaves are in control of SDA at this time). The Master then issues the Broadcast Common Command Code for SETMRL (09h) followed by parity bit T (odd parity = 1 for 09h), and then 2 data bytes (MSB first) to define the maximum number of bytes which can be read from a Slave in a single read operation. Each data byte is followed by a T bit (parity bit – odd parity). After this the Master issues a Repeated START.

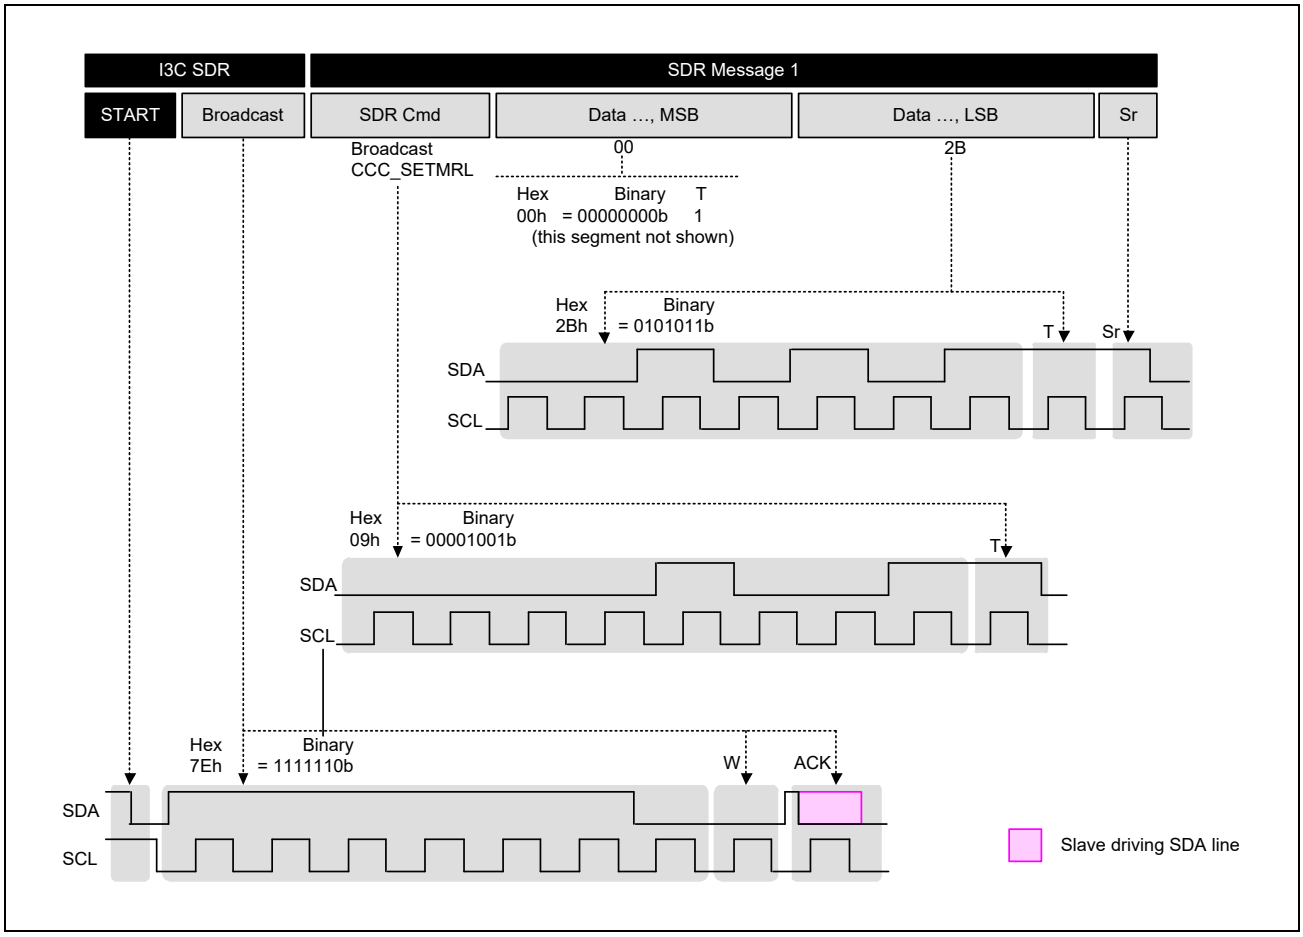

Figure 7.8-53 Example communication using I3C coding SDR with CCC broadcast

(2) Bus Conditions

I3C defines three distinct conditions in which the I3C Bus shall be considered inactive: Bus Free, Bus Available, and Bus Idle (see **Figure 7.8-54**).

(a) Bus Free Condition

State on the I3C Bus where both the SCL line and the SDA line are High for at least the period set by BFRECDT.FRECYC[8:0] bit.

(b) Bus Available Condition [I3C mode]

State on the I3C Bus where both the SCL line and the SDA line are High for at least the period set by BAVLCDT.AVLCYC[8:0] bit.

A Slave may only issue a START Request (For example, for an In-Band Interrupt, or for a Master Handoff Request) after a Bus Available Condition.

(c) Bus Idle Condition [I3C mode]

State on the I3C Bus where both the SCL line and the SDA line are High for at least the period set by BIDLCDT.IDLCYC[17:0] bit.

A Slave may only issue a START Request (For example, for a Hot-Join) after a Bus Idle Condition. Specifications are as follows. IDLE needs to be the largest.

BFRECDT.FRECYC[8:0] < BAVLCDT.AVLCYC[8:0] < BIDLCDT.IDLCYC[17:0]

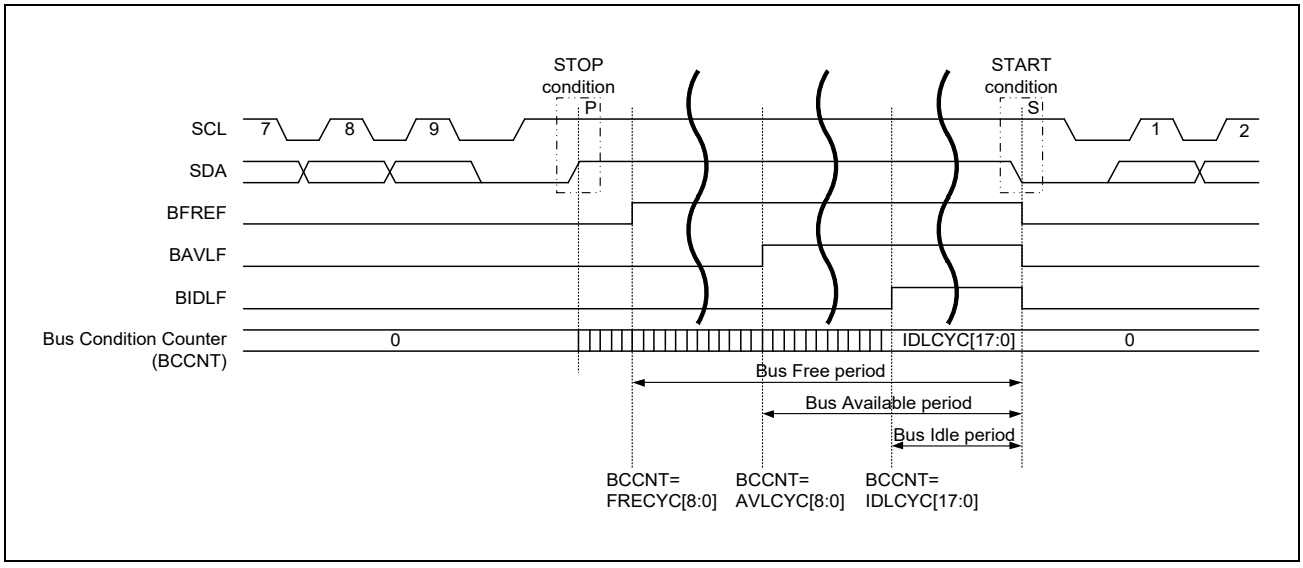

Figure 7.8-54 Bus conditions

(3) START Condition / Repeated START Condition / STOP Condition Issuing Function

(a) Issuing a START Condition

I3C issues a START condition when the CNDCTL.STCND bit is set to 1.

Set the STCND bit to 1b (START condition issuance request) when the BCST.BFREF flag is set to 1b (bus free state).

I3C issues a START condition.

When a START condition is issued normally, I3C automatically shifts to the master transmit mode. A START condition is issued in the following sequence.

[START condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] and the START condition hold time.
- Drive the SCL line low (high level to low level).
- Detect low level of the SCL line and ensure the low-level period of SCL line set in STDBR.SBRLO[7:0].

(b) Issuing a Repeated START Condition

I3C issues a Repeated START condition when the CNDCTL.SRCND bit is set to 1.

When the SRCND bit is set to 1b, a Repeated START condition issuance request is made and I3C issues a Repeated START condition when the BCST.BFREF flag = 0b (bus busy state) and the PRSST.CRMS bit = 1b (master mode).

A Repeated START condition is issued in the following sequence. [Repeated START condition issuance]

- Release the SDA line.
- Ensure the low-level period of SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0].
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0] and the Repeated START condition setup time.
- Drive the SDA line low (high level to low level).
- Ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0] and the Repeated START condition hold time.
- Drive the SCL line low (high level to low level).
- Detect a low level of the SCL line and ensure the low-level period of SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0].

NOTE

When issuing Repeated START conditions request, write the slave address to NTDTBP0 after confirming CNDCTL.SRCND = 0. Data written in the period of CNDCTL.SRCND = 1 is not forwarded because retransmission condition before the occurrence.

To issue a Repeated START condition in Hs-mode, follow the steps below.

1) Wait until PRSTDBG.SCOLV = 0b.
2) Set EXTBR.EBRHO[7:0] to satisfy the hold time of the Repeated START condition.
3) Set the CNDCTL.SRCND bit to 1b.
4) After confirming CNDCTL.SRCND = 0b, wait until PRSTDBG.SCOLV = 0b.
5) Set EXTBR.EBRHO[7:0] according to the High period of the SCL clock in Hs-mode.
6) Write the slave address to NTDTBP0.

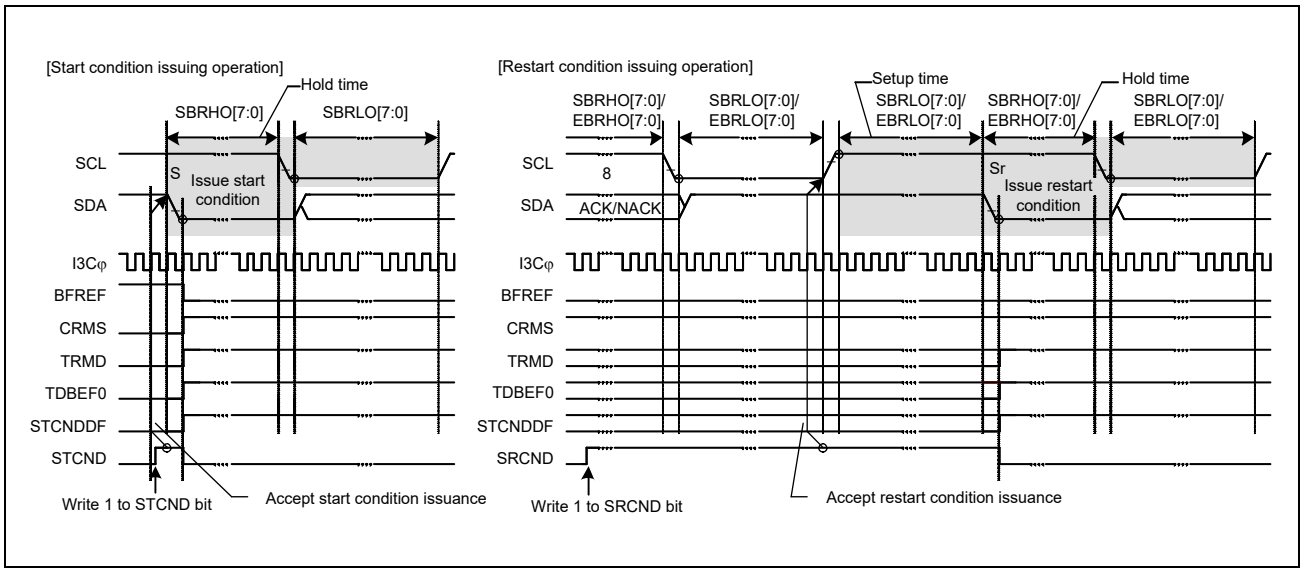

Figure 7.8-55 START condition / repeated START condition issue timing (STCND and SRCND bits)

Figure 7.8-56 shows the operation to issue a Repeated START condition after the master transmission. [Repeated START condition issuance after the master transmission]

- Initial setting. For details, see **7.8.4.3.1 Initial Setting Flow**.
- Read the BFREF flag in BCST to check that the bus is open, and then set the STCND bit in CNDCTL to 1 (START condition issuance request). Upon receiving the request, I3C issues a START condition. At the same time, the BFREF flag is automatically set to 0b and the STCNDDF flag in BST is automatically set to 1b and the STCND bit is automatically set to 0. At this time, if the START condition is detected and the internal levels for the SDA output state and the levels on the SDA line have matched while the STCND bit = 1b, I3C recognizes that issuing of the START condition as requested by the STCND bit has been successfully completed, and CRMS and TRMD bits in PRSST is automatically set to 1b, placing I3C in master transmit mode. The NTST.TDBEF0 flag is also automatically set to 1b in response to setting of the TRMD bit to 1b.
- Check that the NTST.TDBEF0 flag = 1b, and then write the value for transmission (the slave address and the R/W# bit) to NTDTBP0. Once the data for transmission are written to NTDTBP0, the TDBEF0 flag is automatically set to 0b, the data are transferred from NTDTBP0, and the TDBEF0 flag is again set to 1b. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRMD bit is automatically updated to select master transmit or master receive mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, I3C continues in master transmit mode. Since the BST.NACKDF flag being 1b at this time indicates that no slave device recognized the address or there was an error in communications, write 1b to CNDCTL.SPCND bit to issue a STOP condition. For data transmission with an address in the 10-bit format, start by writing 1111 0, the 2 higher-order bits of the slave address, and W to NTDTBP0 as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to NTDTBP0.
- After confirming that the NTST.TDBEF0 flag = 1b, write the data for transmission to the NTDTBP0 register. I3C automatically holds the SCL line low until the data for transmission are ready, a Repeated START condition is issued or a STOP condition is issued.
- After all bytes of data for transmission have been written to the NTDTBP0 register, wait until the value of the BST.TENDF flag returns to 1b, and then, after check that the BST.STCNDDF flag = 1b, set the BST.STCNDDF flag to 0b.
- Set the SRCND bit in CNDCTL to 1b (Repeated START condition issuance request). Upon receiving the request, I3C issues a Repeated START condition.

- After check that the BST.STCNDDF flag = 1, write the value for transmission (the slave address and the R/W# bit) to NTDTBP0.

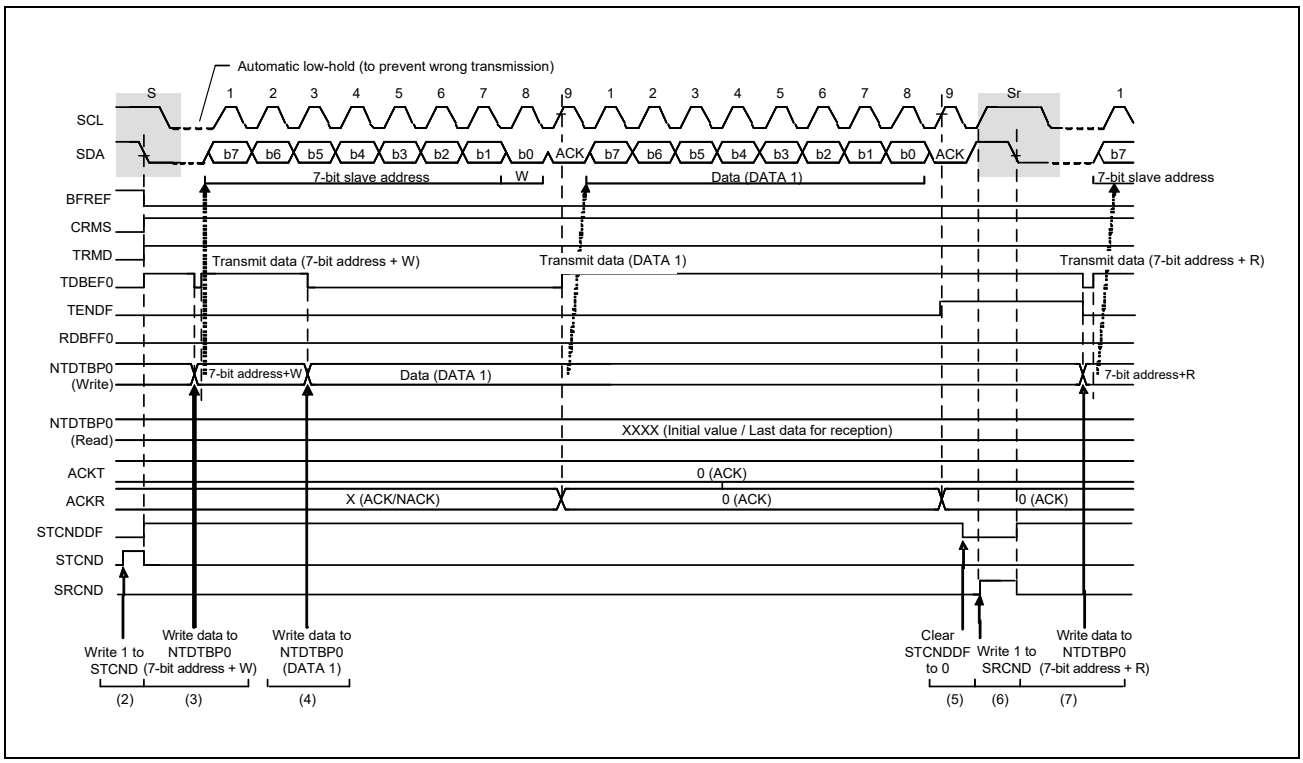

Figure 7.8-56 Repeated START condition issuance after the master transmission timing

(c) Issuing a STOP Condition

I3C issues a STOP condition when the SPCND bit in CNDCTL is set to 1.

When the SPCND bit is set to 1b, a STOP condition issuance request is made and I3C issues a STOP condition when the BCST.BFREF flag = 0b (bus busy state) and the PRSST.MST bit = 1b (master mode).

A STOP condition is issued in the following sequence.

[STOP condition issuance]

- Drive the SDA line low (high level to low level).
- Ensure the low-level period of SCL line set in STDBR.SBRLO[7:0] or EXTBR.EBRLO[7:0].
- Release the SCL line (low level to high level).
- Detect a high level of the SCL line and ensure the time set in STDBR.SBRHO[7:0] or EXTBR.EBRHO[7:0] and the STOP condition setup time.
- Release the SDA line (low level to high level).
- Ensure the time set in BFRECDT.FRECYC[8:0] and the bus free time.
- Set the BFREF flag to 1b (to release the bus mastership).

NOTE

To issue a STOP condition in Hs-mode, follow the steps below.

1) Wait until PRSTDBG.SCOLV=0b.
2) Set EXTBR.EBRHO[7:0] to satisfy the setup time for the STOP condition.
3) Set the CNDCTL.SPCND bit to 1b.
4) Wait until CNDCTL.SPCND=0b.
5) Set EXTBR.EBRHO [7: 0] according to the High period of the SCL clock in Hs-mode.

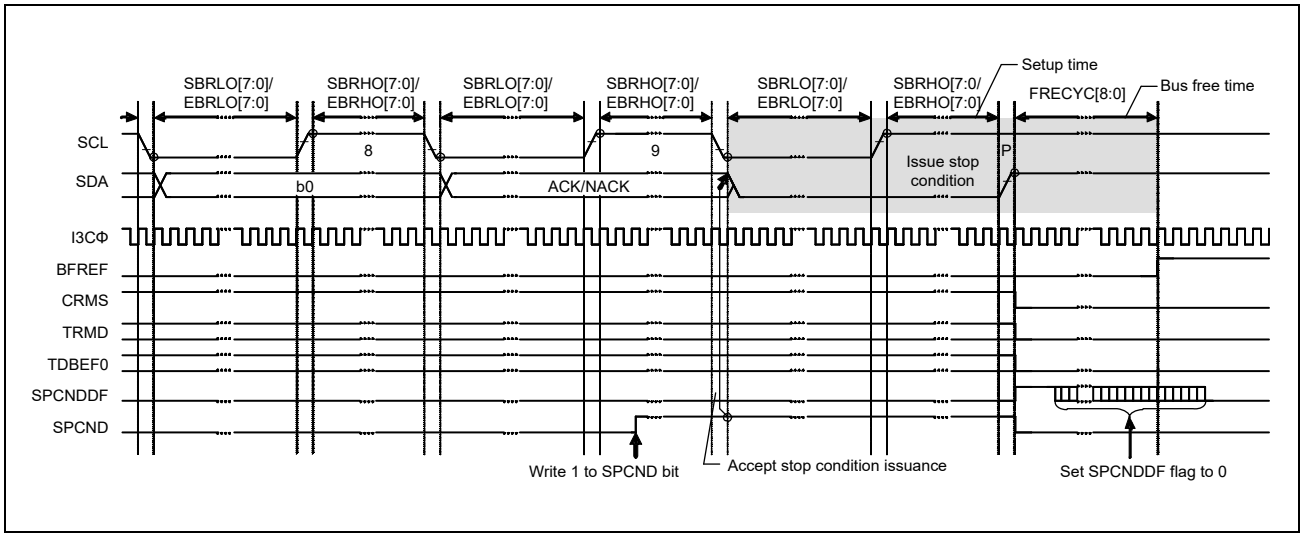

Figure 7.8-57 STOP condition issue timing (SPCND bit)

(4) Address Match Detection

I3C can set three unique slave addresses in addition to the general call address and host address, and also can set 7- bit or 10- bit slave addresses.

(a) Slave-Address Match Detection [I²C mode]

I3C can set three unique slave addresses, and has a slave address detection function for each unique slave address.

When the SVCTL.SVAEn bit (n = 0 to 2) is set to 1b, the slave addresses set in the SVDVADn register (n = 0 to 2) can be detected.

When I3C detects a match of the set slave address, the corresponding SVST.SVAFn flag (n = 0 to 2) is set to 1b at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1b by the following R/W# bit. This causes a receive data full interrupt (INT_ri3c_rx_n) or transmit data empty interrupt (INT_ri3c_tx_n) to be generated. The SVAFn flag is used to identify which slave address has been specified.

Figure 7.8-58 to **Figure 7.8-60** show the SVAFn flag set timing in three cases.

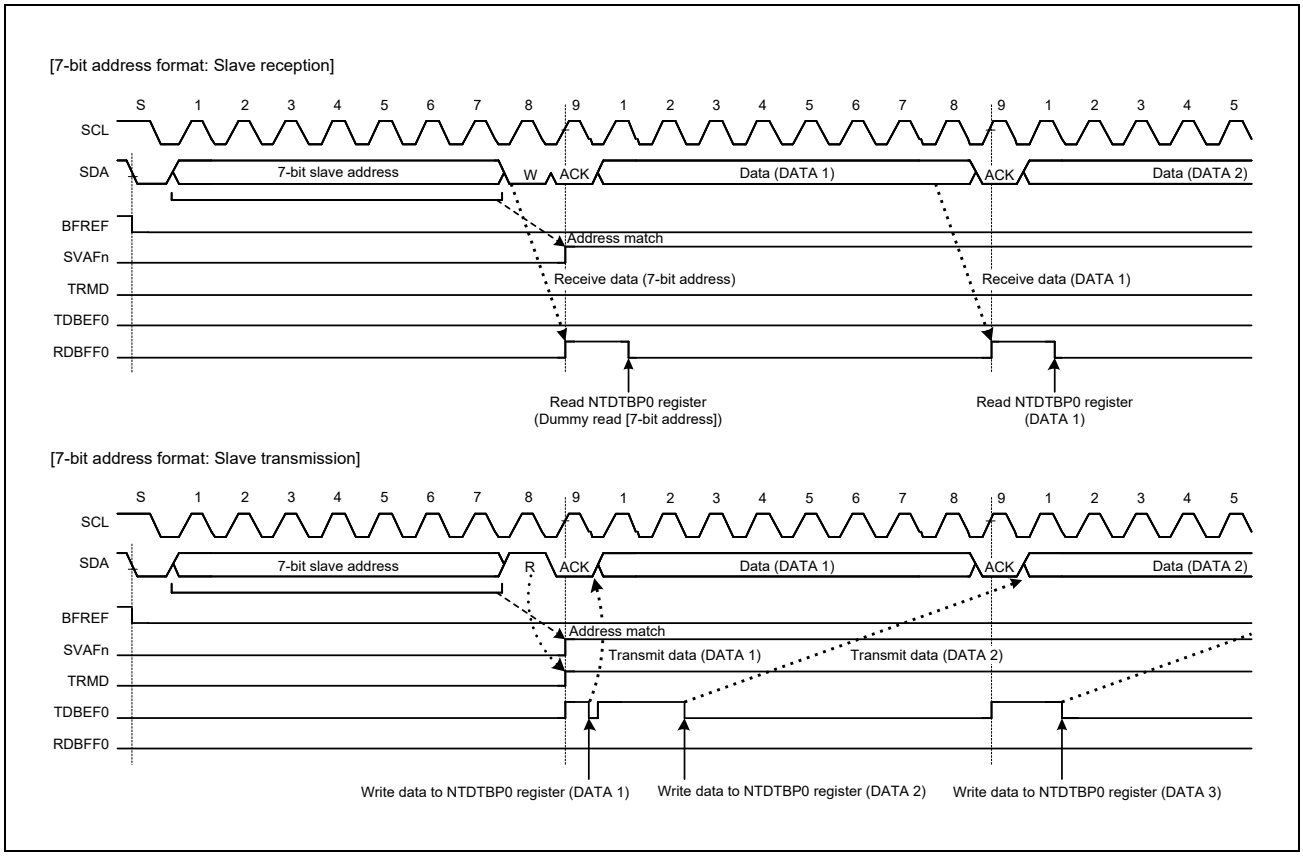

Figure 7.8-58 SVAFn flag set timing with 7-bit address format selected

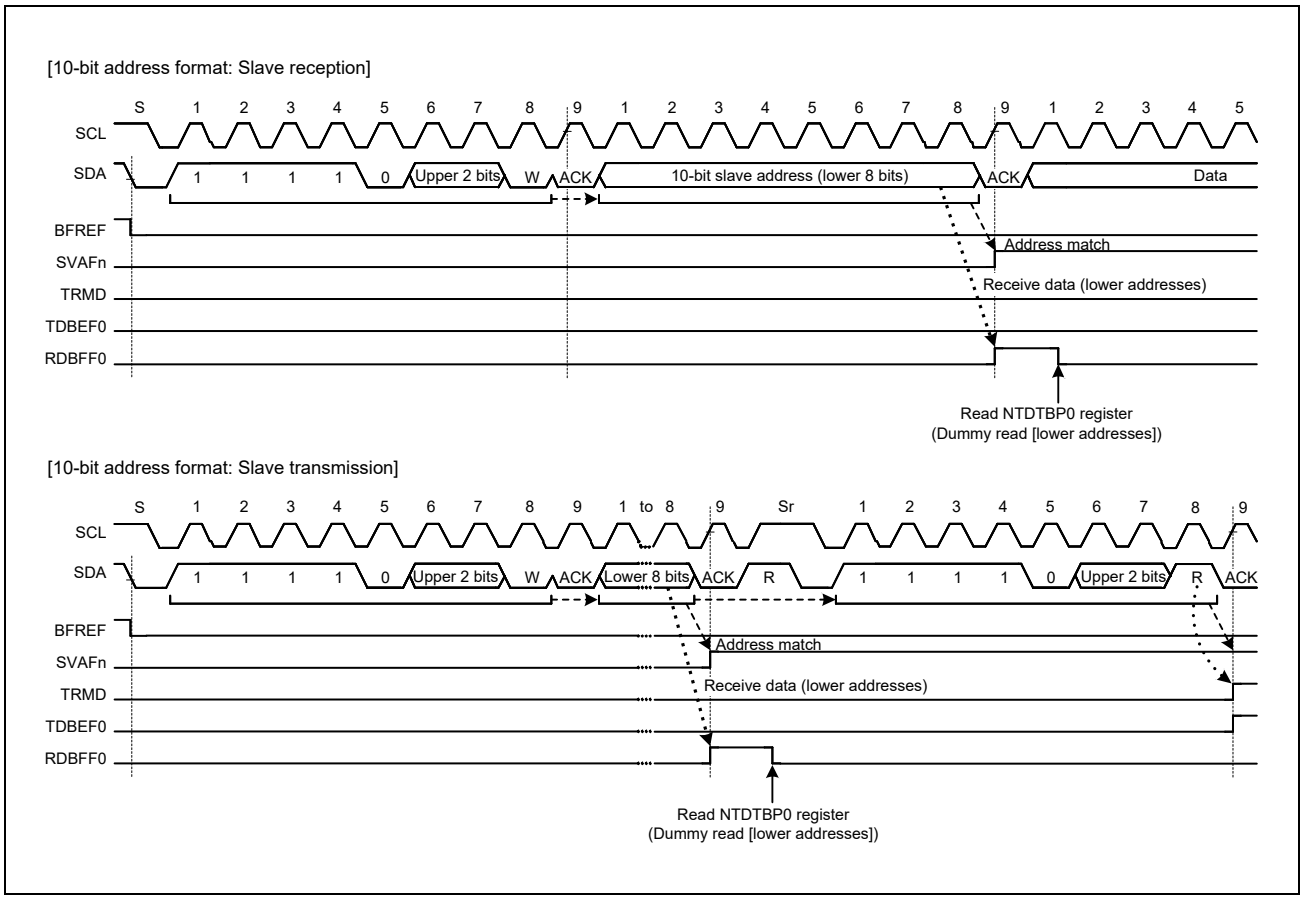

Figure 7.8-59 SVAFn flag set timing with 10-bit address format selected

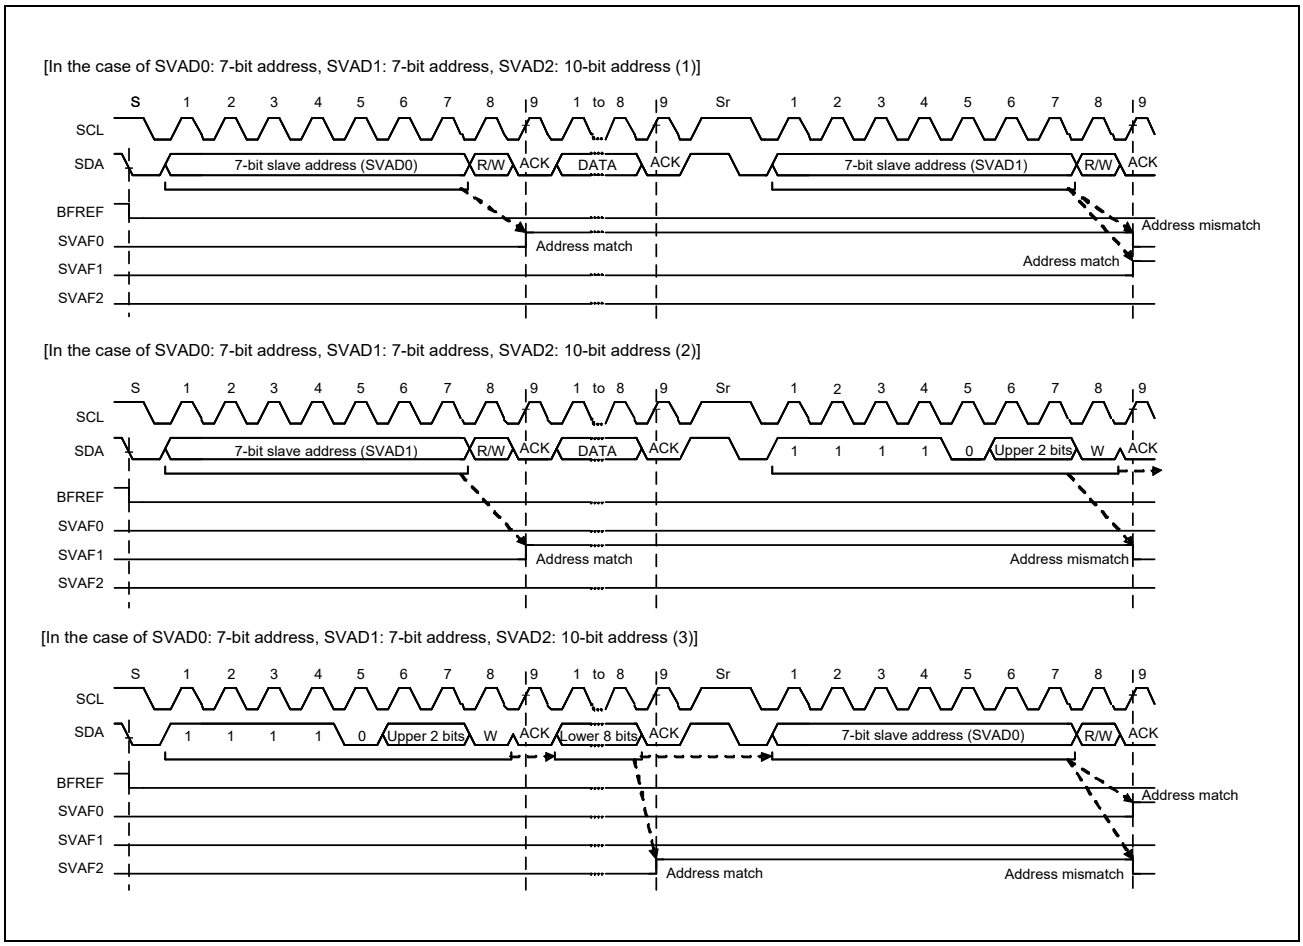

Figure 7.8-60 SVAFn flag set/clear timing with 7-bit/10-bit address formats mixed

(b) Detection of the General Call Address [I²C mode]

I3C has a facility for detecting the general call address (0000 000 + 0 (write)). This is enabled by setting the SVCTL.GCAE bit to 1b.

If the address received after a START or Repeated START condition is issued is 0000 000 + 1 (read) (start byte), I3C recognizes this as the address of a slave device with an all-zero address but not as the general call address.

When I3C detects the general call address, both the SVST.GCAF flag and the NTST.RDBFF0 flag are set to 1b on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive data full interrupt (INT_ri3c_rx_n). The value of the GCAF flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

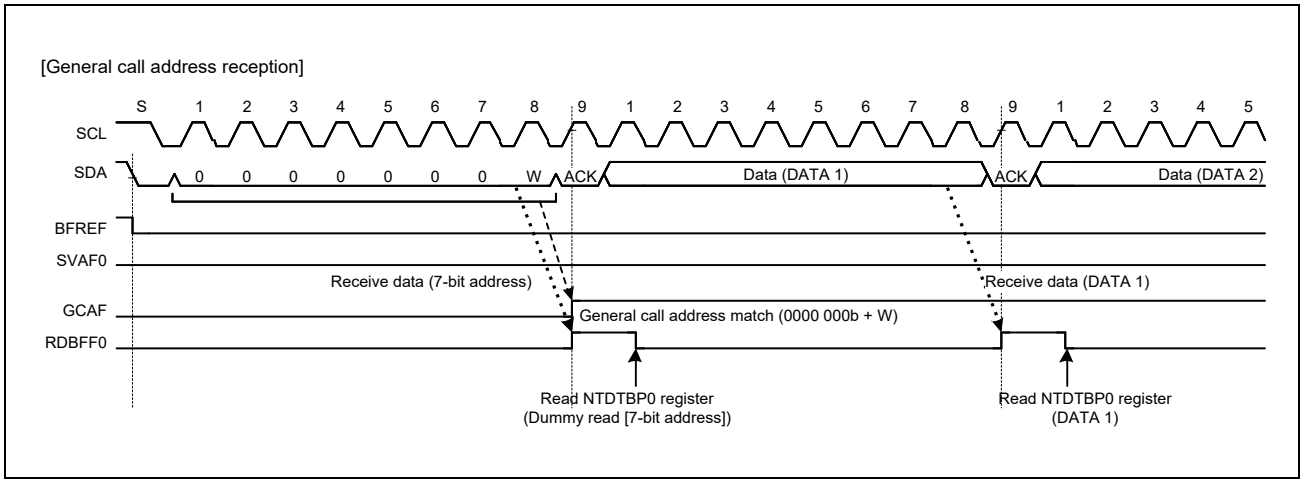

Figure 7.8-61 Timing of GCAF flag setting during reception of general call address

(c) Device-ID Address Detection [I²C mode]

I3C module has a facility for detecting device-ID addresses conformant with the I²C-bus specification (Rev.03). When I3C receives 1111 100b as the first byte after a START condition or Repeated START condition was issued with the SVCTL.DVIDE bit set to 1b, I3C recognizes the address as a device ID, sets the SVST.DVIDF flag to 1b on the rising edge of the ninth SCL clock cycle when the following R/W# bit = 0b, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, I3C sets the corresponding SVST.SVAFn flag (n = 0 to 2) to 1b.

After that, when the first byte received after a START or Repeated START condition is issued matches the device ID address (1111 100b) again and the following R/W# bit = 1, I3C does not compare the second and subsequent bytes and sets the NTST.TDBEF0 flag to 1b.

In the device-ID address detection function, I3C sets the DVIDF flag to 0 if a match with I3C's own slave address is not obtained or a match with the device ID address is not obtained after a match with I3C's own slave address and the detection of a Repeated START condition. If the first byte after detection of a START or Repeated START condition matches the device ID address (1111 100b) and the R/W# bit = 0b, I3C sets the DVIDF flag to 1b and compares the second and subsequent bytes with I3C's slave address. If the R/W# bit = 1b, the DVIDF flag holds the previous value and I3C does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DVIDF flag after confirming that TDBEF0 flag = 1b.

Furthermore, prepare the device-ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

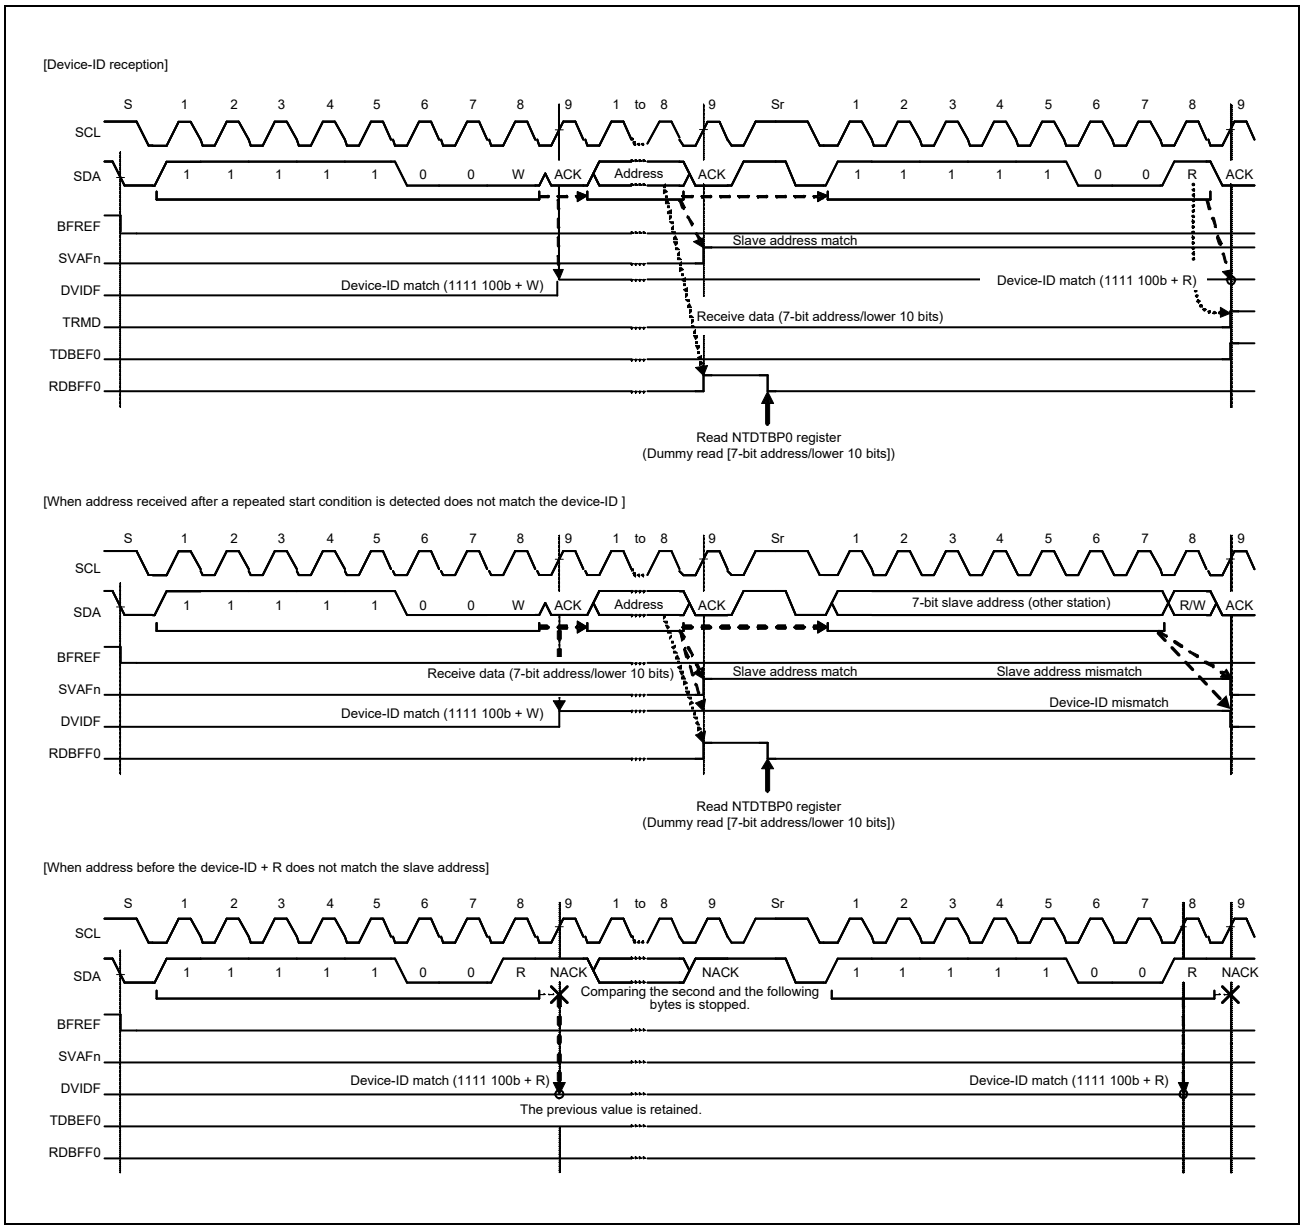

Figure 7.8-62 SVAFn/DVIDF flag set/clear timing during reception of device-ID

(d) Host Address Detection [I²C mode]

I3C has a function to detect the host address while the SMBus is operating. When the SVCTL.HOAE bit is set to 1b while the BFCTL.SMBS bit = 1b, I3C can detect the host address (0001 000) in slave receive mode (bits CRMS and TRMD in the PRSST register = 00b).

When I3C detects the host address, the SVST.HOAF flag is set to 1 at the rising edge of the ninth SCL clock cycle, and at the same time, the NTST.RDBFF0 flag is set to 1b when the R/W# bit = 0b (Wr bit). This causes a receive data full interrupt (INT_ri3c_rx_n) to be generated. The HOAF flag is used to recognize that the host address was sent from the smart battery or other devices.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit = 1b), I3C can also detect the host address. After the host address is detected, I3C operates in the same manner as normal slave operation.

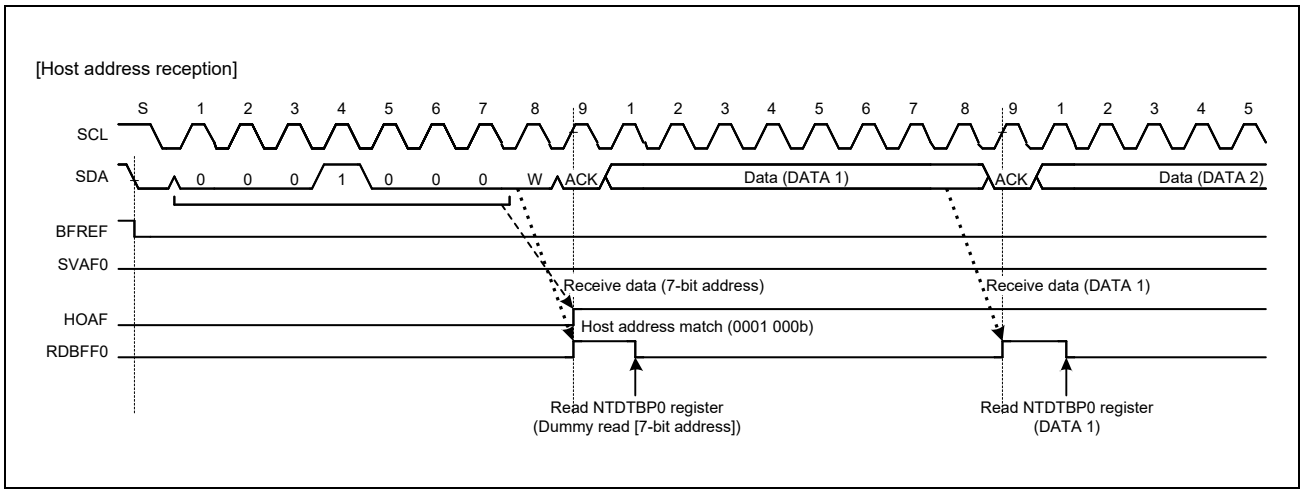

Figure 7.8-63 HOAF flag set timing during reception of host address

(e) Hs-mode master code Detection [I²C mode]

IC has a facility for detecting the Hs-mode master code (0000 1XXXb). When IIC receives the Hs-mode master code (0000 1XXXb) as the first byte after a START condition was issued with the SVCTL.HSMCE bit set to 1b, this module recognizes the address as the Hs-mode master code, sets the SVST.HSMCF flag to 1b on the rising edge of the ninth SCL clock cycle. The first byte after Repeated START after NACK response to Hs-mode master code is recognized as a slave address and compared with the slave address set by SVDVADn.SVAD[9:0] (n = 0 to 2). When IIC detects a match of the set slave address, the corresponding SVST.SVAFn flag (n = 0 to 2) is set to 1 at the rising edge of the ninth SCL clock cycle, and the NTST.RDBFF0 flag or the NTST.TDBEF0 flag is set to 1 by the following R/W# bit. This causes a receive data full interrupt (INT_ri3c_rx_n) or transmit data empty interrupt (INT_ri3c_tx_n) to be generated. The SVAFy flag is used to identify which slave address has been specified. The SVST.HSMCF flag is cleared to 0b when the STOP condition is detected.

NOTE

If the Hs-mode master code (0000 1XXXb) is received with the SVCTL.HSMCE bit set to 0b, other patterns are ignored until the STOP condition is detected.

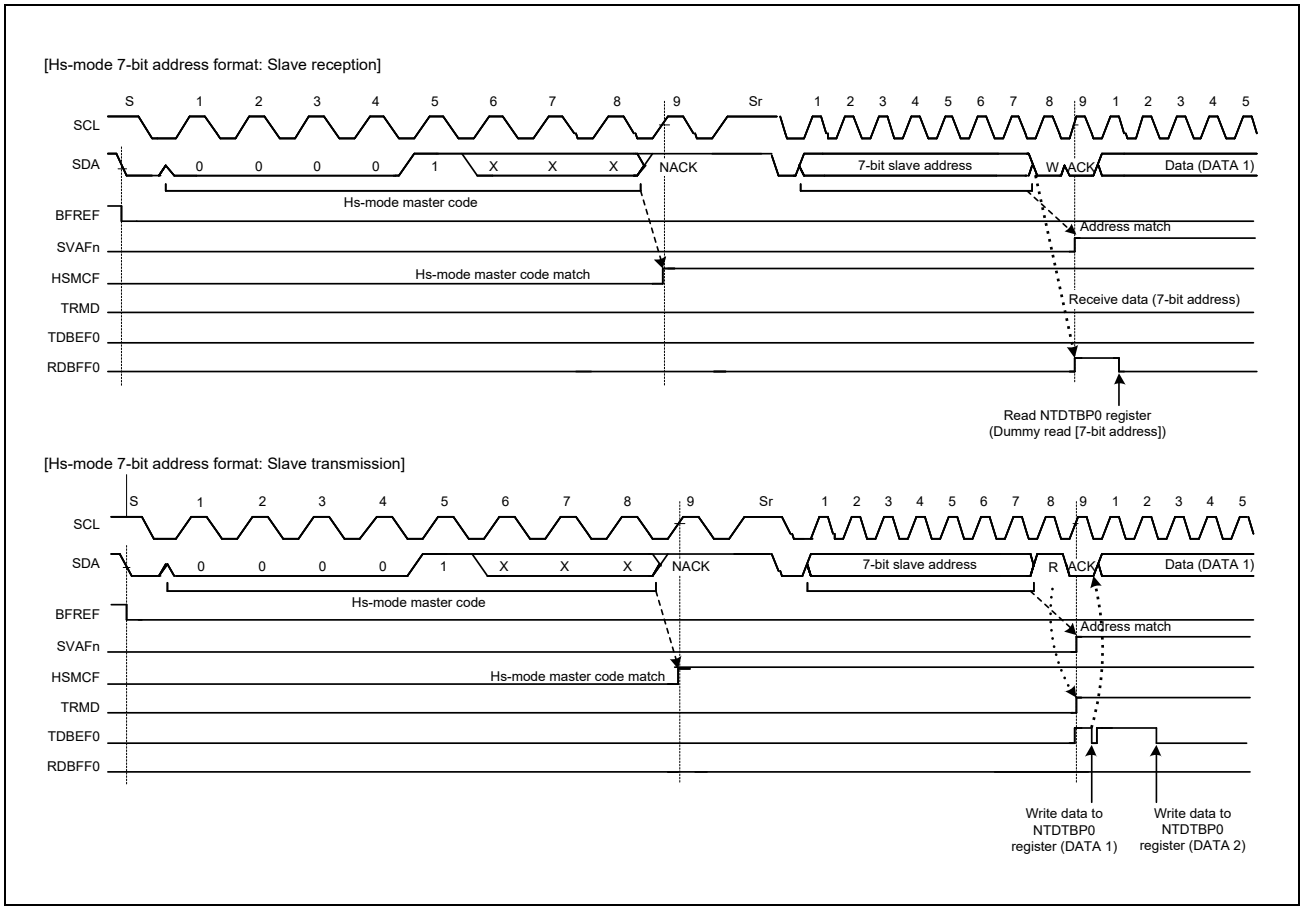

Figure 7.8-64 SVAFn/HSMCF Flag Set Timing during Reception of Hs-mode master code

(f) CCC detection function [I3C mode]

◆ In case of Broadcast CCC

1. It receives Broadcast Address (7Eh) and R/W# = 0 after START condition or Repeated START.
2. Respond to ACK.
3. Receive Common Command Code (CCC).
4. In accordance with the CCC, the following data is stored. (Storage destination: see **Table 7.8-12**)
5. Store the Receive Status Descriptor into the Receive Status Queue.

◆ In case of Broadcast CCC (ENTDAA)

1. It receives Broadcast Address (7Eh) and R/W# = 0b after START condition.
2. Respond to ACK.
3. Receive ENTDAA.
4. If receives Broadcast Address (7Eh) and R/W# = 1b after Repeated START.
5. When the Dynamic Address is not assigned, ACK response is done.
6. This Provisional ID (SDCTPIDH[31:0], SDCTPIDL[15:0]), BCR (SVDCT.TBCR[7:0]) and DCR (SVDCT.TDCR[7:0]) are transmitted.
7. When winning the arbitration in a transmission of the above Step 6, the dynamic address following that is received. When losing arbitration in a transmission of the above Step 6, processing of Step 6 is repeated from Step 4.
8. When parity of the Dynamic Address is valid, ACK response is done.
9. When parity of the Dynamic Address is invalid, NACK replies, and repeat the process from Steps 4 to 7.
10. SDATBAS0.SDDYAD[6:0] is renewed and the SVDVAD0.SDYADV bit is set to 1b.
11. Upon detecting the STOP condition, Store the Receive Status Descriptor into the Receive Status Queue.

◆ In case of Direct Write CCC

1. It receives Broadcast Address (7Eh) and R/W# = 0b after START condition or Repeated START.
2. Respond to ACK.
3. Receive Common Command Code (CCC).
4. Receive Dynamic Address and R/W# = 0b after Repeated START.
5. Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, I3C responds with ACK.
   If they do not match, it responds with NACK and waits for Repeated START or STOP.
6. In accordance with the CCC, the following data is stored. (Storage destination: see **Table 7.8-12**)
7. Store the Receive Status Descriptor into the Receive Status Queue.

◆ In case of Direct Read CCC

1. It receives Broadcast Address (7Eh) and R/W# = 1b after START condition or Repeated START.
2. Respond to ACK.
3. Receive Common Command Code (CCC).

4. Receive Dynamic Address and R/W# = 1b after Repeated START.
5. Compare the received Dynamic Address with the assigned Dynamic Address, and if it matches, I3C responds with ACK.
   If they do not match, it responds with NACK and waits for Repeated START or STOP.
6. Respond from SFR according to CCC. (Responding CCC: see **Table 7.8-12**)
7. Store the Receive Status Descriptor into the Receive Status Queue.

Table 7.8-12 Common command code operation

Command Code	CCC Type	Command Name	With Data	Auto Response	Storage
00h	Broadcast	ENEC	Yes	—	SFR
01h	Broadcast	DISEC	Yes	—	SFR

(5) Arbitration-Lost Detection [I²C mode]

In addition to the normal arbitration-lost detection function defined by the I²C-bus specification, the I3C has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration- lost in slave transmit mode.

(a) Master Arbitration-Lost Detection (MALE Bit)

The I3C drives the SDA line low to issue a start condition. However, if the SDA line has already been driven low by another master device issuing a START condition, this module causes arbitration to be lost, so priority is given to transfer by the other master device. Similarly, if the CNDCTL.STCND bit is set to 1 while the BCST.BFREF flag is 0 (bus busy state), arbitration is lost, so priority is given to transfer by the other master device. No start condition is issued in this case.

When a start condition is issued successfully, if the data for transmission including the address bits (the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output, that is, the SDA30 pin is in the high-impedance state) and the low level is detected on the SDA line, the I3C loses in arbitration.

I3C detects master arbitration-lost when the following conditions are met while the BSTE.ALE bit = 1b and the BFCTL.MALE bit = 1b (master arbitration-lost detection enabled).

If arbitration of mastership is lost, I3C immediately enters slave receive mode.

If a slave address (including the general call address) matches its own address at this time, I3C continues in slave operation.

[Conditions for master arbitration-lost]

- Non-matching of the internal level for output on SDA and the level on the SDA line after a START condition was issued by setting the CNDCTL.STCND bit to 1b while the BCST.BFREF flag was set to 1b (erroneous issuing of a START condition)
- Setting of the CNDCTL.STCND bit to 1b (START condition double-issue error) while the BFREF flag is set to 0

Remark I3C does not issue a START condition.

- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDA line in master transmit mode (bits CRMS and TRMD in the PRSST register = 11)

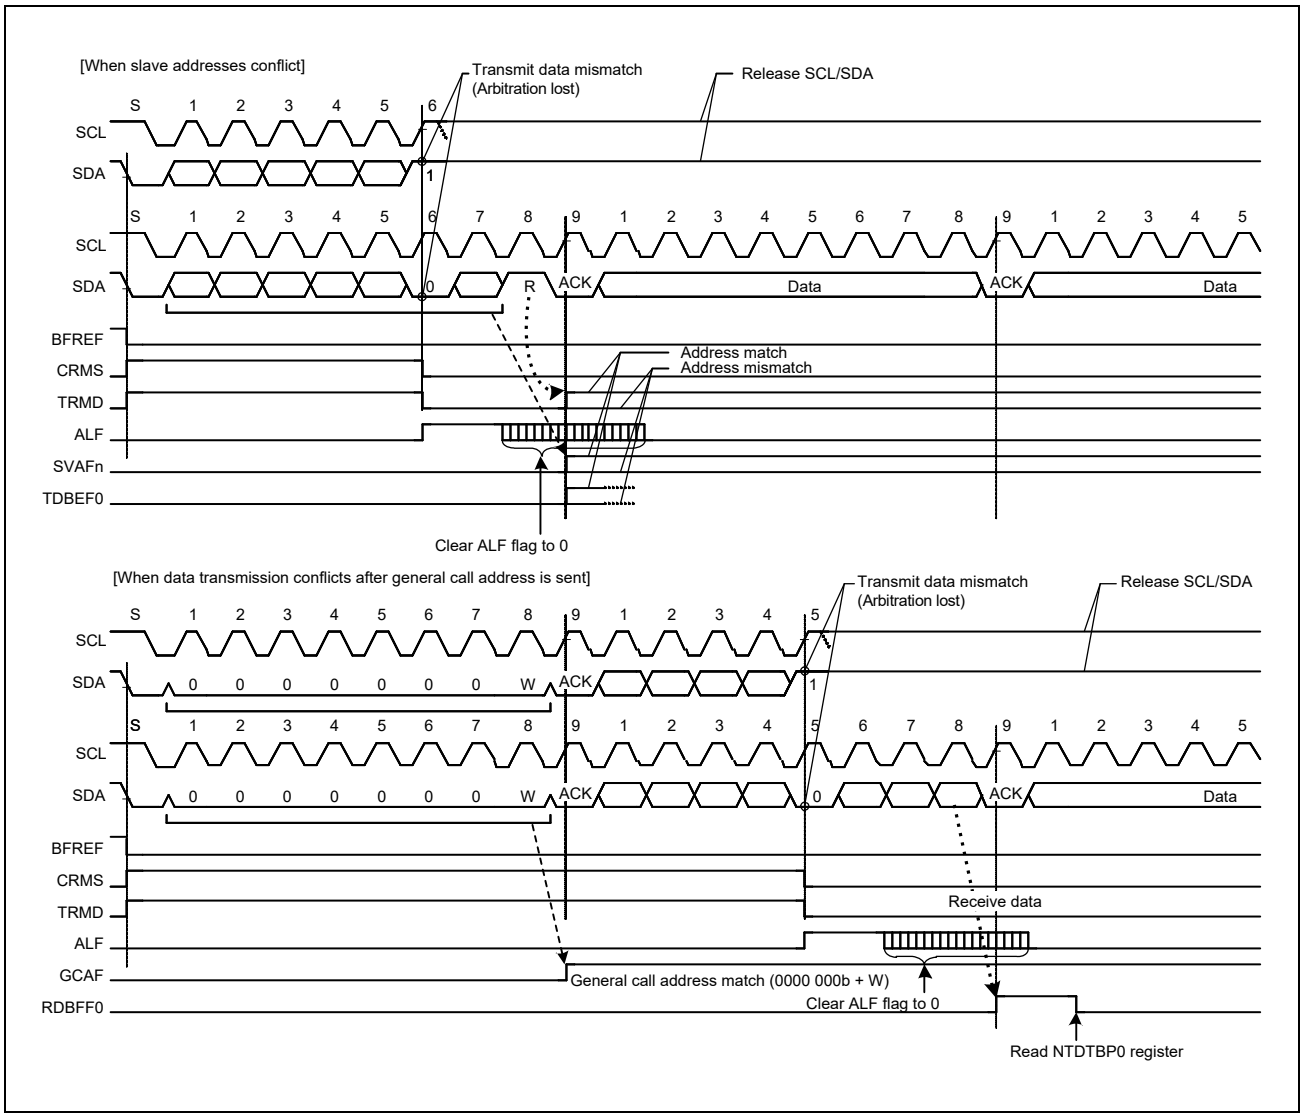

Figure 7.8-65 Examples of master arbitration-lost detection (MALE = 1b)

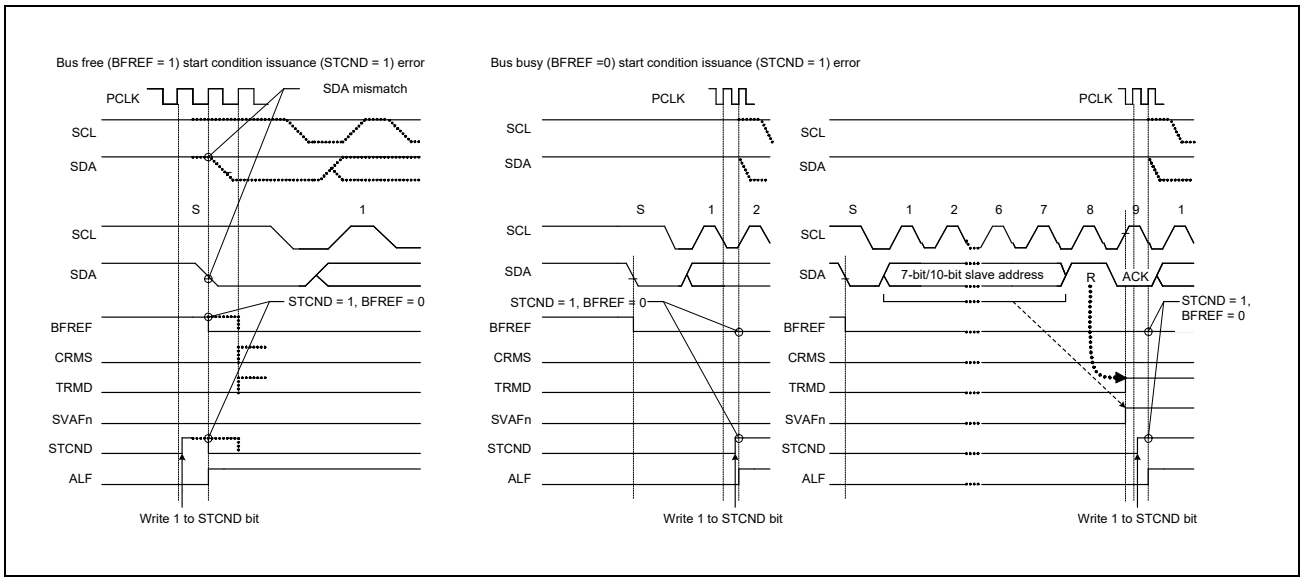

Figure 7.8-66 Arbitration-lost detection when a START condition is issued (MALE = 1b)

(b) Arbitration-Lost Detection during NACK Transmission (NALE Bit)

The I3C has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDA line (the high output as the internal SDA output; i.e. the SDA pin is in the high-impedance state) and the low level is detected on the SDA line during transmission of NACK in receive mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device.

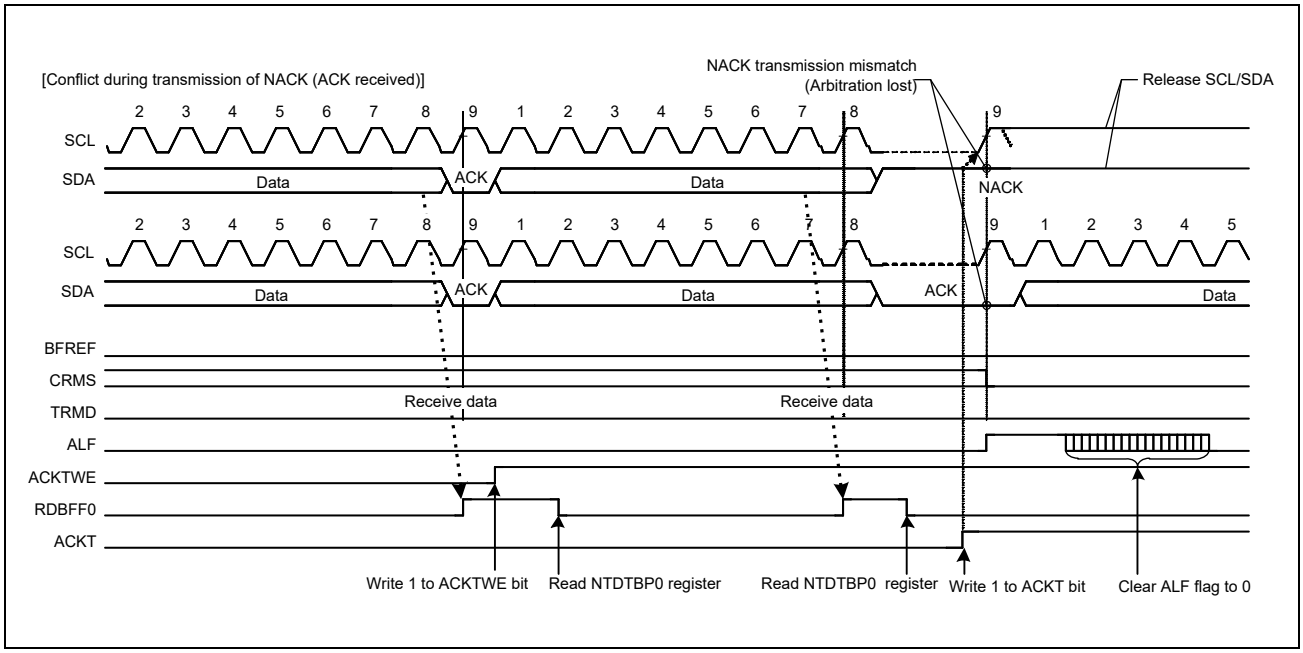

Figure 7.8-67 Example of arbitration-lost detection during transmission of NACK (NALE = 1b)

The following section explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. In this example, master A sends NACK when it has received 2 final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received the necessary 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition. Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When this module receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, this module is immediately released from the slave-matched state and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing (such as FFh transmission processing)

necessary if the UDID (Unique Device Identifier) of assign address does not match in the Get UDID (general) processing after the Assign Address command.

The I3C detects arbitration-lost during transmission of NACK when the following condition is met while the BSTE.ALE bit = 1b and the BFCTL.NALE bit = 1b (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDA line (ACK is received) during transmission of NACK (ACKCTL.ACKT bit = 1b)

(c) Slave Arbitration-Lost Detection (SALE Bit)

The I3C has a function to cause arbitration to be lost if the data for transmission (the internal SDA output level) and the level on the SDA line do not match (the high output as the internal SDA output, that is, the SDA pin is in the high-impedance state and the low level is detected on the SDA line in slave transmit mode). This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

If arbitration is lost during transmission of DATA, this module is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminate subsequent redundant processing (processing for the transmission of FFh).

The I3C detects slave arbitration-lost when the following condition is met while the BSTE.ALE bit = 1b and the BFCTL.SALE bit = 1b (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDA line in slave transmit mode (bits CRMS and TRMD in the PRSST register = 01b).

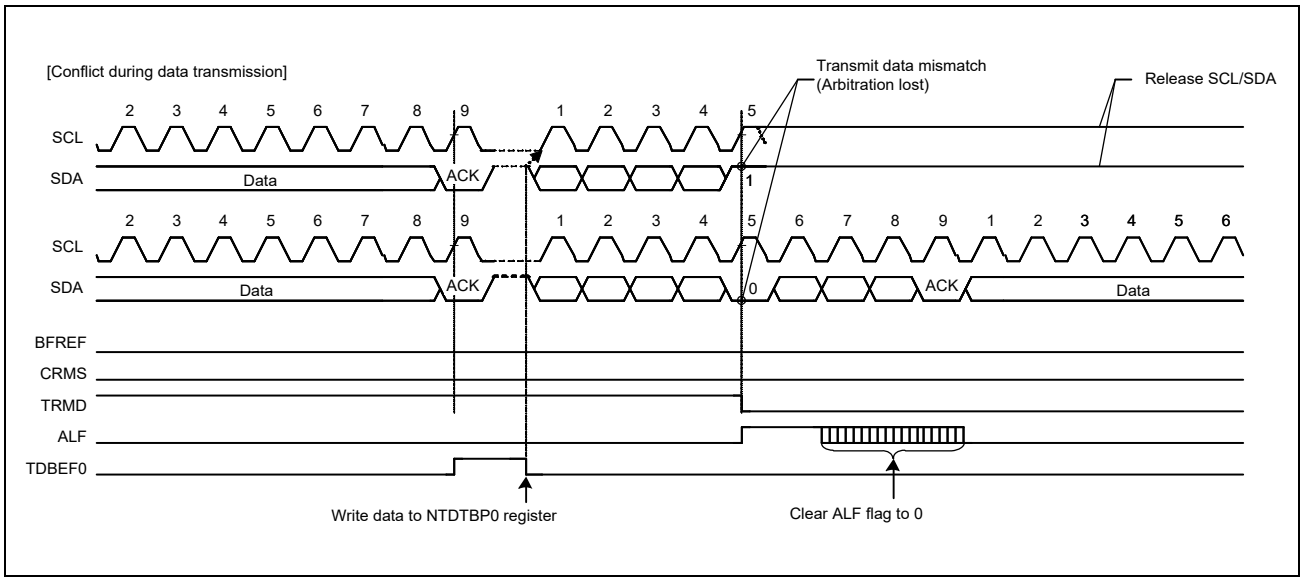

Figure 7.8-68 Example of slave arbitration-lost detection (SALE = 1)

(6) Clock Stretching [I²C mode]

(a) Function to Prevent Wrong Transmission of Transmit Data

When data have not been written to the I²C bus transmit data register (NTDTBP0) with I3C in transmission mode (PRSST.TRMD = 1b), the SCL line is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

Master transmit mode

- Low-level interval after a START condition or Repeated START condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

Slave transmit mode

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

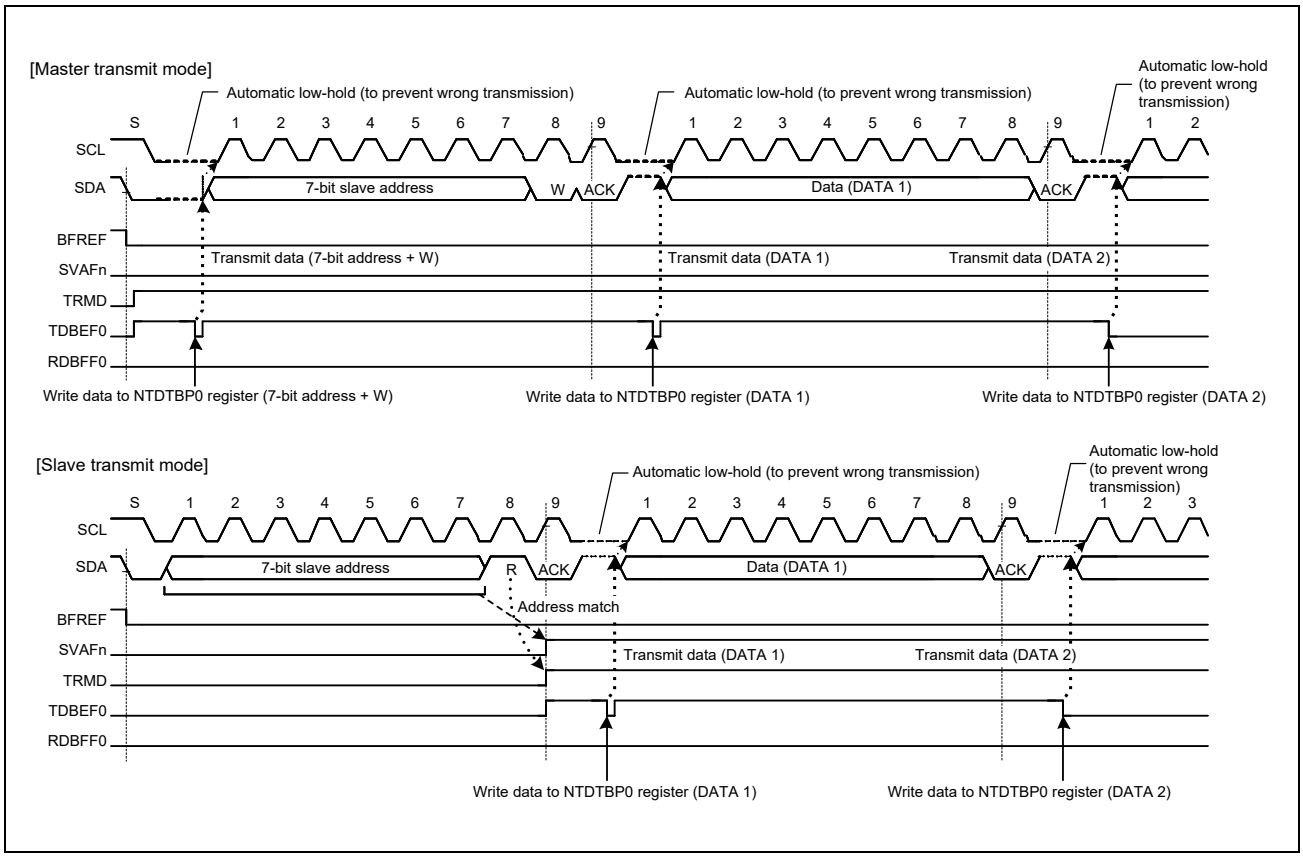

Figure 7.8-69 Automatic low-hold operation in transmit mode

(b) NACK Reception Transfer Abort Function

I3C has a function to abort transfer operation when NACK is received in transmit mode (PRSST.TRMD = 1b). This function is enabled when the BSTE.NACKDE bit is set to 1b (transfer abort enabled). If the next transmit data has already been written (NTST.TDBEF0 = 0b) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically aborted. This prevents the SDA line output level from being held low when the MSB of the next transmit data is 0b.

If the transfer operation is aborted by this function (BST.NACKDF = 1b), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to set the NACKDF flag to 0b. In master transmit mode, restore operation using either of the methods below:

- After issuing a Repeated START condition, set the NACKDF flag to 0b
- After issuing a STOP condition, set the NACKDF flag to 0b and then issue a START condition

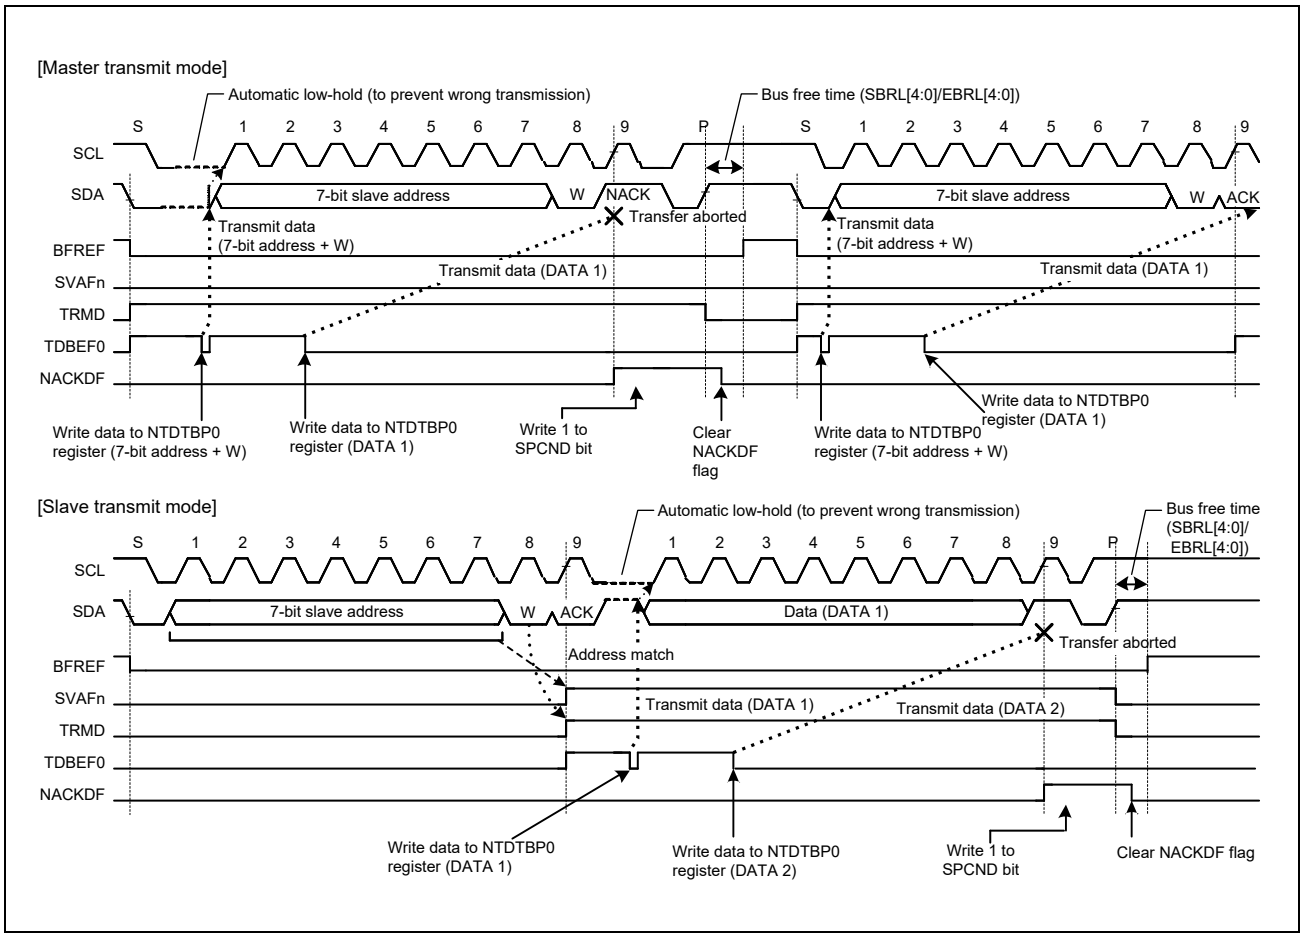

Figure 7.8-70 Abort of data transfer when NACK is received (NACKE = 1b)

(b-1) Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (NTDTBP0) read is delayed for a period of one transfer frame or more with receive data full (NTST.RDBFF0 = 1b) in receive mode (PRSST.TRMD = 0b), I3C holds the SCL line low automatically immediately before the next data is received to prevent failure to receive data.

This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, I3C's own slave address or another slave address is received after a STOP condition is issued.

Sections in which the SCL line is held low can be selected with a combination of the RWE and ACKTWE bits in SCSTRCTL.

(b-2) 1-Byte Receive Operation and Automatic Low-Hold Function Using the RWE Bit

When the SCSTRCTL.RWE bit is set to 1b, I3C performs 1-byte receive operation using the RWE bit function.

Furthermore, when the SCSTRCTL.ACKTWE bit = 0b, I3C automatically sends the ACKCTL.ACKT bit value for the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle, and automatically holds the SCL line low at the falling edge of the ninth SCL clock cycle using the RWE bit function. This low-hold is released by reading data from NTDTBP0, which enables bytewise receive operation.

The RWE bit function is enabled for receive frames after a match with I3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

(b-3) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the ACKTWE Bit

When the SCSTRCTL.ACKTWE bit is set to 1b, I3C performs 1-byte receive operation using the ACKTWE bit function.

When the ACKTWE bit is set to 1b, the NTST.RDBFF0 flag (receive data full) is set to 1b at the rising edge of the eighth SCL clock cycle, and the SCL line is automatically held low at the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the ACKCTL.ACKT bit, but cannot be released by reading data from NTDTBP0, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.

The ACKTWE bit function is enabled for receive frames after a match with I3C's own slave address (including the general call address and host address) is obtained in master receive mode or slave receive mode.

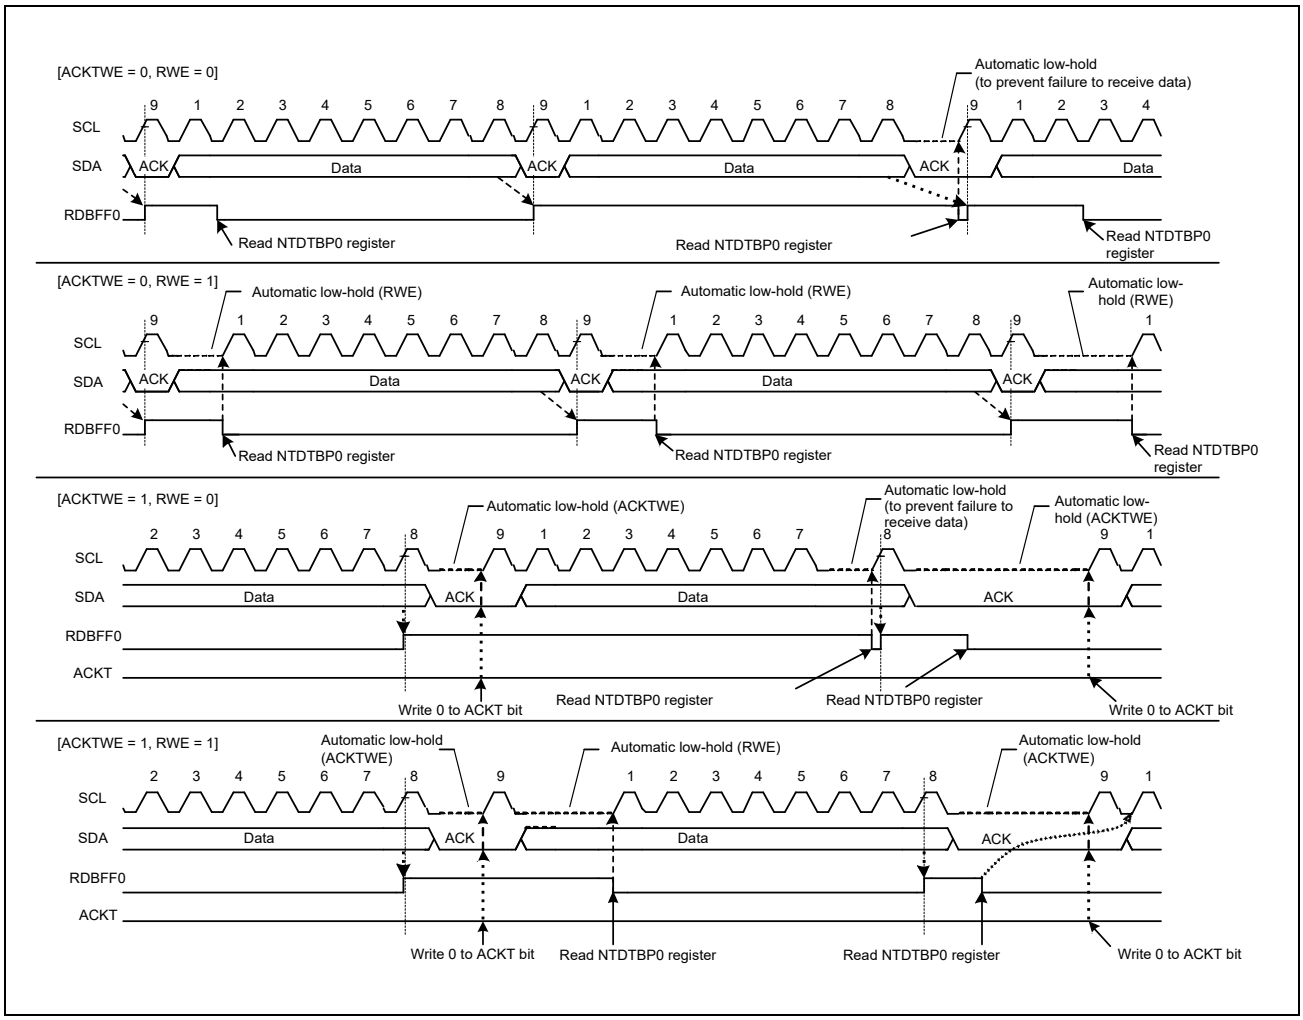

Figure 7.8-71 Automatic low-hold operation in receive mode (using ACKTWE and RWE bits)

(7) Clock Stalling [I3C mode]

I3C has the function of stalling the SCL during the SCL Low period.

The SCL stall control is described in the table below.

Table 7.8-13 I3C clock stalling

Clock stalling condition	Clock stalling control	Clock stalling period
I3C Transfer, ACK/NACK Phase	SCSTLCTL.ACKPE bit setting	During the count period of SCSTLCTL.STLCYC [15: 0] value
	Transmit Data FIFO Empty	Until data is written to the Transmit FIFO
	Receive Data FIFO Full	Until data is read from the Receive FIFO
I3C Write Data Transfer, Parity Bit	SCSTLCTL.PARPE bit setting	During the count period of SCSTLCTL.STLCYC [15: 0] value
	Transmit Data FIFO Empty	Until data is written to the Transmit FIFO
I3C Read Transfer, Transition Bit	Receive Data FIFO Full	Until data is read from the Receive FIFO
Assigned Address Phase	SCSTLCTL.AAPE bit setting	During the count period of SCSTLCTL.STLCYC [15: 0] value

The following figure shows the stalling timing of each Condition.

(a) I3C Transfer, ACK/NACK Phase

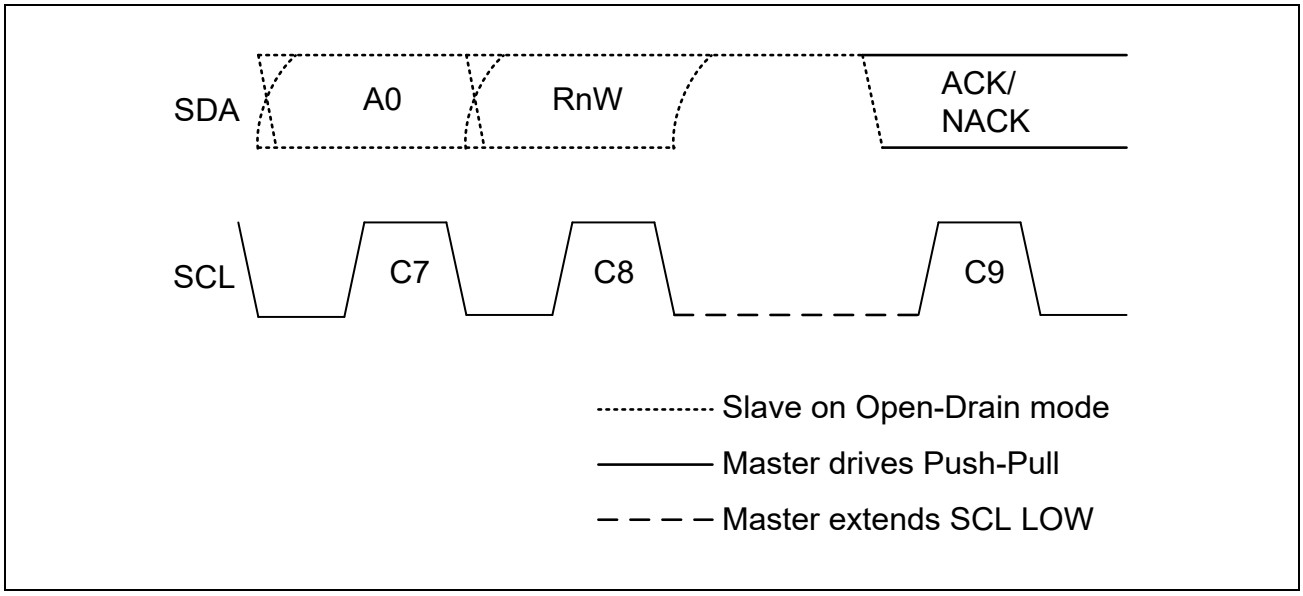

Figure 7.8-72 Master clock stalling in ACK phase

(b) I3C Write Data Transfer, Parity Bit

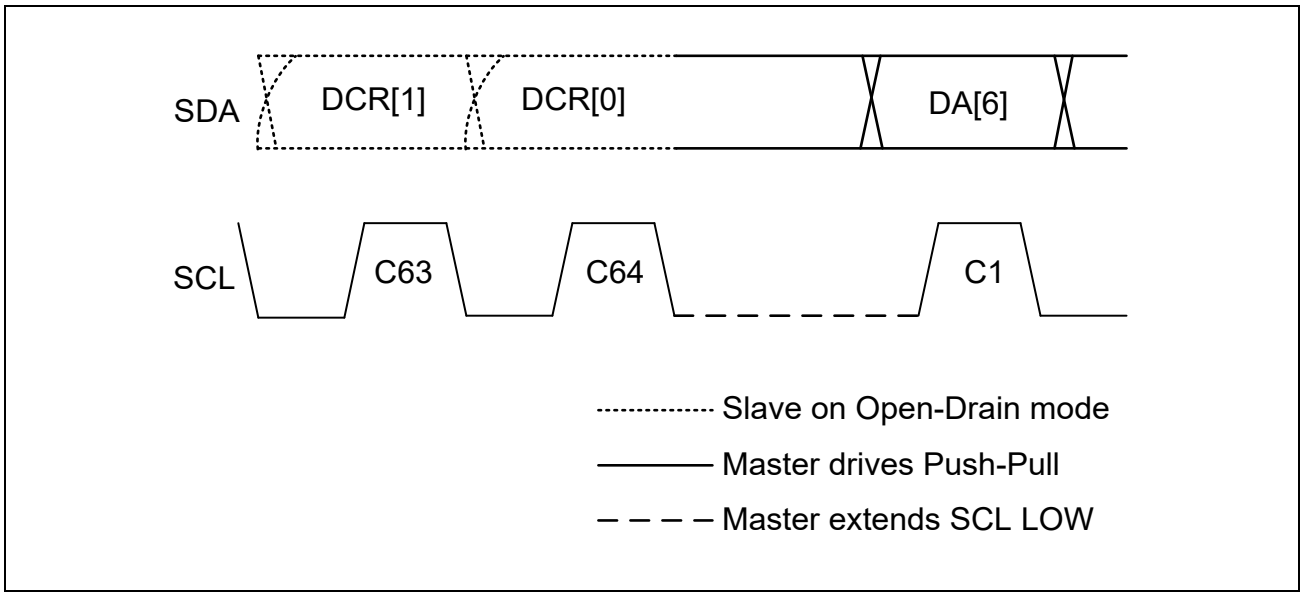

Figure 7.8-77 Master clock stalling in dynamic address first bit

(8) In-Band Interrupt [I3C mode]

I3C detects In-Band Interrupt in the arbitrated Address Header following a START condition (but not following a Repeated START). If START Request (SDA Low Drive) is issued from Slave Device, I3C drives SCL low and completes START condition. After that, it supplies SCL and receives In-Band Interrupt Request.

The In-Band Interrupt to be detected is classified into the following three types.

- Slave Interrupt Request
- Mastership Request
- Hot-Join Event

The operation when detecting each In-Band Interrupt is described below.

(a) Slave Interrupt Request

1. Detect Slave Address with RnW bit High in Address Header.
2. Compare the detected Slave Address with the DVDYAD[7:0] in each DAT (DATBASm register).
3. When it does not match DAT.DVDYAD[7:0]:
   Responds NACK, then issues the STOP condition. When it matches the DAT.DVDYAD[7:0] bits and the DAT.DVSIRRJ bit = 1b:
   It operates in the following order:
   (a) Responds NACK.
   (b) Issues Repeated START condition, then automatically issues Direct DISEC CCC to the detected Slave.
   (c) Issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and the DAT.DVSIRRJ bit = 0b:
   Responds ACK.
4. When DAT.DVIBIPL = 0b:
   Issues the STOP condition.
   When DAT.DVIBIPL = 1b:
   Drives the SCL to receive the IBI Data from the Slave following the ACK response and receives IBI Data.
   It stores the received IBI Data into the IBI Data Queue.
   Each time IBI Data of the size set by the NQTHCTL.IBIDSSZ[7:0] bits is received, the IBI Status Descriptor is stored in the IBI Status Queue.
5. After detection of Low of T-bit following IBI Data, issues STOP condition.
6. After issues of STOP condition NACK response:
   – If IBINCTL.NRSIRCTL = 0b, the IBI Status Descriptor is not stored into the IBI Status Queue.
   – If IBINCTL.NRSIRCTL = 1b, the IBI Status Descriptor is stored into the IBI Status Queue.
   ACK response:
   Stores the IBI Status Descriptor into the IBI Status Queue.

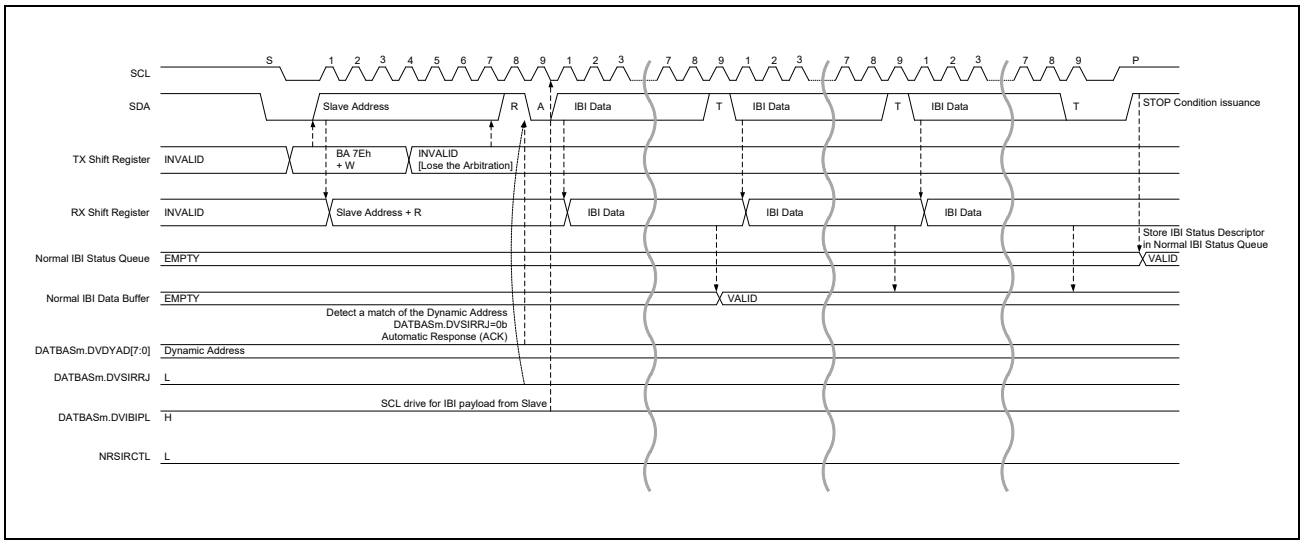

Figure 7.8-78 Slave interrupt request: ACK and DVIBIPL = 1

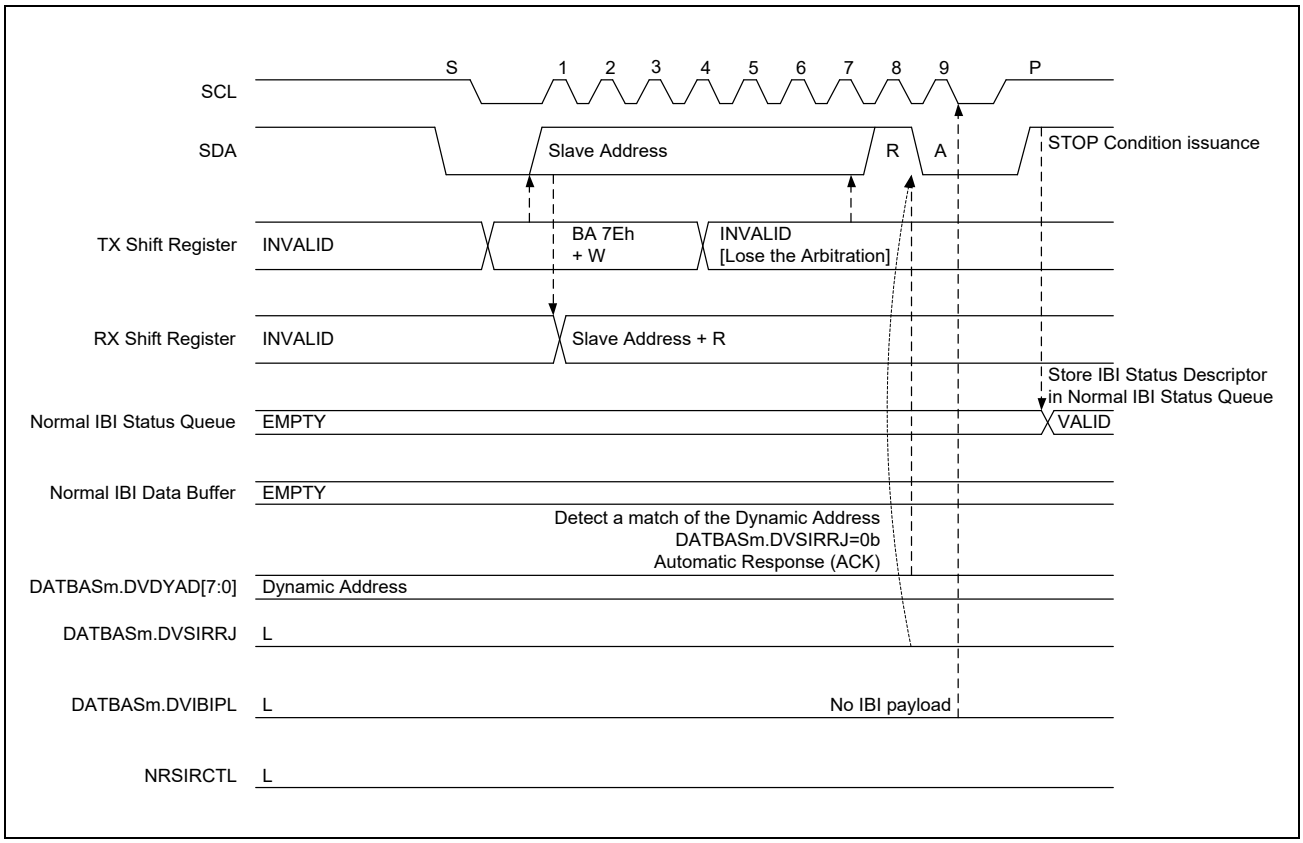

Figure 7.8-79 Slave interrupt request: ACK and DVIBIPL = 0

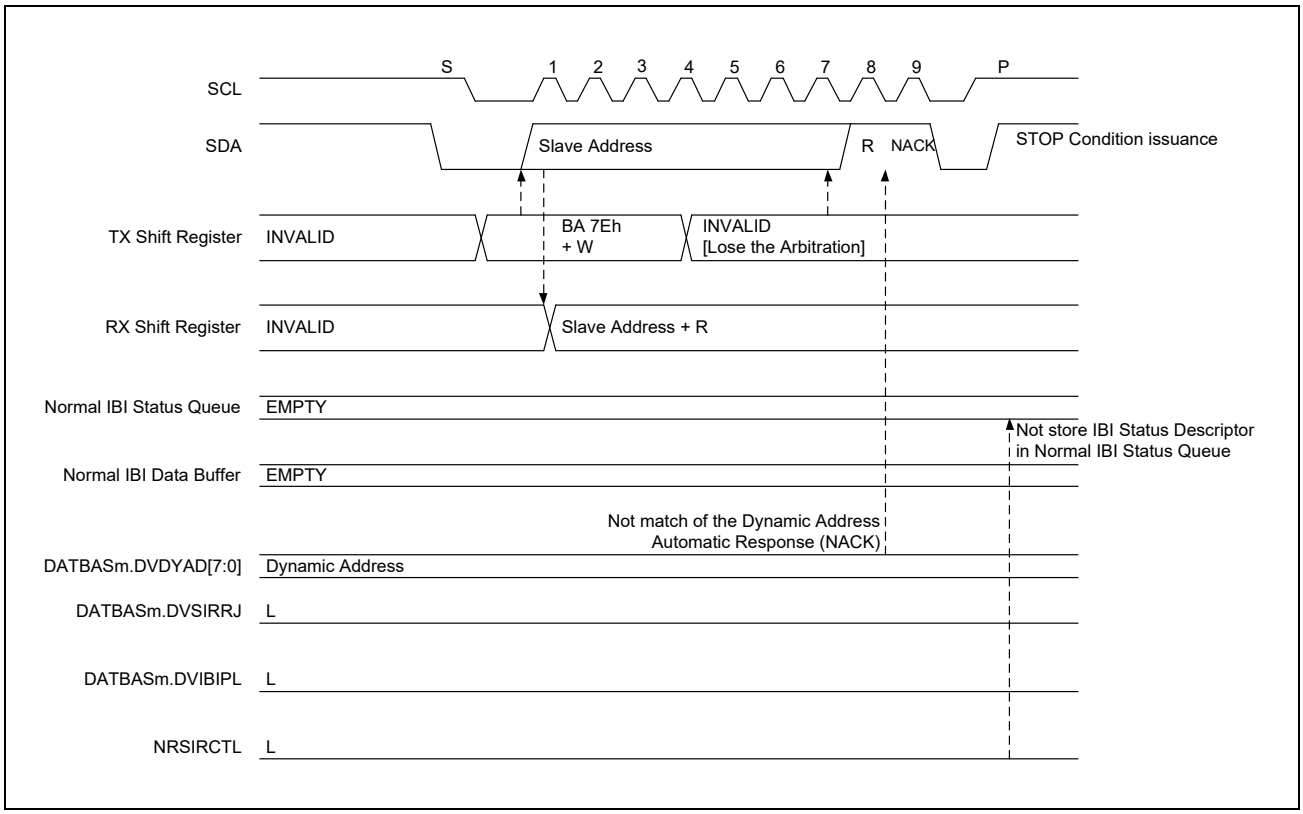

Figure 7.8-80 Slave interrupt request: NACK (not match the SDATBAS0.SDDYAD[6:0]) and NRSIRCTL = 0

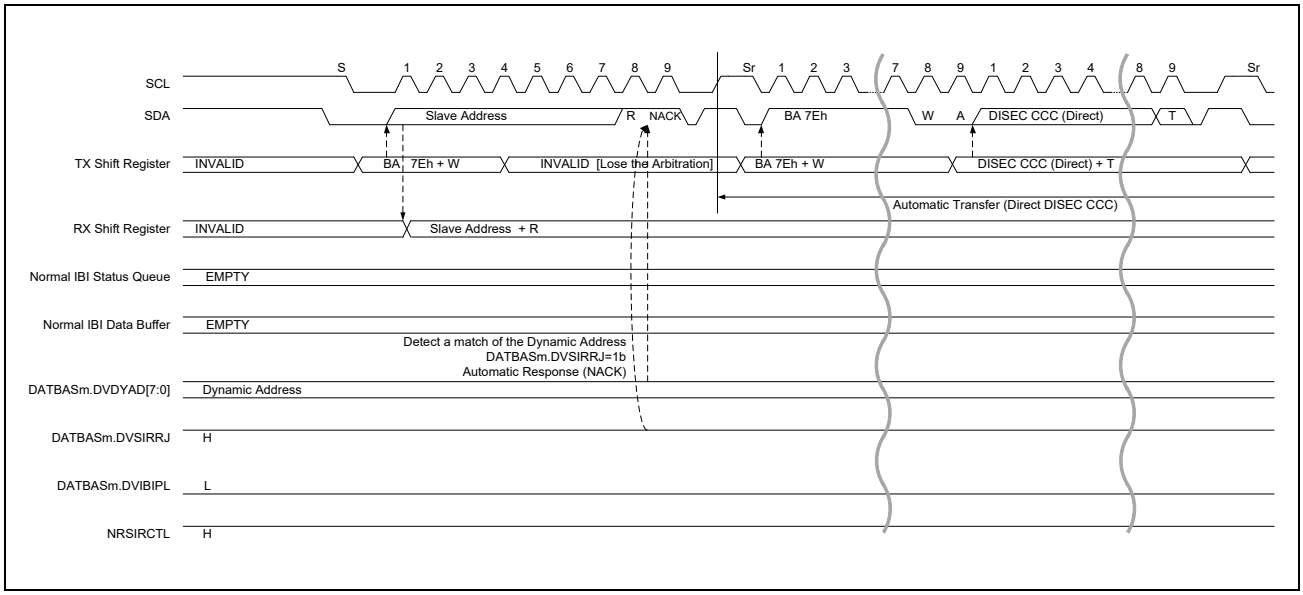

Figure 7.8-81 Slave interrupt request: NACK (DVSIRRJ = 1) and NRSIRCTL = 1 (1/2)

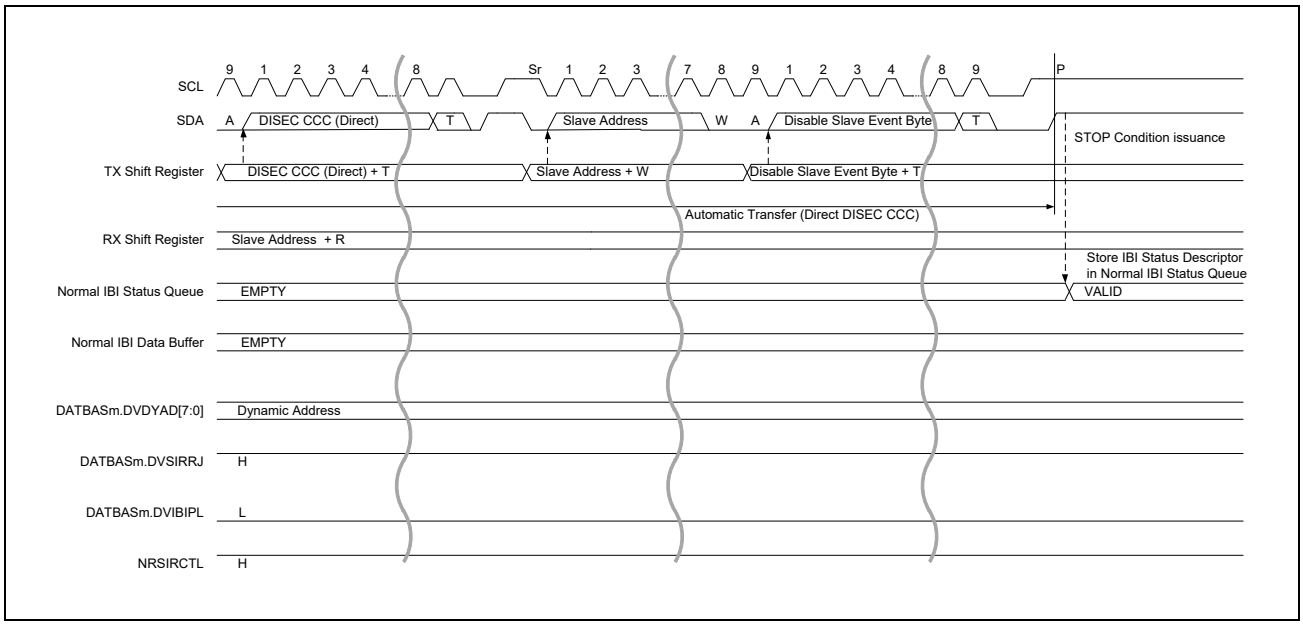

Figure 7.8-82 Slave interrupt request: NACK (DVSIRRJ = 1) and NRSIRCTL = 1 (2/2)

(b) Mastership Request

1. Detect Slave Address with RnW bit Low in Address Header.
2. Compare the detected Slave Address with the DVDYAD[7:0] in each DAT (DATBASm register).
3. When it does not match DAT.DVDYAD[7:0]:
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and Device Role[1:0] in RBCR (MSDCTm) is other than I3C Master (01):
   Responds NACK, then issues the STOP condition.
   When it matches the DAT.DVDYAD[7:0] bits and Device Role[1:0] in RBCR (MSDCTm) is I3C Master (01):
   - When DAT.DVMRRJ = 1b
     It operates in the following order.
     (a) Responds NACK.
     (b) Issued Repeated START condition and automatically issues Direct DISEC CCC to the detected Slave.
     (c) Issues the STOP condition.
   - When DAT.DVMRRJ = 0b
     Responds ACK, then issues STOP condition.
4. After issues of STOP condition,
   NACK response:
   – If IBINCTL.NRMRCTL = 0b, the IBI Status Descriptor is not stored into the IBI Status Queue.
   – If IBINCTL.NRMRCTL = 1b, the IBI Status Descriptor is stored into the IBI Status Queue.
   ACK response:
   Stores the IBI Status Descriptor into the IBI Status Queue.

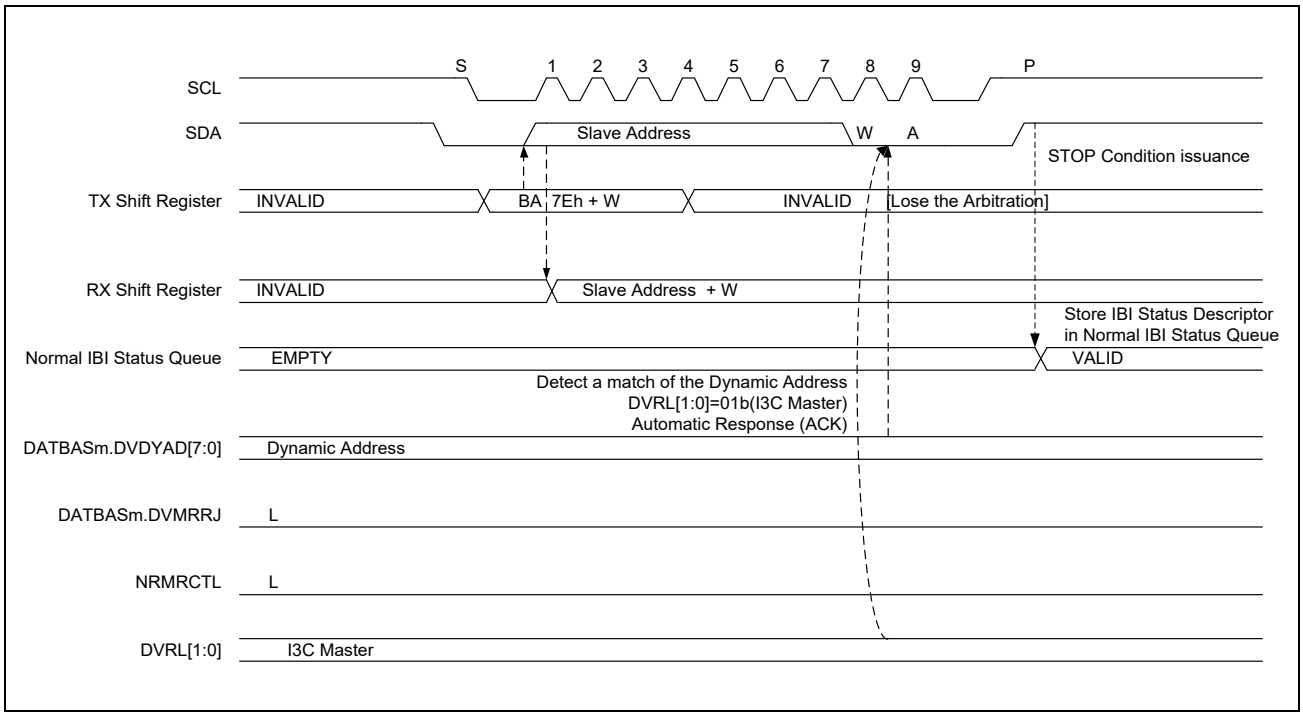

Figure 7.8-83 Mastership request: ACK

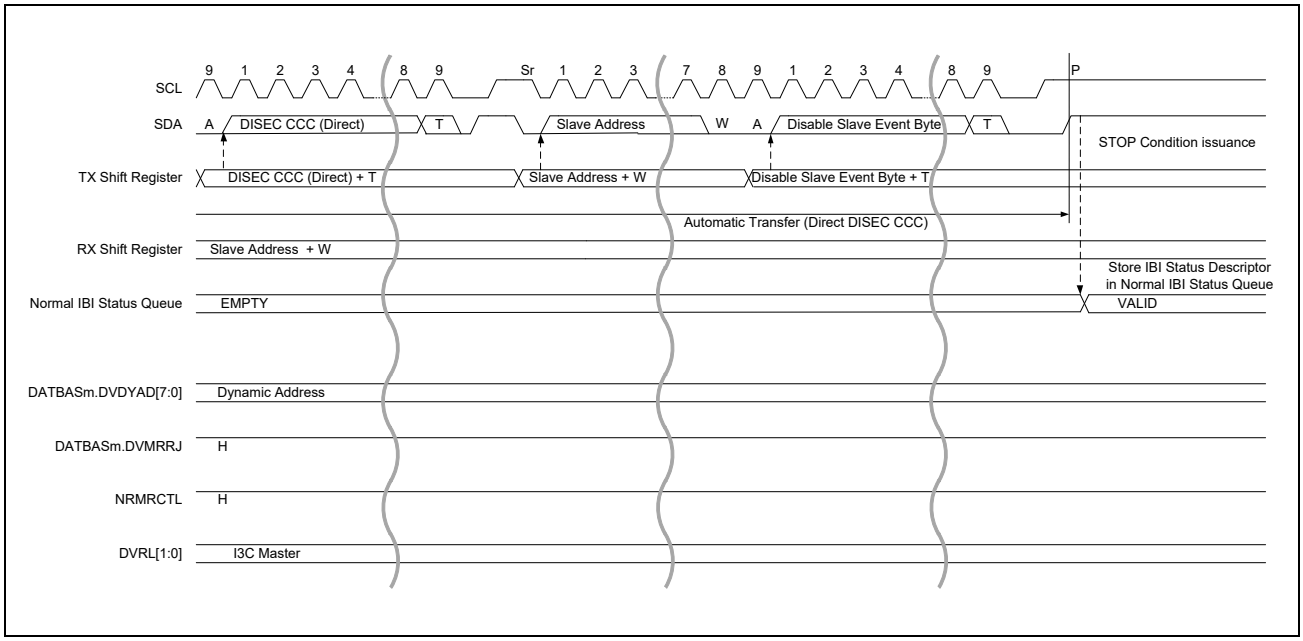

Figure 7.8-87 Mastership request: NACK (DVMRRJ = 1) and NRMRCTL = 1 (2/2)

(c) Hot-Join Event

1. Detect the Hot-Join Address (02h) with RnW bit Low in the Address Header.
2. When BCTL.HJACKCTL = 1b,
   It operates in the following order.
   (a) Responds NACK.
   (b) Issues Repeated START condition and automatically issues Broadcast DISEC CCC.
   (c) Issues the STOP condition.
   When BCTL.HJACKCTL = 0b,
   Responds ACK, then issues STOP condition.
3. After issues of STOP condition, NACK response:
   – If IBINCTL.NRHJCTL = 0b, the IBI Status Descriptor is not stored into the IBI Status Queue.
   – If IBINCTL.NRHJCTL = 1b, store the IBI Status Descriptor into the IBI Status Queue.
   ACK response:
   Stores the IBI Status Descriptor into the IBI Status Queue.

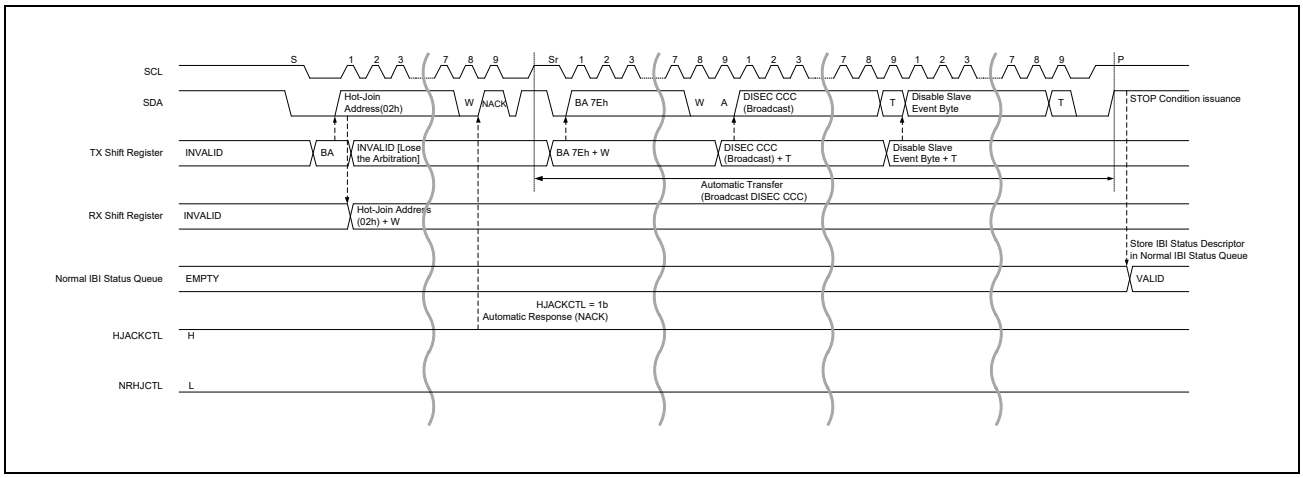

Figure 7.8-90 Hot-join event: NACK (HJACKCTL = 1) and NRHJCTL = 1

(9) Timing Control [I3C mode]

Timing Control is a function that enables Master to efficiently read data from Slave by controlling and grasping the timing at which the Slave Device samples the sensor value.

For details, refer to *5.1.8 Timing Control* of *MIPI I3C Specification v1.0*.

In I3C, Timing Control supports the following three modes.

- Sync Mode
- Async Mode 0 (Asynchronous Basic Mode)
- Async Mode 1 (Asynchronous Advanced Mode)

The resources for realizing Timing Control in each mode are described below.

(a) Sync Mode

1. **<I3C Master>**
   When STCTL.STOE is set to 1, when the master sends an ST message (SETXTIME CCC with ST subcommand), there is a function to issue an event (ri3c_elcstev) under the START condition of the ST message.
   While measuring the T_ph period with an external timer, the start of T_ph and the Delay Time [DT] of the ST message can be measured by capturing the count value with the ri3c_elcstev event.
   The measured value of Delay Time is sent as a DT message (SETXTIME CCC with DT subcommand) following the ST message.
2. **<I3C Slave>**
   When STCTL.STOE is set to 1, there is a function to issue an event (ri3c_elcstev) for each START condition.
   STCTL.STOE is cleared when an ST message is received (SETXTIME CCC using the ST subcommand).
   Check the reception of the ST message with the Receive Status Descriptor, and use an external timer to correct the T_ph period based on the count value captured in the ri3c_elcstev event and the Delay Time obtained from the DT message.
   While measuring the T_ph period with an external timer, the start of T_ph and the Delay Time [DT] of the ST message can be measured by capturing the count value with the ri3c_elcstev event.
   The sampling timing is recalculated by the corrected T_ph.

(b) Async Mode 0 (Asynchronous Basic Mode)

For timing control in Async Mode 0, set the ATCTL register if necessary.

1. **<I3C Master>**
   I3C has counters of MREF (32bit) and MC2 (16bit) for Async Mode 0.

   <MREF Counter>
   When ATCCNTE.ATCE is enabled, the counter starts counting.
   Its value is captured as MREF on the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave.

   <MC2 Counter>
   After enabling ATCCNTE.ATCE, the counter counts up from the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave to the SCL rise edge next to the Tbit after Mandatory Byte, and its value is captured as MC2.
   The MREF and MC2 capture values are stored next to the IBI Status Descriptor when IBI is received from the I3C Slave with the DATBASm.DVIBITS bit set to 1.
   The MREF counter implemented in I3C is a 32-bit counter.

However, if the 32-bit counter is insufficient due to system requirements, I3C has events (ri3c_mrefovf, ri3c_mrefcpt) for expansion. These events are enabled by setting ATCTL.MREFOE to 1b.
ri3c_mrefovf is output when the internal MREF counter overflows.
The MREF counter can be extended by using it as a count event for an external timer. ri3c_mrefcpt is output at the same timing as the capture timing of the internal MREF counter. By using it as the capture timing of the external timer, it can be used as an MREF counter concatenated with the value stored in the IBI Data buffer.

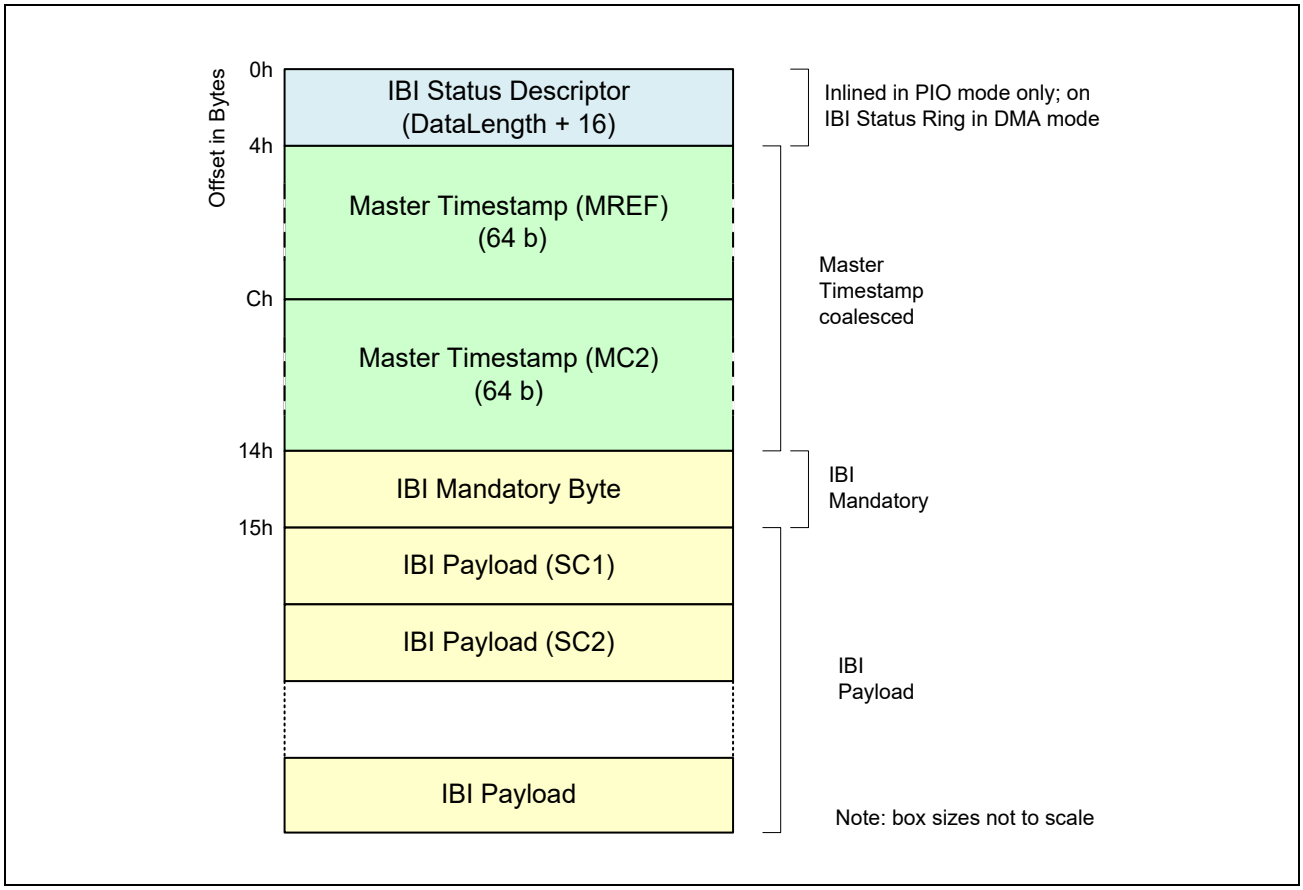

Figure 7.8-91 Master Timestamp Counters for IBI Event

Remark Please evaluate the Sensor Event time of I3C Slave according to the calculation formula of the MIPI I3C specification v1.0 document.

2. **<I3C Slave>**

I3C has counters of SC1 (16bit) and SC2 (8bit) for Async Mode 0.

<SC1 Counter>

After enabling ATCCNTE.ATCE, the counter counts up from SC1 count trigger (ATTRG.ATSTRG bit) to SCL rise edge next to ACK for the IBI, and its value is captured as SC1.

<SC2 Counter>

After enabling ATCCNTE.ATCE, the counter counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and its value is captured as SC2.
When the CETSS.ASYNE [0] bit = 1b and the ITS bit in Command Descriptor for issuing IBI is 1b, the SC1 and SC2 capture values are transmitted following the IBI Mandatory Byte as shown in the following figure.

If the SC1 and SC2 counters overflow, FFFFh and FFh are captured and CETSS.ICOVF is set to 1b.
The DATA_LENGTH[15:0] bits value of the Command Descriptor sets a value obtained by adding the number of data of SC1 and SC2 to the number of transmission data.

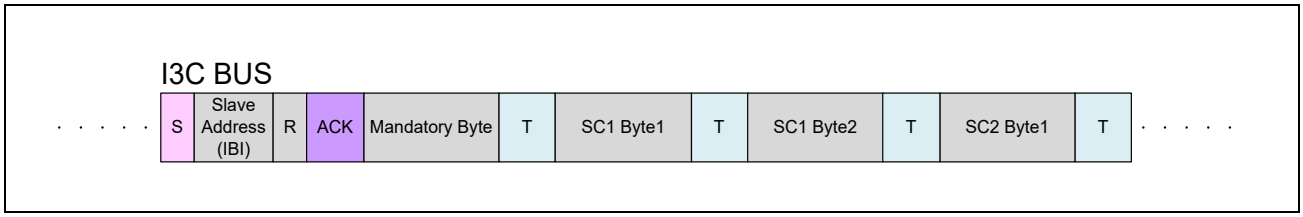

Figure 7.8-92 Example of Asynchronous Mode 0 Timestamp Data Transfer

(c) Async Mode 1 (Asynchronous Advanced Mode)
For timing control in Async Mode 1, set the ATCTL register if necessary.

1. **<I3C Master>**

I3C has counters of MREF (32bit), MSyncCNT (32bit) and MC2 (16bit) for Async Mode 1.

<MREF Counter>
When ATCCNTE.ATCE is enabled, the counter starts counting.
Its value is captured as MREF at the SCL rise edge next to ACK for the IBI transmitted from the I3C Slave.
The MREF extension method described in “1. I3C Master” of “(b) Async Mode 0” is also possible in Async Mode 1.

<MSyncCNT Counter>
When ATCCNTE.ATCE is enabled, the counter starts counting.
Its value is captured as MSyncCNT for each aME (SDA falling edge of START condition), and stored in the capture register.

<MC2 Counter>
After enabling ATCCNTE.ATCE, the counter counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and its value is captured as MC2.
The MREF and MC2 capture values are stored next to the IBI Status Descriptor when the IBI is received from the I3C Slave with the DATBASm.DVIBITS bit set to 1b. (Same as Async Mode 0)
When ATCTL.AMEOE is enabled, an aME Event (ri3c_elcamev) is issued for each aME. Use that event as a trigger to read the MSyncCNT capture value from the MRCCPT register and hold it in an external memory.

2. **<I3C Slave>**

I3C has counters of SC1 (16bit), SC2 (8bit) and aME_TICK (8bit) for Async Mode 1.

<SC1 Counter>
After enabling ATCCNTE.ATCE, the counter counts up from SC1 count trigger*1 to the first aME, and its value is captured as SC1.

<SC2 Counter>
After enabling ATCCNTE.ATCE, the counter counts up from SCL rise edge next to ACK for the IBI transmitted from I3C Slave to SCL rise edge next to Tbit after Mandatory Byte, and its value is captured as SC2.

<aME_TICK Counter>

After enabling ATCCNTE.ATCE, the counter counts every aME, and its value is captured as aME_TICK at the SCL rise edge next to ACK for the IBI.
The aME_TICK counter is cleared on the first aME after the SC1 count trigger.

When the CETSS.ASYNE[1] bit = 1b and the ITS bit in Command Descriptor for issuing IBI is 1b, the SC1, SC2 and aME_TICK capture values are transmitted following the IBI Mandatory Byte as shown in the following figure.
If the SC1 and SC2 counters overflow, FFFFh and FFh are captured and CETSS.ICOVF is set to 1b.
The DATA_LENGTH[15:0] bits value of the Command Descriptor sets a value obtained by adding the number of data of SC1, SC2 and aME_TICK to the number of transmission data.

Note 1. SW or external trigger can be selected by selection bits.
The SC1 count trigger select method described in “2. I3C Slave” of “(b) Async Mode 0” is also possible in Async Mode 1

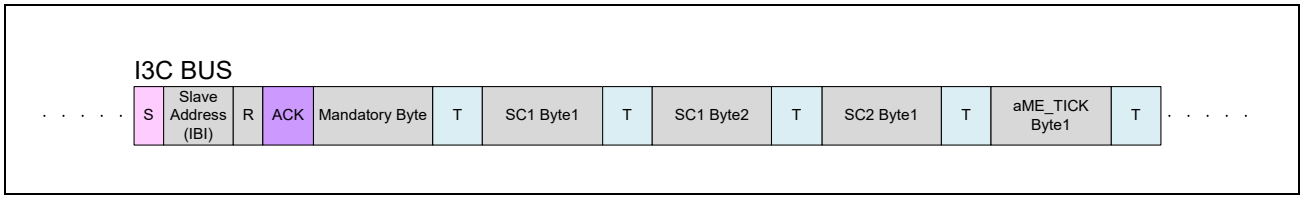

Figure 7.8-93 Example of Asynchronous Mode 1 Timestamp Data Transfer

(10) Port Control

(a) Extra SCL Clock Cycle Output Function

In master mode, I3C module has a facility for the output of extra SCL clock cycles to release the SDA line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.

This function is mainly used in master mode to release the SDA line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from I3C with single cycles of the SCL clock as the unit in the case of a bus error where I3C cannot issue a Repeated START condition or a STOP condition because the slave device is holding the SDA line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.

When the OUTCTL.EXCYC bit is set to 1b, an additional clock pulse at the frequency set by the REFCKCTL.IREFCKS[2:0] bits and the STDBR.SBRHO[7:0] and STDBR.SBRLO[7:0] registers is output from the SCL pin. After output of this clock pulse, the EXCYC bit automatically becomes 0b. After confirming that the EXCYC bit is 0, wait for the setup time of the Repeated START condition or STOP condition, and then confirm the detection of the Repeated START condition or STOP condition. If the Repeated START condition or STOP condition is not detected, consecutive additional clock pulses can be output by writing 1b to the EXCYC bit again.

When I3C module is in master mode and the slave device is holding the SDA line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a Repeated START condition or a STOP condition is not possible. The facility for output of an extra cycle of the SCL clock can be used to output extra cycles of SCL one by one to make the slave device release the SDA line from being held at the low level, thus recovering the bus from an unusable state. Release of the SDA line by the slave device can be monitored by reading the SDILV bit in PRSTDBG. After the SDA line has been released by the slave device, the preset of a Repeated START condition or a STOP condition is issued.

Use this function with the BFCTL.MALE bit set to 0b (master arbitration-lost detection is disabled).

[Output conditions for using the EXCYC bit in OUTCTL]

- When the bus is free (BFREF flag in BCST = 1b) or in master mode (CRMS bit = 1b in PRSST and BFREF flag = 0b in BCST)
- When the communication device does not hold the SCL line low

Figure 7.8-94 shows the operation timing of the extra SCL clock cycle output function (EXCYC bit).

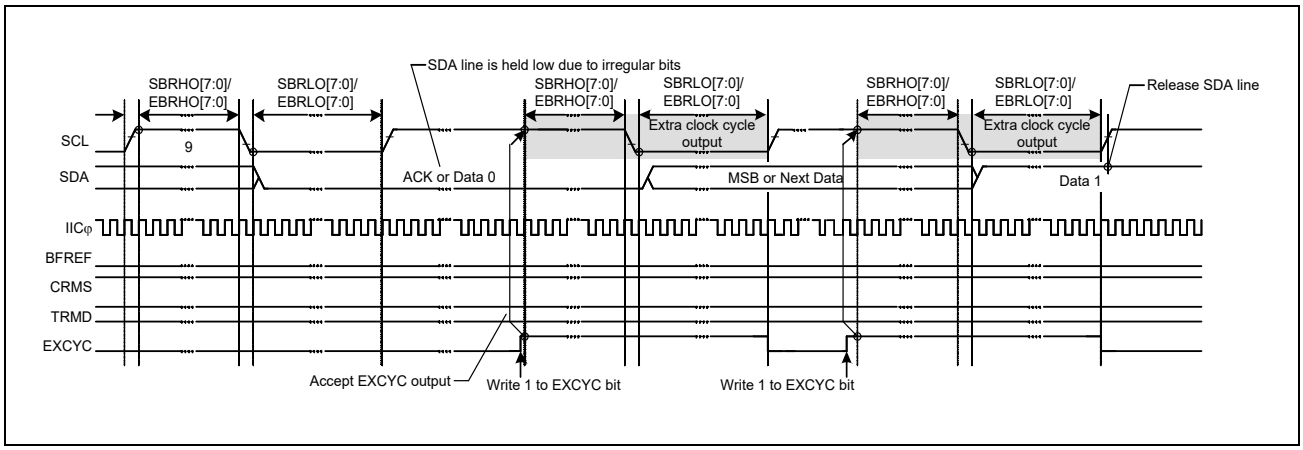

Figure 7.8-94 Extra SCL clock cycle output function (EXCYC bit)

(11) SMBus Operation [I²C mode]

I3C is available for data communication conforming to the SMBus (Version 2.0). To perform SMBus communication, set the BFCTL.SMBS bit to 1b. To use the transfer rate within a range of 10 kbps to 100 kbps of the SMBus specification, set the REFCKCTL.IREFCKS[2:0] bits, the STDBR.SBRHO[7:0] bits, and the STDBR.SBRLO[7:0] bits. In addition, determine the values of the OUTCTL.SDODCS bit and the OUTCTL.SDOD[2:0] bits to meet the data hold time specification of 300 ns or more. If I3C is used only as an I²C slave device, the transfer rate setting is not necessary, whereas the STDBR.SBRLO[7:0] bits needs to be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001b), use one of the slave device address table basic registers 0 to 2 (SDATBASn.SDSTAD[6:0] bits (n = 0 to 2)), and set the corresponding SDATBASn.SDADLS bit (7-bit/10-bit address format select) (n = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the BFCTL.SALE bit to 1b to enable the slave arbitration-lost detection function.

(a) SMBus Timeout Measurement

(a-1) Measuring timeout of slave device

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication.

- From START condition to STOP condition

To measure timeout for slave devices, measure the period from START condition detection to STOP condition detection with the GPT timer using a START condition detection interrupt (INT_ri3c_st_n) and STOP condition detection interrupt (INT_ri3c_sp_n) of I3C. The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:SEXT}$: 25 ms (max.) of the SMBus specification.

If the time measured with the GPT exceeds the clock low-level detection timeout TTIMEOUT: 25 ms (min.) of the SMBus specification, the slave device must release the bus by writing 1b to the RSTCTL.INTLRST bit to issue an internal reset of I3C. When an internal reset is issued, I3C stops driving the bus for the SCL pin and SDA pin and make the SCL/SDA pin outputs high-impedance, which releases the bus.

(a-2) Measuring timeout of master device

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication.

- From START condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to STOP condition

To measure timeout for master devices, measure these periods with the GPT timer using a START condition detection interrupt (INT_ri3c_st_n), STOP condition detection interrupt (INT_ri3c_sp_n), and transmit end interrupt (I3Cn_TEND) or receive data buffer full interrupt (INT_ri3c_rx_n) of I3C. The measured timeout period must be within the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification, and the total of all $T_{LOW:MEXT}$ from START condition to STOP condition must be within $T_{LOW:SEXT}$: 25 ms (max.).

For the ACK receive timing (rising edge of the ninth SCL clock cycle), monitor the BST.TENDF flag in master transmit mode (master transmitter) and the NTST.RDBFF0 flag in master receive mode (master receiver). For this reason, perform bytewise transmit operation in master transmit mode, and hold the SCSTRCTL.ACKTWE bit 0 until the byte just before reception of the final byte in master receive mode. While the ACKTWE bit = 0b, the RDBFF0 flag is set to 1b at the rising edge of the ninth SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (max.) of the SMBus specification or the total of measured periods exceeds the clock low-level detection timeout

TTIMEOUT: 25 ms (min.) of the SMBus specification, the master device must stop the transaction by issuing a STOP condition. In master transmit mode, immediately stop the transmit operation (writing data to NTDTBP0).

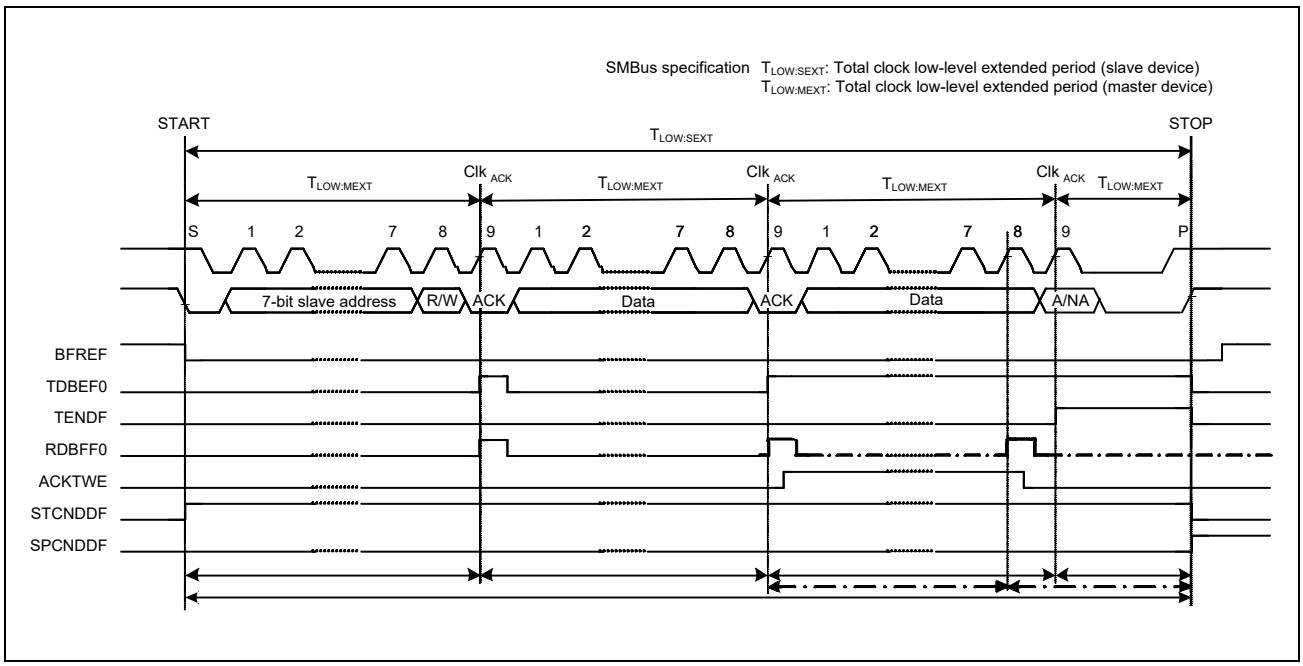

Figure 7.8-95 SMBus timeout measurement

(b) Packet Error Code (PEC)

This product incorporates a CRC calculator. The CRC calculator enables transmission of a packet error code (PEC) or checking the received data of the SMBus in data communication of I3C. For the CRC generating polynomials of the CRC calculator, see **7.6 CRC Operation Unit (CRC)**.

The PEC data in master transmit mode can be generated by writing all transmit data to the CRC data input register (CRCDIR) in the CRC calculator.

The PEC data in master receive mode can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC data output register (CRCDOR) with the received PEC data.

To send ACK or NACK according to the match or mismatch result when the final byte is received as a result of the PEC code check, set the SCSTRCTL.ACKTWE bit to 1 before the rising edge of the eighth SCL clock cycle during reception of the final byte, and hold the SCL line low at the falling edge of the eighth clock cycle.

(c) SMBus Host Notification Protocol (Notify ARP Master Command)

In communications over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address or to request its own slave address from the SMBus host.

For this product to operate as an SMBus host (or ARP master), the host address (0001 000b) sent from the slave device must be detected as a slave address, so I3C has a function for detecting the host address. To detect the host address as a slave address, set the BFCTL.SMBS bit and the SVCTL.HOAE bit to 1b. Operation after the host address has been detected is the same as normal slave operation.

(12) Common Command Codes (CCC) [I3C mode]

For the common command code (CCC), refer to *5.1.9 Common Command Codes (CCC)* in *MIPI I3C Specification v1.0*. This I3C is based on *Table 15 I3C Common Command Codes* in *5.1.9.3 Common Command Definitions* of *MIPI I3C Specification v1.0*.

The MIPI Reserved area and Vendor Extension area of Command Code are described below.

- I3C Master mode:
  When sending CCCs in the MIPI Reserved area and Vendor Extension area from the I3C Master, only Broadcast/Direct SET CCCs using the Immediate Transfer Command can be sent.
  Sending Direct GET CCC is not supported.
- I3C Slave mode:
  Only Broadcast/Direct SET CCC can be received for CCC in MIPI Reserved area and Vendor Extension area.
  Receiving Direct GET CCC is not supported.

7.8.4.2.4 Error Detection

(1) SDR Error Detection and Recovery Methods for I3C Slave Devices [I3C mode]

The seven error types summarized in **Table 7.8-14** are supported for all I3C slave devices. Each error type is further explained below the table.

Table 7.8-14 SDR slave error types

Error type	Description	Error detection method
S0	Broadcast address/W (= 7Eh/W) or Dynamic address/RW	Detect any of the following: 3Eh/W 5Eh/W 6Eh/W 76h/W 7Ah/W 7Ch/W 7Fh/W 7Eh/R
S1	CCC code	Parity check, using T-Bit
S2	Write data	Parity check, using T-Bit
S3	Assigned address during Dynamic address arbitration	Parity check, using PAR Bit
S4	7Eh/R after Sr during Dynamic address arbitration	Detect any value other than 7Eh/R after Sr during Dynamic Address Arbitration
S5	Transaction after detecting CCC	Detect illegally formatted CCC
S6 (optional)	Monitoring error	Slave detects (through monitoring) that transmitted Data differs from what it intended to transmit (Does not apply during Dynamic address arbitration)

(2) SDR Error Detection and Recovery Methods for I3C Master Devices [I3C mode]

The two error types summarized in **Table 7.8-15** are supported for all I3C master devices. Each error type is further explained below the table.

Table 7.8-15 SDR master error types

Error type	Description	Error detection method
M0	Transaction after sending CCC	Detect illegally formatted CCC
M1 (optional)	Monitoring error	Master detects (through monitoring) transmitted data different from what it intended to transmit (Does not apply during Dynamic address arbitration)
M2	No response to Broadcast address (7Eh)	Master detects NACK after Broadcast address (7Eh) transmission

(3) Timeout Error Detection

I3C includes a timeout function for detecting when the SCL line has been stuck longer than the predetermined time. I3C can detect an abnormal bus state by monitoring that the SCL line is stuck low or high for a predetermined time.

The timeout function monitors the SCL line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCL line changes (rising or falling), but continues to count unless the SCL line changes. If the internal counter overflows due to no SCL line change, I3C can detect the timeout and report the bus hung state.

This timeout function is enabled when BSTE.TODE = 1b. It detects a hung state that the SCL line is stuck low or high during the following conditions: (When TMOCTL.TOMDS[1:0] = 00b)

- The bus is busy (BCST.BFREF = 0b) in master mode (PRSST.CRMS = 1b).
- I3C's own slave address is detected (SVST register is not 0000h) and the bus is busy (BCST.BFREF = 0b) in slave mode (PRSST.CRMS = 0b).
- The bus is free (BCST.BFREF = 1b) while generation of a START condition is requested (CNDCTL.STCND = 1b).

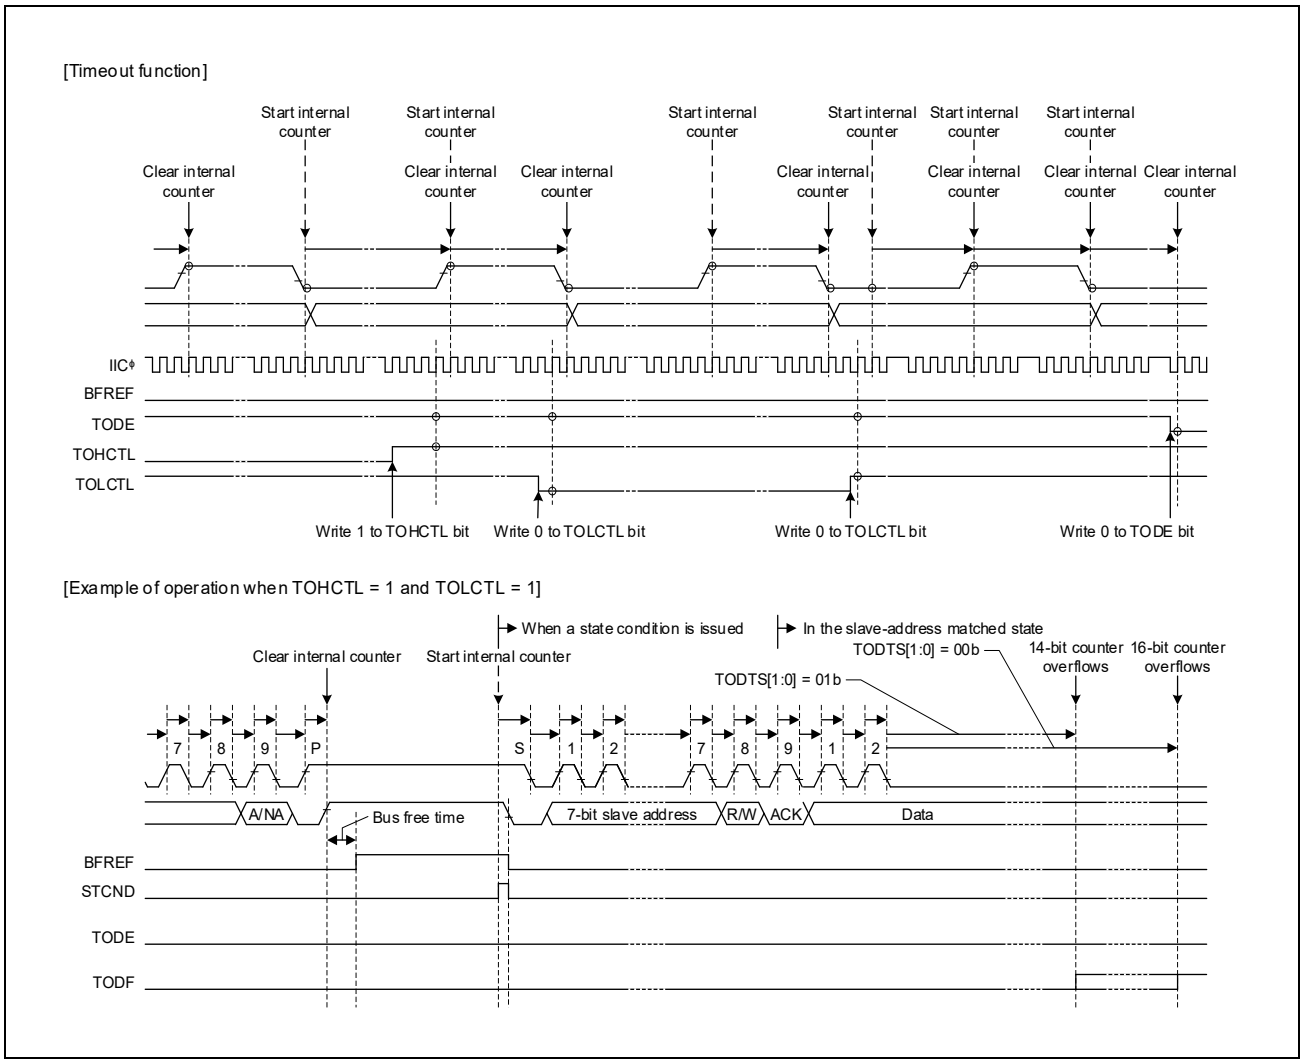

Figure 7.8-96 Timeout error detection (TODE, TODTS[1:0], TOHCTL, and TOLCTL bits)

(4) Resume Operation [I3C mode]

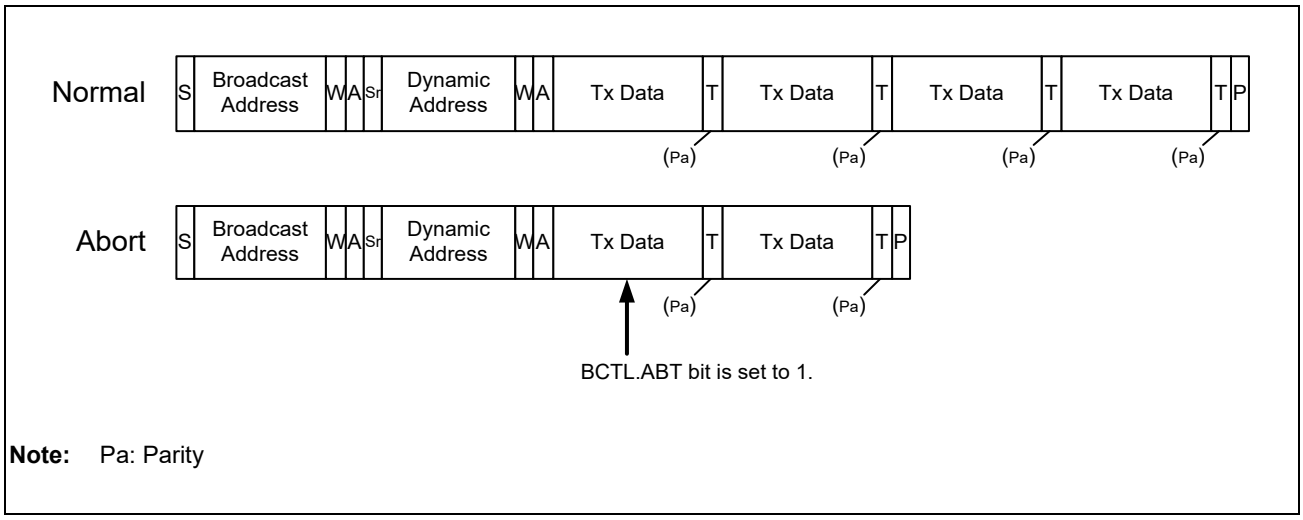
I3C enters the Halt state as a result of any type of error occurring in a transfer.

The error type is indicated by the field ERR_STATUS in Response Descriptor or Receive Status Descriptor. After I3C has entered the Halt state, the user must write the value 1 to the RSM bit to resume operation. I3C shall auto-clear the RSM bit once it has initiated the next Command transfer or detected the START condition.

(5) Abort Operation [I3C mode]

When the BCTL.ABT bit is set to 1b, I3C relinquish control of the bus before completing the currently issued transfer. In response to an abort request, I3C issues the STOP condition on the bus after the complete data byte is transferred or received. After I3C has aborted, the user shall clear the BCTL.ABT bit to allow operation on the bus.

Remark For Read transaction, when BCTL.ABT is set to 1b, that receive data is stored in Receive data buffer.



Note: Pa: Parity

Figure 7.8-97 Abort operation of SDR write transfer

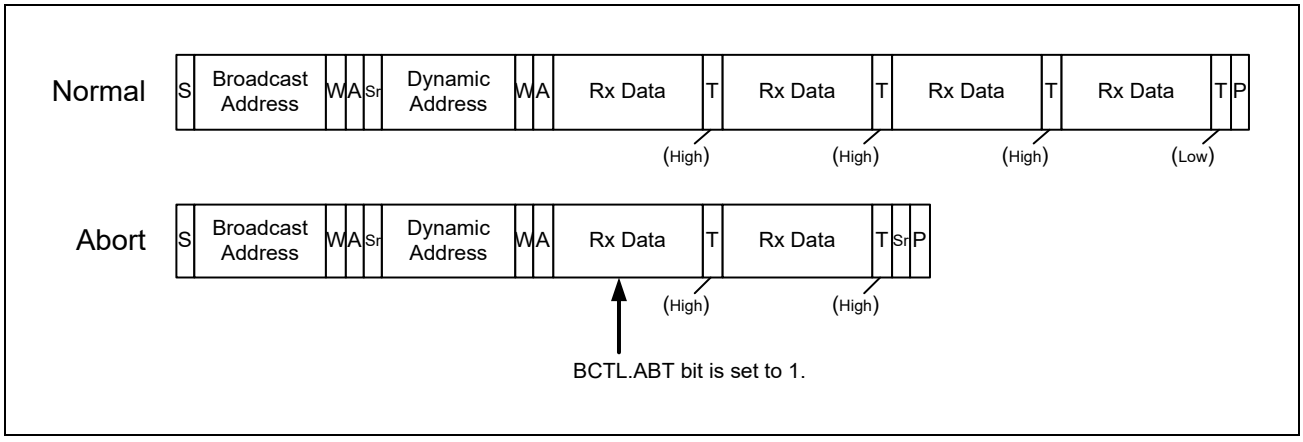


Figure 7.8-98 Abort operation of SDR read transfer

(6) Error Recovery Operation [I3C mode]

(a) Error Recovery Operation

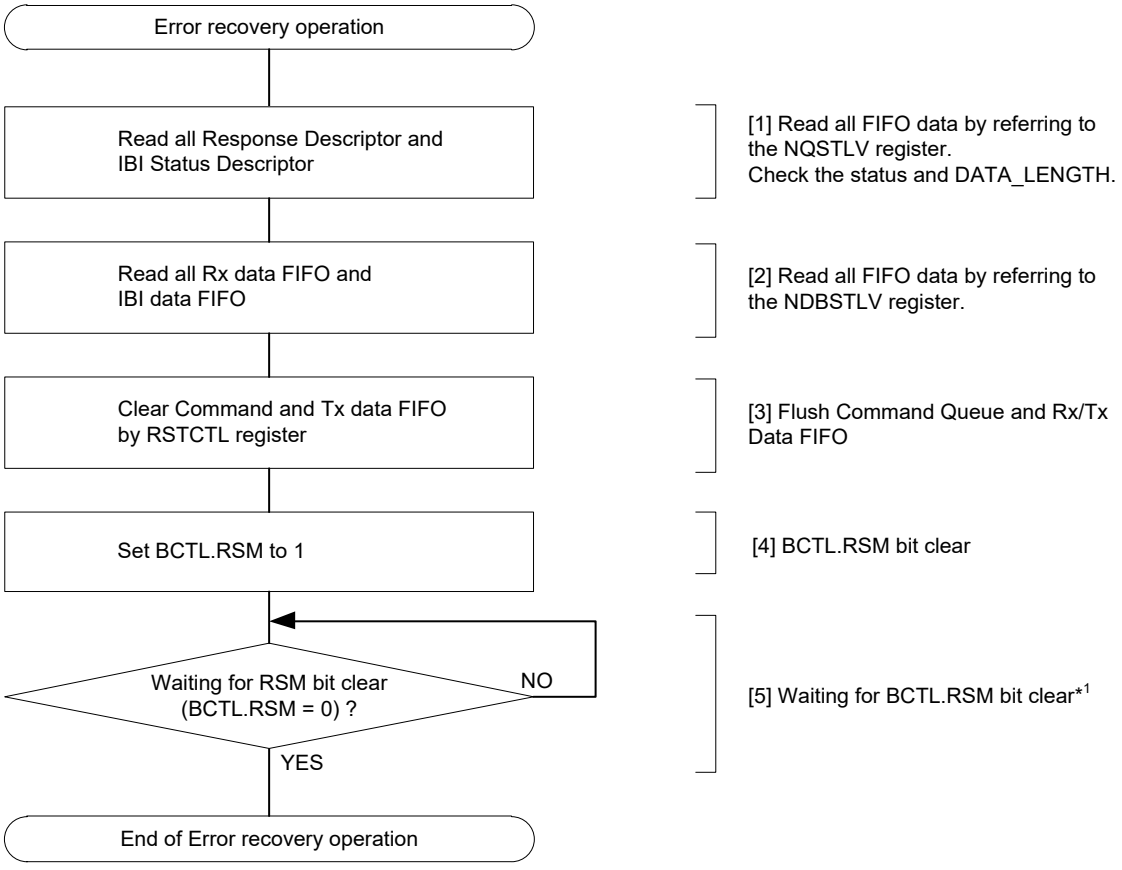
When an error occurs, the flags of INST.INEF, NTST.TEF, NTST.TABTF, HTST.TEF and HTST.TABTF are set to 1b according to the cause of the error.

Or the interrupts INT_ri3c_ierr_n, INT_ri3c_terr_n and INT_ri3c_abort_n associated with each flags are asserted. (When detection and interrupts are enabled.)

There is a possibility of communication error or I3C internal error.

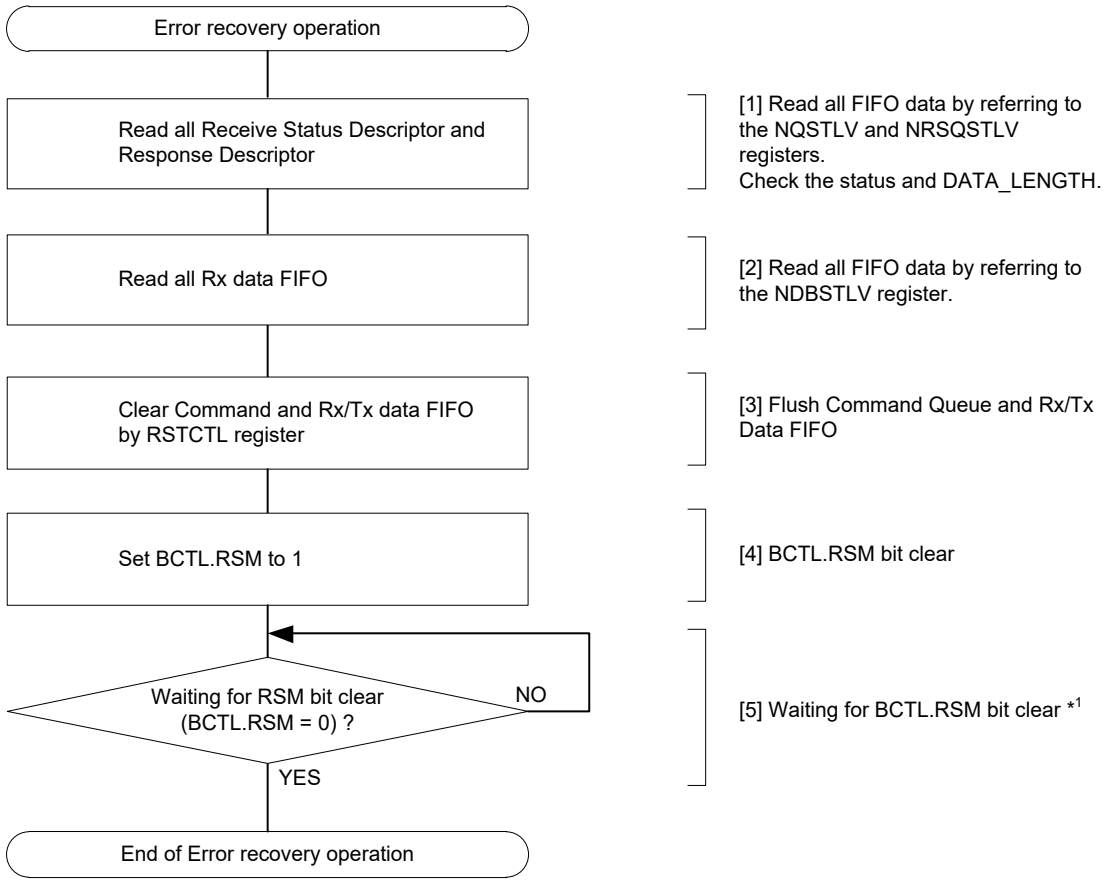
If an error occurs, I3C will be suspended. (BCTL.RSM becomes 1b.) After I3C is suspended, the application must write the value 1 to the BCTL.RSM bit to resume I3C operation and recover from the suspended state.

The error recovery flow is shown in **Figure 7.8-99** and **Figure 7.8-100**.



Note 1. The Command Descriptor can be written to the Command Queue via writing to the Command Queue Port (NCMDQP) before the RSM bit is cleared.

Figure 7.8-99 Example of Error Recovery Operation Flowchart for I3C Master



Note 1. The Command Descriptor for issuing IBI can be written to the Command Queue via writing to the Command Queue Port (NCMDQP) before the RSM bit is cleared.

Figure 7.8-100 Example of Error Recovery Operation Flowchart for I3C Slave

When I3C Slave recovers from an error according to the error recovery flow, after setting BCTL.RSM to 1b, BCTL.RSM becomes 0b after detecting a state in which Bus Available period communication is not performed on I3C Bus.

If communication occurs on the I3C bus within the Bus Available period, BCTL.RSM will not be set to 0b and error recovery will not be completed, and a NACK response will be transmitted.

(b) Master Error Detection and Escalation Handling

If the Master does not receive an ACK of a transmitted private Message to a Slave and Steps 1 and 2 described in Chapter 5.1.10.2.4 of MIPI I3C Spec v1.0 fail, the processing flow of Step 3 shown in **Figure 7.8-101** and **Figure 7.8-102** is followed.

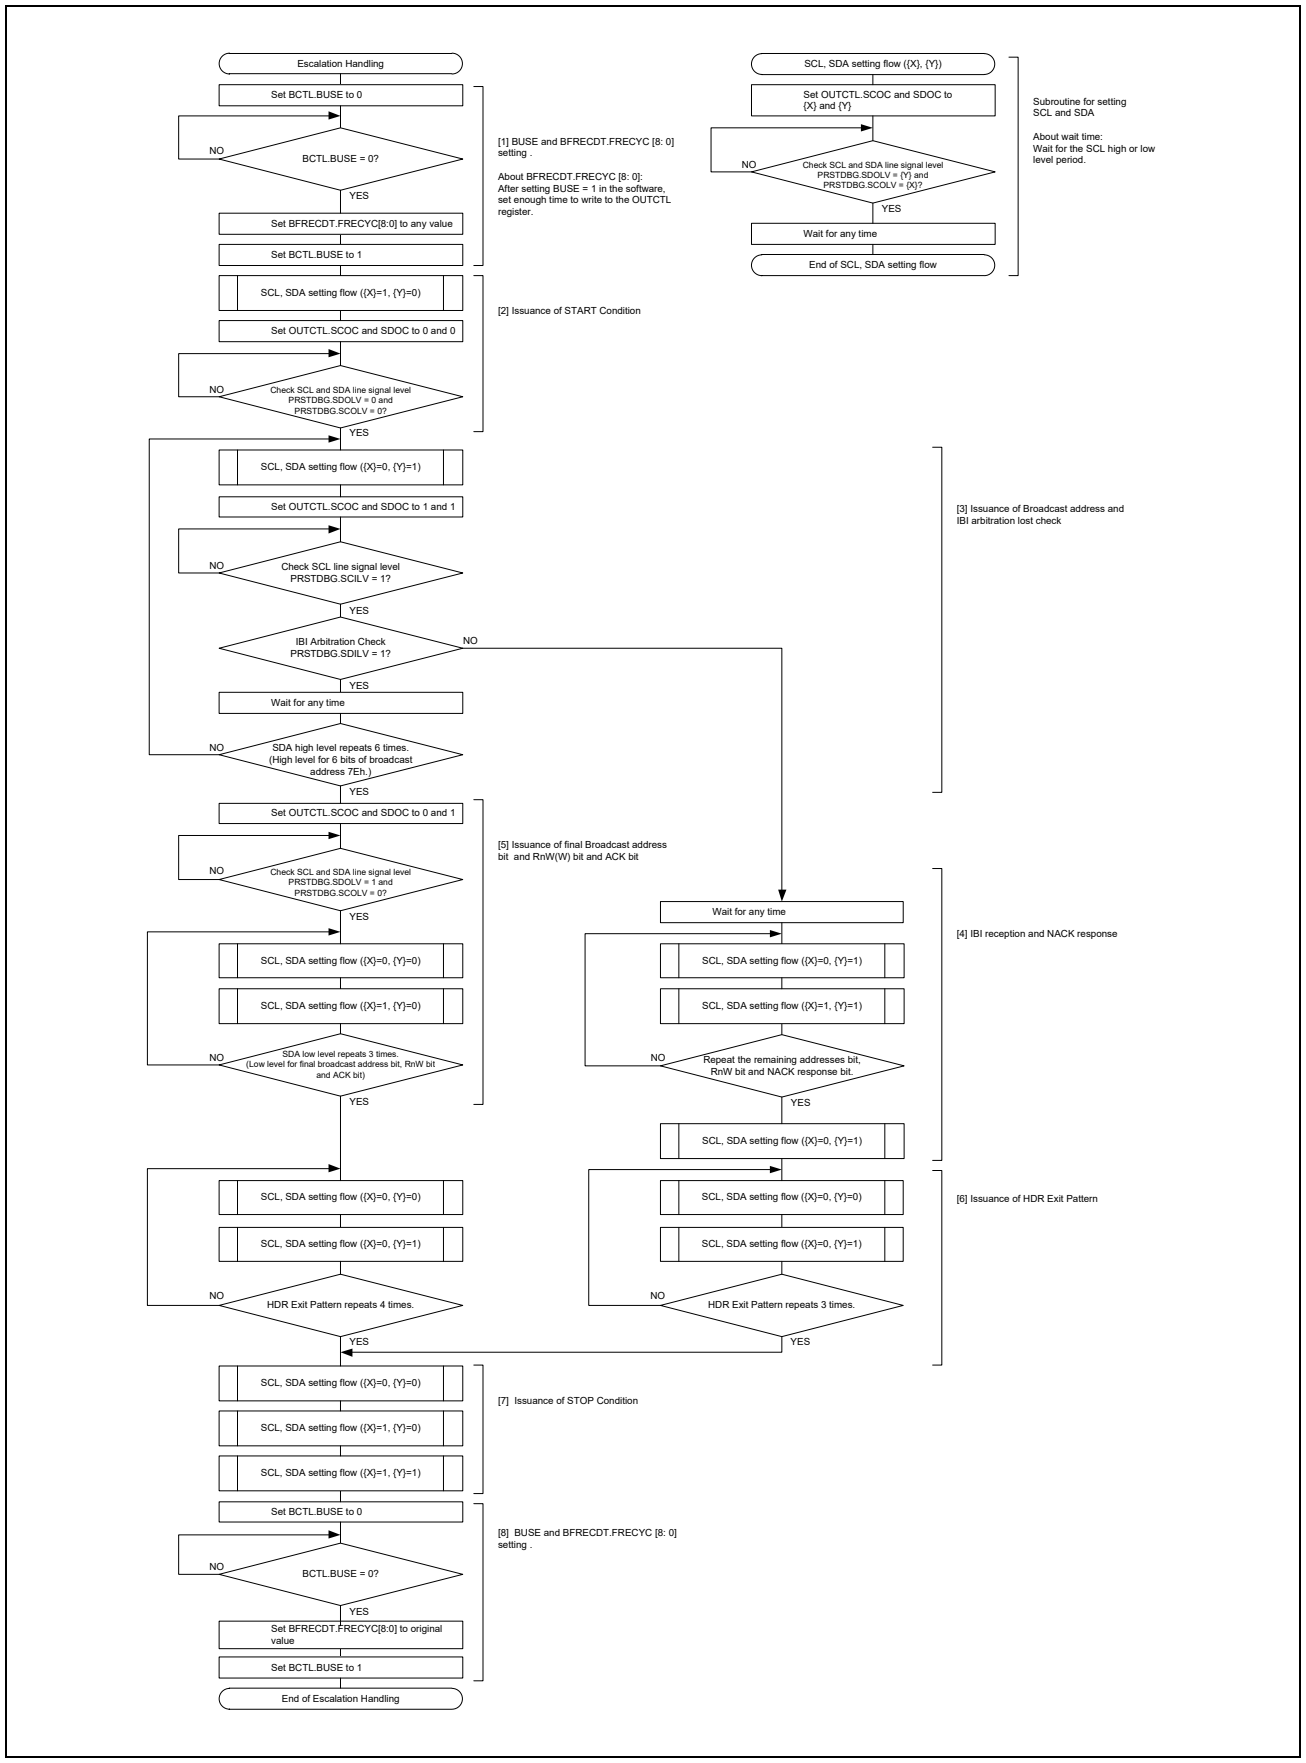


Figure 7.8-101 Escalation Handling Flowchart for I3C Master

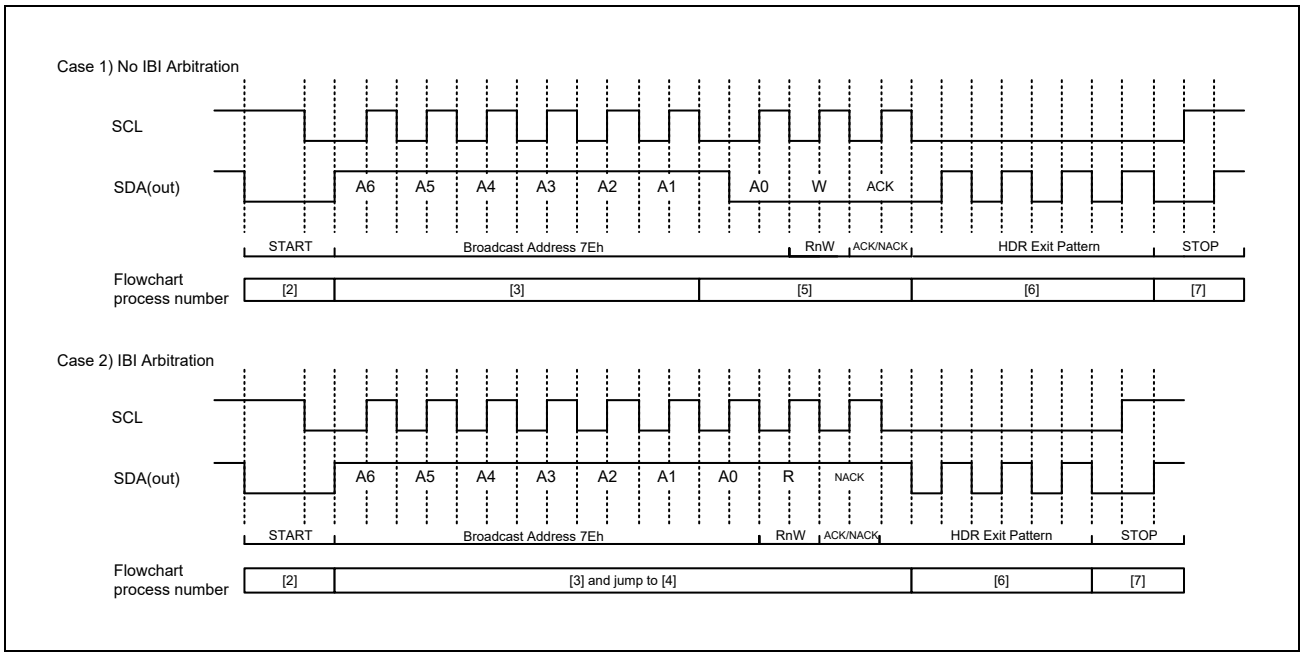

Figure 7.8-102 Escalation Handling timing chart for I3C Master

7.8.4.2.5 Low Power Function [I²C/I3C common]

(1) Wake-Up Function [I²C mode]

This module is equipped with the Wake-up function that causes the microcomputer to transition from low power consumption mode with system clock is stopped (software standby mode, snooze, etc.) to the normal operation. The Wake-up function is used to generate a Wake-Up interrupt signal when the received data matches the address set to Wake-Up interrupt factor also receives data in a state where the operating clock (I3C_0_PCLK/I3C_0_TCLK) is stopped (I3C_0_PCLK/I3C_0_TCLK asynchronous operation). This wake-up interrupt signal causes the microcomputer to transition to the normal operation. After Wake-Up interrupt occurs, switch I3C to I3C_0_PCLK/I3C_0_TCLK synchronous operation, it will be able to continue the communication operation.

The Wake-up function has four wake-up operation modes (normal WU mode 1, normal WU mode 2, command recovery mode, and EEP response mode). The table below describes the behavior in these four wake-up operation modes.

Table 7.8-16 Wake-Up Operation Mode

Mode	ACK Response Timing	ACK Type Responded before Recovery to I3C_0_PCLK/I3C_0_TCLK synchronous operation	SCL State before Recovery to I3C_0_PCLK/I3C_0_TCLK synchronous operation
Normal WU mode 1	Before recovery to I3C_0_PCLK/I3C_0_TCLK synchronous operation*1	ACK	Fixed to “L”
Normal WU mode 2	After recovery to I3C_0_PCLK/I3C_0_TCLK synchronous operation*2	Before recovery: no response (NACK level retained) After recovery: ACK response	Fixed to “L”
Command recovery mode	Before recovery to I3C_0_PCLK/I3C_0_TCLK synchronous operation*1	ACK	Open
EEP response mode	Before recovery to I3C_0_PCLK/I3C_0_TCLK synchronous operation*1	NACK	Open

Note 1. Switching timing from I3C_0_PCLK/I3C_0_TCLK asynchronous operation to I3C_0_PCLK/I3C_0_TCLK Synchronous operation is the fall of the 9th clock of SCL.

Note 2. Switching timing from I3C_0_PCLK/I3C_0_TCLK asynchronous operation to I3C_0_PCLK/I3C_0_TCLK Synchronous operation is the fall of the 8th clock of SCL.

The following can be selected as Wake-Up interrupt factor.

- Host address detection (valid when SVCTL.HOAE=1b)
- General call address detection (valid when SVCTL.GCAE=1b)
- Slave address 0*1 detection (valid when SVCTL.SVAE0=1b)
- Slave address 1*1 detection (valid when SVCTL.SVAE1=1b)
- Slave address 2*1 detection (valid when SVCTL.SVAE2=1b)

Note 1. Only 7-bit address can be set. Please set SDADLS bit to “0b” in SDATBASn.

(a) Normal Wake-Up mode 1

This section describes the behavior, the timing, and a use case of normal WU mode 1.

1. A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below.

   <Before Wake-Up recovery>
   ACK is sent in response to the data received with its own slave address.

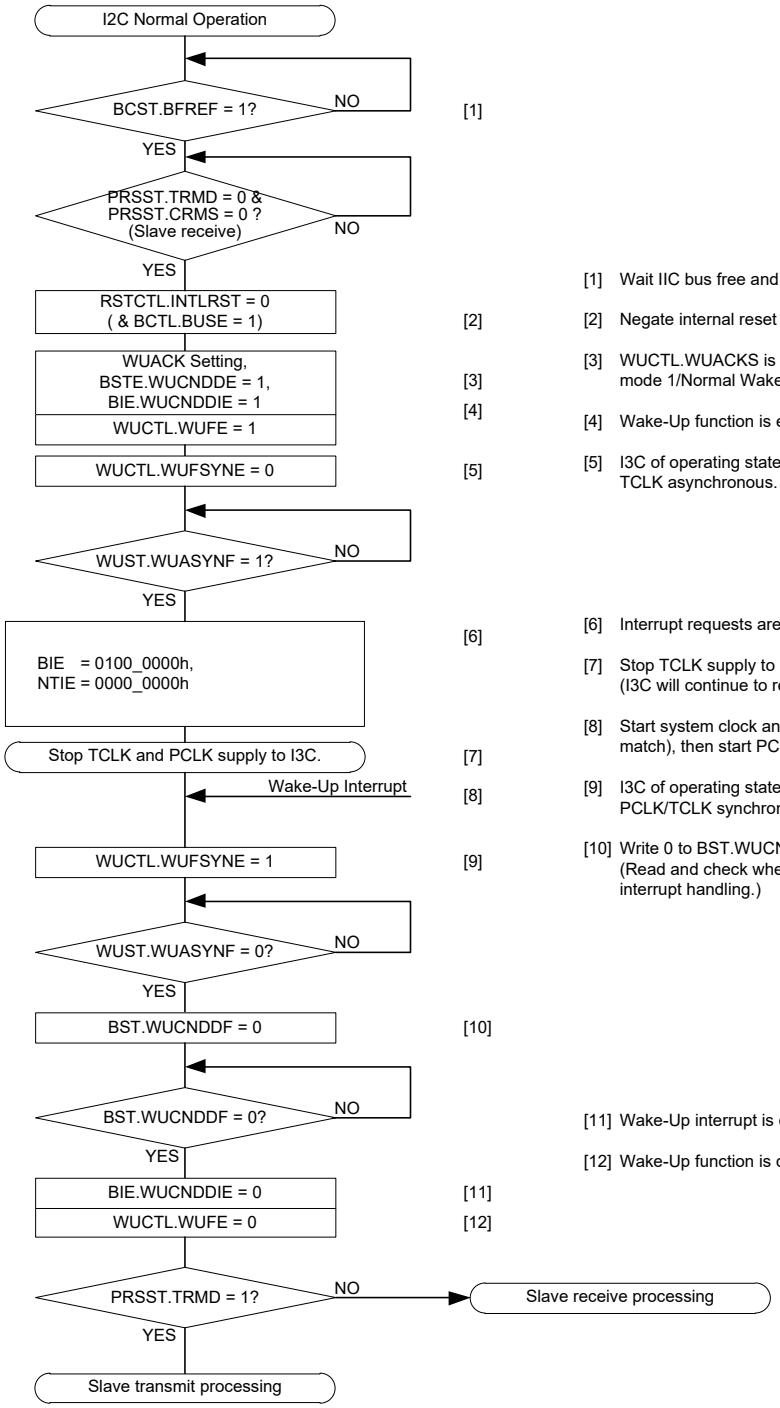
   <During Wake-Up recovery>
   ACK response is made at the 9th clock cycle of SCL, and the SCL is held low afterwards.*[1]

   <After Wake-Up recovery>
   Normal operation continues.

   If the slave address does not match, the SCL line is not held low after the fall of the 9th clock cycle of SCL, and the slave operation continues. See **Figure 7.8-103** below for a use case.

2. A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to **Figure 7.8-104**.

Note 1. Between ninth clock cycle and first clock cycle during Wake-Up recovery, SCSTRCTL.RWE=1 does not work.



[1] Wait IIC bus free and I3C stay in the standby state.

[2] Negate internal reset if assert the internal reset.

[3] WUCTL.WUACKS is set up according to each mode. (Normal Wake-Up mode 1/Normal Wake-Up mode 2) Wake-Up Interrupt is enabled.

[4] Wake-Up function is enabled.

[5] I3C of operating state is changed from PCLK/TCLK synchronous to PCLK/TCLK asynchronous.

[6] Interrupt requests are disabled except WUI.

[7] Stop TCLK supply to I3C, then stop PCLK supply to I3C. (I3C will continue to receive)

[8] Start system clock and TCLK supply to I3C by Wake-Up interrupt (address match), then start PCLK supply to I3C.

[9] I3C of operating state is changed from PCLK/TCLK asynchronous to PCLK/TCLK synchronous.

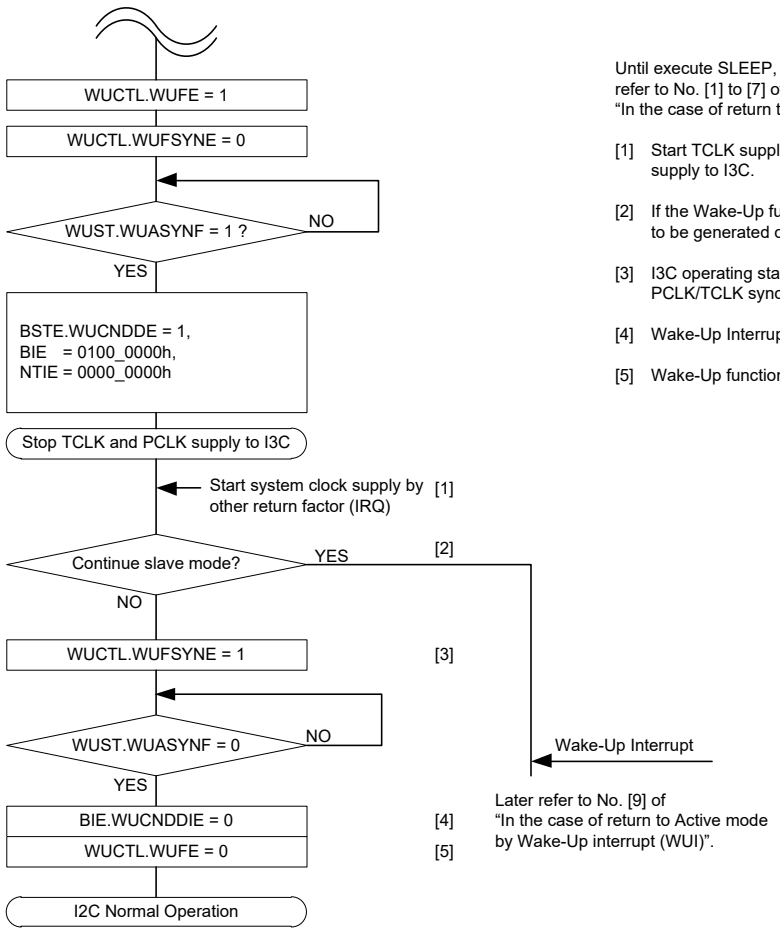
[10] Write 0 to BST.WUCNDDF.
(Read and check whether clearing has been completed befor return from interrupt handling.)

[11] Wake-Up interrupt is disabled.

[12] Wake-Up function is disabled.

Note: TCLK = I3C_0_TCLK
PCLK = I3C_0_PCLK

Figure 7.8-103 Use Case of Normal WU Mode 1 (Wake-up recovery by a wake-up interrupt triggered by the match of the slave address)



Until execute SLEEP, it is the same method,
refer to No. [1] to [7] of
“In the case of return to Active mode by Wake-Up interrupt (WUI)”.

[1] Start TCLK supply to I3C by other return factor (IRQ), then start PCLK supply to I3C.

[2] If the Wake-Up function is used continuously by the slave mode, wait to be generated of the Wake-Up interrupt request.

[3] I3C operating state is changed from PCLK/TCLK asynchronous to PCLK/TCLK synchronous.

[4] Wake-Up Interrupt is disabled.

[5] Wake-Up function is disabled.

Note: TCLK = I3C_0_TCLK
PCLK = I3C_0_PCLK

Figure 7.8-104 Use Case of Normal WU Modes 1 and 2 (Wake-up recovery by other recovery causes (IRQ))

(b) Normal Wake Up Mode2

This section describes the behavior, the timing, and a use case of normal WU mode 2.

1. A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below.

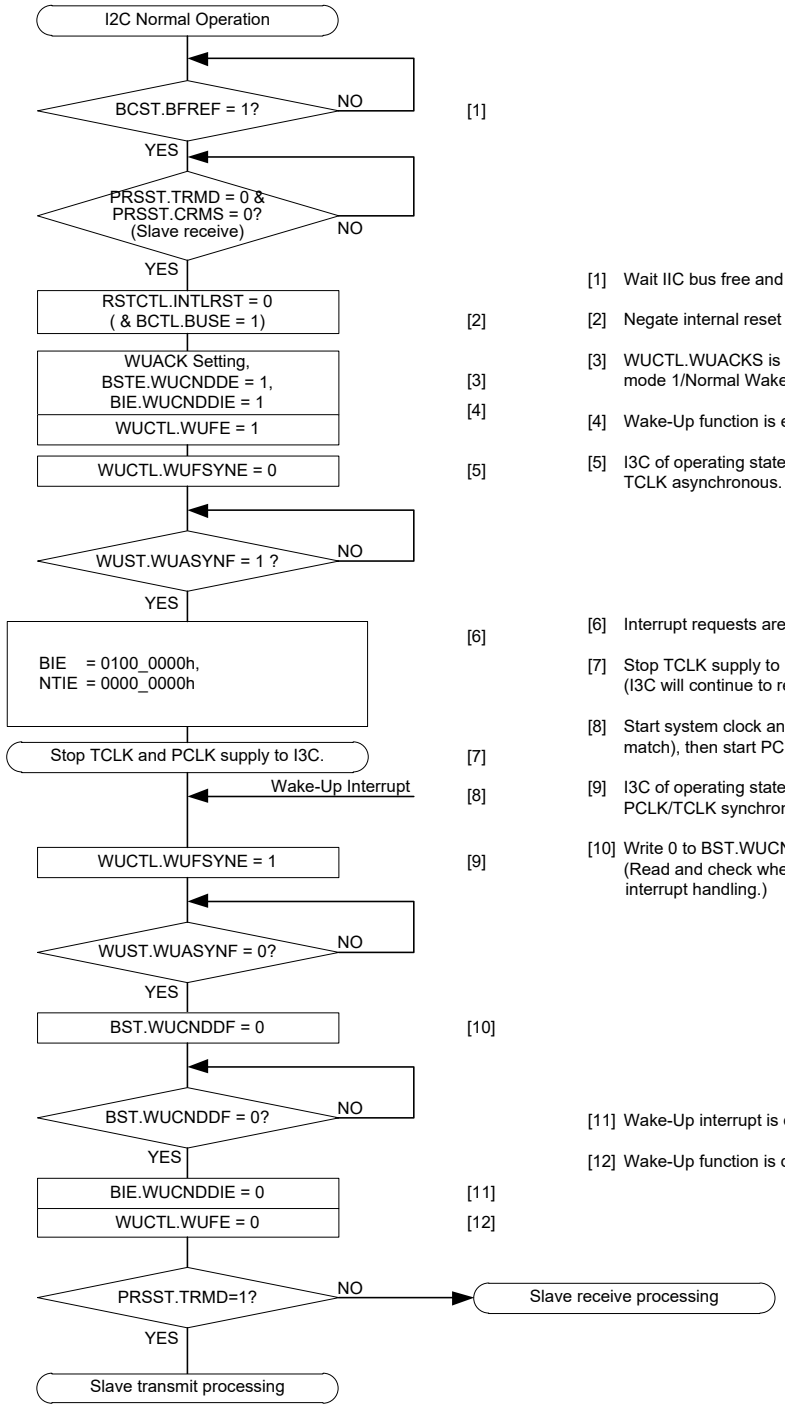
   <Before Wake-Up recovery>
   No response to the data received with its own slave address (until 8th SCL cycle end)

   <During Wake-Up recovery>
   Holding the SCL line low during the 8th and 9th clock cycles

   <After Wake-Up recovery>
   Returning ACK at the 9th clock cycle of SCL, and continuing the normal operation

   If the slave address does not match, the SCL line is not held low after the fall of the 8th SCL clock cycle. The slave operation continues. See **Figure 7.8-105** below for a use case.

2. A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to **Figure 7.8-104**.



[1] Wait IIC bus free and I3C stay in the standby state.

[2] Negate internal reset if assert the internal reset.

[3] WUCTL.WUACKS is set up according to each mode. (Normal Wake-Up mode 1/Normal Wake-Up mode 2) Wake-Up Interrupt is enabled.

[4] Wake-Up function is enabled.

[5] I3C of operating state is changed from PCLK/TCLK synchronous to PCLK/TCLK asynchronous.

[6] Interrupt requests are disabled except WUI.

[7] Stop TCLK supply to I3C, then stop PCLK supply to I3C. (I3C will continue to receive)

[8] Start system clock and TCLK supply to I3C by Wake-Up interrupt (address match), then start PCLK supply to I3C.

[9] I3C of operating state is changed from PCLK/TCLK asynchronous to PCLK/TCLK synchronous.

[10] Write 0 to BST.WUCNDDF. (Read and check whether clearing has been completed befor return from interrupt handling.)

[11] Wake-Up interrupt is disabled.

[12] Wake-Up function is disabled.

Note: TCLK = I3C_0_TCLK
PCLK = I3C_0_PCLK

Figure 7.8-105 Use Case of Normal WU Mode 2 (Wake-up recovery by a wake-up interrupt triggered by the match of the slave address)

(c) Command recovery mode/ EEP response mode (Special Wake Up mode)

In the command recovery mode and EEP response mode, the SCL line is not held low during the wake-up recovery period (after the rise of the 9th clock cycle of SCL), so other I^2C/I3C devices can use the I^2C bus during this period. This section describes the behavior, the timing, and use cases of the command recovery mode and the EEP response mode.

1. A wake-up interrupt triggered by the match of the slave address makes the transition to the normal operation in the manner described below.

   <Before Wake-Up recovery>
   In response to the data received with its own slave address, ACK (command recovery mode) or NACK (EEP response mode) is returned.

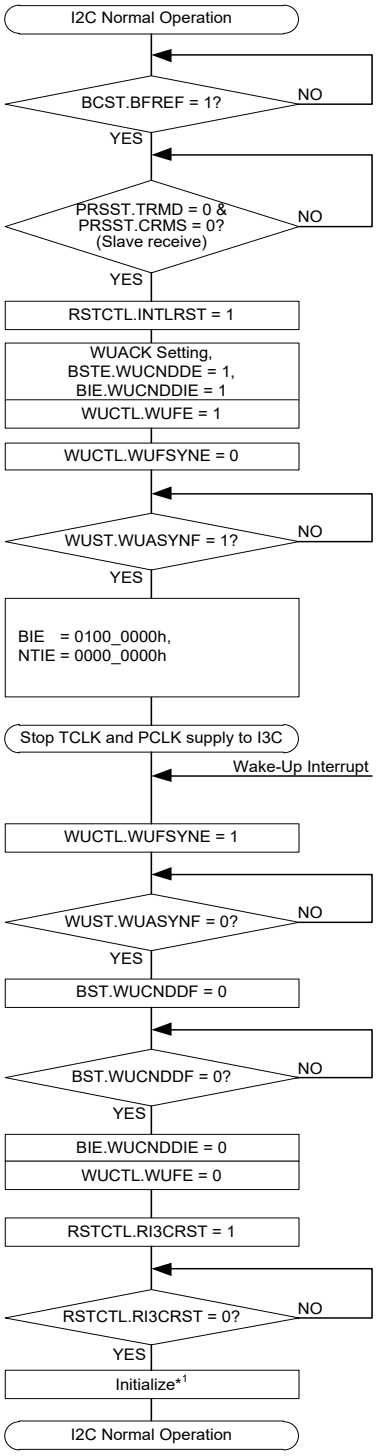
   <During Wake-Up recovery>
   The SCL line is not held low.

   <After Wake-Up recovery>
   Normal operation continues after I3C initial setting. If the slave address does not match, the slave operation continues. See **Figure 7.8-106** below for a use case.

Remark 1. Because the SCL line is not held low during wake-up recovery, the transmission/reception of the data that follows the slave address is not possible.

Remark 2. The command recovery mode and the EEP response mode are internal reset (RSTCTL.INTLRST= 1b) states. Therefore, the match of the slave address does not set the SVST flags (HOAF, GCAF, and SVAF2, SVAF1, SVAF0).

2. A wake-up interrupt is not generated at the transition to the normal operation if the transition is triggered by a cause (other recovery causes (IRQ)) other than a wake-up interrupt signal generated by a slave address match. BST.WUCNDDF is not set in this case. Carry out the following processing according to **Figure 7.8-107**.



[1] Waite IIC bus free and I3C stay in the standby state.

[2] Assert the internal reset.

[3] WUCTL.WUACKS is set up according to each mode. (Command return mode/EEP response mode) Wake-Up Interrupt is enabled.

[4] Wake-Up function is enabled.

[5] I3C of operating state is changed from PCLK/TCLK synchronous to PCLK/TCLK asynchronous.

[6] Interrupt requests are disabled except WUI.

[7] Stop TCLK supply to I3C, then stop PCLK supply to I3C. (I3C will continue to receive)

[8] Start system clock and TCLK supply to I3C by Wake-Up interrupt (address match), then start PCLK supply to I3C.

[9] I3C of operating state is changed from PCLK/TCLK asynchronous to PCLK/TCLK synchronous.

[10] Write 0 to BST.WUCNDDF. (Read and check whether clearing has been completed befor return from interrupt handling.)

[11] Wake-Up interrupt is disabled.

[12] Wake-Up function is disabled.

[13] I3C software reset.

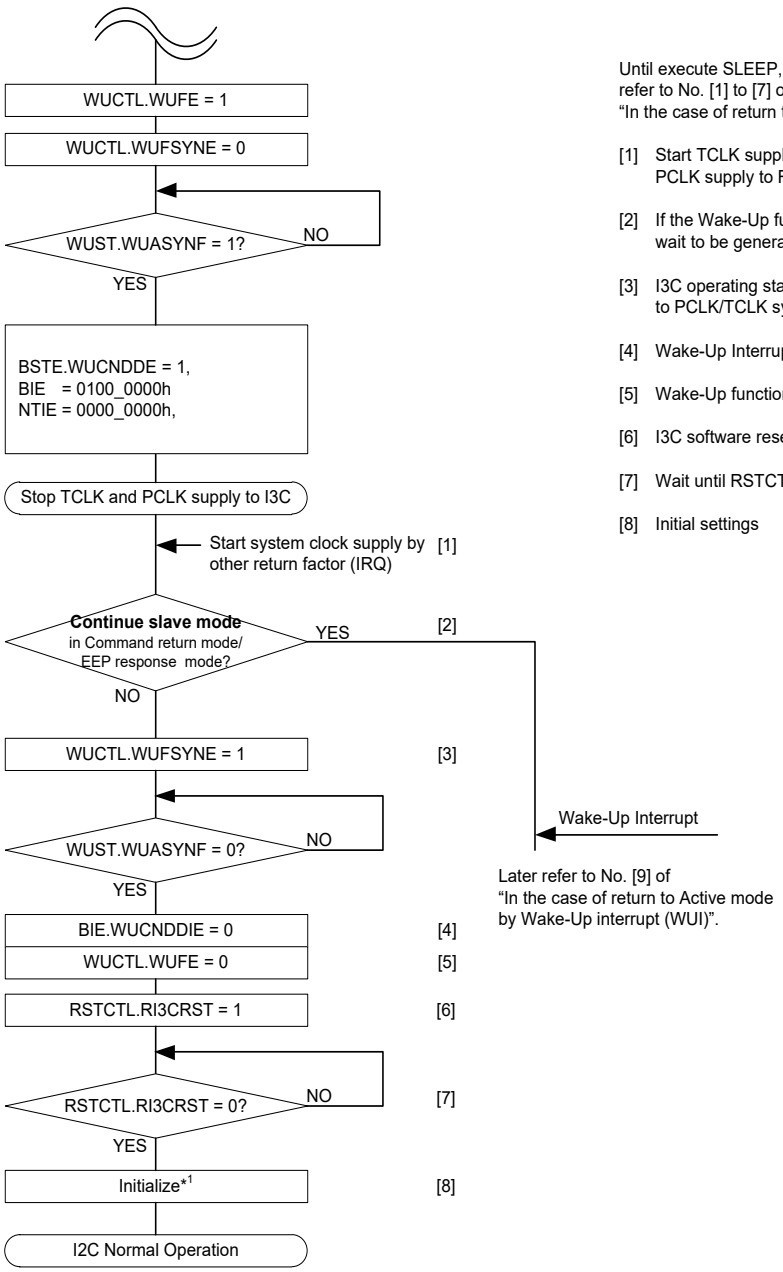
[14] Wait until RSTCTL.RI3CRST becomes 0.

[15] Initial settings

Note: TCLK = I3C_0_TCLK
PCLK = I3C_0_PCLK

Note 1. Refer to **7.8.4.3.1 Initial Setting Flow** for details of initialization.

Figure 7.8-106 Use Case of Command Recover Mode and EEP Response Mode (Wake-up recovery by a wake-up interrupt triggered by the match of the slave address)



Until execute SLEEP, it is the same method,
refer to No. [1] to [7] of
"In the case of return to Active mode by Wake-Up interrupt (WUI)".

[1] Start TCLK supply to I3C by other return factor (IRQ), then start PCLK supply to R-I3C.

[2] If the Wake-Up function is used continuously by the slave mode, wait to be generated of the Wake-Up interrupt request.

[3] I3C operating state is changed from PCLK/TCLK asynchronous to PCLK/TCLK synchronous.

[4] Wake-Up Interrupt is disabled.

[5] Wake-Up function is disabled.

[6] I3C software reset.

[7] Wait until RSTCTL.RI3CRST becomes 0.

[8] Initial settings

Note: TCLK = I3C_0_TCLK
PCLK = I3C_0_PCLK

Note 1. Refer to **7.8.4.3.1 Initial Setting Flow** for details of initialization.

Figure 7.8-107 Use Case of Command Recover Mode and EEP Response Mode (Wake-up recovery by other recovery causes (IRQ))

(d) Precautions on the use of the Wake-Up function.

Precautions on the use of the Wake-Up function are shown below.

1. Do not change the registers in the I3C except the WUCTL.WUFSYNE bit while the WUST.WUASYNF flag = 1b (during I3C_0_PCLK/I3C_0_TCLK asynchronous operation).
2. Set WUCTL.WUFE = BSTE.WUCNDDE = BIE.WUCNDDIE = 1b and PRSST.CRMS = PRSST.TRMD = 0b (slave reception mode) before switching I3C_0_PCLK/I3C_0_TCLK asynchronous mode.
3. You cannot select the device ID and the 10-bit slave address for Wake-Up interrupt factor. Set the DVIDE bit in SVCTL and SDADLS bit in SDATBASn to 0b.
4. Set all bits in BIE(TENDIE, NACKDIE, SPCNDDIE, STCNDDIE, ALIE, TODIE) and TDBEIE and RDBFIE bits in HTIE to 0b (Interrupt disabled) before switching the asynchronous operation.
5. Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE=1b).
6. Wake-up interrupt is generated during I3C_0_PCLK/I3C_0_TCLK asynchronous operation (when WUST.WUASYNF=1b). In case of detecting slave address matching in I3C_0_PCLK/I3C_0_TCLK synchronous mode (WUST.WUASYNF=0), Wake-Up interrupt does not occur, and BST.WUCNDDF flag will not be set.
7. In I3C_0_PCLK/I3C_0_TCLK synchronous operation mode, the I3C may initiate the next reception upon detecting a conflict between the timing of writing “0b” to the WUCTL.WUFSYNE bit and the START condition. In this case, when data communication ends and a STOP condition is detected, the WUST.WUASYNF flag becomes 1b (I3C_0_PCLK/I3C_0_TCLK asynchronous mode transition) and Wake-Up event detection starts.
8. If you want to switch from I3C_0_PCLK/I3C_0_TCLK asynchronous operation to I3C_0_PCLK/I3C_0_TCLK synchronous operation without address match detection, it will switch on the STOP condition detection. When the WUCTL.WUFSYNE bit is set to 1 in a bus free state, I3C_0_PCLK/I3C_0_TCLK asynchronous operation continues (Reception operation: waiting communication frame). WUST.WUASYNF flag becomes to 0b when I3C detects the STOP condition of the next communication frame, and I3C switches to I3C_0_PCLK/I3C_0_TCLK synchronous operation.
9. After writing 0 to WUFSYNE bit in WUCTL, do not change I3C operation mode setting register (BFCTL, SCSTRCTL, ACKCTL, INCTL, SVCTL, SDATBASn) until switched to the I3C_0_PCLK/I3C_0_TCLK asynchronous operation from I3C_0_PCLK/I3C_0_TCLK synchronous operation (while WUST.WUASYNF flag = 1b). If register value changes by the interrupt processing etc. in this period, the I3C might malfunction without succeeding to the setting to the asynchronous operation.
10. During I3C_0_PCLK/I3C_0_TCLK asynchronous operation (WUST.WUASYNF = 1b), do not refer to each flag of SVST, BST, HTST register and BCST.BFREF flag.
11. Do not set ACKCTL.ACKT = 1b in order to make an ACK response in the synchronization unit when Wake-Up is performed by slave address match in Normal Wake-Up Mode 2.

(2) Wake-Up Function [I3C mode]

(a) I3C Master Wake-Up

Wake-Up interrupt causes of I3C Master are shown below.

- SDA Low detection (IBI request from I3C Slave)

See below for details on the master Wake-Up operation.

1. **<Before Wake-Up recovery>**
   SDA Low Drive is detected and the INTWU interrupt is asserted.

2. **<During Wake-Up recovery>**
   Keep SCL Line High.

3. **<After Wake-Up recovery>**
   Drive SCL Low and complete START condition. SCL is supplied on the I3C Bus and IBI from I3C Slave is received.

Remark 1. If active mode (normal operation) is entered due to other factors, disable the Wake-Up function as necessary.

Remark 2. After confirming PRSTDBG.SDILV = 1b, set WUCTL.WUFE = 0b.

Remark 3. Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE=1b).

(b) I3C Slave Wake-Up

Wake-Up interrupt causes of I3C Slave are shown below.

- Broadcast Address (7Eh) and detection of its own Slave Address match

See below for details on the slave Wake-Up operation.

1. **<Before Wake-Up recovery>**
   STEP 1:
   If I3C detects BA (7Eh/W) following a START (or Repeated START) Condition, then I3C shall generates ACK (after 7Eh/W).

   STEP 2:
   If I3C detects its own Dynamic Address after a Repeated START condition following Step1,
   then I3C shall generates NACK (after its own Dynamic Address) and then issues a INTWU interrupt.

   <During Wake-Up recovery>
   I3C always generates NACK.

   <After Wake-Up recovery>
   Normal operation continues.

Remark 1. If active mode (normal operation) is entered due to other factors, disable the Wake-Up function as necessary.

Remark 2. Do not use the timeout function while the Wake-up function is enabled (WUCTL.WUFE=1b).

7.8.4.2.6 Other

(1) SCL Synchronization Circuit [I²C mode]

This function is enabled while the PRTS.PRTMD bit is set to 1.

In generation of the SCL clock, I3C starts counting out the value for width at high level specified in STDBR.SBRHO[7:0] when it detects a rising edge on the SCL line and drives the SCL line low once counting of the width at high level is complete.

When I3C detects the falling edge of the SCL line, it starts counting out the width at low level period specified in STDBR.SBRLO[7:0], and then stops driving the SCL line (releases the line) once counting of the width at low level is complete. The SCL clock is thus generated.

If multiple master devices are connected to the I²C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, I3C is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCL line while in master mode.

When I3C has detected a rising edge on the SCL line and thus started counting out the width at high level specified in STDBR.SBRHO[7:0], and the level on the SCL line falls because an SCL signal is being generated by another master device, I3C stops counting when it detects the falling edge, drives the level on the SCL line low, and starts counting out the width at low level specified in STDBR.SBRLO[7:0]. When I3C finishes counting out the width at low level, it stops driving the SCL line to the low level (releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in this module, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCL line has been released. When I3C finishes outputting the low-level period of the SCL clock, the SCL line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the SCSYNE bit in BFCTL is set to 1b.

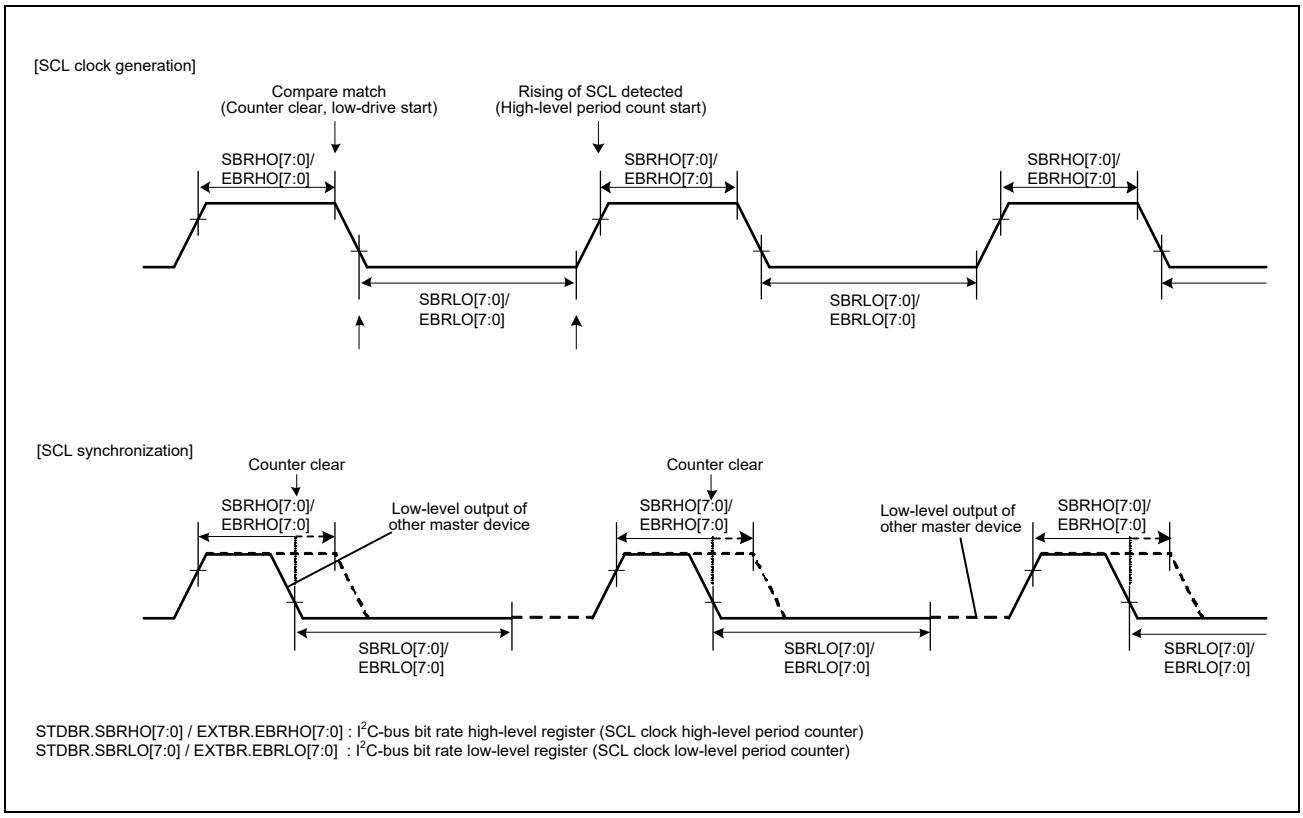


Figure 7.8-108 Generation and synchronization of the SCL signal

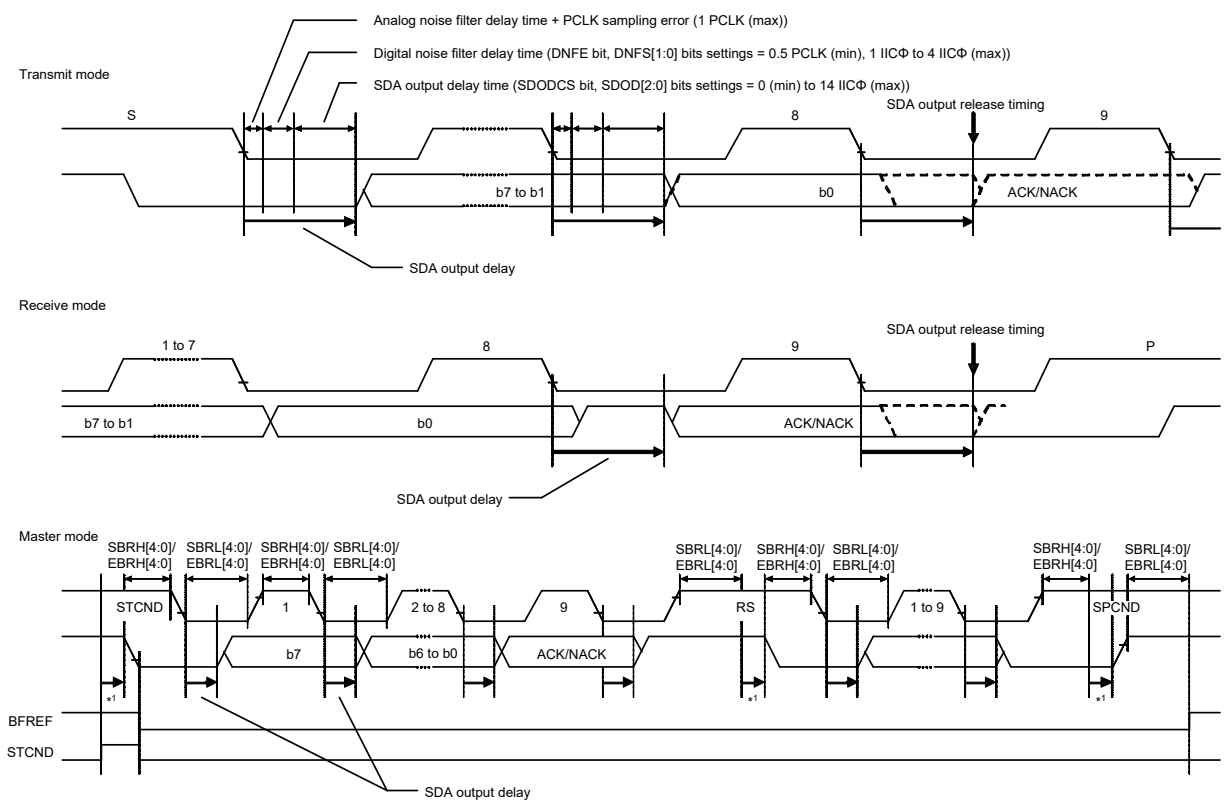
(2) Facility for Delaying SDA Output [I²C mode]

I3C module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (issuing of the START, Repeated START, and STOP conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL clock is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices, with the aim of satisfying the 300 ns (minimum) data- hold time requirement of the SMBus specification.

The output delay facility is enabled by setting the SDOD[2:0] bits in OUTCTL to any value other than 000b, and disabled by setting the same bits to 000b.

While the SDA output delay facility is enabled (while the SDOD[2:0] bits in OUTCTL are set to any value other than 000b), the SDODCS bit in OUTCTL selects the clock source for counting by the SDA output delay counter as the internal base clock (I3Cϕ) for I3C module or as a clock signal derived by dividing the frequency of the internal base clock by two (I3Cϕ/2). The counter counts the number of cycles set in the SDOD[2:0] bits in OUTCTL. After counting of the set number of cycles of delay is completed, I3C module places the required output (START, Repeated START, or STOP condition, data, or an ACK or NACK signal) on the SDA line.



Note: PCLK = I3C_0_PCLK

Note 1. The output delay function is set by the SDODCS and SDOD[2:0] bits when a start (STCND), repeated start (SRCND), or stop (SPCND) condition is issued.

Figure 7.8-109 SDA output delay facility

(3) Digital Noise-Filter Circuits [I²C mode]

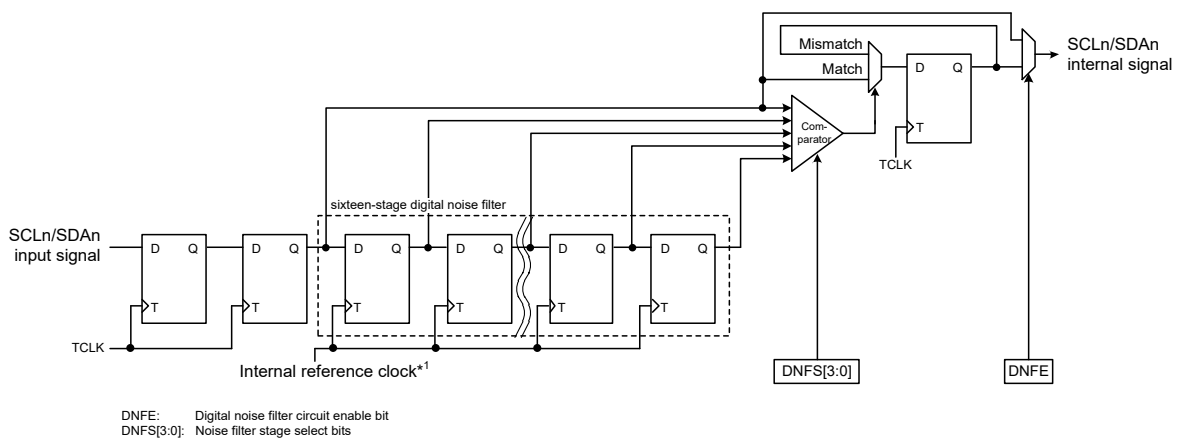
The states of the SCL and SDA pins are conveyed to the internal circuitry through digital noise-filter circuits. **Figure 7.8-110** is a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of I3C consists of 16 flip-flop circuit stages connected in series and a match detection circuit. During the Hs-mode transfer, only the first four flip-flop circuits stages are enabled.

The number of effective stages in the digital noise filter is selected by the INCTL.DNFS[3:0] bits. The selected number of effective stages determines the noise-filtering capability as a period from one to sixteen I3Cϕ cycles.

The input signal to the SCL pin (or SDA pin) is sampled on rising edges of the I3Cϕ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the INCTL.DNFS[3:0] bits, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (I3C_0_TCLK) and the transfer rate is small (For example, data transfer at 400 kbps with I3C_0_TCLK = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise.



Note: TCLK = I3C_0_TCLK

Note 1. Internal reference clock = I3Cϕ

Figure 7.8-110 Block diagram of digital noise filter circuit

7.8.4.3 Operation

7.8.4.3.1 Initial Setting Flow

(1) I^2C Initial Setting Flow (Single Buffer Transfer)

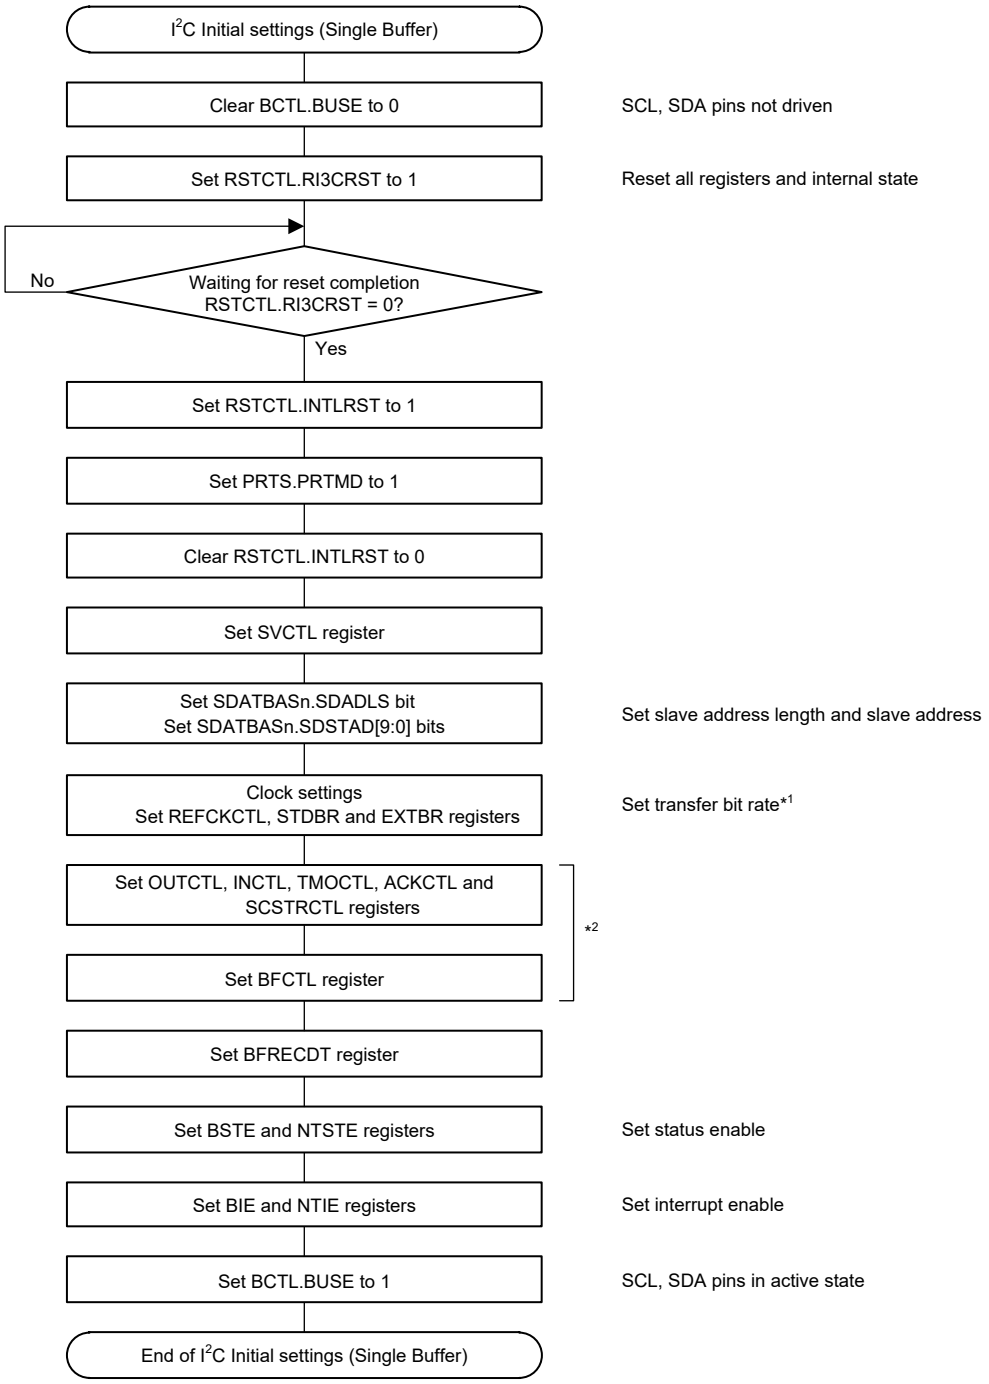
Before starting data transmission and reception, initialize I3C according to the procedure in **Figure 7.8-111**.

First, set the BCTL.BUSE bit to 0b (SCL, SDA pins not driven).

Next, set the RSTCTL.RI3CRST bit to 1b (I3C reset). This initializes all registers and the internal state. Then, waits for RI3CRST to become 0b.

This initializes the various flags and some registers. See **7.8.7 Reset Descriptions**.

After that, set registers SDATBASn.SDADLS, SDATBASn.SDSTAD[9:0], STDBR, INCTL, OUTCTL, TMOCTL, SCSTRCTL, ACKCTL, and BFCTL, then set the other registers as necessary (for initial settings of I3C, see **Figure 7.8-111**).



Note: n = 0 to 2

Note 1. When the I3C is used only in slave mode, set the STDBR register to a value longer than the data setup time.

Note 2. Set these registers as necessary.

Figure 7.8-111 Example of I²C Initialization Flowchart (Single Buffer Transfer)

(2) I3C Initial Setting Flow

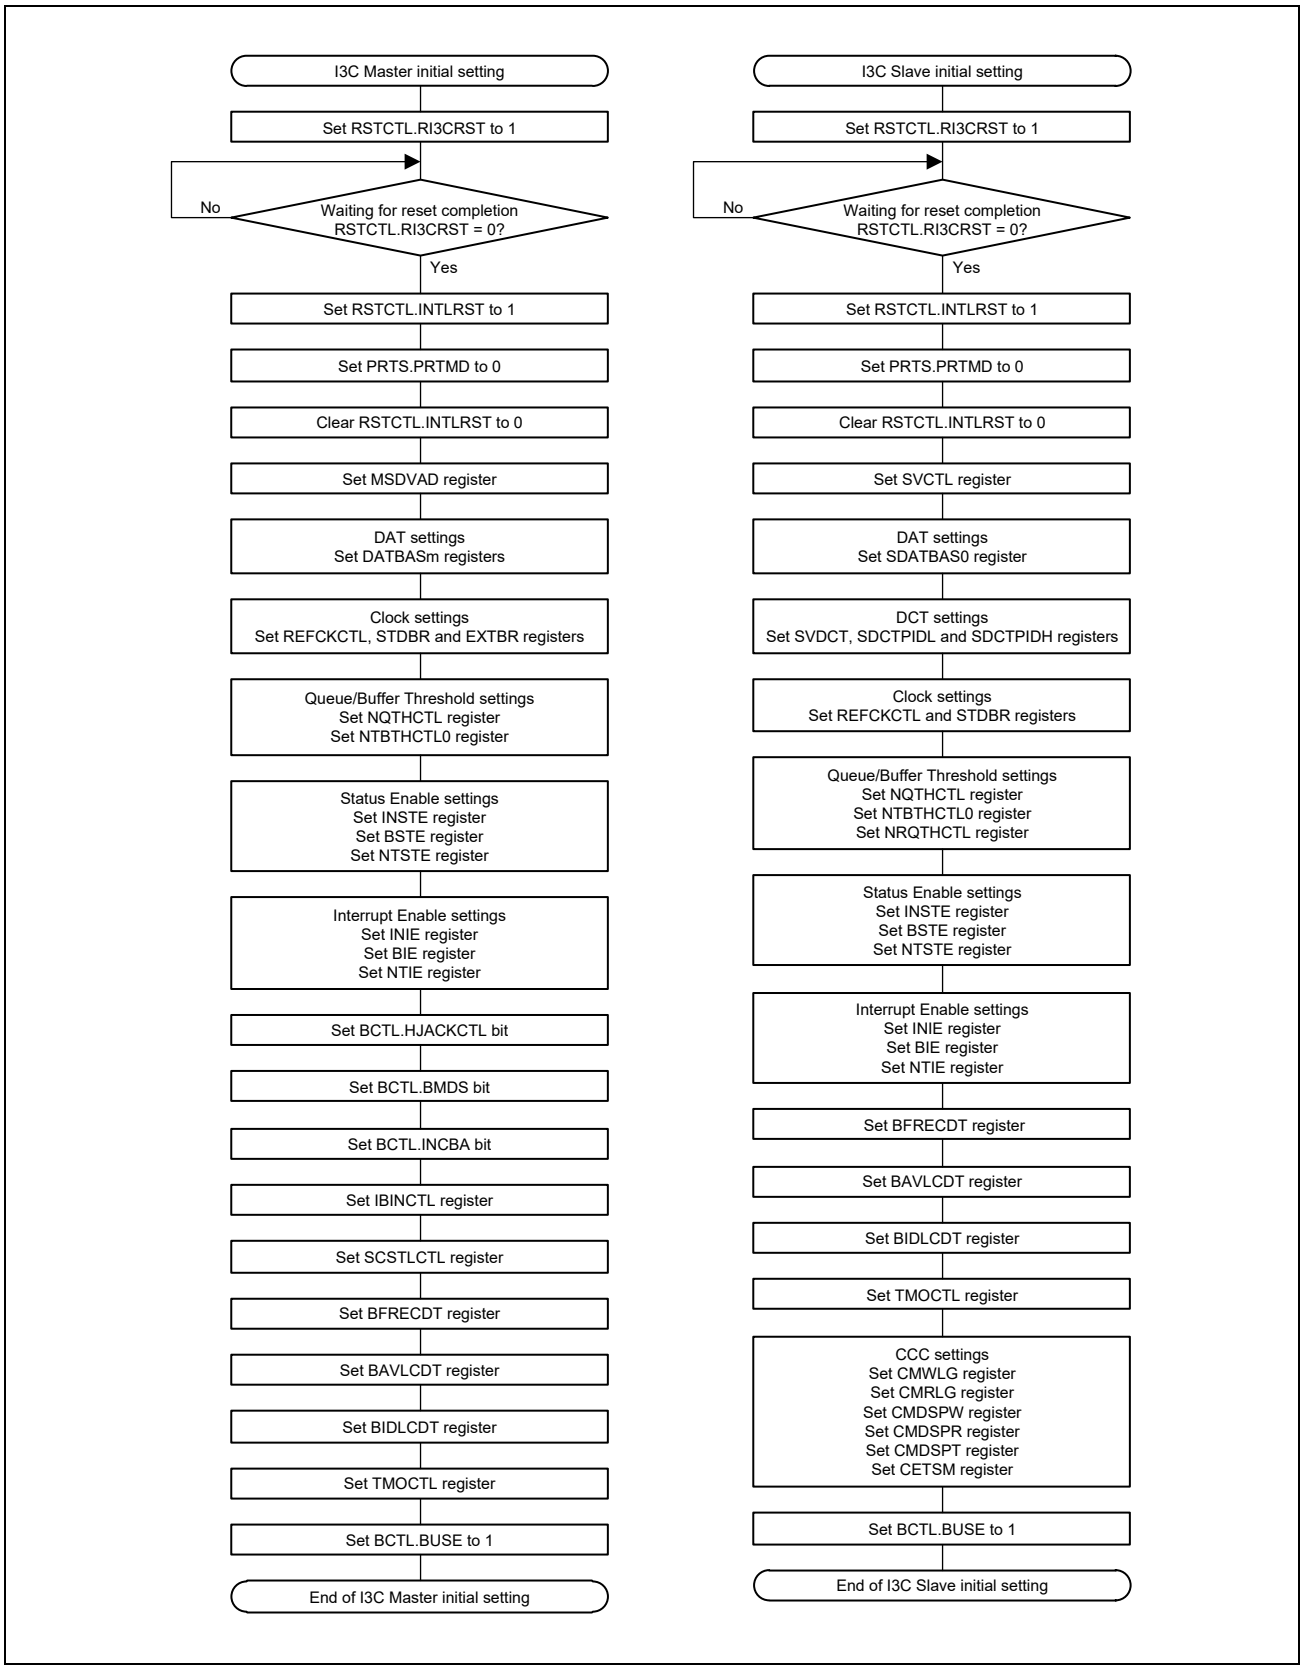


Figure 7.8-112 Example of I3C initialization flowchart

7.8.4.3.2 I3C Communication Flow

Figure 7.8-113 illustrates how I3C communication is initiated:

- All I3C communication occurs within a frame. The frame begins with a START, followed by one or more transfers, and a STOP.

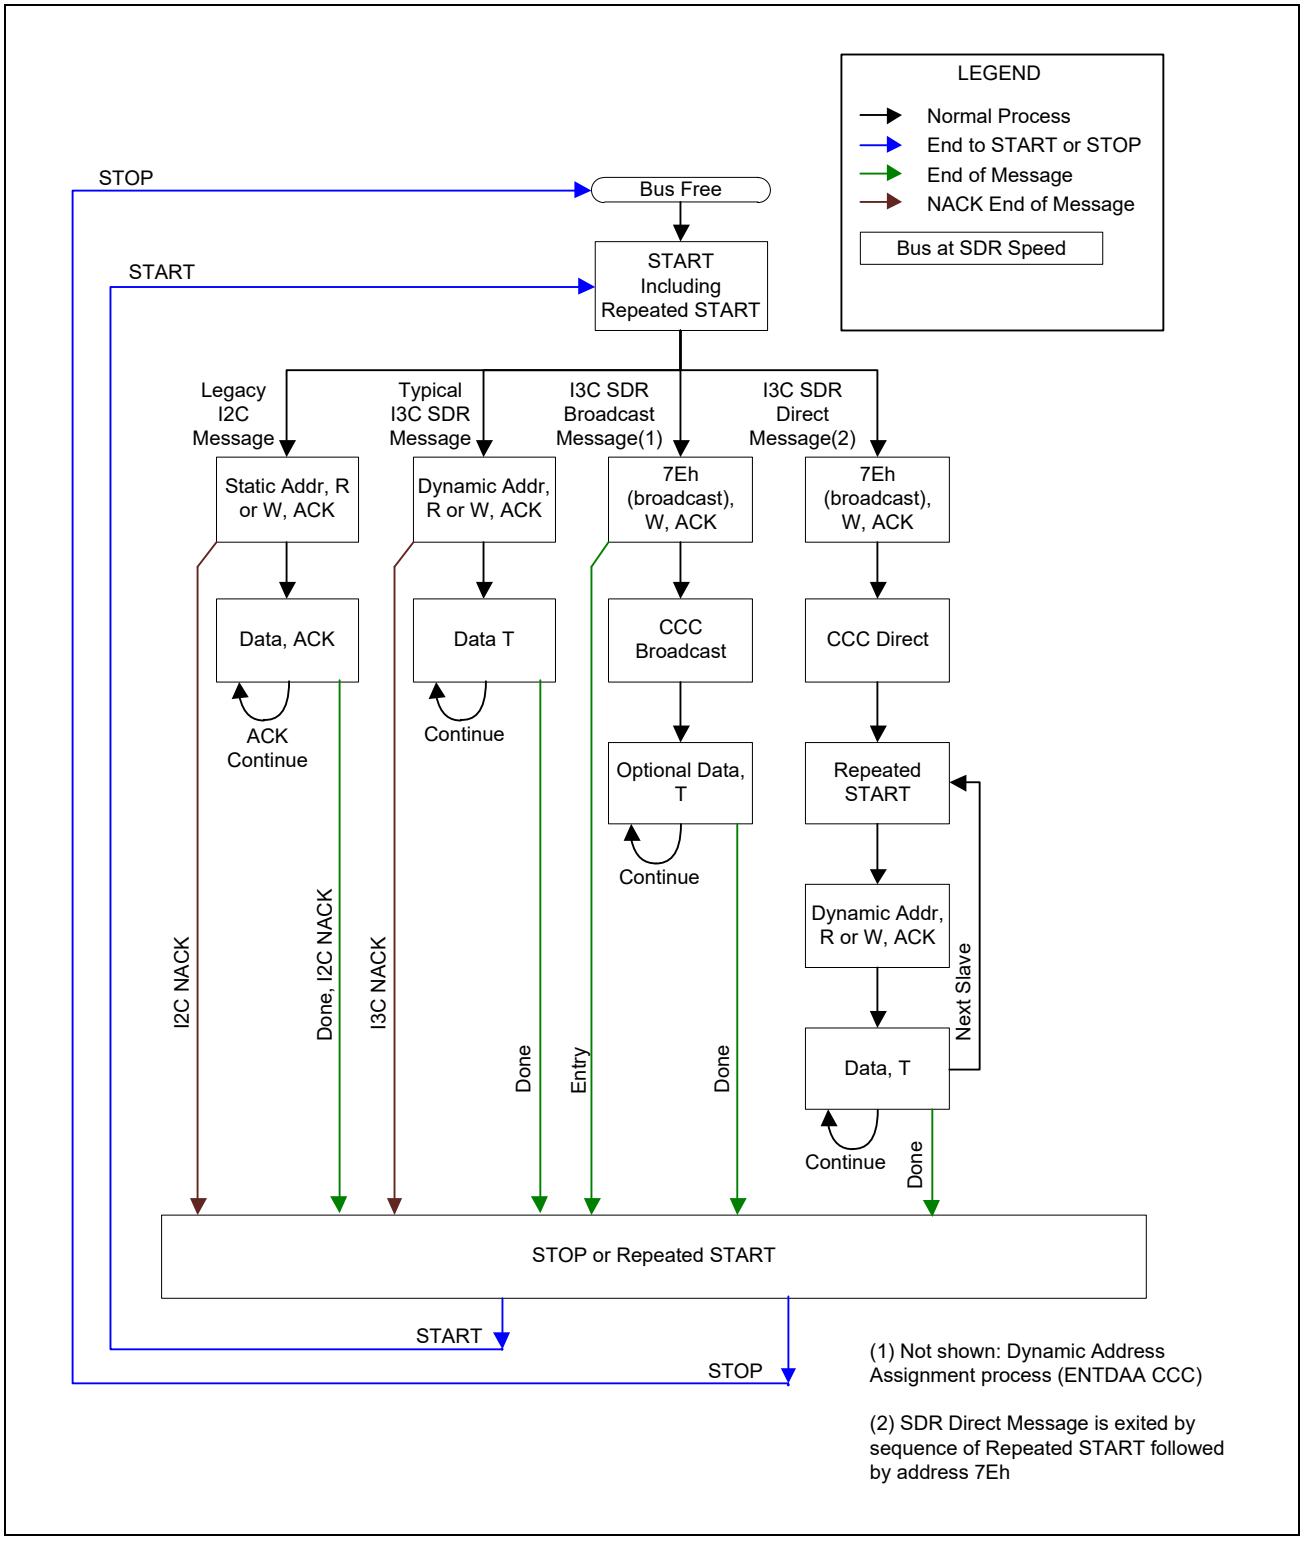

Figure 7.8-113 I3C communication flow

I3C is based on a frame encapsulation approach. A frame includes a data payload. The transfer protocol for the data payload is either SDR. Frames are bordered by I^2C-like bus management.

The I3C frame always includes at least the START, the Header, the Data, and the STOP. The Header following a START allows for Bus Arbitration. The Master uses the Header to address Slave device (s). Slave devices (s) may use the Header Arbitration for multiple purposes: for In-Band Interrupt, for Hot-Join, and for Secondary Master functionality.

I3C allows only one Master to have control of the I3C bus at a time. Mechanisms for handoff of the Master role from one device to another device are provided.

7.8.4.3.3 Master Mode Communication Flow

(1) I²C Master Transmission Flow (Single Buffer Transfer)

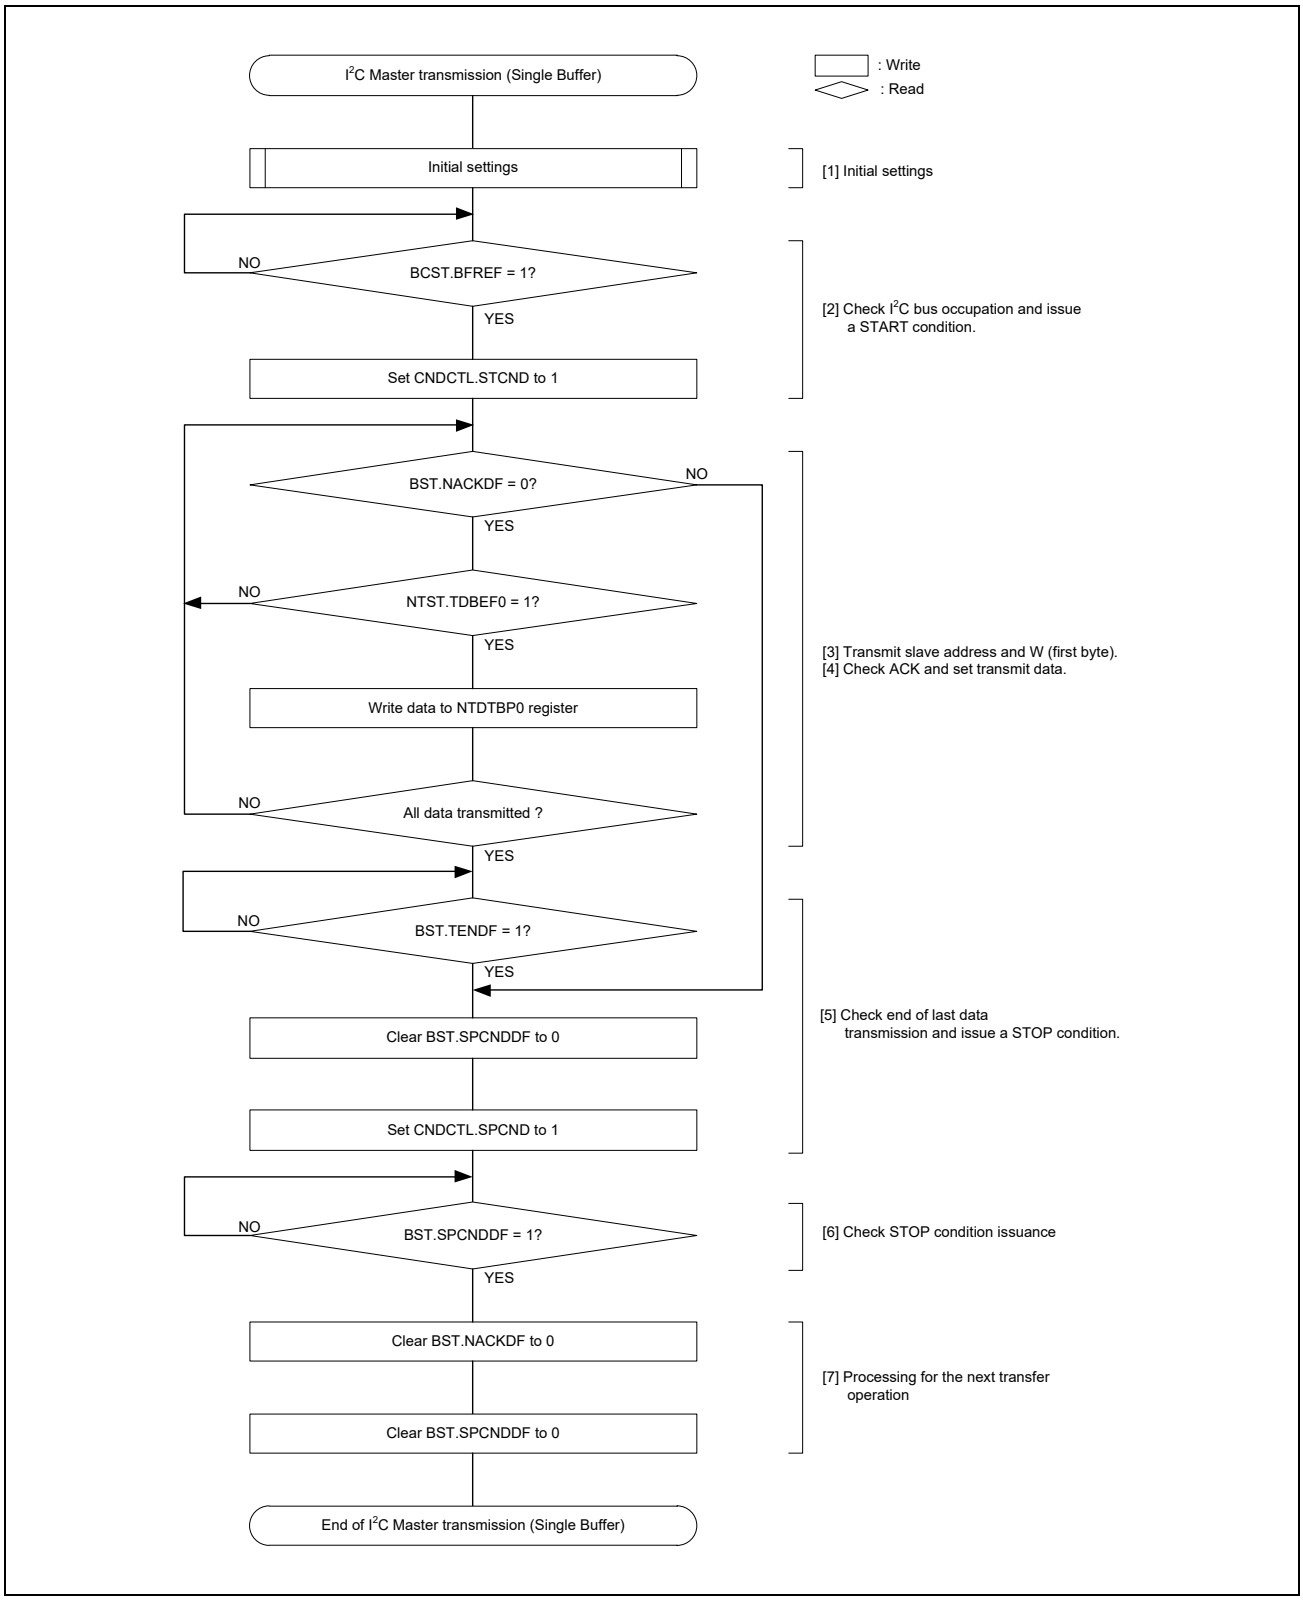

Figure 7.8-114 Example of I²C master transmission flowchart (single buffer transfer)

(2) I²C Master Reception Flow (Single Buffer Transfer)

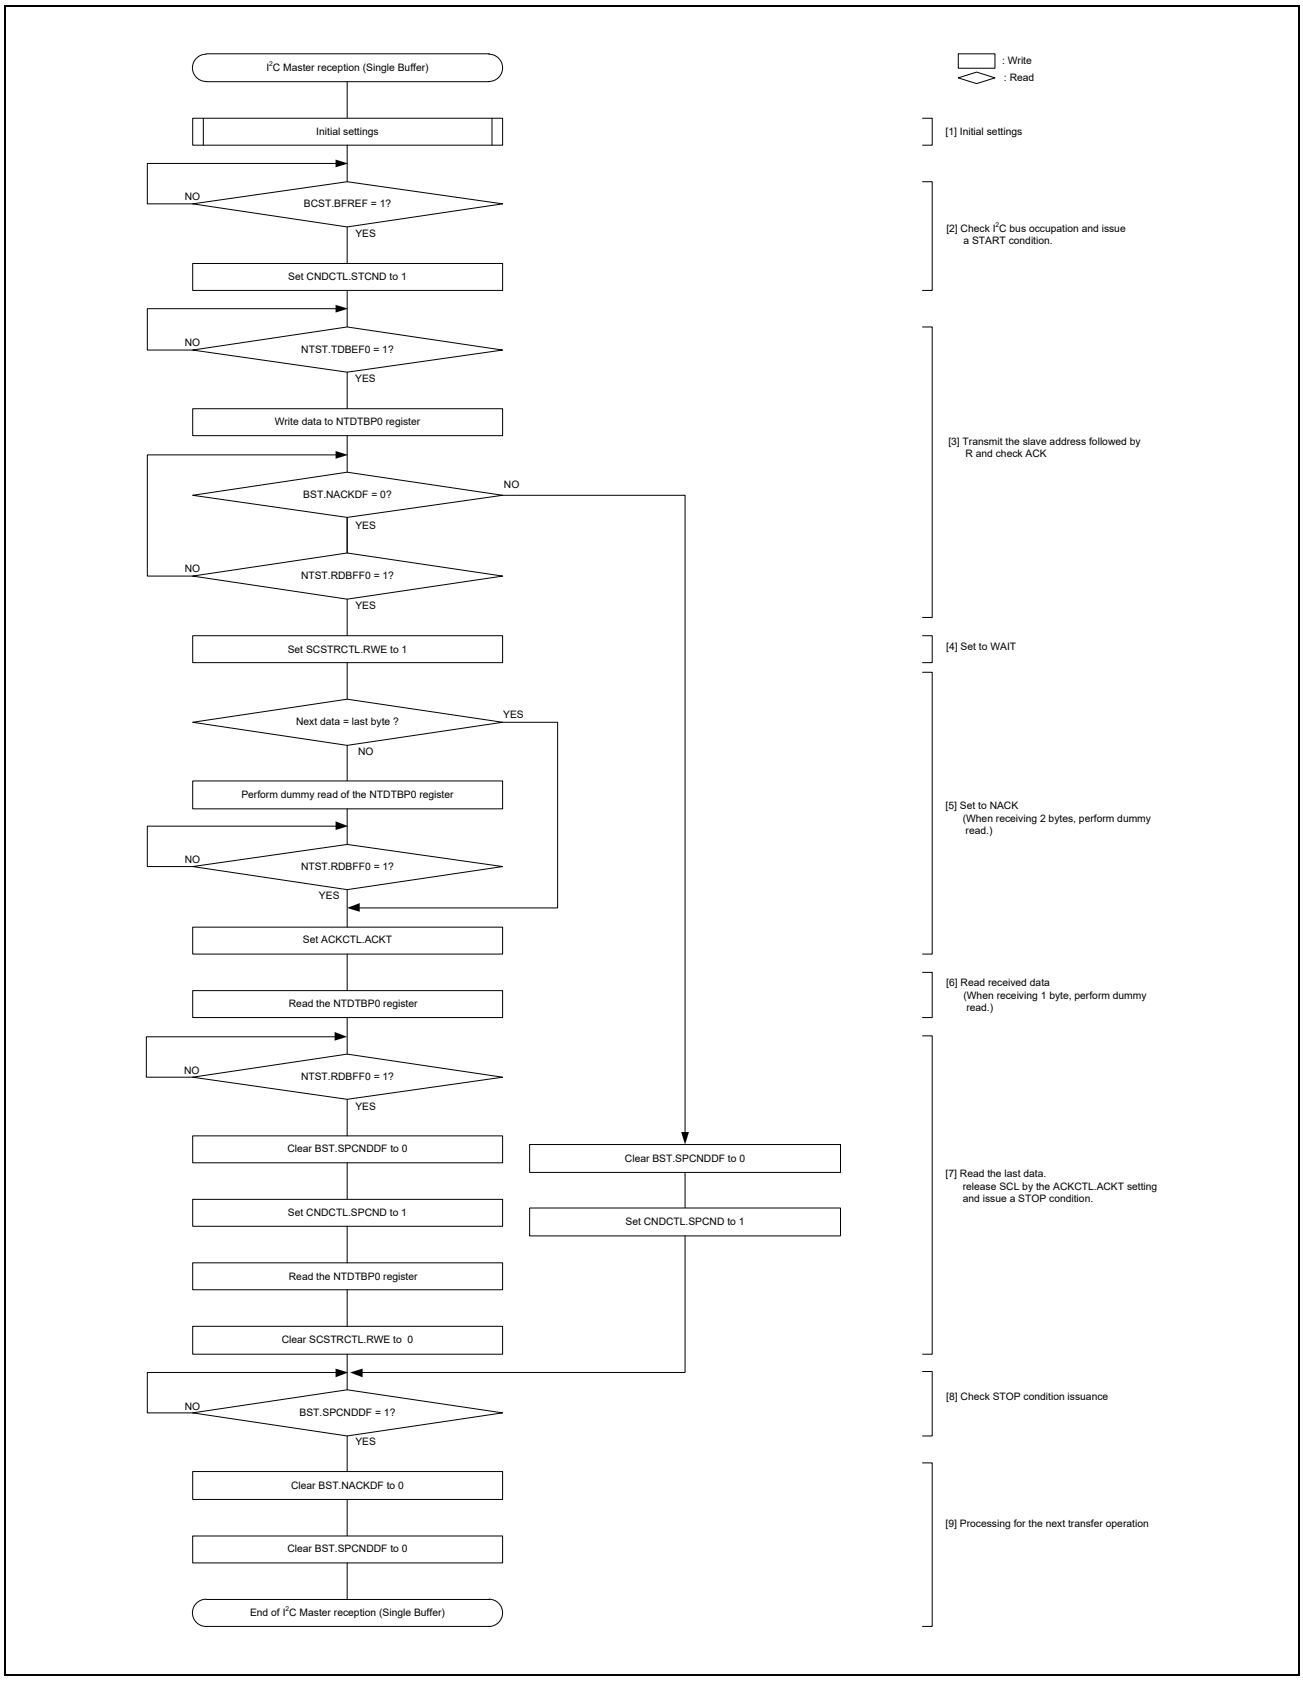

Figure 7.8-115 Example of I²C master reception flowchart (7-bit address format, 1 or 2 bytes)

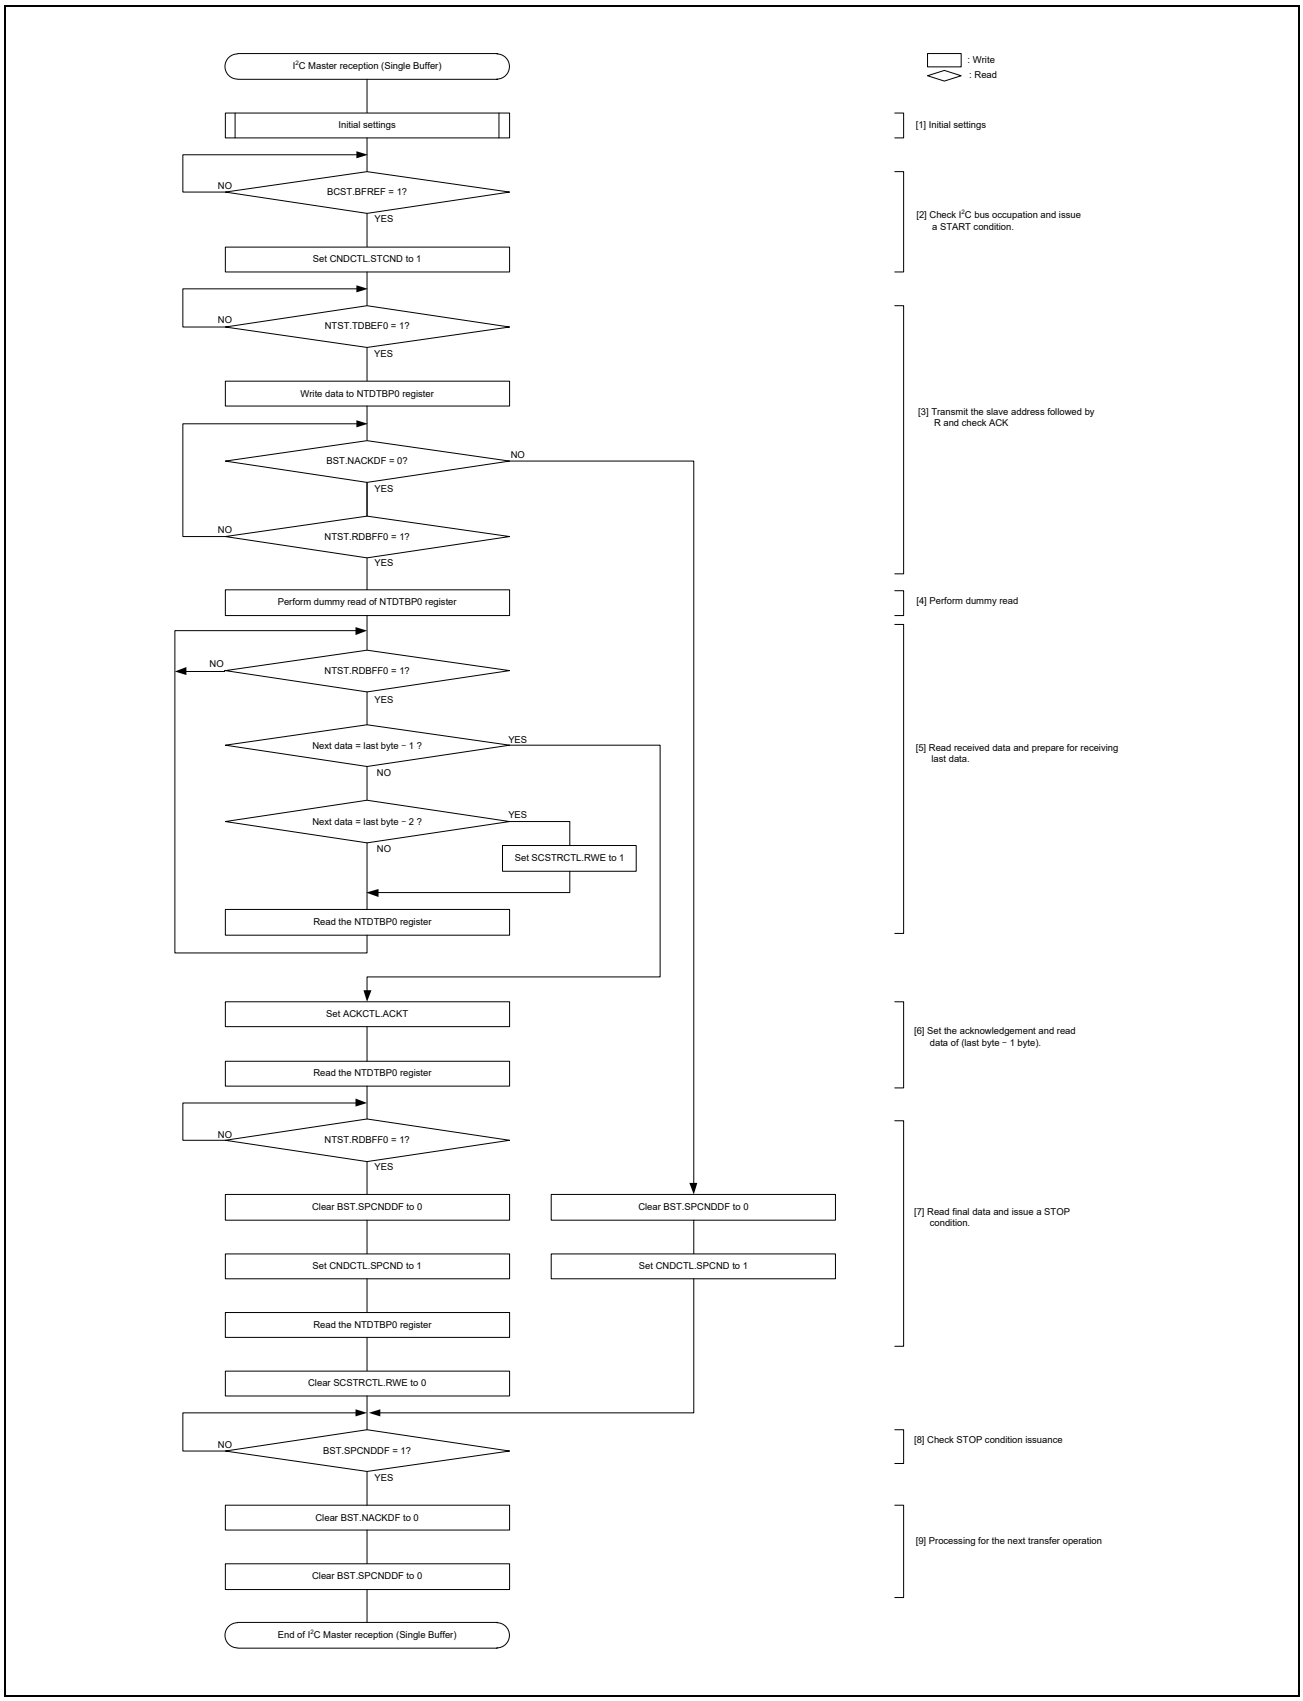

Figure 7.8-116 Example of I²C master reception flowchart (7-bit address format, 3 bytes or more)

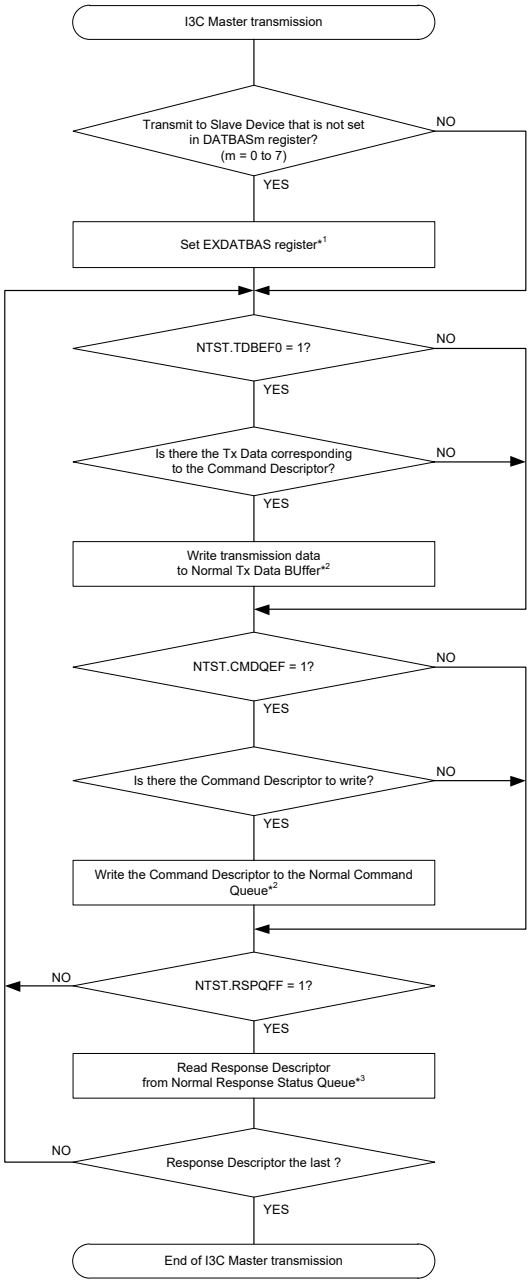
(3) I3C Master Transmission Flow (Normal FIFO Buffer Transfer)

Master transmission flow in I3C normal FIFO buffer transfer is common to Legacy I^2C and SDR (Private Transfer, Broadcast CCC, Direct CCC).



Note 1. Changing the EXDATBAS register is prohibited until all response descriptors of command for the Slave device set in the EXDATBAS register are stored.

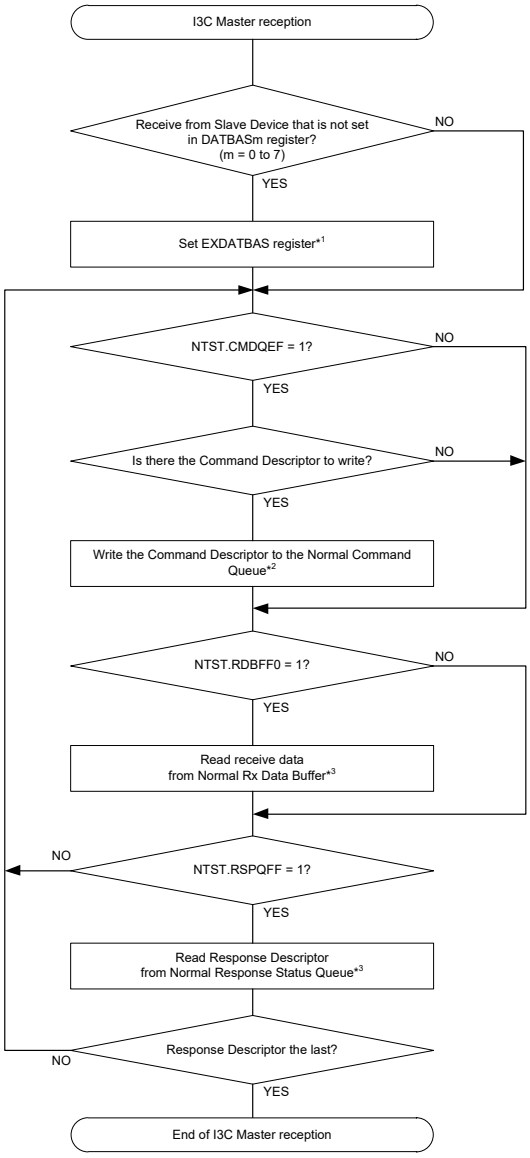
Note 2. In the case the register is written by a way other than DMAC, clear corresponding flags after write access.

Note 3. In the case the register is read by a way other than DMAC, clear corresponding flags after read access.

Figure 7.8-117 Example of I3C master transmission flowchart (normal FIFO buffer transfer)

(4) I3C Master Reception Flow (Normal FIFO Buffer Transfer)

Master reception flow in I3C normal FIFO buffer transfer is common to Legacy I^2C and SDR (Private Transfer, Broadcast CCC, Direct CCC).



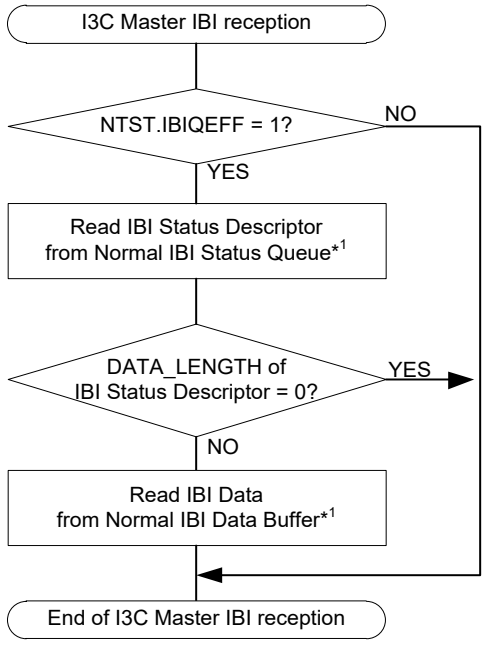
Note 1. Changing the EXDATBAS register is prohibited until all response descriptors of command for the Slave device set in the EXDATBAS register are stored.

Note 2. In the case the register is written by a way other than DMAC, clear corresponding flags after write access.

Note 3. In the case the register is read by a way other than DMAC, clear corresponding flags after read access.

Figure 7.8-118 Example of I3C master reception flowchart (normal FIFO buffer transfer)

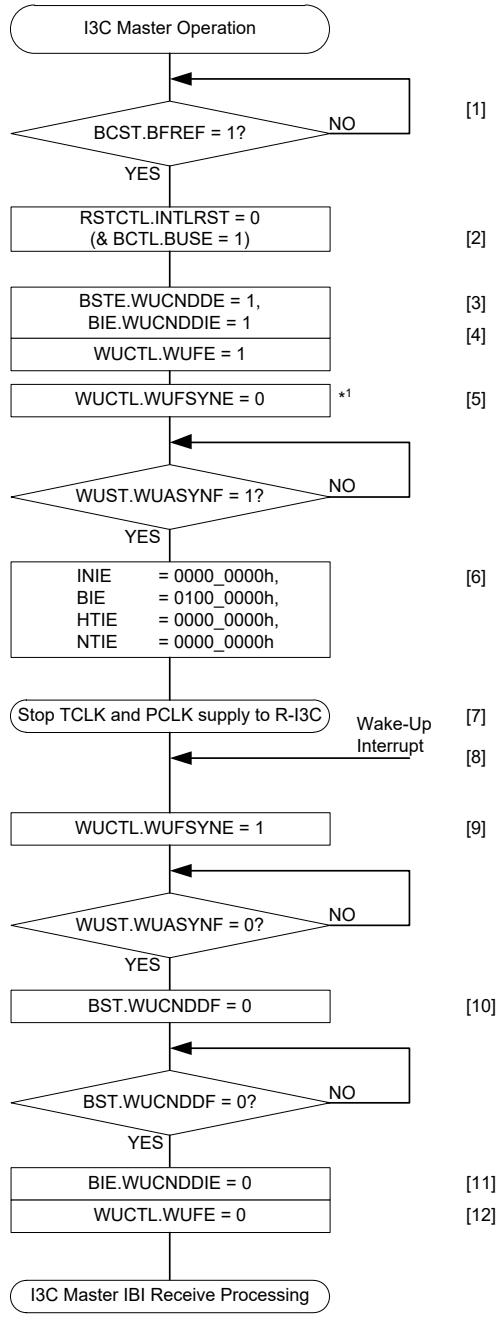
(5) I3C Master IBI Reception Flow



Note 1. In the case the register is read by a way other than DMAC, clear corresponding flags after read access.

Figure 7.8-119 Example of I3C master IBI reception flowchart

(6) I3C Master Wake-Up Flow



[1] [1] Wait I3C bus free and I3C stay in the standby state.

[2] [2] Negate internal reset if assert the internal reset.

[3] [3] Wake-Up Interrupt is enabled.

[4] [4] Wake-Up function is enabled.

[5] [5] R-I3C of operating state is changed from I3C_0_PCLK / I3C_0_TCLK synchronous to I3C_0_PCLK / I3C_0_TCLK asynchronous.

[6] [6] Interrupt requests are disabled except WUI.

[7] [7] Stop I3C_0_TCLK supply to R-I3C, then stop I3C_0_PCLK supply to I3C. (I3C will continue to receive)

[8] [8] Start system clock and I3C_0_TCLK supply to R-I3C by Wake-Up interrupt,then start I3C_0_PCLK supply to I3C.

[9] [9] R-I3C of operating state is changed from I3C_0_PCLK / I3C_0_TCLK asynchronous to I3C_0_PCLK / I3C_0_TCLK synchronous.

[10] [10] Write 0 to BST.WUCNDDF.
(Read and check whether clearing has been completed befor return from interrupt handling.)

[11] [11] Wake-Up interrupt is disabled.

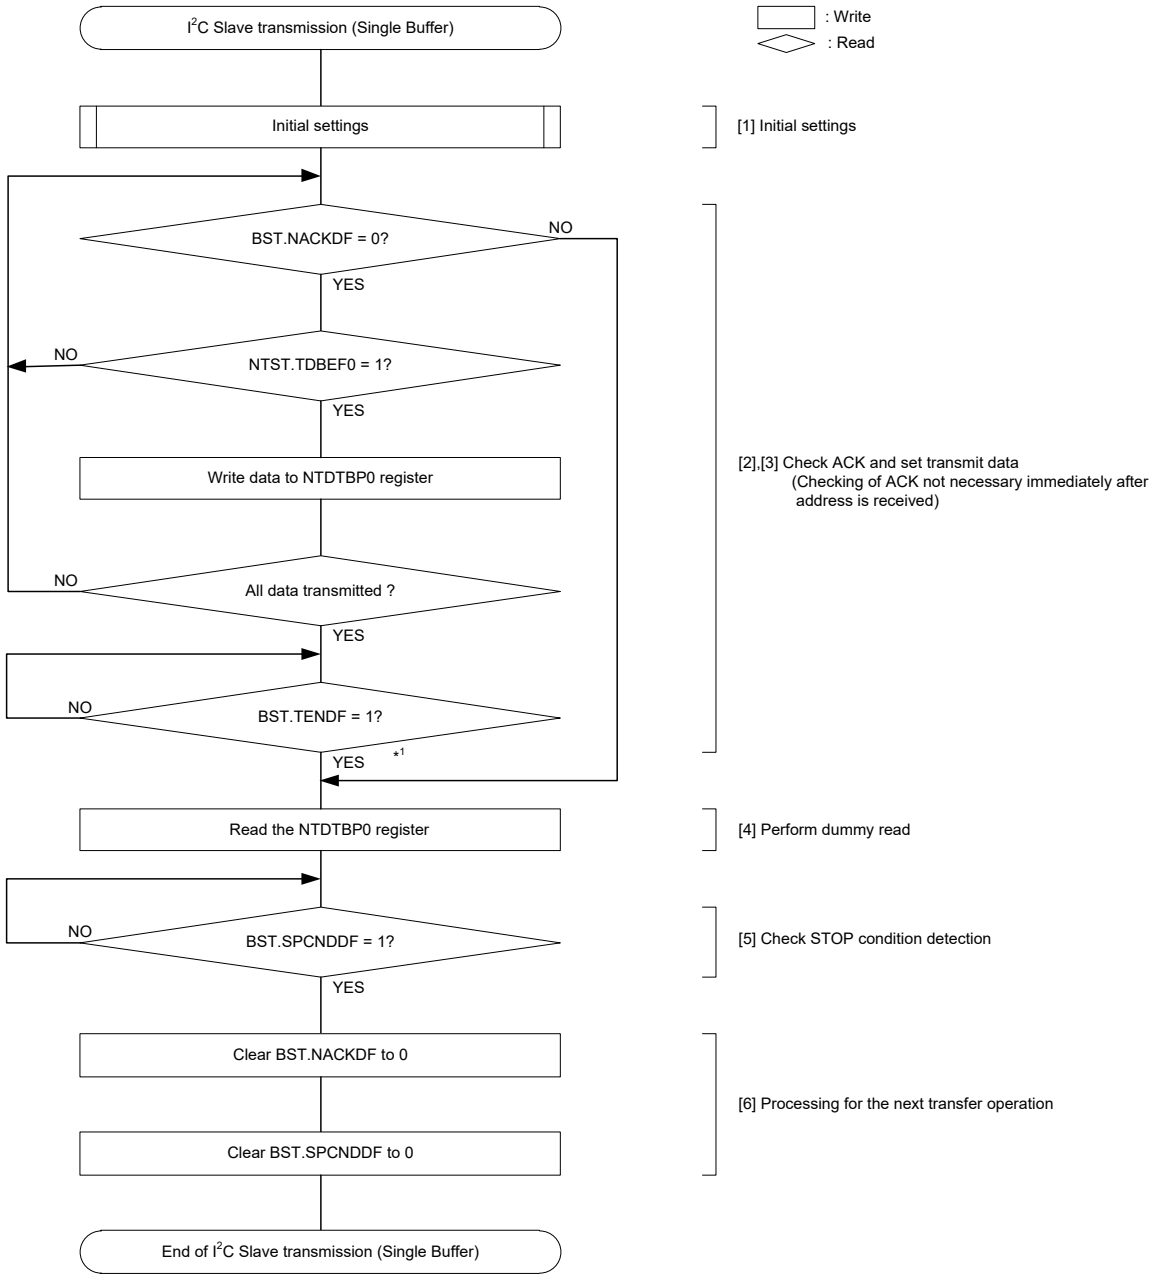
[12] [12] Wake-Up function is disabled.

Note 1. After switching the SDA pin to the general I/O port (Input) in the I/O port function setting, set WUCTL.WUFSYNE to 1. Then wait until WUST.WUASYNF = 1, and switch the SDA pin to the peripheral function in the I/O port function setting.

Figure 7.8-120 Use Case of I3C Master Wake-Up

7.8.4.3.4 Slave Mode Communication Flow

(1) I²C Slave Transmission Flow (Single Buffer Transfer)



Note 1. Normally, Master responds to the last byte with NACK, so when BST.TENDF=1, BST.NACKDF will also 1.
If BST.NACKDF is 0 after BST.TENDF=1, the master may be hung up, so reset I3C with RSTCTL.INTLRST.

Figure 7.8-121 Example of I²C slave transmission flowchart (single buffer transfer)

(2) I²C Slave Reception Flow (Single Buffer Transfer)

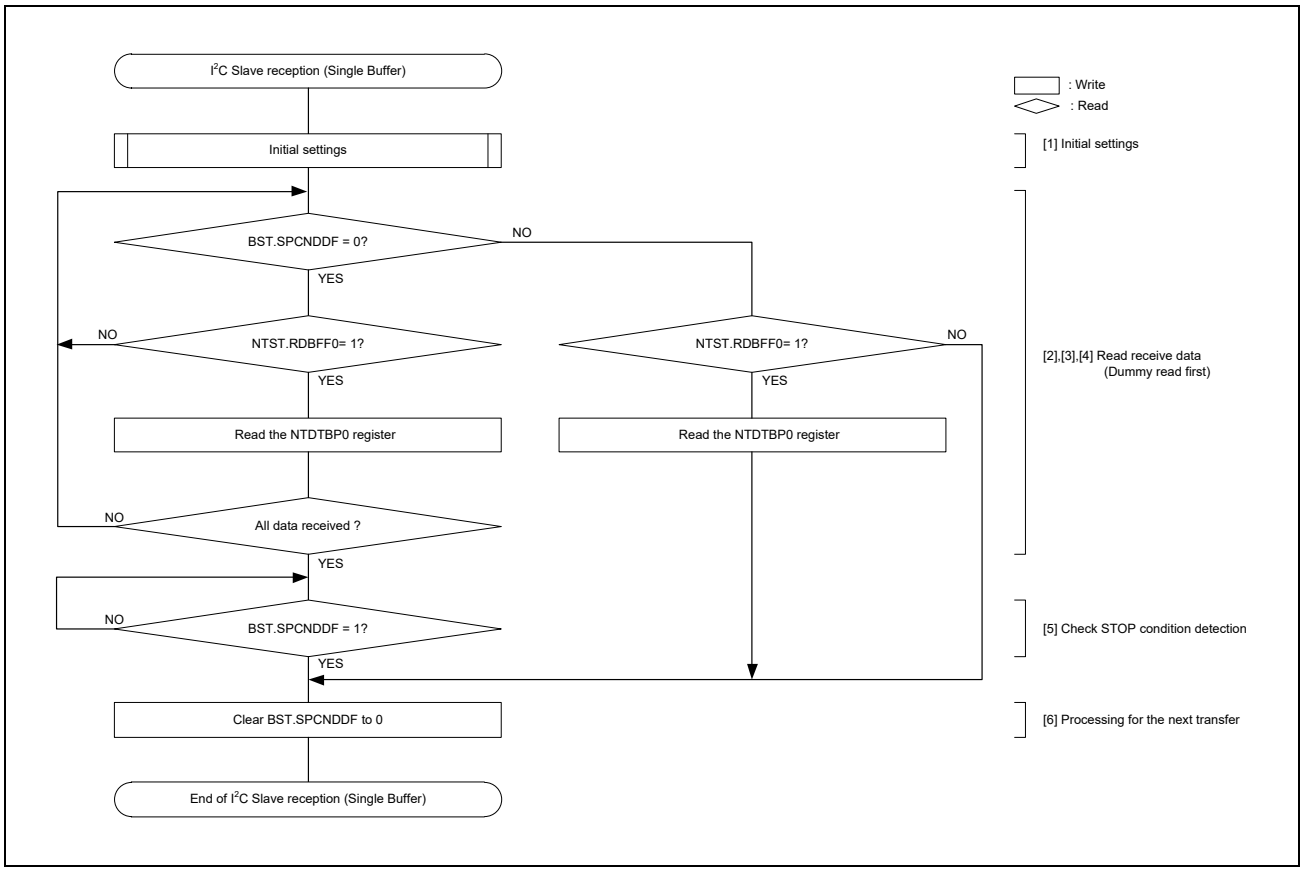


Figure 7.8-122 Example of I²C slave reception flowchart (single buffer transfer)

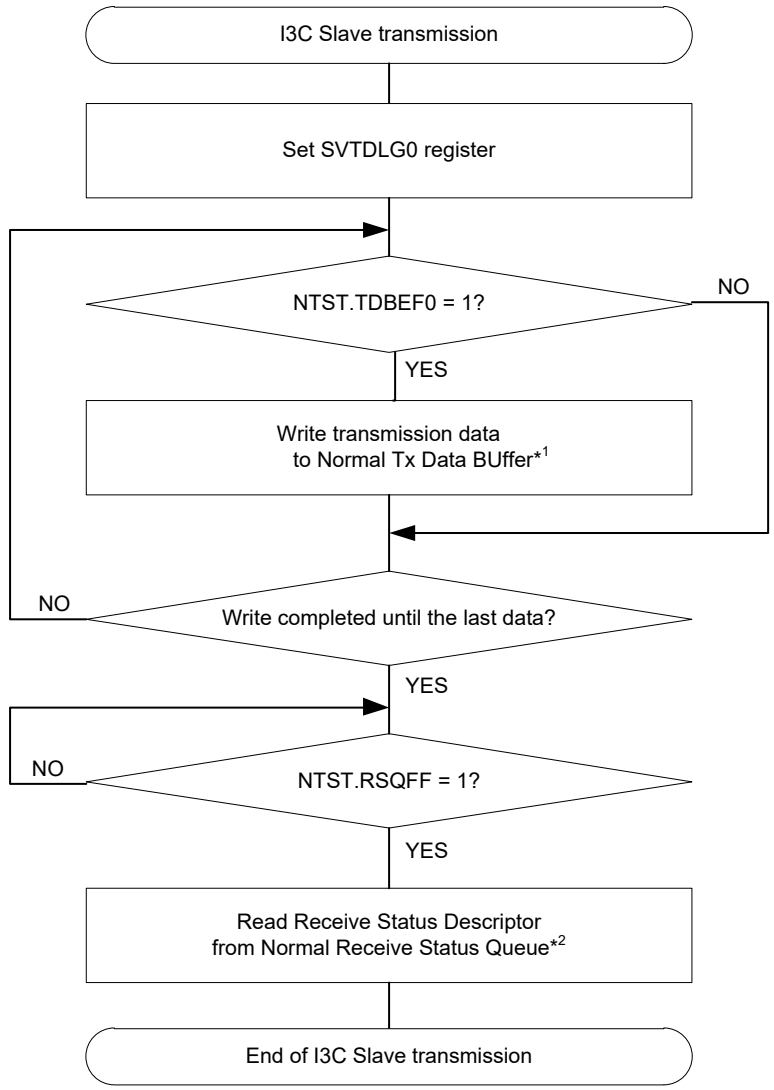
(3) I3C Slave Transmission Flow (Normal FIFO Buffer Transfer)

Slave Transmission Flow in I3C normal FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).



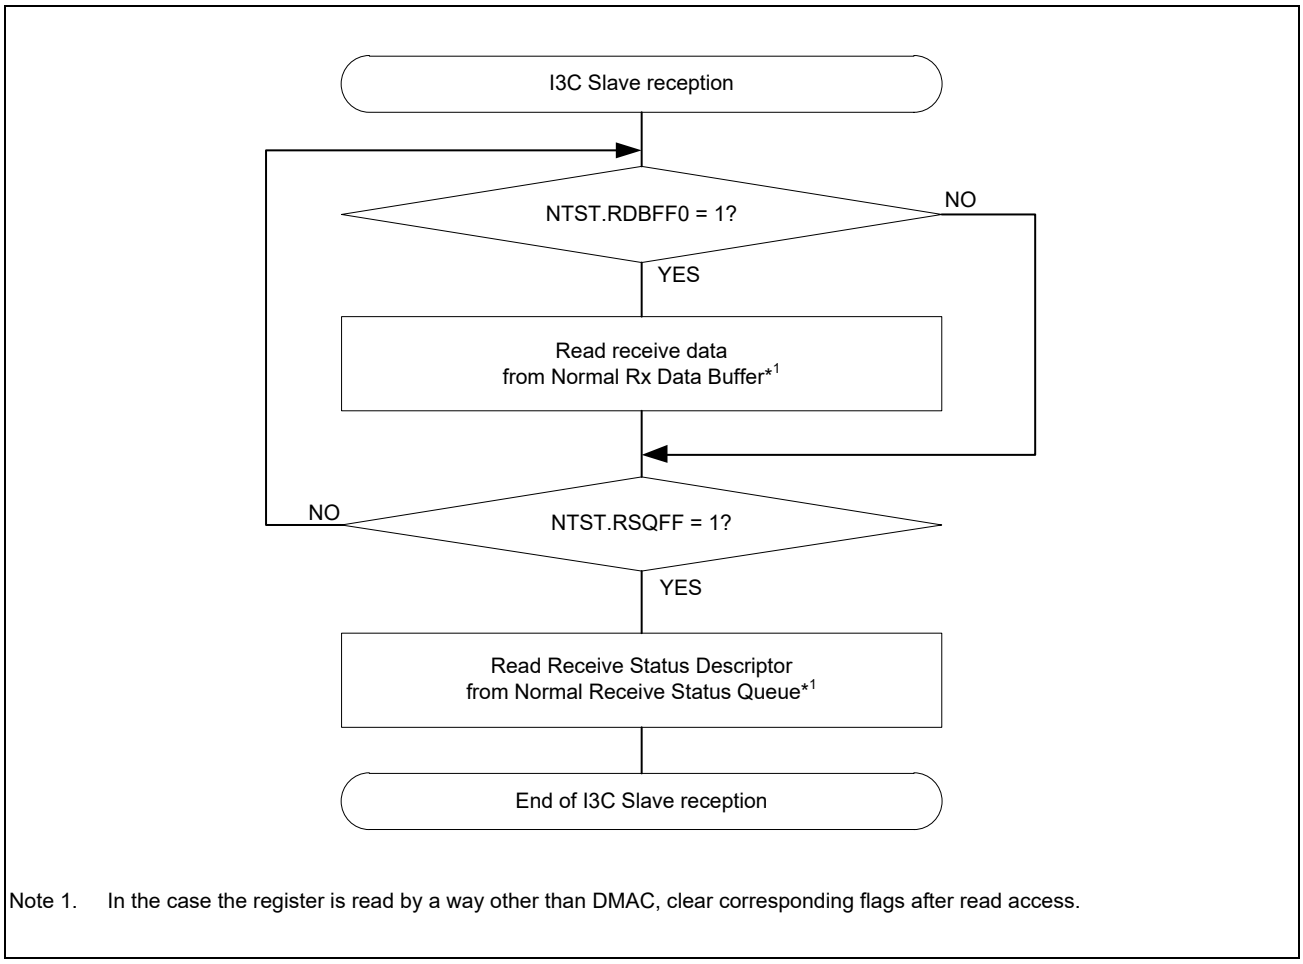
Note 1. In the case the register is written by a way other than DMAC, clear corresponding flags after write access.

Note 2. In the case the register is read by a way other than DMAC, clear corresponding flags after read access.

Figure 7.8-123 Example of I3C slave transmission flowchart (normal FIFO buffer transfer)

(4) I3C Slave Reception Flow (Normal FIFO Buffer Transfer)

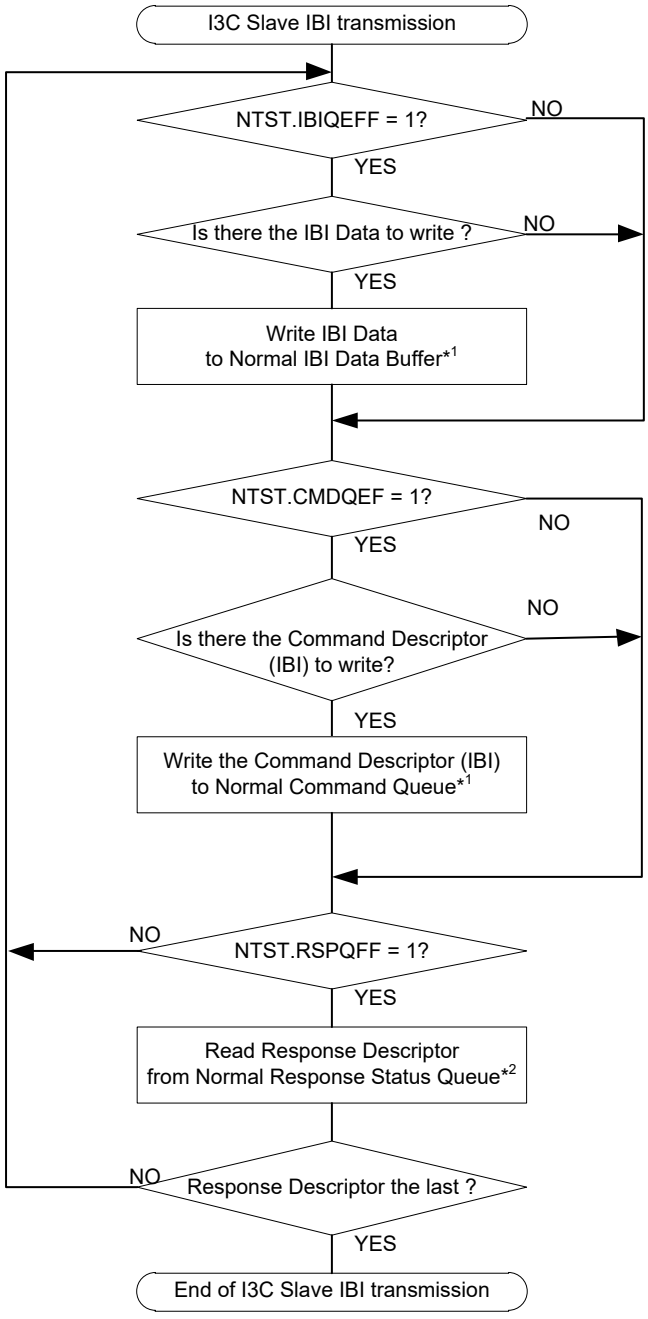
Slave Reception Flow in I3C normal FIFO buffer transfer is common to Legacy I^2C, SDR (Private Transfer, Broadcast CCC, Direct CCC).



Note 1. In the case the register is read by a way other than DMAC, clear corresponding flags after read access.

Figure 7.8-124 Example of I3C slave reception flowchart (normal FIFO buffer transfer)

(5) I3C Slave IBI Transmission Flow



Note 1. In the case the register is written by a way other than DMAC, clear corresponding flags after write access.

Note 2. In the case the register is read by a way other than DMAC, clear corresponding flags after read access.

Figure 7.8-125 Example of I3C slave IBI transmission flowchart

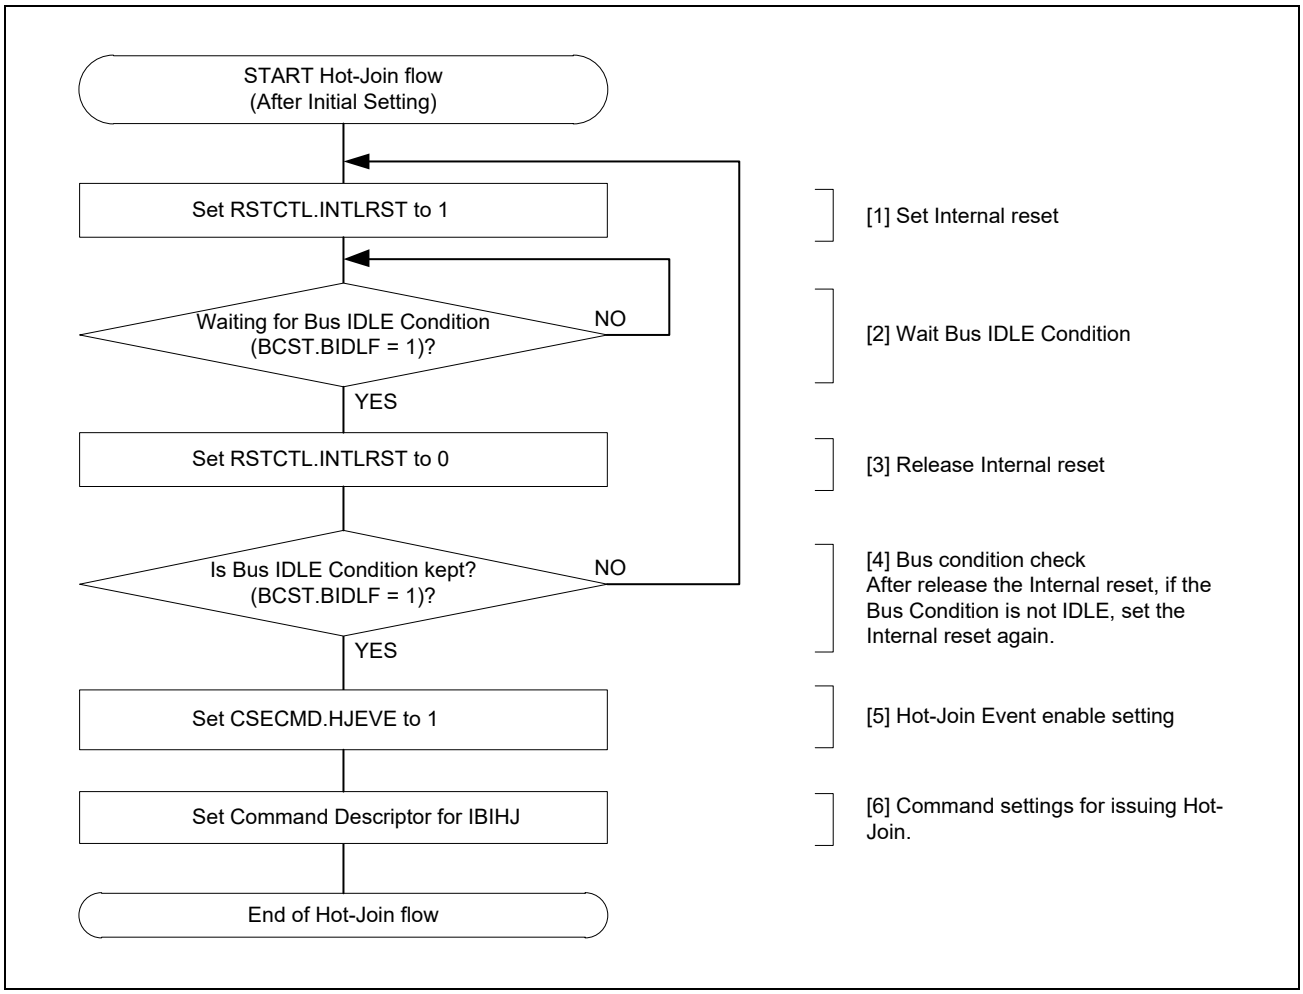


Figure 7.8-126 Hot-Join Flowchart after the I3C Bus has already been configured

(6) I3C Slave Wake-Up Flow

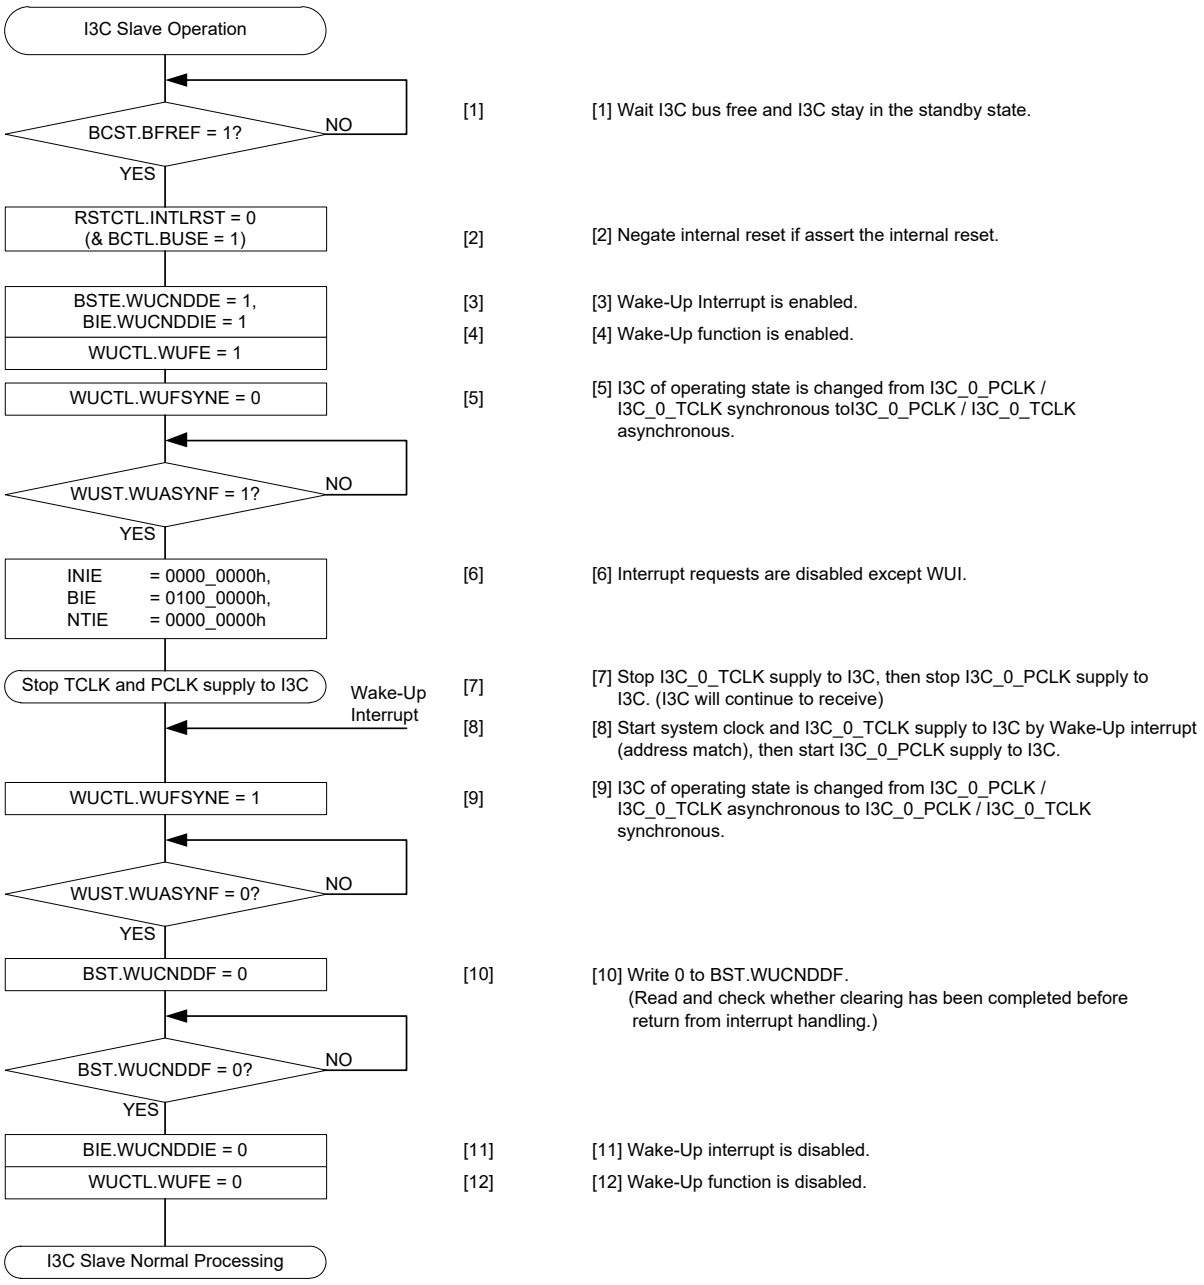

Figure 7.8-127 Use Case of I3C Slave Wake-Up (Wake-up recovery by a wake-up interrupt triggered by the match of the slave address)

7.8.5 Interrupt Sources

I3C can generate the following interrupt requests:

7.8.5.1 Overview

The I3C has the interrupt factors shown in **Table 7.8-17**.

The interrupt indicated by Possible in the DMAC Activation column are capable of activating data transfer by the DMAC.

Table 7.8-17 Interrupt Generation

Symbol	Interrupt source	Interrupt flag	Support				DMAC Activation
			I^2C	I3CM	I3C2M	I3CS	
INT_ri3c_resp_n	Normal response status buffer full	NTST.RSPQFF	—	✓	✓	✓	Not possible
INT_ri3c_cmd_n	Normal command buffer empty	NTST.CMDQEF	—	✓	✓	✓	Not possible
INT_ri3c_ibi_n	Normal IBI status buffer empty/full	NTST.IBIQEFF	—	✓	✓	✓	Not possible
INT_ri3c_rx_n	Normal receive data buffer full	NTST.RDBFF0	✓	✓	✓	✓	Possible
INT_ri3c_tx_n	Normal transmit data buffer empty	NTST.TDBEF0	✓	✓	✓	✓	Possible
INT_ri3c_rcv_n	Normal receive status buffer full	NTST.RSQFF	—	—	✓	✓	Not possible

7.8.6 Event Link Output

I3C handles event output for the event link controller (ELC) corresponding to the following sources.

(1) Communication event

When a Communication event (arbitration-lost detection, detection of NACK, detection of timeout, detection of a START condition, or detection of a STOP condition) occurs, the corresponding event signal can be output for another module via the ELC.

(2) Receive data full

When a receive data register becomes full, the corresponding event signal can be output for another module via the ELC.

(3) Transmit data empty

When a transmit data register becomes empty, the corresponding event signal can be output for another module via the ELC.

(4) Transmit end

On completion of transfer, the corresponding event signal can be output for another module via the ELC.

All event signals from I3C to ELC are shown in **Table 7.8-18**.

Table 7.8-18 Event Signals

Signal Name	Description	Support			
		I^2C	I3CM	I3C2M	I3CS
ri3c_elccommu	Communication event	✓	✓	✓	✓
ri3c_elcresp	Normal response status buffer full event	—	✓	✓	✓

7.8.6.1 Interrupt Handling and Event Linking

I3C module produces four kinds of interrupt: communication event (arbitration-lost detection, detection of NACK, detection of timeout, detection of a START condition, or detection of a STOP condition), receive data full, transmit data empty, and transmit end interrupts. Each of these has an enable bit to control enabling and disabling of the interrupt signal. An interrupt request signal is output for the CPU when an interrupt source condition is satisfied while the setting of the corresponding enable bit is enabled.

The corresponding event link output signals are sent to other modules as event signals via the ELC when the interrupt source conditions are satisfied, regardless of the settings of the interrupt enable bits. For details on interrupt sources, see **7.8.5.1 Overview**.

SECTION 7 LOW-SPEED INTERFACE

7.9 CAN-FD Interface (CANFD)

7.9.1 Overview

The LSI has a 6-channel CAN-FD module (CANFD) that complies with ISO 11898-1 (2015) Standards. CANFD transmits and receives both formats of messages, namely the standard identifier (11 bits) (identifier is hereafter referred to as ID) and extended ID (29 bits). **Table 7.9-1** lists the specifications of the CANFD, **Figure 7.9-1** shows a block diagram of the CANFD, and **Table 7.9-2** lists the I/O pins.

Table 7.9-1 CANFD Specifications (1/2)

Parameter	Description
Number of channels	Six channels
Protocol	CAN-FD ISO 11898-1 (2015)
Communication speed	• Classical CAN mode: 1 Mbps • CAN FD mode*1 Nominal bit rate: Max. 1 Mbps Data bit rate: Max. 8 Mbps
Buffer	Total 320 buffers (when frame size is 76 bytes) • Individual buffers: 192 buffers (32 buffers × 6 channels) Transmit buffer: 32 buffers per channel Transmit queue: 4 queues per channel (shared with transmit buffer, up to 16 buffers allocatable) • Shared buffers: 384 buffers for all channels Receive buffer: 0 to 96 buffers Receive FIFO buffer: 8 FIFO buffers (up to 384 buffers allocatable to each) Transmit/receive FIFO buffer: 3 FIFO buffers per channel (up to 384 buffers allocatable to each)
Reception function	• Receives data frames and remote frames • Selects ID format (standard ID, extended ID, or both IDs) to be received • Sets interrupt enable/disable for each FIFO • Mirror function (reception of messages transmitted from the CAN node itself) • Timestamp function (to record message reception time as a 16-bit timer value)
Reception filter function	• Selects receive message according to 768 receive rules • Sets the number of receive rules (0 to 127) for each channel • Acceptance filter processing: Sets ID and mask for each receive rule • DLC filter processing: Enables DLC filter check for each acceptance rule
Receive message transfer function	• Routing function Transfers receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, and/or transmit/receive FIFO buffer • Label addition function Stores label information together with a message in a receive buffer and FIFO buffer
Transmission function	• Transmits data frames and remote frames • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted • Sets interrupt enable/disable for each transmit buffer and transmit/receive FIFO buffer • Selects ID priority transmission or transmit buffer number priority transmission • Transmit request can be aborted (possible to confirm with a flag) • One-shot transmission function
Interval transmission function	Transmit message at configurable intervals (transmit mode or gateway mode of transmit/receive FIFO buffers)

Table 7.9-1 CANFD Specifications (2/2)

Parameter	Description
Transmit queue function	Transmits all stored messages according to the ID priority
Transmit history function	Stores the history information of transmission-completed messages Adds timestamp (recording message transmission time as a 16-bit timer value) to the history information
Gateway function	Transmits a received message automatically
Bus off recovery mode selection	Selects the method for returning from bus-off state. • ISO 11898-1 compliant • Automatic entry to channel halt mode at bus-off entry • Automatic entry to channel halt mode at bus-off end • Transition to channel halt mode by program request • Transition to the error-active state by program request (forcible return from the bus-off state)
Error status monitoring	• Monitors CAN protocol errors (stuff error, from error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock) • Defects error status transitions (error warning, error passive, bus-off entry, and bus-off recovery) • Reads the error counter • Monitors DLC errors
Interrupt source	8 interrupt sources • Global interrupts (2 sources) RX FIFO interrupt Global error interrupt • Channel interrupts (3 sources/channel) Channel transmit interrupt Channel error interrupt Common RX FIFO interrupt 14 DMA requests • 8 for RX FIFO • 6 for the first common FIFO (1 source/channel)
CAN clock source	CANFD_0_clkc (80 MHz)
Test function	Test function for user evaluation • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • Restricted operation mode • RAM test (read/write test) • Inter-channel communication test (CRC error test enabled)

Note 1. 176 LQFP and 128 LQFP products do not support CAN-FD mode.

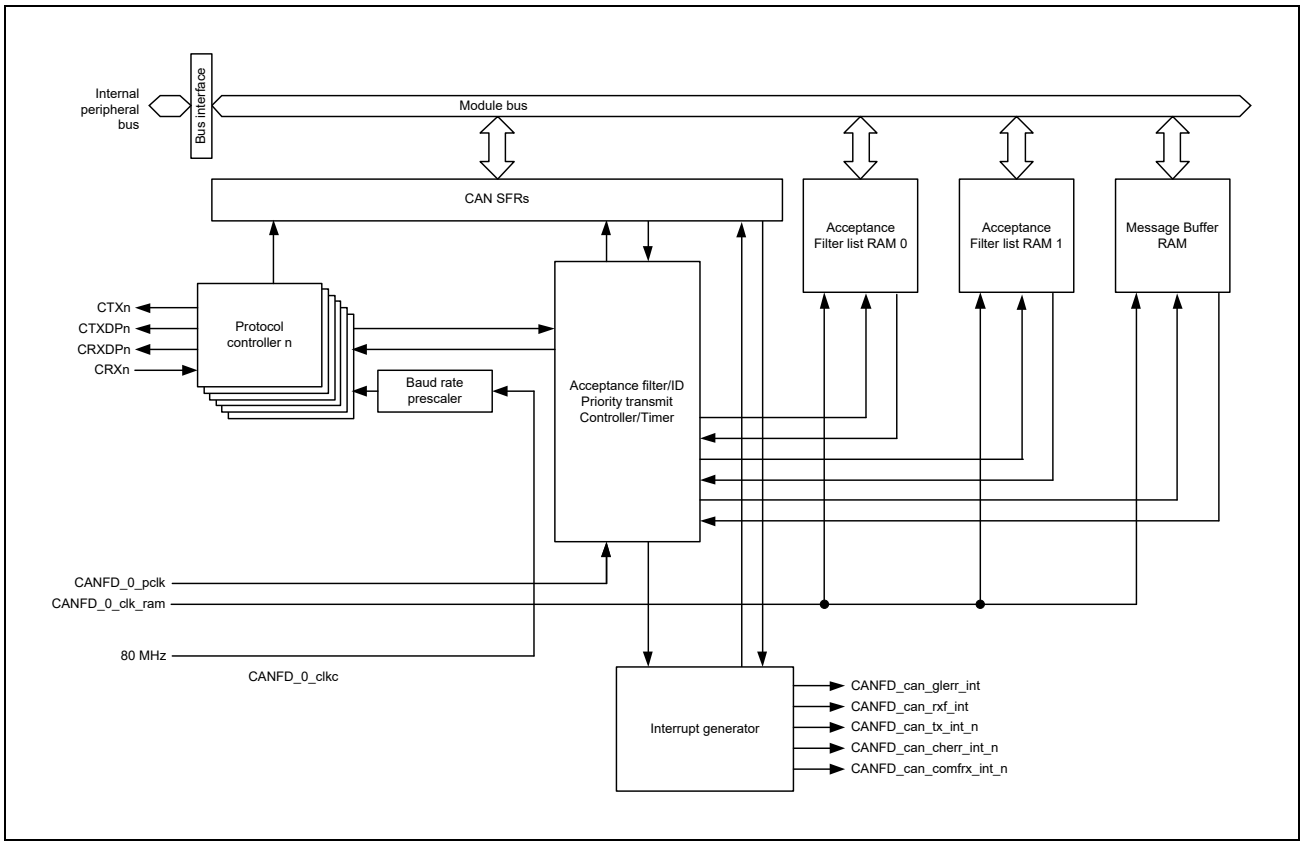

Figure 7.9-1 Block Diagram of CANFD

Table 7.9-2 lists the input/output pins of the CANFD module.

Table 7.9-2 Pin Configuration of CANFD

Channel	Pin Name	Input/Output	Function
CANFDn	CRXn	Input	CANFDn receive data input
	CTXn	Output	CANFDn transmit data output
	CRXDPn	Output	CANFDn receive data phase output This signal indicates the received data phase of a CAN-FD frame (active high).
	CTXDPn	Output	CANFDn transmit data phase output This signal indicates the transmission data phase of a CAN-FD frame (active high).

Note: n = 0 to 5

Table 7.9-3 CANFD Interrupt Sources

Name	Interrupt Sources	DMAC Activation
CANFD_can_rxf_int	RX FIFO interrupt	Not possible
CANFD_can_glerr_int	Global error interrupt	Not possible
CANFD_can_rf_dmareg_m	RX FIFO m DMA request	Possible
CANFD_can_tx_int_n	Channel n TX interrupt	Not possible
CANFD_can_cherr_int_n	Channel n CAN error interrupt	Not possible
CANFD_nan_comfrx_int_n	Channel n Common RX FIFO or TXQ interrupt	Not possible
CANFD_can_cf_dmareg_n	Channel n First common FIFO DMA request	Possible

Note: m = 0 to 7, n = 0 to 5

7.9.2 CANFD Registers

The base address for the CANFD is as follows.

Table 7.9-4 Register Base Address

Base Register Name	Base Address
<CFD_base>	0_1244_0000h (5244_0000h*1, 4244_0000h*2)

Note 1. CM33 Address Space Non-Secure

Note 2. CM33 Address Space Secure

7.9.2.1 List of Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]*1
Channel 0 Nominal Bit Rate Configuration Register	CFDC0NCFG	0000_0000h	0000h	8, 16, 32
Channel 0 Control Register	CFDC0CTR	0000_0005h	0004h	8, 16, 32
Channel 0 Status Register	CFDC0STS	0000_0005h	0008h	8, 16, 32
Channel 0 Error Flag Register	CFDC0ERFL	0000_0000h	000Ch	8, 16, 32
Channel 1 Nominal Bit Rate Configuration Register	CFDC1NCFG	0000_0000h	0010h	8, 16, 32
Channel 1 Control Register	CFDC1CTR	0000_0005h	0014h	8, 16, 32
Channel 1 Status Register	CFDC1STS	0000_0005h	0018h	8, 16, 32
Channel 1 Error Flag Register	CFDC1ERFL	0000_0000h	001Ch	8, 16, 32
Channel 2 Nominal Bit Rate Configuration Register	CFDC2NCFG	0000_0000h	0020h	8, 16, 32
Channel 2 Control Register	CFDC2CTR	0000_0005h	0024h	8, 16, 32
Channel 2 Status Register	CFDC2STS	0000_0005h	0028h	8, 16, 32
Channel 2 Error Flag Register	CFDC2ERFL	0000_0000h	002Ch	8, 16, 32
Channel 3 Nominal Bit Rate Configuration Register	CFDC3NCFG	0000_0000h	0030h	8, 16, 32
Channel 3 Control Register	CFDC3CTR	0000_0005h	0034h	8, 16, 32
Channel 3 Status Register	CFDC3STS	0000_0005h	0038h	8, 16, 32
Channel 3 Error Flag Register	CFDC3ERFL	0000_0000h	003Ch	8, 16, 32
Channel 4 Nominal Bit Rate Configuration Register	CFDC4NCFG	0000_0000h	0040h	8, 16, 32
Channel 4 Control Register	CFDC4CTR	0000_0005h	0044h	8, 16, 32
Channel 4 Status Register	CFDC4STS	0000_0005h	0048h	8, 16, 32
Channel 4 Error Flag Register	CFDC4ERFL	0000_0000h	004Ch	8, 16, 32
Channel 5 Nominal Bit Rate Configuration Register	CFDC5NCFG	0000_0000h	0050h	8, 16, 32
Channel 5 Control Register	CFDC5CTR	0000_0005h	0054h	8, 16, 32
Channel 5 Status Register	CFDC5STS	0000_0005h	0058h	8, 16, 32
Channel 5 Error Flag Register	CFDC5ERFL	0000_0000h	005Ch	8, 16, 32
Reserve	-	-	0060h to 007Fh	-
Global IP Version Register	CFDGIPV	1124_0043h	0080h	8, 16, 32
Global Configuration Register	CFDGCFG	0000_0000h	0084h	8, 16, 32
Global Control Register	CFDGCTR	0000_0005h	0088h	8, 16, 32
Global Status Register	CFDGSTS	0000_000Dh	008Ch	8, 16, 32
Global Error Flag Register	CFDGERFL	0000_0000h	0090h	8, 16, 32
Global Timestamp Counter Register	CFDGTSC	0000_0000h	0094h	16, 32

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]*1
Global Acceptance Filter List Entry Control Register	CFDGAFLECTR	0000_0000h	0098h	8, 16, 32
Global Acceptance Filter List Configuration Register 0	CFDGAFLCFG0	0000_0000h	009Ch	8, 16, 32
Global Acceptance Filter List Configuration Register 1	CFDGAFLCFG1	0000_0000h	00A0h	8, 16, 32
Global Acceptance Filter List Configuration Register 2	CFDGAFLCFG2	0000_0000h	00A4h	8, 16, 32
Reserve	-	-	00A8h to 00ABh	-
RX Message Buffer Number Register	CFDRMNB	0000_0000h	00ACh	8, 16, 32
RX Message Buffer New Data Register t	CFDRMNDt	0000_0000h	00B0h + t x 0004h	8, 16, 32
Reserve	-	-	00BCh to 00BFh	-
RX FIFO Configuration/Control Register 0	CFDRFCC0	0000_0000h	00C0h	8, 16, 32
RX FIFO Configuration/Control Register 1	CFDRFCC1	0000_0000h	00C4h	8, 16, 32
RX FIFO Configuration/Control Register 2	CFDRFCC2	0000_0000h	00C8h	8, 16, 32
RX FIFO Configuration/Control Register 3	CFDRFCC3	0000_0000h	00CCh	8, 16, 32
RX FIFO Configuration/Control Register 4	CFDRFCC4	0000_0000h	00D0h	8, 16, 32
RX FIFO Configuration/Control Register 5	CFDRFCC5	0000_0000h	00D4h	8, 16, 32
RX FIFO Configuration/Control Register 6	CFDRFCC6	0000_0000h	00D8h	8, 16, 32
RX FIFO Configuration/Control Register 7	CFDRFCC7	0000_0000h	00DCh	8, 16, 32
RX FIFO Status Register 0	CFDRFSTS0	0000_0001h	00E0h	8, 16, 32
RX FIFO Status Register 1	CFDRFSTS1	0000_0001h	00E4h	8, 16, 32
RX FIFO Status Register 2	CFDRFSTS2	0000_0001h	00E8h	8, 16, 32
RX FIFO Status Register 3	CFDRFSTS3	0000_0001h	00ECh	8, 16, 32
RX FIFO Status Register 4	CFDRFSTS4	0000_0001h	00F0h	8, 16, 32
RX FIFO Status Register 5	CFDRFSTS5	0000_0001h	00F4h	8, 16, 32
RX FIFO Status Register 6	CFDRFSTS6	0000_0001h	00F8h	8, 16, 32
RX FIFO Status Register 7	CFDRFSTS7	0000_0001h	00FCh	8, 16, 32
RX FIFO Pointer Control Register 0	CFDRFPCTR0	0000_0000h	0100h	8, 16, 32
RX FIFO Pointer Control Register 1	CFDRFPCTR1	0000_0000h	0104h	8, 16, 32
RX FIFO Pointer Control Register 2	CFDRFPCTR2	0000_0000h	0108h	8, 16, 32
RX FIFO Pointer Control Register 3	CFDRFPCTR3	0000_0000h	010Ch	8, 16, 32
RX FIFO Pointer Control Register 4	CFDRFPCTR4	0000_0000h	0110h	8, 16, 32
RX FIFO Pointer Control Register 5	CFDRFPCTR5	0000_0000h	0114h	8, 16, 32
RX FIFO Pointer Control Register 6	CFDRFPCTR6	0000_0000h	0118h	8, 16, 32
RX FIFO Pointer Control Register 7	CFDRFPCTR7	0000_0000h	011Ch	8, 16, 32
Common FIFO Configuration/Control Register n	CFDCFCCn	0000_0000h	0120h + n x 0004h	8, 16, 32
Reserve	-	-	016Ch to 017Fh	-
Common FIFO Configuration/Control Enhancement Register n	CFDCFCCEn	0000_0000h	0180h + n x 0004h	8, 16, 32
Reserve	-	-	01CCh to 01DFh	-
Common FIFO Status Register n	CFDCFSTSn	0000_0001h	01E0h + n x 0004h	8, 16, 32
Reserve	-	-	022Ch to 023Fh	-
Common FIFO Pointer Control Register n	CFDCFPCTRn	0000_0000h	0240h + n x 0004h	8, 16, 32
Reserve	-	-	028Ch to 029Fh	-
FIFO Empty Status Register	CFDFESTS	0000_3FFFh	02A0h	8, 16, 32
FIFO Full Status Register	CFDFFSTS	0000_0000h	02A4h	8, 16, 32

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]*1
FIFO Message Lost Status Register	CFDFMSTS	0000_0000h	02A8h	8, 16, 32
RX FIFO Interrupt Flag Status Register	CFDRFISTS	0000_0000h	02ACh	8, 16, 32
Common FIFO RX Interrupt Flag Status Register	CFDCFRISTS	0000_0000h	02B0h	8, 16, 32
Common FIFO TX Interrupt Flag Status Register	CFDCFTISTS	0000_0000h	02B4h	8, 16, 32
Common FIFO One Frame RX Interrupt Flag Status Register	CFDCFOFRISTS	0000_0000h	02B8h	8, 16, 32
Common FIFO One Frame TX Interrupt Flag Status Register	CFDCFOFTISTS	0000_0000h	02BCh	8, 16, 32
Common FIFO Message Overwrite Status Register	CFDCFMOWSTS	0000_0000h	02C0h	8, 16, 32
FIFO FDC Full Status Register	CFDFFFSTS	0000_0000h	02C4h	8, 16, 32
Reserve	-	-	02C8h to 02CFh	-

Note 1. The read access size is fixed at 32 bits.

7.9.2.2 CANFD Register Description

7.9.2.2.1 Channel n Nominal Bit Rate Configuration Register (CFDCnNCFG) (n = 0 to 5)

The CFDCnNCFG register is used to configure the transmission/reception nominal bit rate parameters of the channels. Do not write this register in CH_OPERATION or CH_SLEEP mode. Set this register in CH_RESET or CH_HALT mode.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0000h + n x 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

16 to 10	NSJW[6:0]	0h	RW	Nominal Bit Rate Resynchronization Jump Width Control 00h: Setting prohibited 01h: 2 Tq ⋮ 7Eh: 127 Tq 7Fh: 128 Tq
9 to 0	NBRP[9:0]	0h	RW	Nominal Bit Rate Prescaler Nominal bit rate prescaler division ratio setting

NBRP[9:0] bits (Nominal Bit Rate Prescaler)

The NBRP[9:0] bits are used to define the peripheral bus clock periods contained in a time quantum.

NSJW[6:0] bits (Nominal Bit Rate Resynchronization Jump Width Control)

The NSJW[6:0] bits set the synchronization jump width. A value from 1 to 128 time quanta can be set.

NTSEG1[7:0] bits (Nominal Bit Rate Time Segment 1 Control)

The NTSEG1[7:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. These bits contain the propagation segment. Configure a Tq value only between 2 and 256, inclusive. See **7.9.4.1.2 CAN Bit Timing** for more details.

NTSEG2[6:0] bits (Nominal Bit Rate Time Segment 2 Control)

The NTSEG2[6:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. Configure a Tq value only between 2 and 128, inclusive.

7.9.2.2.2 Channel n Control Register (CFDCnCTR) (n = 0 to 5)

The CFDCnCTR register controls the modes of the related channel. It is used to enable generation of interrupts if errors are detected on the CAN bus connected to this channel. It is also used to configure the channel in test mode.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0004h + n x 0010h
Initial Value : 0000_0005h

8	BEIE	0h	RW	Bus Error Interrupt Enable 0b: Bus error interrupt disabled 1b: Bus error interrupt enabled
7 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3	RTBO	0h	RW	Forcible Return from Bus-Off When this bit is set to 1b, forcible return from the bus-off state is made. This bit is always read as 0b.
2	CSLPR	1h	RW	Channel Stop Mode 0b: Other than Channel Stop mode 1b: Channel Stop mode
1, 0	CHMDC[1:0]	1h	RW	Mode Select 00b: Channel Communication mode 01b: Channel Reset mode 10b: Channel Halt mode 11b: Setting prohibited

Note 1. These bits are not available in the classical CAN function.

CHMDC[1:0] bits (Mode Select)

The CHMDC[1:0] bits can be used to configure modes of the CAN channel.

CAN mode transitions are described in more details in **7.9.3.3 Channel Modes**.

Setting CHMDC[1:0] bits to 11b has no effect. When the CAN-FD module is in GL_HALT mode, these bits can only be set to 10b or 01b. These bits cannot be set in CH_SLEEP mode.

These bits can change automatically when transitioning to Halt mode by the CFDCnCTR.BOM settings.

If CPU write access to CFDCnCTR.CHMDC occurs at the same time when the CAN channel enters Halt mode (at the start of bus-off when CFDCnCTR.BOM[1:0] = 01b, or at the end of bus-off when CFDCnCTR.BOM[1:0] = 10b), then the CPU write access has the highest priority.

The CAN channel changes the value of CFDCnCTR.CHMDC within the Channel Control Registers for the specified cases only if the CFDCnCTR.CHMDC[1:0] value is 00b (Operation mode).

CSLPR bit (Channel Stop Mode)

When the CSLPR bit is 1b, a Sleep mode request is generated for the corresponding CAN channel.

When this bit is 0b, a request to exit Sleep mode is generated for the related CAN-FD channel.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

RTBO bit (Forcible Return from Bus-Off)

When the protocol controller of the CAN channel enters bus-off state, you can force a recovery from bus-off state by setting the RTBO bit in the Channel Control Register to 1b.

The error state changes from bus-off state to integrating with a maximum delay of 1 CAN bit time.

When the RTBO bit is set to 1b, the REC and TEC registers are initialized and the Bus-Off Status bit (Channel Bus-off Status, CFDCnSTS.BOSTS) is set to 0b.

Registers other than the REC and TEC registers are not initialized by this command. Even if CFDCnCTR.BORIE is set, a bus-off recovery interrupt is not generated by this recovery from the bus-off state.

The RTBO bit cannot be set in CH_SLEEP mode. Setting this bit in any state other than bus-off state has no effect and the bit is cleared immediately. The read value is always 0b.

Return from the Bus-Off command should be used only when CFDCnCTR.BOM[1:0] is set to 00b.

Only write to this bit when the related CAN-FD channel is in CH_OPERATION mode. This bit is automatically cleared when set by software.

BEIE bit (Bus Error Interrupt Enable)

When the BEIE and the CFDCnERFL.BEF bits are both 1b, an error interrupt request is generated.

This bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

EWIE bit (Error Warning Interrupt Enable)

When the EWIE and the CFDCnERFL.EWF bits are both 1b, an error interrupt request is generated.

The EWIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

EPIE bit (Error Passive Interrupt Enable)

An error interrupt request is generated when the EPIE bit and the CFDCnERFL.EPF are both 1b.

The EPIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

BOEIE bit (Bus-Off Entry Interrupt Enable)

When the BOEIE and the CFDCnERFL.BOEF bits are both 1b, an error interrupt request is generated.

The BOEIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

BORIE bit (Bus-Off Recovery Interrupt Enable)

When the BORIE and the CFDCnERFL.BORF bits are both 1b, an error interrupt request is generated.

The BORIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

OLIE bit (Overload Interrupt Enable)

When the OLIE and the CFDCnERFL.OVLF bits are both 1b, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

BLIE bit (Bus Lock Interrupt Enable)

When the BLIE and the CFDCnERFL.BLF bits are both 1b, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

ALIE bit (Arbitration Lost Interrupt Enable)

When the ALIE and the CFDCnERFL.ALF bits are both 1b, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

TAIE bit (Transmission Abort Interrupt Enable)

When the TAIE bit is 1b and a transmission is successfully aborted from the transmit buffer, an interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

EOCOIE bit (Error Occurrence Counter Overflow Interrupt Enable)

When the EOCOIE bit is 1b and the CFDCnFDSTS.EOCO bit belonging to the corresponding CAN channel is 1b, an error interrupt request is generated.

The EOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

SOCOIE bit (Successful Occurrence Counter Overflow Interrupt Enable)

When the SOCOIE bit is 1b and the CFDCnFDSTS.SOCO bit belonging to the corresponding CAN channel is 1b, an error interrupt request is generated.

The SOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

TDCVFIE bit (Transceiver Delay Compensation Violation Interrupt Enable)

When the TDCVFIE bit is 1b and the CFDCnFDSTS.TDCVF bit belonging to the corresponding CAN channel is 1b, an error interrupt request is generated.

The TDCVFIE bit cannot be set in CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode. Do not set this bit when in Classical-only mode.

Note: This bit is not available in the classical CAN function.

BOM[1:0] bits (Bus-Off Recovery Mode Select)

The BOM[1:0] bits control the timing of the recovery from Bus-Off mode of the CAN-FD Channel.

Do not write to these bits in CH_SLEEP mode. Only write to these bits when the related CAN-FD channel is in CH_RESET mode.

ERRD bit (Error Display Mode Select)

The ERRD bit controls the display mode of the error flag bits [14:8] in the Channel Error Flag Register (CFDCnERFL).

If the ERRD bit is 0b and more than one errors occur at the same time, the error flag bits are set for all the errors that occurred at the same time. No further errors are flagged until the error flag bits [14:8] are cleared.

Do not write to the ERRD bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

CTME bit (Communication Test Mode Enable)

The CTME bit enables the channel test modes.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_HALT mode.

CTMS[1:0] bits (Communication Test Mode Select)

The CTMS[1:0] bits are used to select the required test mode.

Do not write to these bits in CH_SLEEP or CH_RESET mode. Only write to these bits when the related CAN-FD channel is in CH_HALT mode.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

CRCT bit (CRC Error Test Enable)

The CRCT bit checks the internal CRC generator logic of the protocol controller.

This bit inverts the first bit (ID bit) of the CAN message data stream that is being received, so that the internal generated CRC result does not match the received CRC value of the frame. Refer to the bit stuffing rule when using this feature for the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The internal generated CRC value is always observed in the following registers:

- CFDCnERFL.CRCREG (classical CAN frames)
- CFDCnFDCRC.CRCREG (CAN-FD frames)

Some limitations exist when using this bit:

- It is not possible to use this feature with CAN nodes connected to the device externally, only with nodes connected to the internal CAN bus communication can be used
- One CAN node can send a reference message and the receiver node can invert one bit of the incoming bit stream

Note: The transmitter and receiver modes share the same CRC generator, therefore it is not necessary to consider the modes separately when testing this limitation.

The CRC Error Test mode is enabled if the CRCT (new control signal that inverts the first bit of the bit stream) and CTME bits are both 1b.

Do not write to the CRCT bit in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_HALT mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

ROM bit (Restricted Operation Mode Enable)

When the ROM and CTME bits are both 1b, the restricted operation mode is enabled. This mode should only be used in basic test mode (CFDCnCTR.CTMS[1:0] = 00b).

The ROM bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CAN-FD channel is in CH_HALT mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. Do not set this bit when in Classical-only mode.

Note: This bit is not available in the classical CAN function.

7.9.2.2.3 Channel n Status Register (CFDCnSTS) (n = 0 to 5)

The CFDCnSTS register shows the mode, error, and transmission/reception status of the related channel together with its reception and transmission error count values.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0008h + n x 0010h
Initial Value : 0000_0005h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	TEC[7:0]	0h	R	Transmission Error Count The transmit error counter (TEC) can be read.
23 to 16	REC[7:0]	0h	R	Reception Error Count The receive error counter (REC) can be read.
15 to 9	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
8	ESIF*1	0h	RW	Error State Indication Flag 0b: No CANFD message whose ESI bit is recessive has been received 1b: At least one CANFD message whose ESI bit is recessive has been received
7	COMSTS	0h	R	Communication Status Flag 0b: Communication is not ready 1b: Communication is ready
6	RECSTS	0h	R	Receive Status Flag 0b: Bus idle, in transmission or bus off state 1b: In reception
5	TRMSTS	0h	R	Transmit Status Flag 0b: Bus idle or in reception 1b: In transmission or bus off state
4	BOSTS	0h	R	Bus-Off Status Flag 0b: Not in bus-off state 1b: In bus-off state
3	EPSTS	0h	R	Error Passive Status Flag 0b: Not in error passive state 1b: In error passive state
2	CSLPSTS	1h	R	Channel Stop Status Flag 0b: Not in Channel Sleep mode 1b: In Channel Sleep mode
1	CHLTSTS	0h	R	Channel Halt Status Flag 0b: Not in Channel Halt mode 1b: In Channel Halt mode
0	CRSTSTS	1h	R	Channel Reset Status Flag 0b: Not in Channel Reset mode 1b: In Channel Reset mode

Note 1. This bit is not available in the classical CAN function.

CRSTSTS bit (Channel Reset Status Flag)

The CRSTSTS bit indicates whether the related CAN channel is in Reset mode.

This bit is set automatically when the related CAN channel enters Channel Reset mode. When the mode is changed from Reset mode to Sleep mode, the CRSTSTS bit remains 1b.

This bit is cleared automatically when the related CAN channel exits the Channel Reset mode, except when changing to Sleep mode.

CHLTSTS bit (Channel Halt Status Flag)

The CHLTSTS bit indicates whether the related CAN channel is in Halt mode.

This bit is set automatically when the related CAN module enters Halt mode, and is cleared automatically when the related CAN module exits Halt mode.

CSLPSTS bit (Channel Stop Status Flag)

The CSLPSTS bit indicates whether the related CAN channel is in Sleep mode.

This bit is set automatically when the related CAN-FD channel enters Sleep mode, and is cleared automatically when the related CAN-FD channel exits Sleep mode.

EPSTS bit (Error Passive Status Flag)

The EPSTS bit indicates whether the related CAN-FD channel has entered the error passive state.

This bit is set automatically when the value of the CAN Transmission or Reception Counter Register exceeds the value of 7Fh.

This bit is cleared automatically when the related CAN-FD channel exits the error passive state or enters Reset mode.

BOSTS bit (Bus-Off Status Flag)

The BOSTS bit indicates whether the related CAN-FD channel has entered the error bus-off state.

This bit is set automatically when the value of the related CAN Transmission Error Count Register exceeds FFh and the related CAN-FD channel is in the bus-off state (CAN Transmission Error Count Register > FFh).

This bit is cleared automatically when the related CAN-FD channel exits bus-off state.

TRMSTS bit (Transmit Status Flag)

The TRMSTS bit indicates whether the related CAN-FD channel is transmitting a message.

This bit is set automatically when the related CAN-FD channel is operating as a transmitter node or is in the bus-off state.

This bit is cleared automatically when the related CAN-FD channel is in the bus-idle state or starts operating as a receiver node.

RECSTS bit (Receive Status Flag)

The RECSTS bit indicates whether the related CAN-FD channel is receiving a message.

This bit is set automatically when the related CAN-FD channel is operating as a receiver node.

This bit is cleared automatically when the related CAN-FD channel is in the bus-idle state or starts operating as a transmitter node.

COMSTS bit (Communication Status Flag)

The COMSTS bit indicates whether the related CAN-FD channel is ready for communication.

This bit is set automatically when the related CAN-FD channel is ready to perform communication following the detection of 11 consecutive recessive bits after exiting the Reset or Halt mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

Note: This bit is 1b during bus-off state.

ESIF bit (Error State Indication Flag)

The ESIF bit is set when the ESI bit is sampled recessive for a reception CAN message without any error. When in Loopback or Mirror mode, the self-transmitted messages are considered reception messages.

If a set from the CAN-FD channel occurs simultaneously with a clear by a write access, then the bit is set.

This bit is cleared by writing 0b to it. This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

Note: This bit is not available in the classical CAN function.

REC[7:0] bits (Reception Error Count)

The REC[7:0] bits increment or decrement the counter value according to error status of the CAN-FD channel during reception, and display the value of the REC error counter.

The value in bus-off state is indeterminate.

These bits are cleared automatically when the CAN-FD module enters GL_RESET or the CAN-FD channel is in CH_RESET mode.

TEC[7:0] bits (Transmission Error Count)

The TEC[7:0] bits increment or decrement the counter value according to error status of the CAN-FD channel during transmission, and display the value of the TEC error counter.

Only write to these bits when in test mode and CAN-FD channel is in CH_HALT mode.

Do not read data from this register while CFDCnCTR.TRWE is set.

These bits are cleared automatically when CAN-FD module is in GL_RESET or CAN-FD channel is in CH_RESET mode.

7.9.2.2.4 Channel n Error Flag Register (CFDCnERFL) (n = 0 to 5)

The CFDCnERFL register shows the status of various error conditions detectable regardless of the setting of the related CAN Channel Error Interrupt Enable Register. It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) for a description of error occurrence conditions.

Only write to this register when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 000Ch + n x 0010h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8	SERR	0h	RW*1	Stuff Error Flag 0b: Channel stuff error not detected 1b: Channel stuff error detected
7	ALF	0h	RW*1	Arbitration Lost Flag 0b: Channel arbitration-lost not detected 1b: Channel arbitration-lost detected
6	BLF	0h	RW*1	Bus Lock Flag 0b: Channel bus lock not detected 1b: Channel bus lock detected
5	OVLF	0h	RW*1	Overload Flag 0b: Channel overload not detected 1b: Channel overload detected

Bit	Bit Name	Initial Value	R/W	Description
4	BORF	0h	RW*1	Bus-Off Recovery Flag 0b: Channel bus-off recovery not detected 1b: Channel bus-off recovery detected
3	BOEF	0h	RW*1	Bus-Off Entry Flag 0b: Channel bus-off entry not detected 1b: Channel bus-off entry detected
2	EPF	0h	RW*1	Error Passive Flag 0b: Channel error passive not detected 1b: Channel error passive detected
1	EWF	0h	RW*1	Error Warning Flag 0b: Channel error warning not detected 1b: Channel error warning detected
0	BEF	0h	RW*1	Bus Error Flag 0b: Channel bus error not detected 1b: Channel bus error detected

Note 1. To clear each flag of this register, software must write 0b to the corresponding bit. These flags cannot be set to 1 by software.

BEF bit (Bus Error Flag)

The BEF bit indicates a detection of a CAN channel bus error state, flagged by bits [14:8] in this register.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

This bit is set automatically when a bus error is detected, and is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

EWF bit (Error Warning Flag)

The EWF bit indicates whether an error warning condition has been detected for the CAN channel.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

This bit is set automatically when either TEC or REC exceeds 5Fh.

The setting of this bit only occurs when the TEC or REC initially exceeds 5Fh. Therefore, if the TEC or REC remains > 5Fh and the EWF bit is cleared by software, it is not set again until both the TEC and REC go below 60h and either TEC or REC crosses over again from a value 5Fh to a value > 5Fh.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

EPF bit (Error Passive Flag)

The EPF bit indicates a detection of a CAN channel error passive state.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

This bit is set automatically when the CAN error state becomes error passive state.

The setting of this bit only occurs when the TEC or REC initially exceeds 7Fh. Therefore, if the TEC or REC remains > 7Fh and the bit is cleared by software, it is not set again until both the TEC and REC go below 80h and either TEC or REC crosses over again from a value ≤ 7Fh to a value > 7Fh.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

BOEF bit (Bus-Off Entry Flag)

The BOEF bit indicates a detection of a CAN channel bus-off entry state.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

This bit is set automatically when the CAN error state enters the bus-off state.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the bit is set.

BORF bit (Bus-Off Recovery Flag)

The BORF bit indicates a detection of a CAN channel bus-off recovery state.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

This bit is set automatically if CAN channel recovers from bus-off state in the following conditions:

- When CFDCnCTR.BOM[1:0] is 00b and normal recovery (11 consecutive recessive bits × 128 times detected) occurs
- When CFDCnCTR.BOM[1:0] is 10b and normal recovery (11 consecutive recessive bits × 128 times detected) occurs
- When CFDCnCTR.BOM[1:0] is 11b and normal recovery (11 consecutive recessive bits × 128 times detected) occurs.

The bit is not set if CAN channel recovers from bus-off state in the following conditions:

- When CAN Reset mode is requested
- When CFDCnCTR.RTBO is set to 1b (the CAN channel returns to error active)
- When CFDCnCTR.BOM[1:0] is 01b
- When CFDCnCTR.BOM[1:0] is 11b and a halt request is asserted before the CAN channel reaches the end of the bus- off state.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set.

OVLF bit (Overload Flag)

The OVLF flag indicates a detection of a CAN channel overload state.

The OVLF bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

This bit is set automatically when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

BLF bit (Bus Lock Flag)

The BLF bit indicates a detection of a CAN channel bus lock condition.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

This bit is set automatically when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

ALF bit (Arbitration Lost Flag)

The ALF bit indicates a detection of a CAN channel bus arbitration-lost condition.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

The bit is set automatically when an arbitration-lost condition is detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

SERR bit (Stuff Error Flag)

The SERR bit indicates a detection of a CAN stuff error.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a stuff error is detected. If CFDCnCTR.ERRD bit is 1b and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0b and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 000_0000b.

FERR bit (Form Error Flag)

The FERR bit indicates a detection of a CAN form error.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected. If CFDCnCTR.ERRD bit is 1b and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0b and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 000_0000b.

AERR bit (Acknowledge Error Flag)

The AERR bit indicates a detection of a CAN acknowledge error.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.

2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when an acknowledge error is detected. If CFDCnCTR.ERRD bit is 1b and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0b and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 000_0000b.

CERR bit (CRC Error Flag)

The CERR bit indicates a detection of a CAN CRC error.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a CRC error is detected. If CFDCnCTR.ERRD bit is 1b and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0b and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 000_0000b.

B1ERR bit (Recessive Bit Error Flag)

The B1ERR bit indicates a detection of a recessive bit error.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a recessive bit error (expected recessive bit, sampled as dominant bit) is detected. If CFDCnCTR.ERRD bit is 1b and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0b and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 000_0001b.

B0ERR bit (Dominant Bit Error Flag)

The B0ERR bit indicates a detection of a dominant bit error.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a dominant bit error (expected dominant bit, sampled as recessive bit) is detected. If CFDCnCTR.ERRD bit is 1b and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0b and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 000_0000b.

ADERR bit (Acknowledge Delimiter Error Flag)

The ADERR bit indicates a detection of an acknowledge delimiter bit error.

This bit is cleared by writing 0b to it, and can only be set by CAN-FD module logic. Writing 1b has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected during the acknowledge delimiter state of frame transmission. If CFDCnCTR.ERRD bit is 1b and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode. If CFDCnCTR.ERRD bit is 0b and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at the error flag bits [14:8] in the CFDCnERFL register is already set. Otherwise, this bit is set if the error flag bits [14:8] in the CFDCnERFL register is 000_0000b.

CRCREG[14:0] bits (CRC Calculation Data (CRC length: 15 bits))

The CRCREG[14:0] bits read the calculated CRC value when CFDCnCTR.CTME bit is 1b for the channel.

If CFDCnCTR.CTME bit is 0b, then these bits are always read as 0b.

These bits show the CAN2.0 CRC value calculated by the CAN-FD channel logic when the CTME bit is enabled.

The CFDCnERFL.CRCREG value is updated in the first bit of the CRC field of the CAN frame (reception and transmission).

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

7.9.2.2.5 Channel n Data Bit Rate Configuration Register (CFDCnDCFG) (n = 0 to 5)

This register is not available in the classical CAN function.

The CFDCnDCFG register configures the transmission/reception data bit rate parameters of the channels.

The channel of Classical-only mode does not perform configuration of this register.

Do not write to this register in CH_OPERATION or CH_SLEEP mode. Only write to this register in CH_RESET or CH_HALT mode.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1400h + n x 0020h

Initial Value : 0000_0000h

7 to 0	DBRP[7:0]	0h	RW	Data Bit Rate Prescaler Division Ratio Setting When the set value = P (0 to 255), the data bit rate prescaler divides fCAN by (P + 1).

DBRP[7:0] bits (Data Bit Rate Prescaler Division Ratio Setting)

The DBRP[7:0] bits define the peripheral bus clock periods contained in a time quantum.

DTSEG1[4:0] bits (Data Bit Rate Time Segment 1 Control)

The DTSEG1[4:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. A value from 2 to 32 time quanta can be set.

The DTSEG1[4:0] bits are also used to set the propagation segment.

Do not write any other value to these bits. See **7.9.4.1.2 CAN Bit Timing** for more details.

DTSEG2[3:0] bits (Data Bit Rate Time Segment 2 Control)

The DTSEG2[3:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error. A value from 2 to 16 time quanta can be set.

Do not write any other value to these bits.

DSJW[3:0] bits (Data Bit Rate Resynchronization Jump Width Control)

The DSJW[3:0] bits set the synchronization jump width. A value from 1 to 16 time quanta can be set.

7.9.2.2.6 Channel n CAN-FD Configuration Register (CFDCnFDCFG) (n = 0 to 5)

The CFDCnFDCFG register configures which communication direction (transmitter/receiver) errors are counted.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1404h + n x 0020h

Initial Value : 0000_0000h

Note 1. This bit is set to 1b for this LSI with CANFD disabled.

Note 2. These bits are not available in the classical CAN function.

EOCCFG[2:0] bits (Error Occurrence Counter Configuration)

The EOCCFG[2:0] bits select which type of CAN frame configuration and direction, including protocol errors are counted.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

TDCOC bit (Transmitter Delay Compensation Offset Configuration)

The TDCOC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CAN- FD channel. If the bit is set to 0b, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1b, the position of the SSP is defined only by the offset.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

TDCE bit (Transceiver Delay Compensation Enable)

The TDCE bit enables the transceiver delay compensation for the CAN-FD channel.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

ESIC bit (Error State Indication Configuration)

Bus controllers that are used as CAN-to-CAN gateway support that in every forwarded CAN-FD message. The ESI flag does not change to reflect the status of the gateway, bridge, or router but instead the flag is sent as it was in the original message.

The ESIC bit controls the transmission of either the ESI flag information or the message of ESI flag information (CFDCFFDCSTSn.CFESI or CFDTMFDCTRn.TMESI).

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

TDCO[7:0] bits (Transceiver Delay Compensation Offset)

The TDCO[7:0] bits set the secondary sample point offset. How this value is used, depends on the CFDCnFDCFG.TDCOC setting.

If CFDCnFDCFG.TDCOC = 0b, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in CFDCnFDCFG.TDCO, rounded down to the nearest integer number of time quanta. Otherwise, the result is equal to the value in CFDCnFDCFG.TDCO. See **7.9.4.1.5 Transmitter Delay Compensation** for details on how CFDCnFDCFG.TDCO is used.

The actual offset value is interpreted as TDCO + 1. For example, if 4 is set in TDCO, the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.

Do not write to the TDCO[7:0] bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode. Do not set to this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

GWEN bit (CAN2.0, CAN-FD Multi Gateway Enable)

When the GWEN bit is enabled, a multi gateway is enabled. Message received on one node can be routed to another node using the COM FIFO when they are configured as gateway FIFO (CFDCFCCn.CFM[1:0] = 10b). Furthermore, when TX Queue is set as Gateway mode, the message received on one node can be stored in TX Queue and can be sent to another node.

The FDF and BRS bits of the routed message can be changed by the configuration value of the CFDCnFDCFG.GWFDF and CFDCnFDCFG.GWBRS bits. By this, the transmitted value of these bits can be replaced.

Example)

CFDCnFDCFG.GWEN = 1b on channel y
CFDCnFDCFG.GWFDF = 1b

If a Classical CAN frame is received on channel x and routed to a gateway FIFO or TX Queue of channel y, then this CAN frame is sent on channel y as a CAN-FD frame because of the CFDCnFDCFG.GWFDF bit.

Table 7.9-5 shows how the message information is changed depending on the received and configured data.

Table 7.9-5 Modified Message Information by Received and Configured Data

Routed CAN Frame	Routed Received DLC	CAN BRS Bit	Configured CFDCnFDCFG.GWFDF Bit	Gateway Message DLC	Gateway Message BRS Bit	Gateway Message Frame Type
CAN2.0	≤ 8	N/A	1	≤ 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN2.0	> 8	N/A	1	= 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN-FD	≤ 8	None	1	≤ 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN-FD	> 8	None	1	> 8	Based on configuration of CFDCnFDCFG.GWBRS	CAN-FD
CAN2.0	≤ 8	N/A	0	≤ 8	N/A	CAN2.0
CAN2.0	> 8	N/A	0	> 8	N/A	CAN2.0
CAN-FD	≤ 8	None	0	≤ 8	N/A	CAN2.0
CAN-FD	> 8	None	0	= 8	N/A	CAN2.0

Note: This gateway is limited to an 8-byte data payload for different frame type. If routing and target frame type is the same, the data length code (DLC) value remains the same. If the source frame is a CAN-FD with more than 8 data bytes, then on classical destination node, the data payload is reduced to 8 bytes. Only the first 8 bytes of data perform gateway transmission.

Note: Transmission buffers other than the gateway FIFO are not affected by this feature.

Do not route remote frames through the gateway when CFDCnFDCFG.GWEN is set. When a destination node is CFDCnFDCFG.FDOE = 1b, set CFDCnFDCFG.GWEN and CFDCnFDCFG.GWFDF to 1b. When a destination node is CFDCnFDCFG.CLOE = 1b, set CFDCnFDCFG.GWEN = 1b and CFDCnFDCFG.GWFDF = 0b.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode.

This bit is not available in the classical CAN function.

GWFDF bit (Gateway FDF Configuration Bit)

When the GWEN bit is set to 1b, the FDF bit of the transmitting gateway frame is replaced by the value of the GWFDF bit.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CAN-FD module is in CH_RESET mode. Do not set this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

GWBRS bit (Gateway BRS Configuration Bit)

When the GWEN bit is set to 1b, the BRS bit of the transmitting gateway frame is replaced by the value of CFDCnFDCFG.GWBRS.

In classical CAN frames, the GWBRS bit is invalid.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CAN-FD channel is in CH_RESET mode. Do not set this bit when in Classical-only mode.

This bit is not available in the classical CAN function.

FDOE bit (FD-Only Enable)

The FDOE bit enables the reception and transmission of CAN-FD-only frames. If enabled, communication in Classical CAN frame format is disabled. Transmission of Classical CAN frames is not possible because the FDF bit of the message buffer is a don’t care (CFDCFFDCSTSn.CFFDF/CFDTMFDCTRn.TMFDF).

If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and response with error frames. When a Classical CAN frame is configured for transmitting, the FDF bit is sent as recessive, therefore an FD frame is sent. If the data length code (DLC) is configured of greater than 8 bytes, the remaining data bytes are padded with CCh.

The FDOE bit cannot be written in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Do not set CFDCnFDCFG.FDOE and CFDCnFDCFG.CLOE simultaneously.

This bit is not available in the classical CAN function.

REFE bit (RX Edge Filter Enable)

The REFE bit enables the RX edge filter during the IDLE detection (bus integration). When the bit is enabled, two consecutive dominant time quanta are required to detect a synchronization edge.

The REFE bit cannot be written in CH_OPERATION, CH_HALT and CH_SLEEP mode. Do not set this bit when in Classical-only mode and when CFDCnFDCFG.CFDTE = 0b (disabled CAN-FD frame distinction).

CLOE bit (Classical CAN-Only Enable)

The CLOE bit enables the Classical CAN-only mode. If this bit is 1b, the protocol controller can only send classical frames and response with a form or CRC error on FD frames.

Do not set CFDCnFDCFG.CLOE and CFDCnFDCFG.FDOE simultaneously.

CFDCnFDCFG.CLOE	CFDCnFDCFG.FDOE	Channel mode
0	0	CAN-FD mode (Dual mode)
0	1	FD-only mode
1	0	Classical CAN-only mode
1	1	Reserved

Do not write to this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the CAN-FD channel is in CH_RESET mode.

This bit is not available in the classical CAN function.

CFDTE bit (CAN-FD Frame Distinction Enable)

The CFDTE bit enables the CAN-FD frame distinction function. The CFDTE bit is required for Classical CAN-only mode (CFDCnFDCFG.CLOE = 1b).

If this bit is 0b, the protocol controller can only send Classical frames and response with a Form or CRC error on FD frames.

If this bit is 1b, the protocol controller behaves according to the ISO 11898-1 (DIS 2015) specification. If the FDF bit is detected recessive, then the protocol controller enters the protocol exception state, and attempts to integrate back to the CAN communication.

Do not write this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the related CAN-FD channel is in CH_RESET mode.

7.9.2.2.7 Channel n CAN-FD Control Register (CFDCnFDCTR) (n = 0 to 5)

The CFDCnFDCTR register (n = 0 to 5) controls the error and successful occurrence counters.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1408h + n x 0020h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	EOCCLR	0h	RW	Error Occurrence Counter Clear 0b: No error occurrence counter clear 1b: Clear error occurrence counter

EOCCLR bit (Error Occurrence Counter Clear)

The EOCCLR bit is used to clear the error occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0b.

This bit is cleared automatically by the CAN-FD logic and when the related CAN-FD channel is in CH_RESET mode.

SOCCLR bit (Successful Occurrence Counter Clear)

The SOCCLR bit is used to clear the successful occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0b.

This bit is cleared automatically by the CAN-FD logic and when the related CAN-FD channel is in CH_RESET mode.

7.9.2.2.8 Channel n CAN-FD Status Register (CFDCnFDSTS) (n = 0 to 5)

The CFDCnFDSTS register (n = 0 to 5) indicates the transceiver compensation delay result and its related FIFO message lost status.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 140Ch + n x 0020h
Initial Value : 0000_0000h

15	TDCVF	0h	RW	Transceiver Delay Compensation Violation Flag 0b: Transceiver delay compensation violation has not occurred 1b: Transceiver delay compensation violation has occurred
14 to 10	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9	SOCO	0h	RW	Successful Occurrence Counter Overflow Flag 0b: Successful occurrence counter has not overflowed 1b: Successful occurrence counter has overflowed
8	EOCO	0h	RW	Error Occurrence Counter Overflow Flag 0b: Error occurrence counter has not overflowed 1b: Error occurrence counter has overflowed
7 to 0	TDCR[7:0]	0h	R	Transceiver Delay Compensation Result

TDCR[7:0] bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.

The measured delay is a multiple of the CAN channel DLL clock. The result depends on the CFDCnFDCFG.TDCOC configuration and the offset value in CFDCnFDCFG.TDCO. See **7.9.4.1.5 Transmitter Delay Compensation** for details on how this value is derived.

The TDCR[7:0] bits are updated at the falling edge between the FDF bit and the RES bit when CFDCnFDCFG.TDCOC = 0b and the transceiver delay compensation is enabled (CFDCnFDCFG.TDCE = 1b).

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

EOCO bit (Error Occurrence Counter Overflow Flag)

The EOCO bit indicates whether the related CAN channel error occurrence counter has overflowed. This bit is cleared by writing 0b to it. Writing 1b has no effect.

This bit is set automatically when CFDCnFDSTS.EOC is FFh and a CAN bus error is detected based on the configuration defined in CFDCnFDCFG.EOCCFG.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit.

SOCO bit (Successful Occurrence Counter Overflow Flag)

The SOCO bit indicates whether the related CAN channel successful occurrence counter has overflowed. This bit is cleared by writing 0b to it. Writing 1b has no effect.

This bit is set automatically when CFDCnFDSTS.SOC is FFh and a successful message reception or successful message transmission occurs.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit.

TDCVF bit (Transceiver Delay Compensation Violation Flag)

The CAN-FD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.

The transceiver delay has some variations depending on the physical parameters such as temperature. The result bit CFDCnFDSTS.TDCR is updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCVF bit captures this violation.

This bit is cleared by writing 0b to it. Writing 1b has no effect.

This bit is set automatically when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times - 2 clk_dlc) and the internal bit is overrun.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit.

EOC[7:0] bits (Error Occurrence Counter)

The EOC[7:0] bits are used together with the SOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

This higher error rate can be detected depending on the configuration of the CFDCnFDCFG.EOCCFG bits.

The EOC[7:0] bits are set only by CAN-FD module logic. These bits are cleared by writing 1b to CFDCnFDCTR.EOCCLR. Writing any other value has no effect.

These bits are updated when an error occurs, according to the configuration of the CFDCnFDCFG.EOCCFG bits. When the counter reaches the value of FFh, the update stops.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

SOC[7:0] bits (Successful Occurrence Counter)

The SOC[7:0] bits are used together with the EOC[7:0] bits to support an option for host-controlled fall-back to payload bit rate identical to arbitration bit rate when messages utilizing the reduced payload bit length have significant higher error rates compared to other messages.

The SOC[7:0] bits are set only by CAN-FD module logic. Writing any other value has no effect.

These bits are updated when the occurrence of any error-free messages on the bus is detected through reception or transmission. When the counter reaches the value of FFh, the update stops. In Loopback mode, the counter is incremented twice.

These bits are cleared by writing 1b to CFDCnFDCTR.SOCCLR.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

7.9.2.2.9 Channel n CAN-FD CRC Register (CFDCnFDCRC) (n = 0 to 5)

The CFDCnFDCRC register (n = 0 to 5) holds the CRC value calculated for the CAN-FD frame.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1410h + n x 0020h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	SCNT[3:0]				-	-	-	-	CRCREG[20:16]				
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CRCREG[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0b is read.
28 to 25	SCNT[3:0]	0h	R	Stuff Bit Count These bits shows the stuff bit count (mod 8) for the CAN-FD frame.
24 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read.
20 to 0	CRCREG[20:0]	0h	R	CRC Register Value These bits show the CRC value calculated for the CAN-FD frame.

CRCREG[20:0] bits (CRC Register Value)

The CRCREG[20:0] bits contain the CRC value calculated by the CAN-FD channel logic when the CFDCnCTR.CTME bit is enabled.

The CFDCnFDCRC.CRCREG value is updated in the first bit of the CRC field of the CAN-FD frame (reception and transmission).

When the CFDCnCTR.CTME bit is 0b, the CRCREG[20:0] bits are always read as 0b.

When bit 17th of the CRC field is used, CRCREG[20:17] are always read as 0b.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

SCNT[3:0] bits (Stuff Bit Count)

The SCNT[3:0] bits contain the stuff count value of the CAN-FD frame. These bits indicate the number of inserted stuff bits (modulo 8, Gray-coded) for a CAN-FD frame when the CFDCnCTR.CTME bit is enabled in CFDCnFDCRC.SCNT[3:1]. SCNT[0] is the parity bit.

When the CFDCnCTR.CTME bit is 0, the SCNT[3:0] bits are always read as 0b.

The SCNT value is updated in the first bit of CRC field of the CAN-FD frame (reception and transmission).

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

7.9.2.2.10 Global IP Version Register (CFDGIPV)

The CFDGIPV register shows the release version of the CAN-FD module.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0080h
Initial Value : 1124_0043h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	PSI[13:0]													
Initial Value	0	0	0	1	0	0	0	1	0	0	1	0	0	1	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	R	Reserved Whenever it is read, 0b is read.
29 to 16	PSI[13:0]	1124h	R	Parameter Status Information These bits show the IP configuration. Bits Description [29:27] Number of channel (010b: 6 channels) [26:24] Number of TXMB (001b: 32/channel) [23:21] Number of AFL entry (001b: 128/channel) [20:17] Number of pool buffer (0010b: 64/channel) [16] Same ID overwrite function of TXQ (0b: Support)
15 to 10	-	All 0	R	Reserved Whenever it is read, 0b is read.
9, 8	IPT[1:0]	0h*1	R	IP Type These bits show the IP type used in the product. 00b: CAN IP 01b: CAN-FD IP 1xb: Reserved
7 to 0	IPV[7:0]	43h	R	IP Version These bits show the main release number.

Note 1. This value depends on the package type.

7.9.2.2.11 Global Configuration Register (CFDGCFG)

The CFDGCFG register is used to select the transmission priority to be used for all the TX message buffers and the clock source for the CAN protocol engine of all CAN channels. The CFDGCFG register is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0084h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7, 6	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5	CMPOC	0h	RW	CAN-FD Message Payload Overflow Configuration 0b: Message is rejected 1b: Message payload is cut to fit to configured message size
4	DCS	0h	RW	Data Link Controller Clock Select 0b: CANFD_0_clkc 1b: Setting prohibited
3	MME	0h	RW	Mirror Mode Enable 0b: Mirror mode disabled 1b: Mirror mode enabled
2	DRE	0h	RW	DLC Replacement Enable 0b: DLC replacement disabled 1b: DLC replacement enabled
1	DCE	0h	RW	DLC Check Enable 0b: DLC check disabled 1b: DLC check enabled

Bit	Bit Name	Initial Value	R/W	Description
0	TPRI	0h	RW	Transmission Priority 0b: ID priority 1b: Message buffer number priority

TPRI bit (Transmission Priority)

The TPRI bit selects the transmission priority for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

Message buffer number priority should not be used together with TX queue transmission.

DCE bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

DRE bit (DLC Replacement Enable)

When the DRE bit is 1b and the DCE is 1b, the CAN-FD stores the configured value (CFDGAFLP0n.GAFLDLC) of the DLC in the destination RX message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination RX message buffer or FIFO buffer is unchanged.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

MME bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for all CAN channels.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

DCS bit (Data Link Controller Clock Select)

The DCS bit selects the clock source for CAN communication.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

CMPOC bit (CAN-FD Message Payload Overflow Configuration)

The CMPOC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size CFDRMNB.RMPLS, CFDRFCCn.RFPLS, and CFDCFCCn.CFPLS. The received message payload is always compared with the available message payload size in the message buffer.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

When this bit is set and payload overflow occurs, the DLC value is stored in the RX message buffer or FIFO buffer unchanged.

TSP[3:0] bits (Timestamp Prescaler)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

TSSS bit (Timestamp Source Select)

The TSSS bit allows the selection of the clock source for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode. Additionally, do not set this bit to 1b when CAN-FD communication is used.

Note: The bit time clock varies depending on the nominal and data rate bit configuration.

TSBTCS[2:0] bits (Timestamp Bit Time Channel Select)

The TSBTCS[2:0] bits allow the selection of the bit time clock of a particular channel for the timestamp counter.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

ITRCP[15:0] bits (Interval Timer Reference Clock Prescaler)

The ITRCP[15:0] bits allow the definition of a reference clock for the FIFO interval timer source clock.

When these bits are 0000h, the timer is disabled.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CAN-FD module is in GL_RESET mode.

7.9.2.2.12 Global Control Register (CFDGCTR)

The CFDGCTR register controls the global mode of the CAN-FD module and the timestamp function. The register also enables and disables the global error interrupts.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0088h
Initial Value : 0000_0005h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

8	DEIE	0h	RW	DLC Check Interrupt Enable 0b: DLC check interrupt disabled 1b: DLC check interrupt enabled
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	GSLPR	1h	RW	Global Sleep Request 0b: Global sleep request disabled 1b: Global sleep request enabled
1, 0	GMDC[1:0]	1h	RW	Global Mode Control 00b: Global operation mode request 01b: Global reset mode request 10b: Global halt mode request 11b: Keep current value

GMDC[1:0] bits (Global Mode Control)

The GMDC[1:0] bits can be used to configure the modes for the CAN-FD module. Additionally, if CFDGCTR.GSLPR bit is 1b when the CAN-FD module is in Reset mode, the CAN-FD module transits to Global Sleep mode. Additionally, if CFDGCTR.GSLPR is 1b when the CAN-FD module is in Reset Mode, then the CAN-FD module transits to Global Sleep Mode.

Setting the GMDC[1:0] bits to 11b has no effect. Mode transition is described in detail in **7.9.3.2 Global Modes**.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

GSLPR bit (Global Sleep Request)

The GSLPR bit globally selects the sleep request for CAN-FD module including all CAN channels. Channel sleep request is set automatically for all channels.

Only write to this bit when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

DEIE bit (DLC Check Interrupt Enable)

When the DEIE bit is 1b, an interrupt is generated if a DLC error is detected in the received frames.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

MEIE bit (Message Lost Error Interrupt Enable)

When the MEIE bit is 1b, an interrupt is generated if a message lost condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

THLEIE bit (TX History List Entry Lost Interrupt Enable)

When the THLEIE bit is 1b, an interrupt is generated if a TX history list entry lost condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CMPOFIE bit (CAN-FD Message Payload Overflow Flag Interrupt Enable)

When the CMPOFIE bit is 1b, an interrupt is generated when a CAN-FD message payload overflow condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

QOWEIE bit (TXQ Message Overwrite Error Interrupt Enable)

When the QOWEIE bit is 1b, an interrupt is generated when a TXQ message overwrite condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

QMEIE bit (TXQ Message Lost Error Interrupt Enable)

When the QMEIE bit is 1b, an interrupt is generated when a TXQ message lost condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

MOWEIE bit (Message Lost Error Interrupt Enable)

When the MOWEIE bit is 1b, an interrupt is generated in GW mode and a GW FIFO message overwrite condition occurs.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

TSRST bit (Timestamp Reset)

When the TSRST bit is 1b, the Global Timestamp Register is reset to 0000h.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode.

Read value is always 0b.

This bit is cleared automatically by the CAN-FD logic.

7.9.2.2.13 Global Status Register (CFDGSTS)

The CFDGSTS register indicates the global status of the CAN-FD module.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 008Ch
Initial Value : 0000_000Dh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read.
3	GRAMINIT	1h	R	Global RAM Initialization 0b: RAM initialization is complete 1b: RAM initialization is ongoing
2	GSLPSTS	1h	R	Global Sleep Status 0b: Not in Sleep mode 1b: In Sleep mode
1	GHLTSTS	0h	R	Global Halt Status 0b: Not in Halt mode 1b: In Halt mode
0	GRSTSTS	1h	R	Global Reset Status 0b: Not in Reset mode 1b: In Reset mode

GRSTSTS bit (Global Reset Status)

The GRSTSTS bit indicates the status of Global CAN-FD module Reset mode.

This bit is set automatically when the CAN-FD module enters GL_RESET mode. When the mode changes from GL_RESET mode to GL_SLEEP mode, this bit remains set.

This bit is cleared automatically when the CAN-FD module exits the GL_RESET mode.

GHLTSTS bit (Global Halt Status)

The GHLTSTS bit indicates the status of Global CAN-FD module Halt mode.

This bit is set automatically when the CAN-FD module enters GL_HALT mode.

This bit is cleared automatically when the CAN-FD module exits the GL_HALT mode.

GSLPSTS bit (Global Sleep Status)

The GSLPSTS bit indicates the status of Global CAN-FD module Sleep mode.

This bit is set automatically when the CAN-FD module enters GL_SLEEP mode.

This bit is cleared automatically when the CAN-FD module exits the GL_SLEEP mode.

GRAMINIT bit (Global RAM Initialization)

The GRAMINIT bit indicates the status of Global CAN-FD module RAM initialization.

This bit is set automatically when the CAN-FD module enters GL_SLEEP mode after a hardware reset.

This bit is cleared automatically when the CAN-FD module completed RAM initialization.

7.9.2.2.14 Global Error Flag Register (CFDGERFL)

The CFDGERFL register indicates the detection of global errors.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0090h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	EEF5	EEF4	EEF3	EEF2	EEF1	EEF0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	MOWES	QMES	-	QOWES	CMPOF	THLES	MES	DEF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	R	R	RW	R	RW	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
21 to 16	EEFn	0h	RW	ECC Error Flag for Channel n (n = 0 to 5) 0b: ECC error not detected during TX-SCAN 1b: ECC error detected during TX-SCAN
15 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7	MOWES	0h	R	Message Overwrite Error Status 0b: Message overwrite error not detected 1b: Message overwrite error detected
6	QMES	0h	R	TXQ Message Lost Error Status 0b: TXQ message lost error not detected 1b: TXQ message lost error detected
5	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	QOWES	0h	R	TXQ Message Overwrite Error Status 0b: TXQ message overwrite error not detected 1b: TXQ message overwrite error detected
3	CMPOF	0h	RW	CAN-FD Message Payload Overflow Flag 0b: CAN-FD message payload overflow not detected 1b: CAN-FD message payload overflow detected
2	THLES	0h	R	TX History List Entry Lost Error Status 0b: TX history list entry lost error not detected 1b: TX history list entry lost error detected
1	MES	0h	R	Message Lost Error Status 0b: Message lost error not detected 1b: Message lost error detected
0	DEF	0h	RW	DLC Error Flag 0b: DLC error not detected 1b: DLC error detected

DEF bit (DLC Error Flag)

The DEF bit indicates the error status of the DLC.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is set automatically when a DLC error is detected in a received frame.

The bit is cleared by writing 0b to it.

This bit is cleared automatically in GL_RESET mode.

MES bit (Message Lost Error Status)

The MES bit indicates status of the message lost error.

This bit is set automatically when a FIFO message lost error is detected.

This bit is cleared automatically when:

- All FIFO message lost flags are cleared
- The CAN-FD module is in GL_RESET mode.

THLES bit (TX History List Entry Lost Error Status)

The THLES bit indicates status of the TX history list entry lost error.

This bit is set automatically when a TX history list entry lost error is detected.

This bit is cleared automatically when:

- All TX history list entry lost flags are cleared
- The CAN-FD module is in GL_RESET mode.

CMPOF bit (CAN-FD Message Payload Overflow Flag)

The CMPOF bit is set automatically when a CAN-FD message payload overflow is detected on at least one channel.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode.

This bit is cleared by writing 0b to it. Writing 1b to this bit has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is cleared automatically in GL_RESET mode.

QOWES bit (TXQ Message Overwrite Error Status)

The QOWES bit is set automatically when a TXQ message overwrite error is detected.

This bit is cleared automatically when all TXQ message overwrite flags are cleared.

This bit is cleared automatically in GL_RESET mode.

QMES bit (TXQ Message Lost Error Status)

The QMES bit is set automatically when a TXQ message lost error is detected.

This bit is cleared automatically when all TXQ message lost flags are cleared.

This bit is cleared automatically in GL_RESET mode.

MOWES bit (Message Overwrite Error Status)

The MOWES bit is set automatically when GW mode and COMFIFO message overwrite error is detected.

This bit is cleared automatically when all COMFIFO Message Overwrite flags are cleared.

This bit is cleared automatically in GL_RESET mode.

EEFn bit (ECC Error Flag for Channel n) (n = 0 to 5)

The EEFn bit specifies whether an ECC error has occurred on Channel n.

Do not write to this bit when the CAN-FD module is in GL_SLEEP or GL_RESET mode. Writing 1b to this bit has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

The bit is cleared by writing 0b to it. This bit is cleared automatically in GL_RESET mode.

7.9.2.2.15 Global TX Interrupt Status Register 0 (CFDGTINTSTS0)

The CFDGTINTSTS0 register indicates the detection of transmit specific interrupts.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1300h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	TSIF0	0h	R	TX Successful Interrupt Flag Channel 0 0b: Channel 0 TX Successful Interrupt flag not set 1b: Channel 0 TX Successful Interrupt flag set

TSIFn bit (TX Successful Interrupt Flag Channel n (n = 0 to 3))

The CFDGTINTSTS0.TSIFn bit is set to 1b when the TX Successful Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TAIFn bit (TX Abort Interrupt Flag Channel n (n = 0 to 3))

The CFDGTINTSTS0.TAIFn bit is set to 1b when the TX Abort Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQIFn bit (TX Queue Interrupt Flag Channel n (n = 0 to 3))

The CFDGTINTSTS0.TQIFn bit is set to 1b when the TX Queue Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX Queue Interrupt flag is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

CFTIFn bit (COM FIFO in TX/GW Mode Interrupt Flag Channel n (n = 0 to 3))

The CFDGTINTSTS0.CFTIFn bit is set to 1b when the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

THIFn bit (TX History List Interrupt Flag Channel n (n = 0 to 3))

The CFDGTINTSTS0.THIFn bit is set to 1b when the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQOFIFn bit (TX Queue One Frame Transmission Interrupt Flag Channel n (n = 0 to 3))

The CFDGTINTSTS0.TQOFIFn bit is set to 1b when the TX Queue One Frame Transmission Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX Queue One Frame Transmission Interrupt flag is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

CFOTIFn bit (COM FIFO One Frame Transmission Interrupt Flag Channel n (n = 0 to 3))

The CFDGTINTSTS0.CFOTIFn bit is set to 1b when the related COM FIFO One Frame Transmission Interrupt flag (CFDCFSTSn.CFOFTXIF) is set (when the Interrupt is enabled).

This bit is cleared automatically:

- When the related COM FIFO One Frame Transmission Interrupt flag (CFDCFSTSn.CFOFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

7.9.2.2.16 Global TX Interrupt Status Register 1 (CFDGTINTSTS1)

The CFDGTINTSTS1 register indicates the detection of transmit specific interrupts.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1304h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	TAIF4	0h	R	TX Abort Interrupt Flag Channel 4 0b: Channel 4 TX Abort Interrupt flag not set 1b: Channel 4 TX Abort Interrupt flag set

Bit	Bit Name	Initial Value	R/W	Description
0	TSIF4	0h	R	TX Successful Interrupt Flag Channel 4 0b: Channel 4 TX Successful Interrupt flag not set 1b: Channel 4 TX Successful Interrupt flag set

TSIFn bit (TX Successful Interrupt Flag Channel n (n = 4, 5))

The CFDGTINTSTS0.TSIFn bit is set to 1b when the TX Successful Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TAIFn bit (TX Abort Interrupt Flag Channel n (n = 4, 5))

The CFDGTINTSTS0.TAIFn bit is set to 1b when the TX Abort Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQIFn bit (TX Queue Interrupt Flag Channel n (n = 4, 5))

The CFDGTINTSTS0.TQIFn bit is set to 1b when the TX Queue Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX Queue Interrupt flag is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

CFTIFn bit (COM FIFO in TX/GW Mode Interrupt Flag Channel n (n = 4, 5))

The CFDGTINTSTS0.CFTIFn bit is set to 1b when the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related COM TX/GW FIFO Mode Interrupt flag (CFDCFSTSn.CFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

THIFn bit (TX History List Interrupt Flag Channel n (n = 4, 5))

The CFDGTINTSTS0.THIFn bit is set to 1b when the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX History List Interrupt flag (CFDTHLSTSn.THLIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQOFIFn bit (TX Queue One Frame Transmission Interrupt Flag Channel n (n = 4, 5))

The CFDGTINTSTS0.TQOFIFn bit is set to 1b when the TX Queue One Frame Transmission Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX Queue One Frame Transmission Interrupt flag is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

CFOTIFn bit (COM FIFO One Frame Transmission Interrupt Flag Channel n (n = 4, 5))

The CFDGTINTSTS0.CFOTIFn bit is set to 1b when the related COM FIFO One Frame Transmission Interrupt flag (CFDCFSTSn.CFOFTXIF) is set (when the Interrupt is enabled).

This bit is cleared automatically:

- When the related COM FIFO One Frame Transmission Interrupt flag (CFDCFSTSn.CFOFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

7.9.2.2.17 Global Timestamp Counter Register (CFDGTSC)

The CFDGTSC register stores the timestamp based on the selected configuration.

Access Size : 16, 32 bits
Address : <CFD_base> + 0094h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read.
15 to 0	TS[15:0]	0h	R	Timestamp value

TS[15:0] bits (Timestamp value)

The Timestamp value is stored in the Global Timestamp Counter register based on the configuration of TSSS, TSBTCS, and TSP. The proper incrementing of the timestamp counter cannot be guaranteed when transitioning to halt state.

Do not write to bits TS[15:0] when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

The TS[15:0] bits are cleared automatically in GL_RESET mode.

7.9.2.2.18 Global Acceptance Filter List Entry Control Register (CFDGAFLECTR)

The CFDGAFLECTR register is used to select the Global Acceptance Filter List page for reading or writing entries into the Global Acceptance Filter List.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0098h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	AFLDAE	-	-	AFLPN[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
8	AFLDAE	0h	RW	Acceptance Filter List Data Access Enable 0b: Acceptance Filter List data access disabled 1b: Acceptance Filter List data access enabled
7 to 6	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5 to 0	AFLPN[5:0]	0h	RW	Acceptance Filter List Page Number Select an Acceptance Filter List page (Set from 0 to 47.)

AFLPN[5:0] bits (Acceptance Filter List Page Number)

The AFLPN[5:0] bits select the page number to access the desired RAM area of the Acceptance Filter List. One Acceptance Filter List page consists of 16 Acceptance Filter List entries.

Read/write accesses to the Acceptance Filter List can only be performed through a fixed window.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode. Enter only the values between 0h and 2Fh, inclusive.

AFLDAE bit (Acceptance Filter List Data Access Enable)

The AFLDAE bit prevents write access to the Acceptance Filter List when cleared after configuration of the Acceptance Filter List.

Data can be read from the Acceptance Filter List independent of the status of this bit.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Set this bit to enable write access for the Acceptance Filter List.

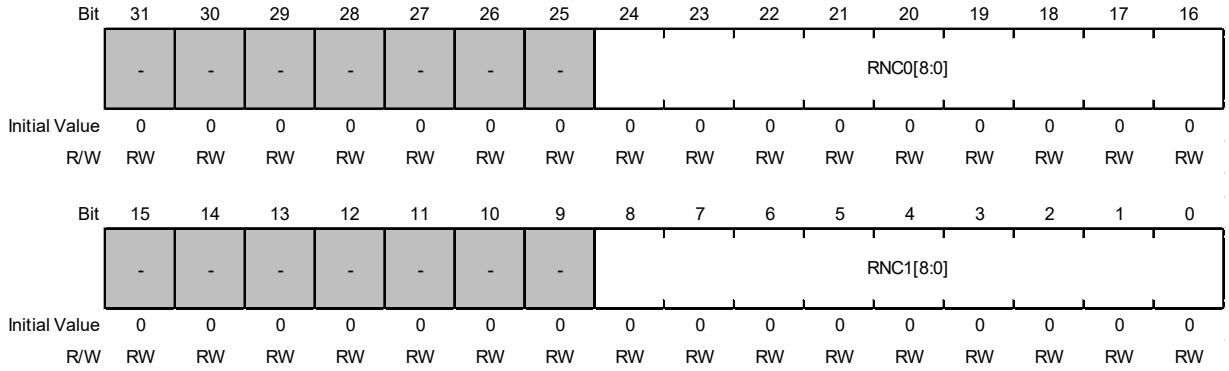
7.9.2.2.19 Global Acceptance Filter List Configuration Register w (CFDGAFLCFGw) (w = 0, 1, 2)

The CFDGAFLCFGw register is used to define the number of rules for entries in the Acceptance Filter List, applicable for channels 0 to 5.

The total number of available entries in the Acceptance Filter List is 256 for 2 CAN channels. However, the filters can be allocated flexibly to the different channels depending on requirements as long as both of the following conditions are satisfied:

- The maximum number of acceptance filter per channel is 256
- The total number of rules defined for all channels is not exceeding the number of available entries in the Acceptance Filter List.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 009Ch + w x 0004h
Initial Value : 0000_0000h



Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	RW	Reserved Whenever it is read, 0 is read. The written value should always be 0b.
24 to 16	RNC0[8:0]	0h	RW	Rule Number for Channel 0 Number of rules dedicated to channel 0
15 to 9	-	All 0	RW	Reserved Whenever it is read, 0 is read. The written value should always be 0b.
8 to 0	RNC1[8:0]	0h	RW	Rule Number for Channel 1 Number of rules dedicated to channel 1

RNCn[8:0] bits (Rule Number for Channel n (n = 0 to 5))

The RNCn[8:0] bits define the number of rules in the Acceptance Filter List for channel n.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

7.9.2.2.20 Global Acceptance Filter List ID Register n (CFDGAFLIDn) (n = 1 to 16)

The CFDGAFLIDn register (n = 1 to 16) is used to configure the ID field for the rules of entries in the Global Acceptance Filter List.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1800h + (n - 1) x 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLIDE	GAFLRTR	GAFLLB	GAFLID[28:16]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GAFLID[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	GAFLIDE	0h	RW	Global Acceptance Filter List Entry IDE Field 0b: Standard identifier of rule entry ID is valid for acceptance filtering 1b: Extended identifier of rule entry ID is valid for acceptance filtering
30	GAFLRTR	0h	RW	Global Acceptance Filter List Entry RTR Field 0b: Data frame 1b: Remote frame
29	GAFLLB	0h	RW	Global Acceptance Filter List Entry Loopback Configuration 0b: Global Acceptance Filter List entry ID for acceptance filtering with attribute RX 1b: Global Acceptance Filter List entry ID for acceptance filtering with attribute TX
28 to 0	GAFLID[28:0]	0h	RW	Global Acceptance Filter List Entry ID Field ID part of the Global Acceptance Filter List entry

GAFLID[28:0] bits (Global Acceptance Filter List Entry ID Field)

The GAFLID[28:0] bits represent the CAN identifier (ID) field of each entry in the Global Acceptance Filter List.

The acceptance filter process compares this field against the ID of a received CAN message. For alignment of these bits in standard and extended frame formats, see **7.9.2.2.89 Identifier Bits Alignment**.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLLB bit (Global Acceptance Filter List Entry Loopback Configuration)

The GAFLLB bit selects whether entry in the Global Acceptance Filter List gets the attribute RX or TX.

This attribute determines the validity of the entry in Mirror mode, Loopback test mode, and during standard (non-loopback) reception. See **7.9.5.5 Loopback Modes** for detailed description of the validity of the Global Acceptance Filter List entry depending on transmitter/receiver case, the type of loopback mode, and RX/TX attribute.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLRTR bit (Global Acceptance Filter List Entry RTR Field)

The GAFLRTR bit allows the configuration of the specified frame format (data frame or remote frame) for each entry of the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the RTR bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIDE bit (Global Acceptance Filter List Entry IDE Field)

The GAFLIDE bit allows the configuration of the ID format (standard ID or extended ID) for each entry in the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the IDE bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

7.9.2.2.21 Global Acceptance Filter List Mask Register n (CFDGAFLMn) (n = 1 to 16)

The CFDGAFLMn register (n = 1 to 16) is used to configure the Mask field of each rule for entries in the Global Acceptance Filter List.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1804h + (n - 1) x 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GAFLIDEM	GAFLRTRM	GAFLIFL1	GAFLIDM[28:16]

Bit	Bit Name	Initial Value	R/W	Description
31	GAFLIDEM	0h	RW	Global Acceptance Filter List IDE Mask 0b: IDE bit is not used for ID matching 1b: IDE bit is used for ID matching
30	GAFLRTRM	0h	RW	Global Acceptance Filter List Entry RTR Mask 0b: RTR bit is not used for ID matching 1b: RTR bit is used for ID matching
29	GAFLIFL1	0h	RW	Global Acceptance Filter List Information Label 1 Global Acceptance Filter List information label bit 1
28 to 0	GAFLIDM[28:0]	0h	RW	Global Acceptance Filter List ID Mask Field Global Acceptance Filter List Mask field bits for ID field

GAFLIDM[28:0] bits (Global Acceptance Filter List ID Mask Field)

GAFLIDM[28:0] bits are the filter mask bits for the related bits in the CAN Identifier field of each Global Acceptance Filter List entry.

0: Corresponding STD-ID/EXT-ID bit is not used for ID matching
1: Corresponding STD-ID/EXT-ID bit is used for ID matching

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0b.
Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIFL1 bit (Global Acceptance Filter List Information Label 1)

The GAFLIFL1 bit allows the configuration of a 2-bit information label to be attached to a received message accepted by the associated entry in the Global Acceptance Filter List. This bit is a MSB bit of an information label.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

This bit is stored in the Information Label Field [1] (CFDRMFDSTS.RMIFL[1], CFDRFFDSTS.RFIFL[1], CFDCFFDCSTSn.CFIFL[1]) of the storage location of an incoming message.

Note: This bit is stored in CFDTHLACC1n.TIFL[1] when CFDTHLCCn.THLDGE = 1b is set up using Gateway function.

GAFLRTRM bit (Global Acceptance Filter List Entry RTR Mask)

The GAFLRTRM bit allows the configuration of the RTR mask bit for each entry in the Global Acceptance Filter List.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLIDEM bit (Global Acceptance Filter List IDE Mask)

The GAFLIDEM bit allows the configuration of the IDE mask bit for each entry in the Global Acceptance Filter List.

When the IDE mask bit is 0b, the ID comparison depends on the received IDE bit.

If the received IDE bit is 0b, the STD-ID comparison takes place.

If the received IDE bit is 1b, the EXT-ID comparison takes place.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to this bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

7.9.2.2.22 Global Acceptance Filter List Pointer 0 Register n (CFDGAFLP0n) (n = 1 to 16)

The CFDGAFLP0n register (n = 1 to 16) is used to configure the data length code (DLC), software pointer, single message buffer select, and message buffer direction pointer for each rule entry in the Global Acceptance Filter List.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1808h + (n - 1) x 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4	GAFLSRD0	0h	RW	Global Acceptance Filter List Select Routing Destination 0 0b: Routing target is CFIFO0 1b: Routing target is TX Queue 0 instead of CFIFO0
3 to 0	GAFLDLC[3:0]	0h	RW	Global Acceptance Filter List DLC Field Minimum number of data bytes in a data frame required for acceptance

GAFLDLC[3:0] bits (Global Acceptance Filter List DLC Field)

The GAFLDLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Global Acceptance Filter List (automatic DLC filter function).

DLC filter process is only passed if the DLC value of the message accepted by an entry in the Global Acceptance Filter List is equal to or higher than the DLC value configured for this associated Global Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding rule entry when this field is set to 0b.

Table 7.9-6 shows DLC value that can be configured.

Table 7.9-6 Configuration of DLC Value

Format	DLC[3:0]	Description
CAN and CAN-FD	0000b	DLC of received message = 0 or more (DLC filter check is disabled)
CAN and CAN-FD	0001b	DLC of received message = 1 or more
CAN and CAN-FD	0010b	DLC of received message = 2 or more
CAN and CAN-FD	0011b	DLC of received message = 3 or more
CAN and CAN-FD	0100b	DLC of received message = 4 or more
CAN and CAN-FD	0101b	DLC of received message = 5 or more
CAN and CAN-FD	0110b	DLC of received message = 6 or more
CAN and CAN-FD	0111b	DLC of received message = 7 or more
CAN	1xxxb	DLC of received message = 8 or more
CAN-FD	1000b	DLC of received message = 8 or more*1
CAN-FD	1001b	DLC of received message = 12 or more*1
CAN-FD	1010b	DLC of received message = 16 or more*1
CAN-FD	1011b	DLC of received message = 20 or more*1
CAN-FD	1100b	DLC of received message = 24 or more*1
CAN-FD	1101b	DLC of received message = 32 or more*1
CAN-FD	1110b	DLC of received message = 48 or more*1
CAN-FD	1111b	DLC of received message = 64*1

Note 1. This setting is not available in the classical CAN function.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD0 bit (Global Acceptance Filter List Select Routing Destination 0)

The GAFLSRD0 bit changes a copy destination to CFIFO0 or TXQ0 by routing.

If this bit is set as 1b, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ0.

If this bit is set to 0b, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO0.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD1 bit (Global Acceptance Filter List Select Routing Destination 1)

The GAFLSRD1 bit changes a copy destination to CFIFO1 or TXQ1 by routing.

If this bit is set to 1b, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ1.

If this bit is set to 0b, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO1.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLSRD2 bit (Global Acceptance Filter List Select Routing Destination 2)

The GAFLSRD2 bit changes a copy destination to CFIFO2 or TXQ2 by routing.

If this bit is set to 1b, the preset value of CFDGAFLP1n.GAFLFDP selects TXQ2.

If this bit is set to 0b, the preset value of CFDGAFLP1n.GAFLFDP selects CFIFO2.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to the bit when the CAN-FD module is in CH_RESET or CH_HALT mode.

GAFLIFL0 bit (Global Acceptance Filter List Information Label 0)

The GAFLIFL0 bit allows the configuration of a 2-bit information label that can be attached to a received message accepted by the related Global Acceptance Filter List entry. This bit is a LSB bit of an information label.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to the bit when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

This bit is stored in Information Label Field[0] (CFDRMFDSTS.RMIFL[0], CFDRFFDSTS.RFIFL[0], CFDCFFDCSTSn.CFIFL[0]) of the storage location of an incoming message.

This bit is stored in CFDTHLACC1n.TIFL[0] when CFDTHLCCn.THLDGE = 1b is set up using the gateway function.

GAFLRMDP[4:0] bits (Global Acceptance Filter List RX Message Buffer Direction Pointer)

The GAFLRMDP[4:0] bits allow the configuration of a single reception message buffer as the destination target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. The value entered is the single destination message buffer number.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

CFDRMNB.NRXMB[7:0] is the value entered in the RX Message Buffer Number Register to configure the number of RX message buffers. The value to be entered in CFDGAFLP0n.GAFLRMDP[4:0] bits should only be between 00h and CFDRMNB.NRXMB[7:0] to 1 less.

If CFDRMNB.NRXMB[7:0] = 00h, the GAFLRMV bit should be configured as 0b.

GAFLRMV bit (Global Acceptance Filter List RX Message Buffer Valid)

The GAFLRMV bit allows the enabling or disabling of a single reception message buffer as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

GAFLPTR[15:0] bits (Global Acceptance Filter List Pointer)

The GAFLPTR[15:0] bits allow the configuration of a 16-bit pointer to be attached to a received message accepted by the related Global Acceptance Filter List entry. The pointer is added during message storage in the Message Buffer area and can be used by the application as a support function. The pointer information can be used for example, to support PDU Identifier allocation for the received message in AUTOSAR systems.

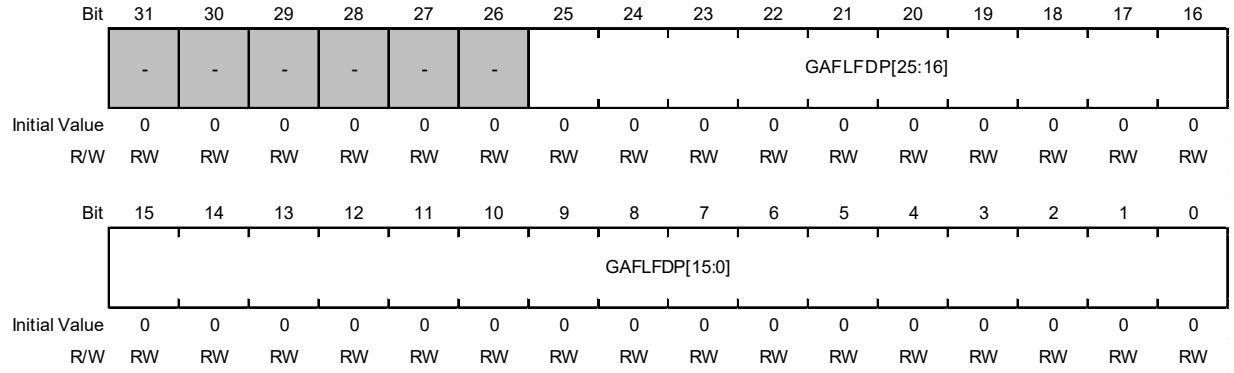
Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0b.

Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

7.9.2.2.23 Global Acceptance Filter List Pointer 1 Register n (CFDGAFLP1n) (n = 1 to 16)

The CFDGAFLP1n register (n = 1 to 16) is used to configure the FIFO direction pointer fields in each Rule Entry of the Global Acceptance Filter List.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 180Ch + (n - 1) x 0010h
Initial Value : 0000_0000h



Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
25 to 0	GAFLFDP [25:0]	0h	RW	Global Acceptance Filter List FIFO Direction Pointer FIFO direction pointer bits for received message storage

GAFLFDP[25:0] bits (Global Acceptance Filter List FIFO Direction Pointer)

The GAFLFDP[25:0] bits allow the configuration of FIFO buffers as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. Each bit of the CFDGAFLP1n.GAFLFDP[25:0] is configured as dedicated FIFO.

Bit	Value (binary)	Function
0	0	Disable RX FIFO 0 as target for reception
	1	Enable RX FIFO 0 as target for reception
1	0	Disable RX FIFO 1 as target for reception
	1	Enable RX FIFO 1 as target for reception
2	0	Disable RX FIFO 2 as target for reception
	1	Enable RX FIFO 2 as target for reception
3	0	Disable RX FIFO 3 as target for reception
	1	Enable RX FIFO 3 as target for reception
4	0	Disable RX FIFO 4 as target for reception
	1	Enable RX FIFO 4 as target for reception
5	0	Disable RX FIFO 5 as target for reception
	1	Enable RX FIFO 5 as target for reception
6	0	Disable RX FIFO 6 as target for reception
	1	Enable RX FIFO 6 as target for reception
7	0	Disable RX FIFO 7 as target for reception
	1	Enable RX FIFO 7 as target for reception
8	0	Disable Common FIFO 0 and Channel 0 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0b: Enable Common FIFO 0 as target for reception GAFLSRD0 = 1b: Enable Channel 0 TX Queue 0 as target for reception

Bit	Value (binary)	Function
9	0	Disable Common FIFO 1 and Channel 0 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0b: Enable Common FIFO 1 as target for reception GAFLSRD1 = 1b: Enable Channel 0 TX Queue 1 as target for reception
10	0	Disable Common FIFO 2 and Channel 0 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0b: Enable Common FIFO 2 as target for reception GAFLSRD2 = 1b: Enable Channel 0 TX Queue 2 as target for reception
11	0	Disable Common FIFO 3 and Channel 1 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0b: Enable Common FIFO 3 as target for reception GAFLSRD0 = 1b: Enable Channel 1 TX Queue 0 as target for reception
12	0	Disable Common FIFO 4 and Channel 1 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0b: Enable Common FIFO 4 as target for reception GAFLSRD1 = 1b: Enable Channel 1 TX Queue 1 as target for reception
13	0	Disable Common FIFO 5 and Channel 1 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0b: Enable Common FIFO 5 as target for reception GAFLSRD2 = 1b: Enable Channel 1 TX Queue 2 as target for reception
14	0	Disable Common FIFO 6 and Channel 2 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0b: Enable Common FIFO 6 as target for reception GAFLSRD0 = 1b: Enable Channel 2 TX Queue 0 as target for reception
15	0	Disable Common FIFO 7 and Channel 2 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0b: Enable Common FIFO 7 as target for reception GAFLSRD1 = 1b: Enable Channel 2 TX Queue 1 as target for reception
16	0	Disable Common FIFO 8 and Channel 2 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0b: Enable Common FIFO 8 as target for reception GAFLSRD2 = 1b: Enable Channel 2 TX Queue 2 as target for reception
17	0	Disable Common FIFO 9 and Channel 3 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0b: Enable Common FIFO 9 as target for reception GAFLSRD0 = 1b: Enable Channel 3 TX Queue 0 as target for reception
18	0	Disable Common FIFO 10 and Channel 3 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0b: Enable Common FIFO 10 as target for reception GAFLSRD1 = 1b: Enable Channel 3 TX Queue 1 as target for reception
19	0	Disable Common FIFO 11 and Channel 3 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0b: Enable Common FIFO 11 as target for reception GAFLSRD2 = 1b: Enable Channel 3 TX Queue 2 as target for reception
20	0	Disable Common FIFO 12 and Channel 4 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0b: Enable Common FIFO 12 as target for reception GAFLSRD0 = 1b: Enable Channel 4 TX Queue 0 as target for reception
21	0	Disable Common FIFO 13 and Channel 4 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0b: Enable Common FIFO 13 as target for reception GAFLSRD1 = 1b: Enable Channel 4 TX Queue 1 as target for reception
22	0	Disable Common FIFO 14 and Channel 4 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0b: Enable Common FIFO 14 as target for reception GAFLSRD2 = 1b: Enable Channel 4 TX Queue 2 as target for reception
23	0	Disable Common FIFO 15 and Channel 5 TX Queue 0 as target for reception
	1	GAFLSRD0 = 0b: Enable Common FIFO 15 as target for reception GAFLSRD0 = 1b: Enable Channel 5 TX Queue 0 as target for reception
24	0	Disable Common FIFO 16 and Channel 5 TX Queue 1 as target for reception
	1	GAFLSRD1 = 0b: Enable Common FIFO 16 as target for reception GAFLSRD1 = 1b: Enable Channel 5 TX Queue 1 as target for reception

Bit	Value (binary)	Function
25	0	Disable Common FIFO 17 and Channel 5 TX Queue 2 as target for reception
	1	GAFLSRD2 = 0b: Enable Common FIFO 17 as target for reception GAFLSRD2 = 1b: Enable Channel 5 TX Queue 2 as target for reception

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0b. Only write to these bits when the related CAN-FD channel is in CH_RESET or CH_HALT mode.

For storage in TX queue, TX queue buffers of a target that is in GW mode is possible.

Only one of the following configurations is valid:

- Up to 8 destination FIFO buffers
- 7 destination FIFO buffers plus one RX message buffer
- 8 destination TX queue buffers
- 7 destination TX queue buffers plus one RX message buffer
- A maximum of 8 destinations in all at FIFO buffer and TX queue buffer.

7.9.2.2.24 RX Message Buffer Number Register (CFDRMNB)

The CFDRMNB register is used to configure the total number of RX message buffers allocated to all channels.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 00ACh
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
10 to 8	RMPLS*[1][2:0]	0h	RW	Reception Message Buffer Payload Data Size 000b: 8 bytes 001b: 12 bytes 010b: 16 bytes 011b: 20 bytes 100b: 24 bytes 101b: 32 bytes 110b: 48 bytes 111b: 64 bytes
7 to 0	NRXMB[7:0]	0h	RW	Number of RX Message Buffers

Note 1. These bits are not available in the classical CAN function.

NRXMB[7:0] bits (Number of RX Message Buffers)

The NRXMB[7:0] bits are used to configure the number of RX message buffers.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

Enter only values between 0 and 32 inclusive, with 00h indicating that no RX message buffer is allocated.

RMPLS[2:0] bits (Reception Message Buffer Payload Data Size)

The RMPLS[2:0] bits are used to configure the message buffer payload data size.

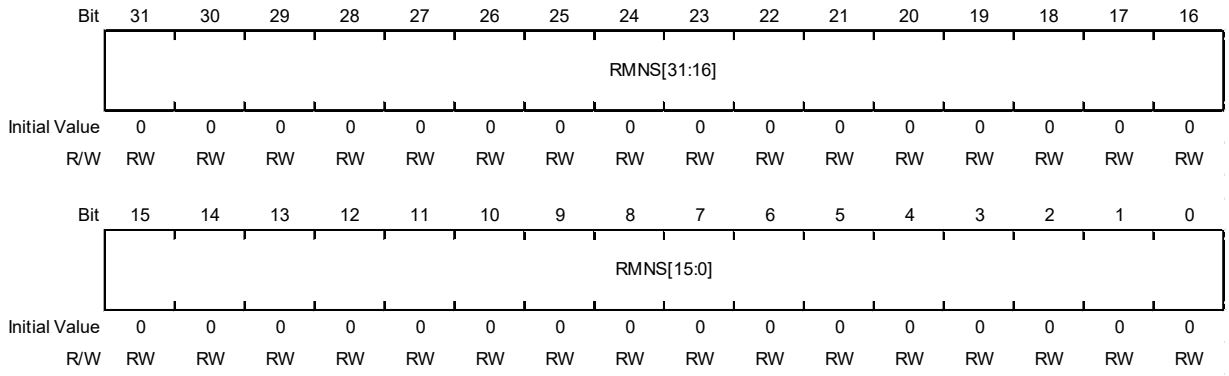
Only write to these bits when the CAN-FD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

7.9.2.2.25 RX Message Buffer New Data Register t (CFDRMNDt) (t = 0 to 2)

The CFDRMNDt specifies the new data storage status of the RX message buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 00B0h + t x 0004h
Initial Value : 0000_0000h



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RMNS[31:0]	0h	RW	RX Message Buffer New Data Status 0b: New data not stored in corresponding RX message buffer 1b: New data stored in corresponding RX message buffer

RMNS[31:0] bits (RX Message Buffer New Data Status)

The RMNSu[31:0] bits indicate the status of new data for the corresponding RX message buffer. RMNS bit [0] corresponds to RX message buffer [0] and so on.

no_of_channels = 6
no_of_CFDRMBCPs_per_channel = (number of RX message buffer components per channel) = 16
no_of_CFDRMBCPs = no_of_channels × no_of_CFDRMBCPs_per_channel (6 × 16 = 96)
no_of_bits_per_register = 32
no_of_CFDRMNDs (number of CFDRMND Registers) = no_of_CFDRMBCPs/no_of_bits_per_register (96/32 = 3)
t = [0 ... no_of_CFDRMNDs − 1]
u = [t × 32 ... (no_of_CFDRMBCPs − ((no_of_CFDRMNDs − 1 − t) × 32) − 1)]

t can be calculated from the target of the New Data Status flag (u) using the formula t = floor (u/32)

Bit position can be calculated using the formula (u − (t × 32))

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode. Writing 1b has no effect.

These bits cannot be cleared when message storage in the corresponding RX message buffer is in progress.

Do not use the bit clear instruction to clear these bits. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

These bits are set automatically when storage of new messages are in the corresponding RX message buffer. These bits are cleared by writing 0b. These bits are cleared automatically when the CAN-FD module is in GL_RESET mode.

When CFDRMNB.RMPLS = 000b (maximum 8 bytes payload), the duration of message storage is 6 CANFD_0_pclk cycles.

When CFDRMNB.RMPLS > 000b, the duration of message storage is 6 CANFD_0_pclk cycles + 1 for each 4 bytes (maximum of 20 CANFD_0_pclk cycles for 64 bytes).

Note: This feature is not available in the classical CAN function.

7.9.2.2.26 RX FIFO Configuration/Control Register n (CFDRFCCn) (n = 0 to 7)

The CFDRFCCn registers (n = 0 to 7) are used to configure and control the eight RX FIFOs.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 00C0h + n x 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

10 to 8	RFDC[2:0]	0h	RW	RX FIFO Depth Configuration 000b: FIFO Depth = 0 messages 001b: FIFO Depth = 4 messages 010b: FIFO Depth = 8 messages 011b: FIFO Depth = 16 messages 100b: FIFO Depth = 32 messages 101b: FIFO Depth = 48 messages 110b: FIFO Depth = 64 messages 111b: FIFO Depth = 128 messages
7	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
6 to 4	RFPLS*1[2:0]	0h	RW	Rx FIFO Payload Data Size Configuration 000b: 8 bytes 001b: 12 bytes 010b: 16 bytes 011b: 20 bytes 100b: 24 bytes 101b: 32 bytes 110b: 48 bytes 111b: 64 bytes
3, 2	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

Bit	Bit Name	Initial Value	R/W	Description
1	RFIE	0h	RW	RX FIFO Interrupt Enable 0b: FIFO interrupt generation disabled 1b: FIFO interrupt generation enabled
0	RFE	0h	RW	RX FIFO Enable 0b: FIFO disabled 1b: FIFO enabled

Note 1. These bits are not available in the classical CAN function.

RFE bit (RX FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0b, the RX FIFO is cleared to empty.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

This bit can only be set if the configured FIFO depth is greater than 000b (CFDRFCCn.RFDC[2:0] > 000b).

Set the RFE bit with a separate write access to the CFDRFCCn register, after all the other bits in the CFDRFCCn register are set.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

RFIE bit (RX FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

RFPLS[2:0] bits (Rx FIFO Payload Data Size Configuration)

The RFPLS[2:0] bits define the message data payload allocation in the RAM.

This is the maximum number of bytes which can be received by this FIFO.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

RFDC[2:0] bits (RX FIFO Depth Configuration)

The RFDC[2:0] bits select the depth of the FIFO in terms of the number of messages. If the FIFO depth is configured to 0 messages, the FIFO cannot be used.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

RFIM bit (RX FIFO Interrupt Mode)

The RFIM bit selects the interrupt generation condition for the FIFO.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

RFIGCV[2:0] bits (RX FIFO Interrupt Generation Counter Value)

The RFIGCV[2:0] bits select the counter value of the FIFO for generation of FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

The setting of the RFIGCV[2:0] bits should be synchronized with the RFDC[2:0] bits.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

RFFIE bit (RX FIFO Full Interrupt Enable)

The RFFIE bit enables generation of the RX FIFO full interrupt. Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

The following content shows examples of interruptions:

- Interruption output in number of arbitrary stages (CFDRFCCn.RFIGCV)
- Interruption output in FIFO full state.

Note: Management of the receiving data of FIFO can be performed by these notices of interruption.

7.9.2.2.27 RX FIFO Status Register n (CFDRFSTSn) (n = 0 to 7)

The CFDRFSTSn register (n = 0 to 7) shows the status of messages stored in the corresponding FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 00E0h + n x 0004h
Initial Value : 0000_0001h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RFFIF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFMC[7:0]								-	-	-	-	RFIF	RFMLT	RFFLL	RFEMP
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
16	RFFIF	0h	RW	RX FIFO Full Interrupt Flag 0b: FIFO full interrupt condition not satisfied 1b: FIFO full interrupt condition satisfied
15 to 8	RFMC[7:0]	0h	R	RX FIFO Message Count Number of messages stored in FIFO
7 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3	RFIF	0h	RW	RX FIFO Interrupt Flag 0b: FIFO interrupt condition not satisfied 1b: FIFO interrupt condition satisfied
2	RFMLT	0h	RW	RX FIFO Message Lost 0b: No message lost in FIFO 1b: FIFO message lost
1	RFFLL	0h	R	RX FIFO Full 0b: FIFO not full 1b: FIFO full
0	RFEMP	1h	R	RX FIFO Empty 0b: FIFO not empty 1b: FIFO empty

RFEMP bit (RX FIFO Empty)

The RFEMP bit is set automatically when:

- The RFMC bit is 0b
- RX FIFO is disabled by setting the CFDRFCCn.RFE bit to 0b
- The CAN-FD module is in GL_RESET mode.

The RFEMP bit is cleared automatically when the first message is stored in the RX FIFO buffer.

RFFLL bit (RX FIFO Full)

The RFFLL bit is set automatically when the number of CAN messages stored in the FIFO buffer matches the configured FIFO depth.

The RFFLL is cleared automatically when:

- The number of CAN messages stored in the FIFO buffer is less than the configured FIFO depth

- RX FIFO is disabled by setting the CFDRFCCn.RFE bit to 0b
- The CAN-FD module is in GL_RESET mode.

RFMLT bit (RX FIFO Message Lost)

Only write to the RFMLT bit when CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is set automatically whenever a message is lost due to attempted storage when the FIFO buffer is already full. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0b to it
- When the CAN-FD module is in GL_RESET mode.

RFIF bit (RX FIFO Interrupt Flag)

The RFIF bit is set automatically when the configured interrupt condition is satisfied. This bit is not automatically cleared when the RX FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

The bit is cleared by writing 0b to it. The bit is also cleared when CAN-FD module is in GL_RESET mode.

RFMC[7:0] bits (RX FIFO Message Count)

The RFMC[7:0] bits indicate the number of CAN messages stored in the RX FIFO buffer that can be read by the CPU.

These bits are cleared automatically when the FIFO is disabled and when the CAN-FD module is in GL_RESET mode.

RFFIF bit (RX FIFO Full Interrupt Flag)

The RFFIF bit is not cleared automatically when the RX FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is set automatically when the FIFO full interrupt condition is satisfied. If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared by writing 0b to it.

The bit is also cleared when the CAN-FD module is in GL_RESET mode.

7.9.2.2.28 RX FIFO Pointer Control Register n (CFDRFPCTRn) (n = 0 to 7)

The CFDRFPCTRn register (n = 0 to 7) can be used to increment the read pointer of the corresponding RX FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0100h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	RFPC[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7 to 0	RFPC*[1][7:0]	0h	RW	RX FIFO Pointer Control Increments read pointer of the corresponding RX FIFO buffers

Note 1. These bits are not available in the classical CAN function.

RFPC[7:0] bits (RX FIFO Pointer Control)

When the value FFh is written to the RFPC bits, the pointer of the corresponding RX FIFO buffer is moved to the next FIFO entry. Only write FFh to these registers when the corresponding RX FIFO buffer is enabled and not empty.

The read value from these bits is always 00h.

Only write to these bits when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

Do not write to the RX FIFO Pointer Control registers when DMA is enabled.

7.9.2.2.29 Common FIFO Configuration/Control Register n (CFDCFCCn) (n = 0 to 17)

The CFDCFCCn register (n = 0 to 17) is used to configure the Common FIFOs.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0120h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	CFRXIE	0h	RW	Common FIFO RX Interrupt Enable 0b: FIFO interrupt generation disabled for Frame RX 1b: FIFO interrupt generation enabled for Frame RX
0	CFE	0h	RW	Common FIFO Enable 0b: FIFO disabled 1b: FIFO enabled

Note 1. These bits are not available in the classical CAN function.

CFE bit (Common FIFO Enable)

The CFE bit enables the FIFO when set. FIFO is disabled when this bit is cleared.

This bit can also be used, by clearing it, to abort transmission from Common FIFO when configured in TX mode or GW mode, or to stop reception into the Common FIFO in RX mode.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO.

This bit can only be set if the configured FIFO depth is greater than 0 (CFDC bit > 0).

Set the CFE bit with a separate write access to the CFDCFCCn register, after all the other bits in this register are set.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

This bit is also cleared automatically when the related channel is in CH_RESET mode if the FIFO is configured in TX or GW mode.

CFRXIE bit (Common FIFO RX Interrupt Enable)

The CFRXIE bit enables generation of FIFO interrupts when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFTXIE bit (Common FIFO TX Interrupt Enable)

The CFTXIE bit enables generation of common FIFO interrupts when the interrupt flag is set after transmission of a frame from the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFPLS[2:0] bits (Common FIFO Payload Data Size Configuration)

The CFPLS[2:0] bits define the message data payload allocation in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.

For details, see **7.9.6 FIFO Buffers and Normal Message Buffer Configuration**.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

CFM[1:0] bits (Common FIFO Mode)

The CFM[1:0] bits select the mode of the FIFO. When a hardware reset is applied, all the Common FIFO buffers are configured in RX FIFO mode. Do not configure these bits to 11b.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFITSS bit (Common FIFO Interval Timer Source Select)

The CFITSS bit selects the basic clock source for the Interval Transmission Timer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. In addition, do not write to this bit when the CFE bit is set to 1b.

Do not write 1b to this bit when CAN-FD communication is used.*[1]

Note: The bit time clock can vary depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

CFITR bit (Common FIFO Interval Timer Resolution)

The CFITR bit selects the resolution of the reference clock for the Interval Transmission Timer (peripheral clock is the source for the reference clock).

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1b.

CFIM bit (Common FIFO Interrupt Mode)

The CFIM bit selects the interrupt generation condition for the FIFO buffer.

Do not write to this bit in GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

CFIGCV[2:0] bits (Common FIFO Interrupt Generation Counter Value)

The CFIGCV[2:0] bits select the message counter value for the generation of FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

The setting of these bits should be synchronized with the CFDC[2:0] bits.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFTML[4:0] bits (Common FIFO TX Message Buffer Link)

The CFTML[4:0] bits select the normal transmit message buffer position where the TX or GW FIFO is linked to, for transmission scanning.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

CFDC[2:0] bits (Common FIFO Depth Configuration)

The CFDC[2:0] bits select the depth of the common FIFO in terms of the number of messages. If the FIFO depth is configured to 0 message, the FIFO cannot be used.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

CFITT[7:0] bits (Common FIFO Interval Transmission Time)

The CFITT[7:0] bits select the delay in the start of transmission for all messages transmitted from this FIFO buffer when configured in TX or GW mode. The delay is a multiple of the basic interval timer clock source period (reference clock × 1, reference clock × 10, or bit time clock of the related CAN channel).

Do not write to these bits when the CAN-FD module is in GL_SLEEP mode.

Do not write to these bits when the CFE bit is set to 1b.

When CFDGCFG.ITRCP[15:0] = 0000h, set the CFITT[7:0] bits to 0000h.

7.9.2.2.30 Common FIFO Configuration/Control Enhancement Register n (CFDCFCCEn) (n = 0 to 17)

The CFDCFCCEn register (n = 0 to 17) is used to configure the Common FIFOs.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0180h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	CFOFRXIE	0h	RW	Common FIFO One Frame Reception Interrupt Enable 0b: One Frame RX interrupt generation disabled 1b: One Frame RX interrupt generation enabled
0	CFFIE	0h	RW	Common FIFO Full Interrupt Enable 0b: FIFO Interrupt generation disabled 1b: FIFO Interrupt generation enabled

CFFIE bit (Common FIFO Full Interrupt Enable)

The CFFIE bit enables generation of the FIFO full interrupt when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

The following content shows examples of interruptions:

1. Interruption output in number of arbitrary stages (CFDCFCCn.CFIGCV).
2. Interruption output in FIFO full state.

Management of the receiving data of FIFO can be performed by these notices of interruption.

CFOFRXIE bit (Common FIFO One Frame Reception Interrupt Enable)

The CFOFRXIE bit enables generation of the one frame reception interrupt when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFOFTXIE bit (Common FIFO One Frame Transmission Interrupt Enable)

The CFOFTXIE bit enables generation of the one frame transmission interrupt when the interrupt flag is set after transmission of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

CFMOWM bit (Common FIFO Message Overwrite Mode)

When the CFMOWM bit is 0b, a receiving message is discarded and FIFO is full. When the CFMOWM bit is 1b, a receiving message is overwritten and FIFO is full.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode.

Only write 1b to this bit when the common FIFO is in GW mode.

Do not write 1b to this bit when the CFE bit is 1b.

CFBME bit (Common FIFO Buffering Mode Enable)

When the CFBME bit is 0b, messages are transmitted from FIFO. When the CFBME bit is 1b, messages are not transmitted from FIFO.

Do not write to this bit when the CAN-FD module is in GL_SLEEP mode. Additionally, do not write 1b to this bit when the CFE bit is 1b.

7.9.2.2.31 Common FIFO Status Register n (CFDCFSTSn) (n = 0 to 17)

The CFDCFSTSn register (n = 0 to 17) shows the status of messages stored in the corresponding FIFO buffers.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 01E0h + n x 0004h

Initial Value : 0000_0001h

31 to 25	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
24	CFMOW	0h	RW	Common FIFO Message Overwrite 0b: No message overwrite occurred in FIFO 1b: Message overwrite occurred in FIFO
23 to 19	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
18	CFOFTXIF	0h	RW	Common FIFO One Frame Transmission Interrupt Flag For each FIFO that transmits a frame, a corresponding interrupt is set.
17	CFOFRXIF	0h	RW	Common FIFO One Frame Reception Interrupt Flag For each FIFO that receives a frame, a corresponding interrupt is set.
16	CFFIF	0h	RW	Common FIFO Full Interrupt Flag 0b: Interrupt condition not satisfied for FIFO full interrupt 1b: Interrupt condition satisfied for FIFO full interrupt
15 to 8	CFMC[7:0]	0h	R	Common FIFO Message Count Number of messages stored in FIFO
7 to 5	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	CFTXIF	0h	RW	Common TX FIFO Interrupt Flag 0b: FIFO interrupt condition not satisfied after frame transmission 1b: FIFO Interrupt condition satisfied after frame transmission
3	CFRXIF	0h	RW	Common RX FIFO Interrupt Flag 0b: FIFO interrupt condition not satisfied after frame reception 1b: FIFO interrupt condition satisfied after frame reception
2	CFMLT	0h	RW	Common FIFO Message Lost 0b: FIFO message not lost 1b: FIFO message lost
1	CFFLL	0h	R	Common FIFO Full 0b: FIFO not full 1b: FIFO full
0	CFEMP	1h	R	Common FIFO Empty 0b: FIFO not empty 1b: FIFO empty

CFEMP bit (Common FIFO Empty)

The CFEMP bit is set automatically when:

- The CPU has read all messages from the FIFO configured in RX mode
- All messages have been transmitted from the FIFO configured in TX or GW mode
- The FIFO is disabled by setting the CFE bit to 0b

- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET when FIFO configured in TX or GW mode.

The CFEMP bit is cleared automatically when:

- The first reception message is stored in the FIFO buffer when configured in RX mode
- The first message to be transmitted is stored in the FIFO buffer when configured in TX or GW mode.

CFFLL bit (Common FIFO Full)

The CFFLL bit is set automatically when the number of CAN messages stored in the FIFO matches the configured FIFO depth.

The CFFLL bit is cleared automatically when:

- The number of CAN messages stored in the FIFO is less than the configured FIFO depth
- The FIFO is disabled by setting the CFE bit to 0b
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode when FIFO buffer is configured in TX or GW mode.

CFMLT bit (Common FIFO Message Lost)

The CFMLT bit is set automatically whenever a message is lost due to attempted storage of a new message when FIFO is already full in RX or GW mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

The CFMLT bit is cleared:

- By writing 0b to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFRXIF bit (Common RX FIFO Interrupt Flag)

The CFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers when configured in GW mode or RX mode.

The CFRXIF bit is cleared:

- By writing 0b to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in GW mode.

CFTXIF bit (Common TX FIFO Interrupt Flag)

The CFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO buffer configured as TX or GW FIFO. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers configured in GW or TX mode.

The CFTXIF bit is cleared:

- By writing 0b to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFMC[7:0] bits (Common FIFO Message Count)

The CFMC[7:0] bits indicate the following:

- Number of CAN messages stored by the CPU in the FIFO buffer configured in TX mode pending for transmission
- Number of CAN messages stored in the FIFO buffer configured in RX mode by CAN-FD to be read by the CPU
- Number of CAN messages stored by the CAN-FD in the GW FIFO pending for transmission.

The CFMC[7:0] bits are cleared automatically when:

- The FIFO is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFFIF bit (Common FIFO Full Interrupt Flag)

The CFFIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO configured as TX or GW FIFO. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is set automatically when the FIFO Full Interrupt condition is satisfied for Common FIFO buffers when configured in GW or RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The CFFIF bit is cleared:

- By writing 0b to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

CFOFRXIF bit (Common FIFO One Frame Reception Interrupt Flag)

The CFOFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for the FIFO buffer configured as TX or GW FIFO. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is set automatically when the One Frame Reception Interrupt condition is satisfied for the Common FIFO buffers when configured in GW or RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The CFOFRXIF bit is cleared:

- By writing 0b to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

This bit is not affected by the CFIM bit of CFDCFCCn.

CFOFTXIF bit (Common FIFO One Frame Transmission Interrupt Flag)

The CFOFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFOs configured as TX or GW FIFO. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is set automatically when the One Frame Transmission Interrupt condition is satisfied for Common FIFO buffers configured in GW mode or TX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

The bit is cleared:

- By writing 0b to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO is configured in TX or GW mode.

This bit is not affected by the CFIM bit of CFDCFCCn.

CFMOW bit (Common FIFO Message Overwrite)

The CFMOW bit is set automatically whenever a message is an overwrite storage of a new message when CFDCFCCEn.CFMOWM = 1b and FIFO is already full in GW mode.

If the set from the CAN channel occurs simultaneously with the clear by a write access, the bit is set.

Only write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode and the related CAN-FD channel is not in CH_RESET mode for FIFO buffer configured as TX or GW FIFO. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

The CFMOW bit is cleared:

- By writing 0b to it
- When the CAN-FD module is in GL_RESET mode
- When the related CAN-FD channel is in CH_RESET mode if the FIFO buffer is configured in TX or GW mode.

7.9.2.2.32 Common FIFO Pointer Control Register n (CFDCFPCTRn) (n = 0 to 17)

The CFDCFPCTRn register (n = 0 to 17) can be used to increment the read or write pointer of the corresponding Common FIFO buffer.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 0240h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	CFPC[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	W	Reserved The written value should always be 0b.
7 to 0	CFPC[7:0]	0h	W	Common FIFO Pointer Control Increments read or write pointer of the corresponding Common FIFO buffers depending on the mode configuration.

CFPC[7:0] bits (Common FIFO Pointer Control)

When the value FFh is written into the CFPC[7:0] bits, the read pointer of the corresponding Common FIFO buffer (when configured in RX mode), or the write pointer of the corresponding Common FIFO buffer (when configured in TX mode) moves to the next FIFO entry.

The read value from these bits is always 00h.

Only write to these bits when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

Only write FFh to this register when:

- The Common FIFO buffer is enabled and is not empty if configured in RX mode
- The Common FIFO buffer is enabled and is not full if configured in TX mode
- The Common FIFO buffer is enabled and is not configured in GW mode.

Do not write to the Common FIFO Pointer Control registers when DMA is enabled.

7.9.2.2.33 FIFO Empty Status Register (CFDFESTS)

The CFDFESTS register shows status of the empty bits of the FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 02A0h
Initial Value : 0000_3FFFh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	CFXEMP[17:8]									
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CFXEMP[7:0]								RFXEMP[7:0]							
Initial Value	0	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read.
25 to 8	CFXEMP[17:0]	3Fh	R	Common FIFO Empty Status 0b: Corresponding FIFO not empty 1b: Corresponding FIFO empty
7 to 0	RFXEMP[7:0]	FFh	R	RX FIFO Empty Status 0b: Corresponding FIFO not empty 1b: Corresponding FIFO empty

RFXEMP[7:0] bits (RX FIFO Empty Status)

Bit [7] (RFXEMP[7]) is associated with FIFO index 7 and bit [0] (RFXEMP[0]) is associated with FIFO index 0.

The RFXEMP[7:0] bits are set when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXEMP[17:0] bits (Common FIFO Empty Status)

Bit [25] (CFXEMP[17]) is associated with common FIFO index 17 and bit [8] (CFXEMP[0]) is associated with common FIFO index 0.

The CFXEMP[17:0] bits are set when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

7.9.2.2.34 FIFO Full Status Register (CFDFFSTS)

The CFDFFSTS register shows status of the full bits of the FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 02A4h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	CFXFLL[17:8]									
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CFXFLL[7:0]								RFXFLL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read.
25 to 8	CFXFLL[17:0]	0h	R	Common FIFO Full Status 0b: Corresponding FIFO not full 1b: Corresponding FIFO full
7 to 0	RFXFLL[7:0]	0h	R	RX FIFO Full Status 0b: Corresponding FIFO not full 1b: Corresponding FIFO full

RFXFLL[7:0] bits (RX FIFO Full Status)

The RFXFLL[7:0] bits are cleared when CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXFLL[17:0] bits (Common FIFO Full Status)

The CFXFLL[17:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

7.9.2.2.35 FIFO Message Lost Status Register (CFDFMSTS)

The CFDFMSTS register shows status of the message lost bits of the FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 02A8h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	CFXMLT[17:8]									
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CFXMLT[7:0]								RFXMLT[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read.
25 to 8	CFXMLT[17:0]	0h	R	Common FIFO Message Lost Status 0b: Corresponding FIFO Message Lost flag not set 1b: Corresponding FIFO Message Lost flag set
7 to 0	RFXMLT[7:0]	0h	R	RX FIFO Message Lost Status 0b: Corresponding FIFO Message Lost flag not set 1b: Corresponding FIFO Message Lost flag set

RFXMLT[7:0] bits (RX FIFO Message Lost Status)

The RFXMLT[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFXMLT[17:0] bits (Common FIFO Message Lost Status)

The CFXMLT[17:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

7.9.2.2.36 RX FIFO Interrupt Flag Status Register (CFDRFISTS)

The CFDRFISTS register shows status of the interrupt flag bits of the RX FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 02ACh
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	RFXFFLL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	RFXIF[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read.
23 to 16	RFXFFLL[7:0]	0h	R	RX FIFO[x] Interrupt Full Flag Status 0b: Corresponding RX FIFO Interrupt Full flag not set 1b: Corresponding RX FIFO Interrupt Full flag set
15 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read.
7 to 0	RFXIF[7:0]	0h	R	RX FIFO[x] Interrupt Flag Status 0b: Corresponding RX FIFO Interrupt flag not set 1b: Corresponding RX FIFO Interrupt flag set

RFXIF[7:0] bits (RX FIFO[x] Interrupt Flag Status)

Each bit is set automatically when the corresponding interrupt flag bit is set in the RX FIFO Status Registers.

The RFXIF[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt flag bit is cleared in the RX FIFO Status Registers.

RFXFFLL[7:0] bits (RX FIFO[x] Interrupt Full Flag Status)

Each bit is set automatically when the corresponding interrupt full flag bit is set in the RX FIFO Status Registers.

The RFXFFLL[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt full flag bit is cleared in the RX FIFO Status Registers.

7.9.2.2.37 Common FIFO RX Interrupt Flag Status Register (CFDCFRISTS)

The CFDCFRISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 02B0h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CFXRXIF[17:16]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CFXRXIF[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read.
17 to 0	CFXRXIF[17:0]	0h	R	Common FIFO RX Interrupt Flag Status 0b: Corresponding Common FIFO RX Interrupt flag not set 1b: Corresponding Common FIFO RX Interrupt flag set

CFXRXIF[17:0] bits (Common FIFO RX Interrupt Flag Status)

Each bit is set automatically when the corresponding RX interrupt flag bit is set in the Common FIFO Status Registers.

The CFXRXIF[17:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding RX interrupt flag bit is cleared in the Common FIFO Status Registers.

7.9.2.2.38 Common FIFO TX Interrupt Flag Status Register (CFDCFTISTS)

The CFDCFTISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 02B4h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CFXTXIF[17:16]

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read.
17 to 0	CFXTXIF[17:0]	0h	R	Common FIFO TX Interrupt Flag Status 0b: Corresponding Common FIFO TX Interrupt flag not set 1b: Corresponding Common FIFO TX Interrupt flag set

CFXTXIF[17:0] bits (Common FIFO TX Interrupt Flag Status)

Each bit is set automatically when the corresponding TX interrupt flag bit is set in the Common FIFO Status Registers.

The CFXTXIF[17:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding TX interrupt flag bit is cleared in the Common FIFO Status Registers.

7.9.2.2.39 FIFO FDC Full Status Register (CFDFFFSTS)

The CFDFFFSTS register shows status of the full interrupt flag bits of the FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 02C4h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	CFXFFLL[17:8]									
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CFXFFLL[7:0]								RFXFFLL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read.
25 to 8	CFXFFLL[17:0]	0h	R	COMMON FIFO FDC Level Full Status 0b: Corresponding FIFO full interrupt not set 1b: Corresponding FIFO full interrupt set
7 to 0	RFXFFLL[7:0]	0h	R	RX FIFO FDC Level Full Status 0b: Corresponding FIFO full interrupt not set 1b: Corresponding FIFO full interrupt set

RFXFFLL[7:0] bits (RX FIFO FDC Level Full Status)

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

The RFXFFLL[7:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

CFXFFLL[17:0] bits (COMMON FIFO FDC Level Full Status)

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

The CFXFFLL[17:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

7.9.2.2.40 Common FIFO Message Overwrite Status Register (CFDCFMOWSTS)

The CFDCFMOWSTS register shows the status of the Interrupt Flag bits of the Common FIFO Buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 02C0h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

17 to 0	CFXMOW[17:0]	0h	R	Common FIFO Massage Overwrite Status 0b: Corresponding FIFO Overwrite flag not set 1b: Corresponding FIFO Overwrite flag set

CFXMOW[17:0] bits (Common FIFO Massage Overwrite Status)

The CFXMOW[17:0] bits are cleared when the CAN-FD module is in GL_RESET mode. This register is only valid in GW mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

7.9.2.2.41 Common FIFO One Frame RX Interrupt Flag Status Register (CFDCFOFRISTS)

The CFDCFOFRISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 02B8h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

17 to 0	CFXOFRXIF [17:0]	0h	R	Common FIFO One Frame RX Interrupt Flag Status 0b: Corresponding Common FIFO One Frame RX Interrupt flag not set 1b: Corresponding Common FIFO One Frame RX Interrupt flag set

CFXOFRXIF[17:0] bits (Common FIFO One Frame RX Interrupt Flag Status)

Each bit is set automatically when the corresponding One Frame RX Interrupt flag bit is set in the Common FIFO Status Registers.

The CFXOFRXIF[17:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding One Frame RX Interrupt flag bit is cleared in the Common FIFO Status Registers.

7.9.2.2.42 Common FIFO One Frame TX Interrupt Flag Status Register (CFDCFOFTISTS)

The CFDCFOFTISTS register shows status of the interrupt flag bits of the Common FIFO buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 02BCh
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

17 to 0	CFXOFTXIF [17:0]	0h	R	Common FIFO One Frame TX Interrupt Flag Status 0b: Corresponding Common FIFO One Frame TX Interrupt flag not set 1b: Corresponding Common FIFO One Frame TX Interrupt flag set

CFXOFTXIF[17:0] bits (Common FIFO One Frame TX Interrupt Flag Status)

Each bit is set automatically when the corresponding One Frame TX Interrupt flag bit is set in the Common FIFO Status Registers.

The CFXOFTXIF[17:0] bits are cleared when the CAN-FD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding One Frame TX Interrupt flag bit is cleared in the Common FIFO Status Registers.

7.9.2.2.43 DMA Transfer Control Register (CFDCDTCT)

The CFDCDTCT register controls the start and stop of DMA transfer operation.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1330h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	RFDMAE1	0h	RW	DMA Transfer Enable for RX FIFO 1 0b: DMA transfer request disabled 1b: DMA transfer request enabled

Bit	Bit Name	Initial Value	R/W	Description
0	RFDMAE0	0h	RW	DMA Transfer Enable for RX FIFO 0 0b: DMA transfer request disabled 1b: DMA transfer request enabled

RFDMAEn (n = 0 to 7) bit (DMA Transfer Enable for RX FIFOn)

Number of RX FIFOs = 8

The RFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMAEn (n = 0 to 5) bit (DMA Transfer Enable for Common FIFO 0 of Channels 0 to 5)

The CFDMAEn bit enables or disables DMA transfer request for common FIFO 0 of channels 0 to 5. Only Common FIFO 0 can be linked to a DMA channel with this bit. Common FIFO 1 cannot be linked to a DMA channel.

To link Common FIFO 2, see bit CFDCDTTCT.CFDMAEn in **7.9.2.2.45 DMA TX Transfer Control Register (CFDCDTTCT)**.

The CFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

Do not enable a DMA transfer for a Common FIFO that is configured as TX or GW FIFO.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

7.9.2.2.44 DMA Transfer Status Register (CFDCDTSTS)

The CFDCDTSTS register shows the status of the DMA transfer.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1334h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1	RFDMASTS1	0h	R	DMA Transfer Status for RX FIFO 1 0b: DMA transfer stopped 1b: DMA transfer ongoing

Bit	Bit Name	Initial Value	R/W	Description
0	RFDMASTS0	0h	R	DMA Transfer Status for RX FIFO 0 0b: DMA transfer stopped 1b: DMA transfer ongoing

RFDMASTSn (n = 0 to 7) bit (DMA Transfer Status for RX FIFO n)

Number of RX FIFOs = 8

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.RFDMAEn (see CFDCDTCT.RFDMAEn bit in **7.9.2.2.43 DMA Transfer Control Register (CFDCDTCT)**) is set to 0b while DMA transfer for the corresponding FIFO is ongoing, the RFDMASTSn bit becomes 0b when the DMA transfer is complete.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMASTSn bit (DMA Transfer Status only for Common FIFO 0 of Channels 0 to 5)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty.

Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.CFDMAEn (see CFDCDTCT.CFDMAEn bit in **7.9.2.2.43 DMA Transfer Control Register (CFDCDTCT)**) is set to 0b while DMA transfer for the corresponding FIFO is ongoing, the CFDMASTSn bit becomes 0b when the DMA transfer is complete.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

7.9.2.2.45 DMA TX Transfer Control Register (CFDCDTTCT)

The CFDCDTTCT register controls the start and stop of DMA transfer operation.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1340h
Initial Value : 0000_0000h

7 to 6	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

Bit	Bit Name	Initial Value	R/W	Description
5	TQ0DMAE5	0h	RW	DMA TX Transfer Enable for TXQ 0 of Channel 5 0b: DMA TX transfer request disabled 1b: DMA TX transfer request enabled
4	TQ0DMAE4	0h	RW	DMA TX Transfer Enable for TXQ 0 of Channel 4 0b: DMA TX transfer request disabled 1b: DMA TX transfer request enabled
3	TQ0DMAE3	0h	RW	DMA TX Transfer Enable for TXQ 0 of Channel 3 0b: DMA TX transfer request disabled 1b: DMA TX transfer request enabled
2	TQ0DMAE2	0h	RW	DMA TX Transfer Enable for TXQ 0 of Channel 2 0b: DMA TX transfer request disabled 1b: DMA TX transfer request enabled
1	TQ0DMAE1	0h	RW	DMA TX Transfer Enable for TXQ 0 of Channel 1 0b: DMA TX transfer request disabled 1b: DMA TX transfer request enabled
0	TQ0DMAE0	0h	RW	DMA TX Transfer Enable for TXQ 0 of Channel 0 0b: DMA TX transfer request disabled 1b: DMA TX transfer request enabled

TQ0DMAEn (n = 0 to 5) bit (DMA TX Transfer Enable for TXQ 0 of Channel n)

The TQ0DMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

TQ3DMAEn (n = 0 to 5) bit (DMA TX Transfer Enable for TXQ 3 of Channel n)

The TQ3DMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

CFDMAEn (n = 0 to 5) bit (DMA TX Transfer Enable for Common FIFO 2 of Channel n)

The CFDMAEn bit cannot be set in GL_SLEEP or GL_RESET mode.

Only common FIFO 2 can be linked to a DMA channel with this bit. Common FIFO 1 cannot be linked to a DMA channel. To link Common FIFO 0, see CFDCDTCT.CFDMAEn bit in **7.9.2.2.43 DMA Transfer Control Register (CFDCDTCT)**.

Do not enable a DMA transfer for a Common FIFO that is configured as RX or GW FIFO.

The CFDMAEn bit is cleared when the CAN-FD module is in GL_RESET mode.

7.9.2.2.46 DMA TX Transfer Status Register (CFDCDTTSTS)

The CFDCDTTSTS register shows the status of the DMA TX transfer.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1344h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	TQ0DMASTS0	0h	R	DMA TX Transfer Status for TXQ0 of Channel 0 0b: DMA TX transfer stopped 1b: DMA TX transfer enabled

TQ0DMASTSn (n = 0 to 5) bit (DMA TX Transfer Status for TXQ 0 of Channel n)

The TQ0DMASTSn bit is set when the CFDCDTTCT.TQ0DMAEn bit in the corresponding CFDCDTTCT register is set (see **7.9.2.2.45 DMA TX Transfer Control Register (CFDCDTTCT)**).

This bit is cleared when:

- The CFDCDTTCT.TQ0DMAEn bit in the corresponding CFDCDTTCT register is cleared
- The CAN-FD module is in GL_RESET mode.

TQ3DMASTSn (n = 0 to 5) bit (DMA TX Transfer Status for TXQ 3 of Channel n)

The TQ3DMASTSn bit is set when the CFDCDTTCT.TQ3DMAEn bit in the corresponding CFDCDTTCT register is set (see **7.9.2.2.45 DMA TX Transfer Control Register (CFDCDTTCT)**).

This bit is cleared when:

- The CFDCDTTCT.TQ3DMAEn bit in the corresponding CFDCDTTCT register is cleared
- The CAN-FD module is in GL_RESET mode.

CFDMASTSn (n = 0 to 5) bit (DMA TX Transfer Status only for Common FIFO 2 of Channel n)

The CFDMASTSn bit is set when the CFDCDTTCT.CFDMAEn bit in the corresponding CFDCDTTCT register is set (see **7.9.2.2.45 DMA TX Transfer Control Register (CFDCDTTCT)**).

This bit is cleared when:

- The CFDCDTTCT.CFDMAEn bit in the corresponding CFDCDTTCT register is cleared
- The CAN-FD module is in GL_RESET mode.

7.9.2.2.47 Global RX Interrupt Status Register n (CFDGRINTSTSn) (n = 0 to 5)

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1350h + n x 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3	-	0h	R	Reserved Whenever it is read, 0b is read.
2 to 0	QFIF[2:0]	0h	R	TXQ Full Interrupt Flag Channel n (n = 0 to 5) 0b: Corresponding TXQ Full Interrupt flag is not set 1b: Corresponding TXQ Full Interrupt flag is set

QFIF[2:0] bits (TXQ Full Interrupt Flag Channel n (n = 0 to 5))

The QFIF[2:0] bits are set automatically when the TXQ Full Interrupt flag of the related channel is set when the interrupt is enabled.

The QFIF[2:0] bits are cleared automatically when:

- The related TXQ result status bits are cleared or the interrupt enable is disabled

- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

BQFIF[1:0] bits (Borrowed TXQ Full Interrupt Flag Channel n (n = 0 to 5))

The BQFIF[1:0] bits are set when a flexible transmission buffer assignment function is used and the borrowed TXQ is in full status. Operation is the same as CFDGRINTSTSn.QFIF.

The bit of the channel that lends TXMB is a reserved bit.

QOFRIF[2:0] bits (TXQ One Frame RX Interrupt Flag Channel n (n = 0 to 5))

The QOFRIF[2:0] bits are set automatically when the TXQ One Frame RX Interrupt flag of the related channel is set when the interrupt is enabled.

The QOFRIF[2:0] bits are cleared automatically when:

- The related TXQ result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET or CH_RESET mode.

BQOFRIF[1:0] bits (Borrowed TXQ One Frame RX Interrupt Flag Channel n (n = 0 to 5))

The BQOFRIF[1:0] bits are set when a flexible transmission buffer assignment function is used and the borrowed TXQ receives one frame. Operation is the same as CFDGRINTSTSn.QOFRIF.

The bit of the channel that lends TXMB is a reserved bit.

CFRIF[2:0] bits (Common FIFO RX Interrupt Flag Channel n (n = 0 to 5))

The CFRIF[2:0] bits are set automatically when the Common FIFO RX Interrupt flag of the related channel is set when the interrupt is enabled.

The CFRIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET or CH_RESET mode.

CFRFIF[2:0] bits (Common FIFO FDC Level Full Interrupt Flag Channel n (n = 0 to 5))

The CFRFIF[2:0] bits are set automatically when the Common FIFO Full Interrupt flag of the related channel is set when the interrupt is enabled.

The CFRFIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

CFOFRIF[2:0] bits (Common FIFO One Frame RX Interrupt Flag Channel n (n = 0 to 5))

The CFOFRIF[2:0] bits are set automatically when the Common FIFO One Frame RX Interrupt flag of the related channel is set when the interrupt is enabled.

The CFOFRIF[2:0] bits are cleared automatically when:

- The related Common FIFO RX result status bits are cleared or the interrupt enable is disabled
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

7.9.2.2.48 TX Message Buffer Control Register n (CFDTMCn) (n = 0 to 383)

The CFDTMCn register (n = 0 to 383) configures the TX message buffer functions.

Access Size : 8 bits
Address : <CFD_base> + 02D0h + n x 0001h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	TMOM	TMTAR	TMTR
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	TMOM	0h	RW	TX Message Buffer One-shot Mode 0b: TX message buffer not configured in one-shot mode 1b: TX message buffer configured in one-shot mode
1	TMTAR	0h	RW	TX Message Buffer Transmission Abort Request 0b: TX message buffer transmission request abort not requested 1b: TX message buffer transmission request abort requested
0	TMTR	0h	RW	TX Message Buffer Transmission Request 0b: TX Message buffer transmission not requested 1b: TX message buffer transmission requested

TMTR bit (TX Message Buffer Transmission Request)

When the TMTR bit is set, the CAN-FD module logic tries to transmit the message stored in the corresponding message buffer.

Only write to this bit when the related CAN-FD module is in CH_HALT or CH_OPERATION mode.

Do not set this bit if the corresponding TX message buffer is linked to a COM FIFO in TX or GW mode or is a part of TX Queue.

This bit cannot be directly cleared by a CPU write access.

This bit can only be set when the Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the CFDTMSTSn register corresponding to the message buffer are cleared to 00b.

The TMTR bit is automatically cleared by the:

- CAN-FD module logic at the end of a successful transmission
- CAN-FD module logic at the end of a transmission abort, requested by the corresponding CFDTMCn.TMTAR bit
- CAN-FD module logic when there is a detection of a CAN bus error or arbitration loss if CFDTMCn.TMOM bit is set for the message buffer
- CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTAR bit (TX Message Buffer Transmission Abort Request)

When the TMTAR bit is set, the CAN-FD module logic tries to abort the transmission of the frame stored in the corresponding message buffer.

In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame may be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (RX pin) before it starts transmission from the selected message buffer.

Only write to the TMTAR bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. This bit can only be set when the related transmit request TMTR bit is set.

The TMTAR bit cannot be cleared by a CPU write access. Clearing of this bit by CAN-FD has priority over setting by a CPU write access.

The TMTAR bit is automatically cleared by:

- The CAN-FD module logic at the end of a successful transmission
- The CAN-FD module logic at the end of a transmission abort
- The CAN-FD module logic when there is detection of a CAN bus error or arbitration loss
- The CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel enters CH_RESET mode.

TMOM bit (TX Message Buffer One-shot Mode)

When the TMOM bit is set, the CAN-FD module logic tries to transmit the message only once.

If the transmission is successful, the CFDTMSTSn.TMTRF[1:0] bits are set to 10b or 11b. Otherwise, the transmission is automatically aborted and CFDTMSTSn.TMTRF[1:0] bits are set to 01b due to a bus error or a bus arbitration lost.

The TMOM bit remains set if the transmission has completed successfully or aborted due to an error or a loss of arbitration.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Set this bit at the same time as the TMTR bit. Clear this bit with a write access.

If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.

The TMOM bit is automatically cleared by the CAN-FD module logic when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

7.9.2.2.49 TX Message Buffer Status Register n (CFDTMSTSn) (n = 0 to 383)

The CFDTMSTSn register (n = 0 to 383) shows status of the transmission and transmission abort for the corresponding message buffers.

Access Size : 8 bits
Address : <CFD_base> + 07D0h + n x 0001h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	R	R	RW	RW	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4	TMTARM	0h	R	TX Message Buffer Transmission Abort Request Mirrored 0b: TX message buffer transmission request abort not requested 1b: TX message buffer transmission request abort requested
3	TMTRM	0h	R	TX Message Buffer Transmission Request Mirrored 0b: TX message buffer transmission not requested 1b: TX message buffer transmission requested
2, 1	TMTRF[1:0]	0h	RW	TX Message Buffer Transmission Result Flag 00b: No result 01b: Transmission aborted from the TX message buffer 10b: Transmission successful from the TX message buffer and transmission abort was not requested 11b: Transmission successful from the TX message buffer and transmission abort was requested
0	TMTSTS	0h	R	TX Message Buffer Transmission Status 0b: No on-going transmission 1b: On-going transmission

TMTSTS bit (TX Message Buffer Transmission Status)

The TMTSTS bit is set automatically at the start of the transmission from the corresponding TX message buffer.

This bit is cleared automatically when:

- Transmission stops
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

TMTRF[1:0] bits (TX Message Buffer Transmission Result Flag)

The TMTRF[1:0] bits show the result for the corresponding TX message buffer. The status is as follows:

- 00b: Transmission in progress or has not been requested
- 01b: Transmission has been aborted from the corresponding TX message buffer
- 10b: Transmission was successful from the corresponding TX message buffer and the CFDTMCn.TMTAR bit was not set for this TX message buffer
- 11b: Transmission was successful from the corresponding TX message buffer, but the CFDTMCn.TMTAR bit was set for this TX message buffer.

Only write to these bits when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

The TMTRF[1:0] bits are cleared automatically when the CAN-FD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTRM bit (TX Message Buffer Transmission Request Mirrored)

The TMTRM bit is set when the CFDTMCn.TMTR bit in the corresponding CFDTMCn register is set.

This bit is cleared when the CFDTMCn.TMTR bit in the corresponding CFDTMCn register is cleared.

TMTARM bit (TX Message Buffer Transmission Abort Request Mirrored)

The TMTARM bit is set when the CFDTMCn.TMTAR bit in the corresponding CFDTMCn register is set.

This bit is cleared when the CFDTMCn.TMTAR bit in the corresponding CFDTMCn register is cleared.

7.9.2.2.50 TX Message Buffer Transmission Request Status Register f (CFDTMTRSTSf) (f = 0 to 11)

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 0CD0h + f x 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TMTRSTS[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read.
15 to 0	TMTRSTS[15:0]	0h	R	TX Message Buffer Transmission Request Status 0b: Transmission not requested for corresponding TX message buffer 1b: Transmission requested for corresponding TX message buffer

TMTRSTS[15:0] bits (TX Message Buffer Transmission Request Status)

The TMTRSTS[15:0] bits show status of the CFDTMCn.TMTR bits of the TX Message Buffer Control Registers.

Alignment of the TMTRSTS[15:0] bits is shown in **Table 7.9-7**.

Table 7.9-7 Alignment of TMTRSTS[15:0] Mirror Bits

Bit Position	TX Message Buffer Number
n × 64 − fmin × 32	n × 64 + 0
n × 64 + 1 − fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 15 − fmin × 32	n × 64 + 15
n × 64 + 32 − fmax × 32	n × 64 + 32
⋮	⋮
n ×64 + 46 − fmax × 32	n × 64 + 46
n × 64 + 47 − fmax × 32	n × 64 + 47

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3
When n = 2, fmin = 4, fmax = 5
When n = 3, fmin = 6, fmax = 7
When n = 4, fmin = 8, fmax = 9
When n = 5, fmin = 10, fmax = 11

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers (CFDTMCn), and only when the message buffer does not belong to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

7.9.2.2.51 TX Message Buffer Transmission Abort Request Status Register f (CFDTMTARSTSf) (f = 0 to 11)

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 0D70h + f x 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TMTARSTS[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read.
15 to 0	TMTARSTS [15:0]	0h	R	TX Message Buffer Transmission Abort Request Status 0b: Transmission abort not requested for corresponding TX message buffer 1b: Transmission abort requested for corresponding TX message buffer

TMTARSTS[15:0] bits (TX Message Buffer Transmission Abort Request Status)

The TMTARSTS[15:0] bits show status of the CFDTMCn.TMTAR bits of the TX Message Buffer Control Registers. Alignment of the TMTARSTS[15:0] bits is shown in **Table 7.9-8**.

Table 7.9-8 Alignment of TMTARSTS[15:0] Mirror Bits

Bit Position	TX Message Buffer Number
n × 64 − fmin × 32	n × 64 + 0
n × 64 + 1 − fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 15 − fmin × 32	n × 64 + 15
n × 64 + 32 − fmax × 32	n × 64 + 32
⋮	⋮
n × 64 + 46 − fmax × 32	n × 64 + 46
n × 64 + 47 − fmax × 32	n × 64 + 47

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3
When n = 2, fmin = 4, fmax = 5
When n = 3, fmin = 6, fmax = 7
When n = 4, fmin = 8, fmax = 9
When n = 5, fmin = 10, fmax = 11

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers, and when the message buffer belongs to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

7.9.2.2.52 TX Message Buffer Transmission Completion Status Register f (CFDTMTCSTSf) (f = 0 to 11)

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 0E10h + f x 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TMTCSTS[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read.
15 to 0	TMTCSTS [15:0]	0h	R	TX Message Buffer Transmission Completion Status 0b: Transmission not completed for corresponding TX message buffer 1b: Transmission completed for corresponding TX message buffer

TMTCSTS[15:0] bits (TX Message Buffer Transmission Completion Status)

The TMTCSTS[15:0] bits show status of successful completion of the TX Message Buffer Status Registers.

Alignment of the TMTCSTS[15:0] bits is shown in **Table 7.9-9**.

Table 7.9-9 Alignment of TMTCSTS[15:0] Mirror Bits

Bit Position	TX Message Buffer Number
n × 64 − fmin × 32	n × 64 + 0
n × 64 + 1 − fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 15 − fmin × 32	n × 64 + 15
n × 64 + 32 − fmax × 32	n × 64 + 32
⋮	⋮
n × 64 + 46 − fmax × 32	n × 64 + 46
n × 64 + 47 − fmax × 32	n × 64 + 47

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3
When n = 2, fmin = 4, fmax = 5
When n = 3, fmin = 6, fmax = 7
When n = 4, fmin = 8, fmax = 9
When n = 5, fmin = 10, fmax = 11

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Status Registers.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Status Registers
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

If a CAN channel enters CH_RESET mode, then the bits related to that channel are cleared.

7.9.2.2.53 TX Message Buffer Transmission Abort Status Register f (CFDTMTASTSf) (f = 0 to 11)

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 0EB0h + f x 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TMTASTS[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read.
15 to 0	TMTASTS [15:0]	0h	R	TX Message Buffer Transmission Abort Status 0b: Transmission not aborted for corresponding TX message buffer 1b: Transmission aborted for corresponding TX message buffer

TMTASTS[15:0] bits (TX Message Buffer Transmission Abort Status)

The TMTASTS[15:0] bits show status of the successful transmission abort of the corresponding TX message buffer.

Alignment of the TMTASTS[15:0] bits is shown in **Table 7.9-10**.

Table 7.9-10 Alignment of TMTASTS[15:0] Mirror Bits

Bit Position	TX Message Buffer Number
n × 64 − fmin × 32	n × 64 + 0
n × 64 + 1 − fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 15 − fmin × 32	n × 64 + 15
n × 64 + 32 − fmax × 32	n × 64 + 32
⋮	⋮
n × 64 + 46 − fmax × 32	n × 64 + 46
n × 64 + 47 − fmax × 32	n × 64 + 47

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3
When n = 2, fmin = 4, fmax = 5
When n = 3, fmin = 6, fmax = 7
When n = 4, fmin = 8, fmax = 9
When n = 5, fmin = 10, fmax = 11

Each bit is set automatically when the CFDTMSTSn.TMTRF[1:0] bits are set to 01b in the corresponding TX Message Buffer Status Register.

Each bit is cleared automatically when:

- The CFDTMSTSn.TMTRF[1:0] bits are cleared in the corresponding TX Message Buffer Status Register
- The CAN-FD module is in GL_RESET mode
- The related CAN-FD channel is in CH_RESET mode.

7.9.2.2.54 TX Message Buffer Transmission Interrupt Enable Register f (CFDTMIECf) (f = 0 to 11)

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 0F50h + f x 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
15 to 0	TMIE[15:0]	0h	RW	TX Message Buffer Interrupt Enable 0b: TX message buffer interrupt disabled for corresponding TX message buffer 1b: TX message buffer interrupt enabled for corresponding TX message buffer

TMIE[15:0] bits (TX Message Buffer Interrupt Enable)

If the TMIE[15:0] bits are set, an interrupt is generated at the end of a successful transmission from the corresponding message buffer.

See **7.9.7 Interrupt and DMA** for TX Message Buffer Interrupt specification.

Alignment of the TMIE[15:0] bits is shown in **Table 7.9-11**.

Table 7.9-11 Alignment of TMIE[15:0] bits

Bit Position	TX Message Buffer Number
n × 64 − fmin × 32	n × 64 + 0
n × 64 + 1 − fmin × 32	n × 64 + 1
⋮	⋮
n × 64 + 15 − fmin × 32	n × 64 + 15
n × 64 + 32 − fmax × 32	n × 64 + 32
⋮	⋮
n × 64 + 46 − fmax × 32	n × 64 + 46
n × 64 + 47 − fmax × 32	n × 64 + 47

Note: When n = 0, fmin = 0, fmax = 1
When n = 1, fmin = 2, fmax = 3
When n = 2, fmin = 4, fmax = 5
When n = 3, fmin = 6, fmax = 7
When n = 4, fmin = 8, fmax = 9
When n = 5, fmin = 10, fmax = 11

Do not write to the TMIE[15:0] bits when:

- The CAN-FD module is in GL_SLEEP mode
- The related CAN-FD channel is in CH_SLEEP mode
- The corresponding TX message buffer is part of a TX Queue
- The corresponding TX message buffer is linked to a Common FIFO with the CFDCFCCn.CFTML[4:0] bits.

7.9.2.2.55 TX Queue Configuration/Control Register 0n (CFDTXQCC0n) (n = 0 to 5)

The CFDTXQCC0n register (n = 0 to 5) is used to configure the TX Queue transmission.

TXQ0 is composed of TXMB0 to TXMB15 (at the maximum) when TXQE is enabled.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1000h + n x 0004h

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 00h (CFDTXQCC0n.TXQDC[4:0] = 00h).

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

The TXQE bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue GW mode.

When this bit is set, CPU must not access the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC0n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC0n.TXQE bit is 1b.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP

- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[0] up to MB[15] depending on the configured depth.

When using TXQ1 and TXQ0 simultaneously, the total depth of TXQ1 and TXQ0 should be 16 or less.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQFIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1b to this bit in Gateway mode (CFDTXQCC0n.TXQGWE = 1b).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQOFRXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1b to this bit in GW mode (CFDTXQCC0n.TXQGWE = 1b).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS0n.TXQOFTXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.2.56 TX Queue Configuration/Control Register 1n (CFDTXQCC1n) (n = 0 to 5)

The CFDTXQCC1n register (n = 0 to 5) is used to configure the TX Queue transmission.

TXQ1 is composed of TXMB15 to TXMB0 (at the maximum) when TXQE is enabled.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1060h + n x 0004h

Initial Value : 0000_0000h

0	TXQE	0h	RW	TX Queue Enable 0b: TX Queue disabled 1b: TX Queue enabled

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 00h (CFDTXQCC1n.TXQDC[4:0] = 00h).

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue Gateway mode.

When this bit is set, CPU must not access the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC1n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC1n.TXQE bit is 1.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP

- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[15] down to MB[0] depending on the configured depth.

When using TXQ1 and TXQ0 simultaneously, the total depth of TXQ1 and TXQ0 should be 16 or less.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQFIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1b to this bit when in Gateway mode (CFDTXQCC1n.TXQGWE = 1b).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQOFRXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1b to this bit when in Gateway mode (CFDTXQCC1n.TXQGWE = 1b).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS1n.TXQOFTXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.2.57 TX Queue Configuration/Control Register 2n (CFDTXQCC2n) (n = 0 to 5)

The CFDTXQCC2n register (n = 0 to 5) is used to configure the TX Queue transmission.

TXQ2 is composed of TXMB32 to TXMB47 (at the maximum) when TXQE is enabled.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 10C0h + n x 0004h

Initial Value : 0000_0000h

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 00h (CFDTXQCC2n.TXQDC[4:0] = 00h).

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

TXQGWE bit (TX Queue Gateway Mode Enable)

When the TXQGWE bit is set, the TX Queue is in TX Queue Gateway mode. When this bit is set, CPU must not access the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC2n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC2n.TXQE bit is 1b.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP

- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[32] up to MB[47] depending on the configured depth.

When using TXQ3 and TXQ2 simultaneously, the total depth of TXQ3 and TXQ2 should be 16 or less.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION

TXQFIE bit (TXQ Full Interrupt Enable)

When the TXQFIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQFIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1b to this bit when in GW mode (CFDTXQCC2n.TXQGWE = 1b).

TXQOFRXIE bit (TXQ One Frame Reception Interrupt Enable)

When the TXQOFRXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQOFRXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

Only write 1b to this bit when in GW mode (CFDTXQCC2n.TXQGWE = 1b).

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS2n.TXQOFTXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.2.58 TX Queue Configuration/Control Register 3n (CFDTXQCC3n) (n = 0 to 5)

The CFDTXQCC3n register (n = 0 to 5) is used to configure the TX Queue transmission.

TXQ3 is composed of TXMB47 to TXMB32 (at the maximum) when TXQE is enabled.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1120h + n x 0004h

5	TXQTXIE	0h	RW	TX Queue TX Interrupt Enable 0b: TX Queue TX interrupt disabled 1b: TX Queue TX interrupt enabled
4, 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	TXQOWE	0h	RW	TX Queue Overwrite Mode Enable 0b: TX Queue OW mode disabled 1b: TX Queue OW mode enabled
1	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	TXQE	0h	RW	TX Queue Enable 0b: TX Queue disabled 1b: TX Queue enabled

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 00h (CFDTXQCC3n.TXQDC[4:0] = 00h).

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

TXQOWE bit (TX Queue Overwrite Mode Enable)

When the TXQOWE bit is set, the TX Queue is in TX Queue Overwrite mode.

An overwrite function is valid when the same ID such as ID of the data written in from the gateway or CPU is in TX Queue. For example, when a frame is received and is stored into the TX Queue, if a message with the same ID is stored in the TX Queue, the old message is overwritten by the new message.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

When using the function in GW mode, the depth of TXQ (CFDTXQCC3n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3.

The function is valid for the standard ID frame but is invalid for the extended ID frame.

Do not modify this bit when the CFDTXQCC3n.TXQE bit is 1b.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[4:0] bits (TX Queue Depth Configuration)

The TXQDC[4:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[47] down to MB[32] depending on the configured depth.

When using TXQ3 and TXQ2 simultaneously, the total depth of TXQ3 and TXQ2 should be 16 or less.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQOFTXIE bit (TXQ One Frame Transmission Interrupt Enable)

When the TXQOFTXIE bit is set, an interrupt is generated based on the setting of the CFDTXQSTS3n.TXQOFTXIF bit.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the related CAN-FD channel is in CH_SLEEP mode.

7.9.2.2.59 TX Queue Status Register 0n (CFDTXQSTS0n) (n = 0 to 5)

The CFDTXQSTS0n register (n = 0 to 5) shows the status of the TX Queue of corresponding CAN channel.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1020h + n x 0004h

Initial Value : 0000_0001h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

18	TXQOFTXIF	0h	RW	TXQ One Frame Transmission Interrupt Flag When one frame is transmitted from TXQ, an interrupt is set.
17	TXQOFRXIF	0h	RW	TXQ One Frame Reception Interrupt Flag When TXQ receives one frame, an interrupt is set.
16	TXQFIF	0h	RW	TXQ Full Interrupt Flag When TXQ is in full status, an interrupt is set.
15, 14	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
13 to 8	TXQMC[5:0]	0h	R	TX Queue Message Count Number of messages in the TX Queue.
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	TXQTXIF	0h	RW	TX Queue TX Interrupt Flag 0b: TX Queue interrupt condition not satisfied after a frame TX 1b: TX Queue interrupt condition satisfied after a frame TX
1	TXQFLL	0h	R	TX Queue Full 0b: TX Queue not full 1b: TX Queue full
0	TXQEMP	1h	R	TX Queue Empty 0b: TX Queue not empty 1b: TX Queue empty

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Only in Gateway mode (CFDTXQCC0n.TXQGWE = 1b) that this bit is set automatically when the TX Queue transits to a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in Gateway mode of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in Gateway mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC0n.TXQOWE = 1b and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

7.9.2.2.60 TX Queue Status Register 1n (CFDTXQSTS1n) (n = 0 to 5)

The CFDTXQSTS1n register (n = 0 to 5) shows the status of the TX Queue of corresponding CAN channel.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1080h + n x 0004h

Initial Value : 0000_0001h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
20	TXQMOW	0h	RW	TXQ Message Overwrite 0b: No message overwrite in TXQ 1b: Message overwrite in TXQ
19	TXQMLT	0h	RW	TXQ Message Lost 0b: No message lost in TXQ 1b: TXQ message lost
18	TXQOFTXIF	0h	RW	TXQ One Frame Transmission Interrupt Flag When one frame is transmitted from TXQ, an interrupt is set.
17	TXQOFRXIF	0h	RW	TXQ One Frame Reception Interrupt Flag When TXQ receives one frame, an interrupt is set.
16	TXQFIF	0h	RW	TXQ Full Interrupt Flag When TXQ is in full status, an interrupt is set.
15, 14	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
13 to 8	TXQMC[5:0]	0h	R	TX Queue Message Count Number of messages in the TX Queue
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	TXQTXIF	0h	RW	TX Queue TX Interrupt Flag 0b: TX Queue interrupt condition not satisfied after a frame TX 1b: TX Queue interrupt condition satisfied after a frame TX
1	TXQFLL	0h	R	TX Queue Full 0b: TX Queue not full 1b: TX Queue full
0	TXQEMP	1h	R	TX Queue Empty 0b: TX Queue not empty 1b: TX Queue empty

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

Only in Gateway mode (CFDTXQCC1n.TXQGWE = 1b) that this bit is set automatically when TX Queue transits to a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in Gateway mode of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in Gateway mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC1n.TXQOWE = 1b and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

7.9.2.2.61 TX Queue Status Register 2n (CFDTXQSTS2n) (n = 0to 5)

The CFDTXQSTS2n register (n = 0 to 5) shows the status of the TX Queue of corresponding CAN Channel.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 10E0h + n x 0004h
Initial Value : 0000_0001h

16	TXQFIF	0h	RW	TXQ Full Interrupt Flag When TXQ is in full status, an interrupt is set.
15, 14	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
13 to 8	TXQMC[5:0]	0h	R	TX Queue Message Count Number of messages in the TX Queue.
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	TXQTXIF	0h	RW	TX Queue TX Interrupt Flag 0b: TX Queue interrupt condition not satisfied after a frame TX 1b: TX Queue interrupt condition satisfied after a frame TX
1	TXQFLL	0h	R	TX Queue Full 0b: TX Queue not full 1b: TX Queue full
0	TXQEMP	1h	R	TX Queue Empty 0b: TX Queue not empty 1b: TX Queue empty

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQFIF bit (TXQ Full Interrupt Flag)

The TXQFIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

Only in Gateway mode (CFDTXQCC2n.TXQGWE = 1b) that this bit is set automatically when the TX Queue transits to a buffer full status.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFRXIF bit (TXQ One Frame Reception Interrupt Flag)

The TXQOFRXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When receiving data is stored in the TX Queue in Gateway mode, this bit is set automatically.

This function can only be used in Gateway mode of the TX queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

The bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMLT bit (TXQ Message Lost)

The TXQMLT bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When a message lost occurs in Gateway mode of the TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC2n.TXQOWE = 1b and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

7.9.2.2.62 TX Queue Status Register 3n (CFDTXQSTS3n) (n = 0 to 5)

The CFDTXQSTS3n register (n = 0 to 5) shows the status of the TX Queue of corresponding CAN Channel.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1140h + n x 0004h

Initial Value : 0000_0001h

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
20	TXQMOW	0h	RW	TXQ Message Overwrite 0b: No message overwrite in TXQ 1b: Message overwrite in TXQ
19	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
18	TXQOFTXIF	0h	RW	TXQ One Frame Transmission Interrupt Flag When one frame is transmitted from TXQ, an interrupt is set.
17 to 14	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
13 to 8	TXQMC[5:0]	0h	R	TX Queue Message Count Number of messages in the TX Queue
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	TXQTXIF	0h	RW	TX Queue TX Interrupt Flag 0b: TX Queue interrupt condition not satisfied after a frame TX 1b: TX Queue interrupt condition satisfied after a frame TX
1	TXQFLL	0h	R	TX Queue Full 0b: TX Queue not full 1b: TX Queue full
0	TXQEMP	1h	R	TX Queue Empty 0b: TX Queue not empty 1b: TX Queue empty

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CAN-FD channel is in CH_RESET mode.

This bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

TXQFLL bit (TX Queue Full)

The TXQFLL bit is set automatically when the number of CAN messages stored in the TX Queue matches the configured TX Queue depth.

This bit is cleared automatically when:

- The number of CAN messages stored in the TX Queue is less than the configured TX Queue depth
- The related CAN-FD channel is in CH_RESET mode.

TXQTXIF bit (TX Queue TX Interrupt Flag)

The TXQTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of the TX Queue.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is set automatically when the configured interrupt condition is satisfied for the TX Queue.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMC[5:0] bits (TX Queue Message Count)

The TXQMC[5:0] bits show the number of CAN messages in the TX Queue.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

TXQOFTXIF bit (TXQ One Frame Transmission Interrupt Flag)

The TXQOFTXIF bit is not cleared automatically if the TX Queue is disabled.

When stopping the TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue. When transmission is successful in the TX Queue, this bit is set automatically.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

TXQMOW bit (TXQ Message Overwrite)

The TXQMOW bit is not cleared automatically if the TX Queue is disabled.

When stopping TX Queue, this bit should be cleared, after disabling TXQE and checking an empty state of TX Queue.

When CFDTXQCC3n.TXQOWE = 1b and message overwrite occurs in TX Queue, this bit is set automatically.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b. Writing 1b has no effect.

You cannot write to this bit when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

7.9.2.2.63 TX Queue Pointer Control Register 0n (CFDTXQPCTR0n) (n = 0 to 5)

The CFDTXQPCTR0n register (n = 0 to 5) is used to confirm storage of a full message in the corresponding TX Queue buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1040h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	W	Reserved The written value should always be 0b.
7 to 0	TXQPC[7:0]	0h	W	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value FFh is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 00h. Do not write to the FIFO control registers when DMA is enabled.

You cannot write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Only write FFh to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

7.9.2.2.64 TX Queue Pointer Control Register 1n (CFDTXQPCTR1n) (n = 0 to 5)

The CFDTXQPCTR1n register (n = 0 to 5) is used to confirm storage of a full message in the corresponding TX Queue buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 10A0h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 8	-	All 0	W	Reserved The written value should always be 0b.
7 to 0	TXQPC[7:0]	0h	W	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value FFh is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 00h. You cannot write to the FIFO control registers when DMA is enabled.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Only write FFh to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

7.9.2.2.65 TX Queue Pointer Control Register 2n (CFDTXQPCTR2n) (n = 0 to 5)

The CFDTXQPCTR2n register (n = 0 to 5) is used to confirm storage of a full message in the corresponding TX Queue buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1100h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 0	TXQPC[7:0]	0h	W	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value FFh is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 00h. You cannot write to the FIFO control registers when DMA is enabled.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Only write FFh to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in GW mode.

7.9.2.2.66 TX Queue Pointer Control Register 3n (CFDTXQPCTR3n) (n = 0 to 5)

The CFDTXQPCTR3n register (n = 0 to 5) is used to confirm storage of a full message in the corresponding TX Queue buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1160h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7 to 0	TXQPC[7:0]	0h	W	TX Queue Pointer Control Increments the write pointer to the TX Queue buffer in the corresponding channel

TXQPC[7:0] bits (TX Queue Pointer Control)

When the value FFh is written to the TXQPC[7:0] bits, the write pointer of the corresponding TX Queue buffer is updated and a transmit request is initiated for this message.

The read value from these bits is always 00h. Do not write to the FIFO control registers when DMA is enabled.

You cannot write to these bits when the related CAN-FD channel is in CH_SLEEP or CH_RESET mode.

Only write FFh to this register when:

- The corresponding TX Queue is enabled and not full
- The Common FIFO is enabled and is not configured in Gateway mode.

7.9.2.2.67 TX Queue Empty Status Register (CFDTXQESTS)

The CFDTXQESTS register shows the status of the empty bits of the TXQ buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1180h
Initial Value : 0000_00FFh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	TXQxEMP[23:16]

17	Channel 4 TX Queue 1
18	Channel 4 TX Queue 2
19	Reserved
20	Channel 5 TX Queue 0
21	Channel 5 TX Queue 1
22	Channel 5 TX Queue 2
23	Reserved

7.9.2.2.70 TX Queue Interrupt Status Register (CFDTXQISTS)

The CFDTXQISTS register shows the status of the interrupt flag of the TXQ buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1190h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	TXQ5ISF[3:0]				TXQ4ISF[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXQ3ISF[3:0]				TXQ2ISF[3:0]				TXQ1ISF[3:0]				TXQ0ISF[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read.
23 to 0	TXQnISF[3:0]	0h	R	TXQ Interrupt Status Flag for Channel n (n = 0 to 5) 0b: TXQ Interrupt flag not set 1b: TXQ Interrupt flag set

TXQnISF[3:0] (n = 0 to 5) bits (TXQ Interrupt Status Flag)

Each bit is set automatically when the corresponding bit is set in the TX Queue Interrupt Status Register.

Each bit is cleared automatically when the corresponding bit is cleared in the TX Queue Interrupt Status Register.

This bit is cleared when the CAN-FD module is in GL_RESET mode.

Bit Position	Corresponding TX Queue
0	Channel 0 TX Queue 0
1	Channel 0 TX Queue 1
2	Channel 0 TX Queue 2

7.9.2.2.71 TX Queue One Frame TX Interrupt Status Register (CFDTXQOFTISTS)

The CFDTXQOFTISTS register shows the status of the One Frame TX Interrupt flag of the TXQ buffers.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1194h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

9	THLIM	0h	RW	TX History List Interrupt Mode 0b: Interrupt generated if TX History List level reaches ¾ of the TX History List depth 1b: Interrupt generated for every successfully stored entry
8	THLIE	0h	RW	TX History List Interrupt Enable 0b: TX History List Interrupt disabled 1b: TX History List Interrupt enabled
7 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	THLE	0h	RW	TX History List Enable 0b: TX History List disabled 1b: TX History List enabled

THLE bit (TX History List Enable)

The THLE bit enables the TX History List buffer when it is set.

You cannot write to this bit when the related CAN-FD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CAN-FD channel is in CH_RESET mode.

THLIE bit (TX History List Interrupt Enable)

The THLIE bit enables the generation of the TX History List interrupt when it is set.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

THLIM bit (TX History List Interrupt Mode)

The THLIM bit selects the interrupt generation condition for the FIFO.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

THLDTE bit (TX History List Dedicated TX Enable)

The THLDTE bit selects the condition for storing an entry in the TX History List after successful transmission.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

THLDGE bit (TX History List Dedicated Gateway Enable)

The THLDGE bit selects the condition for storing an entry in the TX History List after successful transmission.

You cannot write to this bit when the CAN-FD module is in GL_SLEEP mode.

Do not write to this bit when the CAN-FD module is in GL_HALT or GL_OPERATION mode.

7.9.2.2.75 TX History List Status Register n (CFDTHLSTSn) (n = 0 to 5)

The CFDTHLSTSn register (n = 0 to 5) shows the status of data stored in the TX History List buffer.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1220h + n x 0004h
Initial Value : 0000_0001h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	THLMC[5:0]						-	-	-	-	THLIF	THLELT	THLFLL	THLEMP
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	RW	RW	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
13 to 8	THLMC[5:0]	0h	R	TX History List Message Count Number of messages stored in TX History List
7 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3	THLIF	0h	RW	TX History List Interrupt Flag 0b: TX History List interrupt condition not satisfied 1b: TX History List interrupt condition satisfied
2	THLELT	0h	RW	TX History List Entry Lost 0b: No entry lost in TX History List 1b: TX History List entry Lost
1	THLFLL	0h	R	TX History List Full 0b: TX History List not full 1b: TX History List full
0	THLEMP	1h	R	TX History List Empty 0b: TX History List not empty 1b: TX History List empty

THLEMP bit (TX History List Empty)

The THLEMP bit is set automatically when the CPU has read all the entries from the TX History List buffer.

This bit is cleared automatically when the first entry is stored to the TX History List.

This bit is set automatically when:

- TX History List is disabled
- The related CAN-FD channel is in CH_RESET mode.

THLFLL bit (TX History List Full)

The THLFLL bit is set automatically when the number of entries in the TX History List buffer matches the TX History List depth.

Each TX History List can store up to 32 entries (each channel has a dedicated TX History List).

This bit is cleared automatically when:

- The number of entries in the TX History List buffer is less than the TX History List depth
- The TX History List is disabled

- The related CAN-FD channel is in CH_RESET mode.

THLELT bit (TX History List Entry Lost)

The THLELT bit is set when a new entry cannot be stored because the related TX History List buffer is already full.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

THLIF bit (TX History List Interrupt Flag)

The THLIF bit is set when the configured interrupt condition is satisfied.

Only write to this bit when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode. Writing 1b has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1b.

This bit is cleared:

- By writing 0b to it
- When the related CAN-FD channel is in CH_RESET mode.

This bit is automatically cleared in CH_RESET mode.

THLMC[5:0] bits (TX History List Message Count)

The THLMC[5:0] bits show the number of transmitted messages stored in the TX History List.

These bits are cleared automatically when the related CAN-FD channel is in CH_RESET mode.

7.9.2.2.76 Channel n TX History List Access Register 0 (CFDTHLACC0n) (n = 0 to 5)

The CFDTHLACC0n register (n = 0 to 5) provides access to the entry in the TX History List based on the read timestamp value.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 8000h + n x 0008h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMTS[15:0]

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TGW	-	-	-	-	-	BN[6:0]							BT[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	TMTS[15:0]	0h	R	Transmit Timestamp Transmit timestamp value for software drivers
15	TGW	0h	R	Transmit Gateway Buffer Indication 0b: No transmission from gateway 1b: Transmission from gateway
14 to 10	-	All 0	R	Reserved Whenever it is read, 0b is read.
9 to 3	BN[6:0]	0h	R	Buffer Number Number of the message buffer
2 to 0	BT[2:0]	0h	R	Buffer Type 001b: Flat TX message buffer 010b: TX FIFO message buffer number and gateway FIFO message number 100b: TX Queue message buffer number Others: Setting prohibited

BT[2:0] bits (Buffer Type)

The BT[2:0] bits indicate whether data has been stored following a transmission from a FIFO buffer, a TX Queue or a TX message buffer.

BN[6:0] bits (Buffer Number)

The BN[6:0] bits show the message buffer from which transmission was successfully completed. If a message from a Common FIFO is transmitted, then these bits show the message buffer that is linked to the Common FIFO for transmission.

TGW bit (Transmit Gateway Buffer Indication)

The TGW bit is automatically set to 1b when transmission is completed in GW mode.

TMTS[15:0] bits (Transmit Timestamp)

The TMTS[15:0] bits indicate the timestamp for use by software drivers.

7.9.2.2.77 Channel n TX History List Access Register 1 (CFDTHLACC1n) (n = 0 to 5)

The CFDTHLACC1n register (n = 0 to 5) provides access to entry in the TX History List based on the read pointer value.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 8004h + n x 0008h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	TIFL[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TID[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read.
17, 16	TIFL[1:0]	0h	R	Transmit Information Label These bits indicate that message buffer information label, TX FIFO information label, or AFL information label is stored for software drivers.
15 to 0	TID[15:0]	0h	R	Transmit ID These bits indicate that message buffer reference ID, TX FIFO reference ID, or AFL pointer field is stored for software drivers.

TID[15:0] bits (Transmit ID)

The TID[15:0] bits indicate whether the message buffer reference ID (CFDTMFDCTRn.TMPTR) or the TX FIFO reference ID (CFDCFFDCSTSn.CFPTR) is for use by software drivers.

When transmission in Gateway mode, these bits indicate the AFL pointer field (CFDGAFLP0n.GAFLPTR) instead of the message buffer reference ID (CFDTMFDCTRn.TMPTR).

TIFL[1:0] bits (Transmit Information Label)

The TIFL[1:0] bits indicate whether the message buffer information label (CFDTMFDCTRn.TMIFL) or the TX FIFO information label (CFDCFFDCSTSn.CFIFL) is for use by software drivers.

When transmission in Gateway mode, these bits indicate the AFL pointer field (CFDGAFLMn.GAFLIFL1 and CFDGAFLP0n.GAFLIFL0) instead of the MB information label (CFDTMFDCTRn.TMIFL).

7.9.2.2.78 TX History List Pointer Control Register n (CFDTHLPCTRn) (n = 0 to 5)

The CFDTHLPCTRn register (n = 0 to 5) is used to increment the read pointer of the TX History List.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1240h + n x 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

	-	-	-	-	-	-	-	-	THLPC[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	W	Reserved The written value should always be 0b.
7 to 0	THLPC[7:0]	0h	W	TX History List Pointer Control Increments the write pointer to the TX History List in the corresponding channel

THLPC[7:0] bits (TX History List Pointer Control)

When FFh is written to the THLPC[7:0] bits, the read pointer of the TX History List is moved to the next TX History List entry address.

The read value from these bits is always 00h. Only write to these bits when the related CAN-FD channel is in CH_HALT or CH_OPERATION mode.

Only write FFh to these registers when the corresponding TX History List is enabled and not empty.

7.9.2.2.79 Global Reset Control Register (CFDGRSTC)

Access Size : 16, 32 bits
Address : <CFD_base> + 1380h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	KEY[7:0]								-	-	-	-	-	-	-	SRST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
15 to 8	KEY[7:0]	All 0	W	Key Code These bits control the validity of rewriting of the SRST bit.
7 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	SRST	0h	RW	Software Reset 0b: Normal state 1b: Software reset state

SRST bit (Software Reset)

When the SRST bit is set, the CAN-FD module is in the same state as hardware reset. When a reset is required, write 1b then write 0b to this bit.

This bit is cleared when the CAN-FD module is in GL_SLEEP mode.

When this bit is cleared, the RAM initialization sequence does not operate. The configuration of RAM is performed by software.

The RAM is not initialized when software reset is performed during the initialization of RAM. Software must perform the initialization of RAM.

KEY[7:0] bits (Key Code)

When C4h is written in the KEY[7:0] bits, a write to the SRST bit is valid.

The read value from these bits is always 00h.

7.9.2.2.80 Global Flexible CAN Mode Configuration Register (CFDGFCMC)

Flexible CAN mode configured in the CFDGFCMC register and Flexible transmission buffer assignment configured in the CFDGFTBAC register should not be used simultaneously.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1384h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	FLXC2	0h	RW	Flexible CAN mode between Channel 4 and Channel 5 0b: Normal mode 1b: Flexible CAN mode
1	FLXC1	0h	RW	Flexible CAN mode between Channel 2 and Channel 3 0b: Normal mode 1b: Flexible CAN mode
0	FLXC0	0h	RW	Flexible CAN mode between Channel 0 and Channel 1 0b: Normal mode 1b: Flexible CAN mode

FLXC0 bit (Flexible CAN Mode between Channel 0 and Channel 1)

When the FLXC0 bit is set, Channel 0 and Channel 1 of a CAN-FD module are in Flexible CAN mode.

Channel 1 uses TX/RX terminal of Channel 0. The TX/RX terminal of Channel 1 cannot be used.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

FLXC1 bit (Flexible CAN Mode between Channel 2 and Channel 3)

When the FLXC1 bit is set, Channel 2 and Channel 3 of a CAN-FD module are in Flexible CAN mode.

Channel 3 uses TX/RX terminal of Channel 2. The TX/RX terminal of Channel 3 cannot be used.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

FLXC2 bit (Flexible CAN Mode between Channel 4 and Channel 5)

When the FLXC2 bit is set, Channel 4 and Channel 5 of a CAN-FD module are in Flexible CAN mode.

Channel 5 uses TX/RX terminal of Channel 4. The TX/RX terminal of Channel 5 cannot be used.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

7.9.2.2.81 Global Flexible Transmission Buffer Assignment Configuration Register (CFDGFTBAC)

Flexible transmission buffer assignment configured in the CFDGFTBAC register and Flexible CAN mode configured in the CFDGFCMC register should not be used simultaneously.

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 138Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	FLXMB3[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
19 to 16	FLXMB3[3:0]	0h	RW	Flexible transmission buffer assignment between Channel 4 and Channel 5 By setting these bits the even channel can use the configured number of TX mailboxes of the odd channel 0000b: 0 0001b: 4 0010b: 8 0011b: 12 0100b: 16 0101b: 20 0110b: 24 0111b: 28 1000b: 32
15 to 12	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
11 to 8	FLXMB1[3:0]	0h	RW	Flexible transmission buffer assignment between Channel 2 and Channel 3 By setting these bits the even channel can use the configured number of TX mailboxes of the odd channel 0000b: 0 0001b: 4 0010b: 8 0011b: 12 0100b: 16 0101b: 20 0110b: 24 0111b: 28 1000b: 32
7 to 4	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
3 to 0	FLXMB0[3:0]	0h	RW	Flexible transmission buffer assignment between Channel 0 and Channel 1 By setting these bits the even channel can use the configured number of TX mailboxes of the odd channel 0000b: 0 0001b: 4 0010b: 8 0011b: 12 0100b: 16 0101b: 20 0110b: 24 0111b: 28 1000b: 32

FLXMB0[3:0] bits (Flexible Transmission Buffer Assignment between Channel 0 and Channel 1)

Channel 0 can use the number TXMB of channel 1 from 0 to 32 by the configuration of these bits.

Only write to this bit when the CAN-FD module is in GL_RESET mode.

7.9.2.2.82 Global Test Configuration Register (CFDGTSTCFG)

The CFDGTSTCFG register is used to configure the CAN channels joining the internal CAN bus communication test mode and the RAM test mode page.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1308h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
25 to 16	RTMPS[9:0]	0h	RW	RAM Test Mode Page Select Select a RAM test mode page
15 to 6	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5 to 0	CnICBCE	0h	RW	Channel n Internal CAN Bus Communication Test Mode Enable (n = 0 to 5) 0b: Channel n internal CAN bus communication disabled 1b: Channel n internal CAN bus communication enabled

CnICBCE (n = 0 to 5) bits (Channel n Internal CAN Bus Communication Test Mode Enable)

When the CnICBCE bits are set and CAN-FD module is configured in the internal CAN bus communication test mode, then CAN channel n joins the internal CAN bus communication test mode operation.

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

Only write to these bits when the CAN-FD module is in GL_HALT mode.

These bits are cleared automatically when the CAN-FD module is in GL_RESET mode.

RTMPS[9:0] bits (RAM Test Mode Page Select)

The RTMPS[9:0] bits select the RAM page mode for CPU read/write access when the CAN-FD module is configured in RAM test mode.

See **7.9.9.2.1 RAM Test Mode** for the RAM test mode specification.

Do not write to these bits when the CAN-FD module is in GL_RESET or GL_SLEEP mode.

Only enter values from 0 to 0 to 47 (02Fh) for the AFL RAM and 48 to 228 (0E4h) for the message buffer RAM.

The setting range of these bits depends on the combination of parameters.

Only write to these bits when the CAN-FD module is in GL_HALT mode.

These bits are cleared automatically when the related CAN-FD channel is in GL_RESET mode.

7.9.2.2.83 Global Test Control Register (CFDGTSTCTR)

The CFDGTSTCTR register is used to control the global test modes of the CAN-FD module.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 130Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	RTME	0h	RW	RAM Test Mode Enable 0b: RAM test mode disabled 1b: RAM test mode enabled
1	-	0h	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	ICBCTME	0h	RW	Internal CAN Bus Communication Test Mode Enable 0b: Internal CAN Bus Communication test mode disabled 1b: Internal CAN Bus Communication test mode enabled

ICBCTME bit (Internal CAN Bus Communication Test Mode Enable)

When the ICBCTME bit is set, internal CAN bus communication is enabled for the CAN channels that are configured for internal CAN bus communication participation. See **7.9.9.2.2 Internal CAN Bus Communication Mode** for the specification of internal CAN bus communication test mode.

Only write to this bit when the CAN-FD module is in GL_HALT mode.

Clear this bit when the CAN-FD module is in GL_HALT mode.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

RTME bit (RAM Test Mode Enable)

When the RTME bit is set, the CAN-FD module is configured in RAM test mode. See **7.9.9.2.1 RAM Test Mode** for RAM test mode specification.

Only write to this bit when the CAN-FD module is in GL_HALT mode.

Clear this bit when the CAN-FD module is in GL_HALT mode.

This bit is cleared automatically when the CAN-FD module is in GL_RESET mode.

7.9.2.2.84 Global FD Configuration Register (CFDGFDCFG)

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1314h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	TSCCFG[1:0]		-	-	-	-	-	-	-	RPED
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9, 8	TSCCFG[1:0]	0h	RW	Timestamp Capture Configuration 00b: Timestamp capture at the sample point of SOF (start of frame) 01b: Timestamp capture at frame valid indication 10b: Timestamp capture at the sample point of RES bit 11b: Reserved
7 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	RPED	0h	RW	RES Bit Protocol Exception Disable 0b: Protocol exception event detection enabled 1b: Protocol exception event detection disabled

RPED bit (RES Bit Protocol Exception Disable)

The RPED bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is enabled, the protocol exception event detection is disabled, and the protocol controller transmits an error frame when the protocol exception event is detected (RES bit is sampled recessive).

Only write to this bit when the CAN-FD module is in GL_RESET mode.

TSCCFG[1:0] bits (Timestamp Capture Configuration)

The TSCCFG[1:0] bits configure the different capture points of the timestamp for transmission and reception.

When CFDGFDCFG.TSCCFG[1:0] = 10b, the timestamp capture is performed for CAN-FD frames at RES bit and for Classical frames at the start of frame.

Only write to these bits when the CAN-FD module is in GL_RESET mode.

7.9.2.2.85 Global Lock Key Register (CFDGLOCKK)

The CFDGLOCKK register is a write-only register that is used to unlock the protection for special test bits. See **7.9.9.2 Global Test Modes** for Lock key specification.

Access Size : 16, 32 bits
Address : <CFD_base> + 131Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	W	Reserved The written value should always be 0b.
15 to 0	LOCK[15:0]	0h	W	Lock Key Key bits for unlocking the protection of test modes

LOCK[15:0] bits (Lock Key)

The unlock key sequence must be written in the LOCK[15:0] bits to configure the CAN-FD module in RAM test modes.

The read value from these bits is always 0000h.

You cannot write to these bits when the CAN-FD module is in GL_SLEEP or GL_RESET mode.

Do not write to these bits when the CAN-FD module is in GL_OPERATION mode.

7.9.2.2.86 RAM Test Page Access Register n (CFDRPGACCn) (n = 0 to 63)

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 8400h + n x 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDTA[31:0]	0h	RW	RAM Data Test Access RAM data bytes

RDTA[31:0] bits (RAM Data Test Access)

Data can be read from or written into the RDTA[31:0] bits when the CAN-FD module is configured in RAM test mode.

Only write to this bit when the CAN-FD module is in GL_HALT mode and RAM test mode is enabled.

If data is read when RAM test mode is not enabled, then it is always read as 0000_0000h.

Software data should be read/written in the RAM Test Page Access registers during RAM test mode.

7.9.2.2.87 Channel n Bus Load Control Register (CFDCnBLCT) (n = 0 to 5)

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 1418h + n x 0020h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	W	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
8	BLCLD	0h	W	Bus Load Counter Load When CFDCnBLCT.BLCLD is set, it is reset after a bus load counter value is loaded.
7 to 1	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	BLCE	0h	RW	Bus Load Counter Enable 0b: Bus load counter disabled 1b: Bus load counter enabled

BLCE bit (Bus Load Counter Enable)

The BLCE bit indicates the enabling signal of a bus load counter. Write to this bit after setting up the CFDCnNCFG register.

When this bit is 0b, the bus load counter stops but the counter is not clear.

The bit is cleared when the related CAN-FD channel is in CH_RESET mode.

Do not write to this bit in CH_SLEEP mode.

BLCLD bit (Bus Load Counter Load)

When the BLCLD bit is set, the bus load counter value is loaded into CFDCnBLSTS.BLC and the bus load counter is reset.

The read value is always 0b.

7.9.2.2.88 Channel n Bus Load Status Register (CFDCnBLSTS) (n = 0 to 5)

Access Size : 8, 16, 32 bits

Address : <CFD_base> + 141Ch + n x 0020h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BLC[28:13]

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	BLC[28:0]	0h	R	Bus Load Counter Status These bits indicate the bus load counter value.
2 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read.

BLC[28:0] bits (Bus Load Counter Status)

When the CFDCnBLCT.BLCLD bit is set, the bus load counter value is loaded to BLC[28:0] bits and the bus load counter is reset.

These bits are set only by the CAN-FD module. Writing any value has no effect.

7.9.2.2.89 Identifier Bits Alignment

Standard Identifier (11 bits) format: ID28 – ID18 is aligned to b10 to b0, b11 to b28 should be 0b.

Extended Identifier (29 bits) format: ID28 – ID0 is aligned to b28 – b0

Table 7.9-12 Standard Identifier (11-Bit Format)

b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

7.9.2.3 Message Buffer Component Structure

7.9.2.3.1 Start Addresses

The start address for each of the Message Buffer component is calculated using the number of related Message Buffer components and the number of channels.

- number_of_channels: 6
- number_of_RMBCPs_per_channel: 16
- number_of_RFMBCPs: 8
- number_of_CFMBCPs_per_channel: 3
- number_of_TMBCPs_per_channel: 64

The start addresses for each register in the Message Buffer component are depicted in **Table 7.9-14**.

Table 7.9-14 Message Buffer Component Register Start Addresses

b = Message Buffer Component Index	MBCP	Register	p	Start Address (n = 0 to 5)
0 to number_of_RMBCPs_per_channel - 1	RMBCPb[i]	RMID	x	2000h + b × 0080h + n × 800h
		RMPTR	x	2004h + b × 0080h + n × 800h
		RMFDSTS	x	2008h + b × 0080h + n × 800h
		RMDFp	0 to 15	200Ch + p × 0004h + b × 0080h + n × 800h
0 to number_of_RFMBCPs - 1	RFMBCPb[i]	RFID	x	6000h + b × 0080h
		RFPTR	x	6004h + b × 0080h
		RFFDSTS	x	6008h + b × 0080h
		RFDFp	0 to 15	600Ch + p × 0004h + b × 0080h
0 to number_of_CFMBCPs_per_channel - 1	CFMBCPb[i]	CFID	x	6400h + b × 0080h + n × 180h
		CFPTR	x	6404h + b × 0080h + n × 180h
		CFFDCSTS	x	6408h + b × 0080h + n × 180h
		CFDFp	0 to 15	640Ch + p × 0004h + b × 0080h + n × 180h
0 to number_of_TMBCPs_per_channel - 1	TMBCPb[i]	TMID	x	10000h + b × 0080h + n × 2000h
		TMPTR	x	10004h + b × 0080h + n × 2000h
		TMFDCTR	x	10008h + b × 0080h + n × 2000h
		TMDFp	0 to 15	1000Ch + p × 0004h + b × 0080h + n × 2000h

The message buffer configuration consists of four types of Message Buffer components:

- RX Message Buffer Component (CFDRMBCPb[i])
- RX FIFO Access Message Buffer Component (CFDRFMBCPb[i])
- Common FIFO Access Message Buffer Component (CFDCFMBCPb[i])
- TX Message Buffer Component (CFDTMBCPb[i]).

Where b = the Message Buffer component index having a range that varies based on the type of Message Buffer component and i = channel index that has a range from 0 to n.

For a summary of this configuration, see **Figure 7.9-28**. For a detailed description of the number of and the different types of message buffers, see **7.9.6 FIFO Buffers and Normal Message Buffer Configuration**.

As described in **7.9.2 CANFD Registers**, each Message Buffer component consists of the following registers:

- Identifier (ID)
- Pointer (PTR)
- Data Field (DFp).

p is the Data Field register index having a range that varies based on the type of Message Buffer component.

Rc is the Message Buffer Component register where c = Message Buffer Component register index having a range that varies based on the type of Message Buffer component.

A description of the registers, their associated bits and their accessibility are shown below the summary and detailed figures of each component.

In each of the figures, a cell that contains '-' means reserved and has the same behavior as reserved bits for registers in **7.9.2.3 Message Buffer Component Structure**.

(1) RX Message Buffer ID Register n (CFDRMIDn) (n = 0 to 95)

The CFDRMIDn register (n = 0 to 95) stores the ID field, IDE bit, and RTR bit of the received message.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 2000h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMIDE	RMRTR	-	RMID[28:16]												
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RMID[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	RMIDE	0h	R	RX Message Buffer IDE Bit 0b: STD-ID is stored 1b: EXT-ID is stored
30	RMRTR	0h	R	RX Message Buffer RTR Bit 0b: Data frame 1b: Remote frame
29	-	0h	R	Reserved Whenever it is read, 0b is read.
28 to 0	RMID[28:0]	0h	R	RX Message Buffer ID Field STD-ID/EXT-ID fields

RMID[28:0] bits (RX Message Buffer ID Field)

The RMID[28:0] are the bits of the STD-ID/EXT-ID fields of the message stored in the RX message buffer.

For alignment of these bits in standard and extended frame format, see **7.9.2.2.89 Identifier Bits Alignment**.

See **7.9.2.3.1 Start Addresses** for details on how to interpret the structure of this buffer component.

RMRTR bit (RX Message Buffer RTR Bit)

The RMRTR bit shows whether a data frame or a remote frame was stored in the RX message buffer.

Note: There are no remote frames in CAN-FD format. When a CAN-FD frame is received, the register reflects the state of the received value (the RRS bit in FD frame format).

RMIDE bit (RX Message Buffer IDE Bit)

The RMIDE bit shows whether message with Standard Identifier or Extended Identifier was stored in the RX message buffer.

(2) RX Message Buffer Pointer Register (CFDRMPTRn) (n = 0 to 95)

The CFDRMPTRn register (n = 0 to 95) stores the DLC and Timestamp fields for the received message.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 2004h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMDLC[3:0]				-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RMTS[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	RMDLC[3:0]	0h	RW	RX Message Buffer DLC Field Number of data bytes received in a CAN frame.
27 to 16	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
15 to 0	RMTS[15:0]	0h	RW	RX Message Buffer Timestamp Field Timestamp value stored for the message in the RX message buffer

RMTS[15:0] bits (RX Message Buffer Timestamp Field)

The RMTS[15:0] bits store the timestamp value taken at the capture point as configured by CFDGFDCFG.TSCCFG of the received message.

RMDLC[3:0] bits (RX Message Buffer DLC Field)

The RMDLC[3:0] bits store the number of data bytes that were received in the RX message buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

Note: The maximum capacity of the buffer belongs to CFDRMNB.RMPLS and this is not available in the classical CAN function.

(3) RX Message Buffer CAN-FD Status Register (CFDRMFDSTSn) (n = 0 to 95)

The CFDRMFDSTSn register (n = 0 to 95) shows the status of the FDF, BRS, and ESI bits, and pointer of the received CAN-FD frame.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 2008h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMPTR[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	RMIFL[1:0]		-	-	-	-	-	RMFDF	RMBRS	RMESI
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	RMPTR[15:0]	0h	RW	RX Message Buffer Pointer Field
15 to 10	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9, 8	RMIFL[1:0]	0h	RW	RX Message Buffer Information Label Field
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	RMFDF*[1]	0h	RW	CAN FD Format bit 0b: No CAN-FD frame received 1b: CAN-FD frame received
1	RMBRS*[1]	0h	RW	Bit Rate Switch bit 0b: CAN-FD frame received with no bit rate switch 1b: CAN-FD frame received with bit rate switch
0	RMESI*[1]	0h	RW	Error State Indicator bit 0b: CAN-FD frame received from error active node 1b: CAN-FD frame received from error passive node

Note 1. This bit is not available in the classical CAN function.

RMESI bit (Error State Indicator bit)

The RMESI bit has the same value as the ESI bit of the received CAN-FD frame.

When the received FDF bit is 0b, this means a CAN2.0 frame is received and 0b is stored to this bit.

Note: This bit is not available in the classical CAN function.

RMBRS bit (Bit Rate Switch bit)

The RMBRS bit has the same value as the BRS bit of the received CAN-FD frame.

When the received FDF bit is 0b, this means a CAN2.0 frame is received and 0b is stored to this bit.

Note: This bit is not available in the classical CAN function.

RMFDF bit (CAN FD Format bit)

The RMFDF bit has the same value as the FDF bit of the received CAN-FD frame.

Note: This bit is not available in the classical CAN function.

RMIFL[1:0] bits (RX Message Buffer Information Label Field)

The RMIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

RMPTR[15:0] bits (RX Message Buffer Pointer Field)

The RMPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

(4) RX Message Buffer Data Field p Register n (CFDRMDFp_n) (p = 0 to 15, n = 0 to 95)

The CFDRMDFp_n register (p = 0 to 15, n = 0 to 95) stores the data bytes (4 × p) to data bytes (4 × p + 3) of the received message.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 200Ch + p x 0004h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RMDB_HH[7:0]								RMDB_HL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RMDB_LH[7:0]								RMDB_LL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	RMDB_HH*[1] [7:0]	0h	RW	RX Message Buffer Data Byte (4 × p + 3)
23 to 16	RMDB_HL[7:0]	0h	RW	RX Message Buffer Data Byte (4 × p + 2)
15 to 8	RMDB_LH[7:0]	0h	RW	RX Message Buffer Data Byte (4 × p + 1)
7 to 0	RMDB_LL[7:0]	0h	RW	RX Message Buffer Data Byte (4 × p)

Note 1. These bits are not available in the classical CAN function.

RMDB_LL[7:0] bits (RX Message Buffer Data Byte (4 × p))

The RMDB_LL[7:0] bits store data bytes (4 × p) of the message in the RX message buffer. Unused data bytes are filled with 00h.

RMDB_LH[7:0] bits (RX Message Buffer Data Byte (4 × p + 1))

The RMDB_LH[7:0] bits store data bytes (4 × p + 1) of the message in the RX message buffer. Unused Data Bytes are filled with 00h.

RMDB_HL[7:0] bits (RX Message Buffer Data Byte (4 × p + 2))

The RMDB_HL[7:0] bits store data bytes (4 × p + 2) of the message in the RX message buffer. Unused data bytes are filled with 00h.

RMDB_HH[7:0] bits (RX Message Buffer Data Byte (4 × p + 3))

The RMDB_HH[7:0] bits store data bytes (4 × p + 3) of the message in the RX message buffer. Unused data bytes are filled with 00h.

These bits are not available in the classical CAN function.

(5) RX FIFO Access ID Register n (CFDRFIDn) (n = 0 to 7)

The CFDRFIDn register (n = 0 to 7) stores the ID field, IDE bit, and RTR bit of the message.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 6000h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFIDE	RFRTR	-	RFID[28:16]

Bit	Bit Name	Initial Value	R/W	Description
31	RFIDE	0h	R	RX FIFO Buffer IDE bit 0b: STD-ID has been received 1b: EXT-ID has been received
30	RFRTR	0h	R	RX FIFO Buffer RTR bit 0b: Data frame 1b: Remote frame
29	-	0h	R	Reserved Whenever it is read, 0b is read.
28 to 0	RFID[28:0]	0h	R	RX FIFO Buffer ID Field STD-ID/EXT-ID fields

RFID[28:0] bits (RX FIFO Buffer ID Field)

The RFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

For alignment of these bits in standard and extended frame format, see **7.9.2.2.89 Identifier Bits Alignment**.

RFRTR bit (RX FIFO Buffer RTR bit)

The RFRTR bit shows whether a data frame or a remote frame was stored in the FIFO buffer.

Note: There are no remote frames in CAN-FD format. When a CAN-FD frame was received, the register reflects the state of the received value (RRS bit in FD frame format).

RFIDE bit (RX FIFO Buffer IDE bit)

The RFIDE bit shows whether message with the Standard Identifier or Extended Identifier was received in the FIFO buffer.

(6) RX FIFO Access Pointer Register n (CFDRFPTRn) (n = 0 to 7)

The CFDRFPTRn register (n = 0 to 7) stores the DLC and Timestamp fields for the received message.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 6004h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFDLC[3:0]				-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFTS[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	RFDLC[3:0]	0h	R	RX FIFO Buffer DLC Field Number of data bytes received in a CAN frame
27 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read.
15 to 0	RFTS[15:0]	0h	R	RX FIFO Timestamp Value Timestamp value of the received CAN frame

RFTS[15:0] bits (RX FIFO Timestamp Value)

The RFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message.

RFDLC[3:0] bits (RX FIFO Buffer DLC Field)

The RFDLC[3:0] bits store the number of data bytes that were received in the RX FIFO buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

(7) RX FIFO Access CAN-FD Status Register n (CFDRFFDSTSn) (n = 0 to 7)

The CFDRFFDSTSn register (n = 0 to 7) shows the status of the FDF, BRS, and ESI bits, including the pointer of the received CAN-FD frame.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 6008h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CFDRFPTR[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	CFDRFPTR [15:0]	0h	R	RX FIFO Buffer Pointer Field
15 to 10	-	All 0	R	Reserved Whenever it is read, 0b is read.
9, 8	RFIFL[1:0]	0h	R	RX FIFO Buffer Information Label Field
7 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read.
2	RFFDF*1	0h	R	CAN FD Format bit 0b: No CAN-FD frame received 1b: CAN-FD frame received
1	RFBRS*1	0h	R	Bit Rate Switch bit 0b: CAN-FD frame received with no bit rate switch 1b: CAN-FD frame received with bit rate switch
0	RFESI*1	0h	R	Error State Indicator bit 0b: CAN-FD frame received from error active node 1b: CAN-FD frame received from error passive node

Note 1. This bit is not available in the classical CAN function.

RFESI bit (Error State Indicator bit)

The RFESI bit has the same value as the ESI bit of the received CAN-FD frame.

When the received FDF bit is 0b, this means a CAN2.0 frame is received and 0b is stored to this bit.

Note: This bit is not available in the classical CAN function.

RFBRS bit (Bit Rate Switch bit)

The RFBRS bit has the same value as the BRS bit of the received CAN-FD frame.

When the received FDF bit is 0b, this means a CAN2.0 frame is received and 0b is stored to this bit.

Note: This bit is not available in the classical CAN function.

RFFDF bit (CAN FD Format bit)

The RFFDF bit has the same value as the FDF bit of the received CAN-FD frame.

Note: This bit is not available in the classical CAN function.

RFIFL[1:0] bits (RX FIFO Buffer Information Label Field)

The RFIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

CFDRFPTR[15:0] bits (RX FIFO Buffer Pointer Field)

The CFDRFPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

(8) RX FIFO Access Data Field p Register n (CFDRFDFpn) (p = 0 to 15, n = 0 to 7)

The CFDRFDFpn register (p = 0 to 15, n = 0 to 7) stores data bytes (4 × p) to data bytes (4 × p + 3) of the received message.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 600Ch + p x 0004h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFDB_HH[7:0]								RFDB_HL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFDB_LH[7:0]								RFDB_LL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	RFDB_HH[7:0]	0h	R	RX FIFO Buffer Data Byte (4 × p + 3)
23 to 16	RFDB_HL[7:0]	0h	R	RX FIFO Buffer Data Byte (4 × p + 2)
15 to 8	RFDB_LH[7:0]	0h	R	RX FIFO Buffer Data Byte (4 × p + 1)
7 to 0	RFDB_LL[7:0]	0h	R	RX FIFO Buffer Data Byte (4 × p)

RFDB_LL[7:0] bits (RX FIFO Buffer Data Byte (4 × p))

The RFDB_LL[7:0] bits store data bytes (4 × p) of the message present in the FIFO buffer. Unused data bytes are filled with 00h according to the configured data payload size CFDRFCCn.RFPLS.

RFDB_LH[7:0] bits (RX FIFO Buffer Data Byte (4 × p + 1))

The RFDB_LH[7:0] bits store data bytes (4 × p + 1) of the message present in the FIFO buffer. Unused data bytes are filled with 00h.

RFDB_HL[7:0] bits (RX FIFO Buffer Data Byte (4 × p + 2))

The RFDB_HL[7:0] bits store data bytes (4 × p + 2) of the message present in the FIFO buffer. Unused data bytes are filled with 00h.

RFDB_HH[7:0] bits (RX FIFO Buffer Data Byte (4 × p + 3))

The RFDB_HH[7:0] bits store data bytes (4 × p + 3) of the message present in the FIFO buffer. Unused data bytes are filled with 00h.

(9) Common FIFO Access ID Register n (CFDCFIDn) (n = 0 to 17)

The CFDCFIDn register (n = 0 to 17) stores the ID field, IDE bit, and RTR bit of the message.

Remark In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 6400h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31	CFIDE	0h	RW	Common FIFO Buffer IDE bit 0b: STD-ID is to be transmitted or has been received 1b: EXT-ID is to be transmitted or has been received
30	CFRTR	0h	RW	Common FIFO Buffer RTR bit 0b: Data frame 1b: Remote frame
29	THLEN	0h	RW	THL Entry Enable TX FIFO mode: 0b: Entry is not to be stored in THL after successful TX 1b: Entry is to be stored in THL after successful TX RX FIFO mode: Reserved, This bit is read as 0b.
28 to 0	CFID[28:0]	0h	RW	Common FIFO Buffer ID Field STD-ID/EXT-ID fields

CFID[28:0] bits (Common FIFO Buffer ID Field)

The CFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

For alignment of these bits in standard and extended frame format, see **7.9.2.2.89 Identifier Bits Alignment**.

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

THLEN bit (THL Entry Enable)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFRTR bit (Common FIFO Buffer RTR bit)

The CFRTR bit selects whether a data frame or a remote frame is to be transmitted from or was received in the FIFO buffer.

Note: There are no remote frames in CAN FD format. When a CAN-FD frame is received (RX mode), the register reflects the state of the received value (RRS bit in FD frame format). When CAN-FD transmission (TX or GW mode CFDCFID.CFFDF = 1b), the bit is always transmitted dominant (data frame).

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFIDE bit (Common FIFO Buffer IDE bit)

The CFIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from or was received in the FIFO buffer.

In TX mode, you can write and read data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

(10) Common FIFO Access Pointer Register n (CFDCFPTRn) (n = 0 to 17)

The CFDCFPTRn register (n = 0 to 17) stores the DLC and Timestamp fields.

Remark In TX mode, you can read data from the FIFO buffer, only for the current entry based on the write pointer value, and not for the other entries.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 6404h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	CFDLC[3:0]	0h	RW	Common FIFO Buffer DLC Field Number of data bytes received in a CAN frame, or transmitted in a CAN frame.
27 to 16	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
15 to 0	CFTS[15:0]	0h	RW	Common FIFO Timestamp Value Timestamp value of the received CAN frame (FIFO in RX mode).

CFTS[15:0] bits (Common FIFO Timestamp Value)

The CFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message (if FIFO is configured in RX mode).

In TX mode, you can read and write data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFDLC[3:0] bits (Common FIFO Buffer DLC Field)

The CFDLC[3:0] bits store the number of data bytes that were received in the FIFO buffer or are to be transmitted.

See *Table 5* in *ISO 11898-1 (2015) Specification* for details in defining the number of data bytes.

In TX mode, you can read and write data from the FIFO buffers. Do not read data for the other entries in the FIFO when configured in TX mode.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

(11) Common FIFO Access CAN-FD Control/Status Register n (CFDCFFDCSTSn) (n = 0 to 17)

The CFDCFFDCSTSn register (n = 0 to 17) shows the status of the FDF, BRS, and ESI bits, including the pointer of the received CAN-FD frame or the CAN-FD frame to transmit.

Remark In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 6408h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	CFPTR[15:0]	0h	RW	Common FIFO Buffer Pointer Field
15 to 10	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9, 8	CFIFL[1:0]	0h	RW	COMMON FIFO Buffer Information Label Field
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	CFFDF*[1]	0h	RW	CAN FD Format bit 0b: No CAN-FD frame received or to transmit 1b: CAN-FD frame received or to transmit
1	CFBRS*[1]	0h	RW	Bit Rate Switch bit 0b: CAN-FD frame received or to transmit with no bit rate switch 1b: CAN-FD frame received or to transmit with bit rate switch
0	CFESI*[1]	0h	RW	Error State Indicator bit 0b: CAN-FD frame received or to transmit by error active node 1b: CAN-FD frame received or to transmit by error passive node

Note 1. This bit is not available in the classical CAN function.

CFESI bit (Error State Indicator bit)

In TX mode, you can read and write data from FIFO buffers. In this mode, when the CAN-FD module is not in error passive, the CFESI bit equals the write value. Otherwise, it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, the CFESI bit is updated with the ESI bit value of the CAN-FD frame when it has been received, indicating the error state of the transmitting node. In RX or GW mode, 0b is stored to this bit when the received FDF bit is 0b, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFBRS bit (Bit Rate Switch bit)

In TX mode, you can read and write data from FIFO buffers. In this mode, the CAN-FD module either transmits a 0b to indicate no bit rate switch in the frame to be transmitted or a 1 to indicate a bit rate switch in the frame to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, the CFBRS bit is updated with the BRS bit value of the CAN-FD frame when it has been received, indicating whether there is a bit rate switch (1) or (0) on the CAN-FD frame.

In RX or GW mode, 0b is stored to the CFBRS bit when the received FDF bit is 0b, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFFDF bit (CAN FD Format bit)

In TX mode, you can read and write data from FIFO buffers. In this mode, the CAN-FD module either transmits a 0b to indicate a CAN 2.0 frame is to be transmitted or a 1 to indicate a CAN-FD frame is to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, the CFFDF bit is updated with the FDF bit value of the CAN frame when it has been received, indicating whether it is a CAN 2.0 frame (0) or a CAN-FD frame (1).

This bit is not available in the classical CAN function.

CFIFL[1:0] bits (COMMON FIFO Buffer Information Label Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTSn.CFIFL[1:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The information label value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX or GW mode).

In TX mode, you can read and write data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

CFPTR[15:0] bits (Common FIFO Buffer Pointer Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTSn.CFPTR[15:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The pointer value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX or GW mode).

In TX mode, you can read and write data from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

(12) Common FIFO Access Data Field p Register n (CFDCFDFpn) (p = 0 to 15, n = 0 to 17)

The CFDCFDFpn register (p = 0 to 15, n = 0 to 17) stores data bytes (4 × p) to data bytes (4 × p + 3) of the message.

Remark In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 640Ch + p x 0004h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	CFDB_LH[7:0]								CFDB_LL[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	CFDB_HH[7:0]	0h	RW	Common FIFO Buffer Data Byte (4 × p + 3)
23 to 16	CFDB_HL[7:0]	0h	RW	Common FIFO Buffer Data Byte (4 × p + 2)
15 to 8	CFDB_LH[7:0]	0h	RW	Common FIFO Buffer Data Byte (4 × p + 1)
7 to 0	CFDB_LL[7:0]	0h	RW	Common FIFO Buffer Data Byte (4 × p)

CFDB_LL[7:0] bits (Common FIFO Buffer Data Byte (4 × p))

The CFDB_LL[7:0] bits store data bytes (4 × p) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with 00h, according to their configured data payload size CFDCFCCn.CFPLS.*[1]

CFDB_LH[7:0] bits (Common FIFO Buffer Data Byte (4 × p + 1))

The CFDB_LH[7:0] bits store data bytes (4 × p + 1) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with 00h, according to their configured data payload size CFDCFCCn.CFPLS.*[1]

CFDB_HL[7:0] bits (Common FIFO Buffer Data Byte (4 × p + 2))

The CFDB_HL[7:0] bits store data bytes (4 × p + 2) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with 00h, according to their configured data payload size CFDCFCCn.CFPLS.*[1]

CFDB_HH[7:0] bits (Common FIFO Buffer Data Byte (4 × p + 3))

The CFDB_HH[7:0] bits store data bytes (4 × p + 3) of the message present in the FIFO buffer.

In TX mode, you can read and write data from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In GW mode, you cannot write data to the FIFO buffers.

In RX or GW mode, unused data bytes are filled with 00h, according to their configured data payload size CFDCFCCn.CFPLS.*[1]

Note 1. In RX or GW mode, unused data bytes are filled with 00h according to the configured data payload size CFDCFCCn.CFPLS, which is a CAN-FD feature not found in classical CAN.

(13) TX Message Buffer ID Register n (CFDTMIDn) (n = 0 to 383)

The CFDTMIDn register (n = 0 to 383) stores the ID, IDE, RTR fields and history configuration of the message to be transmitted from the associated buffer.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1_0000h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	TMIDE	0h	RW	TX Message Buffer IDE bit 0b: STD-ID is transmitted 1b: EXT-ID is transmitted
30	TMRTR	0h	RW	TX Message Buffer RTR bit 0b: Data frame 1b: Remote frame
29	THLEN	0h	RW	Tx History List Entry 0b: Entry not stored in THL after successful TX 1b: Entry stored in THL after successful TX
28 to 0	TMID[28:0]	0h	RW	TX Message Buffer ID Field STD-ID/EXT-ID fields

TMID[28:0] bits (TX Message Buffer ID Field)

The TMID[28:0] bits are bits of the STD-ID/EXT-ID fields of the message stored in this TX message buffer.

For alignment of these bits in standard and extended frame format, see **7.9.2.2.89 Identifier Bits Alignment**.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

THLEN bit (Tx History List Entry)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMRTR bit (TX Message Buffer RTR bit)

The TMRTR bit selects whether a data frame or remote frame is to be transmitted from this TX message buffer.

Note: There are no remote frames in CAN-FD format. For a CAN-FD transmission (CFDTMFDCTR.CFFDF = 1b), this bit is always transmitted dominant (data frame).

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMIDE bit (TX Message Buffer IDE bit)

The TMIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from this TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

(14) TX Message Buffer Pointer Register n (CFDTMPTRn) (n = 0 to 383)

The CFDTMPTRn register (n = 0 to 383) stores the DLC fields of the message to transmit from the associated buffer.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1_0004h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMDLC[3:0]				-	-	-	-	-	-	-	-	-	-	-	-

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	TMDLC[3:0]	0h	RW	TX Message Buffer DLC Field Number of data bytes to be transmitted in a CAN frame.
27 to 0	-	All 0	RW	Reserved Whenever it is read, undefined value is read. The written value should always be 0b.

TMDLC[3:0] bits (TX Message Buffer DLC Field)

The TMDLC[3:0] bits select the number of data bytes to be transmitted from this TX message buffer when the corresponding TMRTR bit is configured as 0b.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes to be transmitted.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

(15) TX Message Buffer CAN-FD Control Register n (CFDTMFDCTRn) (n = 0 to 383)

The CFDTMFDCTRn register (n = 0 to 383) shows the status of the FDF, BRS, and ESI bits, including the pointer fields of the CAN-FD frame to be transmitted.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1_0008h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	TMPTR[15:0]	0h	RW	TX Message Buffer Pointer Field
15 to 10	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9, 8	TMIFL[1:0]	0h	RW	TX Message Buffer Information Label Field
7 to 3	-	All 0	RW	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	TMFDF*1	0h	RW	CAN FD Format bit 0b: No CAN-FD frame to transmit 1b: CAN-FD frame to transmit
1	TMBRS*1	0h	RW	Bit Rate Switch bit 0b: CAN-FD frame to transmit with no bit rate switch 1b: CAN-FD frame to transmit with bit rate switch
0	TMESI*1	0h	RW	Error State Indicator bit 0b: CAN-FD frame to transmit by error active node 1b: CAN-FD frame to transmit by error passive node

Note 1. This bit is not available in the classical CAN function.

TMESI bit (Error State Indicator bit)

If the channel is not in error passive, then the TMESI bit equals the write value, otherwise it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

Do not write to the TMESI bit when the related CAN-FD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMBRS bit (Bit Rate Switch bit)

Do not write to the TMBRS bit when the related CAN-FD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMFDF bit (CAN FD Format bit)

Do not write to the TMFDF bit when the related CAN-FD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMIFL[1:0] bits (TX Message Buffer Information Label Field)

The TMIFL[1:0] bits store the information label value to be copied, together with additional message information, in the TX History List after successful transmission of the message.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMPTR[15:0] bits (TX Message Buffer Pointer Field)

The TMPTR[15:0] bits store the pointer value to be copied, together with additional message information in the TX History List after successful transmission of the message.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

(16) TX Message Buffer Data Field p Register n (CFDTMDFp_n) (p = 0 to 15, n = 0 to 383)

The CFDTMDFp_n register (p = 0 to 15, n = 0 to 383) stores data bytes (4 × p) to data bytes (4 × p + 3) of the message to transmit from the associated buffer.

Access Size : 8, 16, 32 bits
Address : <CFD_base> + 1_000Ch + p x 0004h + n x 0080h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	TMDB_HH[7:0]	0h	RW	TX Message Buffer Data Byte (4 × p + 3)
23 to 16	TMDB_HL[7:0]	0h	RW	TX Message Buffer Data Byte (4 × p + 2)
15 to 8	TMDB_LH[7:0]	0h	RW	TX Message Buffer Data Byte (4 × p + 1)
7 to 0	TMDB_LL[7:0]	0h	RW	TX Message Buffer Data Byte (4 × p)

TMDB_LL[7:0] bits (TX Message Buffer Data Byte (4 × p))

Data bytes (4 × p)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_LH[7:0] bits (TX Message Buffer Data Byte (4 × p + 1))

Data bytes (4 × p + 1)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_HL[7:0] bits (TX Message Buffer Data Byte (4 × p + 2))

Data bytes (4 × p + 2)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

TMDB_HH[7:0] bits (TX Message Buffer Data Byte (4 × p + 3))

Data bytes (4 × p + 3)[7:0] of the message stored in the TX message buffer.

Do not write to these bits when the related CAN-FD channel is in CH_SLEEP mode.

7.9.3 Operation

7.9.3.1 Overview

The modes of the CAN-FD module can be classified into 2 groups:

- Global modes
- Channel modes

7.9.3.2 Global Modes

Global modes are applicable for the complete CAN-FD module. The global modes of the CAN-FD module are:

- Global Sleep
- Global Reset
- Global Halt
- Global Operation

Figure 7.9-2 shows the possible transitions between the Global modes.

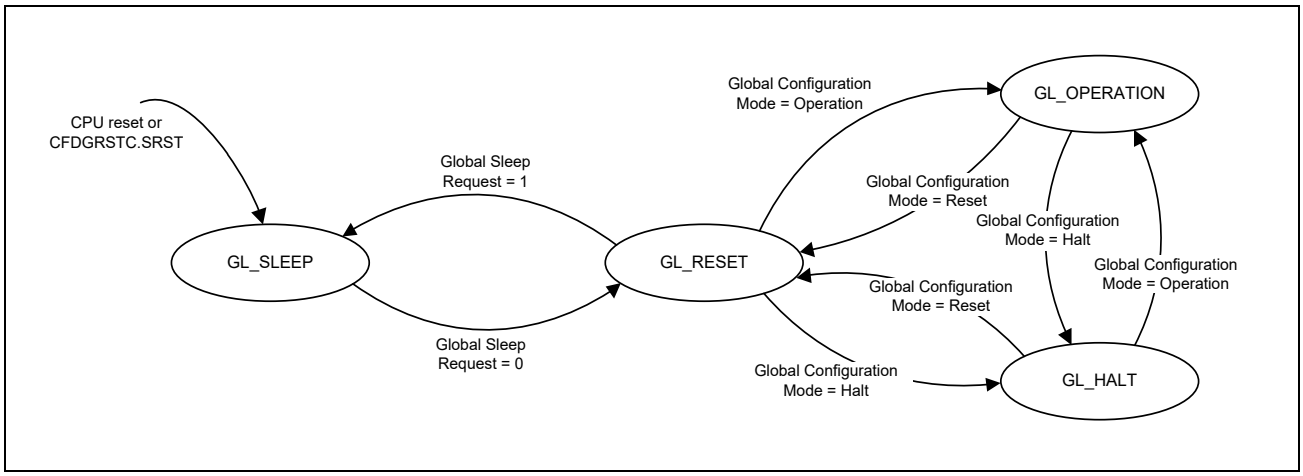

Figure 7.9-2 Transition between CAN-FD Global Modes

Changes in the Global mode can affect the Channel mode. **Table 7.9-15** shows the effect of a Global mode transition on a Channel mode.

Table 7.9-15 Possible CAN-FD Channel Modes and Global Modes

Current Global Mode	Target Global Mode			
	Sleep	Reset	Halt	Operation
Sleep	—	Ch-Sleep: Keep Ch-Reset: N/A Ch-Halt: N/A Ch-Oper: N/A	—	—
Reset	Ch-Sleep: Keep Ch-Reset: → Ch-Sleep Ch-Halt: N/A Ch-Oper: N/A	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A
Halt	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: N/A	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: N/A
Operation	—	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: → Ch-Reset	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: → Ch-Halt	—

7.9.3.2.1 Global Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, the CAN-FD module automatically enters Global Sleep mode.

The CAN-FD module also enters the Global Sleep mode when the Global Sleep Request bit is set while it is in Global Reset mode. This control bit cannot be set in Global Halt mode or Global Operation mode.

Setting the Global Sleep Request bit sets all Channel Sleep Request bits and forces all channels into the Channel Sleep mode. Sleep mode is used for power saving purpose. When CAN-FD module is in Global Sleep mode, only the clock for CPU write access to the Global Sleep Mode Request bit is active. All other clocks are stopped and all other functions of the CAN-FD module are suspended.

Read access from all registers is still possible and all register values are preserved.

In Global Sleep mode, RAM access is prohibited because the logic which generates a RAM address does not operate.

After setting the Global Sleep Request bit, it is necessary to confirm that the Global Sleep status has been updated, indicating successful transition to Global Sleep mode before the Global Sleep Request bit can be cleared again.

Figure 7.9-3 shows the procedure for entering Global Sleep mode and **Figure 7.9-4** shows the procedure for exiting Global Sleep mode.

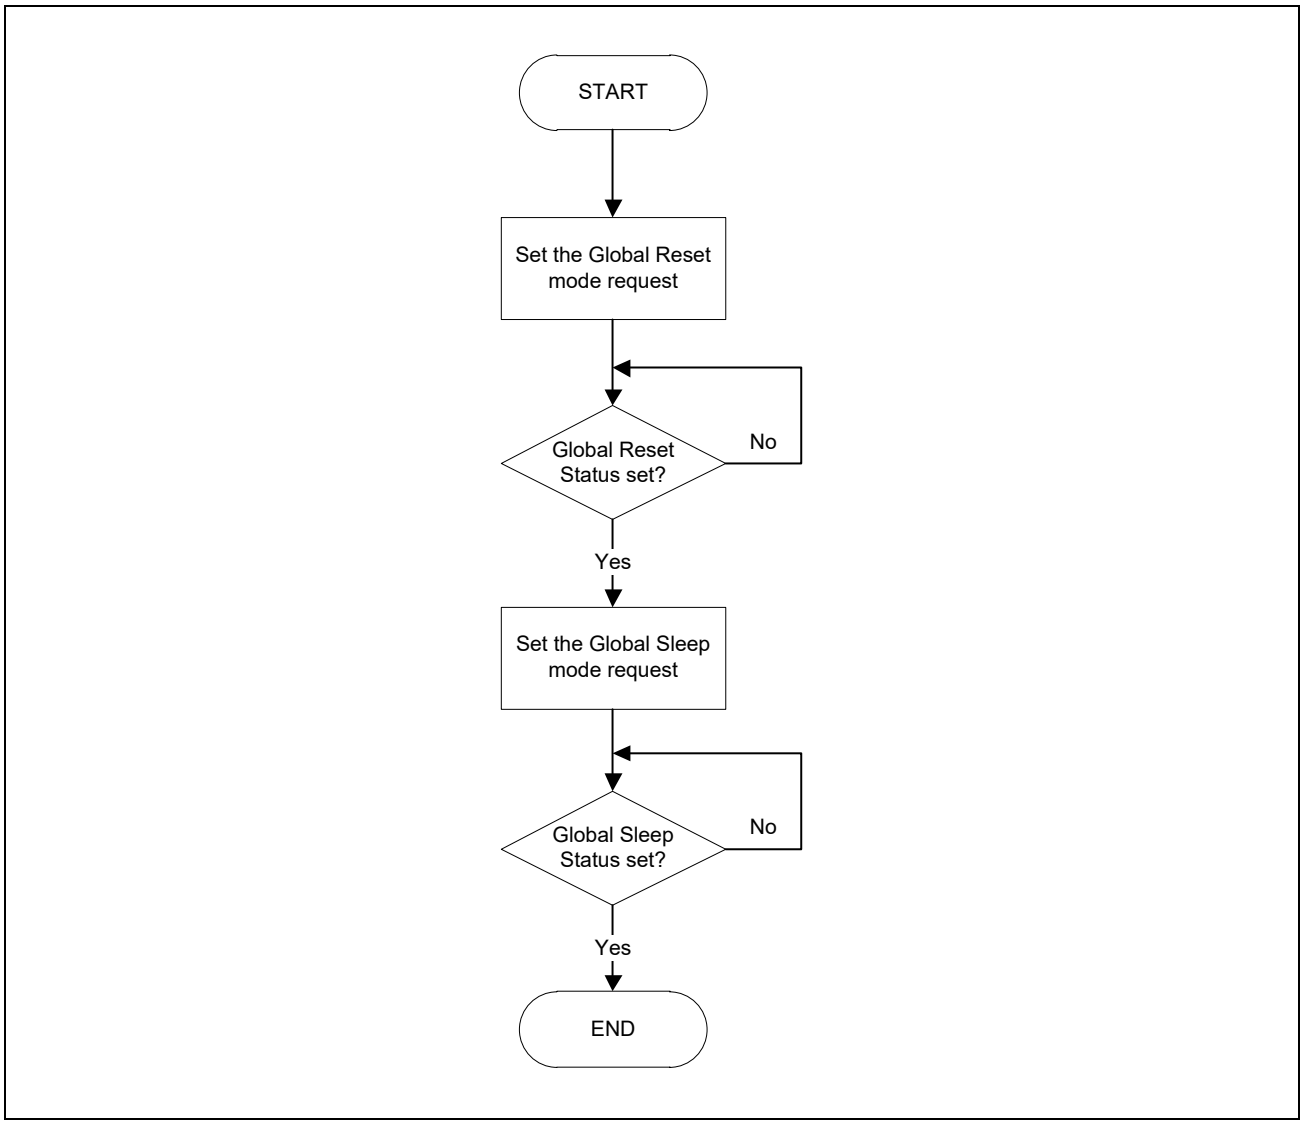

Figure 7.9-3 Procedure for Entering Global Sleep Mode

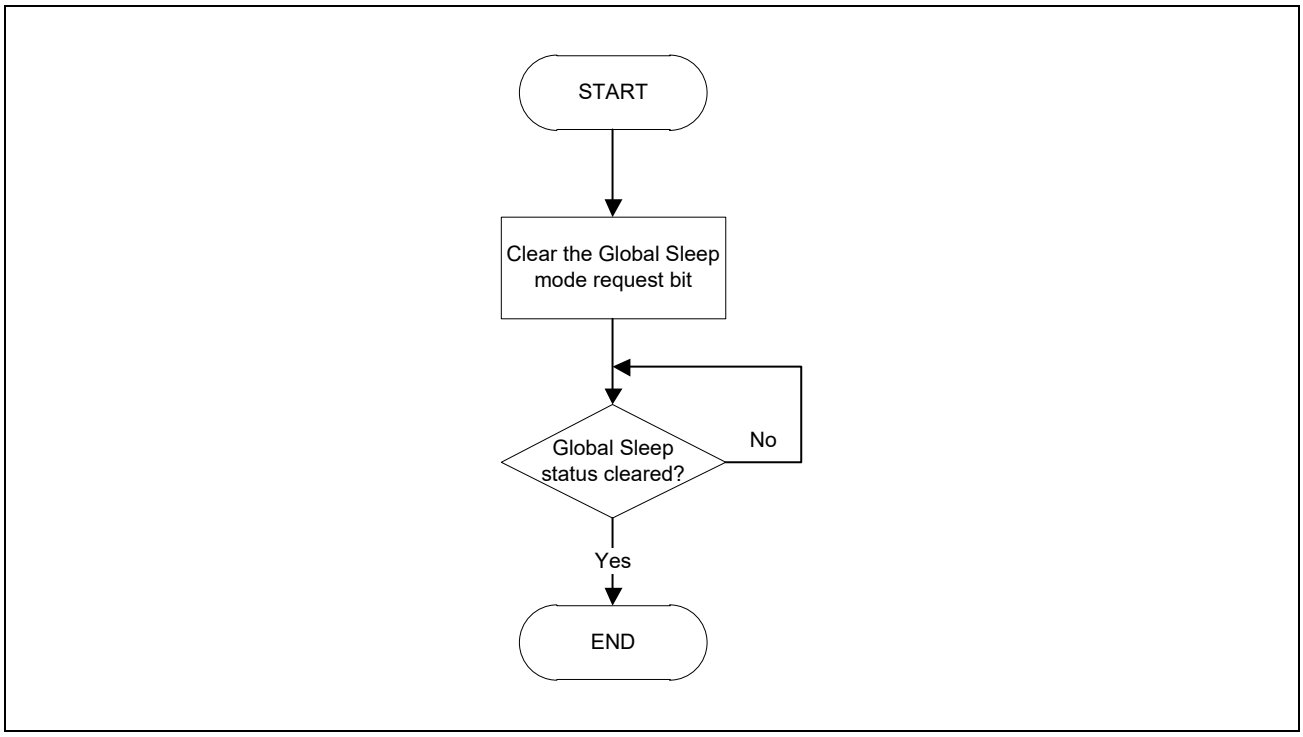

Figure 7.9-4 Procedure for Exiting Global Sleep Mode

7.9.3.2.2 Global Reset Mode

The CAN-FD module enters the Global Reset mode in the following ways:

- Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register is configured for Global Reset mode while the CAN-FD module is in Global Halt or Global Operation mode.
- Global Sleep Mode Request bit is cleared while CAN-FD module is in Global Sleep mode.

In Global Reset mode, all CAN-FD module functions are suspended and all status and flag registers are initialized.

Additionally all FIFOs and all channel TX Queues are disabled and transmission control bits are cleared.

Configuration registers (except the test mode registers) are not initialized in this mode to their device reset values and the CAN-FD module can be configured.

See **7.9.3.4 Global Mode and Channel Mode Transition Interactions** for a detailed description of the behavior of all registers when transition to Global Reset mode.

Setting the Global mode to Reset by setting the Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register to 01b sets all Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers to 01b and forces all channels into the Channel Reset mode.

For channels that are already in Channel Reset mode or Channel Sleep mode, this automatic transition is not performed (CFDCnCTR.CHMDC[1:0] of related channel already set to 01b).

After setting Global Mode Control bits CFDGCTR.GMDC[1:0] to Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDGSTS.GRSTSTS in the Global Status Register has been updated, indicating successful transition to Global Reset mode before CFDGCTR.GMDC can be changed again.

Figure 7.9-5 shows the procedure for entering Global Reset mode and **Figure 7.9-6** shows the procedure for exiting Global Reset mode.

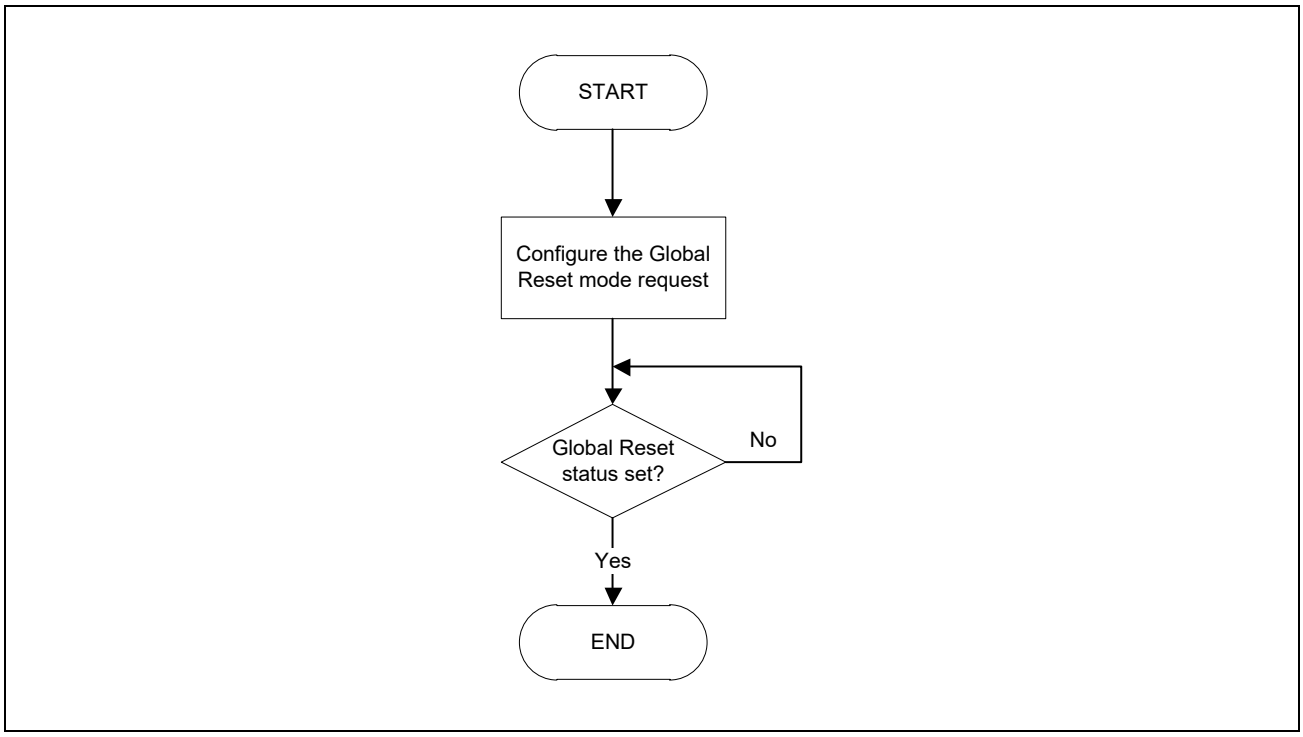

Figure 7.9-5 Procedure for Entering Global Reset Mode

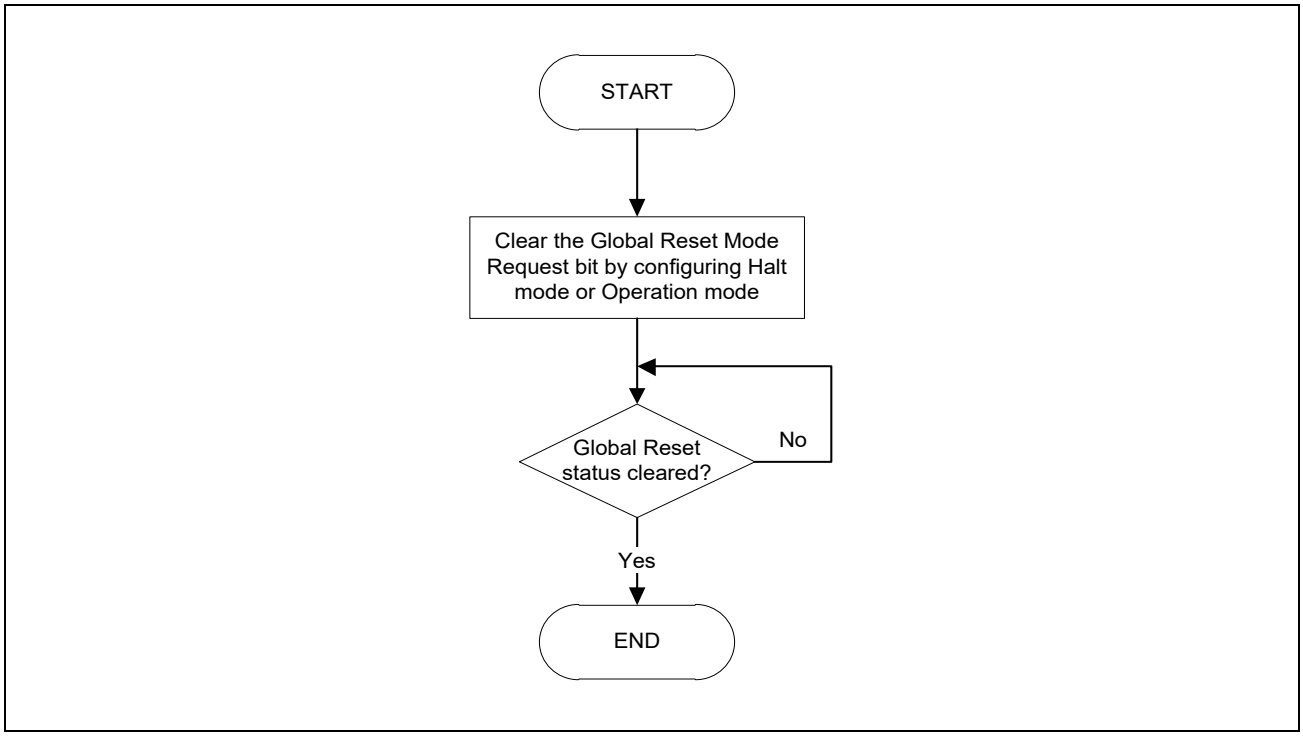

Figure 7.9-6 Procedure for Exiting Global Reset Mode

7.9.3.2.3 Global Halt Mode

The CAN-FD module enters the Global Halt mode in the following ways:

- Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register is configured for Global Halt mode while the CAN-FD module is in Global Reset mode:
  - The channel is in either Channel Reset or Channel Sleep mode and remains in this mode.
- Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register is configured for Global Halt mode while the CAN-FD module is in Global Operation mode:
  - All channels in Channel Reset, Channel Halt, or Channel Sleep mode remain in this mode
  - All channels in Channel Operation mode transit to Channel Halt mode
  - Global Halt Mode Status bit is set when all channels have left Channel Operation mode.

If a transmission or reception is ongoing for a channel, the transition to Channel Halt mode is delayed until completion of the communication.

Similarly, if a channel is in bus-off state, the full bus-off recovery sequence may be delayed depending on the channel configuration.

In Global Halt mode, all communications are suspended and CAN-FD logic does not cause any change to the Status and Flag registers (only when a channel is in the bus-off state that its REC and TEC values are cleared). Additionally, the test mode configuration and control registers are not initialized in this mode.

The Global Halt mode should be used to configure global module test modes.

See **7.9.3.4 Global Mode and Channel Mode Transition Interactions** for a detailed description of the behavior of all registers when transition to Global Halt mode is performed.

Setting the Global mode to Halt mode by setting the Global Mode Control bits CFDGCTR.GMDC[1:0] in the Global Control Register to 10b sets all Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers to 10b for the channels that are in Channel Operation mode and forces these channels into the Channel Halt mode.

For channels that are already in Channel Reset, Channel Halt, or Channel Sleep mode, this automatic transition is not performed.

Therefore, the Global Halt mode request can be used to shut down all CAN-FD channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).

After setting the Global Mode Control bits CFDGCTR.GMDC[1:0] to Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register has been updated to indicate a successful transition to Global Halt mode. Do not specify any other SFR setting until confirming CFDGSTS.GHLTSTS is set.

Figure 7.9-7 shows the procedure for entering Global Halt mode and **Figure 7.9-8** shows the procedure for exiting Global Halt mode.

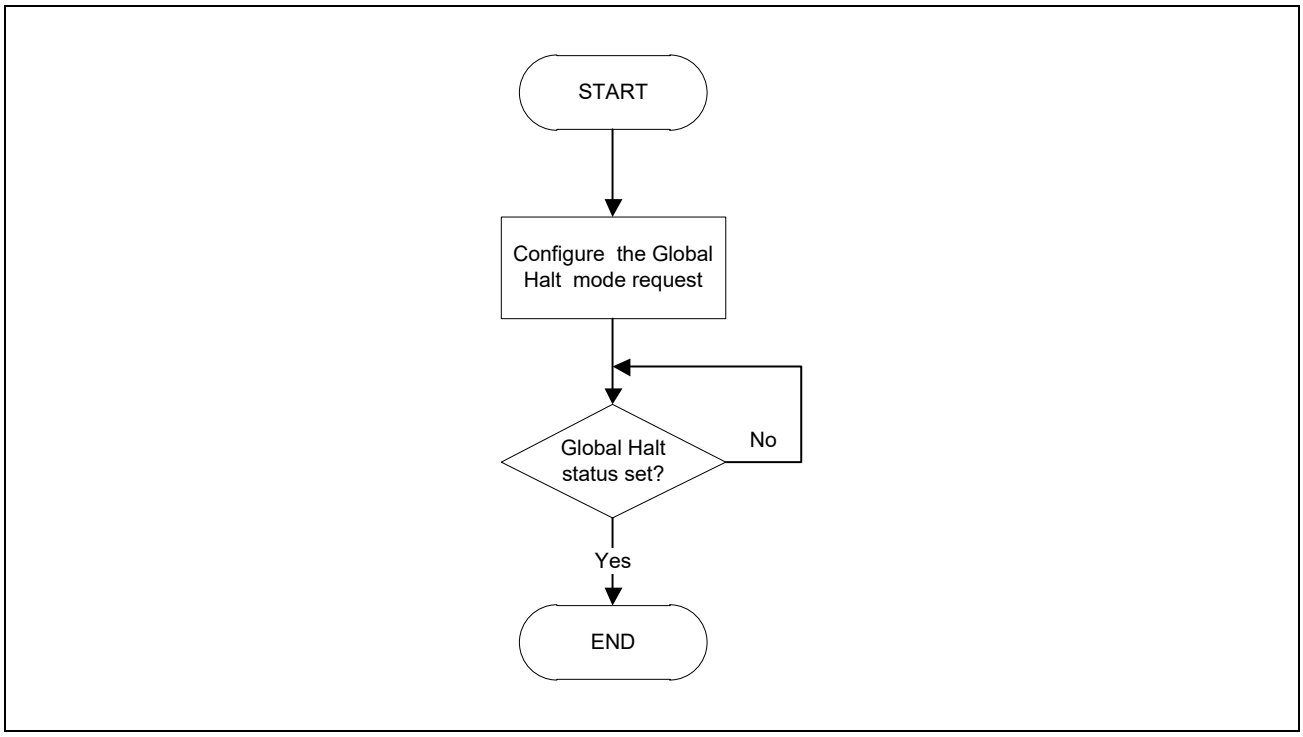

Figure 7.9-7 Procedure for Entering Global Halt Mode

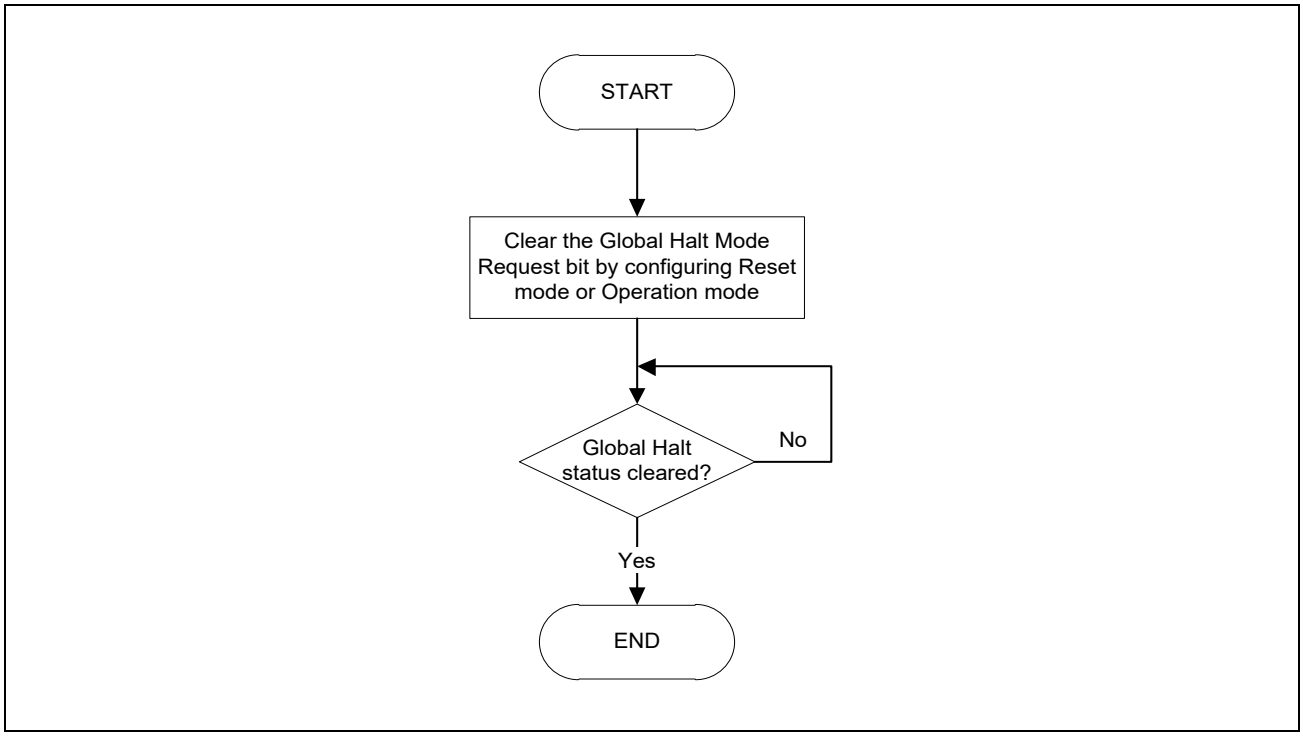

Figure 7.9-8 Procedure for Exiting Global Halt Mode

7.9.3.2.4 Global Operation Mode

The CAN-FD module enters the Global Operation mode when the Global Mode Configuration bits are set to Global Operation mode.

The CAN-FD channels can only be set to Channel Operation mode and start CAN communication when CAN-FD is in Global Operation mode.

After setting the Global Mode Control bits CFDGCTR.GMDC[1:0] to Global Operation mode, it is necessary to confirm that the Global Reset Mode Status bit CFDGSTS.GRSTSTS and the Global Halt Mode Status bit CFDGSTS.GHLTSTS in the Global Status Register have been cleared to indicate a successful transition to Global Operation mode before CFDGCTR.GMDC can be modified again.

Figure 7.9-9 shows the procedure for entering Global Operation mode and **Figure 7.9-10** shows the procedure for exiting Global Operation mode.

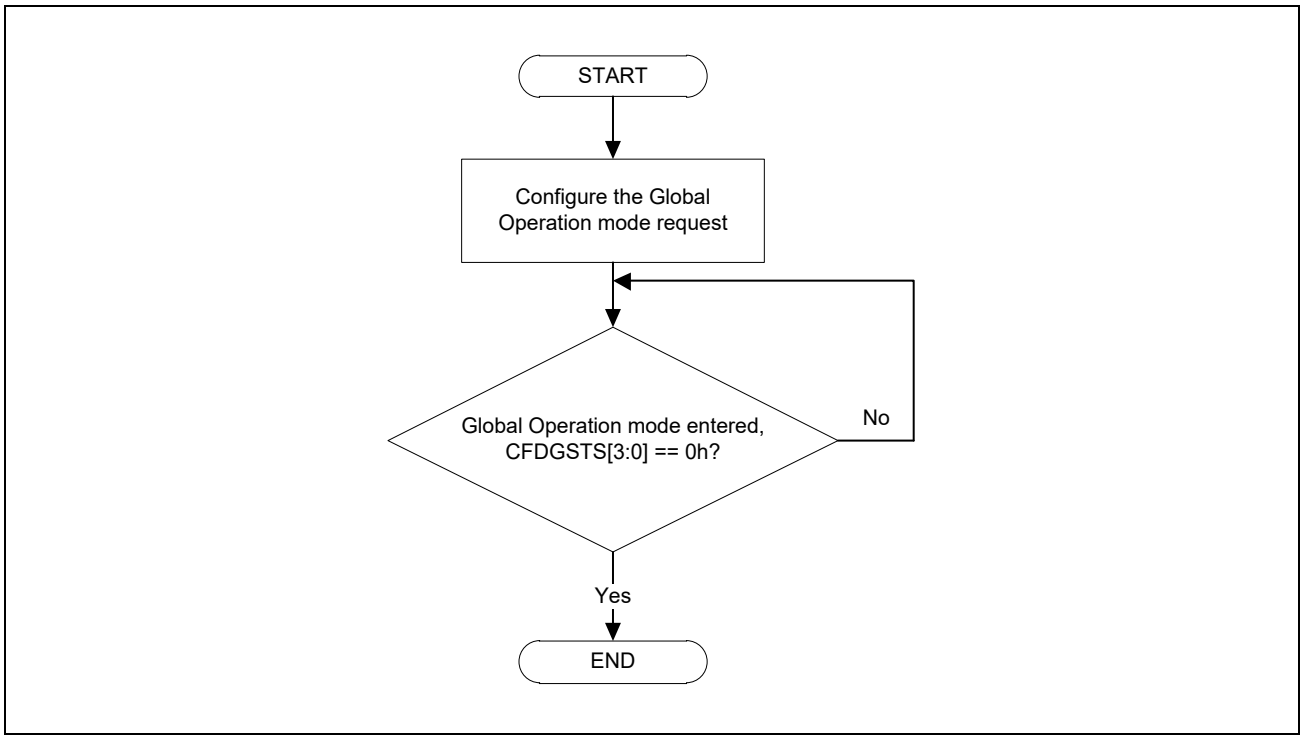

Figure 7.9-9 Procedure for Entering Global Operation Mode

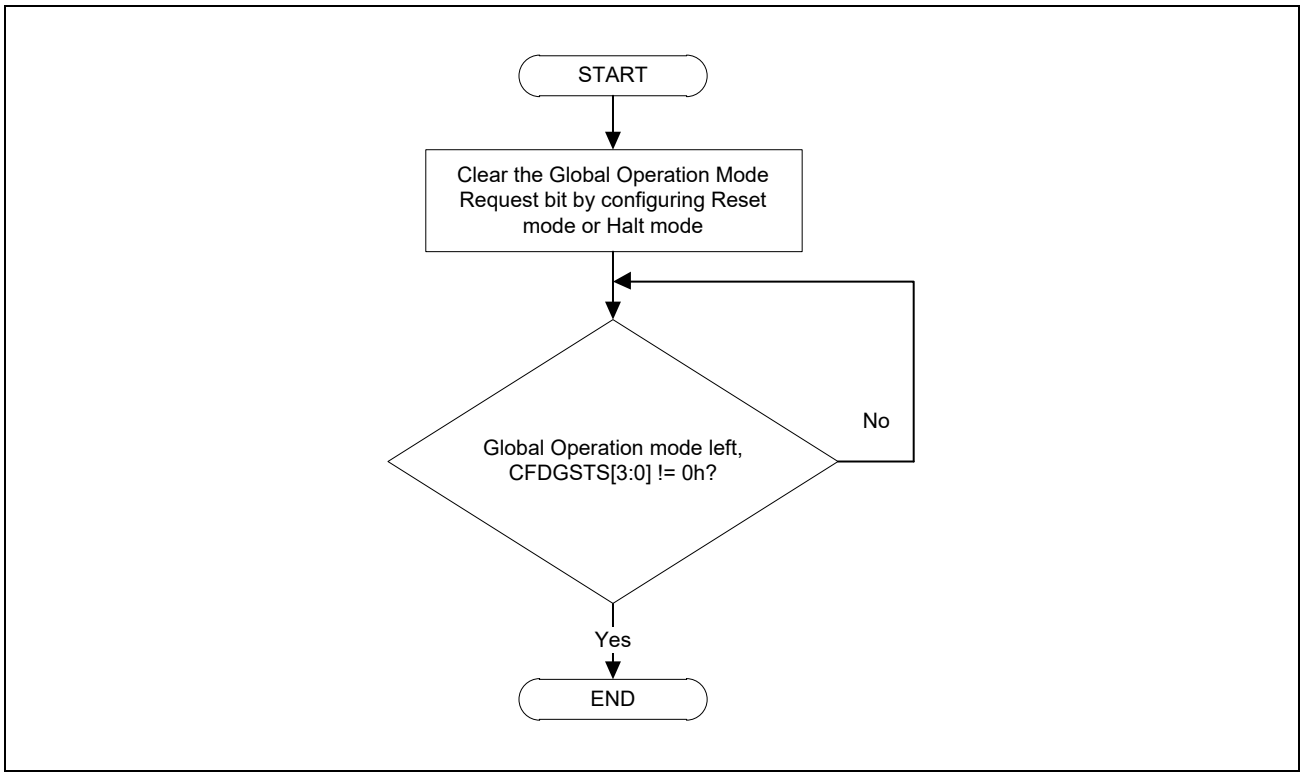

Figure 7.9-10 Procedure for Exiting Global Operation Mode

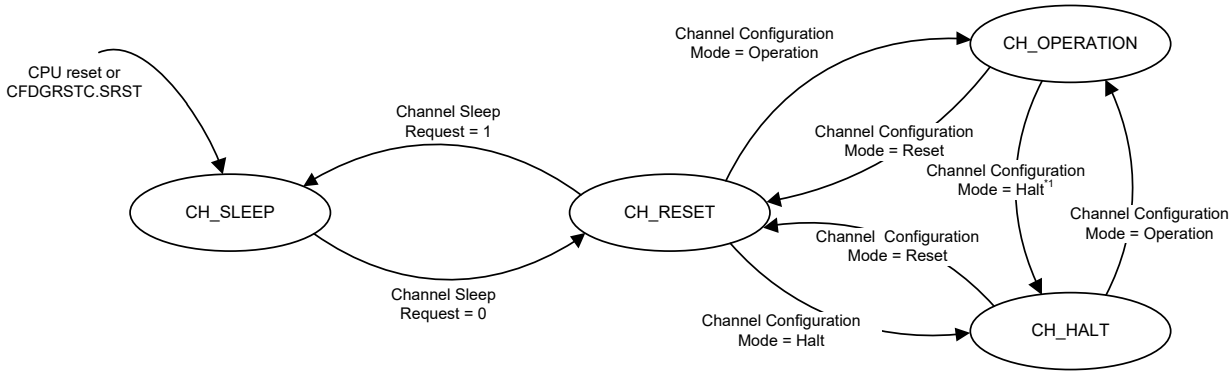
7.9.3.3 Channel Modes

Each CAN channel can be in one of the following four channel modes:

- Reset
- Halt
- Operation
- Sleep

Figure 7.9-11 shows possible transitions between the channel modes.



Note 1. The transition timing depends on BOM[1:0] setting in the Channel Control Register (CFDCnCTR):
When BOM[1:0] = 01b, the state transition timing is immediate after entering bus-off state
When BOM[1:0] = 10b, the state transition timing is at the end of bus-off state
When BOM[1:0] = 11b, the state transition timing is matching with the setting of CHMDC to HALT mode

Figure 7.9-11 Transition between CAN Channel Modes

7.9.3.3.1 CAN Channel Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, each CAN channel of the CAN- FD module automatically enters Channel Sleep mode.

Each CAN channel also enters Channel Sleep mode when the related Channel Sleep Mode Request bit is set while the CAN channel is in Channel Reset mode. Do not set this control bit in Channel Halt mode or Channel Operation mode.

Entering the CAN Channel Sleep mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.

After setting the Channel Sleep Mode Request bit, it is necessary to confirm that the Channel Sleep mode status has been updated to indicate a successful transition to Channel Sleep mode before the Channel Sleep Mode Request bit can be cleared again.

During Channel Sleep mode, do not write to channel related registers. Read operation is still possible.

7.9.3.3.2 CAN Channel Reset Mode

A CAN-FD CAN channel enters the CAN Channel Reset mode in the following ways:

- Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers is configured for Channel Reset mode while the related CAN channel is in Channel Halt mode or Channel Operation mode
- Channel Sleep Mode Request bit is cleared while the related CAN channel is in Channel Sleep mode
- Global Mode Control bits CFDGCTR.GMDC[1:0] is set to Global Reset mode and CAN channel is not in Channel Sleep mode or Channel Reset mode.

In Channel Reset mode, all CAN channel status and flag registers are initialized.

Additionally all channel-related transmission control bits are cleared and the channel-related TX Queue is disabled.

Configuration registers (except the Channel Test Mode registers) are not initialized in this mode and the CAN channel can be configured for communication.

See **7.9.3.4 Global Mode and Channel Mode Transition Interactions** for a detailed description of the behavior of all registers when transition to Channel Reset mode is performed.

After setting the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] to Channel Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDCnSTS.CRSTSTS in the related Channel Status Registers has been updated to indicate a successful transition to Channel Reset mode before the related CFDCnCTR.CHMDC[1:0] bits can be modified again.

See **Table 7.9-16** for the behavior of transitioning to Channel Reset mode while CAN communication is ongoing.

Table 7.9-16 Transition Behavior in CAN Reset Mode and Halt Mode

Mode	State		
	Receiver	Transmitter	Bus-Off
CAN Channel Reset mode (CFDCnCTR.CHMDC[1:0] = 01b)	The CAN channel transits to Channel Reset mode without waiting for the completion of the ongoing reception.*1	The CAN channel transits to Channel Reset mode without waiting for the completion of the ongoing transmission.*1	The CAN channel transits to Channel Reset mode without waiting for the completion of the bus-off recovery.
CAN Channel Halt Mode (CFDCnCTR.CHMDC[1:0] = 10b)	The CAN channel transits to Channel Halt mode at the end of the ongoing reception or error.*2	The CAN channel transits to Channel Halt mode after completion of the ongoing transmission.	When CFDCnCTR.BOM[1:0] is set to 00b, a Channel Halt mode request is accepted only after the completion of the full bus-off recovery sequence. When CFDCnCTR.BOM[1:0] is set to 10b, the CAN channel transits automatically to Channel Halt mode after waiting for the completion of the bus-off recovery. When CFDCnCTR.BOM[1:0] is set to 01b, the CAN channel transits automatically to Channel Halt mode without waiting for the completion of the bus-off recovery. When CFDCnCTR.BOM[1:0] is set to 11b, the CAN channel transits to Channel Halt mode as soon as Channel Halt mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to Channel Reset is required only at the end of an ongoing communication, then Channel Halt mode can be requested first to prevent interruption of CAN communication by direct transition to Channel Reset mode. After the CAN channel enters Channel Halt mode, the Channel Reset mode can be requested.

Note 2. If CAN communication is locked at a dominant level after an error flag, software can detect this situation by monitoring the channel related Bus Lock flag and resolve the lock condition by setting the CAN channel to Channel Reset mode.

7.9.3.3.3 CAN Channel Halt Mode

A CAN-FD CAN channel enters the CAN Channel Halt mode in the following ways:

- Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers are configured for Channel Halt mode while the related CAN channel is in Channel Reset mode or Channel Operation mode
- Global Mode Control bits CFDGCTR.GMDC[1:0] are set to Global Halt mode and CAN channel is in Channel Operation mode.

In Channel Halt mode, all channel CAN communication is suspended but all status and flag registers remain unchanged during Channel Halt mode entry (except for the bus-off case where REC and TEC values are cleared for the channel).

In addition, the Channel Test Mode Configuration and Control registers are not initialized in this mode.

The Channel Halt mode should be used to configure Channel Test modes.

See **7.9.3.4 Global Mode and Channel Mode Transition Interactions** for a detailed description of the behavior of all registers when transition to Channel Halt mode is performed.

After setting the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] to Channel Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDCnSTS.CHLTSTS in the related Channel Status Register is updated to indicate a successful transition to Channel Halt mode before the related CFDCnCTR.CHMDC[1:0] bits can be modified again.

See **Table 7.9-16** for the behavior of transitioning to Channel Halt mode while CAN communication is ongoing.

7.9.3.3.4 CAN Channel Operation Mode

The Channel Operation mode is activated by setting the CFDCnCTR.CHMDC[1:0] bits to 00b. If 11 consecutive recessive bits are detected after entering CAN Channel Operation mode, the CFDCnSTS.COMSTS bit is set and the CAN channel:

- Enables the functions of the channel communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters

At this point, the CAN channel can start transmission and reception of CAN messages.

Within the CAN Channel Operation mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (see **Figure 7.9-12**):

- Channel idle: The CAN channel is neither receiving nor transmitting
- Channel receives: The channel is receiving a CAN message sent by another CAN node
- Channel transmits: The channel is transmitting a CAN message

  Note: The channel may receive its own message simultaneously when Self Test mode is enabled.
- Channel is in bus-off state: The CAN channel is cut-off from CAN bus communication.

After setting the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] to Channel Operation mode, it is necessary to confirm that the Channel Reset Mode Status bit CFDCnSTS.CRSTSTS and the Channel Halt Mode Status bit CFDCnSTS.CHLTSTS in the Channel Status Register have been updated to indicate a successful transition to Channel Operation mode before the related CFDCnCTR.CHMDC[1:0] bits can be changed again.

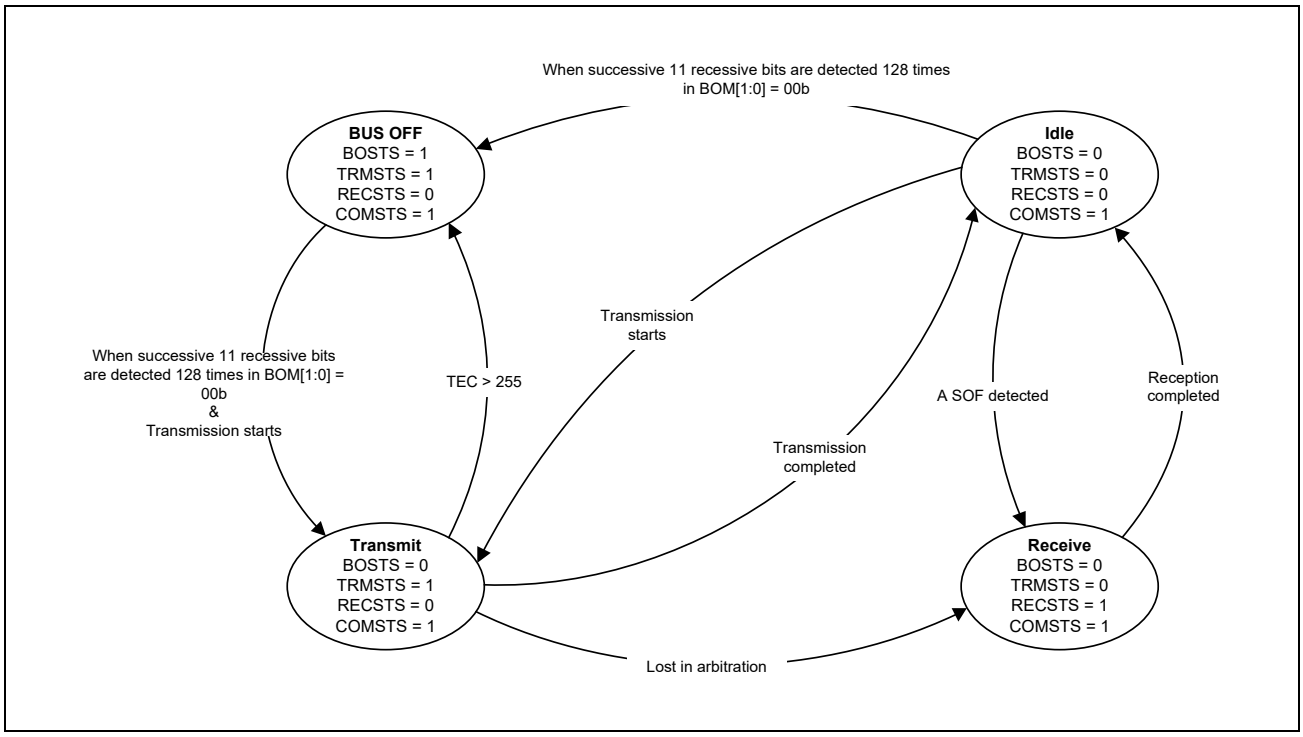


Figure 7.9-12 Sub-Modes of CAN Channel Operation Mode (Only when BOM[1:0] = 00b)

7.9.3.3.5 CAN Channel Bus-Off State

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CAN Channel Operation mode from the bus-off state:

- CFDCnCTR.BOM[1:0] = 00b:
  Bus-Off recovery is compliant to ISO 11898-1, namely the CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. TEC and REC counters are initialized to 0b. The Bus- Off Recovery Flag CFDCnERFL.BORF is set in this case.
- CFDCnCTR.BOM[1:0] = 01b:
  The CAN channel changes the value of the CFDCnCTR.CHMDC[1:0] bits within the CAN Channel Control Register to 10b and switches immediately to Channel Halt mode automatically after entering bus-off state. TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDCnERFL.BORF is not set in this case.
- CFDCnCTR.BOM[1:0] = 10b:
  The CAN channel changes the value of the CFDCnCTR.CHMDC[1:0] bits within the CAN Channel Control Register to 10b as soon as it reaches bus-off state and enters Channel Halt mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). TEC and REC counters are initialized to 0b and the Bus-Off Recovery Flag CFDCnERFL.BORF is set in this case.
- CFDCnCTR.BOM[1:0] = 11b:
  Bus-off recovery is initiated but CAN channel can immediately enter Channel Halt mode when still in bus-off state if a request is made to enter Channel Halt mode.
  TEC and REC counters are initialized to 0b and the Bus-Off Recovery Flag CFDCnERFL.BORF is not set. Without setting CFDCnCTR.CHMDC[1:0] = 10b and when 11 recessive bits is detected 128 times continuously, transition conditions become the same as CFDCnCTR.BOM[1:0] = 00b.

Note: If the recovery from bus-off occurs normally in Channel Halt mode (after waiting for 128 sequences of 11 consecutive recessive bits), and no halt request has been generated during this period, then the Bus-Off Recovery flag CFDCnERFL.BORF is set.

When software writes to the CFDCnCTR.CHMDC[1:0] bit at the same time as the CAN channel enters Halt mode (at the start of bus-off when CFDCnCTR.BOM[1:0] = 01b, or at the end of bus-off when CFDCnCTR.BOM[1:0] = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CFDCnCTR.CHMDC[1:0] bits to Channel Halt mode request is performed when the CFDCnCTR.CHMDC[1:0] bits value is previously 00b (Channel Operation mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting CFDCnCTR.RTBO to 1b. The error state changes from bus-off state to integrating state with a maximum delay of 1 CAN bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The Bus-Off Recovery Flag is not set in this case, and the TEC and REC counters are initialized to 0b.

Before setting CFDCnCTR.RTBO to 1b, all pending transmissions from the TX message buffers, TX Queues and/or Common FIFO in TX or GW mode should be disabled.

The disable of the pending transmission message buffer, TX Queue or FIFO must be confirmed by the corresponding acknowledge flags.

For the TX message buffer, the acknowledge flags are the Transmission Result Flags (CFDTMSTSn.TMTRF[1:0]). For the TX Queue, it is the TX Queue Empty flag (CFDTXQSTSn.TXQEMP). For the FIFO, it is the FIFO Empty flag (CFDCFSTSn.CFEMP).

The CFDCnCTR.RTBO bit should be used for bus-off recovery only when CFDCnCTR.BOM[1:0] is set to 00b.

Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.

Table 7.9-17 shows the settings for the Bus-Off Entry flag CFDCnERFL.BOEF and the Bus-Off Recovery flag CFDCnERFL.BORF for the different configurations of CFDCnCTR.BOM[1:0].

Table 7.9-17 Behavior of Bus-off Entry and Recovery Flags

BOM[1:0]	BOEF Bit Setting	BORF Bit Setting
00b	Always (on entry to bus-off)	Always (on exit from bus-off)
00b CFDCnCTR.RTBO set to 1b	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software sets CFDCnCTR.RTBO to 1b
01b	Always (on entry to bus-off)	Never
10b	Always (on entry to bus-off)	Always (on exit from bus-off)
11b	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software issues a Halt request

For an efficient software procedure, it is not necessary to wait for the bus-off recovery sequence to end.

It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in **Figure 7.9-13**.

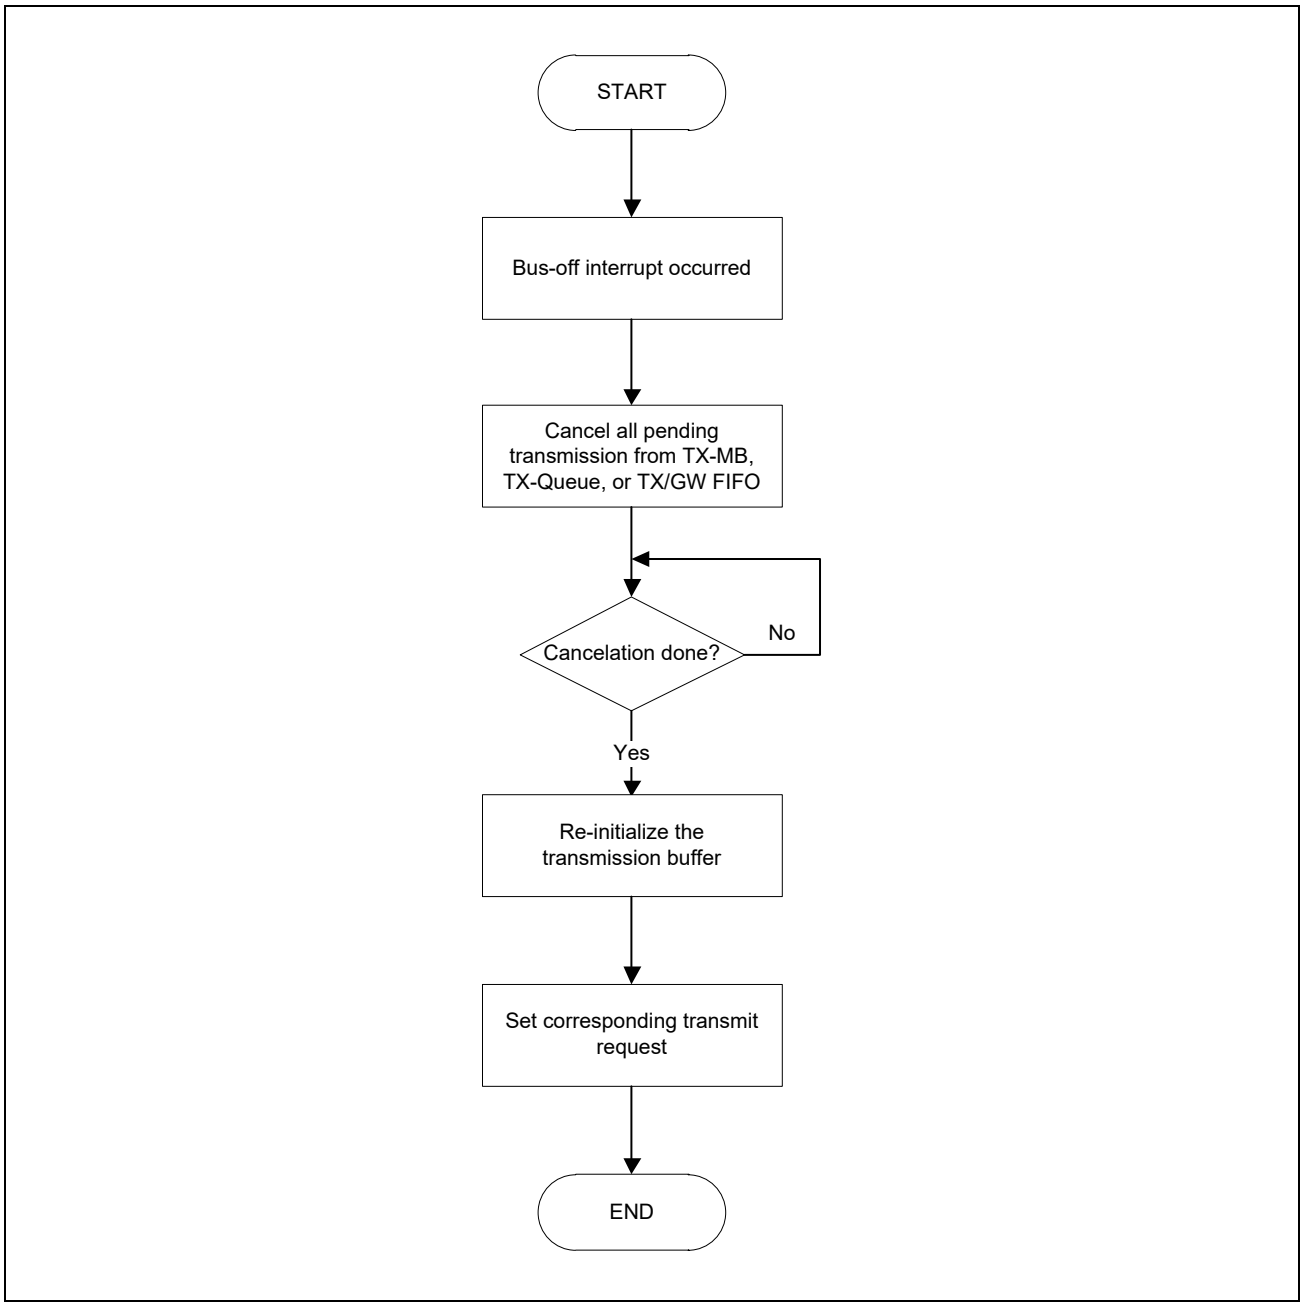

Figure 7.9-13 Transmission Re-Initialization during Bus-Off State

7.9.3.4 Global Mode and Channel Mode Transition Interactions

The interaction between Global mode setting and Channel mode setting is as follows:

- Changing the Channel Mode Control bits CFDCnCTR.CHMDC[1:0] in the Channel Control Registers does not affect the Global Mode Control bits CFDGCTR.GMDC[1:0].
- Changing the Global Mode Control bits CFDGCTR.GMDC[1:0] affects the channel mode control as described in **Table 7.9-18**.

Table 7.9-18 Instruction between Global and Channel Mode Transition

Global Mode Change	Channel Mode	Channel Mode Transition Action
Sleep → Reset	Sleep	Channel remains in Sleep mode
Sleep → Halt	— (Global mode change not possible)	
Sleep → Operation	— (Global mode change not possible)	
Reset → Sleep	Sleep	Channel remains in Sleep mode
	Reset	Channel Sleep request bit is set automatically, channel transits to Sleep mode
Reset → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Reset → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Halt → Sleep	— (Global mode change not possible)	
Halt → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel transits to Reset mode
Halt → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
Operation → Sleep	— (Global mode change not possible)	
Operation → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel transits to Reset mode
	Operation	Channel mode control is set to Reset mode, channel transits to Reset mode
Operation → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
	Operation	Channel mode control is set to Halt mode, channel transits to Halt mode after communication finished

7.9.3.4.1 Timing of Global Mode Change

The transition time for the Global mode changes are shown in the following table.

From	To	Maximum Transition Time
GL_SLEEP	GL_RESET	3 peripheral clock cycles*2
GL_RESET	GL_SLEEP	3 peripheral clock cycles
GL_RESET	GL_HALT	10 peripheral clock cycles
GL_RESET	GL_OPERATION	10 peripheral clock cycles
GL_HALT	GL_RESET	2 CAN bit times
GL_HALT	GL_OPERATION	3 peripheral clock cycles
GL_OPERATION	GL_RESET	2 CAN bit times
GL_OPERATION	GL_HALT	3 CAN frames*1,*3

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.

Note 2. Exit GL_SLEEP mode only when CFDGSTS.GRAMINIT is cleared.

Note 3. TQ, CAN frame, and CAN bits are related to the individual channels. For maximum transition time, the channel with the lowest baud rate must be used.

7.9.3.4.2 Timing of Channel Mode Change

The transition time for the Channel mode changes are shown in the following table.

From	To	Maximum transition time
CH_SLEEP	CH_RESET	3 peripheral clock cycles
CH_RESET	CH_SLEEP	3 peripheral clock cycles
CH_RESET	CH_HALT	3 CAN bit times
CH_RESET	CH_OPERATION	4 CAN bit times
CH_HALT	CH_RESET	2 CAN bit times
CH_HALT	CH_OPERATION	4 CAN bit times*2
CH_OPERATION	CH_RESET	2 CAN bit times
CH_OPERATION	CH_HALT	2 CAN frames*1,*3

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CFDCnCTR.BOM[1:0] bits.

Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.

Note 3. In general, if the baud rate prescaler value CFDCnNCFG.NBRP is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the TQ clock, and new BRP value is captured when the counter reaches the value 0.

7.9.4 Initialization

Before joining CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data rate)
- Baud rate setting (nominal and data rate)
- CAN-FD setting
- Acceptance filter setting (configuration of Global Acceptance Filter List)
- Reception, Transmission and GW-FIFO setting
- CAN Operation mode setting

7.9.4.1 Initialization of CAN Clock, Bit Timing and Baud Rate

7.9.4.1.1 Bit Timing Conditions

The following lines describe the composition of each segment and the limitations that apply to the segment setting.

1. Each segment setting SS = Fixed to 1 TQ
   TSEG1 = Refer to (CFDCnNCFG) and (CFDCnDCFG)
   TSEG2 = Refer to (CFDCnNCFG) and (CFDCnDCFG)
   SJW = Refer to (CFDCnNCFG) and (CFDCnDCFG)
   SS + TSEG1 + TSEG2 = 5 to 49 TQs for data bit rate and 8 to 385 for nominal bit rate
2. Limitations on TSEG1, TSEG2 and SJW
   TSEG1 (N) > TSEG2 (N) ≥ SJW (N)
   TSEG1 (D) ≥ TSEG2 (D) ≥ SJW (D)
   When only classical frames are used, configure the bit fields TSEG1 and TSEG2 of CFDCnDCFG to valid values.
   Table 7.9-19 shows an example of how to set the bit timing to achieve the required Sample Point settings.

Table 7.9-19 Transition Behavior in CAN Reset Mode and Halt Mode (1/2)

	Set Value (TQ)				
1 Bit	SS	TSEG1	TSEG2	SJW	Sample Point*1 (%)
5 TQ	1	2	2	1	60.00
8 TQ	1	4	3	1	62.50
	1	5	2	1	75.00
10 TQ	1	6	3	1	70.00
	1	7	2	1	80.00
12 TQ	1	8	3	1	75.00
	1	9	2	1	83.33
15 TQ	1	10	4	1	73.33
	1	11	3	1	80.00
16 TQ	1	10	5	1	68.75
	1	11	4	1	75.00
20 TQ	1	12	7	1	65.00
	1	13	6	1	70.00

Table 7.9-19 Transition Behavior in CAN Reset Mode and Halt Mode (2/2)

1 Bit	Set Value (TQ)				Sample Point*1 (%)
	SS	TSEG1	TSEG2	SJW	
24 TQ	1	15	8	1	66.66
	1	16	7	1	70.83
50 TQ	1	39	10	4	80.00

Note 1. Sample Point (in Case of 75%)

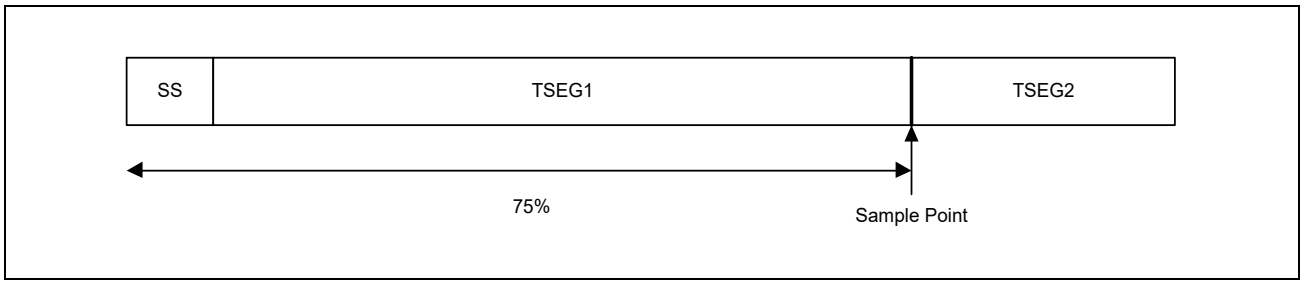

Figure 7.9-14 Sample Point (in Case of 75%)

7.9.4.1.2 CAN Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured individually for each channel using the related CFDCnNCFG and CFDCnDCFG registers.

Figure 7.9-15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (TQ), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the baud rate prescaler (nominal and data rate).

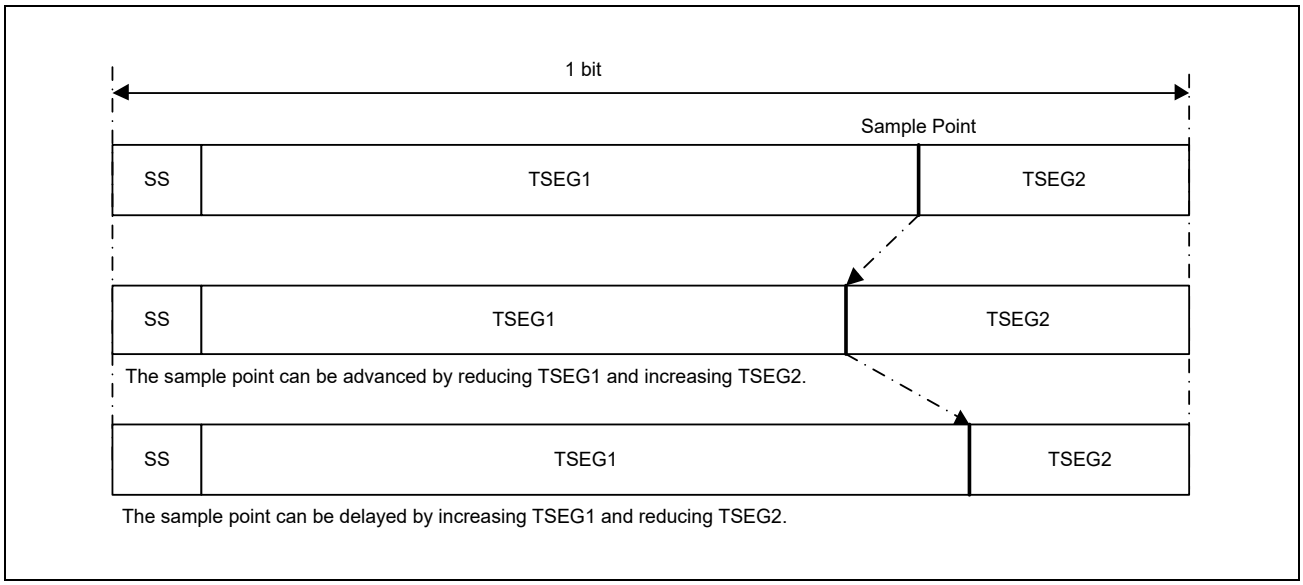

Figure 7.9-15 Segment Composition of a Bit and the Sample Point

1. SS: Synchronization Segment
   This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. This comprises of intermission, suspend transmission, bus idle, during bus idle, and all nodes that can start transmission.
2. TSEG1: Time Segment 1
   This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
   This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.
4. SJW: Resynchronization Jump Width
   This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 7.9-15 shows only one symbolic sample point.

7.9.4.1.3 Baud Rate

Either CANFD_0_pclk or CANFD_0_clkc can be selected globally for all CAN channels as CAN communication clock.

The transfer speed is determined by the DLL clock, the divide-by-N value of the baud rate prescaler, and the number of TQs in one bit.

$$\text{baud rate} = \frac{\text{DLL\_Clock}}{(\text{number\_of\_time\_quanta\_per\_bit}) \times (\text{BRP} + 1)}$$

Figure 7.9-16 shows a block diagram of the circuit that generates the CAN channel system clock, **Table 7.9-20** and **Table 7.9-21** show baud rate examples.

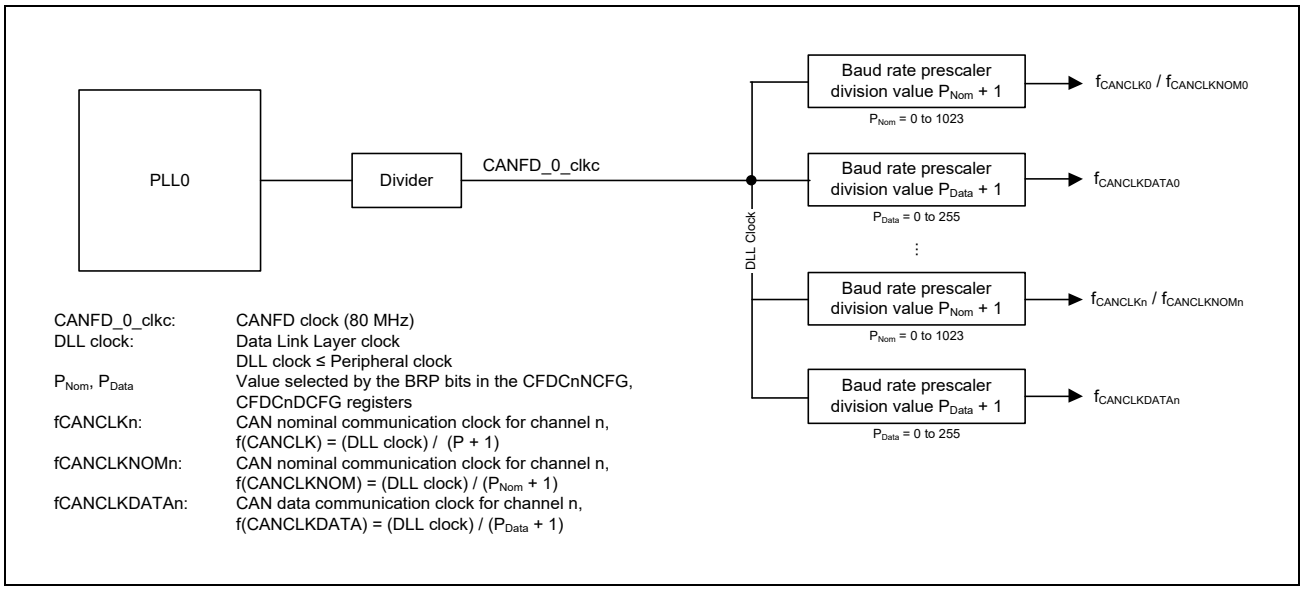

Figure 7.9-16 Block Diagram of the Circuit that Generates the CAN Channel Communication Clock

Table 7.9-20 Nominal Baud Rate Calculation Formula and Example CAN Communication Configurations

Baud Rate Calculation Formula	(DLL Clock) (Baud Rate Prescaler Divide-By-N Value*1) × (Number of TQs in One Bit)			
	80 MHz	40 MHz	100 MHz	75 MHz
1 Mbps	8 TQ (10) 20 TQ (4)	8 TQ (5) 20 TQ (2)	10 TQ (10) 20 TQ (5)	15 TQ (5)
500 Kbps	8 TQ (20) 20 TQ (8)	8 TQ (10) 20 TQ (4)	10 TQ (20) 20 TQ (10)	15 TQ (10)
250 Kbps	8 TQ (40) 20 TQ (16)	8 TQ (20) 20 TQ (8)	10 TQ (40) 20 TQ (20)	15 TQ (20)
125 Kbps	8 TQ (80) 20 TQ (32)	8 TQ (40) 20 TQ (16)	10 TQ (80) 20 TQ (40)	15 TQ (40)
83.3 Kbps	8 TQ (120) 12 TQ (80) 16 TQ (60) 24 TQ (40)	8 TQ (60) 12 TQ (40) 16 TQ (30) 24 TQ (20)	8 TQ (150) 10 TQ (120) 12 TQ (100) 15 TQ (80) 16 TQ (75) 20 TQ (60) 24 TQ (50)	10 TQ (90) 12 TQ (75) 15 TQ (60) 20 TQ (45)
33.3 Kbps	8 TQ (300) 12 TQ (200) 16 TQ (150) 20 TQ (120) 24 TQ (100)	8 TQ (150) 12 TQ (100) 16 TQ (75) 20 TQ (60) 24 TQ (50)	8 TQ (375) 10 TQ (300) 12 TQ (250) 15 TQ (200) 20 TQ (150) 24 TQ (125)	10 TQ (225) 15 TQ (150) 18 TQ (125)

Note: Shown in ( ) are the baud rate prescaler divided-by-N values.

Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 to 1023), P: value selected by the BRP bits in the Channel Configuration Registers.

Table 7.9-21 Baud Rate Calculation Example for Nominal and Data Bit Rate CAN Communication Configurations

Baud Rate Calculation Formula	(DLL Clock) (Baud Rate Prescaler Divide-By-N Value*1) × (Number of TQs in One Bit)			
	80 MHz	40 MHz	100 MHz	75 MHz
Nominal 1 Mbps Data 8 Mbps	80 TQ (1)	40 TQ (1)	100 TQ (1)	75 TQ (1)
	10 TQ (1)	5 TQ (1)	Not possible	Not possible
Nominal 1 Mbps Data 5 Mbps	80 TQ (1)	40 TQ (1)	100 TQ (1)	75 TQ (1)
	16 TQ (1)	8 TQ (1)	20 TQ (1)	15 TQ (1)
Nominal 500 Kbps Data 2 Mbps	160 TQ (1)	80 TQ (1)	200 TQ (1)	150 TQ (1)
	40 TQ (1)	20 TQ (1)	50 TQ (1)	Not possible

Note: Shown in ( ) are the baud rate prescaler divided-by-N values.

Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 to 1023), P: value selected by the BRP bits in the Channel Configuration Registers.

For optimum clock tolerance in networks using the FD frame format, the length of the time quantum should be the same in nominal bit time and in data bit time. This means CFDCnNCFG.NBRP = CFDCnDCFG.DBRP.

Additionally, if transceiver delay compensation is used, do not program the CFDCnDCFG.DBRP[7:0] bits to be greater than 1, as 1 means divide by 2.

7.9.4.1.4 Setting of CAN Clock, Bit Timing and Baud Rate

Figure 7.9-17 shows the procedure for setting the CAN clock and the baud rate for each channel.

These settings should be performed during Channel Reset mode (Configuration mode) for the CAN channels.

Before going to channel communication state, the baud rate must be configured, otherwise the mode does not switch correctly.

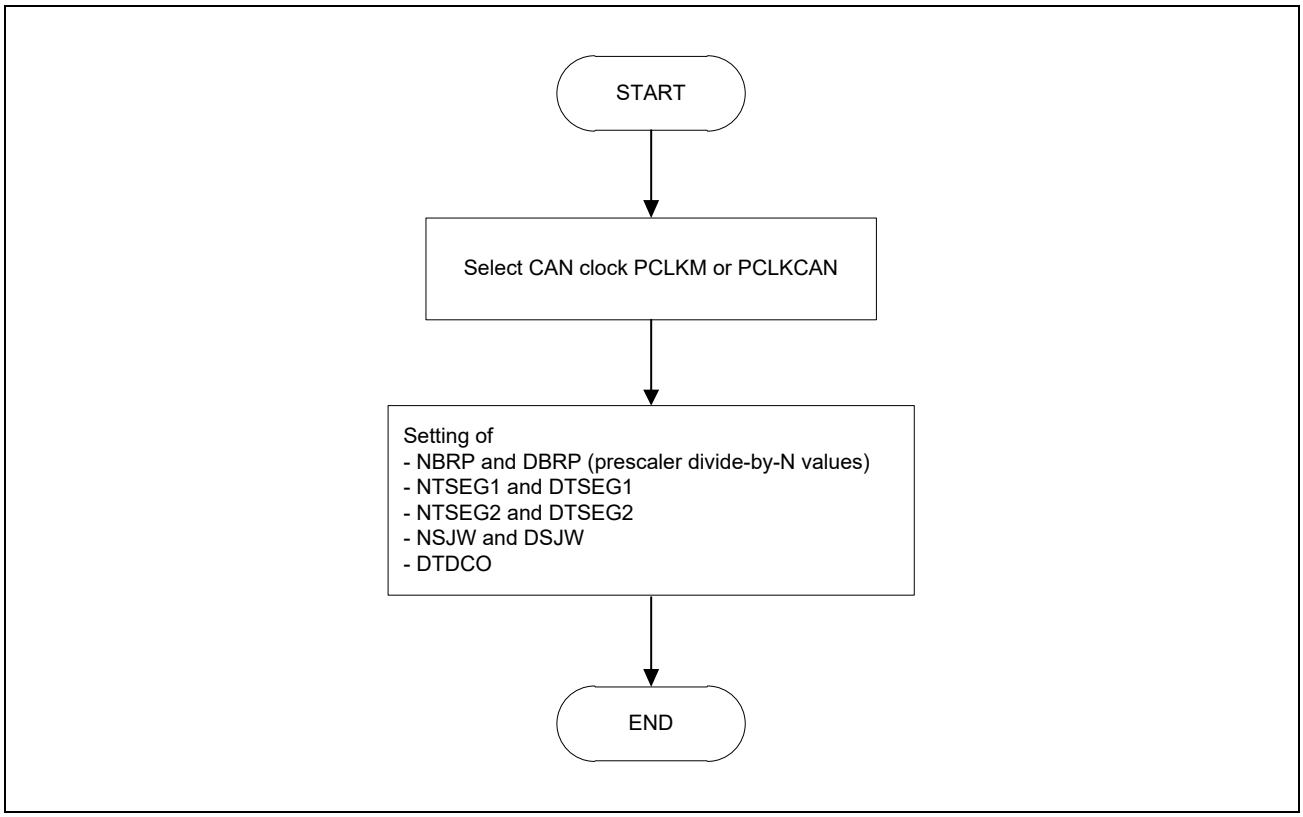

Figure 7.9-17 Procedure for Setting the CAN Bit Timing and Baud Rate

7.9.4.1.5 Transmitter Delay Compensation

When a high baud rate is used such as 5 to 8 Mbps for the data phase, the transmitter delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CAN-FD frame. The TDC compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CAN-FD frames. This is derived from the Transceiver Delay Compensation Result bit (CFDCnFDSTS.TDCR) as shown in **Figure 7.9-18**.

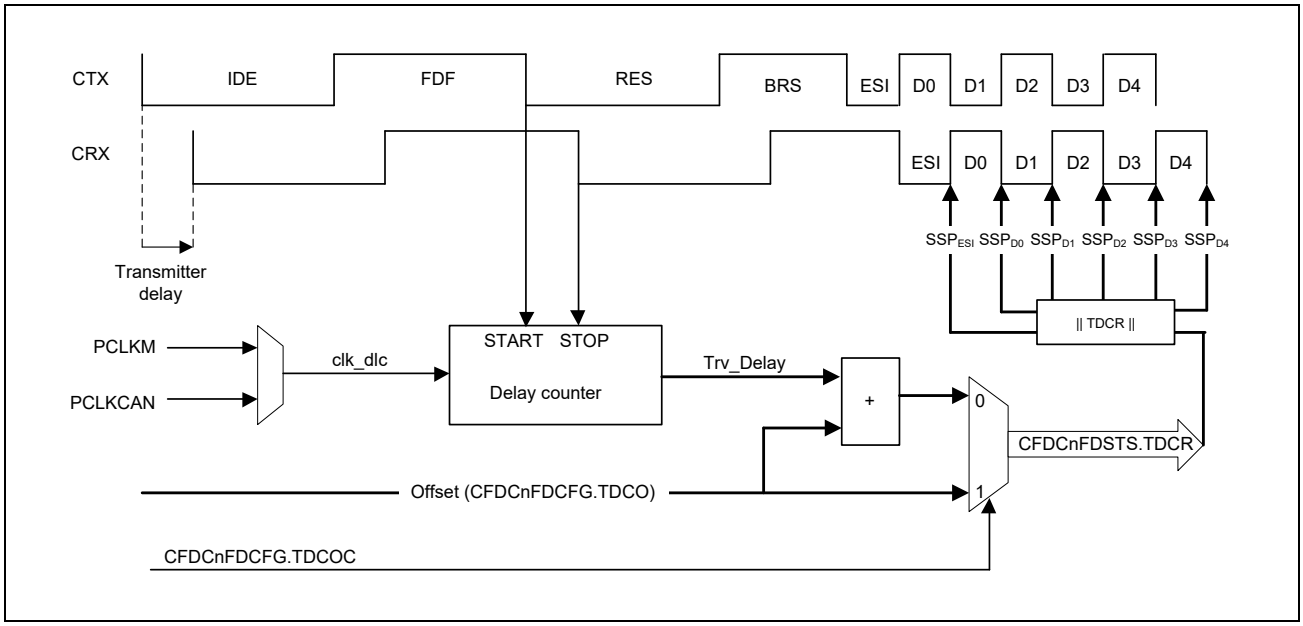

Figure 7.9-18 Transmitter Delay Compensation

The measured Trv_Delay is based on the number of clk_dlc clock cycles. The delay is counted up by 1 for each started clock until the dominant value is seen on CAN_RX. **Figure 7.9-19** shows the measured result. Trv_Delay counted to maximum 127 with a clk_dlc clock.

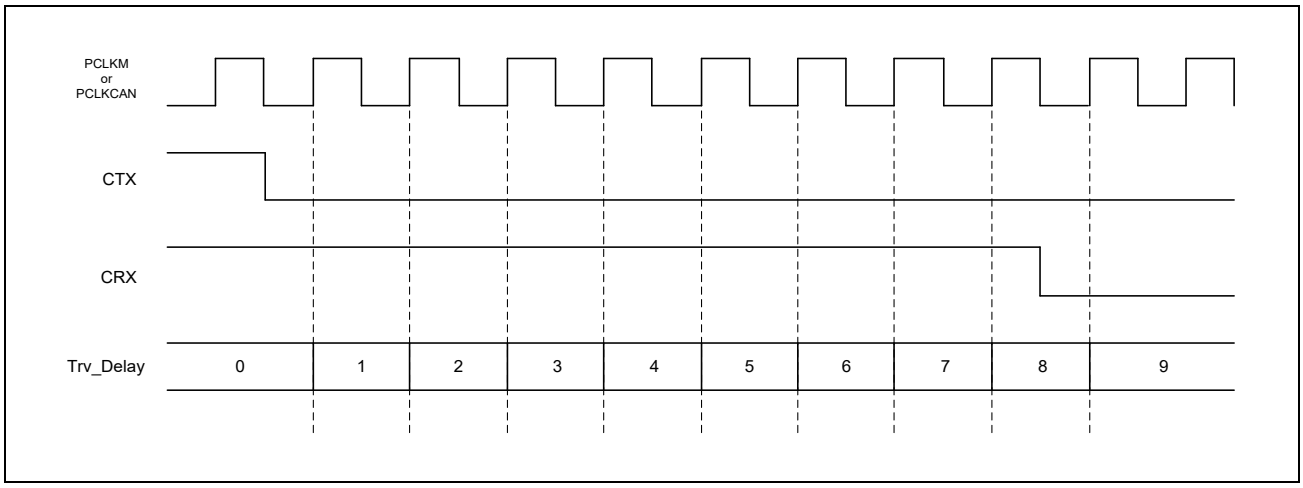

Figure 7.9-19 Trv_Delay Measurement Example

The SSP is calculated by taking the result from CFDCnFDSTS.TDCR and rounding the value down to the nearest integer number of data time quanta.

Figure 7.9-20 shows the positioning of the secondary sample point. When CFDCnFDCFG.TDCOC is equal to 0, the SSP is equal to the Trv_Delay (measured delay) + CFDCnFDCFG.TDCO, rounded down to the nearest integer number of time quanta. Usually, the TDCO value should have the size of (Sync Segment data + TSEG1 data) to position the SSP to a theoretical location of the sample point.

If the CFDCnFDCFG.TDCOC is equal to 1, the SSP is defined by CFDCnFDCFG.TDCO. If CFDCnDCFG.DBRP[7:0] is greater than 0, the value is also rounded down to the nearest integer number of time quanta.

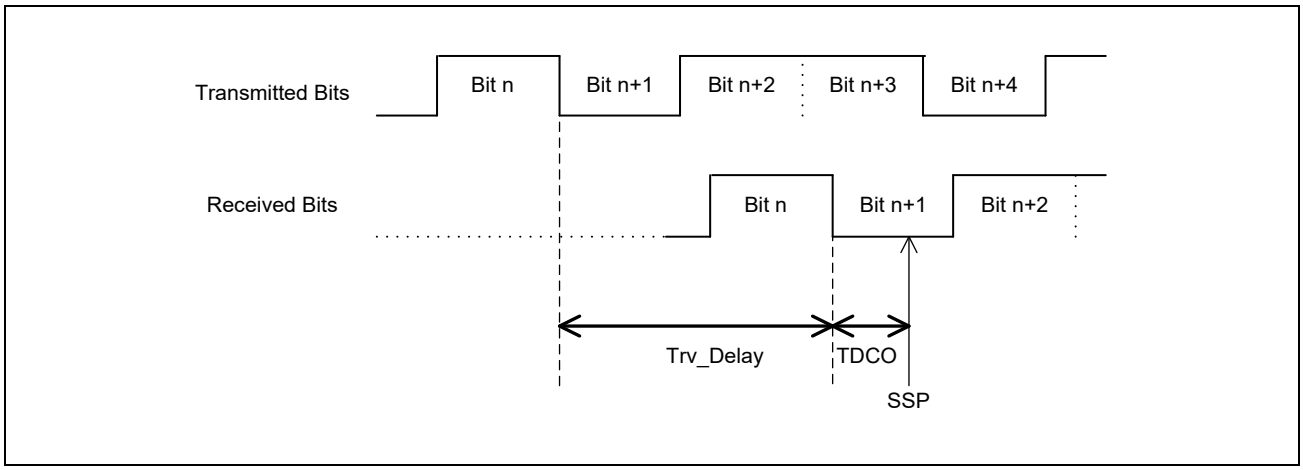

Figure 7.9-20 Position of the Secondary Sample Point

The maximum delay (Trv_Delay + TDCO) which can be compensated by the CAN-FD module is (6 data bits - 2clk_dlc).

The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom.

If different values are used for CFDCnNCFG.NBRP and CFDCnDCFG.DBRP, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in **Figure 7.9-21**.

The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means CFDCnNCFG.NBRP = CFDCnDCFG.DBRP.

Different bit rates can be achieved by selecting different configuration values for the Time Segments. The nominal bit rate can be configured from 8 to 385 TQs and the data bit rate from 5 to 49 TQs.

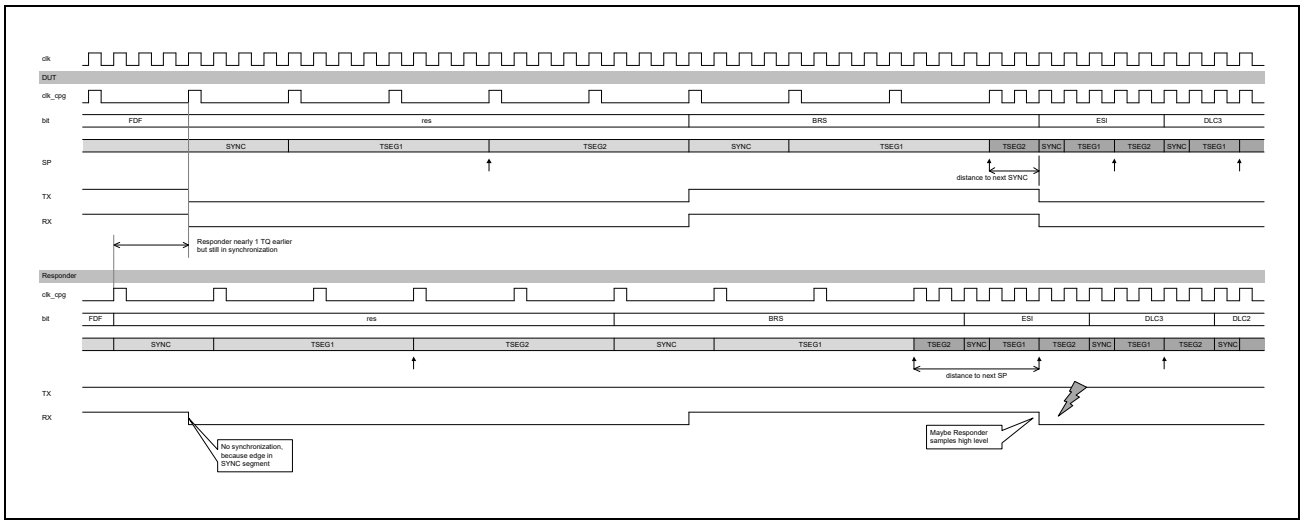

Figure 7.9-21 Loss of Synchronization between 2 CAN Nodes

The transmitter delay compensation measurement result is updated at the falling edge from FDF bit to RES bit when configured accordingly (CFDCnFDCFG.TDCE = 1b, CFDCnFDCFG.TDCOC = 0b).

Figure 7.9-22 shows the read flow to get the measured transmitter delay compensation result.

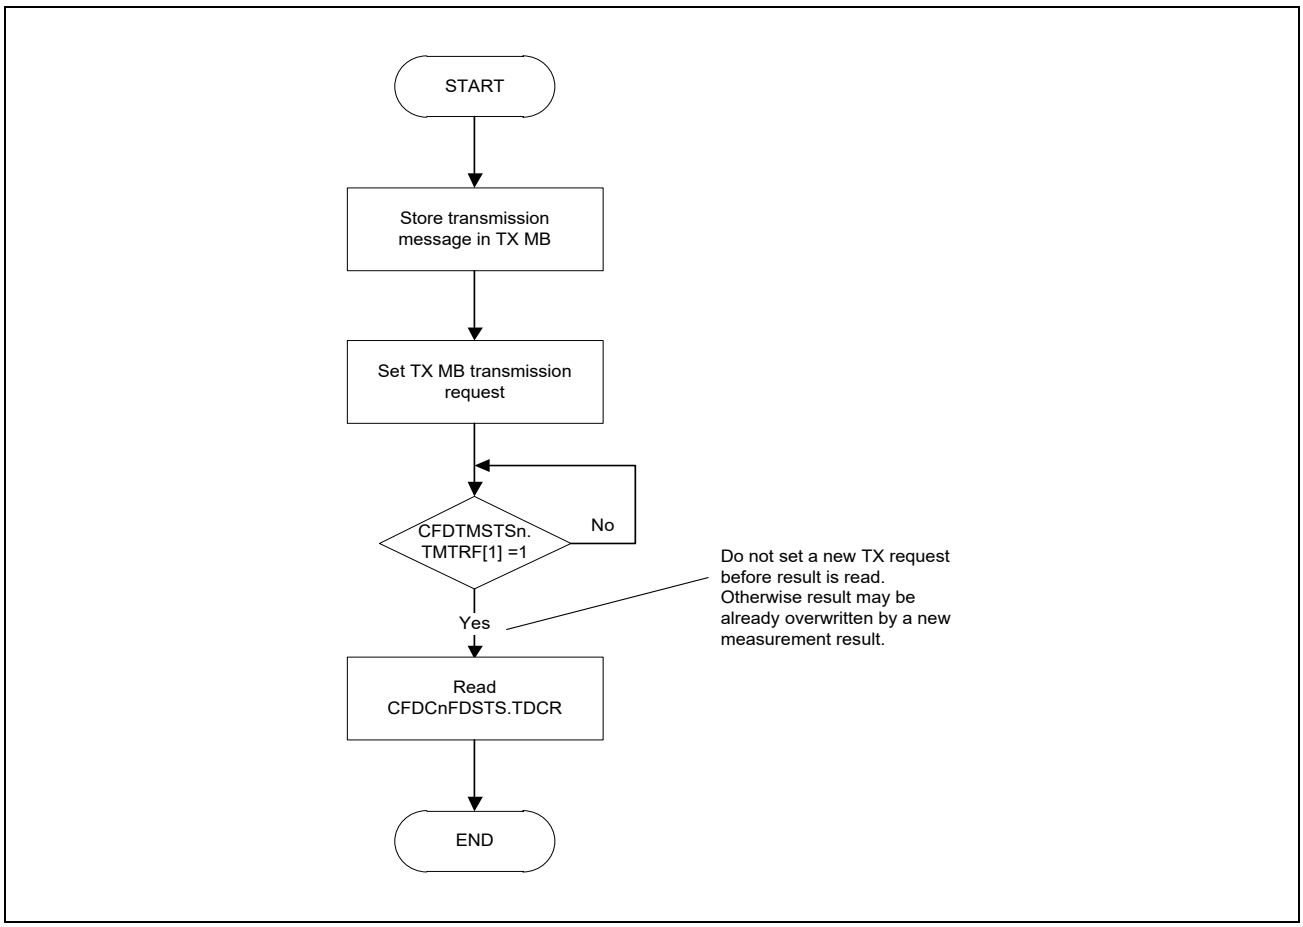

Figure 7.9-22 TDC Result Read Flow

7.9.4.1.6 CAN Module Configuration after Hardware Reset

After a hardware reset (power on reset) or after setting and clearing the CFDGRSTC.SRST bit, the CAN-FD module enters Global Sleep mode automatically.

To enable configuration of the CAN-FD module, you must exit Sleep mode by clearing the Global Sleep Request bit CFDGCTR.GSLPR to 0b.

After a hardware reset, the module starts RAM initialization, the CFDGSTS.GRAMINIT bit in the Global Status Register is set automatically to indicate that the CAN-FD logic is initializing the RAM.

After RAM initialization is complete, this bit is cleared automatically.

RAM initialization is necessary to avoid setting of false ECC error flag after hardware resets the random data presented in the RAM.

Do not access registers of the CAN-FD in either read or write until RAM initialization is complete and the CFDGSTS.GRAMINIT bit is cleared.

Before going to communication mode, the Global Acceptance Filter List and message FIFO buffers must be configured. In addition, each required CAN channel must be configured such as CAN bit timing. For this configuration, all required CAN channels must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

For this, all required CAN channels must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

Figure 7.9-23 shows the configuration procedure. For details about each step, see **7.9.5 Acceptance Filtering Function using Global Acceptance Filter List (AFL)**, **7.9.6 FIFO Buffers and Normal Message Buffer Configuration**, **7.9.7 Interrupt and DMA**, and **7.9.4.1.3 Baud Rate**.

The CAN-FD module does not perform RAM initialization sequence after executing a software reset by setting CFDGRSTC.SRST.

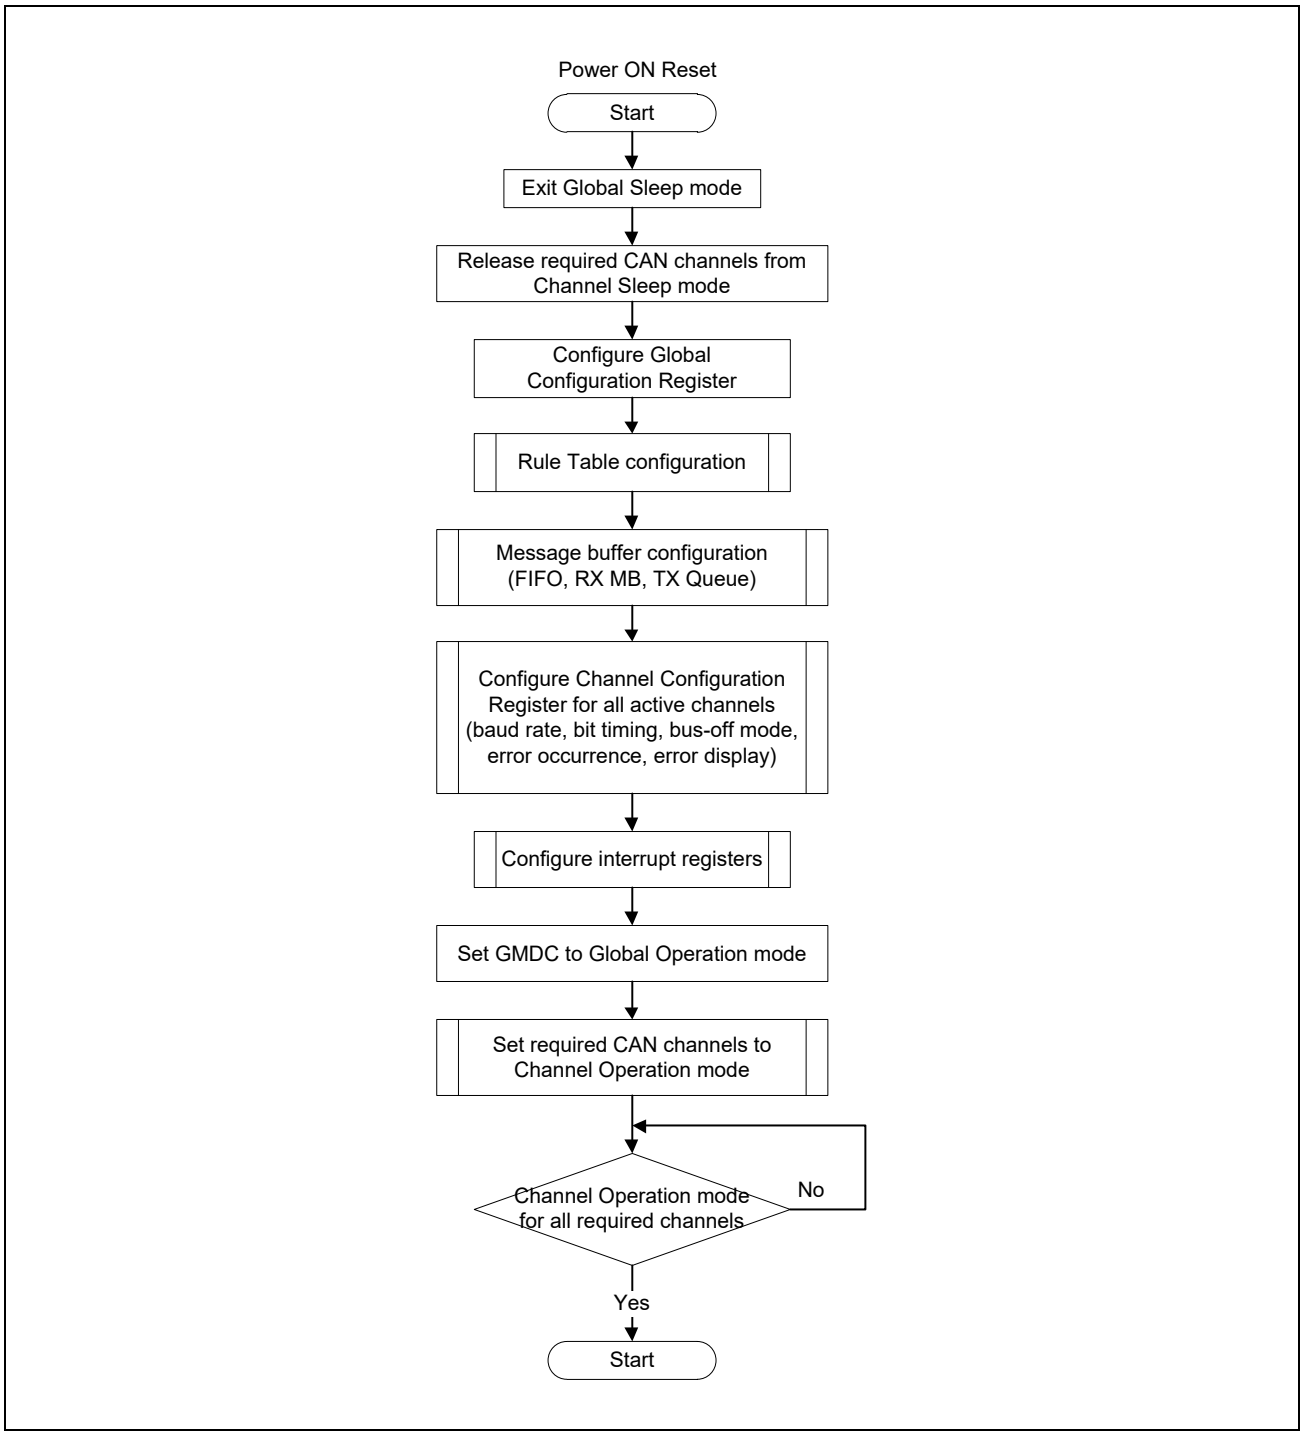

Figure 7.9-23 Configuration Procedure after a Hardware Reset

7.9.5 Acceptance Filtering Function using Global Acceptance Filter List (AFL)

7.9.5.1 Overview

The CAN-FD module can handle message acceptance filtering for all channels with a global Acceptance Filter List (AFL). Each element of the AFL defines a filter rule for messages received on a specific channel.

The following actions are performed based on the AFL entries:

- Acceptance filtering based on received CAN identifier and masking
- DLC filtering based on received DLC value
- Message data payload according to the CFDGCFG.CMPOC bit
- Storage of accepted messages in the message buffer objects defined in the related AFL entry
- Attaching a 16-bit pointer to the stored messages defined in the related AFL entry, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages defined in the related AFL entry

The 6-channel CAN-FD module allows a maximum of 768 AFL entries across all channels with a maximum of 128 AFL entries per channel.

During the acceptance filtering process, each AFL entry in a channel is checked against the received message by the acceptance filter unit. The check starts from the lowest AFL entry number for this channel.

The AFL search stops when a match of the received identifier with a configured identifier/mask combination occurs or when the received identifier has been compared against all AFL entries defined for the related channel. If no match occurs, then the received message is rejected. No notification is given to the application in this case.

Additionally, an automatic DLC filtering is performed for each accepted message if DLC check is globally enabled. If the DLC value of the received message is equal to or higher than the configured DLC value in the matching AFL entry, the DLC check is passed.

If DLC replacement (CFDGCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than 0h and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received on the CAN bus are not stored in the destination RXMB or FIFO Buffer. These additional data bytes are stored as 00h in the destination RXMB or FIFO Buffer.

If DLC replacement is enabled and DLC value of matching AFL entry is 0h, then the received value of DLC is stored in the destination RX MB or FIFO Buffer.

If DLC replacement (the CFDGCFG.DRE bit) is disabled and DLC check passes, then the received value of DLC on the CAN bus is stored in the destination RXMB or FIFO buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received from the CAN bus are also stored in the destination RXMB or FIFO buffer.

If DLC value of the received message is less than the configured DLC value in the matching AFL entry, then DLC check fails. In this case, the received message is rejected and is not stored in any RXMB or FIFO buffer.

Additionally, DLC check failure is flagged by the DLC Error Flag in the Global Error Flag Register. If configured, an error interrupt is also generated. The DLC replacement configuration has no impact if the DLC check fails.

If a message has passed both acceptance filtering and DLC filtering, it is stored in a single reception message buffer and/or in FIFO buffers configured for reception or gateway function.

This message storage target information is also defined in the same AFL entry. Do not set a target at the AFL entry which is not configured.

Each accepted received message can be stored into a maximum of 8 different target destinations (single reception message buffer and/or FIFO buffers).

The programming of more than eight target destinations is not allowed. When more destinations are programmed then internal timing, a race condition can occur and received message may not be stored to the message RAM. Correct configuration of the numbers of target destination is the responsibility of the application.

Additional protection mechanism is made for the case when a received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS[2:0], CFDRFCCn.RFPLS[2:0] or CFDCFCCn.CFPLS[2:0]).

If CFDGCFG.CMPOC = 0b, the message is completely rejected and is stored in the target destination. When CFDGCFG.CMPOC = 0b and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS[2:0], CFDRFCCn.RFPLS[2:0] or CFDCFCCn.CFPLS[2:0]), the corresponding CFDFMSTS.RFXMLT[7:0] or CFDFMSTS.CFXMLT[17:0] bits are not set to 1b, respectively.

When CFDGCFG.CMPOC = 1b, the received data bytes greater than CFDRMNB.RMPLS is rejected. When CFDGCFG.CMPOC = 1b and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS[2:0], CFDRFCCn.RFPLS[2:0] or CFDCFCCn.CFPLS[2:0]), the corresponding CFDFMSTS.RFXMLT[7:0] or CFDFMSTS.CFXMLT[17:0] bits are set to 1b, respectively.

Depending on the CFDGCFG.DRE bit, the original received DLC or the DLC value configured at the AFL entry is stored.

Regardless of the CFDGCFG.CMPOC bit setting, CFDGERFL.CMPOF is set to 1b if a payload overflow condition is detected.

The DLC filtering is performed before the payload overflow function. So for one reception frame, only one flag can be set at the same time with CFDGERFL.DEF or CFDGERFL.CMPOF.

7.9.5.2 Allocation of AFL Entries to Each CAN Channel

The number of AFL entries per channel can be configured using the dedicated field in the related Global Acceptance Filter Configuration Registers (see **Figure 7.9-24**).

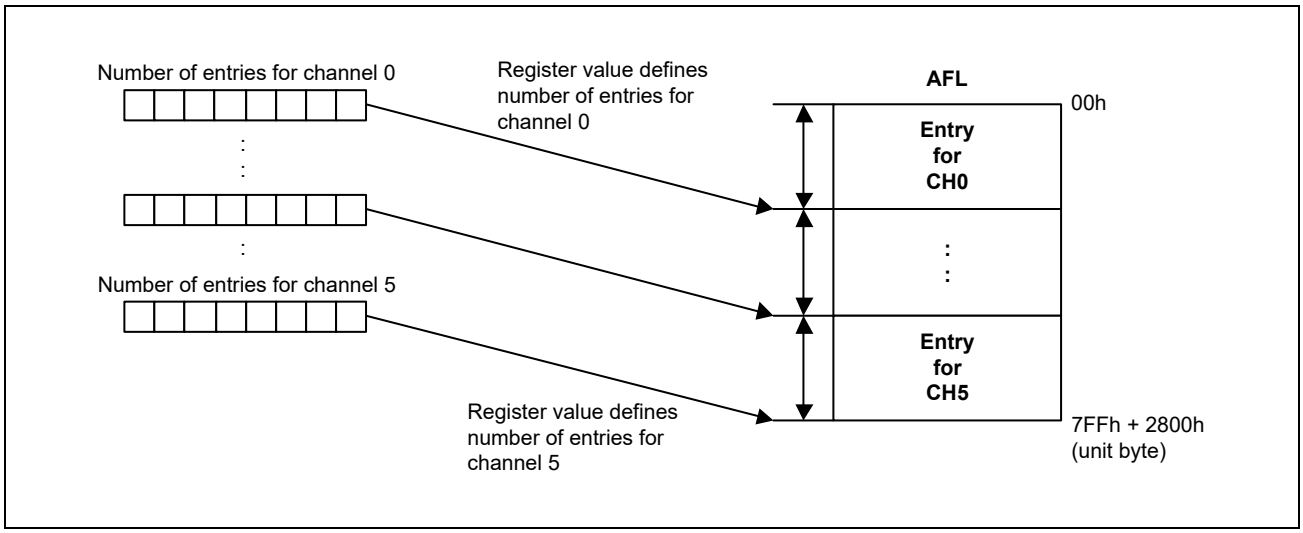

Figure 7.9-24 Configuration of AFL for Each Channel

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries for one channel is 128. The total number of entries for all channels should not exceed the maximum limit of (n + 1) × 128.

All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.

The CAN-FD module does not flag errors related to the configuration of the AFL.

7.9.5.3 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.

Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier (11 bits for Standard Frame format, 29 bits for Extended Frame format):
  Acceptance filter unit checks the identifier field of the received message against the identifier field of each AFL entry (full 29 bits masking of identifier bits is possible, see information that follows).
- IDE bit:
  Acceptance filter unit checks the IDE bit of the received message against this bit and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, see the information that follows).
- RTR bit:
  Acceptance filter unit only accepts data frames (RTR = 0b) or remote frames (RTR = 1b) according to the setting of this bit (masking of RTR bit is possible, see the information that follows).
- Loopback Configuration bit:
  This bit can enable or disable the AFL entry depending on the Loopback Configuration or Mirror mode condition.
- Mask for Identifier bits (29 bits):
  Each bit in the identifier mask can mask the corresponding identifier bit in the AFL entry during acceptance filtering, see **Figure 7.9-25**.
- Mask for IDE bit:
  If this Mask bit masks the IDE bit of the AFL entry in both Standard Identifier and Extended Identifier format, messages can be accepted by this AFL entry. The identifier of the received message is compared against the Standard Identifier part of the AFL entry for Standard Identifier format messages and against the Extended Identifier part of the AFL entry for Extended Identifier format messages.
- Mask for RTR bit:
  If this Mask bit masks the RTR bit of the AFL entry in both frame formats, data frame and remote frame formats are accepted by this AFL entry.
- Pointer information (16 bits):
  This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added during message storage in the message buffer area and can be used by application as support function. The pointer information can be used for example to support PDU identifier allocation for the received message in AUTOSAR systems.
- Information label (2 bits):
  This 2-bit label is attached to a received message accepted by the related AFL entry. The label is added during message storage in the message buffer area and can be used by application as support function.
- DLC value for automatic DLC filtering:
  If the DLC value of the received message is equal or higher than the configured DLC value, the DLC check is passed. If the DLC value in this AFL entry is configured to 0b, DLC filtering is effectively disabled for this entry (all accepted messages pass DLC filtering).

Each AFL entry contains the following information for the handling of received messages:

- Message buffer number of one single reception message buffer as target for received message storage
- Single reception message buffer enable bit to configure the single reception message buffer number to be valid or invalid, as target for received message storage
- FIFO direction pointer - each bit of the FIFO direction pointer configures a dedicated FIFO as possible target for a received message

Note: A message received on channel A can be routed to Common FIFO buffer of another channel. If this Common FIFO buffer is configured in Gateway mode, then the message stored in this Common FIFO Buffer is transmitted on that channel because Common FIFO buffer is associated with channel.

There is no hardware protection against such storage of message. Therefore, the FIFO direction pointer must be configured carefully.

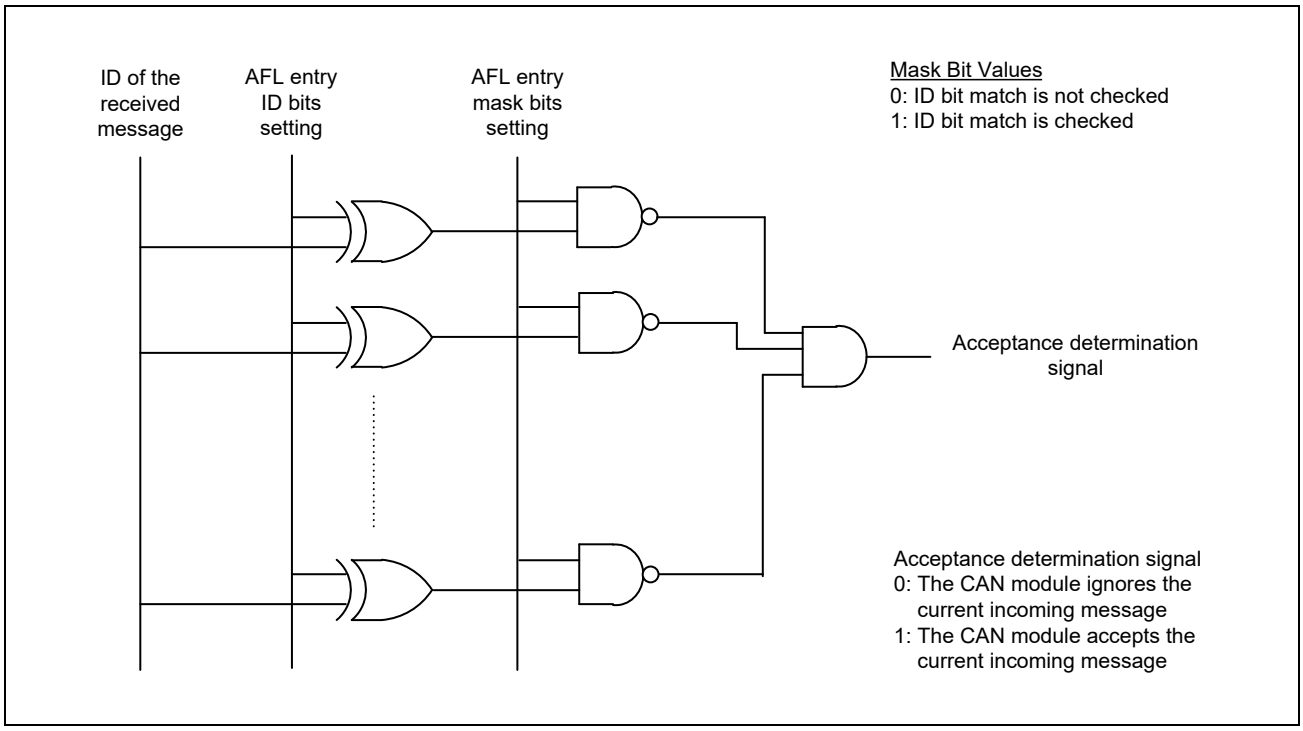

Figure 7.9-25 Acceptance Function

7.9.5.4 Entering Entries in the AFL

Application software can enter one full entry into the AFL using the following registers:

- Global AFL ID Entry Register: Part 1 of the AFL entry
- Global AFL Mask Entry Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Entry Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Entry Register: Part 4 of the AFL entry

16 sets of these registers form a group of AFL entries. Each group can be accessed through a page mechanism. For the CAN-FD module, 6-channel version, 48 of these pages exist to allow access to the whole AFL range. The AFL should only be configured in CH_RESET or CH_HALT mode. Pages are linked to the AFL entries in the following way:

Table 7.9-22 Mapping between Pages and AFL Entries

Page 0	Entry 0 - 15
Page 1	Entry 16 - 31
Page 2	Entry 32 - 47

Page 47	Entry 752 - 767

The selection of the AFL access page is done using the Global Acceptance Filter List Entry Control Register (CFDGAFLECTR) (see **Figure 7.9-26**). This register has the following fields:

- 4 bits to select the AFL page number
- 1 bit to enable or disable the AFL data access to prevent unwanted write access to the AFL

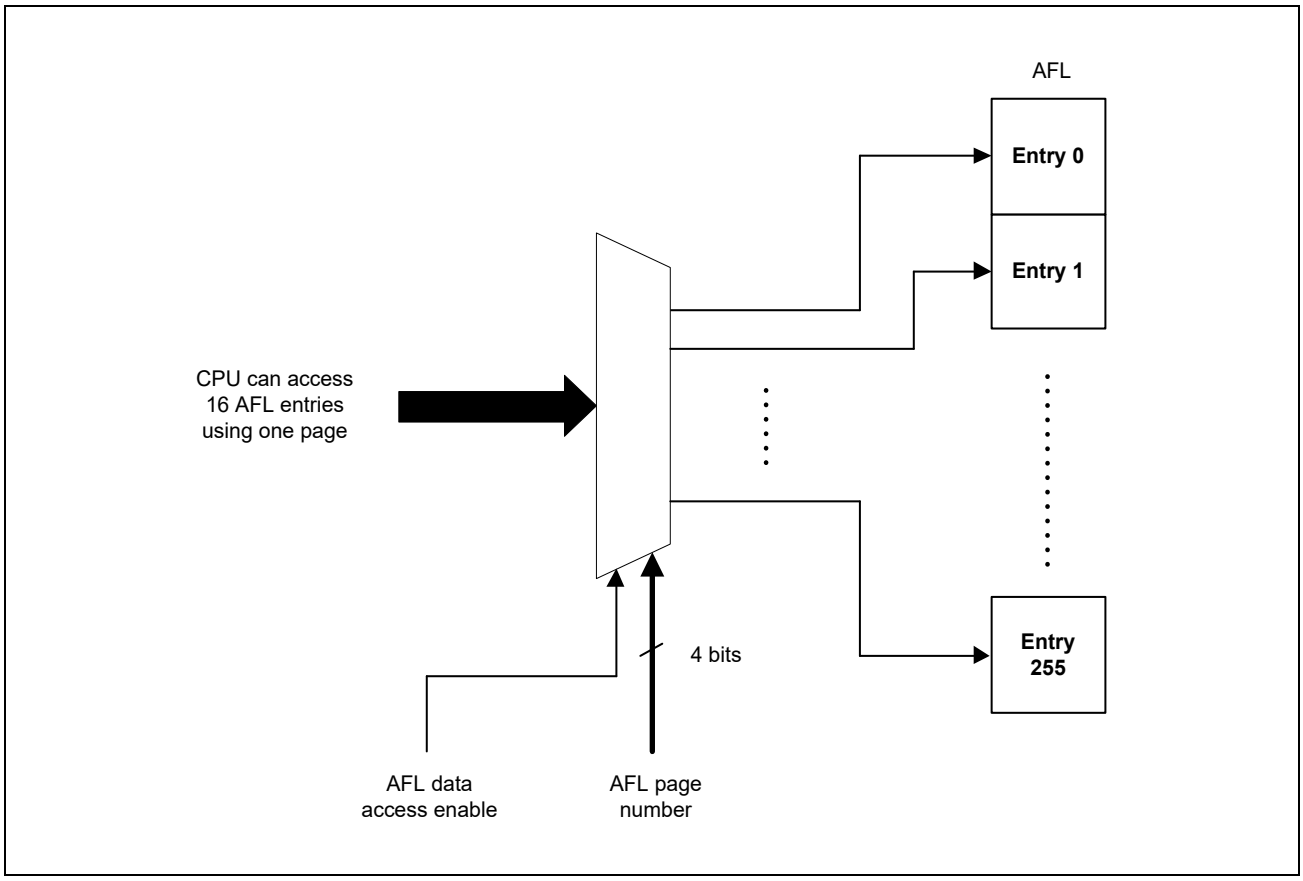

Figure 7.9-26 AFL Page Access

Application software should not write numbers higher than Fh for the AFL page number.

Follow the configuration shown in **Figure 7.9-27** to program the AFL.

After entering all entries in Configuration mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION) if the lock bit is set.

Read access to AFL is still possible during all Global modes even when AFL data access is disabled (consistency check of AFL contents is possible during run time).

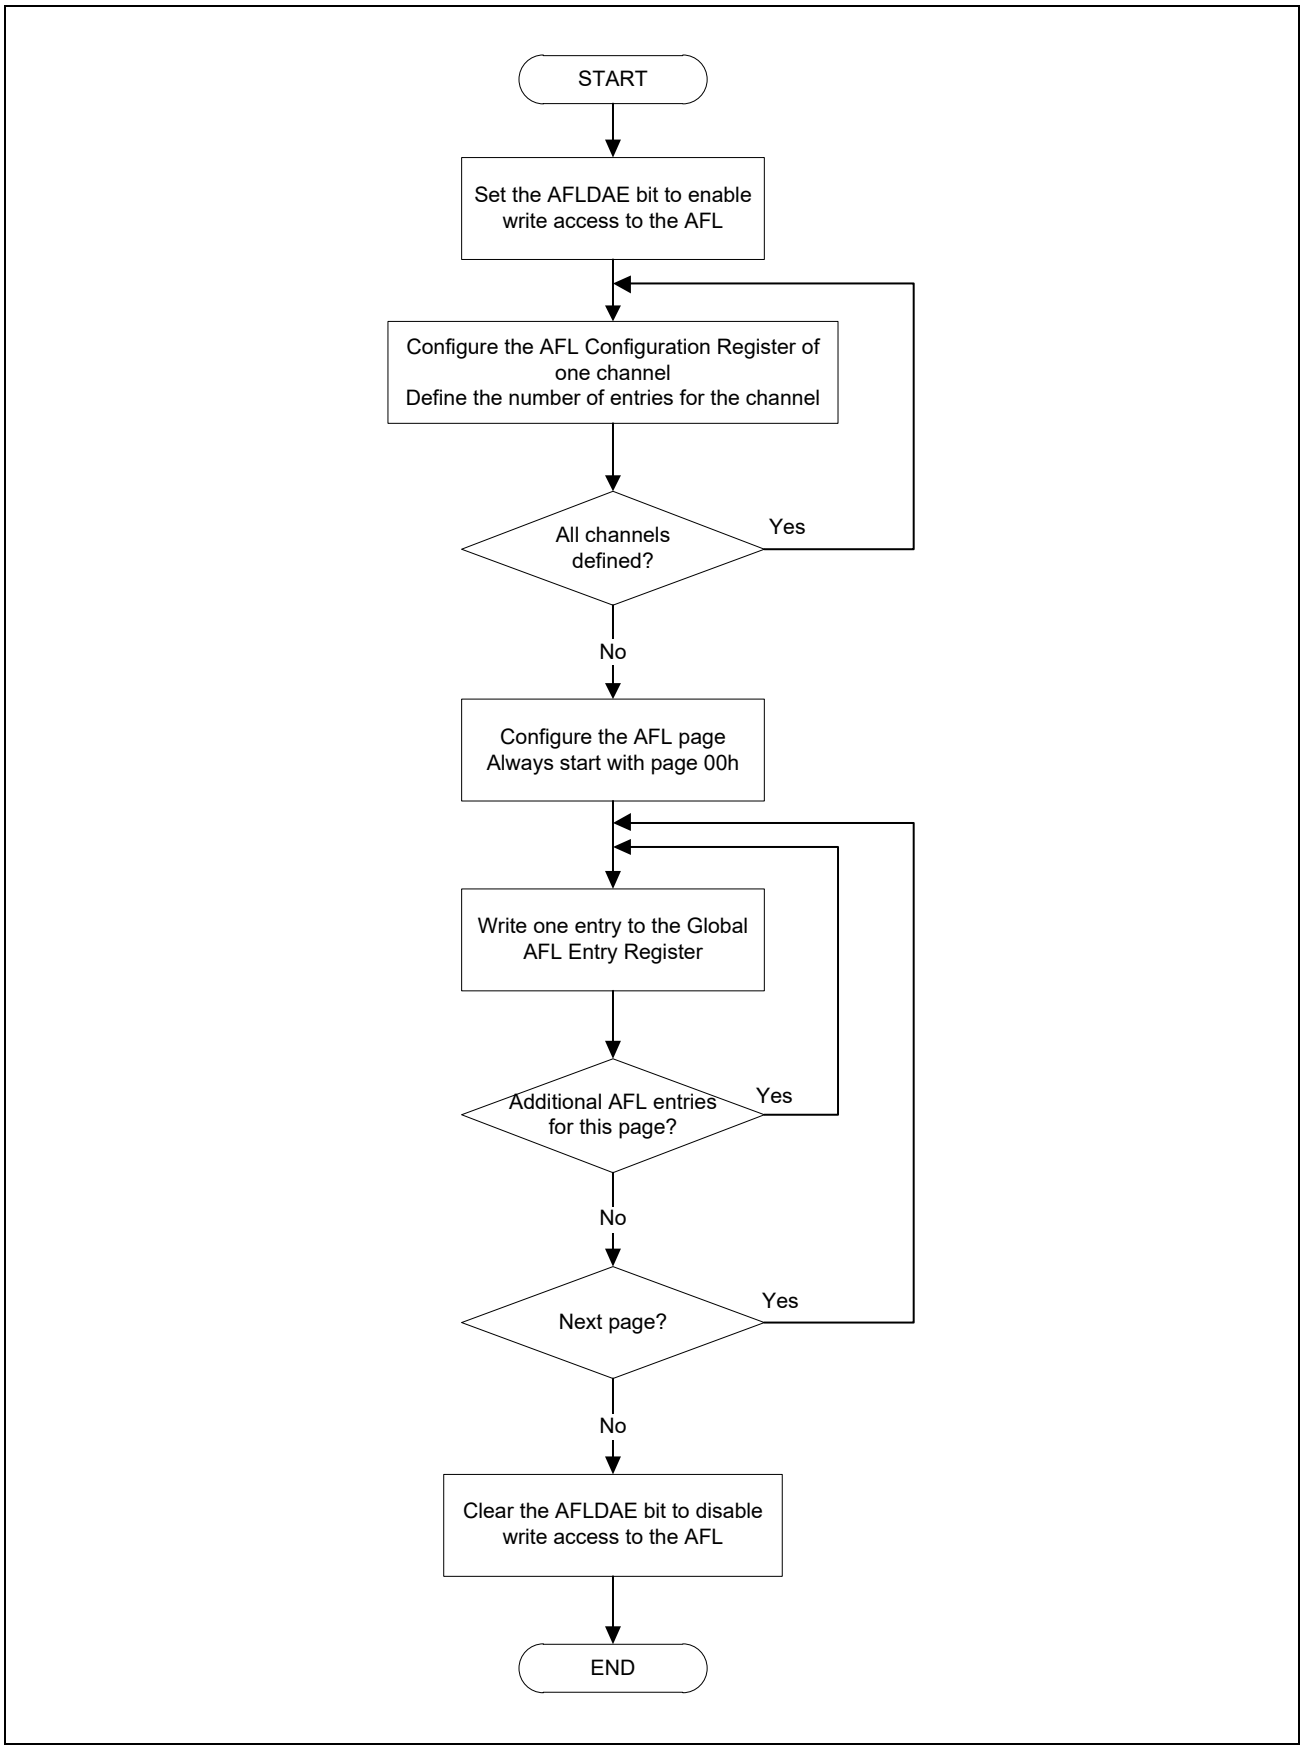

Figure 7.9-27 AFL Configuration Flow

7.9.5.5 Loopback Modes

If the Loopback Configuration bit is set, the AFL entry is only valid in loopback test mode (Self test mode 0 or Self test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus. The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID respectively.

If the Loopback Configuration bit is 0b, the AFL entry is only valid for:

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other CAN nodes or the CAN channel itself in loopback test mode.

The mirror mode can be enabled with the CFDGCFG.MME bit in the Global Configuration Register. If CFDGCFG.MME bit is set, then a successfully transmitted message can be stored back in an RX message buffer or FIFO buffer if a matching entry is configured in the AFL for that channel.

The Loopback Configuration bit in the matching AFL entry must be set to store this frame.

If mirror mode and loopback test mode are configured at the same time, the loopback test mode behavior applies.

Table 7.9-23 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 7.9-23 Behavior of Acceptance Filter Based on the Loopback Configuration Setting in AFL Entry

Mirror Mode Enable (MME Configuration Bit)	Loopback in Test Mode (Self test mode 0 or Self test mode 1)	Channel Mode	Loopback Configuration Bit in AFL Entry	AFL Entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

7.9.5.6 IDE Masking

When the GAFLIDEM bit is 0b in an AFL entry, the IDE bit configured in the AFL entry is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

Consider the following example:

- The ID and Mask fields of an AFL entry x is configured as follows:
  - CFDGAFLID [x] = C055_3A20h → IDE = 1b, RTR = 1b, LLB = 0b, ID[10:0] = 220h/ID[28:0] = 055_3A20h
  - CFDGAFLMn = 0000_FFFFh → IDEM = 0b, RTRM = 0b, IDM[10:0] = 7FFh/IDM[28:0] = 0000_FFFFh
- The comparison result for the four different received IDs with AFL entry x is described as follows:
  - If a frame with IDE = 0b and ID = 220h is received, this is considered as a match
  - If a frame with IDE = 0b and ID = 320h is received, this is not a match
  - If a frame with IDE = 1b and ID = 1FFF_3A20h is received, this is considered as a match
  - If a frame with IDE = 1b and ID = 0880_3220h is received, this is not a match.

7.9.6 FIFO Buffers and Normal Message Buffer Configuration

This section describes the process for configuring the number of RX message buffers, the FIFO buffers, and the flat TX message buffers in the CAN-FD module. The message buffers are mapped as shown in **Figure 7.9-28**.

The RX message buffers can be accessed with the RX Message Buffer Registers.

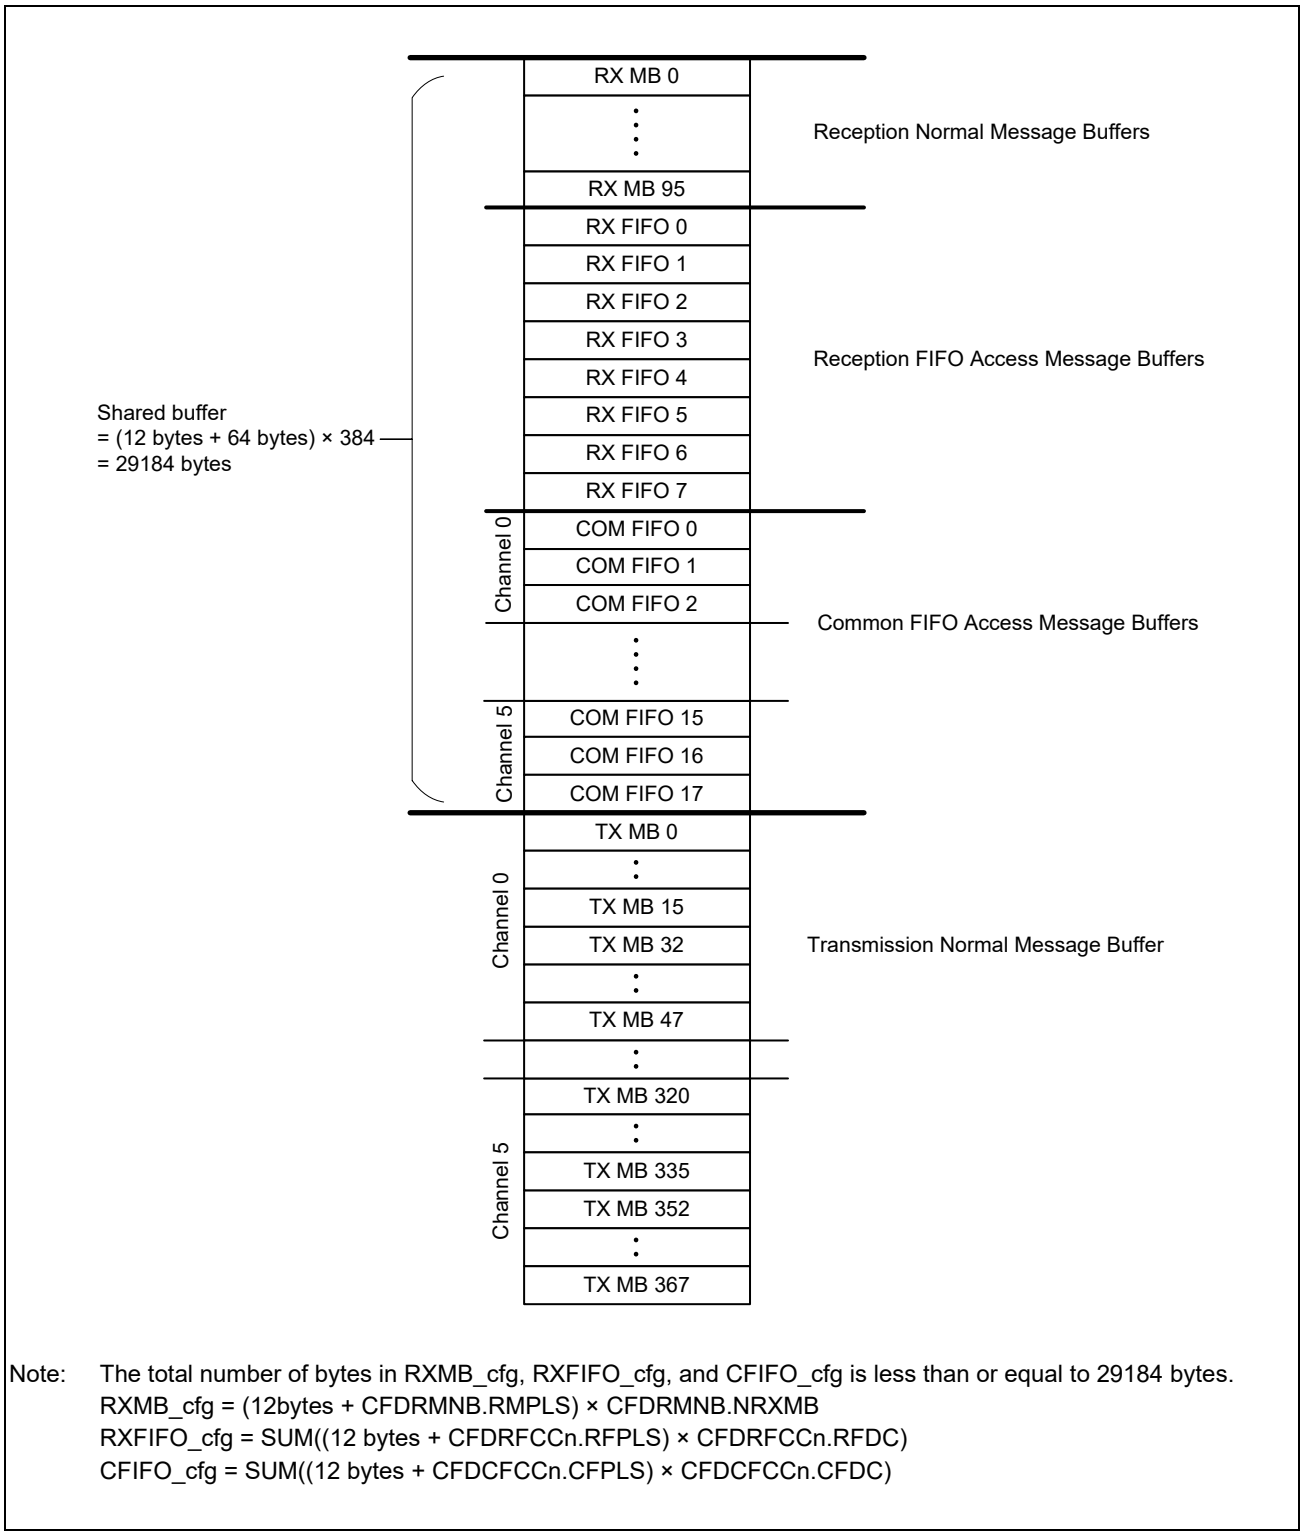
The RX FIFO buffers and the common FIFO buffers configured in RX mode, TX mode, or GW mode can only be accessed with the FIFO Access Registers.

If the common FIFO is configured in TX mode, you can only write data into the FIFO buffer using the FIFO Access registers.

If the common FIFO is configured in GW mode or RX mode, you can only read data from the FIFO Access Registers.

The TX message buffers can be accessed with the TX Message Buffer Registers.

If unused message buffer locations are read, the message buffer locations are read as unknown values.



Note: The total number of bytes in RXMB_cfg, RXFIFO_cfg, and CFIFO_cfg is less than or equal to 29184 bytes.
RXMB_cfg = (12bytes + CFDRMNB.RMPLS) × CFDRMNB.NRXMB
RXFIFO_cfg = SUM((12 bytes + CFDRFCCn.RFPLS) × CFDRFCCn.RFDC)
CFIFO_cfg = SUM((12 bytes + CFDCFCCn.CFPLS) × CFDCFCCn.CFDC)

Figure 7.9-28 Message Buffer Configuration

7.9.6.1 Normal RX Message Buffers

In CAN-FD module, the frames received by various channels can be stored in normal RX message buffers based on the configuration of the AFL entries.

Additionally, the number of normal RX message buffers required in the system can be chosen up to a fixed maximum limit.

7.9.6.1.1 Normal RX Message Buffer Configuration

In CAN-FD module, the number of normal RX message buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of message buffers are:

- Minimum value = 00h (no normal RX MB)
- Maximum value = (16 × number of CAN channels) = 16 × 6 = 96 = 60h (96 flat RX MBs for 6 channels)

Do not use values outside these limits.

The AFL entries for routing the received messages to normal RX message buffers must be configured to match the requirements of the system.

The AFL entries must also be configured properly, and an AFL entry for normal RX message buffers should not exceed the number of message buffers configured in the RX Message Buffer Number Register.

Note: There is no internal check procedure provided in CAN-FD module against incorrect configuration of the AFL.

The data field size of the RX message buffer can be configured with the CFDRMNB.RMPLS[2:0] bits. The default size is 8 bytes and the maximum data payload size is 64 bytes.

When the receiving frame exceeds the data field size, then the acceptance depends on the configuration of CFDGCFG.CMPOC (message rejecting or data payload cut).

7.9.6.2 FIFO Buffer

The CAN-FD module provides a fixed number of FIFO buffers to support storage of frames for reception, transmission and gateway functions for various CAN channels.

The number of reception-only FIFO buffers is fixed to 8. However, 3 common FIFO buffers per channel can be configured to store messages for transmission, reception, or gateway function.

These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- Size
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the TX FIFO or GW FIFO

When the receiving frame exceeds the data field size, the acceptance depends on the configuration of the CFDGCFG.CMPOC bit (message rejecting or data payload cut).

7.9.6.2.1 FIFO Buffers Configuration

In CAN-FD module, the FIFO buffers can be configured to match the system requirements.

The total number of FIFO buffers = 8 RX FIFO buffers + 18 common FIFO buffers = 26 FIFO buffers for 6 channels and message overwrite mechanism.

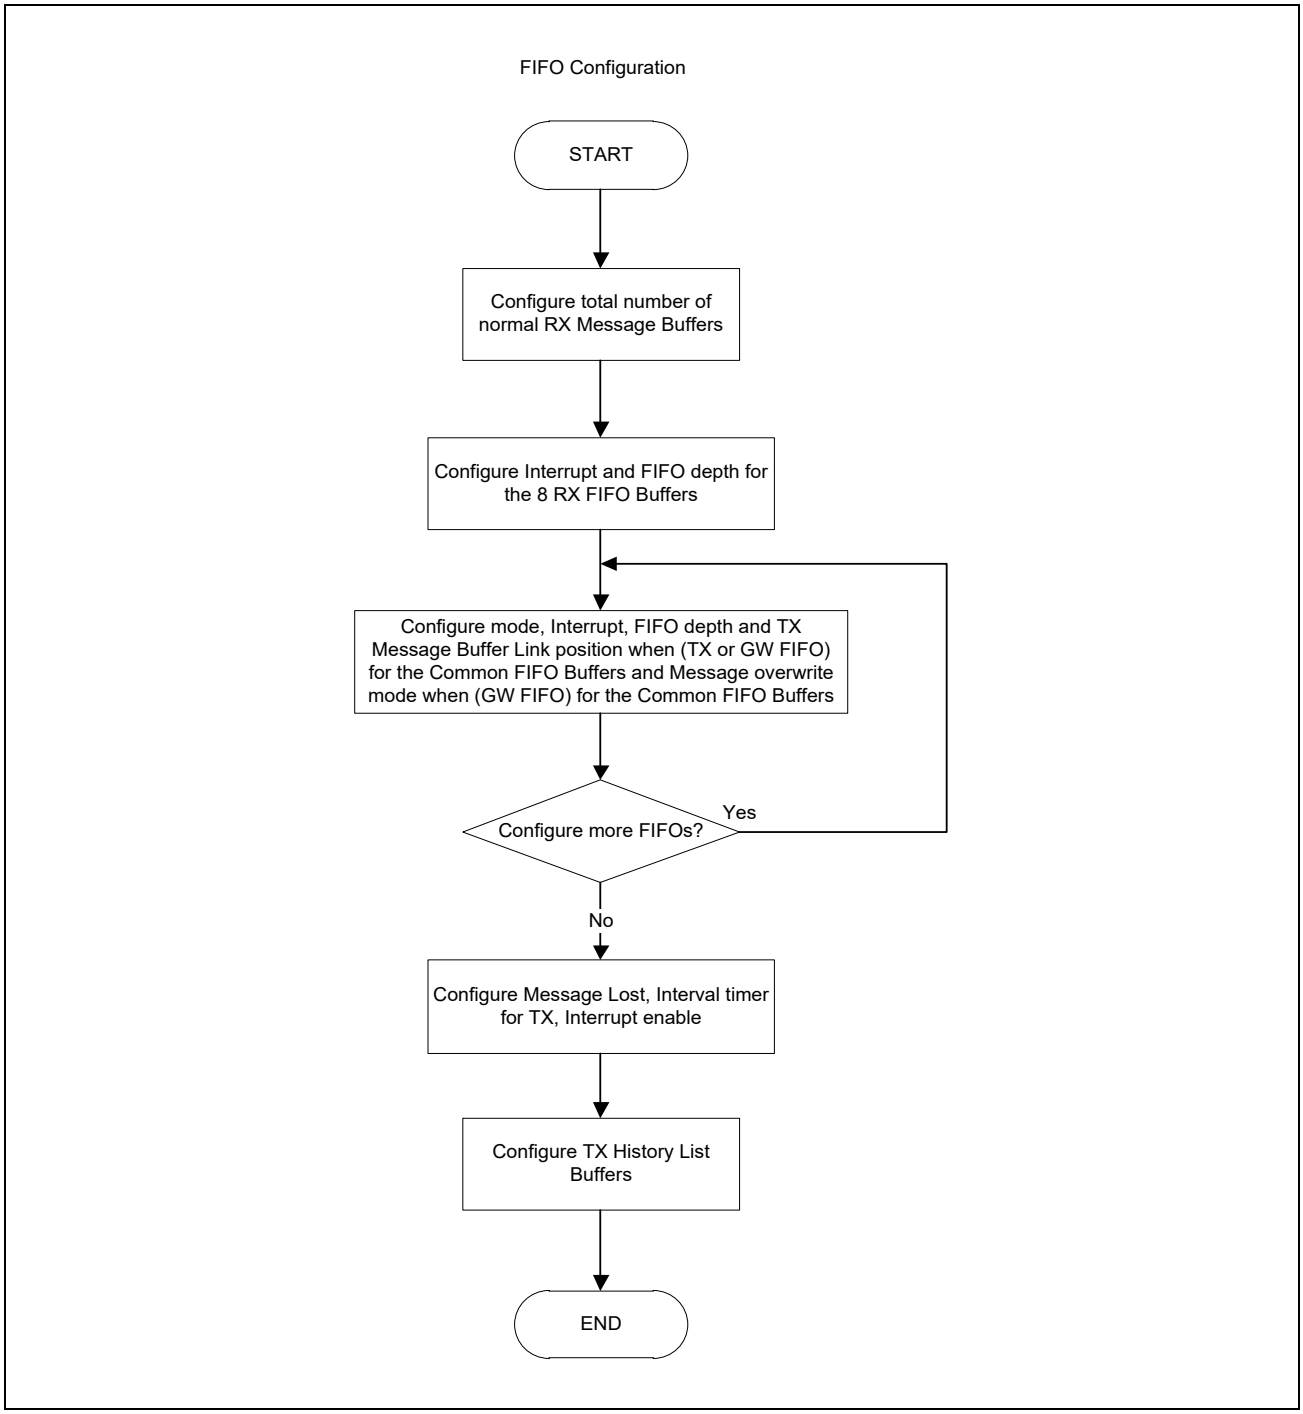


Figure 7.9-29 FIFO Buffer Configuration Flow in CAN-FD Module

As shown in **Figure 7.9-29**, the various FIFO buffers can be configured by writing to the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

For the 8 RX FIFO buffers, the following parameters can be configured:

- Interrupts
- FIFO depth
- FIFO payload data size

For the common FIFO buffers, the following parameters can be configured:

- Mode
- Interrupts FIFO depth
- FIFO payload data size
- FIFO TX link position

(1) FIFO Mode Configuration of Common FIFO Buffers

The mode of the common FIFO buffers can be configured by writing to the CFDCFCCn.CFM[1:0] bits in the Common FIFO Configuration/Control Registers. The possible modes of configuration for Common FIFO buffers are:

- 00b: RX mode (default mode after hardware reset)
- 01b: TX mode
- 10b: GW mode
- 11b: Reserved (do not write this value to the register bits)

Messages can only be read from the RX FIFO buffers and the Common FIFO buffers configured in RX mode. Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Common FIFO buffers configured in TX mode. These messages are transmitted on the appropriate CAN channel.

Messages can only be read from the Common FIFO buffers configured in GW mode. However, the CPU read access has no impact on the read or write pointers. The pointers can only be incremented when a new message is stored in the FIFO buffer and decremented when a message is transmitted on the corresponding CAN channel by the CAN-FD module.

After a hardware reset, all the Common FIFO buffers are configured in RX mode by default. Only enable the FIFO buffers after configuring the Common FIFO buffers in the required modes.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting the CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0b:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded, and CFDCFSTSn.CFMLT bit is set to 1b.
- When CFDCFCCEn.CFMOWM = 1b:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message. The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message. The CFDCFSTSn.CFMOW bit is then set to 1b, which notifies that the oldest message has been overwritten with the received message.
  In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in the transmit/receive

FIFO buffer full, the transmitting message is lost and retransmission for the message is not performed. The read point is then moves to the next message automatically. Do not write to this bit when the CFDCFCCn.CFE bit is 1b.

(2) FIFO TX Message Buffer Link Configuration

When the common FIFO is configured as TX or GW FIFO, the FIFO buffer must be linked to a normal TX message buffer to participate in the transmission scan of a CAN channel.

The link to a normal TX message buffer must be unique, for example the same TX message buffer cannot be shared between 2 or more common FIFO buffers.

Do not write data into a TX message buffer that is linked to a Common FIFO buffer. Also, the TX message buffer linked to a Common FIFO buffer should not be a part of the TX Queue.

The TX message buffer link of each Common FIFO buffer can be configured by writing to the CFDCFCCn.CFTML[4:0] bits in the Common FIFO Configuration/Control Registers. Available options for TX message buffer link configuration are:

- 00h: TX Message Buffer 32
- 01h: TX Message Buffer 33
  ⋮
- 0Fh: TX Message Buffer 47

(3) FIFO Depth Configuration

The depth of each FIFO buffer can be configured by writing to the CFDRFCCn.RFDC[2:0] bits and CFDCFCCn.CFDC[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/ Control Registers. The 8 available options for depth configuration are:

- 000b: 0 Messages (FIFO buffer cannot be enabled)
- 001b: 4 Messages
- 010b: 8 Messages
- 011b: 16 Messages
- 100b: 32 Messages
- 101b: 48 Messages
- 110b: 64 Messages
- 111b: 128 Messages

The RAM allocation for RX message buffers along with FIFO buffers is limited to (n + 1) × 256 messages. Configuration of the RX message buffers, along with FIFO buffers, which exceed this maximum limit should not be done.

CAN-FD module logic does not check the validity of the configuration.

Note: If the FIFO depth of a common FIFO is 4 messages or more (CFDCFCCn.CFDC[2:0] > 000b), then the Common FIFO TX message buffer link is valid when the FIFO is disabled or enabled.

Note: If FIFO depth is 0 messages, then the Common FIFO TX message buffer link is not valid when the FIFO is disabled or enabled.

(4) FIFO Payload Size Configuration

The data size of each FIFO buffer can be configured by writing to the CFDRFCCn.RFPLS[2:0] bits and CFDCFCCn.CFPLS[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The eight available options for depth configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

(5) FIFO Interrupt Configuration

The interrupt generation conditions for the FIFO buffers can be configured by writing to the CFDRFCCn.RFIM bit and the CFDCFCCn.CFIM bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The two available options are:

- 0b:
  - RX FIFO mode: Interrupt generated when the Common FIFO counter reaches CFDRFCCn.RFIGCV/CFDCFCCn.CFIGCV value
  - TX FIFO mode: Interrupt generated when the Common FIFO transmits the last message successfully
  - GW FIFO mode
    Frame RX: Interrupt generated when message counter increments and reaches the interrupt threshold value
    Frame TX: Interrupt generated when the last message is transmitted successfully from FIFO
- 1b:
  - RX FIFO mode: Interrupt generated at the end of storage of every received message
  - TX FIFO mode: Interrupt generated for every successfully transmitted message
  - GW FIFO mode
    Frame RX: Interrupt generated when message is stored in the FIFO
    Frame TX: Interrupt generated when message is successfully transmitted from the FIFO

If the Interrupt Mode bit is 0b for a RX FIFO, then interrupt is generated based on the configuration of the CFDRFCCn.RFIGCV[2:0] bits.

Similarly, if the Interrupt Mode bit is 0b for a Common FIFO configured in RX mode, then interrupt is generated based on the configuration of CFDCFCCn.CFIGCV[2:0] bits.

The eight available options for configuring the FIFO counter value for generation of an interrupt are:

- 000b: Interrupt generated when FIFO is 1/8th Full
- 001b: Interrupt generated when FIFO is 1/4th Full
- 010b: Interrupt generated when FIFO is 3/8th Full
- 011b: Interrupt generated when FIFO is 1/2 Full

- 100b: Interrupt generated when FIFO is 5/8th Full
- 101b: Interrupt generated when FIFO is 3/4th Full
- 110b: Interrupt generated when FIFO is 7/8th Full
- 111b: Interrupt generated when FIFO is Full

In this case, an interrupt is generated when the message count matches the configured value.

However, there are some limitations on the configuration of the CFDRFCCn.RFIGCV[2:0] and CFDCFCCn.CFIGCV[2:0] bits depending on the FDC[2:0] bits (FIFO Depth Configuration), see **Table 7.9-24**.

Table 7.9-24 FIFO Interrupt Generation Counter and FIFO Depth Configuration

RFDC[2:0] (FDC[2:0])	RFIGCV[2:0] (CFGCV[2:0])							
	111b	110b	101b	100b	011b	010b	001b	000b
000b	Don't care (FIFO cannot be enabled)							
001b	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed
010b	Allowed							
011b	Allowed							
100b	Allowed							
101b	Allowed							
110b	Allowed							
111b	Allowed							

Common FIFO buffer can set an interrupt output at the completion time of transmitting one frame, or the completion of reception. In addition, Common FIFO and RX FIFO can set an interrupt output, when stored to the setup number (CFDC/ RFDC) of FIFO stages.

7.9.6.2.2 FIFO Buffers Control

The FIFO interrupt must be enabled by setting any one of the following bits in the RX FIFO Configuration/Control Registers:

- CFDRFCCn.RFIE
- CFDRFCCn.RFFIE

In addition, the FIFO interrupt must be enabled by setting any one of the following bits in the Common FIFO Configuration/Control Registers:

- CFDCFCCn.CFRXIE
- CFDCFCCn.CFTXIE
- CFDCFCCEn.CFFIE
- CFDCFCCEn.CFOFRXIE
- CFDCFCCEn.CFOFTXIE

After configuration is complete, each FIFO can be enabled by setting the CFDRFCCn.RFE and CFDCFCCn.CFE bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers to allow transmission and reception of messages.

When CFDCFCCEn.CFBME = 1b, it becomes FIFO buffering mode, send data is stored in the Common FIFO, and transmission is stopped. Transmission starts when CFDCFCCEn.CFBME = 0b.

Do not write 1b from 0b for this bit when the CFDCFCCn.CFE bit is 1b.

7.9.7 Interrupt and DMA

7.9.7.1 Interrupts

The CAN-FD module generates several interrupts. The interrupt output, which is connected to the Interrupt Controller Unit (ICU), can be controlled by the corresponding interrupt enable bit.

The status flag is set independent from this enable bit.

The channel transmission interrupt has an additional Status Flag register. These status bits are only set when the corresponding interrupt enables are set.

The Status Flag register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The interrupts in the CAN-FD module can be classified into 2 groups, global interrupts and channel interrupts:

- Global interrupts

The CAN-FD module can generate 2 global interrupts:

1. One Global interrupt for successful reception into the 8 RX FIFO buffers
2. One Global error interrupt

- Channel interrupts:

Each channel of the CAN-FD module can generate 3 channel interrupts:

1. Channel transmission
   Transmission completion from channel
   Transmission abort from channel
   Transmission from TX Queue for a channel
   Channel THL Interrupt
   Successful transmission from a Common FIFO in TX or GW mode for a channel
2. Channel error interrupt
3. Successful reception in a Common FIFO in RX or GW mode for a channel or successful routing in a TXQ

The interrupts are cleared when the corresponding flag bits are cleared or interrupt enable bits are cleared.

Table 7.9-25 provides an overview of interrupt.

Table 7.9-25 Overview of Interrupt Source

Parameter	Interrupt	Interrupt Source	Interrupt Clearing
Global Interrupts	Successful reception into at least one RX FIFO	Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the interrupt flag of corresponding RX FIFO buffer for which interrupt is enabled
	FIFO full into at least one RX FIFO	FIFO Full Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the FIFO Full Interrupt flags of corresponding RX FIFO buffer for which interrupt is enabled
	Global error	Any of the following: • DLC Error flag • Message Lost Status bit • Message Overwrite Status bit • TXQ Message Lost Status bit • TXQ Message Overwrite Status bit • TX History Entry Lost Status bit • CAN-FD Message Payload overflow flag	Clear all of: • DLC Error flag • Message Lost flags in all of the FIFO Status Registers • Message Overwrite flags in all of the Common FIFO Status Registers • Message Lost flags in all of the TXQ Status Registers • Message Overwrite Flags in all of the TXQ Status Registers • TX History List Entry Lost flag • CAN-FD Message Payload Overflow flag
Channel Transmission Interrupts	Channel n successful transmission	Any channel related TX MB Successful flag when interrupt is enabled Separate interrupts are provided for common FIFO buffers and TX Queue*1	Clear all channel related TX MB Result Status bits for which the interrupt is enabled
	Channel n abort	Any channel related TX MB Abort flag when interrupt is enabled Separate interrupts are provided for common FIFO buffers and TX Queue*1	Clear all channel related TX MB Result Status bits for which the interrupt is enabled globally
	Channel n transmission from TX Queue	Related channel TX Queue Interrupt flag	Clear related channel TX Queue Interrupt flag
	Channel n THL Interrupt	Channel n THL Interrupt Status flag	Clear the relevant THL Interrupt Status flag
	Channel n COM FIFO TX Interrupt	Interrupt flag for Common FIFOs in TX or GW mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in TX or GW mode belonging to the related channel
	Channel n COM FIFO One Frame TX Interrupt	One Frame Transmission Interrupt flag for Common FIFOs belonging to the related channel	Clear the One Frame Transmission Interrupt flags of Common FIFOs belonging to the related channel
	Channel n TXQ One Frame TX Interrupt	One Frame Transmission Interrupt flag for TXQs belonging to the related channel	Clear the One Frame Transmission Interrupt flags of TXQs belonging to the related channel
Channel COM RX FIFO Interrupt	Channel n COM FIFO RX Interrupt	Interrupt flag for Common FIFOs in RX or GW mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in RX or GW mode belonging to the related channel
	Channel n COM FIFO One Frame RX Interrupt	One Frame Reception Interrupt flag for Common FIFOs belonging to the related channel	Clear the One Frame Reception Interrupt flags of Common FIFOs belonging to the related channel
	Channel n COM FIFO Full Interrupt	FIFO Full Interrupt flag for Common FIFOs in RX or GW mode belonging to the related channel	Clear the FIFO Full Interrupt flags of Common FIFOs in RX or GW mode belonging to the related channel
	Channel n TXQ One Frame Routing Interrupt	One Frame Routing Interrupt flag for TXQs in GW mode belonging to the related channel	Clear the One Frame Routing Interrupt flags of TXQs in GW mode belonging to the related channel
	Channel n TXQ Full Interrupt	TXQ Full Interrupt flag for TXQs in GW mode belonging to the related channel	Clear the FIFO Full Interrupt flags of TXQs in GW mode belonging to the related channel
Channel Error Interrupt	Channel n Error	Any channel related error flag in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register	Clear all channel related error flags in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register

Note 1. These interrupts are only set for TX Message Buffers that do not belong to an enabled TX Queue and are not pointing to a common FIFO.

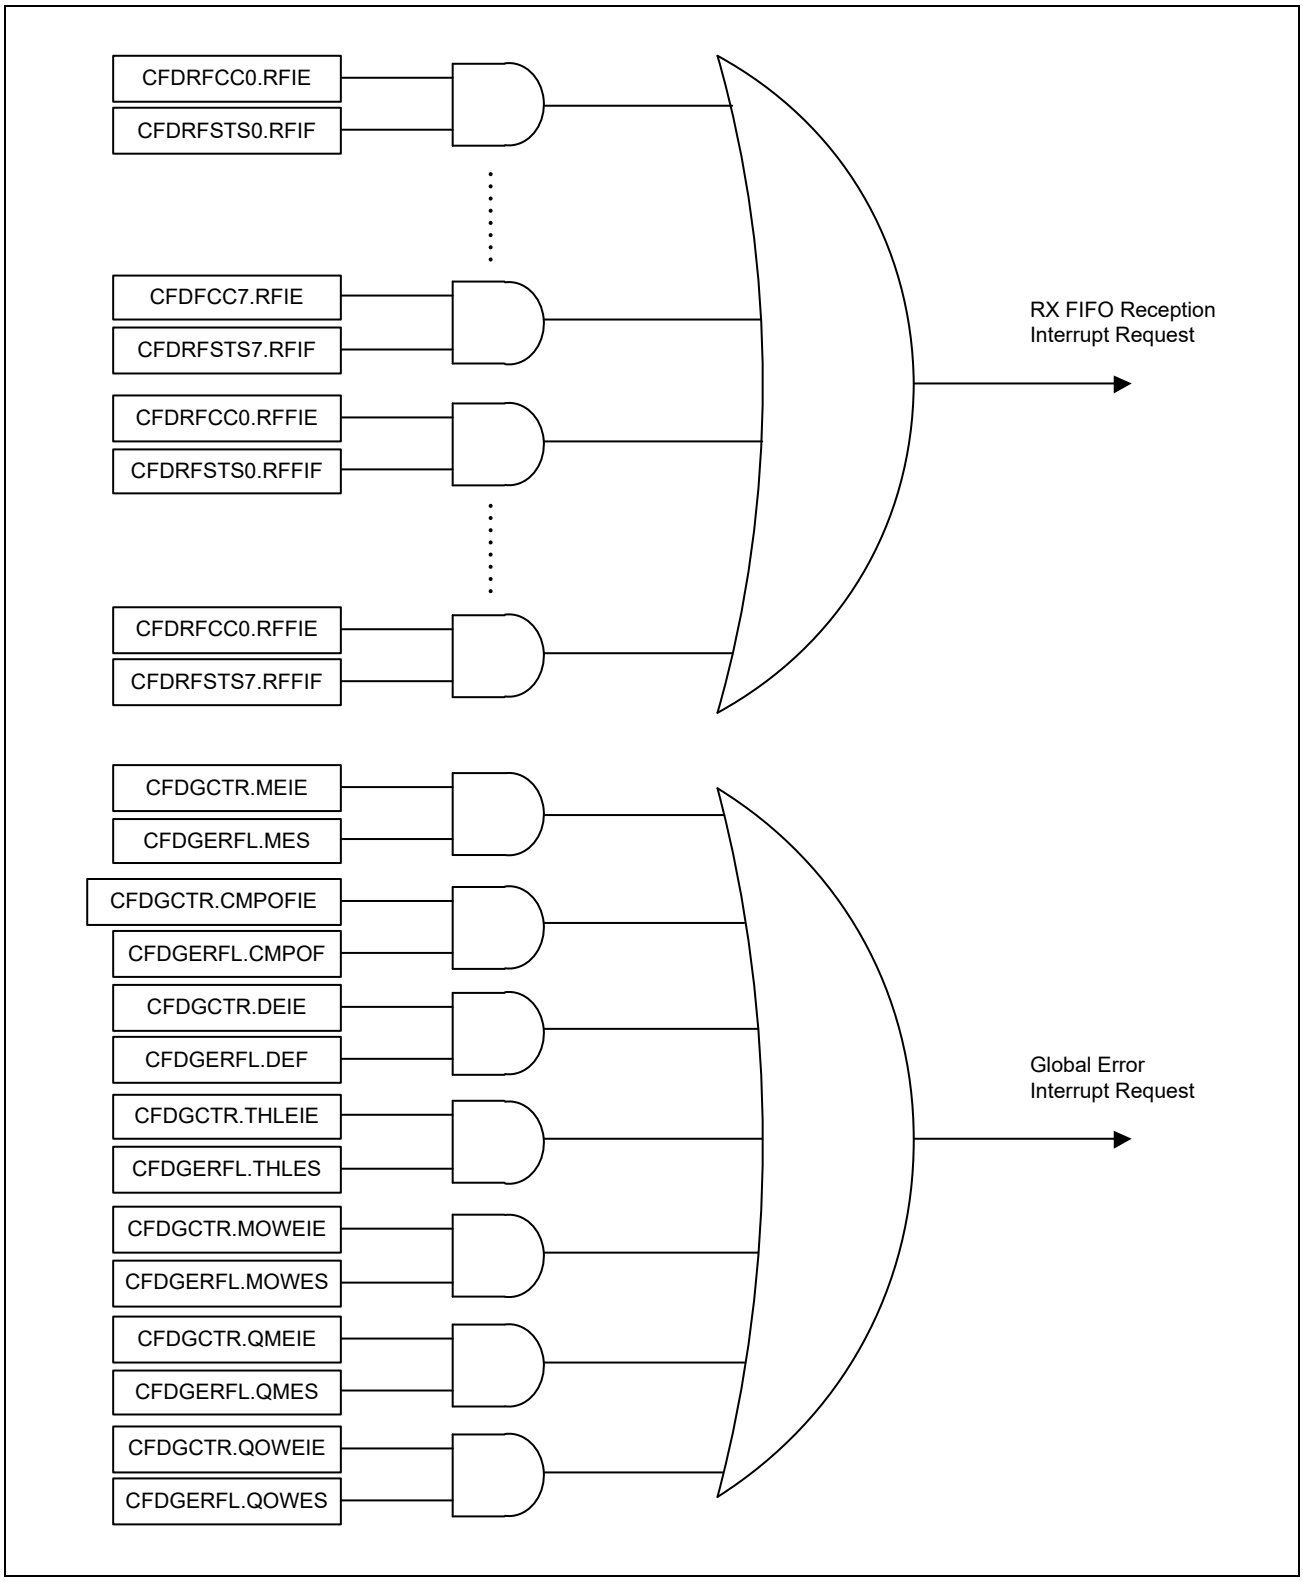

Figure 7.9-30 Block Diagram of Global Interrupt

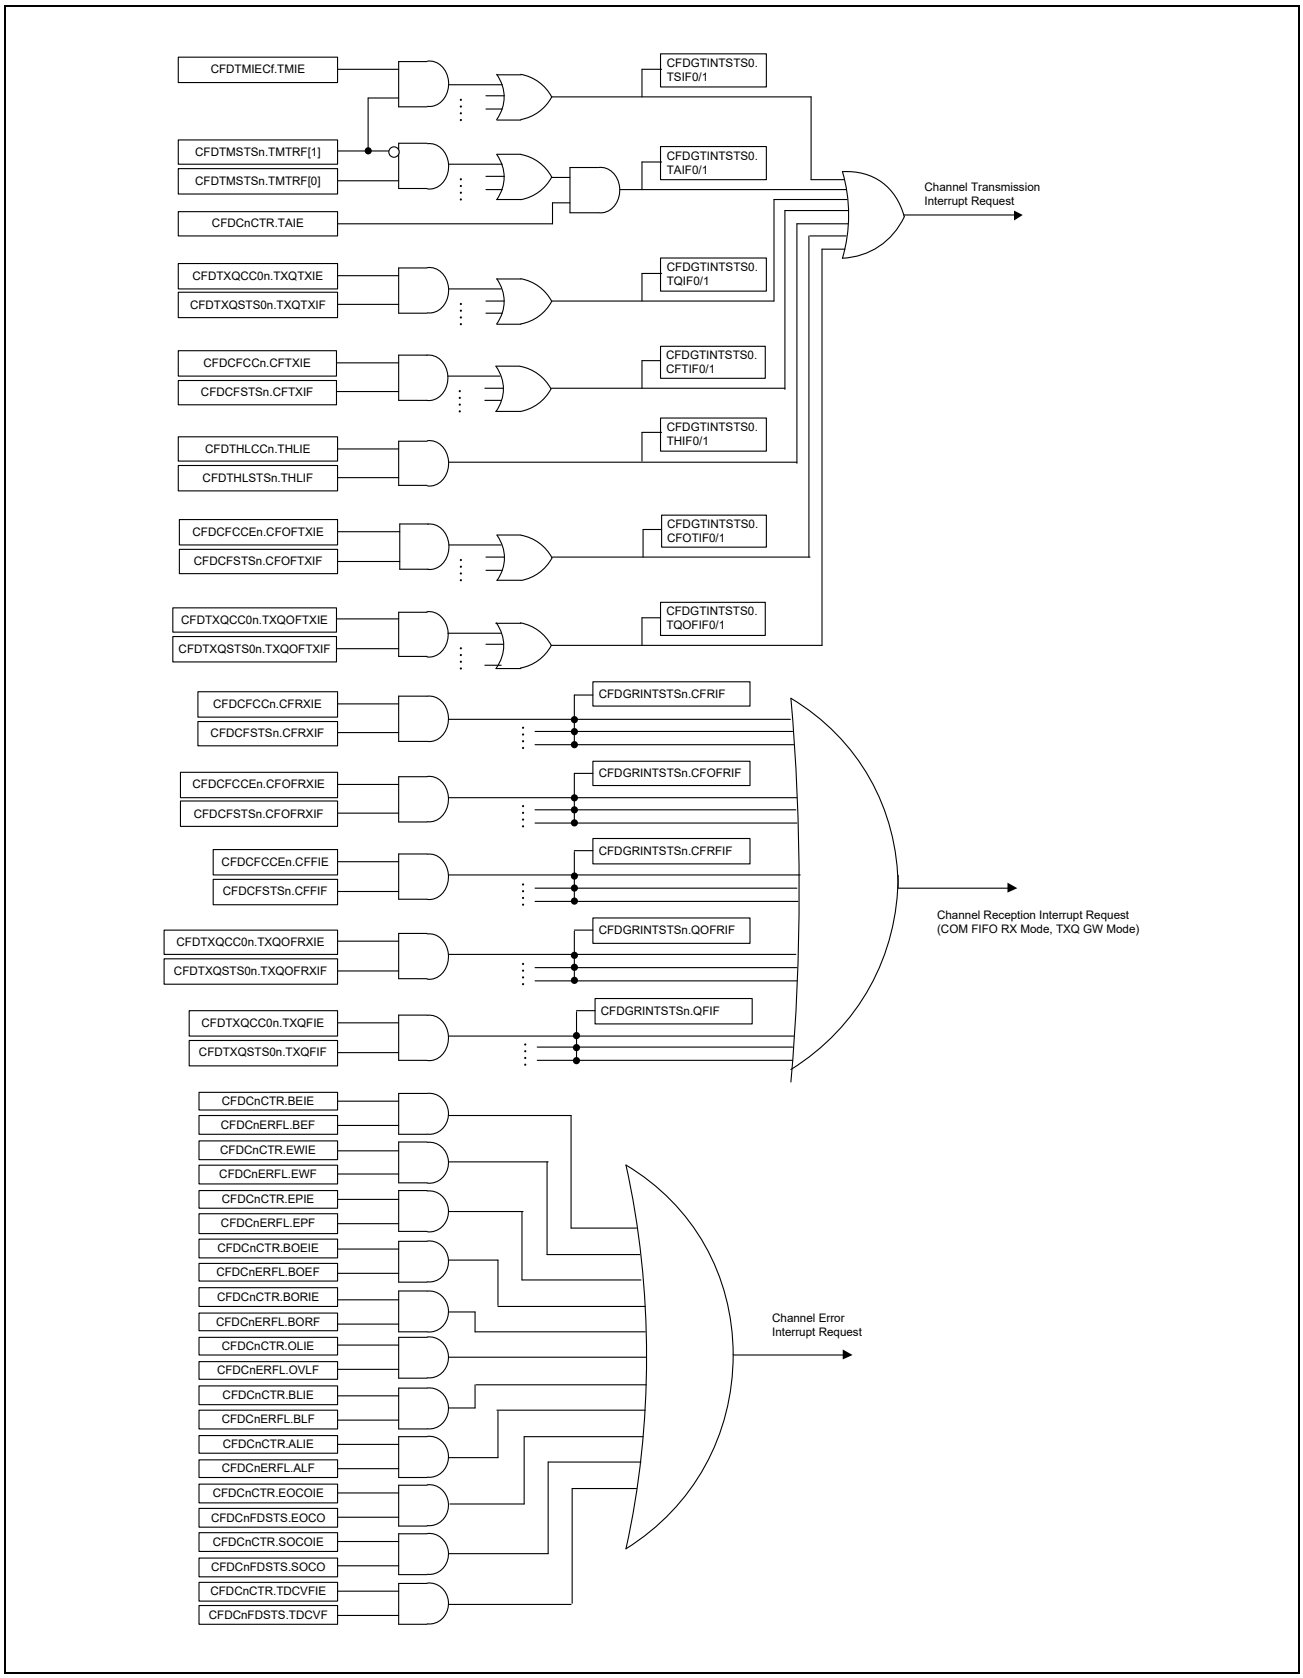

Figure 7.9-31 Block Diagram of Channel Interrupt

7.9.7.2 DMA Transfer

The CAN-FD module has some message buffer which can be associated with a DMA channel:

- Reception DMA
  - 8 RX FIFO Message Buffers
  - 6 Common FIFO Message Buffers
- Transmission DMA
  - 16 TXQ Message Buffers (TXQ0, TXQ3)
  - 6 Common FIFO Message Buffer

Figure 7.9-32 shows the potential DMA channels.

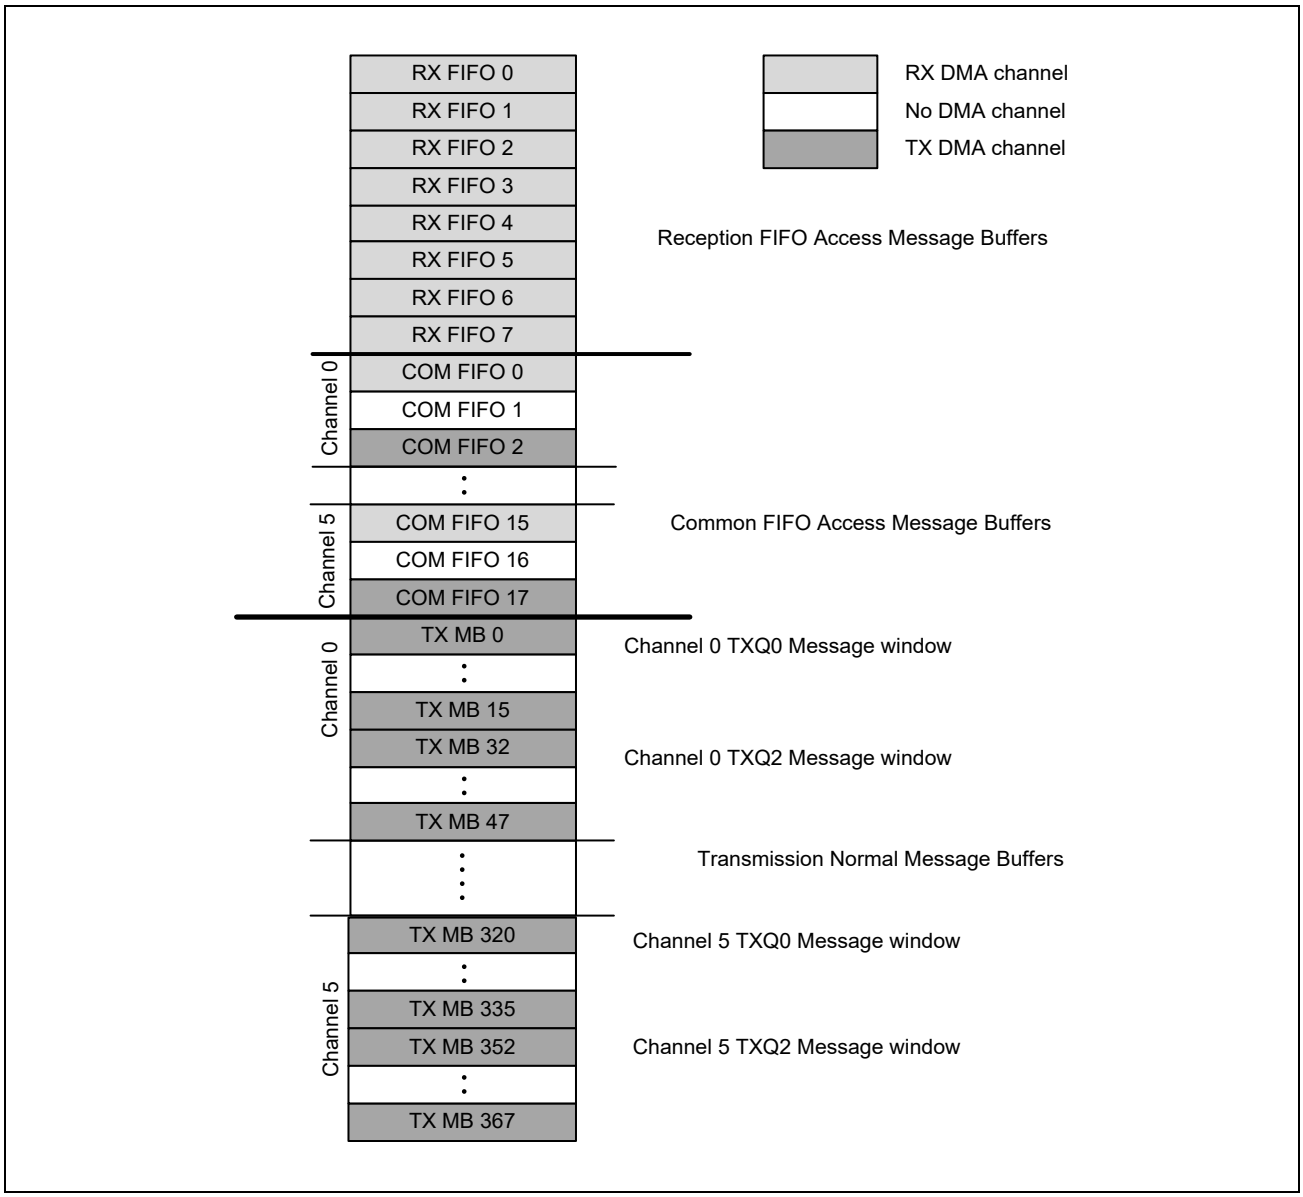

Figure 7.9-32 Message Buffer Connectable to DMA Channel

A DMA channel transfer request is generated for each FIFO entry to the DMAC when the related CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE is set to 1b and the belonging FIFO is not empty.

Reception FIFO interrupt should be disabled for this particular FIFO (CFDRFCCn.RFIE or CFDCFCCn.CFRXIE).

Use the regular start address for the DMA access window address and add 8000h to the regular start address for the debugger access window. See **Table 7.9-26**.

Table 7.9-26 DMA Channel Access Window Address

b = Message Buffer Component.Index	MBCP	Register	p	Start Address n = 0, 1
0 to number_of_RFMBCPs - 1	RFMBCPb	RFID	x	6000h + b × 0080h
		RFPTR	x	6004h + b × 0080h
		RFFDSTS	x	6008h + b × 0080h
		RFDFp	0 to 15	600Ch + p × 0004h + b × 0080h
0 to number_of_CFMBCPs_per_channel - 1	CFMBCPb	CFID	x	6400h + b × 0080h + n × 0180h
		CFPTR	x	6404h + b × 0080h + n × 0180h
		CFFDCSTS	x	6408h + b × 0080h + n × 0180h
		CFDFp	0 to 15	640Ch + p × 0004h + b × 0080h + n × 0180h

DMA FIFO pointer decrement is done automatically by reading the last configured data payload byte (CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

Note: The DMA must read the exact length of the configured data payload size (CFDRFCCn.RFPLS or CFDCFCCn.CFPLS).

The software debugger must access outside of the regular SFR address range from E000h to EFFFh.

Do not write to the FIFO and TXQ control registers when DMA is enabled.

The DMA enable of the particular DMA FIFO (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE) can be set at any time, the procedure in this section is a configuration flow for an initial setup.

When CFDCDTTCT.TQ0DMAE or CFDCDTTCT.TQ3DMAE or CFDCDTTCT.CFDMAE is set, the messages of the corresponding TXQ or Common FIFO can be handled by DMA controller.

Use the following procedure when the TXQ or the Common FIFO can be handled by DMA controller.

1. CPU checks the TXQ or the Common FIFO is not full.
2. When transmit data can be used, CPU sets this data to Common FIFO or TXQ.
   When using Common FIFO, transmit data is write in CFDCFID, CFDCFPTR, CFDCFFDCSTS, and CFDTMBCPb[i] registers.
   When using TXQ, transmit data is write in CFDTMID, CFDTMPTR, CFDTMFDCTR, and CFDTMDFp registers.
3. For Common FIFO, the common FIFO pointer is incremented automatically when DMA controller writes the last data payload byte configured by CFDCFCCn.CFPLS.
   For TXQ, if the data of 64 data payload is written, a TXQ pointer increases automatically. When payload data is less than 64 bytes, dummy data must be written in and 64 data payload size must be done.

Note: Only 32-bit write-access can be possible on the DMA message handling.

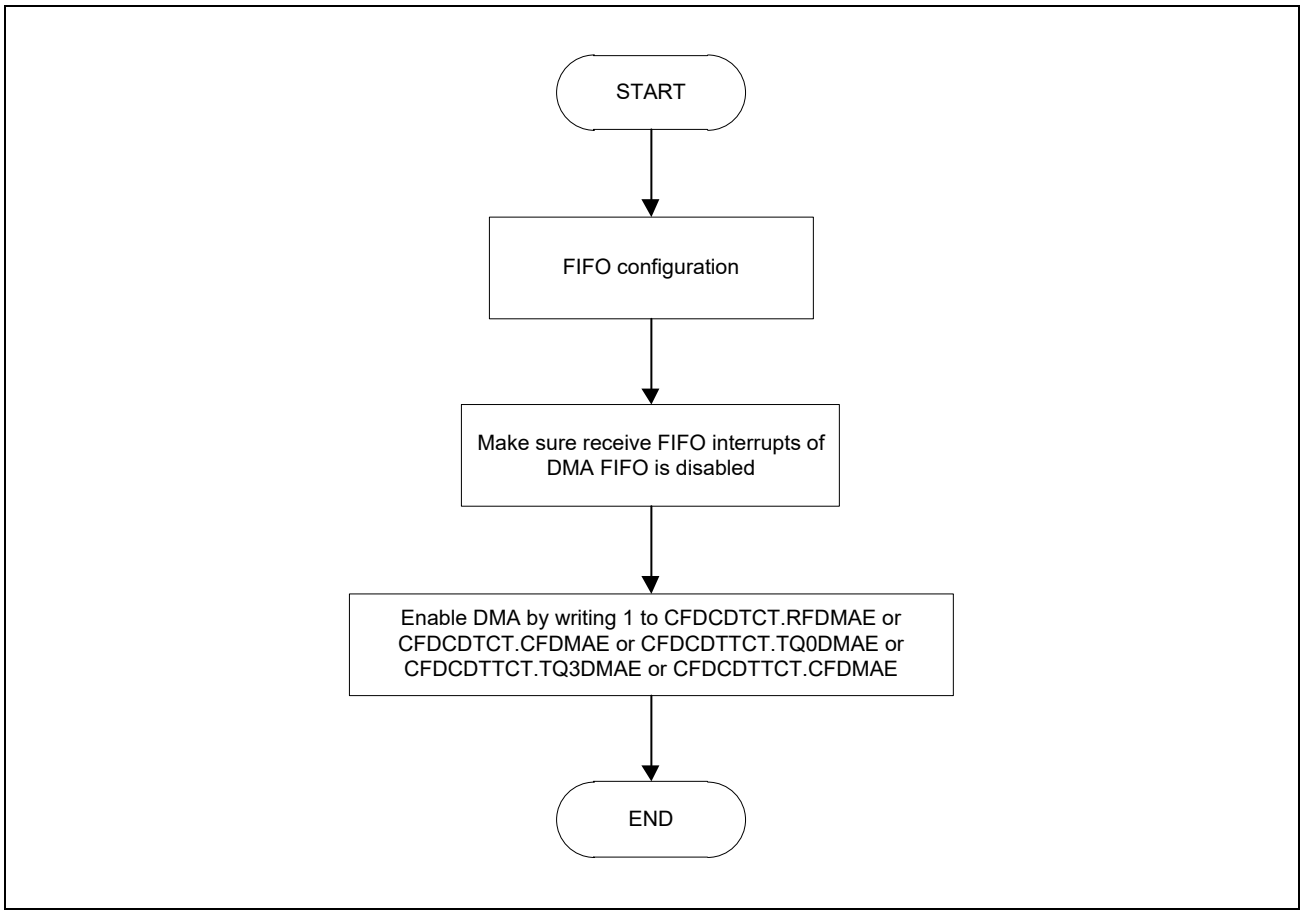

Figure 7.9-33 DMA Enable Flow

To disable a DMA transfer requested, disable the particular DMA enable bit (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer, then this must be completed first before further action can be taken. The transfer status can be identified by the CFDCDTSTS.RFDMASTS or CFDCDTSTS.CFDMASTS. For reference, see the flow in **Figure 7.9-34**. When the DMA is disabled, then consider what to do with the remaining or new incoming messages to this particular FIFO reception.

When the FIFO is not disabled, reception to the FIFO continues.

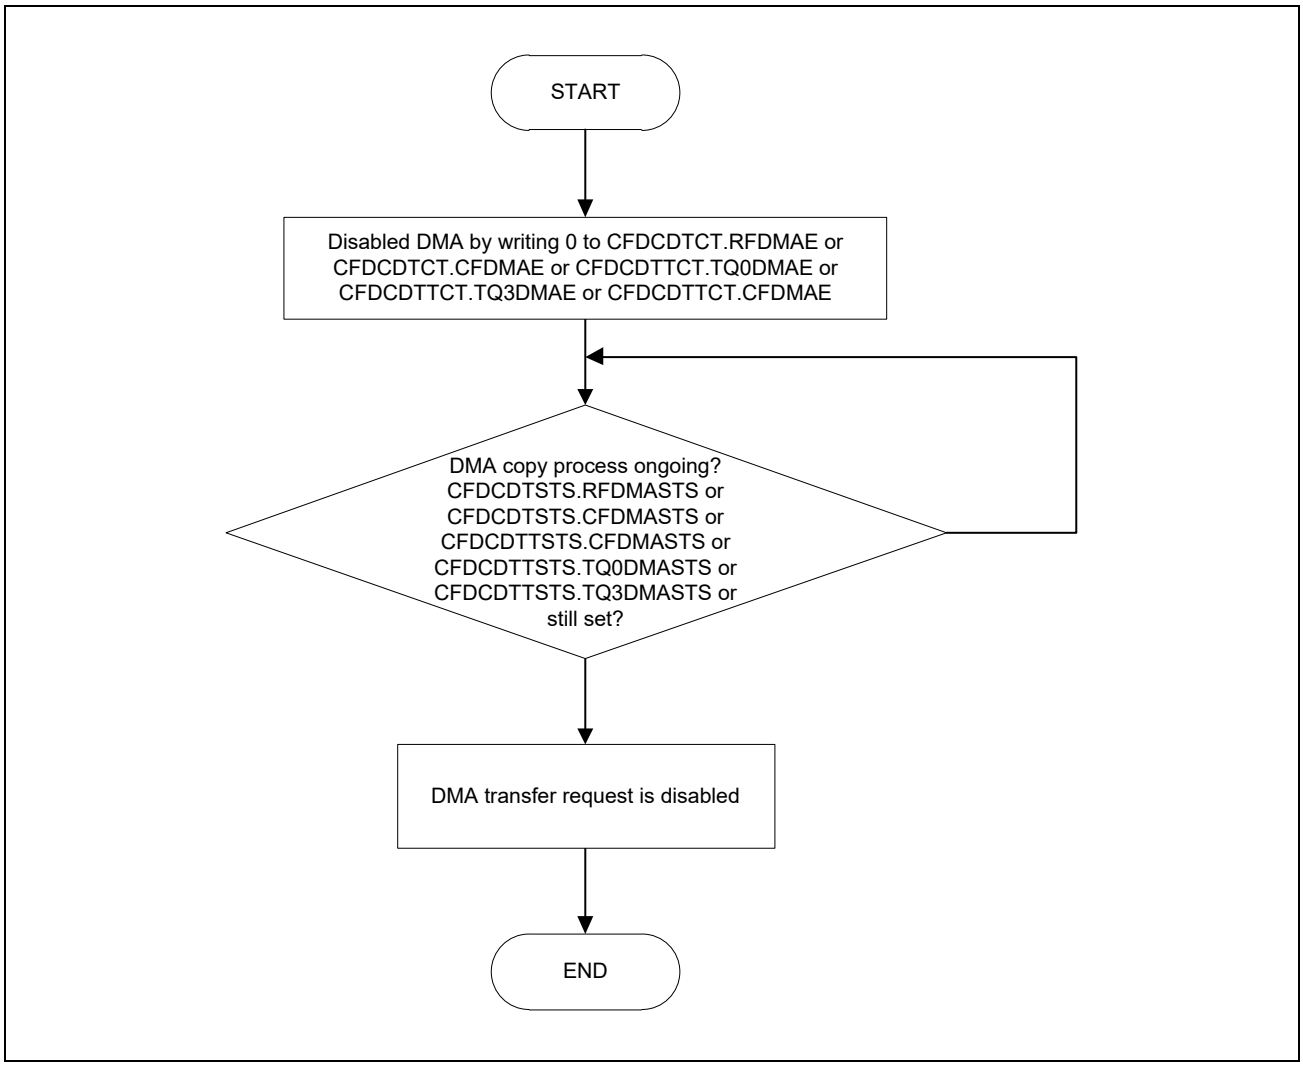

Figure 7.9-34 DMA Disable Flow

7.9.8 Reception and Transmission

7.9.8.1 Reception

FIFO buffers or Common FIFO buffers configured in RX mode or GW mode depending on the Acceptance Filter List entries are as follows:

- Up to 32 RX Message Buffers can be configured
- 8 RX FIFO buffers available
- Up to 6 Common FIFO buffers can be configured in RX mode or GW mode
- Up to 4 TX Queues can be configured in GW mode

7.9.8.1.1 Message Storage in RX Message Buffers

When a message is successfully received and stored in a RX Message Buffer, the corresponding New Data flag is set in the RX Message Buffer New Data Register.

The CAN message can be read from the corresponding RX Message Buffer.

If a new message is stored into a RX Message Buffer before the previous message in this message buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX Message Buffer. If such a loss of messages is not acceptable, then RX FIFO should be used to store related messages.

Note: Interrupts are not provided for the RX Message Buffers in the CAN-FD module and so the RX Message Buffer New Data Register should be accessed periodically to check if a new message has been stored in the RX Message Buffers.

Note: Unused data bytes are filled with 00h depending on the DLC value.

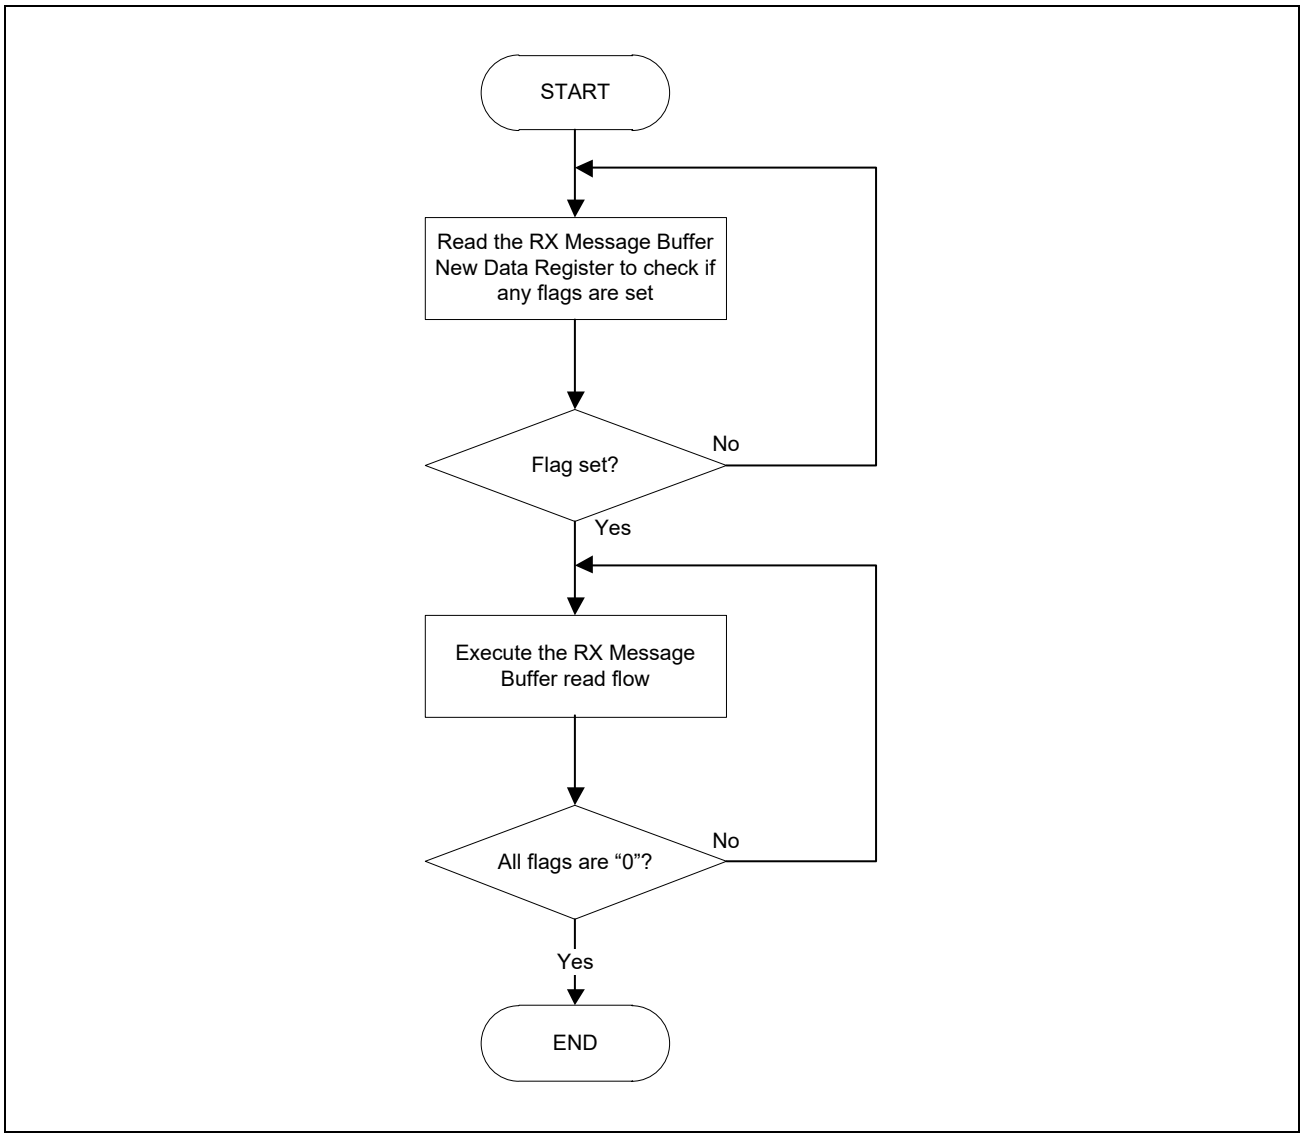

Figure 7.9-35 RX Message Buffer Message Access Flow

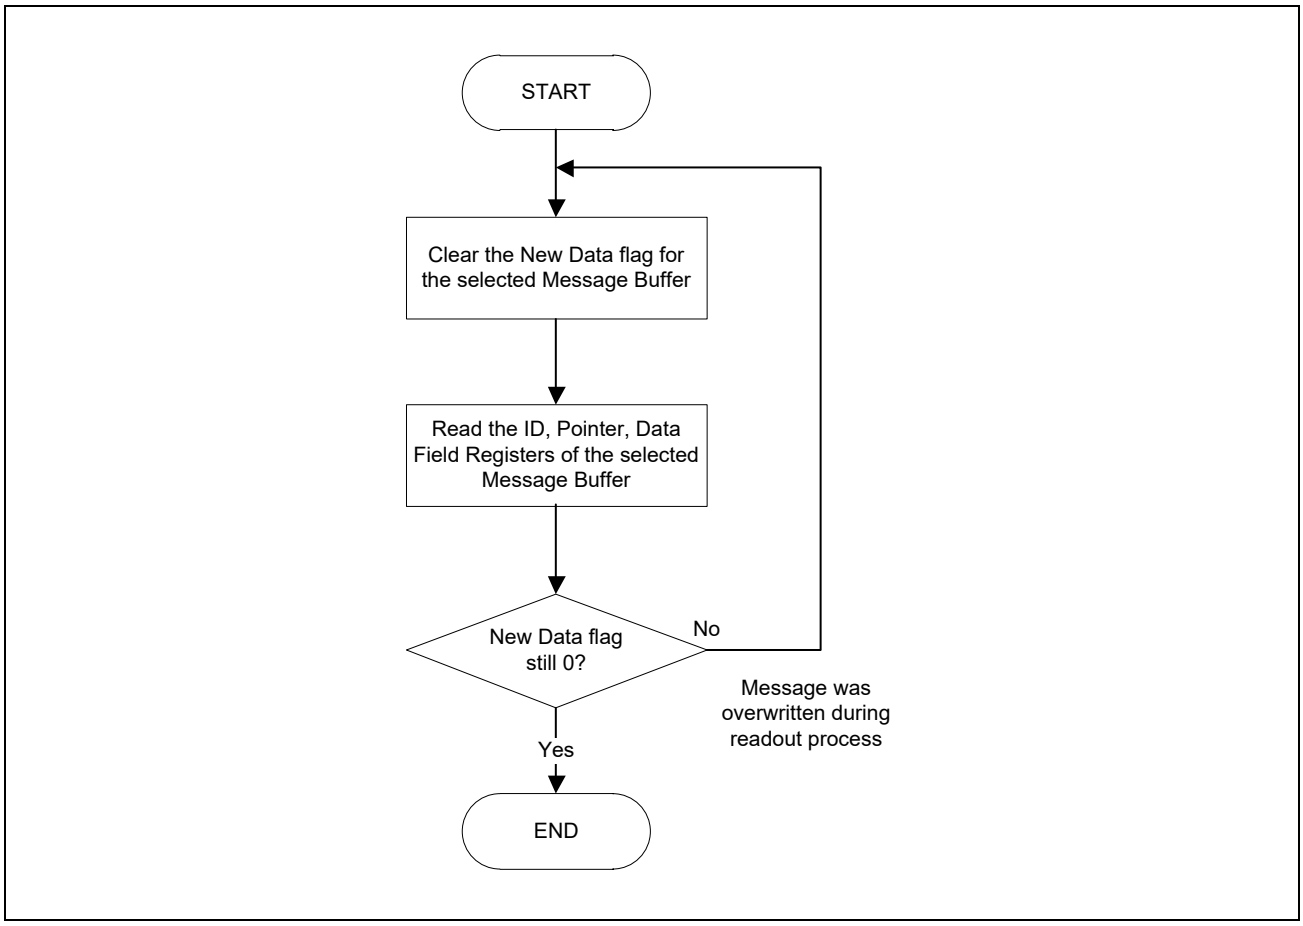

Figure 7.9-36 RX Message Buffer Read Flow

7.9.8.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Common FIFO buffers configured in RX or GW mode should be configured based on system requirements.

The CFDGAFLP1n.GAFLFDP[31:0] field in the matching AFL entry selects the FIFO buffers to which the related reception message is stored.

When the received message is stored in one or more RX FIFO buffers or Common FIFO buffers configured in RX mode or GW mode, the message counter value is incremented in the corresponding RX FIFO Status Registers or Common FIFO Status Registers.

Depending on the configuration of the FIFO buffers, an interrupt may also be generated.

The message can be read from the corresponding FIFO Access registers.

Note: Because many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, the FIFO Full flag is set.

When the value FFh is written to the corresponding FIFO Pointer Control Register, the message count is decremented by 1.

Only write FFh to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO Full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a message due to overrun condition.

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0b:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded and CFDCFSTSn.CFMLT bit is set to 1b.
- When CFDCFCCEn.CFMOWM = 1b:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message.
  The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.
  The CFDCFSTSn.CFMOW bit is then set to 1b, which notifies that the oldest message has been overwritten with the received message.
  In addition, if a CAN bus error or arbitration-lost for the transmitting message occurs in the transmit/receive FIFO buffer full, the transmitting message is lost and retransmission of the message is not performed. The read point moves to the next message automatically.

Do not write change for this bit when the CFDCFCCn.CFE bit is 1b. Common FIFO can set interrupt when:

- CAN frame reception is completed
- FIFO is in full status in RX mode or GW mode

Note: The message lost can be set only in RX or GW mode by CAN, the flag is not set when the CPU is overloading the FIFO buffers.

Note: When CFDGAFLP0n.GAFLSRDi (i = 0 to 2) is set and CFDTXQCCin.TXQGWE (i = 0 to 2, n = 0, 1) is also set, a receiving frame is stored in the target TXQ as send data by routing.

The RX FIFO Buffers and the Common FIFO Buffers configured in RX or GW mode can be disabled at any time by clearing the CFDRFCCn.RFE or CFDCFCCn.CFE bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

When the CFDRFCCn.RFE or CFDCFCCn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO Buffers are lost and no further messages can be stored into the FIFO.

When the RX FIFO Buffers or Common FIFO Buffers configured in RX mode are assigned as DMA channel, software should not access the FIFO Access Register of this FIFO buffer or write FFh to the FIFO Pointer Control Register (CFDCFPCTRn.CFPC or CFDRFPCTRn.RFPC), because this could lead to unintended FIFO message decrement. The DMA channel controls the FIFO decrement automatically.

Note: If the interrupt flag is set for a FIFO Buffer and then the FIFO is disabled, the interrupt flag is not automatically cleared. The interrupt flag should be cleared before disabling the FIFO.

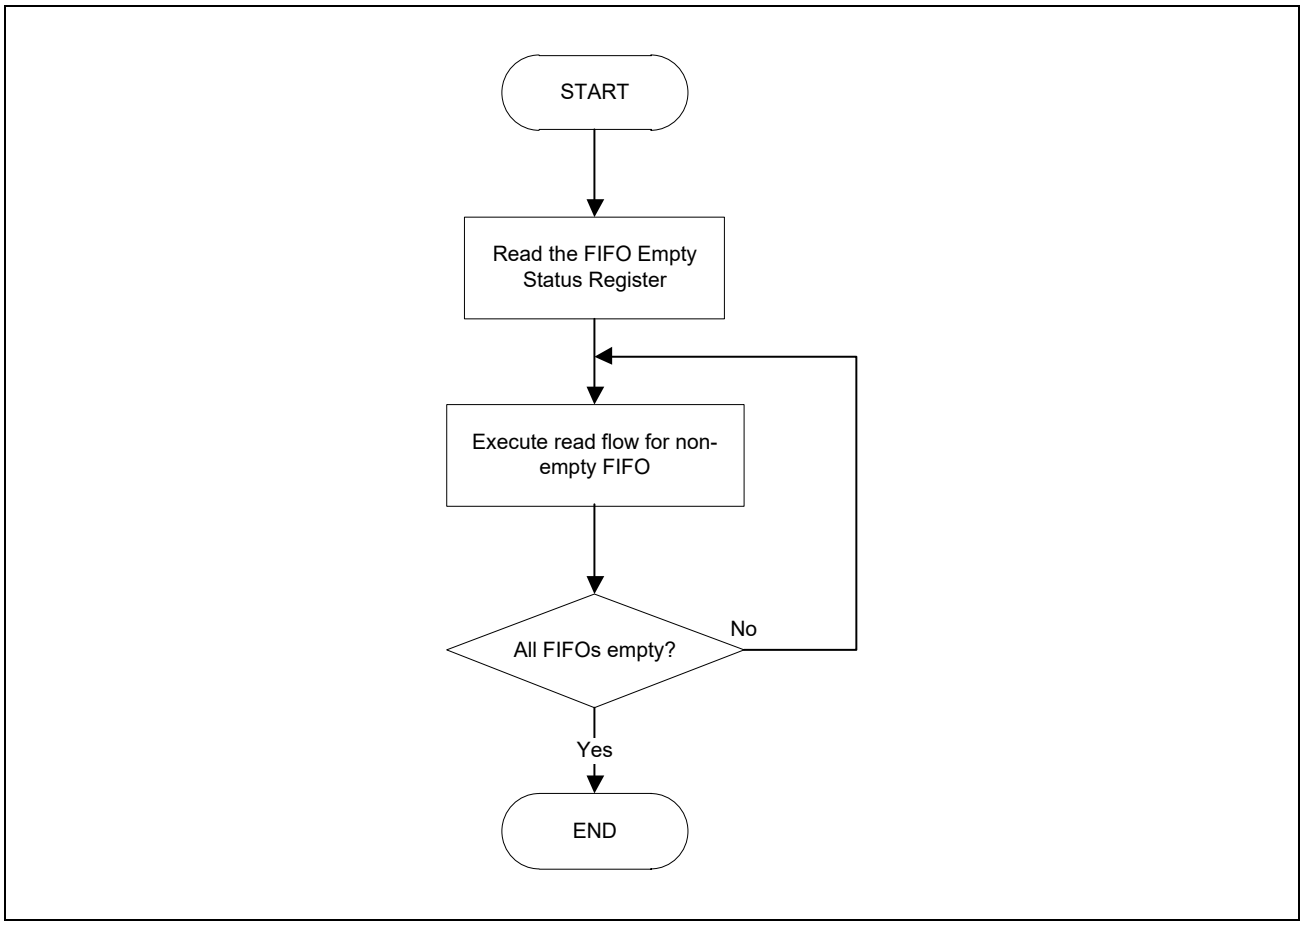

Figure 7.9-37 FIFO Buffer Message Access Flow (Example for Polling Case)

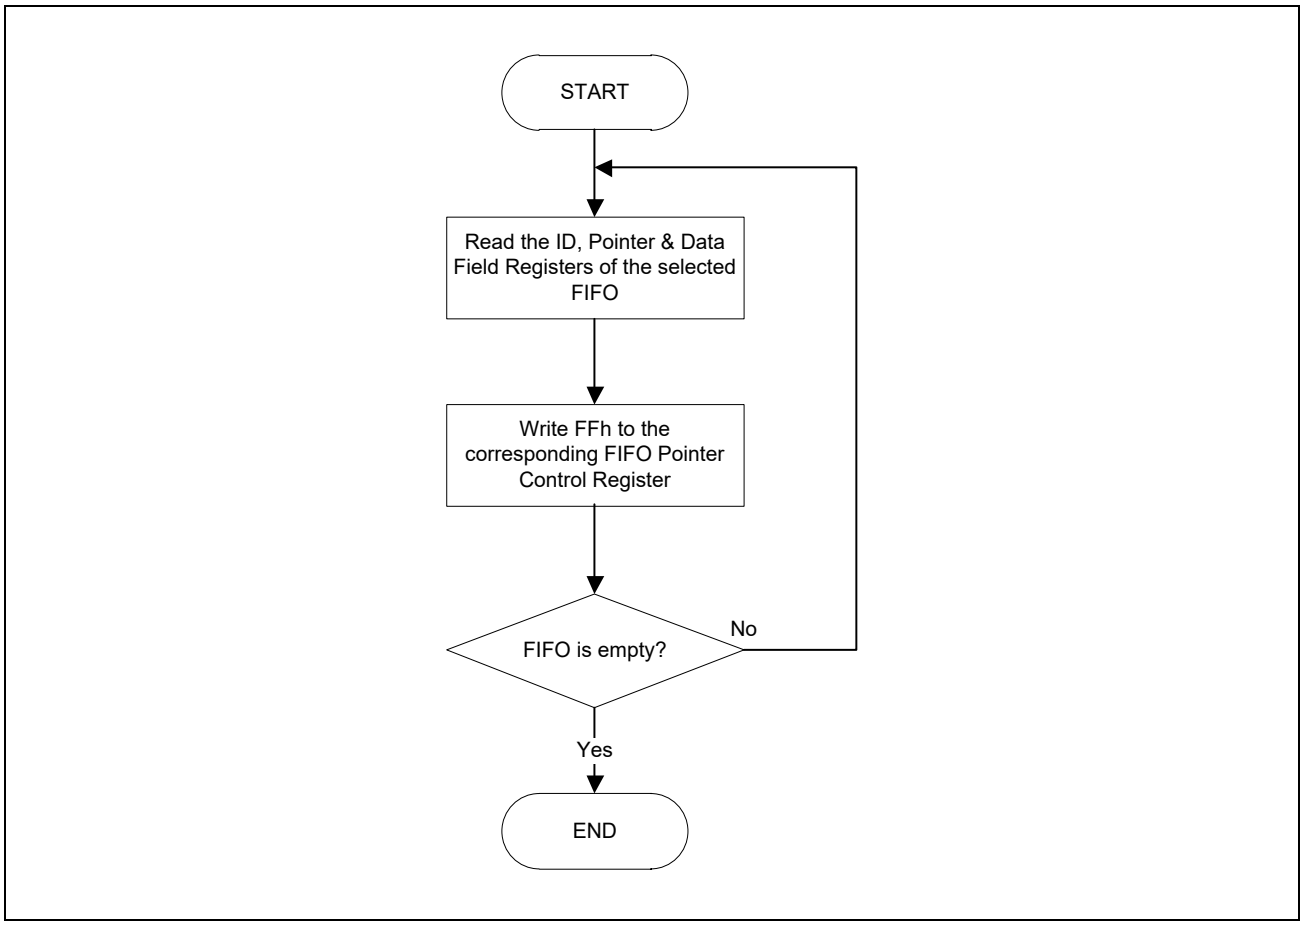

Figure 7.9-38 RX FIFO Buffer Read Flow (Example for Polling Case)

Note: When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even if it clears an interruption flag after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the deadline, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

7.9.8.1.3 Timestamp

The Timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value is captured based on the CFDGFDCFG.TSCCFG[1:0] configuration (at the sample point of start of frame, point in time when the frame is valid, or for CAN-FD frames also at the sample point of the RES bit). For reception, it is stored together with the message ID and Data into the target RX Message Buffer or RX/GW FIFO.

For transmit message, the Timestamp counter value is stored as part of the TX History List entry.

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured with the CFDGCFG.TSSS bit of the Global Configuration Register. If it is 0b, the peripheral clock is used. If it is 1b, the selected CAN channel bit time clock is used.

The channel selection is done with the CFDGCFG.TSBTCS bit of the Global Configuration Register.

Care must be taken when using selected CAN channel bit time clock as the clock source. When entering Channel Halt mode or Channel Reset mode for this channel, the Timestamp counter is stopped. Therefore, for other CAN channels, the Timestamp counter value is also not updated.

If peripheral clock is selected as the Timestamp counter clock source, Channel modes do not influence the Timestamp counter function.

The source clock for the Timestamp counter can be divided by a factor defined by the CFDGCFG.TSP bits (Timestamp Prescaler) in the Global Configuration Register.

The Timestamp counter can be reset to 0000h with the CFDGCTR.TSRST bit (Timestamp Reset).

7.9.8.2 Transmission

There are several possible transmission configurations for each channel:

- Normal transmission
- FIFO transmission
- Gateway transmission
- TX Queue transmission
  A fixed number of transmission message buffers (32 TX message buffers) are dedicated for each channel. These message buffers are only used for transmission and cannot be configured for reception.
  Additionally transmission from TX Queue and/or Common FIFO in TX or GW mode can be configured in the following way (see **Figure 7.9-39**):
  - TX Queue: Up to 16 transmission message buffers for one channel can be grouped to form a TX Queue with a common access window.
    Upper transmission message buffers are used to form the TXQ1 or TXQ3. Lower transmission message buffers are used to form the TXQ0 or TXQ2.
    Transmission control and status registers of these transmission message buffers should not be used. One channel has four TX Queues. Each TXQ has an access window:
    - TXQ0 is transmission Message Buffer 0 of each channel
    - TXQ1 is transmission Message Buffer 31 of each channel
    - TXQ2 is transmission Message Buffer 32 of each channel
    - TXQ3 is transmission Message Buffer 63 of each channel

    When using TXQ1 and TXQ0 simultaneously, the sum of the depths of TXQ1 and TXQ0 should not exceed 16.
    When using TXQ3 and TXQ2 simultaneously, the sum of the depths of TXQ3 and TXQ2 should not exceed 16.
- Common FIFO (TX/GW mode): Each Common FIFO in TX or GW mode is linked to a dedicated channel.
  Each channel has a fixed number of three Common FIFOs assigned to it. Within the channel, a Common FIFO configured in TX or GW mode, can be freely linked (assigned) between 32 and 47 transmission message buffers (only one FIFO to one transmission message buffer).
  The Common FIFO buffer then replaces the transmission message buffer linked to it.
  Transmission control and status registers of these transmission message buffers should not be used.

See **Figure 7.9-28** for information on Common FIFO buffer assignment to related channels.

Note: Common FIFO buffers should not be linked to TX message buffers that are already part of a TX Queue.

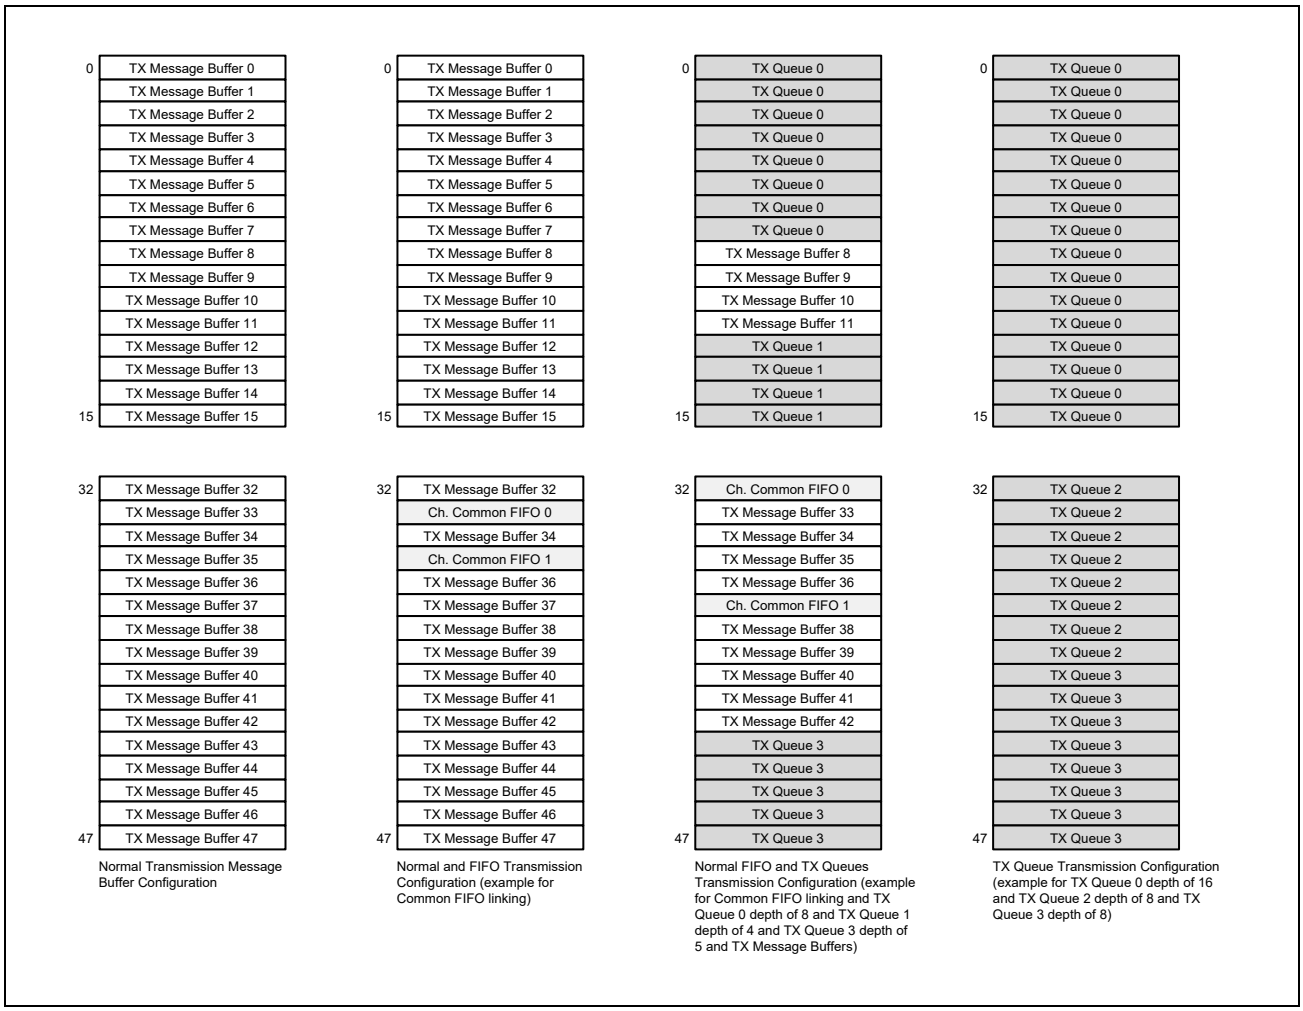

Figure 7.9-39 Channel Transmission Message Buffer Configuration

7.9.8.2.1 Transmission Priority

If two or more transmission message buffers of a channel are configured for transmission, the transmission priority in the CAN-FD module can be selected from the following two modes:

- CAN ID priority
- Message buffer number priority

The transmission priority mode is common for all message buffers and all CAN channels. It can be configured with the CFDGCFG.TPRI bit in the Global Configuration Register.

For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the TX message buffers linked to the Common FIFO buffers configured in TX mode or GW mode.

However, message buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All TX message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the TX message buffers linked to the Common FIFO buffers configured in TX mode or GW mode and includes the TX Queue message buffers.

If the ID of two or more message buffers is the same, the smaller message buffer number has higher priority for transmission.

Note: For Common FIFO buffers configured in TX mode or GW mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.
If the message is being transmitted from the FIFO, the next pending message within the same FIFO will be considered in the transmission arbitration.
In contrast to this, all transmission message buffers of a TX Queue participate in internal transmission arbitration.

Figure 7.9-40 shows the transmission configuration flow.

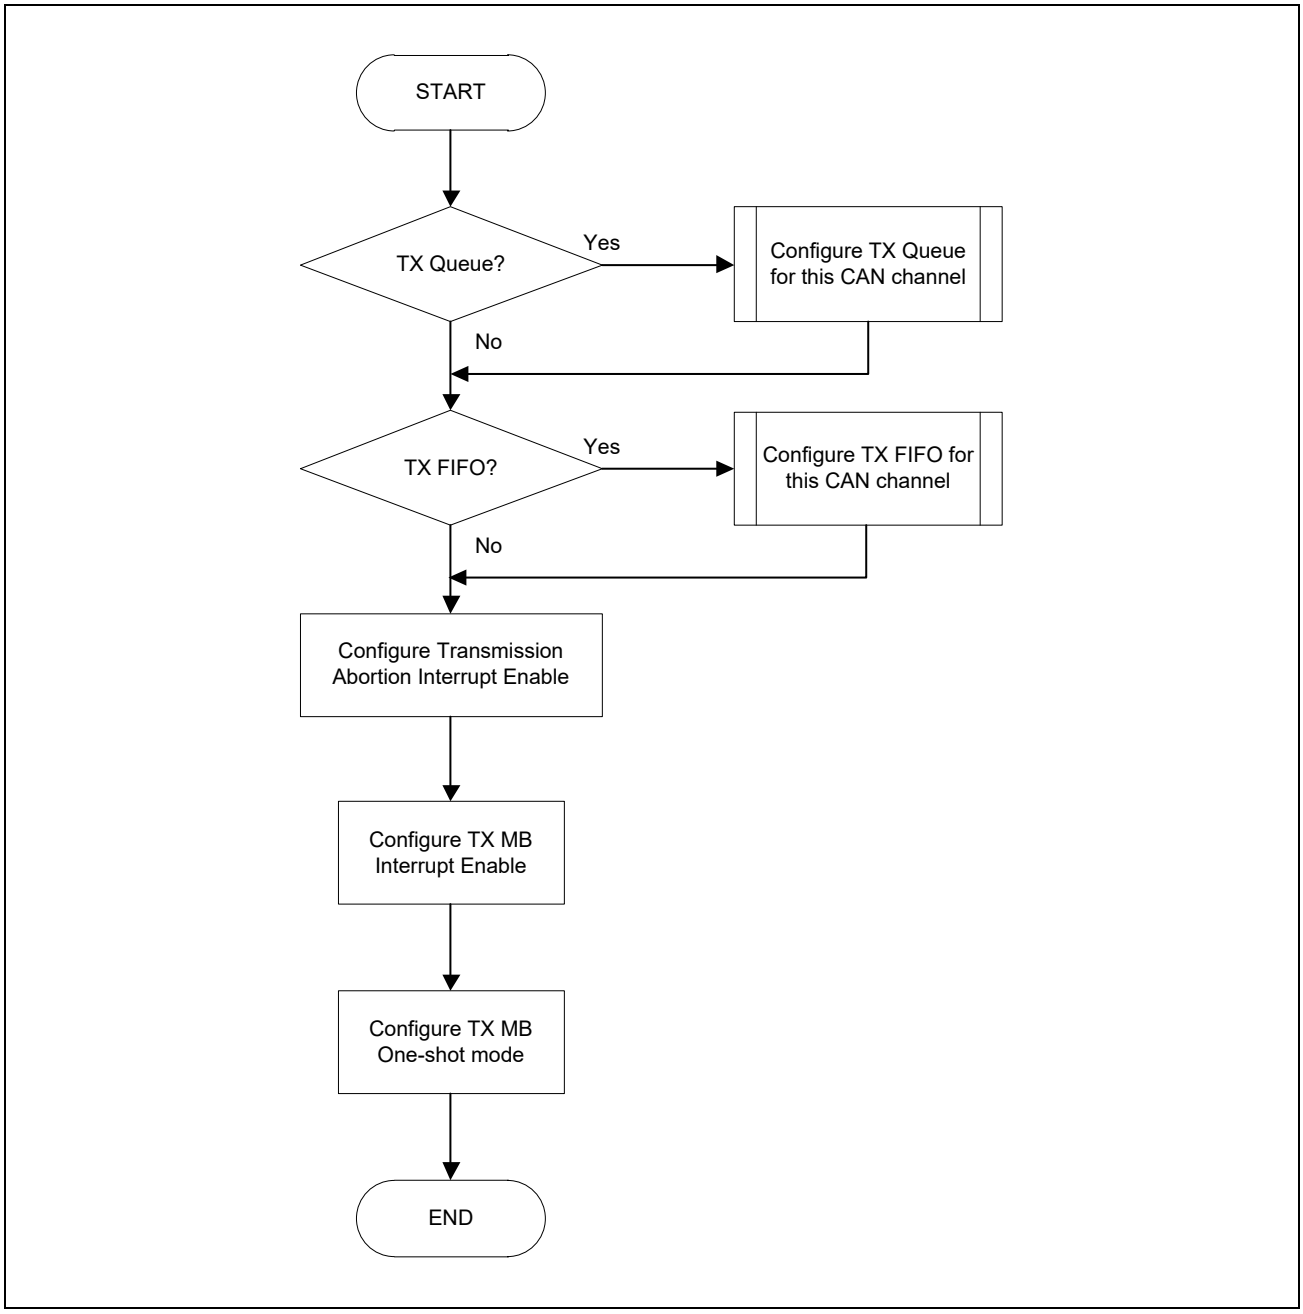

Figure 7.9-40 Transmission Configuration Flow

7.9.8.2.2 Normal Transmission

Each transmission message buffer has two modes of message transmission:

- Regular transmission mode
  If the message buffer is placed in regular transmission mode, the data frame or remote frame set in that message buffer can be transmitted.
  Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the TX Message Buffer Status Registers. These bits are set to 10b or 11b when the regular transmission is successful.
  When arbitration is lost or an error occurs, message transmission will be attempted further if no transmission abort request is set for this transmission message buffer.
  New internal transmission arbitration for this channel is performed for all message buffers with transmission request.
- One-shot transmission mode
  When the CFDTMCn.TMOM bit of the TX Message Buffer Control Registers is set for a transmission message buffer, then the message buffer is placed in one-shot transmission mode and attempts to transmit a message only once.
  Completion of one-shot transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSn.TMTRF[1:0]) in the TX Message Buffer Status Registers. The CFDTMSTSn.TMTRF[1:0] bits are set to 10b or 11b when the one-shot transmission is successful.
  The CFDTMSTSn.TMTRF[1:0] bits are set to 01b when arbitration is lost or an error occurs during the transmission of the related message buffer.
  Additional message transmission will not be attempted in this case.

The regular transmission request procedure after a configuration is shown in **Figure 7.9-41**.

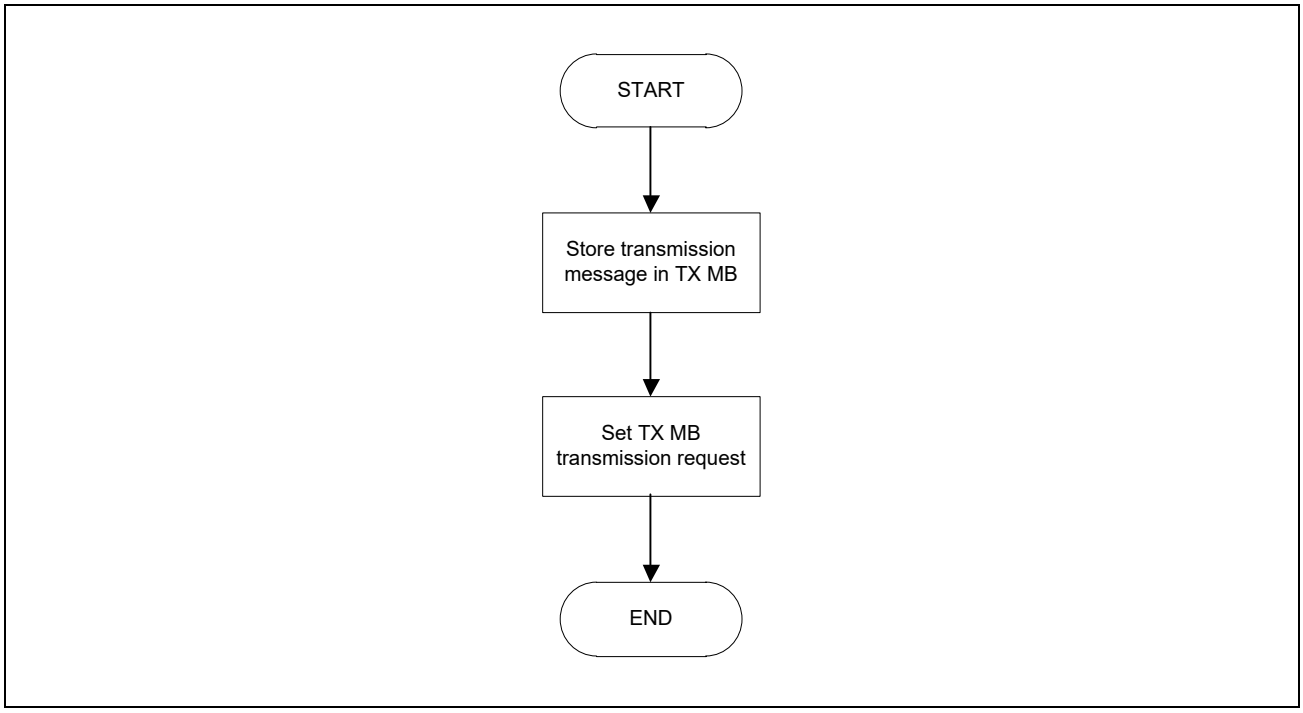

Figure 7.9-41 Transmission Request Procedure Using Normal TX Message Buffer Mode

(1) TX Message Buffer Control Register Setting

Table 7.9-27 shows configuration of the normal CAN transmission mode.

Table 7.9-27 Configuration of CAN Transmission Mode

Transmission Request CFDTMCn.TMTR	Transmission Abortion Request CFDTMCn.TMTAR	One Shot Enable CFDTMCn.TMOM	Communication Activity
0	0	0	Message buffer is disabled
0	0	1	Message buffer is disabled
1	0	0	Configured as a transmission message buffer for a data frame or a remote frame
1	0	1	Configured as a one shot transmission message buffer for a data frame or a remote frame
1	1	0	Transmission abortion is requested
1	1	1	One shot transmission abortion is requested

The configuration bits can be configured in the TX Message Buffer Control Registers.

Figure 7.9-42 shows timings for successful transmission for two message buffers of one channel.

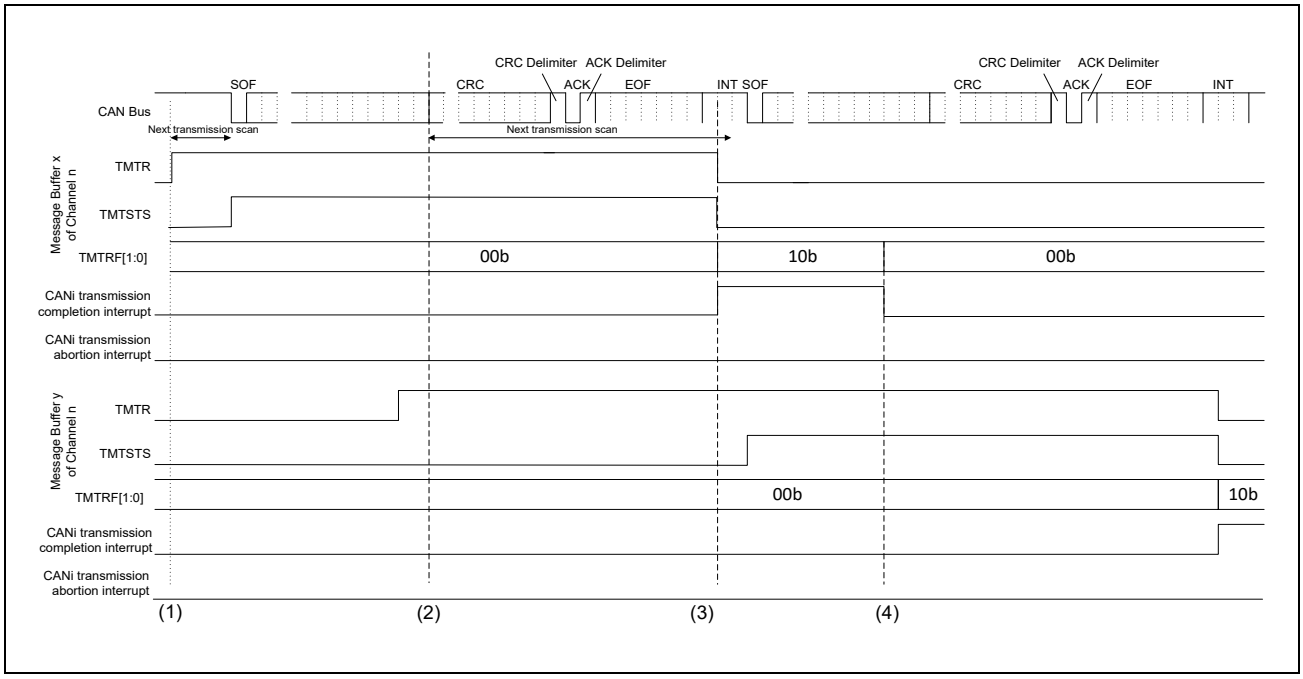

Figure 7.9-42 Timing of Request and Flag Bits for Successful Transmission

1. If the CFDTMCn.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, message buffer scanning procedure starts to determine the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSn.TMTSTS bit in the related TX Message Buffer Status Registers is set (Transmitting/Transmitter), and CAN channel starts the transmission*1.
2. On the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.
   The scan time can be delayed due to other transmission scan on other channels, but it will be finished before Intermission 3 to be able to continue transmission without any gaps.

3. If the message is successfully transmitted, the CFDTMSTSn.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 10b and CFDTMSTSn.TMTSTS and the CFDTMCn.TMTR bits are cleared. When the TMIE bits in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line the CFDTMSTSn.TMTRF flag bits must be cleared.
4. Before starting the next transmission, clear the CFDTMSTSn.TMTRF[1:0] bits. Load the next message in the transmission message buffer and set the CFDTMCn.TMTR bit again. CFDTMCn.TMTR bit cannot be set again before CFDTMSTSn.TMTRF[1:0] bits are cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSn.TMTSTS bit is cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs either during the transmission or following the loss of arbitration, then during Error Frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

Note: The setting point of CFDTMSTSn.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

Figure 7.9-43 shows timings for transmission abort for two message buffers of one channel.

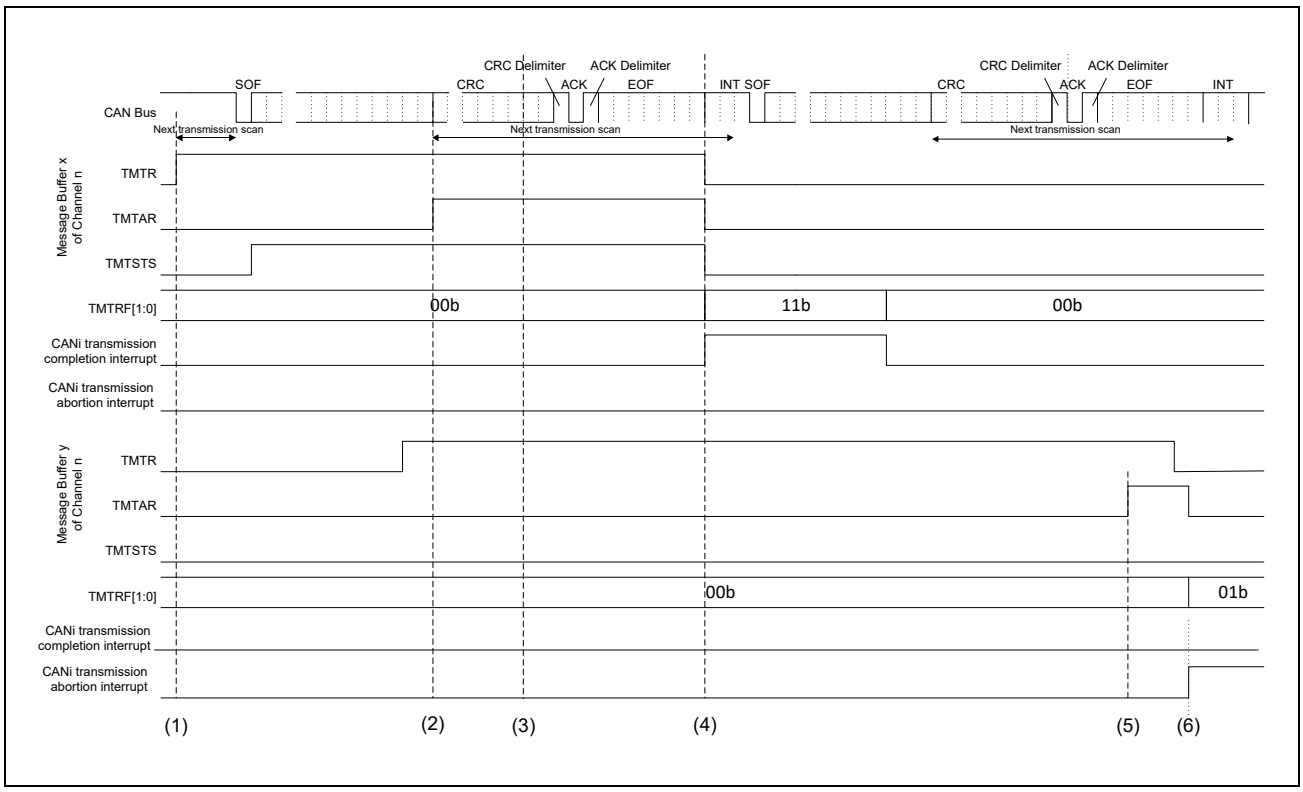

Figure 7.9-43 Timing of Request and Flag Bits for Transmission Abort

1. If the CFDTMCn.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, message buffer scanning procedure starts to determine the highest priority message buffer for transmission.
   When the transmission message buffer is determined, the CFDTMSTSn.TMTSTS bit in the TX Message Buffer Status Registers is set (Transmitting/Transmitter), and CAN channel starts the transmission*[1].

2. If the CFDTMCn.TMTAR bit is set when the related message buffer is already selected for transmission or currently transmitting, the message is not aborted, if no error occurs or arbitration is lost.
3. On the first CRC bit, the transmission scanning procedure starts for the next transmission. In this example timing diagram, message buffer y is not selected as the next transmission message buffer.
   The scan time can be delayed due to other transmission scan on other channels, but it will be finished before Intermission 3 to be able to continue transmission without any gaps.
4. If the message is successfully transmitted, the CFDTMSTSn.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 11b and CFDTMSTSn.TMTSTS and the CFDTMCn.TMTR bits are cleared. When the TMIE bits in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated.
   To clear the related interrupt line, clear the CFDTMSTSn.TMTRF[1:0] bits.
5. Another CAN node is transmitting on the CAN bus (CFDTMSTSn.TMTSTS not set). If the CFDTMCn.TMTAR bit is set when the related channel is under transmission scan, the transmission request cannot be cleared.
6. After internal processing time, the transmission is aborted and the CFDTMSTSn.TMTRF[1:0] bits are set to 01b. If the message buffer is not transmitting or selected as the next transmission message buffer or under transmit scan, then the abort is immediately accepted and the corresponding CFDTMSTSn.TMTRF[1:0] bits in the TX Message Buffer Status Registers are set to 01b.
   In addition, CFDTMCn.TMTR, and CFDTMCn.TMTAR bits are cleared automatically.
   When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set, an interrupt is generated for successful transmission abort.
   To clear the related interrupt line, clear the CFDTMSTSn.TMTRF[1:0] bits.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSn.TMTSTS is cleared. The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit. If an error occurs, either during the transmission, or following the loss of arbitration, then during Error Frame, the transmission scanning procedure is performed again to search for the highest priority transmission Message Buffer.

7.9.8.2.3 TX FIFO or GW FIFO Transmission

Three common FIFO buffers are assigned to each channel. The three FIFO buffers can be linked to any normal TX Message Buffer position for this channel by the CFDCFCCn.CFTML[4:0] bits in the Common FIFO Configuration/Control Register if configured in TX or GW mode.

When the transmission scan starts and the FIFO buffer corresponding to this TX Message Buffer is enabled, the relevant message in the FIFO buffer participates in the transmission scan.

Configuration of a TX Message Buffer linked to a FIFO buffer configured in TX or GW mode should not be done.

(1) TX FIFO Operation

CAN messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value FFh is written into the corresponding FIFO Pointer Control Register, the message count of the related FIFO is incremented by 1.

Only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers.

If the message count matches the FIFO Depth, the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding CAN-FD module channel logic.

When a message is successfully transmitted from the TX FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The interrupt generation conditions for the TX FIFO buffers can be configured by configuring the CFDCFCCn.CFIM bit in the corresponding Common FIFO Configuration/Control Registers.

If CFDCFCCn.CFIM bit is 0b, an interrupt is generated when the last message is successfully transmitted from the TX FIFO buffer.

If CFDCFCCn.CFIM bit is 1b, an interrupt is generated for every successfully transmitted message from the TX FIFO buffer.

Common FIFO can set interrupt, when CAN frame transmitted is completed.

The Common FIFO buffers configured in TX mode can be disabled by clearing the CFDCFCCn.CFE bit in the Common FIFO Configuration/Control Registers. If this bit is cleared to 0b, the FIFO Empty flag is set as follows:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission.

Note: The Common FIFO buffer is considered as disabled after clearing the CFDCFCCn.CFE bit only when the Empty flag is set for the corresponding Common FIFO Buffer.

Other possible messages pending from the TX FIFO are lost and their transmission must be requested again. Before CFDCFCCn.CFE is set again, ensure that CFDCFSTSn.CFEMP bit is set and that there is no pending abort from the TX FIFO.

When the CFDCFCCn.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after configuration is shown in **Figure 7.9-44**.

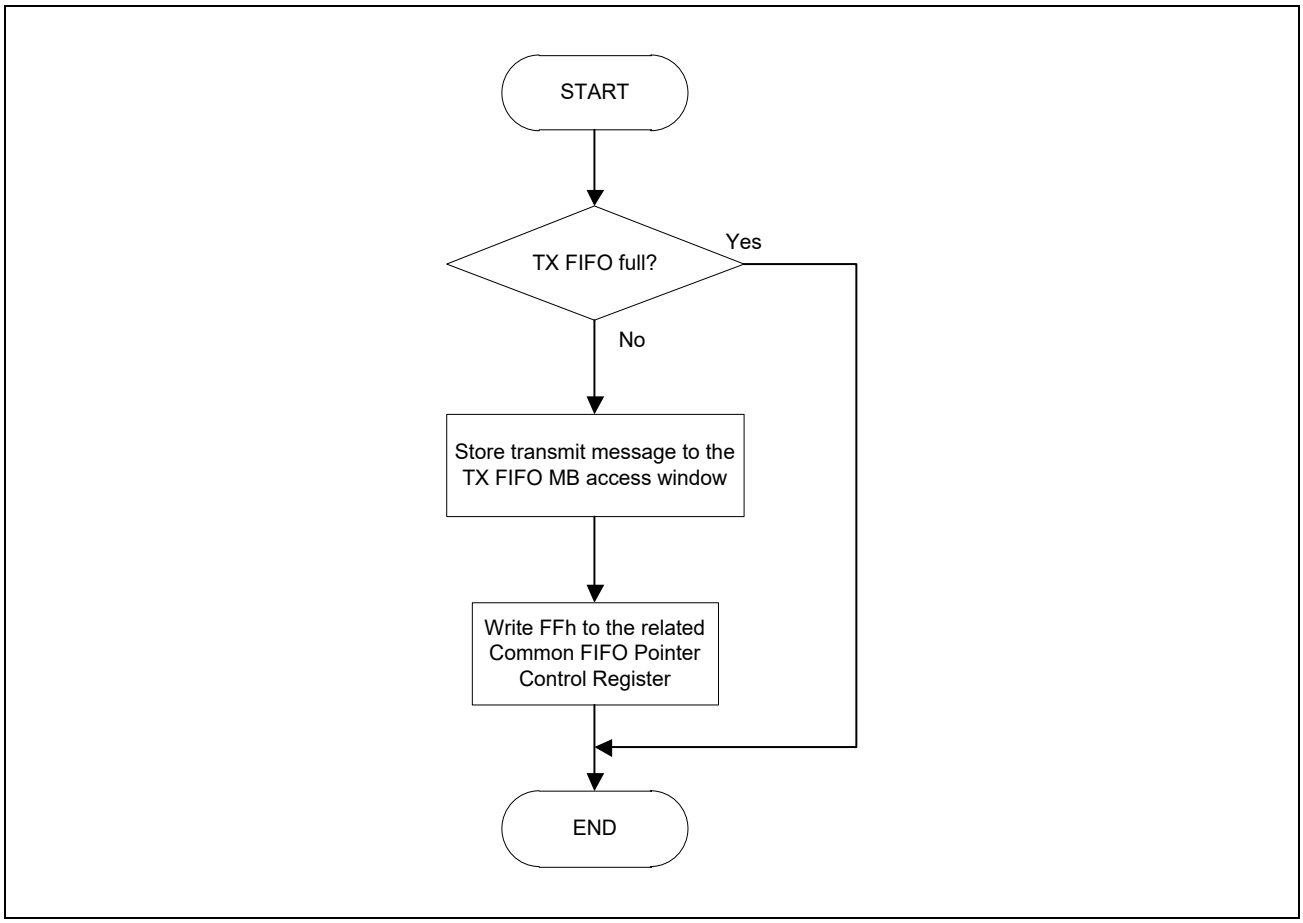

Figure 7.9-44 TX FIFO Transmission Request Procedure

(2) GW FIFO Operation

The AFL entries for routing the received messages to GW FIFO buffers should be configured based on the requirements of the system. The matching AFL entry selects the GW FIFO buffer for storage of a received message on any of the CAN channels.

When a message is successfully received and stored in a GW FIFO buffer, the FIFO message count in the corresponding FIFO Status Register is incremented by 1.

If the message count matches the FIFO depth, then the FIFO Full flag is set.

The oldest message in the GW FIFO is included in the scan for transmission by the corresponding CAN-FD module channel logic.

When a message is successfully transmitted from the GW FIFO, the message count value is decremented by 1. When all the messages from the GW FIFO are transmitted, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

In GW mode, when a transmit/receive FIFO buffer is trying to receive a new message while the transmit/receive FIFO buffer is already full of data, the oldest data of the buffer is overwritten with the message received or the message is discarded. The behavior is determined by setting CFDCFCCEn.CFMOWM bit.

- When CFDCFCCEn.CFMOWM = 0b:
  When writing of data is required due to reception of a new message while a transmit/receive FIFO buffer is full of data, the received message is discarded and CFDCFSTSn.CFMLT bit is set to 1b.
- When CFDCFCCEn.CFMOWM = 1b:
  When writing of data is required due to reception of a new message while a transmit/receive. FIFO buffer is full of data, the oldest data in the buffer is overwritten with the received message.
  The read pointer of the transmit/receive FIFO buffer simultaneously moves to the next oldest message.
  The CFDCFSTSn.CFMOW bit is then set to 1b, which notifies that the oldest message is overwritten with the received message.
  In addition, when a CAN bus error or arbitration-lost for the transmitting message occurs in transmit/receive FIFO buffer full, the transmitting message is lost and retransmission for the message is not performed. The read point moves to the next message automatically.

The interrupt generation conditions for the GW FIFO buffers can be configured by configuring the CFDCFCCn.CFIM bit in the corresponding Common FIFO Configuration/Control Registers.

If CFDCFCCn.CFIM bit is 0b, then RX interrupt flag is set when FIFO counter increments and reaches value configured by CFDCFCCn.CFIGCV and the TX interrupt flag is set when FIFO transmits the last message successfully.

If CFDCFCCn.CFIM bit is 1b, then RX interrupt flag is set at the end of storage of every received message and TX interrupt flag is set if a message is successfully transmitted from the FIFO.

Common FIFO can set interrupt when:

- CAN frame transmitted is completed
- CAN frame reception is completed
- FIFO is in full status in RX mode or GW mode

When CFDCFCCEn.CFBME = 1b, it becomes FIFO buffering mode, send data is stored in Common FIFO, and transmission is stopped. Transmission will be started if it is set as CFDCFCCEn.CFBME = 0b.

The Common FIFO buffers configured in GW mode can be disabled by clearing the CFDCFCCn.CFE bit in the Common FIFO Configuration/Control Register. If this bit is cleared, the GW FIFO becomes empty as follows:

- Immediately if the message from the GW FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the GW FIFO is already scheduled for transmission or already in transmission

Other possible messages pending from the GW FIFO are lost.

Before CFDCFCCn.CFE is set again, ensure that the CFDCFSTSn.CFEMP bit is set and that there is no pending abort from the GW FIFO.

When the CFDCFCCn.CFE bit is cleared and the CFDCFSTSn.CFEMP bit is set, the message read and write pointers of the GW FIFO are cleared and are no longer active. Therefore, all messages in the GW FIFO buffers are lost and no further message can be stored into the GW FIFO.

In applications intended to be used as CAN-to-CAN gateways, it is useful if the Error State Indication (ESI) information of the routing messages is not replaced by the sending node Error State Indication. For this, each channel has the control function register CFDCnFDCFG.ESIC to replace their own ESI information by the routing ESI information.

Note: If the sending node is error passive, the ESI bit is sent anyway as error passive (ESI = 1b).

(3) Interval Timer for FIFO Transmission

For each Common FIFO in TX or GW mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFDCFCCn.CFE bit is set.

When the Common FIFO in TX or GW mode is enabled, the first message is transmitted without considering this interval time.

The interval timer stops counting when:

- FIFO is disabled by clearing the CFDCFCCn.CFE bit
- CAN channel is in CH_RESET mode

The interval time is specified by the CFDCFCCn.CFITT value in the Common FIFO Configuration/Control Register and can be specified from 0 to 255 timer units.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission, a value of 0 should be selected.

The timer source can be selected by the configuration bit CFITSS in the Common FIFO Configuration/Control Register. For the timer source the CAN bit timing clock of the FIFO related channel or a global reference clock can be selected.

If CAN channel bit time clock is configured as clock source and the CAN channel enters CH_HALT or CH_RESET or CH_SLEEP mode, the interval timer is stopped for that channel.

If peripheral clock is selected as interval timer clock source, then the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value CFDGCFG.ITRCP in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

See **Table 7.9-28** for CFDGCFG.ITRCP configuration values to achieve different reference clock periods based on the peripheral clock frequency/period.

Table 7.9-28 Configuration Example for the FIFO Interval Timer Reference Clock

Peripheral Clock (CANFD_0_pclk)	Reference Clock		
	1 µs	100 µs	500 µs
75 MHz / 13.33 ns	75	7500	37500
100 MHz / 10 ns	100	10000	50000

Additionally, the reference clock resolution can be specified by the interval timer reference clock resolution value CFDCFCCn.CFITR in the Common FIFO Configuration/Control Register.

The interval time is based on the reference clock period multiplied by the configured value (×1 or ×10).

The reference clock based interval timer can be used to follow the requirements of the ISO 15765-2 Separation Time. The whole range for the separation time from 100 µs to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX/GW FIFO. Therefore, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message is sent at earliest after this interval time.

Figure 7.9-45 shows an example timing of the internal processing.

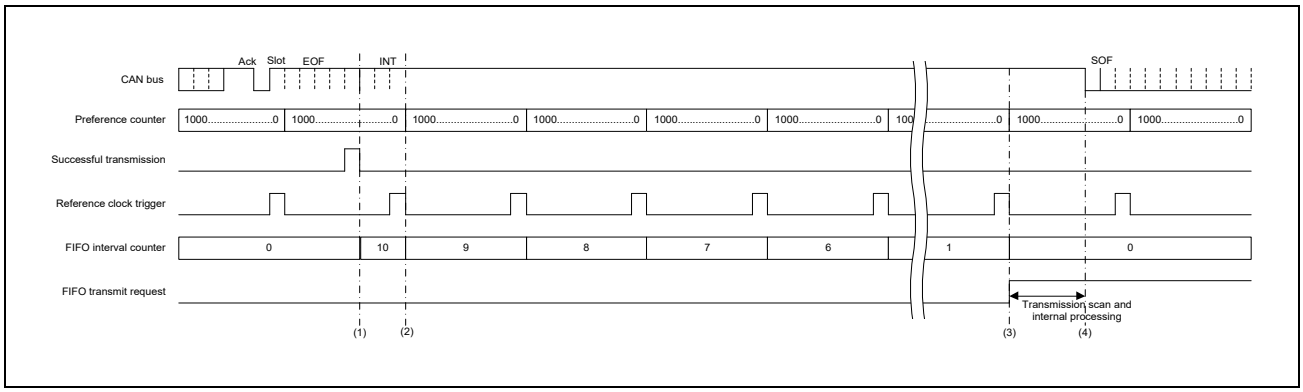

Figure 7.9-45 Example for Interval Processing Time

The configuration for the above timing is as follows:

- Peripheral clock frequency = 100 MHz
- Interval timer reference clock (CFDGCFG.ITRCP) = 1000 times
- Reference clock due to the above settings = 10 µs
- Common FIFO interval timer source selection (CFDCFCCn.CFITSS) = 0b
- Common FIFO interval timer resolution (CFDCFCCn.CFITR) = 0b
- Common FIFO interval transmission time (CFDCFCCn.CFITT) = 10 times
- Theoretical message separation interval = 100 µs

1. Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore, the first interval is counting less or equal to one reference clock interval.
2. With the next reference clock trigger, the FIFO interval timer is decremented.
3. When the FIFO interval timer reached the value 0 the FIFO transmit request is set.
4. When the FIFO is selected for transmission, the transmission starts. Due to internal processing this usually takes less than 3 CAN bit time, between internal FIFO transmit request set 3 and actual transmission.

In the worst case when multi events such as reception scan, internal message routing, transmit scan on all channels occur, then it can take up to 432 peripheral clock cycles.

As shown in **Figure 7.9-45**, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure CFDCFCCn.CFITT to the required minimum value + 1.

If additional TX message buffers or TX/GW FIFOs are configured for transmission for the same channel, the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time due to higher priority message transmission from these TX message buffers or TX/GW FIFOs.

Figure 7.9-46 shows a block diagram of the FIFO interval time generation circuit.

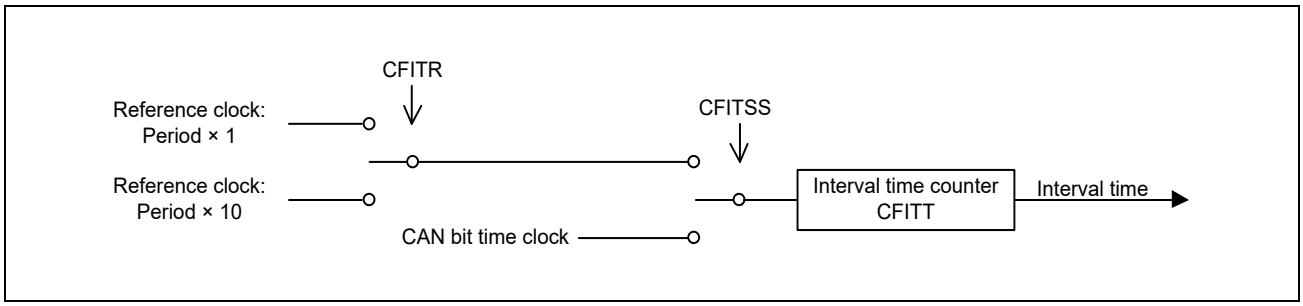

Figure 7.9-46 Block Diagram of FIFO Interval Timer

7.9.8.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of 3 to 32 TX message buffers, which are accessed by one access window. One channel has 4 TX Queues. One TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 0 as access window (referred to as TXQ0). The second TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 31 as access window (referred to as TXQ1). The third TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 32 as access window (referred to as TXQ2). The fourth TX Queue can be configured with a depth of 3 up to 32 buffers and it uses TX Message Buffer No. 63 as access window (referred to as TXQ3).

All TXQ0, TXQ1, TXQ2, and TXQ3 messages enter the priority comparison for the transmission, which should be only ID Priority (CFDGCFG.TPRI = 0b).

The registers for TXQ0 are CFDTXQCC0n, CFDTXQSTS0n, and CFDTXQPCTR0n.
The registers for TXQ1 are CFDTXQCC1n, CFDTXQSTS1n, and CFDTXQPCTR1n.
The registers for TXQ2 are CFDTXQCC2n, CFDTXQSTS2n, and CFDTXQPCTR2n.
The registers for TXQ3 are CFDTXQCC3n, CFDTXQSTS3n, and CFDTXQPCTR3n.

When access window TX Message Buffer No.63 (TXQ3) or TX Message Buffer No.32 (TXQ2) or TX Message Buffer No.31 (TXQ1) or TX Message Buffer No.0 (TXQ0) is used, refer to the related access registers TX Message Buffer ID Registers (CFDTMIDn), TX Message Buffer Pointer Registers (CFDTMPTRn), TX Message Buffer Data Field 0 Registers (CFDTMDF0_n), and TX Message Buffer Data Field 1 Registers (CFDTMDF1_n).

The depth of each TXQ0 buffer can be configured by writing to the CFDTXQCC0n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ0 can set from TXMB0 to TXMB15 as a queue buffer at the maximum.

The 15 available options for depth configuration are:

- 00h: TX Queue disabled
- 01h: Reserved
- 02h: 3 messages
  ⋮
- 0Dh: 14 messages
- 0Eh: 15 messages
- 0Fh: 16 messages

The depth of each TXQ1 buffer can be configured by writing to the CFDTXQCC1n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ1 can set from TXMB15 to TXMB0 as a queue buffer at the maximum.

The 15 available options for depth configuration are:

- 00h: TX Queue disabled
- 01h: Reserved
- 02h: 3 messages
  ⋮
- 0Dh: 14 messages
- 0Eh: 15 messages
- 0Fh: 16 messages

The depth of each TXQ2 buffer can be configured by writing to the CFDTXQCC2n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ2 can set from TXMB32 to TXMB47 as a queue buffer at the maximum.

The 15 available options for depth configuration are:

- 00h: TX Queue disabled
- 01h: Reserved
- 02h: 3 messages
  ⋮
- 0Dh: 14 messages
- 0Eh: 15 messages
- 0Fh: 16 messages

The depth of each TXQ3 buffer can be configured by writing to the CFDTXQCC3n.TXQDC[4:0] bits of the TX Queue Configuration/Control Register.

TXQ3 can set from TXMB47 to TXMB32 as a queue buffer at the maximum.

The 15 available options for depth configuration are:

- 00h: TX Queue disabled
- 01h: Reserved
- 02h: 3 messages
  ⋮
- 0Dh: 14 messages
- 0Eh: 15 messages
- 0Fh: 16 messages

When using TXQ1 and TXQ0 simultaneously, the depth of TXQ is 16 or less in total.

When using TXQ3 and TXQ2 simultaneously, the depth of TXQ is 16 or less in total.

Do not access all the TX message buffers forming the TX Queue directly (except TX Message Buffer No. 63, TX Message Buffer No. 32, TX Message Buffer No. 31 and TX Message Buffer No. 0, which acts as TX Queue access window).

When CFDGAFLP0n.GAFLSRD i (i = 0 to 2) is set and the CFDTXQCCin.TXQGWE (i = 0 to 2, n = 0, 1) is also set, a receiving frame is stored in the target TXQ as send data by routing.

When CFDTXQCCn.TXQOWE bit is 1b, the TX Queue is in TX Queue overwrite mode. If the message of the same ID is stored in TX Queue when a frame is received and it is stored in TX Queue, an old message is overwritten by a new message. Therefore, an old message is not transmitted. When the old message of the same ID is transmitting and a CAN bus error and an arbitration-lost occur, the message of old ID is not resent.

When using the function in GW mode and TX Queue overwrite mode, the depth of TXQ (CFDTXQCC0n.TXQDC) should be configured to the value which is the various number of ID that is used in the TX Queue plus 3. If it accesses by routing in gateway mode when a TXQ buffer is full, CFDTXQSTS.TXQMLT is set and send data is thrown away.

The function is valid for the standard ID frame and is invalid for the extended ID frame.

Explanation of operation of the TX Queue with same ID over-writing function in GW mode is shown in **Figure 7.9-47**.

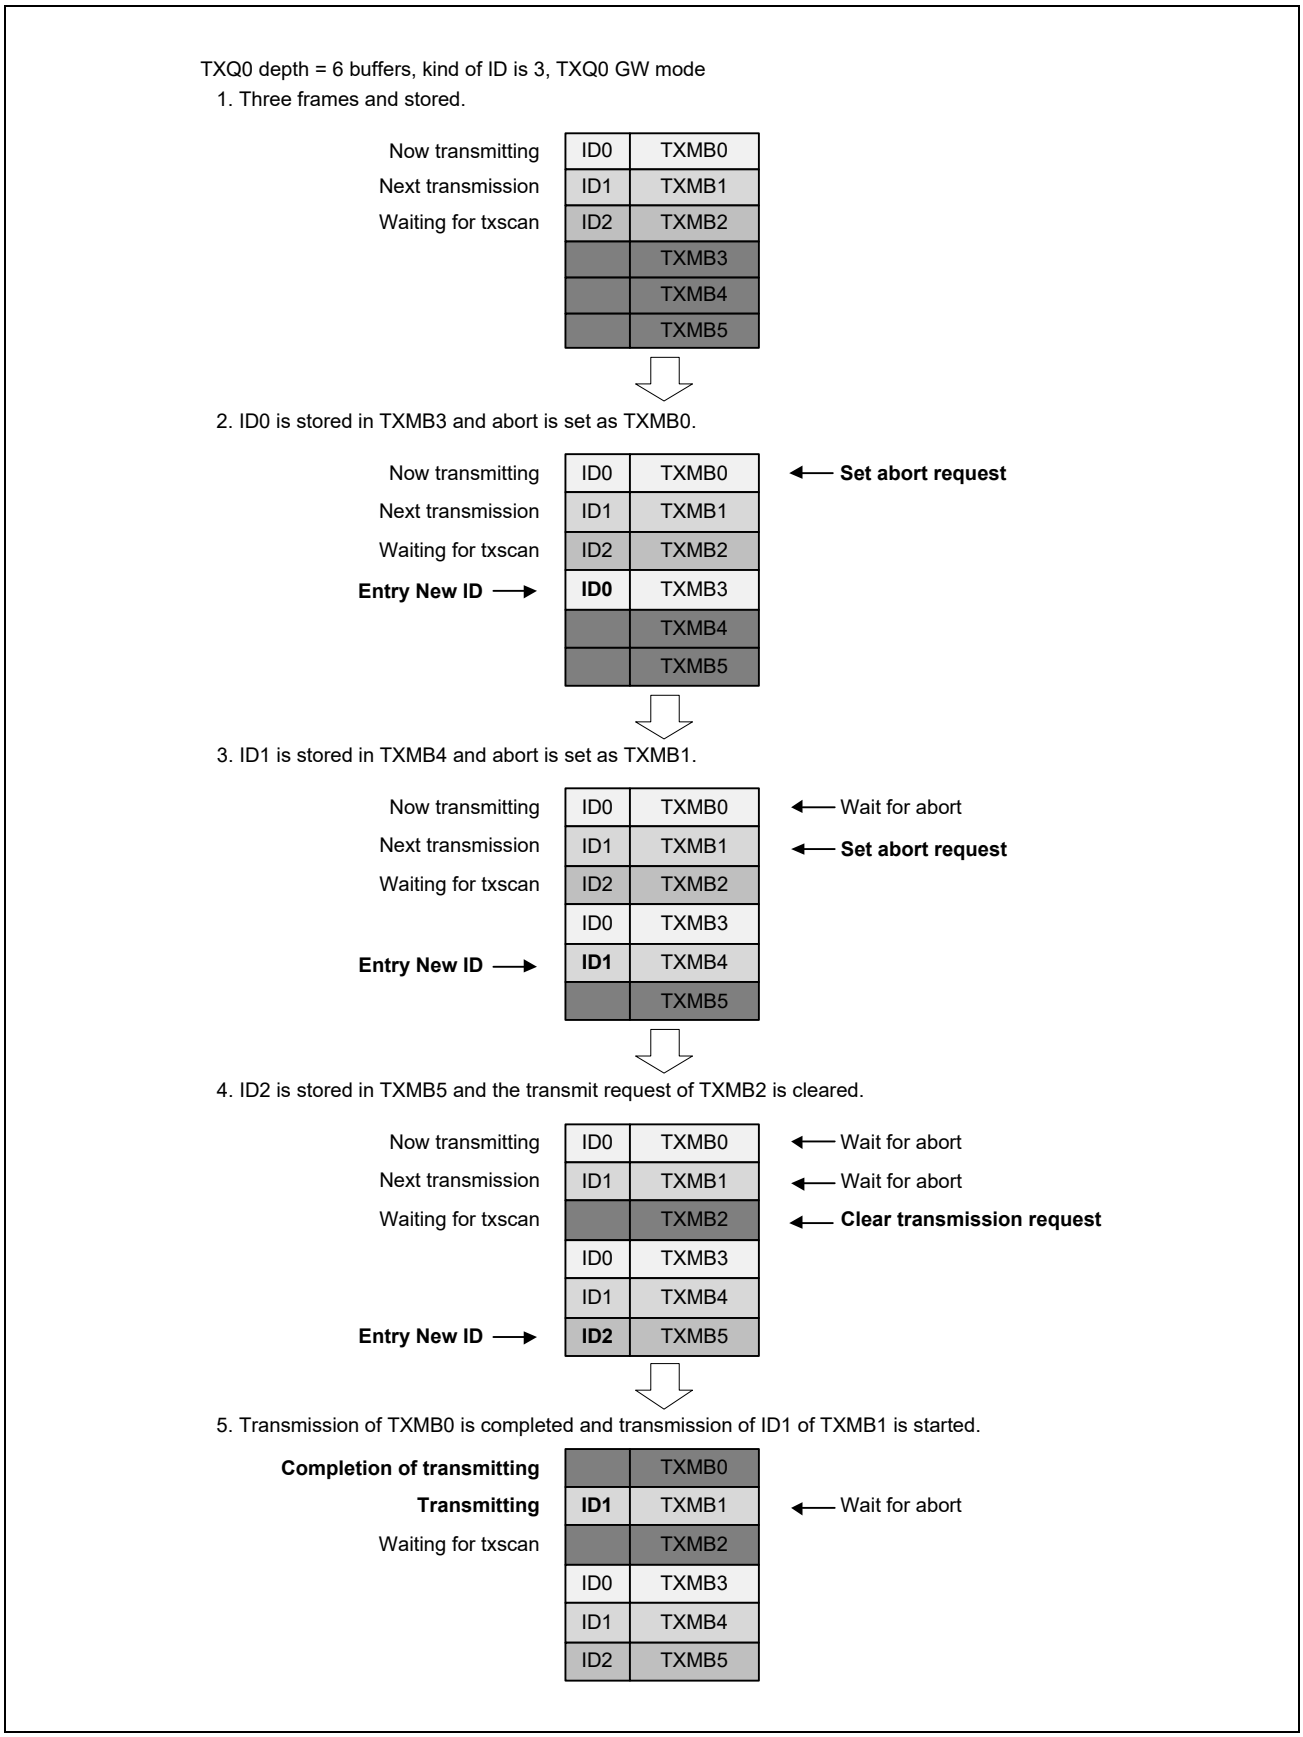

Figure 7.9-47 Operation of TXQ0 in Gateway Mode

When a system writes in TXQ, a system should write in send data, after checking the state of TXQ.

Do not access or configure the related TX Message Buffer Control Registers.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full then no further access should be done to the queue, until it is no longer full. If it accesses by software writing in when the buffer of TXQ is full, send data is overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue Empty flag is set as follows:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission.

Note: The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission must be requested again.

Before TXQE is set again, ensure that the CFDTXQSTSn.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared, all messages in the TX Queue buffers are lost and no further message should be stored into the TX Queue.

When a message has been stored to the TX Queue, FFh must be written into the TX Queue Pointer Control Register. This sets the transmit request automatically and changes the internal message buffer pointer to the next free message buffer location of the TX Queue.

Note: If two messages with the same identifier are stored in the TX Queue, then the order of transmission of these messages can be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same identifier is stored in the TX Queue. Or if TX queue overwrite mode is used, the frame of the same ID is rewritten on a new frame.

For the TX Queue a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the CFDTXQCCn.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in **Figure 7.9-48**.

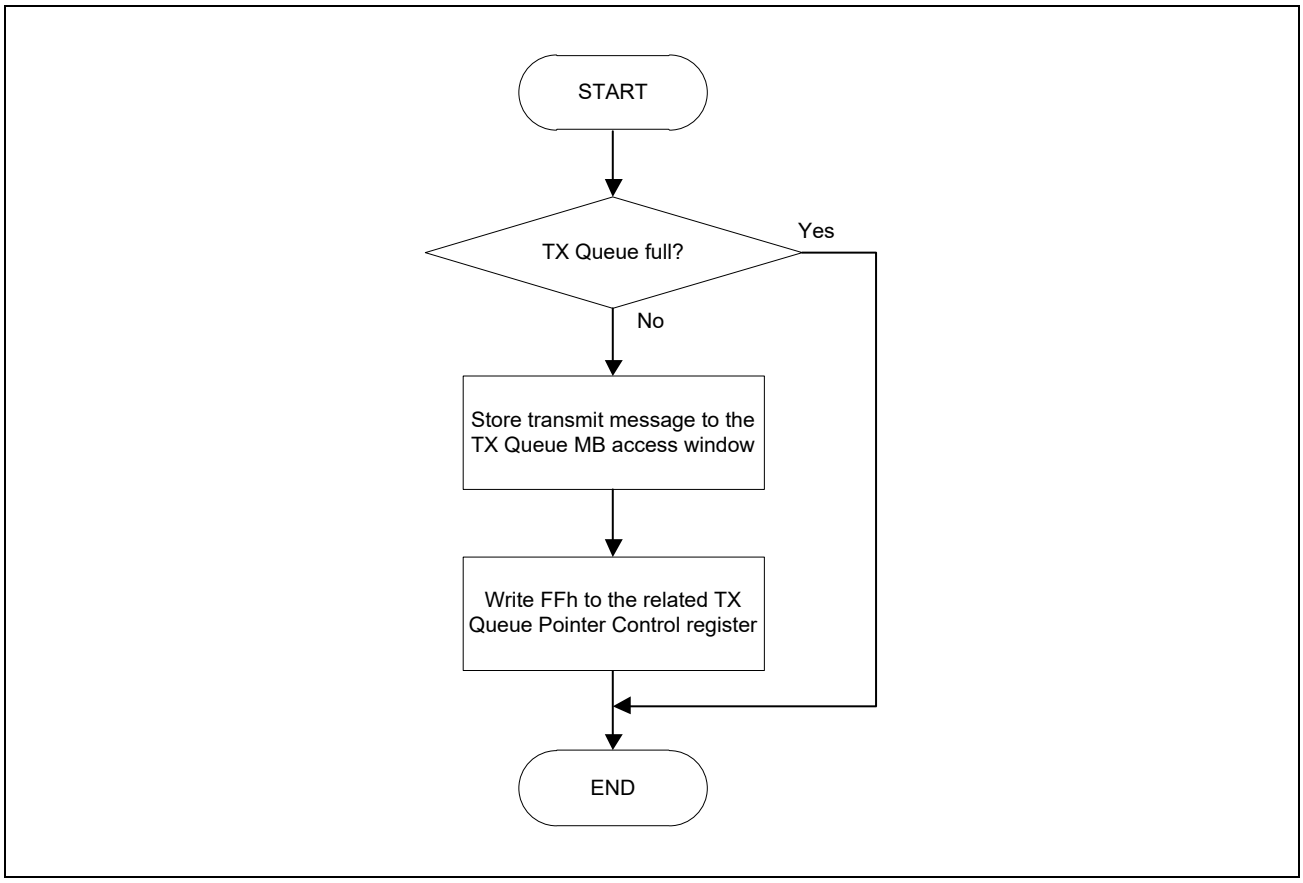

Figure 7.9-48 TX Queue Transmission Request

TXQ Name	Access Window	Range Width	Direction	Hardware Routing Access Point	CPU Access Point	DMA Access Point	Note
TXQ0	TXMB0	0, 3-16	TXMB0 → TXMB15	Yes	Yes	Yes	When using both TXQ0/1, the total number of stages is 16 or less
TXQ1	TXMB31	0, 3-16	TXMB15 → TXMB0	Yes	Yes	No	
TXQ2	TXMB32	0, 3-16	TXMB32 → TXMB47	Yes	Yes	No	When using both TXQ2/3, the total number of stages is 16 or less
TXQ3	TXMB63	0, 3-16	TXMB47 → TXMB32	No	Yes	Yes	

TXQ0 can use hardware routing, CPU access, and DMA access.

Hardware routing access, CPU access, and DMA access should not be used simultaneously. Choose one access method.

7.9.8.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List buffers for each CAN channel. Two TX History List buffers are provided for each CAN channel and each TX History List buffer can store up to 16 TX History List entries for a CAN channel.

The CFDTHLCCn.THLDTE bit of the TX History List Configuration/Control Register can be used to configure if only message information from TX FIFOs/TX Queue is stored or if all transmit message information from TX Queue, TX FIFO or normal TX message buffers should be stored in the TX History List for a CAN channel.

When a CFDTHLCCn.THLDGE bit is set up, the information on all the frames transmitted in GW mode is stored in TX History List.

Each transmit message can be individually configured for acceptance to the TX History List by the CFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted on that CAN channel.

Storing to the List is not synchronized with the status of CFDTMSTSn.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the List can happen with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF bit is set to 1b when the THLIE is configured to 1b or when the TX History List counter CFDTHLSTSn.THLMC[5:0] is increased.

The delay time is dependent on the number of channels due to internal processing.

- Maximum delay time from setting the CFDTMSTSn.TMTRF to storing the TX History List data is 224 peripheral bus clock cycles.

The History list records the following information of the transmitted message:

- Buffer type:
  - 001b: TX Message Buffer
  - 010b: TX FIFO
  - 100b: TX Queue
- Buffer number:
  TX Message Buffer, TX Queue Message Buffer or TX Message Buffer Link for the Common FIFO Buffer from which the transmission occurred. The number depends on the buffer type, see **Table 7.9-29**.
- Transmission ID:
  Transmission pointer stored in the transmission message
- Transmit timestamp:
  Message timestamp captured at the capture point as configured by CFDGFDCFG.TSCCFG.
- Transmission information label:
  Transmission information label stored in the transmission message.
- Transmit gateway buffer indication:
  For data transmitted from the gateway, CFDTHLACC0n.TGW bit is set to 1b.

Table 7.9-29 TX History List Buffer Number Entry

CFDTHLACC0n.BT[2:0] Buffer Type		
001b	101b	100b
TX Message Buffer	TX FIFO	TX Queue
TXMB0	—	Number shown corresponds to the message buffer belonging to the TX Queue for which the frame was transmitted.
TXMB1		
TXMB2		
⋮		
TXMB13		
TXMB14		
TXMB15		
TXMB32	Number shown corresponds to the common FIFO. TX Message Buffer Link CFTML of the related Common FIFO Configuration	
TXMB33		
TXMB34		
⋮		
TXMB45		
TXMB46		
TXMB47		

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the CFDCFFDCSTSn.CFPTR[15:0] part of the Common FIFO Access Pointer Register for a TX FIFO or to the CFDTMFDCTRn.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window message buffer.

When the message is successfully transmitted, the identification number is then stored together with the other message related information to the TX History List and can be read with the Transmission ID (TID) of the TX History List Access Register.

Also for normal TX message buffers, the CFDTMFDCTRn.TMPTR[15:0] part of the TX Message Buffer Pointer Register is stored in the Transmission History List. Information label is the same.

Figure 7.9-49 shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register is done for every single entry.

After reading one entry, FFh must be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

Figure 7.9-50 shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the CFDTHLCCn.THLIM bit of the corresponding TX History List Configuration/Control Registers and enabled with the CFDTHLCCn.THLIE bit of the same registers, either to generate an interrupt when the history list reached a filling level of 75% or for every new TX History List entry.

An entry lost indication is flagged by the CFDTHLSTSn.THLELT bit in the TX History List Status Register.

Status of this bit is also shown by the THLES bit in the Global Error Flag Register.

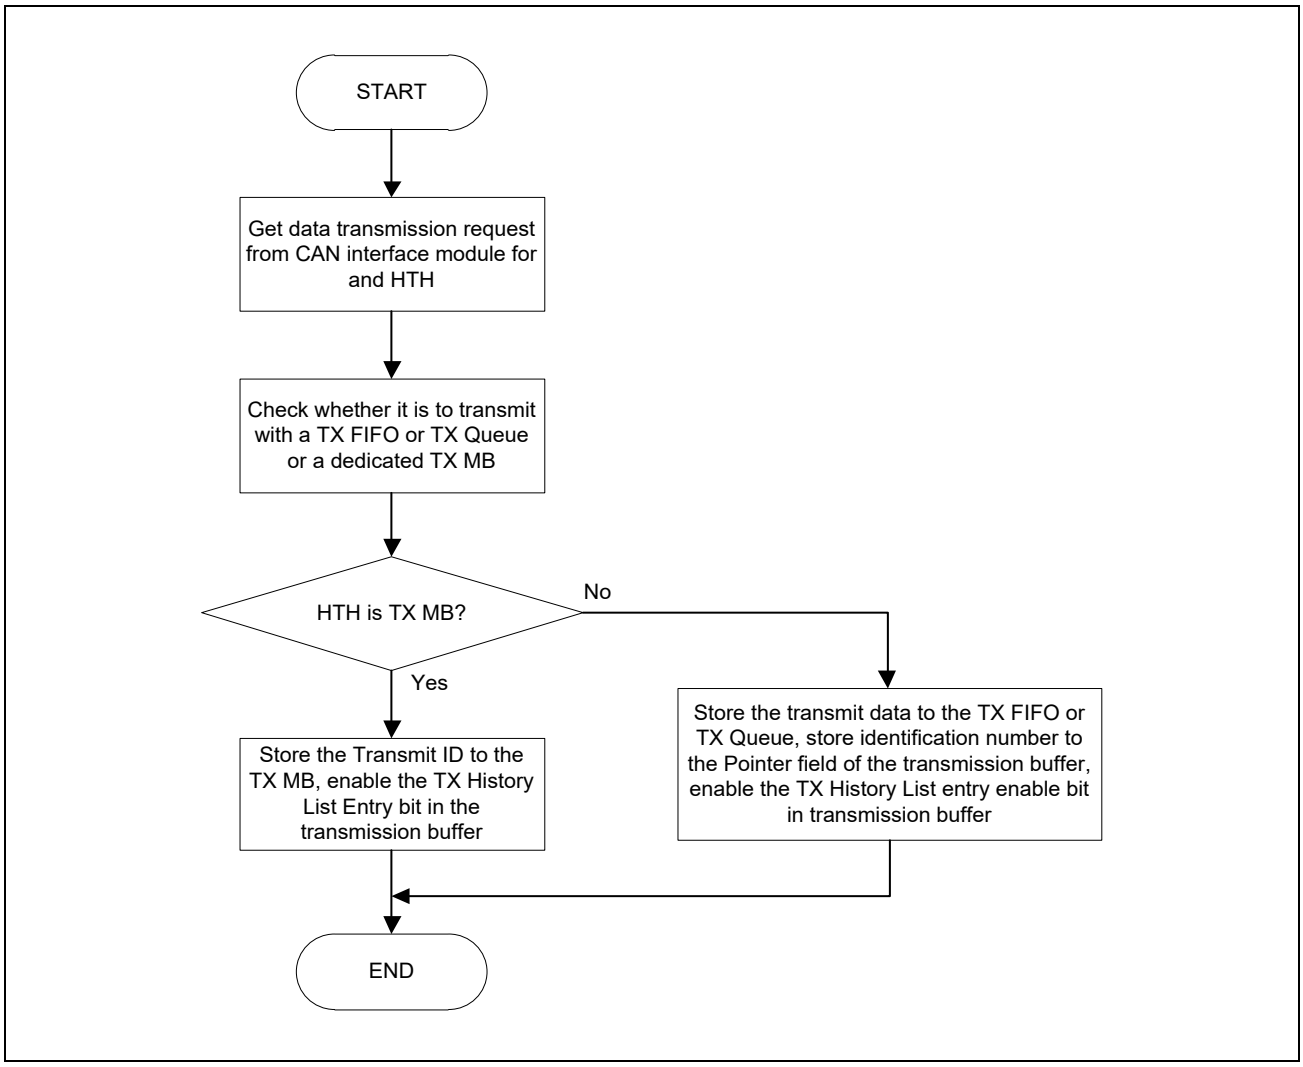

Figure 7.9-49 Transmission Preparation Flow when TX History List is Used

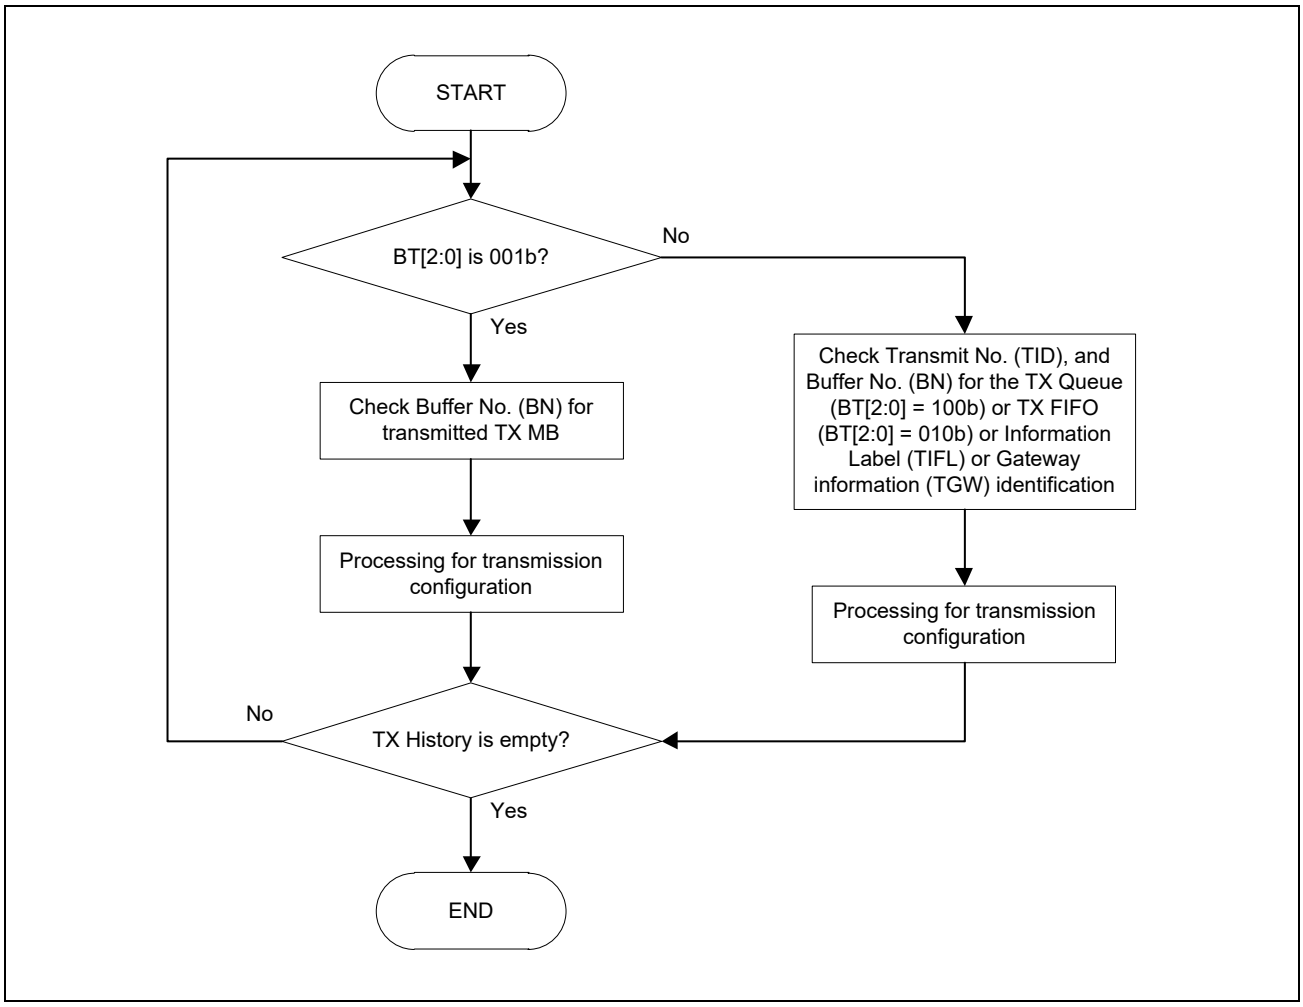

Figure 7.9-50 Example Flow for Processing TX History List Information

7.9.8.2.6 TX Data Padding

If the data length code (DLC) of the transmitting message has a higher number of data bytes than the buffer size, then the data bytes beyond the restricted range are replaced by bytes with the value of CC HEX.

This can happen for Common FIFOs configured as (TX or GW) when the transmit message DLC is higher than CFDCFCCn.CFPLS.

This can also happen in FD-only mode, if a Classical Frame is configured with a DLC larger than 8.

7.9.9 Test Mode

The CAN-FD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CAN-FD module in test modes.

All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combinations of the various test modes specified in this section.

The test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes

7.9.9.1 Channel Specific Test Modes

Each CAN channel can be configured into the following test modes:

- Basic test mode
- Listen-only mode
- Self-test mode 0 (External Loop Back mode)
- Self-test mode 1 (Internal Loop Back mode)
- Restricted operation mode

7.9.9.1.1 Basic Test Mode

The Basic test mode should be used when a particular test setting must be enabled other than when in Listen-Only and Self- test modes.

7.9.9.1.2 Listen-Only Mode

The ISO 11898-1 recommends an optional Bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit.

If the CAN engine is required to send a dominant bit (ACK bit, Overload flag, Active Error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin remains in recessive state.

This mode can be used for baud rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX Message Buffer or TX-/GW-FIFO of this channel.

Note: If a message is stored in GW FIFO or Routing TXQ, ensure that the transmitting channel is not in Listen-only mode so that transmission is not requested for this channel from the GW FIFO or Routing TXQ.

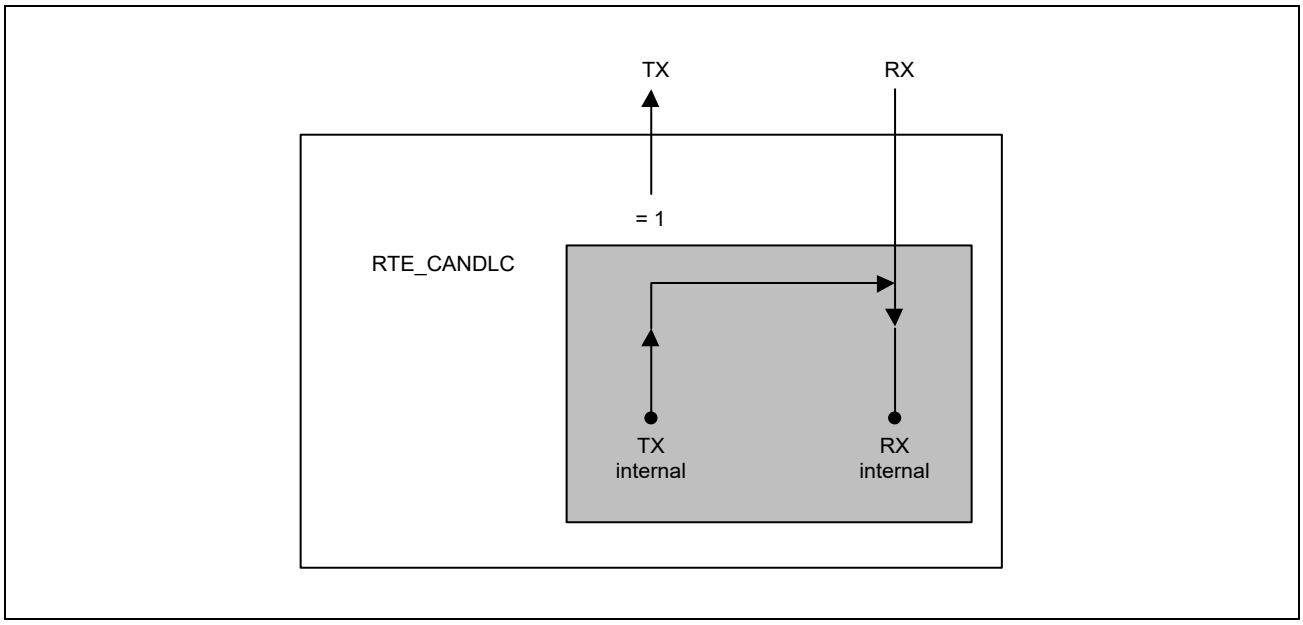

Figure 7.9-51 Listen-Only Mode

7.9.9.1.3 Self-Test Mode 0 (External Loop Back Mode)

In Self-test mode 0, the CAN engine treats its own transmitted messages as received messages through the CAN transceiver and can store them into its receive message buffers.

To be independent from external stimulation, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests.

The RX/TX pins should be connected to the transceiver.

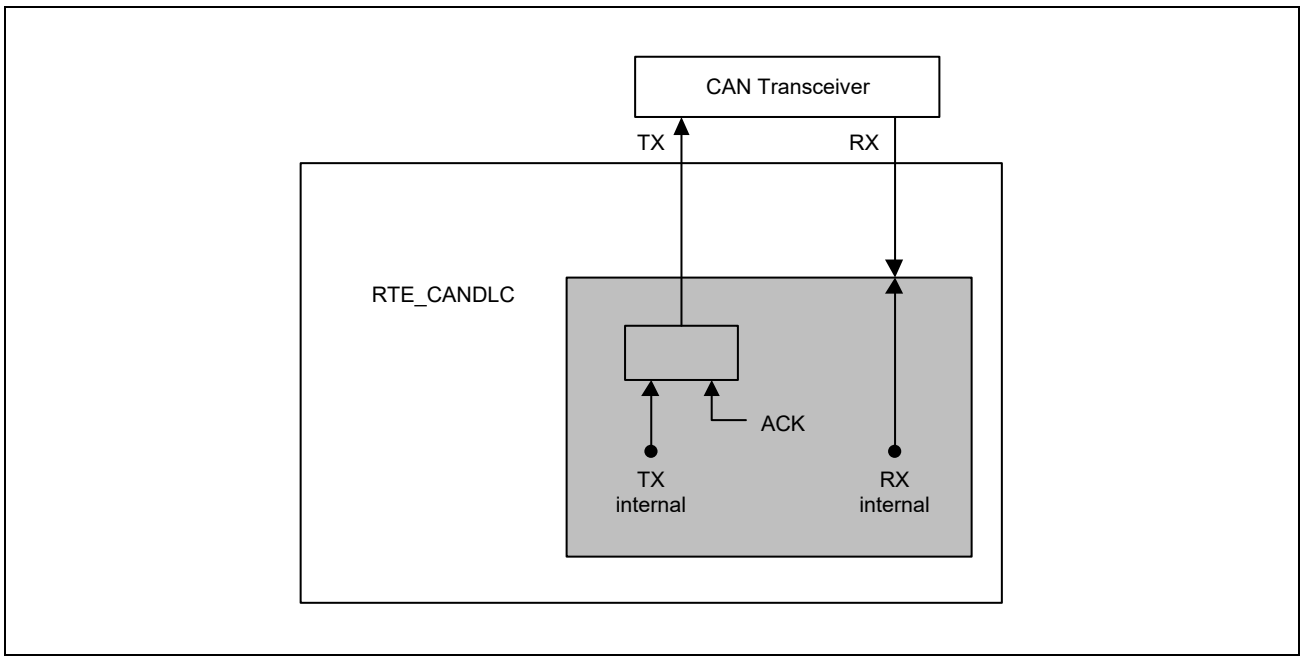

Figure 7.9-52 Self-Test Mode 0 (External Loop Back Mode)

7.9.9.1.4 Self-Test Mode 1 (Internal Loop Back Mode)

In Self-test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation, the CAN engine generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to RX internal. The actual value of the external RX input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits.

The RX/TX pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the internal CAN bus communication line.

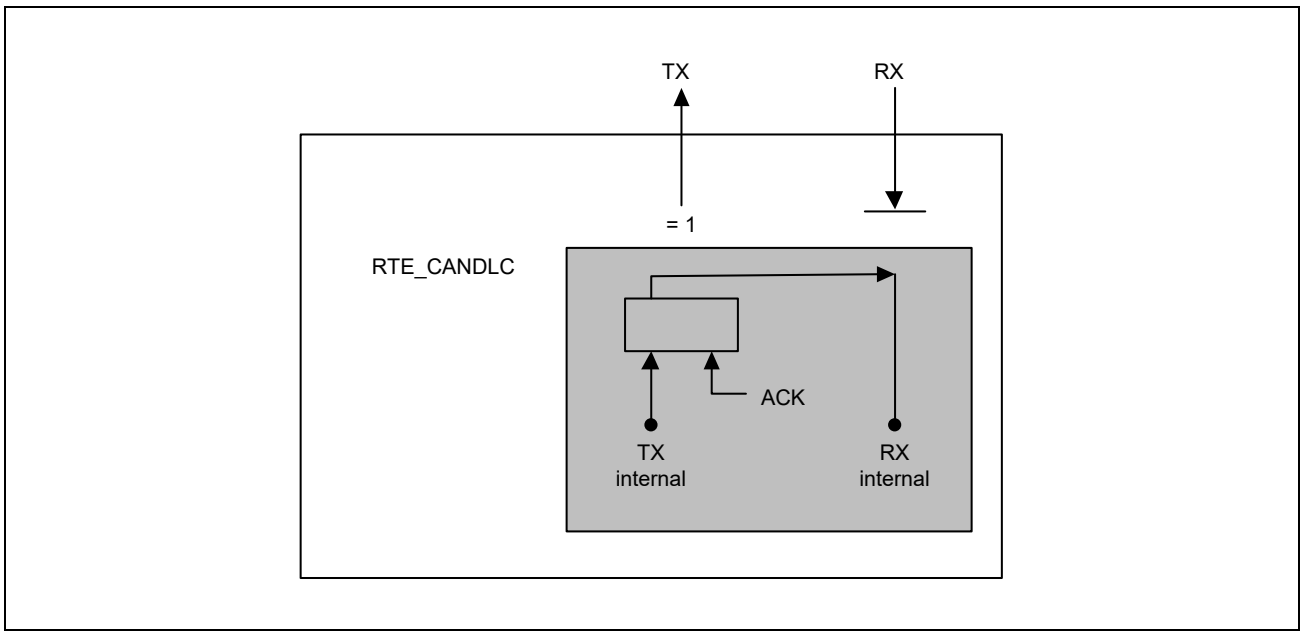

Figure 7.9-53 Self-Test Mode 1 (Internal Loop Back Mode)

7.9.9.1.5 Restricted Operation Mode

In Restricted operation mode, the CAN node is able to receive valid data and remote frames that generates the Acknowledge bit.

Active error and overload frames cannot be transmitted, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.

Additionally, the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors.

The mode is specified as in ISO 11898-1. However, it is permitted to set any requested transmit.

7.9.9.2 Global Test Modes

The CAN-FD module can be configured into the following test modes:

- RAM test mode
- Internal CAN bus communication mode
- CRC error test

These test modes are protected by a special software procedure to enable the mode. This software procedure enables write access to the test mode by a specific unlock key, the related unlock key can be seen in the following table.

Test Mode	Unlock Key 1	Unlock Key 2
RAM test mode	7575h	8A8Ah

If the software sequence of the two consecutive unlock key write accesses (half-word or word accesses) is interrupted by any other write access to the SFR or if incorrect data is written to the Global Unlock Key Register then the corresponding test mode cannot be set and the sequence must be restarted.

After the two unlock key write accesses, the next write access should be to set the corresponding Test Mode Enable bit. If this is not followed, the unlock mechanism resets and the Test Mode Enable bit cannot be set. At this time, the unlock sequence must be restarted.

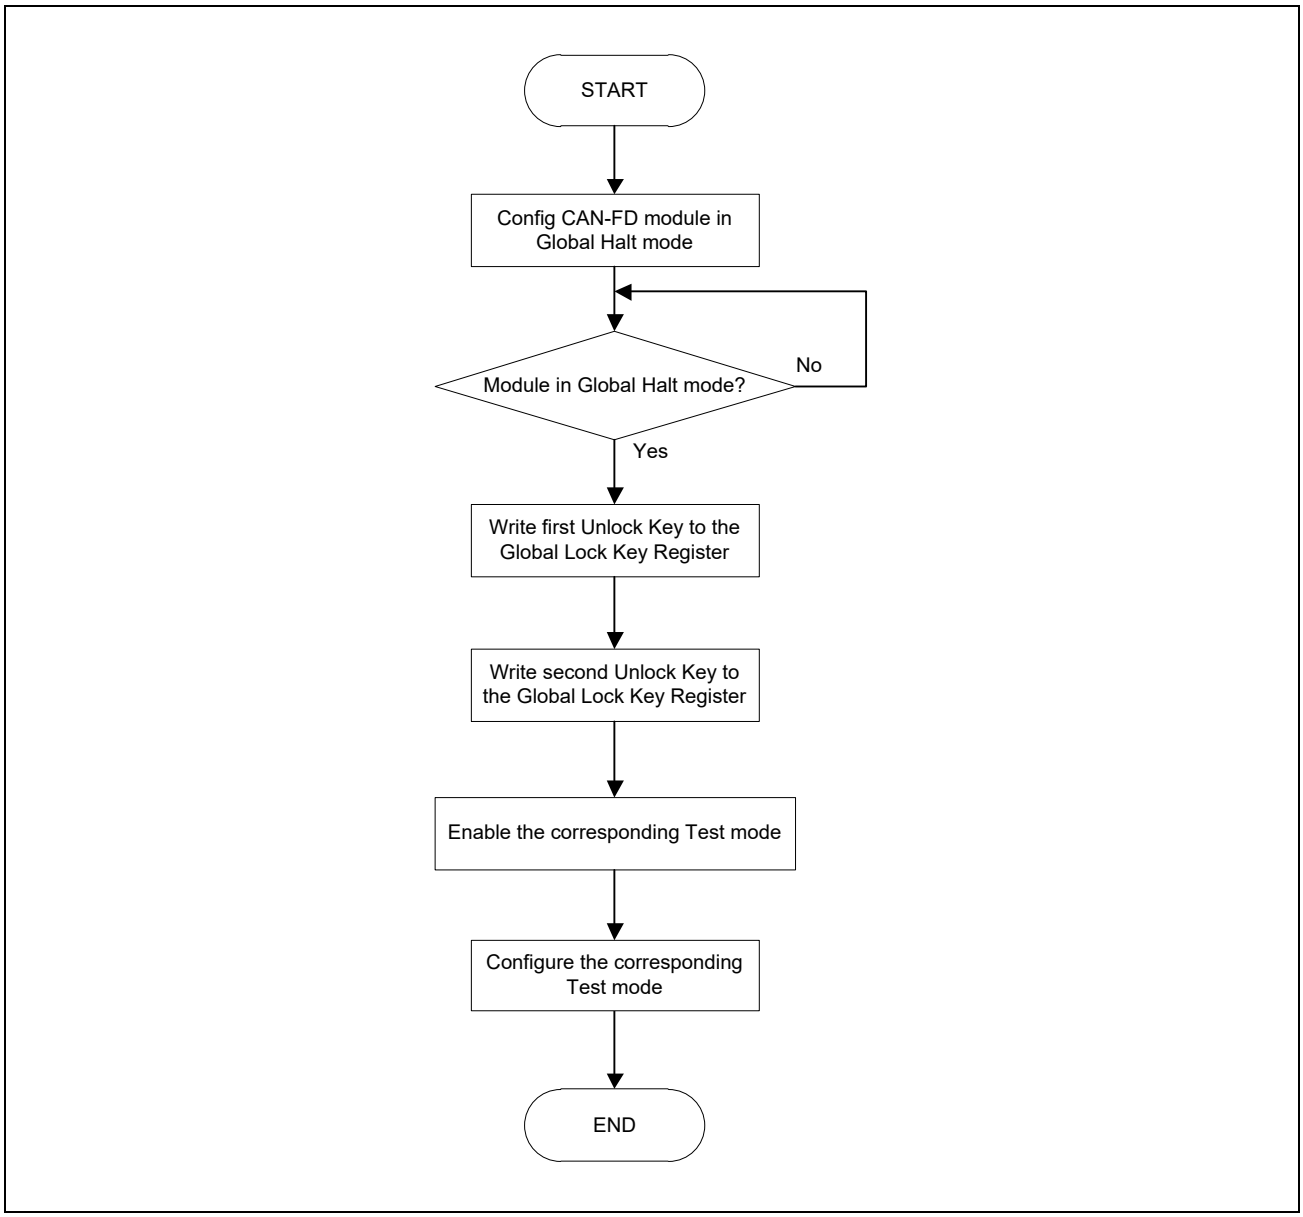

Figure 7.9-54 Unlock Software Protection Routine

7.9.9.2.1 RAM Test Mode

The CAN-FD module can be configured in RAM test mode by setting the CFDGTSTCTR.RTME bit in the Global Test Control Register when the corresponding lock key is previously written. This is a special test mode, in which, the complete RAM area can be accessed.

In this mode, the RAM area is split into number of pages (pn) of 256 bytes each. Which can be accessed with the CFDRPGACCn register.

The page should be selected for read/write access by writing to the CFDGTSTCFG.RTMPS[9:0] bits in the Global Test Control Register. Data can then be read from or written into the RAM Test Page Access Registers.

Figure 7.9-55 shows the structure of the pages in the RAM when performing a RAM test mode.

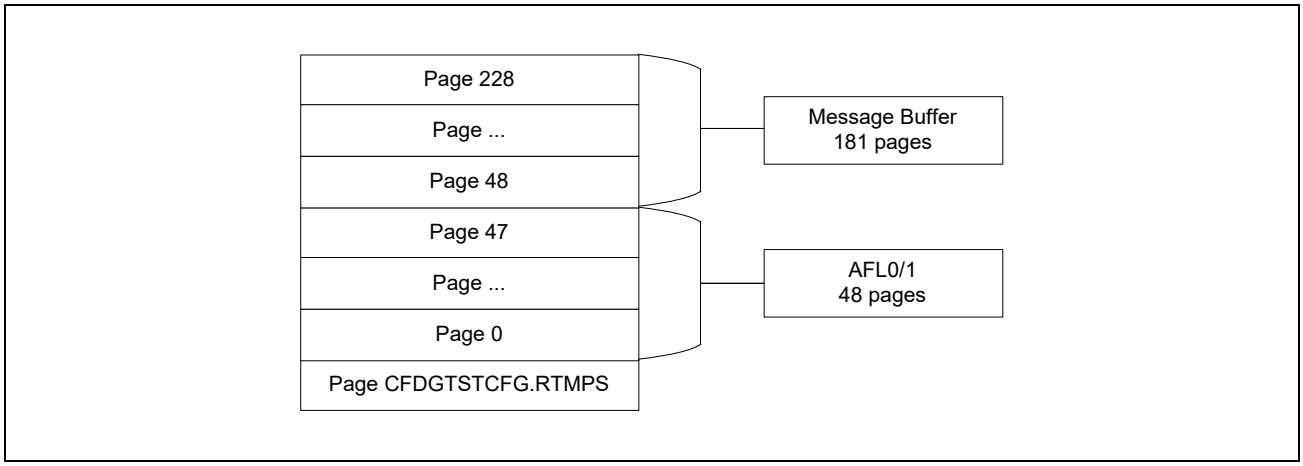

Figure 7.9-55 RAM Page Structure

The total available RAM size for a 6-CAN channel version is 12288 bytes for the AFL RAM and 46272 bytes for the Message Buffer RAM.

AFL RAM0/1 can treat RAM test mode as one RAM.

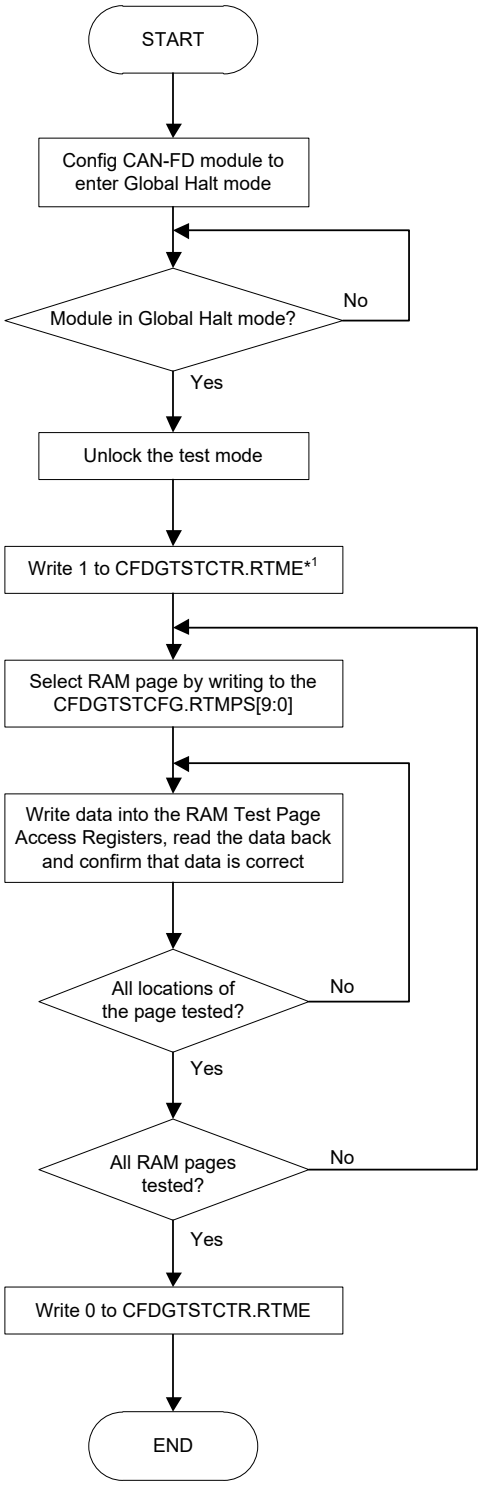
The number of pages (pn) and CFDGTSTCFG.RTMPS[9:0] values for the AFL and MB RAMs are calculated in the following way:

pn = ceil (total RAM size in bytes/number of bytes per page)

- AFL RAM:
  pn = ceil (12288/256) = 48 pages
  CFDGTSTCFG.RTMPS[9:0] = 0 to 47 (02Fh) inclusive
- MB RAM:
  pn = ceil (46272/256) = 181 pages
  CFDGTSTCFG.RTMPS[9:0] = 48 to 228 (0E4h) inclusive

Do not access more than 192 bytes of RAM on the last page (RTMPS[9:0] = 0E4h).

Figure 7.9-56 shows the software flow for RAM test mode.



Note 1. Change into the following status before changing to RAMTEST.
- Cancel of a request of transmission
- Disable of all the FIFO and TXQ
- Clear of the receiving flag of a receiving buffer

Figure 7.9-56 Software Flow of RAM Test Mode

To exit this test mode, clear the CFDGTSTCTR.RTME bit. The CFDGTSTCTR.RTME bit is cleared by writing 0b to it.

The CFDGTSTCTR.RTME bit is cleared automatically when the CAN-FD module enters Global Reset mode from the test mode.

7.9.9.2.2 Internal CAN Bus Communication Mode

The CAN-FD module can be configured in Internal CAN bus communication test mode by setting the CFDGTSTCTR.ICBCTME bit in the Global Test Control Register. This is a special test mode, in which the CAN channels can be connected together internally to generate a CAN cluster within the CAN-FD module.

Only use the following sequence to enter Internal CAN bus communication test mode:

1. Configure all channels in Halt mode and check that all channels have entered Global Halt mode.
2. Write data into the Global Test Configuration Register to select the channels participating in the Internal CAN bus communication test.
3. Set the CFDGTSTCTR.ICBCTME bit of the Global Test Control Register.
4. Check that CFDGTSTCTR.ICBCTME bit is set in the Global Test Control Register.

In this mode, the TXD outputs of the channels participating (configured) in Internal CAN bus communication mode are connected together using AND gate. The output of the AND gate is connected to the RXD inputs of all participating channels to create a CAN cluster within the CAN-FD module. The channels are isolated from the external CAN bus while the CAN-FD module is in this test mode.

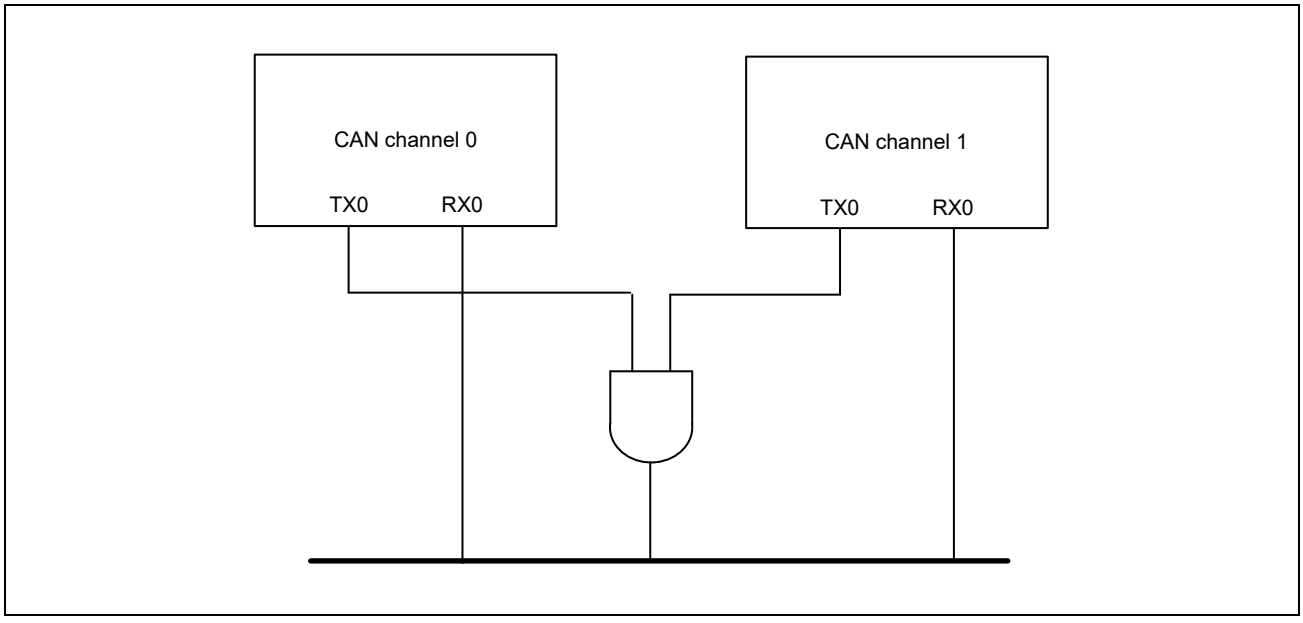


Figure 7.9-57 Internal CAN Bus Connections

The AFL, Flat RX message buffers, FIFO buffers, Flat TX message buffers, and various registers can now be configured as normal to start communication between channels.

The channels not participating in Internal CAN bus should only be configured in Halt mode.

7.9.9.2.3 CRC Error Test

After the CAN-FD module has been configured in Internal CAN bus communication test mode, use the following sequence to perform CRC error testing. In the following sequence, channel x is the reference transmitter CAN-FD module and channel y is the receiver CAN-FD module where (x, y = [0, …, n] and x ≠ y):

1. Configure channel x node to transmit one reference message.
2. Set the CFDCyCTR.CRCT bit to 1b, in order to invert the first bit of the incoming bit stream from channel x.
3. Set the CFDTMCx.TMTR.
4. Read either CFDCyERFL.CRCREG or CFDCyFDCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from channel x.
5. Check that CFDCyERFL.CERR is 1b.

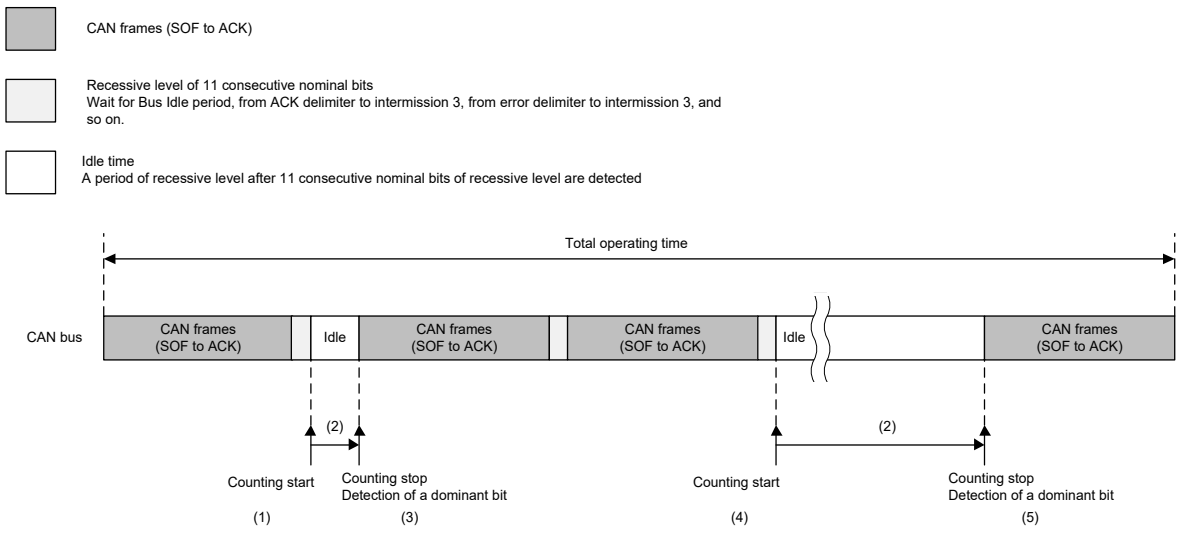
As the CRC generator logic is shared for RX and TX there is no need to create a separate TX CRC error test.

7.9.10 Bus Traffic Measurement

The idle time of the CAN bus can be measured using CANFD_0_pclk or CANFD_0_clkc. Bus traffic can be calculated based on the measurement results.

7.9.10.1 How to Count the CAN Bus Idle Time

Figure 7.9-58 shows the concept of measuring the idle time of the CAN bus.



(1) With the CANFD_0_pclk clock, counting of the idle time starts after a recessive level input of 11 consecutive nominal bits are detected.

(2) The counting continues until a dominant level is detected on the CAN bus.

(3) The counting stops after a dominant level is detected on the CAN bus.

(4) After that, the counting restarts when 11 consecutive nominal bits are detected.

Figure 7.9-58 How to Measure Idle Time of the CAN Bus

7.9.10.2 Operations and Measurement Procedure

The following procedure is for measuring the idle time of the CAN bus.

1. The channel to be measured transits to operation mode.
2. Write 1b to CFDCnBLCT.BLCE bit to set the measuring counter to operating mode.
3. Write 1b to CFDCnBLCT.BLCLD bit to clear the counter register.
4. Detect a recessive level input of 11 consecutive nominal bits.
5. Start counting the bus idle time.
6. Detect a dominant level.
7. The counting stops.
8. Detect a recessive level input of 11 consecutive nominal bits.
9. The counting starts.

10. Write 1b to CFDCnBLCT.BLCLD bit to clear the counter register and simultaneously load the counter value to CFDCnBLSTS.
11. Read the value of CFDCnBLSTS.

To stop the measurement counter, write 0b to CFDCnBLCT.BLCE bit.

To initialize the counter, write 1b to CFDCnBLCT.BLCLD bit.

This measurement is enabled when the channel to be measured is in Operation mode.

When the relevant channels are in reset mode, the counter does not operate.

Also, accurate measurements are not available in test mode.

Write 1b to CFDCnBLCT.BLCLD bit to clear the counter register and simultaneously load the value of the counter to CFDCnBLSTS.

The lower 3 bits of CFDCnBLSTS are fixed to 0b.

Based on the values of the counter, software can calculate the CAN bus traffic according to the following formulas:

$$\frac{(\text{Total operating time} - \text{Total idle time})}{\text{Total operating time}} = \frac{\text{Bus operating time}}{\text{Total operating time}} = \text{Bus usage ratio}$$

- Total idle time: a value read from CFDCnBLSTS × a clock cycle of CANFD_0_pclk
- Total operating time: a setting interval of CFDCnBLCT.BLCLD bit

Example: Below is a calculation example under the following conditions:

- Conditions: nominal bit rate = 1 Mbps
- CANFD_0_clkc = 80 MHz (= 12.5ns)
- A setting interval of CFDCnBLCT.BLCLD bit = cycle of 1 ms
- A read value of CFDCnBLSTS register = 4E20h

$$\frac{(\text{Total operating time} - \text{Total idle time})}{\text{Total operating time}} = \frac{(1000000\ \text{ns} - 20000 \times 12.5\ \text{ns})}{1000000\ \text{ns}} = 75\%$$

7.9.11 Flexible CAN mode

In this mode, it is possible to connect 2 channels of the CAN module to a single CAN driver.

The pairs of channels in Flexible CAN mode are as follows.

- When the CFDGFCMC.FLXC0 bit is set, channels 0 and 1 of the RS-CAN-FD module are in Flexible CAN mode.
- When the CFDGFCMC.FLXC1 bit is set, channels 2 and 3 of the RS-CAN-FD module are in Flexible CAN mode.
- When the CFDGFCMC.FLXC2 bit is set, channels 4 and 5 of the RS-CAN-FD module are in Flexible CAN mode.

Channel n+1 uses the TX/RX terminal of channel n.

The TX/RX terminal of channel n+1 cannot be used.

In Flexible CAN mode, each channel performs communication processing independently.

However, when one of the channels transmits, the other channel will not return an acknowledge bit.

Remark When operating in Flexible CAN mode, the error counters (TEC/REC) of the two CAN nodes are not synchronized with each other.

Flexible transmission buffer assignment configured in the CFDGFTBAC register and Flexible CAN mode configured in the CFDGFCMC register should not be used simultaneously.

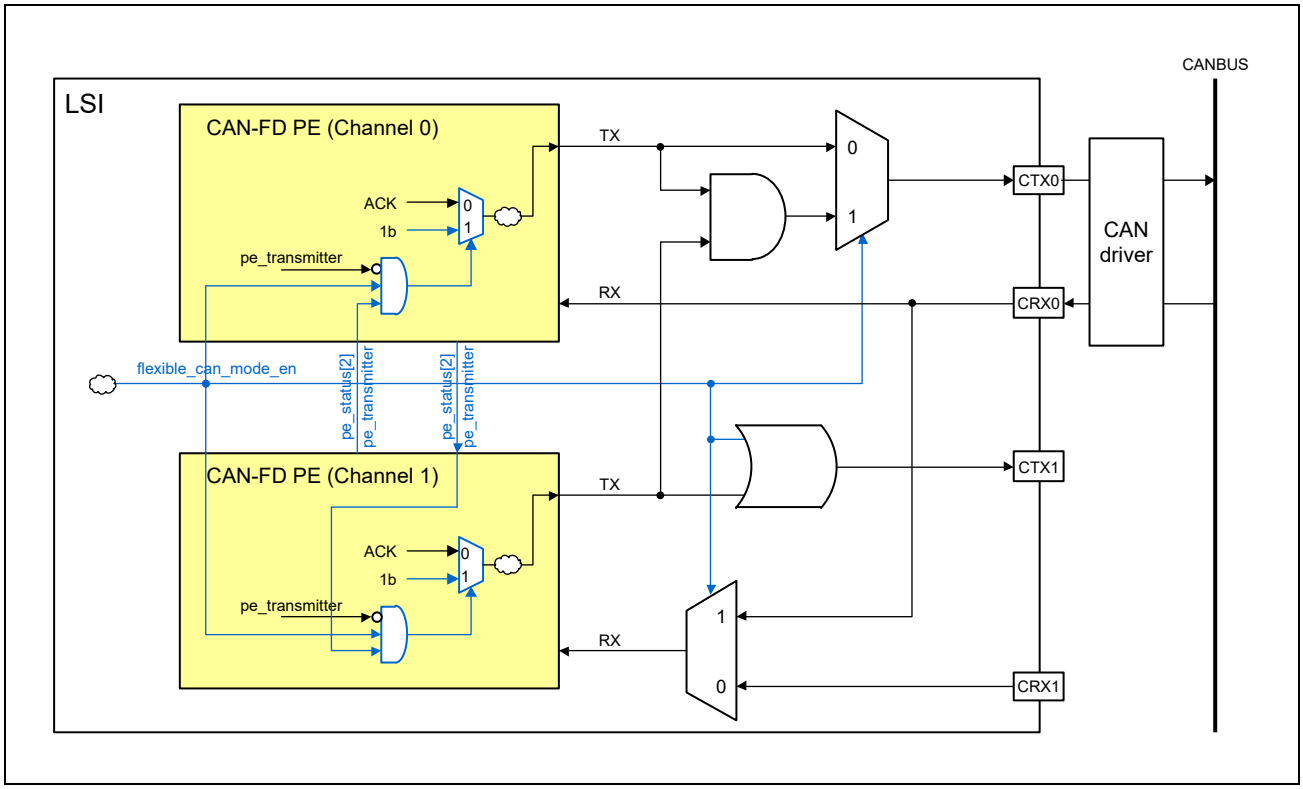


Figure 7.9-59 Diagram of the Flexible CAN for Channel 0 and Channel 1

7.9.12 Flexible Transmission Buffer Assignment

Each channel has 32 transmit buffers for exclusive use.

This channel can borrow up to 16 TXMBs from the next channel in case it runs out of TXMBs.

Buffers that can be rented range from 4 to 16 buffers in increments of 4 units.

The pairs of channels in Flexible CAN mode are as follows.

- When the CFDGFTBAC.FLXMB0 bit is set, flexible transmission buffer assignment between channel 0 and channel 1.
- When the CFDGFTBAC.FLXMB1 bit is set, flexible transmission buffer assignment between channel 2 and channel 3.
- When the CFDGFTBAC.FLXMB2 bit is set, flexible transmission buffer assignment between channel 4 and channel 5.

Flexible transmission buffer assignment configured in the CFDGFTBAC register and Flexible CAN mode configured in the CFDGFCMC register should not be used simultaneously.

The interrupt of the rented buffer is output to the interrupt of the rented channel.

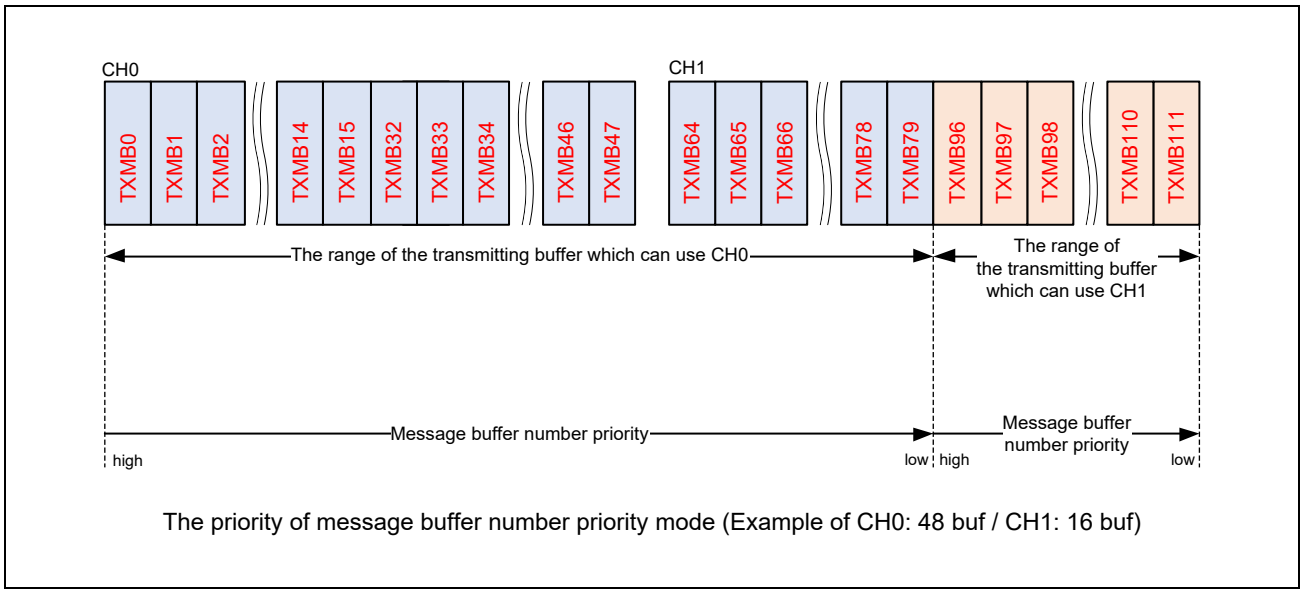
When using TXQ through the rented buffer, TXQ should only be set within the rented range.

The rented TXMB operates in the mode of the channel to be used.

For example, if channel 1 is in reset mode, channel 0 transmission is possible using a rented TXMB.

Also, the rented TXMB is affected by the transmission status of the rented channel, TX SCAN PROCESS, or aborted transmission.

In message buffer number priority mode, TXMB0 has a higher priority and TXMB79 (when 16 buffers are borrowed) has a lower priority. The priority of the rented TXMB is lowered.



The priority of message buffer number priority mode (Example of CH0: 48 buf / CH1: 16 buf)

Figure 7.9-60 Example of Message Buffer Number Priority Mode

The example of a rental channel 0 and channel 1 is shown below.

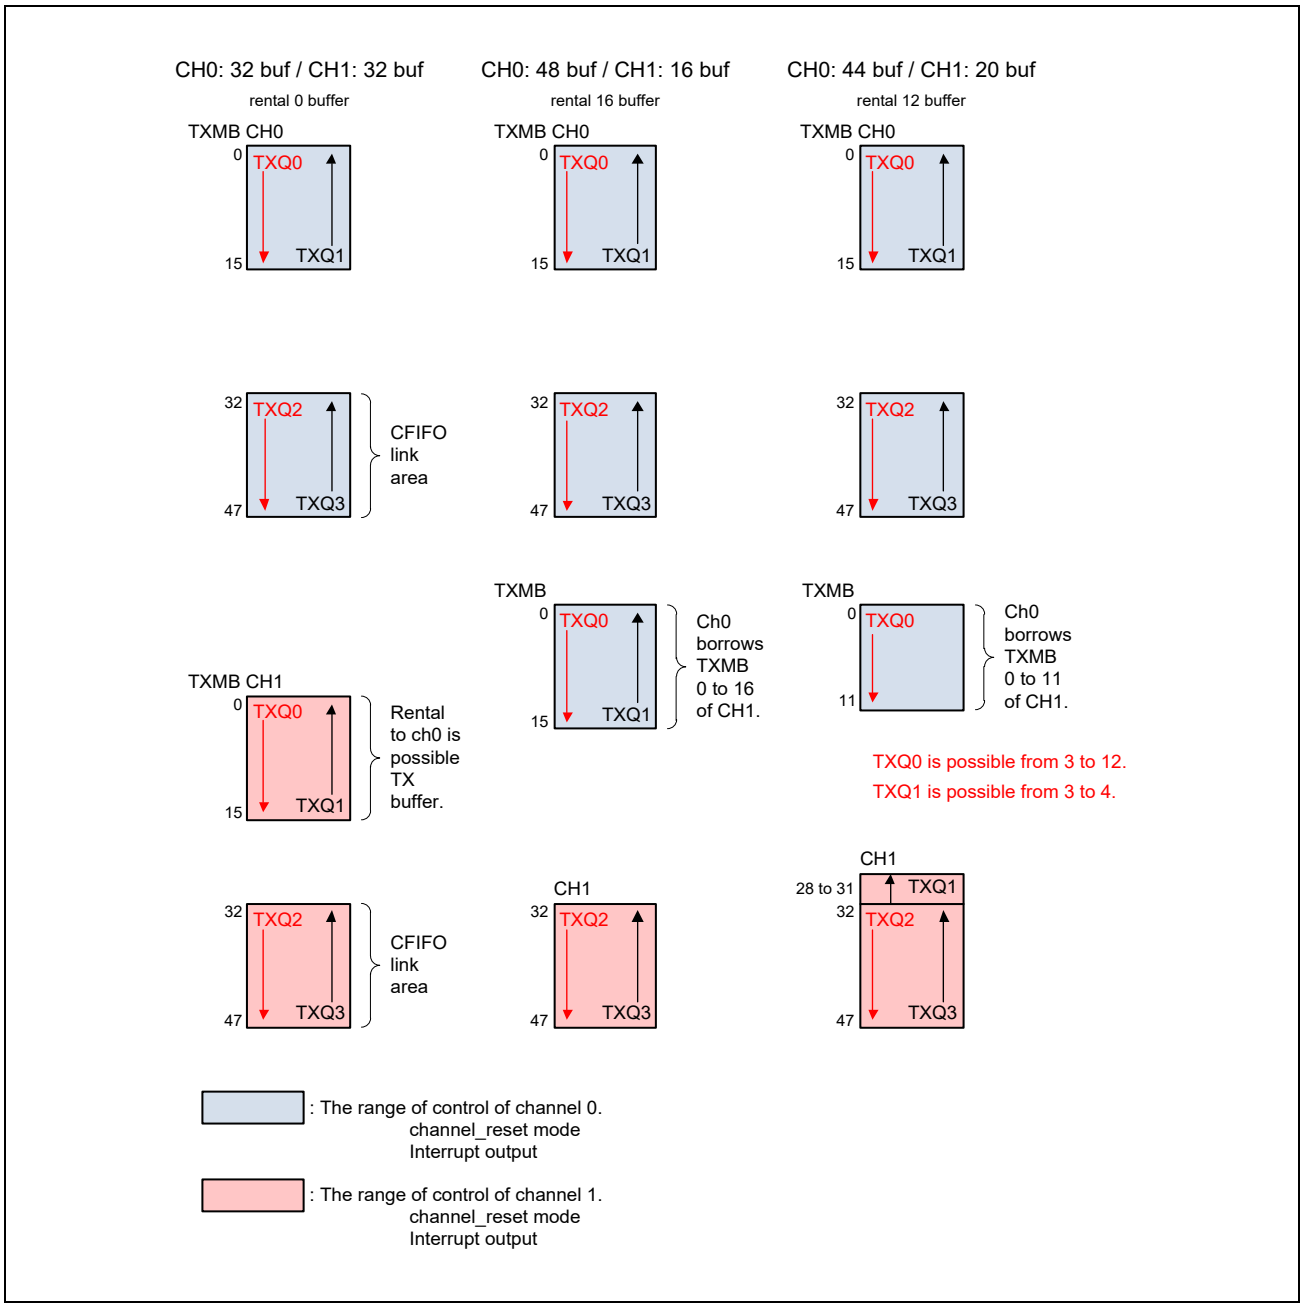


Figure 7.9-61 Example of Message Buffer Number Priority Mode (Channels 0 and 1)

SECTION 7 LOW-SPEED INTERFACE

7.10 12-Bit A/D Converter (ADC)

7.10.1 Overview

This LSI incorporates three units of 12-bit successive approximation A/D converter. Analog inputs of up to 8 channels are selectable per unit and total up to 24 channels.

Each unit of the 12-bit A/D converter converts analog inputs of up to 8 selected channels to a 12-bit digital value through successive approximation.

The 12-bit A/D converter has three operating modes: single scan mode in which analog inputs selected arbitrarily are converted only once in ascending order of channel number; continuous scan mode in which analog inputs selected arbitrarily are continuously converted in ascending order of channel number; and group scan mode in which analog inputs are arbitrarily selected and divided into two groups (group A and group B) or three groups (group A, group B and group C), and then analog inputs of channels selected for each group are converted in ascending order of channel number.

In group scan mode, the conditions for scanning start of each groups (A, B or A, B, C) (internal trigger) can be independently selected, thus allowing A/D conversion of each groups to be started independently. In addition to the above actions, the group priority operation in group scan mode accepts the start of scanning the priority group during the scan of the low priority group, interrupts the scan of the low priority group, and starts the scan of the priority group. The priority of group priority operations is group A > group B > group C. In group priority operation, if the scan start of group B is accepted during the scan of group C, the scan of group C is interrupted and the scan of group B is started. If the scan start of group A is accepted during the scan of group C, the scan of group A is started. The scan of Group C is interrupted and the scan of Group A is started. Similarly, if the scan start of Group A is accepted during the scan of Group B, the scan of Group B is interrupted and the scan of Group A is started. The interrupted group scan is able to resume after the priority group scan is complete also.

In double trigger mode, one analog input channel arbitrarily selected is converted in single scan mode or group scan mode (group A), and the resulting data of A/D conversion started by the first and second internal triggers are stored into different registers (duplication of A/D conversion data).

Safety features such as data register overwrite check and automatic clearing of data registers are available.

The compare function is a function that outputs an interrupt (ada_compai_n / ada_compbi_n) when the A/D conversion value of the selected channel by specifying the upper and lower reference values for each window A/B matches the comparison conditions. The event (ada_elccondmtch / ada_elccondunmtch) is output according to the event conditions (A or B, A and B, A exor B). In addition, a comparator operation that compares the A/D conversion value with the lower reference value is also possible.

Table 7.10-1 lists the specifications of the 12-bit A/D converter and **Table 7.10-2** indicates the functions of the 12-bit A/D converter. **Figure 7.10-1** shows a block diagram of the 12-bit A/D converter.

Table 7.10-1 ADC Specifications (1/2)

Item	Description
Number of units	3 units
Input channels	• Up to 8 channels per unit • Up to 24 channels in total for 3 units
A/D conversion method	Successive approximation method

Table 7.10-1 ADC Specifications (2/2)

Item	Description
Resolution	Selectable from 12 bits or 8 bits
Sampling rate	• 2.5 Msps (when A/D conversion clock ADC_m_ADCLK is 50 MHz) (m = 0 to 2) • 2.0 Msps (when A/D conversion clock ADC_m_ADCLK is 40 MHz) (m = 0 to 2) • 1.0 Msps (when A/D conversion clock ADC_m_ADCLK is 20 MHz) (m = 0 to 2) • 0.5 Msps (when A/D conversion clock ADC_m_ADCLK is 10 MHz) (m = 0 to 2) • 0.25 Msps (when A/D conversion clock ADC_m_ADCLK is 5 MHz) (m = 0 to 2)
A/D conversion clock	ADC_m_ADCLK (50 MHz / 40 MHz / 20 MHz / 10 MHz / 5 MHz) (m = 0 to 2)
Operating modes	• Single scan mode: A/D conversion is performed only once on the analog inputs of arbitrarily selected channels • Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs of arbitrarily selected channels • Group scan mode: Two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used. Only the combination of groups A and B can be selected when the number of the groups is two. Analog inputs that are arbitrarily selected are divided into two groups (group A and B) or three groups (group A, B, and C), and A/D conversion of the analog input selected on a group basis is performed only once. The conditions for scanning start of groups A, B, and C (internal trigger) can be independently selected, thus allowing A/D conversion of each group to be started independently. • Group scan mode (when Group A is given priority): If a priority-group trigger is input during scanning of the low-priority group, scan of the low-priority group is stopped and scan of the priority group is started. The priority order is group A (highest) > group B > group C (lowest). Whether or not to restart scanning of the low-priority group after processing for the high- priority group completes, is selectable. Rescan can also be set to start either from the beginning of the selected channel or the channel on which A/D conversion is not completed.
Conditions for A/D conversion start	• Software trigger • Internal trigger Trigger by the multi-function timer pulse unit (GPT) and event link controller (ELC)*1 • External trigger A/D conversion can be triggered by the external trigger ADTRG.
Functions	• Selectable A/D-converted value addition mode or average mode • Double-trigger mode (duplication of A/D conversion data) • Automatic clear function for A/D data registers • Digital comparison of values in the comparison and data registers, and between values in the data registers • Overwrite checking function of the A/D data register
Interrupt sources and ELC events	• ada_adireq_n: A/D scan end interrupt , A/D scan end interrupt for Group A) • ada_gbadireq_n: A/D scan end interrupt for Group B • ada_gcadireq_n: A/D scan end interrupt for Group C • ada_compai_n: Window A compare match • ada_compbi_n: Window B compare match • ada_adelcreq: A/D scan end interrupt for ELC • ada_elccondmtch: compare match • ada_elccondunmtch: compare unmatch • ada_adereq_n: A/D error interrupt request by overwrite check
ELC interface	• An ELC event is generated upon completion of all scans • Able to start scanning by a trigger from the ELC
Power-Down mode	The A/D converter can be set to power-down mode.

Note 1. The ELC is included in the Interrupt Control Unit (ICU).

7.10.2 ADC Registers

The base address for the ADC is as follows.

Table 7.10-4 Register Base Address

Base Register Name	ADC ch	Base Address
<ADC0_base>	ADC0	0_11C0_0000h (51C0_0000h*1, 41C0_0000h*2)
<ADC1_base>	ADC1	0_11C0_2800h (51C0_2800h*1, 41C0_2800h*2)
<ADC2_base>	ADC2	0_11C0_2C00h (51C0_2C00h*1, 41C0_2C00h*2)

Note 1. CM33 Address Space Non-Secure

Note 2. CM33 Address Space Secure

7.10.2.1 List of Registers

The registers are listed below. (m = 0 to 2)

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
A/D Control Register	ADCm_ADCSR	0000h	0000h	16
A/D Conversion Status Register	ADCm_ADREF	00h	0002h	8
Reserve	-	-	0003h	
A/D Channel Select Register A0	ADCm_ADANSA0	0000h	0004h	16
Reserve	-	-	0006h to 0007h	-
A/D-Converted Value Addition/Average Function Channel Select Register 0	ADCm_ADADS0	0000h	0008h	16
Reserve	-	-	000Ah to 000Bh	-
A/D-Converted Value Addition/Average Count Select Register	ADCm_ADADC	00h	000Ch	8
Reserve	-	-	000Dh	-
A/D Control Extended Register	ADCm_ADCER	0000h	000Eh	16
A/D Conversion Start Trigger Select Register	ADCm_ADSTRGR	0000h	0010h	16
Reserve	-	-	0012h to 0013h	-
A/D Channel Select Register B0	ADCm_ADANSB0	0000h	0014h	16
Reserve	-	-	0016h to 0017h	-
A/D Data Duplication Register	ADCm_ADDBLDR	0000h	0018h	16
A/D Data Register 0	ADCm_ADDR0	0000h	0020h	16
A/D Data Register 1	ADCm_ADDR1	0000h	0022h	16
A/D Data Register 2	ADCm_ADDR2	0000h	0024h	16
A/D Data Register 3	ADCm_ADDR3	0000h	0026h	16
A/D Data Register 4	ADCm_ADDR4	0000h	0028h	16
A/D Data Register 5	ADCm_ADDR5	0000h	002Ah	16
A/D Data Register 6	ADCm_ADDR6	0000h	002Ch	16
A/D Data Register 7	ADCm_ADDR7	0000h	002Eh	16
Reserve	-	-	0030h to 007Ch	-
A/D Event Link Control Register	ADCm_ADELCCR	00h	007Dh	8
Reserve	-	-	007Eh to 007Fh	-
A/D Group Scan Priority Control Register	ADCm_ADGSPCR	0000h	0080h	16

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Reserve	-	-	0082h to 0083h	-
A/D Data Duplication Register A	ADCm_ADDBLDRA	0000h	0084h	16
A/D Data Duplication Register B	ADCm_ADDBLDRB	0000h	0086h	16
Reserve	-	-	0088h to 008Bh	-
A/D Compare Function Window A/B Status Monitoring Register	ADCm_ADWINMON	00h	008Ch	8
Reserve	-	-	008Dh to 008Fh	-
A/D Compare Function Control Register	ADCm_ADCMPCR	0000h	0090h	16
Reserve	-	-	0092h to 0093h	-
A/D Compare Function Window A Channel Select Register 0	ADCm_ADCMPANSR0	0000h	0094h	16
Reserve	-	-	0096h to 0097h	-
A/D Compare Function Window A Comparison Condition Setting Register 0	ADCm_ADCMPLR0	0000h	0098h	16
Reserve	-	-	009Ah to 009Bh	-
A/D Comparison Function Window A Lower Level Setting Register	ADCm_ADCMPDR0	0000h	009Ch	16
A/D Comparison Function Window A Upper Level Setting Register	ADCm_ADCMPDR1	0000h	009Eh	16
A/D Comparison Function Window A Channel Status Register 0	ADCm_ADCMPSR0	0000h	00A0h	16
Reserve	-	-	00A2h to 00A5h	-
A/D Compare Function Window B Channel Select Register	ADCm_ADCMPBNSR	00h	00A6h	8
Reserve	-	-	00A7h	-
A/D Compare Function Window B Lower-Side Level Setting Register	ADCm_ADWINLLB	0000h	00A8h	16
A/D Compare Function Window B Upper-Side Level Setting Register	ADCm_ADWINULB	0000h	00AAh	16
A/D Compare Function Window B Status Register	ADCm_ADCMPBSR	00h	00ACh	8
Reserve	-	-	00ADh to 00D3h	-
A/D Channel Select Register C0	ADCm_ADANSC0	0000h	00D4h	16
Reserve	-	-	00D6h to 00D8h	-
A/D Group C Trigger Select Register	ADCm_ADGCTRGR	00h	00D9h	8
Reserve	-	-	00DAh to 01E1h	-
A/D Error Control Register	ADCm_ADERCR	00h	1E2h	8
A/D Error Clear Register	ADCm_ADERCLR	00h	1E3h	8
Reserve	-	-	01E4h to 01E7h	-
A/D Overwrite Error Register	ADCm_ADOWER	0000h	1E8h	16
A/D Overwrite Error Extended Register	ADCm_ADOWEER	0000h	1EAh	16

7.10.2.2 ADC Register Descriptions

The prefix (ADCm_) of the register names is omitted in this and subsequent sections.

7.10.2.2.1 A/D Data Registers

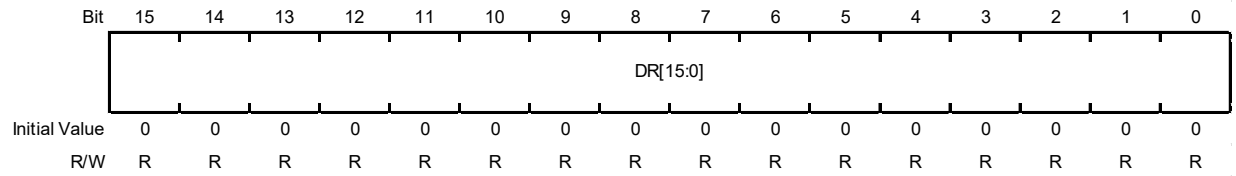
The A/D-converted value has a 12-bit/8-bit accuracy. The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFMT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the A/D conversion accuracy specify bits (ADCER.ADPRC[1:0]) (12-bit or 8-bit accuracy is selectable.)
- The setting of the Addition count select bits (ADADC.ADC[2:0]) (once, twice, three times, four times, or sixteen times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

When the number of the conversion count is set from one to four in the addition mode, the A/D conversion addition result is expanded by 2 bits and stored in the A/D data register. When the number of the conversion count is sixteen in the addition mode, the A/D conversion addition result is expanded by 4 bits and stored in the A/D data register.

(1) A/D Data Register n (ADCm_ADDRn) (n = 0 to 7)

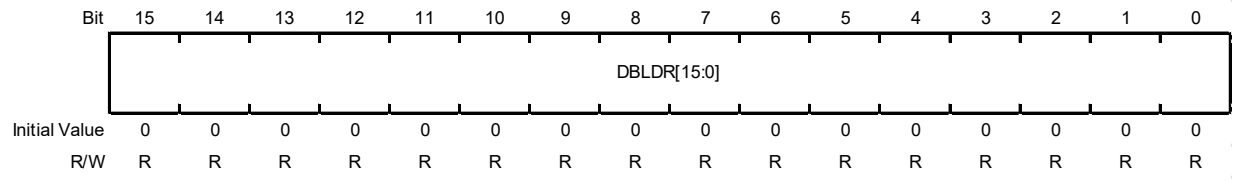
Access Size : 16 bits
Address : <ADCm_base> + 0020h + n x 0002h
Initial Value : 0000h



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DR[15:0]	0h	R	The result of A/D conversion (n: Number of channel)

(2) A/D Data Duplication Register (ADCm_ADDBLDR)

Access Size : 16 bits
Address : <ADCm_base> + 0018h
Initial Value : 0000h



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DBLDR[15:0]	0h	R	The result of A/D conversion in response to the second trigger in double trigger mode.

(3) A/D Data Duplication Register A (ADCm_ADDBLDRA)

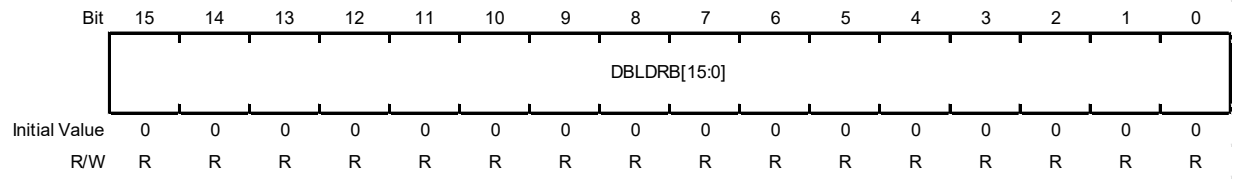
Access Size : 16 bits
Address : <ADCm_base> + 0084h
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DBLDRA[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DBLDRA[15:0]	0h	R	The result of A/D conversion during extended operation in double trigger mode

(4) A/D Data Duplication Register B (ADCm_ADDBLDRB)

Access Size : 16 bits
Address : <ADCm_base> + 0086h
Initial Value : 0000h



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DBLDRB[15:0]	0h	R	The result of A/D conversion during extended operation in double trigger mode

7.10.2.2.2 A/D Control Register (ADCm_ADCSR)

Access Size : 16 bits

Address : <ADCm_base> + 0000h

Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADST	ADCS[1:0]		ADIE	-	-	TRGE	EXTRG	DBLE	GBADIE	-	DBLANS[4:0]				
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	R	R	RW	RW	RW	RW	R	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15	ADST	0h	RW	A/D conversion Start 0b: Stops A/D conversion process 1b: Starts A/D conversion process
14, 13	ADCS[1:0]	0h	RW	Scan Mode Select 00b: Single scan mode 01b: Group scan mode 10b: Continuous scan mode 11b: Setting prohibited
12	ADIE	0h	RW	Scan End Interrupt Enable 0b: Disables ada_adireq_n interrupt generation upon scan completion 1b: Enables ada_adireq_n interrupt generation upon scan completion
11, 10	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9	TRGE	0h	RW	Trigger Start Enable 0b: Disables A/D conversion to be started by the internal or external trigger 1b: Enables A/D conversion to be started by the internal or external trigger
8	EXTRG	0h	RW	Trigger Select 0b: A/D conversion is started by the internal trigger (GPT, ELC) 1b: A/D conversion is started by the external trigger (ADTRG)
7	DBLE	0h	RW	Double Trigger Mode Select 0b: Deselects double trigger mode 1b: Selects double trigger mode
6	GBADIE	0h	RW	Group B Scan End Interrupt Enable 0b: Disables ada_gbadireq_n interrupt generation upon group B scan completion 1b: Enables ada_gbadireq_n interrupt generation upon group B scan completion
5	-	0h	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
4 to 0	DBLANS[4:0]	0h	RW	Double Trigger Channel Select These bits select one analog input channel for double triggered operation. The setting is only valid while double trigger mode is selected.

7.10.2.2.3 A/D Conversion Status Register (ADCm_ADREF)

The ADREF register indicates the status of the A/D conversion.

Access Size : 8 bits
Address : <ADCm_base> + 0002h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	ADSCACT	-	-	-	-	-	-	ADF
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	ADSCACT	0h	R	0b: A/D conversion is not in progress. 1b: A/D conversion is in progress.
6 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read.
0	ADF	0h	R	Reserved The read value is undefined.

7.10.2.2.4 A/D Channel Select Register (ADCm_ADANSA0)

Access Size : 16 bits
Address : <ADCm_base> + 0004h
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	ANSA0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7 to 0	ANSA0[7:0]	0h	RW	A/D conversion Analog input Channel Select ANSA0[0] bit corresponds to ch0 and ANSA0[7] corresponds to ch7. 0b: ch0-ch7 are not subjected to conversion. 1b: ch0-ch7 are subjected to conversion.

7.10.2.2.5 A/D-Converted Value Addition/Average Function Channel Select Register 0 (ADCm_ADADS0)

Access Size : 16 bits

Address : <ADCm_base> + 0008h

Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	ADS0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7 to 0	ADS0[7:0]	0h	RW	A/D-Converted Value Addition/Average Channel Select ADS0[0] bit corresponds to ch0 and ADS0[7] corresponds to ch7. 0b: A/D-converted value addition/average mode for ch0 to ch7 is not selected 1b: A/D-converted value addition/average mode for ch0 to ch7 is selected

7.10.2.2.6 A/D-Converted Value Addition/Average Count Select Register (ADCm_ADADC)

Access Size : 8 bits
Address : <ADCm_base> + 000Ch
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	AVEE	-	-	-	-	ADC[2:0]		
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7	AVEE	0h	RW	Average Mode Enable 0b: Addition mode is selected 1b: Average mode is selected
6 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2 to 0	ADC[2:0]	0h	RW	Addition Count Select 000b: 1-time conversion (no addition; same as normal conversion) 001b: 2-time conversion (addition once) 010b: 3-time conversion (addition twice)*1 011b: 4-time conversion (addition three times) 101b: 16-time conversion (addition 15 times)*2 Others: Setting prohibited

Note 1. When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the Addition count to 3 times (ADADC.ADC[2:0] = 010b).

Note 2. For the 12-bit conversion accuracy, the Addition count can only be set to select 16 times (ADADC. ADC[2:0] = 101b).

7.10.2.2.7 A/D Control Extended Register (ADCm_ADCER)

Access Size : 16 bits

Address : <ADCm_base> + 000Eh

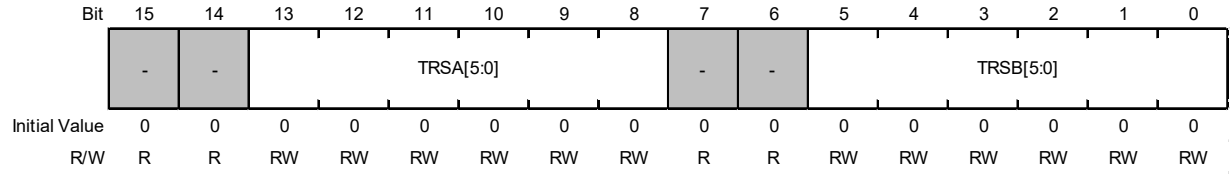
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ADRFMT	-	-	-	-	-	-	-	-	-	ACE	-	-	ADPRC[1:0]		-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	R	R	R	R	R	R	R	R	R	RW	R	R	RW	RW	R

Bit	Bit Name	Initial Value	R/W	Description
15	ADRFMT	0h	RW	A/D Data Register Format Select 0b: Right-alignment is selected for the A/D data register format 1b: Left-alignment is selected for the A/D data register format
14 to 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5	ACE	0h	RW	A/D Data Register Automatic Clearing Enable 0b: Disables automatic clearing 1b: Enables automatic clearing
4, 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2, 1	ADPRC[1:0]	0h	RW	A/D Conversion Accuracy Specify 00b: A/D conversion is performed with 12-bit accuracy 10b: A/D conversion is performed with 8-bit accuracy Others: Setting prohibited
0	-	0h	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

7.10.2.2.8 A/D Conversion Start Trigger Select Register (ADCm_ADSTRGR)

Access Size : 16 bits
Address : <ADCm_base> + 0010h
Initial Value : 0000h



Bit	Bit Name	Initial Value	R/W	Description
15, 14	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
13 to 8	TRSA[5:0]	0h	RW	A/D Conversion Start Trigger Select Select the A/D conversion start trigger in single scan mode and continuous mode. In group scan mode, the A/D conversion start trigger for group A is selected. See **Table 7.10-6** for details.
7, 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5 to 0	TRSB[5:0]	0h	RW	A/D Conversion Start Trigger Select for Group B Select the A/D conversion start trigger for group B in group scan mode. See **Table 7.10-5** for details.

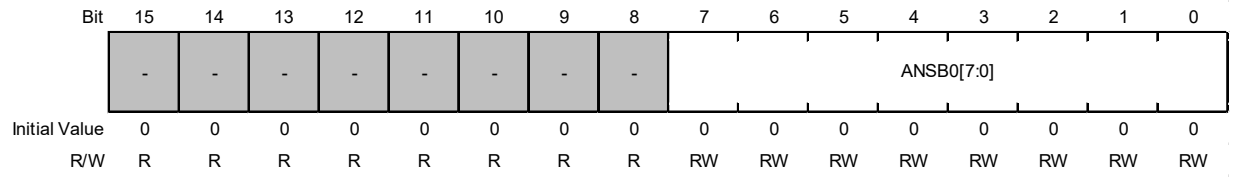
7.10.2.2.9 A/D Channel Select Register B0 (ADCm_ADANSB0)

Access Size : 16 bits

Address : <ADCm_base> + 0014h

Initial Value : 0000h



Bit	Bit Name	Initial Value	R/W	Description
15 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7 to 0	ANSB0[7:0]	0h	RW	A/D Conversion Analog Input Channel Select ANSB0[0] bit corresponds to ch0 and ANSB0[7] corresponds to ch7. 0b: ch0-ch7 are not subjected to conversion 1b: ch0-ch7 are subjected to conversion

7.10.2.2.10 A/D Error Control Register (ADCm_ADERCR)

ADERCR controls the error detection function. For details about errors, see **7.10.3.10 Error Detection Function (Overwrite Check Function)**.

Access Size : 8 bits
Address : <ADCm_base> + 01E2h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	OWEIE	-	-
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	RW	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	OWEIE	0h	RW	Overwrite Error Interrupt Enable 0b: Disables interrupt generation when an overwrite error is detected. 1b: Enables interrupt generation when an overwrite error is detected.
1, 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

7.10.2.2.11 A/D Error Clear Register (ADCm_ADERCLR)

The A/D error clear register is a write-only register for clearing errors.

Access Size : 8 bits
Address : <ADCm_base> + 01E3h
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	OWEC	-	-
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	RW	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	OWEC	0h	RW	Overwrite Error Clear Writing 0b: Disables clearing overwrite errors. Writing 1b: Enables clearing overwrite errors.
1, 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.

7.10.2.2.12 A/D Overwrite Error Register (ADCm_ADOWER)

The ADOWER register is a status register that indicates that the results of A/D conversion in the ADDRn register were not read and an overwrite occurred.

Access Size : 16 bits
Address : <ADCm_base> + 01E8h
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	OWE[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read.
7 to 0	OWE[7:0]	0h	R	Overwrite Error OWE[0] bit corresponds to ch0 and OWE[7] corresponds to ch7. 0b: No overwrite error occurred in ADDR0 to ADDR7. 1b: An overwrite error occurred in ADDR0 to ADDR7.

7.10.2.2.13 A/D Overwrite Error Extended Register (ADCm_ADOWEER)

The ADOWEER register is a status register that indicates that the results of A/D conversion in the ADDBLDRB, ADDBLDRA, ADDBLDR registers were not read and an overwrite occurred.

Access Size : 16 bits
Address : <ADCm_base> + 01EAh
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	DOWE	DAOWE	DBOWE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read.
2	DOWE	0h	R	A/D Data Duplication Register overwrite Error 0b: No overwrite error occurred in ADDBLDR. 1b: An overwrite error occurred in ADDBLDR.
1	DAOWE	0h	R	A/D Data Duplication Register A overwrite Error 0b: No overwrite error occurred in ADDBLDRA. 1b: An overwrite error occurred in ADDBLDRA.
0	DBOWE	0h	R	A/D Data Duplication Register B overwrite Error 0b: No overwrite error occurred in ADDBLDRB. 1b: An overwrite error occurred in ADDBLDRB.

7.10.2.2.14 A/D Event Link Control Register (ADCm_ADELCCR)

Access Size : 8 bits
Address : <ADCm_base> + 007Dh
Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	GCELC	ELCC[1:0]	
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
2	GCELC	0h	RW	Event control bit for Group C 0b: Not output event signal at the end of group scan of group C. 1b: Output event signal at the end of group scan of group C.
1, 0	ELCC[1:0]	0h	RW	Event link control bits Control the end of scan event (ada_adelcreq). To enable the ELCC[1:0] setting, set GCELC to 0. 00b: Output event signal at the end of scan except the end of group scan of group B, C 01b: Output event signal at the end of group scan of group B 1xb: Output event signal at the end of scan

7.10.2.2.15 A/D Group Scan Priority Control Register (ADCm_ADGSPCR)

Access Size : 16 bits
Address : <ADCm_base> + 0080h
Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GBRP	LGRRS	-	-	-	-	-	-	-	-	-	-	-	-	GBRSCN	PGS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15	GBRP	0h	RW	Low priority Group Single Scan Continuous Start*2 (Enabled only when PGS = 1b. Set 0 when PGS = 0b.) 0b: Single scan for Low priority group is not continuously activated 1b: Single scan for Low priority group is continuously activated
14	LGRRS	0h	RW	Restart Channel Select (Enabled only when PGS = 1b and GBRSCN = 1b, Set 0b when PGS = 0b.) 0b: Restart scan with first channel 1b: Restart scan with suspended channel
13 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1	GBRSCN	0h	RW	Low priority Group Restart Setting (Enabled only when PGS = 1b. Set 0 when PGS = 0b.) 0b: Scanning for group is not restarted when priority control is performed 1b: Scanning for group is restarted when priority control is performed
0	PGS	0h	RW	Group Priority Control Setting*1 0b: Operation is without group priority control 1b: Operation is with group priority control

Note 1. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation cannot be guaranteed.

Note 2. When the GBRP bit has been set to 1, single scan is performed continuously for low priority group regardless of the setting of the GBRSCN bit.

7.10.2.2.16 A/D Compare Function Window A/B Status Monitoring Register (ADCm_ADWINMON)

Access Size : 8 bits

Offset Address : <ADCm_base> + 008Ch

Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	MONCMPB	MONCMPA	-	-	-	MONCOMB
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7, 6	-	All 0	R	Reserved Whenever it is read, 0b is read.
5	MONCMPB	0h	R	Comparing result monitor for window B 0b: Window B comparing condition does not match. 1b: Window B comparing condition match.
4	MONCMPA	0h	R	Comparing result monitor for window A 0b: Window A comparing condition does not match. 1b: Window A comparing condition match.
3 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read.
0	MONCOMB	0h	R	Combination result monitor 0b: Window A/B combination condition does not match. 1b: Window A/B combination condition match.

7.10.2.2.17 A/D Compare Function Control Register (ADCm_ADCMPCR)

Access Size : 16 bits

Offset Address : <ADCm_base> + 0090h

Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMPAIE	WCMPE	CMPBIE	-	CMPAE	-	CMPBE	-	-	-	-	-	-	-	CMPAB[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	R	RW	R	RW	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15	CMPAIE	0h	RW	Compare window A Interrupt Enable 0b: Generation of an ada_compai_n interrupt in response to matches with a condition for comparison is disabled. 1b: Generation of an ada_compai_n interrupt in response to matches with a condition for comparison is enabled.
14	WCMPE	0h	RW	Window Function enable 0b: Window function disabled 1b: Window function enabled
13	CMPBIE	0h	RW	Compare window B Interrupt Enable 0b: Generation of an ada_compbi_n interrupt in response to matches with a condition for comparison is disabled. 1b: Generation of an ada_compbi_n interrupt in response to matches with a condition for comparison is enabled.
12	-	0h	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
11	CMPAE	0h	RW	Window A operation permission 0b: Window A is not in operation. Output of ada_elccondmtch/ada_elccondummtch is not permitted. 1b: Window A is in operation.
10	-	0h	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
9	CMPBE	0h	RW	Window B operation permission 0b: Window B is not in operation. Output of ada_elccondmtch/ada_elccondummtch is not permitted. 1b: Window B is in operation.
8 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
1, 0	CMPAB[1:0]	0h	RW	Window A/B combination condition setting This bit is valid when both windows A/B are valid (CMPAE = 1b and CMPBE = 1b). 00b: Output ada_elccondmtch when window A comparison condition match OR window B comparison condition match, otherwise output ada_elccondummtch 01b: Output ada_elccondmtch when window A comparison condition match EXOR window B comparison condition match, otherwise output ada_elccondummtch 10b: Output ada_elccondmtch when window A comparison condition match AND window B comparison condition match, otherwise output ada_elccondummtch 11b: Setting prohibited.

7.10.2.2.18 A/D Compare Function Window A Channel Select Register 0 (ADCm_ADCMPANSR0)

Access Size : 16 bits

Offset Address : <ADCm_base> + 0094h

Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	CMPCHA0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7 to 0	CMPCHA0[7:0]	0h	RW	Window A Channel Select Set the CMPCHA0[7:0] bits when ADCSR.ADST = 0b. CMPCHA0[0] bit corresponds to ch0 and CMPCHA0[7] corresponds to ch7. 0b: Channel is not target 1b: Channel is target

7.10.2.2.19 A/D Compare Function Window A Comparison Condition Setting Register 0 (ADCm_ADCMPLR0)

Access Size : 16 bits

Offset Address : <ADCm_base> + 0098h

Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	CMPLCHA0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

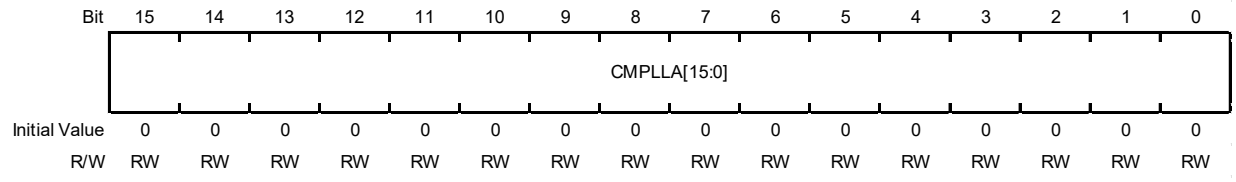
Bit	Bit Name	Initial Value	R/W	Description
15 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7 to 0	CMPLCHA0 [7:0]	0h	RW	Window A comparison condition for target channel (ch0-7) setting CMPLCHA0[7] corresponds to channel 7 and CMPLCHA0[0] corresponds to channel 0. When the comparison result of each channel input matches the set condition, the ADCMPSR0.CMPSTCHA0n bit is set to 1b and a compare interrupt (ada_compai_n) is generated. - When window function is disabled (ADCMPCR.WCMPE = 0-: 0b: ADCMPDR0 register value > A/D-converted value 1b: ADCMPDR0 register value < A/D-converted value - When window function is enabled (ADCMPCR.WCMPE = 1)- 0b: A/D-converted value < ADCMPDR0 register value or ADCMPDR1 register value < A/D-converted value 1b: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value

7.10.2.2.20 A/D Comparison Function Window A Lower Level Setting Register (ADCm_ADCMPDR0)

Access Size : 16 bits

Offset Address : <ADCm_base> + 009Ch

Initial Value : 0000h



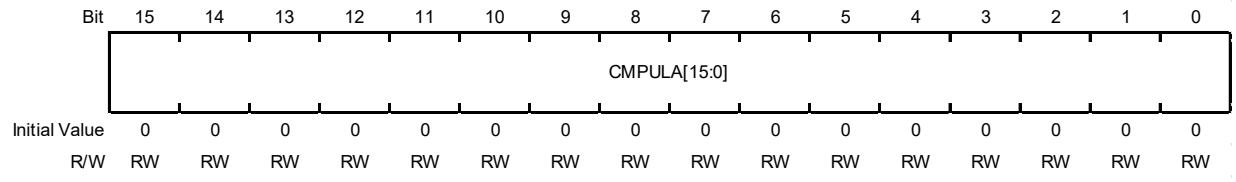
Bit	Bit Name	Initial Value	R/W	Description
15 to 0	CMPLLA[15:0]	0h	RW	Reference Lower data setting when using the compare function window A

7.10.2.2.21 A/D Comparison Function Window A Upper Level Setting Register (ADCm_ADCMPDR1)

Access Size : 16 bits

Offset Address : <ADCm_base> + 009Eh

Initial Value : 0000h



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	CMPULA[15:0]	0h	RW	Reference Upper data setting when using the compare function window A

7.10.2.2.22 A/D Comparison Function Window A Channel Status Register 0 (ADCm_ADCMPSR0)

Access Size : 16 bits

Address : <ADCm_base> + 00A0h

Initial Value : 0000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	CMPSTCHA0[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
7 to 0	CMPSTCHA0 [7:0]	0h	RW	Window A Status Flag CMPSTCHA0[0] bit corresponds to ch0 and CMPSTCHA0[7] corresponds to ch7. This flag shows the comparison result of each targeted channel, when window A is operating (ADCMPCR.CMPAE = 1b). If this flag is set while ADCMPCR.CMPAIE = 1b, a compare interrupt (ada_compai_n) request is generated. 0b: Condition does not match 1b: Condition matches

7.10.2.2.23 A/D Compare Function Window B Channel Select Register (ADCm_ADCMPBNSR)

Access Size : 8 bits

Address : <ADCm_base> + 00A6h

Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	CMPLB	-	CMPCHB[5:0]					
Initial Value	0	0	0	0	0	0	0	0
R/W	RW	R	RW	RW	RW	RW	RW	RW

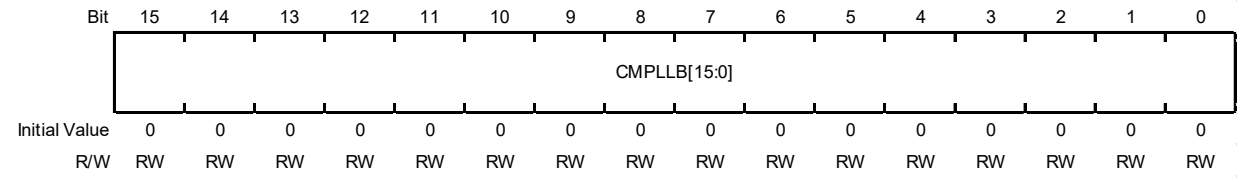
Bit	Bit Name	Initial Value	R/W	Description
7	CMPLB	0h	RW	Window B Comparison Condition Setting When the comparison result of target input matches the set condition, the ADCMPBSR0.CMPSTB bit is set to 1b and a compare interrupt (ada_compbi_n) is generated. - When window function is disabled (ADCMPCR.WCMPE = 0b)- 0b: ADWINLLB register value > A/D-converted value. 1b: ADWINLLB register value < A/D-converted value. - When window function is enabled (ADCMPCR.WCMPE = 1b)- 0b: A/D-converted value < ADWINLLB register value or ADWINULB register value < A/D-converted value. 1b: ADWINLLB register value < A/D-converted value < ADWINULB register value.
6	-	0h	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
5 to 0	CMPCHB[5:0]	0h	RW	Window B Channel Select Select channels for comparing with window B condition. Set the CMPCHB[5:0] bits when the ADCSR.ADST bit is 0b. 00h: ch0 01h: ch1 02h: ch2 : 07h: ch7 3Fh: No channel is selected Others: Setting prohibited

7.10.2.2.24 A/D Compare Function Window B Lower-Side Level Setting Register (ADCm_ADWINLLB)

Access Size : 16 bits

Address : <ADCm_base> + 00A8h

Initial Value : 0000h



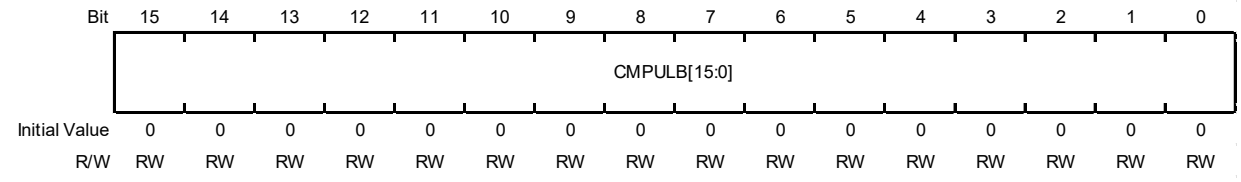
Bit	Bit Name	Initial Value	R/W	Description
15 to 0	CMPLLB[15:0]	0h	RW	Reference lower data setting when using the compare function window B

7.10.2.2.25 A/D Compare Function Window B Upper-Side Level Setting Register (ADCm_ADWINULB)

Access Size : 16 bits

Address : <ADCm_base> + 00AAh

Initial Value : 0000h



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	CMPULB[15:0]	0h	RW	Reference upper data setting when using the compare function window B

7.10.2.2.26 A/D Compare Function Window B Status Register (ADCm_ADCMPBSR)

Access Size : 8 bits

Address : <ADCm_base> + 00ACh

Initial Value : 00h

Bit	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	CMPSTB
Initial Value	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW0

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value should always be 0b.
0	CMPSTB	0h	RW0	Window B Flag When window B operation is enabled (ADCMPCR.CMPBE = 1b), this bit indicates the comparison result of channels to which window B comparison conditions are applied. 0b: Comparison conditions are not met 1b: Comparison conditions are met

7.10.2.2.27 A/D Channel Select Register C0 (ADCm_ADANSC0)

7.10.3 Operation

7.10.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

There are three operating modes: single scan mode, continuous scan mode, and group scan mode. In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until the ADCSR.ADST bit is cleared to 0b from 1b. In group scan mode, the selected channels of group A and the selected channels of group B (and the selected channels of group C) are scanned once after starting to be scanned according to the respective internal triggers (GPT, ELC).

In single scan mode and continuous scan mode, A/D conversion is performed for ANn pins selected by the ADANSA0 register, starting from the pin with the smallest number n. In group scan mode, A/D conversion is performed for ANn pins selected by the ADANSA0 register for group A, and performed for ANn pins selected by the ADANSB0 register for group B and performed for ANn pins selected by the ADANSC0 register for group C, respectively, starting from the pin with the smallest number n.

Double trigger mode is to be used with single scan mode or group scan mode. With double trigger mode being enabled, A/D conversion data of a channel selected by the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by any of the internal triggers (GPT, ELC) selected by the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use the double trigger.

To enable double trigger extended mode, select double trigger mode, and then select the internal trigger by the ADSTRGR.TRSA[5:0].

- ADSTRGR.TRSA[5:0] = 100101b
  GTADTRA4N or GTAGTRB4N
- ADSTRGR.TRSA[5:0] = 101000b
  GTADTRA7N or GTADTRB7N

In the double trigger extended mode, in addition to the normal double trigger mode operation, the A/D conversion data activated by the odd number trigger (GTADTRA4N , GTADTRA7N) is stored in the A/D data duplex register A (ADDBLDRA), and the A/D conversion data activated by the even number trigger (GTADTRB4N , GTADTRB7N) is stored in the A/D Data Duplication register B (ADDBLDRB).

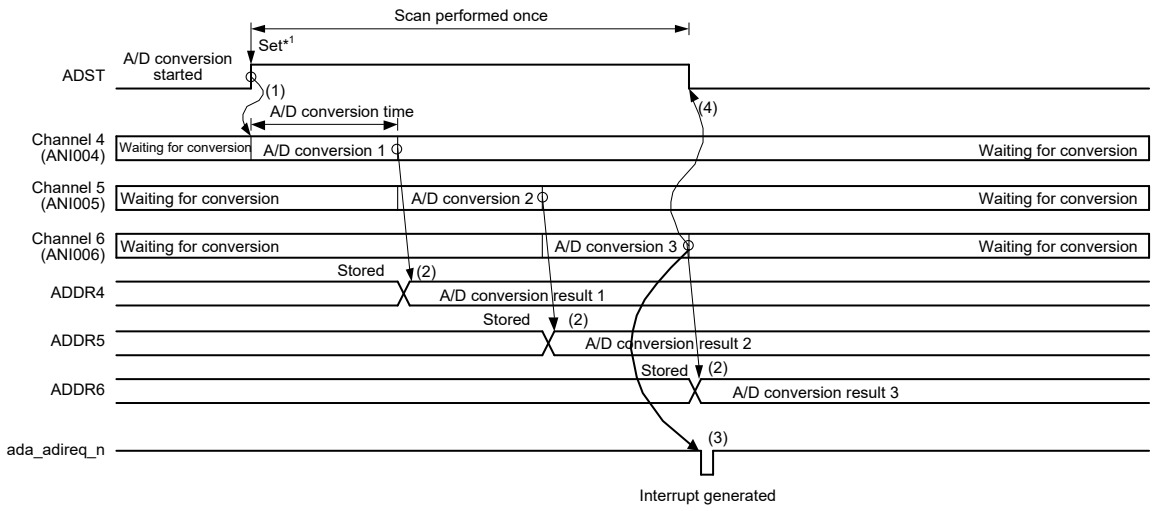
If two types of trigger source occur at the same time, the data is not sorted by the trigger factor and the A/D conversion data is stored in the Data Duplication register B (ADDBLDRB). If one trigger is performing A/D conversion and the other trigger is input, the other trigger will be ignored.

7.10.3.2 Single Scan Mode

7.10.3.2.1 Basic operation

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as below.

1. When the ADCSR.ADST bit becomes 1b (A/D conversion start) due to software or internal trigger (GPT, ELC) input, A/D conversion starts in ascending order of n of ANn selected in the ADANSA0 register.
2. When the A/D conversion of one channel is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
3. If the ADCSR.ADIE bit is set to 1b (ada_adireq_n interrupt enabled at the end of scanning) after A/D conversion of all selected channels is completed, an ada_adireq_n interrupt request is generated.
4. ADCSR.ADST bit holds 1b (A/D conversion start) during A/D conversion and is automatically cleared when A/D conversion of all selected channels is completed, and the 12-bit A/D converter goes into a standby state.



Note 1. The arrows in this figure indicate instruction execution by software.

Figure 7.10-2 Example of Operation in Single Scan Mode (Basic Operation ANI004 to ANI006 Selected)

7.10.3.2.2 A/D conversion in double trigger mode

When double trigger mode is selected in single scan mode, A/D conversion is performed for two rounds of single scan operation started by a internal trigger (GPT, ELC).

A/D conversion Data Duplication is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting ADCSR.DBLE to 1b. When ADCSR.DBLE is set to 1b, the channel selection of the ADANSA0 register is disabled.

To select the double trigger mode, use ADSTRGR.TRSA[5:0] to select the internal trigger (GPT, ELC), set the ADCSR.EXTRG bit to 0b, and set the ADCSR.TRGE bit to 1b. Also, do not use software trigger.

1. When the ADCSR.ADST bit becomes 1b (A/D conversion start) due to the internal trigger (GPT, ELC) input, the A/D conversion of the 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
2. When the A/D conversion is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
3. ADCSR.ADST is automatically cleared and the 12-bit A/D converter is in the standby state. At this time, the ada_adireq_n interrupt does not occur regardless of the setting of the ADCSR.ADIE bit (ada_adireq_n interrupt enabled by the end of scanning).
4. When the ADCSR.ADST bit becomes 1b (A/D conversion start) by the second internal trigger input, A/D conversion of the 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
5. When the A/D conversion is completed, the A/D conversion result is stored in the A/D Data Duplication register (ADDBLDR) dedicated to the double trigger mode.
6. If the ADCSR.ADIE bit is set to 1 (ada_adireq_n interrupt enabled at the end of scanning), an ada_adireq_n interrupt request is generated.
7. The ADCSR.ADST bit holds 1 (A/D conversion start) during A/D conversion, is automatically cleared when A/D conversion is completed, and the 12-bit A/D converter is in the standby state.

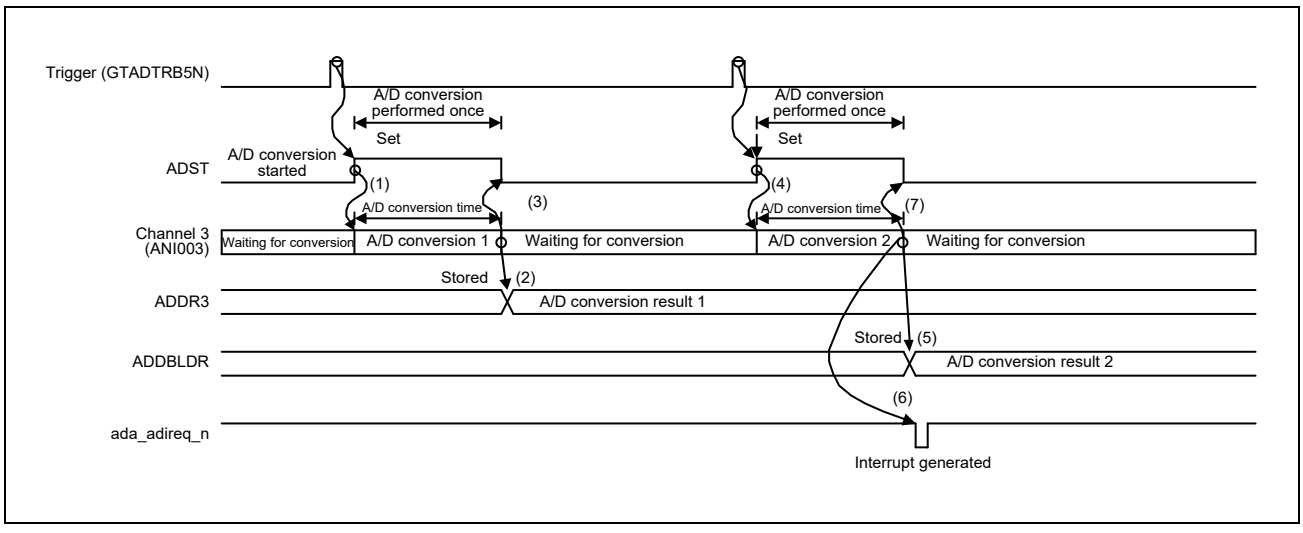


Figure 7.10-3 Example of Operation in Single Scan Mode (Double Trigger Mode, ANI003 Duplicated, GTADTRB5N is Selected as the Trigger)

7.10.3.2.3 Extended operations when double trigger mode is selected

When double trigger mode is selected in single scan mode, single scan is performed twice.

To enable double trigger extended mode, and then select the following internal trigger by the ADSTRGR.TRSA[5:0].

- ADSTRGR.TRSA[5:0] = 100001b
  GTADTRA0N or GTADTRB0N
- ADSTRGR.TRSA[5:0] = 100110b
  GTADTRA5N or GTADTRB5N

And set the ADCSR.EXTRG bit to 0b and the ADCSR.TRGE bit to 1b. Also, do not use software trigger.

A/D conversion Data Duplication is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting ADCSR.DBLE to 1b. When ADCSR.DBLE is set to 1b, the channel selection of the ADANSA0 register is disabled.

1. When the ADCSR.ADST bit becomes 1b (A/D conversion start) by GTADTRA0N, A/D conversion of 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
2. When the A/D conversion is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy) and A/D Data Duplication register A (ADDBLDRA).
3. ADCSR.ADST is automatically cleared and the 12-bit A/D converter is in the standby state. At this time, the ada_adireq_n interrupt does not occur regardless of the setting of the ADCSR.ADIE bit (ada_adireq_n interrupt enabled by the end of scanning).
4. When the ADCSR.ADST bit becomes 1b (A/D conversion start) by GTADTRB0N input, A/D conversion of 1 channel selected by the ADCSR.DBLANS[4:0] bits starts.
5. When the A/D conversion is completed, the A/D conversion result is stored in the A/D Data Duplication register (ADDBLDR) and the A/D Data Duplication register B (ADDBLDRB).
6. If the ADCSR.ADIE bit is set to 1b (ada_adireq_n interrupt enabled at the end of scanning), an ada_adireq_n interrupt request is generated.
7. The ADCSR.ADST bit holds 1b (A/D conversion start) during A/D conversion, is automatically cleared when A/D conversion is completed, and the 12-bit A/D converter is in the standby state.

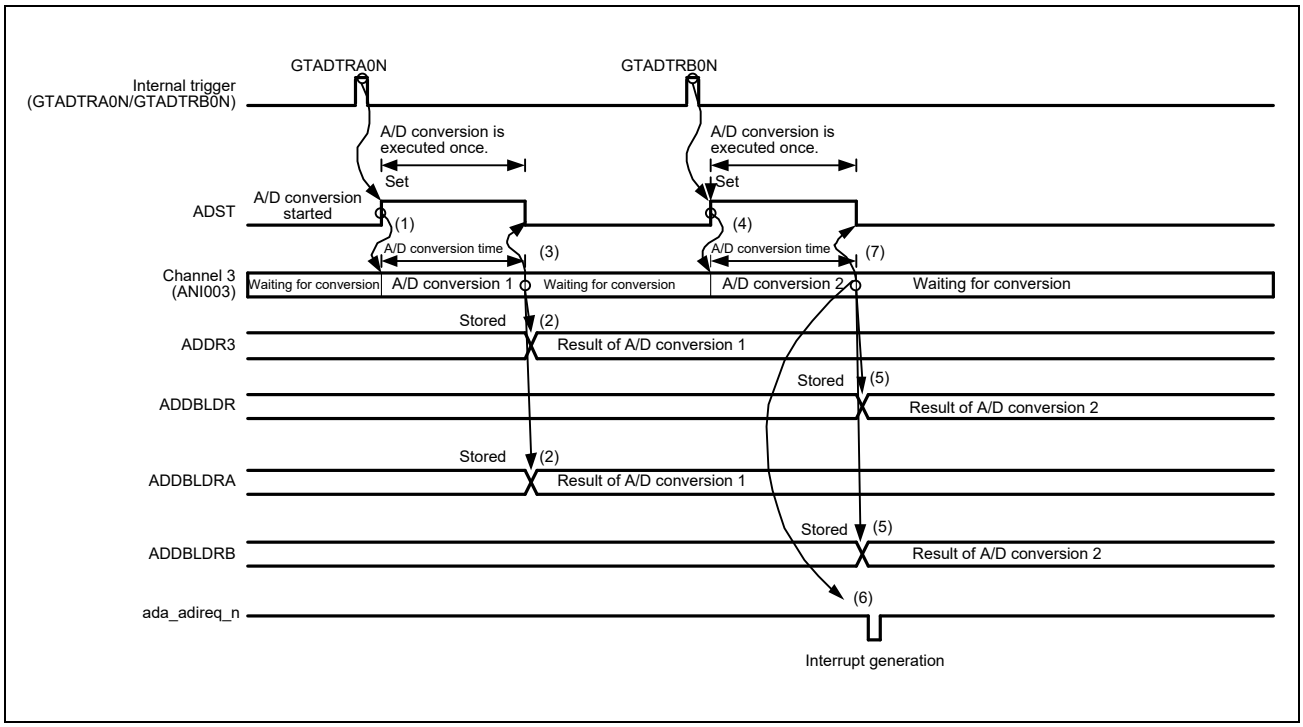

Figure 7.10-4 Example of Extended Operation in Double Trigger Mode (Duplication Selected for ANI003, GTADTRA0N , GTADTRB0N Selected)

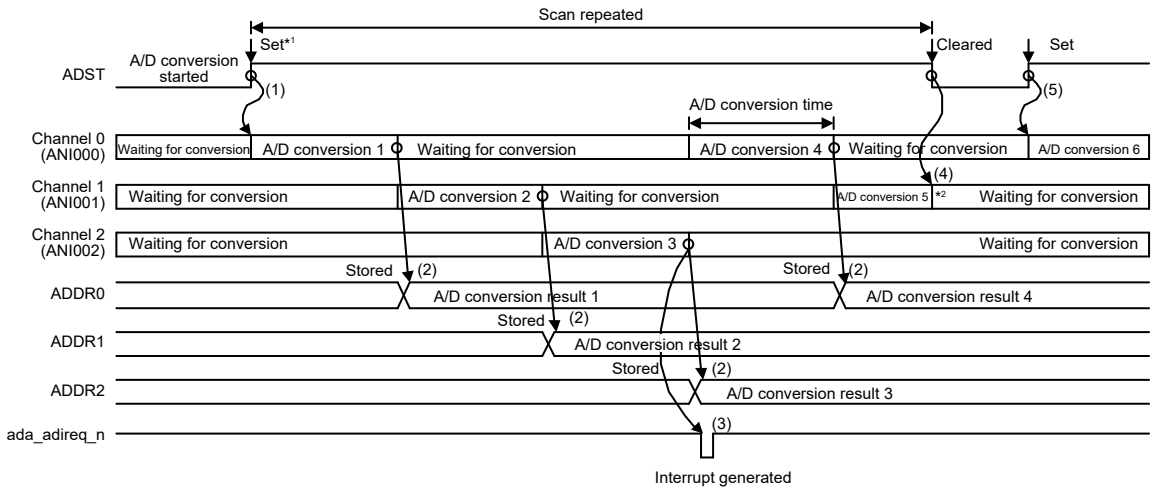
7.10.3.3 Continuous Scan Mode

7.10.3.3.1 Basic operation (not use S/H circuits)

In basic operation of continuous scan mode, A/D conversion is performed repeatedly on the analog input of the channels selected by the ADANSA0 register.

1. When the ADCSR.ADST bit becomes 1 (A/D conversion start) by software, internal trigger (GPT, ELC), or external trigger, A/D conversion starts in ascending order of n of ANn selected in the ADANSA0 register.
2. When the A/D conversion of one channel is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy).
3. If the ADCSR.ADIE bit is set to 1b (ada_adireq_n interrupt enabled at the end of scanning) after A/D conversion of all selected channels is completed, an ada_adireq_n interrupt request is generated. In addition, the 12-bit A/D converter continuously starts A/D conversion in ascending order of n of ANn selected in the ADANSA0 register.
4. The ADCSR.ADST bit is not cleared automatically, and (2) to (3) are repeated during 1b (A/D conversion start). When the ADCSR.ADST bit is set to 0b (A/D conversion stopped), A/D conversion is stopped and the 12-bit A/D converter is in the standby state.
5. After that, when the ADCSR.ADST bit becomes 1b (A/D conversion starts), A/D conversion starts again in ascending order of n of ANn selected in the ADANSA0 register.



Note 1. Ignored the result of A/D conversion 5.

Figure 7.10-5 Example of Operation in Continuous Scan Mode (Basic Operation ANI000 to ANI002 Selected)

7.10.3.4 Group Scan Mode

7.10.3.4.1 Basic operation

In basic operation of group scan mode, A/D conversion is performed once on the analog inputs of all the specified channels in each group (A and B or A, B and C) after scanning is started by an internal trigger (GPT, ELC). Scan operation of each group is similar to the scan operation in single scan mode.

To set the trigger for group scan mode, select the trigger for group A with the ADSTRGR.TRSA[5:0] bits, select the trigger for group B with the ADSTRGR.TRSB[5:0] bits, and select the trigger for group C with the ADGCTRGR.TRSC[5:0] bits. Triggers for groups A, B, and C should be separate triggers so that scans for groups A, B, and C do not occur at the same time. Also, do not use software triggers. For the channels to be scanned, select the group A channel in the ADANSA0 register, select the group B channel in the ADANSB0 register, and select the group C channel in the ADANSC0 register.

The following is an example of the operation of the group scan mode by the internal trigger from the GPT. Group A is set to start conversion with a GTADTRA0N trigger from GPT, Group B is set to start conversion with a GTADTRA3N trigger from GPT, and Group C is set to start conversion with a GTADTRA4N trigger from GPT.

1. Start scanning of group A with GTADTRA0N trigger from GPT.
2. If the ADCSR.ADIE bit is set to 1b (ada_adireq_n interrupt enabled) at the end of group A scanning, the ada_adireq_n interrupt is output.
3. Start scanning Group B with GTADTRA3N trigger from GPT.
4. If the ADCSR.GBADIE bit is set to 1b (ada_gbadireq_n interrupt enabled) at the end of Group B scanning, an ada_gbadireq_n interrupt is output.
5. Trigger GTADTRA4N from GPT to start scanning for Group C.
6. If the ADGCTRGR.GCADIE bit is set to 1b (ada_gcadireq_n interrupt enabled) at the end of Group C scanning, an ada_gcadireq_n interrupt is output.

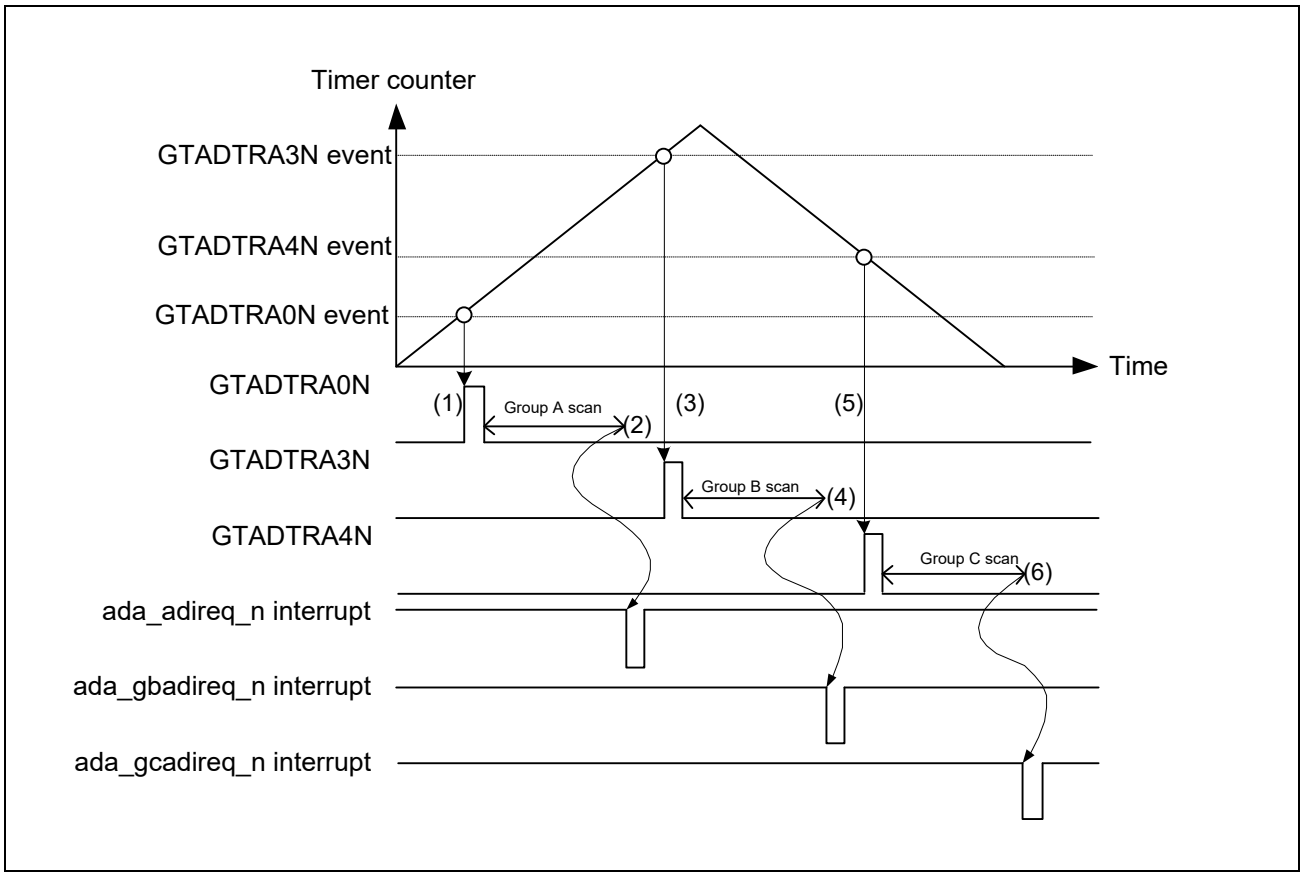


Figure 7.10-6 Example of Operation in Group Scan Mode (Basic Operation Trigger from GPT)

7.10.3.4.2 A/D conversion in double trigger mode

When double trigger mode is selected in group scan mode, group A controls two single scan mode executions starting with an internal trigger (GPT, ELC) as a series of operations. Group B and Group C behave in the same way as single scan mode started with an internal trigger (GPT, ELC).For group scan mode trigger settings, the ADSTRGR.TRSA[5:0] bits select the trigger for group A, the ADSTRGR.TRSB[5:0] bits select the trigger for group B, and ADGCTRGR.TRSC[5:0] bits selects the trigger for Group C. Triggers for groups A, B, and C should be separate triggers so that scans for groups A, B, and C do not occur at the same time. Also, do not use software triggers.

If you select “GTADTRA0N or GTADTRB0N” to “GTADTRA15N or GTADTRB15N” as the trigger for group A in the ADSTRGR.TRSA[5:0] bits, it operates in double trigger extended mode.

For the channels to be scanned, select the group A channel with the ADCSR.DBLANS[4:0] bits, select the group B channel with the ADANSB0 register, and select the group C channel with the ADANSC0 register.

A/D conversion Data Duplication is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following shows an operation example when the group scan mode and double trigger mode are set by the internal trigger from the GPT. Group A is set to start conversion with a GTADTRA1N trigger from GPT, Group B is set to start conversion with a GTADTRB7N trigger from GPT, and Group C is set to start conversion with a GTADTRA5N trigger from GPT.

1. Start scanning Group C with the GTADTRA5N trigger from the GPT.
2. If the ADGCTRGR.GCADIE bit is set to 1 (ada_gcadireq_n interrupt enabled) at the end of Group C scanning, the ada_gcadireq_n interrupt is output.
3. The GTADTRB7N trigger from the GPT starts scanning for group B.
4. If the ADCSR.GBADIE bit is set to 1b (ada_gbadireq_n interrupt enabled) at the end of Group B scanning, an ada_gbadireq_n interrupt is output.
5. The first GTADTRA1N trigger from the GPT will start the first scan of Group A.
6. At the end of the first scan of Group A, the converted data is stored in ADDRy, and the ada_adireq_n interrupt request does not occur regardless of the setting of the ADCSR.ADIE bit.
7. The second GTADTRA1N trigger from the GPT will start the second scan of Group A.
8. At the end of the second scan of group A, the conversion data is stored in ADDBLDR, and if the ADCSR.ADIE bit is set to 1b (ada_adireq_n interrupt enabled), the ada_adireq_n interrupt is output.
9. The second GTADTRB7N trigger from the GPT starts the second scan of group B.
10. At the end of the second scan of Group B, if the ADCSR.GBADIE bit is set to 1b (ada_gcadireq_n interrupt enabled), an ada_gbadireq_n interrupt is output.
11. The second GTADTRA5N trigger from the GPT starts the second scan of Group C.
12. At the end of the second scan of Group C, if the ADGCTRGR.GCADIE bit is set to 1b (ada_gcadireq_n interrupt enabled), an ada_gcadireq_n interrupt is output.

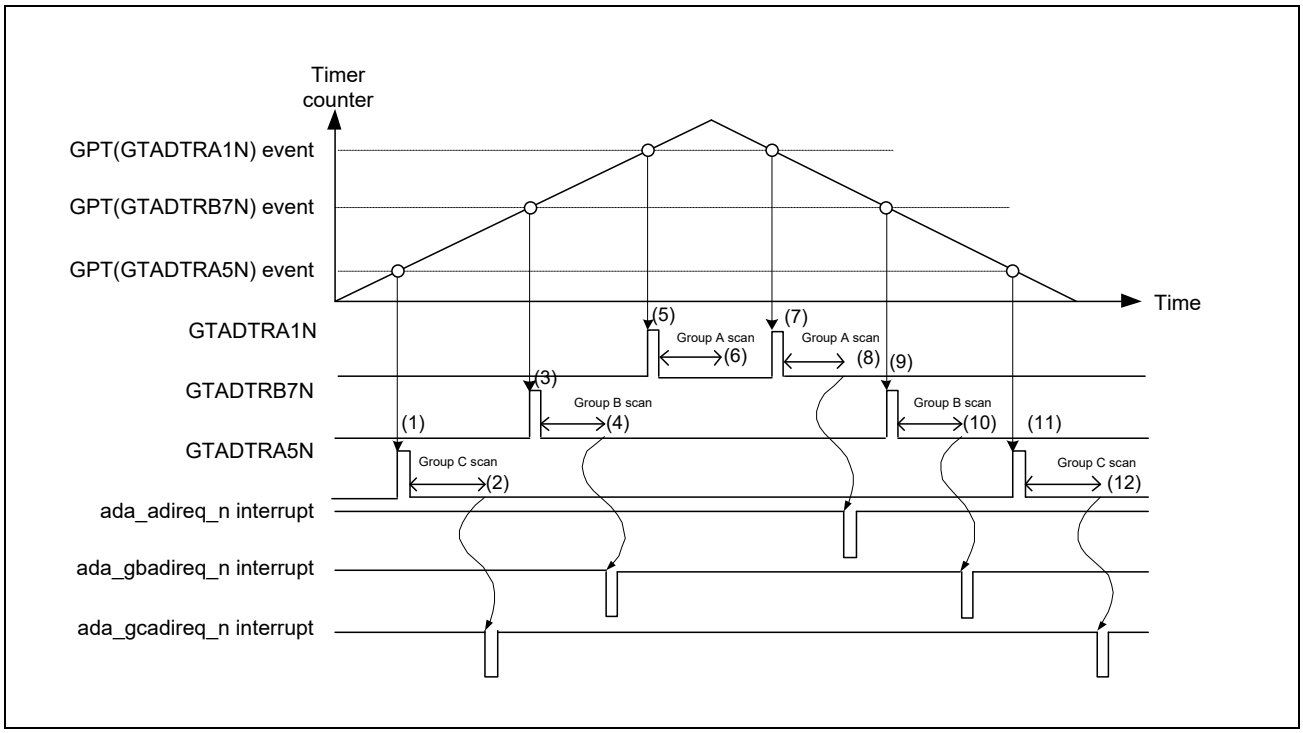

Figure 7.10-7 Example of Operation in Group Scan Mode with Double Trigger (Trigger from GPT)

7.10.3.4.3 Operation under Group Priority Control

When the ADGSPCR.PGS bit is set to 1b in group scan mode, group priority operation is performed. Group priority is in the order of group A > group B > group C. The number of groups used in group scan mode can be selected from either 2 (Groups A, B) or 3 (Groups A, B, C) depending on the setting of ADGCTRGR.GRCE. When setting the PGS bit in the ADPGSCR register to 1, follow the procedure in **Figure 7.10-8** to set the relevant registers. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

In the basic operation of group scan mode, the trigger input generated during scanning of groups A, B, and C is ignored, and the scanning operation of groups A, B, and C is the same as that of single scan mode.

In the group priority operation, if there is a trigger input of the priority group during the scan of the low priority group, the scan of the low priority group is interrupted and the priority group is scanned.

When the ADGSPCR.GBRSCN bit is 0b, the low priority group is in the standby state after the priority group scan is completed. Also, the low priority group trigger input that occurs during the scan is ignored.

When the ADGSPCR.GBRSCN bit is 1b, the scan of the low priority group is automatically re-executed after the scan of the priority group is completed. In addition, the trigger input of the low priority group that occurred during the scan of the priority group is valid, and the scan of the low priority group is automatically executed after the scan of the priority group is completed.

When the ADGSPCR.GBRSCN bit is 1b and the ADGSPCR.LGRRS is 0b, the scan of the low priority group is restarted from the beginning. Also, when ADGSPCR.LGRRS is 1b, the scan of the low priority group is re-executed from the interrupted channel.

Table 7.10-8 shows the setting of the ADGSPCR.GBRSCN bit and the operation when a trigger is input during scanning.

When the ADGSPCR.GBRP bit is set to 1, the scan operation of the lowest priority group is the operation of executing a single scan continuously.

For the trigger setting in group scan mode, select the group A internal trigger with the ADSTRGR.TRSA[5:0] bits, and set the group B internal trigger different from the group A trigger with the ADSTRGR.TRSB[5:0] bits. Select a Group C internal trigger that is different from the Group A and B triggers on the ADGCTRGR.TRSC[5:0] bits.

When the group scan mode is set to 2 groups (ADGCTRGR.GRCE bit is set to 0b) and the ADGSPCR.GBRP bit is set to 1, the ADSTRGR.TRSB[5:0] bits is set to 3Fh.

If the group scan mode is set to 3 groups (ADGCTRGR.GRCE bit is set to 1) and the ADGSPCR.GBRP bit is set to 1, set the ADGCTRGR.TRSC[5:0] bits to 3Fh.

For the channels to be scanned, select the group A channel in the ADANSA0 register, select the group B channel in the ADANSB0 register, and select the group C channel in the ADANSC0 register.

Table 7.10-9 shows Group priority operation setting and operation mode of 2 groups, and **Table 7.10-10** shows Group priority operation setting and operation mode of 3 groups.

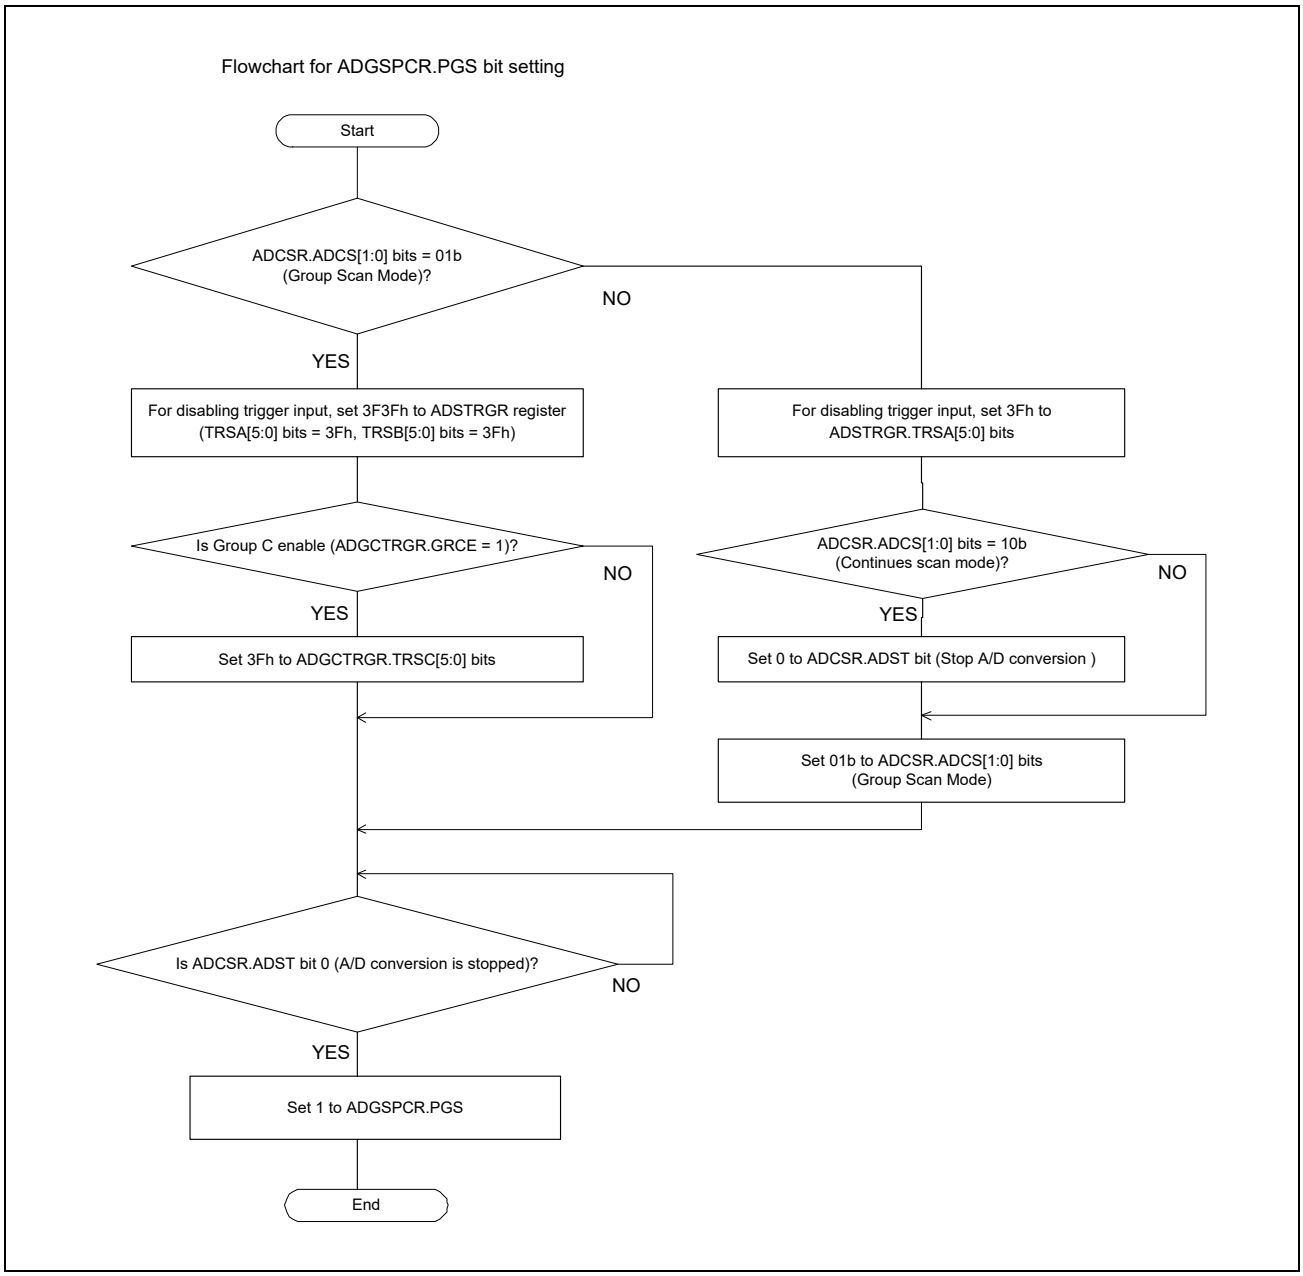

Figure 7.10-8 Flowchart for ADGSPCR.PGS Bit Setting

Table 7.10-8 Control of A/D Conversion Operations according to the Settings of the ADGSPCR.GBRSCN Bit

A/D Conversion Operation	Trigger Input	ADGSPCR.GBRSCN = 0b	ADGSPCR.GBRSCN = 1b
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion is performed on group B after A/D conversion on group A is completed.
	Input of trigger for group C	Trigger input is ineffective.	A/D conversion is performed on group C after A/D conversion on group A is completed.
When A/D conversion for group B is in progress	Input of trigger for group A	Conversion for group B that is in progress is discontinued and conversion for group A starts.	• Conversion in progress for group B is discontinued and conversion for group A starts. • Conversion for group B starts after conversion for group A is completed.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group C	Trigger input is ineffective.	A/D conversion is performed on group C after A/D conversion on group B is completed.

Table 7.10-9 Group Priority Operation Setting and Operation Mode for 2 Groups (ADGSPCR.PGS = 1b, ADGCTRGR.GRCE = 0b)

ADGSPCR			
GBRSCN	LGRRS	GBRP	Operation Mode
0	—	0	Group priority operation of 2 groups (groups A and B). When the trigger of group A is input, the scan of group B ends (does not re-execute).
1	0	0	Group priority operation of 2 groups (groups A and B). After the scan of group B is interrupted, group B restarts the scan from the beginning of the channel specified by ADANSB0 after the scan of group A is completed.
1	1	0	Group priority operation of 2 groups (groups A and B). After the scan of group B is interrupted, group B resumes the scan from the interrupted channel among the channels specified by ADANSB0 after the scan of group A is completed.
—	0	1	Group priority operation of 2 groups (groups A and B). Group B continuously performs a single scan without inputting a start trigger. After the group B scan is interrupted, the single scan is restarted from the beginning of the channel specified by ADANSB0 after the group A scan is completed.
1	1	1	Group priority operation of 2 groups (groups A and B). Group B continuously performs a single scan without inputting a start trigger. After the scan of group B is interrupted, the single scan is restarted from the interrupted channel among the channels specified by ADANSB0 after the scan of group A is completed.

Table 7.10-10 Group Priority Operation Setting and Operation Mode for 3 Groups (ADGSPCR.PGS = 1b, ADGCTRGR.GRCE = 1b)

ADGSPCR			
GBRSCN	LGRRS	GBRP	Operation Mode
0	—	0	Group priority operation of 3 groups (groups A, B, C). When the trigger of group A is input, the scan of group B ends (does not re-execute). When the trigger of group A or group B is input, the scan of group C ends (does not re- execute).
0	—	1	Group priority operation of 3 groups (groups A, B, C). When the trigger of group A is input, the scan of group B ends (does not re-execute). Group C continuously performs a single scan without inputting a start trigger. After the group C scan is interrupted, the scan is restarted from the beginning of the channel specified by ADANSC0 after the group A/B scan is completed.
1	0	0	Group priority operation of 3 groups (groups A, B, C). After the scan of group B is suspended, the scan restarts from the top channel of the channels specified by ADANSB0 after the group A scan is completed. After the scan of group C is suspended, the scan restarts from the top channel of the channels specified by ADANSC0 after the group A/B scan is completed.
1	1	0	Group priority operation of 3 groups (groups A, B, C). After the scan of group B is suspended, the scan restarts from the interrupted channel of the channels specified by ADANSB0 after the group A scan is completed. After the scan of group C is suspended, the scan restarts from the interrupted channel of the channels specified by ADANSC0 after the group A/B scan is completed.
1	0	1	Group priority operation of 3 groups (groups A, B, C). After the scan of group B is interrupted, the scan is restarted from the beginning of the channel specified by ADANSB0 after the scan of group A is completed. Group C continuously performs a single scan without inputting a start trigger. After the group C scan is interrupted, the single scan is restarted from the beginning of the channel specified by ADANSC0 after the group A/B scan is completed.
1	1	1	Group priority operation of 3 groups (groups A, B, C). After the A/D conversion process of group B is interrupted, the interrupted channel is restarted from the channels specified by ADANSB0 after the scan of group A is completed. Group C continuously performs a single scan without inputting a start trigger. After the group C scan is interrupted, the single scan is restarted from the interrupted channel among the channels specified by ADANSC0 after the group A/B scan is completed.

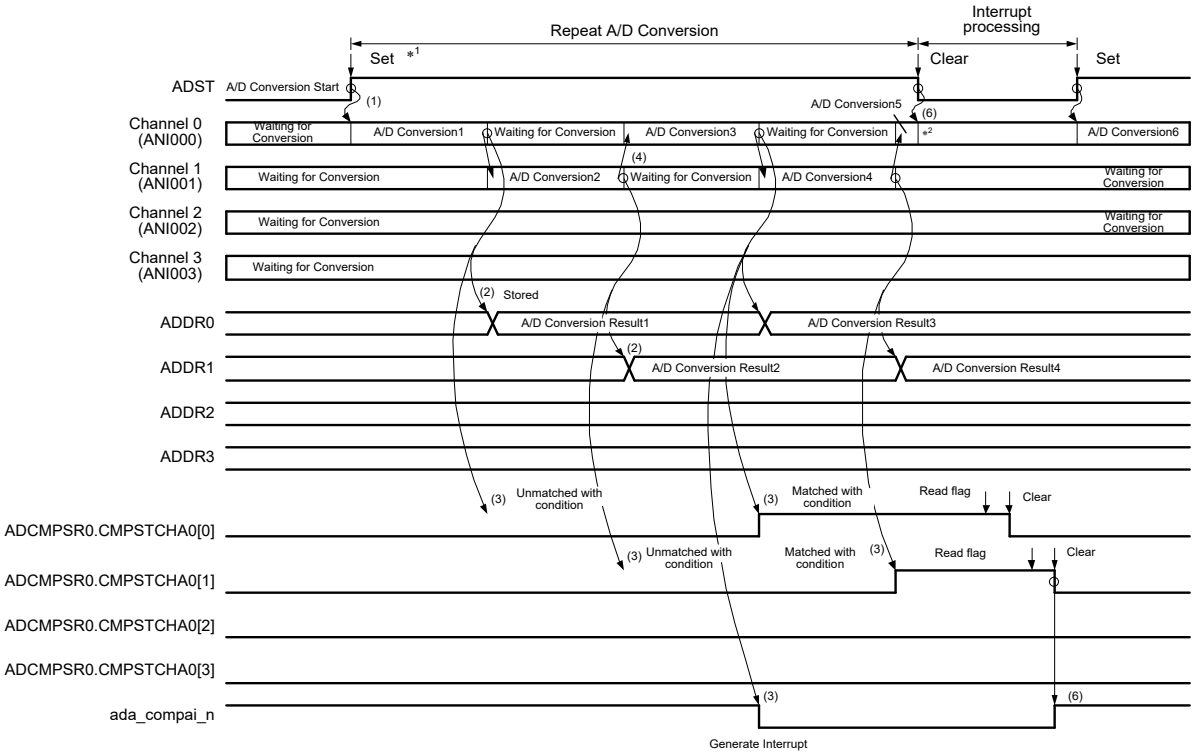
7.10.3.5 Compare Function (Window A, Window B)

7.10.3.5.1 Compare function window A/B

The compare function is a function that compares the reference value set in the register with the A/D conversion result, and the reference value can be set for each window (A/B). Double trigger mode cannot be used when using the compare function. The major difference between window A and window B is that window B has one selectable channel and different interrupt output signals.

Operation using compare function in combination with continuous scan mode is described below.

1. When the ADCSR.ADST bit becomes 1b (A/D conversion start) by software, internal trigger (GPT, ELC), or external trigger, A/D conversion of the selected channel is started.
2. When the A/D conversion is completed, the A/D conversion result is stored in the corresponding A/D data register (ADDRy). When ADCMPCR.CMPAE = 1b, if it is set for window A in the ADCMPANSR0 register, it is compared with the ADCMPDR0 register setting value. When ADCMPCR.CMPBE = 1b, if the ADCMPBNSR register is set for window B, it will be compared with the ADWINULB/ADWINLLB register setting value.
3. As a result of comparison, when the condition set in ADCMPLR0 is matched in window A, the flag (ADCMPSR0. CMPSTCHA0n) bit of the compare function window A is set to 1b. At this time, if the ADCMPCR.CMPAIE bit is set to 1b, an ada_compai_n interrupt request (level) is generated. Similarly, when window B matches the conditions set in ADCMPBNSR.CMPLB, the compare function window B flag (ADCMPBSR.CMPSTB) bit is set to 1. At this time, if the ADCMPCR.CMPBIE bit is set to 1b, an ada_compbi_n interrupt request (level) is generated.
4. When all the selected A/D conversions and comparisons are completed, scanning is performed again.
5. After accepting the ada_compai_n/ ada_compbi_n interrupt, set the ADCSR.ADST bit to 0b (A/D conversion stopped) and execute processing for the channel for which the compare flag is set.
6. When all the compare flags in window A are cleared, the ada_compai_n interrupt request is canceled. Similarly, clearing the compare window B flag cancels the ada_compbi_n interrupt request. If you want to perform the compare again, start the A/D conversion again.



Note 1. The data under conversion is ignored.

Figure 7.10-9 Example of Operation of Compare Function (Compare Target: ANI000-ANI003)

7.10.3.5.2 Event output in compare function

For the event output of the compare function, specify the upper and lower reference values for each of windows A/B, compare the A/D conversion value of the selected channel with the upper/lower reference values, and then the event (ada_elccondmtch / ada_elccondunmtch) is output according to the event condition (A or B, A and B, A exor B) from the result of satisfying/failing the comparison condition of windows A and B. When using this function, perform A/D conversion in single scan mode.

In window A, any channel of ANn00-ANn07 can be selected. When multiple channels are selected in window A and the comparison condition is satisfied in one of the channels, the comparison condition is satisfied in window A. In window B, one channel of ANn00-ANn15 can be selected.

The setting procedure and setting example when using the event output of the compare function are shown below.

1. ADCSR.ADCS bit must be 00b (single scan mode).
2. Select the channel to be used for window A in the ADCMPANSR0 register, set the comparison condition of the compare function window in the ADCMPLR0 register, and set the upper/lower reference value in the ADCMPDR0/1 register.
3. Select the channel to be used for window B and the comparison condition in the ADCMPBNSR register, and set the upper/lower reference values in the ADWINULB/ADWINLLB registers.
4. In the ADCMPCR register, set the window A/B compound condition, window A/B operation permission, and interrupt output permission.

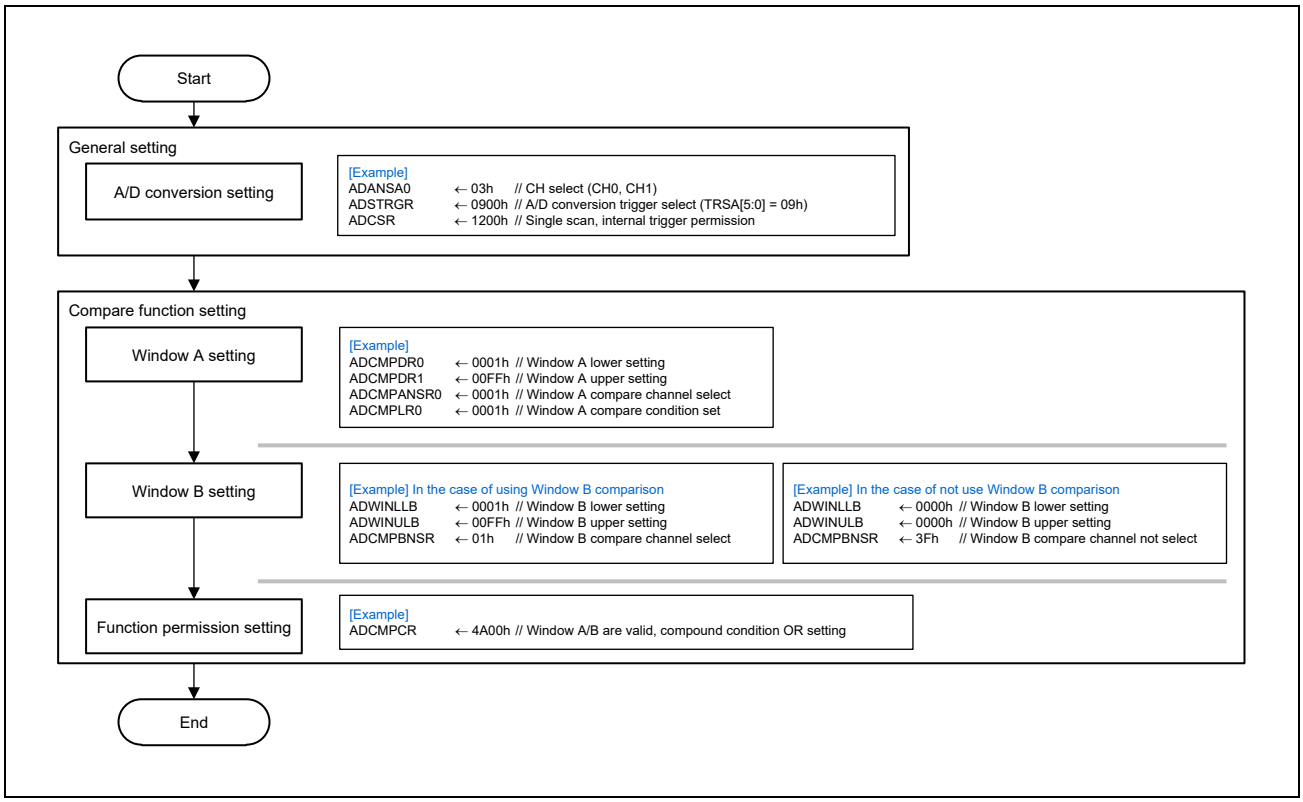


Figure 7.10-10 Example of Setting for Using Event Output of Compare Function

Precautions when using event output using only window A of the compare function

- Enable both windows A and B. (ADCMPCR.CMPAE = 1b, ADCMPCR.CMPBE = 1b)
- Set the compound condition setting for windows A and B to “OR condition”. (ADCMPCR.CMPAB[1:0] = 00b)

- Set the comparison target channel in window B to “Unselected”. (ADCMPBNSR.CMPCHB[5:0] = 111111b).
- Set the comparison condition of window B to 0 < conversion result < 0, which is “always inconsistent”. (ADCMPCR.WCMPE = 1b, ADWINLLB.CMPLLB[15:0] = ADWINULB.CMPULB[15:0] = 0000h, ADCMPBNSR.CMPLB = 1b)

Figure 7.10-11 shows example of event output operation of compare function.

The scan end event is output when one single scan ends. Also, depending on the setting of ADCMPCR.CMPAB[1:0], the match/unmatch event (ada_elccondmtch / ada_elccondunmtch) is output with a delay of 1.

NOTE

Match/unmatch events are exclusive outputs, and both events are not output at the same time.

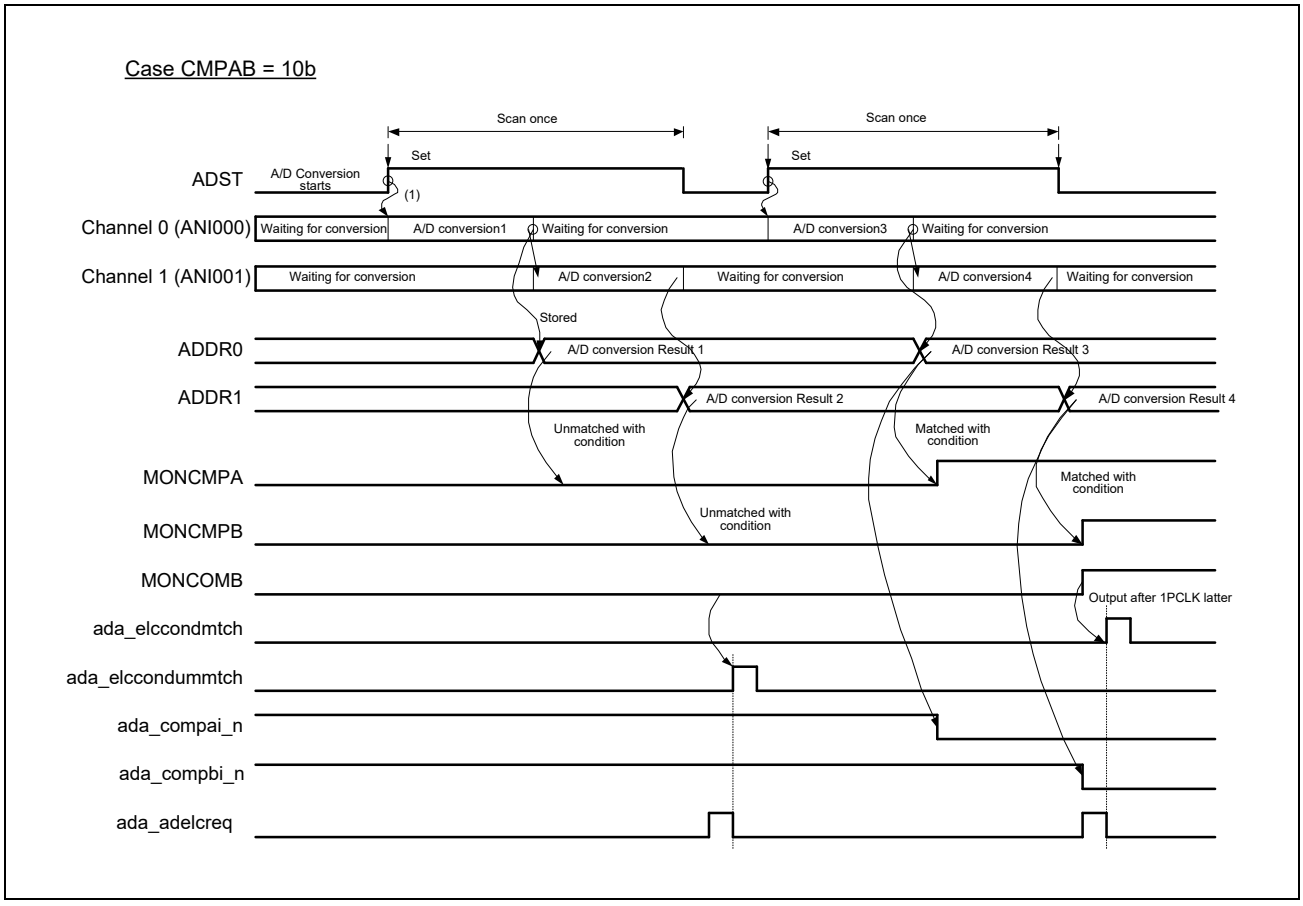

Figure 7.10-11 Example of Operation for Event Output of Compare Function

Precautions when using event output of the compare function

The event output of the compare function outputs match/unmatch according to the setting of ADCMPCR.CMPAB[1:0] from the comparison result of window A and the comparison result of window B. The comparison result of window A is the logical sum of the comparison result of the channel to be compared in window A.

The comparison result of window A and the comparison result of window B are updated every A/D conversion of the channel to be compared, and the comparison result is retained even after the single scan is completed. To clear the comparison result (0), set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0b.

7.10.3.5.3 Compare function constraint

The compare function has the following restrictions.

- Double trigger mode cannot be used together.
  (ADDBLDR, ADDBLDRA, ADDBLDRB are not subject to the compare function.)
- If you want to use match/unmatch event output, set the single scan mode.
- The same CH cannot be set in window A and window B.
- Set so that the upper reference value ≥ the lower reference value.

7.10.3.6 A/D Data Register Automatic Clearing Function

By setting the ADCER.ACE bit to 1b, these are used when the CPU and DMAC read the A/D data registers (ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB). The register can be cleared automatically to 0000h.

By using this function, it is possible to detect an un-updated failure of the ADDRy, ADDBLDR, ADDBLDRA, and ADDBLDRB registers. The following is an example when the automatic clear function of the ADDRy register is disabled/ enabled.

When the ADCER.ACE bit is 0b (automatic clearing prohibited), the old data (0111h) becomes the value of the ADDRy register when the A/D conversion result (0222h) is not written to the ADDRy register for some reason. Furthermore, when the value of this ADDRy register is read to the general-purpose register by using the A/D conversion end interrupt, the old data (0111h) can be saved in the general-purpose register. However, when checking for un-updated data, it is necessary to check while holding old data in RAM and general-purpose registers one by one.

When the ADCER.ACE bit is 1 (automatic clearing enabled), the ADDRy register is automatically cleared to 0000h when ADDRy = 0111h is read by the CPU and DMAC. After that, when 0222h of the A/D conversion result cannot be transferred to the ADDRy register for some reason, the cleared data (0000h) remains as the ADDRy register value. If the value of this ADDRy register is read to a general-purpose register by using the A/D conversion end interrupt, 0000h is held in the general-purpose register. By simply checking that the read data value is 0000h, it can be determined that there was an un-updated failure of the ADDRy register.

7.10.3.7 A/D-Converted Value Addition/Average Function

In A/D-converted value addition function, the same channel is A/D-converted two, three, four or sixteen consecutive times and the sum of the converted values is stored in the data register. In A/D-converted value average function, the same channel is A/D-converted two or four consecutive times and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that affect A/D conversion. This function, however, cannot always guarantee an improvement in A/D conversion accuracy. The A/D-converted value addition/average mode can be specified when A/D conversion of the analog input of the selected channels is selected.

7.10.3.8 Starting A/D Conversion with External Trigger

The A/D conversion can be started by the input of an external trigger. To start up the A/D converter by an external trigger, the A/D conversion start trigger select bits (ADSTRGR.TRSA[5:0]) should be set to 00_0000b and a low-level signal should be input to the external trigger (ADTRG). Both the ADCSR.TRGE and ADCSR.EXTRG bits then should be set to 1b.

Internal triggers cannot be selected for groups B and C used in group scan mode.

7.10.3.9 Starting A/D Conversion with Internal Trigger from Peripheral Module

A/D conversion can be started by the internal trigger from GPT and ELC. When starting A/D conversion with an internal trigger, the ADCSR.TRGE bit is set to 1b, the ADCSR.EXTRG bit is set to 0b, the ADSTRGR.TRSA[5:0], ADSTRGR.TRSB[5:0], and ADGCTRGR.TRSC[5:0] bits are set to the appropriate trigger factor.

7.10.3.10 Error Detection Function (Overwrite Check Function)

The overwrite error detection function detects update of the A/D conversion results held in various A/D data registers, without a need of reading those results. The 12-bit A/D converter can generate an ada_adereq_n interrupt, which is an overwrite error interrupt request to the error control module (ECM).

Setting the ADERCR.OWEIE to 1b enables generation of an ada_adereq_n interrupt and clearing the bit to 0b disables generation of an ada_adereq_n interrupt. Reading the ADOWER and ADOWEER registers can determine the A/D data register in which the overwrite error occurred. Writing 1b to the ADERCLR.OWEC clears all the overwrite error flags held in the ADOWER and ADOWEER registers.

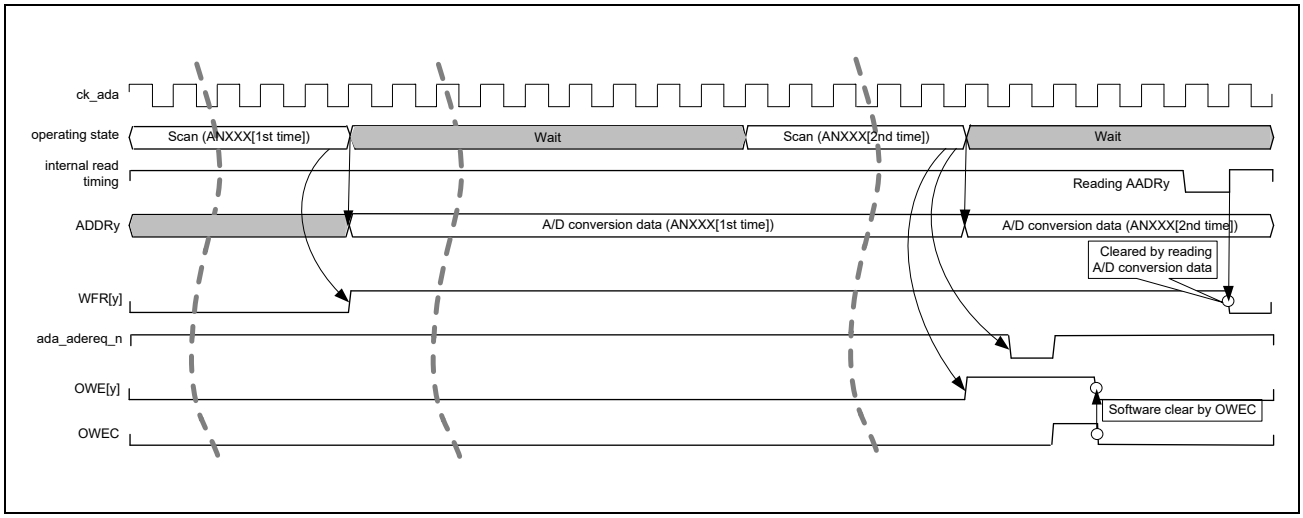

Figure 7.10-12 Example of Generation of AD Overwrite Error Interrupt

7.10.3.11 Event Link Function

7.10.3.11.1 Event output to ELC

ELC can use the ada_adireq_n interrupt request signal as an event signal (ada_adelcreq) to link to a preset module (ada_gbadireq_n / ada_gcadireq_n interrupt, ada_compai_n/ ada_compbi_n interrupt cannot be used as an event signal). The event signal can be output regardless of the setting of the corresponding interrupt request permission bit.

The 12-bit A/D converter outputs the scan end event (ada_adelcreq), compare function match event (ada_elccondmtch), and unmatch event (ada_elccondunmtch). The scan end event (ada_adelcreq) outputs a “High pulse” for 1 cycle of ADC_m_PCLK (m = 0 to 2) at the same output timing as the interrupt output (ada_adireq_n) regardless of the setting of ADCSR.ADIE.

The compare match/unmatch event (ada_elccondmtch / ada_elccondunmtch) to ELC outputs a “High pulse” for 1 cycle of ADC_m_PCLK (m = 0 to 2) at a timing delayed by 1 cycle of ADC_m_PCLK (m = 0 to 2) from the interrupt output (ada_adireq_n) regardless of the setting of ADCSR.ADIE. When using the compare match/unmatch event to ELC (ada_elccondmtch / ada_elccondunmtch), set it to single scan mode.

7.10.3.11.2 Starting A/D conversion with ELC event

The 12-bit A/D converter can start A/D conversion by a preset event by setting EVTSELx in ICU.

7.10.3.11.3 Notes on ELC trigger

The trigger from the ELC (ELCTRG0) is invalid during A/D conversion.

7.10.4 Usage Notes

7.10.4.1 Notes on Reading Data Registers

The A/D data registers, A/D data duplication registers, A/D data duplication register A, and A/D data duplication register B must be read in 16-bit word units, to avoid unmatch with the upper value and lower value by reading in byte units separately.

7.10.4.2 Notes on Stopping A/D Conversion

7.10.4.2.1 A/D conversion stop procedure

When using an external or internal trigger as the A/D conversion start condition, follow the procedure in the flowchart in **Figure 7.10-13** to stop the A/D conversion.

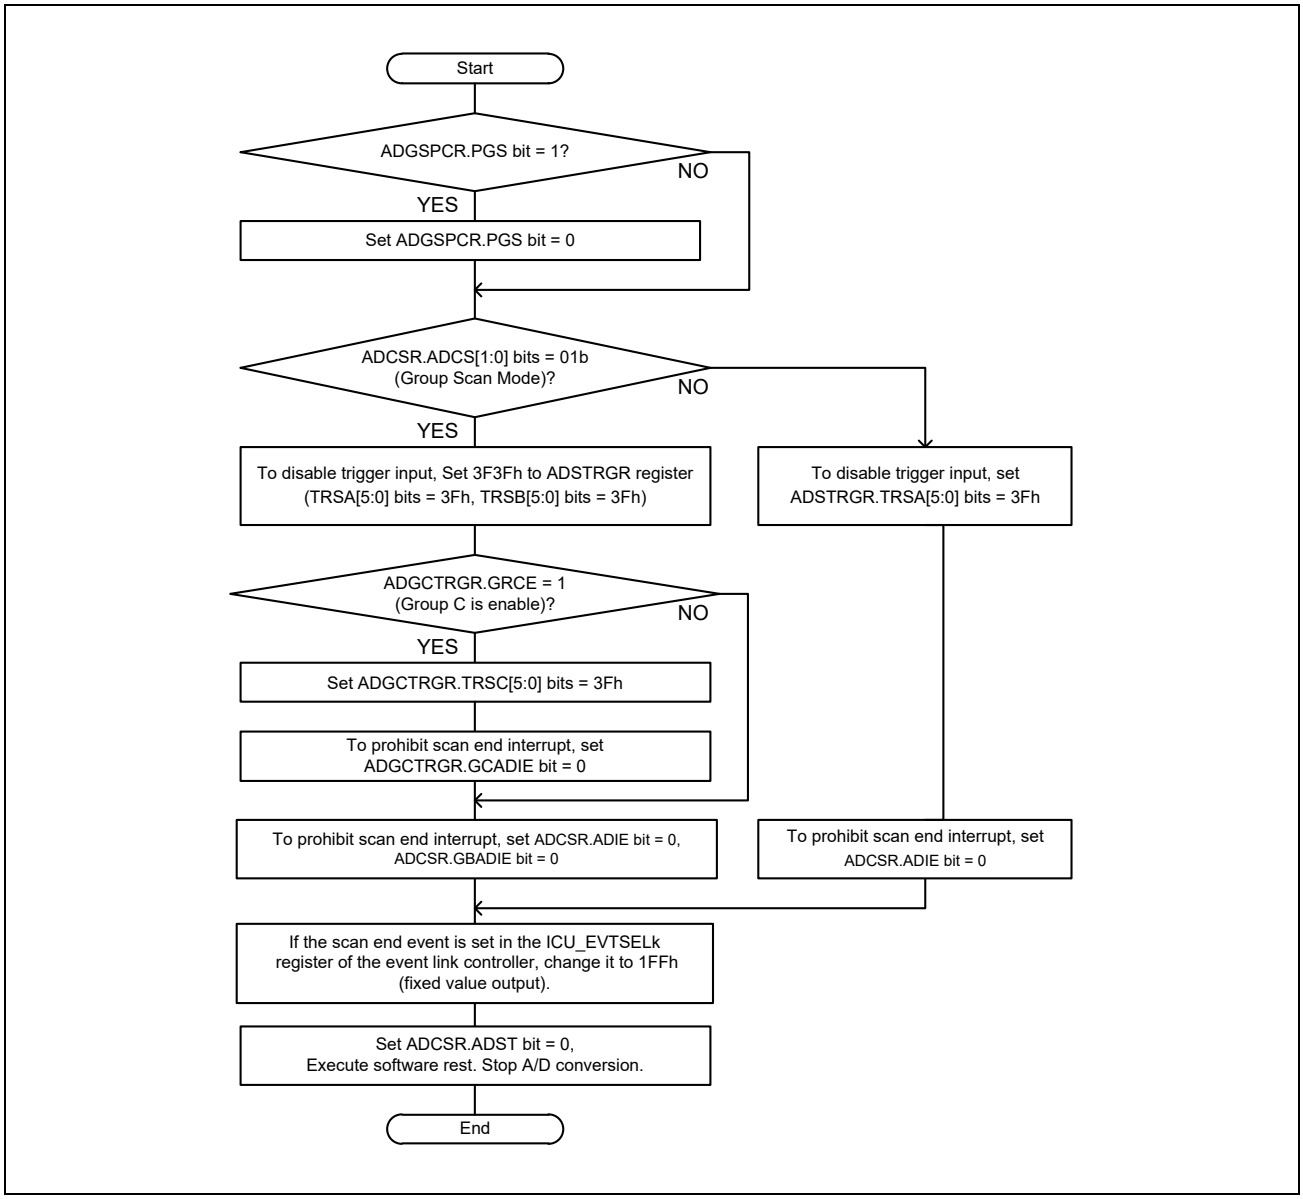

Figure 7.10-13 A/D Conversion Stop Procedure

It takes 2 cycles of ADC_m_ADCLK (m = 0 to 2) from a software clear until the soft macro stops scanning. If you want to set the following after executing a software clear, enter a wait of 2 cycles of ADC_m_ADCLK (m = 0 to 2) or more.

- Scan end interrupt enabled
- Event link controller scan end event valid setting
- Start of A/D conversion by software
- Trigger input valid setting

7.10.4.2.2 Notes on mode/status bits

Initialize or reset the odd/even judgment and monitor bits of the compare function in the double trigger mode as necessary.

- Double trigger mode starts from the first scan operation when ADCSR.DBLE is set from 0b to 1b.
- To initialize the monitor bits (MONCMPA, MONCMPB) of the compare function, set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0b.

7.10.4.3 A/D conversion Forced Stop and Operation Timing at Starts

Up to 6 cycles of the ADC_m_ADCLK (m = 0 to 2) are required to start the A/D converter by setting the ADCSR.ADST bit = 1b from the stopped status.

When the ADCSR.ADST bit is set to 0b and the A/D conversion is forcibly stopped, the analog part of the 12-bit A/D converter requires a maximum of 2 ADC_m_ADCLK (m = 0 to 2) cycles to stop operating.

7.10.4.4 Notes on Scan End Interrupt Processing

When scanning the same analog input twice using any trigger, if the CPU does not complete reading out the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated, the first A/D-converted data is overwritten with the second A/D-converted data and an overwrite error occurs. For details on how to detect overwrite errors in A/D conversion results, please see **7.10.3.10 Error Detection Function (Overwrite Check Function)**.

7.10.4.5 Notes on Using Hardware and Software Triggers Simultaneously.

If the next A/D conversion start trigger is input during A/D conversion, the trigger will be ignored. Therefore, when using hardware trigger (i.e., internal or external trigger) and software trigger at the same time, ensure that the hardware trigger is not input during the execution of A/D conversion started by the software trigger. Also, ensure that the software trigger is not input during A/D conversion started by the hardware trigger. Software can check whether A/D conversion is in progress by ADREF. ADSCACT bit.

7.10.4.6 Power-down Mode Settings

The 12-bit A/D converter can be set to power-down mode by SYS_ADC_CFG.SY_MSTP_ADA bit. By default, the A/D converter is in power-down mode (SYS_ADC_CFG.SY_MSTP_ADA = 1b). After leaving power-down mode by setting the SYS_ADC_CFG.SY_MSTP_ADA bit to 0b, it is necessary to wait at least 20 µs with ADC_m_ADCLK (m = 0 to 2) running before starting A/D conversion. When entering power-down mode, the SYS_ADC_CFG.SY_MSTP_ADA bit must be set to 1b before stopping ADC_m_ADCLK (m = 0 to 2).

a) Procedure for leaving power-down mode

1. Set the SYS_ADC_CFG.SY_MSTP_ADA bit to 0b.
2. Wait at least 20 µs with ADC_m_ADCLK (m = 0 to 2) running (CPG_CLKON_16.CLK8_ON = 1b) before starting A/D conversion.

b) Procedure for entering power-down mode

1. If A/D conversion is in operation, stop A/D conversion according to **7.10.4.2.1 A/D conversion stop procedure**.
2. Set the SYS_ADC_CFG.SY_MSTP_ADA bit to 1b.
3. Stop ADC_m_ADCLK (m = 0 to 2).

7.10.4.7 Notes on Entering Low Power Consumption States

When transitioning to module standby mode or power-down mode, stop A/D conversion. When stopping the A/D conversion, it is necessary to secure the time until the analog part of the 12-bit A/D converter stops after setting the ADCSR.ADST bit to 0b. For details, see **7.10.4.2.1 A/D conversion stop procedure**.

SECTION 7 LOW-SPEED INTERFACE

7.11 Temperature Sensor Unit (TSU)

This section describes the functions of the temperature sensor unit (TSU).

7.11.1 Functional Overview

The temperature sensor unit (TSU) includes a temperature sensor IP to acquire a code corresponding to the temperature. The temperature sensor IP is composed of a main sensor and an ADC that converts analog outputs of the sensor to digital code.

The acquired temperature code is readable via the APB. Additionally, an interrupt can be output in response to the result of comparison with set upper and lower limits of the temperature code.

There are two ways to start conversion: by software through a register setting and by an ELC trigger. The conversion mode is single scan mode in which conversion is only performed once with averaging of the set number of samples.

Table 7.11-1 TSU Functions in Outline

Classification	Function	Description
Temperature sensor unit	Temperature code read	• Temperature sensor IP control function • Temperature code averaging function • Comparison with the upper and lower limit settings • Interrupt function • Conversion start trigger (by software and by an ELC trigger) • Single scan
AMBA interface	APB slave interface	• Register access

7.11.2 Connection Configuration

Figure 7.11-1 shows the connection configuration of the TSU.

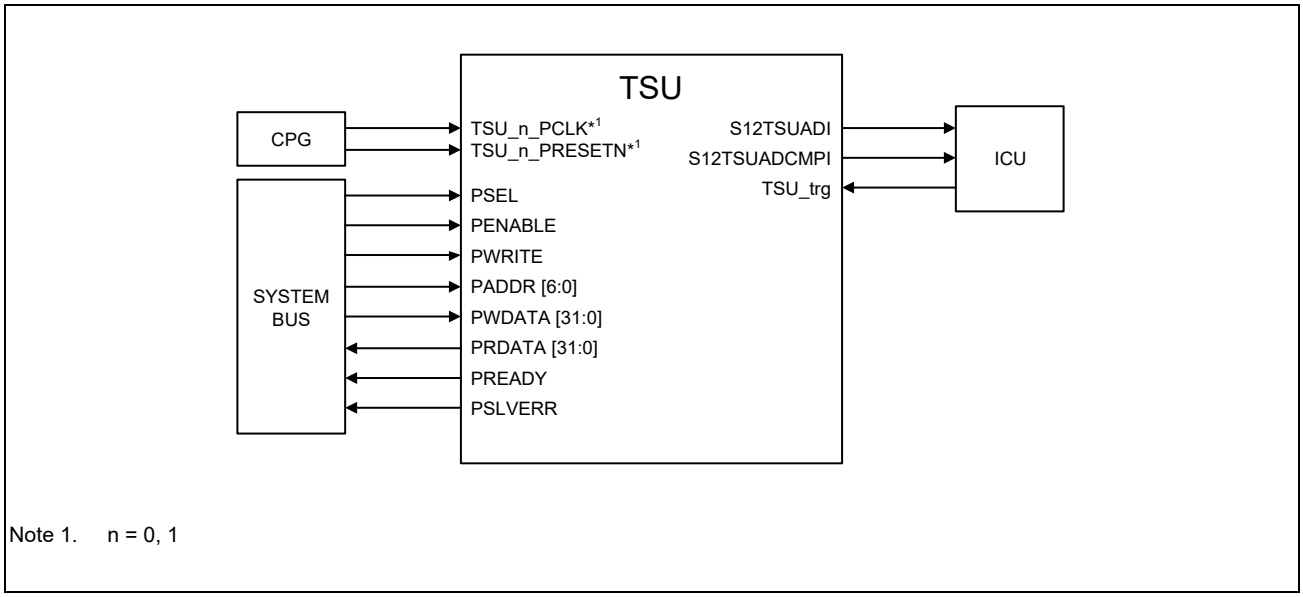

Figure 7.11-1 TSU Connection Configuration Diagram

Table 7.11-2 lists the connected units.

Table 7.11-2 List of Connected Units

Unit Name	Connected Unit Name	Function of Connected Unit
TSU	CPG	Clock pulse generator
	SYSTEM BUS	System bus
	ICU	Interrupt control unit

7.11.3 Pin Description

7.11.3.1 List of Internal Pins

Table 7.11-3 lists the internal pins of the TSU.

Table 7.11-3 List of Internal I/O Pins

Pin Name	Input/ Output	Description
Clock & Reset		
TSU_0_PCLK	Input	Ch0 APB port clock
TSU_1_PCLK	Input	Ch1 APB port clock
TSU_0_PRESETN	Input	Ch0 APB port reset
TSU_1_PRESETN	Input	Ch1 APB port reset
IP Control Interface		
TSU_trg	Input	Conversion start trigger by the ELC (via the ICU) (pulse)
S12TSUADI	Output	Conversion complete interrupt signal (pulse)
S12TSUADCMPI	Output	Comparison result interrupt signal (level)

7.11.3.2 Internal Pin Functions

7.11.3.2.1 Clock and Reset

Clock and reset inputs of the TSU:

■ **TSU_n_PCLK (n = 0, 1)**

A clock input of the TSU as a whole. The frequency is fixed to 24 MHz.

■ **TSU_n_PRESETN (n = 0, 1)**

A reset input of the TSU as a whole. This signal resets the TSU when low and releases the reset when high.

7.11.3.2.2 Control Interface

The signals to control the TSU:

■ **TSU_trg**

This conversion start trigger signal is input to the TSU from the ELC unit via the ICU. This signal is active low and asynchronous relative to TSU_n_PCLK (n = 0, 1), and is effective when a low pulse with a length of eight cycles at 100 MHz is input. After synchronization within the TSU, conversion starts in response to the detection of a falling edge.

■ **S12TSUADI**

This active-low interrupt output (pulse) signal is generated after the completion of conversion.
It can be masked by a register setting.

■ **S12TSUADCMPI**

This active-low interrupt output (level) signal is generated when the conditions are met in temperature code comparison.
It can be masked by a register setting.

7.11.4 Clock

7.11.4.1 Clock Signals

Table 7.11-4 Clock Pins

Pin Name	Input/ Output	Frequency (MHz)	Duty Cycle (%)	Function	Value after Reset	Handling of Pins when Not in Use
TSU_0_PCLK	Input	24	—	APB port clock for ch0	—	Low
TSU_1_PCLK	Input	24	—	APB port clock for ch1	—	Low

CAUTION

Fix the TSU_n_PCLK (n = 0, 1) frequency of this unit to 24 MHz. When it is lower than 24 MHz, the temperature sensor IP cannot operate.

7.11.5 Interrupts

The TSU has two interrupt signals, a conversion complete interrupt (S12TSUADI) and a comparison result interrupt (S12TSUADCMPI).

An interrupt enable/disable switching bit, status confirmation bit, and status clearing bit are in place for each of these signals.

7.11.5.1 Conversion Complete Interrupt

A conversion complete interrupt is generated on completion of conversion.

- When the interrupt is enabled (the ADIE bit of the sensor interrupt enable register = 1)
  - The S12TSUADI signal is low during the period of one TSU_n_PCLK (n = 0, 1) clock cycle and the conversion complete interrupt is generated on completion of conversion by the TSU.
  - The ADF bit of the sensor interrupt status register is set to 1 and the conversion complete status flag is set on completion of conversion by the TSU.
  - Writing 1 to the ADCLR bit of the sensor interrupt clear register sets the ADF bit of the sensor interrupt status register to 0 to clear the status flag (the ADF bit retains the value 1 unless 1 is written to the ADCLR bit).
- When the interrupt is disabled (the ADIE bit of the sensor interrupt enable register = 0)
  - The S12TSUADI signal is not driven to the low level even when conversion by the TSU is completed, and the conversion complete interrupt is not generated.
  - The ADF bit of the sensor interrupt status register is set to 1 on completion of conversion by the TSU and the conversion complete status flag is set, but the interrupt is masked.
  - Writing 1 to the ADCLR bit of the sensor interrupt clear register sets the ADF bit of the sensor interrupt status register to 0 to clear the status flag (the ADF bit retains the value 1 unless 1 is written to the ADCLR bit).

Remark The conversion complete status flag (the ADF bit) is always set to 1 on completion of conversion regardless of the value of the interrupt enable bit ADIE. After the completion of conversion, write 1 to the ADCLR bit to clear the status flag.

7.11.5.2 Comparison Result Interrupt

A comparison result interrupt is generated according to the selected condition for comparison when the result of comparison meets the condition.

- When the interrupt is enabled (the CMPIE bit of the sensor interrupt enable register = 1)
  - The S12TSUADCMPI signal is driven to the low level when the result of comparison meets the condition (**Figure 7.11-2**), and the comparison result interrupt is generated.
  - At that time, the CMPF bit of the sensor interrupt status register is set to 1 and the comparison result interrupt status flag is set.
  - Writing 1 to the CMPCLR bit of the sensor interrupt clear register sets the CMPF bit of the sensor interrupt status register to 0 to clear the status flag (the CMPF bit retains the value 1 unless 1 is written to the CMPCLR bit).

- When the interrupt is disabled (when the CMPIE bit of the sensor interrupt enable register = 0)
  - The S12TSUADCMPI signal is not driven to the low level and the comparison result interrupt is not generated.
  - The CMPF bit of the sensor interrupt status register is set to 1 when the result of comparison meets the condition (**Figure 7.11-2**) and the comparison result interrupt status flag is set, but the interrupt is masked.
  - Writing 1 to the CMPCLR bit of the sensor interrupt clear register sets the CMPF bit of the sensor interrupt status register to 0 to clear the status flag (the CMPF bit retains the value 1 unless 1 is written to the CMPCLR bit).

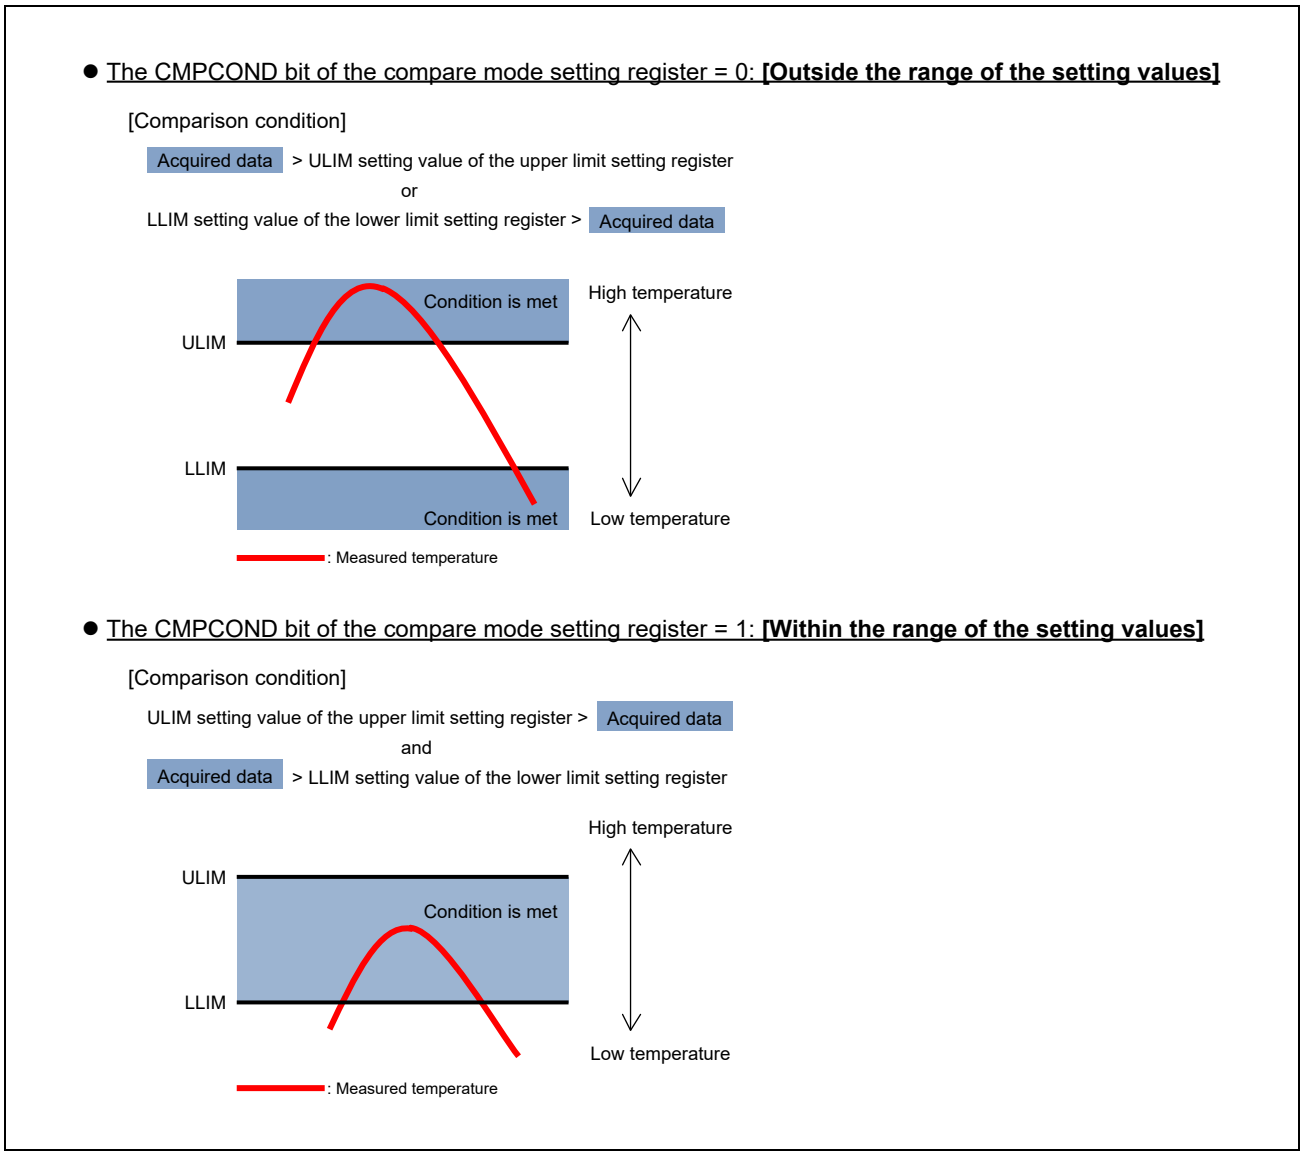

Figure 7.11-2 Comparison Conditions

7.11.6 Registers

The register addresses of TSU are given as offsets from the individual base addresses <TSUm_base>. The register base addresses of each TSU are listed in the following table.

Table 7.11-5 Register Base Addresses

Base Address Name	Unit Name	Base Address
<TSU0_base>	TSU0	0_1100_0000h (5100_0000h*1, 4100_0000h*2)
<TSU1_base>	TSU1	0_1400_2000h (5400_2000h*1, 4400_2000h*2)

Note 1. CM33 Address Space Non-Secure

Note 2. CM33 Address Space Secure

7.11.6.1 List of Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Sensor Suspend Register	TSUm_SSUSR	0000_0006h	0000h	32
Sensor Trigger Register	TSUm_STRGR	0000_0000h	0004h	32
Sensor Operation Setting 1 Register	TSUm_SOSR1	0000_000Bh	0008h	32
Reserve	-	-	000Ch to 000Fh	-
Sensor Code Read Register	TSUm_SCRR	0000_0000h	0010h	32
Sensor Status Register	TSUm_SSR	0000_0000h	0014h	32
Compare Mode Setting Register	TSUm_CMSR	0000_0003h	0018h	32
Lower Limit Setting Register	TSUm_LLSR	0000_0000h	001Ch	32
Upper Limit Setting Register	TSUm_ULSR	0000_0000h	0020h	32
Reserve	-	-	0024h to 002Fh	-
Sensor Interrupt Status Register	TSUm_SISR	0000_0000h	0030h	32
Sensor Interrupt Enable Register	TSUm_SIER	0000_0000h	0034h	32
Sensor Interrupt Clear Register	TSUm_SICR	0000_0000h	0038h	32

7.11.6.2 Register Descriptions

The function description of each register is described below.

7.11.6.2.1 Sensor Suspend Register (TSUm_SSUSR)

This register controls settings related to suspension of the temperature sensor IP.

Access Size : 32 bits
Address : <TSUm_base> + 0000h
Initial Value : 0000_0006h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	SOC_TS_EN	ADC_PD_TS	EN_TS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	SOC_TS_EN	1h	RW	SOC_TS Enable 0b: SOC_TS disabled (SOC_TS fixed low) 1b: SOC_TS enabled
1	ADC_PD_TS	1h	RW	ADC Power Down 0b: Normal ADC operation 1b: ADC power down
0	EN_TS	0h	RW	Temperature Sensor Enable 0b: Temperature sensor power down 1b: Normal temperature sensor operation

7.11.6.2.2 Sensor Trigger Register (TSUm_STRGR)

This register controls the start trigger for the ADC in the temperature sensor IP.

Access Size : 32 bits

Address : <TSUm_base> + 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	ADST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W1	W1

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read.
1	-	0h	W1	Reserved This bit is read as 0b. The write value should always be 0b.
0	ADST	0h	W1	TSU ADC Start Trigger 0b: Invalid 1b: Conversion starts

7.11.6.2.3 Sensor Operation Setting 1 Register (TSUm_SOSR1)

This register controls settings related to operation of the ADC.

Access Size : 32 bits

Address : <TSUm_base> + 0008h

Initial Value : 0000_000Bh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	OUTSEL	-	-	-	-	ADCS	TRGE	-	ADCT[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1
R/W	R	R	R	R	R	R	RW	R	R	R	R	RW	RW	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
9	OUTSEL	0h	RW	Select data read from Sensor Code Read register 0b: Latest read data 1b: Average data
8 to 5	-	All 0	R	Reserved Whenever it is read, an undefined value is read. The written value will be ignored.
4	ADCS	0h	RW	ADC Scan Mode Select 0b: Single scan 1b: Setting prohibited
3	TRGE	1h	RW	TSU_trg Enable 0b: TSU_trg pin disabled 1b: TSU_trg pin enabled
2	-	0h	R	Reserved Whenever it is read, an undefined value is read. The written value will be ignored.
1, 0	ADCT[1:0]	3h	RW	AD Count Setting 00b: 1 01b: 2 10b: 4 11b: 8

7.11.6.2.4 Sensor Code Read Register (TSUm_SCRR)

This register is a read-only register to read acquired code data. Any written values are ignored.

Access Size : 32 bits
Address : <TSUm_base> + 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	OUT12BIT_TS[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	OUT12BIT_TS [11:0]	0h	R	Temperature sensor code data

7.11.6.2.5 Sensor Status Register (TSUm_SSR)

This register is a read-only register to read the TSU operating status. Any written values are ignored.

Access Size : 32 bits
Address : <TSUm_base> + 0014h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CONV
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	CONV	0h	R	TSU operating status 0b: Conversion is finished. 1b: Conversion is in progress. Set: Setting of the ADST bit of the Sensor Trigger Register or assertion of the signal on the TSU_trg pin. Reset: Completion of AD conversion the number of times required for averaging.

7.11.6.2.6 Compare Mode Setting Register (TSUm_CMSR)

This register controls settings related to compare operation.

Access Size : 32 bits

Address : <TSUm_base> + 0018h

Initial Value : 0000_0003h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CMPCOND	CMPEN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	CMPCOND	1h	RW	Compare Mode Setting 0b: CMP judges that lower limit (LLILM) > code data or code data > upper limit (ULIM). 1b: CMP judges that lower limit (LLILM) < code data < upper limit (ULIM).
0	CMPEN	1h	RW	Compare Enable 0b: Comparison disabled 1b: Comparison enabled

7.11.6.2.7 Lower Limit Setting Register (TSUm_LLSR)

This register controls the lower limit value to be compared with the acquired code data.

Access Size : 32 bits
Address : <TSUm_base> + 001Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	LLIM[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	LLIM[11:0]	0h	RW	Lower limit setting value

7.11.6.2.8 Upper Limit Setting Register (TSUm_ULSR)

This register controls the upper limit value to be compared with the acquired code data.

Access Size : 32 bits

Address : <TSUm_base> + 0020h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	ULIM[11:0]											
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 0	ULIM[11:0]	0h	RW	Upper limit setting value

7.11.6.2.9 Sensor Interrupt Status Register (TSUm_SISR)

This register a read-only register which monitors the interrupt status.

Access Size : 32 bits
Address : <TSUm_base> + 0030h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CMPF	ADF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	CMPF	0h	R	Compare result detect flag 0b: Undetected 1b: Detected Set condition: The comparison conditions are met. Reset condition: The CMPCLR bit of the sensor interrupt clear register is set to 1b.
0	ADF	0h	R	AD conversion complete flag 0b: Not completed 1b: Completed Set condition: Completion of AD conversion the number of times required for averaging. Reset condition: The ADCLR bit of the sensor interrupt clear register is set to 1b.

7.11.6.2.10 Sensor Interrupt Enable Register (TSUm_SIER)

This register enables or disables output of the interrupt request output signals (S12TSUADI and S12TSUADCMPI).

Access Size : 32 bits
Address : <TSUm_base> + 0034h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CMPIE	ADIE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
1	CMPIE	0h	RW	Compare Result Detect Interrupt Enable 0b: Interrupt disabled 1b: Interrupt enabled
0	ADIE	0h	RW	AD Conversion Complete Interrupt Enable 0b: Interrupt disabled 1b: Interrupt enabled

7.11.6.2.11 Sensor Interrupt Clear Register (TSUm_SICR)

This register clears the interrupt status.

Access Size : 32 bits

Address : <TSUm_base> + 0038h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CMPCLR	ADCLR
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W1	W1

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, an undefined value is read. The written value will be ignored.
1	CMPCLR	0h	W1	The read value is undefined Compare Result Detect Interrupt Clear Write only. This bit is read as 0b. 0b: No operation 1b: Interrupt cleared
0	ADCLR	0h	W1	The read value is undefined AD Conversion Complete Interrupt Clear Write only. This bit is read as 0b. 0b: No operation 1b: Interrupt cleared

7.11.7 Functional Description

This section describes the functions of the TSU.

The prefix (TSUm_) of the register names is omitted in this and subsequent sections.

7.11.7.1 Acquiring Temperature Code

Conversion starts on reception of the conversion start trigger (when the ADST bit of the sensor trigger register is set to 1b or the TSU_trg signal is 0). When the OUT12BIT_TS bit of the sensor code read register is read after the completion of conversion, a 12-bit temperature code can be acquired.

If the conversion start trigger comes within 120T (CLK_TS period) after release of the temperature sensor and ADC from the power-down state (setting the sensor suspend register so that the ADC_PD_TS bit is 0b and the EN_TS bit is 1b), conversion only starts after 120T has elapsed following release.

7.11.7.2 Temperature Code Averaging Function

The temperature codes acquired within the TSU are averaged the number of times set by the ADCT[1:0] bits of the sensor operation setting 1 register.

7.11.7.3 Temperature Code Reading Function

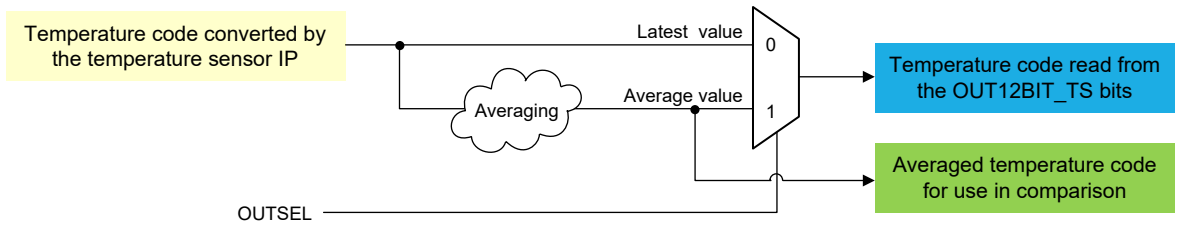
The temperature code can be read from the sensor code read register via the APB.

When the OUTSEL bit of the sensor operation setting 1 register is 0b, the latest converted value is read. When it is 1b, the average value is read.

7.11.7.4 Temperature Code Comparison Functions

This function compares the averaged temperature code and the values set by the LLIM[11:0] bits of the lower limit setting register and the ULIM[11:0] bits of the upper limit setting register when the CMPEN bit of the compare mode setting register is 1b.

The temperature code for use in the comparison function is the averaged temperature code, so the OUTSEL bit of the sensor operation setting 1 register must be set to 1b (average data output) when reading the temperature code for use in comparison. When the averaging count setting is 1, however, the latest value is the same as the average value, so the temperature code for use in comparison will be read regardless of the setting of the OUTSEL bit (see **Figure 7.11-3**).



- When the OUTSEL bit = 0b

  After conversion has proceeded the set number of times for averaging, the latest value is read from the OUT12BIT_TS bits.

  [Example] When ADCT[1:0] =11b (the count setting is 8), the latest value is the 8th converted temperature code.

- When the OUTSEL bit = 1b

  After conversion has proceeded the set number of times for averaging, the average value is read from the OUT12BIT_TS bits.
  The average value is also used for the comparison function.

  [Example] When ADCT[1:0] = 11b (the count setting is 8), the average value is the average of 8 sampled temperature codes.

Averaging: Acquiring temperature codes the number of times set by the ADCT[1:0] bits of the sensor operation setting 1 register and averaging the codes.

[Example] When ADCT[1:0] = 11b (the count setting is 8), 8 temperature codes are acquired and averaged.

Note: When the averaging count setting is 1, only one temperature code is acquired, so the latest value is the same as the average value.

Figure 7.11-3 OUTSEL Bit Setting when Temperature Code Comparison is Used

The CMPF bit of the sensor interrupt status register is set to 1b when the value meets the selected condition for comparison as shown in **Figure 7.11-2**.

The values set in the LLIM[11:0] and ULIM[11:0] bits can be calculated from the formula shown in **7.11.7.9 Comparison Setting Value Calculation**.

7.11.7.5 Interrupt Output Function

An interrupt is output when conversion is completed and the result of temperature code comparison meets the condition.

For details of the interrupt output function, see **7.11.5 Interrupts**.

7.11.7.6 Conversion Start Trigger

There are two ways to start conversion by the TSU: by software through a register setting and by an ELC trigger (TSU_trg).

The TRGE bit of the sensor operation setting 1 register is used to set the ELC trigger.

(TRGE bit = 0b: TSU_trg disabled; TRGE bit = 1b: TSU_trg enabled)

7.11.7.7 Single Scan

In single scan mode, conversion is only performed once with averaging of the number of samples set by the ADCT[1:0] bits of the sensor operation setting 1 register.

Single scan mode is set by default in the ADCS bit of the sensor operation setting 1 register.

(ADCS bit = 0b: Single scan mode; ADCS bit = 1b: Setting prohibited)

7.11.7.8 Temperature Compensation Calculation

After acquiring the temperature, the compensated temperature T (°C) must be calculated from the value (a) of the OUT12BIT_TS bits of the sensor code read register and the values (b) to (c) read from the SYS register.

Follow the procedure below to calculate the compensated temperature. (Maximum error is ±5°C)

$$\mathrm{T(°C)} = \left(\frac{e-d}{c-b}\right) \times (a-b) + d$$

Remarks: *b* = SYS: OTPTSUnTRMVAL0[11:0]
c = SYS: OTPTSUnTRMVAL1[11:0]
d = −41
e = 126

7.11.7.9 Comparison Setting Value Calculation

The comparison setting values (a) can be calculated from each temperature T (°C) you want to set and the values from (b) to (c) which are read from the SYS register.

$$\mathrm{a} = \frac{(T-d) \times (c-b)}{(e-d)} + b$$

Remarks: *b* = SYS: OTPTSUnTRMVAL0[11:0]
c = SYS: OTPTSUnTRMVAL1[11:0]
d = −41
e = 126

Set the calculated values (a) in the LLIM[11:0] bits of the low limit setting register and the ULIM[11:0] bits of the upper limit setting register.

Calculation of the comparison setting values is a reverse calculation of the (**7.11.7.8 Temperature Compensation Calculation**).

- Temperature compensation calculation: Calculate the temperature T (°C) from the acquired temperature code (a).
- Comparison setting value calculation: Calculate the temperature code (a) from the temperature T (°C) you want to set.

7.11.8 Operation Procedure

The TSU is mainly used in the following two ways. This section describes the procedures of operations for usage in each of these ways.

- Using an interrupt for each completion of conversion (**7.11.8.1 Using Interrupt for Each Completion of Conversion**)

  Conversion is started by software or an ELC trigger and the interrupt is generated on completion of conversion.

  After generation of the interrupt, the temperature code is read.

  The comparison function is enabled by default. The upper and lower limit settings for use in comparison are both all 0s by default and the conditions for comparison are not met even while the comparison function is enabled, but the conditions may inadvertently be met if operation proceeds after the upper and lower limits have been set.

  When the comparison function is not to be used, set the CMPEN bit of the compare mode setting register to 0b to disable the comparison function.

- Using the comparison result interrupt (**7.11.8.2 Using Comparison Result Interrupt**)

  Conversion is started by software or an ELC trigger after the conditions for comparison (within or outside the range, and the upper and lower limits) have been set and the interrupt is generated when the result of comparison with the settings meets the conditions.

  After generation of the interrupt, the temperature code is read.

7.11.8.1 Using Interrupt for Each Completion of Conversion

7.11.8.1.1 Single Scan, Start by Software

Table 7.11-6 shows an example of the procedure for operations when an interrupt is to be used to indicate each completion of conversion (single scan, start by software). This is an example of reading the average value when the number of samples for averaging is 8.

Table 7.11-6 Operation Procedure Example when Interrupt is to be Used for Each Completion of Conversion (Single Scan, Start by Software) (1/2)

Step		Register Name	Bit Name	Processing Details	Outline
(1)	Supply TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKON_16	CLK9_ONWEN, CLK9_ON(TSU0)/ CLK10_ONWEN, CLK10_ON(TSU1)	Write “1b” (_ONWEN is write enable)	Supply TSU_0_PCLK/TSU_1_PCLK to TSU0/TSU1.
(2)	Check TSU_n_PCLK (n = 0, 1) supply.	CPG:CPG_CLKMON_8	CLK9_MON(TSU0)/ CLK10_MON(TSU1)	Read “1b”	Check that TSU_0_PCLK/TSU_1_PCLK was supplied to TSU0/TSU1.
(3)	De-assert TSU_n_PRESETN (n = 0, 1).	CPG:CPG_RST_15	RSTB7_WEN, RSTB7(TSU0)/ RSTB8_WEN, RSTB8(TSU1)	Write “1b” (_WEN is write enable)	De-assert TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1.
(4)	Check TSU_n_PRESETN (n = 0, 1) de-assertion.	CPG:CPG_RSTMON_7	RST8_MON(TSU0)/ RST9_MON(TSU1)	Read “0b”	Check that TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1 was de-asserted.

Table 7.11-6 Operation Procedure Example when Interrupt is to be Used for Each Completion of Conversion (Single Scan, Start by Software) (2/2)

Step		Register Name	Bit Name	Processing Details	Outline
(5)	Release the temperature sensor IP from the power-down state.	Sensor Suspend Register	SOC_TS_EN	Write “1b”	Enable the SOC_TS signal.
			ADC_PD_TS	Write “0b”	Normal ADC operation
			EN_TS	Write “1b”	Normal temperature sensor operation
(6)	Set the operating mode.	Sensor Operation Setting 1 Register	OUTSEL	Write “1b”	Average data output
			ADCS	Write “0b”	Single scan mode
			TRGE	Write “0b”	Disable the ELC trigger.
			ADCT[1:0]	Write “11b”	Set the number of samples for averaging to 8.
		Compare Mode Setting Register	CMPCOND	Write “0b”	The setting remains default.
			CMPEN	Write “0b”	Disable the comparison function.
		Sensor Interrupt Enable Register	CMPIE	Write “0b”	Mask the comparison result interrupt.
			ADIE	Write “1b”	Enable the conversion complete interrupt.
(7)	Check the conversion status.	Sensor Status Register	CONV	Read “0b”	Read the CONV bit as 0b (conversion is not in progress).
(8)	Start conversion.	Sensor Trigger Register	ADST	Write “1b”	Start conversion by software.
(9)	The conversion complete interrupt is generated. → Check the interrupt status.	Sensor Interrupt Status Register	ADF	Read “1b”	Read the conversion complete status flag.
(10)	Check the conversion status.	Sensor Status Register	CONV	Read “0b”	Read the CONV bit as 0b (conversion is not in progress).
(11)	Read the converted code.	Sensor Code Read Register	OUT12BIT_TS[11:0]	12-bit read	Read the 12-bit converted temperature code.
(12)	Calculate the temperature compensation.	See **7.11.7.8 Temperature Compensation Calculation**.			
(13)	Clear the interrupt status.	Sensor Interrupt Clear Register	ADCLR	Write “1b”	Clear the conversion complete status flag.
(14)	Check the interrupt status.	Sensor Interrupt Status Register	ADF	Read “0b”	Check that the conversion complete status flag was cleared.
(15)	Power down the temperature sensor IP.	Sensor Suspend Register	SOC_TS_EN	Write “0b”	Disable the SOC_TS signal.
			ADC_PD_TS	Write “1b”	Power down the ADC.
			EN_TS	Write “0b”	Power down the temperature sensor.
(16)	Assert TSU_n_PRESETN (n = 0, 1).	CPG:CPG_RST_15	RSTB7_WEN, RSTB7(TSU0)/ RSTB8_WEN, RSTB8(TSU1)	Write “0b” (_WEN is write enable)	Assert TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1.
(17)	Check TSU_n_PRESETN (n = 0, 1) assertion.	CPG:CPG_RSTMON_7	RST8_MON(TSU0)/ RST9_MON(TSU1)	Read “1b”	Check that TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1 was asserted.
(18)	Stop TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKON_16	CLK9_ONWEN, CLK9_ON(TSU0)/ CLK10_ONWEN, CLK10_ON(TSU1)	Write “0b” (_ONWEN is write enable)	Stop TSU_0_PCLK/TSU_1_PCLK to TSU0/TSU1.
(19)	Check stopping of TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKMON_8	CLK9_MON(TSU0)/ CLK10_MON(TSU1)	Read “0b”	Check that TSU_0_PCLK/TSU_1_PCLK supply to TSU0/TSU1 was stopped.

7.11.8.1.2 Single Scan, Start by an ELC Trigger

Table 7.11-7 shows an example of the procedure for operations when an interrupt is to be used to indicate each completion of conversion (single scan, start by an ELC trigger). This is an example of reading the average value when the number of samples for averaging is 8.

Table 7.11-7 Operation Procedure Example when Interrupt is to be Used for Each Completion of Conversion (Single Scan, Start by ELC Trigger) (1/2)

Step		Register Name	Bit Name	Processing Details	Outline
(1)	Supply TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKON_16	CLK9_ONWEN, CLK9_ON(TSU0)/ CLK10_ONWEN, CLK10_ON(TSU1)	Write “1b” (_ONWEN is write enable)	Supply TSU_0_PCLK/TSU_1_PCLK to TSU0/TSU1.
(2)	Check TSU_n_PCLK (n = 0, 1) supply.	CPG:CPG_CLKMON_8	CLK9_MON(TSU0)/ CLK10_MON(TSU1)	Read “1b”	Check that TSU_0_PCLK/TSU_1_PCLK was supplied to TSU0/TSU1.
(3)	De-assert TSU_n_PRESETN (n = 0, 1).	CPG:CPG_RST_15	RSTB7_WEN, RSTB7(TSU0)/ RSTB8_WEN, RSTB8(TSU1)	Write “1b” (_WEN is write enable)	De-assert TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1.
(4)	Check TSU_n_PRESETN (n = 0, 1) de-assertion.	CPG:CPG_RSTMON_7	RST8_MON(TSU0)/ RST9_MON(TSU1)	Read “0b”	Check that TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1 was de-asserted.
(5)	Release the temperature sensor IP from power down.	Sensor Suspend Register	SOC_TS_EN	Write “1b”	Enable the SOC_TS signal.
			ADC_PD_TS	Write “0b”	Normal ADC operation
			EN_TS	Write “1b”	Normal temperature sensor operation
(6)	Set the operating mode.	Sensor Operation Setting 1 Register	OUTSEL	Write “1b”	Average data output
			ADCS	Write “0b”	Single scan mode
			TRGE	Write “1b”	Enable the ELC trigger.
			ADCT[1:0]	Write “11b”	Set the number of samples for averaging to 8.
		Compare Mode Setting Register	CMPCOND	Write “0b”	The setting remains default.
			CMPEN	Write “0b”	Disable the comparison function.
		Sensor Interrupt Enable Register	CMPIE	Write “0b”	Mask the comparison result interrupt.
			ADIE	Write “1b”	Enable the conversion complete interrupt.
(7)	Check the conversion status.	Sensor Status Register	CONV	Read “0b”	Read the CONV bit as 0 (conversion is not in progress).
(8)	Set the ELC trigger.	ICU:EVTSEL5(TSU0)/EVTSEL6(TSU1)	TSU0: Bit position [29:20] TSU1: Bit position [9:0]	Write the ELC no.*1 of the event to be used.	Select the ELC trigger to be used from the ICU register.
(9)	Start conversion.	—	—	—	Receive the ELC trigger from the ICU.
(10)	The conversion complete interrupt is generated. → Check the interrupt status.	Sensor Interrupt Status Register	ADF	Read “1b”	Read the conversion complete status flag.
(11)	Check the conversion status.	Sensor Status Register	CONV	Read “0b”	Read the CONV bit as 0 (conversion is not in progress).
(12)	Read the converted code.	Sensor Code Read Register	OUT12BIT_TS[11:0]	12-bit read	Read the 12-bit converted temperature code.-

Table 7.11-7 Operation Procedure Example when Interrupt is to be Used for Each Completion of Conversion (Single Scan, Start by ELC Trigger) (2/2)

Step		Register Name	Bit Name	Processing Details	Outline
(13)	Calculate the temperature compensation.	See **7.11.7.8 Temperature Compensation Calculation**.			
(14)	Clear the interrupt status.	Sensor Interrupt Clear Register	ADCLR	Write “1b”	Clear the conversion complete status flag.
(15)	Check the interrupt status.	Sensor Interrupt Status Register	ADF	Read “0b”	Check that the conversion complete status flag was cleared.
(16)	Power down the temperature sensor IP.	Sensor Suspend Register	SOC_TS_EN	Write “0b”	Disable the SOC_TS signal.
			ADC_PD_TS	Write “1b”	Power down the ADC.
			EN_TS	Write “0b”	Power down the temperature sensor.
(17)	Assert TSU_n_PRESETN (n = 0, 1).	CPG:CPG_RST_15	RSTB7_WEN, RSTB7(TSU0)/ RSTB8_WEN, RSTB8(TSU1)	Write “0b” (_WEN is write enable)	Assert TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1.
(18)	Check TSU_n_PRESETN (n = 0, 1) assertion.	CPG:CPG_RSTMON_7	RST8_MON(TSU0)/ RST9_MON(TSU1)	Read “1b”	Check that TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1 was asserted.
(19)	Stop TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKON_16	CLK9_ONWEN, CLK9_ON(TSU0)/ CLK10_ONWEN, CLK10_ON(TSU1)	Write “0b” (_ONWEN is write enable)	Stop TSU_0_PCLK/TSU_1_PCLK to TSU0/TSU1.
(20)	Check stopping of TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKMON_8	CLK9_MON(TSU0)/ CLK10_MON(TSU1)	Read “0b”	Check that TSU_0_PCLK/TSU_1_PCLK supply to TSU0/TSU1 was stopped.

Note 1. For the ELC no., refer to the ICU document “Event_list file”.

7.11.8.2 Using Comparison Result Interrupt

7.11.8.2.1 Single Scan, Start by Software

Table 7.11-8 shows an example of the procedure for operations when the comparison result interrupt is to be used (single scan, start by software). This is an example of reading the average value when the number of samples for averaging is 8.

Table 7.11-8 Operation Procedure Example when Comparison Result Interrupt is to be Used (Single Scan, Start by Software) (1/2)

Step		Register Name	Bit Name	Processing Details	Outline
(1)	Supply TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKON_16	CLK9_ONWEN, CLK9_ON(TSU0)/ CLK10_ONWEN, CLK10_ON(TSU1)	Write “1b” (_ONWEN is write enable)	Supply TSU_0_PCLK/TSU_1_PCLK to TSU0/TSU1.
(2)	Check TSU_n_PCLK (n = 0, 1) supply.	CPG:CPG_CLKMON_8	CLK9_MON(TSU0)/ CLK10_MON(TSU1)	Read “1b”	Check that TSU_0_PCLK/TSU_1_PCLK was supplied to TSU0/TSU1.
(3)	De-assert TSU_n_PRESETN (n = 0, 1).	CPG:CPG_RST_15	RSTB7_WEN, RSTB7(TSU0)/ RSTB8_WEN, RSTB8(TSU1)	Write “1b” (_WEN is write enable)	De-assert TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1.
(4)	Check TSU_n_PRESETN (n = 0, 1) de-assertion.	CPG:CPG_RSTMON_7	RST8_MON(TSU0)/ RST9_MON(TSU1)	Read “0b”	Check that TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1 was de-asserted.
(5)	Release the temperature sensor IP from the power-down state.	Sensor Suspend Register	SOC_TS_EN	Write “1b”	Enable the SOC_TS signal.
			ADC_PD_TS	Write “0b”	Normal ADC operation
			EN_TS	Write “1b”	Normal temperature sensor operation
(6)	Set the operating mode.	Sensor Operation Setting 1 Register	OUTSEL	Write “1b”	Average data output
			ADCS	Write “0b”	Single scan mode
			TRGE	Write “0b”	Disable the ELC trigger.
			ADCT[1:0]	Write “11b”	Set the number of samples for averaging to 8.
		Compare Mode Setting Register	CMPCOND	Write “1b”	Compare mode (within the range setting)
			CMPEN	Write “1b”	Enable the comparison function.
		Sensor Interrupt Enable Register	CMPIE	Write “1b”	Enable the comparison result interrupt.
			ADIE	Write “0b”	Enable the conversion complete interrupt.
(7)	Set the comparison setting values.	Lower Limit Setting Register	LLIM[11:0]	12-bit write	For how to calculate the comparison setting values, see **7.11.7.9 Comparison Setting Value Calculation**.
		Upper Limit Setting Register	ULIM[11:0]	12-bit write	For how to calculate the comparison setting values, see **7.11.7.9 Comparison Setting Value Calculation**.
(8)	Check the conversion status.	Sensor Status Register	CONV	Read “0b”	Read the CONV bit as 0b (conversion is not in progress).
(9)	Start conversion.	Sensor Trigger Register	ADST	Write “1b”	Start conversion by software.

Table 7.11-8 Operation Procedure Example when Comparison Result Interrupt is to be Used (Single Scan, Start by Software) (2/2)

Step		Register Name	Bit Name	Processing Details	Outline
(10)	The comparison result interrupt is generated. → Check the interrupt status.	Sensor Interrupt Status Register	CMPF, ADF	Read “11b”	Read the comparison result status and conversion complete status flags.
(11)	Check the conversion status.	Sensor Status Register	CONV	Read “0b”	Read the CONV bit as 0b (conversion is not in progress).
(12)	Read the converted code.	Sensor Code Read Register	OUT12BIT_TS[11:0]	12-bit read	Read the 12-bit converted temperature code.
(13)	Calculate the temperature compensation.	See **7.11.7.8 Temperature Compensation Calculation**.			
(14)	Clear the interrupt status.	Sensor Interrupt Clear Register	CMPCLR, ADCLR	Write “1b”	Clear the comparison result status and conversion complete status flags.
(15)	Check the interrupt status.	Sensor Interrupt Status Register	CMPF,ADF	Read “00b”	Check that the comparison result status and conversion complete status flags were cleared.
(16)	Power down the temperature sensor IP.	Sensor Suspend Register	SOC_TS_EN	Write “0b”	Disable the SOC_TS signal.
			ADC_PD_TS	Write “1b”	Power down the ADC.
			EN_TS	Write “0b”	Power down the temperature sensor.
(17)	Assert TSU_n_PRESETN (n = 0, 1).	CPG:CPG_RST_15	RSTB7_WEN, RSTB7(TSU0)/ RSTB8_WEN, RSTB8(TSU1)	Write “0b” (_WEN is write enable)	Assert TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1.
(18)	Check TSU_n_PRESETN (n = 0, 1) assertion.	CPG:CPG_RSTMON_7	RST8_MON(TSU0)/ RST9_MON(TSU1)	Read “1b”	Check that TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1 was asserted.
(19)	Stop TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKON_16	CLK9_ONWEN, CLK9_ON(TSU0)/ CLK10_ONWEN, CLK10_ON(TSU1)	Write “0b” (_ONWEN is write enable)	Stop TSU_0_PCLK/TSU_1_PCLK to TSU0/TSU1.
(20)	Check stopping of TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKMON_8	CLK9_MON(TSU0)/ CLK10_MON(TSU1)	Read “0b”	Check that TSU_0_PCLK/TSU_1_PCLK supply to TSU0/TSU1 was stopped.

7.11.8.2.2 Single Scan, Start by an ELC Trigger

Table 7.11-9 shows an example of the procedure for operations when the comparison result interrupt is to be used (single scan, start by an ELC trigger). This is an example of reading the average value when the number of samples for averaging is 8.

Table 7.11-9 Operation Procedure Example when Comparison Result Interrupt is to be Used (Single Scan, Start by ELC Trigger) (1/2)

Step		Register Name	Bit Name	Processing Details	Outline
(1)	Supply TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKON_16	CLK9_ONWEN, CLK9_ON(TSU0)/ CLK10_ONWEN, CLK10_ON(TSU1)	Write “1b” (_ONWEN is write enable)	Supply TSU_0_PCLK/TSU_1_PCLK to TSU0/TSU1.
(2)	Check TSU_n_PCLK (n = 0, 1) supply.	CPG:CPG_CLKMON_8	CLK9_MON(TSU0)/ CLK10_MON(TSU1)	Read “1b”	Check that TSU_0_PCLK/TSU_1_PCLK was supplied to TSU0/TSU1.
(3)	De-assert TSU_n_PRESETN (n = 0, 1).	CPG:CPG_RST_15	RSTB7_WEN, RSTB7(TSU0)/ RSTB8_WEN, RSTB8(TSU1)	Write “1b” (_WEN is write enable)	De-assert TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1.
(4)	Check TSU_n_PRESETN (n = 0, 1) de-assertion.	CPG:CPG_RSTMON_7	RST8_MON(TSU0)/ RST9_MON(TSU1)	Read “0b”	Check that TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1 was de-asserted.
(5)	Release the temperature sensor IP from the power-down state.	Sensor Suspend Register	SOC_TS_EN	Write “1b”	Enable the SOC_TS signal.
			ADC_PD_TS	Write “0b”	Normal ADC operation
			EN_TS	Write “1b”	Normal temperature sensor operation
(6)	Set the operating mode.	Sensor Operation Setting 1 Register	OUTSEL	Write “1b”	Average data output
			ADCS	Write “0b”	Single scan mode
			TRGE	Write “1b”	Enable the ELC trigger.
			ADCT[1:0]	Write “11b”	Set the number of samples for averaging to 8.
		Compare Mode Setting Register	CMPCOND	Write “1b”	Compare mode (within the range setting)
			CMPEN	Write “1b”	Enable the comparison function.
		Sensor Interrupt Enable Register	CMPIE	Write “1b”	Enable the comparison result interrupt.
			ADIE	Write “0b”	Enable the conversion complete interrupt.
(7)	Set the comparison setting values.	Lower Limit Setting Register	LLIM[11:0]	12-bit write	For how to calculate the comparison setting values, see **7.11.7.9 Comparison Setting Value Calculation**.
		Upper Limit Setting Register	ULIM[11:0]	12-bit write	For how to calculate the comparison setting values, see **7.11.7.9 Comparison Setting Value Calculation**.
(8)	Check the conversion status.	Sensor Status Register	CONV	Read “0b”	Read the CONV bit as 0 (conversion is not in progress).
(9)	Set the ELC trigger.	ICU:EVTSEL5(TSU0)/EVTSEL6(TSU1)	TSU0: Bit position [29:20] TSU1: Bit position [9:0]	Write the ELC no.*1 of the event to be used.	Select the ELC trigger to be used from the ICU register.
(10)	Start conversion.	—	—	—	Receive the ELC trigger from the ICU.

Table 7.11-9 Operation Procedure Example when Comparison Result Interrupt is to be Used (Single Scan, Start by ELC Trigger) (2/2)

Step		Register Name	Bit Name	Processing Details	Outline
(11)	The comparison result interrupt is generated. → Check the interrupt status.	Sensor Interrupt Status Register	CMPF, ADF	Read “11b”	Read the comparison result status and conversion complete status flags.
(12)	Check the conversion status.	Sensor Status Register	CONV	Read “0b”	Read the CONV bit as 0b (conversion is not in progress).
(13)	Read the converted code.	Sensor Code Read Register	OUT12BIT_TS[11:0]	12-bit read	Read the 12-bit converted temperature code.
(14)	Calculate the temperature compensation.	See **7.11.7.8 Temperature Compensation Calculation**.			
(15)	Clear the interrupt status.	Sensor Interrupt Clear Register	CMPCLR, ADCLR	Write “1b”	Clear the comparison result status and conversion complete status flags.
(16)	Check the interrupt status.	Sensor Interrupt Status Register	CMPF, ADF	Read “00b”	Check the comparison result status and conversion complete status flags were cleared.
(17)	Power down the temperature sensor IP.	Sensor Suspend Register	SOC_TS_EN	Write “0b”	Disable the SOC_TS signal.
			ADC_PD_TS	Write “1b”	Power down the ADC.
			EN_TS	Write “0b”	Power down the temperature sensor.
(18)	Assert TSU_n_PRESETN (n = 0, 1).	CPG:CPG_RST_15	RSTB7_WEN, RSTB7(TSU0)/ RSTB8_WEN, RSTB8(TSU1)	Write “0b” (_WEN is write enable)	Assert TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1.
(19)	Check TSU_n_PRESETN (n = 0, 1) assertion.	CPG:CPG_RSTMON_7	RST8_MON(TSU0)/ RST9_MON(TSU1)	Read “1b”	Check that TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1 was asserted.
(20)	Stop TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKON_16	CLK9_ONWEN, CLK9_ON(TSU0)/ CLK10_ONWEN, CLK10_ON(TSU1)	Write “0b” (_ONWEN is write enable)	Stop TSU_0_PCLK/TSU_1_PCLK to TSU0/TSU1.
(21)	Check stopping of TSU_n_PCLK (n = 0, 1).	CPG:CPG_CLKMON_8	CLK9_MON(TSU0)/ CLK10_MON(TSU1)	Read “0b”	Check that TSU_0_PCLK/TSU_1_PCLK supply to TSU0/TSU1 was stopped.

Note 1. For the ELC no., refer to the ICU document “Event_list file”.

7.11.8.3 Initialization Procedure

Returning the TSU to its initial state requires asserting the reset signal from the CPG register and then de-asserting the signal.

Follow the procedure in **Table 7.11-10** to perform initialization.

Table 7.11-10 TSU Initialization Procedure

Step		Register Name	Bit Name	Processing Details	Outline
(1)	Assert TSU_n_PRESETN (n = 0, 1).	CPG:CPG_RST_15	RSTB7_WEN, RSTB7(TSU0)/ RSTB8_WEN, RSTB8(TSU1)	Write “0b” (_WEN is write enable)	Assert TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1.
(2)	Check TSU_n_PRESETN (n = 0, 1) assertion.	CPG:CPG_RSTMON_7	RST8_MON(TSU0)/ RST9_MON(TSU1)	Read “1b”	Check that TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1 was asserted.
(3)	De-assert TSU_n_PRESETN (n = 0, 1).	CPG:CPG_RST_15	RSTB7_WEN, RSTB7(TSU0)/ RSTB8_WEN, RSTB8(TSU1)	Write “1b” (_WEN is write enable)	De-assert TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1.
(4)	Check TSU_n_PRESETN (n = 0, 1) de-assertion.	CPG:CPG_RSTMON_7	RST8_MON(TSU0)/ RST9_MON(TSU1)	Read “0b”	Check that TSU_0_PRESETN/TSU_1_PRESETN of TSU0/TSU1 was de-asserted.

7.11.8.4 Procedure for Changing Operating Mode

The operating mode can be changed while conversion is stopped. **Table 7.11-11** shows the procedure for changing the operating mode after checking the CONV bit of the sensor status register = 0.

Table 7.11-11 Procedure for Changing Operating Mode

Step		Register Name	Bit Name	Processing Details	Outline
(1)	Check the conversion status.	Sensor Status Register	CONV	Read “0b”	Read the CONV bit as 0b (conversion is not in progress).
(2)	Set the operating mode.	Set the operating mode to change.			

7.11.9 Usage Notes

7.11.9.1 Release from Power-down

Set the SOC_TS_EN bit of the Sensor Suspend Register to 1b at the same time or before setting the EN_TS bit of the same register to 1b and the ADC_PD_TS bit to 0b to release the temperature sensor IP from the power-down state.

7.11.9.2 Conversion Start Trigger

Before making the setting to start conversion by software or an ELC trigger, check that the CONV bit of the sensor status register is 0b.

7.11.9.3 Restarting the Stopped Clock

Restarting the clock after having stopped it requires placing the module in the power-down state once and then releasing it from the power-down state.

- Power down: Sensor Suspend Register

  SOC_TS_EN bit = 0b
  ADC_PD_TS bit = 1b
  EN_TS bit = 0b

- Release from power-down: Sensor Suspend Register

  SOC_TS_EN bit = 1b
  ADC_PD_TS bit = 0b
  EN_TS bit = 1b

SECTION 8 AUDIO

8.1 Audio Overview

8.1.1 Overview

This section describes the data path between audio modules, list of routings, and transfer flow.

8.1.1.1 Features

The audio module is a module connecting ADMAC, SCU, SSIU, SPDIF, PDM, and ADG.

Refer to the section of each module for the detailed function.

8.1.1.2 Block Diagram

Figure 8.1-1 is a block diagram of the audio module. **Figure 8.1-2** shows the data paths between SSIU and SCU and ADMAC.

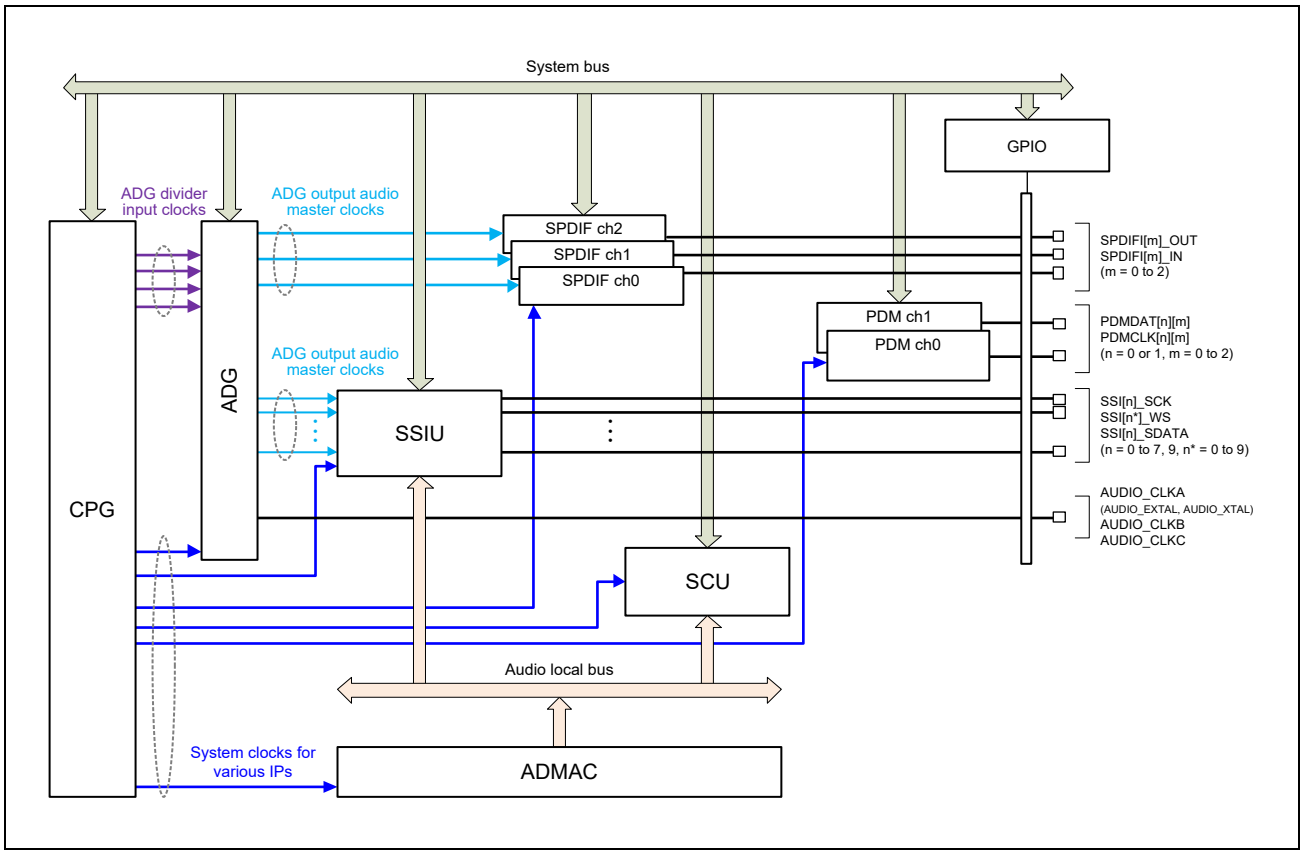


Figure 8.1-1 Audio Module Block Diagram

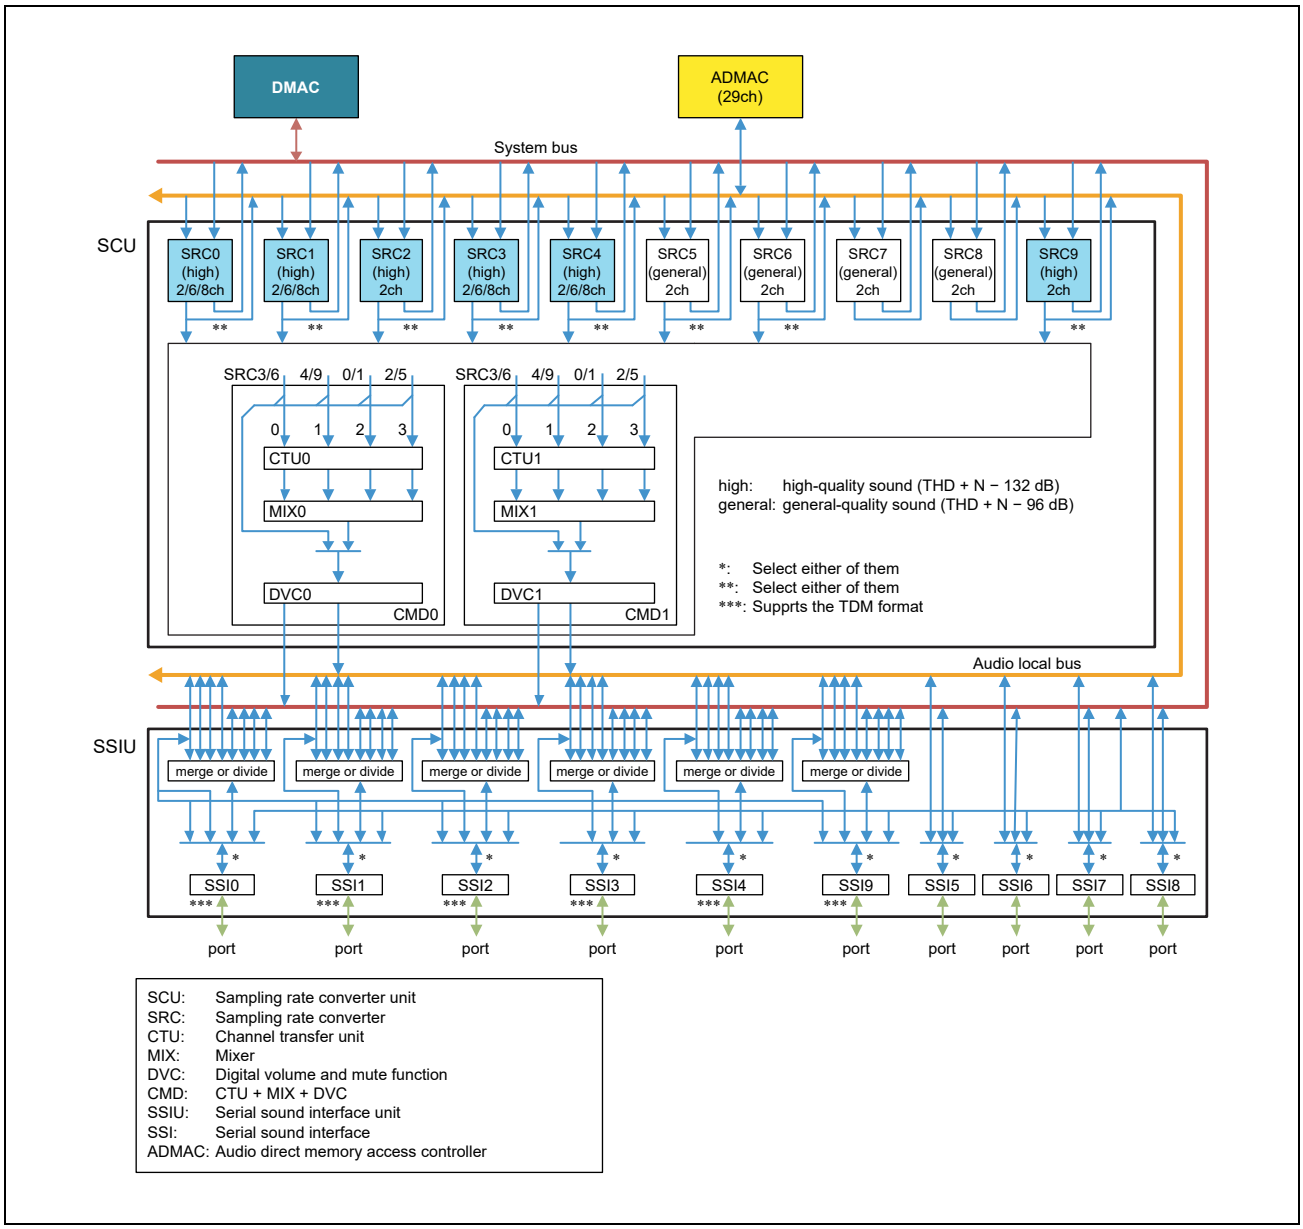

Figure 8.1-2 Data Paths between Audio Modules

8.1.1.3 External Pins

Refer to the following sections for more information about terminal information.

- Section ADG
- Section SSIU
- Section SPDIF
- Section PDM

8.1.1.4 Register Configuration

The audio module does not have a register.

8.1.1.5 Connected Module

Table 8.1-1 Connected Modules

Module Name		Connected Module Name	Function of Connected Module
Audio	Related	SYSTEMBUS	System bus (access the register)
		GPIO	General-purpose I/O, pin function controller
		CPG	Clock pulse generator (Clock ON/OFF, software reset ON/OFF)
		ICU	Interrupt control unit
	Including	SSIU	Serial sound interface unit
		SSI	Serial sound interface
		ADG	Audio clock generator (Output clocks for audio module)
		SCU	Sampling rate converter unit
		SPDIF	SPDIF interface
		PDM	Pulse density modulation
		DMAC	Direct memory access controller
		ADMAC	Audio-DMAC-Peripheral-Peripheral (for audio modules connected to the audio local bus)

8.1.2 Register Description

The audio module does not have a register.

8.1.3 Operation

8.1.3.1 Audio Module Description

1. Audio-DMAC-Peripheral-Peripheral (ADMAC)

The ADMAC controls data transfer between the audio modules (SSIU, SCU) connected to the audio local bus.

- Number of channels: 29 channels
- Data transfer size: Longword (4 bytes)
- Addressing mode: Dual addressing; fixed access size
- Transfer count: Not programmable
- Interrupt processing: None

2. Sampling Rate Converter Unit (SCU)

The SCU has ten SRC modules (six for high-sound-quality type; four for general-sound-quality type) that are useful for synchronization of asynchronous data, which is necessary for data transfer with external memory or external devices. It also provides the functions to change the number of channels, perform mixing, and control the volume.

2-1) Sampling Rate Converter (SRC)

- Asynchronous sampling rate conversion is available
- Supports resolutions up to 24 bits
- High-sound-quality type (THD + N*[1] is − 132 dB) and general-sound-quality type (THD + N*[1] is -96 dB)
- Automatically generates antialiasing filter coefficients
- Four modules support one, two, four, six, or eight channels, and six modules support one or two channels.

Note 1. Total harmonic distortion plus noise

2-2) Channel Transfer Unit (CTU)

- Downmixing and splitter functions
  - Conversion of eight input channels into two output channels
  - Conversion of six input channels into two output channels
  - Conversion of two input channels into four sets of two output channels
  - Conversion of one input channel into eight sets of one output channel
  - No conversion

2-3) Mixer (MIX)

- Mixing (adds) two to four sources into one
- Ratio for adding sources is selectable
- Ratio is dynamically changeable
- Mixing with volume ramp is available (ramp period is selectable)

2-4) Digital Volume and Mute Function (DVC)

- Volume control function including digital volume, volume ramp, and zero-crossing mute
- The digital volume function is specified by a 24-bit fixed-point value within the range from 0 to 8 times (mute or -120 to 18 dB)
- The volume ramp function can be used for soft mute, fade-in, fade-out, or desired volume adjustment
- The volume ramp period can be changed within the sampling range from the 0th to 23rd power of 2
- The zero-crossing mute function silences the sound at the zero-crossing point of the audio data

Remark The CTU, MIX, and DVC functional blocks are collectively called “CMD”.

3. Serial Sound Interface Unit (SSIU)

The SSIU, incorporating ten SSI modules, allows independent operation of SSI modules, operation of multiple SSI modules sharing the same serial clock, and connection or split of multichannel data.

- Incorporates ten SSI modules.
- Supports 6 channels/1 sound source with three SSI modules (SSI0, SSI1, and SSI2).
- Supports 8 channels/1 sound source with four SSI modules (SSI0, SSI1, SSI2, and SSI9).
- Operation of multiple modules on the same serial clock (SSI0/SSI1/SSI2/SSI3/SSI9, SSI3/SSI4/SSI9, SSI5/SSI6, or SSI7/SSI8).
- TDM format (Basic Configuration) corresponds to 4, 6, or 8-channel data.
- Handles 8-channel data on the serial bus and 6-channel data in the SoC (TDM extend mode).
- Handles 6-channel data on the serial bus and 8-channel data in the SoC (TDM extend mode).
- Connects monaural or stereo data to output TDM format data (TDM split mode).
- Splits TDM format input data into monaural or stereo data (TDM split mode).
- Connects stereo or multi data to output TDM format data (TDM ex-split mode).
- Splits TDM format input data into stereo or multi data (TDM ex-split mode).
- The frequency range of SCK signal is from 297.3 kHz to 12.5 MHz in master mode, and from 297.3 kHz to 12.5 MHz in slave mode.

4. SPDIF Interface (SPDIF)

The SPDIF is an interface that complies with the IEC60958 standard. Three SPDIF IPs are incorporated in the chip.

- Compliant with the IEC60958 standard (stereo and consumer use modes only)
- Sampling frequency: 32 kHz, 44.1 kHz, 48 kHz
- Audio word size: 16 to 24 bits/sample
- Biphase mark encoding
- Double buffer for data
- Serial data with parity
- Capable of simultaneous transmission and reception

- The receiver autodetects the IEC61937 compressed mode data.

5. Pulse Density Modulation (PDM)

The PDM has 3 PDM function channels and allows independent operation of each channel. 2 PDM IPs are incorporated in the chip.

- Capable of filtering 1-bit digital input data PDMDATnm (n = 0, 1; m = 0 to 2) and converting them into 20-bit or 16-bit digital data. The bit order is little-endian.
- IP supports stereo microphone (L/R sampling by rising/falling clock edge).
- IP supports sound activity detector.
- Each channel of IP includes programmable filters: 4th order sinc filter, high-pass filter (for suppression of DC bias), correction filter (for sinc passband distortion), half-band decimation filter (for aliasing distortion).
- IP supports programmable and flexible decimation ratios.
- The sinc filter is selectable as first-, second-, third-, fourth-order.
- IP supports DMA operation through APB.
- Each channel of IP has an internal buffer.
- 64 stages
- Capable of storing voice data during low power mode
- Error detection functions can be used for debugging.

6. Audio Clock Generator (ADG)

The ADG selects and supplies the necessary clock for the SSIU, SCU, or SPDIF module. It also divides the frequency of the selected clock and sends it outside the chip.

- Selects the clock signal from the AUDIO_CLKA, AUDIO_CLKB, or AUDIO_CLKC pin or the internal clock and supplies it to the SSIU, SCU, or SPDIF module.
- The frequency of the clock signals from the AUDIO_CLKA, AUDIO_CLKB, and AUDIO_CLKC pins and the internal clock can be divided before use.
- The divided clock can be output through the AUDIO_CLKOUT pin.

8.1.3.2 List of Routings

Data transmission paths in the audio module are shown in **Figure 8.1-3**.

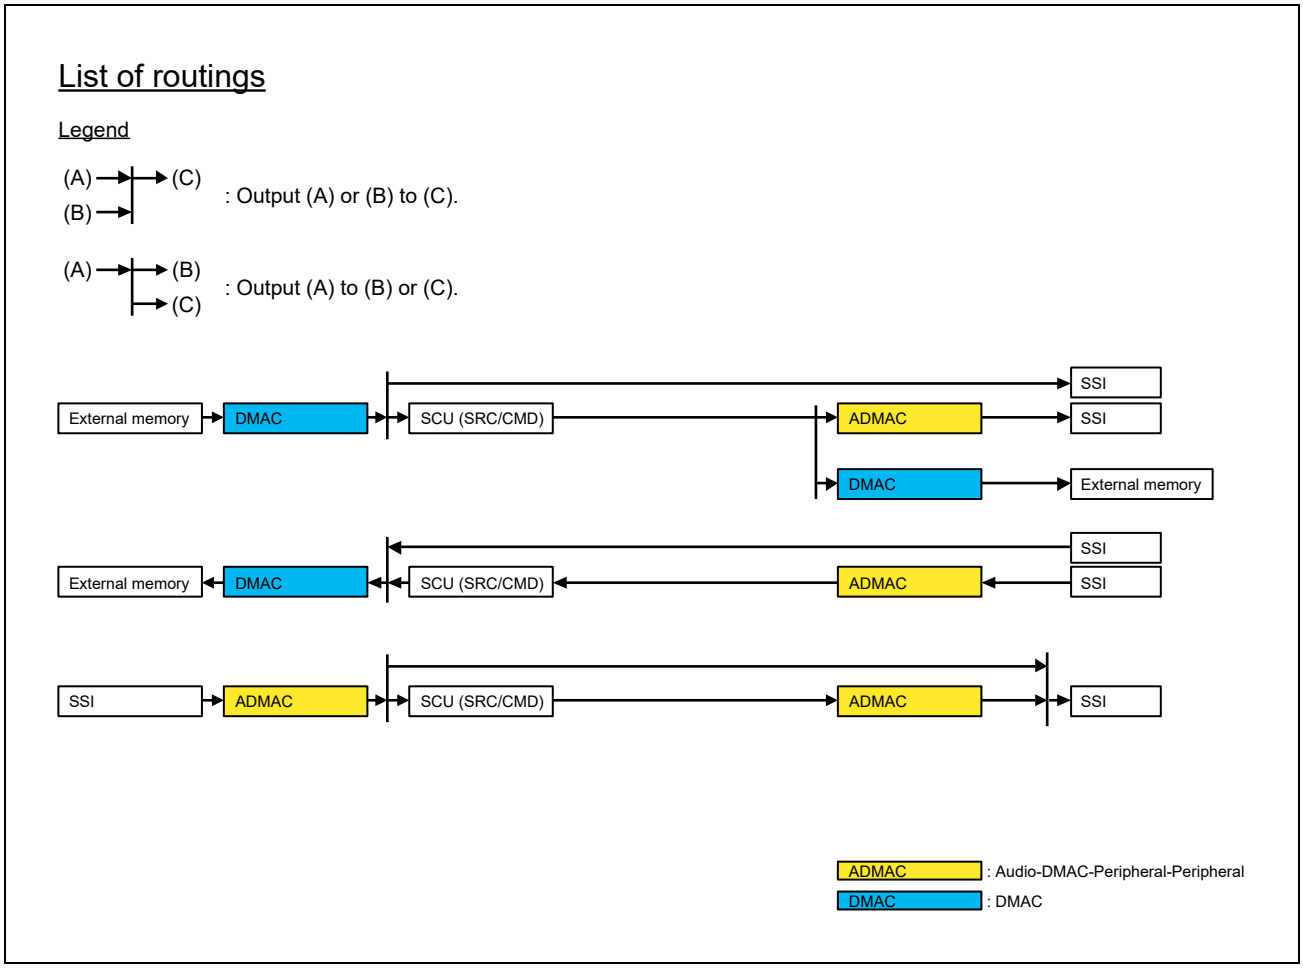

Figure 8.1-3 List of Routings

8.1.3.3 DMAC

The DMAC is used to transfer data between the internal/external memory of the chip and the audio module. **Table 8.1-2** lists the settings of the DMAC source/destination addresses.

SSI_BASE and SCU_BASE represent the base addresses of the SSI and SCU, respectively. For details, refer to section Address Map.

Table 8.1-2 DMAC Source/Destination Address Settings (1/2)

Name of Register	DMASAR/DMADAR	
SSI0-0_BUSIF	SSI_BASE	0000h
SSI0-1_BUSIF		0400h
SSI0-2_BUSIF		0800h

CMD1out_BUSIF*2		8400h

Note 1. Used only by DMASAR.

Note 2. Used only by DMADAR.

8.1.3.4 Data Format on Audio Local Bus

Figure 8.1-4 shows data format processing on the audio local bus. When write/read data passes through the DMAC, the order of data is rearranged to the appropriate data format in **Figure 8.1-4**.

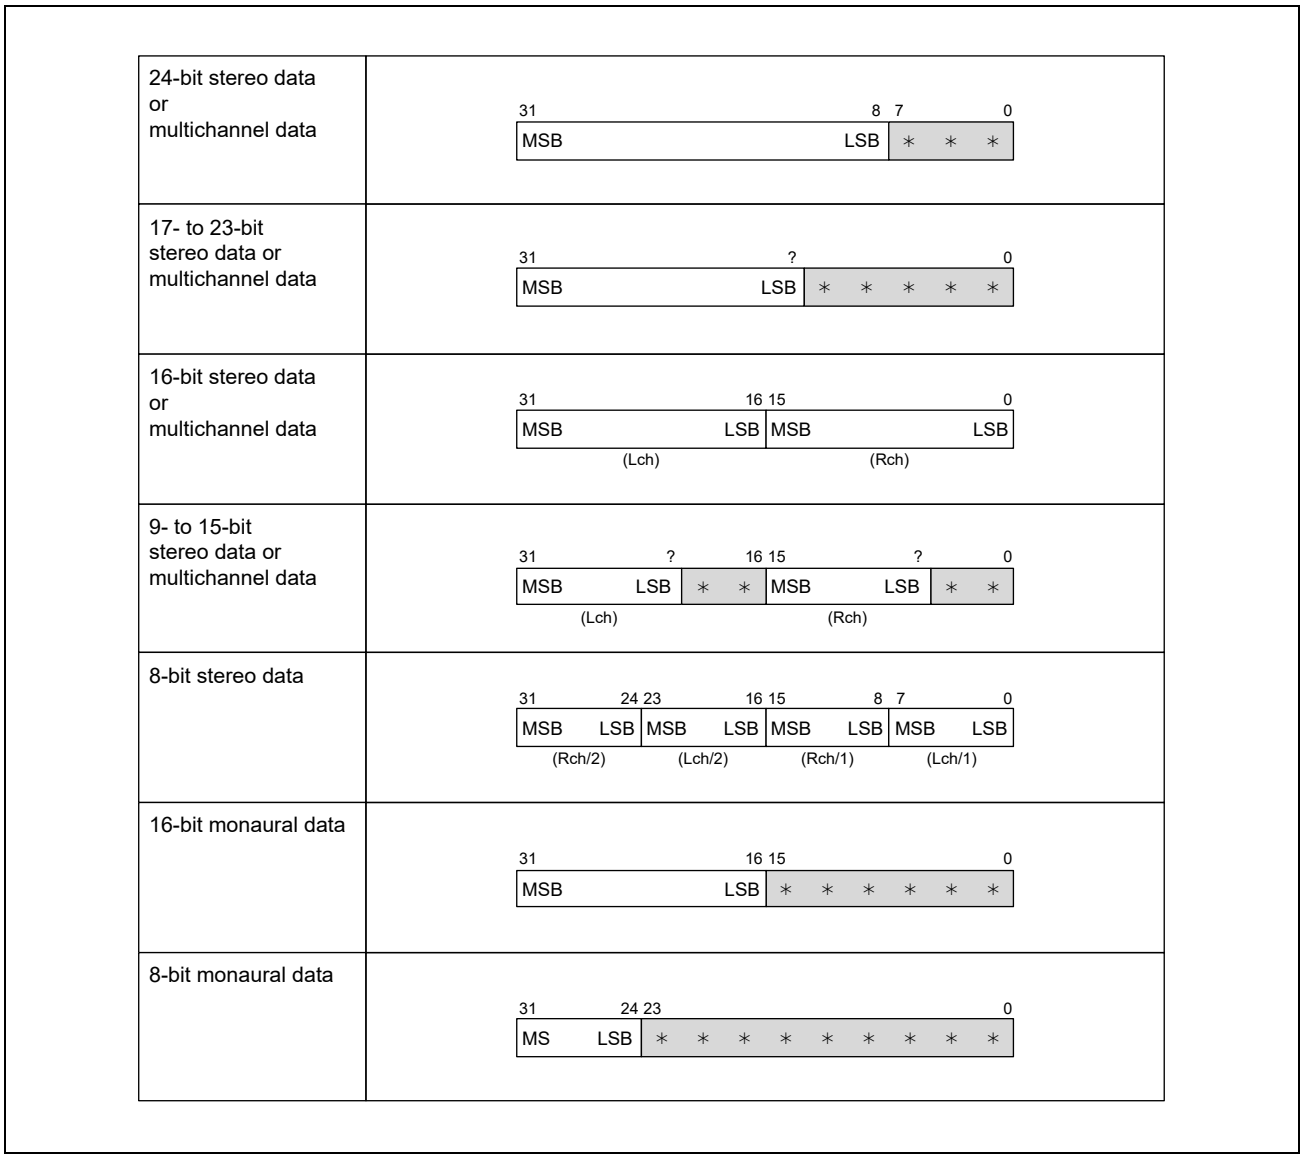

Figure 8.1-4 Data Format

Remark 1. Write 0 to the * bits in the figure when writing data. When reading data, ignore the values read from these bits.

Remark 2. In the 8-bit stereo data format, (Lch/1) and (Rch/1) indicate the data pair to be processed first and (Lch/2) and (Rch/2) indicate the next data pair to be processed.

Remark 3. Only the MSB-first data formats can be used.

8.1.3.5 Rearranging the Order of Data

For the audio modules (SSI, SCU), rearranging the order of data is possible in the channel unit. Places of data in each data format are defined as in **Table 8.1-3**.

Table 8.1-3 Definition of Data Places in Each Data Format (1)

SSI • Stereo (2 channels)	SSI • Stereo × 3 (6 channels)	SSI • TDM (6 channels)	SSI • Stereo × 4 (8 channels)	SSI • TDM (8 channels)	
Table 8.1-3 Definition of Data Places in Each Data Format (2)

8.1.3.6 Clock and Reset

The clock and reset signals for the audio modules (ADG, ADMAC, SCU, SSIU, SPDIF, and PDM) can be switched on or off by setting the registers of the CPG.

8.1.3.6.1 Clock and Reset Configuration

Figure 8.1-5 shows the clock and reset configuration of the audio modules (ADG, ADMAC, SCU, SSIU, SPDIF, and PDM).

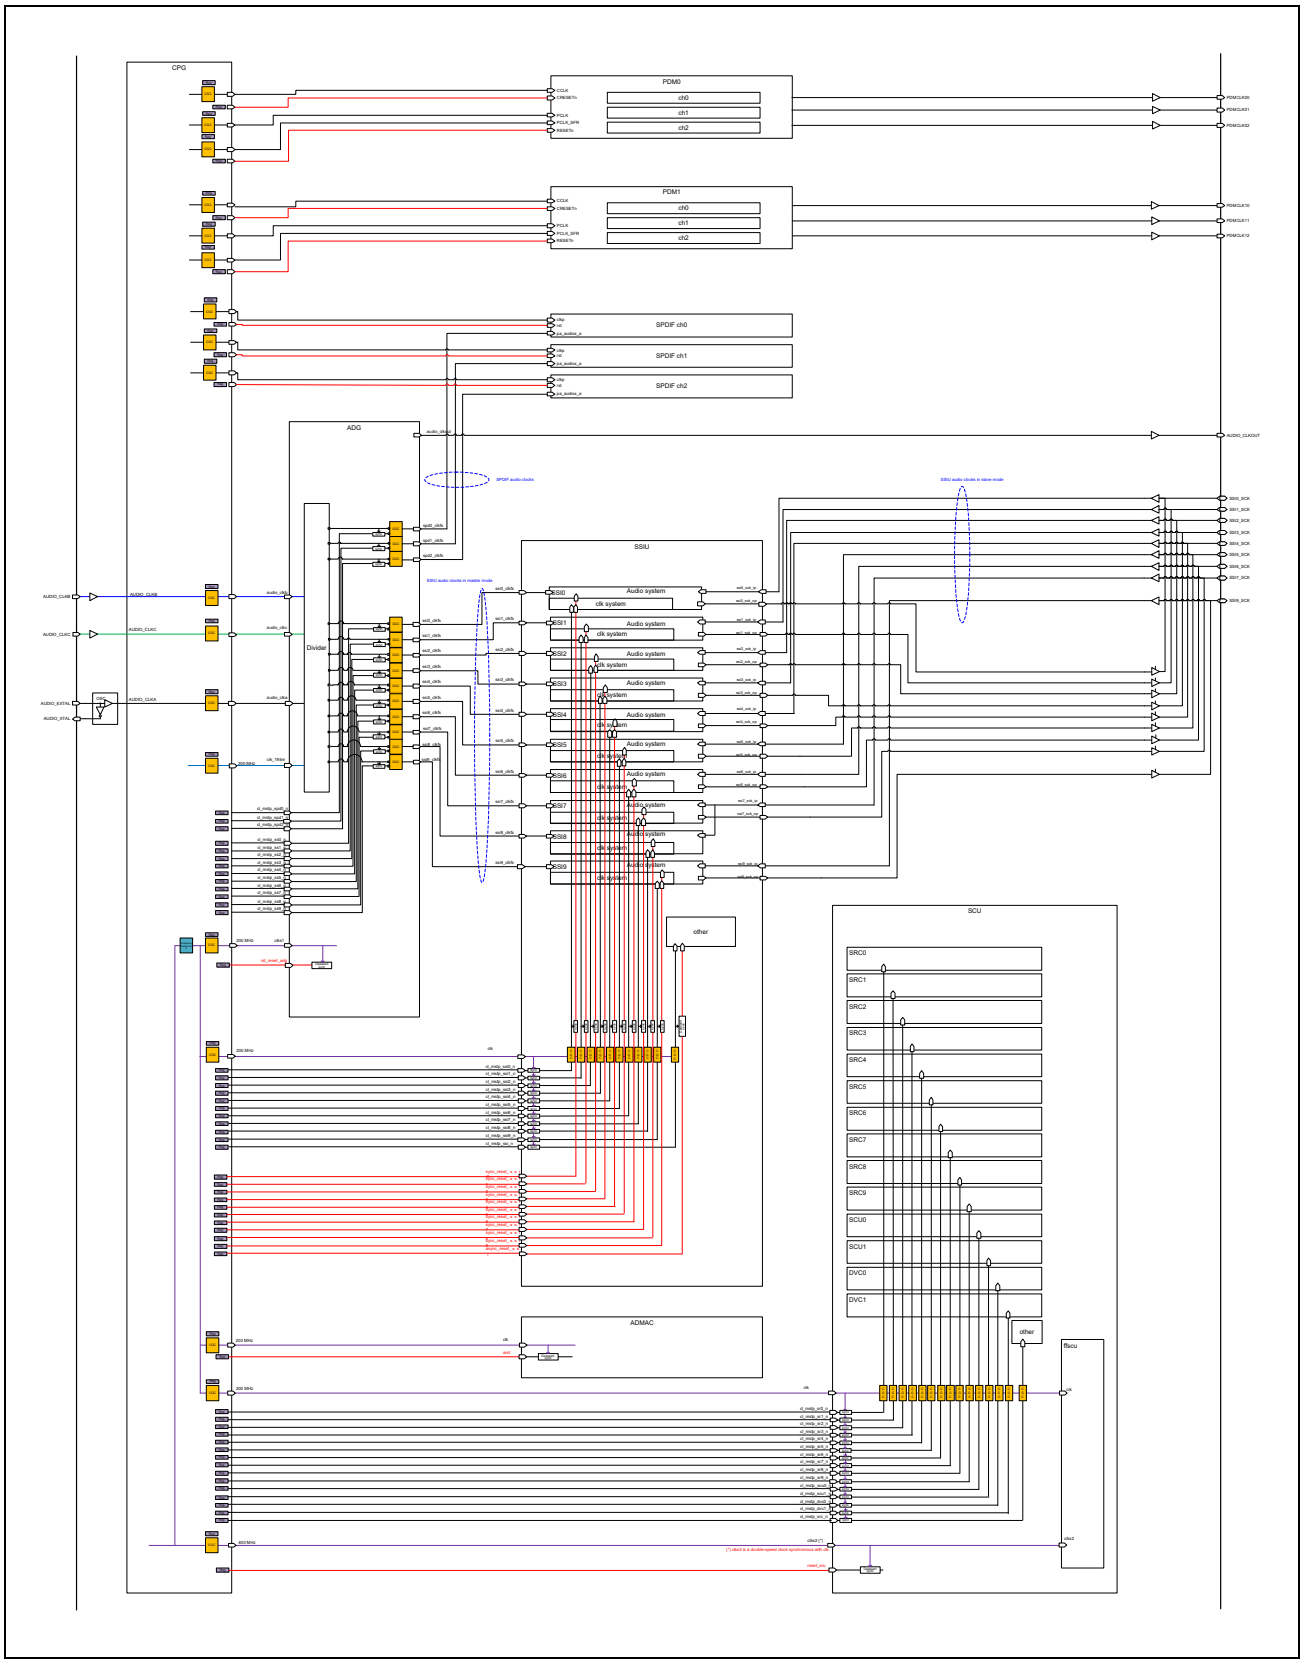

Figure 8.1-5 Clock and Reset Configuration of Audio Module

8.1.3.6.2 System Clock for IP

The system clock for each IP can be supplied or stopped by using the corresponding register of the CPG. The system clock for each IP is also used as a bus clock. Supply the system clock to the target IP before access to the register.

(1) System Clock for ADG

The system clock clks1 input to the ADG can be supplied or stopped by using the CLK9_ON bit of the CPG_CLKON_15 register. The clock is stopped at its initial state after power is on.

Table 8.1-4 ADG System Clock Control

Register Name	Bit	Function
CPG_CLKON_15	CLK9_ON	Supplying or stopping the system clock clks1 input to ADG (0: Stopped; 1: Supplied)

(2) System Clock for ADMAC

The system clock clk input to the ADMAC can be supplied or stopped by using the CLK8_ON bit of the CPG_CLKON_15 register. The clock is stopped at its initial state after power is on.

Table 8.1-5 ADMAC System Clock Control

Register Name	Bit	Function
CPG_CLKON_15	CLK8_ON	Supplying or stopping the system clock clk input to ADMAC (0: Stopped; 1: Supplied)

(3) System Clock for SCU

The system clocks clk and clkx2 input to the SCU can be supplied or stopped by using the CLK6_ON and CLK7_ON bits of the CPG_CLKON_15 register. The clocks are stopped at their initial states after power is on.

Table 8.1-6 SCU System Clock Control

Register Name	Bit	Function
CPG_CLKON_15	CLK6_ON	Supplying or stopping the system clock clk input to SCU (0: Stopped; 1: Supplied)
	CLK7_ON	Supplying or stopping the system clock clkx2 input to SCU (0: Stopped; 1: Supplied)

The system clocks clk and clkx2 input to the SCU are distributed to the given function modules within the SCU via the CGC cells. The system clock for the function modules can be supplied or stopped individually by using the CLK0_ON to CLK14_ON bits of the CPG_CLKON_23 register.

Table 8.1-7 System Clock Control for Internal Modules of SCU

Register Name	Bit	Function
CPG_CLKON_23	CLK0_ON	Supplying or stopping the system clock supplied to the DVC ch0 module of SCU (0: Stopped; 1: Supplied)
	CLK1_ON	Supplying or stopping the system clock supplied to the DVC ch1 module of SCU (0: Stopped; 1: Supplied)
	CLK2_ON	Supplying or stopping the system clock supplied to the CTU/MIX ch0 module of SCU (0: Stopped; 1: Supplied)
	CLK3_ON	Supplying or stopping the system clock supplied to the CTU/MIX ch1 module of SCU (0: Stopped; 1: Supplied)
	CLK4_ON	Supplying or stopping the system clock supplied to the SRC ch0 module of SCU (0: Stopped; 1: Supplied)
	CLK5_ON	Supplying or stopping the system clock supplied to the SRC ch1 module of SCU (0: Stopped; 1: Supplied)
	CLK6_ON	Supplying or stopping the system clock supplied to the SRC ch2 module of SCU (0: Stopped; 1: Supplied)
	CLK7_ON	Supplying or stopping the system clock supplied to the SRC ch3 module of SCU (0: Stopped; 1: Supplied)
	CLK8_ON	Supplying or stopping the system clock supplied to the SRC ch4 module of SCU (0: Stopped; 1: Supplied)
	CLK9_ON	Supplying or stopping the system clock supplied to the SRC ch5 module of SCU (0: Stopped; 1: Supplied)
	CLK10_ON	Supplying or stopping the system clock supplied to the SRC ch6 module of SCU (0: Stopped; 1: Supplied)
	CLK11_ON	Supplying or stopping the system clock supplied to the SRC ch7 module of SCU (0: Stopped; 1: Supplied)
	CLK12_ON	Supplying or stopping the system clock supplied to the SRC ch8 module of SCU (0: Stopped; 1: Supplied)
	CLK13_ON	Supplying or stopping the system clock supplied to the SRC ch9 module of SCU (0: Stopped; 1: Supplied)
	CLK14_ON	Supplying or stopping the system clock supplied to the modules other than SCU (0: Stopped; 1: Supplied)

Table 8.1-8 shows the relationship between the CPG registers (CPG_CLKON_15 and CPG_CLKON_23 registers) and the target function modules for clock control.

Note 1. Function modules excluding SRC0 to SRC9, DVC0 and DVC1, CTU0 and CTU1, and MIX0 and MIX1 (including the setting registers, etc.)

(4) System clock for SSIU

The system clock clk input to the SSIU can be supplied or stopped by using the CLK5_ON bit of the CPG_CLKON_15 register. The clock is stopped at its initial state after power is on.

Table 8.1-9 SSIU System Clock Control

Register Name	Bit	Function
CPG_CLKON_15	CLK5_ON	Supplying or stopping the system clock clk input to SSIU (0: Stopped; 1: Supplied)

The system clock clk input to the SSIU is distributed to the given function modules within the SSIU via the CGC cells. The system clock for the function modules can be supplied or stopped individually by using the CLK0_ON to CLK10_ON bits of the CPG_CLKON_24 register.

Table 8.1-10 System Clock Control for Internal Modules of SSIU

Register Name	Bit	Function
CPG_CLKON_24	CLK0_ON	Supplying or stopping the system clock supplied to other modules (0: Stopped; 1: Supplied)
	CLK1_ON	Supplying or stopping the system clock supplied to the SSI ch0 module of SSIU (0: Stopped; 1: Supplied)
	CLK2_ON	Supplying or stopping the system clock supplied to the SSI ch1 module of SSIU (0: Stopped; 1: Supplied)

0	—	—	—	—	—	—	—	—	—	—	—	Stop all system clocks

—: Don’t care

Note 1. Function modules excluding SSI ch0 to SSI ch9 (including the setting registers, etc.)

(5) System Clock for SPDIF

The system clock input to ch0 and ch1 of the SPDIF and the system clock input to ch2 of the SPDIF can be supplied or stopped by using the CLK14_ON and CLK15_ON bits of the CPG_CLKON_15 register and the CLK0_ON bit of the CPG_CLKON_16 register, respectively. The clocks are stopped at their initial states after power is on.

Table 8.1-12 System Clock Control for SPDIF Ch0 and Ch1

Register Name	Bit	Function
CPG_CLKON_15	CLK14_ON	Supplying or stopping the system clock input to SPDIF ch0 (0: Stopped; 1: Supplied)
CPG_CLKON_15	CLK15_ON	Supplying or stopping the system clock input to SPDIF ch1 (0: Stopped; 1: Supplied)

Table 8.1-13 System Clock Control for SPDIF Ch2

Register Name	Bit	Function
CPG_CLKON_16	CLK0_ON	Supplying or stopping the system clock input to SPDIF ch2 (0: Stopped; 1: Supplied)

(6) System Clock for PDM

The system clock input to ch0 of the PDM and the system clock input to ch1 of the PDM can be supplied or stopped by using the CLK1_ON to CLK3_ON bits of the CPG_CLKON_16 register and the CLK4_ON to CLK6_ON bits of the CPG_CLKON_16 register, respectively. The clocks are stopped at their initial states after power is on.

Table 8.1-14 System Clock Control for PDM Ch0

Register Name	Bit	Function
CPG_CLKON_16	CLK1_ON	Supplying or stopping the system clock PCLK input to PDM ch0 (0: Stopped; 1: Supplied)
	CLK2_ON	Supplying or stopping the system clock PCLK_SFR input to PDM ch0 (0: Stopped; 1: Supplied)

Table 8.1-15 External I/F Reference Clock Control for PDM Ch0

Register Name	Bit	Function
CPG_CLKON_16	CLK3_ON	Supplying or stopping the external I/F reference clock CCLK for PDM ch0 (0: Stopped; 1: Supplied)

Table 8.1-16 System Clock Control for PDM Ch1

Register Name	Bit	Function
CPG_CLKON_16	CLK4_ON	Supplying or stopping the system clock PCLK input to PDM ch1 (0: Stopped; 1: Supplied)
	CLK5_ON	Supplying or stopping the system clock PCLK_SFR input to PDM ch1 (0: Stopped; 1: Supplied)

Table 8.1-17 External I/F Reference Clock Control for PDM Ch1

Register Name	Bit	Function
CPG_CLKON_16	CLK6_ON	Supplying or stopping the external I/F reference clock CCLK for PDM ch1 (0: Stopped; 1: Supplied)

8.1.3.6.3 ADG Divider Input Clocks

The clocks input to the divider within the ADG can be supplied or stopped by using the CLK10_ON to CLK13_ON bits of the CPG_CLKON_15 register. The clocks are stopped at their initial states after power is on.

After releasing the ADG from the reset state, set the operating mode by the corresponding register of the ADG before supplying the target clock input to the divider.

Table 8.1-18 ADG Internal Divider Input Clock Control

Register Name	Bit	Function
CPG_CLKON_15	CLK10_ON	Supplying or stopping the internal clock (200 MHz) input to ADG (0: Stopped; 1: Supplied)
	CLK11_ON	Supplying or stopping the audio_clka clock input to ADG (0: Stopped; 1: Supplied)
	CLK12_ON	Supplying or stopping the audio_clkb clock input to ADG (0: Stopped; 1: Supplied)
	CLK13_ON	Supplying or stopping the audio_clkc clock input to ADG (0: Stopped; 1: Supplied)

8.1.3.6.4 ADG Output Audio Master Clocks

(1) ADG Output Audio Master Clocks (for SSIU)

Audio master clocks input to the SSIU (ssi[0-9]_clkfs) are generated via the divider within the ADG. The audio master clocks generated by the ADG can be supplied or stopped by using the CLK0_ON to CLK9 _ON bits of the CPG_CLKON_22 register. The clocks are stopped at their initial states after power is on.

Table 8.1-19 ADG Output Audio Master Clock Control (for SSIU)

Register Name	Bit	Function
CPG_CLKON_22	CLK0_ON	Supplying or stopping the audio master clock ssi0_clkfs output by ADG for SSI ch0 (0: Stopped; 1: Supplied)
	CLK1_ON	Supplying or stopping the audio master clock ssi1_clkfs output by ADG for SSI ch1 (0: Stopped; 1: Supplied)
	CLK2_ON	Supplying or stopping the audio master clock ssi2_clkfs output by ADG for SSI ch2 (0: Stopped; 1: Supplied)
	CLK3_ON	Supplying or stopping the audio master clock ssi3_clkfs output by ADG for SSI ch3 (0: Stopped; 1: Supplied)
	CLK4_ON	Supplying or stopping the audio master clock ssi4_clkfs output by ADG for SSI ch4 (0: Stopped; 1: Supplied)
	CLK5_ON	Supplying or stopping the audio master clock ssi5_clkfs output by ADG for SSI ch5 (0: Stopped; 1: Supplied)
	CLK6_ON	Supplying or stopping the audio master clock ssi6_clkfs output by ADG for SSI ch6 (0: Stopped; 1: Supplied)
	CLK7_ON	Supplying or stopping the audio master clock ssi7_clkfs output by ADG for SSI ch7 (0: Stopped; 1: Supplied)
	CLK8_ON	Supplying or stopping the audio master clock ssi8_clkfs output by ADG for SSI ch8 (0: Stopped; 1: Supplied)
	CLK9_ON	Supplying or stopping the audio master clock ssi9_clkfs output by ADG for SSI ch9 (0: Stopped; 1: Supplied)

When stopping the audio master clocks, only do so after stopping operation of the target SSIU channels.

The audio master clocks should be supplied after setting the ADG registers related to the selection of the frequency and clock source of the audio master clock and setting the registers related to the operating mode of the target SSIU channels.

(2) ADG Output Audio Master Clocks (for SPDIF)

Audio master clocks input to the SPDIF (spd[0-2]_clkfs) are generated via the divider within the ADG. The audio master clocks generated by the ADG can be supplied or stopped by using the CLK10_ON to CLK12 _ON bits of the CPG_CLKON_22 register. The clocks are stopped at their initial states after power is on.

Table 8.1-20 ADG Output Audio Master Clock Control (for SPDIF)

Register Name	Bit	Function
CPG_CLKON_22	CLK10_ON	Supplying or stopping the audio master clock spd0_clkfs output by ADG for SPDIF ch0 (0: Stopped; 1: Supplied)
	CLK11_ON	Supplying or stopping the audio master clock spd1_clkfs output by ADG for SPDIF ch1 (0: Stopped; 1: Supplied)
	CLK12_ON	Supplying or stopping the audio master clock spd2_clkfs output by ADG for SPDIF ch2 (0: Stopped; 1: Supplied)

When stopping the audio master clocks, only do so after stopping operation of the target SPDIF channels.

The audio master clocks should be supplied after setting the ADG registers related to the selection of the frequency and clock source of the audio master clock and setting the registers related to the operating mode of the target SPDIF channels.

8.1.3.6.5 Reset for IP

Initialization of each IP can be controlled by using the corresponding register of the CPG. Be sure to release the target IP from the reset state before access to the register for the IP.

(1) Reset for ADG

For the ADG, initialization of the whole IP can be controlled by using the RSTB14 bit of the CPG_RST_14 register.

Note that the ADG should be reset after stopping operation of the SSIU, SCU, and SPDIF. Otherwise, correct operation is not guaranteed. When releasing the ADG from the reset state, only do so after supplying the system clock for the ADG.

Table 8.1-21 ADG Reset Control

Register Name	Bit	Function
CPG_RST_14	RSTB14	Resetting the whole ADG or releasing the reset (0: Reset; 1: Release from reset)

(2) Reset for ADMAC

For the ADMAC, initialization of the whole IP can be controlled by using the RSTB13 bit of the CPG_RST_14 register.

Note that the ADMAC should be reset after stopping operation of the target channels of the IP involved in the data transfer path. Otherwise, correct operation is not guaranteed. When releasing the ADMAC from the reset state, only do so after supplying the system clock for the ADMAC.

Table 8.1-22 ADMAC Reset Control

Register Name	Bit	Function
CPG_RST_14	RSTB13	Resetting the whole ADMAC or releasing the reset (0: Reset; 1: Release from reset)

(3) Reset for SCU

For the SCU, initialization of the whole IP can be controlled by using the RSTB12 bit of the CPG_RST_14 register.

Note that the SCU should be reset after stopping operation of the target channels of the IP involved in the data transfer path. Otherwise, correct operation is not guaranteed. When releasing the SCU from the reset state, only do so after supplying the system clock for the SCU.

Table 8.1-23 SCU Reset Control

Register Name	Bit	Function
CPG_RST_14	RSTB12	Resetting the whole SCU or releasing the reset (0: Reset; 1: Release from reset)

(4) Reset for SSIU

For the SSIU, initialization of the whole SSIU or initialization of the individual modules within the SSIU can be controlled by using the RSTB1 to RSTB11 bits of the CPG_RST_14 register.

Note that the SSIU should be reset after stopping operation of the target channels of the IP involved in the data transfer path. Otherwise, correct operation is not guaranteed. When releasing the SSIU from the reset state, only do so after supplying the system clock for the SSIU.

Table 8.1-24 SSIU Reset Control

Register Name	Bit	Function
CPG_RST_14	RSTB1	Resetting the modules other than those below (the setting register modules, etc.) or releasing the reset (0: Reset; 1: Release from reset)
	RSTB2	Resetting the SSI ch0 module or releasing the reset (0: Reset; 1: Release from reset)
	RSTB3	Resetting the SSI ch1 module or releasing the reset (0: Reset; 1: Release from reset)
	RSTB4	Resetting the SSI ch2 module or releasing the reset (0: Reset; 1: Release from reset)
	RSTB5	Resetting the SSI ch3 module or releasing the reset (0: Reset; 1: Release from reset)
	RSTB6	Resetting the SSI ch4 module or releasing the reset (0: Reset; 1: Release from reset)
	RSTB7	Resetting the SSI ch5 module or releasing the reset (0: Reset; 1: Release from reset)
	RSTB8	Resetting the SSI ch6 module or releasing the reset (0: Reset; 1: Release from reset)
	RSTB9	Resetting the SSI ch7 module or releasing the reset (0: Reset; 1: Release from reset)
	RSTB10	Resetting the SSI ch8 module or releasing the reset (0: Reset; 1: Release from reset)
	RSTB11	Resetting the SSI ch9 module or releasing the reset (0: Reset; 1: Release from reset)

Table 8.1-25 lists the RSTB1 to RSTB11 bits of the CPG_RST_14 register and the system clock settings required for resetting the target channels or releasing them from the reset state.

Table 8.1-25 SSIU Reset Control Registers and Required System Clock Settings

Clock setting required for reset or reset release operation by RSTB1 to RSTB11 of CPG_RST_14 register	CPG_CLKON_15 register	CPG_CLKON_24 register										
	CLK5_ON bit	CLK0_ON bit	CLK1_ON bit	CLK2_ON bit	CLK3_ON bit	CLK4_ON bit	CLK5_ON bit	CLK6_ON bit	CLK7_ON bit	CLK8_ON bit	CLK9_ON bit	CLK10_ON bit
RSTB1	1	1	—	—	—	—	—	—	—	—	—	—
RSTB2	1	—	1	—	—	—	—	—	—	—	—	—
RSTB3	1	—	—	1	—	—	—	—	—	—	—	—
RSTB4	1	—	—	—	1	—	—	—	—	—	—	—
RSTB5	1	—	—	—	—	1	—	—	—	—	—	—
RSTB6	1	—	—	—	—	—	1	—	—	—	—	—
RSTB7	1	—	—	—	—	—	—	1	—	—	—	—
RSTB8	1	—	—	—	—	—	—	—	1	—	—	—
RSTB9	1	—	—	—	—	—	—	—	—	1	—	—
RSTB10	1	—	—	—	—	—	—	—	—	—	1	—
RSTB11	1	—	—	—	—	—	—	—	—	—	—	1

(5) Reset for SPDIF

For ch0 of the SPDIF, initialization of the whole IP can be controlled by using the RSTB15 bit of the CPG_RST_14 register. For ch1 and ch2 of the SPDIF, initialization of the whole IP can be controlled by using the RSTB0 and RSTB1 bits of the CPG_RST_15 register.

Note that the SPDIF should be reset after stopping operation of the target channels of the IP involved in the data transfer path. Otherwise, correct operation is not guaranteed. When releasing the SPDIF from the reset state, only do so after supplying the system clock for the SPDIF.

Table 8.1-26 SPDIF Reset Control (1)

Register Name	Bit	Function
CPG_RST_14	RSTB15	Resetting SPDIF ch0 or releasing the reset (0: Reset; 1: Release from reset)

Table 8.1-26 SPDIF Reset Control (2)

Register Name	Bit	Function
CPG_CLKON_15	RSTB0	Resetting SPDIF ch1 or releasing the reset (0: Reset; 1: Release from reset)
	RSTB1	Resetting SPDIF ch2 or releasing the reset (0: Reset; 1: Release from reset)

(6) Reset for PDM

For ch0 of the PDM, initialization of the whole IP can be controlled by using the RSTB2 and RSTB3 bits of the CPG_RST_15 register. For ch1 of the PDM, initialization of the whole IP can be controlled by using the RSTB4 and RSTB5 bits of the CPG_RST_15 register.

Note that the PDM should be reset after stopping operation of the target channels of the IP involved in the data transfer path. Otherwise, correct operation is not guaranteed. When releasing the PDM from the reset state, only do so after supplying the system clock for the PDM.

Table 8.1-27 PDM Reset Control (1)

Register Name	Bit	Function
CPG_RST_15	RSTB2	Resetting the PCK/PCLK_SFR clock circuit for PDM ch0 or releasing the reset (0: Reset; 1: Release from reset)
	RSTB3	Resetting the CCLK clock circuit for PDM ch0 or releasing the reset (0: Reset; 1: Release from reset)

Table 8.1-27 PDM Reset Control (2)

Register Name	Bit	Function
CPG_CLKON_15	RSTB4	Resetting the PCK/PCLK_SFR clock circuit for PDM ch1 or releasing the reset (0: Reset; 1: Release from reset)
	RSTB5	Resetting the CCLK clock circuit for PDM ch1 or releasing the reset (0: Reset; 1: Release from reset)

8.1.3.6.6 Module Reset for SCU

Table 8.1-28 lists the software reset registers of the SCU. By using these registers, the SCU can control initialization of the target function modules and the associated registers (excluding the software reset registers).

Table 8.1-28 SCU Internal Software Reset Control

Register Name	Bit	Function
SRCm_SWRSR (m = 0 to 9)	SWRST	Resetting the circuit of the corresponding SRC channel within SCU and the associated register (excluding SRC[m]_SWRSR) or releasing the reset (0: Reset; 1: Release from reset)
CTUn_SWRSR (n = 00, 01, 02, 03, 10, 11, 12, or 13)	SWRST	Resetting the circuit of the corresponding CTU channel within SCU and the associated register (excluding CTU[n]_SWRSR) or releasing the reset (0: Reset; 1: Release from reset)
MIXp_SWRSR (p = 0 or 1)	SWRST	Resetting the circuit of the corresponding MIX channel within SCU and the associated register (excluding MIX[p]_SWRSR) or releasing the reset (0: Reset; 1: Release from reset)
DVCp_SWRSR (p = 0 or 1)	SWRST	Resetting the circuit of the corresponding DVC channel within SCU and the associated register (excluding DVC[p]_SWRSR) or releasing the reset (0: Reset; 1: Release from reset)

For reset or reset release operations using the software reset registers, the system clock must be supplied to the target function modules beforehand. **Table 8.1-29** lists the relationship between the software reset registers of the SCU and the clock settings required for initialization control.

Table 8.1-29 SCU Internal Software Reset Control Registers and Required Clock Settings

Software reset register within SCU	CPG_CLKON_15 register		CPG_CLKON_23 register

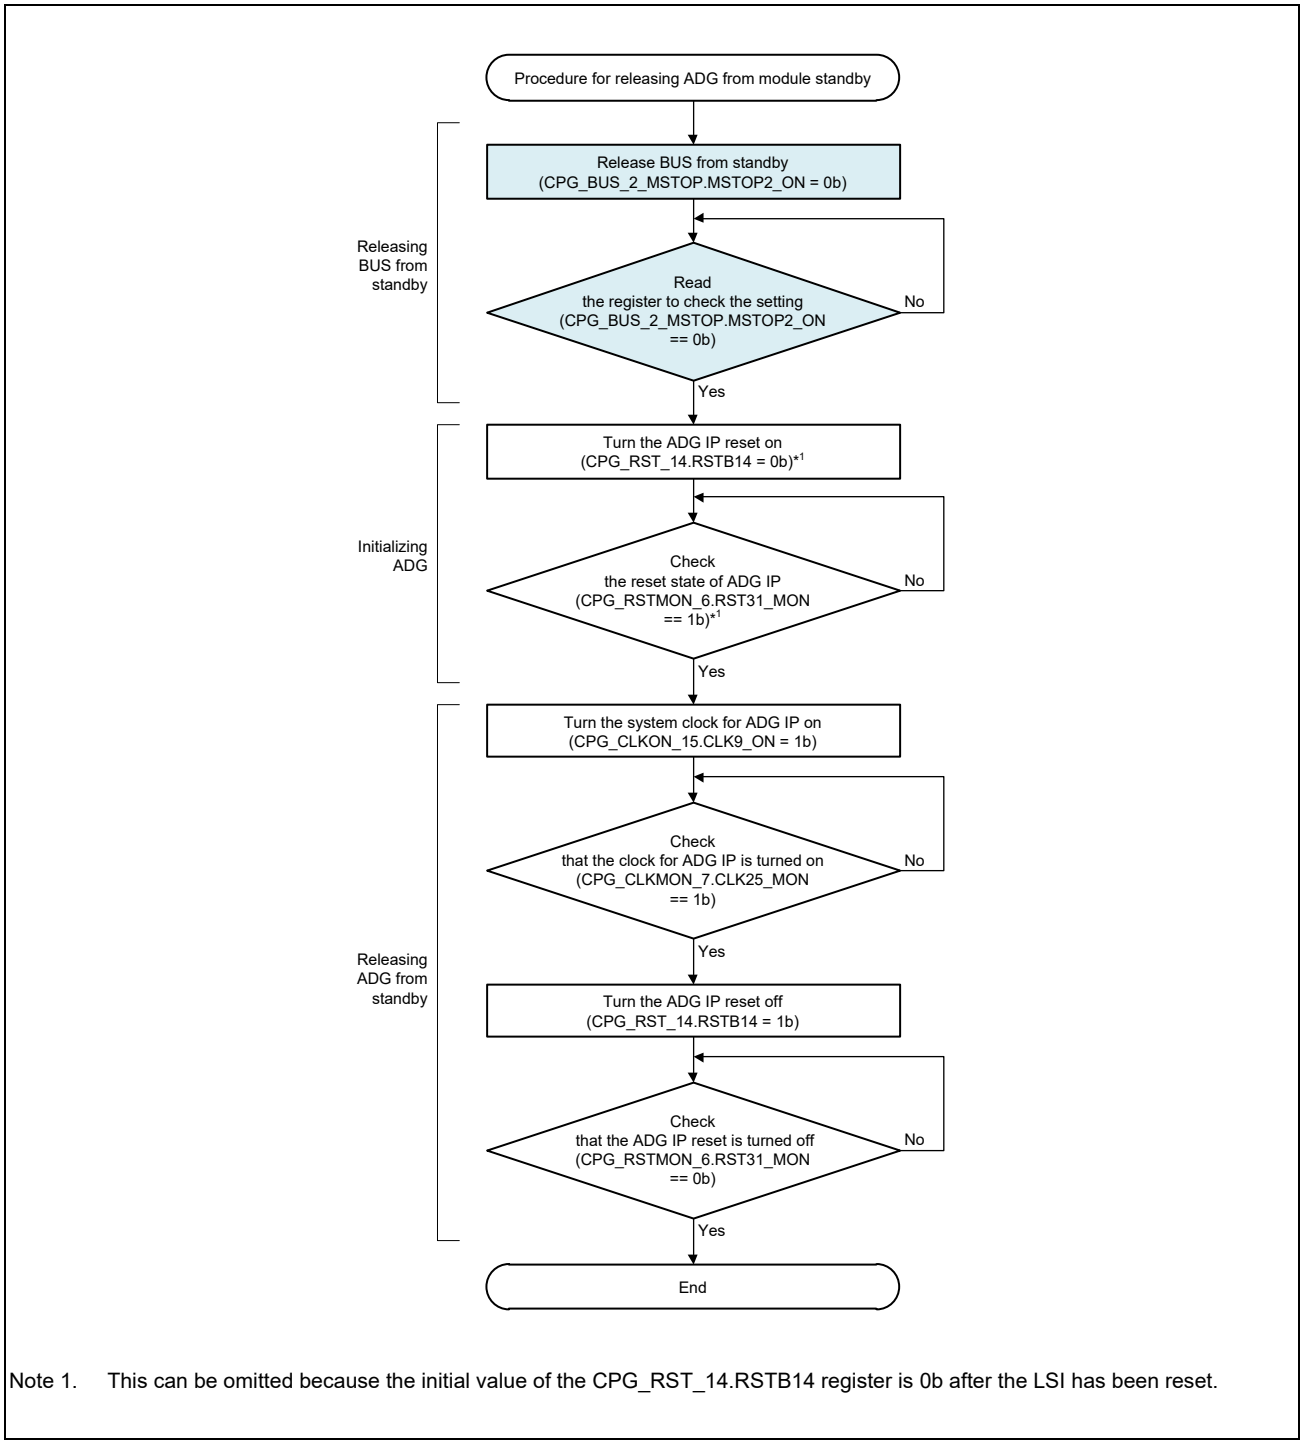
8.1.3.7 Procedure for Releasing IP from Module Standby

The following describes the procedure for releasing each IP from module standby.

8.1.3.7.1 Procedure for Releasing ADG from Module Standby

Figure 8.1-6 shows the procedure for releasing the ADG from module standby.

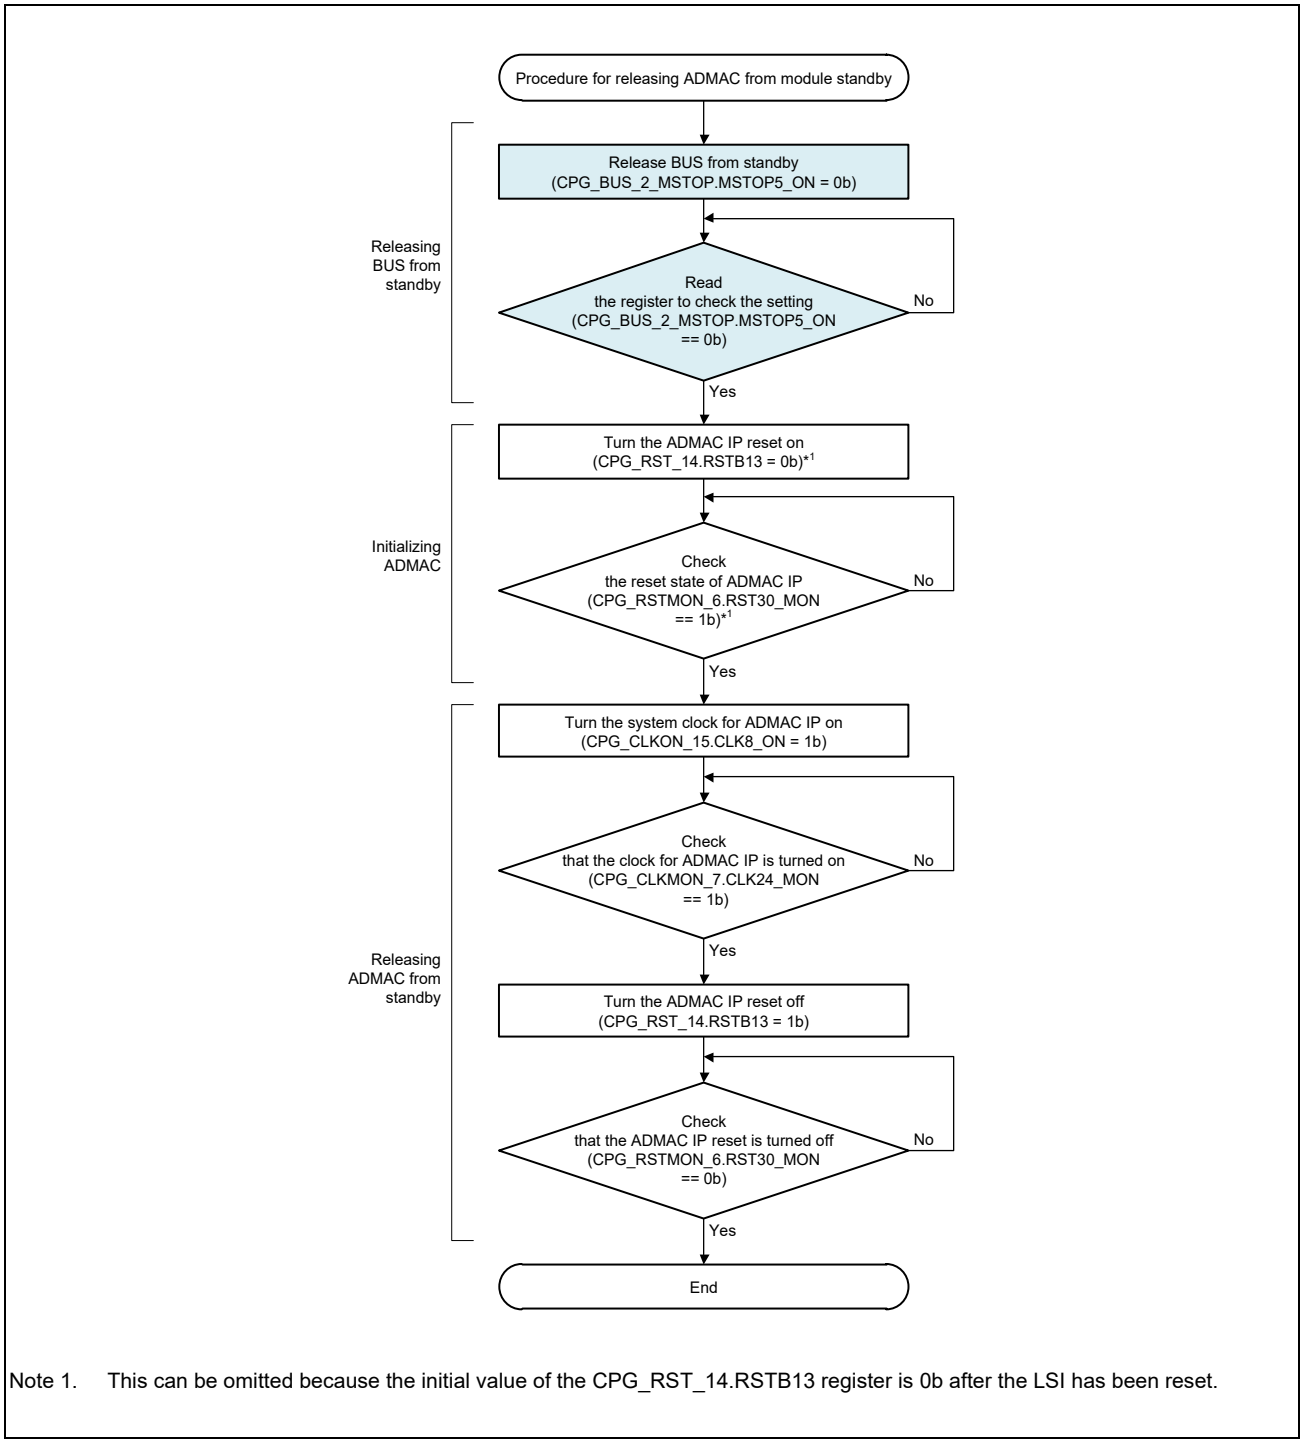


Note 1. This can be omitted because the initial value of the CPG_RST_14.RSTB14 register is 0b after the LSI has been reset.

Figure 8.1-6 Procedure for Releasing ADG from Module Standby

8.1.3.7.2 Procedure for Releasing ADMAC from Module Standby

Figure 8.1-7 shows the procedure for releasing the ADMAC from module standby.

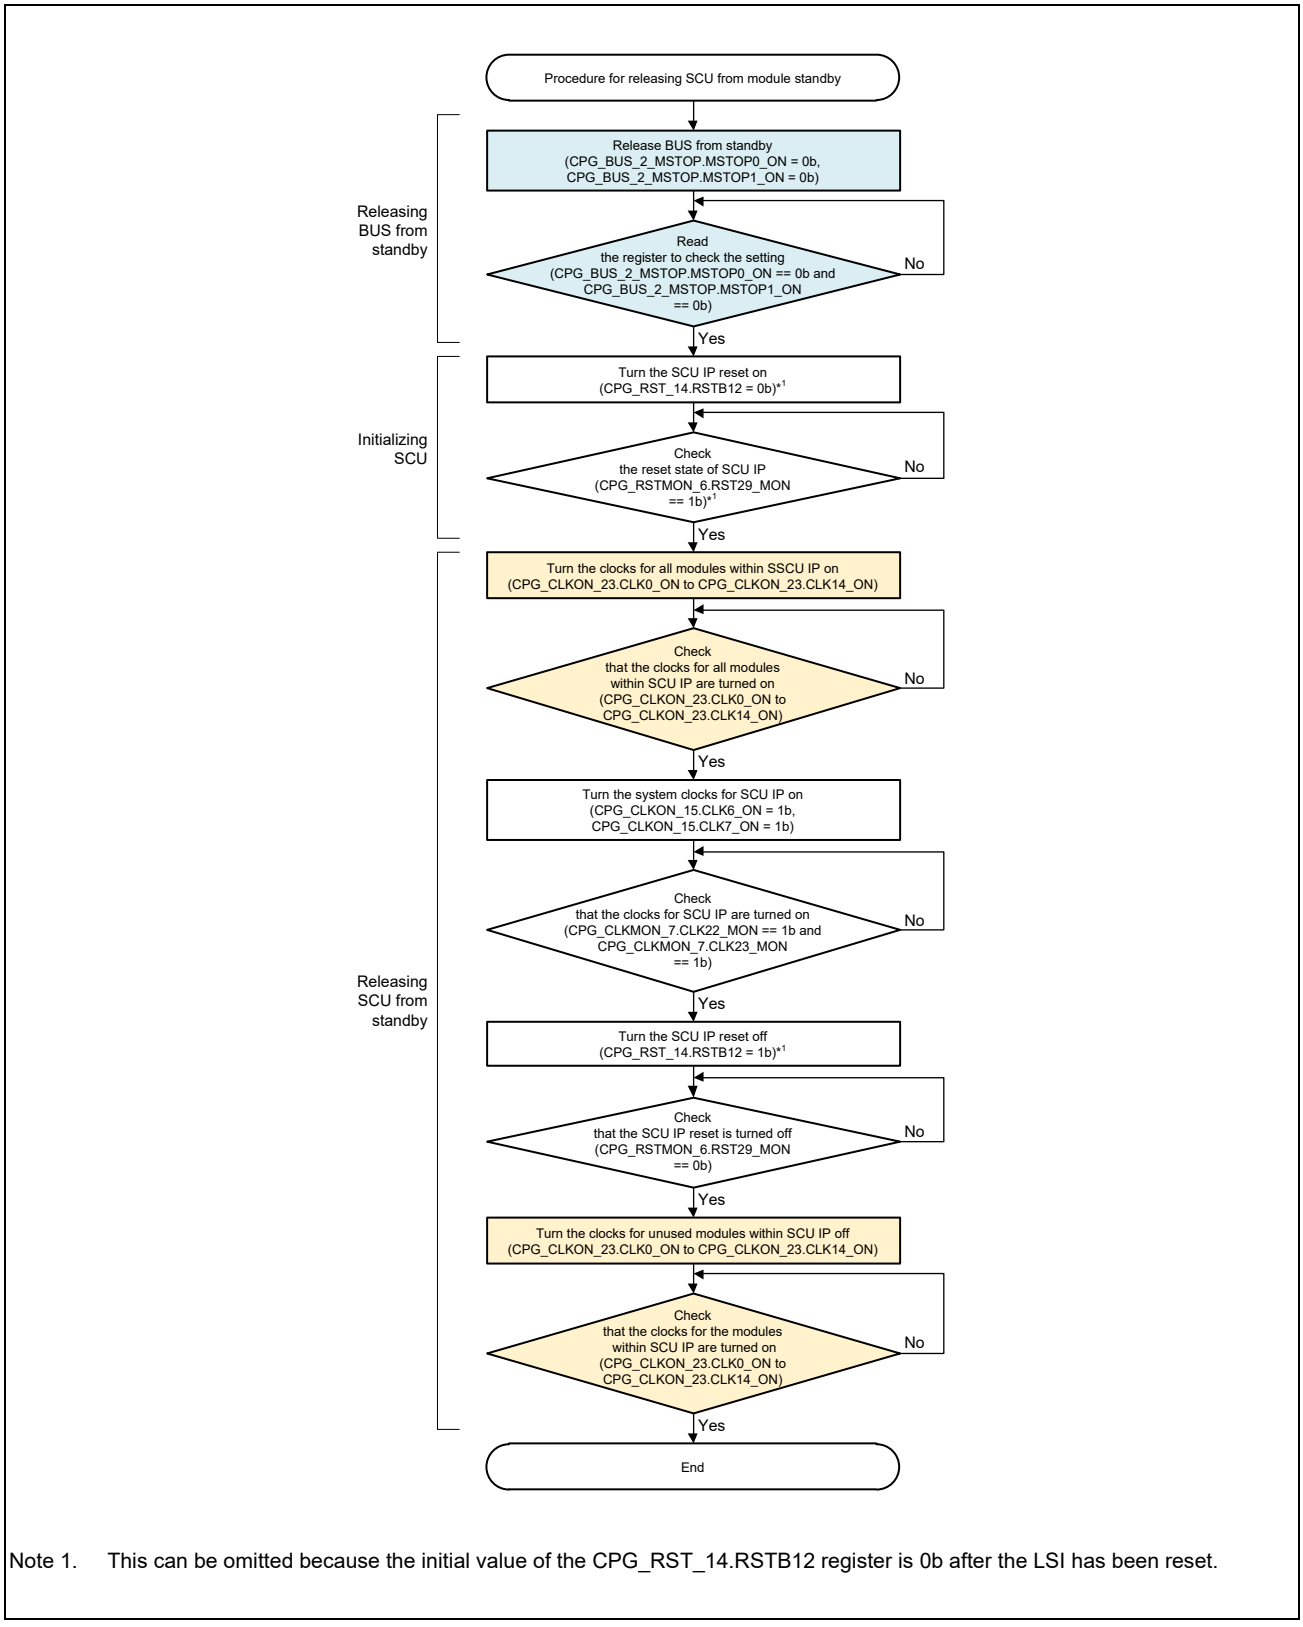


Note 1. This can be omitted because the initial value of the CPG_RST_14.RSTB13 register is 0b after the LSI has been reset.

Figure 8.1-7 Procedure for Releasing ADMAC from Module Standby

8.1.3.7.3 Procedure for Releasing SCU from Module Standby

Figure 8.1-8 shows the procedure for releasing the SCU from module standby.

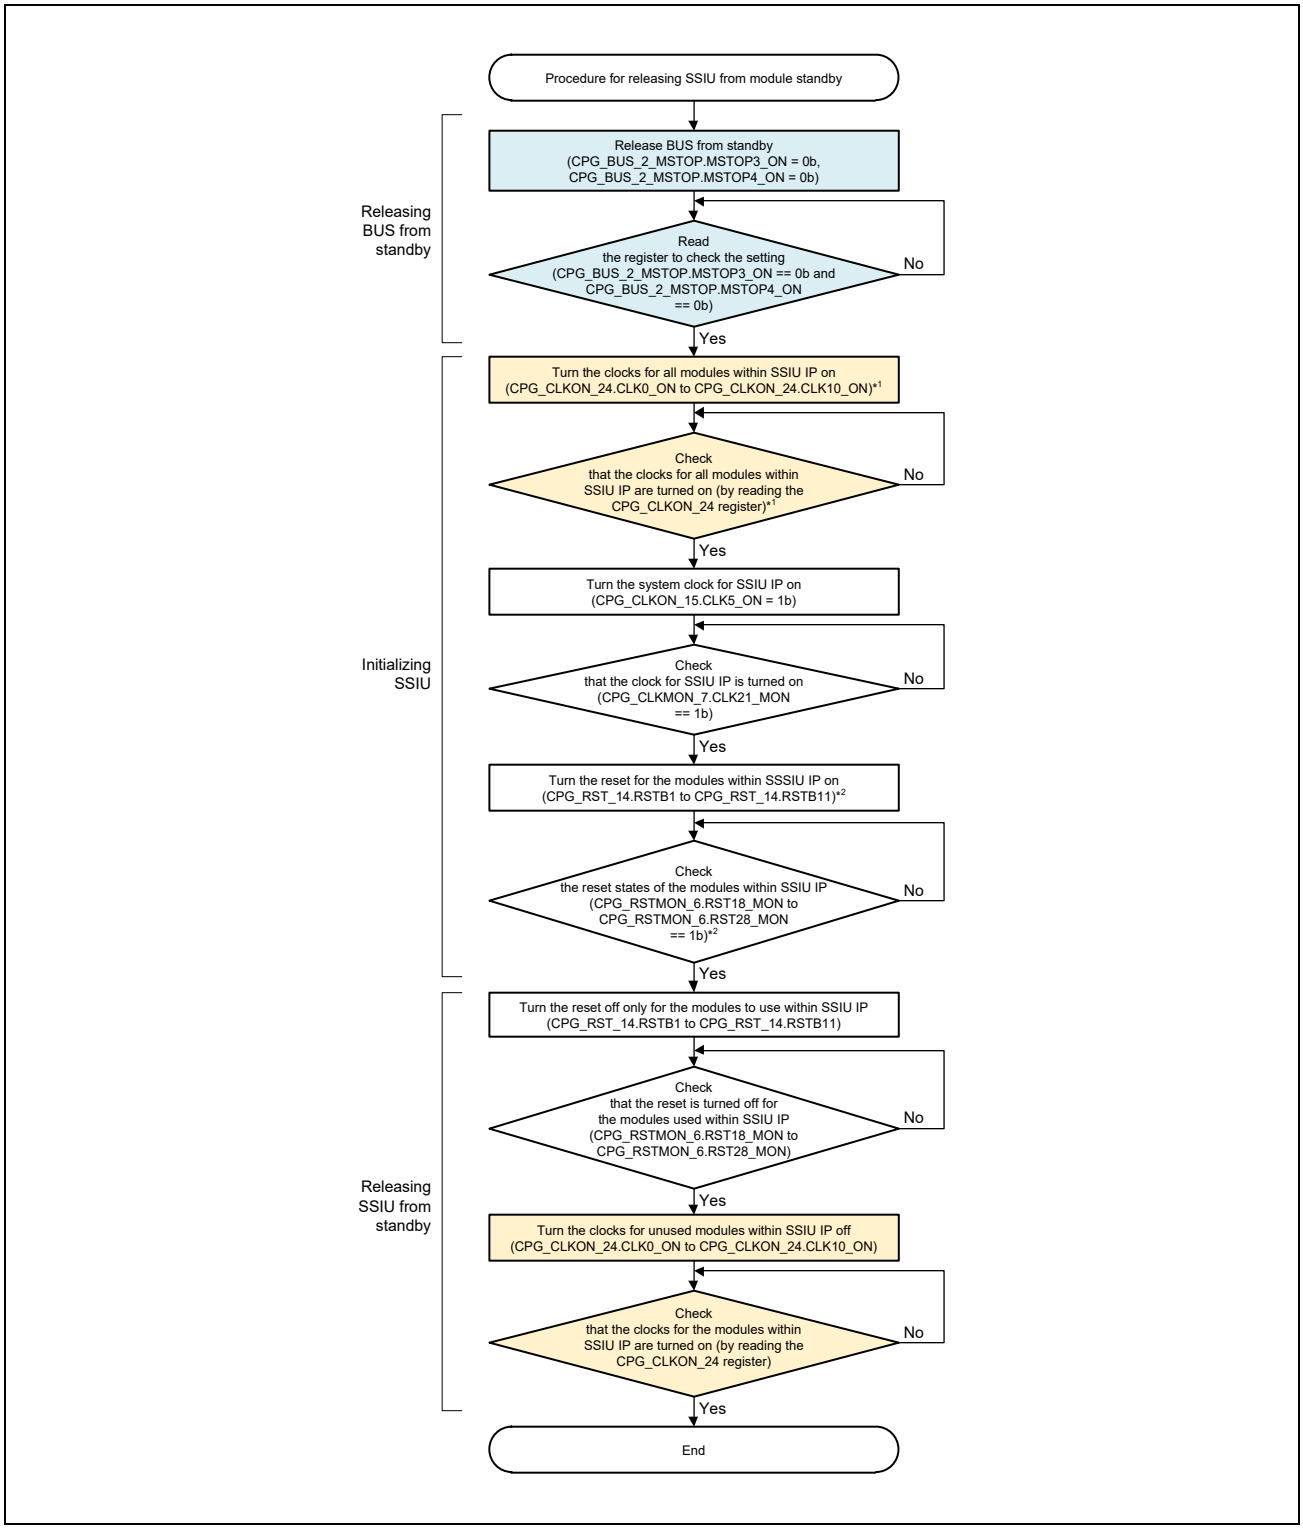


Note 1. This can be omitted because the initial value of the CPG_RST_14.RSTB12 register is 0b after the LSI has been reset.

Figure 8.1-8 Procedure for Releasing SCU from Module Standby

8.1.3.7.4 Procedure for Releasing SSIU from Module Standby

Figure 8.1-9 shows the procedure for releasing the SSIU from module standby.



(Continued on next page)

(Continued from previous page)

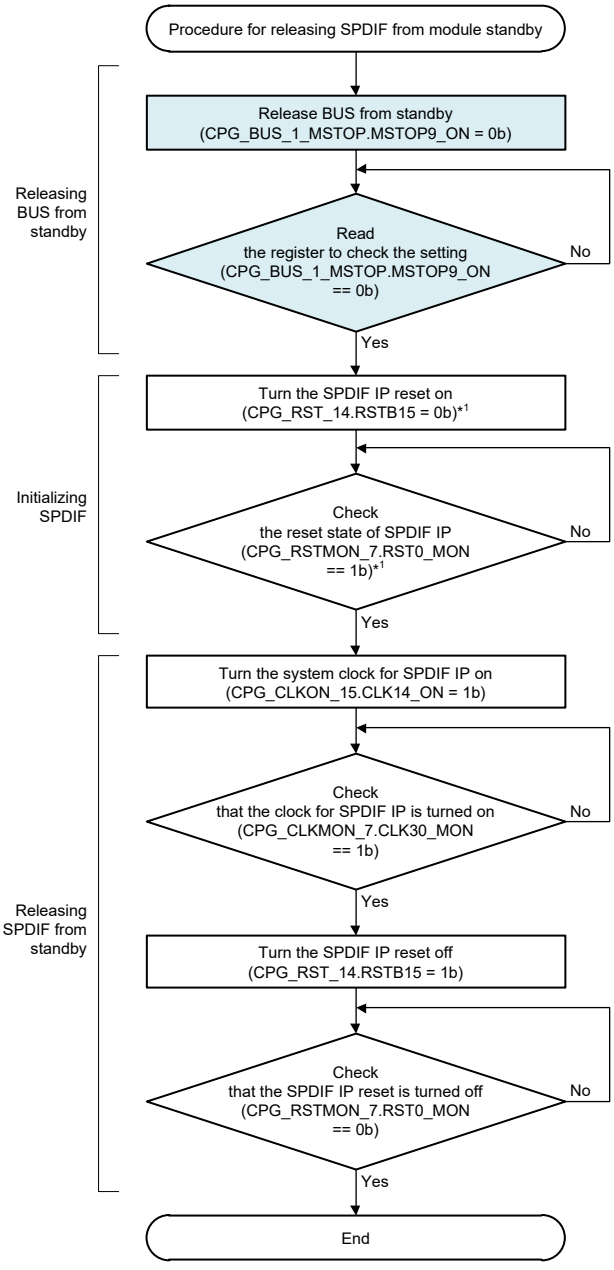
Note 1. This can be omitted because the initial value of the CPG_CLKON_24.CLK0_ON to CPG_CLKON_24.CLK10_ON registers is 1b after the LSI has been reset.

Note 2. This can be omitted because the initial value of the CPG_RST_14.RSTB1 to CPG_RST_14.RSTB11 registers is 0b after the LSI has been reset.

Figure 8.1-9 Procedure for Releasing SSIU from Module Standby

8.1.3.7.5 Procedure for Releasing SPDIF from Module Standby

Figure 8.1-10 shows the procedure for releasing the SPDIF from module standby, taking SPDIF IP ch0 as an example.

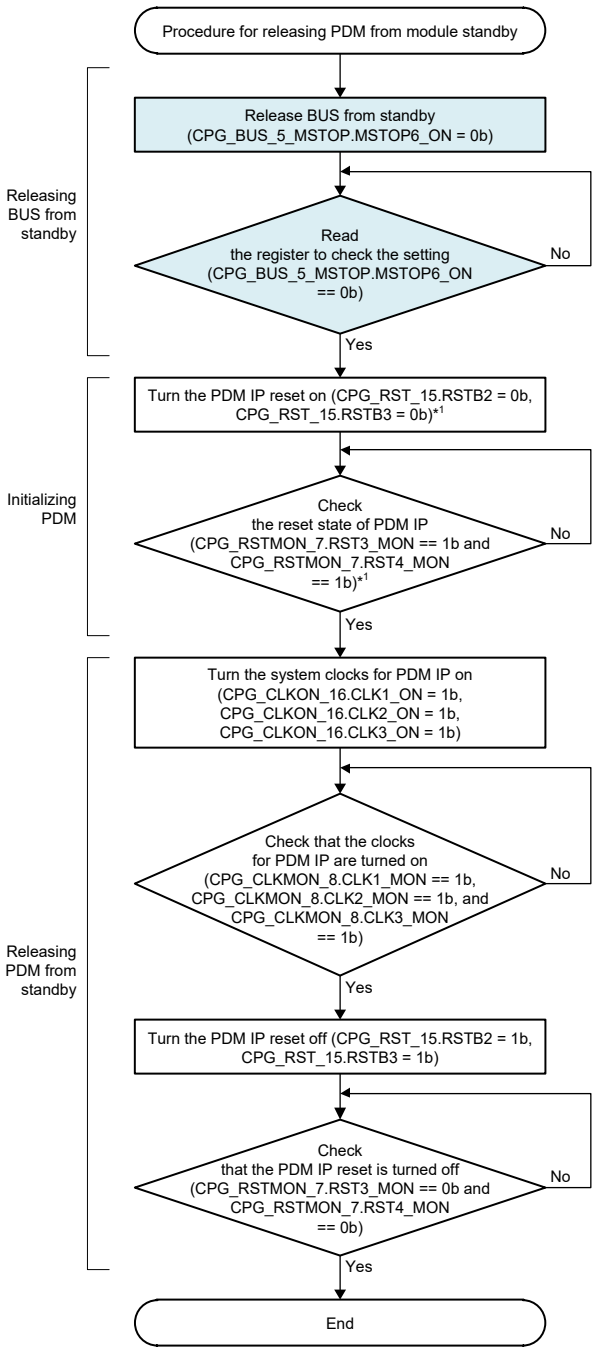


Note 1. This can be omitted because the initial value of the CPG_RST_14.RSTB15 register is 0b after the LSI has been reset.

Figure 8.1-10 Procedure for Releasing SPDIF from Module Standby

8.1.3.7.6 Procedure for Releasing PDM from Module Standby

Figure 8.1-11 shows the procedure for releasing the PDM from module standby, taking PDM IP ch0 as an example.



Note 1. This can be omitted because the initial value of the CPG_RST_15.RSTB2 and CPG_RST_15.RSTB3 registers is 0b after the LSI has been reset.

Figure 8.1-11 Procedure for Releasing PDM from Module Standby

8.1.3.8 SSIU/SCU Setup Procedure Overview

Before setting up the audio related modules, you must set the pin functions and release the IPs to use from module standby.

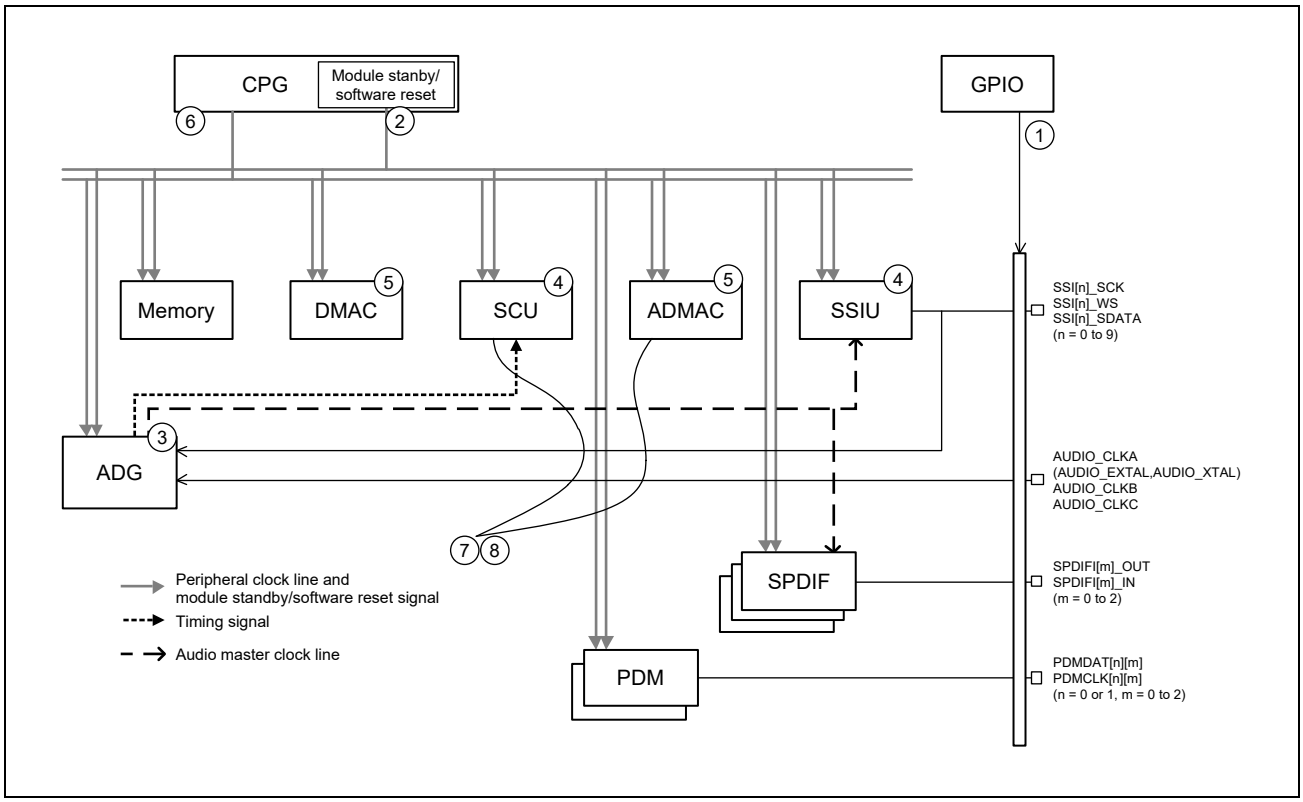


Figure 8.1-12 SSIU/SCU Setup Procedure Diagram

The following is the procedure in outline.

1. Set the pin functions (GPIO).
2. Release module standby (software reset).
3. Set ADG mode.
4. Set SCU/SSIU mode.
5. Set DMAC/ADMAC mode.
6. Turn the audio clocks on (CPG).
   Supply the ADG frequency-divided input audio clocks (on*[1]) and supply the ADG output audio master clocks for the SSIU (on*[2]).
7. Initiate transfer between the DMAC/ADMAC and SCU and SSIU.
8. Stop transfer between the DMAC/ADMAC and SCU and SSIU.
9. Restart transfer between the DMAC/ADMAC and SCU and SSIU.

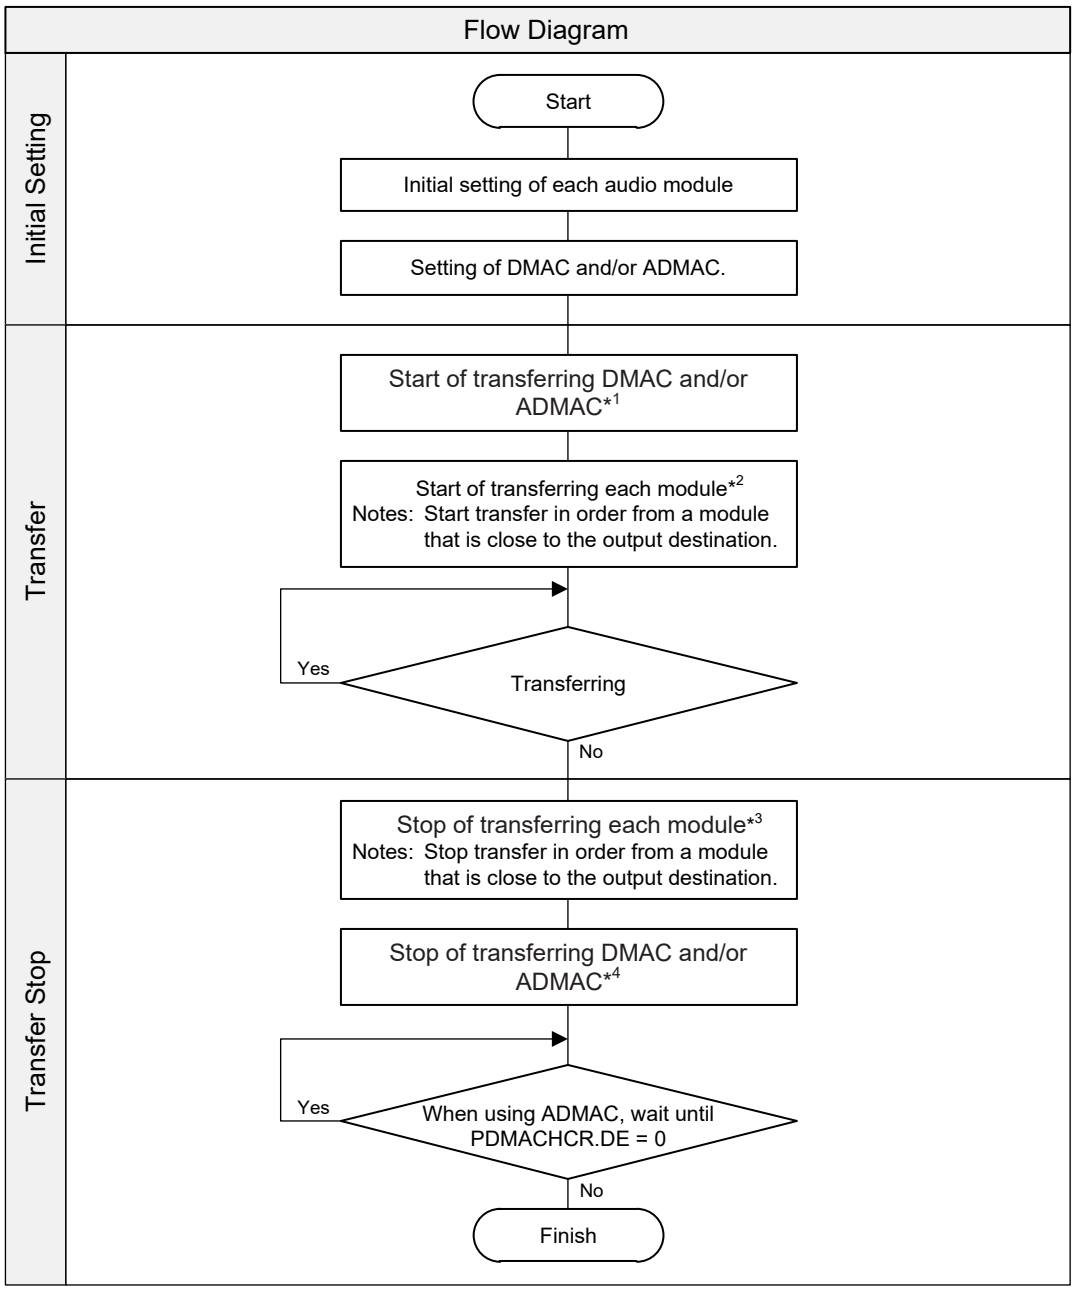
When restarting transfer at step 9, follow the procedure from step 7. You do not need to follow the order of steps 3 to 5 to make initial settings for the audio related modules. Regarding the mode setting registers of the individual IPs, refer to the functional specifications of these IPs.

Note 1. CLK9_ON to CLK13_ON of the CPG_CLKON_15 register. Only the clocks required for operation are turned on.

Note 2. CLK0_ON to CLK9_ON of the CPG_CLKON_22 register. Only the clocks required for operation are turned on.

8.1.3.8.1 Transfer Flow

When data transfer is performed between the audio modules, use the DMAC and ADMAC to perform settings in accord with the transfer flow shown in **Figure 8.1-13**.



Note 1. For DMAC, set CHCTRL_n.SETEN.
For ADMAC, set PDMACHCR.DE.
Set up registers except the above in “setting of DMAC and/or ADMAC”.

(*Continued on next page*)

(*Continued from previous page*)

Note 2. For SSI (except for the case when TDM split mode, SSI0, SSI1, SSI2, or SSI9, and SSI3 or SSI4 are used at the same time), when transmitting (from SSI to the external device), set SSIq/r_CONTROL.start after setting SSICR.EN/DMEN). When receiving (from the external device to SSI), set SSICR.EN/DMEN after setting SSIq/r_CONTROL.start.
For SSI (in the case of TDM split mode) regardless of transmission and reception, set SSIq/r_CONTROL.start after setting SSICR.EN/DMEN.

For SSI (when using SSI0, SSI1, SSI2, or SSI9 and SSI3 or SSI4 at the same time), when transmitting (from SSI to the external device), set SSIq/r_CONTROL.start after setting SSI_CONTROL. When receiving (from the external device to SSI), set SSI_CONTROL after setting SSIq/r_CONTROL.start. (Set SSICR.DMEN at the time of the initial setting.)
For SCU, Set SRCm_CONTROL and CMDn_CONTROL.

Set up registers except the above in “initial setting of each audio module”.

Note 3. For SSI (except for the case when TDM split mode, SSI0, SSI1, SSI2, or SSI9, and SSI3 or SSI4 are used at the same time), when transmitting (from SSI to the external device), clear SSIq/r_CONTROL.start after clearing SSICR.EN/DMEN. When receiving (from the external device to SSI), clear SSICR.EN/DMEN after clearing SSIq/r_CONTROL.start.

For SSI (in the case of TDM split mode), regardless of transmission and reception, clear all SSIq/r_CONTROL.start of the relevant channels to clear SSICR.EN/DMEN.

For SSI (when using SSI0, SSI1, SSI2, or SSI9 and SSI3 or SSI4 at the same time), when transmitting (from SSI to the external device), clear SSIq/r_CONTROL.start after clearing SSICR.DMEN of each module and SSI_CONTROL. When receiving (from the external device to SSI), clear SSICR.DMEN of each module and SSI_CONTROL after clearing SSIq/r_CONTROL.start.

For SCU, clear SRCm_CONTROL and CMDn_CONTROL.

Because transfer is stopped in order from a module that is close to the output destination, overflow may occur in a preceding module. Be careful.

Note 4. For ADMAC, clear PDMACHCR.DE. At this time, other bits must not be changed.
For DMAC, clear CHCTRL_n.SETEN. Clear processing of DMAC can be cleared anywhere in a TransferStop sequence.

Figure 8.1-13 Transfer Flow

8.1.3.9 SPDIF Setup Procedure Overview

Before setting up the audio related modules, you must set the pin functions and release the IPs to use from module standby.

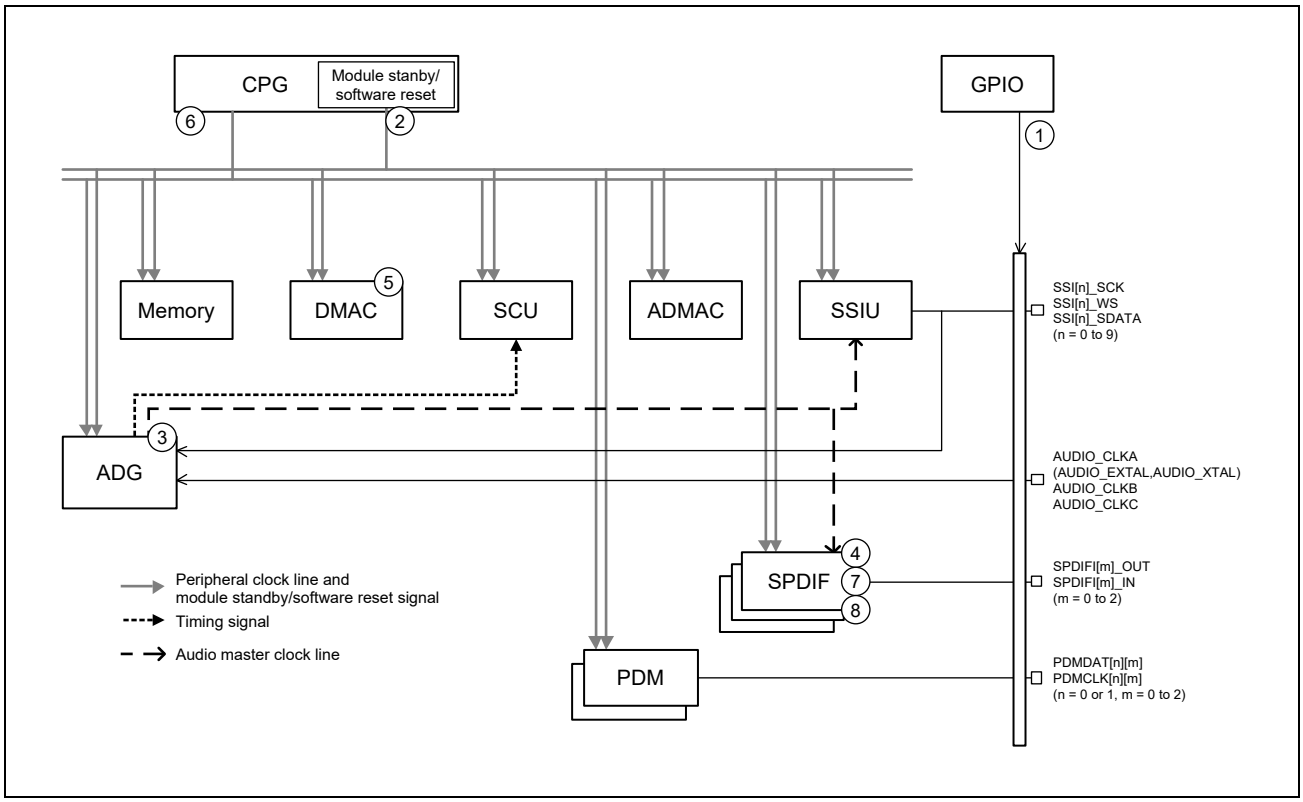


Figure 8.1-14 SPDIF Setup Procedure Diagram

The following is the procedure in outline.

1. Set the pin functions (GPIO).
2. Release module standby (software reset).
3. Set the audio clocks (ADG).
4. Set SPDIF mode.
5. Set DMAC mode.
6. Turn the audio clocks on (CPG).
   Supply the ADG frequency-divided input audio clocks (on*[1]) and supply the ADG output audio master clocks for the SPDIF (on*[2]).
7. Initiate transfer between the DMAC and SPDIF.
8. Stop transfer between the DMAC and SPDIF.
9. Restart transfer between the DMAC and SPDIF.

When restarting transfer at step 9, follow the procedure from step 7. You do not need to follow the order of steps 3 to 5 to make initial settings for the audio related modules. Regarding the mode setting registers of the individual IPs, refer to the functional specifications of these IPs.

Note 1. CLK9_ON to CLK13_ON of the CPG_CLKON_15 register. Only the clocks required for operation are turned on.

Note 2. CLK10_ON to CLK12_ON of the CPG_CLKON_22 register. Only the clocks required for operation are turned on.

8.1.3.10 PDM Setup Procedure Overview

Before setting up the audio related modules, you must set the pin functions and release the IPs to use from module standby.

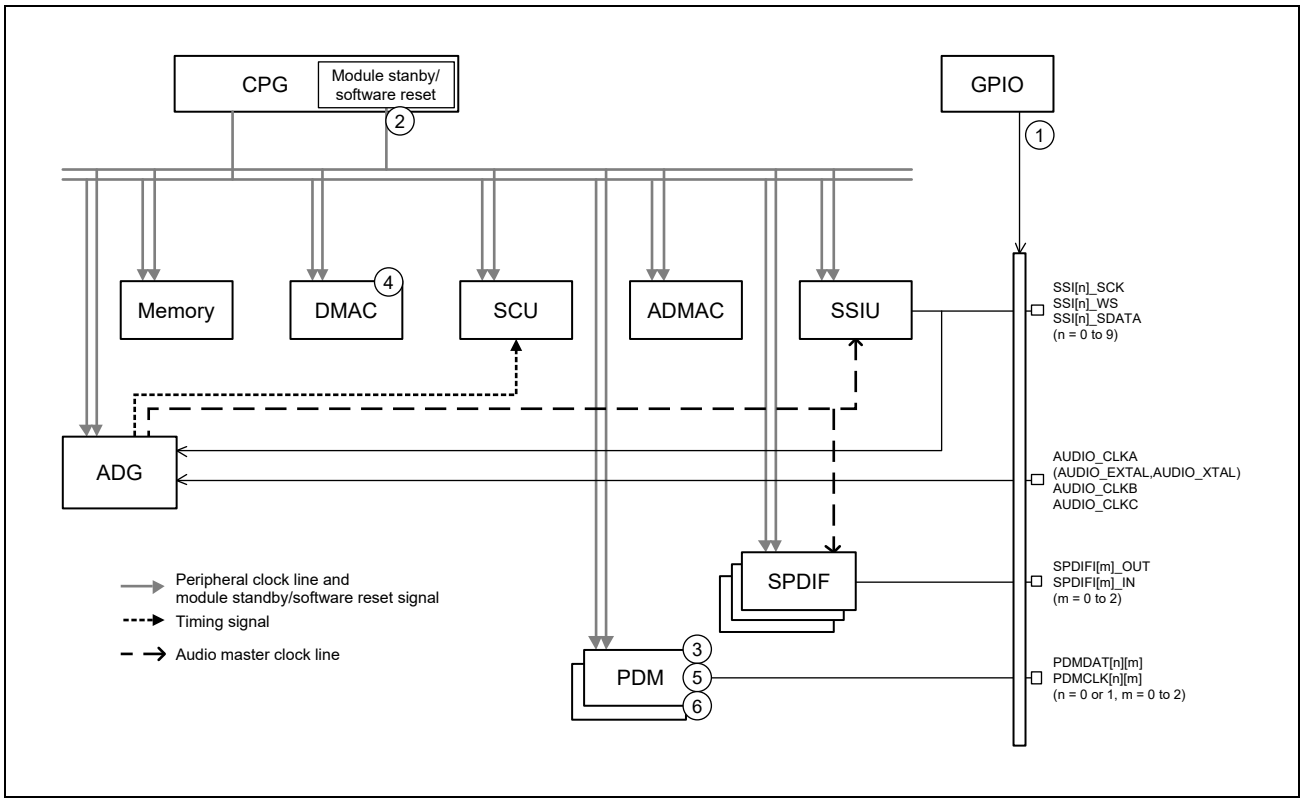

Figure 8.1-15 PDM Setup Procedure Diagram

The following is the procedure in outline.

1. Set the pin functions (GPIO).
2. Release module standby (software reset).
3. Set PDM mode.
4. Set DMAC mode.
5. Initiate transfer between the DMAC and PDM.
6. Stop transfer between the DMAC and PDM.
7. Restart transfer between the DMAC and PDM.

When restarting transfer at step 7, follow the procedure from step 5.

You do not need to follow the order of steps 3 and 4 to make initial settings for the PDM and DMAC

Regarding the mode setting registers of the individual IPs, refer to the functional specifications of these IPs.

8.1.3.11 Module Standby Function

For the register settings to make a transition to or from module standby mode, refer to section CPG.

8.1.3.11.1 Transition to Module Standby Mode

To make a transition to module standby mode by the module standby function, refer to the following transition procedure for each module.

(1) ADG

1. Set the CLK0_ON to CLK9_ON bits in CPG_CLKON_22 register to 0
2. Set the CLK9_ON bit in CPG_CLKON_15 register to 0

Remark The above bits should be set while the module operation has been completed and is placed in the idle state in which the module cannot be activated by external pins or other modules.

(2) ADMAC

1. Set the CLK8_ON bit in CPG_CLKON_15 register to 0

Remark The above bits should be set while the module operation has been completed and is placed in the idle state in which the module cannot be activated by external pins or other modules.

(3) SCU

1. Check the following registers' settings.
   - All bits in the SRCm control register (SRCm_CONTROL) (m = 0 to 9) are cleared to 0 (data transfer stopped).
   - All bits in the CMDn control register (CMDn_CONTROL) (n = 0, 1) are cleared to 0 (data transfer stopped).
   - All bits in the SRCm interrupt enable register 0 (SRCm_INT_ENABLE0) (m = 0 to 6, 9) are cleared to 0 (interrupt disabled).
   - All bits in the SRCn interrupt enable register 0 (SRCn_INT_ENABLE0) (n = 7, 8) are cleared to 0 (interrupt disabled).
2. Set the CLK0_ON to CLK14_ON bits in CPG_CLKON_23 register to 0.

Remark The above bits should be set while the module operation has been completed and is placed in the idle state in which the module cannot be activated by external pins or other modules.

(4) SSIU

1. Check the following registers' settings.

[SSIU]

- All bits in the SSIq control register (SSIq_CONTROL) (q = 0-0, 1-0, 2-0, 3-0, 4-0, or 9-0) are cleared to 0 (data transfer stopped).
- All bits in the SSIr control register (SSIr_CONTROL) (r = 5 to 8) are cleared to 0 (data transfer stopped).
- All bits in the SSIq interrupt enable register (SSIq_INT_ENABLE_MAIN) (q = 0-0, 1-0, 2-0, 3-0, 4-0, or 9-0) are cleared to 0 (interrupt disabled).
- All bits in the SSIr interrupt enable register (SSIr_INT_ENABLE_MAIN) (r = 5 to 8) are cleared to 0 (interrupt disabled).
- All bits in the SSI control register (SSI_CONTROL) are cleared to 0 (data transfer stopped)

[SSI]

- The DMEN and EN bits in the control register (SSICRn) (n = 0 to 9) are cleared to 0 (disabled).
- The IDST bit in the status register (SSISRn) (n = 0 to 9) is set to 1.
- The CONT bit in the WS mode register (SSIWSRn) (n = 0 to 9) is cleared to 0 (disabled).

2. Set the CLK0_ON to CLK10_ON bits in CPG_CLKON_24 register to 0

Remark The above bits should be set while the module operation has been completed and is placed in the idle state in which the module cannot be activated by external pins or other modules.

(5) SPDIF

1. If the module is SPDIF ch0, set the CLK14_ON bit in CPG_CLKON_15 register to 0.
   If the module is SPDIF ch1, set the CLK15_ON bit in CPG_CLKON_15 register to 0.
   If the module is SPDIF ch2, set the CLK0_ON bit in CPG_CLKON_16 register to 0.

Remark The above bits should be set while the module operation has been completed and is placed in the idle state in which the module cannot be activated by external pins or other modules.

(6) PDM

1. If the module is PDM ch0, set the CLK1_ON to CLK3_ON bits in CPG_CLKON_16 register to 0.
   If the module is PDM ch1, set the CLK4_ON to CLK6_ON bits in CPG_CLKON_16 register to 0.

Remark The above bits should be set while the module operation has been completed and is placed in the idle state in which the module cannot be activated by external pins or other modules.

8.1.3.11.2 Releasing and Restarting from Module Standby Mode

After the transition to module standby mode, modules can be released from module standby mode by a power-on reset or the appropriate procedure from the list below.

(1) ADG

1. Supply the clock signal to ADG modules.
2. Set the CLK9_ON bit in CPG_CLKON_15 register to 1.

(2) ADMAC

1. Set the CLK8_ON bit in CPG_CLKON_15 register to 1.

(3) SCU

1. Set the CLK0_ON to CLK14_ON bits in CPG_CLKON_23 register to 1.

(4) SSIU

1. Supply the clock signal to SSIU modules.
2. Set the CLK0_ON to CLK10_ON bits in CPG_CLKON_24 register to 1

(5) SPDIF

1. If the module is SPDIF ch0, set the CLK14_ON bit in CPG_CLKON_15 register to 1.
   If the module is SPDIF ch1, set the CLK15_ON bit in CPG_CLKON_15 register to 1.
   If the module is SPDIF ch2, set the CLK0_ON bit in CPG_CLKON_16 register to 1.

(6) PDM

1. If the module is PDM ch0, set the CLK1_ON to CLK3_ON bits in CPG_CLKON_16 register to 1.
   If the module is PDM ch1, set the CLK4_ON to CLK6_ON bits in CPG_CLKON_16 register to 1.

8.1.4 Usage Notes

8.1.4.1 Notes on Route Switching and Setting Changes

When switching the transfer route, stop the current transfer, specify the new transfer route, and then start transfer. Also, when changing the quantization bit count or the formats, once stop transfer, and then start transfer again after resetting. If this procedure is not followed, correct operation is not guaranteed.

8.1.4.2 Note when SSI0, SSI1, and SSI2, or SSI0, SSI1, SSI2, and SSI9 are Used for Single-Source Audio Data

When SSI0, SSI1, and SSI2, or SSI0, SSI1, SSI2, and SSI9 are used for single-source audio data, specifying eight-bit quantization and six- or eight-channel operation at the same time is not possible.

8.1.4.3 Note on Transfer

When an underflow or an overflow occurs in any audio module, stop the transfer.

8.1.4.4 Note on Usage of the SCU Module

Before starting data transfer, the SCU module needs certain “input data timing” and “output data timing”. When “input data timing” and “output data timing” are not inputted before the transmission starts, it does not operate correctly.

In addition, if the SSI module operates in master mode, and if the WS signal is used as “input/output timing signal for the SRC”, set SSIWSRn.CONT to 1.
(The WS signal inputted into the ADG module is the same signal as the SSI_WS terminal.)

8.1.4.5 Note on Software Reset During Data Transfer

If software reset*[1] is performed during data transfer, abnormal operation may occur. At this time, normal values cannot be guaranteed for the transferred data.

Note 1. RSTB1 to RSTB15 bits of CPG_RST_14 register in the CPG module
RSTB0 to RSTB5 bits of CPG_RST_15 register in the CPG module
SWRST bit of SRCm_SWRSR register (m = 0 to 9) in the SCU module
SWRST bit of CTUn_SWRSR register (n = 00, 01, 02, 03, 10, 11, 12, or 13) in the SCU module
SWRST bit of MIXp_SWRSR register (p = 0 or 1) in the SCU module
SWRST bit of DVCp_SWRSR register (p = 0 or 1) in the SCU module

8.1.4.6 Notes when Issuing SCU/SSIU Transfer Instructions

Follow the order below to issue an instruction to start or stop transfer by SCU and SSIU.

<To start transfer>

Issue the instruction to start DMAC/ADMAC transfer, then issue the transfer start instruction in order from the module on the output side of the path.

<To stop transfer>

Issue the transfer stop instruction in order from the module on the output side of the path, then issue the instruction to stop DMAC/ADMAC transfer.

The following describes two use cases as examples.

(1) In transmission (Memory → DMAC → SCU → ADMAC → SSIU)

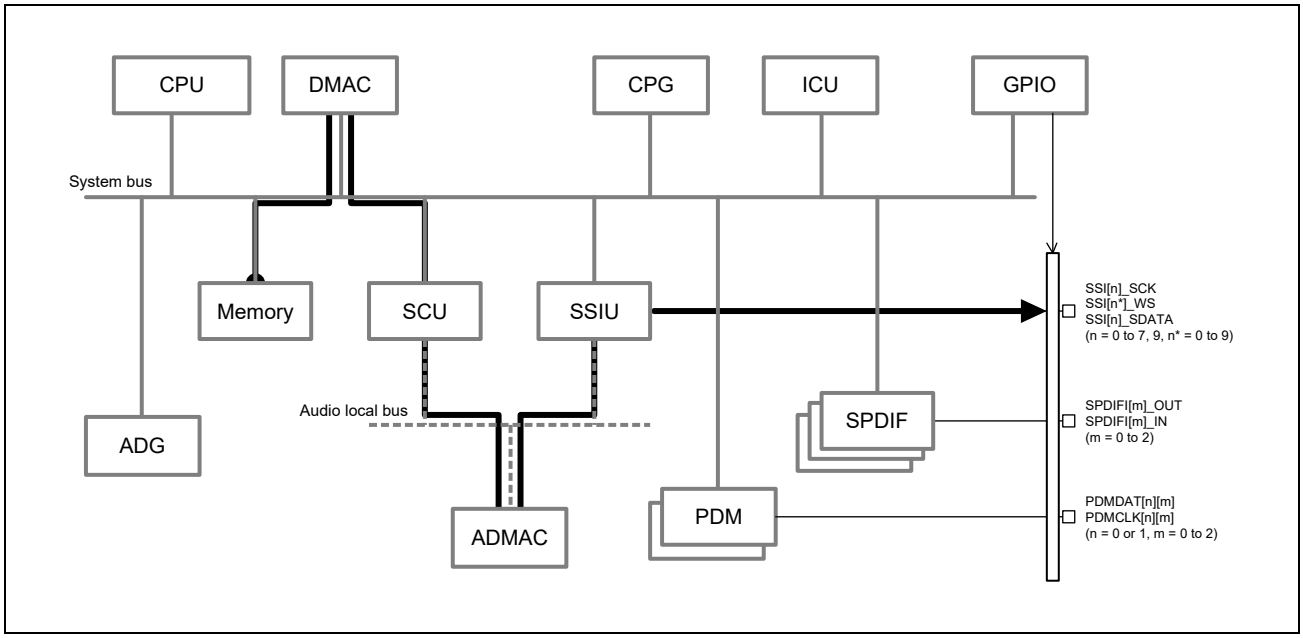

Figure 8.1-16 When Transmission is in the Order “Memory → DMAC → SCU → ADMAC → SSIU”

The order of issuing the transfer start instructions:

1. DMAC/ADMAC transfer start instruction
2. SSIU transfer start instruction
3. SCU transfer start instruction

The order of issuing the transfer stop instructions:

1. SSIU transfer stop instruction
2. SCU transfer stop instruction
3. DMAC/ADMAC transfer stop instruction

(2) In reception (SSIU → ADMAC → SCU → DMAC → Memory)

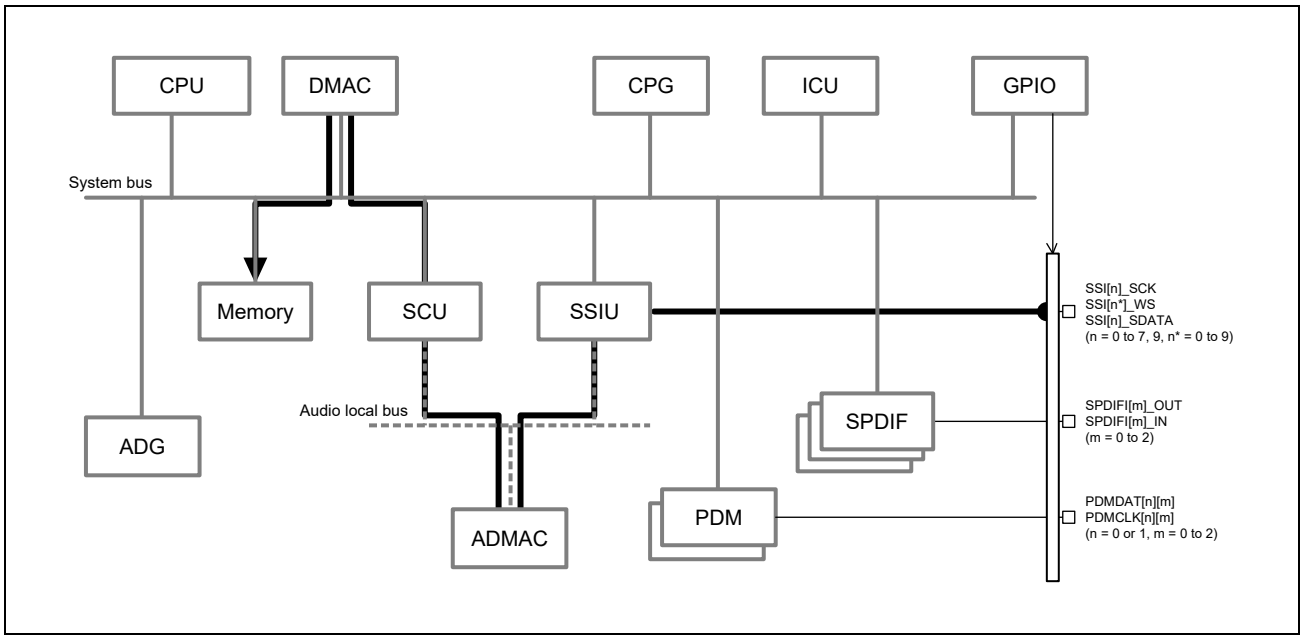

Figure 8.1-17 When Reception is in the Order “SSIU → ADMAC → SCU → DMAC → Memory”

Preparation to initiate transfer:

1. DMAC/ADMAC transfer start instruction
2. SCU transfer start instruction
3. SSIU transfer start instruction

Preparation to stop transfer:

1. SCU transfer stop instruction
2. SSIU transfer stop instruction
3. DMAC/ADMAC transfer stop instruction

SECTION 8 AUDIO

8.2 Sampling Rate Converter Unit (SCU)

This manual is a simplified version. For more information, refer to the User's Manual Additional Document.

8.2.1 Overview

The SCU has ten SRC modules (six for high-sound-quality type; four for general-sound-quality type) that are useful for synchronization of asynchronous data, which is necessary for data transfer with external memory or external devices. It also provides the functions to change the number of channels, perform mixing, and control the volume.

Remark When the SRCs are not in use, configure the system with the same clock sources for AUDIO CLOCK that is input to ADG or devices for I2S that are connected to external modules, and all thus operate at the same sampling frequency.

8.2.1.1 Features

Sampling Rate Converter (SRC)

- Asynchronous sampling rate conversion is available
- Supports resolutions up to 24 bits
- High-sound-quality type (THD + N*[1] is −132 dB) and general-sound-quality type (THD + N*[1] is −96 dB)
- Automatically generates antialiasing filter coefficients
- Four modules support one, two, four, six, or eight channels, and six modules support one or two channels.

Note 1. Total harmonic distortion plus noise

Channel Transfer Unit (CTU)

- Downmixing and splitter functions
  - Conversion of eight input channels into two output channels
  - Conversion of six input channels into two output channels
  - Conversion of two input channels into four sets of two output channels
  - Conversion of one input channel into eight sets of one output channel
  - No conversion

Mixer (MIX)

- Mixing (adds) two to four sources into one
- Ratio for adding sources is selectable
- Ratio is dynamically changeable
- Mixing with volume ramp is available (ramp period is selectable)

Digital Volume and Mute Function (DVC)

- Volume control function including digital volume, volume ramp, and zero-crossing mute
- The digital volume function is specified by a 24-bit fixed-point value within the range from 0 to 8 times (mute or -120 to 18 dB)
- The volume ramp function can be used for soft mute, fade-in, fade-out, or desired volume adjustment
- The volume ramp period can be changed within the sampling range from the 0th to 23rd power of 2
- The zero-crossing mute function silences the sound at the zero-crossing point of the audio data

The CTU, MIX, and DVC functional blocks are collectively called “CMD”.

SECTION 8 AUDIO

8.3 Audio Clock Generator (ADG)

This manual is a simplified version. For more information, refer to the User's Manual Additional Document.

8.3.1 Overview

The audio clock generator (ADG) selects and supplies the necessary clock for the SSIU, SCU, and SPDIF modules. It also divides the frequency of the selected clock and sends it outside the chip.

8.3.1.1 Features

- Selects the clock signal from the AUDIO_CLKA, AUDIO_CLKB, or AUDIO_CLKC pin or the internal clock and supplies it to the SSIU, SCU, and SPDIF modules.
- The frequency of the clock signals from the AUDIO_CLKA, AUDIO_CLKB, and AUDIO_CLKC pins and the internal clock can be divided before use.
- The divided clock can be output through the AUDIO_CLKOUT pin.

SECTION 8 AUDIO

8.4 Audio-DMAC-Peripheral-Peripheral (ADMAC)

This manual is a simplified version. For more information, refer to the User's Manual Additional Document.

8.4.1 Overview

The Audio-DMAC-Peripheral-Peripheral module controls data transfer between the audio modules (SSIU, SCU) connected to the audio local bus.

8.4.1.1 Features

- Number of channels: 29 channels
- Data transfer size: Longword (4 bytes)
- Addressing mode: Dual addressing; fixed access size
- Transfer count: Not programmable
- Interrupt processing: None

SECTION 8 AUDIO

8.5 Serial Sound Interface Unit (SSIU)

This manual is a simplified version. For more information, refer to the User's Manual Additional Document.

8.5.1 Overview

The SSIU, incorporating ten SSI modules, allows independent operation of SSI modules, operation of multiple SSI modules sharing the same serial clock, and connection or split of multi-channel data.

The serial sound interface (hereinafter referred to as the "SSI") is a transceiver module designed to send or receive audio data interfacing with a variety of devices offering I2S format. It also supports multi-channel mode in addition to other common formats.

Remark Configure the system so that connected external devices can operate on the same clock source.

8.5.1.1 Features

- Incorporates ten SSI modules.
- Supports 6 channels/1 sound source with three SSI modules (SSI0, SSI1, and SSI2).
- Supports 8 channels/1 sound source with four SSI modules (SSI0, SSI1, SSI2, and SSI9).
- Operation of multiple modules on the same serial clock (SSI0/SSI1/SSI2/SSI3/SSI9, SSI3/SSI4/SSI9, SSI5/SSI6, or SSI7/SSI8).
- TDM format (Basic Configuration) corresponds to 4, 6, or 8-channel data.
- Handles 8-channel data on the serial bus and 6-channel data in the SoC (TDM extend mode).
- Handles 6-channel data on the serial bus and 8-channel data in the SoC (TDM extend mode).
- Connects monaural or stereo data to output TDM format data (TDM split mode).
- Splits TDM format input data into monaural or stereo data (TDM split mode).
- Connects stereo or multi data to output TDM format data (TDM ex-split mode).
- Splits TDM format input data into stereo or multi data (TDM ex-split mode).
- The frequency range of SCK signal is from 297.3 kHz to 12.5 MHz at master mode, and from 297.3 kHz to 12.5 MHz at slave mode.

The SSI has the following features:

- Number of channels: Maximum of four (when a multi-channel format is specified).
- The SSI module can serve as both a transmitter and a receiver.
- Asynchronous transfer takes place between the data buffer and the shift register.
- Only the MSB first data alignment is supported.
- A value as the dividing ratio for the clock used by the serial bus interface is selectable.

- Controlling of data transmission or reception with DMAC or interrupt requests is possible.
- TDM format is supported.
- The frequency range of SCK signal is from 297.3 kHz to 12.5 MHz at master mode, and from 297.3 kHz to 12.5 MHz at slave mode.
- The WS continue function by which operation can be performed without stopping the WS signal is supported.
- Monaural mode (8 bits or 16 bits) is supported.
- In monaural mode, the pulse width of the WS signal can be changed (short or long frame).
- If the sampling clock frequency is switched during transfer, the CPU is notified of an interrupt (a function to detect the frequency switching).
- Operating mode: Non-compressed mode (not support for compressed mode).
- Supports versatile serial audio formats (I2S/left justified/right justified).
- Supports master/slave functions.
- Programmable word clock, bit clock generation functions.

SECTION 8 AUDIO

8.6 SPDIF Interface (SPDIF)

This section describes the SPDIF interface (SPDIF).

8.6.1 Overview

The SPDIF complies with the IEC 60958 standard. For the features and configuration of the SPDIF, see the following subsections.

8.6.1.1 Features

The features of the SPDIF are described below.

- Compliant with the IEC 60958 standard (stereo and consumer use modes only)
- Sampling frequency: 32 kHz, 44.1 kHz, 48 kHz
- Audio word size: 16 to 24 bits/sample
- Biphase mark encoding
- Double buffer for data
- Serial data with parity
- Capable of simultaneous transmission and reception
- The receiver autodetects the IEC 61937 compressed mode data.
- DMAC support

The following restrictions apply to the SPDIF macro.

— Only an external-facing SPDIF device that can support 512 fs can be connected.

— Set the externally input oversampling clock (pa_audiox_a) frequency to 512 fs.

8.6.1.2 SPDIF Frame Format

A frame for the SPDIF consists of two sub-frames (channels 1 and 2), each containing a 4-bit preamble, up to 24 bits of audio data, V flag, user bit, channel status bit, and even parity bit. **Figure 8.6-1** shows the format of a sub-frame. The SPDIF performs modulation (channel coding) based on the biphase mark method, which minimizes the DC component on the transmission line for this format.

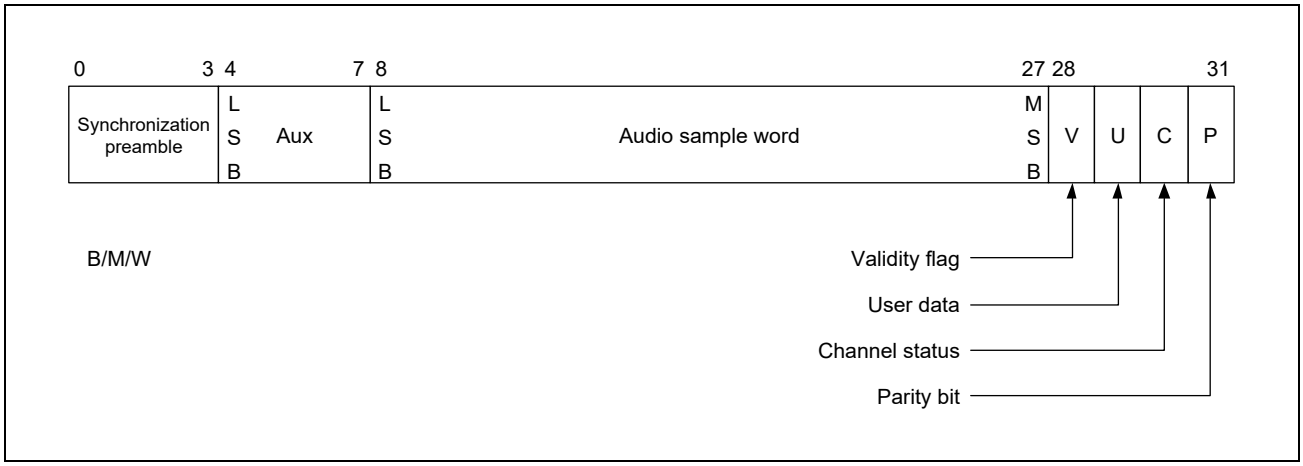

Figure 8.6-1 Sub-Frame Format

Figure 8.6-2 shows the format of a block, which consists of consecutive 192 frames. One block extends from the start frame (preamble B) to frame 191, which is the 192nd frame, and each sub-frame is identified by a preamble. 384 sub-frames are in one block and the frames consist of three types of sub-frames: sub-frame 0 indicating the start of a block, sub-frame 1 (generally, left channel), and sub-frame 2 (generally, right channel). Generally, the music data that are transmitted and received by the SPDIF are consecutive, so the data are transferred in consecutive blocks.

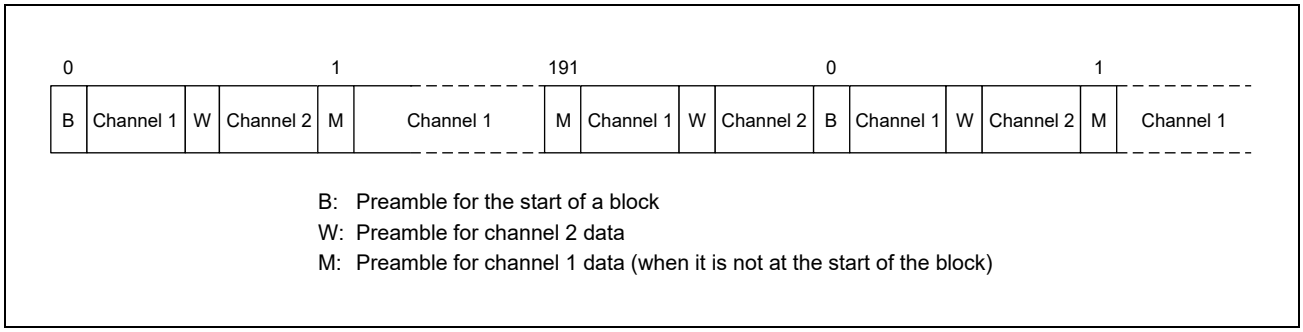

Figure 8.6-2 Block Format

Table 8.6-1 shows the values of the SPDIF preambles (in binary). The state of the preceding symbol (parity bit) determines the logical sense of each preamble.

Table 8.6-1 Preamble Values

Preamble	State of Preceding Symbol = 0	State of Preceding Symbol = 1
B	11101000	00010111
M	11100010	00011101
W	11100100	00011011

***Remark*:** As shown in **Figure 8.6-1**, the even parity bit in time slot 31 of the sub-frame determines the preamble type in one transmission. Therefore, one of the set states to be normally sent via the SPDIF is selected. However, in IEC 60958 and so on, decoding of both types is defined in consideration of connection of the preamble with its polarity reversed. The SPDIF decodes preambles as listed in **Table 8.6-1**.

The channel status information is encoded in one bit of each sub-frame. Therefore, the amount of channel status information for one block is 192 bits for each of sub-frames 1 and 2. For the format of the channel status, refer to the IEC 60958 standard.

8.6.1.3 About Sampling Frequency Selection Method

The SPDIF macro supports three sampling frequencies: 1) 32 kHz, 2) 44.1 kHz, and 3) 48 kHz. To support each sampling frequency, the oversampling clock at a frequency of 512 fs must be entered through the input terminal for the oversampling clock (pa_audiox_a) of the SPDIF macro. The pa_audio_a terminal input clock frequencies for each of the sampling frequencies are listed below.

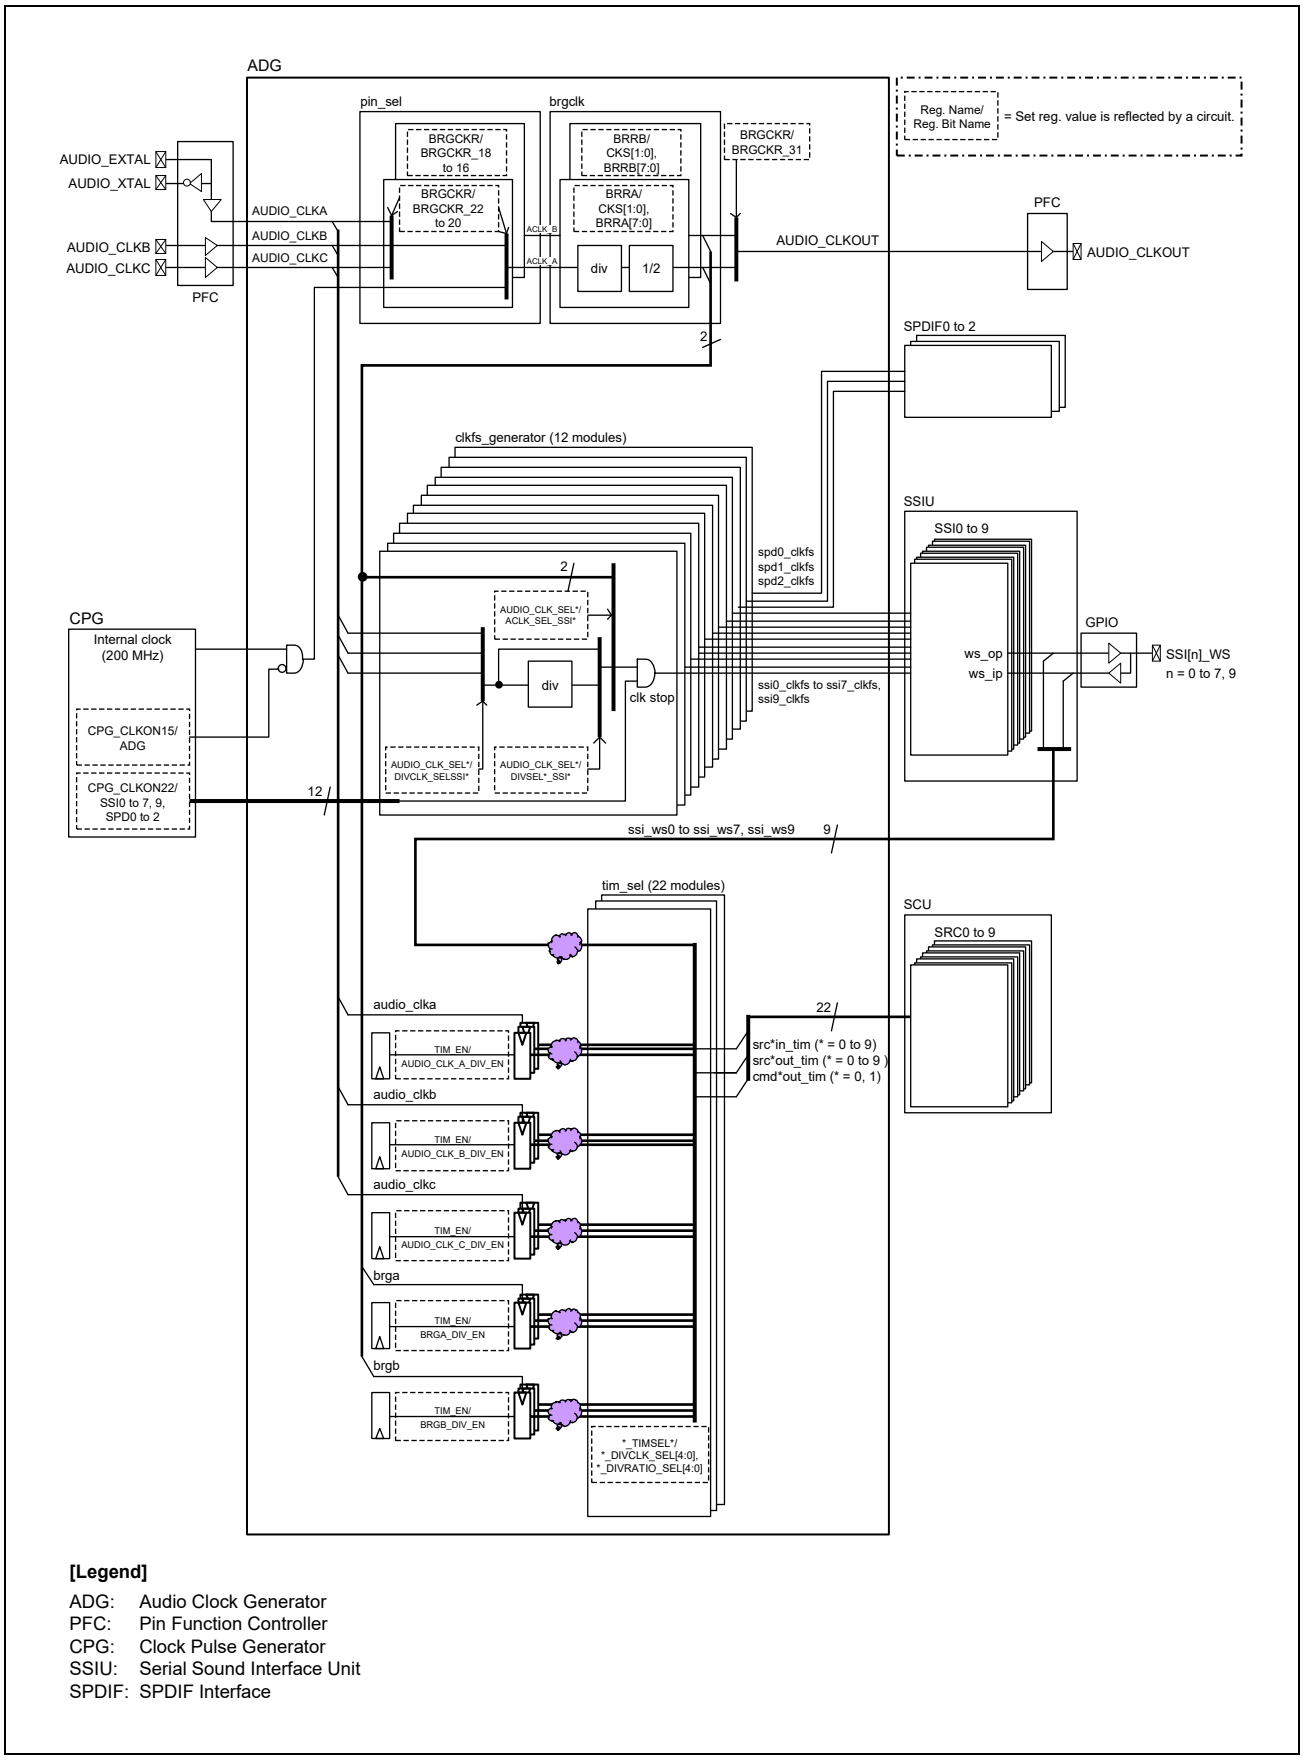
Table 8.6-2 Sampling Frequency versus pa_audio_a Terminal Input Clock Frequency

Sampling Frequency	pa_audio_a Terminal Input Clock Frequency (512 fs)
32 kHz	16.384 MHz
44.1 kHz	22.5792 MHz
48 kHz	24.576 MHz

Clock input to the SPDIF pa_audiox_a terminal is possible from any of the following three externally input pins.

1) AUDIO_EXTAL/AUDIO_XTAL
2) AUDIO_CLKB
3) AUDIO_CLKC

For selection of the external input, see the sections PFC and ADG.



[Legend]

ADG: Audio Clock Generator
PFC: Pin Function Controller
CPG: Clock Pulse Generator
SSIU: Serial Sound Interface Unit
SPDIF: SPDIF Interface

Figure 8.6-3 SPDIF External Clock Input Configuration

8.6.1.4 Block Diagram

The figure below is a block diagram of the SPDIF.

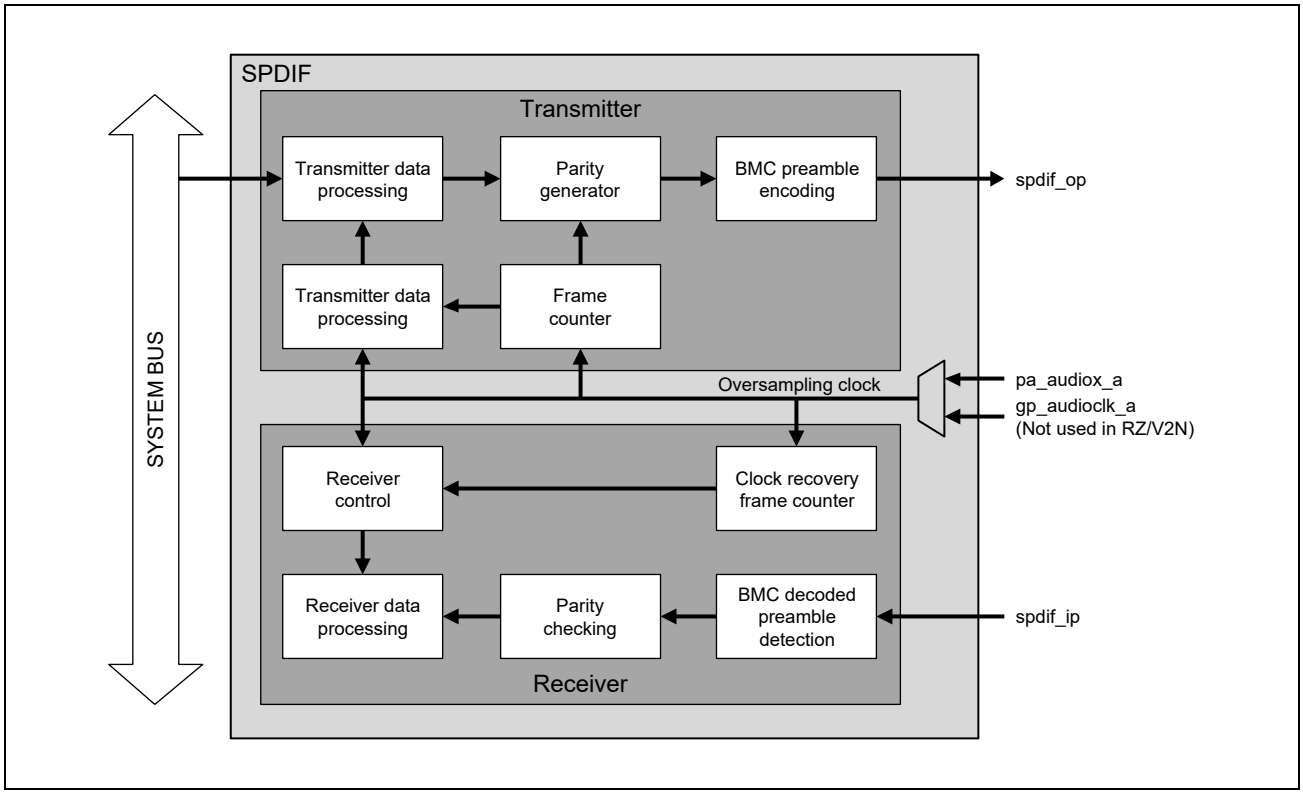


Figure 8.6-4 Block Diagram of SPDIF

8.6.1.5 External Pins

Table 8.6-3 lists the specifications of the SPDIF external pins.

Table 8.6-3 Pin Configuration

Pin Name	Input/ Output	Function
SPDIFn_OUT	Output	SPDIF signal transmission pin
SPDIFn_IN	Input	SPDIF signal reception pin

Note: n = 0 to 2

8.6.1.6 Connected Units

Table 8.6-4 lists the units that are connected to the SPDIF.

Table 8.6-4 Connected Units

Unit Name	Connected Unit Name	Function of Connected Unit
SPDIF	CPG	Clock pulse generator (CPG)
	SYSTEM BUS	Internal bus
	ICU	Interrupt control unit (ICU_TOP)
	PFC	Pin Function Controller (PFC)
	ADG	Audio clock generator (ADG)

8.6.2 Registers

The base addresses for the respective channels are as follows.

Table 8.6-5 Register Base Addresses

Base Register Name	Unit Name	Base Address
<SPDIF0_base>	SPDIF0	0_1440_2400h (5440_2400h*1, 4440_2400h*2)
<SPDIF1_base>	SPDIF1	0_1440_2800h (5440_2800h*1, 4440_2800h*2)
<SPDIF2_base>	SPDIF2	0_1440_2C00h (5440_2C00h*1, 4440_2C00h*2)

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

8.6.2.1 List of Registers

The registers are listed below.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
Transmitter Channel 1 Audio Register	SPDIFm_TLCA	0000_0000h	0000h	32
Transmitter Channel 2 Audio Register	SPDIFm_TRCA	0000_0000h	0004h	32
Transmitter Channel 1 Status Register	SPDIFm_TLCS	0000_0000h	0008h	32
Transmitter Channel 2 Status Register	SPDIFm_TRCS	0000_0000h	000Ch	32
Transmitter User Data Register	SPDIFm_TUI	0000_0000h	0010h	32
Receiver Channel 1 Audio Register	SPDIFm_RLCA	0000_0000h	0014h	32
Receiver Channel 2 Audio Register	SPDIFm_RRCA	0000_0000h	0018h	32
Receiver Channel 1 Status Register	SPDIFm_RLCS	0000_0000h	001Ch	32
Receiver Channel 2 Status Register	SPDIFm_RRCS	0000_0000h	0020h	32
Receiver User Data Register	SPDIFm_RUI	0000_0000h	0024h	32
Control Register	SPDIFm_CTRL	0000_0000h	0028h	32
Status Register	SPDIFm_STAT	0000_C000h	002Ch	32
Transmitter DMA Audio Data Register	SPDIFm_TDAD	0000_0000h	0030h	32
Receiver DMA Audio Data Register	SPDIFm_RDAD	0000_0000h	0034h	32

Always access the above registers as 32-bit units because they are all longword registers.

Always write 0 to a bit for which the writing of 0 is stated in the register descriptions on the following pages (when the bit is writable). 0 is always read from the bit when such a bit is read (when the bit is readable).

8.6.3 Register Description

The prefix (SPDIFm_) of the register names is omitted in this and subsequent sections.

8.6.3.1 Transmitter Channel 1 Audio Register (SPDIFm_TLCA)

This register is for writing the channel 1 audio PCM data for the transmitter.

Access Size : 32 bits
Address : <SPDIFm_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	PCM_DATA[23:16]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PCM_DATA[15:0]

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	W	Reserved A register that can be written. Reading is invalid. The write value should always be 0b.
23 to 0	PCM_DATA [23:0]	0h	W	The read value is undefined Audio PCM data PCM-encoded audio data (stored flush against the LSB side)

8.6.3.2 Transmitter Channel 2 Audio Register (SPDIFm_TRCA)

This register is for writing the channel 2 audio PCM data for the transmitter.

Access Size : 32 bits
Address : <SPDIFm_base> + 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	PCM_DATA[23:16]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	W	Reserved A register that can be written. Reading is invalid. The write value should always be 0b.
23 to 0	PCM_DATA [23:0]	0h	W	The read value is undefined Audio PCM data PCM-encoded audio data (stored flush against the LSB side)

8.6.3.3 Transmitter Channel 1 Status Register (SPDIFm_TLCS)

The channel status information to be transmitted is stored in a 30-bit register. The channel status information for each channel consists of 192 bits per one frame. However, the essential data are only the 30 bits to be set in the register below, so 0 is transmitted after transmission of the first 30 bits.

Refer to IEC 60958 regarding the values to be set in the fields.

Access Size : 32 bits
Address : <SPDIFm_base> + 0008h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	CLAC[1:0]		FS[3:0]				CHNO[3:0]				SRCNO[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	W	Reserved A register that can be written. Reading is invalid. The write value should always be 0b.
29, 28	CLAC[1:0]	0h	W	The read value is undefined Clock accuracy 00b: Level 2 01b: Level 1 10b: Level 3 11b: Reserved
27 to 24	FS[3:0]	0h	W	The read value is undefined Sampling frequency (fs) 0000b: 44.1 kHz 0100b: 48 kHz 1100b: 32 kHz
23 to 20	CHNO[3:0]	0h	W	The read value is undefined Channel number 0000b: Unspecified 0001b: A (left channel) 0010b: B (right channel) 0011b: C
19 to 16	SRCNO[3:0]	0h	W	The read value is undefined Transmission source number 0000b: Unspecified 0001b: 1 0010b: 2 0011b: 3
15 to 8	CATCD[7:0]	0h	W	The read value is undefined Category code (example) 0000_0000b: 2-channel general-purpose format 0000_0001b: 2-channel compact disk (IEC 908) 0000_0010b: 2-channel PCM encoder/decoder 0000_0011b: 2-channel digital audio tape recorder
7, 6	-	All 0	W	Reserved A register that can be written. Reading is invalid. The write value should always be 0b.
5 to 1	CTL[4:0]	0h	W	The read value is undefined Control The control bits are copied from the transmission source (refer to the IEC 60958 standard).
0	-	0h	W	Reserved A register that can be written. Reading is invalid. The write value should always be 0b.

8.6.3.4 Transmitter Channel 2 Status Register (SPDIFm_TRCS)

The channel status information to be transmitted is stored in a 30-bit register. The channel status information for each channel consists of 192 bits per one frame. However, the essential data are only the 30 bits to be set in the register below, so 0 is transmitted after transmission of the first 30 bits.

Refer to IEC 60958 regarding the values to be set in the fields.

Access Size : 32 bits
Address : <SPDIFm_base> + 000Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	CLAC[1:0]		FS[3:0]				CHNO[3:0]				SRCNO[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	W	Reserved A register that can be written. Reading is invalid. The write value should always be 0b.
29, 28	CLAC[1:0]	0h	W	The read value is undefined Clock accuracy 00b: Level 2 01b: Level 1 10b: Level 3 11b: Reserved
27 to 24	FS[3:0]	0h	W	The read value is undefined Sampling frequency (fs) 0000b: 44.1 kHz 0100b: 48 kHz 1100b: 32 kHz
23 to 20	CHNO[3:0]	0h	W	The read value is undefined Channel number 0000b: Unspecified 0001b: A (left channel) 0010b: B (right channel) 0011b: C
19 to 16	SRCNO[3:0]	0h	W	The read value is undefined Transmission source number 0000b: Unspecified 0001b: 1 0010b: 2 0011b: 3
15 to 8	CATCD[7:0]	0h	W	The read value is undefined Category code (example) 0000_0000b: 2-channel general-purpose format 0000_0001b: 2-channel compact disk (IEC 908) 0000_0010b: 2-channel PCM encoder/decoder 0000_0011b: 2-channel digital audio tape recorder
7, 6	-	All 0	W	Reserved A register that can be written. Reading is invalid. The write value should always be 0b.
5 to 1	CTL[4:0]	0h	W	The read value is undefined Control The control bits are copied from the transmission source (refer to the IEC 60958 standard).
0	-	0h	W	Reserved A register that can be written. Reading is invalid. The write value should always be 0b.

8.6.3.5 Transmitter User Data Register (SPDIFm_TUI)

This register is for writing the U-bit data of the sub-frame. Update the U-bit data every 16 frames because the data are transmitted in order of sub-frame 1 and then sub-frame 2. For the contents of the user byte, refer to the standard for the user information that corresponds to the SPDIF device to be used. The user bits to be transmitted are set in order from the LSB side.

Access Size : 32 bits
Address : <SPDIFm_base> + 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BYTE4[7:0]								BYTE3[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BYTE2[7:0]								BYTE1[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	BYTE4[7:0]	0h	W	The read value is undefined The U-bit information is stored.
23 to 16	BYTE3[7:0]	0h	W	The read value is undefined The U-bit information is stored.
15 to 8	BYTE2[7:0]	0h	W	The read value is undefined The U-bit information is stored.
7 to 0	BYTE1[7:0]	0h	W	The read value is undefined The U-bit information is stored.

8.6.3.6 Receiver Channel 1 Audio Register (SPDIFm_RLCA)

This register is for reading the channel 1 audio PCM data for the receiver.

Access Size : 32 bits
Address : <SPDIFm_base> + 0014h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	PCM_DATA[23:16]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PCM_DATA[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
23 to 0	PCM_DATA [23:0]	0h	R	Audio PCM data PCM-encoded audio data (stored flush against the LSB side)

8.6.3.7 Receiver Channel 2 Audio Register (SPDIFm_RRCA)

This register is for reading the channel 2 audio PCM data for the receiver.

Access Size : 32 bits

Address : <SPDIFm_base> + 0018h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	PCM_DATA[23:16]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
23 to 0	PCM_DATA [23:0]	0h	R	Audio PCM data PCM-encoded audio data (stored flush against the LSB side)

8.6.3.8 Receiver Channel 1 Status Register (SPDIFm_RLCS)

The channel status is stored from the start of the block to received sub-frame 1 in order from the LSB bit of this register. For the contents of the channel status, refer to IEC 60958.

Access Size : 32 bits
Address : <SPDIFm_base> + 001Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	CLAC[1:0]		FS[3:0]				CHNO[3:0]				SRCNO[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
29, 28	CLAC[1:0]	0h	R	Clock accuracy 00b: Level 2 01b: Level 1 10b: Level 3 11b: Reserved
27 to 24	FS[3:0]	0h	R	Sampling frequency (fs) 0000b: 44.1 kHz 0100b: 48 kHz 1100b: 32 kHz
23 to 20	CHNO[3:0]	0h	R	Channel number 0000b: Unspecified 0001b: A (left channel) 0010b: B (right channel) 0011b: C
19 to 16	SRCNO[3:0]	0h	R	Transmission source number 0000b: Unspecified 0001b: 1 0010b: 2 0011b: 3
15 to 8	CATCD[7:0]	0h	R	Category code (example) 0000_0000b: 2-channel general-purpose format 0000_0001b: 2-channel compact disk (IEC 908) 0000_0010b: 2-channel PCM encoder/decoder 0000_0011b: 2-channel digital audio tape recorder
7, 6	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
5 to 1	CTL[4:0]	0h	R	Control The control bits are copied from the transmission source (refer to the IEC 60958 standard).
0	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.

8.6.3.9 Receiver Channel 2 Status Register (SPDIFm_RRCS)

The channel status is stored from the start of the block to received sub-frame 2 in order from the LSB bit of the register. For the contents of the channel status, refer to IEC 60958.

Access Size : 32 bits
Address : <SPDIFm_base> + 0020h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	CLAC[1:0]		FS[3:0]				CHNO[3:0]				SRCNO[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
29, 28	CLAC[1:0]	0h	R	Clock accuracy 00b: Level 2 01b: Level 1 10b: Level 3 11b: Reserved
27 to 24	FS[3:0]	0h	R	Sampling frequency (fs) 0000b: 44.1 kHz 0100b: 48 kHz 1100b: 32 kHz
23 to 20	CHNO[3:0]	0h	R	Channel number 0000b: Unspecified 0001b: A (left channel) 0010b: B (right channel) 0011b: C
19 to 16	SRCNO[3:0]	0h	R	Transmission source number 0000b: Unspecified 0001b: 1 0010b: 2 0011b: 3
15 to 8	CATCD[7:0]	0h	R	Category code (example) 0000_0000b: 2-channel general-purpose format 0000_0001b: 2-channel compact disk (IEC 908) 0000_0010b: 2-channel PCM encoder/decoder 0000_0011b: 2-channel digital audio tape recorder
7, 6	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
5 to 1	CTL[4:0]	0h	R	Control The control bits are copied from the transmission source (refer to the IEC 60958 standard).
0	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.

8.6.3.10 Receiver User Data Register (SPDIFm_RUI)

This register stores the U-bit data of the sub-frame. Read the U-bit data every 16 frames because the data are stored in order of sub-frame 1 and then sub-frame 2 from the LSB side. For the contents of the user byte, refer to the standard that corresponds to the device to be used.

Access Size : 32 bits
Address : <SPDIFm_base> + 0024h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BYTE4[7:0]								BYTE3[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
28	-	0h	RW	Reserved. The write value should always be 0.
27	-	0h	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
26	-	0h	RW	Reserved. The write value should always be 0.
25, 24	RASS[1:0]	0h	RW	Receiver audio sample bit size (audio word size) Specify the number of the receiver audio sample bits (16, 20, or 24 bits) for data alignment. 00b: 16-bit sample 01b: 20-bit sample 10b: 24-bit sample 11b: Reserved
23, 22	TASS[1:0]	0h	RW	Transmitter audio sample bit size (audio word size) Specify the number of the transmitter audio sample bits (16, 20, or 24 bits) for data alignment. 00b: 16-bit sample 01b: 20-bit sample 10b: 24-bit sample 11b: Reserved
21	RDE	0h	RW	Receiver DMA enable Enables receiver DMA requests. 0b: Disables receiver DMA. 1b: Enables receiver DMA.
20	TDE	0h	RW	Transmitter DMA enable Enables transmitter DMA requests. 0b: Disables transmitter DMA. 1b: Enables transmitter DMA.
19	NCSI	0h	RW	New channel status information Set this bit to 1 when new channel status information that requires correction is present in the transmitter. 0b: No new channel status information is present. 1b: Channel status information is present.
18	AOS	0h	RW	Audio only sample Set this bit to 0 when user information is present in the user data register. When this bit is set to 1, the user bits are set to all 0s. 0b: User information is present. 1b: No user information is present.
17	RME	0h	RW	Receiver enable Enables the receiver. 0b: The receiver is disabled. 1b: The receiver is enabled.

Bit	Bit Name	Initial Value	R/W	Description
16	TME	0h	RW	Transmitter enable Enables the transmitter. 0b: The transmitter is disabled. 1b: The transmitter is enabled.
15	REIE	0h	RW	Receiver error interrupt enable Clearing this bit masks all error interrupts from the receiver. Setting this bit to 1 enables all receiver error interrupts. 0b: Disables receiver error interrupts. 1b: Enables receiver error interrupts.
14	TEIE	0h	RW	Transmitter error interrupt enable Clearing this bit masks all error interrupts from the transmitter. Setting this bit to 1 enables all transmitter error interrupts. 0b: Disables transmitter error interrupts. 1b: Enables transmitter error interrupts.
13	UBOI	0h	RW	User buffer overrun interrupt enable Enables the user buffer overrun interrupt. 0b: Disables the user buffer overrun interrupt. 1b: Enables the user buffer overrun interrupt.
12	UBUI	0h	RW	User buffer underrun interrupt enable Enables the user buffer underrun interrupt. 0b: Disables the user buffer underrun interrupt. 1b: Enables the user buffer underrun interrupt.
11	CREI	0h	RW	Clock recovery error interrupt enable Enables the clock recovery error interrupt. 0b: Disables the clock recovery error interrupt. 1b: Enables the clock recovery error interrupt.
10	PAEI	0h	RW	Parity error interrupt enable Enables the parity checking error interrupt. 0b: Disables the parity checking error interrupt. 1b: Enables the parity checking error interrupt.
9	PREI	0h	RW	Preamble error interrupt enable Enables the preamble checking error interrupt. 0b: Disables the preamble error interrupt. 1b: Enables the preamble error interrupt.
8	CSEI	0h	RW	Channel status error interrupt enable Enables the channel status error interrupt. 0b: Disables the channel status error interrupt. 1b: Enables the channel status error interrupt.
7	ABOI	0h	RW	Audio buffer overrun interrupt enable Enables the receiver audio buffer overrun interrupt. 0b: Disables the audio buffer overrun interrupt. 1b: Enables the audio buffer overrun interrupt.
6	ABUI	0h	RW	Audio buffer underrun interrupt enable Enables the transmitter audio buffer underrun interrupt. 0b: Disables the audio buffer underrun interrupt. 1b: Enables the audio buffer underrun interrupt.
5	RUII	0h	RW	Receiver user information interrupt enable Enables the receiver user information register full interrupt. 0b: Disables the receiver user information interrupt. 1b: Enables the receiver user information interrupt.
4	TUII	0h	RW	Transmitter user information interrupt enable Enables the transmitter user information register empty interrupt. 0b: Disables the transmitter user information interrupt. 1b: Enables the transmitter user information interrupt.
3	RCSI	0h	RW	Receiver channel status interrupt enable Enables the receiver channel status register full interrupt. 0b: Disables the receiver channel status interrupt. 1b: Enables the receiver channel status interrupt.
2	RCBI	0h	RW	Receiver channel buffer interrupt enable Enables the receiver audio channel buffer full interrupt. 0b: Disables the receiver audio channel interrupt. 1b: Enables the receiver audio channel interrupt.

Bit	Bit Name	Initial Value	R/W	Description
1	TCSI	0h	RW	Transmitter channel status interrupt enable Enables the transmitter channel status register empty interrupt. 0b: Disables the transmitter channel status interrupt. 1b: Enables the transmitter channel status interrupt.
0	TCBI	0h	RW	Transmitter channel buffer interrupt enable Enables the transmitter audio channel buffer empty interrupt. 0b: Disables the transmitter audio channel interrupt. 1b: Enables the transmitter audio channel interrupt.

8.6.3.12 Status Register (SPDIFm_STAT)

This register indicates the status information of the SPDIF unit.

Access Size : 32 bits
Address : <SPDIFm_base> + 002Ch
Initial Value : 0000_C000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	CMD
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RIS	TIS	UBO	UBU	CE	PARE	PREE	CSE	ABO	ABU	RUIR	TUIR	CSRX	CBRX	CSTX	CBTX
Initial Value	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	RW0	RW0	RW0	RW0	RW0	RW0	RW0	RW0	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
16	CMD	0h	R	Compressed mode data This bit is set when the received data are compressed mode data (the V flag and bit 1 of channel status = 1). 0b: The data are not compressed mode data. 1b: The data are compressed mode data.
15	RIS	1h	R	Receiver idle state This bit is set when the receiver is in the idle state. 0b: The receiver is not in the idle state. 1b: The receiver is in the idle state.
14	TIS	1h	R	Transmitter idle state This bit is set when the transmitter is in the idle state. 0b: The transmitter is not in the idle state. 1b: The transmitter is in the idle state.
13	UBO	0h	RW0	User buffer overrun*1 This bit is set in the case of an overrun of the receiver user buffer. This bit is cleared by writing 0 to it. When the REIE and UBOI bits of the control register are set, an interrupt occurs. 0b: The user buffer has not overrun. 1b: The user buffer has overrun.
12	UBU	0h	RW0	User buffer underrun*1 This bit is set in the case of an underrun of the transmitter user buffer. This bit is cleared by writing 0 to it. When the TEIE and UBUI bits of the control register are set, an interrupt occurs. 0b: The user buffer has not underrun. 1b: The user buffer has underrun.
11	CE	0h	RW0	Clock error*1 This bit is set when synchronization cannot be obtained in clock recovery. This bit is cleared by writing 0 to it. When the REIE and CREI bits of the control register are set, an interrupt occurs. 0b: Normal clock recovery 1b: Clock recovery error
10	PARE	0h	RW0	Parity error*1 This bit is set when the result of parity checking is the detection of an error. This bit is cleared by writing 0 to it. When the REIE and PAEI bits of the control register are set, an interrupt occurs. 0b: The result of parity checking is normal. 1b: Parity error

Bit	Bit Name	Initial Value	R/W	Description
9	PREE	0h	RW0	Preamble error*1 This bit is set when a preamble is undefined or a preamble does not appear in the right position. This bit is cleared by writing 0 to it. When the REIE and PREI bits of the control register are set, an interrupt occurs. Note: The bit is only set after a start of block preamble. 0b: A preamble is in the right position. 1b: Preamble error
8	CSE	0h	RW0	Channel status error*1 This bit is set when the channel status information is written before the 32nd frame that is in the transfer state. This bit is cleared by writing 0 to it. When the TEIE and CSEI bits of the control register are set, an interrupt occurs. 0b: Normal channel status 1b: Channel status error
7	ABO	0h	RW0	Audio buffer overrun*1 This bit indicates that both the first and second stages of the receiver audio buffer are full so that further received data will be written over data that have already been received. This bit is cleared by writing 0 to it. When the REIE and ABOI bits of the control register are set, an interrupt occurs. 0b: The receiver audio buffer has not overrun. 1b: The receiver audio buffer has overrun.
6	ABU	0h	RW0	Audio buffer underrun*1 This bit indicates that both the first and second stages of the transmitter audio buffer are empty so that further transmission will be repetition of the last data to have been transmitted. This bit is cleared by writing 0 to it. When the TEIE and ABUI bits of the control register are set, an interrupt occurs. 0b: The transmitter audio buffer has not underrun. 1b: The transmitter audio buffer has underrun.
5	RUIR	0h	R	Receiver user information register This bit indicates the state of the receiver user information register. Reading the receiver user register clears this bit. When the RUII bit of the control register is set, an interrupt occurs. 0b: The receiver user information register is empty. 1b: The receiver user information register is full.
4	TUIR	0h	R	Transmitter user information register This bit indicates the state of the transmitter user information register. Writing to the transmitter user register clears this bit. When the TUII bit of the control register is set, an interrupt occurs. 0b: The transmitter user information register is full. 1b: The transmitter user information register is empty.
3	CSRX	0h	R	Channel 1 and 2 status (for receiver) This bit indicates the state of the receiver channel status register. Reading the receiver channel status register clears this bit. When the RCSI bit of the control register is set, an interrupt occurs. 0b: The receiver channel status register is empty. 1b: The receiver channel status register is full.
2	CBRX	0h	R	Channel 1 and 2 buffers (for receiver) This bit indicates the state of the receiver audio channel register. Reading the receiver audio channel register clears this bit. When the RCBI bit of the control register is set, an interrupt occurs. 0b: The receiver audio channel register is empty. 1b: The receiver audio channel register is full.
1	CSTX	0h	R	Channel 1 and 2 status (for transmitter) This bit indicates the state of the transmitter channel status register. Writing the transmitter channel status register clears this bit. When the TCSI bit of the control register is set, an interrupt occurs. 0b: The transmitter channel status register is full. 1b: The transmitter channel status register is empty.
0	CBTX	0h	R	Channel 1 and 2 buffers (for transmitter) This bit indicates the state of the transmitter audio channel register. Writing to the transmitter audio channel register clears this bit. When the TCBI bit of the control register is set, an interrupt occurs. 0b: The transmitter audio channel register is full. 1b: The transmitter audio channel register is empty.

Note 1. When an error bit is detected during DMA transfer, re-making the DMA transfer settings is required. In this case, set the enable bit (the RME or TME bit) and the DMA enable bit (the RDE or TDE bit) to "disabled" to release the error state, and then re-set the direct memory access controller. After that, set the module enable bit to "enabled", and the DMA transfer can be resumed.

8.6.3.13 Transmitter DMA Audio Data Register (SPDIFm_TDAD)

This register is for DMA writing of the channel 1/2 audio PCM data for the transmitter.

Access Size : 32 bits
Address : <SPDIFm_base> + 0030h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	PCM_DATA[23:16]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PCM_DATA[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	W	Reserved A register that can be written. Reading is invalid. The write value should always be 0b.
23 to 0	PCM_DATA [23:0]	0h	W	The read value is undefined Audio PCM data PCM-encoded audio data (stored flush against the LSB side)

8.6.3.14 Receiver DMA Audio Data Register (SPDIFm_RDAD)

This register is for DMA reading of the channel 1/2 audio PCM data for the receiver.

Access Size : 32 bits

Address : <SPDIFm_base> + 0034h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	PCM_DATA[23:16]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PCM_DATA[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0 is read. The written value will be ignored.
23 to 0	PCM_DATA [23:0]	0h	R	Audio PCM data PCM-encoded audio data (stored flush against the LSB side)

8.6.4 Operation

8.6.4.1 Transmitter Control

8.6.4.1.1 Overview of Transmitter Control

The transmitter encodes the PCM data and auxiliary information to be sent with the biphase mark modulation in conformance with the IEC 60958 standard (SPDIF) and sends them.

■ **Clock**

The clock for the transmitter is the externally supplied oversampling clock. An oversampling value that is 8 times the clock frequency required for the biphase mark encoding is usually selected for this clock. In this case, the clock frequency that is required for transmitting the 32 time slots in a sub-frame will be 512 times the sampling frequency of the audio data.

■ **Audio Data and Channel Status Information**

The audio data and channel status information for channel 1 and then channel 2 of the module are written.

Writing of the channel status is only required when the information is changed. Writing of the channel status information will be required by the SPDIF module after 30 frames (when all transmission of the current channel status data has been completed), so write it from the 31st frame and before the next block (= 192 frames) starts.

Audio data are stored in a double-buffer configuration. There are two ways to check that data are not present in the first stage of the double buffer.

- Sending an interrupt request
- Reading the status register

■ **DMA Transfer**

Channel 1 audio data are transmitted with the use of DMA transfer in response to the first request and channel 2 audio data are transmitted in response to the second request.

■ **Channel Status**

The channel status information to be transmitted is set in the 30-bit registers for channels 1 and 2. Each block has 192 bits per channel of channel status information. However, only 30 of the 192 bits are essential data, so 0 is transmitted after the first 30 bits have been transmitted until completion of the block.

■ **User Data**

User data are in a 32-bit double-buffer arrangement. Issue an interrupt request or read the status register to check that the first stage of the double buffer is empty. Generally, the data length between blocks is insufficient for the user data information, and the user data information is transmitted in order of channel 1 and channel 2. After the 384 bits of user data in the interval of one block have been transmitted, the next block is transmitted in succession.

■ **Audio Data**

The format of audio data handled by the SPDIF is linear PCM, and the maximum settable size is 24 bits. For this reason, the V flag that indicates the audio data are linear PCM is always 0. No register setting is required in relation to the V flag. An even parity bit is generated for each 32 bits of the serial output data (that is, without including the preamble).

8.6.4.1.2 Transmitter Initialization

The transmitter is placed in the idle state by default after a reset. It can also be placed in the idle state by writing 0 to the TME bit of the CTRL register. In the idle state, the settings of the transmitter will be as follows.

- The idle status bit (TIS) of the transmitter is set to 1, and the other status bits are all cleared to 0.
- Preamble generation is invalid.
- Synchronization of channels 1 and 2 is set to 0 (channel 1: 0, channel 2: 1).
- The word count and frame count will become 0.
- Output from the encoder based on the biphase mark will be 0.

The channel status register, user data register, and audio data register retain their values before the state transition to the idle state. Write 1 to the TME bit of the CTRL register to cause return from the idle state.

8.6.4.1.3 Transmitter Initialization Settings

Setting the TME bit to 1 causes the TUIR and CSTX bits to be set to 1. At this time, writing data in the order 1) TUI, then 2) TLCS, TRCS causes a channel status error. To suppress the occurrence of an error, write data in the order 1) TLCS, TRCS, then 2) TUI.

In addition, after the TME bit is set to 1, writing of the first audio data (writing to TLCA and TRCA by CPU access or writing to TDAD by DMA transfer) should proceed after clearing of CSTX and TUIR has been checked following writing to TLCS, TRCS, and TUI.

8.6.4.1.4 Data Transfer to the Transmitter

When the transmitter has returned from the idle state, it is ready for data transfer. Data transfer can be started in any of three ways:

- Using interrupts
- Using DMA requests
- Reading the status register

Interrupt signals that are common to transmission and reception and individual DMA request signals for the transmitter are prepared.

For details of the transfer of data in response to a DMA request, see **8.6.4.1.5 DMA Data Transfer to the Transmitter**.

Figure 8.6-5 shows the flow of data transfer to the transmitter by using interrupts.

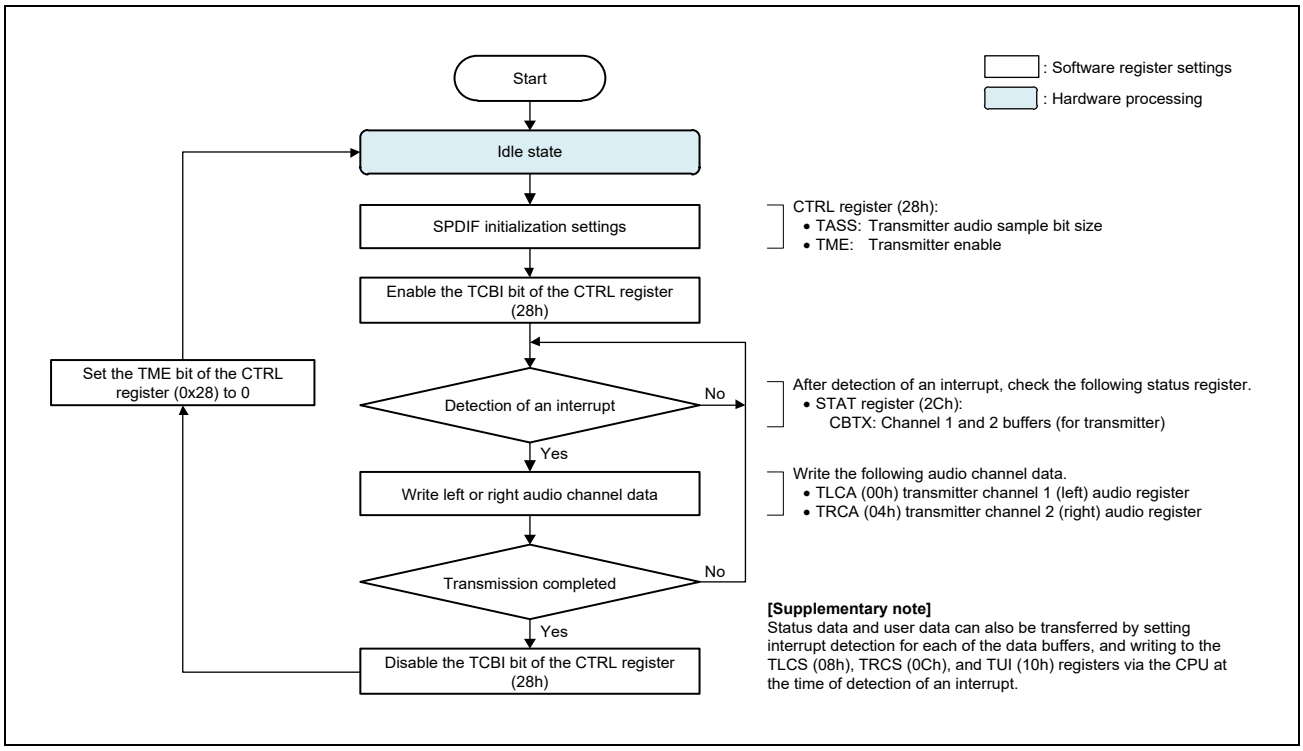

Figure 8.6-5 Flow of Data Transfer to the Transmitter (Using Interrupts)

The channel status information is updated in response to a change in the information.

Because the updating should proceed before transmission of the next block, write the channel status information for updating after the transmission of 30 frames has been completed. Completion of the transmission of 30 frames can be indicated by an interrupt or detected by reading the status bit. Writing the channel status information before the transmission of 30 frames has been completed (during transmission of the current information) leads to setting of the channel status error bit (CSE) of the status register and generates an interrupt.

Remark All valid information of one channel status block can be transmitted with 30 frames.

8.6.4.1.5 DMA Data Transfer to the Transmitter

This section describes the procedure for transmitting the SPDIF data with the use of the DMAC for DMA transfer.

Figure 8.6-6 shows the flow of data transfer to the transmitter by using DMA requests.

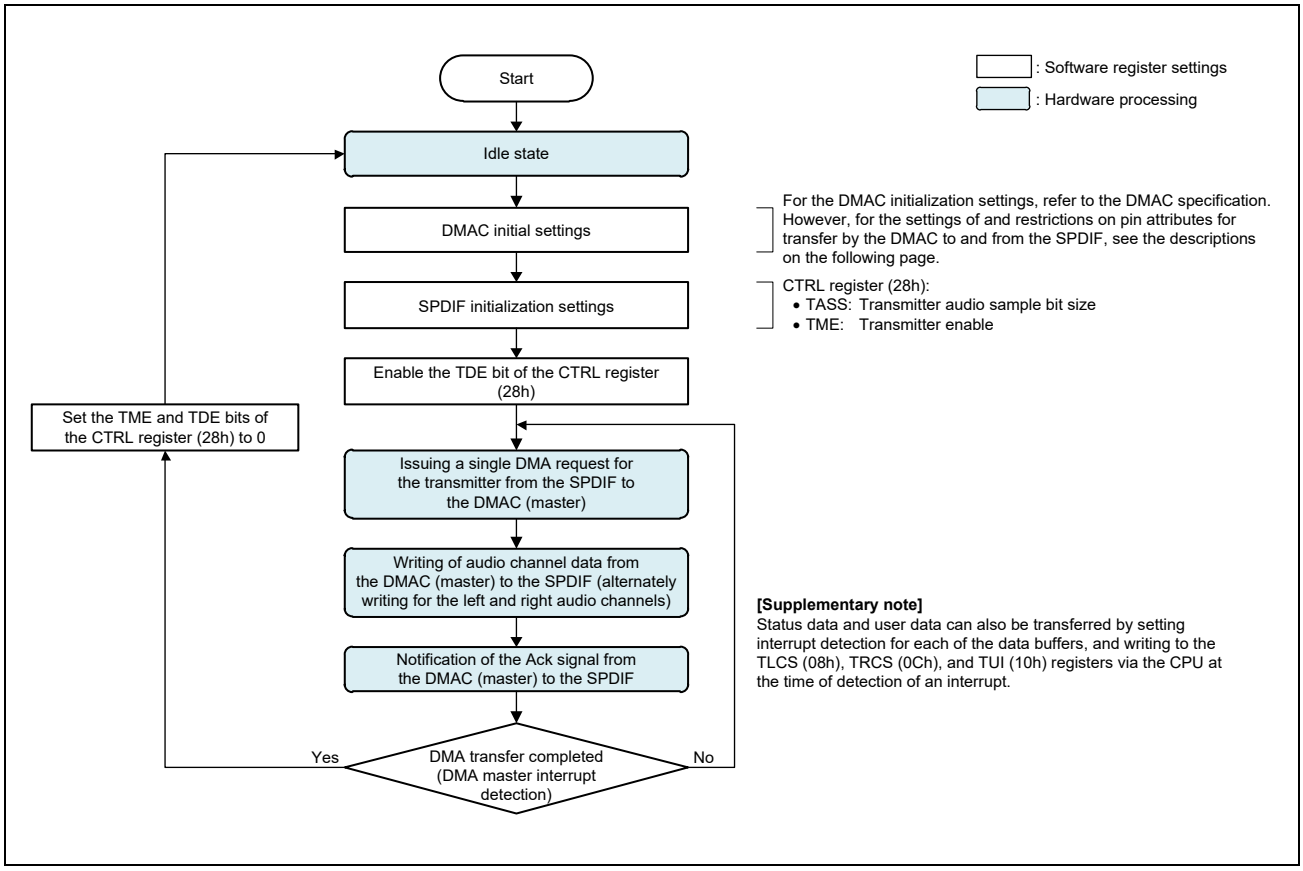

Figure 8.6-6 Flow of Data Transfer to the Transmitter (Using DMA Requests)

Set the DMAC master (in the CHCFG register) at the time of data transfer by DMA for the transmitter as follows.

1. Set the single transfer mode (one round of DMA transfer processing proceeds in response to one DMA request).
   Register setting on the DMA master side: the TM bit: 0b

2. DMA transfer is in 32-bit units.
   Register setting on the DMA master side: the DDS bit: 32-bit setting

3. Set DMAC REQ and DMAC ACK as level signals (DMA ACK is asserted until DMA REQ is deasserted). The active sense of the REQ signal is set to the high level.
   Register settings on the DMA master side: AM[2:0] = 001b, LVL = 1b, HIEN = 1b, LOEN = 0b

   Note: The active sense of the ACK signal is fixed to the high level.

4. Set the DMAC ACK signal to be activated at the time of write access to the SPDIF.
   Register setting on the DMA master side: REQD = 1

5. Data for DMA transfer are written to the TDAD register (transmission) of the SPDIF unit.

6. When writing to the TDAD register at the time of DMA transfer, audio data are alternately written to the left and right channels.

For the SPDIF initialization at the time of DMA transfer, initialize the SPDIF unit according to **8.6.4.1.2 Transmitter Initialization**. At that time, enabling DMA transfer by setting the DMA enable bit (TDE = 1b) of the SPDIF unit is also required.

8.6.4.2 Receiver Control

8.6.4.2.1 Overview of Receiver Control

The receiver demodulates the data and clock signals from the input encoded in accord with the IEC 60958 standard.

The demodulated data are stored in the audio data register in a linear PCM format, and the channel status and user information that are received at the same time as auxiliary information are stored in the appropriate registers.

■ **Clock**

The main clock for the receiver is the externally supplied oversampling clock.
The receiver operates at 4 times the frequency of the oversampling clock.

Remark The oversampling clock is the same for the transmitter and receiver.

■ **Clock Recovery**

Clock recovery proceeds with the use of the pulse-width counter and averaging filter, and the sampling pulse is generated at the mid-point of each bit of the input data. The clock error status bit indicates that clock synchronization has failed. Synchronization starts when a first preamble appears in the input data. As long as changes in the jitter and clock frequency are in the range of clock recovery specification, effects of these changes on clock recovery can be constrained by continual adjustment.

When the clock recovery has been successful, the decoder starts preamble detection with the use of the biphase mark method. The decoder searches for a preamble to indicate the start of a block (see **Table 8.6-1**). The preamble error status bit indicates that the next preamble did not appear with the right timing. This can be considered as being due to an omission or the failure of transfer.

■ **Parity Checking**

An even-parity checking is run on the decoded data. If a mismatch is encountered, the parity error status bit is set.

■ **Audio Data**

Audio data are stored in a double-buffer configuration. Data can be detected to be readable by transmitting an interrupt request due to the buffer-full state or reading the corresponding status bit. Channel 1 audio data are transmitted with the use of DMA transfer in response to the first request and channel 2 audio data are transmitted in response to the second request.

■ **User Data and Channel Status Information**

The SPDIF module acquires the user data and channel status information as well as the audio data.

The channel status information is stored in a 30-bit register. Storage in the register is not completed until a total of 30 frames for each channel have been received because one bit is received per sub-frame. The new channel status information is compared with the current value, and the CPU only reads the new information if a change has occurred. The user data are also received at the same time. However, the reception is completed per 16 frames because the user data are stored in the register per sub-frame.

Remark 1. Requests for channel status information cannot be transferred by DMA transfer.

Remark 2. When an overrun of the receiver user buffer occurs, the current data in the SPDIF buffer are overwritten by the next data input from the SPDIF.

8.6.4.2.2 Receiver Initialization

The receiver is placed in the idle state by default after a reset. It can also be placed in the idle state by writing 0 to the RME bit of the CTRL register. In the idle state, the settings of the receiver will be as follows.

- The idle status bit of the receiver is set to 1, and the other status bits are all cleared to 0.
- Synchronization of channels 1 and 2 is set to 0 (channel 1: 0, channel 2: 1).
- The word count and frame count will become 0.

The channel status register, user data register, and audio data register retain their values before the state transition to the idle state. Write 1 to the RME bit of the CTRL register to cause return from the idle state.

8.6.4.2.3 Data Transfer from the Receiver

When the receiver has returned from the idle state, it is ready for data transfer. Data transfer can be started in any of three ways:

- Using interrupts
- Reading the status register
- Using DMA requests

For details of the transfer of data in response to a DMA request, see **8.6.4.2.4 DMA Data Transfer from the Receiver**.

Interrupt signals that are common to transmission and reception and individual DMA request signals for the receiver are prepared. An interrupt may be generated by an error signal due to any of the following factors during data transfer from the receiver.

1. Clock recovery error
2. Failure of or a fault in transfer is indicated by a preamble error
3. Parity checking error

A failure of or fault in transfer may lead to the preamble for starting a sub-frame or block having a shifted position or not appearing.

A parity checking error occurs when the parity bit is wrong. This error may occur due to any of the factors above.

■ **Tolerance of Clock Recovery**

The margin for clock recovery in reception is expressed by the following formula.

$$M = \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\%$$

M: Reception margin
N: Oversampling rate
L: Frame length = 33
D: Duty cycle = 0.6
F: Oversampling clock deviation = Level II accuracy = $1000 \times 10e^{-6}$

Figure 8.6-7 shows the reception margin M.

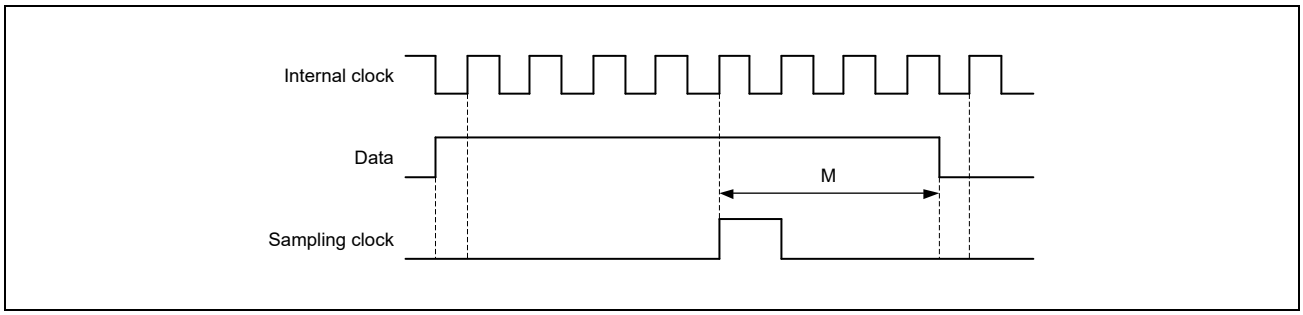

Figure 8.6-7 Reception Margin

Introducing jitter causes the previous formula to become the following inequality.

$$J \leq \left| \left(0.5 - \frac{1}{2N}\right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100\%$$

J: Clock jitter
8 times the oversampling rate: reception margin = 39.25%
4 times the oversampling rate: reception margin = 31.75%
Twice the oversampling rate: reception margin = 16.75%

The fastest sampling frequency is 48 kHz. In this case, the required clock frequency will be 128 × 48 kHz = 6.144 MHz. In this case, the worst-case jitter in one cycle is defined as 40 ns = 24.5% of a cycle. Therefore, the above inequality will be satisfied when the oversampling rate is greater than or equal to 4.

Figure 8.6-8 shows the flow of data transfer from the receiver by using interrupts.

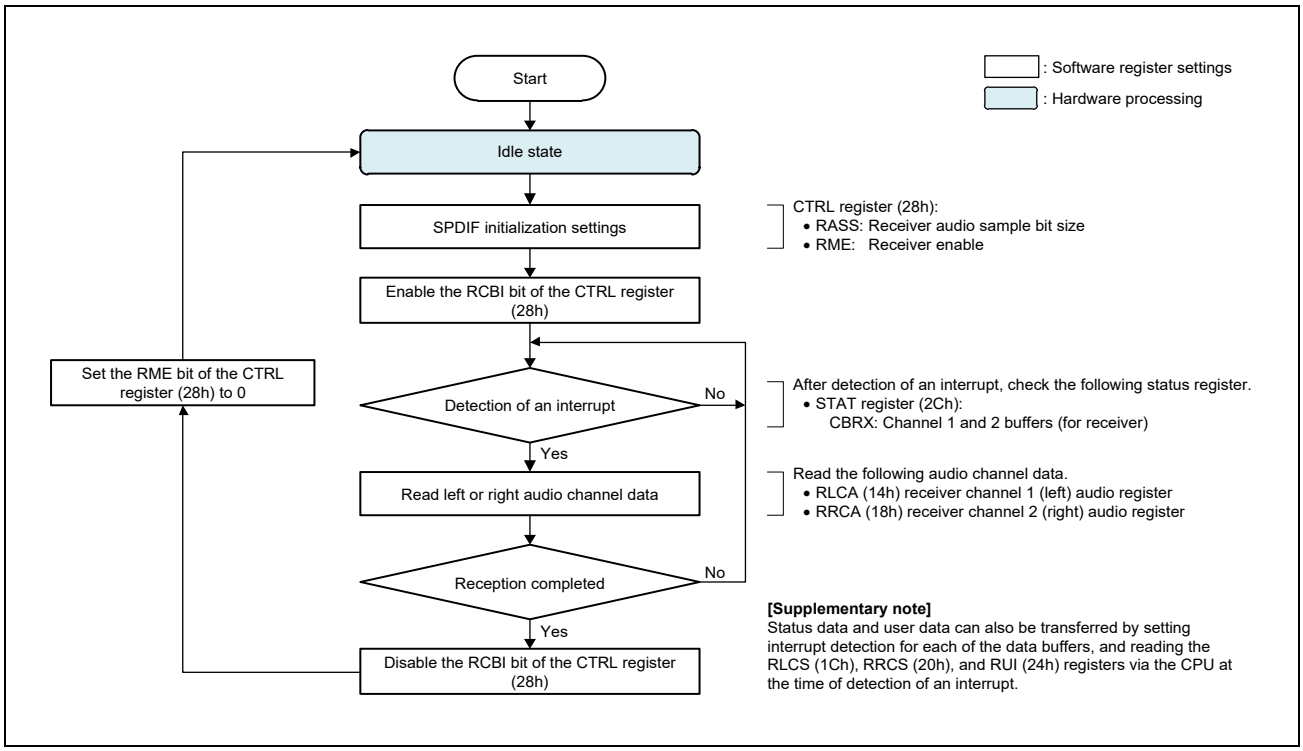

Figure 8.6-8 Flow of Data Transfer from the Receiver (Using Interrupts)

The interrupt that provides notification of information having been stored in the channel status information register is only generated when the information is found to have changed after reception of the 30th frame has been completed.

8.6.4.2.4 DMA Data Transfer from the Receiver

This section describes the procedure for receiving the SPDIF data with the use of the DMAC for DMA transfer.

Figure 8.6-9 shows the flow of data transfer from the receiver by using DMA requests.

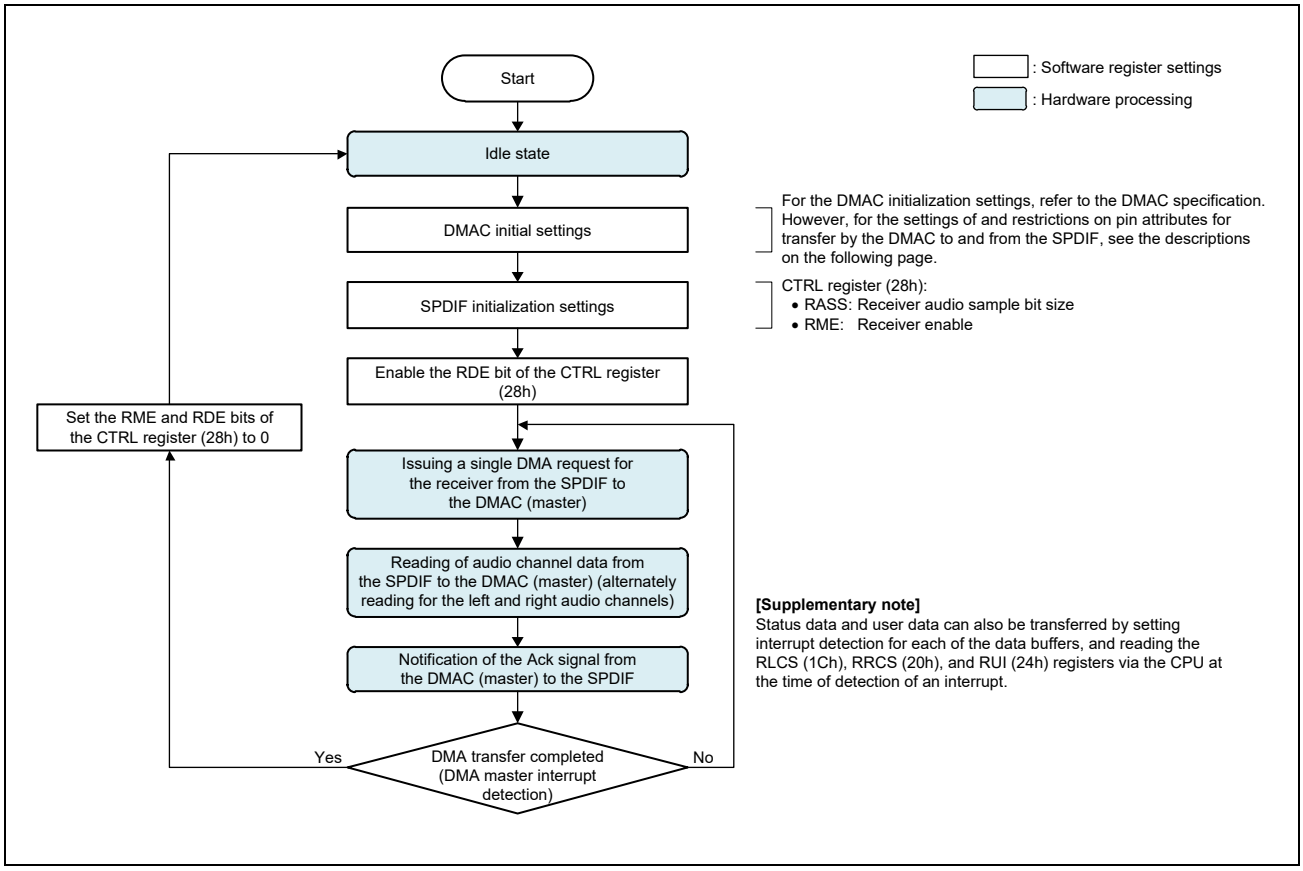

Figure 8.6-9 Flow of Data Transfer from the Receiver (Using DMA Requests)

Set the DMAC master (in the CHCFG register) at the time of data transfer by DMA from the receiver as follows.

1. Set the single transfer mode (one round of DMA transfer processing proceeds in response to one DMA request).
   Register setting on the DMA master side: the TM bit: 0b

2. One DMA transfer is in 32-bit units.
   Register setting on the DMA master side: the SDS bit: 32-bit setting

3. Set DMAC REQ and DMAC ACK as level signals (DMA ACK is asserted until DMA REQ is deasserted). The active sense of the REQ signal is set to the high level.
   Register settings on the DMA master side: AM[2:0] = 001b, LVL = 1b, HIEN = 1b, LOEN = 0b

   Note: The active sense of the ACK signal is fixed to the high level.

4. Set the DMAC ACK signal to be activated at the time of read access to the SPDIF.
   Register setting on the DMA master side: REQD = 0b

5. Data for DMA transfer are read from the RDAD register (reception) of the SPDIF unit.

6. Reading of the RDAD register at the time of DMA transfer is alternately of data for the left and right channels.

For the SPDIF initialization at the time of DMA transfer, initialize the SPDIF unit according to **8.6.4.2.2 Receiver Initialization**. At that time, enabling DMA transfer by setting the DMA enable bit (RDE = 1b) of the SPDIF unit is also required.

8.6.4.3 Stopping Transmitter and Receiver

The operation of the transmitter and receiver can be invalidated by writing 0b to the enable bits in the control register (the TME bit for the transmitter, and the RME bit for the receiver). This idle state can be detected by reading the idle bits (the TIS bit for the transmitter, and the RIS bit for the receiver).

8.6.4.4 Compressed Mode Data

Compressed mode data is defined in the IEC 61937 specification. The SPDIF module only detects the compressed mode data. Check the validity flag (V flag) and bit 1 of the channel status data, and when both are 1, set the CMD bit of the status register to 1 to select compressed mode data.

Remark Only the receiver detects compressed mode data. This information has no effect on the transmitter.

8.6.4.5 Reset and Clock Control

In terms of controlling a reset and clock, the following reset and clock pins require control.

Table 8.6-6 Relationship between Reset and Clock

	Reset Signal	Clock Signal	Description
System 1	rst	clkp	For internal bus control circuit
System 2	rst*1	pa_audio_a	For external interface control circuit

Note 1. No measures for non-synchronization with the circuit.

The above reset and clock pins are controlled by the CPG unit, and each reset and clock signal can be switched off and on by the CPG register. The mechanism for stopping the clkp clock before and after release from the reset when the rst reset is released is implemented on the CPG side. However, a mechanism for stopping before and after release from the rst reset is not implemented for the pa_audio_a clock, so handling of reset and clock control in the way described below is required as a measure for non-synchronization. Perform the reset and clock control while the operation of the SPDIF unit is stopped, and while access by related units is also stopped.

1. Release the SPDIF from the reset state and supply the clock:
   Step1: Start supply of the clkp clock through the register setting of the CPG unit.
   Step 2: Release (deassert) the rst reset signal through the register setting of the CPG unit.
   Step 3: Start supply of the pa_audiox_a clock through the register setting of the CPG unit.

   Note: The state immediately after starting the device is as stated below.
   clkp clock: Supply stopped state, pa_audiox_a clock: Supply stopped state, rst reset: Reset state

2. Enable the SPDIF reset and stop the clock:
   Step 1: Stop supply of the pa_audiox_a clock through the register setting of the CPG unit.
   Step 2: Enable (assert) the rst reset signal through the register setting of the CPG unit.
   Step 3: Stop supply of the clkp clock through the register setting of the CPG unit.

3. Apply a brief hardware reset of the whole SPDIF macro.
   Step 1: Activate (assert) the rst reset signal through the register setting of the CPG unit.
   Step 2: Stop supply of the pa_audiox_a clock through the register setting of the CPG unit.
   Step 3: Release (deassert) the rst reset signal through the register setting of the CPG unit.
   Step 4: Start supply of the pa_audiox_a clock through the register setting of the CPG unit.

   Note: The above steps are performed while the clkp clock is being supplied.

8.6.5 Interrupt

8.6.5.1 Interrupt List

Table 8.6-7 lists the interrupt signal of this unit.

Table 8.6-7 Interrupt List

Interrupt signal	Function	Pulse/Level	Min. Pulse	Active Level	Clock
intreq_spdif_n	SPDIF interrupt signal	Level	—	Low	clkp

The above interrupt signal operates as the logical OR of multiple interrupt sources.

The specifiable interrupt sources are as follows.

- Receiver error interrupt
- Transmitter error interrupt
- User buffer overrun interrupt
- User buffer underrun interrupt
- Clock recovery error interrupt
- Parity error interrupt
- Preamble error interrupt
- Channel status error interrupt
- Audio buffer overrun interrupt
- Audio buffer underrun interrupt
- Receiver user information interrupt
- Transmitter user information interrupt
- Receiver channel status interrupt
- Receiver channel buffer interrupt
- Transmitter channel status interrupt
- Transmitter channel buffer interrupt

Switching the interrupt sources listed above on and off can be specified in the control register (CRTL).

Checking the interrupt source when an interrupt occurs and clearing the source can be done through the status register (STAT).

8.6.6 Usage Notes

8.6.6.1 Clearing TUIR

After writing to TUI and until TUIR is cleared, a wait for the completion of the transmission of up to 1 frame is required. When writing data to TUI in response to a transmitter user information interrupt, check that TUIR has been cleared, and then stop the interrupt processing routine to prevent the interrupt being accepted again.

8.6.6.2 Frequency of Audio Input Clock

The frequency of the externally input oversampling clock (pa_audiox_a) requires setting to 512 fs.

In addition, the frequency of the externally input oversampling clock (pa_audiox_a) must be kept lower than the SPDIF internal HPB bus clock (clkp) frequency.

SECTION 8 AUDIO

8.7 PDM Interface (PDM)

This section describes the PDM interface.

8.7.1 Overview

This PDM interface is a unit for receiving voice data from an external PDM (pulse density modulation) device. For features and configuration, see the following sections.

8.7.1.1 Feature

Table 8.7-1 lists the features of this PDM interface.

Table 8.7-1 PDM-IF IP Specifications

Item	Description
Number of channels	Maximum 3 channels per 1 IP (× 2 units)
Functions	• Capable of filtering 1-bit digital input data PDM_DATn (n = 0, 1, 2) and converting them into 20-bit or 16-bit digital data. The bit order is little-endian. • The IP supports stereo microphone (L/R sampling by rising/falling clock edge). • The IP supports sound activity detector. • Each channel of IP includes programmable filters: 4th order sinc filter, high-pass filter (for suppression of DC bias), correction filter (for sinc passband distortion), half-band decimation filter (for aliasing distortion). – IP supports programmable and flexible decimation ratios. – The sinc filter is selectable as first-, second-, third-, and fourth-order. • The IP supports DMA operation through APB. • Each channel of IP has an internal buffer. – 64 stages when designed – Capable of storing voice data during low power mode • Error detection functions can be used for debugging.
Interrupt sources	Maximum 7 sources in 1 IP 1. Data reception interrupt per channel (Maximum 3 interrupts) 2. Sound detection interrupt (shared between channels) 3. Error detection interrupt per channel (Maximum 3 interrupts)
Low power consumption function	The IP supports microphone low power configuration (slower clock). The IP can switch to the higher clock speed after sound detection recognized.
Bus interface	The IP has an APB interface which is confirmed to APB4.

Since this LSI supports 24 MHz/5 = 4.8 MHz CLK (CCLK), the PDM_CLK frequency can be discretely selected in the range of 2.4 MH to 0.15 MHz for the following target sampling frequencies. For details, see **8.7.3.1 Clock Specifications**.

Target sampling frequencies: 48, 40, 30, 25, 24, 20, 16, 15, 12, 10, 8 kHz

8.7.1.2 Block Diagram

The following is a block diagram of the PDM interface.

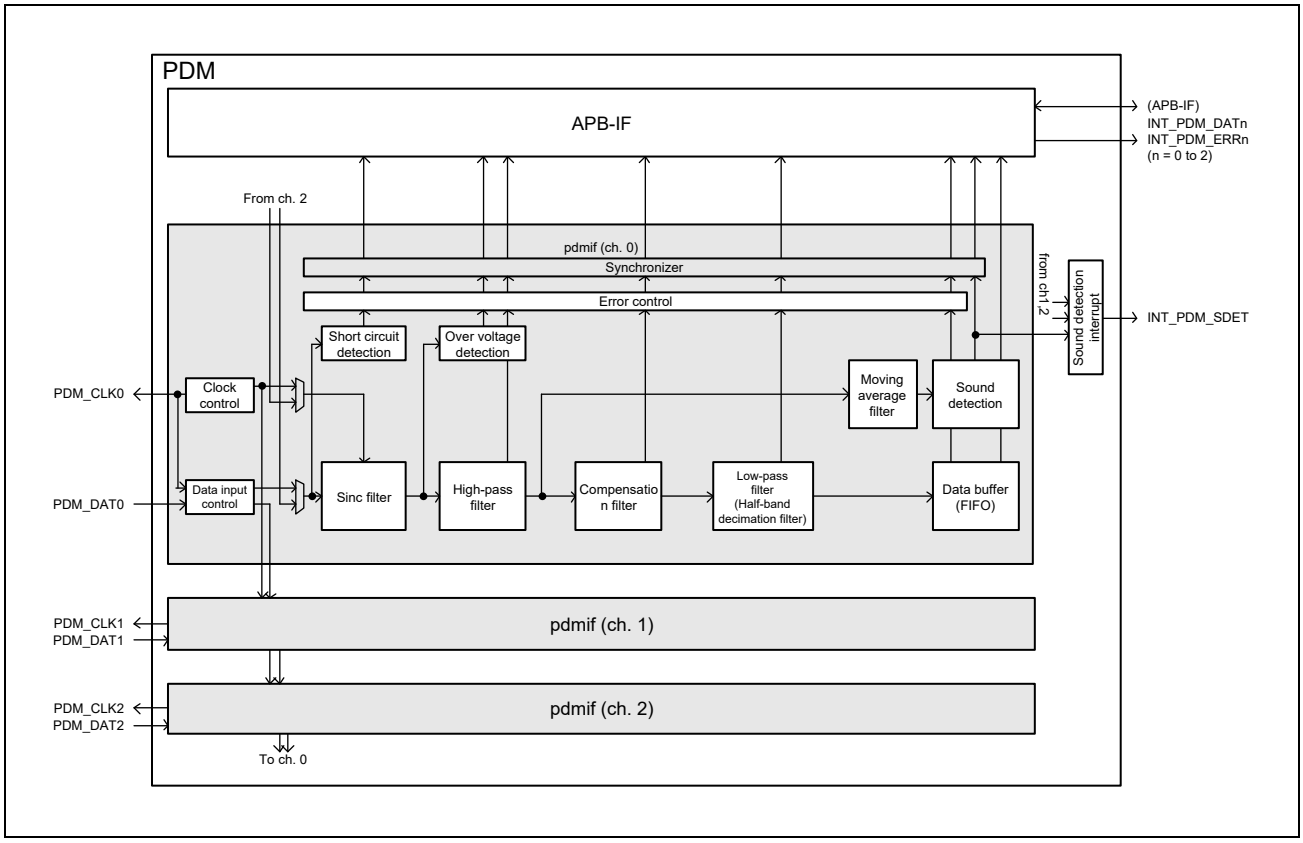

Figure 8.7-1 Three-Channel PDM-IF Block Diagram

Each channel of PDM-IF consists of following blocks:

- Clock control: Generates PDM_CLKn (n = 0, 1, 2) to the microphone, and internal timing signals to the sinc filter.
- Data input control: Receives PDM_DATn (n = 0, 1, 2) from the microphone.
- Sinc filter: Converts the 1-bit digital data stream input from PDM_DATn (n = 0, 1, 2) to 34-bit signed data. Then, the 34-bit signed data is clipped to 20-bit signed data.
- High-pass filter: A filter for suppression of DC bias
- Compensation filter: A filter for sinc passband distortion
- Low-pass (half-band decimation) filter: A filter for aliasing distortion
- Moving average filter: A simple filter for noise reduction before sound detection
- Sound detection: Generates the wakeup interrupt to recover from low power mode.
- Data buffer: Stores 20-bit or 16-bit data filtered by some filters.
- Short circuit detection: Detects the short circuit error which indicates consecutive 0’s or 1’s input from PDM_DATn (n = 0, 1, 2).
- Overvoltage detection: Detects the overvoltage error.
- Error control: Generates error flags from other blocks.

The 1-bit digital data stream input from PDM_DATn pin (n = 0, 1, 2) is converted to 34-bit signed data by the sinc filter and then the data is clipped to 20-bit signed data. The 20-bit singed data is used for sound detection and data storing in buffer.

The sound detection block receives 20-bit signed data through high-pass filter block and moving average filter block. The block compares received data to the programmed thresholds and generates a wakeup interrupt in case that the data is above the upper threshold or below the lower threshold.

The data buffer block receives 20-bit signed data through high-pass filter, compensation filter, and low-pass filter. The block stores the 20-bit signed data or the clipped 16-bit signed data. And then the block sends the 20-bit signed data or 16-bit signed data to APB-IF once APB read access occurs.

8.7.1.3 External Pins

Table 8.7-2 lists the PDM external pin specifications.

Table 8.7-2 Pin Configuration

External Pin Name	Input/Output	Function	Pin Name in This Section
PDMDATn0	Input	External PDM CH0 data reception pin	PDM_DAT0
PDMDATn1	Input	External PDM CH1 data reception pin	PDM_DAT1
PDMDATn2	Input	External PDM CH2 data reception pin	PDM_DAT2
PDMCLKn0	Output	External PDM CH0 clock output pin	PDM_CLK0
PDMCLKn1	Output	External PDM CH1 clock output pin	PDM_CLK1
PDMCLKn2	Output	External PDM CH2 clock output pin	PDM_CLK2

Note: n = 0, 1

8.7.1.4 Connected Unit

Table 8.7-3 lists the connected units.

Table 8.7-3 Connected Unit

Unit Name	Connected Unit Name	Function of Connected Unit
PDMm	CPG	Clock pulse generator (CPG)
	SYSTEMBUS	System bus
	ICU	Interrupt control unit (ICU)
	PFC	Pin function controller (PFC)

8.7.2 Registers

The register addresses of PDM are given as offsets from the individual base addresses <PDMm_base>. The register base addresses of each PDM are listed in the following table.

Table 8.7-4 Register Base Addresses

Base Address Name	Unit	Base Address
<PDM0_base>	PDM0	0_1104_0000h (5104_0000h*1, 4104_0000h*2)
<PDM1_base>	PDM1	0_1105_0000h (5105_0000h*1, 4105_0000h*2)

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

8.7.2.1 List of Registers

The list of PDM registers and the memory addresses are as follows.

For the actual addresses, the offset values indicated in the following table are added to the base addresses.

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]*1
Channel Software Start Trigger Register	PDMm_PDCSTRTR	0000_0000h	0000h	8, 16, 32
Channel Software Stop Trigger Register	PDMm_PDCSTPTR	0000_0000h	0004h	8, 16, 32
Channel Software Change Trigger Register	PDMm_PDCCHGTR	0000_0000h	0008h	8, 16, 32
Channel Interrupt Control Register	PDMm_PDCICR	0000_0000h	000Ch	8, 16, 32
Channel Status Register	PDMm_PDCSR	0000_0000h	0010h	8, 16, 32
Channel Status Clear Register	PDMm_PDCSCR	0000_0000h	0014h	8, 16, 32
Reserve	-	-	0018h to 001Fh	-
Channel Sound Detection Control Register	PDMm_PDCSDCR	0000_0000h	0020h	8, 16, 32
Channel Data Read Control Register	PDMm_PDCDRCR	0000_0000h	0024h	8, 16, 32
Channel Data Clear Register	PDMm_PDCDCR	0000_0000h	0028h	8, 16, 32
Reserve	-	-	002Ch to 007Fh	-
Version Register	PDMm_PDVR	0000_0010h	0080h	8, 16, 32
Reserve	-	-	0084h to 00FFh	-
Software Start Trigger Register Channel 0	PDMm_PDSTRTRCH0	0000_0000h	0100h	8, 16, 32
Software Stop Trigger Register Channel 0	PDMm_PDSTPTRCH0	0000_0000h	0104h	8, 16, 32
Software Change Trigger Register Channel 0	PDMm_PDCHGTRCH0	0000_0000h	0108h	8, 16, 32
Interrupt Control Register Channel 0	PDMm_PDICRCH0	0000_0000h	010Ch	8, 16, 32
Status Detection Control Register Channel 0	PDMm_PDSDCRCH0	0000_0000h	0110h	8, 16, 32
Status Register Channel 0	PDMm_PDSRCH0	0000_0000h	0114h	8, 16, 32
Status Clear Register Channel 0	PDMm_PDSCRCH0	0000_0000h	0118h	8, 16, 32

Note 1. The read access size is fixed to 32 bits.

8.7.2.2 Register Description

The prefix (PDMm_) of the register names is omitted in this and subsequent sections.

8.7.2.2.1 Channel Software Start Trigger Register (PDMm_PDCSTRTR) (m = 0, 1)

Access Size : 8, 16, 32 bits
Address : <PDMm_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	STRTRG[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0W	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	STRTRG[2:0]	0h	R0W	The read value is always 0b. Channel n start trigger 0b: Do nothing 1b: Start channel n

Note: The read access size is fixed to 32 bits.

8.7.2.2.2 Channel Software Stop Trigger Register (PDMm_PDCSTPTR) (m = 0, 1)

Access Size : 8, 16, 32 bits

Address : <PDMm_base> + 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	STPTRG[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0W	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	STPTRG[2:0]	0h	R0W	The read value is always 0b. Channel n stop trigger 0b: Do nothing 1b: Stop channel n

Note: The read access size is fixed to 32 bits.

8.7.2.2.3 Channel Software Change Trigger Register (PDMm_PDCCHGTR) (m = 0, 1)

Access Size : 8, 16, 32 bits

Address : <PDMm_base> + 0008h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	CHGTRG[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0W	R0W	R0W	R0	R0	R0	R0	R0	R0W	R0W	R0W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
10 to 8	-	All0	R0W	Reserved. This register is readable and the initial value can be written to it.
7 to 3	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	CHGTRG[2:0]	0h	R0W	The read value is always 0b. Channel n change trigger 0b: Do nothing 1b: Change clock (PDM_CLKn) setting

Note: The read access size is fixed to 32 bits.

8.7.2.2.4 Channel Interrupt Control Register (PDMm_PDCICR) (m = 0, 1)

Access Size : 8, 16, 32 bits

Address : <PDMm_base> + 000Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	IEDE[2:0]			-	-	-	-	-	IDRE[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	RW	RW	RW	R0	R0	R0	R0	R0	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	ISDE[2:0]			-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	RW	RW	RW	R0	R0	R0	R0	R0	R0	R0	R0

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
26 to 24	IEDE[2:0]	0h	RW	Channel n error detection interrupt enable bit 0b: Don't allow to issue INT_PDM_ERRn interrupt 1b: Allow to issue INT_PDM_ERRn interrupt
23 to 19	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18 to 16	IDRE[2:0]	0h	RW	Channel n data reception interrupt enable bit 0b: Don't allow to issue INT_PDM_DATn interrupt 1b: Allow to issue INT_PDM_DATn interrupt
15 to 11	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
10 to 8	ISDE[2:0]	0h	RW	Channel n sound detection interrupt enable bit 0b: Don not allow to issue INT_PDM_SDET interrupt when the sound for channel n is detected. 1b: Allow to issue INT_PDM_SDET interrupt when the sound for channel n is detected.
7 to 0	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Note: The read access size is fixed to 32 bits.

8.7.2.2.5 Channel Status Register (PDMm_PDCSR) (m = 0, 1)

Access Size : 8, 16, 32 bits
Address : <PDMm_base> + 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	EDF[2:0]			-	-	-	-	-	DRF[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R	R	R	R0	R0	R0	R0	R0	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	SDF[2:0]			-	-	-	-	-	STATE[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R	R	R	R0	R0	R0	R0	R0	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
26 to 24	EDF[2:0]	0h	R	Channel n error detection flag 0b: Indicates that no data is detected. 1b: Indicates that an error is detected. Refer to the PDSRCHn register for details of errors.
23 to 19	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18 to 16	DRF[2:0]	0h	R	Channel n data reception flag 0b: Indicates that the number of data stored in buffer does not exceed the threshold. 1b: Indicates that the number of data stored in buffer exceeded the threshold.
15 to 11	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
10 to 8	SDF[2:0]	0h	R	Channel n sound detection flag 0b: Indicates that the sound which exceeded the threshold is not detected. 1b: Indicates that the sound which exceeded the threshold is detected.
7 to 3	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	STATE[2:0]	0h	R	Channel n state 0b: Channel n stop 1b: Channel n in operation

Note: The read access size is fixed to 32 bits.

EDFn

[Condition to become “1b”]

- When any error occurs. Refer to the PDSRCHn register for the kind of error.

[Condition to become “0b”]

- When all error flags are cleared by writing the PDSCRCHn, this flag is also cleared.

DRFn

Refer to **8.7.3.7 Data Buffer** for details.

[Condition to become “1b”]

- When PDCDRCR.DATREn = 1b and PDDSRCHn.DATNUM[7:0] is greater than or equal to a threshold which is configured by PDDBCRCHn.DATRITHR[2:0].

[Condition to become “0b”]

- When PDCDRCR.DATREn = 0b or PDDSRCHn.DATNUM[7:0] is less than a threshold.

SDFn

Refer to **8.7.3.6 Sound Detection** for details.

[Conditions to become “1b”]

- When PDCSDCR.SDEn = 1b and a moving average filter result is greater than or equal to PDSDUTRCHn.SDETU[19:0].
- When PDCSDCR.SDEn = 1b and a moving average filter result is less than or equal to PDSDLTRCHn.SDETL[19:0].

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDCSCR.SDFCn).

STATEn

Refer to **8.7.3.2 Channel Start and Channel Stop** for details.

[Condition to become “1b”]

- When “1b” is written to PDCSTRTR.STRTRGn.

[Condition to become “0b”]

- When “1b” is written to PDCSTPTR.STPTRGn.

8.7.2.2.6 Channel Status Clear Register (PDMm_PDCSCR) (m = 0, 1)

Access Size : 8, 16, 32 bits

Address : <PDMm_base> + 0014h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	SDFC[2:0]			-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0W	R0W	R0W	R0	R0	R0	R0	R0	R0	R0	R0

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
10 to 8	SDFC[2:0]	0h	R0W	The read value is always 0b. Channel n sound detection flag clear 0b: Do nothing 1b: Clear PDCSR.SDFn
7 to 0	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Note: The read access size is fixed to 32 bits.

8.7.2.2.7 Channel Sound Detection Control Register (PDMm_PDCSDCR) (m = 0, 1)

Access Size : 8, 16, 32 bits

Address : <PDMm_base> + 0020h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	SDE[2:0]		
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2 to 0	SDE[2:0]	0h	RW	Channel n sound detection enable bit 0b: Do not allow to detect sound 1b: Allow to detect sound

Note: The read access size is fixed to 32 bits.

8.7.2.2.8 Channel Data Read Control Register (PDMm_PDCDRCR) (m = 0, 1)

Access Size : 8, 16, 32 bits

Address : <PDMm_base> + 0024h

Initial Value : 0000_0000h

Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27	BFOWDF	0h	R	Buffer overwriting detection flag 0b: Indicates that buffer overwriting does not occur. 1b: Indicates that buffer overwriting occurred.
26 to 19	-	All0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18	OVUDF	0h	R	Overvoltage upper limit exceeded detection flag 0b: Indicates that the data is not above the upper limit 1b: Indicates that the data has exceeded the upper limit
17	OVLDF	0h	R	Overvoltage lower limit exceeded detection flag 0b: Indicates that the data is not below the lower limit 1b: Indicates that the data has falling below the lower limit
16	SCDF	0h	R	Short circuit detection flag 0b: Indicates that the PDM_DATn pin short circuit is not detected 1b: Indicates that a short circuit on the PDM_DATn pin has been detected
15 to 3	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
2	DRF	0h	R	Data reception flag 0b: Indicates that the number of data stored in buffer is less than a threshold 1b: Indicates that the number of data stored in buffer is greater than or equal to a threshold
1	SDF	0h	R	Sound detection flag 0b: Indicates that the sound is not detected 1b: Indicates that the sound is detected
0	STATE	0h	R	State 0b: Channel stop 1b: Channel in operation

Note: The read access size is fixed to 32 bits.

BFOWDF

Refer to **8.7.3.7 Data Buffer** for details.

[Condition to become “1b”]

- When PDSDCRCHn.BFOWDE = 1b and data buffer is full and data is written to the buffer without reading.

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDSCRCHn.BFOWDFC).

OVUDF

Refer to **8.7.3.9 Overvoltage Detection** for details.

[Condition to become “1b”]

- When PDSDCRCHn.OVUDE = 1b and a clipped sinc filter result is larger than an upper limit (PDOVUTRCHn.OVDU[19:0]).

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDSCRCHn.OVUDFC).

OVLDF

Refer to **8.7.3.9 Overvoltage Detection** for details.

[Condition to become “1b”]

- When PDSDCRCHn.OVLDE = 1b and a clipped sinc filter result is smaller than a lower limit (PDOVLTRCHn.OVDL[19:0]).

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDSCRCHn.OVLDFC).

SCDF

Refer to **8.7.3.8 Short-Circuit Detection** for details.

[Conditions to become “1b”]

- When PDSDCRCHn.SCDE = 1b and 1b is continuously input to the PDM_DATn pin, exceeding the number of times set in PDSCTSRCHn.SCDH[12:0].
- When PDSDCRCHn.SCDE = 1b and 0b is continuously input to the PDM_DATn pin, exceeding the number of times set in PDSCTSRCHn.SCDL[12:0].

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDSCRCHn.SCDFC).

DRF

Refer to **8.7.3.7 Data Buffer** for details.

[Condition to become “1b”]

- When PDDRCRCHn.DATRE = 1b and PDDSRCHn.DATNUM[7:0] is greater than or equal to a threshold which is configured by PDDBCRCHn.DATRITHR[2:0].

[Condition to become “0b”]

- When PDDRCRCHn.DATRE = 0b or PDDSRCHn.DATNUM[7:0] is less than a threshold.

SDF

Refer to **8.7.3.6 Sound Detection** for details.

[Conditions to become “1b”]

- When PDSDCRCHn.SDE = 1b and a moving average filter result is PDSDUTRCHn.SDETU[19:0] or greater.
- When PDSDCRCHn.SDE = 1b and a moving average filter result is PDSDLTRCHn.SDETL[19:0] or less.

[Condition to become “0b”]

- When writing 1b to a flag clear register bit (PDSCRCHn.SDFC).

STATE

Refer to **8.7.3.2 Channel Start and Channel Stop** for details.

[Condition to become “1b”]

- When “1b” is written to PDSTRTRCHn.STRTRG.

[Condition to become “0b”]

- When “1b” is written to PDSTPTRCHn.STPTRG.

8.7.2.2.17 Status Clear Register Channel n (PDMm_PDSCRCHn) (m = 0 to 1, n = 0 to 2)

Access Size : 8, 16, 32 bits

Address : <PDMm_base> + 0118h + n × 0100h

Initial Value : 0000_0000h

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	DBIS[3:0]	0h	RW	Data buffer input shift setting 0000b: 20-bit mode, {1{S},[18:0]} 0001b: 20-bit mode, {2{S},[18:1]} 0010b: 20-bit mode, {3{S},[18:2]} 0011b: 20-bit mode, {4{S},[18:3]} (0100b-0111b: Setting prohibited) 1000b: 16-bit mode, {S,D[18:4]} 1001b: 16-bit mode, {S,D[17:3]} 1010b: 16-bit mode, {S,D[16:2]} 1011b: 16-bit mode, {S,D[15:1]} 1100b: 16-bit mode, {S,D[14:0]} (1101b-1111b: Setting prohibited) *S: Sign bit
27, 26	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25, 24	SDMAMD[1:0]	0h	RW	Moving average mode for sound detection data 00b: 1-order (filter is skipped) (default) 01b: 2-order 10b: 4-order 11b: Setting prohibited
23 to 21	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	-	0h	RW	Reserved This register is readable and the initial value can be written to it.
19	-	0h	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
18	-	0h	RW	Reserved This register is readable and the initial value can be written to it.
17, 16	LFIS[1:0]	0h	RW	Low-pass (half-band decimation) filter input shift setting 00b: No shift 01b: 1-bit right shift 10b: 2-bit right shift 11b: 3-bit right shift
15	-	0h	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
14	-	0h	RW	Reserved This register is readable and the initial value can be written to it.
13, 12	CFIS[1:0]	0h	RW	Compensation filter input shift setting 00b: No shift 01b: 1-bit right shift 10b: 2-bit right shift 11b: 3-bit right shift

Bit	Bit Name	Initial Value	R/W	Description
11	-	0h	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
10	-	0h	RW	Reserved This register is readable and the initial value can be written to it.
9, 8	HFIS[1:0]	0h	RW	High-pass filter input shift setting 00b: No shift 01b: 1-bit right shift 10b: 2-bit right shift 11b: 3-bit right shift
7	-	0h	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
6 to 4	SFMD[2:0]	0h	RW	Sinc filter mode setting 001b: 1-order 010b: 2-order 011b: 3-order Other: 4-order (default)
3 to 1	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	INPSEL	0h	RW	Input data select 0b: Rise-edge data of channel n 1b: Fall-edge data of channel n-1 (In case of n = 0, fall-edge data of channel 2 is selected.)

Note: The read access size is fixed to 32 bits.

8.7.2.2.19 Sinc Filter Control Register Channel n (PDMm_PDSFCRCHn) (m = 0 to 1, n = 0 to 2)

See **Table 8.7-8** for the setting values of SINCDEC[7:0] and SINCRNG[4:0].

Access Size : 8, 16, 32 bits
Address : <PDMm_base> + 0124h + n × 0100h
Initial Value : 057C_0000h

R/W	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	R0	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
28 to 24	SINCRNG[4:0]	5h	RW	Sinc filter output valid range 00000b: {S, [32:14]} 10000b: {S, [16:0],00b} 00001b: {S, [31:13]} 10001b: {S, [15:0],000b} 00010b: {S, [30:12]} 10010b: {S, [14:0],0000b} 00011b: {S, [29:11]} 10011b: {S, [13:0],00000b} 00100b: {S, [28:10]} 10100b: {S, [12:0],000000b} 00101b: {S, [27:9]} (default) 10101b: {S, [11:0],0000000b} 00110b: {S, [26:8]} 10110b: {S, [10:0],00000000b} 00111b: {S, [25:7]} 10111b: {S, [9:0],000000000b} 01000b: {S, [24:6]} 11000b: {S, [8:0],0000000000b} 01001b: {S, [23:5]} 11001b: {S, [7:0],00000000000b} 01010b: {S, [22:4]} 11010b: {S, [6:0],000000000000b} 01011b: {S, [21:3]} 11011b: {S, [5:0],0000000000000b} 01100b: {S, [20:2]} 11100b: {S, [4:0],00000000000000b} 01101b: {S, [19:1]} 11101b: {S, [3:0],000000000000000b} 01110b: {S, [18:0]} 11110b: {S, [2:0],0000000000000000b} 01111b: {S, [17:0], 0b} 11111b: {S, [1:0],00000000000000000b} (prohibited) S: Signed bit. When the overflow occurs, 7FFFFh is output. When the underflow occurs, 80000h is output.
23 to 16	SINCDEC[7:0]	7Ch	RW	Sinc filter decimation ratio M indicates the decimation ratio. Decimation ratio M is set as follows. M = SINCDEC + 1 00h: M = 1 (prohibited) 01h: M = 2 (prohibited) 02h: M = 3 (prohibited) 03h: M = 4 … 7Ch: M = 125 (default) ... FFh: M = 256 Setting a value less than M = 4 is prohibited. If such a value is set, operation of the sinc filter is not guaranteed. The setting should satisfy D*M > 12. Otherwise, operation of other filters is not guaranteed. (D: PDM_CLKn's division ratio)
15 to 4	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	CKDIV[3:0]	0h	RW	PDM_CLKn's division ratio to core clock 0000b: 1/2 (default) 0001b: 1/4 0010b: 1/6 ... 1101b: 1/28 1110b: 1/30 1111b: 1/32

Note: The read access size is fixed to 32 bits.

8.7.2.2.20 High-Pass Filter Coefficient s(0) Register Channel n (PDMm_PDHFCS0RCHn) (m = 0 to 1, n = 0 to 2)

Access Size : 8, 16, 32 bits

Address : <PDMm_base> + 0128h + n × 0100h

Initial Value : 0000_3F61h

	-	-	-	-	-	-	-	-	DATNUM[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R0	R0	R0	R0	R0	R0	R0	R0	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All0	R0	Reserved Whenever it is read, 0b is read. The written value will be ignored.
7 to 0	DATNUM[7:0]	0h	R	Number of data stored in buffer When PDDRCRCHn.DATRE = 0b, 0b is read out. When PDDRCRCHn.DATRE = 1b, the number of data stored in buffer is read out. In case that buffer size is 64 stages, the maximum value is 63.

Note: The read access size is fixed to 32 bits.

8.7.2.3 Mirroring Register

The common registers except for the version register have mirroring registers in each channel. PDCSR.EDFn is a register which ORs all the error flags of the mirroring registers in each channel.

Use the common registers for synchronous control between channels.

Table 8.7-5 Mirroring Register

Common Register		Mirroring Register in Each Channel	
Register Name	Bit Name	Register Name	Bit Name
PDCSTRTR	STRTRGn	PDSTRTRCHn	STRTRG
PDCSTPTR	STPTRGn	PDSTPTRCHn	STPTRG
PDCCHGTR	CHGTRGn	PDCHGTRCHn	CHGTRG
PDCICR	ISDEn	PDICRCHn	ISDE
	IDREn		IDRE
	IEDEn		IEDE
PDCSR	STATEn	PDSRCHn	STATE
	SDFn		SDF
	DRFn		DRF
	EDFn		SCDF or OVLDF or OVUDF or BFOWDF
PDCSCR	SDFCn	PDSCRCHn	SDFC
PDCSDCR	SDEn	PDSDCRCHn	SDE
PDCDRCR	DATREn	PDDRCRCHn	DATRE
PDCDCR	DATCn	PDDCRCHn	DATC

8.7.3 Operation

This section describes the PDM basic control method. See **8.7.4.6 Setting PDM_CLKn (n = 0, 1, 2) Frequency and Sampling Frequency Generated by the Unit** for information on setting the PDM_CLKn (n = 0, 1, 2) frequency and the sampling frequency generated by the PDM unit, and see **8.7.4.7 DMA Transfer Method** for information on transferring data with the DMA master.

8.7.3.1 Clock Specifications

The frequency-divided core clock is generated and output to PDM_CLKn.

Table 8.7-6 lists the guaranteed clock frequency and clock mode in PDM-IF. Core clock (CCLK) and PCLK are asynchronous.

Table 8.7-6 Guaranteed Clock Frequency and Clock Mode

CCLK	PCLK PCLK_SFR	PDM_CLKn		
Frequency (MHz)	Frequency (MHz)	Frequency (MHz)	Supported Core Clock Division Ratio	Setting Value (PDSFCRCHn.CKDIV[3:0])
4.8	1 to 100	2.4	2	0000b
		1.2	4	0001b
		0.8	6	0010b
		0.6	8	0011b
		0.48	10	0100b
		0.4	12	0101b
		0.34	14	0110b
		0.3	16	0111b
		0.27	18	1000b
		0.24	20	1001b
		0.22	22	1010b
		0.2	24	1011b
		0.18	26	1100b
		0.17	28	1101b
		0.16	30	1110b
		0.15	32	1111b

8.7.3.2 Channel Start and Channel Stop

The channel start and the channel stop is controlled by the registers listed in **Table 8.7-7**.

Set the channels to be synchronized to 1 at the same time by using the common registers.

Set the channel start according to **8.7.4.1 Start Flow**.

Set the channel stop according to **8.7.4.2 Stop Flow**.

Table 8.7-7 Channel Start Trigger and Channel Stop Trigger

	Register Bit Name	
Category	Common Register	Channel Register
Channel start	PDCSTRTR.STRTRG0	PDSTRTRCH0.STRTRG
	PDCSTRTR.STRTRG1	PDSTRTRCH1.STRTRG
	PDCSTRTR.STRTRG2	PDSTRTRCH2.STRTRG
Channel stop	PDCSTPTR.STPTRG0	PDSTPTRCH0.STPTRG
	PDCSTPTR.STPTRG1	PDSTPTRCH1.STPTRG
	PDCSTPTR.STPTRG2	PDSTPTRCH2.STPTRG

8.7.3.3 PDM_CLKn's Frequency Change

The external microphone transitions the power mode according to the input clock frequency. PDM-IF enables the transition of microphone's power mode by changing PDM_CLKn's operating frequency which is output to the microphone when operating. The PDM_CLKn's operating frequency can be changed by using the PDSFCRCHn.CKDIV[3:0] bits. When the frequency is changed, the decimation ratio of the sinc filter also needs to be changed. Set PDSFCRCHn.SINCDEC[7:0] in accordance with the sampling frequency after the decimation. Furthermore, when the decimation ratio of the sinc filter is changed, its output range is changed. Set PDSFCRCHn.SINCRNG[4:0] together in accordance with the output range. Refer to **Table 8.7-8**, which lists example settings when the sampling frequency after the decimation is 30 kHz*[1].

For the method of calculating the set values of PDSFCRCHn.CKDIV[3:0], PDSFCRCHn.SINCDEC[7:0], and PDSFCRCHn.SINCRNG[4:0] for the expected sampling frequency of PDM_CLKn, refer to **8.7.4.6 Setting PDM_CLKn (n = 0, 1, 2) Frequency and Sampling Frequency Generated by the Unit**.

After changing the configuration of these registers, software needs to wait for the settling time of microphone and PDM-IF channel. Refer to **8.7.4.4 Low Power Mode Transition Flow** and **8.7.4.5 Normal Mode Transition Flow** for details.

Note 1. If the same filter coefficient has been set in filtering after the sinc filter, the characteristics of the filter changes with the change of the sampling frequency.

8.7.3.4 Filter

8.7.3.4.1 Data Clipping and Shifting between Filters

Voice sample data is clipped or shifted between filters. **Figure 8.7-2** shows this operation.

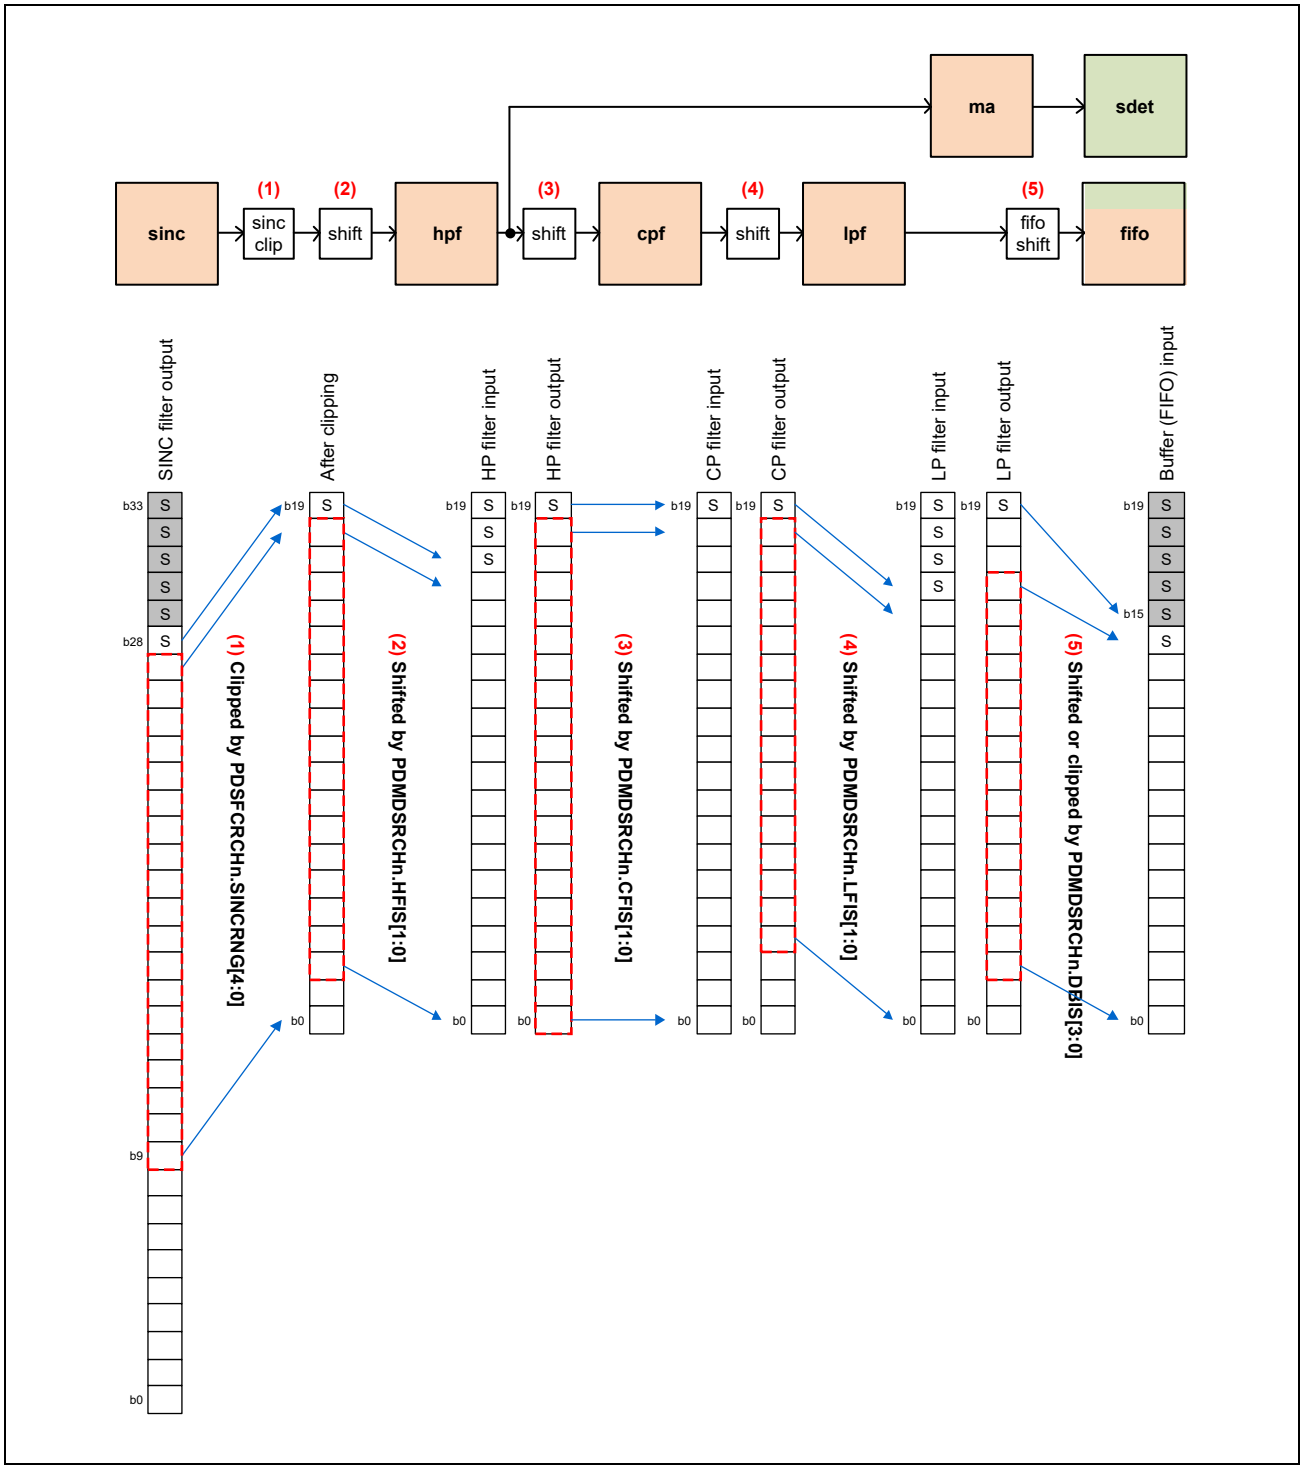

Figure 8.7-2 Data Clipping and Shifting between Filters

a) Sinc filter output clip

It is controlled by PDSFCRCHn.SINCRNG[4:0].

Table 8.7-8 lists the possible combinations of settings when the sampling frequency is 30 kHz.

Table 8.7-8 Sinc Filter Output Clip (1/2)

CCLK (MHz)	Sinc Filter Order	PDMDSRCHn. SFMD[2:0]	PDM_CLK's Division Ratio	PDSFCRCHn. CKDIV[3:0]	Sinc filter Decimation Ratio	PDSFCRCHn. SINCDEC[7:0]	Sinc Filter Output Effective Bits	Sinc Filter Output Clipping (20 bits)	PDSFCRCHn. SINCRNG[4:0]	Resolution	PDM_CLKn Frequency (MHz)	PDMIF Output Sampling Frequency (kHz)

			22	Ah	4	3h	b3 to b0	b3 to b0, 00000000000000000b	11110b	10	0.22	27.27

An overflow or an underflow never occurs as long as the combinations which are shown in **Table 8.7-8** are set to PDMDSRCHn.SFMD[2:0], PDSFCRCHn.CKDIV[3:0], PDSFCRCHn.SINCDEC[7:0] and PDSFCRCHn.SINCRNG[4:0]. However, when other combinations are set to them, the overflow or the underflow might occur. When the overflow occurs, 7FFFFh is output. When the underflow occurs, 80000h is output. Use the overvoltage detection function if you want to know if the overflow or the underflow occurs.

b) High-pass filter input shift

The clipped sinc filter output is right-shifted and input to the high-pass filter.

It is controlled by PDMDSRCHn.HFIS[1:0].

Table 8.7-9 High-Pass Filter Input Shift

PDMDSRCHn.HFIS[1:0]	Function	Shifted Data*1
0h	No shift	S, b18-b0
1h	1-bit right-shift	S, S, b18-b1
2h	2-bit right-shift	S, S, S, b18-b2
3h	3-bit right-shift	S, S, S, S, b18-b3

Note 1. S: Signed bit (= bit 19)

c) Compensation filter input shift

The high-pass filter output is right-shifted and input to the compensation filter.

It is controlled by PDMDSRCHn.CFIS[1:0].

Table 8.7-10 Compensation Filter Input Shift

PDMDSRCHn.CFIS[1:0]	Function	Shifted Data*1
0h	No shift	S, b18-b0
1h	1-bit right-shift	S, S, b18-b1
2h	2-bit right-shift	S, S, S, b18-b2
3h	3-bit right-shift	S, S, S, S, b18-b3

Note 1. S: Signed bit (= bit 19)

d) Low-pass filter input shift

The compensation filter output is right-shifted and input to the low-pass (half-band decimation) filter.

It is controlled by PDMDSRCHn.LFIS[1:0].

Table 8.7-11 Low-Pass Filter Input Shift

PDMDSRCHn.LFIS[1:0]	Function	Shifted Data*1
0h	No shift	S, b18-b0
1h	1-bit right-shift	S, S, b18-b1
2h	2-bit right-shift	S, S, S, b18-b2
3h	3-bit right-shift	S, S, S, S, b18-b3

Note 1. S: Signed bit (= bit 19)

e) Buffer input shift or clip

The compensation filter output is right-shifted, or 16-bit data is clipped from the compensation filter output. Then, the shifted or clipped data is input to buffer.

It is controlled by PDMDSRCHn.DBIS[3:0].

Table 8.7-12 Buffer Input Shift or Clip

PDMDSRCHn.DBIS[3:0]	Function	Valid Data Width	Shifted or Clipped Data*1
0000b	No shift	20-bit	S, b18-b0
0001b	1-bit right-shift	20-bit	S, S, b18-b1
0010b	2-bit right-shift	20-bit	S, S, S, b18-b2
0011b	3-bit right-shift	20-bit	S, S, S, S, b18-b3
1000b	Signed bit and b18-b4 is clipped	16-bit	S, b18-b4
1001b	Signed bit and b17-b3 is clipped*2	16-bit	S, b17-b3
1010b	Signed bit and b16-b2 is clipped*2	16-bit	S, b16-b2
1011b	Signed bit and b15-b1 is clipped*2	16-bit	S, b15-b1
1100b	Signed bit and b14-b0 is clipped*2	16-bit	S, b14-b0

Note 1. S: Signed bit (= bit 19)

Note 2. When an overflow occurs, 7FFFh is input to the buffer.
When an underflow occurs, 8000h is input to the buffer.

8.7.3.4.2 Sinc Filter

The operating clock of the sinc filter is CCLK. Sinc filter is operated by using the 1-bit stream data latched with PDM_CLKn's rise-edge or fall-edge. Refer to **8.7.3.5 Data Input Control for Stereo Sound** for details.

Figure 8.7-3 shows a sinc filter block diagram.

The differentiation stage is operated by decimation clock (the frequency is 1/M of PDM_CLKn). M is the decimation ratio and is set in the PDSFCRCHn.SINCDEC[7:0] bits. The filter result is output in register every decimation clock.

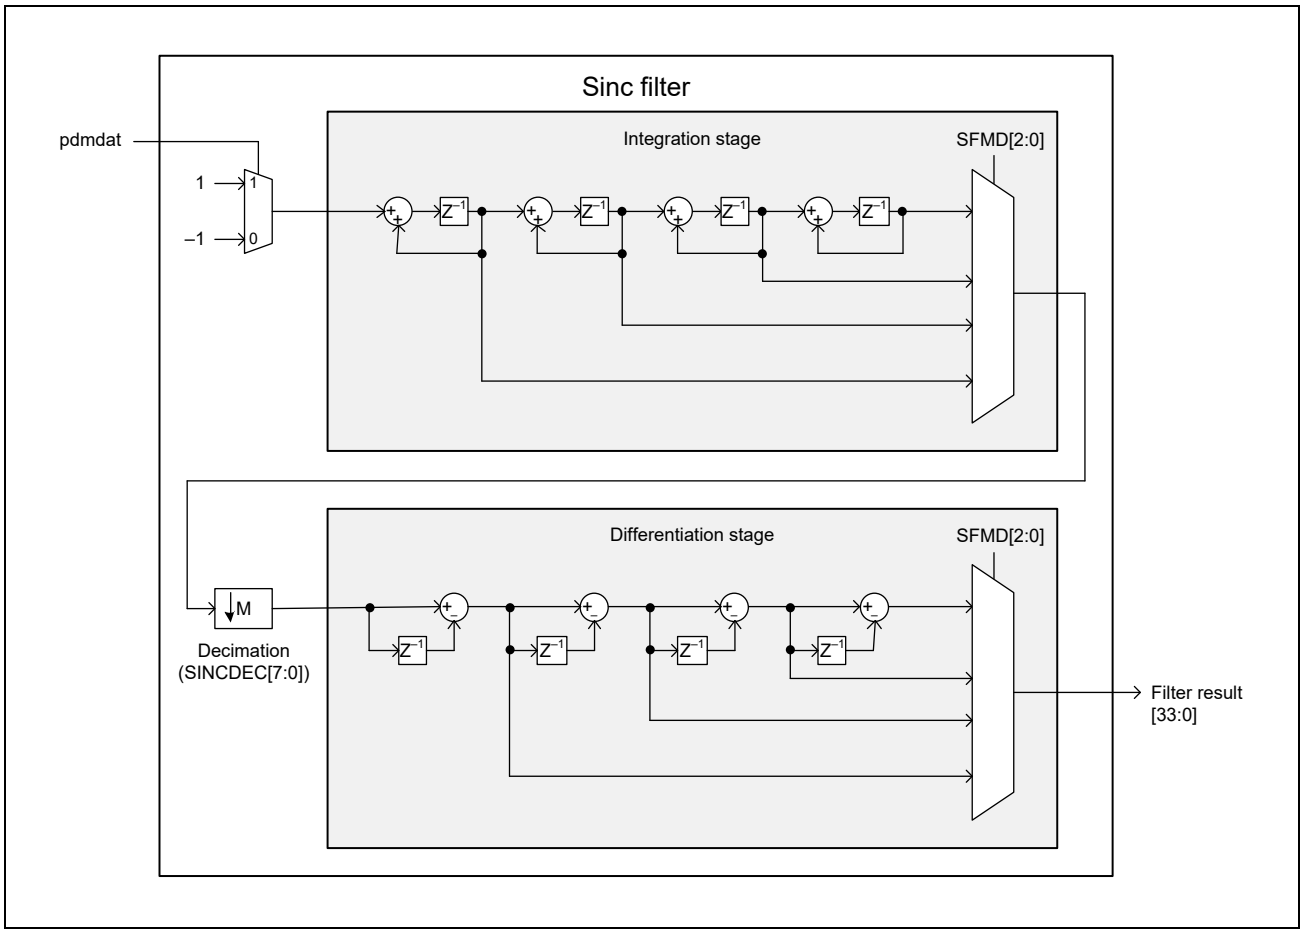

Figure 8.7-3 Sinc Filter Block Diagram

8.7.3.4.3 High-Pass Filter

The operating clock of the high-pass filter is CCLK. The high-pass filter is operated by using the result of the sinc filter.

Figure 8.7-4 shows a high-pass filter block diagram.

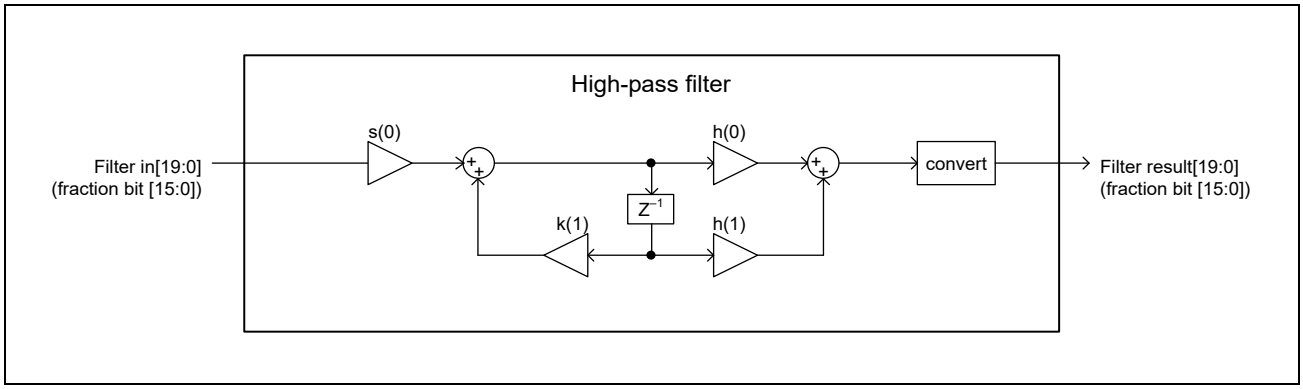

Figure 8.7-4 High-Pass Filter Block Diagram

Table 8.7-13 lists the high-pass filter specification.

Table 8.7-13 High-Pass Filter Specification

Function		Specification
Input	Bit width	Signed 20-bit (fraction 16-bit)
Output	Bit width	Signed 20-bit (fraction 16-bit)
Coefficient	Bit width	Signed 16-bit (fraction 14-bit) Refer to **8.7.2.2.20 High-Pass Filter Coefficient s(0) Register Channel n (PDMm_PDHFCS0RCHn) (m = 0 to 1, n = 0 to 2)**, **8.7.2.2.21 High-Pass Filter Coefficient k(1) Register Channel n (PDMm_PDHFCK1RCHn) (m = 0 to 1, n = 0 to 2)**, and **8.7.2.2.22 High-Pass Filter Coefficient h(p) Register Channel n (PDMm_PDHFCHpRCHn) (m = 0 to 1, n = 0 to 2, p = 0 to 1)** for details.
Delay Z	Bit width	Signed 32-bit (fraction 18-bit)
Multiplier	Input A bit width	Signed 32-bit (fraction 18-bit)
	Input B bit width	Signed 16-bit (fraction 14-bit)
	Output bit width	Signed 47-bit (fraction 32-bit)
Adder	Input A bit width	Signed 32-bit (fraction 18-bit)
	Input B bit width	Signed 32-bit (fraction 18-bit)
	Output bit width	Signed 33-bit (fraction 18-bit)
Output conversion	Input bit width	Signed 32-bit (fraction 18-bit)
	Output bit width	Signed 20-bit (fraction 16-bit)
Excessive fraction bits processing		Excessive fraction bits are rounded down at functional unit input or final output.

8.7.3.4.4 Compensation Filter

The operating clock of the compensation filter is CCLK. The compensation filter is operated by using the result of the high-pass filter.

Figure 8.7-5 shows a compensation filter block diagram.

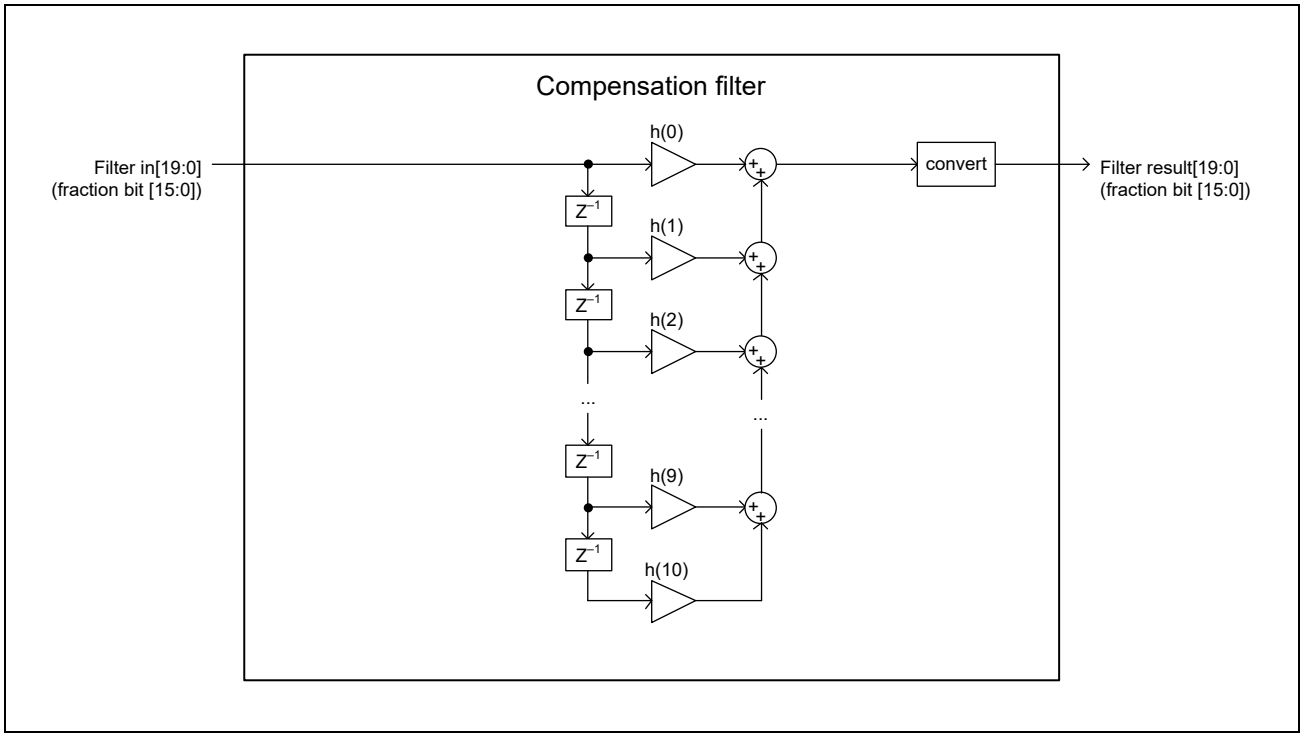

Figure 8.7-5 Compensation Filter Block Diagram

Table 8.7-14 shows a compensation filter specification.

Table 8.7-14 Compensation Filter Specification

Function		Specification
Input	Bit width	Signed 20-bit (fraction 16-bit)
Output	Bit width	Signed 20-bit (fraction 16-bit)
Coefficient	Bit width	Signed 13-bit (fraction 11-bit) Refer to **8.7.2.2.23 Compensation Filter Coefficient h(p) Register Channel n (PDMm_PDCFCHpRCHn) (m = 0 to 1, n = 0 to 2, p = 00 to 10)** for details.
Delay Z	Bit width	Signed 20-bit (fraction 16-bit)
Multiplier	Input A bit width	Signed 20-bit (fraction 16-bit)
	Input B bit width	Signed 13-bit (fraction 11-bit)
	Output bit width	Signed 32-bit (fraction 27-bit)
Adder	Input A bit width	Signed 22-bit (fraction 18-bit)
	Input B bit width	Signed 22-bit (fraction 18-bit)
	Output bit width	Signed 23-bit (fraction 18-bit)
Output conversion	Input bit width	Signed 22-bit (fraction 18-bit)
	Output bit width	Signed 20-bit (fraction 16-bit)
Excessive fraction bits processing		Excessive fraction bits are rounded down at functional unit input or final output.

8.7.3.4.5 Low-Pass (Half-Band Decimation) Filter

The operating clock of the low-pass filter is CCLK. The low-pass filter is operated by using the result of the compensation filter. Output data is decimated to a half of input data.

Figure 8.7-6 shows a low-pass filter block diagram.

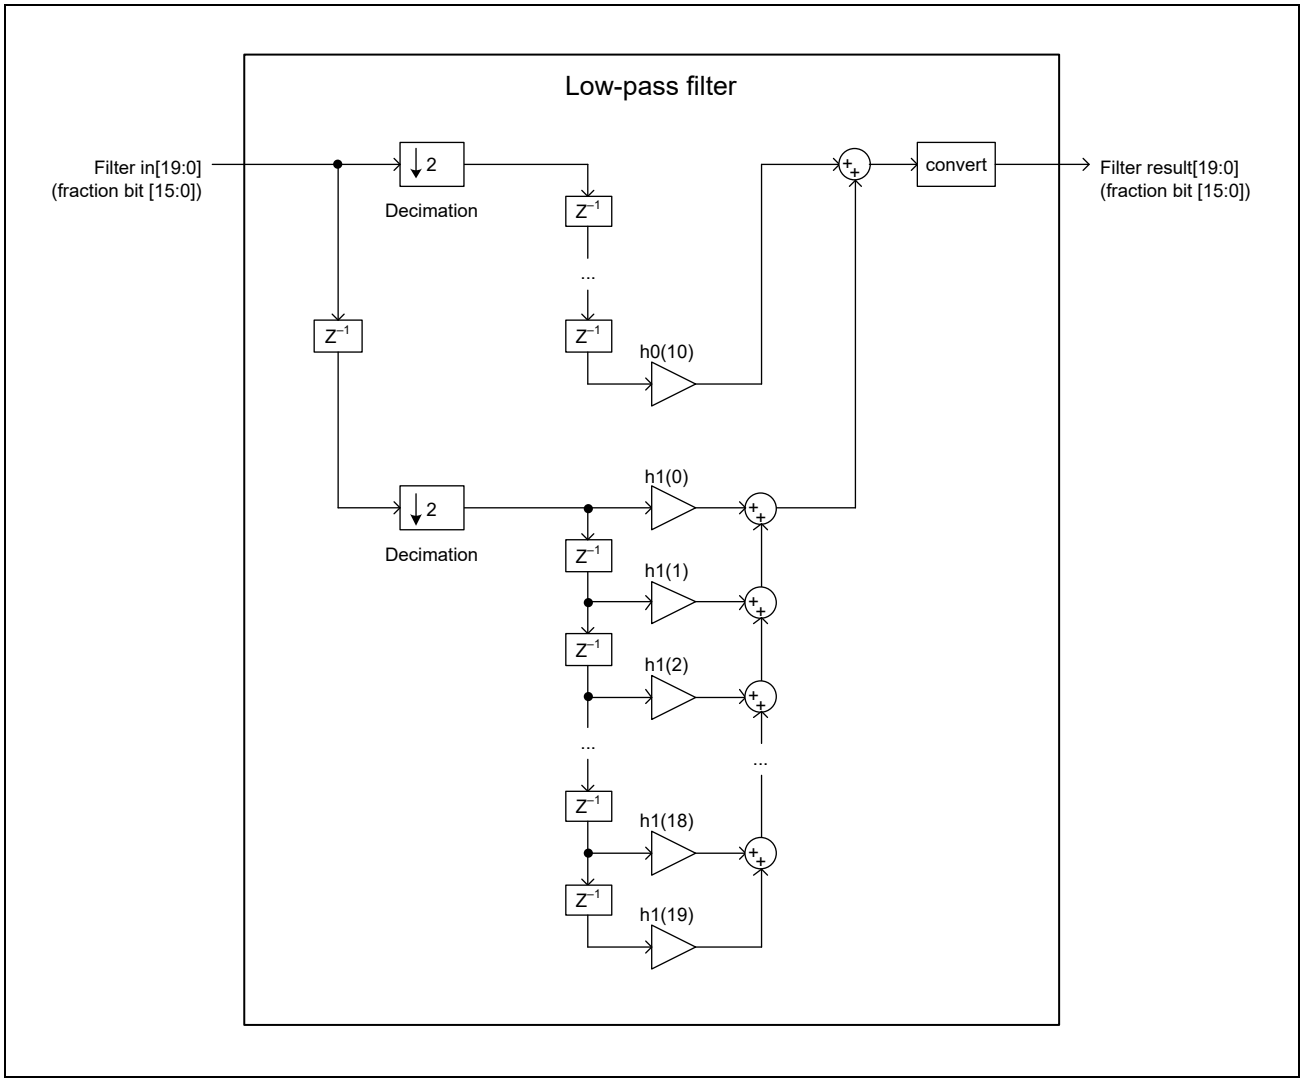

Figure 8.7-6 Low-Pass Filter Block Diagram

Table 8.7-15 lists a low-pass filter specification.

Table 8.7-15 Low-Pass Filter Specification

Function		Specification
Input	Bit width	Signed 20-bit (fraction 16-bit)
Output	Bit width	Signed 20-bit (fraction 16-bit)
Coefficient	Bit width	Signed 13-bit (fraction 11-bit) Refer to **8.7.2.2.24 Low-Pass Filter Coefficient h0(10) Register Channel n (PDMm_PDLFCH010RCHn) (m = 0 to 1, n = 0 to 2)** and **8.7.2.2.25 Low-Pass Filter Coefficient h1(p) Register Channel n (PDMm_PDLFCH1pRCHn) (m = 0 to 1, n = 0 to 2, p = 0 to 19)** for details.
Delay Z	Bit width	Signed 20-bit (fraction 16-bit)
Multiplier	Input A bit width	Signed 20-bit (fraction 16-bit)
	Input B bit width	Signed 13-bit (fraction 11-bit)
	Output bit width	Signed 32-bit (fraction 27-bit)
Adder	Input A bit width	Signed 22-bit (fraction 18-bit)
	Input B bit width	Signed 22-bit (fraction 18-bit)
	Output bit width	Signed 23-bit (fraction 18-bit)
Output conversion	Input bit width	Signed 22-bit (fraction 18-bit)
	Output bit width	Signed 20-bit (fraction 16-bit)
Excessive fraction bits processing		Excessive fraction bits are rounded down at functional unit input or final output.

8.7.3.4.6 Moving Average Filter

The operating clock of the moving average filter is CCLK. The moving average filter is operated by using the result of the high-pass filter. The order of the moving average filter can be changed by the setting of the PDMDSRCHn.SDMAMD[1:0] bits.

Figure 8.7-7 shows a moving average filter block diagram.

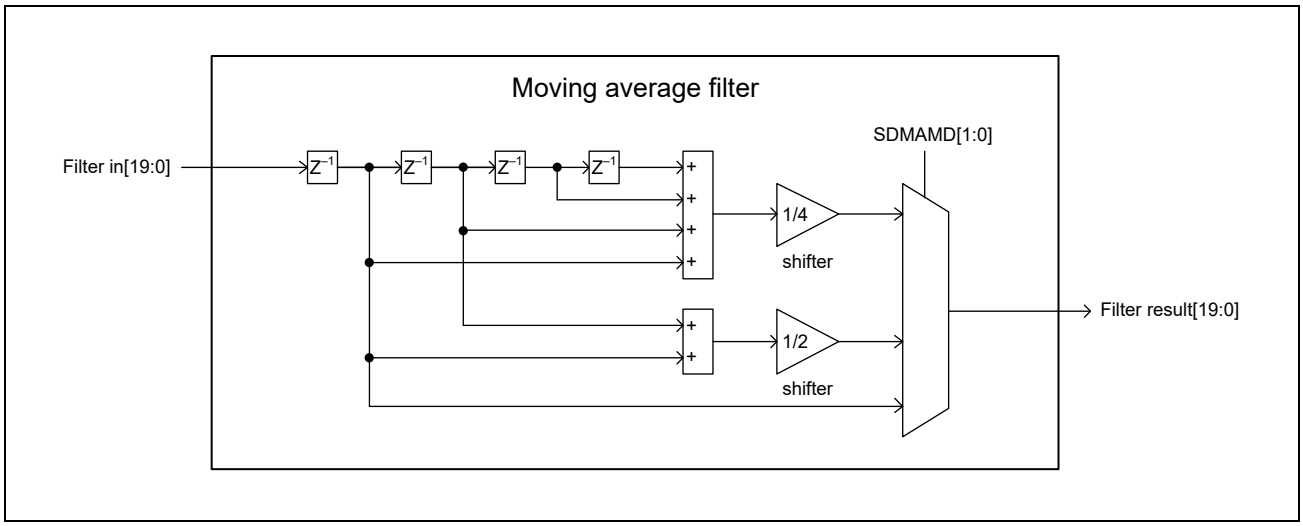

Figure 8.7-7 Moving Average Filter Block Diagram

Table 8.7-16 lists a moving average filter specification.

Table 8.7-16 Moving Average Filter Specification

Function		Specification
Input	Bit width	Signed 20-bit (fraction 16-bit)
Output	Bit width	Signed 20-bit (fraction 16-bit)
Delay Z	Bit width	Signed 20-bit (fraction 16-bit)
Excessive fraction bits processing		Excessive fraction bits are rounded down at shifter.

8.7.3.4.7 Settling Time of Channel Activation / Setting Change

The settling time of channel activation is the time after a start trigger PDCSTRTR.STRTRGn (or PDSTRTRCHn.STRTRG) is set before the filter result is stable and output. The settling time of channel setting change is the time after a change trigger PDCCHGTR.CHGTRGn (or PDCHGTRCHn.CHGTRG) is set before the filter result is stable and output. **Figure 8.7-8** shows the settling time measurement point.

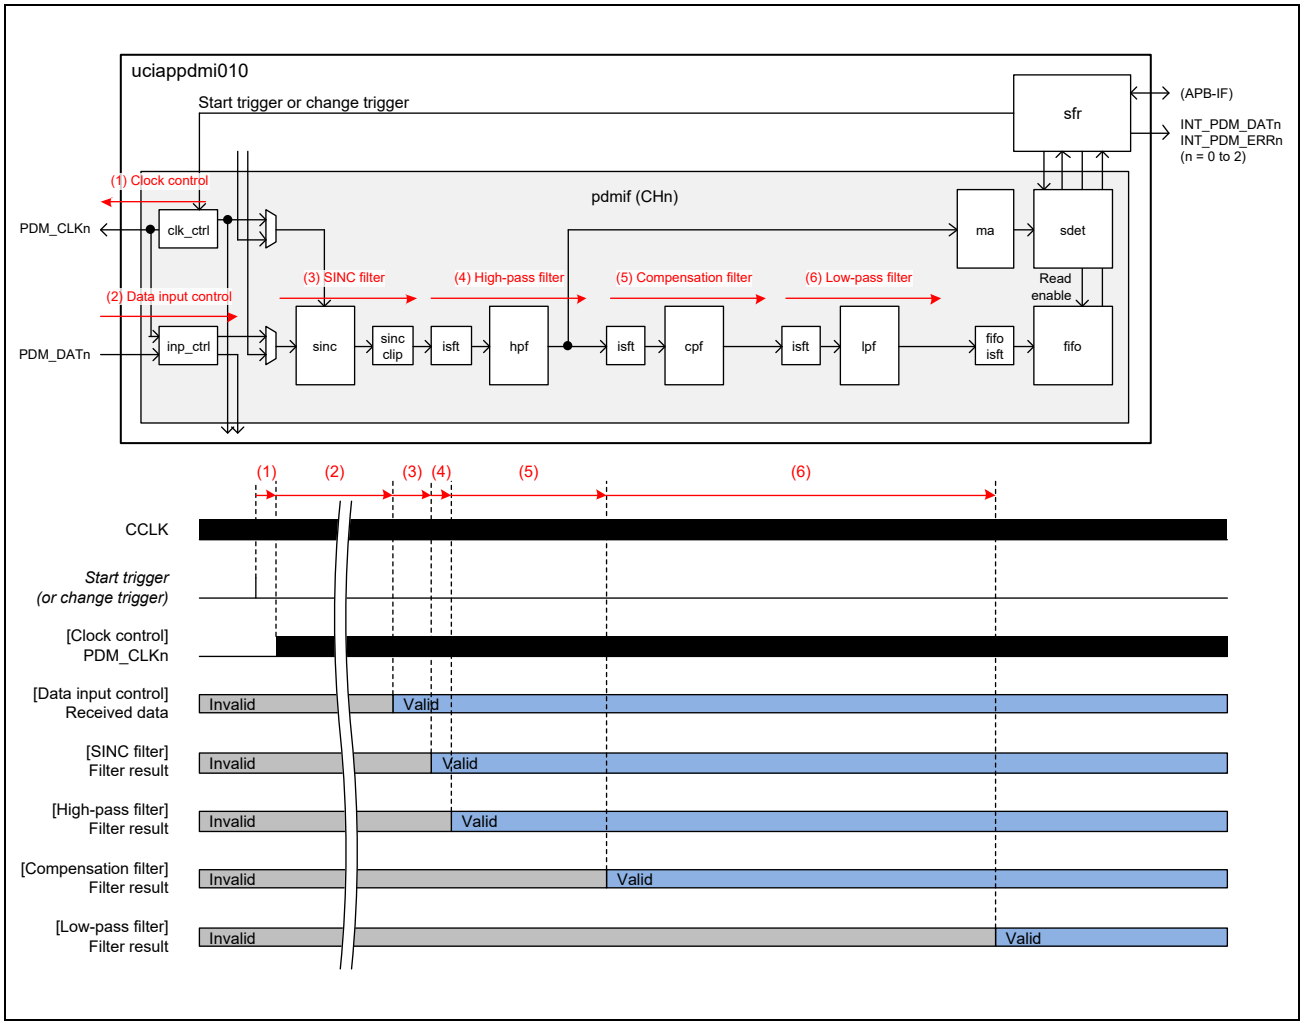

Figure 8.7-8 Settling Time of Channel Activation

The settling time is calculated as shown in **Table 8.7-17**.

Table 8.7-17 Settling Time of Channel Activation / Setting Change

No.	Function	Settling Time	
		Channel Activation	Channel Setting Change
(1)	Clock control	(4 + (D/2)) × Cp	(3 + Do + (D/2)) × Cp
(2)	Data input control	(D/2) × Cp + (Stable time for microphone*1)	
(3)	Sinc filter	(K × D × M) × Cp	
(4)	High-pass filter	(D × M + 5) × Cp	
(5)	Compensation filter	(10 × D × M + 12) × Cp	
(6)	Low-pass filter	(38 × D × M + 22) × Cp	

Note: Cp: CCLK period
D: PDM_CLKn's division ratio
Do: PDM_CLKn's division ratio (old setting)
K: Sinc filter order
M: Sinc filter decimation ratio

Note 1. Wakeup time from low power mode, Switching time, etc. Refer to the datasheet of microphone for details.

8.7.3.5 Data Input Control for Stereo Sound

The microphone which supports the stereo sound outputs the right sound synchronized with PDM_CLKn's rise-edge and the left sound synchronized with PDM_CLKn's fall-edge.

PDM-IF can process the right sound and the left sound using different channels.

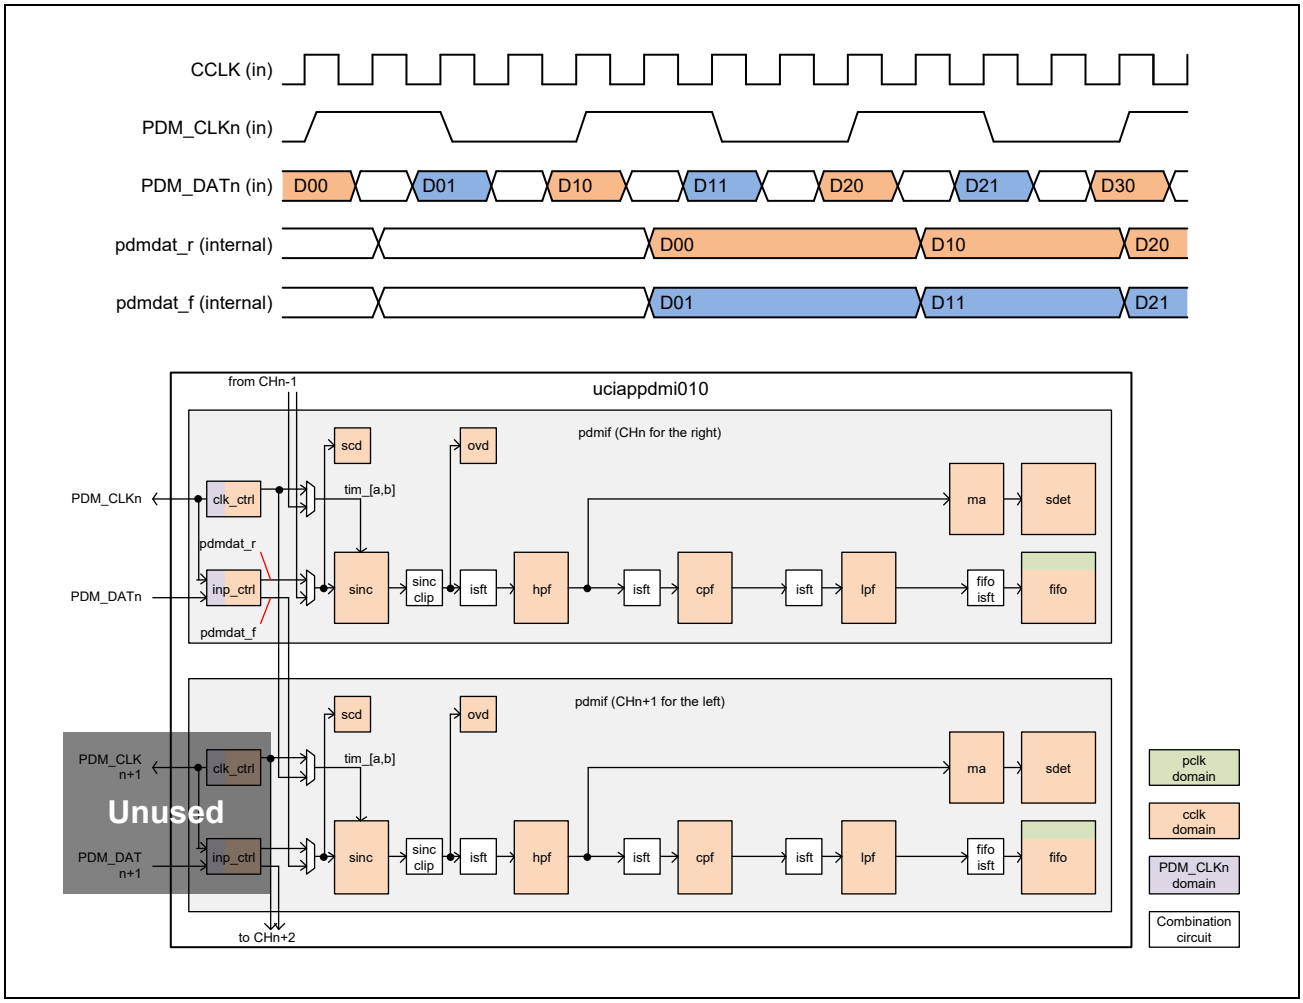

Figure 8.7-9 Data Input Control for Stereo Sound

Table 8.7-18 lists the channel combinations of stereo sound processing.

Table 8.7-18 Channel Combinations of Stereo Sound Processing

Input	Three Channels PDM-IF		Two Channels PDM-IF	
	Data Processing Latched at Rise-Edge (Right Sound)	Data Processing Latched at Fall-Edge (Left Sound)	Data Processing Latched at Rise-Edge (Right Sound)	Data Processing Latched at Fall-Edge (Left Sound)
PDM_CLK0 PDM_DAT0	Channel 0	Channel 1	Channel 0	Channel 1
PDM_CLK1 PDM_DAT1	Channel 1	Channel 2	Channel 1	Channel 0
PDM_CLK2 PDM_DAT2	Channel 2	Channel 0	Not implemented	

Table 8.7-19 lists an example of register settings for stereo sound processing using channel 0 and channel 1.

Table 8.7-19 Register Settings for Stereo Sound Processing

Register	Bit	Channel 0 Setting	Channel 1 Setting
PDICRCHn	All bits	Channel unique settings	Channel unique settings
PDSDCRCHn	All bits	Channel unique settings	Channel unique settings
PDMDSRCHn	INPSEL	0 (Use channel 0 data synchronized with rise-edge)	1 (Use channel 0 data synchronized with fall-edge)
	SFMD[2:0]	Same settings for channel 0 and channel 1 (Mandatory)	
	HFIS[1:0]	Channel unique settings	Channel unique settings
	HFMD	Same settings for channel 0 and channel 1 (Mandatory)	
	CFIS[1:0]	Channel unique settings	Channel unique settings
	CFMD	Same settings for channel 0 and channel 1 (Mandatory)	
	LFIS[1:0]	Channel unique settings	Channel unique settings
	LFMD	Same settings for channel 0 and channel 1 (Mandatory)	
	SDHFMD	Same settings for channel 0 and channel 1 (Mandatory)	
	SDMAMD[1:0]	Same settings for channel 0 and channel 1 (Mandatory)	
	DBIS[3:0]	Channel unique settings	Channel unique settings
PDSFCRCHn	CKDIV[3:0]	Setting of the clock which is supplied to the microphone connected to channel 0	Unuse
	SINCDEC[7:0]	Same settings for channel 0 and channel 1 (Mandatory)	
	SINCRNG[4:0]	Same settings for channel 0 and channel 1 (Mandatory)	
PDHFCS0RCHn	All bits	Channel unique settings	Channel unique settings
PDHFCK1RCHn	All bits	Channel unique settings	Channel unique settings
PDHFCH0RCHn	All bits	Channel unique settings	Channel unique settings
PDHFCH1RCHn	All bits	Channel unique settings	Channel unique settings
PDCFCHmRCHn	All bits	Channel unique settings	Channel unique settings

PDLFCH1mRCHn	All bits	Channel unique settings	Channel unique settings
PDSDLTRCHn	All bits	Channel unique settings	Channel unique settings
PDSDUTRCHn	All bits	Channel unique settings	Channel unique settings
PDDBCRCHn	All bits	Same settings for channel 0 and channel 1 (Mandatory)	
PDSCTSRCHn	All bits	Channel unique settings	Channel unique settings
PDOVLTRCHn	All bits	Channel unique settings	Channel unique settings
PDOVUTRCHn	All bits	Channel unique settings	Channel unique settings

8.7.3.6 Sound Detection

The operating clock of the sound detection function is CCLK. When PDSDCRCHn.SDE = 1b, the function judges the sound detection using the moving average filter results.

A sound detection flag (PDSRCHn.SDF) is set to 1b when the result is above the upper limit PDSDUTRCHn.SDETU[19:0]. The sound detection flag is also set to 1b when the result is below the lower limit PDSDLTRCHn.SDETL[19:0]. The sound detection flag is cleared to 0b when 1b is written to PDSCRCHn.SDFC.

Figure 8.7-10 shows the sound detection function.

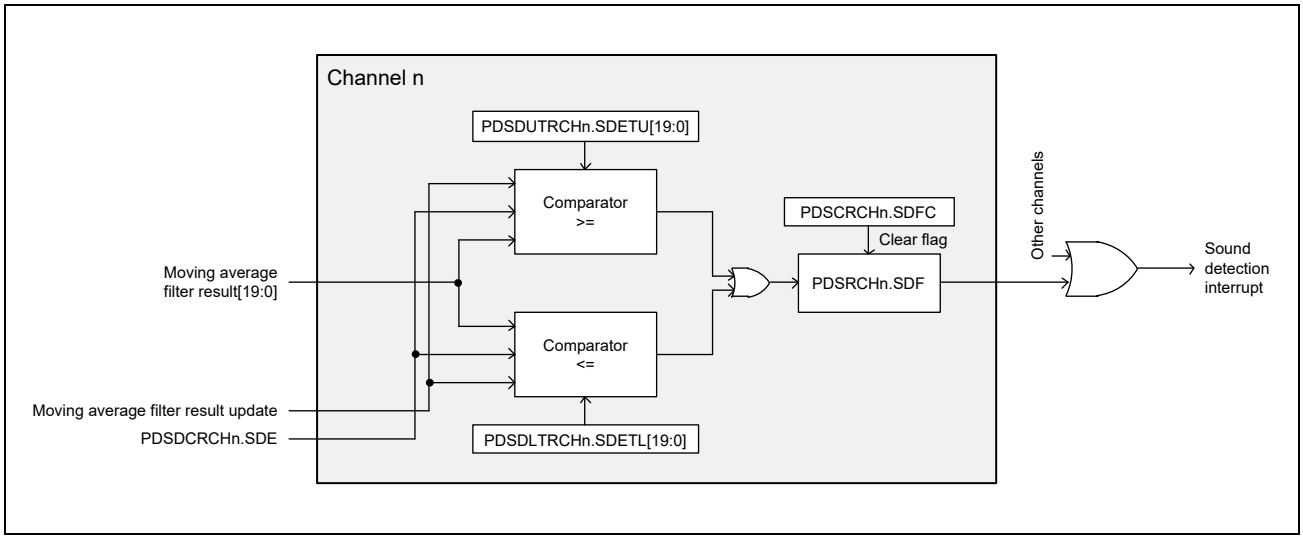

Figure 8.7-10 Sound Detection Function

8.7.3.7 Data Buffer

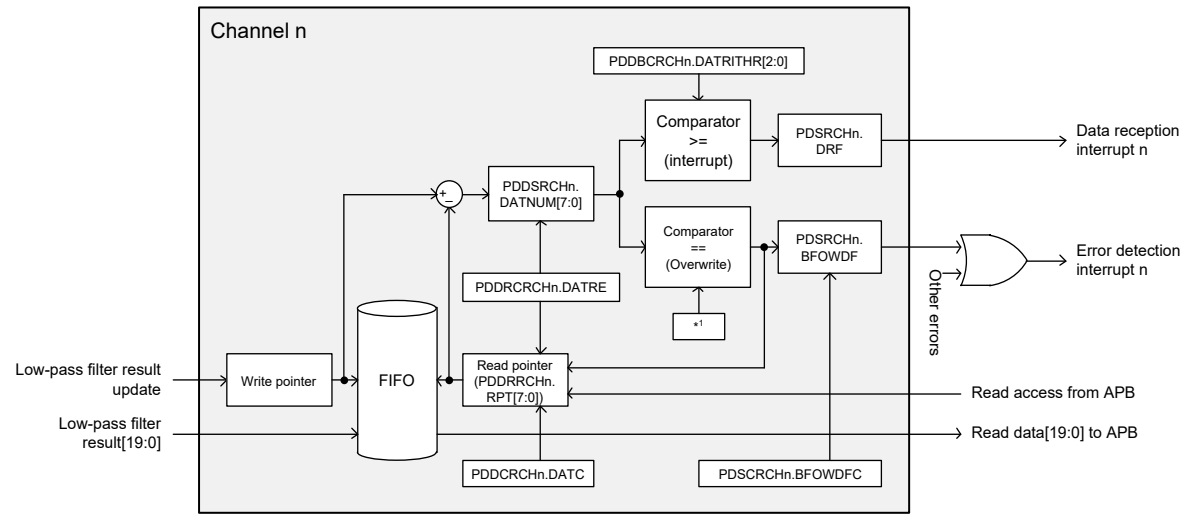
Data buffer writes sound data to FIFO synchronizing with CCLK and reads sound data from FIFO synchronizing with PCLK. Data buffer stores sound data in FIFO until it is read out.

While PDDRCRCHn.DATRE = 0b (hereinafter, DATRE), PDDSRCHnDATNUM[7:0] (hereinafter, DATNUM[7:0]) shows 0 and PDM-IF does not allow to read sound data. After DATRE is changed from 0b to 1b, DATNUM[7:0] shows the buffer size minus 2 and PDM-IF allows to read sound data. While DATRE = 1b, data buffer increments DATNUM[7:0] when data is written and decrements DATNUM[7:0] when data is read.

When DATNUM[7:0] is greater than or equal to a threshold which is configured by PDDBCRCHn.DATRITHR[2:0], a data reception flag PDSRCHn.DRF (hereinafter, DRF) is set to 1b. When DATNUM[7:0] is less than the threshold by reading data or etc., a data reception flag DRF is cleared to 0b.

When DATNUM[7:0] is the buffer size minus 2 and data is written without reading, data buffer overwrites the oldest data with a new one and a buffer overwriting detection flag PDSRCHn.BFOWDF (hereinafter, BFOWDF) is set to 1b. And then DATNUM[7:0] is set to the buffer size minus 2 again after overwriting. However, data buffer overwrites but BFOWDF is not set after DATRE changes from 0b to 1b to before the first data is read.

Figure 8.7-11 shows the data buffer function.



Note 1. Buffer size - 1 (In case that buffer size is 32 stages, this value is 31.)

Figure 8.7-11 Data Buffer Function

8.7.3.8 Short-Circuit Detection

When Short-circuit detection enable (PDSDCRCHn.SCDE) is valid, the short-circuit detection can operate.

A dedicated 13-bit counter counts consecutive 0's or 1's input from pdm_dat which is outputs by data input control block of channel n or channel n+1.

When the number of consecutive 0's exceeds the value set in the PDSCTSRCHn.SCDL[12:0] register or the number of consecutive 1's exceeds the value set in the PDSCTSRCHn.SCDH[12:0] register, a short-circuit detection interrupt request is generated.

Figure 8.7-12 shows the configuration for the short-circuit detection function.

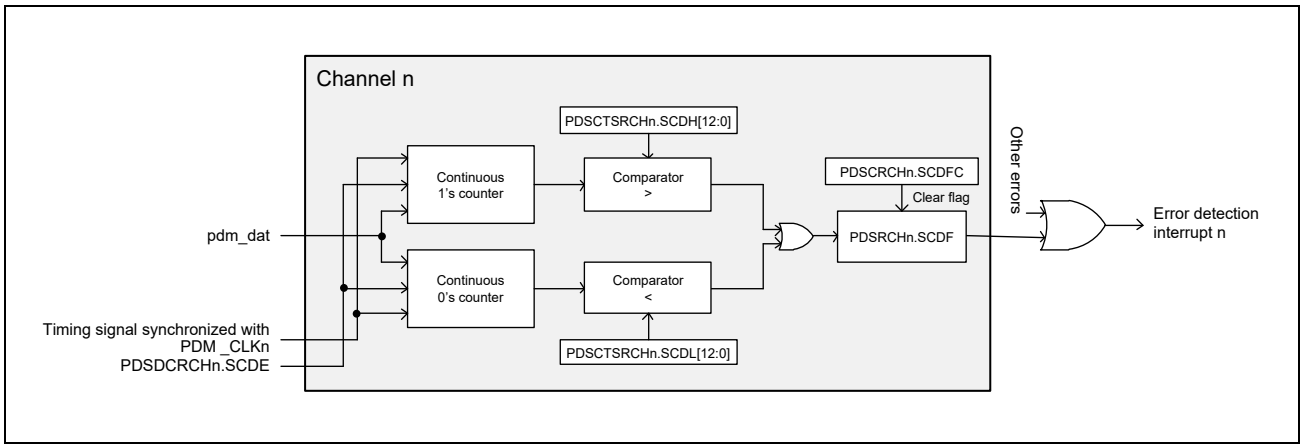


Figure 8.7-12 Short-Circuit Detection Function

8.7.3.9 Overvoltage Detection

When the overvoltage upper limit detection enable (PDSDCRCHn.OVUDE) is valid, the overvoltage upper limit detection can operate. When the overvoltage lower limit detection enable (PDSDCRCHn.OVLDE) is valid, the overvoltage lower limit detection can operate.

The sound data is clipped as a 20-bit data from 34-bit data output from sinc filter by the setting of the PDSFCRCHn.SINCRNG[4:0] bits. Refer to **Table 8.7-8** for details.

An overvoltage upper limit detection flag is set to 1b when the clipped sound data is greater than PDOVUTRCHn.OVDU[19:0].

An overvoltage lower limit detection flag is set to 1b when the clipped sound data is less than PDOVLTRCHn.OVDL[19:0].

Figure 8.7-13 shows the overvoltage detection function.

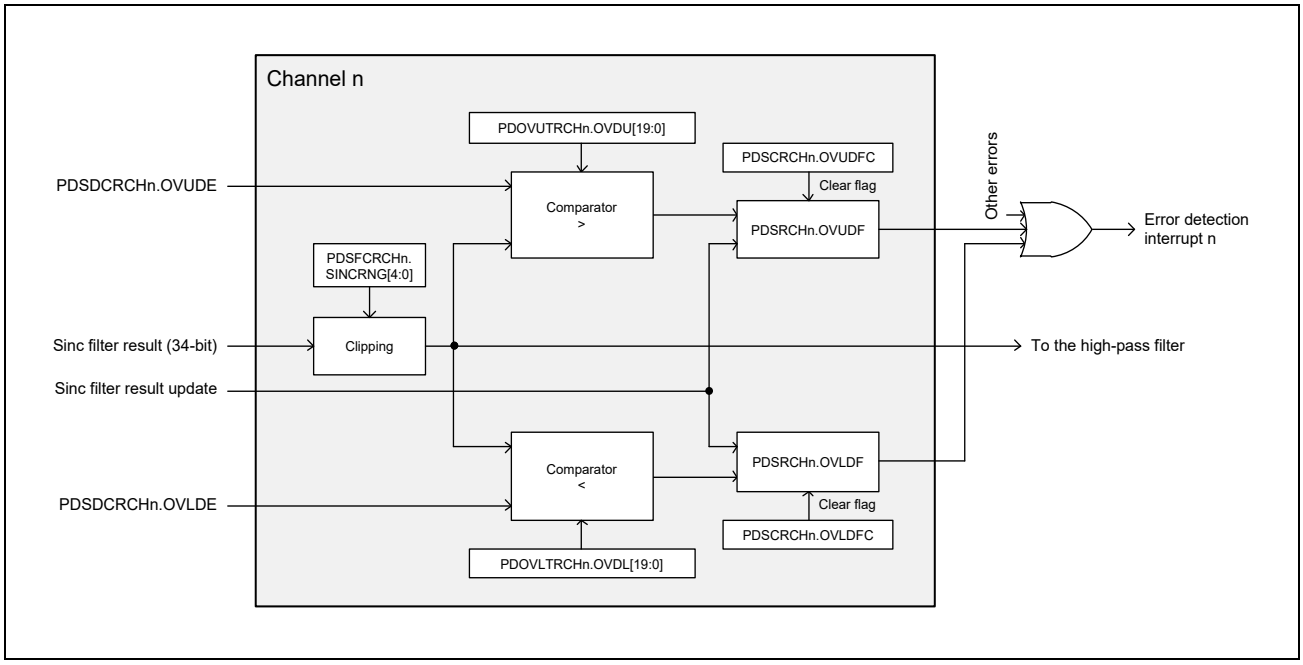

Figure 8.7-13 Overvoltage Detection Function

8.7.3.10 Error

Table 8.7-20 shows a PDM-IF error list.

Table 8.7-20 PDM-IF Error List

No.	Register Name	Description	Comment	Function (Related Section)
1	PDSRCHn.SCDF	Short circuit detection flag		**8.7.3.8 Short-Circuit Detection**
2	PDSRCHn.OVLDF	Overvoltage lower limit detection flag		**8.7.3.9 Overvoltage Detection**
3	PDSRCHn.OVUDF	Overvoltage upper limit detection flag		**8.7.3.9 Overvoltage Detection**
4	PDSRCHn.BFOWDF	Buffer overwriting detection flag	For debugging	**8.7.3.7 Data Buffer**

The errors in No.4 are for debugging. Software needs to set registers and operate PDM-IF so that these errors do not occur. If any of these error occur, stop PDM-IF following **8.7.4.2 Stop Flow** and change the settings.

8.7.3.11 Interrupt Function

PDM-IF has the following interrupt function.

Table 8.7-21 PDM-IF Interrupt List

No.	Signal Name	Interrupt Name	Number of Signals	Pulse or Level	Related Register Bit Name		Function (Related Section)
					Common Register	Channel Register	
1	INT_PDM_DATn (n = 0, 1, 2)	Data reception interrupt CHn	3	Level	PDCSR.DRFn	PDSRCHn.DRF	**8.7.3.7 Data Buffer**
2	INT_PDM_SDET	Sound detection interrupt (3-channel status flags are ORed.)	1	Level	PDCSR.SDFn	PDSRCHn.SDF	**8.7.3.6 Sound Detection**
3	INT_PDM_ERRn (n = 0, 1, 2)	Error detection interrupt CHn	3	Level	PDCSR.EDFn	PDSRCHn.SCDF	**8.7.3.8 Short-Circuit Detection**
						PDSRCHn.OVLDF	**8.7.3.9 Overvoltage Detection**
						PDSRCHn.OVUDF	**8.7.3.9 Overvoltage Detection**
						PDSRCHn.BFOWDF	**8.7.3.7 Data Buffer**

8.7.4 Setting Flow

Figure 8.7-14 and **Figure 8.7-15** show the example of the main procedure of PDM-IF.

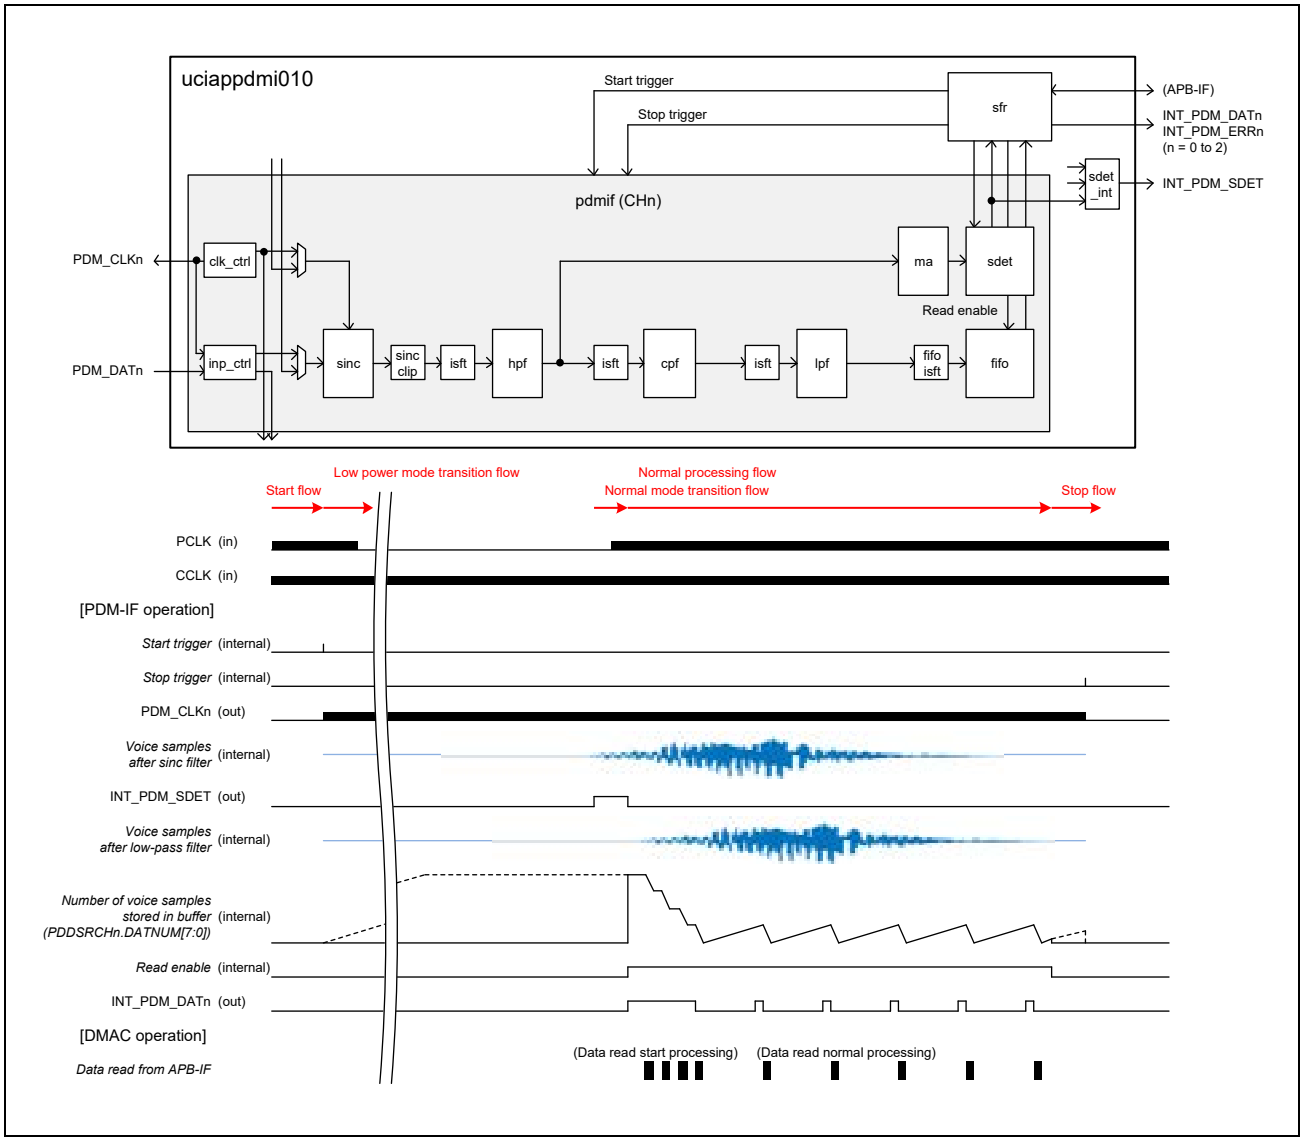

Figure 8.7-14 PDM-IF Operation Example

Figure 8.7-19 shows the example of the normal processing procedure of PDM-IF.

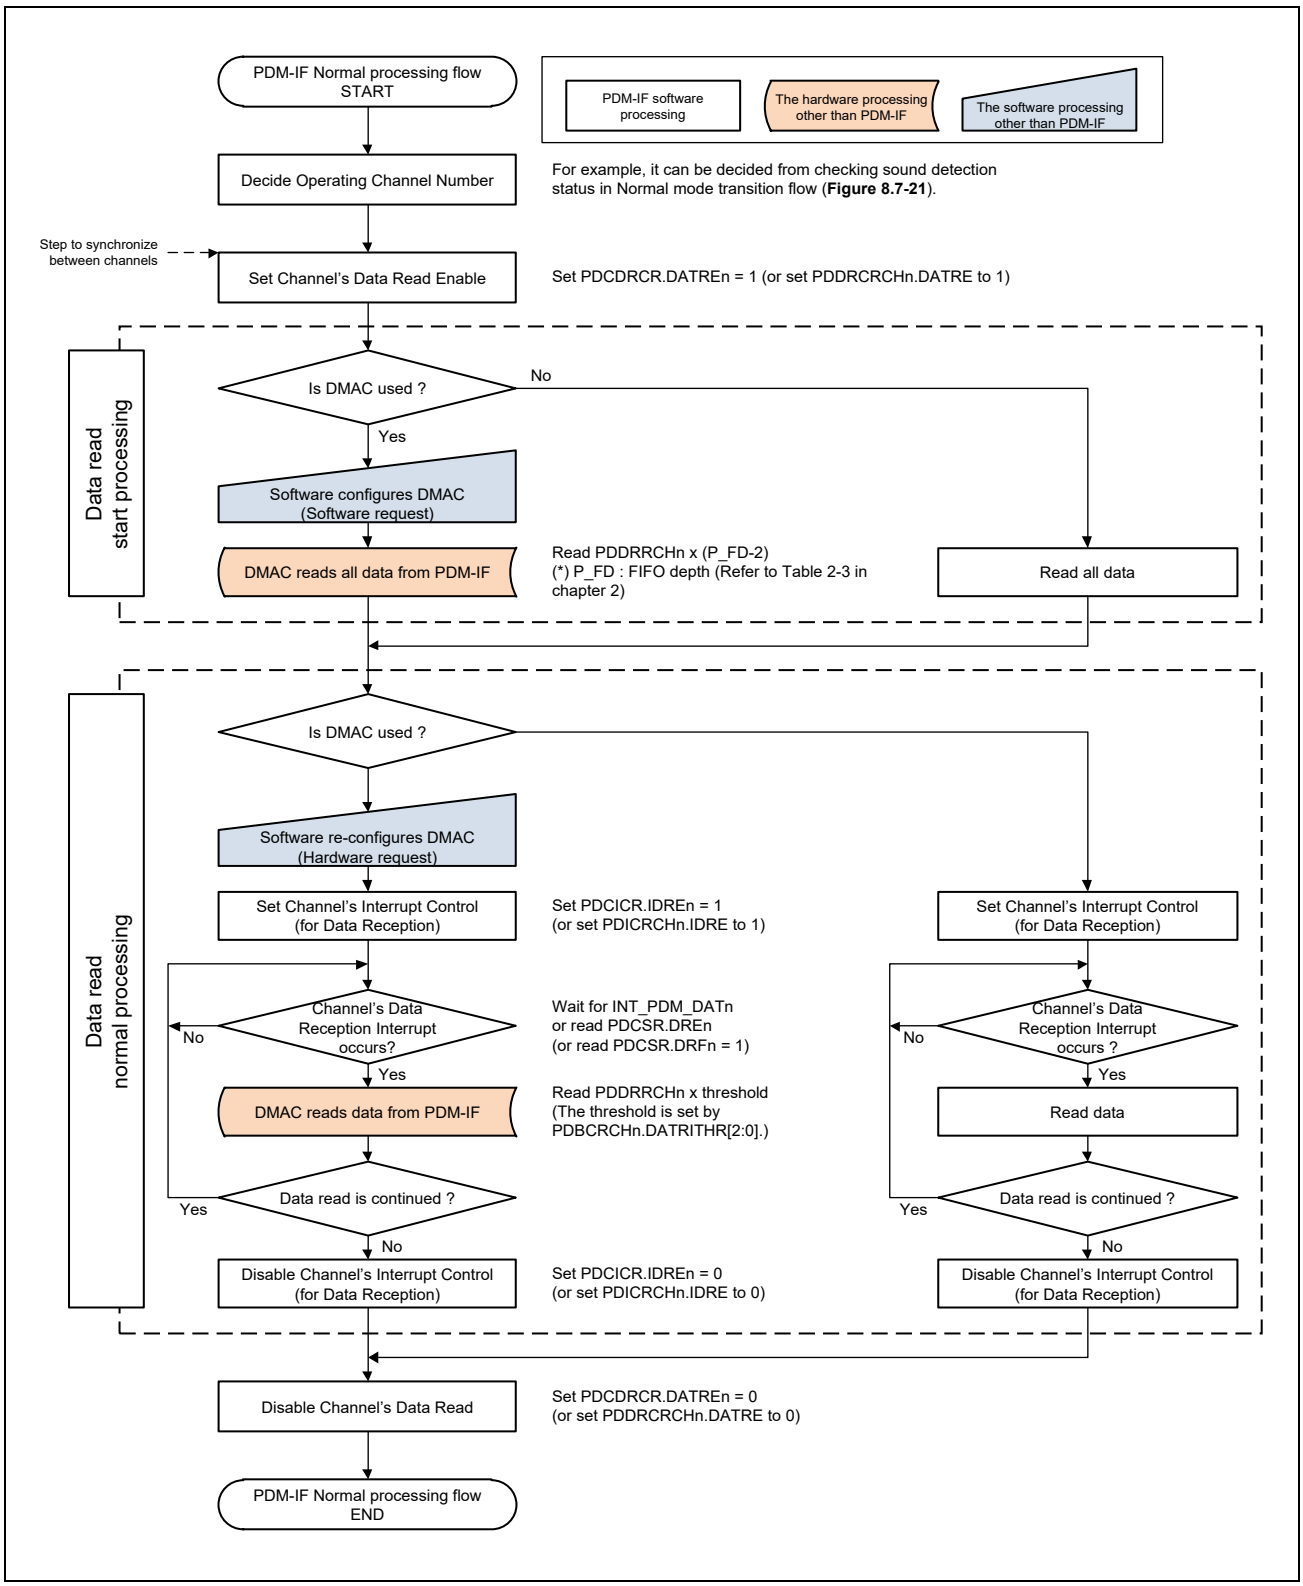

Figure 8.7-19 PDM-IF Normal Processing Flow

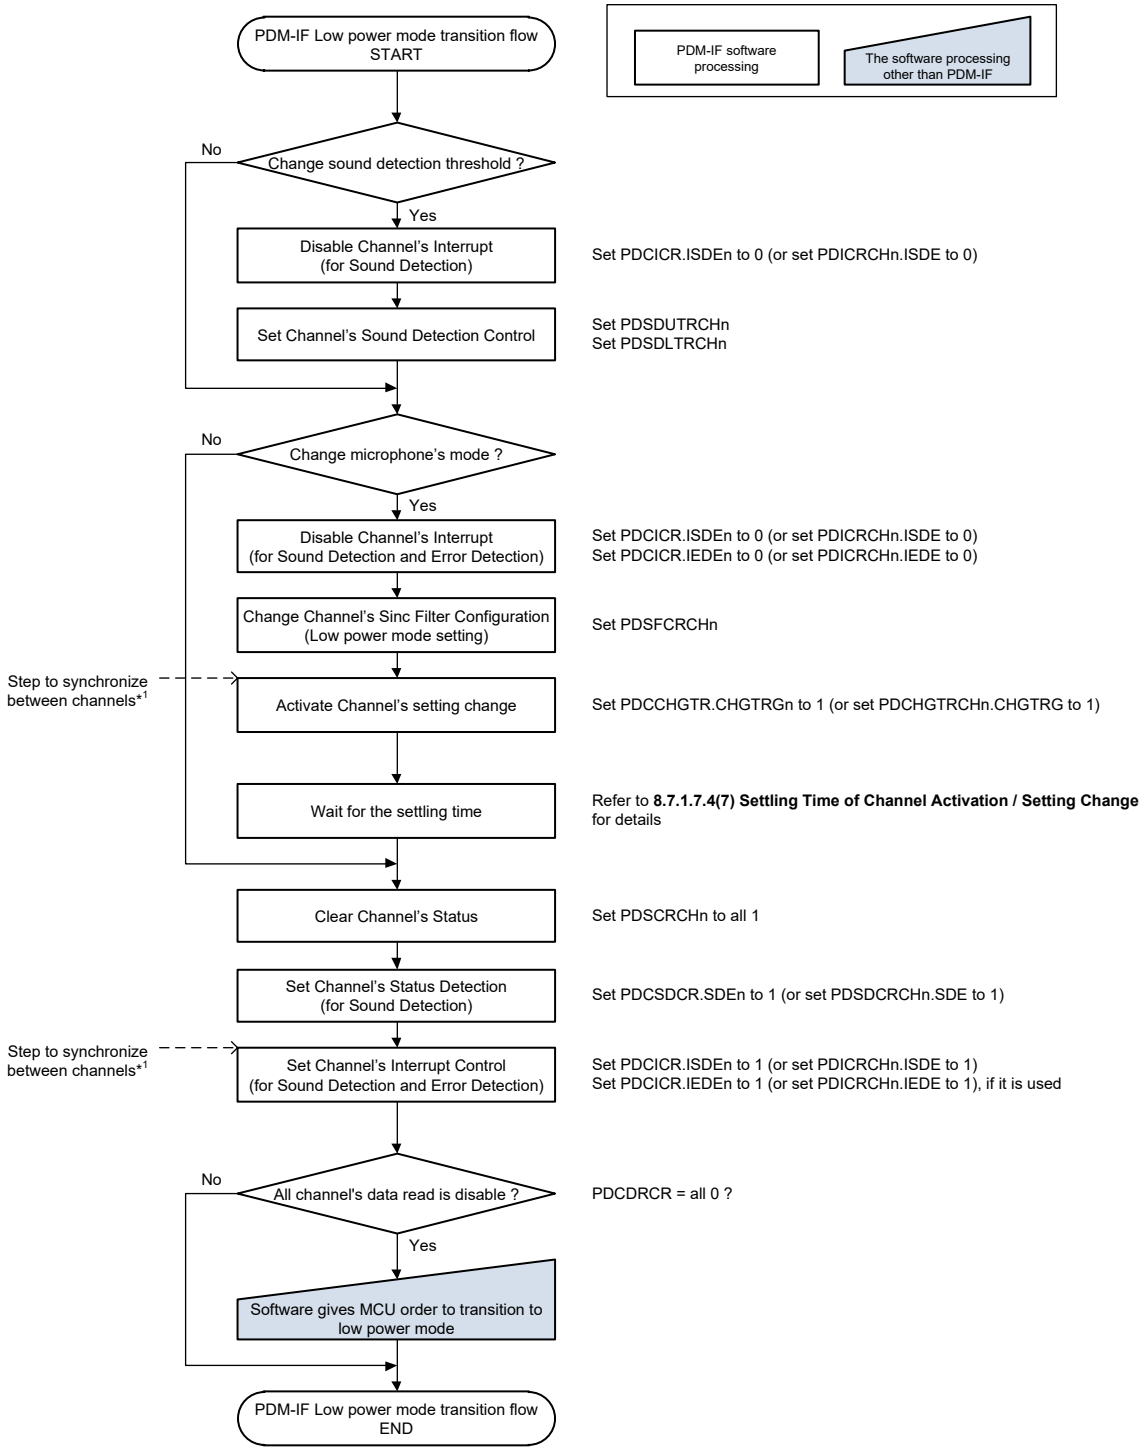
8.7.4.4 Low Power Mode Transition Flow

Figure 8.7-20 shows the example of the low power mode transition procedure of PDM-IF.

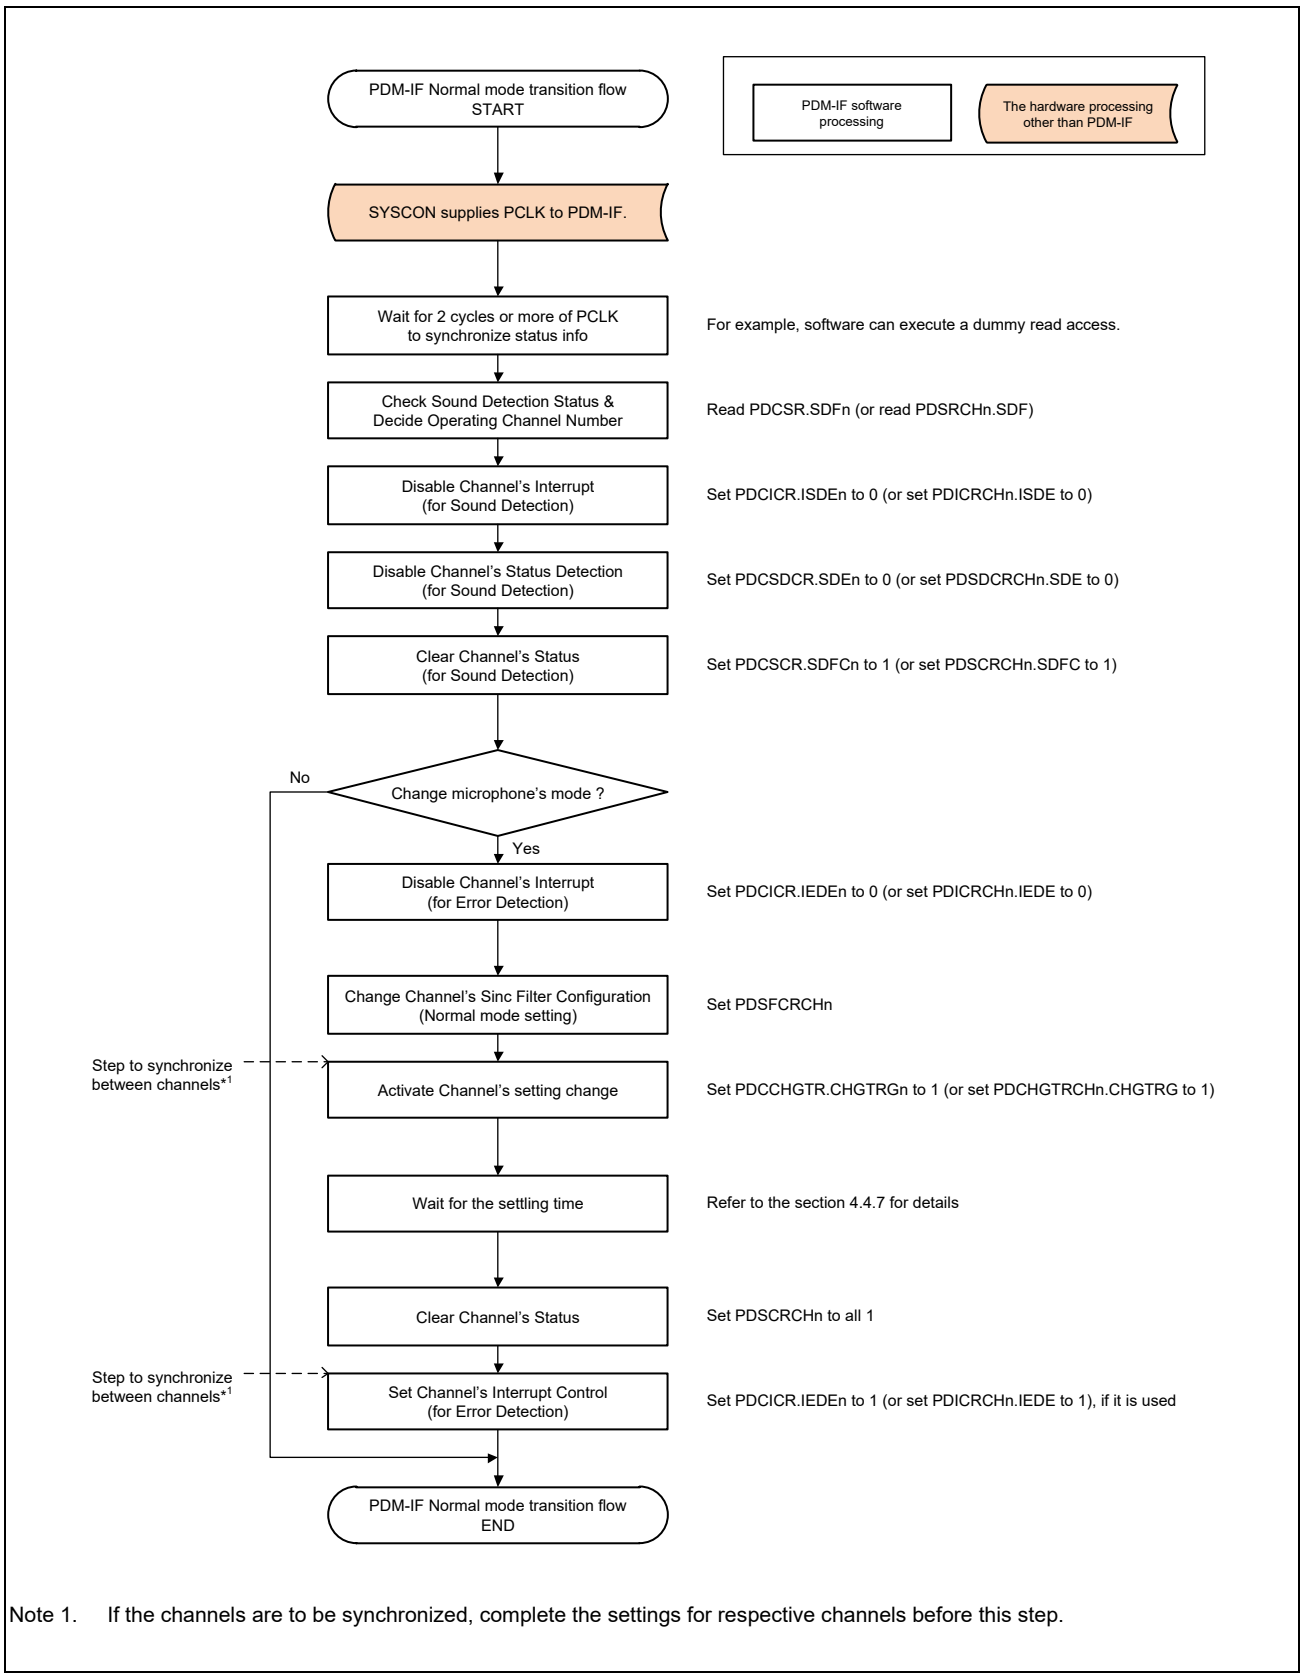


Note 1. If the channels are to be synchronized, complete the settings for respective channels before this step.

Figure 8.7-20 PDM-IF Low Power Mode Transition Flow

8.7.4.5 Normal Mode Transition Flow

Figure 8.7-21 shows the example of normal mode transition procedure of PDM-IF.



Note 1. If the channels are to be synchronized, complete the settings for respective channels before this step.

Figure 8.7-21 PDM-IF Normal Mode Transition Flow

8.7.4.6 Setting PDM_CLKn (n = 0, 1, 2) Frequency and Sampling Frequency Generated by the Unit

The frequency of PDM_CLKn (n = 0, 1, 2), which is the reference for receiving data from the external device, and the sampling frequency generated by the PDM unit for external input PDM data can be changed by setting the register. The PDM_CLKn (n = 0, 1, 2) frequency must match the clock input specifications of the external device. The sampling frequency generated by the unit should be set to the expected value.

In this LSI, the PDM reference clock CCLK is fixed at 4.8 MHz, so the PDM_CLK output frequency and the unit-generation sampling frequency follow the equation below when implementing the circuit.

- PDM_CLKn (n = 0, 1, 2) frequency

$$= \frac{\text{CCLK frequency}}{(\text{CKDIV} + 1) \times 2};$$

- Unit-generation sampling frequency

$$= \frac{\text{PDM\_CLK frequency}}{(\text{SINCDEC} + 1) \times 2^{*1}} = \frac{\text{CCLK frequency}}{(\text{CKDIV} + 1) \times 2} \div (\text{SINCDEC} + 1) \times 2^{*1};$$

Remark: CKDIV: PDSFCRCHn.CKDIV[3:0] register set value (Set the PDM_CLKn division ratio to CCLK)
SINCDEC: PDSFCRCHn.SINCDEC[7:0] register set value (Set the decimation ratio of the Sinc filter)

Note 1. Reason for ×2: Low-pass filter decimation ratio

- PDMIF sampling rate:

$$\frac{\text{CCLK frequency}}{\big((\text{CKDIV} + 1) \times 2\big) \times (\text{SINCDEC} + 1) \times 2}$$

The output range of the sinc filter is changed by changing the decimation ratio of the sinc filter (SINCDEC) with the change of the sampling frequency above. Since the maximum number of effective bits for processing of audio data within the PDM following sinc filtering is 20 bits, PDSFCRCHn.SINCRNG[4:0] must also be changed according to the output range of the sinc filter. This allows avoiding the occurrence of overflow and underflow and maximizing the effective audio amplitude.

Recommended setting: Set PDSFCRCHn.SINCRNG[4:0] such that the higher-order 20 bits of valid data of the sinc filter output are effective in calculation processing following sinc filtering.

For details on clipping or sifting of the sinc filter output, see **8.7.3.4.1 Data Clipping and Shifting between Filters**.

- Output range of the sinc filter
  = ±decimation ratio (PDSFCRCHn.SINCDEC[7:0]) ^ order (PDMDSRCHn.SFMD[2:0]);

[Example]

When SINCDEC[7:0] = 27h (decimation ratio: 40) and SFMD[2:0] = 0 (4-order), the output range of the sinc filter is ±2560000 (23 bits consisting of 22 bits of significant digits and a sign bit). The recommended setting of PDSFCRCHn.SINCRNG[4:0] in this case is 0_1011b (b22-b3).

The following describes the impact of the circuit structure on the frequency calculations.

The table below shows the relationship between the selectable N/M values (register settings) with respect to the PDM_CLKn (n = 0, 1, 2) frequency and the unit-generation sampling frequency, according to the above calculation formula, and the target-generated sampling frequency.

In the table below, “Not selectable” indicates that the N value or M value cannot be selected for the target-generated sampling frequency. Since the N value can be selected from 2 to 32 in multiples of 2 and the M value can only be selected as an integer of 1, 2, 3, ..., 256, the corresponding target-generated sampling frequency may not be generated. However, in some cases, a frequency near the target-generation sampling frequency may be selectable. If that frequency is acceptable, refer to the PDM_CLKn (n = 0, 1, 2) frequency and unit-generation sampling frequency calculation formula above to derive the desired N value/M value and the corresponding register setting value.

Table 8.7-22 Selectable PDM_CLKn (n = 0, 1, 2) Frequency and Unit-Generation Sampling Frequency

	Sampling frequency (kHZ)	48	40	30	25	24	20	16	15	12	10	8
N value	PDM_CLK frequency (MHz)	M value	M value	M value	M value	M value	M value	M value	M value	M value	M value	M value
2	2.4	25	30	40	48	50	60	75	80	100	120	150
4	1.2	Not selectable	15	20	24	25	30	Not selectable	40	50	60	75
6	0.8	Not selectable	10	Not selectable	16	Not selectable	20	25	Not selectable	Not selectable	40	50
8	0.6	Not selectable	Not selectable	10	12	Not selectable	15	Not selectable	20	25	30	Not selectable
10	0.48	5	6	8	Not selectable	10	12	15	16	20	24	30
12	0.4	Not selectable	5	Not selectable	8	Not selectable	10	Not selectable	Not selectable	Not selectable	20	25
14	0.342857143	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable
16	0.3	Not selectable	Not selectable	5	6	Not selectable	Not selectable	Not selectable	10	Not selectable	15	Not selectable
18	0.266666667	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable
20	0.24	Not selectable	3	4	Not selectable	5	6	Not selectable	8	10	12	15
22	0.218181818	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable
24	0.2	Not selectable	Not selectable	Not selectable	4	Not selectable	5	Not selectable	Not selectable	Not selectable	10	Not selectable
26	0.184615385	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable
28	0.171428571	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable	Not selectable
30	0.16	Not selectable	2	Not selectable	Not selectable	Not selectable	4	5	Not selectable	Not selectable	8	10
32	0.15	Not selectable	Not selectable	Not selectable	3	Not selectable	Not selectable	Not selectable	5	Not selectable	Not selectable	Not selectable

The N value/M value in the above table is based on the following formula.

Definition of N value: (CKDIV + 1) × 2
Definition of M value: (SINCDEC + 1)

Remark: CKDIV: PDSFCRCHn.CKDIV[3:0] register set value
SINCDEC: PDSFCRCHn.SINCDEC[7:0] register set value

8.7.4.7 DMA Transfer Method

This PDM unit can only receive voice data from external sources, and does not have a transmit function. The PDM unit does not have a dedicated REQ/ACK signal to the DMAC master, but only reads data from the PDM buffer read register via the APB I/F. Reading data via the CPU and reading data via the DMAC master are not different in terms of PDM functionality.

Figure 8.7-22 shows an overview of the PDM data read process.

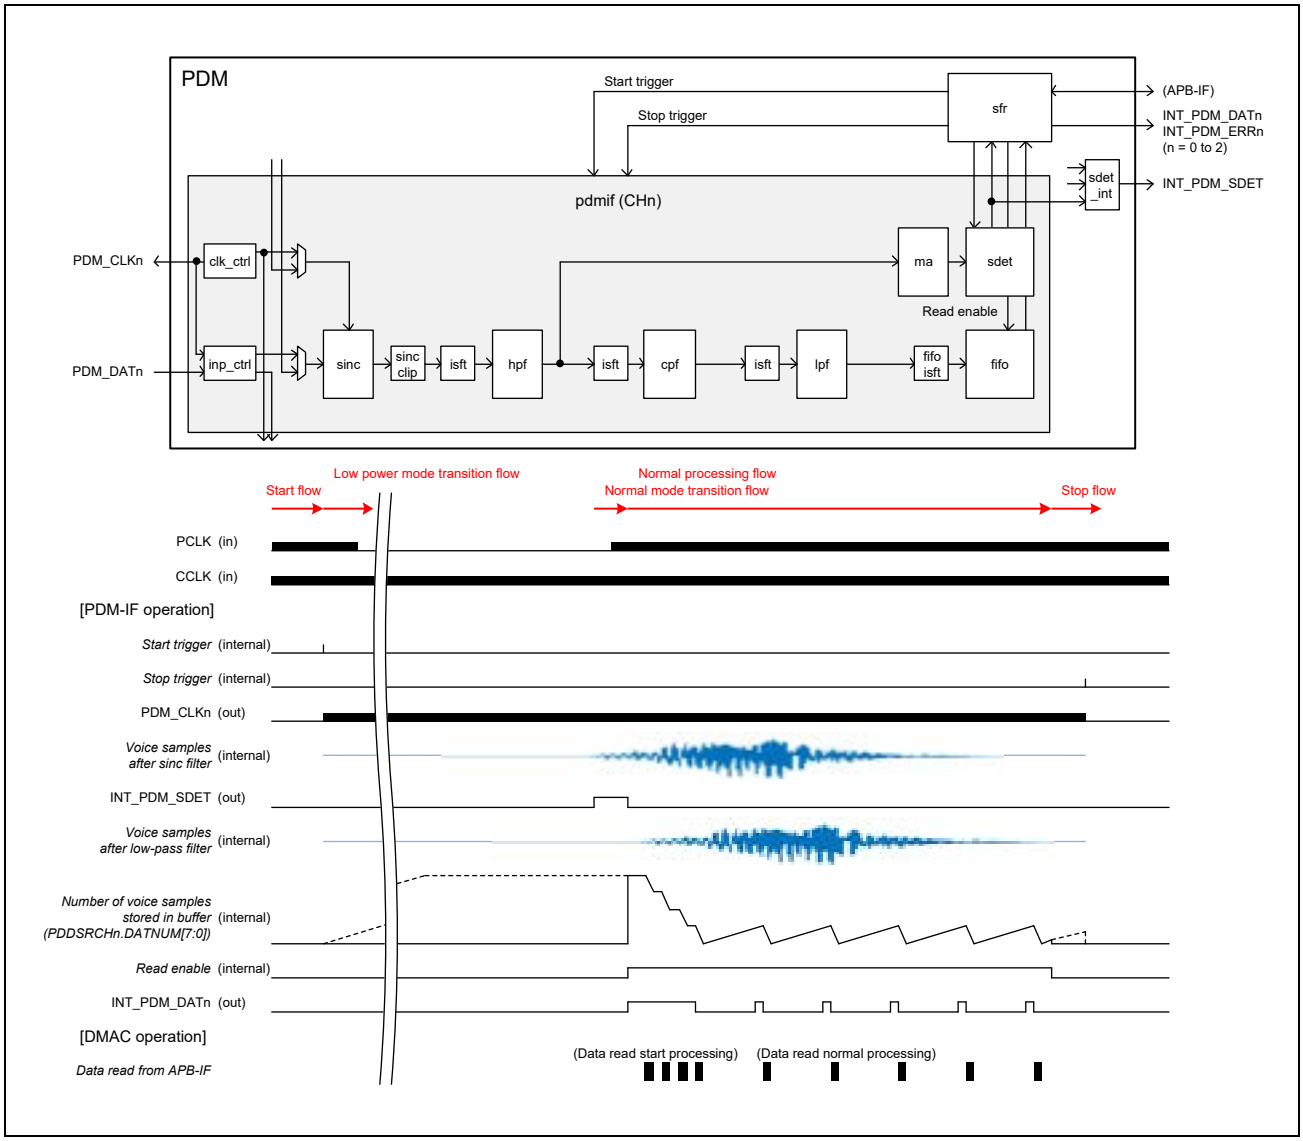


Figure 8.7-22 PDM-IF Operation Example

The DMA data transfer using the DMA master must follow the description in **8.7.4.3 Normal Processing Flow**. The following explains the connection configuration with the DMA master, initialization settings on the DMA master, and recommended settings for the INT_PDM_DAT0/1/2 signal at PDM initialization.

The connection configuration with the DMA master in this LSI is as follows, issuing a DMA request to the DMA master based on the INT_PDM_DAT0/1/2 signal of the PDM. The INT_PDM_DAT0/1/2 interrupt signal is active (high) depending on the amount of data stored in the receive buffer in the PDM (the amount of interrupt generation buffer can be changed by setting the register / PDDBCRCHn (n = 0, 1, 2).DATRITHR[2:0]).

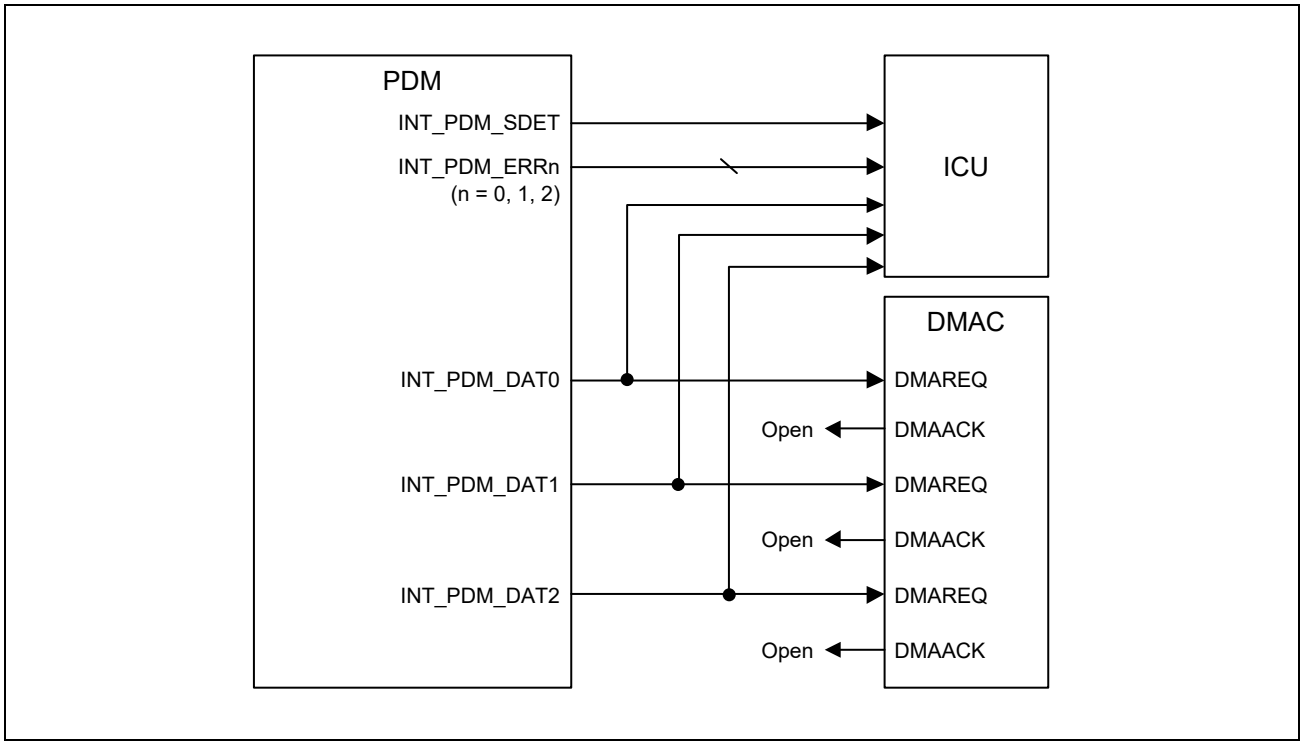

Figure 8.7-23 PDM Connection Configuration

This section describes the restrictions at DMA transfer and the active condition of the INT_PDM_DAT0/1/2 signal at PDM initialization.

1) Restrictions at DMA transfer:

The initialization setting on the DMA master is required in “Software configures DMAC/Software re-configures DMAC” in **Figure 8.7-19** of **8.7.4.3 Normal Processing Flow**. The restrictions on PDM DMA transfers are described below.

- DMA transfer mode (1): Single

  (One DMA transfer process is performed for one DMA request.)
  Reference value for the DMA master setting: TM register = 0b

- DMA transfer mode (2): Bus cycle mode

  (DMAREQ is masked in the bus cycle period (while DMAACK is active.))
  Reference value for the DMA master setting: AM[2:0] = 010b

- One DMA transfer: 32 bits

  Reference value for the DMA master: SDS register = 32 bits

- DMA REQ signal attribute: Level/High

  (The active polarity of the INT_PDM_DAT0/1/2 signal is high, so the DMA request signal must also be high.)
  Reference value for the DMA master: LVL = 1b, HIEN = 1b, LOEN = 0b

- DMA REQ signal active release timing: After the completion of data read from the PDM unit

  (DMA REQ is masked while DMA ACK is enabled.)
  Reference value for the DMA master: REQD = 0b

- DMA transfer data read register: PDDRRCHn (n = 0, 1, 2).DAT[19:0] register

2) Interrupt setting of the INT_PDM_DAT0/1/2 signal in the PDM receive initialization setting:

The interrupt setting for the INT_PDM_DAT0/1/2 signal is required in “Set Channel’s Data Buffer Control” in **Figure 8.7-17** of **8.7.4.1 Start Flow**.
As the receive buffer amount of PDM in this LSI is fixed at 64 stages, it is recommended to set PDDBCRCHn (n = 0, 1, 2).DATRITHR[2:0] = 4 (16 stages). Since a time difference may occur between the active timing of the INT_PDM_DAT0/1/2 signal and the request decision on the DMA master, the active timing of the INT_PDM_DAT0/1/2 signal must always be selected to be at least 2 stages.

8.7.4.8 Reset Clock Control

For the reset clock control, the following reset clock pins must be controlled.

Table 8.7-23 List of Reset Clocks

	Reset Signal	Clock Signal	Clock Source	Description
System 1	PRESETn	PCLK, PCLK_SFR	CPG unit (Divider clock for CPG PLL output)	For internal bus control circuit
System 2	CRESETn	CCLK	CPG unit (External system clock: 4.8 MHz fixed at 24 MHz divided by 5)	For external IF control circuit

The above reset clock pins are controlled by the CPG unit, and each reset clock can be controlled ON/OFF with the CPG register. When each reset is released, a feature is implemented on the CPG to stop the target clock before and after the reset is released.

For each system, reset and clock control should be performed according to the following procedure.

However, the reset and clock control between the two systems below are independent, and there are no restrictions on the order of settings between the systems.

Furthermore, when controlling the reset clock, the PDM unit should be stopped and accesses from related units should also be stopped.

1. Reset (PRESETn) and clock (PCLK, PCLK_SFR) for the internal bus control circuit:
   — PDM operation start condition (reset/clock supply): clock supply → reset release
   — PDM stop condition (reset/clock stop): reset enabled → clock stop
   — PDM reset (reset ON/OFF, clock supply continued): Reset can be enabled or disabled at any timing

2. Reset (CRESETn) and clock (CCLK) for the external IF control circuit:
   — PDM operation start condition (reset/clock supply): clock supply → reset release
   — PDM stop condition (reset/clock stop): reset enabled → clock stop
   — PDM reset (reset ON/OFF, clock supply continued): Reset can be enabled or disabled at any timing

As for PCLK/PCLK_SFR, the CPG unit can change the clock frequency variable (100 MHz, 50 MHz, 25 MHz, 12.5 MHz, 3.125 MHz). When lowering the PCLK/PCLK_SFR frequency, the performance of reading voice data from the PDM unit will be degraded. Use caution when lowering the frequency.

8.7.5 Interrupt

8.7.5.1 Interrupt List

Table 8.7-24 is a list of interrupt signals for this unit. For details on interrupts, refer to **4.6 Interrupt Controller**.

Table 8.7-24 PDM-IF Interrupt List

No.	Signal Name	Interrupt Name	Number of Signals	Pulse or Level	Related Register Bit Name		Function (Related Section)
					Common Register	Channel Register	
1	INT_PDM_DATn (n = 0, 1, 2)	Data reception interrupt CHn (n = 0, 1, 2)	3	Level	PDCSR.DRFn	PDSRCHn (n = 0, 1, 2).DRF	**8.7.3.7 Data Buffer**
2	INT_PDM_SDET	Sound detection interrupt (3-channel status flags are ORed.)	1	Level	PDCSR.SDFn	PDSRCHn (n = 0, 1, 2).SDF	**8.7.3.6 Sound Detection**
3	INT_PDM_ERRn (n = 0, 1, 2)	Error detection interrupt CHn (n = 0, 1, 2)	3	Level	PDCSR.EDFn	PDSRCHn (n = 0, 1, 2).SCDF	**8.7.3.8 Short-Circuit Detection**
						PDSRCHn (n = 0, 1 ,2).OVLDF	**8.7.3.9 Overvoltage Detection**
						PDSRCHn (n = 0, 1, 2).OVUDF	**8.7.3.9 Overvoltage Detection**
						PDSRCHn (n = 0, 1, 2) BFOWDF	**8.7.3.7 Data Buffer**

8.7.6 Usage Notes

8.7.6.1 Data Reception Interrupt Threshold Register Setting

A data reception interrupt INT_PDM_DATn is issued as a level output. Therefore, if the number of samples in buffer still exceeds the data reception interrupt threshold set in PDDBCRCHn.DATRITHR[2:0] when data reading of DMA finishes, the interrupt controller might not detect the edge of INT_PDM_DATn. The situation happens if data reading time exceeds sampling rate*1 x threshold. Set the appropriate threshold so that the interrupt controller can detect the interrupt.

In case the threshold cannot avoid the situation, read PDDBCRCHn.DATRITHR[2:0] and re-start DMA by software after reading the data.

Note 1. Sampling rate: Time to spend to store a sample in buffer.

8.7.6.2 Frequency Characteristics of Filters with Default Settings

The following figure and table show the frequency characteristics of the filters with the default settings*1 for reference information.

Note 1. SINC filter output sampling frequency = 32 kHz
PDM output sampling frequency = 16 kHz

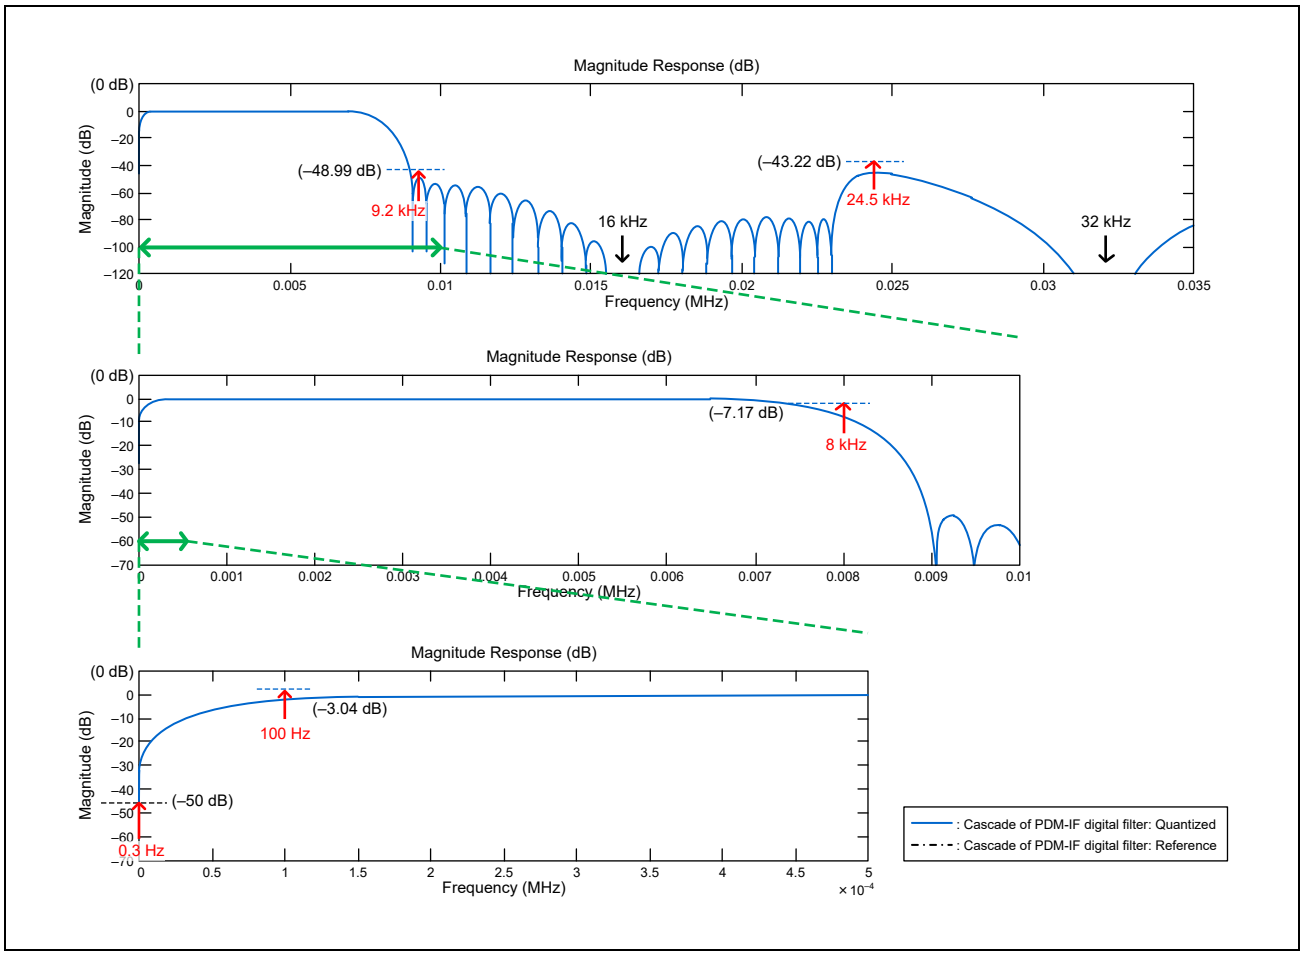

Figure 8.7-24 Frequency Characteristics of Filters with Default Settings

Table 8.7-25 Frequency Characteristics of Filters with Default Settings

Frequency (Hz)		Magnitude (dB)
Cut-off frequency of LPF	24.5 kHz	−43.22
	…	…
	9.2 kHz	−48.99
	8 kHz	−7.17
Passband	7 kHz	−0.39
	6 kHz	−0.07
	…	…
	150 Hz	−1.63
	100 Hz	−3.04
Cut-off frequency of HPF	50 Hz	−7.02
	0.3 Hz	−50.00

SECTION 9 IMAGE

9.1 Image Overview

This sections describes the Image unit of this LSI. For details, refer to the sections of each unit.

■ Camera Data Receive Unit (CRU) (See 9.2)

This LSI equips 2ch of CRU.

■ Image Scaling Unit (ISU) (See 9.3)

■ LCD Controller (LCDC) (See 9.4)

■ MIPI DSI (See 9.5)

Conforms to the following standards.

- MIPI® Alliance Specification for Display Serial Interface Version 1.3.1
- MIPI® Alliance Specification for D-PHY Version 1.2

■ H.265/H.264 Multi Codec (VCD) (See 9.6)

■ 3D Graphics Engine (GE3D) (See 9.7)

This LSI includes the Arm® Mali™-G31 GPU as a 3D Graphics Engine (GE3D). This unit is an optional function.

■ Image Signal Processor (ISP) (See 9.8)

This LSI includes the Arm® Mali™-C55 ISP core.

SECTION 9 IMAGE

9.2 Camera Data Receiver Unit (CRU)

9.2.1 Overview

Each CRU has an MIPI CSI-2 input and then decodes the data type specified by the packet, handles conversion of the color space of pixels, LUT conversion, pixel format conversion, and image conversion such as demosaicing and obtaining statistics. After converting processed data to various pixel formats, it transfers the data to external memory.

Each CRU consists of the MIPI CSI2 block and an image converter. The main functions of each of these blocks are as follows.

MIPI CSI2

The MIPI CSI2 block receives signals compliant with the MIPI CSI-2 V2.1(DPHY V1.2) standard, extracts video signals from various packets, and sends data to the image converter, which is the next stage. Output from CRU0 to CRU1 is possible.
The details of its functions are described in **9.2.3 MIPI CSI2**.

Image Converter

The image converter receives video data from the MIPI CSI2 block, that is, from the previous stage, and handles image processing corresponding to the given data. MIPI CSI2 data input to CRU0 can be selected for CRU1. Data to which image processing has been applied are initially stored in a FIFO buffer and then transferred to external memory.
The details of its functions are described in **9.2.4 Image Converter**.

Figure 9.2-1 is a schematic diagram of the CRUs. A total of two CRU channels are present.

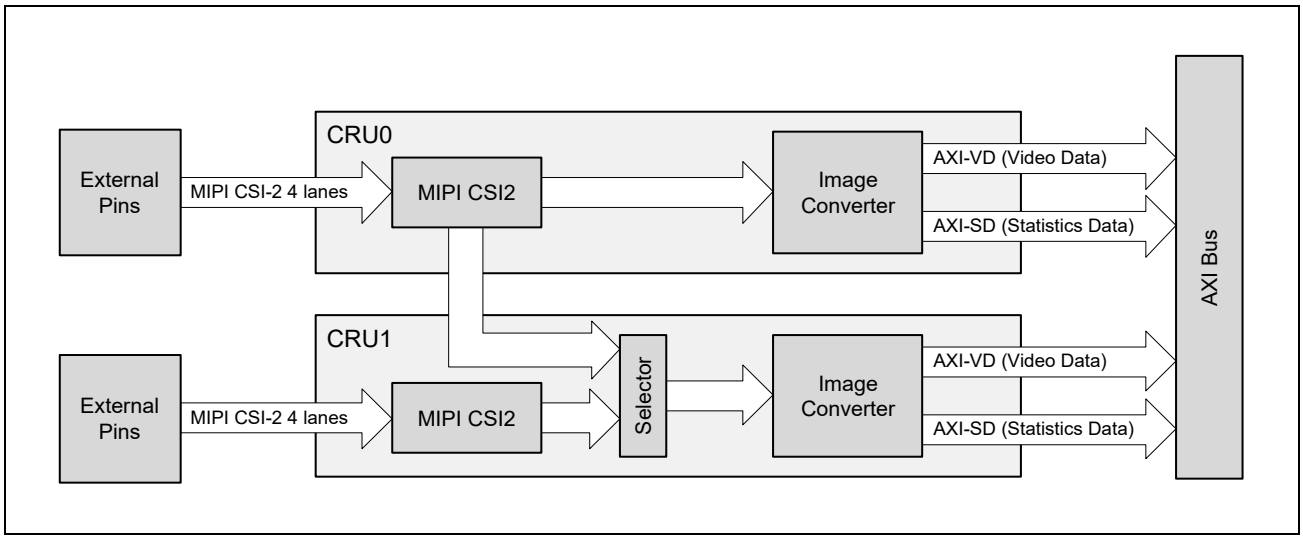

Figure 9.2-1 Schematic Diagram of CRU

9.2.2 Connected Units

Table 9.2-1 lists differences between the functions of CRU0 to 1.

Figure 9.2-2 and **Figure 9.2-3** show the units that are connected to CRU0 and 1, respectively.

Table 9.2-1 Differences between Functions of CRU0 to 1

Ch.	Image Converter Input Data Ch. Selection
CRU0	CRU0
CRU1	CRU0/1

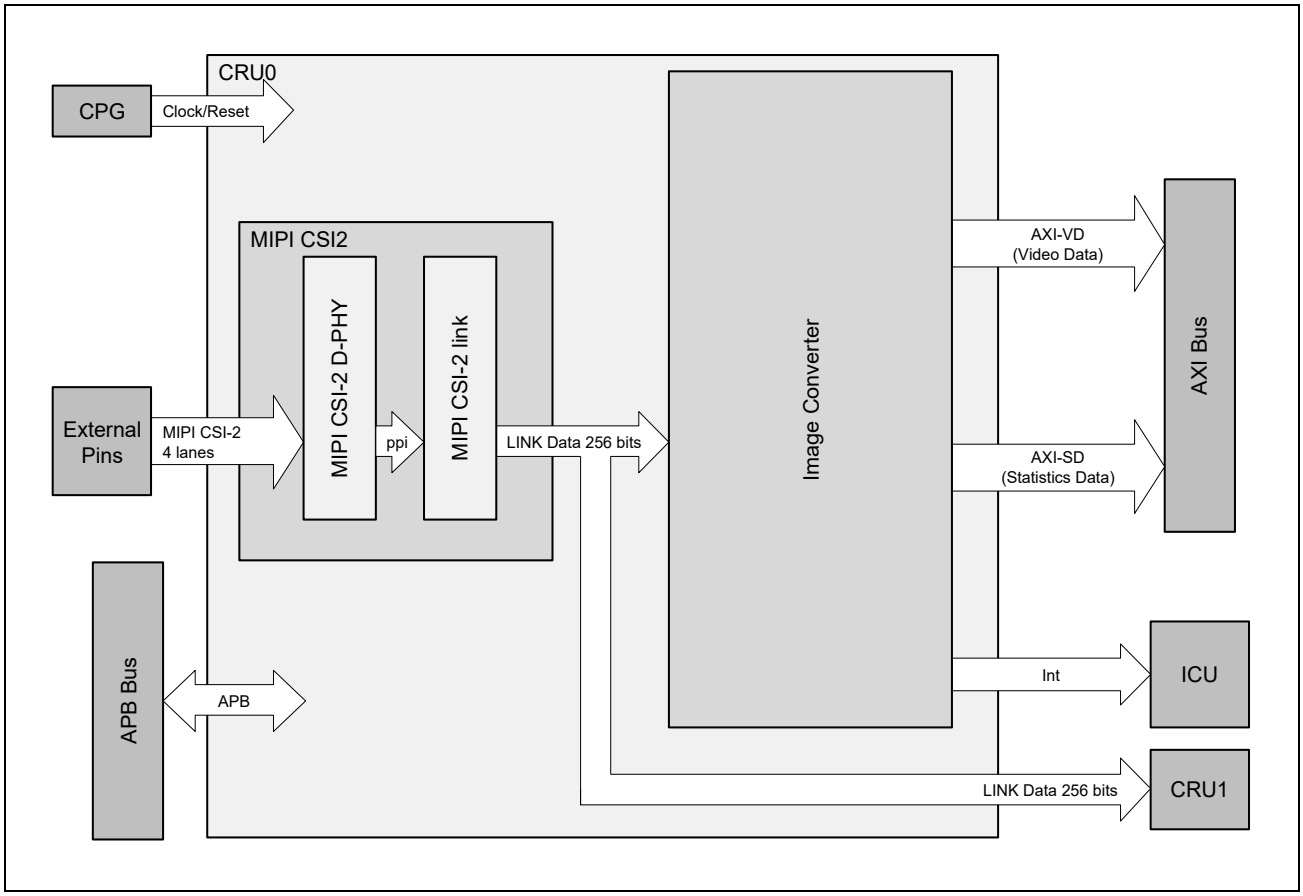

Figure 9.2-2 Block Diagram of CRU0

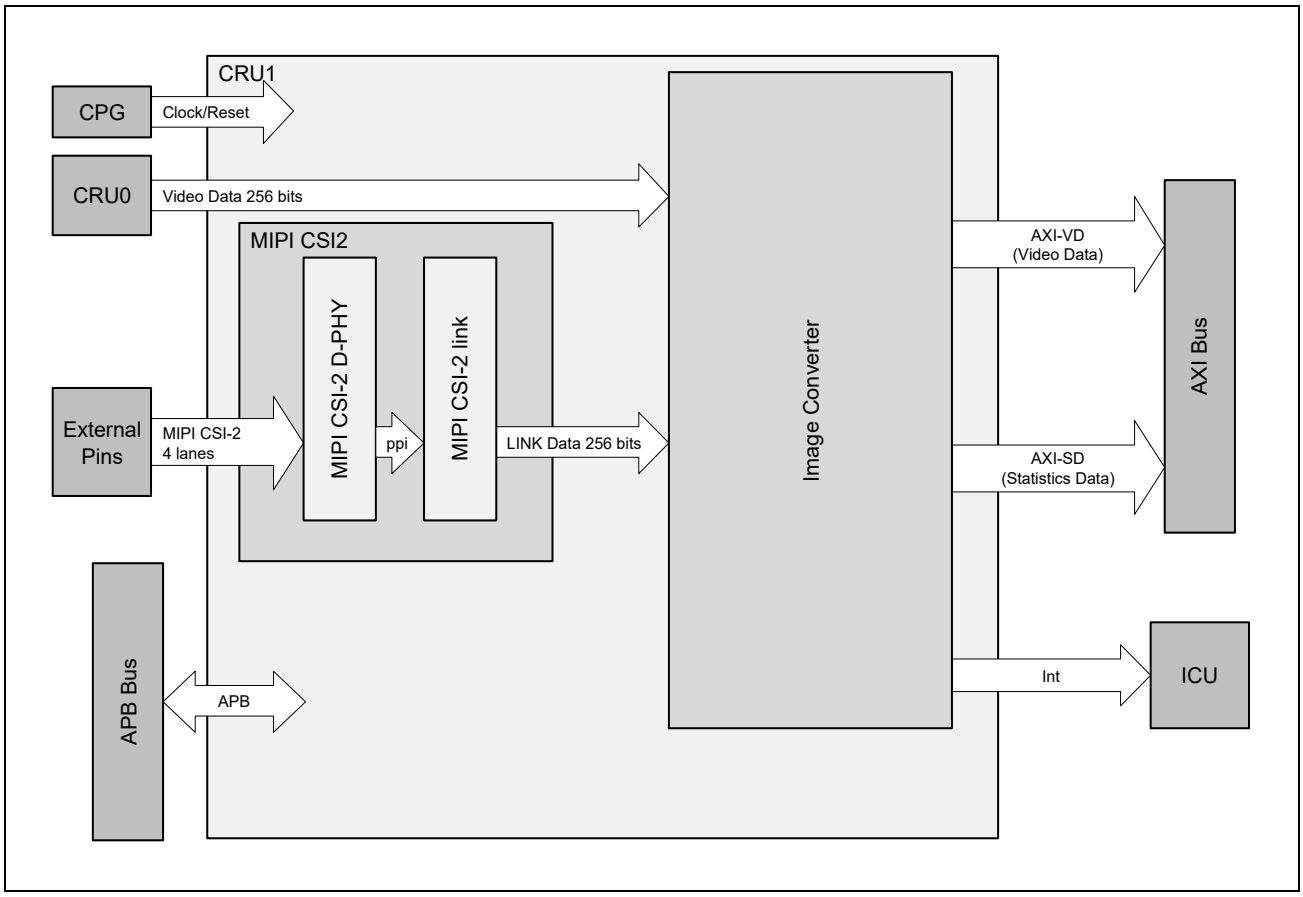

Figure 9.2-3 Block Diagram of CRU1

9.2.3 MIPI CSI2

9.2.3.1 Overview

MIPI CSI2 (camera serial interface 2) receives signals compliant with the DPHY standard from a camera module connected to external pins and decodes them as image data.

Data decoded by this module are sent to the image converter block as the next stage.

9.2.3.1.1 Features

This module has the following functions.

COMMON

1) Data input range

[Pixel size]

- Maximum number of pixels: 8.8 Mpixels; minimum number of pixels: QVGA (320 × 240) = 76.8 Kpixels
- Maximum number of effective pixels in the horizontal direction: 4096 pixels / 8192 pixels*1
- Maximum number of effective pixels in the vertical direction: 4096 lines / 8192 pixels*1

[Other than images]

- Data size range of input long packets: 1 to 24576 bytes

Note 1. 4096 lines when image processing and non-image are selected
8192 lines when full bypass is selected

2) Restrictions on the input bandwidth

Use the input bandwidth within the range which satisfies all conditions in **Table 9.2-2** and **Table 9.2-3**.

Table 9.2-2 Maximum Rate per Lane

	Transfer Rate per Lane (Mbps)		Transfer Rate for All Lanes (Mbps)	
Lane to be Used	MIN	MAX	MIN	MAX
1	80	2100	80	2100
2	80	2100	160	4200
4	80	2100	320	8400

Table 9.2-3 Maximum Transfer Rate per Format for Total of Four Lanes (1/2)

CRUnCTRL.ATH	Input Format	MIPI CSI-2 Transfer Rate (Mbps (max.))
0	YUV422 8-bit	8400
0	YUV422 10-bit	8400
0	RGB444	8400
0	RGB555	8400
0	RGB565	8400
0	RGB666	8400
0	RGB888	8400

Table 9.2-3 Maximum Transfer Rate per Format for Total of Four Lanes (2/2)

CRUnCTRL.ATH	Input Format	MIPI CSI-2 Transfer Rate (Mbps (max.))
0	RAW6	3751
0	RAW7	4359
0	RAW8	5040
0	RAW10	6203
0	RAW12	7331
0	RAW14	8400
0	RAW16	8400
0	RAW20	8400
1 (full bypass)	MIPI recommended memory storage format	8400

3) Restrictions on blanking

At least the time given below is required during the period from the last valid data on a line to the first valid data on the next line.

- When demosaicing is in use: (300 + H-size) × 1/vclk (MHz) or more
  e.g. when vclk = 630 MHz, for VGA (640x480): (300 + 640) × 1/630 (MHz) = approx. 1.50 µs or more
- When demosaicing is not in use: 300 × 1/vclk (MHz) or more
  e.g. when vclk = 630 MHz: 300 × 1/630 (MHz) = approx. 477 ns or more

4) Compliant with the specification for camera serial interface 2 (CSI-2)^{SM}

5) Receiver error detection and reporting

- D-PHY level errors
- Packet level errors
- Protocol decoding level errors

D-PHY

1) Support MIPI D-PHY V1.2 (80 Mbps to 2100 Mbps/lane)

2) Support 1, 2, and 4 lanes

3) Support for receiver deskewing by D-PHY

- In operation at over 1.5 Gbps, periodic deskewing is essential.
- The timing for periodic deskewing calibration: 2^{13} to 10 µs
- The timing for initial deskewing calibration: 2^{15} UI to 100 µs

4) D-PHY Data lane type: CIL-SFEN (forward ULPS only).

5) Low Power Mode Max Speed 10 Mbps

LINK

1) Support MIPI CSI-2 V2.1

2) Support data de-scrambling

3) Support latency reduction and transport efficiency (LRTE)

4) ECC 1-bit error correction and 2-bit error detection in packet headers

5) CRC checking for payload data

6) Support 16 virtual channels

Note: Although the MIPI CSI2 block can receive 16 virtual channels (VC0 to VC15), 4 virtual channels can be selected from VC0 to VC15 in the image converter. Refer to **9.2.4.1.1 Features** for more detail.

7) Number of stages of the FIFO for generic short packets: 16

8) Support data interleaving

- Data type interleaving
  - Packet-level interleaved data transmission
  - Frame-level interleaved data transmission
- Virtual channel identifier interleaving

9.2.3.1.2 Block Diagram

Figure 9.2-4 is a block diagram of MIPI CSI2.

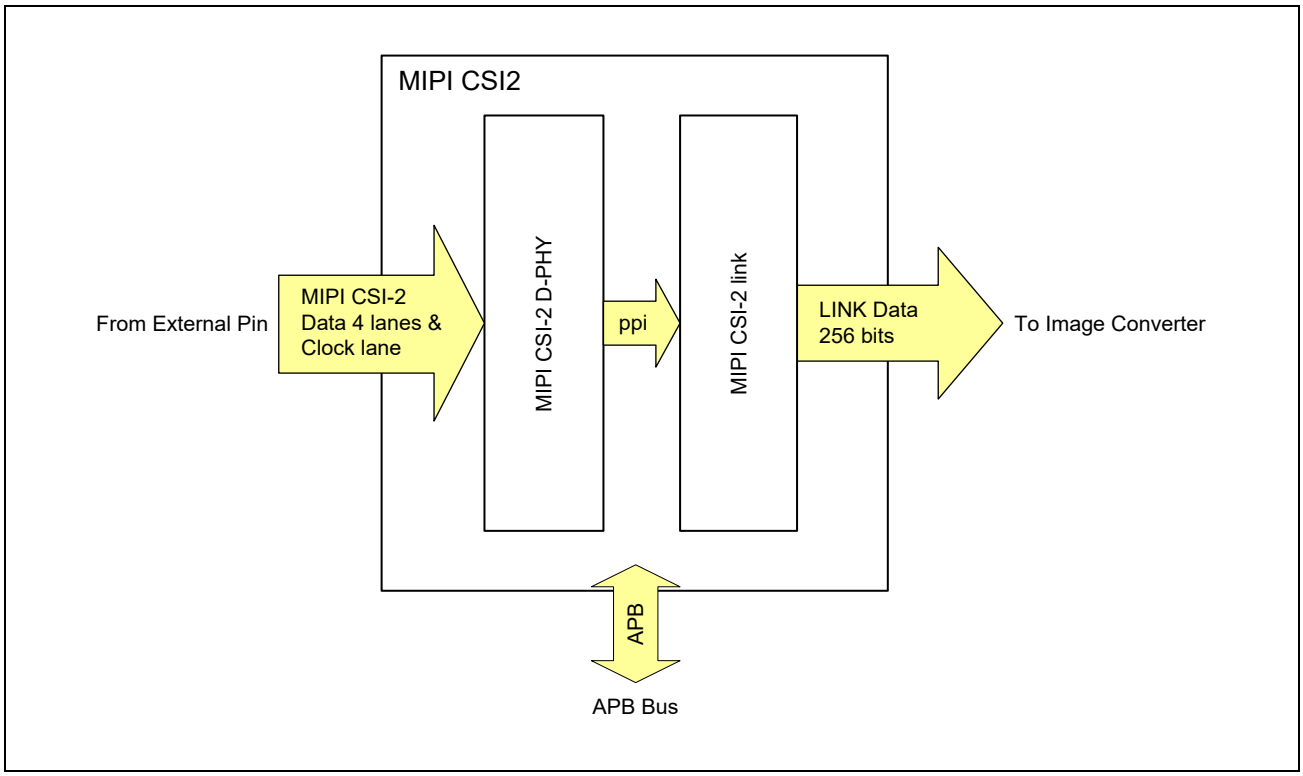

Figure 9.2-4 Block Diagram of MIPI-CSI2

9.2.3.1.3 External Pins

Table 9.2-4 lists the input/output pins of MIPI CSI2.

Table 9.2-4 MIPI CSI2 Input/Output Pins

Category	Pin Name	Input/Output	Description
DPHY Interface for MIPI CSI-2	CSI0_CLKP	Input	MIPI CSI-2 Rx clock input for CRU0 (positive)
	CSI0_CLKN	Input	MIPI CSI-2 Rx clock input for CRU0 (negative)
	CSI0_DATA0P	Input	MIPI CSI-2 Rx serial data input lane 0 for CRU0 (positive)
	CSI0_DATA0N	Input	MIPI CSI-2 Rx serial data input lane 0 for CRU0 (negative)
	CSI0_DATA1P	Input	MIPI CSI-2 Rx serial data input lane 1 for CRU0 (positive)
	CSI0_DATA1N	Input	MIPI CSI-2 Rx serial data input lane 1 for CRU0 (negative)
	CSI0_DATA2P	Input	MIPI CSI-2 Rx serial data input lane 2 for CRU0 (positive)
	CSI0_DATA2N	Input	MIPI CSI-2 Rx serial data input lane 2 for CRU0 (negative)
	CSI0_DATA3P	Input	MIPI CSI-2 Rx serial data input lane 3 for CRU0 (positive)
	CSI0_DATA3N	Input	MIPI CSI-2 Rx serial data input lane 3 for CRU0 (negative)
DPHY Interface for MIPI CSI-2	CSI1_CLKP	Input	MIPI CSI-2 Rx clock input for CRU1 (positive)
	CSI1_CLKN	Input	MIPI CSI-2 Rx clock input for CRU1 (negative)
	CSI1_DATA0P	Input	MIPI CSI-2 Rx serial data input lane 0 for CRU1 (positive)
	CSI1_DATA0N	Input	MIPI CSI-2 Rx serial data input lane 0 for CRU1 (negative)
	CSI1_DATA1P	Input	MIPI CSI-2 Rx serial data input lane 1 for CRU1 (positive)
	CSI1_DATA1N	Input	MIPI CSI-2 Rx serial data input lane 1 for CRU1 (negative)
	CSI1_DATA2P	Input	MIPI CSI-2 Rx serial data input lane 2 for CRU1 (positive)
	CSI1_DATA2N	Input	MIPI CSI-2 Rx serial data input lane 2 for CRU1 (negative)
	CSI1_DATA3P	Input	MIPI CSI-2 Rx serial data input lane 3 for CRU1 (positive)
	CSI1_DATA3N	Input	MIPI CSI-2 Rx serial data input lane 3 for CRU1 (negative)

9.2.3.2 MIPI CSI2 Registers

The base addresses of the CRUm registers are shown below.

Base Address Name	Base Address
<CRU0_base>	0_1600_0000h (5600_0000h*1, 4600_0000h*2)
<CRU1_base>	0_1601_0000h (5601_0000h*1, 4601_0000h*2)

Note 1. CM33 address space (non-secure)

Note 2. CM33 address space (secure)

9.2.3.2.1 List of Registers

(1) CRU LINK Registers (m = 0, 1)

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]

9.2.3.2.2 Register Descriptions

(1) Module Configuration Register (CRUm_CSI2nMCG) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0400h
Initial Value : 0010_0400h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	GSNM[7:0]							
Initial Value	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	SDLN[3:0]				-	-	-	-	VER[3:0]			
Initial Value	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
23 to 16	GSNM[7:0]	10h	R	Indicate the number of stages of the generic short packet FIFO (16 stages).
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11 to 8	SDLN[3:0]	4h	R	Indicate the supported maximum number of data lanes. 4h: Operable with four lanes, two lanes or one lane.
7 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3 to 0	VER[3:0]	0h	R	Indicate the version of this core.

(2) Module Control Register 0 (CRUm_CSI2nMCT0) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0410h
Initial Value : 0200_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	LFSREN	ECCV13	-	-	-	-	RVMD	-	EDMD	ZLMD
Initial Value	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	RW	RW	R	R	R	R0W	RW	R	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	VDLN[3:0]			
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25	LFSREN	1h	RW	Enables or disables de-scrambling. 0b: Disables de-scrambling. 1b: Enables de-scrambling.
24	ECCV13	0h	RW	CSI-2 specification-compliant mode for ECC checking 0b: 26 bits to be checked by ECC 1b: 24 bits to be checked by ECC It is prohibited to set this bit to 1b when receiving a packet whose virtual channel ID is from 4 to 15.
23 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	-	0h	R0W	The read value is always 0b. Do not change the value of this bit from 0h.
19	RVMD	0h	RW	For a packet whose data type is 38h to 3Fh (“Reserved” in "Table 10 Data Type Classes" of the CSI-2 specification), set the receive operation mode to 0. 0b: Discards the data (notifies an ErrID). 1b: Receives data as a long packet (outputs data to the image processing module when the corresponding bit in CSI2nDTEH is 1b, or discards the data and notifies an ErrID when the corresponding bit in CSI2nDTEH is 0b).
18	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	EDMD	0h	RW	Notifies ErrFrameData when an ECC 2-bit error or a packet of less than four bytes is received between FS and FE. 0b: Does not notify ErrFrameData. 1b: Notifies ErrFrameData.
16	ZLMD	0h	RW	Sets whether to output a long packet whose word count is 0 to the image processing module. Set this bit to 0b. 0b: Output 1b: No output
15 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3 to 0	VDLN[3:0]	4h	RW	Set the number of used data lanes. Change this field when CSI2nMCT3.RXEN = 0b. A value equal to or less than the CSI2nMCG.SDLN value can be specified. 1h: Operation with one lane 2h: Operation with two lanes 4h: Operation with four lanes Others: Setting prohibited

(3) Module Control Register 2 (CRUm_CSI2nMCT2) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0418h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	FRRSKW[8:0]								
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	FRRCLK[8:0]								
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
24 to 16	FRRSKW[8:0]	0h	RW	Internal setting parameter Set the following value by using the ROUNDDOWN function that rounds down the decimal places. (ROUNDDOWN((3 * vclk frequency/hsclk1 frequency), 0) + 1) where vclk = 630 MHz, hsclk1 = transfer rate/8 Example: Set 10h when the vclk frequency is 630 MHz and the transfer rate is 1 Gbps. ROUNDDOWN((3 × 630/(1000/8)), 0) + 1 = 16d
15 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8 to 0	FRRCLK[8:0]	0h	RW	Parameter for the IP to determine whether packets have been received if RxWordClkHS stops at the timing when the IP cannot recognize that RxValidHS is low. Set the following value by using the ROUNDDOWN function that rounds down the decimal places. (ROUNDDOWN((1.5 * vclk frequency/hsclk1 frequency), 0) + 1) where vclk = 630 MHz, hsclk1 = transfer rate/8 Example: Set 8h when the vclk frequency is 266 MHz and the transfer rate is 1 Gbps. ROUNDDOWN((1.5 × 630/(1000/8)), 0) + 1 = 8d

(4) Module Control Register 3 (CRUm_CSI2nMCT3) (m = 0, 1)

Access Size : 32 bits

Address : <CRUm_base> + 041Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RXEN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	RXEN	0h	RW	Enables LINK data reception. 0b: Disables reception. 1b: Enables reception.

(5) Reset Control Register (CRUm_CSI2nRTCT) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0428h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	VSRST
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R0W1

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	VSRST	0h	R0W1	The read value is always 0b. Writing 1 to this bit resets the internal LINK signal by a software reset.

(6) Reset Status Register (CRUm_CSI2nRTST) (m = 0, 1)

Access Size : 32 bits

Address : <CRUm_base> + 042Ch

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	VSRSTS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	VSRSTS	0h	R	Indicates the execution status of the software reset generated by CSI2nRTCT.VSRST. 0b: Not during a reset 1b: During a reset

(7) EPD Option Control Register (CRUm_CSI2nEPCT) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0440h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EPDEN	SSP[14:0]														
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EPDOP	SLP[14:0]														
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	EPDEN	0h	RW	Enables the EPD. 0b: Disables the EPD. 1b: Enables the EPD.
30 to 16	SSP[14:0]	0h	RW	Specify the number of spacers inserted after a short packet. This field is valid when EPDEN = 1b. The following shows the specifiable minimum number of spacers when EPDEN = 1b. Setting a value less than the minimum value is prohibited. When EPDOP = 1b, the minimum spacer value is (1) The larger value of the following two values: • Minimum number of spacers due to the D-PHY setting • Minimum number of spacers due to the number of used lanes (2) Minimum number of spacers due to the D-PHY setting: The minimum value can be found by using the ROUNDUP function that rounds up the decimal places. ROUNDUP(((105/UI[ns] + 20) / 8), 0) (3) Minimum number of spacers due to the number of used lanes: 1 lane: minimum spacer = 64 2 lanes: minimum spacer = 32 4 lanes: minimum spacer = 32
15	EPDOP	0h	RW	Selects an EPD option. Set this bit to 1b. 0b: D-PHY EPD Option 1 (0 cannot be set when EPDEN = 1b) 1b: D-PHY EPD Option 2
14 to 0	SLP[14:0]	0h	RW	Specify the number of spacers inserted after a long packet. This field is valid when EPDEN = 1b. When EPDEN = 1b, the minimum number of spacers is the value described in the SSP field. Setting a value less than the minimum value is prohibited.

(8) Module Interrupt Status Register (CRUm_CSI2nMIST) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0450h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	VC15S	VC14S	VC13S	VC12S	VC11S	VC10S	VC9S	VC8S	VC7S	VC6S	VC5S	VC4S	VC3S	VC2S	VC1S	VC0S
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	RXS	GSTS	PMS	-	-	-	-	DL3S	DL2S	DL1S	DL0S
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	VC15S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 15. Check the CSI2nVCST15 register for the details of the interrupt source.
30	VC14S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 14. Check the CSI2nVCST14 register for the details of the interrupt source.
29	VC13S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 13. Check the CSI2nVCST13 register for the details of the interrupt source.
28	VC12S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 12. Check the CSI2nVCST12 register for the details of the interrupt source.
27	VC11S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 11. Check the CSI2nVCST11 register for the details of the interrupt source.
26	VC10S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 10. Check the CSI2nVCST10 register for the details of the interrupt source.
25	VC9S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 9. Check the CSI2nVCST9 register for the details of the interrupt source.
24	VC8S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 8. Check the CSI2nVCST8 register for the details of the interrupt source.
23	VC7S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 7. Check the CSI2nVCST7 register for the details of the interrupt source.
22	VC6S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 6. Check the CSI2nVCST6 register for the details of the interrupt source.
21	VC5S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 5. Check the CSI2nVCST5 register for the details of the interrupt source.
20	VC4S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 4. Check the CSI2nVCST4 register for the details of the interrupt source.
19	VC3S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 3. Check the CSI2nVCST3 register for the details of the interrupt source.
18	VC2S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 2. Check the CSI2nVCST2 register for the details of the interrupt source.
17	VC1S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 1. Check the CSI2nVCST1 register for the details of the interrupt source.
16	VC0S	0h	R	When this bit is set to 1b, there is an interrupt source for virtual channel 0. Check the CSI2nVCST0 register for the details of the interrupt source.
15 to 11	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
10	RXS	0h	R	When this bit is set to 1b, there is an interrupt source for the reception in general. Check the CSI2nRXST register for the details of the interrupt source.
9	GSTS	0h	R	When this bit is set to 1b, there is an interrupt source for reception of generic short packets. Check the CSI2nGSST register for the details of the interrupt source.
8	PMS	0h	R	When this bit is set to 1b, there is an interrupt source for the power management. Check the CSI2nPMST register for the details of the interrupt source.
7 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
3	DL3S	0h	R	When this bit is set to 1b, there is an interrupt source for data lane 3. Check the CSI2nDLST3 register for the details of the interrupt source.
2	DL2S	0h	R	When this bit is set to 1b, there is an interrupt source for data lane 2. Check the CSI2nDLST2 register for the details of the interrupt source.
1	DL1S	0h	R	When this bit is set to 1b, there is an interrupt source for data lane 1. Check the CSI2nDLST1 register for the details of the interrupt source.
0	DL0S	0h	R	When this bit is set to 1b, there is an interrupt source for data lane 0. Check the CSI2nDLST0 register for the details of the interrupt source.

(9) Receive Data Type Enable Low Register (CRUm_CSI2nDTEL) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0460h
Initial Value : 0000_000Fh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DTEN[31:16]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DTEN[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W	RW	RW	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DTEN[31:0]	0000_000Fh	RW (R)	Receive data of a packet in which data type is one of the following. 0b: Does not receive data. 1b: Receives data. Note: After multiple data types are selected here, only one data type is selected by the INF[5:0] bits in the ICnIPMC_C0/1/2/3 register in the image processing module. See **Table 9.2-5** for details on setting this bit.

Table 9.2-5 Receive Data Type Enable Low Register (CSI2nDTEL)

Bit	Data Type	R/W	Description
31	YUV422 10-bit	RW	When this bit is set to 1b, data is output to the image processing module.
30	YUV422 8-bit	RW	
29	YUV420 10-bit	RW	
28	YUV420 8-bit	RW	
27	Reserved	RW	
26	Legacy YUV420 8-bit	RW	
25	YUV420 10-bit	RW	
24	YUV420 8-bit	RW	
23	Reserved	RW	
22	Generic long packet data type 4	RW	
21	Generic long packet data type 3	RW	
20	Generic long packet data type 2	RW	
19	Generic long packet data type 1	RW	
18	Embedded 8-bit non-image data	RW	
17	Blanking data	RW	
16	Null	RW	
15	Generic Short Packet Code 8	RW	Fixed to 1b for each bit.
14	Generic Short Packet Code 7	RW	When each bit is set to 1b and CSI2nGSCT.GFIF = 1, data is output to the generic short packet FIFO.
13	Generic Short Packet Code 6	RW	
12	Generic Short Packet Code 5	RW	
11	Generic Short Packet Code 4	RW	
10	Generic Short Packet Code 3	RW	
9	Generic Short Packet Code 2	RW	
8	Generic Short Packet Code 1	RW	
7 to 4	Reserved	R	Fixed to 0.
3 to 0	Reserved	R	Fixed to 1.

(10) Receive Data Type Enable High Register (CRUm_CSI2nDTEH) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0464h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DTEN[63:48]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DTEN[47:32]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DTEN[63:32]	0000_0000h	RW	Receive data of a packet in which data type is one of the following. 0b: Does not receive data. 1b: Receives data. Note: See **Table 9.2-6** for details on setting this bit.

Table 9.2-6 Receive Data Type Enable High Register (CSI2nDTEH)

Bit	Data Type	R/W	Description
31	Reserved	RW	Changing the reserved bit from the initial value is prohibited.
30 to 24	Reserved	RW	When this bit is set to 1b and CSI2nMCT0.RVMD = 1, data is output to the image processing module.
23	User Defined 8-bit Data Type 8	RW	When this bit is set to 1b, data is output to the image processing module.
22	User Defined 8-bit Data Type 7	RW	
21	User Defined 8-bit Data Type 6	RW	
20	User Defined 8-bit Data Type 5	RW	
19	User Defined 8-bit Data Type 4	RW	
18	User Defined 8-bit Data Type 3	RW	
17	User Defined 8-bit Data Type 2	RW	
16	User Defined 8-bit Data Type 1	RW	
15	RAW20	RW	
14	RAW16	RW	
13	RAW14	RW	
12	RAW12	RW	
11	RAW10	RW	
10	RAW8	RW	
9	RAW7	RW	
8	RAW6	RW	
7 to 5	Reserved	RW	
4	RGB888	RW	
3	RGB666	RW	
2	RGB565	RW	
1	RGB555	RW	
0	RGB444	RW	

(11) Receive Status Register (CRUm_CSI2nRXST) (m = 0, 1)

Access Size : 32 bits

Address : <CRUm_base> + 0470h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RACTDET	RACT
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FRM15	FRM14	FRM13	FRM12	FRM11	FRM10	FRM9	FRM8	FRM7	FRM6	FRM5	FRM4	FRM3	FRM2	FRM1	FRM0
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RACTDET	0h	R	When this bit is set to 1b, CSI2nRXST.RACT = 1b has been detected. Write 1 to CSI2nRXSC.RACTDETC to clear this bit.
16	RACT	0h	R	Indicates that this IP is receiving packets.
15	FRM15	0h	R	Indicates that frames on virtual channel = 15 are being processed.
14	FRM14	0h	R	Indicates that frames on virtual channel = 14 are being processed.
13	FRM13	0h	R	Indicates that frames on virtual channel = 13 are being processed.
12	FRM12	0h	R	Indicates that frames on virtual channel = 12 are being processed.
11	FRM11	0h	R	Indicates that frames on virtual channel = 11 are being processed.
10	FRM10	0h	R	Indicates that frames on virtual channel = 10 are being processed.
9	FRM9	0h	R	Indicates that frames on virtual channel = 9 are being processed.
8	FRM8	0h	R	Indicates that frames on virtual channel = 8 are being processed.
7	FRM7	0h	R	Indicates that frames on virtual channel = 7 are being processed.
6	FRM6	0h	R	Indicates that frames on virtual channel = 6 are being processed.
5	FRM5	0h	R	Indicates that frames on virtual channel = 5 are being processed.
4	FRM4	0h	R	Indicates that frames on virtual channel = 4 are being processed.
3	FRM3	0h	R	Indicates that frames on virtual channel = 3 are being processed.
2	FRM2	0h	R	Indicates that frames on virtual channel = 2 are being processed.
1	FRM1	0h	R	Indicates that frames on virtual channel = 1 are being processed.
0	FRM0	0h	R	Indicates that frames on virtual channel = 0 are being processed.

(12) Receive Status Clear Register (CRUm_CSI2nRXSC) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0474h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RACTDETC	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R0W1	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RACTDETC	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nRXST.RACTDET. Writing 0b to this bit has no effect.
16 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

(13) Receive Interrupt Enable Register (CRUm_CSI2nRXIE) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0478h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RACTDETE	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RACTDETE	0h	RW	Enables interrupts generated by CSI2nRXST.RACTDET. 0b: Does not assert csi2_int_rx when CSI2nRXST.RACTDET = 1b. 1b: Asserts csi2_int_rx when CSI2nRXST.RACTDET = 1b.
16 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

(14) Data Lane (N) Status Register (CRUm_CSI2nDLST(N)) (m = 0, 1)

(N) indicates a logical data lane number.
(N) = 0, 1, 2, or 3

Access Size : 32 bits
Address : <CRUm_base> + 0480h + (N) x 010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	ULP (N)	-	-	-	-	-	-	RUL (N)	EUL (N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	EES (N)	ECT (N)	-	ESH (N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
24	ULP(N)	0h	R	Indicates the RxUlpsEsc status of logical data lane (N).
23 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RUL(N)	0h	R	When this bit is set to 1b, logical data lane (N) has transitioned to the ULPS receive mode (RxUlpsEsc). Write 1b to CSI2nDLSC(N).RULC(N) to clear this bit.
16	EUL(N)	0h	R	When this bit is set to 1b, logical data lane (N) has exited from the ULPS receive mode (RxUlpsEsc). Write 1b to CSI2nDLSC(N).EULC(N) to clear this bit.
15 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	EES(N)	0h	R	When this bit is set to 1b, an escape mode entry error (ErrESC) has occurred on logical data lane (N). Write 1b to CSI2nDLSC(N).EESC(N) to clear this bit.
2	ECT(N)	0h	R	When this bit is set to 1b, a control error (ErrControl) has occurred on logical data lane (N). Write 1b to CSI2nDLSC(N).ECTC(N) to clear this bit.
1	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	ESH(N)	0h	R	When this bit is set to 1b, an SoT error (ErrSotHS) has occurred on logical data lane (N). Write 1b to CSI2nDLSC(N).ESHC(N) to clear this bit.

(15) Data Lane (N) Status Clear Register (CRUm_CSI2nDLSC(N)) (m = 0, 1)

(N) indicates a logical data lane number.
(N) = 0, 1, 2, or 3

Access Size : 32 bits
Address : <CRUm_base> + 0484h + (N) x 010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RULC (N)	EULC (N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R0W1	R0W1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	EESC (N)	ECTC (N)	-	ESHC (N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R0W1	R0W1	R	R0W1

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RULC(N)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nDLST(N).RUL(N). Writing 0b to this bit has no effect.
16	EULC(N)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nDLST(N).EUL(N). Writing 0b to this bit has no effect.
15 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	EESC(N)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nDLST(N).EES(N). Writing 0b to this bit has no effect.
2	ECTC(N)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nDLST(N).ECT(N). Writing 0b to this bit has no effect.
1	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	ESHC(N)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nDLST(N).ESH(N). Writing 0b to this bit has no effect.

(16) Data Lane (N) Interrupt Enable Register (CRUm_CSI2nDLIE(N)) (m = 0, 1)

(N) indicates a logical data lane number.
(N) = 0, 1, 2, or 3

Access Size : 32 bits
Address : <CRUm_base> + 0488h + (N) x 010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	RULE (N)	EULE (N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	EESE (N)	ECTE (N)	-	ESHE (N)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW	R	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	RULE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).RUL(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).RUL(N) = 1b. 1b: Asserts csi2_int_dl when CSI2nDLST(N).RUL(N) = 1b.
16	EULE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).EUL(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).EUL(N) = 1b. 1b: Asserts csi2_int_dl when CSI2nDLST(N).EUL(N) = 1b.
15 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	EESE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).EES(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).EES(N) = 1b. 1b: Asserts csi2_int_dl when CSI2nDLST(N).EES(N) = 1b.
2	ECTE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).ECT(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).ECT(N) = 1b. 1b: Asserts csi2_int_dl when CSI2nDLST(N).ECT(N) = 1b.
1	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	ESHE(N)	0h	RW	Enables interrupts generated by CSI2nDLST(N).ESH(N). 0b: Does not assert csi2_int_dl when CSI2nDLST(N).ESH(N) = 1b. 1b: Asserts csi2_int_dl when CSI2nDLST(N).ESH(N) = 1b.

(17) Virtual Channel (M) Status Register (CRUm_CSI2nVCST(M)) (m = 0, 1)

(M) indicates a virtual channel number.
(M) = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, or 15

Access Size : 32 bits
Address : <CRUm_base> + 0500h + (M) x 010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	LER (M)	LSR (M)	FER (M)	FSR (M)	-	-	-	-	-	-	-	OVF (M)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	-	-	-	-	-	-	FRD (M)	FRS (M)	-	ECN (M)	ECC (M)	WCE (M)	IDE (M)	CRC (M)	ECD (M)	MLF (M)
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27	LER(M)	0h	R	When this bit is set to 1b, a packet whose data type is “Line End Code” has been received. Write 1b to CSI2nVCSC(M).LERC(M) to clear this bit.
26	LSR(M)	0h	R	When this bit is set to 1b, a packet whose data type is “Line Start Code” has been received. Write 1b to CSI2nVCSC(M).LSRC(M) to clear this bit.
25	FER(M)	0h	R	When this bit is set to 1b, a packet whose data type is “Frame End Code” has been received. Write 1b to CSI2nVCSC(M).FERC(M) to clear this bit.
24	FSR(M)	0h	R	When this bit is set to 1b, a packet whose data type is “Frame Start Code” has been received. Write 1b to CSI2nVCSC(M).FSRC(M) to clear this bit.
23 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	OVF(M)	0h	R	When this bit is set to 1b, the generic short packets on virtual channel M have been discarded due to an overflow of the generic short packet FIFO. Write 1b to CSI2nVCSC(M).OVFC(M) to clear this bit.
15 to 10	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
9	FRD(M)	0h	R	When this bit is set to 1b, ErrFrameData has been detected. This bit is set to 1 if any of the following errors occurs during the period between FS and FE: • ErrCRC • ErrWC • ECC 2-bit error (when CSI2nMCT0.EDMD = 1b) • Reception of a packet of less than four bytes (when CSI2nMCT0.EDMD = 1b) Note that this bit is set to 1 if virtual channel = 0 between FS and FE because the virtual channel for the packet with an ECC 2-bit error or the virtual channel which has received a packet of less than four bytes cannot be determined. Write 1b to CSI2nVCSC(M).FRDC(M) to clear this bit.
8	FRS(M)	0h	R	When this bit is set to 1b, ErrFrameSync has been detected. This bit is set to 1b if any of the following conditions occurs: • After an FS was received, another FS has been received on the same virtual channel without receiving an FE. • Although an FE was received, an FS has not been received on the same virtual channel. Write 1b to CSI2nVCSC(M).FRSC(M) to clear this bit.
7	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
6	ECN(M)	0h	R	When this bit is set to 1b, no error was found in ECC checking on the received packets. Write 1b to CSI2nVCSC(M).ECNC(M) to clear this bit.
5	ECC(M)	0h	R	When this bit is set to 1b, a 1-bit error was found in ECC checking on the received packets and the error was corrected. Write 1b to CSI2nVCSC(M).ECCC(M) to clear this bit.

Bit	Bit Name	Initial Value	R/W	Description
4	WCE(M)	0h	R	When this bit is set to 1b, the data payload length of the packet being shorter than the value indicated by WC has been detected. Write 1b to CSI2nVCSC(M).WCEC(M) to clear this bit.
3	IDE(M)	0h	R	When this bit is set to 1b, an ErrID was detected and the packet was discarded. This bit is set to 1 if any of the following conditions occurs: • A packet which is defined as “Reserved” in “Chapter 9 Low Level Protocol” of the CSI-2 specification has been received. - A packet whose data type is 04h to 07h has been received. - A packet whose data type is 38h to 3Fh has been received when CSI2nMCT0.RVMD = 0b. • A generic short packet (data type = 08h to 0Fh) for which the corresponding bit in CSI2nDTEL.DTEN is 0 has been received. • A long packet (data type = 10h to 3Fh) for which the corresponding bit in CSI2nDTEL(H).DTEN is 0 has been received. Write 1 to CSI2nVCSC(M).IDEC(M) to clear this bit. Note that this bit may also be set to 1b if more spacers than the count specified in CSI2nEPCT.SSP/SLP are received when EPD option 2 is in use.
2	CRC(M)	0h	R	When this bit is set to 1b, a CRC error was detected in the received packet. Write 1b to CSI2nVCSC(M).CRCC(M) to clear this bit.
1	ECD(M)	0h	R	When this bit is set to 1b, a 2-bit error was found in ECC checking on the received packets. Because the virtual channel for the packet with an error cannot be determined, the ECD0 field is set to 1b for all virtual channels. To clear the ECD0 field for all virtual channels, write 1b to CSI2nVCSC(M).AECDC(M) for any virtual channel. To clear the ECD0 field of virtual channel M, write 1b to CSI2nVCSC(M).ECDC(M).
0	MLF(M)	0h	R	When this bit is set to 1b, a packet of less than 4 bytes has been received. Because the virtual channel for the packet with an error cannot be determined, the MLF0 field is set to 1b for all virtual channels. To clear the MLF0 field for all virtual channels, write 1b to CSI2nVCSC(M).AMLFC(M) for any virtual channel. To clear the MLF0 field of virtual channel 0, write 1b to CSI2nVCSC(M).MLFC(M).

(18) Virtual Channel (M) Status Clear Register (CRUm_CSI2nVCSC(M)) (m = 0, 1)

(M) indicates a virtual channel number.
(M) = 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, or 15

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27	LERC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).LER(M). Writing 0b to this bit has no effect.
26	LSRC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).LSR(M). Writing 0b to this bit has no effect.
25	FERC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).FER(M). Writing 0b to this bit has no effect.
24	FSRC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).FSR(M). Writing 0b to this bit has no effect.
23 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	OVFC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).OVF(M). Writing 0b to this bit has no effect.
15	AECDC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).ECD(M) for all virtual channels. Writing 0b to this bit has no effect.
14	AMLFC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).MLF(M) for all virtual channels. Writing 0b to this bit has no effect.
13 to 10	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
9	FRDC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).FRD(M). Writing 0b to this bit has no effect.
8	FRSC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).FRS(M). Writing 0b to this bit has no effect.
7	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
6	ECNC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).ECN(M). Writing 0b to this bit has no effect.
5	ECCC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).ECC(M). Writing 0b to this bit has no effect.

Bit	Bit Name	Initial Value	R/W	Description
4	WCEC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear the CSI2nVCST(M).WCE(M). Writing 0b to this bit has no effect.
3	IDEC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).IDE(M). Writing 0b to this bit has no effect.
2	CRCC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).CRC(M). Writing 0b to this bit has no effect.
1	ECDC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).ECD(M). Writing 0b to this bit has no effect.
0	MLFC(M)	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nVCST(M).MLF(M). Writing 0b to this bit has no effect.

(19) Virtual Channel (M) Interrupt Enable Register (CRUm_CSI2nVCIE(M)) (m = 0, 1)

(M) indicates a virtual channel number.

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27 to 24	DLUL[3:0]	0h	R	Indicate the RxUlpsEsc status of a logical data lane. Bit 0: RxUlpsEsc of logical lane 0 Bit 1: RxUlpsEsc of logical lane 1 Bit 2: RxUlpsEsc of logical lane 2 Bit 3: RxUlpsEsc of logical lane 3
23 to 20	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
19 to 16	DLSS[3:0]	Fh	R	Indicate the stop state of a logical data lane. Bit 0: Stop state of logical lane 0 Bit 1: Stop state of logical lane 1 Bit 2: Stop state of logical lane 2 Bit 3: Stop state of logical lane 3
15	CLUL	0h	R	Indicates the inverted state of RxUlpsClkNot of the PPI clock lane. 0b: Not in ULPS 1b: In ULPS
14	CLSS	1h	R	Indicates the stop state of the PPI clock lane. 0b: Not in the stop state 1b: In the stop state
13 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
7	CUN	0h	R	When this bit is set to 1b, the clock lane has transitioned to ULPS mode (inverse of RxUlpsClkNot). Write 1b to CSI2nPMSC.CUNC to clear this bit.
6	CUX	0h	R	When this bit is set to 1b, the clock lane has transitioned from ULPS mode (inverse of RxUlpsClkNot) to non-ULPS mode. Write 1b to CSI2nPMSC.CUXC to clear this bit.
5	DUN	0h	R	When this bit is set to 1b, all valid data lanes have transitioned to ULPS mode. Write 1b to CSI2nPMSC.DUNC to clear this bit.
4	DUX	0h	R	When this bit is set to 1b, all valid data lanes have transitioned from ULPS mode to any other state. Write 1b to CSI2nPMSC.DUXC to clear this bit.
3	CSN	0h	R	When this bit is set to 1b, the clock lane has transitioned to the stop state. Write 1b to CSI2nPMSC.CSNC to clear this bit.
2	CSX	0h	R	When this bit is set to 1b, the clock lane has transitioned from the stop state to a non-stop state. Write 1b to CSI2nPMSC.CSXC to clear this bit.
1	DSN	0h	R	When this bit is set to 1b, all valid data lanes have transitioned to the stop state. Write 1b to CSI2nPMSC.DSNC to clear this bit.
0	DSX	0h	R	When this bit is set to 1b, all valid data lanes have transitioned from the stop state to any other state. Write 1b to CSI2nPMSC.DSXC to clear this bit.

3	CSNC	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nPMST.CSN. Writing 0b to this bit has no effect.
2	CSXC	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nPMST.CSX. Writing 0b to this bit has no effect.
1	DSNC	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nPMST.DSN. Writing 0b to this bit has no effect.
0	DSXC	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nPMST.DSX. Writing 0b to this bit has no effect.

(22) Power Management Interrupt Enable Register (CRUm_CSI2nPMIE) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0608h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	CUNE	CUXE	DUNE	DUXE	CSNE	CSXE	DSNE	DSXE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
7	CUNE	0h	RW	Enables interrupts generated by CSI2nPMST.CUN. 0b: Does not assert csi2_int_pm when CSI2nPMST.CUN = 1b. 1b: Asserts csi2_int_pm when CSI2nPMST.CUN = 1b.
6	CUXE	0h	RW	Enables interrupts generated by CSI2nPMST.CUX. 0b: Does not assert csi2_int_pm when CSI2nPMST.CUX = 1b. 1b: Asserts csi2_int_pm when CSI2nPMST.CUX = 1b.
5	DUNE	0h	RW	Enables interrupts generated by CSI2nPMST.DUN. 0b: Does not assert csi2_int_pm when CSI2nPMST.DUN = 1b. 1b: Asserts csi2_int_pm when CSI2nPMST.DUN = 1b.
4	DUXE	0h	RW	Enables interrupts generated by CSI2nPMST.DUX. 0b: Does not assert csi2_int_pm when CSI2nPMST.DUX = 1b. 1b: Asserts csi2_int_pm when CSI2nPMST.DUX = 1b.
3	CSNE	0h	RW	Enables interrupts generated by CSI2nPMST.CSN. 0b: Does not assert csi2_int_pm when CSI2nPMST.CSN = 1b. 1b: Asserts csi2_int_pm when CSI2nPMST.CSN = 1b.
2	CSXE	0h	RW	Enables interrupts generated by CSI2nPMST.CSX. 0b: Does not assert csi2_int_pm when CSI2nPMST.CSX = 1b. 1b: Asserts csi2_int_pm when CSI2nPMST.CSX = 1b.
1	DSNE	0h	RW	Enables interrupts generated by CSI2nPMST.DSN. 0b: Does not assert csi2_int_pm when CSI2nPMST.DSN = 1b. 1b: Asserts csi2_int_pm when CSI2nPMST.DSN = 1b.
0	DSXE	0h	RW	Enables interrupts generated by CSI2nPMST.DSX. 0b: Does not assert csi2_int_pm when CSI2nPMST.DSX = 1b. 1b: Asserts csi2_int_pm when CSI2nPMST.DSX = 1b.

(23) Generic Short Packet Control Register (CRUm_CSI2nGSCT) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0680h
Initial Value : 0001_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	GFIF
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R0W	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	SHTH[6:0]						
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	-	0h	R0W	The read value is always 0b. Do not change the value of this bit from 0h.
16	GFIF	1h	RW	When this bit is set to 1b, the received generic short packet is stored in the generic short packet FIFO (GS FIFO).
15 to 7	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
6 to 0	SHTH[6:0]	0h	RW	Asserts CSI2nGSST.GTH while the number of packets stored in the generic short packet FIFO equals or exceeds the value of this field + 1. Set this field to 15 or less when using CSI2nGSST.GTH. Set the default value when not using CSI2nGSST.GTH.

(24) Generic Short Packet Status Register (CRUm_CSI2nGSST) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0684h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	STRDS	GCD
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PNUM[7:0]								-	-	-	GOV	-	-	GTH	GNE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
17	STRDS	0h	R	Indicates whether the received generic short packets can be stored in the generic short packet FIFO. 0b: Can be stored in the generic short packet FIFO. 1b: Cannot be stored in the generic short packet FIFO. This field indicates an inverted value of the store_en signal described in **9.2.3.3.1 Data Reception** with a delay for an internal latency. The previous value may be read depending on the signal change timing.
16	GCD	0h	R	When this bit is set to 1b, the GS FIFO is being cleared by CSI2nGSCT.GFCLR.
15 to 8	PNUM[7:0]	0h	R	Indicate the number of packets stored in the generic short packet FIFO.
7 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	GOV	0h	R	When this bit is set to 1b, the generic short packet FIFO has overflowed. Write 1b to CSI2nGSSC.GOVC to clear this bit.
3, 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	GTH	0h	R	When this bit is set to 1b, the number of packets stored in the generic short packet FIFO equals or exceeds “CSI2nGSCT.SHTH + 1”.
0	GNE	0h	R	When this bit is set to 1b, the generic short packet FIFO is not empty.

(25) Generic Short Packet Status Clear Register (CRUm_CSI2nGSSC) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0688h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	GOVC	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R0W1	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	GOVC	0h	R0W1	The read value is always 0b. Write 1b to this bit to clear CSI2nGSST.GOV. Writing 0b to this bit has no effect.
3 to 0	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

(26) Generic Short Packet Interrupt Enable Register (CRUm_CSI2nGSIE) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 068Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	GOVE	-	-	GTHE	GNEE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	RW	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
4	GOVE	0h	RW	Enables interrupts generated by CSI2nGSST.GOV. 0b: Does not assert csi2_int_gst when CSI2nGSST.GOV = 1b. 1b: Asserts csi2_int_gst when CSI2nGSST.GOV = 1b.
3, 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	GTHE	0h	RW	Enables interrupts generated by CSI2nGSST.GTH. 0b: Does not assert csi2_int_gst when CSI2nGSST.GTH = 1b. 1b: Asserts csi2_int_gst when CSI2nGSST.GTH = 1b.
0	GNEE	0h	RW	Enables interrupts generated by CSI2nGSST.GNE. 0b: Does not assert csi2_int_gst when CSI2nGSST.GNE = 1b. 1b: Asserts csi2_int_gst when CSI2nGSST.GNE = 1b.

(27) Generic Short Packet Register (CRUm_CSI2nGSHT) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0690h
Initial Value : 0008_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	SPVC[3:0]				-	-	DTYP[5:0]					
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPDT[15:0]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
27 to 24	SPVC[3:0]	0h	R	Indicate the virtual channel.
23, 22	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
21 to 16	DTYP[5:0]	8h	R	Indicate the data type. 08h-0Fh
15 to 0	SPDT[15:0]	0h	R	Indicate 16-bit user-defined data.

(28) Generic Short Packet Information Update Register (CRUm_CSI2nGSIU) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0694h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	GFEN
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R0W1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	GFCLR	-	-	-	-	-	-	-	FINC
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	RW	R	R	R	R	R	R	R	R0W1

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
16	GFEN	0h	R0W1	The read value is always 0b. When the GS FIFO has overflowed, write 1b to this bit to enable storing of generic short packets in the GS FIFO which has been disabled.
15 to 9	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
8	GFCLR	0h	RW	Clears the GS FIFO. Writing 1b to this bit requests clearing of the FIFO. Writing 0b to this bit requests clearing of the FIFO to be released.
7 to 1	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
0	FINC	0h	R0W1	The read value is always 0b. Write 1b to this bit to update data of the packet indicated in the CSI2nGSHT register for the next packet. Writing 0b to this bit has no effect. Writing 1b to this bit while CSI2nGSST.PNUM = 0b is prohibited.

(29) Slave Timing Control Register (CRUm_S_TIMCTL) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 081Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	S_HSSETTLECTL[7:0]								-	-	-	-	-	-	S_CLKSETTLECTL[1:0]	
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
15 to 8	S_HSSETTLECTL[7:0]	0h	RW	Slave Data Lane Control Register for THS-SETTLE. Set the values according to **Table 9.2-7**.
7 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1, 0	S_CLKSETTLECTL[1:0]	0h	RW	Do not change the value of this bit from 0h.

Table 9.2-7 S_TIMCTL.S_HSSETTLECTL[7:0] Register Settings

Transmission Rate TR (Mbps)	S_HSSETTLECTL[7:0]	Transmission Rate TR (Mbps)	S_HSSETTLECTL[7:0]

(30) Slave D-PHY Control Register (MSB) (CRUm_S_DPHYCTL_MSB) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0834h
Initial Value : 0000_0090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	S_DPHYCTL[63:48]															
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	S_DPHYCTL[47:32]															
Initial Value	0	0	0	0	0	0	0	0	1	0	0	1	0	0	0	0
R/W	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	S_DPHYCTL [63:34]	24h	RW	Changing this bit from 24h to a different value is prohibited.
1	S_DPHYCTL [33]	All 0	RW	DeSkew Calibration Function Enable/Disable Control • 0b: DeSkew Calibration Disable • 1b: DeSkew Calibration Enable
0	S_DPHYCTL [32]	All 0	RW	Changing this bit from 0h to a different value is prohibited.

(31) DP/DN Swap Control Register (CRUm_SWAPCTL) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0838h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	S_DPDN_SWAP_DAT	S_DPDN_SWAP_CLK	-	-	M_DPDN_SWAP_DAT	M_DPDN_SWAP_CLK
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	RW	RW	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
5	S_DPDN_SWAP_DAT	0h	RW	Slave PPI signal This signal is for crossing PCB trace lines of DP and DN when it connects the Slave lane to a Master lane on the PCB board. This signal swaps all the DP and DN signals of Slave when set to HIGH. Tie this signal to the ground when the connections are correct.
4	S_DPDN_SWAP_CLK	0h	RW	Slave PPI signal This signal is for crossing PCB trace lines of DP and DN when it connects the Slave lane to a Master lane on the PCB board. This signal swaps all the DP and DN signals of Slave when set to HIGH. Tie this signal to the ground when the connections are correct.
3, 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	M_DPDN_SWAP_DAT	0h	RW	Do not change the value of this bit from 0h.
0	M_DPDN_SWAP_CLK	0h	RW	Do not change the value of this bit from 0h.

(32) RX Skew Calibration Results n (CRUm_S_ATB_OUT_n) (m = 0, 1, n = 0 to 3)

Access Size : 32 bits

Address : <CRUm_base> + 086Ch + n x 0004h

Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	S_ATB_OUT_n	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	S_ATB_OUT_n	0h	R	The initial/periodic deskew calibration status for lane n (for debugging) 0b: Calibration in progress or calibration failed 1b: Calibration completed
0	-	0h	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

9.2.3.3 Operation (Short Packet Reception)

The prefix “CRUm” of the register names is omitted in the following subsections.

9.2.3.3.1 Data Reception

(1) Common between short packets and long packets

Figure 9.2-5 shows the flow when receiving a packet whose data type is A and virtual channel is M (0, 1, 2, to 15).

This flow is common between short packets and long packets.

Upon receiving a packet, the LINK checks the length of the received packet.

If the length of the received packet is less than the packet header length (4 bytes), a virtual channel cannot be determined, resulting in setting CSI2nVCST(M).MLF(M) to 1b for all virtual channels. In addition, this packet is discarded because it is invalid.

When the length of the received packet is 4 bytes or more, ECC checking is performed. The check results are indicated in the CSI2nVCST(M) register.

- 2-bit error: Because the virtual channel of the packet with an error cannot be determined, CSI2nVCST(M).ECD(M) is set to 1b for all virtual channels.
  In addition, the packet is discarded because error correction cannot be performed.
- 1-bit error: CSI2nVCST(M).ECC(M) is set to 1b for the relevant virtual channel.
  Error correction proceeds because it is possible.
  No error: CSI2nVCST(M).ECN(M) is set to 1b for the relevant virtual channel.

If the ECC check results are “1-bit error” or “no error”, the data type field of the packet header is analyzed.

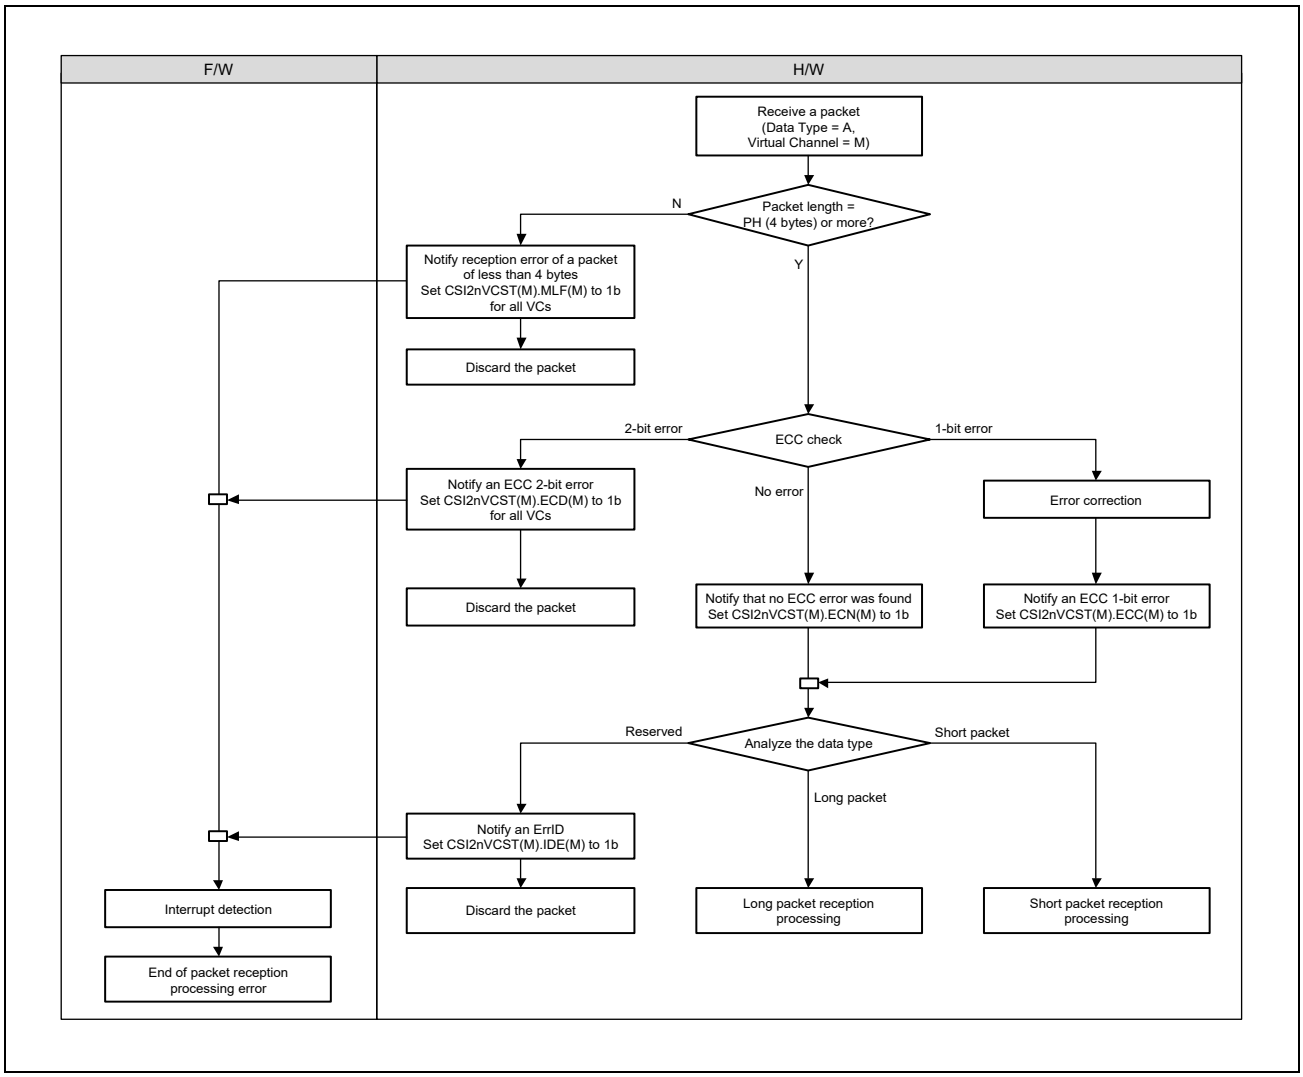

Figure 9.2-5 Packet Reception Processing

(2) Generic short packet data type code

Figure 9.2-6 shows the flow when receiving a packet whose data type is generic short packet code 1 to 8 and virtual channel is M.

When the corresponding bit in CSI2nDTEL.DTEN is set to 0b, CSI2nVCST(M).IDE(M)) is asserted and the packet is discarded.

When the corresponding bit in CSI2nDTEL.DTEN is set to 1b and CSI2nGSCT.GFIF is set to 1b, the generic short packet is output to the generic short packet FIFO. For details on the operation when using the generic short packet FIFO, see the flow in **Figure 9.2-6**.

The initial value of internal signal store_en which is described in the flow is 1. When store_en is set to 1, packets can be stored in the generic short packet FIFO. When it is set to 0, packets cannot be stored in the generic short packet FIFO.

- store_en is set to 0 when the generic short packet FIFO has overflowed.
- store_en is set to 1 when 1b is written to CSI2nGSIU.GFEN.

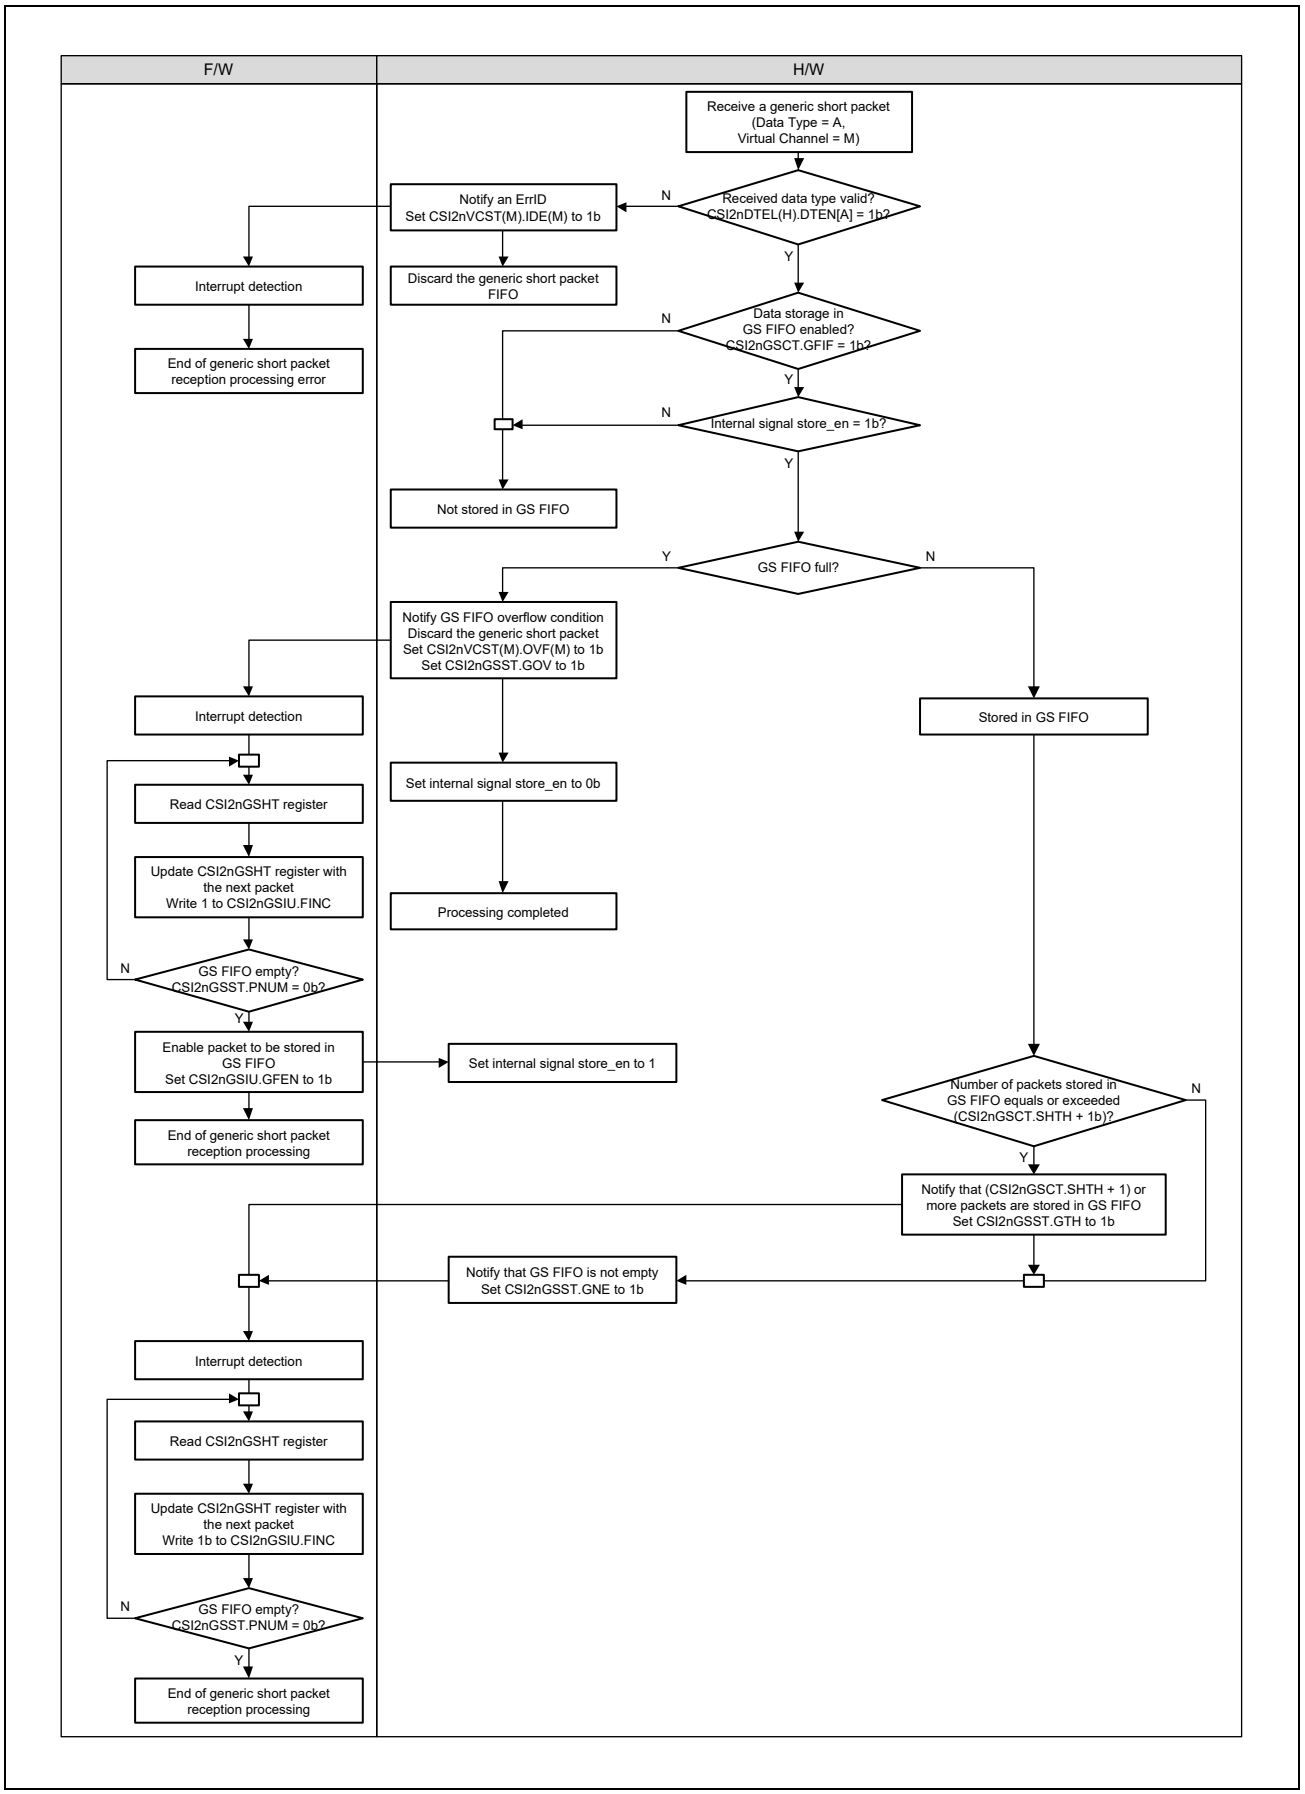

Figure 9.2-6 Generic Short Packet Reception Processing

(3) Clearing the generic short packet FIFO

Figure 9.2-7 shows how the generic short packet FIFO is cleared.

Writing 1b to CSI2nGSIU.GFCLR starts clearing the generic short packet FIFO.

After requesting to clear the generic short packet FIFO, check if CSI2nGSST.GCD is set to 1b to make sure that the FIFO is cleared. Then, writing 0b to CSI2nGSIU.GFCLR cancels the request for clearing the generic short packet FIFO. Check if CSI2nGSST.GCD is set to 0b to make sure that the request for clearing the generic short packet FIFO is canceled.

When CSI2nMCG.GSNM is set to 0b, it is prohibited to clear the generic short packet FIFO.

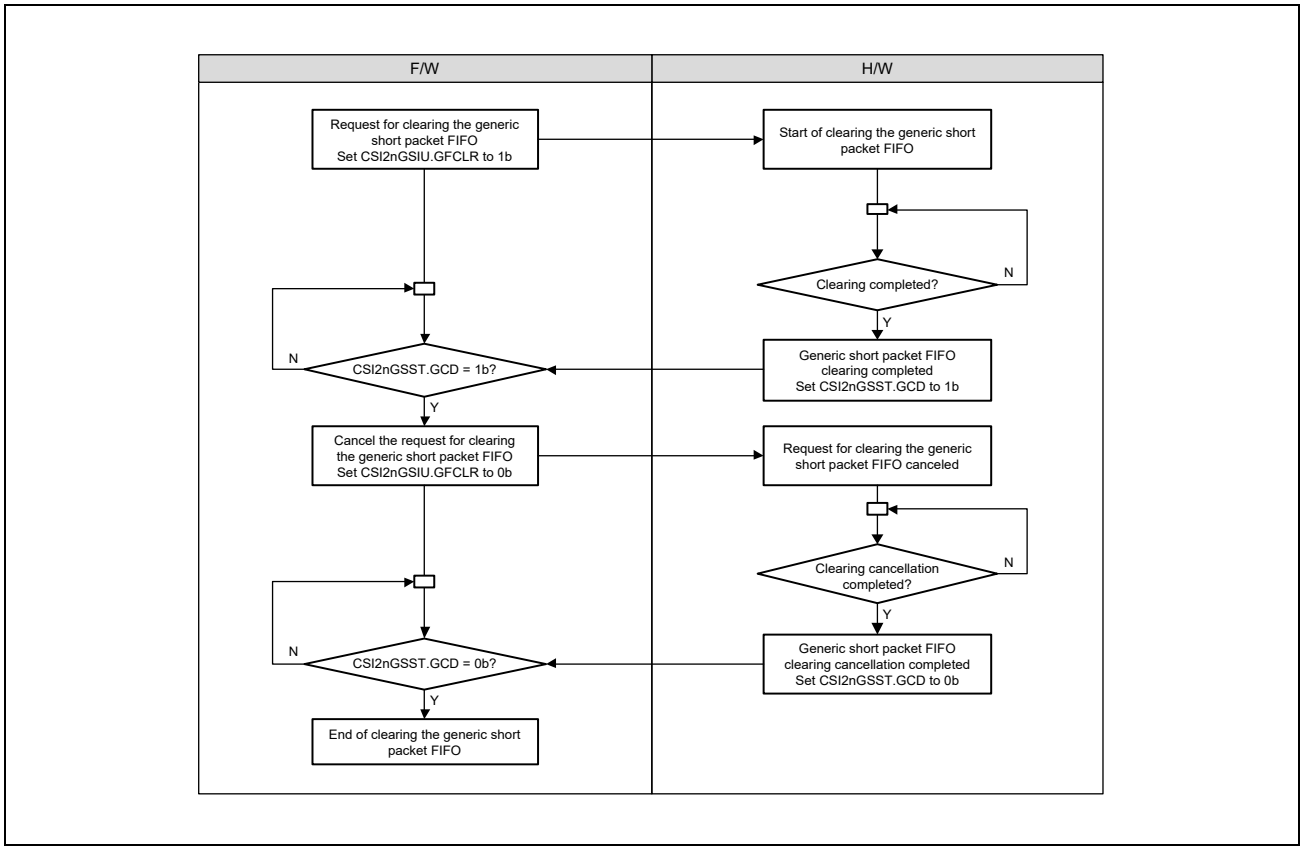

Figure 9.2-7 Clearing the Generic Short Packet FIFO

9.2.3.4 Interrupts

Figure 9.2-8 shows the structure of interrupt signals of MIPI CSI2. CRU0 and 1 each have an interrupt. The conditions for interrupt generation, interrupt source registers, and interrupt enable registers are listed in **Table 9.2-8**, **Table 9.2-9**, and **Table 9.2-10**. The CSI2nMIST register indicates the interrupt output state. When an interrupt is generated, read the CSI2nMIST register to identify the interrupt source.

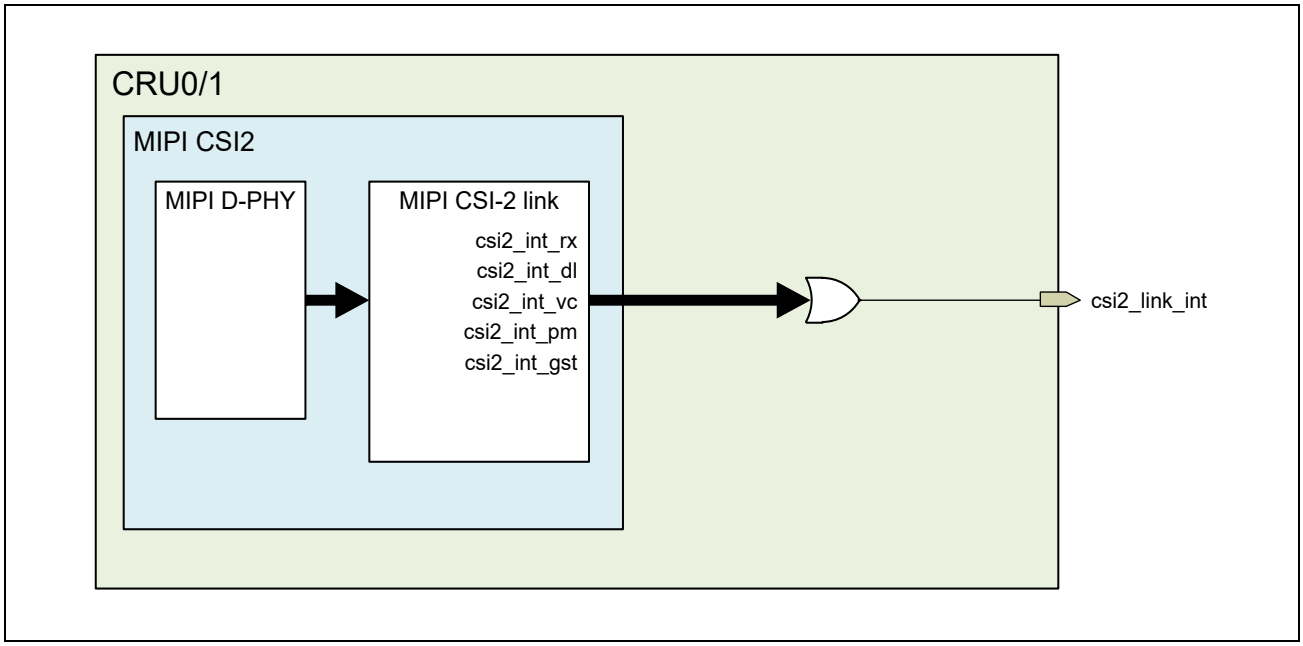

Figure 9.2-8 Interrupt Structure

Table 9.2-8 Interrupt States and Generation Conditions (1)

Interrupt State	Interrupt Source Register Field	Interrupt Enable Register Field	Generation Condition
CSI2nMIST.RXS	CSI2nRXST.RACTDET	CSI2nRXIE.RACTDETE	This IP received a packet.
CSI2nMIST.DLS0	CSI2nDLST0.ESH0	CSI2nDLIE0.ESHE0	ErrSotHS occurred on DL0.
	CSI2nDLST0.ECT0	CSI2nDLIE0.ECTE0	ErrControl occurred on DL0.
	CSI2nDLST0.EES0	CSI2nDLIE0.EESE0	ErrESC occurred on DL0.
	CSI2nDLST0.EUL0	CSI2nDLIE0.EULE0	DL0 exited from the ULPS.
	CSI2nDLST0.RUL0	CSI2nDLIE0.RULE0	DL0 transitioned to the ULPS.
CSI2nMIST.DLS1	CSI2nDLST1.ESH1	CSI2nDLIE1.ESHE1	ErrSotHS occurred on DL1.
	CSI2nDLST1.ECT1	CSI2nDLIE1.ECTE1	ErrControl occurred on DL1.
	CSI2nDLST1.EES1	CSI2nDLIE1.EESE1	ErrESC occurred on DL1.
	CSI2nDLST1.EUL1	CSI2nDLIE1.EULE1	DL1 exited from the ULPS.
	CSI2nDLST1.RUL1	CSI2nDLIE1.RULE1	DL1 transitioned to the ULPS.
CSI2nMIST.DLS2	CSI2nDLST2.ESH2	CSI2nDLIE2.ESHE2	ErrSotHS occurred on DL2.
	CSI2nDLST2.ECT2	CSI2nDLIE2.ECTE2	ErrControl occurred on DL2.
	CSI2nDLST2.EES2	CSI2nDLIE2.EESE2	ErrESC occurred on DL2.
	CSI2nDLST2.EUL2	CSI2nDLIE2.EULE2	DL2 exited from the ULPS.
	CSI2nDLST2.RUL2	CSI2nDLIE2.RULE2	DL2 transitioned to the ULPS.
CSI2nMIST.DLS3	CSI2nDLST3.ESH3	CSI2nDLIE3.ESHE3	ErrSotHS occurred on DL3.
	CSI2nDLST3.ECT3	CSI2nDLIE3.ECTE3	ErrControl occurred on DL3.
	CSI2nDLST3.EES3	CSI2nDLIE3.EESE3	ErrESC occurred on DL3.
	CSI2nDLST3.EUL3	CSI2nDLIE3.EULE3	DL3 exited from the ULPS.
	CSI2nDLST3.RUL3	CSI2nDLIE3.RULE3	DL3 transitioned to the ULPS.

Table 9.2-9 Interrupt States and Generation Conditions (2)

Interrupt State	Interrupt Source Register Field	Interrupt Enable Register Field	Generation Condition
CSI2nMIST.VCS0	CSI2nVCST0.MLF0	CSI2nVCIE0.MLFE0	Malformed packet was received on VC0.
	CSI2nVCST0.ECD0	CSI2nVCIE0.ECDE0	ErrEccDouble occurred on VC0.
	CSI2nVCST0.CRC0	CSI2nVCIE0.CRCE0	ErrCrc occurred on VC0.
	CSI2nVCST0.IDE0	CSI2nVCIE0.IDEE0	ErrID occurred on VC0.
	CSI2nVCST0.WCE0	CSI2nVCIE0.WCEE0	ErrWC occurred on VC0.
	CSI2nVCST0.ECC0	CSI2nVCIE0.ECCE0	ErrEccCorrected occurred on VC0.
	CSI2nVCST0.ECN0	CSI2nVCIE0.ECNE0	ErrEccNoError occurred on VC0.
	CSI2nVCST0.FRS0	CSI2nVCIE0.FRSE0	ErrFrameSync occurred on VC0.
	CSI2nVCST0.FRD0	CSI2nVCIE0.FRDE0	ErrFrameData occurred on VC0.
	CSI2nVCST0.OVF0	CSI2nVCIE0.OVFE0	Generic short packets on VC0 were discarded because GS FIFO overflowed.
	CSI2nVCST0.FSR0	CSI2nVCIE0.FSRE0	Frame start was received on VC0.
	CSI2nVCST0.FER0	CSI2nVCIE0.FERE0	Frame end was received on VC0.
	CSI2nVCST0.LSR0	CSI2nVCIE0.LSRE0	Line start was received on VC0.
	CSI2nVCST0.LER0	CSI2nVCIE0.LERE0	Line end was received on VC0.
CSI2nMIST.VCS1	CSI2nVCST1.MLF1	CSI2nVCIE1.MLFE1	Malformed packet was received on VC1.
	CSI2nVCST1.ECD1	CSI2nVCIE1.ECDE1	ErrEccDouble occurred on VC1.
	CSI2nVCST1.CRC1	CSI2nVCIE1.CRCE1	ErrCrc occurred on VC1.
	CSI2nVCST1.IDE1	CSI2nVCIE1.IDEE1	ErrID occurred on VC1.
	CSI2nVCST1.WCE1	CSI2nVCIE1.WCEE1	ErrWC occurred on VC1.
	CSI2nVCST1.ECC1	CSI2nVCIE1.ECCE1	ErrEccCorrected occurred on VC1.
	CSI2nVCST1.ECN1	CSI2nVCIE1.ECNE1	ErrEccNoError occurred on VC1.
	CSI2nVCST1.FRS1	CSI2nVCIE1.FRSE1	ErrFrameSync occurred on VC1.
	CSI2nVCST1.FRD1	CSI2nVCIE1.FRDE1	ErrFrameData occurred on VC1.
	CSI2nVCST1.OVF1	CSI2nVCIE1.OVFE1	Generic short packets on VC1 were discarded because GS FIFO overflowed.
	CSI2nVCST1.FSR1	CSI2nVCIE1.FSRE1	Frame start was received on VC1.
	CSI2nVCST1.FER1	CSI2nVCIE1.FERE1	Frame end was received on VC1.
	CSI2nVCST1.LSR1	CSI2nVCIE1.LSRE1	Line start was received on VC1.
	CSI2nVCST1.LER1	CSI2nVCIE1.LERE1	Line end was received on VC1.
…	…	…	…

Table 9.2-10 Interrupt States and Generation Conditions (3)

Interrupt State	Interrupt Source Register Field	Interrupt Enable Register Field	Generation Condition
CSI2nMIST.VCS15	CSI2nVCST15.MLF15	CSI2nVCIE15.MLFE15	Malformed packet was received on VC15.
	CSI2nVCST15ECD15	CSI2nVCIE15.ECDE15	ErrEccDouble occurred on VC15.
	CSI2nVCST15.CRC15	CSI2nVCIE15.CRCE15	ErrCrc occurred on VC15.
	CSI2nVCST15.IDE15	CSI2nVCIE15.IDEE15	ErrID occurred on VC15.
	CSI2nVCST15.WCE15	CSI2nVCIE15.WCEE15	ErrWC occurred on VC15.
	CSI2nVCST15.ECC15	CSI2nVCIE15.ECCE15	ErrEccCorrected occurred on VC15.
	CSI2nVCST15.ECN15	CSI2nVCIE15.ECNE15	ErrEccNoError occurred on VC15.
	CSI2nVCST15.FRS15	CSI2nVCIE15.FRSE15	ErrFrameSync occurred on VC15.
	CSI2nVCST15.FRD15	CSI2nVCIE15.FRDE15	ErrFrameData occurred on VC15.
	CSI2nVCST15.OVF15	CSI2nVCIE15.OVFE15	Generic short packets on VC15 were discarded because GS FIFO overflowed.
	CSI2nVCST15.FSR15	CSI2nVCIE15.FSRE15	Frame start was received on VC15.
	CSI2nVCST15.FER15	CSI2nVCIE15.FERE15	Frame end was received on VC15.
	CSI2nVCST15.LSR15	CSI2nVCIE15.LSRE15	Line start was received on VC15.
	CSI2nVCST15.LER15	CSI2nVCIE15.LERE15	Line end was received on VC15.
CSI2nMIST.PMS	CSI2nPMST.DSX	CSI2nPMIE.DSXE	All data lanes exited from the stop state.
	CSI2nPMST.DSN	CSI2nPMIE.DSNE	All data lanes transitioned to the stop state.
	CSI2nPMST.CSX	CSI2nPMIE.CSXE	The clock lane exited from the stop state.
	CSI2nPMST.CSN	CSI2nPMIE.CSNE	The clock lane transitioned to the stop state.
	CSI2nPMST.DUX	CSI2nPMIE.DUXE	All data lanes exited from the ULPS.
	CSI2nPMST.DUN	CSI2nPMIE.DUNE	All data lanes transitioned to the ULPS.
	CSI2nPMST.CUX	CSI2nPMIE.CUXE	The clock lane exited from the ULPS.
	CSI2nPMST.CUN	CSI2nPMIE.CUNE	The clock lane transitioned to the ULPS.
CSI2nMIST.GSTS	CSI2nGSST.GNE	CSI2nGSIE.GNEE	GS FIFO is not empty.
	CSI2nGSST.GTH	CSI2nGSIE.GTHE	Data stored in GS FIFO equals or exceeds the threshold.
	CSI2nGSST.GOV	CSI2nGSIE.GOVE	GS FIFO overflowed.

9.2.4 Image Converter

9.2.4.1 Overview

The image converter module is a data conversion module which handles image clipping, frame subsampling, demosaicing (only selectable for SVC0, and only for RAW input), linear matrix, statistics (only selectable for SVC0, and only for RAW input), color space conversion, LUT conversion, pixel format conversion, and so on. It has an MIPI CSI2 (**9.2.3 MIPI CSI2**) input as an image sensor interface and its processing is roughly divided into two.

- Video system (Image Process, Non Image Process, All Bypass): Data are initially stored in FIFO-VD and transferred to external memory through the internal AXI-VD bus.
- Statistics system: Data are initially stored in FIFO-SD and transferred to external memory through the internal AXI-SD bus.

The video system further has image processing, non-image processing and full bypass systems. Full bypass is used when images are not to be processed by the image converter. Image processing and non-image processing can be used simultaneously (however, the data type cannot be set simultaneously within a single VC). The image processing system handles image processing and the non-image processing system does not handle image processing. Therefore, the data type for image processing, such as RGB, YUV, or RAW, can be selected for image processing, while several data types which are not for image processing, such as embedded 8-bit non-image data and a user-defined 8-bit data type, can be selected for non-image processing. In full bypass (CRUnCTRL.ATH = 1b), image processing within the CRU is not used and data from the MIPI CSI-2 link (in the recommended memory storage format for MIPI CSI-2) are directly transferred to external memory (image processing and non-image processing data cannot be used with full bypass).

The statistics system only handles data processing to produce statistics.

For each MIPI CSI-2 input, up to four channels (SVC0 to 3) can be selected from among 16 virtual channels (VC0 to 15) and only one data type for image processing is processed per channel and several data types can be selected for non-image processing.

Additionally, when only SVC0 is used, some parameters are adjustable from frame to frame, and when demosaicing processing for multiple virtual channels (the image sizes, etc. are the same) is to proceed, control is applied with switching on frame-by-frame demarking by changing a register setting. However, this function cannot be used for sensors that have different VC for each line.

9.2.4.1.1 Features

The operating range of the image converter is as follows.

Image processing

- Range of effective pixels: QVGA (320 × 240) to 8.8 Mpixels
- Range of effective pixels in the horizontal direction: 320 to 4096 pixels
- Range of effective pixels in the vertical direction: 240 to 4096 lines
- Non-image processing and full bypass:
  The size range of application-specific payloads within input packets is from 1 to 24576 bytes.

Common

The maximum transfer rate at the time of MIPI CSI-2 input differs with the input format. For details, see **9.2.3.1.1 Features**.

- Input data format (type): See **9.2.4.3.1 Input Formats and Image Processing**.
  - Image processing:
    Only one data type from among YUV, RGB, RAW, etc. is selectable for each SVC.
  - Non-image processing:
    Several data types such as embedded 8-bit non-image data and user-defined 8-bit data are selectable for each SVC.

- Video output data format (type): Little endian is only supported.
  - 8-bit multiplexing of YCbCr422/YCbCr420 (with support for switching the order of Y and U/V)
  - YC separation of YCbCr422 and YCbCr420 (separation into Y and CbCr components)
  - Extraction of the Y component of YCbCr422
  - U and V in YUV422/YCbCr420 outputs are expressed in offset binary or as two’s complements.
  - RGB-888 (24 bits/pixel)
  - RGB-888 (32 bits/pixel)
  - ARGB-8888 (32 bits/pixel)
  - RAW6, 7, 8, 10, 12, 14, 16, 20
  - MIPI CSI-2 recommended memory storage format

- Demosaicing
  - RAW6, 7, 8, 10, 12, 14, 16, 20 to RGB888

- Color correction by linear matrix operations
  - Offset calculation included

- Color space conversion
  - YCbCr422 to RGB888
  - RGB888 to YCbCr422

- Image format conversion
  - YCbCr422 → YC separation (separation into Y and CbCr components)
  - YCbCr422 → Y component extraction
  - YCbCr422 → YCbCr420
  - RGB-888 → RGB-888 (32 bits/pixel)
  - RGB-888 → ARGB-8888 (32 bits/pixel) B first and A last format
  - RGB-888 → ARGB-8888 (32 bits/pixel) A first and B last format
  - RGB-565 → RGB-888 conversion (intermediate processing)
  - RGB-666 → RGB-888 conversion (intermediate processing)
  - RGB-555 → RGB-888 conversion (intermediate processing)
  - RGB-444 → RGB-888 conversion (intermediate processing)
  - RAW6, 7 → RAW8 conversion (intermediate processing)
  - RAW20: 16 higher-order bits are used for processing (demosaic, statis_cal) (intermediate processing)

- 4 channels (SVC0 to 3) from among virtual channels 0 to 15 can be selected for input (however, only SVC0 is usable for demosaicing and statistics)
- Conversion by a lookup table (LUT): 10-bit to 8-bit conversion
- Data clipping: Suppressing the level of YCbCr data. For details see **9.2.4.3.11 Data Clipping**.
- Image clipping
- Frame subsampling
- Bypassing of each function (not performing the function): Several data types selectable

- Pattern generator (for debugging)
  - Y, U, and V register values are output.

- Statistics (statistical processing operations: horizontal detection area: 320 to 4096 pixels; vertical detection area: 240 to 4096)
  - Accumulation in the (16×16, 32×32, 64×64, and 128×128) areas for each of R, G, and B from RAW6, 7, 8, 10, 12, 14, 16, and 20 data
  - Summation of absolute values for differences from adjacent pixel values of G from RAW6, 7, 8, 10, 12, 14, 16, and 20 data

- FIFO
  - Video system: 16 Kbytes
  - Statistics system: 2 Kbytes

- AXI master: 2 channels (video system, statistics system)
- Memory bank address settings

- Support for 8 bank memory bank addresses (video system)
  - SVC offset address
  - Non-image processing offset address
  - Offset address when separation into Y and UV is selected
- Support for 8 memory bank addresses (statistics system: SVC0)

- Memory addressing
  - Video: Stored with image striding
  - Statistics: Stored with consecutive writing line

- Appending of a header (data type, VC, word count) to the start of a line: turning this off or on is possible.
- Appending of a footer (256'd1/256'd0)

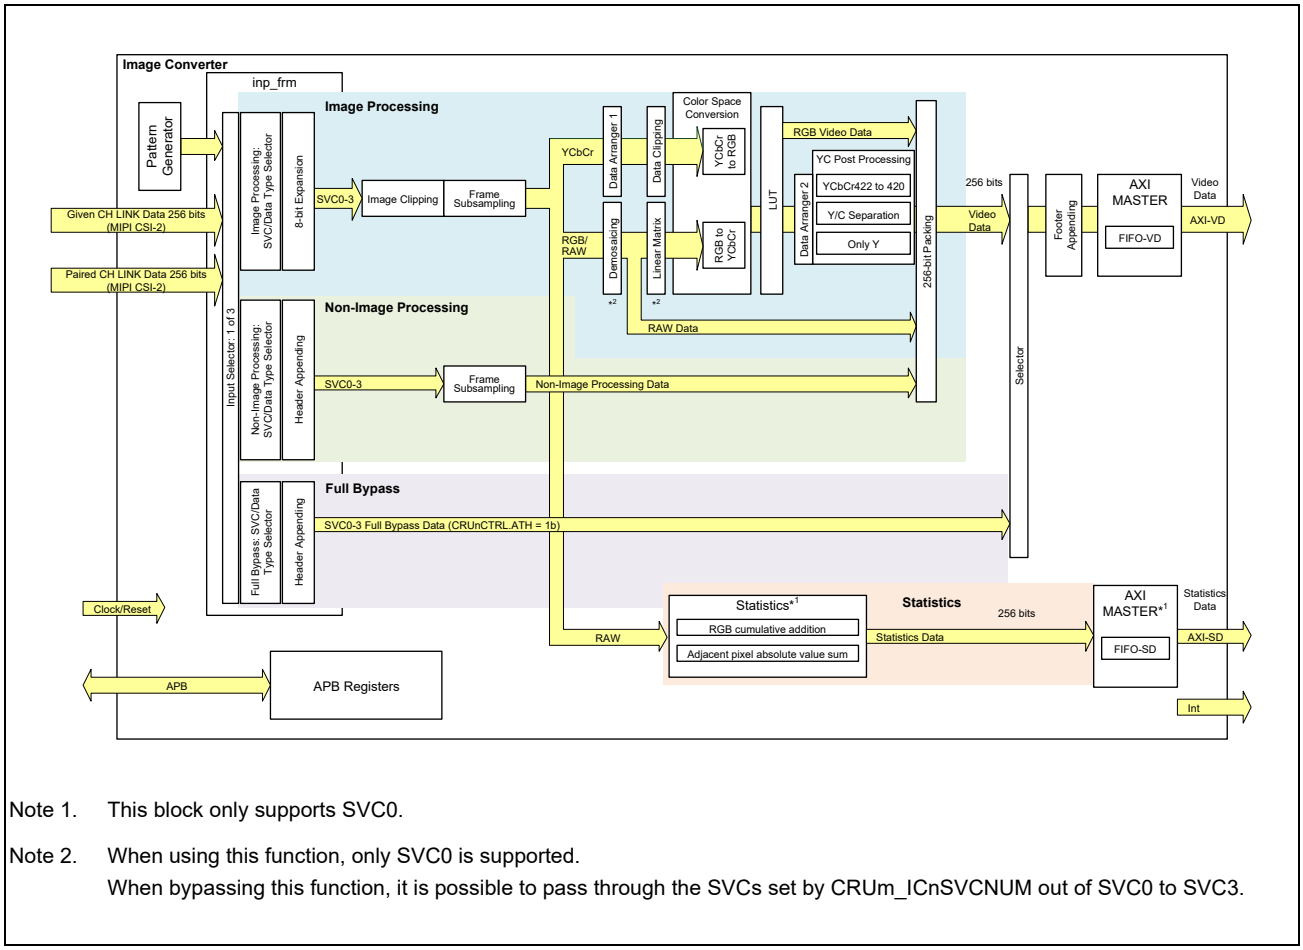
  A footer value (256'd1/256'd0) is inverted when writing to the same bank so that the CPU can judge how far data have been written.
  - Appending of a footer to the end of each line (video system)
  - Appending of a footer to the end of each frame (statistics system)

- APB slave: Only 32-bit access supported

- Interrupt sources
  - Scan line interrupt: 4 sources
  - Start-of-frame/end-of-frame interrupt: 8 sources
  - FIFO overflow interrupt (video system, statistics system): 2 sources
  - AXI SLVERR and DECERR error interrupts (video system, statistics system): 4 sources
  - AXI specified address transfer completed interrupt (video system: 5 addresses; statistics system: 2 addresses): 7 sources

9.2.4.1.2 Block Diagram

Figure 9.2-9 is a block diagram of the image converter.



Note 1. This block only supports SVC0.

Note 2. When using this function, only SVC0 is supported.
When bypassing this function, it is possible to pass through the SVCs set by CRUm_ICnSVCNUM out of SVC0 to SVC3.

Figure 9.2-9 Block Diagram of Image Converter

Pattern Generator

This function is used for debugging and generates image data for testing. The data types are limited to YCbCr422.

Input Selector (1 of 3)

A register setting selects data for input to the image converter from among the following three sources.

- Image data for testing
- Link data from the paired CRU
- Link data from this CRU

Video

- Image Processing
  - SVC/Data Type Selector
    A register setting selects one channel from among 16 VCs (MIPI CSI-2 virtual channels) for use by the image converter. Four channels are selectable and these are treated as SVC0 to 3.
    A register setting selects one data type for use in image processing. Four data types are selectable.

- 8-bit Expansion
  Input data less than 8 bits ((RGB444/RGB555/RGB565/RGB666, RAW6/7) are expanded to 8 bits (RGB888, RAW8).
- Image Clipping
  Input images are cropped to the size selected by register settings for the output of small images.
- Frame Subsampling
  Subsamples input image frames to lower the frame rate. This is used to reduce the bandwidth on the bus.
- Data Arrangers 1 and 2
  Converts the negative expression of the UV component of YUV (YCbC) data.
- Data Clipping
  Limits data values of YUV (YCbCr) to upper and lower limits. This is used when standards having upper and lower limits such as ITU-R BT.601 and 702 are applicable.
- Demosaicing
  Interpolates converted RGB data from RAW (Bayer-array) data.
- Linear Matrix
  Applies matrix operations to correct the colors of RGB data converted by demosaicing.
- Color Space Conversion
  Converts the color space from YCbCr to RGB and vice versa.
- LUT (Lookup Table)
  Converts 10-bit data after color space conversion (YCbCr to RGB or RGB to YCbCr) to a table of 8-bit entries. A basic bit rounding function is set, but the table can also be used for non-linear image correction such as gamma correction.
- YC Post Processing
  - YCbCr422 to 420
    Subsamples YCbCr422 data to convert it into YCbCr422.
  - Y/C Separation
    Sorts and separates YCbCr data into Y and C components.
  - Only Y
    Deletes the C components of YCbCr data so that only Y data remain.
- 256-bit Packing
  Packs data into 256-bit units to suit the bus width for transmission through the AXI.

- Non-Image Processing
  - SVC/Data Type Selector
    The same channels as those set as SVC0 to 3 described under “Image Processing” are used.
    A register setting selects several data types for use in non-image processing.
  - Header Appending
    Since non-image processing and full bypass involve the selection of several data types and storage of the data in a mixed state in the same SVC memory, a header is appended to the start of a line of non-image processing or full bypass data so that the data types and data lengths can be identified when read.
- Full Bypass
  - VC/Data Type Selector
    The same channels as those set as SVC0 to 3 described under “Image Processing” are used.
    A register setting selects several data types for use in full bypass.

- Footer Appending
  Appends 256'd0/d1 as a footer, which is inverted every time the memory bank is overwritten, so that the CPU can recognize the bank number to which the memory data have been written.
- AXI MASTER (AXI-VD)
  Video data are initially stored in a FIFO buffer and then written to the DRAM by the AXI master.

Statistics (only for CRU0 and 1)

- Statistics
  Acquires statistics for each block which is divided from a display for 3A (AE/AWB/AF).
- Footer Appending
  Appends 512 bits as a footer, which is inverted every time the memory bank is overwritten, so that the CPU can recognize the bank number to which the memory data have been written.
  The footer value is written alternately: (1) higher-order 256 bits: reserved (indefinite value); lower-order 256 bits: 256'h1 and (2) higher-order 256 bits: reserved (indefinite value); lower-order 256 bits: 256'h0.
- AXI MASTER (AXI-SD)
  Statistics data are initially stored in a FIFO buffer and then written to the DRAM by the AXI master.

APB Registers

Only 32-bit access is supported.

9.2.4.2 IMC Registers

See **9.2.3.2 MIPI CSI2 Registers** for the CRUm base addresses.

9.2.4.2.1 List of Registers (m = 0, 1)

Register Name	Abbreviation	Initial Value	Offset Address	Access Size [bits]
CRU Control Register	CRUm_CRUnCTRL	0000_0000h	0000h	32
CRU Interrupt Enable Register1	CRUm_CRUnIE1	0000_0000h	0004h	32
CRU Interrupt Enable Register2	CRUm_CRUnIE2	0000_0000h	0008h	32
CRU Interrupt Status Register1	CRUm_CRUnINTS1	0000_0000h	000Ch	32
CRU Interrupt Status Register2	CRUm_CRUnINTS2	0000_0000h	0010h	32
Reserve	-	-	0014h to 0017h	-
CRU Reset Register	CRUm_CRUnRST	0000_0000h	0018h	32
Reserve	-	-	001Ch to 002Bh	-
CRU General Read/Write Register	CRUm_CRUnCOM	0000_0000h	002Ch	32
Reserve	-	-	0030h to 003Fh	-
Memory Bank 1 Base Address Lower Register for Video Data	CRUm_AMnMB1ADDRL	0000_0000h	0040h	32
Memory Bank 1 Base Address Higher Register for Video Data	CRUm_AMnMB1ADDRH	0000_0000h	0044h	32
Memory Bank 2 Base Address Lower Register for Video Data	CRUm_AMnMB2ADDRL	0000_0000h	0048h	32
Memory Bank 2 Base Address Higher Register for Video Data	CRUm_AMnMB2ADDRH	0000_0000h	004Ch	32
Memory Bank 3 Base Address Lower Register for Video Data	CRUm_AMnMB3ADDRL	0000_0000h	0050h	32
Memory Bank 3 Base Address Higher Register for Video Data	CRUm_AMnMB3ADDRH	0000_0000h	0054h	32

9.2.4.2.2 Register Descriptions

(1) Bypass Setting for Each Function

Figure 9.2-10 shows where the bypass settings by the ICnIPMC_C0/1/2/3.*THR and CRUnCTRL.ATH registers work.

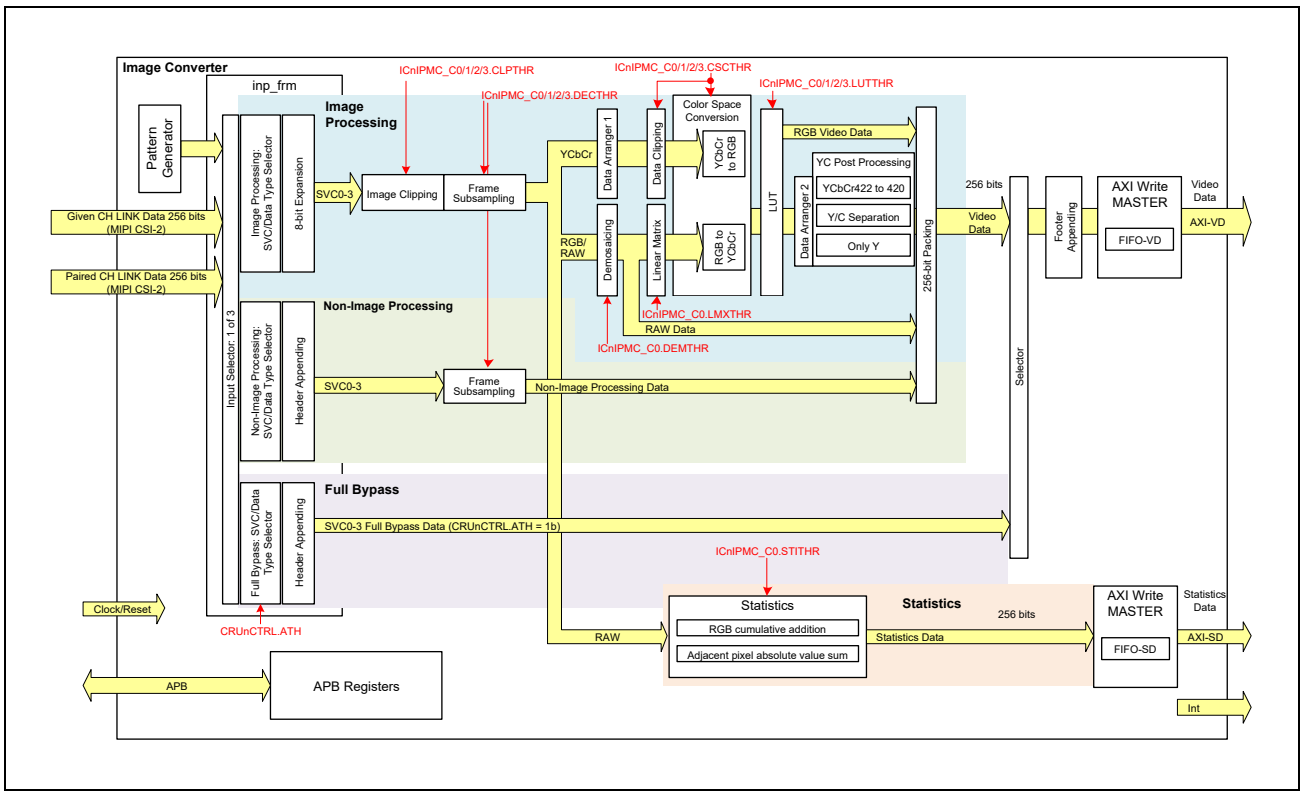

Figure 9.2-10 Bypass Setting for Each Function

(2) CRU Control Register (CRUm_CRUnCTRL) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0000h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	ATH	VINSEL
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
1	ATH	0h	RW	Full bypass setting for the image converter 0b: Normal 1b: Full bypass is performed and the data from the LINK is output as is to the AXI-VD (the virtual channels and data types set by registers ICnSVC and ICnNIPDT_C0~3L/H are bypassed). Note: See **Figure 9.2-10 Bypass Setting for Each Function**.
0	VINSEL	0h	RW	MIPI data input selection (This bit is only valid for CH1 and 3. For CH0 and 2, do not change the value of this bit from 0.) 0b: Given CH LINK input 1b: Paired CH (CH0 for CH1, CH2 for CH3) LINK input Note: This bit is valid when ICnTICTRL1.TIEN = 0b.

(3) CRU Interrupt Enable Register1 (CRUm_CRUnIE1) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0004h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	SDDECEE	SDSLVEE	SDFOE	-	-	-	-	-	DECEE	SLVEE	FOE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	R	R	R	R	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
30 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
10	SDDECEE	0h	RW	AXI-SD DECERR (statistics data-related) interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated. Note: DECERR occurs when the space where the forwarding address is not allowed is accessed. If an error occurs, check that the forwarding address is correct.
9	SDSLVEE	0h	RW	AXI-SD SLVERR (statistics data-related) interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated. Note: SLVERR occurs by the response from the other party as the destination for transfer from this bus. If this happens, check the destination settings.
8	SDFOE	0h	RW	FIFO-SD overflow (statistics data-related) interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
7 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
2	DECEE	0h	RW	AXI-VD DECERR (video data-related) interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated. Note: DECERR occurs when the space where the forwarding address is not allowed is accessed. If an error occurs, check that the forwarding address is correct.
1	SLVEE	0h	RW	AXI-VD SLVERR (video data-related) interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated. Note: SLVERR occurs by the response from the other party as the destination for transfer from this bus. If this happens, check the destination settings.
0	FOE	0h	RW	FIFO-VD overflow (video data-related) interrupt enable control (for debugging) 0b: No interrupts are generated. 1b: Interrupts are generated.

(4) CRU Interrupt Enable Register2 (CRUm_CRUnIE2) (m = 0, 1)

Access Size : 32 bits
Address : <CRUm_base> + 0008h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	SDADR1WE	SDADR0WE	-	-	-	VDADR4WE	VDADR3WE	VDADR2WE	VDADR1WE	VDADR0WE
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	R	R	R	R	RW	RW	R	R	R	RW	RW	RW	RW	RW

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	FE3E	FS3E	SL2E	FE2E	FS2E	SL1E	FE1E	FS1E	SL0E	FE0E	FS0E
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW	RW

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
30	-	0h	RW	Do not change the value of this bit from 0h.
29 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25	SDADR1WE	0h	RW	AXI-SD bus write completion interrupt enable control (video data-related) for designated address 1 (35-bit memory address set by AMnSDIVT1ADDRL and AMnSDIVT1ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
24	SDADR0WE	0h	RW	AXI-SD bus write completion interrupt enable control(statistics data-related) for designated address 0 (35-bit memory address set by AMnSDIVT0ADDRL and AMnSDIVT0ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
23 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	VDADR4WE	0h	RW	AXI-VD bus write completion interrupt enable control (video data-related) for designated address 4 (35-bit memory address set by AMnIVT4ADDRL and AMnIVT4ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
19	VDADR3WE	0h	RW	AXI-VD bus write completion interrupt enable control (video data-related) for designated address 3 (35-bit memory address set by AMnIVT3ADDRL and AMnIVT3ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
18	VDADR2WE	0h	RW	AXI-VD bus write completion interrupt enable control (video data-related) for designated address 2 (35-bit memory address set by AMnIVT2ADDRL and AMnIVT2ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
17	VDADR1WE	0h	RW	AXI-VD bus write completion interrupt enable control (video data-related) for designated address 1 (35-bit memory address set by AMnIVT1ADDRL and AMnIVT1ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
16	VDADR0WE	0h	RW	AXI-VD bus write completion interrupt enable control (video data-related) for designated address 0 (35-bit memory address set by AMnIVT0ADDRL and AMnIVT0ADDRH) 0b: No interrupts are generated. 1b: Interrupts are generated.
15 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11	-	0h	RW	Reserved A register that can be read and written. Do not change the value of this bit from the initial value.
10	FE3E	0h	RW	SVC3 Frame end interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.

Bit	Bit Name	Initial Value	R/W	Description
9	FS3E	0h	RW	SVC3 Frame start interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
8	SL2E	0h	RW	SVC2 Scan line interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
7	FE2E	0h	RW	SVC2 Frame end interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
6	FS2E	0h	RW	SVC2 Frame start interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
5	SL1E	0h	RW	SVC1 Scan line interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
4	FE1E	0h	RW	SVC1 Frame end interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
3	FS1E	0h	RW	SVC1 Frame start interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
2	SL0E	0h	RW	SVC0 Scan line interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
1	FE0E	0h	RW	SVC0 Frame end interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.
0	FS0E	0h	RW	SVC0 Frame start interrupt enable control 0b: No interrupts are generated. 1b: Interrupts are generated.

(5) CRU Interrupt Status Register1 (CRUm_CRUnINTS1) (m = 0, 1)

See **Figure 9.2-9** for where each bit of the interrupt is detected.

Access Size : 32 bits
Address : <CRUm_base> + 000Ch
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	-	-	-	-	-	SDDECES	SDSLVES	SDFOS	-	-	-	-	-	DECES	SLVES	FOS
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW	RW1	RW1	RW1	R	R	R	R	RW	RW1	RW1	RW1

Bit	Bit Name	Initial Value	R/W	Description
31	-	0h	RW	Reserved Whenever it is read, 0 is read. The written value will be ignored.
30 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
11	-	0h	RW	Reserved Whenever it is read, 0 is read. The written value will be ignored.
10	SDDECES	0h	RW1	AXI-SD DECERR (statistics data-related) interrupt status Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE1.SDDECEE = 1b. Note: DECERR occurs when the space where the forwarding address is not allowed is accessed. If an error occurs, check that the forwarding address is correct. Note: This status is detected in the AXI master of statistics data.
9	SDSLVES	0h	RW1	AXI-SD SLVERR (statistics data-related) interrupt status Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE1.SDSLVEE = 1b. Note: SLVERR occurs by the response from the other party as the destination for transfer from this bus. If this happens, check the destination settings. Note: This status is detected in the AXI master of statistics data.
8	SDFOS	0h	RW1	FIFO-SD overflow (statistics data-related) interrupt status Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE1.SDFOE = 1b. Note: This status is detected in the AXI master of statistics data.
7 to 4	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
3	-	0h	RW	Reserved Whenever it is read, 0 is read. The written value will be ignored.
2	DECES	0h	RW1	AXI-VD DECERR (video data-related) interrupt status Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE1.DECEE = 1b. Note: DECERR occurs when the space where the forwarding address is not allowed is accessed. If an error occurs, check that the forwarding address is correct. Note: This status is detected in the AXI master of video data.

Bit	Bit Name	Initial Value	R/W	Description
1	SLVES	0h	RW1	AXI-VD SLVERR (video data-related) interrupt status Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit only is valid when CRUnIE1.SLVEE = 1b. Note: SLVERR occurs by the response from the other party as the destination for transfer from this bus. If this happens, check the destination settings. Note: This status is detected in the AXI master of video data.
0	FOS	0h	RW1	FIFO-VD overflow (video data-related) interrupt status (for debugging) Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE1.FOE = 1b. Note: This status is detected in the AXI master of video data.

(6) CRU Interrupt Status Register2 (CRUm_CRUnINTS2) (m = 0, 1)

See **Figure 9.2-9** for where each bit of the interrupt is detected.

Access Size : 32 bits
Address : <CRUm_base> + 0010h
Initial Value : 0000_0000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	-	-	-	-	-	-	SDADR1WS	-	-	-	-	VDADR4WS	VDADR3WS	VDADR2WS	VDADR1WS	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	RW	RW	R	R	R	R	RW1	R	R	R	R	RW1	RW1	RW1	RW1	R

	-	-	-	-	SL3S	FE3S	FS3S	SL2S	FE2S	FS2S	SL1S	FE1S	FS1S	SL0S	FE0S	FS0S
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	RW1	RW1	RW1	RW1	RW1	RW1	RW1	RW1	RW1	RW1	RW1	RW1

Bit	Bit Name	Initial Value	R/W	Description
31, 30	-	0h	RW	Reserved Whenever it is read, 0 is read. The written value will be ignored.
29 to 26	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
25	SDADR1WS	0h	RW1	AXI-SD bus write completion interrupt status (statistics data-related) for designated address 1 (35 bits) Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE2.SDADR1WE = 1b. Note: This status is detected in the AXI master of statistics data.
24 to 21	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.
20	VDADR4WS	0h	RW1	AXI-VD bus write completion interrupt status (video data-related) for designated address 4 (35 bits) Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE2.VDADR4WE = 1b. Note: This status is detected in the AXI master of video data.
19	VDADR3WS	0h	RW1	AXI-VD bus write completion interrupt status (video data-related) for designated address 3 (35 bits) Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE2.VDADR3WE = 1b. Note: This status is detected in the AXI master of video data.
18	VDADR2WS	0h	RW1	AXI-VD bus write completion interrupt status (video data-related) for designated address 2 (35 bits) Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE2.VDADR2WE = 1b. Note: This status is detected in the AXI master of video data.
17	VDADR1WS	0h	RW1	AXI-VD bus write completion interrupt status (video data-related) for designated address 1 (35 bits) Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE2.VDADR1WE = 1b. Note: This status is detected in the AXI master of video data.
16 to 12	-	All 0	R	Reserved Whenever it is read, 0b is read. The written value will be ignored.

Bit	Bit Name	Initial Value	R/W	Description
11	SL3S	0h	RW1	SVC3 Scan line interrupt status Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE2.SL3E = 1b. Note: This status is detected in SVC3 image clipping.
10	FE3S	0h	RW1	SVC3 Frame end interrupt status Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE2.FE3E = 1b. Note: This status is detected in SVC3 image clipping.
9	FS3S	0h	RW1	SVC3 Frame start interrupt status Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE2.FS3E = 1b. Note: This status is detected in SVC3 image clipping.
8	SL2S	0h	RW1	SVC2 Scan line interrupt status Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE2.SL2E = 1b. Note: This status is detected in SVC2 image clipping.
7	FE2S	0h	RW1	SVC2 Frame end interrupt status Write 0b: Invalid, 1b: Clears the interrupt & status Read 0b: No interrupts generated, 1b: Interrupts generated Note: This bit is only valid when CRUnIE2.FE2E = 1b. Note: This status is detected in SVC2 image clipping.
