Detailed Description

Middleware to implement the ZMOD4XXX sensor interface. This module implements the [ZMOD4XXX Middleware Interface](#).

Overview

This module provides an API for configuring and controlling the ZMOD4XXX sensor. Supported ZMOD4XXX sensors are below.

- ZMOD4410
- ZMOD4450
- ZMOD4510

I2C communication with the ZMOD4XXX sensor is realized by connecting with the `rm_comms_i2c` module.

Features

The ZMOD4XXX sensor interface implementation has the following key features:

- Initialize the sensor for measurement
- Start a measurement at any time
- Read status register for wait until the measurement is done. This will also be signaled by an interrupt
- Get the ADC data from the sensor
- Input the ADC data and acquire the air quality values by calculation in the library.

Configuration

Build Time Configurations for `rm_zmod4xxx`

The following build time configurations are defined in fsp_cfg/rm_zmod4xxx_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled • Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

Configurations for Sensor > ZMOD4XXX Gas Sensor (rm_zmod4xxx)

This module can be added to the Stacks tab via New Stack > Sensor > ZMOD4XXX Gas Sensor (rm_zmod4xxx).

| Configuration | Options | Default | Description |
|--------------------|-------------------------------|-----------------------------|---|
| Name | Manual Entry | g_zmod4xxx_sensor0 | Module name. |
| Comms I2C Callback | Name must be a valid C symbol | zmod4xxx_comms_i2c_callback | A user COMMS I2C callback function can be provided. |
| IRQ Callback | Name must be a valid C symbol | zmod4xxx_irq_callback | A user IRQ callback function can be provided. |

Pin Configuration

This module use SDA and SCL pins of I2C Master and SCI I2C.

Usage Notes

[ZMOD4410 datasheet is here.](#)

The ZMOD4410 has five modes of operation.

The ZMOD4410 will respond to TVOC immediately upon start-up; however, a conditioning period of 48 hours followed by a sensor module restart in an ambient environment is recommended to improve stability and obtain maximum performance.

Best results are achieved with continuous operation because the module algorithm can learn about the environment over time.

| Method | Description |
|------------------------------------|---|
| IAQ 1st Generation Continuous | Measurement of UBA levels for IAQ and eCO ₂ , provides continuous data |
| IAQ 1st Generation Low Power | Measurement of UBA levels for IAQ and eCO ₂ , fixed sampling interval of 6 seconds |
| IAQ 2nd Generation | Using AI for improved ppm TVOC, IAQ and eCO ₂ functionality (recommended for new designs) |
| IAQ 2nd Generation Ultra Low Power | Using AI for improved ppm TVOC, IAQ and eCO ₂ functionality. This method offers a much lower power consumption |
| Relative IAQ | Lightweight algorithm reacts to air quality changes and outputs a relative IAQ |

| | |
|------------------------------------|---|
| Relative IAQ Ultra Low Power | Lightweight algorithm reacts to air quality changes and outputs a relative IAQ. This method offers a much lower power consumption |
| Public Building AQ Standard (PBAQ) | For highly accurate and consistent sensor readings to fulfill public building standards. |
| Odor | Control signal based on Air Quality Changes |
| Sulfur-based Odor Discrimination | The odors in "sulfur" (sulfur based) and "acceptable" (organic based) and shows an intensity level of the smell |

[ZMOD4450 datasheet is here.](#)

The ZMOD4450 has one modes of operation.

The response time for a gas stimulation is always within a few seconds, depending on the gas and its concentration. An active or direct airflow onto the sensor module is not necessary since diffusion of ambient gas does not limit the sensor module response time. The ZMOD4450 will respond to typical refrigeration gases immediate upon start-up; however, a conditioning period of 48 hours in a refrigeration environment is recommended to improve stability and get maximum performance, as the module algorithm is able to learn about the refrigeration environment over time.

| Method | Description |
|--------|--|
| RAQ | Control signal based on Refrigerator Air Quality Changes |

[ZMOD4510 datasheet is here.](#)

The ZMOD4510 has two modes of operation.

The ZMOD4510 in OAQ 1st Gen operation will respond to typical outdoor gases after a warm-up time of 60 min, consisting of 20 min for stabilization and 40 min for baseline finding.

For OAQ 2nd Gen operation a response to ozone will be seen after a warmup time of 30 min.

In all operation modes a conditioning period of 48 hours followed by a sensor module restart in an ambient environment is recommended to improve stability and obtain maximum performance.

| Method | Description |
|--------------------|---|
| OAQ 1st Generation | Measurement of Air Quality |
| OAQ 2nd Generation | Selective Ozone featuring Ultra-Low Power |

A library corresponding to each of these modes is required. By setting in RA Configuration, the library will be generated in the ra/fsp/lib/rm_zmod4xxx folder of your project.

If an RTOS is used, blocking and bus lock is available.

- If blocking of an I2C bus is required, it is necessary to create a semaphore for blocking.
- If bus lock is required, it is necessary to create a mutex for bus lock. Bus lock is only available when a semaphore for blocking is used.

Notifications

The ZMOD4xxx sensor needs a reset before operation; please input a reset signal to the RES_N pin (active low).

Program flow for OAQ 2nd gen is changed in FSP v4.0.0. Please refer to the programming manual

[R36US0004EU] and the application note[R01AN5899].

Bus Initialization

The ZMOD4XXX interface expects a bus instance to be opened before opening any ZMOD4XXX device. The interface will handle switching between devices on the bus but will not open or close the bus instance. The user should open the bus with the appropriate [I2C Master Interface](#) open call.

Initialization

Initialize with [RM_ZMOD4XXX_Open\(\)](#). One channel of timer is required to measure the waiting time at initialization.

From measurement start to data acquisition

After normal completion, start the measurement with [RM_ZMOD4XXX_MeasurementStart\(\)](#). An endless loop continuously checks the status of the ZMOD4XXX sensor and reads its data. The raw data is subsequently processed, and the air quality values are calculated.

If IRQ is enabled

1. Call [RM_ZMOD4XXX_MeasurementStart\(\)](#).
2. Wait until `RM_ZMOD4XXX_EVENT_MEASUREMENT_COMPLETE` is received via IRQ callback.
3. Call [RM_ZMOD4XXX_Read\(\)](#). This function will read the ADC data.
4. Wait until `RM_ZMOD4XXX_EVENT_SUCCESS` is received.
5. Call the DataCalculate API according to the mode.

If IRQ is disabled

1. Call [RM_ZMOD4XXX_MeasurementStart\(\)](#).
2. Wait until `RM_ZMOD4XXX_EVENT_SUCCESS` is received.
3. Call [RM_ZMOD4XXX_StatusCheck\(\)](#). This function will execute a status check over I2C.
4. If `RM_ZMOD4XXX_EVENT_MEASUREMENT_NOT_COMPLETE` is received in callback, user should wait some time and then call [RM_ZMOD4XXX_StatusCheck\(\)](#) again.
5. Wait until `RM_ZMOD4XXX_EVENT_MEASUREMENT_COMPLETE` is received.
6. Call [RM_ZMOD4XXX_Read\(\)](#) and read the ADC data.
7. Wait until `RM_ZMOD4XXX_EVENT_SUCCESS` is received.
8. Call the DataCalculate API according to the mode.

Checking device error for IAQ 2nd Gen.

1. Call [RM_ZMOD4XXX_DeviceErrorCheck\(\)](#). This function will execute a device error check over I2C.
2. If any device error occurs, `RM_ZMOD4XXX_EVENT_DEV_ERR_POWER_ON_RESET` or `RM_ZMOD4XXX_EVENT_DEV_ERR_ACCESS_CONFLICT` are received in callback. If no device error, `RM_ZMOD4XXX_EVENT_SUCCESS` is received in callback.

Configuration

Block Media User has no output config settings.

The user is required to create the config settings etc. in the application.

The figure below is an example of the config definition when the user media in USB PMSC is RAM.

```
const rm_block_media_api_t g_rm_block_media_on_user_media =
{
    .open      = RM_BLOCK_MEDIA_RAM_Open,
    .mediaInit = RM_BLOCK_MEDIA_RAM_MediaInit,
    .read      = RM_BLOCK_MEDIA_RAM_Read,
    .write     = RM_BLOCK_MEDIA_RAM_Write,
    .erase     = RM_BLOCK_MEDIA_RAM_Erase,
    .infoGet   = RM_BLOCK_MEDIA_RAM_InfoGet,
    .statusGet = RM_BLOCK_MEDIA_RAM_StatusGet,
    .close     = RM_BLOCK_MEDIA_RAM_Close,
};

extern void r_usb_pmsc_block_media_event_callback(rm_block_media_callback_args_t *
p_args);

const rm_block_media_cfg_t g_rm_block_media0_cfg =
{.p_extend = NULL, .p_callback = r_usb_pmsc_block_media_event_callback, .p_context =
NULL, };

rm_block_media_instance_t g_rm_block_media0 =
{.p_api = &g_rm_block_media_on_user_media, .p_ctrl = NULL, .p_cfg =
&g_rm_block_media0_cfg, };
```

Note

If you use `block_media_user`, you need to create a function that matches the media you are using.

In the above example, this is the function with `RM_BLOCK_MEDIA_`.

Register the created function in `rm_block_media_api_t`.

The registered `rm_block_media_api_t` is registered in `p_api`, which is a member of `rm_block_media_instance_t`.

Detailed Description

Middleware to implement the block media interface on SPI flash memory. This module implements the [Block Media Interface](#).

Overview

Features

The SPI implementation of the block media interface has the following key features:

- Reading, writing, and erasing data from SPI flash memory
- Provides media information such as sector size and total number of sectors.

Note

By default, Block Media SPI Read, Write, and Erase are blocking operations. Non-blocking operation may be achieved by yielding control within the optional callback function.

Configuration

Build Time Configurations for rm_block_media_spi

The following build time configurations are defined in driver/rm_block_media_spi_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled • Disabled | Default (BSP) | If selected, code for parameter checking is included in the build |

Configurations for Storage > Block Media SPI Flash (rm_block_media_spi)

This module can be added to the Stacks tab via New Stack > Storage > Block Media SPI Flash (rm_block_media_spi).

| Configuration | Options | Default | Description |
|----------------------|---|-------------------|---|
| Module Instance Name | Name must be a valid C symbol | g_rm_block_media0 | Module name |
| Block size (bytes) | Manual Entry | 4096 | Specify the size of a block in bytes. |
| Block count | Minimum block count is 1, maximum is defined by hardware and software design. | 8192 | Number of blocks available for use by this driver instance. |
| Base Address | Manual Entry | 0 | Base address offset (bytes) for instance memory region. |
| Callback Function | Name must be a valid C symbol | NULL | A user callback function can be |

provided. If this callback is provided, it will be called after the completion of Read, Write, and Erase operations, or anytime these functions are waiting on hardware.

Clock Configuration

This module has no required clock configurations.

Pin Configuration

This module does not use I/O pins.

Limitations

Developers should be aware of the following limitations when using RM_BLOCK_MEDIA_SPI:

- Getting and setting Block Protection or Advanced Sector Protection modes is not supported.
- Addressing QSPI memory address ranges greater than 64 MB (one bank) is not supported.

Examples

Basic Example

This is a basic example of minimal use of the SPI block media implementation in an application.

```
#define RM_BLOCK_MEDIA_SPI_BLOCK_SIZE (256U)
uint8_t g_dest[RM_BLOCK_MEDIA_SPI_BLOCK_SIZE] BSP_ALIGN_VARIABLE(4);
uint8_t g_src[RM_BLOCK_MEDIA_SPI_BLOCK_SIZE] BSP_ALIGN_VARIABLE(4);
void rm_block_media_spi_basic_example (void)
{
    /* Initialize g_src to known data */
    for (uint32_t i = 0; i < RM_BLOCK_MEDIA_SPI_BLOCK_SIZE; i++)
    {
        g_src[i] = (uint8_t) ('A' + (i % 26));
    }

    /* Open the RM_BLOCK_MEDIA_SPI driver. */
    fsp_err_t err = RM_BLOCK_MEDIA_SPI_Open(&g_rm_block_media0_ctrl,
&g_rm_block_media0_cfg);

    /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
}
```

```
/* Initialize the SPI flash memory. */
err = RM_BLOCK_MEDIA_SPI_MediaInit(&g_rm_block_media0_ctrl);
assert(FSP_SUCCESS == err);

/* Write a block of data to block 3 of the SPI flash memory. */

Detailed Description

Middleware to implement the block media interface on USB mass storage devices. This module implements the [Block Media Interface](#).

Overview

Features

The USB implementation of the block media interface has the following key features:

- Reading, writing, and erasing data from a USB mass storage device
- Callback called when device insertion or removal is detected
- Provides media information such as sector size and total number of sectors.

Configuration

Build Time Configurations for rm_block_media_usb

The following build time configurations are defined in driver/rm_block_media_usb_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled • Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

Examples

Basic Example

This is a basic example of minimal use of the USB mass storage block media implementation in an application.

```
#define RM_BLOCK_MEDIA_USB_BLOCK_SIZE (512)
volatile bool g_usb_inserted = false;
uint8_t      g_dest[RM_BLOCK_MEDIA_USB_BLOCK_SIZE] BSP_ALIGN_VARIABLE(4);
uint8_t      g_src[RM_BLOCK_MEDIA_USB_BLOCK_SIZE] BSP_ALIGN_VARIABLE(4);
void rm_block_media_usb_basic_example (void)
{
    /* Initialize g_src to known data */
    for (uint32_t i = 0; i < RM_BLOCK_MEDIA_USB_BLOCK_SIZE; i++)
    {
        g_src[i] = (uint8_t) ('A' + (i % 26));
    }
    /* Open the RM_BLOCK_MEDIA_USB driver. */
    fsp_err_t err = RM_BLOCK_MEDIA_USB_Open(&g_rm_block_media0_ctrl,
&g_rm_block_media0_cfg);
    /* Handle any errors. This function should be defined by the user. */
```

```
    assert(FSP_SUCCESS == err);
while (!g_usb_inserted)
    {
/* Wait for a card insertion interrupt. */
    }

/* Initialize the mass storage device. This should not be done until the device is
plugged in and initialized. */
    err = RM_BLOCK_MEDIA_USB_MediaInit(&g_rm_block_media0_ctrl);
    assert(FSP_SUCCESS == err);

/* Write a block of data to sector 3 of an USB mass storage device. */
    err = RM_BLOCK_MEDIA_USB_Write(&g_rm_block_media0_ctrl, g_src, 3, 1);
    assert(FSP_SUCCESS == err);

/* Read a block of data from sector 3 of an USB mass storage device. */
    err = RM_BLOCK_MEDIA_USB_Read(&g_rm_block_media0_ctrl, g_dest, 3, 1);
    assert(FSP_SUCCESS == err);
}
```

Device Insertion

This is an example of using a callback to determine when a mass storage device is plugged in and enumerated.

```
/* The callback is called when a media insertion event occurs. */
void rm_block_media_usb_media_insertion_example_callback
(rm_block_media_callback_args_t * p_args)
{
    if (RM_BLOCK_MEDIA_EVENT_MEDIA_INSERTED == p_args->event)
        {
            g_usb_inserted = true;
        }

    if (RM_BLOCK_MEDIA_EVENT_MEDIA_REMOVED == p_args->event)
        {
            g_usb_inserted = false;
        }
}
```

Detailed Description

Middleware for the Azure RTOS FileX File System control using Block Media on RA MCUs.

Overview

This module provides the hardware port layer for FileX file system. After initializing this module, refer to the FileX API reference to use the file system: <https://docs.microsoft.com/en-us/azure/rtos/filex/>

Features

The FileX Block Media module supports the following features:

- Callbacks for insertion and removal for removable devices.
- ThreadX is typically required for FileX. To use FileX without ThreadX FX_STANDALONE_ENABLE must be defined.
- Unless FX_SINGLE_THREAD or FX_STANDALONE_ENABLE are defined, all FileX operations are thread safe.

Configuration

Build Time Configurations for rm_filex_block_media

The following build time configurations are defined in fsp_cfg/middleware/rm_filex_block_media_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|--|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled • Disabled | Default (BSP) | Selects if code for parameter checking is to be included in the build. |

Configurations for Storage > FileX I/O (rm_filex_block_media)

| Name | Name must be a valid C symbol | g_rm_filex_block_media_0 | Module name. |
| Callback | Name must be a valid C symbol | g_rm_filex_block_media_0_callback | A user callback function can be provided. If this callback function is provided, it will be called when media is inserted or removed. It will also be called during operations by the lower level block media as a way for the user to provide their desired waiting functionality. |

Configurations for Storage > Azure RTOS FileX on Block Media

This module can be added to the Stacks tab via New Stack > Storage > Azure RTOS FileX on Block Media.

| Configuration | Options | Default | Description |
|-------------------|---|-------------|--|
| Name | Name must be a valid C symbol | g_fx_media0 | Symbol used for media_ptr parameter in FileX APIs |

| Number of FATs | Number of FATs must be an integer greater than 0 | 1 | Number of FATs in the media. The minimal value is 1 for the primary FAT. Values greater than 1 result in additional FAT copies being maintained at run-time. |
| Directory Entries | Number of Directory Entries must be an integer greater than 0 | 256 | Number of directory entries in the root directory. |
| Hidden Sectors | Number of Hidden Sectors must be an integer | 0 | Number of sectors hidden before this media's boot sector. If using media formatted with multiple partitions this number should correspond to the starting block number for the desired |

|-----------------------------------|--|-------|--|
| Total Sectors | Total Sectors must be an integer greater than 0 | 65536 | partition. Total number of sectors in the media. When using a Renesas provided block media implementation, total sectors can be fetched by the infoGet from the block media API. Any removable media must be inserted and initialized first to retrieve this info. |
| Bytes per Sector | Bytes per Sector must be multiple of 32 | 512 | Number of bytes per sector, which is typically 512. FileX requires this to be a multiple of 32. When using a Renesas provided block media implementation, bytes per sector can be fetched by the infoGet from the block media API. Any removable media must be inserted and initialized first to retrieve this info. |

Usage Notes

Pending during Read/Write

The FileX Block Media driver provides a number of events in the user callback to handle waiting or pending while it is doing blocking operations. The events received in the callback will differ depending on the lower level block media driver in use.

If the lower level block media driver is `rm_block_media_spi` (SPI blocks on read/write operations):

- The user will receive `RM_BLOCK_MEDIA_EVENT_POLL_STATUS` in the user callback while the lower level driver is polling for the read/write operation to be complete. The user can choose to do a thread sleep or software delay upon receiving this event in the callback.
- Once the operation is complete no other callbacks will be received.

If the lower level block media driver is `rm_block_media_sdmmc` (SDMMC is interrupt based, the FileX Block Media driver will still block while waiting for interrupts from SDMMC):

- The user will receive `RM_BLOCK_MEDIA_EVENT_WAIT` in the user callback when the FileX Block Media driver begins waiting for an interrupt event from SDMMC. This is sent from a thread context. The user can choose to pend on a semaphore, sleep the thread, or do a software delay upon receiving this event in the callback. The FileX Block Media driver thread will block until an interrupt is received.
- Once an SDMMC interrupt is received the user will receive `RM_BLOCK_MEDIA_EVENT_WAIT_END` in the user callback. This is sent from an interrupt context. The user can choose to give a semaphore on this event or do nothing.
- If SDMMC is busy on a long erase after receiving the interrupt the FileX Block Media driver will send `RM_BLOCK_MEDIA_EVENT_POLL_STATUS` to the user callback and proceed to do a blocking poll on SDMMC status. The user can choose to do a thread sleep or software delay upon receiving this event in the callback. This event will not be received by the user on typical operations by FileX.

Partitioned Media

When using `fx_format` to format a partition the number of hidden sectors should match the starting block number of the partition and the total number of sectors should be equal to the number of sectors in the partition.

Unused User Callback Events

Certain events are defined in `rm_block_media_event_t` but not returned by the FileX Block Media user callback:

- `RM_BLOCK_MEDIA_EVENT_OPERATION_COMPLETE`: This event is handled internally and operation success is indicated by FileX API calls returning `FX_SUCCESS`.
- `RM_BLOCK_MEDIA_EVENT_ERROR`: This event is handled internally and operation failure will be indicated by an error return code from FileX API calls.

Using FileX with Custom Block Media Implementations

When using a Custom Block Media implementation with `rm_filex_block_media` the custom implementation must call `rm_filex_block_media_memory_callback` upon the completion of a read/write operation. This callback should be called with an event of `RM_BLOCK_MEDIA_EVENT_OPERATION_COMPLETE` and `p_context` of `rm_filex_block_media_instance_ctrl_t`*. The following example shows how this should be done in the context of a demo RAM block media read function.

```

#define EXAMPLE_BLOCK_MEDIA_RAM_START_ADDR (0x20004AFE)
#define EXAMPLE_BLOCK_MEDIA_RAM_BLOCK_SIZE_BYTES (512)
/* Example implementation of rm_block_media_api_t::read(), user should define custom
block media RAM implementation. */
fsp_err_t RM_BLOCK_MEDIA_CUSTOM_RAM_Read (rm_block_media_ctrl_t * const p_ctrl,
                                           uint8_t * const
                                           p_dest_address,
                                           uint32_t const
block_address,
                                           uint32_t const          num_blocks)
{
    FSP_PARAMETER_NOT_USED(p_ctrl);
    memcpy(p_dest_address,
           (void *) (EXAMPLE_BLOCK_MEDIA_RAM_START_ADDR + (block_address *
EXAMPLE_BLOCK_MEDIA_RAM_BLOCK_SIZE_BYTES)),
           (EXAMPLE_BLOCK_MEDIA_RAM_BLOCK_SIZE_BYTES * num_blocks));
    /* Notify FileX port of operation complete through calling the callback, this is

```

```
required for custom block media/FileX port integration */
rm_block_media_callback_args_t args;
args.event      = RM_BLOCK_MEDIA_EVENT_OPERATION_COMPLETE;
args.p_context  = (void *) &g_filex_block_media0_ctrl;
rm_filex_block_media_memory_callback(&args);
return FSP_SUCCESS;
}
```

Data Structures

Data Structure Documentation

◆ rm_filex_block_media_instance_ctrl_t

```
struct rm_filex_block_media_instance_ctrl_t

Common macro for FSP header files. There is also a corresponding FSP_FOOTER macro at the end of this file. FileX block media private control block. DO NOT MODIFY. Initialization occurs when RM_FILEX_BLOCK_MEDIA_Open is called.

Function Documentation

◆ **RM_FILEX_BLOCK_MEDIA_Open()**

```
fsp_err_t RM_FILEX_BLOCK_MEDIA_Open ( rm_filex_block_media_ctrl_t *const p_ctrl,
rm_filex_block_media_cfg_t const *const p_cfg )
```

The file system relies on the media to be formatted prior to creating directories and files. The sector size and sector count will change depending on the media type and size.

The File Allocation Table (FAT) starts after the reserved sectors in the media. The FAT area is basically an array of 12-bit, 16-bit, or 32-bit entries that determine if that cluster is allocated or part of a chain of clusters comprising a subdirectory or a file. The size of each FAT entry is determined by the number of clusters that need to be represented. If the number of clusters (derived from the total sectors divided by the sectors per cluster) is less than 4,086, 12-bit FAT entries are used. If the total number of clusters is greater than 4,086 and less than or equal to 65,525, 16-bit FAT entries are used. Otherwise, if the total number of clusters is greater than 65,525, 32-bit FAT entries are used. Initializes callback and configuration for FileX Block Media interface. Call this before calling any FileX functions.

Implements `rm_filex_block_media_api_t::open()`.

Return values

| | |
|----------------------|---------------------------------|
| FSP_SUCCESS | Success. |
| FSP_ERR_ASSERTION | An input parameter was invalid. |
| FSP_ERR_ALREADY_OPEN | Module is already open. |

Returns

See [Common Error Codes](#) or functions called by this function for other possible return codes.

◆ **RM_FILEX_BLOCK_MEDIA_Close()**

```
fsp_err_t RM_FILEX_BLOCK_MEDIA_Close ( rm_filex_block_media_ctrl_t *const p_ctrl)
```

Closes media device.

Implements `rm_filex_block_media_api_t::close()`.

Return values

| | |
|-------------------|---------------------------------|
| FSP_SUCCESS | Media device closed. |
| FSP_ERR_ASSERTION | An input parameter was invalid. |
| FSP_ERR_NOT_OPEN | Module not open. |

Returns

See [Common Error Codes](#) or functions called by this function for other possible return codes.

◆ RM_FILEX_BLOCK_MEDIA_BlockDriver()

```
void RM_FILEX_BLOCK_MEDIA_BlockDriver ( FX_MEDIA * p_fx_media)
```

Access Block Media device functions open, close, read, write and control.

The RM_FILEX_BLOCK_MEDIA_BlockDriver function is called from the FileX file system driver and issues requests to a Block Media device through the FSP Block Media Interface. Uses block media driver for accesses.

Parameters

| | | |
|----------|------------|---|
| [in,out] | p_fx_media | FileX media control block. All information about each open media device are maintained in the FX_MEDIA data type. The I/O driver communicates the success or failure of the request through the fx_media_driver_status member of FX_MEDIA (p_fx_media->fx_media_driver_status). Possible values are documented in the FileX User Guide. |
|----------|------------|---|

Return values

| | |
|------|--|
| None | |
|------|--|

Returns

Nothing, but updates FileX media control block.

Functions

```
void RM_FILEX_LEVELX_NOR_DeviceDriver (FX_MEDIA *p_fx_media)
```

Access LevelX NOR device functions open, close, read, write and control. [More...](#)

Detailed Description

Middleware for the Azure RTOS FileX File System control using LevelX NOR on RA MCUs.

Overview

This module provides the hardware port layer for FileX file system. After initializing this module, refer to the FileX API reference to use the file system: <https://docs.microsoft.com/en-us/azure/rtos/filex/>

Features

The FileX LevelX NOR module supports the following features:

- ThreadX is typically required for FileX. To use FileX without ThreadX `FX_STANDALONE_ENABLE` must be defined.
- Unless `FX_SINGLE_THREAD` or `FX_STANDALONE_ENABLE` are defined, all FileX operations are thread safe.

Configuration

Build Time Configurations for `rm_filex_levelx_nor`

| Configuration | Options | Default | Description |
|----------------------------|---|---------|---|
| Common > Max Long Name Len | Value must be greater than or equal to 13 and less than or equal to | | Specifies the maximum file name size for FileX. If left blank the default |

| | | | |
|-----------------------------------|---|--------------------|--|
| | 256, or empty | | value is 256. Legal values range between 13 and 256. |
| Common > Max Last Name Len | Value must be greater than or equal to 13 and less than or equal to 256, or empty | | This value defines the maximum file name length, which includes full path name. If left blank the default value is 256. Legal values range between 13 and 256. |

Configurations for Storage > Azure RTOS FileX on LevelX NOR

This module can be added to the Stacks tab via New Stack > Storage > Azure RTOS FileX on LevelX NOR.

| Configuration | Options | Default | Description |
|----------------|--|-------------|--|
| Name | Name must be a valid C symbol | g_fx_media0 | Symbol used for media_ptr parameter in FileX APIs |
| Volume Name | Name must be a valid C symbol | Volume 1 | Volume name string, which is a maximum of 11 characters. |
| Number of FATs | Number of FATs must be an integer greater than 0 | 1 | Number of FATs in the media. The minimal value is 1 for the primary FAT. Values greater than 1 result in additional FAT copies being maintained at run-time. |

| | | | |
|-----------------------------------|--|-------|---|
| Directory Entries | Number of Directory Entries must be an integer greater than 0 | 256 | Number of directory entries in the root directory. |
| Hidden Sectors | Number of Hidden Sectors must be an integer | 0 | Number of sectors hidden before this media's boot sector. If using media formatted with multiple partitions this number should correspond to the starting block number for the desired partition. |
| Total Sectors | Total Sectors must be an integer greater than 0 | 57337 | Total number of sectors in the media. When using a Renesas provided block media implementation, total sectors can be fetched by the infoGet from the block media API. Any removable media must be inserted and initialized first to retrieve this info. |
| Sectors per Cluster | Sectors per Cluster must be an integer greater than 0 | 1 | Number of sectors in each cluster. The cluster is the minimum allocation unit in a FAT file system. |
| Volume Serial Number (exFAT only) | Volume Serial Number must be an integer greater than 0 | 12345 | Serial number to be used for this volume. exFAT only. |
| Boundary Unit (exFAT only) | Boundary unit must be an integer greater than 0 | 128 | Physical data area alignment size, in number of sectors. exFAT only. |
| Working media memory size | Memory size must be an integer greater than or equal to the size of one sector | 512 | Memory allocated for file system. Memory size must be an integer greater than or equal to the size of one sector. |

Usage Notes

Pending during Write/Erase

If the underlying LevelX NOR driver performs a blocking operation that requires waiting to complete (such as a long write/erase on NOR SPI), a callback can be provided to provide a way to wait with an

OS-specific thread wait. This callback will also pass up block erase events.

Partitioned Media

Partitioned media is not supported directly by the FileX LevelX NOR port.

Function Documentation

◆ **RM_FILEX_LEVELX_NOR_DeviceDriver()**

```
void RM_FILEX_LEVELX_NOR_DeviceDriver ( FX_MEDIA * p_fx_media)
```

Access LevelX NOR device functions open, close, read, write and control.

The RM_FILEX_LEVELX_NOR_DeviceDriver function is called from the FileX file system driver and issues requests to a LevelX NOR device through the LevelX API.

Parameters

| | | |
|----------|------------|---|
| [in,out] | p_fx_media | FileX media control block. All information about each open media device are maintained in the FX_MEDIA data type. The I/O driver communicates the success or failure of the request through the fx_media_driver_status member of FX_MEDIA (p_fx_media->fx_media_driver_status). Possible values are documented in the FileX User Guide. |
|----------|------------|---|

Return values

| | |
|------|--|
| None | |

Returns

Nothing, but updates FileX media control block.

Detailed Description

Driver for the flash memory on RA high-performance MCUs. This module implements the [Flash Interface](#).

Overview

The Flash HAL module APIs allow an application to write, erase and blank check both the data and ROM flash areas that reside within the MCU. The amount of flash memory available varies across MCU parts.

Features

The R_FLASH_HP module has the following key features:

- Blocking and non-blocking erasing, writing and blank-checking of data flash.
- Blocking erasing, writing and blank-checking of code flash.
- Callback functions for completion of non-blocking data flash operations.
- Access window (write protection) for ROM Flash, allowing only specified areas of code flash to be erased or written.
- Boot block-swapping.
- ID code programming support.

Configuration

Build Time Configurations for r_flash_hp

The following build time configurations are defined in fsp_cfg/r_flash_hp_cfg.h:

| Configuration | Options | Default | Description |
|-------------------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> Default (BSP) Enabled Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |
| Code Flash Programming Enable | <ul style="list-style-type: none"> Enabled Disabled | Disabled | Controls whether or not code-flash programming is enabled. Disabling reduces the amount of ROM and RAM used by the API. |
| Data Flash Programming Enable | <ul style="list-style-type: none"> Enabled Disabled | Enabled | Controls whether or not data-flash programming is enabled. Disabling reduces the amount of ROM used by the API. |

Configurations for Storage > Flash (r_flash_hp)

This module can be added to the Stacks tab via New Stack > Storage > Flash (r_flash_hp). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Flash Error Interrupt | MCU Specific Options | | Select the flash error |

Priority

interrupt priority.

Clock Configuration

Flash uses FCLK as the clock source depending on the MCU. When writing and erasing the clock source must be at least 4 MHz.

Pin Configuration

This module does not use I/O pins.

Usage Notes

Warning

It is highly recommended that the developer reviews sections 5 and 6 of the Flash Memory section of the target MCUs Hardware User's Manual prior to using the r_flash_hp module. In particular, understanding ID Code and Access Window functionality can help avoid unrecoverable flash scenarios.

Data Flash Background Operation (BGO) Precautions

When using the data flash BGO (Background Operation) mode, you can still access the user ROM, RAM and external memory. You must ensure that the data flash is not accessed during a data flash operation. This includes interrupts that may access the data flash.

Code Flash Precautions

Code flash cannot be accessed while writing, erasing or blank checking code flash. Code flash cannot be accessed while modifying the access window, selecting the startup area or setting the ID code. In order to support modifying code flash all supporting code must reside in RAM. This is only done when code flash programming is enabled. BGO mode is not supported for code flash, so a code flash operation will not return before the operation has completed. By default, the vector table resides in the code flash. If an interrupt occurs during the code flash operation, then code flash will be accessed to fetch the interrupt's starting address and an error will occur. The simplest work-around is to disable interrupts during code flash operations. Another option is to copy the vector table to RAM, update the VTOR (Vector Table Offset Register) accordingly and ensure that any interrupt service routines execute out of RAM. Similarly, you must insure that if in a multi-threaded environment, threads running from code flash cannot become active while a code flash operation is in progress.

Flash Clock (FCLK)

The flash clock source is the clock used by the Flash peripheral in performing all Flash operations. As part of the [flash_api_t::open](#) function the Flash clock source is checked will return FSP_ERR_FCLK if it is invalid. Once the Flash API has been opened, if the flash clock source frequency is changed, the [flash_api_t::updateFlashClockFreq](#) API function must be called to inform the API of the change. Failure to do so could result in flash operation failures and possibly damage the part.

Interrupts

Enable the flash ready interrupt only if you plan to use the data flash BGO. In this mode, the application can initiate a data flash operation and then be asynchronously notified of its completion, or an error, using a user supplied-callback function. The callback function is passed a structure containing event information that indicates the source of the callback event (for example, [flash_api_t::FLASH_EVENT_ERASE_COMPLETE](#)) When the FLASH FRDYI interrupt is enabled, the

corresponding ISR will be defined in the flash driver. The ISR will call a user-callback function if one was registered with the `flash_api_t::open` API.

Note

The Flash HP supports an additional flash-error interrupt and if the BGO mode is enabled for the FLASH HP then both the Flash Ready Interrupt and Flash Error Interrupts must be enabled (assigned a priority).

Limitations

- Write operations must be aligned on page boundaries and must be a multiple of the page boundary size.
- Erase operations will erase the entire block the provided address resides in.
- Data flash is better suited for storing data as it can be erased and written to while code is still executing from code flash. Data flash is also guaranteed for a larger number of reprogramming/erasure cycles than code flash.
- Read values of erased data flash blocks are not guaranteed to be 0xFF. Blank check should be used to determine if memory has been erased but not yet programmed.

Examples

This is a basic example of erasing and writing to data flash and code flash.

        g_src[i] = (uint8_t) ('A' + (i % 26));
    }
    /* Open the flash hp instance. */
    fsp_err_t err = R_FLASH_HP_Open(&g_flash_ctrl, &g_flash_cfg);

```

```
static flash_cfg_t g_flash_bgo_example_cfg =
{

    .ipl             = 5,
    .irq             = BSP_VECTOR_FLASH_HP_FRDYI_ISR,
};

void r_flash_hp_bgo_example (void)
{
    /* Initialize p_src to known data */
    for (uint32_t i = 0; i < TRANSFER_LENGTH; i++)
    {
        g_src[i] = (uint8_t) ('A' + (i % 26));

    err = R_FLASH_HP_Erase(&g_flash_ctrl, FLASH_DF_BLOCK_0, 1);
    assert(FSP_SUCCESS == err);
    while (!interrupt_called)
    {
        ;
    }
    assert(FLASH_EVENT_ERASE_COMPLETE == flash_event);

    err = R_FLASH_HP_StatusGet(&g_flash_ctrl, &status);
} while ((FSP_SUCCESS == err) && (FLASH_STATUS_BUSY == status));

/* If the interrupt wasn't called process the error. */
assert(interrupt_called);

/* If the event wasn't a write complete process the error. */
assert(FLASH_EVENT_WRITE_COMPLETE == flash_event);

/* Verify the data was written correctly. */
assert(0 == memcmp(g_src, (uint8_t *) FLASH_DF_BLOCK_0,
FLASH_HP_EXAMPLE_WRITE_SIZE));
}

void flash_callback (flash_callback_args_t * p_args)
{
    interrupt_called = true;
    flash_event      = p_args->event;
}
}
```

High-Performance Flash Bank Swap Example

This example demonstrates swapping which flash bank is located at address 0. This feature is only on select MCUs.

```
void r_flash_hp_bankswap_example (void)
{
    /* Open the flash hp instance. */
    fsp_err_t err = R_FLASH_HP_Open(&g_flash_ctrl, &g_flash_cfg);

    /* Handle any errors. */
    assert(FSP_SUCCESS == err);

    /* Write the new application starting at 0x00200000. */
    /* Swap the block at address 0 with the one at 0x00200000 after the next restart.
    * The application at 0x00200000 must be written there by application code. */
    err = R_FLASH_HP_BankSwap(&g_flash_ctrl);
}
```

```

/* Handle any errors. */
    assert(FSP_SUCCESS == err);

/* Handle any pre-reset operations here */

/* Reset the MCU to swap to the other bank */
    __NVIC_SystemReset();
}

```

uint32_t const end_addr )
```

Configure an access window for the Code Flash memory using the provided start and end address. An access window defines a contiguous area in Code Flash for which programming/erase is enabled. This area is on block boundaries. The block containing start_addr is the first block. The block containing end_addr is the last block. The access window then becomes first block -> last block inclusive. Anything outside this range of Code Flash is then write protected.

Note

If the start address and end address are set to the same value, then the access window is effectively removed. This accomplishes the same functionality as R_FLASH_HP_AccessWindowClear().

Implements [flash_api_t::accessWindowSet](#).

```
fsp_err_t R_FLASH_HP_StartUpAreaSelect ( flash_ctrl_t *const p_api_ctrl, flash_startup_area_swap_t swap_type, bool is_temporary )
```

Selects which block, Default (Block 0) or Alternate (Block 1), is used as the startup area block. The provided parameters determine which block will become the active startup block and whether that action will be immediate (but temporary), or permanent subsequent to the next reset. Doing a temporary switch might appear to have limited usefulness. If there is an access window in place such that Block 0 is write protected, then one could do a temporary switch, update the block and switch them back without having to touch the access window. Implements [flash_api_t::startupAreaSelect](#).

```

Swaps the flash bank located at address 0x00000000 and address 0x00200000. This can only be done when in dual bank mode. Dual bank mode can be enabled in the FSP Configuration Tool under BSP Properties. After a bank swap is done the MCU will need to be reset for the changes to take place. [flash_api_t::bankSwap](#).

Detailed Description

Driver for the flash memory on RA low-power MCUs. This module implements the [Flash Interface](#).

Overview

The Flash HAL module APIs allow an application to write, erase and blank check both the data and code flash areas that reside within the MCU. The amount of flash memory available varies across MCU parts.

Features

The Low-Power Flash HAL module has the following key features:

- Blocking and non-blocking erasing, writing and blank-checking of data flash.
- Blocking erasing, writing and blank checking of code flash.
- Callback functions for completion of non-blocking data flash operations.
- Access window (write protection) for code flash, allowing only specified areas of code flash to be erased or written.
- Boot block-swapping.
- ID code programming support.

Configuration

Build Time Configurations for r_flash_lp

The following build time configurations are defined in fsp_cfg/r_flash_lp_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|--|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled | Default (BSP) | If selected code for parameter checking is |

| | | | |
|------------------------|---|----------|---|
| | <ul style="list-style-type: none"> • Disabled | | included in the build. |
| Code Flash Programming | <ul style="list-style-type: none"> • Enabled • Disabled | Disabled | Controls whether or not code-flash programming is enabled. Disabling reduces the amount of ROM and RAM used by the API. |
| Data Flash Programming | <ul style="list-style-type: none"> • Enabled • Disabled | Enabled | Controls whether or not data-flash programming is enabled. Disabling reduces the amount of ROM used by the API. |

Configurations for Storage > Flash (r_flash_lp)

This module can be added to the Stacks tab via New Stack > Storage > Flash (r_flash_lp).

| Configuration | Options | Default | Description |
|---------------------------------|---|----------|---|
| Name | Name must be a valid C symbol | g_flash0 | Module name. |
| Data Flash Background Operation | <ul style="list-style-type: none"> • Enabled • Disabled | Enabled | Enabling allows Flash API calls that reference data-flash to return immediately, with the operation continuing in the background. |
| Callback | Name must be a valid C symbol | NULL | A user callback function can be specified. Callback function called when a Data Flash Background Operation completes or errors. |
| Flash Ready Interrupt Priority | MCU Specific Options | | Select the flash ready interrupt priority. |

Clock Configuration

Flash either uses FCLK or ICLK as the clock source depending on the MCU. When writing and erasing the clock source must be at least 4 MHz.

Pin Configuration

This module does not use I/O pins.

Usage Notes

Warning

It is highly recommended that the developer reviews sections 5 and 6 of the Flash Memory section of the target MCUs Hardware User's Manual prior to using the r_flash_lp module. In particular, understanding ID Code and Access Window functionality can help avoid unrecoverable flash scenarios.

Data Flash Background Operation (BGO) Precautions

When using the data flash BGO, the code flash, RAM and external memory can still be accessed. You must ensure that the data flash is not accessed during a data flash operation. This includes interrupts that may access the data flash.

Code Flash Precautions

Code flash cannot be accessed while writing, erasing or blank checking code flash. Code flash cannot be accessed while modifying the access window, selecting the startup area or setting the ID code. In order to support modifying code flash all supporting code must reside in RAM. This is only done when code flash programming is enabled. BGO mode is not supported for code flash, so a code flash operation will not return before the operation has completed. By default, the vector table resides in the code flash. If an interrupt occurs during the code flash operation, then code flash will be accessed to fetch the interrupt's starting address and an error will occur. The simplest work-around is to disable interrupts during code flash operations. Another option is to copy the vector table to RAM, update the VTOR (Vector Table Offset Register) accordingly and ensure that any interrupt service routines execute out of RAM. Similarly, you must insure that if in a multi-threaded environment, threads running from code flash cannot become active while a code flash operation is in progress.

Flash Clock Source

The flash clock source is the clock used by the Flash peripheral in performing all Flash operations. As part of the [flash_api_t::open](#) function the Flash clock source is checked will return FSP_ERR_FCLK if it is invalid. Once the Flash API has been opened, if the flash clock source frequency is changed, the [flash_api_t::updateFlashClockFreq](#) API function must be called to inform the API of the change. Failure to do so could result in flash operation failures and possibly damage the part.

Interrupts

Enable the flash ready interrupt only if you plan to use the data flash BGO. In this mode, the application can initiate a data flash operation and then be asynchronously notified of its completion, or an error, using a user supplied-callback function. The callback function is passed a structure containing event information that indicates the source of the callback event (for example, [flash_api_t::FLASH_EVENT_ERASE_COMPLETE](#)) When the FLASH FRDYI interrupt is enabled, the corresponding ISR will be defined in the flash driver. The ISR will call a user-callback function if one was registered with the [flash_api_t::open](#) API.

Note

The Flash HP supports an additional flash-error interrupt and if the BGO mode is enabled for the FLASH HP then both the Flash Ready Interrupt and Flash Error Interrupts must be enabled (assigned a priority).

Limitations

- Write operations must be aligned on page boundaries and must be a multiple of the page boundary size.
- Erase operations will erase the entire block the provided address resides in.
- Data flash is better suited for storing data as it can be erased and written to while code is still executing from code flash. Data flash is also guaranteed for a larger number of

reprogramming/erasure cycles than code flash.

- Read values of erased blocks are not guaranteed to be 0xFF. Blank check should be used to determine if memory has been erased but not yet programmed.

Examples

Low-Power Flash Basic Example

This is a basic example of erasing and writing to data flash and code flash.

```

    {
        g_src[i] = (uint8_t) ('A' + (i % 26));
    }

    /* Open the flash lp instance. */
    fsp_err_t err = R_FLASH_LP_Open(&g_flash_ctrl, &g_flash_cfg);

Low-Power Flash Advanced Example

This example demonstrates using BGO to do non-blocking operations on the data flash.

```
bool interrupt_called;
flash_event_t flash_event;
static flash_cfg_t g_flash_bgo_example_cfg =
{
    .p_callback    = flash_callback,
    .p_context     = 0,
    .p_extend      = NULL,
    .data_flash_bgo = true,
    .ipl           = 5,
    .irq           = BSP_VECTOR_FLASH_LP_FRDYI_ISR,
};
```

```
void R_FLASH_LP_bgo_example (void)
{
    /* Initialize p_src to known data */
    for (uint32_t i = 0; i < TRANSFER_LENGTH; i++)
    {
        g_src[i] = (uint8_t) ('A' + (i % 26));
    }

    /* Open the flash lp instance. */
    fsp_err_t err = R_FLASH_LP_Open(&g_flash_ctrl, &g_flash_bgo_example_cfg);
    /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
    interrupt_called = false;

    /* Erase 1 block of data flash starting at block 0. */
    err = R_FLASH_LP_Erase(&g_flash_ctrl, FLASH_DF_BLOCK_0, 1);
    assert(FSP_SUCCESS == err);
    while (!interrupt_called)
    {
        ;
    }
    assert(FLASH_EVENT_ERASE_COMPLETE == flash_event);
    interrupt_called = false;

    /* Write 32 bytes to the first block of data flash. */
    err = R_FLASH_LP_Write(&g_flash_ctrl, (uint32_t) g_src, FLASH_DF_BLOCK_0,
FLASH_LP_EXAMPLE_WRITE_SIZE);
    assert(FSP_SUCCESS == err);
    flash_status_t status;
    /* Wait until the current flash operation completes. */
    do
    {
        err = R_FLASH_LP_StatusGet(&g_flash_ctrl, &status);
    } while ((FSP_SUCCESS == err) && (FLASH_STATUS_BUSY == status));
    /* If the interrupt wasn't called process the error. */
    assert(interrupt_called);
    /* If the event wasn't a write complete process the error. */
}
```

```
    assert(FLASH_EVENT_WRITE_COMPLETE == flash_event);

    /* Verify the data was written correctly. */
    assert(0 == memcmp(g_src, (uint8_t *) FLASH_DF_BLOCK_0,
FLASH_LP_EXAMPLE_WRITE_SIZE));
}

void flash_callback (flash_callback_args_t * p_args)
{
    interrupt_called = true;
    flash_event      = p_args->event;
}
```

Data Structures

```
struct flash_lp_instance_ctrl_t
```

Data Structure Documentation

◆ flash_lp_instance_ctrl_t

```
struct flash_lp_instance_ctrl_t
```

Flash instance control block. DO NOT INITIALIZE. Initialization occurs when [R_FLASH_LP_Open\(\)](#) is called.

Function Documentation

◆ **R_FLASH_LP_Open()**

```
fsp_err_t R_FLASH_LP_Open ( flash_ctrl_t *const p_api_ctrl, flash_cfg_t const *const p_cfg )
```

Initialize the Low Power flash peripheral. Implements `flash_api_t::open`.

The Open function initializes the Flash.

This function must be called once prior to calling any other FLASH API functions. If a user supplied callback function is supplied, then the Flash Ready interrupt will be configured to call the users callback routine with an Event type describing the source of the interrupt for Data Flash operations.

Example:

```
/* Open the flash lp instance. */
fsp_err_t err = R_FLASH_LP_Open(&g_flash_ctrl, &g_flash_cfg);
```

Note

Providing a callback function in the supplied `p_cfg->callback` field automatically configures the Flash for Data Flash to operate in non-blocking background operation (BGO) mode.

◆ R_FLASH_LP_AccessWindowSet()

```

uint32_t const end_addr )
```

Configure an access window for the Code Flash memory. Implements `flash_api_t::accessWindowSet`.

An access window defines a contiguous area in Code Flash for which programming/erase is enabled. This area is on block boundaries. The block containing `start_addr` is the first block. The block containing `end_addr` is the last block. The access window then becomes first block (inclusive) -> last block (exclusive). Anything outside this range of Code Flash is then write protected. As an example, if you wanted to place an accesswindow on Code Flash Blocks 0 and 1, such that only those two blocks were writable, you would need to specify (address in block 0, address in block 2) as the respective start and end address.

Note

If the start address and end address are set to the same value, then the access window is effectively removed. This accomplishes the same functionality as `R_FLASH_LP_AccessWindowClear()`.

The invalid address and programming boundaries supported and enforced by this function are dependent on the MCU in use as well as the part package size. Please see the User manual and/or requirements document for additional information.

Selects which block - Default (Block 0) or Alternate (Block 1) is used as the startup area block. The provided parameters determine which block will become the active startup block and whether that action will be immediate (but temporary), or permanent subsequent to the next reset. Doing a temporary switch might appear to have limited usefulness. If there is an access window in place such that Block 0 is write protected, then one could do a temporary switch, update the block and switch them back without having to touch the access window.

Detailed Description

Middleware for the FAT File System control on RA MCUs.

Overview

This module provides the hardware port layer for FreeRTOS+FAT file system. After initializing this module, refer to the FreeRTOS+FAT API reference to use the file system:

https://www.freertos.org/FreeRTOS-Plus/FreeRTOS_Plus_FAT/index.html

Features

The FreeRTOS+FAT port module supports the following features:

- Callbacks for insertion and removal for removable devices.
- Helper function to initialize FF_Disk_t
- Blocking read and write port functions that use FreeRTOS task notification to pend if FreeRTOS is used
- FreeRTOS is optional

Configuration

Build Time Configurations for rm_freertos_plus_fat

The following build time configurations are defined in fsp_cfg/middleware/rm_freertos_plus_fat_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled • Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

Configurations for Storage > FreeRTOS+FAT Port for RA (rm_freertos_plus_fat)

| Configuration | Options | Default | Description |
|-------------------------|--------------------------------|--------------------------|--|
| Name | Name must be a valid C symbol | g_rm_freertos_plus_fat_0 | Module name. |
| Total Number of Sectors | Must be a non-negative integer | 31293440 | Enter the total number of sectors on the device. If this is not known, update rm_freertos_plus_fat_disk_cfg_t::num_blocks after calling RM_FREERTOS_PLUS_FAT_MediaInit() . |
| Sector Size (bytes) | Must be a power of 2 | 512 | Select the sector size. |

| | | | |
|--------------------|--------------------------------------|------|---|
| | multiple of 512 | | Must match the underlying media sector size and at least 512. If this is not known, update <code>rm_freertos_plus_fat_disk_cfg_t::num_blocks</code> after calling <code>RM_FREERTOS_PLUS_FAT_MediaInit()</code> . |
| Cache Size (bytes) | Must be a power of 2 multiple of 512 | 1024 | Select the cache size. Must be a multiple of the sector size and at least 2 times the sector size. |
| Partition Number | Must be a non-negative integer | 0 | Select the partition number for this disk. |
| Callback | Name must be a valid C symbol | NULL | A user callback function can be provided. If this callback function is provided, it will be called when a card is inserted or removed. |

Usage Notes

Pending during Read/Write

If the underlying driver supports non-blocking operations, the FreeRTOS+FAT port pends the active FreeRTOS task during read and write operations so other tasks can run in the background.

If FreeRTOS is not used, the FreeRTOS+FAT port spins in a while loop waiting for read and write operations to complete.

FreeRTOS+FAT without FreeRTOS

To use FreeRTOS+FAT without FreeRTOS, copy `FreeRTOSConfigMinimal.h` to one of your project's include paths and rename it `FreeRTOSConfig.h`.

Also, update the Malloc function to `malloc` and the Free function to `free` in the Common configurations.

Detailed Description

Middleware for using Azure RTOS LevelX on NOR SPI memory.

Overview

This module provides the hardware port layer for LevelX on NOR SPI flash memory. Setup for this module is done solely through calling LevelX APIs. Please refer to the LevelX API reference: <https://docs.microsoft.com/en-us/azure/rtos/levelx/>

Configuration

Build Time Configurations for `rm_levelx_nor_spi`

The following build time configurations are defined in `fsp_cfg/middleware/rm_levelx_nor_spi_cfg.h`:

| Configuration | Options | Default | Description |
|--------------------------|--|---------------|--|
| Parameter Checking | <ul style="list-style-type: none"> Default (BSP) Enabled Disabled | Default (BSP) | Selects if code for parameter checking is to be included in the build. |
| Write Verify | <ul style="list-style-type: none"> Enabled Disabled | Disabled | When enabled reads back data written to SPI memory in order to verify it. |
| Page Buffer Size (bytes) | Size should be greater than zero | 256 | When direct read is enabled in LevelX a situation can occur where the driver has to write to SPI memory with the source location also being within the SPI memory address range. In this situation the driver needs a buffer that is at least the same size as a page in order to temporarily store data |

to write out.

Configurations for Storage > LevelX NOR Port (rm_levelx_nor_spi)

| Configuration | Options | Default | Description |
|-------------------------------------|---|----------------------|--|
| Name | Name must be a valid C symbol | g_rm_levelx_nor_spi0 | Module name. |
| Memory Start Address Offset (bytes) | Offset should be greater than or equal to zero | 0 | Enter the starting offset to use in the SPI memory. The starting address for LevelX memory will be the SPI memory base address plus this offset. |
| Memory Size (bytes) | Size should be greater than zero | 33554432 | Enter the size that the LevelX Memory should be. This can be smaller than the SPI memory size in order to use a subset of SPI memory. |
| Poll Status Count | Poll Status Count should be greater than or equal to zero | 0xFFFFFFFF | Number of times to poll for operation complete status for blocking memory operations. |

Build Time Configurations for lx

The following build time configurations are defined in fsp_cfg/azure/lx/lx_user.h:

| Configuration | Options | Default | Description |
|-------------------------------|---|--------------------|--|
| NOR > Direct Read | <ul style="list-style-type: none"> Enabled (default) Disabled | Enabled (default) | When enabled, this option bypasses the NOR flash driver read routine in favor of reading the NOR memory directly, resulting in a significant performance increase. |
| NOR > Free Sector Data Verify | <ul style="list-style-type: none"> Enabled Disabled (default) | Disabled (default) | When enabled, this causes the LevelX NOR instance open logic to verify free NOR sectors are all ones. |
| NOR > Extended Cache | <ul style="list-style-type: none"> Enabled (default) Disabled | Enabled (default) | Enables the extended NOR cache. |
| NOR > Extended Cache Size | Manual Entry | | If not set this value defaults to 8, which represents a maximum |

| | | | |
|-----------------------------------|---|--------------------|--|
| NOR > Sector Mapping Cache Size | Value must be greater than or equal to 8 and a power of 2, or empty | | of 8 sectors that can be cached in a NOR instance. |
| NAND > Sector Mapping Cache Size | Value must be greater than or equal to 8 and a power of 2, or empty | | If not set this value defaults to 16 and defines the logical sector mapping cache size. Large values improve performance, but cost memory. The minimum size is 8 and all values must be a power of 2. |
| NAND > Flash Direct Mapping Cache | <ul style="list-style-type: none"> • Enabled • Disabled (default) | Disabled (default) | When enabled, this creates a direct mapping cache, such that there are no cache misses. It also required that LX_NAND_SECTOR_MAPPING_CACHE_SIZE represents the exact number of total pages in your flash device. |
| Thread Safe | <ul style="list-style-type: none"> • Enabled • Disabled (default) | Disabled (default) | When enabled, this makes LevelX thread-safe by using a ThreadX mutex object throughout the API. |
| Standalone Mode | <ul style="list-style-type: none"> • Enabled • Disabled (default) | Disabled (default) | When enabled, allows LevelX to be used in standalone mode (without Azure RTOS). |

Usage Notes

Pending during Erase/Write

The LevelX NOR SPI driver is blocking on all SPI operations and will poll device status for operation completion on Writes and Erases. A callback can be provided by the user to wait with an OS-specific thread wait in these instances.

Closing the driver

When `lx_nor_flash_close` is called to close the LevelX instance it does not call any services within the LevelX NOR SPI driver to close out the driver instance. The user should call the generated close function (i.e. `g_rm_levelx_nor_spi0_close`) in order to close out the driver instance.

Erasing Flash Memory Prior to Usage

The area of the flash memory being used for the LevelX instance should be erased using the lower level flash API prior to usage. Otherwise, LevelX API may fail on `lx_nor_flash_open` due to any areas in flash memory that have been written/set.

Examples

Callback Wait Example

This shows how to use the LevelX NOR SPI driver callback with ThreadX in order to wait for operations to complete.

```

/* Callback called by LevelX NOR SPI driver needs to wait on operation. */

```

```

void rm_levelx_nor_spi_callback_wait_example (rm_levelx_nor_spi_callback_args_t *
p_args)
{
    if (p_args->event & RM_LEVELX_NOR_SPI_EVENT_BUSY)
    {
        /* Put the thread to sleep while waiting for operation to complete. */
        tx_thread_sleep(1);
    }
}

Detailed Description

Middleware for the LittleFS File System control on RA MCUs.

Overview

This module provides the hardware port layer for the LittleFS file system. After initializing this module, refer to the LittleFS documentation to use the file system:

<https://github.com/ARMmbed/littlefs>

Configuration

Build Time Configurations for rm_littlefs_flash

The following build time configurations are defined in fsp_cfg/rm_littlefs_flash_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> Default (BSP) Enabled Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

Configurations for Storage > LittleFS on Flash (rm_littlefs_flash)

| Configuration | Options | Default | Description |
|---------------|--------------------------------|----------------|---|
| Name | Name must be a valid C symbol | g_rm_littlefs0 | Module name. |
| Read Size | Must be a non-negative integer | 1 | Minimum size of a block read. All read operations will be a multiple of this value. |
| Program Size | Must be a non-negative integer | 4 | Minimum size of a block program. All program operations will be a multiple of this value. |

| | | | |
|--------------------|--------------------------------------|---------------------------------|---|
| Block Size (bytes) | Must be a multiple of 64 | 128 | Size of an erasable block. This does not impact RAM consumption and may be larger than the physical erase size. However, non-inlined files take up at minimum one block. Must be a multiple of the read and program sizes. |
| Block Count | Manual Entry | (BSP_DATA_FLASH_SIZE_BYTES/128) | Number of erasable blocks on the device. |
| Block Cycles | Must be an integer | 1024 | Number of erase cycles before LittleFS evicts metadata logs and moves the metadata to another block. Suggested values are in the range 100-1000, with large values having better performance at the cost of less consistent wear distribution. Set to -1 to disable block-level wear-leveling. |
| Cache Size | Must be a non-negative integer | 64 | Size of block caches. Each cache buffers a portion of a block in RAM. The LittleFS needs a read cache, a program cache, and one additional cache per file. Larger caches can improve performance by storing more data and reducing the number of disk accesses. Must be a multiple of the read and program sizes, and a factor of the block size. |
| Lookahead Size | Must be a non-negative multiple of 8 | 16 | Size of the lookahead buffer in bytes. A larger lookahead buffer increases the number of blocks found during an allocation pass. The lookahead buffer is |

stored as a compact bitmap, so each byte of RAM can track 8 blocks. Must be a multiple of 8.

Common LittleFS Configuration

Build Time Configurations for LittleFS

The following build time configurations are defined in arm/littlefs/lfs_util.h:

| Configuration | Options | Default | Description |
|---------------------------------|---|----------------|--|
| Custom lfs_util.h | Manual Entry | | Add a path to your custom lfs_util.h file. It can be used to override some or all of the configurations defined here, and to define additional configurations. |
| Thread Safe | <ul style="list-style-type: none"> • Enabled • Disabled | Disabled | Enables thread safety in LittleFS. |
| Use Malloc | <ul style="list-style-type: none"> • Enabled • Disabled | Enabled | Configures the use of malloc by LittleFS. |

| Warning Messages | <ul style="list-style-type: none"> • Enabled • Disabled | Disabled | Configures warning messages. |
| Error Messages | <ul style="list-style-type: none"> • Enabled • Disabled | Disabled | Configures error messages. |
| Trace Messages | <ul style="list-style-type: none"> • Enabled • Disabled | Disabled | Configures trace messages. |
| Intrinsics | <ul style="list-style-type: none"> • Enabled • Disabled | Enabled | Configures intrinsic functions such as <code>__builtin_clz</code> . |
| Instance Name for STDIO wrapper | Name must be a valid C symbol | g_rm_littlefs0 | The <code>rm_littlefs</code> instance name to use with the STDIO wrapper. |

Usage Notes

Blocking Read/Write/Erase

The LittleFS port blocks on Read/Write/Erase calls until the operation has completed.

Memory Constraints

The block size defined in the LittleFS configuration must be a multiple of the data flash erase size of the MCU. It must be greater than 104bytes which is the minimum block size of a LittleFS block. For information about data flash erase sizes refer to the "Specifications of the code flash memory and data flash memory" table of the "Flash Memory" chapter's "Overview" section.

Limitations

This module is not thread safe.

Detailed Description

Driver for the OSPI peripheral on RA MCUs. This module implements the [SPI Flash Interface](#).

Overview

The OSPI peripheral interfaces with an external OctaFlash and/or OctaRAM chip(s) to perform data I/O Operations. When both OctaFlash and OctaRAM devices are interfaced, they must be connected to their own chip-select lines. The devices cannot share a single chip-select line.

Features

The OSPI driver has the following key features to support the **OctaFlash** device:

- Perform data I/O Operation in both SPI and OPI modes
- Can be configured with OctaFlash device on either of the 2 channels
- Memory mapped read access to the OctaFlash
- Programming the OctaFlash device using single continuous write
- Erasing the OctaFlash device
- Sending device specific commands and reading back responses
- Entering and exiting XIP (Single Continuous Read) mode
- 3 byte addressing for SPI
- 4 byte addressing for SPI and OPI
- Auto-calibration for OPI mode (SOPI and DOPI)

The OSPI driver has the following key features to support the **OctaRAM** device:

- Perform data I/O Operation in DOPI mode
- Can be configured with OctaRAM device on either of the 2 channels
- Memory mapped read and write access to the OctaRAM using single continuous mode
- Sending device specific commands and reading back responses
- Auto-calibration for DOPI mode
- Uninitialized global variables or buffers can be allocated in the OSPI RAM address space.

Additional build-time features:

- Optional (build-time) DMAC support for data transmission when used with OctaFlash.

Note

For OctaFlash, use of DMAC for data transmission is strongly recommended. Without the use of DMAC, due to the high-speed hardware design of the OSPI peripheral, data transmission can be sensitive to timing variance, which could cause software-based memory-mapped operations to fail unexpectedly.

Clock Configuration

PCLKB is the Octal-SPI bus interface, and PCLKA is used to set OSPI registers.

The signals to the OSPI device are derived from OCTASPICK. The OMSCLK signal is OCTASPICK / 2. Data can be output at the OCTASPICK rate if SPI Protocol is set to Dual Data Rate OPI.

The PCLKB, PCLKA, and OCTASPICK frequencies can be set on the **Clocks** tab of the RA Configuration editor.

Pin Configuration

The following pins are available to connect to an external OSPI device:

- OMCLK: OSPI clock output (OCTASPICLK / 2)
- OMDQS: OSPI data strobe signal
- OMCS0: OSPI device 0 select
- OMCS1: OSPI device 1 select
- OMSIO0: Data 0 I/O
- OMSIO1: Data 1 I/O
- OMSIO2: Data 2 I/O
- OMSIO3: Data 3 I/O
- OMSIO4: Data 4 I/O
- OMSIO5: Data 5 I/O
- OMSIO6: Data 6 I/O
- OMSIO7: Data 7 I/O

Note

Data pins must be configured with IOPORT_CFG_DRIVE_HS_HIGH.

Chip Select pins should be configured with at least IOPORT_CFG_DRIVE_MEDIUM.

Usage Notes

Usage Notes for OctaFlash support

Enabling DMAC

DMAC data transmission support is configurable for OSPI Flash and is disabled from the build by default. Use of a high-priority (low channel number) DMAC for data transmission is strongly recommended.

For further details on DMAC please refer [Transfer \(r_dmac\)](#).

OSPI Memory Mapped Access

After [R_OSPI_Open\(\)](#) completes successfully, the OctaFlash device contents are mapped to address 0x68000000 (channel 0) or 0x70000000 (channel 1) based on the channel configured and can be read like on-chip flash. Channel 0 supports 128 MB while Channel 1 supports 256 MB of address space.

Auto-calibration

Auto-calibration procedure is triggered automatically when the 'Data latching delay' field in the configurator properties is set to 0. The user application is responsible for setting the appropriate preamble pattern before calling [R_OSPI_Open\(\)](#) with SOPI/DOPI mode or changing the SPI protocol to SOPI/DOPI using [R_OSPI_SpiProtocolSet\(\)](#) API. The appropriate preamble pattern can be written to the desired address using the [R_OSPI_Write\(\)](#) API while in the SPI mode (recommended). Ensure that the same address is passed through the configurator. If the OctaFlash chip is already in SOPI/DOPI mode, the preamble pattern must be programmed using the debugger before calling [R_OSPI_Open\(\)](#).

Chip Select Latencies

Chip select latencies can be set through the configurator. The default settings support SOPI and SPI at minimum latency. In case the driver is opened in SPI mode and will be switched to DOPI mode later using [R_OSPI_SpiProtocolSet\(\)](#), please select latencies required for DOPI before calling [R_OSPI_Open\(\)](#).

OctaFlash Commands

- Set the erase commands based on intended mode of operation (SPI or OPI). These commands cannot be changed during run-time.
- Read, Write and Status commands for both SPI and OPI are configured allowing switching between the modes at run-time.

Usage Notes for OctaRAM support

OSPI Memory Mapped Access

After `R_OSPI_Open()` completes successfully, the OctaRAM device contents are mapped to address 0x68000000 (channel 0) or 0x70000000 (channel 1) based on the channel configured and can be written to or read from like on-chip RAM. Channel 0 and 1 support 8 MB of address space.

Auto-calibration

Since the OctaRAM only supports DOPI mode, the driver allows the user to call `R_OSPI_Open()` without performing the auto-calibration procedure automatically when 'Data latching delay' field is set to 0 in the configurator properties. This is done so that the user can write the appropriate preamble pattern to the desired address using memory mapped writes while in DOPI mode. Ensure that the same address is passed through the configurator. `R_OSPI_AutoCalibrate()` should be then called to perform auto-calibration.

Chip Select Latencies

Chip select latencies can be set through the configurator. The default settings support DOPI at minimum latency.

Limitations

Developers should be aware of the following limitations when using the OSPI driver:

OctaFlash

- Single continuous read in SPI mode is not supported by the peripheral. The maximum amount of data that can be read using a single read command is 4-bytes (When doing a 32-bit access).
- Fast Reads would be slower than regular reads as the SPI mode cannot be operated with an OMCLK greater than 50MHz.

Examples

OSPI Flash:

Basic Example

This is a basic example of minimal use of the OSPI in an application with OctaFlash.

```
#define OSPI_EXAMPLE_DATA_LENGTH (1024)
uint8_t g_dest[OSPI_EXAMPLE_DATA_LENGTH];

/* Place data in the .ospi_flash section to flash it during programming. */
const uint8_t g_src[OSPI_EXAMPLE_DATA_LENGTH] BSP_PLACE_IN_SECTION(".ospi_flash") =
```

```
"ABCDEFGHIJKLMNOPQRSTUVWXYZ";

/* Place code in the .code_in_ospi section to flash it during programming. */
void r_ospi_example_function(void) BSP_PLACE_IN_SECTION(".code_in_ospi")
__attribute__((noinline));

void r_ospi_example_function (void)
{
    /* Add code here. */
}

void r_ospi_basic_example (void)
{
    /* Open the OSPI instancee */
    fsp_err_t err = R_OSPI_Open(&g_ospi0_ctrl, &g_ospi0_cfg);
    assert(FSP_SUCCESS == err);

    /* (Optional) Change SPI to DOPI mode */
    r_ospi_example_spi_to_dopi();

    /* After R_OSPI_Open() and any required device specific initialization, data can be
read directly from the OSPI flash. */
    memcpy(&g_dest[0], &g_src[0], OSPI_EXAMPLE_DATA_LENGTH);

    /* After R_OSPI_Open() and any required device specific initialization, functions in
the OSPI flash can be called. */
    r_ospi_example_function();
}
```

Reading Status Register Example (R_OSPI_DirectTransfer)

This is an example of using R_OSPI_DirectWrite followed by R_OSPI_DirectRead to send the read status register command and read back the status register from the device.

```
#define OSPI_COMMAND_READ_STATUS_REGISTER (0x05U)

Octaclk Update Example (R_OSPI_SpiProtocolSet)

This is an example of using R_BSP_OctaclkUpdate to change the Octal-SPI clock frequency during run time. The OCTACLK frequency must be updated before calling the R_OSPI_SpiProtocolSet with appropriate clock source and divider settings required to be set for the new SPI protocol mode. Ensure that the clock source selected is started.

```
static void ospi_example_change_omclk (void)
{
    /* Ensure clock source (PLL2 in this example) is running before changing the OCTACLK
frequency */
    bsp_octaclk_settings_t octaclk_settings;

    octaclk_settings.divider      = BSP_CLOCKS_OCTACLK_DIV_2;
    R_BSP_OctaclkUpdate(&octaclk_settings);
}
```

OSPI Data and IAR

Clock Configuration

The QSPI clock is derived from PCLKA.

Pin Configuration

The following pins are available to connect to an external QSPI device:

- QSPCLK: QSPI clock output
- QSSL: QSPI slave select
- QIO0: Data 0 I/O
- QIO1: Data 1 I/O
- QIO2: Data 2 I/O
- QIO3: Data 3 I/O

Note

It is recommended to configure the pins with IOPORT_CFG_DRIVE_HIGH.

Usage Notes

QSPI Memory Mapped Access

After [R_QSPI_Open\(\)](#) completes successfully, the QSPI flash device contents are mapped to address 0x60000000 and can be read like on-chip flash.

Limitations

Developers should be aware of the following limitations when using the QSPI driver:

- Only P305-P310 are currently supported by the J-Link driver to flash the QSPI.
- The default J-Link downloader requires the device to be in extended SPI mode (not QPI mode).

Examples

Basic Example

This is a basic example of minimal use of the QSPI in an application.

```
#define QSPI_EXAMPLE_DATA_LENGTH (1024)
uint8_t g_dest[QSPI_EXAMPLE_DATA_LENGTH];
/* Place data in the .qspi_flash section to flash it during programming. */
const uint8_t g_src[QSPI_EXAMPLE_DATA_LENGTH] BSP_PLACE_IN_SECTION(".qspi_flash") =
"ABCDEFGHIJKLMNOPQRSTUVWXYZ";
/* Place code in the .code_in_qspi section to flash it during programming. */
void r_qspi_example_function(void) BSP_PLACE_IN_SECTION(".code_in_qspi")
__attribute__((noinline));
void r_qspi_example_function (void)
{
    /* Add code here. */
}
void r_qspi_basic_example (void)
{
    /* Open the QSPI instance. */
    fsp_err_t err = R_QSPI_Open(&g_qspi0_ctrl, &g_qspi0_cfg);
    assert(FSP_SUCCESS == err);
    /* (Optional) Send device specific initialization commands. */
    r_qspi_example_init();
    /* After R_QSPI_Open() and any required device specific initialization, data can be
read directly from the QSPI flash. */
    memcpy(&g_dest[0], &g_src[0], QSPI_EXAMPLE_DATA_LENGTH);
    /* After R_QSPI_Open() and any required device specific initialization, functions in
the QSPI flash can be called. */
    r_qspi_example_function();
}
```

Initialization Command Structure Example

This is an example of the types of commands that can be used to initialize the QSPI.

```
#define QSPI_COMMAND_WRITE_ENABLE (0x06U)
#define QSPI_COMMAND_WRITE_STATUS_REGISTER (0x01U)
#define QSPI_COMMAND_ENTER_QPI_MODE (0x38U)
#define QSPI_EXAMPLE_STATUS_REGISTER_1 (0x40)
#define QSPI_EXAMPLE_STATUS_REGISTER_2 (0x00)
static void r_qspi_example_init (void)
{
    /* Write status registers */
    /* Write one byte to enable writing to the status register, then deassert QSSL. */
    uint8_t data[4];
    fsp_err_t err;
    data[0] = QSPI_COMMAND_WRITE_ENABLE;
    err = R_QSPI_DirectWrite(&g_qspi0_ctrl, &data[0], 1, false);
    assert(FSP_SUCCESS == err);
    /* Write 3 bytes, including the write status register command followed by values for
both status registers. In the
    * status registers, set QE to 1 and other bits to their default setting. After all
data is written, deassert the
    * QSSL line. */
    data[0] = QSPI_COMMAND_WRITE_STATUS_REGISTER;
    data[1] = QSPI_EXAMPLE_STATUS_REGISTER_1;
    data[2] = QSPI_EXAMPLE_STATUS_REGISTER_2;
    err = R_QSPI_DirectWrite(&g_qspi0_ctrl, &data[0], 3, false);
    assert(FSP_SUCCESS == err);
    /* Wait for status register to update. */
    spi_flash_status_t status;
    do
    {
        (void) R_QSPI_StatusGet(&g_qspi0_ctrl, &status);
    } while (true == status.write_in_progress);
    /* Write one byte to enter QSPI mode, then deassert QSSL. After entering QPI mode on
the device, change the SPI
```

```
* protocol to QPI mode on the MCU peripheral. */

{
    /* Read a status register. */
    /* Write one byte to read the status register. Do not deassert QSSL. */
    uint8_t data;
    fsp_err_t err;
    data = QSPI_COMMAND_READ_STATUS_REGISTER;
    err = R_QSPI_DirectWrite(&g_qspi0_ctrl, &data, 1, true);
    assert(FSP_SUCCESS == err);
    /* Read one byte. After all data is read, deassert the QSSL line. */
    err = R_QSPI_DirectRead(&g_qspi0_ctrl, &data, 1);
    assert(FSP_SUCCESS == err);
    /* Status register contents are available in variable 'data'. */

Interrupt Configurations:

The following interrupts are required to use the r_sdhi module:

Using SD/MMC with DTC:

- Access Interrupt
- DTC Interrupt

Using SD/MMC with DMAC:

- Access Interrupt
- DMAC Interrupt (in DMAC instance)

The Card interrupt is optional and only available on MCU packages that have the SDnCD pin (n = channel number).

Clock Configuration

The SDMMC MCU peripheral (SDHI) uses the PCLKA for its clock source. The SDMMC driver selects the optimal built-in divider based on the PCLKA frequency and the maximum clock rate allowed by the device obtained at media initialization.

Pin Configuration

The SDMMC driver supports the following pins (n = channel number):

- SDnCLK
- SDnCMD
- SDnDAT0
- SDnDAT1
- SDnDAT2
- SDnDAT3
- SDnDAT4 (not available on all MCUs)
- SDnDAT5 (not available on all MCUs)
- SDnDAT6 (not available on all MCUs)
- SDnDAT7 (not available on all MCUs)
- SDnCD (not available on all MCUs)
- SDnWP

The drive capacity for each pin should be set to "Medium" or "High" for most hardware designs. This can be configured in the **Pins** tab of the RA Configuration editor by selecting the pin under Pin Selection -> Ports.

Usage Notes

Card Detection

When Card Detection is configured to "CD Pin" in the RA Configuration editor, interrupt flags are cleared and card detection is enabled during [R_SDHI_Open\(\)](#).

[R_SDHI_StatusGet\(\)](#) can be called to retrieve the current status of the card (including whether a card is present). If the Card Interrupt Priority is enabled, a callback is called when a card is inserted or removed.

If a card is removed and reinserted, [R_SDHI_MediaInit\(\)](#) must be called before reading from the card or writing to the card.

Note

[R_SDHI_StatusGet\(\)](#) should be used to initially determine the card state after opening the interface.

DMA Request Interrupt Priority

When data transfers are not 4-byte aligned or not a multiple of 4 bytes, a software copy of the block size (up to 512 bytes) is done in the DMA Request interrupt. This blocks all other interrupts that are a lower or equal priority to the access interrupt until the software copy is complete.

Timing Notes for R_SDHI_MediaInit

The [R_SDHI_MediaInit\(\)](#) API completes the entire device identification and configuration process. This involves several command-response cycles at a bus width of 1 bit and a bus speed of 400 kHz or less.

Limitations

Developers should be aware of the following limitations when using the SDHI:

Blocking Calls

The following functions block execution until the response is received for at least one command:

- [R_SDHI_MediaInit](#)
- [R_SDHI_Erase](#)

Once the function returns the status of the operation can be determined via [R_SDHI_StatusGet](#) or through receipt of a callback.

Note

Due to the variability in clocking configurations it is recommended to determine blocking delays experimentally on the target system.

Data Alignment and Size

Data transfers should be 4-byte aligned and a multiple of 4 bytes in size whenever possible. This recommendation applies to the `read()`, `write()`, `readloExt()`, and `writeloxExt()` APIs. When data transfers are 4-byte aligned and a multiple of 4-bytes, the `r_sdhi` driver is zero copy and takes full advantage of hardware acceleration by the DMAC or DTC. When data transfers are not 4-byte aligned or not a multiple of 4 bytes an extra CPU interrupt is required for each block transferred and a software copy is used to move data to the destination buffer.

Examples

Basic Example

This is a basic example of minimal use of the `r_sdhi` in an application.

```
uint8_t g_dest[SDHI_MAX_BLOCK_SIZE] BSP_ALIGN_VARIABLE(4);
uint8_t g_src[SDHI_MAX_BLOCK_SIZE] BSP_ALIGN_VARIABLE(4);
uint32_t g_transfer_complete = 0;
void r_sdhi_basic_example (void)
{
    /* Initialize g_src to known data */
    for (uint32_t i = 0; i < SDHI_MAX_BLOCK_SIZE; i++)
    {
        g_src[i] = (uint8_t) ('A' + (i % 26));
    }
    /* Open the SDHI driver. */
    fsp_err_t err = R_SDHI_Open(&g_sdmmc0_ctrl, &g_sdmmc0_cfg);
    assert(FSP_SUCCESS == err);
}
```

```
/* A device shall be ready to accept the first command within 1ms from detecting VDD
min. Reference section 6.4.1.1
 * "Power Up Time of Card" in the SD Physical Layer Simplified Specification Version
6.00. */
R_BSP_SoftwareDelay(1U, BSP_DELAY_UNITS_MILLISECONDS);
/* Initialize the SD card. This should not be done until the card is plugged in for
SD devices. */
err = R_SDHI_MediaInit(&g_sdmmc0_ctrl, NULL);
assert(FSP_SUCCESS == err);
err = R_SDHI_Write(&g_sdmmc0_ctrl, g_src, 3, 1);
assert(FSP_SUCCESS == err);
while (!g_transfer_complete)
{
/* Wait for transfer. */
}
err = R_SDHI_Read(&g_sdmmc0_ctrl, g_dest, 3, 1);
assert(FSP_SUCCESS == err);
while (!g_transfer_complete)
{
/* Wait for transfer. */
}
}
/* The callback is called when a transfer completes. */
void r_sdhi_example_callback (sdmmc_callback_args_t * p_args)
{
if (SDMMC_EVENT_TRANSFER_COMPLETE == p_args->event)
{
g_transfer_complete = 1;
}
}
}
```

Card Detection Example

This is an example of using SDHI when the card may not be plugged in. The card detection interrupt must be enabled to use this example.

```
bool g_card_inserted = false;
void r_sdhi_card_detect_example (void)
{
    /* Open the SDHI driver. This enables the card detection interrupt. */
    fsp_err_t err = R_SDHI_Open(&g_sdmmc0_ctrl, &g_sdmmc0_cfg);
    /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
    /* Check if card is inserted. */
    sdmmc_status_t status;
    err = R_SDHI_StatusGet(&g_sdmmc0_ctrl, &status);
    assert(FSP_SUCCESS == err);
    if (!status.card_inserted)
    {
        while (!g_card_inserted)
        {
            /* Wait for a card insertion interrupt. */
        }
    }
    /* A device shall be ready to accept the first command within 1ms from detecting VDD
min. Reference section 6.4.1.1
    * "Power Up Time of Card" in the SD Physical Layer Simplified Specification Version
6.00. */
    R_BSP_SoftwareDelay(1U, BSP_DELAY_UNITS_MILLISECONDS);
    /* Initialize the SD card after card insertion is detected. */
    err = R_SDHI_MediaInit(&g_sdmmc0_ctrl, NULL);
    assert(FSP_SUCCESS == err);
}
/* The callback is called when a card detection event occurs if the card detection
interrupt is enabled. */
void r_sdhi_card_detect_example_callback (sdmmc_callback_args_t * p_args)
{
    if (SDMMC_EVENT_CARD_INSERTED == p_args->event)
    {
        g_card_inserted = true;
    }
}
```

```

    }
    if (SDMMC_EVENT_CARD_REMOVED == p_args->event)
    {
        g_card_inserted = false;
    }
}

```

Detailed Description

Virtual EEPROM on RA MCUs. This module implements the [Virtual EEPROM Interface](#).

Overview

This VEE module emulates basic EEPROM capabilities. Support is provided for reading and writing both common records and reference data (originally programmed during product assembly or test). A count of the number of segments erased throughout the lifetime of the application is maintained and can be accessed at any time. Wear leveling is handled automatically by the driver.

Features

- Writing and reading user defined records of any length to data flash.
- Wear leveling is handled automatically.
- Reference data such as calibration data programmed at assembly or test time is preserved.
- Reference data can be updated at run time.
- Fault resilient design.

Data Flash Segmentation

Wear leveling is handled by changing the location in the data flash where a record is stored every time that it is updated. This change in physical location of the record is transparent to the user. Any time an update for a specific record ID is written, it is written to the next unused location in data flash and its location is stored in RAM for quick look-up later. When required, only the most recent version of these records is automatically copied to the next blank segment in data flash. The data flash area is divided into a number of equal-size segments. There is only one segment active at a time. A segment contains two areas- the record area (which is the vast majority of the segment) and

the reference data area which contains optional data typically programmed during assembly or final test. Records and updated reference data are written to this segment until one of the two areas becomes full. The record area must be able to hold at least one of every record ID possible and still have space left over for record updates.

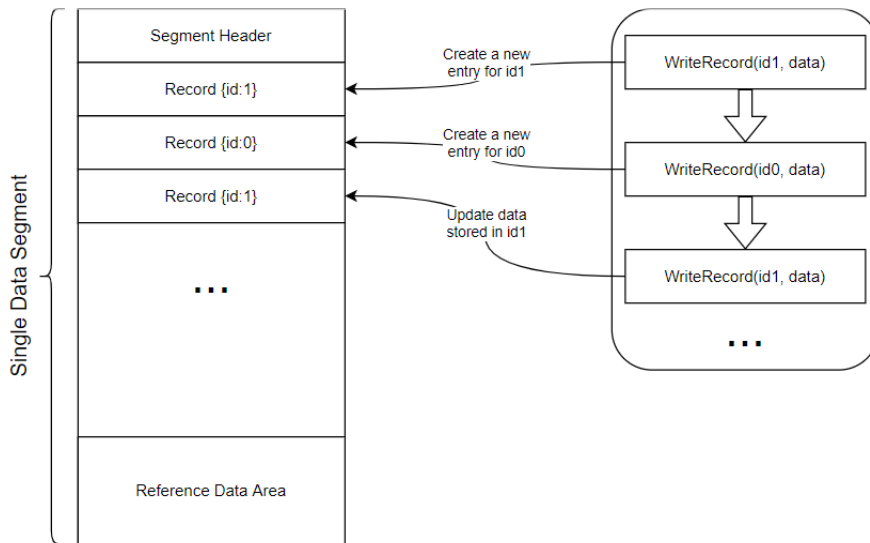

Figure 226: Segment Data Format

When a segment does not have sufficient space for additional records or updated reference data, a Refresh occurs. This process copies the most recent record for each ID as well as the latest version of reference data (if any) to the next segment. The very first time VEE runs on an MCU, it marks the last segment as active whether there is reference data configured or not. The end of VEE data flash area is used to provide an easily identified physical flash address that can be used while programming reference data without requiring Virtual EEPROM middleware.

Figure 227: Refresh Operation

Record Format

Each record begins with a header that contains the record size, followed by the data, and the trailer. The trailer contains a validation code which is used for internal purposes only and is not a 16-bit CRC or ECC value. If that level of error checking is desired, the user should include that in the record data passed to the driver. Padding is added between the end of user data and the trailer to ensure the trailer is aligned properly.

Figure 228: Record Format

Reference Data Area

VEE can be configured for the presence of reference data. The original programmed reference data must be located at the end of the VEE data flash area. An area of equal size is reserved below this in case updated reference data becomes available later. Below that is a header which indicates whether the update area has been written to.

Figure 229: Reference Data Area Format

Just as with records, the validation code is used for internal purposes only and is not a 16-bit CRC or ECC value. If that level of error checking is desired, the user should include that in the updated reference data passed to the driver.

Fault Tolerance

The Virtual EEPROM has a fault tolerant design. If for any reason an operation fails before it is completed the next time the module is opened a refresh will occur. Any corrupted data will be discarded.

Configuration

Build Time Configurations for rm_vee_flash

The following build time configurations are defined in fsp_cfg/rm_vee_flash_cfg.h:

| Configuration | Options | Default | Description |
|------------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> Default (BSP) Enabled Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |
| Reference Data Support | <ul style="list-style-type: none"> Enabled Disabled | Disabled | Support writing reference data to the end of the segment. |

| | | | |
|---------------------|--|----|---|
| Refresh Buffer Size | Value must be an integer greater than 0 and a multiple of 4 bytes. | 32 | The size of the internal buffer used to copying data from one flash segment to another during a refresh operation. This is required because data flash to data flash transfers are not supported by the hardware. |
|---------------------|--|----|---|

Configurations for Storage > Virtual EEPROM on Flash (rm_vee_flash)

This module can be added to the Stacks tab via New Stack > Storage > Virtual EEPROM on Flash (rm_vee_flash). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|---------------------|-------------------------------|------------------------------------|---|
| Name | Name must be a valid C symbol | g_vee0 | Module name. |
| Record Max ID | Value must be an integer. | 16 | Set this value to the highest record ID in use. |
| Number of Segments | Value must be an integer. | 2 | Set value to number of segments desired in data flash (minimum 2). The fewer the segments, the fewer refreshes occur, but the longer refreshes take to complete (erase time). |
| Start Address | Manual Entry | BSP_FEATURE_FLASH_DATA_FLASH_START | Start address of the flash area used by Virtual EEPROM. |
| Total Size | Manual Entry | BSP_DATA_FLASH_SIZE_BYTES | The total size (In bytes) of the flash area used by Virtual EEPROM. |
| Reference Data Size | Value must be an integer. | 0 | The size of the reference area (In bytes) used by Virtual EEPROM. |
| Callback | Name must be a valid C symbol | vee_callback | A user callback function can be provided. If this callback function is provided, it will be called from the flash interrupt service |

routine (ISR).

Clock Configuration

There is no clock configuration for the RM_VEE_FLASH module.

Pin Configuration

This module does not use I/O pins.

Usage Notes

A refresh buffer is required to copy data between segments. Data flash cannot be simultaneously read from and written to. Data will be temporarily copied into RAM during refresh operations.

◆ **RM_VEE_FLASH_Open()**

```
fsp_err_t RM_VEE_FLASH_Open ( rm_vee_ctrl_t *const p_api_ctrl, rm_vee_cfg_t const *const p_cfg )
```

Open the RM_VEE_FLASH driver module

Implements [rm_vee_api_t::open](#)

Initializes the driver's internal structures and opens the Flash driver. The Flash driver must be closed prior to opening VEE. The error code FSP_SUCCESS_RECOVERY indicates that VEE detected corrupted data; most likely due to a power loss during a data flash write or erase. In these cases, an automatic internal Refresh is performed and the partially written data is lost.

Return values

| | |
|--------------------------|---|
| FSP_SUCCESS | Successful. FSP_SUCCESS_RECOVERY changed to FSP_SUCCESS |
| FSP_ERR_ASSERTION | An input parameter is NULL. |
| FSP_ERR_ALREADY_OPEN | This function has already been called. |
| FSP_ERR_PE_FAILURE | This error indicates that a flash programming, erase, or blankcheck operation has failed in hardware. |
| FSP_ERR_TIMEOUT | Interrupts disabled outside of VEE |
| FSP_ERR_NOT_INITIALIZED | Corruption found. A refresh is required. |
| FSP_ERR_INVALID_ARGUMENT | The supplied configuration is invalid. |

```

Writes a record to data flash.

Implements `rm_vee_api_t::recordWrite`

This function writes `num_bytes` of data pointed to by `p_rec_data` to data flash. This function returns immediately after starting the flash write. BE SURE NOT TO MODIFY the data buffer contents until after the write completes. This includes exiting the calling function when the data buffer is a local variable (stack may be used by another function and corrupt the data buffer contents).

Return values

| | |
|--------------------------|---|
| FSP_SUCCESS | Write started successfully. |
| FSP_ERR_NOT_OPEN | The module has not been opened. |
| FSP_ERR_ASSERTION | An input parameter is NULL. |

| FSP_ERR_IN_USE | Last API call still executing. |
| FSP_ERR_PE_FAILURE | This error indicates that a flash programming, erase, or blankcheck operation has failed in hardware. |
| FSP_ERR_TIMEOUT | Flash write timed out (Should not be possible when flash bgo is used). |

◆ RM_VEE_FLASH_RefDataWrite()

```
fsp_err_t RM_VEE_FLASH_RefDataWrite ( rm_vee_ctrl_t *const p_api_ctrl, uint8_t const *const p_ref_data )
```

Return values

| | |
|-------------------------|---|

| FSP_ERR_NOT_OPEN | The module has not been opened. |
| FSP_ERR_IN_USE | Last API call still executing. |
| FSP_ERR_ASSERTION | An input parameter is NULL. |
| FSP_ERR_INVALID_MODE | The operation cannot be started in the current mode. |
| FSP_ERR_PE_FAILURE | This error indicates that a flash programming, erase, or blankcheck operation has failed in hardware. |
| FSP_ERR_TIMEOUT | Flash write timed out (Should not be possible when flash bgo is used). |
| FSP_ERR_UNSUPPORTED | Reference data is not supported in the current configuration. |
| FSP_ERR_NOT_INITIALIZED | Corruption found. A refresh is required. |

◆ **RM_VEE_FLASH_RecordPtrGet()**

uint8_t **const pp_rec_data, uint32_t *const p_num_bytes )
```

Gets a pointer to the most recent record data.

Implements `rm_vee_api_t::recordPtrGet`

This function sets the argument pointer to the most recent version of the record data in flash. Flash cannot be accessed for reading and writing at the same time. Therefore, reading the data at `p_ref_data` must be completed prior to initiating any type of Flash write.

Return values

| | |
|--------------------------|---|
| FSP_SUCCESS | Successful. |
| FSP_ERR_NOT_OPEN | The module has not been opened. |
| FSP_ERR_IN_USE | Last API call still executing. |
| FSP_ERR_ASSERTION | <code>p_ref_data</code> is NULL. |
| FSP_ERR_INVALID_ARGUMENT | Record data not configured. |
| FSP_ERR_NOT_FOUND | The record associated with the requested ID could not be found. |

◆ **RM_VEE_FLASH_RefDataPtrGet()**

```
fsp_err_t RM_VEE_FLASH_RefDataPtrGet ( rm_vee_ctrl_t *const p_api_ctrl, uint8_t **const
pp_ref_data )
```

Gets a pointer to the most recent reference data.

Implements `rm_vee_api_t::recordPtrGet`

This function sets the argument pointer to the most recent version of the reference data in flash. Flash cannot be accessed for reading and writing at the same time.

Return values

| | |
|---------------------|---|
| FSP_SUCCESS | Successful. |
| FSP_ERR_NOT_OPEN | The module has not been opened. |
| FSP_ERR_IN_USE | Last API call still executing. |

Manually start a refresh operation

Implements `rm_vee_api_t::refresh`

This function is used to start a segment Refresh at any time. The Refresh process by default occurs automatically when no more record or reference data space is available and a Write is requested. However, the app may desire to force a refresh when it knows it is running low on space and large amounts of data are about to be recorded.

Return values

| | |
|-------------------------|---|

Detailed Description

Driver for the CGC peripheral on RA MCUs. This module implements the [CGC Interface](#).

Note

This module is not required for the initial clock configuration. Initial clock settings are configurable on the **Clocks** tab of the RA Configuration editor. The initial clock settings are applied by the BSP during the startup process before main.

Overview

Features

The CGC module supports runtime modifications of clock settings. Key features include the following:

- Supports changing the system clock source to any of the following options (provided they are supported on the MCU):
 - High-speed on-chip oscillator (HOCO)
 - Middle-speed on-chip oscillator (MOCO)
 - Low-speed on-chip oscillator (LOCO)
 - Main oscillator (external resonator or external clock input frequency)
 - Sub-clock oscillator (external resonator)
 - PLL/PLL2 (not available on all MCUs)
- When the system core clock frequency changes, the following things are updated:
 - The CMSIS standard global variable SystemCoreClock is updated to reflect the new clock frequency.
 - Wait states for ROM and RAM are adjusted to the minimum supported value for the new clock frequency.
 - The operating power control mode is updated to the minimum supported value for the new clock settings.
- Supports starting or stopping any of the system clock sources
- Supports changing dividers for the internal clocks
- Supports the oscillation stop detection feature

Internal Clocks

The RA microcontrollers have up to seven internal clocks. Not all internal clocks exist on all MCUs. Each clock domain has its own divider that can be updated in [R_CGC_SystemClockSet\(\)](#). The dividers are subject to constraints described in the footnote of the table "Specifications of the Clock Generation Circuit for the internal clocks" in the hardware manual.

The internal clocks include:

- System clock (ICLK): core clock used for CPU, flash, internal SRAM, DTC, and DMAC
- PCLKA/PCLKB/PCLKC/PCLKD: Peripheral clocks, refer to the table "Specifications of the Clock Generation Circuit for the internal clocks" in the hardware manual to see which peripherals are controlled by which clocks.
- FCLK: Clock source for reading data flash and for programming/erasure of both code and data flash.
- BCLK: External bus clock

Configuration

Note

The initial clock settings are configurable on the **Clocks** tab of the RA Configuration editor.

There is a configuration to enable the HOCO on reset in the OFSI settings on the BSP tab.

The following clock related settings are configurable in the RA Common section on the BSP tab:

- Main Oscillator Wait Time
- Main Oscillator Clock Source (external oscillator or crystal/resonator)
- Subclock Populated
- Subclock Drive
- Subclock Stabilization Time (ms)

The default stabilization times are determined based on development boards provided by Renesas, but are generally valid for most designs. Depending on the target board hardware configuration and requirements these values may need to be adjusted for reliability or startup speed.

Build Time Configurations for r_cg

The following build time configurations are defined in fsp_cfg/r_cg_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled • Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

Configurations for System > Clock Generation Circuit (r_cg)

This module can be added to the Stacks tab via New Stack > System > Clock Generation Circuit (r_cg). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|---------------|-------------------------------|---------|---|
| Name | Name must be a valid C symbol | g_cg0 | Module name. |
| NMI Callback | Name must be a valid C symbol | NULL | A user callback function must be provided if oscillation stop detection is used. If this callback function is provided, it is called from the NMI handler if the main oscillator stops. |

Clock Configuration

This module is used to configure the system clocks. There are no module specific clock configurations required to use it.

Pin Configuration

The CGC module controls the output of the CLOCKOUT signal.

If an external oscillator is used the XTAL and EXTAL pins must be configured accordingly. When running from an on chip oscillator there is no requirement for the main clock external oscillator. In this case, the XTAL and EXTAL pins can be set to a different function in the RA Configuration editor.

The functionality of the subclock external oscillator pins XCIN and XCOU is fixed.

Usage Notes

NMI Interrupt

The CGC timer uses the NMI for oscillation stop detection of the main oscillator after `R_CGC_OscStopDetectEnable` is called. The NMI is enabled by default. No special configuration is required. When the NMI is triggered, the callback function registered during `R_CGC_Open()` is called.

Starting or Stopping the Subclock

If the Subclock Populated property is set to Populated on the BSP configuration tab, then the subclock is started in the BSP startup routine. Otherwise, it is stopped in the BSP startup routine. Starting and stopping the subclock at runtime is not recommended since the stabilization requirements typically negate the negligible power savings.

The application is responsible for ensuring required clocks are started and stable before accessing MCU peripheral registers.

Warning

The subclock can take up to several seconds to stabilize. RA startup code does not wait for subclock stabilization unless the subclock is the main clock source. In this case the default wait time is 1000ms (1 second). When running AGT or RTC off the subclock, the application must ensure the subclock is stable before starting operation. Because there is no hardware stabilization status bit for the subclock `R_CGC_ClockCheck` cannot be used to optimize this wait.

Changing the subclock state during `R_CGC_ClocksCfg()` is not supported.

Low Power Operation

If "Use Low Voltage Mode" is enabled in the BSP MCU specific properties (not available on all MCUs), the MCU is always in low voltage mode and no other power modes are considered. The following conditions must be met for the MCU to run in low voltage mode:

- Requires HOCO to be running, so HOCO cannot be stopped in low voltage mode
- Requires PLL to be stopped, so PLL APIs are not available in low voltage mode
- Requires ICLK \leq 4 MHz
- If oscillation stop detection is used, dividers of 1 or 2 cannot be used for any clock

If "Use Low Voltage Mode" is not enabled, the MCU applies the lowest power mode by searching through the following list in order and applying the first power mode that is supported under the current conditions:

- Subosc-speed mode (lowest power)
 - Requires system clock to be LOCO or subclock
 - Requires MOCO, HOCO, main oscillator, and PLL (if present) to be stopped
 - Requires ICLK and FCLK dividers to be 1
- Low-speed mode
 - Requires PLL to be stopped
 - Requires ICLK \leq 1 MHz
 - If oscillation stop detection is used, dividers of 1, 2, 4, or 8 cannot be used for any clock

- Middle-speed mode (not supported on all MCUs)
 - Requires ICLK ≤ 8 MHz
- High-speed mode
 - Default mode if no other operating mode is supported

Refer to the section "Function for Lower Operating Power Consumption" in the "Low Power Modes" chapter of the hardware manual for MCU specific information about operating power control modes.

Note

The DCDC regulator (if present) is only available in Middle- and High-speed modes. The BSP will automatically switch between DCDC and LDO when switching between compatible and incompatible modes if the DCDC regulator is in use. Switching to the LDO incurs a 60 microsecond critical section wherein all interrupts AND peripherals are stopped. Switching back to DCDC from the LDO incurs an additional 22 microsecond critical section (peripherals running).

When low voltage mode is not used, the following functions adjust the operating power control mode to ensure it remains within the hardware specification and to ensure the MCU is running at the optimal operating power control mode:

- R_CGC_ClockStart()
- R_CGC_ClockStop()
- R_CGC_SystemClockSet()
- R_CGC_OscStopDetectEnable()
- R_CGC_OscStopDetectDisable()

Note

FSP APIs, including these APIs, are not thread safe. These APIs and any other user code that modifies the operating power control mode must not be allowed to interrupt each other. Proper care must be taken during application design if these APIs are used in threads or interrupts to ensure this constraint is met.

No action is required by the user of these APIs. This section is provided for informational purposes only.

    /* Initializes the CGC module. */
    err = R_CGC_Open(&g_cgc0_ctrl, &g_cgc0_cfg);

    /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);

    /* Change the system clock to LOCO for power saving. */
    /* Start the LOCO. */

/* Wait for the LOCO stabilization wait time.

 * NOTE: The MOCO, LOCO and subclock do not have stabilization status bits, so any
stabilization time must be

oscillators, R_CGC_ClockCheck can

Function Documentation

◆ **R_CGC_Open()**

```
fsp_err_t R_CGC_Open ( cgc_ctrl_t *const p_ctrl, cgc_cfg_t const *const p_cfg )
```

Initialize the CGC API. Implements `cgc_api_t::open`.

Example:

```
/* Initializes the CGC module. */
err = R_CGC_Open(&g_cgc0_ctrl, &g_cgc0_cfg);
```

Return values

| | |
|----------------------|-------------------------------|
| FSP_SUCCESS | CGC successfully initialized. |
| FSP_ERR_ASSERTION | Invalid input argument. |
| FSP_ERR_ALREADY_OPEN | Module is already open. |

◆ **R_CGC_ClocksCfg()**

```
fsp_err_t R_CGC_ClocksCfg ( cgc_ctrl_t *const p_ctrl, cgc_clocks_cfg_t const *const p_clock_cfg )
```

Reconfigures all main system clocks. This API can be used for any of the following purposes:

- start or stop clocks
- change the system clock source
- configure the PLL/PLL2 multiplication and division ratios when starting the PLL
- change the system dividers

If the requested system clock source has a stabilization flag, this function blocks waiting for the stabilization flag of the requested system clock source to be set. If the requested system clock source was just started and it has no stabilization flag, this function blocks for the stabilization time required by the requested system clock source according to the Electrical Characteristics section of the hardware manual. If the requested system clock source has no stabilization flag and it is already running, it is assumed to be stable and this function will not block. If the requested system clock is the subclock, the subclock must be stable prior to calling this function.

The internal dividers (`cgc_clocks_cfg_t::divider_cfg`) are subject to constraints described in footnotes of the hardware manual table detailing specifications for the clock generation circuit for the internal clocks for the MCU. For example:

- RA6M3: see footnotes of Table 9.2 "Specifications of the clock generation circuit for the internal clocks" in the RA6M3 manual R01UH0886EJ0100
- RA2A1: see footnotes of Table 9.2 "Clock generation circuit specifications for the internal clocks" in the RA2A1 manual R01UH0888EJ0100

Do not attempt to stop the requested clock source or the source of a PLL if the PLL will be running after this operation completes.

Implements `cgc_api_t::clocksCfg`.

Example:

```
/* Assuming the system clock is MOCO, switch to HOCO. */
```

```

cgc_clocks_cfg_t clocks_cfg;

clocks_cfg.system_clock           = CGC_CLOCK_PLL;
clocks_cfg.pll_state              = CGC_CLOCK_CHANGE_NONE;
clocks_cfg.pll_cfg.source_clock   = CGC_CLOCK_MAIN_OSC; // unused
clocks_cfg.pll_cfg.multiplier     = CGC_PLL_MUL_10_0;   // unused

clocks_cfg.moco_state            = CGC_CLOCK_CHANGE_STOP;
clocks_cfg.loco_state            = CGC_CLOCK_CHANGE_NONE;

err = R_CGC_ClocksCfg(&g_cgc0_ctrl, &clocks_cfg);

The requested clock source must be running and stable prior to calling this function. The internal dividers are subject to constraints described in the hardware manual table "Specifications of the Clock Generation Circuit for the internal clocks".

The internal dividers (`p_divider_cfg`) are subject to constraints described in footnotes of the hardware manual table detailing specifications for the clock generation circuit for the internal clocks for the MCU. For example:

- RA2A1: see footnotes of Table 9.2 "Clock generation circuit specifications for the internal clocks" in the RA2A1 manual R01UH0888EJ0100

This function also updates the RAM and ROM wait states, the operating power control mode, and the SystemCoreClock CMSIS global variable.

Example:

```
/* Set divisors. Divisors for clocks that don't exist on the MCU are ignored. */
cgc_divider_cfg_t dividers =
{
```

```

/* PCLKB is not used in this application, so select the maximum divisor for lowest

`fsp_err_t R_CGC_OscStopDetectEnable (cgc_ctrl_t *const p_ctrl)`

Enable the oscillation stop detection for the main clock. Implements `cgc_api_t::oscStopDetectEnable`.

The MCU will automatically switch the system clock to MOCO when a stop is detected if Main Clock is the system clock. If the system clock is the PLL, then the clock source will not be changed and the PLL free running frequency will be the system clock frequency.

Example:

```
/* Enable oscillation stop detection. The main oscillator must be running at this
point. */

Detailed Description

Driver for the ELC peripheral on RA MCUs. This module implements the [ELC Interface](#).

Overview

The event link controller (ELC) uses the event requests generated by various peripheral modules as source signals to connect (link) them to different modules, allowing direct cooperation between the modules without central processing unit (CPU) intervention. The conceptual diagram below illustrates a potential setup where a pin interrupt triggers a timer which later triggers an ADC conversion and CTSU scan, while at the same time a serial communication interrupt automatically starts a data transfer. These tasks would be automatically handled without the need for polling or interrupt management.

Figure 230: Event Link Controller Conceptual Diagram

In essence, the ELC is an array of multiplexers to route a wide variety of interrupt signals to a subset of peripheral functions. Events are linked by setting the multiplexer for the desired function to the desired signal (through `R_ELC_LinkSet`). The diagram below illustrates one peripheral output of the ELC. In this example, a conversion start is triggered for ADC0 Group A when the GPT0 counter overflows:

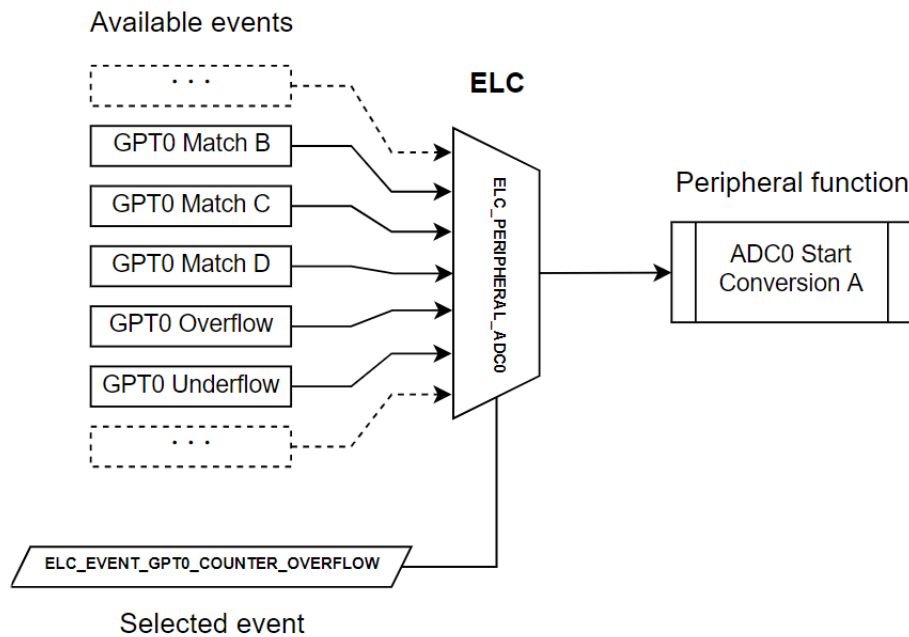

Figure 231: ELC Example

Features

The ELC HAL module can perform the following functions:

- Initialize the ELC to a pre-defined set of links
- Create an event link between two blocks
- Break an event link between two blocks
- Generate one of two software events that interrupt the CPU
- Globally enable or disable event links

A variety of functions can be activated via events, including:

- General-purpose timer (GPT) control
- ADC and DAC conversion start
- Synchronized I/O port output (ports 1-4 only)
- Capacitive touch unit (CTSUs) measurement activation

Note

The available sources and peripherals may differ between devices. A full list of selectable peripherals and events is available in the User's Manual for your device.

Some peripherals have specific settings related to ELC event generation and/or reception. Details on how to enable event functionality for each peripheral are located in the usage notes for the related module(s) as well as in the User's Manual for your device.

Configuration

Note

Event links will be automatically generated based on the selections made in module properties. To view the currently linked events check the [Event Links tab in the RA Configuration editor](#).

Calling [R_ELC_Open](#) followed by [R_ELC_Enable](#) will automatically link all events shown in the Event Links tab.

To manually link an event to a peripheral at runtime perform the following steps:

1. Configure the operation of the destination peripheral (including any configuration necessary to receive events)
2. Use `R_ELC_LinkSet` to set the desired event link to the peripheral
3. Use `R_ELC_Enable` to enable transmission of event signals
4. Configure the signaling module to output the desired event (typically an interrupt)

To disable the event, either use `R_ELC_LinkBreak` to clear the link for a specific event or `R_ELC_Disable` to globally disable event linking.

Note

The ELC module needs no pin, clocking or interrupt configuration; it is merely a mechanism to connect signals between peripherals. However, when linking I/O Ports via the ELC the relevant I/O pins need to be configured as inputs or outputs.

Build Time Configurations for r_elc

The following build time configurations are defined in `fsp_cfg/r_elc_cfg.h`:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled • Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

Configurations for System > Event Link Controller (r_elc)

This module can be added to the Stacks tab via `New Stack > System > Event Link Controller (r_elc)`. Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|---------------|--|--------------------|--|
| Name | ELC instance name must be <code>g_elc</code> to match <code>elc_cfg_t</code> data structure created in <code>elc_data.c</code> | <code>g_elc</code> | Module name. Fixed to <code>g_elc</code> . |

Usage Notes

Limitations

Developers should be aware of the following limitations when using the ELC:

- To link events it is necessary for the ELC and the related modules to be enabled. The ELC cannot operate if the related modules are in the module stop state or the MCU is in a low power consumption mode for which the module is stopped.
- If two modules are linked across clock domains there may be a 1 to 2 cycle delay between event signaling and reception. The delay timing is based on the frequency of the slowest clock.

Examples

Basic Example

Below is a basic example of minimal use of event linking in an application.

```
/* This struct is automatically generated based on the events configured by
peripherals in the RA Configuration editor. */
static const elc_cfg_t g_elc_cfg =
{
    .link[ELC_PERIPHERAL_GPT_A] = ELC_EVENT_ICU_IRQ0,
    .link[ELC_PERIPHERAL_IOPORT1] = ELC_EVENT_GPT4_COUNTER_OVERFLOW
};

void elc_basic_example (void)
{
    fsp_err_t err = FSP_SUCCESS;
    /* Initializes the software and sets the links defined in the control structure. */
    err = R_ELC_Open(&g_elc_ctrl, &g_elc_cfg);
    /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
    /* Create or modify a link between a peripheral function and an event source. */
    err = R_ELC_LinkSet(&g_elc_ctrl, ELC_PERIPHERAL_ADC0,
ELC_EVENT_GPT4_COUNTER_OVERFLOW);
    assert(FSP_SUCCESS == err);
    /* Globally enable event linking in the ELC. */
    err = R_ELC_Enable(&g_elc_ctrl);
    assert(FSP_SUCCESS == err);
}
```

Software-Generated Events

This example demonstrates how to use a software-generated event to signal a peripheral. This can be useful when the desired event source is not supported by the ELC hardware.

```
/* Interrupt handler for peripheral event not supported by the ELC */
void peripheral_isr (void)
{
    fsp_err_t err;
    /* Generate an event signal through software to the linked peripheral. */
```

```
err = R_ELC_SoftwareEventGenerate(&g_elc_ctrl, ELC_SOFTWARE_EVENT_0);
assert(FSP_SUCCESS == err);
}
void elc_software_event (void)
{
    fsp_err_t err = FSP_SUCCESS;
    /* Open the module. */
    err = R_ELC_Open(&g_elc_ctrl, &g_elc_cfg);
    /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
    /* Link ADC0 conversion start to software event 0. */
    err = R_ELC_LinkSet(&g_elc_ctrl, ELC_PERIPHERAL_ADC0,
ELC_EVENT_ELC_SOFTWARE_EVENT_0);
    assert(FSP_SUCCESS == err);
    while (true)
    {
        /* Application code here. */
    }
}
```

Detailed Description

Driver for the I/O Ports peripheral on RA MCUs. This module implements the [I/O Port Interface](#).

Overview

The I/O port pins operate as general I/O port pins, I/O pins for peripheral modules, interrupt input pins, analog I/O, port group function for the ELC, or bus control pins.

Features

The IOPORT HAL module can configure the following pin settings:

- Pin direction
- Default output state
- Pull-up
- NMOS/PMOS
- Drive strength
- Event edge trigger (falling, rising or both)
- Whether the pin is to be used as an IRQ pin
- Whether the pin is to be used as an analog pin
- Peripheral connection

The module also provides the following functionality:

- Read/write GPIO pins/ports
- Sets event output data
- Reads event input data

Configuration

The I/O PORT HAL module must be configured by the user for the desired operation. The operating state of an I/O pin can be set via the RA Configuraton tool. When the project is built a pin configuration file is created. The BSP will automatically configure the MCU IO ports accordingly at startup using the same API functions mentioned in this document.

Build Time Configurations for r_ioport

The following build time configurations are defined in fsp_cfg/r_ioport_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled • Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

C symbol

configuration structure

Clock Configuration

The I/O PORT HAL module does not require a specific clock configuration.

Pin Configuration

The IOPORT module is used for configuring pins.

Usage Notes

Port Group Function for ELC

Depending on pin configuration, the IOPORT module can perform automatic reads and writes on 4 ports (RA2 series support 2 ports only, see the table of ELC triggers below) on receipt of an ELC event.

| ELC triggers | RA6T2 | RA2XX | All others |
|--------------|--------|--------|------------|
| 1st Port | Port B | Port 1 | Port 1 |
| 2nd Port | Port C | Port 2 | Port 2 |
| 3rd Port | Port D | NA | Port 3 |
| 4th Port | Port E | NA | Port 4 |

When an event is received by a port, the state of the input pins on the port is saved in a hardware register. Simultaneously, the state of output pins on the port is set or cleared based on settings configured by the user. The functions [R_IOPORT_PinEventInputRead](#) and [R_IOPORT_PortEventInputRead](#) allow reading the last event input state of a pin or port, and event-triggered pin output can be configured through [R_IOPORT_PinEventOutputWrite](#) and [R_IOPORT_PortEventOutputWrite](#).

In addition, each pin on these ports can be configured to trigger an ELC event on rising, falling or both edges. This event can be used to activate other modules when the pin changes state.

Note

The number of ELC-aware ports vary across MCUs. Refer to the Hardware User's Manual for your device for more details.

Examples

Basic Example

This is a basic example of minimal use of the IOPORT in an application.

```
void basic_example ()
{
    bsp_io_level_t readLevel;
    fsp_err_t      err;
```

```
/* Initialize the IOPORT module and configure the pins
 * Note: The default pin configuration name in the RA Configuraton tool is
g_bsp_pin_cfg */
    err = R_IOPORT_Open(&g_ioport_ctrl, &g_bsp_pin_cfg);
/* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
/* Call R_IOPORT_PinsCfg if the configuration was not part of initial configurations
made in open */
    err = R_IOPORT_PinsCfg(&g_ioport_ctrl, &g_runtime_pin_cfg);
    assert(FSP_SUCCESS == err);
/* Set Pin 00 of Port 06 to High */
    err = R_IOPORT_PinWrite(&g_ioport_ctrl, BSP_IO_PORT_06_PIN_00, BSP_IO_LEVEL_HIGH
);
    assert(FSP_SUCCESS == err);
/* Read Pin 00 of Port 06*/
    err = R_IOPORT_PinRead(&g_ioport_ctrl, BSP_IO_PORT_06_PIN_00, &readLevel);
    assert(FSP_SUCCESS == err);
}
```

Blinky Example

This example uses IOPORT to configure and toggle a pin to blink an LED.

```
void blinky_example ()
{
    fsp_err_t err;
/* Initialize the IOPORT module and configure the pins */
    err = R_IOPORT_Open(&g_ioport_ctrl, &g_bsp_pin_cfg);
/* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
/* Configure Pin as output
 * Call the R_IOPORT_PinCfg if the configuration was not part of initial
configurations made in open */
    err = R_IOPORT_PinCfg(&g_ioport_ctrl, BSP_IO_PORT_06_PIN_00,
IOPORT_CFG_PORT_DIRECTION_OUTPUT);
```

```
    assert(FSP_SUCCESS == err);
    bsp_io_level_t level = BSP_IO_LEVEL_LOW;
    while (1)
    {
        /* Determine the next state of the LEDs */
        if (BSP_IO_LEVEL_LOW == level)
        {
            level = BSP_IO_LEVEL_HIGH;
        }
        else
        {
            level = BSP_IO_LEVEL_LOW;
        }
        /* Update LED on RA6M3-PK */
        err = R_IOPORT_PinWrite(&g_ioport_ctrl, BSP_IO_PORT_06_PIN_00, level);
        assert(FSP_SUCCESS == err);
        /* Delay */
        R_BSP_SoftwareDelay(100, BSP_DELAY_UNITS_MILLISECONDS); // NOLINT
    }
}
```

ELC Example

This is an example of using IOPORT with ELC events. The ELC event system allows the captured data to be stored when it occurs and then read back at a later time.

```

static elc_cfg_t g_elc_cfg;
void ioport_elc_example ()

    /* Initializes the software and sets the links defined in the control structure. */
    err = R_ELC_Open(&g_elc_ctrl, &g_elc_cfg);
    /* Handle any errors. This function should be defined by the user. */
}
```

```
    assert(FSP_SUCCESS == err);

    /* Create or modify a link between a peripheral function and an event source. */
    err = R_ELC_LinkSet(&g_elc_ctrl, (elc_peripheral_t) ELC_PERIPHERAL_IOPORT2,

    /* Initialize the IOPORT module and configure the pins */
    err = R_IOPORT_Open(&g_ioport_ctrl, &g_bsp_pin_cfg);

    assert(FSP_SUCCESS == err);

    /* Call the R_IOPORT_PinCfg if the configuration was not part of initial

    err = R_IOPORT_PinCfg(&g_ioport_ctrl, BSP_IO_PORT_02_PIN_00,
IOPORT_CFG_PORT_DIRECTION_INPUT);

    assert(FSP_SUCCESS == err);

    /* Generate an event signal through software to the linked peripheral. */
    err = R_ELC_SoftwareEventGenerate(&g_elc_ctrl, ELC_SOFTWARE_EVENT_0);

Function Documentation

◆ R_IOPORT_Open()

```
fsp_err_t R_IOPORT_Open ( ioport_ctrl_t *const p_ctrl, const ioport_cfg_t * p_cfg )
```

Initializes internal driver data, then calls pin configuration function to configure pins.

Return values

| | |
|----------------------|---|
| FSP_SUCCESS | Pin configuration data written to PFS register(s) |
| FSP_ERR_ASSERTION | NULL pointer |
| FSP_ERR_ALREADY_OPEN | Module is already open. |

◆ R_IOPORT_Close()

```
fsp_err_t R_IOPORT_Close ( ioport_ctrl_t *const p_ctrl)
```

Resets IOPORT registers. Implements `ioport_api_t::close`

Return values

| | |
|-------------------|---|
| FSP_SUCCESS | The IOPORT was successfully uninitialized |
| FSP_ERR_ASSERTION | p_ctrl was NULL |
| FSP_ERR_NOT_OPEN | The module has not been opened |

◆ **R_IOPORT_PinsCfg()**

```
fsp_err_t R_IOPORT_PinsCfg ( ioport_ctrl_t *const p_ctrl, const ioport_cfg_t * p_cfg )
```

Configures the functions of multiple pins by loading configuration data into pin PFS registers. Implements `ioport_api_t::pinsCfg`.

This function initializes the supplied list of PmnPFS registers with the supplied values. This data can be generated by the Pins tab of the RA Configuration editor or manually by the developer. Different pin configurations can be loaded for different situations such as low power modes and testing.

Return values

| | |
|-------------------|---|
| FSP_SUCCESS | Pin configuration data written to PFS register(s) |
| FSP_ERR_NOT_OPEN | The module has not been opened |
| FSP_ERR_ASSERTION | NULL pointer |

◆ **R_IOPORT_PinCfg()**

```
fsp_err_t R_IOPORT_PinCfg ( ioport_ctrl_t *const p_ctrl, bsp_io_port_pin_t pin, uint32_t cfg )
```

Configures the settings of a pin. Implements `ioport_api_t::pinCfg`.

Return values

| | |
|-------------------|--------------------------------|
| FSP_SUCCESS | Pin configured |
| FSP_ERR_NOT_OPEN | The module has not been opened |
| FSP_ERR_ASSERTION | NULL pointer |

Note

This function is re-entrant for different pins. This function will change the configuration of the pin with the new configuration. For example it is not possible with this function to change the drive strength of a pin while leaving all the other pin settings unchanged. To achieve this the original settings with the required change will need to be written using this function.

◆ **R_IOPORT_PinRead()**

```
fsp_err_t R_IOPORT_PinRead ( ioport_ctrl_t *const p_ctrl, bsp_io_port_pin_t pin, bsp_io_level_t *
p_pin_value )
```

Reads the level on a pin. Implements `ioport_api_t::pinRead`.

Return values

| | |
|-------------------|--------------------------------|
| FSP_SUCCESS | Pin read |
| FSP_ERR_ASSERTION | NULL pointer |
| FSP_ERR_NOT_OPEN | The module has not been opened |

Note

This function is re-entrant for different pins.

◆ **R_IOPORT_PortRead()**

```
fsp_err_t R_IOPORT_PortRead ( ioport_ctrl_t *const p_ctrl, bsp_io_port_t port, ioport_size_t *
p_port_value )
```

Reads the value on an IO port. Implements `ioport_api_t::portRead`.

The specified port will be read, and the levels for all the pins will be returned. Each bit in the returned value corresponds to a pin on the port. For example, bit 7 corresponds to pin 7, bit 6 to pin 6, and so on.

Return values

| | |
|-------------------|--------------------------------|
| FSP_SUCCESS | Port read |
| FSP_ERR_ASSERTION | NULL pointer |
| FSP_ERR_NOT_OPEN | The module has not been opened |

Note

This function is re-entrant for different ports.

◆ R_IOPORT_PortWrite()

```
fsp_err_t R_IOPORT_PortWrite ( ioport_ctrl_t *const p_ctrl, bsp_io_port_t port, ioport_size_t value,
ioport_size_t mask )
```

Writes to multiple pins on a port. Implements `ioport_api_t::portWrite`.

The input value will be written to the specified port. Each bit in the value parameter corresponds to a bit on the port. For example, bit 7 corresponds to pin 7, bit 6 to pin 6, and so on. Each bit in the mask parameter corresponds to a pin on the port.

Only the bits with the corresponding bit in the mask value set will be updated. For example, value = 0xFFFF, mask = 0x0003 results in only bits 0 and 1 being updated.

Return values

| | |
|--------------------------|--------------------------------|
| FSP_SUCCESS | Port written to |
| FSP_ERR_INVALID_ARGUMENT | The port and/or mask not valid |
| FSP_ERR_NOT_OPEN | The module has not been opened |
| FSP_ERR_ASSERTION | NULL pointerd |

Note

This function is re-entrant for different ports. This function makes use of the PCNTR3 register to atomically modify the levels on the specified pins on a port.

◆ R_IOPORT_PinWrite()

```
fsp_err_t R_IOPORT_PinWrite ( ioport_ctrl_t *const p_ctrl, bsp_io_port_pin_t pin, bsp_io_level_t
level )
```

Sets a pin's output either high or low. Implements `ioport_api_t::pinWrite`.

Return values

| | |
|--------------------------|--------------------------------|
| FSP_SUCCESS | Pin written to |
| FSP_ERR_INVALID_ARGUMENT | The pin and/or level not valid |
| FSP_ERR_NOT_OPEN | The module has not been opene |
| FSP_ERR_ASSERTION | NULL pointerd |

Note

This function is re-entrant for different pins. This function makes use of the PCNTR3 register to atomically modify the level on the specified pin on a port.

◆ R_IOPORT_PortDirectionSet()

```
fsp_err_t R_IOPORT_PortDirectionSet ( ioport_ctrl_t *const p_ctrl, bsp_io_port_t port, ioport_size_t
direction_values, ioport_size_t mask )
```

Sets the direction of individual pins on a port. Implements `ioport_api_t::portDirectionSet()`.

Multiple pins on a port can be set to inputs or outputs at once. Each bit in the mask parameter corresponds to a pin on the port. For example, bit 7 corresponds to pin 7, bit 6 to pin 6, and so on. If a bit is set to 1 then the corresponding pin will be changed to an input or an output as specified by the direction values. If a mask bit is set to 0 then the direction of the pin will not be changed.

Return values

| | |
|--------------------------|--------------------------------|
| FSP_SUCCESS | Port direction updated |
| FSP_ERR_INVALID_ARGUMENT | The port and/or mask not valid |
| FSP_ERR_NOT_OPEN | The module has not been opened |
| FSP_ERR_ASSERTION | NULL pointer |

Note

This function is re-entrant for different ports.

◆ R_IOPORT_PortEventInputRead()

```
fsp_err_t R_IOPORT_PortEventInputRead ( ioport_ctrl_t *const p_ctrl, bsp_io_port_t port,
ioport_size_t * p_event_data )
```

Reads the value of the event input data. Implements `ioport_api_t::portEventInputRead()`.

The event input data for the port will be read. Each bit in the returned value corresponds to a pin on the port. For example, bit 7 corresponds to pin 7, bit 6 to pin 6, and so on.

The port event data is captured in response to a trigger from the ELC. This function enables this data to be read. Using the event system allows the captured data to be stored when it occurs and then read back at a later time.

Return values

| | |
|--------------------------|--------------------------------|
| FSP_SUCCESS | Port read |
| FSP_ERR_INVALID_ARGUMENT | Port not a valid ELC port |
| FSP_ERR_ASSERTION | NULL pointer |
| FSP_ERR_NOT_OPEN | The module has not been opened |

Note

This function is re-entrant for different ports.

◆ R_IOPORT_PinEventInputRead()

```
fsp_err_t R_IOPORT_PinEventInputRead ( ioport_ctrl_t *const p_ctrl, bsp_io_port_pin_t pin,
bsp_io_level_t * p_pin_event )
```

Reads the value of the event input data of a specific pin. Implements `ioport_api_t::pinEventInputRead`.

The pin event data is captured in response to a trigger from the ELC. This function enables this data to be read. Using the event system allows the captured data to be stored when it occurs and then read back at a later time.

Return values

| | |
|--------------------------|--------------------------------|
| FSP_SUCCESS | Pin read |
| FSP_ERR_ASSERTION | NULL pointer |
| FSP_ERR_NOT_OPEN | The module has not been opened |
| FSP_ERR_INVALID_ARGUMENT | Port is not valid ELC PORT. |

Note

This function is re-entrant.

◆ R_IOPORT_PortEventOutputWrite()

```
fsp_err_t R_IOPORT_PortEventOutputWrite ( ioport_ctrl_t *const p_ctrl, bsp_io_port_t port,
ioport_size_t event_data, ioport_size_t mask_value )
```

This function writes the set and reset event output data for a port. Implements `ioport_api_t::portEventOutputWrite`.

Using the event system enables a port state to be stored by this function in advance of being output on the port. The output to the port will occur when the ELC event occurs.

The input value will be written to the specified port when an ELC event configured for that port occurs. Each bit in the value parameter corresponds to a bit on the port. For example, bit 7 corresponds to pin 7, bit 6 to pin 6, and so on. Each bit in the mask parameter corresponds to a pin on the port.

Return values

| | |
|--------------------------|--------------------------------|
| FSP_SUCCESS | Port event data written |
| FSP_ERR_INVALID_ARGUMENT | Port or Mask not valid |
| FSP_ERR_NOT_OPEN | The module has not been opened |
| FSP_ERR_ASSERTION | NULL pointer |

Note

This function is re-entrant for different ports.

◆ R_IOPORT_PinEventOutputWrite()

```
fsp_err_t R_IOPORT_PinEventOutputWrite ( ioport_ctrl_t *const p_ctrl, bsp_io_port_pin_t pin,
bsp_io_level_t pin_value )
```

This function writes the event output data value to a pin. Implements [ioport_api_t::pinEventOutputWrite](#).

Using the event system enables a pin state to be stored by this function in advance of being output on the pin. The output to the pin will occur when the ELC event occurs.

Return values

| | |
|--------------------------|--------------------------------|
| FSP_SUCCESS | Pin event data written |
| FSP_ERR_INVALID_ARGUMENT | Port or Pin or value not valid |
| FSP_ERR_NOT_OPEN | The module has not been opened |
| FSP_ERR_ASSERTION | NULL pointer |

Note

This function is re-entrant for different ports.

Detailed Description

Driver for the POEG peripheral on RA MCUs. This module implements the [POEG Interface](#).

Overview

The POEG module can be used to configure events to disable GPT GTIOC output pins.

Features

The POEG module has the following features:

- Supports disabling GPT output pins based on GTETRGR input pin level.
- Supports disabling GPT output pins based on comparator crossing events (configurable in the [Comparator, High-Speed \(r_acmphs\)](#) driver).

- Supports disabling GPT output pins when GTIOC pins are the same level (configurable in the [Timer, General PWM \(r_gpt\)](#) driver).
- Supports disabling GPT output pins when main oscillator stop is detected.
- Supports disabling GPT output pins by software API.
- Supports notifying the application when GPT output pins are disabled by POEG.
- Supports resetting POEG status.

Configuration

Build Time Configurations for r_poeg

The following build time configurations are defined in fsp_cfg/r_poeg_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled • Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

Configurations for Timers > Port Output Enable for GPT (r_poeg)

This module can be added to the Stacks tab via New Stack > Timers > Port Output Enable for GPT (r_poeg). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|-------------------------------|---|-------------|---|

| General > Channel | Must be a valid POEG channel | 0 | Specify the hardware channel. |
| General > Trigger | MCU Specific Options | | Select the trigger sources that will enable POEG. Software disable is always supported. This configuration can only be set once after reset. It cannot be modified after the initial setting. |
| Input > GTETR Polarity | <ul style="list-style-type: none"> • Active High • Active Low | Active High | Select the polarity of the GTETR pin. Only applicable if GTETR pin is selected under Trigger. |
| Input > GTETR Noise Filter | <ul style="list-style-type: none"> • Disabled • PCLKB/1 • PCLKB/8 • PCLKB/32 • PCLKB/128 | Disabled | Configure the noise filter for the GTETR pin. Only applicable if GTETR pin is selected under Trigger. |

| | | | |
|---------------------------------|-------------------------------|------|--|

| Interrupts > Interrupt Priority | MCU Specific Options | | Select the POEG interrupt priority. |

Clock Configuration

The POEG clock is based on the PCLKB frequency.

Pin Configuration

This module can use GTETRGA, GTETRGB, GTETRGC, or GTETRGD as an input signal to disable GPT output pins.

Usage Notes

POEG GTETRGR Pin and Channel

The POEG channel number corresponds to the GTETRGR input pin that can be used with the channel. GTETRGA must be used with POEG channel 0, GTETRGB must be used with POEG channel 1, etc.

Limitations

The user should be aware of the following limitations when using POEG:

- The POEG trigger source can only be set once per channel. Modifying the POEG trigger source after it is set is not allowed by the hardware.
- The POEG cannot be disabled using this API. The interrupt is disabled in [R_POEG_Close\(\)](#), but the POEG will still disable the GPT output pins if a trigger is detected even if the module is closed.

Examples

POEG Basic Example

This is a basic example of minimal use of the POEG in an application.

```
void poeg_basic_example (void)
{
    fsp_err_t err = FSP_SUCCESS;

    /* Initializes the POEG. */
    err = R_POEG_Open(&g_poeg0_ctrl, &g_poeg0_cfg);
}
```

```

/* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
}

```

POEG Callback Example

This is an example of a using the POEG callback to restore GPT output operation.

```

/* Example callback called when POEG disables GPT output pins. */
void poeg_callback (poeg_callback_args_t * p_args)
{
    FSP_PARAMETER_NOT_USED(p_args);

    /* (Optional) Determine the cause of the POEG event. */
    poeg_status_t status;

    (void) R_POEG_StatusGet(&g_poeg0_ctrl, &status);

    /* Correct the cause of the POEG event before resetting POEG. */
    /* Reset the POEG before exiting the callback. */
    (void) R_POEG_Reset(&g_poeg0_ctrl);

    /* Wait for the status to clear after reset before exiting the callback to ensure
the interrupt does not fire
    * again. */
    do
    {
        (void) R_POEG_StatusGet(&g_poeg0_ctrl, &status);
    } while (POEG_STATE_NO_DISABLE_REQUEST != status.state);

    /* Alternatively, if the POEG cannot be reset, disable the POEG interrupt to prevent
it from firing continuously.

    * Update the 0 in the macro below to match the POEG channel number. */
    NVIC_DisableIRQ(VECTOR_NUMBER_POEG0_EVENT);
}

```

Data Structures

struct poeg_instance_ctrl_t
```

Data Structure Documentation

◆ poeg_instance_ctrl_t

Detailed Description

Driver for the RTC peripheral on RA MCUs. This module implements the [RTC Interface](#).

Overview

The RTC HAL module configures the RTC module and controls clock, calendar and alarm functions. A callback can be used to respond to the alarm and periodic interrupt.

Features

- RTC time and date get and set.
- RTC time and date alarm get and set.
- RTC alarm and periodic event notification.

The RTC HAL module supports three different interrupt types:

- An alarm interrupt generated on a match of any combination of year, month, day, day of the week, hour, minute or second
- A periodic interrupt generated every 2, 1, 1/2, 1/4, 1/8, 1/16, 1/32, 1/64, 1/128, or 1/256 second(s)
- A carry interrupt is used internally when reading time from the RTC calendar to get accurate time readings.

Note

See section "23.3.5 Reading 64-Hz Counter and Time" of the RA6M3 manual R01UH0886EJ0100 for more details.

A user-defined callback function can be registered (in the [rtc_api_t::open](#) API call) and will be called from the interrupt service routine (ISR) for alarm and periodic interrupt. When called, it is passed a pointer to a structure ([rtc_callback_args_t](#)) that holds a user-defined context pointer and an indication of which type of interrupt was fired.

Date and Time validation

"Parameter Checking" needs to be enabled if date and time validation is required for `calendarTimeSet` and `calendarAlarmSet` APIs. If "Parameter Checking" is enabled, the 'day of the week' field is automatically calculated and updated by the driver for the provided date. When using the `calendarAlarmSet` API, only the fields which have their corresponding match flag set are written to the registers. Other register fields are reset to default value.

Sub-Clock error adjustment (Time Error Adjustment Function)

The time error adjustment function is used to correct errors, running fast or slow, in the time caused by variation in the precision of oscillation by the sub-clock oscillator. Because 32,768 cycles of the sub-clock oscillator constitute 1 second of operation when the sub-clock oscillator is selected, the clock runs fast if the sub-clock frequency is high and slow if the sub-clock frequency is low. The time error adjustment functions include:

- Automatic adjustment
- Adjustment by software

The error adjustment is reset every time RTC is reconfigured or time is set.

Note

RTC driver configurations do not do error adjustment internally while initializing the driver. Application must make calls to the error adjustment api's for desired adjustment. See section 26.3.8 "Time Error Adjustment Function" of the RA6M3 manual R01UH0886EJ0100) for more details on this feature

Configuration

Build Time Configurations for r_rtc

The following build time configurations are defined in fsp_cfg/r_rtc_cfg.h:

| Configuration | Options | Default | Description |
|--------------------------|--|---------------|--|
| Parameter Checking | <ul style="list-style-type: none"> Default (BSP) Enabled Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

Note

See 23.2.20 Frequency Register (RFRH/RFL) of the RA6M3 manual R01UH0886EJ0100 for more details

Interrupt Configuration

To activate interrupts for the RTC module, the desired interrupts must be enabled, The underlying implementation will be expected to handle any interrupts it can support and notify higher layers via callback.

Clock Configuration

The RTC HAL module can use the following clock sources:

- LOCO (Low Speed On-Chip Oscillator) with less accuracy
- Sub-clock oscillator with increased accuracy

Users have to select the right source for their application. LOCO is the default during configuration when it is available.

Pin Configuration

This module does not use I/O pins.

Usage Notes

System Initialization

- RTC driver does not start the sub-clock. The application is responsible for ensuring required clocks are started and stable before accessing MCU peripheral registers.

Warning

The subclock can take seconds to stabilize. The RA startup code does not wait for subclock stabilization unless the subclock is the main clock source. When running AGT or RTC off the subclock, the application must ensure the subclock is stable before starting operation.

- Carry interrupt priority must be set to avoid incorrect time returned from `calendarTimeGet` API during roll-over.
- Even when only running in Periodic Interrupt mode `R_RTC_CalendarTimeSet` must be called successfully to start the RTC.
- In case of warm start or a hard reset (when VBATT powers RTC in case of power loss), user might not want to reinitialize the clock source after reset. In this case, disable the Set Source Clock in Open property for RTC and call `R_RTC_ClockSourceSet()` only when RTC clock source needs to be set. Application should check for the reset type and should accordingly call the `R_RTC_ClockSourceSet()`.

Limitations

Developers should be aware of the following limitations when using the RTC:

- `R_RTC` operates in 24-hour mode.
- Binary-count mode is not supported.
- The `R_RTC_CalendarTimeGet()` cannot be used from an interrupt that has higher priority than the carry interrupt. Also, it must not be called with interrupts disabled globally, as this API internally uses carry interrupt for its processing. API may return incorrect time if this is done.

Examples

RTC Basic Example

This is a basic example of minimal use of the RTC in an application.

```
/* rtc_time_t is an alias for the C Standard time.h struct 'tm' */
rtc_time_t set_time =
{
    .tm_sec = 10,
    .tm_min = 11,
    .tm_hour = 12,
    .tm_mday = 6,
    .tm_wday = 3,
    .tm_mon = 11,
    .tm_year = YEARS_SINCE_1900,
};
rtc_time_t get_time;
void rtc_example ()
{
```

```
fsp_err_t err = FSP_SUCCESS;

/* Open the RTC module */
err = R_RTC_Open(&g_rtc0_ctrl, &g_rtc0_cfg);

/* Handle any errors. This function should be defined by the user. */
assert(FSP_SUCCESS == err);

/* Set the RTC clock source. Can be skipped if "Set Source Clock in Open" property
is enabled. */
R_RTC_ClockSourceSet(&g_rtc0_ctrl);

/* Set the calendar time */
R_RTC_CalendarTimeSet(&g_rtc0_ctrl, &set_time);

/* Get the calendar time */
R_RTC_CalendarTimeGet(&g_rtc0_ctrl, &get_time);
}
```

RTC Clock Source Set Example

```
void rtc_clock_source_set_example ()
{
    fsp_err_t err = FSP_SUCCESS;

    /* Open the RTC module*/
    err = R_RTC_Open(&g_rtc0_ctrl, &g_rtc0_cfg);

    /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);

    /* This condition can differ based on use case. */
    if (R_SYSTEM->RSTSR0 == 1)
    {
        /* Set the RTC clock source. Can be skipped if "Set Source Clock in Open" property
is enabled. */
        R_RTC_ClockSourceSet(&g_rtc0_ctrl);
    }

    /* R_RTC_CalendarTimeSet must be called at least once to start the RTC */
    R_RTC_CalendarTimeSet(&g_rtc0_ctrl, &set_time);

    /* Set the periodic interrupt rate to 1 second */
}
```

```
R_RTC_PeriodicIrqRateSet(&g_rtc0_ctrl, RTC_PERIODIC_IRQ_SELECT_1_SECOND);  
  
/* Wait for the periodic interrupt */  
while (1)  
{  
    /* Wait for interrupt */  
}}
```

RTC Periodic interrupt example

This is an example of periodic interrupt in RTC.

```
void rtc_periodic_irq_example ()  
{  
    fsp_err_t err = FSP_SUCCESS;  
    /* Open the RTC module*/  
    err = R_RTC_Open(&g_rtc0_ctrl, &g_rtc0_cfg);  
    /* Handle any errors. This function should be defined by the user. */  
    assert(FSP_SUCCESS == err);  
    /* Set the RTC clock source. Can be skipped if "Set Source Clock in Open" property  
is enabled. */  
    R_RTC_ClockSourceSet(&g_rtc0_ctrl);  
    /* R_RTC_CalendarTimeSet must be called at least once to start the RTC */  
    R_RTC_CalendarTimeSet(&g_rtc0_ctrl, &set_time);  
    /* Set the periodic interrupt rate to 1 second */  
    R_RTC_PeriodicIrqRateSet(&g_rtc0_ctrl, RTC_PERIODIC_IRQ_SELECT_1_SECOND);  
    /* Wait for the periodic interrupt */  
    while (1)  
    {

Detailed Description

Driver for 3-phase motor control using the GPT peripheral on RA MCUs. This module implements the

Three-Phase Interface.

Overview

The General PWM Timer (GPT) Three-Phase driver provides basic functionality for synchronously starting and stopping three PWM channels for use in 3-phase motor control applications. A function is additionally provided to allow setting duty cycle values for all three channels, optionally with double-buffering.

Features

The GPT Three-Phase driver provides the following functions:

- Synchronize configuration of three GPT channels
- Synchronously start, stop and reset all three GPT channels
- Set duty cycle on all three channels with one function

Configuration

Build Time Configurations for r_gpt_three_phase

The following build time configurations are defined in fsp_cfg/r_gpt_three_phase_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|---|
| Parameter Checking | <ul style="list-style-type: none"> • Default (BSP) • Enabled • Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

Configurations for Timers > Three-Phase PWM (r_gpt_three_phase)

This module can be added to the Stacks tab via New Stack > Timers > Three-Phase PWM (r_gpt_three_phase). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |

Setting the period to 0x100000000 raw counts results in the maximum period. Set the period to 0x100000000 raw counts for a free running timer or an input capture configuration. The period can be set up to 0x4000000000, which will use a divider of 1024 with the maximum period. |
| General > Period Unit | <ul style="list-style-type: none"> • Raw Counts • Nanoseconds • Microseconds • Milliseconds • Seconds • Hertz • Kilohertz | Kilohertz | Unit of the period specified above |

| General > GPT V-Channel | Value must be an integer greater than or equal to 0 | 1 | Specify the GPT channel for V signal output. |

If the requested period cannot be achieved, the settings with the largest possible period that is less than or equal to the requested period are used. The theoretical calculated period is printed in a comment in the generated [timer_cfg_t](#) structures for each timer.

Pin Configuration

Please refer to the [Timer, General PWM \(r_gpt\)](#) section for more information.

Usage Notes

Warning

Be sure the GTIOCA/B stop level and dead time values are set appropriately for your application before attempting to drive a motor. Failure to do so may result in damage to the motor drive circuitry and/or the motor itself if the timer is stopped by software.

Initial Setup

The following should be configured once the GPT Three-Phase module has been added to a project:

1. Set "Pin Output Support" in one of the GPT submodules to "Enabled with Extra Features"
2. Configure common settings in the GPT Three-Phase module properties
3. Set the crest and trough interrupt priority and callback function in **one** of the three GPT submodules (if desired)
4. Set the "Extra Features -> Output Disable" settings in each GPT submodule as needed for your application

Note

Because all three modules are operated synchronously with the same period interrupts only need to be enabled in one of the three GPT modules.

Buffer Modes

There are two buffering modes available for duty cycle values - single- and double-buffered. In single buffer mode only the values specified in the duty array element of `three_phase_duty_cycle_t` are used by `R_GPT_THREE_PHASE_DutyCycleSet`. At the next trough or crest event the output duty cycle will be internally updated to the set values.

In double buffer mode the `duty_buffer` array values are used as buffer values for the duty elements. Once passed to `R_GPT_THREE_PHASE_DutyCycleSet`, the next trough or crest event will update the output duty cycle to the values specified in `duty` as before. However, at the following crest or trough event the output duty cycle will be updated to the values in `duty_buffer`. This allows the duty cycle for both sides of an asymmetric PWM waveform to be set at only one trough or crest event per period instead of at every event.

Examples

GPT Three-Phase Basic Example

This is a basic example of minimal use of the GPT Three-Phase module in an application. The duty cycle is updated at every timer trough with the previously loaded buffer value, then the duty cycle buffer is reloaded in the trough interrupt callback.

```
void gpt_callback (timer_callback_args_t * p_args)
{
    fsp_err_t          err;
    three_phase_duty_cycle_t duty_cycle;

    if (TIMER_EVENT_TROUGH == p_args->event)
    {
        /* Update duty cycle values (example) */
        duty_cycle.duty[THREE_PHASE_CHANNEL_U] =
```

```

get_duty_counts(THREE_PHASE_CHANNEL_U);
    duty_cycle.duty[THREE_PHASE_CHANNEL_V] =
get_duty_counts(THREE_PHASE_CHANNEL_V);
    duty_cycle.duty[THREE_PHASE_CHANNEL_W] =
get_duty_counts(THREE_PHASE_CHANNEL_W);
/* Update duty cycle values */
    err = R_GPT_THREE_PHASE_DutyCycleSet(&g_gpt_three_phase_ctrl, &duty_cycle);
    assert(FSP_SUCCESS == err);
}
else
{
/* Handle crest event. */
}
}
void gpt_three_phase_basic_example (void)
{
fsp_err_t err = FSP_SUCCESS;
/* Initializes the module. */
    err = R_GPT_THREE_PHASE_Open(&g_gpt_three_phase_ctrl, &g_gpt_three_phase_cfg);
/* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
/* Start the timer. */
    (void) R_GPT_THREE_PHASE_Start(&g_gpt_three_phase_ctrl);
}

```

Return values

|-------------------|-----------------------------------|
| FSP_SUCCESS | Counters were reset successfully. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance is not opened. |

◆ **R_GPT_THREE_PHASE_DutyCycleSet()**

```
fsp_err_t R_GPT_THREE_PHASE_DutyCycleSet ( three_phase_ctrl_t *const p_ctrl,
three_phase_duty_cycle_t *const p_duty_cycle )
```

Sets duty cycle for all three timers. Implements `three_phase_api_t::dutyCycleSet`.

In symmetric PWM mode duty cycle values are reflected after the next trough. In asymmetric PWM mode values are reflected at the next trough OR crest, whichever comes first.

When double-buffering is enabled the values in `three_phase_duty_cycle_t::duty_buffer` are set to the double-buffer registers. When values are reflected the first time the single buffer values (`three_phase_duty_cycle_t::duty`) are used. On the second reflection the `duty_buffer` values are used. In asymmetric PWM mode this enables both count-up and count-down PWM values to be set at trough (or crest) exclusively.

Note

It is recommended to call this function in a high-priority callback to ensure that it is not interrupted and that no GPT events occur during setting that would result in a duty cycle buffer load operation.

Example:

```
/* Update duty cycle values */
err = R_GPT_THREE_PHASE_DutyCycleSet(&g_gpt_three_phase_ctrl, &duty_cycle);
assert(FSP_SUCCESS == err);
```

Return values

| | |
|--------------------------|--|
| FSP_SUCCESS | Duty cycle updated successfully. |
| FSP_ERR_ASSERTION | p_ctrl was NULL |
| FSP_ERR_NOT_OPEN | The instance is not opened. |
| FSP_ERR_INVALID_ARGUMENT | One or more duty cycle count values was outside the range 0..(period - 1). |

◆ R_GPT_THREE_PHASE_CallbackSet()

```
fsp_err_t R_GPT_THREE_PHASE_CallbackSet ( three_phase_ctrl_t *const p_ctrl,
void(*) (timer_callback_args_t *) p_callback, void const *const p_context, timer_callback_args_t
*const p_callback_memory )
```

Updates the user callback for the GPT U-channel with the option to provide memory for the callback argument structure. Implements [three_phase_api_t::callbackSet](#).

Return values

| | |
|-------------------|--|
| FSP_SUCCESS | Callback updated successfully. |
| FSP_ERR_ASSERTION | A required pointer is NULL. |
| FSP_ERR_NOT_OPEN | The control block has not been opened. |

◆ R_GPT_THREE_PHASE_Close()

```

Return values

| | |
|-------------------|-----------------------------|
| FSP_SUCCESS | Successful close. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance is not opened. |

Overview

The GPT module can be used to count events, measure external input signals, generate a periodic interrupt, or output a periodic or PWM signal to a GTIOC pin.

This module supports the GPT peripherals GPT32EH, GPT32E, GPT32, and GPT16. GPT16 is a 16-bit timer. The other peripherals (GPT32EH, GPT32E, and GPT32) are 32-bit timers. The 32-bit timers are all treated the same in this module from the API perspective.

Selecting a Timer

RA MCUs have two timer peripherals: the General PWM Timer (GPT) and the Asynchronous General Purpose Timer (AGT). When selecting between them, consider these factors:

| | GPT | AGT |
|--------------------|--|---|
| Low Power Modes | The GPT can operate in sleep mode. | The AGT can operate in all low power modes. |
| Available Channels | The number of GPT channels is device specific. All currently supported MCUs have at least 7 GPT channels. | All MCUs have 2 AGT channels. |
| Timer Resolution | All MCUs have at least one 32-bit GPT timer. | The AGT timers are 16-bit timers. |
| Clock Source | The GPT runs off PCLKD with a configurable divider up to 1024. It can also be configured to count ELC events or external pulses. | The AGT runs off PCLKB, LOCO, or subclock. |

Clock Configuration

The GPT clock is based on the PCLKD frequency. You can set the PCLKD frequency using the **Clocks** tab of the RA Configuration editor or by using the CGC Interface at run-time.

Pin Configuration

This module can use GTETRGA, GTETRGB, GTETRGC, GTETRGD, GTIOCA and GTIOCB pins as count sources.

This module can use GTIOCA and GTIOCB pins as output pins for periodic or PWM signals.

This module can use GTIOCA and GTIOCB as input pins to measure input signals.

Usage Notes

Maximum Period

The RA Configuration editor will automatically calculate the period count value and source clock divider based on the selected period time, units and clock speed.

When the selected period unit is "Raw counts", the maximum period setting is 0x4000000000 on a 32-bit timer or 0x0x4000000 on a 16-bit timer. This will configure the timer with the maximum period and a count clock divisor of 1024.

Note

16-bit channels inherently have a reduced maximum period compared to 32-bit channels. When setting period values of hundreds of milliseconds or more on 16-bit channels be sure to check the generated output to confirm the actual configured value as it will clip much earlier than 32-bit channels. In general, it is recommended to use a lower-power timer like AGT or RTC if long hardware delays are required.

Updating Period and Duty Cycle

The period and duty cycle are updated after the next counter overflow after calling [R_GPT_PeriodSet\(\)](#) or [R_GPT_DutyCycleSet\(\)](#). To force them to update before the next counter overflow, call [R_GPT_Reset\(\)](#) while the counter is running.

Note

When manually changing the timer period counts the maximum value for a 32-bit GPT is 0x100000000. This number overflows the 32-bit value for `timer_cfg_t::period_counts`. To configure the timer for the maximum period, set `timer_cfg_t::period_counts` to 0.

One-Shot Mode

The GPT timer does not support one-shot mode natively. One-shot mode is achieved by stopping the timer in the interrupt service routine before the callback is called. If the interrupt is not serviced before the timer period expires again, the timer generates more than one event. The callback is only called once in this case, but multiple events may be generated if the timer is linked to the [Transfer \(r_dtc\)](#).

One-Shot Mode Output

The output waveform in one-shot mode is one PCLKD cycle less than the configured period. The configured period must be at least 2 counts to generate an output pulse.

Examples of one-shot signals that can be generated by this module are shown below:

GPT One-Shot Output

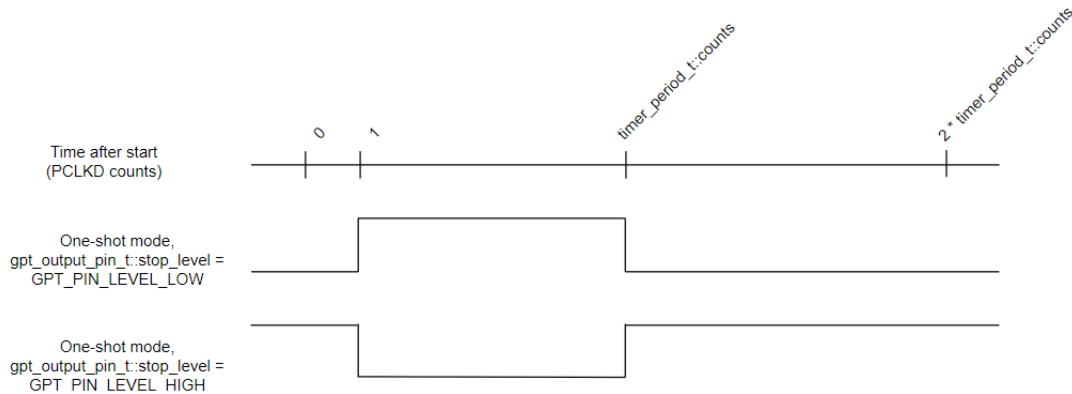

Figure 232: GPT One-Shot Output

One-Shot Pulse Mode

The one-shot pulse mode is an asymmetric PWM mode that provides more control over the rising and falling edges of the output. The user provides a period and initial output level and controls the signal by specifying compare match values for the leading and trailing edges each period.

Note

Despite its name, the One-Shot Pulse Mode operates continuously and does not stop after the first period.

One-Shot Pulse Mode Output

Examples of PWM signals that can be generated by this module are shown below. The leading and trailing edge match values can be modified using [R_GPT_DutyCycleSet\(\)](#) in the overflow interrupt.

GPT One-Shot Pulse Output

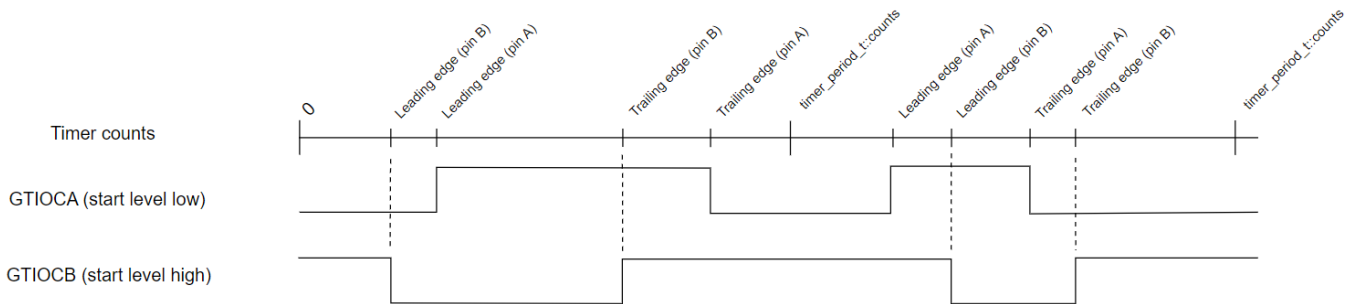

Figure 233: GPT One-Shot Pulse Output (without dead time)

If dead time is enabled only match values for GTIOCnA need to be set; the match values for GTIOCnB will be automatically configured in hardware.

GPT One-Shot Pulse Output (with dead time)

Figure 234: GPT One-Shot Pulse Output (with dead time)

Periodic Output

The GTIOC pin toggles twice each time the timer expires in periodic mode. This is achieved by defining a PWM wave at a 50 percent duty cycle so that the period of the resulting square wave (from rising edge to rising edge) matches the period of the GPT timer. Since the periodic output is actually a PWM output, the time at the stop level is one cycle shorter than the time opposite the stop level for odd period values.

Examples of periodic signals that can be generated by this module are shown below:

GPT Periodic Output

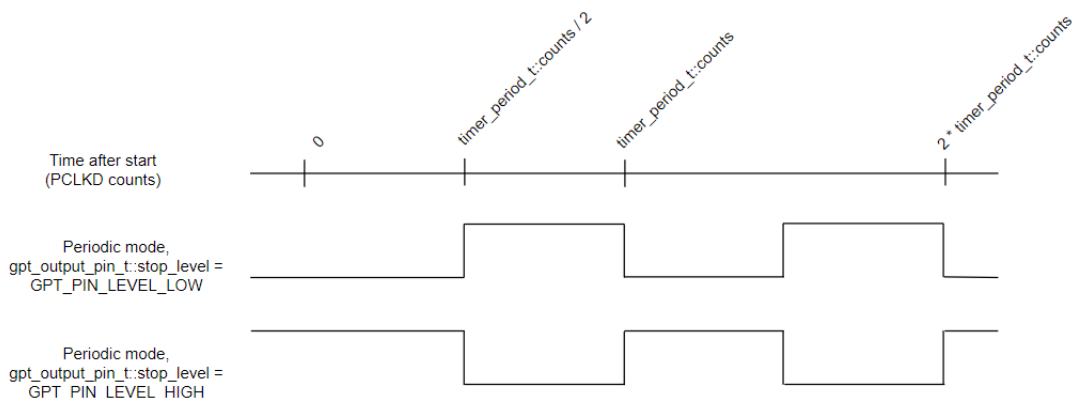

Figure 235: GPT Periodic Output

PWM Output

The PWM output signal is high at the beginning of the cycle and low at the end of the cycle.

Examples of PWM signals that can be generated by this module are shown below:

Figure 236: GPT PWM Output

Triangle-Wave PWM Output

Examples of PWM signals that can be generated by this module are shown below. The `duty_cycle_counts` can be modified using `R_GPT_DutyCycleSet()` in the crest interrupt and updated at the following trough for symmetric PWM or modified in both the crest/trough interrupts and updated at the following trough/crest for asymmetric PWM.

Figure 237: GPT Triangle-Wave PWM Output

PWM Output Delay Circuit

On select MCUs, an additional PWM output delay circuit can be configured in order to fine tune the rising and falling edge delays in increments of 1/32 times the period of the GPT core clock. The PWM output delay function must be configured prior to initializing the GPT channels using `R_GPT_PwmOutputDelayInitialize`.

Note

1. In Saw-wave PWM mode, the output delay setting cannot be changed while the capture compare setting (`GTCCRn`) is greater than or equal the period setting (`GTPR`) - 2.
2. In Triangle PWM modes, the output delay setting cannot be changed while the counter is counting down, and the capture compare setting (`GTCCRn`) is less than or equal to 2.
3. When the PWM Output Delay Circuit is enabled, the PWM signal is delayed by 3 GPT core clock cycles.
4. When the `GPTCLK` is used as the GPT core clock, the following delay is required between writes to the rising or falling edge output delay setting for a given pin: $Write_Interval[ns] = Period_of_PCLKA [ns] \times 6 + Period_of_GPTCLK [ns] \times 4$.

Event Counting

Event counting can be done by selecting up or down counting sources from GTETRГ pins, ELC events, or GTIOC pins. In event counting mode, the GPT counter is not affected by PCLKD.

Note

In event counting mode, the application must call [R_GPT_Start\(\)](#) to enable event counting. The counter will not change after calling [R_GPT_Start\(\)](#) until an event occurs.

Pulse Measurement

If the capture edge occurs before the start edge in pulse measurement, the first capture is invalid (0).

Controlling GPT with GTETRГ Edges

The GPT timer can be configured to stop, start, clear, count up, or count down when a GTETRГ rising or falling edge occurs.

Note

*The GTETRГ pins are shared by all GPT channels.
GTETRГ pins require POEG to be on (example code for this is provided in [GPT Free Running Counter Example](#)).
If input filtering is required on the GTETRГ pins, that must also be handled outside this module.*

Controlling GPT with ELC Events

The GPT timer can be configured to stop, start, clear, count up, or count down when an ELC event occurs.

Note

*The configurable ELC GPT sources are shared by all GPT channels.
The event links for the ELC must be configured outside this module.*

Triggering ELC Events with GPT

The GPT timer can trigger the start of other peripherals. The [Event Link Controller \(r_elc\)](#) guide provides a list of all available peripherals.

Enabling External Sources for Start, Stop, Clear, or Capture

[R_GPT_Enable\(\)](#) must be called when external sources are used for start, stop, clear, or capture.

Interrupt Skipping

When an interrupt skipping source is selected a hardware counter will increment each time the selected event occurs. Each interrupt past the first (up to the specified skip count) will be suppressed. If ADC events are selected for skipping they will also be suppressed except during the timer period leading to the selected interrupt skipping event (see below diagram).

Figure 238: Crest interrupt skipping in triangle-wave PWM modes (skip count 2)

Complementary Output

By using the Custom Waveform option the output pins can be made to output complementary waveforms. To ensure these waveforms stay in sync, the duty cycle for both pins can be set simultaneously by calling `R_GPT_DutyCycleSet` once with a pin parameter of `GPT_IO_PIN_GTIOCA_AND_GTIOCB`.

Note

The pin level for 0% and 100% duty cycle is determined by the Cycle End Output Level in normal PWM mode and the Initial Output Level in triangle PWM modes. 100% duty will output the configured level and 0% will output the opposite. Do not use Pin Level Toggle or Pin Level Retain for the Cycle End Output Level if normal PWM waveforms are desired.

Function Documentation

◆ **R_GPT_Open()**

```
fsp_err_t R_GPT_Open ( timer_ctrl_t *const p_ctrl, timer_cfg_t const *const p_cfg )
```

Initializes the timer module and applies configurations. Implements `timer_api_t::open`.

GPT hardware does not support one-shot functionality natively. When using one-shot mode, the timer will be stopped in an ISR after the requested period has elapsed.

The GPT implementation of the general timer can accept a `gpt_extended_cfg_t` extension parameter.

Example:

```
/* Initializes the module. */
err = R_GPT_Open(&g_timer0_ctrl, &g_timer0_cfg);
```

Return values

| | |
|--------------------------------|--|
| FSP_SUCCESS | Initialization was successful and timer has started. |
| FSP_ERR_ASSERTION | A required input pointer is NULL or the source divider is invalid. |
| FSP_ERR_ALREADY_OPEN | Module is already open. |
| FSP_ERR_IRQ_BSP_DISABLED | <code>timer_cfg_t::mode</code> is <code>TIMER_MODE_ONE_SHOT</code> or <code>timer_cfg_t::p_callback</code> is not NULL, but ISR is not enabled. ISR must be enabled to use one-shot mode or callback. |
| FSP_ERR_INVALID_MODE | Triangle wave PWM is only supported if <code>GPT_CFG_OUTPUT_SUPPORT_ENABLE</code> is 2. Selected channel does not support external count sources. External and event count sources not are available in this mode. |
| FSP_ERR_IP_CHANNEL_NOT_PRESENT | The channel requested in the <code>p_cfg</code> parameter is not available on this device. |

◆ **R_GPT_Stop()**

```
fsp_err_t R_GPT_Stop ( timer_ctrl_t *const p_ctrl)
```

Stops timer. Implements `timer_api_t::stop`.

Example:

```
/* (Optional) Stop the timer. */
(void) R_GPT_Stop(&g_timer0_ctrl);
```

Return values

| | |
|-------------------|-----------------------------|
| FSP_SUCCESS | Timer successfully stopped. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance is not opened. |

◆ **R_GPT_Start()**

```
fsp_err_t R_GPT_Start ( timer_ctrl_t *const p_ctrl)
```

Starts timer. Implements `timer_api_t::start`.

Example:

```
/* Start the timer. */
(void) R_GPT_Start(&g_timer0_ctrl);
```

| | |
|-------------------|-----------------------------|
| FSP_SUCCESS | Timer successfully started. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance is not opened. |

◆ **R_GPT_Reset()**

```
fsp_err_t R_GPT_Reset ( timer_ctrl_t *const p_ctrl)
```

Resets the counter value to 0. Implements `timer_api_t::reset`.

Note

This function also updates to the new period if no counter overflow has occurred since the last call to `R_GPT_PeriodSet()`.

Return values

| | |
|-------------------|-------------------------------------|
| FSP_SUCCESS | Counter value written successfully. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance is not opened. |

◆ **R_GPT_Enable()**

```
fsp_err_t R_GPT_Enable ( timer_ctrl_t *const p_ctrl)
```

Enables external event triggers that start, stop, clear, or capture the counter. Implements `timer_api_t::enable`.

Example:

```
/* Enable captures. Captured values arrive in the interrupt. */
(void) R_GPT_Enable(&g_timer0_ctrl);
```

Return values

| | |
|-------------------|---------------------------------------|
| FSP_SUCCESS | External events successfully enabled. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance is not opened. |

◆ **R_GPT_Disable()**

```
fsp_err_t R_GPT_Disable ( timer_ctrl_t *const p_ctrl)
```

Disables external event triggers that start, stop, clear, or capture the counter. Implements `timer_api_t::disable`.

Note

The timer could be running after `R_GPT_Disable()`. To ensure it is stopped, call `R_GPT_Stop()`.

Example:

```
/* (Optional) Disable captures. */
(void) R_GPT_Disable(&g_timer0_ctrl);
```

Return values

| | |
|-------------------|--|
| FSP_SUCCESS | External events successfully disabled. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance is not opened. |

◆ **R_GPT_PeriodSet()**

```
fsp_err_t R_GPT_PeriodSet ( timer_ctrl_t *const p_ctrl, uint32_t const period_counts )
```

Sets period value provided. If the timer is running, the period will be updated after the next counter overflow. If the timer is stopped, this function resets the counter and updates the period. Implements `timer_api_t::periodSet`.

Warning

If periodic output is used, the duty cycle buffer registers are updated after the period buffer register. If this function is called while the timer is running and a GPT overflow occurs during processing, the duty cycle will not be the desired 50% duty cycle until the counter overflow after processing completes.

Example:

```
/* Get the source clock frequency (in Hz). There are 3 ways to do this in FSP:
 * - If the PCLKD frequency has not changed since reset, the source clock frequency
is
 * BSP_STARTUP_PCLKD_HZ >> timer_cfg_t::source_div
 * - Use the R_GPT_InfoGet function (it accounts for the divider).
 * - Calculate the current PCLKD frequency using
R_FSP_SystemClockHzGet(FSP_PRIV_CLOCK_PCLKD) and right shift
 * by timer_cfg_t::source_div.
 *
```

```

* This example uses the 3rd option (R_FSP_SystemClockHzGet).
*/
uint32_t pclkd_freq_hz = R_FSP_SystemClockHzGet(FSP_PRIV_CLOCK_PCLKD) >>
g_timer0_cfg.source_div;
/* Calculate the desired period based on the current clock. Note that this
calculation could overflow if the
* desired period is larger than UINT32_MAX / pclkd_freq_hz. A cast to uint64_t is
used to prevent this. */
uint32_t period_counts =
    (uint32_t) (((uint64_t) pclkd_freq_hz * GPT_EXAMPLE_DESIRED_PERIOD_MSEC) /
GPT_EXAMPLE_MSEC_PER_SEC);
/* Set the calculated period. */
err = R_GPT_PeriodSet(&g_timer0_ctrl, period_counts);
assert(FSP_SUCCESS == err);

```

Return values

| | |
|-------------------|------------------------------------|
| FSP_SUCCESS | Period value written successfully. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance is not opened. |

◆ R_GPT_DutyCycleSet()

```

fsp_err_t R_GPT_DutyCycleSet ( timer_ctrl_t *const p_ctrl, uint32_t const duty_cycle_counts,
uint32_t const pin )

```

Sets duty cycle on requested pin. Implements [timer_api_t::dutyCycleSet](#).

Duty cycle is updated in the buffer register. The updated duty cycle is reflected after the next cycle end (counter overflow).

Example:

```

/* Get the current period setting. */
timer_info_t info;
(void) R_GPT_InfoGet(&g_timer0_ctrl, &info);
uint32_t current_period_counts = info.period_counts;
/* Calculate the desired duty cycle based on the current period. Note that if the
period could be larger than
* UINT32_MAX / 100, this calculation could overflow. A cast to uint64_t is used to

```

```

prevent this. The cast is
 * not required for 16-bit timers. */
uint32_t duty_cycle_counts =
    (uint32_t) (((uint64_t) current_period_counts *
GPT_EXAMPLE_DESIRED_DUTY_CYCLE_PERCENT) /
                GPT_EXAMPLE_MAX_PERCENT);
/* Set the calculated duty cycle. */
err = R_GPT_DutyCycleSet(&g_timer0_ctrl, duty_cycle_counts, GPT_IO_PIN_GTIOCB);
assert(FSP_SUCCESS == err);

```

Selecting a Timer

RA MCUs have two timer peripherals: the General PWM Timer (GPT) and the Asynchronous General Purpose Timer (AGT). When selecting between them, consider these factors:

| | | |
|--|-----|-----|
| | GPT | AGT |
|--|-----|-----|

| | | |
|--------------------|--|--|
| Low Power Modes | The GPT can operate in sleep mode. | The AGT can operate in all low power modes (when count source is LOCO or subclock). |
| Available Channels | The number of GPT channels is device specific. All currently supported MCUs have at least 7 GPT channels. | All MCUs have 2 AGT channels. |
| Timer Resolution | All MCUs have at least one 32-bit GPT timer. | The AGT timers are 16-bit timers. |
| Clock Source | The GPT runs off PCLKD with a configurable divider up to 1024. It can also be configured to count ELC events or external pulses. | The AGT runs off PCLKB, LOCO, or subclock with a configurable divider up to 8 for PCLKB or up to 128 for LOCO or subclock. |

Configuration

Build Time Configurations for r_agt

The following build time configurations are defined in fsp_cfg/r_agt_cfg.h:

| Configuration | Options | Default | Description |
|--------------------|--|---------------|--|

Configurations for Timers > Timer, Low-Power (r_agt)

This module can be added to the Stacks tab via New Stack > Timers > Timer, Low-Power (r_agt). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

Clock Configuration

The AGT clock is based on the PCLKB, LOCO, or Subclock frequency. You can set the clock frequency using the **Clocks** tab of the RA Configuration editor or by using the CGC Interface at run-time.

Pin Configuration

This module can use the AGTOA and AGTOB pins as output pins for periodic, one-shot, or PWM signals.

For input capture, the input signal must be applied to the AGTIO pin.

For event counting, the AGTEEn enable pin is optional.

Timer Period

The RA Configuration editor will automatically calculate the period count value and source clock divider based on the selected period time, units, and clock speed.

When the selected unit is "Raw counts", the maximum allowed period setting varies depending on the selected clock source:

| Clock source | 16-bit Timer Maximum period (counts) | 32-bit Timer Maximum period (counts) |
|-------------------|--------------------------------------|--------------------------------------|
| LOCO/Subclock | 0x800000 | 0x800000000 |
| PCLKB | 0x80000 | 0x800000000 |
| All other sources | 0x10000 | 0x100000000 |

Note

Though the AGT is a 16-bit timer, because the period interrupt occurs when the counter underflows, setting the period register to 0 results in an effective period of 1 count. For this reason all user-provided raw count values reflect the actual number of period counts (not the raw register values).

Usage Notes

Starting and Stopping the AGT

After starting or stopping the timer, AGT registers cannot be accessed until the AGT state is updated after 3 AGTCLK cycles. If another AGT function is called before the 3 AGTCLK period elapses, the function spins waiting for the AGT state to update. The required wait time after starting or stopping the timer can be determined using the frequency of AGTCLK, which is derived from [timer_cfg_t::source_div](#) and [agt_extended_cfg_t::count_source](#).

The application is responsible for ensuring required clocks are started and stable before accessing MCU peripheral registers.

Warning

The subclock can take seconds to stabilize. The RA startup code does not wait for subclock stabilization unless the subclock is the main clock source. When running AGT or RTC off the subclock, the application must ensure the subclock is stable before starting operation.

Low Power Modes

The AGT1 (channel 1 only) can be used to enter snooze mode or to wake the MCU from snooze, software standby, or deep software standby modes when a counter underflow occurs. The compare match A and B events can also be used to wake from software standby or snooze modes.

One-Shot Mode

The AGT timer does not support one-shot mode natively. One-shot mode is achieved by stopping the timer in the interrupt service routine before the callback is called. If the interrupt is not serviced before the timer period expires again, the timer generates more than one event. The callback is only called once in this case, but multiple events may be generated if the timer is linked to the [Transfer \(r_dtc\)](#).

One-Shot Mode Output

The output waveform in one-shot mode is one AGT clock cycle less than the configured period. The configured period must be at least 2 counts to generate an output pulse.

Examples of one-shot signals that can be generated by this module are shown below:

AGT One-Shot Output

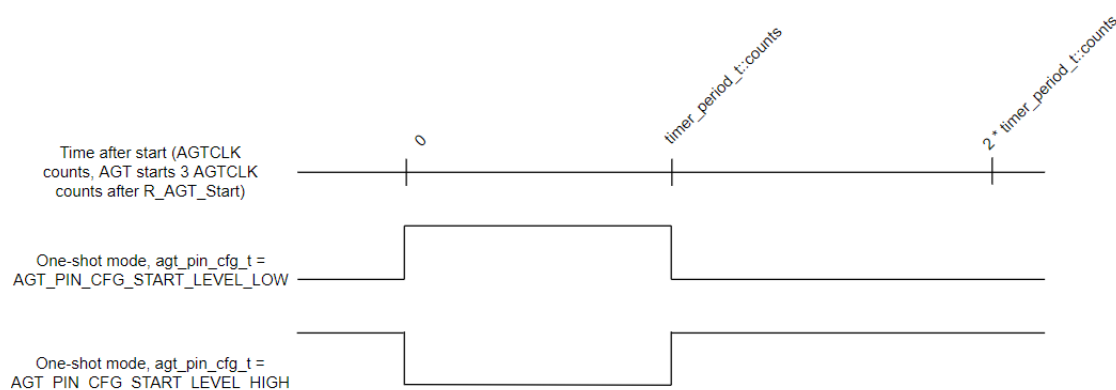

Figure 239: AGT One-Shot Output

Periodic Output

The AGTOA or AGTOB pin toggles twice each time the timer expires in periodic mode. This is achieved by defining a PWM wave at a 50 percent duty cycle so that the period of the resulting square (from rising edge to rising edge) matches the period of the AGT timer. Since the periodic output is actually a PWM output, the time at the stop level is one cycle shorter than the time opposite the stop level for odd period values.

Examples of periodic signals that can be generated by this module are shown below:

AGT Periodic Output

Figure 240: AGT Periodic Output

PWM Output

This module does not support in phase PWM output. The PWM output signal is low at the beginning of the cycle and high at the end of the cycle.

Examples of PWM signals that can be generated by this module are shown below:

Figure 241: AGT PWM Output

Triggering ELC Events with AGT

The AGT timer can trigger the start of other peripherals. The [Event Link Controller \(r_elc\)](#) guide provides a list of all available peripherals.

Function Documentation◆ **R_AGT_Open()**

```
fsp_err_t R_AGT_Open ( timer_ctrl_t *const p_ctrl, timer_cfg_t const *const p_cfg )
```

Initializes the AGT module instance. Implements `timer_api_t::open`.

The AGT hardware does not support one-shot functionality natively. The one-shot feature is therefore implemented in the AGT HAL layer. For a timer configured as a one-shot timer, the timer is stopped upon the first timer expiration.

The AGT implementation of the general timer can accept an optional `agt_extended_cfg_t` extension parameter. For AGT, the extension specifies the clock to be used as timer source and the output pin configurations. If the extension parameter is not specified (NULL), the default clock PCLKB is used and the output pins are disabled.

Example:

```
/* Initializes the module. */
err = R_AGT_Open(&g_timer0_ctrl, &g_timer0_cfg);
```

Return values

| | |
|--------------------------------|--|
| FSP_SUCCESS | Initialization was successful and timer has started. |
| FSP_ERR_ASSERTION | A required input pointer is NULL or the period is not in the valid range of 1 to 0xFFFF. |
| FSP_ERR_ALREADY_OPEN | R_AGT_Open has already been called for this p_ctrl. |
| FSP_ERR_IRQ_BSP_DISABLED | A required interrupt has not been enabled in the vector table. |
| FSP_ERR_IP_CHANNEL_NOT_PRESENT | Requested channel number is not available on AGT. |

◆ **R_AGT_Start()**

```
fsp_err_t R_AGT_Start ( timer_ctrl_t *const p_ctrl)
```

Starts timer. Implements `timer_api_t::start`.

Example:

```
/* Start the timer. */
(void) R_AGT_Start(&g_timer0_ctrl);
```

Return values

| | |
|-------------------|---|
| FSP_SUCCESS | Timer started. |
| FSP_ERR_ASSERTION | p_ctrl is null. |
| FSP_ERR_NOT_OPEN | The instance control structure is not opened. |

◆ **R_AGT_Stop()**

```
fsp_err_t R_AGT_Stop ( timer_ctrl_t *const p_ctrl)
```

Stops the timer. Implements `timer_api_t::stop`.

Example:

```
/* (Optional) Stop the timer. */
(void) R_AGT_Stop(&g_timer0_ctrl);
```

Return values

| | |
|-------------------|---|
| FSP_SUCCESS | Timer stopped. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance control structure is not opened. |

◆ **R_AGT_Reset()**

```
fsp_err_t R_AGT_Reset ( timer_ctrl_t *const p_ctrl)
```

Resets the counter value to the period minus one. Implements `timer_api_t::reset`.

Return values

| | |
|-------------------|---|
| FSP_SUCCESS | Counter reset. |
| FSP_ERR_ASSERTION | p_ctrl is NULL |
| FSP_ERR_NOT_OPEN | The instance control structure is not opened. |

◆ **R_AGT_Enable()**

```
fsp_err_t R_AGT_Enable ( timer_ctrl_t *const p_ctrl)
```

Enables external event triggers that start, stop, clear, or capture the counter. Implements `timer_api_t::enable`.

Example:

```
/* Enable captures. Captured values arrive in the interrupt. */
(void) R_AGT_Enable(&g_timer0_ctrl);
```

Return values

| | |
|-------------------|---------------------------------------|
| FSP_SUCCESS | External events successfully enabled. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance is not opened. |

◆ **R_AGT_Disable()**

```
fsp_err_t R_AGT_Disable ( timer_ctrl_t *const p_ctrl)
```

Disables external event triggers that start, stop, clear, or capture the counter. Implements `timer_api_t::disable`.

Example:

```
/* (Optional) Disable captures. */
(void) R_AGT_Disable(&g_timer0_ctrl);
```

Return values

| | |
|-------------------|--|
| FSP_SUCCESS | External events successfully disabled. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |

◆ **R_AGT_PeriodSet()**

```
fsp_err_t R_AGT_PeriodSet ( timer_ctrl_t *const p_ctrl, uint32_t const period_counts )
```

Updates period. The new period is updated immediately and the counter is reset to the maximum value. Implements `timer_api_t::periodSet`.

Warning

If periodic output is used, the duty cycle buffer registers are updated after the period buffer register. If this function is called while the timer is running and an AGT underflow occurs during processing, the duty cycle will not be the desired 50% duty cycle until the counter underflow after processing completes.

Stop the timer before calling this function if one-shot output is used.

Example:

```
/* Get the source clock frequency (in Hz). There are several ways to do this in FSP:
 * - If LOCO or subclock is chosen in agt_extended_cfg_t::clock_source
 * - The source clock frequency is BSP_LOCO_HZ >> timer_cfg_t::source_div
 * - If PCLKB is chosen in agt_extended_cfg_t::clock_source and the PCLKB frequency
has not changed since reset,
 * - The source clock frequency is BSP_STARTUP_PCLKB_HZ >> timer_cfg_t::source_div
 * - Use the R_AGT_InfoGet function (it accounts for the clock source and divider).
 * - Calculate the current PCLKB frequency using
R_FSP_SystemClockHzGet(FSP_PRIV_CLOCK_PCLKB) and right shift
 * by timer_cfg_t::source_div.
 *
```

```
* This example uses the last option (R_FSP_SystemClockHzGet).
*/
uint32_t timer_freq_hz = R_FSP_SystemClockHzGet(FSP_PRIV_CLOCK_PCLKB) >>
g_timer0_cfg.source_div;
/* Calculate the desired period based on the current clock. Note that this

used to prevent this. */
uint32_t period_counts =
    (uint32_t) (((uint64_t) timer_freq_hz * AGT_EXAMPLE_DESIRED_PERIOD_MSEC) /
AGT_EXAMPLE_MSEC_PER_SEC);
/* Set the calculated period. This will return an error if parameter checking is
enabled and the calculated
* period is larger than UINT16_MAX. */
err = R_AGT_PeriodSet(&g_timer0_ctrl, period_counts);
assert(FSP_SUCCESS == err);
```

Clock Configuration

Pin Configuration

This module does not use I/O pins.

Usage Notes

Transfer Modes

The DMAC Module supports three modes of operation.

- **Normal Mode** - In normal mode, a single data unit is transferred every time the configured ELC event is received by the DMAC channel. A data unit can be 1-byte, 2-bytes, or 4-bytes. The source and destination addresses can be fixed, increment, decrement, or add an offset to the next data unit after each transfer. A 16-bit counter decrements after each transfer. When the counter reaches 0, transfers will no longer be triggered by the ELC event and the CPU can be interrupted to signal that all transfers have finished.
- **Repeat Mode** - Repeat mode works the same way as normal mode, however the length is limited to an integer in the range[1,1024]. When the transfer counter reaches 0, the counter is reset to its configured value, the repeat area (source or destination address) resets to its starting address and the block count remaining will decrement by 1. When the block count reaches 0, transfers will no longer be triggered by the ELC event and the CPU may be interrupted to signal that all transfers have finished.
- **Block Mode** - In block mode, the amount of data units transferred by each interrupt can be set to an integer in the range [1,1024]. The number of blocks to transfer can also be configured to a 16-bit number. After each block transfer the repeat area (source or destination address) will reset to the original address and the other address will be incremented or decremented to the next block.
- **Repeat-Block Mode** - In repeat-block mode, the amount of data units transferred by each interrupt can be set to an integer in the range [1,1024]. The number of blocks to transfer can be configured to a 16 bit number. If the destination address mode is offset mode, maximum configurable number of blocks is 0xFFFF for block size(length) of one with data transfer size as byte,0x7FFF for block size of one with data transfer size as half word and

0x3FFF for block size of one with data size as word. After each block transfer the source address and the destination address will be incremented or decremented to the next block address. In case of offset address mode for source address, the source address size is the total size of source buffer after which the source area is rolled over, block size can be smaller than the source buffer size. For source address mode as offset mode, the maximum configurable source buffer size is 0xFFFF for transfer data size of a byte, 0x7FFF for transfer data size of half word and 0x3FFF for transfer data size of word. Repeat-block mode can be used to implement single ring buffer to multiple ring buffer transfer type design.

Selecting the DTC or DMAC

The Transfer API is implemented by both DTC and the DMAC so that applications can switch between the DTC and the DMAC. When selecting between them, consider these factors:

| | DTC | DMAC |
|---------------------|---|---|
| Repeat Mode | <ul style="list-style-type: none"> Repeats forever Max repeat size is 256 x 4 bytes | <ul style="list-style-type: none"> Configurable number of repeats Max repeat size is 1024 x 4 bytes |
| Block Mode | <ul style="list-style-type: none"> Max block size is 256 x 4 bytes | <ul style="list-style-type: none"> Max block size is 1024 x 4 bytes |
| Channels | <ul style="list-style-type: none"> One instance per interrupt | <ul style="list-style-type: none"> MCU specific (8 channels or less) |
| Chained Transfers | <ul style="list-style-type: none"> Supported | <ul style="list-style-type: none"> Not Supported |
| Software Trigger | <ul style="list-style-type: none"> Must use the software ELC event | <ul style="list-style-type: none"> Has support for software trigger without using software ELC event Supports TRANSFER_START_MODE_SINGLE and TRANSFER_START_MODE_REPEAT |
| Offset Address Mode | <ul style="list-style-type: none"> Not supported | <ul style="list-style-type: none"> Supported |

Interrupts

The DTC and DMAC interrupts behave differently. The DTC uses the configured IELSR event IRQ as the interrupt source whereas each DMAC channel has its own IRQ.

The transfer_info_t::irq setting also behaves a little differently depending on which mode is selected.

Normal Mode

| | DTC | DMAC |
|-------------------|-------------------------------|-------------------------------|
| TRANSFER_IRQ_EACH | Interrupt after each transfer | N/A |
| TRANSFER_IRQ_END | Interrupt after last transfer | Interrupt after last transfer |

Repeat Mode

| | DTC | DMAC |
|--|-----|------|
|--|-----|------|

| | | |
|-------------------|-------------------------------|-------------------------------|
| TRANSFER_IRQ_EACH | Interrupt after each transfer | Interrupt after each repeat |
| TRANSFER_IRQ_END | Interrupt after each repeat | Interrupt after last transfer |

Block Mode

| | DTC | DMAC |
|-------------------|----------------------------|----------------------------|
| TRANSFER_IRQ_EACH | Interrupt after each block | Interrupt after each block |
| TRANSFER_IRQ_END | Interrupt after last block | Interrupt after last block |

Repeat-block Mode

| | DTC | DMAC |
|-------------------|-----|----------------------------|
| TRANSFER_IRQ_EACH | N/A | N/A |
| TRANSFER_IRQ_END | N/A | Interrupt after last block |

Additional Considerations

- The DTC requires a moderate amount of RAM (one `transfer_info_t` struct per open instance + `DTC_VECTOR_TABLE_SIZE`).
- The DTC stores transfer information in RAM and writes back to RAM after each transfer whereas the DMAC stores all transfer information in registers.
- When transfers are configured for more than one activation source, the DTC must fetch the transfer info from RAM on each interrupt. This can cause a higher latency between transfers.

Offset Address Mode

When the source or destination mode is configured to offset mode, a configurable offset is added to the source or destination pointer after each transfer. The offset is a signed 24 bit number.

Examples

Basic Example

This is a basic example of minimal use of the DMAC in an application. In this case, one or more events have been routed to the DMAC for handling so it only needs to be enabled to start accepting transfers.

```
void dmac_minimal_example (void)
{
    /* Open the transfer instance with initial configuration. */
    fsp_err_t err = R_DMAC_Open(&g_transfer_ctrl, &g_transfer_cfg);
    /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
    /* Enable the DMAC so that it responds to transfer requests. */
    err = R_DMAC_Enable(&g_transfer_ctrl);
}
```

```
    assert(FSP_SUCCESS == err);
}
```

CRC32 Example

In this example the DMAC is used to feed the CRC peripheral to perform a CRC32 operation.

```
volatile bool g_transfer_complete = false;
void dmac_callback (dmac_callback_args_t * cb_data)
{
    FSP_PARAMETER_NOT_USED(cb_data);
    g_transfer_complete = true;
}
void dmac_crc_example (void)
{
    uint8_t p_src[TRANSFER_LENGTH];
    /* Initialize p_src to [ABC..OP] */
    for (uint32_t i = 0; i < TRANSFER_LENGTH; i++)
    {
        p_src[i] = (uint8_t) ('A' + (i % 26));
    }
    /* Set transfer source address to p_src */
    g_transfer_cfg.p_info->p_src = (void *) p_src;
    /* Set transfer destination address to the CRC data input register */
    g_transfer_cfg.p_info->p_dest = (void *) &R_CRC->CRCDIR;
    /* Open the transfer instance with initial configuration. */
    fsp_err_t err = R_DMAMC_Open(&g_transfer_ctrl, &g_transfer_cfg);
    /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
    /* Enable DMAC transfers. */
    (void) R_DMAMC_Enable(&g_transfer_ctrl);
    /* Open the CRC module. */
    err = R_CRC_Open(&g_crc_ctrl, &g_crc_cfg);
    assert(FSP_SUCCESS == err);
    /* Clear the transfer complete flag. */
```

```
g_transfer_complete = false;
/* Trigger the transfer using software. */
err = R_DMxAC_SoftwareStart(&g_transfer_ctrl, TRANSFER_START_MODE_SINGLE);
assert(FSP_SUCCESS == err);
while (!g_transfer_complete)
{
/* Wait for transfer complete interrupt */
}
/* Get CRC result and perform final XOR. */
uint32_t crc32;
(void) R_CRC_CalculatedValueGet(&g_crc_ctrl, &crc32);
crc32 ^= CRC32_FINAL_XOR_VALUE;
/* Verify that the CRC32 is calculated correctly. */
/* CRC32("ABCD...NOP") = 0xE0E8FF4D. */
const uint32_t expected_crc32 = 0xE0E8FF4D;
if (expected_crc32 != crc32)
{
/* Handle any CRC errors. This function should be defined by the user. */
handle_crc_error();
}
}

Detailed Description

Driver for the DTC peripheral on RA MCUs. This module implements the [Transfer Interface](#).

Overview

The Data Transfer Controller (DTC) transfers data from one memory location to another without using the CPU.

The DTC uses a RAM based vector table. Each entry in the vector table corresponds to an entry in the ISR vector table. When the DTC is triggered by an interrupt, it reads the DTC vector table, fetches the transfer information, and then executes the transfer. After the transfer is executed, the DTC writes the updated transfer info back to the location pointed to by the DTC vector table.

Features

- Supports multiple transfer modes
 - Normal transfer
 - Repeat transfer
 - Block transfer
- Chain transfers
- Address increment, decrement or fixed modes
- Can be triggered by any event that has reserved a slot in the interrupt vector table.
 - Some exceptions apply, see the Event table in the Event Numbers section of the Interrupt Controller Unit chapter of the hardware manual
- Supports 1, 2, and 4 byte data units

The DTC Module supports three modes of operation.

- **Normal Mode** - In normal mode, a single data unit is transferred every time an interrupt is received by the DTC. A data unit can be 1-byte, 2-bytes, or 4-bytes. The source and destination addresses can be fixed, increment or decrement to the next data unit after each

transfer. A 16-bit counter (length) decrements after each transfer. When the counter reaches 0, transfers will no longer be triggered by the interrupt source and the CPU can be interrupted to signal that all transfers have finished.

- **Repeat Mode** - Repeat mode works the same way as normal mode, however the length is limited to an integer in the range[1,256]. When the transfer counter reaches 0, the counter is reset to its configured value and the repeat area (source or destination address) resets to its starting address and transfers will still be triggered by the interrupt.
- **Block Mode** - In block mode, the amount of data units transferred by each interrupt can be set to an integer in the range [1,256]. The number of blocks to transfer can also be configured to a 16-bit number. After each block transfer the repeat area (source or destination address) will reset to the original address and the other address will be incremented or decremented to the next block.

Note

1. The source and destination address of the transfer must be aligned to the configured data unit.
2. In normal mode the length can be set to [0,65535]. When the length is set to 0, then the transaction will execute 65536 transfers not 0.
3. In block mode, num_blocks can be set to [0,65535]. When the length is set to 0, then the transaction will execute 65536 transfers not 0.

Chaining Transfers

Multiple transfers can be configured for the same interrupt source by specifying an array of `transfer_info_t` structs instead of just passing a pointer to one. In this configuration, every `transfer_info_t` struct must be configured for a chain mode except for the last one. There are two types of chain mode; `CHAIN_MODE_EACH` and `CHAIN_MODE_END`. If a transfer is configured in `CHAIN_MODE_EACH` then it triggers the next transfer in the chain after it completes each transfer. If a transfer is configured in `CHAIN_MODE_END` then it triggers the next transfer in the chain after it completes its last transfer.

1. Counter refers to transfer_info_t.length in normal and repeat mode and transfer_info_t.num_blocks in block mode.

Figure 242: DTC Transfer Flowchart

Selecting the DTC or DMAC

The Transfer API is implemented by both DTC and the DMAC so that applications can switch between the DTC and the DMAC. When selecting between them, consider these factors:

| | DTC | DMAC |
|-------------------|---|---|
| Repeat Mode | <ul style="list-style-type: none"> Repeats forever Max repeat size is 256 x 4 bytes | <ul style="list-style-type: none"> Configurable number of repeats Max repeat size is 1024 x 4 bytes |
| Block Mode | <ul style="list-style-type: none"> Max block size is 256 x 4 bytes | <ul style="list-style-type: none"> Max block size is 1024 x 4 bytes |
| Channels | <ul style="list-style-type: none"> One instance per interrupt | <ul style="list-style-type: none"> MCU specific (8 channels or less) |
| Chained Transfers | <ul style="list-style-type: none"> Supported | <ul style="list-style-type: none"> Not Supported |
| Software Trigger | <ul style="list-style-type: none"> Must use the software ELC event | <ul style="list-style-type: none"> Has support for software trigger without using |

- software ELC event
- Supports TRANSFER_START_MODE_SINGLE and TRANSFER_START_MODE_REPEAT

Offset Address Mode

- Not supported

- Supported

Additional Considerations

- The DTC requires a moderate amount of RAM (one `transfer_info_t` struct per open instance + `DTC_VECTOR_TABLE_SIZE`).
- The DTC stores transfer information in RAM and writes back to RAM after each transfer whereas the DMAC stores all transfer information in registers.
- When transfers are configured for more than one activation source, the DTC must fetch the transfer info from RAM on each interrupt. This can cause a higher latency between transfers.
- The DTC interrupts the CPU using the activation source's IRQ. Each DMAC channel has its own IRQ.

Interrupts

The DTC and DMAC interrupts behave differently. The DTC uses the configured IELSR event IRQ as the interrupt source whereas each DMAC channel has its own IRQ.

The `transfer_info_t::irq` setting also behaves a little differently depending on which mode is selected.

Normal Mode

| | DTC | DMAC |
|-------------------|-------------------------------|-------------------------------|
| TRANSFER_IRQ_EACH | Interrupt after each transfer | N/A |
| TRANSFER_IRQ_END | Interrupt after last transfer | Interrupt after last transfer |

Repeat Mode

| | DTC | DMAC |
|-------------------|-------------------------------|-------------------------------|
| TRANSFER_IRQ_EACH | Interrupt after each transfer | Interrupt after each repeat |
| TRANSFER_IRQ_END | Interrupt after each repeat | Interrupt after last transfer |

Block Mode

| | DTC | DMAC |
|-------------------|----------------------------|----------------------------|
| TRANSFER_IRQ_EACH | Interrupt after each block | Interrupt after each block |
| TRANSFER_IRQ_END | Interrupt after last block | Interrupt after last block |

Note

$$DTC_VECTOR_TABLE_SIZE = (ICU_NVIC_IRQ_SOURCES \times 4) \text{ Bytes}$$

Peripheral Interrupts and DTC

When an interrupt is configured to trigger DTC transfers, the peripheral ISR will trigger on the

following conditions:

- Each transfer completed (transfer_info_t::irq = TRANSFER_IRQ_EACH)
- Last transfer completed (transfer_info_t::irq = TRANSFER_IRQ_END)

For example, if SCI1_RXI is configured to trigger DTC transfers and a SCI1_RXI event occurs, the interrupt will not fire until the DTC transfer is completed. If the DTC transfer_info_t::irq is configured to only interrupt on the last transfer, than no RXI interrupts will occur until the last transfer is completed.

Note

1. The DTC activation source must be enabled in the NVIC in order to trigger DTC transfers (Modules that are designed to integrate the R_DTC module will automatically handle this).
2. The DTC prioritizes activation sources by granting the smaller interrupt vector numbers higher priority. The priority of interrupts to the CPU is determined by the NVIC priority.

Low Power Modes

DTCST must be set to 0 before transitioning to any of the following:

- Module-stop state
- Software Standby mode without Snooze mode transition
- Deep Software Standby mode

Note

1. R_LPM Module stops the DTC before entering deep software standby mode and software standby without snooze mode transition.
2. For more information see 18.9 and 18.10 in the RA6M3 manual R01UH0886EJ0100.

Limitations

Developers should be aware of the following limitations when using the DTC:

- If the DTC is configured to service many different activation sources, the system could run in to performance issues due to memory contention. To address this issue, it is recommended that the DTC vector table and transfer information be moved to their own dedicated memory area (Ex: SRAM0, SRAM1, SRAMHS). This allows memory accesses from different BUS Masters (CPU, DTC, DMAC, EDMAC and Graphics IPs) to occur in parallel.

Examples

Basic Example

This is a basic example of minimal use of the DTC in an application.

```
void dtc_minimal_example (void)
{
    /* Open the transfer instance with initial configuration. */
    fsp_err_t err = R_DTC_Open(&g_transfer_ctrl, &g_transfer_cfg);

    /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
}
```

```

/* Enable the DTC to handle incoming transfer requests. */
err = R_DTC_Enable(&g_transfer_ctrl);
assert(FSP_SUCCESS == err);
}

```

Modules

Arm TrustZone Context RA Port (`rm_tz_context`)

RTOS Context Management for RA MCUs.

5.2.21.1 Arm TrustZone Context RA Port (`rm_tz_context`)

Modules » TrustZone

RTOS Context Management for RA MCUs.

Overview

Add this module to a secure TrustZone project to allow the associated non-secure project to use an RTOS. It is used by an RTOS port for RA MCUs (for example, the [FreeRTOS Port \(`rm_freertos_port`\)](#), which is automatically added to RA projects when FreeRTOS is selected during project creation).

Note

The RTOS Context Management module does not provide any interfaces to the user. To use this module to port an RTOS, consult the Arm documentation at https://arm-software.github.io/CMSIS_5/Core/html/group__context__trustzone__functions.html for further information.

Configuration

Build Time Configurations for `rm_tz_context`

The following build time configurations are defined in `fsp_cfg/rm_tz_context_cfg.h`:

| Configuration | Options | Default | Description |
|---------------------|---|---------|--|
| Process Stack Slots | Value must be a non-negative integer greater than 0 | 8 | The maximum number of threads that can allocate a secure context. For applications using FreeRTOS, the Idle task requires 1 context as well. |

| | | | |
|--------------------|--|-----|--|
| Process Stack Size | Value must be a non-negative multiple of 8 | 256 | The maximum stack size of all non-secure callable functions. |
|--------------------|--|-----|--|

Clock Configuration

This module does not use peripheral clocks.

Pin Configuration

This module does not use I/O pins.

Usage Notes

TrustZone Integration

When using an RTOS in a TrustZone project, Arm recommends keeping the RTOS in the non-secure project. Tasks may call non-secure callable functions if the task has allocated a secure context. To allocate a secure context, reference the documentation for the RTOS port used. For example, reference [TrustZone Integration](#) when FreeRTOS is used.

Sealing the Process Stack

This module seals each process stack by placing the value 0xFE5EDA5 above the stack top. For more information, refer to section 3.5 "Sealing a Stack" in "Secure software guidelines for ARMv8-M": <https://developer.arm.com/documentation/100720/0300>.

5.3.1 ADC Interface

Interfaces

Detailed Description

Interface for A/D Converters.

Summary

The ADC interface provides standard ADC functionality including one-shot mode (single scan), continuous scan and group scan. It also allows configuration of hardware and software triggers for starting scans. After each conversion an interrupt can be triggered, and if a callback function is provided, the call back is invoked with the appropriate event information.

BLE_ERR_INVALID_ARG(0x0003) The reason for this error is as follows.

- The advertising data length set to the advertising set for connectable extended advertising was invalid.
- If `o_addr_type` field in `adv_param` used in [R_BLE_GAP_SetAdvParam\(\)](#) is 0x03, the address which is set in `o_addr` field of `adv_param` has not been registered in Resolving List.

BLE_ERR_INVALID_OPERATION(0x0009) Setting of advertising data/scan response data has not been completed.

BLE_ERR_INVALID_HDL(0x000E) The advertising set specified by [R_BLE_GAP_StartAdv\(\)](#) has not been created.

This function requests for changing the maximum transmission packet size and the maximum packet transmission time. When Controller has received the request from host stack, BLE_GAP_EVENT_SET_DATA_LEN_COMP event is notified to the application layer. When the transmission packet size or the transmission time has been changed, BLE_GAP_EVENT_DATA_LEN_CHG event is notified to the application layer.

◆ R_BLE_GAP_SetPhy()

```
ble_status_t R_BLE_GAP_SetPhy ( uint16_t conn_hdl, st_ble_gap_set_phy_param_t* p_phy_param )
```

Set the phy for connection.

This function sets the PHY preferences for the connection. The result of this API call is notified in BLE_GAP_EVENT_PHY_SET_COMP event. When the PHY has been updated, BLE_GAP_EVENT_PHY_UPD event is notified to the application layer.

After PHY update, the PHY accept configuration of local device is the same as the values in BLE_GAP_EVENT_PHY_UPD event.

For example, after calling R_BLE_GAP_SetPhy(), if tx_phy, rx_phy by BLE_GAP_EVENT_PHY_UPD event are updated to 2M PHY, the PHY accept configuration is 2M PHY only.

Therefore after receiving BLE_GAP_EVENT_PHY_UPD event, if local device wants to accept the other PHY configuration, it needs to call R_BLE_GAP_SetPhy() with the desired PHY accept configuration.

Because the maximum transmission packet size or the maximum transmission time might be updated by PHY update, if the same packet size or transmission time as the previous one is desired, change the maximum transmission packet size or the maximum transmission time by R_BLE_GAP_SetDataLen().

Parameters

The following shall be applied regarding the adv_prop_type field and the data_type field in st_ble_gap_adv_param_t parameter specified in R_BLE_GAP_SetAdvParam().

- When `adv_prop_type` is Legacy Advertising PDU type,
 - it's possible to set advertising data/scan response data up to 31 bytes.
 - advertising data/scan response data can be updated by this function in advertising.
- When `adv_prop_type` is Extended Advertising PDU type,
 - it's possible to set at most 1650 bytes of data as advertising data/scan response data per 1 advertising set.
 - the total buffer size in Controller for advertising data/scan response data is 4250 bytes. Therefore please note that more than 4250 bytes of advertising data/scan response data can not be set to all the advertising sets. Please refer to Figure 1.1 and Figure 1.2 about examples of setting advertising data/scan response data.
 - it's possible to update advertising data/scan response data in advertising, if the `data_length` field in `st_ble_gap_adv_data_t` parameter is up to 251 bytes.

Figure 243: Figure 1.1

Figure 244: Figure 1.2

This function registers the OOB data received from a remote device. When oob_data_flag indicates that the OOB data has been received, the setting regarding OOB data is reflected in pairing. In order to do OOB pairing, set the OOB data received from the remote device before pairing. The result is returned from this API.

Parameters

| [in] | p_addr | The remote device address. | | | | | | |
|-------------------------------------|---|--|-------|-------------|-------------------------------------|--|--------------------------------|---|
| [in] | oob_data_flag | This parameter indicates whether the local device has received the OOB data from the remote device or not. <table border="1" data-bbox="1072 864 1468 1400"> <thead> <tr> <th>macro</th> <th>description</th> </tr> </thead> <tbody> <tr> <td>BLE_GAP_OOB_DATA_NO_T_PRESENT(0x00)</td> <td>Reply that No OOB data has been received when pairing.</td> </tr> <tr> <td>BLE_GAP_OOB_DATA_PRESENT(0x01)</td> <td>Reply that the OOB data has been received when pairing.</td> </tr> </tbody> </table> | macro | description | BLE_GAP_OOB_DATA_NO_T_PRESENT(0x00) | Reply that No OOB data has been received when pairing. | BLE_GAP_OOB_DATA_PRESENT(0x01) | Reply that the OOB data has been received when pairing. |

This function replies to a MTU Exchange Request from a remote device.

BLE_GATTS_EVENT_EX_MTU_REQ event notifies the application layer that a MTU Exchange Request has been received. Therefore when the callback has received the event, call this function.

The new MTU is the minimum of the mtu parameter specified by this function and the mtu field in BLE_GATTS_EVENT_EX_MTU_REQ event.

Default MTU size is 23 bytes.

Register prepare queue and buffer in Host Stack.

This function registers the prepare queue and buffer for long characteristic write and reliable writes. The result of this API call is returned by a return value.

Parameters

| | | |
|------|--------------|--|
| [in] | p_pre_queues | The prepare write queues to be registered. |

Function Documentation

◆ R_BLE_GATTC_Init()

```
ble_status_t R_BLE_GATTC_Init ( uint8_t cb_num)
```

This function initializes the GATT Client and registers the number of the callbacks for GATT Client event.

Specify the `cb_num` parameter to a value between 1 and `BLE_GATTC_MAX_CB`.

[R_BLE_GATTC_RegisterCb\(\)](#) registers the callback.

The result of this API call is returned by a return value.

Parameters

| | | |
|------|---------------------|---|
| [in] | <code>cb_num</code> | The number of callbacks to be registered. |
|------|---------------------|---|

Return values

| | |
|--|--|
| <code>BLE_SUCCESS(0x0000)</code> | Success |
| <code>BLE_ERR_INVALID_ARG(0x0003)</code> | The <code>cb_num</code> parameter is out of range. |

◆ **R_BLE_GATTC_RegisterCb()**

```
ble_status_t R_BLE_GATTC_RegisterCb ( ble_gattc_app_cb_t cb, uint8_t priority )
```

This function registers a callback function for GATT Client event.

The number of the callback that may be registered by this function is the value specified by [R_BLE_GATTC_Init\(\)](#).

The result of this API call is returned by a return value.

Parameters

| | | |
|------|----------|---|
| [in] | cb | Callback function for GATT Client event. |
| [in] | priority | The priority of the callback function. Valid range is $1 \leq \text{priority} \leq \text{BLE_GATTC_MAX_CB}$. A lower priority number means a higher priority level. |

Return values

| | |
|------------------------------|--|
| BLE_SUCCESS(0x0000) | Success |
| BLE_ERR_INVALID_PTR(0x0001) | The cb parameter is specified as NULL. |
| BLE_ERR_INVALID_ARG(0x0003) | The priority parameter is out of range. |

◆ **R_BLE_GATTC_ReliableWrites()**

```

st_ble_gattc_reliable_writes_char_pair_t* p_char_pair, uint8_t pair_num, uint8_t auto_flag )
```

This function performs the Reliable Writes procedure described in GATT Specification.

When the data written to the Characteristic has been transmitted, BLE_GATTC_EVENT_CHAR_PART_WRITE_RSP event is notified to the application layer. If the data included in the event is different from the data that GATT Client has sent, host stack automatically cancels the Reliable Writes.

After all of the contents has been sent to the GATT Server, if the auto_flag parameter has been set to BLE_GATTC_EXEC_AUTO, the GATT Server automatically writes the data to the Characteristic. If the auto_flag parameter has been set to BLE_GATTC_EXEC_NOT_AUTO, BLE_GATTC_EVENT_RELIABLE_WRITES_TX_COMP event notifies the application layer in GATT Client that all of the contents has been sent to the GATT Server. Then GATT Client requests for writing the data to the Characteristic to the GATT Server with R_BLE_GATTC_ExecWrite(). When the write has been done, BLE_GATTC_EVENT_RELIABLE_WRITES_COMP event is notified to the application layer.

Parameters

| [in] | conn_hdl | Connection handle identifying the GATT Server to be written. | | | | | | |
|-------------------------------|---------------------|---|-------|-------------|---------------------------|-----------------|-------------------------------|---------------------|
| [in] | p_char_pair | Pair of Characteristic Value and Characteristic Value Handle identifying the Characteristic to be written by Reliable Writes. | | | | | | |
| [in] | pair_num | The number of the pairs specified by the p_char_pair parameter. Valid range is 0 < pair_num ≤ BLE_GATTC_RELIABLE_WRITES_MAX_CHAR_PAIR. | | | | | | |
| [in] | auto_flag | The flag that indicates whether auto execution or not. <table border="1" data-bbox="1072 1570 1468 1874"> <thead> <tr> <th>macro</th> <th>description</th> </tr> </thead> <tbody> <tr> <td>BLE_GATTC_EXEC_AUTO(0x01)</td> <td>Auto execution.</td> </tr> <tr> <td>BLE_GATTC_EXEC_NOT_AUTO(0x02)</td> <td>Not auto execution.</td> </tr> </tbody> </table> | macro | description | BLE_GATTC_EXEC_AUTO(0x01) | Auto execution. | BLE_GATTC_EXEC_NOT_AUTO(0x02) | Not auto execution. |

| BLE_GATTC_EXEC_AUTO(0x01) | Auto execution. | | | | | | | |
| BLE_GATTC_EXEC_NOT_AUTO(0x02) | Not auto execution. | | | | | | | |

Return values

| BLE_ERR_INVALID_HDL(0x000E) | The GATT Server specified by conn_hdl was not found. |

◆ **R_BLE_GATTC_ExecWrite()**

```
ble_status_t R_BLE_GATTC_ExecWrite ( uint16_t conn_hdl, uint8_t exe_flag )
```

If the auto execute of Reliable Writes is not specified by [R_BLE_GATTC_ReliableWrites\(\)](#), this function is used to execute a write to Characteristic.

When all of the contents has been sent to the GATT Server, BLE_GATTC_EVENT_RELIABLE_WRITES_TX_COMP event notifies the application layer. After this event has been received, execute the write by this function. The result of the write is notified by BLE_GATTC_EVENT_RELIABLE_WRITES_COMP event.

Parameters

| [in] | conn_hdl | Connection handle identifying the target GATT Server. | | | | | | |

Function Documentation

◆ **R_BLE_L2CAP_RegisterCfPsm()**

```
ble_status_t R_BLE_L2CAP_RegisterCfPsm ( ble_l2cap_cf_app_cb_t cb, uint16_t psm, uint16_t lwm )
```

This function registers PSM that uses L2CAP CBFC Channel and a callback for L2CAP event.

Only one callback is available per PSM. Configure in each PSM the Low Water Mark of the LE-Frames that the local device can receive.

When the number of the credit reaches the Low Water Mark, BLE_L2CAP_EVENT_CF_LOW_RX_CRD_IND event is notified to the application layer.

The number of PSM is defined as BLE_L2CAP_MAX_CBFC_PSM.

The result of this API call is returned by a return value.

Parameters

Function Documentation

◆ R_BLE_VS_Init()

```
ble_status_t R_BLE_VS_Init ( ble_vs_app_cb_t vs_cb)
```

This function initializes Vendor Specific API and registers a callback function for Vendor Specific Event.

The result of this API call is returned by a return value.

Parameters

| | | |
|------|-------|-------------------------------------|
| [in] | vs_cb | Callback function to be registered. |
|------|-------|-------------------------------------|

Return values

| | |
|------------------------------|--|
| BLE_SUCCESS(0x0000) | Success |
| BLE_ERR_INVALID_PTR(0x0001) | The vs_cb parameter is specified as NULL. |
| BLE_ERR_CONTEXT_FULL(0x000B) | Callback function has already been registered. |

◆ R_BLE_VS_StartTxTest()

```
ble_status_t R_BLE_VS_StartTxTest ( st_ble_vs_tx_test_param_t * p_tx_test_param)
```

This function starts extended Transmitter Test.

The following extended transmitter test functions of DTM Tx are supported by this function.

- Tx Power
- Tx Modulation Enable/Modulation Disable
- Tx packet transmission/continuous transmission
- Tx packets count

The result of this API call is notified in BLE_VS_EVENT_TX_TEST_START event.

If the num_of_packet field in the p_tx_test_param parameter is other than 0x0000, BLE_VS_EVENT_TX_TEST_TERM event notifies the application layer that the number of packet has been sent.

If R_BLE_VS_EndTest() is called before the specified number of packets completions, BLE_VS_EVENT_TX_TEST_TERM event is not notified to the application layer.

The condition that phy field in the p_tx_test_param parameter is BLE_VS_EH_TEST_PHY_CODED_S_8(0x03) and option field is modulation(bit0:0) & continuous transmission(bit1:1) is not supported.

Parameters

| | | |
|------|-----------------|---------------------|
| [in] | p_tx_test_param | Tx Test parameters. |
|------|-----------------|---------------------|

Return values

| | |
|----------------------------------|---|
| BLE_SUCCESS(0x0000) | Success |
| BLE_ERR_INVALID_PTR(0x0001) | The p_tx_test_param parameter is specified as NULL. |
| BLE_ERR_INVALID_STATE(0x0008) | The task for host stack is not running. |

Vendor Specific API supports the flow control function(TxFlow) for the transmission on L2CAP fixed channel in Basic Mode such as GATT.

Host stack has 10 transmission packet buffers for the transmission.

When the number of the available transmission packet buffers has been less than Low Water Mark, the state of TxFlow transmits into the TxFlow OFF state from the TxFlow ON state that is the initial state and host stack notifies the application layer of timing to stop packet transmission.

When host stack has sent the transmission packets to Controller and the number of the available transmission packet buffers has been more than High Water Mark, the state of TxFlow transmits into the TxFlow ON state from the TxFlow OFF state and host stack notifies the application layer of

timing to restart packet transmission.

It is possible to perform flow control on a fixed channel by using the event notification.

Parameters

| | | |
|------|--------------|---|
| [in] | tx_queue_lwm | Low Water Mark. Set 0-9 less than tx_queue_hwm to the parameter. When the number of the available transmission packet buffers has been less than the value specified by the tx_queue_lwm parameter, host stack notifies the application layer of the timing to stop packet transmission. |
| [in] | tx_queue_hwm | High Water Mark. Set 1-10 more than tx_queue_lwm to the parameter. When the number of the available transmission packet buffers has been more than the value specified by the tx_queue_hwm parameter, host stack notifies the application layer of the timing to restart packet transmission. |

Return values

| | |
|-----------------------------|---|

5.3.23 CGC Interface

Interfaces

Detailed Description

Interface for clock generation.

Summary

The CGC interface provides the ability to configure and use all of the CGC module's capabilities. Among the capabilities is the selection of several clock sources to use as the system clock source. Additionally, the system clocks can be divided down to provide a wide range of frequencies for various system and peripheral needs.

Clock stability can be checked and clocks may also be stopped to save power when not needed. The API has a function to return the frequency of the system and system peripheral clocks at run time. There is also a feature to detect when the main oscillator has stopped, with the option of calling a user provided callback function.

The CGC interface is implemented by:

5.3.24 CRC Interface

Interfaces

Detailed Description

Interface for cyclic redundancy checking.

Summary

The CRC (Cyclic Redundancy Check) calculator generates CRC codes using five different polynomials including 8 bit, 16 bit, and 32 bit variations. Calculation can be performed by sending data to the block using the CPU or by snooping on read or write activity on one of 10 SCI channels.

| [in] | p_data | Pointer to a buffer to write. |
| [in] | length | Number of bytes to transfer. |
| [in] | restart | If true, issue a repeated-start after the transfer is completed (Master only). |

◆ read

```
fsp_err_t(* i3c_api_t::read) (i3c_ctrl_t *const p_ctrl, uint8_t *const p_data, uint32_t length, bool restart)
```

In master mode: Start a read transfer. When the transfer is completed, send a stop condition or a repeated-start. In slave mode: Set the read buffer for storing data read during the transfer. When the buffer is full, the application will receive a callback requesting a new read buffer. If no buffer is provided by the application, the driver will discard any remaining bytes read during the transfer.

Implemented as

- [R_I3C_Read\(\)](#)

Parameters

| | | |
|------|---------|--|
| [in] | p_ctrl | Control block set in i3c_api_t::open call for this instance. |

Field Documentation

◆ open

`fsp_err_t(* jpeg_api_t::open) (jpeg_ctrl_t *const p_ctrl, jpeg_cfg_t const *const p_cfg)`

Initial configuration

Implemented as

- `R_JPEG_Open()`

Precondition

none

Parameters

| | | |
|----------|---------------------|---|
| [in,out] | <code>p_ctrl</code> | Pointer to control block. Must be declared by user. Elements set here. |
| [in] | <code>p_cfg</code> | Pointer to configuration structure. All elements of this structure must be set by user. |

◆ inputBufferSet

```
fsp_err_t(* jpeg_api_t::inputBufferSet) (jpeg_ctrl_t *const p_ctrl, void *p_buffer, uint32_t buffer_size)
```

Assign input data buffer to JPEG codec.

Implemented as

- R_JPEG_InputBufferSet()

Precondition

the JPEG codec module must have been opened properly.

Note

The buffer starting address must be 8-byte aligned.

Parameters

| | | |
|------|-------------|---|
| [in] | p_ctrl | Control block set in jpeg_api_t::open call. |
| [in] | p_buffer | Pointer to the input buffer space |
| [in] | buffer_size | Size of the input buffer |

◆ outputBufferSet

```
fsp_err_t(* jpeg_api_t::outputBufferSet) (jpeg_ctrl_t *const p_ctrl, void *p_buffer, uint32_t buffer_size)
```

Assign output buffer to JPEG codec for storing output data.

Implemented as

- R_JPEG_OutputBufferSet()

Precondition

The JPEG codec module must have been opened properly.

Note

The buffer starting address must be 8-byte aligned. For the decoding process, the HLD driver automatically computes the number of lines of the image to decoded so the output data fits into the given space. If the supplied output buffer is not able to hold the entire frame, the application should call the Output Full Callback function so it can be notified when additional buffer space is needed.

Parameters

| | | |
|------|-------------|---|
| [in] | p_ctrl | Control block set in jpeg_api_t::open call. |
| [in] | p_buffer | Pointer to the output buffer space |
| [in] | buffer_size | Size of the output buffer |

◆ **statusGet**

```
fsp_err_t(* jpeg_api_t::statusGet) (jpeg_ctrl_t *const p_ctrl, jpeg_status_t *const p_status)
```

Retrieve current status of the JPEG codec module.

Implemented as

- [R_JPEG_StatusGet\(\)](#)

Precondition

the JPEG codec module must have been opened properly.

Parameters

| | | |
|-------|----------|---|
| [in] | p_ctrl | Control block set in jpeg_api_t::open call. |
| [out] | p_status | JPEG module status |

◆ **close**

```
fsp_err_t(* jpeg_api_t::close) (jpeg_ctrl_t *const p_ctrl)
```

Cancel an outstanding operation.

Implemented as

- [R_JPEG_Close\(\)](#)

Precondition

the JPEG codec module must have been opened properly.

Note

If the encoding or the decoding operation is finished without errors, the HLD driver automatically closes the device. In this case, application does not need to explicitly close the JPEG device.

Parameters

| | | |
|------|--------|---|
| [in] | p_ctrl | Control block set in jpeg_api_t::open call. |
|------|--------|---|

◆ **horizontalStrideSet**

```
fsp_err_t(* jpeg_api_t::horizontalStrideSet) (jpeg_ctrl_t *const p_ctrl, uint32_t horizontal_stride)
```

Configure the horizontal stride value.

Implemented as

- [R_JPEG_DecodeHorizontalStrideSet\(\)](#)

Precondition

The JPEG codec module must have been opened properly.

Parameters

| | | |
|------|-------------------|--|
| [in] | p_ctrl | Control block set in jpeg_api_t::open call. |
| [in] | horizontal_stride | Horizontal stride value to be used for the decoded image data. |

5.3.50 Key Matrix Interface

Interfaces

Detailed Description

Interface for key matrix functions.

Summary

The KEYMATRIX interface provides standard Key Matrix functionality including event generation on a rising or falling edge for one or more channels at the same time. The generated event indicates all channels that are active in that instant via a bit mask. This allows the interface to be used with a matrix configuration or a one-to-one hardware implementation that is triggered on either a rising or a falling edge.

Field Documentation

◆ open

`fsp_err_t(* smci_api_t::open) (smci_ctrl_t *const p_ctrl, smci_cfg_t const *const p_cfg)`

Open Smart Card Interface Mode (SMCI)

Implemented as

- `R_SCI_SMCI_Open()`

Parameters

| | | |
|----------|-------------------------|--|
| [in,out] | <code>p_ctrl</code> | Pointer to the SMCI control block. Must be declared by user. Value set here. |
| [in] | <code>smci_cfg_t</code> | Pointer to SMCI configuration structure. All elements of this structure must be set by user. |

◆ read

```
fsp_err_t(* smci_api_t::read) (smci_ctrl_t *const p_ctrl, uint8_t *const p_dest, uint32_t const bytes)
```

Read from Smart Card device. The read buffer is used until the read is complete. When a transfer is complete, the callback is called with event SMCI_EVENT_RX_COMPLETE. Bytes received outside an active transfer are received in the callback function with event SMCI_EVENT_RX_CHAR.

Implemented as

- R_SCI_SMCI_Read()

Parameters

| | | |
|------|--------|--|
| [in] | p_ctrl | Pointer to the SMCI control block for the channel. |

```
fsp_err_t(* smci_api_t::write) (smci_ctrl_t *const p_ctrl, uint8_t const *const p_src, uint32_t const bytes)
```

Write to Smart Card device. The write buffer is used until write is complete. Do not overwrite write buffer contents until the write is finished. When the write is complete (all bytes are fully transmitted on the wire), the callback called with event SMCI_EVENT_TX_COMPLETE.

Implemented as

- R_SCI_SMCI_Write()

5.3.78 Timer Interface

Interfaces

Detailed Description

Interface for timer functions.

Summary

The general timer interface provides standard timer functionality including periodic mode, one-shot mode, PWM output, and free-running timer mode. After each timer cycle (overflow or underflow), an interrupt can be triggered.

If an instance supports output compare mode, it is provided in the extension configuration `timer_on_<instance>_cfg_t` defined in `r_<instance>.h`.

Implemented by:

- Timer, General PWM (`r_gpt`)
- Timer, Low-Power (`r_agt`)

Enumeration Type Documentation

◆ **transfer_mode_t**

| enum <code>transfer_mode_t</code> | |
|--|--|
| Transfer mode describes what will happen when a transfer request occurs. | |
| Enumerator | |
| <code>TRANSFER_MODE_NORMAL</code> | In normal mode, each transfer request causes a transfer of <code>transfer_size_t</code> from the source pointer to the destination pointer. The transfer length is decremented and the source and address pointers are updated according to <code>transfer_addr_mode_t</code> . After the transfer length reaches 0, transfer requests will not cause any further transfers. |
| <code>TRANSFER_MODE_REPEAT</code> | Repeat mode is like normal mode, except that when the transfer length reaches 0, the pointer to the repeat area and the transfer length will be reset to their initial values. If DMAC is used, the transfer repeats only <code>transfer_info_t::num_blocks</code> times. After the transfer repeats <code>transfer_info_t::num_blocks</code> times, transfer requests will not cause any further transfers. If DTC is used, the transfer repeats continuously (no limit to the number of repeat transfers). |
| <code>TRANSFER_MODE_BLOCK</code> | In block mode, each transfer request causes <code>transfer_info_t::length</code> transfers of <code>transfer_size_t</code> . After each individual transfer, the source and destination pointers are updated according to <code>transfer_addr_mode_t</code> . After the block transfer is complete, <code>transfer_info_t::num_blocks</code> is decremented. After the <code>transfer_info_t::num_blocks</code> reaches 0, transfer requests will not cause any further transfers. |
| <code>TRANSFER_MODE_REPEAT_BLOCK</code> | In addition to block mode features, repeat-block mode supports a ring buffer of blocks and offsets within a block (to split blocks into arrays of their first data, second data, etc.) |

◆ **transfer_size_t**

| enum transfer_size_t | |
|--|---|
| Transfer size specifies the size of each individual transfer. Total transfer length = <code>transfer_size_t * transfer_length_t</code> | |
| Enumerator | |
| TRANSFER_SIZE_1_BYTE | Each transfer transfers a 8-bit value. |
| TRANSFER_SIZE_2_BYTE | Each transfer transfers a 16-bit value. |
| TRANSFER_SIZE_4_BYTE | Each transfer transfers a 32-bit value. |

◆ **transfer_addr_mode_t**

| enum transfer_addr_mode_t | |
|--|---|
| Address mode specifies whether to modify (increment or decrement) pointer after each transfer. | |
| Enumerator | |
| TRANSFER_ADDR_MODE_FIXED | Address pointer remains fixed after each transfer. |
| TRANSFER_ADDR_MODE_OFFSET | Offset is added to the address pointer after each transfer. |
| TRANSFER_ADDR_MODE_INCREMENTED | Address pointer is incremented by associated transfer_size_t after each transfer. |
| TRANSFER_ADDR_MODE_DECREMENTED | Address pointer is decremented by associated transfer_size_t after each transfer. |

◆ **transfer_repeat_area_t**

| enum transfer_repeat_area_t | |
|--|--|
| Repeat area options (source or destination). In TRANSFER_MODE_REPEAT , the selected pointer returns to its original value after transfer_info_t::length transfers. In TRANSFER_MODE_BLOCK and TRANSFER_MODE_REPEAT_BLOCK , the selected pointer returns to its original value after each transfer. | |
| Enumerator | |
| TRANSFER_REPEAT_AREA_DESTINATION | Destination area repeated in TRANSFER_MODE_REPEAT or TRANSFER_MODE_BLOCK or TRANSFER_MODE_REPEAT_BLOCK . |
| TRANSFER_REPEAT_AREA_SOURCE | Source area repeated in TRANSFER_MODE_REPEAT or TRANSFER_MODE_BLOCK or TRANSFER_MODE_REPEAT_BLOCK . |

◆ **transfer_chain_mode_t**

| enum transfer_chain_mode_t | |
|--|--|
| Chain transfer mode options. | |
| <i>Note</i> <i>Only applies for DTC.</i> | |
| Enumerator | |
| TRANSFER_CHAIN_MODE_DISABLED | Chain mode not used. |
| TRANSFER_CHAIN_MODE_EACH | Switch to next transfer after a single transfer from this transfer_info_t . |
| TRANSFER_CHAIN_MODE_END | Complete the entire transfer defined in this transfer_info_t before chaining to next transfer. |

◆ **transfer_irq_t**

| enum <code>transfer_irq_t</code> | |
|----------------------------------|--|
| Interrupt options. | |
| Enumerator | |
| TRANSFER_IRQ_END | <p>Interrupt occurs only after last transfer. If this transfer is chained to a subsequent transfer, the interrupt will occur only after subsequent chained transfer(s) are complete.</p> <p>Warning DTC triggers the interrupt of the activation source. Choosing TRANSFER_IRQ_END with DTC will prevent activation source interrupts until the transfer is complete.</p> |
| TRANSFER_IRQ_EACH | <p>Interrupt occurs after each transfer.</p> <p><i>Note</i> <i>Not available in all HAL drivers. See HAL driver for details.</i></p> |

◆ **transfer_start_mode_t**

| enum <code>transfer_start_mode_t</code> | |
|--|---|
| Select whether to start single or repeated transfer with software start. | |
| Enumerator | |
| TRANSFER_START_MODE_SINGLE | Software start triggers single transfer. |
| TRANSFER_START_MODE_REPEAT | Software start transfer continues until transfer is complete. |
