# Usage Notes

### Usage Notes for xSPI support

After R_OSPI_B_Open() completes successfully, the xSPI device contents are mapped to the appropriate external memory regions for each OSPI_B unit. For example, on the RA8M1, R_OSPI_B0 maps the CS0 device to address 0x80000000 and the CS1 device to address 0x90000000. After opening, the addresses can be accessed like on-chip flash.

Bank CS0 and CS1 support up to 256 MB of address space each depending on the platform.

### Auto-calibration

If support is enabled, auto-calibration procedures are triggered automatically when the 'Data latching delay' field in the configurator properties is set to 0. The user application is responsible for setting the appropriate preamble pattern before calling R_OSPI_B_Open() when using a data strobe (DS) mode or changing the SPI protocol to a DS mode using the R_OSPI_B_SpiProtocolSet() API. The appropriate preamble pattern can be written to the desired address using the R_OSPI_B_Write() API while in simple SPI mode (recommended), or a non-DS mode. Ensure that the same address is passed through the configurator. If the xSPI device is already in a DS mode, the preamble pattern must be programmed using the debugger before calling R_OSPI_B_Open().

The preamble pattern is expected to be { 0x00, 0x00, 0xFF, 0xFF, 0xFF, 0x00, 0x08, 0x00, 0x00, 0xF7, 0xFF, 0x00, 0x08, 0xF7, 0x00, 0xF7 }.

The autocalibration pattern can be added directly to the binary using the linker script. Please see Programming the Auto-calibration Pattern Using the Linker for an example using LLVM.

### Chip Select Latencies

Chip select latencies can be set through the configurator. The default settings support SPI at minimum latency. In case the driver is opened in SPI mode and will be switched to DOPI mode later using R_OSPI_B_SpiProtocolSet(), please select latencies required for DOPI before calling R_OSPI_B_Open().

### XiP Support

OSPI_B supports eXecute in Place (XiP) modes of operation. This can be used for read-only memory-mapped accesses to reduce overall read latency by skipping the command sequence in the xSPI transaction. Separate XiP enter and exit codes may be specified for either attached target device. Upon calling R_OSPI_B_XipEnter(), the associated memory region for the target device is switched to read-only mode and the enter code sent to the device. Calling R_OSPI_B_XipExit() will transmit the

exit code and transition the memory region back to read-write access.

Only one flash device should be used after entering XiP mode. Once entered, XiP codes will be transmitted to all attached devices.

### xSPI Commands

Command sets and erase commands may be specified individually for each supported protocol mode. By default, the configurator only supports an alternative command set for "High-Speed Mode" (DOPI 8D-8D-8D) mode. The command sets cannot be changed during run-time, but the appropriate command set will be selected when changing protocol modes. If a command set is not found, an FSP_ERR_INVALID_MODE error code will be returned.

If custom DOPI erase commands are not specified, ensure the erase commands are the appropriate 2-byte DOPI commands. The lower byte will be used for 1-byte command protocols.

### DOTF Support

Decryption-On-The-Fly is configurable for OSPI Flash and is disabled from the build by default.

Using the DOTF feature requires first creating the encrypted blob on the PC and then configuring the DOTF module with the appropriate parameters to allow decryption of the blob once it is programmed into OSPI. Use the Security Key Management Tool (https://www.renesas.com/us/en/software-tool/security-key-management-tool) to create the encrypted blob.

Example: To encrypt a 4096 byte area in a input srec file from 0x90000000 to 0x90000FFF using a 128 AES encryption key FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF and IV 00000000000000000000000000000000 use SKMT with the following arguments:

```
skmt.exe /encdotf /keytype "AES-128" /enckey "FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF"
/nonce "00000000000000000000000000000000" /startaddr "90000000" /endaddr "90000FFF"
/prg "input.srec" /incplain /output "encrypted_output.srec"
```

The values for key, iv and decryption area start and end addresses that were used to create the blob using SKMT must be set in the DOTF configuration in FSP.

Make sure that the Key and IV passed into DOTF configuration are 4 byte aligned. This can be done using a compiler alignment attribute as shown below:

```
uint8_t aes_key[] __attribute__((aligned(4))) =
{
    0x00, 0x01, 0x02, 0x03, 0x04, 0x05, 0x06, 0x07, 0x08, 0x09, 0x0a, 0x0b, 0x0c,
0x0d, 0x0e, 0x0f,
    0x10, 0x11, 0x12, 0x13, 0x14, 0x15, 0x16, 0x17, 0x18, 0x19, 0x1a, 0x1b, 0x1c,
0x1d, 0x1e, 0x1f
};
```

### Supported Key Formats

- When the Compatibility Mode stack is added for the crypto engine, the user can provide either a wrapped or plaintext AES key to the DOTF module.
- When the Protected Mode stack is used, only wrapped keys are supported.

When configuring the DOTF options, make sure that the key format is specified.

*Note*

***For a detailed description of the Crypto Engine operating modes, refer to Application Note R11AN0498.***

### SiP Flash

SiP or System-in-Package devices, can contain an internally bonded OSPI flash memory in the package. The BSP supports startup initialization of SiP flash memories using the R_OSPI_B driver. To enable startup initialization, please select an appropriate stack under Storage > SiP Flash and enable the following properties in the BSP section of the configurator: OSPI > SiP Flash Support and RA Common > Early BSP Initialization. Both of these BSP properties must be enabled for successful SiP flash startup and initialization of other memory regions (e.g. RAM) which load data from the SiP flash.

## Limitations

Developers should be aware of the following limitations when using the OSPI_B driver:

### OSPI_B

- The R_OSPI_B driver expects memory devices to have uniform sector sizes. If a design requires using a memory with non-uniform sectors, the end-user application must appropriately manage sectors.
- Prefetch and combination support for memory-mapped access is applied globally to all slave devices per OSPI_B unit.
- Combination writes are limited to a maximum of 64 bytes. The user should verify the write has completed before attempting to write more bytes.
- Writing to the memory-mapped regions with the CPU is restricted to 64-bit accesses with 8-byte destination alignments. This restriction is not applicable to other bus masters (e.g. DTC or DMAC).
- When using Arm LLVM ensure any read-only (const) data used with R_OSPI_B_Write() is word (4-byte) aligned if the DMAC is not being used. If parameter checking is enabled, the source pointer alignment will be verified for calls to R_OSPI_B_Write().
- Take care to restrict concurrent accesses of the OSPI memory area. Collisions on the bus can occur if other bus masters attempt to write to the OSPI memory area while another master is reading the OSPI memory area.
- When using 8D-8D-8D mode, care should be taken to access on even-aligned addresses. Problems may occur if odd address alignment is used. This restriction applies to all bus masters using OSPI_B.
- DOTF: AES-192 is not supported when the Protected Mode stack is used.
- When using the IAR compiler, OSPI data must be const qualified to be downloaded by the debugger.
- Memories which use row-column addressing must be managed by the end-user application to ensure the appropriate memory row is loaded and stored.
- When using SiP Flash with encrypted data, the encryption key and IV must be const qualified if BSP startup initialization is used. The SiP flash is initialized before the C-runtime

has been initialized and before any RAM variables have been loaded from their respective non-volatile memories.
- When using SiP Flash, secure partitions must be 32K aligned or programming and access may fail.

### Reading Status Register Example (R_OSPI_B_DirectTransfer)

This is an example of using R_OSPI_B_DirectWrite followed by R_OSPI_B_DirectRead to send the read status register command and read back the status register from the device.

```
#define OSPI_B_COMMAND_READ_STATUS_REGISTER (0x05U)

       .command_length = 1U,

    {

    }
```

}

### Auto-calibration Example (R_OSPI_B_DirectTransfer, R_OSPI_B_Write, R_OSPI_B_SpiProtocolSet)

This is an example of using R_OSPI_B_SpiProtocolSet to change the operating mode from SPI to DOPI and allow the driver to initiate auto-calibration.

```
#define OSPI_B_DOPI_PREAMBLE_PATTERN_LENGTH_BYTES (16U)
#define OSPI_B_EXAMPLE_PREAMBLE_ADDRESS (0x90000000U) /* Device connected to CS1 */
const uint8_t g_preamble_bytes[OSPI_B_DOPI_PREAMBLE_PATTERN_LENGTH_BYTES] =
{
    0x00, 0x00, 0xFF, 0xFF, 0xFF, 0x00, 0x08, 0x00, 0x00, 0xF7, 0xFF, 0x00, 0x08,
0xF7, 0x00, 0xF7
};
static void ospi_b_wait_until_wip (void)
{
 fsp_err_t          err = FSP_SUCCESS;
 spi_flash_status_t status;
    status.write_in_progress = true;
    uint32_t timeout = UINT32_MAX;
 while ((status.write_in_progress) && (--timeout))
    {
       err = R_OSPI_B_StatusGet(&g_ospi0_ctrl, &status);
      assert(FSP_SUCCESS == err);
    }
 if (0 == timeout)
    {
      assert(FSP_SUCCESS == err);
    }
}
void r_ospi_b_auto_calibrate_example (void)
{
 /* Open the OSPI instance. */
 /* Set data_latch_delay_clocks to 0x0 to enable auto-calibration */
 fsp_err_t err = R_OSPI_B_Open(&g_ospi0_ctrl, &g_ospi0_cfg);
```

```
    assert(FSP_SUCCESS == err);
    uint8_t * preamble_pattern_addr = (uint8_t *) OSPI_B_EXAMPLE_PREAMBLE_ADDRESS;
    err = R_OSPI_B_Write(&g_ospi0_ctrl, g_preamble_bytes, preamble_pattern_addr,
OSPI_B_EXAMPLE_PREAMBLE_ADDRESS);
    assert(FSP_SUCCESS == err);
 /* Wait until write has been completed */
    ospi_b_wait_until_wip();
 /* Change from SPI to DOPI mode */
    ospi_b_change_mode(SPI_FLASH_PROTOCOL_8D_8D_8D);
}
```

### Programming the Auto-calibration Pattern Using the Linker

This is an example of an LLVM LLD linker script which places the auto-calibration pattern into the application binary. For the purposes of this example, the pattern is placed in the second 4K subsector of an ISSI IS25WX memory used on RA8 SiP MCUs.

```
INCLUDE memory_regions.lld
INCLUDE fsp_gen.lld
/* Place the autocalibration pattern in the second 4K subsector. */
OSPI_AUTOCAL_ADDR = SIP_FLASH_START + 0x1000;
SECTIONS
{
    __sip_flash_autocal$$ : AT(OSPI_AUTOCAL_ADDR)
    {
       __sip_flash_autocal$$Base = .;
       LONG(0xFFFF0000)
       LONG(0x000800FF)
       LONG(0x00FFF700)
       LONG(0xF700F708)
       __sip_flash_autocal$$Limit = .;
    }> SIP_FLASH
} INSERT BEFORE .sip_flash.endof;
```

### OctaClk Update Example (R_OSPI_B_SpiProtocolSet)

This is an example of using R_BSP_OctaclkUpdate to change the Octal-SPI clock frequency during run time. The OCTACLK frequency must be updated before calling the R_OSPI_B_SpiProtocolSet with appropriate clock source and divider settings required to be set for the new SPI protocol mode. Ensure that the clock source selected is started.

```
/*
 * Changes the OCTACLK divider; assumes PLL2 is being used as the source for OCTACLK.
 * @param divider New clock divider to switch to.
 */
static void ospi_b_change_omclk (bsp_clocks_octaclk_div_t divider)
{
 /* Ensure clock source (PLL2 in this example) is running before changing the OCTACLK
frequency */
    bsp_octaclk_settings_t octaclk_settings;
    octaclk_settings.source_clock = BSP_CLOCKS_CLOCK_PLL2;
    octaclk_settings.divider      = divider;
    R_BSP_OctaclkUpdate(&octaclk_settings);
}
```

### Using a Custom xSPI Command Set Example

This is an example of using custom command sets for 8D-8D-8D and 4S-4S-4S protocol modes.

```
/* Custom two-byte erase commands. */

},
    {.command = OSPI_B_COMMAND_SECTOR_ERASE_DOPI_MODE, .size =
OSPI_B_SECTOR_ERASE_SIZE     },
    {.command = OSPI_B_COMMAND_CHIP_ERASE_DOPI_MODE, .size =
SPI_FLASH_ERASE_SIZE_CHIP_ERASE},
};
ospi_b_table_t g_2B_erase_table =
{
    .p_table = g_2B_erase_commands,
    .length = (uint8_t) (sizeof(g_2B_erase_commands) / sizeof
```

```
(g_2B_erase_commands[0])),
};
/* Custom command sets. */
ospi_b_xspi_command_set_t g_command_sets[] =
{
 /* 8D-8D-8D example with inverted lower command byte. */
    {

    },

    {
        .protocol             = SPI_FLASH_PROTOCOL_4S_4S_4S,
        .command_bytes       = OSPI_B_COMMAND_BYTES_1,

# Configuration

### Build Time Configurations for r_qspi

The following build time configurations are defined in driver/r_qspi_cfg.h:

| Configuration | Options | Default | Description |
|---|---|---|---|
| Parameter Checking | • Default (BSP)<br>• Enabled<br>• Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |
| Support Multiple Line Program in Extended SPI Mode | • Enabled<br>• Disabled | Disabled | If selected code for programming on multiple lines in extended SPI mode is |

included in the build.

### Configurations for Storage > QSPI (r_qspi)

This module can be added to the Stacks tab via New Stack > Storage > QSPI (r_qspi).

| Configuration | Options | Default | Description |
|---|---|---|---|
| General | | | |
| Name | Name must be a valid C symbol | g_qspi0 | Module name. |
| SPI Protocol | • Extended SPI<br>• QPI | Extended SPI | Select the initial SPI protocol. SPI protocol can be changed in R_QSPI_Direct(). |
| Address Bytes | • 3<br>• 4<br>• 4 with 4-byte read code | 3 | Select the number of address bytes. Selecting '4 with 4-byte read code' converts the default read code determined in Read Mode to the 4-byte version. If 4-byte mode is selected without using 4-byte commands, the application must issue the EN4B command using R_QSPI_Direct(). |
| Read Mode | • Standard Read<br>• Fast Read<br>• Fast Read Dual Output<br>• Fast Read Dual I/O<br>• Fast Read Quad Output<br>• Fast Read Quad I/O | Fast Read Quad I/O | Select the read mode for memory mapped access. |
| Dummy Clocks for Fast Read | Refer to the RA Configuration tool for available options. | Default | Select the number of dummy clocks for fast read operations. Default is 6 clocks for Fast Read Quad I/O, 4 clocks for Fast Read Dual I/O, and 8 clocks for other fast read instructions including Fast Read Quad Output, Fast Read Dual Output, and Fast Read |

The QSPI clock is derived from PCLKA.

### Pin Configuration

The following pins are available to connect to an external QSPI device:

- QSPCLK: QSPI clock output
- QSSL: QSPI slave select
- QIO0: Data 0 I/O
- QIO1: Data 1 I/O
- QIO2: Data 2 I/O

- QIO3: Data 3 I/O

*Note*

*It is recommended to configure the pins with IOPORT_CFG_DRIVE_HIGH.*

# Usage Notes

### QSPI Memory Mapped Access

After R_QSPI_Open() completes successfully, the QSPI flash device contents are mapped to address 0x60000000 and can be read like on-chip flash.

### Limitations

Developers should be aware of the following limitations when using the QSPI driver:

- Only P305-P310 are currently supported by the J-Link driver to flash the QSPI.
- The default J-Link downloader requires the device to be in extended SPI mode (not QPI mode).

# Examples

### Basic Example

This is a basic example of minimal use of the QSPI in an application.

```
#define QSPI_EXAMPLE_DATA_LENGTH (1024)
uint8_t g_dest[QSPI_EXAMPLE_DATA_LENGTH];
/* Place data in the .qspi_flash section to flash it during programming. */
const uint8_t g_src[QSPI_EXAMPLE_DATA_LENGTH] BSP_PLACE_IN_SECTION(".qspi_flash") =
"ABCDEFGHIJKLMNOPQRSTUVWXYZ";
/* Place code in the .qspi_flash_code section to flash it during programming. */
void r_qspi_example_function(void) BSP_PLACE_IN_SECTION(".qspi_flash_code")
__attribute__((noinline));
void r_qspi_example_function (void)
{
 /* Add code here. */
}
void r_qspi_basic_example (void)
{
 /* Open the QSPI instance. */
 fsp_err_t err = R_QSPI_Open(&g_qspi0_ctrl, &g_qspi0_cfg);
    assert(FSP_SUCCESS == err);
```

```
 /* (Optional) Send device specific initialization commands. */
    r_qspi_example_init();
 /* After R_QSPI_Open() and any required device specific intiialization, data can be
read directly from the QSPI flash. */
    memcpy(&g_dest[0], &g_src[0], QSPI_EXAMPLE_DATA_LENGTH);
 /* After R_QSPI_Open() and any required device specific intiialization, functions in
the QSPI flash can be called. */
    r_qspi_example_function();
}
```

### Initialization Command Structure Example

This is an example of the types of commands that can be used to initialize the QSPI.

```
#define QSPI_COMMAND_WRITE_ENABLE (0x06U)
#define QSPI_COMMAND_WRITE_STATUS_REGISTER (0x01U)
#define QSPI_COMMAND_ENTER_QPI_MODE (0x38U)
#define QSPI_EXAMPLE_STATUS_REGISTER_1 (0x40)
#define QSPI_EXAMPLE_STATUS_REGISTER_2 (0x00)
static void r_qspi_example_init (void)
{
 /* Write status registers */
 /* Write one byte to enable writing to the status register, then deassert QSSL. */
    uint8_t   data[4];
 fsp_err_t err;
    data[0] = QSPI_COMMAND_WRITE_ENABLE;
    err    = R_QSPI_DirectWrite(&g_qspi0_ctrl, &data[0], 1, false);
    assert(FSP_SUCCESS == err);
 /* Write 3 bytes, including the write status register command followed by values for
both status registers. In the
  * status registers, set QE to 1 and other bits to their default setting. After all
data is written, deassert the
  * QSSL line. */
    data[0] = QSPI_COMMAND_WRITE_STATUS_REGISTER;
    data[1] = QSPI_EXAMPLE_STATUS_REGISTER_1;
```

```
    data[2] = QSPI_EXAMPLE_STATUS_REGISTER_2;
    err    = R_QSPI_DirectWrite(&g_qspi0_ctrl, &data[0], 3, false);
    assert(FSP_SUCCESS == err);
 /* Wait for status register to update. */
 spi_flash_status_t status;
 do
    {
       (void) R_QSPI_StatusGet(&g_qspi0_ctrl, &status);
    } while (true == status.write_in_progress);
 /* Write one byte to enter QSPI mode, then deassert QSSL. After entering QPI mode on
the device, change the SPI
  * protocol to QPI mode on the MCU peripheral. */
    data[0] = QSPI_COMMAND_ENTER_QPI_MODE;
    err    = R_QSPI_DirectWrite(&g_qspi0_ctrl, &data[0], 1, false);
    assert(FSP_SUCCESS == err);
    (void) R_QSPI_SpiProtocolSet(&g_qspi0_ctrl, SPI_FLASH_PROTOCOL_QPI);
}
```

### Reading Status Register Example (R_QSPI_DirectWrite, R_QSPI_DirectRead)

```
#define QSPI_COMMAND_READ_STATUS_REGISTER (0x05U)
void r_qspi_direct_example (void)
{
 /* Read a status register. */
 /* Write one byte to read the status register. Do not deassert QSSL. */
    uint8_t   data;
 fsp_err_t err;
    data = QSPI_COMMAND_READ_STATUS_REGISTER;
    err = R_QSPI_DirectWrite(&g_qspi0_ctrl, &data, 1, true);
    assert(FSP_SUCCESS == err);
 /* Read one byte. After all data is read, deassert the QSSL line. */
    err = R_QSPI_DirectRead(&g_qspi0_ctrl, &data, 1);
```

```
    assert(FSP_SUCCESS == err);
 /* Status register contents are available in variable 'data'. */
}
```

### Configurations for Storage > SD/MMC (r_sdhi)

This module can be added to the Stacks tab via New Stack > Storage > SD/MMC (r_sdhi). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|---|---|---|---|
| Name | Name must be a valid C symbol | g_sdmmc0 | Module name. |

| | | | |
|---|---|---|---|
| Channel | Value must be a non-negative integer | 0 | Select the channel. |
| Bus Width | MCU Specific Options | | Select the bus width. |
| Card Detection | • Not Used<br>• CD Pin | CD Pin | Select the card detection method. |
| Write Protection | • Not Used<br>• WP Pin | WP Pin | Select whether or not to use the write protect pin. Select Not Used if the MCU or device does not have a write protect pin. |
| Callback | Name must be a valid C symbol | NULL | A user callback function can be provided. If this callback function is provided, it will be called from the interrupt service routine (ISR). |
| Access Interrupt Priority | MCU Specific Options | | Select the access interrupt priority. |
| Card Interrupt Priority | MCU Specific Options | | Select the card interrupt priority. |
| DTC Interrupt Priority | MCU Specific Options | | Select the DTC interrupt priority. |

**Interrupt Configurations:**

The following interrupts are required to use the r_sdhi module:

Using SD/MMC with DTC:

- Access Interrupt
- DTC Interrupt

Using SD/MMC with DMAC:

- Access Interrupt
- DMAC Interrupt (in DMAC instance)

The Card interrupt is optional and only available on MCU packages that have the SDnCD pin (n = channel number).

**Clock Configuration**

The SDMMC MCU peripheral (SDHI) uses the PCLKA for its clock source. The SDMMC driver selects the optimal built-in divider based on the PCLKA frequency and the maximum clock rate allowed by the device obtained at media initialization.

**Pin Configuration**

The SDMMC driver supports the following pins (n = channel number):

- SDnCLK
- SDnCMD
- SDnDAT0
- SDnDAT1
- SDnDAT2
- SDnDAT3
- SDnDAT4 (not available on all MCUs)
- SDnDAT5 (not available on all MCUs)
- SDnDAT6 (not available on all MCUs)
- SDnDAT7 (not available on all MCUs)
- SDnCD (not available on all MCUs)
- SDnWP

The drive capacity for each pin should be set to "Medium" or "High" for most hardware designs. This can be configured in the **Pins** tab of the RA Configuration editor by selecting the pin under Pin Selection -> Ports.

# Usage Notes

### Card Detection

When Card Detection is configured to "CD Pin" in the RA Configuration editor, interrupt flags are cleared and card detection is enabled during R_SDHI_Open().

R_SDHI_StatusGet() can be called to retrieve the current status of the card (including whether a card is present). If the Card Interrupt Priority is enabled, a callback is called when a card is inserted or removed.

If a card is removed and reinserted, R_SDHI_MediaInit() must be called before reading from the card or writing to the card.

*Note*

*R_SDHI_StatusGet() should be used to initially determine the card state after opening the interface.*

### DMA Request Interrupt Priority

When data transfers are not 4-byte aligned or not a multiple of 4 bytes, a software copy of the block size (up to 512 bytes) is done in the DMA Request interrupt. This blocks all other interrupts that are a lower or equal priority to the access interrupt until the software copy is complete.

### Timing Notes for R_SDHI_MediaInit

The R_SDHI_MediaInit() API completes the entire device identification and configuration process. This involves several command-response cycles at a bus width of 1 bit and a bus speed of 400 kHz or less.

### Limitations

Developers should be aware of the following limitations when using the SDHI:

### Blocking Calls

The following functions block execution until the response is received for at least one command:

- R_SDHI_MediaInit
- R_SDHI_Erase

Once the function returns the status of the operation can be determined via R_SDHI_StatusGet or through receipt of a callback.

*Note*

*Due to the variability in clocking configurations it is recommended to determine blocking delays experimentally on the target system.*

### Data Alignment and Size

Data transfers should be 4-byte aligned and a multiple of 4 bytes in size whenever possible. This recommendation applies to the read(), write(), readIoExt(), and writeIoExt() APIs. When data transfers are 4-byte aligned and a multiple of 4-bytes, the r_sdhi driver is zero copy and takes full advantage of hardware acceleration by the DMAC or DTC. When data transfers are not 4-byte aligned or not a multiple of 4 bytes an extra CPU interrupt is required for each block transferred and a software copy is used to move data to the destination buffer.

## Examples

### Basic Example

This is a basic example of minimal use of the r_sdhi in an application.

```
uint8_t g_dest[SDHI_MAX_BLOCK_SIZE] BSP_ALIGN_VARIABLE(4);
uint8_t g_src[SDHI_MAX_BLOCK_SIZE] BSP_ALIGN_VARIABLE(4);
uint32_t g_transfer_complete = 0;
void r_sdhi_basic_example (void)
{
 /* Initialize g_src to known data */
 for (uint32_t i = 0; i < SDHI_MAX_BLOCK_SIZE; i++)
    {
       g_src[i] = (uint8_t) ('A' + (i % 26));
    }
 /* Open the SDHI driver. */
 fsp_err_t err = R_SDHI_Open(&g_sdmmc0_ctrl, &g_sdmmc0_cfg);
    assert(FSP_SUCCESS == err);
 /* A device shall be ready to accept the first command within 1ms from detecting VDD
min. Reference section 6.4.1.1
  * "Power Up Time of Card" in the SD Physical Layer Simplified Specification Version
6.00. */
```

```
 R_BSP_SoftwareDelay(1U, BSP_DELAY_UNITS_MILLISECONDS);
 /* Initialize the SD card. This should not be done until the card is plugged in for
SD devices. */
    err = R_SDHI_MediaInit(&g_sdmmc0_ctrl, NULL);
    assert(FSP_SUCCESS == err);
    err = R_SDHI_Write(&g_sdmmc0_ctrl, g_src, 3, 1);
    assert(FSP_SUCCESS == err);
 while (!g_transfer_complete)
    {
 /* Wait for transfer. */
    }
    err = R_SDHI_Read(&g_sdmmc0_ctrl, g_dest, 3, 1);
    assert(FSP_SUCCESS == err);
 while (!g_transfer_complete)
    {
 /* Wait for transfer. */
    }
}
/* The callback is called when a transfer completes. */
void r_sdhi_example_callback (sdmmc_callback_args_t * p_args)
{
 if (SDMMC_EVENT_TRANSFER_COMPLETE == p_args->event)
    {
       g_transfer_complete = 1;
    }
}
```

### Card Detection Example

This is an example of using SDHI when the card may not be plugged in. The card detection interrupt must be enabled to use this example.

```
bool g_card_inserted = false;
void r_sdhi_card_detect_example (void)
{
```

```
/* Open the SDHI driver. This enables the card detection interrupt. */
fsp_err_t err = R_SDHI_Open(&g_sdmmc0_ctrl, &g_sdmmc0_cfg);
/* Handle any errors. This function should be defined by the user. */
   assert(FSP_SUCCESS == err);
/* Check if card is inserted. */
sdmmc_status_t status;
   err = R_SDHI_StatusGet(&g_sdmmc0_ctrl, &status);
   assert(FSP_SUCCESS == err);
if (!status.card_inserted)
   {
while (!g_card_inserted)
     {
/* Wait for a card insertion interrupt. */
     }
   }
/* A device shall be ready to accept the first command within 1ms from detecting VDD
min. Reference section 6.4.1.1
  * "Power Up Time of Card" in the SD Physical Layer Simplified Specification Version
6.00. */
R_BSP_SoftwareDelay(1U, BSP_DELAY_UNITS_MILLISECONDS);
/* Initialize the SD card after card insertion is detected. */
   err = R_SDHI_MediaInit(&g_sdmmc0_ctrl, NULL);
   assert(FSP_SUCCESS == err);
}
/* The callback is called when a card detection event occurs if the card detection
interrupt is enabled. */
void r_sdhi_card_detect_example_callback (sdmmc_callback_args_t * p_args)
{
if (SDMMC_EVENT_CARD_INSERTED == p_args->event)
   {
      g_card_inserted = true;
   }
if (SDMMC_EVENT_CARD_REMOVED == p_args->event)
   {
```

```
        g_card_inserted = false;
    }
}
```

### Detailed Description

Virtual EEPROM on RA MCUs. This module implements the Virtual EEPROM Interface.

# Overview

This VEE module emulates basic EEPROM capabilities. Support is provided for reading and writing both common records and reference data (originally programmed during product assembly or test). A count of the number of segments erased throughout the lifetime of the application is maintained and can be accessed at any time. Wear leveling is handled automatically by the driver.

### Features

- Writing and reading user defined records of any length to data flash.
- Wear leveling is handled automatically.
- Reference data such as calibration data programmed at assembly or test time is preserved.
- Reference data can be updated at run time.
- Fault resilient design.

### Data Flash Segmentation

Wear leveling is handled by changing the location in the data flash where a record is stored every time that it is updated. This change in physical location of the record is transparent to the user. Any time an update for a specific record ID is written, it is written to the next unused location in data flash and its location is stored in RAM for quick look-up later. When required, only the most recent version of these records is automatically copied to the next blank segment in data flash. The data flash area is divided into a number of equal-size segments. There is only one segment active at a time. A segment contains two areas- the record area (which is the vast majority of the segment) and the reference data area which contains optional data typically programmed during assembly or final test. Records and updated reference data are written to this segment until one of the two areas becomes full. The record area must be able to hold at least one of every record ID possible and still have space left over for record updates.

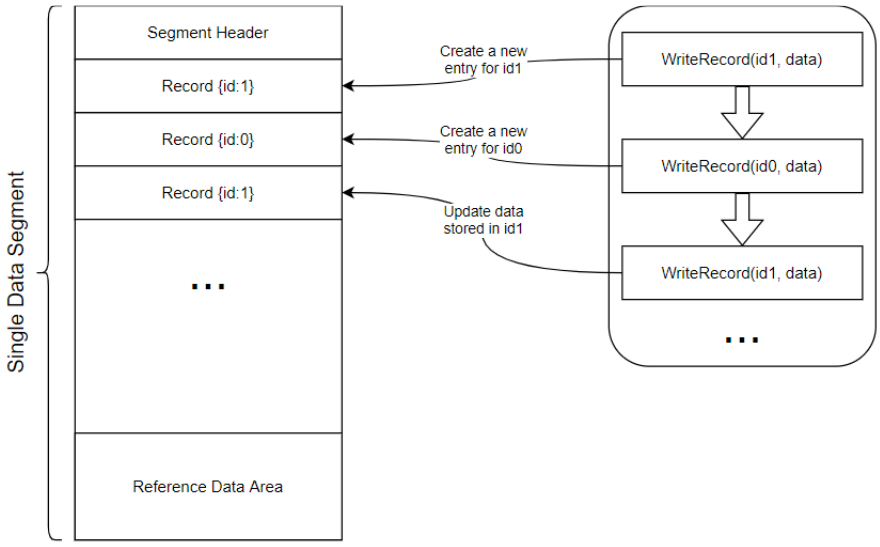

Figure 330: Segment Data Format

When a segment does not have sufficient space for additional records or updated reference data, a Refresh occurs. This process copies the most recent record for each ID as well as the latest version of reference data (if any) to the next segment. The very first time VEE runs on an MCU, it marks the last segment as active whether there is reference data configured or not. The end of VEE data flash area is used to provide an easily identified physical flash address that can be used while programming reference data without requiring Virtual EEPROM middleware.

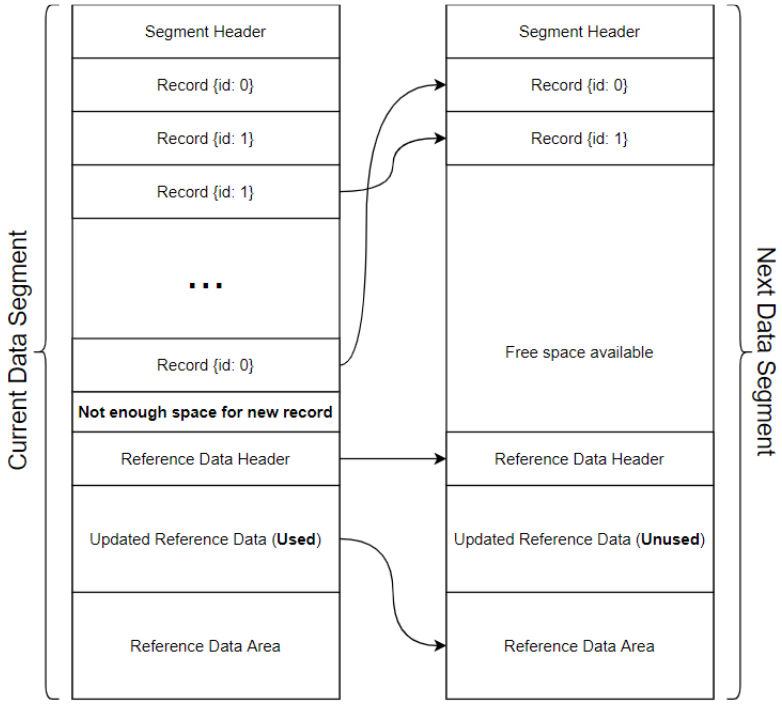

Figure 331: Refresh Operation

### Record Format

Each record begins with a header that contains the record size, followed by the data, and the trailer.

The trailer contains a validation code which is used for internal purposes only and is not a 16-bit CRC or ECC value. If that level of error checking is desired, the user should include that in the record data passed to the driver. Padding is added between the end of user data and the trailer to ensure the trailer is aligned properly.

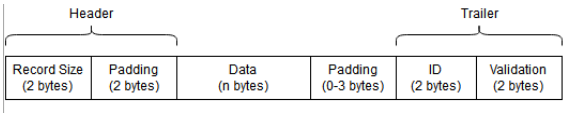

Figure 332: Record Format

### Reference Data Area

VEE can be configured for the presence of reference data. The original programmed reference data must be located at the end of the VEE data flash area. An area of equal size is reserved below this in case updated reference data becomes available later. Below that is a header which indicates whether the update area has been written to.

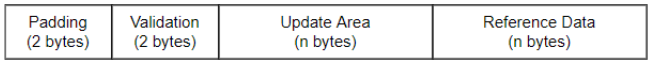

Figure 333: Reference Data Area Format

Just as with records, the validation code is used for internal purposes only and is not a 16-bit CRC or ECC value. If that level of error checking is desired, the user should include that in the updated reference data passed to the driver.

### Fault Tolerance

The Virtual EEPROM has a fault tolerant design. If for any reason an operation fails before it is completed the next time the module is opened a refresh will occur. Any corrupted data will be discarded.

# Configuration

### Build Time Configurations for rm_vee_flash

The following build time configurations are defined in fsp_cfg/rm_vee_flash_cfg.h:

| Configuration | Options | Default | Description |
|---|---|---|---|
| Parameter Checking | • Default (BSP)<br>• Enabled<br>• Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |
| Reference Data Support | • Enabled<br>• Disabled | Disabled | Support writing reference data to the end of the segment. |
| Refresh Buffer Size | Value must be an integer greater than 0 and a multiple of 4 bytes. | 32 | The size of the internal buffer used to copying data from one flash segment to another |

| | | | |
|---|---|---|---|
| | | | during a refresh operation. This is required because data flash to data flash transfers are not supported by the hardware. |

### Configurations for Storage > Virtual EEPROM on Flash (rm_vee_flash)

This module can be added to the Stacks tab via New Stack > Storage > Virtual EEPROM on Flash (rm_vee_flash). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|---|---|---|---|
| Name | Name must be a valid C symbol | g_vee0 | Module name. |
| Record Max ID | Value must be an integer. | 16 | Set this value to the highest record ID in use. |
| Number of Segments | Value must be an integer. | 2 | Set value to number of segments desired in data flash (minimum 2). The fewer the segments, the fewer refreshes occur, but the longer refreshes take to complete (erase time). |
| Start Address | Manual Entry | BSP_FEATURE_FLASH_DATA_FLASH_START | Start address of the flash area used by Virtual EEPROM. |
| Total Size | Manual Entry | BSP_DATA_FLASH_SIZE_BYTES | The total size (In bytes) of the flash area used by Virtual EEPROM. |
| Reference Data Size | Value must be an integer. | 0 | The size of the reference area (In bytes) used by Virtual EEPROM. |
| Callback | Name must be a valid C symbol | vee_callback | A user callback function can be provided. If this callback function is provided, it will be called from the flash interrupt service routine (ISR). |

### Clock Configuration

There is no clock configuration for the RM_VEE_FLASH module.

### Pin Configuration

This module does not use I/O pins.

## Usage Notes

A refresh buffer is required to copy data between segments. Data flash cannot be simultaneously read from and written to. Data will be temporarily copied into RAM during refresh operations.

## Examples

### Detailed Description

Driver for the CGC peripheral on RA MCUs. This module implements the CGC Interface.

*Note*

***This module is not required for the initial clock configuration. Initial clock settings are configurable on the **Clocks** tab of the RA Configuration editor. The initial clock settings are applied by the BSP during the startup process before main.***

# Overview

### Features

The CGC module supports runtime modifications of clock settings. Key features include the following:

- Supports changing the system clock source to any of the following options (provided they are supported on the MCU):
  - High-speed on-chip oscillator (HOCO)
  - Middle-speed on-chip oscillator (MOCO)
  - Low-speed on-chip oscillator (LOCO)
  - Main oscillator (external resonator or external clock input frequency)
  - Sub-clock oscillator (external resonator)
  - PLL/PLL2 (not available on all MCUs)
- When the system core clock frequency changes, the following things are updated:
  - The CMSIS standard global variable SystemCoreClock is updated to reflect the new clock frequency.
  - Wait states for ROM and RAM are adjusted to the minimum supported value for the new clock frequency.
  - The operating power control mode is updated to the minimum supported value for the new clock settings.
- Supports starting or stopping any of the system clock sources
- Supports changing dividers for the internal clocks
- Supports the oscillation stop detection feature

### Internal Clocks

The RA microcontrollers have up to seven internal clocks. Not all internal clocks exist on all MCUs. Each clock domain has its own divider that can be updated in R_CGC_SystemClockSet(). The dividers are subject to constraints described in the footnote of the table "Specifications of the Clock Generation Circuit for the internal clocks" in the hardware manual.

The internal clocks include:

- System clock (ICLK): core clock used for CPU, flash, internal SRAM, DTC, and DMAC
- PCLKA/PCLKB/PCLKC/PCLKD: Peripheral clocks, refer to the table "Specifications of the Clock Generation Circuit for the internal clocks" in the hardware manual to see which peripherals are controlled by which clocks.
- FCLK: Clock source for reading data flash and for programming/erasure of both code and

data flash.
- BCLK: External bus clock

# Configuration

*Note*

*The initial clock settings are configurable on the **Clocks** tab of the RA Configuration editor.*
*There is a configuration to enable the HOCO on reset in the OFS1 settings on the BSP tab.*
*The following clock related settings are configurable in the RA Common section on the BSP tab:*
- *Main Oscillator Wait Time*
- *Main Oscillator Clock Source (external oscillator or crystal/resonator)*
- *Subclock Populated*
- *Subclock Drive*
- *Subclock Stabilization Time (ms)*

*The default stabilization times are determined based on development boards provided by Renesas, but are generally valid for most designs. Depending on the target board hardware configuration and requirements these values may need to be adjusted for reliability or startup speed.*

### Build Time Configurations for r_cgc

### Clock Configuration

This module is used to configure the system clocks. There are no module specific clock configurations required to use it.

### Pin Configuration

The CGC module controls the output of the CLOCKOUT signal.

If an external oscillator is used the XTAL and EXTAL pins must be configured accordingly. When running from an on chip oscillator there is no requirement for the main clock external oscillator. In this case, the XTAL and EXTAL pins can be set to a different function in the RA Configuration editor.

The functionality of the subclock external oscillator pins XCIN and XCOUT is fixed.

## Usage Notes

### Oscillation Stop Detection

CGC driver supports following oscillation stop detection function.

### NMI Interrupt

The CGC driver uses the NMI for oscillation stop detection of the main oscillator after R_CGC_OscStopDetectEnable is called. The NMI is enabled by default. No special configuration is required. When the NMI is triggered, the callback function registered during R_CGC_Open() is called.

### Main Oscillator Stop Detection Interrupt

A main clock oscillation stop detection interrupt (MOSTD_STOP) is generated when the Oscillation Stop Detection for Main Clock is enabled. The main oscillation stop detection interrupt is a maskable interrupt. When the MOSTD_STOP is triggered, the callback function registered during R_CGC_Open() is called.

### Subclk Oscillator Stop Detection Interrupt

A sub clock oscillation stop detection interrupt (SOSC_STOP) is generated when the Oscillation Stop Detection for Sub Clock is enabled. The sub clock oscillation stop detection interrupt is a maskable interrupt. When the SOSC_STOP is triggered, the callback function registered during R_CGC_Open() is called.

### ADC Clock Switching

When Clock Switch Enable for Oscillation Stop Detected is set.

- When MOSC stop is detected when MOSC is selected for SDADCCLK, SDADCCLK is switched to HOCO.
- When SOSC stop is detected when PLL is selected for SDADCCLK, SDADCCLK is switched to HOCO.

### Starting or Stopping the Subclock

If the Subclock Populated property is set to Populated on the BSP configuration tab, then the subclock is started in the BSP startup routine. Otherwise, it is stopped in the BSP startup routine. Starting and stopping the subclock at runtime is not recommended since the stabilization requirements typically negate the negligible power savings.

The application is responsible for ensuring required clocks are started and stable before accessing MCU peripheral registers.

Warning

The subclock can take up to several seconds to stabilize. RA startup code does not wait for subclock stabilization unless the subclock is the main clock source. In this case the default wait time is 1000ms (1 second). When running AGT or RTC off the subclock, the application must ensure the subclock is stable before starting operation. Because there is no hardware stabilization status bit for the subclock R_CGC_ClockCheck cannot be used to optimize this wait.

Changing the subclock state during R_CGC_ClocksCfg() is not supported.

### Low Power Operation

If "Use Low Voltage Mode" is enabled in the BSP MCU specific properties (not available on all MCUs), the MCU is always in low voltage mode and no other power modes are considered. The following conditions must be met for the MCU to run in low voltage mode:

- Requires HOCO to be running, so HOCO cannot be stopped in low voltage mode
- Requires PLL to be stopped, so PLL APIs are not available in low voltage mode
- Requires ICLK <= 4 MHz
- If oscillation stop detection is used, dividers of 1 or 2 cannot be used for any clock

If "Use Low Voltage Mode" is not enabled, the MCU applies the lowest power mode by searching through the following list in order and applying the first power mode that is supported under the current conditions:

- Subosc-speed mode (lowest power)
  - Requires system clock to be LOCO or subclock
  - Requires MOCO, HOCO, main oscillator, and PLL (if present) to be stopped
  - Requires ICLK and FCLK dividers to be 1
- Low-speed mode
  - Requires PLL to be stopped
  - Requires ICLK <= 1 MHz
  - If oscillation stop detection is used, dividers of 1, 2, 4, or 8 cannot be used for any clock
- Middle-speed mode (not supported on all MCUs)
  - Requires ICLK <= 8 MHz
- High-speed mode
  - Default mode if no other operating mode is supported

Refer to the section "Function for Lower Operating Power Consumption" in the "Low Power Modes" chapter of the hardware manual for MCU specific information about operating power control modes.

*Note*

*The DCDC regulator (if present) is only available in Middle- and High-speed modes. The BSP will automatically switch between DCDC and LDO when switching between compatible and incompatible modes if the DCDC regulator is in use. Switching to the LDO incurs a 60 microsecond critical section wherein all interrupts AND peripherals are stopped. Switching back to DCDC from the LDO incurs an additional 22 microsecond critical section (peripherals running).*

When low voltage mode is not used, the following functions adjust the operating power control mode to ensure it remains within the hardware specification and to ensure the MCU is running at the optimal operating power control mode:

- R_CGC_ClockStart()
- R_CGC_ClockStop()
- R_CGC_SystemClockSet()
- R_CGC_OscStopDetectEnable()
- R_CGC_OscStopDetectDisable()

*Note*

*FSP APIs, including these APIs, are not thread safe. These APIs and any other user code that modifies the operating power control mode must not be allowed to interrupt each other. Proper care must be taken during application design if these APIs are used in threads or interrupts to ensure this constraint is met.*

No action is required by the user of these APIs. This section is provided for informational purposes only.

### Basic Example

This is a basic example of minimal use of the CGC in an application.

## Function Documentation

### ◆ R_CGC_Open()

fsp_err_t R_CGC_Open ( cgc_ctrl_t *const *p_ctrl*, cgc_cfg_t const *const *p_cfg* )

Initialize the CGC API. Implements cgc_api_t::open.

```
/* Initializes the CGC module. */
   err = R_CGC_Open(&g_cgc0_ctrl, &g_cgc0_cfg);
```

**Return values**

| | |
|---|---|
| FSP_SUCCESS | CGC successfully initialized. |
| FSP_ERR_ASSERTION | Invalid input argument. |
| FSP_ERR_ALREADY_OPEN | Module is already open. |

### ◆ R_CGC_ClocksCfg()

fsp_err_t R_CGC_ClocksCfg ( cgc_ctrl_t *const *p_ctrl*, cgc_clocks_cfg_t const *const *p_clock_cfg* )

Reconfigures all main system clocks. This API can be used for any of the following purposes:

- start or stop clocks
- change the system clock source
- configure the PLL/PLL2 multiplication and division ratios when starting the PLL
- configure the division ratios when starting the HOCO/MOCO/MOSC
- change the system dividers

If the requested system clock source has a stabilization flag, this function blocks waiting for the stabilization flag of the requested system clock source to be set. If the requested system clock source was just started and it has no stabilization flag, this function blocks for the stabilization time required by the requested system clock source according to the Electrical Characteristics section of the hardware manual. If the requested system clock source has no stabilization flag and it is already running, it is assumed to be stable and this function will not block. If the requested system clock is the subclock, the subclock must be stable prior to calling this function.

The internal dividers (cgc_clocks_cfg_t::divider_cfg) are subject to constraints described in footnotes of the hardware manual table detailing specifications for the clock generation circuit for the internal clocks for the MCU. For example:

- RA6M3: see footnotes of table "Specifications of the clock generation circuit for the internal clocks" in the CGC section of the relevant hardware manual.
- RA2A1: see footnotes of table "Clock generation circuit specifications for the internal clocks" in the CGC section of the relevant hardware manual.

Do not attempt to stop the requested clock source or the source of a PLL if the PLL will be running after this operation completes.

Implements cgc_api_t::clocksCfg.

Example:

```
/* Assuming the system clock is MOCO, switch to HOCO. */
```

```
 cgc_clocks_cfg_t clocks_cfg;
#if !BSP_FEATURE_CGC_REGISTER_SET_B
    clocks_cfg.system_clock                     = CGC_CLOCK_PLL;
    clocks_cfg.pll_state                        = CGC_CLOCK_CHANGE_NONE;
    clocks_cfg.pll_cfg.source_clock             = CGC_CLOCK_MAIN_OSC; // unused
    clocks_cfg.pll_cfg.multiplier               = CGC_PLL_MUL_10_0;   // unused
    clocks_cfg.pll_cfg.divider                  = CGC_PLL_DIV_2;      // unused

 #if BSP_FEATURE_CGC_HAS_MOSC
    clocks_cfg.divider_cfg.mosc_divider = CGC_SYS_CLOCK_DIV_1;
 #endif
#endif
    clocks_cfg.mainosc_state = CGC_CLOCK_CHANGE_NONE;

After clearing the status, oscillation stop detection is no longer enabled.

This register cannot be cleared while the main oscillator is the system clock or the PLL source clock.

Example:

```
/* (Optional) Clear the error flag. Only clear this flag after switching the MCU clock source away from the main
 * oscillator and if the main oscillator is stable again. */

### Detailed Description

Driver for the ELC peripheral on RA MCUs. This module implements the ELC Interface.

# Overview

The event link controller (ELC) uses the event requests generated by various peripheral modules as source signals to connect (link) them to different modules, allowing direct cooperation between the modules without central processing unit (CPU) intervention. The conceptual diagram below illustrates a potential setup where a pin interrupt triggers a timer which later triggers an ADC conversion and CTSU scan, while at the same time a serial communication interrupt automatically starts a data transfer. These tasks would be automatically handled without the need for polling or interrupt management.

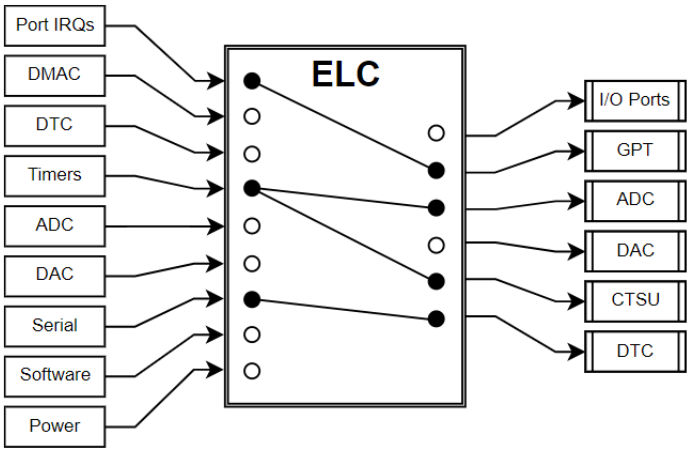

Figure 334: Event Link Controller Conceptual Diagram

In essence, the ELC is an array of multiplexers to route a wide variety of interrupt signals to a subset of peripheral functions. Events are linked by setting the multiplexer for the desired function to the desired signal (through R_ELC_LinkSet). The diagram below illustrates one peripheral output of the ELC. In this example, a conversion start is triggered for ADC0 Group A when the GPT0 counter overflows:

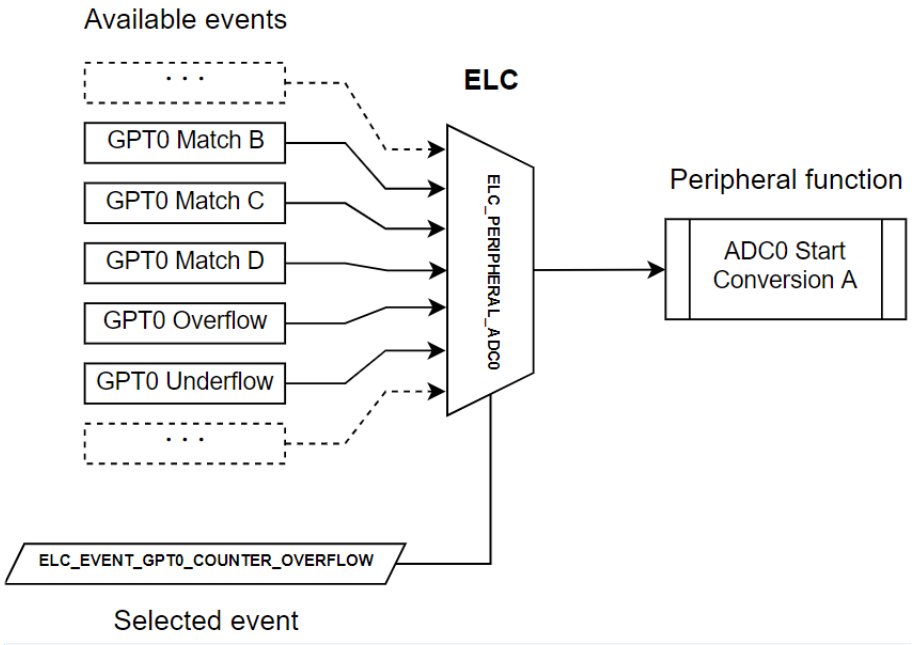

Figure 335: ELC Example

### Features

The ELC HAL module can perform the following functions:

- Initialize the ELC to a pre-defined set of links
- Create an event link between two blocks
- Break an event link between two blocks
- Generate one of two software events that interrupt the CPU
- Globally enable or disable event links

A variety of functions can be activated via events, including:

- General-purpose timer (GPT) control
- ADC and DAC conversion start
- Synchronized I/O port output (ports 1-4 only)
- Capacitive touch unit (CTSU) measurement activation

*Note*

*The available sources and peripherals may differ between devices. A full list of selectable peripherals and events is available in the User's Manual for your device.*
*Some peripherals have specific settings related to ELC event generation and/or reception. Details on how to enable event functionality for each peripheral are located in the usage notes for the related module(s) as well as in the User's Manual for your device.*

# Configuration

*Note*

*Event links will be automatically generated based on the selections made in module properties. To view the currently linked events check the Event Links tab in the RA Configuration editor.*
*Calling R_ELC_Open followed by R_ELC_Enable will automatically link all events shown in the Event Links tab.*

To manually link an event to a peripheral at runtime perform the following steps:

1. Configure the operation of the destination peripheral (including any configuration necessary to receive events)
2. Use R_ELC_LinkSet to set the desired event link to the peripheral
3. Use R_ELC_Enable to enable transmission of event signals
4. Configure the signaling module to output the desired event (typically an interrupt)

To disable the event, either use R_ELC_LinkBreak to clear the link for a specific event or R_ELC_Disable to globally disable event linking.

*Note*

*The ELC module needs no pin, clocking or interrupt configuration; it is merely a mechanism to connect signals between peripherals. However, when linking I/O Ports via the ELC the relevant I/O pins need to be configured as inputs or outputs.*

### Build Time Configurations for r_elc

The following build time configurations are defined in fsp_cfg/r_elc_cfg.h:

| Configuration | Options | Default | Description |
|---|---|---|---|
| Parameter Checking | • Default (BSP)<br>• Enabled<br>• Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

### Configurations for System > Event Link Controller (r_elc)

This module can be added to the Stacks tab via New Stack > System > Event Link Controller (r_elc). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|---|---|---|---|
| Name | ELC instance name must be g_elc to match elc_cfg_t data structure created in elc_data.c | g_elc | Module name. Fixed to g_elc. |

## Usage Notes

### Limitations

Developers should be aware of the following limitations when using the ELC:

- To link events it is necessary for the ELC and the related modules to be enabled. The ELC cannot operate if the related modules are in the module stop state or the MCU is in a low power consumption mode for which the module is stopped.
- If two modules are linked across clock domains there may be a 1 to 2 cycle delay between event signaling and reception. The delay timing is based on the frequency of the slowest clock.

## Examples

### Basic Example

Below is a basic example of minimal use of event linking in an application.

```
/* This struct is automatically generated based on the events configured by
peripherals in the RA Configuration editor. */
static const elc_cfg_t g_elc_cfg =
{
#if (BSP_CFG_MCU_PART_SERIES == 0)
    .link[ELC_PERIPHERAL_TAU01]   = ELC_EVENT_ICU_IRQ0,
    .link[ELC_PERIPHERAL_IOPORT1] = ELC_EVENT_TAU0_TMI01
#else
    .link[ELC_PERIPHERAL_GPT_A]   = ELC_EVENT_ICU_IRQ0,
    .link[ELC_PERIPHERAL_IOPORT1] = ELC_EVENT_GPT4_COUNTER_OVERFLOW
#endif
};
void elc_basic_example (void)
{
 fsp_err_t err = FSP_SUCCESS;
 /* Initializes the software and sets the links defined in the control structure. */
    err = R_ELC_Open(&g_elc_ctrl, &g_elc_cfg);
 /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
 /* Create or modify a link between a peripheral function and an event source. */
#if (BSP_CFG_MCU_PART_SERIES == 0)
    err = R_ELC_LinkSet(&g_elc_ctrl, ELC_PERIPHERAL_AD, ELC_EVENT_TAU0_TMI01);
#else
    err = R_ELC_LinkSet(&g_elc_ctrl, ELC_PERIPHERAL_ADC0,
ELC_EVENT_GPT4_COUNTER_OVERFLOW);
#endif
    assert(FSP_SUCCESS == err);
 /* Globally enable event linking in the ELC. */
    err = R_ELC_Enable(&g_elc_ctrl);
    assert(FSP_SUCCESS == err);
}
```

### Software-Generated Events

This example demonstrates how to use a software-generated event to signal a peripheral. This can be useful when the desired event source is not supported by the ELC hardware.

```
/* Interrupt handler for peripheral event not supported by the ELC */
void peripheral_isr (void)
{
 fsp_err_t err;
 /* Generate an event signal through software to the linked peripheral. */
    err = R_ELC_SoftwareEventGenerate(&g_elc_ctrl, ELC_SOFTWARE_EVENT_0);
    assert(FSP_SUCCESS == err);
}
void elc_software_event (void)
{
 fsp_err_t err = FSP_SUCCESS;
 /* Open the module. */
    err = R_ELC_Open(&g_elc_ctrl, &g_elc_cfg);
 /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
 /* Link ADC0 conversion start to software event 0. */
#if (BSP_CFG_MCU_PART_SERIES == 0)
    err = R_ELC_LinkSet(&g_elc_ctrl, ELC_PERIPHERAL_AD,
ELC_EVENT_ELC_SOFTWARE_EVENT_0);
#else
    err = R_ELC_LinkSet(&g_elc_ctrl, ELC_PERIPHERAL_ADC0,
ELC_EVENT_ELC_SOFTWARE_EVENT_0);
#endif
    assert(FSP_SUCCESS == err);
 while (true)
    {
 /* Application code here. */
    }
}
```

### Detailed Description

Driver for the I/O Ports peripheral on RA MCUs. This module implements the I/O Port Interface.

# Overview

The I/O port pins operate as general I/O port pins, I/O pins for peripheral modules, interrupt input pins, analog I/O, port group function for the ELC, or bus control pins.

### Features

The IOPORT HAL module can configure the following pin settings:

- Pin direction
- Default output state
- Pull-up
- NMOS/PMOS
- Drive strength
- Event edge trigger (falling, rising or both)
- Whether the pin is to be used as an IRQ pin
- Whether the pin is to be used as an analog pin
- Peripheral connection

The module also provides the following functionality:

- Read/write GPIO pins/ports
- Sets event output data
- Reads event input data
- Controlled Current Drive (CCD)

# Configuration

The I/O PORT HAL module must be configured by the user for the desired operation. The operating state of an I/O pin can be set via the RA Configuration tool. When the project is built a pin configuration file is created. The BSP will automatically configure the MCU IO ports accordingly at startup using the same API functions mentioned in this document.

### Build Time Configurations for r_ioport

The following build time configurations are defined in fsp_cfg/r_ioport_cfg.h:

| Configuration | Options | Default | Description |
|---|---|---|---|
| Parameter Checking | • Default (BSP)<br>• Enabled<br>• Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |
| CCD Support | MCU Specific Options | | Enable support for CCD (Controlled Current Drive) port pins. |

### Configurations for System > I/O Port (r_ioport)

This module can be added to the Stacks tab via New Stack > System > I/O Port (r_ioport).

| Configuration | Options | Default | Description |
|---|---|---|---|
| Name | Name must be a valid C symbol | g_ioport | Module name. |
| 1st Port ELC Trigger Source | MCU Specific Options | | ELC source that will trigger the 1st port |
| 2nd Port ELC Trigger Source | MCU Specific Options | | ELC source that will trigger the 2nd port |
| 3rd Port ELC Trigger Source | MCU Specific Options | | ELC source that will trigger the 3rd port |

| | | | |
|---|---|---|---|
| 4th Port ELC Trigger Source | MCU Specific Options | | ELC source that will trigger the 4th port |
| Pin Configuration Name | Name must be a valid C symbol | g_bsp_pin_cfg | Name for pin configuration structure |

### Clock Configuration

The I/O PORT HAL module does not require a specific clock configuration.

### Pin Configuration

The IOPORT module is used for configuring pins.

# Usage Notes

### Port Group Function for ELC

Depending on pin configuration, the IOPORT module can perform automatic reads and writes on 4 ports (RA2 and RA0 series support 2 ports only, see the table of ELC triggers below) on receipt of an ELC event.

| ELC triggers | RA6T2 | RA2XX, RA0XX (with ELC) | RA0XX (without ELC) | All others |
|---|---|---|---|---|
| 1st Port | Port B | Port 1 | NA | Port 1 |
| 2nd Port | Port C | Port 2 | NA | Port 2 |
| 3rd Port | Port D | NA | NA | Port 3 |
| 4th Port | Port E | NA | NA | Port 4 |

When an event is received by a port, the state of the input pins on the port is saved in a hardware register. Simultaneously, the state of output pins on the port is set or cleared based on settings configured by the user. The functions R_IOPORT_PinEventInputRead and R_IOPORT_PortEventInputRead allow reading the last event input state of a pin or port, and event-triggered pin output can be configured through R_IOPORT_PinEventOutputWrite and R_IOPORT_PortEventOutputWrite.

In addition, each pin on these ports can be configured to trigger an ELC event on rising, falling or both edges. This event can be used to activate other modules when the pin changes state.

*Note*

*The number of ELC-aware ports vary across MCUs. Refer to the Hardware User's Manual for your device for more details.*

# Examples

### Basic Example

This is a basic example of minimal use of the IOPORT in an application.

```
void basic_example ()
```

```
{
 bsp_io_level_t readLevel;
 fsp_err_t      err;
 /* Initialize the IOPORT module and configure the pins
  * Note: The default pin configuration name in the RA Configuration tool is
g_bsp_pin_cfg */
    err = R_IOPORT_Open(&g_ioport_ctrl, &g_bsp_pin_cfg);
 /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
 /* Call R_IOPORT_PinsCfg if the configuration was not part of initial configurations
made in open */
    err = R_IOPORT_PinsCfg(&g_ioport_ctrl, &g_runtime_pin_cfg);
    assert(FSP_SUCCESS == err);
 /* Set Pin 00 of Port 06 to High */
    err = R_IOPORT_PinWrite(&g_ioport_ctrl, BSP_IO_PORT_06_PIN_00, BSP_IO_LEVEL_HIGH
);
    assert(FSP_SUCCESS == err);
 /* Read Pin 00 of Port 06*/
    err = R_IOPORT_PinRead(&g_ioport_ctrl, BSP_IO_PORT_06_PIN_00, &readLevel);
    assert(FSP_SUCCESS == err);
}
```

### Blinky Example

This example uses IOPORT to configure and toggle a pin to blink an LED.

```
void blinky_example ()
{
 fsp_err_t err;
 /* Initialize the IOPORT module and configure the pins */
    err = R_IOPORT_Open(&g_ioport_ctrl, &g_bsp_pin_cfg);
 /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
 /* Configure Pin as output
  * Call the R_IOPORT_PinCfg if the configuration was not part of initial
```

```
configurations made in open */
    err = R_IOPORT_PinCfg(&g_ioport_ctrl, BSP_IO_PORT_06_PIN_00,
IOPORT_CFG_PORT_DIRECTION_OUTPUT);
    assert(FSP_SUCCESS == err);
 bsp_io_level_t level = BSP_IO_LEVEL_LOW;
 while (1)
    {
 /* Determine the next state of the LEDs */
 if (BSP_IO_LEVEL_LOW == level)
     {
           level = BSP_IO_LEVEL_HIGH;
      }
 else
     {
           level = BSP_IO_LEVEL_LOW;
      }
 /* Update LED on RA6M3-PK */
       err = R_IOPORT_PinWrite(&g_ioport_ctrl, BSP_IO_PORT_06_PIN_00, level);
     assert(FSP_SUCCESS == err);
 /* Delay */
 R_BSP_SoftwareDelay(100, BSP_DELAY_UNITS_MILLISECONDS); // NOLINT
    }
}
```

### ELC Example

This is an example of using IOPORT with ELC events. The ELC event system allows the captured data to be stored when it occurs and then read back at a later time.

```
static elc_instance_ctrl_t g_elc_ctrl;
static elc_cfg_t g_elc_cfg;
void ioport_elc_example ()
{
 bsp_io_level_t eventValue;
 fsp_err_t      err;
```

```
 /* Initializes the software and sets the links defined in the control structure. */
    err = R_ELC_Open(&g_elc_ctrl, &g_elc_cfg);
 /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
 /* Create or modify a link between a peripheral function and an event source. */
    err = R_ELC_LinkSet(&g_elc_ctrl, (elc_peripheral_t) ELC_PERIPHERAL_IOPORT2,
ELC_EVENT_ELC_SOFTWARE_EVENT_0);
    assert(FSP_SUCCESS == err);
 /* Globally enable event linking in the ELC. */
    err = R_ELC_Enable(&g_elc_ctrl);
    assert(FSP_SUCCESS == err);
 /* Initialize the IOPORT module and configure the pins */
    err = R_IOPORT_Open(&g_ioport_ctrl, &g_bsp_pin_cfg);
    assert(FSP_SUCCESS == err);
 /* Call the R_IOPORT_PinCfg if the configuration was not part of initial
configurations made in open */
    err = R_IOPORT_PinCfg(&g_ioport_ctrl, BSP_IO_PORT_02_PIN_00,
IOPORT_CFG_PORT_DIRECTION_INPUT);
    assert(FSP_SUCCESS == err);
 /* Generate an event signal through software to the linked peripheral. */
    err = R_ELC_SoftwareEventGenerate(&g_elc_ctrl, ELC_SOFTWARE_EVENT_0);
    assert(FSP_SUCCESS == err);
 /* Read Pin Event Input. The data(BSP_IO_LEVEL_HIGH/ BSP_IO_LEVEL_LOW) from
BSP_IO_PORT_02_PIN_00 is read into the
  * EIDR bit */
    err = R_IOPORT_PinEventInputRead(&g_ioport_ctrl, BSP_IO_PORT_02_PIN_00,
&eventValue);
    assert(FSP_SUCCESS == err);
}
```

**Detailed Description**

Driver for the IPC peripheral on RA MCUs. This module implements the IPC Interface.

# Overview

The IPC HAL module supports communication across processors via maskable interrupts and one-way message FIFOs.

*Note*

*IPC semaphores and NMI are handled through BSP APIs. See Inter-Processor Communication (IPC) Support.*

**Features**

- Send and receive messages through IPC FIFOs
- Trigger or receive maskable interrupts with multiple event bits settable per interrupt

# Configuration

**Build Time Configurations for r_ipc**

The following build time configurations are defined in fsp_cfg/r_ipc_cfg.h:

| Configuration | Options | Default | Description |
|---|---|---|---|
| Parameter Checking | • Default (BSP)<br>• Enabled<br>• Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

**Configurations for System > IPC (r_ipc)**

This module can be added to the Stacks tab via New Stack > System > IPC (r_ipc). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|---|---|---|---|
| Name | Name must be a valid C symbol | g_ipc0 | Module name. |
| Channel | MCU Specific Options | | Select the IPC channel. |
| Callback | Name must be a valid C symbol | NULL | A user callback function must be provided when the IPC interrupt is enabled. It will be called from the interrupt service routine (ISR). |
| Interrupt Priority | MCU Specific Options | | Select the IPC interrupt priority. An interrupt is only required for receiving messages and events from the opposing core. |

### Interrupt Configuration

- In order to receive messages, the interrupt must be enabled and a callback must be supplied. If an IPC instance is only being used to send messages or generate events the interrupt doesn't have to be enabled.

# Usage Notes

IPC maskable interrupts and FIFOs share the same interrupt so the IPC driver handles configuration of both similarly:

- The IPC driver will choose which IPC registers to use based on the selected core and channel.
- An interrupt and callback is only required when the IPC instance is being used to receive.
    - When receiving a callback should be used to process any received messages/interrupts.
- The channels across cores should always match up for IPC instances. For example, in order to communicate from Core 0 to Core 1 over channel 0:
    - Core 0 should have an IPC instance configured opened on channel 0
    - Core 1 should have an IPC instance configured opened on channel 0

### IPC Maskable Interrupt Events

Each IPC channel can set multiple "event" bits in a single maskable interrupt. This should be done through ipc_api_t::eventGenerate.

# Examples

### Basic IPC Messaging Example

The following example demonstrates sending a simple message from Core 0 to Core 1 via IPC.

### Core 0 Application

```
#define IPC_SEND_MESSAGE 0xABCD
void r_ipc_basic_messaging_core0_example (void)
{
 /* Open an IPC instance on the core 0 application configured to send a message to
core 1.
  * @ref ipc_cfg_t::direction should be set to IPC_DIRECTION_SEND.
  * @ref ipc_cfg_t::channel should match for IPC instances on both cores.
  */
 fsp_err_t err = R_IPC_Open(&g_ipc0_ctrl, &g_ipc0_cfg);
    assert(FSP_SUCCESS == err);
 /* Send IPC_SEND_MESSAGE to core 1. */
    err = R_IPC_MessageSend(&g_ipc0_ctrl, IPC_SEND_MESSAGE);
    assert(FSP_SUCCESS == err);
}
```

### Core 1 Application

```
void r_ipc_basic_messaging_core1_example (void)
{
 /* Open an IPC instance on the core 1 application configured to receive messages.
  * @ref ipc_cfg_t::direction should be set to IPC_DIRECTION_RECEIVE.
  * @ref ipc_cfg_t::channel should match for IPC instances on both cores.
  */
 fsp_err_t err = R_IPC_Open(&g_ipc0_ctrl, &g_ipc0_cfg);
    assert(FSP_SUCCESS == err);
 /* Wait for message from callback */
 while (!g_callback_called)
    {
       ;
    }
 /* Message will be in g_last_message_received */
    (void) g_last_message_received;
```

```
}
void ipc_message_example_callback (ipc_callback_args_t * p_args)
{
 /* Check for message received event */
 if (IPC_EVENT_MESSAGE_RECEIVED & p_args->event)
    {
       g_callback_called       = true;
       g_last_message_received = p_args->message;
    }
}
```

### Basic IPC Interrupt Event Example

The following example demonstrates triggering an event via maskable interrupt from Core 0 to Core 1.

### Core 0 Application

```
void r_ipc_basic_interrupt_event_core0_example (void)
{
 /* Open an IPC instance on the core 0 application configured to send to core 1.
  * @ref ipc_cfg_t::direction should be set to IPC_DIRECTION_SEND.
  * @ref ipc_cfg_t::channel should match for IPC instances on both cores.
  */
 fsp_err_t err = R_IPC_Open(&g_ipc0_ctrl, &g_ipc0_cfg);
    assert(FSP_SUCCESS == err);
 /* Trigger interrupt on core 1 with event 0 bit set. */
    err = R_IPC_EventGenerate(&g_ipc0_ctrl, IPC_GENERATE_EVENT_IRQ0);
    assert(FSP_SUCCESS == err);
}
```

### Core 1 Application

```
void r_ipc_basic_interrupt_event_core1_example (void)
{
 /* Open an IPC instance on the core 1 application configured to receive.
  * @ref ipc_cfg_t::direction should be set to IPC_DIRECTION_RECEIVE.
```

```
 * @ref ipc_cfg_t::channel should match for IPC instances on both cores.
 */
fsp_err_t err = R_IPC_Open(&g_ipc0_ctrl, &g_ipc0_cfg);
   assert(FSP_SUCCESS == err);
/* Wait for event */
while (!g_event0_triggered)
   {
      ;
   }
}
void ipc_event_example_callback (ipc_callback_args_t * p_args)
{
/* Check for message received event */
if (IPC_EVENT_IRQ0 & p_args->event)
   {
      g_event0_triggered = true;
   }
}
```

### Clock Configuration

The TAU clock is based on the peripheral module clock (PCLKB) which is equal to the system clock (ICLK).

Each TAU channel has certain operation clocks selections, these can be set with the **General>Operation Clock** property in the module configuration. When the operation clock of a channel is set to CK00, CK01, CK02, or CK03, the TAU module provides divisor values for each of those clocks. These divisors may be set in the **Clocks** tab. As such, setting a divisor in the **Clocks** tab affects all TAU channels that use that CK0x clock as an input. Adjusting these settings determines the frequency range achievable by a TAU channel. If a desired frequency is not achievable, the divider in the **Clocks** tab may be adjusted. The clock dividers cannot be adjusted at runtime.

### Pin Configuration

This module should use the TOmn pins as output pins for Square Wave Output, Divider Function

For input source, the input signal must be applied to External Event Counter, Divider, Input Pulse Interval Measurement, Delay Counter, and Measure High-Low Level Pulse Width Function

### Timer Period

The RA Configuration editor will automatically calculate the period count value based on the selected period time, units, operation clock (set by **General>Operation Clock** property in the module configuration), and clock divisor value (set in **Clocks** tab).

When the selected unit is "Raw counts", the maximum and minimum allowed period setting varies depending on the selected clock source:

| Clock divisor | Minimum period (counts) | Maximum period (counts) |
|---|---|---|
| ICLK/1 | 0x00002 | 0x10000 |
| All other divisors | 0x00001 | 0x10000 |

*Note*

*If ICLK (undivided) is selected as the operation clock (CK00, CK01) and TDR0n is set to 0x0000 (n = 0 to 7), interrupt requests output from timer array units cannot be used. For this reason When Clock Source is ICLK, Minimum period (counts) is 0x00002*

| Clock divisor | Minimum Higher 8-bit period (counts) | Maximum Higher 8-bit period (counts) |
|---|---|---|
| All divisors | 0x001 | 0x100 |

*Note*

*Though the TAU is a 16-bit timer, because the period interrupt occurs when the counter underflow, setting the period register to 0 results in an effective period of 1 count. For this reason all user-provided raw count values reflect the actual number of period counts (not the raw register values).*

# Usage Notes

### Interval Timer Function

This function can be used as a reference timer to generate TAU0_TMI0n (timer interrupt) at fixed intervals. The interrupt generation period can be calculated by the following expression.

- Generation period of TAU0_TMI0n (timer interrupt) = Period of count clock × (Set value of TDR0n + 1)

The Interval Timer Function can operate as the higher/lower 8-bits mode.

When "Interrupts > Setting of starting count and interrupt" is "Timer interrupt is generated when counting is started/Start trigger is valid during counting operation.", an interrupt is generated immediately after R_TAU_Start() function is called and timer output also changed.

### Square Wave Output Function

This function can use TO0n to perform a toggle operation as soon as TAU0_TMI0n has been generated, and outputs a square wave with a duty factor of 50%.

The period and frequency for outputting a square wave from TO0n can be calculated by the following expressions.

- Period of square wave output from TO0n = Period of count clock × (Set value of TDR0n + 1) × 2
- Frequency of square wave output from TO0n = Frequency of count clock / {(Set value of TDR0n + 1) × 2}

The Square Wave Output Function can operate as the lower 8-bits mode.

When "Interrupts > Setting of starting count and interrupt" is "Timer interrupt is generated when counting is started/Start trigger is valid during counting operation.", an interrupt is generated immediately after R_TAU_Start() function is called and output pin is also changed.

### External Event Counter Function

The timer array unit can be used as an external event counter that counts the number of times the valid input edge (external event) is detected in the TI0n pin. When a specified count value is reached, the event counter generates an interrupt. The specified number of counts can be calculated by the following expression.

- Specified number of counts = Set value of TDR0n + 1

Instead of using the TI0n pin input, a channel specified for the External Event Counter Function can also use the signal as "Middle-speed on-chip oscillator (MOCO)", "Low-speed on-chip oscillator (LOCO)", "Subsystem clock (FSUB)", and ELC event which selected in **Input>Input Source** property as its input source to drive counting.

The External Event Counter Function can operate as the lower 8-bits mode.

### Delay Counter Function

It is possible to start counting down when the valid edge of the TI0n pin input is detected (an

external event), and then generate TAU0_TMI0n (a timer interrupt) after any specified interval. The interrupt generation period can be calculated by the following expression. Generation period of TAU0_TMI0n (timer interrupt) = Period of count clock × (Set value of TDR0n + 1)

Instead of using the TI0n pin input, a channel specified for the Delay Counter Function can also use the signal as "Middle-speed on-chip oscillator (MOCO)", "Low-speed on-chip oscillator (LOCO)", "Subsystem clock (FSUB)", and ELC event which selected in **Input>Input Source** property as its input source to drive counting.

The Delay Counter Function can operate as the lower 8-bits mode.

When "Interrupts > Setting of starting count and interrupt" is "Timer interrupt is generated when counting is started/Start trigger is valid during counting operation.", a start trigger is valid during counting operation.

**Divider Function**

The timer array unit can be used as a frequency divider that divides a clock input to the TI00 pin and outputs the result from the TO00 pin. The divided clock frequency output from TO00 can be calculated by the following expression. When rising edge/falling edge is selected:

- Divided clock frequency = Input clock frequency / {(Set value of TDR00 + 1) × 2} When both edges are selected:
- Divided clock frequency ≈ Input clock frequency / (Set value of TDR00 + 1)

When "Interrupts > Setting of starting count and interrupt" is "Timer interrupt is generated when counting is started/Start trigger is valid during counting operation.", an interrupt is generated immediately after first input signal is detected and output pin is also changed.

**Input Pulse Interval Measurement Function**

The count value can be captured at the TI0n valid edge and the interval of the pulse input to TI0n can be measured. The pulse interval can be calculated by the following expression.

- TI0n input pulse interval = Period of count clock × ((0x10000 × TSR0n.OVF) + (Captured value of TDR0n + 1))

Instead of using the TI0n pin input, a channel specified for the Input Pulse Interval Measurement can also use the signal as "Middle-speed on-chip oscillator (MOCO)", "Low-speed on-chip oscillator (LOCO)", "Subsystem clock (FSUB)", "Input signal of the RXD pin", and ELC event which selected in **Input>Input Source** property as its input source to drive counting.

**High-Low Level Pulse Width Measurement**

By starting counting at one edge of the TI0n pin input and capturing the number of counts at another edge, the signal width (high-level width or low-level width) of TI0n can be measured. The signal width of TI0n can be calculated by the following expression.

- Signal width of TI0n input = Period of count clock × ((0x10000 × TSR0n.OVF) + (Captured value of TDR0n + 1))

Instead of using the TI0n pin input, a channel specified for the High-Low Level Pulse Width Function can also use the signal as "Middle-speed on-chip oscillator (MOCO)", "Low-speed on-chip oscillator (LOCO)", "Subsystem clock (FSUB)", "Input signal of the RXD pin", and ELC event which selected in **Input>Input Source** property as its input source to drive counting.

### Triggering ELC Events with TAU

The TAU timer can trigger the start of other peripherals. The Event Link Controller (r_elc) guide provides a list of all available peripherals.

### Limitations

- When using pin input a delay of 2 TAU input clocks (ICLK/CK0*) is required between R_TAU_Open() and R_TAU_Start(). When using the noise filter, a delay of 4 clocks is required instead. See in hardware manual: TAU > Timer Input (TI0n) Control > Cautions on Channel Input Operation.
- When using High-Low Level Pulse Width Measurement function, the counter can not be reset by invoking R_TAU_Reset().

# Overview

The POEG module can be used to configure events to disable GPT GTIOC output pins.

### Features

The POEG module has the following features:

- Supports disabling GPT output pins based on GTETRG input pin level.
- Supports disabling GPT output pins based on comparator crossing events (configurable in the Comparator, High-Speed (r_acmphs) driver).
- Supports disabling GPT output pins when GTIOC pins are the same level (configurable in the Timer, General PWM (r_gpt) driver).
- Supports disabling GPT output pins when main oscillator stop is detected.
- Supports disabling GPT output pins by software API.
- Supports notifying the application when GPT output pins are disabled by POEG.
- Supports resetting POEG status.

# Configuration

### Build Time Configurations for r_poeg

The following build time configurations are defined in fsp_cfg/r_poeg_cfg.h:

| Configuration | Options | Default | Description |
|---|---|---|---|
| Parameter Checking | • Default (BSP)<br>• Enabled<br>• Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

### Configurations for Timers > Port Output Enable for GPT (r_poeg)

This module can be added to the Stacks tab via New Stack > Timers > Port Output Enable for GPT (r_poeg). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|---|---|---|---|
| General | | | |
| Name | Name must be a valid C symbol | g_poeg0 | Module name. |
| Channel | Must be a valid POEG channel | 0 | Specify the hardware channel. |
| Trigger | MCU Specific Options | | Select the trigger |

| | | | |
|---|---|---|---|
| | | | sources that will enable POEG. Software disable is always supported. This configuration can only be set once after reset. It cannot be modified after the initial setting. |
| Input | | | |
| GTETRG Polarity | • Active High<br>• Active Low | Active High | Select the polarity of the GTETRG pin. Only applicable if GTETRG pin is selected under Trigger. |
| GTETRG Noise Filter | • Disabled<br>• PCLKB/1<br>• PCLKB/8<br>• PCLKB/32<br>• PCLKB/128 | Disabled | Configure the noise filter for the GTETRG pin. Only applicable if GTETRG pin is selected under Trigger. |

| Interrupt Priority | MCU Specific Options | | Select the POEG interrupt priority. |

### Clock Configuration

The POEG clock is based on the PCLKB frequency.

### Pin Configuration

This module can use GTETRGA, GTETRGB, GTETRGC, or GTETRGD as an input signal to disable GPT output pins.

# Usage Notes

### POEG GTETRG Pin and Channel

The POEG channel number corresponds to the GTETRG input pin that can be used with the channel. GTETRGA must be used with POEG channel 0, GTETRGB must be used with POEG channel 1, etc.

### Limitations

The user should be aware of the following limitations when using POEG:

- The POEG trigger source can only be set once per channel. Modifying the POEG trigger source after it is set is not allowed by the hardware.
- The POEG cannot be disabled using this API. The interrupt is disabled in R_POEG_Close(), but the POEG will still disable the GPT output pins if a trigger is detected even if the module is closed.

# Examples

### POEG Basic Example

This is a basic example of minimal use of the POEG in an application.

```
void poeg_basic_example (void)
{
 fsp_err_t err = FSP_SUCCESS;
 /* Initializes the POEG. */
    err = R_POEG_Open(&g_poeg0_ctrl, &g_poeg0_cfg);
 /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
}
```

### POEG Callback Example

This is an example of a using the POEG callback to restore GPT output operation.

```
/* Example callback called when POEG disables GPT output pins. */
void poeg_callback (poeg_callback_args_t * p_args)
{
 FSP_PARAMETER_NOT_USED(p_args);
 /* (Optional) Determine the cause of the POEG event. */
 poeg_status_t status;
    (void) R_POEG_StatusGet(&g_poeg0_ctrl, &status);
 /* Correct the cause of the POEG event before resetting POEG. */
 /* Reset the POEG before exiting the callback. */
    (void) R_POEG_Reset(&g_poeg0_ctrl);
 /* Wait for the status to clear after reset before exiting the callback to ensure
the interrupt does not fire
  * again. */
```

```
do
   {
     (void) R_POEG_StatusGet(&g_poeg0_ctrl, &status);
   } while (POEG_STATE_NO_DISABLE_REQUEST != status.state);
 /* Alternatively, if the POEG cannot be reset, disable the POEG interrupt to prevent
it from firing continuously.
  * Update the 0 in the macro below to match the POEG channel number. */
   NVIC_DisableIRQ(VECTOR_NUMBER_POEG0_EVENT);
}
```

### Detailed Description

Driver for the RTC peripheral on RA MCUs. This module implements the RTC Interface.

# Overview

The RTC HAL module configures the RTC module and controls clock, calendar and alarm functions. A callback can be used to respond to the alarm and periodic interrupt.

### Features

- RTC time and date get and set.
- RTC time and date alarm get and set.
- RTC alarm and periodic event notification.
- RTC time capture.

The RTC HAL module supports three different interrupt types:

- An alarm interrupt generated on a match of any combination of year, month, day, day of the week, hour, minute or second
- A periodic interrupt generated every 2, 1, 1/2, 1/4, 1/8, 1/16, 1/32, 1/64, 1/128, or 1/256 second(s)
- A carry interrupt is used internally when reading time from the RTC calender to get accurant time readings.
  *Note*
  *See "Reading 64-Hz Counter and Time" in the RTC section of the relevant hardware manual for more details.*
  A user-defined callback function can be registered (in the rtc_api_t::open API call) and will be called from the interrupt service routine (ISR) for alarm and periodic interrupt. When called, it is passed a pointer to a structure (rtc_callback_args_t) that holds a user-defined context pointer and an indication of which type of interrupt was fired.

### Date and Time validation

"Parameter Checking" needs to be enabled if date and time validation is required for calendarTimeSet and calendarAlarmSet APIs. If "Parameter Checking" is enabled, the 'day of the week' field is automatically calculated and updated by the driver for the provided date. When using the calendarAlarmSet API, only the fields which have their corresponding match flag set are written to the registers. Other register fields are reset to default value.

### Sub-Clock error adjustment (Time Error Adjustment Function)

The time error adjustment function is used to correct errors, running fast or slow, in the time caused

by variation in the precision of oscillation by the sub-clock oscillator. Because 32,768 cycles of the sub-clock oscillator constitute 1 second of operation when the sub-clock oscillator is selected, the clock runs fast if the sub-clock frequency is high and slow if the sub-clock frequency is low. The time error adjustment functions include:

- Automatic adjustment
- Adjustment by software

The error adjustment is reset every time RTC is reconfigured or time is set.

*Note*

*RTC driver configurations do not do error adjustment internally while initiliazing the driver. Application must make calls to the error adjustment APIs for desired adjustment. See "Time Error Adjustment Function" in the RTC section of the relevant hardware manual for more details on this feature.*

# Configuration

### Build Time Configurations for r_rtc

The following build time configurations are defined in fsp_cfg/r_rtc_cfg.h:

| Configuration | Options | Default | Description |
|---|---|---|---|
| Parameter Checking | • Default (BSP)<br>• Enabled<br>• Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |
| Set Source Clock in Open | • Enabled<br>• Disabled | Enabled | If enabled RTC source clock is initialized in R_RTC_Open. If disabled, R_RTC_ClockSourceSet must be called to set the RTC source clock. Disable if user wants to control the setting of RTC source clock after warm start. |

### Configurations for Timers > Realtime Clock (r_rtc)

This module can be added to the Stacks tab via New Stack > Timers > Realtime Clock (r_rtc). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|---|---|---|---|
| Name | Name must be a valid C symbol | g_rtc0 | Module name. |
| Clock Source | MCU Specific Options | | Select the RTC clock source. |
| Frequency Comparison Value (LOCO) | Value must be a positive integer between 7 and 511 | 255 | Frequency comparison value when using LOCO |

| Adjustment Type (Plus-Minus) | • NONE<br>• Addition<br>• Subtraction | NONE | Select the Error Adjustment type |
| Error Adjustment Value | Manual Entry | 0 | Specify the Adjustment Value (the number of sub-clock cycles) from the prescaler |
| Callback | Name must be a valid C symbol | NULL | A user callback function can be provided. If this callback function is provided, it will be called from the interrupt service routine (ISR). |
| Alarm Interrupt Priority | MCU Specific Options | | Select the alarm interrupt priority. |
| Period Interrupt Priority | MCU Specific Options | | Select the period interrupt priority. |
| Carry Interrupt Priority | MCU Specific Options | | Select the carry interrupt priority. |

*Note*

*See "Frequency Register (RFRH/RFRL)" in the RTC section of the relevant hardware manual for more details*

### Interrupt Configuration

To activate interrupts for the RTC module, the desired interrupts must be enabled, The underlying implementation will be expected to handle any interrupts it can support and notify higher layers via callback.

### Clock Configuration

The RTC HAL module can use the following clock sources:

- LOCO (Low Speed On-Chip Oscillator) with less accuracy
- Sub-clock oscillator with increased accuracy

Users have to select the right source for their application. LOCO is the default during configuration when it is available.

### Pin Configuration

This module does not use I/O pins.

# Usage Notes

### System Initialization

- RTC driver does not start the sub-clock. The application is responsible for ensuring required clocks are started and stable before accessing MCU peripheral registers.

Warning

The subclock can take seconds to stabilize. The RA startup code does not wait for subclock stabilization unless the subclock is the main clock source. When running AGT or RTC off the subclock, the application must ensure the subclock is stable before starting operation.

- Carry interrupt priority must be set to avoid incorrect time returned from calendarTimeGet API during roll-over.
- Even when only running in Periodic Interrupt mode R_RTC_CalendarTimeSet must be called successfully to start the RTC.
- In case of warm start or a hard reset (when VBATT powers RTC in case of power loss), user might not want to reinitialize the clock source after reset. In this case, disable the Set Source Clock in Open property for RTC and call R_RTC_ClockSourceSet() only when RTC clock source needs to be set. Application should check for the reset type and should accordingly call the R_RTC_ClockSourceSet().

### Limitations

Developers should be aware of the following limitations when using the RTC:

- R_RTC operates in 24-hour mode.
- Binary-count mode is not supported.
- The R_RTC_CalendarTimeGet() cannot be used from an interrupt that has higher priority than the carry interrupt. Also, it must not be called with interrupts disabled globally, as this API internally uses carry interrupt for its processing. API may return incorrect time if this is done.
- Time capture input pins should be configured prior to opening RTC.
- When multiple events are detected, the capture time for the first event is retained. Time capture value must be got and reset status bit for the next capture when having event input.

### VRTC-Domain

VRTC-domain provides power supply to SOSC and RTC on devices with IRTC:

- In case VRTC-domain is invalid, SOSC and RTC will be in undetermined state. Any operation related to RTC and sub-clock should be avoided.
- When VRTC-domain becomes valid again, application is responsible to reinitialize SOSC and RTC. Sub-clock initialization can be done by calling R_BSP_SubclockInitialize().
- BSP provides R_BSP_SubclockStatusGet() to check the status of VRTC domain. But, it is recommended to use LVD to monitor VRTC domain change. Please refer to Low/Programmable Voltage Detection (r_lvd) module for more details.

### Time Capture

The RTC is capable of storing the month, day, hour, minute and second when detecting an edge of a signal on a time capture event input pin. On RA parts up to three capture channels can be configured.

- Use R_RTC_TimeCaptureSet to configure the detection source and noise filter for each capture channel.
- Use R_RTC_TimeCaptureGet to check the latest capture. If no capture has been triggered the function will return FSP_ERR_INVALID_STATE.
- Even when the supply of power from the VCC power supply pin is stopped and VRTC power is being supplied, the time capture function of the time capture event input pins (RTCICn) can be used.

### Detailed Description

Driver for the RTC peripheral on RA MCUs. This module implements the RTC Interface.

# Overview

The RTC HAL module configures the RTC module and controls clock, calendar and alarm functions. A callback can be used to respond to the alarm and periodic interrupt.

### Features

- RTC_C time and date get and set.
- RTC_C time and date alarm get and set.
- RTC_C alarm and periodic event notification.

The RTC HAL module supports two different interrupt types:

- An alarm interrupt generated on a match of any combination of minute, hour and day of the week.
- A periodic interrupt generated every 1 month, 1 day, 1 hour, 1 minute, 1 second and 1/2 second.

A user-defined callback function can be registered (in the rtc_api_t::open API call) and will be called from the interrupt service routine (ISR) for alarm and periodic interrupt. When called, it is passed a pointer to a structure (rtc_callback_args_t) that holds a user-defined context pointer and an indication of which type of interrupt was fired.

### Date and Time validation

"Parameter Checking" needs to be enabled if date and time validation is required for calendarTimeSet and calendarAlarmSet APIs. When using the calendarAlarmSet API, minute, hour and day of the week are written to the related registers.

### Sub-Clock error adjustment (Time Error Adjustment Function)

The time error adjustment function is used to correct errors, running fast or slow, in the time caused by variation in the precision of oscillation by the sub-clock oscillator. Because 32,768 cycles of the sub-clock oscillator constitute 1 second of operation when the sub-clock oscillator is selected, the

clock runs fast if the sub-clock frequency is high and slow if the sub-clock frequency is low.

The error adjustment is reset every time RTC is reconfigured or time is set.

*Note*

*RTC driver configurations do not do error adjustment internally while initializing the driver. Application must make calls to the error adjustment api's for desired adjustment.*

# Configuration

### Build Time Configurations for r_rtc_c

The following build time configurations are defined in fsp_cfg/r_rtc_c_cfg.h:

| Configuration | Options | Default | Description |
|---|---|---|---|

### Configurations for Timers > Realtime Clock (r_rtc_c)

This module can be added to the Stacks tab via New Stack > Timers > Realtime Clock (r_rtc_c).

| Configuration | Options | Default | Description |
|---|---|---|---|
| Name | Name must be a valid C symbol | g_rtc0 | Module name. |
| Operation clock | • FSXP<br>• SOSC/256 (128 Hz) | FSXP | Select the RTC operation clock. If using 'SOSC/256' as the source for RTCCLK, the FSXP source cannot be LOCO in Clock tab. |
| Callback | Name must be a valid C symbol | NULL | A user callback function can be provided. If this callback function is provided, it will be called from the interrupt service routine (ISR). |
| Interrupt Priority | MCU Specific Options | | Select the period or alarm interrupt priority. |

### Interrupt Configuration

To activate interrupts for the RTC module, the desired interrupts must be enabled, The underlying implementation will be expected to handle any interrupts it can support and notify higher layers via callback.

### Clock Configuration

The RTC HAL module can use the following clock sources(setting in clock page):

- Sub-Clock: SOSC (32.768 kHz)
- SOSC/256 (128 Hz)
- LOCO (32.768 kHz)

Users have to select the right source for their application. Sub-Clock is the default during configuration when it is available.

### Pin Configuration

This module does not use I/O pins.

## Usage Notes

### System Initialization

- RTC driver does not start the sub-clock. The application is responsible for ensuring required clocks are started and stable before accessing MCU peripheral registers.

Warning
The subclock can take seconds to stabilize. The RA startup code does not wait for subclock stabilization unless the subclock is the main clock source. When running AGT or RTC off the subclock, the application must ensure the subclock is stable before starting operation.

- Even when only running in Periodic Interrupt mode R_RTC_C_CalendarTimeSet must be called successfully to start the RTC.

### Limitations

Developers should be aware of the following limitations when using the RTC_C:

- R_RTC_C operates in 24-hour mode.
- If using 'SOSC/256' as the source for RTC operation clock, the FSXP source cannot be LOCO in Clock tab.
- Time error correction function can only proceed when the setting of the RTCC0.RTC128EN bit is 0.
- Alarm clock interrupt can work under LOCO clock source, but it is unstable. Please use alarm clock interrupt function under other clocks.

## Examples

### Detailed Description

Driver for 3-phase motor control using the GPT peripheral on RA MCUs. This module implements the Three-Phase Interface.

# Overview

The General PWM Timer (GPT) Three-Phase driver provides basic functionality for synchronously starting and stopping three PWM channels for use in 3-phase motor control applications. A function is additionally provided to allow setting duty cycle values for all three channels, optionally with double-buffering.

### Features

The GPT Three-Phase driver provides the following functions:

- Synchronize configuration of three GPT channels
- Synchronously start, stop and reset all three GPT channels
- Set duty cycle on all three channels with one function

# Configuration

### Build Time Configurations for r_gpt_three_phase

The following build time configurations are defined in fsp_cfg/r_gpt_three_phase_cfg.h:

| Configuration | Options | Default | Description |
|---|---|---|---|
| Parameter Checking | • Default (BSP)<br>• Enabled<br>• Disabled | Default (BSP) | If selected code for parameter checking is included in the build. |

### Configurations for Timers > Three-Phase PWM (r_gpt_three_phase)

This module can be added to the Stacks tab via New Stack > Timers > Three-Phase PWM (r_gpt_three_phase). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Configuration | Options | Default | Description |
|---|---|---|---|
| General | | | |
| Name | Name must be a valid C symbol | g_three_phase0 | Module name. |
| Mode | • Triangle-Wave Symmetric PWM<br>• Triangle-Wave Asymmetric PWM<br>• Triangle-Wave Asymmetric PWM (Mode 3) | Triangle-Wave Symmetric PWM | Mode selection. Triangle-Wave Symmetric PWM: Generates symmetric PWM waveforms with duty cycle determined by compare match set during a crest interrupt and updated at the next trough. Triangle-Wave Asymmetric PWM: Generates asymmetric PWM waveforms with duty cycle determined by compare match set during a crest/trough interrupt and updated at the next trough/crest. |
| Period | Value must be a non-negative integer less than or equal to 0x40000000000 | 15 | Specify the timer period in units selected below. Setting the period to 0x100000000 raw counts results in the maximum period. Set the period to 0x100000000 raw counts for a free running timer or an input capture configuration. The period can be set up to 0x40000000000, which will use a divider of 1024 with the maximum period.<br><br>If the requested period cannot be achieved, the settings with the largest possible period |

| | | | |
|---|---|---|---|
| | | | that is less than or equal to the requested period are used. The theoretical calculated period is printed in a comment in the generated timer_cfg_t structures for each timer. |
| Period Unit | • Raw Counts<br>• Nanoseconds<br>• Microseconds<br>• Milliseconds<br>• Seconds<br>• Hertz<br>• Kilohertz | Kilohertz | Unit of the period specified above |
| GPT U-Channel | Value must be an integer greater than or equal to 0 | 0 | Specify the GPT channel for U signal output. |
| GPT V-Channel | Value must be an integer greater than or equal to 0 | 1 | Specify the GPT channel for V signal output. |
| GPT W-Channel | Value must be an integer greater than or equal to 0 | 2 | Specify the GPT channel for W signal output. |
| Callback Channel | • U-Channel<br>• V-Channel<br>• W-Channel | U-Channel | Specify the GPT channel to set a callback for when using R_GPT_THREE_PHASE_CallbackSet. |
| Buffer Mode | • Single Buffer<br>• Double Buffer | Single Buffer | When Double Buffer is selected the 'duty_buffer' array in three_phase_duty_cycle_t is used as a buffer for the 'duty' array. This allows setting the duty cycle for the next two crest/trough events in asymmetric mode with only one call to R_GPT_THREE_PHASE_DutyCycleSet. |
| GTIOCA Stop Level | • Pin Level Low<br>• Pin Level High | Pin Level Low | Select the behavior of the output pin when the timer is stopped. |
| GTIOCB Stop Level | • Pin Level Low<br>• Pin Level High | Pin Level Low | Select the behavior of the output pin when the timer is stopped. |

Extra Features

Extra Features > Dead Time

| | | | |
|---|---|---|---|
| Dead Time Count Up (Raw Counts) | Must be a valid non-negative integer with a maximum configurable value of 4294967295 (0xffffffff). | 0 | Select the dead time to apply during up counting. This value also applies during down counting for the GPT32 and GPT16 variants. |
| Dead Time Count Down (Raw Counts) (GPTE/GPTEH only) | Must be a valid non-negative integer with a maximum configurable value of 4294967295 (0xffffffff). | 0 | Select the dead time to apply during down counting. This value only applies to the GPT32E and GPT32EH variants. |

### Clock Configuration

Please refer to the Timer, General PWM (r_gpt) section for more information.

### Pin Configuration

Please refer to the Timer, General PWM (r_gpt) section for more information.

# Usage Notes

Warning

Be sure the GTIOCA/B stop level and dead time values are set appropriately for your application before attempting to drive a motor. Failure to do so may result in damage to the motor drive circuitry and/or the motor itself if the timer is stopped by software.

### Initial Setup

The following should be configured once the GPT Three-Phase module has been added to a project:

1. Set "Pin Output Support" in one of the GPT submodules to "Enabled with Extra Features"
2. Configure common settings in the GPT Three-Phase module properties
3. Set the crest and trough interrupt priority and callback function in **one** of the three GPT submodules (if desired)
4. Set the "Extra Features -> Output Disable" settings in each GPT submodule as needed for your application

*Note*

*Because all three modules are operated synchronously with the same period interrupts only need to be enabled in one of the three GPT modules.*

### Buffer Modes

There are two buffering modes available for duty cycle values - single- and double-buffered. In single buffer mode only the values specified in the duty array element of three_phase_duty_cycle_t are used by R_GPT_THREE_PHASE_DutyCycleSet. At the next trough or crest event the output duty cycle will be internally updated to the set values.

In double buffer mode the duty_buffer array values are used as buffer values for the duty elements. Once passed to R_GPT_THREE_PHASE_DutyCycleSet, the next trough or crest event will update the output duty cycle to the values specified in duty as before. However, at the following crest or trough event the output duty cycle will be updated to the values in duty_buffer. This allows the duty cycle for both sides of an asymmetric PWM waveform to be set at only one trough or crest event per period instead of at every event.

# Examples

### GPT Three-Phase Basic Example

This is a basic example of minimal use of the GPT Three-Phase module in an application. The duty cycle is updated at every timer trough with the previously loaded buffer value, then the duty cycle buffer is reloaded in the trough interrupt callback.

```
void gpt_callback (timer_callback_args_t * p_args)
{
 fsp_err_t                err;
 three_phase_duty_cycle_t duty_cycle;
 if (TIMER_EVENT_TROUGH == p_args->event)
    {
 /* Update duty cycle values (example) */
       duty_cycle.duty[THREE_PHASE_CHANNEL_U] =
get_duty_counts(THREE_PHASE_CHANNEL_U);
       duty_cycle.duty[THREE_PHASE_CHANNEL_V] =
get_duty_counts(THREE_PHASE_CHANNEL_V);
       duty_cycle.duty[THREE_PHASE_CHANNEL_W] =
get_duty_counts(THREE_PHASE_CHANNEL_W);
 /* Update duty cycle values */
       err = R_GPT_THREE_PHASE_DutyCycleSet(&g_gpt_three_phase_ctrl, &duty_cycle);
       assert(FSP_SUCCESS == err);
    }
 else
    {
 /* Handle crest event. */
    }
}
void gpt_three_phase_basic_example (void)
{
```

```
fsp_err_t err = FSP_SUCCESS;
/* Initializes the module. */
   err = R_GPT_THREE_PHASE_Open(&g_gpt_three_phase_ctrl, &g_gpt_three_phase_cfg);
/* Handle any errors. This function should be defined by the user. */
   assert(FSP_SUCCESS == err);
/* Start the timer. */
   (void) R_GPT_THREE_PHASE_Start(&g_gpt_three_phase_ctrl);
}
```

### ◆ R_GPT_THREE_PHASE_DutyCycleSet()

fsp_err_t R_GPT_THREE_PHASE_DutyCycleSet ( three_phase_ctrl_t *const *p_ctrl*, three_phase_duty_cycle_t *const *p_duty_cycle* )

Sets duty cycle for all three timers. Implements three_phase_api_t::dutyCycleSet.

In symmetric PWM mode duty cycle values are reflected after the next trough. In asymmetric PWM mode values are reflected at the next trough OR crest, whichever comes first.

When double-buffering is enabled the values in three_phase_duty_cycle_t::duty_buffer are set to the double-buffer registers. When values are reflected the first time the single buffer values (three_phase_duty_cycle_t::duty) are used. On the second reflection the duty_buffer values are used. In asymmetric PWM mode this enables both count-up and count-down PWM values to be set at trough (or crest) exclusively.

***Note***

*It is recommended to call this function in a high-priority callback to ensure that it is not interrupted and that no GPT events occur during setting that would result in a duty cycle buffer load operation.*

Example:

```
/* Update duty cycle values */
      err = R_GPT_THREE_PHASE_DutyCycleSet(&g_gpt_three_phase_ctrl, &duty_cycle);
      assert(FSP_SUCCESS == err);
```

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Duty cycle updated successfully. |
| FSP_ERR_ASSERTION | p_ctrl was NULL |
| FSP_ERR_NOT_OPEN | The instance is not opened. |
| FSP_ERR_INVALID_ARGUMENT | One or more duty cycle count values was outside the range 0..(period - 1). |

### ◆ R_GPT_THREE_PHASE_CallbackSet()

fsp_err_t R_GPT_THREE_PHASE_CallbackSet ( three_phase_ctrl_t *const *p_ctrl*, void(*)(timer_callback_args_t *) *p_callback*, void *const *p_context*, timer_callback_args_t *const *p_callback_memory* )

Updates the user callback for the GPT U-channel with the option to provide memory for the callback argument structure. Implements three_phase_api_t::callbackSet.

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Callback updated successfully. |
| FSP_ERR_ASSERTION | A required pointer is NULL. |
| FSP_ERR_NOT_OPEN | The control block has not been opened. |

### ◆ R_GPT_THREE_PHASE_Close()

fsp_err_t R_GPT_THREE_PHASE_Close ( three_phase_ctrl_t *const *p_ctrl*)

Stops counters, disables output pins, and clears internal driver data. Implements three_phase_api_t::close.

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Successful close. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance is not opened. |

### Detailed Description

Driver for the TML peripherals on RA MCUs. This module implements the Timer Interface.

# Overview

The TML module can be used to count or count input events. TML operates with the HOCO, MOCO, MOSC, LOCO/SOSC clock or the event input from the ELC, which is asynchronous to CPU operation.

### Features

The TML module has the following features:

- Supports 8-bit counter mode: 4 independent channels (Channel 0,Channel 1,Channel 2 and Channel 3).
- Supports 16-bit counter mode: 2 independent channels (Channel 0 and Channel 2).
- Supports 32-bit counter mode: 1 channel (channel 0).
- Supports 16-bit capture mode: 1 channel (channel 0).
- Supports count source of HOCO, MOCO, MOSC, LOCO/SOSC clock or ELC events.
- Configurable period (counts per timer cycle).
- Supports runtime reconfiguration of period.
- Supports capture-start by external sources from ELC events.
- APIs are provided to start, stop, and reset the counter.
- APIs are provided to get the current period, source clock frequency, and count direction.
- APIs are provided to get the current timer status.

### Selecting a Timer

RA MCUs have different timer peripherals: the General PWM Timer (GPT), the 32-bit Interval Timer (TML), Timer Array Unit (TAU), and the Asynchronous General Purpose Timer (AGT). Some MCUs have multiple timer modules. When selecting between them, consider these factors:

| | GPT | TML | AGT | TAU |
|---|---|---|---|---|
| Low Power Modes | The GPT can operate in sleep mode. | The TML can operate in all low power modes. | The AGT can operate in all low power modes. | The TAU can not operate in all low power modes. |
| Available Channels | The number of GPT channels is device specific. Currently supported MCUs have at least 7 GPT channels. | Currently supported MCUs have 4 TML channels. | Currently supported MCUs have 2 AGT channels. | Currently supported MCUs have 8 TAU channels. |
| Timer Resolution | Currently | The TML timers | The AGT timers | The TAU timers |

| | | | | |
|---|---|---|---|---|
| | supported MCUs have at least one 32-bit GPT timer. | are 32-bit/16-bit/8-bit timers. | are 16-bit timers. | are 16-bit/8-bit timers. |
| Clock Source | The GPT runs off PCLKD with a configurable divider up to 1024. It can also be configured to count ELC events or external pulses. | The TML runs off MOSC, LOCO/SOSC, HOCO, MOCO with a configurable divider up to 128 or ELC events. | The AGT runs off PCLKB, LOCO, or subclock. | The TAU runs off PCLK with a configurable divider up to 32768 |

### Clock Configuration

The TML operating clock is based on the HOCO, MOCO, MOSC, or LOCO/SOSC. The operating frequency will be based on the source chosen and the divider selected. You can set the clock frequencies using the **Clocks** tab of the RA Configuration editor or change the clock divider for the capture mode channel by **Capture Mode Settings->Capture Clock Divider**.

*Note*

*The TML channels may be alternatively configured to use an event input from the ELC as a count clock in case no frequency/duration can be input, only "Raw Counts".*

### Pin Configuration

# Usage Notes

### Maximum Period

In capture mode, the clock divider for the capture channel has to be selected in **Capture Mode Settings->Capture Clock Divider**. If ITLCMP01 is the capture trigger input, the clock divider for channels 2 + 3 is not available.

When no capture mode is active, the RA Configuration editor will automatically calculate the period count value and source clock divider based on the selected period time, units and clock speed.

When the selected period unit is "Raw counts", the maximum period setting is 0x8000000000/0x800000/0x8000 on a 32-bit/16-bit/8-bit timer. This will configure the timer with the maximum period and a count clock divisor of 128.

*Note*

*When an event input from ELC is used as an operation clock, the automatic calculation of the period count value and source clock divider is not available.*

### Updating Period

The period is updated after calling R_TML_PeriodSet().

*Note*

*The period is only updated when the counter is stopped.*
*When using the API to set the period counts, the maximum timer_cfg_t::period_counts for 8-bit and 16-bit modes are 0x100 and 0x10000, respectively. To set the the maximum count for 32-bit mode, set the timer_cfg_t::period_counts to 0 (as 0x10000000 is outside the 32-bit range).*
*In the 16-bit capture mode, if the interrupt on compare match with ITLCMP01 is used as trigger source, the period counts of the 16-bit timer channels 2 + 3 can be changed at run-time.*

### Capture mode

When the 16-bit capture mode is to be used for channels 0 and 1, the counter value is stored in interval timer capture register 00 (ITLCAP00) in response to the selected capture trigger.

*Note*

*When Channels 0 and 1 are in capture mode, Channels 2 and 3 can be used to trigger the capture when ITLCMP01 is the capture trigger. In this case the counter setup for Channels 2 and 3 are in **Capture Mode Settings->16-Bit Counter Input Settings**. If ITLCMP01 is not the capture trigger input, Channels 2 and 3 may be setup as an independent instance of 16-bit Counter channel.*
*When a capture trigger is generated when the timer is not running, the previous counter value of the capture channel is still copied to the Interval Timer Capture Register (ITLCAP00).*
*The **Common->16-bit Capture Mode Support** property in the module configuration must be enabled to use the capture operation.*

### Controlling TML with ELC Events

The TML timer can be configured to start count down or trigger capture when an ELC event occurs.

*Note*

*The configurable ELC TML sources are shared by all TML channels.*
*The event links for the ELC must be configured outside this module.*

### Triggering ELC Events with TML

The TML timer can trigger the start of other peripherals. The Event Link Controller (r_elc) guide provides a list of all available peripherals.

### TML Capture Example

This is an example of using the TML to capture the counter value of configured channel.

```

      g_captured_time    = (period * g_capture_overflows) + p_args->capture;
      g_capture_overflows = 0U;
   }
 if (TIMER_EVENT_CYCLE_END == p_args->event)
   {
 /* An overflow occurred during capture. This must be accounted for at the
application layer. */
      g_capture_overflows++;
   }
}

 /* Initializes the module. */
   err = R_TML_Open(&g_timer0_ctrl, &g_timer0_cfg);
 /* Handle any errors. This function should be defined by the user. */
   assert(FSP_SUCCESS == err);
 /* There are 4 ways to trigger the capture:
  * - Use software trigger by set the ITLCC0.CAPR bit to 1 directly after call start
  * - Use ELC event and wait for valid input
  * - Use LOCO/SOSC clock and wait for valid edge
  * - Use interrupt on compare match with ITLCPM01
  *
  * This example uses the last option.
  */
   (void) R_TML_Start(&g_timer0_ctrl);
}
```

 /* Calculate the desired period based on the current clock. Note that this
calculation could overflow if the
  * desired period is larger than UINT32_MAX. A cast to uint64_t is used to prevent
this. */
    uint32_t period_counts =
       (uint32_t) (((uint64_t) timer_freq_hz * TML_EXAMPLE_DESIRED_PERIOD_MSEC) /
TML_EXAMPLE_MSEC_PER_SEC);
 /* Set the calculated period. */

## Function Documentation

### ◆ R_TML_Open()

fsp_err_t R_TML_Open ( timer_ctrl_t *const *p_ctrl*, timer_cfg_t const *const *p_cfg* )

Initializes the timer module and applies configurations. Implements timer_api_t::open.

TML hardware does not support one-shot functionality natively. If one shot mode is desired, the user code should stop the timer after the timer expires the first time in an ISR after the requested period has elapsed.

The TML implementation of the general timer can accept a tml_extended_cfg_t extension parameter.

Example:

```
/* Initializes the module. */
   err = R_TML_Open(&g_timer0_ctrl, &g_timer0_cfg);
```

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Initialization was successful and timer has started. |
| FSP_ERR_ASSERTION | A required input pointer is NULL or the source divider is invalid. |
| FSP_ERR_ALREADY_OPEN | Module is already open. |
| FSP_ERR_IRQ_BSP_DISABLED | timer_cfg_t::p_callback is not NULL, but ISR is not enabled. ISR must be enabled to use one-shot mode or callback. |
| FSP_ERR_IP_CHANNEL_NOT_PRESENT | The channel requested in the p_cfg parameter is not available on this device. |
| FSP_ERR_INVALID_CHANNEL | Selected channel is invalid |

### ◆ R_TML_Enable()

fsp_err_t R_TML_Enable ( timer_ctrl_t *const *p_ctrl*)

Enable the interrupt generation from the selected channel timer_api_t::enable.

Example:

```
/* (Optional) Disable the mask to use the interrupt. */
   (void) R_TML_Enable(&g_timer0_ctrl);
```

### Detailed Description

Driver for the GPT32 and GPT16 peripherals on RA MCUs. This module implements the Timer Interface.

# Overview

The GPT module can be used to count events, measure external input signals, generate a periodic interrupt, or output a periodic or PWM signal to a GTIOC pin.

This module supports the GPT peripherals GPT32EH, GPT32E, GPT32, and GPT16. GPT16 is a 16-bit timer. The other peripherals (GPT32EH, GPT32E, and GPT32) are 32-bit timers. The 32-bit timers are all treated the same in this module from the API perspective.

### Features

The GPT module has the following features:

- Supports periodic mode, one-shot mode, and PWM mode.
- Supports count source of PCLK, GTETRG pins, GTIOC pins, or ELC events.
- Supports debounce filter on GTIOC pins.
- Signal can be output to a pin.
- Configurable period (counts per timer cycle).
- Configurable duty cycle in PWM mode.
- Supports runtime reconfiguration of period.

- Supports runtime reconfiguration of duty cycle in PWM mode.

- Supports GTIOCnA and GTIOCnB input/output polarity control.

### Selecting a Timer

RA MCUs have two timer peripherals: the General PWM Timer (GPT) and the Asynchronous General Purpose Timer (AGT). When selecting between them, consider these factors:

| | GPT | AGT |
|---|---|---|
| Low Power Modes | The GPT can operate in sleep mode. | The AGT can operate in all low power modes. |
| Available Channels | The number of GPT channels is device specific. All currently supported MCUs have at least 7 GPT channels. | All MCUs have 2 AGT channels. |
| Timer Resolution | All MCUs have at least one 32-bit GPT timer. | The AGT timers are 16-bit timers. |
| Clock Source | The GPT runs off PCLKD with a configurable divider up to 1024. It can also be configured to count ELC events or external pulses. | The AGT runs off PCLKB, LOCO, or subclock. |

### Clock Configuration

The GPT clock is based on the PCLKD frequency. You can set the PCLKD frequency using the **Clocks** tab of the RA Configuration editor or by using the CGC Interface at run-time.

### Pin Configuration

This module can use GTETRGA, GTETRGB, GTETRGC, GTETRGD, GTIOCA and GTIOCB pins as count sources.

This module can use GTIOCA and GTIOCB pins as output pins for periodic or PWM signals.

This module can use GTIOCA and GTIOCB as input pins to measure input signals.

## Usage Notes

### Maximum Period

The RA Configuration editor will automatically calculate the period count value and source clock divider based on the selected period time, units and clock speed.

When the selected period unit is "Raw counts", the maximum period setting is 0x40000000000 on a 32-bit timer or 0x4000000 on a 16-bit timer. This will configure the timer with the maximum period and a count clock divisor of 1024.

*Note*

*16-bit channels inherently have a reduced maximum period compared to 32-bit channels. When setting period values of hundreds of milliseconds or more on 16-bit channels be sure to check the generated output to confirm the actual configured value as it will clip much earlier than 32-bit channels. In general, it is recommended to use a lower-power timer like AGT or RTC if long hardware delays are required.*

### Updating Period and Duty Cycle

The period and duty cycle are updated after the next counter overflow after calling R_GPT_PeriodSet() or R_GPT_DutyCycleSet(). To force them to update before the next counter overflow, call R_GPT_Reset() while the counter is running.

*Note*

*When manually changing the timer period counts the maximum value for a 32-bit GPT is 0x100000000. This number overflows the 32-bit value for timer_cfg_t::period_counts. To configure the timer for the maximum period, set timer_cfg_t::period_counts to 0.*
*When changing the period and duty cycle at the same time when Parameter Checking is enabled, call R_GPT_PeriodSet first followed by R_GPT_DutyCycleSet to ensure input validation is performed correctly.*

### One-Shot Mode

The GPT timer does not support one-shot mode natively. One-shot mode is achieved by stopping the timer in the interrupt service routine before the callback is called. If the interrupt is not serviced before the timer period expires again, the timer generates more than one event. The callback is only called once in this case, but multiple events may be generated if the timer is linked to the Transfer (r_dtc).

### One-Shot Mode Output

The output waveform in one-shot mode is one PCLKD cycle less than the configured period. The configured period must be at least 2 counts to generate an output pulse.

Examples of one-shot signals that can be generated by this module are shown below:

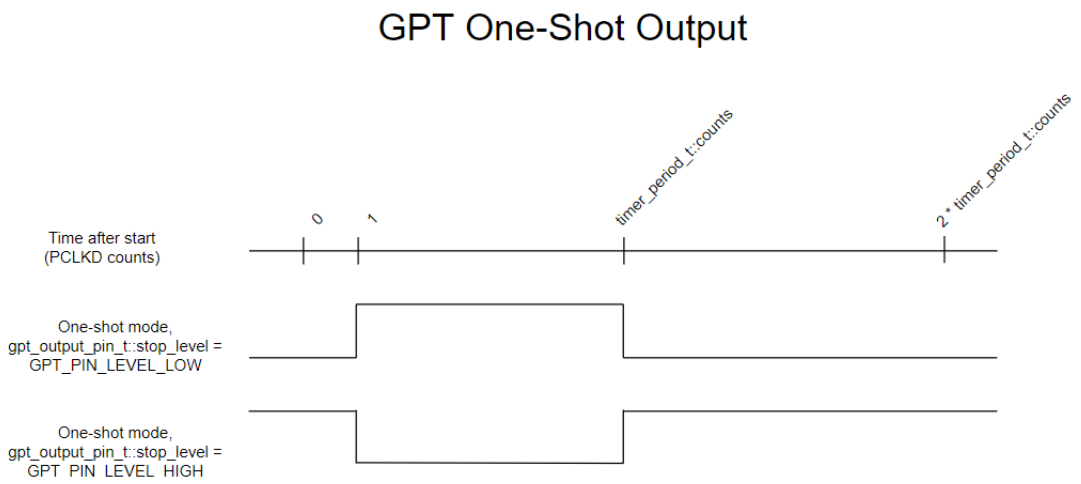

Figure 336: GPT One-Shot Output

### One-Shot Pulse Mode

The one-shot pulse mode is an asymmetric PWM mode that provides more control over the rising and falling edges of the output. The user provides a period and initial output level and controls the signal by specifying compare match values for the leading and trailing edges each period.

*Note*

*Despite its name, the One-Shot Pulse Mode operates continuously and does not stop after the first period.*

### One-Shot Pulse Mode Output

Examples of PWM signals that can be generated by this module are shown below. The leading and trailing edge match values can be modified using R_GPT_DutyCycleSet() in the overflow interrupt.

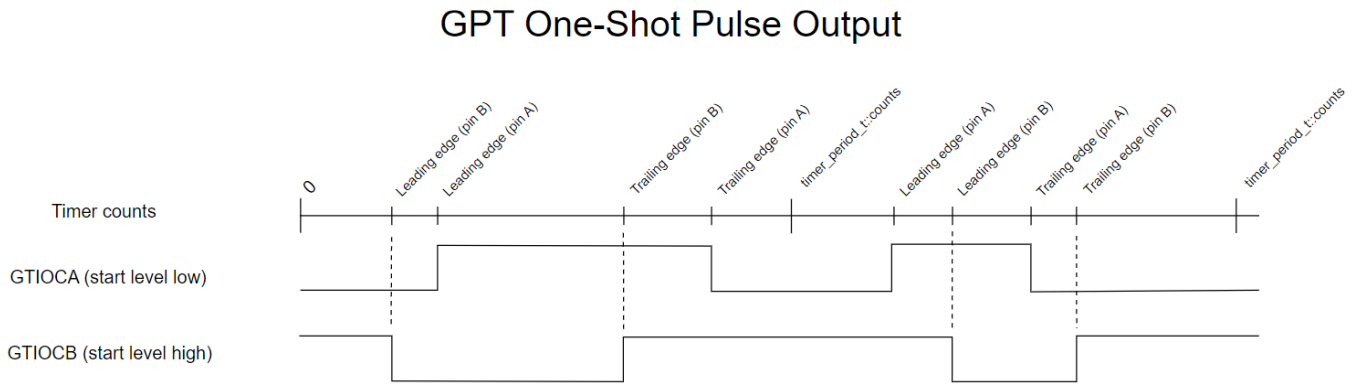

Figure 337: GPT One-Shot Pulse Output (without dead time)

If dead time is enabled only match values for GTIOCnA need to be set; the match values for GTIOCnB will be automatically configured in hardware.

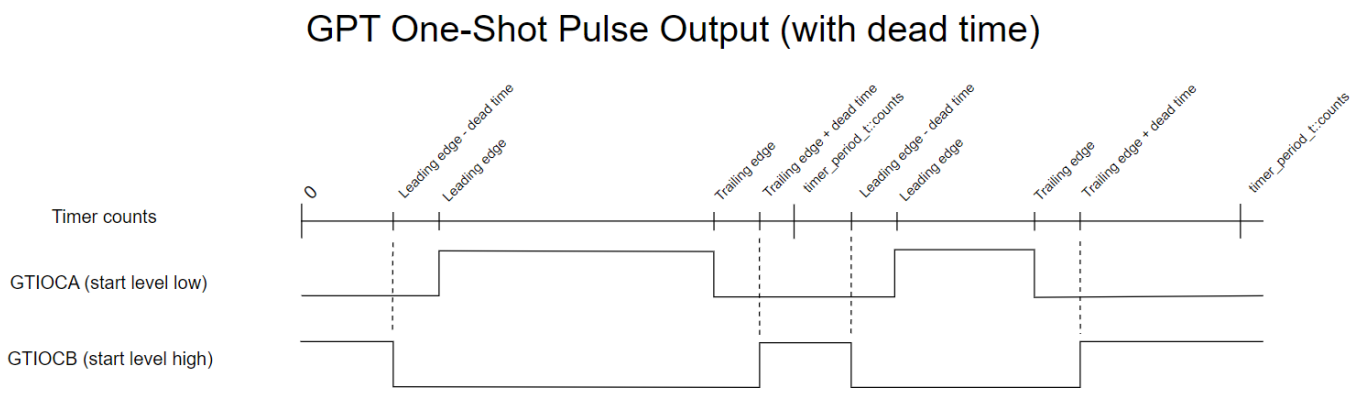

Figure 338: GPT One-Shot Pulse Output (with dead time)

### Periodic Output

The GTIOC pin toggles twice each time the timer expires in periodic mode. This is achieved by defining a PWM wave at a 50 percent duty cycle so that the period of the resulting square wave (from rising edge to rising edge) matches the period of the GPT timer. Since the periodic output is actually a PWM output, the time at the stop level is one cycle shorter than the time opposite the stop level for odd period values.

Examples of periodic signals that can be generated by this module are shown below:

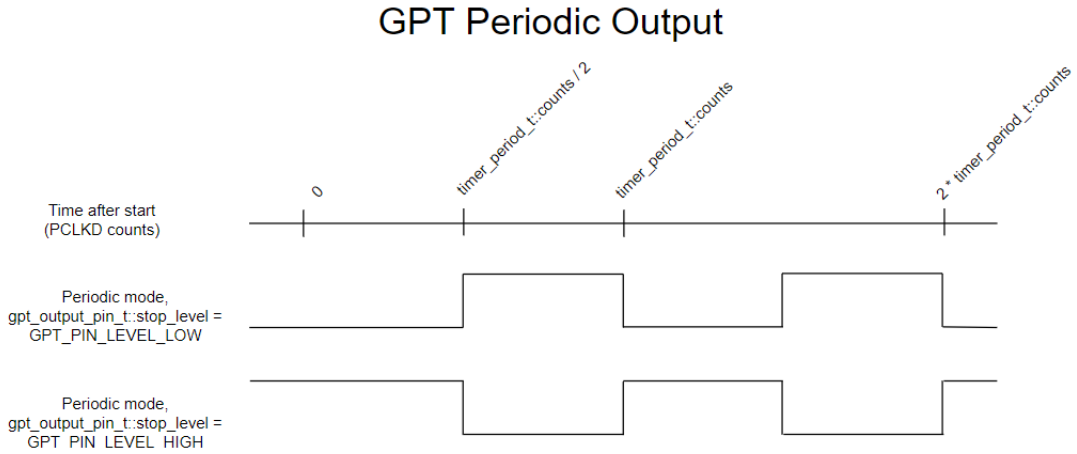

Figure 339: GPT Periodic Output

### PWM Output

The PWM output signal is high at the beginning of the cycle and low at the end of the cycle.

Examples of PWM signals that can be generated by this module are shown below:

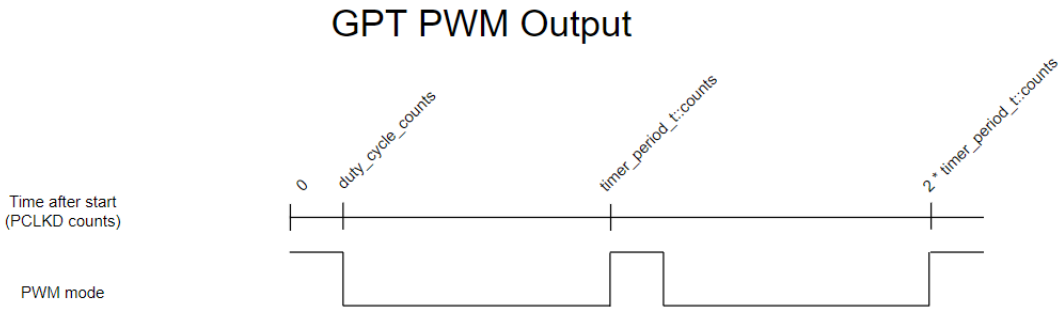

Figure 340: GPT PWM Output

### Triangle-Wave PWM Output

Examples of PWM signals that can be generated by this module are shown below. The duty_cycle_counts can be modified using R_GPT_DutyCycleSet() in the crest interrupt and updated at the following trough for symmetric PWM or modified in both the crest/trough interrupts and updated at the following trough/crest for asymmetric PWM.

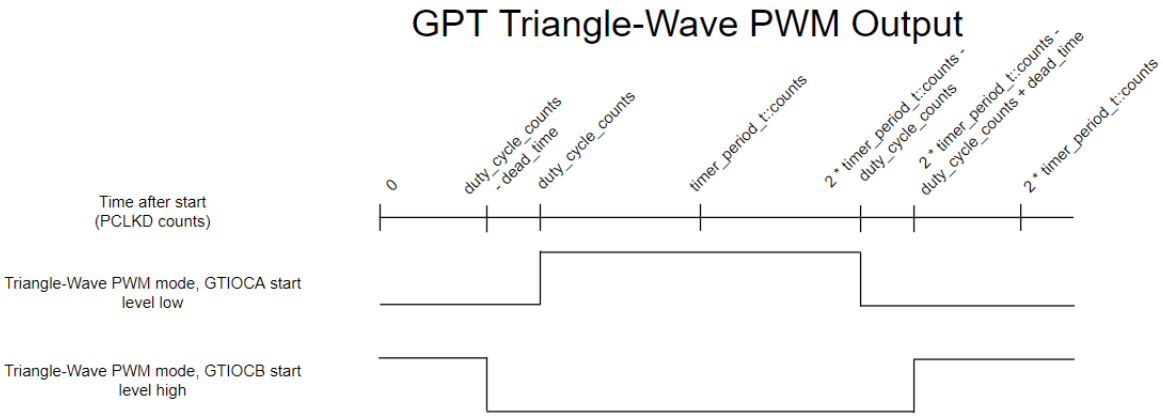

Figure 341: GPT Triangle-Wave PWM Output

### PWM Output Delay Circuit

On select MCUs, an additional PWM output delay circuit can be configured in order to fine tune the rising and falling edge delays in increments of 1/32 times the period of the GPT core clock. The PWM output delay function must be configured prior to initializing the GPT channels using R_GPT_PwmOutputDelayInitialize.

*Note*

*1. In Saw-wave PWM mode, the output delay setting cannot be changed while the capture compare setting (GTCCRn) is greater than or equal the period setting (GTPR) - 2.*
*2. In Triangle PWM modes, the output delay setting cannot be changed while the counter is counting down, and the capture compare setting (GTCCRn) is less than or equal to 2.*
*3. When the PWM Output Delay Circuit is enabled, the PWM signal is delayed by 3 GPT core clock cycles.*
*4. When the GPTCLK is used as the GPT core clock, the following delay is required between writes to the rising or falling edge output delay setting for a given pin: Write_Interval[ns] = Period_of_PCLKA [ns] × 6 + Period_of_GPTCLK [ns] × 4).*

### Event Counting

Event counting can be done by selecting up or down counting sources from GTETRG pins, ELC events, or GTIOC pins. In event counting mode, the GPT counter is not affected by PCLKD.

*Note*

*In event counting mode, the application must call R_GPT_Start() to enable event counting. The counter will not change after calling R_GPT_Start() until an event occurs.*

### Pulse Measurement

If the capture edge occurs before the start edge in pulse measurement, the first capture is invalid (0).

### Controlling GPT with GTETRG Edges

The GPT timer can be configured to stop, start, clear, count up, or count down when a GTETRG rising or falling edge occurs.

*Note*

*The GTETRG pins are shared by all GPT channels.*
*GTETRG pins require POEG to be on (example code for this is provided in GPT Free Running Counter Example).*
*If input filtering is required on the GTETRG pins, that must also be handled outside this module.*

### Controlling GPT with ELC Events

The GPT timer can be configured to stop, start, clear, count up, or count down when an ELC event occurs.

*Note*

*The configurable ELC GPT sources are shared by all GPT channels.*
*The event links for the ELC must be configured outside this module.*

### Triggering ELC Events with GPT

The GPT timer can trigger the start of other peripherals. The Event Link Controller (r_elc) guide provides a list of all available peripherals.

### Enabling External Sources for Start, Stop, Clear, or Capture

R_GPT_Enable() must be called when external sources are used for start, stop, clear, or capture.

### Interrupt Skipping

When an interrupt skipping source is selected a hardware counter will increment each time the selected event occurs. Each interrupt past the first (up to the specified skip count) will be suppressed. If ADC events are selected for skipping they will also be suppressed except during the timer period leading to the selected interrupt skipping event (see below diagram).

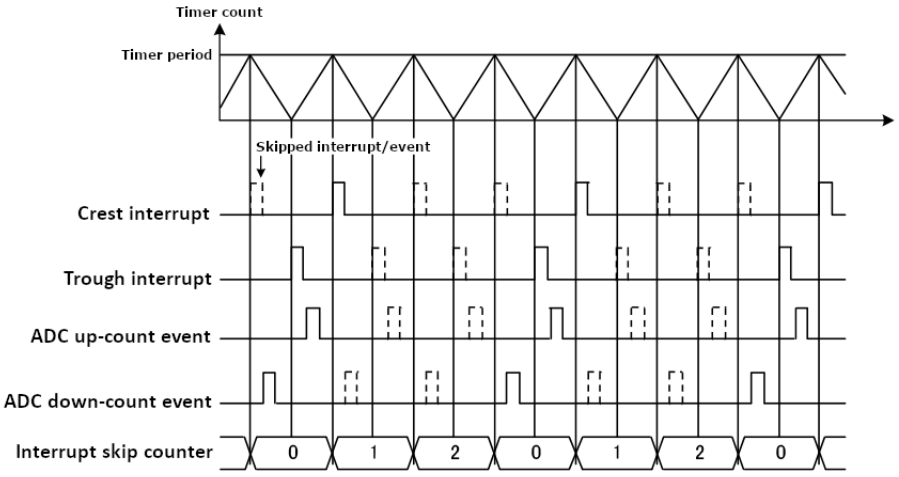

Figure 342: Crest interrupt skipping in triangle-wave PWM modes (skip count 2)

### Complementary Output

By using the Custom Waveform option the output pins can be made to output complementary waveforms. To ensure these waveforms stay in sync, the duty cycle for both pins can be set simultaneously by calling R_GPT_DutyCycleSet once with a pin parameter of GPT_IO_PIN_GTIOCA_AND_GTIOCB.

*Note*

*The pin level for 0% and 100% duty cycle is determined by the Cycle End Output Level in normal PWM mode and the Initial Output Level in triangle PWM modes. 100% duty will output the configured level and 0% will output the opposite. Do not use Pin Level Toggle or Pin Level Retain for the Cycle End Output Level if normal PWM waveforms are desired.*

## Function Documentation

### ◆ R_GPT_Open()

fsp_err_t R_GPT_Open ( timer_ctrl_t *const *p_ctrl*, timer_cfg_t const *const *p_cfg* )

Initializes the timer module and applies configurations. Implements timer_api_t::open.

GPT hardware does not support one-shot functionality natively. When using one-shot mode, the timer will be stopped in an ISR after the requested period has elapsed.

The GPT implementation of the general timer can accept a gpt_extended_cfg_t extension parameter.

Example:

```
/* Initializes the module. */
   err = R_GPT_Open(&g_timer0_ctrl, &g_timer0_cfg);
```

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Initialization was successful and timer has started. |
| FSP_ERR_ASSERTION | A required input pointer is NULL or the source divider is invalid. |
| FSP_ERR_ALREADY_OPEN | Module is already open. |
| FSP_ERR_IRQ_BSP_DISABLED | timer_cfg_t::mode is TIMER_MODE_ONE_SHOT or timer_cfg_t::p_callback is not NULL, but ISR is not enabled. ISR must be enabled to use one-shot mode or callback. |
| FSP_ERR_INVALID_MODE | Triangle wave PWM is only supported if GPT_CFG_OUTPUT_SUPPORT_ENABLE is 2. Selected channel does not support external count sources. External and event count sources not are available in this mode. |
| FSP_ERR_IP_CHANNEL_NOT_PRESENT | The channel requested in the p_cfg parameter is not available on this device. |

### ◆ R_GPT_Stop()

   (void) R_GPT_Stop(&g_timer0_ctrl);
```

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Timer successfully stopped. |

### ◆ R_GPT_PeriodSet()

fsp_err_t R_GPT_PeriodSet ( timer_ctrl_t *const *p_ctrl*, uint32_t const *period_counts* )

Sets period value provided. If the timer is running, the period will be updated after the next counter overflow. If the timer is stopped, this function resets the counter and updates the period. Implements timer_api_t::periodSet.

**Warning**

If periodic output is used, the duty cycle buffer registers are updated after the period buffer register. If this function is called while the timer is running and a GPT overflow occurs during processing, the duty cycle will not be the desired 50% duty cycle until the counter overflow after processing completes.

Example:

```
 /* Get the source clock frequency (in Hz). There are 3 ways to do this in FSP:
  * - If the PCLKD frequency has not changed since reset, the source clock frequency
is
  * BSP_STARTUP_PCLKD_HZ >> timer_cfg_t::source_div
  * - Use the R_GPT_InfoGet function (it accounts for the divider).
  * - Calculate the current PCLKD frequency using
R_FSP_SystemClockHzGet(FSP_PRIV_CLOCK_PCLKD) and right shift
  * by timer_cfg_t::source_div.
  *
```

```
  * This example uses the 3rd option (R_FSP_SystemClockHzGet).
  */
    uint32_t pclkd_freq_hz = R_FSP_SystemClockHzGet(FSP_PRIV_CLOCK_PCLKD) >>
g_timer0_cfg.source_div;
 /* Calculate the desired period based on the current clock. Note that this
calculation could overflow if the
  * desired period is larger than UINT32_MAX / pclkd_freq_hz. A cast to uint64_t is
used to prevent this. */
    uint32_t period_counts =
       (uint32_t) (((uint64_t) pclkd_freq_hz * GPT_EXAMPLE_DESIRED_PERIOD_MSEC) /
GPT_EXAMPLE_MSEC_PER_SEC);
 /* Set the calculated period. */
    err = R_GPT_PeriodSet(&g_timer0_ctrl, period_counts);
    assert(FSP_SUCCESS == err);
```

**Return values**

Sets duty cycle on requested pin. Implements timer_api_t::dutyCycleSet.

Duty cycle is updated in the buffer register. The updated duty cycle is reflected after the next cycle end (counter overflow).

Example:

```
 /* Get the current period setting. */
 timer_info_t info;
    (void) R_GPT_InfoGet(&g_timer0_ctrl, &info);
    uint32_t current_period_counts = info.period_counts;
 /* Calculate the desired duty cycle based on the current period. Note that if the
period could be larger than
  * UINT32_MAX / 100, this calculation could overflow. A cast to uint64_t is used to
```

```
prevent this. The cast is
  * not required for 16-bit timers. */
    uint32_t duty_cycle_counts =
       (uint32_t) (((uint64_t) current_period_counts *
GPT_EXAMPLE_DESIRED_DUTY_CYCLE_PERCENT) /
                   GPT_EXAMPLE_MAX_PERCENT);
 /* Set the calculated duty cycle. */
    err = R_GPT_DutyCycleSet(&g_timer0_ctrl, duty_cycle_counts, GPT_IO_PIN_GTIOCB);
    assert(FSP_SUCCESS == err);
```

less than or equal to period value. */

### Selecting a Timer

RA MCUs have two timer peripherals: the General PWM Timer (GPT) and the Asynchronous General Purpose Timer (AGT). When selecting between them, consider these factors:

| | GPT | AGT |
|---|---|---|
| Low Power Modes | The GPT can operate in sleep mode. | The AGT can operate in all low power modes (when count source is LOCO or subclock). |
| Available Channels | The number of GPT channels is device specific. All currently supported MCUs have at least 7 GPT channels. | All MCUs have at least 2 AGT channels. |
| Timer Resolution | All MCUs have at least one 32-bit GPT timer. | The AGT timers can be 16-bit or 32-bit timers. |
| Clock Source | The GPT runs off PCLKD with a configurable divider up to 1024. It can also be configured to count ELC events or external pulses. | The AGT runs off PCLKB, LOCO, or subclock with a configurable divider up to 8 for PCLKB or up to 128 for LOCO or subclock. |

### Configurations for Timers > Timer, Low-Power (r_agt)

This module can be added to the Stacks tab via New Stack > Timers > Timer, Low-Power (r_agt). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

| Trigger Edge | • Trigger Edge Rising<br>• Trigger Edge Falling<br>• Trigger Edge Both | Trigger Edge Rising | Select the trigger edge. Applies if measurement mode is pulse period, or if the count source is P402, P403, or AGTIO. Do not select Trigger Edge Both with pulse period measurement. |
| Interrupts | | | |
| Callback | Name must be a valid C symbol | NULL | A user callback function. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the timer period elapses. |
| Underflow Interrupt Priority | MCU Specific Options | | Timer interrupt priority. |

When using the AGT module on devices with both AGT and AGTW peripherals, the channel numbers used with the AGT driver are combined between both peripherals; AGTW channels are listed first followed by AGT. For example, on the RA2A2 there are 2 AGTW channels and 8 AGT channels. These correspond to channels 0-1 for AGTW0-AGTW1 and 2-9 for AGT0-AGT7.

### Clock Configuration

The AGT clock is based on the PCLKB, LOCO, or Subclock frequency. You can set the clock frequency using the **Clocks** tab of the RA Configuration editor or by using the CGC Interface at run-time.

### Pin Configuration

This module can use the AGTOA and AGTOB pins as output pins for periodic, one-shot, or PWM signals.

For input capture, the input signal must be applied to the AGTIOn pin.

For event counting, the AGTEEn enable pin is optional.

### Timer Period

The RA Configuration editor will automatically calculate the period count value and source clock divider based on the selected period time, units, and clock speed.

When the selected unit is "Raw counts", the maximum allowed period setting varies depending on the selected clock source:

| Clock source | 16-bit Timer Maximum period (counts) | 32-bit Timer Maximum period (counts) |
|---|---|---|
| LOCO/Subclock | 0x800000 | 0x8000000000 |
| PCLKB | 0x80000 | 0x800000000 |
| All other sources | 0x10000 | 0x100000000 |

*Note*

*The period interrupt occurs when the counter underflows, setting the period register to 0 results in an effective period of 1 count. For this reason all user-provided raw count values reflect the actual number of period counts (not the raw register values).*
*When using a 32-bit channel (AGTW), a special period count value of 0 is used to obtain an actual period register value of 0xFFFFFFFF.*

# Usage Notes

### Starting and Stopping the AGT

After starting or stopping the timer, AGT registers cannot be accessed until the AGT state is updated after 3 AGTCLK cycles. If another AGT function is called before the 3 AGTCLK period elapses, the function spins waiting for the AGT state to update. The required wait time after starting or stopping the timer can be determined using the frequency of AGTCLK, which is derived from timer_cfg_t::source_div and agt_extended_cfg_t::count_source.

The application is responsible for ensuring required clocks are started and stable before accessing MCU peripheral registers.

Warning

The subclock can take seconds to stabilize. The RA startup code does not wait for subclock stabilization unless the subclock is the main clock source. When running AGT or RTC off the subclock, the application must ensure the subclock is stable before starting operation.

### Low Power Modes

The AGT1 (channel 1 only) can be used to enter snooze mode or to wake the MCU from snooze, software standby, or deep software standby modes when a counter underflow occurs. The compare match A and B events can also be used to wake from software standby or snooze modes.

### One-Shot Mode

The AGT timer does not support one-shot mode natively. One-shot mode is achieved by stopping the timer in the interrupt service routine before the callback is called. If the interrupt is not serviced before the timer period expires again, the timer generates more than one event. The callback is only called once in this case, but multiple events may be generated if the timer is linked to the Transfer (r_dtc).

### One-Shot Mode Output

The output waveform in one-shot mode is one AGT clock cycle less than the configured period. The configured period must be at least 2 counts to generate an output pulse.

Examples of one-shot signals that can be generated by this module are shown below:

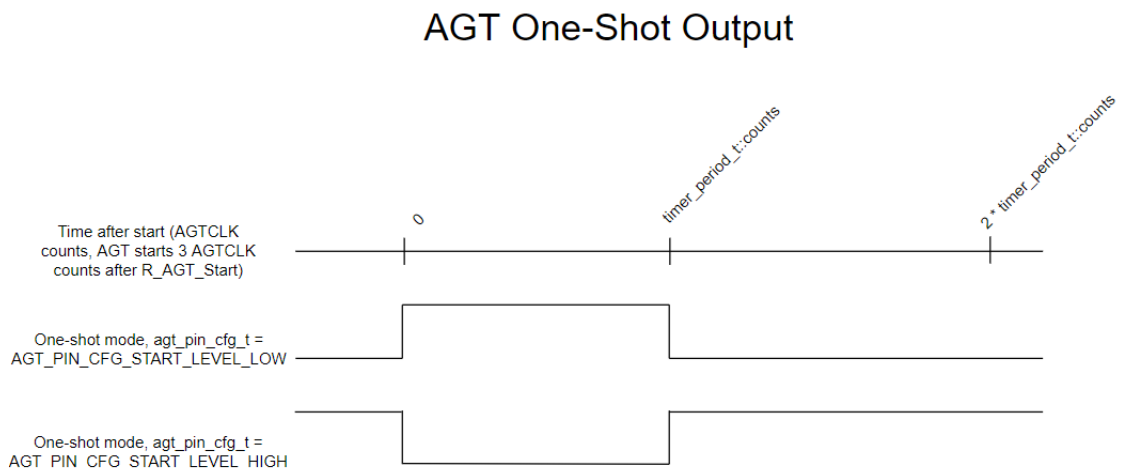

Figure 343: AGT One-Shot Output

### Periodic Output

The AGTOA or AGTOB pin toggles twice each time the timer expires in periodic mode. This is achieved by defining a PWM wave at a 50 percent duty cycle so that the period of the resulting square (from rising edge to rising edge) matches the period of the AGT timer. Since the periodic output is actually a PWM output, the time at the stop level is one cycle shorter than the time opposite the stop level for odd period values.

Examples of periodic signals that can be generated by this module are shown below:

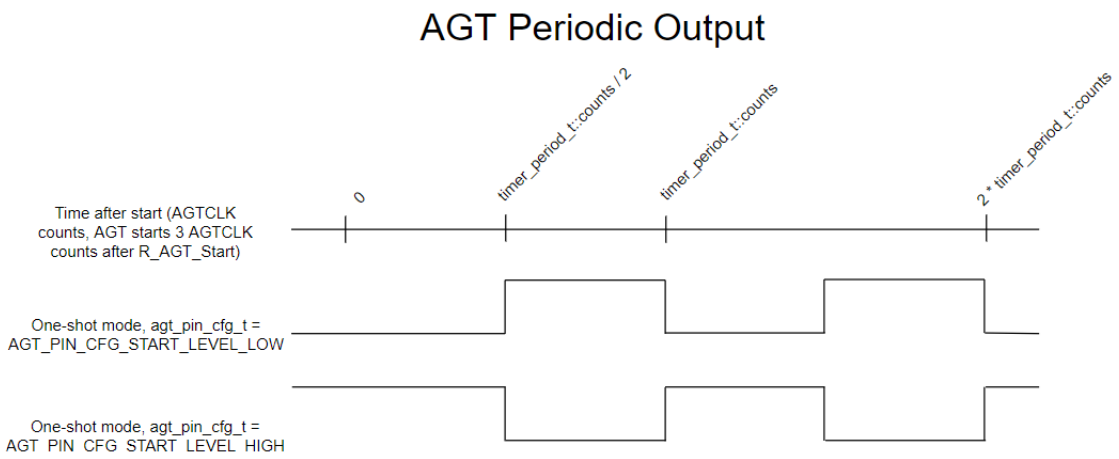

Figure 344: AGT Periodic Output

### PWM Output

This module does not support in phase PWM output. The PWM output signal is low at the beginning of the cycle and high at the end of the cycle.

Examples of PWM signals that can be generated by this module are shown below:

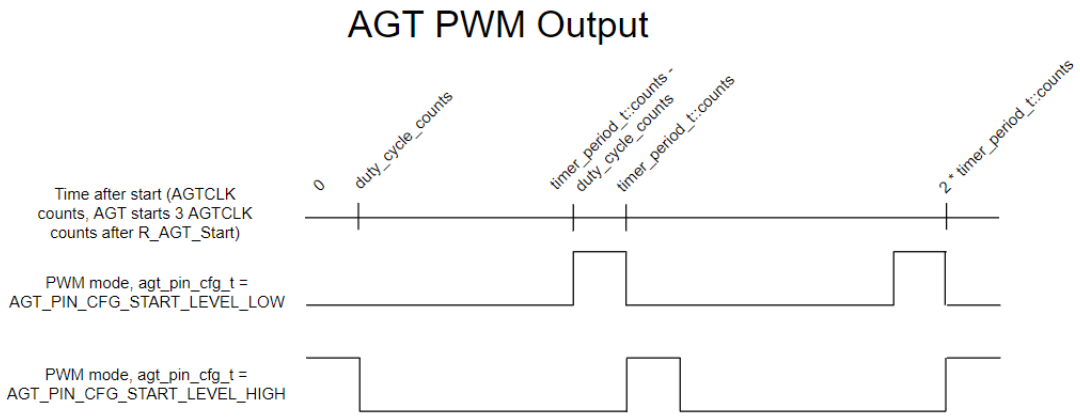

Figure 345: AGT PWM Output

### Triggering ELC Events with AGT

The AGT timer can trigger the start of other peripherals. The Event Link Controller (r_elc) guide provides a list of all available peripherals.

## Function Documentation

### ◆ R_AGT_Open()

fsp_err_t R_AGT_Open ( timer_ctrl_t *const *p_ctrl*, timer_cfg_t const *const *p_cfg* )

Initializes the AGT module instance. Implements timer_api_t::open.

The AGT hardware does not support one-shot functionality natively. The one-shot feature is therefore implemented in the AGT HAL layer. For a timer configured as a one-shot timer, the timer is stopped upon the first timer expiration.

The AGT implementation of the general timer can accept an optional agt_extended_cfg_t extension parameter. For AGT, the extension specifies the clock to be used as timer source and the output pin configurations. If the extension parameter is not specified (NULL), the default clock PCLKB is used and the output pins are disabled.

Example:

```
/* Initializes the module. */
   err = R_AGT_Open(&g_timer0_ctrl, &g_timer0_cfg);
```

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Initialization was successful and timer has started. |
| FSP_ERR_ASSERTION | A required input pointer is NULL or the period is not in the valid range of 1 to 0xFFFF. |
| FSP_ERR_ALREADY_OPEN | R_AGT_Open has already been called for this p_ctrl. |
| FSP_ERR_IRQ_BSP_DISABLED | A required interrupt has not been enabled in the vector table. |
| FSP_ERR_IP_CHANNEL_NOT_PRESENT | Requested channel number is not available on AGT. |

### ◆ R_AGT_Start()

fsp_err_t R_AGT_Start ( timer_ctrl_t *const *p_ctrl*)

Starts timer. Implements timer_api_t::start.

```
/* Start the timer. */
   (void) R_AGT_Start(&g_timer0_ctrl);
```

**Return values**

|---|---|
| FSP_SUCCESS | Timer started. |
| FSP_ERR_ASSERTION | p_ctrl is null. |

/* (Optional) Stop the timer. */
   (void) R_AGT_Stop(&g_timer0_ctrl);
```

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Timer stopped. |
| FSP_ERR_ASSERTION | p_ctrl was NULL. |
| FSP_ERR_NOT_OPEN | The instance control structure is not opened. |

### ◆ R_AGT_Reset()

Resets the counter value to the period minus one. Implements timer_api_t::reset.

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Counter reset. |
| FSP_ERR_ASSERTION | p_ctrl is NULL |
| FSP_ERR_NOT_OPEN | The instance control structure is not opened. |

### ◆ R_AGT_Enable()

fsp_err_t R_AGT_Enable ( timer_ctrl_t *const *p_ctrl*)

Enables external event triggers that start, stop, clear, or capture the counter. Implements timer_api_t::enable.

Example:

```
/* Enable captures. Captured values arrive in the interrupt. */

```
/* (Optional) Disable captures. */
   (void) R_AGT_Disable(&g_timer0_ctrl);
```

**Return values**

| | |

### ◆ R_AGT_PeriodSet()

fsp_err_t R_AGT_PeriodSet ( timer_ctrl_t *const *p_ctrl*, uint32_t const *period_counts* )

Updates period. The new period is updated immediately and the counter is reset to the maximum value. Implements timer_api_t::periodSet.

**Warning**

If periodic output is used, the duty cycle buffer registers are updated after the period buffer register. If this function is called while the timer is running and an AGT underflow occurs during processing, the duty cycle will not be the desired 50% duty cycle until the counter underflow after processing completes.
Stop the timer before calling this function if one-shot output is used.

Example:

```
/* Get the source clock frequency (in Hz). There are several ways to do this in FSP:
 * - If LOCO or subclock is chosen in agt_extended_cfg_t::clock_source
 * - The source clock frequency is BSP_LOCO_HZ >> timer_cfg_t::source_div
 * - If PCLKB is chosen in agt_extended_cfg_t::clock_source and the PCLKB frequency
has not changed since reset,
 * - The source clock frequency is BSP_STARTUP_PCLKB_HZ >> timer_cfg_t::source_div
 * - Use the R_AGT_InfoGet function (it accounts for the clock source and divider).
 * - Calculate the current PCLKB frequency using
R_FSP_SystemClockHzGet(FSP_PRIV_CLOCK_PCLKB) and right shift
 * by timer_cfg_t::source_div.
 *
```

```
  * This example uses the last option (R_FSP_SystemClockHzGet).
  */
    uint32_t timer_freq_hz = R_FSP_SystemClockHzGet(FSP_PRIV_CLOCK_PCLKB) >>
g_timer0_cfg.source_div;
 /* Calculate the desired period based on the current clock. Note that this
calculation could overflow if the
  * desired period is larger than UINT32_MAX / pclkb_freq_hz. A cast to uint64_t is
used to prevent this. */
    uint32_t period_counts =
       (uint32_t) (((uint64_t) timer_freq_hz * AGT_EXAMPLE_DESIRED_PERIOD_MSEC) /
AGT_EXAMPLE_MSEC_PER_SEC);
 /* Set the calculated period. This will return an error if parameter checking is
enabled and the calculated
  * period is larger than UINT16_MAX. */
    err = R_AGT_PeriodSet(&g_timer0_ctrl, period_counts);
    assert(FSP_SUCCESS == err);
```

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Period value updated. |
| FSP_ERR_ASSERTION | A required pointer was NULL, or the period was not in the valid range of 1 to 0xFFFF. |
| FSP_ERR_NOT_OPEN | The instance control structure is not opened. |

   (void) R_AGT_InfoGet(&g_timer0_ctrl, &info);
   uint32_t current_period_counts = info.period_counts;
/* Calculate the desired duty cycle based on the current period. */
   uint32_t duty_cycle_counts = (current_period_counts *
AGT_EXAMPLE_DESIRED_DUTY_CYCLE_PERCENT) /
                                AGT_EXAMPLE_MAX_PERCENT;
/* Set the calculated duty cycle. */
   err = R_AGT_DutyCycleSet(&g_timer0_ctrl, duty_cycle_counts, AGT_OUTPUT_PIN_AGTOA
);
   assert(FSP_SUCCESS == err);
```

**Clock Configuration**

The TAU PWM clock is based on the peripheral module clock (PCLKB) which is equal to the system clock (ICLK).

Each TAU PWM channel has certain operation clocks selections, these can be set with the **General>Operation Clock** property in the module configuration. When the operation clock of a channel is set to CK00, or CK01, the TAU_PWM module provides divisor values for each of those clocks. These divisors may be set in the **Clocks** tab. As such, setting a divisor in the **Clocks** tab affects all TAU PWM and TAU channels that use that CK0x clock as an input. Adjusting these settings determines the frequency range achievable by a TAU_PWM channel. If a desired frequency is not achievable, the divider in the **Clocks** tab may be adjusted. The clock dividers cannot be adjusted at runtime.

**Pin Configuration**

This module can use the TOmn pins as output pins for One-shot and PWM signals.

This module can use the TImn pin as the input pin for One-shot signals.

### Timer Period And Duty Cycle

The RA Configuration editor will automatically calculate the period/pulse width/duty cycle percent based on the selected period time, units, clock source, clock divider and mode.

When the selected unit is "Raw counts", the maximum and minimum allowed period/pulse width/duty cycle setting are presented by the following tables:

In One-shot pulse output mode:

| Clock divider | Minimum period (counts) | Maximum period (counts) | Minimum pulse width (counts) | Maximum pulse width (counts) |
|---|---|---|---|---|
| PCLK/1 | 0x00003 | 0x10001 | 0x0001 | 0xffff |
| PCLK/2 to PCLK/32768 | 0x00002 | 0x10000 | 0x0000 | 0xffff |

In PWM output mode:

| Clock divider | Minimum period (counts) | Maximum period (counts) | Minimum duty cycle (%) | Maximum duty cycle (%) |
|---|---|---|---|---|
| PCLK/1 | 0x00002 | 0x10001 | 0 | 100 |
| PCLK/2 to PCLK/32768 | 0x00001 | 0x10000 | 0 | 100 |

*Note*

*If PCLK (undivided) is selected as the operation clock (CK00, CK01) and TDR0n is set to 0x0000 (n = 0 to 7), interrupt requests output from timer array units cannot be used. So, when PCLK is undivided, the minimum period must be plus one.*
*Because the period interrupt occurs when the counter underflows, setting the period register to 0 results in an effective period of 1 count. For this reason, all user-provided raw count values reflect the actual number of period counts (not the raw register values).*

## Usage Notes

### Updating Period and Duty Cycle

The period and duty cycle are updated after the next counter underflow after calling R_TAU_PWM_PeriodSet() or R_TAU_PWM_DutyCycleSet().

### One-Shot Pulse Output Mode

By using two channels as a set, a one-shot pulse having any delay pulse width can be generated from the signal input to the TI0n pin.

The delay time is counted by the master channel, and the pulse width is counted by the slave channel.

### PWM Output

Two channels can be used as a set to generate a pulse of any period and duty factor (duty cycle). By extending the PWM function and using multiple slave channels, many PWM waveforms with different

duty values can be output.

When multiple slaves are to be connected to a single master, the build time option for multiple slaves needs to be set.

*Note*

*When two or more master channels are to be used, slave channels with a master channel between them may not be set. For example, if channels 0 and 4 are set as master channels, channels 1 to 3 can be set as the slave channels of master channel 0, channels 5 to 7 cannot be set as the slave channels of master channel 0.*

The period is counted by the master channel, and the duty cycle is counted by the slave channel.

### Controlling TAU_PWM with ELC Events

The TAU_PWM timer can be configured to trigger the timer counter when an ELC event occurs.

*Note*

*Triggering the timer using ELC events is supported only when master channel is set to 0 and mode is set to One-shot pulse output.*
*The event links for the ELC must be configured outside this module.*

### Triggering ELC Events with TAU_PWM

The TAU_PWM timer can trigger the start of other peripherals. The Event Link Controller (r_elc) guide provides a list of all available peripherals.

*Note*

*Only event signals from channel 00 to 03 are available.*

### Limitations

- None

# Examples

### TAU_PWM Basic Example

This is a basic example of minimal use of the TAU PWM (in PWM Output mode) in an application.

```
void tau_pwm_basic_example (void)
{
 fsp_err_t err = FSP_SUCCESS;
 /* Initializes the module. */
    err = R_TAU_PWM_Open(&g_timer0_ctrl, &g_timer0_cfg);
 /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
 /* Start the timer. */
    (void) R_TAU_PWM_Start(&g_timer0_ctrl);
```

```
}
```

### TAU_PWM Callback Example

This is an example of a timer callback.

*Note*

*The callback function always called after the period time (in PWM output mode) or delay time (in One-shot pulse output mode) has expired. Additionally, it can be optionally called after the duty cycle (in PWM output mode) or pulse width (in One-shot pulse output mode) has expired by enabling the slave channel's interrupt.*

```
uint32_t g_timer_master_cycle_end_counter = 0;
uint32_t g_timer_slave_cycle_end_counter = 0;
/* Example callback called when timer expires. */
void timer_callback (timer_callback_args_t * p_args)
{
 if (TIMER_EVENT_MASTER_CYCLE_END == p_args->event)
    {
       g_timer_master_cycle_end_counter++;
    }
 if (TIMER_EVENT_SLAVE_CYCLE_END == p_args->event)
    {
       g_timer_slave_cycle_end_counter++;
    }
}
```

```

**Return values**

### Selecting a Timer

RA MCUs can have multiple timer peripherals: the General PWM Timer (GPT) and the Asynchronous General Purpose Timer, and the Ultra Low Power Timer (ULPT). When selecting between them, consider these factors:

| | GPT | AGT | ULPT |
|---|---|---|---|

| | | | |
|---|---|---|---|
| Low Power Modes | The GPT can operate in sleep mode. | The AGT can operate in all low power modes (when count source is LOCO or subclock). | The ULPT can operate in all low power up to DSTBYs (when count source is LOCO or subclock). |
| Available Channels | The number of GPT channels is device specific. All currently supported MCUs have at least 7 GPT channels. | All MCUs have 2 AGT channels. | The number of ULPT channels is device specific, 2 is common. |
| Timer Resolution | All MCUs have at least one 32-bit GPT timer. | The AGT timers are 16-bit timers. | The ULPT timers are 32-bit timers. |
| Clock Source | The GPT runs off PCLKD with a configurable divider up to 1024. It can also be configured to count ELC events or external pulses. | The AGT runs off PCLKB, LOCO, or subclock with a configurable divider up to 8 for PCLKB or up to 128 for LOCO or subclock. | The ULPT runs off PCLKB. LOCO, or subclock are count sources with a configurable divider up to 128. |

This module can be added to the Stacks tab via New Stack > Timers > Timer, Ultra-Low-Power (r_ulpt). Non-secure callable guard functions can be generated for this module by right clicking the module in the RA Configuration tool and checking the "Non-secure Callable" box.

### Clock Configuration

The ULPT subsystem is driven by the PCLKB, but countdown is driven LOCO, Subclock, or event input. You can set the clock frequency using the **Clocks** tab of the RA Configuration editor or by using the CGC Interface at run-time.

### Pin Configuration

This module can use the ULPTO, ULPTOA and ULPTOB pins as output pins for periodic, one-shot, or PWM signals.

For event counting, the input clocking signal must be applied to the ULPTEVIn pin.

### Timer Period

The RA Configuration editor will automatically calculate the period count value and source clock divider based on the selected period time, units, and clock speed.

When the selected unit is "Raw counts", the maximum allowed period setting varies depending on the selected clock source:

| Clock source | Maximum period (counts) |
|---|---|
| LOCO/Subclock | 0xFFFFFFFF |

| | |
|---|---|
| All other sources | 0xFFFFFFFF |

*Note*

*Though the ULPT is a 32-bit timer, because the period interrupt occurs when the counter underflows, setting the period register to 0 results in an effective period of 1 count. For this reason all user-provided raw count values reflect the actual number of period counts (not the raw register values).*

# Usage Notes

### Starting and Stopping the ULPT

After starting or stopping the timer, ULPT registers cannot be accessed until the ULPT state is updated after 3 ULPTCLK cycles. If another ULPT function is called before the 3 ULPTCLK period elapses, the function spins waiting for the ULPT state to update. The required wait time after starting or stopping the timer can be determined using the frequency of ULPTCLK, which is derived from timer_cfg_t::source_div and ulpt_extended_cfg_t::count_source.

The application is responsible for ensuring required clocks are started and stable before accessing MCU peripheral registers.

Warning

The subclock can take seconds to stabilize. The RA startup code does not wait for subclock stabilization unless the subclock is the main clock source. When running ULPT or RTC off the subclock, the application must ensure the subclock is stable before starting operation.

### Low Power Modes

The ULPT can be used to enter snooze mode or to wake the MCU from snooze, software standby, or deep software standby modes when a counter underflow occurs. The compare match A and B events can also be used to wake from software standby or snooze modes.

### One-Shot Mode

The ULPT timer does support one-shot mode natively. The interrupt with put the module in the stop state. The callback is only called once in this case. If needed the timer needs to be re-started via the driver call.

### Periodic Output

The ULPTO toggles each time the counter underflows.

Examples of periodic signals that can be generated by this module are shown below:

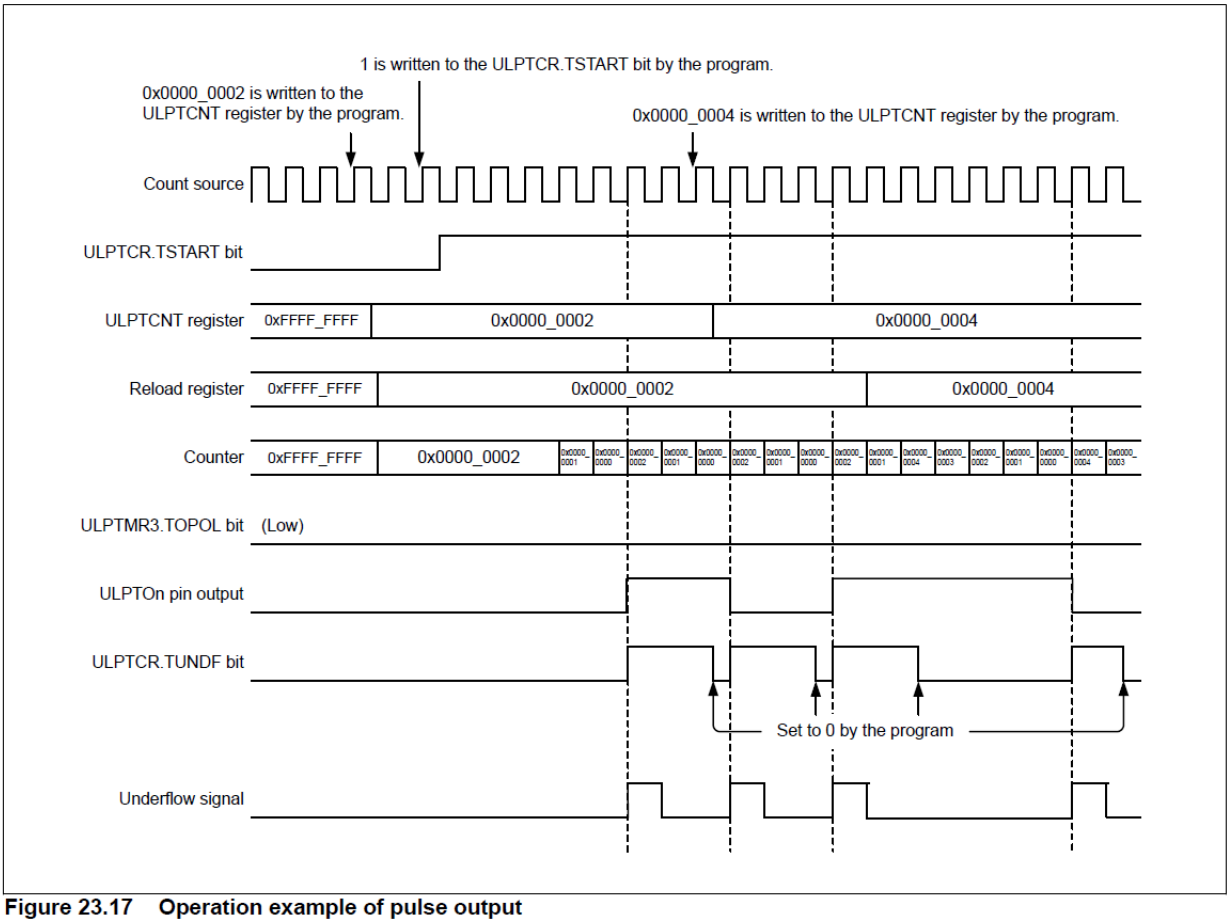

**Figure 23.17 Operation example of pulse output**

Figure 346: ULPT Periodic Output

### PWM Output

The ULPTOA or ULPTOB pin toggles each time the compare match timer matches the down counter. It also toggles once the underflow occurs in periodic mode. for example setting the ULPT counter to 0x1000, and compare match A to half (0x800) will created a 50% duty cycle output on ULPTOA. Setting ULPTB to a quarter of that (0x400) will create a 25% duty cycle wave. Since the periodic output is actually a PWM output, the time at the stop level is one cycle shorter than the time opposite the stop level for odd period values.

Examples of periodic signals that can be generated by this module are shown below:

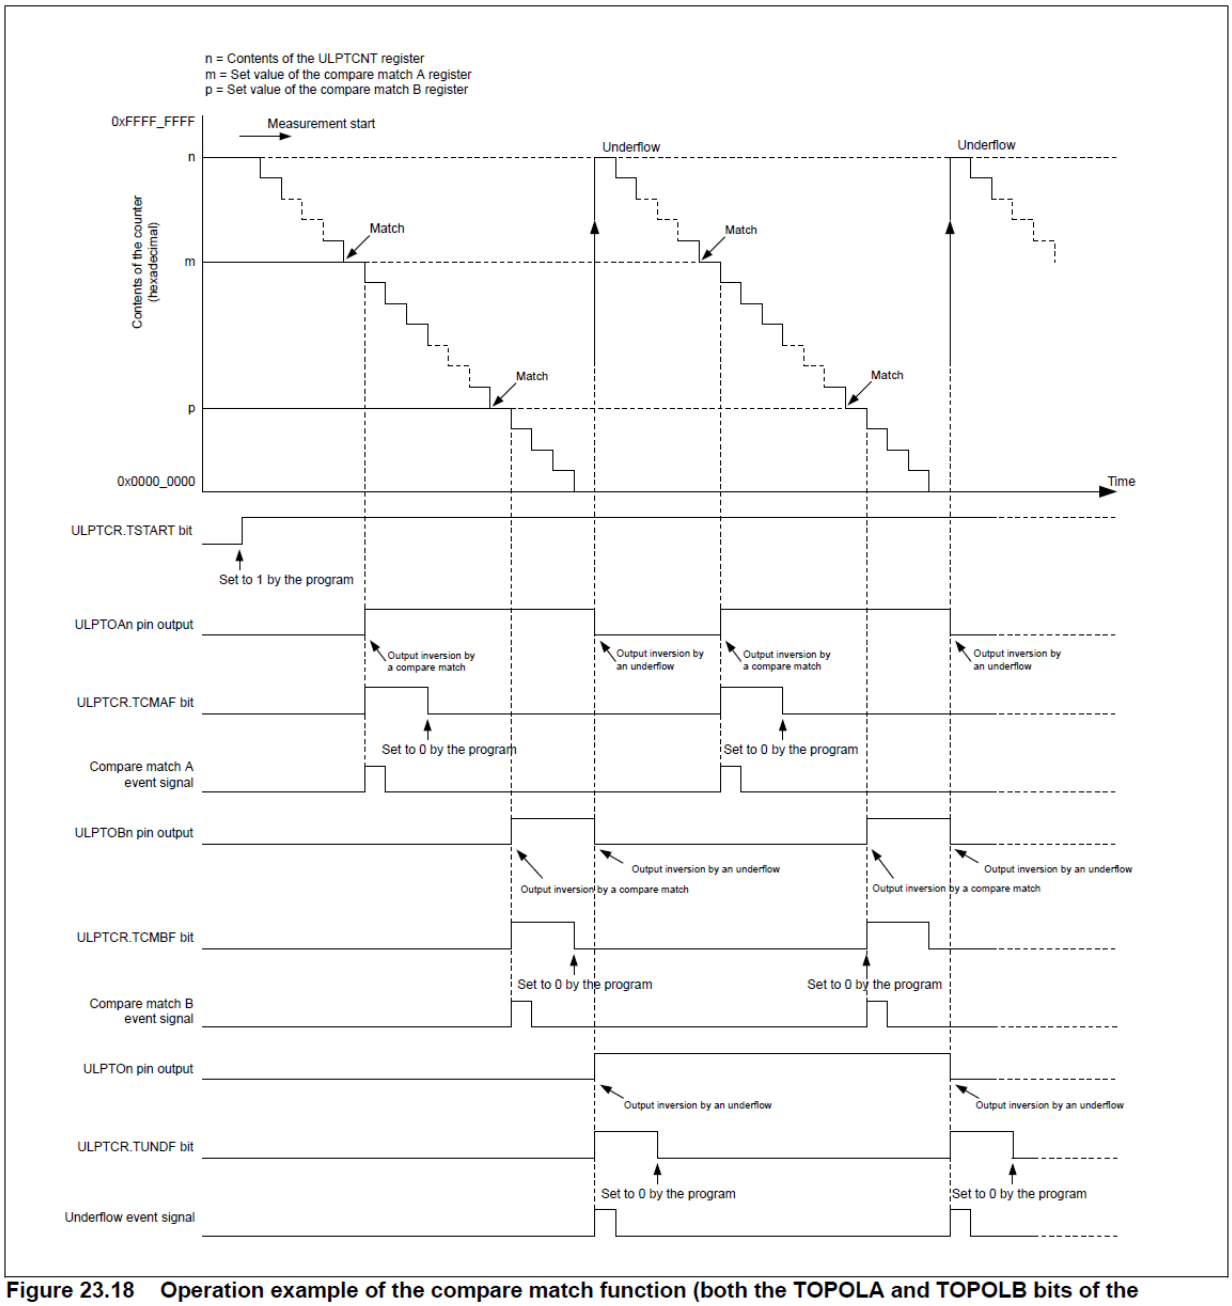

**Figure 23.18 Operation example of the compare match function (both the TOPOLA and TOPOLB bits of the ULPTCMSR register are set to 0)**

### Triggering ELC Events with ULPT

The ULPT timer can trigger the start of other peripherals. The Event Link Controller (r_elc) guide provides a list of all available peripherals.

    {
 /* Add application code to be called periodically here. */
    }
}
```

### ULPT Free Running Counter Example

## Function Documentation

### ◆ R_ULPT_Open()

fsp_err_t R_ULPT_Open ( timer_ctrl_t *const *p_ctrl*, timer_cfg_t const *const *p_cfg* )

Initializes the ULPT module instance. Implements timer_api_t::open.

The ULPT implementation of the general timer can accept an optional ulpt_extended_cfg_t extension parameter. For ULPT, the extension specifies the clock to be used as timer source and the output pin configurations. If the extension parameter is not specified (NULL), the default clock LOCO is used and the output pins are disabled.

Example:

```
/* Initializes the module. */
   err = R_ULPT_Open(&g_timer0_ctrl, &g_timer0_cfg);
```

**Return values**

| | |
|---|---|
| FSP_SUCCESS | Initialization was successful and timer has started. |
| FSP_ERR_ASSERTION | A required input pointer is NULL or the period is not in the valid range of 1 to 0xFFFF. |
| FSP_ERR_ALREADY_OPEN | R_ULPT_Open has already been called for this p_ctrl. |
| FSP_ERR_IRQ_BSP_DISABLED | A required interrupt has not been enabled in the vector table. |
| FSP_ERR_IP_CHANNEL_NOT_PRESENT | Requested channel number is not available on ULPT. |

Updates period. The new period is updated immediately and the counter is reset to the maximum value. Implements timer_api_t::periodSet.

**Warning**

If periodic output is used, the duty cycle buffer registers are updated after the period buffer register. If this function is called while the timer is running and an AGT underflow occurs during processing, the duty cycle will not be the desired 50% duty cycle until the counter underflow after processing completes.
Stop the timer before calling this function if one-shot output is used.

Example:

```
/* Set the calculated period. This will return an error if parameter checking is
enabled and the calculated
 * period is larger than UINT16_MAX. */
  err = R_ULPT_PeriodSet(&g_timer0_ctrl, period_counts);
  assert(FSP_SUCCESS == err);
```

fsp_err_t R_ULPT_DutyCycleSet ( timer_ctrl_t *const *p_ctrl*, uint32_t const *duty_cycle_counts*, uint32_t const *pin* )

Example:

```
/* Set the calculated duty cycle. */

### Clock Configuration

The DMAC peripheral module uses ICLK as the clock source. The ICLK frequency is set by using the **Clocks** tab of the RA Configuration editor prior to a build, or by using the CGC module at run-time.

### Pin Configuration

This module does not use I/O pins.

# Usage Notes

### Source and Destination Configuration

R_DMAC_Reset() API function should be called to set the source and destination before starting transfer operation.

### Transfer Modes

The DMAC Module supports three modes of operation.

- **Normal Mode** - In normal mode, a single data unit is transferred every time the configured ELC event is received by the DMAC channel. A data unit can be 1-byte, 2-bytes, or 4-bytes. The source and destination addresses can be fixed, increment, decrement, or add an offset to the next data unit after each transfer. A 16-bit counter decrements after each transfer. When the counter reaches 0, transfers will no longer be triggered by the ELC event and the CPU can be interrupted to signal that all transfers have finished.
- **Repeat Mode** - Repeat mode works the same way as normal mode, however the length is limited to an integer in the range[1,1024]. When the transfer counter reaches 0, the counter is reset to its configured value, the repeat area (source or destination address) resets to its starting address and the block count remaining will decrement by 1. When the block count reaches 0, transfers will no longer be triggered by the ELC event and the CPU may be interrupted to signal that all transfers have finished.
- **Block Mode** - In block mode, the amount of data units transferred by each interrupt can be set to an integer in the range [1,1024]. The number of blocks to transfer can also be configured to a 16-bit number. After each block transfer the repeat area (source or destination address) will reset to the original address and the other address will be incremented or decremented to the next block.
- **Repeat-Block Mode** - In repeat-block mode, the amount of data units transferred by each interrupt can be set to an integer in the range [1,1024]. The number of blocks to transfer can be configured to a 16 bit number. If the destination address mode is offset mode,

maximum configurable number of blocks is 0xFFFF for block size(length) of one with data transfer size as byte,0x7FFF for block size of one with data transfer size as half word and 0x3FFF for block size of one with data size as word. After each block transfer the source address and the destination address will be incremented or decremented to the next block address. In case of offset address mode for source address, the source address size is the total size of source buffer after which the source area is rolled over, block size can be smaller than the source buffer size.For source address mode as offset mode, the maximum configurable source buffer size is 0xFFFF for transfer data size of a byte,0x7FFF for transfer data size of half word and 0x3FFF for transfer data size of word. Repeat-block mode can be used to implement single ring buffer to multiple ring buffer transfer type design.

**Selecting the DTC or DMAC**

The Transfer API is implemented by both DTC and the DMAC so that applications can switch between the DTC and the DMAC. When selecting between them, consider these factors:

| | DTC | DMAC |
|---|---|---|
| Repeat Mode | • Repeats forever<br>• Max repeat size is 256 x 4 bytes | • Configurable number of repeats<br>• Max repeat size is 1024 x 4 bytes |
| Block Mode | • Max block size is 256 x 4 bytes | • Max block size is 1024 x 4 bytes |
| Channels | • One instance per interrupt | • MCU specific (8 channels or less) |
| Chained Transfers | • Supported | • Not Supported |
| Software Trigger | • Must use the software ELC event | • Has support for software trigger without using software ELC event<br>• Supports TRANSFER_START_MODE_SINGLE and TRANSFER_START_MODE_REPEAT |
| Offset Address Mode | • Not supported | • Supported |

**Interrupts**

The DTC and DMAC interrupts behave differently. The DTC uses the configured IELSR event IRQ as the interrupt source whereas each DMAC channel has its own IRQ.

The transfer_info_t::irq setting also behaves a little differently depending on which mode is selected.

## Normal Mode

| | DTC | DMAC |
|---|---|---|
| TRANSFER_IRQ_EACH | Interrupt after each transfer | N/A |
| TRANSFER_IRQ_END | Interrupt after last transfer | Interrupt after last transfer |

## Repeat Mode

| | DTC | DMAC |
|---|---|---|
| TRANSFER_IRQ_EACH | Interrupt after each transfer | Interrupt after each repeat |
| TRANSFER_IRQ_END | Interrupt after each repeat | Interrupt after last transfer |

### Block Mode

| | DTC | DMAC |
|---|---|---|
| TRANSFER_IRQ_EACH | Interrupt after each block | Interrupt after each block |
| TRANSFER_IRQ_END | Interrupt after last block | Interrupt after last block |

### Repeat-block Mode

| | DTC | DMAC |
|---|---|---|
| TRANSFER_IRQ_EACH | N/A | N/A |
| TRANSFER_IRQ_END | N/A | Interrupt after last block |

#### Additional Considerations

- The DTC requires a moderate amount of RAM (one transfer_info_t struct per open instance + DTC_VECTOR_TABLE_SIZE).
- The DTC stores transfer information in RAM and writes back to RAM after each transfer whereas the DMAC stores all transfer information in registers.
- When transfers are configured for more than one activation source, the DTC must fetch the transfer info from RAM on each interrupt. This can cause a higher latency between transfers.

#### Offset Address Mode

When the source or destination mode is configured to offset mode, a configurable offset is added to the source or destination pointer after each transfer. The offset is a signed 24 bit number.

## Examples

### Basic Example

This is a basic example of minimal use of the DMAC in an application. In this case, one or more events have been routed to the DMAC for handling so it only needs to be enabled to start accepting transfers.

```
void dmac_minimal_example (void)
{
 /* Open the transfer instance with initial configuration. */
 fsp_err_t err = R_DMAC_Open(&g_transfer_ctrl, &g_transfer_cfg);
 /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
 /* Enable the DMAC so that it responds to transfer requests. */
```

```
    err = R_DMAC_Enable(&g_transfer_ctrl);
    assert(FSP_SUCCESS == err);
}
```

### CRC32 Example

In this example the DMAC is used to feed the CRC peripheral to perform a CRC32 operation.

```
volatile bool g_transfer_complete = false;
void dmac_callback (dmac_callback_args_t * cb_data)
{
 FSP_PARAMETER_NOT_USED(cb_data);
    g_transfer_complete = true;
}
void dmac_crc_example (void)
{
    uint8_t p_src[TRANSFER_LENGTH];
 /* Initialize p_src to [ABC..OP] */
 for (uint32_t i = 0; i < TRANSFER_LENGTH; i++)
    {
       p_src[i] = (uint8_t) ('A' + (i % 26));
    }
 /* Set transfer source address to p_src */
    g_transfer_cfg.p_info->p_src = (void *) p_src;
 /* Set transfer destination address to the CRC data input register */
    g_transfer_cfg.p_info->p_dest = (void *) &R_CRC->CRCDIR;
 /* Open the transfer instance with initial configuration. */
 fsp_err_t err = R_DMAC_Open(&g_transfer_ctrl, &g_transfer_cfg);
 /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
 /* Enable DMAC transfers. */
    (void) R_DMAC_Enable(&g_transfer_ctrl);
 /* Open the CRC module. */
    err = R_CRC_Open(&g_crc_ctrl, &g_crc_cfg);
    assert(FSP_SUCCESS == err);
```

```
/* Clear the transfer complete flag. */
   g_transfer_complete = false;
/* Trigger the transfer using software. */
   err = R_DMAC_SoftwareStart(&g_transfer_ctrl, TRANSFER_START_MODE_SINGLE);
   assert(FSP_SUCCESS == err);
while (!g_transfer_complete)
   {
/* Wait for transfer complete interrupt */
   }
/* Get CRC result and perform final XOR. */
   uint32_t crc32;
   (void) R_CRC_CalculatedValueGet(&g_crc_ctrl, &crc32);
   crc32 ^= CRC32_FINAL_XOR_VALUE;
/* Verify that the CRC32 is calculated correctly. */
/* CRC32("ABCD...NOP") = 0xE0E8FF4D. */
const uint32_t expected_crc32 = 0xE0E8FF4D;
if (expected_crc32 != crc32)
   {
/* Handle any CRC errors. This function should be defined by the user. */
      handle_crc_error();
   }
}
```

### Detailed Description

Driver for the DTC peripheral on RA MCUs. This module implements the Transfer Interface.

# Overview

The Data Transfer Controller (DTC) transfers data from one memory location to another without using the CPU.

The DTC uses a RAM based vector table. Each entry in the vector table corresponds to an entry in the ISR vector table. When the DTC is triggered by an interrupt, it reads the DTC vector table, fetches the transfer information, and then executes the transfer. After the transfer is executed, the DTC writes the updated transfer info back to the location pointed to by the DTC vector table.

### Features

- Supports multiple transfer modes
  - Normal transfer
  - Repeat transfer
  - Block transfer
- Chain transfers
- Address increment, decrement or fixed modes
- Can be triggered by any event that has reserved a slot in the interrupt vector table.
  - Some exceptions apply, see the Event table in the Event Numbers section of the Interrupt Controller Unit chapter of the hardware manual
- Supports 1, 2, and 4 byte data units

### Clock Configuration

The DTC peripheral module uses ICLK as the clock source. The ICLK frequency is set by using the **Clocks** tab of the RA Configuration editor prior to a build or by using the CGC module at runtime.

### Pin Configuration

This module does not use I/O pins.

# Usage Notes

### Source and Destination Configuration

R_DTC_Reset() API function should be called to set the Source and Destination address before starting the transfer operation.

### Transfer Modes

The DTC Module supports three modes of operation.

- **Normal Mode** - In normal mode, a single data unit is transferred every time an interrupt is received by the DTC. A data unit can be 1-byte, 2-bytes, or 4-bytes. The source and destination addresses can be fixed, increment or decrement to the next data unit after each transfer. A 16-bit counter (length) decrements after each transfer. When the counter reaches 0, transfers will no longer be triggered by the interrupt source and the CPU can be interrupted to signal that all transfers have finished.
- **Repeat Mode** - Repeat mode works the same way as normal mode, however the length is limited to an integer in the range[1,256]. When the tranfer counter reaches 0, the counter is reset to its configured value and the repeat area (source or destination address) resets to its starting address and transfers will still be triggered by the interrupt.
- **Block Mode** - In block mode, the amount of data units transferred by each interrupt can be set to an integer in the range [1,256]. The number of blocks to transfer can also be configured to a 16-bit number. After each block transfer the repeat area (source or destination address) will reset to the original address and the other address will be incremented or decremented to the next block.

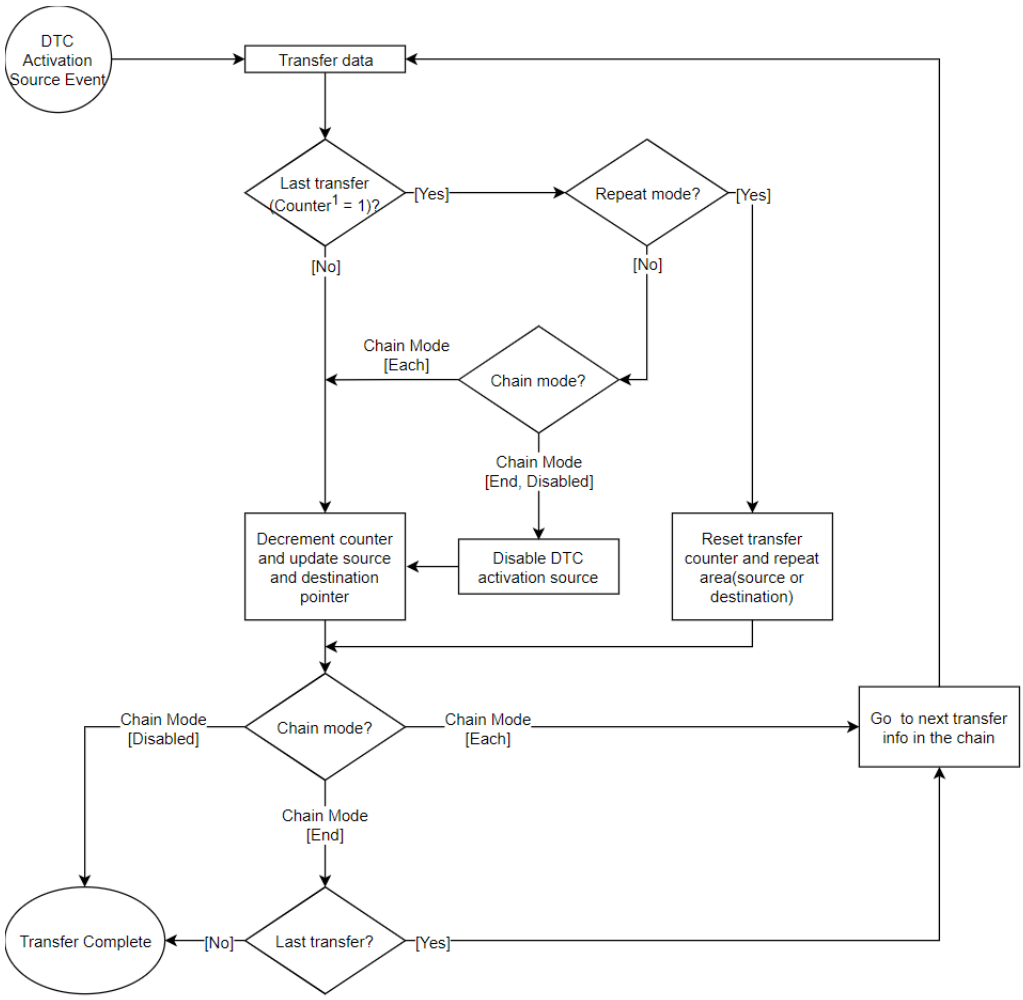
*Note*

*The source and destination address of the transfer must be aligned to the configured data unit.*

### Chaining Transfers

Multiple transfers can be configured for the same interrupt source by specifying an array of transfer_info_t structs instead of just passing a pointer to one. In this configuration, every transfer_info_t struct must be configured for a chain mode except for the last one. There are two types of chain mode; CHAIN_MODE_EACH and CHAIN_MODE_END. If a transfer is configured in

CHAIN_MODE_EACH then it triggers the next transfer in the chain after it completes each transfer. If a transfer is configured in CHAIN_MODE_END then it triggers the next transfer in the chain after it completes its last transfer.



1. **Counter** refers to transfer_info_t::**length** in normal and repeat mode and transfer_info_t::**num_blocks** in block mode.

Figure 348: DTC Transfer Flowchart

### Selecting the DTC or DMAC

The Transfer API is implemented by both DTC and the DMAC so that applications can switch between the DTC and the DMAC. When selecting between them, consider these factors:

| | DTC | DMAC |
|---|---|---|
| Repeat Mode | • Repeats forever<br>• Max repeat size is 256 x 4 bytes | • Configurable number of repeats<br>• Max repeat size is 1024 x 4 bytes |
| Block Mode | • Max block size is 256 x 4 bytes | • Max block size is 1024 x 4 bytes |
| Channels | • One instance per interrupt | • MCU specific (8 channels or less) |

| | | |
|---|---|---|
| Chained Transfers | • Supported | • Not Supported |
| Software Trigger | • Must use the software ELC event | • Has support for software trigger without using software ELC event<br>• Supports TRANSFER_START_MODE_SINGLE and TRANSFER_START_MODE_REPEAT |
| Offset Address Mode | • Not supported | • Supported |

**Additional Considerations**

- The DTC requires a moderate amount of RAM (one transfer_info_t struct per open instance + DTC_VECTOR_TABLE_SIZE).
- The DTC stores transfer information in RAM and writes back to RAM after each transfer whereas the DMAC stores all transfer information in registers.
- When transfers are configured for more than one activation source, the DTC must fetch the transfer info from RAM on each interrupt. This can cause a higher latency between transfers.
- The DTC interrupts the CPU using the activation source's IRQ. Each DMAC channel has its own IRQ.
- The necessary alignment of the transfer_info_t structs depends on the underlying MCU. The DTC_TRANSFER_INFO_ALIGNMENT macro is supplied to align the structs as necessary.

**Interrupts**

The DTC and DMAC interrupts behave differently. The DTC uses the configured event IRQ as the interrupt source whereas each DMAC channel has its own IRQ.

The transfer_info_t::irq setting also behaves a little differently depending on which mode is selected.

- **Normal Mode**

| | DTC | DMAC |
|---|---|---|
| TRANSFER_IRQ_EACH | Interrupt after each transfer | N/A |
| TRANSFER_IRQ_END | Interrupt after last transfer | Interrupt after last transfer |

- **Repeat Mode**

| | DTC | DMAC |
|---|---|---|
| TRANSFER_IRQ_EACH | Interrupt after each transfer | Interrupt after each repeat |
| TRANSFER_IRQ_END | Interrupt after each repeat | Interrupt after last transfer |

- **Block Mode**

| | DTC | DMAC |
|---|---|---|
| TRANSFER_IRQ_EACH | Interrupt after each block | Interrupt after each block |
| TRANSFER_IRQ_END | Interrupt after last block | Interrupt after last block |

*Note*

*DTC_VECTOR_TABLE_SIZE = (ICU_NVIC_IRQ_SOURCES x 4) Bytes*

### Peripheral Interrupts and DTC

When an interrupt is configured to trigger DTC transfers, the peripheral ISR will trigger on the following conditions:

- Each transfer completed (transfer_info_t::irq = TRANSFER_IRQ_EACH)
- Last transfer completed (transfer_info_t::irq = TRANSFER_IRQ_END)

For example, if SCI1_RXI is configured to trigger DTC transfers and a SCI1_RXI event occurs, the interrupt will not fire until the DTC transfer is completed. If the DTC transfer_info_t::irq is configured to only interrupt on the last transfer, then no RXI interrupts will occur until the last transfer is completed.

*Note*

*1. The DTC activation source must be enabled in the NVIC in order to trigger DTC transfers (Modules that are designed to integrate the R_DTC module will automatically handle this).*
*2. The DTC prioritizes activation sources by granting the smaller interrupt vector numbers higher priority. The priority of interrupts to the CPU is determined by the NVIC priority.*

### Low Power Modes

DTCST must be set to 0 before transitioning to any of the following:

- Module-stop state
- Software Standby mode without Snooze mode transition
- Deep Software Standby mode

*Note*

*1. R_LPM Module stops the DTC before entering deep software standby mode and software standby without snooze mode transition.*
*2. For more information see "Snooze Control Interface" and "Module-Stop Function" in the DTC section of the relevant hardware manual.*

### Limitations

Developers should be aware of the following limitations when using the DTC:

- If the DTC is configured to service many different activation sources, the system could run in to performance issues due to memory contention. To address this issue, it is recommended that the DTC vector table and transfer information be moved to their own dedicated memory area (Ex: SRAM0, SRAM1, SRAMHS). This allows memory accesses from different BUS Masters (CPU, DTC, DMAC, EDMAC and Graphics IPs) to occur in parallel.

## Examples

### Basic Example

This is a basic example of minimal use of the DTC in an application.

```
void dtc_minimal_example (void)

```

```
{
 /* Open the transfer instance with initial configuration. */
 fsp_err_t err = R_DTC_Open(&g_transfer_ctrl, &g_transfer_cfg);
 /* Handle any errors. This function should be defined by the user. */
    assert(FSP_SUCCESS == err);
 /* Enable the DTC to handle incoming transfer requests. */
    err = R_DTC_Enable(&g_transfer_ctrl);
    assert(FSP_SUCCESS == err);
}
```

Modules » TrustZone

RTOS Context Management for RA MCUs.

# Overview

Add this module to a secure TrustZone project to allow the associated non-secure project to use an RTOS. It is used by an RTOS port for RA MCUs (for example, the FreeRTOS Port (rm_freertos_port), which is automatically added to RA projects when FreeRTOS is selected during project creation).

*Note*

*The RTOS Context Management module does not provide any interfaces to the user. To use this module to port an*

*RTOS, consult the Arm documentation at https://arm-software.github.io/CMSIS_5/Core/html/group__context__trustzone__functions.html for further information.*

# Configuration

### Build Time Configurations for rm_tz_context

The following build time configurations are defined in fsp_cfg/rm_tz_context_cfg.h:

| Configuration | Options | Default | Description |
|---|---|---|---|
| Process Stack Slots | Value must be a non-negative integer greater than 0 | 8 | The maximum number of threads that can allocate a secure context. For applications using FreeRTOS, the Idle task requires 1 context as well. |
| Process Stack Size | Value must be a non-negative multiple of 8 | 256 | The maximum stack size of all non-secure callable functions. |

### Clock Configuration

This module does not use peripheral clocks.

### Pin Configuration

This module does not use I/O pins.

# Usage Notes

### TrustZone Integration

When using an RTOS in a TrustZone project, Arm recommends keeping the RTOS in the non-secure project. Tasks may call non-secure callable functions if the task has allocated a secure context. To allocate a secure context, reference the documentation for the RTOS port used. For example, reference TrustZone Integration when FreeRTOS is used.

### Sealing the Process Stack

This module seals each process stack by placing the value 0xFEF5EDA5 above the stack top. For more information, refer to section 3.5 "Sealing a Stack" in "Secure software guidelines for ARMv8-M": https://developer.arm.com/documentation/100720/0300.

**Detailed Description**

Interface for A/D Converters.

# Summary

The ADC interface provides standard ADC functionality including one-shot mode (single scan), continuous scan and group scan. It also allows configuration of hardware and software triggers for starting scans. After each conversion an interrupt can be triggered, and if a callback function is provided, the call back is invoked with the appropriate event information.

Interface for CEC peripheral.

# Summary

The CEC interface provides common APIs for CEC HAL drivers and supports the following features:

- Opening and closing the CEC module.
- Allocation for full range of local address settings (TV, Recording Device, Playback Device, etc.)
- Supports a user-callback function (required), invoked when transmit, receive, or error interrupts are received.

## Field Documentation

### ◆ open

fsp_err_t(* jpeg_api_t::open) (jpeg_ctrl_t *const p_ctrl, jpeg_cfg_t const *const p_cfg)

Initial configuration

**Precondition**
none

**Parameters**

| | | |
|---|---|---|
| [in,out] | p_ctrl | Pointer to control block. Must be declared by user. Elements set here. |
| [in] | p_cfg | Pointer to configuration structure. All elements of this structure must be set by user. |

### ◆ inputBufferSet

fsp_err_t(* jpeg_api_t::inputBufferSet) (jpeg_ctrl_t *const p_ctrl, void *p_buffer, uint32_t buffer_size)

Assign input data buffer to JPEG codec.

**Precondition**
the JPEG codec module must have been opened properly.

***Note***
*The buffer starting address must be 8-byte aligned.*

**Parameters**

| | | |
|---|---|---|
| [in] | p_ctrl | Control block set in jpeg_api_t::open call. |
| [in] | p_buffer | Pointer to the input buffer space |
| [in] | buffer_size | Size of the input buffer |

### ◆ outputBufferSet

fsp_err_t(* jpeg_api_t::outputBufferSet) (jpeg_ctrl_t *const p_ctrl, void *p_buffer, uint32_t buffer_size)

Assign output buffer to JPEG codec for storing output data.

**Precondition**

The JPEG codec module must have been opened properly.

***Note***

*The buffer starting address must be 8-byte aligned. For the decoding process, the HLD driver automatically computes the number of lines of the image to decoded so the output data fits into the given space. If the supplied output buffer is not able to hold the entire frame, the application should call the Output Full Callback function so it can be notified when additional buffer space is needed.*

**Parameters**

| | | |
|---|---|---|
| [in] | p_ctrl | Control block set in jpeg_api_t::open call. |
| [in] | p_buffer | Pointer to the output buffer space |
| [in] | buffer_size | Size of the output buffer |

### ◆ statusGet

fsp_err_t(* jpeg_api_t::statusGet) (jpeg_ctrl_t *const p_ctrl, jpeg_status_t *const p_status)

Retrieve current status of the JPEG codec module.

**Precondition**

the JPEG codec module must have been opened properly.

**Parameters**

| | | |
|---|---|---|
| [in] | p_ctrl | Control block set in jpeg_api_t::open call. |
| [out] | p_status | JPEG module status |

### ◆ close

fsp_err_t(* jpeg_api_t::close) (jpeg_ctrl_t *const p_ctrl)

Cancel an outstanding operation.

**Precondition**

the JPEG codec module must have been opened properly.

***Note***

*If the encoding or the decoding operation is finished without errors, the HLD driver automatically closes the device. In this case, application does not need to explicitly close the JPEG device.*

**Parameters**

| | | |
|---|---|---|
| [in] | p_ctrl | Control block set in jpeg_api_t::open call. |

### 5.3.8.2 Key Matrix Interface

Interfaces » Input

### Detailed Description

Interface for key matrix functions.

# Summary

The KEYMATRIX interface provides standard Key Matrix functionality including event generation on a rising or falling edge for one or more channels at the same time. The generated event indicates all channels that are active in that instant via a bit mask. This allows the interface to be used with a matrix configuration or a one-to-one hardware implementation that is triggered on either a rising or a falling edge.

## Field Documentation

### ◆ open

fsp_err_t(* lvd_api_t::open) (lvd_ctrl_t *const p_ctrl, lvd_cfg_t const *const p_cfg)

Initializes a low voltage detection driver according to the passed-in configuration structure.

**Parameters**

| | | |
|---|---|---|
| [in] | p_ctrl | Pointer to control structure for the driver instance |
| [in] | p_cfg | Pointer to the configuration structure for the driver instance |

### ◆ statusGet

fsp_err_t(* lvd_api_t::statusGet) (lvd_ctrl_t *const p_ctrl, lvd_status_t *p_lvd_status)

Get the current state of the monitor, (threshold crossing detected, voltage currently above or below threshold). Must be used if the peripheral was initialized with lvd_response_t set to LVD_RESPONSE_NONE.

**Parameters**

| | | |
|---|---|---|
| [in] | p_ctrl | Pointer to the control structure for the driver instance |
| [in,out] | p_lvd_status | Pointer to a lvd_status_t structure |

### ◆ statusClear

fsp_err_t(* lvd_api_t::statusClear) (lvd_ctrl_t *const p_ctrl)

Clears the latched status of the monitor. Must be used if the peripheral was initialized with lvd_response_t set to LVD_RESPONSE_NONE.

**Parameters**

| | | |
|---|---|---|
| [in] | p_ctrl | Pointer to the control structure for the driver instance |

### ◆ callbackSet

fsp_err_t(* lvd_api_t::callbackSet) (lvd_ctrl_t *const p_ctrl, void(*p_callback)(lvd_callback_args_t *), void *const p_context, lvd_callback_args_t *const p_callback_memory)

Specify callback function and optional context pointer and working memory pointer.

**Parameters**

| | | |
|---|---|---|
| [in] | p_ctrl | Pointer to the LVD control block. |
| [in] | p_callback | Callback function |
| [in] | p_context | Pointer to send to callback function |
| [in] | p_working_memory | Pointer to volatile memory where callback structure can be allocated. Callback arguments allocated here are only valid during the callback. |

### ◆ close

fsp_err_t(* lvd_api_t::close) (lvd_ctrl_t *const p_ctrl)

Disables the LVD peripheral. Closes the driver instance.

**Parameters**

| | | |
|---|---|---|
| [in] | p_ctrl | Pointer to the control structure for the driver instance |

### ◆ lvd_instance_t

struct lvd_instance_t

This structure encompasses everything that is needed to use an instance of this interface.

Data Fields

| | | |
|---|---|---|
| lvd_ctrl_t * | p_ctrl | Pointer to the control structure for this instance. |
| lvd_cfg_t const * | p_cfg | Pointer to the configuration structure for this interface instance. |
| lvd_api_t const * | p_api | Pointer to the API structure for this interface instance. |

## Typedef Documentation

### ◆ lvd_ctrl_t

| typedef void lvd_ctrl_t |
| --- |
| LVD control block. Allocate an instance specific control block to pass into the LVD API calls. |

This function add an event in the BLE protocol stack internal queue. The event is handled in R_BLE_Execute just like Bluetooth event. This function is intended to be called in hardware interrupt context. Even if calling this function with the same cb before the cb is invoked, only one event is registered. The maximum number of the events can be registered at a time is eight.

This function sets the PHY preferences for the connection. The result of this API call is notified in BLE_GAP_EVENT_PHY_SET_COMP event. When the PHY has been updated, BLE_GAP_EVENT_PHY_UPD event is notified to the application layer.

After PHY update, the PHY accept configuration of local device is the same as the values in BLE_GAP_EVENT_PHY_UPD event.
For example, after calling R_BLE_GAP_SetPhy(), if tx_phy, rx_phy by BLE_GAP_EVENT_PHY_UPD event are updated to 2M PHY, the PHY accept configuration is 2M PHY only.
Therefore after receiving BLE_GAP_EVENT_PHY_UPD event, if local device wants to accept the other PHY configuration, it needs to call R_BLE_GAP_SetPhy() with the desired PHY accept configuration.

Because the maximum transmission packet size or the maximum transmission time might be updated by PHY update, if the same packet size or transmission time as the previous one is desired, change the maximum transmission packet size or the maximum transmission time by R_BLE_GAP_SetDataLen().

This function copies SDU payload into host's buffer and push the buffer into host's TX queue. Once the payload is accepted by controller scheduler, BLE_ISO_EVENT_ISO_TX_COMP event is sent back to application. Due to limitation of host buffer capacity, the maximum size of SDU payload is 251 bytes (BLE_ISO_DATA_MAX_PDU).

**Parameters**

| | | |
|---|---|---|
| [in] | p_sdu_info | SDU info and data |

**Return values**

| | |
|---|---|
| BLE_SUCCESS(0x0000) | Success |

### ◆ R_BLE_ISO_SendDataNoCopy()

ble_status_t R_BLE_ISO_SendDataNoCopy ( st_ble_iso_sdu_t * *p_sdu_info*)

Send SDU payload to a ISO channel of conn_hdl without copying data.

This function behaviors similar to R_BLE_ISO_SendData, but without copying SDU payload to the buffer in host. For this reason application should hold the buffer until a BLE_ISO_EVENT_ISO_TX_COMP event with the same conn_hdl and seq_number of p_sdu_info is received. The maximum size of SDU payload defined by BLE_ISO_DATA_MAX_SDU.

**Parameters**

| | | |
|---|---|---|
| [in] | p_sdu_info | SDU info and data |

**Return values**

| | |
|---|---|
| BLE_SUCCESS(0x0000) | Success |

**Parameters**

| | | |
|---|---|---|
| [in] | conn_hdl | Connection handle of the CIS or BIS. |
| [in] | payload_type | Configuration of SDUs in the payload. |

### ◆ R_BLE_GATTS_RspExMtu()

ble_status_t R_BLE_GATTS_RspExMtu ( uint16_t *conn_hdl*, uint16_t *mtu* )

This function replies to a MTU Exchange Request from a remote device.

BLE_GATTS_EVENT_EX_MTU_REQ event notifies the application layer that a MTU Exchange Request has been received. Therefore when the callback has received the event, call this function.
The new MTU is the minimum of the mtu parameter specified by this function and the mtu field in BLE_GATTS_EVENT_EX_MTU_REQ event.
Default MTU size is 23 bytes.
The result of this API call is returned by a return value.

**Parameters**

| | | |
|---|---|---|
| [in] | conn_hdl | Connection handle identifying the remote device to be sent MTU Exchange Response. |
| [in] | mtu | The maximum size(in bytes) of the GATT PDU that GATT Server can receive.<br>Valid range is 23 <= mtu <= 247. |

**Return values**

| | |
|---|---|
| BLE_SUCCESS(0x0000) | Success |
| BLE_ERR_INVALID_ARG(0x0003) | The mtu parameter is out of range. |
| BLE_ERR_INVALID_OPERATION(0x0009) | This function was called while processing other request. |
| BLE_ERR_MEM_ALLOC_FAILED(0x000C) | Insufficient memory is needed to generate this function. |
| BLE_ERR_INVALID_HDL(0x000E) | The remote device specified by conn_hdl was not found. |

### ◆ R_BLE_GATTS_SetPrepareQueue()

ble_status_t R_BLE_GATTS_SetPrepareQueue ( st_ble_gatt_pre_queue_t * *p_pre_queues*, uint8_t *queue_num* )

Register prepare queue and buffer in Host Stack.

This function registers the prepare queue and buffer for long chracteristic write and reliable writes. The result of this API call is returned by a return value.

**Parameters**

| | | |
|---|---|---|
| [in] | p_pre_queues | The prepare write queues to be registered. |
| [in] | queue_num | The number of prepare write queues to be registered. |

**Return values**

| | |
|---|---|
| BLE_SUCCESS(0x0000) | Success |
| BLE_ERR_INVALID_PTR(0x0001) | The p_pre_queue parameter is specified as NULL. |

### Function Documentation

#### ◆ R_BLE_GATTC_Init()

ble_status_t R_BLE_GATTC_Init ( uint8_t *cb_num*)

This function initializes the GATT Client and registers the number of the callbacks for GATT Client event.

Specify the cb_num parameter to a value between 1 and BLE_GATTC_MAX_CB.
R_BLE_GATTC_RegisterCb() registers the callback.
The result of this API call is returned by a return value.

**Parameters**

| | | |
|---|---|---|
| [in] | cb_num | The number of callbacks to be registered. |

**Return values**

| | |
|---|---|
| BLE_SUCCESS(0x0000) | Success |
| BLE_ERR_INVALID_ARG(0x0003) | The cb_num parameter is out of range. |

### ◆ R_BLE_GATTC_RegisterCb()

ble_status_t R_BLE_GATTC_RegisterCb ( ble_gattc_app_cb_t *cb*, uint8_t *priority* )

This function registers a callback function for GATT Client event.

The number of the callback that may be registered by this function is the value specified by R_BLE_GATTC_Init().
The result of this API call is returned by a return value.

**Parameters**

| | | |
|---|---|---|
| [in] | cb | Callback function for GATT Client event. |
| [in] | priority | The priority of the callback function.<br>Valid range is 1 <= priority <= BLE_GATTC_MAX_CB.<br>A lower priority number means a higher priority level. |

**Return values**

| | |
|---|---|
| BLE_SUCCESS(0x0000) | Success |
| BLE_ERR_INVALID_PTR(0x0001) | The cb parameter is specified as NULL. |
| BLE_ERR_INVALID_ARG(0x0003) | The priority parameter is out of range. |
| BLE_ERR_CONTEXT_FULL(0x000B) | Host stack has already registered the maximum number of callbacks. |

### ◆ R_BLE_GATTC_DeregisterCb()

ble_status_t R_BLE_GATTC_DeregisterCb ( ble_gattc_app_cb_t *cb*)

This function deregisters the callback function for GATT Client event.

The result of this API call is returned by a return value.

**Parameters**

| | | |
|---|---|---|
| [in] | cb | The callback function to be deregistered. |

**Return values**

| | |
|---|---|
| BLE_SUCCESS(0x0000) | Success |
| BLE_ERR_INVALID_PTR(0x0001) | The cb parameter is specified as NULL. |
| BLE_ERR_NOT_FOUND(0x000D) | The callback has not been registered. |

### ◆ R_BLE_GATTC_ReqExMtu()

ble_status_t R_BLE_GATTC_ReqExMtu ( uint16_t *conn_hdl*, uint16_t *mtu* )

This function sends a MTU Exchange Request PDU to a GATT Server in order to change the current MTU.

MTU Exchange Response is notified by BLE_GATTC_EVENT_EX_MTU_RSP event.
The new MTU is the minimum value of the mtu parameter specified by this function and the mtu field in BLE_GATTC_EVENT_EX_MTU_RSP event. Default MTU size is 23 bytes.
The result of this API call is returned by a return value.

**Parameters**

| | | |
|---|---|---|
| [in] | conn_hdl | Connection handle identifying the GATT Server to be sent. |
| [in] | mtu | The maximum size(in bytes) of the GATT PDU that GATT Client can receive.<br>Valid range is 23 <= mtu <= 247. |

**Return values**

| | |
|---|---|
| BLE_SUCCESS(0x0000) | Success |
| BLE_ERR_INVALID_ARG(0x0003) | The mtu parameter is out of range. |

This function performs the Reliable Writes procedure described in GATT Specification.

When the data written to the Characteristic has been transmitted, BLE_GATTC_EVENT_CHAR_PART_WRITE_RSP event is notified to the application layer.
If the data included in the event is different from the data that GATT Client has sent, host stack automatically cancels the Reliable Writes.
After all of the contents has been sent to the GATT Server, if the auto_flag parameter has been set to BLE_GATTC_EXEC_AUTO, the GATT Server automatically writes the data to the Characteristic.
If the auto_flag parameter has been set to BLE_GATTC_EXEC_NOT_AUTO, BLE_GATTC_EVENT_RELIABLE_WRITES_TX_COMP event notifies the application layer in GATT Client that all of the contents has been sent to the GATT Server. Then GATT Client requests for writing the data to the Characteristic to the GATT Server with R_BLE_GATTC_ExecWrite().
When the write has been done, BLE_GATTC_EVENT_RELIABLE_WRITES_COMP event is notified to the application layer.

**Parameters**

Vendor Specific API supports the flow control function(TxFlow) for the transmission on L2CAP fixed channel in Basic Mode such as GATT.
Host stack has 10 transmission packet buffers for the transmission.
When the number of the available transmission packet buffers has been less than Low Water Mark, the state of TxFlow transmits into the TxFlow OFF state from the TxFlow ON state that is the initial state and host stack notifies the application layer of timing to stop packet transmission.
When host stack has sent the transmission packets to Controller and the number of the available transmission packet buffers has been more than High Water Mark, the state of TxFlow transmits into the TxFlow ON state from the TxFlow OFF state and host stack notifies the application layer of

timing to restart packet transmission.
It is possible to perform flow control on a fixed channel by using the event notification.

### Detailed Description

Interface for accessing low power modes.

# Summary

This section defines the API for the LPM (Low Power Mode) Driver. The LPM Driver provides functions for controlling power consumption by configuring and transitioning to a low power mode. The LPM driver supports configuration of MCU low power modes using the LPM hardware peripheral. The LPM driver supports low power modes deep standby, standby, sleep, and snooze.

*Note*

*Not all low power modes are available on all MCUs.*

### 5.3.16.1 CGC Interface

Interfaces » System

#### Detailed Description

Interface for clock generation.

## Summary

The CGC interface provides the ability to configure and use all of the CGC module's capabilities. Among the capabilities is the selection of several clock sources to use as the system clock source. Additionally, the system clocks can be divided down to provide a wide range of frequencies for various system and peripheral needs.

Clock stability can be checked and clocks may also be stopped to save power when not needed. The API has a function to return the frequency of the system and system peripheral clocks at run time. There is also a feature to detect when the main oscillator has stopped, with the option of calling a user provided callback function.

## Typedef Documentation

### ◆ transfer_ctrl_t

| typedef void transfer_ctrl_t |
|---|
| Transfer control block. Allocate an instance specific control block to pass into the transfer API calls. |

## Enumeration Type Documentation

### ◆ transfer_mode_t

| enum transfer_mode_t | |
|---|---|
| Transfer mode describes what will happen when a transfer request occurs. | |
| Enumerator | |
| TRANSFER_MODE_NORMAL | In normal mode, each transfer request causes a transfer of transfer_size_t from the source pointer to the destination pointer. The transfer length is decremented and the source and address pointers are updated according to transfer_addr_mode_t. After the transfer length reaches 0, transfer requests will not cause any further transfers. |
| TRANSFER_MODE_REPEAT | Repeat mode is like normal mode, except that when the transfer length reaches 0, the pointer to the repeat area and the transfer length will be reset to their initial values. If DMAC is used, the transfer repeats only transfer_info_t::num_blocks times. After the transfer repeats transfer_info_t::num_blocks times, transfer requests will not cause any further transfers. If DTC is used, the transfer repeats continuously (no limit to the number of repeat transfers). |
| TRANSFER_MODE_BLOCK | In block mode, each transfer request causes transfer_info_t::length transfers of transfer_size_t. After each individual transfer, the source and destination pointers are updated according to transfer_addr_mode_t. After the block transfer is complete, transfer_info_t::num_blocks is decremented. After the transfer_info_t::num_blocks reaches 0, transfer requests will not cause any further transfers. |
| TRANSFER_MODE_REPEAT_BLOCK | In addition to block mode features, repeat-block mode supports a ring buffer of blocks and offsets within a block (to split blocks into arrays of their first data, second data, etc.) |

### ◆ transfer_size_t

| enum transfer_size_t | |
|---|---|
| Transfer size specifies the size of each individual transfer. Total transfer length = transfer_size_t * transfer_length_t | |
| Enumerator | |
| TRANSFER_SIZE_1_BYTE | Each transfer transfers a 8-bit value. |
| TRANSFER_SIZE_2_BYTE | Each transfer transfers a 16-bit value. |
| TRANSFER_SIZE_4_BYTE | Each transfer transfers a 32-bit value. |
| TRANSFER_SIZE_8_BYTE | Each transfer transfers a 64-bit value. |

### ◆ transfer_addr_mode_t

| enum transfer_addr_mode_t | |
|---|---|
| Address mode specifies whether to modify (increment or decrement) pointer after each transfer. | |
| Enumerator | |
| TRANSFER_ADDR_MODE_FIXED | Address pointer remains fixed after each transfer. |
| TRANSFER_ADDR_MODE_OFFSET | Offset is added to the address pointer after each transfer. |
| TRANSFER_ADDR_MODE_INCREMENTED | Address pointer is incremented by associated transfer_size_t after each transfer. |
| TRANSFER_ADDR_MODE_DECREMENTED | Address pointer is decremented by associated transfer_size_t after each transfer. |

### ◆ transfer_repeat_area_t

| enum transfer_repeat_area_t | |
|---|---|
| Repeat area options (source or destination). In TRANSFER_MODE_REPEAT, the selected pointer returns to its original value after transfer_info_t::length transfers. In TRANSFER_MODE_BLOCK and TRANSFER_MODE_REPEAT_BLOCK, the selected pointer returns to its original value after each transfer. | |
| Enumerator | |
| TRANSFER_REPEAT_AREA_DESTINATION | Destination area repeated in TRANSFER_MODE_REPEAT or TRANSFER_MODE_BLOCK or TRANSFER_MODE_REPEAT_BLOCK. |
| TRANSFER_REPEAT_AREA_SOURCE | Source area repeated in TRANSFER_MODE_REPEAT or TRANSFER_MODE_BLOCK or TRANSFER_MODE_REPEAT_BLOCK. |

### ◆ transfer_chain_mode_t

| enum transfer_chain_mode_t | |
|---|---|
| Chain transfer mode options.<br><br>***Note***<br>*Only applies for DTC.* | |
| Enumerator | |
| TRANSFER_CHAIN_MODE_DISABLED | Chain mode not used. |
| TRANSFER_CHAIN_MODE_EACH | Switch to next transfer after a single transfer from this transfer_info_t. |
| TRANSFER_CHAIN_MODE_END | Complete the entire transfer defined in this transfer_info_t before chaining to next transfer. |

### ◆ transfer_irq_t

| enum transfer_irq_t | |
|---|---|
| Interrupt options. | |
| Enumerator | |
| TRANSFER_IRQ_END | Interrupt occurs only after last transfer. If this transfer is chained to a subsequent transfer, the interrupt will occur only after subsequent chained transfer(s) are complete.<br><br>Warning<br>DTC triggers the interrupt of the activation source. Choosing TRANSFER_IRQ_END with DTC will prevent activation source interrupts until the transfer is complete. |
| TRANSFER_IRQ_EACH | Interrupt occurs after each transfer.<br><br>*Note*<br>*Not available in all HAL drivers. See HAL driver for details.* |

### ◆ transfer_start_mode_t

| enum transfer_start_mode_t | |
|---|---|
| Select whether to start single or repeated transfer with software start. | |
| Enumerator | |
| TRANSFER_START_MODE_SINGLE | Software start triggers single transfer. |
| TRANSFER_START_MODE_REPEAT | Software start transfer continues until transfer is complete. |
