Disable arc drawing support	No (Disabled)	If defined, removes support for the arc-drawing functions circle, arc, pie, and ellipse.
Disable software decoder support	No (Disabled)	If defined, reduce the GUIX library footprint when runtime decode of jpg or png files is not required.
Disable binary resource support	No (Disabled)	If defined, reduce your GUIX library footprint when only C source code format resource files are used.

Repeat button initial tics	10	This value defines how long the button waits before beginning to send repeated GX_EVENT_CLICKED events.
Maximum number of unique dirty list entries	64	This value defines the maximum number of unique dirty list entries that can be maintained by one canvas.
Maximum nesting of context	8	This value defines the maximum nesting of the drawing context stack.
Maximum input capture nesting	4	This value defines size of the stack used to maintain the list of widgets that have captures the user input.
Cursor blink interval	20	This value defines the rate at which the input cursor blinks for text input widgets.
Multi line index cache size	32	This value defines the size of the list-start index cache maintained by the multi-line text view and multi-line text input widgets.
Multi line text button maximum lines	4	This value determines the number of text pointers needed by the worst case multi-line text button.
Maximum number of polygon edges	10	This value determines the most complex polygon that can be drawn by GUIX.
Numeric scroll wheel string buffer size	16	This value determines the maximum length of the string required to display the assigned integer values.
Circular gauge animation delay	5	This value defines the number of GUIX timer ticks (50 ms) between updates of a circular gauge configured to animate the needle movement between last and current angular position.
Numeric prompt buffer size	16	This value defines the size of buffer allocated to convert an integer value assigned to the prompt to an ascii string.

Animation pool size	6	This value defines the size of animation pool from which animation information structures can be dynamically allocated and returned.
Mouse support	Disabled	Enables the mouse support. This definition should only be enabled when a mouse (not a touch screen) must be supported.
Hardware mouse support	Disabled	When enabled, the GUIX display driver utilizes hardware mouse cursor drawing support.
Font kerning support	Disabled	Enables font kerning support.
Maximum string length	102400	This value defines the maximum length of a string, which is used to test invalid strings.
Disable brush alpha support	No (Disabled)	Allows brush alpha support to be disabled. This helps eliminate runtime overhead and library footprint increase for drawing non-arc graphics, pixelmaps, and fonts with an alpha value defined by the drawing context brush while running at 16 bpp and higher color depths.
Maximum string length	102400	This value defines the maximum length of a string, which is used to test invalid strings.

GUIX Options Available in the Azure RTOS User Guide (Non-configurable in ISDE)

MACRO	Default value	Description
GX_SYSTEM_TIMER_TICKS	2 ticks (20 ms)	GUIX timer frequency (interval on which the timer thread entry function checks for tasks (for example, periodic tasks, timeouts) that need to be executed.
GX_TICKS_SECOND	2 ticks	This is only used if porting GUIX to another RTOS other than ThreadX.
GX_MAX_VIEWS	32	Number of simultaneous views.

GX_MAX_ACTIVE_TIMERS	32	Number of timers available in GUIX to be assigned to one or more widgets.
GX_DISABLE_THREADX_BINDING	Not enabled	If not defined, GUIX expects a ThreadX RTOS; GUIX can work with other RTOSs, but this is not supported in Synergy.
GX_DISABLE_THREADX_TIMER_SOURCE	Not enabled	If defined, disables ThreadX timer source to use a different timer source.

Disabling Multithread Support

The gx_system_initialize API creates the GUIX drawing and event processing thread. That thread is started when the gx_system_start API is called. GUIX application threads may wish to invoke the GUIX API while the GUIX system thread is running. An application thread could, for example, create a pop-up error window and display it by attaching it to the root window. The problem is that two or more threads accessing internal GUIX resources simultaneously will cause undefined results. Therefore, in a multithreaded environment, GUIX must protect critical code sections where it updates linked lists and other internal objects. To do so, GUIX uses mutexes to guard critical code sections. If Multithread Support property is not disabled, GUIX macros enable protection of the critical sections. It is generally recommended that if a system is not severely constrained by resources (memory), that this option be left disabled.

If the application does not call any GUIX API, then the only thread affecting GUIX is the system thread; disabling multithreaded support will reduce the overhead of protecting critical code sections and improve performance.

GUIX System Timer

The GUIX System timer is the interval on which the GUIX timer executes and is used by GUIX for periodic processing needs inside GUIX. The system timer It should be a multiple of the ThreadX timer, which is typically defined to be 10 ms (100 ticks/sec). Example:

GUIX System Timer is to 10

ThreadX timer is 100

GUIX timer tick = ((10 ms * 100 ticks per second) / 1000 ms per second) == 1 tick

This sets the GUIX timer tick to one tick. If the GUIX System timer is not a multiple of the ThreadX timer, it will be rounded down. In the example above, if it were set to 17, the GUIX timer tick would still be "1". To make the GUIX timer tick every other ThreadX timer tick, set the System timer property in GX_SRC to 20;

GUIX timer tick = ((20 * 100) / 1000) == 2.

UTF8 Support

By default, UTF8 is enabled. If UTF8 is disabled, GUIX is limited to ASCII type (one byte per glyph). There is always runtime overhead associated with UTF8 support even if the application is only using ASCII. This is because GUIX has to call a function to compute the next character value in the string when using UTF8 because it cannot assume it is a one-byte character.

In lieu of disabling UTF8, the application can avoid using character values higher than 255. When UTF8 is disabled, this tells GUIX that each character is simply one byte and it does not need to call the next-character-compute function.

Display Memory Architecture

There are several display memory architectures supported by GUIX. The display memory architecture is really defined by the display driver, which is a very small hardware porting layer, and does not affect the core GUIX library code. The most common model is to provide two canvas memory areas: one the "working" buffer and one the "visible" buffer. GUIX executes drawing updates to the working canvas, then toggles the working and visible canvas buffers when a drawing sequence is completed.

Four basic memory models are described as follows:

Models 1 and 2 contain only GRAM and Frame Buffer respectively in the following diagram, and would be recommended for only very small displays as it is slow. In Model 1, the display provides its own memory large enough to hold the pixel data. This external memory is usually called "GRAM" or Graphics Ram, and some non-random access such as SPI access is provided to the core CPU. In this model, the display driver executes all drawing operations by writing pixel data over the SPI interface.

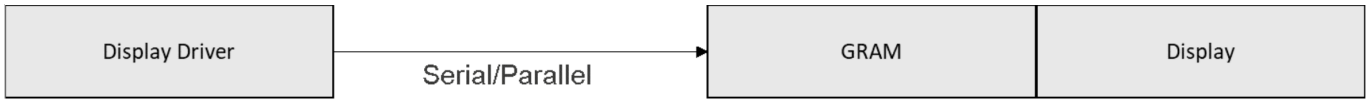

Figure 410: Model 1

Figure 411: Model 2

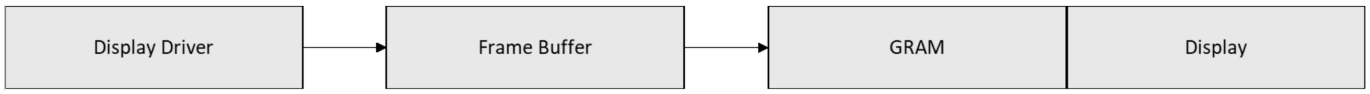

Figure 412: Model 3 (Local Frame Buffer + External GRAM)

Model 3 is a combination of the first two models. In this model, sufficient local memory exists to hold one frame buffer. In addition, the display device provides an external GRAM and automatically refreshes itself using the data provided in the GRAM. This architecture benefits from improved update efficiency because the user can transfer the modified portion of the local frame buffer to the external GRAM in one block transfer, often utilizing on-board DMA channels. This model also eliminates the tearing and flicker that can be present in either of the first two models, because only completed graphics content is copied to the external GRAM.

Model 4 requires that sufficient memory is present to provide two local frame buffers. In this case, GUIX treats one frame buffer as the active frame buffer, and the other as the working frame buffer. When a display update or drawing operation is in progress, it takes place in the working buffer. When the drawing operation completes, the buffers are toggled, and the working buffer becomes the active buffer and the active buffer becomes the working buffer. Like Model 3, this model also eliminates screen flicker and tearing that can be observed in a single buffered system.

Model 4 Ping Pong frame buffers:

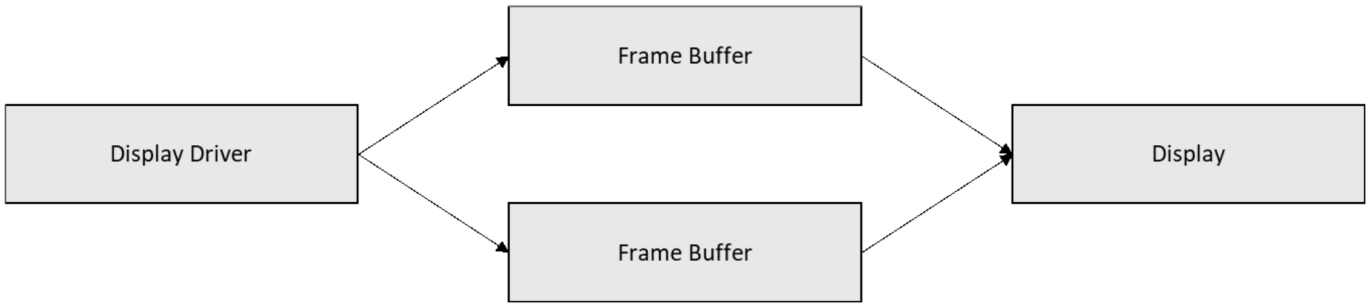

Figure 413: Model 4 (Ping-Pong Frame Buffers)

Synergy (SF_EL_GX module) implements Model 4 (although Model 3 is also possible).

Receiving Events from the Hardware

Signals in GUIX

Signals are used to get information such as hardware events up to the GUIX level. Hardware events are transduced by the hardware and message framework drivers into GX_SIGNALs by the time they reach the GUIX event queue. The GX_SIGNAL macro is a macro that combines the ID of the widget (user defined in GUIX Studio) that generated an event with the event type the widget has generated into a unique gx_event_type identifier code. For more details about GX_EVENT types and signals, please see the GUIX™ Synergy Port Framework Module Guide.

Drivers for the Hardware Interface

In the Synergy driver hardware, a ThreadX periodic thread task is created that continually checks for hardware events. When an event is detected, the hardware driver transmits information about this event to the thread task. The Touch Panel V2 Framework module scans data from a touch controller and invokes the user-registered touch panel callback when a touch event occurs. If the user callback is not registered, the sf_touch_panel_v2_api_t::touchDataGet API function can be used to retrieve the data. In the example of the touchscreen, the touch panel driver would relay X and Y coordinates, and event type.

```
/* User callback*/
typedef struct st_sf_touchpanel_v2_callback_args
{
    sf_touch_panel_v2_payload_t     payload;       // Touch data and event provided
to the user during callback
    void const                  * p_context;      // Context provided to user during
callback
} sf_touchpanel_v2_callback_args_t;
/* Touch data payload */
typedef struct st_sf_touch_panel_v2_payload
```

```
{
    int16_t                         x;              // X coordinate.
    int16_t                         y;              // Y coordinate.
    sf_touch_panel_v2_event_t       event_type;     // Touch event type.
} sf_touch_panel_v2_payload_t;
```

The user callback must be registered to obtain touch data. The Touch Panel V2 Framework module scans data from a touch controller and invokes the user-registered callback. If the user callback is not registered, the sf_touch_panel_v2_api_t::touchDataGet API function can be used to retrieve the data. If the user callback is registered, then the framework will invoke the callback when touch events occur.

Example: (User-defined touch panel callback function)

```
void g_sf_touch_panel_cb(sf_touchpanel_callback_args_t * p_args)
{
    bool send_event = true;
        GX_EVENT gxe;
        switch (p_args->payload.event_type)
        {
        case SF_TOUCH_PANEL_V2_EVENT_DOWN:
            gxe.gx_event_type = GX_EVENT_PEN_DOWN;
            break;
        case SF_TOUCH_PANEL_V2_EVENT_UP:
            gxe.gx_event_type = GX_EVENT_PEN_UP;
            break;
        case SF_TOUCH_PANEL_V2_EVENT_HOLD:
        case SF_TOUCH_PANEL_V2_EVENT_MOVE:
            gxe.gx_event_type = GX_EVENT_PEN_DRAG;
            break;
        case SF_TOUCH_PANEL_V2_EVENT_INVALID:
            send_event = false;
            break;
        default:
            break;
        }
```

```
    if (send_event)
    {
        /* Send event to GUIX */
        gxe.gx_event_sender         = GX_ID_NONE;
        gxe.gx_event_target         = 0;  /* the event to be routed to the widget
that has input focus */
        gxe.gx_event_display_handle = 0;
        gxe.gx_event_payload.gx_event_pointdata.gx_point_x = p_args->payload.x;
  #if defined(BSP_BOARD_S7G2_SK)
        gxe.gx_event_payload.gx_event_pointdata.gx_point_y = (GX_VALUE)(320 -
p_payload->y);
  #else
        gxe.gx_event_payload.gx_event_pointdata.gx_point_y = p_args->payload.y;
  #endif
        gx_system_event_send(&gxe);
    }
}
```

The user callback function can update the GX_EVENT data type and fill in the following fields as needed:

```
     /* Send event to GUIX */
        gxe.gx_event_sender         = GX_ID_NONE;
        gxe.gx_event_target         = 0;  /* the event to be routed to the widget
that has input focus */
        gxe.gx_event_display_handle = 0;
        gxe.gx_event_payload.gx_event_pointdata.gx_point_x = p_args->payload.x;
  #if defined(BSP_BOARD_S7G2_SK)
        gxe.gx_event_payload.gx_event_pointdata.gx_point_y = (GX_VALUE)(320 -
p_payload->y);
  #else
        gxe.gx_event_payload.gx_event_pointdata.gx_point_y = p_args->payload.y;
  #endif
        gx_system_event_send(&gxe);
```

SF_TOUCH_PANEL_V2_EVENT_DOWN, SF_TOUCH_PANEL_V2_EVENT_UP, and other touchscreen panel events are defined in the touchscreen header files. The touchscreen driver also defines its only payload field, since it needs to communicate some value(s) to the application besides event type. For a touchscreen event, the touchscreen payload includes an x and y coordinate. The GX_EVENT contains a union of field for payload. In this case, the GX_EVENT gx_event_payload field uses the GX_POINT gx_event_pointdata which holds two values for x and y coordinates.

Now, the application can send this event over to the GUIX event queue to let GUIX handle it by calling gx_system_event_send API.

GUIX periodically checks the event queue, and sees the event just added to the queue. In the case of the touchscreen panel, it uses the x,y coordinates to find the window widget currently attached to the root window, and searches all the child widgets contained by that window for the highest one (Z order) that contains this coordinate. Then GUIX typically defers to the child widget's parent event handler for passing off further handling of the event.

Screen Management

Root and Child Windows

Each visible canvas has a root window. The root window is the container for all windows and widgets of the display.

Attaching and Detaching Screens

If the new screen is a child of the parent screen, the application must attach the new screen and detach the old screen using gx_widget_attach and gx_widget_detach (order is not important). If moving back to a parent screen, the application does not attach the parent screen but calls gx_window_show on the parent screen. A simple algorithm for swapping out screens follows:

```
void ToggleScreen(GX_WIDGET *new_win, GX_WIDGET *old_win)
{
    if (!new_win->gx_widget_parent)
    {
        gx_widget_attach(root, new_win);
    }
    else
    {
        gx_widget_show(new_win);
    }
    gx_widget_hide(old_win);
}
```

In the following code, GUIX has detected a button widget clicked in window1, for switching from

window1 to window2. It attaches the new window (window2) to the root window, and detaches the old window (window1):

```
UINT window1_handler(GX_WINDOW *widget, GX_EVENT *event_ptr)
{
    gx_window_event_process(widget, event_ptr);
    switch (event_ptr->gx_event_type)
    {
        case GX_SIGNAL(ID_WINDOWCHANGER, GX_EVENT_CLICKED):
        if(button_enabled)
        {
            show_window((GX_WINDOW*)&window2, (GX_WIDGET*)widget, true);
        }
        break;
       default:
        gx_window_event_process(widget, event_ptr);
        break;
    }
    return result;
}
static UINT show_window(GX_WINDOW * p_new, GX_WIDGET * p_widget, bool detach_old)
{
UINT result = gx_window_event_process(widget, event_ptr);
switch (event_ptr->gx_event_type)
{
   case GX_SIGNAL(ID_WINDOWCHANGER, GX_EVENT_CLICKED):
      if (!p_new->gx_widget_parent)
{
err = gx_widget_attach(p_window_root, p_new);
}
else
{
err = gx_widget_show(p_new);
}
gx_system_focus_claim(p_new);
```

```
GX_WIDGET * p_old = p_widget;
if (p_old && detach_old)
{
if (p_old != (GX_WIDGET*)p_new)
{
gx_widget_detach(p_old);
}
}
break;
   default:
gx_window_event_process(widget, event_ptr);
break;
}
return result;
}
```

Both methods are perfectly acceptable ways to move between screens, with the latter having more complexity. It does not matter which order is followed in attaching or detaching screens. GUIX just marks the to-be visible window as dirty and re-draws that window after the application is finished modifying the tree* of visible widgets. In other words, GUIX does not actually draw the window as part of the "attach" API call.

Note

GUIX maintains a tree structured lists of visible objects for linking child widgets (many) to their parent widget (one). When a window is swapped out with another, the tree is modified to include the new (visible) window and remove the old (soon to be not visible) window.

Attaching and Detaching Widgets

GUIX keeps a linked list of child widgets (a window is a widget type) that belong to or are attached to a parent. Child windows are attached to the root window. When a widget is attached, it is added to the end of the list. There is a first and last child marker of this list (not a circular list). Before a child widget can be attached to a parent widget, it must not be a child of another parent. If so, it is detached from that parent first.

When it is detached, it is removed from the list. However, it is not deleted, so it is still available to be reattached without needing to be recreated. In the meantime, it cannot draw, and it has no parent, but it can still receive events and the control block for that widget is still valid.

Detaching vs Deleting Widgets

When a widget is detached, it is removed from the active list of widgets maintained by GUIX. However, it is not deleted, so it is still available to be reattached without needing to be recreated. In the meantime, it cannot draw, and it has no parent, but it can still receive events and the control

block for that widget is still valid.

The gx_widget_delete API first detaches the widget if it still has a parent, then, it clears out the control block. If the control block was dynamically allocated, the memory for the control block is freed. If the gx_widget_delete API was applied to a widget, the widget will need to be re-created before it can be displayed again.

When to Create Widgets

GUIX Studio enables a developer to create screens, name widgets, set event and draw callback functions much more easily than creating them by source code in GUIX APIs. In GUIX Studio, the developer can choose which widgets are created at start up time (default setting), or it can enable runtime creation by checking the Run Time Allocation property of a widget. If this is enabled, the application must create the widget when it needs it. Otherwise, all the 'static' widgets are created at start up. This requires that there be enough memory for these 'static' widgets. If there is, there really is no reason to not create all the widgets at start time. However, in an application with a large number of screens, or limited memory, it may be necessary to create widgets as needed at runtime.

To designate a widget for dynamic memory allocation, check the box for Runtime Allocate in GUIX Studio. In the specification files created by GUIX Studio, the 'style flag' of the widget (and any children of the widget) sets the GX_ STYLE_DYNAMICALLY_ALLOCATED attribute. When the application creates the widgets, it will allocate memory using the memory allocator specified in gx_system_memory_allocator_set. Note that this requires that the application set up a memory pool before starting the GUIX services. The project for this module guide demonstrates this.

Drawing at Run Time

Some screens require drawing at run time inevitably. These would be line draw and text writing API for updating information on a screen in real time. Dynamic string creation is accomplished using sprintf and gx_utility_ltoa functions; these are useful for printing run time values in the string. Some of the APIs used for that screen for drawing are listed below as examples:

```
UINT _gx_canvas_line_draw(GX_VALUE x_start, GX_VALUE y_start, GX_VALUE x_end,
GX_VALUE y_end);
UINT _gx_canvas_text_draw(GX_VALUE x_start, GX_VALUE y_start, GX_CONST GX_CHAR
*string, INT length);
```

Normally, drawing to a screen is done by a method called deferred drawing, where GUIX internally manages when a window or part of a window should be redrawn so as to improve drawing efficiency.

However, when an application wants immediate drawing to a canvas, it must call the gx_canvas_drawing_initiate API before drawing anything. When completed, the application calls gx_canvas_drawing_complete to signal GUIX to let deferred drawing resume.

Run time drawing requiring memory allocation and deallocation is demonstrated in the rotation of the thermostat in the gux_gx_src_mg_ap.c file in the module guide project.

Note that in SSP 1.3.0/GUIX 5.3.3, to 'rotate' or otherwise redraw an image at run time the pixelmap data must not be compressed. If you anticipate needing to redraw an image differently, such as using rotation, make sure to uncheck the **Compress Output** for the **pixelmap** resource in GUIX

Studio (v5.3.3.7 and later). To edit a pixelmap resource, open the **Pixelmaps** bar by clicking on the (+**) icon -> click on **Custom** -> double click on the graphic item -> **Uncheck Compress Output** (it is enabled by default).

Memory Allocation in GUIX Applications

Allocating Memory

Dynamic memory allocation is supported (for example, heap memory) in GUIX. The gx_system_memory_allocator_set API lets the application assign a memory allocation and a memory free service. This API is called at program startup, after gx_system_initialize, and before any GUIX services that require dynamic memory allocation.

GUIX services that require a runtime memory allocation and de-allocation service include:

- Loading binary resources from external storage into the GUIX runtime environment.
- The software runtime jpeg image decoder.
- The software runtime png image decoder.
- Using text widgets with GX_STYLE_TEXT_COPY.
- Runtime pixelmap resize and rotation utility functions.
- Runtime screen and widget control block allocation.

Dynamic memory allocation is required for pixelmap rotation in the project for this module guide.

Dynamic allocation lets an application import resources like fonts, language, and images at runtime from non-volatile memory like a flash drive or a URL source. Most GUIX applications are small enough that this is not required. GUIX resources can be loaded and statically linked at compile time using the pixelmaps created in GUIX studio, which decode the resource from jpeg to pixelmap format.

Widget Creation: Static vs Runtime

If you have plenty of memory and your control blocks are all statically allocated, for example, the **Runtime Allocated** property for the widget in GUIX Studio is not checked, then there is no reason not to create them during program startup. Creating your GUIX screens is just setting their initial parameters using the data written to the specifications file. You can always modify any of these parameters at any time after the screen has been created.

If you want your application to be more RAM efficient, set the **Runtime Allocated** property for some or all of your screen widgets in GUIX Studio. In your application, set up a memory pool to use for dynamically allocating your control blocks. This is done by calling the gx_system_memory_allocator_set API, which takes as its input a memory allocate function pointer and a memory release function pointer. These user defined functions will typically use the ThreadX tx_byte_allocate and tx_byte_release API, respectively, but other memory allocation services can be used.

Dynamic widget allocation is generally handled in the GUIX Studio specification file. In the specification file, gx_studio_widget_create will dynamically allocate those widget control blocks assigned for dynamic allocation. In the following example, the medical screen widget is designated for dynamic allocation as indicated by the style symbol: GX_STYLE_DYNAMICALLY_ALLOCATED:

```
GX_CONST GX_STUDIO_WIDGET meds_screen_define =

{
```

```
    "meds_screen",
    GX_TYPE_TEMPLATE,   /* widget type                 */
    ID_MEDS_SCREEN,   /* widget id                    */
    GX_STYLE_BORDER_THIN|GX_STYLE_DYNAMICALLY_ALLOCATED,   /* style flags   */
    GX_STATUS_ACCEPTS_FOCUS,   /* status flags             */
```

Then widget create handler in the specification file will check if a widget should be allocated dynamically:

```
static GX_WIDGET *gx_studio_nested_widget_create(GX_BYTE *control,
GX_CONST GX_STUDIO_WIDGET *definition, GX_WIDGET *parent)
{
    UINT status = GX_SUCCESS;
    GX_WIDGET *widget = GX_NULL;
    while(definition && status == GX_SUCCESS)
    {
                if (definition->style & GX_STYLE_DYNAMICALLY_ALLOCATED)
                {
                    status = gx_widget_allocate(&widget,
definition -> control_block_size);
                    ...
```

Note that the application can call gx_widget_allocate at runtime as well.

When gx_widget_delete is called on this widget, GUIX will call the memory free function specified by the application to release the control block memory. Applications that have hundreds of screens and limited RAM would almost always be set up this way.

When a widget is dynamically allocated, the control blocks for any child widget automatically become dynamically allocated. You cannot and are not required to set this flag for child widgets. Once you set the flag at any level in e^2 studio, all children of the dynamically allocated parent also become dynamically allocated.

Multiple Canvases and Layers

GUIX in Synergy is limited to one 'simple' canvas. A simple canvas is an off-screen drawing area used by the application. GUIX does nothing directly with a simple canvas, but the application can use a simple canvas to render complex drawing to an off-screen buffer, and then use this off-screen buffer to refresh the visible canvas when needed. Synergy does not currently support multiple canvases. Most GUIX applications are simple enough that multiple canvases not required. The benefit of using multiple canvases is being able to assign one or more canvases to fast memory to

meet performance requirements. Multiple canvases can also be used for special effects such as fading in and fading out.

Support for multiple graphics layers (multiple overlaid frame buffers) is also not supported.

Timers

The gx_system_timer start API is called on a widget after GUIX services are initialized and running. The input includes a timer ID for this timer (zero is not allowed) defined by the application. To stop the timer, the gx_system_timer_stop API is called on the same widget. If a non-zero timer ID is provided, GUIX will search for all timers attached to this widget for one matching that ID. If a zero timer ID is provided, GUIX will stop and detach all timers for the specified widget.

On starting a timer, an available timer is allocated from GUIX's free list of timers and added to the list of active timers. When a timer is stopped it is moved back from the active list of timers to the free list.

When a timer expires, GUIX sends the GX _EVENT_TIMEOUT for that widget (timer owner). The event handler for that widget should handle the timeout event and perform any necessary tasks. A timer will be reset up to the number of times specified in the gx_system_timer_start API.

GUIX uses ThreadX timer for certain visual effects as well as time out expiration events. Fading out and sprite animation are two examples.

Versions in GUIX and GUIX Studio

GUIX library and Studio versions work as follows. The GUIX library has major.minor.service_pack version information. So it is always 5.3.3 or 5.4.0, three fields. The Studio version number is <GUIX_LIB_VERSION>.Studio Revision. Do not forget that Studio requires the GUIX library as part of the Studio build, this is how we render the GUIX widgets within the Studio target view panel. So the first Studio release based on 5.3.3 library is 5.3.3.0. The latest Studio release based on 5.3.3 library is 5.3.3.7. The first Studio release based on upcoming 5.4.0 library will be 5.4.0.0. So Studio release adds one field to GUIX library release.

Porting GUIX projects from SSP 1.2.0 and 1.2.1 to SSP 1.3.0

- To port GUIX projects previously built using SSP 1.2.0 or 1.2.1, follow these steps:
    1. Install GUIX Studio 5.3.3.7.
    2. Open the gxp project file used for the GUIX project in 1.2.0/1.2.1 in GUIX Studio 5.3.3.7.
    3. Update the GUIX Library Version in the **Configure Display** screen (right click on the main display window) and choose 5.3.3.
    4. Generate the new specification and resource files and copy them to your project file if they do not already get written to your src folder or subfolder automatically.
    5. In the Synergy configurator, choose **SSP 1.3.0**, and click on **Generate Project Content**.
    6. Build the project.
- If compile errors result referring to dlist_start and dlist_indirect not being defined, delete the tes and sf_tes_2d_draw folder in the synergy\ssp\src\framework folder. Then regenerate project files by clicking on **Generate Project Content** and the **Build project** icon.
- Compile errors result referring to the following undefined GUIX functions may result if the wrong version of GUIX is set in GUIX Studio:
    1. _gx_dave2d_glyph_8bit_draw
    2. _gx_dave2d_glyph_4bit_draw
    3. _gx_dave2d_glyph_1bit_draw

Check the headers in the specification and resource files to verify which version of GUIX Studio was used. You can check function headers in any GUIX source file (assuming you have access to it) to verify the GUIX version is 5.3.3.

GUIX GX_SRC Framework Module Important Operational Notes and Limitations

GUIX GX_SRC Framework Module Operational Notes

GUIX GX_SRC Framework Module Limitations

- GUIX in Synergy does not support 4bpp (grayscale) or 1bpp (monochrome)
- SF_EL_GX does not support a system with more than two frame buffers.
- SF_EL_GX supports only one GUIX canvas system.
- SF_EL_GX makes use of only one graphics layer in the DISPAY module.
- Refer to the most recent SSP Release notes for additional limitations when using this module.

4.3.5.4 Including the GUIX GX_SRC Framework Module in an Application

This section describes how to include the GUIX GX_SRC Framework module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the GUIX GX_SRC Framework module to an application, click on the Add GUIX Source block below the *GUIX on gx* component in the Thread Stack Panel and choose New.

GUIX GX_SRC Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
GUIX Source	Threads	**New Stack**> **X-Ware**> **GUIX**> **GUIX Source**

When the GUIX GX_SRC Framework module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

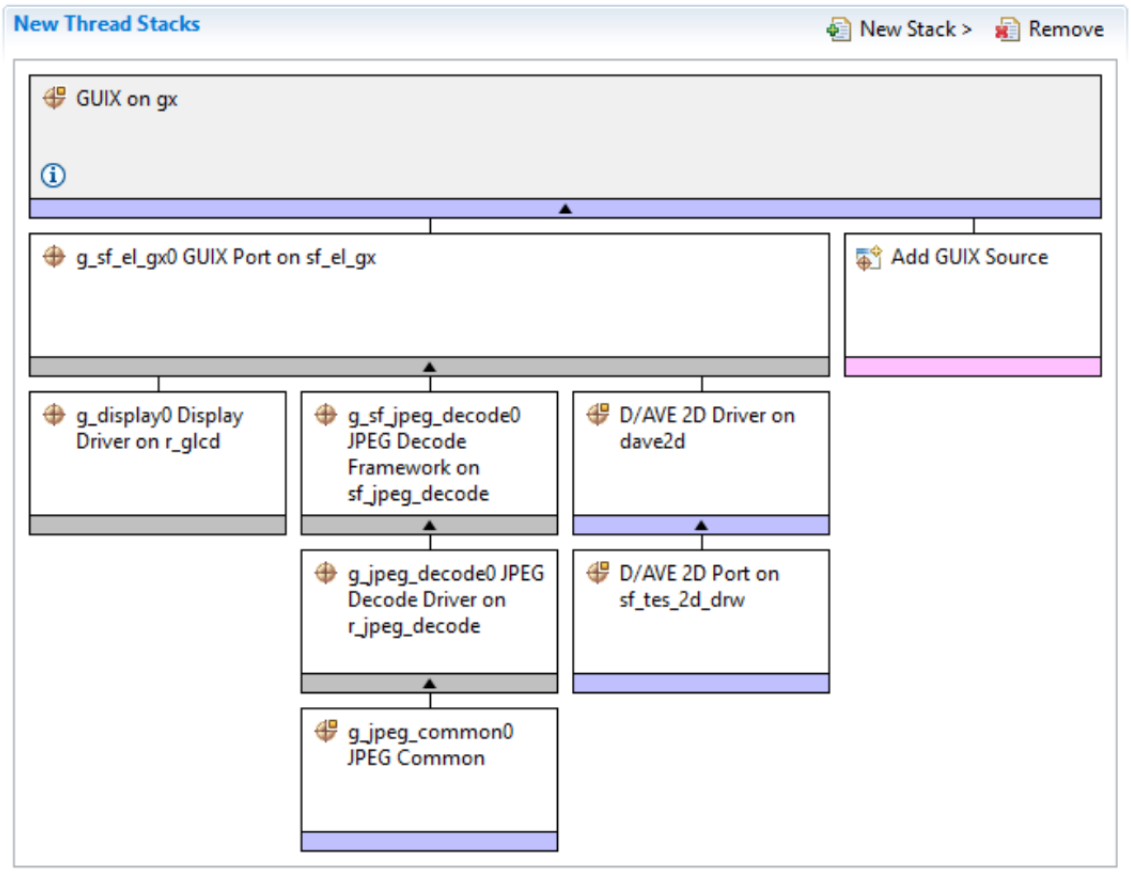

Figure 414: GUIX GX_SRC Framework Module Stack

4.3.5.5 Configuring the GUIX GX_SRC Framework Module

The GUIX GX_SRC Framework module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the GUIX GX_SRC Framework

ISDE Property	Value	Description
GUIX Stack Size		GUIX internal thread stack size in bytes. Must be greater than zero or empty.

GUIX System Timer (Milliseconds)		GUIX system timer. Must be a multiple of TX_TIMER_TICKS_PER_SECOND or empty.
GUIX Timer Rate		GUIX timer rate as a multiple of the ThreadX tick interrupt rate. Must be greater than zero or empty.
Disable Multithread Support	Yes, No Default: No	If your application has only one thread which utilizes the GUIX API services, say yes to reduce system overhead.
Disable UTF8 Support	Yes, No Default: No	GUIX disables UTF8 support if you say yes.
GUIX Event Queue Size		Size of GUIX Event Queue Size. Must be greater than zero or empty.
GUIX Thread Priority	16	Priority of GUIX Internal Thread. The value must be between 0 to 31.
GUIX Thread Time Slice	10	Time Slice value of GUIX Internal Thread. The value must be between 0(TX_NO_TIME_SLICE) to 0xFFFFFFFF.
Use User Data Field in GX_WIDGET Structure	Yes, No Default: No	GUIX allows users to use gx_widget_user_data member in GX_WIDGET Structure if you say yes.
Enable partial canvas frame buffer	Yes, No Default: No	Enabling this option will define the GX_ENABLE_CANVAS_PARTIAL_FRAME_BUFFER to use the partial canvas frame buffer feature.
Enable horizontal canvas refresh direction	Yes, No Default: No	Specify the canvas refresh directions for the partial canvas frame buffer feature. By default, the canvas refreshes its dirty areas one by one. If the application requires refreshing the canvas in horizontal direction to mitigate tearing effects,this can be used.

Enable vertical canvas refresh direction	Yes, No Default: No	Specify the canvas refresh directions for the partial canvas frame buffer feature. By default, the canvas refreshes its dirty areas one by one. If the application requires refreshing the canvas in vertical direction to mitigate tearing effects,this option can be used.
Disable arc drawing support	Yes, No Default: No	Reduce the GUIX library code size and GX_DISPLAY structure size by removing support for the arc-drawing functions circle, arc, pie, and ellipse.
Disable software decoder support	Yes, No Default: No	If your application does not require runtime decode of jpg or png files, select yes to reduce the GUIX library footprint.
Disable binary resource support	Yes, No Default: No	If your application is using only C source code format resource files, select yes to reduce your GUIX library footprint.
Repeat button initial tics		This value defines how long the button waits before beginning to send repeated GX_EVENT_CLICKED events.
Maximum number of unique dirty list entries		This value defines the maximum number of unique dirty list entries that can be maintained by one canvas.
Maximum nesting of context		This value defines the maximum nesting of the drawing context stack.
Maximum input capture nesting		This value defines size of the stack used to maintain the list of widgets that have captures the user input.
Cursor blink interval		This value defines the rate at which the input cursor blinks for text input widgets.
Multi line index cache size		This value defines the size of the list-start index cache maintained by the multi-line text view and multi-line text input widgets.

Multi line text button maximum lines		This value determines the number of text pointers needed by the worst case multi-line text button.
Maximum number of polygon edges		This value determines the most complex polygon that can be drawn by GUIX.
Numeric scroll wheel string buffer size		This value determines the maximum length of the string required to display the assigned integer values.
Circular gauge animation delay		This value defines the number of GUIX timer ticks (50 ms) between updates of a circular gauge configured to animate the needle movement between last and current angular position.
Numeric prompt buffer size		This value defines the size of buffer allocated to convert an integer value assigned to the prompt to an ascii string.
Animation pool size		This value defines the size of animation pool from which animation information structures can be dynamically allocated and returned.
Mouse support	Enabled, Disabled Default: Disabled	Enables the mouse support. This definition should only be enabled when a mouse (not a touch screen) must be supported.
Hardware mouse support	Enabled, Disabled Default: Disabled	When enabled, the GUIX display driver utilizes hardware mouse cursor drawing support.
Font kerning support	Enabled, Disabled Default: Disabled	Enables font kerning support.
Maximum string length		This value defines the maximum length of a string, which is used to test invalid strings.

Disable brush alpha support	Yes, No Default: No	When running at 16 bpp and higher color depths, GUIX optionally supports drawing non-arc graphics, pixelmaps, and fonts with an alpha value defined by the drawing context brush. Supporting this drawing mode introduces a small runtime overhead and library footprint increase, which can be eliminated by defining this flag if the application do not require alpha-blending drawing support.
Show linkage warning	Enabled, Disabled Default: Enabled	Select whether or not to show linkage warning.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

GUIX GX_SRC Framework Module Clock Configuration

The GUIX GX_SRC Module is a logical module and therefore does not require any hardware setting except setting the ARM Cortex-M core SysTick timer.

GUIX GX_SRC Framework Module Pin Configuration

The GUIX GX_SRC Module is a logical module and therefore does not require pin settings.

4.3.5.6 Using the GUIX GX_SRC Framework Module in an Application

The typical steps in using the GUIX Framework module in an application are (assuming the instance of the GUIX driver is g_sf_el_gx and the instance of the SPI driver for the LCD is g_rspi_lcdc):

1. Create a memory pool for dynamic allocation in GUIX.
2. Initialize GUIX with the gx_system_initialize function.
3. Set the memory rotate and memory free services for GUIX to use using the gx_system_memory_allocator_set API
4. Initialize GUIX drivers using the open API (g_sf_el_gx.p_api->open)
5. Create and initialize the main display usingthe gx_studio_display_configure API. This uses the open function of the SF_EL_GX driver instance as one of the input parameters.
6. Initialize the memory address of the canvas with the canvasInit API for the SF_EL_GX driver
7. Loop through all the widgets defined in the GUIX studio resource files. Create the root window and each widget using the gx_studio_named_widget_create API.
8. Show the root window using the gx_widget_show API.
9. Start the GUIX system with the gx_system_start API.
10. Open the SPI driver to initialize the LCD using the open API for the SF_EL_GX driver.
11. Set up the LCD display with the ILI9341V_Init function.

The next steps describe the invoking of the touch panel user callback function when a touch event occurs and use GUIX services to process them and update the image display:

1. Register a touch panel user callback in the application code to receive touch data. (Get the data using the sf_touch_panel_v2_api_t::touchDataGet API function if the user callback is not registered.)
2. Operate on the received touch data as needed.
3. Send the event to the GUIX engine to render an updated image using the gx_system_event_send API.

These common steps are illustrated in a typical operational flow in the following figure:

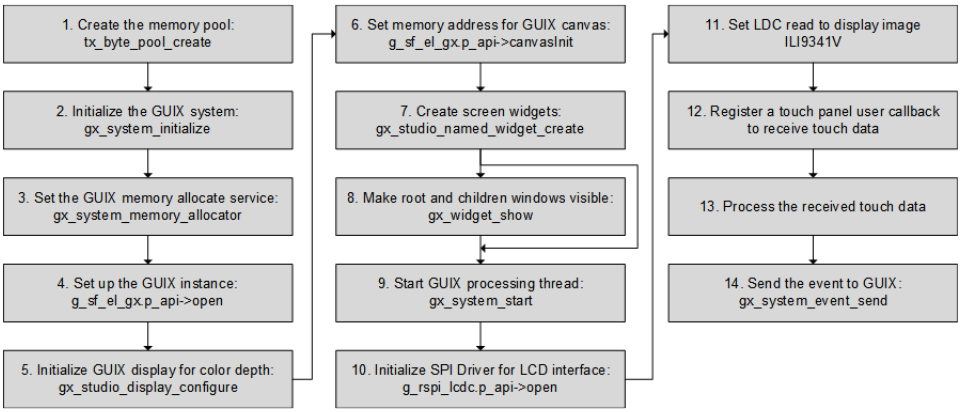

Figure 415: Flow Diagram of a Typical GUIX GX_SRC Framework Module Application

The GUIX Studio project includes a callback function for the Event Function of the main window in this project. When this callback, thermos_screen_event_handler, is invoked by GUIX, it computes how to adjust the needle on the thermostat in the image and forwards that information back to GUIX for how to render an updated image based on a user touch event:

1. Determine event type from the event_ptr input from GUIX
2. Get the current needle angle data from GUIX using the gx_circular_gauge_angle_get API.
3. Send the updated information about the event to GUIX using the gx_window_event_process API.

The GUIX Studio project includes a callback function for the Draw Function of the "plus" and "minus" buttons in the main screen. When this callback, custom_pixelmap_button_draw, is invoked by GUIX, it redraws the buttons to add the "+" or "-" depending on which button is pressed. This does not have a great deal of functionality per se, but demonstrates how the draw function callback works with GUIX.

4.3.6 LevelX Port Framework on sf_el_lx_nor

4.3.6.1 Port LevelX Framework Module Introduction

The Port LevelX Framework implements the driver APIs (sector read, sector write, block erase and block erased verify) mandated by Azure RTOS LevelX NOR component. In addition to implementing the LevelX NOR driver method, it is also responsible for updating the flash geometry to perform

LevelX NOR initialization. It uses the sf_memory_api implementation to perform operations on the NOR flash.

Unsupported Features

LevelX NAND is not supported in this version of SSP.

Port LevelX Framework Module Features

- Implements LevelX NOR driver APIs to perform operations on NOR flash memory device.
- Set up NOR flash geometry.

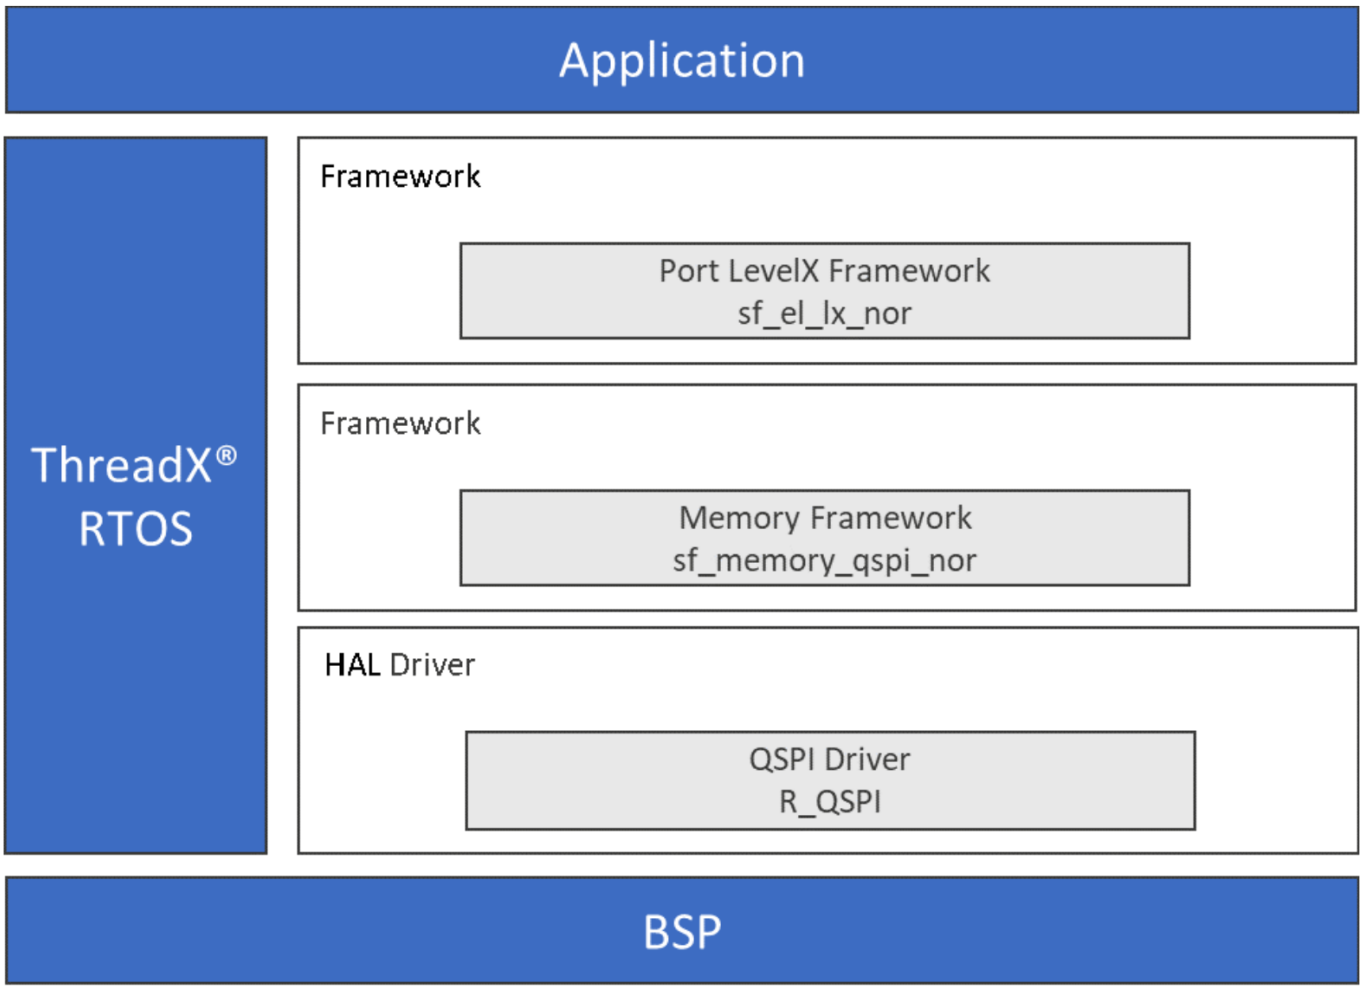

Figure 416: Port LevelX Framework Module Block Diagram

4.3.6.2 Port LevelX Framework Module APIs Overview

The Port LevelX Framework defines API functions to open, read from, write to and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Port LevelX Framework Module API Summary

Function Name	Example API Call and Description

SF_EL_LX_NOR_Open	g_sf_el_lx_nor0.p_api->SF_EL_LX_NOR_Open(g_sf_el_lx_nor0.p_ctrl, g_sf_el_lx_nor0.p_cfg); Initializes lower-level driver initialization function.
SF_EL_LX_NOR_Read	g_sf_el_lx_nor0.p_api->SF_EL_LX_NOR_Read(g_sf_el_lx_nor0.p_ctrl, p_flash, p_dest, word_count); This is responsible for reading a specific sector in a specific block of the NOR flash. All error checking and correcting logic is the responsibility of this service.
SF_EL_LX_NOR_Write	g_sf_el_lx_nor0.p_api->SF_EL_LX_NOR_Write(g_sf_el_lx_nor0.p_ctrl, p_flash, p_src, word_count); This is responsible for writing a specific sector into a block of the NOR flash. All error checking is the responsibility of this service.
SF_EL_LX_NOR_BlockErase	g_sf_el_lx_nor0.p_api->SF_EL_LX_NOR_BlockErase(g_sf_el_lx_nor0.p_ctrl, block, erase_count); This is responsible for erasing the specified block of the NOR flash.
SF_EL_LX_NOR_BlockErasedVerify	g_sf_el_lx_nor0.p_api->SF_EL_LX_NOR_BlockErasedVerify(g_sf_el_lx_nor0.p_ctrl, block); This is responsible for verifying that the specified block of the NOR flash is erased.
SF_EL_LX_NOR_Close	g_sf_el_lx_nor0.p_api->SF_EL_LX_NOR_Close(g_sf_el_lx_nor0.p_ctrl); This is responsible for closing the driver properly.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_ASSERTION	p_ctrl or p_cfg in NULL.
SSP_ERR_ALREADY_OPEN	Driver is already in OPEN state.
SSP_ERR_INVALID_ARGUMENT	Requested range can't fit in the flash address range.
SSP_ERR_NOT_OPEN	Driver not in OPEN state for writing.
SSP_ERR_NOT_ERASED	The block in not erased properly.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.6.3 Port LevelX Framework Module Operational Overview

The Port LevelX Framework is simply an abstract interface using function pointers instead of direct function calls. Functions are called between LevelX or FileX and the SSP memory interface implementations such as sf_memory_qspi_nor. Memory adaptation drivers, such as sf_memory_qspi_nor, are accessed through the Port LevelX Framework and provide device specific code needed to perform data I/O operations.

Port LevelX Framework Module Important Operational Notes and Limitations

Port LevelX Framework Module Operational Notes

None.

Port LevelX Framework Module Limitations

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.6.4 Including the Port LevelX Framework Module in an Application

This section describes how to include the Port LevelX Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Port LevelX Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Port LevelX Framework is g_sf_el_lx_nor0. This name can be changed in the associated Properties window.)

Port LevelX Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_el_lx_nor0 Port LevelX Framework on sf_el_lx_nor	Threads	**New Stack**> **Framework**> **LevelX**> **Port LevelX Framework on sf_el_lx_nor**

When the Port LevelX Framework on sf_el_lx_nor is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

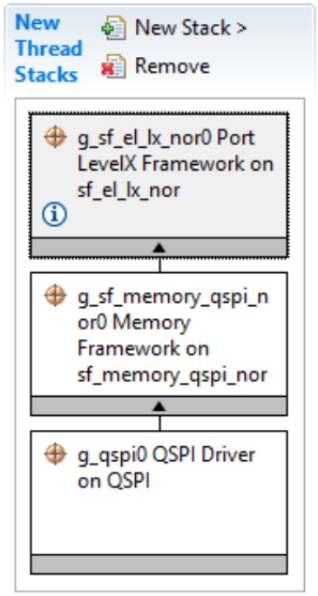

Figure 417: Port LevelX Framework Module Stack

4.3.6.5 Configuring the Port LevelX Framework Module

The Port LevelX Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Port LevelX Framework Module on sf_el_lx_nor

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_sf_el_lx_nor0	Module name.
Event Callback	NULL	Name of the function to call when an event occurs.
Memory Partition Size Unit in (KB/MB)	Kilobyte (KB), Megabyte (MB) Default: Kilobyte (KB)	The units of memory.

Memory Partition Size	Positive Integer Number Default: 0	Size of the NOR Flash partition region.
Memory Partition Start Address(in hex format)	Positive Integer Number in Hex Default: 0x00000000	The starting address of the partition region.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Port LevelX Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the Memory Framework on sf_memory_qspi_nor

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_sf_memory_qspi_nor0	Module name.
Write of Erase Timeout (in ticks)	30000	Timeout ticks for waiting on write or erase to complete.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the QSPI HAL Module on r_qspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_qspi0	Module name.
Addressing Mode	3-BYTE, 4-BYTE Default: 3-BYTE	Addressing modes of flash memory For memory > 16 MB, 4-Byte addressing mode should be selected

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have

different default values and available configuration settings.

Port LevelX Framework Module Clock Configuration

The Port LevelX Framework module uses the QSPI peripheral which uses PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

Port LevelX Framework Module Pin Configuration

To use the Port LevelX Framework module, the port pins for the QSPI peripheral must be set as needed. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection for the Memory Framework Module on sf_memory_qspi_nor

Resource	ISDE Tab	Pin selection Sequence
QSPI	Pins	Select **Peripherals**> **Storage:QSPI QSPI0**

4.3.6.6 Using the Port LevelX Framework Module in an Application

The typical steps in using the Port LevelX Framework module in an application are:

1. Initialize the module using the lx_nor_flash_initialize API function (g_common_init calls it automatically).

2. Open the module for I/O operations using the LevelX NOR API function SF_EL_LX_NOR_Open (if using with FileX fx_media_open opens the media automatically).

3. Read the media as required using the SF_EL_LX_NOR_Read API function (lx_nor_flash_sector_read calls this automatically).

4. Write to media as required using the SF_EL_LX_NOR_Write API function (lx_nor_flash_sector_write calls this automatically).

5. A block can be erased using the SF_EL_LX_NOR_BlockErase API function.

6. A block can be verified whether it is erase or not using the SF_EL_LX_NOR_BlockErasedVerify API function.

Note

After a successful SF_EL_LX_NOR_Open call, all LevelX NOR APIs can be used, not only read and write.

These common steps are illustrated in a typical operational flow diagram in the following figure:

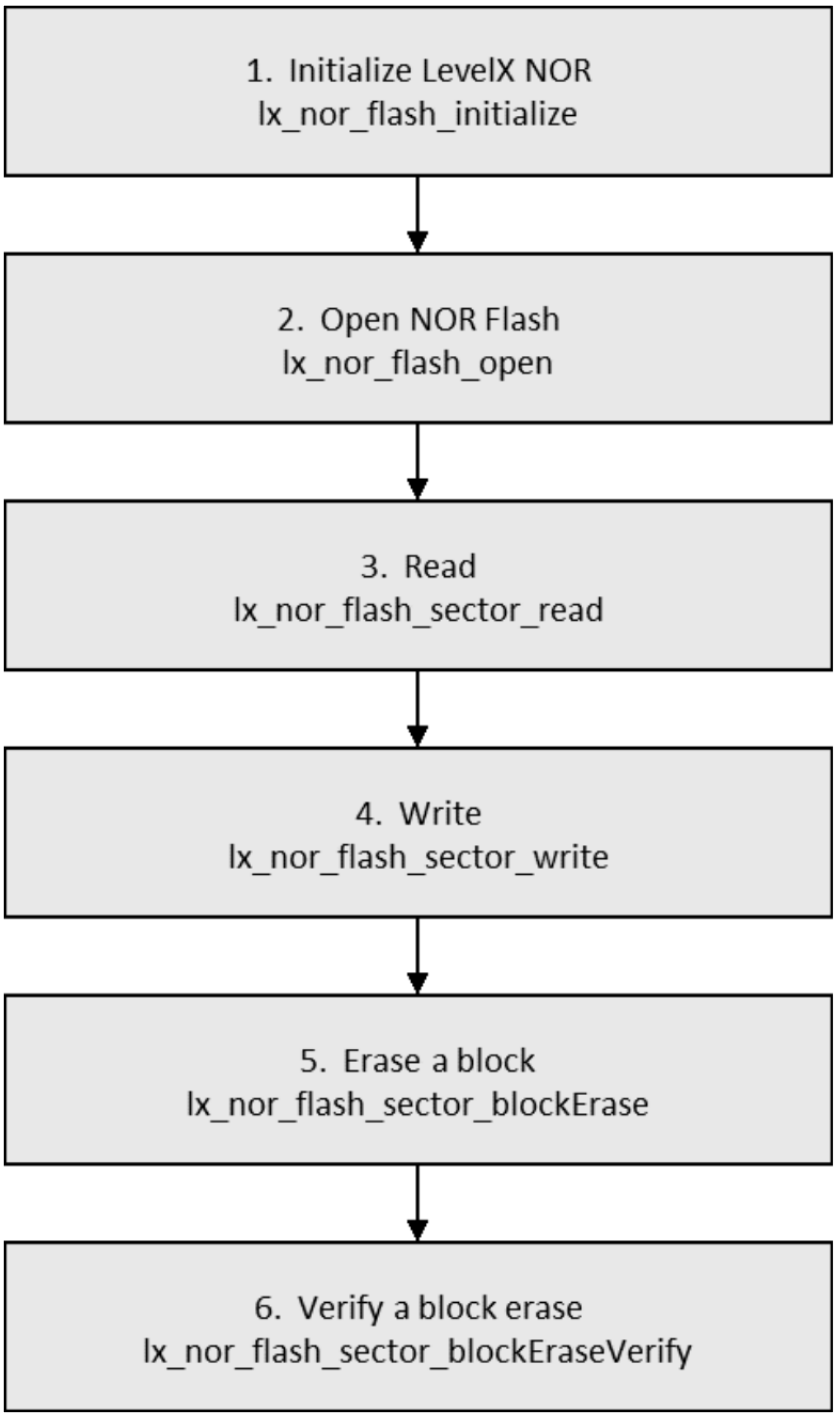

Figure 418: Flow Diagram of a Typical Port LevelX Framework Module Application

4.3.7 NetX Port Ether

4.3.7.1 NetX Port Ether Module Introduction

The Azure RTOS NetX Port Ether module (sf_el_nx) for NetX and NetX Duo is integrated into the SSP. Its function is to interface the NetX and NetX Duo software with the Synergy hardware. This module includes the MAC driver, the PHY driver, additional glue logic and utility functions.

Note

Unless otherwise stated, there is no difference in how this module works between NetX or NetX Duo projects.

NetX Port Ether Module Features

- High-level interface for NetX and NetX Duo for the Synergy Platform
- Channel Selection
- PHY Reset support
- Static MAC Address configuration
- Dynamic MAC Address configuration
- Callbacks are provided for unknown packet reception
- Selectable Ethernet Interrupt Priority
- Link status monitoring support
- Configurable Number of Receive/Transmit Buffer Descriptors
- Supports the use of an external PHY chip

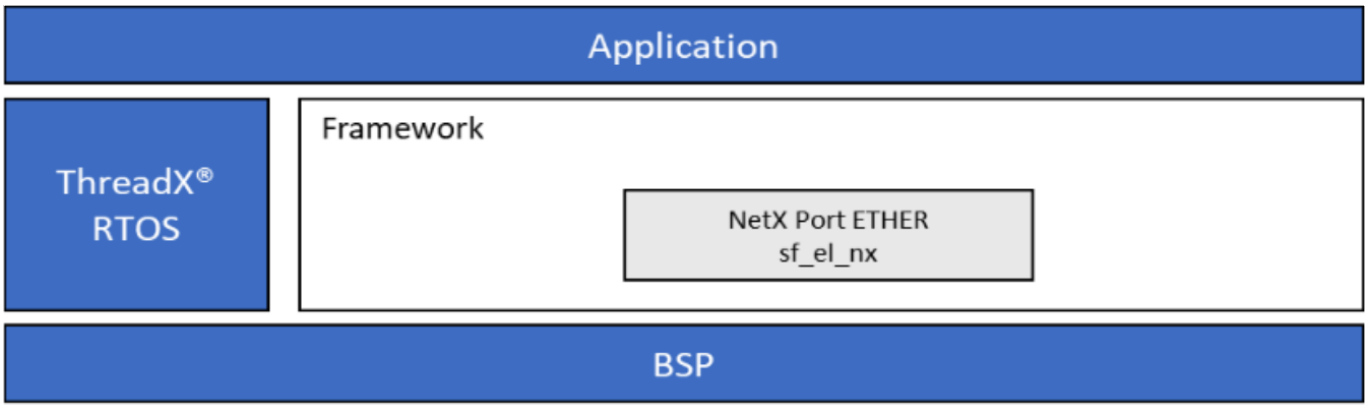

Figure 419: NetX Port Ether Module Block Diagram

4.3.7.2 NetX Port Ether Module APIs Overview

The NetX Port Ether module has a narrow API, used internally by NetX and by the module itself. It includes the Ethernet driver entry point (nx_ether_driver_eth0, nx_ether_driver_eth1), the Ethernet interrupt handler and other functions used internally by the module but externally visible.

4.3.7.3 NetX Port Ether Module Operational Overview

The NetX Port Ether module is a high-performance real-time implementation of the NetX Ethernet driver for the Renesas Synergy software and Synergy Ethernet IP.

Note

NetX assumes the existence of ThreadX and depends on its thread execution, suspension, periodic timers and mutual exclusion facilities.

Each IP instance in NetX has a primary interface which is identified by its device driver specified in the nx_ip_create service. The network driver is responsible for handling various NetX requests, including packet transmission, packet reception, and requests for status and control.

For a multi-home system, the IP instance can be configured for multiple interfaces, each with an associated network driver that performs these tasks for the respective interface. The network driver must also handle asynchronous events occurring on the media. Asynchronous events from the media include packet reception, packet transmission completion, and status changes. NetX provides the network driver with several access functions to handle various events. These functions are designed to be called from the interrupt service routine portion of the network driver. For IP networks, the network driver should forward all ARP packets received to the nx_arp_packet_deferred_receive internal function. All RARP packets should be forwarded to nx_rarp_packet_deferred_receive internal function. There are two options for IP packets:

If fast dispatch of IP packets is required, incoming IP packets are forwarded to nx_ip_packet_receive for immediate processing; this greatly improves NetX performance in handling IP packets. Otherwise, IP packets are forwarded to nx_ip_packet_deferred_receive. This service places the IP packet in the deferred processing queue where it is then handled by the internal IP thread, which results in the least amount of ISR processing time.

The network driver can also defer interrupt processing to run out of the context of the IP thread. In this mode, the ISR shall save the necessary information, call the internal function nx_ip_driver_deferred_processing, and acknowledge the interrupt controller. This service notifies IP thread to schedule a callback to the network driver to complete the process of the event that causes the interrupt.

Key Configuration Property Settings:

Multi-Channel

Multi-Channel determines which interface the ethernet driver is applied to. It may need to be modified from the default value of zero. See Section 5 "Configuring the NetX Port Ether".

Channel 0/1 Phy Reset Pin

PHY reset is supported through I/O port pins. This property depends on the value of the Channel property above.

Note

For different Synergy Kits different I/O PINs are being utilized, for this purpose it may need to be modified from the default value.

Static MAC Address Configuration

These properties set the device MAC address on the respective channel interface at compile time. To set the MAC address at run time, see the description of the Dynamic MAC Address Configuration callback property below.

Dynamic MAC Address Configuration

This property defines the user defined callback function which sets MAC address at runtime (network link initialization). The default value is NULL and the MAC address is assigned using the Channel MAC Address High/Low Bits settings.

Unknown Ethernet Packet Receive Callback

This property configures callback for letting user process unsupported/custom EtherType packets.

This call-back can be used in conjugation with nx_ether_custom_packet_send Ethernet API to send

and receive custom Ethernet packet types.

Name

This property names the instance of the NetX Port Ether driver. For an IP instance configured with multiple network interfaces, the application must add an instance of the driver and give it a unique name (or compile errors will result). The default name is g_sf_el_nx.

Ethernet Interrupt Priority

This property sets the driver interrupt priority. The default value is disabled. The dropdown list indicates valid and invalid priorities depending on the MCU target.

Link Status Monitoring

This property lets user choose link status monitoring method. There two options available: PHY Polling and PHY Interrupt (Uses LINKSTA Pin).

PHY polling utilizes an internal monitoring thread for auto negotiation to notify user when link is lost or established.

PHY Interrupt method requires PHY status pin to be connected to LINKSTA pin of Ethernet controller and utilize Ethernet interrupt to notify user when link is lost or established.

This notification though happens through the callback registered with IP instance.

Number of Receive/Transmit Buffer Descriptors

These properties set the number of buffer descriptors (BDs) for receiving and transmitting packets. When the Receive BDs are initialized, the driver allocates a packet for each BD. Therefore, the number of receive BDs should not deplete the IP instance packet pool from which it allocates packets.

The NetX Port Ether driver supports packet chaining for both receiving and transmitting packets (where packets are chained in the application layer). If a packet is received on the network that exceeds the size of the IP default packet pool payload, the driver can allocate additional packets and process the incoming packet as a packet chain.

Parameter Checking

This is low level error checking for each component of the project hardware layer. By default, it is set to Default (BSP) which means this property inherits the same property in the BSP.

NetX Port Ether Module Important Operational Notes and Limitations

NetX Port Ether Module Operational Notes

NetX Source Properties

There are two ways to modify NetX source properties- using the source code property directly in the source element or defining the source code symbol directly. For example, to change the number of physical network interfaces, one can either set the Maximum Physical Interfaces property in the NetX Source or NetX Duo Source element, or one can define the source code symbol NX_MAX_PHYSICAL_INTERFACES directly. In either case, it is still necessary to include the NetX and NetX Duo Source component, generate the project files and to rebuild the NetX library.

TCP Options Field Parameters

Maximum Segment Size

The Maximum Segment Size (MSS) is the maximum amount of bytes a TCP host can receive without being fragmented by the underlying IP layer. During TCP connection establishment phase, both ends exchanges its own TCP MSS value, so that the sender does not send a TCP data segment that is larger than the receiver's MSS. NetX TCP module will optionally validate its peer's advertised MSS value before establishing a connection. By default NetX does not enable such a check.

The nx_tcp_socket_mss_set() API sets a specified socket's Maximum Segment Size (MSS). The MSS value must be within the network interface IP Maximum Transfer Unit (MTU), allowing room for IP and TCP headers. This service should be used before a TCP socket starts the connection process. If the service is used after a TCP connection is established, the new value has no effect on the connection. To retrieve the MSS value use the nx_tcp_socket_mss_get() API after the TCP connection is established.

Using the External PHY with the NetX Port Ether Module

The NetX Port Ether Module can be used along with an external PHY chip, other than the on-board Micrel PHY chip (KSZ8081 and KSZ8091) found on Synergy Platform Kits. The following steps need to be performed to use a different external PHY chip:

1. Remove or undefine the macro BSP_BOARD_PHY_KSZ8081 or BSP_BOARD_PHY_KSZ8091 in the board BSP file (Example: For the S7G2_DK board, the BSP file is located in synergy/board/s7g2_dk/bsp_ethernet_phy.h).
2. Implement a new PHY driver for the specific PHY chip..Implement the functions defined in the interface file synergy/ssp/inc/framework/instances/sf_el_nx.h
3. Build and run the application

Note

The above steps also apply to existing projects using an external PHY.

Additional Information

Refer to the NetX User Guide for the Renesas Synergy™ Platform and NetX Duo User Guide for the Renesas Synergy™ Platform for additionaloperational details.

NetX Port Ether Module Limitations

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.3.7.4 Including the NetX Port Ether Module in an Application

This section describes how to include the NetX Port Ether Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

The NetX Port Ether Framework is used as a lower level module and is not available to add as a separate stack. An example is illustrated in the following figure where a module must be selected to Add NetX Network Driver. The following figure shows the selection of the NetX Port Ether Framework

to complete the stack for the module.

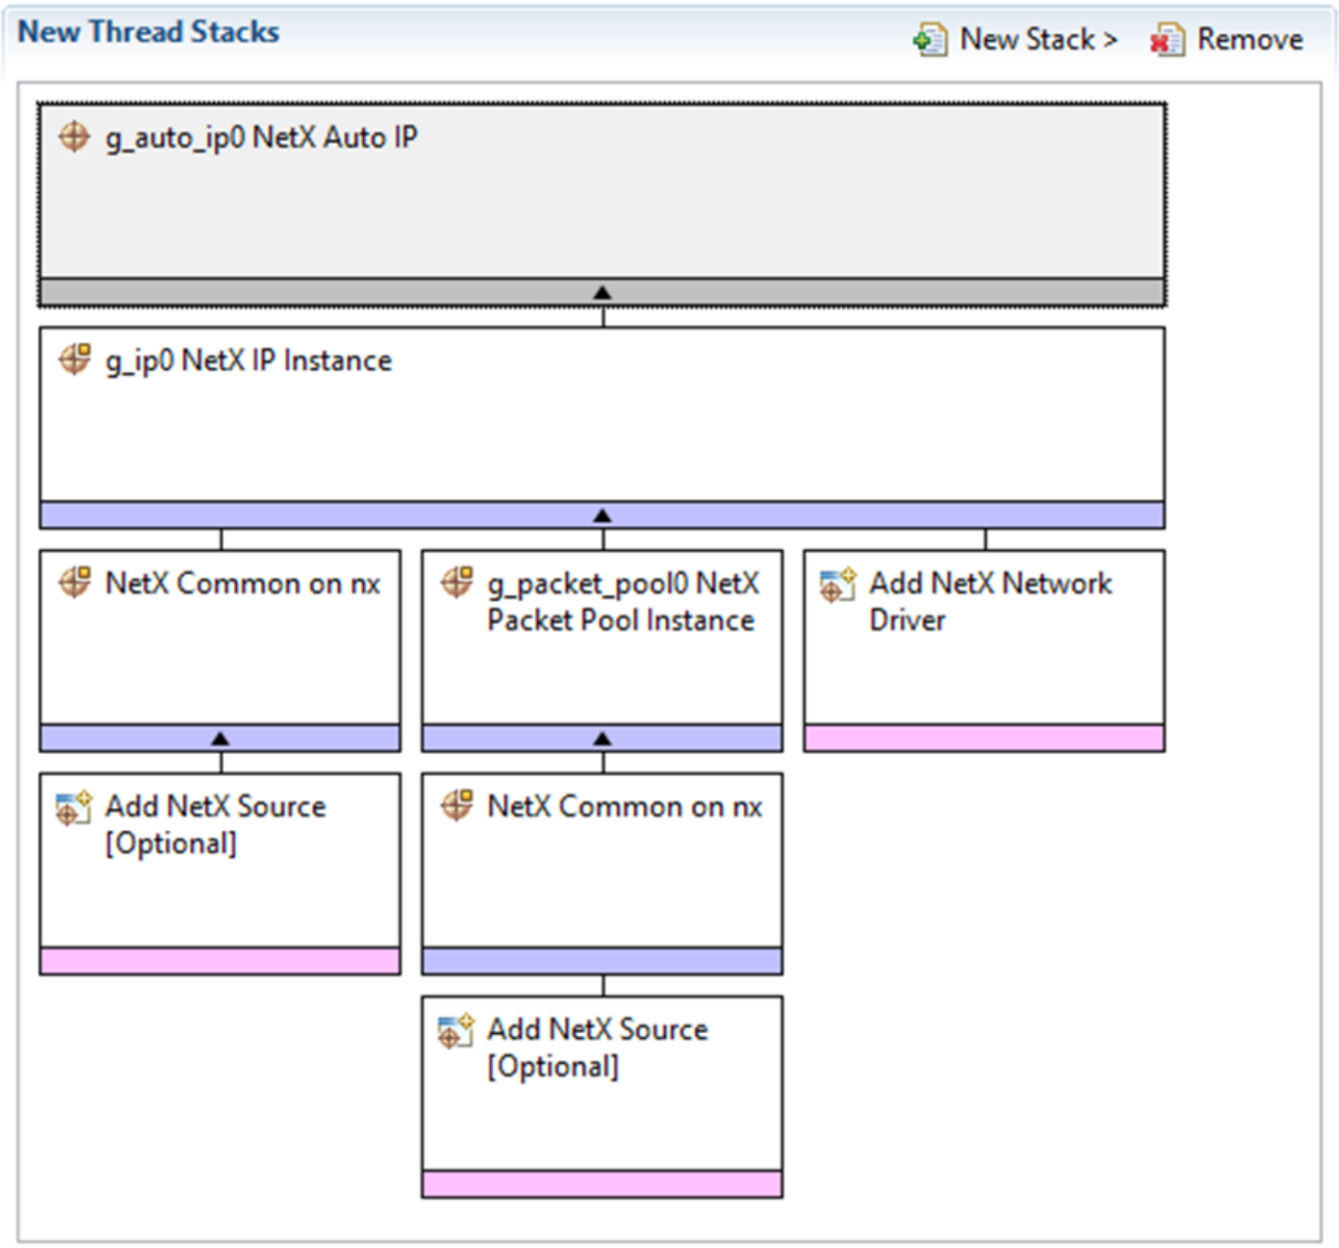

Figure 420: NetX Port Ether Module Stack

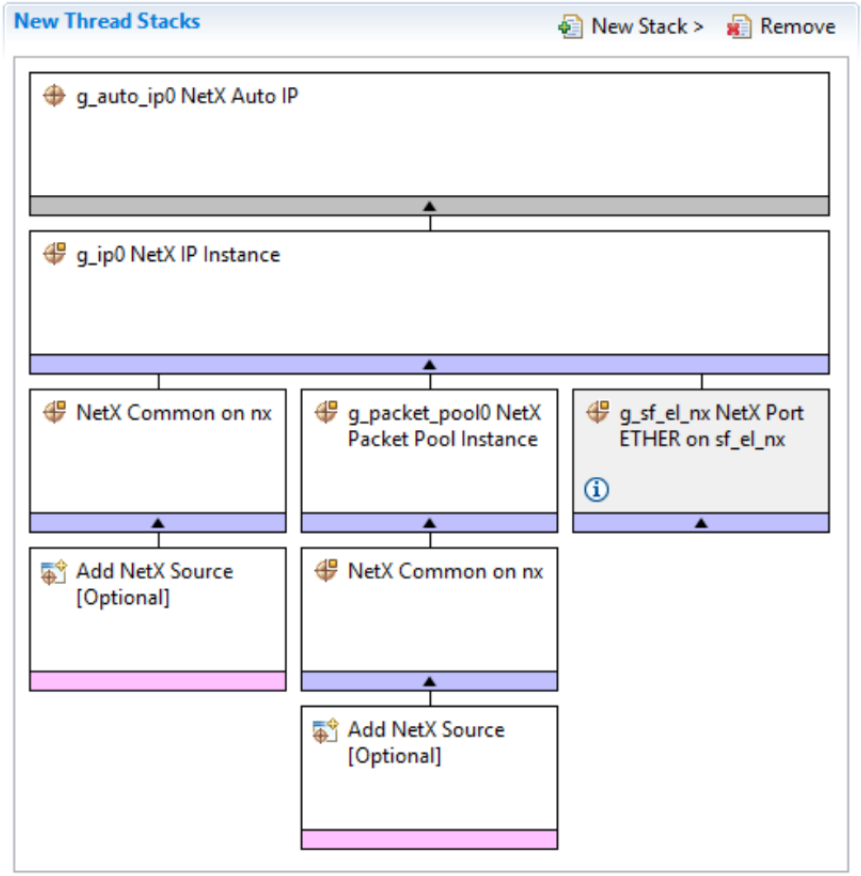

Figure 421: NetX Port Ether Module Stack

4.3.7.5 Configuring the NetX Port Ether Module

The NetX Port Ether Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Port Ether Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.

Channel 0 Phy Reset Pin	IOPORT_PORT_09_PIN_03	Channel 0 Phy reset pin selection.
Channel 0 MAC Address High Bits	0x00002E09	Channel 0 MAC address high bits selection.
Channel 0 MAC Address Low Bits	0x0A0076C7	Channel 0 MAC address low bits selection.
Channel 1 Phy Reset Pin	IOPORT_PORT_07_PIN_06	Channel 1 Phy reset pin selection.
Channel 1 MAC Address High Bits	0x00002E09	Channel 1 MAC address high bits selection.
Channel 1 MAC Address Low Bits	0x0A0076C8	Channel 1 MAC address low bits selection.
Number of Receive Buffer Descriptors	8	Number of receive buffer descriptors selection.
Number of Transmit Buffer Descriptors	32	Number of transmit buffer descriptors selection.
Ethernet Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 lowest - not valid if using ThreadX) Default: Priority 12	Ethernet interrupt priority selection.
Link status monitoring method	PHY Interrupt (Uses LINKSTA Pin), PHY Polling Default: PHY Polling	PHY interrupt requires LINKSTA Pin connection to PHY.
Name	g_sf_el_nx	Module name.
Channel	0	Channel selection.
MAC address change callback	NULL	MAC address change callback selection.
Unknown packet receive callback	NULL	Unknown packet receive callback selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

4.3.7.6 Using the NetX Port Ether Module in an Application

The NetX Port Ether Module should be used in combination with NetX. Examples illustrating the modules use in an implementation for Auto-IP protocol use follow. Other protocols will follow a similar use flow. The steps performed by the Synergy Software Package (SSP) automatically in a NetX application support are:

1. Initialize the system with nx_system_initialize.
2. Create a packet pool with nx_packet_pool_create. This creates the IP default packet pool, to be used by the IP instance and the ethernet driver.

3. Create an IP Instance with nx_ip_create.
4. Enable ARP with nx_arp_enable.
5. Enable Link status change notify call back with nx_ip_link_status_change_notify_set.
6. Set gateway IP address for created IP instance nx_ip_gateway_address_set.
7. Create an AutoIP instance with nx_auto_ip_create.

The following steps are performed directly by the application to set up and run the Auto IP thread task.

1. Check if the network link is enabled with the nx_ip_interface_status_check API.
2. Verify the device does not have an IP address by calling the nx_ip_interface_address_get API.
3. Set the IP addreess notification callback by calling the nx_ip_address_change_notify API.
4. Start the Auto IP instance with the nx_auto_ip_start API.
5. Wait for the IP address change callback to set the flag that the IP instance has an IP address.
6. Stop the AutoIP task by calling the nx_auto_ip_stop API.
7. Verify the IP instance has a non-zero IP address by calling the nx_ip_interface_address_get API again.

These common steps are illustrated in a typical operational flow diagram in the following figure:

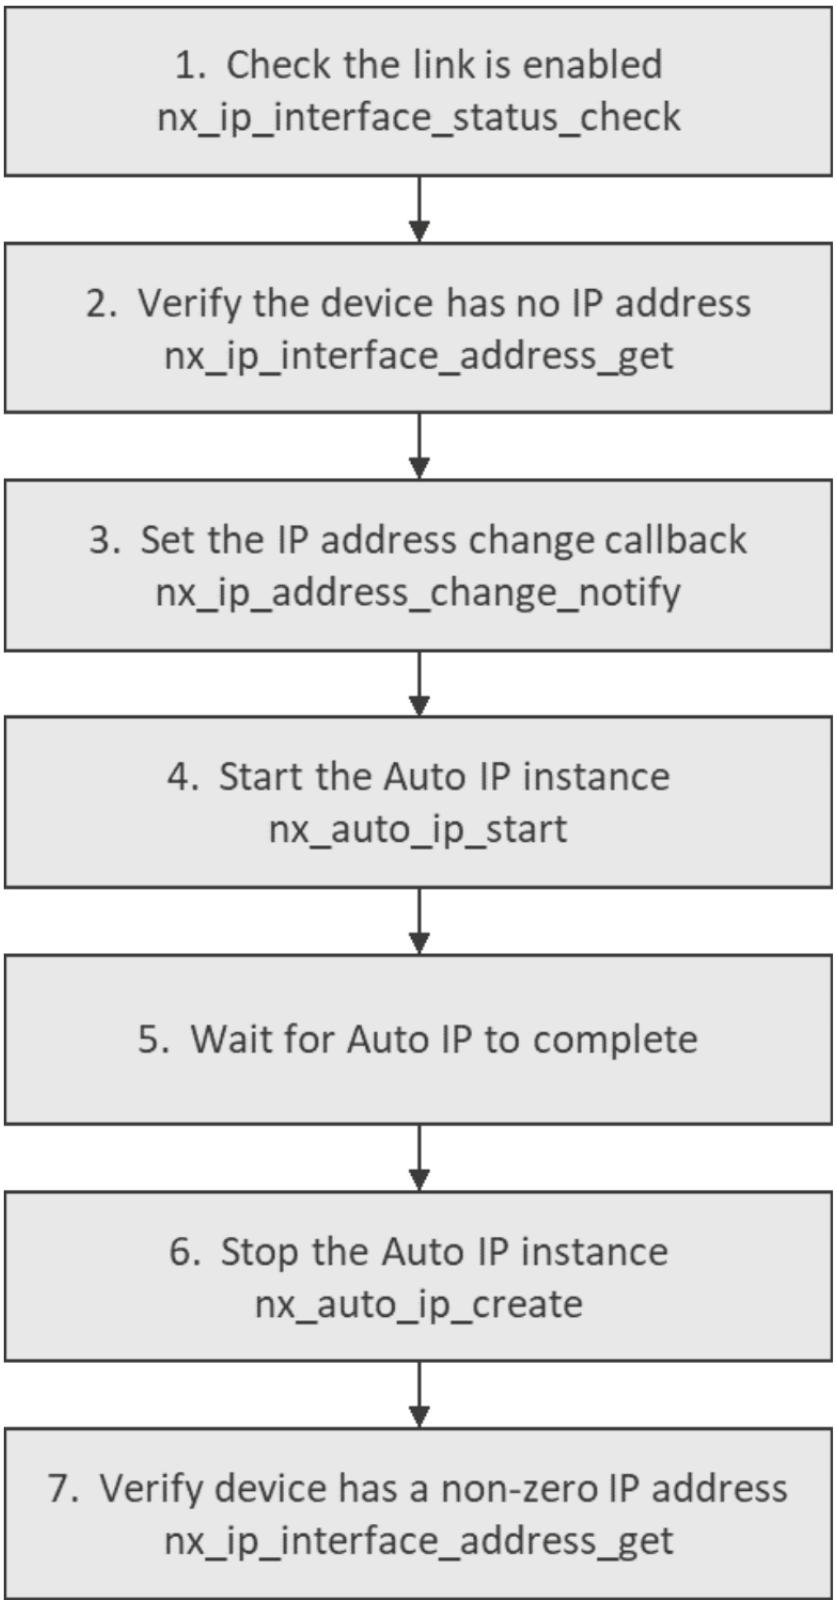

Figure 422: Flow Diagram of a Typical NetX Port Ether Module Application

4.3.8 NetX Port Using PPP

4.3.8.1 NetX Port Using PPP Module Introduction

The Azure RTOS NetX Port PPP module (nx_ppp) for NetX and NetX Duo is integrated into the SSP. Its function is to interface the NetX and NetX Duo software with the Synergy hardware. Point-to-Point Protocol (PPP) is a data link layer (layer 2) communication between two directly connected (point to point) devices. It can provide data transmission, authentication, and encryption functionality.

NetX Port Using PPP Module Features

- High-level interface for NetX and NetX Duo for the Renesas Synergy™ Platform
- CHAP authentication support
- PAP authentication support
- IPCP response support
- Handler provided for invalid packets

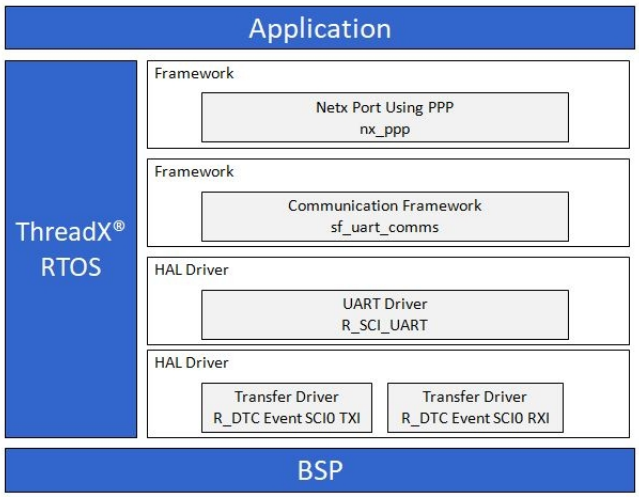

Figure 423: NetX Port Using PPP Module Block Diagram

4.3.8.2 NetX Port Using PPP Module APIs Overview

The NetX Port using PPP Module defines APIs for creating, authentication and assigns addresses. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX/NetX Duo Port using PPP Module API Summary

Function Name	Example API Call and Description
nx_ppp_create	nx_ppp_create(&ppp_ptr, name, &ip_ptr, stack_memory_ptr, stack_size, thread_priority, &pool_ptr, ppp_non_ppp_packet_handler, ppp_byte_send); Creates PPP instance for given IP instance.

nx_ppp_dns_address_set	nx_ppp_dns_address_set(&ppp_ptr,& dns_address); Sets the primary DNS address for the PPP device.
nx_ppp_secondary_dns_address_set	nx_ppp_secondary_dns_address_set(&ppp_ptr, &secondary_dns_address); Sets secondary DNS address for the PPP device.
nx_ppp_ip_address_assign	nx_ppp_ip_address_assign(&ppp_ptr, local_ip_address, peer_ip_address); Assigns Local and Peer IP address.
nx_ppp_link_down_notify	nx_ppp_link_down_notify(&ppp_ instance, link_down_callback); Registers a callback for link down event.
nx_ppp_link_up_notify	nx_ppp_link_up_notify(&ppp_instance, link_up_callback); Registers a callback for link up event.
nx_ppp_nak_authentication_notify	nx_ppp_nak_authentication_notify(&ppp_ptr, nak_auth_callback); Registers a callback for authentication NAK received from peer.
nx_ppp_chap_enable	nx_ppp_chap_enable(&ppp_instance, get_challenge_values, get_responder_values, get_verification_values); Enables CHAP authentication for given PPP instance.
nx_ppp_pap_enable	nx_ppp_pap_enable(&ppp_instance, generate_login, verify_login); Enables PAP authentication for given PPP instance.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

Status Return Values

Name	Description
NX_SUCCESS	Valid PPP pointer.
NX_PTR_ERROR	Invalid pointer input.
NX_CALLER_ERROR	Invalid caller of this service.
NX_NOT_IMPLEMENTED	PAP logic was disabled via NX_PPP_DISABLE_PAP. CHAP logic was disabled via NX_PPP_DISABLE_CHAP.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

These are error codes which are only returned if error checking is enabled. Refer to the *NetX User Guide* for the Renesas Synergy™ Platform or *NetX Duo User's Guide* for the Renesas Synergy™ Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.8.3 NetX Port Using PPP Module Operational Overview

The NetX PPP package requires the application to provide a serial communication driver. The driver must support 8-bit characters and may also employ software flow control. It is the application's responsibility to initialize the driver, which should be done prior to creating the PPP instance. In order to send PPP packets, a serial driver output byte routine must be provided to PPP (specified in the nx_ppp_create function). This serial driver byte output routine will be called repetitively in order to transmit the entire PPP packet. It is the serial driver's responsibility to buffer the output. On the receive side, the application's serial driver must call the PPP nx_ppp_byte_receive function whenever a new byte arrives. This is typically done from within the context of an Interrupt Service Routine(ISR). The nx_ppp_byte_receive function places the incoming byte into a circular buffer and alerts the PPP receive thread of its presence.

NetX Port Using PPP Module Important Operational Notes and Limitations

NetX Port Using PPP Module Operational Notes

If a modem is required for connection to the internet, some special considerations are required in order to use PPP. Basically, using a modem introduces additional initialization logic and logic for loss of communication. In addition, most of the additional modem logic is done outside the context of NetX PPP. The basic flow of using the NetX PPP with a modem is:

1. Initialize the Modem
2. Dial Internet Service Provider (ISP)
3. Wait for Connection
4. Wait for UserID Prompt
5. Start NetX PPP [PPP in operation]
6. Loss of Communication
7. Stop NetX PPP (or restart via nx_ppp_restart)

Additional Information

Refer to the NetX User Guide for the Renesas Synergy™ Platform and NetX Duo User Guide for the Renesas Synergy™ Platform for additional operational details.

NetX Port Using PPP Module Limitations

- No PPP Client XML support as it may not be useful.
- Current XML supports only PPP and not PPPoE.
- sf_comms_telnet, sf_ux_comms_v2 are not supported.

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.3.8.4 Including the NetX Port Using PPP Module in an Application

This section describes how to include either or both NetX/NetX Duo Port using PPP module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of

the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo Port using PPP module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

The NetX Port using PPP Framework is used as a lower level module and is not available to add as a separate stack. An example is illustrated in the following figure where a module must be selected to Add NetX Network Driver. The following figure shows the selection of the NetX Port using PPP Framework to complete the stack for the module.

NetX/NetX Duo Port Using PPP Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_nx_ppp0 NetX Port on nx_ppp	Threads	**New Stack> X-Ware> NetX> NetX IP Instance**
g_nxd_ppp0 NetX Duo Port on nxd_ppp	Threads	**New Stack> X-Ware> NetX Duo> NetX Duo Instance**

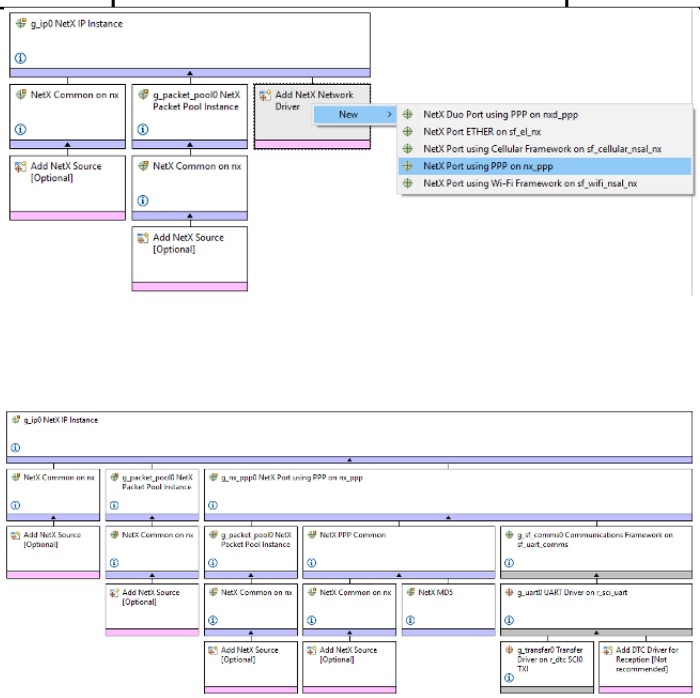

Figure 424: NetX Port Using PPP Module Stack

4.3.8.5 Configuring the NetX Port Using PPP Module

The NetX Port using PPP Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Port using PPP Module

ISDE Property	Value	Description
CHAP authentication support	Enable, Disable Default: Enable	CHAP authentication selection.
PAP authentication support	Enable, Disable Default: Enable	PAP authentication selection.
DNS Option in IPCP response support	Enable, Disable Default: Enable	IPCP response selection.
Maximum DNS address request retires from the peer	2	Specifies the maximum number of DNS address request retries from the peer.
Data packet allocation timeout (seconds)	4	Timeout for data packet allocation.
Retry interval (seconds)	1	Specifies interval in seconds to wait before processing.
Maximum retries for reallocating packet	4	Specifies the maximum number of retries for reallocating packet.
Maximum retries for protocol request response	4	Specifies the maximum number of retries for protocol request response.
Maximum retries for LCP configure request	20	Specifies the maximum number of retries for LCP configure request.
Maximum retries for PAP authentication request	20	Specifies the maximum number of retries for PAP configure request.
Maximum retries for CHAP challenge message	20	Specifies the maximum number of retries for CHAP challenge message.
Maximum retries for IPCP configure request	20	Specifies the maximum number of retries for IPCP configure request.
Name	g_nx_ppp0	Name of PPP instance.
Internal thread priority	2	Internal thread priority selection.
Internal thread stack size (bytes)	2048	Thread Stack Size(bytes) selection.

Read thread priority	10	Thread Priority selection.
Peer IPV4 Address	192.168.0.111	IPv4 Address selection.
Name of invalid packet handler function	invalid_packet_handler	Name of invalid packet handler function selection.
Name of generated initialization function	nx_ppp_init0	Name of generated initialization function selection.
Auto initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Port Using PPP Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection.
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection

Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection
Link status change callback	NULL	Link status change callback selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes		Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the UART Communications Framework Module on sf_uart_comms

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if parameter checking is included.
Read Input Queue Size (4-Byte Words)	15	Buffer size for data reception queue. sf_uart_comms utilizes the ThreadX Queue for the queue management.
Name	g_sf_comms0	Name of UART communications framework module.
Name of generated initialization function	sf_comms_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the UART HAL Module on r_sci_uart

ISDE Property	Value	Description

External RTS Operation	Enable, Disable Default: Disable	Enable an IOPORT pin to be used as RTS signal. For RTS functionality set this configuration parameter to **Enable** and specify the configuration **Name of UART callback function for the RTS external pin control**.
Reception	Enable, Disable Default: Enable	Enable or disable UART reception for all UART channels on SCI. Setting this configuration parameter to **Disable** reduces code size because the portion of code for UART reception is not compiled. You cannot set this parameter for individual UART channels.
Transmission	Enable, Disable Default: Enable	Enable or disable UART transmission for all UART channels on SCI. Setting **Disable** to this configuration allows to get smaller code size due to the portion of code for UART transmission is compiled out, however, you can only set **Disable** to this configuration if any other SCI channels which work as UART ports do not perform the transmission.
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_uart0	The name to be used for UART on SCI module control block instance. This name is also used as the prefix of the other variable instances.
Channel	0	SCI channel number.
Baud Rate	9600	Baud rate selection.
Data Bits	7 bits, 8, bits, 9 bits Default: 8 bits	UART data bits.
Parity	None, Odd, Even Default: None	UART parity bits.
Stop Bits	1 bit, 2 bits Default: 1 bit	UART stop bits.

CTS/RTS Selection	CTS (Note that RTS is available when enabling External RTS Operation mode which uses 1 GPIO pin), RTS (CTS is disabled) Default: RTS (CTS is disabled)	Select CTS or RTS for the CTSn/RTSn pin of SCI channel n. The SCI hardware supports either the CTS or the RTS control signal on this pin but not both. For an application that uses both CTS and RTS, select **CTS** for this configuration parameter and enable the configuration **External RTS Operation** specifying the configuration **Name of UART callback function for the RTS external pin control**.
Name of UART callback function to be defined by user	NULL	Name must be a valid C symbol.
Name of UART callback function for the RTS external pin control to be defined by user	NULL	Name must be a valid C symbol.
Clock Source	Internal Clock, External Clock 8x baudrate, External Clock 16x baudrate Default: Internal Clock	Selection of the clock source to be used in the baud-rate clock generator block.
Baudrate Clock Output from SCK pin	Enable, Disable Defaualt: Disable	Optional setting to output the baud-rate clock on the SCKn pin for the selected channel n.
Start bit detection	Fallling Edge, Low Level Default: Falling Edge	Start bit detection mode in the reception; usually set **Falling Edge** to this configuration.
Noise Cancel	Enable, Disable Defaualt: Disable	Enable the digital noise cancellation on RXDn pin. The digital noise filter block in SCI consists of two-stage flip-flop circuits. For detail, refer to the Noise cancellation section in the Renesas Synergy™ hardware manual.
Bit Rate Modulation Enable	Enable, Disable Defaualt: Enable	Bit rate modulation enable selection.
Receive FIFO Trigger Level	One, Max Default: Max	Receive FIFO trigger level selection.

Receive Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit interrupt priority selecition.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Error interrupt priority selection.
Baud rate Percent Error	Value must be greater than 0.0 and less than 15.0 Default; 2.0	Maximum baudrate percent error allowed in order for the module to function.
UART Communication Mode	RS232, RS485 Default: RS232	UART communication mode selection, usually it is RS232 mode.
.UART RS485 Communication Mode	Half Duplex, Full Duplex Default: Half duplex	UART RS485 communication mode selection as half duplex or full duplex.
RS485 DE Port	00 to 11 Default: 09	Select the port number of Driver Enable pin.
RS485 DE Pin	00 to 15 Default: 14	Select the pin number of Driver Enable pin.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.

Software Start	Enabled, Disabled Defaualt: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_transfer1	Module name.

Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

4.3.8.6 Using the NetX Port Using PPP Module in an Application

The steps in using the NetX/NetX Duo Port using PPP module in a typical application are:

Auto Generated code to initialize NetX and NetX Duo Port using PPP in the Application (common_data.c)

- Create Packet pool using the nx_packet_pool_create API
- Create PPP using nx_ppp_create API
- Define IP address using the nx_ppp_ip_address_assign API
- Create IP instance using nx_ip_create() API
- Enable ARP using the nx_arp_enable API
- Enable TCP using the nx_tcp_enable API
- Enable UDP using the nx_udp_enable API
- Enable ICMP using the nx_icmp_enable API
- Enable IGMP using the nx_igmp_enable API

User Application Code (<thread>_entry.c)

- Call Link-up callback nx_ppp_link_up_notify() function (optional)
- Call Link-down callback nx_ppp_link_down_notify() (optional)
- Enable PAP using nx_ppp_pap_enable() API (optional)
- Wait for IP status check using nx_ip_status_check().
- Check IP and new mask assigned using nx_ip_interface_address_get().
- Wait till link is established using nx_ppp_status_get().
- Ping the client IP address to check the PPP connection using nx_icmp_ping().

4.3.9 NetX/NetX Duo Source

4.3.9.1 NetX and NetX Duo Source Module Introduction

TheNetX™ and NetX Duo™ source modules allow the developer to modify some of the key properties that control NetX operations. Adding the NetX or NetX Duo source component enables you in the Synergy configurator environment to customize the NetX and NetX Duo libraries, change values from default settings, and enable or disable certain features. Otherwise they must use the prebuilt NetX or NetX Duo library. In most projects beyond simple socket programs, you will typically want to customize their NetX or NetX Duo environment. Note that the ThreadX® source component is automatically added when adding a NetX or NetX Duo source component.

Without adding the NetX or NetX Duo source component, the Synergy ISDE configurator will use a prebuilt library with NetX and NetX Duo default settings.

4.3.9.2 NetX and NetX Duo Source Module APIs Overview

There are no APIs associated with the NetX or NetX Duo source module. This module is used to configure various NetX or NetX Duo properties.INote: Lower level drivers may return Common Error Codes. Refer to the *SSP User's Manual,* API References for the associated module for a definition of all relevant status return values.

4.3.9.3 NetX and NetX Duo Source Module Operational Overview

Using the NetX or NetX Duo source module is a bit different than using other SSP modules. The NetX or NetX Duo source module is used to configure networking operations; it doesn't provide API functions, callbacks or other typical module functions. There is no typical operational overview of the NetX or NetX Duo module. Refer to the NetX User's Manual, available from the Synergy Gallery for the operational details of NetX.

Using TraceX with NetX and NetX Duo

If TraceX is enabled in the ThreadX source component, it is automatically included when adding NetX or NetX Duo source components. The project containing the ThreadX and NetX, or NetX Duo library must be rebuilt. Otherwise the TraceX macros that log events will not be executed.

4.3.9.4 Including the NetX and NetX Duo Source Module in an Application

A network project generated in the e^2 studio configurator will automatically include an object Add

NetX Source.

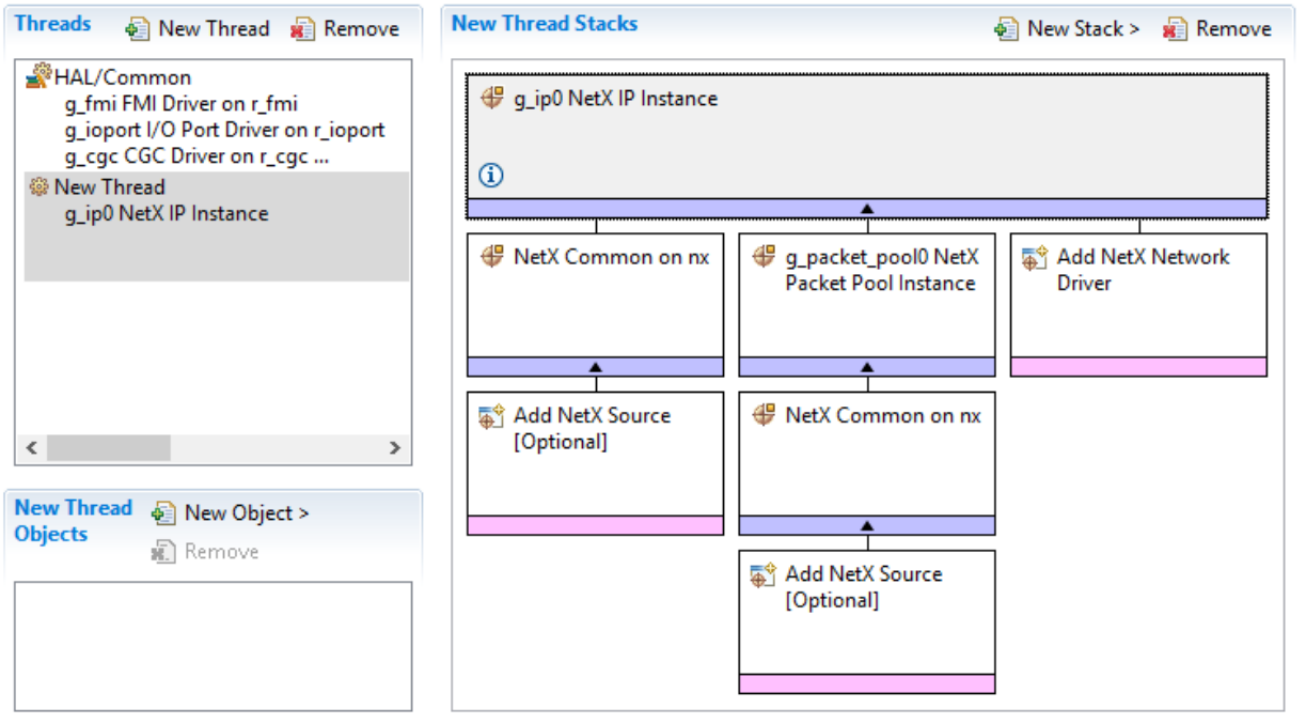

Figure 425: NetX and NetX Duo Source Module Stack

To add the NetX or NetX Duo source component to a project, click on the Add NetX Source (optional) or Add NetX Duo Source (optional) object) for NetX Duo in the e^2 studio configurator and choose New. If there are multiple Add NetX Source boxes, all of them will be updated automatically. Note that a ThreadX source component is added automatically.

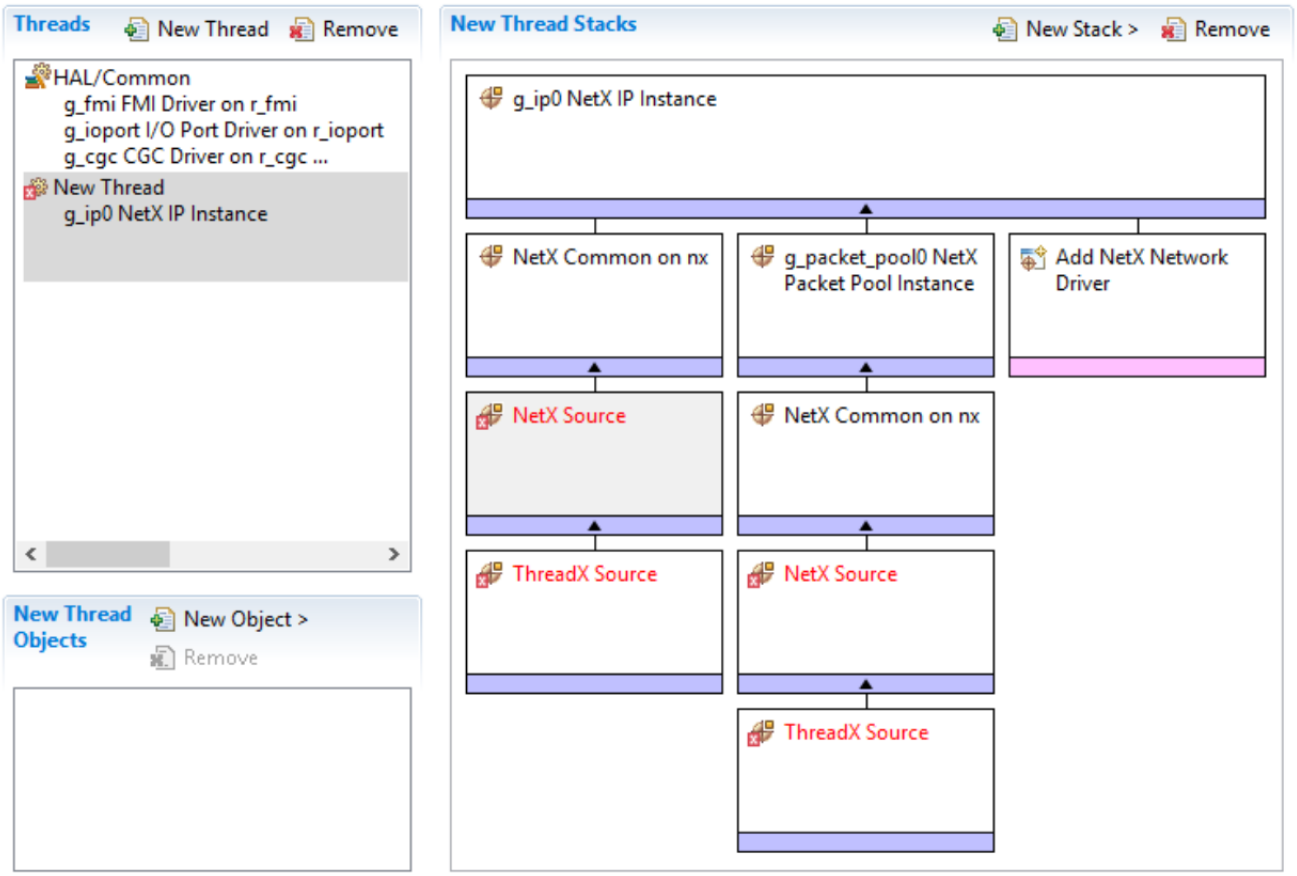

Figure 426: NetX and NetX Duo Source with ThreadX Source Stack

4.3.9.5 Configuring the NetX and NetX Duo Source Module

The list of properties below may not match the order of the NetX or NetX Duo property table. They are grouped according to general categories; ARP, TCP and IGMP for easier reference.

NetX or NetX Duo Source Module Configurable Properties

This section describes the configurable properties available to the NetX or NetX Duo source module and in what cases they can be changed from the default values to customize NetX or NetX Duo operations.

Note

*After changing NetX and NetX Duo property settings, the developer must click on the **Generate Project Content** button to update the project configurator in the ISDE. Then the NetX or NetX Duo library **must** rebuild the project. Changing a property (or applying a #define in the preprocessor list) without rebuilding the project will not affect any change. The Synergy™ Software Package (SSP) ISDE will use the previously built library.*

NetX or NetX Duo Properties Notes

These are some important notes that need to be understood by the developer before diving into the details of the large number of properties available for the NetX or Net Duo source module.

Default Settings. Most default settings are derived from RFC recommendations for the protocol relevant to the property.

IP Helper Thread Stack Size (bytes) – default value 1024. This is the stack size of the IP thread task which processes application NetX API calls, periodic events and deferred ISR events; packets received. There are some cases where a larger stack size will be required. Optimal stack size is usually determined empirically for an individual application.

IP fragmentation – default value enabled. To enable/disable fragmentation use the NetX/NetX Duo Source Fragmentation Option property. This property in the IP instance component is being deprecated.

__IP Helper Thread Priority – default value 3.__ This is the priority at which the IP thread task operates. Under some circumstances it might work best to increase this to 1 (highest valid priority). For example, if there are multiple network application thread tasks (DNS, HTTP, DHCP) in a project, then an IP helper thread at a higher priority (higher than network application threads) can service all network operations with higher priority, effectively improving responsiveness of the application thread tasks.

IP Layer Properties

Error Checking – default value enabled. It is generally enabled during development and debugging phase, and disabled when building a release version. When enabled, the NetX and NetX Duo include error checking services that will checks input and other parameters before calling the actual API. Some of the things it checks for are:

- NULL pointer input
- Invalid non-pointer parameters, such as an invalid IP address type or IP address equal to zero.
- Required configurable option must be enabled e.g. TCP must be enabled to use the nx_tcp_socket_receive API.
- The NetX or NetX Duo data structure IDs must match what is expected:

```
ip_ptr -> nx_ip_id == NX_IP_ID /* check the IP instance structure */
```

- Size of the data structure; the IP instance, matches the size of the data structure in the NetX library.

These last two checks guard against an application using a different version of the NetX or NetX Duo library than the application is using.

Static Routing – default value disabled allows certain destinations to be routed through a specific router. Normally a packet being transmitted is routed through the IP instance gateway/router as the next hop. When static routing is enabled, NetX checks the static routing table to determine if a packet's **next hop** address should go through a specific router rather than the IP instance gateway. The static routing table is limited to NX_IP_ROUTING_TABLE_SIZE entries, and there are various API such as nx_ip_static_route_add for managing the routing table. This is not commonly used but there are certain situations where it is necessary.

Physical Header and Physical Trailer – default value 16 and 4 bytes respectively: the type of network medium determines the physical (sometimes referred to as frame) header. An Ethernet network has a header of size 16 bytes. Wi-Fi has a larger header. The physical trailer is currently not being used for Ethernet but may need to be configured, depending on the physical network being used by the application. If the physical header is not set correctly, packets will not be assembled and most NetX packet send and receive services will not function correctly.

Maximum Listen Requests – default value 10 – This value is used by the TCP server applications to define the TCP listen queue size. When a TCP server socket binds a port (using the nx_tcp_server_socket_listen API), it requests a listen request on the IP instance. When it unlistens on that port, (using the nx_tcp_server_socket_unlisten API) the listen request is released, and the port is available to listen by another socket. This default value is not usually changed.

Driver Deferred Processing – default value Enabled – this feature enables the IP thread task to defer handling of the packet receive interrupts to the context of the IP thread task. Otherwise a packet receive event is handled in the context of the interrupt. This might lead to faster response to a specific packet but makes the overall system performance slower.

Loopback Interface – default value Enabled – if enabled, the NetX creates a loopback interface for sending and receiving packets to itself. Note that this is not counted as a physical interface. An application needs to be concerned about the number of network interfaces if they are using multiple physical interfaces. The loopback interface is not counted as a physical network interface (see below).

Maximum Physical Interfaces – default value 1 – The default is one network interface, generally referred to as the primary interface. The IP instance keeps a table of interfaces, and the primary interface is at index 0. For secondary interface(s), the Maximum Physical Interface value should be incremented by one for each secondary interface. Typical scenarios for multiple interface use is a router, with a local or private network on one interface and a global or public interface on the other. Another scenario is a device with two different network interfaces; ethernet and Wi-Fi.

To attach secondary interfaces to the IP instance, use the nx_ip_interface_attach API. When an interface is not referenced in an API, the action is on the primary interface. For example, nx_ip_status_check operates on the primary interface, while nx_ip_interface_status_checkperforms the operation on a specific interface.

Note: Some developers have used multiple IP instances to handle multiple physical networks. It is strongly not recommended to create multiple IP instances!

NAT (available in NetX Duo only) – default value disabled – NAT is a protocol that allows NetX Duo to map packets between the local/private and public/global networks, acting as a kind of router. To do this, the NetX Duo must be enabled to forward packets from a local host onto the global network with the host's global IP address and a port that the NetX Duo host determines. When NAT is enabled on the IP instance, NetX Duo can now forward packets in the manner. Note that NAT also requires that **Maximum Physical Interfaces** must be set to 2. SWIOT-5387 has an example project for setting up NAT.

Note

NAT is only available in NetX Duo.

Fragmentation option – default value enabled – Fragmentation occurs when the packet data exceeds the device MTU (maximum transfer unit) which is most typically 1518 bytes including frame header for Ethernet networks. An application should avoid fragmentation at the IP layer if possible, although there is not much one can do on the receiving side.

Another aspect of fragmentation to consider is the potential to deplete the packet pool used to receive packet fragments. When NetX is receiving many packet fragments, the packet pool used to receive these packets can easily be depleted, since packets cannot be returned to the packet pool until the entire packet is assembled by the IP layer and forwarded to the application. This can be remedied by increasing the number of packets in the packet pool at start up time (cannot be done at run time), if the board has sufficient memory to do so.

Note

This should not be confused with segmentation which is performed at the TCP layer. See TCP MSS Minimum for more details on segmentation.

Packet Header Pad Size – **default value 0 (no padding)** – Hardware operations on some boards require memory to be certain cache line is aligned. In those cases, the size of a NetX or NetX Duo packet instance must be aligned based on hardware requirements. For example, if the hardware requires the starting address of the data buffer to be 32-byte aligned and the size of the NX_PACKET header size is 56-bytes, defining the Packet Header ad size to be 8, can bring the starting address of the packet buffer to be 32-byte aligned.

Checksums – default value enabled – In NetX and NetX Duo, checksums for incoming (RX) and outgoing (TX) packets can be separately enabled or disabled. Checksums should not be disabled unless the RFC for that particular network protocol; UDP, TCP, or ICMP, indicate a zero checksum is allowable. Checksums generally need to be enabled. Disabling checksums might increase throughput but might also cause packets to be dropped by the other side of a connection.

Extended Notify Support – default value Disabled – When enabled, NetX will notify the application of various events related to TCP socket connections, above and beyond what NetX normally does (e.g. the callbacks specified in the nx_tcp_socket_receive_notify and nx_udp_socket_receive_notify APIs).

Extended Notify Support is required by NetX and NetX Duo BSD sockets.

The APIs enabled for this feature are listed below. They allow NetX to notify the application when NetX receives a TCP connection request, a TCP connection is completed, a TCP disconnect on a socket is completed, and to set the TCP socket state in the timed wait state. This is necessary for a TCP to operate in a non-blocking context.

nx_tcp_socket_syn_received_notify

nx_tcp_establish_notify

nx_tcp_disconnect_complete_notify

nx_tcp_timed_wait_callback

Source Address Check – default value Disabled – This checks all incoming packets for an invalid IP address. Specifically, it checks if 1) the IP address bits masked with the network mask does not equal the 1s complement of the network mask; 0xFF, 2) the IP address is not zero and the unmasked address bits do not equal zero, and 3) the address is not type D address (0xE0000000). This extra bit of processing at the IP level in NetX incurs a small performance penalty.

ICMP Address Check – default value Disabled – When enabled, the source address of ICMP packet is checked.

Maximum String Length – default value 1024 – This option specifies the maximum string length.

Enable random IP id – default value Disabled – When enabled, the default IP id is increased by one for each packet.

Enable VLAN – default value Disabled – When enabled, the VLAN feature is enabled.

IGPMP/MultiCast Properties

Maximum multicast groups – default value 7 – Defines the size of the multicast table in effect set the limit on the number of multicast groups that can be joined. Not generally modified.

IGMPV – default value Enabled – IGMPv2 is enabled by default. IGMPv2, unlike IGMPv1, allows group-specific join queries, leave messages and a method for determining which router will forward queries (instead of all IGMP routers on the network).

ARP Properties

ARP cache storage units – default in Bytes – Defines the ARP storage type in bytes. User can also select the option in Entries to define the number of ARP entries in table which will be aligned to the size of ARP.

ARP Cache size (in storage units) – default value 520 – Defines the size of the ARP cache in bytes. If user selects the storage units in Entries, then the value should be an integer. If user selects the storage units in Bytes, then the value should be a multiple of size of ARP (52 Bytes). This table holds all the ARP entries. If a table is full, no more ARP entries can be added till existing entries 'age' (see explanation of ARP Expiration Rate in this section) and are removed. There are some configurable options listed with the NetX/Duo Source element that can affect the number of ARP entries added to the table, such as ARP Auto ARP Entry and ARP Expiration Rate defined in this section.

The ARP cache size may need to be increased if the node is expected to communicate with large amount of the nodes on its local network.

ARP Auto ARP Entry – default value Enabled – This allows NetX to add an ARP entry when an ARP packet is received for which the table has no matching IP address. This will happen regardless of whether the response was directed to/from the NetX device. The idea behind auto ARP entry is to increase the efficiency of NetX by reducing the need to send ARP queries if the data is already in its ARP table. The downside is the ARP table can fill up and no more new ARP queries can be added. To prevent this, disable this feature. When disabled, NetX will only save ARP entries if the request was generated by NetX or directed to the NetX device.

This option is not required for most applications.

Alternatively, one can leave the Auto ARP Entry enabled, and set the expiration rate to non-zero to guarantee the entries will expire (and therefore be deleted) if not used. See **ARP Expiration Rate** for more details on the table entry expiration in this section.

ARP Expiration Rate – default value 0 seconds – By default ARP entries in NetX are **static**. They have no expiration rate and thus do not age. Otherwise, as an ARP entry ages, its timeout value decreases. When the timeout value reaches zero, the ARP entry is removed. If a new query pertaining to that ARP entry is received, the timeout value is reset. The timeout is also reset if the entry is accessed by the IP layer to transmit a packet. To determine if entries are being aged/deleted, an application can call the nx_arp_info_get API for statistics on aged entries as well as other useful statistics on ARP table management.

ARP Update Rate – default value 10 seconds – This is the interval between retransmission of ARP queries. When the number of retries reaches the ARP Maximum Retries, NetX abandons the attempt to find a physical mapping of IP address to a MAC address. There is no side effect to reducing this value to a smaller value.

ARP Maximum Queue Depth – default value 4 – This is the maximum number of IPv4 packets from the application trying to transmit packets for which NetX has no MAC address mapping. These packets are enqueued while NetX tries to find the MAC address mapping. When the queue is full, the

oldest packet is removed. To determine if this is happening, an application can check the nx_ip_transmit_resource_errors field in the IP instance data structure using the Expressions view in e^2 studio. Currently there is no API for obtaining this statistic.

This value does not need to be changed except under exceptional conditions. It is unusual for the queue to fill up using this default value. If the destination IP address is alive, an ARP response will be received by NetX and corresponding packets on the ARP queue will be transmitted. If the destination IP is dead, it does not make sense to queue any more packets to be sent to that address.

ARP Maximum Retries – default value 18 – This is the number of times NetX retransmits an ARP query for an IP address mapping before it gives up. There is no side effect to reducing this value to a smaller value.

ARP Defend by Reply – default value Disabled – This is intended for use with hosts who need to keep their current IP address.

Normally when a host gets an ARP packet with a matching source IP address but different MAC address, NetX may broadcast an ARP request to **announce** that it owns the IP address. It can only do so if it has not received a conflicting ARP packet within the interval of time specified by the **ARP Defend Interval** property (defined in this section). If it does send a defend reply, it resets the timeout to wait before responding to the next ARP conflict, if one occurs. If this is not the first conflicting ARP packet the host has seen, and the time recorded for the previous conflicting ARP packet is within the **ARP Defend Interval**, then the host MUST immediately cease using this address. This is necessary to ensure that two hosts do not get stuck in an endless loop with both hosts trying to defend the same address.

For more details on ARP conflicts, see *RFC 5227 IPv4 Address Conflicts Section 2.4 (b)*.

When **ARP Defend by Reply** is defined, an ARP reply is broadcast in addition to the one sent once the **ARP Defend Interval** expires. There is no requirement for a wait interval to expire for this ARP defend packet. This property is used because Windows XP ignores ARP request packets sent out when the **ARP Defend Interval** timeout expires.

ARP Defend Interval – default value 10 seconds – this is the interval during a NetX host that may not send an ARP defend packet if it receives a conflict ARP packet. 10 seconds is the default value recommended in the RFC 5227 for handling IPv4 address conflicts. After NetX sends the ARP defend packet, it resets the timeout back to this value.

ARP Mac Change Notification – default value Disabled – If NetX receives an ARP packet whose MAC address matches an entry in the ARP cache table, and this feature is enabled, NetX will call the ARP collision handler for the application to examine the packet and decide what to do with it. Without this feature, NetX will update the entry in its ARP table to the new MAC address. This behavior, that is a normal ARP protocol, can be taken advantage of in what is called the **man in the middle attack**, ARP cache poisoning or **spoofing**. This enables an attacker to redirect packets from one host to another by altering the MAC address information in the ARP table. NetX has internal handlers for these situations so applications need not handle them.

TCP Properties

Regarding the following group of rate setting properties, NetX timing is based on the NX_IP_PERIODIC_RATE setting. NX_IP_PERIODIC_RATE is derived directly from TX_TIMER_TICKS_PER_SECOND. The latter defaults to 100 but can be user defined, optionally in tx_port.h. If it is, NX_IP_PERIODIC_RATE is set to that value. If it is not, then NetX defaults it to 100 ticks (10 msec/tick).

TCP Fast Timer Rate – default value 10 – This determines the interval on how the fast timer periodic executes in NetX. If set to 10, and NX_IP_PERIODIC_RATE is set to 100, the fast periodic timer executes every 100 msec.

This timer is used to decrement the delayed ACK timeout (see **TCP ACK Timer Rate**) and the socket timeout (see **TCP Transmit Timer Rate**) for when to retransmit the ACK and data packets respectively. Increasing the **TCP Faster Timer Rate** shortens intervals between how the fast timer executes. In fact, it can potentially degrade performance for the extra overhead of processing the fast periodic timer more often.

TCP Retransmit Timer Rate – default value 1 (1 second) – This value is used to set the TCP socket timeout value. When a TCP socket sends or receives a SYN packet, or sends a data packet, it waits for an acknowledgment (ACK). If the socket timeout expires before receiving an ACK, the timeout is reset (and the packet retransmitted) up to a maximum of the **TCP Maximum Retries**. After that, NetX closes the connection.

It is generally not recommended to reduce this value. It will not make the TCP transactions happen quicker.

TCP ACK Timer Rate – default value 5 – This determines the interval between what NetX retransmits an ACK for missing data (or ACK probe). The NetX fast periodic timer decrements this timeout on each iteration of the faster timer periodic. If it expires, NetX sends another ACK packet. If a data packet is received, NetX resets the timeout. When data is sent from the NetX, it will also reset the timeout. If it expires, NetX increments the number of retries and resends an ACK. When the maximum number retries is reached (see **TCP Maximum Retries** defined in this section), NetX closes the connection.

A setting of 5, with NX_IP_PERIODIC_RATE set to 100, yields a delayed timeout of 200 msec. The greater the NX_TCP_ACK_TIMER_RATE the smaller the ACK timeout. Increasing the value does not increase performance or response time to the **NetX ACK**. It only sends them after a shorter interval.

TCP Maximum Retries – default value 10 – When a socket timeout expires without receiving a response from the TCP peer, the socket timeout is reset up until the number of retries equals the **TCP Maximum Retries**.

TCP Retry Shift – default value 0 – This is the bit shift applied to the retransmission interval. The default value of zero keeps the interval constant between socket retries (to get a response from the TCP peer). If it is set to 1, it doubles the interval; bit-shifts the timeout value by 1. This value is not often modified.

TCP Maximum TX Queue – default value 20 – This is the maximum number of packets that NetX will enqueue on a TCP socket for transmission and retransmission. A packet is enqueued when the socket is waiting to receive an ACK for the data, or it is waiting for the receive window of the other side to increase so it can send the data. For applications using smaller packet pools; limited memory resources, this value can be reduced to prevent packet pool depletion where a significant number of packets are sitting on the transmit queue, unavailable for other packet transmissions.

When the TCP socket has reached the maximum number of packets it can enqueue, the tcp socket will send call returns an NX_TCP_QUEUE_DEPTH error. If it cannot send a packet because the TCP receive window is too small it returns an NX_WINDOW_OVERFLOW error.

TCP Keepalive – default value disabled – The Keepalive feature starts a timer on the TCP socket in the established state; connected to a peer. When the timer expires, NetX sends a Keepalive ACK to the peer. Receiving a SYN or ACK packet, an ACK packet in response to NetX device's Keep Alive Ack, or any TCP packet with a valid sequence number resets the timer and the retry count.

When NetX initiates a Keepalive ACK exchange, it sends a Keepalive ACK packet with the ACK packet's sequence number decreased by one. This is how a TCP peer can distinguish a keepalive ACK from an ACK that indicates 1 byte of data has been sent.

When Keepalive is enabled on a socket, NetX also periodically checks if the other side has sent a Keepalive ACK.

If the Keepalive timer expires without a response from the peer, the number of Keepalive retries is incremented. If the retries reaches the TCP Keepalive Retries maximum, NetX deems the connection broken and terminates it. Without Keepalive, a TCP connection can persist indefinitely if neither side is transmitting a packet. In that situation, there is no way to know if the socket connection should be closed or remain open.

TCP Keepalive Retries – default value 10 - After 10 tries to get a response to a keepalive ACK, NetX resets **closes** the connection.

TCP Keepalive Initial – default value 7200 seconds (2 hours) – this is the interval before the first Keepalive is sent when a connection is completed, or a response is received from a previously sent Keepalive packet.

TCP Keepalive Retry – default value 75 seconds – NetX waits for the time specified by this option before resending another Keepalive packet, unless it has received a response to a previously sent Keepalive packet from the TCP peer.

TCP Window Scaling – default value Disabled – This feature allows a TCP receive window to exceed 65k up to a theoretical maximum of 1,073,725,440 bytes. When a NetX TCP Client socket initiates a connection, NetX computes a scaling factor based on the window size (set when the TCP socket is created). The window scaling values are exchanged during the TCP connection establishment phase. Note that the lack of window scaling option in peer's SYN packet is an indication that the peer does not support window scaling. In this situation, window scaling is not used for this connection.

TCP Maximum Out of Order Packets – default value disabled – If enabled, this option sets the maximum number of out of order packets that can be stored on the TCP socket receive queue. Subsequent out of order packets received are dropped if the socket receive queue has the maximum out of order packets. Eventually the NetX host should send an ACK indicating the missing data to the sender and get the dropped packet retransmitted. At this point, NetX can quickly process all the rest of the data on the receive queue and release the packets.

This feature is useful in the following scenario:

If a packet is lost or dropped, and the sender keeps sending packets, the TCP socket must enqueue all the packets back to the missing packet on its receive queue. It cannot release any because it is waiting for the missing data to be retransmitted. If the depth of the receive queue is not limited, this can starve the packet pool, rendering the NetX host effectively unresponsive. This can happen in a **bursty** data transmission, where many packets are sent by the TCP peer. A dropped packet may subsequently lead to many packets enqueued on the TCP receive queue.

TCP MSS Minimum – default value 128 – MSS, or maximum segment size is the largest amount of TCP data that will not require fragmentation. The **minimum** MSS is the lowest MSS that a NetX TCP socket will accept from a TCP peer. If the MSS parsed from the TCP header option data is below this value, the connection is dropped.

The intended usage of this is when an application wants to reject connections with small MSS values.

TCP ACK every N Packets – default is disabled – To enable this feature, enter a positive number. NetX sends an ACK out for every other data packet with new data, not retransmitted data. This is usually the optimal setting to minimize network traffic, packet processing and keep the TCP peer advertise window up to date. Note that if **TCP Immediate ACK** is enabled, this value is overridden; set to 1 automatically. Increasing the value increases the possibility the other side must wait on the **nth ACK** to know that the advertise window has increased enough to send more data. This may result in slower network throughput. The optimal setting is generally based on testing.

This ratio of ACKs per N packets is associated with the **delayed ACK** logic in TCP. For applications like Telnet, a higher N can greatly optimize the work on the Telnet Server receiving many 1 byte packets.

TCP Immediate ACK – default value disabled – If enabled, NetX sends an ACK for every packet of new data received. This is useful where a delayed ACK is not desirable.

Reset Disconnect – default value Enabled – When enabled, this allows an application to call a disconnect on a TCP socket with a zero wait option without sending a RST packet. It simply sends a FIN packet to indicate it is initiating a disconnection and closes the socket. It does not wait for an ACK or FIN ACK from the TCP peer. This is useful for hosts that do not want to wait to close a socket, such as servers wishing to free up sockets for the next Client request, and can do so without indicating something is wrong like a RST packet usually does.

RX Size Checking – default value Enabled – If enabled, NetX checks that a received packet has at least enough room for the IP or transport layer header; TCP, UDP, IGMP and ICMP depending on where the packet is being processed. In the IP layer, for example, NetX checks if the packet has at least enough room for the IP header. In the TCP layer, NetX checks if the packet has at least enough room for the TCP header.

As a packet travels up the stack in NetX, the packet **prepend** pointer and packet length are adjusted for each network layer. When the packet passes from the IP layer to the TCP layer, it moves the prepend pointer to the start of the TCP header, and subtracts the size of the packet length by the size of the IP layer. Similarly, going from the TCP layer to the application layer, the prepend pointer is moved past the TCP header to the application data or header in the case of something like an HTTP packet. The packet length is subtracted by the size of the TCP header.

This internal manipulation of the packet eliminates the need for the application adjust pointers and data size. An application or NetX protocol will typically make a socket call such as the nx_tcp_socket_receive API. If any packets are waiting on a socket receive queue, the application receives the packet and knows where the data is located and how much there is. The application can use the_nx_packet_length_getAPI (preferably) to obtain the packet data size, or access the nx_packet_length field in the NX_PACKET instance directly.

TCP/IP offload feature – default value disabled – If enabled, TCP/IP offload feature will be enabled. This feature enables NetX Duo to support a network interface card that offers TCP/IP service on the hardware. Certain WiFi modules offer TCP/IP processing on the module, and applications on MCU send and receive packets through APIs to access its TCP/IP stack. With this feature enabled, developers can run native NetX Duo applications directly.

Configure the "Enable the extra capability of the link driver" property to define **NX_ENABLE_INTERFACE_CAPABILITY** to enable the TCP/IP offload feature. This property is **disabled** by default.

Disable Assertion – default value disabled – If enabled, Assert is disabled.

Assert Fail – default value disabled – If enabled, the assert fail process is defined.

NetX and NetX Duo Statistics Properties

If enabled, NetX keeps statistics on its internal operations. These statistics are at the component level, like IP, TCP, ARP and Packet (pool). For TCP and UDP, there are statistics for all TCP/UDP transmissions and statistics per socket. Disabling these statistics reduces processing time slightly.

The value of these statistics is to be able to diagnose problems or optimize network performance without having to stop or interrupt program flow, or write tedious debug code.

Examples:

nx_packet_pool_info_get.c

If an application does not appear to be sending or transmitting packets, check the nx_packet_pool_empty_requests statistic. This is incremented every time nx_packet_allocatefails because no packets are in the packet pool. This is helpful if nx_packet_allocate is called from a void function or by a NetX protocol which may return a different value.

nx_ip_info_get.c

If an application is not receiving data, but packets are visible on a third-party packet trace, check the nx_ip_total_packets_received statistic to see if the data is forwarded at least as far as the IP level. Similarly, for not seeing packets from the NetX device on a packet trace is to check the nx_ip_total_packets_sent statistic.

The following is a partial list APIs for NetX statistics:

IP info – Statistics at the level of the IP layer receiving packets from the driver, and forwarding packets from the transport layer to the driver:

```
UINT  _nx_ip_info_get(NX_IP *ip_ptr, ULONG *ip_total_packets_sent,
ULONG *ip_total_bytes_sent, ULONG *ip_total_packets_received,
ULONG *ip_total_bytes_received, ULONG *ip_invalid_packets,
ULONG *ip_receive_packets_dropped, ULONG *ip_receive_checksum_errors,
ULONG *ip_send_packets_dropped, ULONG *ip_total_fragments_sent,
ULONG *ip_total_fragments_received)
```

nx_ip_interface_info_get.c is the same but specific to the specified interface.

ARP Info – Statistics on ARP packets sent and received, and ARP table statistics:

```
UINT  _nx_arp_info_get(NX_IP *ip_ptr, ULONG *arp_requests_sent,
ULONG *arp_requests_received,
                       ULONG *arp_responses_sent, ULONG *arp_responses_received,
                       ULONG *arp_dynamic_entries, ULONG *arp_static_entries,
                       ULONG *arp_aged_entries, ULONG *arp_invalid_messages)
```

Packet Pool Info – Statistics on available packets, empty packet (pool) requests, and invalid packet releases; invalid packet pool or packet pointer supplied.

```
INT  _nx_packet_pool_info_get(NX_PACKET_POOL *pool_ptr, ULONG *total_packets,
ULONG *free_packets,
                        ULONG *empty_pool_requests, ULONG *empty_pool_suspensions,
                        ULONG *invalid_packet_releases)
```

TCP Info – Statistics on the total number of TCP packets sent/received, number of connections and disconnections, dropped and retransmitted packets. The socket specific API includes the receive window size.

```
UINT  _nx_tcp_info_get(NX_IP *ip_ptr, ULONG *tcp_packets_sent, ULONG
*tcp_bytes_sent,
                        ULONG *tcp_packets_received, ULONG *tcp_bytes_received,
                      ULONG *tcp_invalid_packets,
ULONG *tcp_receive_packets_dropped,
                      ULONG *tcp_checksum_errors, ULONG *tcp_connections,
                     ULONG *tcp_disconnections, ULONG *tcp_connections_dropped,
                ULONG *tcp_retransmit_packets)
UINT  _nx_tcp_socket_info_get(NX_TCP_SOCKET *socket_ptr, ULONG *tcp_packets_sent,
ULONG *tcp_bytes_sent,
                ULONG *tcp_packets_received, ULONG *tcp_bytes_received,
                       ULONG *tcp_retransmit_packets, ULONG *tcp_packets_queued,
                 ULONG *tcp_checksum_errors, ULONG *tcp_socket_state,
                 ULONG *tcp_transmit_queue_depth,
ULONG *tcp_transmit_window,
                  ULONG *tcp_receive_window)
```

UDP Info – Statistics on the total number of UDP packets sent/received, dropped packets, improperly formed packets to send or receive. The socket specific API does not include the count of invalid packets received.

```
UINT  _nx_udp_info_get (NX_IP *ip_ptr, ULONG *udp_packets_sent, ULONG
*udp_bytes_sent,
```

```
                    ULONG *udp_packets_received, ULONG *udp_bytes_received,
                       ULONG *udp_invalid_packets,
ULONG *udp_receive_packets_dropped,
                     ULONG *udp_checksum_errors)
UINT  _nx_udp_socket_info_get (NX_UDP_SOCKET *socket_ptr, ULONG *udp_packets_sent,
ULONG *udp_bytes_sent, ULONG *udp_packets_received,
ULONG *udp_bytes_received, ULONG *udp_packets_queued,
                    ULONG *udp_receive_packets_dropped,
ULONG *udp_checksum_errors)
```

ICMP Info – Satistics on control message transmission, including count of unsupported ICMP messages, ping requests that timed out, and responses to ping request.

```
UINT  _nx_icmp_info_get(NX_IP *ip_ptr, ULONG *pings_sent, ULONG *ping_timeouts,
                    ULONG *ping_threads_suspended,

4.3.10 Azure RTOS NetX Overview

4.3.10.1 Azure RTOS NetX Interface

Azure RTOS NetX is a high-performance real-time implementation of the TCP/IP standards designed exclusively for embedded ThreadX-based applications. The Azure RTOS NetX networking stack (nx) is integrated into the Renesas SSP. The Azure RTOS NetX Interface provides the means for SSP projects to access the capabilities of NetX.

For more information about NetX (including API references), refer to the *NetX User Guide* available

as part of the Azure RTOS Components documentation pack here: https://www.renesas.com/en-us/products/synergy/software/ssp.html

Unsupported Features

The following driver requests are not implemented in sf_el_nx:

- Get link speed
- Get duplex type
- Get error count
- Get receive packet count
- Get transmit packet count
- Get allocation errors
- User commands

Azure RTOS NetX with TraceX

If TraceX is enabled in the ThreadX source component, it is automatically included when adding the NetX source components. When enabled, the project containing the ThreadX and NetX library must be rebuilt or TraceX macros that log events will not be executed.

Azure RTOS NetX Protocol Modules

A wide variety of popular networking protocol functions are supported within the Azure RTOS NetX Interface for SSP. Each available protocol function has its own module overview section in this document. These overviews provide sufficient background to determine if the module provides the functions needed by the application.

Complete Application Projects (APs) are also available showing a working project for a typical NetX Protocol application targeted for a Renesas Synergy hardware kit. APs are available from the Renesas Synergy web site here: https://www.renesas.com/us/en/support/document-search?title=&doc_file_all_types%5BSample+Code%5D=Sample+Code&doc_category_tier_1=467666&doc_category_tier_2=469306&doc_category_tier_3=&doc_category_tier_4=&doc_part_numbers=&sort_order=DESC&sort_by=field_document_revision_date

Azure RTOS NetX Configuration Notes

When a protocol module is added to a project, a prebuilt library of the application code is added. For each protocol component, there is an analogous component ending in '_src' that contains protected source files. The '_src' component can be added in addition to the prebuilt library module. Do not add the '_src' component without the prebuilt library module.

If the NetX Source module is added to the project, the Properties window provides advanced configurations for the NetX source library. Highlight a configuration option to view a description of the option in the bottom left corner of the e^2 studio GUI. If the configuration option is empty, the default value is used. The default values of configuration options are defined in ssp/inc/framework/el/nx/nx_port.h. Refer to the Configuration Options chapter of the *NetX User Guide* for more information.

A detailed NetX and NetX Duo Source Module Overview is available in this document. It covers the configurable networking operations available within the source module. It is highly recommended that this is read and understood before attempting to modify any NetX or NetX Duo source configuration settings.

Azure RTOS NetX Limitations

- Azure RTOS NetX cannot be used in the same application as Azure RTOS NetX Duo. Only one or the other can be used per application.
- When using NetX BSD with the GCC compiler, build with the macro _POSIX_SOURCE defined to avoid compilation errors.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

Azure RTOS NetX Supported Devices

- Refer to the associated SSP Release Notes for a complete list of the supported MCU devices.

4.3.11 Azure RTOS NetX Duo Overview

4.3.11.1 Azure RTOS NetX Duo Interface

Azure RTOS NetX Duo is a high-performance real-time implementation of the TCP/IP standards designed exclusively for embedded ThreadX-based applications. The Azure RTOS NetX Duo networking stack (nxd) is integrated into the Renesas SSP. The Azure RTOS NetX Duo Interface provides the means for SSP projects to access the capabilities of NetX Duo.

For more information about NetX Duo (including API references), refer to the *NetX Duo User Guide* available as part of the Azure RTOS Components documentation pack here: https://www.renesas.com/en-us/products/synergy/software/ssp.html.

Unsupported Features

The following driver requests are not implemented in sf_el_nx (SSP)

- Get link speed
- Get duplex type
- Get error count
- Get receive packet count
- Get transmit packet count
- Get allocation errors
- User commands

Azure RTOS NetX Duo with TraceX

If TraceX is enabled in the ThreadX source component, is automatically included when adding NetX Duo source components, the project containing the ThreadX and NetX Duo library must be rebuilt or TraceX macros that log events will not be executed.

4.3.11.2 Azure RTOS NetX Duo Protocol Modules

A wide variety of popular networking protocol functions are supported within the Azure RTOS NetX Duo Interface for SSP. Each available protocol function has its own module overview section in this document. These overviews provide sufficient background to determine if the module provides the functions needed by the application.

Complete Application Projects (APs) are also available showing a working project for a typical NetX Protocol application targeted for a Renesas Synergy hardware kit. APs are available from the Renesas Synergy web site here: https://www.renesas.com/us/en/support/document-search?title=&doc_file_all_types%5BSample+Code%5D=Sample+Code&doc_category_tier_1=467666&doc_category_tier_2=469306&doc_category_tier_3=&doc_category_tier_4=&doc_part_numbers=&sort_order=DESC&sort_by=field_document_revision_date

4.3.11.3 Azure RTOS NetX Duo Limitations

- Azure RTOS NetX Duo cannot be used in the same application as Azure RTOS NetX. Only one or the other can be used per application.
- When using NetX Duo BSD with the GCC compiler, build with the macro _POSIX_SOURCE defined to avoid compilation errors.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.11.4 Azure RTOS NetX Duo Supported Devices

- Refer to the associated SSP Release Notes for a complete list of the supported MCU devices.

4.3.12 NetX/NetX Duo Auto IP

4.3.12.1 NetX/NetX Duo Auto IP Introduction

The Auto IP Protocol is designed to dynamically configure IPv4 addresses on a local network without requiring a server, unlike the Dynamic Host Configuration Protocol (DHCP). The Auto IP uses address resolution protocol (ARP) for automatic IP address assignment and allocates addresses in the range of 169.254.1.0 through 169.254.254.255.

Note

Except for internal processing, the NetX Duo™ Auto IP module is identical in the application, set-up and running of an Auto IP session as the NetX™ Auto IP module.

NetX/NetX Duo Auto IP Module Features

- Compliant with RFC3927 and related RFCs
- Uses ARP probes to check for address conflicts
- Uses the collision handler notification in NetX to detect an address already in use
- Registers a valid Auto IP address with the IP instance
- Provides high-level APIs for:
    - Creating and deleting an Auto IP instance
    - Starting and stopping the Auto IP thread task
    - Specifying the network interface on which to run Auto IP

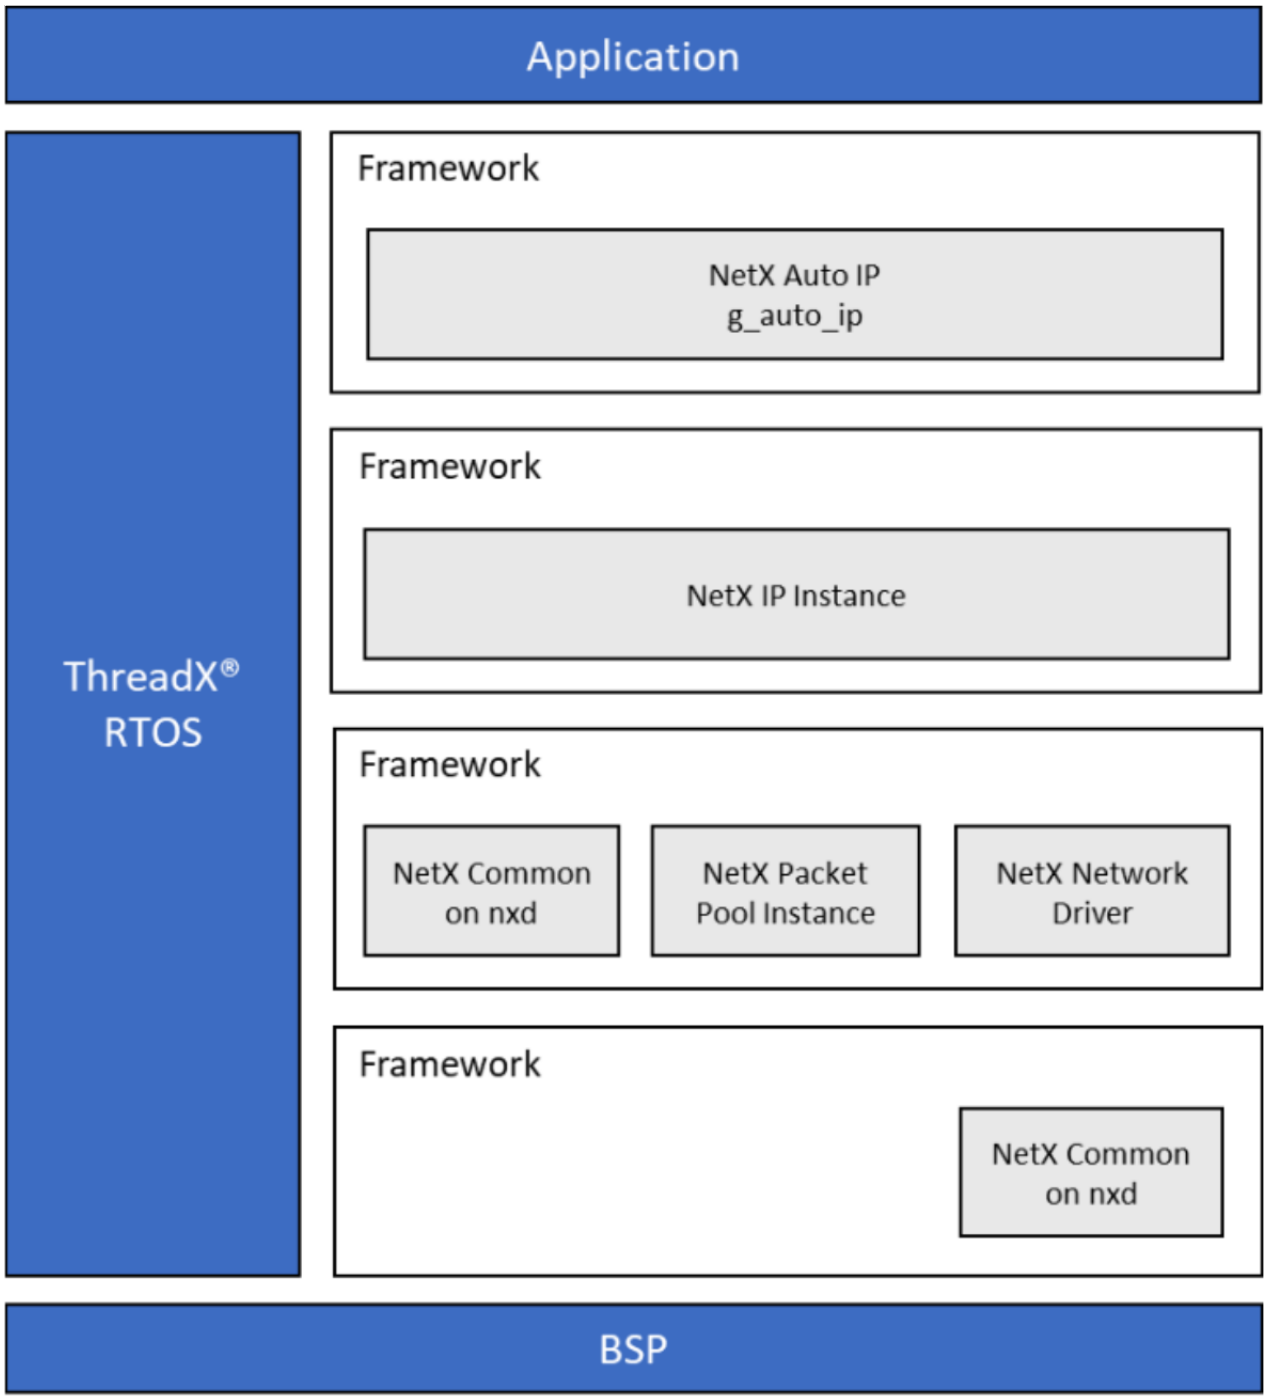

Figure 427: NetX/NetX Duo Auto IP Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX/NetX Duo Auto IP Module in an Application for additional details.

4.3.12.2 NetX/NetX Duo Auto IP Module APIs Overview

The NetX Auto IP defines APIs for creating, deleting, getting and setting addresses. A complete list of the available APIs, an example API call and a short description of each can be found in the following

table. A table of status return values follows the API summary table.

NetX/NetX Duo Auto IP Module API Summary

Function Name	Example API Call and Description
nx_auto_ip_create	nx_auto_ip_create(&g_auto_ip0, "AutoIP 0", &g_ip0, stack_pointer, stack_size, priority); Create an Auto IP instance.
nx_auto_ip_delete	nx_auto_ip_delete(&g_auto_ip_0); Delete Auto IP instance.
nx_auto_ip_get_address	nx_auto_ip_get_address(&g_auto_ip_0, &local_address); Get current Auto IP address.
nx_auto_ip_set_interface	nx_auto_ip_set_interface(&g_auto_ip_0, interface_index); Set network interface needing an Auto IP address.
nx_auto_ip_start	nx_auto_ip_start(&g_auto_ip_0, IP_ADDRESS(0,0,0,0)); Start Auto IP processing. If the address input is NULL. NetX Auto IP randomly assigns an address in the Auto IP address range.
nx_auto_ip_stop	nx_auto_ip_stop(&g_auto_ip_0); Stop Auto IP processing.
nx_dhcp_server_stop	nx_dhcp_server_stop(&dhcp_server); Stop DHCP server processing.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

Status Return Values

Name	Description
NX_SUCCESS	Successful AutoIP function.
NX_AUTO_IP_ERROR	Error creating components of Auto IP instance.
NX_PTR_ERROR*	Invalid pointer input.
NX_CALLER_ERROR*	Invalid caller of this service.
NX_AUTO_IP_NO_LOCAL	No Auto IP address registered with the NetX IP instance.
NX_AUTO_IP_BAD_INTERFACE_INDEX	Invalid network interface.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

- These are error codes which are only returned if error checking is enabled. Refer to the *NetX User Guide* for the Renesas Synergy™ Platform or *NetX Duo User's Guide* for the Renesas Synergy™ Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.12.3 NetX/NetX Duo Auto IP Module Operational Overview

The NetX Auto IP protocol first selects a random address within the Auto IP IPv4 address range of 169.254.1.0 through 169.254.254.255. Alternatively, the application may force a starting IP address by providing it to the nx_auto_ip_startservice; this is useful in situations where an Auto IP address has been used previously.

Once an auto IP address is selected, the NetX Auto IP sends out a series of ARP probes for the selected address. An ARP probe consists of an ARP request message with the sender address set to 0.0.0.0 and the target address set to the desired Auto IP address. A series of these ARP probes are sent (the actual number is set by the ARP probes to send property of the NetX Auto IP instance); if another network node responds to this probe or sends an identical probe for the same address, a new auto IP address is randomly selected within the auto IP IPv4 address range and the probe processing repeats.

If ARP probes to send and probes are sent without any responses, the NetX Auto IP issues many ARP announcements (set by the Number of ARP announces property) for the selected address. An ARP announcement consists of an ARP request message with both the sender and target address in the ARP message set to the selected auto IP address. If another network node responds to an announced message or sends an identical announcement for the same address, a new auto IP address is randomly selected within the auto IP IPv4 address range, and the probe processing starts over. When the probe and announcement completes without any detected conflicts, the selected auto IP address is considered valid and the address is registered with the IP instance.

The NetX Auto IP registers the auto IP-generated IP address with the NetX IP instance successful probe and announcement processing. The Auto IP application can be notified of address changes using the nx_ip_address_change_notify callback in NetX, or it can use the nx_ip_status_check to determine when a valid IP address is assigned. Once a valid address is assigned, the application should stop the auto IP task using the nx_auto_ip_stop service. The address change callback notifies the application of address changes after the auto IP thread task is suspended. Possible reasons for an address changing without explicitly being done with an auto IP may be due to auto IP-address conflicts with other nodes, or a DHCP address resolution to replace the auto IP address.

NetX/NetX Duo Auto IP Module Important Operational Notes and Limitations

NetX/NetX Duo Auto IP Module Operational Notes

- The NetX DHCP Client and NetX Auto IP can both be used to ensure a host has a valid IP address. Typically, the DHCP Client attempts to contact a server. If none of the servers responds to the DHCP Client, the client is suspended and the auto IP task is started. Auto IP generally guarantees a local address even if no DHCP Server is available. The DHCP Client can try later to broadcast requests to a DHCP Server; this process, if successful, automatically overwrites the auto IP local address.
- When the IP address changes, the application is responsible for closing out existing socket connections.

NetX/NetX Duo Auto IP Module Limitations

- If the NetX DHCP is used with the auto IP, the DHCP thread created must have a higher priority than the auto IP thread.

- The NetX Auto IP does not provide a mechanism to retain previously used IP address.
- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.3.12.4 Including the NetX/NetX Duo Auto IP Module in an Application

This section describes how to include either or both NetX/NetX Duo Auto IP module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo Auto IP module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo Auto IP Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_auto_ip0 NetX Auto IP	Threads	**New Stack**> **X-Ware**> **NetX**> **Protocols**> **NetX Auto IP**
g_auto_ip0 NetX Duo Auto IP	Threads	**New Stack**> **X-Ware**> **NetX Duo**> **Protocols**> **NetX Duo Auto IP**

When the NetX/NetX Duo Auto IP module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

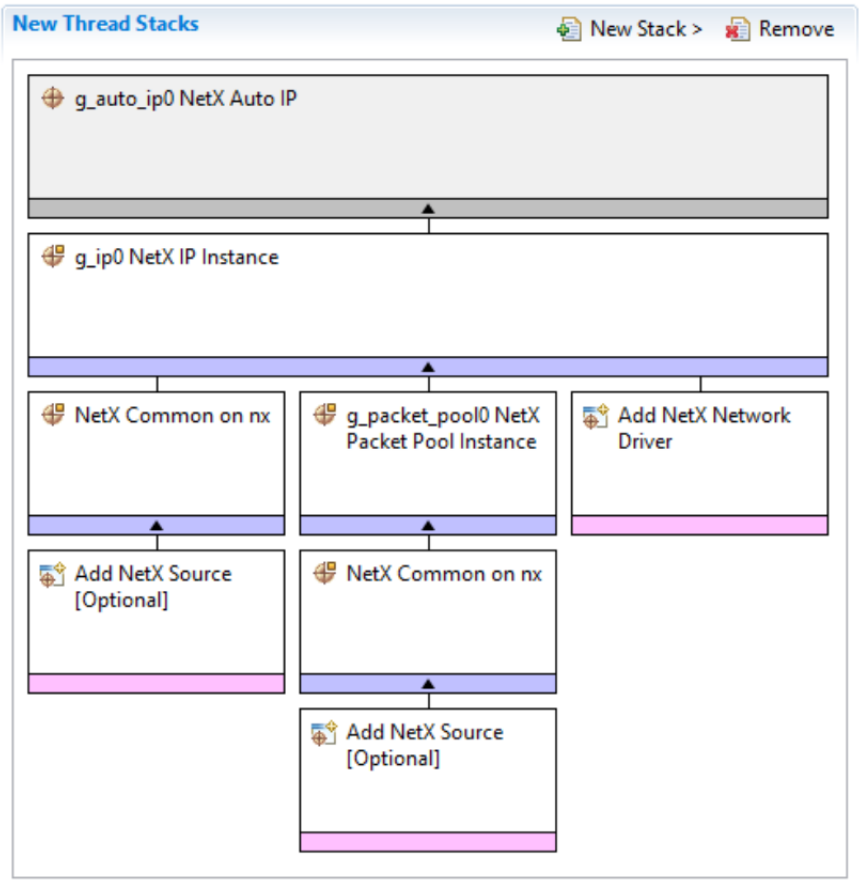

Figure 428: NetX/NetX Duo Auto IP Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.12.5 Configuring the NetX/NetX Duo Auto IP Module

The NetX/NetX Duo Auto IP module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo Auto IP Module

ISDE Property	Value	Description
Wait before sending first probe (seconds)	1	Wait before sending first probe selection.
ARP probes to send	3	ARP probes to send selection.
Minimum wait between probes (seconds)	1	Minimum wait between probes selection.
Maximum wait between probes (seconds)	2	Maximum wait between probes selection.
Maximum conflicts before increasing processing delay	10	Maximum conflicts before increasing processing delay selection.
Wait extend after maximum conflicts (seconds)	60	Wait extend after maximum conflicts selection.
Wait before announcement (seconds)	2	Wait before announcement selection.
Number of ARP announces	2	Number of ARP announces selection.
Wait between announces (seconds)	2	Wait between announces selection.
Wait between defense announces (seconds)	10	Wait between defense announces selection.
Name	g_auto_ip0	Module name.
Internal thread stack size (bytes)	2048	Internal thread stack size selection.
Internal thread priority	3	Internal thread priority selection.
Name of generated initialization function	auto_ip_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different addresses for the Ethernet port. The configurable properties for

the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo Auto IP Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name.
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection.
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection.
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection.
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection.
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection.
IP Helper Thread Priority	3	IP Helper Thread Priority selection.
ARP	Enable	ARP selection.
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection.
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection.
TCP	Enable, Disable Default: Enable	TCP selection.
UDP	Enable, Disable Default: Enable	UDP selection.

ICMP	Enable, Disable Default: Enable	ICMP selection.
IGMP	Enable, Disable Default: Enable	IGMP selection.
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection.
Name of generated initialization function	ip_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name.
Packet Size in Bytes	640	Packet size selection.
Number of Packets in Pool	16	Number of packets in pool selection.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo Auto IP Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX/NetX Duo Auto IP Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select **Peripherals**> **Connectivity:ETHERC**> **ETHERC1.RMII**

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1.
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection.
REF50CK	P701	REF50CK pin.
TXD0	P700	TXD0 pin.
TXD1	P406	TXD1 pin.
TXD_EN	P405	TXD_EN pin.
RXD0	P702	RXD0 pin.
RXD1	P703	RXD1 pin.
RX_ER	P704	RX_ER pin.
CRS_DV	P705	CRS_DV pin.

MDC	P403	MDC pin.
MDIO	P404	MDIO pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.12.6 Using the NetX/NetX Duo Auto IP Module in an Application

In a typical application, it is assumed that an IP instance has been created and an ARP is enabled. Once this IP instance is accomplished, the typical steps in using the NetX Auto IP in an application are:

1. Allow time for the IP thread task and the network driver to get initialized (2-3 seconds) using the tx_thread_sleep API.
2. Set the address change notification with the nx_ip_address_change_notify API [Optional].
3. Start the Auto IP instance with the nx_auto_ip_start API.
4. Check for a valid address for the IP instance using either the nx_ip_status_check or nx_auto_ip_get_address API. The nx_ip_status_check API defaults to the primary address. If running Auto IP on a secondary interface, use the nx_ip_interface_status_check. Note that nx_auto_ip_get_address API works for Auto IP on either primary or secondary addresses.
5. If a valid local IP address is assigned, stop the auto IP thread task using the nx_auto_ip_stop API.

The following figure illustrates common steps in a typical operational flow diagram:

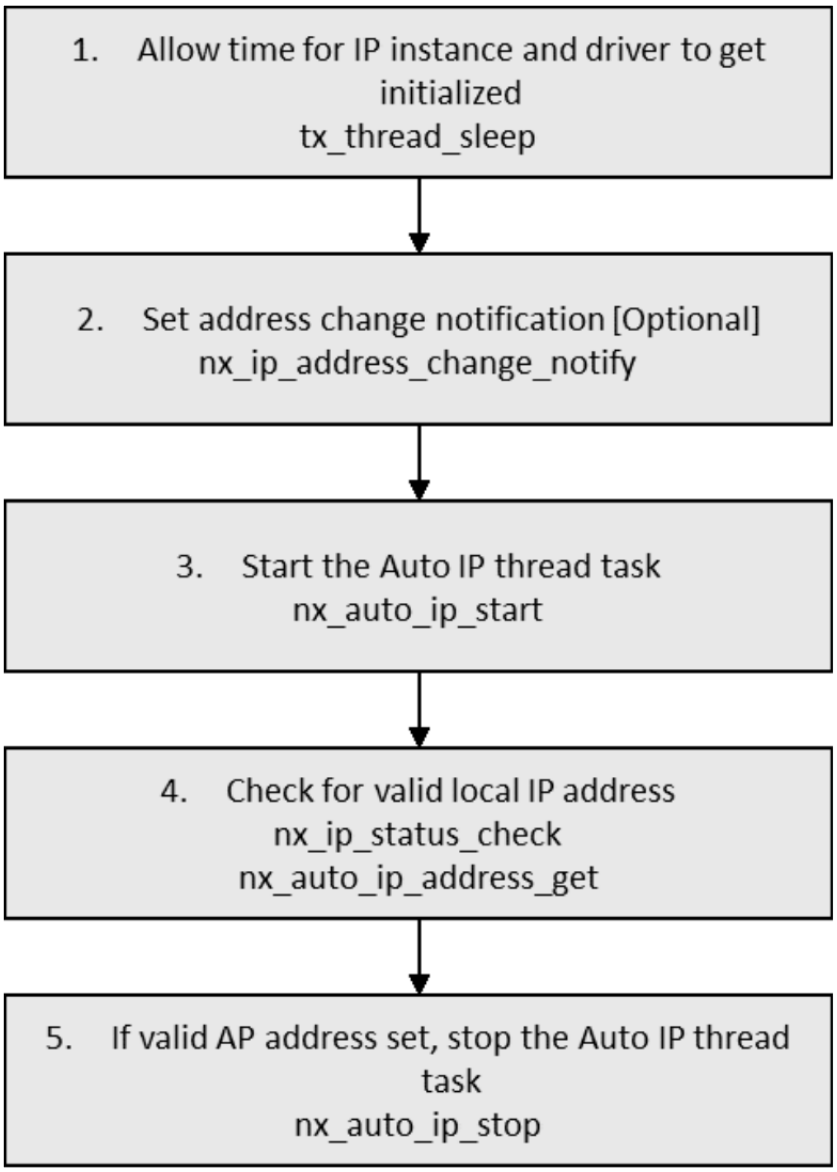

Figure 429: Flow Diagram of a Typical NetX/NetX Duo Auto IP Module Application

4.3.13 NetX/NetX Duo BSD Support

4.3.13.1 NetX/NetX Duo BSD Support Introduction

The BSD Socket API Compliancy Wrapper (NetX™ BSD) supports a subset of the basic BSD Socket API calls (with some limitations) using NetX™ services.

Note

Except for internal processing, the NetX Duo™ BSD Support module is identical in the application, set-up and running of an BSD Support session as the NetX™ BSD Support module.

Unsupported Features

BSD with DNS support has not been tested in this version of SSP.

NetX/NetX Duo BSD Support Module Features

- The NetX BSD Support module is compliant with BSD 4.3.
- Provides high-level APIs to:
    - Create and delete sockets
    - Set socket options
    - Request TCP connections and listen for connection requests
    - Send and receive packets
    - Raw packet support**
    - PPP over Ethernet support**

** NetX Duo BSD only

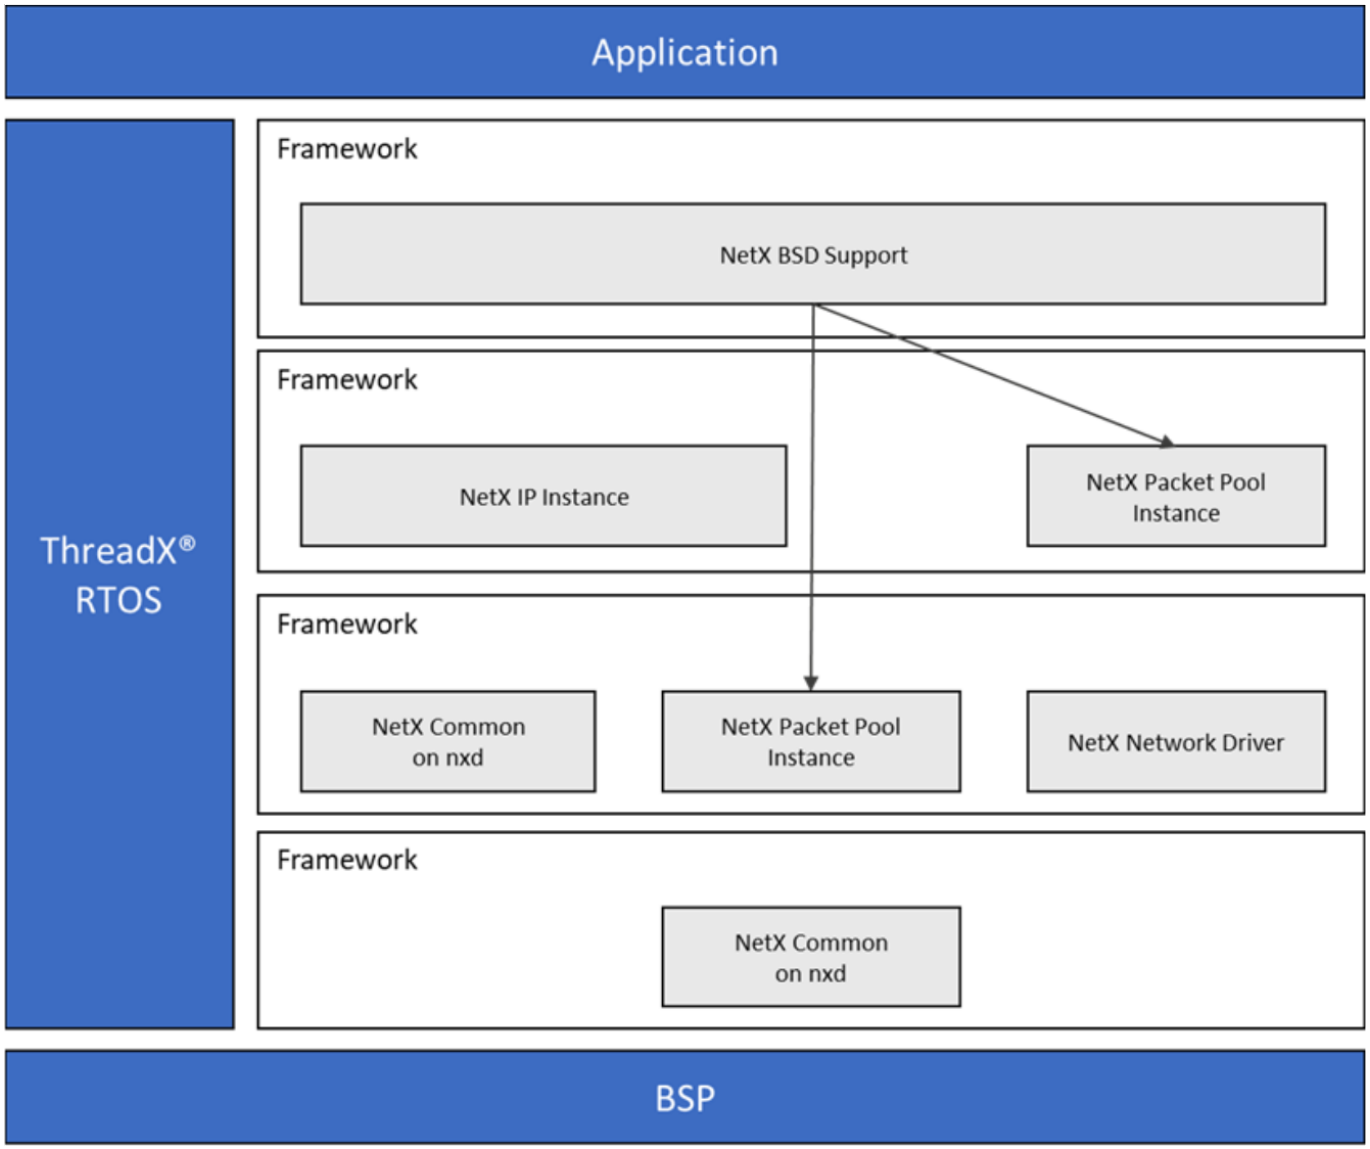

Figure 430: NetX/NetX Duo BSD Support Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver modules has multiple implementation options

available. See the description just after the module stack figure in the Including the NetX/NetX Duo BSD Support Module in an Application section for additional details.

4.3.13.2 NetX/NetX Duo BSD Support Module APIs Overview

The NetX BSD Support module provides the standard BSD API functions for connecting, binding, listening, sending and receiving. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. Services that are implemented by NetX and NetX Duo BSD begin with nx_, and are listed at the end of this table.

NetX/NetX Duo BSD Support Module API Summary

Function Name	Example API Call and Description
accept	accept(INT sockID, struct sockaddr *ClientAddress, INT *addressLength); TCP server socket waits to make a TCP connection.
bsd_initialize	bsd_initialize(NX_IP *default_ip, NX_PACKET_POOL *default_pool, CHAR *bsd_thread_stack_area, ULONG bsd_thread_stack_size, UINT bsd_thread_priority); Sets up BSD Support Module to use NetX and BSD services. (Called by the NetX BSD Support Module automatically.)
bind	bind(INT sockID, struct sockaddr *localAddress, INT addressLength); Bind TCP or UDP socket to a local port.
connect	connect(INT sockID, struct sockaddr *remoteAddress, INT addressLength); Connect to a TCP peer; if the remoteAddress indicates raw or UDP socket, then if the address is NULL this dis-associates the peer from this socket.
fcntl	fcntl(INT sock_ID, UINT flag_type, UINT f_options); Sets socket options for the specified socket.
freeaddrinfo	freeaddrinfo(struct addrinfo *res); Releases memory allocated by the getaddrinfo service.
getnameinfo	getnameinfo(const struct sockaddr *sa, socklen_t salen, char *host, size_t hostlen, char *serv, size_t servlen, int flags); Converts a socket address to a corresponding host and service string.
getpeername	getpeername(INT sockID, struct sockaddr *remoteAddress, INT *addressLength); Return remote peer's IP address and port.

getsockname	getsockname(INT sockID, struct sockaddr *localAddress, INT *addressLength); Return the socket's primary IP address and source port. In NetX Duo, this would be the address as index 1 in the IP interface table.
getsockopt	getsockopt(INT sockID, INT option_level, INT option_name, VOID *option_value, INT *option_length); Return the status of the specified socket option.
getaddrinfo	getaddrinfo(const CHAR *node, const CHAR *service, const struct addrinfo *hints, struct addrinfo **res); Fills in the addrinfo for the indicated node (host) based on hints in the addrinfo input.
ioctl	ioctl(INT sockID, INT command, INT *result); Carry out the command on the specified socket. Only two options supported FIONREAD (extract number of bytes on socket queue) and FIONBIO (enable/disable non blocking as per the result flag).
inet_addr	inet_addr(const CHAR *buffer); Convert an IP address from a string buffer to a number.
inet_ntoa	inet_ntoa(struct in_addr address_to_convert); Convert an IP address to a string.
inet_aton	inet_aton(const CHAR * address_buffer_ptr, struct in_addr *addr); Converts hexadecimal characters into an ASCII IP address representation.
inet_pton	inet_pton(INT af, const CHAR *src, VOID *dst); Converts an IP address from string to numeric format.
inet_ntop	inet_ntop(INT af, const VOID *src, CHAR *dst, socklen_t size); Converts an IP address from numeric format to string presentation.
listen	listen(INT sockID, INT backlog); Bind a TCP server socket to a local port on which to listen for connection requests.
recvfrom	recvfrom(INT sockID, CHAR *buffer, INT buffersize, INT flags,struct sockaddr *fromAddr, INT *fromAddrLen); Receive up to the specified number of bytes on the specified socket (either UDP or TCP).

recv	recv(INT sockID, VOID *rcvBuffer, INT bufferLength, INT flags) Copies up to a specified number of bytes received on the socket into specified location. The given socket can be UDP or TCP, but must be in the connected state.
send	send(INT sockID, const CHAR *msg, INT msgLength, INT flags) Send the specified buffer out on the socket; the actual number of bytes sent is returned in msglength. Does not support raw sockets.
sendto	sendto(INT sockID, CHAR *msg, INT msgLength, INT flags, struct sockaddr *destAddr, INT destAddrLen); Send the specified buffer out on the socket; the actual number of bytes sent is returned in msglength. The socket must be in a connected state. Supports raw sockets (NetX Duo BSD only).
select	select(INT nfds, fd_set *readfds, fd_set *writefds, fd_set *exceptfds, struct timeval *timeout); Check all sockets specified in the fd_set inputs to be checked for read request (incoming packets), write request (outgoing packets), and exception request input.
soc_close	soc_close(INT sockID); Close the specified socket.
socket	socket(INT protocolFamily, INT type, INT protocol); Creates and endpoint for communication and returns a file descriptor for the socket.
setsockopt	setsockopt(INT sockID, INT option_level, INT option_name, const VOID *option_value, INT option_length); Enable the input socket option on the socket.
fcntl	fcntl(INT sock_ID, UINT flag_type, UINT f_options); Sets flag options for the specified socket.
nx_bsd_raw_packet_info_extract**	nx_bsd_raw_packet_info_extract(NX_PACKET *packet_ptr, NXD_ADDRESS *nxd_address, UINT *interface_index); Extracts source IP address and interface index of the IP address in the IP interface table.

nx_bsd_socket_set_inherited_settings	nx_bsd_socket_set_inherited_settings(UINT master_sock_id, UINT secondary_sock_id); Apply the socket options of the specified master socket to the specified child secondary socket; requires NX_BSD_INHERIT_LISTENER_SOCKET_SETTINGS be defined. If it is not, this function has no effect.
nx_bsd_set_service_list	nx_bsd_set_service_list(struct NX_BSD_SERVICE_LIST *serv_list_ptr, ULONG serv_list_len); Define the service list used by getaddrinfo with the specified service list.

Note

*When inet_ntop() function is used in the application to convert IP address from ULONG to string, IP address gets reversed (From SSP 2.0.0 and later). Hence IP address has to be passed in Network byte order. The function '**htonl()**' has to be used to convert IP address into network byte order.*
For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo FTP Client. For definitions of of NetX Duo specific data types, see the*NetX Duo User Guide for the Renesas Synergy™ Platform*.

4.3.13.3 NetX/NetX Duo BSD Support Module Operational Overview

To utilize NetX and BSD services, the NetX BSD Support module automatically creates an IP instance, and creates memory space for the internal BSD thread stack. The packet pool can be the IP default packet pool (g_packet_pool0) or by clicking on **Add NetX Packet Pool (or Add NetX Duo Packet Pool)**> **New**, a separate packet pool, g_packet_pool1, will be used for BSD packet transmissions. For memory space, the defining parameters are the internal_thread_stack_sizeand internal_thread_priorityproperties of the NetX BSD Support stack element.

Before using NetX BSD services, the application creates one or more sockaddr_in instances local and peer hosts. A server application will only need to create a sock_addr for itself. (These are limited to IPv4 addressing.) For IPv6 addresses (which requires NetX Duo BSD), the application creates one or more sockaddr_in6instances. A socket of type TCP or UDP is created using the socket service; the protocol must be AF_INET for IPv4 or AF_INET6 for IPv6.

For raw packets (NetX Duo BSD only), the socket must be of type AF_PACKET.

Optionally, the application can set socket options such as non-blocking using the fnctl and ioctl services.

For TCP and UDP clients, the socket must bind a local-source port using the bind service. A value of zero for the port in the sockaddr_in the data instance will inform NetX to assign a local port. For the TCP sockets, the client socket connects to a TCP server using the connect service.

Both the UDP and TCP sockets can then send and receive data. Because the BSD is a streaming based protocol, data is delivered to and from the application in user-defined buffers. Internally, NetX sends and transmits data using packets from the packet pools transparently to the application. There is no requirement to release received packets or allocated packets that NetX was not able to send.

To close a client socket, the application calls soc_close. There is no need to unbind the socket when

closing it using soc_close.

For TCP servers, the application chooses a local port to listen on by the specified master socket using the listen service. The master socket then checks for connection requests using the select service. When one is detected, it calls the accept service and assigns a secondary socket to handle the connection. In this manner, the BSD can maintain multiple connections simultaneously.

To close a server socket, the application calls soc_close. Unlike NetX TCP sockets, there is no need to call the nx_tcp_server_socket_unlisten or nx_tcp_server_socket_unaccept API on the TCP socket in NetX BSD.

Eliminating an Internal BSD Thread

By default, BSD utilizes an internal thread to perform some of its processing. In systems with tight memory constraints, NetX BSD can be built with NX_BSD_TIMEOUT_PROCESS_IN_TIMER defined, which eliminates the internal BSD thread and alternatively uses an internal timer to perform the same processing. This eliminates the memory required for the internal BSD thread control block and stack. The timer processing is significantly increased and the BSD processing may also execute at a higher priority than needed.

To configure BSD sockets to run in the ThreadX-timer context, define NX_BSD_TIMEOUT_PROCESS_IN_TIMER in the project. If the BSD layer is configured to execute the BSD tasks in the timer context, the following properties of the BSD stack element are ignored:

- internal_thread_stack_size
- internal_thread_priority

NetX BSD with DNS Support

If NX_BSD_ENABLE_DNS is defined, NetX BSD can send DNS queries to obtain hostname or host IP information. This feature requires a NetX DNS Client instance to be previously created. The BSD link to this DNS instance is via an extern NX_DNS *_nx_dns_instance_ptr. When the BSD application calls getnameinfo with an address or getaddrinfo with a hostname, NetX BSD will call various NetX DNS Client services to obtain the host name or IP address, respectively. Refer to the *NetX DNS Client User Guide* for the Renesas Synergy Platform, available as described at the Reference section at the end of this document, for more details on setting up a DNS Client in an application.

Raw Socket Support (NetX Duo BSD only)

To use raw sockets in the NetX Duo BSD, the NetX Duo library must be compiled with NX_ENABLE_IP_RAW_PACKET_FILTERdefined in the project. By default, it is not defined. To define it, right click on the project in the **Synergy Configuration pane**> **Properties**> **Cross ARM C Compiler**> **Preprocessor** and add this to the list of defined symbols by clicking on the (+) icon.

The application must then enable raw socket processing for a previously created IP instance by calling the nx_ip_raw_packet_enable service before using NetX Duo BSD services. To create a raw socket in NetX Duo BSD, the application uses the socket service and specifies the protocol family, socket type, and protocol:

sock_1 = socket(INT protocolFamily, INT socket_type, INT protocol)

The NetX BSD supports these values for protocol Family : AF_INET for IPv4 sockets, AF_INET6 for IPv6 sockets, and AF_PACKET for raw sockets. The socket_type must be set to SOCK_RAW. The protocol is application specific.

To send and receive raw packets as well as close a raw socket, the application typically uses the same BSD services as the UDP like sendto, recvfrom, select, andsoc_close. Raw sockets do not support either accept or listen BSD services.

- By default, received IPv4 raw data includes the IPv4 header. Conversely, received IPv6 raw data does not include the IPv6 header.
- By default, when sending either raw IPv6 or IPv4 packets, the BSD wrapper layer adds the IPv6 or IPv4 header before sending the data.

The NetX Duo BSD supports additional raw socket options, includingIP_RAW_RX_NO_HEADER, IP_HDRINCL and IP_RAW_IPV6_HDRINCL. If IP_RAW_RX_NO_HEADER is set, the IPv4 header is removed so that the received data does not contain the IPv4 header, and the reported message length does not include the IPv4 header. For IPv6 sockets, by default the raw socket receive does not include the IPv6 header, equivalent to having the IP_RAW_RX_NO_HEADER option set. The application may use the setsockopt service to clear the IP_RAW_RX_NO_HEADER option. Once the IP_RAW_RX_NO_HEADEROption is cleared, the received IPv6 raw data would include the IPv6 header, and the reported message length includes the IPv6 header. This option has no effect on IPv4 or IPv6 transmitted data.

If IP_HDRINCL is set, the application includes the IPv4 header when sending data. This option has no effect on IPv6 transmission and is not defined by default. If the IP_RAW_IPV6_HDRINCL is set, the application includes the IPv6 header when sending data. This option has no effect on IPv4 transmission and is not defined by default.

IP_HDRINCLand IP_RAW_IPV6_HDRINCL have no effect on IPv4 or IPv6 reception.

Note

The BSD 4.3 Socket specification specifies that the kernel must copy the raw packet to each socket receive buffer. However, in NetX Duo BSD, if multiple sockets are created sharing the same protocol, the behavior is undefined.

Raw Packet Support for PPPoE (NetX Duo BSD only)

To enable the raw packet support for PPPoE, NX_BSD_RAW_PPPOE_SUPPORT must be defined in the project. To define it, right click on the project in the **Synergy Configuration pane**> **Properties**> **Cross ARM C Compiler**> **Preprocessor** and add this to the list of defined symbols by clicking on the (+) icon. This does not require that the NetX Duo library be rebuilt.

The following command creates a BSD socket to handle PPPoE raw packets:

sockfd = socket(AF_PACKET, SOCK_RAW, protocol);

The current BSD implementation only supports two protocol types in AF_PACKET family:

- ETHERTYPE_PPPOE_DISC: PPPoE Discovery packets. In the MAC data frame, the Discovery packets have the Ethernet frame type 0x8863.
- ETHERTYPE_PPPOE_SESS: PPP Session packets. In the MAC data frame, the Session packets have the Ethernet frame type 0x8864.

The data type sockaddr_ll (the ll stands for link layer) is used to specify parameters when sending or receiving PPPoE frames.

struct sockaddr_ll is declared as:

```
struct sockaddr_ll
```

```
{
USHORT sll_family; /* Must be AF_PACKET */
USHORT sll_protocol; /* LL frame type */
INTsll_ifindex; /* Interface Index. */
USHORT sll_hatype; /* Header type */
UCHAR sll_pkttype; /* Packet type */
UCHAR sll_halen; /* Length of address */
UCHAR sll_addr[8]; /* Physical layer address */
};
```

Note that not every field in the structure is used by sendto() or recvfrom(). See the following description on how to set up the sockaddr_ll for sending and receiving PPPoE packets.

A socket created in the AF_PACKET family can be used to send either PPPoE discovery packets or PPP session packets, regardless of the protocol specified. When transmitting a PPPoE packet, application must prepare the buffer that includes properly formatted PPPoE frame, including the MAC headers (destination MAC address, source MAC address, and frame type.) The size of the buffer includes the 14-byte Ethernet header.

In thesockaddr_ll struct, the sll_ifindex is used to indicate the physical interface to be used for sending this packet. The rest of the fields in the structure are not used. Values set to the unused fields are ignored by the BSD internal process.

The following code block illustrates how to transmit a PPPoE packet:

```
struct sockaddr_ll peer_addr;
/* Transmit the PPPoE frame using the primary network interface. */
peer_addr.sll_ifindex = 0;
n = sendto(sockfd, frame, frame_size, 0, (struct
sockaddr*)&peer_addr, sizeof(peer_addr));
```

The return value indicates the number of bytes transmitted. Since PPPoE packets are message-based, on a successful transmission, the number of bytes sent matches the size of the packet, including the 14-byte Ethernet header.

PPPoE packets can be received using recvfrom(). The receive buffer must be big enough to accommodate a message of ethernet MTU size. The received PPPoE packet includes a 14-byte ethernet header. On receiving PPPoE packets, PPPoE discovery packets can only be received by socket created with protocol ETHERTYPE_PPPOE_DISC. Similarly, PPP session packets can only be received by socket created with protocol ETHERTYPE_PPPOE_SESS. If multiple sockets are created for the same protocol type, arriving PPPoE packets are forwarded to the socket created first. If the first socket created for the protocol is closed, the next socket in the order of creation is used for receiving these packets.

After a PPPoE packet is received, the following fields in the sockaddr_ll structure are valid:

- sll_family: Set by the BSD internal to be AF_PACKET
- sll_ifindex: Indicates the interface from which the packet is received
- sll_protocol: Set to the type of packet received: ETHERTYPE_PPPOE_DISC or ETHERTYPE_PPPOE_SESS

NetX/NetX Duo BSD Support Module Important Operational Notes and Limitations

NetX/NetX Duo BSD Support Module Operational Notes

NetX BSD Build Requirements

- Add the NetX Source element to the configuration and set the Extended Notify Support property to enabled.
- Define the following property in the ThreadX Source element: TX_THREAD_EXTENSION_2 int bsd_errno; By default, all the EXTENSION macros are undefined;bsd_errno can also be defined as TX_THREAD_EXTENSION_1 or TX_THREAD_EXTENSION_0.

NetX BSD Socket Options

NetX BSD socket options can be enabled (or disabled) at run time on a per socket basis using the setsockopt service, which takes as one of its inputs option_level. There are two different settings for option_level. The first type is SOL_SOCKET for socket level options. The list of supported options are:

- SO_BROADCAST

  If set, this enables sending and receiving broadcast packets from NetX sockets. This is the default behavior for NetX Duo. All sockets have this capability.

- SO_ERROR

  Used to obtain socket status on the previous socket operation of the specified socket, using the getsockoptservice. All sockets have this capability.

- SO_KEEPALIVE

  If set, this enables the TCP Keep Alive feature. This requires the NetX Duo library to be built with NX_TCP_ENABLE_KEEPALIVE defined (setting the TCP Keepalive property to enabled in the NetX and NetX Duo Common stack element). By default, this feature is disabled.

- SO_RCVTIMEO

  This sets the wait option in seconds for receiving packets on NetX Duo BSD sockets. The default value is the NX_WAIT_FOREVER (0xFFFFFFFF) or, if non-blocking is enabled, NX_NO_WAIT (0x0).

- SO_RCVBUF

  This sets the window size of the TCP socket. The default value, NX_BSD_TCP_WINDOW, is set to 64 k for BSD TCP sockets. To set the size over 65535 requires the NetX Duo library to be built with the NX_TCP_ENABLE_WINDOW_SCALINGbe defined (setting the TCP Keepaliveproperty to enabled in the NetX and NetX Duo Common stack element).

- SO_REUSEADDR

If set, this enables multiple sockets to be mapped to one port. The typical usage is for the TCP Server socket. This is the default behavior of NetX sockets.

Note

The SO_ERROR option requires that the bsd_errno is defined. To define bsd_errno, add a NetX Source Stack below the NetX Common on the nx element. Or if using NetX Duo, add a NetX Duo Source element below the NetX Duo Common on the nxd element. Then add a ThreadX Source Stack element in the NetX Duo Source. Scroll down the list of Properties and choose one of the TX_THREAD_EXTENSION macros (0?2). Set the value as follows:

- int bsd_errno;

  This is explained in NetX BSD Build Requirements section above.

  The other type is IP_PROTO for options that are implemented at the IP layer and affect all sockets. The list of run time IP level options is shown below:

- IP_MULTICAST_TTL

  This sets the time to live for UDP sockets. The default value is NX_IP_TIME_TO_LIVE (0x80) when the socket is created. This value can be overridden by calling setsockoptwith this socket option before calling the socket service.

- IP_ADD_MEMBERSHIP

  If set, this option enables the BSD socket (applies only to UDP sockets) to join the specified IGMP group.

- IP_DROP_MEMBERSHIP

  If set, this option enables the BSD socket (applies only to UDP sockets) to leave the specified IGMP group.

The following options are only supported in NetX Duo BSD:

- IP_HDRINCL

  If this option is set, the calling application must append the IP header and optionally application headers to data being transmitted on raw IPv4 sockets created in BSD. To use this option, raw socket processing must be enabled on the IP task. See the previous section Raw Socket Support for specific details.

- IP_RAW_IPV6_HDRINCL

  If this option is set, the calling application must append an IPv6 header and optionally application headers to data being transmitted on raw IPv6 sockets created by BSD. To use this option, raw socket processing must be enabled on the IP task. See the previous section Raw Socket Support for specific details.

- IP_RAW_RX_NO_HEADER

  If cleared, the IPv6 header is included with the received data for raw IPv6 sockets created in BSD. IPv6 headers are removed by default in BSD raw IPv6 sockets, and the packet length does not include the IPv6 header. If set, the IPv4 header is removed from received data on

BSD raw sockets of type IPv4. IPv4 headers are included by default in BSD raw IPv4 sockets and packet length includes the IPv4 header. This option has no effect on either IPv4 or IPv6 transmission data. See the previous section Raw Socket Support for specific details on enabling raw packet support.

To retrieve an option setting, call getsockopt for the option name with option_level again set to SOL_SOCKET for socket level options or IP_PROTOfor IP level options.

More details on run time socket level options are available in the *NetX™ BSD 4.3 Socket API Wrapper for NetX User's Guide* for the Renesas Synergy™ Platform and *NetX Duo™ BSD 4.3 Socket API Wrapper for NetX Duo User's Guide* for the Renesas Synergy™ Platform documents available as described previously in the Introduction section.

- On some systems, there may be a conflict with definition of types in the native BSD. If this happens, include _POSIX_SOURCE among the project preprocessor definitions. This is done by right clicking at the top level of the project, **Properties**> **C/C++ Build**> **Settings**> **Cross ARM C Compiler (if using that project platform)**> **Preprocessor**.

NetX BSD Build Requirements

- Add the NetX Source element to the configuration and set the Extended Notify Support property to enabled.

- Define the following property in the ThreadX Source element:

  TX_THREAD_EXTENSION_2 int bsd_errno; By default, all the EXTENSION macros are undefined;bsd_errno can also be defined as TX_THREAD_EXTENSION_1 or TX_THREAD_EXTENSION_0.

NetX BSD Socket Options

NetX BSD socket options can be enabled (or disabled) at run time on a per socket basis using the setsockopt service, which takes as one of its inputs option_level. There are two different settings for option_level. The first type is SOL_SOCKET for socket level options. The list of supported options are:

- SO_BROADCAST

  If set, this enables sending and receiving broadcast packets from NetX sockets. This is the default behavior for NetX Duo. All sockets have this capability.

- SO_ERROR

  Used to obtain socket status on the previous socket operation of the specified socket, using the getsockoptservice. All sockets have this capability.

- SO_KEEPALIVE

  If set, this enables the TCP Keep Alive feature. This requires the NetX Duo library to be built with NX_TCP_ENABLE_KEEPALIVE defined (setting the TCP Keepalive property to enabled in the NetX and NetX Duo Common stack element). By default, this feature is disabled.

- SO_RCVTIMEO

This sets the wait option in seconds for receiving packets on NetX Duo BSD sockets. The default value is the NX_WAIT_FOREVER (0xFFFFFFFF) or, if non-blocking is enabled, NX_NO_WAIT (0x0.

- SO_RCVBUF

  This sets the window size of the TCP socket. The default value, NX_BSD_TCP_WINDOW, is set to 64 k for BSD TCP sockets. To set the size over 65535 requires the NetX Duo library to be built with the NX_TCP_ENABLE_WINDOW_SCALINGbe defined (setting the TCP Keepaliveproperty to enabled in the NetX and NetX Duo Common stack element).

- SO_REUSEADDR

  If set, this enables multiple sockets to be mapped to one port. The typical usage is for the TCP Server socket. This is the default behavior of NetX sockets.

Note

The SO_ERROR option requires that the bsd_errno is defined. To define bsd_errno, add a NetX Source Stack below the NetX Common on the nx element. Or if using NetX Duo, add a NetX Duo Source element below the NetX Duo Common on the nxd element. Then add a ThreadX Source Stack element in the NetX Duo Source. Scroll down the list of Properties and choose one of the TX_THREAD_EXTENSION macros (0?2). Set the value as follows:

- int bsd_errno;

  This is explained in NetX BSD Build Requirements section above.

  The other type is IP_PROTO for options that are implemented at the IP layer and affect all sockets. The list of run time IP level options is shown below:

- IP_MULTICAST_TTL

  This sets the time to live for UDP sockets. The default value is NX_IP_TIME_TO_LIVE (0x80) when the socket is created. This value can be overridden by calling setsockoptwith this socket option before calling the socket service.

- IP_ADD_MEMBERSHIP

  If set, this option enables the BSD socket (applies only to UDP sockets) to join the specified IGMP group.

- IP_DROP_MEMBERSHIP

  If set, this option enables the BSD socket (applies only to UDP sockets) to leave the specified IGMP group.

The following options are only supported in NetX Duo BSD:

- IP_HDRINCL

  If this option is set, the calling application must append the IP header and optionally application headers to data being transmitted on raw IPv4 sockets created in BSD. To use this option, raw socket processing must be enabled on the IP task. See the previous section Raw Socket Support for specific details.

- IP_RAW_IPV6_HDRINCL

  If this option is set, the calling application must append an IPv6 header and optionally application headers to data being transmitted on raw IPv6 sockets created by BSD. To use this option, raw socket processing must be enabled on the IP task. See the previous section Raw Socket Support for specific details.

- IP_RAW_RX_NO_HEADER

  If cleared, the IPv6 header is included with the received data for raw IPv6 sockets created in BSD. IPv6 headers are removed by default in BSD raw IPv6 sockets, and the packet length does not include the IPv6 header. If set, the IPv4 header is removed from received data on BSD raw sockets of type IPv4. IPv4 headers are included by default in BSD raw IPv4 sockets and packet length includes the IPv4 header. This option has no effect on either IPv4 or IPv6 transmission data. See the previous section Raw Socket Support for specific details on enabling raw packet support.

To retrieve an option setting, call getsockopt for the option name with option_level again set to SOL_SOCKET for socket level options or IP_PROTOfor IP level options.

More details on run time socket level options are available in the *NetX™ BSD 4.3 Socket API Wrapper for NetX User's Guide* for the Renesas Synergy™ Platform and *NetX Duo™ BSD 4.3 Socket API Wrapper for NetX Duo User's Guide* for the Renesas Synergy™ Platform documents available as described previously in the Introduction section.

- On some systems, there may be a conflict with definition of types in the native BSD. If this happens, include _POSIX_SOURCE among the project preprocessor definitions. This is done by right clicking at the top level of the project, **Properties**> **C/C++ Build**> **Settings**> **Cross ARM C Compiler (if using that project platform)**> **Preprocessor**.

NetX/NetX Duo BSD Support Module Limitations

- Only MSG_DONTWAIT and MSG_PEEK flags are supported for send, recv, sendto and recvfrom calls.
- NetX BSD socket level options are limited to:
  - SO_BROADCAST
  - SO_ERROR
  - SO_KEEPALIVE
  - SO_RCVTIMEO
  - SO_RCVBUF
  - SO_REUSEADDR
- NetX BSD IP level options are limited to:
  - IP_MULTICAST_TTL
  - IP_RAW_IPV6_HDRINCL (NetX Duo BSD only)
  - IP_ADD_MEMBERSHIP
  - IP_DROP_MEMBERSHIP
  - IP_HDRINCL(NetX Duo BSD only, raw sockets must be enabled)
  - IP_RAW_RX_NO_HEADER (NetX Duo BSD only, raw sockets must be enabled)
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.13.4 Including the NetX/NetX Duo BSD Support Module in an Application

This section describes how to include either or both the NetX and NetX Duo BSD Support module in

an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo BSD Support module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo BSD Support Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
NetX BSD Support	Threads	**New Stack**> **X-Ware**> **NetX**> **Protocols**> **NetX BSD Support**
NetX Duo BSD Support	Threads	**New Stack**> **X-Ware**> **NetX Duo**> **Protocols**> **NetX Duo BSD Support**

When the NetX and/or NetX Duo BSD Support module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

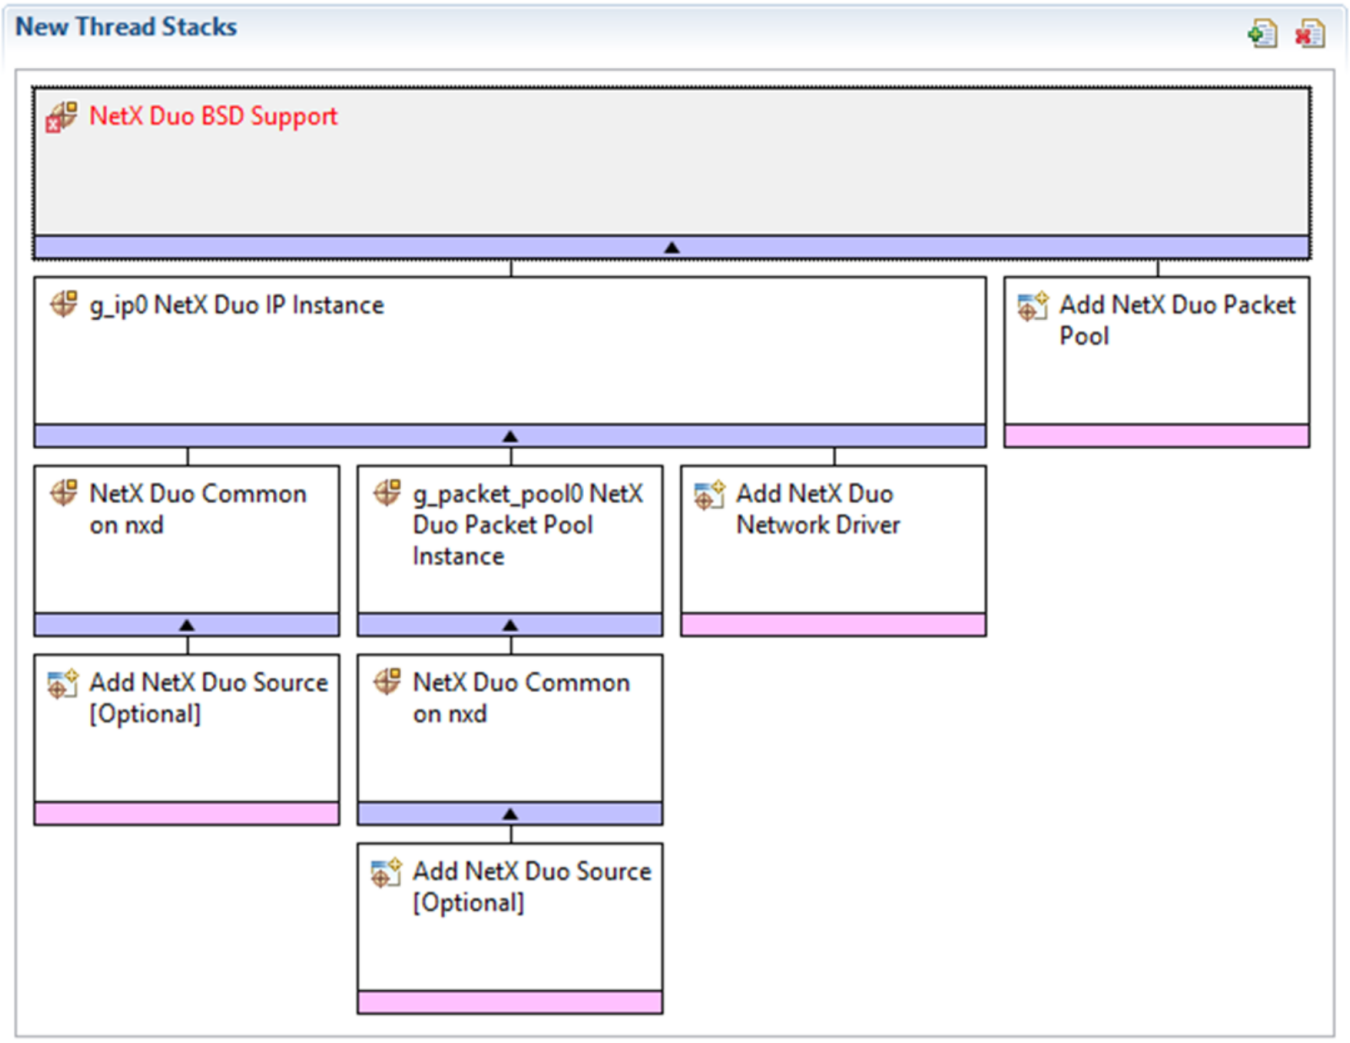

Figure 431: NetX/NetX Duo BSD Support Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.13.5 Configuring the NetX/NetX Duo BSD Support Module

The NetX/NetX Duo BSD Support module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This

approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo BSD Support Module

ISDE Property	Value	Description
NetX BSD Warning	Enable, Disable Default: Enable	NetX BSD warning selection.
Internal thread stack size(bytes)	2048	Internal thread stack size selection.
Internal thread priority	3	Internal thread priority selection.
Name of generated initialization function	nx_bsd_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different MAC or IP Addresses. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo BSD Support Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description

Name	g_ip0	Module name.
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection.
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection.
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection.
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection.
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection.
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection.
IP Helper Thread Priority	3	IP Helper Thread Priority selection.
ARP	Enable	ARP selection.
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection.
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection.
TCP	Enable, Disable Default: Enable	TCP selection.
UDP	Enable, Disable Default: Enable	UDP selection.
ICMP	Enable, Disable Default: Enable	ICMP selection.
IGMP	Enable, Disable Default: Enable	IGMP selection.
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection.
Name of generated initialization function	ip_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function.

Link status change callback	NULL	Link status change callback selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name.
Packet Size in Bytes	640	Packet size selection.
Number of Packets in Pool	16	Number of packets in pool selection.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo BSD Support Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator **Clock** tab prior to a build or by using the CGC interface at run-time.

NetX/NetX Duo BSD Support Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent

table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select **Peripherals**> **Connectivity:ETHERC**> **ETHERC1.RMII**

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1.
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection.
REF50CK	P701	REF50CK pin.
TXD0	P700	TXD0 pin.
TXD1	P406	TXD1 pin.
TXD_EN	P405	TXD_EN pin.
RXD0	P702	RXD0 pin.
RXD1	P703	RXD1 pin.
RX_ER	P704	RX_ER pin.
CRS_DV	P705	CRS_DV pin.
MDC	P403	MDC pin.
MDIO	P404	MDIO pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.13.6 Using the NetX/NetX Duo BSD Support Module in an Application

The steps in using the NetX and NetX Duo BSD Support module in a typical application are:

NetX BSD Client:

1. Poll the nx_ip_status_check API for when the IP instance has a valid IP address.
2. Create a socket using the socket API.
3. Create sockaddr_in for client and server defining IP address and port for client and server.
4. Bind to a local source port using the bind API.
5. Connect to the server using the connect API.
6. Obtain connection information using getpeername, getsockname services [Optional].
7. Send a packet to the Server using the send API.
8. Receive a packet using the recv API.
9. Close the socket using the soc_close API.

NetX BSD Server:

1. Poll the nx_ip_status_check API for when the IP instance has a valid IP address.

2. Create a master socket using the socket API.

3. Create sockaddr_in defining IP address and port for server.

4. Bind the socket to a port using the bind API.

5. Assign a local source port to listen for client requests using the listen API.

6. Check for socket requests (read, write, exception) using the select API.

7. Accept client requests and hand off the connection to a secondary socket using the accept API.

8. Receive packets using the recv API.

9. Send packets using the send API.

10. Close the socket using the soc_close API.

The following figure illustrates common steps in a typical operational flow diagram:

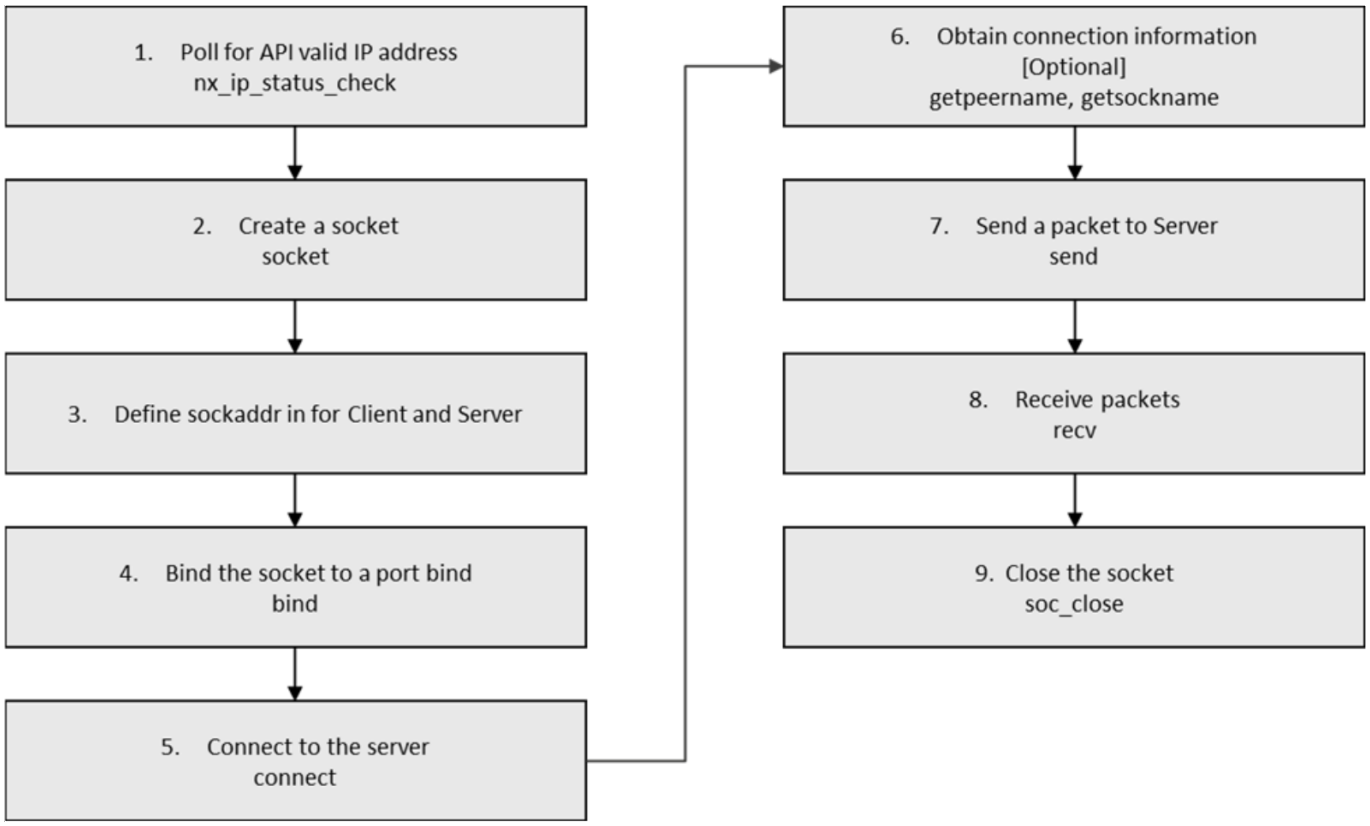

Figure 432: Flow Diagram of a Typical NetX BSD Client Module Application

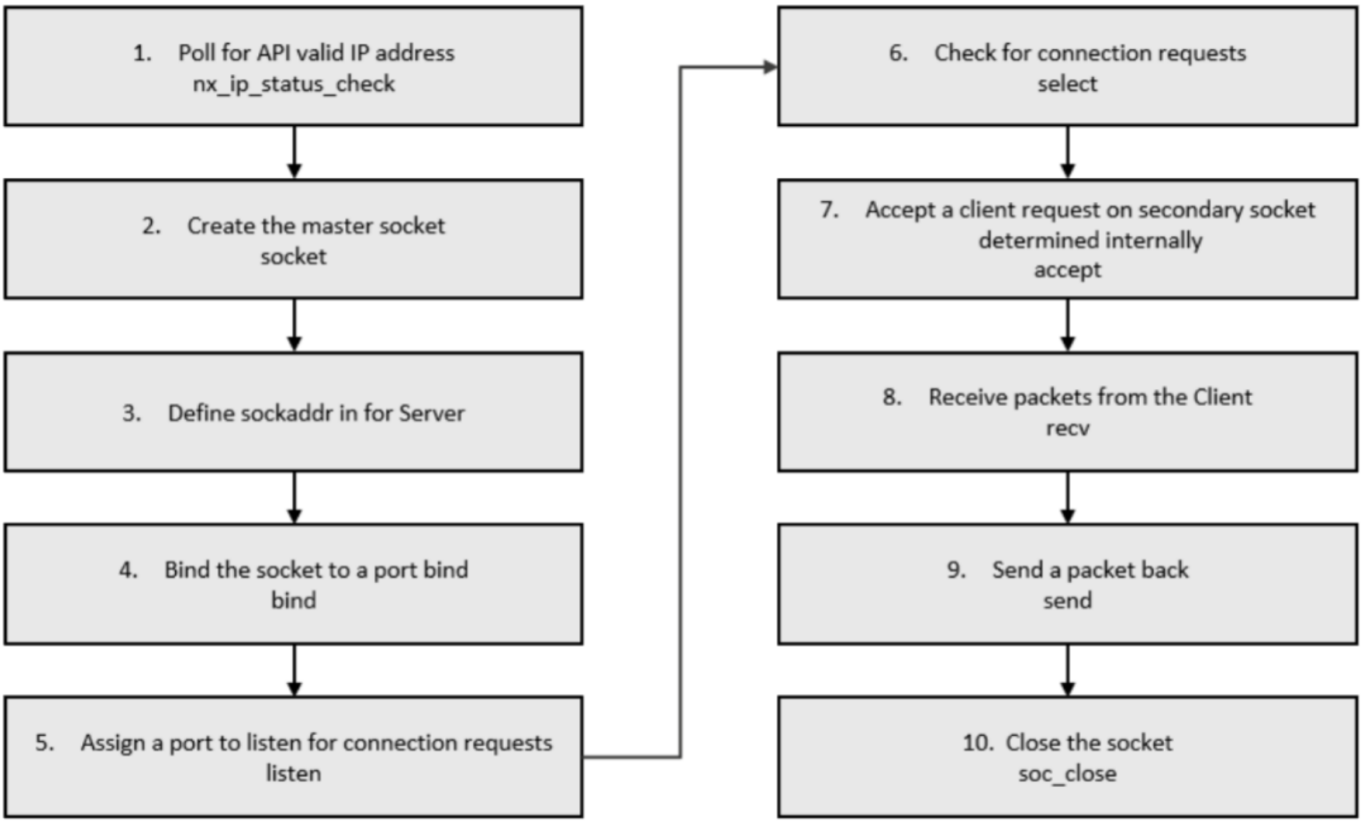

Figure 433: Flow Diagram of a Typical NetX BSD Server Module Application

NetX Duo BSD Client

1. Poll the nx_ip_status_check API for when the IP instance has a valid IP address.
2. Create a socket using the socket API.
3. Create sockaddr_in (or sockaddr_in6 for IPv6) defining IP (or IPv6) address and port for client and server.
4. Bind to a local source port using the bind API.
5. Connect to the server using the connect API.
6. Obtain connection information using getpeername, getsockname services [Optional]
7. Send a packet using the send API.
8. Receive packets using the recv and send API.
9. Close the socket using the soc_close API.

NetX Duo BSD Server

1. Poll the nx_ip_status_check API for when the IP instance has a valid IP address.
2. Create a master socket using the socket API.
3. Create sockaddr_in (or sockaddr_in6 for IPv6) defining IP (or IPv6) address and port for server Set socket options using the ioctl, setsockopt APIs
4. Bind the socket to a port using the bind API.
5. Assign a local source port to listen for client requests using the listen API.
6. Check for socket requests (read, write, exception) using the select API.
7. Accept client requests and hand off the connection to a secondary socket using the accept API.
8. Receive packets using the recv API.
9. Send packets using the send API.
10. Close the socket using the soc_close API

The following figure illustrates common steps in a typical operational flow diagram:

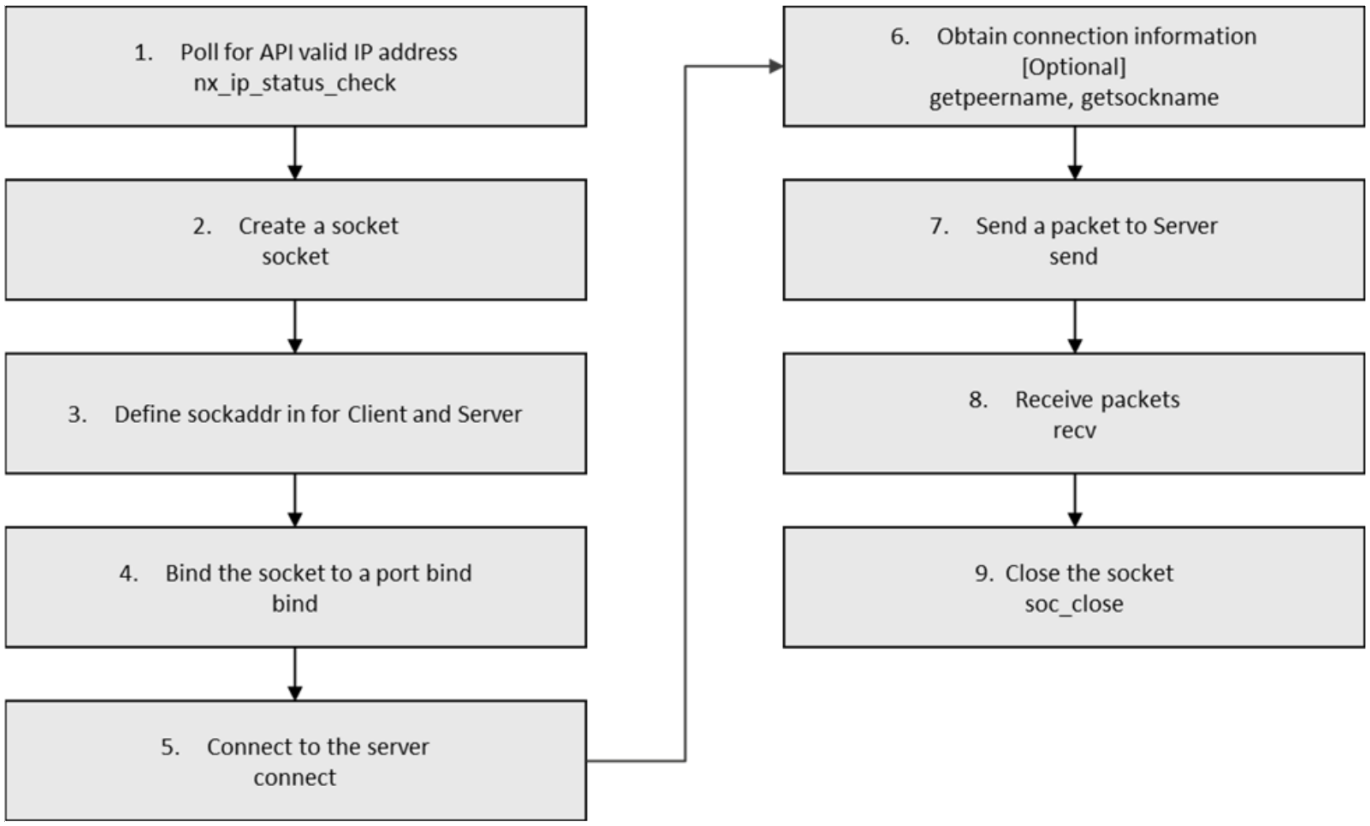

Figure 434: Flow Diagram of a Typical NetX Duo BSD Client Module Application

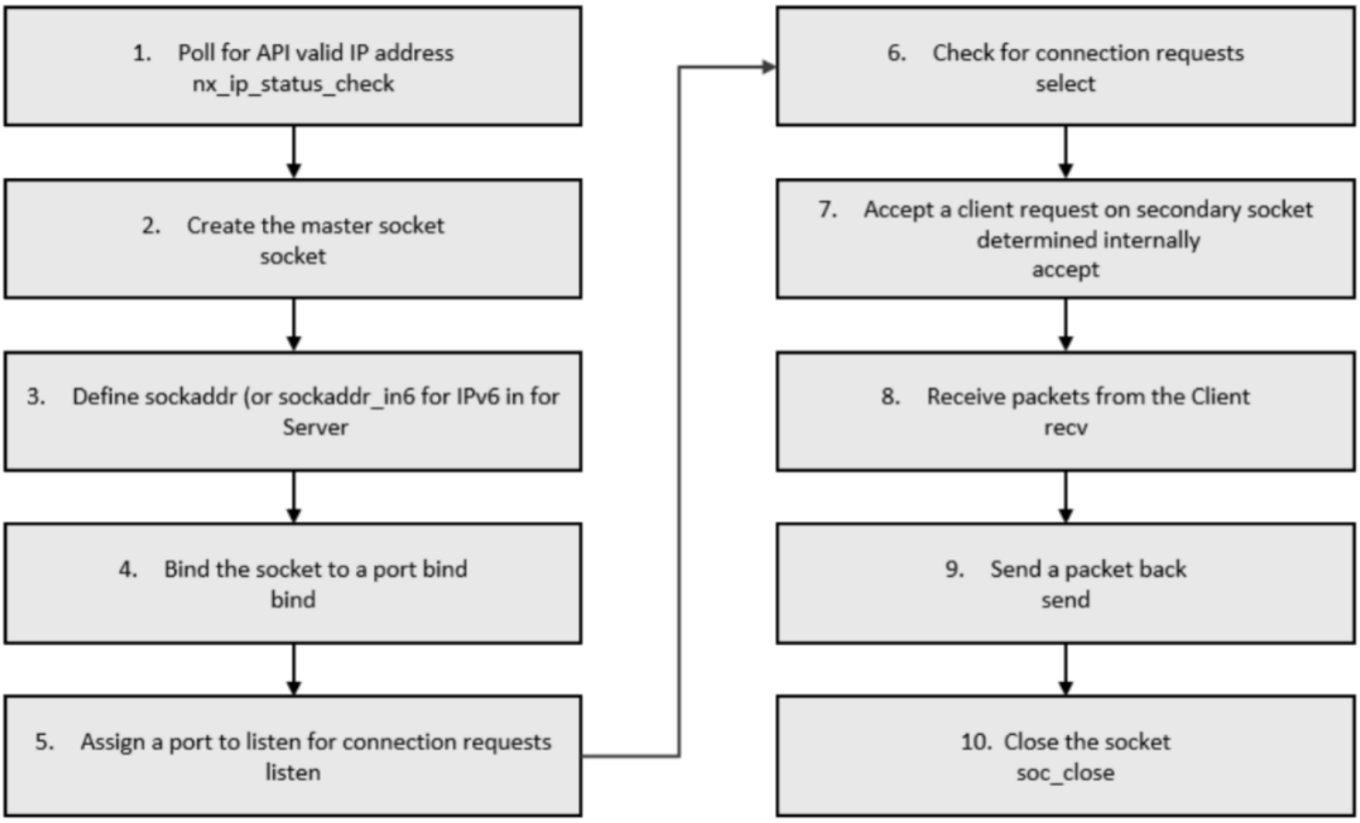

Figure 435: Flow Diagram of a Typical NetX Duo BSD Server Module Application

4.3.14 NetX/NetX Duo DHCP Client

4.3.14.1 NetX/NetX Duo DHCP Client Introduction

The Dynamic Host Configuration Protocol (DHCP) is used to obtain an IP address and network parameters. The DHCP is designed to extend the basic functionality of the BOOTP (which is limited to static address configuration) to include a completely dynamic IP address allocation through "leasing" an IP address to a client for a specified period of time. The DHCP can also be configured to allocate IP addresses in a static manner (like the BOOTP). An application's IP address is one of the supplied parameters for the NetX™ component. Supplying the IP address poses no problem if the IP address is known to the application, either statically or through the user configuration. When the application does not know or care what its IP address is, the NetX is initialized with a zero IP address; a DHCP client component added to NetX can then dynamically obtain an IP address.

In IPv6 networks, the DHCP protocol is of no use because it is limited to IPv4. Therefore, the DHCPv6 is the protocol used for dynamic global IPv6 address assignment from a DHCPv6 Server. This guide covers only the IPv4 version of DHCP, but applies to NetX™ and NetX™ Duo. A note will clearly identify where there are any differences in use between NetX and NetX Duo. To simplify wording in this document, NetX DHCPv4 will be used to stand for NetX and NetX Duo DHCP for IPv4.

NetX/NetX Duo DHCP Client Module Features

- The NetX/NetX Duo DHCP Client module is compliant with RFC2132, RFC2131 and related RFCs.
- The module provides high-level APIs to:
    - Create and delete a DHCP client instance
    - Start, stop, and reinitialize the DHCP client (to restart the DHCP client protocol)
    - Request a specific IP Address from the server
    - Specify the network interface to run the DHCP client on
    - Supply an application-created packet pool to the DHCP client

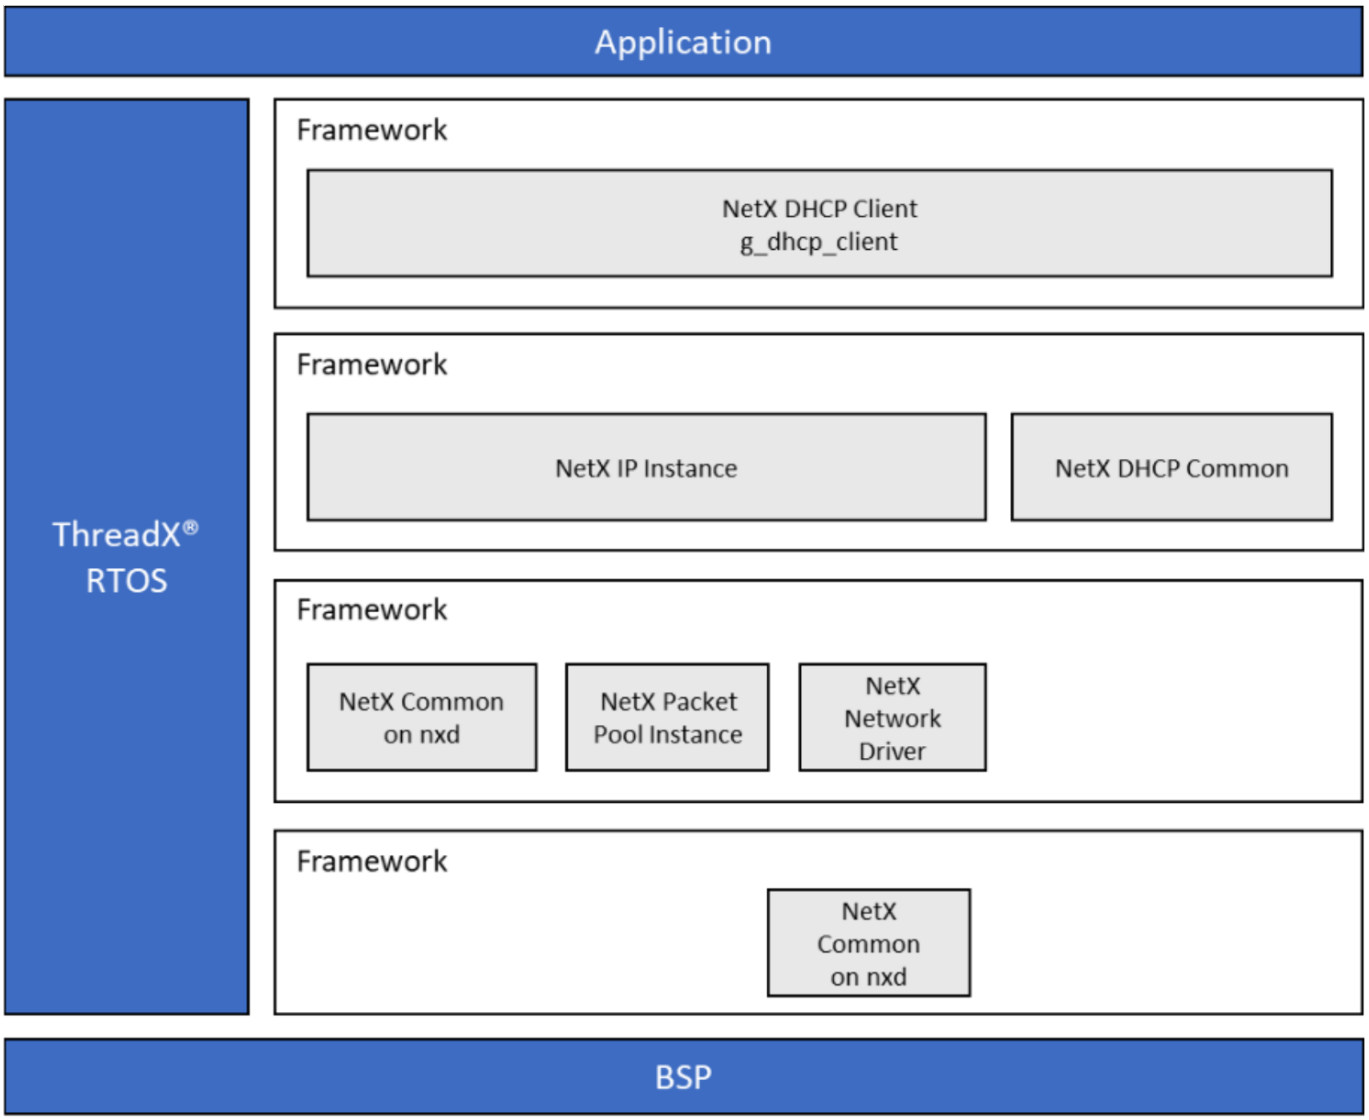

Figure 436: NetX/NetX Duo DHCP Client Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX/NetX Duo DHCP Client Module in an Application for additional details.

4.3.14.2 NetX/NetX Duo DHCP Client Module APIs Overview

The NetX/NetX Duo DHCP Client module defines APIs for creating and starting the DHCP client. Internally, the DHCP client handles all communication with the DHCP server to obtain an IP address. A list of the key API functions, an example API function call and a short description of each can be found in the following table. Additional function calls are described in the NetX DHCP Client User's Manual as describe in the note below the table. A table of status return values follows the API summary table.

NetX/NetX Duo DHCP Client Module API Summary

Function Name	Example API Call and Description

nx_dhcp_create	nx_dhcp_create(&my_dhcp, &my_ip, "My DHCP"); Create a DHCP instance.
nx_dhcp_clear_broadcast_flag	nx_dhcp_clear_broadcast_flag(&my_dhcp, NX_TRUE); Clear broadcast flag on Client messages.
nx_dhcp_delete	nx_dhcp_delete(&my_dhcp); Delete a DHCP instance.
nx_dhcp_decline	nx_dhcp_decline(&my_dhcp); Send Decline message to server.
nx_dhcp_force_renew	nx_dhcp_force_renew(&my_dhcp); Handle Server force renew message.

nx_dhcp_packet_pool_set	nx_packet_pool_create(&dhcp_pool, "DHCP Client Packet Pool",
	NX_DHCP_PACKET_PAYLOAD, pointer, (15 * NX_DHCP_PACKET_PAYLOAD));
	nx_dhcp_create(&dhcp_0, &ip_0, "janetsdhcp1");
	nx_dhcp_packet_pool_set(&my_dhcp, packet_pool_ptr);
	Set the DHCP Client packet pool. By default, the DHCP Client creates its own packet pool.

nx_dhcp_release	nx_dhcp_release(&my_dhcp); Send Release message to server.
nx_dhcp_reinitialize	nx_dhcp_reinitialize(&my_dhcp); Clear DHCP client network parameters and clear IP address and gateway registered with the IP instance.
nx_dhcp_request_client_ip	nx_dhcp_request_client_ip(&my_dhcp, IP(192,168,0,6), NX_TRUE); Request a specific IP address.
nx_dhcp_send_request	nx_dhcp_send_request(&my_dhcp, NX_DHCP_TYPE_INFORMREQUEST); Send DHCP message to server (only INFORM_REQUEST is allowed).
nx_dhcp_server_address_get	nx_dhcp_server_address_get(&dhcp_0, &server_address); Retrieve DHCP Client's DHCP server address*.*
nx_dhcp_set_interface_index	nx_dhcp_set_interface_index(&my_dhcp, 1); Specify the network interface to run DHCP Client.
nx_dhcp_start	nx_dhcp_start(&my_dhcp); Start DHCP processing.
nx_dhcp_state_change_notify	nx_dhcp_state_change_notify(&my_dhcp, my_state_change); Notify application of DHCP state change.

nx_dhcp_stop	nx_dhcp_stop(&my_dhcp); Stop DHCP processing.
nx_dhcp_user_option_retrieve	nx_dhcp_user_option_retrieve(&my_dhcp,NX_DHCP_OPTION_DNS_SVR,dns_ip_string, &size); Retrieve the specified DHCP option*.*
nx_dhcp_user_option_convert	nx_dhcp_user_option_convert(dns_ip_string); Convert four bytes to ULONG.
The following services require that *Persistent client state* be enabled	
nx_dhcp_suspend	nx_dhcp_suspend(&g_dhcp_client0); Suspend the DHCP Client thread.
nx_dhcp_resume	nx_dhcp_resume (&g_dhcp_client0); Resume the DHCP Client thread.
nx_dhcp_client_update_time_remaining	nx_dhcp_client_update_time_remaining(*g_dhcp_client0, 1000) This updates the time remaining on the IP lease by the input time in timer ticks, such as the time interval while the DHCP Client thread was suspended.
nx_dhcp_client_create_record	nx_dhcp_client_create_record(&g_dhcp_client0) This fills in a client record structure associated with the DHCP Client based on Client lease data.
nx_dhcp_client_restore_record	nx_dhcp_client_restore_record(&g_dhcp_client, client_record_ptr, time_elapsed)The Client record points to data to restore to the DHCP Client itself, and time elapsed is subtracted from the DHCP Client time remaining on its lease.

Note

For details on operation and definitions for additional API functions, the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual available in the Azure RTOS Component Documents for Renesas Synergy" zip file located at the bottom of the Renesas Synergy SSP web page here: https://www.renesas.com/en-us/products/synergy/software/ssp.html.

Status Return Values

Name	Description
NX_SUCCESS	Successful API call.
NX_PTR_ERROR*	Invalid pointer input.
NX_THREADS_ONLY_CALLER_CHECKING*	Invalid caller of this service.
NX_INVALID_INTERFACE	NetX is not enabled on the input interface
NX_NOT_ENABLED	Not enabled to set the DHCP Client packet pool.
NX_DHCP_NOT_STARTED	DHCP Client not started.

NX_DHCP_NOT_BOUND	The IP address has not been leased so the current operation is not allowed.
NX_DHCP_INVALID_MESSAGE	Illegal message type to send.
NX_DHCP_BAD_INTERFACE_INDEX*	An invalid network interface supplied.
NX_DHCP_UNKNOWN_OPTION	Unknown DHCP option to extract from DHCP server response.
NX_DHCP_INVALID_IP_REQUEST*	Invalid address for the DHCP Client to request.
NX_DHCP_INVALID_PAYLOAD	Packet pool for the DHCP Client has insufficient payload.
NX_DHCP_ALREADY_STARTED	DHCP Client thread task has already started.
NX_DHCP_PARSE_ERROR	Unable to parse requested option from Server response.
NX_DHCP_DEST_TO_SMALL	Supplied buffer too small to hold the requested option data for user requesting option data.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

- These are error codes which are only returned if error checking is enabled. Refer to the *NetX User Guide* for the Renesas Synergy™ Platform or *NetX Duo User's Guide* for the Renesas Synergy™ Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.14.3 NetX/NetX Duo DHCP Client Module Operational Overview

The DHCP Client module handles all the details in obtaining an IP address, registering it with the IP instance, and renewing the IP address lease before the lease expires.

A NetX IP instance is created; it has a zero IP address and is enabled for User Datagram Protocol (UDP) and the Address Resolution Protocol (ARP), respectively. The Reverse ARP (RARP) should not be enabled; a DHCP Client is then created. Its creation creates an UDP socket for sending and receiving DHCP messages. By default, the DHCP Client creates its own packet pool based on the settings *Minimum packet payload size* and *Number of packets in packet pool* (see the following table). The *Minimum Client packet payload size* must be large enough to include DHCP data, IP, UDP headers, and the physical frame header.

- For Ethernet networks, this minimum payload is 592 bytes, which is the default setting of *Minimum Client packet payload size.*
- For other network types (such as Wi-Fi), the frame-header size is larger, and minimum size must be increased correspondingly.

When the packet pool is created, the DHCP Client verifies that the packet payload is not less than the minimum required payload size.

The DHCP Client can request a specific IP address using the nx_dhcp_request_client_ip service and supply a non-zero IP address before starting the DHCP Client. Normally, the request is useful for a device previously assigned an IP address that wishes to keep the same IP address. Note: the server is not obligated to accommodate this request.

When the DHCP Client is started, it binds the socket to a DHCP port (by default 68) and begins sending and receiving packets through that socket. When the client is assigned an IP address, it automatically registers the IP address with NetX. The server supplies the network mask and network gateway, and the DHCP Client module updates NetX with that information.

When the server assigns the Client an IP address, it may also supply other network information, such as the DNS server and the NTP server. The application can obtain those values using the nx_dhcp_user_option_retrieve service.

The DHCP Client keeps track of the time remaining on the IP lease. It automatically sends Renew requests to the DHCP Server when time to renew. If the server is no longer on the network, or is otherwise not responding, the client sends broadcast requests to any DHCP Server on the network. If the lease expires without a renewal or rebinding, the client is returned to the NX_DHCP_STATE_INIT state. The device may continue to use the IP address. If a DHCP Server is later available, and the device is able to request an IP address, it must no longer use the old IP address.

In busy networks, a DHCP Client socket queue can fill up with non-specific DHCP broadcast packets intended for other DHCP Client hosts. If the DHCP Client socket receive-queue fills up, any packets intended for the device may get dropped. To avoid this problem, the DHCP Client continually clears non-specific broadcast packets from the socket.

The DHCP client module can register a callback to add options to the DHCP protocol using the nx_dhcp_user_option_add_callback_set API function. The DHCP option 60 (Vendor Class Identifier), and DHCP option 61 (Client Identifier), as well as other options, can be added for DHCP request using the registered callback. The DHCP module can chain multiple options and the options must fit in the normal payload. The Synergy configurator provides a default DHCP Option 60 addition callback. To enable the default callback, the **DHCP Option addition** and **DHCP Option addition function** properties must be set to Enable in the configurator.

NetX/NetX Duo DHCP Client Module Important Operational Notes and Limitations

NetX/NetX Duo DHCP Client Module Operational Notes

Instead of the DHCP Client module creating the packet pool, the developer may prefer to supply a previously created packet pool. To do so, enable the *Use application packet pool* option, then use the nx_dhcp_packet_pool_set service to set the DHCP Client's packet pool.

The DHCP Client verifies that the packet payload is not less than the minimum required packet size.

The IP address offered to the client should be tested for 'uniqueness' on the local network, since the DHCP protocol does not require the server to check. To configure the DHCP Client to check, enable the *Send ARP probe* option.

The DHCP Client sends a series of ARP "probes" with its assigned IP address out on the network. If any host responds to these ARP requests/probes, the DHCP Client automatically sends a DECLINE message to the server, and restarts the DHCP protocol to request another IP address. Otherwise, the DHCP Client proceeds to the bound state. The states of the client in the DHCP protocol are:

NX_DHCP_STATE_NOT_STARTED

NX_DHCP_STATE_INIT

NX_DHCP_STATE_SELECTING NX_DHCP_STATE_REQUESTING

NX_DHCP_STATE_BOUND

NX_DHCP_STATE_RENEWING

NX_DHCP_STATE_REBINDING

Note

If ARP probe is enabled, the NetX DHCP Client enters a temporary state called NX_DHCP_STATE_ADDRESS_PROBING before the NX_DHCP_STATE_BOUND state.*

The application can detect if the DHCP Client has completed (has an IP address) in a couple of ways. First, it can call the nx_ip_status_check service with the NX_IP_ADDRESS_RESOLVED option. Alternatively, it can use the _nx_dhcp_state_change_notify service which notifies the application when the DHCP Client state changes. When the DHCP Client reaches the bound state, (state == NX_DHCP_STATE_BOUND) it has a valid IP address.

If there is a need to stop the DHCP Client thread task, call the nx_dhcp_stop service. To restart the Client, first call the nx_dhcp_reinitialize service to clear the DHCP Client data and also clear network parameters registered with NetX. Then, the DHCP Client is restarted with the nx_dhcp_start call.

NetX/NetX Duo DHCP Client Module Limitations

- The DHCP Client does not support the INFORM_REQUEST message. The application can send this message out using the nx_dhcp_send_request service, but the data from the Server is not extracted and saved to the DHCP Client.
- The options supported _nx_dhcp_user_option_retrieve are limited to the following:
  - NX_DHCP_OPTION_SUBNET_MASK
  - NX_DHCP_OPTION_TIME_OFFSET
  - NX_DHCP_OPTION_GATEWAYS
  - NX_DHCP_OPTION_TIMESVR
  - NX_DHCP_OPTION_DNS_SVR
  - NX_DHCP_OPTION_NTP_SVR
  - NX_DHCP_OPTION_DHCP_LEASE
  - NX_DHCP_OPTION_DHCP_SERVER
  - NX_DHCP_OPTION_RENEWAL
  - NX_DHCP_OPTION_REBIND
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.14.4 Including the NetX/NetX Duo DHCP Client Module in an Application

This section describes how to include either or both the NetX and NetX Duo DHCP Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo DHCP Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo DHCP Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence

g_dhcp_client0 NetX DHCP Client	Threads	**New Stack> X-Ware> NetX> Protocols> NetX DHCP Client**
g_dhcp_client0 NetX Duo DHCP IPv4 Client	Threads	**New Stack> X-Ware> NetX Duo> Protocols> NetX Duo DHCP IPv4 Client**

When the NetX and/or NetX Duo DHCP Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

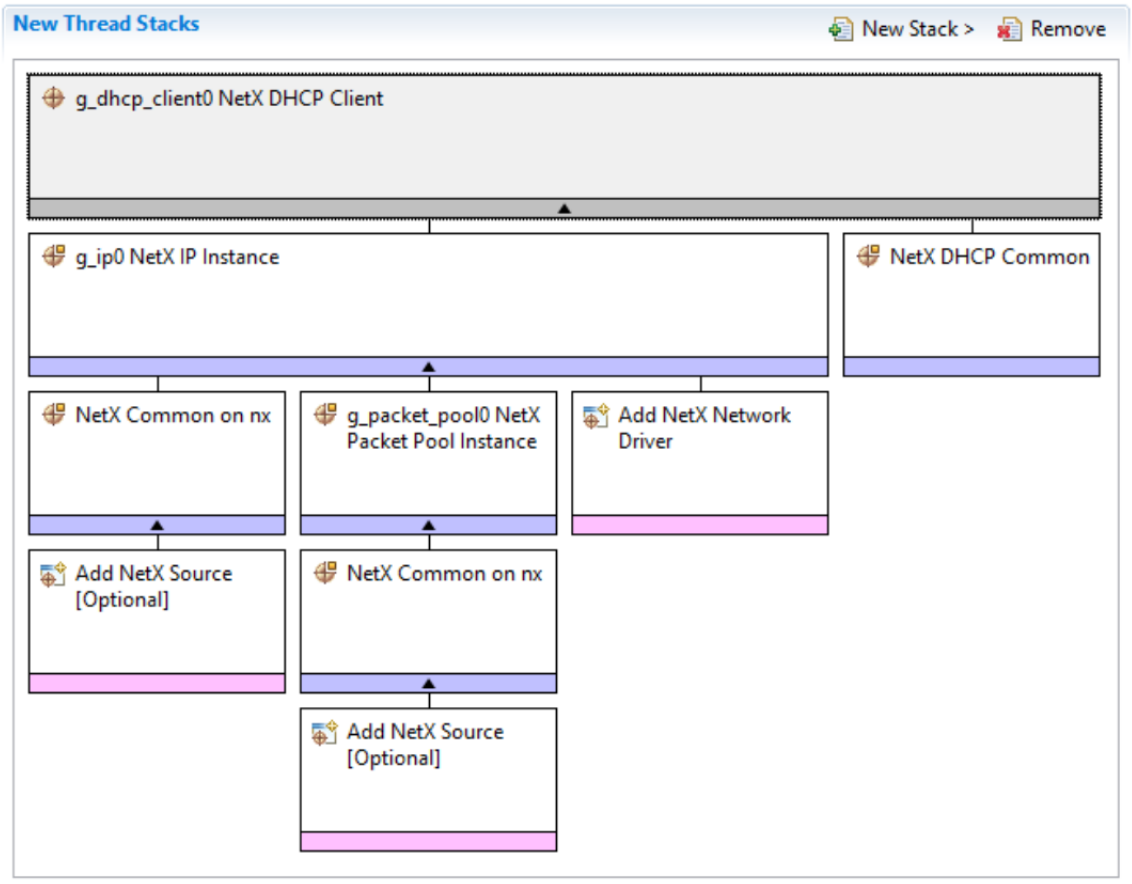

Figure 437: NetX/NetX Duo DHCP Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.14.5 Configuring the NetX/NetX Duo DHCP Client Module

The NetX/NetX Duo DHCP Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo DHCP Client Module

ISDE Property	Value	Description
Internal thread priority	3	Internal thread priority selection.
Internal thread stack size (bytes)	NetX Default: 2048 NetX Duo Default: 4096	Internal thread stack size (bytes) selection.
Timeout between DHCP messages processed (seconds)	1	Timeout between DHCP messages processed (seconds) selection.
Use BOOTP	Enable, Disable Default: Disable	Use BOOTP selection.
Send ARP probe	Enable, Disable Default: Disable	Send ARP probe selection.
ARP probe wait time (seconds)	1	ARP probe wait time selection.
Minimum ARP probe wait time (seconds)	1	Minimum ARP probe wait time selection.
Minimum ARP probe wait time (seconds)	2	Minimum ARP probe wait time selection.
ARP probe count	2	ARP probe count selection.

Maximum retransmission timeout (seconds)	64	Maximum retransmission timeout (seconds) selection.
Minimum renew timeout (seconds)	60	Minimum renew timeout (seconds) selection.
Minimum retransmission timeout (seconds)	4	Minimum retransmission timeout (seconds) selection.
Client packet payload size (bytes)	592	Client packet payload size (bytes) selection.
Number of packets in internal packet pool	5	Number of packets in internal packet pool selection.
Persistent client state	Enable, Disable Default: Disable	Persistent client state selection.
Use application packet pool	Enable, Disable Default: Disable	Use application packet pool selection.
Maximum message size support	Enable, Disable Default: Disable	Maximum message size support selection.
DHCP options buffer size (bytes)	312	DHCP options buffer size (bytes) selection.
Maximum DHCP client state record on an interface	1	Maximum DHCP client state record on an interface selection.
Wait before restarting the configuration process (seconds)	10	Wait before restarting the configuration process selection.
Name	g_dhcp_client0	Module name.
Name of generated initialization function	dhcp_client_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.
*DHCP Option addition	Enable, Disable Default: Enable	Enable or Disable feature to add DHCP Option to DHCP message.
*DHCP Option addition function	Enable, Disable Default: Enable	Enable or Disable Option Addition function.
*Name of the DHCP option addition function	dhcp_user_option_add_client0	Name for the option add function provided by the user.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

** Settings available in NetX implementation only.*

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different Ethernet interface pins and resets. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo DHCP Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name.
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection.
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection.
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection.
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection.
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection.
IP Helper Thread Priority	3	IP Helper Thread Priority selection.
ARP	Enable	ARP selection.
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection.
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection.
TCP	Enable, Disable Default: Enable	TCP selection.

UDP	Enable, Disable Default: Enable	UDP selection.
ICMP	Enable, Disable Default: Enable	ICMP selection.
IGMP	Enable, Disable Default: Enable	IGMP selection.
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection.
Name of generated initialization function	ip_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.
Link status change callback	Default: NULL	Name of user defined callback function if needed- otherwise set as NULL.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo DHCP Common Instance

ISDE Property	Value	Description
Type of Service for UDP requests	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Type of service UDP requests selection.
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragmentation option selection.
Time to live	128	Time to live selection.
Packet Queue depth	5	Packet queue depth selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name.
Packet Size in Bytes	640	Packet size selection.
Number of Packets in Pool	16	Number of packets in pool selection.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo DHCP Client Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX/NetX Duo DHCP Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence

ETHERC	Pins	Select **Peripherals**> **Connectivity:ETHERC**> **ETHERC1.RMII**

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1.
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection.
REF50CK	P701	REF50CK pin.
TXD0	P700	TXD0 pin.
TXD1	P406	TXD1 pin.
TXD_EN	P405	TXD_EN pin.
RXD0	P702	RXD0 pin.
RXD1	P703	RXD1 pin.
RX_ER	P704	RX_ER pin.
CRS_DV	P705	CRS_DV pin.
MDC	P403	MDC pin.
MDIO	P404	MDIO pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.14.6 Using the NetX/NetX Duo DHCP Client Module in an Application

The following example assumes a system that is already established with a working and enabled IP, ARP and UDP, and the link is running. Additionally, set the DHCP features for the DHCP Client (request specific IP address, clear the broadcast flag, set the interface on which DHCP Client runs, or set callback to configure the user options) before starting the DHCP Client. [Optional]

The steps in using the NetX/NetX Duo DHCP Client module in a typical application are:

1. Set the DHCP features for the DHCP Client (request specific IP address, clear the broadcast flag, set the interface on which DHCP Client runs) before starting the DHCP Client. [Optional]
2. Start the DHCP using the nx_dhcp_start API.
3. Wait for IP Address resolution by calling nx_ip_status_check (a NetX library service call) or check for the bound state in the DHCP Client state-change callback function.

4. A valid IP Address is now on lease and the application can start using NetX services for sending and receiving packets.
5. The DHCP Client will automatically request IP lease renewal based on the time remaining on the IP lease (as long as the DHCP Client thread task is still running). [Optional]
6. To stop the DHCP Client thread task, call the nx_dhcp_stop API.
7. To restart the DHCP Client, call the nx_dhcp_reinitialize API and then call the nx_dhcp_start API. [Optional]
8. Add or modify the existing DHCP Client settings. [Optional]

The following figure illustrates common steps in a typical operational flow diagram:

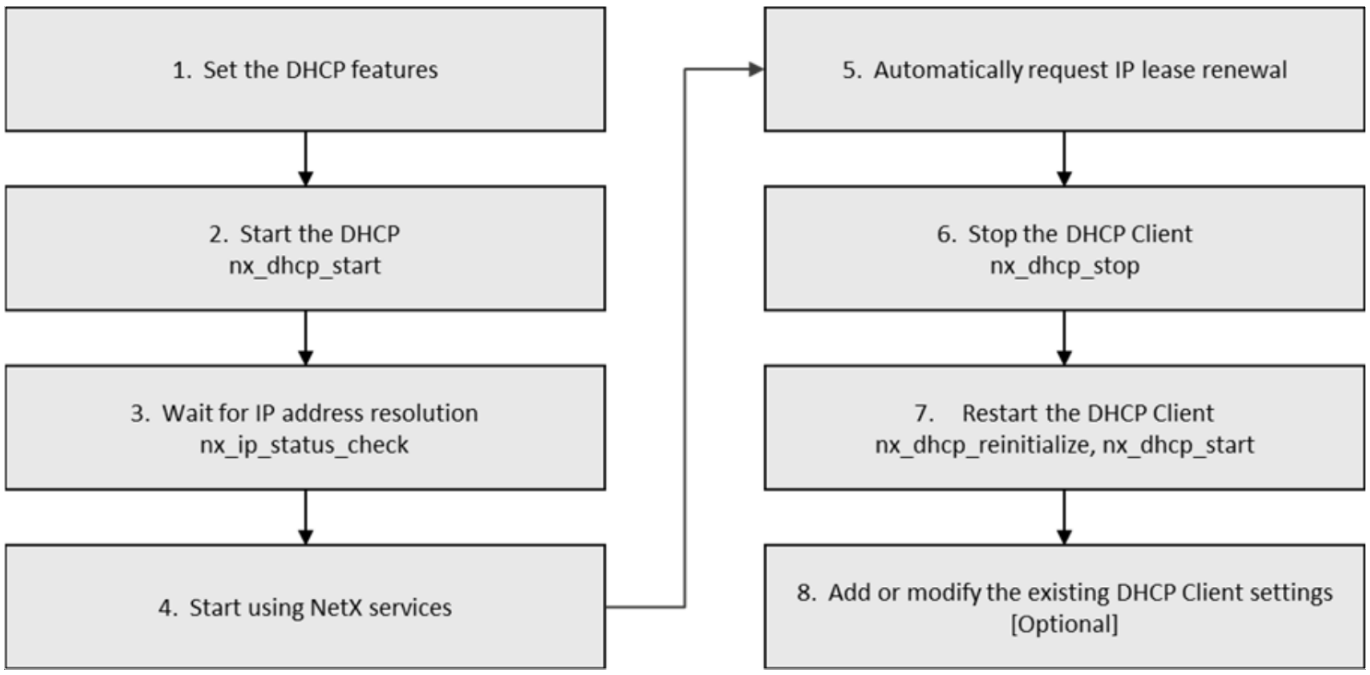

Figure 438: Flow Diagram of a Typical NetX/NetX Duo DHCP Client Module Application

4.3.15 NetX/NetX Duo DHCP Server

4.3.15.1 NetX/NetX Duo DHCP Server Introduction

The Dynamic Host Configuration Protocol (DHCP) is designed to completely automate DHCP Server allocation and dynamic IP address allocation through leasing an IP address to a client for a specified time.

In IPv6 networks, the DHCP protocol is of no use because it is limited to IPv4. Therefore, the DHCPv6 is the protocol used for dynamic global IPv6 address assignment from a DHCPv6 Server. This guide covers only the IPv4 version of DHCP, but applies to NetX™ and NetX™ Duo. A note will clearly identify where there are any differences in use between NetX and NetX Duo. To simplify wording in this document, NetX DHCPv4 will be used to stand for NetX and NetX Duo DHCP for IPv4.

NetX/NetX Duo DHCP Server Module Features

- The NetX DHCP is compliant with RFC2132, RFC2131 and related RFCs.
- Provides high-level APIs for:
    - Creating and deleting a DHCPv4 Server instance
    - Setting network parameters for DHCPv4 Server messages to the client
    - Creating a pool of assignable IP addresses
    - Starting and stopping the DHCP Server task thread

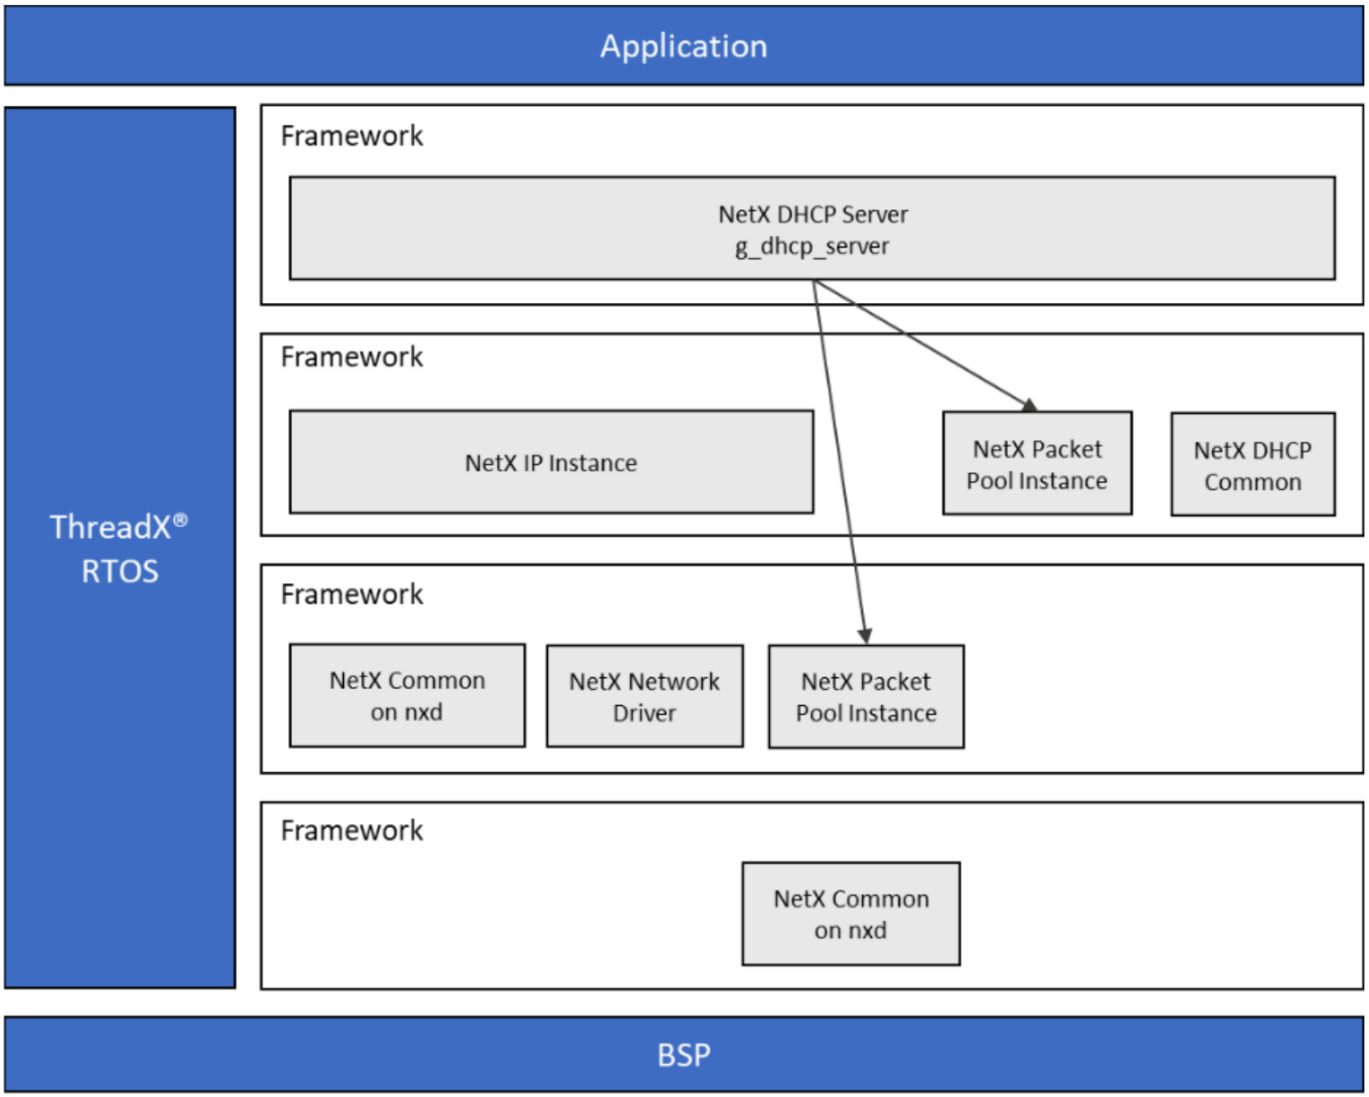

Figure 439: NetX/NetX Duo DHCP Server Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX/NetX Duo DHCP Server Module in an Application for additional details.

4.3.15.2 NetX/NetX Duo DHCP Server Module APIs Overview

The NetX DHCP Server defines APIs for creating, deleting, removing, starting, and stopping the server, for creating the pool of assignable IP addresses, and for setting up the network information for the client. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary

table.

NetX/NetX Duo DHCP Server Module API Summary

Function Name	Example API Call and Description
nx_dhcp_server_create	nx_dhcp_server_create(&dhcp_server, &server_ip, pointer, DEMO_SERVER_STACK_SIZE, SERVER_IP_ADDRESS_LIST, "DHCP server", &server_pool); Create a DHCP Server instance.
nx_dhcp_create_server_ip_address_list	nx_dhcp_create_server_ip_list (&dhcp_server, iface_index, START_IP_ADDRESS_LIST, END_IP_ADDRESS_LIST, &addresses_added); Create pool of available IP addresses to assign to DHCP Clients on the specified network index.
nx_dhcp_clear_client_record	nx_dhcp_clear_client_record (&dhcp_server, &dhcp_client_ptr); Remove Client record in the Server database.
nx_dhcp_set_interface_network_parameters	nx_dhcp_set_interface_network_parameters(&dhcp_server, iface_index, NX_DHCP_SUBNET_MASK, NX_DHCP_DEFAULT_GATEWAY, NX_DHCP_DNS_SERVER); Set DHCP options for adding critical network parameters on specified interface in messages to Clients.
nx_dhcp_server_delete	nx_dhcp_server_delete(&dhcp_server); Delete a DHCP Server instance.
nx_dhcp_server_start	nx_dhcp_server_start(&dhcp_server); Start or resume DHCP Server processing.
nx_dhcp_server_stop	nx_dhcp_server_stop(&dhcp_server); Stop DHCP server processing.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

Status Return Values

Name	Description
NX_SUCCESS	Successful DHCP call.
NX_PTR_ERROR*	Invalid pointer input.
NX_DHCP_PARAMETER_ERROR	Invalid non-pointer input.
NX_DHCP_INADEQUATE_PACKET_POOL_PAYLOAD	Packet payload too small error.

NX_DHCP_NO_SERVER_OPTION_LIST	Missing option list; cannot create Server.
NX_DHCP_SERVER_BAD_INTERFACE_INDEX	Index does not match addresses.
NX_DHCP_INVALID_IP_ADDRESS	Invalid IP address or network interface for creating Server address list.
NX_DHCP_INVALID_IP_ADDRESS_LIST	Illogical start/end IP addresses for Server list.
NX_DHCP_INVALID_NETWORK_PARAMETERS	Invalid network parameters for DHCP messages to Client.
NX_DHCP_SERVER_ALREADY_STARTED	The DHCP instance has already been started.
NX_DHCP_SERVER_NOT_STARTED	DHCP Server not started.
NX_CALLER_ERROR*	Invalid caller of service.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

- These are error codes which are only returned if error checking is enabled. Refer to the *NetX User Guide* for the Renesas Synergy™ Platform or *NetX Duo User's Guide* for the Renesas Synergy™ Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.15.3 NetX/NetX Duo DHCP Server Module Operational Overview

The DHCP server utilizes the UDP protocol to receive DHCP Client requests and transmit responses. It handles all details of creating an IP instance, initializing the driver, creating the UDP socket, and binding to the well-known DHCP port 67 to receive client requests.

The DHCP Server is assigned a packet pool when it is created. It can share the packet pool used by the IP instance (the IP default packet pool) or the module can create a separate one for the server. The packet payload must be large enough to include DHCP data, IP and UDP headers, and the physical frame header. DHCP data size is set by the Size of the BOOT Buffer (bytes) property, which defaults to 548 bytes.

Before starting the DHCP Server, the application must create a pool of assignable IP addresses; it does so by calling the nx_dhcp_create_server_ip_address_listservice. This service takes as input a starting IP address and an ending IP address. The server verifies the addresses are local network addresses. The DHCP Server services are interface-specific, including creating the IP address list and setting network parameters. The assumed network interface the DHCP Server is running on is the primary interface (index is zero). It fills a table of IP addresses sequentially starting at the starting IP address. The addresses_added pointer input returns the number of addresses added, which is equal to or less than the size of this table. The IP address table size is defined by the Maximum size of an IP addresses list property, which defaults to 20. There is one such table for each network interface on which the DHCP Server is receiving DHCP Client requests.

The DHCP Server keeps a record of each client (or rather the client's DISCOVER request) in its client record table. The record lives for as long as the client keeps the assigned IP address. If the client fails to renew, or fails to respond to the DHCP protocol before reaching the bound (IP address assigned) state, the record is deleted. One table holds all client records from all network interfaces on which the server receives DHCP requests. The size of the table is set by the Size of client record table (units) property, which defaults to 50.

Once the DHCP Server is running and has created client records and assigned IP addresses, it periodically checks the time remaining on each of the client IP leases. The length of the IP lease is set in the Client IP address lease time (seconds) property. The default value of 0xFFFFFFFF is essentially a permanent lease. To assign leases of finite length, set the lease to a more standard time. An example lease time might be 10 days (0x0d5930 or 874,800 seconds). The interval on which the DHCP Server checks the time remaining on assigned IP leases is set to 1000 seconds*.* If a lease expires, the server simply removes the client record from the client record table, and returns that IP address back to the pool of assignable IP addresses. No message is sent to the client. The client should have initiated renew or rebind requests before its lease expired; or possibly the client has left the network.

The DHCP Server also keeps an inactivity timeout on each client session. When a client sends a packet, the inactivity timeout for that client is reset. The interval on which the DHCP Server checks the time remaining is the Fast-periodic timer interval to check valid sessions (ticks), which defaults to 10 ticks*.* This session timeout is this value multiplied by the ratio of ticks per second to produce a session timeout of 10 seconds. If a client record session time out expires, that client's IP address is returned to the pool of assignable IP addresses and the client record is cleared. No message is sent to the client.

NetX/NetX Duo DHCP Server Module Important Operational Notes and Limitations

NetX/NetX Duo DHCP Server Module Operational Notes

- The options the DHCP Server provides to the client for critical network parameters are defined in the Server option list property and set to the default value 1 3 6, which are the option codes for the Subnet Mask, Router/Gateway address, and DNS Server IP address, respectively. The number of options is set in the Server option list size property, which defaults to 3.
- The DHCP Type (Option 53) and DHCP Server Identifier (Option 54) are the DHCP parameters the server must supply to the DHCP Client.

NetX/NetX Duo DHCP Server Module Limitations

- The choice of options the DHCP Server provides are limited to some or all the following: Subnet Mask (Option 1), Router/Gateway address (Option 3), and DNS Server IP address (Option 6). Therefore, setting the Server option list size to greater than three has no effect. Setting the list of options to an option other than 1,3 or 6 has no effect.
- The NetX DHCP Server does not verify that its assignable IP addresses are not in use elsewhere in the network. It is expected that the client will check the uniqueness of its IP address it is assigned.
- The NetX DHCP Server does not support the FORCE RENEW message.
- The Relay agent field of the DHCP header is left null because the NetX DHCP Server does not support out-of-network DHCP requests.
- The DHCP Server does not correctly update the time remaining on the assigned IP leased. The slow periodic timer interval is set to 1000 ticks. Internally, that value is converted to seconds, so the actual interval on which the server checks the IP lease timeout is about 1000 * 100 assuming there are 100 ticks per second on the NetX device. If the client lease time is left at the default value of 0xFFFFFFFF, this is a permanent lease until the client decides to release it and should not be affected by this bug.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.15.4 Including the NetX/NetX Duo DHCP Server Module in an Application

This section describes how to include either or both the NetX and NetX Duo DHCP Server module in

an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo DHCP Server module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo DHCP Server Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_dhcp_Server0NetXDHCPServer	Threads	**New Stack**> **X-Ware**> **NetX**> **Protocols**> **NetXDHCPServer**
g_dhcp_Server0NetX Duo DHCP IPv4Server	Threads	**New Stack**> **X-Ware**> **NetX Duo**> **Protocols**> **NetX Duo DHCP IPv4Server**

When the NetX and/or NetX Duo DHCP Server module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

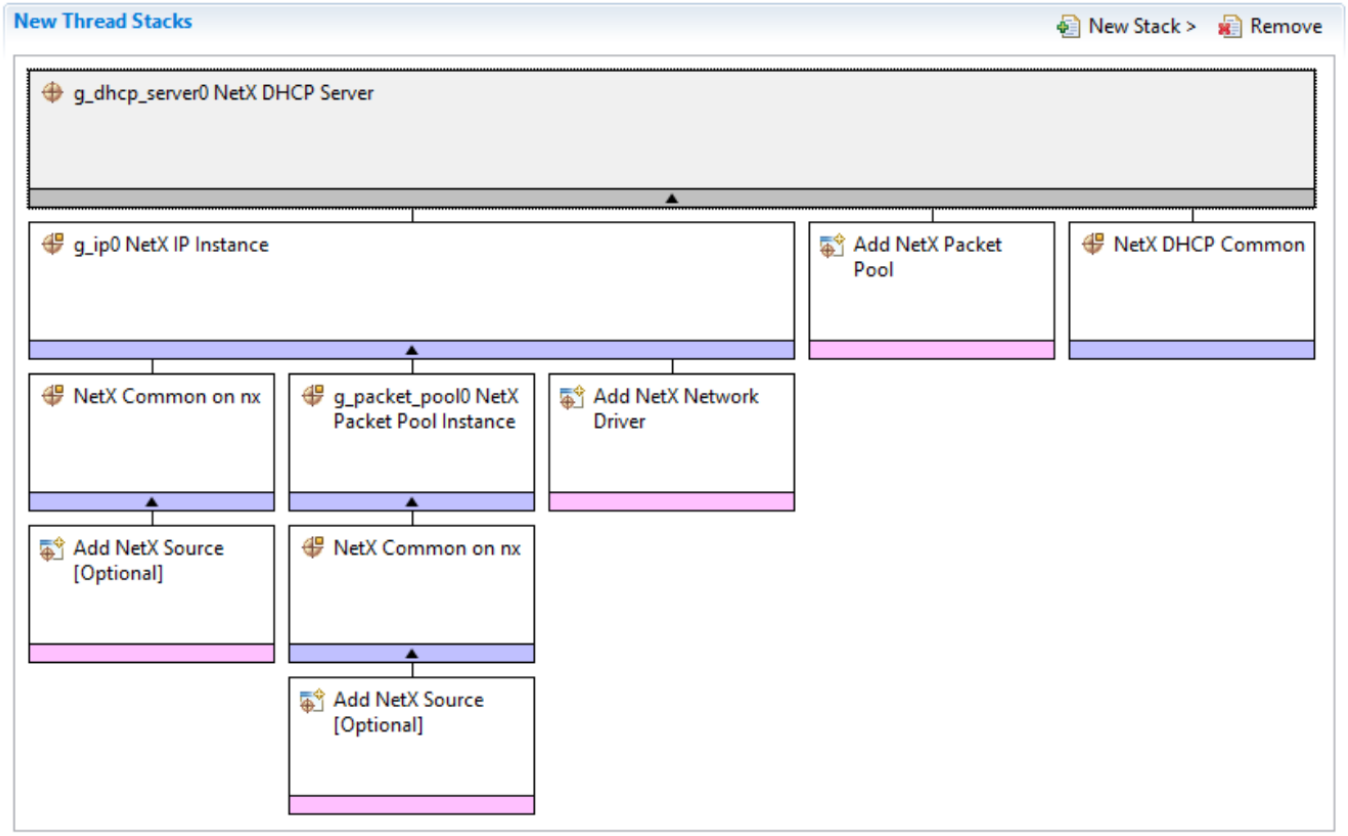

Figure 440: NetX/NetX Duo DHCP Server Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.15.5 Configuring the NetX/NetX Duo DHCP Server Module

The NetX/NetX Duo DHCP Server module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo DHCP Server Module

ISDE Property	Value	Description
Internal thread priority	1	Internal thread priority selection.
Packet allocate timeout (seconds)	2	Packet allocate timeout selection.
Fast periodic timer interval to check valid sessions (ticks)	10	Fast periodic timer interval to check valid sessions selection.
DHCP Client Session timeout - multiple of Fast periodic interval (seconds)	10	DHCP Client session timeout selection.
Client IP address default lease time (seconds)	0xFFFFFFFF	Client IP address lease time selection.
Slow periodic timer inverval to check IP lease expiration (seconds)	1000	Slow periodic timer inverval to check IP lease expiration selection.
Size of the array to contain options in client request (units)	12	Size of the array containing current requested options selection.
Server option list (optional - use space for separation	1 3 6	Module server option list selection.
Server option list size (optional)	3	Server option list size selection.
Size of the server host main buffer (bytes)	32	Size of the server host main buffer selection.
Size of the current client hostname buffer (byte)	32	Size of the current client hostname buffer selection.
Maximum size of an IP addresses list (units)	20	Maximum size of an IP addresses list selection.
Size of the client record table (units)	50	Size of the client record table selection.
Size of the BOOT buffer (bytes)	548	Size of the BOOT buffer selection.
Name	g_dhcp_server0	Module name.
Internal thread stack size (bytes)	NetX Default: 2048 NetX Duo Default: 4096	Internal thread stack size selection.
Name of generated initialization function	nx_dhcp_server_init0	Name of generated initialization function selection.

Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different Ethernet interface pins and resets. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo DHCP Server Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name.
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection.
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection.
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection.
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection.
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection.
IP Helper Thread Priority	3	IP Helper Thread Priority selection.
ARP	Enable	ARP selection.
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection.
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection.

TCP	Enable, Disable Default: Enable	TCP selection.
UDP	Enable, Disable Default: Enable	UDP selection.
ICMP	Enable, Disable Default: Enable	ICMP selection.
IGMP	Enable, Disable Default: Enable	IGMP selection.
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection.
Name of generated initialization function	ip_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo DHCP Common Instance

ISDE Property	Value	Description
Type of Service for UDP requests	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Type of service UDP requests selection.
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragmentation option selection.
Time to live	128	Time to live selection.
Packet Queue depth	5	Packet queue depth selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name.
Packet Size in Bytes	640	Packet size selection.
Number of Packets in Pool	16	Number of packets in pool selection.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo DHCP Server Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX/NetX Duo DHCP Server Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence

ETHERC	Pins	Select **Peripherals**> **Connectivity:ETHERC**> **ETHERC1.RMII**

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1.
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection.
REF50CK	P701	REF50CK pin.
TXD0	P700	TXD0 pin.
TXD1	P406	TXD1 pin.
TXD_EN	P405	TXD_EN pin.
RXD0	P702	RXD0 pin.
RXD1	P703	RXD1 pin.
RX_ER	P704	RX_ER pin.
CRS_DV	P705	CRS_DV pin.
MDC	P403	MDC pin.
MDIO	P404	MDIO pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.15.6 Using the NetX/NetX Duo DHCP Server Module in an Application

The steps in using the NetX/NetX Duo DHCP Server module in a typical application are:

1. Create a pool of assignable IP addresses using the nx_dhcp_create_server_ip_address_list API.
2. Set network parameters that will be returned by the server using the nx_dhcp_set_interface_network_parameters API.
3. Start the DHCPv4 server with the nx_dhcp_server_start API.

The following figure illustrates common steps in a typical operational flow diagram:

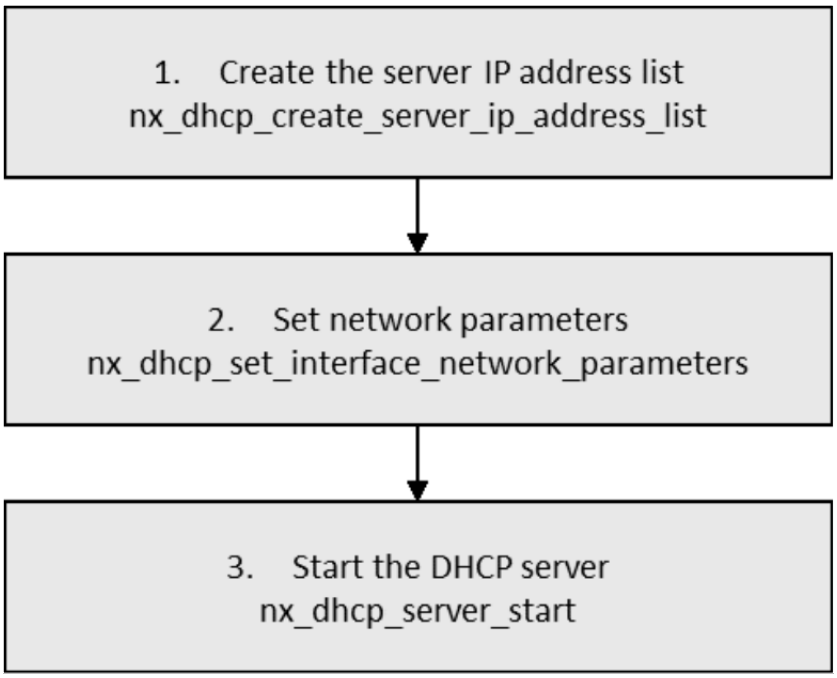

Figure 441: Flow Diagram of a Typical NetX/NetX Duo DHCP Server Module Application

4.3.16 NetX Duo DHCPv6 Client

4.3.16.1 NetX Duo DHCP IPv6 Client Introduction

The Dynamic Host Configuration Protocol (DHCP) is used to obtain an IP address and network parameters. The DHCP is designed to extend the basic functionality of the BOOTP (which is limited to static address configuration) to include a completely dynamic IP address allocation through "leasing" an IP address to a client for a specified period of time. The DHCP can also be configured to allocate IP addresses in a static manner (like the BOOTP). An application's IP address is one of the supplied parameters for the NetX™ component. Supplying the IP address poses no problem if the IP address is known to the application, either statically or through the user configuration. When the application does not know or care what its IP address is, the NetX is initialized with a zero IP address; a DHCP client component added to NetX can then dynamically obtain an IP address.

The document covers the NetX Duo DHCPv6 Client API and how it is used to obtain IPv6 addresses. In IPv6 networks, DHCPv6 (instead of DHCP) is used for dynamic global IPv6 address assignment from a DHCPv6 server. DHCPv6 offers many of the same features, as well as several enhancements.

NetX Duo DHCP IPv6 Client Module Features

- NetX Duo DHCPv6 Client is compliant with RFC 3315, RFC 3646, and related RFCs.
- Provides high-level APIs for:
    - Creating and deleting a DHCPv6 Client instance
    - Starting and stopping a DHCPv6 Client
    - Message sending and processing
    - Retrieving DHCPv6 data from the DHCPv6 Client

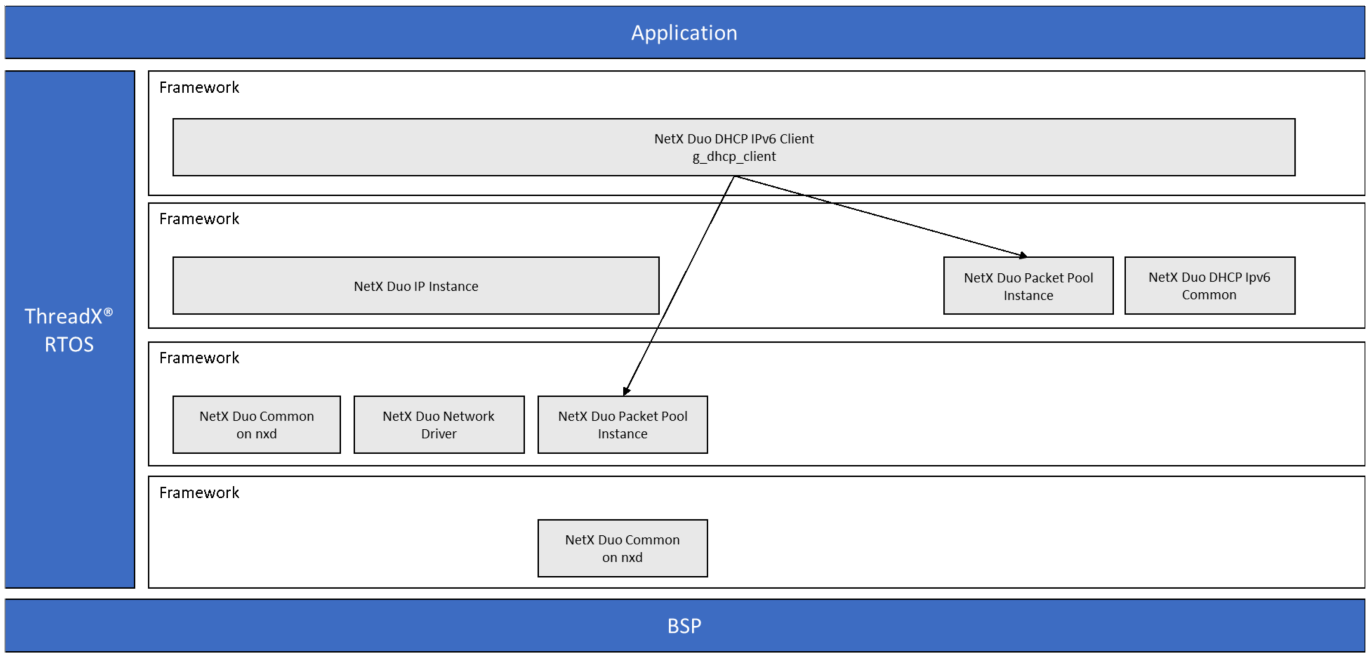

Figure 442: NetX Duo DHCP IPv6 Client Module Block Diagram

Note

In the figure above, the NetX Duo Network Driver module has multiple implementation options available. See the description just after the module stack figure in Including the NetX Duo DHCP IPv6 Client Module in an Application for additional details.

4.3.16.2 NetX Duo DHCP IPv6 Client Module APIs Overview

The NetX Duo DHCPv6 Client framework defines APIs for creating, deleting, adding and getting client information. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX Duo DHCP IPv6 Client Module API Summary

Function Name	Example API Call and Description
nx_dhcpv6_client_create	nx_dhcpv6_client_create(&dhcp_0, &ip_0, "DHCPv6 Client", &pool_0,NULL, NULL, pointer, 2048, dhcpv6_state_change_notify, dhcpv6_server_error_handler); Create a DHCPv6 Client instance.
nx_dhcpv6_client_delete	nx_dhcpv6_client_delete(&my_dhcp); Delete a DHCPv6 Client instance.
nx_dhcpv6_client_set_interface	nx_dhcpv6_client_set_interface(&dhcp_0, index); Set the Client network interface for communications with the DHCPv6 Server.
nx_dhcpv6_create_client_duid	nx_dhcpv6_create_client_duid(&dhcp_0, NX_DHCPV6_DUID_TYPE_LINK_TIME, NX_DHCPV6_HW_TYPE_IEEE_802, 0) Create a DHCPv6 Client DUID.

nx_dhcpv6_create_client_ia	nx_dhcpv6_create_client_ia(&dhcp_0, &ipv6_address, NX_DHCPV6_PREFERRED_LIFETIME, NX_DHCPV6_VALID_LIFETIME); Legacy Add a DHCPv6 Client Identity Address (IA).
nx_dhcpv6_create_client_iana	nx_dhcpv6_create_client_iana(&dhcp_0, DHCPV6_IA_ID, DHCPV6_T1, DHCPV6_T2); Create a DHCPv6 Client Identity Association for Non-Temporary Addresses (IANA).
nx_dhcpv6_add_client_ia	nx_dhcpv6_add_client_ia(&dhcp_0, &ipv6_address, NX_DHCPV6_PREFERRED_LIFETIME, NX_DHCPV6_VALID_LIFETIME); Add a DHCPv6 Client Identity Address (IA).
nx_dhcpv6_get_client_duid_time_id	nx_dhcpv6_get_client_duid_time_id(&dhcp_0, &time_ID); Get the time ID from DHCPv6 Client DUID.

nx_dhcpv6_get_ip_address	nx_dhcpv6_get_IP_address(&dhcp_0, &ipv6_address);
	nxd_ipv6_address_set(&ip_0, 0, &ipv6_address, 64, &address_index);
	Get the global IPv6 address assigned to the DHCPv6 client.

nx_dhcpv6_get_lease_time_data	nx_dhcpv6_get_lease_time_data(&dhcp_0, &T1, &T2, &preferred_lifetime, &valid_lifetime); Get T1 and T2 in the Identity Association (IANA) leased to the DHCPv6 Client.
nx_dhcpv6_get_iana_lease_time	nx_dhcpv6_get_iana_lease_time(&dhcp_0, &T1, &T2); Get T1, T2, valid and preferred lifetimes for the DHCPv6 Client IPv6 address by address index.
nx_dhcpv6_get_valid_ip_address_count	nx_dhcpv6_get_valid_ip_address_count(&dhcp_0, &address_count); This service retrieves the count of the Client's valid IPv6 addresses. A valid IPv6 address is bound (assigned) to the Client and registered with the IP instance. Also useful for determining if the DHPCv6 Client has reached the bound state.
nx_dhcpv6_get_valid_ip_address_lease_time	nx_dhcpv6_get_valid_ip_address_lease_time(&dhcp_0, &ip_address, &preferred_lifetime, &valid_lifetime); Get T1, T2, valid and preferred lifetimes for the DHCPv6 Client IPv6 address by address index.
nx_dhcpv6_get_DNS_server_address	nx_dhcpv6_get_DNS_server_address(&dhcp_0, index, &server_address); Get DNS Server address at the specified index into the DHCPv6 Client DNS server list.

nx_dhcpv6_get_other_option_data	nx_dhcpv6_get_other_option_data(&dhcp_0, option_code, buffer); Get the specified option data, such as domain name or time zone server.
nx_dhcpv6_get_time_accrued	nx_dhcpv6_get_time_accrued(&dhcp_0, &time_accrued); Get the time accrued the global IPv6 address lease has been bound to the DHCPv6 Client.
nx_dhcpv6_get_time_server_address	nx_dhcpv6_get_time_server_address(&dhcp_0, index, &server_address); Get Time Server address at the specified index into the DHCPv6 Client Time server list.
nx_dhcpv6_reinitialize	nx_dhcpv6_reinitialize(&dhcp_0); Reinitialize the DHCPv6 for restarting the DHCPv6 Client state machine and rerunning the DHCPv6 protocol.
nx_dhcpv6_request_confirm	nx_dhcpv6_request_confirm(&dhcp_0); Send a CONFIRM request to the Server.
nx_dhcpv6_request_inform_request	nx_dhcpv6_request_inform_request(&dhcp_0); Send an INFORM REQUEST message to the Server.
nx_dhcpv6_request_option_DNS_server	nx_dhcpv6_request_option_DNS_server(&dhcp_0, NX_TRUE); Add the DNS server option to the Client option request data in request messages to the Server.
nx_dhcpv6_request_option_FQDN	nx_dhcpv6_request_option_FQDN(&dhcp_0, "DHCPv6_Client", NX_DHCPV6_CLIENT_DESIRES_NO_SERVER_DNS_UPDATE); Add the FQDN option to the Client option request data in request messages to the Server.
nx_dhcpv6_request_option_domain_name	nx_dhcpv6_request_option_domain_name(&dhcp_0, NX_TRUE); Add the domain name option to the Client option request data in request messages to the Server.
nx_dhcpv6_request_option_time_server	nx_dhcpv6_request_option_time_server(&dhcp_0, NX_TRUE); Add the time server option to the Client option request data in request messages to the Server.
nx_dhcpv6_request_option_timezone	nx_dhcpv6_request_option_timezone(&dhcp_0, NX_TRUE); Add the time zone option to the Client option request data in request messages to the Server.
nx_dhcpv6_request_release	nx_dhcpv6_request_release(&dhcp_0); Send a RELEASE request to the Server.
nx_dhcpv6_request_solicit	nx_dhcpv6_request_solicit(&dhcp_0); Send a DHCPv6 SOLICIT request to any Server on the Client network (broadcast).

nx_dhcpv6_request_solicit_rapid	nx_dhcpv6_request_solicit_rapid(&dhcp_0); Send a DHCPv6 SOLICIT request to any Server on the Client network (broadcast) with the Rapid Commit option set.
nx_dhcpv6_resume	nx_dhcpv6_resume(&dhcp_0); Resume DHCPv6 Client processing.
nx_dhcpv6_set_time_accrued	nx_dhcpv6_set_time_accrued(&dhcp_0, time_accrued); Set the time accrued on the global Client IPv6 address lease in the Client record.
nx_dhcpv6_start	nx_dhcpv6_start(&dhcp_0); Start the DHCPv6 Client thread task. Note this is not equivalent to starting the DHCPv6 state machine and does not send a SOLICIT request.
nx_dhcpv6_stop	nx_dhcpv6_stop(&dhcp_0); Stop the DHCPv6 Client thread task.
nx_dhcpv6_suspend	nx_dhcpv6_suspend(&dhcp_0); Suspend the DHCPv6 Client thread task.
The following services are available if NX_DHCPV6_CLIENT_RESTORE_STATE is defined for the project:	
nx_dhcpv6_client_get_record	nx_dhcpv6_client_get_record(dhcpv6_ptr, client_record_ptr); Obtain a record of the client state (to save to non-volatile memory)
nx_dhcpv6_client_restore_record	nx_dhcpv6_client_restore_record(dhcpv6_ptr, client_record_ptr, time_elapsed); Apply saved client record to the current Client instance. Note the DHCPv6 Client thread must be not be running when this task is called.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

Status Return Values

Name	Description
NX_SUCCESS	Successful API call.
NX_PTR_ERROR*	Invalid pointer input.
NX_CALLER_ERROR*	Must be called from thread.
NX_DHCPV6_PARAM_ERROR	Invalid non pointer input.
NX_INVALID_INTERFACE	Invalid interface index input.
NX_DHCPV6_UNSUPPORTED_DUID_TYPE	DUID type unknown or not supported.

NX_DHCPV6_UNSUPPORTED_DUID_HW_TYPE	DUID hardware type unknown or not supported.
NX_DHCPV6_IA_ADDRESS_ALREADY_EXIST	Duplicate IA address.
NX_DHCPV6_REACHED_MAX_IA_ADDRESS	IA exceeds the max IAs Client can store.
NX_DHCPV6_INVALID_IA_ADDRESS	Invalid (for example, null) IA address in IA.
NX_DHCPV6_IA_ADDRESS_NOT_VALID	IPv6 address successfully assigned.
NX_DHCPV6_UNKNOWN_OPTION	Unknown/unsupported option code.
NX_DHCPV6_ALREADY_STARTED	DHCPv6 Client is already running.
NX_DHCPV6_NOT_STARTED	DHCPv6 Client task not started.
NX_DHCPV6_MISSING_REQUIRED_OPTIONS	Client missing required options.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

- These are error codes which are only returned if error checking is enabled. Refer to the *NetX User Guide* for the Renesas Synergy™ Platform or *NetX Duo User's Guide* for the Renesas Synergy™ Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.16.3 NetX Duo DHCP IPv6 Client Module Operational Overview

The DHCPv6 protocol also uses the UDP to dynamically obtain IPv6 addresses. A NetX Duo IP instance is created automatically, and UDP, IPv6, and ICMPv6 are enabled on the IP instance prior to creating the DHCPv6 Client. When the DHCPv6 Client is created, a UDP socket is created and bound to port 546. The *IPv6 Global Address* property of the IP instance is locked to a zero IPv6 address; otherwise, the IPv4 address may be any network IP address. If the IP instance *IPv6 Link Local Address* property is set to zero, the DHCPv6 Client creates the link local address from the MAC address. The MAC address is set in the NetX Port ETHER instance. See *Channel 1 MAC Address High Bits* and *Channel 1 MAC Address Low Bits* properties. This is the source address for DHCPv6 messages to the server.

To begin the process of requesting a global IPv6 address assignment, a Client first broadcasts a SOLICIT message using the nx_dhcpv6_request_solicit service. In IPv6, the broadcast address is the All_DHCP_Relay_Agents_and_Servers address (FF02::1:2.). A DHCPv6 Server responds with an ADVERTISE message containing a global IPv6 address (not a link local address) for the Client, the IPv6 address lease time, and any additional information requested by the client. The DHCPv6 protocol requires the client to wait for a period of time to receive ADVERTISE messages from all DHCPv6 Servers on the network. The client pre-processes each ADVERTISE message to be a valid message and scans the option data for various DHCPv6 parameters; it also checks the preference value in the preference option, if supplied by the server. If more than one ADVERTISE message is received, the NetX DHCPv6 Client chooses the ADVERTISE message with the highest preference value received by the end of the wait period. If the Client receives an ADVERTISE message with a preference value of 255, it accepts that message immediately and discards all subsequent ADVERTISE messages.

The client extracts data from the ADVERTISE message and broadcasts (so all DHCPv6 Servers are informed) a REQUEST message specifying which server the client chooses; that server then confirms the assigned address information and lease times with a REPLY message to complete the protocol.

The DHCPv6 Client is promoted to the bound state and automatically registers the assigned IPv6 address with the IP instance.

Notification of Successful Address Assignment and Validation

The application can determine when the DHCPv6 Client is bound to an IPv6 address in two ways: the first is to query the DHCPv6 Client itself for a valid IPv6 address using the nx_dhcpv6_get_IP_address service for clients for applications using only one global IPv6 address assigned, (the general case) or nx_dhcpv6_get_valid_ip_address_count service for clients with more than one IPv6 address assigned. The second way requires the DHCPv6 Client be configured with the state change callback, the *Name of state change notification function* property* of the DHCPv6 Client stack element.

If the DHCPv6 Client receives a response from the server, but the server is unable to assign the address, the server returns an error status. The application is notified of the error status received if configured with the DHCPv6 Client server-error callback - the *Name of server error handler* property of the DHCPv6 Client stack element.

These callbacks must be defined by the application because these callback functions are called from the DHCPv6 Client thread task; the client application must NOT call any NetX Duo DHCPv6 Client services that require mutex control of the DHCPv6 Client (such as nx_dhcpv6_start, nx_dhcpv6_stop), and any of the APIs that send messages directly from the callback (such as nx_dhcpv6_request_release).

The states of the DHCP IPv6 protocol are:

NX_DHCPV6_STATE_INIT

NX_DHCPV6_STATE_SENDING_SOLICIT

NX_DHCPV6_STATE_SENDING_REQUEST

NX_DHCPV6_STATE_SENDING_RENEW

NX_DHCPV6_STATE_SENDING_REBIND

NX_DHCPV6_STATE_SENDING_DECLINE

NX_DHCPV6_STATE_SENDING_INFORM_REQUEST

NX_DHCPV6_STATE_BOUND_TO_ADDRESS

Duplicate Address Detection of the IPv6 address

If configured for the Duplicate Address Detection (DAD) protocol, enabled by default in NetX Duo *Duplicate Address Detection property*, NetX Duo automatically sends "Neighbor Solicit" messages to verify the assigned address is unique on the network. If the IPv6 address is unique, NetX Duo notifies the DHCPv6 Client when the assigned address has been promoted from NX_IPV6_ADDR_STATE_TENTATIVE to NX_IPV6_ADDR_STATE_VALID internally. The application must allow time for the DAD to finish processing, which takes about 4-5 seconds. If the DAD is not enabled, the IP instance marks the address VALID immediately.

Once an IPv6 address is valid, the device may use that IPv6 address to send and transmit IPv6 messages.

If the DAD protocol fails, NetX Duo notifies the DHCPv6 Client to send a DECLINE message to the

server and restart the DHCPv6 Client at the INIT state.

Retransmission of DHCPv6 Client Solicitations

The DHCPv6 Client times out waiting for a server reply before sending another DHCPv6 message and defaults to 1 second on the first retransmit, per RFC 3315 recommendations. If the DHCPv6 Client fails to receive a valid server response to the SOLICIT message, each subsequent retransmission interval doubles up to a maximum of 120 seconds by default.

DHCPv6 Lease Timeouts

The IPv6 lease assigned by the server contains two timeout parameters (T1 and T2) in the DHCPv6 Client Identity Association – Non-Temporary Addresses, (IANA), which is the data type specified by RFC 3315 to store IPv6 address data in DHCPv6.

When the time elapsed on an assigned IPv6 address reaches T1, the DHCPv6 Client automatically sends a RENEW message. If the elapsed time reaches T2 without a successful renewal, DHCPv6 Client automatically sends a REBIND message. If it still receives no response, the DHCP Client unregisters the IPv6 address with the IP instance and restarts the DHCPv6 protocol at the INIT state. Two other IPv6 lease parameters, preferred and valid lifetime, are assigned automatically to the Identity Association (IA) contained in the IANA in the DHCPv6 process. When the preferred and valid lifetimes expire, the assigned IPv6 address is either deprecated or rendered invalid; meaning a valid T1 must be less than the preferred lifetime and a T2 must be less than the valid lifetime.

NetX Duo DHCP IPv6 Client Module Important Operational Notes and Limitations

NetX Duo DHCP IPv6 Client Module Operational Notes

- The NetX Duo Source element has a few key properties for supporting DHCPv6: The *NetX Duo IPv6 Support* property, the *Checksum computation support on received ICMPV6 packets,* and the *Checksum computation support on transmitted ICMPv6 packets*. The latter two ensure that incoming and outgoing packets have an ICMPv6 checksum in the ICMPv6 header; these are automatically enabled for the DHCPv6 Client module. If the NetX Duo Source element is added to the project, check to make sure these properties are enabled.
- The DHCPv6 Client creation requires a previously created packet pool. The application can use the IP default packet pool (g_packet_pool0) used by the IP instance or it can create its own (usually g_packet_pool1.)
- Before sending a SOLICIT request, the Client must create a DHCP Unique Identifier (DUID) to uniquely define the client on the network. The MAC address is usually used but can be another unique identifier. A typical invocation of this service is:

```
nx_dhcpv6_create_client_duid(&g_dhcpv6_client0,
NX_DHCPV6_DUID_TYPE_LINK_TIME /* Use MAC address */,
              NX_DHCPV6_HW_TYPE_IEEE_802,
              0 /* Client DUID time, usually set to zero */);
```

- The DHCPv6 Client must also create the IANA for the client; this structure holds IPv6 lease information such as IPv6 addresses and T1 and T2 times. (The client can use the IANA to request lease times.) To create an IANA, use thenx_dhcpv6_client_create_iana service:

```
status = nx_dhcpv6_create_client_iana(&g_dhcpv6_client0,
DHCPV6_IANA_ID /* ULONG unique ID */,
DHCPV6_T1 /* Request T1 time in seconds or
             set to TX__WAIT_FOREVER */,
DHCPV6_T2 /* Request T2 time;must be longer
          than T1 */);
```

- In the SOLICIT request, the client may request the assignment of a specific IPv6 address from the server by calling the nx_dhcpv6_add_client_ia service before calling nx_dhcpv6_request_solicit. This service uses an NXD_ADDRESS address data type for the IPv6 address. See *NetX Duo User Guide for the Renesas Synergy™ Platform* for details on the data type definition in NetX Duo.
- To request network information such as a DNS server, NTP server, and other options, the application can all these APIs before calling nx_dhcpv6_request_solicit:
    - nx_dhcpv6_request_option_timezone(&g_dhcpv6_client, NX_TRUE);
    - nx_dhcpv6_request_option_DNS_server(&g_dhcpv6_client, NX_TRUE);
    - nx_dhcpv6_request_option_time_server(&g_dhcpv6_client, NX_TRUE);
    - nx_dhcpv6_request_option_domain_name(&g_dhcpv6_client, NX_TRUE);
- If the client needs to release an assigned IPv6 address, it informs the DHCPv6 server by calling the nx_dhcpv6_request_release service. The DHCPv6 Client sends a unicast RELEASE message to the server and should wait for the server REPLY.
- For DHCPv6 Client services that retrieve information about the DHCPv6 Client, an address index may need to be specified. Most clients have one IPv6 global address assigned, so the address index is 0.
- To obtain specific information about lease times, use the nx_dhcpv6_get_valid_ip_address_lease_time service. This requires an address index input (usually 0.)

NetX Duo DHCP IPv6 Client Module Limitations

- The NetX Duo DHCPv6 Client does not support the server unicast option for sending unicast DHCPv6 messages to the DHCPv6 Server even if the server indicates this is permitted.
- The NetX Duo DHCPv6 Client only supports DUIDs for LINK (MAC address) and LINK TIME (MAC address and time input.)
- The NetX Duo DHCPv6 Client does not support the reconfigure request in which a server initiates IPv6 address changes to the clients on the network.
- The NetX Duo DHCPv6 Client does not support the enterprise format for the DHCPv6 unique identifier control block; it only supports Link Layer and Link Layer Plus Time formats.
- The NetX Duo DHCPv6 Client does not support Temporary Association (TA) address requests, but does support Non Temporary (IANA) option requests.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.16.4 Including the NetX Duo DHCP IPv6 Client Module in an Application

This section describes how to include either or both the NetX Duo DHCP IPv6 Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo DHCP IPv6 Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX Duo DHCP IPv6 Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_dhcp_client0 NetX Duo DHCP IPv6 Client	Threads	**New Stack> X-Ware> NetX Duo> Protocols> NetX Duo DHPC IPv6 Client**

When the NetX Duo DHCP IPv6 Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

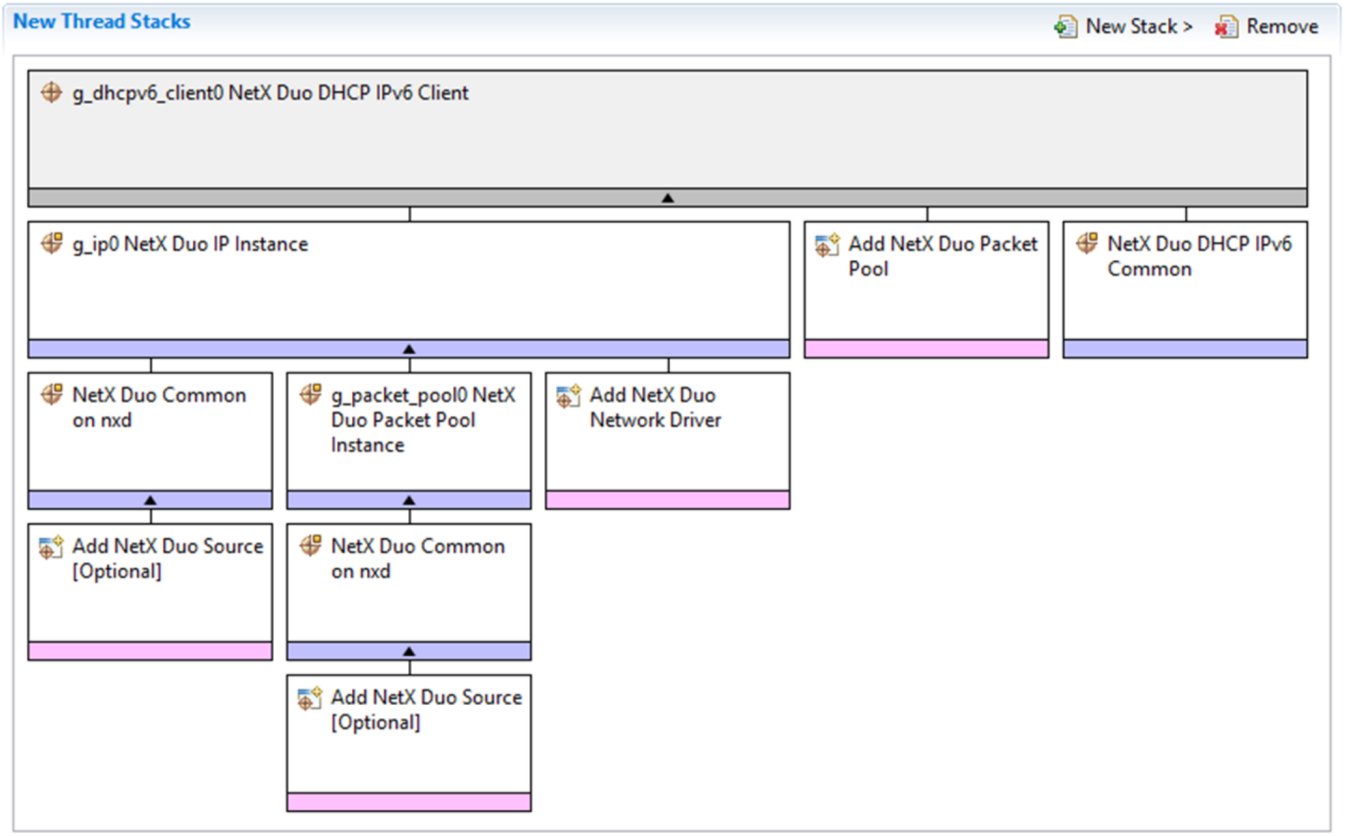

Figure 443: NetX Duo DHCP IPv6 Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.16.5 Configuring the NetX Duo DHCP IPv6 Client Module

The NetX Duo DHCP IPv6 Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo DHCP IPv6 Client Module

ISDE Property	Value	Description
Internal Thread Priority	3	Internal thread priority selection.
Time out for obtaining DHCPv6 client mutex (ticks)	TX_WAIT_FOREVER	Time out for obtaining DHCPv6 client mutex selection.
Time interval between current IP address lease time update (seconds)	1	Time interval between current IP address lease time update selection.
Maximum IA addresses allowed in client record	1	Maximum IA addresses allowed in client record selection.
Number of DNS servers the client will store	2	Number of DNS servers the client will stored selection.
Number of time servers the client will store	1	Number of time servers the client will store selection.
Domain name buffer size (bytes)	32	Domain name buffer size selection.
Current time zone information buffer size (bytes)	16	Current time zone information buffer size selection.

Maximum DHCPv6 server messages buffer size (bytes)	100	Maximum DHCPv6 server messages buffer size selection.
Name	g_dhcpv6_client0	Module name.
Internal thread stack size (bytes)	4096	Internal thread stack size selection.
Name of state change notification function	dhcpv6_state_change_notify	Name of state change notification function selection.
Name of server error handler	dhcpv6_server_error_handler	Name of server error handler selection.
Name of generated initialization function	nx_dhcpv6_client_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different Ethernet interface pins and resets. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX Duo DHCP IPv6 Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name.
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection.
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection.
IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection.

IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection.
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection.
IP Helper Thread Priority	3	IP Helper Thread Priority selection.
ARP	Enable	ARP selection.
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection.
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection.
TCP	Enable, Disable Default: Enable	TCP selection.
UDP	Enable, Disable Default: Enable	UDP selection.
ICMP	Enable, Disable Default: Enable	ICMP selection.
IGMP	Enable, Disable Default: Enable	IGMP selection.
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection.
Name of generated initialization function	ip_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo DHCP IPv6 Common Instance

ISDE Property	Value	Description
Type of Service for UDP requests	Normal, Minimum delay, Maximum data, Maximum reliabililty, Minimum cost Default: Normal	Type of service UDP requests selection

Time to live	128	Time to live selection
Packet Queue depth	5	Packet queue depth selection
packet alocation timeout (seconds)	3	Packet allocation timeout selection
Interval for active session time update (seconds)	3	Interval for active session time update selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX Duo DHCP IPv6 Client Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX Duo DHCP IPv6 Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select **Peripherals**> **Connectivity:ETHERC**> **ETHERC1.RMII**

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1.
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection.
REF50CK	P701	REF50CK pin.
TXD0	P700	TXD0 pin.
TXD1	P406	TXD1 pin.
TXD_EN	P405	TXD_EN pin.
RXD0	P702	RXD0 pin.
RXD1	P703	RXD1 pin.
RX_ER	P704	RX_ER pin.
CRS_DV	P705	CRS_DV pin.
MDC	P403	MDC pin.
MDIO	P404	MDIO pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.16.6 Using the NetX Duo DHCP IPv6 Client Module in an Application

The following example assumes a system that is already established with a working and enabled IP,

ARP and UDP, and the link is running.

The steps in using the NetX Duo DHCP IPv6 Client module in a typical application are:

1. Create a Client DUID for the DHCPv6 Client using the nx_dhcpv6_create_client_duid.
2. Create an IANA for the DHCPv6 Client using the nx_dhcpv6_create_client_iana.
3. Request network options (such as DNS server and time server) using the nx_dhcpv6_request_option_DNS_server and nx_dhcpv6_request_option_time_server API [Optional].
4. Start the DHCPv6 Client with the nx_dhcpv6_start API. This sets the DHCPv6 Client state and binds the client socket, in effect getting the DHCPv6 Client ready to exchange messages with the server.
5. Send the SOLICIT message to the server using the nx_dhcpv6_request_solicit API. The DHCPv6 Client internally manages the rest of the DHCPv6 protocol.
6. Check for IPv6 Address resolution using the nx_dhcpv6_get_valid_ip_address_count API to return with an address_count > 0. The DHCPv6 Client now as a valid IPv6 address.

The following figure illustrates common steps in a typical operational flow diagram:

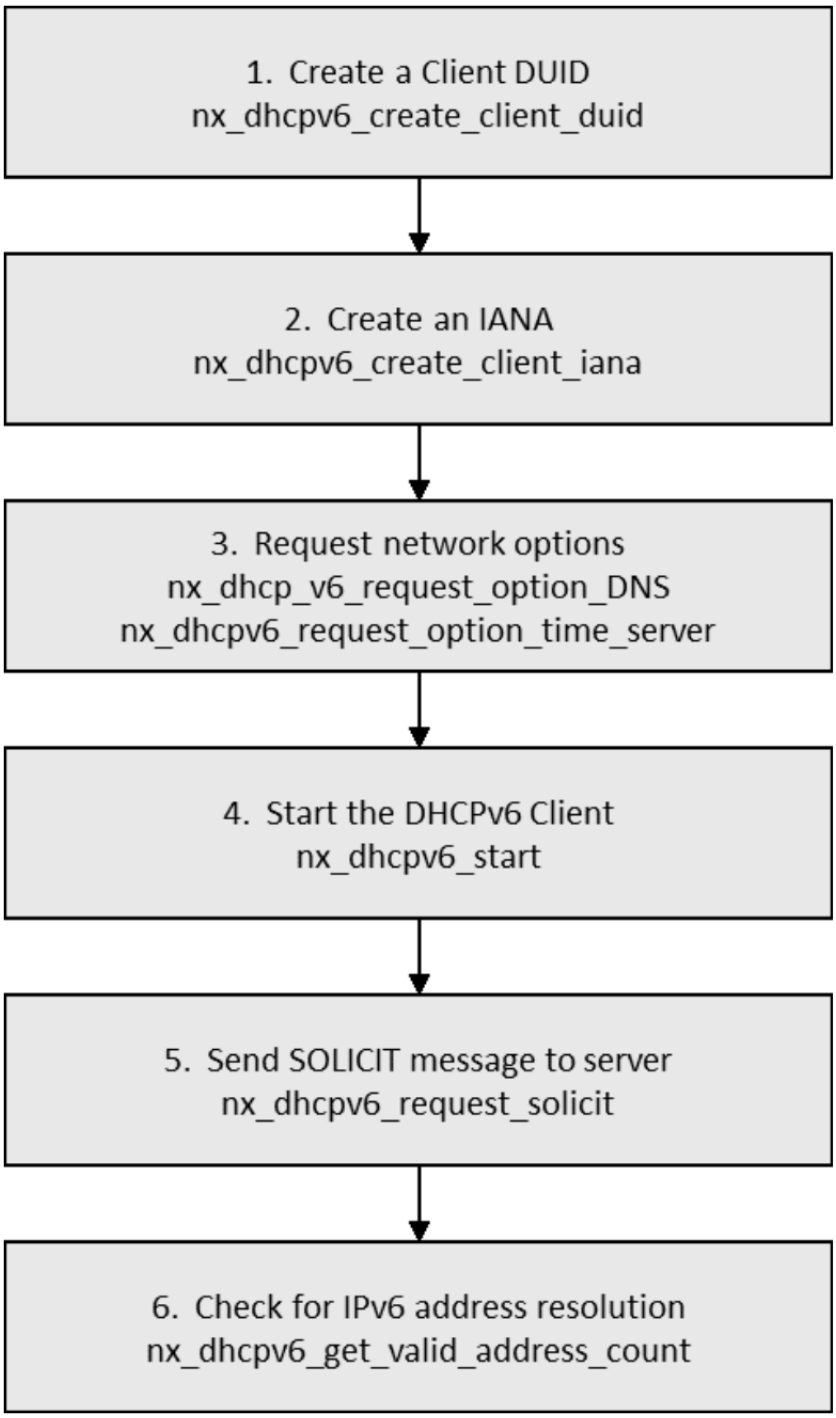

Figure 444: Flow Diagram of a Typical NetX Duo DHCP IPv6 Client Module Application

4.3.17 NetX Duo DHCPv6 Server

4.3.17.1 NetX Duo DHCP IPv6 Server Introduction

The Dynamic Host Configuration Protocol (DHCP) is used to obtain an IP address and network parameters. The DHCP is designed to extend the basic functionality of the BOOTP (which is limited to static address configuration) to include a completely dynamic IP address allocation through "leasing" an IP address to a client for a specified period of time. The DHCP can also be configured to allocate IP addresses in a static manner (like the BOOTP). An application's IP address is one of the supplied parameters for the NetX™ component. Supplying the IP address poses no problem if the IP address is known to the application, either statically or through the user configuration. When the application does not know or care what its IP address is, the NetX is initialized with a zero IP address; a DHCP client component added to NetX can then dynamically obtain an IP address.

In IPv6 networks, DHCPv6 replaces DHCP (which is limited to IPv4) for dynamic global IPv6 address assignment from a DHCPv6 Server. The DHCPv6 offers most of the same features, as well as many enhancements, and explains how the NetX Duo™ DHCPv6 Server API is used for DHCPv6 Client IPv6 address requests.

NetX Duo DHCP IPv6 Server Module Features

- The NetX Duo DHCPv6 Server is compliant with RFC 3315, RFC 3646 and related RFCs.
- Provides high-level APIs for:
    - Creating and deleting a DHCPv6 Server instance
    - Starting and stopping a DHCPv6 Server thread task
    - Creating a pool of IPv6 addresses for lease
    - Maintaining a table of DHCPv6 leases assignable to requesting clients

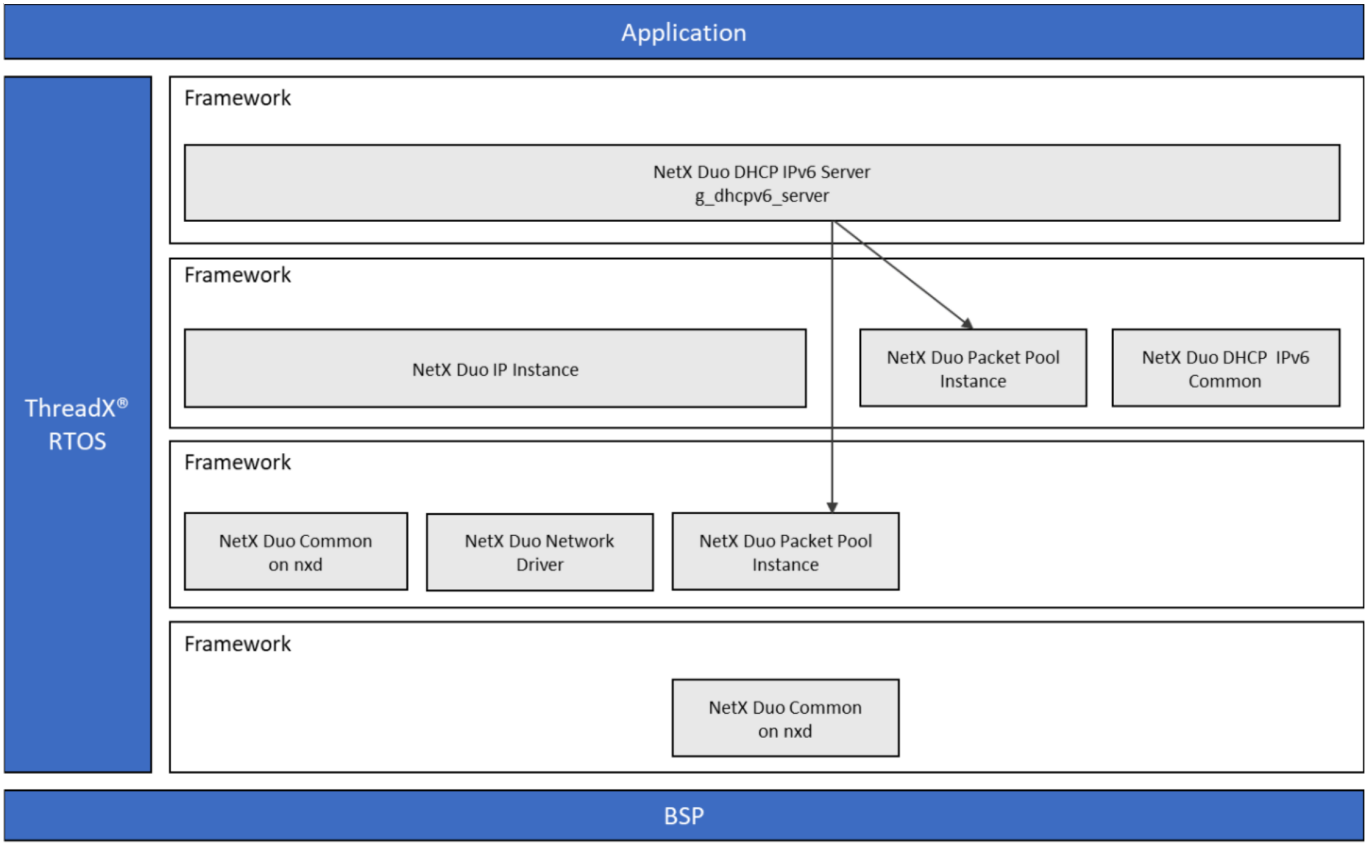

Figure 445: NetX Duo DHCP IPv6 Server Module Block Diagram

Note

In the figure above, the NetX Duo Network Driver module has multiple implementation options available. See the description just after the module stack figure in Including the NetX Duo DHCP IPv6 Server Module in an Application for additional details.

4.3.17.2 NetX Duo DHCP IPv6 Server Module APIs Overview

The NetX Duo DHCPv6 Server module defines APIs for creating, deleting, adding and getting server information. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX Duo DHCP IPv6 Server Module API Summary

Function Name	Example API Call and Description
nx_dhcpv6_server_create	nx_dhcpv6_server_create(&g_dhcpv6_server0, &server_ip_address, "DHCPv6 Server", &g_packet_pool0, stack_pointer, NX_DHCPV6_SERVER_THREAD_STACK_SIZE, address_declined_handler, option_request_handler); Create a DHCPv6 Server instance.
nx_dhcpv6_server_delete	nx_dhcpv6_client_delete(&g_dhcpv6_server0); Delete a DHCPv6 Server instance and release resources (unbind port, delete socket, timers and thread).
nx_dhcpv6_create_ip_address_lease	nx_dhcpv6_create_ip_address_range(&g_dhcpv6_server0, &start_ipv6_address, &end_ipv6_address, &addresses_added); Create the Server's IPv6 address lease pool.
nx_dhcpv6_reserve_ip_address_range	nx_dhcpv6_reserve_ip_address_range(&g_dhcpv6_server0, &start_ipv6_address, &end_ipv6_address, &addresses_reserved); Reserve the specified range of IPv6 addresses not to be leased out to a requesting Client.
nx_dhcpv6_add_ip_address_lease	nx_dhcpv6_add_ip_address_lease(&g_dhcpv6_server0, table_index, &lease_IP_address, T1, T2, valid_lifetime, preferred_lifetime); Copy an IPv6 lease record into the specified index into the Server table. Intended for use in non-volatile storage of IPv6 lease data.
nx_dhcpv6_add_client_record	nx_dhcpv6_add_client_record(&g_dhcpv6_server0, table_index, message_xid, &client_address, client_state, IP_lease_time_accrued, valid_lifetime, duid_type, duid_hardware, physical_address_msw, physical_address_lsw, duid_time, duid_vendor_number, duid_vendor_private, duid_private_length); Copy a Client record into the specified index into the Server table. Intended for use in non-volatile storage of Client IPv6 address data.

nx_dhcpv6_create_dns_address	nx_dhcpv6_create_dns_address(&g_dhcpv6_server0, &dns_ipv6_address); Set the DNS server address to include in network parameters sent to clients.
nx_dhcpv6_retrieve_client_record	nx_dhcpv6_retrieve_client_record(&g_dhcpv6_server0, table_index, message_xid, &client_address, client_state, IP_lease_time_accrued, valid_lifetime, duid_type, duid_hardware, physical_address_msw, physical_address_lsw, duid_time, duid_vendor_number, duid_vendor_private, duid_private_length); Retrieve items from the Client specified by the index into the Server table. Intended for use in non-volatile storage of Client IPv6 address data.
nx_dhcpv6_retrieve_ip_address_lease	nx_dhcpv6_retrieve_ip_address_lease(&g_dhcpv6_server0, table_index, &lease_IP_address, T1, T2, valid_lifetime, preferred_lifetime); Retrieve items from the IPv6 lease specified by the index into the Server table. Intended for use in non-volatile storage of IPv6 lease data.
nx_dhcpv6_server_interface_set	nx_dhcpv6_server_interface_set(&g_dhcpv6_server0, 0, 1); Set the interface the DHCPv6 Server will run on, and the global address the DHCPv6 Server will use in messages to Clients. By default, the DHCPv6 Server runs on the primary interface (index 0).
nx_dhcpv6_set_server_duid	nx_dhcpv6_set_server_duid(&g_dhcpv6_server0, NX_DHCPV6_SERVER_DUID_TYPE, NX_DHCPV6_SERVER_HW_TYPE, physical_address_msw, physical_address_lsw, duid_time); Create the Server DUID which is a required part of the DHCPv6 header and uniquely identifies the DHCPv6 Server.
nx_dhcpv6_server_start	nx_dhcpv6_server_start(&g_dhcpv6_server0); Start the DHCPv6 thread task.
nx_dhcpv6_server_suspend	nx_dhcpv6_server_suspend(&g_dhcpv6_server0); Suspend the DHCPv6 server task.
nx_dhcpv6_server_resume	nx_dhcpv6_server_resume(&g_dhcpv6_server0); Resume the DHCPv6 server task.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

Status Return Values

Name	Description
NX_SUCCESS	Successful API call.
NX_PTR_ERROR*	Invalid pointer input.
NX_CALLER_ERROR*	Must be called from thread.
NX_DHCPV6_PARAM_ERROR	Invalid non pointer input.
NX_INVALID_INTERFACE	Invalid interface index input.
NX_DHCPV6_UNSUPPORTED_DUID_TYPE	DUID type unknown or not supported.
NX_DHCPV6_UNSUPPORTED_DUID_HW_TYPE	DUID hardware type unknown or not supported.
NX_DHCPV6_IA_ADDRESS_ALREADY_EXIST	Duplicate IA address.
NX_DHCPV6_REACHED_MAX_IA_ADDRESS	IA exceeds the max IAs Client can store.
NX_DHCPV6_INVALID_IA_ADDRESS	Invalid (for example, null) IA address in IA.
NX_DHCPV6_IA_ADDRESS_NOT_VALID	IPv6 address successfully assigned.
NX_DHCPV6_UNKNOWN_OPTION	Unknown/unsupported option code.
NX_DHCPV6_ALREADY_STARTED	DHCPv6 Client is already running.
NX_DHCPV6_NOT_STARTED	DHCPv6 Client task not started.
NX_DHCPV6_MISSING_REQUIRED_OPTIONS	Client missing required options.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

- These are error codes which are only returned if error checking is enabled. Refer to the *NetX User Guide* for the Renesas Synergy™ Platform or *NetX Duo User's Guide* for the Renesas Synergy™ Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.17.3 NetX Duo DHCP IPv6 Server Module Operational Overview

The NetX Duo DHCPv6 Server module creates a NetX Duo IP instance for the server and a UDP socket bound to the well-known DHCPv6 Server port 547 to listen for client requests. Before starting DHCPv6, the server needs a global IPv6 address by setting the IPv6 Global Address property in the IP NetX Duo Instance property box. (Note that this is a 128-bit long address, compared to the 32-bit long IPv4 address.)

The DHCPv6 Server should wait for the IPv4 address to be validated using the nx_ip_status_check service, even if the server does not use this IP address for DHCPv6 messages. The driver needs to be initialized with information from the IP layer and the link needs to be enabled, all of which happens with IPv4 address-registration.

Before an application can start the DHCPv6 Server, it must create a pool of assignable IPv6 addresses using the nx_dhcpv6_create_ip_address_range service. The application must also create a server DUID (DHCP Unique Identifier, usually based on the MAC address, and is required in all DHCPv6 Server messages using the nx_dhcp_set_server_duid service. Optionally, it can set the network DNS Server to include in the DHCPv6 option data to clients using the nx_dhcpv6_create_dns_server service; now the server can be started with the

nx_dhcpv6_server_start service.

Note

All properties referenced in text are found in the NetX Duo DHCP IPv6 Server properties box, unless otherwise noted.

The server maintains a table of IPv6 addresses, updates their status, and indicates whether any addresses are leased out. For leased out addresses, the table indicates the client to which the address is leased. The size of this table is set by the Maximum Size of the Server's IP lease table property, and should be equal to or greater than the number of IPv6 addresses in the IPv6 address pool. The server maintains another table for client records; the size of this table is set by the Size of Server's Client record table property portion of the DHCP Server properties box and should be at least the size of the IPv6 lease table. If the server receives a Client Release or Decline, the server updates the IPv6 lease table and client record table, accordingly.

The DHCPv6 Server creates two timers. The first timer keeps track of the time remaining on IPv6 addresses leased to clients. The interval at which the server checks client leases is set by the Client lease time expiration check interval property, which defaults to 60 seconds. If the server issues leases with extremely short lease-expirations, that value should be reduced to approximately 10 or 20 percent of the timeout value. If a lease timeout expires, the lease is returned to the pool of IPv6 addresses and the client record is deleted. The second timer is used to monitor client-session inactivity; the default timeout for session inactivity timeout is 20 seconds. The interval in which the server checks its client records for an expired session inactivity timeout is the Interval for active session time update property in the NetX Duo DHCP IPv6 Common properties box, with the interval having a 3-second default time.

NetX Duo DHCP IPv6 Server Module Important Operational Notes and Limitations

NetX Duo DHCP IPv6 Server Module Operational Notes

- IPv6 and ICMPv6 must be enabled in NetX Duo. Verify that the NetX Duo IPv6 Support property is enabled in the NetX Duo Source properties box; this setting automatically enables ICMPv6.

If the underlying hardware supports ICMPv6 checksum computation, the following values can be left disabled:

- By default, the ICMPv6 checksum is disabled. To enable the checksum (assuming the hardware does not compute ICMPv6 checksums), locate the Checksum computation support on transmitted ICMPv6 packets property in the NetX Duo Source properties box, and set it to enabled. The Checksum computation support on received ICMPv6 packets property should also be enabled.
- Duplicate Address Detection (DAD) is recommended to verify the uniqueness of the server's global IPv6 address. This protocol is similar to sending gratuitous ARP probes in IPv4 to determine the uniqueness of an IPv4 address, but it is only applicable to IPv6 addresses. To enable DAD (which is disabled by default), set the Duplicate Address Detection support property to enabled in the NetX Duo Source properties box. The number of solicitation packets sent out for DAD is set by the Neighbor Solicitation message count before interface address marked valid property, which by default is 3 (and sent about a second apart). With this configuration, the application thread should wait about 4 seconds to let the DAD protocol complete.
- The following DHCPv6 parameters are supplied in DHCPv6 Server responses to the client:
    - T1 time: when the client should begin renewing its IPv6 address lease, is set by the Server interval for first client IP address renewal attempt property.
    - Preferred time: when the client IPv6 address is deprecated, is set by the Time

interval after which the client IP is deprecated property. This should be double the T1 time, as per RFC 3315 recommendations.
    - T2 time: when the client should begin rebinding an IPv6 address if renewing efforts failed, is set by the Server interval for the second client IP address renewal attempt property.
    - Valid lifetime: when the client IPv6 address is obsolete and should no longer be used by the client. This is set by the Time interval after which leased IP is invalid property, and should be double the preferred time, as per RFC 3315 recommendations.
    - There is no upper limit on the IPv6 lease time (valid lifetime), but the relative interval of these four time parameters must permit the logical order of renew and, if necessary, rebind state of the DHCPv6 protocol.
- The address-declined handler callback for handling a Client Decline message is not implemented on the current NetX Duo DHCPv6 Server. This callback is suggested by the RFC 3315 DHCPv6 specification for the server to notify the application of a declined address event.

NetX Duo DHCP IPv6 Server Module Limitations

- Rapid Commit option: optimizes the DHCPv6 address request process to just the Solicit and Reply message-exchange
- Reconfigure option: allows the server to initiate changes to the client's IP address status
- Unicast option: all client messages must be sent to All_DHCP_Relay_Agents_and_Servers multicast address rather than to the DHCPv6 Server directly.
- Identity Association for the Temporary Addresses (IA_TA) option: a temporary IP address granted to a client
- Multiple IA (IPv6 addresses) option: per client request
- Relay host between DHCPv6 Client and Server: client and server must be on the same network
- NetX Duo DHCPv6 Server: directly supports only the DNS Server option request
- Prefix Delegation option: is not supported.
- Option request callback: intended for the application and determines which DHCPv6 options to support and which information to supply to the DHCPv6 Server in response to the client. However, the processing of this information into the DHCPv6 Server response is not implemented. This callback has no effect on DHCPv6 Server messages
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.17.4 Including the NetX Duo DHCP IPv6 Server Module in an Application

This section describes how to include either or both the NetX Duo DHCP IPv6 Server module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo DHCP IPv6 Server module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX Duo DHCP IPv6 Server Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence

g_dhcp_server0NetX Duo DHCP IPv6 Server	Threads	**New Stack> X-Ware> NetX Duo> Protocols> NetX Duo DHPC IPv6 Server**

When the NetX Duo DHCP IPv6 Server module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

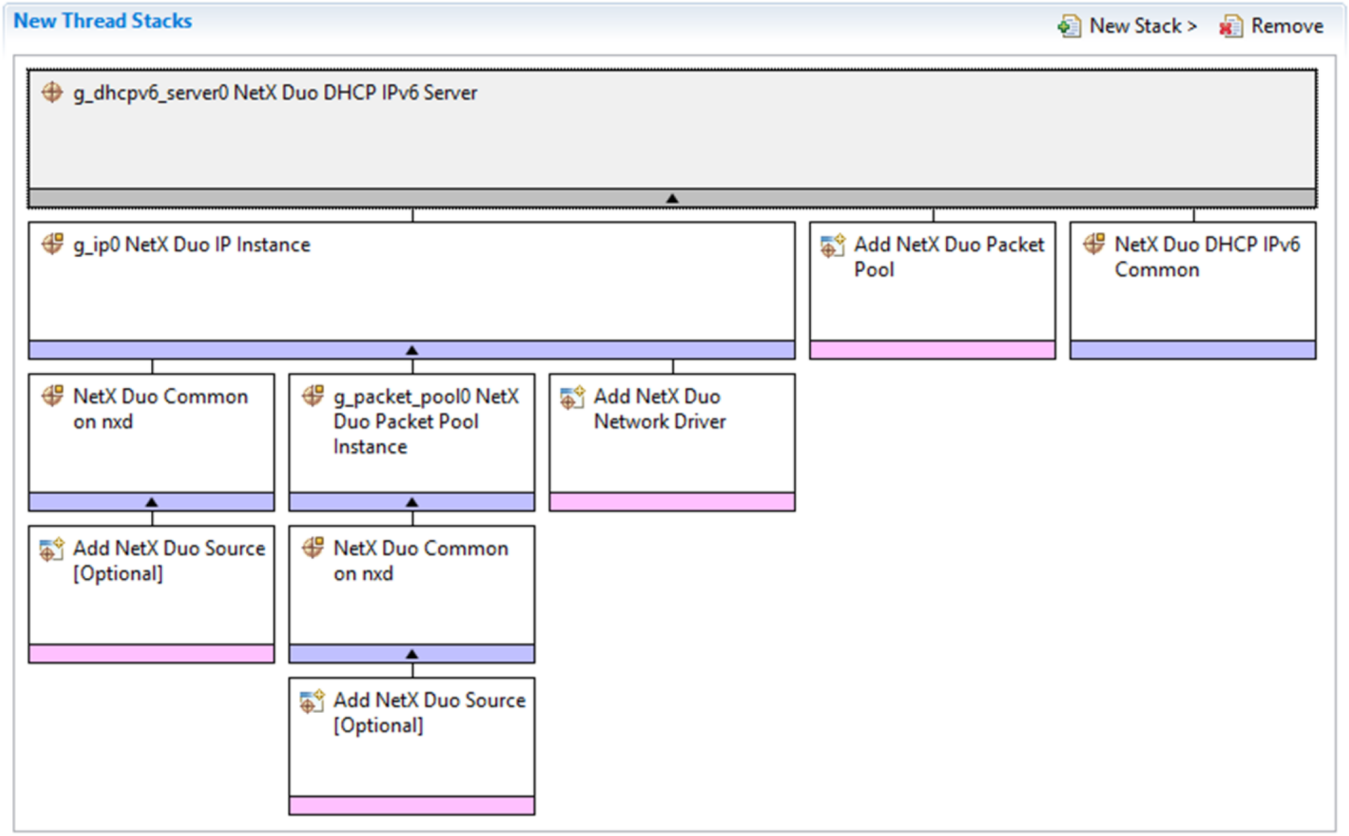

Figure 446: NetX Duo DHCP IPv6 Server Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp

- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.17.5 Configuring the NetX Duo DHCP IPv6 Server Module

The NetX Duo DHCP IPv6 Server module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo DHCP IPv6 Server Module

ISDE Property	Value	Description
Internal thread priority	1	Internal thread priority selection.
Client lease time expiration check interval (seconds)	60	Client lease time expiration check interval selection.
DHCPv6 packet receive timeout (seconds)	1	DHCPv6 packet receive timeout selection.
Server preference ranking for clients	0	Server preference ranking for clients selection.
Maximum options to extract from a client message	6	Maximum options to extract from a client message selection.
Server interval for first client IP address renewal attempt (seconds)	2000	Server interval for first client IP address renewal attempt selection.
Server interval for second client IP address renewal attempt (seconds)	3000	Server interval for second client IP address renewal attempt selection.
Time interval after which client IP is deprecated (seconds)	2*NX_DHCPV6_DEFAULT_T1_TIME	Time interval after which client IP is deprecated selection.
Time interval after which leased IP in invalid (seconds)	2*NX_DHCPV6_DEFAULT_PREFERRED_TIME	Time interval after which leased IP in invalid selection.
Maximum server status option message size (bytes)	100	Maximum server status option message size selection.
Maximum Size of the Server's IP lease table (count)	100	Maximum Size of the Server's IP lease table selection.

Size of the Server's Client record table (count)	120	Size of the Server's Client record table selection.
Server socket fragmentation option	Don't fragment, fragment okay Default: Don't fragment	Server socket fragmentation option selection.
Vendor assigned unique ID	abcdefghijklmnopqrstuvwxyz	Vendor assigned unique ID selection.
Private vendor ID	0x12345678	Private vendor ID selection.
Size of Vendor ID buffer (bytes)	48	Size of vendor ID buffer selection.
Client request success message: granted	IA OPTION GRANTED	Client request successmessage: granted selection.
Client request failure message: Failure unspecified	IA OPTION NOT GRANTED - FAILURE UNSPECIFIED	Client request failure message: Failure unspecified selection.
Client request failure message: No addresses available	IA OPTION NOT GRANTED - NO ADDRESSES AVAILABLE	Client request failure message: No addresses available selection.
Client request failure message: Invalid client request	IA OPTION NOT GRANTED - INVALID CLIENT REQUEST	Client request failure message: Invalid client request selection.
Client request failure message: Client not on link	IA OPTION NOT GRANTED - CLIENT NOT ON LINK	Client request failure message: Client not on link selection.
Client request failure message: Client must use multicast	IA OPTION NOT GRANTED - CLIENT MUST USE MULTICAST	Client request failure message: Client must use multicast selection.
Session inactivity timeout (seconds)	20	Session inactivity timeout selection.
Name	g_dhcpv6_server0	Module name.
Internal thread stack size (bytes)	4096	Internal thread stack size selection.
Name of address declined handler function	dhcpv6_address_declined_handler	Name of address declined handler function selection.
Name of option request handler	dhcpv6_option_request_handler	Name of option request handler selection.
Name of generated initialization function	dhcpv6_server_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it

might be useful to select different Ethernet interface pins and resets. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX Duo DHCP IPv6 Server Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection.
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection.
IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection.
IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection.
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection.
IP Helper Thread Priority	3	IP Helper Thread Priority selection.
ARP	Enable	ARP selection.
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection.
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection.
TCP	Enable, Disable Default: Enable	TCP selection.
UDP	Enable, Disable Default: Enable	UDP selection.

ICMP	Enable, Disable Default: Enable	ICMP selection.
IGMP	Enable, Disable Default: Enable	IGMP selection.
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection.
Name of generated initialization function	ip_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo DHCP IPv6 Common Instance

ISDE Property	Value	Description
Type of Service for UDP requests	Normal, Minimum delay, Maximum data, Maximum reliabililty, Minimum cost Default: Normal	Type of service UDP requests selection.
Time to live	128	Time to live selection.
Packet Queue depth	5	Packet queue depth selection.
packet alocation timeout (seconds)	3	Packet allocation timeout selection.
Interval for active session time update (seconds)	3	Interval for active session time update selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name.
Packet Size in Bytes	640	Packet size selection.
Number of Packets in Pool	16	Number of packets in pool selection.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G 2Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX Duo DHCP IPv6 Server Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX Duo DHCP IPv6 Server Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select **Peripherals**> **Connectivity:ETHERC**> **ETHERC1.RMII**

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description

Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1.
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection.
REF50CK	P701	REF50CK pin.
TXD0	P700	TXD0 pin.
TXD1	P406	TXD1 pin.
TXD_EN	P405	TXD_EN pin.
RXD0	P702	RXD0 pin.
RXD1	P703	RXD1 pin.
RX_ER	P704	RX_ER pin.
CRS_DV	P705	CRS_DV pin.
MDC	P403	MDC pin.
MDIO	P404	MDIO pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.17.6 Using the NetX Duo DHCP IPv6 Server Module in an Application

The following example assumes a system that is already established with a working and enabled IP, ARP and UDP, and the link is running.

The steps in using the NetX Duo DHCP IPv6 Server module in a typical application are:

1. Create a DUID for the DHCPv6 Server using the nx_dhcpv6_set_server_duid API.
2. Create a pool of assignable IPv6 addresses for the DHCPv6 Server using the nx_dhcpv6_create_ip_address_range API.
3. Set the DNS Server option for IPv6 using the nx_dhcpv6_create_dns_address API [Optional].
4. Start the DHCPv6 Server with the nx_dhcpv6_server_start API.
5. The DHCPv6 Server can be suspended as needed using thenx_dhcpv6_server_suspend API.
6. The DHCPv6 Server can be resumed using nx_dhcpv6_server_resume API [Optional].
7. Delete the DHCPv6 Server using the nx_dhcpv6_server_delete API.

The following figure illustrates common steps in a typical operational flow diagram:

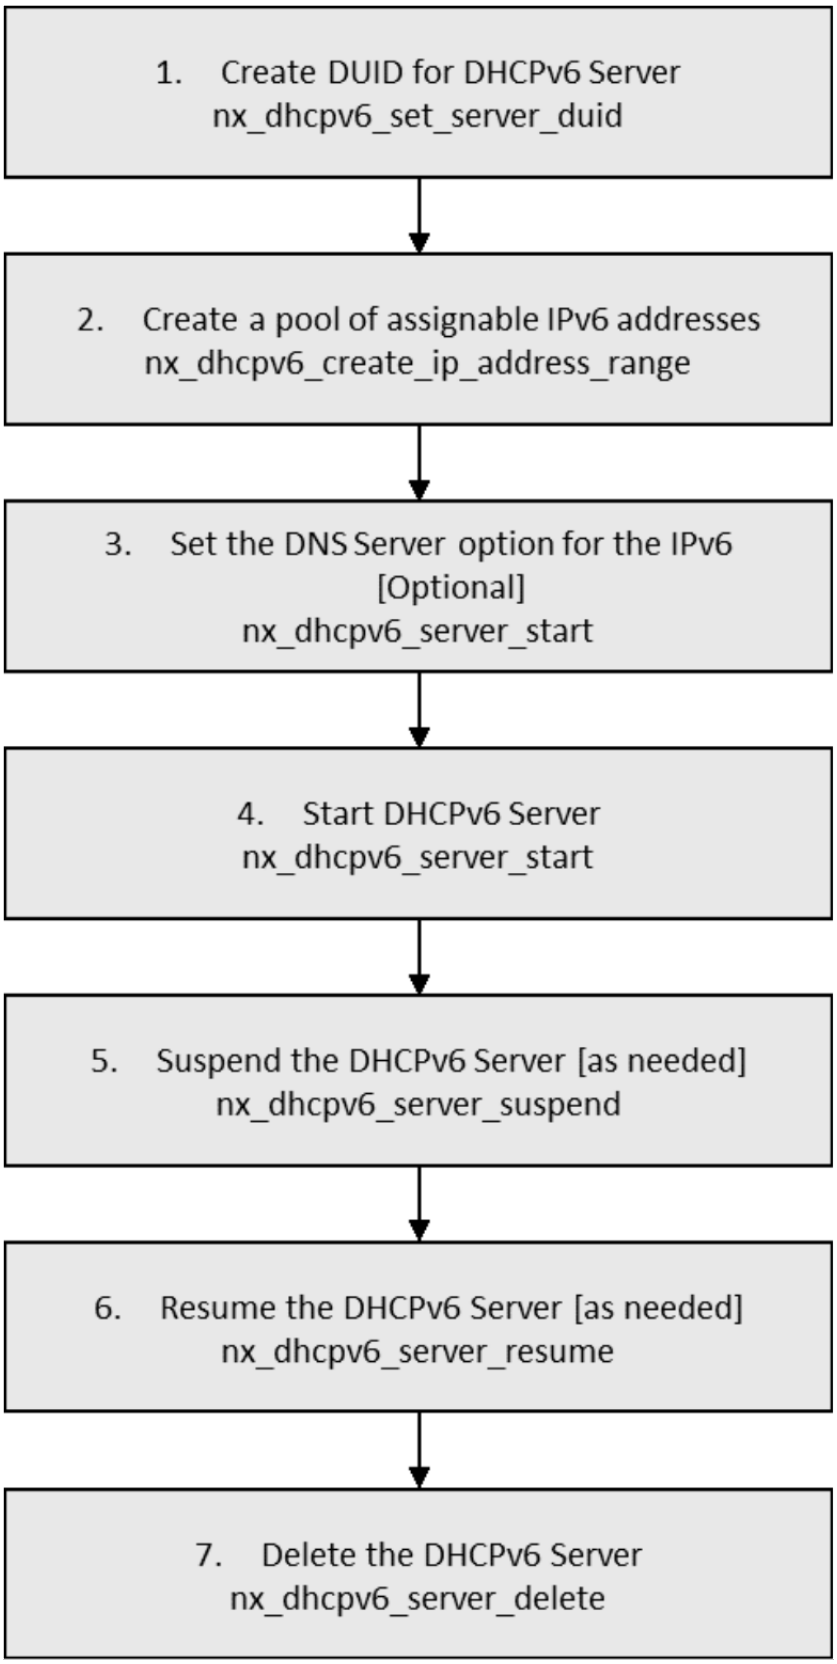

Figure 447: Flow Diagram of a Typical NetX Duo DHCP IPv6 Server Module Application

4.3.18 NetX/NetX Duo DNS Client

4.3.18.1 NetX/NetX Duo DNS Client Introduction

The Domain Name System (DNS) provides a distributed database that contains mapping between domain names and physical IP addresses. The database is referred to as "distributed" because there is no single entity on the Internet that contains the complete mapping. An entity that maintains a portion of the mapping is called a DNS server. The Internet is composed of numerous DNS servers, each of which contains a subset of the database. DNS servers also respond to DNS client requests for domain name mapping information, only if the server has the requested mapping. The DNS client protocol for NetX and NetX Duo provides the application with services to request mapping information from one or more DNS Servers.

Note

Except where noted, the NetX Duo DNS Client module is identical in the application, set-up and running of DNS queries as the NetX DNS Client module. For setting up the IP instance for IPv6 in NetX Duo, please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform.

Unsupported Features

Cache support has not been tested in this version of SSP.

IPV6 has not been tested for NetX Duo in this version of SSP.

NetX/NetX Duo DNS Client Module Features

- Optional creation of separate packet pool for DNS operations
- Support of Type A, AAAA, and NS DNS queries
- Support of CNAME, SRV, TXT, SOA, and MX DNS resource types
- Support for DNS cache for storing and retrieving cached DNS data
- High-level APIs for:
    - Name and IP address lookup
    - Adding and removing DNS servers
    - Creating and deleting the DNS instance
- NetX DNS is compliant with the following RFCs:
    - RFC1034 Domain Names – Concepts and Facilities
    - RFC1035 Domain Names - Implementation and Specification
    - RFC1480 The US Domain
    - RFC 2782 A DNS RR for specifying the location of services (DNS SRV)
    - RFC 3596 DNS Extensions to Support IP Version 6

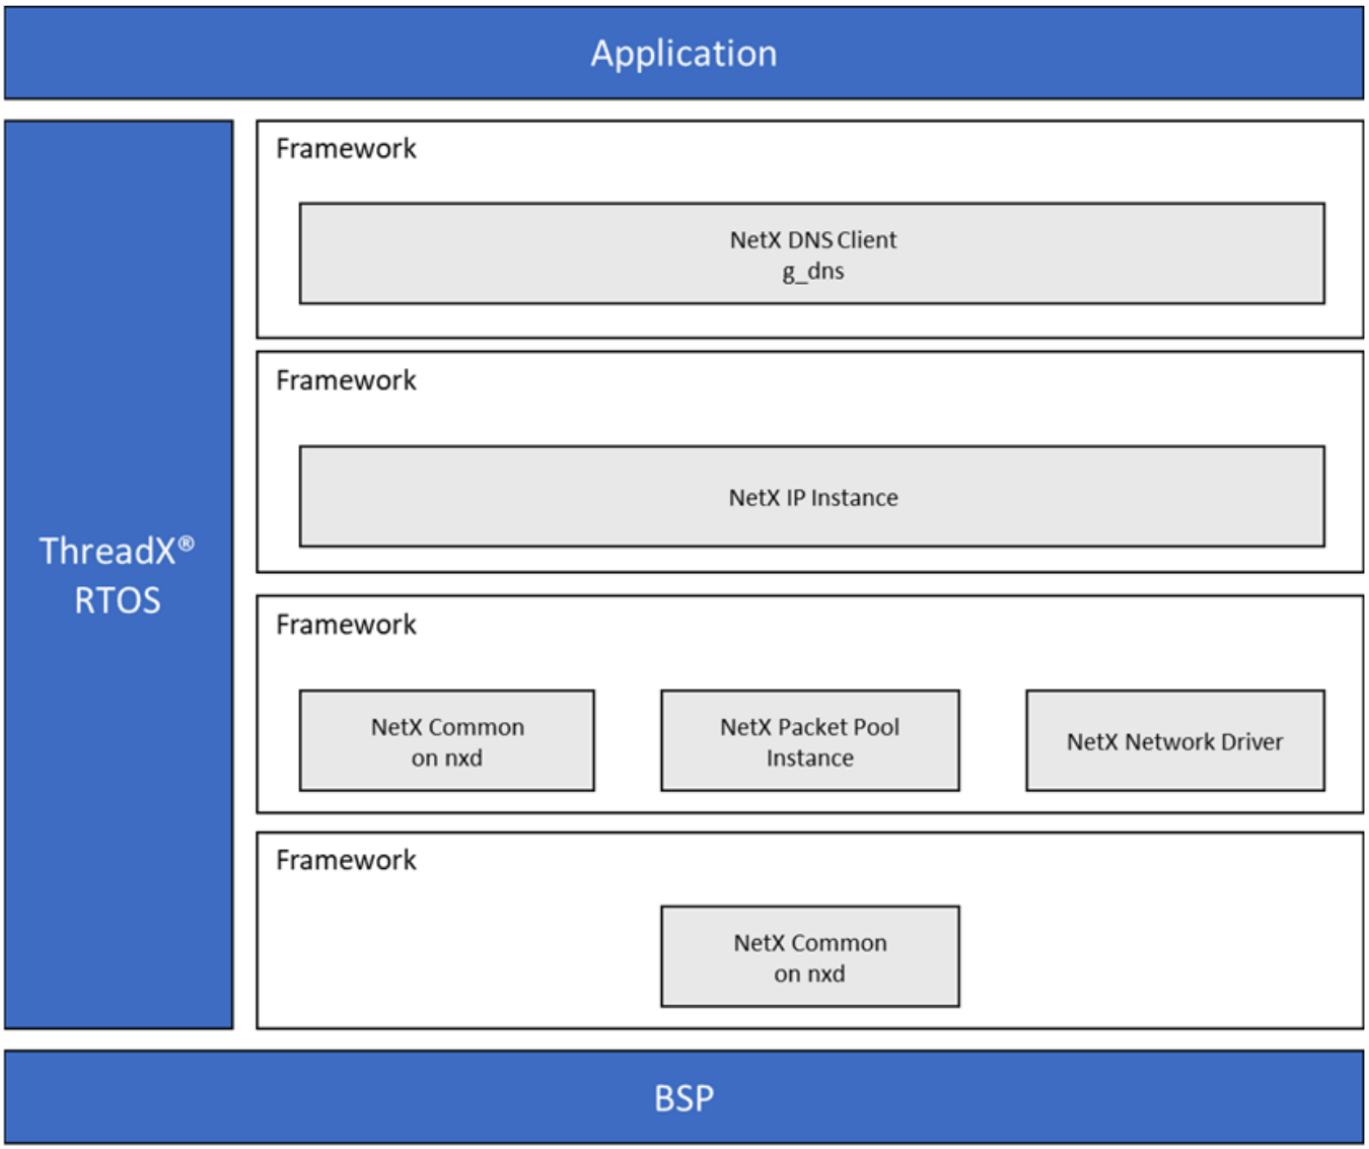

Figure 448: NetX/NetX Duo DNS Client Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX/NetX Duo DNS Client Module in an Application for additional details.

4.3.18.2 NetX/NetX Duo DNS Client Module APIs Overview

The NetX/NetX Duo DNS Client module defines API functions for connecting, binding, listening, sending and receiving. A complete list of the available API functions, an example API function call and a short description of each can be found in the following table.

NetX/NetX Duo DNS Client Module API Summary

Function Name	Example API Call and Description
nx_dns_create	nx_dns_create(&my_dns, &my_ip, "My DNS"); Create a DNS Client instance.

nx_dns_delete	nx_dns_delete(&my_dns); Delete a DNS Client instance.
nx_dns_packet_pool_set	nx_dns_packet_pool_set(&my_dns, &packet_pool); Set the DNS Client packet pool.
nx_dns_get_serverlist_size	nx_dns_get_serverlist_size (&my_dns, 5); Return the size of the DNS Client's Server list.
nx_dns_info_by_name_get	nx_dns_info_by_name_get(&my_dns, "www.abc1234.com", ip_address, &port, 200); Return IPv4 address, port querying on input host name.
nx_dns_ipv4_address_by_name_get	nx_dns_ipv4_address_by_name_get(&client_dns, (UCHAR *)"www.my_example.com", record_buffer,sizeof(record_buffer),&record_count,500); Look up the IPv4 address for the specified host name.
nx_dns_host_by_address_get	nx_dns_host_by_address_get(&my_dns, IP_ADDRESS(192.2.2.10), &resolved_name[0], BUFFER_SIZE, 450); Look up a host name from a specified IP address (supports only IPv4 addresses).
nx_dns_host_by_name_get	nx_dns_host_by_name_get(&my_dns, "www.my_example.com", &ip_address, 4000); Look up an IP address from the host name (supports only IPv4 addresses).
nx_dns_server_add	nxd_dns_server_add(&my_dns, server_address); Add a DNS Server of the specified IP address to the Client's Server list (supports only IPv4).
nx_dns_server_get	nx_dns_server_get(&my_dns, 5, &my_server_address); Return the DNS Server in the Client list at the specified index (supports only IPv4 addresses).
nx_dns_server_remove	nx_dns_server_remove(&my_dns, IP_ADDRESS(202,2,2,13)); Remove a DNS Server from the Client list (supports only IPv4 addresses).
nx_dns_server_remove_all	nx_dns_server_remove_all(&my_dns); Remove all DNS Servers from the Client list.
nx_dns_cache_initialize	nx_dns_cache_initialize(&my_dns, &dns_cache, 2048); Initialize a DNS Cache.
nx_dns_cache_notify_clear	nx_dns_cache_notify_clear(&my_dns); Clear the DNS cache full notify function.

nx_dns_cache_notify_set	nx_dns_cache_notify_set(&my_dns, cache_full_notify_cb); Set the DNS cache full notify function.
nx_dns_cname_get	nx_dns_cname_get(&client_dns, (UCHAR *)"www.my_example.com ", record_buffer, sizeof(record_buffer), 500); Look up the canonical domain name for the input domain name alias.
nx_dns_authority_zone_start_get	nx_dns_authority_zone_start_get(&client_dns, (UCHAR *)"www.my_example.com", record _buffer, sizeof(record_buffer), &record_count, 500); Look up the start of a zone of authority associated with the specified host name.
nx_dns_domain_name_server_get	nx_dns_domain_name_server_get(&client_dns, (UCHAR *)" www.my_example.com ", record_buffer, sizeof(record_buffer), &record_count, 500); Look up the authoritative name servers for the input domain zone
nx_dns_domain_mail_exchange_get	nx_dns_domain_mail_exchange_get(&client_dns, (UCHAR *)" www.my_example.com",record_buffer, sizeof(record_buffer), &record_count, 500); Look up the mail exchange associated with the specified host name.
nx_dns_domain_service_get	nx_dns_domain_service_get(&client_dns, (UCHAR *)"www.my_example.com ", record_buffer, sizeof(record_buffer), &record_count, 500); Look up the service(s) associated with the specified host name.
nxd_dns_ipv6_address_by_name_get**	nxd_dns_ipv6_address_by_name_get(&client_dns , (UCHAR *)"www.my_example.com", record__buffer, sizeof(record_buffer), &record_count, 500); Look up the IPv6 address from the specified host name.
nxd_dns_host_by_address_get**	nxd_dns_host_by_address_get(&my_dns, &host_address, resolved_name, sizeof(resolved_name), 4000); Look up a host name from the input IP address (supports both IPv4 and IPv6 addresses).
nxd_dns_host_by_name_get**	nxd_dns_host_by_name_get(&my_dns, "www.my_example.com", &ip_address, 4000, NX_IP_VERSION_V4); Look up an IP address from the input host name (supports both IPv4 and IPv6 addresses).

nxd_dns_server_add**	nxd_dns_server_add(&my_dns, &server_address); Add the input DNS Server to the Client server list (supports both IPv4 and IPv6 addresses).
nxd_dns_server_get**	nxd_dns_server_get(&my_dns, 5, &my_server_address); Return the DNS Server in the Client list at the specified index (supports both IPv4 and IPv6 addresses).
nxd_dns_server_remove**	nxd_dns_server_remove(&my_dns,& server_ADDRESS); Remove a DNS Server of the specified IP address from the Client list (supports both IPv4 and IPv6 addresses).

Note

Fordetails on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo DNS Client. For definitions of of NetX Duo specific data types, see the *NetX Duo User Guide for the Renesas Synergy™ Platform*.

Status Return Values

Name	Description
NX_SUCCESS	API Call Successful.
NX_DNS_NO_SERVER	Client server list is empty.
NX_DNS_QUERY_FAILED	No valid DNS response received.
NX_DNS_NEED_MORE_RECORD_BUFFER	Input buffer size insufficient to hold the minimum data.
NX_PTR_ERROR*	Invalid IP or DNS pointer.
NX_CALLER_ERROR*	Invalid caller of this service.
NX_DNS_ERROR	Internal error in DNS Client processing.
NX_DNS_PARAM_ERROR	Invalid non-pointer input.
NX_DNS_CACHE_ERROR	Invalid Cache pointer.
NX_DNS_TIMEOUT	Timed out on obtaining DNS mutex.
NX_DNS_BAD_ADDRESS_ERROR	Null input address.
NX_DNS_INVALID_ADDRESS_TYPE	Index points to invalid address type (for example, IPv6).
NX_DNS_IPV6_NOT_SUPPORTED	Cannot process record with IPv6 disabled.
NX_NOT_ENABLED	Client not configured for this option.
NX_DNS_DUPLICATE_ENTRY	DNS Server is already in the Client list.
NX_NO_MORE_ENTRIES	No more DNS Servers allowed (list is full).

NX_DNS_SERVER_NOT_FOUND	Server not in client list.

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

- These error codes are only returned if error checking is enabled. For details on error-checking services, see *NetX User Guide for the Renesas Synergy™ Platform* or *NetX Duo User Guide for the Renesas Synergy™ Platform in NetX and NetX Duo*, respectively.

4.3.18.3 NetX/NetX Duo DNS Client Module Operational Overview

DNS Messages

The NetX DNS Client module creates the IP instance, enables UDP services in NetX, and initializes the network driver while registering a valid IP address. The module creates an UDP socket for sending and receiving DNS messages to DNS servers listening on port 53 for DNS queries.

To obtain a mapping, the DNS client prepares a DNS query message containing the name or the IP address to be resolved. The message goes to the first DNS server in the server list. If the server has a mapping, it replies to the DNS client using a DNS response message containing the requested mapping. If the server does not respond, the DNS client queries the next server on its list until all its DNS servers have been queried. If no response is received from all its DNS servers, the DNS client retransmits the DNS message starting back at the top of the server list. DNS queries are sent until the retransmission timeout expires. Until a response is received, each iteration down the list of servers doubles the retransmission timeout until the maximum transmission timeout is reached. This timeout is set in the *Maximum duration to retransmit a DNS query (seconds)* property. The default value is 64 seconds; the maximum number of times the DNS client iterates down the server list, which is set by the *Maximum retries for a server* property and defaults to 3.

The typical NetX DNS Client queries are:

- IPv4 address lookups (type A) by using the nx_dns_host_by_name_get service.
- Reverse lookups of IP addresses (type PTR queries) to obtain web host names using the nx_dns_host_by_address_get service.
- IPv6 address lookups (type AAAA) or IPv4 address lookups (type A), specified in the IP address data type input, in the nxd_dns_host_by_name_get service. (This is only available in the NetX Duo DNS Client.)
- Reverse lookups of IP addresses (type PTR queries) to obtain web-host names using the nxd_dns_host_by_address_get service. (This is only available in the NetX Duo DNS Client.)

The NetX Duo DNS Client module still supports nx_dns_host_by_name_get and nx_dns_host_by_address_get services. These are equivalent services, but they are limited to IPv4 network communication, so developers are encouraged to use the nxd_dns_host_by_name_get and nxd_dns_host_by_address_get services instead.

Extended DNS Resource Record Types

If the *Extended RR types support* property is enabled, the NetX DNS Client module also supports the following record type queries:

CNAME contains the canonical name for an alias

TXT contains a text string

NS contains an authoritative name server

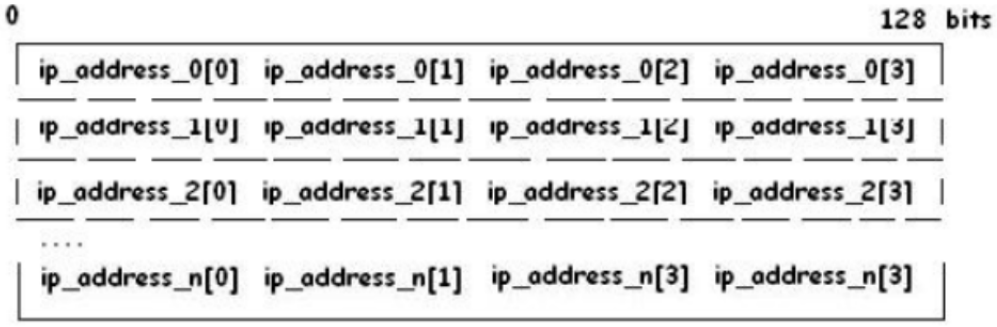
SOA contains the start of a zone of authority

MX used for mail exchange

SRV contains information on the service offered by the domain

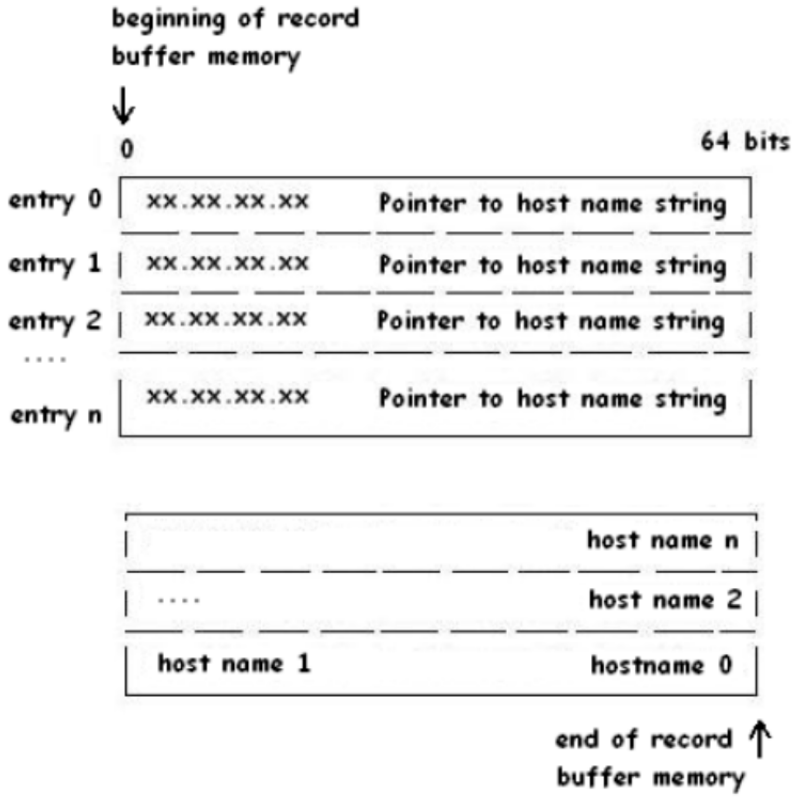
With the exception of CNAME and TXT record types, the application must supply a 4-byte aligned buffer to receive the DNS data record.

In the NetX DNS Client module, the record data is stored to make efficient use of buffer space. The following example shows a record buffer of fixed length (type AAAA record):



For queries whose record types have a variable data-length (such as NS records with variable-length host names), the NetX DNS Client module saves the data using the following methodology:

- Organizes the buffer supplied in the DNS Client query into fixed-length data and unstructured memory areas.
- Organizes the top of the memory buffer into 4-byte aligned record entries.
- For each record entry, holds the IP address and a pointer to the variable-length data for that IP address.
- Stores variable-length data for each IP address in unstructured area memory starting at the end of the memory buffer.
- Saves variable-length data for each successive record entry in the next area of memory, adjacent to the previous record entries' variable data.
- 'Grows' the variable data towards the structured area of memory holding record entries until there is insufficient memory to store another record entry and variable data (see following figure).



The NetX DNS Client queries use the record storage format to return the number of records saved to the record buffer; this information enables the application to extract NS records from the record buffer. After calling the nx_dns_domain_service_get with the receive_buffer pointer to the storage space, the application extracts the SRV data sequentially, taking advantage of the known size of the SRV entry:

```
NX_DNS_SRV_ENTRY *nx_dns_srv_entry_ptr[RECORD_COUNT];
status = nx_dns_domain_service_get(&client_dns,
                   (UCHAR *)"www.my_example.com",
                   &record_buffer[0], BUFFER_SIZE, &record_count,
                   NX_IP_PERIODIC_RATE);
for(i =0; i< record_count; i++)
{
    nx_dns_srv_entry_ptr[i] =
            (NX_DNS_SRV_ENTRY *)(record_buffer + i * sizeof(NX_DNS_SRV_ENTRY));
}
```

DNS Cache

If the *Cache support* property is enabled, the NetX DNS Client module supports the DNS cache feature. The application must set up the DNS cache using the nx_dns_cache_initialize service. When caching is enabled, the DNS client checks the DNS cache resource records before sending a DNS query. If it finds the answer in the cache, it directly returns it to the application. Otherwise, it sends out a query message to a DNS server and waits for the reply. When the DNS client gets the response message, it adds a resource record to the cache, if there is a cache entry available.

Each cache entry is a data structure used to hold a resource record. String entries (resource record name and data) in resource records are variable length, and as such, are not stored directly in the resource record. Instead, the resource record sets a pointer to the actual memory location in the cache where the strings are stored. Strings and resource records share the cache. Records are stored from the beginning of the cache and grow towards the end of the cache. String entries start from the end of the cache and grow towards the beginning of the cache. Each string entry has a length field and a counter field. When a string entry is added to the cache, and the same string is already present in the table, the counter value is incremented and no memory is allocated for the string. The cache is considered full if no more resource records or new string entries can be added to the cache.

NetX/NetX Duo DNS Client Module Important Operational Notes and Limitations

NetX/NetX Duo DNS Client Module Operational Notes

The NetX DNS Client requires a packet pool for transmitting DNS messages; by default, the application must set the packet pool before using DNS client services. This can either be the packet pool used by the IP instance (g_packet_pool0), or it can be a separate packet pool added to the project: **Azure RTOS**> **NetX Duo**> **NetX Duo Packet Pool Instance** (or **Azure RTOS**> **NetX**> **NetX Packet Pool Instance in NetX DNS Client**).

If the *Use application packet pool* is disabled, the DNS Client module creates the packet pool when the DNS client is created. The *Maximum DNS queries size* property determines the size of the packet payload and defaults to 512 bytes. The *Packets in DNS packet pool* property sets the number of packets in the DNS Client packet pool (defaults to 6).

Note

For user?created packet pools, the packet size holds the DNS maximum message size property. The default message size is 512 bytes, plus room for the UDP header (8 bytes), IPv4 header (20 bytes), or IPv6 header (40 bytes), and the network frame header. The Ethernet frame header is rounded up to 16 bytes for 4-byte alignment. This user-created packet pool is only used to send DNS packets. The IP packet pool is set to a 1568?byte packet payload. This packet pool setting works best for the Synergy network driver and the device MTU (typically, 1518 bytes), and it also avoids the need to chain packets in the driver layer.

Before sending DNS queries, the application must add one or more DNS servers to the server list kept by the DNS client. The maximum server list size is set by the *Maximum number of DNS Servers in the Client server list* property.

To add a DNS server, the application can use either the nx_dns_server_add service (limited to IPv4 packets) or the nxd_dns_server_add service supporting IPv4 and IPv6 packets.

Note

In the NetX Duo DNS Client, enabling the Client has DNS and Gateway Server property has no effect in the latest SSP release. When the DNS client is created, the IP instance does not have a router/gateway address set.

In the NetX DNS Client, enabling the *Client has Gateway Server* should be disabled. The IP instance

cannot have its gateway address by the time the DNS client is created and initialized by the configurator build process, and *DNS Client IP instance gateway* should not be used. To set a DNS server, it is recommended to use the nx_dns_server_add.

- To set up the DNS cache, the application can use the nx_dns_cache_initialize service with the cache memory buffer pointing to a previously defined buffer. To be notified if the cache is full, use the nx_dns_cache_notify_set service. This callback can be 'disabled' by clearing the callback using the nx_dns_cache_notify_clear service.
- A useful feature is the *Clear previous DNS queries from queue* property; this property enables the DNS client to remove any old DNS server responses from the DNS client receive queue when looking for a response that matches the current query. This means older packets received from previous DNS queries are discarded to prevent the DNS client socket from overflowing and dropping valid packets.
- Refer to the following list for NetX DNS services and their NetX Duo DNS equivalents:

NetX DNS API Service (IPv4 only)	NetX Duo DNS API Service (IPv4 and IPv6 supporte)
nx_dns_host_by_name_get	nxd_dns_host_by_name_get
nx_dns_host_by_address_get	nxd_dns_host_by_address_get
nx_dns_server_get	nxd_dns_server_get
nx_dns_server_add	nxd_dns_server_add
nx_dns_server_remove	nxd_dns_server_remove

NetX/NetX Duo DNS Client Module Limitations

- The DNS client supports one DNS request at a time; threads attempting to make another DNS request are temporarily blocked until the previous DNS request is complete.
- The NetX DNS Client module does not use data from authoritative answers to forward additional DNS queries to other DNS servers.
- Refer to the latest *SSP Release Notes* for any additional operational limitations for this module.

4.3.18.4 Including the NetX/NetX Duo DNS Client Module in an Application

This section describes how to include either or both the NetX and NetX Duo DNS Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo DNS Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo DNS Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_dns0 NetX DNS Client	Threads	**New Stack**> **X-Ware**> **NetX**> **Protocols**> **NetX DNS Client**

g_dns0 NetX Duo DNS Client	Threads	**New Stack**> **X-Ware**> **NetX Duo**> **Protocols**> **NetX Duo DNS Client**

When the NetX and/or NetX Duo DNS Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

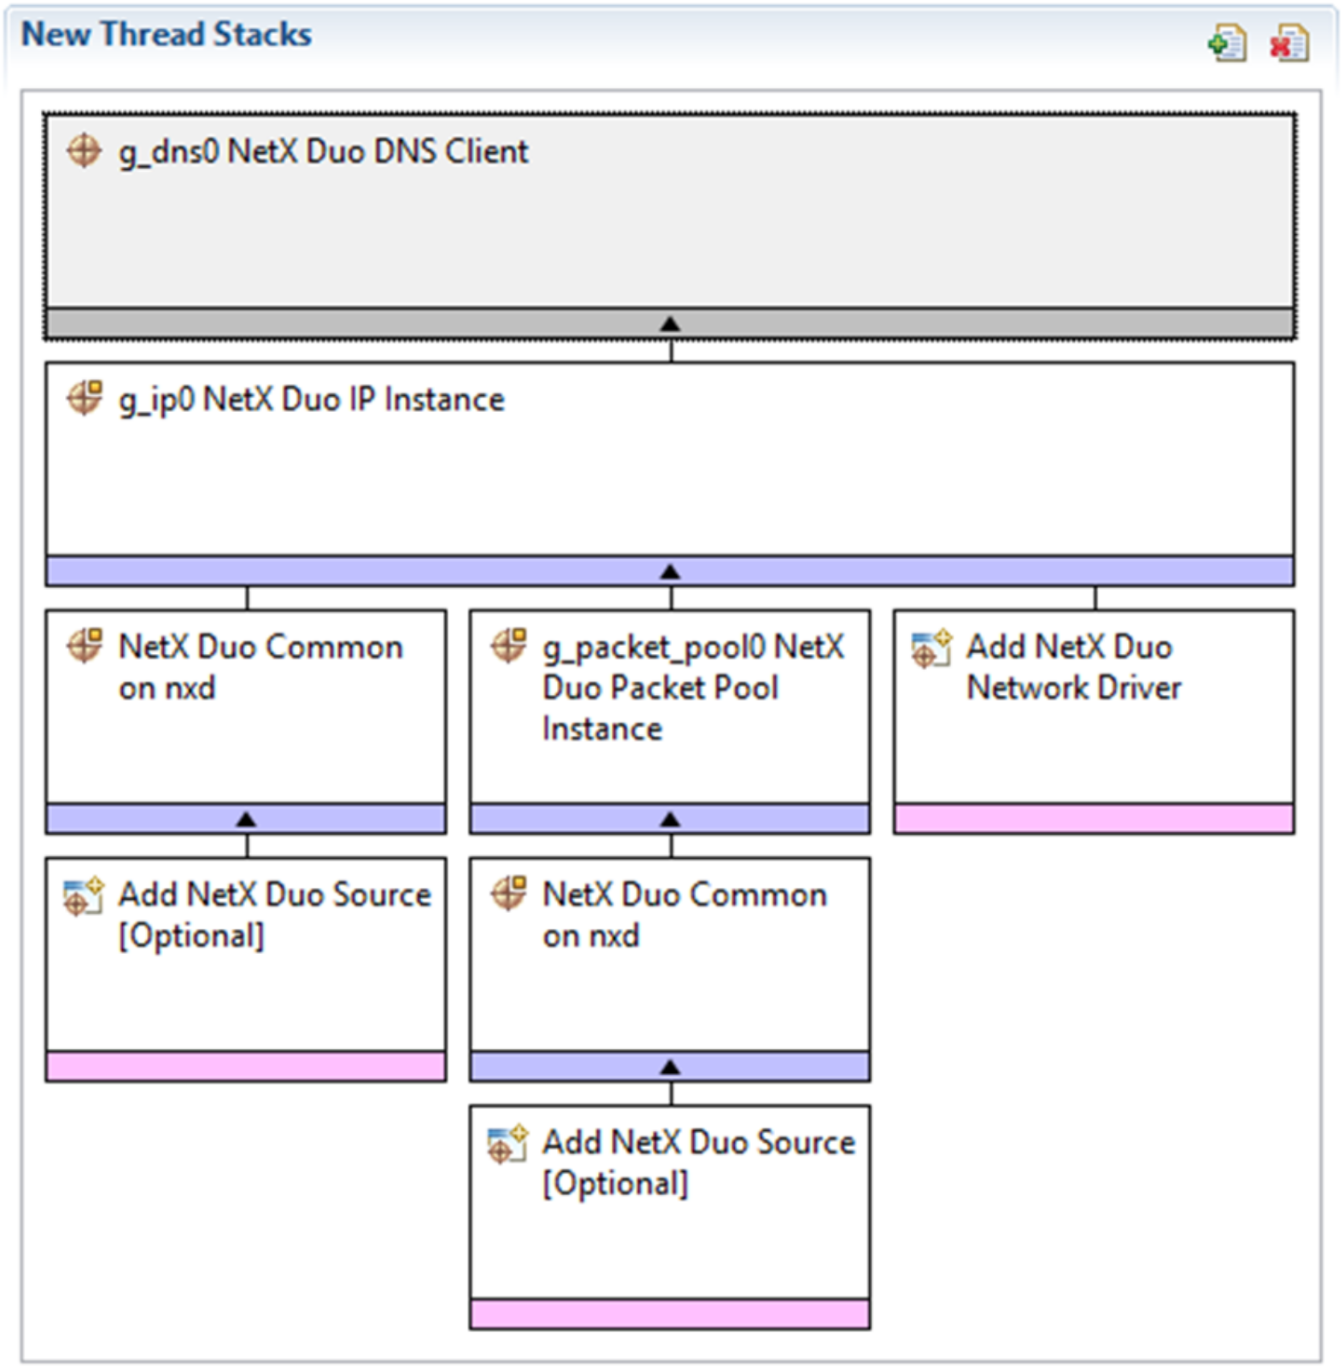


Figure 449: NetX/NetX Duo DNS Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp

- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.18.5 Configuring the NetX/NetX Duo DNS Client Module

The NetX/NetX Duo DNS Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo DNS Client Module

ISDE Property	Value	Description
DNS Control Type of Service	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	DNS control type of service selection.
Socket fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Socket fragmentation option selection.
Time to live	128	Time to live selection.
**Client DNS IP version	IPv4, IPv6 Default: IPv4	Client DNS IP version selection.
Maximum number of DNS Servers in Client server list	5	Maximum number of DNS Servers in Client server list selection.
Maximum DNS queries size (bytes)	512	Maximum DNS queries size selection.
Packets in DNS packet pool (units)	16	Packets in DNS packet pool selection.
Maximum retries for a server	3	Maximum retries for a server selection.
Maximum duration to retransmit a DNS query (seconds)	64	Maximum duration to retransmit a DNS query selection.

Packet allocate timeout (seconds)	1	Packet allocate timeout selection.
Client has DNS and Gateway server	Enable, Disable Default: Disable	DNS control type of service selection.
DNS Client IP instance gateway (use commas for separation) (Not included in NetX Duo)	192,16,0,1	DNS client IP instance gateway selection.
Use application packet pool	Enable, Disable Default: Enable	Use application packet pool selection.
Clear previous DNS queries from queue	Enable, Disable Default: Disable	Clear previous DNS queries from queue selection.
Extended RR types support	Enable, Disable Default: Disable	Extended RR types support selection.
Cache support	Enable, Disable Default: Disable	Cache support selection.
Name	g_dns0	Module name.
Name of generated initialization function	dns_client_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different MAC or IP Addresses. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo DNS Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the

module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name.
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection.
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection.
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection.
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection.
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection.
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection.
IP Helper Thread Priority	3	IP Helper Thread Priority selection.
ARP	Enable	ARP selection.
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection.
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection.
TCP	Enable, Disable Default: Enable	TCP selection.
UDP	Enable, Disable Default: Enable	UDP selection.
ICMP	Enable, Disable Default: Enable	ICMP selection.
IGMP	Enable, Disable Default: Enable	IGMP selection.
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection.
Name of generated initialization function	ip_init0	Name of generated initialization function selection.

Auto Initialization	Enable, Disable Default: Enable	Auto initialization function.
Link status change callback	NULL	Link status change callback selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name.
Packet Size in Bytes	640	Packet size selection.
Number of Packets in Pool	16	Number of packets in pool selection.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo DNS Client Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX/NetX Duo DNS Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin Selection Sequence
ETHERC	Pins	Select **Peripherals**> **Connectivity:ETHERC**> **ETHERC1.RMII**

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1.
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection.
REF50CK	P701	REF50CK pin.
TXD0	P700	TXD0 pin.
TXD1	P406	TXD1 pin.
TXD_EN	P405	TXD_EN pin.
RXD0	P702	RXD0 pin.
RXD1	P703	RXD1 pin.
RX_ER	P704	RX_ER pin.
CRS_DV	P705	CRS_DV pin.
MDC	P403	MDC pin.
MDIO	P404	MDIO pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.18.6 Using the NetX/NetX Duo DNS Client Module in an Application

The steps in using the NetX/NetX Duo DNS Client module in a typical application are:

1. Wait for valid IP address using the nx_ip_status_check API.

2. Enable DNS caching by calling the nx_dns_cache_initialize [optional].

3. Add one or more servers to the client list using the nx_dns_server_add API.

4. Send DNS name query using nxd_dns_host_by_name_get API to obtain an IP address.

5. Extract DNS server resource records using known size and arrangement of records packaged by the DNS client.

The following figure illustrates common steps in a typical operational flow diagram:

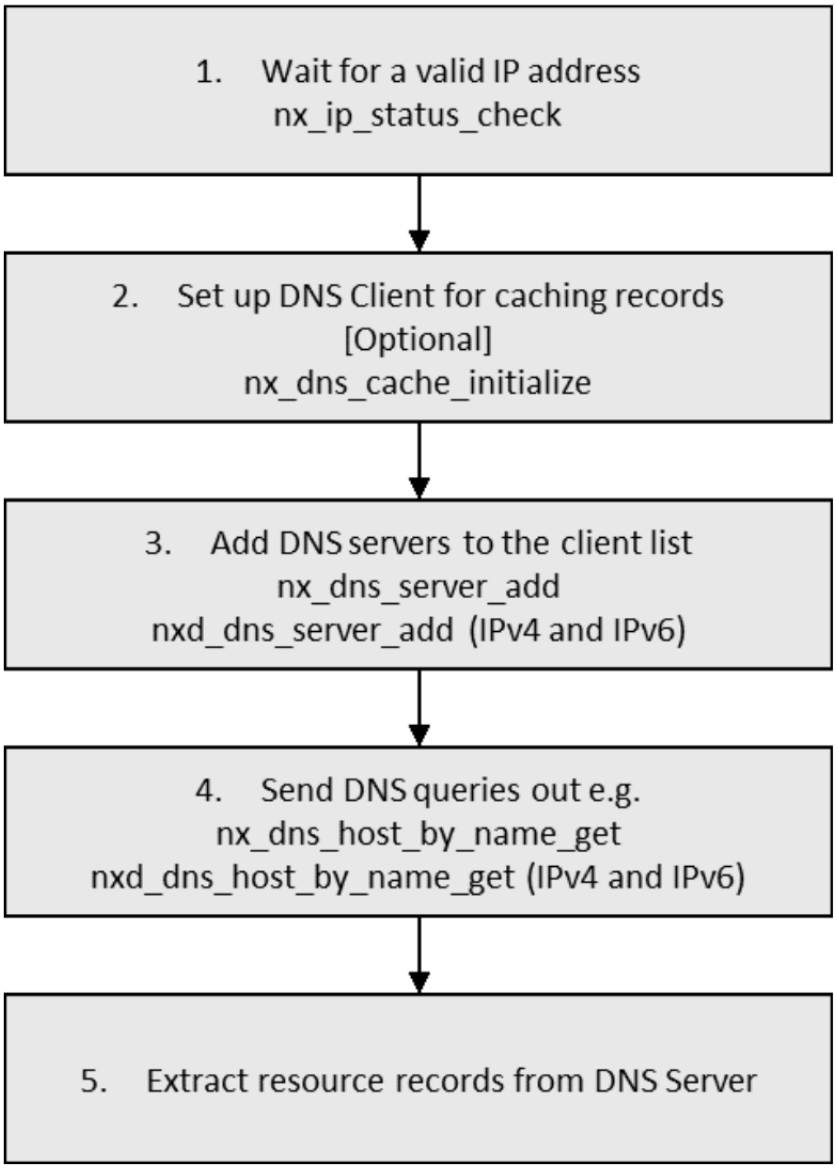

Figure 450: Flow Diagram of a Typical NetX/NetX Duo DNS Client Module Application

4.3.19 NetX/NetX Duo FTP Client

4.3.19.1 NetX/NetX Duo FTP Client Introduction

The File Transfer Protocol (FTP) is a protocol designed for file transfers. The FTP utilizes reliable Transmission Control Protocol (TCP) services to perform its file transfer function. The actual FTP file transfer is performed on a dedicated FTP connection.

Note

The NetX™ FTP Client module supports IPv4 only. The NetX Duo™ FTP Client module accommodates both IPv4 and IPv6 networks. IPv6 does not directly change the FTP protocol, although some changes in the original NetX FTP APIs are necessary to accommodate IPv6 and will be described in this document.

Unsupported Features

Multi-thread support has not been tested in this version of SSP.

Passive transfer mode has not been tested for NetX Duo in this version of SSP.

NetX/NetX Duo FTP Client Module Features

- Multi-thread support
  - High level APIs
  - Connecting and disconnecting
  - Directory operations
  - File operations

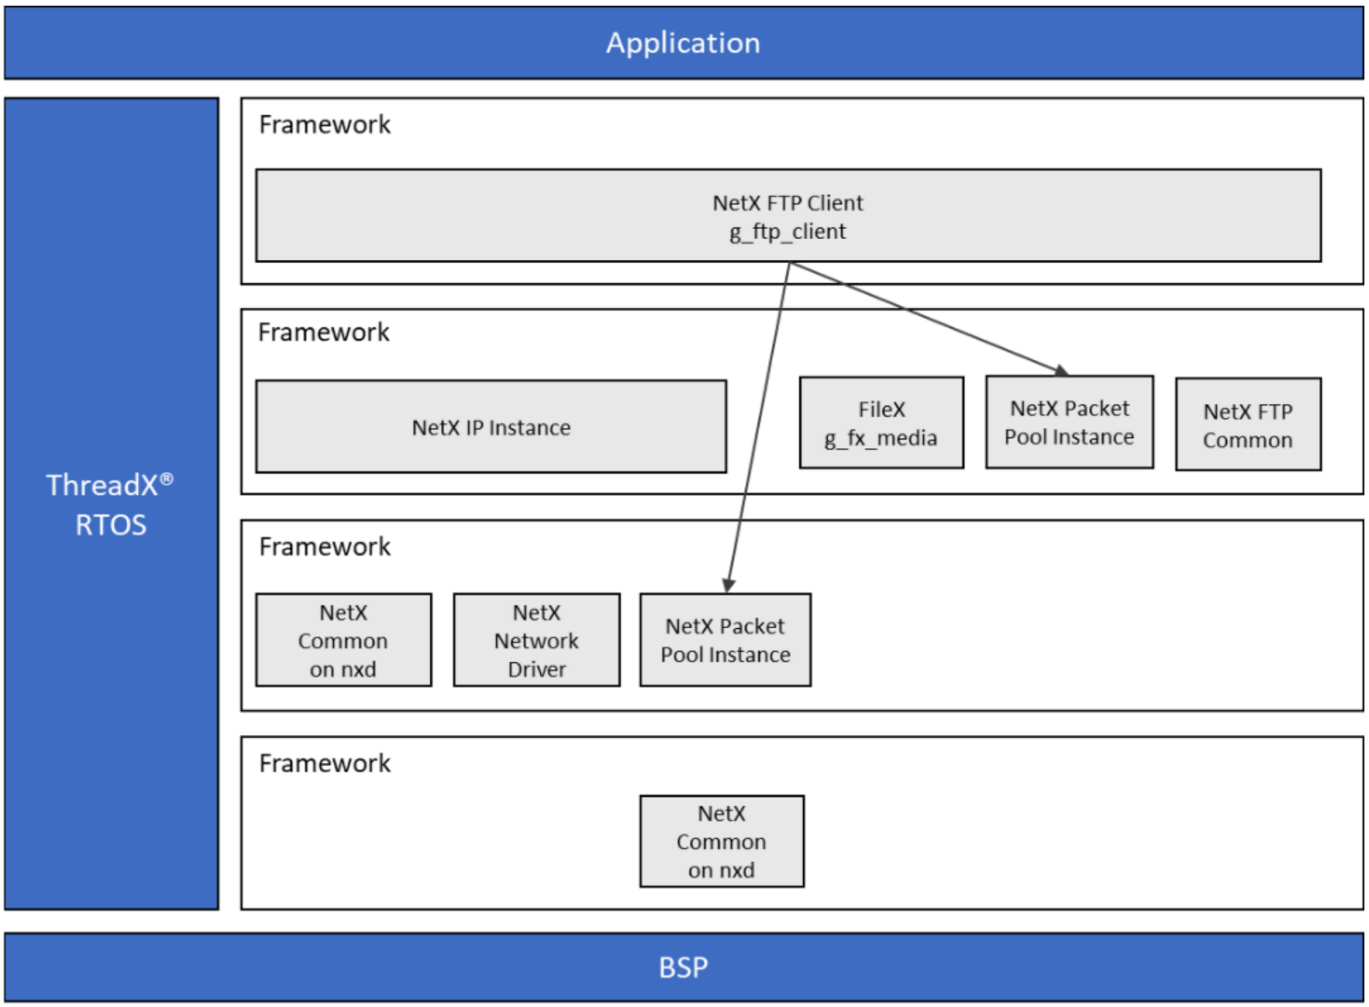

Figure 451: NetX/NetX Duo FTP Client Module Block Diagram

Note

In the figure above, the FileX and NetX (or NetX Duo) Network Driver modules have multiple implementation options available. See the descriptions just after the module stack figure in Including the NetX/NetX Duo FTP Client Module in an Application for additional details.

4.3.19.2 NetX/NetX Duo FTP Client Module APIs Overview

The NetX/NetX Duo FTP Client defines APIs for client creation/deletion, connecting/disconnecting to and from the server, directory operations and file operations. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX/NetX Duo FTP Client Module API Summary

Function Name	Example API Call and Description
nx_ftp_client_create	nx_ftp_client_create(&my_client, "My Client", &client_ip, 2000, &client_pool); Delete an FTP Client instance.

nx_ftp_client_delete	nx_ftp_client_delete(&my_client); Delete an FTP Client instance.
nx_ftp_client_connect	nxd_ftp_client_connect(&my_client, server_ip_addr, NULL, NULL, 100); Connect to an FTP Server with IPv6 and IPv4 support.
**nxd_ftp_client_connect	nxd_ftp_client_connect(&my_client, server_ip_addr, NULL, NULL, 100); Connect to an FTP Server with IPv6 and IPv4 support.
nx_ftp_client_disconnect	nx_ftp_client_disconnect(&my_client, 200); Disconnect from the FTP Server.
nx_ftp_client_create	nx_ftp_client_directory_create(&my_client, "my_dir", 200); Create a directory on the server.
nx_ftp_client_directory_set	nx_ftp_client_directory_listing_set(&my_client, "my_dir", &my_packet, 200); Get a directory listing from the server.
nx_ftp_client_directory_delete	nx_ftp_client_directory_delete(&my_client, "my_dir", 200); Delete a directory on the server.
nx_ftp_client_directory_listing_get	nx_ftp_client_directory_listing_get(&my_client, "my_dir", &my_packet, 200); Get a directory listing from the server.
nx_ftp_client_directory_listing_continue	nx_ftp_client_directory_listing_continue(&my_client, &my_packet, 200); Continue a directory listing from the server.
nx_ftp_client_file_open	nx_ftp_client_file_open(&my_client, "my_file.txt", NX_FTP_OPEN_FOR_READ, 200); Open a file on the server.
nx_ftp_client_file_close	nx_ftp_client_file_close(&my_client, 200); Close the currently open file on the server.
nx_ftp_client_file_read	nx_ftp_client_file_read(&my_client, &my_packet, 200); Read from a file already open on the server.
nx_ftp_client_file_write	nx_ftp_client_file_write(&my_client, my_packet, 200); Write to an already open file on the server.
nx_ftp_client_file_rename	nx_ftp_client_file_rename(&my_client, "my_file.txt", "new_file.txt", 200); Rename a file on the server.

nx_ftp_client_file_delete	nx_ftp_client_file_delete(&my_client, "my_file.txt", 200); Delete a file on the server.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo FTP Client. For definitions of NetX Duo specific data types, see the *NetX Duo User Guide for the Renesas Synergy™ Platform*.

Status Return Values

Name	Description
NX_SUCCESS	Successful FTP function.
NX_FTP_NOT_DISCONNECTED	FTP client is already connected.
NX_FTP_200_CODE_NOT_RECEIVED	Server rejects FTP connection.
NX_FTP_300_CODE_NOT_RECEIVED	Server rejects user/password.
NX_PTR_ERROR	Invalid FTP, username, or password pointer.
NX_CALLER_ERROR	Invalid caller of this service.
NX_IP_ADDRESS_ERROR	Invalid IP address.
NX_FTP_NO_2XX_RESPONSE_XXD	FTP server error response.
NX_FTP_NO_2XX_RESPONSE_PORT	FTP server response to PORT.
NX_FTP_NO_1XX_RESPONSE	FTP server response to NLST.
NX_FTP_END_OF_LISTING	No more entries in directory.
NX_FTP_NO_2XX_RESPONSE_DISCONNECT	FTP server response to disconnect.

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.19.3 NetX/NetX Duo FTP Client Module Operational Overview

FTP Client Requirements

To function properly, the NetX FTP Client package requires NetX. Similarly, the NetX Duo FTP Client package relies on NetX Duo. The host application must create an IP instance for running NetX services and periodic tasks. If running the FTP host application over an IPv6 network, IPv6, and ICMPv6 must be enabled on the IP task. TCP must be also enabled for either IPv6 or IPv4 networks. The IPv6 host application must set its link local and global IPv6 address using the IPv6 API and/or DHCPv6.

The FTP Server and Client are also designed to work with the FileX® embedded file system. If FileX is not available, the host developer can implement or substitute their own file system along the guidelines suggested in filex_stub.h by defining each of the services listed in that file.

The FTP Client portion of the NetX FTP package has no further requirements.

FTP File Names

FTP file names should be in the format of the target file system, usually FileX. They should be NULL terminated ASCII strings, with full path information if necessary. There is no specified limit for the size of FTP file names in the NetX FTP implementation. The packet pool payload size should be able to accommodate the maximum path and file name.

FTP Client Commands

The FTP has a simple mechanism for opening connections and performing file and directory operations. There is basically a set of standard FTP commands that are issued by the Client after a connection has been successfully established on the TCP well-known port 21. The following shows some of the basic FTP commands. Note that the only difference when FTP runs over IPv6 is that the PORT command is replaced with the EPRT command:

FTP Client Commands

FTP Command	Meaning
CWD path	Change working directory.
DELE filename	Delete specified file name.
EPRT ip_address, port	Provide IPv6 address and Client data port.
LIST directory	Get directory listing.
MKD directory	Make new directory.
NLST directory	Get directory listing.
NOOP	No operation, returns success.
PASS password	Provide password for login.
PORT ip_address,port	Provide IP address and Client data port.
PWD path	Pickup current directory path.
QUIT	Terminate Client connection.
RETR filename	Read specified file.
RMD directory	Delete specified directory.
RNFR oldfilename	Specify file to rename.
RNTO newfilename	Rename file to supplied file name.
STOR filename	Write specified file.
TYPE I	Select binary file image.
USER username	Provide username for login.

Note

These ASCII commands are used internally by the NetX FTP Client software to perform FTP operations with the FTP Server.

FTP Server Responses

Once the FTP Server processes the Client request, it returns a 3-digit coded response in ASCII followed by optional ASCII text. The numeric response is used by the FTP Client software to determine whether the operation succeeded or failed. The following list shows various FTP Server responses to Client requests:

First Numeric Field

First Numeric Field	Meaning
1xx	Positive preliminary status – another reply coming.
2xx	Positive completion status.
3xx	Positive preliminary status – another command must be sent.
4xx	Temporary error condition.
5xx	Error condition.

Second Numeric Field

Second Numeric Field	Meaning
0xx	Syntax error in command.
1xx	Positive preliminary status – another reply coming.
2xx	Positive completion status.
3xx	Positive preliminary status – another command must be sent.
4xx	Temporary error condition.
5xx	Error condition.

FTP Write Requests:

1. Client issues TCP connect to Server port 21.
2. Server sends 220 response to signal success.
3. Client sends USER message with username.
4. Server sends 331 response to signal success.
5. Client sends PASS message with password.
6. Server sends 230 response to signal success.
7. Client sends TYPE I message for binary transfer.
8. Server sends 200 response to signal success.
9. IPv6 applications: Client sends EPRT message with IP address and port. IPv4 applications: Client sends PORT message with IP address and port.
10. Server sends 200 response to signal success.
11. Client sends STOR message with file name to write.
12. Server creates data socket and connects with client data port specified in the previous EPRT or PORT command.
13. Server sends 125 response to signal file write has started.

14. Client sends contents of file through the data connection. This process continues until file is completely transferred.
15. When finished, Client disconnects data connection.
16. Server sends 250 response to signal file write is successful.
17. Clients sends QUIT to terminate FTP connection.
18. Server sends 221 response to signal disconnect is successful.
19. Server disconnects FTP connection.

FTP Authentication

Whenever a FTP connection takes place, the Client must provide the Server with a username and password. Some FTP sites allow what is called Anonymous FTP, that allows FTP access without a specific username and password. For this type of connection, anonymous should be supplied for username and the password should be a complete e-mail address.

You are responsible for supplying the NetX FTP Client and the NetX Duo FTP Client with login and logout authentication routines. These are supplied during the nxd_ftp_server_create and nx_ftp_server_create services and called from the password processing. The difference between the two is the nxd_ftp_server_create input function pointers to login and logout authenticate functions expect the NetX Duo address type NXD_ADDRESS. This data type holds both IPv4 or IPv6 address formats, making this function the Duo service supporting both IPv4 and IPv6 networks. The nx_ftp_server_create input function pointers to login and logout authenticate functions expect ULONG IP address type. This function is limited to IPv4 networks. You are encouraged to use the Duo service whenever possible.

If the login function returns NX_SUCCESS, the connection is authenticated and the FTP operations are allowed. Otherwise, if the login function returns something other than NX_SUCCESS, the connection attempt is rejected.

NetX/NetX Duo FTP Client Module Important Operational Notes and Limitations

NetX/NetX Duo FTP Client Module Operational Notes

FTP Multi-Thread Support

- The NetX FTP Client services can be called from multiple threads simultaneously. However, read or write requests for a particular FTP Client instance should be done in sequence from the same thread.

RFCs

- NetX Duo FTP is compliant with RFC 959, RFC 2428 and related RFCs.

NetX/NetX Duo FTP Client Module Limitations

FTP Constraints

The FTP standard has many options regarding the representation of file data. NetX FTP does not implement switch options like ls – al. The NetX FTP Server and the NetX Duo FTP Server expect to receive requests and their arguments in a single packet rather than consecutive packets.

Like UNIX implementations, NetX FTP assumes the following file format constraints:

- File Type: Binary
- File Format: Nonprint Only

- File Structure: File Structure Only

4.3.19.4 Including the NetX/NetX Duo FTP Client Module in an Application

This section describes how to include either or both the NetX and NetX Duo FTP Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo FTP Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo FTP Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_dns0 NetX FTP Client	Threads	**New Stack**> **X-Ware**> **NetX**> **Protocols**> **NetX FTP Client**
g_dns0 NetX Duo FTP Client	Threads	**New Stack**> **X-Ware**> **NetX Duo**> **Protocols**> **NetX Duo FTP Client**

When the NetX and/or NetX Duo FTP Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

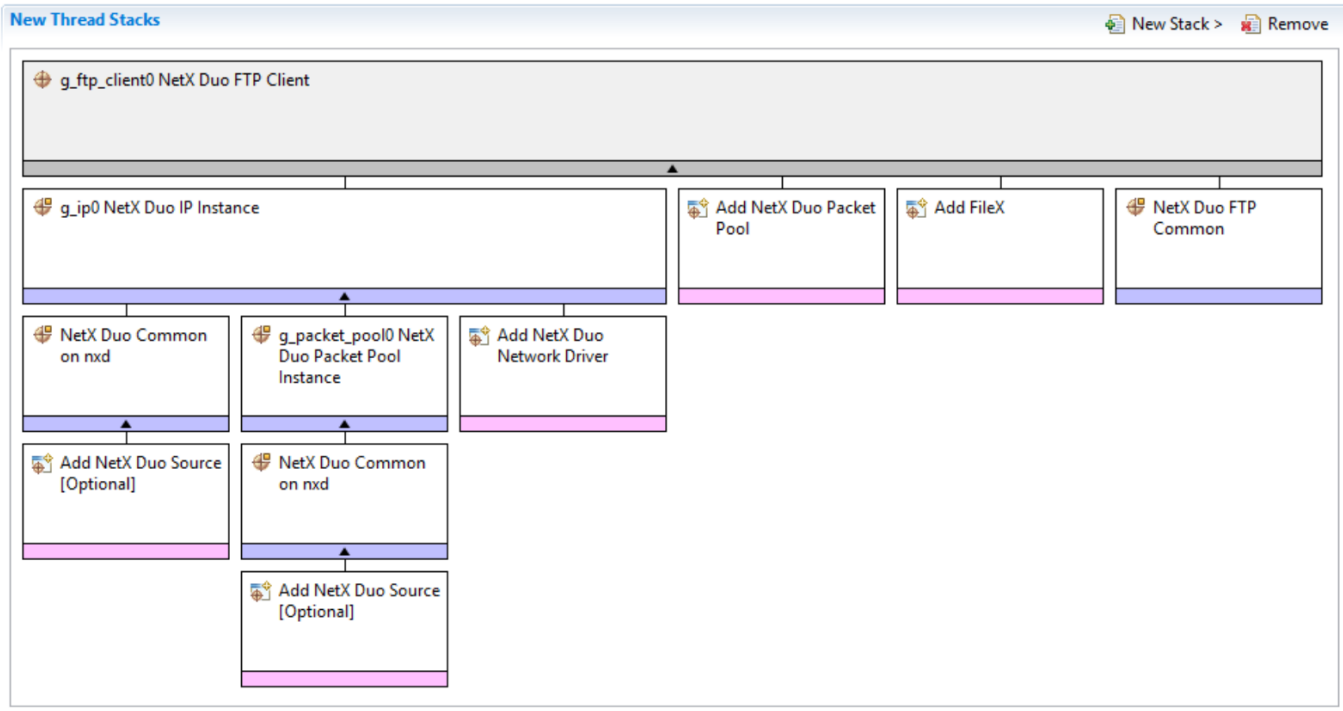

Figure 452: NetX/NetX Duo FTP Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

Additionally, in the stack above, the FileX stack has also not been populated yet. There are multiple possible selections for the FileX module; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- FileX Stub
- FileX on Block Media (implemented on Block Media Framework on sf_block_media_ram)
- FileX on USB Mass Storage (implemented on USBX Host Class Mass Storage)

4.3.19.5 Configuring the NetX/NetX Duo FTP Client Module

The NetX/NetX Duo FTP Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous

manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo FTP Client Module

ISDE Property	Value	Description
**TCP socket to use	NX_ANY_PORT	TCP socket to use selection
Name	g_ftp_client0	Module name.
TCP socket window size (bytes)	2048	TCP socket window size selection
Name of generated initialization function	ftp_client_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different pins for the Ethernet peripheral. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo FTP Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name.
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection.

Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection.
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection.
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection.
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection.
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection.
IP Helper Thread Priority	3	IP Helper Thread Priority selection.
ARP	Enable	ARP selection.
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection.
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection.
TCP	Enable, Disable Default: Enable	TCP selection.
UDP	Enable, Disable Default: Enable	UDP selection.
ICMP	Enable, Disable Default: Enable	ICMP selection.
IGMP	Enable, Disable Default: Enable	IGMP selection.
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection.
Name of generated initialization function	ip_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function.
Link status change callback	NULL	Link status change callback selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have

different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo FTP Common Instance

ISDE Property	Value	Description
FileX support	Enabled, Disabled Default: Enabled	FileX support selection.
Control Type of Service	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Control type of service selection.
Data Type of Service	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Data type of service selection.
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragment option selection.
Time to live	128	Time to live selection.
Duration between client inactivity check (seconds)	60	Duration between client inactivity check selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name.

Packet Size in Bytes	640	Packet size selection.
Number of Packets in Pool	16	Number of packets in pool selection.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo FTP Client Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX/NetX Duo FTP Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin Selection Sequence
ETHERC	Pins	Select **Peripherals**> **Connectivity:ETHERC**> **ETHERC1.RMII**

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1.
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection.
REF50CK	P701	REF50CK pin.

TXD0	P700	TXD0 pin.
TXD1	P406	TXD1 pin.
TXD_EN	P405	TXD_EN pin.
RXD0	P702	RXD0 pin.
RXD1	P703	RXD1 pin.
RX_ER	P704	RX_ER pin.
CRS_DV	P705	CRS_DV pin.
MDC	P403	MDC pin.
MDIO	P404	MDIO pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.19.6 Using the NetX/NetX Duo FTP Client Module in an Application

The steps in using the NetX/NetX Duo FTP Client module in a typical application are:

Step 1. Create FTP Client using the nx_ftp_client_create API.

Step 2. Connect to the FTP Server using the nx_ftp_client_connect API.

The following steps can be used for writing to a file.

Step 3. Open a file using the nx_ftp_client_open API.

Step 4. Write to a file as needed using the nx_ftp_client_write API.

Step 5. Close a file using the nx_ftp_client_close API.

The following steps can be taken for reading from a file.

Step 6. Open a file using the nx_ftp_client_open API.

Step 7. Read from a file as needed using the nx_ftp_client_read API.

Step 8. Close a file using the nx_ftp_client_close API.

The following figure illustrates common steps in a typical operational flow diagram:

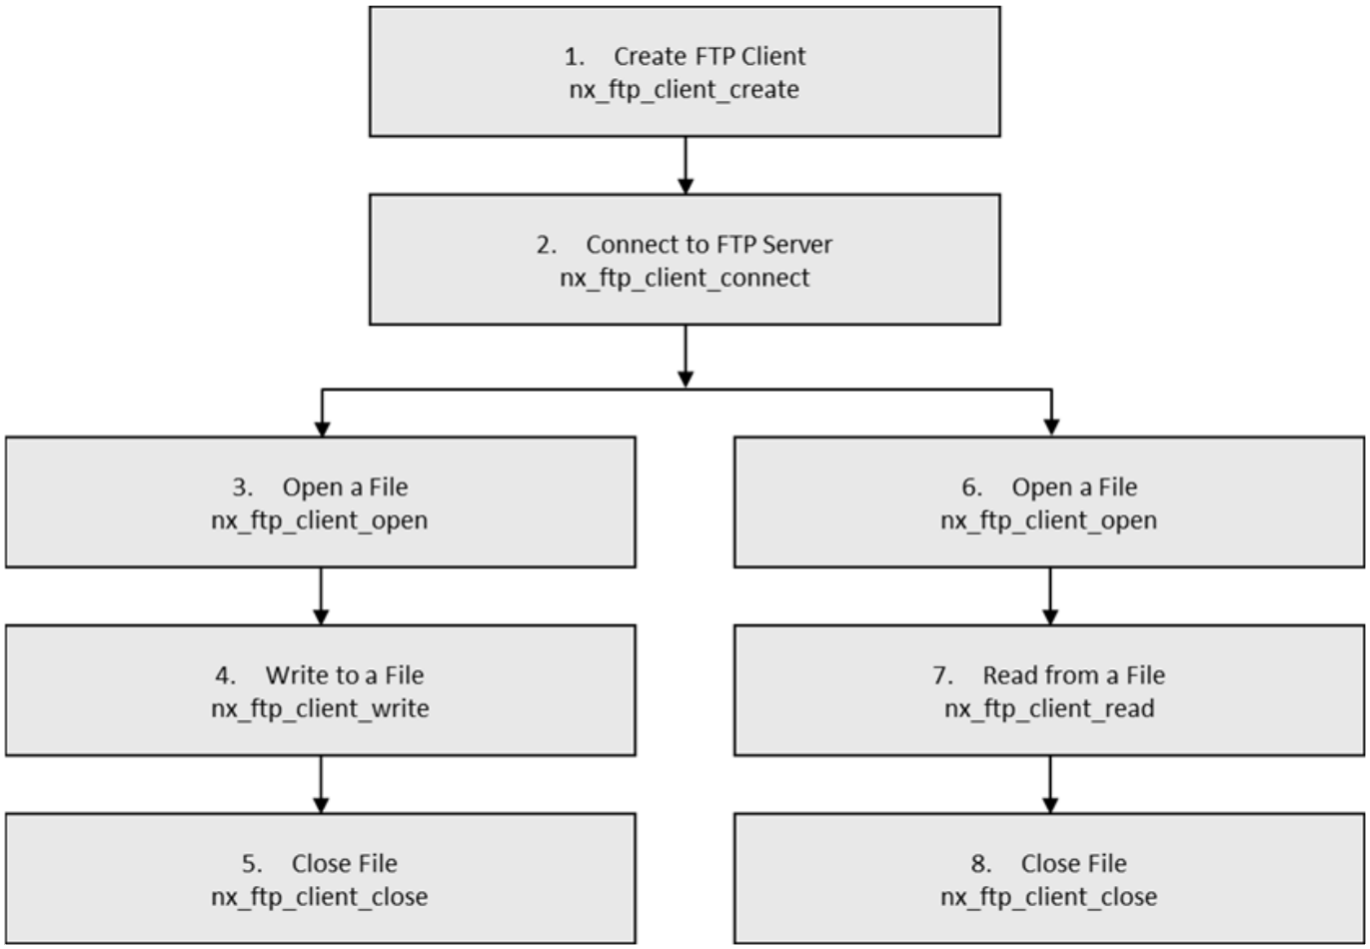

Figure 453: Flow Diagram of a Typical NetX/NetX Duo FTP Client Module Application

4.3.20 NetX/NetX Duo FTP Server

4.3.20.1 NetX/NetX Duo FTP Server Introduction

The File Transfer Protocol (FTP) is a protocol designed for file transfers. FTP utilizes reliable Transmission Control Protocol (TCP) services to perform its file transfer function. The actual FTP file transfer is performed on a dedicated FTP connection.

Note

The NetX™ FTP Server module is specific to IPv4. The NetX Duo™ FTP Server module accommodates both IPv4 and IPv6 networks. IPv6 does not directly change the FTP protocol, although some changes in the original NetX FTP APIs are necessary to accommodate IPv6 and will be described in this document.

Unsupported Features

Passive transfer mode has not been tested for NetX in this version of SSP.

NetX/NetX Duo FTP Server Module Features

- NetX is IPv4 specific
- NetX Duo supports both IPv4 and IPv6 networks
- Works with FileX® file system
- No limit to file name size; uses NULL terminated ASCII strings
- Supports TCP port 21 to field client requests
- Provide high-Level APIs for creating, starting, stopping and deleting service
- NetX FTP and NetX Duo FTP are compliant with RFC 959, RFC 2428 and related RFCs.

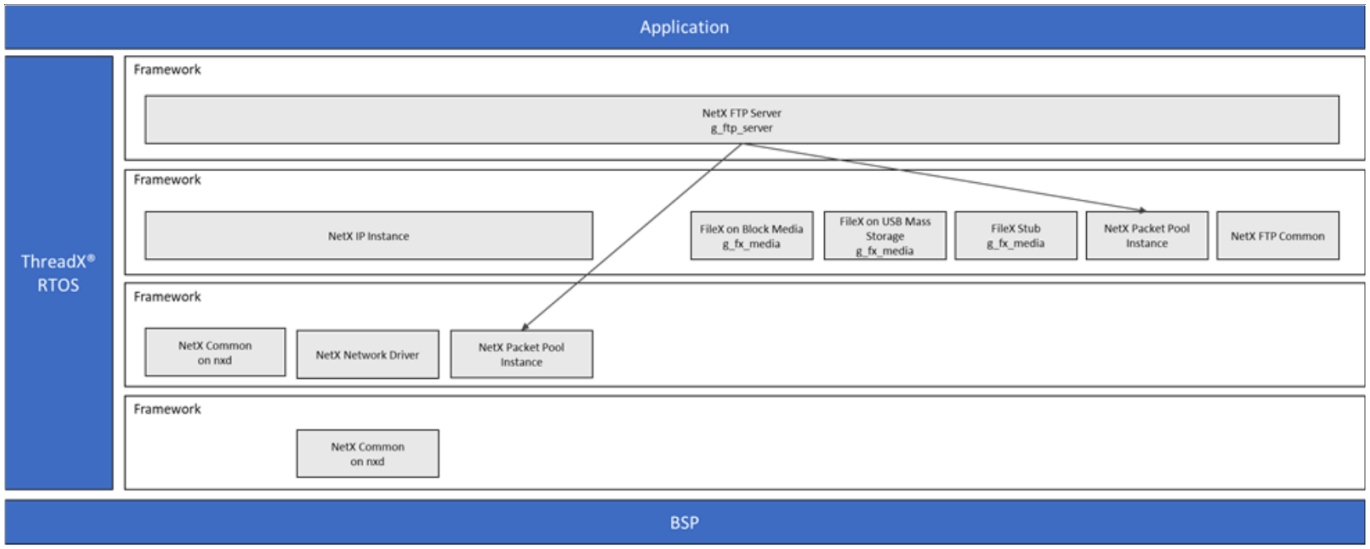

Figure 454: NetX/NetX Duo FTP Server Module Block Diagram

Note

In the figure above, the FileX and NetX (or NetX Duo) Network Driver modules have multiple implementation options available. See the descriptions just after the module stack figure in Including the NetX/NetX Duo FTP Server Module in an Application for additional details.

4.3.20.2 NetX/NetX Duo FTP Server Module APIs Overview

The NetX FTP Server defines APIs for creating, deleting, starting and stopping service. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX/NetX Duo FTP Server Module API Summary

Function Name	Example API Call and Description
nx_ftp_server_create	nx_ftp_server_create(&my_server, "My Server Name", &ip_0, &ram_disk, stack_ptr, stack_size, &pool_0, my_login, my_logout); Create FTP Server with IPv4 support only.
**nxd_ftp_server_create	nxd_ftp_server_create(&my_server, "My Server Name", &ip_0, &ram_disk, stack_ptr, stack_size, &pool_0, my_duo_login, my_duo_logout); Create FTP Server with IPv4 and IPv6 support.
nx_ftp_server_delete	nx_ftp_server_delete(&my_server); Delete FTP Server.

nx_ftp_server_start	nx_ftp_server_start(&my_server); Start FTP Server.
nx_ftp_server_stop	nx_ftp_server_stop(&my_server); Stop FTP Server.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo FTP Client. For definitions of of NetX Duo specific data types, see the *NetX Duo User Guide for the Renesas Synergy™ Platform*.

Status Return Values

Name	Description
NX_SUCCESS	Successful FTP server function.
NX_PTR_ERROR	Invalid FTP pointer.
NX_CALLER_ERROR	Invalid caller of this service.

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.20.3 NetX/NetX Duo FTP Server Module Operational Overview

Because FTP Client and Server operations are so closely linked, the following descriptions cover key elements of both Client and Server operations.

FTP Requirements

The NetX FTP package requires NetX or NetX Duo for proper operation. The host application must create an IP instance for running NetX services and periodic tasks. If running the FTP host application over an IPv6 network, IPv6, and ICMPv6 must be enabled on the IP task. TCP must be also enabled for either IPv6 or IPv4 networks. The IPv6 host application must set its linklocal and global IPv6 address using the IPv6 API and/or DHCPv6.

The FTP Server and Client are also designed to work with the FileX embedded file system. If FileX is not available, the host developer can implement or substitute their own file system along the guidelines suggested in filex_stub.h by defining each of the services listed in that file. This is discussed in later sections of this guide.

The FTP Client portion of the NetX FTP package has no further requirements.

The FTP Server portion of the NetX FTP package has several additional requirements. It requires complete access to TCP well-known port 21 for handling all Client FTP command requests and well-known port 20 for handling all Client FTP data transfers.

FTP File Names

FTP file names should be in the format of the target file system, usually FileX. They should be NULL terminated ASCII strings, with full path information if necessary. There is no specified limit for the

size of FTP file names in the NetX FTP implementation. The packet pool payload size should be able to accommodate the maximum path and/or file name.

FTP Client Commands

The FTP has a simple mechanism for opening connections and performing file and directory operations. There is a set of standard FTP commands that are issued by the Client after a connection has been successfully established on the TCP well-known port 21. The following table shows some of the basic FTP commands. Note that the only difference when FTP runs over IPv6 is that the PORT command is replaced with the EPRT command:

FTP Server Commands

FTP Command	Meaning
CWD path	Change working directory
DELE filename	Delete specified file name
EPRT ip_address, port	Provide IPv6 address and Client data port
LIST directory	Get directory listing
MKD directory	Make new directory
NLST directory	Get directory listing
NOOP	No operation, returns success
PASS password	Provide password for login
PORT ip_address,port	Provide IP address and Client data port
PWD path	Pickup current directory path
QUIT	Terminate Client connection
RETR filename	Read specified file
RMD directory	Delete specified directory
RNFR oldfilename	Specify file to rename
RNTO newfilename	Rename file to supplied file name
STOR filename	Write specified file
TYPE I	Select binary file image
USER username	Provide username for login

These ASCII commands are used internally by the NetX FTP Client software to perform FTP operations with the FTP Server.

FTP Server Responses

Once the FTP Server processes the Client request, it returns a 3-digit coded response in ASCII followed by optional ASCII text. The numeric response is used by the FTP Client software to determine whether the operation succeeded or failed. The following list shows various FTP Server responses to Client requests:

First Numeric Field

First Numeric Field	Meaning
1xx	Positive preliminary status – another reply coming.
2xx	Positive completion status.
3xx	Positive preliminary status – another command must be sent.
4xx	Temporary error condition.
5xx	Error condition.

Second Numeric Field

Second Numeric Field	Meaning
x0x	Syntax error in command.
x1x	Informational message.
x2x	Connection related.
x3x	Authentication related.
x4x	Unspecified.
x5x	File system related.

For example, a Client request to disconnect a FTP connection with the QUIT command will typically be responded with a 221 code from the Server – if the disconnect is successful.

FTP Communication

The FTP Server utilizes the well-known TCP port 21 to field Client requests. FTP Clients may use any available TCP port. The general sequence of FTP events are as follows. As mentioned previous, the only difference with FTP running over IPv6 is the PORT command is replaced with the EPRT command:

FTP Read File Requests:

1. Client issues TCP connect to Server port 21.
2. Server sends 220 response to signal success.
3. Client sends USER message with "username."
4. Server sends 331 response to signal success.
5. Client sends PASS message with "password."
6. Server sends 230 response to signal success.
7. Client sends TYPE I message for binary transfer.
8. Server sends 200 response to signal success.
9. Client sends PORT message with IP address and port.
10. Server sends 200 response to signal success.
11. Client sends RETR message with file name to read.
12. Server creates data socket and connects with client data port specified in the EPRT command.
13. Server sends 125 response to signal file read has started.

14. Server sends contents of file through the data connection. This process continues until file is completely transferred.
15. When finished, Server disconnects data connection.
16. Server sends 250 response to signal file read is successful.
17. Clients sends QUIT to terminate FTP connection.
18. Server sends 221 response to signal disconnect is successful.
19. Server disconnects FTP connection.

FTP Write Requests:

1. Client issues TCP connect to Server port 21.
2. Server sends 220 response to signal success.
3. Client sends USER message with "username."
4. Server sends 331 response to signal success.
5. Client sends PASS message with "password."
6. Server sends 230 response to signal success.
7. Client sends TYPE I message for binary transfer.
8. Server sends 200 response to signal success.
9. IPv6 applications: Client sends EPRT message with IP address and port. IPv4 applications: Client sends PORT message with IP address and port.
10. Server sends 200 response to signal success.
11. Client sends STOR message with file name to write.
12. Server creates data socket and connects with client data port specified in the previous EPRT or PORT command.
13. Server sends 125 response to signal file write has started.
14. Client sends contents of file through the data connection. This process continues until file is completely transferred.
15. When finished, Client disconnects data connection.
16. Server sends 250 response to signal file write is successful.
17. Clients sends QUIT to terminate FTP connection.
18. Server sends 221 response to signal disconnect is successful.
19. Server disconnects FTP connection.

FTP Authentication

Whenever a FTP connection takes place, the Client must provide the Server with a username and password. Some FTP sites allow what is called Anonymous FTP, which allows FTP access without a specific username and password. For this type of connection, **anonymous** should be supplied for username and the password should be a complete e-mail address.

You are responsible for supplying NetX FTP with login and logout authentication routines. These are supplied during the nxd_ftp_server_create and nx_ftp_server_create services and called from the password processing. The difference between the two is the nxd_ftp_server_create input function pointers to login and logout authenticate functions expect the NetX Duo address type NXD_ADDRESS. This data type holds both IPv4 or IPv6 address formats, making this function the duo service supporting both IPv4 and IPv6 networks. The nx_ftp_server_create input function pointers to login and logout authenticate functions expect ULONG IP address type. This function is limited to IPv4 networks. You are encouraged to use the duo service whenever possible.

If the login function returns NX_SUCCESS, the connection is authenticated and FTP operations are allowed. Otherwise, if the login function returns something other than NX_SUCCESS, the connection attempt is rejected.

NetX/NetX Duo FTP Server Module Important Operational Notes and Limitations

NetX/NetX Duo FTP Server Module Operational Notes

FTP Multi-Thread Support

- The NetX FTP Client services can be called from multiple threads simultaneously. However, read or write requests for a particular FTP Client instance should be done in sequence from the same thread.

RFCs

- NetX Duo FTP is compliant with RFC 959, RFC 2428 and related RFCs.

NetX/NetX Duo FTP Server Module Limitations

FTP Constraints

The FTP standard has many options regarding the representation of file data. NetX FTP does not implement switch options like ls – al. The NetX FTP Server and the NetX Duo FTP Server expect to receive requests and their arguments in a single packet rather than consecutive packets.

Like UNIX implementations, NetX FTP assumes the following file format constraints:

- File Type: Binary
- File Format: Nonprint Only
- File Structure: File Structure Only

4.3.20.4 Including the NetX/NetX Duo FTP Server Module in an Application

This section describes how to include either or both the NetX and NetX Duo FTP Server module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo FTP Server module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo FTP Server Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_dns0 NetX FTPServer	Threads	**New Stack**> **X-Ware**> **NetX**> **Protocols**> **NetX FTPServer**
g_dns0 NetX Duo FTPServer	Threads	**New Stack**> **X-Ware**> **NetX Duo**> **Protocols**> **NetX Duo FTP Server**

When the NetX and/or NetX Duo FTP Server module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink

band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

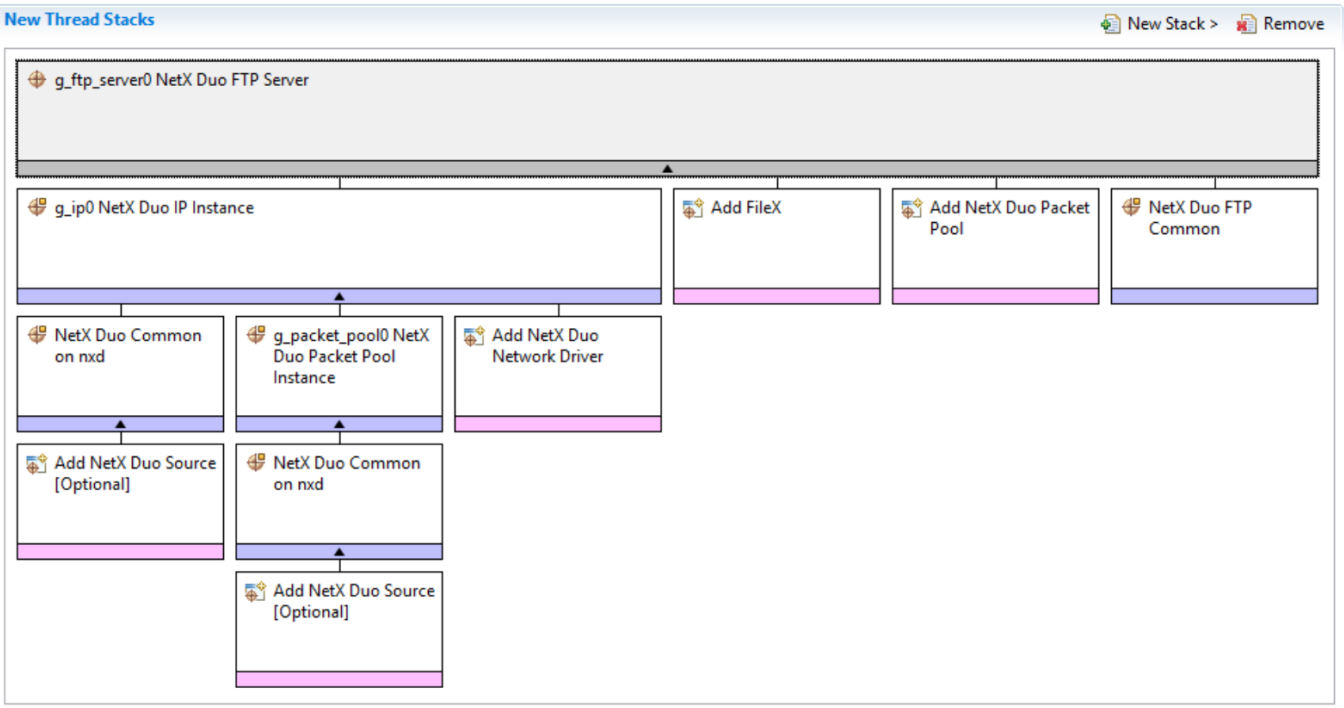

Figure 455: NetX/NetX Duo FTP Server Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

Additionally, in the stack above, the FileX stack has also not been populated yet. There are multiple possible selections for the FileX module; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- FileX Stub
- FileX on Block Media (implemented on Block Media Framework on sf_block_media_ram)
- FileX on USB Mass Storage (implemented on USBX Host Class Mass Storage)

4.3.20.5 Configuring the NetX/NetX Duo FTP Server Module

The NetX/NetX Duo FTP Server module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo FTP Server Module

ISDE Property	Value	Description
Internal Thread Priority	16	Internal thread priority selection.
Internal thread time slicing interval (ticks)	2	Internal thread time slicing interval selection.
Maximum clients to serve simultaneously	4	Maximum number of clients allowed.
Control window size (bytes)	400	Control window size selection.
Data window size (bytes)	2048	Data window size selection.
Duration internal services will suspend for (seconds)	1	Duration internal services will suspend for selection.
Maxixum username length (bytes)	20	Maximum username length selection.
Maximum password length (bytes)	20	Maximum password length selection.
Duration allowed with no activity (seconds)	240	Duration allowed with no activity.
Socket retransmit timeout (seconds)	2	Duration for initial timeout.
Maximum queued transmit packets	20	Maximum queued transmit selection.
Number of socket retransmissions	10	Maximum retries per selection.
Binary left shift as multiplier for retry duration	1	Binary left shift as multiplier for retry duration selection.
Name	g_ftp_server0	Module name.

Internal thread stack size (bytes)	4096	Internal thread stack size stacks selection.
Name of Login Function	ftp_login	Name of login function selection.
Name of Logout Function	ftp_logout	Name of logout function selection.
Name of generated initialization function	ftp_server_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different MAC Addresses. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo FTP Server Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name.
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection.
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection.
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection.
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection.
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection.

IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection.
IP Helper Thread Priority	3	IP Helper Thread Priority selection.
ARP	Enable	ARP selection.
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection.
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection.
TCP	Enable, Disable Default: Enable	TCP selection.
UDP	Enable, Disable Default: Enable	UDP selection.
ICMP	Enable, Disable Default: Enable	ICMP selection.
IGMP	Enable, Disable Default: Enable	IGMP selection.
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection.
Name of generated initialization function	ip_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function.
Link status change callback	NULL	Link status change callback selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo FTP Common Instance

ISDE Property	Value	Description
FileX support	Enabled, Disabled Default: Enabled	FileX support selection.

Control Type of Service	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Control type of service selection.
Data Type of Service	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Data type of service selection.
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragment option selection.
Time to live	128	Time to live selection.
Duration between client inactivity check (seconds)	60	Duration between client inactivity check selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name.
Packet Size in Bytes	640	Packet size selection.
Number of Packets in Pool	16	Number of packets in pool selection.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo FTP Server Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX/NetX Duo FTP Server Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin Selection Sequence
ETHERC	Pins	Select **Peripherals**> **Connectivity:ETHERC**> **ETHERC1.RMII**

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1.
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection.
REF50CK	P701	REF50CK pin.
TXD0	P700	TXD0 pin.
TXD1	P406	TXD1 pin.
TXD_EN	P405	TXD_EN pin.
RXD0	P702	RXD0 pin.
RXD1	P703	RXD1 pin.
RX_ER	P704	RX_ER pin.
CRS_DV	P705	CRS_DV pin.

MDC	P403	MDC pin.
MDIO	P404	MDIO pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.20.6 Using the NetX/NetX Duo FTP Server Module in an Application

The steps in using the NetX/NetX Duo FTP Server module in a typical application are:

1. Create the FTP Server using the nx_ftp_server_create (or the nxd_ftp_server_create API for NetX Duo systems).

2. Start the FTP Server using the nx_ftp_server_start API.

3. Create the FTP Client using nx_ftp_client_create API.

4. Connect to the FTP Server using the nx_ftp_client_connect API.

5. Open a file using the nx_ftp_client_open API.

6. Read from a file using the nx_ftp_client_read API.

7. Close a file using the nx_ftp_client_close API.

The following figure illustrates common steps in a typical operational flow diagram:

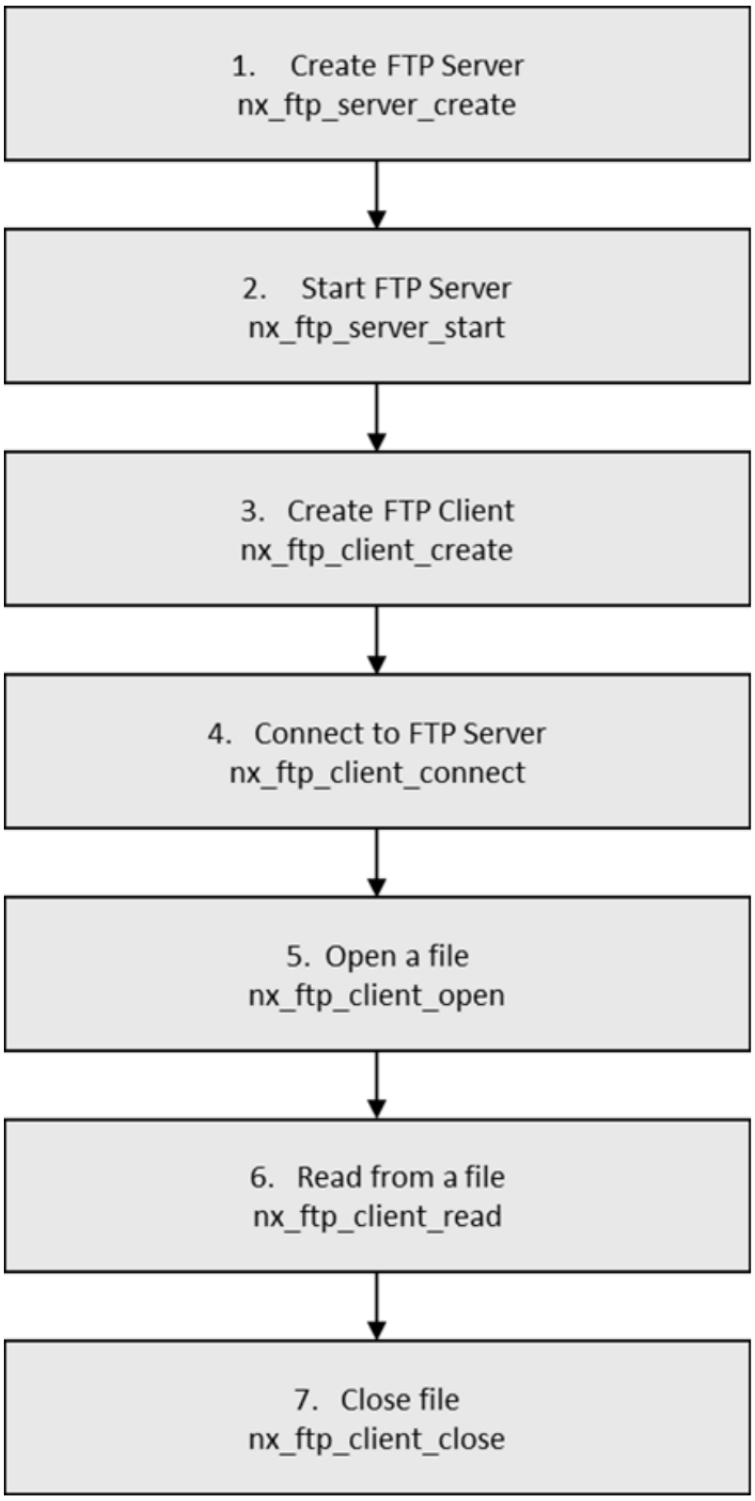

Figure 456: Flow Diagram of a Typical NetX/NetX Duo FTP Server Module Application

4.3.21 NetX/NetX Duo HTTP Client

4.3.21.1 NetX/NetX Duo HTTP Client Introduction

The Hypertext Transfer Protocol (HTTP) is a protocol designed for transferring content on the web. HTTP is a simple protocol that utilizes reliable Transmission Control Protocol (TCP) services to perform its content-transfer function. All operations on the web utilize the HTTP protocol.

Note

The NetX Duo™ HTTP Client accommodates both IPv4 and IPv6 networks while the NetX™ HTTP Client only supports IPv4 communications. IPv6 does not directly affect the HTTP protocol; some differences with the NetX HTTP Client are necessary to accommodate IPv6 and will be described in this document.

Unsupported Features

Multi-thread support has not been tested in this version of SSP. Multi-part support has not been tested in this version of SSP.

NetX/NetX Duo HTTP Client Module Features

- Provides high-level APIs to:
  - Create and delete an HTTP client instance
  - Send Get and Put requests to HTTP servers
- The NetX HTTP is compliant with RFC1945, Hypertext Transfer Protocol/1.0, RFC 2581, TCP Congestion Control, RFC 1122, Requirements for Internet Hosts and related RFCs.

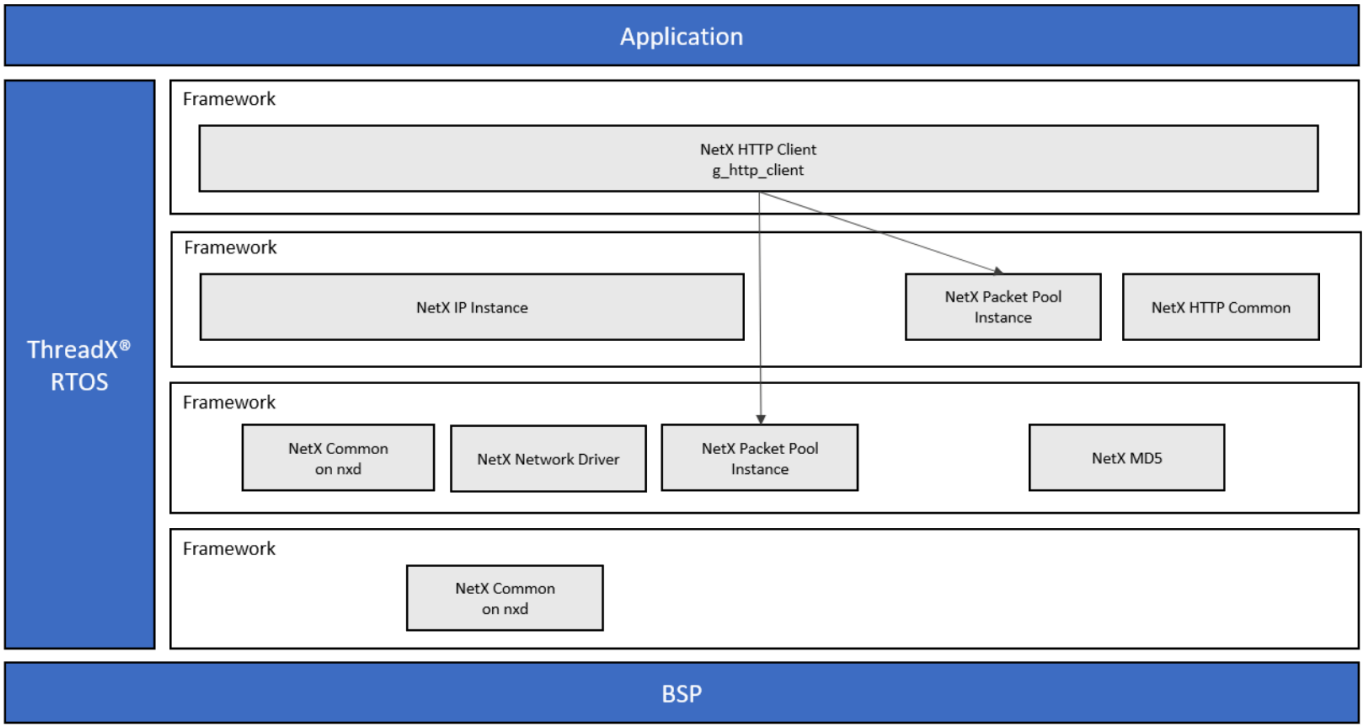

Figure 457: NetX/NetX Duo HTTP Client Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX/NetX Duo HTTP Client Module in an Application for additional details.

4.3.21.2 NetX/NetX Duo HTTP Client Module APIs Overview

The NetX HTTP Client module defines APIs for creating, deleting, getting and putting. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX/NetX Duo HTTP Client Module API Summary

Function Name	Example API Call and Description
nx_http_client_create	nx_http_client_create(&my_client, "my client", &ip_0, &pool_0, 100); Create an HTTP Client Instance.
nx_http_client_delete	nx_http_client_delete(&my_client); Delete an HTTP Client instance.
nx_http_client_get_start	nx_http_client_get_start(&my_client, IP_ADDRESS(1,2,3,5), "/TEST.HTM", NX_NULL, 0, "myname", "mypassword", 1000); Start an HTTP GET request (IPv4 only).
nxd_http_client_get_start**	nxd_http_client_get_start(&my_client, &server_ip_address, "/TEST.HTM", NX_NULL, 0, "myname", "mypassword", 1000); Start an HTTP GET request (IPv4 or IPv6)
nx_http_client_get_packet	nx_http_client_get_packet(&my_client, &next_packet, 1000); Get next resource data packet.
nx_http_client_put_start	nx_http_client_put_start(&my_client, IP_ADDRESS(1, 2, 3, 5), "/TEST.HTM", "myname", "mypassword", 20, NX_WAIT_FOREVER); Start an HTTP PUT request (IPv4 only).
nxd_http_client_put_start**	nxd_http_client_put_start(&my_client, &server_ip_address, "/client_test.htm", "name", "password", 103, 50); Start an HTTP PUT request (IPv4 or IPv6)
nx_http_client_put_packet	nx_http_client_put_packet(&my_client, packet_ptr, NX_WAIT_FOREVER); Send next resource data packet.
nx_http_client_set_connect_port**	nx_http_client_set_connect_port(&g_http_client0, 81); Connect to the HTTP server port on the specified port. Intended for situations where the Client must use another port beside 80.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo HTTP Client. For definitions of of NetX Duo specific data types, see the *NetX Duo User Guide for the Renesas Synergy™ Platform*.

Status Return Values

Name	Description
NX_SUCCESS	Successful HTTP function
NX_CALLER_ERROR**	Invalid caller of the service
NX_PTR_ERROR**	Invalid HTTP, ip_ptr, or packet pool pointer
NX_INVALID_PORT**	Invalid port input
NX_HTTP_POOL_ERROR	Invalid payload size in packet pool
NX_HTTP_NOT_READY	HTTP Client not in ready state
NX_HTTP_PASSWORD_TOO_LONG	Password exceeded expected length
NX_HTTP_AUTHENTICATION_ERROR	Invalid name and/or password
NX_HTTP_FAILED	HTTP client error communicating with the HTTP server
NX_HTTP_GET_DONE	HTTP client get packet operation is complete
NX_HTTP_BAD_PACKET_LENGTH	Invalid packet received - length incorrect
NX_HTTP_INCOMPLETE_PUT_ERROR	Server responds before PUT is complete
NX_HTTP_REQUEST_UNSUCCESSFUL_CODE	Received an error code instead of 2xx from server
NX_HTTP_PASSWORD_TOO_LONG	Password exceeded expected length
NX_HTTP_USERNAME_TOO_LONG	Username exceeded expected length
NX_SIZE_ERROR	Invalid total size of resource in PUT request
NX_INVALID_PACKET	Invalid TCP packet; not enough room for packet header

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

**These are error codes which are only returned if error checking is enabled. Refer to the *NetX User's Guide* for the Renesas Synergy Platform or *NetX Duo User's Guide* for the Renesas Synergy Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.21.3 NetX/NetX Duo HTTP Client Module Operational Overview

The NetX HTTP Client module creates an IP instance which carries out NetX operations and enables TCP services in the NetX library. It creates the HTTP client instance and a TCP socket for sending and receiving HTTP messages to the server listening on port 80. The HTTP client requires a packet pool; the module can supply one by sharing the IP default packet pool (g_packet_pool0), or by creating a new one. The minimum packet payload is set by the Minimum packet size property of the HTTP client instance. This packet pool is used by the HTTP client only to transmit packets, so the packet-pool size and payload can be optimized based on the expected size and the number of HTTP client packets sent out.

The NetX Duo HTTP Client supports both IPv4 and IPv6 connections; if the HTTP client needs to use

IPv6 to connect to a server, make sure the NetX Duo IPv6 Support property is enabled in the NetX Duo Source element. It may also be necessary to enable ICMPv6 checksum computation for the underlying ICMPv6 protocols; to do so, set the Checksum computation support on transmitted ICMPv6 packets and Checksum computation support on received ICMPv6 packets properties of the NetX Duo source element to be enabled. (If the host hardware automatically computes ICMPv6 checksums, these can be left disabled.) Make sure the IPv6 Global Address of the Client host is set in the IP instance element; NetX Duo will do the necessary processing to enable IPv6 and ICMPv6 services required for IPv6 underlying protocols.

Once the HTTP client has a valid IP address, it can make PUT and GET requests. To upload packets, use the nx_http_client_put_start service. This service has a server IP address input, so the HTTP client can connect to the server. If the data to upload exceeds more than one packet, the application uses the nx_http_client_put_packet service until all the data is uploaded. To download data from the server, use the nx_http_client_get_start service; this requires the server IP address so the HTTP client can connect to the server. If the data to download exceeds more than one packet, the application uses the nx_http_client_get_packet service until all the data is downloaded; this is indicated by getting the NX_HTTP_GET_DONE status return.

In the NetX Duo HTTP Client module, the application can use the nxd_http_client_put_start for IPv4 connections, and the nxd_http_client_get_start service for either IPv4 or IPv6 connections; nx_http_client_put_start and nx_http_client_get_start services are also available in the Net Duo HTTP Client. The nx_http_client_put_packet and nx_http_client_get_packet services do not require an HTTP Server IP address, so there is no Duo-equivalent APIs for these services.

In NetX Duo HTTP Client, the nx_http_client_set_connect_port service is available for those circumstances where the HTTP client needs to connect to the HTTP server on a port other than the default of Port 80.

HTTP Server Responses

Once the HTTP server processes the client command, it returns an ASCII response string that includes a 3-digit numeric-status code listed in the following table. The numeric response is used by the HTTP client software to determine whether the operation succeeded or failed.

Various HTTP server responses to client commands

Numeric Field	Meaning
200	Request was successful
400	Request was not formed properly
401	Unauthorized request, client needs to send authentication
404	Specified resource in request was not found
500	Internal HTTP server error
501	Request not implemented by HTTP server
502	Service is not available

For example, a successful client request to PUT the file test.htm is responded to with the message HTTP/1.0 200 OK.

NetX/NetX Duo HTTP Client Module Important Operational Notes and Limitations

NetX/NetX Duo HTTP Client Module Operational Notes

- The HTTP client packet pool must be large enough to hold the complete HTTP header.
- The wait option for disconnecting from the server before deleting the client TCP socket is set by the Operation Timeout property; the wait option for all other HTTP client services is set in the API.
- Both GET and PUT start services require a resource, username and password as an input. The maximum size of each is set by the Maximum resource name length, Maximum username length and Maximum password length properties in the NetX HTTP Common element. When the GET and PUT operation is completed, the HTTP client disconnects from the server.
- The HTTP client TCP socket receive window is set by the TCP socket window size property. This is used in the TCP protocol for one peer to let the other know not to send more data pending-acknowledgment packets for data already received.

NetX/NetX Duo HTTP Client Module Limitations

- The HTTP protocol in NetX and NetX Duo implements the HTTP 1.0 standard; it does not support 1.1. The constraints are as follows:
  - Persistent connections are not supported
  - Request pipelining is not supported
  - Content compression is not supported
  - TRACE, OPTIONS, and CONNECT requests are not supported
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.21.4 Including the NetX/NetX Duo HTTP Client Module in an Application

This section describes how to include either or both the NetX and NetX Duo HTTP Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo HTTP Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo HTTP Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_dns0 NetXHTTP Client	Threads	New Stack> X-Ware> NetX> Protocols> NetXHTTP Client
g_dns0 NetX Duo HTTP Client	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo HTTP Client

When the NetX and/or NetX Duo HTTP Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink

band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

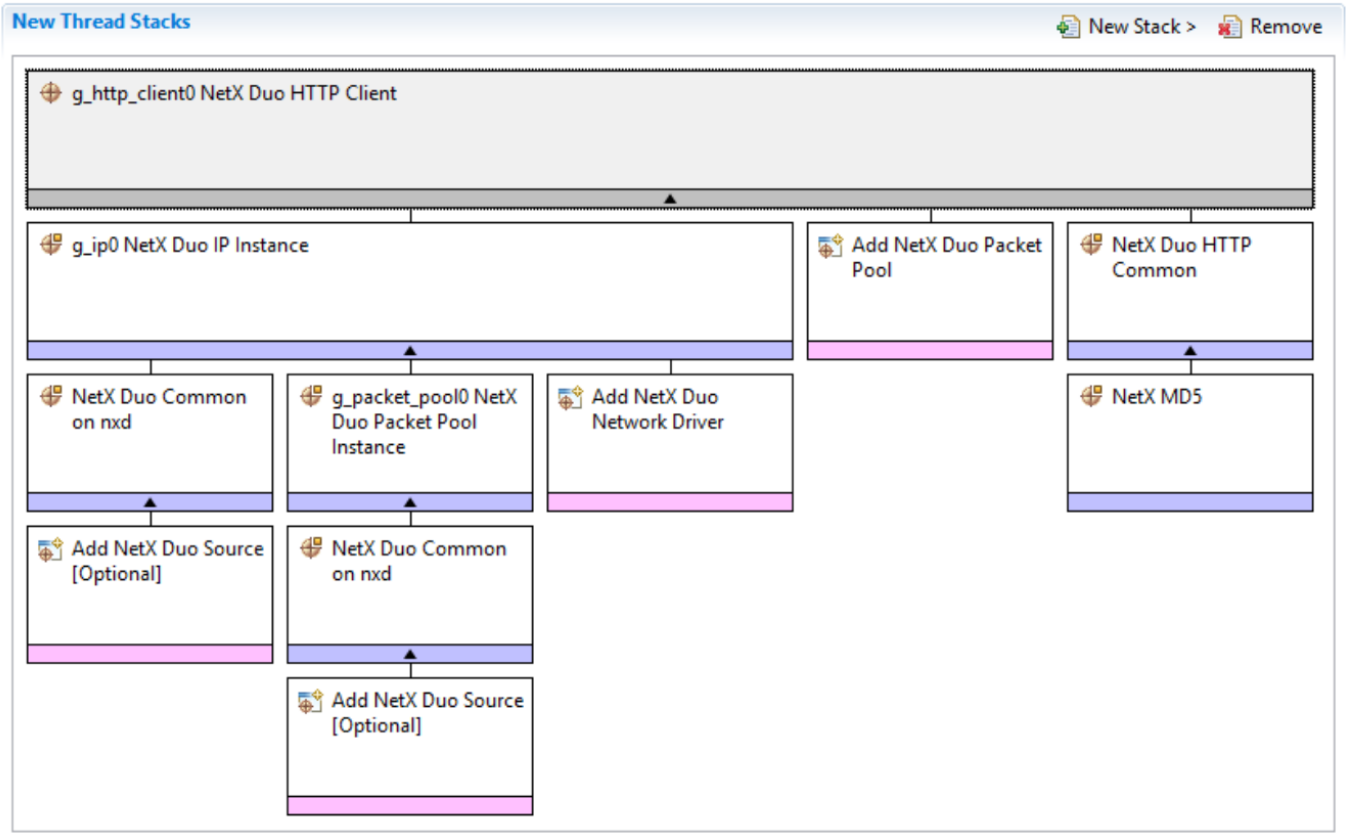

Figure 458: NetX/NetX Duo HTTP Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.21.5 Configuring the NetX/NetX Duo HTTP Client Module

The NetX/NetX Duo HTTP Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes

and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo HTTP Client Module

ISDE Property	Value	Description
Minimum packet size (bytes)	300	Minimum packet size selection
Operation timeout (seconds)	10	Operation timeout selection
*Maximum password length (bytes)	20	Maximum password length selection
*Maximum username length (bytes)	20	Maximum username length selection
Name	g_http_client0	Module name
TCP socket window size (bytes)	1024	TCP socket window size selection
Name of generated initialization function	http_client_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

*Indicates properties that are not available in NetX Duo.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different pins for the Ethernet peripheral. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo HTTP Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the

module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection

Auto Initialization	Enable, Disable Default: Enable	Auto initialization function
Link status change callback	NULL	Link status change callback selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo HTTP Common Instance

ISDE Property	Value	Description
Type of Service	Normal, Minimum delay, Maximum data, Maximum reliabililty, Minimum cost Default: Normal	Type of service UDP requests selection
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragment option selection
Time to live	128	Time to live selection
MD5 Support	Enable, Disable Default: Disable	MD5 support selection
Maximum resource name length (bytes)	40	Packet queue depth selection
**Maximum password length (bytes)	20	Maximum password length selection
**Maximum username length (bytes)	20	Minimum username length selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection

Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX MD5 Instance

ISDE Property	Value	Description
No configurable properties		

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo HTTP Client Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX/NetX Duo HTTP Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin Selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.21.6 Using the NetX/NetX Duo HTTP Client Module in an Application

The steps in using the NetX/NetX Duo HTTP Client module in a typical application are:

1. Wait for valid IP address and network driver initialization using the nx_ip_status_check API.

2. Upload data to the HTTP server with the nx_http_client_put_start API. For IPv6 connections, use the nxd_http_client_put_start API in the NetX Duo HTTP Client (which can also be used for IPv4 connections).

3. Download data from the HTTP server with the nx_http_client_get_start API. For IPv6 connections,

use the nxd_http_client_get_start API in the NetX Duo HTTP Client (which can also be used for IPv4 connections).

4. Delete the HTTP client with the nx_http_client_delete API. (Note that the packet pool can also be deleted if it's not used elsewhere in the application.)

The following figure illustrates common steps in a typical operational flow diagram:

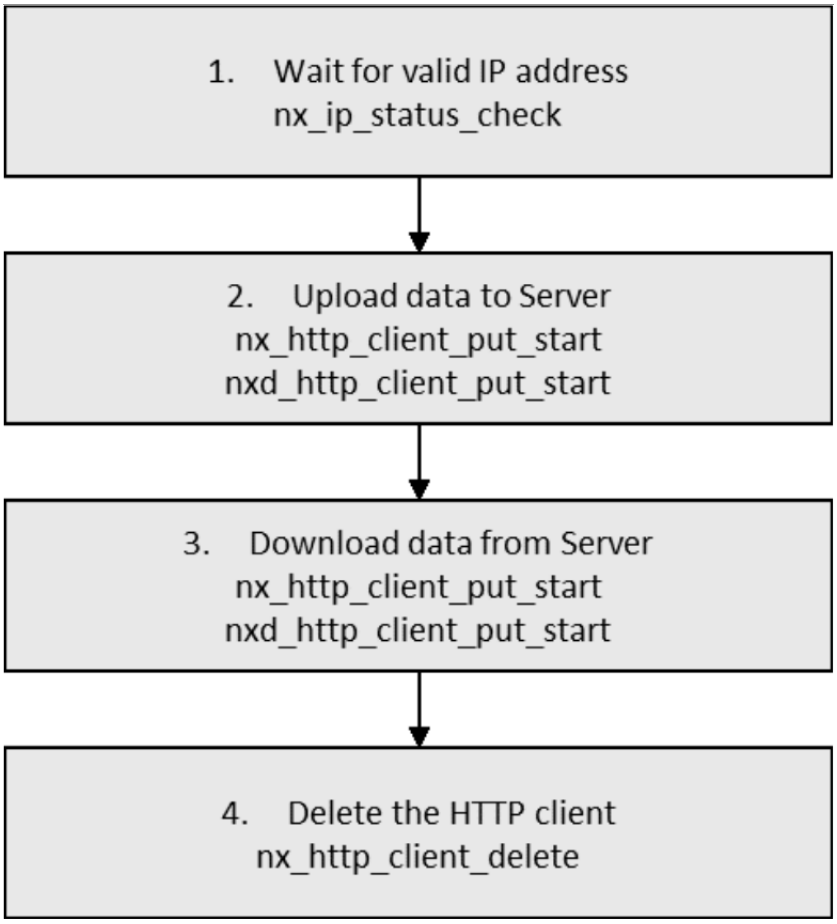

Figure 459: Flow Diagram of a Typical NetX/NetX Duo HTTP Client Module Application

4.3.22 NetX/NetX Duo HTTP Server

4.3.22.1 NetX/NetX Duo HTTP Server Introduction

The Hypertext Transfer Protocol (HTTP) utilizes reliable Transmission Control Protocol (TCP) services to perform its content transfer function; all operations on the Web utilize the HTTP protocol. The NetXTM Duo HTTP Server accommodates both IPv4 and IPv6 networks, while the NetXTM HTTP Server only supports IPv4 communications. IPv6 does not directly affect the HTTP protocol; however, some differences with the NetX HTTP Server are necessary to accommodate IPv6 and are noted in this document.

Note

Except for internal processing, the NetX Duo HTTP Server module is almost identical in the application, set up and running of an HTTP session as the NetX HTTP Server module. Where they differ is noted in this document.

Unsupported Features

HTTP Insert GMT Date Header Callback has not been tested in this version of SSP. HTTP Cache Info Get Callback has not been tested in this version of SSP.

NetX/NetX Duo HTTP Server Module Features

- Compliant with Request for Comments (RFC) RFC1945 Hypertext Transfer Protocol/1.0, RFC 2581 TCP Congestion Control, RFC 1122 Requirements for Internet Hosts, and related RFCs.
- Multipart support
- Basic and digest authentication support
- Callback support for several key functions:
    - HTTP Authentication Callback
    - HTTP Request Notify Callback
    - HTTP Invalid Username/Password Callback
    - HTTP Insert GMT Date Header Callback
    - HTTP Cache Info Get Callback

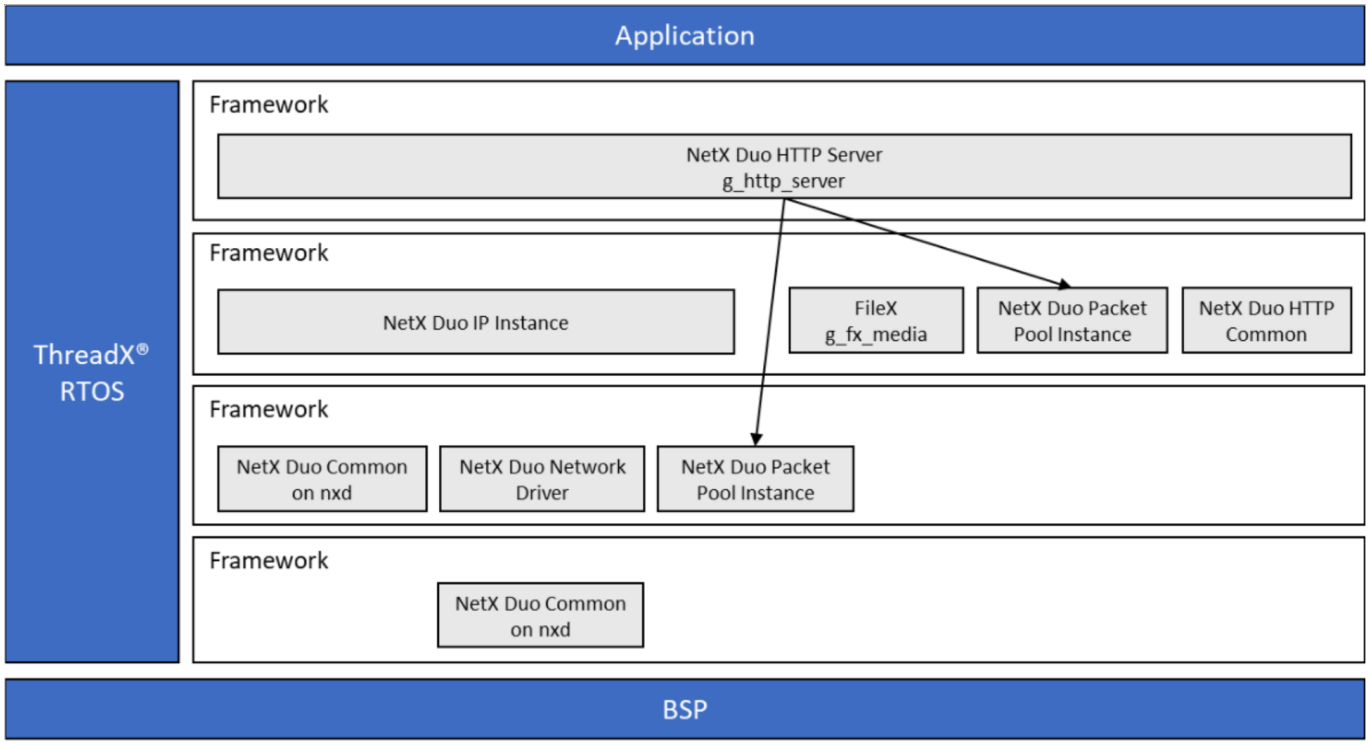

Figure 460: NetX/NetX Duo HTTP Server Module Block Diagram

Note

In the figure above, the FileX and NetX (or NetX Duo) Network Driver modules have multiple implementation options available. See the descriptions just after the module stack figure in Including the NetX/NetX Duo HTTP Server Module in an Application for additional details.

4.3.22.2 NetX/NetX Duo HTTP Server Module APIs Overview

The NetX HTTP Server module defines APIs for creating, deleting, generating response packets, response sending and getting information from a received packet. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX/NetX Duo HTTP Server Module API Summary

Function Name	Example API Call and Description
nx_http_server_cache_info_callback_set	nx_http_server_cache_info_callback_set(&my_server, cache_info_get); Set callback to retrieve age and last modified date of specified URL.

nx_http_server_callback_data_send	nx_http_server_callback_data_send(server_ptr, "HTTP/1.0 200 rnContent-Length: 103rnContent-Type: text/htmlrnrn",63);
	nx_http_server_callback_data_send(server_ptr, "<HTML>rn<HEAD><TITLE>NetX HTTP Test </TITLE></HEAD>rn <BODY>rn<H1>NetX Test Page </H1>rn</BODY>rn</HTML>rn", 103);
	Send HTTP data from callback function.

nx_http_server_callback_generate_response_header	nx_http_server_callback_generate_response_header (server_ptr, &packet_ptr, status_code, content_length, content_type, additional_header); Create response header in callback functions.
nx_http_server_callback_packet_send	nx_http_server_callback_packet_send(server_ptr, packet_ptr); Send an HTTP packet from an HTTP callback.
nx_http_server_callback_response_send	nx_http_server_callback_response_send(server_ptr,"HTTP/1.0 404 ", "NetX HTTP Server unable to find file: ", resource); Send response from callback function.
nx_http_server_content_get	nx_http_server_content_get(server_ptr, packet_ptr, 0, my_buffer, 100, &actual_size); Get content from the request.
nx_http_server_content_get_extended	nx_http_server_content_get_extended(server_ptr, packet_ptr, 0, my_buffer, 100, &actual_size); Get content from the request; supports empty (zero Content Length) requests.
nx_http_server_content_length_get	nx_http_server_content_length_get(packet_ptr); Get length of content in the request. Length is the status return value. A length of zero indicates an error.
nx_http_server_content_length_get_extended	nx_http_server_content_length_get_extended(packet_ptr, &content_length); Get length of content in the request; supports empty (zero Content Length) requests.

nx_http_server_create	nx_http_server_create(&my_server, "my server", &ip_0, &ram_disk, stack_ptr, stack_size, &pool_0, my_authentication_check, my_request_notify); Create an HTTP Server instance.
nx_http_server_delete	nx_http_server_delete(&my_server); Delete an HTTP Server instance.
nx_http_server_get_entity_content	nx_http_server_get_entity_content(server_ptr, &packet_ptr, &offset, &length); Return size and location of entity content in URL.
nx_http_server_get_entity_header	nx_http_server_get_entity_header(server_ptr, &packet_ptr, entity_header_buffer, buffer_size); Extract URL entity header into specified buffer.
nx_http_server_gmt_callback_set	nx_http_server_gmt_callback_set(&my_server, gmt_get); Set callback to retrieve GMT date and time.
**nx_http_server_invalid_userpassword_notify_set	nx_http_server_invalid_userpassword_notify_set(&my_server, invalid_username_password_callback); Set callback for when invalid username and password is received in a Client request.
nx_http_server_mime_maps_additional_set	nx_http_server_mime_maps_additional_set(&my_server, &my_mime_maps[0], 2); Define additional mime maps for HTML.
nx_http_server_packet_content_find	nx_http_server_packet_content_find(server_ptr, packet_ptr, &content_length); Extract content length in HTTP header and set pointer to start of content data.
nx_http_server_packet_get	nx_http_server_packet_get(server_ptr, &packet_ptr); Receive client packet directly.
nx_http_server_param_get	nx_http_server_param_get(packet_ptr, 0, param_destination, 30); Get parameter from the request.
nx_http_server_query_get	nx_http_server_query_get(packet_ptr, 0, query_destination, 30); Get query from the request.
nx_http_server_start	nx_http_server_start(&my_server); Start the HTTP Server.
nx_http_server_stop	nx_http_server_stop(&my_server); Stop the HTTP Server.
nx_http_server_type_get	nx_http_server_type_get(server_ptr, resource_name, type_string); Extract HTTP type e.g. text/plain from header. Type is returned in the status return. A value of zero indicates an error.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo HTTP Server. For definitions of of NetX Duo specific data types, see the *NetX Duo User Guide for the Renesas Synergy™ Platform*.

Status Return Values

Name	Description
NX_SUCCESS	Successfully performed function
NX_PTR_ERROR**	Invalid pointer input
NX_CALLER_ERROR **	Invalid caller of service
NX_HTTP_DATA_END	End of request content
NX_HTTP_TIMEOUT	HTTP Server timeout in getting next packet of content
NX_CALLER_ERROR	Invalid caller of this service
NX_HTTP_INCOMPLETE_PUT_ERROR	Improper HTTP header format
NX_HTTP_POOL_ERROR	Packet payload of pool is not large enough to contain complete HTTP request
NX_HTTP_BOUNDARY_ALREADY_FOUND	Content for the HTTP server internal multipart markers is already found
NX_HTTP_NOT_FOUND	Entity header field or client request parameter or multipart component not found
NX_HTTP_IMPROPERLY_TERMINATED_PARAM	Client request parameter not properly terminated
NX_HTTP_NO_QUERY_PARSED	Server unable to find query in client request
NX_HTTP_TIMEOUT	No packet received in the specified wait interval
NX_HTTP_ERROR	Internal HTTP Server error
NX_HTTP_SERVER_DEFAULT_MIME	No matching extension type found. Return the default MIME type. Not an error status.
NX_SIZE_ERROR	Invalid total size of resource in PUT request
NX_INVALID_PACKET	Invalid TCP packet; not enough room for packet header

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

**These are error codes which are only returned if error checking is enabled. Refer to the *NetX User's Guide* for the Renesas Synergy Platform or *NetX Duo User's Guide* for the Renesas Synergy Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.22.3 NetX/NetX Duo HTTP Server Module Operational Overview

The NetX HTTP Server module creates an IP instance that carries out NetX operations and enables it for TCP services in the NetX library; it then creates the HTTP Server instance and TCP socket for listening to client requests on port 80. The HTTP Server requires a packet pool; the module can supply one either by sharing the IP default packet pool (g_packet_pool0) or create a new one. The minimum packet payload is set by the Minimum size of packets in pool property of the HTTP Server module. This packet pool is used by the HTTP Server only to transmit packets, so the packet pool size and payload can be optimized on the expected size and number of HTTP Server packets sent out.

The NetX Duo HTTP Server supports both IPv4 and IPv6 connections. If the HTTP Server has clients desiring to connect over IPv6, make sure the NetX Duo IPv6 Support property is enabled in the NetX Duo Source element. It may be necessary to enable ICMPv6 checksum computation for the underlying ICMPv6 protocols. To do so, set the Checksum computation support on transmitted ICMPv6 packets and Checksum computation support on received ICMPv6 packets properties of the NetX Duo Source element to Enabled. (If the host hardware automatically computes ICMPv6 checksums, these can be left disabled.) Make sure the IPv6 Global Address of the Client host is set in the IP instance element. Thereafter, the NetX Duo does the necessary processing to enable IPv6 and ICMPv6 services required for IPv6 underlying protocols.

The HTTP Server is also designed for use with the FileX® embedded file system.

HTTP Server Responses

When the HTTP Server processes the client command, it returns an ASCII response string that includes a 3-digit numeric status code. The numeric response is used by the HTTP Client software to determine whether the operation succeeded or failed. Following is a list of various HTTP Server responses to client commands:

HTTP Server responses to client commands

Numeric Field	Meaning
200	Request was successful
400	Request was not formed properly
401	Unauthorized request, client needs to send authentication
404	Specified resource in request was not found
500	Internal HTTP Server error
501	Request not implemented by HTTP Server
502	Service is not available

For example, a successful client request to PUT the file test.htm is responded to with the message HTTP/1.0 200 OK.

HTTP Authentication

HTTP authentication is optional and is not required for all web requests. There are two types of authentication, basic and digest. Basic authentication is equivalent to the name and password authentication found in many protocols. In HTTP basic authentication, the name and passwords are concatenated and encoded in the base64 format. The main disadvantage of basic authentication is the name and password are transmitted openly in the request, making it easy for the name and

password to be stolen. Digest authentication addresses this problem by never transmitting the name and password in the request. Instead, an algorithm is used to derive a 128-bit key or digest from the name, password, and other information. The NetX HTTP Server supports the standard MD5 digest algorithm.

The HTTP Server authentication callback can decide if a requested resource requires authentication. If authentication is required and the client request did not include the proper authentication, an HTTP/1.0 401 Unauthorized response with the type of authentication required is sent to the client. The client is then expected to form a new request with the proper authentication.

HTTP Authentication Callback

The HTTP Server authentication callback routine is specified by the Name of Authentication Checking Function property of the HTTP Server Thread. This function is called at the beginning of each HTTP Client request.

The callback routine provides the NetX HTTP Server with the username, password, and realm strings associated with the resource and returns the type of authentication necessary. If no authentication is necessary for the resource, the authentication callback should return the value of NX_HTTP_DONT_AUTHENTICATE. If basic authentication is required for the specified resource, the routine should return NX_HTTP_BASIC_AUTHENTICATE. If MD5 digest authentication is required, the callback routine should return NX_HTTP_DIGEST_AUTHENTICATE.

The format of the authenticate callback routine is defined as:

```
UINT nx_http_server_authentication_check(NX_HTTP_SERVER *server_ptr, UINT
request_type, CHAR *resource, CHAR **name, CHAR **password, CHAR **realm);
```

The input parameters are defined as follows:

Input Parameters Definitions

Parameter	Meaning
request_type	Specifies the HTTP Client request, valid requests are defined as: NX_HTTP_SERVER_GET_REQUEST NX_HTTP_SERVER_POST_REQUEST NX_HTTP_SERVER_HEAD_REQUEST NX_HTTP_SERVER_PUT_REQUEST NX_HTTP_SERVER_DELETE_REQUEST
resource	Specific resource requested.
name	Destination for the pointer to the required username.
password	Destination for the pointer to the required password.
realm	Destination for the pointer to the realm for this authentication.

Name, password, and realm pointers are not used if NX_HTTP_DONT_AUTHENTICATE is returned by the authentication callback routine. The HTTP Server developer must ensure that the maximum size of the username and password (defined by the Maximum username length and Maximum password length properties of the NetX HTTP Common) are large enough for the username and password specified in the authentication callback. These are both defaulted to size 20 characters.

HTTP Server Request Notify callback

If a request callback is specified, (the Name of Request Notify Callback Function property of the NetX HTTP Server module) the NetX HTTP Server forwards requests to the specified function after authentication and validity of the client request is completed without errors. The callback should indicate (by the return status) if no more processing of the client request is required (return status NX_HTTP_CALLBACK_COMPLETED), if there was an error in the callback processing, (status is non-zero), or the process was completed successfully and the HTTP Server should continue processing the client request. The format of this callback is:

```
UINT        request_notify(NX_HTTP_SERVER *server_ptr, UINT request_type, CHAR
*resource,
NX_PACKET *packet_ptr)
```

To disable the request notify callback, set the Name of Request Notify Callback Function property to NULL.

HTTP Invalid Username/Password Callback

The optional Invalid Username/Password callback in the NetX HTTP Server module is invoked if the HTTP Server receives an invalid username-and-password combination in a client request. To set the Invalid Username/Password callback function, use the nx_http_server_invalid_user_password_set service. Note that for NetX Duo HTTP Server module, this takes a NXD_ADDRESS *client_ip_address, while NetX HTTP Server module takes a ULONG client_ip_address.

HTTP Insert GMT Date Header Callback

The NetX HTTP Server supports an optional callback to insert a date header in its response messages. This callback is invoked when the Server responds to a Client PUT or GET request. To set the GMT callback use the nx_http_server_gmt_callback service before starting the NetX HTTP Server thread.

HTTP Cache Info Get Callback

The NetX HTTP Server has an optional callback to request the maximum age and date from the HTTP application for a specific resource. This information is used to determine if the HTTP server sends the entire page in response to a Client Get request. If the if modified since in the Client request is not found or does not match the last modified date returned by the get-cache callback, the entire page is sent. To set a cache callback function, use the nx_http_server_cache_info_callback_set service.

HTTP Multipart Support

Multipurpose Internet Mail Extensions (MIME) was originally intended for the SMTP protocol, but its use has spread to HTTP. MIME allows messages to contain mixed message types (for example, image/jpg and text/plain) within the same message. The NetX HTTP Server has added services to

determine content type in HTTP messages containing MIME from the client. To enable multipart support, set the Multipart HTTP requests support property of the NetX HTTP Server module to enable.

NetX/NetX Duo HTTP Server Module Important Operational Notes and Limitations

NetX/NetX Duo HTTP Server Module Operational Notes

- The NetX HTTP Server module requires a FileX media (Block media or USB Mass Storage). When an HTTP Server stack element is added to the project, an Add FileX box is attached to it. The configurator automatically sets up and initializes the FileX media for the server before the server is started. For more details for configuring FileX, see *FileX™ User's Guide for the Renesas Synergy™ Platform*.
- The NetX HTTP Server also requires a packet pool for transmitting packets. It can share the IP default packet pool or create a separate packet pool. See the section on *Including the NetX HTTP Server Module in an Application* for details on setting the HTTP Server packet pool.

NetX/NetX Duo HTTP Server Module Limitations

- Persistent connections are not supported.
- Request pipelining is not supported.
- The HTTP Server supports both basic and MD5 digest authentication, but not MD5-sess.
- No content compression is supported.
- Trace, Options, and Connect requests are not supported.
- The packet pool associated with the HTTP Server must be large enough to hold the complete HTTP header.

4.3.22.4 Including the NetX/NetX Duo HTTP Server Module in an Application

This section describes how to include either or both the NetX and NetX Duo HTTP Server module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo HTTP Server module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo HTTP Server Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_http_server0 NetX HTTP Server	Threads	New Stack> X-Ware> NetX> Protocols> NetX HTTP Server
g_http_server0 NetX Duo HTTP Server	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo HTTP Server

When the NetX and/or NetX Duo HTTP Server module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink

band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

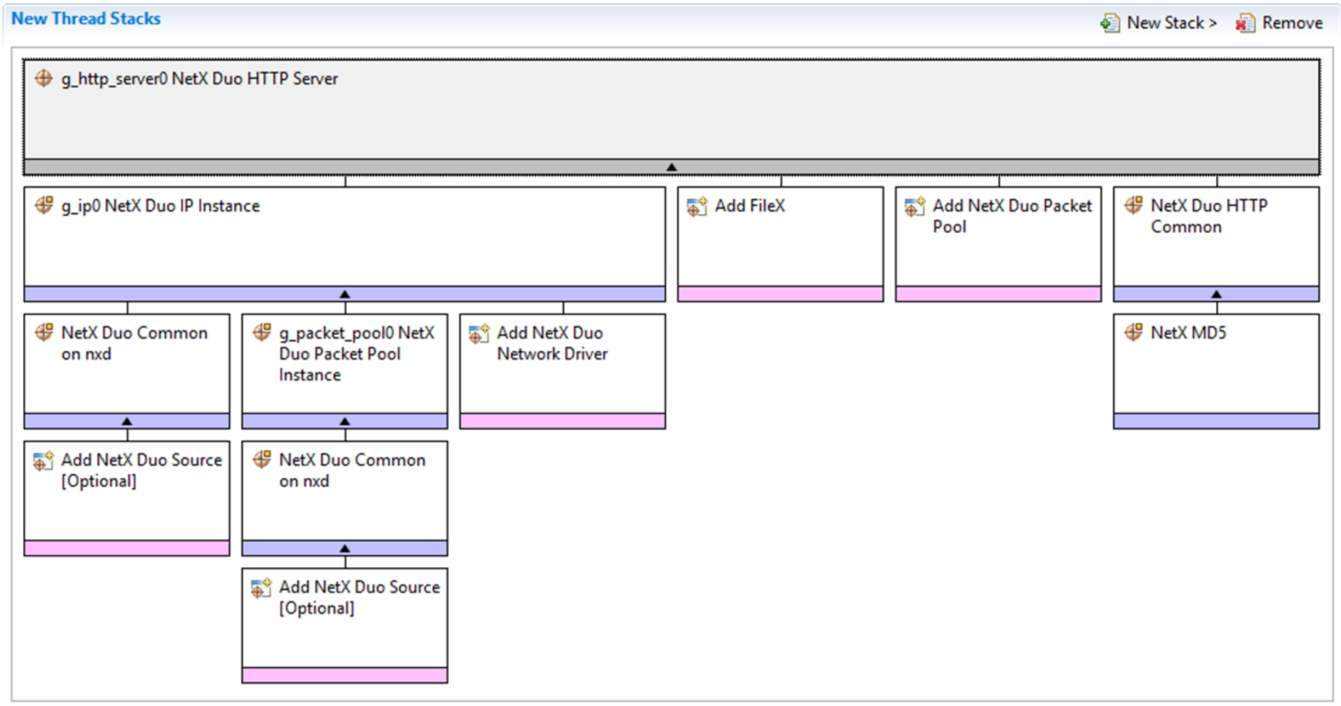

Figure 461: NetX/NetX Duo HTTP Server Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

Additionally, in the stack above, the FileX stack has also not been populated yet. There are multiple possible selections for the FileX module; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- FileX Stub
- FileX on Block Media (implemented on Block Media Framework on sf_block_media_ram)
- FileX on USB Mass Storage (implemented on USBX Host Class Mass Storage)

4.3.22.5 Configuring the NetX/NetX Duo HTTP Server Module

The NetX/NetX Duo HTTP Server module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo HTTP Server Module

ISDE Property	Value	Description
FileX Support	Enable, Disable Default: Enable	FileX support selection
Multipart HTTP requests support	Enable, Disable Default: Disable	Multipart HTTP requests support selection
Internal thread priority	16	Internal thread priority selection
Internal thread time slicing interval (bytes)	NetX Default: 1 NetX Duo Default: 2	Internal thread time slicing interval selection
Server socket window size (bytes)	2048	Server socket window size selection
Server time out (seconds)	10	Server time out selection
Server time out for accept (seconds)	10	Server time out for accept selection
Server time out for disconnect (seconds)	10	Server time out for disconnect selection
Server time out for receive (seconds)	10	Server time out for receive selection
Server time out for send (seconds)	10	Server time out for send selection
Maximum size of header field (bytes)	256	Maximum size of header field selection
Maximum connections in queue	5	Maximum connections in queue selection

Maximum client user user name length (bytes)	20	Maximum client user password length selection
Maximum client user password length (bytes)	20	Minimum size of packets in pool selection
Minimum size of packets in pool (bytes)	600	Minimum size of packets in pool selection
Name	g_http_server0	Module name
Internal thread stack size (bytes)	4096	Internal thread stack size selection
Name of Authentication Checking Function	authentication_check	Name of Authentication Checking Function selection
Name of Request Notify Callback Function	request_notify	Name of Authentication Checking Function selection
Name of generated initialization function	http_server_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different IP masks and addresses. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo HTTP Server Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection

Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function
Link status change callback	NULL	Link status change callback selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo HTTP Common Instance

ISDE Property	Value	Description
Type of Service	Normal, Minimum delay, Maximum data, Maximum reliabililty, Minimum cost Default: Normal	Type of service UDP requests selection
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragment option selection
Time to live	128	Time to live selection
MD5 Support	Enable, Disable Default: Disable	MD5 support selection
Maximum resource name length (bytes)	40	Packet queue depth selection
**Maximum password length (bytes)	20	Maximum password length selection
**Maximum username length (bytes)	20	Minimum username length selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection

Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX MD5 Instance

ISDE Property	Value	Description
No configurable properties		

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo HTTP Server Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX/NetX Duo HTTP Server Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin Selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description

Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.22.6 Using the NetX/NetX Duo HTTP Server Module in an Application

The steps in using the NetX/NetX Duo HTTP Server module in a typical application are:

Auto Generated code to initialize NetX and NetX Duo HTTP Server in the Application (common_data.c)

- Create HTTP Packet pool using the nx_packet_pool_create API
- Create IP Instance using the nx_ip_create API
- Enable ARP using the nx_arp_enable API
- Enable TCP using the nx_tcp_enable API
- Create HTTP Server using the nx_http_server_create API

User Application Code (<thread>_entry.c)

1. Wait for valid IP address using the nx_ip_status_check API.
2. Start HTTP Server using the nx_http_server_start API.
3. Handle optional callbacks if registered with the HTTP Server (Authentication Check, Request Notify, GMT set, Cache get and Invalid Username).
4. Stop HTTP Server using the nx_http_server_stop API.
5. Delete HTTP Server using the nx_http_server_delete API.

Note

If the server packet pool is used only by the server, this can be deleted too using the nx_packet_pool_delete API.

Users do not have to worry about auto-generated code. Auto-generated code is included once the

user generates the project after configuring the stack. Users only need to write the user application code in the associated file (typically <thread>_entry.c).

The following figure illustrates common steps in a typical operational flow diagram:

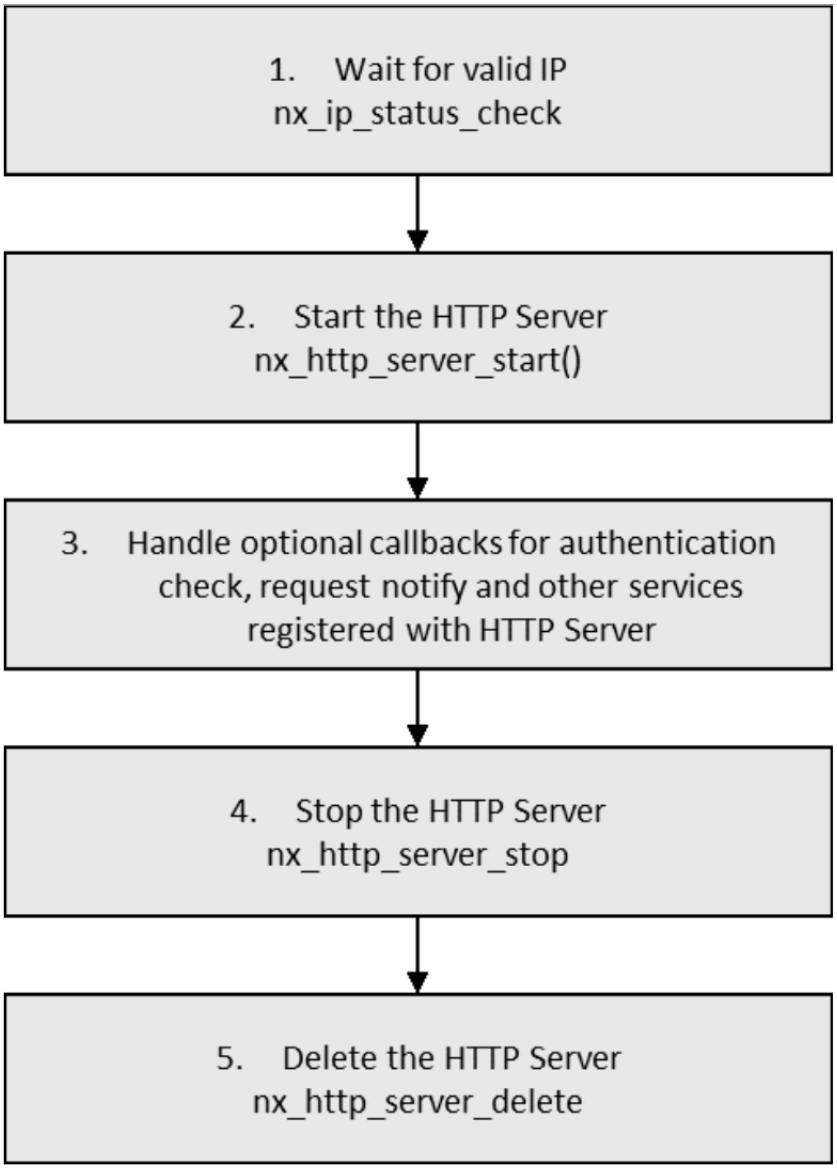

Figure 462: Flow Diagram of a Typical NetX/NetX Duo HTTP Server Module Application

4.3.23 NetX Duo HTTP Client (HTTPS/HTTPS 1.1)

4.3.23.1 NetX Duo Web HTTP/HTTPs Client Introduction

The NetX Web HTTP/HTTPs Client module provides a high-level API for Hyper Text Transport Protocol(HTTP) for transferring content on the web. The HTTP protocol utilizes Transmission Control Protocol (TCP) services to perform its content transfer function. HTTPs is the secure version of the

HTTP protocol which uses HTTP on top of the Transport Layer Security (TLS) protocol to secure underlying TCP connection.

HTTP/HTTPs client is implemented on top of NetX Duo IP and NetX Duo Packet Pool. NetX Duo IP attaches itself to appropriate link layer driver such ethernet/Wi-Fi/cellular. HTTP client can optionally connect to HTTP server over secure connection and in such case, it uses service provided by NetX Duo TLS Common

Unsupported Features

- HTTP Client authentication using username and password integrated but not tested. Request pipelining is not supported
- At present, the HTTP Client supports only basic authentication. When using TLS for HTTPS, HTTP authentication may still be used.
- No content compression is supported.
- TRACE, OPTIONS, and CONNECT requests are not supported.
- The packet pool associated with the HTTP Server or Client must be large enough to hold the complete HTTP header.

NetX Duo Web HTTP/HTTPs Client Module Features

- NetX Web HTTP/HTTPs client is compliant with below RFCs
    - RFC1945 "Hypertext Transfer Protocol/1.0"
    - RFC 2616 "Hypertext Transfer Protocol – HTTP/1.1"
    - RFC 2818 "HTTP Over TLS"
    - RFC 2581 "TCP Congestion Control"
    - RFC 1122 "Requirements for Internet Hosts", and related RFCs.
    - RFC 2818 "HTTP over TLS" for HTTPS
- Support HTTP Get/POST/HEAD/PUT/DELETE commands. Note that these commands are generated internally by NetX Web HTTP/HTTPs client APIs.
- Support basic authentication. When using TLS for HTTPs, HTTP authentication may still be used
- Provides option to enable/disable TLS for secure communication using NetX Secure in SSP

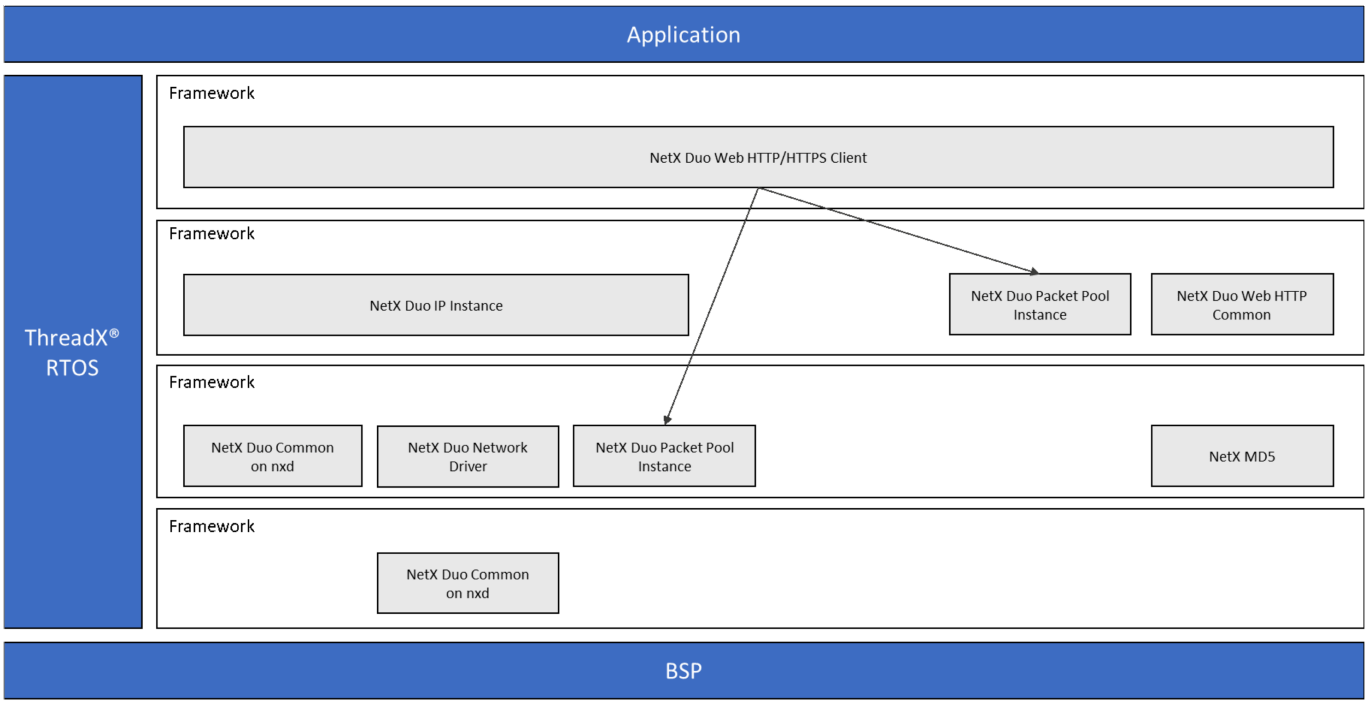

Figure 463: NetX Duo Web HTTP/HTTPs Client Module Block Diagram

Note

In the figure above, the NetX Duo Network Driver module has multiple implementation options available. See the description just after the module stack figure in Including the NetX Duo Web HTTP/HTTPs Client Module in an Application for additional details.

4.3.23.2 NetX Duo Web HTTP/HTTPs Client Module APIs Overview

The NetX Duo Web HTTP/HTTPs Client module defines APIs for creating, deleting, getting and putting. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX Duo Web HTTP/HTTPs Client Module API Summary

Function Name	Example API Call and Description
nx_web_http_client_connect	nx_web_http_client_connect(NX_WEB_HTTP_CLIENT *client_ptr, NXD_ADDRESS *server_ip, UINT server_port, ULONG wait_option); Open a plaintext socket to an HTTP server for custom requests.
nx_web_http_client_create	nx_web_http_client_create(NX_WEB_HTTP_CLIENT *client_ptr, CHAR *client_name, NX_IP *ip_ptr, NX_PACKET_POOL *pool_ptr, ULONG window_size); Create an HTTP Client Instance.

nx_web_http_client_delete	nx_web_http_client_delete(NX_WEB_HTTP_CLIENT *client_ptr); Delete an HTTP Client Instance.
nx_web_http_client_delete_start	nx_web_http_client_delete_start(NX_WEB_HTTP_CLIE NT *client_ptr, NXD_ADDRESS ip_address, UINT server_port, CHAR *resource, CHAR *host, CHAR *username, CHAR *password, ULONG wait_option); Start a plaintext HTTP DELETE request.
nx_web_http_client_delete_secure_start	nx_web_http_client_delete_secure_start(NX_WEB_HTTP_CLIENT *client_ptr, NXD_ADDRESS ip_address, UINT server_port, CHAR *resource, CHAR *host, CHAR *username, CHAR *password, UINT (*tls_setup)(NX_WEB_HTTP_CLIENT *client_ptr, NX_SECURE_TLS_SESSION *tls_session), ULONG wait_option); Start an encrypted HTTPS DELETE request.
nx_web_http_client_get_start	nx_web_http_client_get_start(NX_WEB_HTTP_CLIENT *client_ptr, NXD_ADDRESS ip_address, UINT server_port, CHAR *resource, CHAR *host, CHAR *username, CHAR *password, ULONG wait_option); Start a plaintext HTTP GET request.
nx_web_http_client_get_secure_start	nx_web_http_client_get_secure_start(NX_WEB_HTTP_CLIENT *client_ptr, NXD_ADDRESS ip_address, UINT server_port, CHAR *resource, CHAR *host, CHAR *username, CHAR *password, UINT (*tls_setup)(NX_WEB_HTTP_CLIENT *client_ptr, NX_SECURE_TLS_SESSION *tls_session), ULONG wait_option); Start an encrypted HTTPS GET request.
nx_web_http_client_head_start	nx_web_http_client_head_start(NX_WEB_HTTP_CLIEN T *client_ptr, NXD_ADDRESS ip_address, UINT server_port, CHAR *resource, CHAR *host, CHAR *username, CHAR *password, ULONG wait_option); Start a plaintext HTTP HEAD request.

nx_web_http_client_head_secure_start	nx_web_http_client_head_secure_start(NX_WEB_HTTP_CLIENT *client_ptr, NXD_ADDRESS ip_address, UINT server_port, CHAR *resource, CHAR *host, CHAR *username, CHAR *password, UINT (*tls_setup)(NX_WEB_HTTP_CLIENT *client_ptr, NX_SECURE_TLS_SESSION *tls_session), ULONG wait_option); Start an encrypted HTTPS HEAD request.
nx_web_http_client_post_start	nx_web_http_client_post_start(NX_WEB_HTTP_CLIENT *client_ptr, NXD_ADDRESS ip_address, UINT server_port, CHAR *resource, CHAR *host, CHAR *username, CHAR *password, ULONG total_bytes, ULONG wait_option); Start an HTTP POST request.
nx_web_http_client_post_secure_start	nx_web_http_client_post_secure_start(NX_WEB_HTTP_CLIENT *client_ptr, NXD_ADDRESS ip_address, UINT server_port, CHAR *resource, CHAR *host, CHAR *username, CHAR *password, ULONG total_bytes, UINT (*tls_setup)(NX_WEB_HTTP_CLIENT *client_ptr, NX_SECURE_TLS_SESSION *tls_session), ULONG wait_option); Start an encrypted HTTPS POST request.
nx_web_http_client_put_start	nx_web_http_client_put_start(NX_WEB_HTTP_CLIENT *client_ptr, NXD_ADDRESS ip_address, UINT server_port, CHAR *resource, CHAR *host, CHAR *username, CHAR *password, ULONG total_bytes, ULONG wait_option); Start an HTTP PUT request.
nx_web_http_client_put_secure_start	nx_web_http_client_put_secure_start(NX_WEB_HTTP_CLIENT *client_ptr, NXD_ADDRESS ip_address, UINT server_port, CHAR *resource, CHAR *host, CHAR *username, CHAR *password, ULONG total_bytes, UINT (*tls_setup)(NX_WEB_HTTP_CLIENT *client_ptr, NX_SECURE_TLS_SESSION *tls_session), ULONG wait_option); Start an encrypted HTTPS PUT request.

nx_web_http_client_put_packet	nx_web_http_client_put_packet(NX_WEB_HTTP_CLIEN T *client_ptr, NX_PACKET *packet_ptr, ULONG wait_option); Send next resource data packet.
nx_web_http_client_request_header_add	nx_web_http_client_request_header_add(NX_WEB_HTTP_CLIENT *client_ptr, CHAR *field_name, UINT name_length, CHAR *field_value, UINT value_length, UINT wait_option); Add a custom header to a custom HTTP request.
nx_web_http_client_request_initialize	nx_web_http_client_request_initialize (NX_WEB_HTTP_CLIENT *client_ptr, UINT method, CHAR *resource, CHAR *host, UINT input_size, UINT transfer_encoding_trunked, CHAR *username, CHAR *password, UINT wait_option); Initialize a custom HTTP request.
nx_web_http_client_request_send	nx_web_http_client_request_send(NX_WEB_HTTP _CLI ENT *client_ptr, UINT wait_option); Send a custom HTTP request.
nx_web_http_client_response_body_get	nx_web_http_client_response_body_get(NX_WEB_HTTP_CLIENT *client_ptr, NX_PACKET **packet_ptr, ULONG wait_option); Get next resource data packet.
nx_web_http_client_response_header_callback_s et	nx_web_http_client_response_header_callback_s et(NX_WEB_HTTP_CLIENT *client_ptr, VOID (*callback_function)(NX_WEB_HTTP_CLIENT *client_ptr, CHAR *field_name, UINT field_name_length, CHAR *field_value, UINT field_value_length)); Set callback to invoke when processing HTTP headers.
nx_web_http_client_secure_connect	nx_web_http_client_secure_connect(NX_WEB_HT TP_C LIENT *client_ptr, NXD_ADDRESS *server_ip, UINT server_port, UINT (*tls_setup)(NX_WEB_HTTP_CLIENT *client_ptr, NX_SECURE_TLS_SESSION *tls), ULONG wait_option); Open a TLS session to an HTTPS server for custom requests.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures

and function variables, review the associated Azure RTOS User's Manual in the References section.

Status Return Values

Name	Description
NX_SUCCESS	Successful connection of TCP socket.
NX_PTR_ERROR	Invalid pointer input.
NX_WEB_HTTP_NOT_READY	Another request is already in progress.
NX_WEB_HTTP_POOL_ERROR	Invalid payload size in packet pool
NX_CALLER_ERROR	Invalid caller of this service.
NX_HTTP_PASSWORD_TOO_LONG	Password exceeded expected length
NX_WEB_HTTP_ERROR	Internal HTTP Client error.
NX_WEB_HTTP_NOT_READY	HTTP Client not ready.
NX_WEB_HTTP_FAILED	HTTP Client error communicating with the HTTP Server.
NX_WEB_HTTP_AUTHENTICATION_ERROR	Invalid name and/or password.
NX_WEB_HTTP_USERNAME_TOO_LONG	Username too large for buffer.
NX_SIZE_ERROR	Invalid total size of resource.
NX_WEB_HTTP_REQUEST_UNSUCCESSFUL_CODE	Received Server error code
NX_WEB_HTTP_BAD_PACKET_LENGTH	Invalid packet length.
NX_WEB_HTTP_INCOMPLETE_PUT_ERROR	Server responds before PUT is complete.
NX_INVALID_PACKET	Packet too small for TCP header.
NX_WEB_HTTP_METHOD_ERROR	Some required information was missing (e.g. input_size for PUT or POST).
NX_WEB_HTTP_GET_DONE	HTTP Client get packet is done.

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.23.3 NetX Duo Web HTTP/HTTPs Client Module Operational Overview

HTTP (Hyper Text Transport Protocol) is used to exchange hypertext between HTTP client and server. An HTTP client initiates a HTTP request such as Get/POST/HEAD/PUT/DELETE by establishing a TCP connection to particular port on HTTP server e.g. port 80, port 443. An HTTP server listening on that port waits for a client's request message. Upon receiving the request, the server sends back a status message such as "HTTP/1.1 200 ok" followed by a message of its own.

The NetX Web HTTP/HTTPs client module can be used in the normal mode or secure mode

NetX Web HTTP/HTTPs client module Normal Mode Operational Description

In normal mode, the communication between HTTP client and server is not secure.

Netx Web HTTP/HTTPs client module Secure Mode Operational Description

In Secure mode, the communication between HTTP client and server is secured using the TLS protocol. In the thread pane, TLS protocol is represented by "Add NetX Duo TLS common [Optional]" block as shown in the figure below

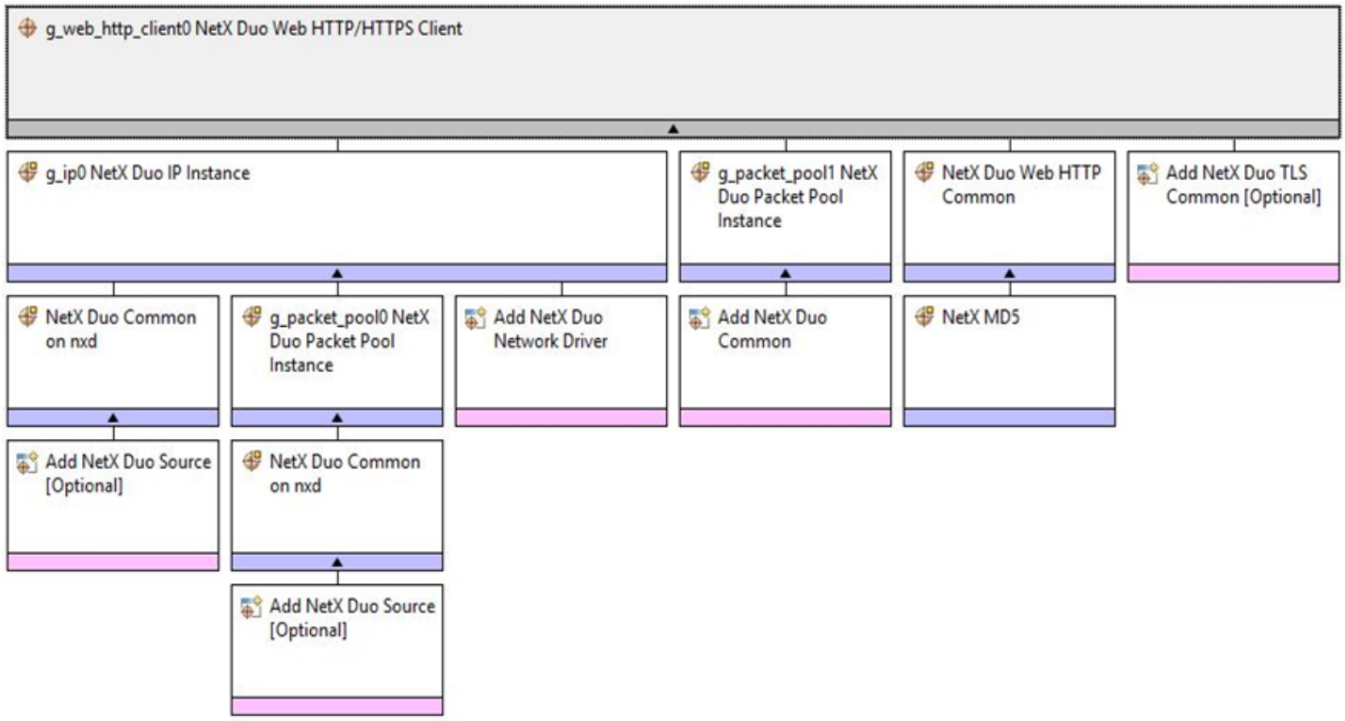

Figure 464: NetX Duo Web HTTP/HTTPs Client Module Component Thread-Pane View

Adding NetX Duo TLS Common block enables TLS support and internally defines the NX_SECURE_ENABLE macro. The figure below shows the thread pane view of HTTP client with TLS support enabled.

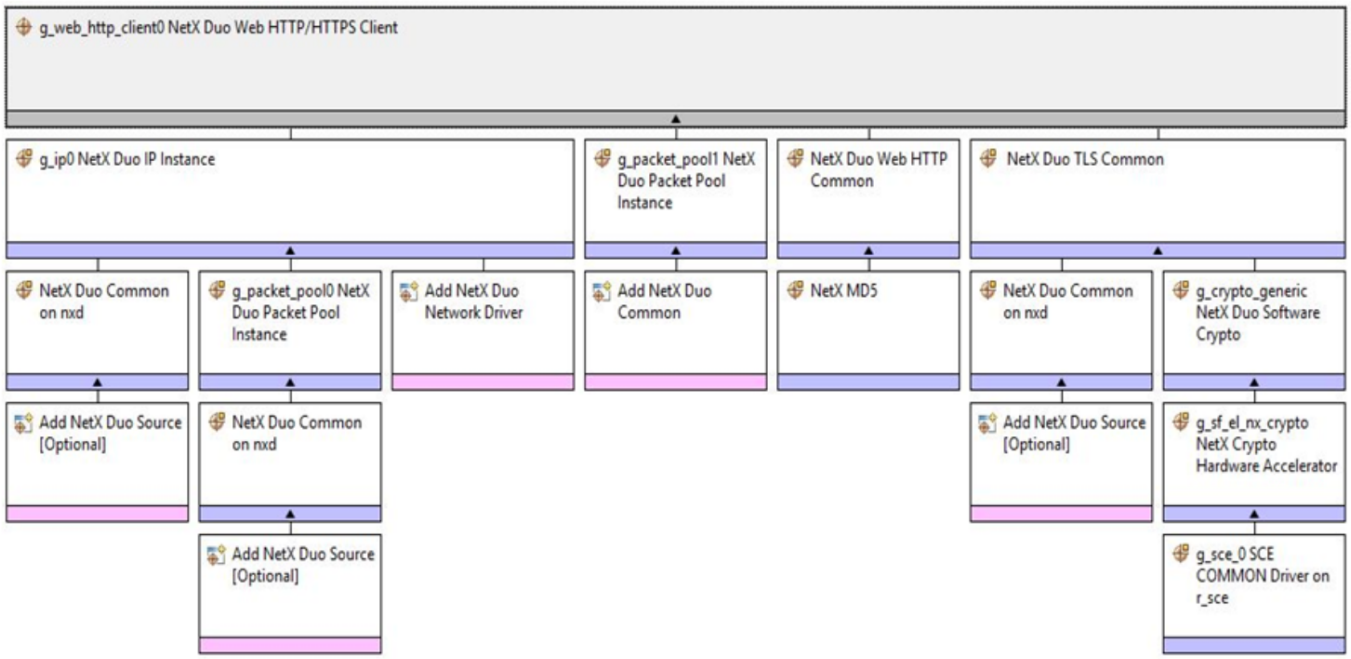

Figure 465: NetX Duo Web HTTP/HTTPs Client Module Component with TLS Support Enabled

NetX Duo Web HTTP/HTTPs Client Module Important Operational Notes and Limitations

NetX Duo Web HTTP/HTTPs Client Module Operational Notes

The NetX Web HTTP/HTTPs Client component is added by clicking on the (+) sign in the thread pane window -> Azure RTOS -> NetX Duo -> Protocols -> NetX Web HTTP/HTTPs Client.

Adding the NetX Web HTTP/HTTPs Client component to a project automatically adds the option to add the NetX Duo TLS component required for secure HTTP client.

The NetX Web HTTP/HTTPs Client properties are listed in the following table:

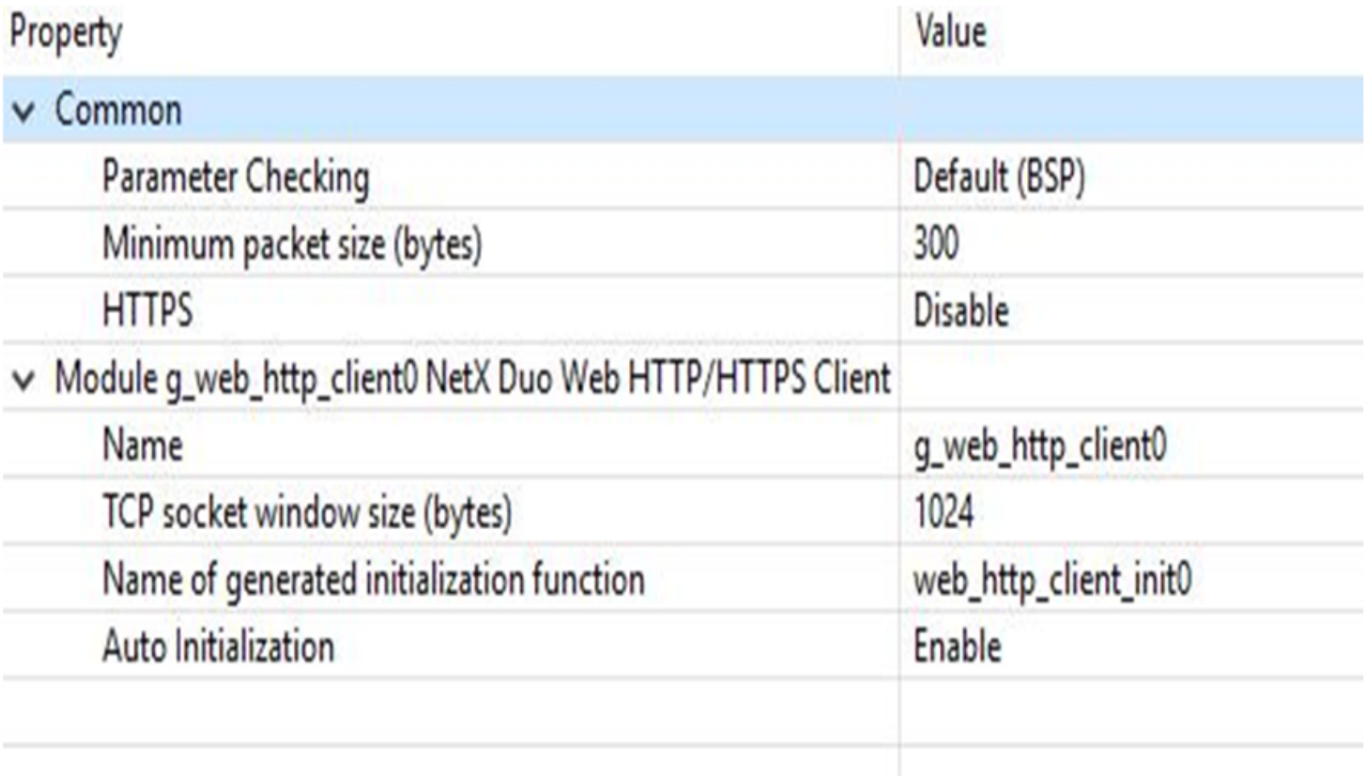

Figure 466: NetX Duo Web HTTP/HTTPs Client Module Component Configurable Properties

In the figure above, "Common" properties are those configurable options in the NetX Web HTTP/HTTPs Client that are common to all instances of the HTTP/HTTPs client in the project. The "Module" properties are specific to each instance of HTTP/HTTPs Client in the project.

Common Properties

- Parameter Checking: This enables/disables basic HTTP error checking. It is typically used after the application has been debugged. The default value is BSP.
- Minimum Packet Size (bytes): The minimum size of the packets in the pool specified at Client creation. The minimum size is needed to ensure the complete HTTP header can be contained in one packet. The default value is 300 bytes.
- HTTPS: This enables/disables TLS which is used to establish secure channel. The default value is disable.

Module Properties

- Name: Name of the HTTP/HTTPs client instance.
- TCP socket window size(bytes) : Set the size of client's TCP socket receive window size. The default is 1024 bytes.
- Name of generated initialization function: Name of initialization function which creates HTTP/HTTPs client instance. The default is the auto-generated function named web_http_client_init0.
- Auto Initialization: Enable/disable call to initialization function. This determines if the function specified in the Name of Generated Initialization function option is called. If set to Enable, it will invoke this function. Otherwise if set to Disable, the application must call the nx_web_http_client_create() API before using any NetX Web HTTP/HTTPs Client services.

NetX Duo Web HTTP Common Configurable Properties

The common properties are listed in the following table:

Property	Value
Common	
Type of Service	Normal
Fragmentation option	Don't fragment
MD5 Support	Disable
Time to live	128
Maximum password length (bytes)	20
Maximum username length (bytes)	20

Figure 467: NetX Duo Web HTTP/HTTPs Client Module Component Common Configurable Properties

- Type of Service: Type of network service required for the HTTP TCP requests. The network service can be of type (Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost) and the default value is Normal.
- Fragmentation Option: This enables/disables TCP fragmentation for HTTP client request. The default value is Don't Fragment.
- MD5 Support: This enables/disables MD5 digest support required for digest authentication. The default value is disable.
- Time to live: This specifies maximum no. of routers the HTTP packet can pass through before it get discarded. The default is 128.
- Maximum password length (bytes): This defines the maximum length of client supplied password. The default is 20.
- The Maximum username length (bytes): This defines the maximum length of client supplied username. The default is 20.

NetX Duo Web HTTP/HTTPs Client Module Limitations

- Request pipelining is not supported
- No content compression is not supported
- TRACE, OPTIONS, and CONNECT HTTP requests are not supported
- The packet pool associated with client must be large enough to hold the complete HTTP header
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.23.4 Including the NetX Duo Web HTTP/HTTPs Client Module in an Application

This section describes how to include either or both the NetX Duo Web HTTP/HTTPs Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo Web HTTP/HTTPs Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX Duo Web HTTP/HTTPs Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_web_http_client0 NetX Duo Web HTTP/HTTPs Client	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo Web HTTP/HTTPs Client

When the NetX Duo Web HTTP/HTTPs Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

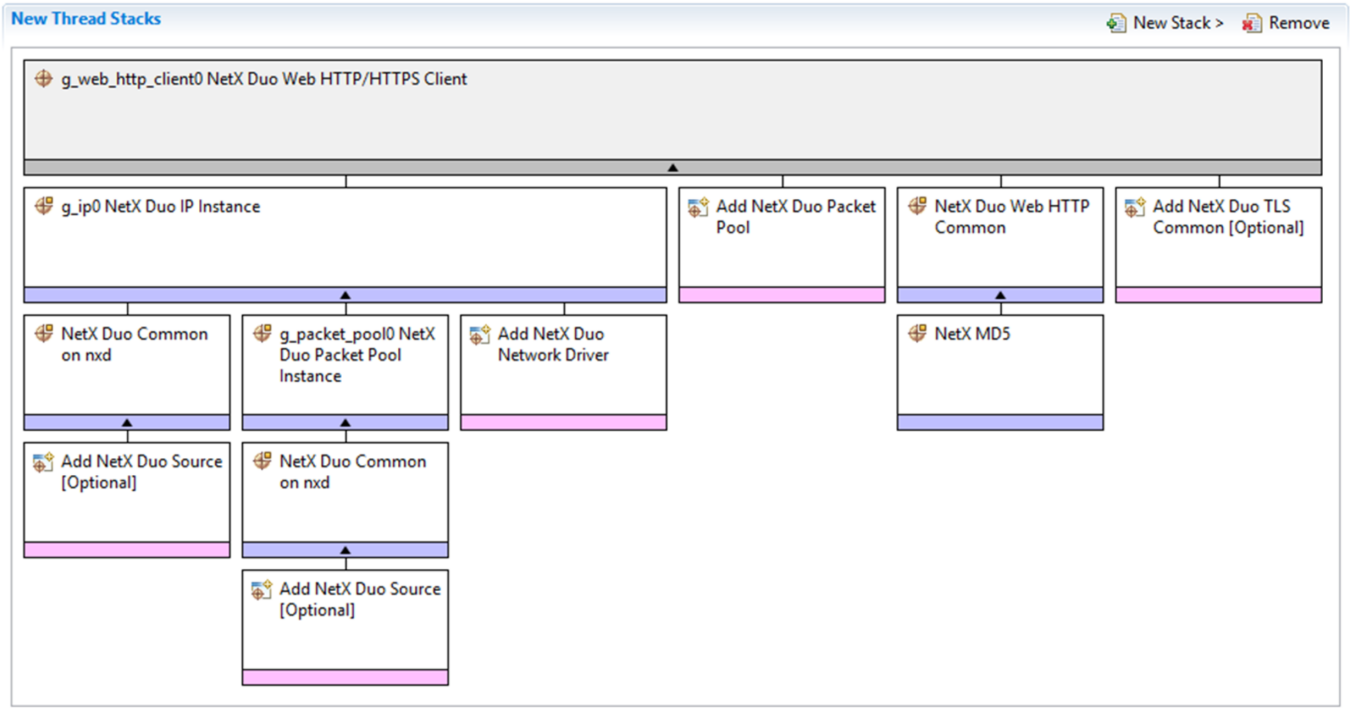

Figure 468: NetX Duo Web HTTP/HTTPs Client Module Stack

In the stack above, the NetX Duo Network Driver has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx

- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.23.5 Configuring the NetX Duo Web HTTP/HTTPs Client Module

The NetX Duo Web HTTP/HTTPs Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo Web HTTP/HTTPs Client Module

ISDE Property	Value	Description
Parameter Checking	Enable, Disable, BSP Default: BSP	Selects if code for parameter checking is to be included in the build.
Minimum packet size (bytes)	300	Select the minimum packet size in bytes.
HTTPS Support	Enable, Disable Default: Disable	Select whether to enable HTTPS support.
Name	g_web_http_client0	Module name.
TCP socket window size (bytes)	1024	Select the TCP socket window size in bytes.
Name of generated initialization	web_http_client_init0	Name of generated initialization selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different pins for the Ethernet peripheral. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX Duo Web HTTP/HTTPs Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection
IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Disable	TCP selection
UDP	Enable, Disable Default: Disable	UDP selection
ICMP	Enable, Disable Default: Disable	ICMP selection

IGMP	Enable, Disable Default: Disable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function
Link status change callback	NULL	Link status change callback selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Web HTTP Common Instance

ISDE Property	Value	Description
Type of Service	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Type of service selection.
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragmentation option selection.
MD5 Support	Enable, Disable Default: Disable	MD5 support selection.
Time to live	128	Time to live selection.
Maximum password length (bytes)	20	Maximum password length in bytes.
Maximum username length (bytes)	20	Maximum username length in bytes.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Common Instance

ISDE Property	Value	Description

Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX MD5 Instance

ISDE Property	Value	Description
No configurable properties		

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX Duo Web HTTP/HTTPs Client Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX Duo Web HTTP/HTTPs Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin Selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.23.6 Using the NetX Duo Web HTTP/HTTPs Client Module in an Application

Once the module has been configured and the files auto generated, the NetX Web HTTP/HTTPs client Module is ready to be used in an application. Note that the auto generated code includes the initialization function with the name specified under the Name of generated initialization function property. This function internally calls the nx_web_http_client_create() API to create a HTTP/HTTPs client instance with the name specified under the Name property. Calls to this initialization function will be enabled or disabled depending the Auto Initialization property value. Once the client instance is created, the typical steps in using the module in an application are:

1. The application can connect to a plaintext HTTP server by invoking nx_web_http_client_connect(). If the application needs to use secure connection, it can connect to a secure HTTP server by invoking nx_web_http_client_secure_connect(). Note that application needs to implement the TLS setup callback function for secure connection. If needed, the application can include additional server certificate validation using DNS validation, certificate revocation and certificate policy enforcement. This can be done by invoking nx_secure_tls_session_certificate_callback_set() inside the TLS setup callback function. A reference implementation of TLS setup callback function is provided in Figure 1 of appendix.These APIs just opens a plain or secure connection to server but does not send any request.
2. After connecting to the server, the client can create a custom HTTP request such as GET by calling nx_web_http_- client_request_initialize().
3. The client can add custom header to request created in step 2 by invoking nx_web_http_client_request_header_add()API.
4. After connecting to the server, the client can send request to server using nx_web_http_client_request_send() API.
5. The application can retrieve the response sent by the server by repeatedly calling the nx_web_http_client_response_body_get() API until the entire response is retrieved.
6. The application should invoke nx_web_http_client_delete() to delete all the resources associated with HTTP client instance.

Note

If the application does not want to create custom requests, then it can use nx_web_http_*_start() APIs to send a standard request. For example, to send a standard GET request to plain text server, the application can use nx_web_http_client_get_start(). Similarly, the application can use nx_web_http_client_get_secure_start() to send a standard GET request over a secure channel to server. The nx_web_http_*_start() APIs internally uses nx_web_http_client_request_initialize() to create and send the desired HTTP request.

The following figure illustrates common steps in a typical operational flow diagram:

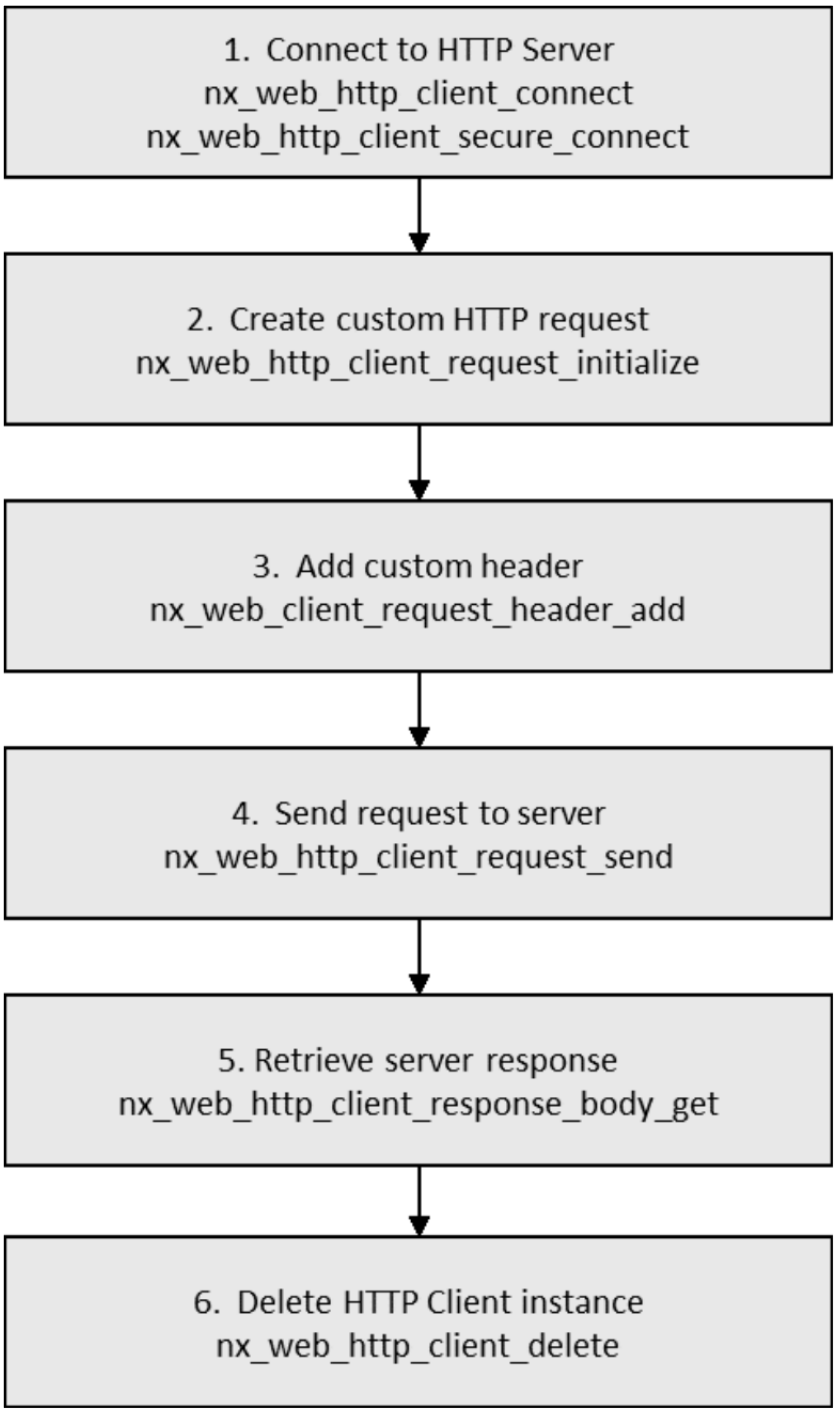

Figure 469: Flow Diagram of a Typical NetX Duo Web HTTP/HTTPs Client Module Application

4.3.24 NetX/NetX Duo HTTP/HTTPS Web Server Framework

4.3.24.1 NetX Duo Web HTTP/HTTPs Server Introduction

The NetX Duo Web HTTP/HTTPs Server module provides a high-level API for hosting Hyper Text

Transport Protocol (HTTP) Server on the web. The HTTP protocol utilizes Transmission Control Protocol (TCP) services to perform its function. HTTPs is the secure version of the HTTP protocol which uses HTTP on top of the Transport Layer Security (TLS) protocol to secure underlying TCP connection.

HTTP/HTTPs server is implemented on top of NetX Duo IP and NetX Duo Packet Pool. NetX Duo IP attaches itself to appropriate link layer driver such as Ethernet/Wi-Fi/Cellular. Web HTTP server can be started over secure connection and in such case, it uses service provided by NetX Duo TLS Common.

Unsupported Features

NetXDuo HTTPs Server has not been tested on the Cellular CAT1 and Quectel BG96 Cellular Modules.

NetX Duo Web HTTP/HTTPs Server Module Features

- NetX Web HTTP/HTTPs server is compliant with below RFCs
  - RFC1945 "Hypertext Transfer Protocol/1.0"
  - RFC 2616 "Hypertext Transfer Protocol – HTTP/1.1"
  - RFC 2818 "HTTP over TLS"
  - RFC 2581 "TCP Congestion Control"
  - RFC 1122 "Requirements for Internet Hosts", and related RFCs
- Multipart support
- Basic and digest authentication support
- Custom MIME Support
- Callback support for several key functions:
  - HTTP Authentication Callback
  - HTTP Request Notify Callback
  - HTTP Invalid Username/Password Callback
  - HTTP Insert GMT Date Header Callback
  - HTTP Cache Info Get Callback
- Provides option to enable/disable TLS for secure communication using NetX Secure in SSP

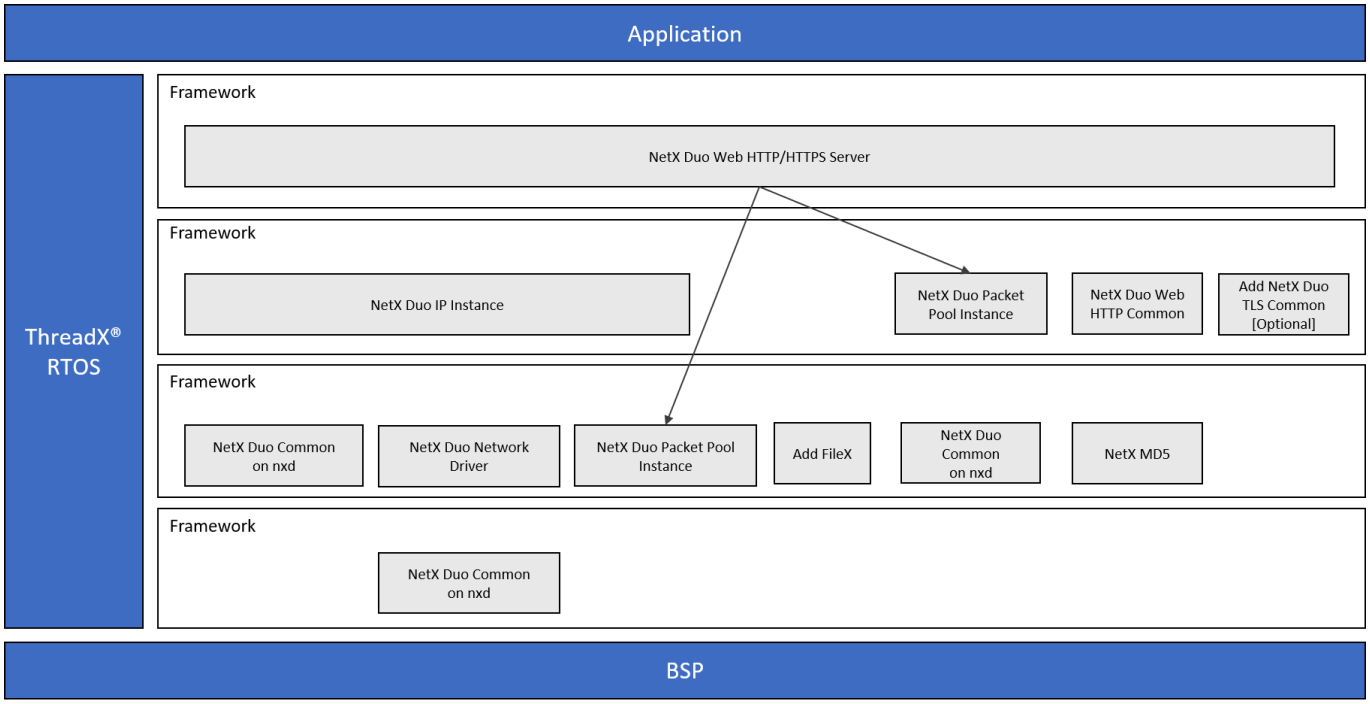

Figure 470: NetX Duo Web HTTP/HTTPs Server Module Block Diagram

Note

In the figure above, the NetX Duo Network Driver module has multiple implementation options available. See the description just after the module stack figure in Including the NetX Duo Web HTTP/HTTPs Server Module in an Application for additional details.

4.3.24.2 NetX Duo Web HTTP/HTTPs Server Module APIs Overview

The NetX Duo Web HTTP/HTTPs Server module defines APIs for creating, deleting, starting, stopping, response sending and getting information for a received HTTP request. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX Duo Web HTTP/HTTPs Server Module API Summary

Function Name	Example API Call and Description
nx_web_http_server_cache_info_callback_set	nx_web_http_server_cache_info_callback_set(NX_WEB_HTTP_SERVER *server_ptr, UINT (*cache_info_get)(CHAR *resource, UINT *max_age, NX_WEB_HTTP_SERVER_DATE *date)); Set the callback to retrieve URL max age and date
nx_web_http_server_callback_data_send	nx_web_http_server_callback_data_send(NX_WEB_HTTP_SERVER *server_ptr, VOID *data_ptr, ULONG data_length); Send data from callback function
nx_web_http_server_callback_generate_response_header	nx_web_http_server_callback_generate_response_header(NX_WEB_HTTP_SERVER *server_ptr, NX_PACKET **packet_pptr, CHAR *status_code, UINT content_length, CHAR *content_type, CHAR* additional_header); Create a response header in a callback function
nx_web_http_server_callback_packet_send	nx_web_http_server_callback_packet_send(NX_WEB_HTTP_SERVER *server_ptr, NX_PACKET *packet_ptr); Send an HTTP packet from callback function
nx_web_http_server_callback_response_send	nx_web_http_server_callback_response_send(NX_WEB_HTTP_SERVER *server_ptr, CHAR *header, CHAR *information, CHAR additional_info); Send response from callback function

nx_web_http_server_content_get	nx_web_http_server_content_get(NX_WEB_HTTP_SERVER *server_ptr, NX_PACKET *packet_ptr, ULONG byte_offset, CHAR *destination_ptr, UINT destination_size, UINT *actual_size); Get content from the request
nx_web_http_server_content_get_extended	nx_web_http_server_content_get_extended(NX_WEB_HTTP_SERVER *server_ptr, NX_PACKET *packet_ptr, ULONG byte_offset, CHAR *destination_ptr, UINT destination_size, UINT *actual_size); Get content from the request/supports zero length Content Length
nx_web_http_server_content_length_get	nx_web_http_server_content_length_get(NX_PACKET *packet_ptr, UINT *content_length); Get length of content in the request/supports Content Length of zero value
nx_web_http_server_create	nx_web_http_server_create(NX_WEB_HTTP_SERVER *http_server_ptr, CHAR *http_server_name, NX_IP *ip_ptr, UINT server_port, FX_MEDIA *media_ptr, VOID *stack_ptr, ULONG stack_size, NX_PACKET_POOL *pool_ptr, UINT (*authentication_check)(NX_WEB_HTTP_SERVER *server_ptr, UINT request_type, CHAR *resource, CHAR **name, CHAR **password, CHAR **realm), UINT (*request_notify)(NX_WEB_HTTP_SERVER *server_ptr, UINT request_type, CHAR *resource, NX_PACKET *packet_ptr)); Create an HTTP Server instance
nx_web_http_server_delete	nx_web_http_server_delete(NX_WEB_HTTP_SERVER *http_server_ptr); Delete an HTTP Server instance
nx_web_http_server_get_entity_content	nx_web_http_server_get_entity_content(NX_WEB_HTTP_SERVER *server_ptr, NX_PACKET **packet_pptr, ULONG *available_offset, ULONG *available_length); Retrieve the location and length of entity data
nx_web_http_server_get_entity_header	nx_web_http_server_get_entity_header(NX_WEB_HTTP_SERVER *server_ptr, NX_PACKET **packet_pptr, UCHAR *entity_header_buffer, ULONG buffer_size); Retrieve the contents of entity header

nx_web_http_server_gmt_callback_set	nx_web_http_server_gmt_callback_set(NX_WEB_HTTP_SERVER *server_ptr, VOID (*gmt_get)(NX_WEB_HTTP_SERVER_DATE *date); Set the callback to obtain GMT date and time
nx_web_http_server_invalid_userpassword_notify_set	nx_web_http_server_invalid_userpassword_notify_set(NX_WEB_HTTP_SERVER *http_server_ptr, UINT (*invalid_username_password_callback)(CHAR *resource, ULONG client_address, UINT request_type)); Set the callback to handle invalid user/password
nx_web_http_server_mime_maps_additional_set	nx_web_http_server_mime_maps_additional_set(NX_WEB_HTTP_SERVER *server_ptr, NX_WEB_HTTP_SERVER_MIME_MAP *mime_maps, UINT mime_maps_num); Set additional MIME maps for HTML
nx_web_http_server_response_packet_allocate	nx_web_http_server_response_packet_allocate(NX_WEB_HTTP_SERVER *server_ptr, NX_PACKET **packet_ptr, ULONG wait_option); Allocate a HTTP(S) packet
nx_web_http_server_packet_content_find	nx_web_http_server_packet_content_find(NX_WEB_HTTP_SERVER *server_ptr, NX_PACKET **packet_ptr, UINT *content_length); Extract content length and set pointer to start of data
nx_web_http_server_packet_get	nx_web_http_server_packet_get(NX_WEB_HTTP_SERVER *server_ptr, NX_PACKET **packet_ptr); Receive the next HTTP packet
nx_web_http_server_param_get	nx_web_http_server_param_get(NX_PACKET *packet_ptr, UINT param_number, CHAR *param_ptr, UINT *param_size, UINT max_param_size); Get parameter from the request
nx_web_http_server_query_get	nx_web_http_server_query_get(NX_PACKET *packet_ptr, UINT query_number, CHAR *query_ptr, CHAR *query_size, UINT max_query_size); Get query from the request
nx_web_http_server_response_chunked_set	nx_web_http_server_response_chunked_set(NX_WEB_HTTP_SERVER *server_ptr, UINT chunk_size, NX_PACKET *packet_ptr); Set chunked transfer for HTTP(S) response

nx_web_http_server_secure_configure	nx_web_http_server_secure_configure(NX_WEB_HTTP_SERVER *http_server_ptr, const NX_SECURE_TLS_CRYPTO *crypto_table, VOID *metadata_buffer, ULONG metadata_size, UCHAR* packet_buffer, UINT packet_buffer_size, NX_SECURE_X509_CERT *identity_certificate, NX_SECURE_X509_CERT *trusted_certificates[], UINT trusted_certs_num, NX_SECURE_X509_CERT *remote_certificates[], UINT remote_certs_num, UCHAR *remote_certificate_buffer, UINT remote_cert_buffer_size); Configure an HTTP Server to use TLS for secure HTTPS *Note* *Parameter crypto_table is a pointer to crypto cipher suite table. Suggested ciphersuite to be used is "nx_crypto_tls_ciphers_synergys7" which is a cipher suite table under NetX in SSP. For further information on Ciphersuite Refer NetX TLS User Manual.*
nx_web_http_server_start	nx_web_http_server_start(NX_WEB_HTTP_SERVER *http_server_ptr); Start the HTTP Server
nx_web_http_server_stop	nx_web_http_server_stop(NX_WEB_HTTP_SERVER *http_server_ptr); Stop the HTTP Server
nx_web_http_server_type_get	nx_web_http_server_type_get(NX_WEB_HTTP_SERVER *http_server_ptr, CHAR *name, CHAR *http_type_string, UINT *string_size); Extract file type from Client HTTP request

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

Status Return Values

Name	Description
NX_SUCCESS	Successful connection of TCP socket.
NX_PTR_ERROR	Invalid pointer input.
NX_WEB_HTTP_DATA_END	End of request content
NX_WEB_HTTP_POOL_ERROR	Invalid payload size in packet pool
NX_CALLER_ERROR	Invalid caller of this service.

NX_WEB_HTTP_TIMEOUT	HTTP Server timeout in getting next packet of content
NX_WEB_HTTP_ERROR	Internal HTTP Server error.
NX_WEB_HTTP_FAILED	Query size too small
NX_CALLER_ERROR	Invalid caller of this service
NX_WEB_HTTP_BOUNDARY_ALREADY_FOUND	Content for the HTTP server internal multipart markers is already found
NX_WEB_HTTP_NOT_FOUND	Entity header field/query not found
NX_NO_PACKET	No packet available
NX_WAIT_ABORTED	Requested suspension was aborted
NX_WEB_HTTP_INCOMPLETE_PUT_ERROR	Improper HTTP header format
NX_INVALID_PARAMETERS	Packet size cannot support protocol
NX_WEB_HTTP_IMPROPERLY_TERMINATED_PARAM	Request parameter not properly terminated
NX_WEB_HTTP_NO_QUERY_PARSED	No query in Client request
NX_NOT_CONNECTED	The underlying TCP socket is no longer connected.
NX_SECURE_TLS_UNRECOGNIZED_MESSAGE_TYPE	A received TLS message type is incorrect.
NX_SECURE_TLS_UNSUPPORTED_CIPHER	Cipher provided by the remote host is not supported.
NX_SECURE_TLS_HANDSHAKE_FAILURE	Message processing during the TLS handshake has failed.
NX_SECURE_TLS_HASH_MAC_VERIFY_FAILURE	An incoming message failed a hash MAC check.
NX_SECURE_TLS_TCP_SEND_FAILED	An underlying TCP socket send failed.
NX_SECURE_TLS_INCORRECT_MESSAGE_LENGTH	An incoming message had an invalid length field.
NX_SECURE_TLS_BAD_CIPHERSPEC	An incoming ChangeCipherSpec message was incorrect.
NX_SECURE_TLS_INVALID_SERVER_CERT	An incoming TLS certificate is unusable for identifying the remote TLS server.
NX_SECURE_TLS_UNSUPPORTED_PUBLIC_CIPHER	The public-key cipher provided by the remote host is unsupported
NX_SECURE_TLS_NO_SUPPORTED_CIPHERS	The remote host has indicated no ciphersuites that are supported by the NetX Secure TLS stack.
NX_SECURE_TLS_UNKNOWN_TLS_VERSION	A received TLS message had an unknown TLS version in its header.

NX_SECURE_TLS_UNSUPPORTED_TLS_VERSION	A received TLS message had a known but unsupported TLS version in its header.
NX_SECURE_TLS_ALLOCATE_PACKET_FAILED	An internal TLS packet allocation failed.
NX_SECURE_TLS_INVALID_CERTIFICATE	The remote host provided an invalid certificate.
NX_SECURE_TLS_ALERT_RECEIVED	The remote host sent an alert indicating an error and ending the TLS session.
NX_SECURE_TLS_MISSING_CRYPTO_ROUTINE	An entry in the ciphersuite table had a NULL function pointer.
NX_WEB_HTTP_EXTENSION_MIME_DEFAULT	Default "text/plain" returned

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.24.3 NetX Duo Web HTTP/HTTPs Server Module Operational Overview

The NetX Duo Web HTTP Server module creates an IP instance that carries out NetX Duo operations and enables it for TCP services in the NetX Duo library; it then creates the Web HTTP Server instance and TCP socket for listening to client requests on configured port number. The Web HTTP Server requires a packet pool; the module can supply one either by sharing the IP default packet pool (g_packet_pool0) or create a new one. The minimum packet payload is set by the Minimum size of packets in pool property of the Web HTTP Server module. This packet pool is used by the Web HTTP Server only to transmit packets, so the packet pool size and payload can be optimized on the expected size and number of HTTP Server packets sent out.

The NetX Duo Web HTTP Server supports both IPv4 and IPv6 connections. If the HTTP Server has clients desiring to connect over IPv6, make sure the NetX Duo IPv6 Support property is enabled in the NetX Duo Source element. It may be necessary to enable ICMPv6 checksum computation for the underlying ICMPv6 protocols. To do so, set the Checksum computation support on transmitted ICMPv6 packets and Checksum computation support on received ICMPv6 packets properties of the NetX Duo Source element to Enabled. (If the host hardware automatically computes ICMPv6 checksums, these can be left disabled.) Make sure the IPv6 Global Address of the Client host is set in the IP instance element. Thereafter, the NetX Duo does the necessary processing to enable IPv6 and ICMPv6 services required for IPv6 underlying protocols.

The NetX Duo Web HTTP Server is also designed for use with the FileX embedded file system.

The NetX Duo Web HTTP/HTTPs server module can be used in the normal mode or secure mode

NetX Duo Web HTTP/HTTPs server module Normal Mode Operational Description

In normal mode, the communication between HTTP client and server is not secure.

Netx Duo Web HTTP/HTTPs server module Secure Mode Operational Description

In Secure mode, the communication between HTTP client and server is secured using the TLS protocol. In the thread pane, TLS protocol is represented by "Add NetX Duo TLS common [Optional]" block as shown in the figure below

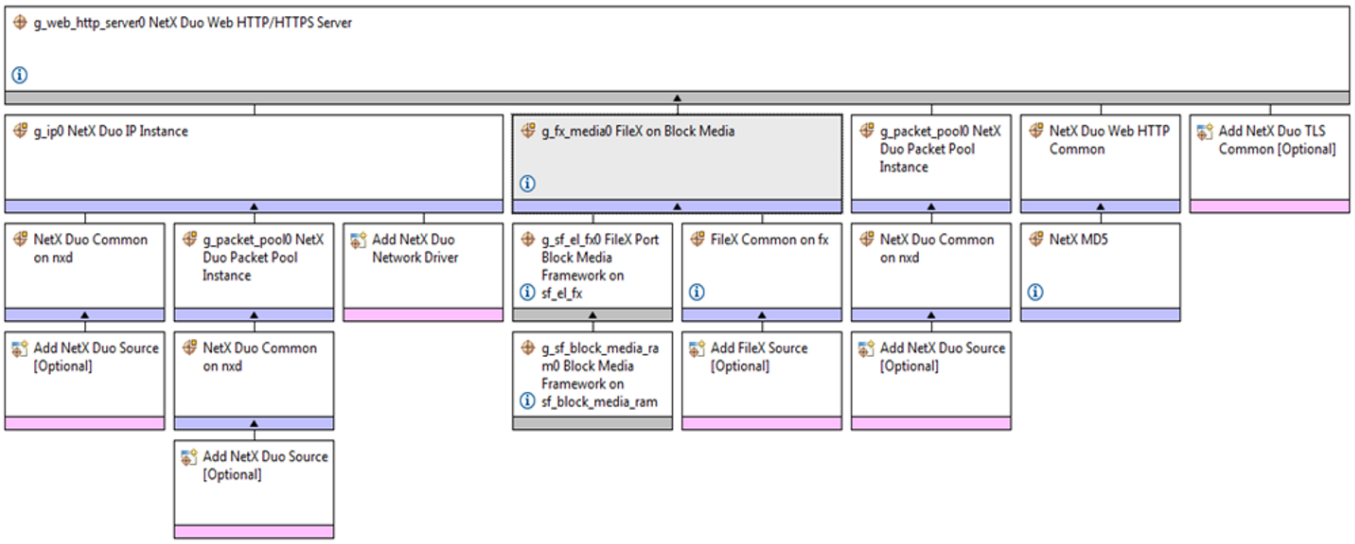

Figure 471: NetX Duo Web HTTP/HTTPs Server Module Component Thread-Pane View

Adding NetX Duo TLS Common block enables TLS support. The figure below shows the thread pane view of Web HTTP server with TLS support enabled.

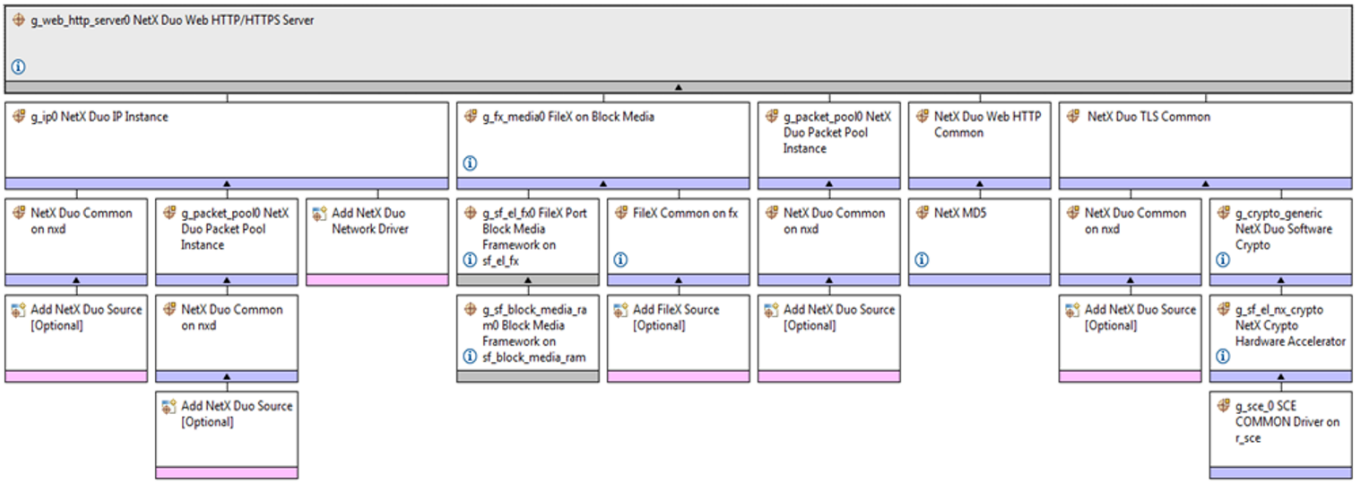

Figure 472: NetX Duo Web HTTP/HTTPs Server Module Component with TLS Support Enabled

NetX Duo Web HTTP Server Responses

When the Web HTTP Server processes the client command, it returns an ASCII response string that includes a 3-digit numeric status code. The numeric response is used by the HTTP Client software to determine whether the operation succeeded or failed. Following is a list of various HTTP Server responses to client commands:

Web HTTP Server responses to client commands

Numeric Field	Meaning
200	Request was successful

400	Request was not formed properly
401	Unauthorized request, client needs to send authentication
404	Specified resource in request was not found
500	Internal HTTP Server error
501	Request not implemented by HTTP Server
502	Service is not available

For example, a successful client request to PUT the file test.htm is responded to with the message HTTP/1.0 200 OK.

NetX Duo Web HTTP Authentication

HTTP authentication is optional and is not required for all web requests. There are two types of authentication, basic and digest. Basic authentication is equivalent to the name and password authentication found in many protocols. In HTTP basic authentication, the name and passwords are concatenated and encoded in the base64 format. The main disadvantage of basic authentication is the name and password are transmitted openly in the request, making it easy for the name and password to be stolen. Digest authentication addresses this problem by never transmitting the name and password in the request. Instead, an algorithm is used to derive a 128-bit key or digest from the name, password, and other information. The NetX Web HTTP Server supports the standard MD5 digest algorithm.

The Web HTTP Server authentication callback can decide if a requested resource requires authentication. If authentication is required and the client request did not include the proper authentication, an HTTP/1.0 401 Unauthorized response with the type of authentication required is sent to the client. The client is then expected to form a new request with the proper authentication.

NetX Duo Web HTTP Authentication Callback

The Web HTTP Server authentication callback routine is specified by the Name of Authentication Checking Function property of the HTTP Server Thread. This function is called at the beginning of each HTTP Client request.

The callback routine provides the NetX Web HTTP Server with the username, password, and realm strings associated with the resource and returns the type of authentication necessary. If no authentication is necessary for the resource, the authentication callback should return the value of NX_WEB_HTTP_DONT_AUTHENTICATE. If basic authentication is required for the specified resource, the routine should return NX_WEB_HTTP_BASIC_AUTHENTICATE. If MD5 digest authentication is required, the callback routine should return NX_WEB_HTTP_DIGEST_AUTHENTICATE.

The format of the authenticate callback routine is defined as:

UINT nx_web_http_server_authentication_check(NX_WEB_HTTP_SERVER *server_ptr, UINT request_type, CHAR *resource, CHAR **name, CHAR **password, CHAR **realm);

The input parameters are defined as follows:

Input Parameters Definitions

Parameter	Meaning

request_type	Specifies the HTTP Client request, valid requests are defined as: NX_WEB_HTTP_SERVER_GET_REQUEST NX_WEB_HTTP_SERVER_POST_REQUEST NX_WEB_HTTP_SERVER_HEAD_REQUEST NX_WEB_HTTP_SERVER_PUT_REQUEST NX_WEB_HTTP_SERVER_DELETE_REQUEST
resource	Specific resource requested.
name	Destination for the pointer to the required username.
password	Destination for the pointer to the required password.
realm	Destination for the pointer to the realm for this authentication.

Name, password, and realm pointers are not used if NX_WEB_HTTP_DONT_AUTHENTICATE is returned by the authentication callback routine. The HTTP Server developer must ensure that the maximum size of the username and password (defined by the Maximum username length and Maximum password length properties of the NetX Duo Web HTTP Common) are large enough for the username and password specified in the authentication callback. These are both defaulted to size 20 characters.

NetX Duo Web HTTP Server Request Notify callback

If a request callback is specified, (the Name of Request Notify Callback Function property of the NetX Web HTTP Server module) the NetX Web HTTP Server forwards requests to the specified function after authentication and validity of the client request is completed without errors. The callback should indicate (by the return status) if no more processing of the client request is required (return status NX_WEB_HTTP_CALLBACK_COMPLETED), if there was an error in the callback processing, (status is non-zero), or the process was completed successfully, and the Web HTTP Server should continue processing the client request. The format of this callback is:

UINT request_notify(NX_WEB_HTTP_SERVER *server_ptr, UINT request_type, CHAR *resource, NX_PACKET *packet_ptr);

To disable the request notify callback, set the Name of Request Notify Callback Function property to NULL.

NetX Duo Web HTTP Invalid Username/Password Callback

The optional Invalid Username/Password callback in the NetX Web HTTP Server module is invoked if the HTTP Server receives an invalid username-and-password combination in a client request. To set the Invalid Username/Password callback function, use the nx_web_http_server_invalid_userpassword_notify_set service.

NetX Duo Web HTTP Insert GMT Date Header Callback

The NetX Web HTTP Server supports an optional callback to insert a date header in its response messages. This callback is invoked when the Server responds to a Client PUT or GET request. To register a GMT date callback with the HTTP Server, the nx_web_http_server_gmt_callback_set service is used.

NetX Duo Web HTTP Cache Info Get Callback

The NetX Web HTTP Server has an optional callback to request the maximum age and date from the HTTP application for a specific resource. This information is used to determine if the HTTP server sends the entire page in response to a Client Get request. If the if modified since in the Client request is not found or does not match the last modified date returned by the get-cache callback, the entire page is sent. To register the callback with the HTTP server nx_web_http_server_cache_info_callback_set service is used.

NetX Duo Web HTTP Multipart Support

Multipurpose Internet Mail Extensions (MIME) was originally intended for the SMTP protocol, but its use has spread to HTTP. MIME allows messages to contain mixed message types (for example, image/jpg and text/plain) within the same message. The NetX Web HTTP Server has added services to determine content type in HTTP messages containing MIME from the client. To enable multipart support, set the Multipart HTTP requests support property of the NetX Web HTTP Server module to enable.

NetX Duo Web HTTP/HTTPs Server Module Important Operational Notes and Limitations

NetX Duo Web HTTP/HTTPs Server Module Operational Notes

- The NetX Duo Web HTTP Server module requires a FileX media (Block media or USB Mass Storage). When an HTTP Server stack element is added to the project, an Add FileX box is attached to it. The configurator automatically sets up and initializes the FileX media for the server before the server is started. For more details for configuring FileX, see *FileX User's Guide for the Renesas Synergy Platform*.
- The NetX Duo Web HTTP Server also requires a packet pool for transmitting packets. It can share the IP default packet pool or create a separate packet pool.
- The NetX Duo Web HTTP/HTTPs Server component is added by clicking on the (+) sign in the thread pane window -> Azure RTOS -> NetX Duo -> Protocols -> NetX Duo Web HTTP/HTTPs Server
- Adding the NetX Duo Web HTTP/HTTPs Server component to a project automatically adds the option to add the NetX Duo TLS component required for secure HTTP server

The NetX Duo Web HTTP/HTTPs Server properties are listed in the following table:

Property	Value
◢ Common	
Parameter Checking	Default (BSP)
HTTPS Support	Disable
FileX Support	Enable
Multipart HTTP requests support	Disable
Server thread priority	16
Server thread time slicing interval (ticks)	2
Server socket window size (bytes)	2048
Server time out (seconds)	10
Server time out for accept (seconds)	10
Server time out for disconnect (seconds)	10
Server time out for receive (seconds)	10
Server time out for send (seconds)	10
Maximum size of header field (bytes)	256
Maximum connections in queue	4
Maximum length of resource name	40
Number of simultaneous sessions for server	2
Minimum size of packets in pool (bytes)	600
Maximum number of queued transmit packets (units)	20
Server Socket Re-transmission Timeout (seconds)	2
Maximum number of retries per packet	10
Server Next Re-transmission timeout shift	1
◢ Module g_web_http_server0 NetX Duo Web HTTP/HTTPS Server	
Name	g_web_http_server0
Internal thread stack size (bytes)	4096
TCP listening port for HTTP/HTTPS Server	80
Name of Authentication Checking Callback Function	NULL
Name of Request Notify Callback Function	NULL
Name of generated initialization function	web_http_server_init0
Auto Initialization	Enable

Figure 473: NetX Duo Web HTTP/HTTPs Server Module Component Configurable Properties

In the figure above, "Common" properties are those configurable options in the NetX Duo Web HTTP/HTTPs Server that are common to all instances of the HTTP/HTTPs server in the project. The "Module" properties are specific to each instance of HTTP/HTTPs Server in the project.

NetX Duo Web HTTP/HTTPs Server Module Common Properties

- Parameter Checking:This option removes the basic HTTP error checking. It is typically used after the application has been debugged. Default value is BSP.
- HTTPS Support: If defined, this macro enables TLS and HTTPS. Leave undefined to free up resources if only plaintext HTTP is desired. Default value is Disable.
- FileX Support: This option provides User to select either "FileX Stub", "FileX on USB Mass Storage" or "FileX on Block Media". Default value is Enable.
- Multipart HTTP requests support: If defined, this option enables HTTP Server to support multipart HTTP requests. Default value is Disable.
- Server Thread Priority: The priority of the HTTP Server thread. Default value is 16.
- Server Thread time slicing interval (ticks): The number of timer ticks the Server thread is allowed to run before yielding to threads of the same priority. Default value is 2 ticks.
- Server socket window size (bytes): Size of the Server TCP socket receive window. Default value is 2048 bytes.
- Server time out (seconds): Time period for which internal services of server will suspend. Default value is set to 10 seconds (10 * NX_IP_PERIODIC_RATE).
- Server time out for accept (seconds): Time period for which internal services will suspend for in internal nx_tcp_server_socket_accept() calls. The default value is set to 10 seconds (10 * NX_IP_PERIODIC_RATE).
- Server time out for disconnect (seconds): Specifies the number of ThreadX ticks that internal services will suspend for in internal nx_tcp_socket_disconnect() calls. The default

value is set to 10 seconds (10 * NX_IP_PERIODIC_RATE)
- Server time out for receive (seconds): Specifies the number of ThreadX ticks that internal services will suspend for in internal nx_tcp_socket_receive() calls. The default value is set to 10 seconds (10 * NX_IP_PERIODIC_RATE)
- Server time out for send (seconds): Specifies the number of ThreadX ticks that internal services will suspend for in internal nx_tcp_socket_send() calls. The default value is set to 10 seconds (10 * NX_IP_PERIODIC_RATE)
- Maximum size of header field (bytes): Specifies the maximum size of the HTTP header field. Default value is 256 bytes.
- Maximum connections in queue: Specifies the number of connections that can be queued for the HTTP Server. The default value is 4 (twice the maximum number of server sessions).
- Maximum length of resource name: Specifies the length of the resource name. Default value is 40.
- Number of simultaneous sessions for server: Specifies the number of simultaneous sessions for an HTTP or HTTPS server. A TCP socket and a TLS session (if HTTPS is enabled) are allocated for each session. Default value is 2.
- Minimum size of packets in pool (bytes): Specifies the minimum size of the packets in the pool specified at Server creation. The minimum size is needed to ensure the complete HTTP header can be contained in one packet. Default value is 600 bytes.
- Maximum number of queued transmit packets (units): This option specifies the maximum number of packets that can be enqueued on the Server socket re-transmission queue. If the number of packets enqueued reaches this number, no more packets can be sent until one or more enqueued packets are released. Default value is 20 units.
- Server Socket Re-transmission Timeout (seconds): Timeout for Server socket re-transmission. Default value is 2 seconds.
- Maximum number of retries per packet: This parameter sets the maximum number of re-transmissions on Server socket. Default value is 10.
- Server Next Re-transmission timeout shift: This value is used to set the next re-transmission timeout. The current timeout is multiplied by the number of re-transmissions thus far, shifted by the value of the socket timeout shift. Default value is 1 for doubling the timeout

NetX Duo Web HTTP/HTTPs Server Module Properties

- Name: Name of Web HTTP/HTTPs server instance. Default value is g_web_http_server0
- Internal Thread stack size (bytes): HTTP Server thread stack size. Used as a parameter while creating web HTTP Server instance. Default value is 4096 bytes
- TCP listening port for HTTP/HTTPS Server: TCP listening port for secured/unsecured HTTP server instance. Default value is 80.

Note: *If user wants to start Web HTTP server in secured mode then user can set the port number accordingly using this property. For example, user can set 443 as port number for secured HTTP server and can set port number as 80 for unsecured HTTP server.*

- Name of authentication checking callback function: Application's authentication checking routine. If specified, this routine is called for each HTTP Client request. If this parameter is NULL, no authentication will be performed. Default value is NULL.
- Name of request notify callback function: Application's request notify routine. If specified, this routine is called prior to the HTTP server processing of the request. This allows the resource name to be redirected or fields within a resource to be updated prior to completing the HTTP Client request. Default value is NULL.
- Name of generated initialization function: Name of initialization function under whichweb HTTP Server instance is created. Default value is web_http_server_init0.
- Auto Initialization: Enable/disable call to initialization function. This determines if the function specified in the Name of Generated Initialization function option is called. If set to Enable, it will invoke this function. Otherwise if set to Disable, the application must call the

nx_web_http_server_create() API before using any NetX Web HTTP/HTTPs Server services.

NetX Duo Web HTTP Common Configurable Properties

The common properties are listed in the following table:

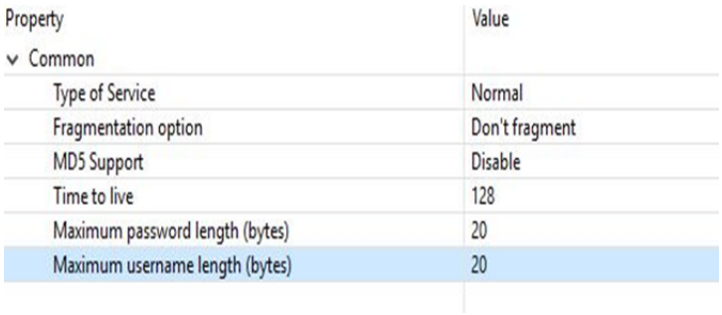

Figure 474: NetX Duo Web HTTP/HTTPs Client Module Component Common Configurable Properties

- Type of Service: Type of network service required for the HTTP TCP requests. The network service can be of type (Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost) and the default value is Normal.
- Fragmentation Option: This enables/disables TCP fragmentation for HTTP client request. The default value is Don't Fragment.
- MD5 Support: This enables/disables MD5 digest support required for digest authentication. The default value is disable.
- Time to live: This specifies maximum no. of routers the HTTP packet can pass through before it get discarded. The default is 128.
- Maximum password length (bytes): This defines the maximum length of client supplied password. The default is 20.
- The Maximum username length (bytes): This defines the maximum length of client supplied username. The default is 20.

NetX Duo Web HTTP/HTTPs Server Module Limitations

- TRACE, OPTIONS, and CONNECT HTTP requests are not supported.
- The HTTP Server supports both basic and MD5 digest authentication, but not MD5-sess.
- No content compression is supported.
- The packet pool associated with the HTTP Server must be large enough to hold the complete HTTP header.
- Request pipelining is not supported

4.3.24.4 Including the NetX Duo Web HTTP/HTTPs Server Module in an Application

This section describes how to include either or both the NetX Duo Web HTTP/HTTPs Server module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo Web HTTP/HTTPs Server module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX Duo Web HTTP/HTTPs Server Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_web_http_server0 NetX Duo WebHTTP/HTTPsServer	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo Web HTTP/HTTPsServer

When the NetX Duo Web HTTP/HTTPs Server module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

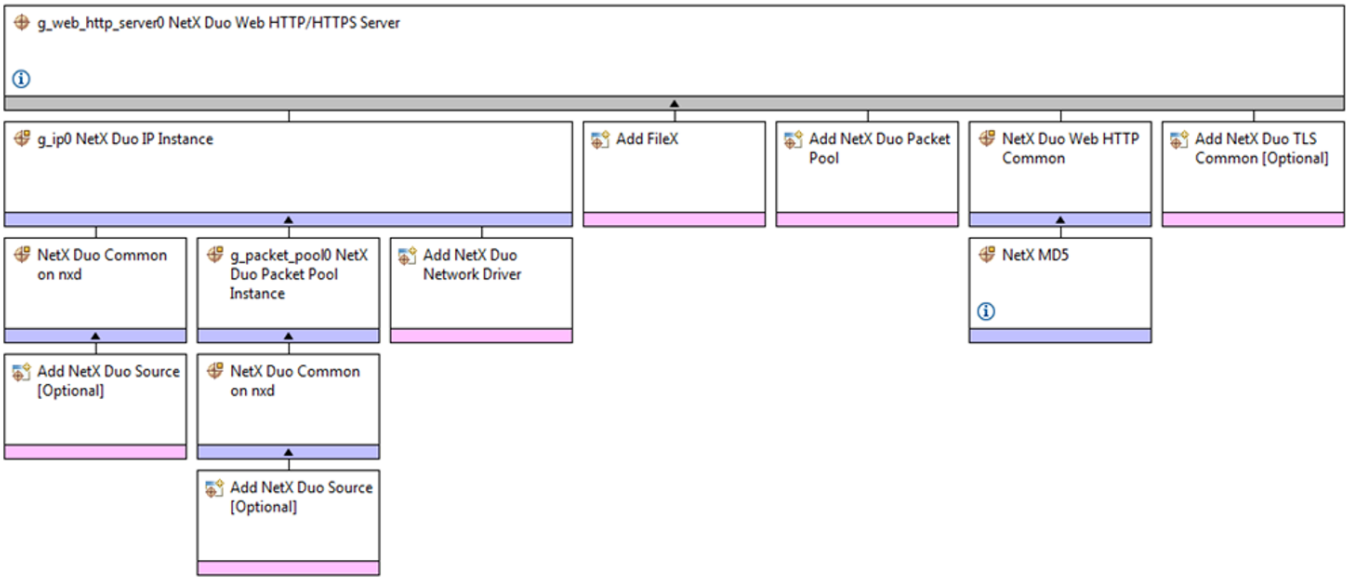

Figure 475: NetX Duo Web HTTP/HTTPs Server Module Stack

In the stack above, the NetX Duo Network Driver has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

Additionally, in the stack above, the FileX stack has also not been populated yet. There are multiple possible selections for the FileX module; they are not all provided so as not to needlessly complicate

the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- FileX Stub
- FileX on Block Media (implemented on Block Media Framework on sf_block_media_ram)
- FileX on USB Mass Storage (implemented on USBX Host Class Mass Storage)

4.3.24.5 Configuring the NetX Duo Web HTTP/HTTPs Server Module

The NetX Duo Web HTTP/HTTPs Server module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo Web HTTP/HTTPs Server Module

ISDE Property	Value	Description
Parameter Checking	Enable, Disable, BSP Default: BSP	Selects if code for parameter checking is to be included in the build.
HTTPS Support	Enable, Disable Default: Disable	Select whether to enable HTTPS support.
FileX Support	Enable, Disable Default: Enable	This option provides User to select either "FileX Stub", "FileX on USB Mass Storage" or "FileX on Block Media"
Multipart HTTP requests support	Enable, Disable Default: Disable	Option enables HTTP Server to support multipart HTTP requests
Server Thread Priority	16	Priority of the HTTP Server thread
Server Thread time slicing interval (ticks)	2	Number of timer ticks the Server thread is allowed to run before yielding to threads of the same priority.
Server socket window size (bytes)	2048	Size of the Server TCP socket receive window
Server time out (seconds)	10	Server time out selection

Server time out for accept (seconds)	10	Server time out for accept selection
Server time out for disconnect (seconds)	10	Server time out for disconnect selection
Server time out for receive (seconds)	10	Server time out for receive selection
Server time out for send (seconds)	10	Server time out for send selection
Maximum size of header field (bytes)	256	maximum size of the HTTP header field
Maximum connections in queue	4	Number of connections that can be queued for the HTTP Server
Maximum length of resource name	40	Length of the resource name
Number of simultaneous sessions for server	2	Number of simultaneous sessions for an HTTP or HTTPS server. A TCP socket and a TLS session (if HTTPS is enabled) are allocated for each session.
Minimum size of packets in pool (bytes)	600	Minimum size of the packets in the pool specified at Server creation.
Maximum number of queued transmit packets (units)	20	Specifies the maximum number of packets that can be enqueued on the Server socket re-transmission queue.
Server Socket Re-transmission Timeout (seconds)	2	Timeout for Server socket re-transmission
Maximum number of retries per packet	10	Maximum number of re-transmissions on Server socket.
Server Next Re-transmission timeout shift	1	This value is used to set the next re-transmission timeout. The current timeout is multiplied by the number of re-transmissions thus far, shifted by the value of the socket timeout shift.
Name	g_web_http_server0	Name of Web HTTP server instance
Internal Thread stack size (bytes)	4096	HTTP Server thread stack size
TCP listening port for HTTP/HTTPS Server	80	TCP listening port for secured/unsecured HTTP server instance

Name of authentication checking callback function	NULL	Name of Authentication Checking Function selection
Name of request notify callback function	NULL	Name of Request notify Function selection
Name of generated initialization function	web_http_server_init0	Name of initialization function under which web HTTP Server instance is created
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S5D9 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different pins for the Ethernet peripheral. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX Duo Web HTTP/HTTPs Server Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection
IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection

IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP cache storage units	Bytes, Entries Default: Bytes	ARP cache storage units selection
ARP cache size (in storage units)	520	ARP Cache Size in Bytes/Entries selection Note: 1 Entry = 52 Bytes
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function
Link status change callback	NULL	Link status change callback selection

Note

The example settings and defaults are for a project using the Synergy S5D9 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Web HTTP Common Instance

ISDE Property	Value	Description
Type of Service	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Type of service selection.
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragmentation option selection.
MD5 Support	Enable, Disable Default: Disable	MD5 support selection.
Time to live	128	Time to live selection.
Maximum password length (bytes)	20	Maximum password length in bytes.
Maximum username length (bytes)	20	Maximum username length in bytes.

Note

The example settings and defaults are for a project using the S5D9Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S5D9Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	1568	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection

Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S5D9Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo FileX on Block Media

ISDE Property	Value	Description
Name	g_fx_media0	Module name
Format media during initialization	Enable, Disable Default: Enabled	Enabling this will format the media
File System is on block media	True, False Default: True	Whether or not the media as filesystem support
Volume Name	Volume 1	Volume name string
Number of FATs	1	Number of FATs in the media
Directory Entries	256	Number of directory entries in the root directory
Hidden Sectors	0	Number of sectors hidden before this media's boot sector
Total Sectors	3751936	Total number of sectors in the media
Bytes per Sector	512	Number of bytes per sector
Sectors per Cluster	1	Number of sectors in each cluster
Working media memory size	512	Memory allocated for file system
Name of generated initialization function	fx_media_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S5D9Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX MD5 Instance

ISDE Property	Value	Description

No configurable properties		

Note

The example settings and defaults are for a project using the S5D9 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

4.3.24.6 Using the NetX Duo Web HTTP/HTTPs Server Module in an Application

Once the module has been configured and the files auto generated, the NetX Web HTTP/HTTPs server module is ready to be used in an application. Note that the auto generated code includes the initialization function with the name specified under the Name of generated initialization function property. This function internally calls the nx_web_http_server_create() API to create a HTTP/HTTPs server instance with the name specified under the Name property. Calls to this initialization function will be enabled or disabled depending on the Auto Initialization property value. Once the server instance is created, the typical steps in using the module in an application are:

1. Wait for valid IP address using the nx_ip_status_check API.
2. Start the Web HTTP Server.
    a. If user wants to start a secured HTTP server i.e HTTPS, the application should initialize device certificates by invoking the nx_secure_x509_certificate_initialize() API. The application should then configure an HTTP server to use TLS for secure HTTPS by invoking the nx_web_http_server_secure_configure() API. The application can start HTTPS server by invoking the nx_web_http_server_start() API.
    b. If user wants plain HTTP Server, application can start HTTP server by just invoking nx_web_http_server_start() API.
3. Handle optional callbacks if registered with the HTTP Server (Authentication Check, Request Notify, GMT set, Cache get and Invalid Username).
    a. The *authentication_check* callback routine provides the NetX Duo Web HTTP Server with the username, password, and realm strings associated with the resource and return the type of authentication necessary. If this callback is set to NULL, no authentication will be performed.
    b. The *request_notify* routine is called prior to the HTTP server processing of the request. This allows the resource name to be redirected or fields within a resource to be updated prior to completing the HTTP Client request.
4. Once the HTTP/HTTPS server is started, HTTP client can send GET/PUT/POST/HEAD/DELETE requests to the Web HTTP/HTTPS server.
5. The application should invoke nx_web_http_server_stop() to stop the server.
6. The application should invoke nx_web_http_server_delete () to delete all the resources associated with Web HTTP server instance.

Users do not have to worry about auto-generated code. Auto-generated code is included once the user generates the project after configuring the stack. Users only need to write the user application code in the associated file.

The following figure illustrates common steps in a typical operational flow diagram:

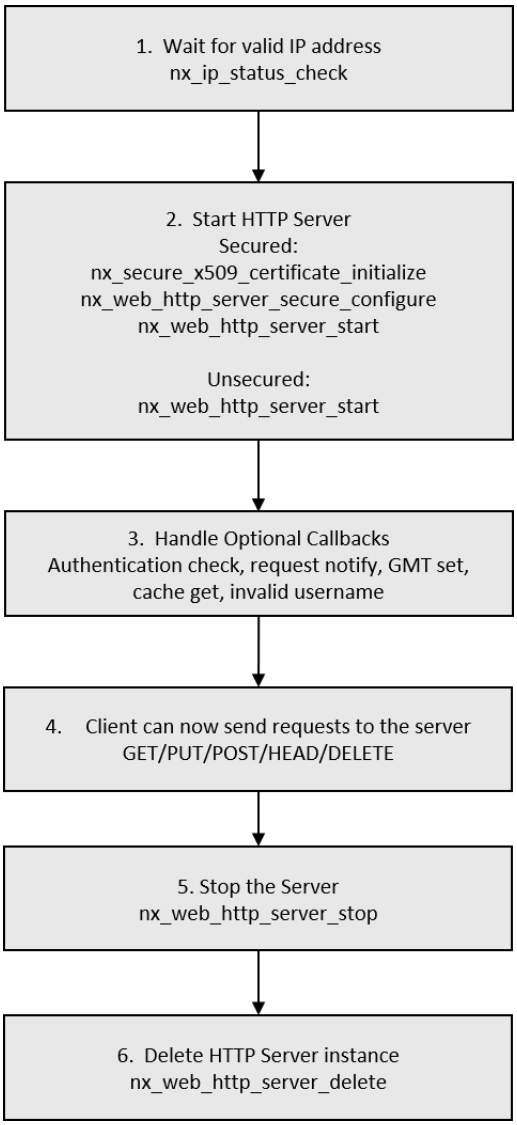

Figure 476: Flow Diagram of a Typical NetX Duo Web HTTP/HTTPs Server Module Application

4.3.25 NetX/NetX Duo SMTP Client

4.3.25.1 NetX/NetX Duo SMTP Client Introduction

The Simple Mail Transfer Protocol (SMTP) is a protocol for sending mail across networks and the Internet and utilizes the reliable Transmission Control Protocol (TCP) services to perform its content transfer function.

Note

Except for internal processing, the NetX Duo™ SMTP Client module is identical in the application, set-up and running of an SMTP Client session as the NetX™ SMTP Client module. For setting up the IP instance for IPv6 in NetX Duo, please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform.

Unsupported Features

Multiple network interface has not been tested for NetX Duo in this version of SSP.

NetX/NetX Duo SMTP Client Module Features

- The NetX SMTP Client API is compliant with RFC2821 "Simple Mail Transfer Protocol" and RFC 2554 "SMTP Service Extension for Authentication."
- Provides high-level APIs for:
  - Creating and deleting an SMTP Client
  - Sending mail messages

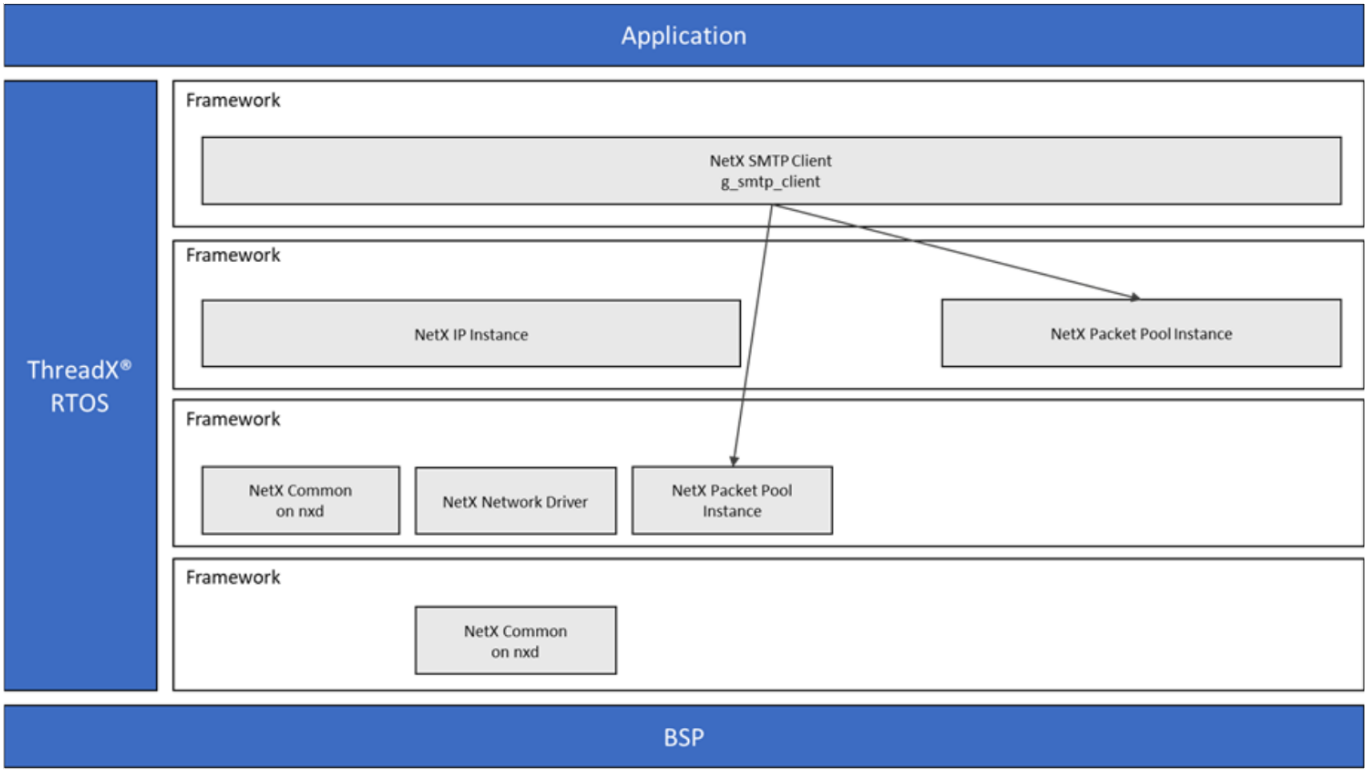

Figure 477: NetX/NetX Duo SMTP Client Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX/NetX Duo SMTP Client Module in an Application for additional details.

4.3.25.2 NetX/NetX Duo SMTP Client Module APIs Overview

The NetX SMTP Client defines APIs for creating, deleting and sending mail. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX/NetX Duo SMTP Client Module API Summary

Function Name	Example API Call and Description

nx_smtp_client_create	nxd_smtp_client_create(&demo_client, &client_ip, &client_packet_pool,USERNAME,PASSWORD, FROM_ADDRESS, LOCAL_DOMAIN, CLIENT_AUTHENTICATION_TYPE, server_ip_address, SERVER_PORT); Create an SMTP Client Instance.
**nxd_smtp_client_create	nxd_smtp_client_create(&demo_client, &client_ip, client_packet_pool, USERNAME, PASSWORD, from_address, client_domain, authentication_type, &server_address, port); Create an SMTP Client instance for IPv4 or IPv6 networks.
nx_smtp_client_delete	nx_smtp_client_delete(&demo_client); Delete an SMTP Client instance.
nx_smtp_mail_send	nx_smtp_mail_send(&demo_client, recipient_address, NX_SMTP_MAIL_PRIORITY_NORMAL, SUBJECT_LINE, MAIL_BODY, strlen(MAIL_BODY)); Create and send an SMTP Mail item.

Note

Fordetails on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo SMTP Client. Please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform for definition of NetX Duo specific data types.

Status Return Values

Name	Description
NX_SUCCESS	SMTP call successful
NX_CALLER_ERROR*	Invalid caller of this service
NX_PTR_ERROR*	Invalid input pointer parameter
NX_SMTP_INVALID_PARAM*	Invalid non-pointer input
NX_IP_ADDRESS_ERROR*	Invalid IP address type
NX_SMTP_CLIENT_NOT_INITIALIZED	SMTP Client instance initialized for SMTP session

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

- These are error codes which are only returned if error checking is enabled. Refer to the *NetX User Guide* for the Renesas Synergy™ Platform or *NetX Duo User's Guide* for the Renesas Synergy™ Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.25.3 NetX/NetX Duo SMTP Client Module Operational Overview

A NetX IP instance is created and enabled for TCP services. The SMTP Client is created with a previously created packet pool as input, as well as information from the host, including the host's email address, mail domain, authentication type and server IP address** (Server IPv4 Address in the SMTP Client Module configuration table found below) and port (Server port in the SMTP Client Module configuration table found below). Server port defaults to the well-known SMTP port 25.

Note

nx_smtp_client_create is also available in NetX Duo POP3 Client; in this case, setting the Server IPv4 Address is correct. However, to use the SMTP Client with an IPv6 server, the application must supply an IPv6 address.

The payload of the packet pool used by the SMTP Client should be optimized to the typical SMTP data size plus network headers (IP, TCP and physical frame). For messages exceeding that packet payload, the SMTP Client will allocate additional packets for messages that exceed the packet payload. In the Packet Pool Instance configuration table found below, the setting for the packet pool payload defaults to 512 and the number of packets defaults to 16.

Note

The SMTP Client instance must have a fully qualified email address (Client Address in the SMTP Client Module configuration table found below). A fully qualified domain name contains a local-part and a domain name, separated by an '@' character. The domain name, which is usually the right half after the '@' symbol of the Client address, must also be specified (Client Domain in the configuration table below). This is used in the SMTP Client HELO and EHLO greeting to the Server.

NetX SMTP Authentication

The creation of the SMTP Client also requires setting Authentication type, Client Name and Client Password (In the SMTP Client Module configuration table found below). Client Names can either be fully qualified domain names or display user names.

Authentication is a way for SMTP Clients to prove their identity to the SMTP Server and have their mail delivered as trusted users. Most commercial SMTP Servers require that Clients be authenticated.

Typically, authentication data consists of the sender's username and password. During an authentication challenge, the Server prompts for this information and the Client responds by sending the requested data in encoded format. The Server decodes the data and attempts to find a match in its user database. If found, the Server indicates the authentication is successful.

There are two flavors of authentication: basic and digest. Digest is not supported in the current NetX SMTP Client, and will not be discussed here. Basic authentication is equivalent to the name and password authentication described above. In SMTP basic authentication, the name and passwords are base64 encoded. The advantage of basic authentication is its ease of implementation and widespread use. The main disadvantage of basic authentication is name and password data is transmitted openly in the request.

Plain Authentication

The NetX SMTP Client sends an AUTH command with the PLAIN parameter. The NetX SMTP Server will indicate if it supports this type of authentication. If so, the Client replies with a single base64 encoded username and password message to the Server. The Server responds with a status code indicating if the Client authentication is successful or not.

Login Authentication

The NetX SMTP Client sends an AUTH command with the LOGIN parameter. The SMTP Server will

indicate if it supports this type of authentication and start the authentication 'challenge'. It sends a base64 encoded prompt back to the Client which is typically "Username". The Client decodes the prompt, and replies with a base64 encoded username. If the Server accepts the Client username, it sends out a base64 encoded prompt for the Client password. The Client responds with a base64 encoded password. The Server will indicate if Client authentication is successful.

No Authentication

Some SMTP Servers are configured without authentication. If so, their 250 response to the Client EHLO message will not list any authentication types. However, no authentication types listed does not necessarily mean the Server does not require or support authentication. If the Client is configured for PLAIN or LOGIN authentication in this situation, the NetX Client thread task will default to PLAIN. If the Client is configured for NONE, the authentication step is skipped and the SMTP state advances to the MAIL state.

Note that if the Client is configured for no authentication and the SMTP Server does support authentication, the Client authentication type is switched to PLAIN.

Sending a Mail Message

After the SMTP Client is created, the SMTP Client application can start sending messages by calling the nx_smtp_mail_send service. Each time this service is called, NetX SMTP Client creates a new TCP connection with the SMTP server and begins an SMTP session. In this session, the Client sends a series of commands to the SMTP Server as part of the SMTP protocol, including passing authentication, and culminating in sending out the actual mail message. The TCP connection is then terminated, regardless of the outcome of the SMTP session. If the mail message is successfully sent, NX_SUCCESS is returned. If not the error code reflects either the SMTP Client error, e.g. failing authentication, or the underlying NetX error, e.g. failing to connect to the server.

After an SMTP session, regardless of success or failure in sending out a mail message, the SMTP Client is returned to the 'initial' state, and ready for another SMTP session (with the same SMTP server).

NetX/NetX Duo SMTP Client Module Important Operational Notes and Limitations

NetX/NetX Duo SMTP Client Module Operational Notes

- NetX SMTP Client API is compliant with RFC2821 "Simple Mail Transfer Protocol" and RFC 2554 "SMTP Service Extension for Authentication."

NetX/NetX Duo SMTP Client Module Limitations

- The NetX SMTP Client does not support CRAM-MD5 digest authentication.
- The NetX SMTP Client messages are limited to one recipient per mail item, and only one mail message per TCP connection with the SMTP server.
- SMTP commands VRFY, SEND, SOML, EXPN, SAML, ETRN, TURN and SIZE SMTP options are not supported.
- The SMTP Client is not mail browser ("mail user agent") which is typically used for creating the mail message. It is a "mail transfer agent" only. It will provide the necessary processing of the mail message body for SMTP transport as specified in RFC 2821. It does not check the contents for correct syntax e.g. the recipient and reverse pathway. There is no restriction what is in the mail buffer e.g. MIME data or clear text messages. Mail message format, specified in RFC 2822 for including headers and message body is beyond the scope of the SMTP Client API.
- Refer to the "NetX™ Simple Mail Transfer Protocol (SMTP) Client User Guide for the Renesas

Synergy™ Platform" for additional information on limitations.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.25.4 Including the NetX/NetX Duo SMTP Client Module in an Application

This section describes how to include either or both the NetX and NetX Duo SMTP Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo SMTP Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo SMTP Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_smtp_client0 NetX SMTP Client	Threads	New Stack> X-Ware> NetX> Protocols> NetX SMTP Client
g_smtp_client0 NetX Duo SMTP Client	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo SMTP Client

When the NetX and/or NetX Duo SMTP Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

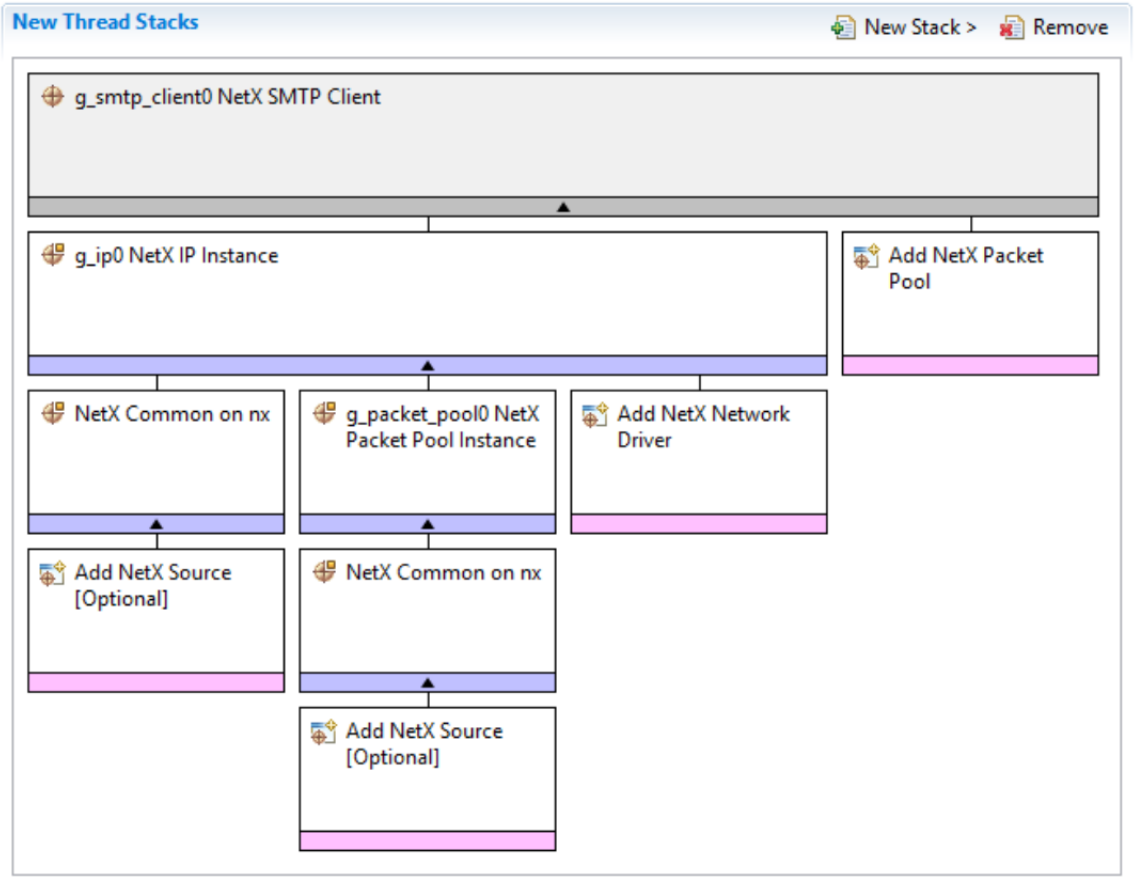

Figure 478: NetX/NetX Duo SMTP Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.25.5 Configuring the NetX/NetX Duo SMTP Client Module

The NetX/NetX Duo SMTP Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo SMTP Client Module

ISDE Property	Value	Description
TCP window size (bytes)	1460	TCP window size selection
Packet allocation timeout (seconds)	2	Packet allocation timeout selection
TCP socket connect timeout (seconds)	10	TCP socket connect timeout selection
TCP socket disconnect timeout (seconds)	5	TCP socket disconnect timeout selection
Server greeting reply timeout	10	Server greeting reply timeout selection
Command timeout (seconds)	10	Command timeout selection
Mail data request timeout (seconds)	30	Mail data request timeout selection
TCP socket send completion timeout (seconds)	5	TCP socket send completion timeout selection
Server challenge maximum string length (bytes)	200	Server challenge maximum string length selection
Maximum password length (bytes)	20	Maximum password length selection
Maximum username length (bytes)	40	Maximum username length selection
Name	g_smtp_client0	Name selection
**Use server address type	IPv4, IPv6 Default: IPv6	Use server address type selection
Server IPv4 Address (use commas for separation)	192, 168, 0, 2	Server IPv4 Address selection
**Server IPv6 Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	Server IPv6 Address selection
Server Port	25	Server Port selection
Client Name	username	Client Name selection
Client Password	password	Client Password selection
Client Address	username@domain.com	Client Address selection
Client Domain	domain.com	Client Domain selection

Authentication Type	Login	Authentication Type selection
Name of generated initialization function	smtp_client_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different addresses for the Ethernet port. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo SMTP Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection

ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo SMTP Client Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX/NetX Duo SMTP Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1

Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.25.6 Using the NetX/NetX Duo SMTP Client Module in an Application

The steps in using the NetX/NetX Duo SMTP Client module in a typical application are:

1. Create a mail message to send with nx_smtp_mail_send.
2. Continue sending mail messages as needed.
3. When done, delete the SMTP Client when done sending messages by calling nx_smtp_client_delete.

The following figure illustrates common steps in a typical operational flow diagram:

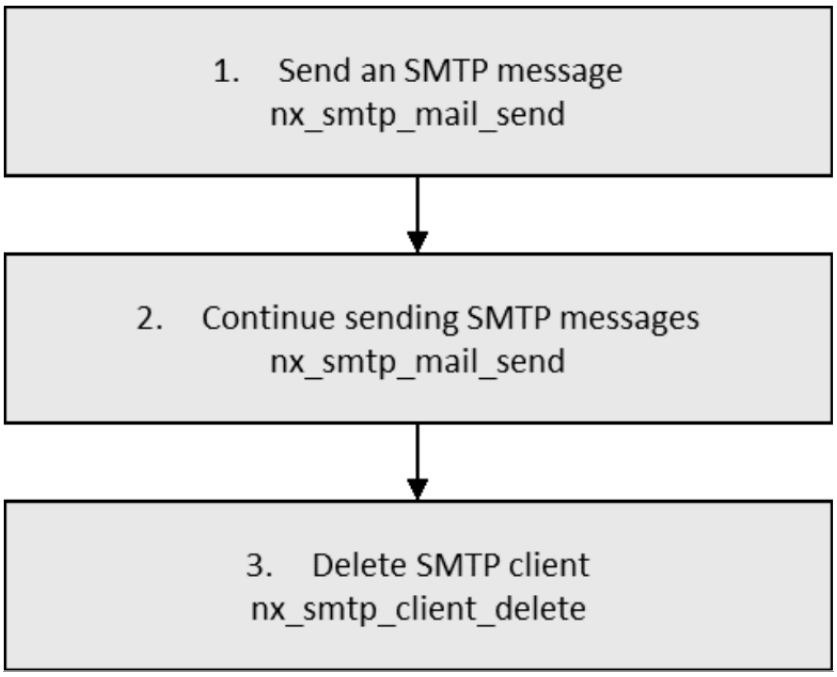

Figure 479: Flow Diagram of a Typical NetX/NetX Duo SMTP Client Module Application

4.3.26 NetX/NetX Duo SNMP Agent

4.3.26.1 NetX/NetX Duo SNMP Agent Introduction

The NetX/NetX Duo SNMP Agent module provides a high-level API for implementing the SNMP agent for the SSP architecture and is part of the NetX and NetX Duo application bundle included in the SSP Azure RTOS integration. This module is MCU independent, so any MCU that supports NetX and NetX Duo can implement the SNMP agent.

Note

Except for internal processing, the NetX Duo™ SNMP Agent module is identical in the application, set-up and running of an SNMP Agent session as the NetX™ SNMP Agent module.

NetX/NetX Duo SNMP Agent Module Features

- The NetX/NetX Duo SNMP Agent module is compliant with RFC1155, RFC1157, RFC1215, RFC1901, RFC1905, RFC1906, RFC1907, RFC1908, RFC2571, RFC2572, RFC2574, RFC2575, RFC 3414 and related RFCs.
- Operates only in UDP. TCP is not supported.
- Doesn't support Transport Layer Security (TLS) or Datagram Transport Layer Security (DTLS).
- The NetX/NetX Duo SNMP protocol implements SNMP Version 1, 2 and 3. The SNMPv3 implementation supports MD5 and Secure Hash Algorithm 1(SHA-1) authentication and Data Encryption Standard (DES) encryption. This version of the NetX and NetX Duo SNMP Agent has the following constraints:
    - One SNMP Agent per NetX IP Instance.
    - No support for RMON.

- SNMP v3 Inform messages are not supported
- Provides a mechanism to register callbacks for handling username, get, set and getnext when creating a SNMP agent.

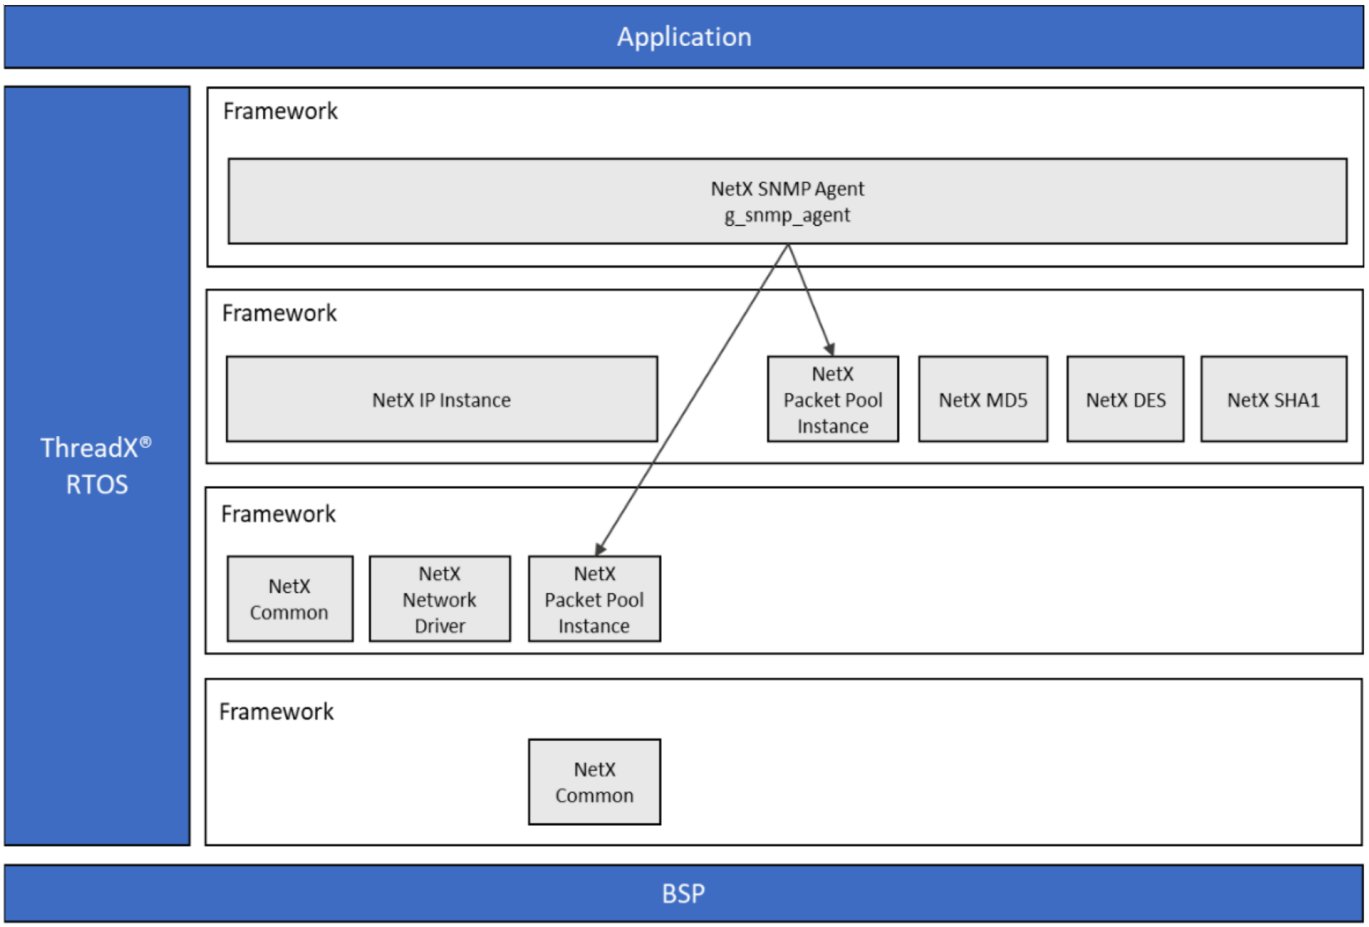

Figure 480: NetX/NetX Duo SNMP Agent Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX/NetX Duo SNMP Agent Module in an Application for additional details.

4.3.26.2 NetX/NetX Duo SNMP Agent Module APIs Overview

The NetX Duo SNMP Agent defines APIs for creating and deleting the SNMP Agent instance and getting its messages. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX/NetX Duo SNMP Agent Module API Summary (Part 1)

Function Name	Example API Call and Description

nx_snmp_agent_authenticate_key_use	(NX_SNMP_AGENT *agent_ptr, NX_SNMP_SECURITY_KEY *key); Register a previously created authentication key with the SNMP Agent for SNMP Agent responses
nx_snmp_agent_auth_trap_key_use	(NX_SNMP_AGENT *agent_ptr, NX_SNMP_SECURITY_KEY *key); Register a previously created authentication key with the SNMP Agent for SNMP trap messages.
nx_snmp_agent_community_get	(NX_SNMP_AGENT *agent_ptr, UCHAR **community_string_ptr); Retrieve the community string from the SNMP manager GET or GETNEXT request. The SNMP Agent should compare that to its own community string (see the nx_snmp_agent_public_string_test API description).
nx_snmp_agent_context_engine_set	(NX_SNMP_AGENT *agent_ptr, UCHAR *context_engine, UINT context_engine_size); Set the context engine ID of the SNMP Agent. Must specify the size of the ID string. Only used in SNMPv3 to identify the Agent to the SNMP Manager.
nx_snmp_agent_context_name_set	(NX_SNMP_AGENT *agent_ptr, UCHAR *context_name, UINT context_name_size); Set the context name of the SNMP Agent. This string must be null terminated and the size of the name must be specified. This name must be known to the SNMP Manager. Only used in SNMPv3.

nx_snmp_agent_create	(NX_SNMP_AGENT *agent_ptr, CHAR *snmp_agent_name, NX_IP *ip_ptr, VOID *stack_ptr, ULONG stack_size, NX_PACKET_POOL *pool_ptr, UINT (*snmp_agent_username_process)(struct NX_SNMP_AGENT_STRUCT *agent_ptr, UCHAR *username), UINT (*snmp_agent_get_process)(struct NX_SNMP_AGENT_STRUCT *agent_ptr, UCHAR *object_requested, NX_SNMP_OBJECT_DATA *object_data), UINT (*snmp_agent_getnext_process)(struct NX_SNMP_AGENT_STRUCT *agent_ptr, UCHAR *object_requested, NX_SNMP_OBJECT_DATA *object_data), UINT (*snmp_agent_set_process)(struct NX_SNMP_AGENT_STRUCT *agent_ptr, UCHAR *object_requested, NX_SNMP_OBJECT_DATA *object_data)); Create the SNMP Agent and set the Agent thread task size, packet pool for transmitting SNMP messages, and user defined callbacks for handling GET, GETNEXT, SET and username requests.
nx_snmp_agent_current_version_get	(NX_SNMP_AGENT *agent_ptr, UINT *version); Obtain the current version of SNMP based on the last message received.
nx_snmp_agent_delete	(NX_SNMP_AGENT *agent_ptr); Delete the SNMP instance
nx_snmp_agent_md5_key_create	(NX_SNMP_AGENT *agent_ptr, UCHAR *password, NX_SNMP_SECURITY_KEY *destination_key); Create a key based on a supplied password and SNMP Agent context engine ID using the MD5 algorithm. This key can be used for authentication or encryption.
nx_snmp_agent_privacy_key_use	(NX_SNMP_AGENT *agent_ptr, NX_SNMP_SECURITY_KEY *key); Register a previously created security key with the SNMP Agent for encrypting and decrypting SNMPv3 messages.
nx_snmp_agent_priv_trap_key_use	(NX_SNMP_AGENT *agent_ptr, NX_SNMP_SECURITY_KEY *key); Register a previously created security key with the SNMP Agent for encrypting SNMPv3 trap messages.
nx_snmp_agent_private_string_set	(NX_SNMP_AGENT *agent_ptr, UCHAR *private_string); Register a null terminated privacy string to the SNMP Agent. Only used in SNMP1 and SNMPv2.

nx_snmp_agent_private_string_test	(NX_SNMP_AGENT *agent_ptr, UCHAR *community_string, UINT *is_private); The SNMP Agent compares the privacy string in a SET request with the its own privacy string to determine if the SET request will be permitted.
nx_snmp_agent_public_string_set	(NX_SNMP_AGENT *agent_ptr, UCHAR *public_string); Register a null terminated public string to the SNMP Agent. Only used in SNMP1 and SNMPv2.
nx_snmp_agent_public_string_test	(NX_SNMP_AGENT *agent_ptr, UCHAR *community_string, UINT *is_public); The SNMP Agent compares the public string in a GET or GETNEXT request with the its own public string to determine if the request will be permitted.
nx_snmp_agent_request_get_type_test	(NX_SNMP_AGENT *agent_ptr, UINT *is_get_type); Determine if the last SNMP packet received was a GET, GETNEXT, or GET_BULT_REQUEST request type (returns TRUE) or a SET request (returns FALSE). Intended for use in the username callback for type of request received and checking public or private strings in the request message.
nx_snmp_agent_set_interface	(NX_SNMP_AGENT *agent_ptr, UINT if_index); Determine on which network interface to run the SNMP Agent protocol. The default interface is the primary (0) interface.
nx_snmp_agent_sha_key_create	(NX_SNMP_AGENT *agent_ptr, UCHAR *password, NX_SNMP_SECURITY_KEY *destination_key); Create a key based on a supplied password and SNMP Agent context engine ID using the SHA1 algorithm. This key can be used for authentication or encryption.
nx_snmp_agent_start	(NX_SNMP_AGENT *agent_ptr); Start the SNMP Agent thread task. This task waits to receive SNMP messages and formulates the response to the SNMP Manager.
nx_snmp_agent_stop	(NX_SNMP_AGENT *agent_ptr); Stop the SNMP Agent task thread. The SNMP Agent thread can be restarted by calling the nx_snmp_agent_start API.

nx_snmp_agent_trap_send	(NX_SNMP_AGENT *agent_ptr, ULONG ip_address, UCHAR * username, UCHAR *enterprise, UINT trap_type, UINT trap_code, ULONG elapsed_time, NX_SNMP_TRAP_OBJECT *object_list_ptr); Send a trap message in SNMPv1. This does not result from a request from the SNMP Manager. The SNMP application sends out traps as needed.
nx_snmp_agent_trapv2_send	(NX_SNMP_AGENT *agent_ptr, ULONG ip_address, UCHAR *username, UINT trap_type, ULONG elapsed_time, NX_SNMP_TRAP_OBJECT *object_list_ptr); Send a trap message in SNMPv2. This does not result from a request from the SNMP Manager. The SNMP application sends out traps as needed.
nx_snmp_agent_trapv3_send	(NX_SNMP_AGENT *agent_ptr, ULONG ip_address, UCHAR * username, UINT trap_type, ULONG elapsed_time, NX_SNMP_TRAP_OBJECT *object_list_ptr); Send a trap message in SNMPv3. This does not result from a request from the SNMP Manager. The SNMP application sends out traps as needed. Both the SNMP agent and browser must previously agree on the security (authentication and encryption) settings.
nx_snmp_agent_trapv2_oid_send	(NX_SNMP_AGENT *agent_ptr, ULONG ip_address, UCHAR *username, UCHAR *oid, ULONG elapsed_time, NX_SNMP_TRAP_OBJECT *object_list_ptr); Send a trap message in SNMPv2. This differs from nx_snmp_agent_trapv2_send in that it allows the caller to specify the OID directly.
nx_snmp_agent_trapv3_oid_send	(NX_SNMP_AGENT *agent_ptr, ULONG ip_address, UCHAR * username, UCHAR *oid, ULONG elapsed_time, NX_SNMP_TRAP_OBJECT *object_list_ptr); Send a trap message in SNMPv3. This differs from nx_snmp_agent_trapv3_send in that it allows the caller to specify the OID directly.
nx_snmp_agent_v3_context_boots_set	(NX_SNMP_AGENT *agent_ptr, UINT boots); Set the number of times the SNMP Agent has rebooted since the last communication with the SNMP Manager. Used in SNMPv3 only.

nx_snmp_agent_version_set	(NX_SNMP_AGENT *agent_ptr, UINT enabled_v1, UINT enable_v2, UINT enable_v3); Determine which type of SNMP packets the SNMP Agent will process. The application can choose V1, V2 and/or V3. Packets received from which the SNMP Agent is not enabled are dropped.
**nxd_snmp_agent_trap_send	(NX_SNMP_AGENT *agent_ptr, NXD_ADDRESS *ip_address, UCHAR * username, UCHAR *enterprise, UINT trap_type, UINT trap_code, ULONG elapsed_time, NX_SNMP_TRAP_OBJECT *object_list_ptr); Send a trap message in SNMPv1 over IPv6. Note that this takes an NXD_ADDRESS* ip_address instead of ULONG ip_address.
**nxd _snmp_agent_trapv2_send	(NX_SNMP_AGENT *agent_ptr, NXD_ADDRESS *ip_address, UCHAR * username, UINT trap_type, ULONG elapsed_time, NX_SNMP_TRAP_OBJECT *object_list_ptr); Send a trap message in SNMPv2. Note that this takes an NXD_ADDRESS* ip_address instead of ULONG ip_address
**nxd _snmp_agent_trapv3_send	(NX_SNMP_AGENT *agent_ptr, NXD_ADDRESS *ip_address, UCHAR *username, UINT trap_type, ULONG elapsed_time, NX_SNMP_TRAP_OBJECT *object_list_ptr); Send a trap message in SNMPv3. Note that this takes an NXD_ADDRESS* ip_address instead of ULONG ip_address
nx_snmp_agent_trapv2_oid_send	(NX_SNMP_AGENT *agent_ptr, NXD_ADDRESS *ip_address,, UCHAR *username, UCHAR *oid, ULONG elapsed_time, NX_SNMP_TRAP_OBJECT *object_list_ptr); Send a trap message in SNMPv2. Note that this takes an NXD_ADDRESS* ip_address instead of ULONG ip_address
**nxd _snmp_agent_trapv3_oid_send	(NX_SNMP_AGENT *agent_ptr, NXD_ADDRESS *ip_address, UCHAR * username, UCHAR *oid, ULONG elapsed_time, NX_SNMP_TRAP_OBJECT *object_list_ptr); Send a trap message in SNMPv3. Note that this takes an NXD_ADDRESS* ip_address instead of ULONG ip_address

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo SNMP Agent. Please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform for definition of NetX Duo specific data types.

The following API calls are for processing data items into the SNMP Agent response.

NetX/NetX Duo SNMP Agent Module API Summary (Part 2)

Function Name	Example API Call and Description
nx_snmp_object_copy	(UCHAR *source_object_name, UCHAR *destination_object_name); This copies the string pointed to by source_object_name into the destination_object_name buffer (typically a trap message).
nx_snmp_object_counter_get	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data); This extracts the counter data from the location pointed to by source_ptr into the object data. Also used internally to copy internal counters of SNMPv3 statistics into error messages in SNMPv3 messages
nx_snmp_object_counter_set	(VOID *destination_ptr, NX_SNMP_OBJECT_DATA *object_data); This sets the value of data extracted from the object_data into the location pointed to by the destination_ptr.
nx_snmp_object_counter64_get	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data); This extracts the counter data from the location pointed to by source_ptr into the object data. The difference with nx_snmp_objext_counter_get is the value is two words instead of one.
nx_snmp_object_counter64_set	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data); This sets the value of data extracted from the object_data into the location pointed to by the destination_ptr. The difference with nx_snmp_objext_counter_set is the value is two words instead of one.
nx_snmp_object_compare	(UCHAR *requested_object, UCHAR *reference_object); This compares the two input objects and if equal returns NX_SUCCESS.
nx_snmp_object_copy	(UCHAR *source_object_name, UCHAR *destination_object_name) This copies the data pointed to by the source object pointer into memory pointed to by the destination object pointer. Also used internally to copy internal counters of SNMPv3 statistics into error messages in SNMPv3 messages.

nx_snmp_object_end_of_mib	(VOID *not_used_ptr, NX_SNMP_OBJECT_DATA *object_data); This appends an END_OF_MIB_VIEW macro as the input object's value. This signals the end of the MIB. See the snmp_mib_helper.h for an example.
nx_snmp_object_gauge_get	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data); This sets the input object to type SNMP GAUGE and places the value pointed to by the source_ptr into the object value.
nx_snmp_object_gauge_set	(VOID *destination_ptr, NX_SNMP_OBJECT_DATA *object_data); This verifies the input object is an SNMP GAUGE data type, and extracts the value into the location pointed to by the destination pointer.
nx_snmp_object_id_get	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data); This function retrieves the object ID from the specified source location and writes it into the object data value.
nx_snmp_object_id_set	(VOID *destination_ptr, NX_SNMP_OBJECT_DATA *object_data); This function retrieves the ASCII string from the input object and writes it to the area pointed to by the destination pointer.
nx_snmp_object_integer_get	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data); This retrieves the object integer from the specified source location and stores it to the object data.
nx_snmp_object_integer_set	(VOID *destination_ptr, NX_SNMP_OBJECT_DATA *object_data); This retrieves the integer from the input object and places it in the destination.
nx_snmp_object_ip_address_get	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data); This retrieves the IP address from the specified source location and stores it to the object data.
nx_snmp_object_ip_address_set	(VOID *destination_ptr, NX_SNMP_OBJECT_DATA *object_data); This retrieves the IP address from the input object and places it in the destination.
**nx_snmp_object_ipv6_address_get	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data); This retrieves the IPv6 address from the specified source location and stores it to the object data.

**nx_snmp_object_ipv6_address_set	(VOID *destination_ptr, NX_SNMP_OBJECT_DATA *object_data); This retrieves the IPv6 address from the input object and places it in the destination.
nx_snmp_object_octet_string_get	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data, UINT length); This retrieves the string data from the specified source location and stores it to the object data.
nx_snmp_object_octet_string_set	(VOID *destination_ptr, NX_SNMP_OBJECT_DATA *object_data); This retrieves the string from the input object and places it in the destination.
nx_snmp_object_no_instance	(VOID *not_used_ptr, NX_SNMP_OBJECT_DATA *object_data); This function places a no-instance value (NX_SNMP_ANS1_NO_SUCH_INSTANCE) in the object data.
nx_snmp_object_not_found	(VOID *not_used_ptr, NX_SNMP_OBJECT_DATA *object_data); This function places a not-found value (NX_SNMP_ANS1_NO_SUCH_OBJECT) in the object data.
nx_snmp_object_string_get	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data, UINT length); This function retrieves the ASCII string from the specified source location and stores it to the object data.
nx_snmp_object_string_set	(VOID *destination_ptr, NX_SNMP_OBJECT_DATA *object_data); This retrieves the ASCII string from the input object and stores it to the destination.
nx_snmp_object_timetics_get	(VOID *source_ptr, NX_SNMP_OBJECT_DATA *object_data); This function retrieves the data of type timer ticks from the specified source location and stores it to the object data.
nx_snmp_object_timetics_set	(VOID *destination_ptr, NX_SNMP_OBJECT_DATA *object_data); This retrieves the timer tick from the input object and stores it to the destination.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo SNMP Agent. Please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform for definition of NetX Duo specific data types.

Status Return Values

Name	Description
NX_SUCCESS	API Call Successful
NX_PTR_ERROR*	Invalid input pointer parameter
NX_SNMP_UNSUPPORTED_AUTHENTICATION*	The authentication key is of an unknown or unsupported type (for example, not MD5 or SHA).
NX_SNMP_INVALID_PDU_ENCRYPTION*	The encryption key is of an unknown or unsupported type (for example, not MD5 or SHA).
NX_IP_ADDRESS_ERROR*	IP address supplied in a trap send API is null or invalid.
NX_SNMP_ERROR	Internal processing error e.g. not able to append data into the SNMP response.
NX_NOT_ENABLED	SNMP Agent is not enabled with the correct security settings for certain operations such as sending messages or processing authentication and encryption keys.
NX_SNMP_ERROR_TOOBIG	Data exceeds the size of the response buffer or exceed the allowable size of the parameter e.g. NX_SNMP_MAX_USER_NAME.
**NX_SNMP_INVALID_IP_PROTOCOL_ERROR	An IPv6 address is received in a trap send API but the NetX Duo library is not enabled for IPv6.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

- These are error codes which are only returned if error checking is enabled. Refer to the *NetX User Guide* for the Renesas Synergy™ Platform or *NetX Duo User's Guide* for the Renesas Synergy™ Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.26.3 NetX/NetX Duo SNMP Agent Module Operational Overview

The SNMP agent module makes use of the underlying NetX/NetX Duo stack to perform operations. Along with the IP stack, it makes use of the NetX MD5, NetX SHA1 and NetX DES modules for authentication and encryption in SNMP v3 operation.

The SNMP agent module can be created with the nx_snmp_agent_create API. For the implementation of the SNMP agent, the user needs to define the handler functions for username, get, getnext, and set operations.

NetX/NetX Duo SNMP Agent Module Important Operational Notes and Limitations

NetX/NetX Duo SNMP Agent Module Operational Notes

Disabling SNMP Version 1

The SNMP Agent module can disable processing of version 1 requests by selecting **Disable** in the

configuration properties for the SNMP Agent for **SNMP Version 1**. By default, this is enabled. When disabled, the SNMP Agent simply drops the packet with version 1, resulting in a timeout for the SNMP manager.

Disabling SNMP Version 2

The SNMP Agent module can disable processing of version 2 requests by selecting **Disable** in the configuration properties for the SNMP Agent for **SNMP Version 2**. By default, this is enabled. When disabled, the SNMP Agent simply drops the packet with version 2, resulting in a timeout for the SNMP manager.

Disabling SNMP Version 3

The SNMP Agent can disable processing of version 3 requests by selecting **Disable** in the configuration properties for the SNMP Agent for **SNMP Version 3**. By default, this is enabled. When disabled, the SNMP Agent simply drops the packet with version 3 resulting in a timeout for the SNMP manager. Enabling SNMP version 3 requires MD5, SHA1 authentication and DES encryption.

NetX/NetX Duo SNMP Agent Module Limitations

- One SNMP Agent per NetX IP Instance.
- No support for RMON
- SNMP v3 Informs are not supported
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.26.4 Including the NetX/NetX Duo SNMP Agent Module in an Application

This section describes how to include either or both the NetX and NetX Duo SNMP Agent module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo SNMP Agent module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo SNMP Agent Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_snmp_agent0 NetX SNMP Agent	Threads	New Stack> X-Ware> NetX> Protocols> NetX SNMP Agent
g_snmp_agent0 NetX Duo SNMP Agent	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo SNMP Agent

When the NetX and/or NetX Duo SNMP Agent module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink

band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

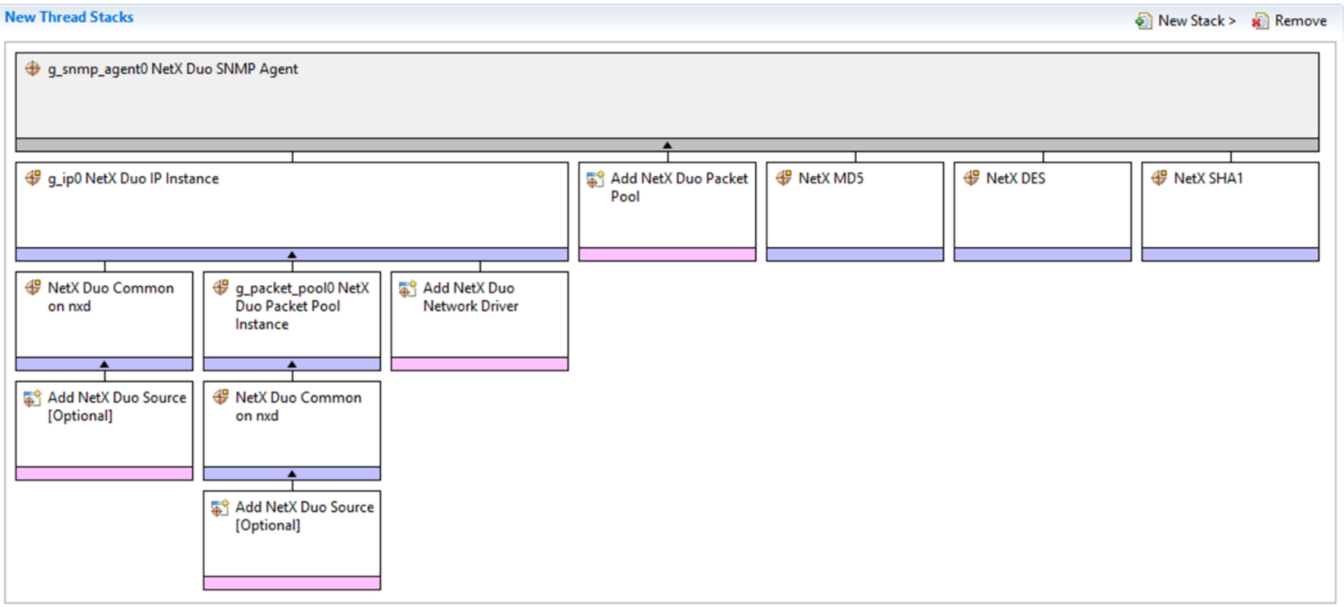

Figure 481: NetX/NetX Duo SNMP Agent Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.26.5 Configuring the NetX/NetX Duo SNMP Agent Module

The NetX/NetX Duo SNMP Agent module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to

learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo SNMP Agent Module

ISDE Property	Value	Description
Internal thread stack size (bytes)	4096	Internal thread stack size selection
SNMP agent priority	16	SNMP agent priority selection
Type of service for SNMP responses	Normal, Minimum Delay, Maximum Delay, Maximum Reliability, Minimum Cost Default: Normal	Type of service for SNMP responses selection
Fragment enable for SNMP PDU requests	Fragment, Don't Fragment Default: Don't Fragment	Fragment enable for SNMP PDU requests selection
SNMP socket time to live	128	SNMP socket time to live selection
Agent timeout	100	Agent timeout selection
Max octet string size	255	Max octet string size selection
Max content string size	32	Max content string size selection
Max User Name Size	64	Max user name size selection
Max security Key Size	64	Max security key size selection
Minimum SNMP packet size	560	Minimum SNMP packet size selection (Value must be between 560 to 1500)
UDP port number	161	UDP port number selection (Value must be between 1 to 65535)
Trap destination port	162	Trap destination port selection
Max trap Name Size	64	Max trap Name Size selection
Max trap Key Size	64	Max trap Key Size selection
Interval between SNMP packet processing timer ticks	100	Interval between SNMP packet processing timer ticks selection
SNMP Version 1	Enable, Disable Default: Enable	SNMP Version 1 selection
SNMP Version 2	Enable, Disable Default: Enable	SNMP Version 2 selection

SNMP Version 3	Enable, Disable Default: Enable	SNMP Version 3 selection
Name	g_snmp_agent0	Name selection
Read Community String	public	Read Community String selection (Must be less than 64 chars)
Write Community String	private	Write Community String selection (Must be less than 64 chars)
Name of SNMP Username Handler	sf_snmp0_username_handler	Name of SNMP Username Handler selection
Name of SNMP GET Handler	sf_snmp0_get_handler	Name of SNMP GET Handler selection
Name of SNMP GETNEXT Handler	sf_snmp0_getnext_handler	Name of SNMP GETNEXT Handler selection
Name of SNMP SET Handler	sf_snmp0_set_handler	Name of SNMP SET Handler selection
Name of generated initialization function	snmp_agent_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto Initialization selection
SNMP agent instance id	0	SNMP agent instance id selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different addresses for the Ethernet port. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo SNMP Agent Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have

different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo MD5 Instance

ISDE Property	Value	Description
No configurable properties		

Note

NetX/NetX Duo SNMP Agent Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX/NetX Duo SNMP Agent Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin

TXD1	P406	TXD1 Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.26.6 Using the NetX/NetX Duo SNMP Agent Module in an Application

The steps in using the NetX/NetX Duo SNMP Agent module in a typical application are:

1. Create an agent with nx_snmp_agent_create API
2. Define handler functions
    a. username handler function nx_snmp_agent_username_process in user code
    b. get handler function nx_snmp_agent_get_process in user code
    c. get next handler function nx_snmp_agent_getnext_process in user code
    d. set handler function nx_snmp_agent_set_process in user code
3. Create a structure to map OIDs to action handlers in user code
4. Configure read, write community strings nx_snmp_agent_public_string_set and nx_snmp_agent_private_string_set
5. If the user wants to use SNMPv3, they must create the keys using the nx_snmp_agent_md5_key_create API or the nx_snmp_agent_sha_key_create and associate the keys with authentication, encryption and trap services nx_snmp_agent_authenticate_key_use, nx_snmp_agent_privacy_key_use, nx_snmp_agent_auth_trap_key_use and nx_snmp_agent_priv_trap_key_use
6. Start the SNMP agent using the nx_snmp_agent_start API

The following figure illustrates common steps in a typical operational flow diagram:

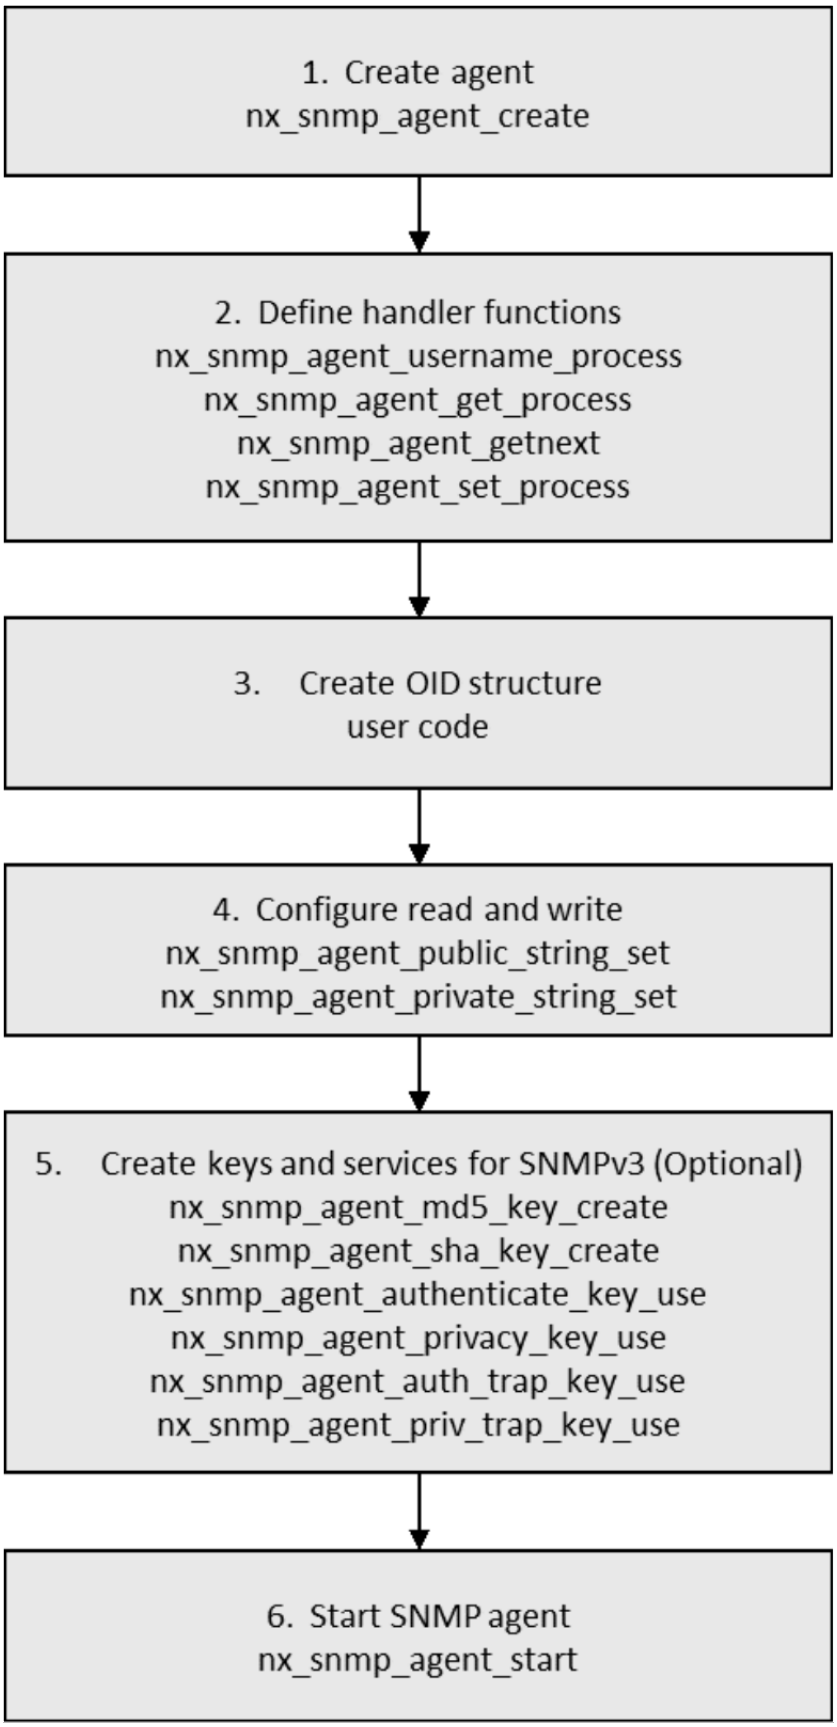

Figure 482: Flow Diagram of a Typical NetX/NetX Duo SNMP Agent Module Application

4.3.27 NetX/NetX Duo SNTP Client

4.3.27.1 NetX/NetX Duo SNTP Client Introduction

The Simple Network Time Protocol (SNTP) is a protocol designed for synchronizing clocks over the Internet. SNTP Version 4 is a simplified protocol based on the Network Time Protocol (NTP) and utilizes User Datagram Protocol (UDP) services to perform time updates in a simple, stateless protocol. On the internet, the SNTP provides accuracies of 1-50 milliseconds, depending on the characteristics of the synchronization source and network paths. The SNTP has many options to provide reliability of receiving time updates. Ability to switch to alternative servers, applying back-off polling algorithms and automatic time server discovery are just a few of the means for an SNTP Client to handle a variable internet time service environment. What it lacks in precision it makes up for in simplicity and ease of implementation. The SNTP is intended primarily for providing comprehensive mechanisms to access national time and frequency dissemination for NTP Server services.

Note

Except for internal processing, the NetX Duo™ SNTP Client is identical in the application, set up and running of an SNTP thread as the NetX™ SNTP Client. This document will clearly identify any differences in use between the NetX and NetX Duo SNTP Client.

Unsupported Features

Broadcast has not been tested in this version of SSP.

Multiple network interface has not been tested in this version of SSP.

NetX/NetX Duo SNTP Client Module Features

- Supports the SNTP standard to obtain time over the internet
- The NetX SNTP client is compliant with RFC4330 Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI and related RFCs
- Supports both unicast and broadcast SNTP messaging
- Utilities for converting NTP time into date and time format.
- Performs sanity checks for valid time reception
- Support for a SNTP Client on secondary interfaces
- Callbacks to be notified of receiving time updates

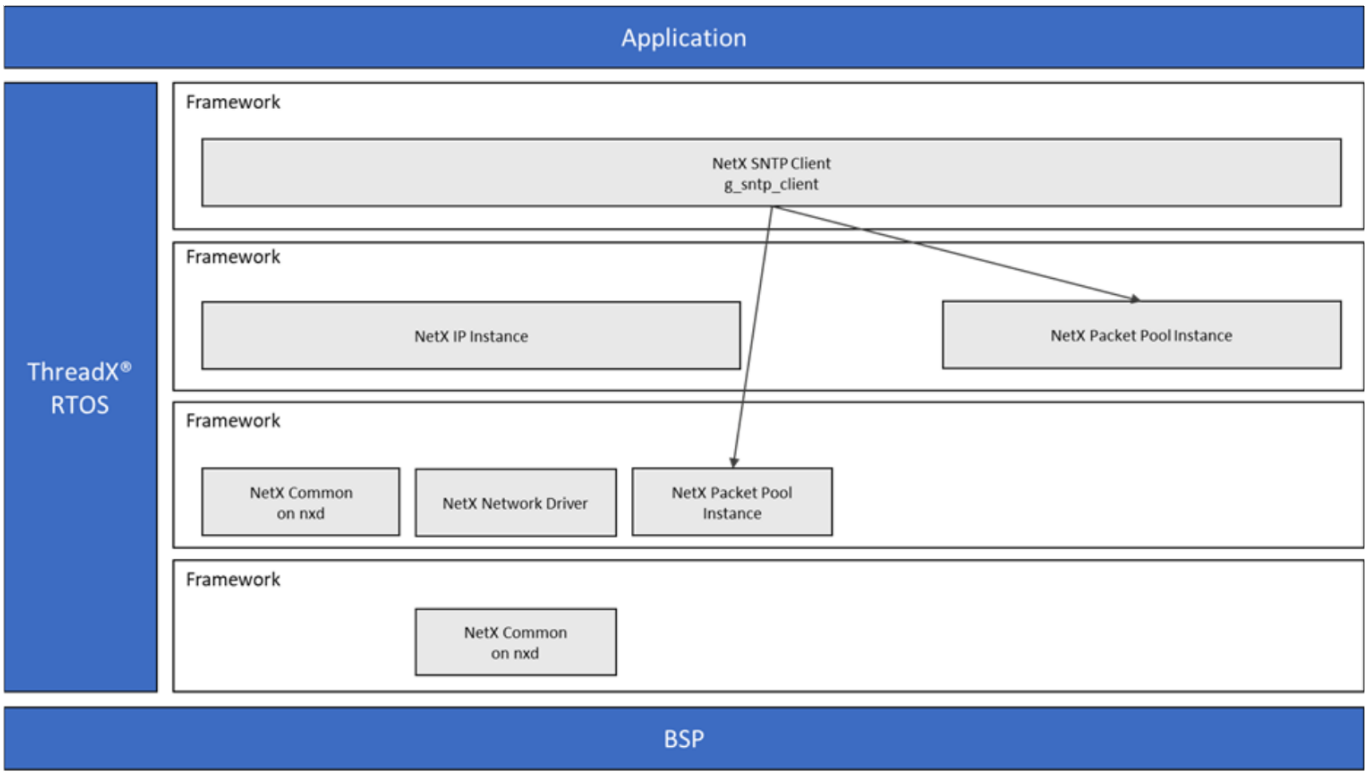

Figure 483: NetX/NetX Duo SNTP Client Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX/NetX Duo SNTP Client Module in an Application for additional details.

4.3.27.2 NetX/NetX Duo SNTP Client Module APIs Overview

The NetX SNTP Client module defines APIs for creating, deleting, generating response packets, response sending and getting information from a received packet. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX/NetX Duo SNTP Client Module API Summary

Function Name	Example API Call and Description
nx_sntp_client_create	nx_sntp_client_create(&demo_client, iface_index,&client_ip, &client_packet_pool, leap_second_handler, kiss_of_death_handler,NULL // no random_number_generator callback); This service creates an SNTP Client instance.
nx_sntp_client_delete	nx_sntp_client_delete(&demo_client); Delete the SNTP Client.
nx_sntp_client_get_local_time	nx_sntp_client_get_local_time(&demo_client, &base_seconds,&base_milliseconds, NX_NULL); Get SNTP Client local time.

nx_sntp_client_initialize_broadcast	nx_sntp_client_initialize_broadcast(&demo_client ,0x0, NX_NULL, IP_ADDRESS(192,2,2,255); Initialize Client for IPv4 broadcast operation.
**nxd_sntp_client_initialize_broadcast	nxd_sntp_client_initialize_broadcast(&demo_clie nt,0x0, NX_NULL, &broadcast_server) Initialize Client for IPv6 or IPv4 broadcast operation.
nx_sntp_client_initialize_unicast	nx_sntp_client_initialize_unicast(&demo_client, IP_ADDRESS(192,2,2,1)); Initialize Client for IPv4 unicast operation.
**nxd_sntp_client_initialize_unicast	nxd_sntp_client_initialize_unicast(&demo_client, *unicast_server); Initialize Client for IPv4 or IPv6 unicast operation.
nx_sntp_client_receiving_updates	nx_sntp_client_receiving_updates(&demo_client, &receive_status); Client is currently receiving valid SNTP updates.
nx_sntp_client_request_unicast_time	nx_sntp_client_request_unicast_time(&demo_clie nt, 400); Send a request asynchronously to NTP server.
nx_sntp_client_run_broadcast	nx_sntp_client_run_broadcast(&demo_client); Receive time updates from server.
nx_sntp_client_run_unicast	nx_sntp_client_run_unicast(&demo_client); Send requests and receive time updates from server.
nx_sntp_client_set_local_time	nx_sntp_client_set_local_time(&demo_client, base_seconds, base_fraction); Set SNTP Client initial local time.
nx_sntp_client_set_time_update_notify	nx_sntp_client_set_time_update_notify(&demo_cl ient, time_update_cb); Sets callback to notify the application when the SNTP Client receives a valid time update.
nx_sntp_client_stop	nx_sntp_client_stop(&demo_client); Stop the SNTP Client thread.
nx_sntp_client_utility_display_date_and_time	nx_sntp_client_utility_display_date_time(&demo_ client, buffer, sizeof(buffer)); Display NTP time in date and time format
nx_sntp_client_utililty_msecs_to_fraction	nx_sntp_client_utility_msecs_to_fraction(millisec onds, &fraction); Convert milliseconds to NTP fraction component.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo SNTP Client. Please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform for definition of NetX Duo specific data types.

Status Return Values

Name	Description
NX_SUCCESS	API Call Successful
NX_SNTP_INSUFFICIENT_PACKET_PAYLOAD	Invalid non-pointer input
NX_PTR_ERROR **	Invalid pointer input
NX_CALLER_ERROR**	Invalid caller of service
NX_INVALID_INTERFACE	Invalid network interface
NX_INVALID_PARAMETERS	Invalid non-pointer input
NX_SNTP_PARAM_ERROR	Invalid non-pointer input
NX_SNTP_CLIENT_NOT_STARTED	SNTP Client not running
NX_SNTP_CLIENT_ALREADY_STARTED	Client already running
NX_SNTP_CLIENT_NOT_INITIALIZED	Client not initialized
NX_SNTP_ERROR_CONVERTING_DATETIME	NX_SNTP_CURRENT_YEAR not defined or no local time established
NX_SNTP_INVALID_DATETIME_BUFFER	Insufficient buffer length
NX_SNTP_OVERFLOW_ERROR	Error converting time to a date
NX_SNTP_INVALID_TIME	Invalid SNTP data input

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

- These are error codes which are only returned if error checking is enabled. Refer to the *NetX User Guide* for the Renesas Synergy™ Platform or *NetX Duo User's Guide* for the Renesas Synergy™ Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.27.3 NetX/NetX Duo SNTP Client Module Operational Overview

The NetX/NetX Duo SNTP Client module creates an IP instance and packet pool. In addition, the UDP is enabled on that IP instance and a UDP socket is created and bound to the well-known port 123 for sending time update requests to and receiving time data from an SNTP Server, although alternative ports will work as well. Broadcast clients should bind the UDP port when their broadcast server is sending on, usually 123. The NetX/NetX Duo SNTP Client application requires a server address to initialize a SNTP Client thread task for either unicast or broadcast operations.

The NetX/NetX Duo SNTP Client can operate in one of two basic modes, unicast or broadcast, to obtain time over the internet. In unicast mode, the Client polls its SNTP Server on regular intervals and waits to receive a reply from that server. When one is received, the client verifies that the reply contains a valid time update by applying a set of sanity checks recommended by RFC 4330. The client then applies the time difference locally, if there is a time difference between the server clock and the local clock. In broadcast mode, the client merely listens for time update broadcasts and maintains its local clock after applying a similar set of sanity checks to verify the update time data.

Before the client can run in either mode, the application can get an estimate of the absolute time. In NTP, that means the number of seconds since Jan 1, 1970 at midnight. For example:

```
    base_seconds = 0xd2c96b90; /* This is the number of seconds since
1970
                                   on Jan 24, 2012 UTC */
    base_fraction = 0xa132db1e; /* between 0-1 seconds, not so critical */
```

It is not required, but if this time is registered with the SNTP Client (using the nx_sntp_client_set_local_time service), it gives the SNTP Client a means to gauge if the first received time update is reasonably accurate. NTP time keepers are more accurate than all but the most demanding time-based applications, but there is the need to check for invalid or rogue SNTP packets. If obtaining this baseline time is not possible, and no local time is set before starting the SNTP Client, the SNTP Client will accept the time updates at face value.

Now the application can prepare the SNTP Client for receiving time updates. This is done by calling either nx_sntp_client_initialize_unicast, or nx_sntp_client_initialize_broadcast for unicast or broadcast modes. (These are limited to IPv4 networks only.) If using the NetX Duo SNTP Client Module, nxd_sntp_client_initialize_broadcast and nxd_sntp_client_initialize_unicast are available services which support both IPv4 and IPv6 networks. If these initialization service calls succeed, the application can start the SNTP Client by calling the nx_sntp_client_run_broadcast or nx_sntp_client_run_unicast services.

The application can set the following parameters to fine-tune SNTP Client operation:

- The maximum time adjustment to make the local clock, which is the Maximum time adjustment allowed to local clock time (milliseconds) property. If there is no notion of local time, the Ignore maximum time adjust limit at startup property can be enabled to skip this check on the first time update.
- The unicast polling rate which is the Starting poll interval for unicast update request (seconds) property. This is the rate at which the SNTP Client polls the NTP time server for an update if running in unicast mode.
- The maximum allowed interval between time requests sent to the server, which is the Maximum time lapse without valid update (seconds) property. If a time request goes unanswered, the SNTP Client doubles the polling interval up to this maximum interval.
- The maximum number of invalid SNTP packets received from a server before marking the server invalid, which is the Invalid message limit to mark server invalid property.

If these limits are exceeded, the SNTP Client continues to run but sets the current SNTP Server status to invalid. The application can call the nx_sntp_client_receiving_updates service periodically to check for valid server status. If this service indicates no updates received, the application should stop the SNTP Client thread using the nx_sntp_client_stop service and use another SNTP Server. To restart the SNTP Client, call either of the two initialize services, nx_sntp_client_initialize_broadcast or nx_sntp_client_initialize_unicast for IPv4 networks (or nxd_sntp_client_initialize_broadcast or nxd_sntp_client_initialize_unicast), then restart the SNTP Client with the nx_sntp_client_run_broadcast or nx_sntp_client_run_unicast services.

Additional details on the topics of local clock operation, SNTP sanity checks, and SNTP asynchronous and unicast requests are described in detail in the *NetX Simple Network Time Protocol (SNTP) Client User Guide* for the Renesas Synergy™ Platform document described in the introduction to this document.

NetX/NetX Duo SNTP Client Module Important Operational Notes and Limitations

NetX/NetX Duo SNTP Client Module Operational Notes

- The application can be notified of time updates if it registers a callback with the SNTP Client. To do so, use the _nx_sntp_client_set_time_update_notify service to specify the callback.
- Once the SNTP Client begins receiving time updates, the application can query the SNTP Client for status on time updates. It can receive the NTP time directly using the nx_sntp_client_get_local_time service, or it can receive a formatted date time output using the _nx_sntp_client_utility_display_date_time service. In the latter case, the application must set the Current calendar year property of the SNTP Client module for SNTP Client to process NTP time data correctly.
- RFC 4330 recommends that SNTP clients should operate only at the highest stratum of their local network and preferably in configurations where no NTP or SNTP Client is dependent on them for synchronization. Stratum level reflects the host position in the NTP time hierarchy where stratum 1 is the highest level (a root time server) and 15 is the lowest allowed level (per client). The SNTP Client default minimum stratum is 2.

NetX/NetX Duo SNTP Client Module Limitations

- Precision in local time representation in NTP time updates handled by the SNTP Client API is limited to millisecond resolution.
- The NetX/NetX Duo SNTP Client only holds a single SNTP Server address at any time. If that server appears to be no longer valid, the application must stop the SNTP Client task and reinitialize it with another SNTP server address, using either broadcast or unicast SNTP communication.
- The NetX/NetX Duo SNTP Client does not support many cast.
- The NetX/NetX Duo SNTP Client does not support authentication mechanisms for verifying received packet data.
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.27.4 Including the NetX/NetX Duo SNTP Client Module in an Application

This section describes how to include either or both the NetX and NetX Duo SNTP Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo SNTP Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo SNTP Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sntp_client0 NetX SNTP Client	Threads	New Stack> X-Ware> NetX> Protocols> NetX SNTP Client
g_sntp_client0 NetX Duo SNTP Client	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo SNTP Client

When the NetX and/or NetX Duo SNTP Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

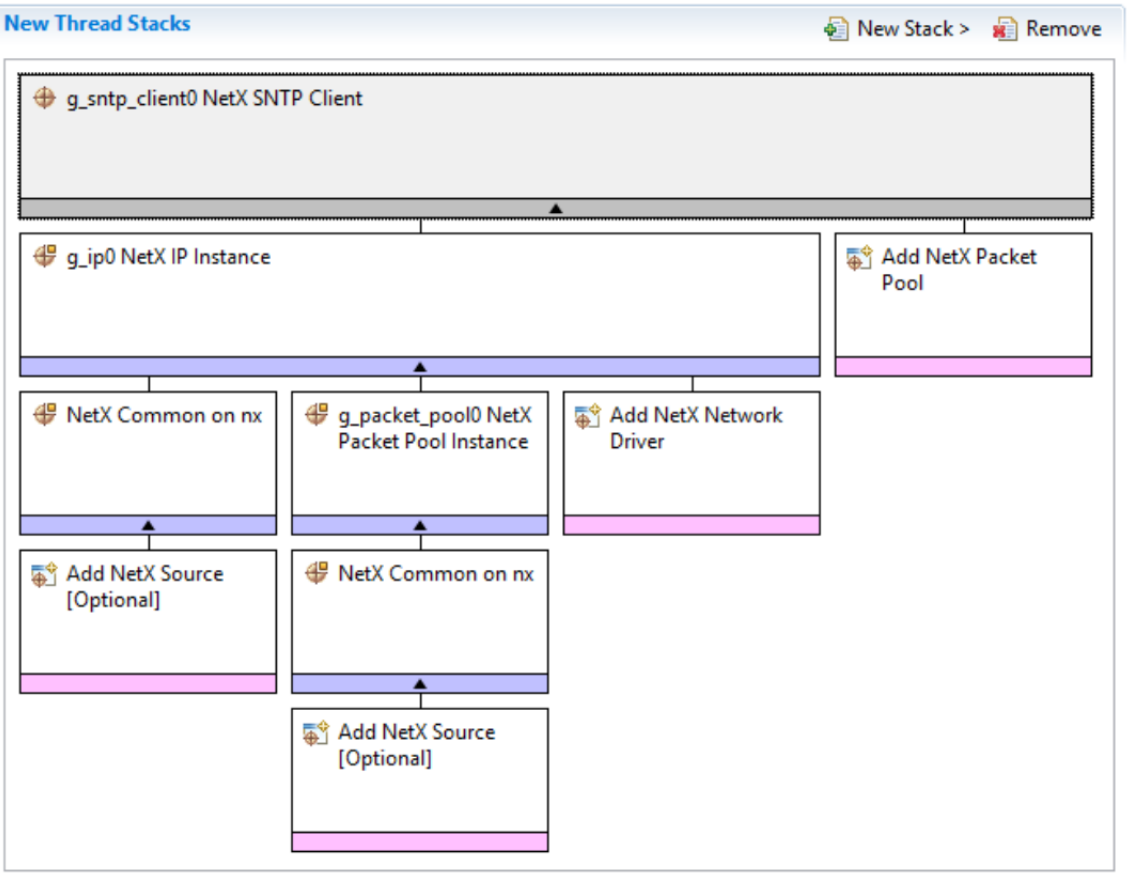

Figure 484: NetX/NetX Duo SNTP Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.27.5 Configuring the NetX/NetX Duo SNTP Client Module

The NetX/NetX Duo SNTP Client module must be configured by the user for the desired operation.

The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo SNTP Client Module

ISDE Property	Value	Description
Internal thread stack size (bytes)	2048	Internal thread stack size selection
SNTP client thread time slicing interval (ticks)	TX_NO_TIME_SLICE	SNTP client thread time slicing interval selection
Internal thread priority	2	Internal thread priority selection
UDP socket name	SNTP Client socket	UDP socket name selection
UDP port number	123	UDP port number selection
Server UDP port	123	Server UPD port selection
Time to live	128	Time to live selection
Maximum UDP packets queue depth (units)	5	Maximum UDP packets queue depth selection
Packet allocation timeout (seconds)	1	Packet allocation timeout selection
SNTP version to use	3	SNTP version to use selection
NTP minimum version	3	NTP minimum version selection
Lowest level server stratum client accepts	2	Lowest level server stratum client accepts selection
Minimum time difference that triggers adjustment (milliseconds)	10	Minimum time difference that triggers adjustment selection
Maximum time adjustment allowed to local clock time (milliseconds)	180000	Maximum time adjustment allowed to local clock time selection
Ignore maximum time adjust limit at startup	True, False Default: True	Ignore maximum time adjust limit at startup selection

Maximum time lapse without valid update (seconds)	7200	Maximum time lapse without valid update selection
Update time remaining timer update interval (seconds)	1	Update time remaining timer update interval selection
Starting poll interval for unicast update request (seconds)	3600	Starting poll interval for unicast update request selection
Poll interval increment after failed time update	2	Poll interval increment after failed time update selection
Calculate round trip time of messages	True, False Default: False	Calculate round trip time of messages selection
**Maximum server clock inaccuracy to accept (to disable set to 0)	50000	Maximum server clock inaccuracy to accept selection
Invalid message limit to mark server invalid	3	Invalid message limit to mark server invalid selection
Randomize update request interval on startup	True, False Default: False	Randomize update request interval on startup selection
Internal Task sleep interval (ticks)	1	Internal task sleep interval selection
Current calendar year	2016	Current calendar year selection
Name	g_sntp_client0	Module name
Index to SNTP Network Interface	0	Index to SNTP network interface selection
Name of Leap Second Handler	leap_second_handler	Name of leap second handler selection
Name of Kiss of Death Handler	kiss_of_death_handler	Name of kiss of death handler selection
Name of Random Number Generator Function (optional)	NULL	Name of random number generator function selection
Name of generated initialization function	sntp_client_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it

might be useful to select different addresses for the Ethernet port. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo SNTP Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection

ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo SNTP Client Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX/NetX Duo SNTP Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin

MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.27.6 Using the NetX/NetX Duo SNTP Client Module in an Application

The steps in using the NetX/NetX Duo SNTP Client module in a typical application are:

1. Wait for a valid IP address using the nx_ip_status_check API.
2. Set the mode for access to the SNTP Server with nx_sntp_client_initialize_unicast or nx_sntp_client_initialize_broadcast API, or if using NetX Duo nxd_sntp_client_initialize_unicast or nxd_sntp_client_initialize_broadcast API.
3. Set the local time with the nx_sntp_client_set_local_time API (optional).
4. Run the client using the nx_sntp_client_run_unicast or nx_sntp_client_run_broadcast API.
5. Check if the SNTP is valid and running with the nx_sntp_client_receiving_updates API (recommended).
6. Get the local time with the nx_sntp_client_get_local_time API or get the local time in date time format with the nx_sntp_client_utility_display_date_time API (optional).
7. Stop the SNTP service with the nx_sntp_client_stop API.

The following figure illustrates common steps in a typical operational flow diagram:

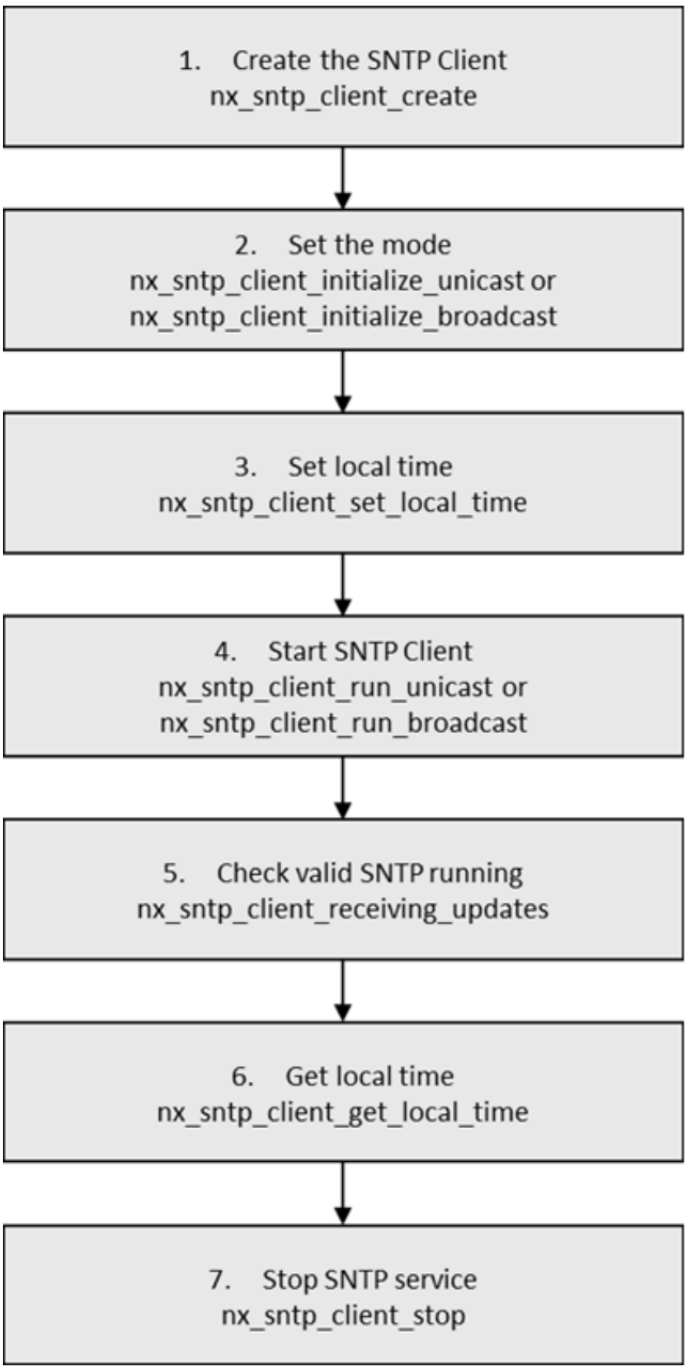

Figure 485: Flow Diagram of a Typical NetX/NetX Duo SNTP Client Module Application

4.3.28 NetX/NetX Duo POP3 Client

4.3.28.1 NetX/NetX Duo POP3 Client Introduction

The Post Office Protocol Version 3 (POP3) is a protocol designed to provide a mail transport system for small workstations to access Client maildrops on POP3 Servers. The POP3 utilizes Transmission

Control Protocol (TCP) services to perform mail transfers.

Client mail is stored on a POP3 Server in a mailbox or "maildrop." A maildrop is represented as a 1-based array of mail items where each mail is retrieved and deleted using its index in the maildrop. Once a mail message is downloaded, the Client typically marks the mail item for deletion in the Server's maildrop (the Server will probably do this automatically anyway). When finished retrieving mail items, the application should delete the POP3 Client instance and close the TCP connection. To retrieve the mail again, another POP3 Client must be created.

Note

Except where noted, the NetX Duo POP3 Client module is identical in the application, set up and running of a POP3 session as the NetX POP3 Client module. For setting up the IP instance for IPv6 in NetX Duo, please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform.

NetX/NetX Duo POP3 Client Module Features

- NetX Client POP3 is compliant with RFC 1939.
- Provides high-level APIs to:
  - Create and delete POP3 Client instances
  - Query for number and size of mail messages to receive
  - Receive individual mail messages
  - Remove mail messages from the Server maildrop box

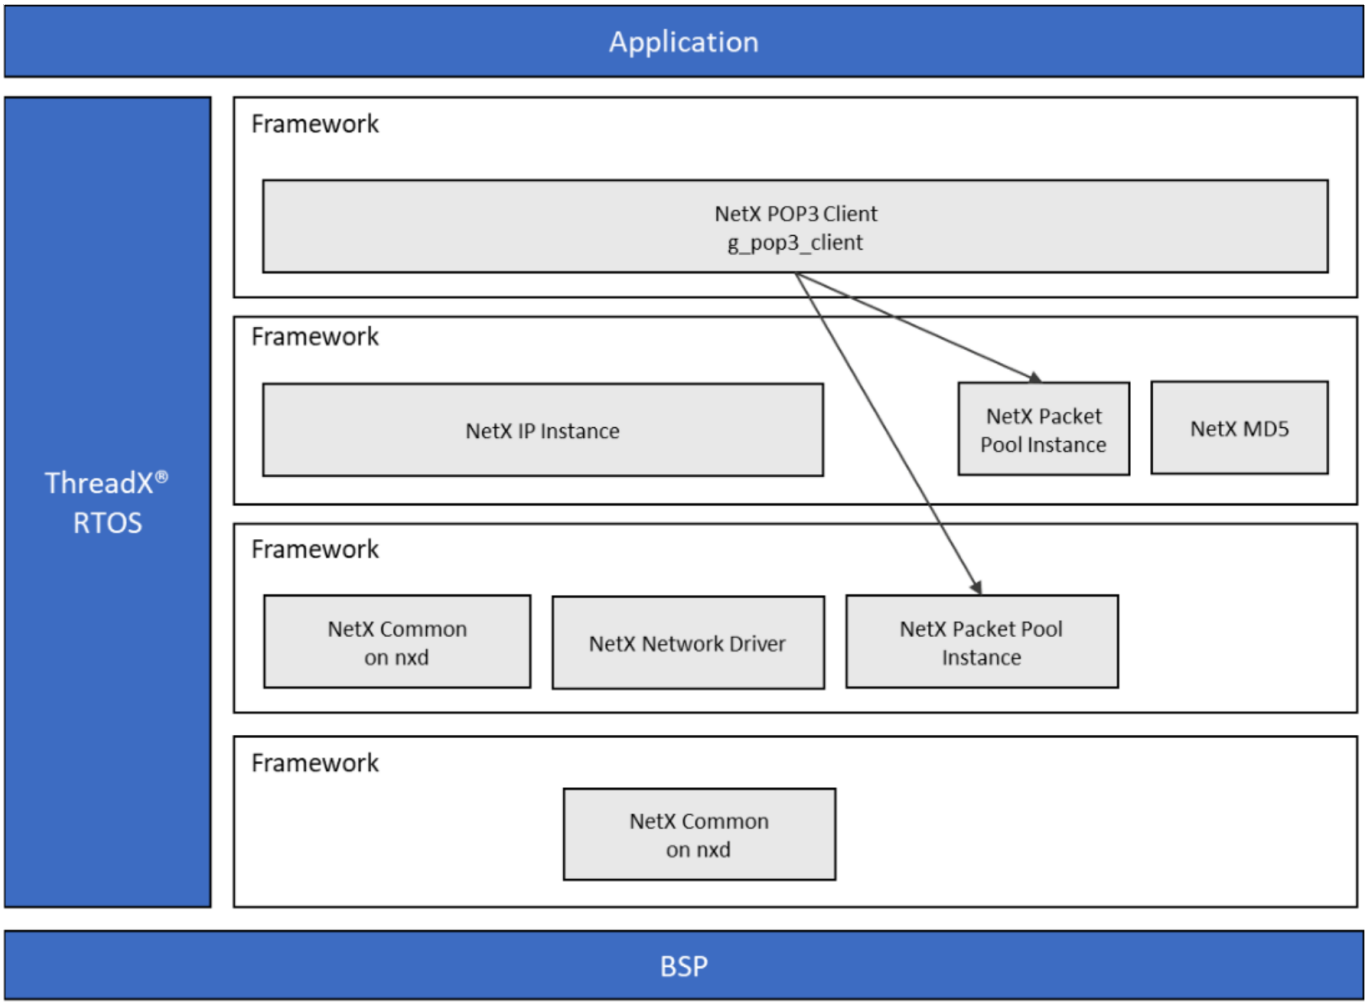

Figure 486: NetX/NetX Duo POP3 Client Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX/NetX Duo POP3 Client Module in an Application for additional details.

4.3.28.2 NetX/NetX Duo POP3 Client Module APIs Overview

The NetX POP3 Client defines APIs for creating and deleting the POP3 instance and getting its messages. A complete list of the available APIs, an example API call and a short description of each can be found in the following table.

NetX/NetX Duo POP3 Client Module API Summary

Function Name	Example API Call and Description
nx_pop3_client_create	nx_pop3_client_create(&demo_client, NX_FALSE/* disable APOP authentication */, &client_ip, &client_packet_pool, POP3_SERVER_ADDRESS, POP3_SERVER_PORT, LOCALHOST, LOCALHOST_PASSWORD); Create a POP3 Client Instance for IPv4 only.
**nxd_pop3_client_create	nxd_pop3_client_create(&demo_client, NX_FALSE/* disable APOP authentication */, &client_ip, &client_packet_pool, *server_ip_address, ULONG server_port, CHAR *client_name, CHAR *client_password); Create a POP3 Client Instance for either IPv4 or IPv6
nx_pop3_client_delete	nx_pop3_client_delete (&demo_client); Delete a POP3 Client Instance
nx_pop3_client_mail_item_delete	nx_pop3_client_mail_item_delete(&demo_client, item_index); Delete a Client mail item for a Server maildrop.
nx_pop3_client_mail_item_get	nx_pop3_client_mail_item_get (&demo_client, 1, &item_size); Retrieve a specific mail message size.
nx_pop3_client_mail_items_get	nx_pop3_client_mail_item_get (&demo_client, 1, &number_mail_items, &maildrop_total_size); Obtain the number of mail items in a maildrop.
nx_pop3_client_mail_item_message_get	nx_pop3_client_mail_item_message_get (&demo_client, &recv_packet_ptr, &bytes_retrieved, &final_packet); Download a specific mail message.
nx_pop3_client_mail_item_size_get	nx_pop3_client_mail_item_size_get (&demo_client, mail_item, &size); Obtain the size of a specific mail item.
nx_pop3_client_quit	nx_pop3_client_quit(&demo_client); Sends a QUIT command to the POP3 server.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo POP3 Client. For definitions of of NetX Duo specific data types, see the *NetX Duo User Guide for the Renesas Synergy™ Platform*.

Status Return Values

Name	Description
NX_SUCCESS	API Call Successful
NX_PTR_ERROR*	Invalid input pointer parameter
NX_POP3_CLIENT_INVALID_INDEX*	Null mail index input
NX_POP3_PARAM_ERROR	Invalid non-pointer input
NX_POP3_APOP_FAILED_MD5_DIGEST	POP3 Client failed APOP authentication
NX_POP3_INVALID_MAIL_ITEM	Invalid mail item index (exceeds number of items in the maildrop box)
NX_POP3_INSUFFICIENT_PACKET_PAYLOAD	Client packet payload too small for POP3 request
NX_POP3_SERVER_ERROR_STATUS	Server replies with error status
NX_POP3_CLIENT_INVALID_STATE	Client not initialized to receive mail messages

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

*These are error codes which are only returned if error checking is enabled. Please refer to the NetX User Guide for the Renesas Synergy™ Platform for more details on error checking services in NetX.

4.3.28.3 NetX/NetX Duo POP3 Client Module Operational Overview

The POP3 protocol requires that Clients maintain the state of the POP3 session. The POP3 Client has three distinct states defined by RFC 1939. The initial state is the authorization state in which it must identify itself to the Server. Then the Client enters the Transaction state where the Client downloads mail. When the POP3 Client chooses to end the session, it enters the Update state to disconnect from the Server.

The NetX POP3 Client requires a previously created NetX IP instance and a packet pool to send POP3 messages to the Server. The NetX POP3 Client needs the packet pool for sending out POP3 messages. It can use the same packet pool used by the IP instance or NetX can create a separate packet pool. POP3 Client messages to the Server are limited to simple POP3 commands and login authentication data. This means that if the NetX POP3 Client is using its own packet pool, it need not set the payload size much greater than 150-200 bytes, depending on the length of POP3 Client username and password. Note that the packet pool used by the IP instance, however, must have a payload large enough for receiving POP3 mail data up to the device MTU (typically 1518 bytes).

Because the NetX POP3 Client utilizes TCP services, the TCP must be enabled on the IP instance.

NetX/NetX Duo POP3 Client Module Important Operational Notes and Limitations

NetX/NetX Duo POP3 Client Module Operational Notes

The NetX Client POP3 is compliant with RFC 1939.

The auto generated Synergy code takes care of these tasks at startup/initialization. IP instance and packet pool creation, as well as enabling TCP services, is done automatically.

The POP3 Client property *Auto initialization* defaults to Disable. You must not enable this property, because the auto generated code will try to connect to the server during initialization before the network link is enabled, and fail. This in turn will abort the application initialization.

So with *Auto initialization* disabled, the application handles connecting to the Server and retrieving its mail.

The following properties are necessary for connecting to the Server:

- APOP authentication: defaults to Disable. This enables username and password to be exchanged in encrypted text and is recommended to avoid exposing this data.
- Server port number: defaults to 110, as recommended in RFC 1939, but can be any value.
- *Server_IPv4 Address: This is the server to connect to if using IPv4 connections*
- Server_IPv6 *Address: This is the server to connect to if using IPv6 connections*
- User server address type: set to IPv4 or IPv6 depending on which your application will use
- Client Name: user name to identify the POP3 client to the server
- Client Password: password which has been previously agreed to if the server requires one

However, because of the structure of the POP3 Client, setting these properties are not accessible to the application. Your application must connect to the server using the nx_pop3_client_create API and input these properties directly.

```
UINT  nx_pop3_client_create(NX_POP3_CLIENT *client_ptr,
                            UINT APOP_authentication, NX_IP *ip_ptr,
                            NX_PACKET_POOL *packet_pool_ptr,
                            ULONG server_ip_address,
                            ULONG server_port,
                            CHAR *client_name,
                            CHAR *client_password)
```

For most applications a typical call might look like:

```
Status = nx_pop3_client_create(&g_pop3_client0, NX_TRUE, &g_ip0,
                            &g_packet_pool0, /* If sharing IP packet pool */
                            IP_ADDRESS(192,168,0,2,
                            110,
                            "myusername",
                            "mypassword")
```

For NetX Duo, the ULONG server_ip_address is replaced by a pointer to an NXD_ADDRESS type:

```
NXD_ADDRESS server_address;
server_address.nxd_ip_version = NX_IP_VERSION_IPv4;  /* e.g. 4 */
/* If the local IP address is 192.168.0.2, use the IP_ADDRESS macro to convert to a
ULONG */
server_address.nxd_ip_address.v4 = IP_ADDRESS(192,168,0,);
status =  nxd_pop3_client_create(&g_pop3_client0, NX_TRUE, &g_ip0,
                            &g_packet_pool0, /* If sharing IP packet pool */
                            &server_address,
                            110,
                            "myusername",
                            "mypassword")
```

This function creates the POP3 Client instance, creates a TCP socket and binds to a local TCP port. Then it attempts to connect to the POP3 Server TCP socket. If this is successful, then it authenticates itself with the user password to the server. More details on POP3 authentication are described later in this section. If all goes well, the POP3 Client is now ready to get its mail.

The application can query the server for how many mail items are in its inbox with the nx_pop3_client*_*mail_items_get API. This will also return the total number of bytes of mail messages, although this should be taken as an estimate. The application can further query the size of each mail item, using the nx_pop3_client_mail_item_size_get API, and again this should be taken as an estimate as the actual size might vary somewhat. Note that the first mail item in the maildrop is at index 1, not zero.

To actually download the mail item, the application indicates to the server which mail item it wants to receive using the nx_pop3_client_get_mail_item service, specifying the index of the mail item. This will also return the mail item size but now the POP3 client can get the message text by calling nx_pop3_client_mail_item_get_message_data. This API will receive one packet at a time. So the application must call it one or more times until the last packet containing the message is received. The Server will indicate the last packet to the Client in the final_packet pointer as shown below:

```
    /* Find out how many items are in our mailbox.  */
    status = nx_pop3_client_mail_items_get(&demo_client, &number_mail_items,
                                           &total_size);
    mail_item = 1;
    /* Download all mail items.  */
    while (mail_item <= number_mail_items)
```

```
    {
        /* Submit a request for the next mail item. */
        status = nx_pop3_client_mail_item_get(&demo_client, mail_item,
                                              &mail_item_size);
        /* Loop to get the next mail message until it is completely downloaded. */
        do
        {
            status = nx_pop3_client_mail_item_message_get(&demo_client, &packet_ptr,

                                                  &bytes_retrieved,
&final_packet);
            /* Determine if this is the last data packet. */
            if (final_packet)
                 status = nx_pop3_client_mail_item_delete(&demo_client, mail_item);
        } while (final_packet == NX_FALSE);
        /* Get the next mail item. */
        mail_item++;
    }
```

After receiving each packet, the application should copy the packet data to a buffer and release the packet back to the packet pool (not shown above). This prevents depleting the packet pool used to receive packets. After downloading a message, it is common practice to mark the mail item for deletion. To do so, the application calls nx_pop3_client_mail_item_delete with the index of the mail item to delete.

When done downloading mail items, the Client quits the session by calling nx_pop3_client_quit. This terminates the TCP session. If no longer using POP3, the application can delete the TCP socket by calling nx_pop3_client_delete. If no other tasks are using the POP3 Client packet pool, the application can delete the packet pool using the nx_packet_pool_delete service.

POP3 Authentication

After the TCP connection is established, a POP3 client needs to identify itself to the POP3 server through authentication to access its mailbox. Authentication is accomplished by sending the server a username and password. The username is typically a fully qualified domain name (contains a local part and a domain name, separated by an '@' character.

To enable APOP Authentication, set the *APOP Authentication* input in the nx_pop3_client_create/nxd_pop3_client_create API to NX_TRUE (or nxd_pop3_client_create API in NetX Duo). APOP Authentication creates an MD5 digest of user name/password supplied to the nx_pop3_client_create/nxd_pop3_client_create call and avoids the security risk of transmitting

username and password in clear text. If APOP authentication fails, the NetX POP3 Client will attempt to login using the username and password without encryption.

NetX/NetX Duo POP3 Client Module Limitations

- The NetX POP3 Client does not support the AUTH command but does support APOP authentication using DIGEST MD5.
- NetX POP3 Client does not implement all POP3 commands (for example, the TOP or UIDL commands).
- See the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.28.4 Including the NetX/NetX Duo POP3 Client Module in an Application

This section describes how to include either or both the NetX and NetX Duo POP3 Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo POP3 Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo POP3 Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_pop3_client0 NetX POP3 Client	Threads	New Stack> X-Ware> NetX> Protocols> NetX POP3 Client
g_pop3_client0 NetX POP3 Client	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo POP3 Client

When the NetX and/or NetX Duo POP3 Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

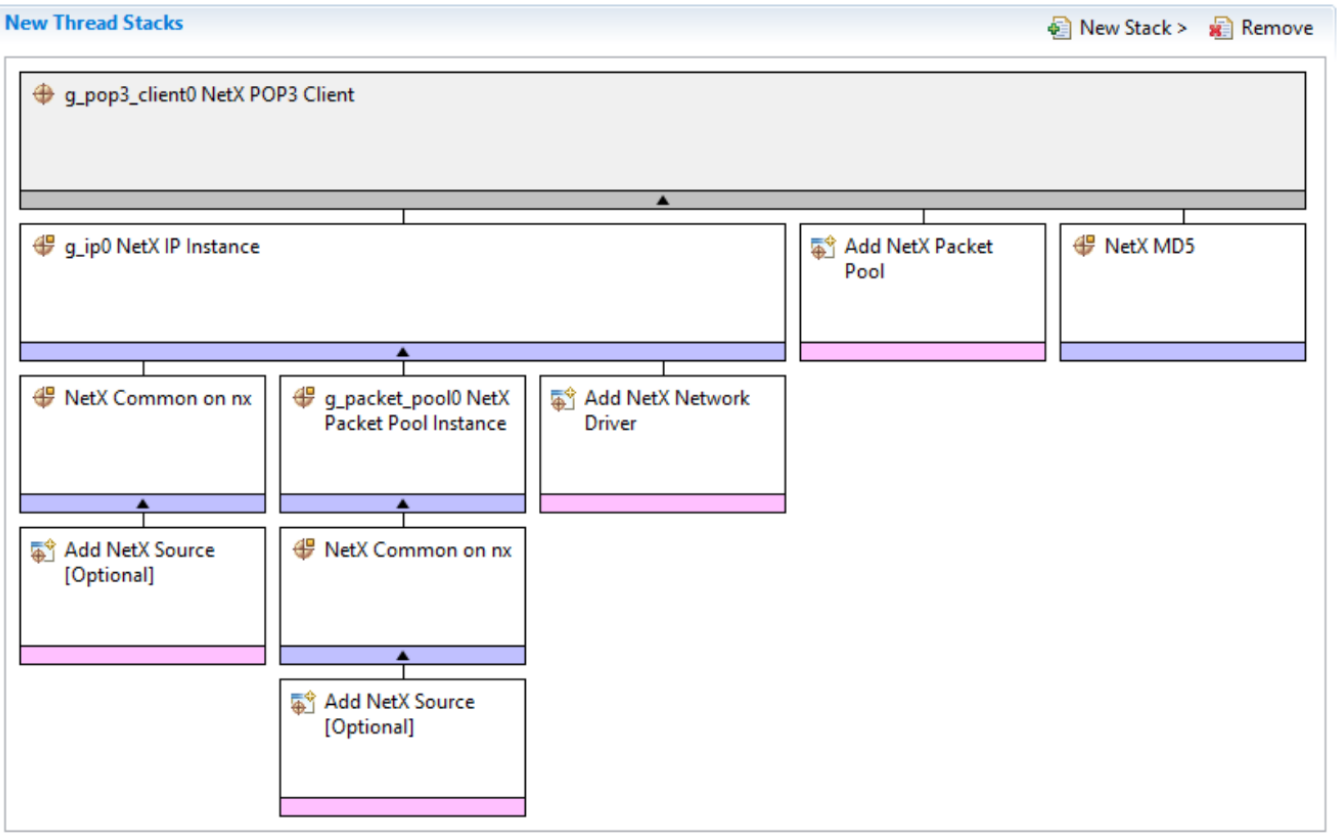

Figure 487: NetX/NetX Duo POP3 Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.28.5 Configuring the NetX/NetX Duo POP3 Client Module

The NetX/NetX Duo POP3 Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo POP3 Client Module

ISDE Property	Value	Description
Maximum buffer size to store messages (bytes)	2000	Maximum buffer size to store messages selection
Packet time out (seconds)	1	Packet time out selection
Connection time out (seconds)	30	Connection time out selection
Disconnect time out (seconds)	2	Disconnect time out selection
TCP socket send wait (seconds)	2	TCP socket send wait selection
Server reply timeout (seconds)	10	Server reply timeout selection
TCP window size (bytes)	1460	TCP window size selection
Maximum user name length (bytes)	40	Maximum user name length selection
Maximum password length (bytes)	20	Maximum password length selection
Name	g_pop3_client0	Module name
APOP Authentication	Enable, Disable Default: Disable	Apop authentication selection
**Use server address type	IPv4, IPv6 Default: IPv6	Use server address type selection
Server IPv4 Address (use commas for separation)	192, 168, 0, 2	Server IPv4 Address selection
**Server IPv6 Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	Server IPv6 Address selection
Server Port number	110	Server Port number selection
Client Name	username@domain.com	Client name selection
Client Password	password	Client password selection
Auto initialization	Enable, Disable Default: Disable	Auto initialization selection
Name of generalized initialization function	pop3_client_init0	Name of generalized initialization function selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different MAC or IP Addresses. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo POP3 Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection

UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function
Link status change callback	NULL	Link status change callback selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection

Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX MD5 Instance

ISDE Property	Value	Description
No configurable properties		

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo POP3 Client Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX/NetX Duo POP3 Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1

Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.28.6 Using the NetX/NetX Duo POP3 Client Module in an Application

The steps in using the NetX and NetX Duo BSD Support module in a typical application are:

Step 1. Wait for the network link to be enabled with the nx_ip_status_check API.

Step 2. Create the POP3 Client using nx_pop3_client_create API (nxd_pop3_client_create in NetX Duo POP3 Client).

Step 3. Send a request to the POP3 Server for the number of mail items in mailbox with the nx_pop3_client_mail_items_get API.

Step 4. Assuming there are one or more items in the POP3 Client maildrop, send a request to the POP3 Server one or all of them by calling the nx_pop3_client_mail_item_get API.

Step 5. After each call to nx_pop3_client_mail_item_get, download the actual mail message data using the nx_pop3_client_mail_message_get API.

Step 6. Copy the packet data into a separate buffer and release the receive packet(s) using the nx_packet_release API [Strongly recommended to avoid packet pool depletion]

Step 7. Check if this is the last packet of the message: the final_packet pointer input of nx_pop3_client_mail_message_get will be TRUE if it is the last packet.

If FALSE, call nx_pop3_client_mail_message_get again. If TRUE, go on to step 8.

Step 8. Mark the current mail item for deletion using the nx_pop3_client_mail_item_delete API. This will send a DELE message to the server for it to delete the mail item at some later time.

Step 9. Check if there are more mail items to download. If yes, get the next mail item by calling

nx_pop3_client_mail_item_get. If no, go on to step 10.

Step 10. Send a QUIT message to the Server with the nx_pop3_client_delete API

Step 11. Delete the POP3 instance by calling nx_pop3_client_delete API.

The following figure illustrates common steps in a typical operational flow diagram:

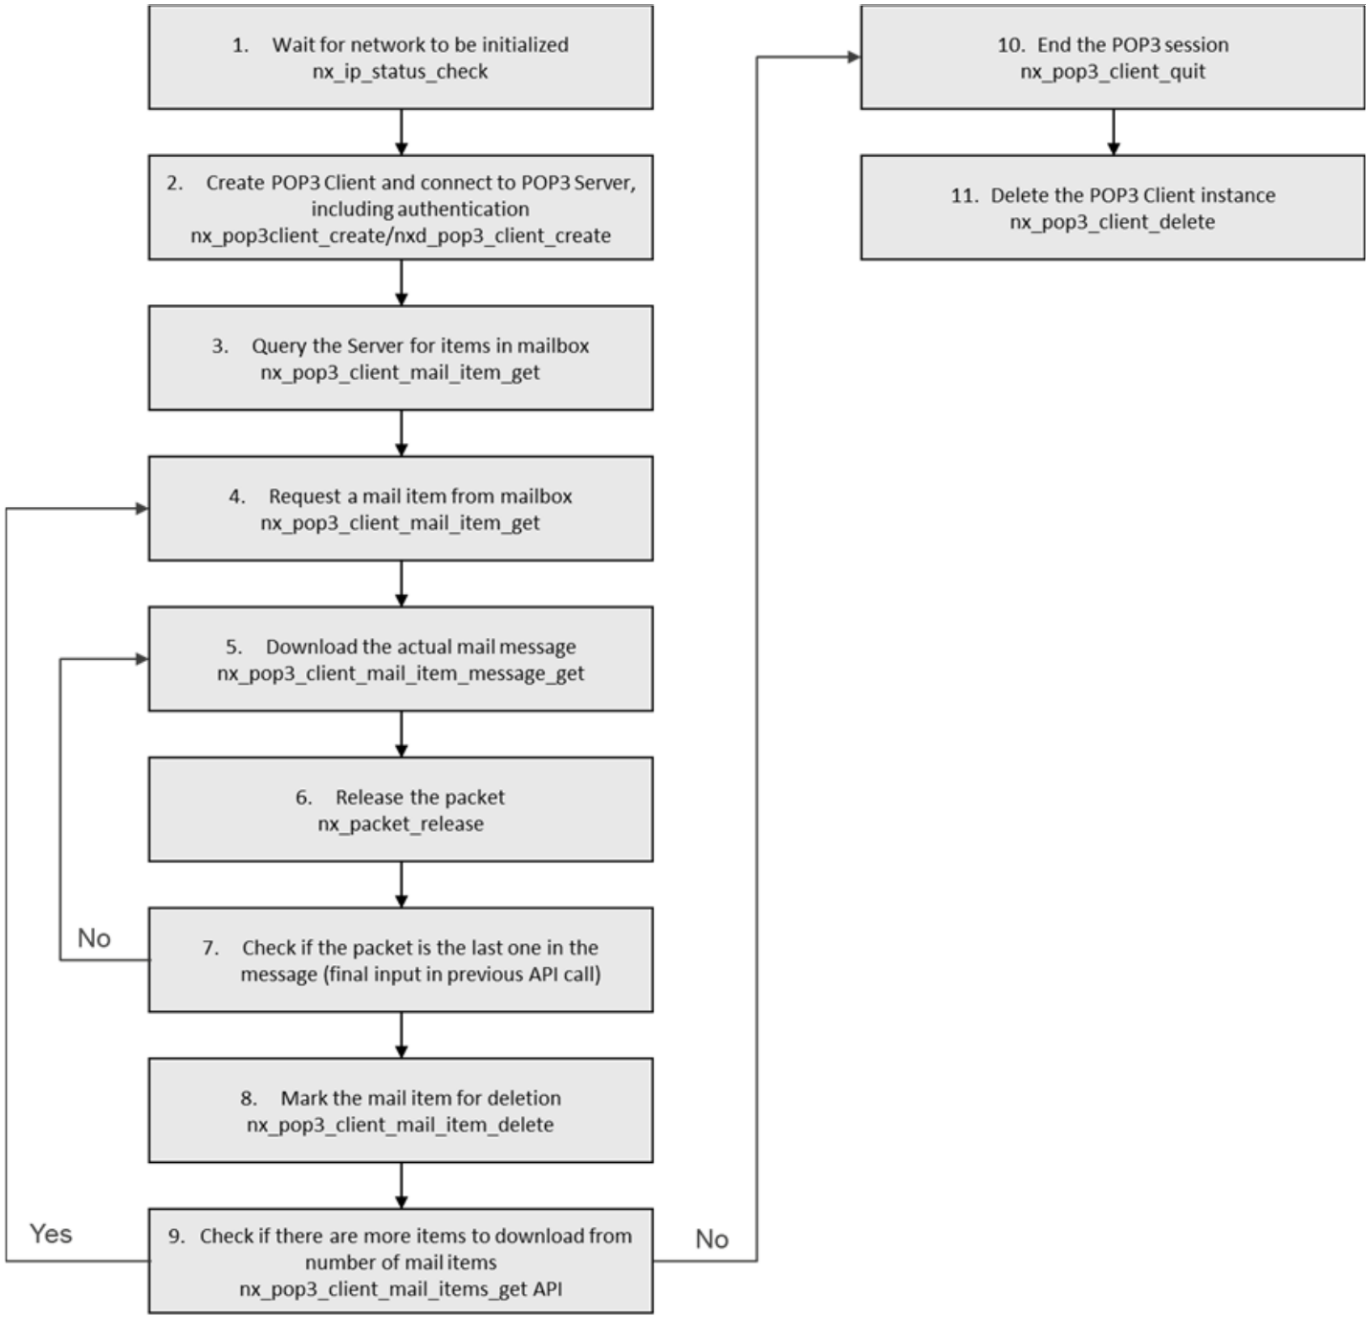

Figure 488: Flow Diagram of a Typical NetX/NetX Duo POP3 Client Module Application

4.3.29 NetX/NetX Duo Telnet Client

4.3.29.1 NetX and NetX Duo Telnet Client Introduction

The Telnet Protocol (Telnet) protocol is designed for transferring commands and responses between two nodes on the Internet. Telnet is a simple protocol that utilizes reliable Transmission Control Protocol (TCP) services to perform its transfer function. The NetX™ Telnet Client provides a high-level API for applications wishing to implement a Telnet Client.

Note

Except for internal processing, the NetX Duo™ Telnet Client is nearly identical in the application, set up and running a Telnet session as the NetX™ Telnet Client (except where noted).

Unsupported Features

Multi-thread support has not been tested in this version of SSP.

NetX and NetX Duo Telnet Client Module Features

- The NetX™ Telnet Client Module is compliant with RFC854 and related RFCs
- Provides high-level APIs to:
    - Create and delete a Telnet Client instance
    - Connect and disconnect a Telnet Client instance
    - Send to and receive packets from a Telnet Server
    - Support multi-thread operation

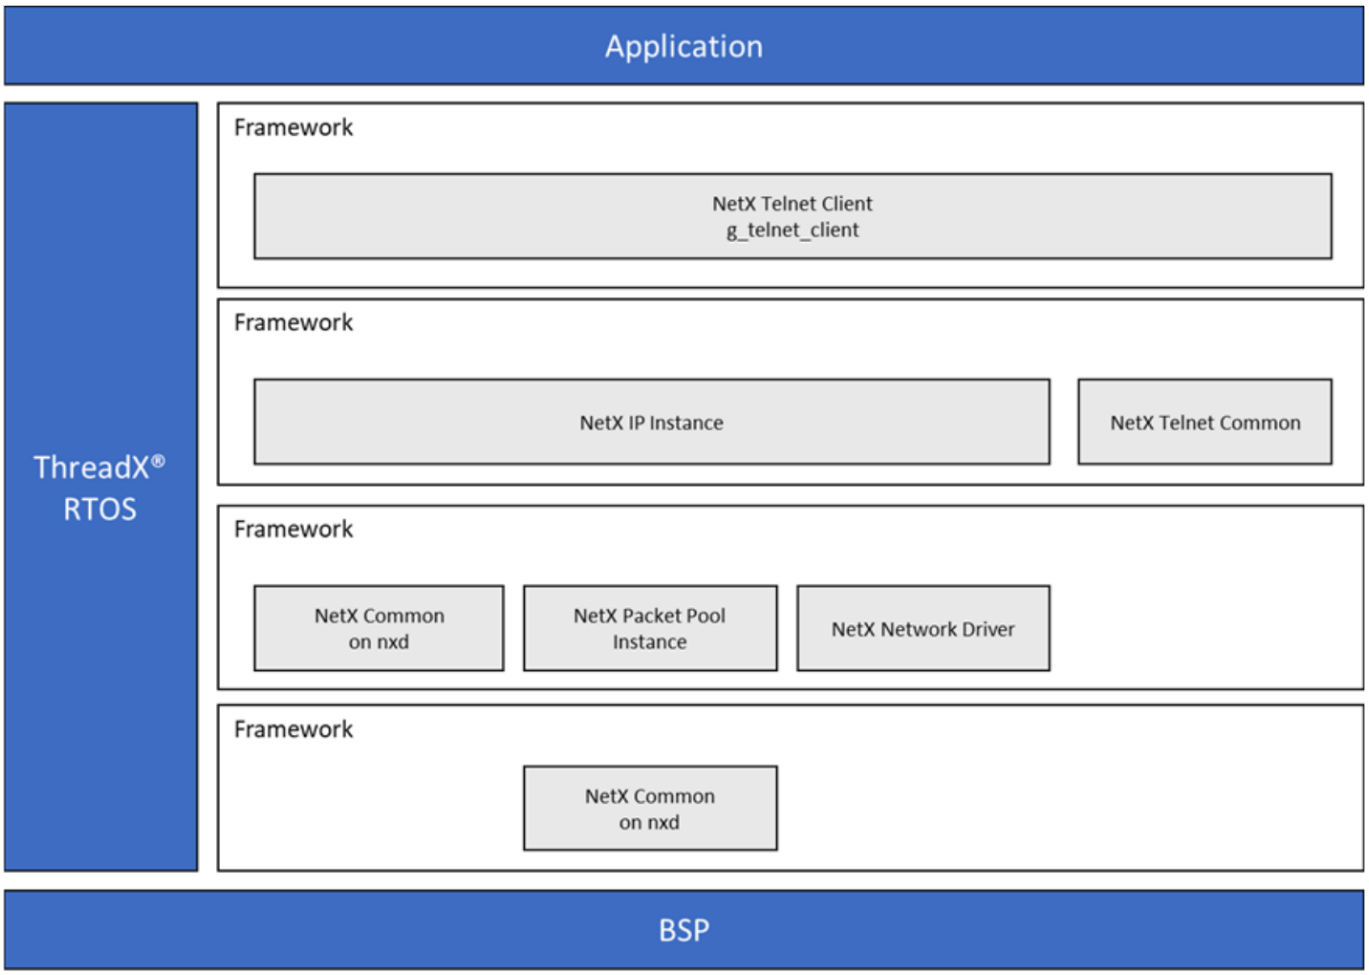

Figure 489: NetX and NetX Duo Telnet Client Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver module has multiple implementation options available. See the description just after the module stack figure in Including the NetX and NetX Duo Telnet Client Module in an Application for additional details.

4.3.29.2 NetX and NetX Duo Telnet Client Module APIs Overview

The NetX™ Telnet Client Module defines APIs for creating, deleting, connecting, disconnecting, receiving and sending telnet communications. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX and NetX Duo Telnet Client Module API Summary

Function Name	Example API Call and Description
nx_telnet_client_connect	nx_telnet_client_connect(&g_telnet_client0, server_ip_address, server_port, NX_WAIT_FOREVER); Connect a Telnet Server. Supports only IPv4.

**nxd_telnet_client_connect	nxd_telnet_client_connect(&g_telnet_client0, &server_ip_address_v6, server_port, NX_WAIT_FOREVER); Connect to a Telnet Server. Supports IPv4 and IPv6.
nx_telnet_client_create	nx_telnet_client_create(&g_telnet_client0, "Telnet Client", &g_ip0, 1024); Create a Telnet Client.
nx_telnet_client_delete	nx_telnet_client_delete(&g_telnet_client0); Delete a Telnet Client.
nx_telnet_client_disconnect	nx_telnet_client_disconnect(&g_telnet_client0, NX_WAIT_FOREVER); Disconnect from the Telnet Server (IPv4 or IPv6).
nx_telnet_client_packet_receive	nx_telnet_client_packet_receive(&g_telnet_client0, &packet_ptr, NX_WAIT_FOREVER); Receive packet from the Telnet Server.
nx_telnet_client_packet_send	nx_telnet_client_packet_send(&g_telnet_client0, packet_ptr, NX_WAIT_FOREVER); Send packet to the Telnet Server (IPv4 or IPv6).

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo Telnet Client. For definitions of NetX Duo specific data types, see the *NetX Duo User Guide for the Renesas Synergy™ Platform*.

Status Return Values

Name	Description
NX_SUCCESS	API Call Successful
NX_TELNET_ERROR	Error while creating TCP socket as part of creating the Telnet Client instance
NX_TELNET_NOT_CONNECTED	Client not disconnected
NX_TELNET_NOT_DISCONNECTED	Client socket is not in closed state (cannot make a TCP connection; cannot delete the Telnet Client if the socket is still connected).
NX_TELNET_INVALID_PARAMETER*	Invalid non-pointer input to Telnet Client create
NX_PTR_ERROR*	Invalid pointer input
NX_IP_ADDRESS_ERROR*	Invalid IP address to connect to Telnet Server
NX_CALLER_ERROR*	Invalid caller of this service

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

*These error codes are only returned if error checking is enabled. Please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform for more details on error checking services in NetX Duo.

4.3.29.3 NetX and NetX Duo Telnet Client Module Operational Overview

In the NetX™ Telnet Client Module, the IP thread task for NetX™ is created and runs, the Telnet Client is created and the TCP socket for connecting to the Telnet Server is ready for use automatically. The Telnet Client connects to the server by calling the nx_telnet_client_connect API. (This API is available in NetX Duo™ Telnet and is limited to IPv4 TCP connections. In NetX Duo™, the application can also use the nxd_telnet_client_connect which supports both IPv4 and IPv6.) If that succeeds, then the Telnet Client should wait to receive a Server 'banner' announcing itself using the nx_telnet_client_packet_receive API. Thereafter the Telnet Client can create packets with single characters of data using the nx_packet_allocate and nx_packet_data_append API. These packets are sent to the Telnet Server by calling the nx_telnet_client_packet_send API.

For a more complete description of the NetX™ Telnet Client and NetX Duo™ Telnet Client operations, refer to the associated User Guides found in the Synergy Gallery, under the SSP Documentation tab as "Azure RTOS and NetX™ Component Documentation for Renesas Synergy". Open the zip file and navigate to the related User Guides for detailed descriptions. This document provides only an introduction to component operations. Module selection, configuration, and example uses are described in detail in the following sections.

NetX and NetX Duo Telnet Client Module Important Operational Notes and Limitations

NetX and NetX Duo Telnet Client Module Operational Notes

- The NetX Duo™ Telnet Client Module services can be called from multiple threads simultaneously. However, read or write requests for a particular Telnet Client instance should be done in sequence from the same thread.

NetX and NetX Duo Telnet Client Module Limitations

- The Telnet Client does not support Telnet negotiation or send IAC and command code sequences.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.29.4 Including the NetX and NetX Duo Telnet Client Module in an Application

This section describes how to include either or both the NetX and NetX Duo Telnet Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX and NetX Duo Telnet Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX and NetX Duo Telnet Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence

g_telnet_client0 NetX™ Telnet Client	Threads	New Stack> X-Ware> NetX™ > Protocols> NetX™ Telnet Client
g_telnet_client0 NetX Duo™ Telnet Client	Threads	New Stack> X-Ware> NetX Duo™ > Protocols> NetX Duo™ Telnet Client

When the NetX and/or NetX Duo Telnet Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

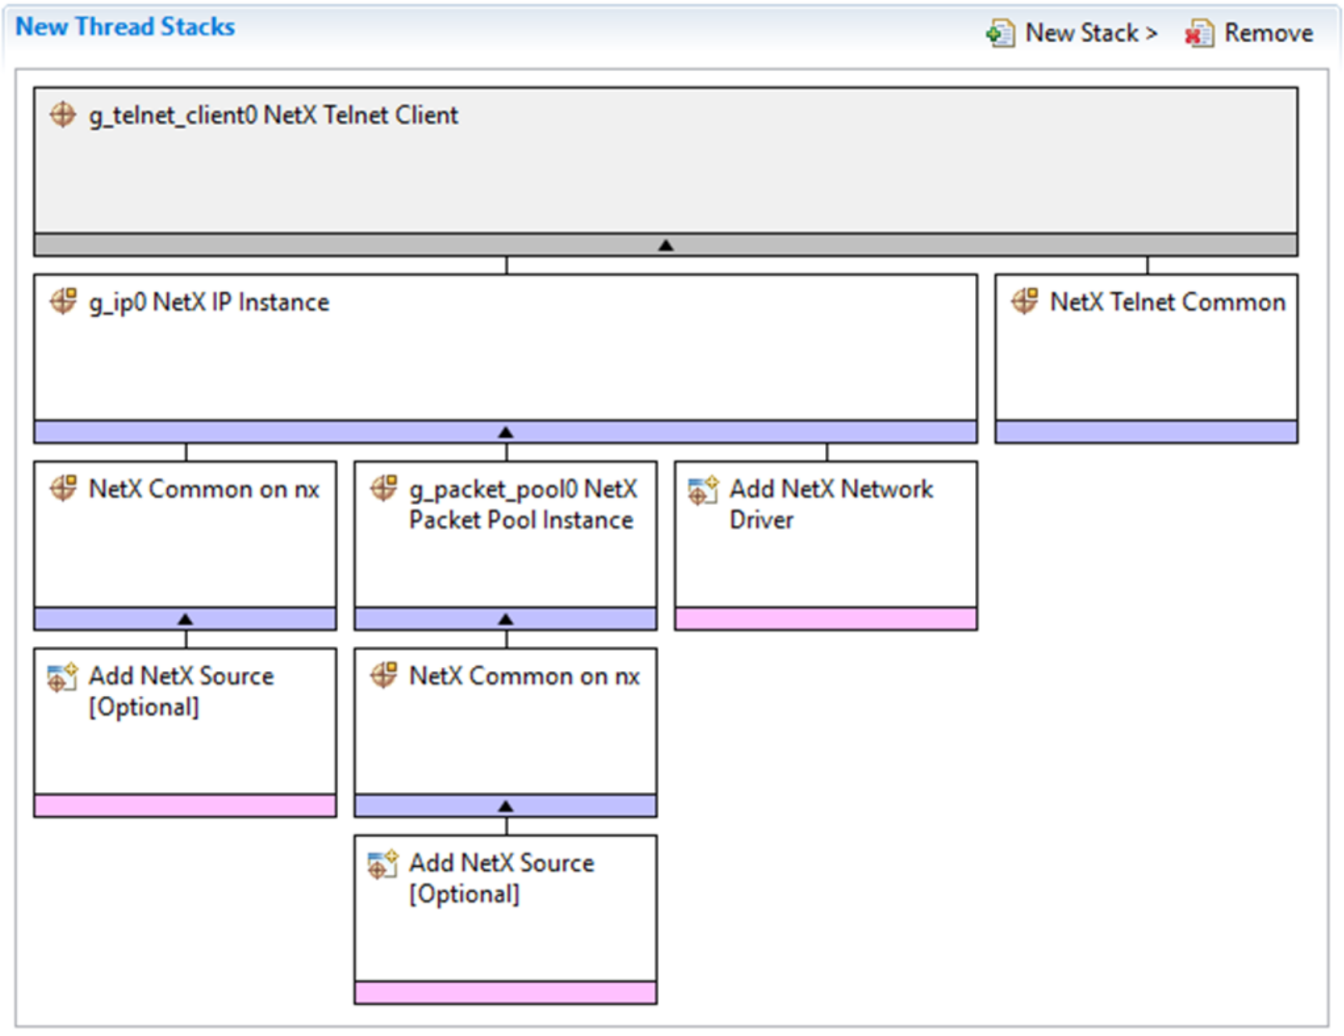

Figure 490: NetX and NetX Duo Telnet Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not

all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.29.5 Configuring the NetX and NetX Duo Telnet Client Module

The NetX and NetX Duo Telnet Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX and NetX Duo Telnet Client Module

ISDE Property	Value	Description
Name	g_telnet_client0	Module name
TCP Socket Window Size in Bytes	1024	TCP socket window size selection
Name of generated initialization function	telnet_client_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different IP addresses and subnet masks. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX and NetX Duo Telnet Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX and NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection

IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function
Link status change callback	NULL	Link status change callback selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX and NetX Duo Telnet Common Instance

ISDE Property	Value	Description
Type of Service for UDP requests	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Type of service UDP requests selection
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragment option selection
Server TCP port number	23	Server TCP port number selection
Time to live	128	Time to live selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX and NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have

different default values and available configuration settings.

Configuration Settings for the NetX and NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX and NetX Duo Telnet Client Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX and NetX Duo Telnet Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin Selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description

Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.29.6 Using the NetX and NetX Duo Telnet Client Module in an Application

The NetX™ Telnet Client Module does not need the usual initialization by an application. A configurator generates initialization process. The user application only needs Telnet communication processing.

The steps in using the NetX and NetX Duo Telnet Client module in a typical application are:

1. Use the nx_ip_status_check API to check that the IP instance is initialized and the application can start using NetX™ services.

2. Connect to the Telnet Server via the nx_telnet_client_connect API. (Note: For NetX Duo™ the preferred API is nxd_telnet_client_connect).

3. Receive the Telnet Server welcome banner using nx_telnet_client_packet_receive API [Optional]

4. Create a packet to send with the nx_packet_allocate and nx_packet_data_append APIs.

5. Send the packet using the nx_telnet_client_packet_send API

6. Receive the Server's response packet using the nx_telnet_client_receive API.

7. Disconnect communication using the nx_telnet_client_disconnect API

8. Delete the instance using the nx_telnet_client_delete API when done sending and receiving.

The following figure illustrates common steps in a typical operational flow diagram:

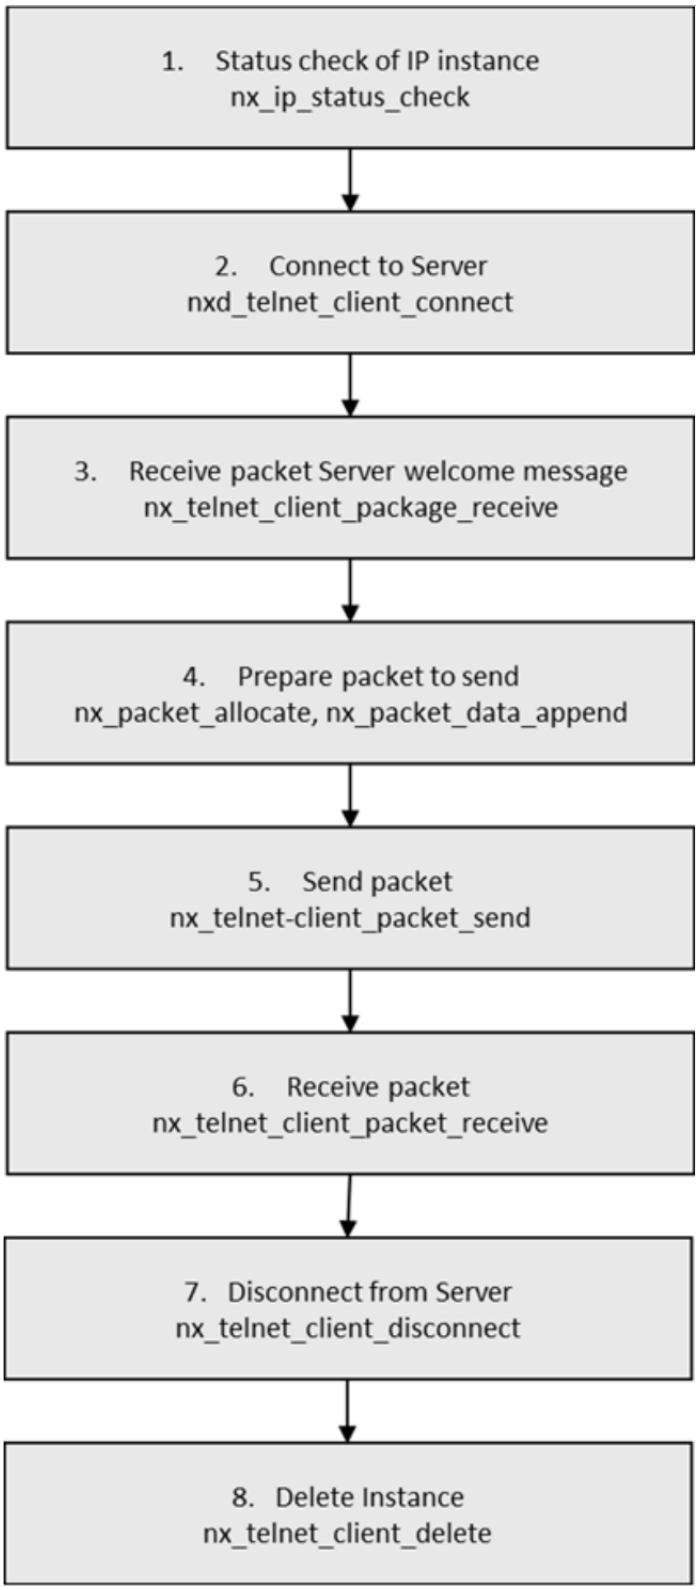

Figure 491: Flow Diagram of a Typical NetX and NetX Duo Telnet Client Module Application

4.3.30 NetX/NetX Duo Telnet Server

4.3.30.1 NetX and NetX Duo Telnet Server Introduction

The Telnet Protocol (Telnet) is a protocol designed for transferring commands and responses between two nodes on the internet. Telnet is a simple protocol that utilizes reliable Transmission Control Protocol (TCP) services to perform its transfer function.

Note

Except for internal processing, the NetX Duo™ Telnet Server is nearly identical in the application, setup and running of a Telnet session as the NetX™ Telnet Server (except where noted).

Unsupported Features

Telnet Option Negotiation has not been tested for NetX Duo Telnet Server in this version of SSP

NetX and NetX Duo Telnet Server Module Features

- The NetX Telnet Server module is compliant with RFC854 and related RFCs.
- Provides high-level APIs to:
    - Support multi-thread operation
    - Support callbacks for common functions
    - Authentication
    - New Connection
    - Receive Data
    - End Connection
- Supports some option negotiation
    - Echo
    - Suppress Go Ahead

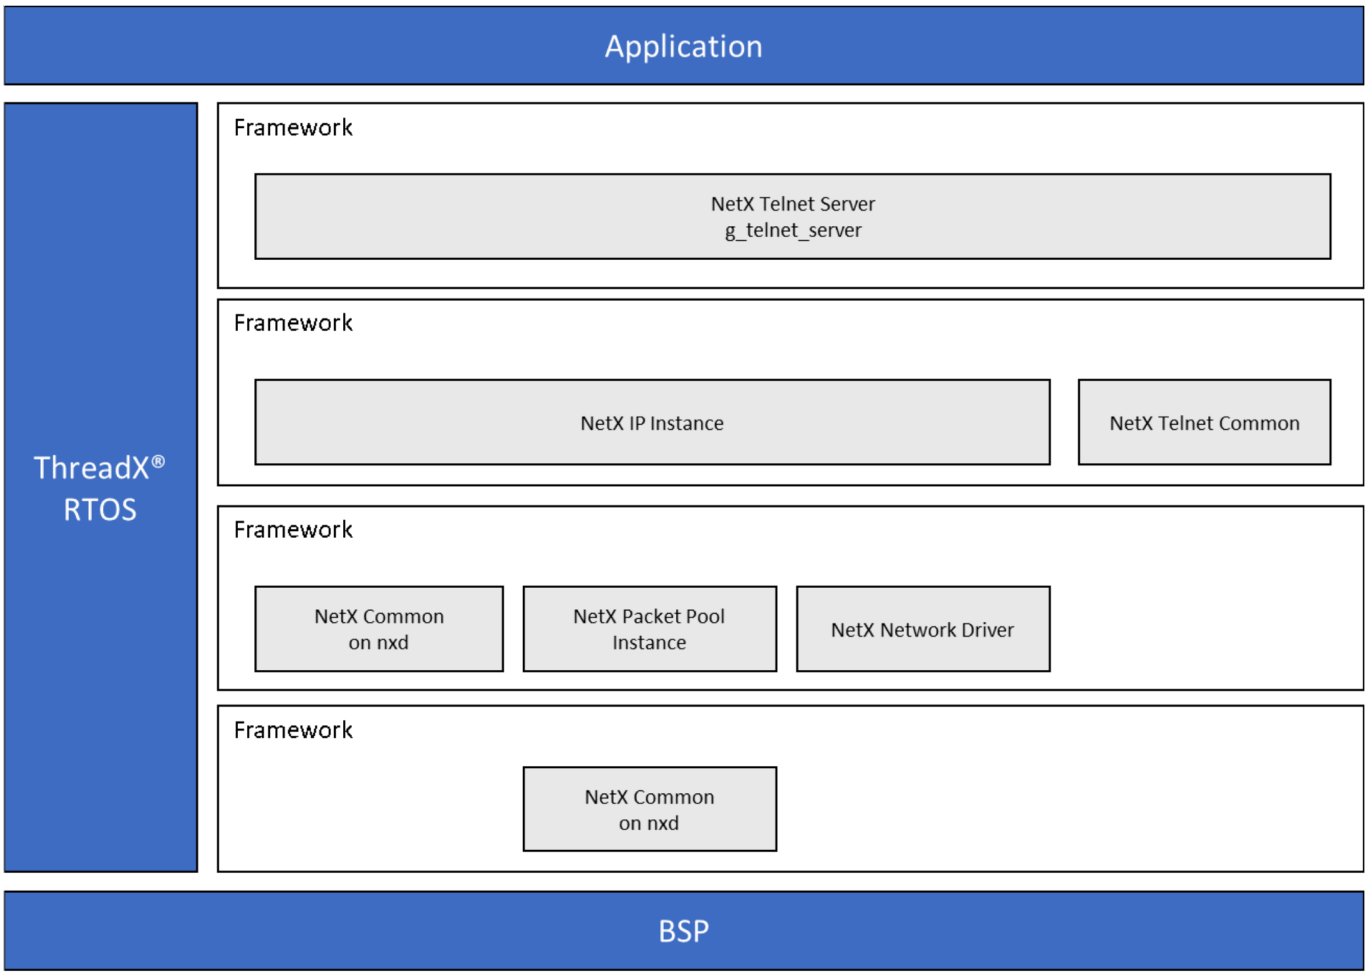

Figure 492: NetX and NetX Duo Telnet Server Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver module has multiple implementation options available. See the description just after the module stack figure in Including the NetX and NetX Duo Telnet Server Module in an Application for additional details.

4.3.30.2 NetX and NetX Duo Telnet Server Module APIs Overview

The NetX Telnet Server module defines APIs for creating, deleting, sending packets, starting and stopping. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX and NetX Duo Telnet Server Module API Summary

Function Name	Example API Call and Description
nx_telnet_server_create	nx_telnet_server_create(&my_server, "Telnet Server", &ip_0,pointer, 2048, telnet_new_connection, telnet_receive_data, telnet_connection_end); Create a Telnet Server.

nx_telnet_server_delete	nx_telnet_server_delete(&my_server); Delete a Telnet Server.
nx_telnet_server_disconnect	nx_telnet_server_disconnect(&my_server, 2); Disconnect the Telnet Client specified by the client list index (2nd input).
nx_telnet_server_get_open_connection_count	nx_telnet_server_get_open_connection_count(&my_server, &conn_count); Retrieve the number of open connections.
nx_telnet_server_packet_send	nx_telnet_server_packet_send(&my_server, 2, my_packet, 100); Send packet to Telnet Client specified by client list index (second input).
nx_telnet_packet_pool_set	nx_telnet_server_packet_pool_set(&my_server, &telnet_server_packet_pool); Set packet pool as Telnet Server packet pool.
nx_telnet_server_start	nx_telnet_server_start(&my_server); Start theTelnet Server.
nx_telnet_server_stop	nx_telnet_server_stop(&my_server); Stop the Telnet Server.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

Status Return Values

Name	Description
NX_SUCCESS	Successful telnet function
NX_PTR_ERROR*	Invalid Server, IP, stack, or application callback pointers
NX_CALLER_ERROR*	Invalid caller of this service
NX_OPTION_ERROR*	Invalid logical connection
NX_IP_ADDRESS_ERROR*	Invalid IP address
NX_TELNET_FAILED	Server packet send failed
NX_TELNET_NO_PACKET_POOL	Cannot start Telnet Server, no packet pool available
NX_TELNET_NOT_CONNECTED	Cannot disconnect Telnet Server because it is not connected
NX_TELNET_NOT_DISCONNECTED	Cannot connect or delete Telnet Server because it is not disconnected

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

*These error codes are only returned if error checking is enabled. Please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform for more details on error checking services in NetX Duo.

4.3.30.3 NetX and NetX Duo Telnet Server Module Operational Overview

The NetX Telnet package requires that a NetX IP instance has already been created. In addition, TCP must be enabled on that same IP instance. The Telnet Client portion of the NetX Telnet package has no further requirements. It also requires complete access to TCP well-known port 23 for handling all Telnet Client requests. The Telnet Server keeps a list of client connections and uses an index into this list to specify certain clients when needed. The size of this list is set in the Maximum clients to server simultaneously property.

The Telnet Server can be enabled for limited Option negotiation with the Telnet Client. To enable this feature, set the Option negotiation to enable. If this feature is enabled, the Telnet Server needs a packet pool. The application can set the packet payload and number of packets; packet_size_inthe pool and Totalpacket_pool_sizeProperties, respectively and let the Telnet Server create the packet pool. When the Telnet Server is deleted, the packet pool is deleted with it.

Alternatively, it can create the packet pool directly and be set as the Telnet Server packet pool by 1) enabling Use application packet pool or by 2) creating the packet pool by calling the NetXnx_packet_pool_create API and 3) setting the packet pool in the Telnet Server using the nx_telnet_server_packet_pool_set API. When the Telnet Server is deleted, the application must delete the packet pool directly (nx_packet_pool_delete API).

Telnet New Connection Callback

The NetX Telnet Server calls the new connection callback function when a new Telnet Client request is received. The callback function is set in the NetX Telnet Server Name of Client Connect Callback Function property. Actions of the new connection callback include sending a banner or prompt to the client. It could also include a prompt for login information if authentication is required. The second argument of the new connection callback specifies the client is connecting.

Telnet Receive Data Callback

The NetX Telnet Server Module calls the data received callback function when a new Telnet Client data is received. The second input of the callback is an index into the Telnet Server's list of clients so the Telnet Server knows which client wants to disconnect. The callback function is set in the Name of Receive Data Callback Function property. Typical actions of the receive data callback include echoing the data back and/or parsing the data and providing data because of interpreting a command from the client.

Note

This callback routine must release the received packet.

Telnet End Connection Callback

The NetX Telnet Server calls the end connection callback function when it receives a Telnet Client disconnect request. The second input of the callback is an index into the Telnet Server's list of clients so the Telnet Server knows which Client wants to disconnect. The callback function is set in the Name of Client Disconnect Callback Function property. Typical actions of the end connection callback include cleaning up resources used for the Telnet Client session.

Telnet Option Negotiation

Upon making a connection with the Telnet Client, the Telnet Server will send out this set of Telnet

options to the client if it has not received option requests from the client:

will echo

don't echo

will sga

When it receives Telnet data from the client, the Telnet Server checks if the first byte is the IAC (Interpret as Command) code; if so, it will process all the options in the client packet. Options not in the list above are not supported and will be ignored.

NetX and NetX Duo Telnet Server Module Important Operational Notes and Limitations

NetX and NetX Duo Telnet Server Module Operational Notes

- For the connect callback, the application can use any packet pool it has created or the IP default packet pool. If nx_telnet_server_packet_send fails, the callback must release that packet.
- The number of active client connections can be obtained at any time by calling the nx_telnet_server_get_open_connection_count API.
- The Telnet Server thread task periodically checks the time remaining on each client connection inactivity timeout. If the timeout has expired, the client connection is dropped. To set the length of the inactivity timeout, set the value of the Client inactivity timeout property of the Telnet Server to the desired value. The interval that the Telnet Server thread task checks the inactivity timeout is the Timeout check period property; this must be less than the client inactivity timeout.
- The Telnet Server can be stopped using the nx_telnet_server_stop API and restarted using the nx_telnet_server_start API. When the Telnet Server is stopped, all client connections are dropped and the server stops listening on the Telnet port.
- Deleting the Telnet Server is like stopping the Telnet Server, but additionally releases all resources used for the Telnet Server; timer, thread, TCP socket and if created by the Telnet Server, the Telnet Packet pool.
- The interpretation and response to Telnet Client commands, indicated by a byte with the value of 255, is the responsibility of the application.

NetX and NetX Duo Telnet Server Module Limitations

- The NetX Telnet Server supports only a limited set of Telnet Option commands.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.30.4 Including the NetX and NetX Duo Telnet Server Module in an Application

This section describes how to include either or both the NetX and NetX Duo Telnet Server module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX and NetX Duo Telnet Server module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX and NetX Duo Telnet Server Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_telnet_server0 NetX Telnet Server	Threads	New Stack> X-Ware> NetX> Protocols> NetX Telnet Server
g_telnet_server0 NetX Duo Telnet Server	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo Telnet Server

When the NetX and/or NetX Duo Telnet Server module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

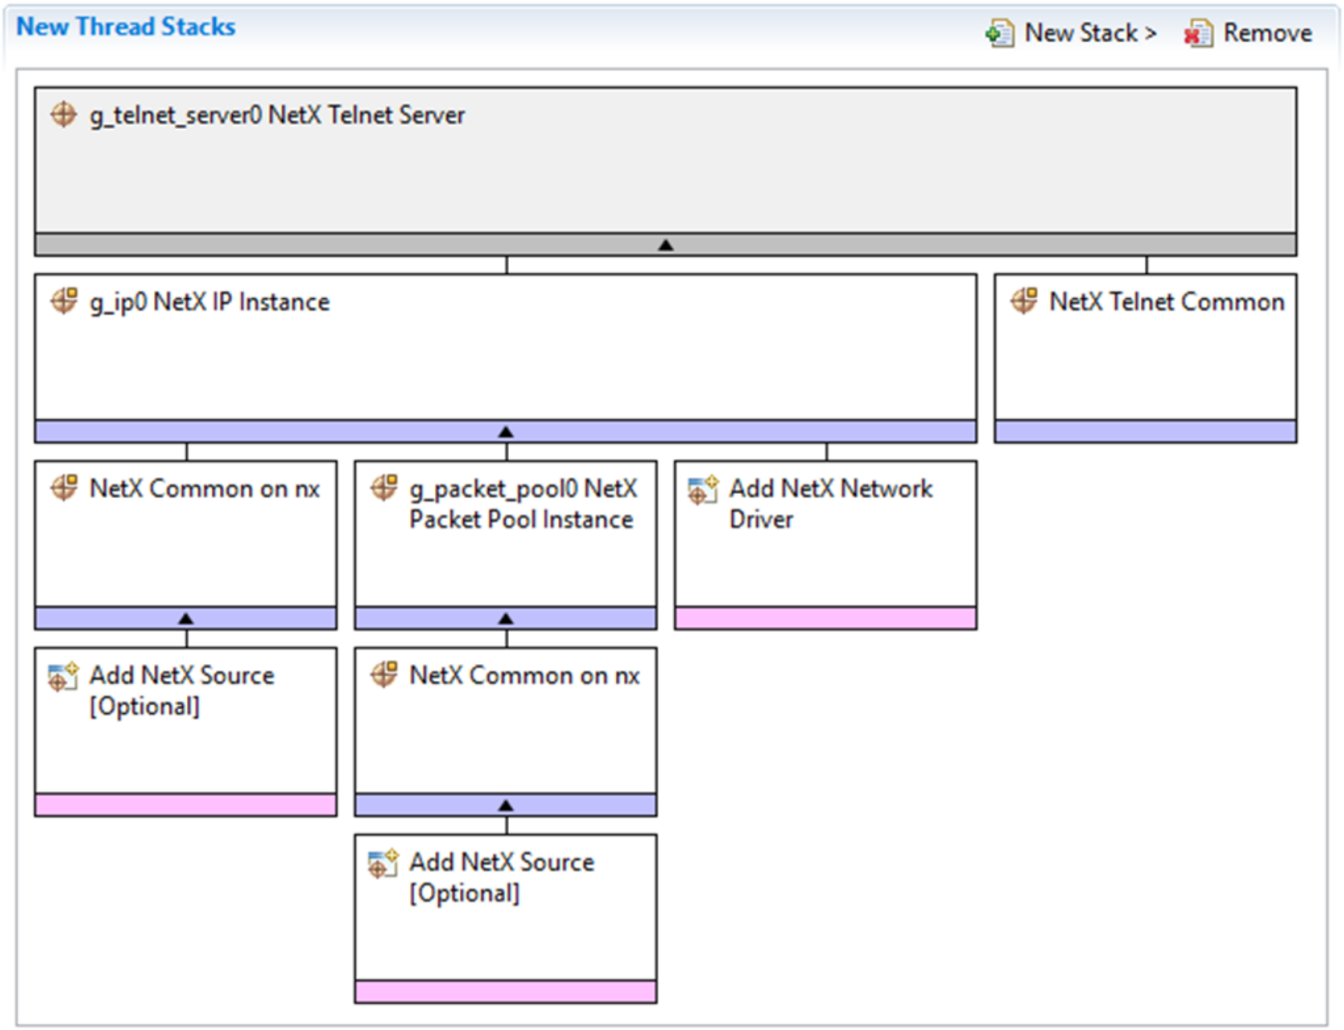

Figure 493: NetX and NetX Duo Telnet Server Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.30.5 Configuring the NetX and NetX Duo Telnet Server Module

The NetX and NetX Duo Telnet Server module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX and NetX Duo Telnet Server Module

ISDE Property	Value	Description
Internal thread priority	16	Internal thread priority selection
Maximum clients to serve simultaneously	4	Maximum clients to serve simultaneously selection
Socket window size (bytes)	2048	Socket window size (bytes) selection
Server time out (seconds)	10	Server time out (seconds) selection
Client inactivity timeout (seconds)	600	Client inactivity timeout (seconds) selection
Timeout check period (seconds)	60	Timeout check period (seconds) selection
Option negotiation	Enable, Disable Default: Enable	Option negotiation selection
Use application packet pool	Enable, Disable Default: Disable	Use application packet pool selection

Packet size in the pool (bytes)	300	Packet size in the pool (bytes) selection
Total packet pool size (bytes)	2048	Total packet pool size (bytes) selection
Name	g_telnet_server0	Name selection
Internal thread stack size (bytes)	2048	Internal thread stack size (bytes) selection
Name of Client Connect Callback Function	telnet_client_connect	Name of Client Connect Callback Function selection
Name of Receive Data Callback Function	telnet_receive_data	Name of Receive Data Callback Function selection
Name of Client Disconnect Callback Function	telnet_client_disconnect	Name of Client Disconnect Callback Function selection
Name of generated initialization function	telnet_server_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different IP addresses and subnet masks. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX and NetX Duo Telnet Server Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX and NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection

Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function
Link status change callback	NULL	Link status change callback selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX and NetX Duo Telnet Common Instance

ISDE Property	Value	Description
Type of Service for UDP requests	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Type of service UDP requests selection
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragment option selection
Server TCP port number	23	Server TCP port number selection
Time to live	128	Time to live selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX and NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX and NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX and NetX Duo Telnet Server Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX and NetX Duo Telnet Server Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin Selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin

MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.30.6 Using the NetX and NetX Duo Telnet Server Module in an Application

The steps in using the NetX and NetX Duo Telnet Server module in a typical application are:

1. Use the nx_ip_status_check API to check that the IP instance can communicate.

2. Configure the Telnet Server to do option negotiation [optional].

3. If options negotiation is enabled, configure the Telnet Server to create its own packet pool (default) or set the Telnet Server pool from the application.

4. Start the Telnet Server using the nx_telnet_server_start API.

5. Process client requests with the callbacks specified at build time.

6. Delete the Telnet Server when done.

7. If the Telnet Server packet pool was created by the application, it can be deleted if not in use by other threads.

The NetX Telnet Server module application needs to execute response processing in the registered callback function. Typically, in callback processing, the content of the received packet is confirmed and data content is transmitted with the nx_telnet_server_packet_send API. When disconnection of communication is required from the server side, call the nx_telnet_server_disconnect API.

The following figure illustrates common steps in a typical operational flow diagram:

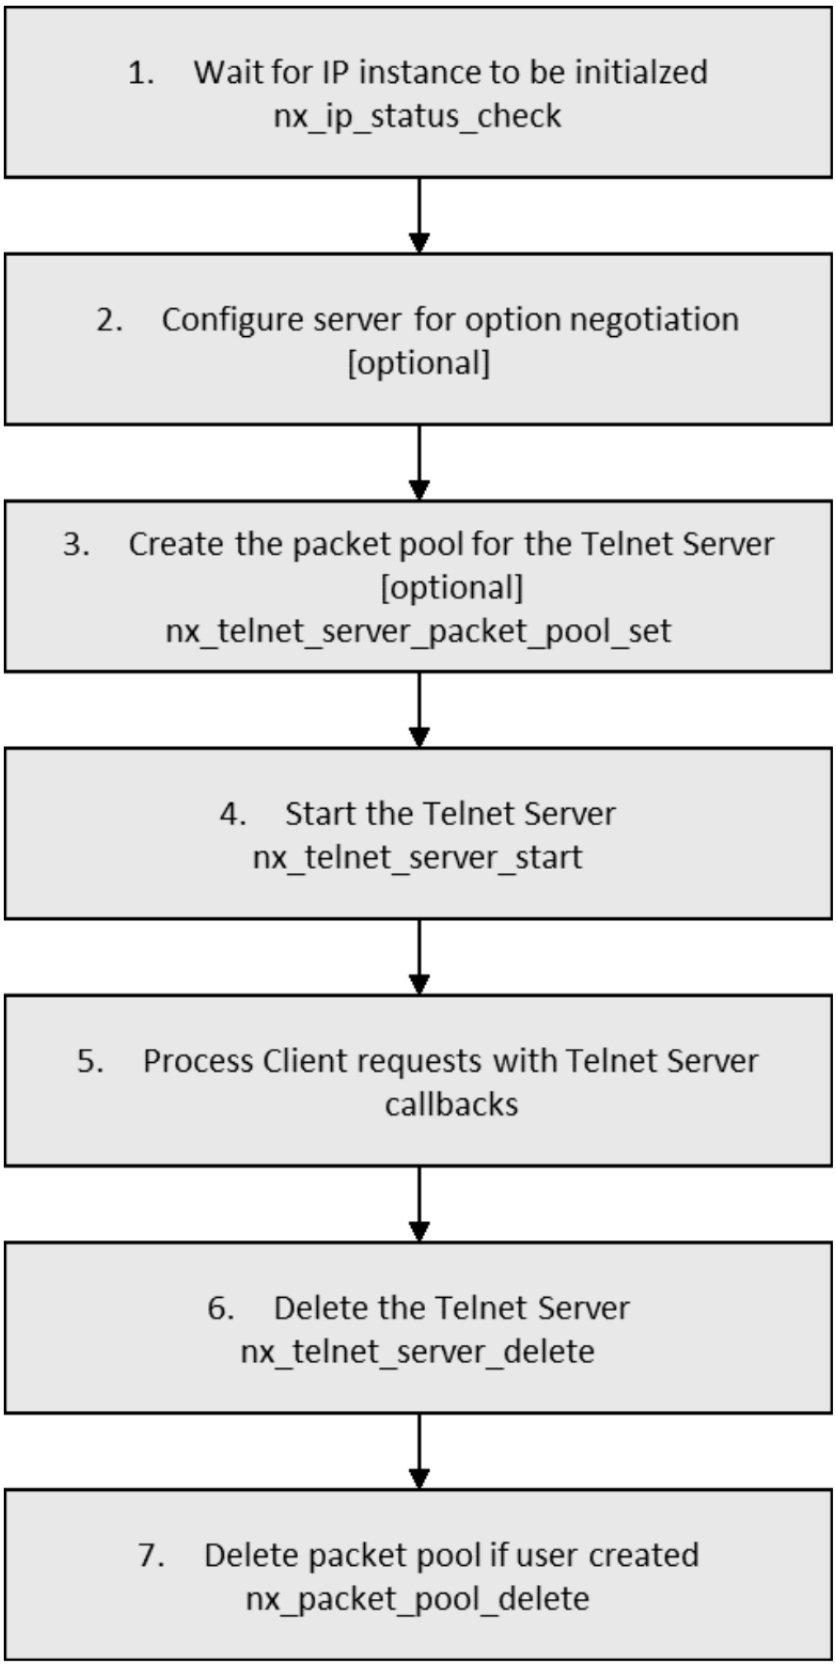

Figure 494: Flow Diagram of a Typical NetX and NetX Duo Telnet Server Module Application

4.3.31 NetX/NetX Duo TFTP Client

4.3.31.1 NetX/NetX Duo TFTP Client Introduction

The Trivial File Transfer Protocol (TFTP) is a lightweight protocol designed for file transfers over UDP. Unlike more robust TCP based protocols, TFTP does not perform extensive error checking and can have limited performance because it is a stop-and-wait protocol. After a TFTP data packet is sent, the sender waits for an ACK to be returned by the recipient. Although this is simple, it does limit the overall TFTP throughput. The TFTP Server utilizes the well-known UDP port 69 to listen for client requests. TFTP Clients may use any available UDP port. Data packets are 512 bytes, until the last packet. A packet containing fewer than 512 bytes signals the end of file.

Note

Except where noted, the NetX Duo TFT Client is identical in application set up and running of a TFTP session as the NetX TFTP Client. For setting up the IP instance for IPv6 in NetX Duo, please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform.

Unsupported Features

Multi-thread support has not been tested in this version of SSP.

NetX/NetX Duo TFTP Client Module Features

- The NetX TFTP Client Module is compliant with RFC 1350 and related RFCs.
- High level APIs for:
  - Creating and deleting a TFTP client
  - Reading and writing files to TFTP recipient (server)
  - Set network interface for TFTP Client to run on

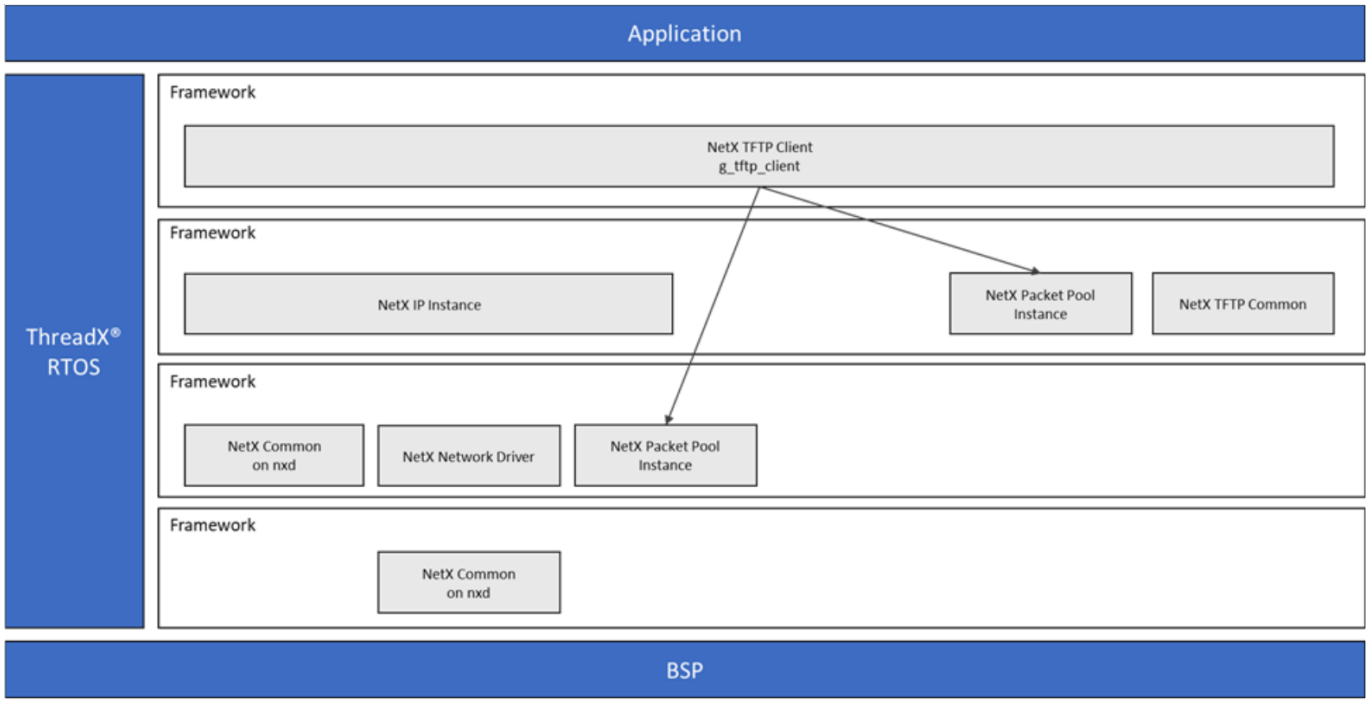

Figure 495: NetX/NetX Duo TFTP Client Module Block Diagram

Note

In the figure above, the NetX (or NetX Duo) Network Driver module has multiple implementation options available. See the description just after the module stack figure in Including the NetX/NetX Duo TFTP Client Module in an Application for additional details.

4.3.31.2 NetX/NetX Duo TFTP Client Module APIs Overview

The NetX/NetX Duo TFTP Client module defines APIs for creating and starting the TFTP Client. Internally, the TFTP Client handles all communication with the TFTP Server to transfer files. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX/NetX Duo TFTP Client Module API Summary

Function Name	Example API Call and Description
nx_tftp_client_file_open	nx_tftp_client_file_open(&g_tftp_client0, "test.txt", server_ip_address, NX_TFTP_OPEN_FOR_READ, NX_WAIT_FOREVER); Open TFTP client file (IPv4 only).
nxd_tftp_client_file_open**	nxd_tftp_client_file_open(&g_tftp_client0, "test.txt", &server_ip_address_v6, NX_TFTP_OPEN_FOR_READ, NX_WAIT_FOREVER, NX_IP_VERSION_V6); Open TFTP client file. Can be IPv4 type or IPv6
nx_tftp_client_create	nx_tftp_client_create(&g_tftp_client0, "TFTP Client", &g_ip0, &g_packet_pool0); Create a TFTP client instance
nxd_tftp_client_create**	nx_tftp_client_create(&g_tftp_client0, "g_tftp_client0 TFTP Client", &g_ip0, &g_packet_pool0, NX_IP_VERSION_V6); Create a TFTP client instance.
nx_tftp_client_delete	nx_tftp_client_delete(&g_tftp_client0); Delete a TFTP client instance.
nxd_tftp_client_delete**	nxd_tftp_client_delete(&g_tftp_client0); Delete a TFTP client instance.
nx_tftp_client_error_info_get	nx_tftp_client_error_info_get(&g_tftp_client0, &error_code, &error_string); Get client error information.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo TFTP Client. For definitions of NetX Duo specific data types, see the *NetX Duo User Guide for the Renesas Synergy™ Platform*.

Status Return Values

Name	Description

NX_SUCCESS	Successful TFTP create
NX_PTR_ERROR*	Invalid IP, pool, or TFTP pointer
NX_CALLER_ERROR *	Invalid caller of this service
NX_TFTP_NOT_CLOSED	Cannot open file; Client already has file open
NX_TFTP_CODE_ERROR	Error status received from TFTP server
NX_INVALID_TFTP_SERVER_ADDRESS	Invalid server address received
NX_TFTP_FAILED	Unknown code received from Server
NX_TFTP_NO_ACK_RECEIVED	No ACK received from server on read or write
NX_TFTP_INVALID_BLOCK_NUMBER	Block of data in TFTP server ACK does not match TFTP Client after read or write request.
NX_TFTP_NOT_OPEN	TFTP client not in the open state for file read or write
NX_IP_ADDRESS_ERROR*	Invalid Server IP address
NX_OPTION_ERROR*	Invalid open type
NX_INVALID_TFTP_SERVER_ADDRESS	Invalid server address received
NX_TFTP_END_OF_FILE	End of file detected (not an error) during file download (read) transfer
NX_TFTP_TIMEOUT	Timeout waiting for Server ACK of write request
NX_TFTP_INVALID_INTERFACE*	Invalid interface input

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

*These error codes are only returned if error checking is enabled. Please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform for more details on error checking services in NetX Duo.

4.3.31.3 NetX/NetX Duo TFTP Client Module Operational Overview

In the NetX/NetX Duo TFTP Client module, the client is automatically created and the UDP socket is created for sending and receiving TFTP packets. In a TFTP Client application, the TFTP Client first 'opens' a file. If the Server returns an acknowledgment, the Client can then request a file transfer for either reading (receiving from) or writing (sending to) the TFTP Server. After each file transfer the TFTP Client closes the file.

A TFTP Server listens for Client requests on the well-known port 69. The TFTP Client socket can bind to any port. When transferring a file in TFTP, the amount of data that added to a packet can only be 512 bytes, unless there is less than 512 bytes left to send. A packet containing fewer than 512 bytes signals the end of file. The general sequence of events is as follows:

TFTP Read File Requests:

1. Client issues an "Open for Read" request with the file name and waits for the Server response.
2. Server sends the first 512 bytes of the file as 'block number 1'

3. Client receives the data, sends an ACK specifying block number is '1' , and waits for the next packet.
4. The Server sends the rest of the data incrementing the block number each time, and the Client ACKs sends an ACK with the corresponding block number each time.
5. The sequence ends when the last packet containing fewer than 512 bytes is received. nx_tftp_client_file_read returns NX_TFTP_END_OF_FILE when the last packet of a file transfer is received.

TFTP Write Requests:

1. Client issues an "Open for Write" request with the file name and waits for an ACK with a block number of 0 from the Server.
2. The Server sends an ACK with a block number of zero.
3. Client sends the first 512 bytes of the file to the Server and waits for an ACK.
4. Server sends ACK after the bytes are written.
5. The sequence ends when the Client completes sends a packet containing fewer than 512 bytes.

NetX/NetX Duo TFTP Client Module Important Operational Notes and Limitations

NetX/NetX Duo TFTP Client Module Operational Notes

- If nx_tftp_client_file_read returns NX_SUCCESS, the caller must release the packet after it is done with it.
- If nx_tftp_client_file_write returns NX_TFTP_NOT_OPEN, the caller must release the packet. In all other cases NetX or NetX TFTP Client Module will release the packet.
- For file data, any data can be used. The NetX TFTP Client Module does not make any changes to send or receive data.
- The NetX TFTP Client Module is compliant with RFC 1350 and related RFCs.

NetX/NetX Duo TFTP Client Module Limitations

- The line feed code of the text file cannot be changed; this must be processed by the user application.
- The NetX TFTP Client Module services can be called from multiple threads simultaneously. However, read or write requests for a particular client instance should be done in sequence from the same thread.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.31.4 Including the NetX/NetX Duo TFTP Client Module in an Application

This section describes how to include either or both the NetX and NetX Duo TFTP Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo TFTP Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX/NetX Duo TFTP Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_tftp0 NetXTFTP Client	Threads	New Stack> X-Ware> NetX> Protocols> NetXTFTP Client
g_tftp0 NetX Duo TFTP Client	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo TFTP Client

When the NetX and/or NetX Duo TFTP Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

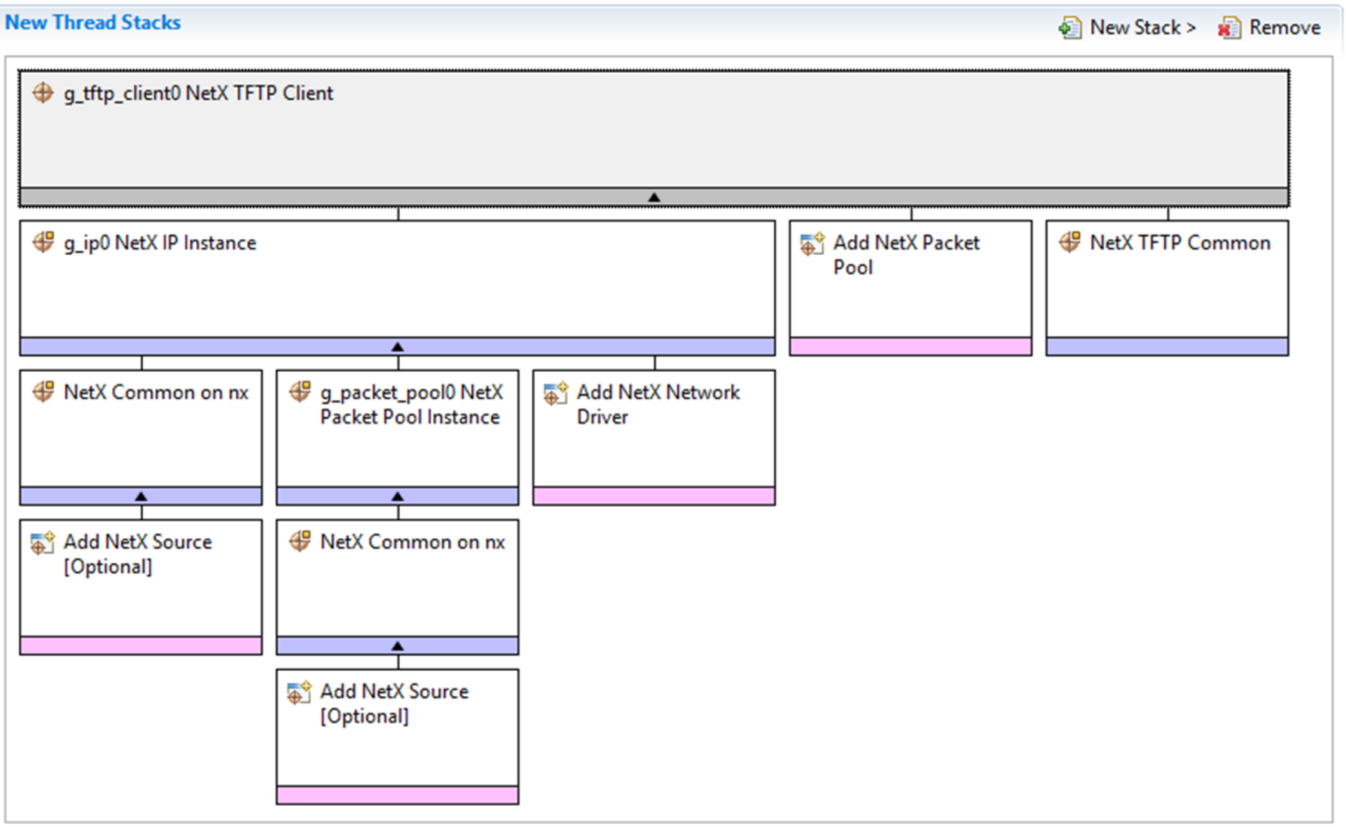

Figure 496: NetX/NetX Duo TFTP Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx

- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.31.5 Configuring the NetX/NetX Duo TFTP Client Module

The NetX/NetX Duo TFTP Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX/NetX Duo TFTP Client Module

ISDE Property	Value	Description
Source port to use	NX_ANY_PORT	Source port to use selection
Name	g_tftp_client0	Module name
Name of generated initialization function	tftp_client_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different pins for the Ethernet peripheral. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX/NetX Duo TFTP Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection

Auto Initialization	Enable, Disable Default: Enable	Auto initialization function
Link status change callback	NULL	Link status change callback selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX/NetX Duo TFTP Common Instance

ISDE Property	Value	Description
Maximum error string length (bytes)	64	Maximum error string length selection
Time to live	128	Time to live selection
Type of Service for UDP requests	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Type of service UDP requests selection
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragment option selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name

Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX/NetX Duo TFTP Client Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX/NetX Duo TFTP Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin Selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin

TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.31.6 Using the NetX/NetX Duo TFTP Client Module in an Application

The following example assumes that a system is already establish with a working IP, ARP and UDP enabled and the link is running.

The steps in using the NetX/NetX Duo TFTP Client module in a typical application are:

1. Poll the nx_ip_status_check API for when the IP instance has a valid IP address.

2. To request a file write, call the nx_tftp_client_file_open API with NX_TFTP_OPEN_FOR_WRITE as the open_type input.

3. Allocate a packet using the nx_tftp_client_packet_allocate API and write the file data into the packet buffer. This packet is ready to send.

4. Send to the Server by calling the nx_tftp_client_file_write API.

5. Repeat until all file data is sent. Unless this API returns NX_TFTP_NOT_OPEN, the application should not release the packet.

6. Close the file by calling the nx_tftp_client_file_close.

7. To request a file read, call the nx_tftp_client_file_open API with NX_TFTP_OPEN_FOR_READ as the open_type input.

8. Receive file data by calling the nx_tftp_client_file_read API.

9. Continue until a packet of less than 512 bytes is received. Release the packets back to the packet pool when done with it.

10. Use the nx_tftp_client_file_close API to close the file.

11. Delete instance by nx_tftp_client_delete API when done with the TFTP Client.

The following figure illustrates common steps in a typical operational flow diagram:

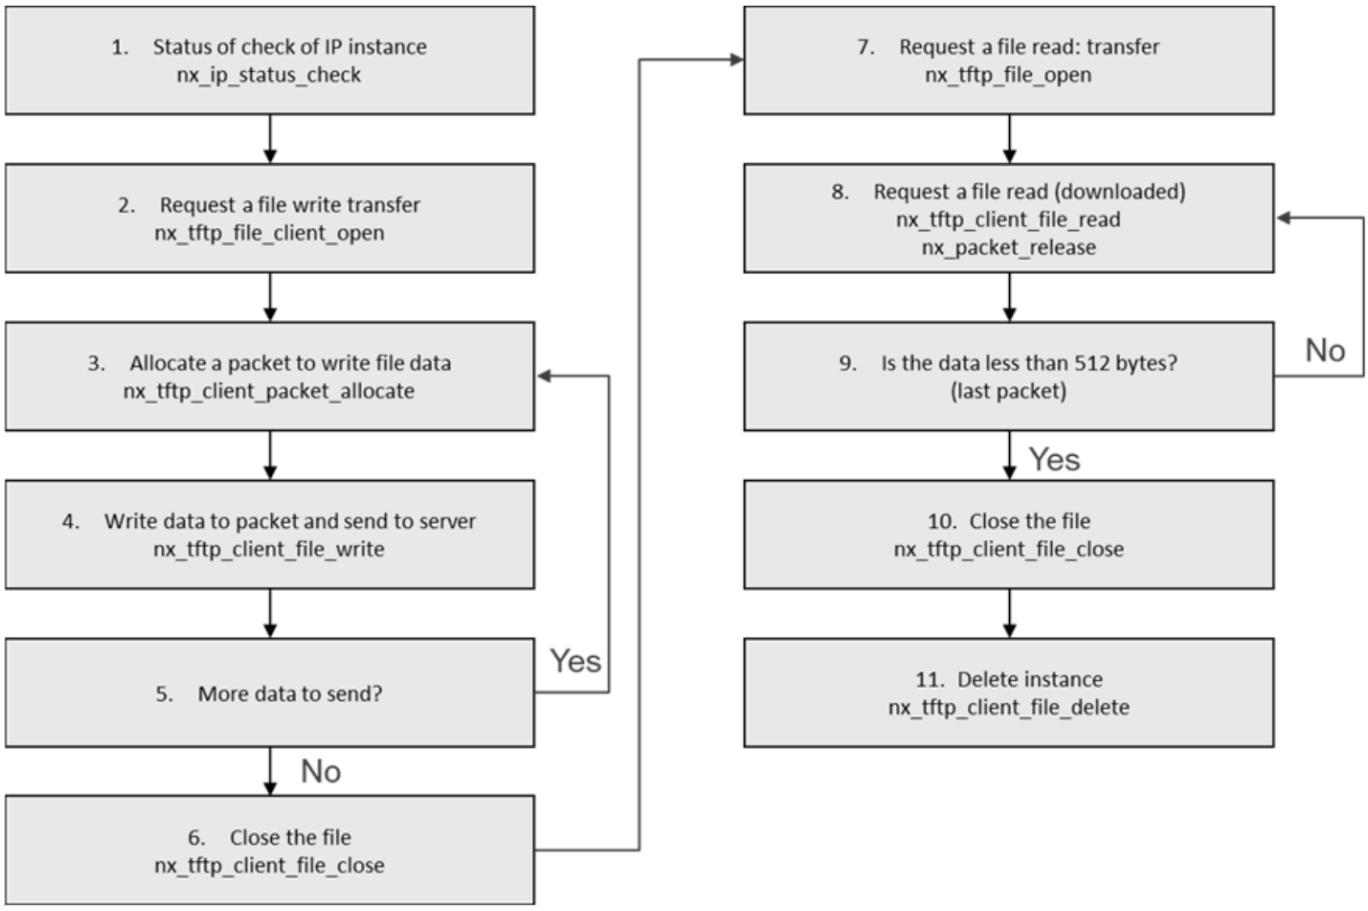

Figure 497: Flow Diagram of a Typical NetX/NetX Duo TFTP Client Module Application

4.3.32 NetX/NetX Duo TFTP Server

4.3.32.1 NetX and NetX Duo TFTP Server Introduction

The NetX™ Trivial File Transfer Protocol (TFTP) is a lightweight protocol designed for file transfers. Unlike more robust protocols, TFTP does not perform extensive error-checking and can have limited performance due to its stop-and-wait protocol. After a TFTP data packet is sent, the sender waits for an ACK to be returned by the recipient. Although this process is simple, it does limit the overall TFTP throughput. The TFTP package enables hosts to use the TFTP protocol over IP networks.

Note

Except for internal processing, the NetX Duo™ TFTP Server is identical to the NetX TFTP when performing the application, setup and running of a TFTP session.

NetX and NetX Duo TFTP Server Module Features

- NetX Server TFTP module is compliant with RFC 1350 and related RFCs.
- Provides high-level APIs for:
  - Creating and deleting a TFTP Server
  - Starting and stopping the TFTP Server task thread

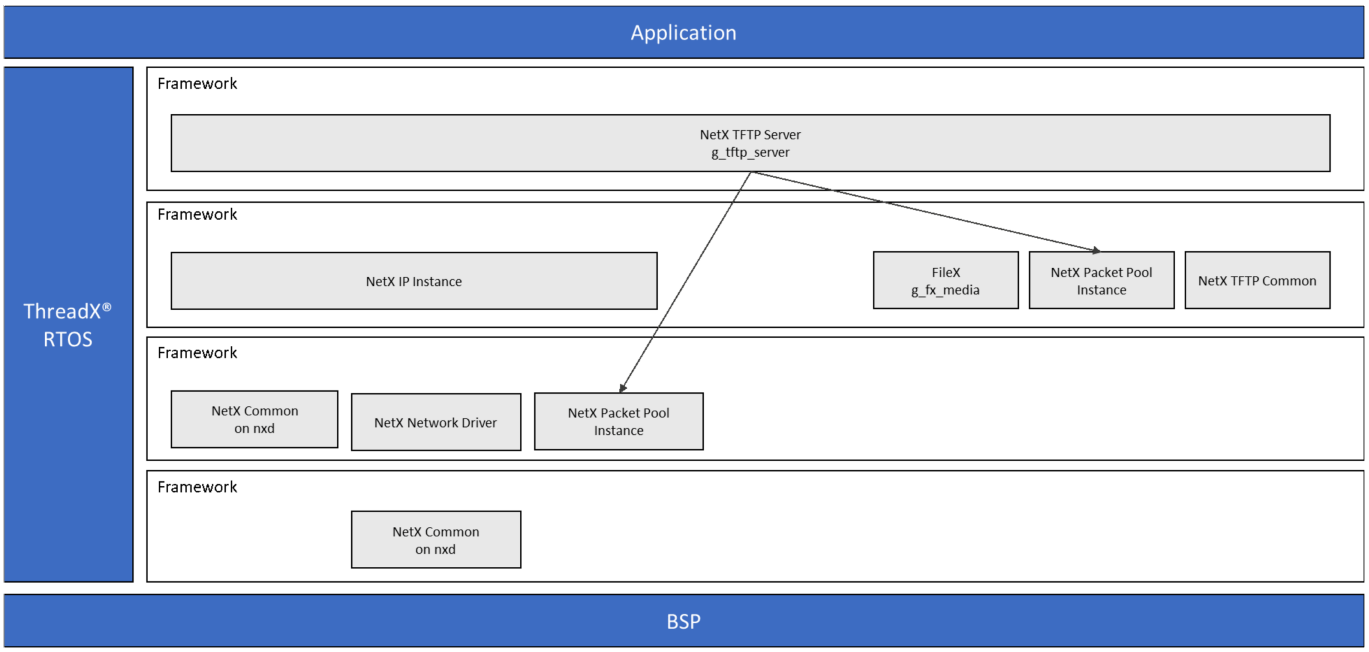

Figure 498: NetX/NetX Duo TFTP Server Module Block Diagram

Note

In the figure above, the FileX and NetX (or NetX Duo) Network Driver modules have multiple implementation options available. See the descriptions just after the module stack figure in Including the NetX and NetX Duo TFTP Server Module in an Application for additional details.

4.3.32.2 NetX and NetX Duo TFTP Server Module APIs Overview

The NetX TFTP Server module defines APIs for creating, deleting, generating response packets, response sending and getting information from a received packet. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX and NetX Duo TFTP Server Module API Summary

Function Name	Example API Call and Description
nx_tftp_server_create	nx_tftp_server_create(&my_server, "My TFTP Server", server_ip, &ram_disk, stack_ptr, 2048, pool_ptr); Create TFTP server (IPv4 only)
nxd_tftp_server_create**	nxd_tftp_server_create(&my_server, "My TFTP Server", &server_ip, &ram_disk, stack_ptr, 2048, pool_ptr); Create TFTP server (IPv4 and IPv6 supported).
nx_tftp_server_delete	nx_tftp_server_delete(&my_server); Delete TFTP server.
nxd_tftp_server_delete**	nxd_tftp_server_delete(&my_server); Delete TFTP server.

nx_tftp_server_start	nx_tftp_server_start(&my_server); Start the TFTP server.
nxd_tftp_server_start**	nxd_tftp_server_start(&my_server); Start the TFTP server.
nx_tftp_server_stop	nx_tftp_server_stop(&my_server); Stop the TFTP server.
nxd_tftp_server_stop**	nxd_tftp_server_stop(&my_server); Stop the TFTP server.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the associated Azure RTOS User's Manual in the References section.

**This API is only available in NetX Duo TFTP Server. For definitions of of NetX Duo specific data types, see the *NetX Duo User Guide for the Renesas Synergy™ Platform*.

Status Return Values

Name	Description
NX_SUCCESS	API Call Successful
NX_TFTP_POOL_ERROR*	Packet pool payload is too small for the 512 bytes of TFTP data.
NX_PTR_ERROR*	Invalid pointer input
NX_CALLER_ERROR*	Invalid caller of this service

Note

Lower-level drivers may return common error codes. See SSP User's Manual API References for the associated module for a definition of all relevant status return values.

*These error codes are only returned if error checking is enabled. Please refer to the NetX Duo User Guide for the Renesas Synergy™ Platform for more details on error checking services in NetX Duo.

4.3.32.3 NetX and NetX Duo TFTP Server Module Operational Overview

To function properly, the TFTP Clients portion of the NetX Duo TFTP package requires an already-created IP instance.

Note

When a TFTP Server instance is added to the project, an IP Instance for the TFTP Server with an ARP and TCP enabled is automatically created.

The UDP must be enabled on that same IP instance. The client portion of the NetX Duo TFTP package has no further requirements.

The TFTP Server portion of the NetX TFTP package requires complete access to the UDP port 69 for handling all client TFTP requests; the TFTP Server is also designed for use with the FileX® embedded file system. If FileX is not available, the user may port portions of the FileX used to their own environment (details in later module guide sections).

File names should be in the format of the target file system. Filenames should be NULL terminated ASCII strings, with full path information, if necessary. There is no specified limit in the size of TFTP file names in the NetX Server TFTP implementation.

TFTP Messages

The TFTP has a simple mechanism for opening, reading, writing and closing files, with 2-4 bytes of the TFTP header underneath the UDP header. The definition of the TFTP file open messages has the following format:

A	B	C	D	Fstart	Fend	0		O	C	T	E	T	0

Where,

File Open protocol field

A	B	C	D	2 Byte Opcode field
0	0	0	1	Open for read
0	0	0	2	Open for write

F_{start} - F_{end}, File name

0, 1-byte NULL termination character.

OCTET, ASCII "OCTET" to specify binary transfer

The definition of the TFTP write, ACK and error messages are slightly different:

| A | B | C | D | W | X | Y | Z | Nstart | Nend | |---|---|---|---|---|---|---|---|---|---|---|

Where,

Protocol field for TFTP write

A	B	C	D	2 Byte Opcode field
0	0	0	3	Data packet
0	0	0	4	ACK for last read
0	0	0	5	Error condition

$\mathbf{N_{start}}$ - $\mathbf{N_{end}}$,, n-byte Data field

WXYZ, 2-byte Block Number field (1-n)

TFTP Communication

The data packet payload containing the file to upload or download is sent in 512 byte chunks until the last packet contains less than 512 bytes, where the packet containing fewer than 512 bytes signals the end of file. The general sequence of events is as follows:

TFTP Read File Requests:

1. The client issues an Open for Read request with the file name and waits for a reply from the server.
2. The server sends the first 512 bytes of the file or less if the file size is less than 512 bytes.
3. The client receives data, sends an ACK, and waits for the next packet from the server for files containing more than 512 bytes.
4. The sequence ends when the client receives a packet containing fewer than 512 bytes.

TFTP Write Requests:

1. The client issues an Open for Write request with the file name and waits for an ACK with a block number of 0 from the server.
2. When the server is ready to write the file, it sends an ACK with a block number of zero.
3. The client sends the first 512 bytes of the file (or less for files less than 512 bytes) to the server and waits for an ACK back.
4. The server sends an ACK after the bytes are written.
5. The sequence ends when the client completes writing a packet containing fewer than 512 bytes.

NetX and NetX Duo TFTP Server Module Important Operational Notes and Limitations

NetX and NetX Duo TFTP Server Module Operational Notes

The NetX TFTP Server module requires FileX media (Block media or USB Mass Storage). When a TFTP Server stack element is added to the project, an **Add FileX** box is attached to it. The configurator automatically sets up and initializes the FileX media for the server before the server is started. For details on configuring FileX, see the *FileX™ User's Guide* for the Renesas Synergy™ Platform.

The NetX TFTP Server also requires a packet pool for transmitting packets; it can share the IP default packet pool or create a separate packet pool. (Details on setting the TFTP Server packet pool are found in Including the NetX and NetX Duo TFTP Server Module in an Application.)

NetX and NetX Duo TFTP Server Module Limitations

- The TFTP Server maintains a TFTP Client session, even when the client stops responding, responses stop if the retransmission on client request support property is not enabled. In this manner, the TFTP Server can potentially fill up with dropped client connections and not be able to accept new client requests.
- The TFTP Server cannot respond to a duplicate client packet if retransmission on client request support property is not enabled. Duplicate packets are simply dropped and the TFTP Server does not send out any ACK or data packets, resulting in the client and the server being deadlocked.
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.32.4 Including the NetX and NetX Duo TFTP Server Module in an Application

This section describes how to include either or both the NetX and NetX Duo TFTP Server module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX/NetX Duo TFTP Server module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX and NetX Duo TFTP Server Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_tftp0 NetX TFTPServer	Threads	New Stack> X-Ware> NetX> Protocols> NetX TFTPServer
g_tftp0 NetX Duo TFTPServer	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo TFTP Server

When the NetX and/or NetX Duo TFTP Server module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

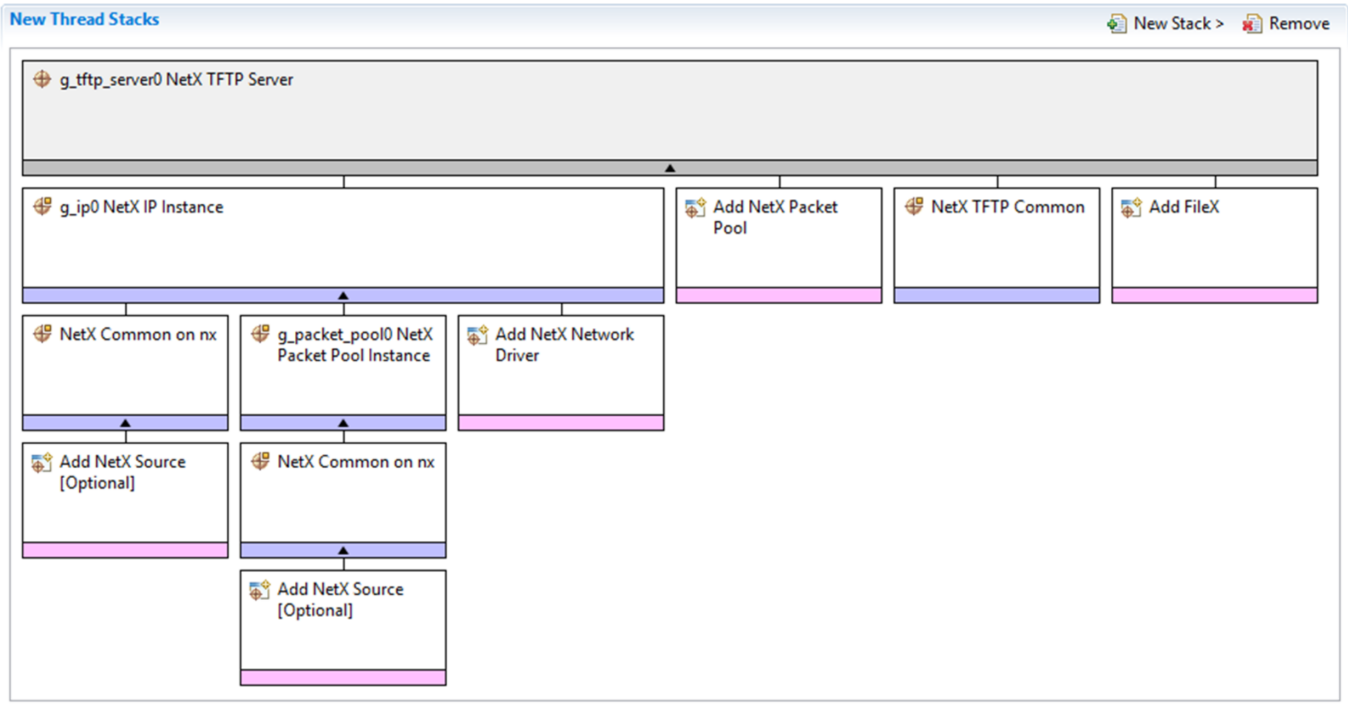

Figure 499: NetX and NetX Duo TFTP Server Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

Additionally, in the stack above, the FileX stack has also not been populated yet. There are multiple possible selections for the FileX module; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- FileX Stub
- FileX on Block Media (implemented on Block Media Framework on sf_block_media_ram)
- FileX on USB Mass Storage (implemented on USBX Host Class Mass Storage)

4.3.32.5 Configuring the NetX and NetX Duo TFTP Server Module

The NetX and NetX Duo TFTP Server module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX and NetX Duo TFTP Server Module

ISDE Property	Value	Description
FileX Support	Enable, Disable Default: Enable	FileX support selection
Retransmission on client request support	Enable, Disable Default: Disable	Retransmission on client request support selection
Internal thread priority	16	Internal thread priority selection
Maximum clients to serve simultaneously	10	Maximum clients to serve simultaneously selection
Time slice for internal thread	2	Time slice for internal thread selection
Client request activity timeout check interval (ticks)	20	Client request activity timeout (ticks) selection

Ack or data retransmission interval (ticks)	200	Ack or data retransmission interval (ticks) selection
Maximum retries for transmission without response	5	Maximum retries for transmission without response selection
Maximum retries for transmission with duplicate response	2	Maximum retries for transmission with duplicate response selection
Name	g_tftp_server0	Module name
Internal thread stack size (bytes)	2048	Internal thread stack size (bytes) selection
Name of generated initialization function	tftp_server_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select different MAC Addresses. The configurable properties for the lower-level stack modules are provided in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX and NetX Duo TFTP Server Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX and NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	192,168,0,2	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
Default Gateway Address (use commas for separation)	0,0,0,0	Default gateway address selection

**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization function
Link status change callback	NULL	Link status change callback selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings for the NetX and NetX Duo TFTP Common Instance

ISDE Property	Value	Description
Maximum error string length (bytes)	64	Maximum error string length selection
Time to live	128	Time to live selection
Type of Service for UDP requests	Normal, Minimum delay, Maximum data, Maximum reliabililty, Minimum cost Default: Normal	Type of service UDP requests selection
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragment option selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX and NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX and NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX and NetX Duo TFTP Server Module Clock Configuration

The ETHERC peripheral module uses the PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator Clock tab prior to a build or by using the CGC interface at run-time.

NetX and NetX Duo TFTP Server Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin Selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.32.6 Using the NetX and NetX Duo TFTP Server Module in an Application

The steps in using the NetX and NetX Duo TFTP Server module in a typical application are:

1. Create the TFTP server using the nx_tftp_server_create API.

2. Prepare the FileX on Block media or USB mass storage API.

3. Start the TFTP Server using the nx_tftp_server_start API.

4. The TFTP Server now periodically checks for inactivity on active client connections.

5. All received packets are checked for being duplicate packets the server already received.

6. Receive a client open for read request (internal operation).

7. Check if the server can accommodate another client request (set by Maximum clients to server simultaneously property) (internal operation).

8. Download packets of file data in 512 chunks till the last packet (internal operation).

9. Close a file and delete the client request (internal operation).

The following figure illustrates common steps in a typical operational flow diagram:

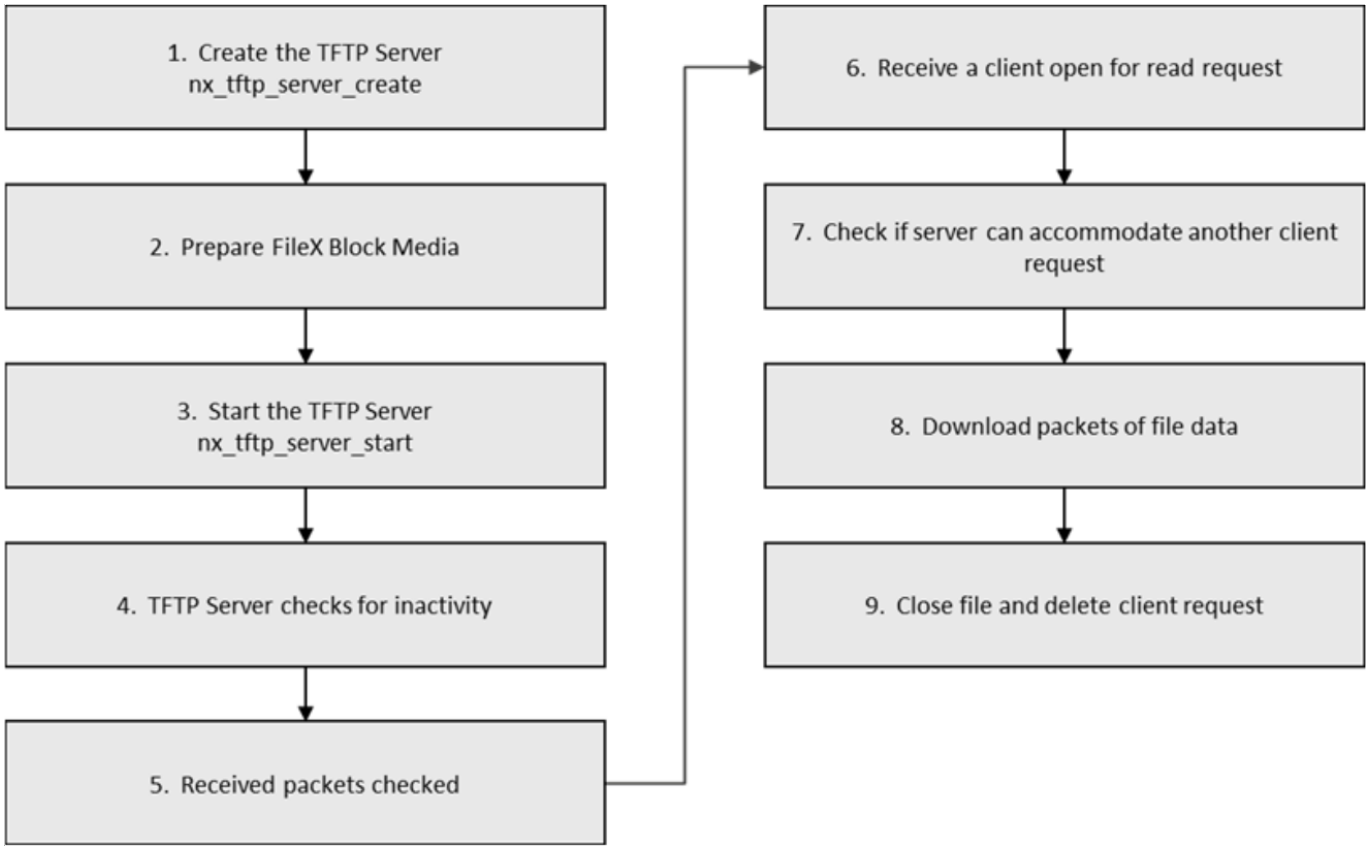

Figure 500: Flow Diagram of a Typical NetX and NetX Duo TFTP Server Module Application

4.3.33 NetX Duo MQTT Client

4.3.33.1 NetX Duo MQTT Client Introduction

The MQTT (Message Queue Telemetry Transport) is a communication protocol based on a publisher/subscriber model. A data producer can publish information to other clients through a broker. Multiple data consumers, if interested in a topic, can subscribe to the topic through the broker. The broker is responsible for authentication and authorization of the clients and delivering published messages to its topic subscribers. In this publisher/subscriber model, multiple clients may publish data with the same topic. A client will receive the messages it publishes if the client subscribes to the same topic.

NetX Duo MQTT Client Module Features

- Compliant with OASIS MQTT Version 3.1.1 Oct 29th, 2014. The specification can be found at: http://mqtt.org/
- Provides option to enable/disable TLS for secure communications using NetX Secure in SSP
- Supports QoS and provides the ability to choose the levels that can be selected while publishing the message
- Internally buffers and maintains queue of received messages
- Provides mechanism to register callback when new message is received.
- Provides mechanism to register callback when connection with the broker is terminated.

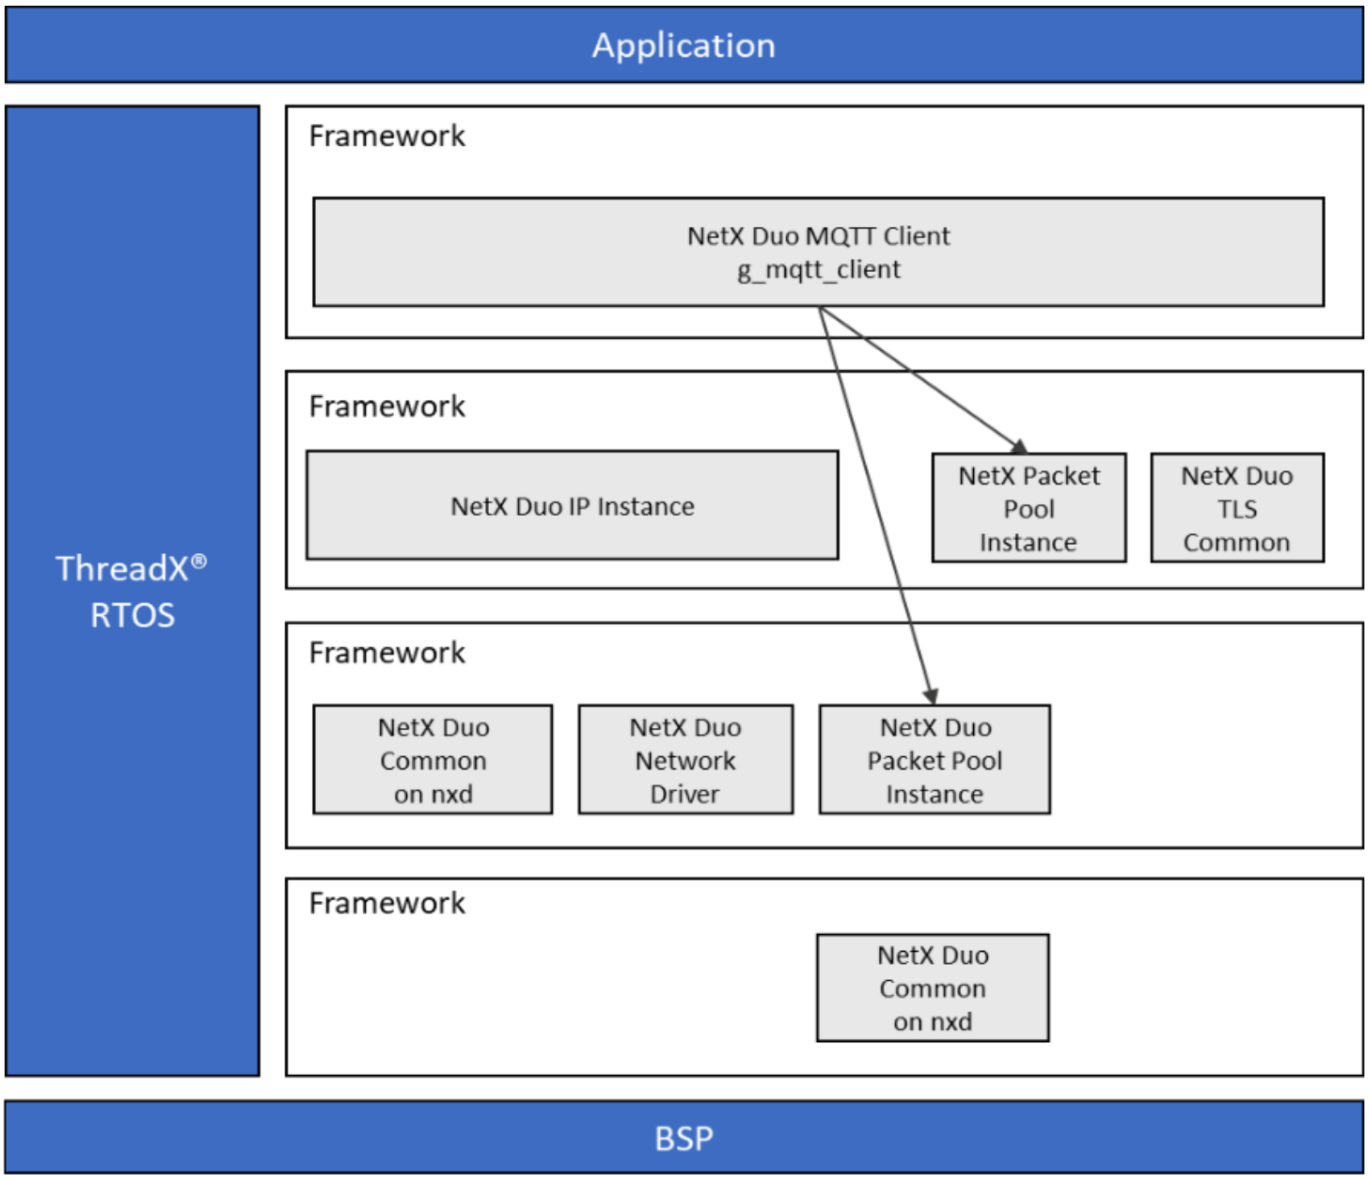

Figure 501: NetX Duo MQTT Client Module Block Diagram

Note

In the figure above, the NetX Duo Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX Duo MQTT Client Module in an Application for additional details.

4.3.33.2 NetX Duo MQTT Client Module APIs Overview

The NetX Duo MQTT Client Support module defines APIs for creating the MQTT Client, connecting to a broker, setting up TLS security and receiving MQTT messages. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX Duo MQTT Client Module API Summary

Function Name	Example API Call and Description

nxd_mqtt_client_create	nxd_mqtt_client_create(&mqtt_client_secure, "my_client", CLIENT_ID_STRING, strlen(CLIENT_ID_STRING), ip_ptr, pool_ptr, (VOID*)mqtt_client_stack, sizeof(mqtt_client_stack), mqtt_thread_priority, (UCHAR*)client_memory, sizeof(client_memory)); Create an MQTT client with the specified Client ID, stack memory and stack size, and message block memory.
nxd_mqtt_client_connect	nxd_mqtt_client_connect(&mqtt_client, &server_ip, NXD_MQTT_PORT, MQTT_KEEP_ALIVE_TIMER, 0, NX_WAIT_FOREVER) Non-secure connect to the MQTT broker specifying broker IP address and port, keep alive timer, and disabling the clean session option
nxd_mqtt_client_secure_connect	nxd_mqtt_client_secure_connect(&mqtt_client_secure, &server_ip, NXD_MQTT_TLS_PORT, tls_setup_amazon, 600, 1, NX_WAIT_FOREVER) Connect to broker with TLS security using the tls_setup_amazon, which is a user-defined function, to set up TLS and set TLS parameters. The clean session option is enabled. This is only available if the NetX Duo library is built with NX_SECURE_ENABLE set, and if the MQTT client property NX Secure is set.
nxd_mqtt_client_login_set	nxd_mqtt_client_login_set(mqtt_client_ptr, "Username", strlen("Username"), "Password", strlen("Password"); Set the optional MQTT username and password. This must be called before the nxd_mqtt_client_connect or nxd_mqtt_client_secure_connect call if the broker requires username and password.
nxd_mqtt_client_message_get	nxd_mqtt_client_message_get(&mqtt_client_secure, &topic, &topic_length, &message, &message_length, &packet_ptr); Retreive a published MQTT message for the specified topic.
nxd_mqtt_client_receive_notify_set	nxd_mqtt_client_receive_notify_set(&mqtt_client_secure, my_notify_func); Specify the function the MQTT Client thread task calls when an MQTT message is received.
nxd_mqtt_client_subscribe	nxd_mqtt_client_subscribe(&mqtt_client_secure, TEST_SUBSCRIBE_TOPIC_NAME, strlen(TEST_SUBSCRIBE_TOPIC_NAME), 0); Send a subscriber message to the broker for the specified topic for QoS (quality of service) level 0.

nxd_mqtt_client_unsubscribe	nxd_mqtt_client_unsubscribe(NXD_MQTT_CLIENT *mqtt_client_pr,CHAR *topic_name, UINT topic_name_length); Send an unsubscriber message to the broker for the specified topic.
nxd_mqtt_client_publish	nxd_mqtt_client_publish(&mqtt_client_secure, TEST_SUBSCRIBE_TOPIC_NAME, strlen(TEST_SUBSCRIBE_TOPIC_NAME), message_buffer, strlen(message_buffer), 0, 1, NX_WAIT_FOREVER); Send a message to the broker for the specified topic previously subscribed to for QoS (quality of service) level 1, and the retain message option disabled.
nxd_mqtt_client_disconnect	nxd_mqtt_client_disconnect(&mqtt_client); Disconnect from the MQTT broker.
nxd_mqtt_client_disconnect_notify_set	nxd_mqtt_client_disconnect_notify_set(mqtt_client_ptr, my_disconnect_notify); Specify the user defined function for the MQTT Client thread task to call if the broker initiates disconnecting from the client.
nxd_mqtt_client_delete	nxd_mqtt_client_delete(mqtt_client_ptr); Delete the MQTT instance, clear transmit and message queue messages
nxd_mqtt_client_will_message_set	nxd_mqtt_client_will_message_set(mqtt_client_ptr, will_topic, will_topic_length, "will_message", strlen("will_message"), 0, 1); Set the optional MQTT Client will message without the retain will message option, for QOS 1. If a will message is needed, this must be called before connecting to the broker.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section. Refer to the Azure RTOS NetX Duo MQTT Client User's Manual for additional information on MQTT Client Module API functions.

4.3.33.3 NetX Duo MQTT Client Module Operational Overview

The MQTT (Message Queue Telemetry Transport) is a protocol based on the NetX Duo TCP/IP stack and a publisher-subscriber model. A client can publish information to other clients through an MQTT Server (broker). A client, if interested in a topic, can subscribe to the topic through the broker. A broker is responsible for delivering published messages to its clients who subscribe to the topic. In this publisher-subscriber model, multiple clients may publish data with the same topic. A client will receive a message it publishes if the client subscribes to the same topic.

The following figure provides an overview of the MQTT Client publish/subscribe model:

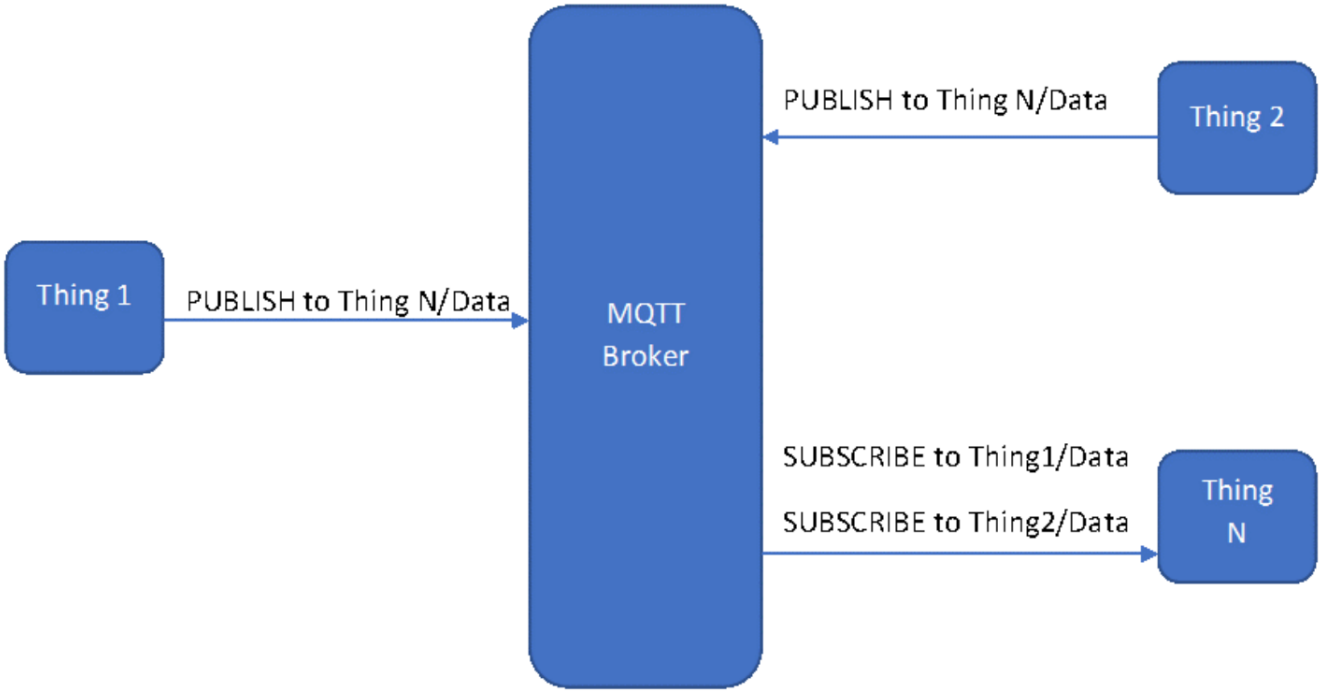

Figure 502: NetX Duo MQTT Client Module MQTT Client Publish/Subscribe Model

NetX Duo MQTT Client Module Publish/Subscribe Model

The NetX Duo MQTT client module can be used in the normal mode or the secure mode.

NetX Duo MQTT Client Module Normal Mode Operational Description

In normal mode, the communication between the MQTT client and broker is not secure.

NetX Duo MQTT Client Module Secure Mode Operational Description

In Secure mode, the communication between the MQTT client and broker is secured using the TLS protocol. In the thread pane, the TLS protocol is represented by "Add NetX Duo TLS common [Optional]" block.

Depending on the use case, a client may choose one of the 3 QoS levels when publishing a message:

QoS 0: The message is delivered at most once. Messages sent with QoS 0 may be lost.

QoS 1: The message is delivered at least once. Messages sent with QoS 1 may be delivered more than once.

QoS 2: The message is delivered exactly once. Messages sent with QoS 2 is guaranteed to be delivered, with no duplication.

Note

This implementation of MQTT client does not support QoS level 2 messages.

Since QoS 1 and QoS 2 are guaranteed to be delivered, the broker keeps track the state of QoS 1 and QoS 2 messages sent to each client. This is particularly important for clients that expect QoS1 or QoS 2 messages. The client may be disconnected from the broker (for example when the client reboots, or the communication link is temporarily lost). The broker must store QoS 1 and QoS 2 messages so the messages can be delivered later once the client is reconnected to the broker.

However, the client may choose not to receive any stale messages from the broker after reconnection. The client can do so by initiating the connection with the clean_session flag set to NX_TRUE (1) in the nxd_mqtt_client_connect API. In this case, upon receiving the MQTT CONNECT message, the broker shall discard any session information associated with this client, including undelivered or unconfirmed QoS 1 or QoS 2 messages.

If the clean_session flag is to NX_FALSE, the server shall resend the QoS 1 and QoS 2 messages. The MQTT Client also resends any un-acknowledged messages if clean_session is set to NX_TRUE. This acknowledgment is different from the TCP socket layer ACK, although that happens as well. The MQTT client sends an MQTT acknowledgment message to the broker upon receipt of a message, and gets one back when it publishes a message.

Incoming MQTT messages are stored in the receive queue of the MQTT client instance. The application retrieves these messages by calling the nxd_mqtt_client_message_get API which returns both the topic and the topic message. The application must ensure to provide a large enough buffer for each. The oldest message in the queue is returned to the caller first. The nxd_mqtt_client_message_get is non-blocking. If the MQTT client receive queue is empty, it returns immediately with an NXD_MQTT_NO_MESSAGE (0x1000A) status. This should not be handled as an error, but that the receive queue is empty.

To avoid polling the receive queue for incoming messages, the application can register a receive message callback function with the MQTT client by calling the nxd_mqtt_client_recieve_notify_set API. The callback function is defined as:

VOID (*receive_notify_callback)(NXD_MQTT_CLIENT *client_ptr, UINT message_count);

As the MQTT client receives messages from the broker, it invokes the callback function if the function is set. The callback function passes the pointer to the client control block and a message count value. The message count value indicates the number of MQTT messages in the receive queue. Note that this callback function executes in the MQTT client thread context. Therefore, the callback function should not execute any procedures that may block the MQTT client thread. The callback function should trigger the application thread to call the nxd_mqtt_client_message_get API to retrieve the messages. This is demonstrated in the module guide project.

To disconnect the MQTT client service, the application shall use the service nxd_mqtt_client_disconnect and nxd_mqtt_client_delete, APIs respectively. Calling nxd_mqtt_client_disconnect disconnects the TCP connection to the broker. It releases messages already received and stored in the receive queue. However, it does not release QoS level 1 messages in the transmit queue. QoS level 1 messages are retransmitted upon connection, assuming the clean_session flag is set to NX_FALSE.

The broker may initiate the disconnect from the client. The application can be notified of the disconnect request by registering a disconnect notify function with the MQTT Client. This is done by calling the nxd_mqtt_client_disconnect_notify_set API.

To delete an MQTT Client, call the nxd_mqtt_client_delete API. This releases all message blocks in the transmit queue and the receive queue. Unacknowledged QoS level 1 messages are also deleted.

Using Secure Communication

To secure the communication between MQTT client and broker, TLS protocol is required. In the thread pane, TLS protocol is represented by "Add NetX Duo TLS common \[Optional]" block. Adding NetX Duo TLS Common block enables the TLS support.

MQTT with TLS/NetX Duo Secure

When using TLS with MQTT Client, it is strongly recommended that the TLS setup callback in the nxd_mqtt_client_secure_connect call contain all of the TLS set up, including creating the TLS instance, defining the local certificates, allocating memory for remote certificate processing, and optional callbacks such as timestamp and certificate authentication. Once the callback has completed its operation successfully it should return Success. If the TLS setup callback returns a failure, the nxd_mqtt_client_secure_connect API also returns a failure to the application program.

Regardless if the MQTT Client was able to connect via TCP successfully or not, or whether the TLS session was successfully started, the application MUST call nxd_mqtt_client_disconnect to properly clear and reset the TLS session before attempting to reconnect again.

If the session was terminated improperly, nxd_mqtt_client_disconnect must still be called for the same reason.

For SSP 1.3.x, the TLS setup callback will need to call a memset on the NXD_SECURE_TLS_SESSION data block before (re)creating a TLS session (nxd_secure_tls_session_create).

The definition of the nxd_mqtt_client_secure_connect API with the TLS setup input is:

```
UINT nxd_mqtt_client_secure_connect(NXD_MQTT_CLIENT *client_ptr,
            NXD_ADDRESS *server_ip,
                                    UINT server_port,
                        UINT (*tls_setup)(
     NXD_MQTT_CLIENT *client_ptr,
     NX_SECURE_TLS_SESSION *session_ptr,
                                         NX_SECURE_X509_CERT
*,
                                         NX_SECURE_X509_CERT *),
                                    UINT keepalive,
                                    UINT clean_session,
                                    ULONG wait_option)
```

Add this logic to the tls_setup callback function (assuming the MQTT Client instance name is g_mqtt_client0):

```
    session_ptr = &(g_mqtt_client0.nxd_mqtt_tls_session);
    memset(session_ptr, 0, sizeof(NX_SECURE_TLS_SESSION));
```

```
status = nxd_secure_tls_session_create(....)
```

If memset is not called, the TLS nxd_secure_tls_session_create call may not succeed. In SSP 1.4.0 it will no longer be necessary to call memset, but it is still strongly recommended to put all TLS setup, including TLS creation in the callback. It may seem wasteful to completely delete and recreate a TLS session. But the manner in which TLS is integrated into MQTT Client makes this the most sensible and reliable method to guarantee successful reconnection attempts.

For more details about TLS protocol, please see the NetX Duo TLS Secure Module Guide.

Multiple Instances of MQTT Client Per Device

For SSP 1.4.0 and earlier, a device cannot safely run multiple instances of the MQTT Client because the MQTT Client in these releases assumes global variables. That should be remedied in a subsequent release.

NetX Duo MQTT Client Module Important Operational Notes and Limitations

NetX Duo MQTT Client Module Operational Notes

The NetX Duo MQTT Client component is added by clicking on the (+) sign in the thread pane window -> Azure RTOS -> NetX Duo -> Protocols -> NetX Duo MQTT Client.

Adding the NetX Duo MQTT Client component to a project automatically adds the option to add the NetX Duo TLS component required for secure MQTT.

The MQTT Client properties are listed in the following table:

Property	Value
◢ Common	
Parameter Checking	Default (BSP)
NX Secure	Enable
Topic Name Max Length	12
Message Max Length	32
Keepalive Timer Rate (s)	1
Ping Timeout Delay (s)	1
Socket Timeout (in timer ticks)	0xFFFFFFFF
◢ Module g_mqtt_client_ethr NetX Duo MQTT Client	
Name	g_mqtt_client_ethr
Client ID Callback	mqtt_client_ethr_id_callback
Client ID Max Length	75
Client Thread Stack Size	4096
Number of Messages to be stored in memory	1
Client thread priority	2
Name of generated initialization function	mqtt_client_init_ethr
Auto Initialization	Enable

Figure 503: NetX Duo MQTT Client Module MQTT Client Block Configurable Properties

In the figure above, "Common" properties are those configurable options in the NetX Duo MQTT Client that are common to all instances of the MQTT client in the project. The "Module" properties are specific to each instance of MQTT Client in the project.

Common Properties

- NX Secure: This enables/disables TLS support. If this property is set to Enabled, the MQTT Client is built with TLS support. Note: enabling the property requires adding the NetX Duo TLS component to the project to supply the necessary source code to the project, or the project will not build. If set to Disabled, adding the NetX Duo TLS component has no effect

though the project will still build and run.
- Topic Name Max Length: The maximum topic length (in bytes) the application is going to subscribe to. The default is 12 bytes.
- Message Max Length: The maximum message length (in bytes) the application is going to send or receive. The default is 32 bytes.
- Keepalive Timer Rate: This timer is used to keep track of the time since last MQTT control message was sent, and sends out an MQTT PINGREQ message before the keep-alive time expires. The default value is 1 second.
- Ping Timeout Delay: The time MQTT client waits for PINGRESP from the broker for after it sends out MQTT PINGREQ. The default value is 1 second.

Module Properties

- Name: Name of the MQTT client instance
- Name of generated initialization function: Name of initialization function which creates MQTT client instance. The default is the auto-generated function auto generated function mqtt_client_init0.
- Auto Initialization: Enable/disable call to initialization function. If disabled, the application thread entry function must obtain the Client ID and create the MQTT Client instance.
- Client ID Callback: Callback function provided by user for the MQTT Client thread task to obtain a unique client ID. If Auto Initialization is disabled, this and the Client ID length have no effect.
- Client ID Max Length: Maximum Length in bytes of the client ID.
- Client Thread Stack Size: MQTT Client thread stack size in bytes.
- Number of Messages to be stored in Memory: MQTT client uses memory area to store messages. The memory needed for MQTT client operation depends on the amount of data being sent or received. The minimal memory size is the size of a single MQTT_MESSAGE_BLOCK instance which is 60 bytes. The default value is 1 MQTT_MESSAGE_BLOCK or 60 bytes. However, this it not a good choice if there will be multiple messages received before the application can receive them. Transmitted messages cannot be released until thee TCP socket receives an ACK for the data, or if the QoS level is 1 or higher and the MQTT Client has received an ACK from the MQTT server. So the module guide project uses 6 message blocks. That number can probably be reduced to 3 or 4.
- Client Thread Priority: MQTT Client thread priority.
- Name of Generated Initialization function: Name of the function that will call the nxd_mqtt_client_create API. If Auto Initialization is disabled, this has no effect. If it is, Synergy will create this function automatically.
- Auto Initialization: This determines if the function specified in the Name of Generated Initialization function option is called. If set to Enable, it will invoke this function. Otherwise if set to Disable, the application must call the nxd_mqtt_client_create API before using any NetX Duo MQTT Client services.

Setting a Unique Client ID

As mentioned previously, an MQTT client instance is created using nxd_mqtt_client_create() API. If the MQTT Client application is letting the ISDE create the MQTT client, then it must define the Client ID Callback. This will be called before the ISDE calls nxd_mqtt_client_create internally with a defined Client ID string. The MQTT Client component allows you to set the Client ID Callback and Client ID Max Length in the list of MQTT Client properties (see above Module Properties).

The Client ID should be unique and is one of the parameters the MQTT broker uses to identify the client.

The prototype for Client ID callback is as follows:

```
void mqtt_client_id_callback(char * p_client_id, uint32_t * p_client_id_length);
```

p_client_id is a pointer to the Client ID to obtain, thus it is an output parameter which will be filled in by this callback function. p_client_id_length is a pointer to the length of the Client ID, thus it is an input and output parameter. This mechanism enables the Client ID to be determined at run time instead of at compile time.

If Client ID Callback is left empty in the properties pane of e^2 studio, a compiler error occurs. NULL is an acceptable entry. If your application prefers to create the MQTT Client directly, set this callback to NULL and set *Auto Initialization* to Disabled. Then when your application calls the nxd_mqtt_client_create API, provide the Client ID string directly, and the length of it as the input parameters:

```
    /* Create MQTT client instance. */
    nxd_mqtt_client_create(&mqtt_client, "my_client", CLIENT_ID_STRING,
strlen(CLIENT_ID_STRING), ip_ptr, pool_ptr, (VOID*)mqtt_client_stack, sizeof
(mqtt_client_stack), MQTT_THREAD_PRIORTY,     (UCHAR*)client_memory, sizeof
(client_memory));
```

Below is the sample reference implementation of the Client ID callback function which copies MAC address to a Client ID:

```
void mqtt_client_id_callback(char *p_client_id, uint32_t *p_client_id_length)
{
    uint32_t id_length;
    UCHAR mac_id[6]  = {0x01, 0x02, 0x03, 0x04, 0x05, 0x06};
    if (*p_client_id_length < sizeof(mac_id))
    {
        id_length = *p_client_id_length;
    }
    else
    {
        id_length = sizeof(mac_id);
    }
     /* Copy MAC address to CLient ID and update client ID length */
     memcpy(p_client_id, mac_id, id_length);
    return;
      }
```

Note

It is possible to have an MQTT session with a zero length Client ID string. If an MQTT Client supplies a zero-byte Client ID, the Client MUST also set the clean_session input in the nxd_mqtt_client_connect API to NX_TRUE (1) as per the MQTT protocol. If the Client supplies a zero-byte Client ID with clean_session set to NX_FALSE (0), the Server will respond to the CONNECT Packet with a CONNACK return code 0x02 (Identifier rejected) and then close the Network Connection.

NetX Duo MQTT Client Module Limitations

- NetX Duo MQTT Client does not support sending or receiving QoS level 2 messages.
- NetX Duo MQTT Client does not support chained packets.
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.33.4 Including the NetX Duo MQTT Client Module in an Application

This section describes how to include either or both the NetX Duo MQTT Client module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo MQTT Client module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX Duo MQTT Client Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_mqtt_client0NetXDuo MQTT Client	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetXDuo MQTT Client

When the NetX Duo MQTT Client module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

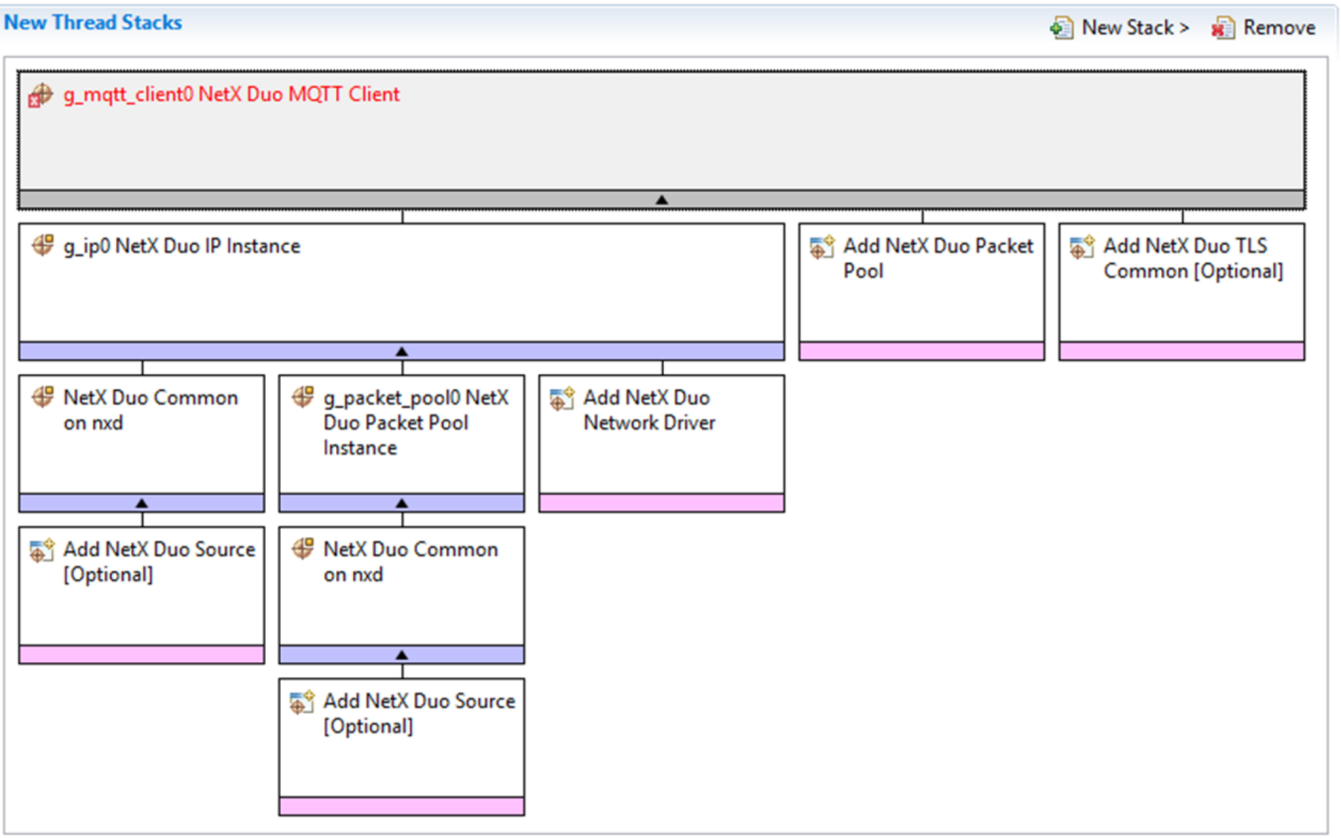

Figure 504: NetX Duo MQTT Client Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.33.5 Configuring the NetX Duo MQTT Client Module

The NetX Duo MQTT Client module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo MQTT Client Module

ISDE Property	Value	Description
NX Secure	Enable, Disable Default: Enable	This enables/disables TLS support. If this property is set to Enabled, the MQTT Client is built with TLS support. Note: enabling the property requires adding the NetX Duo TLS component to the project to supply the necessary source code to the project, or the project will not build. If set to Disabled, adding the NetX Duo TLS component has no effect though the project will still build and run.
Topic Name Max Length	12	The maximum topic length (in bytes) the application is going to subscribe to. The default is 12 bytes.
Message Max Length	32	The maximum message length (in bytes) the application is going to send or receive. The default is 32 bytes.
Keepalive Timer Rate(s)	1	This timer is used to keep track of the time since last MQTT control message was sent, and sends out an MQTT PINGREQ message before the keep-alive time expires. The default value is 1 second.
Ping Timeout Delay(s)	1	The time MQTT client waits for PINGRESP from the broker for after it sends out MQTT PINGREQ. The default value is 1 second.
Name	g_mqtt_client0	Name of the MQTT client instance.

Client ID Callback	mqtt_client_id_callback	Callback function provided by user for the MQTT Client thread task to obtain a unique client ID. If Auto Initialization is disabled, this and the Client ID length have no effect.
Client ID Max Length	12	Maximum Length in bytes of the client ID.
Client Thread Stack Size	4096	MQTT Client thread stack size in bytes.
Number of Messages to be stored in memory	1	MQTT client uses memory area to store messages. The memory needed for MQTT client operation depends on the amount of data being sent or received. The minimal memory size is the size of a single MQTT_MESSAGE_BLOCK instance which is 60 bytes. The default value is 1 MQTT_MESSAGE_BLOCK or 60 bytes. However, this it not a good choice if there will be multiple messages received before the application can receive them. Transmitted messages cannot be released until thee TCP socket receives an ACK for the data, or if the QoS level is 1 or higher and the MQTT Client has received an ACK from the MQTT server. So the module guide project uses 6 message blocks. That number can probably be reduced to 3 or 4.
Client thread priority	2	MQTT Client thread priority.
Name of generated initialization function	mqtt_client_init0	Name of the function that will call the nxd_mqtt_client_create API. If Auto Initialization is disabled, this has no effect. If it is, Synergy will create this function automatically

Auto Initialization	Enable, Disable Default: Enable	This determines if the function specified in the Name of Generated Initialization function option is called. If set to Enable, it will invoke this function. Otherwise if set to Disable, the application must call the nxd_mqtt_client_create API before using any NetX Duo MQTT Client services.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, you may require a longer Client ID string or to disable NX Secure. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX Duo MQTT Client Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection

ARP cache storage units	Bytes, Entries Default: Bytes	ARP cache storage units selection
ARP Cache cache Size (in Bytes or storage units)	520	ARP Cache Size in Bytes/Entries selection. Must be a multiple of 52 Bytes. Note: 1 Entry = 52 Bytes
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	1568	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo TLS Common

ISDE Property	Value	Description
Crypto Engine	Hardware	Crypto engine selection
Self Signed Certificates	Enable, Disable Default: Disable	Self signed certificates selection
PSK Cipher Suite	Enable, Disable Default: Disable	PSK cipher suite selection
ECC Cipher Suite	Enable, Disable Default: Disable	ECC cipher suite selection
X509 Strict Name Compare	Enable, Disable Default: Disable	X509 strict name compare selection
X509 Extended Distinguished Names	Enable, Disable Default: Disable	X509 extended distinguished names selection
Maximum RSA Modulus size (bits)	1024, 2048, 3072, 4096 Default: 4096	Maximum RSA modulus size (bits) selection
Server Mode	Enable, Disable Default: Enable	Server mode selection
Client Mode	Enable, Disable Default: Enable	Client mode selection

Name of generated initialization function	nx_secure_common_init	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Software Crypto

ISDE Property	Value	Description
Name	g_crypto_generic	Module name

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Crypto Hardware Accelerator

ISDE Property	Value	Description
Name	g_sf_el_nx_crypto	Module name

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SCE Common Driver

ISDE Property	Value	Description
Name	g_sce_0	Module name
Endian Flag	CRYPTO_WORD_ENDIAN_BIG, CRYPTO_WORD_ENDIAN_LITTLE Default: CRYPT_WORD_ENDIAN_BIG	Endian flag selection
Interfaces available from the InterfaceGet API		
AES<subset>	Enable, Disable Default: Enable	Enable or disable available interface (Plain-text ECB 128-bit, CBC 128-bit, etc. See configuration properties in the SSP Configurator for a complete list of those available for the target MCU)

RSA<subset>	Enable, Disable Default: Enable	Enable or disable available interface (Plain-text 1024-bit, 2048-bit, etc. See configuration properties in the SSP Configurator for a complete list of those available for the target MCU)
ECC<subset>	Enable, Disable Default: Enable	Enable or disable available interface (Plain-text 192-bit, 256-bit, etc. See configuration properties in the SSP Configurator for a complete list of those available for the target MCU)
HASH<subset>	Enable, Disable Default: Enable	Enable or disable available interface (SHA1, SHA224, etc. See configuration properties in the SSP Configurator for a complete list of those available for the target MCU)
True Random Number Generator	Enable, Disable Default: Enable	Enable or Disable True Random Number Generator interface

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX Duo MQTT Client Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX Duo MQTT Client Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.33.6 Using the NetX Duo MQTT Client Module in an Application

The steps in using the NetX Duo MQTT Client module in a typical application are:

1. Wait for the network link to be enabled by calling the nx_ip_status_check (or if your system has multiple network interfaces, call nx_ip_interface_status_check) with the NX_IP_LINK_ENABLED option.
2. Create an event flag group using the tx_event_flags_create API.
3. Connect to the MQTT server (broker) using the nxd_mqtt_client_connect API.
4. Set a receive notification callback using the nxd_mqtt_client_receive_notify_set API. The receive callback sets a flag when notified by the underlying NetX Duo socket services that it has received a packet on this connection.
5. Subscribe to a topic on the MQTT Server using the nxd_mqtt_client_subscribe API.
6. Publish a message to the topic using the nxd_mqtt_client_publish API.
7. Wait to receive messages by calling the tx_event_flags_get API.
8. Receive the message using the nxd_mqtt_client_message_get API. Note that unlike receiving packets from a socket, the MQTT Client need not be concerned about releasing packets. The MQTT Client thread task handles packet and message block allocate and release.
9. Unsubscribe from the topic by calling the nxd_mqtt_client_unsubscribe API, specifying the topic.
10. Disconnect from the topic by calling nxd_mqtt_client_disconnect API.

The following figure illustrates common steps in a typical operational flow diagram:

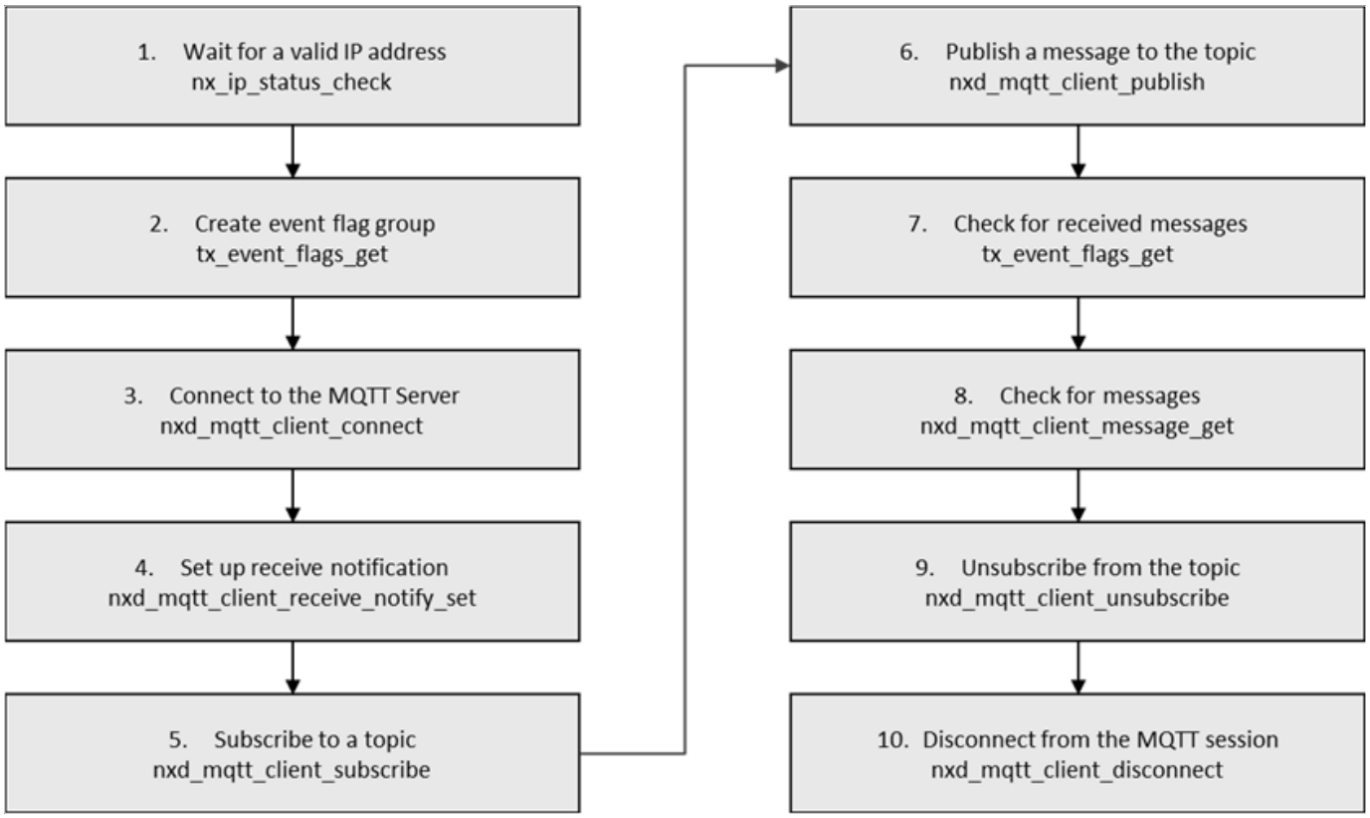

Figure 505: Flow Diagram of a Typical NetX Duo MQTT Client Module Application

4.3.34 NetX Duo NAT

4.3.34.1 NetX Duo NAT Introduction

The IP Network Address Translation (NAT) solves the problem of a limited number of Internet IPv4 addresses that arises when multiple devices need access to the Internet, but only one IPv4 Internet address is assigned by the Internet Service Provider (ISP). A NAT-enabled router is installed between the public and private network to translate between internal private IPv4 addresses and assigned public IPv4 address, so devices on the private network can share the same public IPv4 address.

NetX Duo NAT Module Features

- NetX NAT supports the following RFCs:
  - RFC 2663: IP Network Address Translator (NAT) Terminology and Considerations
  - RFC 3022: Traditional IP Network Address Translator (Traditional NAT)
  - RFC 4787: Network Address Translation (NAT) Behavioral Requirements for Unicast User Datagram Protocol (UDP)
- NetX NAT provides the following high level APIs:
  - Creating and deleting a NAT server
  - Enabling and disabling NAT in NetX Duo

- Set callbacks for NAT to notify application if NAT entry table is full
- Creating static inbound entries in the NAT table

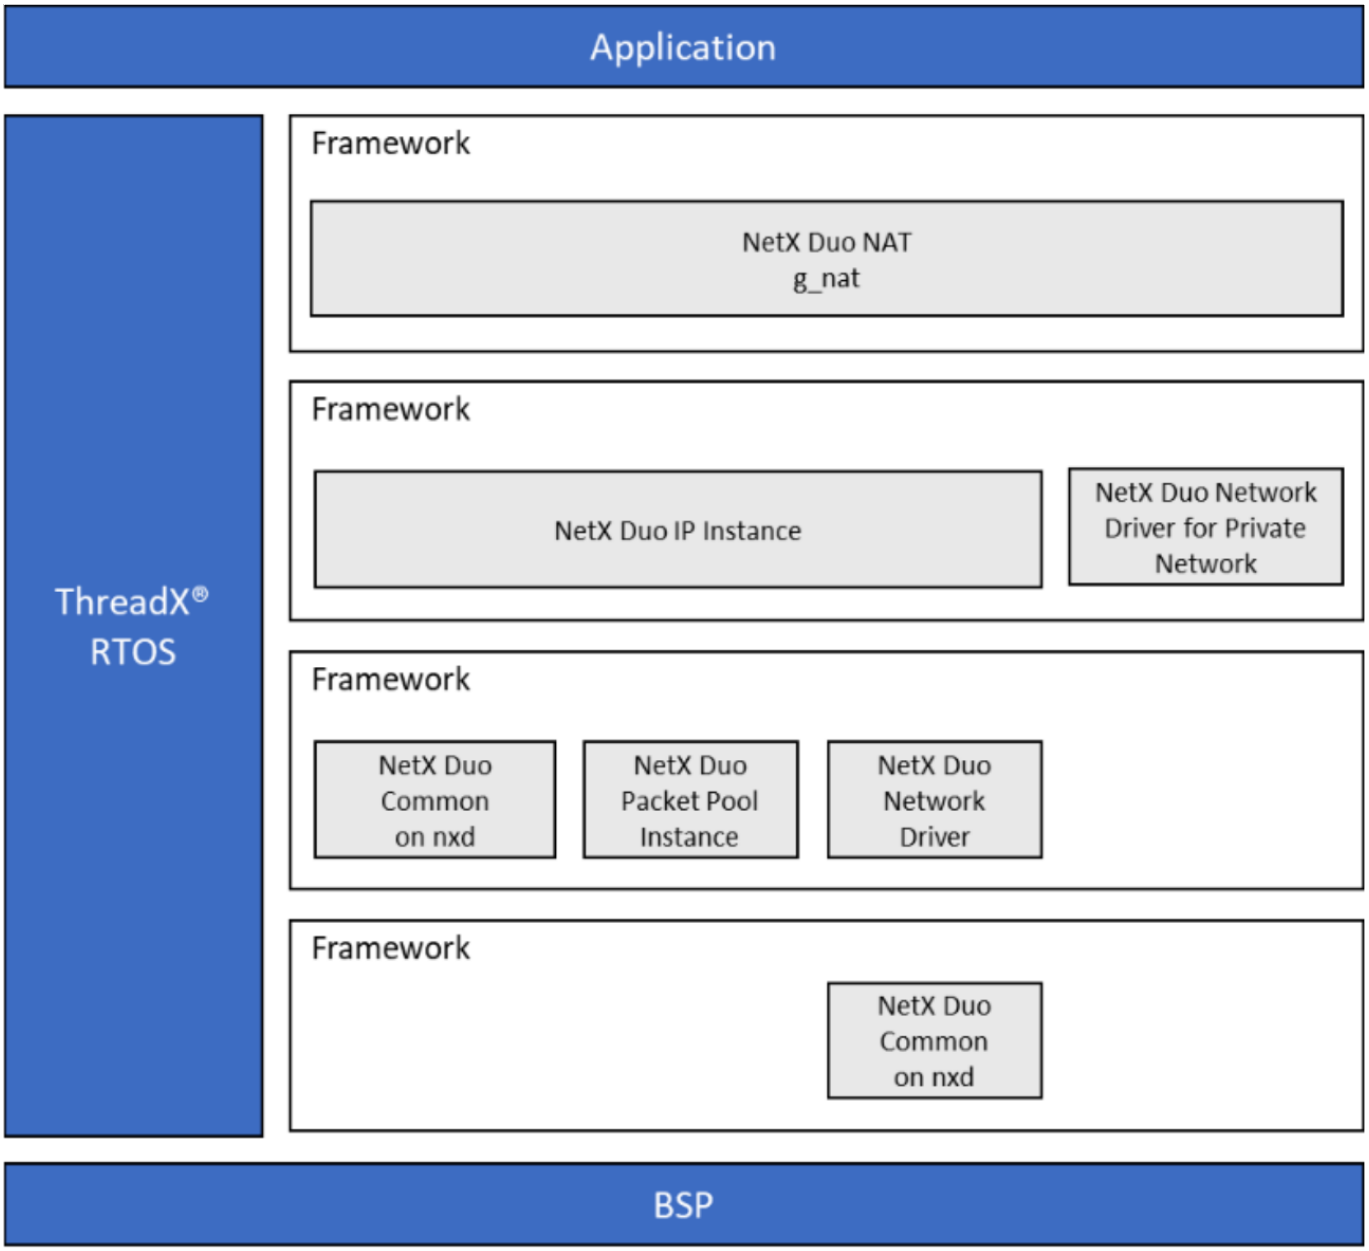

Figure 506: NetX Duo NAT Module Block Diagram

Note

In the figure above, The NetX Duo Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX Duo NAT Module in an Application for additional details.

4.3.34.2 NetX Duo NAT Module APIs Overview

The NetX Duo NAT Module defines APIs for creating, deleting and enabling operations. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX Duo NAT Module API Summary

Function Name	Example API Call and Description
nx_nat_create	nx_nat_create(nat_ptr, ip_ptr, global_interface_index, nat_cache, NX_NAT_ENTRY_CACHE_SIZE); Create a NAT Instance in which the network interface is the global interface (not the local/private network) with the specified network index.
nx_nat_delete	nx_nat_delete (nat_ptr); Delete a NAT instance.
nx_nat_enable	nx_nat_enable (nat_ptr); Enable the NAT server.
nx_nat_disable	nx_nat_disable (nat_ptr); Disable the NAT server.
nx_nat_cache_notify_set	nx_nat_cache_notify_set(nat_ptr, cache_full_notify_cb); Set the NAT cache full notify function to a user-defined notify function.
nx_nat_inbound_entry_create	nx_nat_inbound_entry_create(nat_ptr, entry_ptr, IP_ADDRESS(192,168,2,2), 5001, 5001, NX_PROTOCOL_TCP); Create an inbound translation table entry. This is typically used by application servers to allow clients to initiate a connection externally.
nx_nat_inbound_entry_delete	nx_nat_inbound_entry_delete(nat_ptr, delete_entry_ptr); Delete an inbound translation table entry.

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

Status Return Values

Name	Description
NX_SUCCESS	Successful NAT function
NX_PTR_ERROR*	Invalid input pointer parameter
NX_CALLER_ERROR*	Invalid caller (for example, must be a thread) of a service
NX_NAT_PARAM_ERROR*	Invalid non pointer input
NX_NAT_CACHE_ERROR*	Cache memory not 4 byte aligned, or is too small
NX_NAT_PORT_UNAVAILABLE	Invalid external port for creating static entry

NX_NAT_ENTRY_NOT_FOUND	Entry to delete is not found in Cache table
NX_NAT_ENTRY_TYPE_ERROR*	Invalid entry (not static) to delete

Note

Lower-level drivers may return common error codes. See the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

- These are error codes which are only returned if error checking is enabled. Refer to the *NetX User Guide* for the Renesas Synergy™ Platform or *NetX Duo User's Guide* for the Renesas Synergy™ Platform for more details on error-checking services in NetX and NetX Duo, respectively.

4.3.34.3 NetX Duo NAT Module Operational Overview

A NAT-enabled router typically has two network interfaces: one connected to the public Internet, the other connected to the private network. A typical router in this setup is responsible for routing IP datagrams between the private network and the public network based on the destination IP address. A NAT-enabled router performs address translation before routing an IPv4 datagram between the public and the private interface. Translation is established for each TCP or UDP session, based the internal source address and source port number, as well as the external destination address and destination port number. For the ICMP echo request and response datagram, the Internet Control Message Protocol (ICMP) query ID is used instead of the port number.

Typically, connections across the NAT boundary are initiated by the hosts on the private network sending outbound packets to an external host. In these cases, hosts are usually assigned dynamic (temporary) IP addresses. It is also possible to have connections initiated in the opposite direction if the private network has 'servers' (such as HTTP or FTP) that accept client requests from the external network. NAT applications typically assign these local hosts a static (permanent) IP address port.

The following three illustrations and accompanying steps illustrate the sequence of events when sending packets through a NAT router.

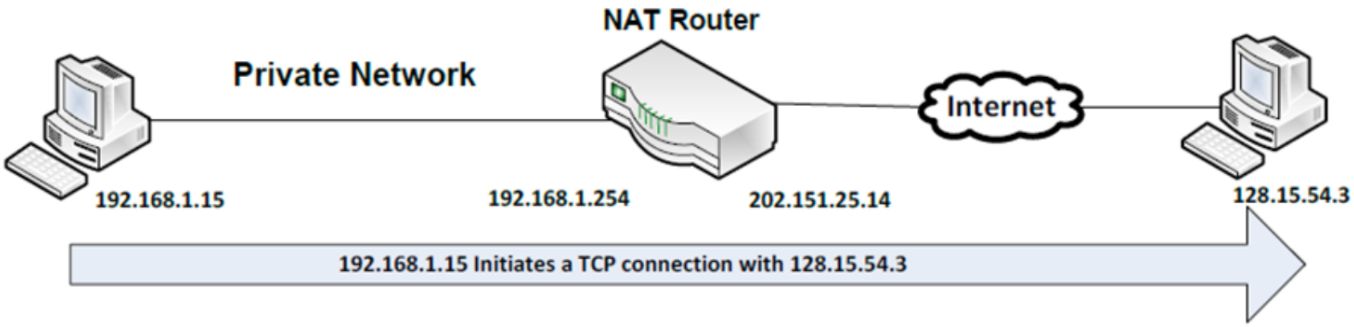

Figure 507: NetX Duo NAT Module Connection Start

Step 1. Client transmits a TCP SYN message to the web server. The Client address on the private network is 192.168.1.15, port number 6732; the destination address is 128.15.54.3, port number 80.

Step 2. The packet from the Client is received on the private network interface by the NAT router. The outbound traffic rule applies to the packet: the sender's (Client's) address is translated to the NAT router's public IP address 202.151.25.14, and sender (Client) source port number is translated to the TCP port number 2015 for transmission out on the public interface.

Step 3. The packet is then transmitted over the Internet and ultimately reaches its destination host 128.15.54.3. On the receiving side, notice in the following figure that the packet appears to have originated from 202.151.25.14, port number 2015 when it was in fact relayed from that IP address and port.

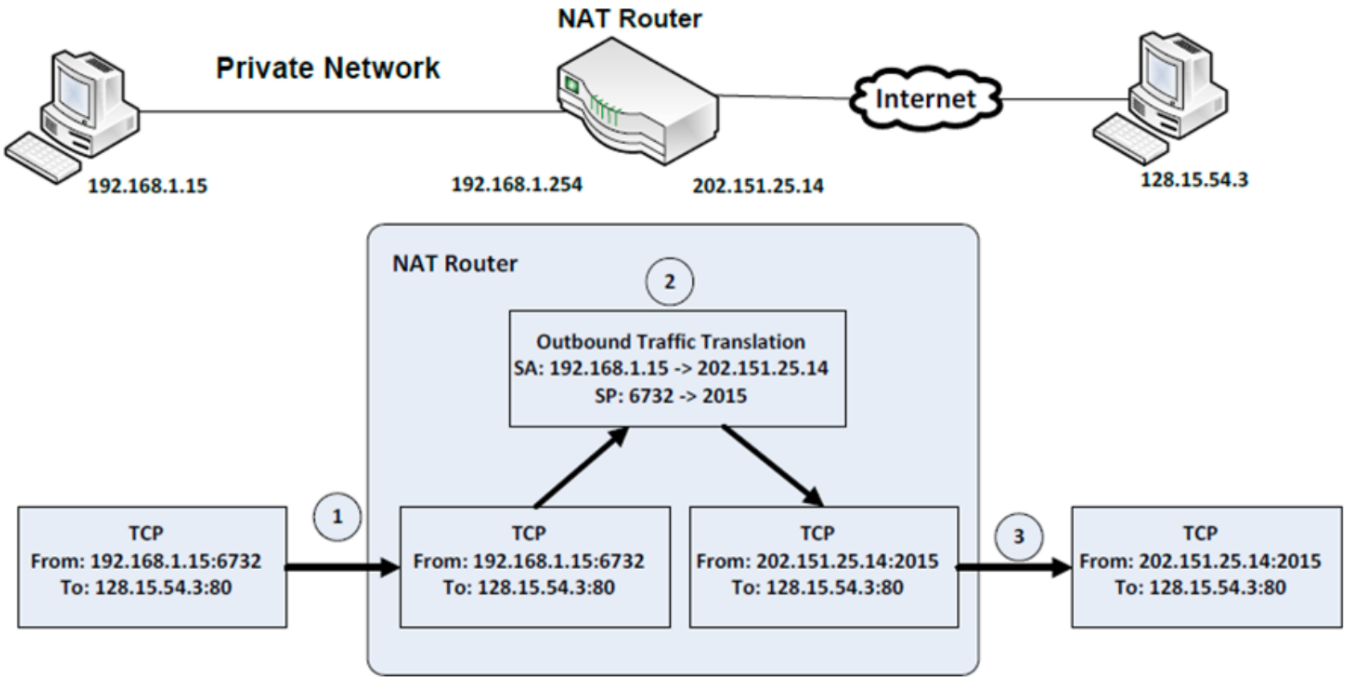

Figure 508: NetX Duo NAT Module Network Address Translation

Step 4. Host 128.15.54.3 sends back a response packet with the NAT router's Internet address as its destination.

Step 5. The packet reaches the NAT router. Since this is an in-bound packet, the in-bound translation rules apply: the destination address is changed back (translated) to the original sender's (Client's) IP address: 192.168.1.15, destination port number 6732.

Step 6. The packet is then forwarded to the Client through the interface connected to the internal network.

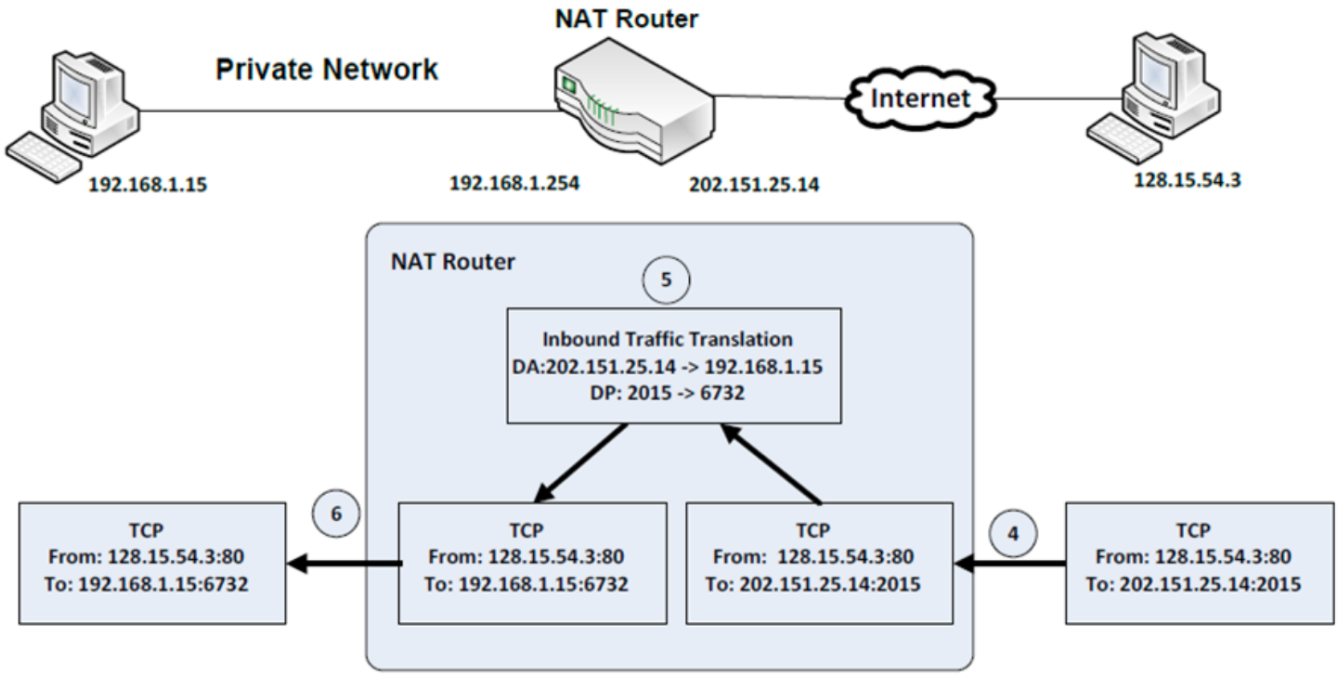

Figure 509: NetX Duo NAT Module Packet Return Path

When sending packets through a NAT router, the sender's Internet network address and port number is not exposed to other hosts on the public Internet.

To keep track of the network address translations for all active connections between local and external networks, the NetX Duo NAT-enabled router maintains a translation table with information about each private host connection that includes source and destination IP address and port number.

NetX Duo NAT is intended for use on an IPv4 router. For the NAT to work, the NetX Duo must be configured to forward-receive packets to an internal NetX Duo NAT handler. The handler determines whether the packet is received from the global network (inbound) or from the private network (outbound).

- For inbound packets, the handler determines whether it can forward (consume) the packet to the host on the private (local) network. To make the determination, the handler looks for a matching entry based on the packet destination address and port in the NAT translation table. If a matching entry is found, the handler translates the destination address to the matching private host IP address and port, and sends the packet to that host. If it cannot find an entry, it lets the NetX Duo process the packet as normal; as if the packet was intended for the NAT device itself.
- For outbound packets, the NAT handler checks the destination IP address to determine whether it can forward the packet out onto the global network or whether NetX Duo should handle the packet as it does normally. If the packet has a broadcast or loopback destination address, or an IP address which does not match the NAT device global network address, the NAT handler lets the NetX Duo handle the packet. Otherwise, the handler looks for a matching entry of the sender's IP and address in the translation table. If it finds a match, it translates the IP address and port to the local IP address and port, and forwards (consumes) the packet to the local host. If a previous entry is not found, the NAT creates an entry in the NAT translation table, translates the sender's IP address for the global interface and forwards the packet to the external host.

NetX Duo NAT Module Important Operational Notes and Limitations

NetX Duo NAT Module Operational Notes

- To enable the NAT, add the NetX Duo Source component to the Configurator pane, and set the *NAT* property of NetX Duo Source. The prebuilt NetX Duo source library does not have NAT enabled.
- The Maximum Physical Interfaces property, also in NetX Duo Source, must be set to 2, assuming one private network and one global network. Auto-generated code creates the IP instance using the global network IP address, and attach the secondary interface as the private network interface.
- There must be two network driver instances. The project for this module uses the NetX Port ETHER framework (sf_el_nx) for both interfaces but one network interface can be on Wi-Fi, or other network media. If using two sf_el_nx driver instances, ensure their names are not the same and that one references channel 0 and the other channel 1. The MAC addresses for a dual-ported driver are in a single NetX Port Ether configuration, so no need to change these but ensure they are not identical between Channel 0 and Channel 1.
- The function specified in the Name of the generated initialization function property must attach the secondary interface and create the NAT instance-if the Auto initialization property of the NAT instance is enabled in the configurator (by default it is enabled). The Private IPv4 Address property is the local IP address of the NAT device (server). The Global network interface index specifies the network interface the global network uses. By default, this index is set to zero (the primary interface of the IP instance), and the secondary interface is the local network (interface index 1).
- If *Auto Initialization* is disabled, then the NAT application must attach a secondary interface and create a NAT instance before using any NAT service. After attaching the secondary interface, the application should wait for the internal NetX Duo processing to enable the link on that interface using the nx_ip_interface_status_check API (see the module guide project example for how this is done).
- At runtime, the NetX Duo NAT Framework also creates a 4-byte aligned table, or cache, to store NAT translation entries. The size of the cache is set by the *Cache Size* property of the NAT instance. The default value is 1024 bytes (a NAT translation record is 28 bytes). The minimum size of a NetX Duo NAT Translation table is three entries. This value is set in the *Minimum count for translation entry* property which defaults to 3 but should be set to a larger number in a busy network with many local hosts.
- By default, entries created by the NAT server when receiving inbound or outbound packets are dynamic entries. They are assigned a timeout value (*Timeout for translation_entry* property); the default value of 240 seconds is the timeout recommended by RFC 2663. When an entry timeout expires, the entry is marked for deletion. However, because the NetX Duo NAT server implementation does not have a timer, it checks the entire table for expired entries and deletes them when adding a new entry to the table. If there are no entries that have expired, and the table is full, the NetX Duo NAT server notifies the application with the cache full callback. The application can set this callback with the nx_nat_cache_notify_set service.
- To create static entries that never expire, the application can use the nx_nat_inbound_entry_create service. These entries can only be created for inbound packets and are sometimes referred to as 'inbound rules.' The entries are intended for server applications, to allow clients to initiate connection sessions with the server. Internally, the NAT verifies whether the global and local ports requested in the inbound rule are available. To delete these entries, the application calls the nx_nat_inbound_entry_delete service.
- The NetX Duo NAT is configured with a range of TCP, UDP and ICMP translation ports to create unique local address: port entries for local hosts connecting with outside hosts.
    - TCP ports available for TCP translation ports are between the minimum value (*Minimum assigned port number for outbound TCP packets* property) and the

maximum value (*Maximum assigned port number for outbound TCP packets* property).
    - Similarly, for UDP entries ports, *Minimum assigned port number for outbound UDP packets* and *Maximum assigned port number for outbound UDP packets* properties.
    - ICMP packets do not have ports; instead, the ICMP ID can be used as the entry translation port, *Minimum ICMP query identifier* and *Maximum ICMP query identifier* properties.
- To start NetX Duo forwarding packets using the NAT protocol, the application calls the nx_nat_enable service. To suspend NetX forwarding, the application calls the nx_nat_disable service.
- Once the NAT is enabled, the NAT thread entry application lets the internal processing for NAT handle packets transmission between the global and local networks. It can create inbound rules at any time to allow a host on the global network to reach a local host, as is typically done for servers on the local network.

NetX Duo NAT Module Limitations

- Internet Group Management Protocol (IGMP) is not supported. NetX Duo NAT supports only TCP, UDP and ICMP.
- NAT protocol does not apply to IPv6 packet transmission.
- NetX Duo NAT does not include DNS or DHCP services, although NetX Duo NAT can integrate those services with its NAT operations.
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.34.4 Including the NetX Duo NAT Module in an Application

This section describes how to include either or both the NetX Duo NAT module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo NAT module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX Duo NAT Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_nat0NetX Duo NAT	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo NAT

When the NetX Duo NAT module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

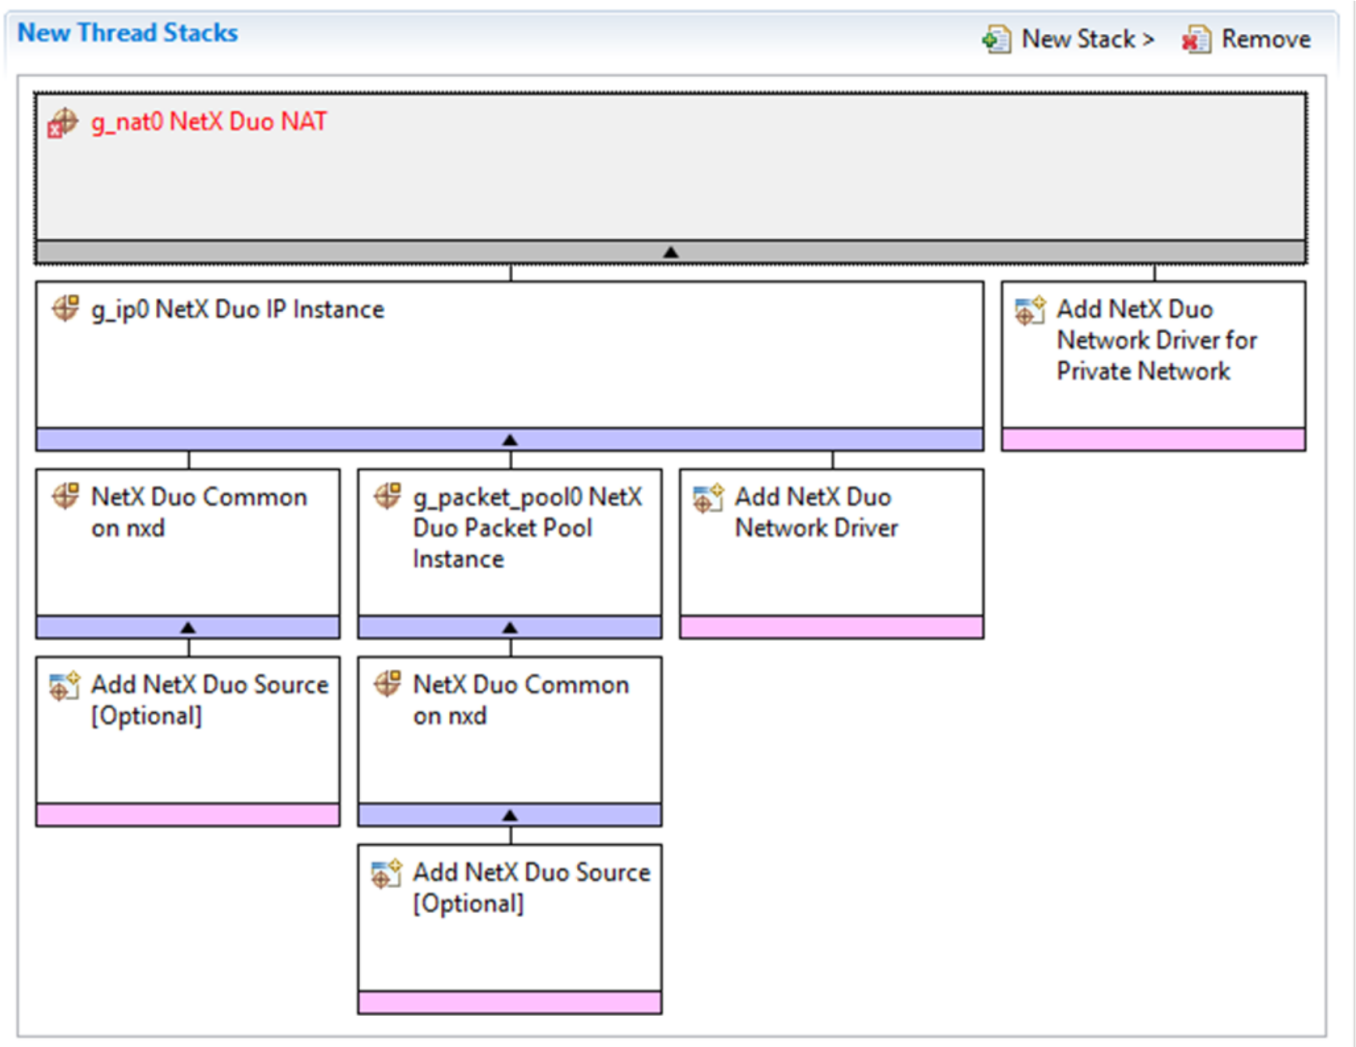

Figure 510: NetX Duo NAT Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.34.5 Configuring the NetX Duo NAT Module

The NetX Duo NAT module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This

approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo NAT Module

ISDE Property	Value	Description
Minimum count for translation entry	3	Minimum count for translation entry selection
Timeout for translation entry (ticks)	240	Timeout for translation entry selection
Minimum assigned port number for outbound TCP packets	20000	Minimum assigned port number for outbound TCP packets selection
Maximum assigned port number for outbound TCP packets	30000	Maximum assigned port number for outbound TCP packets selection
Minimum assigned port number for outbound UDP packets	20000	Minimum assigned port number for outbound UDP packets selection
Maximum assigned port number for outbound UDP packets	30000	Maximum assigned port number for outbound UDP packets selection
Minimum ICMP query identifier	20000	Minimum ICMP query identifier selection
Maximum ICMP query identifier	30000	Maximum ICMP query identifier selection
Name	g_nat0	Module name
Cache size (bytes)	1024	Cache size selection
Private IPv4 Address (use commas for separation)	192,168,0,2	Private IPv4 Address selection
Private IPv4 Netmask (use commas for separation)	255, 255, 255, 0	Private IPv4 Netmask selection
Global network interface index	0	Global network interface index selection
Name of generated initialization function	nat_init0	Name of generated initialization function selection

Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different IP addresses and subnet masks. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX Duo NAT Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP Cache Size in Bytes	512	ARP Cache Size in Bytes selection
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection

TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	640	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection

Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX Duo NAT Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX Duo NAT Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin

RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.34.6 Using the NetX Duo NAT Module in an Application

The following example assumes that a system is already established with a working IP, ARP, ICMP, TCP and UDP enabled, and that the link is running.

The steps in using the NetX Duo NAT module in a typical application are:

1. Wait for the IP instance to initialize the driver and have a valid IP address using the nx_ip_status_check API for the primary ("global") interface.
2. Wait for the IP secondary ("local") interface to also have a valid IP address at this point using the nx_ip_interface_status_check API.
3. Set the cache full callback to be notified when the NAT translation table it full by calling the nx_nat_cache_notify_set API [Optional].
4. Start packet forwarding by the IP layer in NetX as per NAT protocol by calling the nx_nat_enable API. The IP thread task and NAT services handle the rest.
5. Add static entries as desired (for example server applications that are waiting for client requests) by calling the nx_nat_inbound_entry_create [Optional]. Note this can be done before or after enabling NAT services.
6. Suspend NAT by calling the nx_nat_disable API.
7. Delete NAT by calling the nx_nat_delete API.

The following figure illustrates common steps in a typical operational flow diagram:

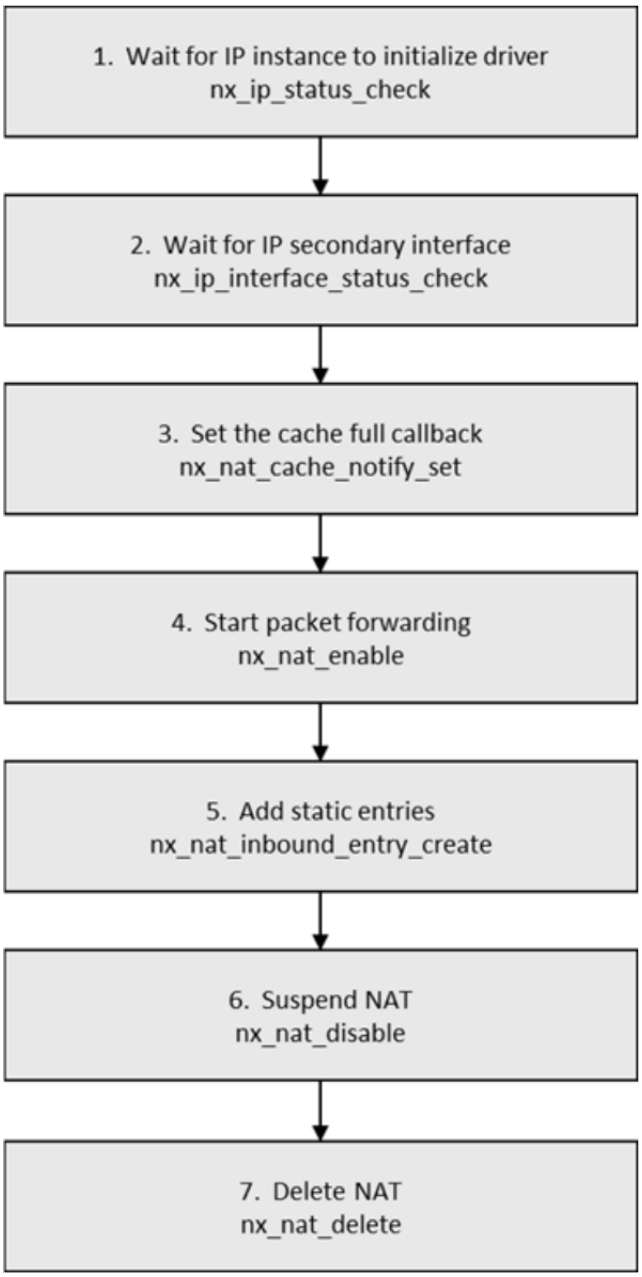

Figure 511: Flow Diagram of a Typical NetX Duo NAT Module Application

4.3.35 NetX Duo TLS Session

4.3.35.1 NetX Duo TLS Session Introduction

The NetX Duo TLS Session Module provides a high-level API for Transport Layer Security (TLS) protocol-based clients. It uses services provided by the Synergy Crypto Engine (SCE) to carry out hardware-accelerated encryption and decryption.

The NetX Duo TLS Session module is based on ThreadX "NetX Duo Secure," which implements the

Secure Socket Layer (SSL) and its replacement Transport Layer Security (TLS) protocol as described in RFCs 5246 (version 1.2) and 8446 (version 1.3). NetX Duo Secure also includes routines for basic X.509 (RFC 5280). NetX Duo Secure is intended for applications using the ThreadX RTOS.

The TLS/SSL protocol provides privacy and reliability between two communicating applications. It has the following basic properties:

- Encryption: The messages exchanged between communicating applications are encrypted to ensure that the connection is private. Symmetric cryptography mechanism such as AES (Advanced Encryption Standard is used for data encryption.
- Authentication: A mechanism to check the peer's identity using certificates
- Integrity: A mechanism to detect message tampering and forgery to ensure that connection is reliable. Message Authentication Code (MAC) such as Secure Hash Algorithm (SHA) is used to ensure message integrity

An application project that demonstrates the use of the TLS as part of an MQTT client is available on the Renesas web site. The "Synergy Enterprise Cloud Toolbox" application project and application note can be found by searching the Renesas web site for "R20AN0485."

NetX Duo TLS Session Module Features

- RFC 5246 The Transport Layer Security (TLS) Protocol Version 1.2
- RFC 8446 The Transport Layer Security (TLS) Protocol Version 1.3

    - *Note*

      TLS v1.0 and v1.1 are not supported by SSP. Users are strongly recommended to migrate their projects to TLS v1.2 or TLS v1.3 in SSP immediately.
- RFC 5280 X.509 PKI Certificates (v3)
- RFC 3268 Advanced Encryption Standard (AES) Cipher suites for Transport Layer Security (TLS)
- RFC 3447 Public-Key Cryptography Standards (PKCS) #1: RSA Cryptography Specifications Version 2.1
- RFC 2104 HMAC: Keyed-Hashing for Message Authentication
- RFC 6234 US Secure Hash Algorithms (SHA and SHA-based HMAC and HKDF)
- RFC 4279 Pre-Shared Key Cipher suites for TLS
- Supports TLS extensions for:
    - Secure Renegotiation Indication: This extension mitigates a Man-in-the-Middle attack vulnerability that could occur during a renegotiation handshake.
    - Server Name Indication: This extension allows a TLS Client to supply a specific DNS name to a TLS Server, allowing the server to select the correct credentials (assumes the server has multiple identity certificates and network entry points).
    - Signature Algorithms: This extension enables a TLS Client to provide a list of acceptable signature and hash algorithms to a TLS Server
- Supports X.509 extensions for:
    - Key Usage: Provides acceptable uses for a certificate's public key in a bitfield
    - Extended Key Usage: Provides additional acceptable uses for a certificate's public key using OIDs
- Certificate verification: Supports SHA-1, SHA-256, SHA-384,and SHA-512 signature hashing algorithms
- Subject Alternative Name: Provides alternative DNS names that are also represented by the certificate

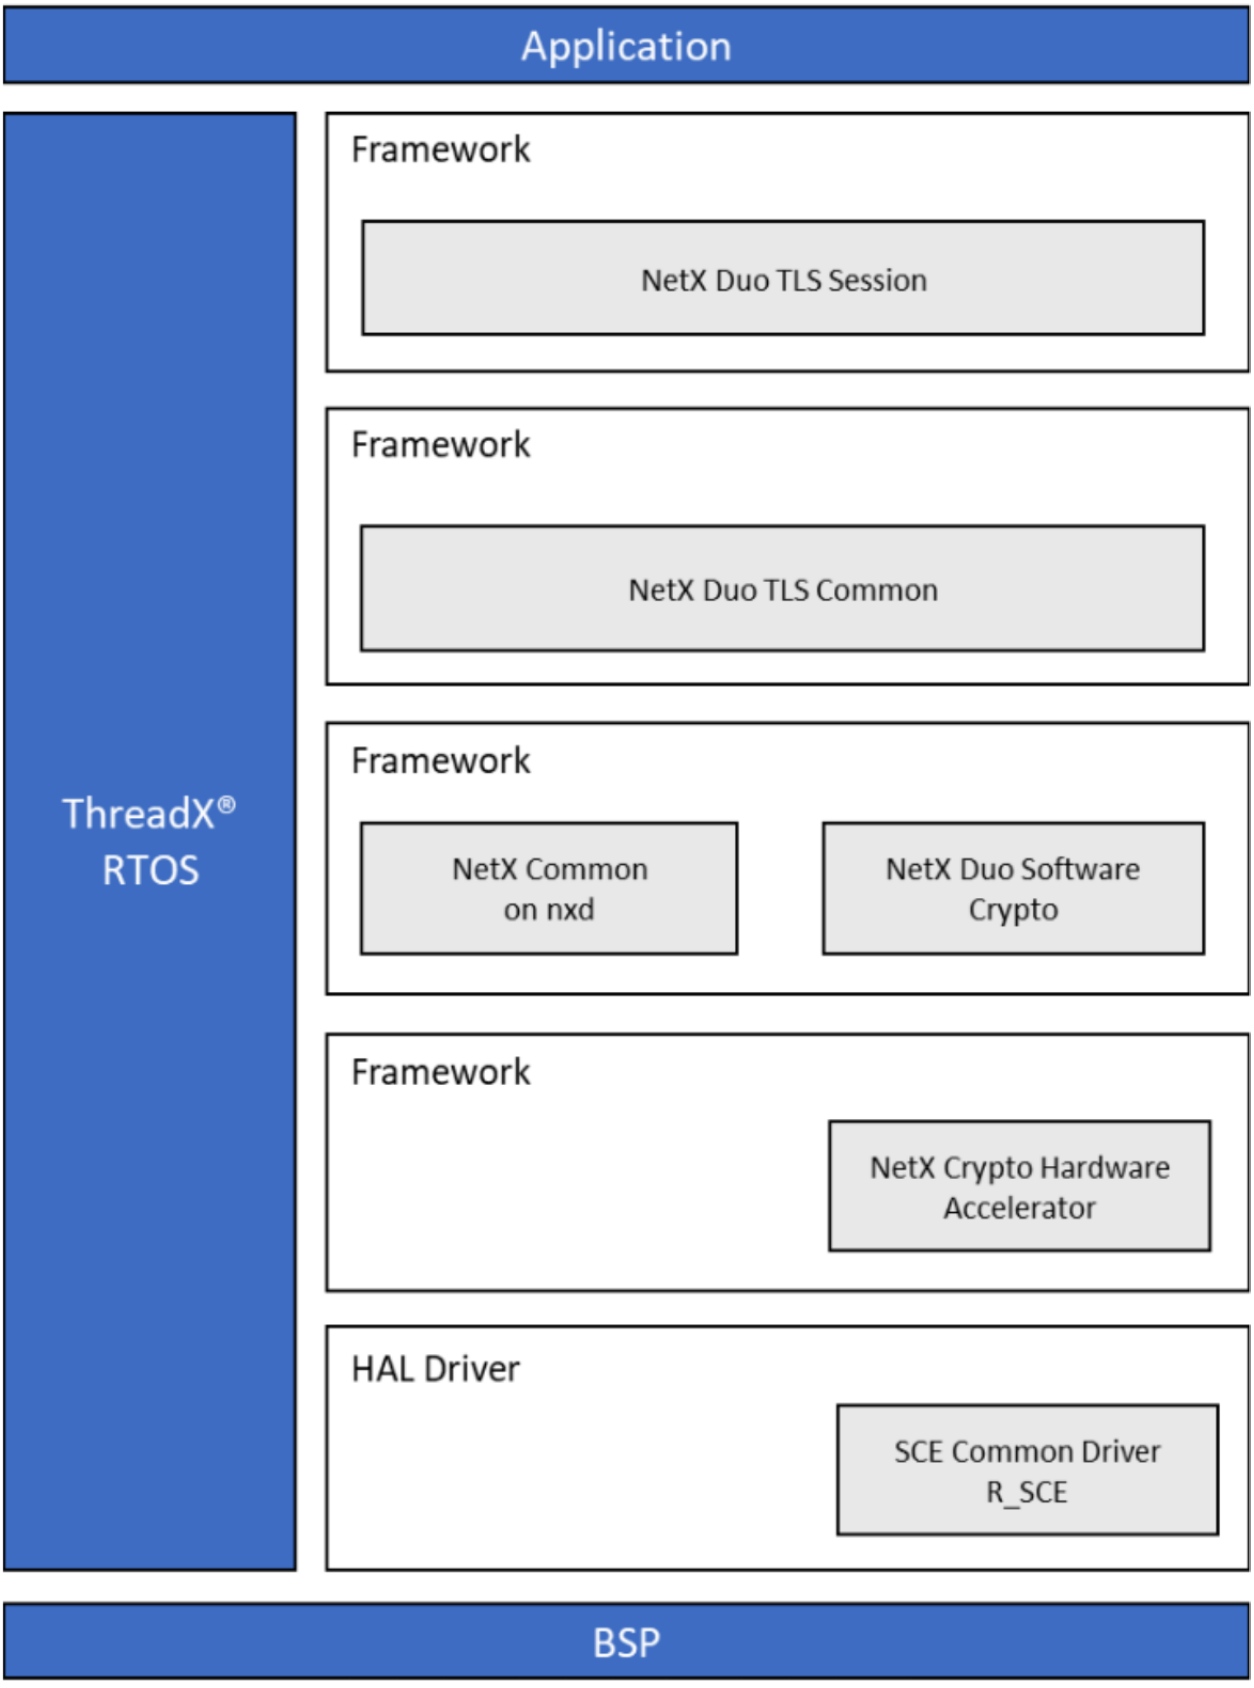

Figure 512: NetX Duo TLS Session Module Block Diagram

4.3.35.2 NetX Duo TLS Session Module APIs Overview

The NetX Duo TLS Support module defines APIs for creating and setting up a TLS security session. A complete list of the available APIs, an example API call and a short description of each can be found in the following table.

NetX Duo TLS Session Module API Summary

Function Name	Example API Call and Description
nx_secure_crypto_table_self_test	nx_secure_crypto_table_self_test(const NX_SECURE_TLS_CRYPTO *crypto_table,VOID *metadata, UINT metadata_size); Perform self-test on the crypto methods
nx_secure_module_hash_compute	nx_secure_module_hash_compute(NX_CRYPTO_METHOD *hamc_ptr,UINT start_address, UINT end_address, UCHAR *key, UINT key_length,VOID *metadata, UINT metadata_size,UCHAR *output_buffer, UINT output_buffer_size, UINT *actual_size); Computes hash value using user-supplied hash function
nx_secure_tls_active_certificate_set	nx_secure_tls_active_certificate_set(NX_SECURE_TLS_SESSION *tls_session,NX_SECURE_X509_CERT *certificate); Set the active identity certificate for a NetX Secure TLS Session
nx_secure_tls_initialize	nx_secure_tls_initialize(VOID); Initializes the NetX Secure TLS module
nx_secure_tls_remote_certificate_buffer_allocate	nx_secure_tls_remote_certificate_buffer_allocate (NX_SECURE_TLS_SESSION *session_ptr,UINT certs_number, VOID *certificate_buffer,ULONG buffer_size); Allocate space for all certificates provided by a remote TLS host
nx_secure_tls_remote_certificate_free_all	nx_secure_tls_remote_certificate_free_all(NX_SECURE_TLS_SESSION *session_ptr); Free space allocated for incoming certificates
nx_secure_tls_server_certificate_add	nx_secure_tls_server_certificate_add(NX_SECURE_TLS_SESSION *session_ptr, NX_SECURE_X509_CERT *certificate, UINT cert_id); Add a certificate specifically for TLS servers using a numeric identifier
nx_secure_tls_server_certificate_find	nx_secure_tls_server_certificate_find(NX_SECURE_TLS_SESSION *session_ptr, NX_SECURE_X509_CERT **certificate, UINT cert_id); Find a certificate using a numeric identifier

nx_secure_tls_server_certificate_remove	nx_secure_tls_server_certificate_remove(NX_SECURE_TLS_SESSION *session_ptr,UINT cert_id); Remove a local server certificate using a numeric identifier
nx_secure_tls_session_client_callback_set	nx_secure_tls_session_client_callback_set(NX_SECURE_TLS_SESSION *tls_session, ULONG (*func_ptr)(NX_SECURE_TLS_SESSION *tls_session, NX_SECURE_TLS_HELLO_EXTENSION *extensions, UINT num_extensions)); Set up a callback for TLS to invoke at the beginning of a TLS Client handshake
nx_secure_tls_session_x509_client_verify_configure	nx_secure_tls_session_x509_client_verify_configure(NX_SECURE_TLS_SESSION *session_ptr,UINT certs_number, VOID *certificate_buffer,ULONG buffer_size); Enable client X.509 verification and allocate space for client certificates
nx_secure_tls_session_renegotiate_callback_set	nx_secure_tls_session_renegotiate_callback_set(NX_SECURE_TLS_SESSION *tls_session, ULONG (*func_ptr)(struct NX_SECURE_TLS_SESSION_struct *session)); Assign a callback that will be invoked at the beginning of a session renegotiation
nx_secure_tls_session_renegotiate	nx_secure_tls_session_renegotiate(NX_SECURE_TLS_SESSION *tls_session, UINT wait_option) Initiate a session renegotiation handshake with the remote host
nx_secure_tls_session_server_callback_set	nx_secure_tls_session_server_callback_set(NX_SECURE_TLS_SESSION *tls_session, ULONG (*func_ptr)(NX_SECURE_TLS_SESSION *tls_session, NX_SECURE_TLS_HELLO_EXTENSION *extensions, UINT num_extensions)); Set up a callback for TLS to invoke at the beginning of a TLS Server handshake
nx_secure_tls_session_sni_extension_parse	nx_secure_tls_session_sni_extension_parse(NX_SECURE_TLS_SESSION *session_ptr, NX_SECURE_TLS_HELLO_EXTENSION *extensions,UINT num_extensions, NX_SECURE_X509_DNS_NAME *dns_name); Parse a Server Name Indication (SNI) extension received from a TLS Client
nx_secure_tls_session_sni_extension_set	nx_secure_tls_session_sni_extension_set(NX_SECURE_TLS_SESSION *session_ptr, NX_SECURE_X509_DNS_NAME *dns_name); Set a Server Name Indication (SNI) extension DNS name to send to a remote Server

nx_secure_tls_timestamp_function_set	nx_secure_tls_timestamp_function_set(NX_SECURE_TLS_SESSION *session_ptr,ULONG (*time_func_ptr)(void)); Assign a timestamp function to a NetX Secure TLS Session
nx_secure_x509_dns_name_initialize	nx_secure_x509_dns_name_initialize(NX_SECURE_X509_DNS_NAME*dns_name, const UCHAR *name_string, UINT length); Initialize an X.509 DNS name structure
nx_secure_x509_extended_key_usage_extension_parse	nx_secure_x509_extended_key_usage_extension_parse(NX_SECURE_X509_CERT*certificate, UINT key_usage); Find and parse an X.509 extended key usage extension in an X.509 certificate
nx_secure_x509_extension_find	nx_secure_x509_extension_find(NX_SECURE_X509_CERT*certificate, NX_SECURE_X509_EXTENSION *extension,USHORTextension_id); Find and return an X.509 extension in an X.509 certificate
nx_secure_x509_key_usage_extension_parse	nx_secure_x509_key_usage_extension_parse(NX_SECURE_X509_CERT*certificate, USHORT *bitfield); Find and parse an X.509 Key Usage extension in an X.509 certificate
nx_secure_tls_local_certificate_add	nx_secure_tls_local_certificate_add (tls_session, certificate); Adds an initialized certificate to a TLS session for use as a local identification certificate - the TLS Server certificate for TLS servers, and the Client certificate for TLS clients.
nx_secure_tls_local_certificate_remove	nx_secure_tls_local_certificate_remove(tls_session, common_name, common_name_length); Removes a certificate instance from the local certificates list, keyed on the Common Name field.
nx_secure_tls_metadata_size_calculate	nx_secure_tls_metadata_size_calculate(cipher_table, metadata_size); Determines the size of the buffer needed by TLS for encryption metadata for a given ciphersuite table
nx_secure_tls_packet_allocate	nx_secure_tls_packet_allocate(tls_session, pool_ptr, packet_ptr, wait_option); Allocates a packet for a TLS application such that it allows additional room for the TLS header

nx_secure_tls_remote_ certificate_allocate	nx_secure_tls_remote_certificate_allocate(tls_session, certificate, raw_certificate_buffer, buffer_size); Adds an uninitialized certificate instance to a TLS session for the purpose of allocating space for certificates provided by a remote host during a TLS session
nx_secure_tls_session_certificate_callback_set	nx_secure_tls_session_certificate_callback_set(tls_session, session); Sets up a function pointer that TLS will invoke when a certificate is received from a remote host, allowing the application to perform validation checks such as certificate revocation and certificate policy enforcement
nx_secure_tls_session_create	nx_secure_tls_session_create(session_ptr, cipher_table, metadata_area, metadata_size); Initializes a TLS session control block for later use in establishing a secure TLS session over a TCP socket or other lower-level networking protocol
nx_secure_tls_session_client_verify_disable	nx_secure_tls_session_client_verify_ disable(tls_session); Disables Client Certificate Verification for a particular TLS Session which previously had it enabled.
nx_secure_tls_session_client_verify_enable	nx_secure_tls_session_client_verify_enable(tls_session); Enables Client Certificate Verification for TLS Server instances. If enabled, the TLS Server will request and verify a remote TLS Client Certificate using all available crypto signature routines.
nx_secure_tls_session_delete	nx_secure_tls_session_delete(tls_session); Deletes a TLS session object, returning any resources to the system
nx_secure_tls_session_end	nx_secure_tls_session_end(tls_session, wait_option); Ends an active TLS session by sending the TLS CloseNotify alert to the remote host, then waiting for the response CloseNotify before returning.
nx_secure_tls_session_packet_buffer_set	nx_secure_tls_session_packet_buffer_set(session_ptr, buffer_ptr, buffer_size); Sets the buffer TLS uses to reassemble incoming messages which may span multiple TCP packets.

nx_secure_tls_session_protocol_oversion_override	nx_secure_tls_session_protocol_version_override(tls_session, protocol_version); Overrides the TLS protocol version to use for the TLS session. This allows for a different version of TLS to be utilized even if a newer version is enabled.
nx_secure_tls_session_receive	nx_secure_tls_session_receive(tls_session, packet_ptr_ptr, wait_option); Receives data from an active TLS session, handling all decryption and verification before returning the data to the caller in the supplied NX_PACKET structure
nx_secure_tls_session_reset	nx_secure_tls_session_reset(session_ptr); Resets a TLS session object, clearing out all data for initialization or re-use.
nx_secure_tls_session_send	nx_secure_tls_session_send(tls_session, packet_ptr, wait_option); Sends data using an active TLS session, handling all encryption and hashing before sending data over the established TCP socket connection
nx_secure_tls_session_start	nx_secure_tls_session_start(tls_session, tcp_socket, wait_option); Starts a TLS session given a TCP socket. The TCP connection must be established before calling this function or the TLS handshake will fail.
nx_secure_tls_session_time_function_set	nx_secure_tls_session_time_function_set(tls_session, time_func_ptr); Sets up a function pointer that TLS will invoke when it needs to get the current time, which is used in various TLS handshake messages and for verification of certificates.
nx_secure_tls_trusted_ certificate_add	nx_secure_tls_trusted_certificate_add(tls_session, certificate); Adds an initialized certificate to a TLS session for use as a trusted Root Certificate
nx_secure_tls_trusted_certificate_remove	nx_secure_tls_trusted_certificate_remove(tls_session, common_name, common_name_length); Removes a certificate instance from the trusted certificates store, keyed on the Common Name field.
nx_secure_tls_remote_certificate_free_all	nx_secure_tls_remote_certificate_free_all(NX_SECURE_TLS_SESSION *session_ptr); Release certificates previously registered with the TLS session.

**nx_secure_tls_psk_add	nx_secure_tls_psk_add(tls_session, pre_shared_key, psk_length, psk_identity, identity_length, hint, hint_length); Adds a pre-shared key (PSK) to a TLS session for use with a PSK ciphersuite. The second parameter is the PSK identity used during the TLS handshake to select the proper key.
**nx_secure_tls_psk_find	nx_secure_tls_psk_find(tls_session, psk_data, psk_length,psk_identity, identity_length); Finds a pre-shared key (PSK) in a TLS session for use with a PSK ciphersuite. The PSK is found using an "identity hint" that should match a field in the PSK structure in the TLS session.
**nx_secure_tls_client_psk_set	nx_secure_tls_client_psk_set(tls_session, pre_shared_key, psk_length, psk_identity, identity_length, hint, hint_length); Sets the pre-shared key (PSK) for a TLS Client in a TLS session control block for use with a remote server that is sing a PSK ciphersuite.
nx_secure_x509_certificate_initialize	nx_secure_x509_certificate_initialize(NX_SECURE_X509_CERT *certificate_ptr, const UCHAR *certificate_data, USHORT certificate_data_length, UCHAR *raw_data_buffer, USHORT buffer_size, const UCHAR *private_key_data, USHORT private_key_data_length, UINT private_key_type); Initialize X.509 Certificate for NetX Secure TLS
nx_secure_x509_common_name_dns_check	nx_secure_x509_common_name_dns_check(&certificate, dns_tld, dns_tld_length) Check DNS name against X.509 Certificate
nx_secure_x509_crl_revocation_ check	nx_secure_x509_crl_revocation_check(&crl_data, crl_length, &cert_store, &certificate) Check X.509 Certificate against a supplied Certificate Revocation List

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

** Requires that the property PSK Cipher Suite of the TLS Common component be enabled.

NetX Duo TLS Session Status Return Values

Please refer *NetX Secure TLS User Guide* section of *Azure RTOS NetX Duo Documentation* for details on status return values by NetX Secure TLS services and NetX secure X.509 Certificate error codes.

4.3.35.3 NetX Duo TLS Session Module Operational Overview

TLS uses TCP and provides secure communications for application layer protocols such as HTTP and MQTT. TLS can also be used in 'bare' TCP socket applications to send and receive TCP packets in a secure session to another TCP peer. The module guide for this project uses this simplified application of TLS to demonstrate a TLS Client TCP and TLS Server TCP sockets exchanging data to a TCP peer.

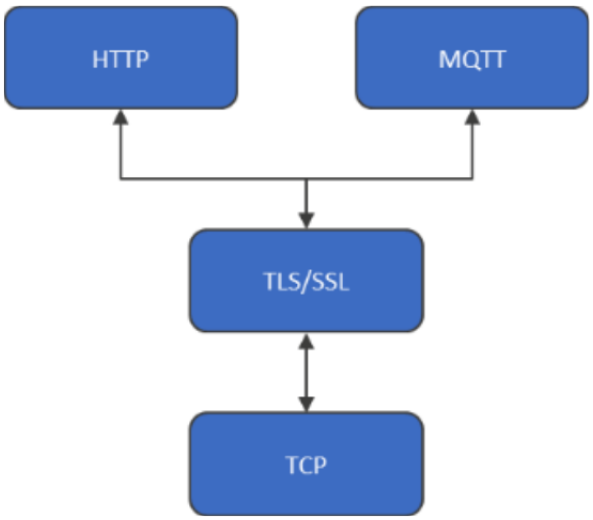

Figure 513: NetX Duo TLS Session Module TLS/SSL Layering

TLS does not have a well-known port number; instead, it uses the designated port number of the secure variant of the higher layer protocol. For example, port number 443 for secure HTTP, port number 8883 for MQTT, etc.

When a secure connection is established using TLS/SSL, for example using HTTPS, messages are exchanged between the client (which always initiates the connection) and a server. The first set of messages execute a Handshake Protocol after which the client and server can securely send/receive data bi-directionally, as shown in the following figure:

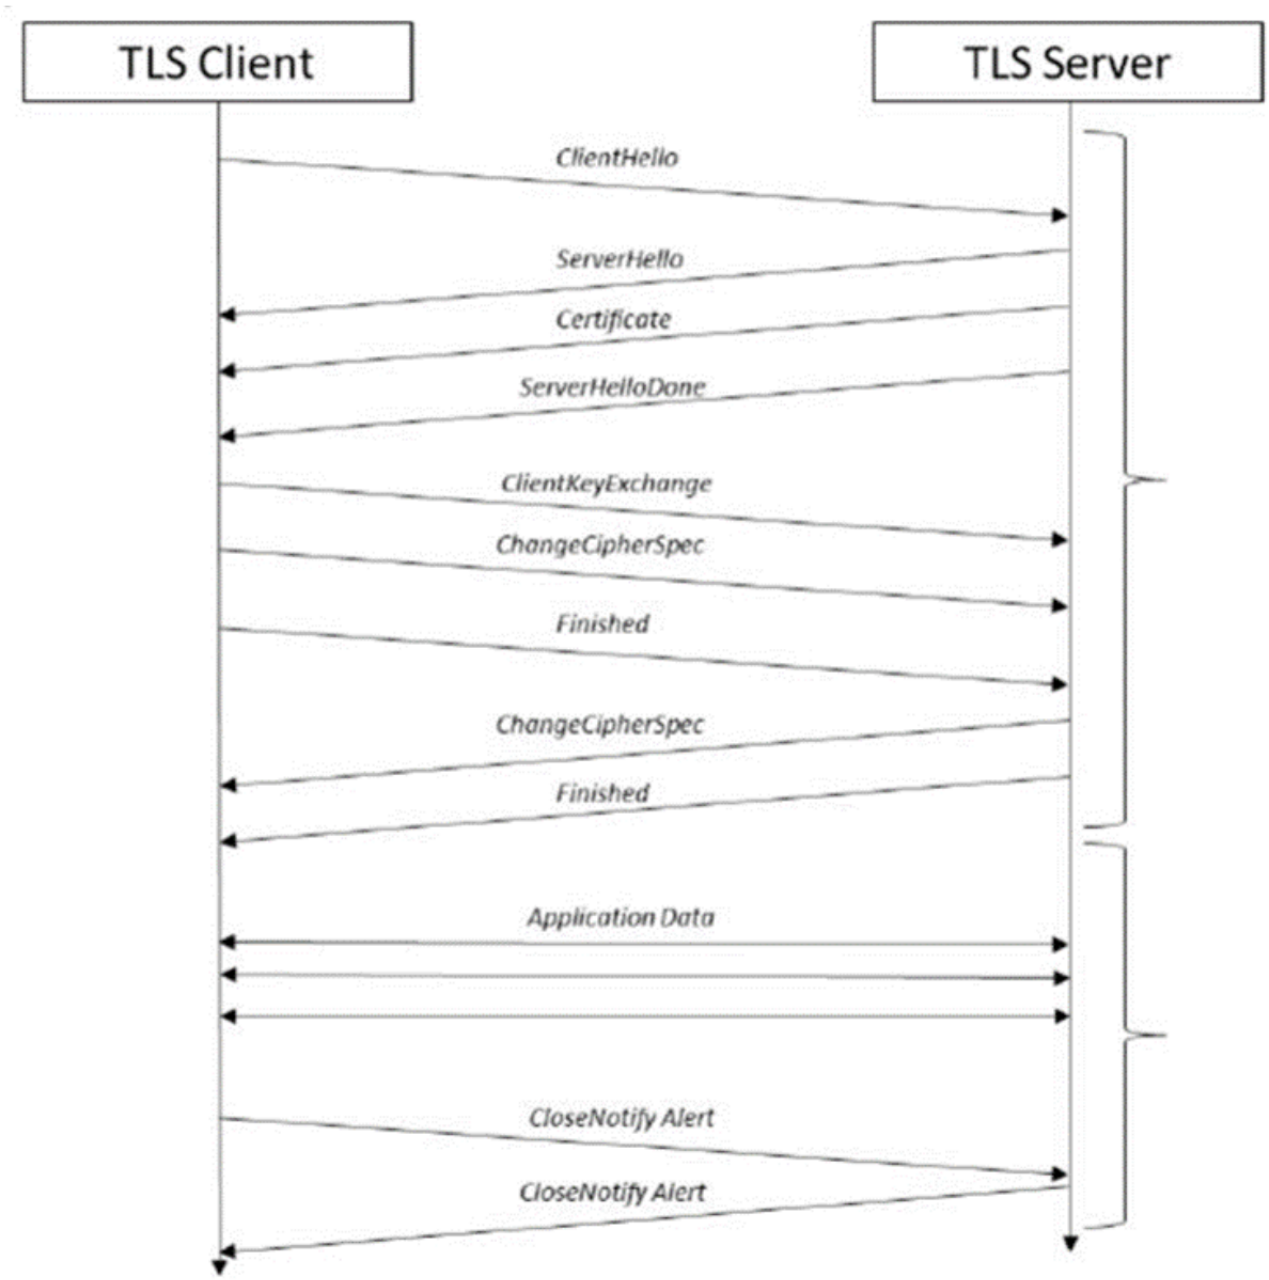

Figure 514: NetX Duo TLS Session Module TLS Protocol Sequences

NetX Duo TLS Session Module Important Operational Notes and Limitations

NetX Duo TLS Session Module Operational Notes

- Before the TLS session is created, the metadata buffer must be allocated. The size of meta data can be set using the properties pane. Also, the user can use NetX Duo Secure nx_secure_metadata_size_calculate API to calculate the required size of metadata buffer. The Metadata size is specified in the "Meta data size" of the TLS session component, or in the nx_secure_tls_session_create call; the default value is 4k but to handle most servers, 8k is recommended if the memory space is available.
- To associate a packet reassembly buffer to a TLS session, use the nx_secure_tls_session_packet_buffer_set API. The reassembly buffer is used to place the incoming TLS records which may span multiple TCP packets. If an incoming TLS record is

larger than the supplied buffer, the TLS session will end with an error. A reasonable packet buffer size is 6-8k.
- Also, before starting a TLS client session, the application must allocate memory for processing Server certificate data in the nx_secure_tls_remote_certificate_allocate call. A reasonable size for most certificates is 2k. The TLS client application should allow for 2-3 certificates from most servers.
- For any incoming certificate, the NetX Duo Secure TLS will perform basic X.509 path validation.
- Additionally, at each stage in the verification process the expiration date of each certificate is checked against the time provided by the application timestamp function. The nx_secure_tls_session_time_function_set API is used to optionally set up a function pointer for application timestamp function that TLS will invoke when it needs to get the current time. The current time is used in some TLS handshake messages for verification of certificates. If a timestamp function is registered with the TLS session, a timestamp will be used in the generation of the Server or Client Hello, and in verifying the remote certificate.
- Before attempting to reconnect to the same or another TLS server, the TLS client must clear the TLS session. This is most easily done by calling nx_secure_tls_session_end. It is recommended to delete the TLS session and recreate it before making another connection attempt. For applications using SSP 1.3.x, the nx_secure_tls_session_create call should be preceded by a memset call on the TLS session to clear the session completely: memset(tls_session_ptr, 0, sizeof(NXD_SECURE_TLS_SESSION));
- The user can use "Netx Duo TLS Common" module to configure Maximum RSA modulus size in bits. When user chooses Maximum RSA Modulus Size as 4096 bits then cryptographic operation for RSA such as encryption/decryption are done in software. Whereas if the user chooses Maximum RSA Modulus size as either 1024 or 2048 bits then cryptographic operations are done using Synergy Crypto Engine (SCE) hardware accelerator.
- TLS1.3 implementation in SSP currently supports only ECC based signature and ECDH key sharing.

NetX Duo TLS Session Module Limitations

- Due to the nature of embedded devices, some systems may not have adequate memory to support the maximum TLS record size of 16 KB. NetX Duo TLS Secure can handle 16KB records on devices with sufficient resources.
- NetX Duo Secure performs basic certificate verification only. NetX Duo TLS Secure will perform basic X.509 chain verification on a certificate to assure that the certificate is valid and signed by a trusted Certificate Authority, and can provide the certificate Common Name for the application to compare against the Top-Level Domain Name of the remote host. However, verification of certificate extensions and other data is the responsibility of the application implementer. Refer to the *Azure RTOS NetX Duo TLS Secure User Guide* available from the Synergy Gallery for more details.
- Software-based cryptography is processor-intensive and not available. Therefore, hardware-based cryptography is used for optimal performance of NetX Duo TLS Secure.
- Refer to the most recent *SSP release notes* for additional limitations on this module.

4.3.35.4 Including the NetX Duo TLS Session Module in an Application

This section describes how to include either or both the NetX Duo TLS Session module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo TLS Session module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

Note

Both TLS and DTLS session modules are included through the same stack as mentioned below.

User need not enable 'DTLS' property of 'NetX Duo TLS Common' to use TLS services.

Note

Both TLS and DTLS session modules are included through the same stack as mentioned below.

User has to enable 'DTLS' property of 'NetX Duo TLS Common' stack to use DTLS services.

NetX Duo TLS Session Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_tls_session0NetX Duo TLS/DTLS Session	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo TLS/DTLS Session

When the NetX Duo TLS/DTLS Session module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

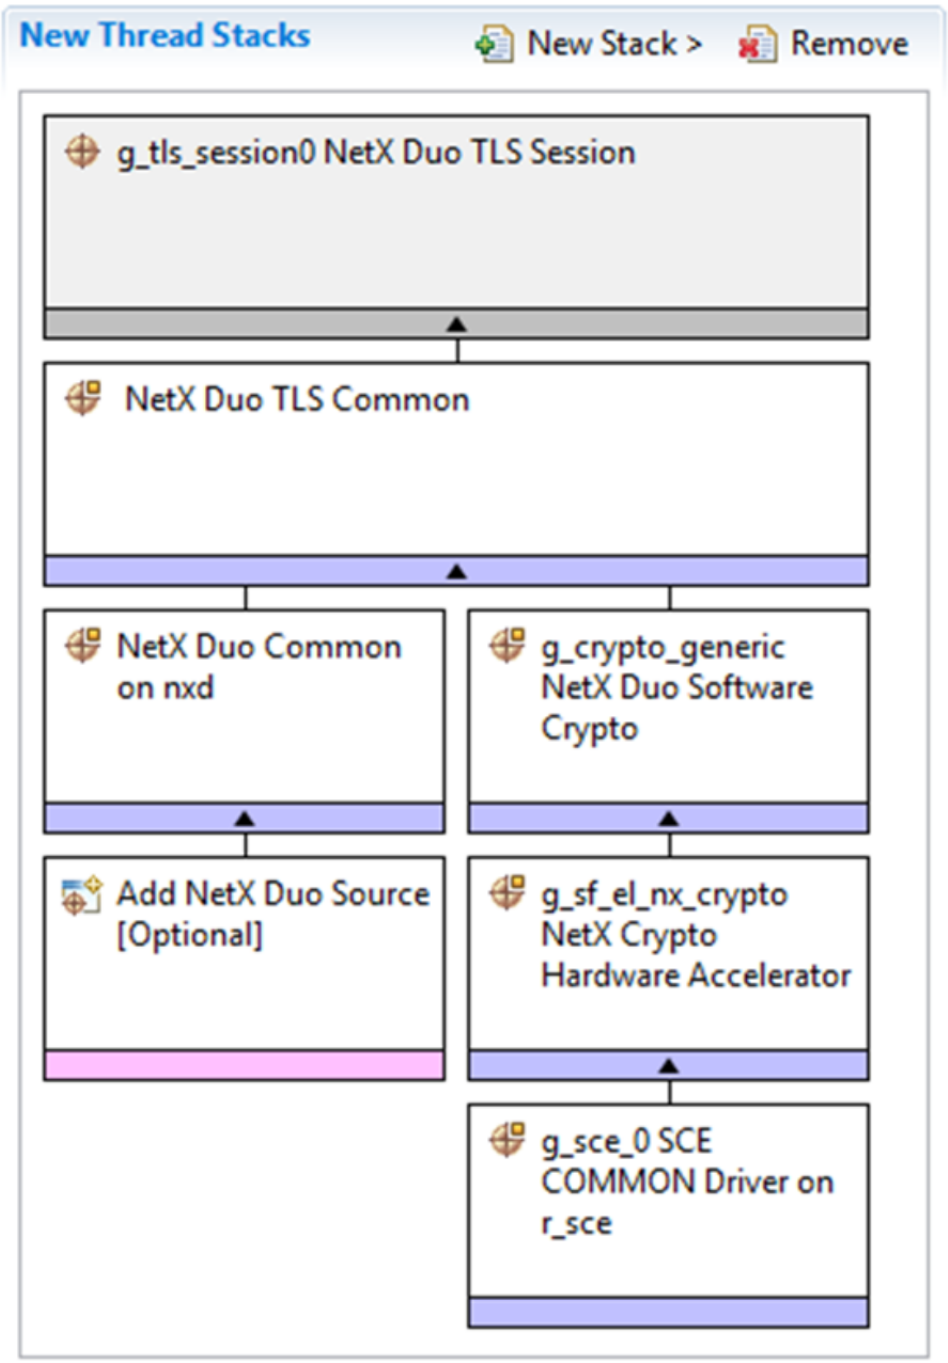

Figure 515: NetX Duo TLS Session Module Stack

4.3.35.5 Configuring the NetX Duo TLS Session Module

The NetX Duo TLS Session module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-

accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo TLS Session Module

ISDE Property	Value	Description
Security Protocol Name	TLS, DTLS Default : TLS	Security protocol Selection
Session Name	g_tls_session0	Module name
Meta data size	4000	Meta data size selection
Auto initialization	Enable, Disable Default : Enable	Auto initialization selection
*Name of Timestamp function	tls_timestamp_callback0	Name of timestamp function
**Name of Certificate Verification function	certificate_verification_callback0	Name of certificate verification function
Name of generated initialization function	tls_dtls_session_init0	Name of generated initialization function

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

*The Time Stamp function is discussed in section 3.1; it is omitted in this module guide in the interests of simplicity but it is typically used to check the expiration date of each certificate against the time provided by the application. Not having a timestamp callback may cause interoperability problems and reduce the security of production release TLS application sessions.

**The Certificate Verification function provides the certificate being verified to the application so additional verification steps may be performed. It is set to NULL in the module guide project for the sake of simplicity but in a real TLS session it would be verification tool.

In some cases, settings other than the defaults for stack modules can be desirable. For example, it might be useful to select different addresses for the Ethernet port. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX Duo TLS Session Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent

user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo TLS Common

ISDE Property	Value	Description
Crypto Engine	Hardware	Crypto engine selection
Self Signed Certificates	Enable, Disable Default: Disable	Self signed certificates selection
PSK Cipher Suite	Enable, Disable Default: Disable	PSK cipher suite selection
ECC Cipher Suite	Enable, Disable Default: Disable	ECC cipher suite selection
AES-GCM Data Buffer Size(Bytes)	Default: 2048	Maximum size of internal data buffer for encryption/decryption process in AES-GCM based cipher-suites.
X509 Strict Name Compare	Enable, Disable Default: Disable	X509 strict name compare selection
X509 Extended Distinguished Names	Enable, Disable Default: Disable	X509 extended distinguished names selection
X509 Certificate Revocation List Check	Enable, Disable Default: Enable	Revocation list check selection
X509	Enable, Disable Default: Enable	X509 feature selection

AEAD Cipher	Enable, Disable Default: Disable	AEAD cipher support selection
AEAD Cipher Check	Enable, Disable Default: Disable	AEAD cipher check selection for the AEAD cipher suites other than AES-CCM or AES-GCM
Additional AEAD Cipher ID	Default: NX_FALSE	Name of a valid additional AEAD cipher ID selection
SCSV Cipher suite	Enable, Disable Default: Disable	SCSV cipher suite selection
Maximum RSA Modulus size (bits)	1024, 2048, 3072, 4096 Default: 4096	Maximum RSA modulus size (bits) selection
TLS v 1.3	Enable, Disable Default: Disable	TLS v 1.3 selection
TLS Version Downgrade	Enable, Disable Default: Enable	TLS version downgrade selection
DTLS	Enable, Disable Default: Disable	DTLS enabling selection
DTLS Cookie Length	32	DTLS cookie length selection
DTLS Retransmit Retries	10	Number of DTLS retransmit retries
DTLS Initial Retransmit Rate(Sec)	1	DTLS initial retransmit rate in seconds
DTLS Maximum Retransmit Rate(Sec)	60	DTLS maximum retransmit rate in seconds
Maximum PSK ID Size	Default: 20	Maximum PSK ID size selection (bytes)
Maximum PSK Keys	Default: 5	Maximum PSK Keys selection
Maximum Size of PSK	Default: 20	Maximum Size of PSK Selection (bytes)
Minimum TLS X509 Certificate Size	Default: 256	Minimum TLS X509 Certificate size selection (bytes)
Minimum TLS Message Buffer Size	Default: 4000	Minimum TLS Message Buffer Size selection (bytes)
Size of TLS Pre-Master Secret	Default: 48	Size of TLS Pre-Master Secret selection (bytes)

Secure Key Clear	Enable, Disable Default: Disable	Secure key clear selection
TLS SNI Extension	Enable, Disable Default: Enable	Server name indication selection
Server Mode	Enable, Disable Default: Enable	Server mode selection
Client Mode	Enable, Disable Default: Enable	Client mode selection
Client Certificate Verify	Enable, Disable Default: Disable	Client certificate verification selection
Name of generated initialization function	nx_secure_common_init	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.
TLS 1.2 will be enabled by default in any NetX Duo TLS applications.
The AES-GCM data Buffer size refers to the internal input/output buffer used for the data encryption/decryption process. The value provided should be greater than or equal to the application data packet size, considering the available RAM space.
The Pre-Master Secret size should be at least 66 bytes when ECC cipher suites are used.
When the AEAD cipher check is enabled, we recommend that the user provide a valid algorithm ID in the additional AEAD cipher ID field

Configuration Settings for the NetX Duo Software Crypto

ISDE Property	Value	Description
Name	g_crypto_generic	Module name

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Crypto Hardware Accelerator

ISDE Property	Value	Description
Name	g_sf_el_nx_crypto	Module name

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have

different default values and available configuration settings.

Configuration Settings for the SCE Common Driver

ISDE Property	Value	Description
Name	g_sce_0	Module name
Endian Flag	CRYPTO_WORD_ENDIAN_BIG, CRYPTO_WORD_ENDIAN_LITTLE Default: CRYPT_WORD_ENDIAN_BIG	Endian flag selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX Duo TLS Session Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX Duo TLS Session Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection

REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.35.6 Using the NetX Duo TLS Session Module in an Application

Autogenerated code includes the initialization function with the name as specified in the *Name of generated initialization function property*, for example, tls_dlts_session_init0(). The TLS Session instance variable specified using the *Name* property of the TLS Session is passed as input to the initialization function and this instance variable can be passed as input to several APIs of the TLS layer. The initialization function internally calls the nx_secure_tls_session_create API to create a TLS session. Calls to the initialization function will be enabled or disabled depending on the *Auto Initialization* property value.

The steps in using the NetX Duo TLS Session module in a typical application are:

1. Packet the reassembly buffer for TLS session using the nx_secure_tls_session_packet_buffer_set API
2. Initialize the root CA certificate using the nx_secure_x509_certificate_initialize API
3. Load the root CA certificate to a trusted store using the nx_secure_tls_trusted_certificate_add API
4. Allocate space for certificates sent by remote server using the nx_secure_tls_remote_certificate_allocate API
5. Start the TLS session using the nx_secure_tls_session_start API
6. Send data over the secure connection using the nx_secure_tls_session_send API
7. Receive data over the secure connection using the nx_secure_tls_session_receive API
8. End the session using the nx_secure_tls_session_end API

The following figure illustrates common steps in a typical operational flow diagram:

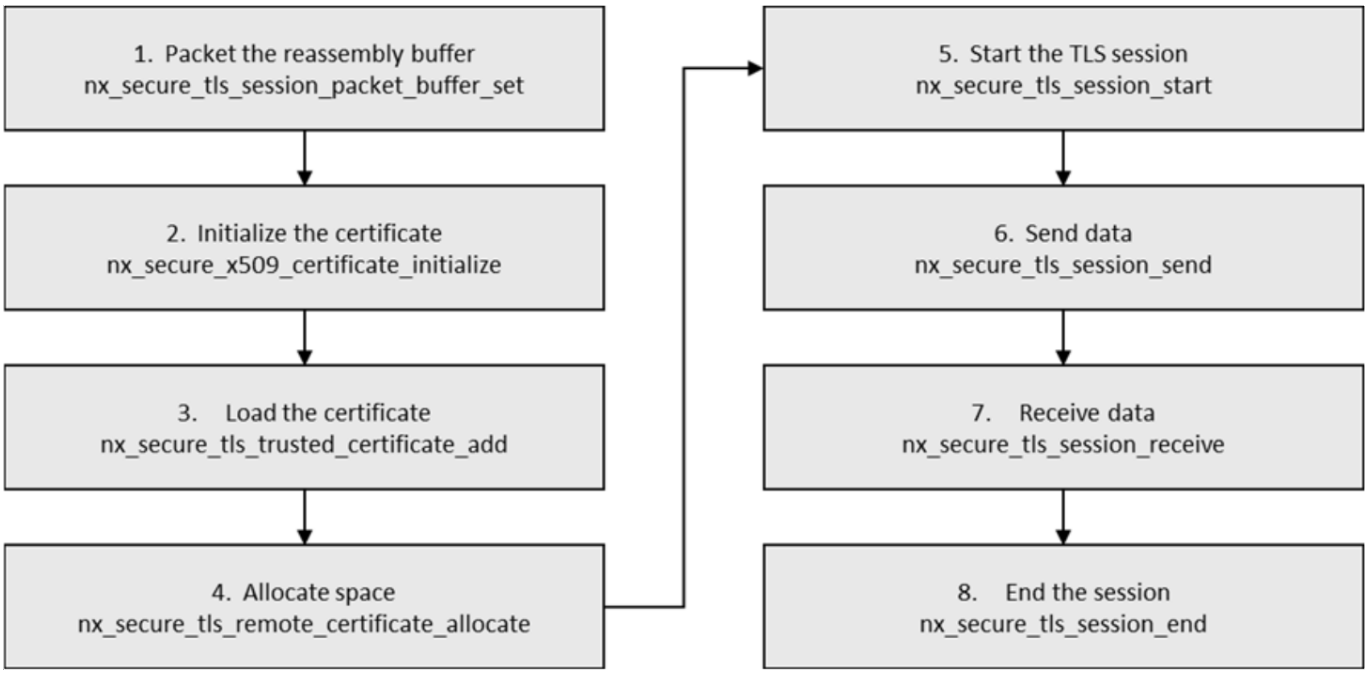

Figure 516: Flow Diagram of a Typical NetX Duo TLS Session Module Application

4.3.36 NetX Duo DTLS Session

4.3.36.1 NetX Duo DTLS Session Introduction

DTLS is closely coupled with TLS, as the underlying security mechanisms are shared between the protocols. However,TLS is designed to work over a transport layer protocol that guarantees about packet delivery and order (almost always TCP in practice) and will not function over an unreliable protocol like UDP. It is precisely because of UDP that DTLS was introduced. DTLS was designed to handle the unreliable nature of UDP and similar protocols. It does this by including ordering and reliability logic (e.g. retransmission of dropped data) similar to reliable protocols like TCP

The NetX Duo DTLS Session Module provides a high-level API for Datagram Transport Layer Security (DTLS) protocol-based clients and servers. It uses services provided by the Synergy Crypto Engine (SCE) to carry out hardware-accelerated encryption and decryption.

The NetX Duo DTLS Session module is based on ThreadX "NetX Duo Secure," which implements the Datagram Transport Layer Security (DTLS) protocol as described in RFCs 6347 (version 1.2). NetX Duo Secure also includes routines for basic X.509 (RFC 5280).

The DTLS protocol provides privacy and reliability between two communicating applications. It has the following basic properties:

- Encryption: The messages exchanged between communicating applications are encrypted to ensure that the connection is private. Symmetric cryptography mechanism such as AES (Advanced Encryption Standard is used for data encryption.
- Authentication: A mechanism to check the peer's identity using certificates
- Integrity: A mechanism to detect message tampering and forgery to ensure that

connection is reliable. Message Authentication Code (MAC) such as Secure Hash Algorithm (SHA) is used to ensure message integrity.

NetX Duo DTLS Session Module Features

- RFC 6347 The Datagram Transport Layer Security (DTLS) Protocol version 1.2
- RFC 5280 X.509 PKI Certificates (v3)
- RFC 3268 Advanced Encryption Standard (AES) Cipher suites for Datagram Transport Layer Security (DTLS)
- RFC 3447 Public-Key Cryptography Standards (PKCS) #1: RSA Cryptography Specifications Version 2.1
- RFC 2104 HMAC: Keyed-Hashing for Message Authentication
- RFC 6234 US Secure Hash Algorithms (SHA and SHA-based HMAC and HKDF)
- RFC 4279 Pre-Shared Key Cipher suites for DTLS
- Supports DTLS extensions for the following:
    1. Secure Renegotiation Indication: This extension mitigates a Man-in-the-Middle attack vulnerability that could occur during a renegotiation handshake.
    2. Server Name Indication: This extension allows a DTLS Client to supply a specific DNS name to a DTLS Server, allowing the server to select the correct credentials (assumes the server has multiple identity certificates and network entry points).
    3. Signature Algorithms: This extension enables a DTLS Client to provide a list of acceptable signature and hash algorithms to a DTLS Server
- Supports X.509 extensions for the following:
    1. Key Usage: Provides acceptable uses for a certificate's public key in a bitfield
    2. Extended Key Usage: Provides additional acceptable uses for a certificate's public key using OIDs
- Certificate verification: Supports SHA-1, SHA-256, SHA-384 and SHA-512 signature hashing algorithms
- Subject Alternative Name: Provides alternative DNS names that are also represented by the certificate.

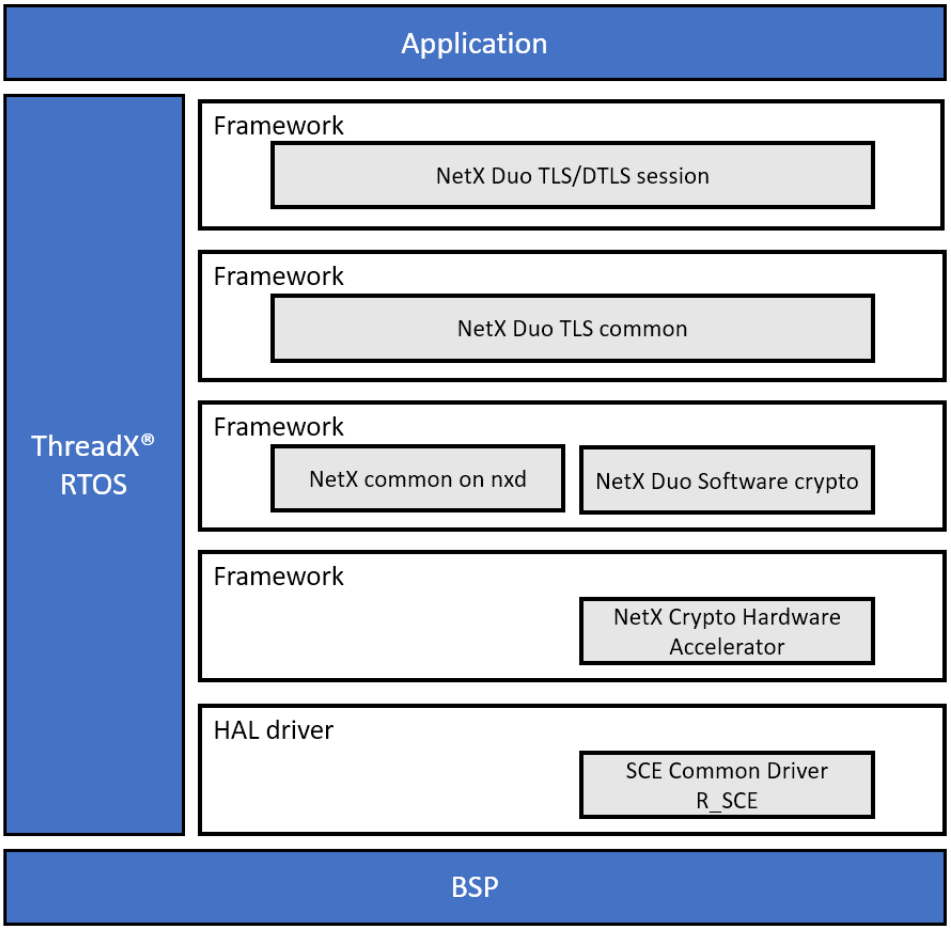

Figure 517: NetX Duo Secure DTLS Session Module Block Diagram

4.3.36.2 NetX Duo DTLS Session Module APIs Overview

The NetX Duo DTLS Session module defines APIs for creating and setting up a DTLS security session. A complete list of the available APIs, an example API call and a short description of each can be found in the following table.

Function Name	Example API Call and Description
nx_secure_dtls_client_session_start	nx_secure_dtls_client_session_start(NX_SECURE_DTLS_SESSION *dtls_session, NX_UDP_SOCKET *udp_socket, NXD_ADDRESS *ip_address, UINT port, UINT wait_option); Starts DTLS client session connecting to the provided server address and port using UDP socket.
nx_secure_dtls_packet_allocate	nx_secure_dtls_packet_allocate(NX_SECURE_DTLS_SESSION *session_ptr, NX_PACKET_POOL *pool_ptr, NX_PACKET **packet_ptr, ULONG wait_option); Allocate a packet for a NetX Secure DTLS Session

nx_secure_dtls_psk_add	nx_secure_dtls_psk_add(NX_SECURE_DTLS_SESSION *session_ptr, UCHAR *pre_shared_key, UINT psk_length, UCHAR *psk_identity, UINT identity_length, UCHAR *hint, UINT hint_length); Add a Pre-Shared Key to a NetX Secure DTLS Session
nx_secure_dtls_server_create	nx_secure_dtls_server_create(NX_SECURE_DTLS_SERVER *server_ptr, NX_IP *ip_ptr, UINT port, ULONG timeout, VOID *session_buffer, UINT session_buffer_size, const NX_SECURE_TLS_CRYPTO *crypto_table, VOID *crypto_metadata_buffer, ULONG crypto_metadata_size, UCHAR *packet_reassembly_buffer, UINT packet_reassembly_buffer_size, UINT (*connect_notify)(NX_SECURE_DTLS_SESSION *dtls_session, NXD_ADDRESS *ip_address, UINT port), UINT (*receive_notify)(NX_SECURE_DTLS_SESSION *dtls_session))); Create a NetX Secure DTLS Server
nx_secure_dtls_server_delete	nx_secure_dtls_server_delete(NX_SECURE_DTLS_SERVER *server_ptr); Free up resources used by a NetX Secure DTLS Server
nx_secure_dtls_server_local_certificate_add	nx_secure_dtls_server_local_certificate_add(NX_SECURE_DTLS_SERVER *server_ptr, NX_SECURE_X509_CERT *certificate, UINT cert_id); Add a local server identity certificate to a NetX Secure DTLS Server
nx_secure_dtls_server_local_certificate_remove	nx_secure_dtls_server_local_certificate_remove(NX_SECURE_DTLS_SERVER *server_ptr, UCHAR *common_name, UINT common_name_length, UINT cert_id); Remove a local server identity certificate from a NetX Secure DTLS Server
nx_secure_dtls_server_notify_set	nx_secure_dtls_server_notify_set(NX_SECURE_DTLS_SERVER *server_ptr, UINT (*disconnect_notify)(NX_SECURE_DTLS_SESSION *dtls_session), UINT (*error_notify)(NX_SECURE_DTLS_SESSION *dtls_session, UINT error_code)); Assign optional notification callback routines to a NetX Secure DTLS Server
nx_secure_dtls_server_psk_add	nx_secure_dtls_server_psk_add(NX_SECURE_DTLS_SERVER *server_ptr, UCHAR *pre_shared_key, UINT psk_length, UCHAR *psk_identity, UINT identity_length, UCHAR *hint, UINT hint_length); Add a Pre-Shared Key to a NetX Secure DTLS Server

nx_secure_dtls_server_session_send	nx_secure_dtls_server_session_send(NX_SECURE_DTLS_SESSION *session_ptr, NX_PACKET *packet_ptr); Send data over a DTLS session established with a NetX Secure DTLS Server
nx_secure_dtls_server_session_start	nx_secure_dtls_server_session_start(NX_SECURE_DTLS_SESSION *session_ptr, UINT wait_option); Start a DTLS Session from a NetX Secure DTLS Server
nx_secure_dtls_server_start	nx_secure_dtls_server_start(NX_SECURE_DTLS_SERVER *server_ptr); Start a NetX Secure DTLS Server instance listening on the configured UDP port
nx_secure_dtls_server_stop	nx_secure_dtls_server_stop(NX_SECURE_DTLS_SERVER *server_ptr); Stop an active NetX Secure DTLS Server instance
nx_secure_dtls_server_trusted_certificate_add	nx_secure_dtls_server_trusted_certificate_add(NX_SECURE_DTLS_SERVER *server_ptr, NX_SECURE_X509_CERT *certificate, UINT cert_id); Add a trusted CA certificate to a NetX Secure DTLS Server
nx_secure_dtls_server_trusted_certificate_remove	nx_secure_dtls_server_trusted_certificate_remove(NX_SECURE_DTLS_SERVER *server_ptr, UCHAR *common_name, UINT common_name_length, UINT cert_id); Remove a trusted CA certificate from a NetX Secure DTLS Server
nx_secure_dtls_server_x509_client_verify_configure	nx_secure_dtls_server_x509_client_verify_configure (NX_SECURE_DTLS_SERVER *server_ptr, UINT certs_per_session, UCHAR *certs_buffer, ULONG buffer_size); Configure a NetX Secure DTLS Server to request and verify client certificates
nx_secure_dtls_server_x509_client_verify_disable	nx_secure_dtls_server_x509_client_verify_disable (NX_SECURE_DTLS_SERVER *server_ptr); Disables client X.509 certificate verification for a NetX Secure DTLS Server
nx_secure_dtls_session_client_info_get	nx_secure_dtls_session_client_info_get(NX_SECURE_DTLS_SESSION *session_ptr, NXD_ADDRESS *client_ip_address, UINT *client_port, UINT *local_port); Get remote client information from a DTLS Server session

nx_secure_dtls_session_create	nx_secure_dtls_session_create(NX_SECURE_DTLS_SESSION *dtls_session, const NX_SECURE_TLS_CRYPTO *crypto_table, VOID *metadata_buffer, ULONG metadata_size, UCHAR *packet_reassembly_buffer, UINT packet_reassembly_buffer_size, UINT certs_number, UCHAR *remote_certificate_buffer, ULONG remote_certificate_buffer_size)); Create and configure a NetX Secure DTLS Session
nx_secure_dtls_session_delete	nx_secure_dtls_session_delete(NX_SECURE_DTLS_SESSION *dtls_session); Free up resources used by a NetX Secure DTLS Session
nx_secure_dtls_session_end	nx_secure_dtls_session_end(NX_SECURE_DTLS_SESSION *dtls_session, UINT wait_option); Shut down an active NetX Secure DTLS Session
nx_secure_dtls_session_local_certificate_add	nx_secure_dtls_session_local_certificate_add(NX_SECURE_DTLS_SESSION *session_ptr, NX_SECURE_X509_CERT *certificate, UINT cert_id); Add a local identity certificate to a NetX Secure DTLS Session
nx_secure_dtls_session_local_certificate_remove	nx_secure_dtls_session_local_certificate_remove(NX_SECURE_DTLS_SESSION *session_ptr, UCHAR *common_name, UINT common_name_length, UINT cert_id); Remove a local identity certificate from a NetX Secure DTLS Session
nx_secure_dtls_session_receive	nx_secure_dtls_session_receive(NX_SECURE_DTLS_SESSION *dtls_session, NX_PACKET **packet_ptr_ptr, UINT wait_option); Receive application data over an established NetX Secure DTLS Session
nx_secure_dtls_session_reset	nx_secure_dtls_session_reset(NX_SECURE_DTLS_SESSION *dtls_session); Clear data in an NetX Secure DTLS Session instance
nx_secure_dtls_session_send	nx_secure_dtls_session_send(NX_SECURE_DTLS_SESSION *session_ptr, NX_PACKET *packet_ptr, NXD_ADDRESS *ip_address, UINT port); Send data over a DTLS session
nx_secure_dtls_session_trusted_certificate_add	nx_secure_dtls_session_trusted_certificate_add(NX_SECURE_DTLS_SESSION *session_ptr, NX_SECURE_X509_CERT *certificate, UINT cert_id); Add a trusted CA certificate to a NetX Secure DTLS Session

nx_secure_dtls_session_trusted_certificate_remove	nx_secure_dtls_session_trusted_certificate_remove(NX_SECURE_DTLS_SESSION *session_ptr, UCHAR *common_name, UINT common_name_length, UINT cert_id); Remove a trusted CA certificate from a NetX Secure DTLS Session

Note

For details on operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS User's Manual in the References section.

NetX Duo DTLS Session Status Return Values

Please refer *NetX Secure DTLS User Guide* section of *Azure RTOS NetX Duo Documentation* for details on status return values by NetX Secure DTLS services and NetX secure X.509 Certificate error codes.

4.3.36.3 NetX Duo DTLS Session Module Operational Overview

DTLS can be used in 'bare' UDP socket applications to send and receive UDP packets in a secure session to another UDP peer.

When a secure connection is established using DTLS, messages are exchanged between the client (which always initiates the connection) and a server. The first set of messages execute a Handshake Protocol after which the client and server can securely send/receive data bi-directionally, as shown in the following figure:

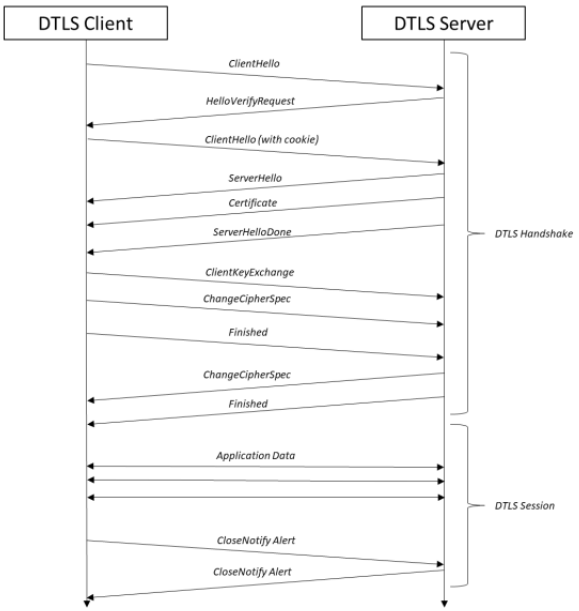

Figure 518: DTLS Protocol

NetX Duo DTLS Session Module Important Operational Notes and Limitations

NetX Duo DTLS Session Module Operational Notes

- For any incoming certificate, the NetX Duo Secure DTLS will perform basic X.509 path validation.

- Before attempting to reconnect to the same or another DTLS server, the DTLS client must clear the DTLS session. This is most easily done by calling nx_secure_dtls_session_end. It is recommended to delete the DTLS session and recreate it before making another connection attempt.
- The user can use "NetX Duo TLS Common" module to configure Maximum RSA modulus size in bits. When user chooses Maximum RSA Modulus Size as 4096 bits then cryptographic operation for RSA such as encryption/decryption are done in software. Whereas if the user chooses Maximum RSA Modulus size as either 1024 or 2048 bits then cryptographic operations are done using Synergy Crypto Engine (SCE) hardware accelerator.

NetX Duo DTLS Session Module Limitations

1. Due to the nature of embedded devices, some applications may not have the resources to support the maximum DTLS record size of 16KB. NetX Secure can handle 16KB records on devices with sufficient resources.
2. Minimal certificate verification. NetX Secure will perform basic X.509 chain verification on a certificate to assure that the certificate is valid and signed by a trusted Certificate Authority and can provide the certificate Common Name for the application to compare against the Top-Level Domain Name of the remote host. However, verification of certificate extensions and other data is the responsibility of the application implementer. Refer to the *Azure RTOS NetX Duo DTLS Secure User Guide* available from the Synergy Gallery for more details.
3. Software-based cryptography is processor-intensive and is currently not supported in SSP. Therefore, hardware-based cryptography is used for optimal performance of NetX Secure DTLS.
4. Auto initialization option for DTLS configurable properties is not supported and must be disabled.
5. Refer to the most recent SSP release notes for additional limitations on this module.

4.3.36.4 Including the NetX Duo DTLS Session Module in an Application

This section describes how to include the NetX Duo DTLS Session module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo DTLS Session module to an application, simply add it to a thread using the stacks selection sequence given in the following table and enable 'DTLS' property of 'NetX Duo TLS Common' stack.

Note

Both TLS and DTLS session modules are included through the same stack as mentioned below.

User has to enable 'DTLS' property of 'NetX Duo TLS Common' stack to use DTLS services.

Resource	ISDE Tab	Stacks Selection Sequence
g_tls_session0NetX Duo TLS/DTLS Session	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetX Duo TLS/DTLS Session

When the NetX Duo TLS/DTLS Session module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the new icon and displays possible choices.

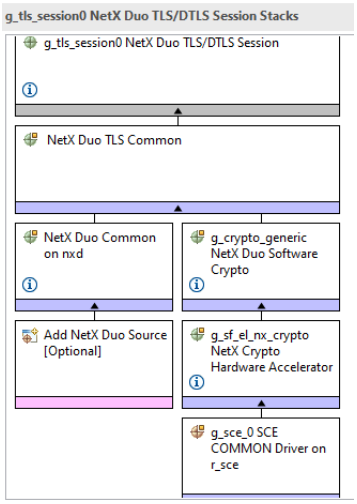

Figure 519: NetX Duo DTLS Session Module Stack

4.3.36.5 Configuring the NetX Duo DTLS Session Module

The NetX Duo DTLS Session module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo DTLS Session Module

ISDE Property	Value**	**Description
Security Protocol Name	TLS, DTLS Default: TLS	Security protocol selection
Session Name	g_tls_session0	Module name

Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection
Meta data size	18000	Size of meta data
Name of Timestamp function	tls_timestamp_callback0	Name of timestamp function
Name of Certificate Verification function	certificate_verification_callback0	Name of certificate verification function
Name of generated initialization function	tls_dtls_session_init0	Name of generated initialization function

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.
Auto Initialization has to be disabled for DTLS Session.
The properties 'Meta data size', 'Name of Timestamp function', 'Name of Certificate Verification function', 'Name of generated initialization function' are applicable only for TLS Session.

Configuration Settings for the NetX Duo DTLS Session Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo TLS Common

ISDE Property	Value	Description
Crypto Engine	Hardware	Crypto engine selection
Self Signed Certificates	Enable, Disable Default: Disable	Self signed certificates selection
PSK Cipher Suite	Enable, Disable Default: Disable	PSK cipher suite selection

ECC Cipher Suite	Enable, Disable Default: Disable	ECC cipher suite selection
AES-GCM Data Buffer Size(Bytes)	Default: 2048	Maximum size of internal data buffer for encryption/decryption process in AES-GCM based cipher-suites.
X509 Strict Name Compare	Enable, Disable Default: Disable	X509 strict name compare selection
X509 Extended Distinguished Names	Enable, Disable Default: Disable	X509 extended distinguished names selection
X509 Certificate Revocation List Check	Enable, Disable Default: Enable	Revocation list check selection
X509	Enable, Disable Default: Enable	X509 feature selection
AEAD Cipher	Enable, Disable Default: Disable	AEAD cipher support selection
AEAD Cipher Check	Enable, Disable Default: Disable	AEAD cipher check selection for the AEAD cipher suites other than AES-CCM or AES-GCM
SCSV Cipher suite	Enable, Disable Default: Disable	SCSV cipher suite selection
Maximum RSA Modulus size (bits)	1024, 2048, 3072, 4096 Default: 4096	Maximum RSA modulus size (bits) selection
TLS v 1.3	Enable, Disable Default: Disable	TLS v 1.3 selection
TLS Version Downgrade	Enable, Disable Default: Enable	TLS version downgrade selection
DTLS	Enable, Disable Default: Disable	DTLS enabling selection
DTLS Cookie Length	32	DTLS cookie length selection
DTLS Retransmit Retries	10	Number of DTLS retransmit retries
DTLS Initial Retransmit Rate(Sec)	1	DTLS initial retransmit rate in seconds

DTLS Maximum Retransmit Rate(Sec)	60	DTLS maximum retransmit rate in seconds
Maximum PSK ID Size	Default: 20	Maximum PSK ID size selection (bytes)
Maximum PSK Keys	Default: 5	Maximum PSK Keys selection
Maximum Size of PSK	Default: 20	Maximum Size of PSK Selection (bytes)
Minimum TLS X509 Certificate Size	Default: 256	Minimum TLS X509 Certificate size selection (bytes)
Minimum TLS Message Buffer Size	Default: 4000	Minimum TLS Message Buffer Size selection (bytes)
Size of TLS Pre-Master Secret	Default: 48	Size of TLS Pre-Master Secret selection (bytes)
Secure Key Clear	Enable, Disable Default: Disable	Secure key clear selection
TLS SNI Extension	Enable, Disable Default: Enable	Server name indication selection
Server Mode	Enable, Disable Default: Enable	Server mode selection
Client Mode	Enable, Disable Default: Enable	Client mode selection
Client Certificate Verify	Enable, Disable Default: Disable	Client certificate verification selection
Name of generated initialization function	nx_secure_common_init	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.
DTLS should be enabled to use DTLS V 1.2 protocol.
The AES-GCM data Buffer size refers to the internal input/output buffer used for the data encryption/decryption process. The value provided should be greater than or equal to the application data packet size, considering the available RAM space.
The Pre-Master Secret size should be at least 66 bytes when ECC cipher suites are used.

Configuration Settings for the NetX Duo Software Crypto

ISDE Property	Value	Description
Name	g_crypto_generic	Module name

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Crypto Hardware Accelerator

ISDE Property	Value	Description
Name	g_sf_el_nx_crypto	Module name

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SCE Common Driver

ISDE Property	Value	Description
Name	g_sce_0	Module name
Endian Flag	CRYPTO_WORD_ENDIAN_BIG, CRYPTO_WORD_ENDIAN_LITTLE Default: CRYPT_WORD_ENDIAN_BIG	Endian flag selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX Duo DTLS Session Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

NetX Duo DTLS Session Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.36.6 Using the NetX Duo DTLS Session Module in an Application

Note

User cannot enable Auto Initialization for DTLS session from SSP configurator. Hence the client and server initialization functions has to be invoked from the application.

The steps in using the NetX Duo DTLS Session module in a typical client application are:

1. Create a DTLS session using the nx_secure_dtls_session_create API.
2. Initialize the root CA certificate using the nx_secure_x509_certificate_initialize API
3. Load the root CA certificate to a trusted store using the nx_secure_dtls_session_trusted_certificate_add API
4. Start DTLS client session using nx_secure_dtls_client_session_start API.

5. Allocate a DTLS packet to send some encrypted data to the server using nx_secure_dtls_packet_allocate API.
6. Populate the packet with some data using nx_packet_data_appendAPI.
7. Send data over the secure connection to the server using nx_secure_dtls_session_sendAPI.
8. Receive data over the secure connection using nx_secure_dtls_session_receive API from the server.
9. End the session using nx_secure_dtls_session_endAPI.

The following figure illustrates common steps of client application in a typical operational flow diagram:

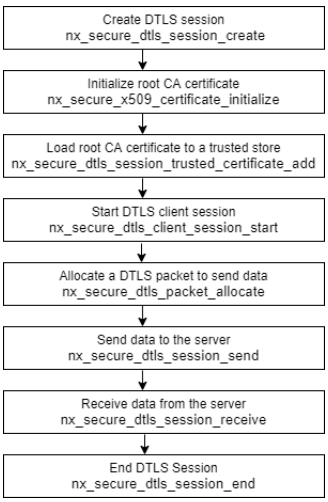

Figure 520: Flow Diagram of a Typical NetX Secure DTLS Session Module Client Application

The steps in using the NetX Duo DTLS Session module in a typical server application are:

1. Create a DTLS server instance using nx_secure_dtls_server_create API. User has to define Connect and Receive Notify callback functions which will be passed as parameters to nx_secure_dtls_server_create API.
2. Initialize local server identity certificate with key and add to server using nx_secure_x509_certificate_initialize API.
3. Add local server identity certificate to DTLS server using nx_secure_dtls_server_local_certificate_addAPI. API.
4. Start DTLS server using nx_secure_dtls_server_startAPI.
5. If there is a connection attempt from the client, start DTLS server session using nx_secure_dtls_server_session_startAPI.
6. Receive the data from connected client using nx_secure_dtls_session_receiveAPI.
7. Send the response to client using nx_secure_dtls_server_session_sendAPI
8. Once server processing is done, stop server instance from accepting connection requests using nx_secure_dtls_server_stopAPI.
9. Delete DTLS server session using nx_secure_dtls_server_deleteAPI.

The following figure illustrates common steps of server application in a typical operational flow diagram:

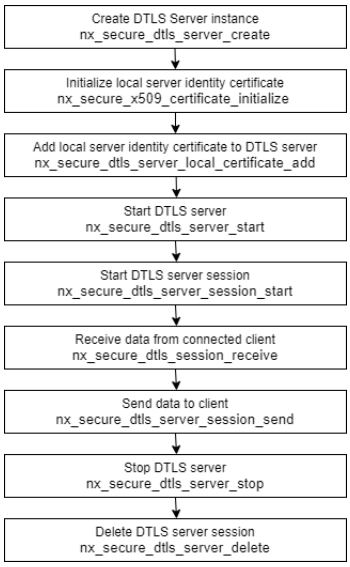

Figure 521: Flow Diagram of a Typical NetX Secure DTLS Session Module Server Application

4.3.37 NetX Duo mDNS/DNS-SD

4.3.37.1 NetX Duo mDNS/DNS-SD Introduction

Multicast DNS/DNS-SD (mDNS) is a protocol that helps in resolving the hostname to IP address in a local network. The mDNS and DNS-SD are protocols designed to augment the traditional DNS service. mDNS provides hostname and service lookup to the nodes on the local network. Each node uses an IPv4 or IPv6 multicast channel to announce services it offers to its neighbors, responds to queries from its neighbors, and sends queries on behalf of its applications. Throughout the document, the term mDNS refers to the services that cover both the mDNS specification and the DNS-SD specification.

NetX Duo mDNS/DNS-SD Module Features

- NetX Duo mDNS/DNS-SD is compliant with RFC 6762 and RFC 6763.
- NetX Duo mDNS/DNS-SD supports both IPv4 and IPv6 networks.
- Optional creation of separate packet pool for mDNS operations.
- Provides high-level APIs for:
    - Creating and deleting mDNS instances.
    - Creating and deleting local services.
    - Perform single shot and continuous service discovery.
    - Service lookup from the local peer service cache.
    - Setting cache and services notify callbacks.

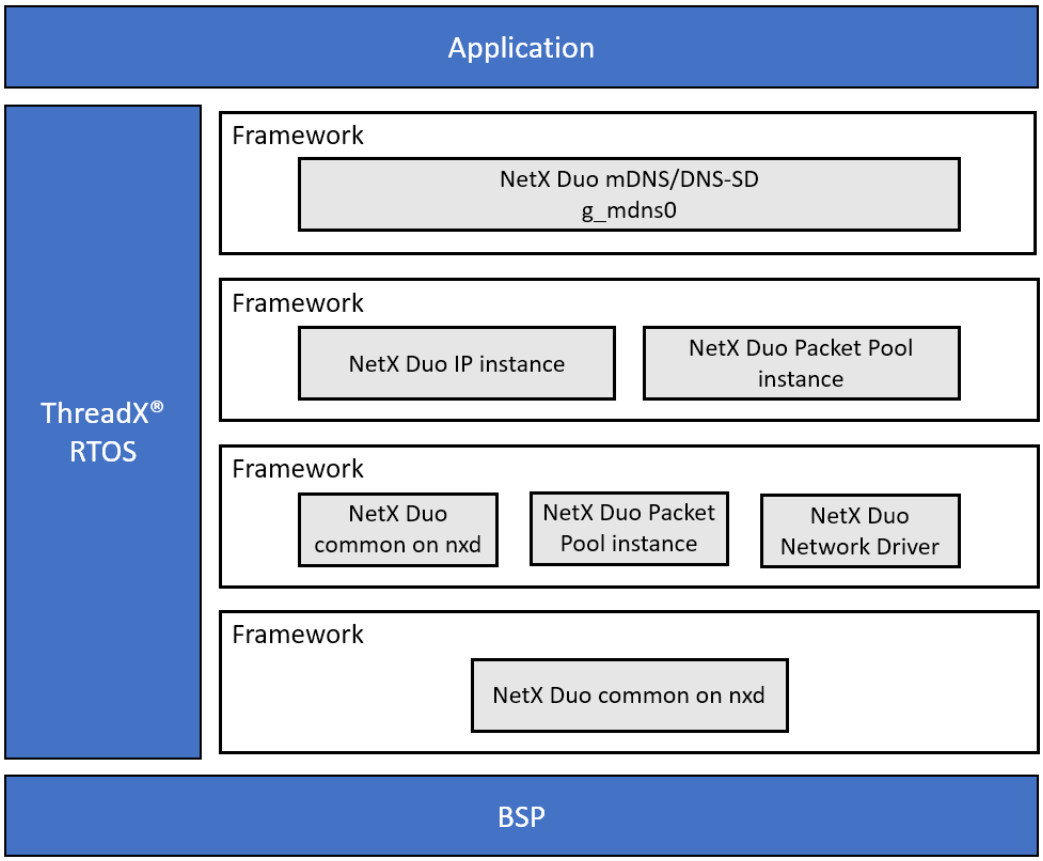

Figure 522: NetX Duo mDNS/DNS-SD Module Block Diagram

Note

In the figure above, the NetX Duo Network Driver modules has multiple implementation options available. See the description just after the module stack figure in Including the NetX Duo mDNS/DNS-SD Module in an Application for additional details.

4.3.37.2 NetX Duo mDNS/DNS-SD Module APIs Overview

The NetX Duo mDNS/DNS-SD Support module defines APIs for creating the mDNS instances, setting domain name, adding mDNS services, performing a one-shot and continuous discovery. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

NetX Duo mDNS Module API Summary

Function Name	Example API Call and Description
nx_mdns_create	nx_mdns_create(&my_mdns, &my_ip, &my_packet_pool, priority, stack_ptr, sizeof(stack_ptr), "NETX-MDNS-HOST", local_cache_ptr, sizeof(local_cache_ptr), peer_cache_ptr, sizeof(peer_cache_ptr), probing_notify); Creates an mDNS instance on the specific IP instance and associated resources.

nx_mdns_delete	nx_mdns_delete(&my_mdns); deletes the mDNS instance and frees its resources.
nx_mdns_enable	nx_mdns_enable(&my_mdns, interface_index); Enables mDNS service on a specific physical interface. Once the service is enabled, the mDNS module first probes all its unique service names on the network before responding to queries received on the interface.
nx_mdns_disable	nx_mdns_disable(&my_mdns, interface_index); Disables mDNS service on the specific physical interface. Once the service is disabled, the mDNS sends "goodbye" messages for every local service to the network that is attached to the interface, so the neighboring nodes are notified.
nx_mdns_cache_notify_set	nx_mdns_cache_notify_set(&my_mdns, cache_full_nofiy_cb); This service installs a user-supplied callback function, which is invoked when either the local service cache or peer service cache becomes full.
nx_mdns_cache_notify_clear	nx_mdns_cache_notify_clear(&my_mdns); Clears a user-supplied service cache notify callback function.
nx_mdns_domain_name_set	nx_mdns_domain_name_set(&my_mdns, "home"); This service sets up the default local domain name. When the mDNS instance is created, the default local domain name is set to ".local". This API allows an application to overwrite the default local domain name.
nx_mdns_service_announcement_timing_set	nx_mdns_service_announcement_timing_set(&my_mdns, t, p, k, retrans_interval, period_interval, max_time); This service reconfigures the timing parameters employed by mDNS when sending the service announcements. Publish period starts from t ticks and can be expanded telescopically with 2 to the power of k factor. The number of repetitions per advertisement is p, the interval between each repeated advertisement is *interval* ticks, and Maximum announcement period is max_time.

nx_mdns_service_add	nx_mdns_service_add(&my_mdns, "NETX-SERVICE", "_http._tcp", NX_NULL, NX_NULL, 0, priority, weight, port,is_unique, interface); This API registers a service offered by the application. If the flag is_unique is set, mDNS probes the service name to make sure it is unique on the local network before starting to announce the service on the network.
nx_mdns_service_delete	nx_mdns_service_delete(&my_mdns, "NETX-SERVICE", "_http._tcp", NX_NULL); This API deletes a previous registered service. As the service is deleted, "goodbye" messages are sent to the local network so the neighboring nodes are notified.
nx_mdns_service_one_shot_query	nx_mdns_service_one_shot_query(&my_mdns, "NETX-SERVICE", "_http._tcp", NX_NULL, service_ptr, wait_option); This service performs a one-shot mDNS query. If the specified service is found in the peer service cache, the first instance is returned. If no services are found in the local peer service cache, the mDNS module issues a query command and waits for a response.
nx_mdns_service_continuous_query	nx_mdns_service_continuous_query(&my_mdns, "NETX-SERVICE", "_http._tcp", NX_NULL); This service starts a continuous query. Note that the service returns immediately. After issuing a continuous query, the application may retrieve service records by using the API nx_mdns_service_lookup.
nx_mdns_service_query_stop	nx_mdns_service_query_stop(&my_mdns, "NETX-SERVICE", "_http._tcp", NX_NULL); Terminates the previous issued continuous service discovery.
nx_mdns_service_lookup	nx_mdns_service_lookup(&my_mdns, "NETX-SERVICE", "_http._tcp", NX_NULL, 0, service_ptr); This service looks up services matching the instance name (if provided) and the type of service in the local peer service cache.
nx_mdns_service_ignore_set	nx_mdns_service_ignore_set(&my_mdns, service_mask); This API configures a mask to ignore services specified by the service_mask bitmask. User may optionally use the service_mask to select service types it does not wish to be cached.

nx_mdns_service_notify_set	nx_mdns_service_notify_set(&my_mdns, service_mask, service_change_notify); This API configures a service change notify callback function. This callback function is invoked when a service offered by other nodes on the network is added, changed, or is no longer available.
nx_mdns_service_notify_clear	nx_mdns_service_notify_clear(&my_mdns); Clear the service change notify callback function.
nx_mdns_host_address_get	nx_mdns_host_address_get(&my_mdns, "MDNS-Host", &ipv4_address, ipv6_address, 500); This service performs an mDNS query on host IPv4 and IPv6 addresses. If the address of the specified hostname is found in the peer service cache, the address is returned. If no address is found in the peer service cache, the mDNS module issues A and AAAA type queries and wait for a response.
nx_mdns_local_cache_clear	nx_mdns_local_cache_clear(&my_mdns); Clears all entries in the local service cache after sending the Goodbye message.
nx_mdns_peer_cache_clear	nx_mdns_peer_cache_clear(&my_mdns); Clears all entries in the peer service cache.

Note

For details on operation and definitions for the functions, data structures, typedefs, defines, API data, API structures, and function variables, review the associated Azure RTOS NetX Duo documentation in the References section.

Status Return Values

Name	Description
NX_MDNS_SUCCESS	mDNS success.
NX_MDNS_ERROR	mDNS internal error.
NX_MDNS_PARAM_ERROR	mDNS parameters error.
NX_MDNS_CACHE_ERROR	The cache size is not enough.
NX_MDNS_UNSUPPORTED_TYPE	The unsupported resource record type.
NX_MDNS_DATA_SIZE_ERROR	The data size is too big.
NX_MDNS_AUTH_ERROR	Attempting to parse too large data.
NX_MDNS_PACKET_ERROR	The packet can not add the resource record.
NX_MDNS_DEST_ADDRESS_ERROR	The destination address error.
NX_MDNS_UDP_PORT_ERROR	The UDP port error.

NX_MDNS_NOT_LOCAL_LINK	The message that not originate from the local link.
NX_MDNS_EXCEED_MAX_LABEL	The data exceed the max label size.
NX_MDNS_EXIST_UNIQUE_RR	At least one unique record in the cache.
NX_MDNS_EXIST_SHARED_RR	At least one shared record in the cache.
NX_MDNS_EXIST_SAME_QUERY	Exist the same query record in the cache.
NX_MDNS_EXIST_SAME_SERVICE	Exist the same service
NX_MDNS_NO_RR	No response for a one-shot query
NX_MDNS_NO_KNOWN_ANSWER	No known answer for the query
NX_MDNS_NAME_MISMATCH	The name mismatch
NX_MDNS_NOT_STARTED	mDNS does not start
NX_MDNS_HOST_NAME_ERROR	mDNS hostname error
NX_MDNS_NO_MORE_ENTRIES	No more entries are found
NX_MDNS_SERVICE_TYPE_MISMATCH	The service type mismatch
NX_MDNS_NOT_ENABLED	mDNS not enabled
NX_MDNS_ALREADY_ENABLED	mDNS already enabled

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.
Refer to the Azure RTOS NetX Duo documentation for additional information on mDNS/DNS-SD Module API functions.

4.3.37.3 NetX Duo mDNS/DNS-SD Module Operational Overview

NetX Duo mDNS/DNS-SD module manages two internal service caches: the local service cache, and the peer service cache.

Local service cache:

The local service cache stores Resource Records related to services offered by applications running on the node. For incoming queries, if the query matches the service offered, mDNS acknowledges with responses stored in the local service cache. Applications register services by calling the API nx_mdns_service_add(). To remove services, applications use the API nx_mdns_service_delete(), which will, in turn, send "goodbye" messages before removing the corresponding entries in the local service cache.

When a service is added, mDNS maintains at least 3 Resource Records in the local service cache: SRV, PTR, and TXT. Additional PTR Resource Record may be added if the service type includes subtype.

For example, an application registers a service:

name._*subtype*._sub._*type*._tcp.local

two PTR Resource Records are added to the local service cache, one for

"*_subtype._*sub*._type._*tcp.local *PTR name.type._*tcp*.*local"

and the other one for

*"_type._*tcp*.*local *PTR name.type._*tcp*.*local"

Peer service cache:

The peer service cache contains mDNS Resource Records received from neighboring nodes. mDNS module collects Resource Records advertised by other nodes on the network, and stores the received information in the peer service cache. When an application queries for information such as host IPv4 or IPv6 addresses, mDNS searches the peer service cache for locally cached responses. When an application queries for services offered by peers, mDNS searches through the cache for related PTR, SRV, TXT, and IPv4/IPv6 address records. The peer service cache also stores queries sent to the node. For example, an application may request a particular service by calling nx_mdns_service_one_shot_query. If the service is not found in the peer service cache, mDNS creates query questions (PTR, SRV, and TXT) in the peer service cache. These query questions will be sent to the network periodically till the service is resolved, or times out. Similarly, the application may use the API nx_mdns_service_continous_query() to request a particular service over a long period of time (application cancels a previously issued continuous query by using the API nx_mdns_service_query_stop()'). To search for a particular service in the peer service cache without sending queries to the network, applications can use the API nx_mdns_serivce_lookup(). This API only searches the resource records in the peer service cache.

Resource Record:

Each Resource Record is stored in a data structure NX_MDNS_RR in the service caches. Strings in Resource Records are of variable length, therefore are not stored in the NX_MDNS_RR structure. The Resource Record contains a pointer to the actual memory location where the string is stored. The string table and the Resource Records share the service cache. Resource Records are stored from the beginning of the service cache, and grow towards the end of the cache. The string table starts from the end of the service cache and grows towards the beginning of the cache. Each string in the string table has a length field and a counter field. When a string is added to the string table, if the same string is already present in the table, the counter value is incremented and no memory is allocated for the string. The service cache is considered full if no more resource records or new strings can be added to the service cache.

There are two ways for an application to find services offered on the local network. It can either issue a specific service look-up through a one-shot query, or it can initiate a continuous query to "monitor" the activities on the network.

One-Shot query:

In the one-short query scenario, the application must specify the service type. mDNS searches through the local service cache and the peer service cache. If a service instance is located, the one-shot query returns with the information found in the Resource Records. If there are no records in the local service cache or peer service cache, mDNS sends out query messages. If the instance name is specified, an ANY type (query the SRV and TXT type) with the specific instance name, in the form of name.type.local, is sent to the local network. If the instance name is not specified, a PTR type of query is sent to the local network. The first complete service received is returned to the caller.

Continuous query:

Continuous query works differently. The typical use case for a continuous query is to monitor the local network for a specific service (for example to constantly look for printing services on the local network). In this case, the application issues a search query (via the API nx_mdns_service_continious_query) for a certain type of service. The caller typically does not wait for a particular response. For queries submitted as continuous queries, the mDNS module transmits the queries periodically with exponentially increasing intervals. To stop the query, an application must use the API nx_mdns_service_query_stop to stop the internal timer in these queries. The query type can be NULL, in which case the query type is set to special PTR type _services._dns-sd._udp.local. This service type is defined by mDNS as a way to discover all services available on the local network. If the instance name is supplied, an ANY type (query the SRV and TXT type) with the specific instance name name.type.local is sent to the local network. If the instance name is NULL, a PTR type of query is sent to the local network, All responses, including responses from unsolicited queries, are recorded in the peer service cache. At a later time, the application uses the API nx_mdns_service_lookup to retrieve specific services from the peer service cache.

NetX Duo mDNS/DNS-SD Important Operational Notes and Limitations

NetX Duo mDNS/DNS-SD Module Operational Notes

The NetX Duo mDNS/DNS-SD requires a packet pool for transmitting mDNS messages; by default, the application must set the packet pool before using mDNS services. This can either be the packet pool used by the IP instance (g_packet_pool0), or it can be a separate packet pool added to the project: Azure RTOS -> NetX Duo -> NetX Duo Packet Pool Instance in NetX Duo mDNS Client.

When mDNS client sends a multicast message/query into the network asking which network participant matches with the hostname, the request goes into the all the participants in the network. The device in the network which matches the request responds to the entire network via multicast. All the participants are informed of the connection between the name and IP address, and can make a corresponding entry in their mDNS cache.

NetX Duo mDNS/DNS-SD Module Limitations

- When using NetX Duo secondary interface feature with mDNS, always use NetX Duo Source. NetX Duo library doesn't support secondary interface feature.
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.37.4 Including the NetX Duo mDNS/DNS-SD Module in an Application

This section describes how to include NetX Duo mDNS/DNS-SD module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread, and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the NetX Duo mDNS/DNS-SD module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

NetX Duo mDNS/DNS-SD Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence

g_mdns0NetXDuo mDNS/DNS-SD	Threads	New Stack> X-Ware> NetX Duo> Protocols> NetXDuo mDNS/DNS-SD

When the NetX Duo mDNS/DNS-SD module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

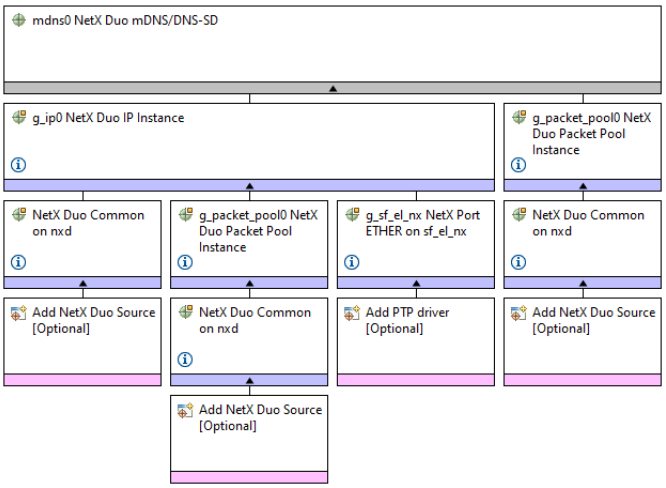

Figure 523: NetX Duo mDNS/DNS-SD Module Stack

In the stack above, the NetX Network Driver (or NetX Duo Network Driver in a NetX Duo stack) has not been populated yet. There are multiple possible selections for the Network Driver; they are all not provided so as not to needlessly complicate the figure and the following configuration tables. The available options depend on the MCU target, but some typical options include:

- NetX Duo Port using PPP on nxd_ppp
- NetX Port ETHER on sf_el_nx
- NetX Port using Cellular Framework on sf_cellular_nsal_nx
- NetX Port using PPP on nx_ppp
- NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

4.3.37.5 Configuring the NetX Duo mDNS/DNS-SD Module

The NetX Duo mDNS/DNS-SD module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-

accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the NetX Duo mDNS/DNS-SD Module

ISDE Property	Value	Description
mDNS/DNS-SD Server Support	Enable, Disable Default: Disable	This enables/disables mDNS/DNS-SD server functionality. Without the server functionality, the mDNS/DNS-SD module does not announce services provided by localhost, nor does it respond to mDNS inquiries.
mDNS/DNS-SD Client Support	Enable, Disable Default: Enable	This enables/disables mDNS/DNS-SD client functionality. Without the client functionality, mDNS/DNS-SD does not send queries, nor does it maintain mDNS query responses received over the network.
Validate address from Received mDNS messages	Enable, Disable Default: Enable	Validates addresses (source address, a destination address, and port numbers) from the received mDNS messages.
Verify multicast queries	Enable, Disable Default: Enable	Passive Observation Of Failures, mDNS /DNS_SD client (querier) observes the multicast queries issued by the other hosts on the network.
Enable mDNS/DNS-SD generating negative response	Enable, Disable Default: Enable	mDNS /DNS-SD server generates negative responses to queries for which it has legitimate ownership
Enable mDNS/DNS-SD IPV6 processing	Enable, Disable Default: Disable	Send/process mDNS message over IPv6 address.
Max IPV6 address count	2	Maximum IPv6 addresses count of the host.

Max string size for host	64	Maximum string size for the host name. *Note* *Does not include the NULL terminator.*
Max string size for service	64	Maximum string size for service name. *Note* *Does not include the NULL terminator.*
Max string size for Domain	16	Maximum string size for the domain name. *Note* *Does not include the NULL terminator.*
Max conflict count for host	8	Maximum conflict count for host name or service name
TTL value for resource records	120	TTL value for resource records with host name, in seconds.
TTL value for other records	4500	TTL value for other resource records, in seconds.
Time interval b/w mDNS probing messages	25	The time interval, in ticks, between mDNS probing messages.
Time interval b/w mDNS announcement messages	25	The time interval, in ticks, between mDNS announcement messages.
Time interval b/w goodbye messages	25	The time interval, in ticks, between repeated "goodbye" messages
Min time interval b/w two queries	100	The minimum time interval, in ticks, between two queries.
Max time interval b/w two queries	360000	The maximum time interval, in ticks, between two queries.
Min delay for sending the first query	2	The minimum delay for sending first query, in ticks.
Delay range for sending the first query	10	The delay range for sending first query, in ticks.

Query response time interval	100	The time interval, in ticks, in responding to a query to ensure an interval of at least 1sec since the last time the record was multicast
Probe query response time	25	The time interval, in ticks, in responding to a probe queries to ensure an interval of at least 250ms since the last time the record was multicast.
Unique query response delay	1	The delay, in ticks, in responding to a query to a service that is unique to the local network.
Minimum delay in responding to a query to a shared resource	2	The minimum delay, in ticks, in responding to a query to a shared resource.
Delay range in responding to a query to a shared resource	10	The delay range, in ticks, in responding to a query to a shared resource.
Minimum delay in responding to a query with TC bit	40	The minimum delay, in ticks, in responding to a query with TC bit.
Delay range in responding to a query with TC bit	10	The delay range, in ticks, in responding to a query with TC bit.
Timer count range	12	When sending out mDNS responses, the packet contains responses that otherwise would be sent within this timer counter range. The timer count range is expressed in ticks.
Number of retransmitted probing messages	3	The number of retransmitted probing messages.
Number of retransmitted goodbye messages	1	The number of retransmitted "goodbye" messages.
Minimum number of the count with no multicast response	2	The number of queries that no multicast response, then the host may take this as an indication that the record may no longer be valid.
Time interval in deleting the record from cache	1000	The time interval, in ticks, in deleting the record from the cache after seeing two or more of these queries, and seeing no multicast response containing the expected answer.

Delay for deleting a resource record	100	The delay for deleting a resource record when the TTL of this record is zero, in ticks.
Name	g_mdns0	Name of the mDNS/DNS-SD instance.
mDNS thread priority	3	Priority of the mDNS thread.
Internal thread stack size	4096	Size of the stack area in bytes
Local service cache size	4096	Storage space for local registered services in bytes.
Peer service cache size	4096	Storage space for service information received in bytes.
Name of Probing notify callback function	probing_notify	Optional callback function invoked at the end of the probing operation. It notifies the application whether the host name (when enabling mDNS on a local interface), or the service name (after registering a service) is unique.
Name of generated initialization function	mdns_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the NetX Duo mDNS/DNS-SD Lower-Level Modules

Only a few number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the NetX Duo IP Instance

ISDE Property	Value	Description
Name	g_ip0	Module name

IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection
IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection
IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection
IP Helper Thread Priority	3	IP Helper Thread Priority selection
ARP	Enable	ARP selection
ARP cache storage units	Bytes, Entries Default: Bytes	ARP cache storage units selection
ARP Cache cache Size (in Bytes or storage units)	520	ARP Cache Size in Bytes/Entries selection. Must be a multiple of 52 Bytes. Note: 1 Entry = 52 Bytes
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection
TCP	Enable, Disable Default: Enable	TCP selection
UDP	Enable, Disable Default: Enable	UDP selection
ICMP	Enable, Disable Default: Enable	ICMP selection
IGMP	Enable, Disable Default: Enable	IGMP selection
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection
Name of generated initialization function	ip_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Common Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name
Packet Size in Bytes	1568	Packet size selection
Number of Packets in Pool	16	Number of packets in pool selection
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

NetX Duo mDNS/DNS-SD Module Clock Configuration

The ETHERC peripheral module uses PCLKA as its clock source. The PCLKA frequency is set using the SSP configurator clock tab prior to a build, or by using the CGC interface at run-time.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group using Ethernet. Other MCUs and other interfaces like Wi-Fi or cellular may have different default values and available configuration settings.

NetX Duo mDNS/DNS-SD Module Pin Configuration

The ETHERC peripheral module uses pins on the MCU device to communicate to external devices. I/O pins must be selected and configured by the external device as required. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent

table illustrates an example selection for the ETHERC pins.

Note

The selected operation mode determines the peripheral signals available and the MCU pins required.

Pin Selection for the ETHERC Module

Resource	ISDE Tab	Pin selection Sequence
ETHERC	Pins	Select Peripherals > Connectivity:ETHERC > ETHERC1.RMII

Note

The selection sequence assumes ETHERC1 is the desired hardware target for the driver.

Pin Configuration Settings for the ETHERC1

Property	Value	Description
Operation Mode	Disabled, Custom, RMII Default: Disabled	Select RMII as the Operation Mode for ETHERC1
Pin Group Selection	Mixed, _A only Default: _A only	Pin group selection
REF50CK	P701	REF50CK Pin
TXD0	P700	TXD0 Pin
TXD1	P406	TXD1 Pin
TXD_EN	P405	TXD_EN Pin
RXD0	P702	RXD0 Pin
RXD1	P703	RXD1 Pin
RX_ER	P704	RX_ER Pin
CRS_DV	P705	CRS_DV Pin
MDC	P403	MDC Pin
MDIO	P404	MDIO Pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.37.6 Using the NetX Duo mDNS/DNS-SD Module in an Application

The steps in using the NetX Duo mDNS/DNS-SD module in a typical application are:

1. Wait for the network link to be enabled by calling the nx_ip_status_check (or if your system has multiple network interfaces, call nx_ip_interface_status_check) with the

NX_IP_LINK_ENABLED option.
2. Set the cache notify callback using the nx_mdns_cache_notify_set API.
3. Enable the mDNS functionality using the nx_mdns_enable API.
4. If the Application is configured as mDNS server then
    a. Register local service using nx_mdns_service_add API by providing the service name, type, subtype, priority, weight, and port.
    b. Once the service is successfully registered then a user-defined probing_notify callback is invoked.
    c. If all the operation is completed delete the service using nx_mdns_service_delete API.
5. If the Application is configured as mDNS client then
    a. Set the service change callback function to listen the service using nx_mdns_service_notify_set API.
    b. Perform single shot or continuous query using nx_mdns_service_one_shot_query and nx_mdns_service_continuous_query API respectively.
    c. Perform Service Lookup for particular service type using nx_mdns_service_lookup API.

The following figure illustrates common steps in a typical operational flow diagram:

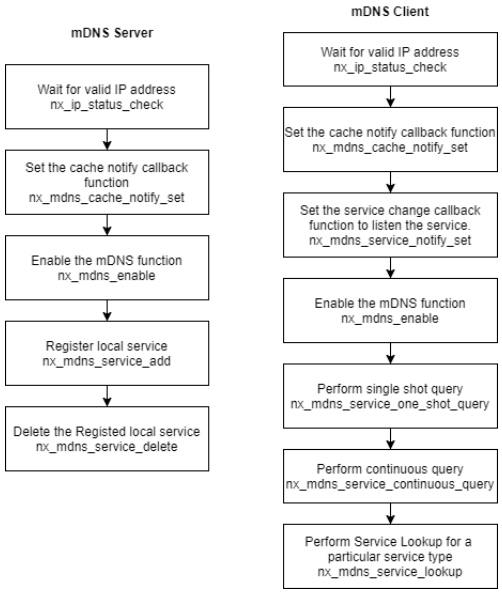

Figure 524: Flow Diagram of a Typical NetX Duo mDNS/DNS-SD Module Application

4.3.38 Azure RTOS USBX Overview

4.3.38.1 Azure RTOS USBX Interface Overview

The Azure RTOS USBX USB stack (ux) is integrated into the SSP. This document provides an overview and summary of the Azure RTOS USBX Interface for SSP. Specific USBX modules in SSP each have their own module overview section. Refer to the appropriate module overview sections in the SSP User's Manual for details on designing with specific modules.

4.3.38.2 What Does the Azure RTOS USBX Module Do?

USBX supports the two existing USB specifications: 1.1 and 2.0. It is designed to be scalable and will accommodate simple USB topologies with only one connected device, as well as complex topologies with multiple devices and cascading hubs. USBX supports both the host and device sides.

4.3.38.3 Supported USB Classes in Azure RTOS USBX

The USBX class modules listed below are fully supported in the Synergy Configuration tool. To use these USBX class modules, go to the Threads tab of the Synergy Configuration tool (configuration.xml), and select any of the USB class modules:

- ux_device_class_cdc_acm
- ux_device_class_hid
- ux_device_class_storage
- ux_host_class_cdc_acm
- ux_host_class_hid
- ux_host_class_printer
- ux_host_class_storage
- ux_host_class_video
- ux_host_class_hub

Note

Refer to the USBX Device Class User Guide, USBX Host Class User Guide or USBX Host Stack UVC User Guide for more information about the USBX Class specification. Each of the modules listed above also has an associated module overview section in the SSP User's Manual. Additionally, Module Guides for each of these modules are available from the Renesas Synergy web site.

The USBX class modules listed below are experimental modules for Synergy parts. The experimental modules are not currently supported in Synergy Configuration. To experiment with these USBX class modules, go to the Components tab of the Synergy Configuration tool (configuration.xml) and select any of the USB class modules:

- ux_device_class_cdc_ecm
- ux_device_class_rndis
- ux_host_class_audio
- ux_host_class_gser
- ux_host_class_prolific
- ux_host_class_swar
- ux_network_driver
- ux_device_class_pima
- ux_host_class_pima
- ux_pictbridge

Note

Any of the USB classes shown above are experimental and not yet tested for Synergy parts; it is not recommended to use them for product developments.

When the components above are added, a prebuilt library of the application code is also added. For each component listed above, there is an analogous component ending in '_src' that contains protected source files. The '_src' component can be added in addition to the prebuilt library module.

Writing an Application with USBX Modules

Refer to the associated module overview section in the SSP User's Manual for details on how to write

an application with USBX modules. Additionally, each of the associated Module Guides have a working application project that illustrates how to use the module in a typical application. Module Guides are available from the Renesas Synergy web site.

Writing an Application with Deprecated Modules

In the SSP version 1.2.0 or later, the USBX stack configuration is supported in the Synergy Configuration tool and the few USBX relevant components, which were defined in previous SSP versions, are now treated as [DEPRECATED] components. They are kept in the SSP version today to provide you with backward compatibility. Anyone using a new version of SSP and wanting to keep their existing application code compatible to an existing SSP version, can use [DEPRECATED] components.

In e^2 studio, create and configure a project and add the drivers:

1. Create the project: Creating a Project.
2. Configure the project: Configuring a Project.
3. Add the following components, if required, the same way as was done when using an existing version of SSP: Adding Drivers to a Thread and Configuring the Drivers.

Azure RTOS USBX Device Class CDC-ACM(option)	Threads	Framework > USB > [DEPRECATED] USBX Device Class CDC-ACM on ux_device_class_cdc_acm
Azure RTOS USBX (option)	Threads	Framework > USB > [DEPRECATED] USBX on ux

Note

Do not use components marked as [DEPRECATED] for new development. Only use these components for existing user applications which were developed with previous SSP releases.

USB Class Stack Configuration Overview

USBX Device Class Stack Configuration

The following figure shows the interface diagram of the USBX Device Class stack. The stack consists of one USBX device class component (ux_device_class_xxx) on the top, the USBX (ux) in the middle and the USBX Port driver (sf_el_ux Device Controller Driver (DCD)) on the bottom of the device class stack. As a recommended option, the SSP Transfer module (r_dmac) supports data transfer between memory and hardware FIFO in Synergy USB peripherals (USBHS or USBFS). To support the USB device stack configuration, there are components named USBX Device Configuration and USBX Interface Configuration. These two components do not represent actual software modules in SSP; they are virtual modules to handle the code generation.

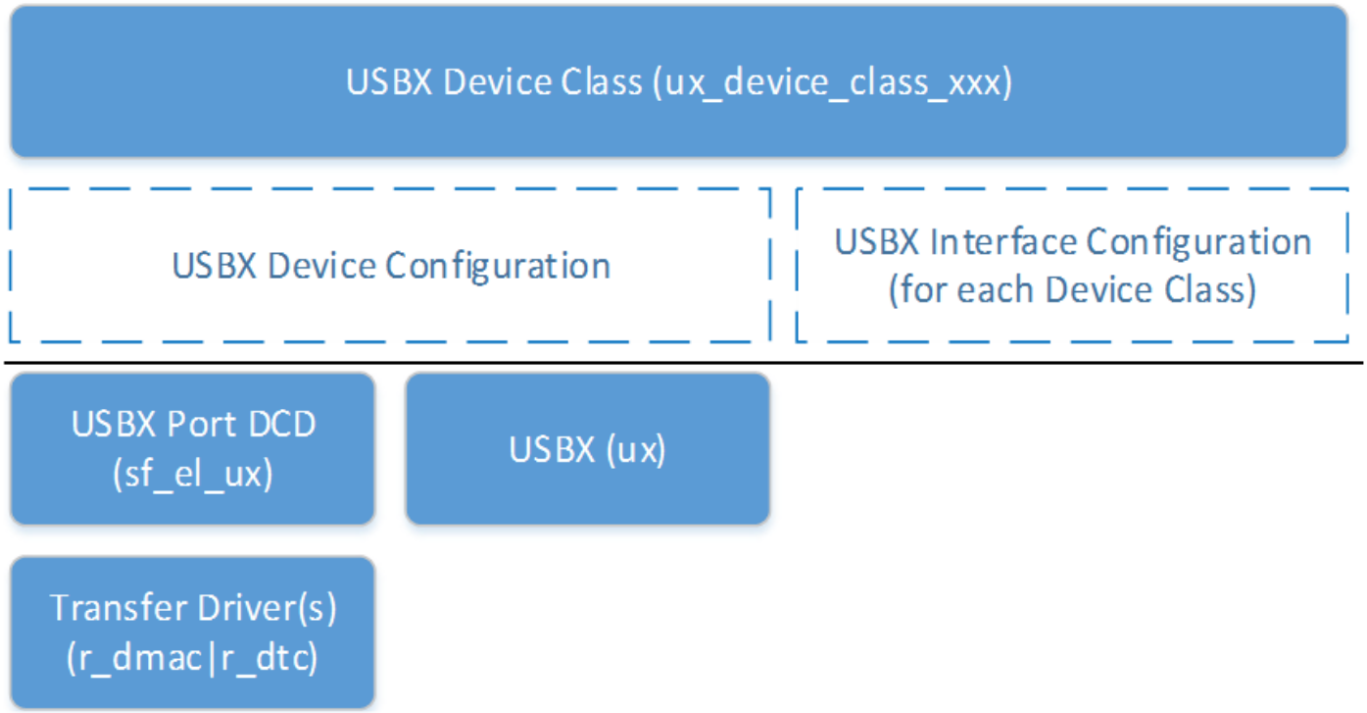

Figure 525: USBX Device Class Stack Configuration

Note: Currently, the r_dtc is not supported for the device side driver (only r_dmac is supported).

USBX Host Class Stack Configuration

The following figure shows the interface diagram of the USBX Host Class stack. The stack consists of one of the USBX Host Class components (ux_host_class_xxx) on the top, the USBX (ux) in the middle and the USBX Port driver component (sf_el_ux Host Controller Driver (HCD)) on the bottom of the host class stack. As a recommended option, the SSP Transfer module (r_dmac) supports data transfer between memory and hardware FIFO in Synergy USB peripherals (USBHS or USBFS). To support the USB host stack configuration, there is a virtual component (USBX Host Configuration) to handle the code generation:

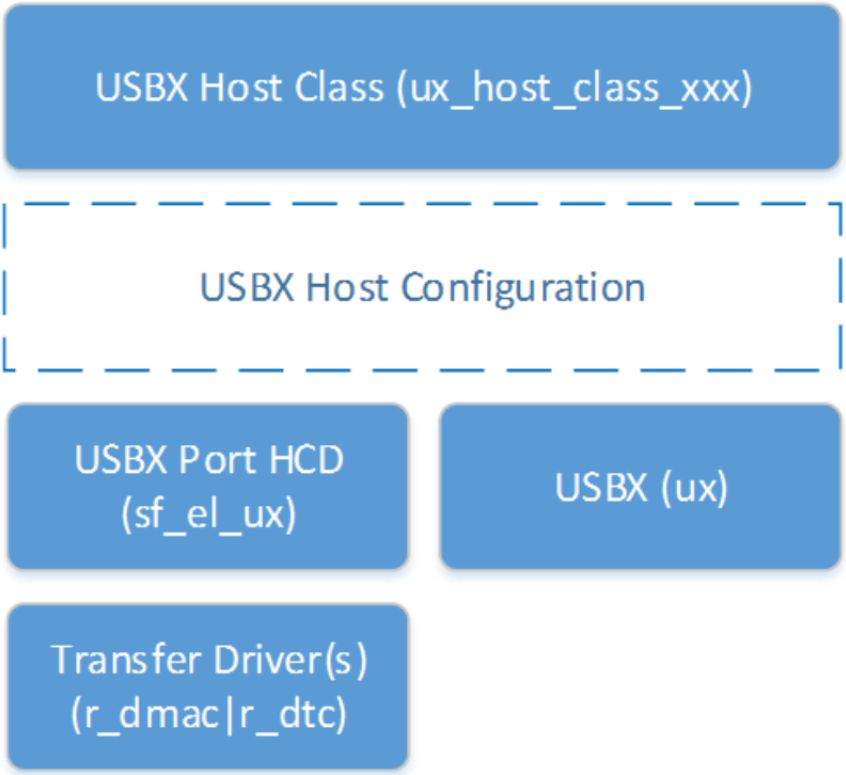

Figure 526: USBX Host Class Stack Configuration

Note

Currently, the r_dtc is not supported for the host side driver (only r_dmac is supported).

USB Device Descriptor Configuration

USBX Device Configuration

The USBX Device Configuration component has configurations, as shown in below table, to auto-generate the USB Device Descriptor and USB Configuration Descriptor. Refer to http://www.usb.org and download USB 2.0 Specification for more information about the specification of USB Device Descriptor and or Configuration Descriptor.

USBX Device Configuration

Configuration	Settings	Description
Composite Device	Enable or Disable (Default)	Enable this configuration only if composite device support is required in the application.
Vendor ID	16-bit arbitrary number (Default: 0x045B)	Specify Vendor ID assigned by USB-IF. This configuration is a part of the USB Device Descriptor (**idVendor**).
Product ID	16-bit arbitrary number (Default: 0x0000)	Specify Product ID assigned by manufacturer. This configuration is a part of the Device Descriptor (**idProduct**).

Device Release Number	16-bit arbitrary number (Default: 0x0000)	Specify Device Release Number in binary-coded decimal. This configuration is a part of the USB Device Descriptor (**bcdDevice**).
Index of Manufacturer String Descriptor	Arbitrary number from 0 to 255 (Default: 0x00)	Specify the Index of Manufacturer String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (**iManufacturer**). Set zero if String Descriptor is not used. See section USBX-String-Framework-Configuration for more information.
Index of Product String Descriptor	Arbitrary number from 0 to 255 (Default: 0x00)	Specify the Index of Product String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (**iProduct**). Set zero if String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Index of Serial Number String Descriptor	Arbitrary number from 0 to 255 (Default: 0x00)	Specify the Index of Serial Number String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (**iSerialNumber**). Set zero if the String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Class Code	Device(0x00), Communications(CDC) (0x02, Default), HID (0x03), Mass Storage (0x08), Miscellaneous (0xEF), Vendor Specific (0xFF)	Select the USB Device Class Code. This configuration is a part of the USB Configuration Descriptor (**bDeviceClass**).
Index of String Descriptor describing this configuration	Arbitrary number from 0 to 255 (Default: 0x00)	Specify the Index of String Descriptor describing this configuration. This configuration is a part of the USB Configuration Descriptor (**iConfiguration**). Set zero if String Descriptor is not used. See section "USBX String Framework Configuration" for more information.

Size of USB Descriptor in bytes for this configuration	0x00 (Default) or value to be set to wTotalLength (calculated by user)	Specify the size of USB Descriptor in bytes. Modify the value for Vendor-specific Class, otherwise you can set zero to calculate the size automatically in the auto-generated code from Synergy Configuration tool. This configuration is a part of the USB Configuration Descriptor (**wTotalLength**).
Number of Interfaces	0x00 (Default) or value to be set to bNumInterfaces (calculated by user).	Specify the Number of interfaces supported by this configuration. Modify the value for Vendor-specific Class, otherwise you can set zero to calculate the value automatically in the auto-generated code from Synergy Configuration tool. This configuration is a part of the USB Configuration Descriptor (**bNumInterfaces**).
Self-Powered	Enable (Default) or Disable	Enable this configuration if your USB Device is a self- powered device. This configuration is a part of the USB Configuration Descriptor (**bmAttributes** bit6)
Remote Wakeup	Enable or Disable (Default)	Enable this configuration if your USB Device supports remote wakeup. This configuration is a part of the USB Configuration Descriptor (**bmAttributes** bit5)
Maximum Power Consumption in 2mA units(0-250)	50 (Default), Integer value from 0 to 250.	Set the maximum power consumption of your device to indicate the amount of bus power required. This configuration is 2mA units, thus, the maximum 500 mA can be specified. This configuration is a part of the USB Configuration Descriptor (**bMaxPower**).
Supported Language Code	16-bit number assigned by Manufacturer (Default: 0x0409)	Specify the Language ID Code. For example, 0x0409 English - United States. This configuration is used for Language ID Framework code generation. See section "USBX Language Framework Configuration" for more information.

Name of USBX String Framework	Arbitrary C language symbol (Default: NULL)	Specify the name of user defined USBX String Framework. This must be a valid C symbol. Set NULL if the String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Total index number in USB String Descriptor in USBX String Framework	Arbitrary integer number (Default: 0)	Specify the total number of index for String Descriptor. See section "USBX String Framework Configuration" for more information.
Name of USB Language Descriptor	Arbitrary C language symbol (Default: NULL)	Specify the name of user defined USBX Language Framework. This must be a valid C symbol. If '0' is set to the property "Total Number of Language Support", this configuration is ignored. See section "USBX Language Framework Configuration" for more information.
Total Number of Language Support	Arbitrary integer number (Default: 0)	Specify the total number of languages to support. See section "USBX String Framework Configuration" for more information. If '0' is set here, US English (0x0409) is applied as the default language.

USBX Device String Framework Configuration

The USBX String Framework is byte stream data to provide USB device information with human readable strings to the USB Host device. Users need to define the byte stream data in their application code if required. See the USBX Device Class User Guide section *Definition of the Strings of the Device Framework* for more information about the USBX String Framework. Here is an example of USBX String Framework, which consists of three indexes String descriptors.

```
const UCHAR g_usb_string_framework[] =
{
    /* Index #1 (this example shows manufacturer information) */
    (uint8_t) (0x0409), /* Byte0 Language Code, US English */
    (uint8_t) (0x0409 >> 8), /* Byte1 Language Code */
    0x01, /* Byte2 Index */
    7, /* Byte3 Length */
```

```
    'R', 'E', 'N', 'E', 'S', 'A', 'S',
    /* Index #2 (this example shows product information) */
    (uint8_t) (0x0409), /* Byte0 Language Code, US English */
    (uint8_t) (0x0409 >> 8), /* Byte1 Language Code */
    0x02, /* Byte2 Index */
    10, /* Byte3 Length */
    'C', 'O', 'M', ' ', 'D', 'E', 'V', 'I', 'C', 'E',
    /* Index #3 (this example shows Device Serial Number information) */
    (uint8_t) (0x0409), /* Byte0 Language Code, US English */
    (uint8_t) (0x0409 >> 8), /* Byte1 Language Code */
    0x03, /* Byte2 Index */
    4, /* Byte3 Length */
    '0', '1', '0', '0'
};
```

You can configure the properties of the USBX Device Configuration component as shown in the following table. Refer to USBX Device Configuration for more information about each configuration in the table.

Example of the USBX String Framework Configuration

Configurations for String Descriptor on Synergy Configuration tool	Setting Example
Name of USB String Framework	g_usb_string_framework
Total index number of USB String Descriptor in USBX String Framework	3 (3 indexes)
Index of Manufacturer String Descriptor	1 (Index #1)
Index of Product String Descriptor	2 (Index #2)
Index of Serial Number String Descriptor	3 (Index #3)
Index of String Descriptor describing this configuration	0 (no string information)
Index of String Descriptor Describing Communications Class interface	0 (no string information)

USBX Device Language Framework Configuration

The USBX Languages Framework is byte stream data to support multiple languages. You need to define the byte stream data in your application code if required. See the USBX Device Class User Guide section *Definition of the Languages Supported by the Device for Each String* for more information. The following is an example of the USBX Language Framework which supports two

Languages:

```
const UCHAR g_usb_language_framework[] =
{
    /* US English */
    (uint8_t) (0x0409),
    (uint8_t) (0x0409 >> 8),
    /* Japanese */
    (uint8_t) (0x0411),
    (uint8_t) (0x0411 >> 8),
};
```

You can configure the properties of USBX Device Configuration component as shown in the following table. See section "USBX Device Configuration" for more information.

Example of the USBX Language Framework Configuration

Configurations for String Descriptor on Synergy Configuration tool	Setting Example
Name of USB Language Descriptor	g_usb_language_framework
Total Number of Language Support	2 (2 languages)

Device-Only Size Optimization

The Azure RTOS USBX module is built in device-only mode to reduce code size for Synergy S1 parts. The configuration (UX_SYSTEM_DEVICE_ONLY) is applied automatically if the S1 board is selected in the Synergy Configuration tool BSP tab. Note that the following configurations are fixed in the device-only mode.

- UX_THREAD_STACK_SIZE=512
- UX_SLAVE_REQUEST_DATA_MAX_LENGTH=512

USBX Hardware support details

	USBX Mass Storage Class				**USBX HID Class**

N/A	Not supported by MCU

✓ * denotes that the HUB class is tested with self-powered hubs only.

4.3.38.4 Azure RTOS USBX Auto-generated Code Procedures

Note

Code samples in this section are subject to change. Note any warranty for contents and possible changes.

USBX Device Stack Auto-generated Code Procedures

The following code sample is pseudo code for USBX Device Classes. The function call sequence is auto-generated from the Synergy Configuration tool if one (or multiple) USBX Device Class component(s) is added to the Synergy Configuration tool. Auto-generated code is emitted to common_data.c file and provides the following features:

- Generates the USB Device Descriptor.
- Initializes the USBX software contexts in the memory pool.
- Initializes the USBX Device Stacks added in the Synergy Configuration tool.
- Initializes Synergy USB controller(s) in device mode. The USBX Device stack supports many-to-one topology between device classes and a device controller. For instance, two USBX Device Classes which consist of a USB composite device can use a single USB controller.

Note

The USBX Device stack does not support using multiple USB controllers simultaneously. Only one of the USB controllers is used at a time, even if the Synergy part has multiple USB controllers (like S7G2 parts).

```
SSP_VECTOR_DEFINE_UNIT();
void g_common_init(void)
{
    // Initialize USBX Memory.
    ux_system_initialize ();
    // Initialize USBX Device stack.
    ux_device_stack_initialize ();
    // Register the Device CDC-ACM Class if the class is used.
    ux_device_stack_class_register();
    // Register the Device HID Class if the class is used.
    ux_device_stack_class_register();
    // Register the Device Mass Storage Class if the class is used.
    ux_device_stack_class_register();
    // Initialize the USB Device Controller. This function calls either of
    // _ux_dcd_synergy_initalize() or
    // _ux_dcd_synergy_initalize_transfer_support()
    ux_dcd_initialize ();
}
```

USBX Host Stack Auto-generated Code Procedures

The following code sample is pseudo code for USBX Host Classes. The function call sequence is auto-generated from the Synergy Configuration tool if one (or multiple) USBX Host Class component(s) is added to the Synergy Configuration tool. Auto-generated code is emitted to the common_data.c file and provides the following features:

- Initializes the USBX software contexts in the memory pool.
- Initializes the USBX Host Stacks added in Synergy Configuration tool. Multi-instances of host class stacks are allowed to be built.
- Initializes the USBX HID Clients if the USBX Host HID Class is added in Synergy Configuration tool.
- Initializes Synergy USB controller(s) in host mode. The USBX Host stack supports Many-to-one or Many-to-many topology between host classes and host controllers. For instance, Two USBX Host Classes can use single USB controller, or Two USBX Host Classes can use different USB controllers individually if the Synergy part has multiple USB controllers (like S7G2 parts).
- Gets a USBX Host Class container for user application.

```
// Interrupt vector registering for USBHS or USBFS controller.
SSP_VECTOR_DEFINE_UNIT();
void g_common_init(void)
{
    // Initialize FileX (ONLY for Mass Storage Class)
    fx_system_initialize ();
    // Initialize USBX Memory.
    ux_system_initialize ();
    // Initialize the USBX Host stack.
    ux_host_stack_initialize ();
    // Register the HUB Class if the class is used.
    ux_host_stack_class_register();
    // Register the Host CDC-ACM Class if the class is used.
    ux_host_stack_class_register();
    // Register the Host HID Class if the class is used.
    ux_host_stack_class_register();
    // Register the Host HID Clents if the HID clients are used.
    ux_host_class_hid_clients_register ();
    // Register the Host Mass Storage Class if the class is used.
    ux_host_stack_class_register();
    // Register and initialize the USB Host Controller.
    ux_host_stack_hcd_register ();
    // Get the USBX Host Class Container for registered classes.
    ux_host_stack_class_get ();
}
```

4.3.38.5 Azure RTOS USBX Application Code Examples

Application projects are available in the module guides for each USBX module. Refer to the module guides for application projects showing working code for typical use cases.

4.3.38.6 Azure RTOS USBX Special Linker Sections

The USBX Device Stack configuration uses the following special memory sections in the linker script files. The order of memory sections in the linker script needs to consist of the USB Device Descriptor byte stream, which is given to _ux_device_stack_initialize() function; the linker script definitions must not be modified.

Memory section for the USBX Device Descriptor

Memory section	USB Descriptor to be defined in the section
.usb_device_desc_fs*	The USB Device Descriptor for FS mode
.usb_config_desc_fs*	The USB Configuration Descriptor for FS mode
.usb_interface_desc_fs*	The USB Interface Descriptor for FS mode
.usb_device_desc_hs*	The USB Device Descriptor for HS mode
.usb_config_desc_hs*	The USB Configuration Descriptor for HS mode
.usb_interface_desc_hs*	The USB Interface Descriptor for HS mode

Note

Memory sections for HS mode only exists for Synergy Parts, which has the USBHS controller.

4.3.38.7 Azure RTOS USBX Memory Requirements

The USBX Device stack and/or USBX Host stack consumes RAM for the control block. The Synergy Configuration tool allocates memory to the USBX memory pool statically in the auto-generated code. The memory consumption is different for each class. Refer to the module overview section in the SSP User's Manual for the USBX memory requirements for a specific module.

4.3.38.8 Azure RTOS USBX Limitations

- Support for the USB Device vender-specific class is not available.
- The module needs the interrupt of a USB Controller enabled. See section "Logic USBX Synergy Port Framework Limitations" for more information.
- USBX classes (ux_device_class_cdc_ecm, ux_device_class_rndis, ux_host_class_audio, ux_host_class_gser, ux_host_class_prolific, ux_host_class_swar) and USBX network driver (ux_network_driver) are experimental modules and not yet tested for Synergy parts in this version of SSP. It is not recommended to use them for product developments.
- Composite device class mode is supported only on S3, S5 and S7 series (not on S1 series).
- Composite device class mode is tested with combination of CDC-CDC as well as CDC-MSC classes on Windows 10 PC acting as Host.
- In case of USBX composite device with DMA, MSC class will be given highest priority. for eg.
    - In case of CDC-MSC, MSC class uses DMA for data transfer and CDC class will use CPU for data transfer.
    - In case of CDC-CDC, one of the CDC class will use DMA for data transfer and other will use CPU for data transfer.
- In case of Device class CDC-ACM Read, there might be no difference between DMA and CPU

performance (Generally DMA should give better performance over CPU).
- When using Device class CDC-ACM Read, DMA will be used only when the requested transfer length is greater than the maximum packet size. For the transfer length less than maximum packet size, CPU will be used even if DMA module is added in ISDE configurator.

4.3.39 USBX Source

4.3.39.1 USBX Source Component Module Introduction

The purpose of this document is to provide an easy reference for the USBX source component in e^2 studio. The properties are explained in greater detail than the footer comment supplied with each property. Context specific usage is included for if and when to change a default value. This document should make it easier to use the USBX source component without having to cross reference with the Azure RTOS USBX User Guide, and help the developer get familiarized more quickly with USBX features.

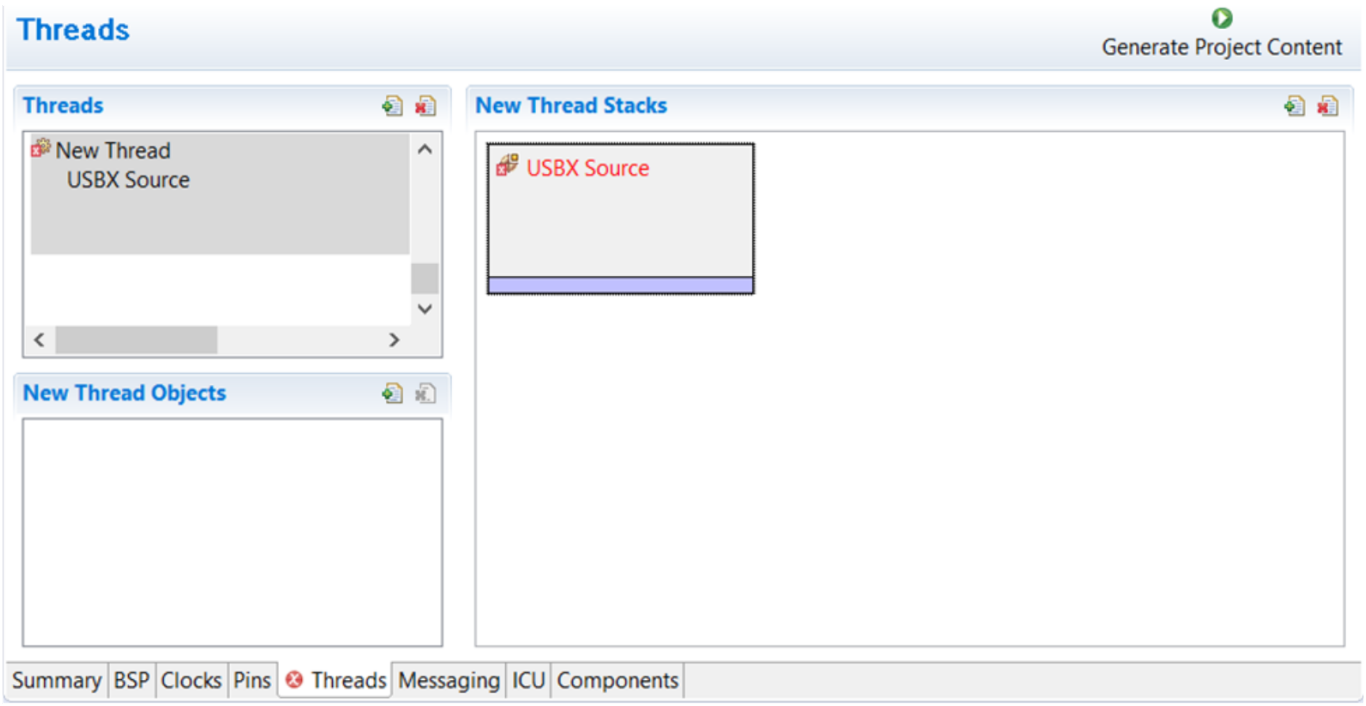
4.3.39.2 When to Include the USBX Source Component

Adding the USBX source component enables the developer in the Synergy configurator environment to customize the USBX library, change values from default settings and enable or disable certain features. Otherwise, they must use the prebuilt USBX library. In most projects beyond the simplest, the developer will typically want to customize their USBX environment. Adding USBX stack component does not add ThreadX stack source component by default.

Without adding the USBX source component, the e^2 studio configurator will use a prebuilt library with the USBX default settings.

4.3.39.3 Adding the USBX Source Component

In the e^2 studio configurator you can add the USBX Source component by selecting any thread from the Threads list and pressing the "New Stack" button and navigating the menu to X-Ware -> USBX -> Common -> USBX Source.



4.3.39.4 Changing the USBX Source Component Properties

After changing USBX property settings, the developer must click on the Generate Project Content button to update the project configurator in e^2 studio; then the USBX library must be rebuilt (for example, rebuild the project). Simply changing a property (or applying a #define in the preprocessor list) without rebuilding the project will not affect any change; e^2 studio will use the previously built library.

Default settings are based on use experience and are often the choice that will apply to the most common use cases.

4.3.39.5 USBX Source Component Overview

The properties of the USBX Source component are given in the order they appear in the properties window of the Synergy configurator.

Ticks per second for USBX system – default value not displayed, the ThreadX value is used – By default, USBX will use the value defined at ThreadX. You should not change this unless you have extensively modified the ThreadX tick timer mechanism.

Maximum Classes – default value not displayed, 8 used – When defined, this value is the maximum number of classes that can be loaded by USBX. This value represents the class container and not the number of instances of a class. For instance, if a particular implementation of USBX needs the hub class, the printer class and the storage class, then the UX_MAX_CLASSES value can be set to 3 regardless of the number of devices that belong to these.

Maximum Slave Classes – default value not displayed, 3 used – When defined, this value is the maximum number of classes in the device stack that can be loaded by USBX.

Maximum Slave Interfaces - default value not displayed, 16 used – When defined, this value

is the maximum number of interfaces in the device framework.

Maximum Host Class Containers - default value not displayed, no maximum set.

Maximum Device Class Containers - default value not displayed, no maximum set.

Maximum Host Controllers - default value not displayed, no maximum set - This value represents the number of different host controllers that are available in the system. For USB 1.1 support, this value will mostly be 1. For USB 2.0 support, this value can be more than 1. This value represents the number of concurrent host controllers running at the same time. If, for instance, there are two instances of OHCI running or one EHCI and one OHCI controllers running, the UX_MAX_HCD should be set to 2.

Maximum Devices - default value not displayed, 8 used – This value represents the maximum number of devices that can be attached to the USB. Normally, the theoretical maximum number on a single USB is 127 devices. This value can be scaled down to conserve memory. It should be noted that this value represents the total number of devices regardless of the number of USB buses in the system.

Maximum EDs - default value not displayed, 80 used – This value represents the maximum number of EDs in the controller pool. This number is assigned to one controller only. If multiple instances of controllers are present, this value is used by each individual controller.

Maximum TDs - default value not displayed, 128 used – This value represents the maximum number of regular TDs in the controller pool. This number is assigned to one controller only. If multiple instances of controllers are present, this value is used by each individual controller.

Note: Sufficient numbers of TDs are required, when user changes this parameter for large size (FS more than 8KB and HS more the 64KB) of data transfer. Sufficient number of 'Maximum TDs' needs to be specified in USBX Source module (USBX Source property >> Common >> Maximum TDs).

- Maximum TDs for FS mode (maximum data transfer size in bytes /64 bytes = TDs + additional TDs for SCSI wrapper commands).
- Maximum TDs for HS mode (maximum data transfer size in bytes /512 bytes = TDs + additional TDs for SCSI wrapper commands).

Maximum Isochronous TDs - default value not displayed, 128 used – This value represents the maximum number of isochronous TDs in the controller pool. This number is assigned to one controller only. If multiple instances of controllers are present, this value is used by each individual controller.

Stack size for USBX threads - default value not displayed, 1024 bytes used on host and mixed controllers, 512 on device only controllers – This value is the size of the stack in bytes for the USBX threads. It can be typically 1024 or 2048 bytes depending on the processor used and the host controller.

USBX Enumeration Thread Priority - default value not displayed, 20 used – This is the ThreadX priority value for the USBX enumeration threads that monitors the bus topology.

USBX Standard Thread Priority - default value not displayed, 20 used – This is the ThreadX priority value for the standard USBX threads.

USBX HID Keyboard Class Thread Priority - default value not displayed, 20 used – This is the ThreadX priority value for the USBX HID keyboard class.

USBX HCD Thread Priority - default value not displayed, 2 used – This is the ThreadX priority value for the host controller thread.

No use of time slice - default value disabled – If enabled the ThreadX target port does not use time slicing.

Maximum Slave Logical Units - default value not displayed, 2 used – This value represents the current number of SCSI logical units represented in the device storage class driver.

Maximum Host Logical Units - default value not displayed, 16 used – This value represents the maximum number of SCSI logical units represented in the host storage class driver.

Slave Request Control Maximum Length - default value not displayed, 256 used – This value represents the maximum number of bytes received on a control endpoint in the device stack. The default is 256 bytes, but can be reduced in memory constraint environments.

Note

Slave request control maximum length value have to increase more than event buffer value, If USBX Device HID class event buffer length value is more then 256 (USBX Device class HID source >> Common >> USBX Device HID Event Buffer Length).

Slave Request Data Maximum Length - default value not displayed, 512 in device only controllers, 4096 otherwise – This value represents the maximum number of bytes received on a bulk endpoint in the device stack. The default is 4096 bytes, but can be reduced in memory constraint environments.

Enforce Safe Alignment - default value is disabled – When enabled the memory allocation scheme enforces alignment. The default alignment value is UX_SAFE_ALIGN.

__Control Transfer Timeout - default value not displayed, 10000 used -__ When set, this value represents the control transfer timeout in milliseconds.

__Non-Control Transfer Timeout - default value not displayed, 50000 used -__ When set, this value represents the non-control transfer timeout in milliseconds.

__Disable CDC-ACM Non-blocking Transmission - default value is yes -__ Select yes to disable the CDC ACM non-blocking transmission support.

Note

To enable CDC-ACM Non-blocking transmission, USBX source and USBX device class CDC-ACM source should be added in thread stack and the property "Disable CDC ACM Non-blocking Transmission" in USBX source should be set to "No".

__Bidirectional Endpoint Support - default value is disabled -__ This property enables support for device bi-directional endpoint.

__Enable Assert Check - default value is yes -__ This property enables assert checks inside USBX.

__Enable Assertion On Failure Detection - default value is no -__ Select yes to take assert actions on failure detection.

__Host Device Class Code Validation - default value is disabled -__ When enabled, the host device class code is validated.

__USBX Standalone Mode - default value is disabled -__ When enabled, the standalone mode of USBX

is supported.

__USBX String Descriptor Requests With Zero Language ID - default value is disabled -__ When enabled, defines the processing of getting String Descriptor requests with zero Language ID.

__USBX Endpoint Buffer Owner - default value is disabled -__ When enabled, this value represents the endpoint buffer owner.

Show linkage warning - default value enabled – By default show linking warnings.

4.3.40 USBX Port

4.3.40.1 USBX Synergy Port Framework Introduction

The Azure RTOS USBX Synergy Port framework module (sf_el_ux) is integrated into the SSP and is used with Azure RTOS USBX. For more information about USBX (including API references), refer to the USBX User Guide.

Unsupported Features

The following features have not been integrated into this version of SSP:

- USBX host class asix
- USBX host class audio
- USBX host class gser
- USBX host class dpump
- USBX device class cdc-ecm
- USBX device class rndis
- USBX device class DFU
- USBX device class DPUMP
- USBX OTG host and device class

The following features are experimental. They have been integrated but not tested:

- USBX PIMA device class
- USBX Pictbridge device implementation

USBX Synergy Port Framework Module Features

The Azure RTOS USBX Synergy Port Framework module supports the following features:

- Implements Azure RTOS USBX in SSP- supports USBX APIs
- Supports the Port Device Controller Driver (DCD) for the USBHS peripheral
- Supports the Port Device Controller Driver (DCD) for the USBFS peripheral
- Supports the Port Host Controller Driver (HCD) for the USBHS peripheral
- Supports the Port Host Controller Driver (HCD) for the USBFS peripheral
- Supports manual switch over between host & device USB stack on same USB(ie USBHS or USBFS) port.
- Supports transfer module operation (optional)

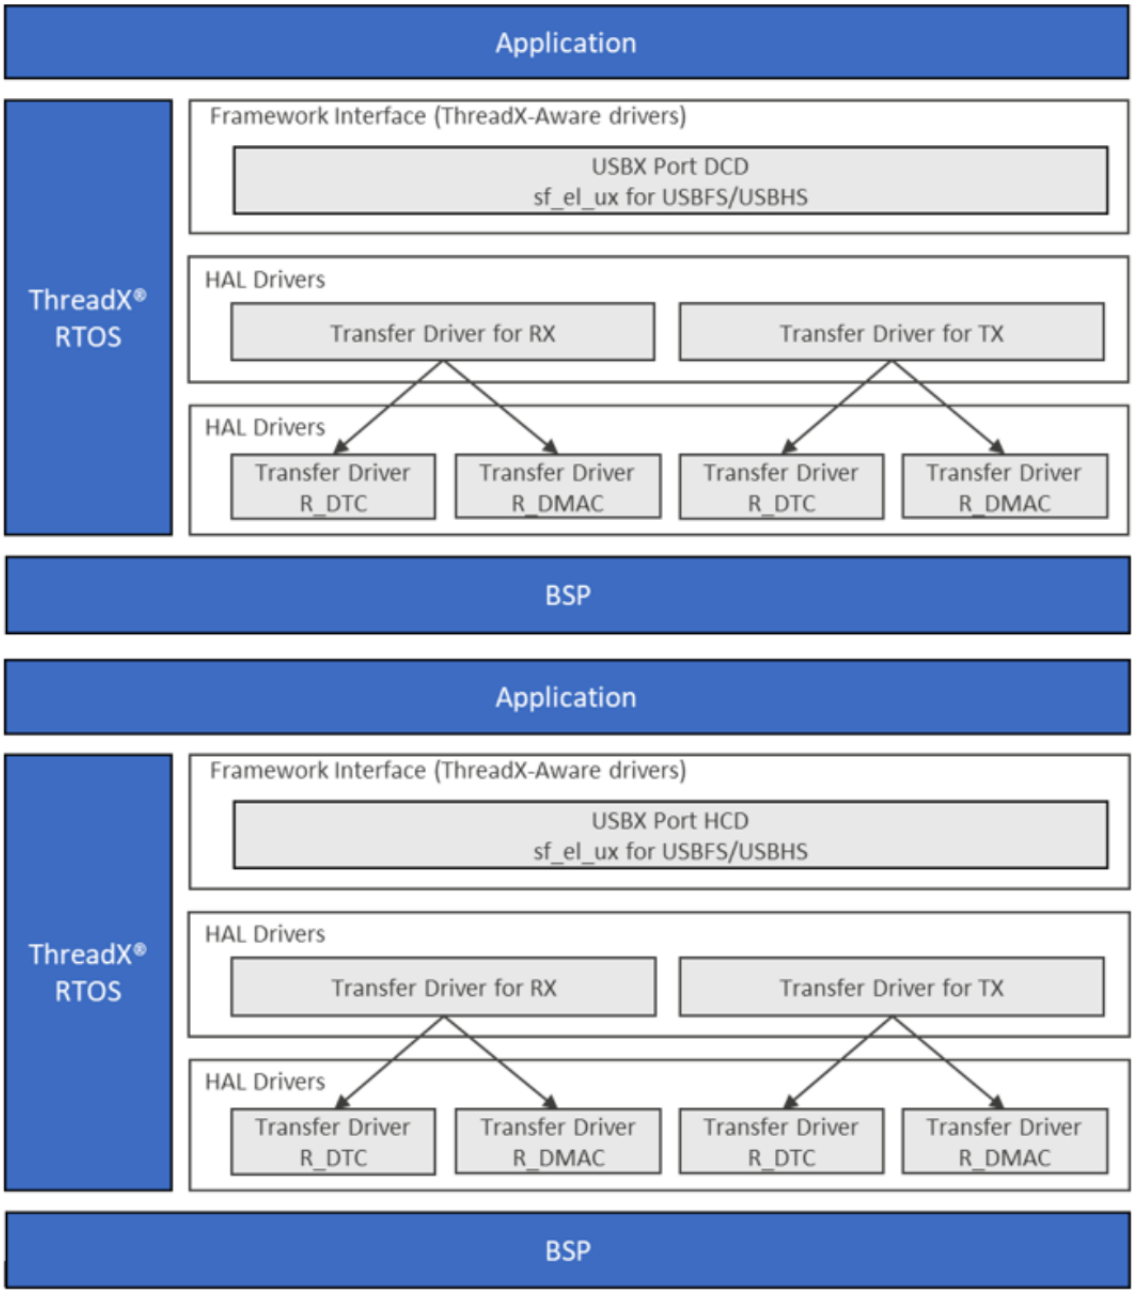


Figure 527: USBX Synergy Port Framework Module Block Diagram

—*

Note

*Currently, the r_dtc is not supported for both the host side driver and device side driver (only r_dmac is supported).****

4.3.40.2 USBX Synergy Port Framework Module APIs Overview

The Azure RTOS USBX Synergy Port Framework module doesn't have API calls of its own- it implements the API calls for the Azure RTOS USBX API calls. Documentation on these APIs is available in the Azure RTOS USBX User Manual.

4.3.40.3 USBX Synergy Port Framework Module Operational Overview

The Azure RTOS USBX Synergy Port framework module provides the Synergy USB hardware port functions required to use the USBX stack on Synergy hardware. Application code using this module is expected to use USBX API calls.

USBX Synergy Port Framework Module Important Operational Notes and Limitations

USBX Synergy Port Framework Module Operational Notes

The Azure RTOS USBX Synergy Port framework module includes the support for the Azure RTOS USBX APIs in SSP. Refer to the Azure RTOS USBX User Manual for a complete description of the available APIs.

The Azure RTOS USBX Synergy Port framework module supports the Port Device Controller Driver (DCD) on USBHS and USBFS peripherals as well as the Port Host Controller Driver (HCD) for the USBHS on USBFS peripherals.

Users have the option of using the Transfer Module for the USBX Synergy Port framework module to get better USB data throughput by transferring data in the block transfer mode. To enable the Transfer module, just add two instances of transfer components to the USBX Class stack in the Synergy Configuration tool and enable the interrupts in the property. The Synergy Configuration tool auto-generates the driver setup code to enable DMAC or DTC transfer in common_data.c.

Note

Currently, DTC is not supported by the host side driver (only DMAC is supported).

The module uses the interrupt of a USB Controller. Set the appropriate interrupt priority level in the Synergy Configuration tool; otherwise it does not work. The module uses the interrupt of a transfer module (implemented as DMAC or DTC) if it is used. Set the appropriate priority level in the Synergy Configuration tool. The priority level of the transfer module must be higher than the priority level for the USB Controller; otherwise it does not work.

USBX Synergy Port Framework Module Limitations

- Synergy USB controllers (USBHS and USBFS) have a limited number of PIPEs you can use for the isochronous transfer type (PIPE1 and PIPE2). This will limit the number of UVC devices (two devices) you can connect to the Synergy board configured as UVC HOST.
- The device side driver (sf_el_ux DCD driver) does not support DTC as the transfer interface.
- The host side driver (sf_el_ux HCD driver) does not support DTC as the transfer interface.
- The isochronous transfer is only supported for USB Host. The transfer type is not supported for USB Device.
- The USBFS controller is unlikely to support typical UVC devices. The maximum packet size of isochronous PIPEs on USBFS controller is limited to 256 bytes. This would impact in the UVC usage.
- Synergy USB controllers (USBHS and USBFS) do not support high-bandwidth isochronous transfer. The controllers support 1 transaction per micro-frame if running at high-speed).
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.40.4 Including the USBX Synergy Port Framework Module in an Application

This section describes how to include the USBX Synergy Port Framework module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the USBX Synergy Port Framework module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

USBX Synergy Port Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_el_ux_hcd_hs_0 USBX Port HCD on sf_el_ux for USBHS	Threads	New Stack> X-Ware> USBX> Host > Synergy Port> USBX Port HCD on sf_el_ux for USBHS
g_sf_el_ux_hcd_fs_0 USBX Port HCD on sf_el_ux for USBFS	Threads	New Stack> X-Ware> USBX> Host > Synergy Port> USBX Port HCD on sf_el_ux for USBFS
g_sf_el_ux_dcd_hs_0 USBX Port HCD on sf_el_ux for USBHS	Threads	New Stack> X-Ware> USBX> Device > Synergy Port> USBX Port HCD on sf_el_ux for USBHS
g_sf_el_ux_dcd_fs_0 USBX Port HCD on sf_el_ux for USBFS	Threads	New Stack> X-Ware> USBX> Device > Synergy Port> USBX Port HCD on sf_el_ux for USBFS

When the USBX Synergy Port Framework module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

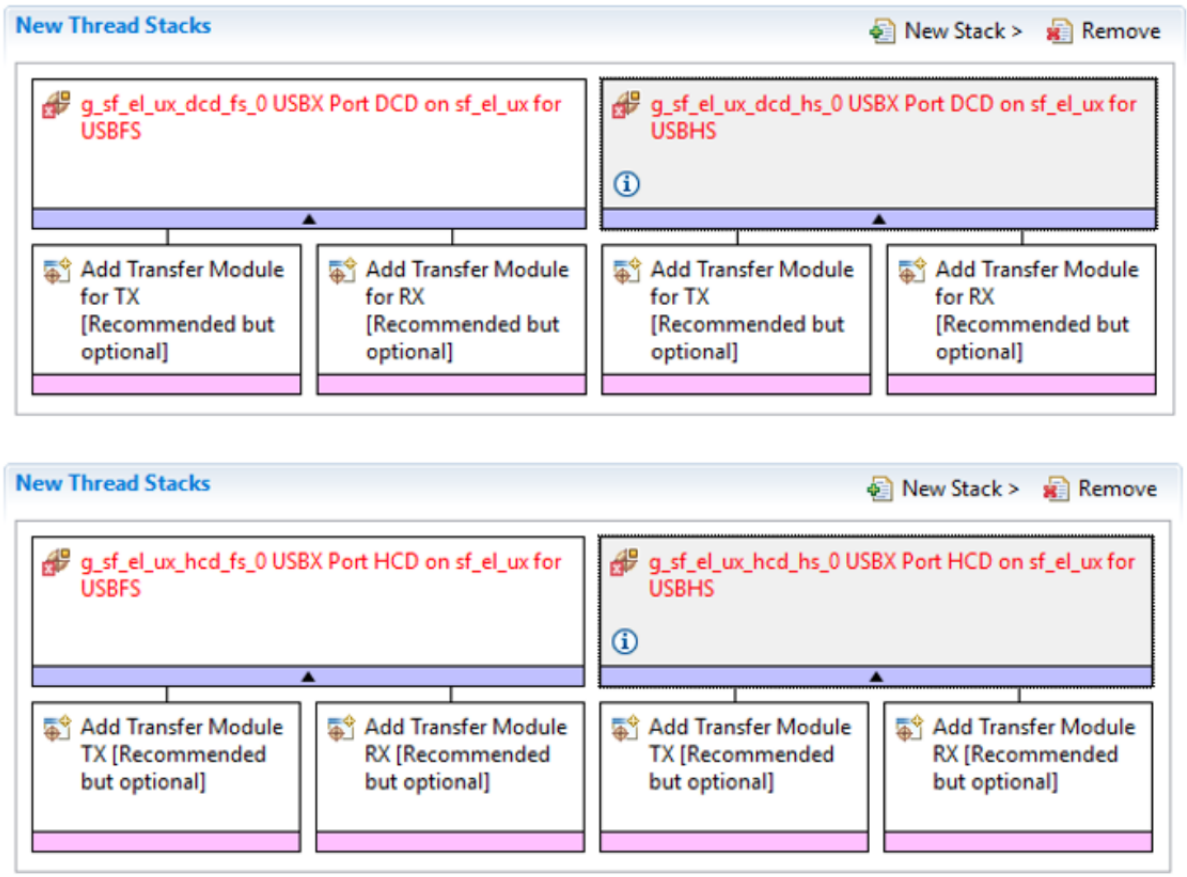

Figure 528: USBX Synergy Port Framework Module Stack

4.3.40.5 Configuring the USBX Synergy Port Framework Module

The USBX Synergy Port Framework module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the USBX Port DCD on sf_el_ux for USBFS

ISDE Property	Value	Description

Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.
LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.
Name	g_sf_el_ux_dcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on sf_el_ux for USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.
Name	g_sf_el_ux_dcd_hs_0	Module name.
USB Controller Selection	USBHS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.
VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.

Name	g_sf_el_ux_hcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.
FIFO size for Bulk/Isochronous Pipes	512, 1024, 1536, 2048 bytes Default: 512 bytes	Select the FIFO size for bulk and isochronous transfers.
Number of Isochronous Pipes Reserved	0,1,2 Default: 0	Select the number of isochronous pipes to reserve.
VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
Enable High Speed	Enable, Disable Default: Enable	Select if high speed should be enabled.
Name	g_sf_el_ux_hcd_hs_0	Module name.
USB Controller Selection	USBHS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.
Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the USBX Synergy Port Framework Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the Transfer Driver on r_dmac

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Name	g_transfer0	Module name.
Channel	0	Specify the hardware channel.
Mode	Block	Select the transfer mode.
Transfer Size	1 Byte	Select the transfer size.
Destination Address Mode	Fixed	Select the address mode for the destination.
Source Address Mode	Incremented	Select the address mode for the source.
Repeat Area (Unused in Normal Mode	Source	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source	Device: Event USBFS FIFO 0 Host: Software Activation	Select the DMAC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback	NULL	A user callback that is called at the end of the transfer.
Transfer End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dmac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Name	g_transfer0	Module name.
Channel	0	Specify the hardware channel.
Mode	Block	Select the transfer mode.
Transfer Size	1 Byte	Select the transfer size.
Destination Address Mode	Incremented	Select the address mode for the destination.
Source Address Mode	Fixed	Select the address mode for the source.
Repeat Area (Unused in Normal Mode	Destination	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source	Device: Event USBFS FIFO 1 Host: Software Activation	Select the DMAC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback	NULL	A user callback that is called at the end of the transfer.
Transfer End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

USBX Synergy Port Framework Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48MHz operation. In the SSP configuration window, select the Clocks tab to view the clock-source setting.

USBX Synergy Port Framework Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external devices. Select I/O pins and configure to the external device requirements. The following table illustrates the pin selection method within the SSP Configuration Window and the subsequent tables demonstrates the selection process using USB pins as an example.

Note

The selected operation mode determines what peripheral signals are available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence
USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

Note

The selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select device as the Operation Mode
USBDP	USBDP	USBDP pin
USBDM	USBDM	USBDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	None	VBUSEN pin
VBUS	None, P407 Default: P407	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID Pin

VCCUSB	VCCUSB	VCCUSB pin
VSSUSB	VSSUSB	VSSUSB pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select Device as the Operation Mode
USBHSDP	USBHSDP	USBHSDP pin
USBHSDM	USBHSDM	USBHSDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	PB00	VBUSEN pin
VBUS	PB01	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID pin
USBHSRREF	USBHSRREF	USBHSRREF pin
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin
PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin
VCCUSBHS	VCCUSBHS	VCCUSBHS pin
VSS1USBHS	VSS1USBHS	VSS1USBHS pin
VSS2USBHS	VSS2USBHS	VSS2USBHS pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.40.6 Using the USBX Synergy Port Framework Module in an Application

Once the Azure RTOS Synergy Port USBX framework module is added to a thread, the Azure RTOS APIs become available for use by higher-level modules. There is usually no need to use the Azure RTOS Synergy Port USBX framework module directly in application code. Refer to the Azure RTOS USBX User's Manual if you need to use the module stand-alone and need to access the associated APIs directly.

Following is the sequence of API's called successfully in a sequential order in an application for

completely deleting detected USB Device class,

!( )[media/sf_el_ux_FD.png)

4.3.41 USBX Device Class CDC-ACM

4.3.41.1 USBX Device Class CDC-ACM Module Introduction

The USBX™ Device Class CDC-ACM module provides a high-level API for USBX Device Class CDC-ACM module applications and uses the USB and data-transfer peripherals on the Synergy MCU. A user defined callback can be created to determine when the stack activates or deactivates the USB CDC-ACM class.

USBX Device Class CDC-ACM Module Features

The USB Device Class CDC-ACM module allows for a USB host-system to communicate with the device as a serial device. This class is based on the USB standard and is a subset of the CDC standard. The USBX Device Class CDC-ACM module includes the following key features:

- Support for USB Full Speed (USBFS) or USB High Speed (USBHS)
- Receive and transmit data-transfer drivers for improved performance
- High-level APIs for reading and writing

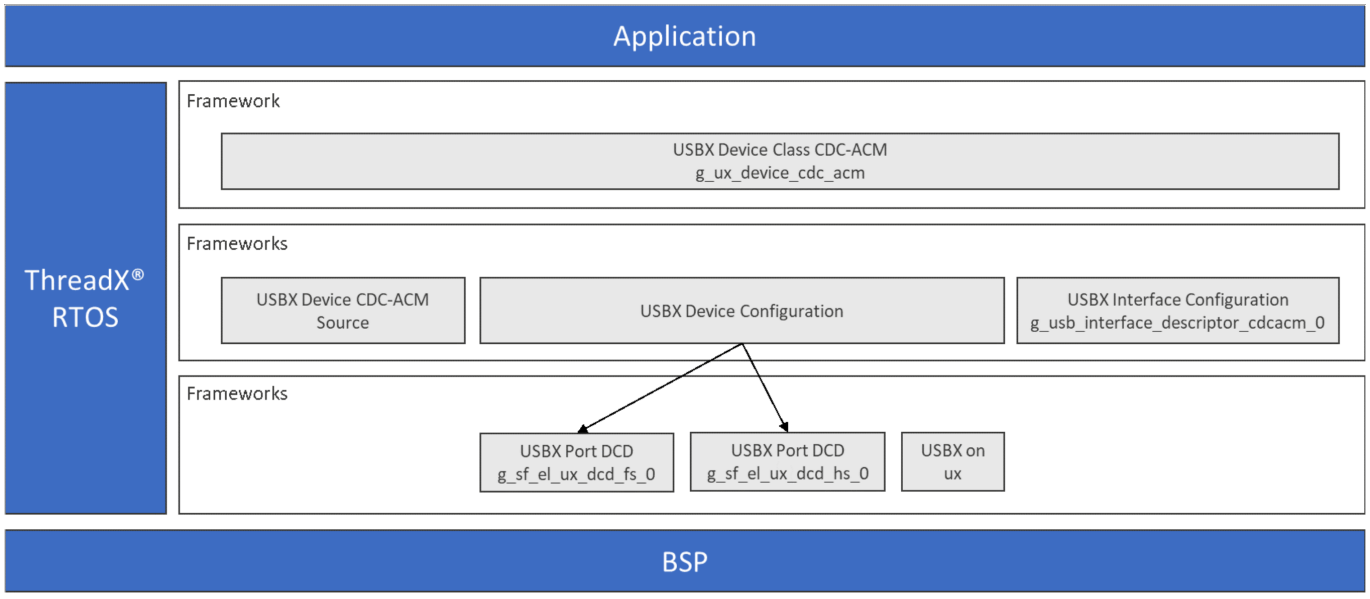

Figure 529: USBX Device Class CDC-ACM Module Block Diagram

4.3.41.2 USBX Device Class CDC-ACM Module APIs Overview

The USBX Device Class CDC-ACM Module defines APIs for reading and writing over the USB peripheral. A complete list of the available APIs, an example API call and a short description of each

can be found in the following table. A table of status return values follows the API summary table.

USBX Device Class CDC-ACM Module Summary

Function Name	Example API Call and Description
ux_device_class_cdc_acm_read	status = ux_device_class_cdc_acm_read(cdc, buffer, UX_DEMO_BUFFER_SIZE, &actual_length); This function is called when an application needs to read from the OUT data pipe (OUT from the host, IN from the device).
ux_device_class_cdc_acm_write	status = ux_device_class_cdc_acm_write(cdc, buffer, UX_DEMO_BUFFER_SIZE, &actual_length); This function is called when an application needs to write to the IN data pipe (IN from the host, OUT from the device).

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
UX_SUCCESS	This operation was successful.
UX_CONFIGURATION_HANDLE_UNKNOWN	Device is no longer in the configured state.
UX_TRANSFER_NO_ANSWER	No answer from device. The device was probably disconnected while the transfer was pending.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.41.3 USBX Device Class CDC-ACM Module Operational Overview

The initialization of the CDC-ACM class expects some specific parameters as illustrated in the application project associated with this module guide.

The CDC-ACM is based on a USB-IF standard and is automatically recognized by Mac OS® and Linux OS®. On Windows® platforms, this class requires a .inf file. Azure RTOS supplies a template for the CDC-ACM class, and it can be found in the usbx_windows_host_files directory. For more recent versions of Windows, the file CDC_ACM_Template_Win7_64bit.inf should be used; this file needs to be modified to reflect the PID/VID used by the device. The PID/VID will be specific to the final customer when the company and the product are registered with the USB-IF. In the .inf file, the fields to modify are described in the application project associated with this module guide.

In the device framework of the USBX CDC-ACM device, the PID/VID are stored in the device descriptor (see the device descriptor declared in the application project referenced in the preceding paragraph).

When a USB host-system discovers the USBX CDC-ACM device, it will mount a serial class and the

device can be used with any serial terminal program. (See the host operating system for reference.)

USBX Device Class CDC-ACM Module Important Operational Notes and Limitations

USBX Device Class CDC-ACM Module Operational Notes

The USBX Device stack or USBX Host stack consumes RAM for the control block. The Synergy Configuration tool allocates memory to the USBX memory pool statically in the auto-generate code as shown in the following table. You need to set the appropriate memory size in bytes to the USBX Pool Memory Size property of the USBX on ux component in the Synergy Configuration tool in section "USBX on ux Configuration." If multiple classes are used, set the total memory size to the property.

Memory (RAM) Requirements for the USBX Memory Pool

USBX Class	S1 Parts	Other Parts
USBX Device CDC-ACM (ux_device_class_cdc_acm)	6.1KB	18KB

Note

The information shown in the table above is valid if compiled with default USBX configurations. The memory size of the USBX Classes in the table above are of the pre-built libraries and the following configuration was applied for the builds:

UX_THREAD_STACK_SIZE: 512 (bytes) for S1 parts; 2048 (bytes) for the other parts

The application needs to save the instance with the callback function registered in USBX CDC-ACM instance_activate Function Callback. Read and write are executed using the saved instance.

USBX Device Class CDC-ACM Module Limitations

- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.41.4 Including the USBX Device Class CDC-ACM Module in an Application

This section describes how to include the USBX Device Class CDC-ACM Module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the USBX Device Class CDC-ACM Module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

USBX Device Class CDC-ACM Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ux_device_class_cdc_acm0 USBX Device Class CDC-ACM	Threads	New Stack> X-Ware> USBX> Device> Classes > CDC-ACM > USBX Device Class CDC-ACM

When the USBX Device Class CDC-ACM Module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

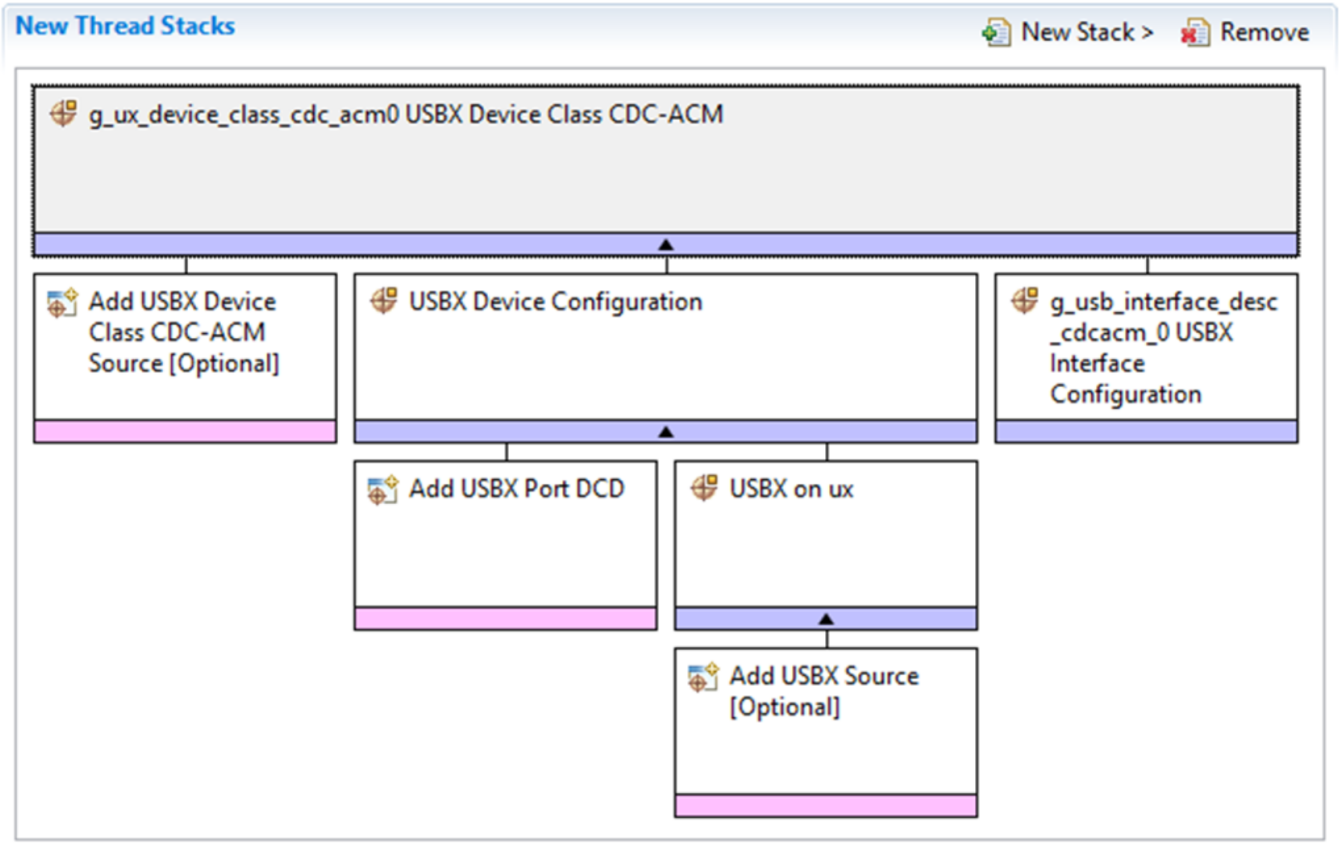

Figure 530: USBX Device Class CDC-ACM Module Stack

4.3.41.5 Configuring the USBX Device Class CDC-ACM Module

The USBX Device Class CDC-ACM Module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the USBX Device Class CDC-ACM Module

ISDE Property	Value	Description
Name	g_ux_device_class_cdc_acm0	Specify the name of the USBX Device CDC-ACM Class module instance. It must be a valid C symbol.
USBX CDC-ACM instance_activate Function Callback	ux_cdc_device0_instance_activate	Specify the name of the instance_activate user callback function for the USBX Device CDC-ACM Class module. Name must be a valid C symbol. See the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device CDC-ACM Class" for more information about the instance_activate callback function.
USBX CDC-ACM instance_deactivate Function Callback	ux-cdc_device0_instance_deactivate	Specify the name of the instance_deactivate user callback function for the USBX Device CDC-ACM Class module. Name must be a valid C symbol. Refer to the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device CDC-ACM Class" for more information about the instance_activate callback function.
USBX CDC-ACM parameter_change Function Callback	NULL	Specify the name of the parameter change user callback function for the USBX Device CDC-ACM Class module. Name must be a valid C symbol. Refer to the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device CDC-ACM Class" for more information about the parameter_change callback function.
Name of generated initialization function	ux_device_class_cdc_acm_init0	Name of generated initialization function selection.

Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the USBX Device Class CDC-ACM Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the USBX Device Class CDC-ACM Source

ISDE Property	Value	Description
Show linkage warning	Enabled, Disabled Default: Enabled	Notification message for users will be shown if "Enabled" option is selected. This is just to warn users possible linkage errors by multiple symbol definitions. Select "Disabled" stops the notification message.
CDC ACM device write auto ZLP enable	Enabled, Disabled Default: Disabled	UX_DEVICE_CLASS_CDC_ACM_WRITE_AUTO_ZLP When enabled, the CDC class sends a ZLP automatically after a buffer is sent.
Device CDC ACM Zero Copy	Enabled, Disabled Default: Disabled	UX_DEVICE_CLASS_CDC_ACM_ZERO_COPY When enabled, device CDC ACM zero copy for bulk in/out endpoints is supported.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Device Configuration Instance

ISDE Property	Value	Description
Vendor ID	0x045B	Specify Vendor ID assigned by USB-IF. This configuration is a part of the USB Device Descriptor (idVendor).

Product ID	0x0000	Specify Product ID assigned by manufacturer. This configuration is a part of the Device Descriptor (idProduct).
Device Release Number	0x0000	Specify Device Release Number in binary-coded decimal. This configuration is a part of the USB Device Descriptor (bcdDevice).
Index of Manufacturing String Descriptor	0x00	Specify the Index of Manufacturer String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iManufacturer). Set zero if String Descriptor is not used. See section USBX-String-Framework-Configuration for more information.
Index of Product String Descriptor	0x00	Specify the Index of Product String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iProduct). Set zero if String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Index of Serial Number String Descriptor	0x00	Specify the Index of Serial Number String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iSerialNumber). Set zero if the String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Class Code	Communications(CDC), HID, Mass Storage, Miscellaneous, Vendor specific Default: Communications(CDC)	Select the USB Device Class Code. This configuration is a part of the USB Configuration Descriptor (bDeviceClass).

Index of String Descriptor describing this configuration	0x00	Specify the Index of String Descriptor describing this configuration. This configuration is a part of the USB Configuration Descriptor (iConfiguration). Set zero if String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Size of USB Descriptor in bytes for this configuration (Modify this value only for Vendor-specific Class, otherwise set zero)	0x00	Specify the size of USB Descriptor in bytes. Modify the value for Vendor-specific Class, otherwise you can set zero to calculate the size automatically in the auto-generated code from Synergy Configuration tool. This configuration is a part of the USB Configuration Descriptor (wTotalLength).
Number of Interfaces (Modify this value only for Vendor-specific Class, otherwise set zero)	0x00	Specify the Number of interfaces supported by this configuration. Modify the value for Vendor-specific Class, otherwise you can set zero to calculate the value automatically in the auto-generated code from Synergy Configuration tool. This configuration is a part of the USB Configuration Descriptor (bNumInterfaces).
Self-Powered	Enable, Disable Default: Enable	Enable this configuration if your USB Device is a self- powered device. This configuration is a part of the USB Configuration Descriptor (bmAttributes bit6).
Remote Wakeup	Enable, Disable Default: Disable	Enable this configuration if your USB Device supports remote wakeup. This configuration is a part of the USB Configuration Descriptor (bmAttributes bit5).
Maximum Power Consumption (in 2mA units)	50	Set the maximum power consumption of your device to indicate the amount of bus power required. This configuration is 2mA units, thus, the maximum 500 mA can be specified. This configuration is a part of the USB Configuration Descriptor (bMaxPower).

Supported Language Code	0x0409	Specify the Language ID Code. For example, 0x0409 English - United States. This configuration is used for Language ID Framework code generation. See section "USBX Language Framework Configuration" for more information.
Name of USBX String Framework	NULL	Specify the name of user defined USBX String Framework. This must be a valid C symbol. Set NULL if the String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Total index number of USB String Descriptors in USB String Framework	0	Specify the total number of index for String Descriptor. See section "USBX String Framework Configuration" for more information.
Name of USBX Language Framework	NULL	Specify the name of user defined USBX Language Framework. This must be a valid C symbol. If '0' is set to the property "Total Number of Language Support", this configuration is ignored. See section "USBX Language Framework Configuration" for more information.
Number of Languages to support (US English is applied if zero is set)	0	Specify the total number of languages to support. See section "USBX String Framework Configuration" for more information. If '0' is set here, US English (0x0409) is applied as the default language.
Name of generated initialization function	ux_device_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Interface Configuration CDC-ACM Instance

ISDE Property	Value	Description
Name	g_usb_interface_desc_cdcacm_0	Specify the name of USBX Interface Descriptor for CDC-ACM. It must be a valid C symbol.
Interface Number of Communications Class interface	0x00	Specify the index number of Communications Class interface. This configuration is a part of the USB Interface Descriptor (bInterface). The number must not be duplicated with the Interface Number of Data Class interface. Also must not be duplicated with any Interface Numbers if your USB device consists of a USB composite device.
Interrupt Transfer endpoint to use for Communications Class	Endpoint 1-9 Default: Endpoint 3	Specify the Endpoint Number of Interrupt Endpoint. It must not be duplicated with ones for the other Endpoints.
Polling period for Interrupt Endpoint (in mS/125us units for FS/HS)	0x0F	Specify the Interval for polling Endpoint transfers. This configuration is valid for Interrupt Endpoint and ignored for Bulk Endpoints. Value is in frame counts (1ms units for FS mode and 125us units for HS mode).
Interface Number of Data Class interface	0x01	Specify the index number of Data Class interface. This configuration is a part of the USB Interface Descriptor (bInterface). The number must not be duplicated with the Interface Number of Communications Class interface. Also must not be duplicated with any Interface Numbers if your USB device consists of a USB composite device.
Bulk In Transfer endpoint to use for Data Class	Endpoint 1-9 Default: Endpoint 1	Specify the Endpoint Number of Bulk In Endpoint. It must not be duplicated with ones for the other Endpoints.
Bulk Out Transfer endpoint to use for Data Class	Endpoint 1-9 Default: Endpoint 2	Specify the Endpoint Number of Bulk Out Endpoint. It must not be duplicated with ones for the other Endpoints.

Index of String Descriptor Describing Communications Class interface (Interface Descriptor: Interface)	0x00	Specify the index number of String Descriptor Describing Communications Class interface. This configuration is a part of the USB Interface Descriptor (iInterface). Set '0' if do not have String information for the interface.
Index of String Descriptor Describing Data Class interface (Interface Descriptor: Interface)	0x00	Specify the index number of String Descriptor Describing Data Class interface. This configuration is a part of the USB Interface Descriptor (iInterface). Set '0' if do not have String information for the interface.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.
LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.
Name	g_sf_el_ux_dcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.

Name	g_sf_el_ux_dcd_hs_0	Module name.
USB Controller Selection	USBHS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX on ux Instance

ISDE Property	Value	Description
USBX Pool Memory Name	g_ux_pool_memory	Name must be a valid C symbol.
USBX Pool Memory Size	18432	See section "Azure RTOS USBX Memory Requirements" for the required memory size for each classes.
User Callback for Host Event Notification (Only valid for USB Host)	NULL	Name must be a valid C symbol. The name of User defined USBX Host event notification can be given to this property.
Name of generated initialization function	ux_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

USBX Device Class CDC-ACM Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48MHz operation. In the SSP configuration window, select the Clocks tab to view the clock-source setting.

USBX Device Class CDC-ACM Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external devices. Select I/O pins and configure to the external device requirements. The following table lists the pin selection method within the SSP Configuration Window and the subsequent tables demonstrate the selection process using USB pins as an example.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence

USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

Note

The selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select device as the Operation Mode
USBDP	USBDP	USBDP pin
USBDM	USBDM	USBDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	None	VBUSEN pin
VBUS	None, P407 Default: P407	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID Pin
VCCUSB	VCCUSB	VCCUSB pin
VSSUSB	VSSUSB	VSSUSB pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select Device as the Operation Mode
USBHSDP	USBHSDP	USBHSDP pin
USBHSDM	USBHSDM	USBHSDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin

VBUSEN	PB00	VBUSEN pin
VBUS	PB01	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID pin
USBHSRREF	USBHSRREF	USBHSRREF pin
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin
PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin
VCCUSBHS	VCCUSBHS	VCCUSBHS pin
VSS1USBHS	VSS1USBHS	VSS1USBHS pin
VSS2USBHS	VSS2USBHS	VSS2USBHS pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.41.6 Using the USBX Device Class CDC-ACM Module in an Application

The configurator generates processing to create and register the USBX Device Class CDC-ACM module; however, communication must be done after the device is connected to the host.

The typical steps in using the USBX Device Class CDC-ACM module in an application are:

1. Wait for the callback function registered in USBX CDC-ACM instance_activate Function Callback to be called.

2. In the callback function, save the instance.

3. For received data reading, use the ux_device_class_cdc_acm_read API.

4. For sending data, use the ux_device_class_cdc_acm_write API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

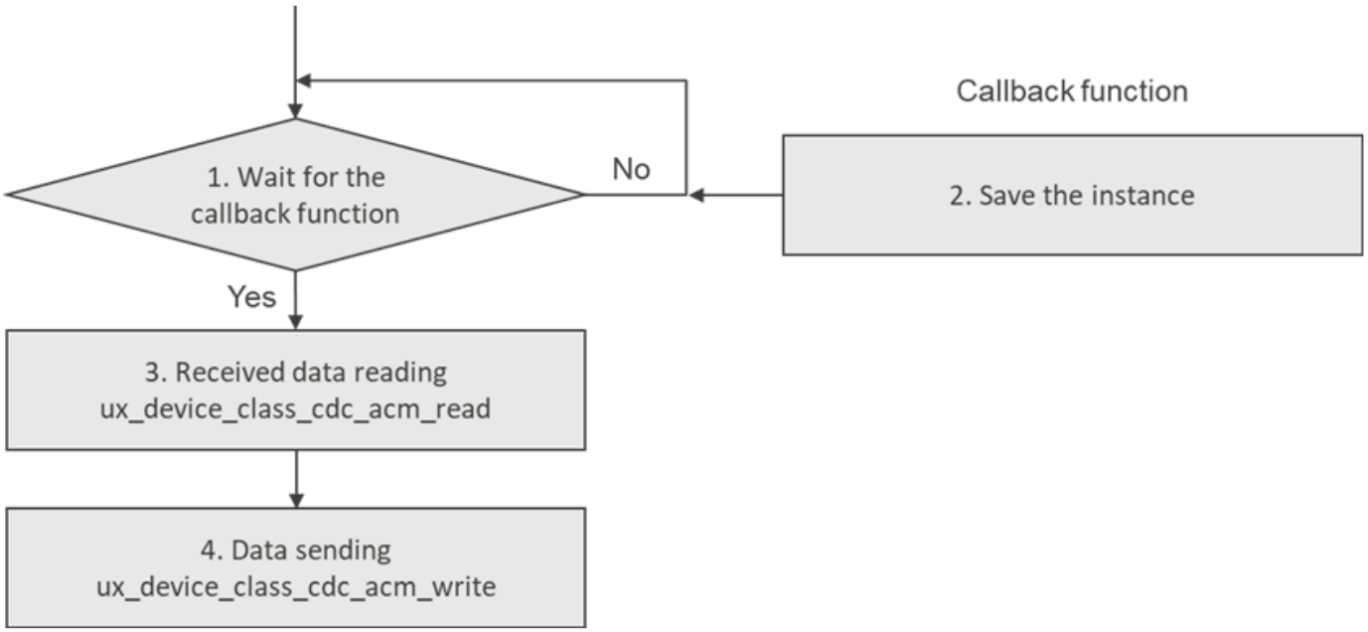

Figure 531: Flow Diagram of a Typical USBX Device Class CDC-ACM Module Application

4.3.42 USBX Device Class HID

4.3.42.1 USBX Device Class HID Module Introduction

The USBXTM Device Class Human Interface Design (HID) module provides a high-level API for HID applications and configures the USBX Device Class HID Source, USBX Host Configuration, USBX Source and USBX Port HCD. The USBX Device Class HID module uses the USB peripheral on the Synergy MCU.

Unsupported Features

USBX composite device class supports only CDC-CDC and CDC-MSC device class.

USBX Device Class HID Module Features

The USB Device Class HID module allows a USB host system to communicate with the device as a keyboard device, a mouse device and other HID devices. This class is based on the USB standard and is a subset of the HID standard. The USBX Device Class HID module includes the following key features:

- Support for USB high speed (USBHS) or full speed (USBFS)
- Uses Receive and Transmit data-transfer drivers for improved performance
- Provides high-level APIs for reading and writing

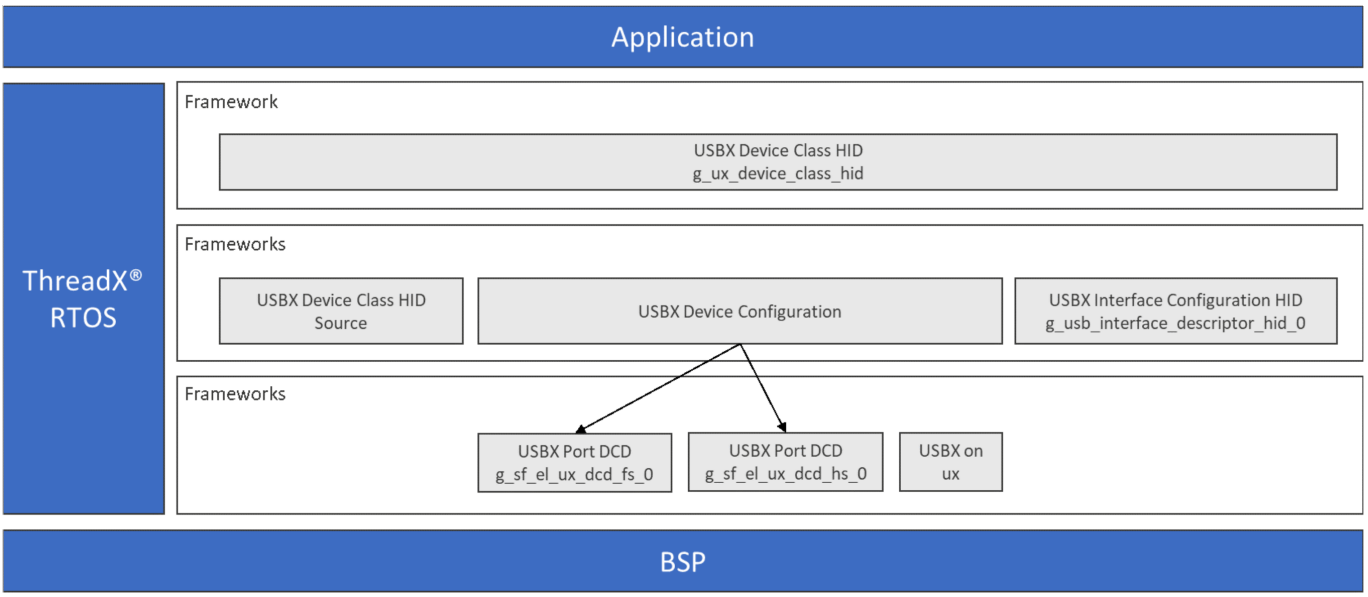

Figure 532: USBX Device Class HID Module Block Diagram

4.3.42.2 USBX Device Class HID Module APIs Overview

The USBX Device Class HID module defines APIs for sending and receiving HID events and reports. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

USBX Device Class HID Module Summary

Function Name	Example API Call and Description
ux_device_class_hid_event_set	ux_device_class_hid_event_set (hid, &hid_event); This function is called when an application needs to send a HID event to the host.
ux_device_class_hid_event_get	ux_device_class_hid_event_get (hid, & hid_event); This function is called when an application needs to receive a HID event from the host.
ux_device_class_hid_report_set	ux_device_class_hid_report_set (hid, descriptor_type, request_index, host_length); This function is called when an application needs to send a HID report to the host.
ux_device_class_hid_report_get	ux_device_class_hid_report_get (hid, descriptor_type, request_index, host_length); This function is called when an application needs to receive a HID report to the host.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
UX_SUCCESS	The data transfer was completed.
UX_TRANSFER_TIMEOUT	Transfer timeout, reading/writing not completed.
UX_MEMORY_INSUFFICIENT	Not enough memory.
UX_HOST_CLASS_UNKNOWN	Wrong class instance.
UX_FUNCTION_NOT_SUPPORTED	Unknown IOCTL function.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.42.3 USBX Device Class HID Module Operational Overview

Initialization of USBX Resources

The USBX has its own memory manager. The memory needs to be allocated to the USBX before the host or device side of the USBX is initialized. The USBX memory manager can accommodate systems where memory can be cached.

Definition of USB Host Controllers

It is required to define at least one USB host controller for USBX to operate in host-mode. The application-initialization file should contain this definition. SSP defines USB host controller when USB host controller driver is added to thread stacks.

Definition of Device Classes

It is required to define one or more device classes(s) with the USBX. A USB class is required to drive a USB device after the USB stack has configured the USB device. A USB class is very specific to the device; one or more classes may be required to drive a USB device depending on the number of interfaces contained in the USB device descriptors.

USB Class Binding

When the device is configured, the topology manager will let the class manager continue the device discovery by looking at the device-interface descriptors. A device can have one or more interface descriptors.

An interface represents a function in a device. For instance, a USB speaker has three interfaces, one for audio streaming, one for audio control, and one to manage the various speaker buttons.

The class manager has two mechanisms to join the device interface(s) to one or more classes. It can either use the combination of a PID/VID (product ID and vendor ID) found in the interface descriptor or the combination of Class/Subclass/Protocol.

The PID/VID combination is valid for interfaces that cannot be driven by a generic class. The Class/Subclass/Protocol combination is used by interfaces that belong to a USB-IF certified class such as a printer, hub, storage, audio, or Human Interface Design (HID).

The class manager contains a list of registered classes from the initialization of the USBX. The class manager will call each class one-at-a-time until one class accepts to manage the interface for that device; each class can only manage one interface. In the case of the USB audio speaker, the class manager will call all the classes for each of the interfaces.

Once a class accepts an interface, a new instance of that class is created; the class manager will then search for the default alternate setting for the interface. A device may have one or more alternate settings for each interface. The alternate setting 0 will be the one used by default until a class decides to change it.

For the default alternate setting, the class manager will mount all the endpoints contained in the alternate setting. If the mounting of each endpoint is successful, the class manager will complete its job by returning to the class that will finish the initialization of the interface.

USBX Device Class HID Module Important Operational Notes and Limitations

USBX Device Class HID Module Operational Notes

The USBX Device stack or USBX Host stack consumes RAM for the control block. The Synergy Configuration tool allocates memory to the USBX memory pool statically in the auto-generate code as shown in the following table. You need to set the appropriate memory size in bytes to the USBX Pool Memory Size property of the USBX on ux component in the Synergy Configuration tool in section "USBX on ux Configuration." If multiple classes are used, set the total memory size to the property.

Memory (RAM) Requirements for the USBX Memory Pool

USBX Class	S1 Parts	Other Parts
USBX Device HID (ux_device_class_hid)	6.1KB + (Add the additional memory as per Note[*1]).	12KB + (Add the additional memory as per Note[*1]).

Note

*[*1]: If maximum number of HID events queue is more than 16(USBX device class HID source module: Property >> Common >> Maximum number of USBX device HID event queue) or HID event buffer length is more than 64(USBX device class HID source module: Property >> Common >> USBX Device HID Event length Buffer) in the XML configurator. Add the additional memory to USBX memory pool as follows:*

- Additional memory calculation for USBX full speed and High speed made.
  - ((Maximum number of USBX device HID event queue - 16) * 12) + ((Maximum number of USBX device HID event queue * USBX Device HID Event length Buffer) - 1024) = Additional memory in bytes.

Note: If HID event buffer value is increased to large value, Application stack size and USBX thread stack size(USBX Source >> Common >> Stack size for USBX threads) need to increase.

Note

The information shown in the table above is valid if compiled with default USBX configurations.
The memory size of the USBX Classes in the table above are of the pre-built libraries and the following configuration was applied for the builds:

UX_THREAD_STACK_SIZE: 512 (bytes) for S1 parts; 2048 (bytes) for the other parts

- The application gets the HID instance of the slave device from the global variable, _ux_system_slave; sends and receives executed using this instance.
- Use the Protocol code property of the USBX Interface Configuration HID Driver to determine

the operation of the actual device.

USBX Device Class HID Module Limitations

- The module needs the interrupt of a USB Controller enabled.
- The module uses the interrupt of a USB Controller. Set the appropriate interrupt-priority level in the Synergy Configuration tool for proper operation.
- The module uses the interrupt of a transfer module (implemented as DMAC or DTC) if it is used. Set the appropriate priority level in the Synergy Configuration tool and the level has to be higher than a USB Controller, otherwise it does not work.
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

Note

Currently, DTC is not supported by the device side driver (only DMAC is supported).

4.3.42.4 Including the USBX Device Class HID Module in an Application

This section describes how to include the USBX Device Class HID Module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the USBX Device Class HID Module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

USBX Device Class HID Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ux_device_class_hid USBX Device Class HID	Threads	New Stack> X-Ware> USBX> Device > Classes > HID > USBX Device Class HID

When the USBX Device Class HID Module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

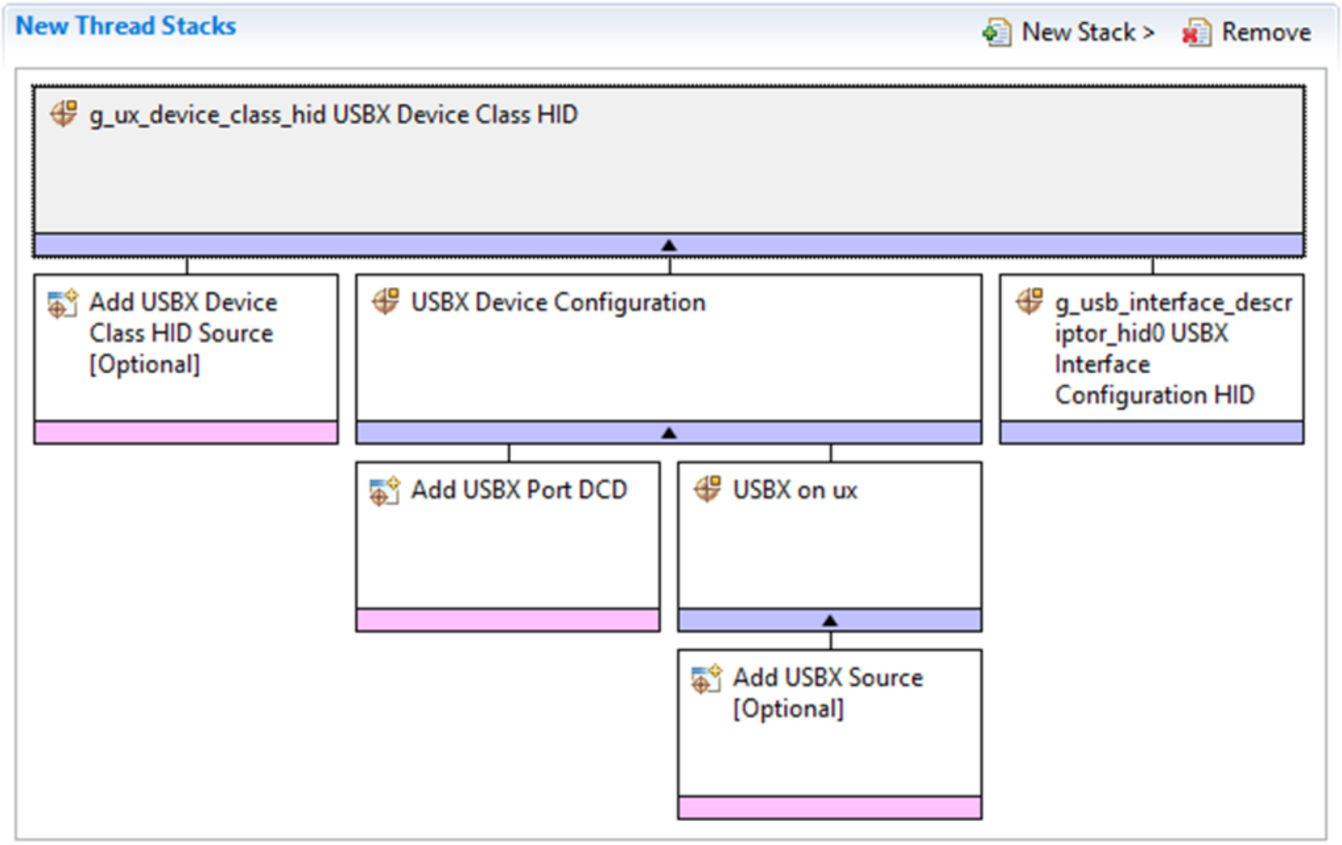

Figure 533: USBX Device Class HID Module Stack

4.3.42.5 Configuring the USBX Device Class HID Module

The USBX Device Class HID Module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the USBX Device Class HID Module

ISDE Property	Value	Description

Name	g_ux_device_class_hid	Specify the name of USBX Interface Descriptor for HID Class. It must be a valid C symbol.
USBX Device HID Entry Function	ux_device_class_hid_entry	Specify the name of a user callback function to get an event from HID Class. Name must be a valid C symbol. Refer to the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device HID Class" for more information about the user callback function.
USBX Device HID User Callback Function	ux_hid_device_callback	Specify the name of user entry function for the USBX Device HID Class module. Name must be a valid C symbol. See the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device HID Class" for more information about the user entry function.
USBX Device HID GetReport Callback Function	NULL	Specify the name of user entry function for the USBX Device HID Class module. Name must be a valid C symbol. See the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device HID Class" for more information about the user entry function.
USBX Device HID Instance Activate Callback Function	NULL	Specify the name of instance_activate user callback function for the USBX Device HID Class module. Name must be a valid C symbol. See the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device HID Class" for more information about the instance_activate callback function.

USBX Device HID Instance Deactivate Callback Function	NULL	Specify the name of instance_deactivate user callback function for the USBX Device HID Class module. Name must be a valid C symbol. Refer to the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device HID Class" for more information about the instance_activate callback function.
Multiple HID Report Support	Enable, Disable Default: Disable	Set Enable to support multiple HID report. This configuration is used to indicate which data fields are represented in each report structure.
Name of generated initialization function	ux_device_class_hid_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the USBX Device Class HID Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the USBX Device Class HID Source

ISDE Property	Value	Description

USBX Device HID Event Buffer Length	Value must be greater than or equal to 32. Default : 64	UX_DEVICE_CLASS_HID_EVENT_BUFFER_LENGTH Defines the size of Event Buffer Length. if the event buffer length value is more than 256. Slave request control maximum length value have to increase more than Event buffer length value. in USBX source module. (USBX Source: Property >> common >> Slave Request Control Maximum Length).
Maximum number of USBX Device HID Event queue.	Value must be greater than or equal to 16. Default: 16.	'UX_DEVICE_CLASS_HID_MAX_EVENTS_QUEUE' This value represents the maximum number of hid event queue, in the USBX Device hid class driver.
Device HID Interrupt Out Support	Enabled, Disabled Default: Disabled	UX_DEVICE_CLASS_HID_INTERRUPT_OUT_SUPPORT When enabled, device HID interrupt OUT transfer is supported.
Device HID Zero Copy	Enabled, Disabled Default: Disabled	UX_DEVICE_CLASS_HID_ZERO_COPY Defined, it enables device HID zero copy and flexible queue support (works if HID owns endpoint buffer).
Show linkage warning	Enabled, Disabled Default: Enabled	Notification message for users will be shown if "Enabled" option is selected. This is just to warn users possible linkage errors by multiple symbol definitions. Select "Disabled" stops the notification message.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Device Configuration Instance

ISDE Property	Value	Description
Vendor ID	0x045B	Specify Vendor ID assigned by USB-IF. This configuration is a part of the USB Device Descriptor (idVendor).

Product ID	0x0000	Specify Product ID assigned by manufacturer. This configuration is a part of the Device Descriptor (idProduct).
Device Release Number	0x0000	Specify Device Release Number in binary-coded decimal. This configuration is a part of the USB Device Descriptor (bcdDevice).
Index of Manufacturing String Descriptor	0x00	Specify the Index of Manufacturer String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iManufacturer). Set zero if String Descriptor is not used. See section USBX-String-Framework-Configuration for more information.
Index of Product String Descriptor	0x00	Specify the Index of Product String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iProduct). Set zero if String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Index of Serial Number String Descriptor	0x00	Specify the Index of Serial Number String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iSerialNumber). Set zero if the String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Class Code	Communications(CDC), HID, Mass Storage, Miscellaneous, Vendor specific Default: Communications(CDC)	Select the USB Device Class Code. This configuration is a part of the USB Configuration Descriptor (bDeviceClass).

Index of String Descriptor describing this configuration	0x00	Specify the Index of String Descriptor describing this configuration. This configuration is a part of the USB Configuration Descriptor (iConfiguration). Set zero if String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Size of USB Descriptor in bytes for this configuration (Modify this value only for Vendor-specific Class, otherwise set zero)	0x00	Specify the size of USB Descriptor in bytes. Modify the value for Vendor-specific Class, otherwise you can set zero to calculate the size automatically in the auto-generated code from Synergy Configuration tool. This configuration is a part of the USB Configuration Descriptor (wTotalLength).
Number of Interfaces (Modify this value only for Vendor-specific Class, otherwise set zero)	0x00	Specify the Number of interfaces supported by this configuration. Modify the value for Vendor-specific Class, otherwise you can set zero to calculate the value automatically in the auto-generated code from Synergy Configuration tool. This configuration is a part of the USB Configuration Descriptor (bNumInterfaces).
Self-Powered	Enable, Disable Default: Enable	Enable this configuration if your USB Device is a self- powered device. This configuration is a part of the USB Configuration Descriptor (bmAttributes bit6).
Remote Wakeup	Enable, Disable Default: Disable	Enable this configuration if your USB Device supports remote wakeup. This configuration is a part of the USB Configuration Descriptor (bmAttributes bit5).
Maximum Power Consumption (in 2mA units)	50	Set the maximum power consumption of your device to indicate the amount of bus power required. This configuration is 2mA units, thus, the maximum 500 mA can be specified. This configuration is a part of the USB Configuration Descriptor (bMaxPower).

Supported Language Code	0x0409	Specify the Language ID Code. For example, 0x0409 English - United States. This configuration is used for Language ID Framework code generation. See section "USBX Language Framework Configuration" for more information.
Name of USBX String Framework	NULL	Specify the name of user defined USBX String Framework. This must be a valid C symbol. Set NULL if the String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Total index number of USB String Descriptors in USB String Framework	0	Specify the total number of index for String Descriptor. See section "USBX String Framework Configuration" for more information.
Name of USBX Language Framework	NULL	Specify the name of user defined USBX Language Framework. This must be a valid C symbol. If '0' is set to the property "Total Number of Language Support", this configuration is ignored. See section "USBX Language Framework Configuration" for more information.
Number of Languages to support (US English is applied if zero is set)	0	Specify the total number of languages to support. See section "USBX String Framework Configuration" for more information. If '0' is set here, US English (0x0409) is applied as the default language.
Name of generated initialization function	ux_device_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Interface Configuration HID Instance

ISDE Property	Value	Description
Name	g_usb_interface_descriptor_hid0	Specify the name of USBX Interface Descriptor for CDC-ACM. It must be a valid C symbol.
Protocol code (None(0) /Keyboard(1) /Mouse(2)/Keyboard+Mouse(3))	0x00	Both the keyboard and mouse interface will be available only if Keyboard+Mouse(3) protocol is selected. Select device class as Device (0x00) in device configuration when protocol selected is (Keyboard+Mouse).
(Keyboard) Interface Number of HID Class interface	0x00	Keyboard Interface will be available for use when protocol code selected is either Keyboard(1) or Keyboard+Mouse(3).
(Keyboard) Endpoint Number to be used for Interrupt-In	Endpoint 1-9 Default: Endpoint 1	Specify the Endpoint Number of Interrupt-In Endpoint. It must not be duplicated with ones for the other Endpoints.
(Keyboard) Maximum packet size in bytes for Interrupt-In	0x8	Specify the maximum packet size this endpoint is capable of sending or receiving when this configuration is selected.
Interval for polling Interrupt-In EP for data transfers (milliseconds)	0x8	Specify the Interval for polling Endpoint transfers. This configuration is valid for Interrupt-In Endpoint. Value is in frame counts (1ms units for FS mode and 125us units for HS mode).
(Keyboard) Interrupt-Out Endpoint (Optional)	Enable, Disable Default: Disable	This configuration is reserved and currently not used.
Endpoint Number for Interrupt-Out (Optional)	Endpoint 1-9 Default: Endpoint 3	This configuration is reserved and currently not used.
(Keyboard) Maximum packet size in bytes for Interrupt-Out EP (Optional)	0x8	This configuration is reserved and currently not used.
(Keyboard) Interval for polling Interrupt-Out EP for data transfers (milliseconds) (Optional)	0x8	This configuration is reserved and currently not used.

(Mouse) Interface Number of HID Class interface	0x01	Mouse Interface will be available for use when protocol code selected is either Mouse(2) or Keyboard+Mouse(3).
(Mouse) Endpoint Number to be used for Interrupt-In	Endpoint 1-9 Default: Endpoint 2	Specify the Endpoint Number of Interrupt-In Endpoint. It must not be duplicated with ones for the other Endpoints.
(Mouse) Maximum packet size in bytes for Interrupt-In	0x8	Specify the maximum packet size this endpoint is capable of sending or receiving when this configuration is selected.
Interval for polling Interrupt-In EP for data transfers (milliseconds)	0x8	Specify the Interval for polling Endpoint transfers. This configuration is valid for Interrupt-In Endpoint. Value is in frame counts (1ms units for FS mode and 125us units for HS mode).
(Mouse) Interrupt-Out Endpoint (Optional)	Enable, Disable Default: Disable	This configuration is reserved and currently not used.
Endpoint Number for Interrupt-Out (Optional)	Endpoint 1-9 Default: Endpoint 4	This configuration is reserved and currently not used.
(Mouse) Maximum packet size in bytes for Interrupt-Out EP (Optional)	0x8	This configuration is reserved and currently not used.
(Mouse) Interval for polling Interrupt-Out EP for data transfers (milliseconds) (Optional)	0x8	This configuration is reserved and currently not used.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.

LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.
Name	g_sf_el_ux_dcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.
Name	g_sf_el_ux_dcd_hs_0	Module name.
USB Controller Selection	USBHS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX on ux Instance

ISDE Property	Value	Description
USBX Pool Memory Name	g_ux_pool_memory	Name must be a valid C symbol.
USBX Pool Memory Size	18432	See section "Azure RTOS USBX Memory Requirements" for the required memory size for each classes.
User Callback for Host Event Notification (Only valid for USB Host)	NULL	Name must be a valid C symbol. The name of User defined USBX Host event notification can be given to this property.
User Callback for Device Event Notification (Only valid for USB Device)	NULL	Name must be a valid C symbol. The name of User defined USBX Device event notification can be given to this property.
Name of generated initialization function	ux_common_init0	Name of generated initialization function selection.

Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

USBX Device Class HID Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48MHz operation. In the SSP configuration window, select the Clocks tab to view the clock-source setting.

USBX Device Class HID Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external devices. Select I/O pins and configure to the external device requirements. The following table lists the pin selection method within the SSP Configuration Window and the subsequent tables demonstrate the selection process using USB pins as an example.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence
USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

Note

The selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select device as the Operation Mode
USBDP	USBDP	USBDP pin
USBDM	USBDM	USBDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	None	VBUSEN pin

VBUS	None, P407 Default: P407	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID Pin
VCCUSB	VCCUSB	VCCUSB pin
VSSUSB	VSSUSB	VSSUSB pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select Device as the Operation Mode
USBHSDP	USBHSDP	USBHSDP pin
USBHSDM	USBHSDM	USBHSDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	PB00	VBUSEN pin
VBUS	PB01	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID pin
USBHSRREF	USBHSRREF	USBHSRREF pin
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin
PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin
VCCUSBHS	VCCUSBHS	VCCUSBHS pin
VSS1USBHS	VSS1USBHS	VSS1USBHS pin
VSS2USBHS	VSS2USBHS	VSS2USBHS pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.42.6 Using the USBX Device Class HID Module in an Application

The configurator generates processing to create and register the USBX Device Class HID module; however, communication must be done after the device is connected to the host.

The typical steps in using the USBX Device Class HID module in an application are:

1. Get the ux_system_slave slave device pointer

2. Wait until slave device's ux_slave_device_state is configured

3. For HID event sending, use the ux_device_class_hid_event_set API

4. For received HID event reading, use the ux_device_class_hid_event_get API

5. For HID report sending, use the ux_device_class_hid_report_set API

6. For received HID report reading, use the ux_device_class_hid_report_get API

These common steps are illustrated in a typical operational flow diagram in the following figure:

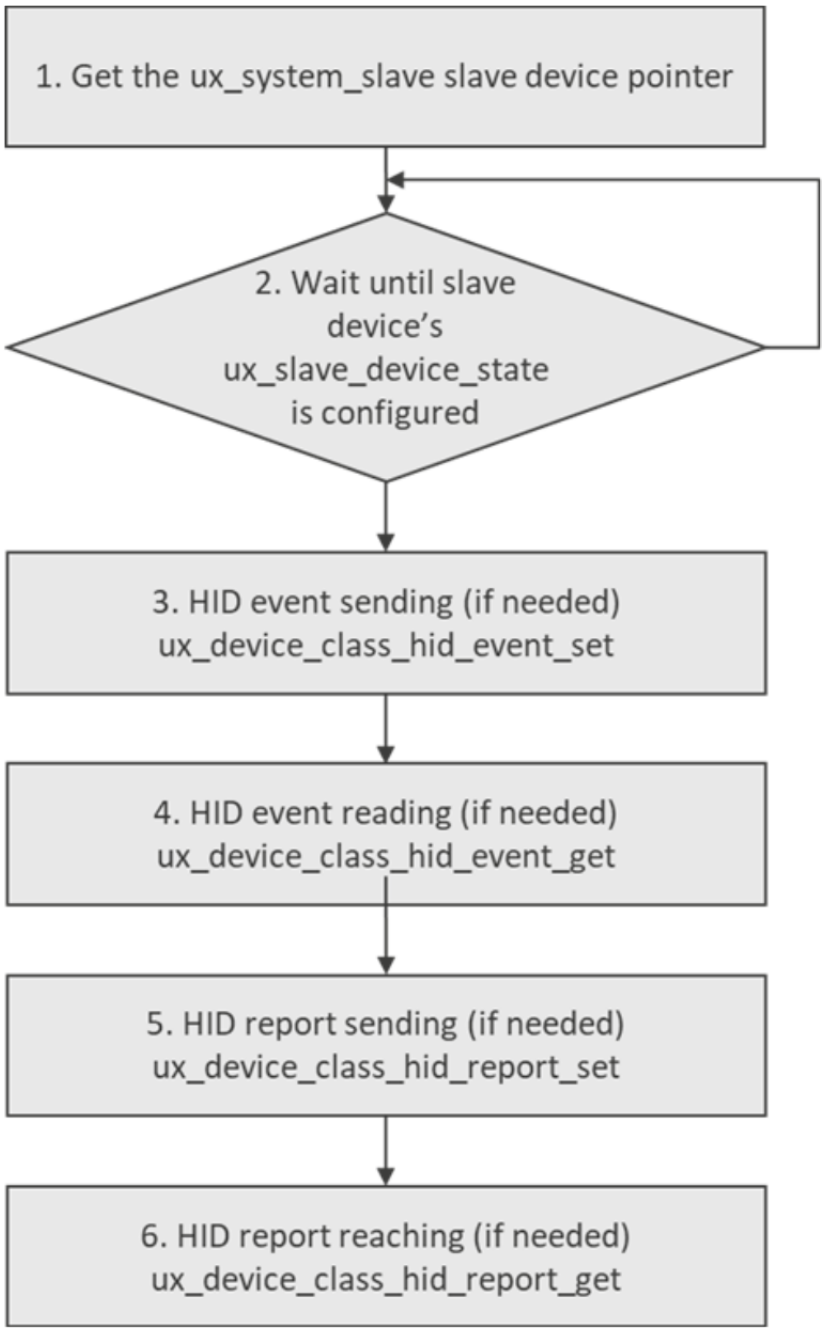

Figure 534: Flow Diagram of a Typical USBX Device Class HID Module Application

4.3.43 USBX Device Class Mass Storage

4.3.43.1 USBX Device Class Mass Storage Introduction

The USBX&trade Device Class Mass Storage module provides a high-level API for USB mass storage applications for USB Full Speed (USBFS) or USB High Speed (USBHS). The USBX Device Class Mass Storage module uses the USB and data-transfer peripherals on the Synergy MCU.

USBX Device Class Mass Storage Module Features

- ThreadX®-aware framework.
- Storage Media Parameter Setup
- Last LBA
- Byte-per-sector
- Type of storage media
- Removable flag
- USB Device Configuration (Device Configuration)
- Vendor ID
- Product ID
- Device Release Number
- Index of Serial Number String Descriptor
- Supported USB Specification (DCD)
- USBFS
- USBHS
- USB Device interrupts (DCD)

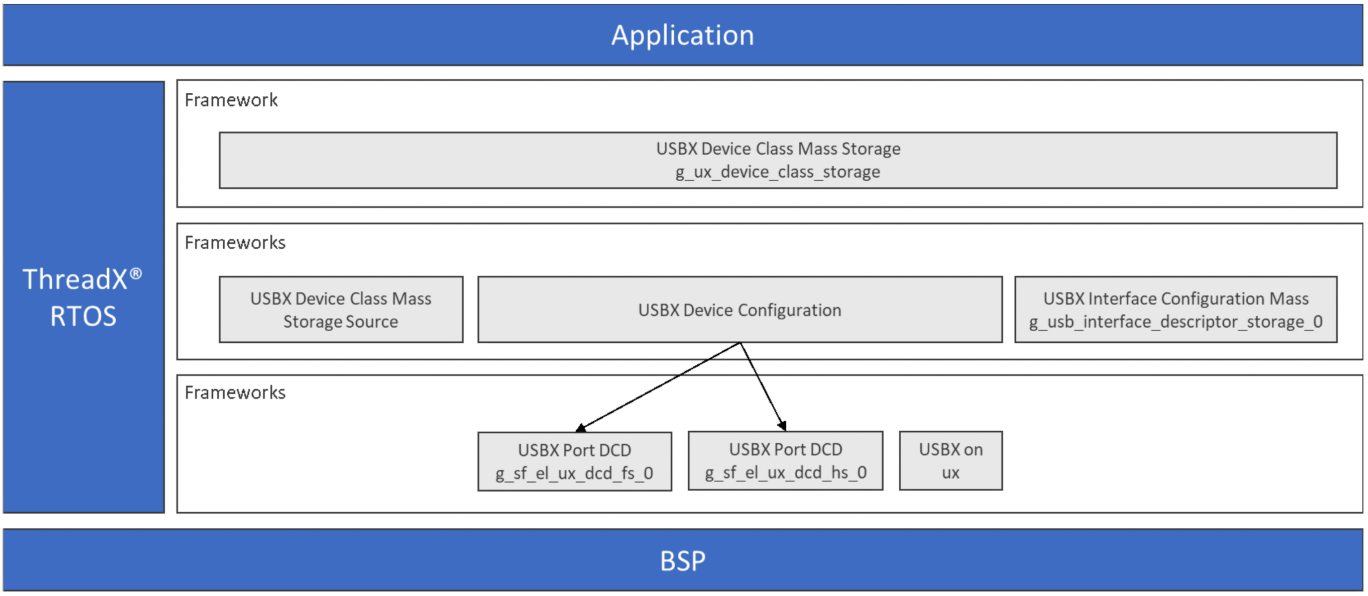

Figure 535: USBX Device Class Mass Storage Module Block Diagram

4.3.43.2 USBX Device Class Mass Storage Module APIs Overview

The USBX Device Class Mass Storage module automatically adds an initialization process; the user application only needs to prepare the callback functions for media access. Unless the functionality of the USBX Device Class Mass Storage module is required, there is no need to use it.

Note

For details on the USBX Device Stack, see the USBX Device Stack User's Manual.

4.3.43.3 USBX Device Class Mass Storage Module Operational Overview

The USBX Device Class Mass Storage module automatically adds an initialization process. The process initializes internal information with the given parameters and creates an internal thread for processing the mass-storage class; this internal thread processes all USB messages.

USBX Device Class Mass Storage Module Important Operational Notes and Limitations

USBX Device Class Mass Storage Module Operational Notes

The USBX Device stack or USBX Host stack consumes RAM for the control block. The Synergy Configuration tool allocates memory to the USBX memory pool statically in the auto-generate code as shown in the following table. You need to set the appropriate memory size in bytes to the USBX Pool Memory Size property of the USBX on ux component in the Synergy Configuration tool in section "USBX on ux Configuration." If multiple classes are used, set the total memory size to the property.

Memory (RAM) Requirements for the USBX Memory Pool

USBX Class	S1 Parts	Other Parts
USBX Device Mass Storage (ux_device_class_storage)	6.1KB	19KB

Note

The information shown in the table above is valid if compiled with default USBX configurations.
The memory size of the USBX Classes in the table above are of the pre-built libraries and the following configuration was applied for the builds:

UX_THREAD_STACK_SIZE: 512(bytes) for S1 parts; 2048(bytes) for the other parts

- The USBX device storage class supports multiple logical unit numbers (LUNs), making it possible to create a storage device that acts simultaneously as a CD-ROM and flash disk.

USBX Device Class Mass Storage Module Limitations

- This module does not support the complex device.
- Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.43.4 Including the USBX Device Class Mass Storage Module in an Application

This section describes how to include the USBX Device Class Mass Storage module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the USBX Device Class Mass Storage module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

USBX Device Class Mass Storage Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ux_device_class_storage USBX Device Class Mass Storage	Threads	New Stack> X-Ware> USBX> Device> Classes> Mass Storage> USBX Device Class Mass Storage

When the USBX Device Class Mass Storage module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

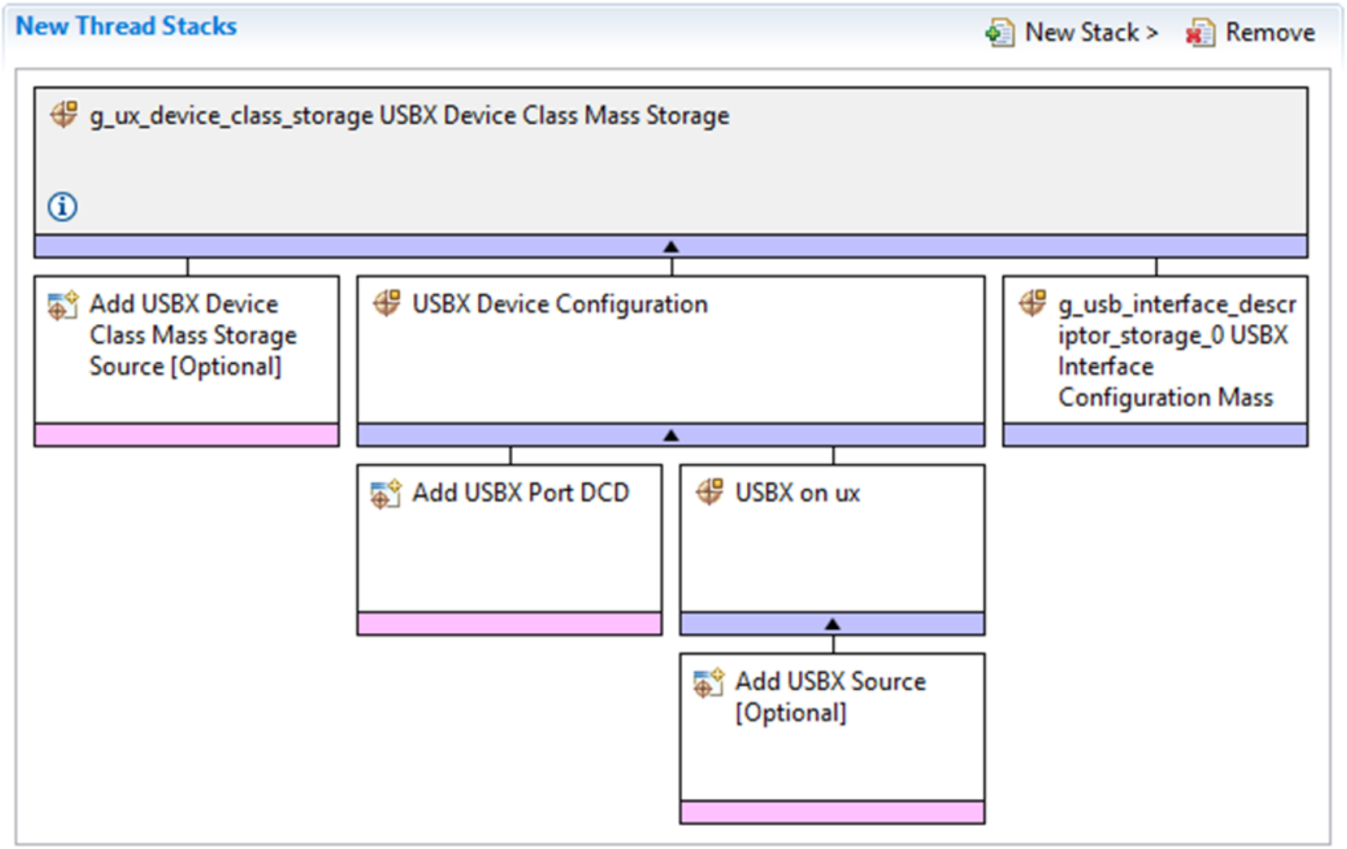

Figure 536: USBX Device Class Mass Storage Module Stack

4.3.43.5 Configuring the USBX Device Class Mass Storage Module

The USBX Device Class Mass Storage module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over

the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the USBX Device Class Mass Storage Module

ISDE Property	Value	Description
Name	g_ux_device_class_storage	Specify the name of USBX Interface Descriptor for Mass Storage Class. It must be a valid C symbol.
Mass Storage Class Parameter Setup	Auto (Simple Auto Setup if LUN is 1), Manual (User Manual Setup if LUN is greater than 1) Default: Auto	Manual (User Manual Setup if LUN is greater than 1). Simple Auto Setup if LUN is 1.
User Setup Callback (Only valid if Parameter Setup is Auto)	ux_device_class_storage_user_setup	Specify the name of user callback function to setup the storage parameter setup. This parameter is only valid when the configuration "Mass Storage Class Parameter Setup" is "Auto".
Last LBA of Storage Media (Only valid if Parameter Setup is Auto)	0	Specify the last LBA of storage media device (the number of sectors available in the media - 1). This parameter is only valid when the configuration "Mass Storage Class Parameter Setup" is "Auto".
Bytes Per Sector of Storage Media (Only valid if Parameter Setup is Auto)	512	Specify the sector size of storage media. It can take multiple of 512 such as 512, 4K bytes. This parameter is only valid when the configuration "Mass Storage Class Parameter Setup" is "Auto".
Type of Storage Media (Only valid if Parameter Setup is Auto)	0	Specify the type of storage media device. Typically, the value takes following values. Flash Drive (0), CD-ROM device (5) This parameter is only valid when the configuration "Mass Storage Class Parameter Setup" is "Auto".

Removable Flag of Storage Media (Only valid if Parameter Setup is Auto)	0x80	Specify the Removable Flag value of Storage Media. This parameter is only valid when the configuration "Mass Storage Class Parameter Setup" is "Auto".
Media Read Function Callback (Only valid if Parameter Setup is Auto)	ux_device_msc_media_read	Specify the C symbol name of Media Read callback for the USBX Device Mass Storage Class. The function is to be called back from the Class library when read access to the USB storage device is requested from user application. Refer USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device Storage Class" for the function definition.
Media Write Function Callback (Only valid if Parameter Setup is Auto)	ux_device_msc_media_write	Specify the C symbol name of Media Write callback for the USBX Device Mass Storage Class. The function is to be called back from the Class library when write access to the USB storage device is requested from user application. Refer USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device Storage Class" for the function definition.
Media Status Function Callback (Only valid if Parameter Setup is Auto)	ux_device_msc_media_status	Specify the C symbol name of Media Status callback for the USBX Device Mass Storage Class. The function is to be called back from the Class library when status inquiry to the USB storage device is requested from user application. Refer USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device Storage Class" for the function definition.

USBX Device Storage Instance Activate Callback Function	NULL	Specify the name of instance_activate user callback function for the USBX Device Mass Storage Class module. Name must be a valid C symbol. See the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device Storage Class" for more information about the instance_activate callback function.
USBX Device Storage Instance Deactivate Callback Function	NULL	Specify the name of instance_deactivate user callback function for the USBX Device Mass Storage Class module. Name must be a valid C symbol. Refer to the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device Storage Class" for more information about the instance_activate callback function
Vendor ID Name	NULL	Specify the name of Vendor ID for the USBX Device Mass Storage Class module. Name must be a valid C symbol.
Product ID Name	NULL	Specify the name of Product ID for the USBX Device Mass Storage Class module. Name must be a valid C symbol.
Product Revision Number	NULL	Specify the number of Product revision for the USBX Device Mass Storage Class module. Value must be a non-negative integer.
Product Serial Number	NULL	Specify the number of Product serial for the USBX Device Mass Storage Class module. Value must be a non-negative integer.
Name of generated initialization function	ux_device_class_storage_init0	Name of generated initialization function selection
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have

different default values and available configuration settings.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the USBX Device Class Mass Storage Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the USBX Device Class Mass Storage Source

ISDE Property	Value	Description
Maximum number of SCSI logical units	Value must be greater than 0 or empty Default: 2	UX_MAX_SLAVE_LUN This value represents the maximum number of SCSI logical units represented in the device storage class driver.
Show linkage warning	Enabled, Disabled Default: Enabled	Notification message for users will be shown if "Enabled" option is selected. This is just to warn users possible linkage errors by multiple symbol definitions. Select "Disabled" stops the notification message.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Device Configuration Instance

ISDE Property	Value	Description
Vendor ID	0x045B	Specify Vendor ID assigned by USB-IF. This configuration is a part of the USB Device Descriptor (idVendor).
Product ID	0x0000	Specify Product ID assigned by manufacturer. This configuration is a part of the Device Descriptor (idProduct).
Device Release Number	0x0000	Specify Device Release Number in binary-coded decimal. This configuration is a part of the USB Device Descriptor (bcdDevice).

Index of Manufacturing String Descriptor	0x00	Specify the Index of Manufacturer String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iManufacturer). Set zero if String Descriptor is not used. See section USBX-String-Framework-Configuration for more information.
Index of Product String Descriptor	0x00	Specify the Index of Product String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iProduct). Set zero if String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Index of Serial Number String Descriptor	0x00	Specify the Index of Serial Number String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iSerialNumber). Set zero if the String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Class Code	Communications(CDC), HID, Mass Storage, Miscellaneous, Vendor specific Default: Communications(CDC)	Select the USB Device Class Code. This configuration is a part of the USB Configuration Descriptor (bDeviceClass).
Index of String Descriptor describing this configuration	0x00	Specify the Index of String Descriptor describing this configuration. This configuration is a part of the USB Configuration Descriptor (iConfiguration). Set zero if String Descriptor is not used. See section "USBX String Framework Configuration" for more information.

Size of USB Descriptor in bytes for this configuration (Modify this value only for Vendor-specific Class, otherwise set zero)	0x00	Specify the size of USB Descriptor in bytes. Modify the value for Vendor-specific Class, otherwise you can set zero to calculate the size automatically in the auto-generated code from Synergy Configuration tool. This configuration is a part of the USB Configuration Descriptor (wTotalLength).
Number of Interfaces (Modify this value only for Vendor-specific Class, otherwise set zero)	0x00	Specify the Number of interfaces supported by this configuration. Modify the value for Vendor-specific Class, otherwise you can set zero to calculate the value automatically in the auto-generated code from Synergy Configuration tool. This configuration is a part of the USB Configuration Descriptor (bNumInterfaces).
Self-Powered	Enable, Disable Default: Enable	Enable this configuration if your USB Device is a self- powered device. This configuration is a part of the USB Configuration Descriptor (bmAttributes bit6).
Remote Wakeup	Enable, Disable Default: Disable	Enable this configuration if your USB Device supports remote wakeup. This configuration is a part of the USB Configuration Descriptor (bmAttributes bit5).
Maximum Power Consumption (in 2mA units)	50	Set the maximum power consumption of your device to indicate the amount of bus power required. This configuration is 2mA units, thus, the maximum 500 mA can be specified. This configuration is a part of the USB Configuration Descriptor (bMaxPower).
Supported Language Code	0x0409	Specify the Language ID Code. For example, 0x0409 English - United States. This configuration is used for Language ID Framework code generation. See section "USBX Language Framework Configuration" for more information.

Name of USBX String Framework	NULL	Specify the name of user defined USBX String Framework. This must be a valid C symbol. Set NULL if the String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Total index number of USB String Descriptors in USB String Framework	0	Specify the total number of index for String Descriptor. See section "USBX String Framework Configuration" for more information.
Name of USBX Language Framework	NULL	Specify the name of user defined USBX Language Framework. This must be a valid C symbol. If '0' is set to the property "Total Number of Language Support", this configuration is ignored. See section "USBX Language Framework Configuration" for more information.
Number of Languages to support (US English is applied if zero is set)	0	Specify the total number of languages to support. See section "USBX String Framework Configuration" for more information. If '0' is set here, US English (0x0409) is applied as the default language.
Name of generated initialization function	ux_device_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Interface Configuration Mass Storage Instance

ISDE Property	Value	Description
Name	g_usb_interface_descriptor_storage_0	Specify the name of USBX Interface Descriptor for CDC-ACM. It must be a valid C symbol.

Interface Number of Bulk Only Data Interface	0x00	Specify the index number of Bulk-Only Data interface. This configuration is a part of the USB Interface Descriptor (bInterface). The number must not be duplicated with any other Interface Numbers if your USB device consists of a USB composite device.
Endpoint Number to be used for Bulk Out Transfer	Endpoint 1-9 Default: Endpoint 1	Specify the Endpoint Number of Bulk Out Endpoint. It must not be duplicated with ones for the other Endpoints.
Endpoint Number to be used for Bulk In Transfer	Endpoint 1-9 Default: Endpoint 2	Specify the Endpoint Number of Bulk In Endpoint. It must not be duplicated with ones for the other Endpoints.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.
LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.
Name	g_sf_el_ux_dcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on USBHS

ISDE Property	Value	Description

High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.
Name	g_sf_el_ux_dcd_hs_0	Module name.
USB Controller Selection	USBHS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX on ux Instance

ISDE Property	Value	Description
USBX Pool Memory Name	g_ux_pool_memory	Name must be a valid C symbol.
USBX Pool Memory Size	18432	See section "Azure RTOS USBX Memory Requirements" for the required memory size for each classes.
User Callback for Host Event Notification (Only valid for USB Host)	NULL	Name must be a valid C symbol. The name of User defined USBX Host event notification can be given to this property.
Name of generated initialization function	ux_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

USBX Device Class Mass Storage Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48MHz operation In the SSP configuration window, select the Clocks tab to view the clock-source setting.

USBX Device Class Mass Storage Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external devices. Select I/O pins and configure to the external device requirements. The following table lists the pin selection method within the SSP Configuration Window and the subsequent tables demonstrate the selection process using USB pins as an example.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence
USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

Note

The selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select device as the Operation Mode
USBDP	USBDP	USBDP pin
USBDM	USBDM	USBDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	None	VBUSEN pin
VBUS	None, P407 Default: P407	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID Pin
VCCUSB	VCCUSB	VCCUSB pin
VSSUSB	VSSUSB	VSSUSB pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description

Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select Device as the Operation Mode
USBHSDP	USBHSDP	USBHSDP pin
USBHSDM	USBHSDM	USBHSDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	PB00	VBUSEN pin
VBUS	PB01	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID pin
USBHSRREF	USBHSRREF	USBHSRREF pin
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin
PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin
VCCUSBHS	VCCUSBHS	VCCUSBHS pin
VSS1USBHS	VSS1USBHS	VSS1USBHS pin
VSS2USBHS	VSS2USBHS	VSS2USBHS pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.43.6 Using the USBX Device Class Mass Storage Module in an Application

- The USBX Device Class Mass Storage module does not need the usual initialization by an application; the application simply prepares the three user callbacks that the USBX Device Class Mass Storage module requires.
- Following is the suggested sequence of API's to be called successfully in a sequential order in an application for completely un-initializing USB Device class,

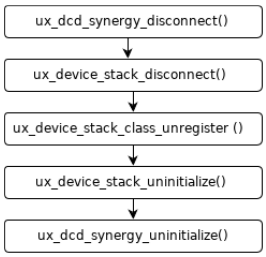

Figure 537: USBX Device Class Mass Storage Typical Application

4.3.44 USBX Host Class CDC-ACM

4.3.44.1 USBX Host Class CDC-ACM Module Introduction

The USBX Host Class CDC-ACM module provides a high-level API for USBX Host Class CDC-ACM applications and configures the USBX Host Class CDC-ACM Source, USBX Host Configuration, USBX Source, USBX Port HCD and a transfer driver. The USBX Host Class CDC-ACM module uses the DMAC/DTC and USB Host Class peripherals on the Synergy MCU.

Note

Currently, DTC is not supported by the host side driver (only DMAC is supported).

USBX Host Class CDC-ACM Module Features

The CDC-ACM class uses a composite device framework to group interfaces (control and data). As a result, care should be taken when defining the device descriptor. The USBX relies on the IAD descriptor to know internally how to bind interfaces. The IAD descriptor should be declared before the interfaces and contain the first interface of the CDC-ACM class and how many interfaces are attached. The CDC-ACM class also uses a union functional descriptor which performs the same function as the newer IAD descriptor. Although a union functional descriptor must be declared for historical reasons and compatibility with the host side, it is not used by the USBX.

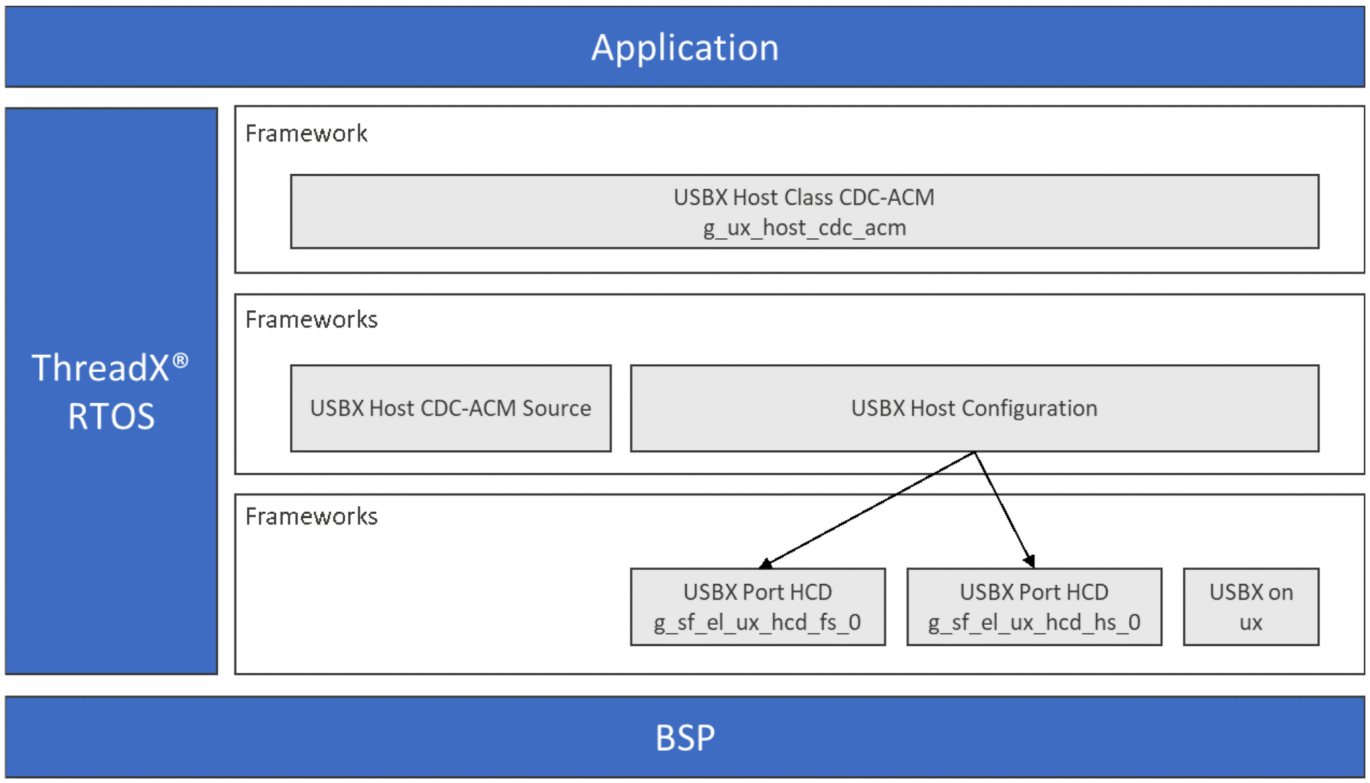

Figure 538: USBX Host Class CDC-ACM Module Block Diagram

4.3.44.2 USBX Host Class CDC-ACM Module APIs Overview

The USBX Host Class CDC-ACM Module defines APIs for reading, writing and ioctl. A complete list of

the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

USBX Host Class CDC-ACM Module Summary

Function Name	Example API Call and Description
ux_host_class_cdc_acm_read	status = ux_host_class_cdc_acm_read(cdc_acm, data_pointer, requested_length,&actual_length); This function reads from the cdc_acm interface. The call is blocking and only returns when there is either an error or when the transfer is complete.
ux_host_class_cdc_acm_write	status = ux_host_class_cdc_acm_write(cdc_acm, data_pointer,requested_length,&actual_length); This function writes to the cdc_acm interface. The call is blocking and only returns when there is either an error or when the transfer is complete.
ux_host_class_cdc_acm_ioctl	status = ux_host_class_cdc_acm_ioctl(cdc_acm, ioctl_function, &parameter_p); This function performs a specific ioctl function to the cdc_acm interface. The call is blocking and only returns when there is either an error or when the command is completed.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
UX_SUCCESS	The data transfer was completed.
UX_TRANSFER_TIMEOUT	Transfer timeout, reading/writing not completed.
UX_MEMORY_INSUFFICIENT	Not enough memory.
UX_HOST_CLASS_UNKNOWN	Wrong class instance.
UX_FUNCTION_NOT_SUPPORTED	Unknown IOCTL function.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.44.3 USBX Host Class CDC-ACM Module Operational Overview

Initialization of USBX Resources

The USBX has its own memory manager. The memory needs to be allocated to the USBX before the host or device side of the USBX is initialized. The USBX memory manager can accommodate systems

where memory can be cached.

Definition of USB Host Controllers

It is required to define at least one USB host controller for USBX to operate in host-mode. The application-initialization file should contain this definition. SSP defines USB host controller when USB host controller driver is added to thread stacks.

Definition of Device Classes

It is required to define one or more device classes(s) with the USBX. A USB class is required to drive a USB device after the USB stack has configured the USB device. A USB class is very specific to the device; one or more classes may be required to drive a USB device depending on the number of interfaces contained in the USB device descriptors.

USB Class Binding

When the device is configured, the topology manager will let the class manager continue the device discovery by looking at the device-interface descriptors. A device can have one or more interface descriptors.

An interface represents a function in a device. For instance, a USB speaker has three interfaces, one for audio streaming, one for audio control, and one to manage the various speaker buttons.

The class manager has two mechanisms to join the device interface(s) to one or more classes. It can either use the combination of a PID/VID (product ID and vendor ID) found in the interface descriptor or the combination of Class/Subclass/Protocol.

The PID/VID combination is valid for interfaces that cannot be driven by a generic class. The Class/Subclass/Protocol combination is used by interfaces that belong to a USB-IF certified class such as a printer, hub, storage, audio, or Human Interface Design (HID).

The class manager contains a list of registered classes from the initialization of the USBX. The class manager will call each class one-at-a-time until one class accepts to manage the interface for that device; each class can only manage one interface. In the case of the USB audio speaker, the class manager will call all the classes for each of the interfaces.

Once a class accepts an interface, a new instance of that class is created; the class manager will then search for the default alternate setting for the interface. A device may have one or more alternate settings for each interface. The alternate setting 0 will be the one used by default until a class decides to change it.

For the default alternate setting, the class manager will mount all the endpoints contained in the alternate setting. If the mounting of each endpoint is successful, the class manager will complete its job by returning to the class that will finish the initialization of the interface.

USBX Host Class CDC-ACM Module Important Operational Notes and Limitations

USBX Host Class CDC-ACM Module Operational Notes

The USBX Device stack or USBX Host stack consumes RAM for the control block. The Synergy Configuration tool allocates memory to the USBX memory pool statically in the auto-generate code as shown in the following table. You need to set the appropriate memory size in bytes to the USBX Pool Memory Size property of the USBX on ux component in the Synergy Configuration tool in section "USBX on ux Configuration." If multiple classes are used, set the total memory size to the property.

Memory (RAM) Requirements for the USBX Memory Pool

USBX Class	S1 Parts	Other Parts
USBX Host CDC-ACM (ux_host_class_cdc_acm)	N/A	30KB

Note

The information shown in the table above is valid if compiled with default USBX configurations. The memory size of the USBX Classes in the table above are of the pre-built libraries and the following configuration was applied for the builds:

UX_THREAD_STACK_SIZE: 512(bytes) for S1 parts; 2048(bytes) for the other parts

- Use a class container for the USBX Host Class CDC-ACM obtained by auto-generated code to get a CDC-ACM instance.
- Poll the flag ux_host_class_cdc_acm_state in the instance and make sure the status is live.
- Check if a DATA class interface is available in the CDC-ACM instance.
- Set up the CDC-ACM reception if required.
- Perform CDC-ACM communication with USB device.

USBX Host Class CDC-ACM Module Limitations

- The module needs the interrupt of a USB Controller to be enabled.
- See SSP Release Notes (sf_el_ux sections) for known limitations.
- The module uses the interrupt of a USB Controller. Set the appropriate interrupt priority level in Synergy Configuration tool. By default, it is disabled.
- The module uses the interrupt of a Transfer module (implemented as DMAC or DTC) if it is used. Set appropriate priority level in the Synergy Configuration tool. The level must be higher than a USB Controller to work properly.
- A zero length packet does not contain the received data, but the application must perform the receive operation.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

Note

Currently, DTC is not supported by the host side driver (only DMAC is supported).

4.3.44.4 Including the USBX Host Class CDC-ACM Module in an Application

This section describes how to include the USBX Host Class CDC-ACM Module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the USBX Host Class CDC-ACM Module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

USBX Host Class CDC-ACM Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ux_device_class_cdc_acm0 USBX Host Class CDC-ACM	Threads	New Stack> X-Ware> USBX> Device> Classes > CDC-ACM > USBX Host Class CDC-ACM

When the USBX Host Class CDC-ACM Module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

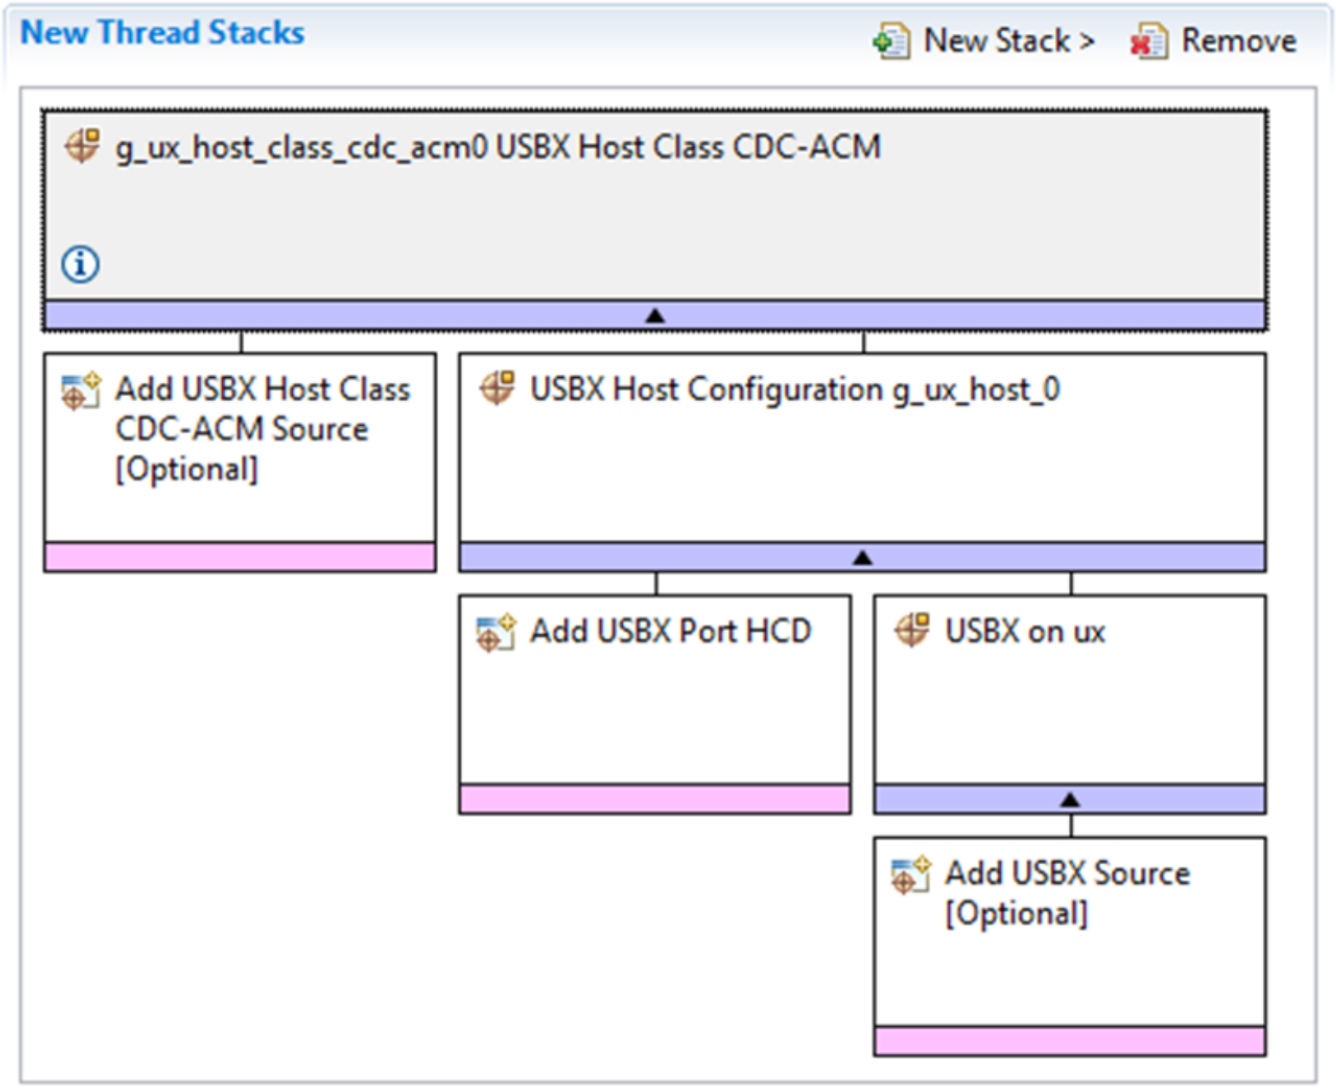

Figure 539: USBX Host Class CDC-ACM Module Stack

4.3.44.5 Configuring the USBX Host Class CDC-ACM Module

The USBX Host Class CDC-ACM Module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the USBX Host Class CDC-ACM Module

ISDE Property	Value	Description
Name	g_ux_host_class_cdc_acm0	Specify the name of USBX Host CDC-ACM Class module instance. It must be a valid C symbol.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the USBX Host Class CDC-ACM Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the USBX Host Class CDC-ACM Source

ISDE Property	Value	Description
Show linkage warning	Enabled, Disabled Default: Enabled	Notification message for users will be shown if "Enabled" option is selected. This is just to warn users possible linkage errors by multiple symbol definitions. Select "Disabled" stops the notification message.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Host Configuration Instance

ISDE Property	Value	Description
Name	g_ux_host0	Specify the name of USBX Host Configuration instance. It must be a valid C symbol.
Name of generated initialization function	ux_host_hid_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.
VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.
Name	g_sf_el_ux_hcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBHS

ISDE Property	Value	Description

High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.
FIFO size for Bulk/Isochronous Pipes	512, 1024, 1536, 2048 bytes Default: 512 bytes	Select the FIFO size for bulk and isochronous transfers.
Number of Isochronous Pipes Reserved	0,1,2 Default: 0	Select the number of isochronous pipes to reserve.
VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
Enable High Speed	Enable, Disable Default: Enable	Select if high speed should be enabled.
Name	g_sf_el_ux_hcd_hs_0	Module name.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX on ux Instance

ISDE Property	Value	Description
USBX Pool Memory Name	g_ux_pool_memory	Name must be a valid C symbol.
USBX Pool Memory Size	18432	See section "Azure RTOS USBX Memory Requirements" for the required memory size for each classes.
User Callback for Host Event Notification (Only valid for USB Host)	NULL	Name must be a valid C symbol. The name of User defined USBX Host event notification can be given to this property.
Name of generated initialization function	ux_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

USBX Host Class CDC-ACM Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48MHz operation. In the SSP configuration window, select the Clocks tab to view the clock-source setting.

USBX Host Class CDC-ACM Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external devices. Select I/O pins and configure to the external device requirements. The following table lists the pin selection method within the SSP Configuration Window and the subsequent tables demonstrate the selection process using USB pins as an example.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence
USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

Note

The selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select device as the Operation Mode
USBDP	USBDP	USBDP pin
USBDM	USBDM	USBDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	None	VBUSEN pin
VBUS	None, P407 Default: P407	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID Pin
VCCUSB	VCCUSB	VCCUSB pin
VSSUSB	VSSUSB	VSSUSB pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select Device as the Operation Mode
USBHSDP	USBHSDP	USBHSDP pin
USBHSDM	USBHSDM	USBHSDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	PB00	VBUSEN pin
VBUS	PB01	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID pin
USBHSRREF	USBHSRREF	USBHSRREF pin
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin
PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin
VCCUSBHS	VCCUSBHS	VCCUSBHS pin
VSS1USBHS	VSS1USBHS	VSS1USBHS pin
VSS2USBHS	VSS2USBHS	VSS2USBHS pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.44.6 Using the USBX Host Class CDC-ACM Module in an Application

The configurator generates processing to create and register the USBX Host Class CDC-ACM module; however, communication must be done after the Host is connected to the host.

The typical steps in using the USBX Host Class CDC-ACM module in an application are:

1. Get the first instance of the connected device with ux_host_stack_class_instance_get API.

2. Wait for the device status to become live.

3. Check that the class of the device is CDC Data Class.

4. If there is the next device, check the status again.

5. For received data reading, use the ux_host_class_cdc_acm_read API.

6. For data sending, use the ux_host_class_cdc_acm_write API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

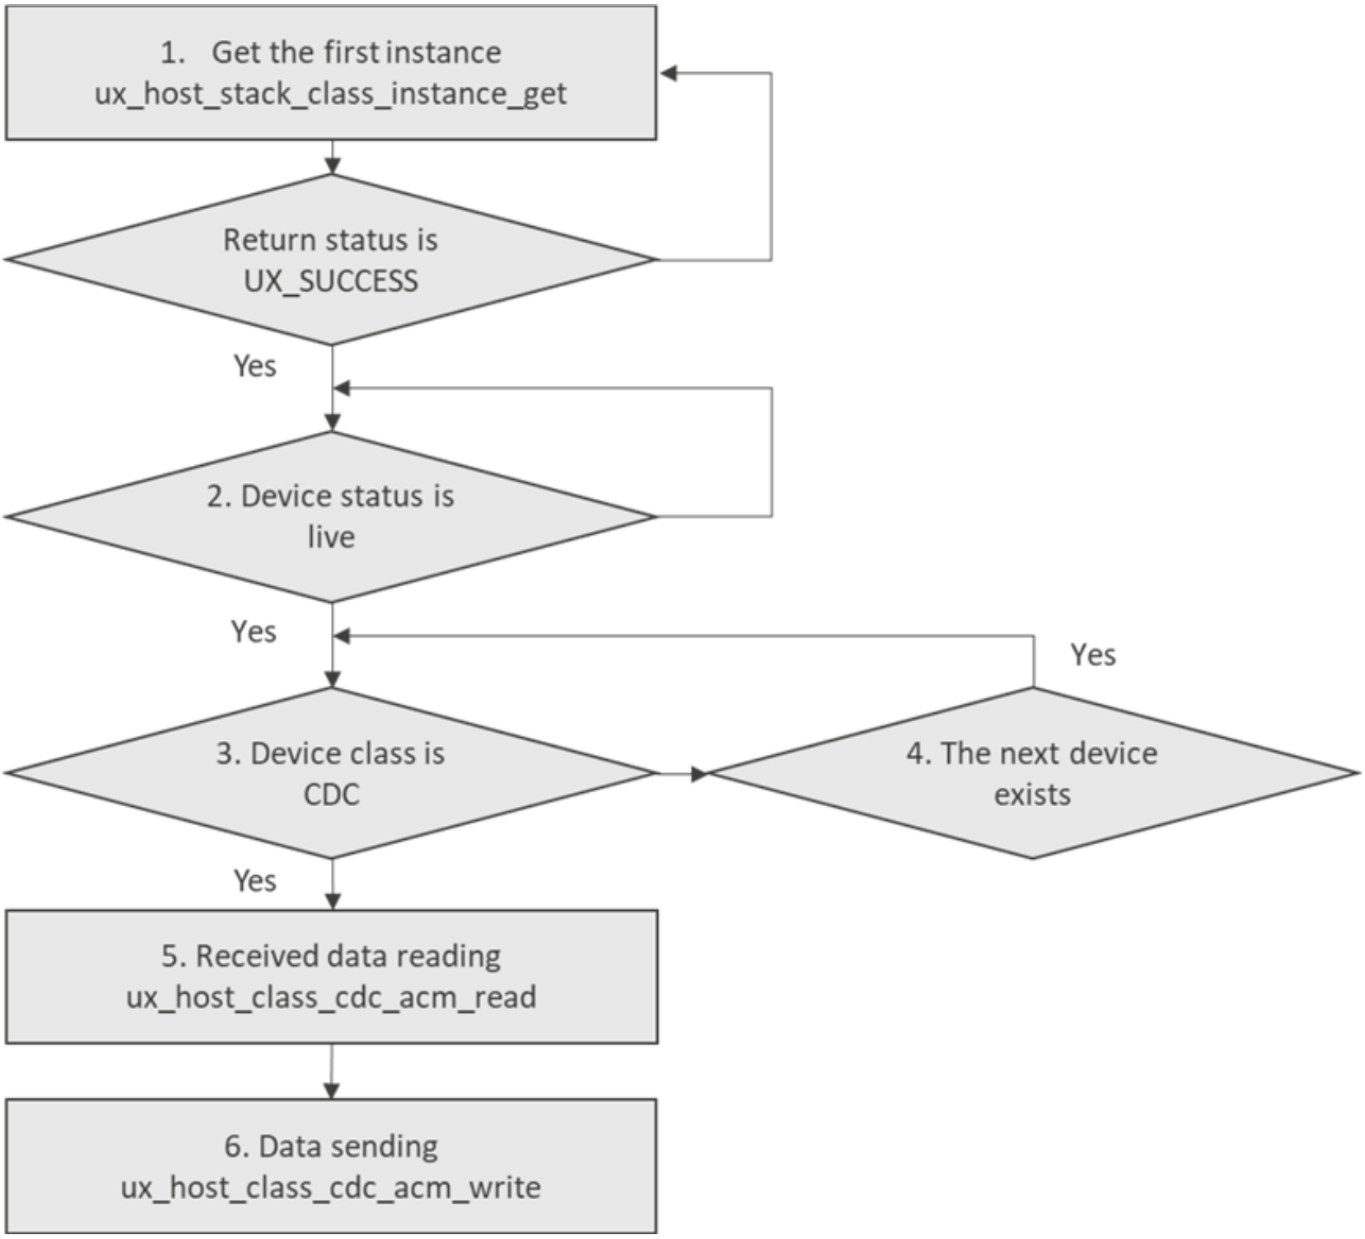

Figure 540: Flow Diagram of a Typical USBX Host Class CDC-ACM Module Application

4.3.45 USBX Host Class HID

4.3.45.1 USBX Host Class HID Module Introduction

The USBX™ Host Class HID module provides a high-level API for human interface device (HID) applications and configures the USBX Host Class HID Source, USBX Host Configuration, USBX Source and USBX Port HCD. The USBX Host Class HID module uses the USB peripheral on the Synergy MCU.

USBX Host Class HID Module Features

The USBX Host Class Human Interface Device (HID) module supports the USBX HID class. It provides the following features:

- Supports HID report data transfers
- Supports the following clients:
  - Keyboard
  - Mouse
  - Remote-Control

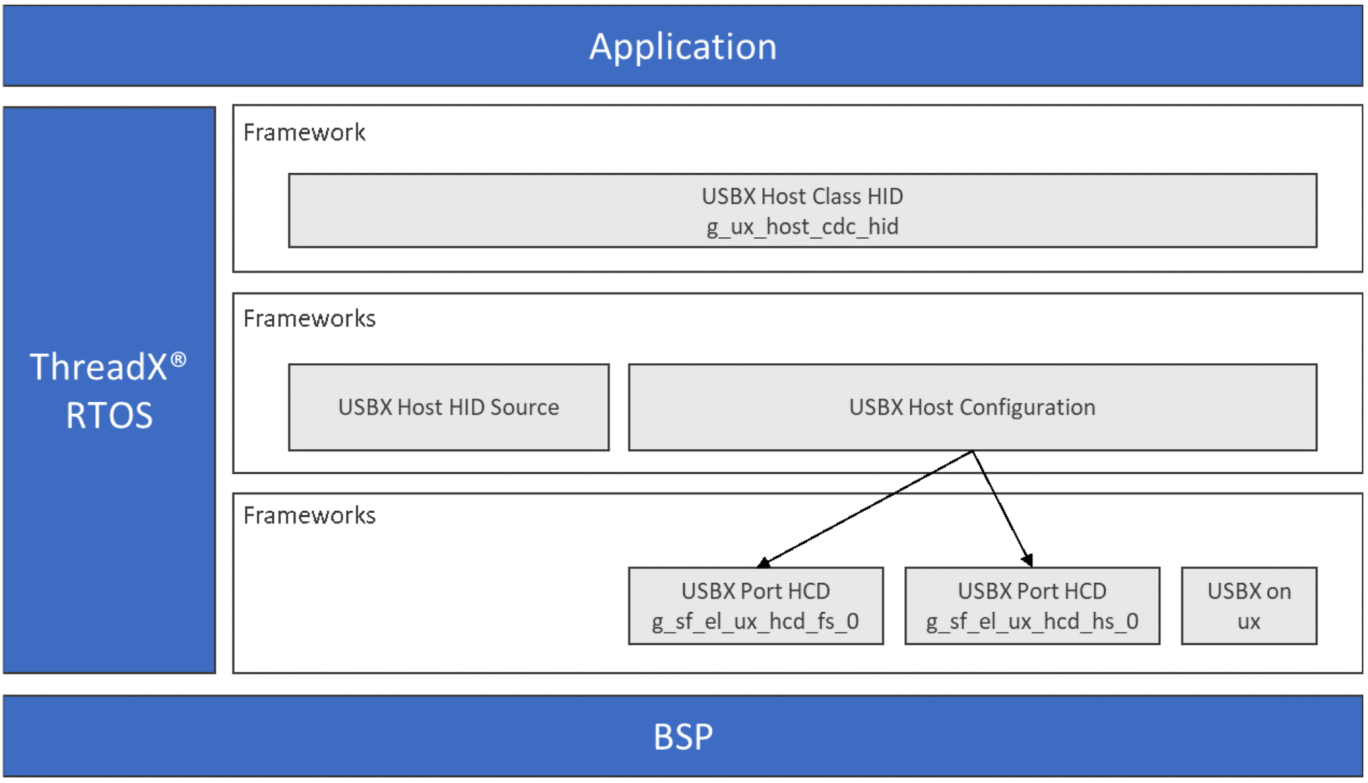

Figure 541: USBX Host Class HID Module Block Diagram

4.3.45.2 USBX Host Class HID Module APIs Overview

The USBX Host Class HID module defines APIs for registering callbacks, starting and stopping periodic reports and reporting gets and sets. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

USBX Host Class HID Module Summary

Function Name	Example API Call and Description

ux_host_class_hid_report_callback_register	ux_host_class_hid_report_callback_register(hid, &call_back); This function is used to register a callback from the HID class to the HID client when a report is received.
ux_host_class_hid_periodic_report_start	ux_host_class_hid_periodic_report_start(hid); This function is used to start the periodic (interrupt) endpoint for the instance of the HID class that is bound to this HID client.
ux_host_class_hid_periodic_report_stop	ux_host_class_hid_periodic_report_stop(hid); This function is used to stop the periodic (interrupt) endpoint for the instance of the HID class that is bound to this HID client.
ux_host_class_hid_report_get	ux_host_class_hid_report_get(hid, &client_report); This function is used to receive a report directly from the device without relying on the periodic endpoint.
ux_host_class_hid_report_set	ux_host_class_hid_report_set(hid, &client_report); This function is used to send a report directly to the device.
ux_host_class_hid_keyboard_key_get	ux_host_class_hid_keyboard_key_get(keyboard_instance, &keyboard_char, &keyboard_state); This function is used to read the keyboard data received from the device.
ux_host_class_hid_mouse_buttons_get	ux_host_class_hid_mouse_buttons_get(&mouse_instance, &mouse_buttons); This function is used to read the mouse button information received from the device.
ux_host_class_hid_mouse_position_get	ux_host_class_hid_mouse_position_get(mouse_instance, &x_position, &y_position); This function is used to read the position information of the mouse received from the device.
ux_host_class_hid_remote_control_usage_get	ux_host_class_hid_remote_control_usage_get(remote_control_instance, &usage, &value); This function is used to read the remote controller information received from the device.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description

UX_SUCCESS	The data transfer was completed.
UX_TRANSFER_TIMEOUT	Transfer timeout, reading/writing not completed.
UX_MEMORY_INSUFFICIENT	Not enough memory.
UX_HOST_CLASS_UNKNOWN	Wrong class instance.
UX_FUNCTION_NOT_SUPPORTED	Unknown IOCTL function.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.45.3 USBX Host Class HID Module Operational Overview

Initialization of USBX Resources

The USBX has its own memory manager. The memory needs to be allocated to the USBX before the host or device side of the USBX is initialized. The USBX memory manager can accommodate systems where memory can be cached.

Definition of USB Host Controllers

It is required to define at least one USB host controller for USBX to operate in host-mode. The application-initialization file should contain this definition. SSP defines USB host controller when USB host controller driver is added to thread stacks.

Definition of Device Classes

It is required to define one or more device classes(s) with the USBX. A USB class is required to drive a USB device after the USB stack has configured the USB device. A USB class is very specific to the device; one or more classes may be required to drive a USB device depending on the number of interfaces contained in the USB device descriptors.

USB Class Binding

When the device is configured, the topology manager will let the class manager continue the device discovery by looking at the device-interface descriptors. A device can have one or more interface descriptors.

An interface represents a function in a device. For instance, a USB speaker has three interfaces, one for audio streaming, one for audio control, and one to manage the various speaker buttons.

The class manager has two mechanisms to join the device interface(s) to one or more classes. It can either use the combination of a PID/VID (product ID and vendor ID) found in the interface descriptor or the combination of Class/Subclass/Protocol.

The PID/VID combination is valid for interfaces that cannot be driven by a generic class. The Class/Subclass/Protocol combination is used by interfaces that belong to a USB-IF certified class such as a printer, hub, storage, audio, or Human Interface Design (HID).

The class manager contains a list of registered classes from the initialization of the USBX. The class manager will call each class one-at-a-time until one class accepts to manage the interface for that device; each class can only manage one interface. In the case of the USB audio speaker, the class manager will call all the classes for each of the interfaces.

Once a class accepts an interface, a new instance of that class is created; the class manager will then search for the default alternate setting for the interface. A device may have one or more alternate settings for each interface. The alternate setting 0 will be the one used by default until a class decides to change it.

For the default alternate setting, the class manager will mount all the endpoints contained in the alternate setting. If the mounting of each endpoint is successful, the class manager will complete its job by returning to the class that will finish the initialization of the interface.

USBX Host Class HID Module Important Operational Notes and Limitations

USBX Host Class HID Module Operational Notes

The USBX Device stack or USBX Host stack consumes RAM for the control block. The Synergy Configuration tool allocates memory to the USBX memory pool statically in the auto-generate code as shown in the following table. You need to set the appropriate memory size in bytes to the USBX Pool Memory Size property of the USBX on ux component in the Synergy Configuration tool in section "USBX on ux Configuration." If multiple classes are used, set the total memory size to the property.

Memory (RAM) Requirements for the USBX Memory Pool

USBX Class	S1 Parts	Other Parts
USBX Host HID (ux_host_class_hid)	N/A	HID Mouse: 38KB HID Keyboard: 46KB

The memory size of the USBX Host HID as shown in the table above is with the following configurations (default settings) being made. The size can be reduced if the Source module is used.

- UX_HOST_CLASS_HID_DECOMPRESSION_BUFFER: 4096(bytes)
- UX_HOST_CLASS_HID_USAGE: 1024(WORDs)

Note

The information shown in the table above is valid if compiled with default USBX configurations.
The memory size of the USBX Classes in the table above are of the pre-built libraries and the following configuration was applied for the builds:

UX_THREAD_STACK_SIZE: 512(bytes) for S1 parts; 2048(bytes) for the other parts

- By default, the module supports keyboard, mouse, and remote control clients.
- Use a class container for the USBX Host Class HID that is obtained by auto-generated code to get an HID instance.
- Pole the flag, ux_host_class_hid_state, in the instance and ensure the status is live.
- Check whether or not a client local instance is available in the HID instance.
- Perform HID communication with the USB device.

USBX Host Class HID Module Limitations

- The module uses the interrupt of the USB Controller, which needs to be enabled. For proper operation, set the appropriate interrupt-priority level in the Synergy Configuration tool.
- If transfer module is used, the module uses the interrupt (implemented as DMAC or DTC). Set the priority level in the Synergy Configuration tool. The level has to be higher than a USB Controller; otherwise, it does not work.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

Note

Currently, DTC is not supported by the host side driver (only DMAC is supported).

4.3.45.4 Including the USBX Host Class HID Module in an Application

This section describes how to include the USBX Host Class HID Module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the USBX Host Class HID Module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

USBX Host Class HID Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ux_host_class_hid0 USBX Host Class HID	Threads	New Stack> X-Ware> USBX> Host > Classes > HID > USBX Host Class HID

When the USBX Host Class HID Module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

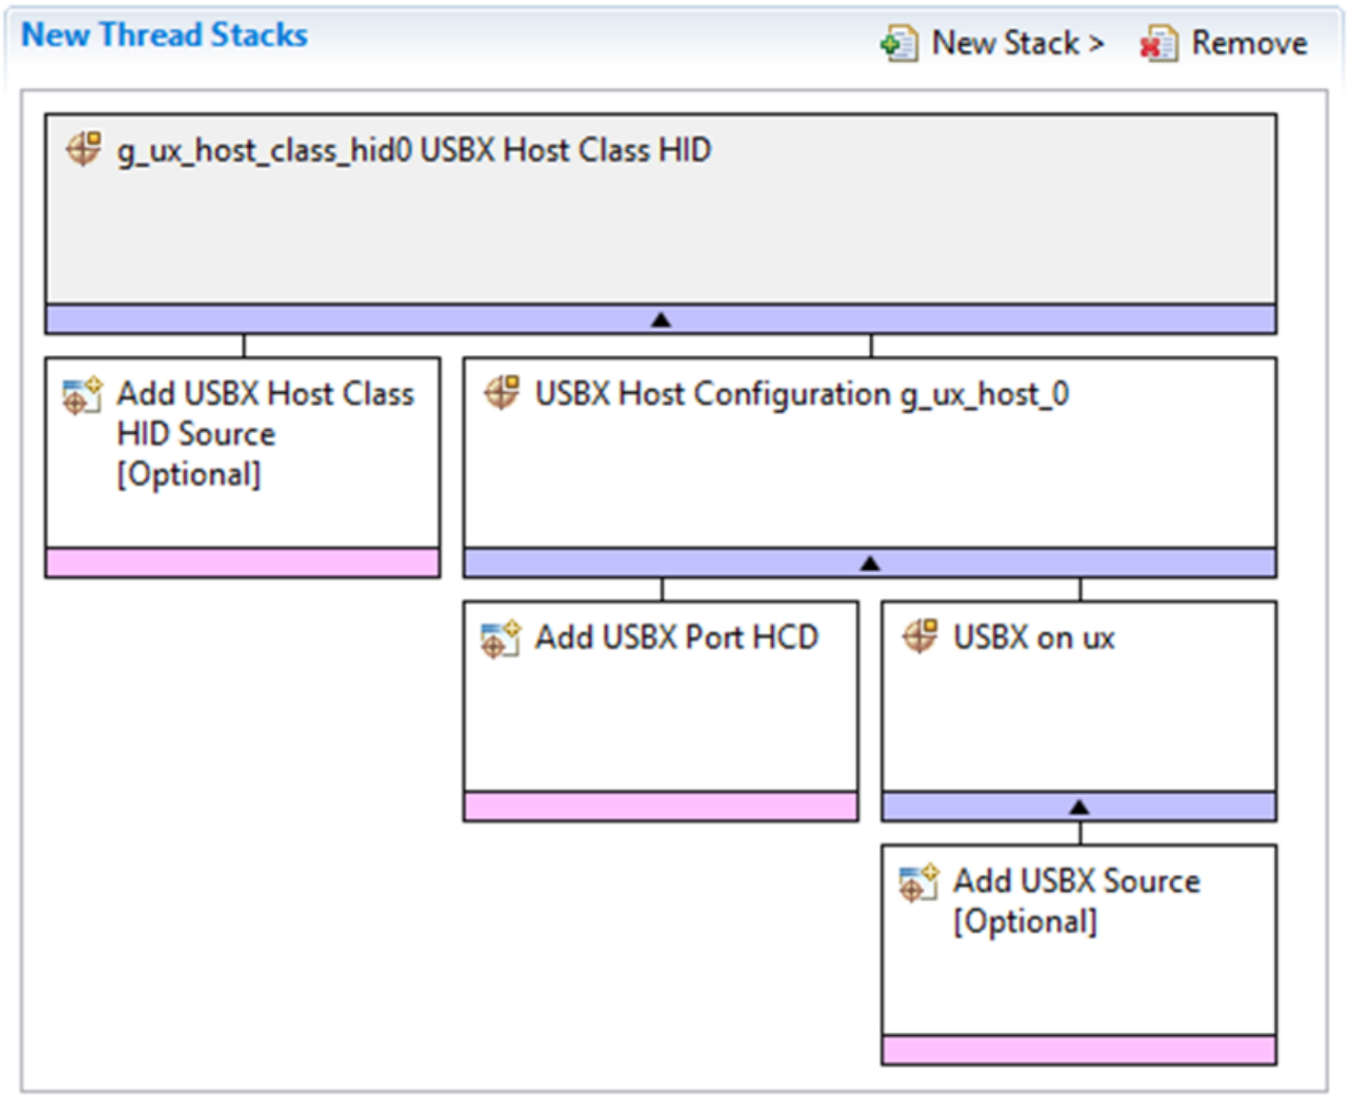

Figure 542: USBX Host Class HID Module Stack

4.3.45.5 Configuring the USBX Host Class HID Module

The USBX Host Class HID Module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the USBX Host Class HID Module

ISDE Property	Value	Description
Name	g_ux_host_class_hid0	Specify the name of USBX Host Mass HID module instance. It must be a valid C symbol.
HID Client - Keyboard Support	Enable, Disable Default: Enable	Set Enable to support USB keyboard devices. This configuration registers the USBX HID Keyboard Client.
HID Client - Mouse Support	Enable, Disable Default: Enable	Set Enable to support USB mouse devices. This configuration registers the USBX HID Mouse Client.
HID Client - Remote Control Support	Enable, Disable Default: Enable	Set Enable to support USB remote control devices. This configuration registers the USBX Remote Control Client.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the USBX Host Class HID Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the USBX Host Class HID Source

ISDE Property	Value	Description
HID Keyboard Thread Priority	Value must be greater than 0 or empty Default: 20	UX_THREAD_PRIORITY_KEYBOARD Define the priority of the HID keyboard thread.
Memory size for HID Report Decompression	Value must be greater than 0 or empty Default: 4096	UX_HOST_CLASS_HID_DECOMPRESSION_BUFFER Define the memory size to build a decompressed report
Number of Entries for HID Local Usage Item Table	Value must be greater than 0 or empty Default: 1024	UX_HOST_CLASS_HID_USAGES Define the size of HID local usage item table. One item entry consumes 4 bytes.

Host HID Interrupt Out Support	Enabled, Disabled Default: Disabled	UX_HOST_CLASS_HID_INTERRUPT_OUT_SUPPORT When enabled, host HID interrupt OUT transfer is supported.
HID report transfer timeout	Value must be greater than 0 or empty Default: 10000	UX_HOST_CLASS_HID_REPORT_TRANSFER_TIMEOUT When set, this represents the HID report transfer timeout value in millisecond.
Show linkage warning	Enabled, Disabled Default: Enabled	Notification message for users will be shown if "Enabled" option is selected. This is just to warn users possible linkage errors by multiple symbol definitions. Select "Disabled" stops the notification message.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Host Configuration Instance

ISDE Property	Value	Description
Name	g_ux_host0	Specify the name of USBX Host Configuration instance. It must be a valid C symbol.
Name of generated initialization function	ux_host_hid_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.

VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.
Name	g_sf_el_ux_hcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.
FIFO size for Bulk/Isochronous Pipes	512, 1024, 1536, 2048 bytes Default: 512 bytes	Select the FIFO size for bulk and isochronous transfers.
Number of Isochronous Pipes Reserved	0,1,2 Default: 0	Select the number of isochronous pipes to reserve.
VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
Enable High Speed	Enable, Disable Default: Enable	Select if high speed should be enabled.
Name	g_sf_el_ux_hcd_hs_0	Module name.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX on ux Instance

ISDE Property	Value	Description
USBX Pool Memory Name	g_ux_pool_memory	Name must be a valid C symbol.

USBX Pool Memory Size	18432	See section "Azure RTOS USBX Memory Requirements" for the required memory size for each classes.
User Callback for Host Event Notification (Only valid for USB Host)	NULL	Name must be a valid C symbol. The name of User defined USBX Host event notification can be given to this property.
Name of generated initialization function	ux_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

USBX Host Class HID Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48MHz operation. In the SSP configuration window, select the Clocks tab to view the clock-source setting.

USBX Host Class HID Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external devices. Select I/O pins and configure to the external device requirements. The following table lists the pin selection method within the SSP Configuration Window and the subsequent tables demonstrate the selection process using USB pins as an example.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence
USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

Note

The selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description

Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select device as the Operation Mode
USBDP	USBDP	USBDP pin
USBDM	USBDM	USBDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	None	VBUSEN pin
VBUS	None, P407 Default: P407	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID Pin
VCCUSB	VCCUSB	VCCUSB pin
VSSUSB	VSSUSB	VSSUSB pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select Device as the Operation Mode
USBHSDP	USBHSDP	USBHSDP pin
USBHSDM	USBHSDM	USBHSDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	PB00	VBUSEN pin
VBUS	PB01	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID pin
USBHSRREF	USBHSRREF	USBHSRREF pin
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin

PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin
VCCUSBHS	VCCUSBHS	VCCUSBHS pin
VSS1USBHS	VSS1USBHS	VSS1USBHS pin
VSS2USBHS	VSS2USBHS	VSS2USBHS pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.45.6 Using the USBX Host Class HID Module in an Application

The configurator generates processing to create and register the USBX Host Class HID Module; however, communication must be done after the Host is connected to the host.

The typical steps in using the USBX Host Class HID Module in an application are:

1. Get the first instance of the connected device with the ux_host_stack_class_instance_get API.

2. Wait for ux_success.

3. Wait for device status live.

4. Wait for client instance live.

5. If the Device is a keyboard.

6. Receive keyboard data using the ux_host_class_hid_keyboard_key_get API.

7. If the Device is a mouse.

8. Receive mouse data using the ux_host_class_hid_mouse_buttons_get API and ux_host_class_hid_mouse_position_get API.

9. If the Device is a remote controller.

10. Receive remote controller data using the ux_host_class_hid_remote_control_usage_get API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

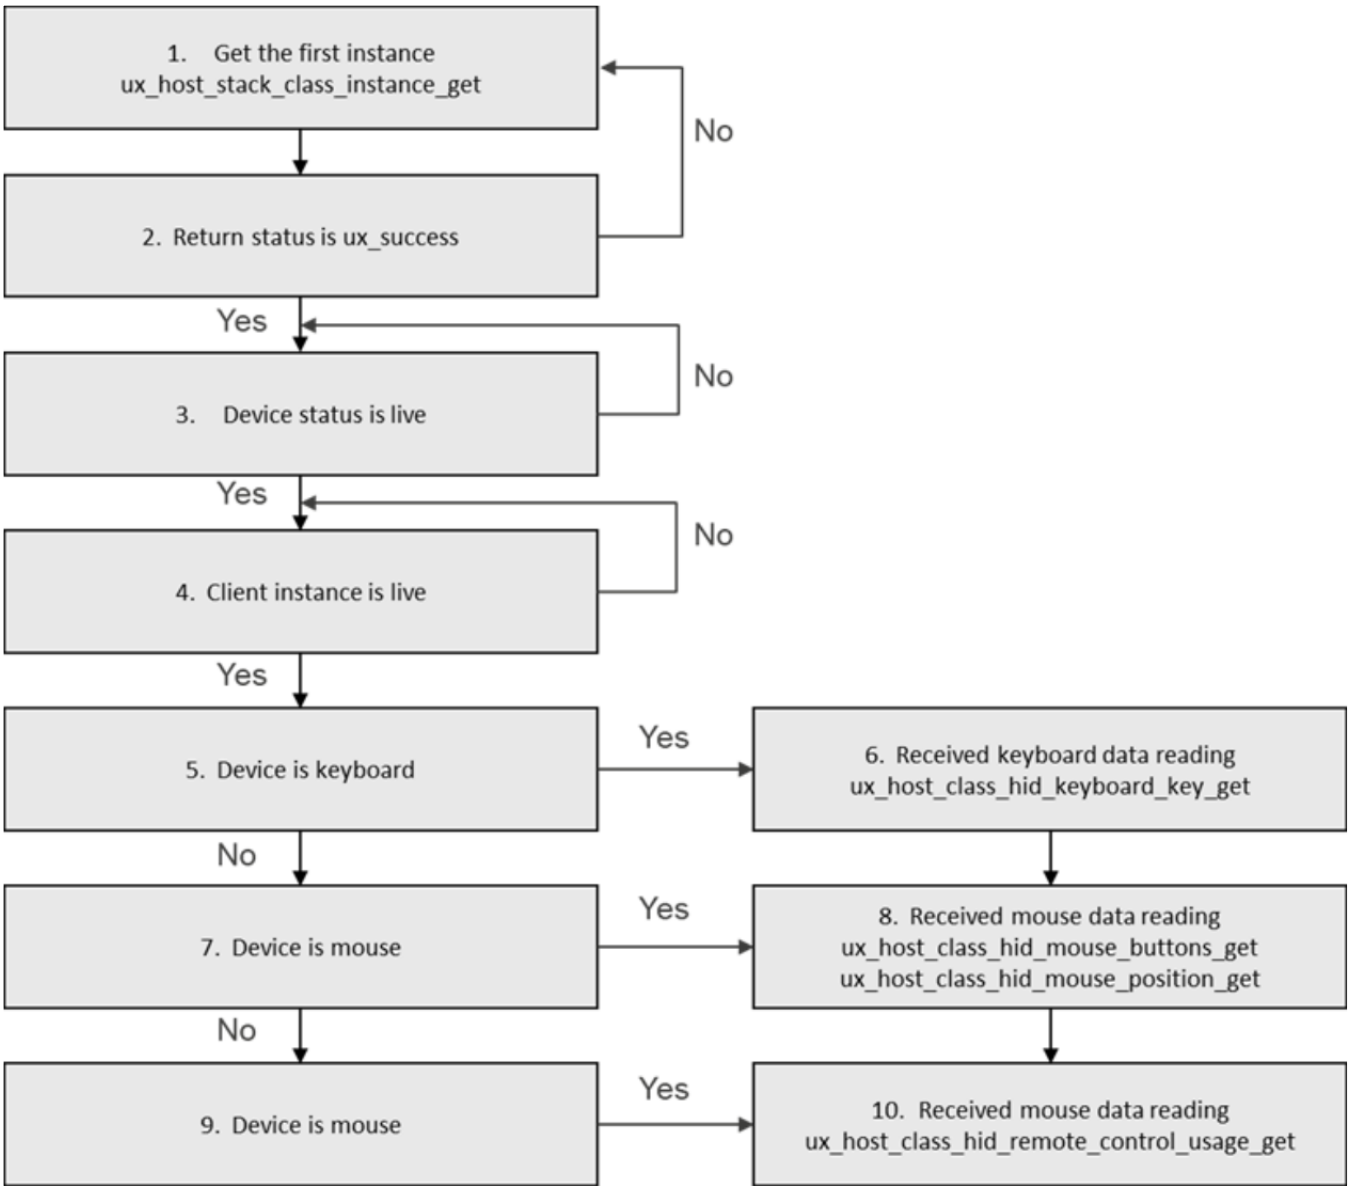

Figure 543: Flow Diagram of a Typical USBX Host Class HID Module Application

4.3.46 USBX Host Class HUB

4.3.46.1 USBX Host Class Hub Module Introduction

The USBX™ Host Class Hub module provides a high-level API for USBX Host Class Hub applications and configures the USBX Host Class Hub Source, USBX Host Configuration, USBX Source and USBX Port Host Controller Device. The USBX Host Class Hub module uses the USB peripheral on the Synergy MCU.

USBX Host Class Hub Module Features

- Supports either a stand-alone hub or functions as part of a compound device such as a keyboard or a monitor.
- Supports either self-powered or bus-powered modes.
- Bus-powered hubs have a maximum of four downstream ports.
- Hubs can be cascaded.
- Up to five hubs can be connected to one another.
- Supports the connection of devices that are either self-powered or bus-powered using less than 100 mA of power.

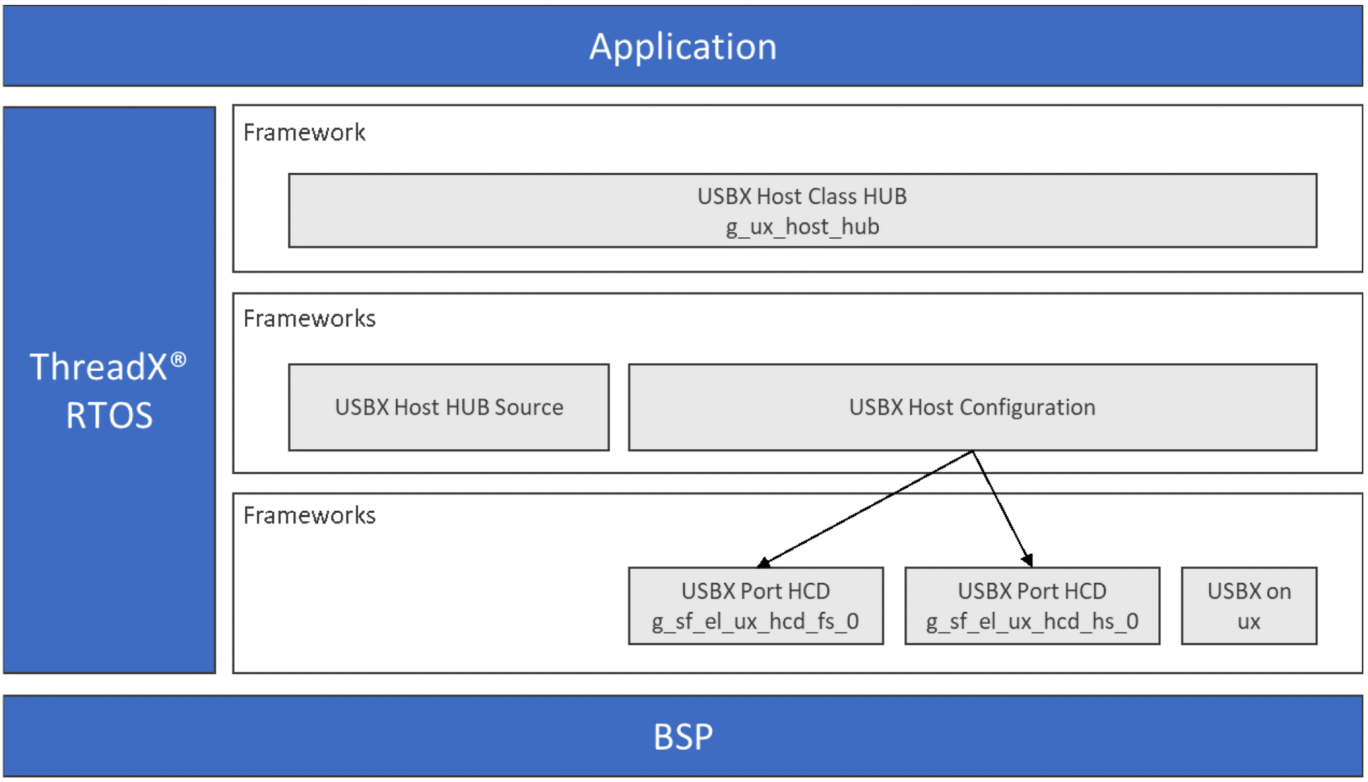

Figure 544: USBX Host Class Hub Module Block Diagram

4.3.46.2 USBX Host Class Hub Module APIs Overview

The USBX Host Class Hub Module does not have an API for the user application.

4.3.46.3 USBX Host Class Hub Module Operational Overview

Initialization of USBX Resources

The USBX has its own memory manager. The memory needs to be allocated to the USBX before the host or device side of the USBX is initialized. The USBX memory manager can accommodate systems where memory can be cached.

Definition of USB Host Controllers

It is required to define at least one USB host controller for USBX to operate in host-mode. The application-initialization file should contain this definition. SSP defines USB host controller when USB host controller driver is added to thread stacks.

Definition of Device Classes

It is required to define one or more device classes(s) with the USBX. A USB class is required to drive a USB device after the USB stack has configured the USB device. A USB class is very specific to the device; one or more classes may be required to drive a USB device depending on the number of interfaces contained in the USB device descriptors.

USB Class Binding

When the device is configured, the topology manager will let the class manager continue the device discovery by looking at the device-interface descriptors. A device can have one or more interface descriptors.

An interface represents a function in a device. For instance, a USB speaker has three interfaces, one for audio streaming, one for audio control, and one to manage the various speaker buttons.

The class manager has two mechanisms to join the device interface(s) to one or more classes. It can either use the combination of a PID/VID (product ID and vendor ID) found in the interface descriptor or the combination of Class/Subclass/Protocol.

The PID/VID combination is valid for interfaces that cannot be driven by a generic class. The Class/Subclass/Protocol combination is used by interfaces that belong to a USB-IF certified class such as a printer, hub, storage, audio, or Human Interface Design (HID).

The class manager contains a list of registered classes from the initialization of the USBX. The class manager will call each class one-at-a-time until one class accepts to manage the interface for that device; each class can only manage one interface. In the case of the USB audio speaker, the class manager will call all the classes for each of the interfaces.

Once a class accepts an interface, a new instance of that class is created; the class manager will then search for the default alternate setting for the interface. A device may have one or more alternate settings for each interface. The alternate setting 0 will be the one used by default until a class decides to change it.

For the default alternate setting, the class manager will mount all the endpoints contained in the alternate setting. If the mounting of each endpoint is successful, the class manager will complete its job by returning to the class that will finish the initialization of the interface.

USBX Host Class Hub Module Important Operational Notes and Limitations

USBX Host Class Hub Module Operational Notes

The Hub class is registered by the auto-generated code. In the user application, no special operation other than the registration of the Hub class is necessary.

USBX Host Class Hub Module Limitations

- The module needs the interrupt of a USB Controller enabled.
- The module uses the interrupt of a USB Controller. Set appropriate interrupt-priority level in the Synergy Configuration tool for proper operation.
- The module uses the interrupt of a transfer module (implemented as DMAC or DTC) if one is implemented. Set the appropriate priority level in the Synergy Configuration tool. The priority level must be higher than that of the USB Controller for proper operation.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

Note

Currently, DTC is not supported by the host side driver (only DMAC is supported).

4.3.46.4 Including the USBX Host Class Hub Module in an Application

This section describes how to include the USBX Host Class Hub Module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the USBX Host Class Hub Module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

USBX Host Class Hub Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ux_host_class_hub0 USBX Host Class Hub	Threads	New Stack> X-Ware> USBX> Host > Classes > Hub > USBX Host Class Hub

When the USBX Host Class Hub Module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

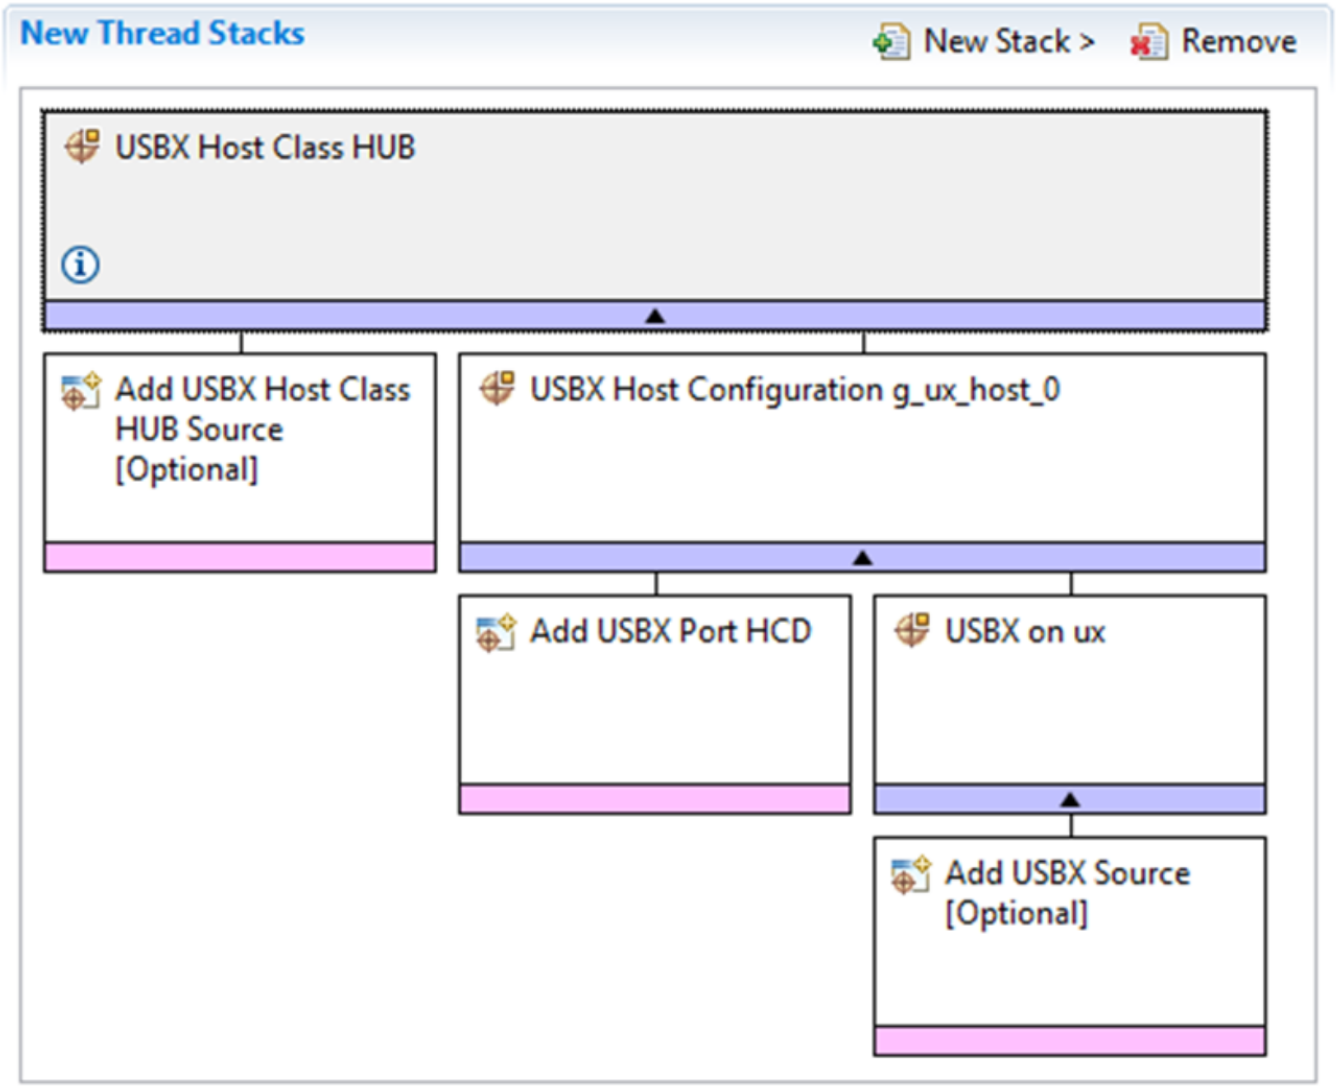

Figure 545: USBX Host Class Hub Module Stack

4.3.46.5 Configuring the USBX Host Class Hub Module

The USBX Host Class Hub Module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the USBX Host Class Hub Module

ISDE Property	Value	Description
No configurable properties		

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the USBX Host Class Hub Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the USBX Host Class Hub Source

ISDE Property	Value	Description
Show linkage warning	Enabled, Disabled Default: Enabled	Notification message for users will be shown if "Enabled" option is selected. This is just to warn users possible linkage errors by multiple symbol definitions. Select "Disabled" stops the notification message.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Host Configuration Instance

ISDE Property	Value	Description
Name	g_ux_host0	Specify the name of USBX Host Configuration instance. It must be a valid C symbol.
Name of generated initialization function	ux_host_hid_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.
VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.
Name	g_sf_el_ux_hcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.
FIFO size for Bulk/Isochronous Pipes	512, 1024, 1536, 2048 bytes Default: 512 bytes	Select the FIFO size for bulk and isochronous transfers.
Number of Isochronous Pipes Reserved	0, 1, 2 Default: 0	Select the number of isochronous pipes to reserve.
VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
Enable High Speed	Enable, Disable Default: Enable	Select if high speed should be enabled.
Name	g_sf_el_ux_hcd_hs_0	Module name.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have

different default values and available configuration settings.

Configuration Settings for the USBX on ux Instance

ISDE Property	Value	Description
USBX Pool Memory Name	g_ux_pool_memory	Name must be a valid C symbol.
USBX Pool Memory Size	18432	See section "Azure RTOS USBX Memory Requirements" for the required memory size for each classes.
User Callback for Host Event Notification (Only valid for USB Host)	NULL	Name must be a valid C symbol. The name of User defined USBX Host event notification can be given to this property.
Name of generated initialization function	ux_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

USBX Host Class Hub Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48MHz operation. In the SSP configuration window, select the Clocks tab to view the clock-source setting.

USBX Host Class Hub Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external devices. Select I/O pins and configure to the external device requirements. The following table lists the pin selection method within the SSP Configuration Window and the subsequent tables demonstrate the selection process using USB pins as an example.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence
USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

Note

The selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select device as the Operation Mode
USBDP	USBDP	USBDP pin
USBDM	USBDM	USBDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	None	VBUSEN pin
VBUS	None, P407 Default: P407	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID Pin
VCCUSB	VCCUSB	VCCUSB pin
VSSUSB	VSSUSB	VSSUSB pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select Device as the Operation Mode
USBHSDP	USBHSDP	USBHSDP pin
USBHSDM	USBHSDM	USBHSDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	PB00	VBUSEN pin
VBUS	PB01	VBUS pin
EXICEN	None	EXICEN pin

ID	None	ID pin
USBHSRREF	USBHSRREF	USBHSRREF pin
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin
PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin
VCCUSBHS	VCCUSBHS	VCCUSBHS pin
VSS1USBHS	VSS1USBHS	VSS1USBHS pin
VSS2USBHS	VSS2USBHS	VSS2USBHS pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.46.6 Using the USBX Host Class Hub Module in an Application

An application typically does not use the Hub module by itself; other classes (CDC-ACM, Storage, HID and so on.) are also used at the same time.

The configurator generates processing to register the USBX Host Class Hub module. Specify the same module as USBX Host Configuration module registered in the class to be used at the same time.

The following figure shows the stack when registered with the USBX Host Class Mass Storage module at the same time:

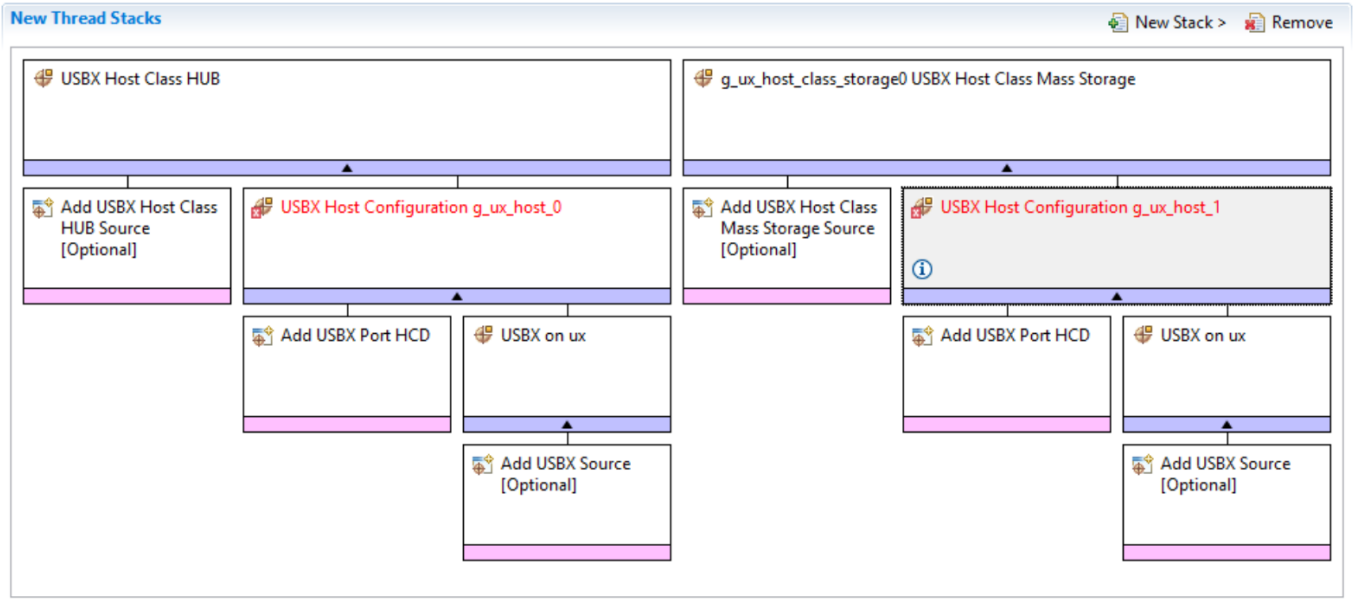

Figure 546: Flow Diagram of a Typical USBX Host Class Hub Module Application

4.3.47 USBX Host Class Printer

4.3.47.1 USBX Host Class Printer Module Introduction

The USBX™ Host Class Printer module provides a high-level API for USBX Host Class Printer module applications and uses the USB and data-transfer peripherals on the Synergy MCU. A user defined callback can be created to determine when the stack activates or deactivates the USB Printer class.

Unsupported Features

USBX host class PIMA is not supported in this version of SSP.

USBX Pictbridge is not supported in this version of SSP.

USBX Host Class Printer Module Features

The USB Host Class Printer module allows for a USB host-system to communicate with the Printer. This class is based on the USB standard. The USBX Host Class Printer module includes the following key features:

- Support for USB Full Speed (USBFS) or USB High Speed (USBHS)
- Receive and transmit data-transfer drivers for improved performance
- High-level APIs for reading and writing

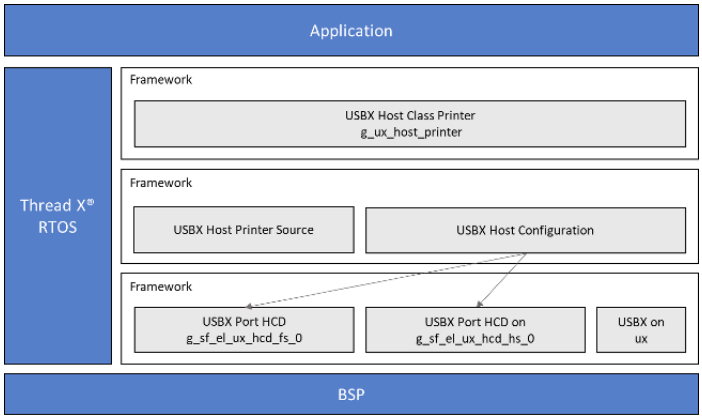

Figure 547: USBX Host Class Printer Module Block Diagram

4.3.47.2 USBX Host Class Printer Module APIs Overview

The USBX Host Class Printer Module defines APIs, which are used to interact with the Printer interface. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

USBX Host Class PRINTER Module Summary

Function Name	Example API Call and Description

ux_host_class_printer_read	UINT ux_host_class_printer_read (UX_HOST_CLASS_PRINTER *printer, UCHAR *data_pointer, ULONG requested_length, ULONG *actual_length) This function reads from the printer interface. The call is blocking and only returns when there is either an error or when the transfer is complete. A read is allowed only on bi-directional printers.
ux_host_class_printer_write	UINT ux_host_class_printer_write (UX_HOST_CLASS_PRINTER *printer,UCHAR *data_pointer, ULONG requested_length,ULONG *actual_length) This function writes to the printer interface. The call is blocking and only returns when there is either an error or when the transfer is complete.
ux_host_class_printer_soft_reset	UINT ux_host_class_printer_soft_reset (UX_HOST_CLASS_PRINTER *printer) This function performs a soft reset to the printer
ux_host_class_printer_status_get	UINT ux_host_class_printer_status_get (UX_HOST_CLASS_PRINTER *printer,ULONG *printer_status) This function obtains the printer status. The printer status is similar to the LPT status (1284 standard).
_ux_host_class_printer_name_get	UINT _ux_host_class_printer_name_get(UX_HOST_CLASS_PRINTER *printer) This function obtains the Device ID string.

Note

for more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Return Values

Name	Description
UX_SUCCESS	This operation was successful.
UX_FUNCTION_NOT_SUPPORTED	Function not supported because the printer is not bi-directional.
UX_TRANSFER_TIMEOUT	Transfer timeout, reading or writing is incomplete, or reset not completed.
UX_MEMORY_INSUFFICIENT	Not enough memory to perform the operation.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.3.47.3 USBX Host Class Printer Module Operational Overview

The initialization of the Printer class expects some specific parameters as illustrated in the application project associated with this module guide.

Printers have two different types of commands: those that transfer data and those that control the USB interface or Printer interface. The host prints something on a printer by delivering data on the Bulk OUT endpoint. This data is in the form of PostScript, HP PCL or any other PDL. This data may also be encapsulated in a PCP, such as IEEE 1284.1, or something that is vendor-specific. In addition, the data may also be simple text, or it may be a proprietary PDL. User application should take care of converting data into printer supported formats. The printer can respond periodically on the Bulk IN endpoint with status regarding the data it is receiving, or because of an asynchronous event. A typical printed page takes the following sequence:

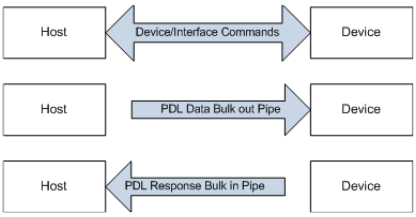

Figure 548: Printing a page

The PDL data is sent to the device on the Bulk OUT pipe. If the device uses a PCP, then the PDL is encapsulated in the PCP; the Bulk IN pipe is used for any responses, such as errors and printer status as defined in the PCP. For a unidirectional interface, the status is retrieved by issuing a port status command on the default pipe, and the status is returned on the default pipe.

USBX Host Class Printer Module Important Operational Notes and Limitations

USBX Host Class Printer Module Operational Notes

The USBX Host stack or USBX Host stack consumes RAM for the control block. The Synergy Configuration tool allocates memory to the USBX memory pool statically in the auto-generate code as shown in the following table. You need to set the appropriate memory size in bytes to the USBX Pool Memory Size property of the USBX on ux component in the Synergy Configuration tool in section "USBX on ux Configuration." If multiple classes are used, set the total memory size to the property.

Memory (RAM) Requirements for the USBX Memory Pool

USBX Class	S1 Parts	Other Parts
USBX HostPrinter(ux_Host_class_printer)	N/A	27KB

Note

the information shown in the table above is valid if compiled with default USBX configurations.
the memory size of the USBX Classes in the table above are of the pre-built libraries and the following configuration was applied for the builds:

UX_THREAD_STACK_SIZE: 2048 (bytes) for the other parts

USBX Host Class Printer Module Limitations

- Refer to the most recent *SSP Release Notes* for any additional operational limitations for

this module.

Note

Currently, DTC is not supported by the host side driver (only DMAC is supported).

4.3.47.4 Including the USBX Host Class Printer Module in an Application

This section describes how to include the USBX Host Class Printer Module in an application using the SSP configurator.

Note

it is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the USBX Host Class Printer Module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

USBXHost Class Printer Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ux_Host_class_printer0 USBX Host Class Printer	Threads	New Stack> X-Ware> USBX>Host> Classes >Printer> USBX Host Class Printer

When the USBX Host Class Printer Module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description includes Add in the text. Clicking on any Pink banded modules brings up the new icon and displays possible choices.

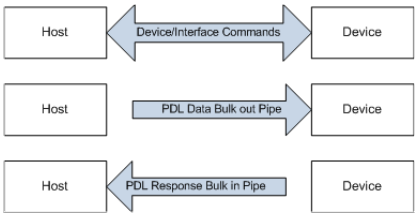

Figure 549: USBX Host Class Printer Module Stack

4.3.47.5 Configuring the USBX Host Class Printer Module

The USBX Host Class Printer Module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than manual

approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the USBX Host Class Printer Module

ISDE Property	Value	Description
Name	g_ux_Host_class_printer0	Specify the name of the USBX Host Printer Class module instance. It must be a valid C symbol.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.
Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the USBX Host Class Printer Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the USBX Host Class Printer Source

ISDE Property	Value	Description
Show linkage warning	Enabled, Disabled Default: Enabled	Notification message for users will be shown if "Enabled" option is selected. This is just to warn user's possible linkage errors by multiple symbol definitions. Select "Disabled" stops the notification message.

Note

the example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Host Configuration Instance

ISDE Property	Value	Description
Name	g_ux_host0	Specify the name of USBX Host Configuration instance. It must be a valid C symbol.

Name of generated initialization function	ux_host_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

the example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.
VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.
Name	g_sf_el_ux_hcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

the example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.
FIFO size for Bulk/Isochronous Pipes	512, 1024, 1536, 2048 bytes Default: 512 bytes	Select the FIFO size for bulk and isochronous transfers.
Number of Isochronous Pipes Reserved	0,1,2 Default: 0	Select the number of isochronous pipes to reserve.

VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
Enable High Speed	Enable, Disable Default: Enable	Select if high speed should be enabled.
Name	g_sf_el_ux_hcd_hs_0	Module name.

Note

the example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings

Configuration Settings for the USBX on ux Instance

ISDE Property	Value	Description
USBX Pool Memory Name	g_ux_pool_memory	Name must be a valid C symbol.
USBX Pool Memory Size		See section "Azure RTOS USBX Memory Requirements" for the required memory size for each class.
User Callback for Host Event Notification (Only valid for USB Host)	NULL	Name must be a valid C symbol. The name of User defined USBX Host event notification can be given to this property.
Name of generated initialization function	ux_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

the example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

USBX Host Class Printer Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48MHz operation. In the SSP configuration window, select the Clocks tab to view the clock-source setting.

USBX Host Class Printer Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external Hosts. Select I/O pins and configure to the external Host requirements. The following table lists the pin selection method within the SSP Configuration Window, and the subsequent tables demonstrate the selection process using USB pins as an example.

Note

the selected operation mode determines what peripheral signals available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence
USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

Note

the selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Host, Host, OTG Default: Custom	Select Host as the Operation Mode
USBDP	USBDP	USBDP pin
USBDM	USBDM	USBDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	None	VBUSEN pin
VBUS	None, P407 Default: P407	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID Pin
VCCUSB	VCCUSB	VCCUSB pin
VSSUSB	VSSUSB	VSSUSB pin

Note

the example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description

Operation Mode	Disabled, Custom, Host, Host, OTG Default: Custom	Select Host as the Operation Mode
USBHSDP	USBHSDP	USBHSDP pin
USBHSDM	USBHSDM	USBHSDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	PB00	VBUSEN pin
VBUS	PB01	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID pin
USBHSRREF	USBHSRREF	USBHSRREF pin
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin
PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin
VCCUSBHS	VCCUSBHS	VCCUSBHS pin
VSS1USBHS	VSS1USBHS	VSS1USBHS pin
VSS2USBHS	VSS2USBHS	VSS2USBHS pin

Note

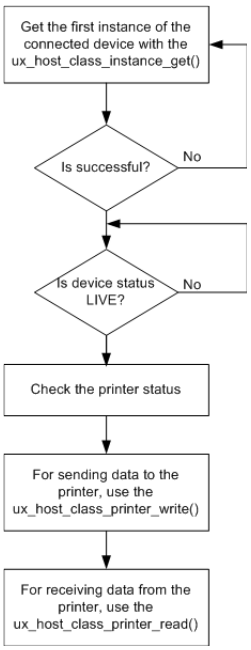
the example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.47.6 Using the USBX Host Class Printer Module in an Application

The configurator generates processing to create and register the USBX Host Class CDC-ACM module; however, communication must be done after the Printer is connected to the host.

The typical steps in using the USBX Host Class Printer module in an application are:

1. Get the first instance of the connected device with the ux_host_class_instance_get API.
2. Wait until successful.
3. Wait for the device status to become live.
4. Check the status of the printer.
5. For data sending to the printer, use the ux_host_class_printer_write API.
6. For data receiving from printer, use the ux_host_class_printer_read API.



4.3.48 USBX Host Class Mass Storage

4.3.48.1 USBX Host Class Mass Storage Module Introduction

The USBX™ Host Class Mass Storage module provides a high-level API for USBX Host Class Mass Storage applications and uses the USB and data-transfer peripherals on the Synergy MCU.

USBX Host Class Mass Storage Module Features

- Host controller for USB 2.0 with support for:
  - Root Hub
  - Power Management
  - Endpoints
  - Transfers
- High-level APIs simplify storage operations
- Supports optional data transfers using MCU hardware for improved efficiency

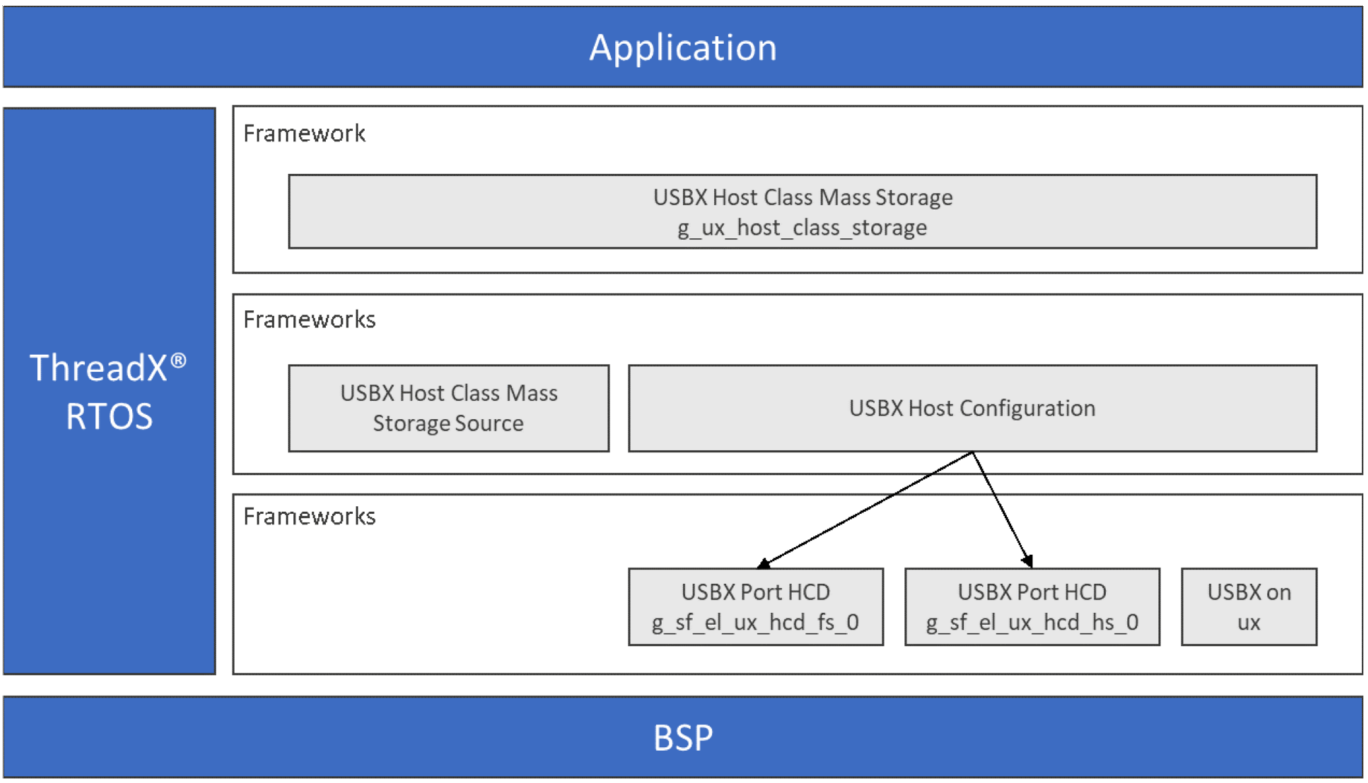


Figure 550: USBX Host Class Mass Storage Module Block Diagram

4.3.48.2 USBX Host Class Mass Storage Module APIs Overview

The USBX Host Class Mass Storage module does not have a separate API available for user applications. When a USB media is connected, it is attached to the FileX® member included in the USBX Host Class Mass Storage instance. The user application uses this FileX member to access files on the USB media. For FileX APIs, refer to the FileX User Guide for the Renesas Synergy™ Platform for more details.

4.3.48.3 USBX Host Class Mass Storage Module Operational Overview

Initialization of USBX Resources

The USBX has its own memory manager. The memory needs to be allocated to the USBX before the host or device side of the USBX is initialized. The USBX memory manager can accommodate systems where memory can be cached.

Definition of USB Host Controllers

It is required to define at least one USB host controller for USBX to operate in host-mode. The application-initialization file should contain this definition. SSP defines USB host controller when USB host controller driver is added to thread stacks.

Definition of Device Classes

It is required to define one or more device classes(s) with the USBX. A USB class is required to drive a USB device after the USB stack has configured the USB device. A USB class is very specific to the device; one or more classes may be required to drive a USB device depending on the number of interfaces contained in the USB device descriptors.

USB Class Binding

When the device is configured, the topology manager will let the class manager continue the device discovery by looking at the device-interface descriptors. A device can have one or more interface descriptors.

An interface represents a function in a device. For instance, a USB speaker has three interfaces, one for audio streaming, one for audio control, and one to manage the various speaker buttons.

The class manager has two mechanisms to join the device interface(s) to one or more classes. It can either use the combination of a PID/VID (product ID and vendor ID) found in the interface descriptor or the combination of Class/Subclass/Protocol.

The PID/VID combination is valid for interfaces that cannot be driven by a generic class. The Class/Subclass/Protocol combination is used by interfaces that belong to a USB-IF certified class such as a printer, hub, storage, audio, or Human Interface Design (HID).

The class manager contains a list of registered classes from the initialization of the USBX. The class manager will call each class one-at-a-time until one class accepts to manage the interface for that device; each class can only manage one interface. In the case of the USB audio speaker, the class manager will call all the classes for each of the interfaces.

Once a class accepts an interface, a new instance of that class is created; the class manager will then search for the default alternate setting for the interface. A device may have one or more alternate settings for each interface. The alternate setting 0 will be the one used by default until a class decides to change it.

For the default alternate setting, the class manager will mount all the endpoints contained in the alternate setting. If the mounting of each endpoint is successful, the class manager will complete its job by returning to the class that will finish the initialization of the interface.

USBX Host Class Mass Storage Module Important Operational Notes and Limitations

USBX Host Class Mass Storage Module Operational Notes

The USBX Device stack or USBX Host stack consumes RAM for the control block. The Synergy Configuration tool allocates memory to the USBX memory pool statically in the auto-generate code as shown in the following table. You need to set the appropriate memory size in bytes to the USBX Pool Memory Size property of the USBX on ux component in the Synergy Configuration tool in section "USBX on ux Configuration." If multiple classes are used, set the total memory size to the property.

__Memory (RAM) Requirements for the USBX Memory Pool__

USBX Class	S1 Parts	Other Parts
USBX Host Mass Storage (ux_host_class_storage)	N/A	Pre-built library: 42KB Source: 39KB + UX_HOST_CLASS_STORAGE_MEMORY_BUFFER_SIZE + UX_HOST_CLASS_STORAGE_THREAD_STACK_SIZE+ (Add the additional memory as per Note*1)

Note

**1: If 'Maximum TDs' is exceeds more then 128 in (USBX Source module: USBX Source property >> Common >> Maximum TDs) in the XML configurator, add the additional memory to the USBX memory pool as follows:*

- *Note*

  *(Maximum TDs - 128)*48 = Additional memory in Bytes.*
  The information shown in the table above is valid if compiled with default USBX configurations.
  The memory size of the USBX Classes in the table above are of the pre-built libraries and the following configuration was applied for the builds: UX_THREAD_STACK_SIZE: 512 (bytes) for S1 parts; 2048 (bytes) for the other parts
  The memory size of the USBX Host Mass Storage is also shown with the case built with the Source module because the size depends on the configuration UX_HOST_CLASS_STORAGE_MEMORY_BUFFER_SIZE and would differ much from the pre-build library's. Note that the size is with following configuration applied: UX_THREAD_STACK_SIZE: 2048 (bytes)

USBX Host Class Mass Storage Module Operational Procedure

- Use a class container for the USBX Host Class Mass Storage module obtained by auto-generated code to get a mass storage instance.
- Poll the flag ux_host_class_storage_state in and make sure the status is live.
- Wait until the first media of the class container is attached.
- Access the file on the media with the FileX API.

USBX Host Class Mass Storage Module Limitations

- The module uses the interrupt of a USB controller; set the appropriate interrupt-priority level in the Synergy Configuration tool to ensure proper operation.
- The module uses the interrupt of a transfer module (implemented as DMAC or DTC); set the appropriate priority level in the Synergy Configuration tool. The level must be higher than a USB Controller to ensure proper operation.
- USBX Host Class Mass storage module only supports the MBR partition type on the storage device.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

Note

Currently, DTC is not supported by the host side driver (only DMAC is supported).

4.3.48.4 Including the USBX Host Class Mass Storage Module in an Application

This section describes how to include the USBX Host Class Mass Storage Module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the USBX Host Class Mass Storage Module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

USBX Host Class Mass Storage Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence

g_ux_host_class_storage USBX Host Class Mass Storage	Threads	New Stack> X-Ware> USBX> Device> Classes> Mass Storage > USBX Host Class Mass Storage

When the USBX Host Class Mass Storage Module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

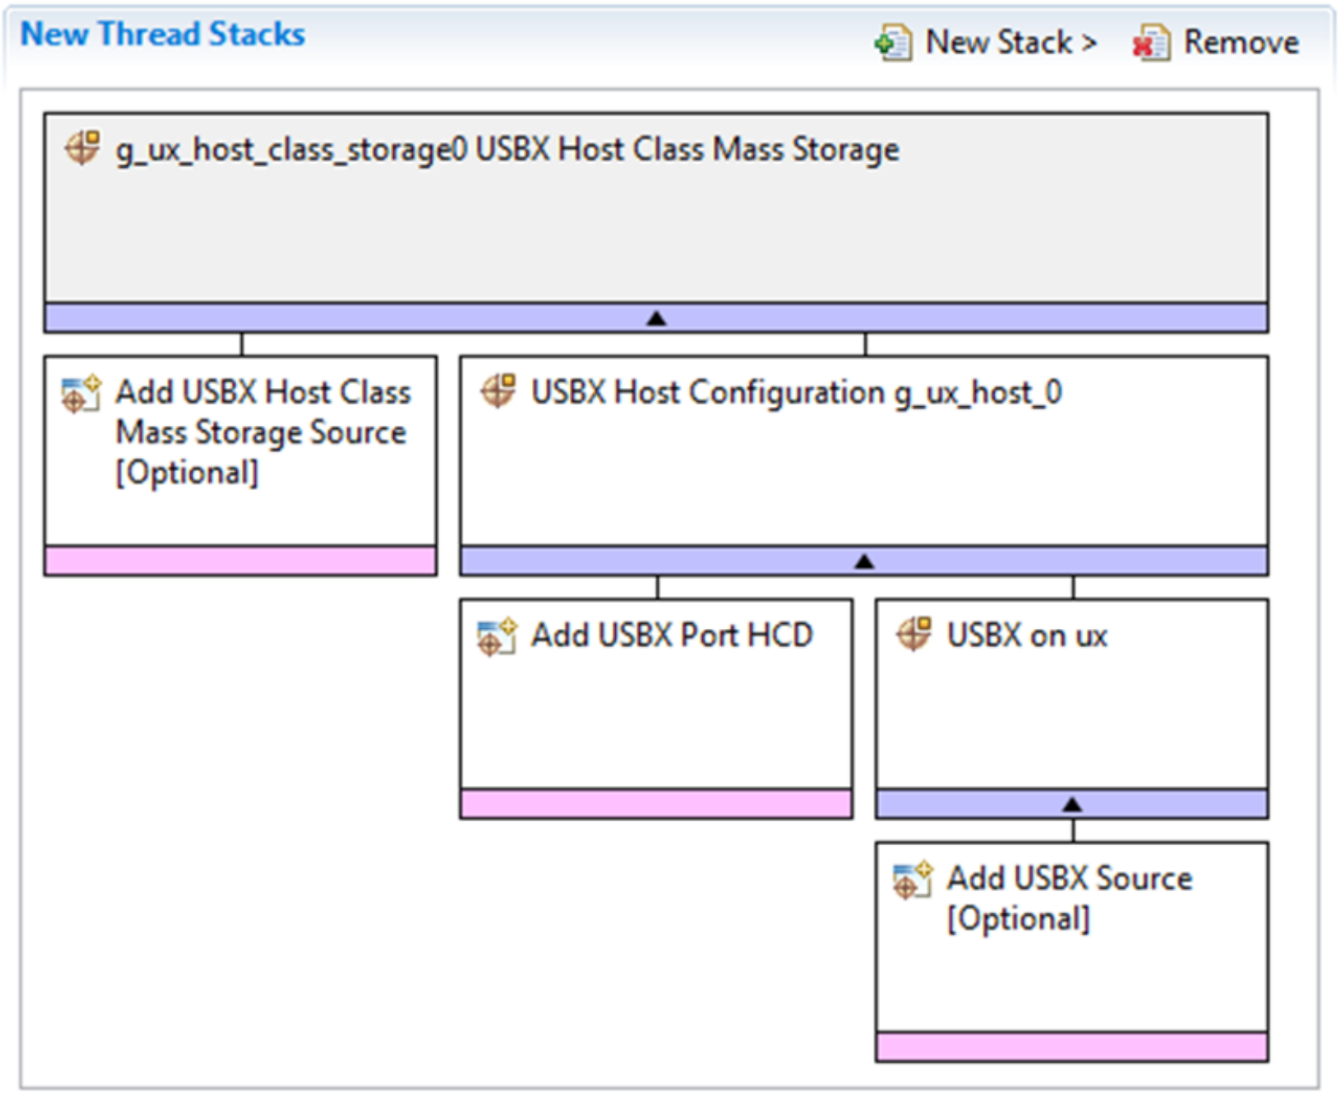

Figure 551: USBX Host Class Mass Storage Module Stack

4.3.48.5 Configuring the USBX Host Class Mass Storage Module

The USBX Host Class Mass Storage Module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the USBX Host Class Mass Storage Module

ISDE Property	Value	Description
Name	g_ux_host_class_storage0	Module name.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the USBX Host Class Mass Storage Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the USBX Host Class Mass Storage Source

ISDE Property	Value	Description
Use FileX Stub	Enabled, Disabled Default: Disabled	UX_NO_FILEX Enable this option only in cases where FileX is not available to use.
Maximum number of SCSI logical units	Value must be greater than 0 or empty Default: 1	UX_MAX_HOST_LUN The value represents the maximum number of SCSI logical units represented in the host storage class driver.

Maximum number of storage media instance	Value must be greater than 0 or empty Default: 1	UX_HOST_CLASS_STORAGE_MAX_MEDIA The value represents the maximum number of storage media instances represented in the host storage class driver.
Storage memory size in bytes for FileX used for data transfer	Value must be greater than 512 or empty Default: 1024	UX_HOST_CLASS_STORAGE_MEMORY_BUFFER_SIZE The value represents the block of memory in bytes for FileX to use when doing transfers. The value can be changed to save on memory space but should not be smaller than the media sector size. Because USB devices are SCSI devices and there is a great deal of overhead when doing read/writes, it is better to increase it for higher data throughput.

Maximum transfer size in bytes in one BOT data-transport phase	Value must be greater than 512 or empty Default: 1024	UX_HOST_CLASS_STORAGE_MAX_TRANSFER_SIZE The value represents maximum size of memory chunk in bytes to send in one data-transport phase in the Bulk-Only Transport protocol. Large size of data transfer request is split into smaller chunks specified by this configuration. It is better to increase it for higher data throughput. Note: Sufficient numbers of TDs are required, when user changes this parameter for large size(FS more than 8KB and HS more the 64KB) of data transfer. Sufficient number of 'Maximum TDs' needs to be specified in USBX Source module(USBX Source property >> Common >> Maximum TDs). - Maximum TDs for FS mode (maximum data transfer size in bytes /64 bytes = TDs + additional TDs for SCSI wrapper commands). - Maximum TDs for HS mode (maximum data transfer size in bytes /512 bytes = TDs + additional TDs for SCSI wrapper commands).
Stack size for the Mass Storage Class internal thread	Value must be greater than 512 or empty Default: 1024	UX_HOST_CLASS_STORAGE_THREAD_STACK_SIZE The value represents the stack size in bytes for Mass Storage Class internal thread named ux_storage_thread.
Timeout (in milliseconds) for a BOT transfer request	Value must be greater than 0 or empty Default: 100000	UX_HOST_CLASS_STORAGE_TRANSFER_TIMEOUT_IN_MS The value represents timeout value in millisecond for a data transfer request in Bulk-Only Transport protocol.

Timeout (in milliseconds) for the status from a command in the Control/Bulk/Interrupt transport	Value must be greater than 0 or empty Default: 30000	UX_HOST_CLASS_STORAGE_CBI_STATUS_TIMEOUT_IN_MS The value represents timeout value in millisecond for the status from a command, which is returned by the interrupt endpoint in the Control/Bulk/Interrupt transport. The transport is mainly used by storage devices that have very slow read/write commands.
Host storage class dependency on Filex	Enabled, Disabled Default: Disabled	UX_HOST_CLASS_STORAGE_NO_FILEX If enabled, Filex dependency on host storage class is removed.
Show linkage warning	Enabled, Disabled Default: Enabled	Notification message for users will be shown if "Enabled" option is selected. This is just to warn users possible linkage errors by multiple symbol definitions. Select "Disabled" stops the notification message.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Host Configuration Instance

ISDE Property	Value	Description
Name	g_ux_host0	Specify the name of USBX Host Configuration instance. It must be a valid C symbol.
Name of generated initialization function	ux_host_hid_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBFS

ISDE Property	Value	Description

Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.
VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.
Name	g_sf_el_ux_hcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port HCD on sf_el_ux for USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.
FIFO size for Bulk/Isochronous Pipes	512, 1024, 1536, 2048 bytes Default: 512 bytes	Select the FIFO size for bulk and isochronous transfers.
Number of Isochronous Pipes Reserved	0, 1, 2 Default: 0	Select the number of isochronous pipes to reserve.
VBUSEN pin Signal Logic	Active Low, Active High Default: Active High	Select the VBUSEN pin signal logic.
Enable High Speed	Enable, Disable Default: Enable	Select if high speed should be enabled.
Name	g_sf_el_ux_hcd_hs_0	Module name.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX on ux Instance

ISDE Property	Value	Description
USBX Pool Memory Name	g_ux_pool_memory	Name must be a valid C symbol.
USBX Pool Memory Size	18432	See section "Azure RTOS USBX Memory Requirements" for the required memory size for each classes.
User Callback for Host Event Notification (Only valid for USB Host)	NULL	Name must be a valid C symbol. The name of User defined USBX Host event notification can be given to this property.
Name of generated initialization function	ux_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

USBX Host Class Mass Storage Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48MHz operation. In the SSP configuration window, select the Clocks tab to view the clock-source setting.

USBX Host Class Mass Storage Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external devices. Select I/O pins and configure to the external device requirements. The following table lists the pin selection method within the SSP Configuration Window and the subsequent tables demonstrate the selection process using USB pins as an example.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence
USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

Note

The selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select device as the Operation Mode
USBDP	USBDP	USBDP pin
USBDM	USBDM	USBDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	None	VBUSEN pin
VBUS	None, P407 Default: P407	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID Pin
VCCUSB	VCCUSB	VCCUSB pin
VSSUSB	VSSUSB	VSSUSB pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select Device as the Operation Mode
USBHSDP	USBHSDP	USBHSDP pin
USBHSDM	USBHSDM	USBHSDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	PB00	VBUSEN pin
VBUS	PB01	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID pin
USBHSRREF	USBHSRREF	USBHSRREF pin
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin

PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin
VCCUSBHS	VCCUSBHS	VCCUSBHS pin
VSS1USBHS	VSS1USBHS	VSS1USBHS pin
VSS2USBHS	VSS2USBHS	VSS2USBHS pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.48.6 Using the USBX Host Class Mass Storage Module in an Application

The configurator generates processing to create and register the USBX Host Class Mass Storage Module; however, communication must be done after the Host is connected to the host.

The typical steps in using the USBX Host Class Mass Storage Module in an application are:

1. Get the first instance of the connected device with the ux_host_stack_class_instance_get API.

2. Wait until successful.

3. Wait for the device status to become live.

4. Wait for media to be mounted.

5. Access the file on the media with the FileX API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

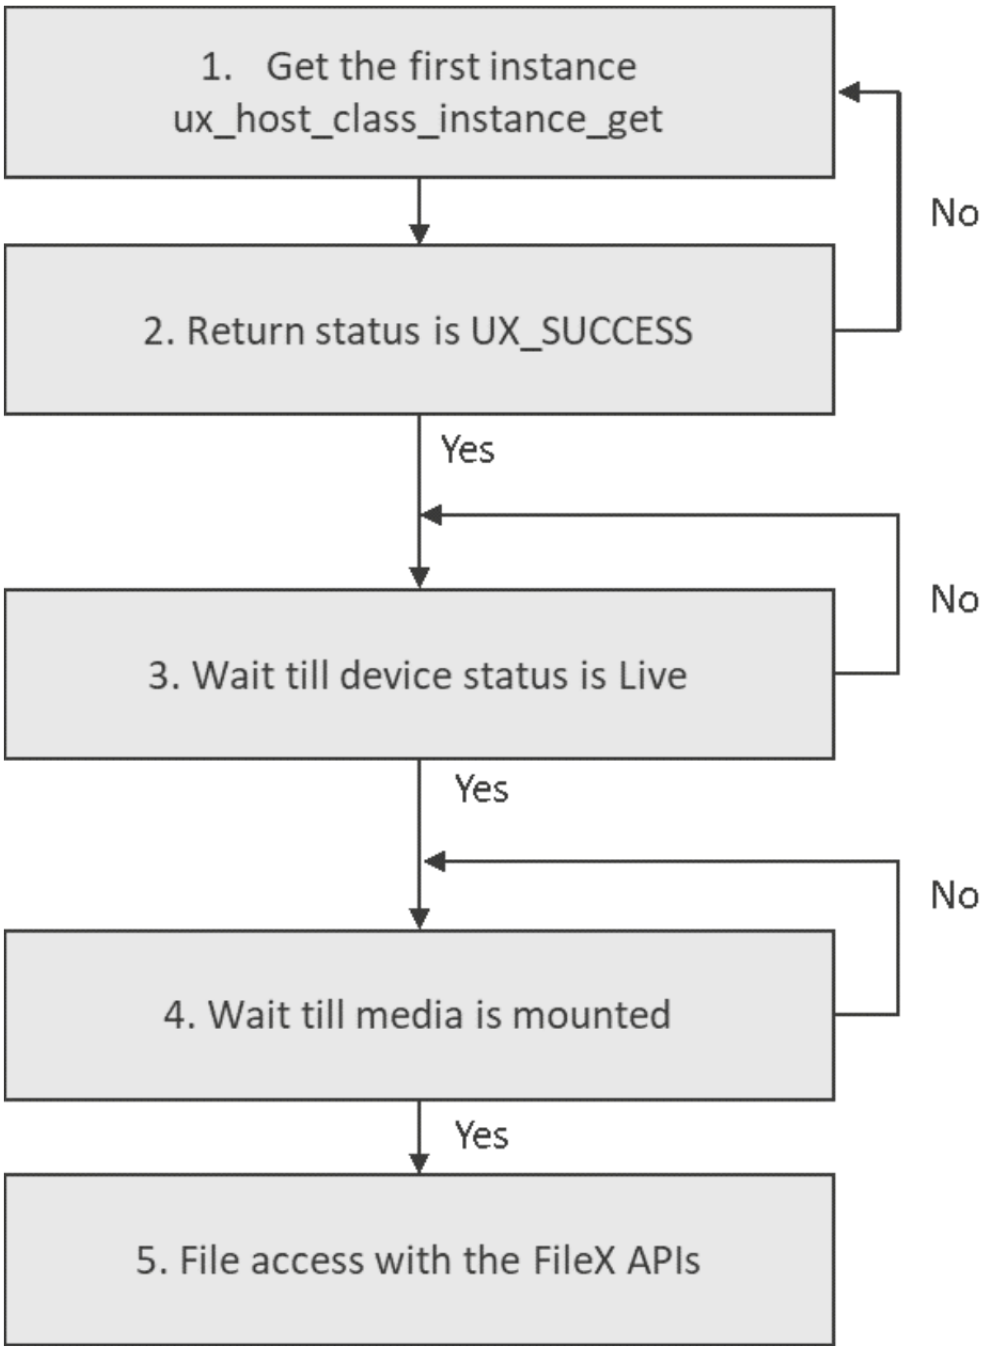

Figure 552: Flow Diagram of a Typical USBX Host Class Mass Storage Module Application

4.3.49 USBX Host Class Video

4.3.49.1 USBX Host Class Video Module Introduction

The USBX™ Host Class Video module provides a high-level API for USBX Host Class Video applications and configures the USBX Host Class Video Source, USBX Host Configuration, USBX

Source and USBX Port Host Controller Device. The USBX Host Class Video module uses the USB peripheral on the Synergy MCU.

Unsupported Features

Multiple instances of the USB device class are not supported on two different physical interfaces.

USBX Host Class Video Module Features

- Supports either a stand-alone hub or functions as part of a compound device such as a keyboard or a monitor.
- Supports either self-powered or bus-powered modes.
- Bus-powered hubs have a maximum of four downstream ports.
- Hubs can be cascaded.
- Up to five hubs can be connected to one another.
- Supports the connection of devices that are either self-powered or bus-powered using less than 100 mA of power.

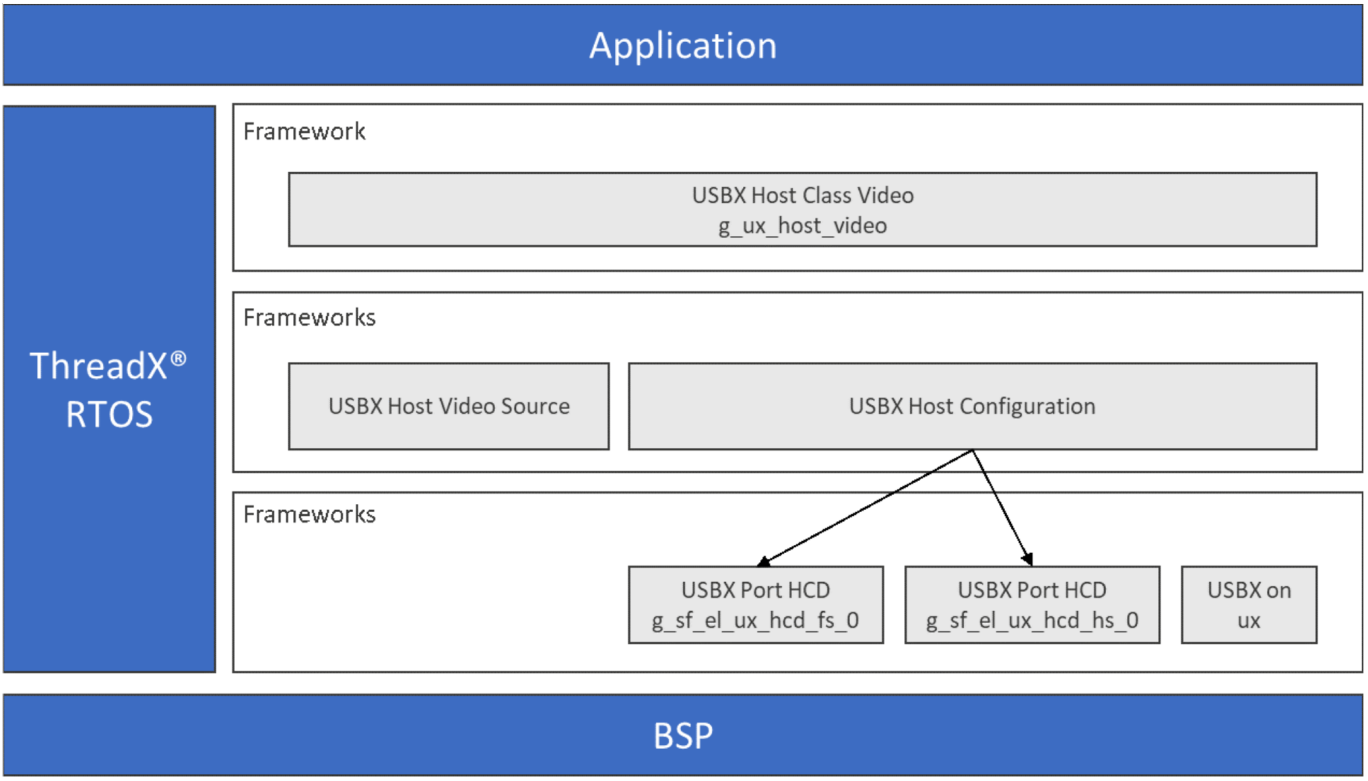

Figure 553: USBX Host Class Video Module Block Diagram

4.3.49.2 USBX Host Class Video Module APIs Overview

The USBX Host Class Video Module does not have an API for the user application.

4.3.49.3 USBX Host Class Video Module Operational Overview

Initialization of USBX Resources

The USBX has its own memory manager. The memory needs to be allocated to the USBX before the host or device side of the USBX is initialized. The USBX memory manager can accommodate systems

where memory can be cached.

Definition of USB Host Controllers

It is required to define at least one USB host controller for USBX to operate in host-mode. The application-initialization file should contain this definition. SSP defines USB host controller when USB host controller driver is added to thread stacks.

Definition of Device Classes

It is required to define one or more device classes(s) with the USBX. A USB class is required to drive a USB device after the USB stack has configured the USB device. A USB class is very specific to the device; one or more classes may be required to drive a USB device depending on the number of interfaces contained in the USB device descriptors.

USB Class Binding

When the device is configured, the topology manager will let the class manager continue the device discovery by looking at the device-interface descriptors. A device can have one or more interface descriptors.

An interface represents a function in a device. For instance, a USB speaker has three interfaces, one for audio streaming, one for audio control, and one to manage the various speaker buttons.

The class manager has two mechanisms to join the device interface(s) to one or more classes. It can either use the combination of a PID/VID (product ID and vendor ID) found in the interface descriptor or the combination of Class/Subclass/Protocol.

The PID/VID combination is valid for interfaces that cannot be driven by a generic class. The Class/Subclass/Protocol combination is used by interfaces that belong to a USB-IF certified class such as a printer, hub, storage, audio, or Human Interface Design (HID).

The class manager contains a list of registered classes from the initialization of the USBX. The class manager will call each class one-at-a-time until one class accepts to manage the interface for that device; each class can only manage one interface. In the case of the USB audio speaker, the class manager will call all the classes for each of the interfaces.

Once a class accepts an interface, a new instance of that class is created; the class manager will then search for the default alternate setting for the interface. A device may have one or more alternate settings for each interface. The alternate setting 0 will be the one used by default until a class decides to change it.

For the default alternate setting, the class manager will mount all the endpoints contained in the alternate setting. If the mounting of each endpoint is successful, the class manager will complete its job by returning to the class that will finish the initialization of the interface.

USBX Host Class Video Module Important Operational Notes and Limitations

USBX Host Class Video Module Operational Notes

The USBX Device stack or USBX Host stack consumes RAM for the control block. The Synergy Configuration tool allocates memory to the USBX memory pool statically in the auto-generate code as shown in the following table. You need to set the appropriate memory size in bytes to the USBX Pool Memory Size property of the USBX on ux component in the Synergy Configuration tool in section "USBX on ux Configuration." If multiple classes are used, set the total memory size to the property.

Memory (RAM) Requirements for the USBX Memory Pool

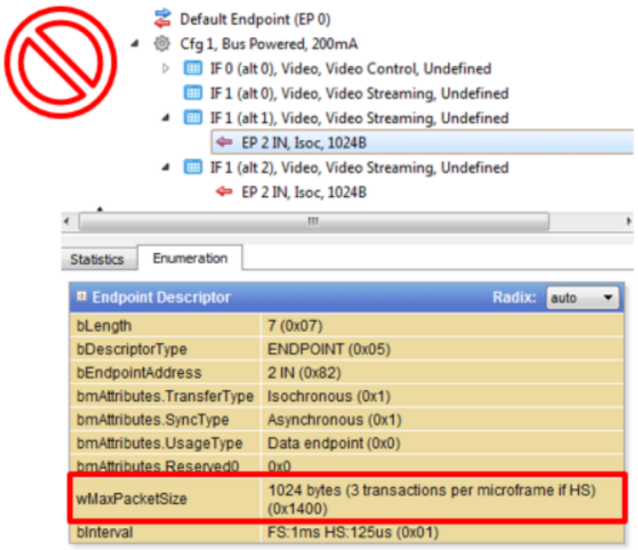
USBX Class	S1 Parts	Other Parts
USBX Host Video (ux_host_class_video)	N/A	35KB

Note

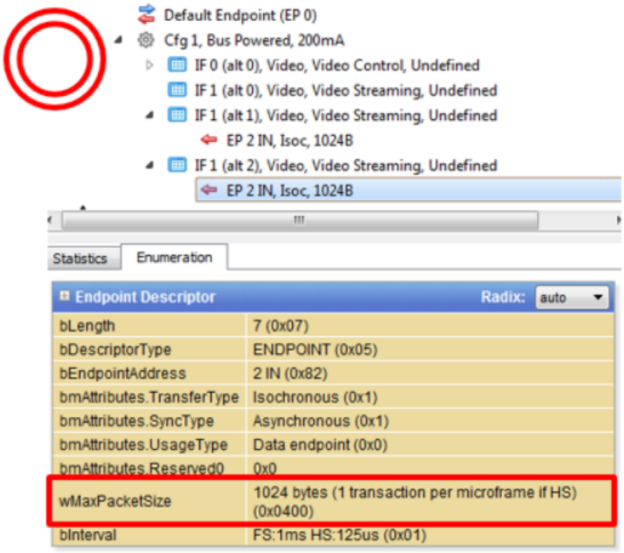
The information shown in the table above is valid if compiled with default USBX configurations.
The memory size of the USBX Classes in the table above are of the pre-built libraries and the following configuration was applied for the builds:UX_THREAD_STACK_SIZE: 512 (bytes) for S1 parts; 2048 (bytes) for the other parts
The USBX Host Video memory pools size may differ according to the type of video device attached to the board. There is no precise formula for memory size. A general idea on a typical USBX Video application is as follows:
(1) Device descriptor: The memory requirement for the device descriptor depends on the video camera in use. Some USB cameras can take 2K memory size while simpler cameras require far less memory for its device descriptors.
(2) End points: around 100 bytes for each end point. The number of end points depends on the device in use. (Could be 5 or more.)
(3) Transfer request buffer: 100 each. The USB control takes one transfer request; the number of transfer requests depends on the application.By default, the USBX video class creates 4 transfer requests.

USBX Host Class Video Module Limitations

To specify an Alt. setting in an interface in the UVC (USB video class) device, you may need to use the USBX API ux_host_class_video_ioctl() instead of ux_host_class_video_start(), specifying UX_HOST_CLASS_VIDEO_IOCTL_CHANNEL_START for the argument "ioctl_function". You also need to specify the argument parameter with setting the member .ux_host_class_video_parameter_channel_bandwidth_selection to match to the wMaxPacketSize of an isochronous endpoint. For instance, if .ux_host_class_video_parameter_channel_bandwidth_selection is set to 1024 for a UVC device with the device descriptor shown in the following figure, the IF1 Alt.1 will not be selected (since it requires high-bandwidth transfer). Instead, IF1 Alt.2 will be selected. For limitations of isochronous transfers, see section "Logic USBX Synergy Port Framework Limitations."



(this will not be selected)



(this will be selected)

Note

Currently, DTC is not supported by the host side driver (only DMAC is supported).

4.3.49.4 Including the USBX Host Class Video Module in an Application

This section describes how to include the USBX Host Class Video Module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the USBX Host Class Video Module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

USBX Host Class Video Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ux_host_class_video0 USBX Host Class Video	Threads	New Stack> X-Ware> USBX> Host > Classes > Video > USBX Host Class Video

When the USBX Host Class Video module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

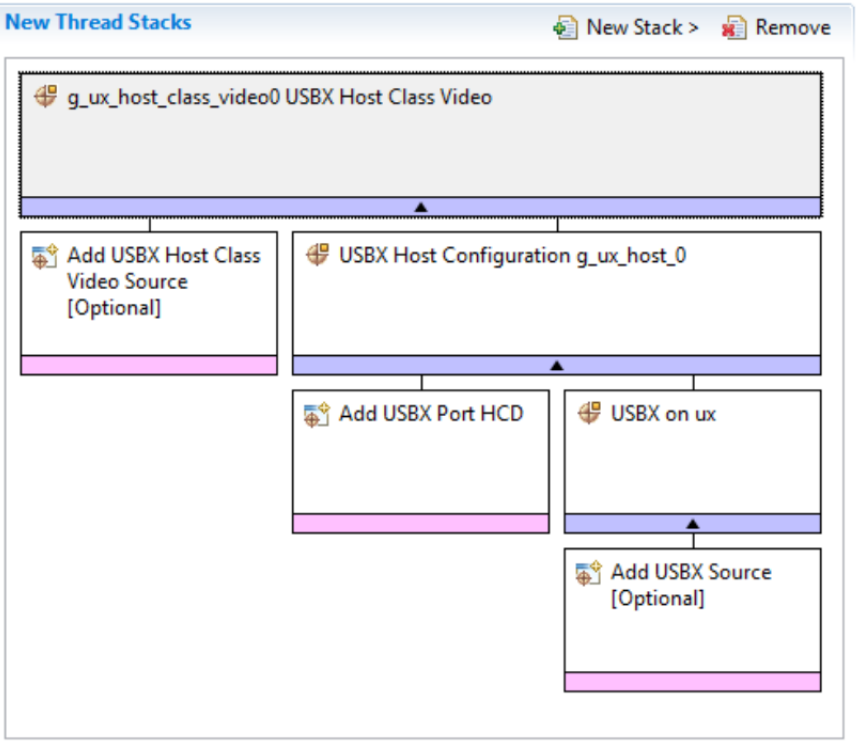


Figure 554: USBX Host Class Video Module Stack

4.3.49.5 Configuring the USBX Host Class Video Module

The USBX Host Class Video Module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the USBX Host Class Video Module

ISDE Property	Value	Description
Class Instance Name	g_ux_host_class_video0	Class instance name.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Note: Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the USBX Host Class Video Lower-Level Modules

The USBX Host Class Printer Module defines APIs, which are used to interact with the Printer interface. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

USBX Host Class PRINTER Module Summary

Function Name	Example API Call and Description
ux_host_class_printer_read	UINT ux_host_class_printer_read (UX_HOST_CLASS_PRINTER *printer, UCHAR *data_pointer, ULONG requested_length, ULONG *actual_length) This function reads from the printer interface. The call is blocking and only returns when there is either an error or when the transfer is complete. A read is allowed only on bi-directional printers.
ux_host_class_printer_write	UINT ux_host_class_printer_write (UX_HOST_CLASS_PRINTER *printer,UCHAR *data_pointer, ULONG requested_length,ULONG *actual_length) This function writes to the printer interface. The call is blocking and only returns when there is either an error or when the transfer is complete.
ux_host_class_printer_soft_reset	UINT ux_host_class_printer_soft_reset (UX_HOST_CLASS_PRINTER *printer) This function performs a soft reset to the printer
ux_host_class_printer_status_get	UINT ux_host_class_printer_status_get (UX_HOST_CLASS_PRINTER *printer,ULONG *printer_status) This function obtains the printer status. The printer status is similar to the LPT status (1284 standard).
_ux_host_class_printer_name_get	UINT _ux_host_class_printer_name_get(UX_HOST_CLASS_PRINTER *printer) This function obtains the Device ID string.

Note

for more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Return Values

Name	Description
UX_SUCCESS	This operation was successful.

UX_FUNCTION_NOT_SUPPORTED	Function not supported because the printer is not bi-directional.
UX_TRANSFER_TIMEOUT	Transfer timeout, reading or writing is incomplete, or reset not completed.
UX_MEMORY_INSUFFICIENT	Not enough memory to perform the operation.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

USBX Host Class Video Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48MHz operation. In the SSP configuration window, select the Clocks tab to view the clock-source setting.

USBX Host Class Video Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external devices. Select I/O pins and configure to the external device requirements. The following table lists the pin selection method within the SSP Configuration Window and the subsequent tables demonstrate the selection process using USB pins as an example.

Note

The selected operation mode determines what peripheral signals available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence
USBFS	Pins	Select Peripherals > Connectivity: USBFS> USBFS0
USBHS	Pins	Select Peripherals > Connectivity: USBHS> USBHS0

Note

The selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select device as the Operation Mode
USBDP	USBDP	USBDP pin
USBDM	USBDM	USBDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin

VBUSEN	None	VBUSEN pin
VBUS	None, P407 Default: P407	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID Pin
VCCUSB	VCCUSB	VCCUSB pin
VSSUSB	VSSUSB	VSSUSB pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select Device as the Operation Mode
USBHSDP	USBHSDP	USBHSDP pin
USBHSDM	USBHSDM	USBHSDM pin
OVRCURB	None	OVRCURB pin
OVRCURA	None	OVRCURA pin
VBUSEN	PB00	VBUSEN pin
VBUS	PB01	VBUS pin
EXICEN	None	EXICEN pin
ID	None	ID pin
USBHSRREF	USBHSRREF	USBHSRREF pin
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin
PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin
VCCUSBHS	VCCUSBHS	VCCUSBHS pin
VSS1USBHS	VSS1USBHS	VSS1USBHS pin
VSS2USBHS	VSS2USBHS	VSS2USBHS pin

Note

The example settings are for a project using the S7G2 Synergy MCU and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.3.49.6 Using the USBX Host Class Video Module in an Application

The configurator generates processing to create and register the USBX Host Class Video Module; however, communication must be done after the Host is connected to the host.

The typical steps in using the USBX Host Class Video Module in an application are:

1. Wait until the device is inserted using the tx_event_flags_get API function

2. Set the camera parameters using the ux_host_class_video_frame_parameters_set API function

3. Set the user callback function using the ux_host_class_video_transfer_callback_set API function

4. Get the maximum memory buffer size using the ux_host_class_video_max_payload_get API function

5. Start video transfer using the ux_host_class_video_start API function

6. Add a video buffer to the video device using the ux_host_class_video_transfer_buffer_add API function

7. Wait for a received data frame using the tx_semiphore_get API function

8. Add the video buffer back using the ux_host_class_video_transfer_buffer_add API function

9. Stop the video transfer using the ux_host_class_video_stop API function

These common steps are illustrated in a typical operational flow diagram in the following figure:

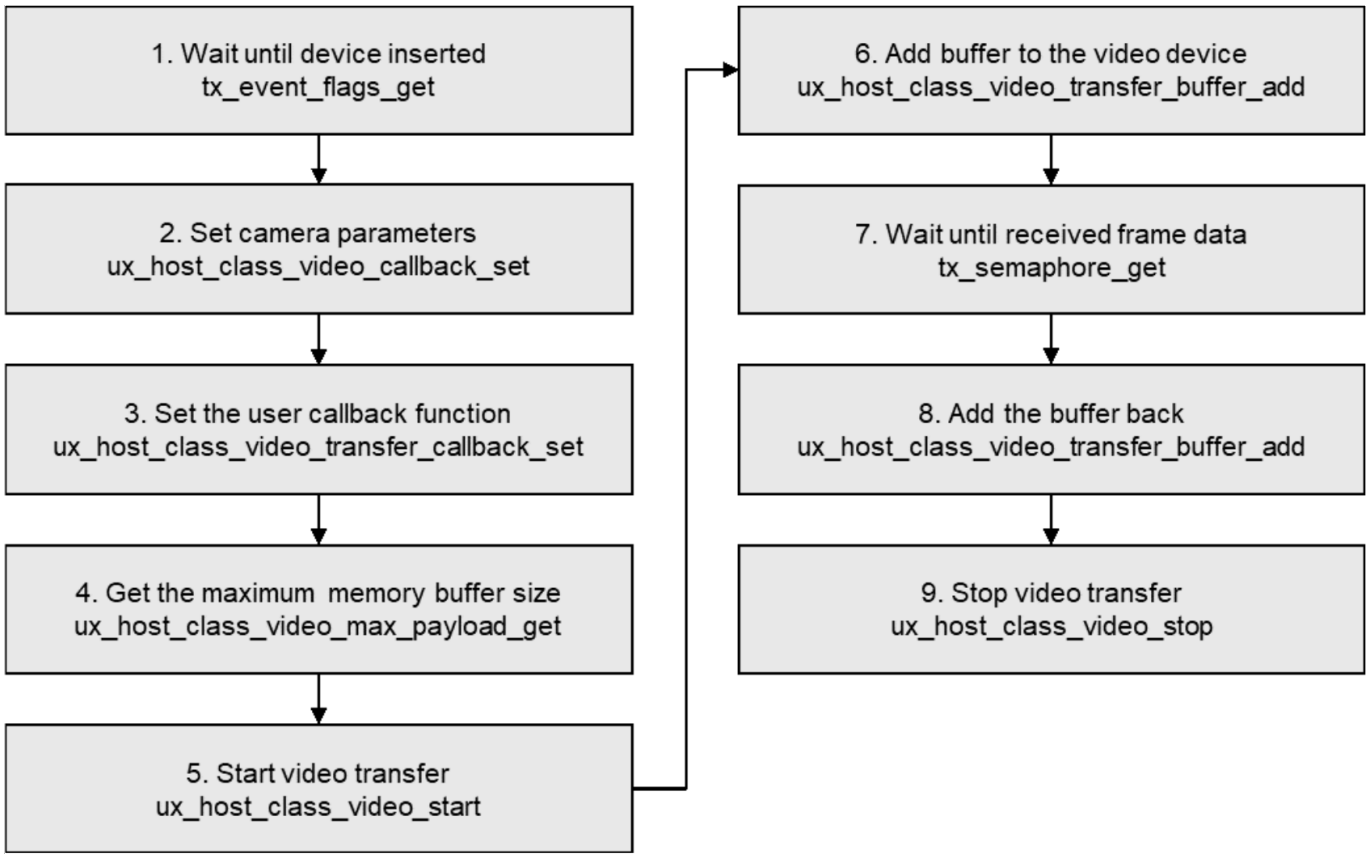

Figure 555: Flow Diagram of a Typical USBX Host Class Video Module Application

Detailed Description

All SSP code at every layer shares these common error codes.

Macro Definition Documentation

◆ SSP_CPP_HEADER

#define SSP_CPP_HEADER
Determine if a C++ compiler is being used. If so, ensure that standard C is used to process the API information.

◆ SSP_PARAMETER_NOT_USED

#define SSP_PARAMETER_NOT_USED (p) (void) ((p))
This macro is used to suppress compiler messages about a parameter not being used in a function. The nice thing about using this implementation is that it does not take any extra RAM or ROM.

Enumeration Type Documentation

◆ ssp_command_t

enum ssp_command_t
ioctl commands.

◆ ssp_err_t

enum ssp_err_t
Common error codes

typedef void	sf_adc_periodic_ctrl_t

Enumerations

enum	sf_adc_periodic_event_t { SF_ADC_PERIODIC_EVENT_NEW_DATA }

Detailed Description

RTOS-integrated ADC Periodic Framework Interface.

Summary

This is a ThreadX aware generic Periodic ADC sampling framework intended to be used to sample the ADC at periodic intervals, buffer the specified number of samples and then notify the application. The driver will use hardware triggers to allow for time-synchronous sampling. After initial configuration and the scan process is started, the framework uses a hardware timer to trigger an ADC scan in one-shot mode. Each scan can consist of one or more channels. When each scan is completed the ADC interrupt is intercepted by the DTC which moves the result of the scan into the user buffer. Each scan is defined as a sampling iteration and the number of samples generated for each scan will be equal to the number of channels if the channels are sequential eg: channels 1, 2, 3, 4. If the channels are not in sequence, eg: channels 1, 3, 4, 5, then the samples generated by each scan will also include data from the unused channels in between. Thus the second example here will result in 5 samples being stored to the user buffer each time even though only 4 channels have been configured for usage.

The user specifies the total number of sample iterations that need to occur before being notified. When the specified number of sampling iterations have occurred and the data for each iteration has been stored into the user buffer, the user is notified via the callback function with an index for the valid data in the buffer and an event indicating that sampling for the specified number of iterations is complete. Unless the user stops the scan process using the stop API call, the scan will continue to be triggered by the timer and data will be written into the user buffer which is treated by the framework as a circular buffer. For this reason, the buffer length must be at least twice the total number of samples that will be generate after all the iterations are completed. In the second example, where there are 5 samples generated for each iteration, if the sample count is set to 3, this will result in 15 samples being available in the buffer before the callback is called. Thus in this example, the buffer length must be set to 30 or larger. The name and length of the buffer is specified via the framework configuration structure.

#include <sf_adc_periodic_api.h>

Data Fields

adc_instance_t const *const	p_lower_lvl_adc Pointer to the ADC instance.
timer_instance_t const *const	p_lower_lvl_timer Pointer to the Timer instance.
transfer_instance_t const *const	p_lower_lvl_transfer Pointer to the Transfer instance.
adc_data_size_t *	p_data_buffer Pointer to the buffer that will store the samples.
bool	lower_level Used to check lower level driver (0 for ADC and 1 for SDADC)
uint32_t	data_buffer_length Length of the data buffer that will store the samples.
uint32_t	sample_count Samples per channel to be buffered before notifying the app.
elc_event_t	scan_trigger

	The hardware trigger that starts the ADC scan.
void(*	p_callback)(sf_adc_periodic_callback_args_t *p_args) Callback function.
void const *	p_context Placeholder for user data.
void const *	p_extend Extension parameter for hardware specific settings.

Detailed Description

Configuration for RTOS integrated ADC driver

The documentation for this struct was generated from the following file:

- sf_adc_periodic_api.h

sf_adc_periodic_api_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » ADC Periodic Framework Interface

#include <sf_adc_periodic_api.h>

Data Fields

ssp_err_t(*	open)(sf_adc_periodic_ctrl_t *const p_ctrl, sf_adc_periodic_cfg_t const *const p_cfg)
ssp_err_t(*	start)(sf_adc_periodic_ctrl_t *const p_ctrl)
ssp_err_t(*	stop)(sf_adc_periodic_ctrl_t *const p_ctrl)
ssp_err_t(*	close)(sf_adc_periodic_ctrl_t *const p_ctrl)
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

Framework Periodic ADC API structure. Implementations will use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_adc_periodic_api_t::close) (sf_adc_periodic_ctrl_t *const p_ctrl)

Releases channel mutex and closes channel at HAL layer.

Parameters

[in]	p_ctrl	Pointer to control block set in SF_ADC_PERIODIC_Open.

◆ open

ssp_err_t(* sf_adc_periodic_api_t::open) (sf_adc_periodic_ctrl_t *const p_ctrl, sf_adc_periodic_cfg_t const *const p_cfg)

Acquires mutex, then initializes driver at the HAL layer

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. Elements initialized here.
[in]	p_cfg	Pointer to configuration structure. All elements of the structure must be set by user.

◆ start

ssp_err_t(* sf_adc_periodic_api_t::start) (sf_adc_periodic_ctrl_t *const p_ctrl)

Starts the scan.

Warning

The driver will enable the ADC to be triggered via timer event; there will be a time delay from the time this function is called to the time the hardware timer count expires and triggers the scan.

Parameters

[in]	p_ctrl	Pointer to control block set in SF_ADC_PERIODIC_Open.

◆ stop

ssp_err_t(* sf_adc_periodic_api_t::stop) (sf_adc_periodic_ctrl_t *const p_ctrl)

Stops the hardware trigger (timer) from triggering any more ADC scans.

Parameters

[in]	p_ctrl	Pointer to control block set in SF_ADC_PERIODIC_Open.

◆ versionGet

ssp_err_t(* sf_adc_periodic_api_t::versionGet) (ssp_version_t *const p_version)

Gets version and stores it in provided pointer p_version.

Parameters

[out]	p_version	Code and API version used.

The documentation for this struct was generated from the following file:

- sf_adc_periodic_api.h

sf_adc_periodic_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » ADC Periodic Framework Interface

#include <sf_adc_periodic_api.h>

Data Fields

sf_adc_periodic_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_adc_periodic_cfg_t const *	p_cfg Pointer to the configuration structure for this instance.

sf_adc_periodic_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

The documentation for this struct was generated from the following file:

- sf_adc_periodic_api.h

SF_AUDIO_PLAYBACK_STATUS_PLAYING,
SF_AUDIO_PLAYBACK_STATUS_WAITING }

Detailed Description

RTOS-integrated Audio Framework Interface.

Summary

The Audio Interface is a ThreadX-aware Audio Framework Interface. The Interface is implemented by the Audio Framework using the Timer driver, the Transfer driver, and a choice of the following drivers for playback: DAC, PWM (to be implemented), or I2S (to be implemented).

Interfaces used:

- Transfer Interface
- DAC Interface
- Timer Interface

Related SSP architecture topics:

- SSP Interfaces
- SSP Predefined Layers
- Using SSP Modules

Audio Framework Interface description: Audio Playback Framework

Macro Definition Documentation

◆ SF_AUDIO_PLAYBACK_API_VERSION_MAJOR

#define SF_AUDIO_PLAYBACK_API_VERSION_MAJOR (2U)
Version of the API defined in this file

◆ SF_AUDIO_PLAYBACK_MAX_VOLUME

#define SF_AUDIO_PLAYBACK_MAX_VOLUME (255)
Macro defining the maximum volume.

◆ SF_AUDIO_PLAYBACK_MESSAGE_WORDS

#define SF_AUDIO_PLAYBACK_MESSAGE_WORDS ((sizeof(sf_message_payload_audio_t) + 3) / 4)
Audio playback message size in 4 byte words, rounded up.

Typedef Documentation

◆ sf_audio_playback_common_ctrl_t

typedef void sf_audio_playback_common_ctrl_t

Audio playback common control block. Allocate an instance specific control block to pass to sf_audio_playback_api_t::open in sf_audio_playback_cfg_t.

Implemented as

- sf_audio_playback_common_instance_ctrl_t

◆ sf_audio_playback_ctrl_t

typedef void sf_audio_playback_ctrl_t

Audio playback framework control block. Allocate an instance specific control block to pass into the audio playback framework API calls.

Implemented as

- sf_audio_playback_instance_ctrl_t

Enumeration Type Documentation

◆ sf_audio_playback_status_t

enum sf_audio_playback_status_t

Audio playback status.

Enumerator	
SF_AUDIO_PLAYBACK_STATUS_STOPPED	Stream is available to be used.
SF_AUDIO_PLAYBACK_STATUS_PAUSED	Stream is paused.
SF_AUDIO_PLAYBACK_STATUS_PLAYING	Stream is playing data.
SF_AUDIO_PLAYBACK_STATUS_WAITING	Stream is between packets, waiting for the next data message.

sf_audio_playback_data_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Audio Framework Interface

#include <sf_audio_playback_api.h>

Data Fields

sf_message_header_t	header Required common members of messaging framework payloads.
sf_audio_playback_data_type_t	type Data type. Must be uncompressed.
uint32_t	size_bytes Size of data in bytes.
void const *	p_data Pointer to data. Data start address must be 4-byte aligned.
UINT	loop_timeout
bool	stream_end

Detailed Description

Audio data for playback.

Field Documentation

◆ loop_timeout

UINT sf_audio_playback_data_t::loop_timeout
ThreadX timeout, select TX_NO_WAIT to play the entire buffer once, TX_WAIT_FOREVER to loop until SF_AUDIO_PLAYBACK_Pause is called from another thread, or any timeout value from (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts to loop until the tick counts expire.

◆ stream_end

bool sf_audio_playback_data_t::stream_end
This releases ownership of the stream and allows other threads to post data. Set to true if not more data will be sent as a part of this logical bitstream. Set to false if more packets are being prepared.

The documentation for this struct was generated from the following file:

- sf_audio_playback_api.h

sf_audio_playback_common_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Audio Framework Interface

#include <sf_audio_playback_api.h>

Data Fields

UINT	priority Priority of the audio playback thread.
sf_audio_playback_hw_instance_t const *	p_lower_lvl_hw Hardware instance.
sf_message_instance_t const *	p_message
TX_QUEUE *	p_queue
void const *	p_extend

Detailed Description

Common configuration for RTOS integrated audio framework. Shared by all streams.

Field Documentation

◆ p_extend

void const* sf_audio_playback_common_cfg_t::p_extend
Implementation specific extension configuration.

◆ p_message

sf_message_instance_t const* sf_audio_playback_common_cfg_t::p_message
Pointer to messaging framework instance used to post audio messages.

◆ p_queue

TX_QUEUE* sf_audio_playback_common_cfg_t::p_queue
Pointer to the messaging framework queue specified for this audio stream. Must be subscribed to the SF_MESSAGE_EVENT_CLASS_AUDIO event class.

The documentation for this struct was generated from the following file:

- sf_audio_playback_api.h

sf_audio_playback_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Audio Framework Interface

#include <sf_audio_playback_api.h>

Data Fields

void(*	p_callback)(sf_message_callback_args_t *p_args)
sf_audio_playback_common_ctrl_t *	p_common_ctrl
sf_audio_playback_common_cfg_t const *	p_common_cfg
uint8_t	class_instance Class instance used to identify the stream to the messaging framework.

Detailed Description

Per stream configuration for RTOS integrated audio framework.

Field Documentation

◆ p_callback

void(* sf_audio_playback_cfg_t::p_callback) (sf_message_callback_args_t *p_args)
Callback called when playback of a buffer passed to sf_audio_playback_api_t::start is complete. Set to NULL for no callback.

◆ p_common_cfg

sf_audio_playback_common_cfg_t const* sf_audio_playback_cfg_t::p_common_cfg
Pointer to common configurations shared by all streams using the same hardware.

◆ p_common_ctrl

sf_audio_playback_common_ctrl_t* sf_audio_playback_cfg_t::p_common_ctrl
Pointer to the hardware control block used by this stream.

Detailed Description

Audio playback API structure. Audio playback implementations use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_audio_playback_api_t::close) (sf_audio_playback_ctrl_t *const p_ctrl)

The close API handles cleans up internal driver data.

Implemented as

- SF_AUDIO_PLAYBACK_Close()

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for audio driver.

◆ open

ssp_err_t(* sf_audio_playback_api_t::open) (sf_audio_playback_ctrl_t *const p_ctrl, sf_audio_playback_cfg_t const *const p_cfg)

Configure the audio framework by creating a thread for audio playback and configuring HAL layer drivers used. This function must be called before any other audio functions.

Implemented as

- SF_AUDIO_PLAYBACK_Open()

Parameters

[in,out]	p_ctrl	Pointer to a device structure allocated by user. The device control structure is initialized in this function.
[in]	p_cfg	Pointer to configuration structure. All elements of the structure must be set by user.

◆ pause

ssp_err_t(* sf_audio_playback_api_t::pause) (sf_audio_playback_ctrl_t *const p_ctrl)

Pause audio playback. This stops the peripheral that triggers the DMA/DTC transfer and posts a flag to notify SF_AUDIO_PLAYBACK_Start() to pause any playback in progress.

Implemented as

- SF_AUDIO_PLAYBACK_Pause()

Precondition

Call SF_AUDIO_PLAYBACK_Start() before using this function. Calling SF_AUDIO_PLAYBACK_Pause() before SF_AUDIO_PLAYBACK_Start() has no effect and does not return an error code.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for audio driver.

◆ resume

ssp_err_t(* sf_audio_playback_api_t::resume) (sf_audio_playback_ctrl_t *const p_ctrl)

Resume audio playback. Posts a flag to notify SF_AUDIO_PLAYBACK_Start() to restart the peripheral that triggers the DMA/DTC transfer.

Implemented as

- SF_AUDIO_PLAYBACK_Resume()

Precondition

Call SF_AUDIO_PLAYBACK_Pause() before using this function. Calling SF_AUDIO_PLAYBACK_Resume() before SF_AUDIO_PLAYBACK_Pause() has no effect and does not return an error code.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for audio driver.

◆ start

ssp_err_t(* sf_audio_playback_api_t::start) (sf_audio_playback_ctrl_t *const p_ctrl, sf_audio_playback_data_t *const p_data, UINT const timeout)

Play audio. Currently only 16-bit mono PCM buffers are supported.

Implemented as

- SF_AUDIO_PLAYBACK_Start()

Precondition

Call SF_MESSAGE_Open to configure the messaging framework control block and queues with the parameters specified in sf_audio_playback_cfg_t::p_message and sf_audio_playback_cfg_t::p_queue.

Parameters

[in,out]	p_ctrl	Pointer to device control block initialized in Open call for audio driver.
[in]	p_data	Pointer to data, description, timeout values, and synchronization options.
[in]	timeout	ThreadX timeout, represents the maximum amount of time to wait to post to the audio queue. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout values from 0x00000001 through 0xFFFFFFFE in ThreadX tick counts.

◆ stop

ssp_err_t(* sf_audio_playback_api_t::stop) (sf_audio_playback_ctrl_t *const p_ctrl)

Stop audio playback. Causes SF_AUDIO_PLAYBACK_Start() halt playback and return.

Implemented as

- SF_AUDIO_PLAYBACK_Stop()

Precondition

Call SF_AUDIO_PLAYBACK_Start() before using this function. Calling SF_AUDIO_PLAYBACK_Stop() before SF_AUDIO_PLAYBACK_Start() has no effect and does not return an error code.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for audio driver.

◆ versionGet

ssp_err_t(* sf_audio_playback_api_t::versionGet) (ssp_version_t *const p_version)

Store version information in provided pointer.

Implemented as

- SF_AUDIO_PLAYBACK_VersionGet()

Parameters

[in]	p_version	Pointer to device control block initialized in Open call for UART driver.

◆ volumeSet

ssp_err_t(* sf_audio_playback_api_t::volumeSet) (sf_audio_playback_ctrl_t *const p_ctrl, uint8_t const volume)

Set software volume control. Software volume control is applied globally to all streams on the hardware.

Implemented as

- SF_AUDIO_PLAYBACK_VolumeSet()

Warning

Software volume control reduces resolution and may require extra memory and processing bandwidth.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for audio driver.
[in]	volume	Volume level requested. Valid range is from 0 (muted, which will stop playback) to 255 (maximum volume, default on open).

The documentation for this struct was generated from the following file:

- sf_audio_playback_api.h

sf_audio_playback_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Audio Framework Interface

#include <sf_audio_playback_api.h>

Data Fields

sf_audio_playback_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_audio_playback_cfg_t const *	p_cfg Pointer to the configuration structure for this instance.

sf_audio_playback_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

The documentation for this struct was generated from the following file:

Enumerations

enum	sf_audio_playback_hw_event_t { SF_AUDIO_PLAYBACK_HW_EVENT_PLAYBACK_COMPLETE, SF_AUDIO_PLAYBACK_HW_EVENT_ERROR }

Detailed Description

RTOS-integrated Audio Playback Framework Interface.

Summary

Audio playback driver to play buffers of audio data.

Implemented by: DAC Audio Playback Framework

Audio Framework Interface description: Audio Playback Framework

Typedef Documentation

◆ sf_audio_playback_hw_ctrl_t

typedef void sf_audio_playback_hw_ctrl_t
Audio playback hardware control block. Allocate an instance specific control block to pass into the audio playback hardware API calls. **Implemented as** ◦ sf_audio_playback_hw_dac_instance_ctrl_t ◦ sf_audio_playback_hw_i2s_instance_ctrl_t

Enumeration Type Documentation

◆ sf_audio_playback_hw_event_t

enum sf_audio_playback_hw_event_t	
Callback event types.	
Enumerator	
SF_AUDIO_PLAYBACK_HW_EVENT_PLAYBACK_COMPLETE	Audio playback complete event.
SF_AUDIO_PLAYBACK_HW_EVENT_ERROR	Audio playback error event.

sf_audio_playback_data_type_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Audio Playback Framework Interface

#include <sf_audio_playback_hw_api.h>

Data Fields

uint8_t	scale_bits_max Maximum data resolution in bits.

bool	is_signed Set to 1 for signed samples, or 0 for unsigned samples.

Detailed Description

Audio data type.

The documentation for this struct was generated from the following file:

- sf_audio_playback_hw_api.h

sf_audio_playback_hw_callback_args_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Audio Playback Framework Interface

#include <sf_audio_playback_hw_api.h>

Data Fields

void *	p_context
sf_audio_playback_hw_event_t	event Event that triggered the callback.

Detailed Description

Callback function parameter data

Field Documentation

◆ p_context

void* sf_audio_playback_hw_callback_args_t::p_context
Placeholder for user data. Set in sf_audio_playback_hw_api_t::open function in sf_audio_playback_hw_cfg_t.

The documentation for this struct was generated from the following file:

- sf_audio_playback_hw_api.h

sf_audio_playback_hw_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Audio Playback Framework Interface

#include <sf_audio_playback_hw_api.h>

Data Fields

void(*	p_callback)(sf_audio_playback_hw_callback_args_t *p_args)
void *	p_context
void const *	p_extend Hardware dependent configuration.

Detailed Description

Audio playback driver configuration.

Field Documentation

◆ p_callback

void(* sf_audio_playback_hw_cfg_t::p_callback) (sf_audio_playback_hw_callback_args_t *p_args)
Callback called when play is complete. Set to NULL for no callback.

◆ p_context

void* sf_audio_playback_hw_cfg_t::p_context
Placeholder for user data. Passed to the user callback in sf_audio_playback_hw_callback_args_t.

The documentation for this struct was generated from the following file:

ssp_err_t(*	close)(sf_audio_playback_hw_ctrl_t *const p_ctrl)
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

Audio playback API definition.

Field Documentation

◆ close

ssp_err_t(* sf_audio_playback_hw_api_t::close) (sf_audio_playback_hw_ctrl_t *const p_ctrl)

Close the audio driver.

Implemented as

- SF_AUDIO_PLAYBACK_HW_DAC_Close()

Parameters

[in]	p_ctrl	Pointer to control block initialized in sf_audio_playback_hw_api_t::open.

◆ dataTypeGet

ssp_err_t(* sf_audio_playback_hw_api_t::dataTypeGet) (sf_audio_playback_hw_ctrl_t *const p_ctrl, sf_audio_playback_data_type_t *const p_data_type)

Stores expected data type in provided pointer p_data_type.

Implemented as

- SF_AUDIO_PLAYBACK_HW_DAC_DataTypeGet()

Parameters

[in]	p_ctrl	Pointer to control block initialized in sf_audio_playback_hw_api_t::open.
[out]	p_data_type	Pointer to audio sample data type required by hardware.

◆ open

ssp_err_t(* sf_audio_playback_hw_api_t::open) (sf_audio_playback_hw_ctrl_t *const p_ctrl, sf_audio_playback_hw_cfg_t const *const p_cfg)

Open a device channel for read/write and control.

Implemented as

- SF_AUDIO_PLAYBACK_HW_DAC_Open()

Parameters

[in,out]	p_ctrl	Pointer to memory allocated for control block.
[in]	p_cfg	Pointer to the hardware configurations.

◆ play

ssp_err_t(* sf_audio_playback_hw_api_t::play) (sf_audio_playback_hw_ctrl_t *const p_ctrl, int16_t const *const p_buffer, uint32_t length)

Play audio buffer.

Implemented as

- SF_AUDIO_PLAYBACK_HW_DAC_Play()

Parameters

[in]	p_ctrl	Pointer to control block initialized in sf_audio_playback_hw_api_t::open.
[in]	p_buffer	Pointer to buffer with PCM samples to play. Data must be scaled for audio playback hardware.
[in]	length	Length of data in p_buffer.

◆ start

ssp_err_t(* sf_audio_playback_hw_api_t::start) (sf_audio_playback_hw_ctrl_t *const p_ctrl)

Start audio playback hardware.

Implemented as

- SF_AUDIO_PLAYBACK_HW_DAC_Start()

Parameters

[in]	p_ctrl	Pointer to control block initialized in sf_audio_playback_hw_api_t::open.

◆ stop

ssp_err_t(* sf_audio_playback_hw_api_t::stop) (sf_audio_playback_hw_ctrl_t *const p_ctrl)
Stop audio playback hardware. **Implemented as** ◦ SF_AUDIO_PLAYBACK_HW_DAC_Stop() **Parameters** [in] p_ctrl — Pointer to control block initialized in sf_audio_playback_hw_api_t::open.

◆ versionGet

ssp_err_t(* sf_audio_playback_hw_api_t::versionGet) (ssp_version_t *const p_version)
Return the version of the driver. **Implemented as** ◦ SF_AUDIO_PLAYBACK_HW_DAC_VersionGet() **Parameters** [out] p_version — Pointer to variable that will be populated with version information.

enum	sf_audio_record_event_t { SF_AUDIO_RECORD_EVENT_NEW_DATA }

Detailed Description

RTOS-integrated Audio Recording Framework Interface.

Summary

The Audio Record Interface is a ThreadX-aware Interface for Audio Recording. The Interface is implemented by the ADC Audio recording Framework using the ADC periodic Framework driver for recording. The interface is implemented by the I2S Audio recording Framework using the I2S driver for recording.

Interfaces used:

- ADC periodic Framework
- I2S Interface

Related SSP architecture topics:

- SSP Interfaces
- SSP Predefined Layers
- Using SSP Modules

Macro Definition Documentation

◆ SF_AUDIO_RECORD_API_VERSION_MAJOR

#define SF_AUDIO_RECORD_API_VERSION_MAJOR (2U)
Version of the API defined in this file

Typedef Documentation

◆ sf_audio_record_ctrl_t

typedef void sf_audio_record_ctrl_t
Audio record framework control block. Allocate an instance specific control block to pass into the audio record framework API calls. **Implemented as** ◦ sf_audio_record_adc_instance_ctrl_t ◦ sf_audio_record_i2s_instance_ctrl_t

Enumeration Type Documentation

◆ sf_audio_record_channel_t

enum sf_audio_record_channel_t	
Definition of audio recording mode.	
Enumerator	
SF_AUDIO_RECORD_CHANNEL_MONO	Support Mono Channel.
SF_AUDIO_RECORD_CHANNEL_STEREO	Support Stereo Channel.

◆ sf_audio_record_data_size_t

enum sf_audio_record_data_size_t	
Definition of audio recording data sample size.	
Enumerator	
SF_AUDIO_RECORD_DATA_SIZE_8BIT	data width in the sample is 8bit
SF_AUDIO_RECORD_DATA_SIZE_16BIT	data width in the sample is 16bit

◆ sf_audio_record_event_t

enum sf_audio_record_event_t	
Definition of events for audio recording.	
Enumerator	
SF_AUDIO_RECORD_EVENT_NEW_DATA	New data is available in the buffer.

#include <sf_audio_record_api.h>

Data Fields

sf_audio_record_data_size_t capture_data_size

	Size of data in the sample 8 or 16 bit.
uint32_t	sampling_rate_hz Sampling rate for audio capture.
void *	p_capture_data_buffer
uint32_t	capture_data_buffer_size
uint32_t	sample_count
void(*	p_callback)(sf_audio_record_callback_args_t *p_args) Callback function.
void const *	p_context Placeholder for user data.
void const *	p_extend

Detailed Description

Configuration for audio recording framework

Field Documentation

◆ capture_data_buffer_size

uint32_t sf_audio_record_cfg_t::capture_data_buffer_size
total size of buffer configured by user to store samples

◆ p_capture_data_buffer

void* sf_audio_record_cfg_t::p_capture_data_buffer
Pointer to the buffer that will store the samples

◆ p_extend

void const* sf_audio_record_cfg_t::p_extend
Extension parameter for hardware specific settings.

◆ sample_count

uint32_t sf_audio_record_cfg_t::sample_count
Samples per channel to be buffered before notifying the user via callback

Detailed Description

Framework Audio Recording API structure. Implementations will use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_audio_record_api_t::close) (sf_audio_record_ctrl_t *const p_ctrl)

Releases channel mutex and closes channel at HAL layer.

Implemented as

- SF_AUDIO_RECORD_ADC_Close()
- SF_AUDIO_RECORD_I2S_Close()

Parameters

[in]	p_ctrl	Pointer to control block.

◆ infoGet

ssp_err_t(* sf_audio_record_api_t::infoGet) (sf_audio_record_ctrl_t *const p_ctrl, sf_audio_record_info_t *p_info)

Gets channel information(Mono/Stereo).

Implemented as

- SF_AUDIO_RECORD_ADC_InfoGet()
- SF_AUDIO_RECORD_I2S_InfoGet()

Parameters

[in]	p_ctrl	Pointer to control block.
[out]	p_info	Pointer to information block.

◆ open

ssp_err_t(* sf_audio_record_api_t::open) (sf_audio_record_ctrl_t *const p_ctrl, sf_audio_record_cfg_t const *const p_cfg)

Initializes audio recording framework.

Implemented as

- SF_AUDIO_RECORD_ADC_Open()
- SF_AUDIO_RECORD_I2S_Open()

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. Elements initialized here.
[in]	p_cfg	Pointer to configuration structure. All elements of the structure must be set by user.

◆ start

ssp_err_t(* sf_audio_record_api_t::start) (sf_audio_record_ctrl_t *const p_ctrl)

Starts audio recording.

Implemented as

- SF_AUDIO_RECORD_ADC_Start()
- SF_AUDIO_RECORD_I2S_Start()

Parameters

[in]	p_ctrl	Pointer to control block set

◆ stop

ssp_err_t(* sf_audio_record_api_t::stop) (sf_audio_record_ctrl_t *const p_ctrl)

Stops audio recording.

Implemented as

- SF_AUDIO_RECORD_ADC_Stop()
- SF_AUDIO_RECORD_I2S_Stop()

Parameters

[in]	p_ctrl	Pointer to control block.

◆ versionGet

ssp_err_t(* sf_audio_record_api_t::versionGet) (ssp_version_t *const p_version)
Gets version and stores it in provided pointer p_version. **Implemented as** ◦ SF_AUDIO_RECORD_ADC_VersionGet() ◦ SF_AUDIO_RECORD_I2S_VersionGet() **Parameters** [out] p_version Code and API version used.

The documentation for this struct was generated from the following file:

Detailed Description

RTOS-integrated SF BLE Framework Interface.

Summary

This SSP Interface provides access to the ThreadX-aware SF BLE Framework.

Macro Definition Documentation

◆ SF_BLE_ADV_DATA_LEN

#define SF_BLE_ADV_DATA_LEN (0x1F)
BLE Advertising Data Length

◆ SF_BLE_API_VERSION_MAJOR

#define SF_BLE_API_VERSION_MAJOR (2U)
Major Version of the API defined in this file

◆ SF_BLE_API_VERSION_MINOR

#define SF_BLE_API_VERSION_MINOR (0U)
Minor Version of the API defined in this file

◆ SF_BLE_GATT_CHAR_DECLARE

#define SF_BLE_GATT_CHAR_DECLARE (0x2803U)
BLE GATT Declare Characteristics

◆ SF_BLE_GATT_INCLUDE_SERVICE

#define SF_BLE_GATT_INCLUDE_SERVICE (0x2802U)
BLE GATT Service type Included

◆ SF_BLE_GATT_LEN_UNDEF

#define SF_BLE_GATT_LEN_UNDEF (0xFF)
Variable length characteristic value which can not be defined

◆ SF_BLE_GATT_PRI_SERVICE

#define SF_BLE_GATT_PRI_SERVICE (0x2800U)
BLE GATT Service type Primary

◆ SF_BLE_MAX_CHAR_UUID_READ_CNT

#define SF_BLE_MAX_CHAR_UUID_READ_CNT (10U)
Maximum characteristics count in result of characteristic read by UUID

◆ SF_BLE_MAX_MULTI_CHAR_READ_CNT

#define SF_BLE_MAX_MULTI_CHAR_READ_CNT (4U)
Maximum characteristics count for multiple read

◆ SF_BLE_TX_POWER_CONNECTION_HANDLE

#define SF_BLE_TX_POWER_CONNECTION_HANDLE (0xFFFFU)
BLE connection handle value when TX power is set

Typedef Documentation

◆ sf_ble_callback_t

typedef void(* sf_ble_callback_t) (sf_ble_event_info_t *ev)
BLE Callback Type

◆ sf_ble_conn_handle_t

typedef uint16_t sf_ble_conn_handle_t
BLE Connection Handle

Enumeration Type Documentation

◆ sf_ble_addr_type_t

enum sf_ble_addr_type_t	
BLE address type	
Enumerator	
SF_BLE_ADDR_TYPE_PUBLIC	BLE address type public.
SF_BLE_ADDR_TYPE_RANDOM	BLE address type random.

◆ sf_ble_adv_chnl_map_t

enum sf_ble_adv_chnl_map_t	
BLE advertisement channel map	
Enumerator	
SF_BLE_ADV_CHNL_37	Enable channel 37 use.
SF_BLE_ADV_CHNL_38	Enable channel 38 use.
SF_BLE_ADV_CHNL_39	Enable channel 39 use.
SF_BLE_ADV_CHNL_ALL_CHANNELS	all channels(37, 38 and 39) enabled

◆ sf_ble_adv_event_type_t

enum sf_ble_adv_event_type_t	
BLE advertising event type	
Enumerator	
SF_BLE_ADV_EVENT_TYPE_CONN_UND_ADV	Connectable undirected advertising.
SF_BLE_ADV_EVENT_TYPE_CONN_DIR_ADV	Connectable directed advertising.
SF_BLE_ADV_EVENT_TYPE_SCANNABLE_UND_ADV	Scannable undirected advertising.
SF_BLE_ADV_EVENT_TYPE_NON_CONN_UND_ADV	Non connectable undirected advertising.
SF_BLE_ADV_EVENT_TYPE_SCAN_RESPONSE	Scan response.

◆ sf_ble_adv_filt_type_t

enum sf_ble_adv_filt_type_t	
BLE advertisement filter type	
Enumerator	
SF_BLE_ADV_FILT_TYPE_ALLOW_ALL	Filter type allow all.
SF_BLE_ADV_FILT_TYPE_ALLOW_SCAN_WLIST_CON_ANY	Filter type scan only whitelist entries, connect to any.
SF_BLE_ADV_FILT_TYPE_ALLOW_SCAN_ANY_CON_WLIST	Filter type scan any, connect to whitelist entries only.
SF_BLE_ADV_FILT_TYPE_ALLOW_WLIST_ONLY	Filter type allow whitelist only for both scan and connection.

◆ sf_ble_adv_type_t

enum sf_ble_adv_type_t	
BLE advertisement type	
Enumerator	
SF_BLE_ADV_TYPE_CONN_UNDIR	Connectable Undirected advertising.
SF_BLE_ADV_TYPE_CONN_DIR_HIGH_DUTY	Connectable high duty cycle directed advertising.
SF_BLE_ADV_TYPE_DISC_UNDIR	Discoverable undirected advertising.
SF_BLE_ADV_TYPE_NONCONN_UNDIR	Non-connectable undirected advertising.
SF_BLE_ADV_TYPE_CONN_DIR_LOW_DUTY	Connectable low duty cycle directed advertising.

◆ sf_ble_attribute_error_code_t

enum sf_ble_attribute_error_code_t	
BLE Attribute write response code	
Enumerator	
SF_BLE_ATTRIBUTE_ERR_SUCCESS	Success.
SF_BLE_ATTRIBUTE_ERR_INVALID_HANDLE	Invalid handle.
SF_BLE_ATTRIBUTE_ERR_WRITE_NOT_PERMITTED	Writing is not permitted.
SF_BLE_ATTRIBUTE_ERR_INSUFF_AUTHEN	Authentication required for the request.
SF_BLE_ATTRIBUTE_ERR_REQUEST_NOT_SUPPORTED	Unsupported request.
SF_BLE_ATTRIBUTE_ERR_INVALID_OFFSET	Invalid offset.
SF_BLE_ATTRIBUTE_ERR_INSUFF_AUTHOR	Authorization required for the request.
SF_BLE_ATTRIBUTE_ERR_ATTRIBUTE_NOT_FOUND	The attribute could not be found.
SF_BLE_ATTRIBUTE_ERR_ATTRIBUTE_NOT_LONG	The attribute is not long enough.
SF_BLE_ATTRIBUTE_ERR_INVALID_ATTRIBUTE_VAL_LEN	Invalid attribute value size.
SF_BLE_ATTRIBUTE_ERR_INSUFF_ENC	Encryption required for the request.
SF_BLE_ATTRIBUTE_ERR_OUT_OF_RANGE	Out of Range.

◆ sf_ble_auth_type_t

enum sf_ble_auth_type_t	
BLE security authorization requirement	
Enumerator	
SF_BLE_AUTH_TYPE_NONE	No Security.
SF_BLE_AUTH_TYPE_UNAUTHENTICATED_NO_MITM	No MITM.
SF_BLE_AUTH_TYPE_AUTHENTICATED_MITM	MITM Protected.

◆ sf_ble_bonding_mode_t

enum sf_ble_bonding_mode_t	
BLE bonding mode	
Enumerator	
SF_BLE_BONDING_MODE_NONBONDABLE	BLE bonding not supported.
SF_BLE_BONDING_MODE_BONDABLE	BLE bonding supported.

◆ sf_ble_char_attr_permissions_t

enum sf_ble_char_attr_permissions_t	
BLE GATT Attribute characteristics permission	
Enumerator	
SF_BLE_ATT_PERMISSIONS_ALLACCESS	Full access.
SF_BLE_ATT_PERMISSIONS_READ_AUTHENTICATION	Read with authentication.
SF_BLE_ATT_PERMISSIONS_READ_ENCRYPTION	Read with encryption.
SF_BLE_ATT_PERMISSIONS_READ_AUTHORIZATION	Read with authorization.
SF_BLE_ATT_PERMISSIONS_READ_FORBIDDEN	Read forbidden.
SF_BLE_ATT_PERMISSIONS_WRITE_AUTHENTICATION	Write with authentication.
SF_BLE_ATT_PERMISSIONS_WRITE_ENCRYPTION	Write with encryption.
SF_BLE_ATT_PERMISSIONS_WRITE_AUTHORIZATION	Write with authorization.
SF_BLE_ATT_PERMISSIONS_WRITE_FORBIDDEN	Write forbidden.
SF_BLE_ATT_PERMISSIONS_NOACCESS	No access.

◆ sf_ble_char_discovery_t

enum sf_ble_char_discovery_t	
Characteristics discovery type	
Enumerator	
SF_BLE_CHAR_DISCOVERY_ALL	Discover all characteristics.
SF_BLE_CHAR_DISCOVERY_UUID	Discover characteristics by UUID.

◆ sf_ble_char_property_t

enum sf_ble_char_property_t	
Characteristic property	
Enumerator	
SF_BLE_CHAR_PROPERTY_BCAST	Permits broadcasts of the Characteristic Value.
SF_BLE_CHAR_PROPERTY_RD	Permits reads of the Characteristic Value.
SF_BLE_CHAR_PROPERTY_WR_NO_RESP	Permits writes of the Characteristic Value without response.
SF_BLE_CHAR_PROPERTY_WR	Permits writes of the Characteristic Value with response.
SF_BLE_CHAR_PROPERTY_NTF	Permits notifications of the Characteristic Value without acknowledgment.
SF_BLE_CHAR_PROPERTY_IND	Permits indications of a Characteristic Value with acknowledgment.
SF_BLE_CHAR_PROPERTY_AUTH	Permits signed writes to the Characteristic Value.
SF_BLE_CHAR_PROPERTY_EXT_PROP	Additional characteristic properties.

◆ sf_ble_char_read_t

enum sf_ble_char_read_t	
Characteristics read type	
Enumerator	
SF_BLE_CHAR_READ_BY_HANDLE	Read single characteristic by handle.
SF_BLE_CHAR_READ_BY_UUID	Read single characteristic by UUID.
SF_BLE_CHAR_READ_LONG_BY_HANDLE	Read single long characteristic by handle.
SF_BLE_CHAR_DESC_READ_BY_HANDLE	Read single characteristic descriptor by handle.
SF_BLE_CHAR_DESC_READ_LONG_BY_HANDLE	Read single long characteristic descriptor by handle.
SF_BLE_CHAR_READ_MULTIPLE_BY_HANDLES	Read multiple characteristics by handles.

◆ sf_ble_char_write_t

enum sf_ble_char_write_t	
Characteristics write type	
Enumerator	
SF_BLE_CHAR_WRITE_NO_RESPONSE	Write single characteristic with no response.
SF_BLE_CHAR_WRITE	Write single characteristic with response.
SF_BLE_CHAR_WRITE_LONG	Write single long characteristic with response.
SF_BLE_CHAR_DESC_WRITE	Write single characteristic descriptor with response.
SF_BLE_CHAR_DESC_WRITE_LONG	Write single long characteristic descriptor with response.

◆ sf_ble_conn_type_t

enum sf_ble_conn_type_t	
BLE connection type	
Enumerator	
SF_BLE_CONN_TYPE_NON_CONNECTABLE	Connection type connection not allowed.
SF_BLE_CONN_TYPE_UNDIRECTED_CONNECTABLE	Connection type undirected.
SF_BLE_CONN_TYPE_DIRECTED_CONNECTABLE	Connection type directed.

◆ sf_ble_disc_type_t

enum sf_ble_disc_type_t	
BLE discovery type	
Enumerator	
SF_BLE_DISC_TYPE_NON_DISCOVERABLE	BLE non-discoverable.
SF_BLE_DISC_TYPE_GENERAL_DISCOVERABLE	BLE discoverable.
SF_BLE_DISC_TYPE_LIMITED_DISCOVERABLE	BLE limited discoverable.

◆ sf_ble_disconnect_reason_t

enum sf_ble_disconnect_reason_t	
BLE security authorization requirement	
Enumerator	
SF_BLE_DISCONNECT_REASON_LOCAL_HOST	Disconnected by local machine.
SF_BLE_DISCONNECT_REASON_REMOTE_USER	Disconnected by remote device.
SF_BLE_DISCONNECT_REASON_ERR	Error in Connection so disconnected.

◆ sf_ble_duplicate_filter_t

enum sf_ble_duplicate_filter_t	
BLE Duplicate Filter Configuration	
Enumerator	
SF_BLE_DUPLICATE_FILTER_ENABLE	Enable Duplicate filter in Scan.
SF_BLE_DUPLICATE_FILTER_DISABLE	Disbale Duplicate filter in Scan.

◆ sf_ble_event_t

enum sf_ble_event_t	
BLE events	
Enumerator	
SF_BLE_EVENT_NONE	BLE user event none.
SF_BLE_EVENT_BONDING_INDICATION	BLE user event indicating reception of bonding request.
SF_BLE_EVENT_CONNECTION_COMP	BLE user event indicating connection completion.
SF_BLE_EVENT_DISCONNECT_COMP	BLE user event indicating disconnect.
SF_BLE_EVENT_SM_TK_REQ_IND	BLE user event indicating request for Temporary key.
SF_BLE_EVENT_SM_KEY_IND	BLE user event indicating received key from user.
SF_BLE_EVENT_SM_CHK_BD_ADDR_REQ	BLE user event indicating validation of remote address.
SF_BLE_EVENT_SM_ENC_START_IND	BLE user event indicating encryption started.
SF_BLE_EVENT_GATT_NOTIFICATION	BLE user event for Notification from peer.
SF_BLE_EVENT_GATT_INDICATION	BLE user event for Indication from peer.
SF_BLE_EVENT_GATT_WRITE_CMD_INDICATION	BLE user event for Write command from peer.
SF_BLE_EVENT_GATT_RESPONSE_TIMEOUT	BLE user event for GATT operation timeout.
SF_BLE_EVENT_GATT_ATTR_WRITE_REQ	BLE user event for Remote Write request on

	user Attributes.
SF_BLE_EVENT_GATT_ATTR_READ_REQ	BLE user event for Remote Read request on user Attributes.
SF_BLE_EVENT_GATT_ATTR_WRITE_COMPLETE	BLE user event Indicating Remote Write complete for user Attributes.
SF_BLE_EVENT_GATT_ATTR_WRITE_CCCD_REQ	BLE user event for Remote CCCD Write request on user Attributes.
SF_BLE_EVENT_GATT_ATTR_WRITE_CCCD_COMPLETE	BLE user event Indicating Remote CCCD Write complete for user Attributes.

◆ sf_ble_execute_write_t

enum sf_ble_execute_write_t	
Characteristic execute write flag	
Enumerator	
SF_BLE_EXECUTE_WRITE_FALSE	Execute write false i.e. cancel write operations.
SF_BLE_EXECUTE_WRITE_TRUE	Execute write true i.e. execute write operations.

◆ sf_ble_gap_role_t

enum sf_ble_gap_role_t	
GAP role	
Enumerator	
SF_BLE_GAP_ROLE_MASTER	GAP role master/central.
SF_BLE_GAP_ROLE_SLAVE	GAP role slave/peripheral.
SF_BLE_GAP_ROLE_OBSERVER	GAP role Observer.
SF_BLE_GAP_ROLE_BROADCASTER	GAP role Broadcaster.

◆ sf_ble_init_filt_type_t

enum sf_ble_init_filt_type_t	
BLE initial filter type	
Enumerator	
SF_BLE_INIT_FILT_TYPE_IGNORE_WLIST	Ignore whitelist.
SF_BLE_INIT_FILT_TYPE_USE_WLIST	Use whitelist.

◆ sf_ble_iocap_t

enum sf_ble_iocap_t	
BLE System IO Capabilities	
Enumerator	
SF_BLE_IO_CAP_DISPLAY_ONLY	Display Only.
SF_BLE_IO_CAP_DISPLAY_YES_NO	Display Yes No.
SF_BLE_IO_CAP_KB_ONLY	Keyboard Only.
SF_BLE_IO_CAP_NO_INPUT_NO_OUTPUT	No Input No Output.
SF_BLE_IO_CAP_KB_DISPLAY	Keyboard Display.

◆ sf_ble_key_dist_t

enum sf_ble_key_dist_t	
BLE security key distribution type	
Enumerator	
SF_BLE_KEY_DIST_NONE	No Keys to distribute.
SF_BLE_KEY_DIST_ENCKEY	Encryption key in distribution.
SF_BLE_KEY_DIST_IDKEY	IRK (ID key)in distribution.
SF_BLE_KEY_DIST_SIGNKEY	CSRK(Signature key) in distribution.

◆ sf_ble_scan_mode_t

enum sf_ble_scan_mode_t	
BLE scan mode	
Enumerator	
SF_BLE_SCAN_MODE_PASSIVE	BLE scan mode passive.
SF_BLE_SCAN_MODE_ACTIVE	BLE scan mode active.

◆ sf_ble_sec_mode_t

enum sf_ble_sec_mode_t	
BLE security mode	
Enumerator	
SF_BLE_SEC_MODE1_LVL1_NO_SEC	BLE no security.
SF_BLE_SEC_MODE1_LVL2_NOAUTH_PAIR_ENC	BLE no authentication pairing encryption.
SF_BLE_SEC_MODE1_LVL3_AUTH_PAIR_ENC	Authenticated pairing with encryption.
SF_BLE_SEC_MODE1_LVL4_AUTHLE_PAIR_ENC	Authenticated LE Secure Connections pairing with encryption.
SF_BLE_SEC_MODE2_LVL1_NOAUTH_DATA_SIGNED	Unauthenticated pairing with data signing.
SF_BLE_SEC_MODE2_LVL2_AUTH_DATA_SIGNED	Authentication pairing with data signing.

◆ sf_ble_service_discovery_t

enum sf_ble_service_discovery_t	
Service discovery type	
Enumerator	
SF_BLE_SERVICE_DISCOVERY_PRIMARY_ALL	Discover all primary services.
SF_BLE_SERVICE_DISCOVERY_PRIMARY_UUID	Discover primary service by UUID.
SF_BLE_SERVICE_DISCOVERY_INCLUDED	Discover includes services.

◆ sf_ble_tx_pwr_state_t

enum sf_ble_tx_pwr_state_t	
BLE Transmit power state	
Enumerator	
SF_BLE_TX_PWR_STATE_NORMAL	Functionality disabled.
SF_BLE_TX_PWR_STATE_ADAPT_NEAR	RF low-power mode.
SF_BLE_TX_PWR_STATE_ADAPT_MIDDLE	RF normal mode.
SF_BLE_TX_PWR_STATE_ADAPT_FAR	RF high-performance mode.

◆ sf_ble_uuid_length_t

enum sf_ble_uuid_length_t	
UUID length	
Enumerator	
SF_BLE_UUID_LENGTH_16BITS	16 bit UUID
SF_BLE_UUID_LENGTH_32BITS	32 bit UUID
SF_BLE_UUID_LENGTH_128BITS	128 bit UUID

◆ sf_ble_write_response_t

enum sf_ble_write_response_t	
Characteristic execute write flag	
Enumerator	
SF_BLE_WRITE_RESPONSE_NOT_REQUIRED	Write response not required.
SF_BLE_WRITE_RESPONSE_REQUIRED	Write response required.

sf_ble_addr_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t	addr [SF_BLE_ADDR_LEN] 6-byte array address value

Detailed Description

BLE address

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_adv_data_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t	data [SF_BLE_ADV_DATA_LEN] Advertising data bytes array.
uint8_t	adv_data_length Advertising data length.

Detailed Description

BLE Advertising data structure

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_event_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

void *	p_data Data for BLE event.
uint16_t	event Event type.

Detailed Description

BLE event info

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_sec_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_sec_mode_t	sec_mode security mode
uint8_t	id_key [SF_BLE_SEC_KEY_LEN] GAP Identity Resolving Security key.
uint8_t	csrk_key [SF_BLE_SEC_KEY_LEN] GAP Connection Signature Resolving Security key.

uint8_t	ltk_key [SF_BLE_SEC_KEY_LEN] GAP Connection Long term Security key.
uint8_t	rand_num [SF_BLE_RAND_NUM_LENGTH] GAP Connection Random number for Long term Security key.
uint16_t	ediv GAP Connection Encrypted Diversifier for Long term Security key.

Detailed Description

Security Related Configuration

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_provisioning_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t	gap_name [SF_BLE_MAX_GAP_NAME_LEN] GAP name.
uint8_t	bcast_mode broadcast mode
sf_ble_bonding_mode_t	bonding_mode bonding mode
sf_ble_sec_info_t	sec_info

	Security information.
sf_ble_gap_role_t	gap_role GAP role (master/slave)
sf_ble_callback_t	p_ble_callback

Detailed Description

BLE provisioning information

Field Documentation

◆ p_ble_callback

sf_ble_callback_t sf_ble_provisioning_t::p_ble_callback
GAP user event callback that runs in driver thread context. Application should make sure callback logic is as minimal as possible without any blocking calls

---

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_scan_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint16_t	total_scan_duration BLE total scan duration in milliseconds.
sf_ble_scan_mode_t	scan_mode BLE scan mode.
sf_ble_disc_type_t	discovery_type

	Specifies discovery type, Used only in active scan.
sf_ble_addr_type_t	address_type BLE address type.
sf_ble_adv_filt_type_t	filt_policy Scan Filter policy.
sf_ble_duplicate_filter_t	duplicate_filt Duplicate filter configuration.

Detailed Description

BLE scan information structure

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_bonding_start_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_iocap_t	iocap IO capabilities.
uint8_t	key_size Encryption key size.
sf_ble_key_dist_t	ikey_dist Initiator key distribution.

sf_ble_key_dist_t	rkey_dist Responder key distribution.

Detailed Description

BLE Bonding Start information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_bonding_response_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t	accept accept or reject bonding
sf_ble_iocap_t	io_cap IO capabilities.
uint8_t	max_key_size Max key size.
sf_ble_key_dist_t	ikeys Initiator key distribution.
sf_ble_key_dist_t	rkeys Responder key distribution.

Detailed Description

Bonding Response Parameter

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_sm_tk_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_conn_handle_t	conhdl Connection handle.
uint8_t	disp_en Whether to enable display.

Detailed Description

Security structures BLE Temporary Key information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_sm_tk_ind_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_sm_tk_info_t	tk_info input parameter,information to app about temporary key request

uint8_t	tk_req_status output parameter: request status, application has to set this in callback event whether request is valid or not
uint8_t	tk_key [SF_BLE_SEC_KEY_LEN] application has to set this in callback event temporary key for encryption

Detailed Description

BLE Temporary Key indication

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_addr_verify_ind_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t	bd_addr [SF_BLE_ADDR_LEN] input parameter specifying bluetooth address of remote device
sf_ble_addr_type_t	addr_type input parameter specifying Address type of remote BLE device
uint8_t	accept_addr output parameter: application has to set this parameter in callback if it accepts this address

Detailed Description

BLE Bluetooth address verification indication

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_sm_key_ind_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t	conn_idx connection index
sf_ble_key_dist_t	key_code type of security key
uint16_t	ediv BLE Security EDIV.
uint8_t	rand_num [SF_BLE_RAND_NUM_LENGTH] Random number for security.
uint8_t	ltk_key [SF_BLE_SEC_KEY_LEN] BLE long term security key.

Detailed Description

BLE Received Key information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_sm_enc_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_conn_handle_t	conn_idx connection index
uint16_t	ediv BLE Security EDIV.
uint8_t	rand_num [SF_BLE_RAND_NUM_LENGTH] Random number for security.
uint8_t	ltk_key [SF_BLE_SEC_KEY_LEN] BLE long term security key.

Detailed Description

BLE Start Encryption information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_sec_enc_start_ind_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_conn_handle_t	conhdl Connection handle of the remote device.

uint8_t	status Result of encryption start, 0 = SUCCESS else error.
uint8_t	key_size Key Size.
sf_ble_auth_type_t	auth_type Security properties.
uint8_t	bonding_status Bonding Status, 0 = Unbonded, 1 = Bonded.

Detailed Description

Encryption Start Indication Event for user

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_scan_response_data_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t	scan_response_data [SF_BLE_ADV_DATA_LEN] Advertising data bytes array.
uint8_t	scan_response_data_length Advertising data length.

Detailed Description

Scan Response Data for advertising

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_adv_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_disc_type_t	disc_mode Discovery mode.
sf_ble_conn_type_t	conn_mode Connection mode.
sf_ble_adv_type_t	adv_type Advertisement type.
uint16_t	adv_intv_min Minimum interval for advertising.
uint16_t	adv_intv_max Maximum interval for advertising.
sf_ble_addr_type_t	own_addr_type Own address type.
sf_ble_addr_type_t	direct_addr_type Direct connection address type.
uint8_t	direct_bd_addr [SF_BLE_ADDR_LEN]

	Direct connection BLE address.
sf_ble_adv_chnl_map_t	adv_chnl_map Advertising channel map.
sf_ble_adv_filt_type_t	adv_filt_policy Advertising filter policy.
sf_ble_scan_response_data_t	scan_response_data Scan Response information, will be advertised only for active scan.
sf_ble_adv_data_t	adv_data Advertising data.

Detailed Description

BLE advertisement information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_scan_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_addr_type_t	addr_type Address type of remote BLE device.
uint8_t	bd_addr [SF_BLE_ADDR_LEN] Remote BLE address.

uint16_t	data_len Scan data length.
uint8_t	data [SF_BLE_MAX_BLE_ADV_DATA_LEN] Scan data.
int16_t	rssi RSSI value.
sf_ble_adv_event_type_t	event_type Advertising event type.

Detailed Description

BLE scan information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_connection_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_init_filt_type_t	init_filt_type Connection filter type.
sf_ble_addr_type_t	addr_type BLE address type.
uint8_t	bd_addr [SF_BLE_ADDR_LEN]

	BLE address.

Detailed Description

BLE connection information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_disconnect_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_disconnect_reason_t	reason Disconnection reason.
uint8_t	status Disconnect status if initiated by local host.
sf_ble_conn_handle_t	conhdl Connection handle of the remote device.

Detailed Description

BLE Disconnect Event Information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_chipset_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint32_t	version chipset version
uint8_t	bd_addr [SF_BLE_ADDR_LEN] BLE address.

Detailed Description

BLE chipset information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_chipset_info_t	chipset Chipset information.
uint16_t	rssi RSSI value.

Detailed Description

BLE module information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_bonding_req_ind_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_addr_t	bd_addr BLE address.
uint8_t	index Connection index.
uint8_t	auth_req Authentication request type.
uint8_t	io_cap IO capability.
uint8_t	oob_data_flg Indicating if OOB data is present.
uint8_t	max_enc_size Maximum encryption key size.
uint8_t	ikey_dist Type of key distributed by the initiator.
uint8_t	rkey_dist Type of key distributed by the responder.

Detailed Description

BLE bonding request indication information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_connect_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t	status Confirmation status.
uint8_t	reserved Reserved.
sf_ble_conn_handle_t	conhdl Connection handle.
uint8_t	peer_addr_type Peer address type.
sf_ble_addr_t	peer_addr Peer BT address.
uint8_t	reserved2 Reserved.
uint16_t	con_interval Connection interval.

uint16_t	con_latency Connection latency.
uint16_t	sup_to Link supervision time-out.
uint8_t	clk_accuracy Clock accuracy.
uint8_t	reserved3 Reserved.

Detailed Description

BLE connection information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_set_tx_pwr_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

int8_t	power_lvl TX power level in dBm.
sf_ble_tx_pwr_state_t	state Operating state to set the transmit power level.

Detailed Description

BLE set TX power information structure

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_uuid_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_uuid_length_t	uuid_length Service UUID length.
uint16_t	uuid16 16 bit UUID
uint32_t	uuid32 32 bit UUID
uint8_t	uuid128 [SF_BLE_128BITS_UUID_LENGTH] 128 bit UUID

Detailed Description

Union holding either 16-bit/32-bit/128-bit UUID

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_svc_attribute_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint16_t	attr_handle Service Handle.
uint16_t	attr_type Attribute type such as SF_BLE_GATT_PRI_SERVICE, SF_BLE_GATT_INCLUDE_SERVICE.
uint16_t	parent_svc_handle parent_svc_handle is service handle of parent service which is already registered More...
uint8_t *	p_attr_value Service UUID Pointer.
sf_ble_uuid_length_t	attr_value_len UUID Length.

Detailed Description

BLE GATT Service Attributes

Field Documentation

◆ parent_svc_handle

uint16_t sf_ble_svc_attribute_t::parent_svc_handle
parent_svc_handle is service handle of parent service which is already registered If service is included service,

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_char_attribute_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_svc_attribute_t *	p_service Service to which this characteristics belongs.
sf_ble_uuid_t	attr_uuid UUID of characteristics value.
uint16_t	attr_declare_handle Characteristics handle.
uint16_t	attr_declare_type Characteristics declare type SF_BLE_GATT_CHAR_DECLARE.
uint16_t	attr_value_handle Characteristics value handle.
sf_ble_char_attr_permissions_t	attr_perm Characteristics permission.
sf_ble_char_property_t	attr_properties Characteristics properties.
uint8_t *	p_attr_value Characteristics value data.
uint8_t	attr_value_len Characteristics value data length.

Detailed Description

BLE GATT Characteristics Attributes

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_gatt_attr_event_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint16_t	attr_handle Attribute handle for which event is generated.
uint16_t	offset The offset at which the client is willing to write.
uint8_t const *	p_value The value at which the client is willing to write.
uint16_t	length The amount of bytes that the client is willing to write as from this offset.
ssp_err_t	response User will update this variable, Pass SSP_SUCCESS if user accepts the remote request.

Detailed Description

BLE GATT Characteristics Remote Event data, passed in provision callback for GATT Custom profile

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_service_discovery_rsp_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint16_t	service_handle Service handle.
sf_ble_uuid_t	uuid Service UUID.
uint16_t	start_handle Start handle of sub-attributes handle range.
uint16_t	end_handle End handle of sub-attributes handle range.

Detailed Description

Service discovery result

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_service_discovery_req_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_uuid_t	uuid Service UUID.
uint16_t	start_handle Discovery start handle.
uint16_t	end_handle Discovery end handle.
sf_ble_service_discovery_t	discovery_type Service discovery type.

Detailed Description

Service discovery request

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_char_discovery_req_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_uuid_t	uuid Characteristic UUID.
uint16_t	start_handle Discovery start handle.

uint16_t	end_handle Discovery end handle.
sf_ble_char_discovery_t	discovery_type Characteristic discovery type.

Detailed Description

Characteristic discovery request

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_char_discovery_rsp_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint16_t	char_handle Characteristic handle.
sf_ble_uuid_t	uuid Characteristic UUID.
uint16_t	value_handle Characteristic value handle.
sf_ble_char_property_t	property Characteristic property.

Detailed Description

Characteristic discovery result

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_char_desc_discovery_rsp_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint16_t	desc_handle Characteristic descriptor handle.
sf_ble_uuid_t	uuid Characteristic descriptor UUID.

Detailed Description

Characteristic descriptor discovery result

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_char_multiple_read_req_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint16_t	handles [SF_BLE_MAX_MULTI_CHAR_READ_CNT] Characteristic handles for multiple read.

uint8_t	expected_result_size [SF_BLE_MAX_MULTI_CHAR_READ_CNT] Expected result length in bytes.

Detailed Description

Multiple Characteristic descriptor read request

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_char_read_req_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_char_read_t	char_read_type Characteristic read type.
uint16_t	handle Characteristic value or descriptor handle.
sf_ble_uuid_t	uuid Characteristic UUID.
uint16_t	offset Offset for long Characteristic value.
sf_ble_char_multiple_read_req_t *	p_mul_read_req Pointer to multiple read Characteristic request.
uint16_t	handles_cnt

	Characteristic handles count for multiple read.

Detailed Description

Read Characteristic request

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_char_multiple_read_rsp_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t *	p_data [SF_BLE_MAX_MULTI_CHAR_READ_CNT] Pointer to Characteristic value.
uint16_t	data_len [SF_BLE_MAX_MULTI_CHAR_READ_CNT] Characteristic value length.

Detailed Description

Read multiple Characteristic response

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_char_read_by_uuid_rsp_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint16_t	handle [SF_BLE_MAX_CHAR_UUID_READ_CNT] Characteristic handles.
uint8_t *	p_data [SF_BLE_MAX_CHAR_UUID_READ_CNT] Pointer to Characteristic value.
uint16_t	data_len [SF_BLE_MAX_CHAR_UUID_READ_CNT] Characteristic value length.

Detailed Description

Read Characteristic by UUID response

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_char_read_by_handle_rsp_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t *	p_data Pointer to Characteristic value.
uint16_t	data_len Characteristic value length.

Detailed Description

Read Characteristic by handle response

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_char_read_rsp_t Union Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_char_read_by_handle_rsp_t *	p_char_read_by_handle_rsp Response for read Characteristic by handle.
sf_ble_char_read_by_uuid_rsp_t *	p_char_read_by_uuid_rsp Response for read Characteristic by UUID.
sf_ble_char_multiple_read_rsp_t *	p_char_multiple_read_rsp Response for read multiple Characteristics.

Detailed Description

Read Characteristic response

The documentation for this union was generated from the following file:

- sf_ble_api.h

sf_ble_char_write_req_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

sf_ble_char_write_t	char_write_type Characteristic write type.
uint16_t	handle Characteristic value or descriptor handle.
uint8_t *	p_data Pointer to data.
uint16_t	offset Offset for long Characteristic value.
uint16_t	data_length Data length.
sf_ble_execute_write_t	auto_execute Automatic execute write flag.

Detailed Description

Write Characteristic request

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_gatt_notif_ind_event_data_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint16_t	handle

	Characteristic value or descriptor handle.
uint8_t *	p_data Pointer to data.
uint16_t	data_length Data length.

Detailed Description

Notification/Indication event data

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_write_cmd_event_data_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint16_t	handle Characteristic value or descriptor handle.
uint16_t	offset Offset for long Characteristic value.
sf_ble_write_response_t	response_required Write response required or not.
uint8_t *	p_data Pointer to data.

uint16_t	data_length Data length.

Detailed Description

Write command event data

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

void *	p_driver_handle Storage for information needed for each BLE device driver in the system.

Detailed Description

BLE Framework control structure

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

uint8_t	bd_addr [SF_BLE_ADDR_LEN] BLE address.
sf_ble_addr_type_t	own_addr_type self address type
uint8_t	max_slaves Maximum slaves allowed to be connected.
uint8_t	update_bd_addr Set this to true to update bluetooth address during SF_BLE_Open.
uint16_t	scan_interval BLE scan interval for receiving advertisement.
uint16_t	scan_window Period of time during which advertising data is received at the scan interval.
uint16_t	disc_time Duration for which the device remain discoverable.
uint16_t	con_interval Interval for transmitting and receiving data periodically after connection establishment.
uint16_t	slave_latency Period of time during which data is transmitted and received at the connection interval.
uint16_t	sup_timeout Link loss time-out.
void const *	p_extend

	Instance specific configuration.

Detailed Description

BLE configuration information

The documentation for this struct was generated from the following file:

- sf_ble_api.h

sf_ble_api_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Framework Interface

#include <sf_ble_api.h>

Data Fields

ssp_err_t(*	open)(sf_ble_ctrl_t *const p_ctrl, const sf_ble_cfg_t *p_cfg) Initializes the interface for data transfers. More...
ssp_err_t(*	close)(sf_ble_ctrl_t *const p_ctrl) De-initialize the interface and may put it in low power mode or power it off. Close the driver, disable the driver link, disable interrupt. More...
ssp_err_t(*	infoGet)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_info_t *p_ble_info) Get BLE module information like chipset information and RSSI value. More...
ssp_err_t(*	provisionGet)(sf_ble_ctrl_t *const p_ctrl, sf_ble_provisioning_t *p_ble_provisioning) Reads the current BLE Provisioning information. More...
ssp_err_t(*	provisionSet)(sf_ble_ctrl_t *const p_ctrl, const sf_ble_provisioning_t *p_ble_provisioning) Provisions the BLE Driver and set bonding and security modes as provisioned. More...

ssp_err_t(*	scan)(sf_ble_ctrl_t *const p_ctrl, sf_ble_scan_t *p_scan, uint8_t *p_cnt, sf_ble_scan_info_t *p_scan_info) Scans for available BLE devices and return the list to the caller. More...
ssp_err_t(*	advertisementStart)(sf_ble_ctrl_t *const p_ctrl, sf_ble_adv_info_t *const p_advt_info) Make the device discoverable by broadcasting device information to remote devices. More...
ssp_err_t(*	advertisementStop)(sf_ble_ctrl_t *const p_ctrl) Stop the device from being discoverable. More...
ssp_err_t(*	whitelistAdd)(sf_ble_ctrl_t *const p_ctrl, const uint8_t *p_bd_addr) Add specified devices to whitelist. More...
ssp_err_t(*	whitelistDel)(sf_ble_ctrl_t *const p_ctrl, const uint8_t *p_bd_addr) Remove specified devices from whitelist. More...
ssp_err_t(*	bondingStart)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, const uint8_t *p_bd_addr, sf_ble_bonding_start_t *p_bonding_start) Initiate bonding process with remote BLE device and exchange security keys if enabled. More...
ssp_err_t(*	bondingResponse)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, const uint8_t *p_bd_addr, sf_ble_bonding_response_t *p_bonding_resp) Respond to the bonding request from the remote BLE device. Send bonding response on reception of bonding indication. More...
ssp_err_t(*	startEncryption)(sf_ble_ctrl_t *const p_ctrl, sf_ble_sm_enc_info_t const *p_enc_info) Start encryption over a connection. More...
ssp_err_t(*	connect)(sf_ble_ctrl_t *const p_ctrl, sf_ble_connection_t const *const p_conn, sf_ble_conn_handle_t *p_handle) Connect to a remote BLE device. More...

ssp_err_t(*	listen)(sf_ble_ctrl_t *const p_ctrl) Listen for connection request from remote device. More...
ssp_err_t(*	authorization)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle) Indicates that the specified remote device has been authorized by user. More...
ssp_err_t(*	disconnect)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle) Terminate connection with remote BLE device. More...
ssp_err_t(*	setTxPower)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *const p_handle, sf_ble_set_tx_pwr_info_t *p_tx_power_info) Sets the transmit power for the procedure specified by the connection handle. More...
ssp_err_t(*	gattAddCustomProfiles)(sf_ble_ctrl_t *const p_ctrl, sf_ble_svc_attribute_t *p_svc_attr, uint32_t svc_attr_len, sf_ble_char_attribute_t *p_char_attr, uint32_t char_attr_len) Add Custom Profile to GATT Database. More...
ssp_err_t(*	gattServiceDiscovery)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_service_discovery_req_t const *const p_sf_ble_svc_dscv_req, sf_ble_service_discovery_rsp_t *const p_sf_ble_svc_dscv_rsp, uint32_t *const p_rsp_cnt) Perform service discovery used by GATT client.Perform service discovery on remote GATT server and get results. More...
ssp_err_t(*	gattCharDiscovery)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_char_discovery_req_t const *const p_sf_ble_char_dscv_req, sf_ble_char_discovery_rsp_t *const p_sf_ble_char_dscv_rsp, uint32_t *const p_rsp_cnt) Perform characteristics discovery used by GATT client.Perform characteristics discovery on remote GATT server and get results. More...
ssp_err_t(*	gattCharDescDiscovery)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, uint16_t start_handle, uint16_t end_handle, sf_ble_char_desc_discovery_rsp_t *const p_sf_ble_chardesc_dscv_rsp, uint32_t *const p_rsp_cnt)

	Perform characteristics descriptor discovery used by GATT client. More...
ssp_err_t(*	gattCharRead)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_char_read_req_t const *const p_char_read_req, sf_ble_char_read_rsp_t *const p_char_read_rsp) Perform read characteristic used by GATT client.Read characteristic value from remote GATT server. More...
ssp_err_t(*	gattCharWrite)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_char_write_req_t const *const p_char_write_req) Perform write characteristic used by GATT client.Write characteristic value on remote GATT server. More...
ssp_err_t(*	gattCharExecuteWrite)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_execute_write_t execute_flag) Perform execute write on all pending write operations, used by GATT client.Execute or cancel all prepared writes of characteristics on remote GATT server. More...
ssp_err_t(*	gattCharWriteLocal)(sf_ble_ctrl_t *const p_ctrl, uint16_t char_handle, uint16_t data_length, uint8_t *const p_data) Perform local characteristic write used by GATT server.Writes local characteristic value on GATT server. More...
ssp_err_t(*	gattSendNotify)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, uint16_t char_handle) Send notification to GATT client, used by GATT server. More...
ssp_err_t(*	gattSendIndicate)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, uint16_t char_handle) Send indication to GATT client, used by GATT server.Send indication to remote GATT client. More...
ssp_err_t(*	gattWriteResponse)(sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, uint16_t handle, sf_ble_attribute_error_code_t error_code) Send response to write operation received by GATT client, used by GATT server.Send response for write request received from remote GATT client. More...

ssp_err_t(*	versionGet)(ssp_version_t *const p_version) Gets version and stores it in provided pointer p_version. More...

Detailed Description

Framework API structure. Implementations will use the following API.

Field Documentation

◆ advertisementStart

ssp_err_t(* sf_ble_api_t::advertisementStart) (sf_ble_ctrl_t *const p_ctrl, sf_ble_adv_info_t *const p_advt_info)

Make the device discoverable by broadcasting device information to remote devices.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_advt_info	Pointer to advertisement information structure

◆ advertisementStop

ssp_err_t(* sf_ble_api_t::advertisementStop) (sf_ble_ctrl_t *const p_ctrl)

Stop the device from being discoverable.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.

◆ authorization

ssp_err_t(* sf_ble_api_t::authorization) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle)

Indicates that the specified remote device has been authorized by user.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_handle	Pointer to connection handle.

◆ bondingResponse

ssp_err_t(* sf_ble_api_t::bondingResponse) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, const uint8_t *p_bd_addr, sf_ble_bonding_response_t *p_bonding_resp)

Respond to the bonding request from the remote BLE device. Send bonding response on reception of bonding indication.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_handle	Pointer to connection handle
[in]	p_bd_addr	Pointer to BLE address
[in]	p_bonding_resp	Pointer to Bonding address

◆ bondingStart

ssp_err_t(* sf_ble_api_t::bondingStart) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, const uint8_t *p_bd_addr, sf_ble_bonding_start_t *p_bonding_start)

Initiate bonding process with remote BLE device and exchange security keys if enabled.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_handle	Pointer to connection handle.
[in]	p_bd_addr	Pointer to BLE address

◆ close

ssp_err_t(* sf_ble_api_t::close) (sf_ble_ctrl_t *const p_ctrl)

De-initialize the interface and may put it in low power mode or power it off. Close the driver, disable the driver link, disable interrupt.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.

◆ connect

ssp_err_t(* sf_ble_api_t::connect) (sf_ble_ctrl_t *const p_ctrl, sf_ble_connection_t const *const p_conn, sf_ble_conn_handle_t *p_handle)

Connect to a remote BLE device.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_conn	Pointer to connection information
[out]	p_handle	Pointer to connection handle

◆ disconnect

ssp_err_t(* sf_ble_api_t::disconnect) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle)

Terminate connection with remote BLE device.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_handle	Pointer to connection handle

◆ gattAddCustomProfiles

ssp_err_t(* sf_ble_api_t::gattAddCustomProfiles) (sf_ble_ctrl_t *const p_ctrl, sf_ble_svc_attribute_t *p_svc_attr, uint32_t svc_attr_len, sf_ble_char_attribute_t *p_char_attr, uint32_t char_attr_len)

Add Custom Profile to GATT Database.

This function is called with list of service and characteristics which is to be added to GATT database. Services and characteristics which were previously added will be removed and newly passed services and characteristics will be added.

If services and characteristics were previously added and now those services and characteristics are to be removed and no new services and characteristics are to be added , then call this API with service and characteristics length as zero

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_svc_attr	List of Services to add
[in]	svc_attr_len	No of elements in services list
[in]	p_char_attr	List of Characteristics to add
[in]	char_attr_len	No of elements in Characteristics list

◆ gattCharDescDiscovery

ssp_err_t(* sf_ble_api_t::gattCharDescDiscovery) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, uint16_t start_handle, uint16_t end_handle, sf_ble_char_desc_discovery_rsp_t *const p_sf_ble_chardesc_dscv_rsp, uint32_t *const p_rsp_cnt)

Perform characteristics descriptor discovery used by GATT client.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Connection handle
[in]	start_handle	Start handle from set of handle ranges to be used in discovery
[in]	end_handle	End handle from set of handle ranges to be used in discovery
[out]	p_sf_ble_chardesc_dscv_rsp	Pointer to characteristics descriptor discovery response
[in,out]	p_rsp_cnt	Input Size specifying maximum number of characteristics descriptor discovery results which can be stored in response, output specifying number of characteristics descriptor discovery results stored in response

◆ gattCharDiscovery

ssp_err_t(* sf_ble_api_t::gattCharDiscovery) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_char_discovery_req_t const *const p_sf_ble_char_dscv_req, sf_ble_char_discovery_rsp_t *const p_sf_ble_char_dscv_rsp, uint32_t *const p_rsp_cnt)

Perform characteristics discovery used by GATT client.Perform characteristics discovery on remote GATT server and get results.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Connection handle
[in]	p_sf_ble_char_dscv_req	Pointer to characteristics discovery request
[out]	p_sf_ble_char_dscv_rsp	Pointer to characteristics discovery response
[in,out]	p_rsp_cnt	Input Size specifying maximum number of characteristics discovery results which can be stored in response, output specifying number of characteristics discovery results stored in response

◆ gattCharExecuteWrite

ssp_err_t(* sf_ble_api_t::gattCharExecuteWrite) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_execute_write_t execute_flag)

Perform execute write on all pending write operations, used by GATT client.Execute or cancel all prepared writes of characteristics on remote GATT server.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Connection handle
[in]	execute_flag	Flag specifying whether to execute or cancel pending writes

◆ gattCharRead

ssp_err_t(* sf_ble_api_t::gattCharRead) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_char_read_req_t const *const p_char_read_req, sf_ble_char_read_rsp_t *const p_char_read_rsp)

Perform read characteristic used by GATT client.Read characteristic value from remote GATT server.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Connection handle
[in]	p_char_read_req	Pointer to characteristic read request
[out]	p_char_read_rsp	Pointer to characteristic read response

◆ gattCharWrite

ssp_err_t(* sf_ble_api_t::gattCharWrite) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_char_write_req_t const *const p_char_write_req)

Perform write characteristic used by GATT client.Write characteristic value on remote GATT server.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Connection handle
[in]	p_char_write_req	Pointer to characteristic write request

◆ gattCharWriteLocal

ssp_err_t(* sf_ble_api_t::gattCharWriteLocal) (sf_ble_ctrl_t *const p_ctrl, uint16_t char_handle, uint16_t data_length, uint8_t *const p_data)

Perform local characteristic write used by GATT server.Writes local characteristic value on GATT server.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	char_handle	Characteristic handle
[in]	data_length	Length of data to write
[in]	p_data	Pointer to data

◆ gattSendIndicate

ssp_err_t(* sf_ble_api_t::gattSendIndicate) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, uint16_t char_handle)

Send indication to GATT client, used by GATT server.Send indication to remote GATT client.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Connection handle
[in]	char_handle	Characteristic handle whose value will be indicated

◆ gattSendNotify

ssp_err_t(* sf_ble_api_t::gattSendNotify) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, uint16_t char_handle)

Send notification to GATT client, used by GATT server.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Connection handle
[in]	char_handle	Characteristic handle whose value will be notified

◆ gattServiceDiscovery

ssp_err_t(* sf_ble_api_t::gattServiceDiscovery) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_service_discovery_req_t const *const p_sf_ble_svc_dscv_req, sf_ble_service_discovery_rsp_t *const p_sf_ble_svc_dscv_rsp, uint32_t *const p_rsp_cnt)

Perform service discovery used by GATT client.Perform service discovery on remote GATT server and get results.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Connection handle
[in]	p_sf_ble_svc_dscv_req	Pointer to service discovery request
[out]	p_sf_ble_svc_dscv_rsp	Pointer to service discovery response
[in,out]	p_rsp_cnt	Input Size specifying maximum number of service discovery results which can be stored in response, output specifying number of service discovery results stored in response

◆ gattWriteResponse

ssp_err_t(* sf_ble_api_t::gattWriteResponse) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, uint16_t handle, sf_ble_attribute_error_code_t error_code)

Send response to write operation received by GATT client, used by GATT server.Send response for write request received from remote GATT client.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Connection handle
[in]	handle	Characteristic handle used for write operation
[in]	error_code	Characteristic write operation error code to be sent in response

◆ infoGet

ssp_err_t(* sf_ble_api_t::infoGet) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_ble_info_t *p_ble_info)

Get BLE module information like chipset information and RSSI value.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_handle	Pointer to connection handle
[out]	p_ble_info	Pointer to module information

◆ listen

ssp_err_t(* sf_ble_api_t::listen) (sf_ble_ctrl_t *const p_ctrl)

Listen for connection request from remote device.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.

◆ open

ssp_err_t(* sf_ble_api_t::open) (sf_ble_ctrl_t *const p_ctrl, const sf_ble_cfg_t *p_cfg)

Initializes the interface for data transfers.

Initial driver configuration, enable the driver link, enable interrupts and make device ready for data transfer.

Parameters

[in,out]	p_ctrl	Pointer to user-provided storage for the control block.
[in]	p_cfg	Pointer to BLE configuration structure.

◆ provisionGet

ssp_err_t(* sf_ble_api_t::provisionGet) (sf_ble_ctrl_t *const p_ctrl, sf_ble_provisioning_t *p_ble_provisioning)

Reads the current BLE Provisioning information.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[out]	p_ble_provisioning	current provisioning information

◆ provisionSet

ssp_err_t(* sf_ble_api_t::provisionSet) (sf_ble_ctrl_t *const p_ctrl, const sf_ble_provisioning_t *p_ble_provisioning)

Provisions the BLE Driver and set bonding and security modes as provisioned.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_ble_provisioning	Pointer to BLE provisioning structure

◆ scan

ssp_err_t(* sf_ble_api_t::scan) (sf_ble_ctrl_t *const p_ctrl, sf_ble_scan_t *p_scan, uint8_t *p_cnt, sf_ble_scan_info_t *p_scan_info)

Scans for available BLE devices and return the list to the caller.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[out]	p_scan	Pointer to scan information structure
[in,out]	p_cnt	Pointer to number of BLE devices scanned
[in]	p_scan_info	Pointer to scan information structure

◆ setTxPower

ssp_err_t(* sf_ble_api_t::setTxPower) (sf_ble_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *const p_handle, sf_ble_set_tx_pwr_info_t *p_tx_power_info)

Sets the transmit power for the procedure specified by the connection handle.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_handle	Pointer to connection handle. If transmit power is to be set before advertisement or connecting to remote device then pass connection handle as SF_BLE_TX_POWER_CONNECTION_HANDLE value else pass connection handle of remote device
[in]	p_tx_power_info	Pointer to TX power information

◆ startEncryption

ssp_err_t(* sf_ble_api_t::startEncryption) (sf_ble_ctrl_t *const p_ctrl, sf_ble_sm_enc_info_t const *p_enc_info)

Start encryption over a connection.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_enc_info	information for starting encryption

◆ versionGet

ssp_err_t(* sf_ble_api_t::versionGet) (ssp_version_t *const p_version)

Gets version and stores it in provided pointer p_version.

Parameters

[out]	p_version	pointer to memory location to return version number

◆ whitelistAdd

ssp_err_t(* sf_ble_api_t::whitelistAdd) (sf_ble_ctrl_t *const p_ctrl, const uint8_t *p_bd_addr)

Add specified devices to whitelist.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_bd_addr	Pointer to BLE address

◆ whitelistDel

ssp_err_t(* sf_ble_api_t::whitelistDel) (sf_ble_ctrl_t *const p_ctrl, const uint8_t *p_bd_addr)

Remove specified devices from whitelist.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.
[in]	p_bd_addr	Pointer to BLE address

◆ SF_BLE_ONBOARD_PROFILE_API_VERSION_MINOR

#define SF_BLE_ONBOARD_PROFILE_API_VERSION_MINOR (0U)
Minor Version of the API defined in this file

Typedef Documentation

◆ sf_ble_profile_callback_t

typedef void(* sf_ble_profile_callback_t) (sf_ble_event_info_t *ev)
User callback type for profile

Enumeration Type Documentation

◆ sf_ble_cccd_val_t

enum sf_ble_cccd_val_t	
Value for BLE CCCD Configuration	
Enumerator	
SF_BLE_CCCD_VAL_STOP_NTFIND	Stop Notification Indication.
SF_BLE_CCCD_VAL_START_NTF	Start Notification.
SF_BLE_CCCD_VAL_START_IND	Start Indication.

◆ sf_ble_onbp_char_t

enum sf_ble_onbp_char_t	
On-Board Profile GATT Characteristics Code	
Enumerator	
SF_BLE_ONBP_CHAR_HRP_HRCP	Heart Rate Control Point Characteristics (Property: Write), Refer sf_ble_prf_hrp_api_hrcp_t. Heart Rate Profile
SF_BLE_ONBP_CHAR_HRP_CCCD_NTF_HRMEAS	Heart Rate Measurement CCCD Characteristics (Property: NTF, Read, Write), Refer sf_ble_hrp_api_hrmeas_t.
SF_BLE_ONBP_CHAR_HRP_BSL	Heart Rate Body Sensor Location Characteristics (Property: Read)
SF_BLE_ONBP_CHAR_ANP_SUP_NEW_ALERT	Supported New Alert Category Characteristics (Property: Read) Alert Notification Profile
SF_BLE_ONBP_CHAR_ANP_CCCD_NTF_NEW_ALERT	New Alert CCCD Characteristics (Property: NTF, Read, Write), Refer sf_ble_anp_api_new_alert_ntf_t.
SF_BLE_ONBP_CHAR_ANP_SUP_UNREAD_ALERT	Supported Unread Alert Category Characteristics (Property: Read)
SF_BLE_ONBP_CHAR_ANP_CCCD_NTF_UNREAD_ALERT_STATUS	Unread Alert Status CCCD Characteristics (Property: NTF, Read, Write), Refer sf_ble_anp_api_unread_alert_ntf_t.
SF_BLE_ONBP_CHAR_ANP_ALERT_NOTIFICATION_CTRL_POINT	Alert Notification Control Point (Property: Write), Refer sf_ble_anp_ancp_t.
SF_BLE_ONBP_CHAR_DIS_MANUF	Device Information Service Manufacturer Name String (Property: Read) Device Information Service Profile
SF_BLE_ONBP_CHAR_DIS_MODEL	Device Information Service Model Number String (Property: Read)
SF_BLE_ONBP_CHAR_DIS_SERNB	Device Information Service Serial number String (Property: Read)
SF_BLE_ONBP_CHAR_DIS_HWREV	Device Information Service HW Revision String

	(Property: Read)
SF_BLE_ONBP_CHAR_DIS_FWREV	Device Information Service Fw Revision String (Property: Read)
SF_BLE_ONBP_CHAR_DIS_SWREV	Device Information Service SW Revision String (Property: Read)
SF_BLE_ONBP_CHAR_DIS_SYSID	Device Information Service system ID (Property: Read)
SF_BLE_ONBP_CHAR_DIS_IEEE	Device Information Service IEEE Certification (Property: Read)
SF_BLE_ONBP_CHAR_DIS_PNPID	Device Information PNPID, Used in services like HOGP (Property: Read)
SF_BLE_ONBP_CHAR_IAS_ALERT_LEVEL	Alert Level (Property: Write), Refer sf_ble_prf_ias_alert_type_t. Immediate Alert Service Profile
SF_BLE_ONBP_CHAR_SCPS_CCCD_NTF_SCAN_REFRESH	Scan Refresh CCCD Characteristics (Property: NTF, Read, Write), Refer sf_ble_prf_scps_scan_refresh_t. Scan Parameters Service Profile
SF_BLE_ONBP_CHAR_SCPS_SCAN_INTERVAL_WINDOW	Scan Interval Window (Property: Write), Refer sf_ble_prf_scps_scan_intv_t.
SF_BLE_ONBP_CHAR_CTS_CCCD_NTF_CURRENT_TIME	Current Time CCCD Characteristics (Property: NTF, Read, Write), Refer sf_ble_cts_curr_time_ntf_t. Current Time Service Profile
SF_BLE_ONBP_CHAR_CTS_CCCD_NTF_CURRENT_TIME_VALUE	Used to read data for current time through read characteristics.
SF_BLE_ONBP_CHAR_CTS_LOCAL_TIME_INFORMATION	Local Time Information (Property: Read)
SF_BLE_ONBP_CHAR_CTS_REFERENCE_TIME_INFORMATION	Reference Time Information (Property: Read)
SF_BLE_ONBP_CHAR_NDCS_TIME_WITH_DST	Time with DST (Property: Read) Next DST Change Service Profile
SF_BLE_ONBP_CHAR_TIME_UPDATE_CONTROL_POINT	Time Update Control Point (Property: Write), Refer sf_ble_prf_rtus_time_updt_state_t. Reference Time Update Service Profile

SF_BLE_ONBP_CHAR_TIME_UPDATE_STATE	Time Update State (Property: Read)
SF_BLE_ONBP_CHAR_CCCD_NTF_CURRENT_TIME	Current Time CCCD Characteristics (Property: NTF, Read, Write), Refer sf_ble_bas_battery_lvl_ntf_t. Time Information Service Profile
SF_BLE_ONBP_CHAR_CCCD_NTF_BATTERY_LEVEL	Battery Level (Property: NTF, Read, Write), Refer sf_ble_prf_bas_battery_lvl_t. Battery Service Profile
SF_BLE_ONBP_CHAR_PXPM_SET_ALERT	PXP Alert char. Alert Level Service Profile
SF_BLE_ONBP_CHAR_PXPM_GET_ALERT_LVL	PXP Get Alert Level.
SF_BLE_ONBP_CHAR_PXPM_GET_TX_POWER_LVL	PXP Get TX Power Level.
SF_BLE_ONBP_CHAR_HTP_TEMP_MEAS_IND	HTPC temp. measurement indication CCCD Characteristics (Property: IND, Read, Write), Refer. Health Thermometer Profile
SF_BLE_ONBP_CHAR_HTP_INTERM_TEMP_NTF	HTPC intermediate temp. notification CCCD Characteristics (Property: NTF, Read, Write), Refer.
SF_BLE_ONBP_CHAR_HTP_MEAS_INTV_IND	HTPC temp. measurement interval indication CCCD Characteristics (Property: IND, Read, Write), Refer.
SF_BLE_ONBP_CHAR_HTP_TEMP_TYPE	HTPC temp. temperature type(Property: Read)
SF_BLE_ONBP_CHAR_HTP_MEAS_INTV	HTPC temp. measurement interval.
SF_BLE_ONBP_CHAR_HTP_MEAS_INTV_RANGE	HTPC temp. measurement interval valid range.
SF_BLE_ONBP_CHAR_CCCD_NTF_REPORT_INPUT	Report Input CCCD Characteristics (Property: NTF, Read, Write), Refer sf_ble_prf_hid_report_desc_t. HID Over GATT Service Profile
SF_BLE_ONBP_CHAR_CCCD_NTF_KB_INPUT_REPORT	Keyboard Input Report CCCD Characteristics (Property: NTF, Read, Write), Refer sf_ble_prf_hid_report_desc_t.
SF_BLE_ONBP_CHAR_CCCD_NTF_KB_INPUT_REPO	

RT_VALUE	Used to read Keyboard Input record value through read characteristics.
SF_BLE_ONBP_CHAR_CCCD_NTF_KB_OUTPUT_REPORT_VALUE	Used to read Keyboard Output record value through read characteristics.
SF_BLE_ONBP_CHAR_CCCD_NTF_MOUSE_INPUT_REPORT	Mouse Input Report CCCD Characteristics (Property: NTF, Read, Write), Refer sf_ble_prf_hid_report_desc_t.
SF_BLE_ONBP_CHAR_CCCD_NTF_MOUSE_INPUT_REPORT_VALUE	Used to read Mouse Input record value through read characteristics.
SF_BLE_ONBP_CHAR_PROTOCOL_MODE	HID boot host protocol mode (Property: Read, Write), Refer sf_ble_prf_hid_protocol_mode_t.
SF_BLE_ONBP_CHAR_CONTROL_POINT	HID report host write control point (Property: Read, Write), Refer sf_ble_prf_hid_ctrl_point_val_t.
SF_BLE_ONBP_CHAR_BLP_CCCD_NTF_INTERM_CUFPRS	Read Cuff Pressure measurement CCCD Characteristics (Property: NTF, Read, Write), Refer sf_ble_blp_meas_info_t. Blood Pressure profile
SF_BLE_ONBP_CHAR_BLP_CCCD_IND_BLDPRS_MEAS	Blood Pressure Measurement CCCD Characteristics (Property: IND, Read, Write), Refer sf_ble_blp_meas_info_t.
SF_BLE_ONBP_CHAR_BLP_RD_BLS_BF	Read Blood Pressure Feature.
SF_BLE_ONBP_CHAR_CCCD_NTF_ALERT_STATUS	Alert Status (Property: NTF, Read, Write), Refer sf_ble_prf_alert_status. Phone Alert Status Service Profile
SF_BLE_ONBP_CHAR_CCCD_NTF_ALERT_STATUS_VALUE	Used to read Alert Status value through read characteristics.
SF_BLE_ONBP_CHAR_CCCD_NTF_RINGER_SETTING	Ringer Settings (Property: NTF, Read, Write), Refer sf_ble_prf_ringer_setting_t.
SF_BLE_ONBP_CHAR_CCCD_NTF_RINGER_SETTING_VALUE	Used to read Ringer Settings value through read characteristics.
SF_BLE_ONBP_CHAR_RINGER_CONTROL_POINT	PAPS Ringer control point write characteristics.

◆ sf_ble_prf_sec_t

enum sf_ble_prf_sec_t	
BLE Profile Security type	
Enumerator	
SF_BLE_PRF_SEC_NONE	No Security.
SF_BLE_PRF_SEC_UNAUTH	Unauthenticated Pairing.
SF_BLE_PRF_SEC_AUTH	Authenticated pairing.
SF_BLE_PRF_SEC_AUTZ	Requires Authorized.
SF_BLE_PRF_SEC_ENC	Encrypted communication.

◆ sf_onbp_t

enum sf_onbp_t	
BLE On-Board Profile types	
Enumerator	
SF_ONBP_ANS_SERVER	Alert Notification Service Server.
SF_ONBP_ANS_CLIENT	Alert Notification Service Client.
SF_ONBP_BAS_SERVER	Battery Service Server.
SF_ONBP_BPS_SERVER	Blood Pressure Service Server.
SF_ONBP_BPS_CLIENT	Blood Pressure Service Client.
SF_ONBP_CTS_SERVER	Current Time Service Server.
SF_ONBP_DIS_SERVER	Device Information Service Server.
SF_ONBP_FMP_SERVER	Find Me Service Server.
SF_ONBP_FMP_CLIENT	Find Me Service Client.
SF_ONBP_HTP_SERVER	Health Thermometer Service Server.
SF_ONBP_HTP_CLIENT	Health Thermometer Service Client.
SF_ONBP_HRS_SERVER	Heart Rate Service Server.

SF_ONBP_HRS_CLIENT	Heart Rate Service Client.
SF_ONBP_HID_SERVER	HID Over GATT Service Server.
SF_ONBP_HID_BHOST_CLIENT	HID Over GATT Boot Host Service Client.
SF_ONBP_HID_RHOST_CLIENT	HID Over GATT Report Host Service Client.
SF_ONBP_IMA_SERVER	Immediate Alert Service Server.
SF_ONBP_LLS_SERVER	Link Loss Service Server.
SF_ONBP_LLS_CLIENT	Link Loss Service Client.
SF_ONBP_NDCS_SERVER	Next Daylight Savings Change Service Server.
SF_ONBP_PAPS_SERVER	Phone Alert Service Server.
SF_ONBP_PAPS_CLIENT	Phone Alert Service Client.
SF_ONBP_PXP_SERVER	Proximity Service Server.
SF_ONBP_PXP_CLIENT	Proximity Service Client.
SF_ONBP_RTUS_SERVER	Reference Time Update Service Server.
SF_ONBP_SCPS_SERVER	Scan Parameter Service Server.
SF_ONBP_SCPS_CLIENT	Scan Parameter Service Client.
SF_ONBP_TIP_SERVER	Time Information Service Server.
SF_ONBP_TIP_CLIENT	Time Information Service Client.
SF_ONBP_TXP_SERVER	Transmit Power Service Server.

sf_ble_onboard_profile_cccd_changed_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE On-Board Profile Framework Interface

#include <sf_ble_onboard_profile_api.h>

Data Fields

sf_ble_conn_handle_t	conn_handle Connection handle.
sf_ble_onbp_char_t	char_code CCCD type that has been changed by the remote node.
sf_ble_cccd_val_t	cccd_val CCCD value.
uint8_t	inst_idx Instance index, Applicable for HOGP.

Detailed Description

BLE Profile CCCD Changed indication data

Detailed Description

BLE Configuration, Control and API structures Framework API structure. Implementations will use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_ble_onboard_profile_api_t::close) (sf_ble_onboard_profile_ctrl_t *const p_ctrl)

De-initialize the interface and may put it in low power mode or power it off. Close the driver, disable the driver link, disable interrupt.

Parameters

[in]	p_ctrl	Pointer to the control block for the BLE module.

◆ onbpClientReadChar

ssp_err_t(* sf_ble_onboard_profile_api_t::onbpClientReadChar) (sf_ble_onboard_profile_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_onbp_t profile, sf_ble_onbp_char_t characteristics)

Reads GATT characteristics from Server Reads GATT characteristics from the Server for the profile specified.

Parameters

[in]	p_ctrl	Pointer to control structure for BLE
[in]	p_handle	Pointer to connection handle
[in]	profile	Profile type
[in]	characteristics	Profile characteristics

◆ onbpClientWriteCCCD

ssp_err_t(* sf_ble_onboard_profile_api_t::onbpClientWriteCCCD) (sf_ble_onboard_profile_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_onbp_t profile, sf_ble_onbp_char_t cccd_char, sf_ble_cccd_val_t cccd_val)

Writes CCCD configuration in Server This API writes CCCD configuration of Server and which enables or disables notification or indication from server.

Parameters

[in]	p_ctrl	Pointer to control structure for BLE
[in]	p_handle	Pointer to connection handle
[in]	profile	Parameter_Description
[in]	cccd_char	CCCD Code
[in]	cccd_val	Configuration data of CCCD

◆ onbpClientWriteChar

ssp_err_t(* sf_ble_onboard_profile_api_t::onbpClientWriteChar) (sf_ble_onboard_profile_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_onbp_t profile, sf_ble_onbp_char_t characteristics, const void *p_data)

Writes GATT characteristics with data passed Writes the GATT characteristics in the Server with the data passed.

Parameters

[in]	p_ctrl	Pointer to control structure for BLE
[in]	p_handle	Pointer to connection handle
[in]	profile	Profile type
[in]	characteristics	GATT characteristics code
[in]	p_data	Pointer to data

◆ onbpDisable

ssp_err_t(* sf_ble_onboard_profile_api_t::onbpDisable) (sf_ble_onboard_profile_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_onbp_t profile)

Disable On-Board Profile Disables On-Board profile on given connection handle and unregisters user callback.

Parameters

[in]	p_ctrl	Pointer to control structure for BLE
[in]	p_handle	Pointer to connection handle
[in]	profile	Profile type to disable

◆ onbpEnable

ssp_err_t(* sf_ble_onboard_profile_api_t::onbpEnable) (sf_ble_onboard_profile_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_onbp_t profile, sf_ble_profile_callback_t p_prf_cb, sf_ble_prf_sec_t sec)

Enable On-Board Profile Enables On-Board profile on given connection handle with specified security type. Registers user callback for the profile.

Parameters

[in,out]	p_ctrl	Pointer to control structure for BLE
[in]	p_handle	Pointer to connection handle
[in]	profile	Profile type to enable
[in]	p_prf_cb	User callback for Profile
[in]	sec	Security type for profile

◆ onbpServerSendIndication

ssp_err_t(* sf_ble_onboard_profile_api_t::onbpServerSendIndication) (sf_ble_onboard_profile_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_onbp_t profile, sf_ble_onbp_char_t characteristics, const void *p_data)

Send Indication from Server Sends Indication which contains profile specific data to client.

Parameters

[in]	p_ctrl	Pointer to control structure for BLE
[in]	p_handle	Pointer to connection handle
[in]	profile	Profile type
[in]	characteristics	Profile characteristics
[in]	p_data	Pointer to data

◆ onbpServerSendNotification

ssp_err_t(* sf_ble_onboard_profile_api_t::onbpServerSendNotification) (sf_ble_onboard_profile_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_onbp_t profile, sf_ble_onbp_char_t characteristics, const void *p_data)

Send notification from Server Sends Notification which will be data specific to On-Board Profile to Client.

Parameters

[in]	p_ctrl	Pointer to control structure for BLE
[in]	p_handle	Pointer to connection handle
[in]	profile	Profile type
[in]	characteristics	Profile characteristics
[in]	p_data	Pointer to data

◆ onbpServerWriteData

ssp_err_t(* sf_ble_onboard_profile_api_t::onbpServerWriteData) (sf_ble_onboard_profile_ctrl_t *const p_ctrl, sf_ble_conn_handle_t *p_handle, sf_onbp_t profile, sf_ble_onbp_char_t characteristics, const void *p_data)

Update Server Local Database Update Local GATT database of Profile Server.

Parameters

[in]	p_ctrl	Pointer to control structure for BLE
[in]	p_handle	Pointer to connection handle
[in]	profile	Profile type
[in]	characteristics	Profile characteristics
[in]	p_data	Pointer to data

◆ open

ssp_err_t(* sf_ble_onboard_profile_api_t::open) (sf_ble_onboard_profile_ctrl_t *const p_ctrl, const sf_ble_onboard_profile_cfg_t *p_cfg)
Initializes the interface for data transfers. Initial driver configuration, enable the driver link, enable interrupts and make device ready for data transfer. **Parameters** [in,out] p_ctrl — Pointer to user-provided storage for the control block. [in] p_cfg — Pointer to BLE configuration structure.

◆ versionGet

ssp_err_t(* sf_ble_onboard_profile_api_t::versionGet) (ssp_version_t *const p_version)
Gets version and stores it in provided pointer p_version. **Parameters** [out] p_version — pointer to memory location to return version number

Detailed Description

RTOS-integrated SF BLE Alert Notification Profile Framework Interface.

Summary

This SSP Interface provides access to the ThreadX-aware SF BLE Alert Notification Profile Framework.

Macro Definition Documentation

◆ SF_BLE_ANP_ALT_TEXT_MAX

#define SF_BLE_ANP_ALT_TEXT_MAX (18U)
Buffer size of data for Alert Notification

Enumeration Type Documentation

◆ sf_ble_prf_anp_category_id

enum sf_ble_prf_anp_category_id	
Alert Notification Control Point Category ID	
Enumerator	
SF_BLE_PRF_ANP_CATEGORY_ID_SIMPLE_ALERT	Simple Alert: General text alert or non-text alert.
SF_BLE_PRF_ANP_CATEGORY_ID_EMAIL	Email Alert.
SF_BLE_PRF_ANP_CATEGORY_ID_NEWS	News feeds Alert.
SF_BLE_PRF_ANP_CATEGORY_ID_CALL	Incoming Call Alert.
SF_BLE_PRF_ANP_CATEGORY_ID_MISSED_CALL	Missed Call Alert.
SF_BLE_PRF_ANP_CATEGORY_ID_SMS_MMS	SMS/MMS Message Alert.
SF_BLE_PRF_ANP_CATEGORY_ID_VOICE_MAIL	Voice Mail Alert.
SF_BLE_PRF_ANP_CATEGORY_ID_SCHEDULE	Alert occurred on calendar, planner.
SF_BLE_PRF_ANP_CATEGORY_ID_HIGH_PRIORITY_ALERT	High Prioritized Alert.
SF_BLE_PRF_ANP_CATEGORY_ID_INSTANT_MESSAGE	Incoming Instant Messages.
SF_BLE_PRF_ANP_CATEGORY_ID_ALL	All Supported Categories.

◆ sf_ble_prf_anp_cmd_id_t

enum sf_ble_prf_anp_cmd_id_t	
Alert Notification Control Point Command ID	
Enumerator	
SF_BLE_PRF_ANP_CMD_ID_NEW_ALERT_ENABLE	Enable New Incoming Alert Notification.
SF_BLE_PRF_ANP_CMD_ID_UNREAD_ALERT_ENABLE	Enable Unread Category Status Notification.
SF_BLE_PRF_ANP_CMD_ID_NEW_ALERT_DISABLE	Disable New Incoming Alert Notification.
SF_BLE_PRF_ANP_CMD_ID_UNREAD_ALERT_DISABLE	Disable Unread Category Status Notification.
SF_BLE_PRF_ANP_CMD_ID_NEW_ALERT_NTF_REQ	Notify New Incoming Alert immediately.
SF_BLE_PRF_ANP_CMD_ID_UNREAD_ALERT_NTF_REQ	Notify Unread Category Status immediately.

◆ sf_ble_prf_anpc_event_t

enum sf_ble_prf_anpc_event_t	
Profile Client user events	
Enumerator	
SF_BLE_PRF_ANPC_EVENT_NONE	Event not supported.
SF_BLE_PRF_ANPC_EVENT_NEW_ALT_NTF	New Alert Data received event, Refer sf_ble_anp_api_new_alert_ntf_t.
SF_BLE_PRF_ANPC_EVENT_UNREAD_ALT_NTF	Unread Alert Data received event, Refer sf_ble_anp_api_unread_alert_ntf_t.
SF_BLE_PRF_ANPC_EVENT_READ_CHAR_RES	Read Char Complete Event.

◆ sf_ble_prf_anps_event_t

enum sf_ble_prf_anps_event_t	
Alert notification server profile user events	
Enumerator	
SF_BLE_PRF_ANPS_EVENT_NONE	Event not supported.
SF_BLE_PRF_ANPS_EVENT_ALT_NF_CP_IND	Alert Notification Control Point Changed indication, Refer sf_ble_anp_ancp_change_t.
SF_BLE_PRF_ANPS_EVENT_CCCD_NTF_IND	CCCD Notification Setting change event.

Profile user client events	
Enumerator	
SF_BLE_PRF_BLPC_EVENT_NONE	Event not supported.
SF_BLE_PRF_BLPC_EVENT_MEAS_NTF_IND	BLE user event indicating BLPC profile measurement notification.
SF_BLE_PRF_BLPC_EVENT_WRITE_CHAR_RES	BLE user event indicating BLPC profile read char response.
SF_BLE_PRF_BLPC_EVENT_READ_CHAR_RES	BLE user event indicating BLPC write char response.

◆ sf_ble_prf_blps_event_t

enum sf_ble_prf_blps_event_t	
Profile user server events	
Enumerator	
SF_BLE_PRF_BLPS_EVENT_NONE	Event not supported.
SF_BLE_PRF_BLPS_EVENT_NTFIND_IND	BLE user event indicating notification indication.

sf_ble_blp_meas_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Blood Pressure Profile Framework Interface

#include <sf_ble_prf_blp_api.h>

Data Fields

uint8_t	flag_stable_meas

	Stable or intermediary type of measurements. Set to 0 if intermediate measurement.
uint8_t	flags flags
int16_t	press_val1 blood pressure value - Systolic or cuff pressure. Cuff pressure has to be filled here
int16_t	press_val2 blood pressure value - Diastolic or subfield1
int16_t	press_val3 blood pressure value - MAP or subfield2
sf_ble_prf_cts_date_time_t	stamp time stamp
int16_t	rate pulse rate
uint8_t	id user ID
uint8_t	reserved Reserved.
uint16_t	meas_sts measurement status

Detailed Description

Blood Pressure Measurements Info

The documentation for this struct was generated from the following file:

enum	sf_ble_prf_alert_setting_t { SF_BLE_PRF_ALERT_NONE, SF_BLE_PRF_ALERT_RINGER, SF_BLE_PRF_ALERT_VIBRATOR, SF_BLE_PRF_ALERT_DISPLAY }

Detailed Description

RTOS-integrated SF BLE Phone Alert Status Profile Framework Interface.

Summary

This SSP Interface provides access to the ThreadX-aware SF BLE Phone Alert Status Profile Framework.

Typedef Documentation

◆ sf_ble_prf_alert_status

typedef uint8_t sf_ble_prf_alert_status
PASP Alert Status

Enumeration Type Documentation

◆ sf_ble_prf_alert_setting_t

enum sf_ble_prf_alert_setting_t	
PASP Alert status	
Enumerator	
SF_BLE_PRF_ALERT_NONE	No active alert.
SF_BLE_PRF_ALERT_RINGER	Ringer State is active.
SF_BLE_PRF_ALERT_VIBRATOR	Vibrate State is active.
SF_BLE_PRF_ALERT_DISPLAY	Display Alert Status State is active.

◆ sf_ble_prf_papsc_event_t

enum sf_ble_prf_papsc_event_t	
Profile Client user events	
Enumerator	
SF_BLE_PRF_PAPSC_EVENT_NONE	Event not supported.
SF_BLE_PRF_PAPSC_EVENT_READ_CHAR_RES	BLE user event indicating PAPS target alert indication received from locator.
SF_BLE_PRF_PAPSC_EVENT_RINGER_SETTING_IND	BLE user event indicating PAPS ringer setting indication, Refer sf_ble_prf_ringer_setting_ntf_t .
SF_BLE_PRF_PAPSC_EVENT_ALERT_STATUS_RES	BLE user event indicating PAPS alert status response, Refer sf_ble_prf_alert_status_ntf_t.

◆ sf_ble_prf_papss_event_t

enum sf_ble_prf_papss_event_t	
Profile Server user events	
Enumerator	
SF_BLE_PRF_PAPSS_EVENT_NONE	Event not supported.
SF_BLE_PRF_PAPSS_EVENT_RINGER_CP_IND	BLE user event indicating ringer control point indication, Refer sf_ble_prf_ringer_cp_change_t .
SF_BLE_PRF_PAPSS_EVENT_CFG_NTF_IND	BLE user event indicating notification indication.

◆ sf_ble_prf_ringer_cp_t

enum sf_ble_prf_ringer_cp_t	
Ringer Control Point value	
Enumerator	
SF_BLE_PRF_RINGER_CP_SILENT_MODE	Silent Mode.
SF_BLE_PRF_RINGER_CP_MUTE_ONCE	Mute Once.
SF_BLE_PRF_RINGER_CP_CANCEL_SILENT_MODE	Cancel Silent Mode.

◆ sf_ble_prf_ringer_setting_t

enum sf_ble_prf_ringer_setting_t	
Ringer Setting Value	
Enumerator	
SF_BLE_PRF_RINGER_SETTING_SILENT	Ringer Silent.
SF_BLE_PRF_RINGER_SETTING_NORMAL	Ringer Normal.

sf_ble_prf_ringer_cp_change_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Phone Alert Status Profile Framework Interface

#include <sf_ble_prf_paps_api.h>

Data Fields

sf_ble_conn_handle_t	conhdl Connection handle.
sf_ble_prf_ringer_cp_t	ringer_cp Ringer control point value.

Detailed Description

Ringer Control Point value changed indication

The documentation for this struct was generated from the following file:

- sf_ble_prf_paps_api.h

sf_ble_prf_ringer_setting_ntf_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Phone Alert Status Profile Framework Interface

#include <sf_ble_prf_paps_api.h>

Data Fields

sf_ble_conn_handle_t	conhdl Connection handle.
sf_ble_prf_ringer_setting_t	ringer_setting Ringer control point value.

Detailed Description

Ringer Setting notification received data

The documentation for this struct was generated from the following file:

- sf_ble_prf_paps_api.h

sf_ble_prf_alert_status_ntf_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Phone Alert Status Profile Framework Interface

#include <sf_ble_prf_paps_api.h>

Data Fields

sf_ble_conn_handle_t	conhdl

	Connection handle.
sf_ble_prf_alert_status	alert_status Ringer control point value.

Detailed Description

Alert Status notification received data

The documentation for this struct was generated from the following file:

- sf_ble_prf_paps_api.h

5.1.2.18 SF BLE Proximity Profile Framework Interface

Renesas Synergy Software Package Reference » Framework Interfaces

RTOS-integrated SF BLE Proximity Profile Framework Interface. More...

Enumerations

enum	sf_ble_prf_pxpr_event_t { SF_BLE_PRF_PXPR_EVENT_NONE, SF_BLE_PRF_PXPR_EVENT_ALT_IND, SF_BLE_PRF_PXPR_EVENT_CMD_DISALLOWED_IND }
enum	sf_ble_prf_pxpm_event_t { SF_BLE_PRF_PXPM_EVENT_NONE, SF_BLE_PRF_PXPM_EVENT_READ_CHAR_RESP, SF_BLE_PRF_PXPM_EVENT_CMD_DISALLOWED_IND, SF_BLE_PRF_PXPM_EVENT_ERROR_IND }

Detailed Description

RTOS-integrated SF BLE Proximity Profile Framework Interface.

Summary

This SSP Interface provides access to the ThreadX-aware SF BLE Proximity Profile Framework.

Enumeration Type Documentation

◆ sf_ble_prf_pxpm_event_t

enum sf_ble_prf_pxpm_event_t	
PXP monitor (client) user events	
Enumerator	
SF_BLE_PRF_PXPM_EVENT_NONE	unsupported event
SF_BLE_PRF_PXPM_EVENT_READ_CHAR_RESP	BLE user event indicating PXPR profile alert indication.
SF_BLE_PRF_PXPM_EVENT_CMD_DISALLOWED_IND	command disallowed error received
SF_BLE_PRF_PXPM_EVENT_ERROR_IND	error received for command issued

◆ sf_ble_prf_pxpr_event_t

enum sf_ble_prf_pxpr_event_t	
PXP reporter (server) user events	
Enumerator	
SF_BLE_PRF_PXPR_EVENT_NONE	unsupported event
SF_BLE_PRF_PXPR_EVENT_ALT_IND	BLE user event indicating PXPR profile alert indication.
SF_BLE_PRF_PXPR_EVENT_CMD_DISALLOWED_IND	command disallowed error received

5.1.2.19 SF BLE Reference Time Update Service Profile Framework Interface

Renesas Synergy Software Package Reference » Framework Interfaces

RTOS-integrated SF BLE Reference Time Update Service Profile Framework Interface. More...

Data Structures

struct	sf_ble_prf_rtus_time_updt_state_t
struct	sf_ble_tip_cp_change_t

Variables

SSP_HEADER typedef	sf_ble_prf_tip_time_ctrl_point_t

uint8_t	

Detailed Description

RTOS-integrated SF BLE Reference Time Update Service Profile Framework Interface.

Summary

This SSP Interface provides access to the ThreadX-aware SF BLE Reference Time Update Service Profile Framework.

Variable Documentation

◆ sf_ble_prf_tip_time_ctrl_point_t

SSP_HEADER typedef uint8_t sf_ble_prf_tip_time_ctrl_point_t
Time Update Control point

sf_ble_prf_rtus_time_updt_state_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Reference Time Update Service Profile Framework Interface

#include <sf_ble_prf_rtus_api.h>

Data Fields

uint8_t	current_state Current state of Reference time.
uint8_t	update_result Result of update.

Detailed Description

Reference Time Update State structure

The documentation for this struct was generated from the following file:

- sf_ble_prf_rtus_api.h

sf_ble_tip_cp_change_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Reference Time Update Service Profile Framework Interface

#include <sf_ble_prf_rtus_api.h>

Data Fields

sf_ble_conn_handle_t	conhdl Connection handle.
sf_ble_prf_tip_time_ctrl_point_t	control_point_value Time Update Control point value.

Detailed Description

Time Update Control Point Change Indication for Server

The documentation for this struct was generated from the following file:

- sf_ble_prf_rtus_api.h

5.1.2.20 SF BLE Scan Parameters Service Profile Framework Interface

Renesas Synergy Software Package Reference » Framework Interfaces

RTOS-integrated SF BLE Scan Parameters Service Profile Framework Interface. More...

Data Structures

struct	sf_ble_prf_scps_scan_intv_t
struct	sf_ble_scps_scan_intv_change_t

Typedefs

typedef uint8_t	sf_ble_prf_scps_scan_refresh_t

Enumerations

enum	sf_ble_prf_scps_event_t { SF_BLE_PRF_SCPS_EVENT_NONE, SF_BLE_PRF_SCPS_EVENT_INDNTF_IND, SF_BLE_PRF_SCPS_EVENT_CHG_EVT }

Detailed Description

RTOS-integrated SF BLE Scan Parameters Service Profile Framework Interface.

Summary

This SSP Interface provides access to the ThreadX-aware SF BLE Scan Parameters Service Profile Framework.

Typedef Documentation

◆ sf_ble_prf_scps_scan_refresh_t

typedef uint8_t sf_ble_prf_scps_scan_refresh_t
Scan Refresh Data value

Enumeration Type Documentation

◆ sf_ble_prf_scps_event_t

enum sf_ble_prf_scps_event_t	
Profile Server user events	
Enumerator	
SF_BLE_PRF_SCPS_EVENT_NONE	Event not supported.
SF_BLE_PRF_SCPS_EVENT_INDNTF_IND	BLE Notification Setting Change Indication.
SF_BLE_PRF_SCPS_EVENT_CHG_EVT	BLE Scan Interval Changed Indication, Refer sf_ble_scps_scan_intv_change_t.

sf_ble_prf_scps_scan_intv_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Scan Parameters Service Profile Framework Interface

#include <sf_ble_prf_scps_api.h>

Data Fields

uint16_t	le_scan_interval scan interval value
uint16_t	le_scan_window scan window value

Detailed Description

Scan interval window characteristic data

The documentation for this struct was generated from the following file:

- sf_ble_prf_scps_api.h

sf_ble_scps_scan_intv_change_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Scan Parameters Service Profile Framework Interface

#include <sf_ble_prf_scps_api.h>

Data Fields

sf_ble_conn_handle_t	conhdl Connection handle.
sf_ble_prf_scps_scan_intv_t	scan_interval_window_val Scan Interval window.

Detailed Description

Scan interval window Change Indication for Sensor

The documentation for this struct was generated from the following file:

- sf_ble_prf_scps_api.h

5.1.2.21 SF BLE Time Information Profile Framework Interface

Renesas Synergy Software Package Reference » Framework Interfaces

RTOS-integrated SF BLE Time Information Profile Framework Interface. More...

Data Structures

union	sf_ble_prf_tip_write_data_t

Enumerations

enum	sf_ble_prf_tipc_event_t { SF_BLE_PRF_TIPC_EVENT_NONE, SF_BLE_PRF_TIPC_EVENT_READ_CHAR_RES, SF_BLE_PRF_TIPC_EVENT_CURR_TIME_NTF }
enum	sf_ble_prf_tips_event_t { SF_BLE_PRF_TIPS_EVENT_NONE, SF_BLE_PRF_TIPS_EVENT_NTF_IND, SF_BLE_PRF_TIPS_EVENT_CP_IND }

Detailed Description

RTOS-integrated SF BLE Time Information Profile Framework Interface.

Summary

This SSP Interface provides access to the ThreadX-aware SF BLE Time Information Profile Framework.

Enumeration Type Documentation

◆ **sf_ble_prf_tipc_event_t**

enum sf_ble_prf_tipc_event_t	
Time Profile Client events	
Enumerator	
SF_BLE_PRF_TIPC_EVENT_NONE	Event not supported.
SF_BLE_PRF_TIPC_EVENT_READ_CHAR_RES	Read Char Complete Event.
SF_BLE_PRF_TIPC_EVENT_CURR_TIME_NTF	Current Time information received, Refer sf_ble_cts_curr_time_ntf_t.

◆ sf_ble_prf_tips_event_t

enum sf_ble_prf_tips_event_t	
Time Profile Server events	
Enumerator	
SF_BLE_PRF_TIPS_EVENT_NONE	Event not supported.
SF_BLE_PRF_TIPS_EVENT_NTF_IND	CCCD Notification Received event.
SF_BLE_PRF_TIPS_EVENT_CP_IND	Time Update control point changed, Refer sf_ble_prf_tip_time_ctrl_point_t.

sf_ble_prf_tip_write_data_t Union Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF BLE Time Information Profile Framework Interface

#include <sf_ble_prf_tip_api.h>

Data Fields

sf_ble_prf_cts_curr_time_t	current_time Current Time Information.
sf_ble_cts_local_time_t	local_time Local Time Information.
sf_ble_cts_ref_time_t	ref_time Reference Time Information.
sf_ble_prf_ndcs_time_dst_t	next_dst Next DST Information.
sf_ble_prf_rtus_time_updt_state_t	update_state Update Status Information.

Detailed Description

Write Local Database Information

The documentation for this union was generated from the following file:

5.1.2.22 Block Media Framework Interface

Renesas Synergy Software Package Reference » Framework Interfaces

RTOS-integrated File system Interface to access Synergy block media devices. More...

Data Structures

struct	sf_block_media_cfg_t
struct	sf_block_media_api_t
struct	sf_block_media_instance_t

Typedefs

typedef void	sf_block_media_ctrl_t

Detailed Description

RTOS-integrated File system Interface to access Synergy block media devices.

The interface provides an adaption layer from the FileX I/O to block media devices.

Summary

Related SSP architecture topics:

- SSP Interfaces
- SSP Predefined Layers
- Using SSP Modules

See also FileX Interface description: FileX on Block Media

Typedef Documentation

◆ sf_block_media_ctrl_t

typedef void sf_block_media_ctrl_t

Block media framework control block. Allocate an instance specific control block to pass into the block media framework API calls.

Implemented as

- sf_block_media_sdmmc_instance_ctrl_t
- sf_block_media_ram_instance_ctrl_t
- sf_block_media_qspi_instance_ctrl_t
- sf_block_media_levelx_nor_instance_ctrl_t

sf_block_media_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Block Media Framework Interface

#include <sf_block_media_api.h>

Data Fields

uint32_t	block_size Block size in bytes.
void const *	p_extend Instance dependent configuration.

Detailed Description

Interface Configuration

The documentation for this struct was generated from the following file:

- sf_block_media_api.h

sf_block_media_api_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Block Media Framework Interface

#include <sf_block_media_api.h>

Data Fields

ssp_err_t(*	open)(sf_block_media_ctrl_t *p_ctrl, sf_block_media_cfg_t const *const p_cfg)
ssp_err_t(*	read)(sf_block_media_ctrl_t *p_ctrl, uint8_t *const p_dest, uint32_t const start_sector, uint32_t const sector_count)
ssp_err_t(*	write)(sf_block_media_ctrl_t *p_ctrl, uint8_t const *const p_src, uint32_t const start_sector, uint32_t const sector_count)
ssp_err_t(*	ioctl)(sf_block_media_ctrl_t *p_ctrl, ssp_command_t const command, void *p_data)
ssp_err_t(*	close)(sf_block_media_ctrl_t *p_ctrl)
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

Shared Interface definition for Block Media

Field Documentation

◆ close

ssp_err_t(* sf_block_media_api_t::close) (sf_block_media_ctrl_t *p_ctrl)

Close the open media channel.

Implemented as

- SF_Block_Media_SDMMC_Close()
- SF_BLOCK_MEDIA_RAM_Close()
- SF_BLOCK_MEDIA_QSPI_Close()
- SF_BLOCK_MEDIA_LX_NOR_Close()

Parameters

[in]	p_cfg	Pointer to the media configuration structure for a channel.

◆ ioctl

ssp_err_t(* sf_block_media_api_t::ioctl) (sf_block_media_ctrl_t *p_ctrl, ssp_command_t const command, void *p_data)

Send control commands to and receives the status from the media port.

Implemented as

- SF_Block_Media_SDMMC_Control()
- SF_BLOCK_MEDIA_RAM_Control()
- SF_BLOCK_MEDIA_QSPI_Control()
- SF_BLOCK_MEDIA_LX_NOR_Control()

Parameters

[in]	p_cfg	Pointer to the media configuration structure for a channel.
[in]	command	Command to execute.
[in,out]	p_data	Void pointer to data in or out.

◆ open

ssp_err_t(* sf_block_media_api_t::open) (sf_block_media_ctrl_t *p_ctrl, sf_block_media_cfg_t const *const p_cfg)

Open a device channel for read/write and control.

Implemented as

- SF_Block_Media_SDMMC_Open()
- SF_BLOCK_MEDIA_RAM_Open()
- SF_BLOCK_MEDIA_QSPI_Open()
- SF_BLOCK_MEDIA_LX_NOR_Open()

Parameters

[in]	p_cfg	Pointer to the media configuration structure for a channel.

◆ read

ssp_err_t(* sf_block_media_api_t::read) (sf_block_media_ctrl_t *p_ctrl, uint8_t *const p_dest, uint32_t const start_sector, uint32_t const sector_count)

Read data from a media channel.

Implemented as

- SF_Block_Media_SDMMC_Read()
- SF_BLOCK_MEDIA_RAM_Read()
- SF_BLOCK_MEDIA_QSPI_Read()
- SF_BLOCK_MEDIA_LX_NOR_Read()

Parameters

[in]	p_cfg	Pointer to the media configuration structure for a channel.
[in]	p_dest	Destination address to read data out.
[in]	start_sector	Beginning sector address to read.
[in]	sector_count	Number of sectors to read.

◆ versionGet

ssp_err_t(* sf_block_media_api_t::versionGet) (ssp_version_t *const p_version)

Return the version of the driver.

Implemented as

- SF_Block_Media_SDMMC_VersionGet()
- SF_BLOCK_MEDIA_RAM_VersionGet()
- SF_BLOCK_MEDIA_QSPI_VersionGet()
- SF_BLOCK_MEDIA_LX_NOR_VersionGet()

Parameters

[in]	p_cfg	Pointer to the media configuration structure for a channel.
[out]	p_version	Memory address to return version information to.

◆ write

ssp_err_t(* sf_block_media_api_t::write) (sf_block_media_ctrl_t *p_ctrl, uint8_t const *const p_src, uint32_t const start_sector, uint32_t const sector_count)

Write data to a media channel.

Implemented as

- SF_Block_Media_SDMMC_Write()
- SF_BLOCK_MEDIA_RAM_Write()
- SF_BLOCK_MEDIA_QSPI_Write()
- SF_BLOCK_MEDIA_LX_NOR_Write()

Parameters

[in]	p_cfg	Pointer to the media configuration structure for a channel.
[in]	p_src	Source address of data for writing.
[in]	start_sector	Beginning sector address to write to.
[in]	sector_count	Number of sectors to write.

The documentation for this struct was generated from the following file:

- sf_block_media_api.h

sf_block_media_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Block Media Framework Interface

#include <sf_block_media_api.h>

Data Fields

sf_block_media_ctrl_t *	p_ctrl Block media pointer to device driver control structure.
sf_block_media_cfg_t const *	p_cfg

	Block media pointer to device driver configuration structure.
sf_block_media_api_t const *	p_api Block media pointer to device driver api structure.

SF_CELLULAR_AIRPLANE_MODE_ON	Airplane mode enabled.

◆ sf_cellular_at_cmd_index_t

enum sf_cellular_at_cmd_index_t	
Enumeration for AT command index	
Enumerator	
SF_CELLULAR_AT_CMD_INDEX_AT	Index for Command AT.
SF_CELLULAR_AT_CMD_INDEX_ATZ0	Index for Command ATZ0.
SF_CELLULAR_AT_CMD_INDEX_AT_CREG_SET_0	Index for Command to set AT+CREG.
SF_CELLULAR_AT_CMD_INDEX_AT_CMEE_SET_0	Index for Command to set AT+CMEE.
SF_CELLULAR_AT_CMD_INDEX_AT_ECHO	Index for Command ATE.
SF_CELLULAR_AT_CMD_INDEX_AT_SAVE	Index for Command AT&W.
SF_CELLULAR_AT_CMD_INDEX_AT_ENTER_CPIN	Index for Command to unlock SIM.
SF_CELLULAR_AT_CMD_INDEX_AT_CPIN_SET	Index for Command to set SIM PIN.
SF_CELLULAR_AT_CMD_INDEX_AT_CGDCONT_SET	Index for Command to set AT+CGDCOND.
SF_CELLULAR_AT_CMD_INDEX_AT_CPOL_SET	Index for Command to set AT+CPOL.
SF_CELLULAR_AT_CMD_INDEX_AT_COPS_GET	

	Index for Command to get current operator details.
SF_CELLULAR_AT_CMD_INDEX_AT_AIRPLANE_OFF	Index for Command to set Airplane mode OFF.
SF_CELLULAR_AT_CMD_INDEX_AT_AIRPLANE_ON	Index for Command to set Airplane mode ON.
SF_CELLULAR_AT_CMD_INDEX_AT_CONTEXT_ACTIVE	Index for Command to activate context.
SF_CELLULAR_AT_CMD_INDEX_AT_CONTEXT_DEACTIVE	Index for Command to deactivate context.
SF_CELLULAR_AT_CMD_INDEX_AT_CGDATA_ACTIVE	Index for Command to activate Data mode.
SF_CELLULAR_AT_CMD_INDEX_AT_CGDATA_DEACTIVE	Index for Command to deactivate Data mode.
SF_CELLULAR_AT_CMD_INDEX_AT_CSQ_GET	Index for Command to get signal quality.
SF_CELLULAR_AT_CMD_INDEX_AT_VER_GET	Index for Command to get Modem stack Version.
SF_CELLULAR_AT_CMD_INDEX_AT_CHIPSET_GET	Index for Command to get chipset details.
SF_CELLULAR_AT_CMD_INDEX_AT_IMEI_GET	Index for Command to get IMEI number.
SF_CELLULAR_AT_CMD_INDEX_AT_MANF_NAME_GET	Index for Command to get manufacturer name.
SF_CELLULAR_AT_CMD_INDEX_AT_SIMID_GET	Index for Command to get SIM Card ID.
SF_CELLULAR_AT_CMD_INDEX_AT_NET_TYPE_STATUS_GET	Index for Command to get network type information.
SF_CELLULAR_AT_CMD_INDEX_AT_NET_STATUS_GET	Index for Command to get network status information.
SF_CELLULAR_AT_CMD_INDEX_AT_DETACH	Index for Command to detach the MT.
SF_CELLULAR_AT_CMD_INDEX_AT_LOCK_SIM	Index for Command to lock SIM card.
SF_CELLULAR_AT_CMD_INDEX_AT_UNLOCK_SIM	Index for Command to unlock SIM card.
SF_CELLULAR_AT_CMD_INDEX_AT_ENTER_DATA_MODE	Index for Command to enter data mode.
SF_CELLULAR_AT_CMD_INDEX_AT_EXIT_DATA_MODE	Index for Command to exit data mode.
SF_CELLULAR_AT_CMD_INDEX_AT_USERNAME_SET	Index for Command to set username.

SF_CELLULAR_AT_CMD_INDEX_AT_PASSWORD_SET	Index for Command to set password.
SF_CELLULAR_AT_CMD_INDEX_AT_AUTH_TYPE_SET	Index for Command to set authorisation type.
SF_CELLULAR_AT_CMD_INDEX_AT_AUTO_TIME_UPDATE_ENABLE_SET	Index for Command to enable auto time update.
SF_CELLULAR_AT_CMD_INDEX_AT_AUTO_TIME_UPDATE_DISABLE_SET	Index for Command to disable auto time update.
SF_CELLULAR_AT_CMD_INDEX_AT_EMPTY_APN_SET	Index for Command to set empty APN.
SF_CELLULAR_AT_CMD_INDEX_AT_GET_IP_ADDR	Index for Command to get IP address.
SF_CELLULAR_AT_CMD_INDEX_AT_NWSCANSEQ_SET	Index for Command to set network fallback sequence.
SF_CELLULAR_AT_CMD_INDEX_AT_NWSCANMODE_SET	Index for Command to set network scan mode.
SF_CELLULAR_AT_CMD_INDEX_AT_IOTOPMODE_SET	Index for Command to Configure Network Category to be Searched under LTE.
SF_CELLULAR_AT_CMD_INDEX_AT_SWITCH_BACK_TO_DATA_MODE	Index for Command to switch back to Data mode.
SF_CELLULAR_AT_CMD_INDEX_AT_GET_IMSI	Index for Command to get IMSI ID.
SF_CELLULAR_AT_CMD_INDEX_AT_IPR_SET	Index for Command to set baud rate of modem.
SF_CELLULAR_AT_CMD_INDEX_AT_BAUD_CHECK	Index for Command to check whether modem is responding after baud update.
SF_CELLULAR_AT_CMD_INDEX_AT_SIM_EFFECT_SET	Index for Command to set SIM priority effect.

◆ sf_cellular_auth_type_t

enum sf_cellular_auth_type_t	
Cellular authentication type	
Enumerator	
SF_CELLULAR_AUTH_TYPE_NONE	No authentication.
SF_CELLULAR_AUTH_TYPE_PAP	PAP.
SF_CELLULAR_AUTH_TYPE_CHAP	CHAP.

◆ sf_cellular_config_at_cmd_index_t

enum sf_cellular_config_at_cmd_index_t	
Enumeration for configurable AT command index	
Enumerator	
SF_CELLULAR_CONFIG_AT_CMD_INDEX_AT_CREG	Index for Command AT+CREG.
SF_CELLULAR_CONFIG_AT_CMD_INDEX_AT_CEREG	Index for Command AT+CEREG.
SF_CELLULAR_CONFIG_AT_CMD_INDEX_AT_COPS_AUTO_SET	Index for Command to set AUTO AT+COPS.
SF_CELLULAR_CONFIG_AT_CMD_INDEX_AT_COPS_MANUAL_SET	Index for Command to set Manual AT+COPS.
SF_CELLULAR_CONFIG_AT_CMD_INDEX_AT_CPIN_STATUS_GET	Index for Command to get status of SIM lock.

◆ sf_cellular_event_t

enum sf_cellular_event_t	
Cellular Framework event codes	
Enumerator	
SF_CELLULAR_EVENT_RX	Packet received event.
SF_CELLULAR_EVENT_PROVISIONSET	Provisioning Set event.

◆ sf_cellular_log_buffer_type_t

enum sf_cellular_log_buffer_type_t	
Command Buffer type specifies the type of data in debug log buffer	
Enumerator	
SF_CELLULAR_LOG_BUFFER_TYPE_COMMAND	Data in logging buffer is an AT command.
SF_CELLULAR_LOG_BUFFER_TYPE_RESPONSE_RECEIVED	Data in logging buffer is complete response received from modem.
SF_CELLULAR_LOG_BUFFER_TYPE_RESPONSE_RECEIVED_WITH_TIMEOUT	Data in logging buffer is response received from modem with timeout.

◆ sf_cellular_network_reg_status_t

enum sf_cellular_network_reg_status_t	
Cellular Network Registration Status	
Enumerator	
SF_CELLULAR_NETWORK_REG_STATUS_NOT_REGISTERED_NO_SEARCH	not registered, MT is not currently searching a new operator to register to
SF_CELLULAR_NETWORK_REG_STATUS_REGISTERED_HOME_NETWORK	registered, home network
SF_CELLULAR_NETWORK_REG_STATUS_NOT_REGISTERED_SEARCHING	not registered, but MT is currently searching a new operator to register to
SF_CELLULAR_NETWORK_REG_STATUS_REGISTRATION_DENIED	registration denied
SF_CELLULAR_NETWORK_REG_STATUS_UNKNOWN	registration status unknown
SF_CELLULAR_NETWORK_REG_STATUS_REGISTERED_ROAMING	Registered, roaming.

◆ sf_cellular_op_name_format_t

enum sf_cellular_op_name_format_t	
Cellular operator name format	
Enumerator	
SF_CELLULAR_OP_NAME_FORMAT_LONG	Long alphanumeric.
SF_CELLULAR_OP_NAME_FORMAT_SHORT	Short alphanumeric.
SF_CELLULAR_OP_NAME_FORMAT_NUMERIC	Numeric.

◆ sf_cellular_op_select_mode_t

enum sf_cellular_op_select_mode_t	
Operator selection mode	
Enumerator	
SF_CELLULAR_OP_SELECT_MODE_AUTO	Automatic Operator selection.
SF_CELLULAR_OP_SELECT_MODE_MANUAL	Manual Operator selection.
SF_CELLULAR_OP_SELECT_MODE_DEREGISTER	De-register from the network.
SF_CELLULAR_OP_SELECT_MODE_MANUAL_FALLBACK	Manual with fallback to automatic.

◆ sf_cellular_pdp_type_t

enum sf_cellular_pdp_type_t	
PDP type	
Enumerator	
SF_CELLULAR_PDP_TYPE_IP	Internet protocol.
SF_CELLULAR_PDP_TYPE_PPP	Point to point protocol.
SF_CELLULAR_PDP_TYPE_IPV6	Internet protocol, version 6.
SF_CELLULAR_PDP_TYPE_IPV4V6	Virtual introduced to handle dual stack UE capability.

◆ sf_cellular_reset_type_t

enum sf_cellular_reset_type_t	
Cellular Module reset type	
Enumerator	
SF_CELLULAR_RESET_TYPE_SOFT	Soft reset module using AT command.
SF_CELLULAR_RESET_TYPE_HARD	Hard reset module by toggling Reset Pin.

◆ sf_cellular_sim_status_t

enum sf_cellular_sim_status_t	
Enumeration for SIM lock status	
Enumerator	
SF_CELLULAR_SIM_STATUS_READY	SIM in Cellular modem is not pending for any password.
SF_CELLULAR_SIM_STATUS_PIN_REQUIRED	SIM in Cellular modem is lock and waiting for (U)SIM PIN to be given.
SF_CELLULAR_SIM_STATUS_PIN_PUK_REQUIRED	SIM in Cellular modem is lock and waiting for (U)SIM PIN and PUK to be given.

◆ sf_cellular_timezone_update_mode_t

enum sf_cellular_timezone_update_mode_t	
Timezone update mode	
Enumerator	
SF_CELLULAR_TIMEZONE_UPDATE_AUTO_DISABLE	Disable automatic time zone update.
SF_CELLULAR_TIMEZONE_UPDATE_AUTO_ENABLE	Enable automatic time zone update.

sf_cellular_provisioning_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

uint8_t	apn [SF_CELLULAR_MAX_STRING_LEN] Access Point Name.
sf_cellular_auth_type_t	auth_type Authentication type: PAP/CHAP.
uint8_t	username [SF_CELLULAR_MAX_STRING_LEN] User name used for authentication.
uint8_t	password [SF_CELLULAR_MAX_STRING_LEN] Password used for authentication.
sf_cellular_airplane_mode_t	airplane_mode Airplane mode.
uint8_t	context_id Context ID to be used for connection.
sf_cellular_pdp_type_t	pdp_type PDP Type for Context.

Detailed Description

Cellular Provisioning information structure

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_cmd_resp_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

uint8_t *	p_buff
uint32_t	buff_len

Detailed Description

Modem Command/Response structure used to send Custom AT command and to receive response for the same

Field Documentation

◆ buff_len

uint32_t sf_cellular_cmd_resp_t::buff_len
AT command/Response buffer length. In case of Response this is both in and out parameter. Input is the length of buffer pointed by p_buff and output is number of bytes of response copied by framework. In case of command it is length of command in p_buff

◆ p_buff

uint8_t* sf_cellular_cmd_resp_t::p_buff
AT command/Response buffer. In case of AT command it is input buffer in which user should pass custom command to be sent. In case of Response it is output buffer in which framework will fill the response

---

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

void *	p_driver_handle Stores information required by underlying Cellular device driver.

Detailed Description

Cellular Framework control structure

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_stats_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

uint32_t	rx_bytes Bytes received successfully.
uint32_t	tx_bytes Bytes transmitted successfully.
uint32_t	rx_err Bytes receive errors.
uint32_t	tx_err Bytes transmit errors.

Detailed Description

The statistic and error counters for this instance

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

uint8_t	mfg_name [SF_CELLULAR_MFG_NAME_LEN] Manufacturer name.
uint8_t	chipset [SF_CELLULAR_CHIPSET_LEN] Pointer to string showing Cellular chipset/driver information.
uint8_t	fw_version [SF_CELLULAR_FWVERSION_LEN] Cellular firmware version.
uint8_t	imei [SF_CELLULAR_IMEI_LEN] IMEI number.
uint16_t	rssi Received signal strength indication.
uint16_t	ber Bit rate error.
uint8_t	ip_addr [SF_CELLULAR_IP_ADDR_LEN] IP address.

Detailed Description

Cellular Driver Information

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_network_status_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

uint16_t	country_code Country code.
uint32_t	operator_code Operator code.
int16_t	rssi RSSI.
uint8_t	cid [SF_CELLULAR_CID_LEN] Cell ID.
uint8_t	imsi [SF_CELLULAR_IMSI_LEN] IMSI.
uint8_t	op_name [SF_CELLULAR_MAX_OPERATOR_NAME_LEN] Operator name.
uint8_t	access_tech_name [SF_CELLULAR_ACESS_TECH_NAME_LEN] Access Technology name.

uint8_t	service_domain Service Domain.
uint8_t	active_band Active Band.
sf_cellular_network_reg_status_t	reg_status Cellular network registration status.

Detailed Description

Network Status information

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_command_parameters_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

uint8_t	retry_count Count for which AT command will be retried.
uint16_t	retry_delay Delay between AT command retry.
sf_cellular_config_at_cmd_index_t	cmd_index configurable AT command index

Detailed Description

Callback Structure to configure AT command parameters from user

---

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_callback_args_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

sf_cellular_event_t	event Event Code.
uint8_t *	p_data Pointer to received data.
uint32_t	length Receive Data Length.
void const *	p_context Context Provided to user during callback.

Detailed Description

Callback structure for Cellular driver to get the data receive notification

---

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_op_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

sf_cellular_op_name_format_t	op_name_format Cellular operator name format.
uint8_t	op_name [SF_CELLULAR_MAX_OPERATOR_NAME_LEN] Cellular operator name.

Detailed Description

Preferred operator selection structure

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_at_cmd_set_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

uint8_t *	p_cmd AT Command.
uint8_t *	p_success_resp Success response string.

uint16_t	max_resp_length Maximum length of expected response.
uint32_t	resp_wait_time AT command response wait time in milliseconds.
uint8_t	retry Retry count.
uint16_t	retry_delay Delay between AT command retry.

Detailed Description

Structure defining AT commands parameters

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_sim_pin_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

sf_cellular_sim_status_t	sim_status
uint8_t *	p_sim_pin SIM Pin is used to unlock the SIM if the SIM is locked for SIM PIN.
uint8_t *	p_sim_puk SIM PUK is used to unlock the SIM if the SIM is locked for SIM PUK.

Detailed Description

Callback Structure to read SIM Pin and PUK from user

Field Documentation

◆ sim_status

sf_cellular_sim_status_t sf_cellular_sim_pin_info_t::sim_status
SIM Pin type expected from user to enter, in case of PUK type, user has to fill SIM Pin and PUK both pins

The documentation for this struct was generated from the following file:

- sf_cellular_api.h

sf_cellular_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR Framework Interface

#include <sf_cellular_api.h>

Data Fields

sf_cellular_op_select_mode_t	op_select_mode Cellular Operator selection mode.
sf_cellular_op_t	op Cellular operator. Valid when operator selection mode is manual.
uint16_t	num_pref_ops Number of preferred operators in the pref_ops array.
sf_cellular_op_t	pref_ops [SF_CELLULAR_MAX_PREFFERED_OPERATOR_COUNT] Array of structures describing preferred operators.
sf_cellular_timezone_update	tz_upd_mode

_mode_t	TimeZone update mode policy.
uint8_t *	p_sim_pin SIM Pin.
uint8_t *	p_puk_pin PUK Pin.
ssp_err_t(*	p_prov_callback)(sf_cellular_callback_args_t *p_args)
void(*	p_recv_callback)(sf_cellular_callback_args_t *p_args)
ssp_err_t(*	p_read_sim_pin_info_callback)(sf_cellular_sim_pin_info_t *p_args)
ssp_err_t(*	p_cmd_param_callback)(sf_cellular_command_parameters_info_t **p_args, uint8_t *p_at_cmd_num)
void const *	p_context User defined context passed into callback function.
void const *	p_extend Instance specific configuration.
sf_cellular_at_cmd_set_t const *	p_cmd_set Instance specific command set.
sf_cellular_at_cmd_set_t *	p_modifiable_cmd_set Instance specific modifiable command set.

Detailed Description

Define the Cellular configuration parameters

Field Documentation

◆ p_cmd_param_callback

ssp_err_t(* sf_cellular_cfg_t::p_cmd_param_callback) (sf_cellular_command_parameters_info_t **p_args, uint8_t *p_at_cmd_num)
Pointer to callback function to configure AT command parameters like retry delay and retry count at runtime

◆ p_prov_callback

ssp_err_t(* sf_cellular_cfg_t::p_prov_callback) (sf_cellular_callback_args_t *p_args)
Pointer to provisioning callback function, used in NSAL

◆ p_read_sim_pin_info_callback

ssp_err_t(* sf_cellular_cfg_t::p_read_sim_pin_info_callback) (sf_cellular_sim_pin_info_t *p_args)
Pointer to callback function to configure the SIM properties at runtime

◆ p_recv_callback

void(* sf_cellular_cfg_t::p_recv_callback) (sf_cellular_callback_args_t *p_args)
This is the receive callback function used by NetX which will take a data packet from the Cellular module and hand it over to NetX for further processing.

Detailed Description

Cellular Framework API structure.

Field Documentation

◆ close

ssp_err_t(* sf_cellular_api_t::close) (sf_cellular_ctrl_t *const p_ctrl)

Disables the Cellular module.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module. .

◆ commandSend

ssp_err_t(* sf_cellular_api_t::commandSend) (sf_cellular_ctrl_t *const p_ctrl, sf_cellular_cmd_resp_t *const p_input_at_command, sf_cellular_cmd_resp_t *const p_output, uint32_t const timeout)

Send AT command directly to Cellular Modem.

This API will send AT command provided by user to the Cellular Modem and will collect the response from the Modem and will send it back to the user. If Modem is in Data Mode when this API is called then Framework will first switch Modem to Command Mode, then send the AT command and collect the response and then switches the Modem back to Data Mode.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	p_input_at_command	Pointer to structure which contains Modem command to send
[in,out]	p_output	Pointer to buffer in which response will be sent to user, Also user will pass the size of the buffer which is pointed by p_output
[in]	timeout	Timeout for which framework will wait for response

◆ fotaCheck

ssp_err_t(* sf_cellular_api_t::fotaCheck) (sf_cellular_ctrl_t *const p_ctrl, void *p_fotacheck)

Checks for Available Firmware upgrade.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	p_fotacheck	Pointer to fota check specific data structure

◆ fotaStart

ssp_err_t(* sf_cellular_api_t::fotaStart) (sf_cellular_ctrl_t *const p_ctrl, void *p_fotastart)

Starts the Firmware upgrade.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	p_fotastart	Pointer to fota start specific data structure

◆ fotaStop

ssp_err_t(* sf_cellular_api_t::fotaStop) (sf_cellular_ctrl_t *const p_ctrl, void *p_fotastop)

Stops the Firmware upgrade.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	p_fotastop	Pointer to fota stop specific data structure

◆ infoGet

ssp_err_t(* sf_cellular_api_t::infoGet) (sf_cellular_ctrl_t *const p_ctrl, sf_cellular_info_t *const p_cellular_info)

Reads the Cellular module's information.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[out]	p_cellular_info	Pointer to Cellular info structure.

◆ networkConnect

ssp_err_t(* sf_cellular_api_t::networkConnect) (sf_cellular_ctrl_t *const p_ctrl)

Initiates the Data connection.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.

◆ networkDisconnect

ssp_err_t(* sf_cellular_api_t::networkDisconnect) (sf_cellular_ctrl_t *const p_ctrl)

Terminates the Data connection.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.

◆ networkStatusGet

ssp_err_t(* sf_cellular_api_t::networkStatusGet) (sf_cellular_ctrl_t *const p_ctrl, sf_cellular_network_status_t *p_network_status)

Get Network Status information.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[out]	p_network_status	Pointer to Network Status structure

◆ open

ssp_err_t(* sf_cellular_api_t::open) (sf_cellular_ctrl_t *p_ctrl, sf_cellular_cfg_t const *const p_cfg)

Initializes and enables the Cellular module.

Parameters

[in,out]	p_ctrl	Pointer to user-provided storage for the control block.
[in]	p_cfg	Pointer to Cellular configuration structure.

◆ provisioningGet

ssp_err_t(* sf_cellular_api_t::provisioningGet) (sf_cellular_ctrl_t *const p_ctrl, sf_cellular_provisioning_t *const p_cellular_provisioning)

Pointer to function to Get the Cellular module provisioning information.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[out]	p_cellular_provisioning	Pointer to Cellular provisioning structure.

◆ provisioningSet

ssp_err_t(* sf_cellular_api_t::provisioningSet) (sf_cellular_ctrl_t *const p_ctrl, sf_cellular_provisioning_t const *const p_cellular_provisioning)

Pointer to function to Set the Cellular module's provisioning information.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	p_cellular_provisioning	Pointer to Cellular provisioning structure.

◆ reset

ssp_err_t(* sf_cellular_api_t::reset) (sf_cellular_ctrl_t *const p_ctrl, sf_cellular_reset_type_t reset_type)

Reset cellular module. This reset() API will only work when module is opened.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	reset_type	Reset type

◆ simIDGet

ssp_err_t(* sf_cellular_api_t::simIDGet) (sf_cellular_ctrl_t *const p_ctrl, uint8_t *p_sim_id)

Gets the SIM ID.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[out]	p_sim_id	SIM ID

◆ simLock

ssp_err_t(* sf_cellular_api_t::simLock) (sf_cellular_ctrl_t *const p_ctrl, uint8_t *const p_pin)

Locks SIM.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	p_pin	PIN number to lock the SIM

◆ simPinSet

ssp_err_t(* sf_cellular_api_t::simPinSet) (sf_cellular_ctrl_t *const p_ctrl, uint8_t *const p_old_pin, uint8_t *const p_new_pin)

Set SIM Pin.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	p_old_pin	Pointer to char array containing current 4 digit pin.
[in]	p_new_pin	Pointer to char array containing new 4 digit pin.

◆ simUnlock

ssp_err_t(* sf_cellular_api_t::simUnlock) (sf_cellular_ctrl_t *const p_ctrl, uint8_t *const p_pin)

Unlocks SIM.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	p_pin	PIN number to unlock the SIM

◆ statisticsGet

ssp_err_t(* sf_cellular_api_t::statisticsGet) (sf_cellular_ctrl_t *const p_ctrl, sf_cellular_stats_t *const p_cellular_device_stats)

Returns statistics information of Cellular module.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[out]	p_cellular_device_stats	Pointer to Cellular statistics information structure.

◆ transmit

ssp_err_t(* sf_cellular_api_t::transmit) (sf_cellular_ctrl_t *const p_ctrl, uint8_t *const p_buf, uint32_t length)

Passes packet buffer to PPP stack for transmission.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	p_buf	Pointer to packet buffer to transmit
[in]	length	Length of packet buffer

◆ versionGet

ssp_err_t(* sf_cellular_api_t::versionGet) (ssp_version_t *const p_version)

Gets version and stores it in provided pointer p_version.

Parameters

[out]	p_version	pointer to memory location to return version number

5.1.2.24 SF CELLULAR NSAL Framework Interface

Renesas Synergy Software Package Reference » Framework Interfaces

RTOS-integrated SF CELLULAR NSAL Framework Interface. More...

Data Structures

struct	sf_cellular_nsal_cfg_t

Functions

ssp_err_t	sf_cellular_deinit (NX_IP_DRIVER *driver_req_ptr, sf_cellular_instance_t const *p_cellular_instance,

	sf_cellular_nsal_cfg_t *p_cellular_nsal_cfg) De-initialize the Cellular NSAL, deletes PPP interface, disconnect the network and close cellular framework. More...

Detailed Description

RTOS-integrated SF CELLULAR NSAL Framework Interface.

Summary

This SSP Interface provides access to the ThreadX-aware SF CELLULAR NSAL Framework.

Function Documentation

◆ sf_cellular_deinit()

ssp_err_t sf_cellular_deinit (NX_IP_DRIVER * *p_driver_req_ptr*, sf_cellular_instance_t const * *p_cellular_instance*, sf_cellular_nsal_cfg_t * *p_cellular_nsal_cfg*)

De-initialize the Cellular NSAL, deletes PPP interface, disconnect the network and close cellular framework.

Function Prototypes

Parameters

[in]	p_driver_req_ptr	Pointer to NetX IP driver
[in]	p_cellular_instance	Pointer to Cellular Framework instance
[in]	p_cellular_nsal_cfg	Pointer to Cellular NSAL configuration structure

Return values

SSP_SUCCESS	Successfully de-initialized the cellular NSAL connection
SSP_ERR_CELLULAR_FAILED	Failed to de-init Cellular Framework or terminate the network connection
SSP_ERR_NOT_OPEN	Cellular driver is not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Wait for the PPP Link down event, LCP Terminate ACK should have been received

Disconnect Network

Close Cellular Driver

Return an error to NetX.

sf_cellular_nsal_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF CELLULAR NSAL Framework Interface

#define SF_CELLULAR_SOCKET_NO_OF_BIT_IN_BYTE (8U)
SF Cellular Number of Bits in a Byte

Typedef Documentation

◆ socklen_t

typedef int32_t socklen_t
Socket address Length

Function Documentation

◆ accept()

int accept (int *sockfd*, struct sockaddr * *p_cliaddr*, socklen_t * *p_addrlen*)

This accepts connection from remote socket.

Accept connection request from remote.

Parameters

[in]	sockfd	Local socket
[out]	p_cliaddr	Pointer to remote socket address which trying to connect
[out]	p_addrlen	Pointer to address length of client socket address

Implements accept This function accepts connection from remote socket. This API is used only with socket type STREAM. The call is blocked if no connection is present or the socket is blocking.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_cliaddr	Remote machine Network address
[out]	p_addrlen	Size of Socket address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error accepting the connection
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Connection is received successfully.

Implements accept This function accepts connection from remote socket. This API is used only with socket type STREAM. The call is blocked if no connection is present or the socket is blocking.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_cliaddr	Remote machine Network address (Can be NULL)
[out]	p_addrlen	Size of Socket address structure(Can be NULL)

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error accepting the connection or invalid input parameters

Returns

Otherwise Connection is received successfully.

◆ bind()

int bind (int *sockfd*, const struct sockaddr * *p_local_sock_addr*, socklen_t *addrlen*)

This binds socket to IP address.

Bind socket to interface which is identified by IP address

Parameters

[in]	sockfd	Local socket
[in]	p_local_sock_addr	Pointer to local socket address
[in]	addrlen	Size of sock address structure

Implements bind This function binds socket to given IP address and port.

Parameters

sockfd	Socket file descriptor
p_local_sock_addr	Socket address structure
addrlen	Size of Socket address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Binding socket failed
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket is bound successfully.

Implements bind This function binds socket to given IP address and port.

Parameters

sockfd	Socket file descriptor
p_local_sock_addr	Socket address structure
addrlen	Size of Socket address structure

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Binding socket failed or invalid input parameters

Returns

Otherwise Socket is bound successfully.

◆ close()

int close (int *sockfd*)

This closes socket.

API which closes socket

Parameters

[in]	sockfd	Local socket

Implements close Close opened socket

Parameters

[in]	sockfd	Socket file descriptor

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Closing socket failed
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket is closed successfully.

Implements close Close opened socket

Parameters

[in]	sockfd	Socket file descriptor

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Closing socket failed or invalid input parameters

Returns

Otherwise Socket is closed successfully.

◆ connect()

int connect (int *sockfd*, const struct sockaddr * *p_serv_addr*, socklen_t *addrlen*)

This connects with remote socket(stream socket).

Establish TCP connection with remote socket

Parameters

[in]	sockfd	Local socket
[in]	p_serv_addr	Pointer to remote socket address

[in]	addrlen	Size of sock address structure

Implements connect This function connects local socket with remote socket. The call is blocked until a connection is established or error is returned.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_serv_addr	Remote machine Network address
[in]	addrlen	Size of Socket address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error occurred.
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket is connected successfully.

Implements connect This function connects local socket with remote socket. The call is blocked until a connection is established or error is returned.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_serv_addr	Remote machine Network address
[in]	addrlen	Size of Socket address structure

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error occurred or invalid input parameters

Returns

Otherwise Socket is connected successfully.

◆ getsockopt()

int getsockopt (int *sockfd*, int *level*, int *optname*, void * *p_optval*, socklen_t * *p_optlen*)

This reads socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Get Socket options.

Parameters

[in]	sockfd	Local socket
[in]	level	Sockets API level
[in]	optname	Option to be get
[out]	p_optval	Option value to be get
[in]	p_optlen	Length of option value

Implements getsockopt This gets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[out]	p_optval	Socket option value
[out]	p_optlen	Size of Socket option

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error reading socket option
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket option read successfully.

This reads socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Implements getsockopt This gets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[out]	p_optval	Socket option value
[out]	p_optlen	Size of Socket option

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error reading socket option or invalid socket descriptor

Returns

Otherwise Socket option read successfully.

◆ listen()

int listen (int *sockfd*, int *backlog*)

This listens for connection on socket.

Listen for tcp connection. Set socket in listen mode for tcp connection.

Parameters

[in]	sockfd	Local socket
[in]	backlog	Max number of connection queue.

Implements listen This function listen for connection on socket.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	backlog	number of maximum connection can be accepted

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Failed to set socket in Listen mode
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Set socket in Listen mode successfully.

Implements listen This function listen for connection on socket.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	backlog	number of maximum connection can be accepted

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Failed to set socket in Listen mode or invalid input parameters

Returns

Otherwise Set socket in Listen mode successfully.

◆ recv()

ssize_t recv (int *sockfd*, void * *p_buf*, size_t *length*, int *flags*)

This receives data over STREAM socket.

Receive data from remote socket.

Parameters

[in]	sockfd	Local socket
[out]	p_buf	Pointer to data buffer where data will be received
[in]	length	Maximum length of data which can be received
[in]	flags	Socket flags

Implements receive This function receives data on a stream socket in connected state. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_buf	Buffer to read data
[in]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Failed to receive data.

Returns

Otherwise Number of Data bytes received successfully.

Implements receive This function receives data on a stream socket in connected state. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_buf	Buffer to read data
[out]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Failed to receive data or invalid input parameters

Returns

Otherwise Data received successfully.

◆ recvfrom()

ssize_t recvfrom (int *sockfd*, void * *p_buf*, size_t *length*, int *flags*, struct sockaddr * *p_src_addr*, socklen_t * *p_addrlen*)

This receives data over DGRAM socket.

Receive data from remote socket.

Parameters

[in]	sockfd	Local socket
[out]	p_buf	Pointer to data buffer where data will be received
[in]	length	Maximum length of data which can be received
[in]	flags	Socket flag
[out]	p_src_addr	Pointer to remote socket address which has sent data
[out]	p_addrlen	Length of socket address structure

Implements recvfrom This function receives data on a dgram socket. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket file descriptor
[out]	p_buf	Data buffer pointer to read data
[in]	length	Length of data to read
[in]	flags	Flags
[in]	p_src_addr	Remote machine network address
[in]	p_addrlen	Size of Remote machine network

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error receiving data

Returns

Otherwise Numbers of data bytes received successfully.

Implements recvfrom This function receives data on a dgram socket. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to

receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket file descriptor
[out]	p_buf	Data buffer pointer to read data
[in]	length	Length of data to read
[in]	flags	Flags
[in]	p_src_addr	Remote machine network address (Can be NULL)
[in]	p_addrlen	Size of Remote machine network (Can be NULL)

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error receiving data or invalid input parameters

Returns

Otherwise Numbers of data bytes received successfully.

◆ select()

int select (int *nfds*, fd_set * *p_readfds*, fd_set * *p_writefds*, fd_set * *p_exceptfds*, struct timeval * *p_timeout*)

This waits for any activity on socket.

Wait on a given socket for specified amount of time. In case of any activity e.g. arrival of packet it comes out of wait.

Parameters

[in]	nfds	Max fd
[in]	p_readfds	Pointer to fd_set to check whether data is available for read
[in]	p_writefds	Pointer to fd_set to check whether data is available for write
[in]	p_exceptfds	Pointer to fd_set to check whether exceptional condition occurred
[in]	p_timeout	Wait time in milliseconds

Implements select Allow an application thread to block on a given socket handle for a specified time period. This API checks for any activity on specified socket, for example arrival of a packet at

the receive queue.

Parameters

[in]	nfds	Number of socket fds in to check
[in]	p_readfds	Read socket fd set
[in]	p_writefds	Write socket fd set. If no descriptor is to be tested for writing, p_writefds should be NULL
[in]	p_exceptfds	Exceptional socket fd set. If no descriptor is to be tested for exceptions, p_exceptfds should be NULL
[in]	p_timeout	Timeout

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Timeout occurred, no activity.

Returns

Otherwise Activity detected(Packet available).

Implements select Allow an application thread to block on a given socket handle for a specified time period. This API checks for any activity on specified socket, for example arrival of a packet at the receive queue.

Parameters

[in]	nfds	Number of socket fds in to check
[in]	p_readfds	Read socket fd set
[in]	p_writefds	Write socket fd set - API does not used this parameter
[in]	p_exceptfds	Exceptional socket fd set - API does not used this parameter
[in]	p_timeout	Timeout

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Timeout occurred, no activity or invalid socket descriptor

Returns

Otherwise Activity detected(Packet available).

◆ send()

ssize_t send (int *sockfd*, const void * *p_buf*, size_t *length*, int *flags*)

This sends data over STREAM socket.

Send data to remote socket.

Parameters

[in]	sockfd	Local socket
[in]	p_buf	Pointer to data buffer
[in]	length	Data buffer length
[in]	flags	Socket flags

Implements send This function sends data on a stream socket in connected state.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data to send
[in]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Failed to send data.

Returns

Otherwise Number of Data bytes sent successfully.

Implements send This function sends data on a stream socket in connected state.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data to send
[in]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Failed to send data or invalid input parameters

Returns

Otherwise Data sent successfully.

◆ sendto()

ssize_t sendto (int *sockfd*, const void * *p_buf*, size_t *length*, int *flags*, const struct sockaddr * *p_dest_addr*, socklen_t *addrlen*)

This sends data over DGRAM socket.

Send data to remote socket.

Parameters

[in]	sockfd	Local socket
[in]	p_buf	Pointer to data buffer to sent
[in]	length	Data buffer length
[in]	flags	Socket flag
[in]	p_dest_addr	Pointer to remote socket address where to send data
[in]	addrlen	Length of socket address structure

Implements sendto This function sends data to remote.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data pointer
[in]	length	Length of data
[in]	flags	Flag
[in]	p_dest_addr	Address of remote UDP server
[in]	addrlen	Size of Network address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error Sending data.

Returns

Otherwise Numbers of bytes sent successfully.

Implements sendto This function sends data to remote.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data pointer
[in]	length	Length of data

[in]	flags	Flag
[in]	p_dest_addr	Address of remote UDP server
[in]	addrlen	Size of Network address structure

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error Sending data or invalid input parameters

Returns

Otherwise Numbers of bytes sent successfully.

◆ setsockopt()

int setsockopt (int *sockfd*, int *level*, int *optname*, const void * *p_optval*, socklen_t *optlen*)

This updates socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Set Socket options.

Parameters

[in]	sockfd	Local socket
[in]	level	Sockets API level
[in]	optname	Option to be set
[in]	p_optval	Option value to be set
[in]	optlen	Length of option value

Implements setsockopt This sets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[in]	p_optval	Socket option value
[in]	optlen	Size of Socket option

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error setting socket option
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket option set successfully.

This updates socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Implements setsockopt This sets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[in]	p_optval	Socket option value
[in]	optlen	Size of Socket option

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error setting socket option or invalid socket descriptor

Returns

Otherwise Socket option set successfully.

◆ socket()

int socket (int *domain*, int *type*, int *protocol*)

This creates socket for communication.

API which creates socket

Parameters

[in]	domain	Socket family
[in]	type	Socket type
[in]	protocol	Protocol type

Implements socket Creates socket with given parameters.

Parameters

[in]	domain	Network Domain
[in]	type	Socket type
[in]	protocol	Protocol type

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Socket creation failed

Returns

Otherwise Socket descriptor of newly created socket

Implements socket Creates socket with given parameters.

Parameters

[in]	domain	Network Domain
[in]	type	Socket type
[in]	protocol	Protocol type

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Socket creation failed

Returns

Otherwise Socket created successfully

Renesas Synergy Software Package Reference » Framework Interfaces » SF Socket CELLULAR Framework Interface

#include <sf_cellular_socket_api.h>

Data Fields

sf_cellular_instance_t *	p_lower_lvl_cellular low level cellular interface

Detailed Description

Socket Interface control structure

The documentation for this struct was generated from the following file:

- sf_cellular_socket_api.h

sf_cellular_socket_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF Socket CELLULAR Framework Interface

#include <sf_cellular_socket_api.h>

Data Fields

sf_cellular_instance_t *	p_lower_lvl_cellular Pointer to SF on-chip stack instance.
void *	p_extend Extended configuration.

Detailed Description

Socket Interface configuration structure

The documentation for this struct was generated from the following file:

- sf_cellular_socket_api.h

sf_cellular_socket_api_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF Socket CELLULAR Framework Interface

#include <sf_cellular_socket_api.h>

Data Fields

ssp_err_t(*	open)(sf_cellular_socket_ctrl_t *p_ctrl, sf_cellular_socket_cfg_t const *const p_cfg) Pointer to function which initializes the network interface for data transfers Initial driver configuration, enable the driver link, enable interrupts and make device ready for data transfer. More...
ssp_err_t(*	close)(sf_cellular_socket_ctrl_t *const p_ctrl) Pointer to function which un-initialize the network interface and may put it in low power mode or power it off. Close the driver, disable the driver link, disable interrupt. More...
ssp_err_t(*	versionGet)(ssp_version_t *const p_version) Gets version and stores it in provided pointer p_version. More...
ssp_err_t(*	ping)(sf_cellular_socket_ctrl_t *const p_ctrl, ULONG *p_ip_addr, uint32_t count, uint32_t interval_ms)

Detailed Description

Socket Interface API

Field Documentation

◆ close

ssp_err_t(* sf_cellular_socket_api_t::close) (sf_cellular_socket_ctrl_t *const p_ctrl)

Pointer to function which un-initialize the network interface and may put it in low power mode or power it off. Close the driver, disable the driver link, disable interrupt.

Parameters

[in,out]	p_ctrl	Pointer to the control block for the Cellular module Socket interface.

◆ open

ssp_err_t(* sf_cellular_socket_api_t::open) (sf_cellular_socket_ctrl_t *p_ctrl, sf_cellular_socket_cfg_t const *const p_cfg)

Pointer to function which initializes the network interface for data transfers Initial driver configuration, enable the driver link, enable interrupts and make device ready for data transfer.

Parameters

[in,out]	p_ctrl	Pointer to the control block for the Cellular module Socket interface.
[in]	p_cfg	Pointer to Cellular Socket interface configuration structure.

◆ ping

ssp_err_t(* sf_cellular_socket_api_t::ping) (sf_cellular_socket_ctrl_t *const p_ctrl, ULONG *p_ip_addr, uint32_t count, uint32_t interval_ms)

Pointer to a function which is used to ping the IP address.

Parameters

[in]	p_ctrl	Pointer to the control block
[in]	p_ip_addr	Pointer to IP address to ping
[in]	count	Number of ping attempts
[in]	interval_ms	Interval between ping attempts

◆ versionGet

ssp_err_t(* sf_cellular_socket_api_t::versionGet) (ssp_version_t *const p_version)		
Gets version and stores it in provided pointer p_version. **Parameters**		
[out]	p_version	Pointer to SSP Version structure

The documentation for this struct was generated from the following file:

- sf_cellular_socket_api.h

sf_cellular_socket_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF Socket CELLULAR Framework Interface

#include <sf_cellular_socket_api.h>

Data Fields

sf_cellular_socket_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_cellular_socket_cfg_t const *	p_cfg Pointer to the configuration structure for this instance.
sf_cellular_socket_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

The documentation for this struct was generated from the following file:

- sf_cellular_socket_api.h

5.1.2.26 Communications Framework Interface

Renesas Synergy Software Package Reference » Framework Interfaces

RTOS-integrated communications Framework Interface. More...

Data Structures

struct	sf_comms_callback_args_t
struct	sf_comms_cfg_t
struct	sf_comms_api_t
struct	sf_comms_instance_t

Macros

#define	SF_COMMS_API_VERSION_MAJOR (2U)

Typedefs

typedef void	sf_comms_ctrl_t

Enumerations

enum	sf_comms_lock_t { SF_COMMS_LOCK_TX = 0, SF_COMMS_LOCK_RX, SF_COMMS_LOCK_ALL }
enum	sf_comms_event_t { SF_COMMS_DISCONNECT_EVENT }

Detailed Description

RTOS-integrated communications Framework Interface.

Implemented by:

- UART Framework Instance - UART implementation
- USB Communication Framework V2 - USBX CDC ACM device implementation
- Telnet Communication Framework on sf_comms_telnet - NetX telnet server with shared IP Instance implementation

Related SSP architecture topics:

- SSP Interfaces
- SSP Predefined Layers
- Using SSP Modules

Macro Definition Documentation

◆ SF_COMMS_API_VERSION_MAJOR

#define SF_COMMS_API_VERSION_MAJOR (2U)
Version of the API defined in this file

Typedef Documentation

◆ sf_comms_ctrl_t

typedef void sf_comms_ctrl_t
Communications framework control block. Allocate an instance specific control block to pass into the communications framework API calls. **Implemented as** ◦ sf_console_instance_ctrl_t

Enumeration Type Documentation

◆ sf_comms_event_t

enum sf_comms_event_t	
Options for the callback events. ***Note*** *Only applies for SF_COMMS_TELNET.*	
Enumerator	
SF_COMMS_DISCONNECT_EVENT	Disconnected the client.

◆ sf_comms_lock_t

enum sf_comms_lock_t	
Communications locks	
Enumerator	
SF_COMMS_LOCK_TX	Lock Transmit.
SF_COMMS_LOCK_RX	Lock Receive.
SF_COMMS_LOCK_ALL	Lock Transmit and Receive.

sf_comms_callback_args_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Communications Framework Interface

#include <sf_comms_api.h>

Data Fields

sf_comms_event_t	event SF_COMMS callback event.

Detailed Description

sf_comms callback arguments definitions.

Note

Only applies for SF_COMMS_TELNET.

The documentation for this struct was generated from the following file:

- sf_comms_api.h

sf_comms_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Communications Framework Interface

#include <sf_comms_api.h>

Data Fields

void const *	p_extend Pointer to lower level communications control structure.

Detailed Description

Configuration for RTOS integrated communications driver

The documentation for this struct was generated from the following file:

- sf_comms_api.h

sf_comms_api_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Communications Framework Interface

#include <sf_comms_api.h>

Data Fields

ssp_err_t(*	open)(sf_comms_ctrl_t *const p_ctrl, sf_comms_cfg_t const *const p_cfg)
ssp_err_t(*	close)(sf_comms_ctrl_t *const p_ctrl)
ssp_err_t(*	read)(sf_comms_ctrl_t *const p_ctrl, uint8_t *const p_dest, uint32_t const bytes, UINT const timeout)
ssp_err_t(*	write)(sf_comms_ctrl_t *const p_ctrl, uint8_t const *const p_src, uint32_t const bytes, UINT const timeout)
ssp_err_t(*	lock)(sf_comms_ctrl_t *const p_ctrl, sf_comms_lock_t lock_type, UINT timeout)
ssp_err_t(*	unlock)(sf_comms_ctrl_t *const p_ctrl, sf_comms_lock_t lock_type)
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

Framework communications API structure. Implementations will use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_comms_api_t::close) (sf_comms_ctrl_t *const p_ctrl)

Clean up communications driver.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for communications driver.

◆ lock

ssp_err_t(* sf_comms_api_t::lock) (sf_comms_ctrl_t *const p_ctrl, sf_comms_lock_t lock_type, UINT timeout)

Lock the communications driver. Reserve exclusive access to the communications driver.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for communications driver.
[in]	lock_type	Locking type, transmission channel or reception channel
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

◆ open

ssp_err_t(* sf_comms_api_t::open) (sf_comms_ctrl_t *const p_ctrl, sf_comms_cfg_t const *const p_cfg)

Initialize communications driver.

Parameters

[in,out]	p_ctrl	Pointer to a control structure allocated by user. The control structure is initialized in this function.
[in]	p_cfg	Pointer to configuration structure. All elements of the structure must be set by user.

◆ read

ssp_err_t(* sf_comms_api_t::read) (sf_comms_ctrl_t *const p_ctrl, uint8_t *const p_dest, uint32_t const bytes, UINT const timeout)

Read data from communications driver. This call will return after the number of bytes requested is read or if a timeout occurs while waiting for access to the driver.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for communications driver.
[in]	p_dest	Destination address to read data out
[in]	bytes	Read data length
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

◆ unlock

ssp_err_t(* sf_comms_api_t::unlock) (sf_comms_ctrl_t *const p_ctrl, sf_comms_lock_t lock_type)

Unlock the communications driver. Release exclusive access to the communications driver.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for communications driver.
[in]	lock_type	Locking type, transmission channel or reception channel

◆ versionGet

ssp_err_t(* sf_comms_api_t::versionGet) (ssp_version_t *const p_version)

Store the driver version in the provided p_version.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for communications driver.
[in]	p_version	Pointer to memory version to be stored.

◆ write

ssp_err_t(* sf_comms_api_t::write) (sf_comms_ctrl_t *const p_ctrl, uint8_t const *const p_src, uint32_t const bytes, UINT const timeout)
Write data to communications driver. This call will return after all bytes are written or if a timeout occurs while waiting for access to the driver.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for communications driver.
[in]	p_src	Source address to read data out from
[in]	bytes	Write data length
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

The documentation for this struct was generated from the following file:

- sf_comms_api.h

sf_comms_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Communications Framework Interface

#include <sf_comms_api.h>

Data Fields

sf_comms_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_comms_cfg_t const *	p_cfg

	Pointer to the configuration structure for this instance.
sf_comms_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

The documentation for this struct was generated from the following file:

ssp_err_t(*	versionGet)(ssp_version_t *const p_version) Stores version information in provided pointer. More...

Detailed Description

Console framework API structure. Console implementations will use the following API.

Field Documentation

◆ argumentFind

ssp_err_t(* sf_console_api_t::argumentFind) (uint8_t const *const p_arg, uint8_t const *const p_str, int32_t *const p_index, int32_t *const p_data)

Finds a command line argument in an input string and returns the index of the character immediately following the argument and any string numbers converted to integers.

Implemented as

- SF_CONSOLE_ArgumentFind()

Parameters

[in]	p_arg	Pointer to argument to find.
[in]	p_src	Pointer to source string to find the argument in.
[out]	p_index	Pointer to location to store index. Set to -1 if argument is not found in input string. Pass NULL if index is not requested.
[out]	p_data	Pointer to location to store data following the argument. Set to -1 if argument is not found in input string. Pass NULL if data is not requested.

◆ close

ssp_err_t(* sf_console_api_t::close) (sf_console_ctrl_t *const p_ctrl)

The close API handles cleans up internal driver data.

Implemented as

- SF_CONSOLE_Close()

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for UART driver.

◆ open

ssp_err_t(* sf_console_api_t::open) (sf_console_ctrl_t *const p_ctrl, sf_console_cfg_t const *const p_cfg)

This function configures the console. This function must be called before any other console functions.

Implemented as

- SF_CONSOLE_Open()

Parameters

[in,out]	p_ctrl	Pointer to a device structure allocated by user. The device control structure is initialized in this function.
[in]	p_cfg	Pointer to configuration structure. All elements of the structure must be set by user.

◆ parse

ssp_err_t(* sf_console_api_t::parse) (sf_console_ctrl_t *const p_ctrl, sf_console_menu_t const *const p_cmd_list, uint8_t const *const p_input, uint32_t const bytes)

Looks for input string in menu, and calls callback function if found.

Implemented as

- SF_CONSOLE_Parse()

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for UART driver.
[in]	p_cmd_list	Pointer to a menu of valid input commands for this prompt
[in]	p_input	Pointer to a null terminated string to search for in the command list
[in]	bytes	Length of the input string.

◆ prompt

ssp_err_t(* sf_console_api_t::prompt) (sf_console_ctrl_t *const p_ctrl, sf_console_menu_t const *const p_menu, UINT const timeout)

Prints prompt string from menu, waits for input, parses input based on menu, and calls callback function if a command is identified.

Implemented as

- SF_CONSOLE_Prompt()

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for UART driver.
[in]	p_menu	Set to NULL to stay on current menu maintained by the console framework. To change menus, pass a pointer to the new menu.
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

◆ read

ssp_err_t(* sf_console_api_t::read) (sf_console_ctrl_t *const p_ctrl, uint8_t *const p_dest, uint32_t const bytes, uint32_t const timeout)

Reads data into the destination byte by byte and echos input to the console. Backspace, delete, and left/right arrow keys supported. Read completes when a line ending CR, CR+LF, or CR+NULL is received, or when the input exceeds the number of bytes input. If the buffer overflows SF_CONSOLE_MAX_INPUT_LENGTH, read will return an error code.

Implemented as

- SF_CONSOLE_Read()

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for UART driver.
[in]	p_dest	Destination address to read data out
[in]	bytes	Read data length
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

◆ versionGet

ssp_err_t(* sf_console_api_t::versionGet) (ssp_version_t *const p_version)

Stores version information in provided pointer.

Implemented as

- SF_CONSOLE_VersionGet()

Parameters

[out]	p_version	Code and API version used stored here.

◆ write

ssp_err_t(* sf_console_api_t::write) (sf_console_ctrl_t *const p_ctrl, uint8_t const *const p_src, uint32_t const timeout)
The write API gets mutex object and handles UART data transmission at UART HAL layer. gets event flag to synchronize to completion of data transfer. **Implemented as** ◦ SF_CONSOLE_Write() **Parameters**

[in]	p_ctrl	Pointer to device control block initialized in Open call for UART driver.
[in]	p_src	Pointer to a NULL terminated string. Length must be less than SF_CONSOLE_MAX_WRITE_LENGTH.
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

Detailed Description

Interface definition for Synergy Crypto Framework module.

Summary

This is the Interface of SF_CRYPTO Framework module.

Crypto Common Framework Interface description: Crypto Framework

Macro Definition Documentation

◆ SF_CRYPTO_API_VERSION_MAJOR

#define SF_CRYPTO_API_VERSION_MAJOR (2U)
The API version of SSP Crypto Framework Common Module

Typedef Documentation

◆ sf_crypto_ctrl_t

typedef void sf_crypto_ctrl_t
SSP Crypto Framework Common Module control block. Allocate an instance specific control block to pass into the SSP Crypto Framework Common Module API calls. **Implemented as** ◦ sf_crypto_instance_ctrl_t

Enumeration Type Documentation

◆ sf_crypto_close_option_t

enum sf_crypto_close_option_t	
SF_CRYPTO Close option. The module executes close operation if any SF_CRYPTO_XXX modules have already closed if SF_CRYPTO_CLOSE_OPTION_DEFAULT option is specified. The module performs close operation regardless of any SF_CRYPTO_XXX module status if SF_CRYPTO_CLOSE_OPTION_FORCE_CLOSE is specified.	
Enumerator	
SF_CRYPTO_CLOSE_OPTION_DEFAULT	Close the module if no any SF_CRYPTO_XXX modules opened.
SF_CRYPTO_CLOSE_OPTION_FORCE_CLOSE	Close the module regardless of SF_CRYPTO_XXX modules status.

◆ sf_crypto_event_t

enum sf_crypto_event_t	
Event code for the SSP Crypto Framework Common Module. This event code is all reserved for the future use.	
Enumerator	
SF_CRYPTO_EVENT_PROCEDURE_DONE	Crypto hardware procedure done.
SF_CRYPTO_EVENT_ERROR	Error occurred.

◆ sf_crypto_key_size_t

enum sf_crypto_key_size_t	
Supported key sizes	
Enumerator	
SF_CRYPTO_KEY_SIZE_RSA_1024	RSA 1024-bit key.
SF_CRYPTO_KEY_SIZE_RSA_2048	RSA 2048-bit key.
SF_CRYPTO_KEY_SIZE_AES_128	AES 128-bit key for CBC, CTR, ECB, GCM chaining modes.
SF_CRYPTO_KEY_SIZE_AES_XTS_128	AES 128-bit key for XTS chaining mode only.
SF_CRYPTO_KEY_SIZE_AES_192	AES 192-bit key for CBC, CTR, ECB, GCM chaining modes.
SF_CRYPTO_KEY_SIZE_AES_256	AES 256-bit key for CBC, CTR, ECB, GCM chaining modes.
SF_CRYPTO_KEY_SIZE_AES_XTS_256	AES 256-bit key for XTS chaining mode only.
SF_CRYPTO_KEY_SIZE_ECC_192	ECC 192-bit key.
SF_CRYPTO_KEY_SIZE_ECC_224	ECC 224-bit key.
SF_CRYPTO_KEY_SIZE_ECC_256	ECC 256-bit key.
SF_CRYPTO_KEY_SIZE_ECC_384	ECC 384-bit key.

◆ sf_crypto_key_type_t

enum sf_crypto_key_type_t	
Supported key types	
Enumerator	
SF_CRYPTO_KEY_TYPE_RSA_PLAIN_TEXT	RSA Key pair in standard format and plain text.
SF_CRYPTO_KEY_TYPE_RSA_CRT_PLAIN_TEXT	RSA Key pair in CRT format and plain text.
SF_CRYPTO_KEY_TYPE_RSA_WRAPPED	RSA Key pair public key in plain text and wrapped standard format private key.
SF_CRYPTO_KEY_TYPE_AES_WRAPPED	Wrapped AES key.
SF_CRYPTO_KEY_TYPE_AES_PLAIN_TEXT	AES Plain text key.
SF_CRYPTO_KEY_TYPE_ECC_PLAIN_TEXT	ECC Key pair in standard format and plain text.
SF_CRYPTO_KEY_TYPE_ECC_WRAPPED	ECC Key pair public key in plain text and wrapped standard format private key.
SF_CRYPTO_KEY_TYPE_ENCRYPTED_RSA_PRIVATE_KEY	RSA private key in encrypted format for installation.
SF_CRYPTO_KEY_TYPE_ENCRYPTED_AES_KEY	AES key in encrypted format for installation.
SF_CRYPTO_KEY_TYPE_ENCRYPTED_ECC_PRIVATE_KEY	ECC private key in encrypted format for installation.

◆ sf_crypto_state_t

enum sf_crypto_state_t	
State codes for the SSP Crypto Framework Common Module	
Enumerator	
SF_CRYPTO_CLOSED	The module is closed.
SF_CRYPTO_OPENED	The module is opened.

sf_crypto_data_handle_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SSP Crypto Framework Common Module Interface

#include <sf_crypto_api.h>

Data Fields

uint8_t *	p_data Pointer to data.
uint32_t	data_length The length of data pointed by p_data.

Detailed Description

A structure to handle data among Crypto Framework modules

The documentation for this struct was generated from the following file:

- sf_crypto_api.h

ssp_err_t(*	versionGet)(ssp_version_t *const p_version)
ssp_err_t(*	statusGet)(sf_crypto_ctrl_t *const p_ctrl, sf_crypto_state_t *p_status)

Detailed Description

Shared Interface definition for the SSP Crypto Framework Common Module

Field Documentation

◆ close

ssp_err_t(* sf_crypto_api_t::close) (sf_crypto_ctrl_t *const p_ctrl)

Close SSP Crypto Framework Common Module. This function is to be called only once when the the Crypto services are no longer required.

Implemented as

- SF_CRYPTO_Close()

Parameters

[in,out]	p_ctrl	Pointer to a Crypto framework control block.

◆ lock

ssp_err_t(* sf_crypto_api_t::lock) (sf_crypto_ctrl_t *const p_ctrl)

Lock shared resources for Cryptography operations. This function is typically called by Crypto Framework modules (SF_CRYPTO_XXX) to protect shared software resources provided in Crypto Framework Common module or shared crypto hardware engine. Once lock() is called by a thread, any Crypto Framework services called by the other thread will be blocked until unlock() is called. The lock and unlock operations are managed by Crypto Framework modules so users do not need to call this function in typical use-cases. However, if this function is called by a user thread, users must be aware that any cryptography operations by the other threads will be locked out until unlock() is called by the thread which called lock().

Implemented as

- SF_CRYPTO_Lock()

Parameters

[in,out]	p_ctrl	Pointer to a Crypto framework control block.

◆ open

ssp_err_t(* sf_crypto_api_t::open) (sf_crypto_ctrl_t *const p_ctrl, sf_crypto_cfg_t const *const p_cfg)

Open SSP Crypto Framework Common Module. This function is to be called only once to initialize the Crypto services.

Implemented as

- SF_CRYPTO_Open()

Parameters

[in,out]	p_ctrl	Pointer to a Crypto framework control block. Must be declared by user.
[in]	p_cfg	Pointer to a Crypto framework configuration structure. All elements of this structure must be set by user.

◆ statusGet

ssp_err_t(* sf_crypto_api_t::statusGet) (sf_crypto_ctrl_t *const p_ctrl, sf_crypto_state_t *p_status)

Get status of SSP Crypto Framework Common Module.

Implemented as

- SF_CRYPTO_StatusGet()

Parameters

[in]	p_ctrl	Pointer to a Crypto framework control block.
[out]	p_status	Memory location to store module status.

◆ unlock

ssp_err_t(* sf_crypto_api_t::unlock) (sf_crypto_ctrl_t *const p_ctrl)

Unlock shared resources for Cryptography operations. This function is typically called by Crypto Framework modules (SF_CRYPTO_XXX) to allow any other threads to access to shared software resources provided in Crypto Framework Common module or shared crypto hardware engine. This function must be called by a thread which called lock(). The lock and unlock operations are managed by Crypto Framework modules so users do not need to call this function in typical use-cases. However, this function must be called by a user thread if the thread has ever called lock().

Implemented as

- SF_CRYPTO_Unlock()

Parameters

[in,out]	p_ctrl	Pointer to a Crypto framework control block.

◆ versionGet

ssp_err_t(* sf_crypto_api_t::versionGet) (ssp_version_t *const p_version)

Get version of SSP Crypto Framework Common Module.

Implemented as

- SF_CRYPTO_VersionGet()

Parameters

[out]	p_version	Pointer to the memory to store the version information.

The documentation for this struct was generated from the following file:

- sf_crypto_api.h

sf_crypto_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SSP Crypto Framework Common Module Interface

#include <sf_crypto_api.h>

Data Fields

sf_crypto_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_crypto_cfg_t const *	p_cfg Pointer to the configuration structure for this instance.
sf_crypto_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

The documentation for this struct was generated from the following file:

enum	sf_crypto_cipher_padding_scheme_t { SF_CRYPTO_CIPHER_PADDING_SCHEME_NO_PADDING, SF_CRYPTO_CIPHER_PADDING_SCHEME_PKCS7, SF_CRYPTO_CIPHER_PADDING_SCHEME_PKCS1_1_5 }

Detailed Description

Interface definition for Synergy Crypto Cipher Framework module.

Summary

This is a ThreadX aware Interface of SF_CRYPTO_CIPHER Framework module which provides encryption and decryption operations for AES and RSA algorithms.

Crypto Cipher Framework Interface description: Crypto Framework

Typedef Documentation

◆ sf_crypto_cipher_algorithm_init_params_t

typedef void sf_crypto_cipher_algorithm_init_params_t

Algorithm specific parameters. Allocate an algorithm specific block to pass into the cipherInit API call.

Implemented as

- sf_crypto_cipher_aes_init_params_t for AES
- sf_crypto_cipher_rsa_init_params_t for RSA.

◆ sf_crypto_cipher_ctrl_t

typedef void sf_crypto_cipher_ctrl_t
SSP Crypto Cipher framework control block. Allocate an instance specific control block to pass into the SSP Crypto framework Cipher API calls. **Implemented as** ◦ sf_crypto_cipher_instance_ctrl_t

Enumeration Type Documentation

◆ sf_crypto_cipher_mode_t

enum sf_crypto_cipher_mode_t	
AES modes for the SSP Crypto Cipher Framework	
Enumerator	
SF_CRYPTO_CIPHER_MODE_ECB	Electronic Code Book chaining mode, default for RSA.
SF_CRYPTO_CIPHER_MODE_CBC	Cipher Block Chaining.
SF_CRYPTO_CIPHER_MODE_CTR	Counter Mode.
SF_CRYPTO_CIPHER_MODE_XTS	XEX-based tweaked-codebook mode with ciphertext stealing.
SF_CRYPTO_CIPHER_MODE_GCM	Galois Counter Mode.

◆ sf_crypto_cipher_op_mode_t

enum sf_crypto_cipher_op_mode_t	
Operating mode for Cipher APIs	
Enumerator	
SF_CRYPTO_CIPHER_OP_MODE_ENCRYPT	The operating mode is set to encryption.
SF_CRYPTO_CIPHER_OP_MODE_DECRYPT	The operating mode is set to decryption.

◆ sf_crypto_cipher_padding_scheme_t

enum sf_crypto_cipher_padding_scheme_t	
Padding mode to be used for Cipher operation - encrypting/ decrypting input data	
Enumerator	
SF_CRYPTO_CIPHER_PADDING_SCHEME_NO_PADDING	No padding scheme.
SF_CRYPTO_CIPHER_PADDING_SCHEME_PKCS7	PKCS#7 padding scheme - applicable only for AES operations.
SF_CRYPTO_CIPHER_PADDING_SCHEME_PKCS1_1_5	PKCS#1 v1.5 padding scheme - applicable only for RSA operations.

sf_crypto_cipher_aes_init_params_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SSP Crypto Cipher Framework Interface

#include <sf_crypto_cipher_api.h>

Data Fields

sf_crypto_data_handle_t *	p_iv pointer to IV for the AES operation.
sf_crypto_data_handle_t *	p_auth_tag

Detailed Description

AES Algorithm specific parameters for cipher operations

Field Documentation

◆ p_auth_tag

sf_crypto_data_handle_t* sf_crypto_cipher_aes_init_params_t::p_auth_tag
Pointer to the GCM Authentication Tag. Only tag length of SF_CRYPTO_CIPHER_AES_GCM_TAG_LENGTH_16_BYTES is supported.

The documentation for this struct was generated from the following file:

- sf_crypto_cipher_api.h

sf_crypto_cipher_rsa_init_params_t Struct Reference

sf_crypto_cipher_api_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SSP Crypto Cipher Framework Interface

#include <sf_crypto_cipher_api.h>

Data Fields

ssp_err_t(*	open)(sf_crypto_cipher_ctrl_t *const p_ctrl, sf_crypto_cipher_cfg_t const *const p_cfg) Opens SSP Crypto Cipher framework. This function initializes a control block of the framework module based on the configuration parameters such as the key type, key size and chaining mode. The module allows users to have multiple instances with different control blocks, if required. More...
ssp_err_t(*	cipherInit)(sf_crypto_cipher_ctrl_t *const p_ctrl, sf_crypto_cipher_op_mode_t cipher_operation_mode, sf_crypto_key_t const *const p_key, sf_crypto_cipher_algorithm_init_params_t *const p_algorithm_specific_params) Initializes a cipher operation. Must be called after open() or

	cipherFinal() is called, to initialize a new cipher operation. Unless a different key type or key size or chaining mode is used, users do not need to close the module for a new cipher operation but can call this function to restart another cipher operation. More...
ssp_err_t(*	cipherUpdate)(sf_crypto_cipher_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_data_in, sf_crypto_data_handle_t *const p_data_out) Encrypts / decrypts input data and writes it to the output buffer. Can be called multiple times for additional blocks of data. If input length is 0 this method does nothing. There may be 0 to (input length+block size - 1) bytes of data for AES operations. For RSA operation there will be no output until cipherFinal() is called. RSA Encryption is only supported with the RSA Public Key. RSA Decryption is only supported with the RSA Private Key. More...
ssp_err_t(*	cipherFinal)(sf_crypto_cipher_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_data_in, sf_crypto_data_handle_t *const p_data_out) Encrypts/decrypts all/last block of data and writes to the output buffer. Once cipherFinal() is called, no additional call of cipherUpdate() is allowed but cipherInit() can be called to initialize a new cipher operation unless another key type / key size/chaining mode is needed. In such a case a call to close() and open() is required. For AES operations, the number of bytes output into output data buffer may be larger or smaller than input length or even 0. RSA Encryption is only supported with the RSA Public Key. RSA Decryption is only supported with the RSA Private Key. More...
ssp_err_t(*	cipherAadUpdate)(sf_crypto_cipher_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_aad) Updates AAD (Additional Authenticated Data) for AES GCM operation. Can be called multiple times for additional blocks of data. This is ONLY to provide AAD for AES GCM operation. Not applicable to any other algorithms or modes. This has to be called prior to processing any plain text / cipher text data. In other words, before any call to cipherUpdate() or cipherFinal() is made. More...
ssp_err_t(*	close)(sf_crypto_cipher_ctrl_t *const p_ctrl) Closes SSP Crypto Cipher framework. This function resets a control block of the framework module and allows users to re-configure the module differently. For instance, users can close the module and re-open it with different key type or key size or chaining mode / algorithm for a new cipher operation. More...
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Get version of SSP Crypto Cipher framework. More...

Detailed Description

Shared Interface definition for the SSP Crypto Cipher framework module

Field Documentation

◆ cipherAadUpdate

ssp_err_t(* sf_crypto_cipher_api_t::cipherAadUpdate) (sf_crypto_cipher_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_aad)

Updates AAD (Additional Authenticated Data) for AES GCM operation. Can be called multiple times for additional blocks of data. This is ONLY to provide AAD for AES GCM operation. Not applicable to any other algorithms or modes. This has to be called prior to processing any plain text / cipher text data. In other words, before any call to cipherUpdate() or cipherFinal() is made.

Implemented as

- SF_CRYPTO_CIPHER_CipherAadUpdate()

Parameters

[in]	p_ctrl	Pointer to Crypto Cipher Framework control block structure.
[in]	p_aad	Pointer to an input data buffer containing AAD and the AAD length.

Note

Data buffer must be WORD aligned.

◆ cipherFinal

ssp_err_t(* sf_crypto_cipher_api_t::cipherFinal) (sf_crypto_cipher_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_data_in, sf_crypto_data_handle_t *const p_data_out)

Encrypts/decrypts all/last block of data and writes to the output buffer. Once cipherFinal() is called, no additional call of cipherUpdate() is allowed but cipherInit() can be called to initialize a new cipher operation unless another key type / key size/chaining mode is needed. In such a case a call to close() and open() is required. For AES operations, the number of bytes output into output data buffer may be larger or smaller than input length or even 0. RSA Encryption is only supported with the RSA Public Key. RSA Decryption is only supported with the RSA Private Key.

Implemented as

- SF_CRYPTO_CIPHER_CipherFinal()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Cipher Framework control block structure.
[in]	p_data_in	Pointer to an input data buffer and the input data length.
[in,out]	p_data_out	Pointer to the output data buffer and the buffer size on input. If there is data to be output, buffer is filled and the length is updated.

Note

Data buffers must be WORD aligned.

◆ cipherInit

ssp_err_t(* sf_crypto_cipher_api_t::cipherInit) (sf_crypto_cipher_ctrl_t *const p_ctrl, sf_crypto_cipher_op_mode_t cipher_operation_mode, sf_crypto_key_t const *const p_key, sf_crypto_cipher_algorithm_init_params_t *const p_algorithm_specific_params)

Initializes a cipher operation. Must be called after open() or cipherFinal() is called, to initialize a new cipher operation. Unless a different key type or key size or chaining mode is used, users do not need to close the module for a new cipher operation but can call this function to restart another cipher operation.

Implemented as

- SF_CRYPTO_CIPHER_CipherInit()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Cipher Framework control block structure.
[in]	cipher_operation_mode	Specifies encrypt or decrypt operation.
[in]	p_key	The key to be used for the cipher operation.
[in]	p_algorithm_specific_params	Algorithm specific parameters. Allocate and fill parameters specific to the algorithm for the key type configured at open().

◆ cipherUpdate

ssp_err_t(* sf_crypto_cipher_api_t::cipherUpdate) (sf_crypto_cipher_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_data_in, sf_crypto_data_handle_t *const p_data_out)

Encrypts / decrypts input data and writes it to the output buffer. Can be called multiple times for additional blocks of data. If input length is 0 this method does nothing. There may be 0 to (input length+block size - 1) bytes of data for AES operations. For RSA operation there will be no output until cipherFinal() is called. RSA Encryption is only supported with the RSA Public Key. RSA Decryption is only supported with the RSA Private Key.

Implemented as

- SF_CRYPTO_CIPHER_CipherUpdate()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Cipher Framework control block structure.
[in]	p_data_in	Pointer to an input data buffer and the input data length.
[in,out]	p_data_out	Pointer to an output data buffer and the buffer size on input. If there is data to be output, buffer is filled and the length is updated.

Note

Data buffers must be WORD aligned.

◆ close

ssp_err_t(* sf_crypto_cipher_api_t::close) (sf_crypto_cipher_ctrl_t *const p_ctrl)

Closes SSP Crypto Cipher framework. This function resets a control block of the framework module and allows users to re-configure the module differently. For instance, users can close the module and re-open it with different key type or key size or chaining mode / algorithm for a new cipher operation.

Implemented as

- SF_CRYPTO_CIPHER_Close()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Cipher Framework control block structure.

◆ open

ssp_err_t(* sf_crypto_cipher_api_t::open) (sf_crypto_cipher_ctrl_t *const p_ctrl, sf_crypto_cipher_cfg_t const *const p_cfg)

Opens SSP Crypto Cipher framework. This function initializes a control block of the framework module based on the configuration parameters such as the key type, key size and chaining mode. The module allows users to have multiple instances with different control blocks, if required.

Implemented as

- SF_CRYPTO_CIPHER_Open()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Cipher Framework control block structure. Caller only needs to allocate sf_crypto_cipher_instance_ctrl_t and not fill any parameters.
[in]	p_cfg	Pointer to sf_crypto_cipher_cfg_t configuration structure. All elements of this structure must be filled by caller.

◆ versionGet

ssp_err_t(* sf_crypto_cipher_api_t::versionGet) (ssp_version_t *const p_version)

Get version of SSP Crypto Cipher framework.

Implemented as

- SF_CRYPTO_CIPHER_VersionGet()

Parameters

[in]	p_version	Pointer to the memory to store the module version.

The documentation for this struct was generated from the following file:

Detailed Description

Interface definition for Synergy Crypto HASH Framework module.

Summary

This is the Interface of SF_CRYPTO_HASH Framework module.

Crypto HASH Framework Interface description: Crypto Framework

Macro Definition Documentation

◆ SF_CRYPTO_HASH_API_VERSION_MAJOR

#define SF_CRYPTO_HASH_API_VERSION_MAJOR (2U)
The API version of SSP Crypto HASH Framework

◆ SF_CRYPTO_HASH_MESSAGE_DIGEST_SIZE_MD5

#define SF_CRYPTO_HASH_MESSAGE_DIGEST_SIZE_MD5 (16U)
Message Digest size for SHA1. Message Digest size for each HASH algorithm in bytes

Typedef Documentation

◆ sf_crypto_hash_ctrl_t

typedef void sf_crypto_hash_ctrl_t
SSP Crypto framework control block. Allocate an instance specific control block to pass into the SSP Crypto framework API calls. **Implemented as** ◦ sf_crypto_instance_ctrl_t

Enumeration Type Documentation

◆ sf_crypto_hash_state_t

enum sf_crypto_hash_state_t	
State codes for the SSP SSP Crypto HASH Framework	
Enumerator	
SF_CRYPTO_HASH_CLOSED	The module is closed.
SF_CRYPTO_HASH_OPENED	The module is opened. The initial message digest is not yet generated.
SF_CRYPTO_HASH_DIGEST_INITIALIZED	Message digest is initialized.
SF_CRYPTO_HASH_DIGEST_UPDATED	Message digest is updated.

◆ sf_crypto_hash_type_t

enum sf_crypto_hash_type_t	
HASH algorithm types for the SSP SSP Crypto HASH Framework	
Enumerator	
SF_CRYPTO_HASH_ALGORITHM_MD5	MD5 algorithm type.
SF_CRYPTO_HASH_ALGORITHM_SHA1	SHA-1 algorithm type.
SF_CRYPTO_HASH_ALGORITHM_SHA224	SHA-224 algorithm type.
SF_CRYPTO_HASH_ALGORITHM_SHA256	SHA-256 algorithm type.

ssp_err_t(*	hashUpdate)(sf_crypto_hash_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_data_in)

ssp_err_t(*	hashFinal)(sf_crypto_hash_ctrl_t *const p_ctrl, sf_crypto_data_handle_t *const p_msg_digest, uint32_t *p_size)
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

Shared Interface definition for the SSP SSP Crypto framework

Field Documentation

◆ close

ssp_err_t(* sf_crypto_hash_api_t::close) (sf_crypto_hash_ctrl_t *const p_ctrl)

Closes SSP Crypto HASH framework. This function de-initializes a control block of the framework module and allow users to re-configure the module differently. For instance, users can close the module and re-open it with different HASH algorithm for a new digest operation.

Implemented as

- SF_CRYPTO_HASH_Close()

Parameters

[in,out]	p_ctrl	Pointer to Crypto HASH Framework control block structure.

◆ hashFinal

ssp_err_t(* sf_crypto_hash_api_t::hashFinal) (sf_crypto_hash_ctrl_t *const p_ctrl, sf_crypto_data_handle_t *const p_msg_digest, uint32_t *p_size)

Hashes the last block of data and returns a message digest in the output buffer. Once hashFinal() is called, no additional call of hashUpdate() is allowed but hashInit() can be called to initialize a new digest operation unless the other HASH algorithm type needed. If the other HASH algorithm is required for a new digest operation, call close() and open(). This is a blocking call.

Implemented as

- SF_CRYPTO_HASH_MessageDigestUpdate()

Parameters

[in]	p_ctrl	Pointer to Crypto HASH Framework control block structure.
[in,out]	p_msg_digest	Pointer to an output data buffer and the buffer size. Message digest will be generated in the buffer. Data buffer must be aligned to word alignment and the size must be sufficient to store the message digest.
[out]	p_size	Pointer to the 32-bit memory space to store the size of message digest.

◆ hashInit

ssp_err_t(* sf_crypto_hash_api_t::hashInit) (sf_crypto_hash_ctrl_t *const p_ctrl)

Initializes a message digest operation. Must be called once open() or hashFinal() is called to initialize a new digest operation. Unless a different HASH type is used, users do not need to close the module for a new digest operation but can call this function to restart another digest operation. This is a blocking call.

Implemented as

- SF_CRYPTO_HASH_MessageDigestInit()

Parameters

[in]	p_ctrl	Pointer to Crypto HASH Framework control block structure.

◆ hashUpdate

ssp_err_t(* sf_crypto_hash_api_t::hashUpdate) (sf_crypto_hash_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_data_in)

Hashes input data and saves it in an internal context buffer. Can be called multiple times for additional blocks of data. This is a blocking call.

Implemented as

- SF_CRYPTO_HASH_MessageDigestUpdate()

Parameters

[in]	p_ctrl	Pointer to Crypto HASH Framework control block structure.
[in]	p_data_in	Pointer to an input data buffer and the data length.

◆ open

ssp_err_t(* sf_crypto_hash_api_t::open) (sf_crypto_hash_ctrl_t *const p_ctrl, sf_crypto_hash_cfg_t const *const p_cfg)

Opens SSP Crypto HASH framework. This function initializes a control block of the framework module based on the configuration parameters such as the HASH algorithm type. The module allows users to have multiple instances with different control blocks, if required.

Implemented as

- SF_CRYPTO_HASH_Open()

Parameters

[in,out]	p_ctrl	Pointer to Crypto HASH Framework control block structure.
[in]	p_cfg	Pointer to sf_crypto_hash_cfg_t configuration structure. All elements of this structure must be set by user.

◆ versionGet

ssp_err_t(* sf_crypto_hash_api_t::versionGet) (ssp_version_t *const p_version)
Get version of SSP Crypto HASH framework. **Implemented as** ◦ SF_CRYPTO_HASH_VersionGet() **Parameters** [in] p_version — Pointer to the memory to store the module version.

The documentation for this struct was generated from the following file:

- sf_crypto_hash_api.h

sf_crypto_hash_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SSP Crypto HASH Framework Interface

#include <sf_crypto_key_api.h>

Data Fields

sf_crypto_key_type_t	key_type Key type to be generated.

sf_crypto_key_size_t	key_size Key size to be generated.
sf_crypto_data_handle_t	domain_params
sf_crypto_data_handle_t	generator_point
sf_crypto_instance_t *	p_lower_lvl_crypto_common Pointer to a Crypto Framework common instance.
void const *	p_extend Extension parameter for hardware specific settings (Future purpose).

Detailed Description

Configuration structure for the SSP SSP Crypto Key framework

Field Documentation

◆ domain_params

sf_crypto_data_handle_t sf_crypto_key_cfg_t::domain_params
Pointer to domain parameters for the requested key type. Structure contains the domain data in the order a||b||p||n for ECC as defined in FIPS186-3 and data length. Length of the data to be in bytes. Should set to NULL for RSA and AES.

◆ generator_point

sf_crypto_data_handle_t sf_crypto_key_cfg_t::generator_point
Pointer to the generator base point of curve in the order Gx||Gy for ECC (where Gx and Gy are x and y coordinates respectively) and data length. Length of the data to be in bytes. This parameter applies only for ECC. For others (AES and RSA), this is UNUSED. Should set to NULL for RSA and AES.

The documentation for this struct was generated from the following file:

- sf_crypto_key_api.h

ssp_err_t(*	keyGenerate)(sf_crypto_key_ctrl_t *const p_ctrl, sf_crypto_key_t *const p_secret_key, sf_crypto_key_t *const p_public_key)
ssp_err_t(*	EcdhSharedSecretCompute)(sf_crypto_key_ctrl_t *const p_ctrl, sf_crypto_key_t *const p_local_secret_key, sf_crypto_key_t *const p_remote_public_key, sf_crypto_key_t *const p_shared_secret)
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

Shared Interface definition for the SSP SSP Crypto framework

Field Documentation

◆ close

ssp_err_t(* sf_crypto_key_api_t::close) (sf_crypto_key_ctrl_t *const p_ctrl)

Close SSP Crypto Key framework.

Implemented as

- SF_CRYPTO_KEY_Close()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Key Framework control block structure.

◆ EcdhSharedSecretCompute

ssp_err_t(* sf_crypto_key_api_t::EcdhSharedSecretCompute) (sf_crypto_key_ctrl_t *const p_ctrl, sf_crypto_key_t *const p_local_secret_key, sf_crypto_key_t *const p_remote_public_key,

sf_crypto_key_t *const p_shared_secret)

Perform scalar multiplication for ECC algorithms only. This is a blocking call.

Implemented as

- SF_CRYPTO_KEY_EcdhSharedSecretCompute

Parameters

[in]	p_ctrl	Pointer to Crypto Key Framework control block structure.
[in]	p_local_secret_key	Pointer to a secret key structure. The pointer to the secret key and it's length in bytes, are to be populated on input. Refer to r_ecc_api.h for ECC key sizes. p_secret_key should be WORD aligned. The memory allocation to store the secret key is user's responsibility.
[in]	p_remote_public_key	pointer to a point on the curve data. The pointer to the point on curve data and its length in bytes, are to be populated on input. Refer to r_ecc_api.h for ECC point on curve sizes. p_point_on_curve should be WORD aligned. The memory allocation to store the point on curve data is user's responsibility.
[in,out]	p_shared_secret	The pointer to the buffer and it's length in bytes, are to be populated on input. On success the resultant point on curve data and it's length in bytes, are returned. Refer to r_ecc_api.h for ECC public key sizes. p_resultant_vector should be WORD aligned. The memory allocation to store the resultant point on curve data is user's responsibility.

◆ keyGenerate

ssp_err_t(* sf_crypto_key_api_t::keyGenerate) (sf_crypto_key_ctrl_t *const p_ctrl, sf_crypto_key_t *const p_secret_key, sf_crypto_key_t *const p_public_key)

Generate a key. This is a blocking call.

Implemented as

- SF_CRYPTO_KEY_Generate()

Parameters

[in]	p_ctrl	Pointer to Crypto Key Framework control block structure.
[in,out]	p_secret_key	Pointer to a secret key structure. The pointer to the buffer and it's length in bytes, are to be populated on input. On success the key and it's length in bytes, are returned. Refer to r_rsa_api.h for RSA secret key sizes. Refer to r_aes_api.h for AES key sizes. Refer to r_ecc_api.h for ECC key sizes. p_secret_key should be WORD aligned. The memory allocation to store the secret key is user's responsibility.
[in,out]	p_public_key	Pointer to a public key structure. The pointer to the buffer and it's length in bytes, are to be populated on input. On success the key and it's length in bytes, are returned. Refer to r_rsa_api.h for RSA public key sizes. Refer to r_ecc_api.h for ECC public key sizes. Should set to NULL for AES. p_public_key should be WORD aligned. The memory allocation to store the public key is user's responsibility.

◆ open

ssp_err_t(* sf_crypto_key_api_t::open) (sf_crypto_key_ctrl_t *const p_ctrl, sf_crypto_key_cfg_t const *const p_cfg)

Open SSP Crypto Key framework for subsequent call / Key generation.

Implemented as

- SF_CRYPTO_KEY_Open()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Key Framework control block structure.
[in]	p_cfg	Pointer to sf_crypto_key_cfg_t configuration structure. All elements of this structure must be set by user.

◆ versionGet

ssp_err_t(* sf_crypto_key_api_t::versionGet) (ssp_version_t *const p_version)

Get version of SSP Crypto Key framework.

Implemented as

- SF_CRYPTO_KEY_VersionGet()

Parameters

[out]	p_version	Pointer to the memory to store the module version.

The documentation for this struct was generated from the following file:

Detailed Description

Shared Interface definition for the SSP Crypto Key Installation Interface framework

Field Documentation

◆ close

ssp_err_t(* sf_crypto_key_installation_api_t::close) (sf_crypto_key_installation_ctrl_t *const p_ctrl)

Close SSP Crypto Key Installation framework.

Implemented as

- SF_CRYPTO_KEY_INSTALLATION_Close()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Key Installation Framework control block structure.

◆ keyInstall

ssp_err_t(* sf_crypto_key_installation_api_t::keyInstall) (sf_crypto_key_installation_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_user_key_rsa_modulus, sf_crypto_data_handle_t const *const p_user_key_input, sf_crypto_key_installation_shared_index_t const shared_index_input, sf_crypto_data_handle_t const *const p_session_key_input, uint32_t const *const p_iv_input, sf_crypto_data_handle_t *const p_key_data_out)

Install a key from the user's encrypted key, a shared index, session key, and an IV generated using a scheme designed to maintain plaintext source key isolation. This returns a wrapped key (sometimes called a key index) that can be used in other crypto APIs in place of the associated plaintext key (stored offline).

Implemented as

- SF_CRYPTO_KEY_INSTALLATION_KeyInstall()

Parameters

[in]	p_ctrl	Pointer to Crypto Key Installation Framework control block structure. Caller should not modify any elements of this structure at any time.
[in]	p_user_key_rsa_modulus	Pointer to sf_crypto_key_handle_t structure which includes a pointer to the WORD aligned buffer which holds the RSA modulus portion of the encrypted user RSA private key and the modulus length. This is only applicable when a RSA standard key is being installed. To be set to NULL otherwise.
[in]	p_user_key_input	Pointer to

		sf_crypto_key_handle_t structure which includes a pointer to the WORD aligned buffer which holds the encrypted user key and length. This is the key to be installed in encrypted format.
[in]	shared_index_input	An enumerated type that reflects the shared key index returned by the DLM Service, accompanied by the session key that follows.
[in]	p_session_key_input	Pointer to sf_crypto_key_handle_t structure which includes a pointer to the WORD aligned buffer which holds the session key and length returned by the DLM Service, accompanied by the shared index key, above.
[in]	p_iv_input	Pointer to the 128-bit IV array used to encrypt p_user_key_input.
[in,out]	p_key_data_out	Pointer to sf_crypto_key_handle_t structure which includes a pointer to the WORD aligned buffer to hold the wrapped key and the buffer length. This is the wrapped key returned after key installation.

Note

It is the user's responsibility to ensure all the above input/output buffers are WORD aligned.
Caller must assign appropriate length to data_length field for all buffers before calling this API.

◆ open

ssp_err_t(* sf_crypto_key_installation_api_t::open) (sf_crypto_key_installation_ctrl_t *const p_ctrl, sf_crypto_key_installation_cfg_t const *const p_cfg)

Open SSP Crypto Key Installation framework for subsequent call / Key installation.

Implemented as

- SF_CRYPTO_KEY_INSTALLATION_Open()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Key Installation Framework control block structure.
[in]	p_cfg	Pointer to sf_crypto_key_installation_cfg_t configuration structure. All elements of this structure must be set by user.

◆ versionGet

ssp_err_t(* sf_crypto_key_installation_api_t::versionGet) (ssp_version_t *const p_version)

Get version of SSP Crypto Key Installation framework.

Implemented as

- SF_CRYPTO_KEY_INSTALLATION_VersionGet()

Parameters

[out]	p_version	Pointer to the memory to store the module version.

The documentation for this struct was generated from the following file:

Detailed Description

Interface definition for Synergy Crypto Signature Framework module.

Summary

The Signature framework module is a ThreadX aware module which provides sign and sign-verify services. They Key type and Key size provided in the configuration parameter determine the cryptography algorithm type and uses the appropriate Driver API interface to provide requested functionality. User can change the operation mode (Sign / Verify), message format and key data input multiple times after opening this module using the Open API. There is no need to close the module using Close API and then re-open the module if the intent is to just change operation mode, message format and/or key data input parameters.

Crypto Signature Framework Interface description: Crypto Framework

Macro Definition Documentation

◆ SF_CRYPTO_SIGNATURE_API_VERSION_MAJOR

#define SF_CRYPTO_SIGNATURE_API_VERSION_MAJOR (2U)
The API version of SSP Crypto Signature Framework

Typedef Documentation

◆ sf_crypto_signature_algorithm_init_params_t

typedef void sf_crypto_signature_algorithm_init_params_t

Algorithm specific parameters. Allocate an algorithm specific block to pass into the contextInit API call.

Implemented as

- sf_crypto_signature_rsa_specific_params_t for RSA

◆ sf_crypto_signature_ctrl_t

typedef void sf_crypto_signature_ctrl_t

SSP Crypto Signature framework control block. Allocate an instance specific control block to pass into the SSP Crypto Signature framework API calls.

Implemented as

- sf_crypto_signature_instance_ctrl_t

Enumeration Type Documentation

◆ sf_crypto_signature_message_operation_t

enum sf_crypto_signature_message_operation_t

Signature message operation

Enumerator	
SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_NONE	Input message is pre-formatted using appropriate format. Sign/verify operation is performed on the input message.
SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_RSA_SHA1_PKCS1_1_5	Generates a 20-byte (SHA-1) digest and signs/verifies the digest using RSASSA-PKCS1 v1.5 padding scheme.
SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_RSA_SHA224_PKCS1_1_5	Generates a 28-byte (SHA-224) digest and signs/verifies the digest using RSASSA-PKCS1 v1.5 padding scheme.
SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_RSA_SHA256_PKCS1_1_5	Generates a 32-byte (SHA-256) digest and signs/verifies the digest using RSASSA-PKCS1 v1.5 padding scheme.

◆ sf_crypto_signature_mode_t

enum sf_crypto_signature_mode_t	
Signature mode, sign or verify	
Enumerator	
SF_CRYPTO_SIGNATURE_MODE_SIGN	Perform Sign Operation.
SF_CRYPTO_SIGNATURE_MODE_VERIFY	Perform Verify Operation.

ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

Shared Interface definition for the SSP Crypto Signature framework

Field Documentation

◆ close

ssp_err_t(* sf_crypto_signature_api_t::close) (sf_crypto_signature_ctrl_t *const p_ctrl)

Close SSP Crypto Signature framework module. This API will free any memory allocated when the signature framework module was opened.

Implemented as

- SF_CRYPTO_SIGNATURE_Close()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Signature Framework control block structure.

◆ contextInit

ssp_err_t(* sf_crypto_signature_api_t::contextInit) (sf_crypto_signature_ctrl_t *const p_ctrl, sf_crypto_signature_mode_t operation_mode, sf_crypto_signature_algorithm_init_params_t *const p_algorithm_specific_params, sf_crypto_key_t const *const p_key)

Perform Signature Module Context Initialization operation. This API initializes the signature module by setting operating mode, the message padding scheme and appropriate key for subsequent calls to signUpdate, verifyUpdate, signFinal and verifyFinal APIs. This API can be called only after this module has be opened using the open API. This API can be called after signFinal or verifyFinal API to initialize context for a new operation. This API sets up the internal context for sign/verify operation.

Implemented as

- SF_CRYPTO_SIGNATURE_ContextInit()

Parameters

[in]	p_ctrl	Pointer to Crypto Signature Framework control block structure.
[in]	operation_mode	Selects Sign or Verify Operation enumeration.
[in]	p_algorithm_specific_params	Algorithm specific parameters.
[in]	p_key	Pointer to a private key for Sign operation OR Pointer to a public key for Verify operation.

Note

p_key should be WORD aligned.

◆ open

ssp_err_t(* sf_crypto_signature_api_t::open) (sf_crypto_signature_ctrl_t *const p_ctrl, sf_crypto_signature_cfg_t const *const p_cfg)

Open SSP Crypto Signature framework. This function sets up a control block of the framework module based on the configuration parameters such as the key type, key size and domain parameters. The module allows users to have multiple instances with different control blocks, if required. This API will allocate memory internally according to the cryptography algorithm selected through key_type and key_size parameters.

Implemented as

- SF_CRYPTO_SIGNATURE_Open()

Parameters

[in,out]	p_ctrl	Pointer to Crypto Signature Framework control block structure.
[in]	p_cfg	Pointer to sf_crypto_signature_cfg_t configuration structure. All elements of this structure must be set by user.

◆ signFinal

ssp_err_t(* sf_crypto_signature_api_t::signFinal) (sf_crypto_signature_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_message, sf_crypto_data_handle_t *const p_dest)

Perform Signature Module Signature-Final Operation. Call to this API generates signature and writes it to p_dest. p_message can be the pointer to last block of input message to be signed or can be passed as NULL if all of the input is passed through one or more signUpdate API call(s).

Implemented as

- SF_CRYPTO_SIGNATURE_SignFinal()

Parameters

[in]	p_ctrl	Pointer to Crypto Signature Framework control block structure.
[in]	p_message	Pointer to data handle containing last block of data and its length. If there is no more data to be passed this param can be set to NULL.
[in,out]	p_dest	Pointer to data handle containing pointer to a buffer for storing signature. The data_length of this handle must be populated with the buffer length. Upon successful return this data_length will be updated with the number of bytes written to this buffer.

Note

p_message should be WORD aligned.
p_dest should be WORD aligned.
p_message can be set to NULL.
In case SF_CRYPTO_SIGNATURE_NO_PADDING is chosen as the padding scheme ensure p_message is a valid message digest in appropriate format.

◆ signUpdate

ssp_err_t(* sf_crypto_signature_api_t::signUpdate) (sf_crypto_signature_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_message)

Perform Signature Module Signature-Update operation. This API can be called multiple times to accumulate the message to be signed. This API can be used when the input message to be signed is not available all at once in a byte array.

Implemented as

- SF_CRYPTO_SIGNATURE_SignUpdate()

Parameters

[in]	p_ctrl	Pointer to Crypto Signature Framework control block structure.
[in]	p_message	Pointer to input message to be signed.

Note

p_message should be WORD aligned.
In case SF_CRYPTO_SIGNATURE_NO_PADDING is chosen as the padding scheme ensure p_message is a valid message digest in appropriate format.

◆ verifyFinal

ssp_err_t(* sf_crypto_signature_api_t::verifyFinal) (sf_crypto_signature_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_signature, sf_crypto_data_handle_t const *const p_message)

Perform Signature Module Signature-Verification-Final Operation. Call to this API performs signature verification operation. p_message can be the pointer to last block of message or can be passed as NULL if all of the message whose signature is to be verified is passed through one or more verifyUpdate API call(s).

Implemented as

- SF_CRYPTO_SIGNATURE_VerifyFinal()

Parameters

[in]	p_ctrl	Pointer to Crypto Signature Framework control block structure.
[in]	p_signature	Pointer to Signature buffer to be verified.
[in]	p_message	Pointer to last block of message whose signature is being verified. If there is no more data to be passed this param can be set to NULL.

Note

p_message should be WORD aligned.
p_message can be set to NULL.

◆ verifyUpdate

ssp_err_t(* sf_crypto_signature_api_t::verifyUpdate) (sf_crypto_signature_ctrl_t *const p_ctrl, sf_crypto_data_handle_t const *const p_message)

Perform Signature Module Signature-Verification-Update operation. This API can be called multiple times to accumulate the message whose signature is to be verified. This API can be used when the input message to be verified against a signature is not available all at once in a byte array.

Implemented as

- SF_CRYPTO_SIGNATURE_VerifyUpdate()

Parameters

[in]	p_ctrl	Pointer to Crypto Signature Framework control block structure.
[in]	p_message	Pointer to message whose signature is to be verified.

Note

p_message should be WORD aligned.

◆ versionGet

ssp_err_t(* sf_crypto_signature_api_t::versionGet) (ssp_version_t *const p_version)

Get version of SSP Crypto Signature framework.

Implemented as

- SF_CRYPTO_SIGNATURE_VersionGet()

Parameters

[out]	p_version	Pointer to the memory to store the module version.

The documentation for this struct was generated from the following file:

- sf_crypto_signature_api.h

sf_crypto_signature_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SSP Crypto Signature Framework Interface

#include <sf_crypto_signature_api.h>

Data Fields

ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

Shared Interface definition for the SSP Crypto framework

Field Documentation

◆ close

ssp_err_t(* sf_crypto_trng_api_t::close) (sf_crypto_trng_ctrl_t *const p_ctrl)

Close SSP Crypto TRNG framework. This API should be called once TRNG services are no longer needed.

Implemented as

- SF_CRYPTO_TRNG_Close()

Parameters

[in,out]	p_ctrl_api	Pointer to Crypto TRNG Framework control block structure.

◆ open

ssp_err_t(* sf_crypto_trng_api_t::open) (sf_crypto_trng_ctrl_t *const p_ctrl, sf_crypto_trng_cfg_t const *const p_cfg)

Open SSP Crypto TRNG framework for true random number generation.

Implemented as

- SF_CRYPTO_TRNG_Open()

Parameters

[in,out]	p_ctrl_api	Pointer to Crypto TRNG Framework control block structure.
[in]	p_cfg	Pointer to sf_crypto_trng_cfg_t configuration structure. All elements of this structure must be set by user.

◆ randomNumberGenerate

ssp_err_t(* sf_crypto_trng_api_t::randomNumberGenerate) (sf_crypto_trng_ctrl_t *const p_ctrl, sf_crypto_data_handle_t *const p_random_number_buff)

Generate a True Random Number of specified size

Implemented as

- SF_CRYPTO_TRNG_RandomNumberGenerate()

Parameters

[in]	p_ctrl_api	Pointer to Crypto TRNG Framework control block structure.
[in,out]	p_random_number_buff	Pointer to sf_crypto_data_handle_t structure storing pointer to buffer and its size where true random number will be returned.

Note

Size value specified under p_random_number_buff must be specified in Bytes.
Size value specified under p_random_number_buff must not be 0 Bytes. Its minimum value is 1.
Pointer to data buffer specified under p_random_number_buff must not be NULL.
Data buffer must be WORD aligned. The memory allocation to store the true random number is user's responsibility.

◆ versionGet

ssp_err_t(* sf_crypto_trng_api_t::versionGet) (ssp_version_t *const p_version)

Get version of SSP Crypto TRNG Framework Module.

Implemented as

- SF_CRYPTO_TRNG_VersionGet()

Parameters

[out]	p_version	Pointer to the memory to store the module version.

The documentation for this struct was generated from the following file:

enum	sf_el_gx_event_t { SF_EL_GX_EVENT_ERROR = 1, SF_EL_GX_EVENT_DISPLAY_VSYNC = 2, SF_EL_GX_EVENT_UNDERFLOW = 3 }

Detailed Description

Interface definition for Adapting Microsoft GUIX for Synergy graphics drivers.

Summary

This is the Interface of SF_EL_GX Framework module which ties Synergy graphics device drivers to GUIX. The interface provides following driver adaptation for GUIX:

- DISPLAY driver for displaying image on LCD(e.g. GLCDC)
- Dave/2d driver for image rendering by 2DG engine
- JPEG driver for the image rendering by JPEG engine
- Software image rendering with no hardware acceleration

Implemented by: GUIX Synergy Port

Related SSP architecture topics:

- SSP Interfaces
- SSP Predefined Layers
- Using SSP Modules

Detailed Description

Shared Interface definition for the SSP GUIX adaptation framework

Field Documentation

◆ canvasInit

ssp_err_t(* sf_el_gx_api_t::canvasInit) (sf_el_gx_ctrl_t *const p_ctrl, GX_WINDOW_ROOT *p_window_root)

Canvas initialization. Set the memory address of the initial canvas.

Implemented as

- SF_EL_GX_CanvasInit()

Parameters

[in,out]	p_ctrl	Pointer to SF_EL_GX control block structure.
[in]	p_window_root	Pointer to GUIX root window context.

◆ close

ssp_err_t(* sf_el_gx_api_t::close) (sf_el_gx_ctrl_t *const p_ctrl)

Close SSP GUIX adaptation framework.

Implemented as

- SF_EL_GX_Close()

Parameters

[in,out]	p_ctrl	Pointer to SF_EL_GX control block structure.

◆ open

ssp_err_t(* sf_el_gx_api_t::open) (sf_el_gx_ctrl_t *const p_ctrl, sf_el_gx_cfg_t const *const p_cfg)

Open SSP GUIX adaptation framework.

Implemented as

- SF_EL_GX_Open()

Parameters

[in,out]	p_ctrl	Pointer to SF_EL_GX control block structure. Must be declared by user. Value set here.
[in]	p_cfg	Pointer to SF_EL_GX configuration structure. All elements of this structure must be set by user.

◆ setup

UINT(* sf_el_gx_api_t::setup) (GX_DISPLAY *p_display)

Microsoft GUIX Driver setup entry.

Implemented as

- SF_EL_GX_Setup()

Parameters

[in]	p_display	Pointer to GUIX display driver setup function.

◆ versionGet

ssp_err_t(* sf_el_gx_api_t::versionGet) (ssp_version_t *p_version)

Get version.

Implemented as

- SF_EL_GX_VersionGet()

Parameters

[in]	p_version	Pointer to the memory to store the version information.

The documentation for this struct was generated from the following file:

sf_external_irq_api_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » External IRQ Framework Interface

#include <sf_external_irq_api.h>

Data Fields

ssp_err_t(*	open)(sf_external_irq_ctrl_t *const p_ctrl, sf_external_irq_cfg_t const *const p_cfg)
ssp_err_t(*	wait)(sf_external_irq_ctrl_t *const p_ctrl, ULONG const timeout)
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)
ssp_err_t(*	close)(sf_external_irq_ctrl_t *const p_ctrl)

Detailed Description

External IRQ framework API structure. External IRQ implementations use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_external_irq_api_t::close) (sf_external_irq_ctrl_t *const p_ctrl)

Close channel at HAL layer and release the RTOS services.

Implemented as

- SF_EXTERNAL_IRQ_Close()

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for this external interrupt.

◆ open

ssp_err_t(* sf_external_irq_api_t::open) (sf_external_irq_ctrl_t *const p_ctrl, sf_external_irq_cfg_t const *const p_cfg)

Create the semaphore, then handle driver initialization at the HAL layer.

Implemented as

- SF_EXTERNAL_IRQ_Open()

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. The device control structure is initialized in this function.
[in]	p_cfg	Pointer to configuration structure. All elements of the structure must be set by user.

◆ versionGet

ssp_err_t(* sf_external_irq_api_t::versionGet) (ssp_version_t *const p_version)

Get version and store it in provided pointer p_version.

Implemented as

- SF_EXTERNAL_IRQ_VersionGet()

Parameters

[out]	p_version	Code and API version used stored here.

◆ wait

ssp_err_t(* sf_external_irq_api_t::wait) (sf_external_irq_ctrl_t *const p_ctrl, ULONG const timeout)

Wait for the next external interrupt expiration, then return.

Precondition

Call SF_EXTERNAL_IRQ_Open to configure the external IRQ before using this function. During SF_EXTERNAL_IRQ_Open, set sf_external_irq_cfg_t::sf_external_irq_event_t to SF_EXTERNAL_IRQ_EVENT_SEMAPHORE_PUT.

Implemented as

- SF_EXTERNAL_IRQ_Wait()

Parameters

[in]	p_ctrl	Handle set in SF_EXTERNAL_IRQ_Open.
[in]	timeout	ThreadX timeout. Select TX_NO_WAIT, a value in system clock counts between 1 and 0xFFFFFFFF, or TX_WAIT_FOREVER.

The documentation for this struct was generated from the following file:

- sf_external_irq_api.h

sf_external_irq_instance_t Struct Reference

SF I2C device state	
Enumerator	
SF_I2C_DEV_STATE_CLOSED	I2C device is closed.
SF_I2C_DEV_STATE_OPENED	I2C device is opened.

sf_i2c_bus_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » I2C Framework

#include <sf_i2c_api.h>

Data Fields

uint8_t	channel Channel.
TX_MUTEX *	p_lock_mutex Lock mutex handle for this channel.
TX_MUTEX	device_count_mutex Device count mutex handle for this device.
TX_EVENT_FLAGS_GROUP *	p_sync_eventflag Pointer to the event flag object for I2C data transfer.
sf_i2c_ctrl_t **	pp_curr_ctrl Current device using the bus (by switching the address)
uint8_t *	p_bus_name User-supplied name to identify the bus. Useful for debugging.
i2c_api_master_t const *	p_lower_lvl_api Pointer to I2C HAL interface to be used in the framework.
uint8_t	device_count Number of devices on the bus; initialize to 0.
sf_i2c_ctrl_t **	pp_curr_bus_ctrl Device configured on the bus (low level configuration)

Detailed Description

Data structure defining a I2C bus.

Detailed Description

Shared Interface definition for I2C Framework

Field Documentation

◆ close

ssp_err_t(* sf_i2c_api_t::close) (sf_i2c_ctrl_t *const p_ctrl)

Disable the I2C device designated by the control handle. Close the RTOS services used by the bus if no devices are connected to the bus.

Implemented as

- SF_I2C_Close()

Parameters

[in]	p_ctrl	Control handle for I2C framework driver context for a device

◆ lock

ssp_err_t(* sf_i2c_api_t::lock) (sf_i2c_ctrl_t *const p_ctrl)

Lock the bus for a device. Locking allows devices to reserve a bus to themselves for a given period of time (i.e. between lock and unlock). This allows devices to complete several reads and writes on the bus without interrupt, which is required in some instances.

Implemented as

- SF_I2C_Lock()

Parameters

[in]	p_ctrl	Control handle for I2C framework driver context for a device

◆ lockWait

ssp_err_t(* sf_i2c_api_t::lockWait) (sf_i2c_ctrl_t *const p_ctrl, uint32_t const timeout)

Lock the I2C bus for a device. Locking reserves exclusive access to the I2C driver. Here a wait option is provided to the user. This allows devices to complete several reads and writes on the bus without interrupt, which is required in some instances.

Implemented as

- SF_I2C_LockWait()

Parameters

[in]	p_ctrl	Control handle for I2C framework driver context for a device
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

◆ open

ssp_err_t(* sf_i2c_api_t::open) (sf_i2c_ctrl_t *p_ctrl, sf_i2c_cfg_t const *const p_cfg)

Open a designated I2C device on a bus.

Implemented as

- SF_I2C_Open()

Parameters

[out]	p_ctrl	Control handle for I2C framework driver context for a device (Value returns from this function). This value must be cleared by user.
[in]	p_cfg	I2C configuration includes I2C bus and low level configuration

◆ read

ssp_err_t(* sf_i2c_api_t::read) (sf_i2c_ctrl_t *const p_ctrl, uint8_t *const p_dest, uint32_t const bytes, bool const restart, uint32_t const timeout)

Receive data from I2C device.

Implemented as

- SF_I2C_Read()

Parameters

[in]	p_ctrl	Pointer to previously opened I2C SF control structure.
[in]	p_dest	Pointer to location to store read data.
[in]	bytes	Number of bytes to read.
[in]	restart	Indicates whether the restart condition should be issued after reading.
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

◆ reset

ssp_err_t(* sf_i2c_api_t::reset) (sf_i2c_ctrl_t *const p_ctrl, uint32_t const timeout)

Abort any in-progress transfer and force the I2C peripheral into a ready state.

Implemented as

- SF_I2C_Reset()

This function safely terminates any in-progress I2C transfer with the device. If a transfer is aborted, the user is be notified via callback with an abort event. Since the callback is optional, this function also returns a specific error code in this situation.

Parameters

[in]	p_ctrl	Pointer to device control block initialized in Open call for I2C driver.
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

◆ unlock

ssp_err_t(* sf_i2c_api_t::unlock) (sf_i2c_ctrl_t *const p_ctrl)

Unlock the bus from a particular device and make it available for other devices. This allows other devices to use bus for reads and writes on the bus.

Implemented as

- SF_I2C_Unlock()

Parameters

[in]	p_ctrl	Control handle for I2C framework driver context for a device

◆ version

ssp_err_t(* sf_i2c_api_t::version) (ssp_version_t *const p_version)

Get I2C framework version.

Implemented as

- SF_I2C_VersionGet()

Parameters

[in]	p_ctrl	Handle for I2C framework control block for a device

◆ write

ssp_err_t(* sf_i2c_api_t::write) (sf_i2c_ctrl_t *const p_ctrl, uint8_t *const p_src, uint32_t const bytes, bool const restart, uint32_t const timeout)

Transmit data to I2C device.

Implemented as

- SF_I2C_Write()

Parameters

[in]	p_ctrl	Pointer to previously opened I2C control structure.
[in]	p_src	Pointer to location to get write data.
[in]	bytes	Number of bytes to write.
[in]	restart	Indicates whether the restart condition should be issued after writing.
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

5.1.2.38 JPEG Decode Framework Interface

Renesas Synergy Software Package Reference » Framework Interfaces

RTOS-integrated JPEG Decode Framework Interface. More...

Data Structures

struct	sf_jpeg_decode_cfg_t
struct	sf_jpeg_decode_api_t
struct	sf_jpeg_decode_instance_t

Macros

#define	SF_JPEG_DECODE_API_VERSION_MAJOR (2U)

Typedefs

typedef void	sf_jpeg_decode_ctrl_t

Detailed Description

RTOS-integrated JPEG Decode Framework Interface.

Summary

This is a ThreadX aware generic JPEG decoding framework for run-time JPEG decode applications. It can be implemented by either hardware or software. For Synergy parts, the interface is implemented by the on-chip JPEG decoding engine. The connection to the HAL layer is established by passing in a driver structure in SF_JPEG_Decode_Open.

Related SSP architecture topics:

- SSP Interfaces
- SSP Predefined Layers
- Using SSP Modules

ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

JPEG Decode API structure. Implementations will use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_jpeg_decode_api_t::close) (sf_jpeg_decode_ctrl_t *const p_ctrl)

Closes JPEG codec device. Un-finished codec operation is interrupted, and output data are discarded.

Parameters

[in]	p_ctrl	Pointer to the control block set in SF_JPEG_Decode_Open().

◆ horizontalStrideSet

ssp_err_t(* sf_jpeg_decode_api_t::horizontalStrideSet) (sf_jpeg_decode_ctrl_t *const p_ctrl, uint32_t horizontal_stride)

Configure the horizontal stride value.

Parameters

[in]	p_ctrl	Pointer to the control block initialized in SF_JPEG_Decode_Open().
[out]	horizontal_stride	Set the horizontal stride value, in pixels

◆ imageSizeGet

ssp_err_t(* sf_jpeg_decode_api_t::imageSizeGet) (sf_jpeg_decode_ctrl_t *const p_ctrl, uint16_t *p_horizontal_size, uint16_t *p_vertical_size)

Obtain the size of the image. This function is only useful for decoding a JPEG image.

Parameters

[in]	p_ctrl	Pointer to the control block initialized in SF_JPEG_Decode_Open().
[out]	p_horizontal_size	Width of the image, in pixels
[out]	p_vertical_size	Height of the image, in pixels

◆ imageSubsampleSet

ssp_err_t(* sf_jpeg_decode_api_t::imageSubsampleSet) (sf_jpeg_decode_ctrl_t *const p_ctrl, jpeg_decode_subsample_t horizontal_subsample, jpeg_decode_subsample_t vertical_subsample)

Configure the horizontal and vertical subsample values. This allows an application to reduce the size of the decoded image.

Parameters

[in]	p_ctrl	Pointer to the control block initialized in SF_JPEG_Decode_Open().
[in]	horizontal_subsample	Set the horizontal subsample value
[in]	vertical_subsample	Set the vertical subsample value

◆ inputBufferSet

ssp_err_t(* sf_jpeg_decode_api_t::inputBufferSet) (sf_jpeg_decode_ctrl_t *const p_ctrl, void *const p_buffer, uint32_t const buffer_size)

Feed data into JPEG codec module.

Parameters

[in]	p_ctrl	Pointer to the control block initialized in SF_JPEG_Decode_Open().
[in]	p_buffer	Buffer contains data to be processed by the JPEG codec module. The buffer starting address must be 8-byte aligned
[in]	buffer_size	Size of the data buffer, must be multiple of 8 bytes

◆ linesDecodedGet

ssp_err_t(* sf_jpeg_decode_api_t::linesDecodedGet) (sf_jpeg_decode_ctrl_t *const p_ctrl, uint32_t *const p_lines)

Obtain number of lines JPEG codec decoded.

Parameters

[in]	p_ctrl	Pointer to the control block initialized in SF_JPEG_Decode_Open().
[out]	p_lines	Number of lines decoded into the output buffer.

◆ open

ssp_err_t(* sf_jpeg_decode_api_t::open) (sf_jpeg_decode_ctrl_t *const p_ctrl, sf_jpeg_decode_cfg_t const *const p_cfg)

Acquire mutex, then handle driver initialization at the HAL layer. This function releases mutex before it returns to the caller.

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. Elements initialized here.
[in]	p_cfg	Pointer to configuration structure. All elements of the structure must be set by user.

◆ outputBufferSet

ssp_err_t(* sf_jpeg_decode_api_t::outputBufferSet) (sf_jpeg_decode_ctrl_t *const p_ctrl, void *p_buffer, uint32_t buffer_size)

Read processed data from JPEG codec module.

Parameters

[in]	p_ctrl	Pointer to the control block initialized in SF_JPEG_Decode_Open().
[in]	p_buffer	User-supplied buffer space to hold output from JPEG codec module. The buffer starting address must be 8-byte aligned
[in]	buffer_size	Size of the output data buffer

◆ pixelFormatGet

ssp_err_t(* sf_jpeg_decode_api_t::pixelFormatGet) (sf_jpeg_decode_ctrl_t *const p_ctrl, jpeg_decode_color_space_t *const p_color_space)

Obtain the pixel format of the image. This function is only useful for decoding a JPEG image.

Parameters

[in]	p_ctrl	Pointer to the control block initialized in SF_JPEG_Decode_Open().
[out]	p_color_space	Color space of the image

◆ statusGet

ssp_err_t(* sf_jpeg_decode_api_t::statusGet) (sf_jpeg_decode_ctrl_t *const p_ctrl, jpeg_decode_status_t *const p_status)

Obtain JPEG codec status

Parameters

[in]	p_ctrl	Pointer to the control block initialized in SF_JPEG_Decode_Open().
[out]	p_status	Status of current JPEG codec module

◆ versionGet

ssp_err_t(* sf_jpeg_decode_api_t::versionGet) (ssp_version_t *const p_version)

Gets version and stores it in provided pointer p_version.

Parameters

[out]	p_version	Code and API version used.

◆ wait

ssp_err_t(* sf_jpeg_decode_api_t::wait) (sf_jpeg_decode_ctrl_t *const p_ctrl, jpeg_decode_status_t *const p_status, uint32_t timeout)

Wait for current JPEG codec operation to finish

Parameters

[in]	p_ctrl	Pointer to the control block initialized in SF_JPEG_Decode_Open().
[out]	p_status	Status of current JPEG codec module
[out]	timeout	Amount of time (in ThreadX ticks) to wait

ssp_err_t(*	close)(sf_memory_ctrl_t *const p_api_ctrl)
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

SF_MEMORY functions implemented at the Framework layer will follow this API.

Field Documentation

◆ close

ssp_err_t(* sf_memory_api_t::close) (sf_memory_ctrl_t *const p_api_ctrl)

Closes the module.

Implemented as

- SF_MEMORY_QSPI_NOR_Close

Parameters

[in]	p_api_ctrl	Control block set in sf_memory_api_t::open call.

◆ erase

ssp_err_t(* sf_memory_api_t::erase) (sf_memory_ctrl_t *const p_api_ctrl, uint32_t const memory_address, uint32_t const num_bytes)

Erases the specified number of bytes from the memory device.

Implemented as

- SF_MEMORY_QSPI_NOR_Erase

Parameters

[in]	p_api_ctrl	Control block set in sf_memory_api_t::open call.
[in]	memory_address	Address to start the erase process at.
[in]	num_bytes	Number of bytes of data to erase.

◆ flush

ssp_err_t(* sf_memory_api_t::flush) (sf_memory_ctrl_t *const p_api_ctrl)

Performs any buffered pending writes. This function MUST be called by the application after the final write is called to complete any pending writes.

Implemented as

- SF_MEMORY_QSPI_NOR_Flush

Parameters

[in]	p_api_ctrl	Control block set in sf_memory_api_t::open call.

◆ infoGet

ssp_err_t(* sf_memory_api_t::infoGet) (sf_memory_ctrl_t *const p_api_ctrl, sf_memory_info_t *const p_info)

Returns information about the memory implementation.

Implemented as

- SF_MEMORY_QSPI_NOR_InfoGet

Parameters

[in]	p_api_ctrl	Control block set in sf_memory_api_t::open call.
[out]	p_info	Pointer to information structure. All elements of this structure will be set by the function.

◆ open

ssp_err_t(* sf_memory_api_t::open) (sf_memory_ctrl_t *const p_api_ctrl, sf_memory_cfg_t const *const p_cfg)

Initialize Memory framework.

Implemented as

- SF_MEMORY_QSPI_NOR_Open

Parameters

[in]	p_api_ctrl	Pointer to control block. Must be declared by user. Elements set here.
[in]	p_config	Pointer to configuration structure. All elements of this structure must be set by user.

◆ read

ssp_err_t(* sf_memory_api_t::read) (sf_memory_ctrl_t *const p_api_ctrl, uint8_t *const p_dest_address, uint32_t const memory_address, uint32_t const num_bytes)

Reads data from the specified memory device address to the location specified by the caller.

Implemented as

- SF_MEMORY_QSPI_NOR_Read

Parameters

[in]	p_api_ctrl	Control block set in sf_memory_api_t::open call.
[in]	p_dest_address	Destination to read the data into.
[in]	memory_address	Address to read the data from.
[in]	num_bytes	Number of bytes of data to read.

◆ versionGet

ssp_err_t(* sf_memory_api_t::versionGet) (ssp_version_t *const p_version)

Gets version and stores it in provided pointer p_version.

Implemented as

- SF_MEMORY_QSPI_NOR_VersionGet

Parameters

[out]	p_version	Code and API version used.

◆ write

ssp_err_t(* sf_memory_api_t::write) (sf_memory_ctrl_t *const p_api_ctrl, uint8_t *const p_src_address, uint32_t const memory_address, uint32_t const num_bytes)

Writes the specified number of data bytes to the specified device memory address.

Implemented as

- SF_MEMORY_QSPI_NOR_Write

Parameters

[in]	p_api_ctrl	Control block set in sf_memory_api_t::open call.
[in]	p_src_address	Address to read the data to be written.
[in]	memory_address	Address to write the data to.
[in]	num_bytes	Number of bytes of data to write.

Messaging Interface description: Messaging Framework

Macro Definition Documentation

◆ SF_MESSAGE_API_VERSION_MAJOR

#define SF_MESSAGE_API_VERSION_MAJOR (2U)
Version of the API defined in this file

Typedef Documentation

◆ sf_message_ctrl_t

typedef void sf_message_ctrl_t
Message framework control block. Allocate an instance specific control block to pass into the message framework API calls. **Implemented as** ◦ sf_message_instance_ctrl_t

Enumeration Type Documentation

◆ sf_message_callback_event_t

enum sf_message_callback_event_t	
Messaging callback response	
Enumerator	
SF_MESSAGE_CALLBACK_EVENT_ACK	ACK response.
SF_MESSAGE_CALLBACK_EVENT_NAK	NAK response.

◆ sf_message_priority_t

enum sf_message_priority_t	
Messaging framework state	
Enumerator	
SF_MESSAGE_PRIORITY_NORMAL	Gives a message to be sent normal priority.
SF_MESSAGE_PRIORITY_HIGH	Gives a message to be sent higher priority than previous ones.

◆ sf_message_release_option_t

enum sf_message_release_option_t	
Messaging option	
Enumerator	
SF_MESSAGE_RELEASE_OPTION_NONE	No option.
SF_MESSAGE_RELEASE_OPTION_FORCED_RELEASE	Buffer forced release option.
SF_MESSAGE_RELEASE_OPTION_ACK	ACK response (note if both ACK and NAK are set at same time, NAK.
SF_MESSAGE_RELEASE_OPTION_NAK	NAK response.

◆ sf_message_state_t

enum sf_message_state_t	
Messaging framework state	
Enumerator	
SF_MESSAGE_STATE_CLOSED	Messaging framework is closed.
SF_MESSAGE_STATE_OPENED	Messaging framework is opened.

sf_message_header_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Messaging Framework Interface

#include <sf_message_api.h>

Detailed Description

Message header definition

The documentation for this struct was generated from the following file:

- sf_message_api.h

sf_message_instance_range_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Messaging Framework Interface

#include <sf_message_api.h>

Data Fields

uint8_t	start Start of the event class instance range.
uint8_t	end End of the event class instance range.

Detailed Description

Subscriber lists definitions

The documentation for this struct was generated from the following file:

- sf_message_api.h

sf_message_subscriber_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Messaging Framework Interface

#include <sf_message_api.h>

Data Fields

TX_QUEUE *	p_queue Pointer to the message queue for subscriber thread.
sf_message_instance_range_t	instance_range Range of the event class instance to receive message.

Detailed Description

Message subscriber

The documentation for this struct was generated from the following file:

ssp_err_t(*	post)(sf_message_ctrl_t *const p_ctrl, sf_message_header_t const *const p_buffer, sf_message_post_cfg_t const *const p_post_cfg, sf_message_post_err_t *const p_post_err, uint32_t const wait_option)
ssp_err_t(*	pend)(sf_message_ctrl_t const *const p_ctrl, TX_QUEUE const *const p_queue, sf_message_header_t **pp_buffer, uint32_t const wait_option)
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

Messaging Framework API structure. Implementations will use the following API.

Field Documentation

◆ bufferAcquire

ssp_err_t(* sf_message_api_t::bufferAcquire) (sf_message_ctrl_t const *const p_ctrl, sf_message_header_t **pp_buffer, sf_message_acquire_cfg_t const *const p_acquire_cfg, uint32_t const wait_option)

Acquire buffer for message passing from the block.

Implemented as

- SF_MESSAGE_BufferAcquire()

Parameters

[in]	p_ctrl	Pointer to the messaging control block
[in,out]	pp_buffer	Pointer to the pointer to the allocated buffer memory
[in]	p_acquire_cfg	Pointer to the buffer acquisition configuration
[in]	wait_option	Wait option (TX_NO_WAIT, TX_WAIT_FOREVER or numerical values)

◆ bufferRelease

ssp_err_t(* sf_message_api_t::bufferRelease) (sf_message_ctrl_t *const p_ctrl, sf_message_header_t *const p_buffer, sf_message_release_option_t const option)

Release buffer obtained from SF_MESSAGE_BufferAcquire().

Implemented as

- SF_MESSAGE_BufferRelease()

Parameters

[in]	p_ctrl	Pointer to the messaging control block
[in]	p_buffer	Pointer to the buffer allocated by SF_MESSAGE_BufferAcquire()
[in]	option	Buffer release option (SF_MESSAGE_RELEASE_OPTION_NONE, SF_MESSAGE_RELEASE_OPTION_ACK, SF_MESSAGE_RELEASE_OPTION_NAK, SF_MESSAGE_RELEASE_OPTION_FORCED_RELEASE)

◆ close

ssp_err_t(* sf_message_api_t::close) (sf_message_ctrl_t *const p_ctrl)

Finalize message framework.

Implemented as

- SF_MESSAGE_Close()

Parameters

[in,out]	p_ctrl	Pointer to the messaging control block

◆ open

ssp_err_t(* sf_message_api_t::open) (sf_message_ctrl_t *const p_ctrl, sf_message_cfg_t const *const p_cfg)

Initialize message framework. Initiate the messaging framework control block, configure the work memory corresponding to the configuration parameters.

Implemented as

- SF_MESSAGE_Open()

Parameters

[in,out]	p_ctrl	Pointer to the messaging control block
[in]	p_cfg	Pointer to configuration structure

◆ pend

ssp_err_t(* sf_message_api_t::pend) (sf_message_ctrl_t const *const p_ctrl, TX_QUEUE const *const p_queue, sf_message_header_t **pp_buffer, uint32_t const wait_option)

Pend message.

Implemented as

- SF_MESSAGE_Pend()

Parameters

[in]	p_ctrl	Pointer to the messaging control block
[in]	p_queue	Pointer to a threadX message queue object
[in,out]	pp_buffer	Pointer to the pointer to the buffer where message is stored.
[in]	wait_option	Wait option (TX_NO_WAIT, TX_WAIT_FOREVER or numerical values)

◆ post

ssp_err_t(* sf_message_api_t::post) (sf_message_ctrl_t *const p_ctrl, sf_message_header_t const *const p_buffer, sf_message_post_cfg_t const *const p_post_cfg, sf_message_post_err_t *const p_post_err, uint32_t const wait_option)

Post message to the subscribers.

Implemented as

- SF_MESSAGE_Post()

Parameters

[in]	p_ctrl	Pointer to the messaging control block
[in]	p_buffer	Pointer to the buffer allocated by SF_MESSAGE_BufferAcquire()
[in]	p_post_cfg	Pointer to the message post configuration
[in]	wait_option	Wait option (TX_NO_WAIT, TX_WAIT_FOREVER or numerical values)

◆ versionGet

ssp_err_t(* sf_message_api_t::versionGet) (ssp_version_t *const p_version)

Get the version of the messaging framework.

Implemented as

- SF_MESSAGE_VersionGet()

Parameters

[in]	p_version	Pointer to the memory where to store the version number

---

The documentation for this struct was generated from the following file:

- sf_message_api.h

sf_message_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Messaging Framework Interface

#include <sf_message_api.h>

Data Fields

sf_message_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_message_cfg_t const *	p_cfg Pointer to the configuration structure for this instance.
sf_message_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

The documentation for this struct was generated from the following file:

Enumerations

enum	sf_power_profiles_v2_event_t { SF_POWER_PROFILES_V2_EVENT_PRE_LOW_POWER, SF_POWER_PROFILES_V2_EVENT_POST_LOW_POWER }

Detailed Description

Power Profiles Framework Interface.

Summary

This framework allows an application to apply power profiles at runtime. There are 2 types of profiles: Run and Low Power. Applying a Run profile will change things like the system clock and IOPORT settings. The MCU will continue to run during this process and will not be put into a low power mode. Applying a Low Power profile will put the MCU into a low power mode. Which low power mode is used is specified by the LPMv2 instance used. IOPORT settings can also be specified which will be applied before entering the low power mode and after waking up.

The Deep Software Standby low power mode, available on some MCUs, will reset the MCU when the woken up. In this case the callback will not be called and the IOPORT configuration will not be applied after waking up.

This framework can be used with, or without, an RTOS.

ssp_err_t(*	close)(sf_power_profiles_v2_ctrl_t *const p_ctrl)
ssp_err_t(*	versionGet)(ssp_version_t *const p_version)

Detailed Description

Framework Power Profiles v2 API structure. Implementations will use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_power_profiles_v2_api_t::close) (sf_power_profiles_v2_ctrl_t *const p_ctrl)

Closes the framework.

Implemented as

- SF_POWER_PROFILES_V2_Close()

Parameters

[in]	p_ctrl	Pointer to control block set in SF_POWER_PROFILES_V2_Open.

◆ lowPowerApply

ssp_err_t(* sf_power_profiles_v2_api_t::lowPowerApply) (sf_power_profiles_v2_ctrl_t *const p_ctrl, sf_power_profiles_v2_low_power_cfg_t const *const p_cfg)

Applies a Low Power profile.

Implemented as

- SF_POWER_PROFILES_V2_LowPowerApply()

Parameters

[in]	p_ctrl	Pointer to control block set in SF_POWER_PROFILES_V2_Open.
[in]	p_cfg	Pointer to configuration structure. Elements of the structure must be set by user.

◆ open

ssp_err_t(* sf_power_profiles_v2_api_t::open) (sf_power_profiles_v2_ctrl_t *const p_ctrl, sf_power_profiles_v2_cfg_t const *const p_cfg)

Initializes the framework.

Implemented as

- SF_POWER_PROFILES_V2_Open()

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. Elements initialized here.
[in]	p_cfg	Pointer to configuration structure. Elements of the structure must be set by user.

◆ runApply

ssp_err_t(* sf_power_profiles_v2_api_t::runApply) (sf_power_profiles_v2_ctrl_t *const p_ctrl, sf_power_profiles_v2_run_cfg_t const *const p_cfg)

Applies a Run profile.

Implemented as

- SF_POWER_PROFILES_V2_RunApply()

Parameters

[in]	p_ctrl	Pointer to control block set in SF_POWER_PROFILES_V2_Open.
[in]	p_cfg	Pointer to configuration structure. Elements of the structure must be set by user.

◆ versionGet

ssp_err_t(* sf_power_profiles_v2_api_t::versionGet) (ssp_version_t *const p_version)
Gets version and stores it in provided pointer p_version. **Implemented as** ◦ SF_POWER_PROFILES_V2_VersionGet() **Parameters** [out] p_version — Code and API version used.

The documentation for this struct was generated from the following file:

- sf_power_profiles_v2_api.h

sf_power_profiles_v2_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Power Profiles V2 Framework Interface

#include <sf_power_profiles_v2_api.h>

Data Fields

sf_power_profiles_v2_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_power_profiles_v2_cfg_t const *	p_cfg Pointer to the configuration structure for this instance.
sf_power_profiles_v2_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

Detailed Description

RTOS-integrated SF Socket WIFI Framework Interface.

Summary

This SSP Interface provides access OnChip stack BSD Socket API.

Macro Definition Documentation

◆ SF_SOCKET_WIFI_API_VER_MAJOR

#define SF_SOCKET_WIFI_API_VER_MAJOR (2U)
Major Version of the API defined in this file

◆ SF_SOCKET_WIFI_API_VER_MINOR

#define SF_SOCKET_WIFI_API_VER_MINOR (0U)
Minor Version of the API defined in this file

◆ SF_SOCKET_WIFI_NO_OF_BIT_IN_BYTE

#define SF_SOCKET_WIFI_NO_OF_BIT_IN_BYTE (8U)
SF WiFi Socket Number of Bits in a Byte

Typedef Documentation

◆ socklen_t

typedef int32_t socklen_t
Socket Structure Length

Function Documentation

◆ accept()

int accept (int *sockfd*, struct sockaddr * *p_cliaddr*, socklen_t * *p_addrlen*)

This accepts connection from remote socket.

Accept connection request from remote.

Parameters

[in]	sockfd	Local socket
[out]	p_cliaddr	Pointer to remote socket address which trying to connect
[out]	p_addrlen	Pointer to address length of client socket address

Implements accept This function accepts connection from remote socket. This API is used only with socket type STREAM. The call is blocked if no connection is present or the socket is blocking.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_cliaddr	Remote machine Network address
[out]	p_addrlen	Size of Socket address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error accepting the connection
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Connection is received successfully.

Implements accept This function accepts connection from remote socket. This API is used only with socket type STREAM. The call is blocked if no connection is present or the socket is blocking.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_cliaddr	Remote machine Network

		address (Can be NULL)
[out]	p_addrlen	Size of Socket address structure(Can be NULL)

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error accepting the connection or invalid input parameters

Returns

Otherwise Connection is received successfully.

◆ bind()

int bind (int *sockfd*, const struct sockaddr * *p_local_sock_addr*, socklen_t *addrlen*)

This binds socket to IP address.

Bind socket to interface which is identified by IP address

Parameters

[in]	sockfd	Local socket
[in]	p_local_sock_addr	Pointer to local socket address
[in]	addrlen	Size of sock address structure

Implements bind This function binds socket to given IP address and port.

Parameters

sockfd	Socket file descriptor
p_local_sock_addr	Socket address structure
addrlen	Size of Socket address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Binding socket failed
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket is bound successfully.

Implements bind This function binds socket to given IP address and port.

Parameters

sockfd	Socket file descriptor
p_local_sock_addr	Socket address structure
addrlen	Size of Socket address structure

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Binding socket failed or invalid input parameters

Returns

Otherwise Socket is bound successfully.

◆ close()

int close (int *sockfd*)

This closes socket.

API which closes socket

Parameters

[in]	sockfd	Local socket

Implements close Close opened socket

Parameters

[in]	sockfd	Socket file descriptor

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Closing socket failed
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket is closed successfully.

Implements close Close opened socket

Parameters

[in]	sockfd	Socket file descriptor

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Closing socket failed or invalid input parameters

Returns

Otherwise Socket is closed successfully.

◆ connect()

int connect (int *sockfd*, const struct sockaddr * *p_serv_addr*, socklen_t *addrlen*)

This connects with remote socket(stream socket).

Establish TCP connection with remote socket

Parameters

[in]	sockfd	Local socket
[in]	p_serv_addr	Pointer to remote socket address

[in]	addrlen	Size of sock address structure

Implements connect This function connects local socket with remote socket. The call is blocked until a connection is established or error is returned.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_serv_addr	Remote machine Network address
[in]	addrlen	Size of Socket address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error occurred.
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket is connected successfully.

Implements connect This function connects local socket with remote socket. The call is blocked until a connection is established or error is returned.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_serv_addr	Remote machine Network address
[in]	addrlen	Size of Socket address structure

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error occurred or invalid input parameters

Returns

Otherwise Socket is connected successfully.

◆ getsockopt()

int getsockopt (int *sockfd*, int *level*, int *optname*, void * *p_optval*, socklen_t * *p_optlen*)

This reads socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Get Socket options.

Parameters

[in]	sockfd	Local socket
[in]	level	Sockets API level
[in]	optname	Option to be get
[out]	p_optval	Option value to be get
[in]	p_optlen	Length of option value

Implements getsockopt This gets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[out]	p_optval	Socket option value
[out]	p_optlen	Size of Socket option

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error reading socket option
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket option read successfully.

This reads socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Implements getsockopt This gets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[out]	p_optval	Socket option value
[out]	p_optlen	Size of Socket option

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error reading socket option or invalid socket descriptor

Returns

Otherwise Socket option read successfully.

◆ listen()

int listen (int *sockfd*, int *backlog*)

This listens for connection on socket.

Listen for tcp connection. Set socket in listen mode for tcp connection.

Parameters

[in]	sockfd	Local socket
[in]	backlog	Max number of connection queue.

Implements listen This function listen for connection on socket.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	backlog	number of maximum connection can be accepted

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Failed to set socket in Listen mode
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Set socket in Listen mode successfully.

Implements listen This function listen for connection on socket.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	backlog	number of maximum connection can be accepted

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Failed to set socket in Listen mode or invalid input parameters

Returns

Otherwise Set socket in Listen mode successfully.

◆ recv()

ssize_t recv (int *sockfd*, void * *p_buf*, size_t *length*, int *flags*)

This receives data over STREAM socket.

Receive data from remote socket.

Parameters

[in]	sockfd	Local socket
[out]	p_buf	Pointer to data buffer where data will be received
[in]	length	Maximum length of data which can be received
[in]	flags	Socket flags

Implements receive This function receives data on a stream socket in connected state. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_buf	Buffer to read data
[in]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Failed to receive data.

Returns

Otherwise Number of Data bytes received successfully.

Implements receive This function receives data on a stream socket in connected state. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_buf	Buffer to read data
[out]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Failed to receive data or invalid input parameters

Returns

Otherwise Data received successfully.

◆ recvfrom()

ssize_t recvfrom (int *sockfd*, void * *p_buf*, size_t *length*, int *flags*, struct sockaddr * *p_src_addr*, socklen_t * *p_addrlen*)

This receives data over DGRAM socket.

Receive data from remote socket.

Parameters

[in]	sockfd	Local socket
[out]	p_buf	Pointer to data buffer where data will be received
[in]	length	Maximum length of data which can be received
[in]	flags	Socket flag
[out]	p_src_addr	Pointer to remote socket address which has sent data
[out]	p_addrlen	Length of socket address structure

Implements recvfrom This function receives data on a dgram socket. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket file descriptor
[out]	p_buf	Data buffer pointer to read data
[in]	length	Length of data to read
[in]	flags	Flags
[in]	p_src_addr	Remote machine network address
[in]	p_addrlen	Size of Remote machine network

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error receiving data

Returns

Otherwise Numbers of data bytes received successfully.

Implements recvfrom This function receives data on a dgram socket. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to

receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket file descriptor
[out]	p_buf	Data buffer pointer to read data
[in]	length	Length of data to read
[in]	flags	Flags
[in]	p_src_addr	Remote machine network address (Can be NULL)
[in]	p_addrlen	Size of Remote machine network (Can be NULL)

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error receiving data or invalid input parameters

Returns

Otherwise Numbers of data bytes received successfully.

◆ select()

int select (int *nfds*, fd_set * *p_readfds*, fd_set * *p_writefds*, fd_set * *p_exceptfds*, struct timeval * *p_timeout*)

This waits for any activity on socket.

Wait on a given socket for specified amount of time. In case of any activity e.g. arrival of packet it comes out of wait.

Parameters

[in]	nfds	Max fd
[in]	p_readfds	Pointer to fd_set to check whether data is available for read
[in]	p_writefds	Pointer to fd_set to check whether data is available for write
[in]	p_exceptfds	Pointer to fd_set to check whether exceptional condition occurred
[in]	p_timeout	Wait time in milliseconds

Implements select Allow an application thread to block on a given socket handle for a specified time period. This API checks for any activity on specified socket, for example arrival of a packet at

the receive queue.

Parameters

[in]	nfds	Number of socket fds in to check
[in]	p_readfds	Read socket fd set
[in]	p_writefds	Write socket fd set. If no descriptor is to be tested for writing, p_writefds should be NULL
[in]	p_exceptfds	Exceptional socket fd set. If no descriptor is to be tested for exceptions, p_exceptfds should be NULL
[in]	p_timeout	Timeout

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Timeout occurred, no activity.

Returns

Otherwise Activity detected(Packet available).

Implements select Allow an application thread to block on a given socket handle for a specified time period. This API checks for any activity on specified socket, for example arrival of a packet at the receive queue.

Parameters

[in]	nfds	Number of socket fds in to check
[in]	p_readfds	Read socket fd set
[in]	p_writefds	Write socket fd set - API does not used this parameter
[in]	p_exceptfds	Exceptional socket fd set - API does not used this parameter
[in]	p_timeout	Timeout

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Timeout occurred, no activity or invalid socket descriptor

Returns

Otherwise Activity detected(Packet available).

◆ send()

ssize_t send (int *sockfd*, const void * *p_buf*, size_t *length*, int *flags*)

This sends data over STREAM socket.

Send data to remote socket.

Parameters

[in]	sockfd	Local socket
[in]	p_buf	Pointer to data buffer
[in]	length	Data buffer length
[in]	flags	Socket flags

Implements send This function sends data on a stream socket in connected state.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data to send
[in]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Failed to send data.

Returns

Otherwise Number of Data bytes sent successfully.

Implements send This function sends data on a stream socket in connected state.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data to send
[in]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Failed to send data or invalid input parameters

Returns

Otherwise Data sent successfully.

◆ sendto()

ssize_t sendto (int *sockfd*, const void * *p_buf*, size_t *length*, int *flags*, const struct sockaddr * *p_dest_addr*, socklen_t *addrlen*)

This sends data over DGRAM socket.

Send data to remote socket.

Parameters

[in]	sockfd	Local socket
[in]	p_buf	Pointer to data buffer to sent
[in]	length	Data buffer length
[in]	flags	Socket flag
[in]	p_dest_addr	Pointer to remote socket address where to send data
[in]	addrlen	Length of socket address structure

Implements sendto This function sends data to remote.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data pointer
[in]	length	Length of data
[in]	flags	Flag
[in]	p_dest_addr	Address of remote UDP server
[in]	addrlen	Size of Network address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error Sending data.

Returns

Otherwise Numbers of bytes sent successfully.

Implements sendto This function sends data to remote.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data pointer
[in]	length	Length of data

[in]	flags	Flag
[in]	p_dest_addr	Address of remote UDP server
[in]	addrlen	Size of Network address structure

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error Sending data or invalid input parameters

Returns

Otherwise Numbers of bytes sent successfully.

◆ setsockopt()

int setsockopt (int *sockfd*, int *level*, int *optname*, const void * *p_optval*, socklen_t *optlen*)

This updates socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Set Socket options.

Parameters

[in]	sockfd	Local socket
[in]	level	Sockets API level
[in]	optname	Option to be set
[in]	p_optval	Option value to be set
[in]	optlen	Length of option value

Implements setsockopt This sets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[in]	p_optval	Socket option value
[in]	optlen	Size of Socket option

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error setting socket option
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket option set successfully.

This updates socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Implements setsockopt This sets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[in]	p_optval	Socket option value
[in]	optlen	Size of Socket option

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error setting socket option or invalid socket descriptor

Returns

Otherwise Socket option set successfully.

◆ socket()

int socket (int *domain*, int *type*, int *protocol*)

This creates socket for communication.

API which creates socket

Parameters

[in]	domain	Socket family
[in]	type	Socket type
[in]	protocol	Protocol type

Implements socket Creates socket with given parameters.

Parameters

[in]	domain	Network Domain
[in]	type	Socket type
[in]	protocol	Protocol type

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Socket creation failed

Returns

Otherwise Socket descriptor of newly created socket

Implements socket Creates socket with given parameters.

Parameters

[in]	domain	Network Domain
[in]	type	Socket type
[in]	protocol	Protocol type

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Socket creation failed

Returns

Otherwise Socket created successfully

Detailed Description

Socket Interface API

Field Documentation

◆ close

ssp_err_t(* sf_socket_api_t::close) (sf_socket_ctrl_t *const p_ctrl)

Pointer to function which un-initialize the network interface and may put it in low power mode or power it off. Close the driver, disable the driver link, disable interrupt.

Parameters

[in,out]	p_ctrl	Pointer to the control block

◆ open

ssp_err_t(* sf_socket_api_t::open) (sf_socket_ctrl_t *p_ctrl, sf_socket_cfg_t const *const p_cfg)
Pointer to function which initializes the network interface for data transfers Initial driver configuration, enable the driver link, enable interrupts and make device ready for data transfer. **Parameters** [in,out] p_ctrl — Pointer to user-provided storage for the control block. [in] p_cfg — Pointer to configuration structure.

◆ versionGet

ssp_err_t(* sf_socket_api_t::versionGet) (ssp_version_t *const p_version)
Gets version and stores it in provided pointer p_version. **Parameters** [out] p_version — pointer to memory location to return version number

Detailed Description

Definition of the SPI framework interface.

Field Documentation

◆ close

ssp_err_t(* sf_spi_api_t::close) (sf_spi_ctrl_t *const p_ctrl)

Disable the SPI device designated by the control handle and close the RTOS services used by the bus if no devices are connected to the bus. This function removes power to the SPI channel designated by the handle and disables the associated interrupts.

Parameters

[in]	p_ctrl	Pointer to the control block for the device.

◆ lock

ssp_err_t(* sf_spi_api_t::lock) (sf_spi_ctrl_t *const p_ctrl)

Lock the bus for a device. The locking allows devices to reserve a bus to themselves for a given period of time (i.e. between lock and unlock). This allows devices to complete several reads and writes on the bus without interrupt.

Parameters

[in]	p_ctrl	Pointer to the control block for the device.

◆ lockWait

ssp_err_t(* sf_spi_api_t::lockWait) (sf_spi_ctrl_t *const p_ctrl, uint32_t const timeout)

Lock the bus for a device. The locking allows devices to reserve a bus to themselves for a given period of time (i.e. between lock and unlock). This allows devices to complete several reads and writes on the bus without interrupt. The wait option allows thread to wait for the specified timeout when acquiring the bus mutex.

Implemented as

- SF_SPI_LockWait()

Parameters

[in]	p_ctrl	Pointer to the control block for the device.
[in]	timeout	ThreadX timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

◆ open

ssp_err_t(* sf_spi_api_t::open) (sf_spi_ctrl_t *p_ctrl, sf_spi_cfg_t const *const p_cfg)

Open a designated SPI device on a bus.

Parameters

[in,out]	p_ctrl	Pointer to user-provided storage for the control block.
[in]	p_cfg	Pointer to SPI Framework configuration structure.

◆ read

ssp_err_t(* sf_spi_api_t::read) (sf_spi_ctrl_t *const p_ctrl, void *const p_dest, uint32_t const length, spi_bit_width_t const bit_width, uint32_t const timeout)

Receive data from SPI device.

Precondition

Call sf_spi_api_t::open to configure the SPI device before using this function.

Parameters

[in]	p_ctrl	Pointer to the control block for the device.
[out]	p_dest	Pointer to destination buffer into which data will be copied that is received from a SPI device. It is the responsibility of the caller to ensure that adequate space is available to hold the requested data count.
[in]	length	Indicates the number of units of data to be transferred (unit size specified by the bit_width).
[in]	bit_width	Indicates data bit width to be transferred.
[in]	timeout	Timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

◆ unlock

ssp_err_t(* sf_spi_api_t::unlock) (sf_spi_ctrl_t *const p_ctrl)

Unlock the bus for a particular device and make the bus usable for other devices.

Parameters

[in]	p_ctrl	Pointer to the control block for the device.

◆ version

ssp_err_t(* sf_spi_api_t::version) (ssp_version_t *const p_version)

Get the version information of the underlying driver.

Parameters

[out]	p_version	pointer to memory location to return version number

◆ write

ssp_err_t(* sf_spi_api_t::write) (sf_spi_ctrl_t *const p_ctrl, void *const p_src, uint32_t const length, spi_bit_width_t const bit_width, uint32_t const timeout)

Transmit data to SPI device.

Precondition

Call sf_spi_api_t::open to configure the SPI device before using this function.

Parameters

[in]	p_ctrl	Pointer to the control block for the device.
[in]	p_src	Pointer to a source data buffer from which data will be transmitted to a SPI device. The argument must not be NULL.
[in]	length	Indicates the number of units of data to be transferred (unit size specified by the bit_width).
[in]	bit_width	Indicates data bit width to be transferred.
[in]	timeout	Timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

◆ writeRead

ssp_err_t(* sf_spi_api_t::writeRead) (sf_spi_ctrl_t *const p_ctrl, void *const p_src, void *const p_dest, uint32_t const length, spi_bit_width_t const bit_width, uint32_t const timeout)

Simultaneously transmit data to an SPI device while receiving data from an SPI device (full duplex).

The writeread API gets mutex object, handles SPI data transmission at SPI HAL layer and receive data from the SPI HAL layer. The API uses the event flag wait to synchronize to completion of data transfer .

Precondition

Call sf_spi_api_t::open to configure the SPI before using this function.

Parameters

[in]	p_ctrl	Pointer to the control block for the channel.
[in]	p_src	Pointer to a source data buffer from which data will be transmitted to a SPI device. The argument must not be NULL.
[out]	p_dest	Pointer to destination buffer into which data will be copied that is received from a SPI device. It is the responsibility of the caller to ensure that adequate space is available to hold the requested data count.
[in]	length	Indicates the number of units of data to be transferred (unit size specified by the bit_width).
[in]	bit_width	Indicates data bit width to be transferred.
[in]	timeout	Timeout. Options include TX_NO_WAIT (0x00000000), TX_WAIT_FOREVER (0xFFFFFFFF), and timeout value (0x00000001 through 0xFFFFFFFE) in ThreadX tick counts.

struct	sf_thread_monitor_instance_t

Macros

#define	SF_THREAD_MONITOR_API_VERSION_MAJOR (2U)

Typedefs

typedef void	sf_thread_monitor_ctrl_t

Detailed Description

RTOS-integrated Framework Interface for monitoring of threads.

Any misbehaving threads cause a reset of the device. Both the WDT and IWDT HAL modules are supported by this framework module.

Summary

This is a ThreadX aware Watchdog Timer Thread Monitor Framework for monitoring threads in an application in which threads are executing at an expected rate. Threads to be monitored register themselves through SF_THREAD_MONITOR_ThreadRegister() and increment a count by calling SF_THREAD_MONITOR_CountIncrement() each time they execute. Each monitored thread also provides expected maximum and minimum count values for normal execution.

The Thread Monitor runs periodically and checks the count value of each monitored thread. If the count value falls outside of the expected range of values, the Watchdog Timer is allowed to reset the device. If all thread counts are within their expected ranges, then the Watchdog Timer is refreshed.

The WDT and IWDT modules are supported by the Thread Monitor.

The Framework Layer can be used to protect the entire software project. This is achieved through a high priority thread (Framework Layer) which runs periodically within the refresh permitted window of the Watchdog Timer selected (IWDT is safest as has its own clock source and is started automatically after reset). This thread monitors the state of every other thread in the system. If any of these threads are not running as expected, then the Watchdog Timer is not refreshed and is not allowed to reset the system. If the threads are running as expected, then the Watchdog Timer is refreshed.

Monitoring the other threads is achieved as follows: Each monitored thread increments a count variable each time it runs. The Thread Monitor thread checks the count variable of each thread to make sure it is within an expected range. If any of the variables are out of range a reset is allowed. Otherwise all variables are cleared to zero and the watchdog is refreshed. A profiling mode is used to establish the expected ranges.

This approach is described in the following article:

Jack Ganssle, "Great Watchdog Timers for Embedded Systems," www.ganssle.com/watchdogs.htm

This method requires the instrumenting of each thread to increment its count variable, but this is little overhead for the massive gain in protection.

Interface used: WDT Interface

typedef void sf_thread_monitor_ctrl_t
Thread monitor control block. Allocate an instance specific control block to pass into the thread monitor API calls. **Implemented as** ◦ sf_thread_monitor_instance_ctrl_t

sf_thread_monitor_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Thread Monitor Framework Interface

#include <sf_thread_monitor_api.h>

Data Fields

wdt_instance_t const *	p_lower_lvl_wdt Pointer to lower level watchdog instance.

bool	profiling_mode_enabled Enables or disables profiling mode.
UINT	priority Priority of thread monitor thread.

Detailed Description

Configuration for RTOS Thread Monitor driver

The documentation for this struct was generated from the following file:

- sf_thread_monitor_api.h

sf_thread_monitor_thread_counter_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Thread Monitor Framework Interface

#include <sf_thread_monitor_api.h>

Data Fields

uint32_t	current_count Current count value for a thread.
uint32_t	minimum_count
uint32_t	maximum_count
bool	active
TX_THREAD *	p_thread Pointer to thread for this counter data.

Detailed Description

Counter block for each monitored thread.

Field Documentation

◆ active

bool sf_thread_monitor_thread_counter_t::active
Indicates to the monitoring thread whether this count data is currently active. When a thread is registered this value will be set to false as the count is likely to be a partial count and so should not be monitored. This value will be set to true by the thread monitor thread when it clears all counts to zero.

◆ maximum_count

uint32_t sf_thread_monitor_thread_counter_t::maximum_count
Maximum expected count value. If the current count is more than this value the watchdog will reset

◆ minimum_count

uint32_t sf_thread_monitor_thread_counter_t::minimum_count
Minimum expected count value. If the current count is less than this value the watchdog will reset.

The documentation for this struct was generated from the following file:

- sf_thread_monitor_api.h

sf_thread_monitor_counter_min_max_t Struct Reference

Detailed Description

Thread monitor API structure. Thread Monitor implementations use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_thread_monitor_api_t::close) (sf_thread_monitor_ctrl_t *const p_ctrl)

Suspends the thread monitoring thread. Watchdog peripheral no longer refreshed.

Implemented as

- SF_THREAD_MONITOR_Close()

Parameters

[in,out]	p_ctrl	Control structure set in SF_THREAD_MONITOR_Open.

◆ countIncrement

ssp_err_t(* sf_thread_monitor_api_t::countIncrement) (sf_thread_monitor_ctrl_t *const p_ctrl)

Safely increments a monitored thread's count value.

Implemented as

- SF_THREAD_MONITOR_CountIncrement()

Parameters

[in,out]	p_ctrl	Control structure set in SF_THREAD_MONITOR_Open.

◆ open

ssp_err_t(* sf_thread_monitor_api_t::open) (sf_thread_monitor_ctrl_t *const p_ctrl, sf_thread_monitor_cfg_t const *const p_cfg)

Configures the WDT or IWDT module. From the configuration data the timeout period of the WDT/IWDT is determined and a thread created monitoring registered threads.

Implemented as

- SF_THREAD_MONITOR_Open()

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. Elements initialized here.
[in]	p_cfg	Pointer to configuration structure. All elements of the structure must be set by user.

◆ threadRegister

ssp_err_t(* sf_thread_monitor_api_t::threadRegister) (sf_thread_monitor_ctrl_t *const p_ctrl, sf_thread_monitor_counter_min_max_t const *p_counter_min_max)

Registers a thread for monitoring.

Implemented as

- SF_THREAD_MONITOR_ThreadRegister()

Parameters

[in,out]	p_ctrl	Control structure set in SF_THREAD_MONITOR_Open.
[in]	p_counter_min_max	Pointer to structure containing min and max values for thread to be registered values.

◆ threadUnregister

ssp_err_t(* sf_thread_monitor_api_t::threadUnregister) (sf_thread_monitor_ctrl_t *const p_ctrl)

Removes a thread from being monitored.

Implemented as

- SF_THREAD_MONITOR_ThreadUnregister()

Parameters

[in,out]	p_ctrl	Control structure set in SF_THREAD_MONITOR_Open.

◆ versionGet

ssp_err_t(* sf_thread_monitor_api_t::versionGet) (ssp_version_t *const p_version)

Get version and store it in provided pointer p_version.

Implemented as

- SF_THREAD_MONITOR_VersionGet()

Parameters

[in,out]	p_version	Pointer to structure storing API and code versions.

The documentation for this struct was generated from the following file:

- sf_thread_monitor_api.h

sf_thread_monitor_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Thread Monitor Framework Interface

#include <sf_thread_monitor_api.h>

Data Fields

sf_thread_monitor_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_thread_monitor_cfg_t const *	p_cfg Pointer to the configuration structure for this instance.
sf_thread_monitor_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

ssp_err_t(*	close)(sf_touch_ctsu_ctrl_t *const p_ctrl)
ssp_err_t(*	versionGet)(ssp_version_t *const p_data)

Detailed Description

Functions implemented at the HAL layer will follow this API.

Field Documentation

◆ callbackSet

ssp_err_t(* sf_touch_ctsu_api_t::callbackSet) (sf_touch_ctsu_ctrl_t *const p_api_ctrl, void(*p_callback)(sf_touch_ctsu_callback_args_t *), void const *const p_context, sf_touch_ctsu_callback_args_t *const p_callback_memory)

Specify callback function and optional context pointer and working memory pointer.

Implemented as

- SF_TOUCH_CTSU_CallbackSet()

Parameters

[in]	p_ctrl	Pointer to the CTSU control block.
[in]	p_callback	Callback function
[in]	p_context	Pointer to send to callback function
[in]	p_working_memory	Pointer to volatile memory where callback structure can be allocated. Callback arguments allocated here are only valid during the callback.

◆ close

ssp_err_t(* sf_touch_ctsu_api_t::close) (sf_touch_ctsu_ctrl_t *const p_ctrl)

Close driver.

Implemented as

- SF_TOUCH_CTSU_Close()

Parameters

[in]	p_ctrl	Pointer to control structure.

◆ dataGet

ssp_err_t(* sf_touch_ctsu_api_t::dataGet) (sf_touch_ctsu_ctrl_t *const p_ctrl, uint64_t *p_button_status, uint16_t *p_slider_position, uint16_t *p_wheel_position)

Data get.

Implemented as

- SF_TOUCH_CTSU_DataGet()

Parameters

[in]	p_ctrl	Pointer to control structure.
[out]	p_button_status	Pointer to get data bitmap.
[out]	p_slider_position	Pointer to get data array.
[out]	p_wheel_position	Pointer to get data array.

◆ open

ssp_err_t(* sf_touch_ctsu_api_t::open) (sf_touch_ctsu_ctrl_t *const p_ctrl, sf_touch_ctsu_cfg_t const *const p_cfg)

Open driver.

Implemented as

- SF_TOUCH_CTSU_Open()

Parameters

[in]	p_ctrl	Pointer to control structure.
[in]	p_cfg	Pointer to pin configuration structure.

◆ scanStart

ssp_err_t(* sf_touch_ctsu_api_t::scanStart) (sf_touch_ctsu_ctrl_t *const p_ctrl)

Scan start.

Implemented as

- SF_TOUCH_CTSU_ScanStart()

Parameters

[in]	p_ctrl	Pointer to control structure.

◆ versionGet

ssp_err_t(* sf_touch_ctsu_api_t::versionGet) (ssp_version_t *const p_data)

Return the version of the driver.

Implemented as

- SF_TOUCH_CTSU_VersionGet()

Parameters

[in]	p_ctrl	Pointer to control structure.
[out]	p_data	Memory address to return version information to.

Detailed Description

Touch panel chip API structure. Touch panel chip implementations use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_touch_panel_chip_api_t::close) (sf_touch_panel_chip_ctrl_t *const p_ctrl)

Close the touch chip.

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. This control structure is initialized in this function.

◆ open

ssp_err_t(* sf_touch_panel_chip_api_t::open) (sf_touch_panel_chip_ctrl_t *const p_ctrl, sf_touch_panel_chip_cfg_t const *const p_cfg)

Initializes the touch chip.

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. This control structure is initialized in this function.
[in]	p_cfg	Pointer to configuration structure. All elements of the structure must be set by user.

◆ payloadGet

ssp_err_t(* sf_touch_panel_chip_api_t::payloadGet) (sf_touch_panel_chip_ctrl_t *const p_ctrl, sf_touch_panel_v2_payload_t *p_payload)

Reads the touch chip and fills in the touch payload data.

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. This control structure is initialized in this function.
[out]	p_payload	Pointer to the payload data structure. Touch data provided should be processed to logical pixel values.

◆ reset

ssp_err_t(* sf_touch_panel_chip_api_t::reset) (sf_touch_panel_chip_ctrl_t *const p_ctrl)

Resets the touch chip.

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. This control structure is initialized in this function.

◆ versionGet

ssp_err_t(* sf_touch_panel_chip_api_t::versionGet) (ssp_version_t *const p_version)

Gets the chip version and stores it in provided pointer p_version.

Parameters

[out]	p_version	Code and API version used are stored here.

The documentation for this struct was generated from the following file:

                                 SF_TOUCH_PANEL_V2_EVENT_UP,
                                SF_TOUCH_PANEL_V2_EVENT_NONE
                                }
```

Detailed Description

RTOS-integrated Touch Panel Framework Interface.

Summary

This module is a ThreadX-aware Touch Panel V2 Framework which scans for touch events and posts them to the user callback. This Interface is implemented by Touch Panel V2 Framework.

Related SSP architecture topics:

- SSP Interfaces
- SSP Predefined Layers
- Using SSP Modules

Touch Panel V2 Framework Interface description: Touch Panel V2 Framework

Typedef Documentation

◆ sf_touch_panel_v2_ctrl_t

typedef void sf_touch_panel_v2_ctrl_t

Touch panel framework control block. Allocate an instance specific control block to pass into the touch panel framework API calls.

Implemented as

- sf_touch_panel_v2_instance_ctrl_t

Enumeration Type Documentation

◆ sf_touch_panel_v2_event_t

enum sf_touch_panel_v2_event_t	
Touch event list.	
Enumerator	
SF_TOUCH_PANEL_V2_EVENT_INVALID	Invalid touch data.
SF_TOUCH_PANEL_V2_EVENT_HOLD	Touch has not moved since last touch event.
SF_TOUCH_PANEL_V2_EVENT_MOVE	Touch has moved since last touch event.
SF_TOUCH_PANEL_V2_EVENT_DOWN	New touch event reported.
SF_TOUCH_PANEL_V2_EVENT_UP	Touch released.
SF_TOUCH_PANEL_V2_EVENT_NONE	No valid touch event happened.

sf_touch_panel_v2_payload_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Touch Panel Framework Interface

#include <sf_touch_panel_v2_api.h>

Data Fields

int16_t	x X coordinate.
int16_t	y Y coordinate.
sf_touch_panel_v2_event_t	event_type Touch event type.

Detailed Description

Touch data payload

The documentation for this struct was generated from the following file:

- sf_touch_panel_v2_api.h

sf_touchpanel_v2_callback_args_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Touch Panel Framework Interface

#include <sf_touch_panel_v2_api.h>

Data Fields

sf_touch_panel_v2_payload_t	payload Touch data and event provided to the user during callback.
void const *	p_context Context provided to user during callback.

Detailed Description

User callback

The documentation for this struct was generated from the following file:

- sf_touch_panel_v2_api.h

sf_touch_panel_v2_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Touch Panel Framework Interface

#include <sf_touch_panel_v2_api.h>

Data Fields

uint16_t	hsize_pixels Horizontal size of screen in pixels.

uint16_t	vsize_pixels Vertical size of screen in pixels.
UINT	priority Priority of the touch panel thread.
uint16_t	update_hz
uint16_t	rotation_angle Touch coordinate rotation angle(0/90/180/270)
void const *	p_extend
void const *	p_context User defined context passed into callback function.

Detailed Description

Configuration for RTOS integrated touch panel framework.

Field Documentation

◆ p_extend

void const* sf_touch_panel_v2_cfg_t::p_extend
Pointer to hardware specific extension.

◆ update_hz

uint16_t sf_touch_panel_v2_cfg_t::update_hz
The frequency to report repeat (SF_TOUCH_PANEL_V2_EVENT_DOWN or SF_TOUCH_PANEL_V2_EVENT_HOLD) touch events in Hertz. ***Note*** *This will be converted to RTOS ticks in the driver and rounded up to the nearest integer value of RTOS ticks.*

The documentation for this struct was generated from the following file:

sf_touch_panel_v2_calibrate_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Touch Panel Framework Interface

#include <sf_touch_panel_v2_api.h>

Data Fields

int32_t	x Expected x coordinate.
int32_t	y Expected y coordinate.
void const *	p_extend

Detailed Description

Calibration data passed to SF_TOUCH_PANEL_V2_Calibrate.

Field Documentation

◆ p_extend

void const* sf_touch_panel_v2_calibrate_t::p_extend
Pointer to hardware specific extension.

The documentation for this struct was generated from the following file:

- sf_touch_panel_v2_api.h

sf_touch_panel_v2_calibrate_factors_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Touch Panel Framework Interface

#include <sf_touch_panel_v2_api.h>

Detailed Description

Calibration factors calculated in order to calibrate the touch data.

The documentation for this struct was generated from the following file:

- sf_touch_panel_v2_api.h

sf_touch_panel_v2_api_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Touch Panel Framework Interface

#include <sf_touch_panel_v2_api.h>

Data Fields

ssp_err_t(*	open)(sf_touch_panel_v2_ctrl_t *const p_ctrl, sf_touch_panel_v2_cfg_t const *const p_cfg) Create required RTOS objects, call lower level module for hardware specific initialization, and create a thread to post touch data to user application. More...

ssp_err_t(*	touchDataGet)(sf_touch_panel_v2_ctrl_t *const p_ctrl, sf_touch_panel_v2_payload_t *p_payload, ULONG const timeout) Reads the touch data and fills in the touch payload data. More...
ssp_err_t(*	stop)(sf_touch_panel_v2_ctrl_t *const p_ctrl) Stop scanning for touch events. More...

ssp_err_t(*	reset)(sf_touch_panel_v2_ctrl_t *const p_ctrl) Reset touch chip if reset pin is provided. More...
ssp_err_t(*	close)(sf_touch_panel_v2_ctrl_t *const p_ctrl) Terminate touch thread and close channel at HAL layer. More...
ssp_err_t(*	versionGet)(ssp_version_t *const p_version) Gets version and stores it in provided pointer p_version. More...

Detailed Description

Touch panel V2 API structure. Touch panel V2 implementations use the following API.

Field Documentation

◆ calibrate

ssp_err_t(* sf_touch_panel_v2_api_t::calibrate) (sf_touch_panel_v2_ctrl_t *const p_ctrl, sf_touch_panel_v2_calibrate_t const *const p_display, sf_touch_panel_v2_calibrate_t const *const p_touchscreen, ULONG const timeout)

Begin calibration routine based on provided expected and actual coordinates.

Implemented as

- SF_TOUCH_PANEL_V2_Calibrate()

Parameters

[in]	p_ctrl	Handle set in sf_touch_panel_v2_api_t::open.
[in]	p_display	Expected coordinates of the display.
[in]	p_touchscreen	Actual coordinates obtained from the touch driver.
[in]	timeout	ThreadX timeout. Select TX_NO_WAIT, a value in system clock counts between 1 and 0xFFFFFFFF, or TX_WAIT_FOREVER.

◆ close

ssp_err_t(* sf_touch_panel_v2_api_t::close) (sf_touch_panel_v2_ctrl_t *const p_ctrl)

Terminate touch thread and close channel at HAL layer.

Implemented as

- SF_TOUCH_PANEL_V2_Close()

Parameters

[in]	p_ctrl	Handle set in sf_touch_panel_v2_api_t::open.

◆ open

ssp_err_t(* sf_touch_panel_v2_api_t::open) (sf_touch_panel_v2_ctrl_t *const p_ctrl, sf_touch_panel_v2_cfg_t const *const p_cfg)

Create required RTOS objects, call lower level module for hardware specific initialization, and create a thread to post touch data to user application.

Implemented as

- SF_TOUCH_PANEL_V2_Open()

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. This control structure is initialized in this function.
[in]	p_cfg	Pointer to configuration structure. All elements of the structure must be set by user.

◆ reset

ssp_err_t(* sf_touch_panel_v2_api_t::reset) (sf_touch_panel_v2_ctrl_t *const p_ctrl)

Reset touch chip if reset pin is provided.

Implemented as

- SF_TOUCH_PANEL_V2_Reset()

Note

This does not include calibration. Use sf_touch_panel_v2_api_t::calibrate from the application after this function if calibration is required after reset.

Parameters

[in]	p_ctrl	Handle set in sf_touch_panel_v2_api_t::open.

◆ start

ssp_err_t(* sf_touch_panel_v2_api_t::start) (sf_touch_panel_v2_ctrl_t *const p_ctrl)

Start scanning for touch events.

Implemented as

- SF_TOUCH_PANEL_V2_Start()

Parameters

[in]	p_ctrl	Handle set in sf_touch_panel_v2_api_t::open.

◆ stop

ssp_err_t(* sf_touch_panel_v2_api_t::stop) (sf_touch_panel_v2_ctrl_t *const p_ctrl)

Stop scanning for touch events.

Implemented as

- SF_TOUCH_PANEL_V2_Stop()

Parameters

[in]	p_ctrl	Handle set in sf_touch_panel_v2_api_t::open.

◆ touchDataGet

ssp_err_t(* sf_touch_panel_v2_api_t::touchDataGet) (sf_touch_panel_v2_ctrl_t *const p_ctrl, sf_touch_panel_v2_payload_t *p_payload, ULONG const timeout)

Reads the touch data and fills in the touch payload data.

Implemented as

- SF_TOUCH_PANEL_V2_TouchDataGet()

Parameters

[in,out]	p_ctrl	Pointer to a structure allocated by user. This control structure is initialized in this function.
[out]	p_payload	Pointer to the payload to data structure. Touch data provided should be processed to logical pixel values.
[in]	timeout	ThreadX timeout. Select TX_NO_WAIT, a value in system clock counts between 1 and 0xFFFFFFFF, or TX_WAIT_FOREVER.

◆ versionGet

ssp_err_t(* sf_touch_panel_v2_api_t::versionGet) (ssp_version_t *const p_version)

Gets version and stores it in provided pointer p_version.

Implemented as

- SF_TOUCH_PANEL_V2_VersionGet()

Parameters

[out]	p_version	Code and API version used stored here.

The documentation for this struct was generated from the following file:

- sf_touch_panel_v2_api.h

sf_touch_panel_v2_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » Touch Panel Framework Interface

#include <sf_touch_panel_v2_api.h>

Data Fields

sf_touch_panel_v2_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_touch_panel_v2_cfg_t const *	p_cfg Pointer to the configuration structure for this instance.
sf_touch_panel_v2_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

The documentation for this struct was generated from the following file:

- sf_touch_panel_v2_api.h

Detailed Description

RTOS-integrated SF WIFI Framework Interface.

Summary

This SSP Interface provides access to the ThreadX-aware SF WIFI Framework.

Macro Definition Documentation

◆ SF_WIFI_API_VERSION_MAJOR

#define SF_WIFI_API_VERSION_MAJOR (2U)
Major Version of the API defined in this file

◆ SF_WIFI_API_VERSION_MINOR

#define SF_WIFI_API_VERSION_MINOR (0U)
Minor Version of the API defined in this file

◆ SF_WIFI_IPV4_ADDRESS

```
#define SF_WIFI_IPV4_ADDRESS ( a, b, c, d  )
((((uint32_t) a) << (24U)) | (((uint32_t) b) << (16U)) | \
                                        (((uint32_t) c) << (8U)) | ((uint32_t) d))
```

IP Address Generation Macro

Enumeration Type Documentation

◆ sf_wifi_access_control_t

enum sf_wifi_access_control_t

WiFi Framework AccessContol mode

Enumerator	
SF_WIFI_ACCESS_CONTROL_DISABLE	Disable MAC address matching.
SF_WIFI_ACCESS_CONTROL_DENY	Deny association to stations on the MAC list.
SF_WIFI_ACCESS_CONTROL_ALLOW	Allow association to stations on the MAC list.

◆ sf_wifi_auto_negotiation_t

enum sf_wifi_auto_negotiation_t

WiFi Auto Negotiation flag

Enumerator	
SF_WIFI_AUTO_NEGOTIATION_DISABLE	Auto negotiation disable.
SF_WIFI_AUTO_NEGOTIATION_ENABLE	Auto negotiation enable.

◆ sf_wifi_bss_type_t

enum sf_wifi_bss_type_t	
WiFi BSS type	
Enumerator	
SF_WIFI_BSS_TYPE_INFRASTRUCTURE	Infrastructure network.
SF_WIFI_BSS_TYPE_ADHOC	802.11 ad-hoc IBSS network
SF_WIFI_BSS_TYPE_ANY	Either infrastructure or ad-hoc network.
SF_WIFI_BSS_TYPE_UNKNOWN	BSS type is unknown.

◆ sf_wifi_encryption_type_t

enum sf_wifi_encryption_type_t	
WiFi Encryption type	
Enumerator	
SF_WIFI_ENCRYPTION_TYPE_AUTO	Automatic selection of encryption protocol.
SF_WIFI_ENCRYPTION_TYPE_TKIP	Temporal Key Integrity Protocol. Used by WPA.
SF_WIFI_ENCRYPTION_TYPE_CCMP	CTR mode with CBC-MAC Protocol. Used by WPA2.
SF_WIFI_ENCRYPTION_TYPE_WEP	WEP mode. Used by WEP.
SF_WIFI_ENCRYPTION_TYPE_NONE	No Encryption. Used by Open Security type.

◆ sf_wifi_event_t

enum sf_wifi_event_t	
WiFi Framework event codes	
Enumerator	
SF_WIFI_EVENT_RX	Packet received event.
SF_WIFI_EVENT_AP_CONNECT	Device Associated Successfully with AP.
SF_WIFI_EVENT_AP_DISCONNECT	Device Disconnected with AP.
SF_WIFI_EVENT_CLIENT_CONNECT	Client Associated Successfully with device AP.
SF_WIFI_EVENT_CLIENT_DISCONNECT	Client Disconnected from device AP.

◆ sf_wifi_high_throughput_t

enum sf_wifi_high_throughput_t	
WiFi High Throughput flag	
Enumerator	
SF_WIFI_HIGH_THROUGHPUT_DISABLE	Disable high throughput mode.
SF_WIFI_HIGH_THROUGHPUT_ENABLE	Enable high throughput mode. Also requires WMM to be enabled.

◆ sf_wifi_interface_hw_mode_t

enum sf_wifi_interface_hw_mode_t	
WiFi Hardware mode	
Enumerator	
SF_WIFI_INTERFACE_HW_MODE_11A	802.11a
SF_WIFI_INTERFACE_HW_MODE_11B	802.11b
SF_WIFI_INTERFACE_HW_MODE_11G	802.11g
SF_WIFI_INTERFACE_HW_MODE_11N	802.11n

◆ sf_wifi_interface_mode_t

enum sf_wifi_interface_mode_t	
WiFi Interface mode	
Enumerator	
SF_WIFI_INTERFACE_MODE_AP	Access Point mode.
SF_WIFI_INTERFACE_MODE_CLIENT	Station Mode.

◆ sf_wifi_ip_addr_version_t

enum sf_wifi_ip_addr_version_t	
IP address version	
Enumerator	
SF_WIFI_IP_ADDR_VERSION_4	IPv4 address.
SF_WIFI_IP_ADDR_VERSION_6	IPv6 address.

◆ sf_wifi_mandatory_high_throughput_t

enum sf_wifi_mandatory_high_throughput_t	
WiFi Mandatory High Throughput flag	
Enumerator	
SF_WIFI_MANDATORY_HIGH_THROUGHPUT_DISABLE	Disable Mandatory HT requirement.
SF_WIFI_MANDATORY_HIGH_THROUGHPUT_ENABLE	Enable mandatory HT requirement.

◆ sf_wifi_preamble_t

enum sf_wifi_preamble_t	
WiFi Preamble type	
Enumerator	
SF_WIFI_PREAMBLE_SHORT	Use short preamble.
SF_WIFI_PREAMBLE_LONG	Use long preamble.

◆ sf_wifi_rts_t

enum sf_wifi_rts_t	
WiFi RTS flag	
Enumerator	
SF_WIFI_RTS_DISABLE	Disable RTS/CTS handshake.
SF_WIFI_RTS_ENABLE	Enable RTS/CTS handshake.

◆ sf_wifi_security_type_t

enum sf_wifi_security_type_t	
WiFi Security type	
Enumerator	
SF_WIFI_SECURITY_TYPE_OPEN	Open. No encryption used.
SF_WIFI_SECURITY_TYPE_WEP	128-bit WEP OPEN ASCII
SF_WIFI_SECURITY_TYPE_WPA	WiFi Protected Access.
SF_WIFI_SECURITY_TYPE_WPA2	WiFi Protected Access v2.

◆ sf_wifi_ssid_broadcast_t

enum sf_wifi_ssid_broadcast_t	
WiFi SSID Broadcast flag	
Enumerator	
SF_WIFI_SSID_BROADCAST_DISABLE	Disable SSID Broadcast.
SF_WIFI_SSID_BROADCAST_ENABLE	Enable SSID Broadcast.

◆ sf_wifi_wds_t

enum sf_wifi_wds_t	
WiFi WDS Flasg	
Enumerator	
SF_WIFI_WDS_DISABLE	Disable WDS.
SF_WIFI_WDS_ENABLE	Enable WDS.

◆ sf_wifi_wep_key_format_t

enum sf_wifi_wep_key_format_t	
WiFi WEP Key Format	
Enumerator	
SF_WIFI_WEP_KEY_FORMAT_ASCII	WEP Key in ASCII.
SF_WIFI_WEP_KEY_FORMAT_HEX	WEP Key in Hex.

◆ sf_wifi_wmm_t

enum sf_wifi_wmm_t	
WiFi WMM flag	
Enumerator	
SF_WIFI_WMM_DISABLE	Disable WMM.
SF_WIFI_WMM_ENABLE	Enable WMM.

◆ sf_wifi_wps_mode_t

enum sf_wifi_wps_mode_t	
WiFi WPS mode	
Enumerator	
SF_WIFI_WPS_MODE_PUSHBUTTON	WPS Push button method.
SF_WIFI_WPS_MODE_PIN	WPS pin method.

sf_wifi_ip_addr_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI Framework Interface

#include <sf_wifi_api.h>

Data Fields

sf_wifi_ip_addr_version_t	version IP Address Version : v4 or v6.
union {	
}	addr IP address.

Detailed Description

IP address information

The documentation for this struct was generated from the following file:

- sf_wifi_api.h

sf_wifi_info_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI Framework Interface

#include <sf_wifi_api.h>

Data Fields

uint8_t *	p_chipset Pointer to sting showing WiFi chipset/driver information.
uint16_t	rssi Received signal strength indication.

uint16_t	noise_level Signal to noise ratio.
uint16_t	link_quality Signal strength / quality.

Detailed Description

Configuration about underlying device driver.

The documentation for this struct was generated from the following file:

- sf_wifi_api.h

sf_wifi_callback_args_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI Framework Interface

#include <sf_wifi_api.h>

Data Fields

sf_wifi_event_t	event Event code.
uint8_t *	p_data Packet data.
uint32_t	length Packet Data length.
uint8_t	mac_addr [SF_WIFI_MAC_ADDR_LENGTH] Client station MAC address.
void const *	p_context

	Context provided to user during callback.

Detailed Description

WiFi framework callback parameter definition

The documentation for this struct was generated from the following file:

- sf_wifi_api.h

sf_wifi_provisioning_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI Framework Interface

#include <sf_wifi_api.h>

Data Fields

sf_wifi_interface_mode_t	mode Select AP or Client mode.
uint8_t	channel RF Channel number.
uint8_t	ssid [SF_WIFI_SSID_LENGTH+1] SSID.
sf_wifi_security_type_t	security Security type.
sf_wifi_encryption_type_t	encryption Encryption type.
uint8_t	key [SF_WIFI_SECURITY_KEY_LENGTH] Pre-shared key.

void(*	p_callback)(sf_wifi_callback_args_t *p_args) Pointer to Connection status notification callback function.

Detailed Description

WiFi Provisioning parameters

The documentation for this struct was generated from the following file:

- sf_wifi_api.h

sf_wifi_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI Framework Interface

#include <sf_wifi_api.h>

Data Fields

uint8_t	mac_addr [6] MAC address of WiFi Device.
sf_wifi_interface_hw_mode_t	hw_mode Modulation type: 11a/b/g/n.
uint8_t	tx_power Sets transmit power in dBm.
sf_wifi_rts_t	rts RTS/CTS handshake flag.
uint16_t	fragmentation Fragmentation threshold.

uint8_t	dtim Delivery traffic indication message interval.
sf_wifi_high_throughput_t	high_throughput High-throughput mode. Only valid for 802.11n.
sf_wifi_preamble_t	preamble Preamble type.
sf_wifi_wmm_t	wmm WiFi Multimedia Mode flag. If enabled, also requires.
uint8_t	max_stations Maximum permitted stations. Valid in AP mode only.
sf_wifi_ssid_broadcast_t	ssid_broadcast SSID broadcast flag. Valid in AP mode only.
sf_wifi_access_control_t	access_control Mode of access control MAC list.
uint32_t	beacon Beacon interval. Valid in AP mode only.
uint32_t	station_inactivity_timeout Station inactivity timeout value. Valid in AP mode only.
sf_wifi_wds_t	wds WDS flag. Valid in AP mode only.
void *	p_buffer_pool_rx Pointer to Network stack Rx buffer pool.
sf_wifi_mandatory_high_thro	req_high_throughput

ughput_t	Only allow HT mode. Valid in AP mode only.
void(*	p_callback)(sf_wifi_callback_args_t *p_args) Pointer to callback function.
void const *	p_context User defined context passed into callback function.
void const *	p_extend Instance specific configuration.

Detailed Description

Define the WiFi configuration parameters

The documentation for this struct was generated from the following file:

- sf_wifi_api.h

sf_wifi_stats_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI Framework Interface

#include <sf_wifi_api.h>

Data Fields

uint32_t	rx_pkts Packets received successfully.
uint32_t	tx_pkts Packets transmitted successfully.
uint32_t	tx_err

	Transmit errors.

Detailed Description

Define the statistic and error counters for this IP instance.

The documentation for this struct was generated from the following file:

- sf_wifi_api.h

sf_wifi_scan_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI Framework Interface

#include <sf_wifi_api.h>

Data Fields

sf_wifi_interface_hw_mode_t	hw_mode Hardware mode 802.11a/b/g/n.
uint8_t	rssi Signal Strength.
uint8_t	ssid [SF_WIFI_SSID_LENGTH+1] SSID name.
uint8_t	bssid [SF_WIFI_MAC_ADDR_LENGTH] Basic Service Set Identification (i.e. MAC address of Access Point)
uint8_t	channel Radio channel that the AP beacon was received on.
sf_wifi_security_type_t	security Security type.

sf_wifi_encryption_type_t	encryption Encryption type.
sf_wifi_bss_type_t	bss_type Network type.

Detailed Description

Define the structure to store the SSID scan information

The documentation for this struct was generated from the following file:

- sf_wifi_api.h

sf_wifi_wps_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI Framework Interface

#include <sf_wifi_api.h>

Data Fields

sf_wifi_wps_mode_t	wps_mode WPS method Push-button or Pin.
uint8_t	wps_key [SF_WIFI_WPS_PIN_LENGTH+SF_WIFI_SIZE_FOR_NULL_BYTE]
uint8_t	timeout_seconds WPS timeout value in seconds.
void(*	p_callback)(sf_wifi_callback_args_t *p_args)

Detailed Description

Define the structure for WiFi WPS Control

Field Documentation

◆ p_callback

void(* sf_wifi_wps_t::p_callback) (sf_wifi_callback_args_t *p_args)
Pointer to callback function to be called on changed in client's connection status with AP or client connected/disconnected

◆ wps_key

uint8_t sf_wifi_wps_t::wps_key[SF_WIFI_WPS_PIN_LENGTH+SF_WIFI_SIZE_FOR_NULL_BYTE]
WPS pin. Used only with WPS pin method, PIN should be NULL terminated

Detailed Description

Framework API structure. Implementations will use the following API.

Field Documentation

◆ ACLAdd

ssp_err_t(* sf_wifi_api_t::ACLAdd) (sf_wifi_ctrl_t *const p_ctrl, uint8_t const *const p_mac)

Adds a MAC address to the Access Control List. Valid in AP mode only.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[in]	p_mac	Pointer to MAC address

◆ ACLDelete

ssp_err_t(* sf_wifi_api_t::ACLDelete) (sf_wifi_ctrl_t *const p_ctrl, uint8_t const *const p_mac)

Deletes a MAC address from Access Control List. Valid in AP mode only.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[in]	p_mac	Pointer to MAC address

◆ close

ssp_err_t(* sf_wifi_api_t::close) (sf_wifi_ctrl_t *const p_ctrl)

De-initialize the network interface and may put it in low power mode or power it off. Close the driver, disable the driver link, disable interrupt.

Parameters

[in,out]	p_ctrl	Pointer to the control block for the WiFi module.

◆ infoGet

ssp_err_t(* sf_wifi_api_t::infoGet) (sf_wifi_ctrl_t *const p_ctrl, sf_wifi_info_t *const p_wifi_info)

Get WiFi module information.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[out]	p_wifi_info	Pointer to WiFi module information structure

◆ macAddressGet

ssp_err_t(* sf_wifi_api_t::macAddressGet) (sf_wifi_ctrl_t *const p_ctrl, uint8_t *const p_mac)

Get WiFi module MAC address.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[out]	p_mac	Pointer to MAC address

◆ macAddressSet

ssp_err_t(* sf_wifi_api_t::macAddressSet) (sf_wifi_ctrl_t *const p_ctrl, uint8_t const *const p_mac)

Set WiFi module MAC address.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[in]	p_mac	Pointer to MAC address

◆ multicastListAdd

ssp_err_t(* sf_wifi_api_t::multicastListAdd) (sf_wifi_ctrl_t *const p_ctrl, uint8_t const *const p_mac_addr)

Add the given MAC address to the multicast filter list.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[in]	p_mac_addr	Pointer to the Mac address.

◆ multicastListDelete

ssp_err_t(* sf_wifi_api_t::multicastListDelete) (sf_wifi_ctrl_t *const p_ctrl, uint8_t const *const p_mac_addr)

Delete the given MAC address from the multicast filter list.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[in]	p_mac_addr	Pointer to the Mac address.

◆ open

ssp_err_t(* sf_wifi_api_t::open) (sf_wifi_ctrl_t *p_ctrl, sf_wifi_cfg_t const *const p_cfg)

Initializes the network interface for data transfers.

Initial driver configuration, enable the driver link, enable interrupts and make device ready for data transfer.

Parameters

[in,out]	p_ctrl	Pointer to user-provided storage for the control block.
[in]	p_cfg	Pointer to WiFi configuration structure.

◆ provisioningGet

ssp_err_t(* sf_wifi_api_t::provisioningGet) (sf_wifi_ctrl_t *const p_ctrl, sf_wifi_provisioning_t *const p_wifi_provisioning)

Get the provisioning information of WiFi module.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[out]	p_wifi_provisioning	Pointer to WiFi provisioning structure

◆ provisioningSet

ssp_err_t(* sf_wifi_api_t::provisioningSet) (sf_wifi_ctrl_t *const p_ctrl, sf_wifi_provisioning_t const *const p_wifi_provisioning)

Set WiFi module provisioning which will configure the module in AP or Client mode.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[in]	p_wifi_provisioning	Pointer to WiFi provisioning structure

◆ scan

ssp_err_t(* sf_wifi_api_t::scan) (sf_wifi_ctrl_t *const p_ctrl, sf_wifi_scan_t *const p_scan, uint8_t *const p_cnt)

Scan for WiFi SSIDs.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[out]	p_scan	Pointer to structure which will hold scan result. It is the responsibility of the caller to ensure that adequate space is available to hold scan results.
[in,out]	p_cnt	Pointer to variable, specifying maximum number of SSID's to scan and will be updated to number of actual SSIDs scanned by device

◆ statisticsGet

ssp_err_t(* sf_wifi_api_t::statisticsGet) (sf_wifi_ctrl_t *const p_ctrl, sf_wifi_stats_t *const p_wifi_device_stats)

Get the interface statistics.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[out]	p_wifi_device_stats	Pointer to the WiFi module data statistics.

◆ transmit

ssp_err_t(* sf_wifi_api_t::transmit) (sf_wifi_ctrl_t *const p_ctrl, uint8_t *const p_buf, uint32_t length)

Transmit data packet.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[in]	p_buf	Pointer to transmit buffer
[in]	length	Transmit buffer length

◆ versionGet

ssp_err_t(* sf_wifi_api_t::versionGet) (ssp_version_t *const p_version)

Gets version and stores it in provided pointer p_version.

Parameters

[out]	p_version	pointer to memory location to return version number

◆ wpsStart

ssp_err_t(* sf_wifi_api_t::wpsStart) (sf_wifi_ctrl_t *const p_ctrl, sf_wifi_wps_t const *const p_wps)

Start WiFi WPS.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[in]	p_wps	Pointer to WiFi WPS configuration

The documentation for this struct was generated from the following file:

- sf_wifi_api.h

sf_wifi_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI Framework Interface

#include <sf_wifi_api.h>

Data Fields

sf_wifi_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_wifi_cfg_t const *	p_cfg Pointer to the configuration structure for this instance.
sf_wifi_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

The documentation for this struct was generated from the following file:

- sf_wifi_api.h

5.1.2.49 SF WIFI NSAL Interface

Renesas Synergy Software Package Reference » Framework Interfaces

RTOS-integrated SF WIFI NSAL Framework Interface. More...

Data Structures

struct	sf_wifi_nsal_cfg_t
struct	sf_wifi_nsal_callback_args_t

Enumerations

enum	sf_wifi_nsal_zero_copy_t { SF_WIFI_NSAL_ZERO_COPY_DISABLE, SF_WIFI_NSAL_ZERO_COPY_ENABLE }

Detailed Description

RTOS-integrated SF WIFI NSAL Framework Interface.

Summary

This SSP Interface provides access to the ThreadX-aware SF WIFI NSAL Framework.

Enumeration Type Documentation

◆ sf_wifi_nsal_zero_copy_t

enum sf_wifi_nsal_zero_copy_t	
Zero Copy Configuration Enumeration	
Enumerator	
SF_WIFI_NSAL_ZERO_COPY_DISABLE	Zero copy is disabled.
SF_WIFI_NSAL_ZERO_COPY_ENABLE	Zero copy is enabled.

sf_wifi_nsal_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI NSAL Interface

#include <sf_wifi_nsal_api.h>

Data Fields

sf_wifi_nsal_zero_copy_t	tx_zero_copy Transmit path zero copy support.
sf_wifi_nsal_zero_copy_t	rx_zero_copy Receive path zero copy support.
uint8_t *	p_tx_packet_buffer Pointer to Tx buffer used to consolidate data from chained NetX packets.

Detailed Description

Define the NSAL configuration parameters

The documentation for this struct was generated from the following file:

- sf_wifi_nsal_api.h

sf_wifi_nsal_callback_args_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI NSAL Interface

#include <sf_wifi_nsal_api.h>

Data Fields

NX_INTERFACE *	p_interface Pointer to NetX interface.
NX_IP *	p_ip Pointer to NetX IP.
sf_wifi_nsal_cfg_t *	p_wifi_nsal_cfg pointer to NSAL configuration

Detailed Description

Define the NSAL callback arguments

The documentation for this struct was generated from the following file:

- sf_wifi_nsal_api.h

5.1.2.50 SF WIFI On-Chip Stack Interface

Renesas Synergy Software Package Reference » Framework Interfaces

RTOS-integrated SF WIFI On-Chip Stack Interface. More...

Data Structures

struct	sf_wifi_onchip_stack_ip_cfg_t
struct	sf_wifi_onchip_stack_cfg_t
struct	sf_wifi_onchip_stack_ctrl_t
struct	sf_wifi_onchip_stack_api_t

ssp_err_t(*	versionGet)(ssp_version_t *const p_version) Gets version and stores it in provided pointer p_version. More...

Detailed Description

Framework API structure. Implementations will use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_wifi_onchip_stack_api_t::close) (sf_wifi_onchip_stack_ctrl_t *const p_ctrl)

Pointer to function which un-initialize the network interface and may put it in low power mode or power it off. Close the driver, disable the driver link, disable interrupt.

Parameters

[in,out]	p_ctrl	Pointer to the control block

◆ dhcpServerStart

ssp_err_t(* sf_wifi_onchip_stack_api_t::dhcpServerStart) (sf_wifi_onchip_stack_ctrl_t *const p_ctrl, sf_wifi_ip_addr_t const *const p_start_ip, sf_wifi_ip_addr_t const *const p_end_ip)

Starts DHCP server on the interface.

Parameters

[in]	p_ctrl	Pointer to the control block
[in]	p_start_ip	Pointer to start IP address
[in]	p_end_ip	Pointer to end IP address

◆ dhcpServerStop

ssp_err_t(* sf_wifi_onchip_stack_api_t::dhcpServerStop) (sf_wifi_onchip_stack_ctrl_t *const p_ctrl)

Stop DHCP server on the interface.

Parameters

[in]	p_ctrl	Pointer to the control block

◆ ipAddressCfg

ssp_err_t(* sf_wifi_onchip_stack_api_t::ipAddressCfg) (sf_wifi_onchip_stack_ctrl_t *const p_ctrl, sf_wifi_onchip_stack_ip_cfg_t *const p_cfg)

Configures IP address of the interface.

Parameters

[in]	p_ctrl	Pointer to the control block
[in,out]	p_cfg	Pointer to IP configuration structure.

◆ open

ssp_err_t(* sf_wifi_onchip_stack_api_t::open) (sf_wifi_onchip_stack_ctrl_t *p_ctrl, sf_wifi_onchip_stack_cfg_t const *const p_cfg)

Pointer to function which initializes the network interface for data transfers.

Initial driver configuration, enable the driver link, enable interrupts and make device ready for data transfer.

Parameters

[in,out]	p_ctrl	Pointer to user-provided storage for the control block.
[in]	p_cfg	Pointer to configuration structure.

◆ versionGet

ssp_err_t(* sf_wifi_onchip_stack_api_t::versionGet) (ssp_version_t *const p_version)		
Gets version and stores it in provided pointer p_version. **Parameters**		
[out]	p_version	pointer to memory location to return version number

SF_WIFI_QCA4010_AT_CMD_INDEX_AT_SET_HARDWARE_MODE	Index for Command ATWPHYMODE.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_RESULT_CODE_FROMAT	Index for Command ATV.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_UART_TRANSMISSION_FLOW_CONTROL_QUERY	Index for Command ATS108?
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_UART_TRANSMISSION_FLOW_CONTROL	Index for Command ATS108=1.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_ESCAPE_GUARD_TIME	Index for Command ATS12=1.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_BUFFER_SIZE	Index for Command Set buffer size for socket receive (ATBSIZE)
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_DISCONNECT_AP	Index for Command disconnect from currently connected Access Point.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_BUFFER_TIMEOUT	Index for Command to the system wait to send UART-received data to network.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_SCAN_SSID	Index for Command to the scan available ssid.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_INITIATE_AP_MODE	Index for Command to initiate AP mode.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_CONNECT_OPEN_AP	Index for Command to the connect open AP.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_CONNECT_WPA_AP	Index for Command to the connect to WPA-

	configured Access Point.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_ASSIGN_AP_CHANNEL	Index for Command to assign channel to AP.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_INITIATE_OPEN_AP	Index for Command to initiate Open AP.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_INITIATE_WPA_AP	Index for Command to initiate WPA/WPA2 AP.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_ASSIGN_WEP_KEY	Index for Command to assign WEP key.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_INITIATE_WEP_AP	Index for Command to initiate WEP AP.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_CONNECT_WEP_AP	Index for Command to connect to WEP AP.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_WIFI_STATUS	Index for Command to the get wifi status.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_DISCONNECT_ACCESS_POINT	Index for Command to disconnect current access point.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_INIT_SECOND_UART	Index for Command to init second uart.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_CHANGE_UART_ASSIGNMENT	Change UART assignments for command and data.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_CHANGE_UART_ASSIGNMENT_IN_CLOSE	Change UART assignments for command and data in close if num_uart = 2.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_SWITCH_BACK_TO_DATA_MODE	Index for Command to switch to data mode.
SF_WIFI_QCA4010_AT_CMD_INDEX_AT_EXIT_DATA_MODE	Index for Command to switch to command mode.

◆ sf_wifi_qca4010_encryption_type_t

enum sf_wifi_qca4010_encryption_type_t	
WiFi Encryption type	
Enumerator	
SF_WIFI_QCA4010_ENCRYPTION_TYPE_TKIP	Temporal Key Integrity Protocol.
SF_WIFI_QCA4010_ENCRYPTION_TYPE_CCMP	CTR mode with CBC-MAC Protocol.

◆ sf_wifi_qca4010_interface_hw_mode_t

enum sf_wifi_qca4010_interface_hw_mode_t	
WiFi Hardware mode	
Enumerator	
SF_WIFI_QCA4010_INTERFACE_HW_MODE_11B	802.11b
SF_WIFI_QCA4010_INTERFACE_HW_MODE_11G	802.11g
SF_WIFI_QCA4010_INTERFACE_HW_MODE_11N	802.11n

◆ sf_wifi_qca4010_interface_mode_t

enum sf_wifi_qca4010_interface_mode_t	
WiFi Interface mode	
Enumerator	
SF_WIFI_QCA4010_INTERFACE_MODE_AP	Access Point mode.
SF_WIFI_QCA4010_INTERFACE_MODE_CLIENT	Station Mode.

◆ sf_wifi_qca4010_reset_type_t

enum sf_wifi_qca4010_reset_type_t	
Wifi Module reset type	
Enumerator	
SF_WIFI_QCA4010_RESET_TYPE_SOFT	Soft reset module using AT command.
SF_WIFI_QCA4010_RESET_TYPE_HARD	Hard reset module by toggling Reset Pin.

◆ sf_wifi_qca4010_security_type_t

enum sf_wifi_qca4010_security_type_t	
WiFi Security type	
Enumerator	
SF_WIFI_QCA4010_SECURITY_TYPE_OPEN	Open. No encryption used.
SF_WIFI_QCA4010_SECURITY_TYPE_WEP	10 or 26 digit hexadecimal string
SF_WIFI_QCA4010_SECURITY_TYPE_WPA	WiFi Protected Access.
SF_WIFI_QCA4010_SECURITY_TYPE_WPA2	WiFi Protected Access v2.

sf_wifi_qca4010_status_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI QCA4010 Framework Interface

#include <sf_wifi_qca4010_api.h>

Data Fields

uint8_t	ssid [SF_WIFI_QCA4010_SSID_LENGTH] SSID.
uint8_t	phy_mode [PHY_MODE_LEN] Phy mode.
uint8_t	mac_addr [MAC_ADDRESS_LEN] Mac addr.
uint8_t	mode [ACCESS_MODE_LEN] Mode.
uint8_t	channel [MAX_CHANNEL_LENGTH] Channel.

Detailed Description

Network Status information

The documentation for this struct was generated from the following file:

- sf_wifi_qca4010_api.h

sf_wifi_qca4010_at_cmd_set_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI QCA4010 Framework Interface

#include <sf_wifi_qca4010_api.h>

Data Fields

uint8_t *	p_cmd AT Command.
uint8_t *	p_success_resp Success response string.
uint16_t	max_resp_length Maximum length of expected response.
uint32_t	resp_wait_time AT command response wait time in milliseconds.
uint16_t	retry_delay Delay between AT command retry.

Detailed Description

Structure defining AT commands parameters

The documentation for this struct was generated from the following file:

- sf_wifi_qca4010_api.h

sf_wifi_qca4010_cmd_resp_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI QCA4010 Framework Interface

#include <sf_wifi_qca4010_api.h>

Data Fields

uint8_t *	p_buff
uint32_t	buff_len

Detailed Description

Modem Command/Response structure used to send Custom AT command and to receive response for the same

Field Documentation

◆ buff_len

uint32_t sf_wifi_qca4010_cmd_resp_t::buff_len

AT command/Response buffer length. In case of Response this is both in and out parameter. Input is the length of buffer pointed by p_buff and output is number of bytes of response copied by framework. In case of command it is length of command in p_buff

◆ p_buff

uint8_t* sf_wifi_qca4010_cmd_resp_t::p_buff

AT command/Response buffer. In case of AT command it is input buffer in which user should pass custom command to be sent. In case of Response it is output buffer in which framework will fill the response

The documentation for this struct was generated from the following file:

- sf_wifi_qca4010_api.h

sf_wifi_qca4010_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI QCA4010 Framework Interface

#include <sf_wifi_qca4010_api.h>

Data Fields

sf_wifi_qca4010_interface_hw_mode_t	hw_mode Modulation type: 11b/g/n.
const uart_instance_t *	p_uart_instances [SF_WIFI_QCA4010_CFG_MAX_NUMBER_UART_PORTS] SCI UART instances.
const uint32_t	num_uarts Number of UART interfaces to use.
void const *	p_context User defined context passed into callback function.
void const *	p_extend Instance specific configuration.
sf_wifi_qca4010_at_cmd_set_t const *	p_cmd_set Instance specific command set.

Detailed Description

Define the WiFi configuration parameters

The documentation for this struct was generated from the following file:

- sf_wifi_qca4010_api.h

sf_wifi_qca4010_provisioning_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI QCA4010 Framework Interface

#include <sf_wifi_qca4010_api.h>

Data Fields

sf_wifi_qca4010_interface_mode_t	mode Select AP or Client mode.
uint8_t	channel RF Channel number.
uint8_t	ssid [SF_WIFI_QCA4010_SSID_LENGTH+1] SSID.
sf_wifi_qca4010_security_type_t	security Security type.
sf_wifi_qca4010_encryption_type_t	encryption Encryption type.
uint8_t	key [SF_WIFI_QCA4010_SECURITY_KEY_LENGTH] Pre-shared key.
uint8_t	index WEP Key index, value ranges between 1 to 4.

Detailed Description

WiFi Provisioning parameters

The documentation for this struct was generated from the following file:

- sf_wifi_qca4010_api.h

sf_wifi_qca4010_scan_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI QCA4010 Framework Interface

#include <sf_wifi_qca4010_api.h>

Data Fields

uint8_t	ssid [SF_WIFI_QCA4010_SSID_LENGTH] SSID name.
uint8_t	bssid [MAC_ADDRESS_LEN] Basic Service Set Identification (i.e. MAC address of Access Point)
uint8_t	channel [MAX_CHANNEL_LENGTH] Radio channel that the AP beacon was received on.
uint8_t	security Security type.

Detailed Description

Define the structure to store the SSID scan information

The documentation for this struct was generated from the following file:

- sf_wifi_qca4010_api.h

sf_wifi_qca4010_uart_extend_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI QCA4010 Framework Interface

#include <sf_wifi_qca4010_api.h>

Data Fields

uart_instance_t const *	p_r_uart_instance Lower level HAL driver instance.

Detailed Description

UART configuration

The documentation for this struct was generated from the following file:

- sf_wifi_qca4010_api.h

sf_wifi_qca4010_queue_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI QCA4010 Framework Interface

#include <sf_wifi_qca4010_api.h>

Data Fields

uint32_t *	p_queue_buffer Queue buffer.
uint32_t	queue_size Queue Size.
uint8_t	ok_check_index Variable to store index for data checking success string response.
uint8_t	error_check_index Variable to store index for data checking error string response.

TX_QUEUE *	p_cmd_queue_ptr Queue.

Detailed Description

Queue configuration

The documentation for this struct was generated from the following file:

- sf_wifi_qca4010_api.h

sf_wifi_qca4010_extended_cfg_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI QCA4010 Framework Interface

#include <sf_wifi_qca4010_api.h>

Data Fields

sf_wifi_qca4010_queue_cfg_t *	p_queue_cfg Queue configuration.
TX_EVENT_FLAGS_GROUP *	p_eventflag [2] Pointer to the event flag object for UART data transfer.
ioport_port_pin_t	pin_reset Port pin used for resetting wifi module.
ioport_level_t	reset_level Module reset level.
void *	p_module_extended_cfg Instance specific module configuration.

Detailed Description

SF wifi framework extended configuration

The documentation for this struct was generated from the following file:

ssp_err_t(*	versionGet)(ssp_version_t *const p_version) Gets version and stores it in provided pointer p_version. More...

Detailed Description

Framework API structure. Implementations will use the following API.

Field Documentation

◆ close

ssp_err_t(* sf_wifi_qca4010_api_t::close) (sf_wifi_qca4010_ctrl_t *const p_ctrl)

De-initialize the network interface and may put it in low power mode or power it off. Close the driver, disable the driver link, disable interrupt.

Parameters

[in,out]	p_ctrl	Pointer to the control block for the WiFi module.

◆ CommandSend

ssp_err_t(* sf_wifi_qca4010_api_t::CommandSend) (sf_wifi_qca4010_ctrl_t *const p_ctrl, sf_wifi_qca4010_cmd_resp_t *const p_input_at_command, sf_wifi_qca4010_cmd_resp_t *const p_output, uint32_t const timeout)

Send AT command given by user.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[in]	p_input_at_command	Pointer to structure which contains Modem command to send
[in,out]	p_output	Pointer to buffer in which response will be sent to user, Also user will pass the size of the buffer which is pointed by p_output
[in]	timeout	Timeout for which framework will wait for response in milliseconds

◆ open

ssp_err_t(* sf_wifi_qca4010_api_t::open) (sf_wifi_qca4010_ctrl_t *p_ctrl, sf_wifi_qca4010_cfg_t const *const p_cfg)

Initializes the network interface for data transfers.

Initial driver configuration, enable the driver link, enable interrupts and make device ready for data transfer.

Parameters

[in,out]	p_ctrl	Pointer to user-provided storage for the control block.
[in]	p_cfg	Pointer to WiFi configuration structure.

◆ provisioningSet

ssp_err_t(* sf_wifi_qca4010_api_t::provisioningSet) (sf_wifi_qca4010_ctrl_t *const p_ctrl, sf_wifi_qca4010_provisioning_t const *const p_wifi_provisioning)

Set WiFi module provisioning which will configure the module in AP or Client mode.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[in]	p_wifi_provisioning	Pointer to WiFi provisioning structure

◆ scan

ssp_err_t(* sf_wifi_qca4010_api_t::scan) (sf_wifi_qca4010_ctrl_t *const p_ctrl, sf_wifi_qca4010_scan_t *const p_scan, uint8_t count)

Scan for WiFi SSIDs.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[out]	p_scan	Pointer to structure which will hold scan result. It is the responsibility of the caller to ensure that adequate space is available to hold scan results.
[in,out]	count	Variable specifying maximum number of SSID's to scan and will be updated to number of actual SSIDs scanned by device

◆ versionGet

ssp_err_t(* sf_wifi_qca4010_api_t::versionGet) (ssp_version_t *const p_version)

Gets version and stores it in provided pointer p_version.

Parameters

[out]	p_version	pointer to memory location to return version number

◆ wifiStatusGet

ssp_err_t(* sf_wifi_qca4010_api_t::wifiStatusGet) (sf_wifi_qca4010_ctrl_t *const p_ctrl, sf_wifi_qca4010_status_t *const p_wifi_status)

Get WiFi module information.

Parameters

[in]	p_ctrl	Pointer to the control block for the WiFi module.
[out]	p_wifi_info	Pointer to WiFi module information structure

The documentation for this struct was generated from the following file:

- sf_wifi_qca4010_api.h

sf_wifi_qca4010_instance_t Struct Reference

Renesas Synergy Software Package Reference » Framework Interfaces » SF WIFI QCA4010 Framework Interface

#include <sf_wifi_qca4010_api.h>

Data Fields

sf_wifi_qca4010_ctrl_t *	p_ctrl Pointer to the control structure for this instance.
sf_wifi_qca4010_cfg_t const *	p_cfg Pointer to the configuration structure for this instance.
sf_wifi_qca4010_api_t const *	p_api Pointer to the API structure for this instance.

Detailed Description

This structure encompasses everything that is needed to use an instance of this interface.

The documentation for this struct was generated from the following file:

- sf_wifi_qca4010_api.h

5.1.2.52 SF WIFI QCA4010 On-Chip Interface

Field Documentation

◆ close

ssp_err_t(* sf_wifi_qca4010_onchip_stack_api_t::close) (sf_wifi_qca4010_onchip_stack_ctrl_t *const p_ctrl)

Pointer to function which un-initialize the network interface and may put it in low power mode or power it off. Close the driver, disable the driver link, disable interrupt.

Parameters

[in,out]	p_ctrl	Pointer to the control block

◆ dhcpServerStart

ssp_err_t(* sf_wifi_qca4010_onchip_stack_api_t::dhcpServerStart) (sf_wifi_qca4010_onchip_stack_ctrl_t *const p_ctrl, ULONG *p_start_ip, ULONG *p_end_ip)

Starts DHCP server

Parameters

[in]	p_ctrl	Pointer to the control block
[in]	p_start_ip	Pointer to Start IP address
[in]	p_end_ip	Pointer to End IP address

◆ dhcpServerStop

ssp_err_t(* sf_wifi_qca4010_onchip_stack_api_t::dhcpServerStop) (sf_wifi_qca4010_onchip_stack_ctrl_t *const p_ctrl, ULONG *p_start_ip, ULONG *p_end_ip)

Stops DHCP server

Parameters

[in]	p_ctrl	Pointer to the control block
[in]	p_start_ip	Pointer to Start IP address
[in]	p_end_ip	Pointer to End IP address

◆ ipAddressCfg

ssp_err_t(* sf_wifi_qca4010_onchip_stack_api_t::ipAddressCfg) (sf_wifi_qca4010_onchip_stack_ctrl_t *const p_ctrl, sf_wifi_qca4010_onchip_stack_ip_cfg_t *const p_ip_cfg)

Configures IP address of the interface.

Parameters

[in]	p_ctrl	Pointer to the control block
[in,out]	p_ip_cfg	Pointer to IP configuration structure.

◆ open

ssp_err_t(* sf_wifi_qca4010_onchip_stack_api_t::open) (sf_wifi_qca4010_onchip_stack_ctrl_t *p_ctrl, sf_wifi_qca4010_onchip_stack_cfg_t const *const p_cfg)

Pointer to function which initializes the network interface for data transfers

Initial driver configuration, enable the driver link, enable interrupts and make device ready for data transfer.

Parameters

[in,out]	p_ctrl	Pointer to user-provided storage for the control block.
[in]	p_cfg	Pointer to configuration structure.

◆ ping

ssp_err_t(* sf_wifi_qca4010_onchip_stack_api_t::ping) (sf_wifi_qca4010_onchip_stack_ctrl_t *const p_ctrl, ULONG *p_ip_addr, uint32_t count, uint32_t interval_ms)

Configures IP address of the interface.

Parameters

[in]	p_ctrl	Pointer to the control block
[in]	p_ip_addr	Pointer to IP address to ping
[in]	count	Number of ping attempts
[in]	interval_ms	Timeout in milliseconds

◆ versionGet

ssp_err_t(* sf_wifi_qca4010_onchip_stack_api_t::versionGet) (ssp_version_t *const p_version)		
Gets version and stores it in provided pointer p_version. **Parameters**		
[out]	p_version	pointer to memory location to return version number

Detailed Description

RTOS-integrated SF Socket WIFI Framework Interface.

Summary

This SSP Interface provides access OnChip stack Socket API.

Macro Definition Documentation

◆ SF_WIFI_QCA4010_SOCKET_API_VERSION_MAJOR

#define SF_WIFI_QCA4010_SOCKET_API_VERSION_MAJOR (2U)
Major Version of the API defined in this file

◆ SF_WIFI_QCA4010_SOCKET_API_VERSION_MINOR

#define SF_WIFI_QCA4010_SOCKET_API_VERSION_MINOR (0U)
Minor Version of the API defined in this file

Typedef Documentation

◆ socklen_t

typedef int32_t socklen_t
Socket address Length

Enumeration Type Documentation

◆ sf_wifi_qca4010_socket_at_cmd_index_t

enum sf_wifi_qca4010_socket_at_cmd_index_t	
Socket specific AT command enumeration	
Enumerator	
SF_WIFI_QCA4010_SOCKET_AT_CMD_INDEX_SOCKET_INDEX	Socket index.
SF_WIFI_QCA4010_SOCKET_AT_CMD_INDEX_SOCKET_CREATE	Socket create.
SF_WIFI_QCA4010_SOCKET_AT_CMD_INDEX_TCP_SERVER	TCP server.
SF_WIFI_QCA4010_SOCKET_AT_CMD_INDEX_TCP_CLIENT	TCP client.
SF_WIFI_QCA4010_SOCKET_AT_CMD_INDEX_UDP_SERVER	UDP server.
SF_WIFI_QCA4010_SOCKET_AT_CMD_INDEX_UDP_CLIENT	UDP client.
SF_WIFI_QCA4010_SOCKET_AT_CMD_INDEX_EXIT_TRANSPARENT_MODE	Exit from transparent mode.
SF_WIFI_QCA4010_SOCKET_AT_CMD_INDEX_CLOSE_NETWORK_SOCKET	Close network socket.
SF_WIFI_QCA4010_SOCKET_AT_CMD_INDEX_UDP_DATA_SEND	Send data to UDP client.
SF_WIFI_QCA4010_SOCKET_AT_CMD_INDEX_SWITCH_TO_DATA_MODE	Switch to data mode.

◆ sf_wifi_qca4010_socket_type_t

enum sf_wifi_qca4010_socket_type_t	
Enumeration for socket type	
Enumerator	
SF_WIFI_QCA4010_SOCKET_TYPE_INVALID	Invalid socket type.
SF_WIFI_QCA4010_SOCKET_TYPE_TCP_SERVER	Data stream socket.
SF_WIFI_QCA4010_SOCKET_TYPE_UDP_SERVER	Datagram socket.
SF_WIFI_QCA4010_SOCKET_TYPE_TCP_CLIENT	Data stream socket.
SF_WIFI_QCA4010_SOCKET_TYPE_UDP_CLIENT	Datagram socket.

◆ sf_wifi_socket_type_t

enum sf_wifi_socket_type_t	
Type of Socket	
Enumerator	
SOCK_STREAM	TCP Socket.
SOCK_DGRAM	UDP Socket.
SOCK_STREAM	TCP Socket.
SOCK_DGRAM	UDP Socket.
SOCK_RAW	RAW Socket.

Detailed Description

Socket Interface API

Field Documentation

◆ close

ssp_err_t(* sf_wifi_qca4010_socket_api_t::close) (sf_wifi_qca4010_socket_ctrl_t *const p_ctrl)

Close lower level driver.

Parameters

[in,out]	p_ctrl	Pointer to the control block

◆ open

ssp_err_t(* sf_wifi_qca4010_socket_api_t::open) (sf_wifi_qca4010_socket_ctrl_t *p_ctrl, sf_wifi_qca4010_socket_cfg_t const *const p_cfg)

Open lower level driver.

Parameters

[in,out]	p_ctrl	Pointer to user-provided storage for the control block.
[in]	p_cfg	Pointer to configuration structure.

◆ socketConnect

ssp_err_t(* sf_wifi_qca4010_socket_api_t::socketConnect) (sf_wifi_qca4010_socket_ctrl_t *p_ctrl, uint8_t socket_no, const struct sockaddr *p_serv_addr, socklen_t addrlen)

Connect to socket.

Parameters

[in]	p_ctrl	pointer to control block
[in]	socket_no	Socket ID number
[in]	p_serv_addr	IP address to connect
[in]	addrlen	Size of socket address structure

◆ socketCreate

ssp_err_t(* sf_wifi_qca4010_socket_api_t::socketCreate) (sf_wifi_qca4010_socket_ctrl_t *p_ctrl, uint8_t socket_no, sf_wifi_socket_type_t type, uint8_t ipversion)

Create a socket.

Parameters

[in]	p_ctrl	pointer to control block
[in]	socket_no	Socket ID number
[in]	type	TCP/UDP socket
[in]	ipversion	Protocol version

◆ socketDisconnect

ssp_err_t(* sf_wifi_qca4010_socket_api_t::socketDisconnect) (sf_wifi_qca4010_socket_ctrl_t *p_ctrl, uint8_t socket_no)

Disconnect socket.

Parameters

[in]	p_ctrl	pointer to control block
[in]	socket_no	Socket ID number

◆ socketRecv

ssp_err_t(* sf_wifi_qca4010_socket_api_t::socketRecv) (sf_wifi_qca4010_socket_ctrl_t *p_ctrl, uint8_t socket_no, uint8_t *const p_data, uint32_t length, uint32_t timeout_ms)

Receive data from connected socket.

Parameters

[in]	p_ctrl	pointer to control block
[in]	socket_no	Socket ID number
[out]	p_data	Data Receive buffer
[in]	length	Data length to be received
[in]	timeout_ms	timeout in milliseconds

◆ socketSend

ssp_err_t(* sf_wifi_qca4010_socket_api_t::socketSend) (sf_wifi_qca4010_socket_ctrl_t *p_ctrl, uint8_t socket_no, const uint8_t *p_data, uint32_t length, uint32_t timeout_ms)

Send data to connected socket.

Parameters

[in]	p_ctrl	pointer to control block
[in]	socket_no	Socket ID number
[in]	p_data	send buffer
[in]	length	Data length to be sent
[in]	timeout_ms	timeout in milliseconds

◆ socketStatusGet

ssp_err_t(* sf_wifi_qca4010_socket_api_t::socketStatusGet) (sf_wifi_qca4010_socket_ctrl_t *p_ctrl, uint8_t socket_no, uint32_t *p_socket_status)

Get Socket status.

Parameters

[in]	p_ctrl	pointer to control block
[in]	socket_no	Socket ID number
[out]	p_socket_status	Pointer to an integer to hold the socket return status

◆ versionGet

ssp_err_t(* sf_wifi_qca4010_socket_api_t::versionGet) (ssp_version_t *const p_version)

Gets version and stores it in provided pointer p_version.

Parameters

[out]	p_version	pointer to memory location to return version number

5.1.2.54 SF WIFI NSAL on NetX

Renesas Synergy Software Package Reference » Framework Interfaces

NetX NSAL interface implementation header file. More...

Functions

ssp_err_t	nsal_netx_driver (NX_IP_DRIVER *driver, sf_wifi_instance_t const

*p_wifi_instance, sf_wifi_nsal_cfg_t *p_wifi_nsal_cfg)

This is NetX interface driver function. More...

Detailed Description

NetX NSAL interface implementation header file.

Summary

This SSP Interface provides access to the ThreadX-aware SF WIFI NSAL NX Framework.

Function Documentation

◆ nsal_netx_driver()

ssp_err_t nsal_netx_driver (NX_IP_DRIVER * *p_driver*, sf_wifi_instance_t const * *p_wifi_instance*, sf_wifi_nsal_cfg_t * *p_wifi_nsal_cfg*)

This is NetX interface driver function.

NSAL NetX Driver Entry function

Parameters

[in]	p_driver	NetX IP driver pointer.
[in]	p_wifi_instance	WiFi Instance.
[in]	p_wifi_nsal_cfg	NSAL configuration.

Return values

SSP_ERR_ASSERTION	WiFi Frameowrk Instance pointer or NSAL configuration pointer is NULL
SSP_SUCCESS	No NULL arguments passed and NetX driver invoked successfully

Check if the link is up

Detailed Description

RTOS-integrated BLE Interface Framework example. Implementation of RL78G1D BLE Driver. It implements the following interfaces:

SF_BLE Framework Interface API on RL78G1D.

- SF BLE Framework Interface

Function Documentation

◆ ble_rl78g1d_connect()

ssp_err_t ble_rl78g1d_connect (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_connection_t const *const *p_conn*, sf_ble_conn_handle_t * *p_handle*, sf_ble_rl78g1d_driver_t * *p_driver_data*)

Connect to a remote BLE device using the information provided by user.

Parameters

[in]	p_ctrl	Pointer to control structure which contains driver information
[in]	p_conn	Pointer to connection information
[out]	p_handle	Pointer to connection handle
[in]	p_driver_data	Pointer to driver data where data is to be copied

Return values

SSP_SUCCESS	Connect success
SSP_ERR_BLE_FAILED	Failed to connect
SSP_ERR_NOT_OPEN	Device Not Opened
SSP_ERR_TIMEOUT	BLE event timeout

◆ ble_rl78g1d_open()

ssp_err_t ble_rl78g1d_open (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_cfg_t const *const *p_cfg*, sf_ble_rl78g1d_driver_t * *p_driver_data*)

Initializes RL78G1D Module as per user configuration, updates the control structure with instance specific information.

Parameters

[in,out]	p_ctrl	Pointer to user-provided storage for the control block.
[in]	p_cfg	Pointer to BLE configuration structure
[in]	p_driver_data	Pointer to driver data where data is to be copied

Return values

SSP_SUCCESS	Module initialization successful
SSP_ERR_BLE_FAILED	Failed to initialize
SSP_ERR_ALREADY_OPEN	Device is already open
SSP_ERR_IN_USE	Module in use
SSP_ERR_TIMEOUT	BLE event timeout
SSP_ERR_INTERNAL	GATT Initialization failure

Copying user configuration to driver buffer for later use

◆ close_rl78g1d()

ssp_err_t close_rl78g1d (sf_ble_ctrl_t *const *p_ctrl*)

Un-Initialize BLE Module, stop RBLE Thread, release thread resources which are in use.

Closes and Stops communication with RL78G1D BLE chip

Parameters

[in]	p_ctrl	Pointer to control structure which contains driver related information

Return values

SSP_SUCCESS	Suspend the driver functionality.
SSP_ERR_BLE_FAILED	Close failure

◆ copy_driver_data()

void copy_driver_data (sf_ble_rl78g1d_driver_t * *p_driver_data*, sf_ble_cfg_t const * *p_cfg*, sf_ble_provisioning_t const * *p_prov*)

Copies user provisioning information or configuration in driver buffer for later use.

Copies the value of BLE configuration and provisioning information into the driver buffer.

Parameters

[in]	p_driver_data	Pointer to driver data where data is to be copied
[in]	p_cfg	User pointer configuration which is to be copied to driver buffer
[in]	p_prov	Pointer BLE provisioning data

Returns

None

◆ rl78g1d_add_to_white_list()

ssp_err_t rl78g1d_add_to_white_list (uint8_t const * *p_bd_addr*)

Adds the BLE device address to white list so that it gets scanned by the Module.

Bluetooth address of peer device is added to the whiteList of Module

Parameters

[in]	p_bd_addr	Pointer to bluetooth address to be added to white list

Return values

SSP_SUCCESS	Whitelist add success
SSP_ERR_BLE_FAILED	Failed to add in white list
SSP_ERR_TIMEOUT	BLE event timeout

◆ rl78g1d_authorization()

ssp_err_t rl78g1d_authorization (sf_ble_conn_handle_t * *p_handle*)

Indicates that the specified remote device has been authorized by user.

Parameters

[in]	p_handle	Pointer to BLE handle

Return values

SSP_SUCCESS	Authorization success
SSP_ERR_BLE_FAILED	Authorization Failed

Pointer to BLE connection handle

◆ rl78g1d_bonding()

ssp_err_t rl78g1d_bonding (sf_ble_rl78g1d_driver_t * *p_driver_data*, uint8_t const * *p_bd_addr*, sf_ble_bonding_start_t * *p_bonding_start*)

Initiates bonding procedure with Remote BLE device with configuration provided by user.

Starts the bonding procedure with peer device

Parameters

[in]	p_driver_data	Pointer to private driver data structure
[in]	p_bd_addr	Pointer to ble device address from which bonding is to be started
[in]	p_bonding_start	Pointer to Bonding Start information structure

Return values

SSP_SUCCESS	Bonding start success
SSP_ERR_BLE_FAILED	Bonding start failure
SSP_ERR_TIMEOUT	BLE event timeout

◆ rl78g1d_bonding_resp()

ssp_err_t rl78g1d_bonding_resp (sf_ble_conn_handle_t * *p_handle*, sf_ble_rl78g1d_driver_t * *p_driver_data*, sf_ble_bonding_response_t * *p_bonding_resp*)

Responds to bonding request from remote device with the security information provided by user.

Parameters

[in]	p_handle	Pointer to BLE handle
[in]	p_driver_data	Pointer to driver data which contains chip related information
[in]	p_bonding_resp	Bonding Response structure

Return values

SSP_SUCCESS	Bonding response success
SSP_ERR_BLE_FAILED	Failed getting bonding response
SSP_ERR_TIMEOUT	BLE event timeout

Pointer to BLE connection handle

◆ rl78g1d_broadcast_disable()

ssp_err_t rl78g1d_broadcast_disable (void)

Disable advertisement of BLE Module so that it does not get discovered.

Disable advertisement of BLE Module.

Return values

SSP_SUCCESS	Stop the broadcast of device successfully
SSP_ERR_BLE_FAILED	Failed to broadcast disable
SSP_ERR_TIMEOUT	BLE event timeout

◆ rl78g1d_broadcast_enable()

ssp_err_t rl78g1d_broadcast_enable (sf_ble_rl78g1d_driver_t * *p_driver_data*, sf_ble_adv_info_t const * *p_adv_info*)

Enables the advertisement of BLE Module so that other devices can find it.

Starts advertisement of BLE Module.

Parameters

[in]	p_driver_data	Driver data which contains chip related information
[in]	p_adv_info	Pointer to user supplied broadcast configuration

Return values

SSP_SUCCESS	Start the broadcast of device successfully
SSP_ERR_BLE_FAILED	Failed to broadcast enable
SSP_ERR_TIMEOUT	BLE event timeout
SSP_ERR_INVALID_MODE	Invalid arguments/parameters

Advertisement Data length

Advertisement Data

◆ rl78g1d_del_from_white_list()

ssp_err_t rl78g1d_del_from_white_list (uint8_t const * *p_bd_addr*)

Deletes BLE device address from white list, so that it does not get discovered.

Bluetooth address of peer device is deleted from the whiteList of Module

Parameters

[in]	p_bd_addr	Pointer to BLE address to be removed from white list

Return values

SSP_SUCCESS	Whitelist delete success
SSP_ERR_BLE_FAILED	Failed to delete from white list
SSP_ERR_TIMEOUT	BLE event timeout

◆ rl78g1d_disconnect()

ssp_err_t rl78g1d_disconnect (sf_ble_conn_handle_t * *p_handle*)

Initiates Disconnection procedure from remote BLE device.

BLE device is disconnected from the peer device

Parameters

[in]	p_handle	Pointer to BLE handle

Return values

SSP_SUCCESS	Disconnect success
SSP_ERR_BLE_FAILED	Disconnect failed
SSP_ERR_TIMEOUT	BLE event timeout

Pointer to BLE connection handle

◆ rl78g1d_enable_gatt()

ssp_err_t rl78g1d_enable_gatt (void)

Enable the GATT in RBLE stack.

Return values

SSP_SUCCESS	Enable the gatt successfully
SSP_ERR_INTERNAL	Failed to enable the gatt

Create semaphore for rble operation complete

◆ rl78g1d_gatt_char_desc_discovery()

ssp_err_t rl78g1d_gatt_char_desc_discovery (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_conn_handle_t * *p_handle*, uint16_t *start_handle*, uint16_t *end_handle*, sf_ble_char_desc_discovery_rsp_t *const *p_sf_ble_chardesc_dscv_rsp*, uint32_t *const *p_rsp_cnt*)

Perform characteristics descriptor discovery used by GATT client.

Perform Characteristic descriptor discovery of remote BLE device and pass all discovered characteristics descriptor to user

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	pointer to Connection handle
[in]	start_handle	Start handle from set of handle ranges to be used in discovery
[in]	end_handle	End handle from set of handle ranges to be used in discovery
[out]	p_sf_ble_chardesc_dscv_rsp	Pointer to characteristics descriptor discovery response
[in,out]	p_rsp_cnt	Input Size specifying maximum number of characteristics descriptor discovery results which can be stored in response, output specifying number of characteristics descriptor discovery results stored in response

Return values

SSP_SUCCESS	Characteristics descriptor discovery successful
SSP_ERR_BLE_FAILED	Characteristics descriptor discovery failed

Pointer to BLE connection handle

Connection handle

API call

Wait for discovery to complete

Update response count

◆ rl78g1d_gatt_char_discovery()

ssp_err_t rl78g1d_gatt_char_discovery (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_conn_handle_t * *p_handle*, sf_ble_char_discovery_req_t const *const *p_sf_ble_char_dscv_req*, sf_ble_char_discovery_rsp_t *const *p_sf_ble_char_dscv_rsp*, uint32_t *const *p_rsp_cnt*)

Perform characteristics discovery used by GATT client.

Perform Characteristic discovery of remote BLE device and pass all discovered characteristics to user

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Pointer to Connection handle
[in]	p_sf_ble_char_dscv_req	Pointer to characteristics discovery request
[out]	p_sf_ble_char_dscv_rsp	Pointer to characteristics discovery response
[in,out]	p_rsp_cnt	Input Size specifying maximum number of characteristics discovery results which can be stored in response, output specifying number of characteristics discovery results stored in response

Return values

SSP_SUCCESS	Characteristics discovery successful
SSP_ERR_BLE_FAILED	Characteristics discovery failed
SSP_ERR_NOT_OPEN	Device Not Opened

Pointer to BLE connection handle

Connection handle

API call

Wait for discovery to complete

Update response count

◆ rl78g1d_gatt_char_execute_write()

ssp_err_t rl78g1d_gatt_char_execute_write (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_conn_handle_t * *p_handle*, sf_ble_execute_write_t *execute_flag*)

Perform execute write on all pending write operations, used by GATT client.

This API writes any characteristics handle which are pending in previous write

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	pointer to Connection handle
[in]	execute_flag	Flag specifying whether to execute or cancel pending writes

Return values

SSP_SUCCESS	Execute write successful
SSP_ERR_BLE_FAILED	Execute write failed

Pointer to BLE connection handle

Connection handle

API Call

Wait for execute write to complete

◆ rl78g1d_gatt_char_read()

ssp_err_t rl78g1d_gatt_char_read (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_conn_handle_t * *p_handle*, sf_ble_char_read_req_t const *const *p_char_read_req*, sf_ble_char_read_rsp_t *const *p_char_read_rsp*)

Perform read characteristic used by GATT client.

GATT client reads the characteristics value of specific characteristics handle of the connected peer device

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	pointer to Connection handle
[in]	p_char_read_req	Pointer to characteristic read request
[out]	p_char_read_rsp	Pointer to characteristic read response

Return values

SSP_SUCCESS	Characteristic read successful
SSP_ERR_BLE_FAILED	Characteristic read failed

Characteristic handle

Characteristic handle size

Characteristic handle count

Characteristic UUID length

Characteristic UUID

Characteristic UUID length

Characteristic UUID

Characteristic UUID count

Characteristic value offset

Characteristic handle

Characteristic handle size

Characteristic handle count

Characteristic descriptor handle

Characteristic descriptor handle size

Characteristic descriptor handle count

Characteristic descriptor value offset

Characteristic descriptor handle

Characteristic descriptor handle size

Characteristic descriptor handle count

◆ rl78g1d_gatt_char_write()

ssp_err_t rl78g1d_gatt_char_write (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_conn_handle_t * *p_handle*, sf_ble_char_write_req_t const *const *p_char_write_req*)

Perform write characteristic used by GATT client.

Write GATT characteristics data in characteristics handle of remote BLE device

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	pointer to Connection handle
[in]	p_char_write_req	Pointer to characteristic write request

Return values

SSP_SUCCESS	Characteristic write successful
SSP_ERR_BLE_FAILED	Characteristic write failed

◆ rl78g1d_gatt_char_write_local()

ssp_err_t rl78g1d_gatt_char_write_local (sf_ble_ctrl_t *const *p_ctrl*, uint16_t *char_handle*, uint16_t *data_length*, uint8_t *const *p_data*)

Perform local characteristic write used by GATT server.

Update local GATT database with user provided data.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	char_handle	Characteristic handle
[in]	data_length	Length of data to write
[in]	p_data	Pointer to data

Return values

SSP_SUCCESS	Local characteristic write successful
SSP_ERR_BLE_FAILED	Local characteristic write failed

Characteristic value handle

Characteristic value length

Characteristic value

API Call

Wait for local write to complete

◆ rl78g1d_gatt_event_callback()

void rl78g1d_gatt_event_callback (RBLE_GATT_EVENT * *p_event*)

GATT Event callback.

Parameters

[in]	p_event	Event details

Return values

None	

All Primary service discovery with 16 bit UUID complete

All Primary service discovery with 128 bit UUID complete

Primary service discovery by UUID complete

Included service discovery complete

All characteristics discovery with 16 bit UUID complete

All characteristics discovery with 128 bit UUID complete

Characteristics discovery by UUID (16 bit) complete

Characteristics discovery by UUID (128 bit) complete

Switch case is broken into different functions in order to reduce the cyclomatic complexity (<=10) of the function

◆ rl78g1d_gatt_send_indicate()

ssp_err_t rl78g1d_gatt_send_indicate (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_conn_handle_t * *p_handle*, uint16_t *char_handle*)

Send indication to GATT client, used by GATT server.

Send the data of CCCD indication to remote GATT client.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Pointer to Connection handle
[in]	char_handle	Characteristic handle whose value will be indicated

Return values

SSP_SUCCESS	Send Indication successful
SSP_ERR_BLE_FAILED	Send Indication failed

Connection handle

Characteristic handle

API Call

Wait for indication send to complete

◆ rl78g1d_gatt_send_notify()

ssp_err_t rl78g1d_gatt_send_notify (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_conn_handle_t * *p_handle*, uint16_t *char_handle*)

Send notification to GATT client, used by GATT server.

Send the data of CCCD notification to remote GATT client.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	pointer to Connection handle
[in]	char_handle	Characteristic handle whose value will be notified

Return values

SSP_SUCCESS	Send notification successful
SSP_ERR_BLE_FAILED	Send notification failed

Pointer to BLE connection handle

Connection handle

Characteristic handle

API Call

◆ rl78g1d_gatt_service_discovery()

ssp_err_t rl78g1d_gatt_service_discovery (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_conn_handle_t * *p_handle*, sf_ble_service_discovery_req_t const *const *p_sf_ble_svc_dscv_req*, sf_ble_service_discovery_rsp_t *const *p_sf_ble_svc_dscv_rsp*, uint32_t *const *p_rsp_cnt*)

GATT Service discovery.

Perform GATT service discovery of remote BLE device and pass all discovered Services to user

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	pointer to Connection handle
[in]	p_sf_ble_svc_dscv_req	Pointer to service discovery request
[out]	p_sf_ble_svc_dscv_rsp	Pointer to service discovery response
[in]	p_rsp_cnt	Input Size specifying maximum number of service discovery results which can be stored in response, output specifying number of service discovery results stored in response

Return values

SSP_SUCCESS	Service discovery successful
SSP_ERR_BLE_FAILED	Service discovery failed
SSP_ERR_NOT_OPEN	Device Not Opened

Pointer to BLE connection handle

Connection handle

API call

Wait for discovery to complete

Update response count

◆ rl78g1d_gatt_write_response()

ssp_err_t rl78g1d_gatt_write_response (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_conn_handle_t * *p_handle*, uint16_t *handle*, sf_ble_attribute_error_code_t *error_code*)

Send response to write operation received by GATT client, used by GATT server.

Parameters

[in]	p_ctrl	Pointer to control structure
[in]	p_handle	Pointer to Connection handle
[in]	handle	Characteristic handle used for write operation
[in]	error_code	Characteristic write operation error code to be sent in response

Return values

SSP_SUCCESS	Send write response successful
SSP_ERR_BLE_FAILED	Send write response failed

Pointer to BLE connection handle

Connection handle

Characteristic handle

API Call

◆ rl78g1d_get_info()

ssp_err_t rl78g1d_get_info (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_chipset_info_t * *p_chipset*)

Gets the BLE module information and put that information in user buffer.

Reads information from RL78G1D device and updates user buffer

Parameters

[in]	p_ctrl	Pointer to control structure which contains driver information
[in]	p_chipset	Pointer to user buffer which will be filled with BLE information

Return values

SSP_SUCCESS	Successfully get the BLE information
SSP_ERR_BLE_FAILED	Failed to get information from chipset
SSP_ERR_TIMEOUT	BLE event timeout

◆ rl78g1d_read_rssi()

ssp_err_t rl78g1d_read_rssi (sf_ble_ctrl_t *const *p_ctrl*, sf_ble_conn_handle_t * *p_handle*, uint16_t * *p_rssi*)

Read RSSI information of the connection handle passed.

Reads the RSSI information of BLE module for the connection handle passed

Parameters

[in]	p_ctrl	Pointer to control structure which contains driver information
[in]	p_handle	Pointer to BLE handle
[in]	p_rssi	Pointer to user buffer in which rssi is read

Return values

SSP_SUCCESS	Successfully read rssi
SSP_ERR_BLE_FAILED	Failed to read rssi value
SSP_ERR_TIMEOUT	BLE event timeout

Pointer to BLE connection handle

◆ rl78g1d_set_provision()

ssp_err_t rl78g1d_set_provision (sf_ble_provisioning_t const * *p_prov*)

Configures the BLE Module as per user provided Provisioning configuration.

Sets bonding and security modes as provisioned.

Parameters

[in]	p_prov	Pointer to user provisioning information

Return values

SSP_SUCCESS	Successfully provisioned the device.
SSP_ERR_BLE_FAILED	Failed to set provision
SSP_ERR_TIMEOUT	BLE event timeout
SSP_ERR_UNSUPPORTED	Unsupported feature

Bonding mode

Variable to store temporary Bonding mode

◆ rl78g1d_set_tx_power()

ssp_err_t rl78g1d_set_tx_power (sf_ble_conn_handle_t *const *p_handle*, sf_ble_set_tx_pwr_info_t * *p_tx_power_info*)

Sets the transmit power for the procedure specified by the connection handle.

Parameters

[in]	p_handle	Pointer to BLE handle
[in]	p_tx_power_info	Pointer to TX power information

Return values

SSP_SUCCESS	TX power set successfully
SSP_ERR_BLE_FAILED	TX power set failed
SSP_ERR_TIMEOUT	BLE event timeout
SSP_ERR_INVALID_ARGUMENT	Invalid transmit power level parameter not supported by device

Pointer to BLE connection handle

◆ rl78g1d_start_encryption()

ssp_err_t rl78g1d_start_encryption (sf_ble_sm_enc_info_t const * *p_enc_info*)

Starts encryption over the BLE link using information received during Bonding procedure.

Parameters

[in]	p_enc_info	BLE Start Encryption information

Return values

SSP_SUCCESS	Successfully when encryption start over the BLE link
SSP_ERR_BLE_FAILED	Failed to start encryption
SSP_ERR_TIMEOUT	BLE event timeout

◆ rl78g1d_start_scan()

ssp_err_t rl78g1d_start_scan (sf_ble_rl78g1d_driver_t * *p_driver_data*, sf_ble_scan_t * *p_scan*, uint8_t * *p_cnt*, sf_ble_scan_info_t * *p_scan_info*)

Starts scanning of available BLE devices and returns the list of available BLE devices.

Starts Scanning of BLE devices either in Passive or Active mode with user provided scan configuration

Parameters

[in]	p_driver_data	Pointer to driver data where data is to be copied
[in,out]	p_scan	Pointer to user supplied scan buffer
[in,out]	p_cnt	Pointer to count variable which is to be updated with number of BLE devices scanned
[in]	p_scan_info	Pointer to scan information structure

Return values

SSP_SUCCESS	Successful scan of available BLE devices
SSP_ERR_BLE_FAILED	Failed to scan
SSP_ERR_TIMEOUT	BLE event timeout
SSP_ERR_INVALID_MODE	Invalid arguments/parameters

In order to start observation or to start passive scan go for observation procedure. Passive scan is only supported through observation procedure

◆ sf_rble_exit_status()

uint8_t sf_rble_exit_status (void)

Returns status whether RL78G1D driver thread should exit or continue.

Return values

SF_BLE_TRUE	RBLE Thread should exit
SF_BLE_FALSE	RBLE Thread should continue execution

Detailed Description

SF_CELLULAR Framework API on Quectel CATM1.

Function Documentation

◆ SF_CELLULAR_QCTLCATM1_Close()

ssp_err_t SF_CELLULAR_QCTLCATM1_Close (sf_cellular_ctrl_t *const *p_ctrl*)

Stop Cellular QuecTel CATM1 driver functionality.

Implements sf_cellular_api_t::close This function deactivates the PDP context and de-initializes the lower level interface

Parameters

[in]	p_ctrl	Cellular control block

Return values

SSP_SUCCESS	Cellular Driver stop successfully.
SSP_ERR_NOT_OPEN	Device is not opened.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver un-initialization failed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

close module

Set module open flag and delete mutex

Delete is used in close API where all resources are released, hence no need to check the return code

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ sf_cellular_qctlcatm1_config_set()

ssp_err_t sf_cellular_qctlcatm1_config_set (sf_cellular_ctrl_t * *p_ctrl*, sf_cellular_cfg_t const * *p_cfg*)

Set Cellular device interface configuration.

Parameters

[in]	p_ctrl	Pointer to cellular control block
[in]	p_cfg	Pointer to Cellular configuration

Return values

SSP_SUCCESS	Success
SSP_ERR_CELLULAR_CONFIG_FAILED	Failed Cellular configuration
SSP_ERR_CELLULAR_INIT_FAILED	Failed due to invalid response received from modem

Local configuration variable

Set Preferred Operators List

Set Cellular operator select mode, in case of manual set operator details

Set cellular SIM priority effect. Due to the unavailability of SIM priority effect command in all the BG96 firmwares do not check the return value of this API

set cellular network fallback sequence

Set TimeZone update mode policy

◆ sf_cellular_qctlcatm1_get_imsi()

ssp_err_t sf_cellular_qctlcatm1_get_imsi (sf_cellular_instance_cfg_t * *p_celr_instance*, uint8_t * *p_imsi*)

Read IMSI ID.

Parameters

[in]	p_celr_instance	Pointer to cellular instance
[out]	p_imsi	IMSI ID

Return values

SSP_SUCCESS	Read IMSI successfully
SSP_ERR_CELLULAR_FAILED	Reading IMSI failed

AT Command used AT+CIMI - Read IMSI

Get response wait time in ticks

Send command to read IMEI number

Expected bytes of successful response

Clear response buffer

Read command response

Ignore first 2 bytes of resp_buff which contains newline ascii character

Reset result value

Delay for next try

◆ SF_CELLULAR_QCTLCATM1_InfoGet()

ssp_err_t SF_CELLULAR_QCTLCATM1_InfoGet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_info_t *const *p_cellular_info*)

Get Cellular module information.

Implements sf_cellular_api_t::infoGet Get Cellular module information like chipset/driver information, RSSI, noise level, link quality

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_cellular_info	Cellular information structure

Return values

SSP_SUCCESS	Successfully get the Cellular information
SSP_ERR_NOT_OPEN	Driver not opened.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Failed reading Cellular information
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_QCTLCATM1_NetworkStatusGet()

ssp_err_t SF_CELLULAR_QCTLCATM1_NetworkStatusGet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_network_status_t * *p_network_status*)

Get Network Status information.

Implements sf_cellular_api_t::networkStatusGet

Parameters

[in]	p_ctrl	Cellular control block
[out]	p_network_status	Cellular network structure

Return values

SSP_SUCCESS	Successfully read the Network status information
SSP_ERR_NOT_OPEN	Cellular driver is not opened
SSP_ERR_CELLULAR_FAILED	Failed reading Network Status information.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_QCTLCATM1_Open()

ssp_err_t SF_CELLULAR_QCTLCATM1_Open (sf_cellular_ctrl_t * *p_ctrl*, sf_cellular_cfg_t const *const *p_cfg*)

Initialize Cellular Quectel CATM1 Cellular driver.

Implements sf_cellular_api_t::open Initializes driver and configures module with given parameters and saves this configuration.

Parameters

[out]	p_ctrl	Cellular control block
[in]	p_cfg	Cellular configuration structure

Return values

SSP_SUCCESS	Driver initialization successfully.
SSP_ERR_ALREADY_OPEN	Cellular QuecTel CATM1 Driver is already opened.
SSP_ERR_CELLULAR_CONFIG_FAILED	Cellular QuecTel CATM1 module Configuration failed
SSP_ERR_CELLULAR_INIT_FAILED	Cellular QuecTel CATM1 module initialization failed
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver initialization failed
SSP_ERR_IN_USE	Device already in use

Create Mutex for Synchronization

Get Mutex Lock

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_QCTLCATM1_ProvisioningSet()

ssp_err_t SF_CELLULAR_QCTLCATM1_ProvisioningSet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_provisioning_t const *const *p_cellular_provisioning*)

Sets the provisioning information.

Implements sf_cellular_api_t::provisioningSet Sets Cellular's provisioning information

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_cellular_provisioning	Cellular provisioning structure

Return values

SSP_SUCCESS	Successfully set the provisioning information.
SSP_ERR_NOT_OPEN	Device not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Provisioning configuration failed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

Set AirPlane Mode on

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_QCTLCATM1_Reset()

ssp_err_t SF_CELLULAR_QCTLCATM1_Reset (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_reset_type_t *reset_type*)

Reset the module.

Implements sf_cellular_api_t::reset This function reset the module as per the reset type

Parameters

[in]	p_ctrl	Cellular control block
[in]	reset_type	Type of reset

Return values

SSP_SUCCESS	Cellular Driver stop successfully.
SSP_ERR_NOT_OPEN	Device is not opened.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver un-initialization failed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command
SSP_ERR_CELLULAR_INIT_FAILED	Failed due to invalid response received from modem

Get Mutex

Reset module

Check whether SIM Pin is required

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_QCTLCATM1_VersionGet()

ssp_err_t SF_CELLULAR_QCTLCATM1_VersionGet (ssp_version_t *const *p_version*)

Get driver version based on compile time macros.

Implements sf_cellular_api_t::versionGet.

Parameters

[out]	p_version	Common version structure

Return values

SSP_SUCCESS	Success.
SSP_ERR_ASSERTION	The parameter p_version is NULL.

5.1.2.57 BSD Socket over Quectel CATM1 on-chip stack API

Detailed Description

SF_CELLULAR Socket Framework API on Quectel CATM1.

Function Documentation

◆ accept()

int accept (int *sockfd*, struct sockaddr * *p_cliaddr*, socklen_t * *p_addrlen*)

This accepts connection from remote socket.

Implements accept This function accepts connection from remote socket. This API is used only with socket type STREAM. The call is blocked if no connection is present or the socket is blocking.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_cliaddr	Remote machine Network address
[out]	p_addrlen	Size of Socket address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error accepting the connection
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Connection is received successfully.

◆ bind()

int bind (int *sockfd*, const struct sockaddr * *p_local_sock_addr*, socklen_t *addrlen*)

This binds socket to IP address.

Implements bind This function binds socket to given IP address and port.

Parameters

sockfd	Socket file descriptor
p_local_sock_addr	Socket address structure
addrlen	Size of Socket address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Binding socket failed
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket is bound successfully.

◆ close()

int close (int *sockfd*)

This closes socket.

Implements close Close opened socket

Parameters

[in]	sockfd	Socket file descriptor

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Closing socket failed
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket is closed successfully.

◆ connect()

int connect (int *sockfd*, const struct sockaddr * *p_serv_addr*, socklen_t *addrlen*)

This connects with remote socket(stream socket).

Implements connect This function connects local socket with remote socket. The call is blocked until a connection is established or error is returned.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_serv_addr	Remote machine Network address
[in]	addrlen	Size of Socket address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error occurred.
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket is connected successfully.

◆ getsockopt()

int getsockopt (int *sockfd*, int *level*, int *optname*, void * *p_optval*, socklen_t * *p_optlen*)

This reads socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Implements getsockopt This gets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[out]	p_optval	Socket option value
[out]	p_optlen	Size of Socket option

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error reading socket option
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket option read successfully.

◆ listen()

int listen (int *sockfd*, int *backlog*)

This listens for connection on socket.

Implements listen This function listen for connection on socket.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	backlog	number of maximum connection can be accepted

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Failed to set socket in Listen mode
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Set socket in Listen mode successfully.

◆ recv()

ssize_t recv (int *sockfd*, void * *p_buf*, size_t *length*, int *flags*)

This receives data over STREAM socket.

Implements receive This function receives data on a stream socket in connected state. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_buf	Buffer to read data
[in]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Failed to receive data.

Returns

Otherwise Number of Data bytes received successfully.

◆ recvfrom()

ssize_t recvfrom (int *sockfd*, void * *p_buf*, size_t *length*, int *flags*, struct sockaddr * *p_src_addr*, socklen_t * *p_addrlen*)

This receives data over DGRAM socket.

Implements recvfrom This function receives data on a dgram socket. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket file descriptor
[out]	p_buf	Data buffer pointer to read data
[in]	length	Length of data to read
[in]	flags	Flags
[in]	p_src_addr	Remote machine network address
[in]	p_addrlen	Size of Remote machine network

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error receiving data

Returns

Otherwise Numbers of data bytes received successfully.

◆ select()

int select (int *nfds*, fd_set * *p_readfds*, fd_set * *p_writefds*, fd_set * *p_exceptfds*, struct timeval * *p_timeout*)

This waits for any activity on socket.

Implements select Allow an application thread to block on a given socket handle for a specified time period. This API checks for any activity on specified socket, for example arrival of a packet at the receive queue.

Parameters

[in]	nfds	Number of socket fds in to check
[in]	p_readfds	Read socket fd set
[in]	p_writefds	Write socket fd set. If no descriptor is to be tested for writing, p_writefds should be NULL
[in]	p_exceptfds	Exceptional socket fd set. If no descriptor is to be tested for exceptions, p_exceptfds should be NULL
[in]	p_timeout	Timeout

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Timeout occurred, no activity.

Returns

Otherwise Activity detected(Packet available).

◆ send()

ssize_t send (int *sockfd*, const void * *p_buf*, size_t *length*, int *flags*)

This sends data over STREAM socket.

Implements send This function sends data on a stream socket in connected state.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data to send
[in]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Failed to send data.

Returns

Otherwise Number of Data bytes sent successfully.

◆ sendto()

ssize_t sendto (int *sockfd*, const void * *p_buf*, size_t *length*, int *flags*, const struct sockaddr * *p_dest_addr*, socklen_t *addrlen*)

This sends data over DGRAM socket.

Implements sendto This function sends data to remote.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data pointer
[in]	length	Length of data
[in]	flags	Flag
[in]	p_dest_addr	Address of remote UDP server
[in]	addrlen	Size of Network address structure

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error Sending data.

Returns

Otherwise Numbers of bytes sent successfully.

◆ setsockopt()

int setsockopt (int *sockfd*, int *level*, int *optname*, const void * *p_optval*, socklen_t *optlen*)

This updates socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Implements setsockopt This sets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[in]	p_optval	Socket option value
[in]	optlen	Size of Socket option

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Invalid input arguments OR Error setting socket option
SF_CELLULAR_QCTLCATM1_SOCKET_SUCCESS	Socket option set successfully.

◆ SF_CELLULAR_QCTLCATM1_SOCKET_Close()

ssp_err_t SF_CELLULAR_QCTLCATM1_SOCKET_Close (sf_cellular_socket_ctrl_t *const *p_ctrl*)

Close the Cellular Device driver.

Implements sf_cellular_socket_api_t::close Calls the low level Cellular device driver's Close API to close the cellular Driver.

Return values

SSP_SUCCESS	Cellular Driver stop successfully.
SSP_ERR_NOT_OPEN	Device is not opened.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver un-initialization failed
SSP_ERR_IN_USE	Device already in use

SF Cellular instance variable

SF Cellular API structure variable

SF Cellular Stack control block structure

◆ SF_CELLULAR_QCTLCATM1_SOCKET_Open()

ssp_err_t SF_CELLULAR_QCTLCATM1_SOCKET_Open (sf_cellular_socket_ctrl_t * *p_ctrl*, sf_cellular_socket_cfg_t const *const *p_cfg*)

Open the Cellular Device driver to use the Socket Layer on Cellular Driver On-Chip stack.

Implements sf_cellular_socket_api_t::open Calls the low level Cellular device driver's Open API to Initialize the Cellular Device Driver, for using Socket Layer on On-Chip stack.

Return values

SSP_SUCCESS	Driver initialization successfully.
SSP_ERR_ALREADY_OPEN	Cellular Quectel CATM1 Driver is already opened.
SSP_ERR_CELLULAR_CONFIG_FAILED	Cellular Quectel CATM1 module Configuration failed
SSP_ERR_CELLULAR_INIT_FAILED	Cellular Quectel CATM1 module initialization failed
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver initialization failed
SSP_ERR_IN_USE	Device already in use

SF Cellular instance variable

SF Cellular API structure variable

SF Cellular configuration structure variable

SF Cellular Stack control block structure

Initialize Cellular Modem

Initialize Socket Interface global variable , if module open successfully or already open

◆ SF_CELLULAR_QCTLCATM1_SOCKET_PING()

ssp_err_t SF_CELLULAR_QCTLCATM1_SOCKET_PING (sf_cellular_socket_ctrl_t *const *p_ctrl*, ULONG * *p_ip_address*, uint32_t *count*, uint32_t *interval_ms*)

Ping an IP address on the network.

Parameters

[in]	p_ctrl	Pointer to control structure.
[in]	p_ip_address	Pointer to IP address.
[in]	count	Number of ping attempts.
[in]	interval_ms	Interval between ping attempts.

Return values

SSP_ERR_UNSUPPORTED	Functionality not supported

◆ SF_CELLULAR_QCTLCATM1_SOCKET_VersionGet()

ssp_err_t SF_CELLULAR_QCTLCATM1_SOCKET_VersionGet (ssp_version_t *const *p_version*)

This function gets the version information of the underlying driver.

Implements sf_cellular_socket_api_t::versionGet

Parameters

[out]	p_version	Driver version information

Return values

SSP_ERR_ASSERTION	Argument NULL is passed
SSP_SUCCESS	Successfully read version information

◆ socket()

int socket (int *domain*, int *type*, int *protocol*)

This creates socket for communication.

Implements socket Creates socket with given parameters.

Parameters

[in]	domain	Network Domain
[in]	type	Socket type
[in]	protocol	Protocol type

Return values

SF_CELLULAR_QCTLCATM1_SOCKET_INVALID_FD	Socket creation failed

Returns

Otherwise Socket descriptor of newly created socket

Detailed Description

SF_CELLULAR Framework API on RYZ014CATM1.

Function Documentation

◆ SF_CELLULAR_RYZ014CATM1_Close()

ssp_err_t SF_CELLULAR_RYZ014CATM1_Close (sf_cellular_ctrl_t *const *p_ctrl*)

Stop Cellular RYZ014 CATM1 driver functionality.

Implements sf_cellular_api_t::close This function deactivates the PDP context and de-initializes the lower level interface

Parameters

[in]	p_ctrl	Cellular control block

Return values

SSP_SUCCESS	Cellular Driver stop successfully.
SSP_ERR_NOT_OPEN	Device is not opened.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver un-initialization failed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

close module

Set module open flag and delete mutex

Delete is used in close API where all resources are released, hence no need to check the return code

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ sf_cellular_ryz014catm1_config_set()

ssp_err_t sf_cellular_ryz014catm1_config_set (sf_cellular_ctrl_t * *p_ctrl*, sf_cellular_cfg_t const * *p_cfg*)

Set Cellular device interface configuration.

Parameters

[in]	p_ctrl	Pointer to cellular control block
[in]	p_cfg	Pointer to Cellular configuration

Return values

SSP_SUCCESS	Success
SSP_ERR_CELLULAR_CONFIG_FAILED	Failed Cellular configuration
SSP_ERR_CELLULAR_INIT_FAILED	Failed due to invalid response received from modem

Set Preferred Operators List

Set Cellular operator select mode, in case of manual set operator details

Set TimeZone update mode policy

◆ sf_cellular_ryz014catm1_get_imsi()

ssp_err_t sf_cellular_ryz014catm1_get_imsi (sf_cellular_instance_cfg_t * *p_celr_instance*, uint8_t * *p_imsi*)

Read IMSI ID.

Parameters

[in]	p_celr_instance	Pointer to cellular instance
[out]	p_imsi	IMSI ID

Return values

SSP_SUCCESS	Read IMSI successfully
SSP_ERR_CELLULAR_FAILED	Reading IMSI failed

AT Command used AT+CIMI - Read IMSI

Get response wait time in ticks

Send command to read IMEI number

Expected bytes of successful response

Clear response buffer

Read command response

Ignore first 2 bytes of resp_buff which contains newline ascii character

Reset result value

Delay for next try

◆ SF_CELLULAR_RYZ014CATM1_InfoGet()

ssp_err_t SF_CELLULAR_RYZ014CATM1_InfoGet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_info_t *const *p_cellular_info*)

Get Cellular module information.

Implements sf_cellular_api_t::infoGet Get Cellular module information like chipset/driver information, RSSI, noise level, link quality

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_cellular_info	Cellular information structure

Return values

SSP_SUCCESS	Successfully get the Cellular information
SSP_ERR_NOT_OPEN	Driver not opened.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Failed reading Cellular information
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_RYZ014CATM1_NetworkStatusGet()

ssp_err_t SF_CELLULAR_RYZ014CATM1_NetworkStatusGet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_network_status_t * *p_network_status*)

Get Network Status information.

Implements sf_cellular_api_t::networkStatusGet

Parameters

[in]	p_ctrl	Cellular control block
[out]	p_network_status	Cellular network structure

Return values

SSP_SUCCESS	Successfully read the Network status information
SSP_ERR_NOT_OPEN	Cellular driver is not opened
SSP_ERR_CELLULAR_FAILED	Failed reading Network Status information.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_RYZ014CATM1_Open()

ssp_err_t SF_CELLULAR_RYZ014CATM1_Open (sf_cellular_ctrl_t * *p_ctrl*, sf_cellular_cfg_t const *const *p_cfg*)

Initialize Cellular RYZ014 CATM1 Cellular driver.

Implements sf_cellular_api_t::open Initializes driver and configures module with given parameters and saves this configuration.

Parameters

[out]	p_ctrl	Cellular control block
[in]	p_cfg	Cellular configuration structure

Return values

SSP_SUCCESS	Driver initialization successfully.
SSP_ERR_ALREADY_OPEN	Cellular RYZ014 CATM1 Driver is already opened.
SSP_ERR_CELLULAR_CONFIG_FAILED	Cellular RYZ014 CATM1 module Configuration failed
SSP_ERR_CELLULAR_INIT_FAILED	Cellular RYZ014 CATM1 module initialization failed
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver initialization failed
SSP_ERR_IN_USE	Device already in use

Create Mutex for Synchronization

Get Mutex Lock

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_RYZ014CATM1_ProvisioningSet()

ssp_err_t SF_CELLULAR_RYZ014CATM1_ProvisioningSet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_provisioning_t const *const *p_cellular_provisioning*)

Sets the provisioning information.

Implements sf_cellular_api_t::provisioningSet Sets Cellular's provisioning information

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_cellular_provisioning	Cellular provisioning structure

Return values

SSP_SUCCESS	Successfully set the provisioning information.
SSP_ERR_NOT_OPEN	Device not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Provisioning configuration failed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

Set AirPlane Mode on

Set provisioning

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_RYZ014CATM1_Reset()

ssp_err_t SF_CELLULAR_RYZ014CATM1_Reset (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_reset_type_t *reset_type*)

Reset the module.

Implements sf_cellular_api_t::reset This function reset the module as per the reset type

Parameters

[in]	p_ctrl	Cellular control block
[in]	reset_type	Type of reset

Return values

SSP_SUCCESS	Cellular Driver stop successfully.
SSP_ERR_NOT_OPEN	Device is not opened.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver un-initialization failed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command
SSP_ERR_CELLULAR_INIT_FAILED	Failed due to invalid response received from modem

Get Mutex

Reset module

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ sf_cellular_ryz014catm1_set_pdp_context_state()

ssp_err_t sf_cellular_ryz014catm1_set_pdp_context_state (sf_cellular_instance_cfg_t * *p_celr_instance*, uint8_t *cid*, uint8_t *activate*)

Activate/Deactivate the PDP context.

Parameters

[in]	p_celr_instance	Pointer to Cellular Instance configuration
[in]	cid	Content ID
[in]	activate	Context status to be set

Return values

SSP_SUCCESS	Successfully activate/deactivate the PDP context
SSP_ERR_CELLULAR_FAILED	Failed to activate/deactivate the PDP context

AT Command used AT+CGACT=socket,1 - To activate the context AT+CGACT=socket,0 - To deactivate the context AT+CGACT=Socket_context,activate or deactivate

Create socket context activation command

Expected bytes of successful response

Create context activation command

Expected bytes of successful response

Store data in string format

numbers of bytes to send

Send command

Get response wait time in ticks

Read response

Check whether expected response present or not

< In case of activation

< In case of de-activation

Delay for next retry

◆ SF_CELLULAR_RYZ014CATM1_VersionGet()

ssp_err_t SF_CELLULAR_RYZ014CATM1_VersionGet (ssp_version_t *const *p_version*)

Get driver version based on compile time macros.

Implements sf_cellular_api_t::versionGet.

Parameters

[out]	p_version	Common version structure

Return values

SSP_SUCCESS	Success.
SSP_ERR_ASSERTION	The parameter p_version is NULL.

Detailed Description

SF_Cellular Framework API Common Code.

Cellular Framework header files Framework header files for this package HAL Layer communication interface header file

Function Documentation

◆ SF_CELLULAR_COMMON_Close()

ssp_err_t SF_CELLULAR_COMMON_Close (sf_cellular_ctrl_t *const *p_ctrl*)

Stop Cellular driver functionality.

Implements sf_cellular_api_t::close This function deactivates the PDP context and Update global variables for future use

Parameters

[in]	p_ctrl	Cellular control block

Return values

SSP_SUCCESS	Cellular Driver stop successfully.
SSP_ERR_NOT_OPEN	Device is not opened.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver un-initialization failed
SSP_ERR_IN_USE	Device already in used
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

Delete is used in close API where all resources are released, hence no need to check the return code

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_CommandSend()

ssp_err_t SF_CELLULAR_COMMON_CommandSend (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_cmd_resp_t *const *p_input_at_command*, sf_cellular_cmd_resp_t *const *p_output*, uint32_t const *timeout*)

Send AT command directly to Cellular Modem.

This API will send AT command provided by user to the Cellular Modem and will collect the response from the Modem and will send it back to the user. If Modem is in Data Mode when this API is called then Framework will first switch Modem to Command Mode, then send the AT command and collect the response and then switches the Modem back to Data Mode.

Parameters

[in]	p_ctrl	Pointer to the control block for the Cellular module.
[in]	p_input_at_command	Pointer to structure which contains Modem command to send
[in,out]	p_output	Pointer to buffer in which response will be sent to user, Also user will pass the size of the buffer which is pointed by p_output
[in]	timeout	Timeout for which framework will wait for response in milliseconds

Return values

SSP_SUCCESS	Successfully sent AT command and collected response from Cellular modem
SSP_ERR_CELLULAR_FAILED	Failed to either send AT command or collect response from Cellular modem
SSP_ERR_NOT_OPEN	Device is not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_IN_USE	Device already in use

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_FotaCheck()

ssp_err_t SF_CELLULAR_COMMON_FotaCheck (sf_cellular_ctrl_t *const *p_ctrl*, void * *p_fotacheck*)

Checks for available firmware upgrade.

Implements sf_cellular_api_t::fotaCheck Checks for available firmware upgrade.

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_fotacheck	Fota check specific structure

Return values

SSP_ERR_UNSUPPORTED	Functionality not supported

◆ SF_CELLULAR_COMMON_FotaStart()

ssp_err_t SF_CELLULAR_COMMON_FotaStart (sf_cellular_ctrl_t *const *p_ctrl*, void * *p_fotastart*)

Perform the firmware upgrade.

Implements sf_cellular_api_t::fotaStart Perform the firmware upgrade.

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_fotastart	Fota start specific structure

Return values

SSP_ERR_UNSUPPORTED	Functionality not supported

◆ SF_CELLULAR_COMMON_FotaStop()

ssp_err_t SF_CELLULAR_COMMON_FotaStop (sf_cellular_ctrl_t *const *p_ctrl*, void * *p_fotastop*)

Stop firmware upgrade.

Implements sf_cellular_api_t::fotaStop Stop firmware upgrade

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_fotastop	Fota stop specific structure

Return values

SSP_ERR_UNSUPPORTED	Functionality not supported

◆ SF_CELLULAR_COMMON_InfoGet()

ssp_err_t SF_CELLULAR_COMMON_InfoGet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_info_t *const *p_cellular_info*)

Get Cellular module information.

Implements sf_cellular_api_t::infoGet Get Cellular module information like chipset/driver information, RSSI, noise level, link quality

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_cellular_info	Cellular information structure

Return values

SSP_SUCCESS	Successfully get the Cellular information
SSP_ERR_NOT_OPEN	Driver not opened.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Failed reading Cellular information
SSP_ERR_IN_USE	Device already in used
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_NetworkConnect()

ssp_err_t SF_CELLULAR_COMMON_NetworkConnect (sf_cellular_ctrl_t *const *p_ctrl*)

Establishes the Data connection.

Implements sf_cellular_api_t::networkConnect Establishes the Network Connection

Parameters

[in]	p_ctrl	Cellular control block

Return values

SSP_SUCCESS	Successfully establishes the Network connection
SSP_ERR_NOT_OPEN	Device not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Failed to establish the Network Connection
SSP_ERR_IN_USE	Device already in used
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

Enter Data Mode

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_NetworkConnectWithCGDATA()

ssp_err_t SF_CELLULAR_COMMON_NetworkConnectWithCGDATA (sf_cellular_ctrl_t *const *p_ctrl*)

Establishes the Data connection using AT+CGDATA command. Limitation: This API activates only one PDP Context Id even though AT+CGDATA command actually supports activation of multiple Context Ids in single command.

Implements sf_cellular_api_t::networkConnect Establishes the Network Connection

Parameters

[in]	p_ctrl	Cellular control block

Return values

SSP_SUCCESS	Successfully establishes the Network connection
SSP_ERR_NOT_OPEN	Device not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Failed to establish the Network Connection
SSP_ERR_IN_USE	Device already in used
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

Enter Data Mode

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_NetworkDisconnect()

ssp_err_t SF_CELLULAR_COMMON_NetworkDisconnect (sf_cellular_ctrl_t *const *p_ctrl*)

Terminates the connection.

Implements sf_cellular_api_t::networkDisconnect

Parameters

[in]	p_ctrl	Cellular control block

Return values

SSP_SUCCESS	Successfully disconnect the connection
SSP_ERR_NOT_OPEN	Cellular driver is not opened
SSP_ERR_CELLULAR_FAILED	Failed to terminate the network connection
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

Exit Data Mode

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_NetworkStatusGet()

ssp_err_t SF_CELLULAR_COMMON_NetworkStatusGet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_network_status_t * *p_network_status*)

Get Network Status information.

Implements sf_cellular_api_t::networkStatusGet

Parameters

[in]	p_ctrl	Cellular control block
[out]	p_network_status	Cellular network structure

Return values

SSP_SUCCESS	Successfully read the Network status information
SSP_ERR_NOT_OPEN	Cellular driver is not opened
SSP_ERR_CELLULAR_FAILED	Failed reading Network Status information.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_Open()

ssp_err_t SF_CELLULAR_COMMON_Open (sf_cellular_ctrl_t * *p_ctrl*, sf_cellular_cfg_t const *const *p_cfg*)

Initialize Cellular driver.

Implements sf_cellular_api_t::open Initializes Cellular Driver and Configure the parameters as per the p_cfg Update global variables for future use.

Parameters

[out]	p_ctrl	Cellular control block
[in]	p_cfg	Cellular configuration structure

Return values

SSP_SUCCESS	Driver initialization successfully.
SSP_ERR_ALREADY_OPEN	Cellular Driver is already opened.
SSP_ERR_CELLULAR_CONFIG_FAILED	Cellular module Configuration failed
SSP_ERR_CELLULAR_INIT_FAILED	Cellular module initialization failed
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver initialization failed
SSP_ERR_IN_USE	Device already in used

Create Mutex for Synchronization

Get Mutex Lock

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_ProvisioningGet()

ssp_err_t SF_CELLULAR_COMMON_ProvisioningGet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_provisioning_t *const *p_cellular_provisioning*)

Reads the provisioning information.

Implements sf_cellular_api_t::provisioningGet Reads Cellular's provisioning information

Parameters

[in]	p_ctrl	Cellular control block
[out]	p_cellular_provisioning	Cellular provisioning structure

Return values

SSP_SUCCESS	Successfully read the provisioning information.
SSP_ERR_NOT_OPEN	Device not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Reading provisioning information failed
SSP_ERR_IN_USE	Device already in used
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

Copy provisioning info to driver structure

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_ProvisioningSet()

ssp_err_t SF_CELLULAR_COMMON_ProvisioningSet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_provisioning_t const *const *p_cellular_provisioning*)

Sets the provisioning information.

Implements sf_cellular_api_t::provisioningSet Sets Cellular's provisioning information

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_cellular_provisioning	Cellular provisioning structure

Return values

SSP_SUCCESS	Successfully set the provisioning information.
SSP_ERR_NOT_OPEN	Device not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Provisioning configuration failed
SSP_ERR_IN_USE	Device already in used
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command
SSP_ERR_CELLULAR_INIT_FAILED	Failed due to invalid response received from modem

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_SimIDGet()

ssp_err_t SF_CELLULAR_COMMON_SimIDGet (sf_cellular_ctrl_t *const *p_ctrl*, uint8_t * *p_sim_id*)

Get SIM ID.

Implements sf_cellular_api_t::simGetID Get SIM ID

Parameters

[in]	p_ctrl	Cellular control block
[out]	p_sim_id	SIM ID

Return values

SSP_SUCCESS	Successfully get the SIM ID.
SSP_ERR_CELLULAR_FAILED	Failed to get the SIM ID
SSP_ERR_NOT_OPEN	Device is not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_SimLock()

ssp_err_t SF_CELLULAR_COMMON_SimLock (sf_cellular_ctrl_t *const *p_ctrl*, uint8_t *const *p_pin*)

Lock the SIM.

Implements sf_cellular_api_t::simLock

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_pin	SIM Pin

Return values

SSP_SUCCESS	Successfully lock the SIM
SSP_ERR_NOT_OPEN	Cellular driver is not opened
SSP_ERR_CELLULAR_FAILED	Failed to Lock the SIM
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_SimPinSet()

ssp_err_t SF_CELLULAR_COMMON_SimPinSet (sf_cellular_ctrl_t *const *p_ctrl*, uint8_t *const *p_old_pin*, uint8_t *const *p_new_pin*)

Set the SIM PIN.

Implements sf_cellular_api_t::simSetPin

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_old_pin	Old SIM Pin
[in]	p_new_pin	New SIM Pin

Return values

SSP_SUCCESS	Successfully set SIM Pin
SSP_ERR_NOT_OPEN	Cellular driver is not opened
SSP_ERR_CELLULAR_FAILED	Failed to set the SIM Pin
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_SimUnlock()

ssp_err_t SF_CELLULAR_COMMON_SimUnlock (sf_cellular_ctrl_t *const *p_ctrl*, uint8_t *const *p_pin*)

Unlock the SIM.

Implements sf_cellular_api_t::simUnlock

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_pin	SIM Pin

Return values

SSP_SUCCESS	Successfully unlock the SIM
SSP_ERR_NOT_OPEN	Cellular driver is not opened
SSP_ERR_CELLULAR_FAILED	Failed to unlock the SIM
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_IN_USE	Device already in use
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

◆ SF_CELLULAR_COMMON_StatisticsGet()

ssp_err_t SF_CELLULAR_COMMON_StatisticsGet (sf_cellular_ctrl_t *const *p_ctrl*, sf_cellular_stats_t *const *p_cellular_device_stats*)

Get the interface statistics.

Implements sf_cellular_api_t::statisticsGet Collect the statistics information of Cellular interface

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_cellular_device_stats	Cellular statistic structure

Return values

SSP_SUCCESS	Successfully get the Statistics information.
SSP_ERR_UNSUPPORTED	Functionality is not supported.
SSP_ERR_NOT_OPEN	Device not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Failed Reading statistics information
SSP_ERR_IN_USE	Device already in used
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

◆ SF_CELLULAR_COMMON_Transmit()

ssp_err_t SF_CELLULAR_COMMON_Transmit (sf_cellular_ctrl_t *const *p_ctrl*, uint8_t *const *p_buf*, uint32_t *length*)

Passes packet buffer to PPP stack for transmission.

Implements sf_cellular_api_t::transmit Send packet buffer to PPP stack

Parameters

[in]	p_ctrl	Cellular control block
[in]	p_buf	transmit byte buffer pointer
[in]	length	Length of data

Return values

SSP_SUCCESS	Successfully send the packet buffer.
SSP_ERR_NOT_OPEN	Device not opened
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Transmitting Data failed
SSP_ERR_IN_USE	Device already in used
SSP_ERR_CELLULAR_INVALID_STATE	Module in Data mode can't send AT command

Get Mutex

The return code is not checked here because tx_mutex_put cannot fail when called with a mutex owned by the current thread. The mutex is owned by the current thread because this call follows a successful call to tx_mutex_get.

Detailed Description

SF_CELLULAR Socket Framework API on RYZ014CATM1.

Function Documentation

◆ accept()

int accept (int *sockfd*, struct sockaddr * *p_cliaddr*, socklen_t * *p_addrlen*)

This accepts connection from remote socket.

Implements accept This function accepts connection from remote socket. This API is used only with socket type STREAM. The call is blocked if no connection is present or the socket is blocking.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_cliaddr	Remote machine Network address (Can be NULL)
[out]	p_addrlen	Size of Socket address structure(Can be NULL)

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error accepting the connection or invalid input parameters

Returns

Otherwise Connection is received successfully.

◆ bind()

int bind (int *sockfd*, const struct sockaddr * *p_local_sock_addr*, socklen_t *addrlen*)

This binds socket to IP address.

Implements bind This function binds socket to given IP address and port.

Parameters

sockfd	Socket file descriptor
p_local_sock_addr	Socket address structure
addrlen	Size of Socket address structure

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Binding socket failed or invalid input parameters

Returns

Otherwise Socket is bound successfully.

◆ close()

int close (int *sockfd*)

This closes socket.

Implements close Close opened socket

Parameters

[in]	sockfd	Socket file descriptor

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Closing socket failed or invalid input parameters

Returns

Otherwise Socket is closed successfully.

◆ connect()

int connect (int *sockfd*, const struct sockaddr * *p_serv_addr*, socklen_t *addrlen*)

This connects with remote socket(stream socket).

Implements connect This function connects local socket with remote socket. The call is blocked until a connection is established or error is returned.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_serv_addr	Remote machine Network address
[in]	addrlen	Size of Socket address structure

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error occurred or invalid input parameters

Returns

Otherwise Socket is connected successfully.

◆ getsockopt()

int getsockopt (int *sockfd*, int *level*, int *optname*, void * *p_optval*, socklen_t * *p_optlen*)

This gets socket specific options.

This reads socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Implements getsockopt This gets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[out]	p_optval	Socket option value
[out]	p_optlen	Size of Socket option

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error reading socket option or invalid socket descriptor

Returns

Otherwise Socket option read successfully.

◆ listen()

int listen (int *sockfd*, int *backlog*)

This listens for connection on socket.

Implements listen This function listen for connection on socket.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	backlog	number of maximum connection can be accepted

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Failed to set socket in Listen mode or invalid input parameters

Returns

Otherwise Set socket in Listen mode successfully.

◆ recv()

ssize_t recv (int *sockfd*, void * *p_buf*, size_t *length*, int *flags*)

This receives data over STREAM socket.

Implements receive This function receives data on a stream socket in connected state. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket File Descriptor
[out]	p_buf	Buffer to read data
[out]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Failed to receive data or invalid input parameters

Returns

Otherwise Data received successfully.

◆ recvfrom()

ssize_t recvfrom (int *sockfd*, void * *p_buf*, size_t *length*, int *flags*, struct sockaddr * *p_src_addr*, socklen_t * *p_addrlen*)

This receives data over DGRAM socket.

Implements recvfrom This function receives data on a dgram socket. If no packet is available, the socket is blocked until it is set to non-blocking. The application must provide a valid buffer to receive the payload. If the buffer length is smaller than the available payload, the API will do a partial copy, and hold on the rest of the payload for a subsequent call to the API.

Parameters

[in]	sockfd	Socket file descriptor
[out]	p_buf	Data buffer pointer to read data
[in]	length	Length of data to read
[in]	flags	Flags
[in]	p_src_addr	Remote machine network address (Can be NULL)
[in]	p_addrlen	Size of Remote machine network (Can be NULL)

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error receiving data or invalid input parameters

Returns

Otherwise Numbers of data bytes received successfully.

◆ select()

int select (int *nfds*, fd_set * *p_readfds*, fd_set * *p_writefds*, fd_set * *p_exceptfds*, struct timeval * *p_timeout*)

This waits for any activity on socket.

Implements select Allow an application thread to block on a given socket handle for a specified time period. This API checks for any activity on specified socket, for example arrival of a packet at the receive queue.

Parameters

[in]	nfds	Number of socket fds in to check
[in]	p_readfds	Read socket fd set
[in]	p_writefds	Write socket fd set - API does not used this parameter
[in]	p_exceptfds	Exceptional socket fd set - API does not used this parameter
[in]	p_timeout	Timeout

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Timeout occurred, no activity or invalid socket descriptor

Returns

Otherwise Activity detected(Packet available).

◆ send()

ssize_t send (int *sockfd*, const void * *p_buf*, size_t *length*, int *flags*)

This sends data over STREAM socket.

Implements send This function sends data on a stream socket in connected state.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data to send
[in]	length	Data length
[in]	flags	Socket flag

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Failed to send data or invalid input parameters

Returns

Otherwise Data sent successfully.

◆ sendto()

ssize_t sendto (int *sockfd*, const void * *p_buf*, size_t *length*, int *flags*, const struct sockaddr * *p_dest_addr*, socklen_t *addrlen*)

This sends data over DGRAM socket.

Implements sendto This function sends data to remote.

Parameters

[in]	sockfd	Socket File Descriptor
[in]	p_buf	Buffer data pointer
[in]	length	Length of data
[in]	flags	Flag
[in]	p_dest_addr	Address of remote UDP server
[in]	addrlen	Size of Network address structure

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error Sending data or invalid input parameters

Returns

Otherwise Numbers of bytes sent successfully.

◆ setsockopt()

int setsockopt (int *sockfd*, int *level*, int *optname*, const void * *p_optval*, socklen_t *optlen*)

This sets socket specific options.

This updates socket specific options. Quectel CATM1 supports following socket options SO_SNDBUF: Transmission packet size TCP_MAX_RETRIES: Maximum Number of retransmission TCP_MAX_RTO: Maximum interval time of TCP retransmission.

Implements setsockopt This sets options for an existing socket.

Parameters

[in]	sockfd	Socket file descriptor
[in]	level	Level
[in]	optname	Socket option name
[in]	p_optval	Socket option value
[in]	optlen	Size of Socket option

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Error setting socket option or invalid socket descriptor

Returns

Otherwise Socket option set successfully.

◆ SF_CELLULAR_RYZ014CATM1_SOCKET_Close()

ssp_err_t SF_CELLULAR_RYZ014CATM1_SOCKET_Close (sf_cellular_socket_ctrl_t *const *p_ctrl*)

Close the Cellular Device driver.

Implements sf_cellular_socket_api_t::close Calls the low level Cellular device driver's Close API to close the cellular Driver.

Return values

SSP_SUCCESS	Cellular Driver stop successfully.
SSP_ERR_NOT_OPEN	Device is not opened.
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver un-initialization failed
SSP_ERR_IN_USE	Device already in used

SF Cellular instance variable

SF Cellular API structure variable

SF Cellular Stack control block structure

Close cellular framework

◆ SF_CELLULAR_RYZ014CATM1_SOCKET_Open()

ssp_err_t SF_CELLULAR_RYZ014CATM1_SOCKET_Open (sf_cellular_socket_ctrl_t * *p_ctrl*, sf_cellular_socket_cfg_t const *const *p_cfg*)

Open the Cellular Device driver to use the Socket Layer on Cellular Driver On-Chip stack.

Implements sf_cellular_socket_api_t::open Calls the low level Cellular device driver's Open API to Initialize the Cellular Device Driver, for using Socket Layer on On-Chip stack.

Return values

SSP_SUCCESS	Driver initialization successfully.
SSP_ERR_ALREADY_OPEN	Cellular RYZ014CATM1 Driver is already opened.
SSP_ERR_CELLULAR_CONFIG_FAILED	Cellular RYZ014CATM1 module Configuration failed
SSP_ERR_CELLULAR_INIT_FAILED	Cellular RYZ014CATM1 module initialization failed
SSP_ERR_ASSERTION	Argument NULL is passed
SSP_ERR_CELLULAR_FAILED	Driver initialization failed
SSP_ERR_IN_USE	Device already in used

SF Cellular instance variable

SF Cellular API structure variable

SF Cellular configuration structure variable

SF Cellular Stack control block structure

Initialize Cellular Modem

Initialize Socket Interface global variable

◆ SF_CELLULAR_RYZ014CATM1_SOCKET_PING()

ssp_err_t SF_CELLULAR_RYZ014CATM1_SOCKET_PING (sf_cellular_socket_ctrl_t *const *p_ctrl*, ULONG * *p_ip_address*, uint32_t *count*, uint32_t *interval_ms*)

Ping an IP address on the network.

Parameters

[in]	p_ctrl	Pointer to control structure.
[in]	p_ip_address	Pointer to IP address.
[in]	count	Number of ping attempts.
[in]	interval_ms	Interval between ping attempts.

Return values

SSP_SUCCESS	Function completed successfully.
SSP_ERR_CELLULAR_FAILED	Driver initialization failed.
SSP_ERR_IN_USE	Device already in use

Get mutex lock

Ping specified IP address

Release the mutex

◆ SF_CELLULAR_RYZ014CATM1_SOCKET_VersionGet()

ssp_err_t SF_CELLULAR_RYZ014CATM1_SOCKET_VersionGet (ssp_version_t *const *p_version*)

This function gets the version information of the underlying driver.

Implements sf_cellular_socket_api_t::versionGet

Parameters

[out]	p_version	Driver version information

Return values

SSP_ERR_ASSERTION	Argument NULL is passed
SSP_SUCCESS	Successfully read version information

◆ socket()

int socket (int *domain*, int *type*, int *protocol*)

This creates socket for communication.

Implements socket Creates socket with given parameters.

Parameters

[in]	domain	Network Domain
[in]	type	Socket type
[in]	protocol	Protocol type

Return values

SF_CELLULAR_RYZ014CATM1_SOCKET_INVALID_FD	Socket creation failed

Returns

Otherwise Socket created successfully

5.1.3 Framework Layer

Renesas Synergy Software Package Reference

Modules

ADC periodic Framework

RTOS-integrated ADC Framework.

Audio Framework

RTOS-integrated Audio Framework.

DAC Audio Playback Framework

RTOS-integrated DAC implementation of Audio Playback Interface.

I2S Audio Playback Framework

RTOS-integrated I2S implementation of Audio Playback Interface.

ADC Audio recording Framework

RTOS-integrated ADC implementation of Audio Recording Interface.

	I2S Audio recording Framework I2S implementation of Audio Recording Interface.
	BLOCK_MEDIA_LEVELX_NOR RTOS-integrated Block Media framework for LEVELX driver.
	BLOCK_MEDIA_QSPI RTOS-integrated Block Media framework for QSPI driver.
	BLOCK_MEDIA_RAM RTOS-integrated Block Media framework for RAM.
	BLOCK_MEDIA_SDMMC RTOS-integrated Block Media framework for SDMMC driver.

	Console Framework RTOS-integrated Console Framework.
	SSP Crypto Common Framework RTOS-integrated Crypto Common Framework Module.
	SSP Crypto Cipher Framework RTOS-integrated Crypto Cipher Framework Module.
	SSP Crypto Hash Framework RTOS-integrated Crypto HASH Framework Module.

	SSP Crypto Key Framework RTOS-integrated Crypto Key Framework Module.
	SSP Crypto Key Installation Framework RTOS-integrated Crypto Key Installation Framework Module.
	SSP Crypto Signature Framework RTOS-integrated Crypto Signature Framework Module.
	SSP Crypto TRNG Framework RTOS-integrated Crypto TRNG Framework Module.
	FX_IO Framework FileX adaptation layer for block media device drivers.
	GUIX Synergy Port GUIX adaptation layer.
	EL_LX_NOR LevelX NOR driver implementation.
	USB Communication Framework V2 RTOS-integrated USBX CDC ACM device implementation.
	External IRQ Framework RTOS-integrated external IRQ Framework.
	I2C Framework RTOS-integrated I2C Framework.
	JPEG Framework RTOS-integrated JPEG Framework.

	Memory framework RTOS-integrated Memory framework for QSPI NOR driver.
	Messaging Framework RTOS-integrated Messaging Framework implementation.
	Power Profiles Framework V2 Power Profiles Framework.
	SPI Framework RTOS-integrated SPI Framework.
	Thread Monitor Framework Framework module providing monitoring of threads.
	CTSU V2 Framework CTSU V2 Framework.
	Touch Panel V2 Framework RTOS-integrated touch panel V2 Framework implementation touch chips.
	UART Framework Instance RTOS-integrated Communications Framework UART implementation.
	NetX Synergy Port RTOS-integrated NetX Ethernet driver for the Renesas Synergy software and Synergy Ethernet IP.
	NetX Synergy Port PHY Driver Interface between SF_EL_NX Ethernet framework and PHY driver.
	BLE Framework on RL78G1D RTOS-integrated BLE Framework example. Implementation of RL78G1D BLE Driver. It implements the following interfaces:

BLE On-Board Profile Framework on RL78G1D

RTOS-integrated BLE On-Board Profile Framework example. Implementation of RL78G1D BLE On-Board Profile Driver. It implements the following interfaces:

Cellular Framework Example using Quectel CATM1

RTOS-integrated Cellular Framework example. Implementation of Cellular Quectel CATM1 Driver. It implements the following interfaces:

BSD Socket over Quectel CATM1 on-chip stack

RTOS-integrated Cellular Socket Framework example. Implementation of Quectel CATM1 Socket layer over Quectel CATM1 On-Chip stack It implements the following interfaces:

Cellular Framework Example using RYZ014 CATM1

RTOS-integrated Cellular Framework example. Implementation of Cellular RYZ014 CATM1 Driver. It implements the following interfaces:

BSD Socket over RYZ014CATM1 on-chip stack

RTOS-integrated Cellular Socket Framework example. Implementation of RYZ014CATM1 Socket layer over RYZ014CATM1 On-Chip stack It implements the following interfaces:

Touch Panel Framework Example for FT5X06

RTOS-integrated touch panel chip ft5x06 example. Implementation of ft5x06 touch chip Driver. It implements the following interfaces:

Touch Panel Framework Example for SX8654

RTOS-integrated touch panel chip sx8654 example. Implementation of sx8654 touch chip Driver. It implements the following interfaces:

WiFi Framework on GT202

RTOS-integrated WiFi Framework example. Implementation of Atheros WiFi Driver. It implements the following interfaces:

WiFi On Chip Stack on GT202

	RTOS-integrated WiFi On Chip Stack Framework example. Implementation of Atheros WiFi Driver. It implements the following interfaces:
	BSD Socket on GT202 Implementation of GT202 Socket layer over GT202 On-Chip stack.
	WiFi Framework on QCA4010 RTOS-integrated WiFi Framework example. Implementation of Silex ULPGN WiFi Driver. It implements the following interfaces:
	WiFi On Chip Stack on QCA4010 RTOS-integrated WiFi On Chip Stack Framework example. Implementation of SILEX WiFi Driver. It implements the following interfaces:
	Socket on QCA4010 Implementation of QCA4010 Socket layer over QCA4010 On-Chip stack.
	USBX Framework RTOS-integrated USBX adaptation framework for Synergy. Implements USB HOST and DEVICE low level device drivers.
	2D Drawing Engine Support Framework

Detailed Description

Detailed Description

RTOS-integrated ADC Framework.

Macro Definition Documentation

◆ SF_ADC_PERIODIC_CODE_VERSION_MAJOR

#define SF_ADC_PERIODIC_CODE_VERSION_MAJOR (2U)
Version of code that implements the API defined in this file

Function Documentation

◆ app_callback()

void app_callback (sf_adc_periodic_callback_args_t * *p_args*)

Callback function that will be called when the requested number of sampling iterations are complete

If the event indicates that new data is available

Assuming only one channel is configured, data for that channel is available via the buffer index. Refer to the usage manual for more details.

◆ SF_ADC_PERIODIC_Close()

ssp_err_t SF_ADC_PERIODIC_Close (sf_adc_periodic_ctrl_t *const *p_api_ctrl*)

The close function acquires the unit's mutex, closes all lower level drivers, releases and deletes the mutex.

Return values

SSP_SUCCESS	Successful close.
SSP_ERR_ASSERTION	One or more pointers point to NULL.
SSP_ERR_NOT_OPEN	Driver control block not valid. Call SF_ADC_PERIODIC_Open to configure.

Get mutex since this will access hardware registers

Close the HAL layer modules

Delete RTOS services used

Clear information from control block so other functions know this instance is closed

◆ sf_adc_periodic_demo_task()

void sf_adc_periodic_demo_task (ULONG *thread_input*)
Initialize the framework
Check for error condition
Start the scan process
Check for error condition
Stop the scan process
Check for error condition
Restart the scan process
Check for error condition
Stop the scan process
Check for error condition
Close the framework
Check for error condition

◆ SF_ADC_PERIODIC_Open()

ssp_err_t SF_ADC_PERIODIC_Open (sf_adc_periodic_ctrl_t *const *p_api_ctrl*, sf_adc_periodic_cfg_t const *const *p_cfg*)

Configures periodic ADC framework and optionally starts the timer.

The SF_ADC_PERIODIC_Open function acquires a mutex for the ADC Unit used, then calls the driver .open function in the p_api parameter. The mutex is released following the driver layer open function.

Return values

SSP_SUCCESS	Initialization was successful.
SSP_ERR_ASSERTION	One of the following parameters may be NULL: p_api_ctrl or p_cfg. See HAL driver for other possible causes.
SSP_ERR_INVALID_ARGUMENT	An invalid argument is used
SSP_ERR_INTERNAL	An internal ThreadX error has occurred. This is typically a failure to create/use a mutex or to create an internal thread.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes.

Save driver structure pointer for use in other framework layer functions

Create a mutex

Initialize the HAL layer

If any of the HAL layer initializations failed, then delete the mutex and exit the function with the error code

Delete the mutex.

Mark control block open so other tasks know it is valid

◆ SF_ADC_PERIODIC_Start()

ssp_err_t SF_ADC_PERIODIC_Start (sf_adc_periodic_ctrl_t *const *p_api_ctrl*)

Gets mutex, starts the periodic ADC scan, and releases mutex.

Warning

The driver will enable the ADC to be triggered via timer event; there will be a time delay from the time this function is called to the time the hardware timer count expires and triggers the scan.

Return values

SSP_SUCCESS	ADC Periodic Scan started successfully.
SSP_ERR_ASSERTION	One or more pointers point to NULL.
SSP_ERR_NOT_OPEN	Driver control block not valid. Call SF_ADC_PERIODIC_Open to configure.
SSP_ERR_INTERNAL	An internal ThreadX error has occurred. This is typically a failure to create/use a mutex or to create an internal thread.
SSP_ERR_IN_USE	The module is currently busy performing another operation

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls:

- adc_api_t::scanStart
- timer_api_t::start

Get mutex, start timer, then release mutex

Enable the ADC to receive hardware triggers

If the scan was successfully enabled in the ADC HAL,

Start the timer to generate the ADC trigger events

Return the mutex.

◆ SF_ADC_PERIODIC_Stop()

ssp_err_t SF_ADC_PERIODIC_Stop (sf_adc_periodic_ctrl_t *const *p_api_ctrl*)

Gets mutex, stops the periodic ADC scan, and releases mutex.

Return values

SSP_SUCCESS	Periodic ADC scan stopped successfully.
SSP_ERR_ASSERTION	One or more pointers point to NULL..
SSP_ERR_NOT_OPEN	Driver control block not valid. Call SF_ADC_PERIODIC_Open to configure.
SSP_ERR_INTERNAL	An internal ThreadX error has occurred. This is typically a failure to create/use a mutex or to create an internal thread.
SSP_ERR_IN_USE	The module is currently busy performing another operation

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls:

- timer_api_t::stop

Get mutex, stop timer, then release mutex

Return the mutex.

◆ SF_ADC_PERIODIC_VersionGet()

ssp_err_t SF_ADC_PERIODIC_VersionGet (ssp_version_t *const *p_version*)

Gets version and stores it in provided pointer p_version.

Return values

SSP_SUCCESS	Version returned successfully.
SSP_ERR_ASSERTION	Parameter p_version was null.

sf_adc_periodic_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » ADC periodic Framework

#include <sf_adc_periodic.h>

Data Fields

uint32_t	open Used by driver to check if pointer to control block is valid.
TX_MUTEX	mutex Mutex used to protect access to lower level driver hardware registers.
adc_instance_t const *	p_lower_lvl_adc Pointer to the ADC instance.
timer_instance_t const *	p_lower_lvl_timer Pointer to the Timer instance.
transfer_instance_t const *	p_lower_lvl_transfer Pointer to the Transfer instance.
void const *volatile	p_src_transfer Source pointer for the low level transfer method.
uint16_t *	p_data_buffer Pointer to the buffer that will store the samples.
uint32_t	data_buffer_length Length of the data buffer that will store the samples.
uint32_t	data_buffer_index Index of the data buffer where data is to be written to next.
uint32_t	sample_count Samples per channel to be buffered before notifying the app.
uint32_t	current_sample_count Current sample count of the output buffer.

uint32_t	dtc_transfer_length Total Length of DTC transfer for requested number of samples.
uint32_t	size_multiplier Multiplier used to treat p_data_buffer as a 32-bit array.
uint16_t	length Length of transfer.
bool	lower_level Used to detect lower level driver.
void(*	p_callback)(sf_adc_periodic_callback_args_t *p_args) Callback function.
void const *	p_context Placeholder for user data.

Detailed Description

Channel instance control block. DO NOT INITIALIZE. Initialization occurs when SF_ADC_PERIODIC_Open is called

Detailed Description

RTOS-integrated Audio Framework.

Summary

This module is a ThreadX-aware Audio Framework. The module implements Audio Framework Interface.

Name of module used by error logger macro

Macro Definition Documentation

◆ SF_AUDIO_PLAYBACK_CODE_VERSION_MAJOR

#define SF_AUDIO_PLAYBACK_CODE_VERSION_MAJOR (2U)
Version of code that implements the API defined in this file

◆ SF_AUDIO_PLAYBACK_STACK_SIZE

#define SF_AUDIO_PLAYBACK_STACK_SIZE (SF_AUDIO_PLAYBACK_CFG_THREAD_STACK_SIZE)
Audio playback internal thread stack size. Varies by application, but rarely requires more than 256 bytes.

Function Documentation

◆ SF_AUDIO_PLAYBACK_Close()

ssp_err_t SF_AUDIO_PLAYBACK_Close (sf_audio_playback_ctrl_t *const *p_api_ctrl*)

Implements sf_audio_playback_api_t::close.

Return values

SSP_SUCCESS	Audio instance successfully closed
SSP_ERR_ASSERTION	p_ctrl is NULL
SSP_ERR_NOT_OPEN	The stream control block p_ctrl is not initialized.

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is not reentrant.

Mark stream as unused in hardware control block and determine if all streams are closed.

Mark hardware control block as unused so it can be reconfigured.

Close lower level drivers

Delete RTOS services used

Mark control block as unused so it can be reconfigured.

◆ SF_AUDIO_PLAYBACK_Open()

ssp_err_t SF_AUDIO_PLAYBACK_Open (sf_audio_playback_ctrl_t *const *p_api_ctrl*, sf_audio_playback_cfg_t const *const *p_cfg*)

Implements sf_audio_playback_api_t::open.

Return values

SSP_SUCCESS	Audio hardware successfully configured.
SSP_ERR_ASSERTION	A pointer is NULL or a parameter is invalid.
SSP_ERR_OUT_OF_MEMORY	The number of streams open at once is limited to SF_AUDIO_PLAYBACK_CFG_MAX_STREAMS. If this number is exceeded, an out of memory error occurs.
SSP_ERR_INTERNAL	An internal ThreadX error has occurred. This is typically a failure to create/use a mutex.

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is not reentrant.

Open hardware if it is not already open.

Enter a critical section before checking the common instance mutex status.

Check if common instance mutex is already created. If not then create the mutex.

Create common_instance_mutex to protect common initialization, including initialization of shared event flags, audio playback thread and lower level hardware.

If mutex create fails, return error.

Exit critical section

Acquire the mutex before accessing the shared resource. Try again if the mutex was deleted in close.

Create event flags to notify playback thread when playback of a buffer is complete.

Store stream pointer in common control block.

Release the mutex.

Mark stream opened so it can be used by other API's.

◆ SF_AUDIO_PLAYBACK_Pause()

ssp_err_t SF_AUDIO_PLAYBACK_Pause (sf_audio_playback_ctrl_t *const *p_api_ctrl*)

Implements sf_audio_playback_api_t::pause.

Return values

SSP_SUCCESS	Audio playback pause message sent to audio playback thread for this stream.
SSP_ERR_ASSERTION	p_ctrl is NULL
SSP_ERR_NOT_OPEN	The stream control block p_ctrl is not initialized.

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is reentrant.

Send message with pause event to audio thread.

◆ SF_AUDIO_PLAYBACK_Resume()

ssp_err_t SF_AUDIO_PLAYBACK_Resume (sf_audio_playback_ctrl_t *const *p_api_ctrl*)

Implements sf_audio_playback_api_t::resume.

Return values

SSP_SUCCESS	Audio playback resume message sent to audio playback thread for this stream.
SSP_ERR_ASSERTION	p_ctrl is NULL
SSP_ERR_NOT_OPEN	The stream control block p_ctrl is not initialized.

Note

This function is reentrant.

Send message with resume event to audio thread.

◆ SF_AUDIO_PLAYBACK_Start()

ssp_err_t SF_AUDIO_PLAYBACK_Start (sf_audio_playback_ctrl_t *const *p_api_ctrl*, sf_audio_playback_data_t *const *p_data*, UINT const *timeout*)

Implements sf_audio_playback_api_t::start.

Return values

SSP_SUCCESS	Buffer successfully sent to audio playback thread
SSP_ERR_ASSERTION	p_ctrl is NULL
SSP_ERR_NOT_OPEN	The stream control block p_ctrl is not initialized.

Note

This function is reentrant.

Ensure that audio data is only posted from the current stream owner.

Store new stream owner if stream is unowned.

Set message header to audio start event. Set instance to stream instance.

Send message with audio data to audio thread.

◆ SF_AUDIO_PLAYBACK_Stop()

ssp_err_t SF_AUDIO_PLAYBACK_Stop (sf_audio_playback_ctrl_t *const *p_api_ctrl*)

Implements sf_audio_playback_api_t::stop.

Return values

SSP_SUCCESS	Audio playback stop message sent to audio playback thread for this stream.
SSP_ERR_ASSERTION	p_ctrl is NULL
SSP_ERR_NOT_OPEN	The stream control block p_ctrl is not initialized.

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is reentrant.

Send message with stop event to audio thread.

◆ SF_AUDIO_PLAYBACK_VersionGet()

ssp_err_t SF_AUDIO_PLAYBACK_VersionGet (ssp_version_t *const *p_version*)

Implements sf_audio_playback_api_t::versionGet.

Return values

SSP_SUCCESS	Version returned successfully.
SSP_ERR_ASSERTION	Parameter p_version was null.

◆ SF_AUDIO_PLAYBACK_VolumeSet()

ssp_err_t SF_AUDIO_PLAYBACK_VolumeSet (sf_audio_playback_ctrl_t *const *p_api_ctrl*, uint8_t const *volume*)

Implements sf_audio_playback_api_t::volumeSet.

Return values

SSP_SUCCESS	Audio playback software volume level updated (applies to all streams).
SSP_ERR_ASSERTION	p_ctrl is NULL
SSP_ERR_NOT_OPEN	The stream control block p_ctrl is not initialized.

Update volume in control block.

sf_audio_playback_common_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » Audio Framework

#include <sf_audio_playback.h>

Public Member Functions

uint8_t stack [SF_AUDIO_PLAYBACK_STACK_SIZE]	BSP_ALIGN_VARIABLE_V2 (BSP_STACK_ALIGNMENT)

Data Fields

uint32_t	open Used to determine if driver is initialized.

void const *	p_next_buffer Pointer to next buffer (to be played when the current buffer completes).
uint32_t	next_length Length of next buffer (to be played when the current buffer completes).
sf_message_instance_t const *	p_message Pointer to message control block.
TX_QUEUE *	p_queue Queue subscribed to SF_MESSAGE_EVENT_CLASS_AUDIO events.
sf_audio_playback_hw_instance_t const *	p_lower_lvl_hw Hardware API's used.
sf_audio_playback_instance_ctrl_t *	p_stream [SF_AUDIO_PLAYBACK_CFG_MAX_STREAMS] Stream specific data.
TX_THREAD	thread Main audio thread.
TX_EVENT_FLAGS_GROUP	flags Event flags used to end wait in audio thread.
sf_audio_playback_data_type_t	data_type Sample format required by the hardware.
uint8_t	volume Volume from 0 (muted) to 255 (maximum, default on open).

uint8_t	buffer_index Which ping pong buffer to use.
int16_t	samples [2][SF_AUDIO_PLAYBACK_CFG_BUFFER_SIZE_BYTES/sizeof(int16_t)]
volatile bool	playing State of audio instance (currently playing if true)
TX_MUTEX	common_instance_mutex Mutex for internal use.

Detailed Description

Audio common instance control block. DO NOT INITIALIZE. Initialization the first time sf_audio_playback_api_t::open is called. Shared by all streams.

Member Function Documentation

◆ BSP_ALIGN_VARIABLE_V2()

uint8_t stack [SF_AUDIO_PLAYBACK_STACK_SIZE]
sf_audio_playback_common_instance_ctrl_t::BSP_ALIGN_VARIABLE_V2 (BSP_STACK_ALIGNMENT)

Stack for audio thread.

Field Documentation

◆ samples

int16_t sf_audio_playback_common_instance_ctrl_t::samples[2][SF_AUDIO_PLAYBACK_CFG_BUFFER_SIZE_BYTES/sizeof(int16_t)]

Ping pong buffers, used to store converted data during transfer.

The documentation for this struct was generated from the following file:

- sf_audio_playback.h

sf_audio_playback_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » Audio Framework

#include <sf_audio_playback.h>

Data Fields

uint32_t	open Used to determine if driver is initialized.
TX_THREAD *	p_owner
void(*	p_callback)(sf_message_callback_args_t *p_args)
uint8_t	class_instance Class instance used to identify the stream to the messaging framework.
uint32_t	samples_remaining Internal state of data samples remaining for this stream.
uint32_t	samples_total Total number of samples to play (independent of sample size like 8/12/16).
uint32_t	index Internal state of current data index for this stream.
uint32_t	end Used to track completion of looped playback.
sf_audio_playback_data_t *	p_data [2] Audio data read from queue.
sf_audio_playback_status_t	status Status of current stream.

sf_audio_playback_common_instance_ctrl_t *	p_common_ctrl

Detailed Description

Audio stream instance control block. DO NOT INITIALIZE. Initialization occurs when sf_audio_playback_api_t::open is called.

Field Documentation

◆ p_callback

void(* sf_audio_playback_instance_ctrl_t::p_callback) (sf_message_callback_args_t *p_args)
Callback called when playback of a buffer passed to sf_audio_playback_api_t::start is complete.

◆ p_common_ctrl

sf_audio_playback_common_instance_ctrl_t* sf_audio_playback_instance_ctrl_t::p_common_ctrl
Pointer to the hardware control block used by this stream.

◆ p_owner

TX_THREAD* sf_audio_playback_instance_ctrl_t::p_owner
Pointer to thread that began the stream at this index. Used to ensure multiple threads don't interleave data on the same stream.

Variables

sf_audio_playback_hw_api_t	g_sf_audio_playback_hw_on_sf_audio_playback_hw_dac

Detailed Description

RTOS-integrated DAC implementation of Audio Playback Interface.

The Audio Playback Framework DAC implementation uses a timer to generate events at the sampling frequency, and uses these events to transfer PCM samples to the DAC.

Function Documentation

◆ SF_AUDIO_PLAYBACK_HW_DAC_Close()

ssp_err_t SF_AUDIO_PLAYBACK_HW_DAC_Close (sf_audio_playback_hw_ctrl_t *const *p_api_ctrl*)

Close open audio driver.

Return values

SSP_SUCCESS	Successful close.
SSP_ERR_ASSERTION	The parameter p_ctrl is NULL.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls

- timer_api_t::close
- dac_api_t::close
- transfer_api_t::close

Note

This function is reentrant for different channels. It is not reentrant for the same channel.

Close timer driver.

Close DAC driver.

Close transfer driver.

◆ SF_AUDIO_PLAYBACK_HW_DAC_DataTypeGet()

ssp_err_t SF_AUDIO_PLAYBACK_HW_DAC_DataTypeGet (sf_audio_playback_hw_ctrl_t *const *p_ctrl*, sf_audio_playback_data_type_t *const *p_data_type*)

Provides the expected data type in the pointer p_data_type.

Return values

SSP_SUCCESS	Data type stored in p_data_type.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_data_type is NULL.

Note

This function is reentrant if the lower level driver functions are reentrant.

Store data type. The Synergy DAC supports only 12-bit unsigned data.

◆ SF_AUDIO_PLAYBACK_HW_DAC_Open()

ssp_err_t SF_AUDIO_PLAYBACK_HW_DAC_Open (sf_audio_playback_hw_ctrl_t *const *p_api_ctrl*, sf_audio_playback_hw_cfg_t const *const *p_cfg*)

Open the DAC audio driver, including the DAC HAL driver and helper timer and transfer HAL drivers.

Return values

SSP_SUCCESS	Configuration of lower level drivers completed successfully.
SSP_ERR_ASSERTION	Null Pointer.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls

- dac_api_t::open
- timer_api_t::open
- transfer_api_t::open
- timer_api_t::close
- dac_api_t::close

Note

This function is reentrant if the lower level driver functions are reentrant.

Open Timer driver at selected frequency

If DTC is selected, register the audio callback with the timer ISR. DTC calls activation source ISR when the transfer is complete.

Open DAC module

Open transfer module to transfer from buffer to DAC output register

Configure transfer size of driver depending upon the underlying DAC resolution

Open transfer driver

Store driver data.

Play linear ramp data to get DAC up to half the maximum output.

◆ SF_AUDIO_PLAYBACK_HW_DAC_Play()

ssp_err_t SF_AUDIO_PLAYBACK_HW_DAC_Play (sf_audio_playback_hw_ctrl_t *const *p_api_ctrl*, int16_t const *const *p_buffer*, uint32_t *length*)

Play a single audio buffer by input samples to the DAC at the sampling frequency configured by the timer.

Return values

SSP_SUCCESS	Buffer playback began successfully.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_buffer is NULL or length is greater than 0x10000UL.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls

- transfer_api_t::reset

Note

This function is reentrant if the lower level driver functions are reentrant.

Reset transfer.

◆ SF_AUDIO_PLAYBACK_HW_DAC_Start()

ssp_err_t SF_AUDIO_PLAYBACK_HW_DAC_Start (sf_audio_playback_hw_ctrl_t *const *p_api_ctrl*)

Start the DAC and timer HAL drivers.

Return values

SSP_SUCCESS	Audio playback hardware started successfully.
SSP_ERR_ASSERTION	The parameter p_ctrl is NULL.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls

- dac_api_t::start
- timer_api_t::start

Note

This function is reentrant if the lower level driver functions are reentrant.

Start DAC.

Start timer.

◆ SF_AUDIO_PLAYBACK_HW_DAC_Stop()

ssp_err_t SF_AUDIO_PLAYBACK_HW_DAC_Stop (sf_audio_playback_hw_ctrl_t *const *p_api_ctrl*)

Stop the DAC and timer HAL drivers.

Return values

SSP_SUCCESS	Audio playback hardware stopped successfully.
SSP_ERR_ASSERTION	The parameter p_ctrl is NULL.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls
- timer_api_t::stop
- dac_api_t::stop

Note

This function is reentrant if the lower level driver functions are reentrant.

Stop timer.

Stop DAC.

◆ SF_AUDIO_PLAYBACK_HW_DAC_VersionGet()

ssp_err_t SF_AUDIO_PLAYBACK_HW_DAC_VersionGet (ssp_version_t *const *p_version*)

Stores the version of the firmware and API in provided pointer p_version.

Return values

SSP_ERR_ASSERTION	The parameter p_version is NULL.
SSP_SUCCESS	Module version successfully stored in p_version.

Note

This function is reentrant.

Variable Documentation

◆ g_sf_audio_playback_hw_on_sf_audio_playback_hw_dac

sf_audio_playback_hw_api_t g_sf_audio_playback_hw_on_sf_audio_playback_hw_dac

Function pointers for DAC implementation of audio playback API.

sf_audio_playback_hw_dac_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » DAC Audio Playback Framework

#include <sf_audio_playback_hw_dac.h>

Data Fields

void(*	p_callback)(sf_audio_playback_hw_callback_args_t *p_args)
void *	p_context
dac_instance_t const *	p_lower_lvl_dac DAC API used to access DAC hardware.
timer_instance_t const *	p_lower_lvl_timer Timer API used to generate sampling frequency.
transfer_instance_t const *	p_lower_lvl_transfer Transfer API used to transfer data each sampling frequency.
volatile bool	is_dac_ramped_up Whether the DAC is ramped up to half of maximum output.

Detailed Description

Hardware dependent control block for DAC audio driver.

Field Documentation

◆ p_callback

void(* sf_audio_playback_hw_dac_instance_ctrl_t::p_callback) (sf_audio_playback_hw_callback_args_t *p_args)
Callback called when play is complete.

◆ p_context

void* sf_audio_playback_hw_dac_instance_ctrl_t::p_context
Placeholder for user data. Passed to the user callback in sf_audio_playback_hw_callback_args_t.

The documentation for this struct was generated from the following file:

- sf_audio_playback_hw_dac.h

Detailed Description

RTOS-integrated I2S implementation of Audio Playback Interface.

The Audio Playback Framework I2S implementation uses the I2S interface for audio playback.

Name of module used by error logger macro

Function Documentation

◆ SF_AUDIO_PLAYBACK_HW_I2S_Close()

ssp_err_t SF_AUDIO_PLAYBACK_HW_I2S_Close (sf_audio_playback_hw_ctrl_t *const *p_api_ctrl*)

Close open audio driver.

Return values

SSP_SUCCESS	Successful close.
SSP_ERR_ASSERTION	The parameter p_ctrl is NULL.

Returns

See Common Error Codes and lower level driver function for other possible return codes.
This function calls:
- i2s_api_t::close

Note

This function is reentrant for different channels. It is not reentrant for the same channel.

Close I2S driver.

◆ SF_AUDIO_PLAYBACK_HW_I2S_DataTypeGet()

ssp_err_t SF_AUDIO_PLAYBACK_HW_I2S_DataTypeGet (sf_audio_playback_hw_ctrl_t *const *p_ctrl*, sf_audio_playback_data_type_t *const *p_data_type*)

Provides the expected data type in the pointer p_data_type.

Return values

SSP_SUCCESS	Data type stored in p_data_type.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_data_type is NULL.

Note

This function is reentrant if the lower level driver functions are reentrant.

Store data type. The audio framework supports only 16-bit signed data.

◆ SF_AUDIO_PLAYBACK_HW_I2S_Open()

ssp_err_t SF_AUDIO_PLAYBACK_HW_I2S_Open (sf_audio_playback_hw_ctrl_t *const *p_api_ctrl*, sf_audio_playback_hw_cfg_t const *const *p_cfg*)

Open the I2S audio driver, including the I2S HAL driver and helper timer and transfer HAL drivers.

Return values

SSP_SUCCESS	Configuration of lower level drivers completed successfully.
SSP_ERR_ASSERTION	One of the following parameter is null: p_ctrl or p_cfg or p_cfg_extend->p_lower_lvl_i2s or p_cfg_extend->p_lower_lvl_i2s->p_api.

Returns

See Common Error Codes and lower level driver function for other possible return codes.
This function calls:
- i2s_api_t::open

Note

This function is reentrant if the lower level driver functions are reentrant.

Open I2S module

Store driver data.

◆ SF_AUDIO_PLAYBACK_HW_I2S_Play()

ssp_err_t SF_AUDIO_PLAYBACK_HW_I2S_Play (sf_audio_playback_hw_ctrl_t *const *p_api_ctrl*, int16_t const *const *p_buffer*, uint32_t *length*)

Play a single audio buffer by input samples to the I2S at the sampling frequency configured by the timer.

Return values

SSP_SUCCESS	Buffer playback began successfully.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_buffer is NULL or length is less than 0x10000U.

Returns

See Common Error Codes and lower level driver function for other possible return codes.
This function calls:
- i2s_api_t::write

Note

This function is reentrant if the lower level driver functions are reentrant.

Reset transfer.

◆ SF_AUDIO_PLAYBACK_HW_I2S_Start()

ssp_err_t SF_AUDIO_PLAYBACK_HW_I2S_Start (sf_audio_playback_hw_ctrl_t *const *p_ctrl*)

Start the I2S and timer HAL drivers.

Return values

SSP_SUCCESS	Audio playback hardware started successfully.

Note

This function is reentrant if the lower level driver functions are reentrant.

This API is not used - I2S is started when write is called from SF_AUDIO_PLAYBACK_HW_I2S_Play.

◆ SF_AUDIO_PLAYBACK_HW_I2S_Stop()

ssp_err_t SF_AUDIO_PLAYBACK_HW_I2S_Stop (sf_audio_playback_hw_ctrl_t *const *p_api_ctrl*)

Stop the I2S and timer HAL drivers.

Return values

SSP_SUCCESS	Audio playback hardware stopped successfully.
SSP_ERR_ASSERTION	The parameter p_ctrl is NULL.

Returns

See Common Error Codes and lower level driver function for other possible return codes.
This function calls:
- i2s_api_t::stop

Note

This function is reentrant if the lower level driver functions are reentrant.

Stop I2S.

◆ SF_AUDIO_PLAYBACK_HW_I2S_VersionGet()

ssp_err_t SF_AUDIO_PLAYBACK_HW_I2S_VersionGet (ssp_version_t *const *p_version*)

Stores the version of the firmware and API in provided pointer p_version.

Return values

SSP_ERR_ASSERTION	The parameter p_version is NULL.
SSP_SUCCESS	Module version successfully stored in p_version.

Note

This function is reentrant.

sf_audio_playback_hw_i2s_instance_ctrl_t Struct Reference

Detailed Description

RTOS-integrated ADC implementation of Audio Recording Interface.

The Audio Recording Framework implementation uses the ADC periodic interface for audio recording.

Macro Definition Documentation

◆ SF_AUDIO_RECORD_CODE_VERSION_MAJOR

#define SF_AUDIO_RECORD_CODE_VERSION_MAJOR (2U)
Version of code that implements the API defined in this file

Function Documentation

◆ SF_AUDIO_RECORD_ADC_Close()

ssp_err_t SF_AUDIO_RECORD_ADC_Close (sf_audio_record_ctrl_t *const *p_api_ctrl*)

Call the ADC periodic framework Close.

Implements

- sf_audio_record_api_t::close.

Return values

SSP_SUCCESS	Successful close.
SSP_ERR_ASSERTION	p_ctrl is NULL.
SSP_ERR_NOT_OPEN	Control block p_ctrl is not initialized. Call SF_AUDIO_RECORD_ADC_Open to configure.

Returns

See Common Error Codes or sf_adc_periodic for other possible return codes or causes. This function calls

- sf_adc_periodic_api_t::close

Call the underlying ADC periodic close

◆ SF_AUDIO_RECORD_ADC_InfoGet()

ssp_err_t SF_AUDIO_RECORD_ADC_InfoGet (sf_audio_record_ctrl_t *const *p_api_ctrl*, sf_audio_record_info_t * *p_info*)

Provide information about the channel supported by audio recording framework(MONO)

Implements

- sf_audio_record_api_t::infoGet.

Return values

SSP_SUCCESS	InfoGet returns successfully.
SSP_ERR_ASSERTION	p_ctrl or p_info is null.
SSP_ERR_NOT_OPEN	Control block p_ctrl is not initialized. Call SF_AUDIO_RECORD_ADC_Open to configure.

Returns

See Common Error Codes or sf_adc_periodic for other possible return codes or causes.

Verify the parameters are valid

Set the channel support as MONO

◆ SF_AUDIO_RECORD_ADC_Open()

ssp_err_t SF_AUDIO_RECORD_ADC_Open (sf_audio_record_ctrl_t *const *p_api_ctrl*, sf_audio_record_cfg_t const *const *p_cfg*)

Configure the ADC with user configurations.

The SF_AUDIO_RECORD_ADC_Open will initialize the configurations for the underlying ADC periodic framework.

Implements

- sf_audio_record_api_t::open.

Return values

SSP_SUCCESS	Initialization was successful.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_cfg is NULL. Or any one of the following p_cfg parameter is NULL/zero. p_cfg->p_capture_data_buffer, p_cfg->sample_count, p_cfg->capture_data_buffer_size, p_cfg->p_callback, p_cfg->sampling_rate_hz. Or resolution or time period is not matching. for other possible causes.
SSP_ERR_IN_USE	The channel specified has already been opened.

Returns

See Common Error Codes or sf_adc_periodic for other possible return codes or causes. This function calls

- sf_adc_periodic_api_t::open

Note

This function is reentrant for any unit.

Initialize the ADC periodic framework

Initialize the configuration parameters for ADC periodic configuration structure

Configure the ADC resolution depending on the data width in cfg

Call the underlying ADC periodic open

◆ SF_AUDIO_RECORD_ADC_Start()

ssp_err_t SF_AUDIO_RECORD_ADC_Start (sf_audio_record_ctrl_t *const *p_api_ctrl*)

Call the ADC periodic framework Start.

Implements

- sf_audio_record_api_t::start.

Return values

SSP_SUCCESS	ADC Periodic Scan started successfully.
SSP_ERR_ASSERTION	p_ctrl is NULL.
SSP_ERR_NOT_OPEN	Control block p_ctrl is not initialized. Call SF_AUDIO_RECORD_ADC_Open to configure.

Returns

See Common Error Codes or sf_adc_periodic for other possible return codes or causes. This function calls

- sf_adc_periodic_api_t::start

Call the underlying ADC periodic start

◆ SF_AUDIO_RECORD_ADC_Stop()

ssp_err_t SF_AUDIO_RECORD_ADC_Stop (sf_audio_record_ctrl_t *const *p_api_ctrl*)

Call the ADC periodic framework Stop.

Implements

- sf_audio_record_api_t::stop.

Return values

SSP_SUCCESS	Periodic ADC scan stopped successfully.
SSP_ERR_ASSERTION	p_ctrl is NULL.
SSP_ERR_NOT_OPEN	Control block p_ctrl is not initialized. Call SF_AUDIO_RECORD_ADC_Open to configure.

Returns

See Common Error Codes or sf_adc_periodic for other possible return codes or causes. This function calls

- sf_adc_periodic_api_t::stop

Call the underlying ADC periodic start

◆ SF_AUDIO_RECORD_ADC_VersionGet()

ssp_err_t SF_AUDIO_RECORD_ADC_VersionGet (ssp_version_t *const *p_version*)
Gets version and stores it in provided pointer p_version. **Implements** ◦ sf_audio_record_api_t::versionGet. **Return values** SSP_SUCCESS — VersionGet returned successfully. SSP_ERR_ASSERTION — Parameter p_version was null.

sf_audio_record_adc_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » ADC Audio recording Framework

Control block for audio recording Initialization occurs when sf_audio_record_api_t::open is called. More...

#include <sf_audio_record_adc.h>

Data Fields

uint32_t	open
TX_MUTEX	mutex
void *	p_capture_data_buffer
uint32_t	sample_count
void(*	p_callback)(sf_audio_record_callback_args_t *p_args) Callback function.
void const *	p_context Placeholder for user data.
sf_adc_periodic_instance_t const *	p_lower_lvl_adc_periodic Lower level ADC periodic instance.

Detailed Description

Control block for audio recording Initialization occurs when sf_audio_record_api_t::open is called.

Field Documentation

◆ mutex

TX_MUTEX sf_audio_record_adc_instance_ctrl_t::mutex
Mutex used to protect access to lower level driver hardware registers

◆ open

uint32_t sf_audio_record_adc_instance_ctrl_t::open
Used by driver to check if pointer to control block is valid

◆ p_capture_data_buffer

void* sf_audio_record_adc_instance_ctrl_t::p_capture_data_buffer
Pointer to the buffer that will store the samples

◆ sample_count

uint32_t sf_audio_record_adc_instance_ctrl_t::sample_count
Samples per channel to be buffered before notifying the app

The documentation for this struct was generated from the following file:

- sf_audio_record_adc.h

5.1.3.6 I2S Audio recording Framework

Renesas Synergy Software Package Reference » Framework Layer

I2S implementation of Audio Recording Interface. More...

Detailed Description

I2S implementation of Audio Recording Interface.

The Audio Recording Framework implementation uses the I2S interface for audio recording.

Macro Definition Documentation

◆ SF_AUDIO_RECORD_I2S_CODE_VERSION_MAJOR

#define SF_AUDIO_RECORD_I2S_CODE_VERSION_MAJOR (2U)
Version of code that implements the API defined in this file

◆ SF_AUDIO_RECORD_I2S_OPEN

#define SF_AUDIO_RECORD_I2S_OPEN (0x49325352)
Macro definitions "I2SR" in ASCII

Function Documentation

◆ SF_AUDIO_RECORD_I2S_Close()

ssp_err_t SF_AUDIO_RECORD_I2S_Close (sf_audio_record_ctrl_t *const *p_api_ctrl*)

Closes I2S driver, releases and deletes the mutex.

Implements

- sf_audio_record_api_t::close.

Return values

SSP_SUCCESS	Successful close.
SSP_ERR_ASSERTION	p_ctrl is NULL.
SSP_ERR_NOT_OPEN	Control block p_ctrl is not initialized.

Returns

See Common Error Codes and lower level driver function for other possible return codes or causes. This function calls

- i2s_api_t::close

Call the underlying I2S close

Post the mutex

If all the HAL layers closed successfully, then delete the mutex and mark module as un-initialized

Clear information from control block so other functions know this instance is closed

◆ SF_AUDIO_RECORD_I2S_InfoGet()

ssp_err_t SF_AUDIO_RECORD_I2S_InfoGet (sf_audio_record_ctrl_t *const *p_api_ctrl*, sf_audio_record_info_t * *p_info*)

Provide information about the channel supported by audio recording framework(stereo)

Implements

- sf_audio_record_api_t::infoGet.

Return values

SSP_SUCCESS	InfoGet returns successfully.
SSP_ERR_ASSERTION	p_ctrl or p_info is null.
SSP_ERR_NOT_OPEN	Control block p_ctrl is not initialized.

Returns

See Common Error Codes for other possible return codes or causes.

◆ SF_AUDIO_RECORD_I2S_Open()

ssp_err_t SF_AUDIO_RECORD_I2S_Open (sf_audio_record_ctrl_t *const *p_api_ctrl*, sf_audio_record_cfg_t const *const *p_cfg*)

Configures the Audio record I2S framework and I2S HAL driver The SF_AUDIO_RECORD_I2S_Open function creates a mutex for the I2S Unit used, then calls the driver open function. The mutex is deleted following the driver layer open function fails.

Implements

- sf_audio_record_api_t::open.

Return values

SSP_SUCCESS	Configuration of lower level drivers completed successfully.
SSP_ERR_ASSERTION	p_ctrl or p_cfg parameter is null:
SSP_ERR_INTERNAL	An internal ThreadX error has occurred. This is typically a failure to create/use a mutex.

Returns

See Common Error Codes and lower level driver function for other possible return codes. This function calls:

- i2s_api_t::open

Open I2S module

Create a mutex to protect access to the control structure and the lower level hardware.

Initialize the configuration parameters

If any of the HAL layer initializations failed, then delete the mutex and exit the function with the error code

Delete the mutex

Mark control block open so other tasks know it is valid

◆ SF_AUDIO_RECORD_I2S_Start()

ssp_err_t SF_AUDIO_RECORD_I2S_Start (sf_audio_record_ctrl_t *const *p_api_ctrl*)

Gets mutex, starts recording data into the buffer.

Implements

- sf_audio_record_api_t::start.

Return values

SSP_SUCCESS	I2S record started successfully.
SSP_ERR_ASSERTION	p_ctrl is NULL.
SSP_ERR_NOT_OPEN	Driver control block not valid.
SSP_ERR_IN_USE	The module is currently busy performing another operation

Returns

See Common Error Codes and lower level driver function for other possible return codes.
This function calls:

- i2s_api_t::read

Get mutex, start i2s

Call the underlying I2S driver read

If any of the HAL layer initializations failed, then delete the mutex and exit the function with the error code

Return the mutex

◆ SF_AUDIO_RECORD_I2S_Stop()

ssp_err_t SF_AUDIO_RECORD_I2S_Stop (sf_audio_record_ctrl_t *const *p_api_ctrl*)

Stops the audio recording and releases mutex.

Implements

- sf_audio_record_api_t::stop.

Return values

SSP_SUCCESS	I2S Record stopped successfully.
SSP_ERR_ASSERTION	The parameter p_ctrl is NULL.
SSP_ERR_NOT_OPEN	Control block p_ctrl is not initialized.
SSP_ERR_INTERNAL	An internal ThreadX error has occurred. This is typically a failure to create/use a mutex.

Returns

See Common Error Codes for other possible return codes or causes. This function calls: i2s_api_t::stop

Return the mutex

If there was a mutex error, return it

◆ SF_AUDIO_RECORD_I2S_VersionGet()

ssp_err_t SF_AUDIO_RECORD_I2S_VersionGet (ssp_version_t *const *p_version*)

Gets version and stores it in provided pointer p_version.

Implements

- sf_audio_record_api_t::versionGet.

Return values

SSP_SUCCESS	VersionGet returned successfully.
SSP_ERR_ASSERTION	Parameter p_version was null.

Copy the version information.

sf_audio_record_i2s_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » I2S Audio recording Framework

#include <sf_audio_record_i2s.h>

Variables

const sf_block_media_api_t	g_sf_block_media_on_sf_block_media_lx_nor

Detailed Description

RTOS-integrated Block Media framework for LEVELX driver.

Macro Definition Documentation

◆ SF_BLOCK_MEDIA_LX_NOR_ERROR_RETURN

#define SF_BLOCK_MEDIA_LX_NOR_ERROR_RETURN (a, err) SSP_ERROR_RETURN((a), (err), &g_module_name[0], &g_block_media_lx_nor_version)
Macro for error logger.

◆ SF_BLOCK_MEDIA_LX_NOR_OPEN

#define SF_BLOCK_MEDIA_LX_NOR_OPEN (0x424D4C4FU)
"BMLO" in ASCII, used to identify block media LevelX handle

Function Documentation

◆ SF_BLOCK_MEDIA_LX_NOR_Close()

ssp_err_t SF_BLOCK_MEDIA_LX_NOR_Close (sf_block_media_ctrl_t *const *p_ctrl*)

Close open Block Media LevelX NOR driver.

Close an open Block Media LevelX NOR driver.

Return values

SSP_SUCCESS	Successfully closed.
SSP_ERR_ASSERTION	p_ctrl or p_nor_flash is NULL.
SSP_ERR_NOT_OPEN	The block media is not open.

Returns

See Common Error Codes or lower level drivers for other possible return codes. This function calls:

- lx_nor_flash_close
- SF_EL_LX_NOR_Close

Validate the parameters

Check whether the instance is in open state

Close the LevelX NOR flash driver.

Close underlying NOR driver, if available

Mark control block close so subsequent calls know the device is close.

◆ SF_BLOCK_MEDIA_LX_NOR_Control()

ssp_err_t SF_BLOCK_MEDIA_LX_NOR_Control (sf_block_media_ctrl_t *const *p_ctrl*, ssp_command_t const *command*, void * *p_data*)

Send control commands to Block Media LevelX NOR driver.

Return values

SSP_SUCCESS	Command executed successfully.
SSP_ERR_ASSERTION	p_ctrl or p_data is Null.
SSP_ERR_NOT_OPEN	The block media is not open.
SSP_ERR_UNSUPPORTED	This module doesn't support requested command.
SSP_ERR_SECTOR_RELEASE_FAILED	Sector release command failed.

Returns

See Common Error Codes or lower level drivers for other possible return codes. This function calls:

- lx_nor_flash_sector_release

Validate the parameters

Check whether the instance is in open state

Get the sector count

LevelX divides each NOR flash block into 512-byte logical sectors

It's not write protected

LevelX supports sector release

Release NOR flash sector.

◆ SF_BLOCK_MEDIA_LX_NOR_Open()

ssp_err_t SF_BLOCK_MEDIA_LX_NOR_Open (sf_block_media_ctrl_t *const *p_ctrl*, sf_block_media_cfg_t const *const *p_cfg*)

Open device for read/write and control.

Open LevelX flash device for read/write and control. This function initializes the LevelX driver and hardware the first time it is called out of reset. The underlying flash needs to either be erased or already initialized with LevelX.

Return values

SSP_SUCCESS	LevelX flash is available and is now open for read, write, and control access.
SSP_ERR_ASSERTION	p_ctrl, p_cfg or an input pointer is NULL.
SSP_ERR_MEDIA_OPEN_FAILED	LevelX NOR or the underlying flash failed to open. The underlying flash needs to either be erased or already initialized with LevelX.
SSP_ERR_ALREADY_OPEN	The block media LevelX NOR instance has already been opened. No configurations were changed. Call the associated Close function or use associated Control commands to reconfigure the instance.

Returns

See Common Error Codes or lower LevelX drivers for other possible return codes. This function calls:

- lx_nor_flash_open

Validate the parameters

Check whether instance is already open

Update instance control block

Open underlying LevelX

Mark control block open so subsequent calls know the device is open.

◆ SF_BLOCK_MEDIA_LX_NOR_Read()

ssp_err_t SF_BLOCK_MEDIA_LX_NOR_Read (sf_block_media_ctrl_t *const *p_ctrl*, uint8_t *const *p_dest*, uint32_t const *start_sector*, uint32_t const *sector_count*)

Read data from flash using LevelX.

Return values

SSP_SUCCESS	Data read successfully.
SSP_ERR_ASSERTION	p_ctrl or p_dest is NULL.
SSP_ERR_NOT_OPEN	The block media is not open.
SSP_ERR_READ_FAILED	Data read failed.

Returns

See Common Error Codes or lower level drivers for other possible return codes. This function calls:

- lx_nor_flash_sector_read

Validate the parameters

Check whether the instance is in open state

Loop to read sectors from flash.

Read a sector from NOR flash.

◆ SF_BLOCK_MEDIA_LX_NOR_VersionGet()

ssp_err_t SF_BLOCK_MEDIA_LX_NOR_VersionGet (ssp_version_t *const *p_version*)

Get version of Block Media LevelX driver.

Return the version of the firmware and API.

Return values

SSP_ERR_ASSERTION	p_version is Pointer.
SSP_SUCCESS	version read successfully.

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is reentrant.

Validate the parameters

◆ SF_BLOCK_MEDIA_LX_NOR_Write()

ssp_err_t SF_BLOCK_MEDIA_LX_NOR_Write (sf_block_media_ctrl_t *const *p_ctrl*, uint8_t const *const *p_src*, uint32_t const *start_sector*, uint32_t const *sector_count*)

Write data to flash using LevelX.

Return values

SSP_SUCCESS	Write finished successfully.
SSP_ERR_ASSERTION	p_ctrl or p_src is NULL.
SSP_ERR_NOT_OPEN	The block media is not open.
SSP_ERR_WRITE_FAILED	Data write failed.

Returns

See Common Error Codes or lower level drivers for other possible return codes. This function calls:

- lx_nor_flash_sector_write

Validate the parameters

Check whether the instance is in open state

Loop to write sectors into flash.

Write a sector into NOR flash.

Variable Documentation

◆ g_sf_block_media_on_sf_block_media_lx_nor

const sf_block_media_api_t g_sf_block_media_on_sf_block_media_lx_nor

Variables

const sf_block_media_api_t	g_sf_block_media_on_sf_block_media_qspi

Detailed Description

RTOS-integrated Block Media framework for QSPI driver.

Macro Definition Documentation

◆ SF_BLOCK_MEDIA_QSPI_ERROR_RETURN

#define SF_BLOCK_MEDIA_QSPI_ERROR_RETURN (a, err) SSP_ERROR_RETURN((a), (err), &g_module_name[0], &g_block_media_qspi_version)
Macro for error logger.

◆ SF_QSPI_OPEN

#define SF_QSPI_OPEN (0x51535049U)
"QSPI" in ASCII, used to identify general SF_BLOCK_MEDIA_QSPI control block

Function Documentation

◆ SF_BLOCK_MEDIA_QSPI_Close()

ssp_err_t SF_BLOCK_MEDIA_QSPI_Close (sf_block_media_ctrl_t *const *p_api_ctrl*)

Close functionality will delete the resources which is initialized in open call.

Return values

SSP_SUCCESS	Successful close.
SSP_ERR_ASSERTION	One of the following parameters may be null: p_api_ctrl.
SSP_ERR_NOT_OPEN	Block media QSPI Framework module is not yet initialized.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls

- qspi_api_t::close

Delete RTOS services allocated during the open call.

◆ SF_BLOCK_MEDIA_QSPI_Control()

ssp_err_t SF_BLOCK_MEDIA_QSPI_Control (sf_block_media_ctrl_t *const *p_api_ctrl*, ssp_command_t const *command*, void * *p_data*)

Send control commands to and receive status of flash.

Return values

SSP_SUCCESS	Command executed successfully.
SSP_ERR_ASSERTION	One of the following parameters may be null: p_api_ctrl.
SSP_ERR_NOT_OPEN	Block media QSPI Framework module is not yet initialized.
SSP_ERR_UNSUPPORTED	Command not support.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls

- qspi_api_t::infoGet

Get the information of Flash

◆ SF_BLOCK_MEDIA_QSPI_Open()

ssp_err_t SF_BLOCK_MEDIA_QSPI_Open (sf_block_media_ctrl_t *const *p_api_ctrl*, sf_block_media_cfg_t const *const *p_cfg*)

Open Block Media QSPI flash device for read/write and control. Parameter checking and Acquires mutex, then handles driver initialization at the HAL QSPI layer and marking the open flag in control block.

Name of module used by error logger macro

Return values

SSP_SUCCESS	Block media for QSPI framework is successfully opened.
SSP_ERR_ASSERTION	One of the following parameters may be null: p_api_ctrl, p_cfg or configuration for qspi.
SSP_ERR_IN_USE	The channel specified has already been opened. or the mutex may be unavailable for the the device. See HAL driver for other possible causes.
SSP_ERR_INTERNAL	An internal ThreadX error has occurred.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls

- qspi_api_t::open

Create a mutex to protect access to the control structure and the lower level hardware.

Calling low level driver

On success populate the control structure

Selecting smallest block erasable by underlying QSPI flash

◆ SF_BLOCK_MEDIA_QSPI_Read()

ssp_err_t SF_BLOCK_MEDIA_QSPI_Read (sf_block_media_ctrl_t *const *p_api_ctrl*, uint8_t *const *p_dest*, uint32_t const *start_block*, uint32_t const *block_count*)

Read requested data from Block Media QSPI Flash through QSPI channel.

Return values

SSP_SUCCESS	QSPI data read successfully.
SSP_ERR_ASSERTION	p_api_ctrl or p_dest is NULL. Or block_count is zero.
SSP_ERR_NOT_OPEN	Block media QSPI Framework module is not yet initialized.
SSP_ERR_IN_USE	The channel specified has already been opened. or the mutex may be unavailable for the the device. See HAL driver for other possible causes.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls

- qspi_api_t::read

Obtain mutex before making HAL-level driver call.

Release mutex

◆ SF_BLOCK_MEDIA_QSPI_VersionGet()

ssp_err_t SF_BLOCK_MEDIA_QSPI_VersionGet (ssp_version_t *const *p_version*)

Get the firmware and API version of Block Media QSPI Framework.

Return values

SSP_SUCCESS	Function executed successfully.
SSP_ERR_ASSERTION	Null Pointer.

Note

This function is reentrant.

◆ SF_BLOCK_MEDIA_QSPI_Write()

ssp_err_t SF_BLOCK_MEDIA_QSPI_Write (sf_block_media_ctrl_t *const *p_api_ctrl*, uint8_t const *const *p_src*, uint32_t const *start_block*, uint32_t const *block_count*)

Program requested data content to the Block Media QSPI flash memory.

Return values

SSP_SUCCESS	Flash write finished successfully.
SSP_ERR_ASSERTION	p_api_ctrl or p_src is NULL. Or block_count is zero.
SSP_ERR_NOT_OPEN	Block media QSPI Framework module is not yet initialized.
SSP_ERR_IN_USE	The channel specified has already been opened. or the mutex may be unavailable for the the device. See HAL driver for other possible causes.
SSP_ERR_UNSUPPORTED	Total number of programmable bytes is greater than total flash capacity

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls

- qspi_api_t::pageProgram

Obtain mutex before making HAL-level driver call.

Get the information of Flash

Calculate the address of flash

Check if total number of bytes programmable into flash is greater than total flash capacity

Calculate the number of iteration required to complete write operation

Write data into the block media QSPI flash

Release mutex

Variable Documentation

ssp_err_t	SF_BLOCK_MEDIA_RAM_VersionGet (ssp_version_t *const p_version) Get version of Block Media RAM framework. More...

Detailed Description

RTOS-integrated Block Media framework for RAM.

Function Documentation

◆ SF_BLOCK_MEDIA_RAM_Close()

ssp_err_t SF_BLOCK_MEDIA_RAM_Close (sf_block_media_ctrl_t *const *p_api_ctrl*)

Close the Framework.

Return values

SSP_SUCCESS	RAM buffer is available and is now open for read, write, and control access.
SSP_ERR_ASSERTION	p_api_ctrl is NULL.
SSP_ERR_NOT_OPEN	Framework is not opened.

Check if Framework is NOT open

Mark Framework as close

◆ SF_BLOCK_MEDIA_RAM_Control()

ssp_err_t SF_BLOCK_MEDIA_RAM_Control (sf_block_media_ctrl_t *const *p_api_ctrl*, ssp_command_t const *command*, void * *p_data*)

Send control commands to and receive status of RAM buffer.

Return values

SSP_SUCCESS	Command executed successfully.
SSP_ERR_ASSERTION	p_api_ctrl or p_data is NULL.
SSP_ERR_NOT_OPEN	Framework is not opened.
SSP_ERR_UNSUPPORTED	Command not supported.

Check if Framework is NOT open

◆ SF_BLOCK_MEDIA_RAM_Open()

ssp_err_t SF_BLOCK_MEDIA_RAM_Open (sf_block_media_ctrl_t *const *p_api_ctrl*, sf_block_media_cfg_t const *const *p_cfg*)

Open device for read/write and control.

Return values

SSP_SUCCESS	RAM buffer is available and is now open for read, write, and control access.
SSP_ERR_ASSERTION	p_api_ctrl, p_cfg, p_cfg->p_extend, or p_block_media_cfg->p_ram_buffer is NULL.
SSP_ERR_IN_USE	Framework is already open by someone else

Check if Framework is already in USE

Copy the block size and RAM buffer memory address to control structure for further operation

Mark device as a open

◆ SF_BLOCK_MEDIA_RAM_Read()

ssp_err_t SF_BLOCK_MEDIA_RAM_Read (sf_block_media_ctrl_t *const *p_api_ctrl*, uint8_t *const *p_dest*, uint32_t const *start_block*, uint32_t const *block_count*)

Read data from RAM buffer.

Return values

SSP_SUCCESS	Data read successfully.
SSP_ERR_ASSERTION	p_api_ctrl, p_dest or internal control block element is NULL.
SSP_ERR_NOT_OPEN	The Framework is not opened.
SSP_ERR_INVALID_BLOCKS	Invalid block passed to API

Check if Framework is NOT open

Copy the content of p_ram_buffer into destination

◆ SF_BLOCK_MEDIA_RAM_VersionGet()

ssp_err_t SF_BLOCK_MEDIA_RAM_VersionGet (ssp_version_t *const *p_version*)

Get version of Block Media RAM framework.

Return the version of the firmware and API.

Return values

SSP_ERR_ASSERTION	p_version is NULL.
SSP_SUCCESS	version read successfully.

Note

This function is reentrant.

◆ SF_BLOCK_MEDIA_RAM_Write()

ssp_err_t SF_BLOCK_MEDIA_RAM_Write (sf_block_media_ctrl_t *const *p_api_ctrl*, uint8_t const *const *p_src*, uint32_t const *start_block*, uint32_t const *block_count*)

Write data to RAM buffer.

Return values

SSP_SUCCESS	Data write successfully.
SSP_ERR_ASSERTION	p_api_ctrl, p_src or internal control block element is NULL.
SSP_ERR_NOT_OPEN	Framework is not opened.
SSP_ERR_INVALID_BLOCKS	Invalid block passed to API

Check if Framework is NOT open

Copy the content of source into p_ram_buffer

sf_block_media_ram_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » BLOCK_MEDIA_RAM

#include <sf_block_media_ram.h>

Data Fields

uint8_t *	p_ram_buffer pointer to RAM buffer address

uint32_t	block_size Block size in bytes.
uint32_t	open Used to determine if framework is initialized.
uint32_t	ram_buffer_size Size of RAM buffer.

Detailed Description

RAM block media instance control block.

The documentation for this struct was generated from the following file:

- sf_block_media_ram.h

5.1.3.10 BLOCK_MEDIA_SDMMC

Renesas Synergy Software Package Reference » Framework Layer

RTOS-integrated Block Media framework for SDMMC driver. More...

Data Structures

Functions

ssp_err_t	SF_Block_Media_SDMMC_Open (sf_block_media_ctrl_t *const p_api_ctrl, sf_block_media_cfg_t const *const p_cfg) Open device for read/write and control. More...
ssp_err_t	SF_Block_Media_SDMMC_Read (sf_block_media_ctrl_t *const p_api_ctrl, uint8_t *const p_dest, uint32_t const start_block, uint32_t const block_count) Read data from SD/MMC. More...

ssp_err_t	SF_Block_Media_SDMMC_Write (sf_block_media_ctrl_t *const p_api_ctrl, uint8_t const *const p_src, uint32_t const start_block, uint32_t const block_count) Write data to SDMMC channel. More...
ssp_err_t	SF_Block_Media_SDMMC_Control (sf_block_media_ctrl_t *const p_api_ctrl, ssp_command_t const command, void *p_data) Send control commands to and receive status of SD/MMC port. More...
ssp_err_t	SF_Block_Media_SDMMC_Close (sf_block_media_ctrl_t *const p_api_ctrl) Close open device port. More...
ssp_err_t	SF_Block_Media_SDMMC_VersionGet (ssp_version_t *const p_version) Get version of Block Media SD/MMC driver. More...

Detailed Description

RTOS-integrated Block Media framework for SDMMC driver.

Function Documentation

◆ SF_Block_Media_SDMMC_Close()

ssp_err_t SF_Block_Media_SDMMC_Close (sf_block_media_ctrl_t *const *p_api_ctrl*)

Close open device port.

Close an open SD/MMC device port.

Return values

SSP_SUCCESS	Successful close.
SSP_ERR_ASSERTION	p_ctrl or p_sdmmc is NULL.
SSP_ERR_NOT_OPEN	The channel is not opened.

Note

This function is reentrant for different channels. It is not reentrant for the same channel.

Mark control block as unused so it can be reconfigured.

◆ SF_Block_Media_SDMMC_Control()

ssp_err_t SF_Block_Media_SDMMC_Control (sf_block_media_ctrl_t *const *p_api_ctrl*, ssp_command_t const *command*, void * *p_data*)

Send control commands to and receive status of SD/MMC port.

Send control commands to the SD/MMC port and receive the status of the SD/MMC port.

Return values

SSP_SUCCESS	Command executed successfully.
SSP_ERR_ASSERTION	p_ctrl or p_sdmmc or p_data is Null.
SSP_ERR_NOT_OPEN	The channel is not opened.

Returns

See Common Error Codes or lower level drivers for other possible return codes. This function calls:

- sdmmc_api_t::control

Note

This function is reentrant for different channels. It is not reentrant for the same channel.

◆ SF_Block_Media_SDMMC_Open()

ssp_err_t SF_Block_Media_SDMMC_Open (sf_block_media_ctrl_t *const *p_api_ctrl*, sf_block_media_cfg_t const *const *p_cfg*)

Open device for read/write and control.

Open an SD or MMC device port for read/write and control. This function initializes the SDMMC driver and hardware the first time it is called out of reset.

Return values

SSP_SUCCESS	Port is available and is now open for read, write, and control access.
SSP_ERR_ASSERTION	p_ctrl, p_cfg, p_block_media_cfg or p_sdmmc is NULL.
SSP_ERR_INTERNAL	OS service call fails.
SSP_ERR_IN_USE	The channel specified has already been opened. No configurations were changed. Call the associated Close function or use associated Control commands to reconfigure the channel.

Returns

See Common Error Codes or lower level drivers for other possible return codes. This function calls:

- sdmmc_api_t::open

Note

This function is reentrant for different channels. It is not reentrant for the same channel.

Create SDMMC event flag and put it into context

Mark the stream as open by initializing "BMSO" in its ASCII equivalent.

Cleanup before logging the error

◆ SF_Block_Media_SDMMC_Read()

ssp_err_t SF_Block_Media_SDMMC_Read (sf_block_media_ctrl_t *const *p_api_ctrl*, uint8_t *const *p_dest*, uint32_t const *start_block*, uint32_t const *block_count*)

Read data from SD/MMC.

Read data from an SD or MMC device port.

Return values

SSP_SUCCESS	Data read successfully.
SSP_ERR_ASSERTION	p_ctrl, p_sdmmc or p_dest is NULL.
SSP_ERR_NOT_OPEN	The channel is not opened.
SSP_ERR_INTERNAL	OS service call fails.
SSP_ERR_READ_FAILED	Data read failed.

Returns

See Common Error Codes or lower level drivers for other possible return codes. This function calls:

- sdmmc_api_t::read

Note

This function is reentrant for different channels. It is not reentrant for the same channel.

Wait until read operation is completed. Event is signaled in event flag object.

◆ SF_Block_Media_SDMMC_VersionGet()

ssp_err_t SF_Block_Media_SDMMC_VersionGet (ssp_version_t *const *p_version*)

Get version of Block Media SD/MMC driver.

Return the version of the firmware and API.

Return values

SSP_ERR_ASSERTION	p_version is Pointer.
SSP_SUCCESS	version read successfully.

Note

This function is reentrant.

◆ SF_Block_Media_SDMMC_Write()

ssp_err_t SF_Block_Media_SDMMC_Write (sf_block_media_ctrl_t *const *p_api_ctrl*, uint8_t const *const *p_src*, uint32_t const *start_block*, uint32_t const *block_count*)

Write data to SDMMC channel.

Return values

SSP_SUCCESS	Card write finished successfully.
SSP_ERR_ASSERTION	p_ctrl, p_sdmmc or p_src is NULL.
SSP_ERR_NOT_OPEN	The channel is not opened.
SSP_ERR_INTERNAL	OS service call fails.
SSP_ERR_WRITE_FAILED	Data write failed.

Returns

See Common Error Codes or lower level drivers for other possible return codes. This function calls:

- sdmmc_api_t::write

Note

This function is reentrant for different channels.

Wait until write operation is completed. Event is signaled in event flag object.

sf_block_media_sdmmc_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » BLOCK_MEDIA_SDMMC

#include <sf_block_media_sdmmc.h>

Data Fields

uint32_t	block_size Block size in bytes.
sdmmc_instance_t *	p_lower_lvl_sdmmc Pointer to SDMMC instance structure.
TX_EVENT_FLAGS_GROUP	eventflag Pointer to the event flag object for SDMMC data transfer.
uint32_t	open

	Used to determine if framework is initialized.

Detailed Description

SDMMC block media instance control block.

The documentation for this struct was generated from the following file:

- sf_block_media_sdmmc.h

5.1.3.11 Cellular NSAL Implementation on NetX

Renesas Synergy Software Package Reference » Framework Layer

Cellular NetX NSAL interface implementation header file. More...

Macros

#define	SF_CELR_NSALNX_CODE_VERSION_MAJOR (2U)
#define	SF_CELR_NSALNX_CODE_VERSION_MINOR (0U)

Functions

void	sf_cellular_nsal_netx_driver (NX_IP_DRIVER *driver_req_ptr, sf_cellular_instance_t const *p_cellular_instance, sf_cellular_nsal_cfg_t *p_cellular_nsal_cfg) NetX IP Driver entry function. More...
void	sf_cellular_nsal_ppp_send_byte (UCHAR byte, sf_cellular_instance_t const *p_celr_instance) PPP Send Byte Callback function call from PPP Stack. More...
void	sf_cellular_nsal_invalid_packet_handler (NX_PACKET *p_packet_ptr, sf_cellular_instance_t const *p_celr_instance) Cellular framework nsal invalid callback handler. More...

Detailed Description

Cellular NetX NSAL interface implementation header file.

Macro Definition Documentation

◆ SF_CELR_NSALNX_CODE_VERSION_MAJOR

#define SF_CELR_NSALNX_CODE_VERSION_MAJOR (2U)
Version of code that implements the API defined in this file Major Version of code that implements the API defined in this file

◆ SF_CELR_NSALNX_CODE_VERSION_MINOR

#define SF_CELR_NSALNX_CODE_VERSION_MINOR (0U)
Minor Version of code that implements the API defined in this file

Function Documentation

◆ sf_cellular_nsal_invalid_packet_handler()

void sf_cellular_nsal_invalid_packet_handler (NX_PACKET * *p_packet_ptr*, sf_cellular_instance_t const * *p_celr_instance*)

Cellular framework nsal invalid callback handler.

Parameters

[in]	p_packet_ptr	Pointer to invalid PPP Packet received
[in]	p_celr_instance	Pointer to cellular framework instance

Cellular framework nsal invalid callback handler.

Parameters

[in]	p_packet_ptr	Pointer to invalid PPP Packet received
[in]	p_celr_instance	Pointer to cellular framework instance

variable to get Memory compare result

Check whether packet contains "NO CARRIER" string, we are ignoring first and last 2 bytes of packet which are Carriage Return and Line Feed.

check whether no carrier string present

Disconnect Network

Soft reset the module

Provision the Module using callback

Reestablish data connection

Restart PPP

Release the packet

◆ sf_cellular_nsal_netx_driver()

void sf_cellular_nsal_netx_driver (NX_IP_DRIVER * *driver_req_ptr*, sf_cellular_instance_t const * *p_cellular_instance*, sf_cellular_nsal_cfg_t * *p_cellular_nsal_cfg*)

NetX IP Driver entry function.

Parameters

[in]	driver_req_ptr	Pointer to NetX IP Driver
[in]	p_cellular_instance	Pointer to cellular framework instance
[in]	p_cellular_nsal_cfg	Pointer to cellular nsal configuration structure

NetX IP Driver entry function.

Parameters

[in]	driver_req_ptr	Pointer to NetX IP Driver
[in]	p_cellular_instance	Pointer to cellular framework instance
[in]	p_cellular_nsal_cfg	Pointer to cellular nsal configuration structure

Interface link is UP. Send the packet

◆ sf_cellular_nsal_ppp_send_byte()

void sf_cellular_nsal_ppp_send_byte (UCHAR *byte*, sf_cellular_instance_t const * *p_celr_instance*)

PPP Send Byte Callback function call from PPP Stack.

NSAL PPP Send bytes callback API

Parameters

[in]	byte	Byte to send
[in]	p_celr_instance	Pointer to cellular framework instance
[in]	byte	Byte to send
[in]	p_celr_instance	Pointer to cellular framework instance

Transmit byte

ssp_err_t	SF_COMMS_TELNET_VersionGet (ssp_version_t *const p_version) Get driver version. More...

Detailed Description

RTOS-integrated Communications Framework NetX telnet server implementation.

Macro Definition Documentation

◆ SF_COMMS_TELNET_OPEN

#define SF_COMMS_TELNET_OPEN (0x434D544EU)
"CMTN" in ASCII, used to identify general timer handle

Function Documentation

◆ SF_COMMS_TELNET_Close()

ssp_err_t SF_COMMS_TELNET_Close (sf_comms_ctrl_t *const *p_api_ctrl*)

Disconnect Telnet server and clean up resources.

Return values

SSP_SUCCESS	Connection successfully closed
SSP_ERR_ASSERTION	Parameter check failed for one of the following: • Pointer p_api_ctrl is NULL • p_ctrl->p_telnet_server is NULL • Telnet server field nx_telnet_server_id indicate this instance is not created already thus invlaid instance of Telnet server.
SSP_ERR_NOT_OPEN	Connection is not open

Note

- For Telnet server specific API details, refer Telnet server user manual.
- For NetX specific API details, refer NetX user manual.
- For ThreadX specific API details, refer ThreadX user manual.
- This function is reentrant.

Check if connection is open

Update connection record.

Return connection not open if no record found

Stop and release Telnet server and ThreadX resources for this connection

Mark this connection uninitialized.

◆ SF_COMMS_TELNET_Lock()

ssp_err_t SF_COMMS_TELNET_Lock (sf_comms_ctrl_t *const *p_api_ctrl*, sf_comms_lock_t *lock_type*, UINT *timeout*)

Acquire lock type for the Telnet comms instance.

Return values

SSP_SUCCESS	Acquired requested lock on given connection.
SSP_ERR_ASSERTION	Pointer p_api_ctrl is NULL.
SSP_ERR_NOT_OPEN	Connection is not open.
SSP_ERR_TIMEOUT	Acquiring requested lock timed-out.

Note

- For Telnet server specific API details, refer Telnet server user manual.
- For NetX specific API details, refer NetX user manual.
- For ThreadX specific API details, refer ThreadX user manual.

Check if connection is open

Get both lock if requested

Else get the lock type requested

◆ SF_COMMS_TELNET_Open()

ssp_err_t SF_COMMS_TELNET_Open (sf_comms_ctrl_t *const *p_api_ctrl*, sf_comms_cfg_t const *const *p_cfg*)

Initializes the Telnet server and other operating system resources.

Return values

SSP_SUCCESS	comms Telnet instance opened successfully.
SSP_ERR_IN_USE	comms Telnet maximum connection limit reached.
SSP_ERR_ALREADY_OPEN	comms Telnet instance already open.
SSP_ERR_ASSERTION	Parameter check failed for one of the following: • Pointer p_api_ctrl is NULL. • Pointer p_cfg is NULL • Pointer p_cfg->p_extend is NULL • Pointer p_cfg_extend->p_telnet_server is NULL • Pointer p_cfg_extend->p_ip is NULL • Pointer p_cfg_extend->p_stack is NULL • Pointer p_cfg_extend->stack_size is invalid i.e. zero
SSP_ERR_INTERNAL	An internal ThreadX Or NetX error has occurred. This is typically a failure to create/use thread mutex or failure create/enable an internal thread/feature for NetX service.

Note

- Do not modify sf_comms_ctrl_t structure returned by this API as it is for module's internal purpose.
- For Telnet server specific API details, refer Telnet server user manual.
- For NetX specific API details, refer NetX user manual.
- For ThreadX specific API details, refer ThreadX user manual.
- This function is reentrant.

Initialize and start Telnet server and ThreadX resources for this connection

Mark this connection initialized.

◆ SF_COMMS_TELNET_Read()

ssp_err_t SF_COMMS_TELNET_Read (sf_comms_ctrl_t *const *p_api_ctrl*, uint8_t *const *p_dest*, uint32_t const *bytes*, UINT const *timeout*)

Read data from the Telnet comms connection.

Return values

SSP_SUCCESS	Data reception ends successfully.
SSP_ERR_ASSERTION	One of the following invalid parameter passed. • Pointer p_api_ctrl is NULL • Pointer p_dest is NULL • Invalid read length i.e. bytes value is zero
SSP_ERR_NOT_OPEN	Connection is not open
SSP_ERR_TIMEOUT	One of the following operation timed out. • 'Event flags get' timed out • 'Receive mutex get' timed out • 'Queue receive' timed out
SSP_ERR_INTERNAL	An internal ThreadX Or NetX error has occurred. This is typically a failure to create/use thread mutex or failure create/enable an internal thread/feature for NetX service.

Note

- For Telnet server specific API details, refer Telnet server user manual.
- For NetX specific API details, refer NetX user manual.
- For ThreadX specific API details, refer ThreadX user manual.
- This API is reentrant.

Check if connection is open

Check and wait for client to be connected with timeout.

Get read lock.

Get data from read queue.

Release read lock.

◆ SF_COMMS_TELNET_Unlock()

ssp_err_t SF_COMMS_TELNET_Unlock (sf_comms_ctrl_t *const *p_api_ctrl*, sf_comms_lock_t *lock_type*)

Release lock type for the Telnet comms instance.

Return values

SSP_SUCCESS	Released requested lock on given connection..
SSP_ERR_ASSERTION	Pointer p_api_ctrl is NULL.
SSP_ERR_NOT_OPEN	Connection is not open.

Note

- For Telnet server specific API details, refer Telnet server user manual.
- For NetX specific API details, refer NetX user manual.
- For ThreadX specific API details, refer ThreadX user manual.

Check if connection is open

Release Lock(s) on this connection.

◆ SF_COMMS_TELNET_VersionGet()

ssp_err_t SF_COMMS_TELNET_VersionGet (ssp_version_t *const *p_version*)

Get driver version.

Return values

SSP_SUCCESS	Operation successful
SSP_ERR_ASSERTION	p_version pointer is NULL

Note

- This function is reentrant.

◆ SF_COMMS_TELNET_Write()

ssp_err_t SF_COMMS_TELNET_Write (sf_comms_ctrl_t *const *p_api_ctrl*, uint8_t const *const *p_src*, uint32_t const *bytes*, UINT const *timeout*)

Write data to the Telnet comms connection.

Return values

SSP_SUCCESS	Data transmission finished successfully.
SSP_ERR_ASSERTION	One of the following invalid parameter passed. • Pointer p_api_ctrl is NULL. • Pointer p_src is NULL. • Invalid write length i.e. bytes value is zero.
SSP_ERR_NOT_OPEN	Connection is not open
SSP_ERR_TIMEOUT	One of the following operation timed out. • 'Event flags get' timed out • 'Transmit mutex get' timed out
SSP_ERR_OUT_OF_MEMORY	Couldn't allocate pool memory for Telnet server
SSP_ERR_INTERNAL	An internal ThreadX Or NetX error has occurred. This is typically a failure to create/use thread mutex or failure create/enable an internal thread/feature for NetX service.

Note

- For Telnet server specific API details, refer Telnet server user manual.
- For NetX specific API details, refer NetX user manual.
- For ThreadX specific API details, refer ThreadX user manual.
- This function is reentrant.

Check if connection is open

Check and wait for client to be connected with timeout.

Get write lock.

Send data to the connected client.

Release write lock.

sf_comms_telnet_instance_ctrl_t Struct Reference
Renesas Synergy Software Package Reference » Framework Layer » Telnet Communication Framework on sf_comms_telnet

Detailed Description

RTOS-integrated Console Framework.

This is a ThreadX aware console framework implemented using the SSP communications framework.

Macro Definition Documentation

◆ SF_CONSOLE_CODE_VERSION_MAJOR

#define SF_CONSOLE_CODE_VERSION_MAJOR (2U)
Version of code that implements the API defined in this file

Function Documentation

◆ SF_CONSOLE_ArgumentFind()

ssp_err_t SF_CONSOLE_ArgumentFind (uint8_t const *const *p_arg*, uint8_t const *const *p_str*, int32_t *const *p_index*, int32_t *const *p_data*)

Finds a command line argument in an input string and returns the index of the character immediately following the argument and any string numbers converted to integers.

Return values

SSP_SUCCESS	Argument found successfully
SSP_ERR_ASSERTION	p_arg or p_str is NULL
SSP_ERR_INTERNAL	String passed after parsing command is NULL_CODE.

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is reentrant for any channel.

Search for first letter match at beginning of word.

If the input string matches the input argument, store the index of the character following the argument in p_index and the data at that index in p_data. Then return.

◆ SF_CONSOLE_CallbackNextMenu()

void SF_CONSOLE_CallbackNextMenu (sf_console_callback_args_t * *p_args*)

Callback provided to continue parsing the next menu down.

Parameters

[in]	p_args	Pointer to callback arguments to use in the next menu.

Next level menu is passed in as the user context parameter

Update current menu.

Check to see if the next menu command was input in the remaining string.

◆ SF_CONSOLE_Close()

ssp_err_t SF_CONSOLE_Close (sf_console_ctrl_t *const *p_api_ctrl*)

Close the communications driver.

Return values

SSP_SUCCESS	Console successfully closed
SSP_ERR_ASSERTION	Pointer to control block is NULL

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is reentrant for any channel.

Close UART driver

◆ SF_CONSOLE_Open()

ssp_err_t SF_CONSOLE_Open (sf_console_ctrl_t *const *p_api_ctrl*, sf_console_cfg_t const *const *p_cfg*)

Initialize console framework and open low-level communication driver.

Return values

SSP_SUCCESS	Console channel is successfully opened
SSP_ERR_ASSERTION	Parameter check failed for one of the following : -Pointer to the control block is NULL -Pointer to the config block is NULL -Pointer p_cfg->p_initial_menu is NULL -Pointer p_cfg->p_comms is NULL -Pointer p_cfg->p_comms->p_api is NULL -Pointer p_cfg->p_comms->p_api->open is NULL

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is reentrant for any channel.

Open UART driver

Store echo configuration and initial menu in control block

Prompt for input autostart is true

◆ SF_CONSOLE_Parse()

ssp_err_t SF_CONSOLE_Parse (sf_console_ctrl_t *const *p_api_ctrl*, sf_console_menu_t const *const *p_menu*, uint8_t const *const *p_input*, uint32_t const *bytes*)

Looks for input string in menu, and calls callback function if found.

Return values

SSP_SUCCESS	Data parsed successfully, command found and callback called.
SSP_ERR_UNSUPPORTED	Command not found in the current menu.
SSP_ERR_ASSERTION	One or more input parameter pointers are invalid.

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is reentrant for any channel.

Print help menu if help command is entered

Go back one menu if previous menu command is entered.

Go back to root menu if root menu command is entered.

Look for matching commands, call callback if command found.

◆ SF_CONSOLE_Prompt()

ssp_err_t SF_CONSOLE_Prompt (sf_console_ctrl_t *const *p_api_ctrl*, sf_console_menu_t const *const *p_menu*, UINT const *timeout*)

Prompt the user to input a command.

Return values

SSP_SUCCESS	Received valid command and called callback
SSP_ERR_ASSERTION	p_ctrl is NULL
SSP_ERR_UNSUPPORTED	Command not found in the current menu.

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is reentrant for any channel.

Update stored current menu pointer if a new pointer is specified.

Print menu name followed by ">" to prompt for user input.

Lock the console UART framework to reserve exclusive access until the command completes.

Note

Transmission is only locked while the menu name is printed and while the input command is non-zero in length. This allow debug messages to print from other threads while echo is off or no input command has been entered.

Wait for input

Parse input and call associated user callback.

Command is complete, so unlock comms reception.

◆ SF_CONSOLE_Read()

ssp_err_t SF_CONSOLE_Read (sf_console_ctrl_t *const *p_api_ctrl*, uint8_t *const *p_dest*, uint32_t const *bytes*, uint32_t const *timeout*)

Reads data into the destination byte by byte and echos input to the console.

Return values

SSP_SUCCESS	Data read completed successfully
SSP_ERR_ASSERTION	Parameter check failed for one of the following : -Pointer p_dest is NULL -Pointer to the control block is NULL -Pointer p_ctrl->p_comms is NULL -Pointer p_ctrl->p_comms->p_api is NULL -Pointer p_ctrl->p_comms->p_api->lock is NULL -Pointer p_ctrl->p_comms->p_api->unlock is NULL

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is reentrant for any channel.

Lock the communications framework reception until carriage return is received.

Read one byte at a time, checking for carriage returns, backspace, delete, and escape codes.

Unlock the communications framework reception

◆ SF_CONSOLE_VersionGet()

ssp_err_t SF_CONSOLE_VersionGet (ssp_version_t *const *p_version*)

Console version get function.

Parameters

[in]	p_version	Version information stored here.

Return values

SSP_SUCCESS	Version stored in provided pointer.
SSP_ERR_ASSERTION	p_version was null.

Set version pointer

◆ SF_CONSOLE_Write()

ssp_err_t SF_CONSOLE_Write (sf_console_ctrl_t *const *p_api_ctrl*, uint8_t const *const *p_src*, uint32_t const *timeout*)

Write a NULL terminated string to the console.

Return values

SSP_SUCCESS	Data write completed successfully
SSP_ERR_ASSERTION	Pointer to the control block is NULL
SSP_ERR_INVALID_SIZE	If length passed is zero or length passed is greater than 128U (max value).

Returns

See Common Error Codes or lower level drivers for other possible return codes.

Note

This function is reentrant for any channel.

Write null terminated string. Calculate the length. If it isn't longer than the maximum, write the entire string to the console.

sf_console_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » Console Framework

#include <sf_console.h>

Data Fields

sf_console_menu_t const *	p_current_menu Current menu is stored here.
sf_comms_instance_t const *	p_comms Pointer to communications driver instance.
uint8_t	new_line Whether to echo input commands to transmitter.
bool	echo Whether to echo input commands to transmitter.

uint8_t	input [SF_CONSOLE_MAX_INPUT_LENGTH] Input buffer used to store user input.

Detailed Description

Console instance control block. DO NOT INITIALIZE. Initialization occurs when sf_console_api_t::open is called

Detailed Description

RTOS-integrated Crypto Common Framework Module.

Macro Definition Documentation

◆ SF_CRYPTO_CODE_VERSION_MAJOR

#define SF_CRYPTO_CODE_VERSION_MAJOR (2U)
The API version of SSP Crypto Framework Common Module

Function Documentation

◆ SF_CRYPTO_Close()

ssp_err_t SF_CRYPTO_Close (sf_crypto_ctrl_t *const *p_api_ctrl*)

SSP Crypto Framework Common Close operation.

Parameters

[in,out]	p_api_ctrl	Pointer to a Crypto framework control block

Return values

SSP_SUCCESS	Module was successfully closed.
SSP_ERR_NOT_OPEN	Module has not opened.
SSP_ERR_ASSERTION	NULL pointer is passed as an input parameter.
SSP_ERR_INTERNAL	RTOS service returned a unexpected error.
SSP_ERR_CRYPTO_HAL_ERROR	Unable to successfully close the Crypto Common HAL module.

Check if the module has been opened. If not, return error.

Close a lower level crypto driver.

◆ SF_CRYPTO_Lock()

ssp_err_t SF_CRYPTO_Lock (sf_crypto_ctrl_t *const *p_api_ctrl*)

Locks the module. This API is utilized for locking shared resources.

Parameters

[in,out]	p_api_ctrl	Pointer to a Crypto framework control block

Return values

SSP_SUCCESS	Module resources are successfully locked.
SSP_ERR_TIMEOUT	Unable to get ownership of the mutex within the specified time.
SSP_ERR_INTERNAL	Thread suspension was aborted. Critical error.
SSP_ERR_ASSERTION	NULL pointer is passed.as an input parameter.
SSP_ERR_NOT_OPEN	The module is not yet opened.

Check if the module has been opened. If not, return error.

Acquire the mutex.

◆ SF_CRYPTO_Open()

ssp_err_t SF_CRYPTO_Open (sf_crypto_ctrl_t *const *p_api_ctrl*, sf_crypto_cfg_t const *const *p_cfg*)

SSP Crypto Framework Common Open operation.

Parameters

[in,out]	p_api_ctrl	Pointer to a Crypto framework control block
[in]	p_cfg	Pointer to a Crypto framework configuration structure

Return values

SSP_SUCCESS	Crypto framework was successfully opened.
SSP_ERR_ASSERTION	NULL pointer is passed.
SSP_ERR_INTERNAL	RTOS service returned a unexpected error.
SSP_ERR_CRYPTO_HAL_ERROR	Crypto HAL driver retuned an error.

Check if the module has been opened. If opened, return error.

Open a lower level crypto driver and ensure the engine is initialized here or already in other SCE supported stack.

◆ SF_CRYPTO_StatusGet()

ssp_err_t SF_CRYPTO_StatusGet (sf_crypto_ctrl_t *const *p_api_ctrl*, sf_crypto_state_t * *p_status*)

Gets the Crypto Common Framework module status.

Parameters

[in]	p_api_ctrl	Pointer to a Crypto framework control block
[out]	p_status	Memory location to store module status.

Return values

SSP_SUCCESS	Status returned successfully.
SSP_ERR_ASSERTION	The parameter p_status is NULL.
SSP_ERR_CRYPTO_COMMON_NOT_OPENED	This common module is not yet opened.

Check if the module has a valid / known status else return error.

Return the module status.

◆ SF_CRYPTO_Unlock()

ssp_err_t SF_CRYPTO_Unlock (sf_crypto_ctrl_t *const *p_api_ctrl*)

Unlocks the module. This API is utilized for unlocking shared resources.

Parameters

[in,out]	p_api_ctrl	Pointer to a Crypto framework control block

Return values

SSP_SUCCESS	Module resources are successfully unlocked.
SSP_ERR_ASSERTION	NULL pointer is passed as an input parameter.
SSP_ERR_INTERNAL	Mutex is not owned by a caller thread.
SSP_ERR_NOT_OPEN	The module is not yet opened.

Check if the module has been opened. If not, return error.

Return the mutex.

◆ SF_CRYPTO_VersionGet()

ssp_err_t SF_CRYPTO_VersionGet (ssp_version_t *const *p_version*)

Gets the version of Crypto Common Framework module.

Parameters

[out]	p_version	Pointer to the memory to store the version information.

Return values

SSP_SUCCESS	Successful close.
SSP_ERR_ASSERTION	The parameter p_version is NULL.

Return the module version.

Enumeration Type Documentation

◆ sf_crypto_cipher_state_t

enum sf_crypto_cipher_state_t

States the SSP Crypto Cipher Framework module can go through.

Enumerator	
SF_CRYPTO_CIPHER_STATE_CLOSED	The Cipher module is closed.
SF_CRYPTO_CIPHER_STATE_OPENED	The Cipher module is opened.
SF_CRYPTO_CIPHER_STATE_INITIALIZED	The cipher operation is initialized.
SF_CRYPTO_CIPHER_STATE_UPDATED	The cipher operation is updated.
SF_CRYPTO_CIPHER_STATE_FINALIZED	The cipher operation is finalized.

Function Documentation

◆ sf_crypto_cipher_aes_aad_update()

ssp_err_t sf_crypto_cipher_aes_aad_update (sf_crypto_cipher_instance_ctrl_t * *p_ctrl*, sf_crypto_data_handle_t const *const *p_aad*)

Subroutine to update the AAD for the cipher operation.

Parameters

[in,out]	p_ctrl	Pointer to the cipher framework module control block used in the open() call.
[in]	p_aad	Pointer to the input data structure - has the pointer to input AAD and the data length

Return values

SSP_SUCCESS	AAD was updated successfully.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes.

Check if there is data in the aad block buffer. If so first fill it from the input data

Update the number of bytes remaining in the input buffer to be processed.

If data is block length, encrypt it.

Check if the input data is a multiple of block size

Update the number of bytes remaining in the input buffer to be processed.

If any bytes remain that is less than the block size, copy to the partial buffer

Update the size of the data in the partial block

◆ sf_crypto_cipher_aes_decrypt_final()

ssp_err_t sf_crypto_cipher_aes_decrypt_final (sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*, sf_crypto_data_handle_t const *const *p_data_in*, sf_crypto_data_handle_t *const *p_data_out*)

Subroutine to finalize the cipher decrypt operation.

Parameters

[in,out]	p_ctrl	Pointer to the cipher framework module control block used in the open() call.
[in,out]	p_data_in	Pointer to the input data structure - has the pointer to input data and the data length
[in,out]	p_data_out	Pointer to the output data structure - has the pointer to output data and the data length.

Return values

SSP_SUCCESS	Cipher operation was finalized successfully.
SSP_ERR_INVALID_ARGUMENT	Input data is invalid.
SSP_ERR_INVALID_SIZE	The out buffer is inadequate to hold the output data.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes.

Validate the input parameters

Process the input data

If GCM check if there is any partial AAD remaining, if so call to update AAD

If GCM set the tag

For GCM compute and verify the tag - return error to indicate if the data is valid or not.

◆ sf_crypto_cipher_aes_encrypt_final()

ssp_err_t sf_crypto_cipher_aes_encrypt_final (sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*, sf_crypto_data_handle_t const *const *p_data_in*, sf_crypto_data_handle_t *const *p_data_out*)

Subroutine to finalize the cipher encrypt operation.

Parameters

[in,out]	p_ctrl	Pointer to the cipher framework module control block used in the open() call.
[in,out]	p_data_in	Pointer to the input data structure - has the pointer to input data and the data length
[in,out]	p_data_out	Pointer to the output data structure - has the pointer to output data and the data length.

Return values

SSP_SUCCESS	Cipher operation was finalized successfully.
SSP_ERR_INVALID_ARGUMENT	Input data is invalid.
SSP_ERR_INVALID_SIZE	The out buffer is inadequate to hold the output data.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes.

Validate the input parameters

Process the input data

Handle padding for ECB, CBC modes

Add padding and encrypt the last block.

If there is a remaining partial block process it. For GCM zero padding is automatic

Now that the possible AAD update and plain text encryption is done, get the GCM tag

◆ sf_crypto_cipher_aes_final()

ssp_err_t sf_crypto_cipher_aes_final (sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*, sf_crypto_data_handle_t const *const *p_data_in*, sf_crypto_data_handle_t *const *p_data_out*)

Sub-routine for Crypto Cipher Framework to call the appropriate routine for final encryption based on the algorithm for the cipherFinal operation. This function is called by SF_CRYPTO_CIPHER_CipherFinal().

Parameters

[in,out]	p_ctrl	Pointer to the Cipher framework module instance control block.
[in]	p_data_in	Pointer to the input data buffer and the length of the input data.
[in,out]	p_data_out	Pointer to the output data buffer and the buffer length on input. If data is output, the length of the data will be updated.

Return values

SSP_SUCCESS	The cipher update operation was successful.
SSP_ERR_UNSUPPORTED	The module does not support the algorithm bbased on the key type specified by the user.

Returns

See Common Error Codes for other possible return codes.

Validate that there is some input data provided / processed before the finalizing operation Applies to both encrypt and decrypt operations. AES GCM is the only exception.

◆ sf_crypto_cipher_aes_init()

ssp_err_t sf_crypto_cipher_aes_init (sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*, sf_crypto_cipher_op_mode_t *cipher_operation_mode*, sf_crypto_key_t const *const *p_key*, sf_crypto_cipher_algorithm_init_params_t * *p_algorithm_specific_params*)

Subroutine to initialize the AES cipher operation.

Parameters

[in,out]	p_ctrl	Pointer to the cipher framework module control block used in the open() call.
[in]	cipher_operation_mode	The cipher operation mode - encrypt / decrypt.
[in]	p_key	Pointer to the key to be used for the cipher operations.
[in]	p_algorithm_specific_params	Pointer to the algorithm specific parameters.

Return values

SSP_SUCCESS	All of the input parameters are validated successfully.
SSP_ERR_INVALID_ARGUMENT	An input for the required cipher operation is invalid.

All buffers within the context buffer are allocated at Open. Now just zeroise their contents.

Copy the init parameters to the context buffer

◆ sf_crypto_cipher_aes_interface_get()

void sf_crypto_cipher_aes_interface_get (sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*)

Subroutine to get a pointer to the AES HAL API instance.

Parameters

[in,out]	p_ctrl	Pointer to a Cipher framework control block, whose p_hal_api is filled with HAL AES interface. This will be NULL, for MCUs /feature/ configuration parameters not supported

Get a Crypto common control block and the HAL instance.

Check the AES key type and size and get an appropriate API instance.

Get the HAL API instance for a selected algorithm type.

◆ sf_crypto_cipher_aes_update()

ssp_err_t sf_crypto_cipher_aes_update (sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*, sf_crypto_data_handle_t const *const *p_data_in*, sf_crypto_data_handle_t *const *p_data_out*)

Subroutine to update the cipher AES operation.

Parameters

[in,out]	p_ctrl	Pointer to the cipher framework module control block used in the open() call.
[in,out]	p_data_in	Pointer to the input data structure - has the pointer to input data and the data length
[in,out]	p_data_out	Pointer to the output data structure - has the pointer to output data and the data length.

Return values

SSP_SUCCESS	Cipher operation was updated successfully.
SSP_ERR_INVALID_SIZE	The out buffer is inadequate to hold the output data.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes.

If GCM check if there is any partial AAD remaining. This is to be processed only if the cipher is in initialized state. Once the update is done AAD calculations should not be done. if so call to update AAD

Set the data out length before starting cipher operation.

Update the number of bytes remaining in the input buffer to be processed.

If data is block length, process it. That is encrypt / decrypt it.

Check if the remaining input data is a multiple of block size

Update the number of bytes written to the output buffer.

Update the number of bytes remaining in the input buffer to be processed.

If any bytes remain that is less than the block size, copy to the partial buffer

Update the size of the data in the partial block

◆ sf_crypto_cipher_aes_validate_aad_update_params_context()

ssp_err_t sf_crypto_cipher_aes_validate_aad_update_params_context (
sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*)

Subroutine to validate the context buffer parameters for the cipherAadUpdate operation.

Parameters

[in,out]	p_ctrl	Pointer to the cipher framework module control block used in the open() call.

Return values

SSP_SUCCESS	Parameters were validated successfully.
SSP_ERR_ASSERTION	At least one of the buffer is set to NULL.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes.

◆ SF_CRYPTO_CIPHER_CipherAadUpdate()

ssp_err_t SF_CRYPTO_CIPHER_CipherAadUpdate (sf_crypto_cipher_ctrl_t *const *p_api_ctrl*, sf_crypto_data_handle_t const *const *p_aad*)

Updates Additional Authenticated Data. This is applicable only to AES GCM. Can be called multiple times for chunks of data.

Return values

SSP_SUCCESS	The function updated the AAD successfully.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.
SSP_ERR_UNSUPPORTED	Key types / algorithms are not supported for the MCU part.
SSP_ERR_INVALID_CALL	Function call was made if the module state had not yet transitioned to SF_CRYPTO_CIPHER_STATE_INITIALIZED.

Returns

See Common Error Codes for other possible return codes.

Note

1. *This is a blocking call.*
2. *This function has to be called before any call to cipherUpdate / cipherFinal is made.*
3. *The data buffer must be WORD aligned.*

do nothing - similar to the cipherUpdate API

Get a Crypto Framework common control block and the interface.

Check if the Crypto Cipher Framework is in the correct state to execute this operation. If module is not opened or initialized, return an error.

Acquire the lock from the common module to access the Crypto HAL driver.

AAD is optional so no need to track if it is updated.

Unlock the module.

if update processing has succeeded return the error from unlock.

◆ SF_CRYPTO_CIPHER_CipherFinal()

ssp_err_t SF_CRYPTO_CIPHER_CipherFinal (sf_crypto_cipher_ctrl_t *const *p_api_ctrl*, sf_crypto_data_handle_t const *const *p_data_in*, sf_crypto_data_handle_t *const *p_data_out*)

SSP Crypto Cipher Framework - Generates encrypted / decrypted output from all/last input data. This function processes any remaining input data buffered by one or more calls to the cipherUpdate()API as well as input data supplied in the input parameter. This function must be invoked to complete a cipher operation.

Return values

SSP_SUCCESS	The module updated a message Digest successfully.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.
SSP_ERR_UNSUPPORTED	Key types / algorithms are not supported for the MCU part.
SSP_ERR_INVALID_CALL	Function call was made if the module state had not yet transitioned to SF_CRYPTO_CIPHER_STATE_INITIALIZED or SF_CRYPTO_CIPHER_STATE_UPDATED.

Returns

See Common Error Codes for other possible return codes.

Note

1. This is a blocking call.
2. On encryption and decryption operations, block alignment considerations may require that the number of bytes written into output buffer be larger or smaller than input data length or even 0.
3. The output data area must not partially overlap the input data area such that the input data is modified before it is used else incorrect output may result.
4. Except for GCM, if the length of input data is 0 and no input was provided through update, an error is returned.
5. On decryption operations the padding bytes are not written to p_data_out.p_data.
6. The input and output buffers must be WORD aligned.

Get a Crypto Framework common control block and the interface.

Check if the Crypto Cipher Framework is in the correct state to execute this operation. If module is not opened or initialized, return an error.

Acquire the lock from the common module to access to Crypto HAL driver.

Mark the module status as 'Finalized'.

Unlock the module.

if final processing has succeeded return the error from unlock.

◆ SF_CRYPTO_CIPHER_CipherInit()

ssp_err_t SF_CRYPTO_CIPHER_CipherInit (sf_crypto_cipher_ctrl_t *const *p_api_ctrl*, sf_crypto_cipher_op_mode_t *cipher_operation_mode*, sf_crypto_key_t const *const *p_key*, sf_crypto_cipher_algorithm_init_params_t *const *p_algorithm_specific_params*)

SSP Crypto Framework Cipher Init operation. The input parameters initialize the cipher operation. Some of the parameters are algorithm specific. The input parameters are validated and then copied into the context buffer. Refer to sf_crypto_cipher_aes_init_params_t or sf_crypto_cipher_rsa_init_params_t.

Return values

SSP_SUCCESS	The module is initialized for cipher operation successfully.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.
SSP_ERR_INVALID_ARGUMENT	One of the input parameters is invalid.
SSP_ERR_UNSUPPORTED	The module does not support the key type specified by user.

Returns

See Common Error Codes for other possible return codes.

Validate cipher operation mode

Check if the module can transition to the initialized state.

Note: sf_crypto.lock() is not called because the HAL driver does not access HW during init. If HW will be accessed through the HAL driver, lock should be acquired.

Do algorithm specific init

Mark the module status as 'Initialized'.

◆ SF_CRYPTO_CIPHER_CipherUpdate()

ssp_err_t SF_CRYPTO_CIPHER_CipherUpdate (sf_crypto_cipher_ctrl_t *const *p_api_ctrl*, sf_crypto_data_handle_t const *const *p_data_in*, sf_crypto_data_handle_t *const *p_data_out*)

SSP Crypto Cipher Framework - Encrypts / Decrypts the input data and writes the cipher-text or plain-text to the output buffer. Can be called multiple times for chunks of data.

Return values

SSP_SUCCESS	The function updated a cipher operation successfully.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.
SSP_ERR_UNSUPPORTED	Key types / algorithms are not supported for the MCU part.
SSP_ERR_INVALID_CALL	Function call was made if the module state had not yet transitioned to SF_CRYPTO_CIPHER_STATE_INITIALIZED.

Returns

See Common Error Codes for other possible return codes.

Note

1. This is a blocking call.
2. The input and output buffers have to be WORD aligned.
3. On encryption and decryption operations, block alignment considerations may require that the number of bytes written into output buffer be larger or smaller than input data length or even 0.
4. The output data area must not partially overlap the input data area such that the input data is modified before it is used else incorrect output may result.
5. If the length of input data is 0 this method does nothing.
6. For all Cipher operations cipherFinal() must be called to finalize the operation.
7. For RSA Operations, no data is output unless cipherFinal() is called.

If input data length is 0 - do nothing return success.

The status will be set to 'updated' only when data is processed.

Get a Crypto Framework common control block and the interface.

Check if the Crypto Cipher Framework is in the correct state to transition to do the update operation. If module is not opened or initialized, return an error.

Acquire the lock from the common module to access the Crypto HAL driver.

If update processing has succeeded return the error from unlock.

◆ SF_CRYPTO_CIPHER_Close()

ssp_err_t SF_CRYPTO_CIPHER_Close (sf_crypto_cipher_ctrl_t *const *p_api_ctrl*)

SSP Crypto Cipher Framework Close operation.

Return values

SSP_SUCCESS	The module was successfully closed.
SSP_ERR_ASSERTION	One or more input parameters maybe NULL.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.

Returns

See Common Error Codes for other possible return codes.

Get a Crypto common control block and the interface.

Check if the Crypto Framework Cipher module has been opened. If not yet opened, return an error.

Note: sf_crypto.lock() is not called because the HAL driver does not access HW during close. If HW will be accessed through the HAL driver, lock should be acquired.

Free the memory allocated for this instance and close the HAL driver.

◆ sf_crypto_cipher_deinitialize_aes_instance()

ssp_err_t sf_crypto_cipher_deinitialize_aes_instance (sf_crypto_cipher_instance_ctrl_t * *p_ctrl*)

closes the underlying HAL instance and releases the memory for the instance.

Parameters

[in,out]	p_ctrl	Pointer to Crypto Cipher Framework instance control block structure.

Return values

SSP_SUCCESS	The module instantiated successfully.
SSP_ERR_TIMEOUT	Was unable to allocate the memory within the specified time to wait.
SP_ERR_OUT_OF_MEMORY	Requested size is zero or larger than the pool.
SSP_ERR_INTERNAL	RTOS service returned a unexpected error.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls: sf_crypto_cipher_instance_memory_allocate sf_crypto_cipher_hal_open

◆ sf_crypto_cipher_deinitialize_rsa_instance()

ssp_err_t sf_crypto_cipher_deinitialize_rsa_instance (sf_crypto_cipher_instance_ctrl_t * *p_ctrl*)

closes the underlying HAL instance and releases the memory for the instance.

Parameters

[in,out]	p_ctrl	Pointer to Crypto Cipher Framework instance control block structure.

Return values

SSP_SUCCESS	The module instantiated successfully.
SSP_ERR_TIMEOUT	Was unable to allocate the memory within the specified time to wait.
SP_ERR_OUT_OF_MEMORY	Requested size is zero or larger than the pool.
SSP_ERR_INTERNAL	RTOS service returned a unexpected error.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls: sf_crypto_cipher_instance_memory_allocate sf_crypto_cipher_hal_open

First close the Framework TRNG instance.

Then close the HAL RSA instance.

◆ sf_crypto_cipher_initialize_aes_instance()

ssp_err_t sf_crypto_cipher_initialize_aes_instance (sf_crypto_cipher_instance_ctrl_t * *p_ctrl*, sf_crypto_cipher_cfg_t const *const *p_cfg*)

Allocates memory for the instance and opens the underlying HAL instance.

Parameters

[in,out]	p_ctrl	Pointer to Crypto Cipher Framework instance control block structure.
[in]	p_cfg	Pointer to the configuration structure for Cipher module .

Return values

SSP_SUCCESS	The module instantiated successfully.
SSP_ERR_TIMEOUT	Was unable to allocate the memory within the specified time to wait.
SP_ERR_OUT_OF_MEMORY	Requested size is zero or larger than the pool.
SSP_ERR_INTERNAL	RTOS service returned a unexpected error.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls: sf_crypto_cipher_instance_memory_allocate sf_crypto_cipher_hal_open

◆ sf_crypto_cipher_initialize_rsa_instance()

ssp_err_t sf_crypto_cipher_initialize_rsa_instance (sf_crypto_cipher_instance_ctrl_t * *p_ctrl*, sf_crypto_cipher_cfg_t const *const *p_cfg*)

Allocates memory for the instance and opens the underlying HAL instance.

Parameters

[in,out]	p_ctrl	Pointer to Crypto Cipher Framework instance control block structure.
[in]	p_cfg	Pointer to the configuration structure for Cipher module .

Return values

SSP_SUCCESS	The module instantiated successfully.
SSP_ERR_TIMEOUT	Was unable to allocate the memory within the specified time to wait.
SP_ERR_OUT_OF_MEMORY	Requested size is zero or larger than the pool.
SSP_ERR_INTERNAL	RTOS service returned a unexpected error.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes. This function calls: sf_crypto_cipher_instance_memory_allocate sf_crypto_cipher_hal_open

◆ sf_crypto_cipher_is_key_type_aes()

bool sf_crypto_cipher_is_key_type_aes (sf_crypto_key_type_t *key_type*)

Subroutine to check if the key type enum provided is a valid AES key type for cipher operation.

Parameters

[in]	key_type	The key type to be tested.

Return values

true	The key is a valid AES key type.
false	The key is NOT a valid AES key type.

Check the key type and and determine the algorithm.

◆ sf_crypto_cipher_is_key_type_rsa()

bool sf_crypto_cipher_is_key_type_rsa (sf_crypto_key_type_t *key_type*)

Subroutine to check if key type is RSA.

Parameters

[in]	key_type	Key type enum.

Return values

true	Key type is RSA plain text (standard or CRT)/ wrapped.
false	Key type is not RSA.

Check the key type is valid for RSA operations.

◆ SF_CRYPTO_CIPHER_Open()

ssp_err_t SF_CRYPTO_CIPHER_Open (sf_crypto_cipher_ctrl_t *const *p_api_ctrl*, sf_crypto_cipher_cfg_t const *const *p_cfg*)

SSP Crypto Cipher Framework Open operation.

The SF_CRYTO_CIPHER_Open function: Allocates memory required for the cipher operations based on the configuration parameters. Acquires lock for the shared crypto resources. Gets the interface to the HAL driver based on the config parameters. Calls the .open function of the HAL API. On successful open, the module status is updated as such. The shared resources are unlocked before exit.

Return values

SSP_SUCCESS	The module was successfully opened.
SSP_ERR_ASSERTION	One or more input parameters maybe NULL.
SSP_ERR_INVALID_ARGUMENT	An invalid argument is used.
SSP_ERR_CRYPTO_COMMON_NOT_OPENED	Crypto Framework Common Module has yet been opened.
SSP_ERR_ALREADY_OPEN	The module has been already opened.
SSP_ERR_UNSUPPORTED	The module does not support the key type specified by user.
SSP_ERR_INTERNAL	An internal ThreadX error has occurred. This is typically a failure to create/use a mutex or to create an internal thread.

Returns

See Common Error Codes for other possible return codes.

Get a Crypto common control block and the interface.

Get the pointers to TRNG control and API structures from the instance pointed to by the config structure.

Check if the Crypto Framework has been opened. If not yet opened, return an error.

Check if the Cipher module has been already opened. If opened, return an error.

Validate the cfg parameters

Fill the control block with the validated cfg parameters

Determine and fill the algorithm type in the control block.

Note: sf_crypto.lock() is not called because the HAL driver does not access HW during open. The HAL interfaceGet API is also called which does not access HW either. If HW will be accessed through the HAL driver, lock should be acquired.

Allocate memory resources used by this framework instance and open HAL driver

◆ SF_CRYPTO_CIPHER_RSA_EB_SIZE_BYTES()

__STATIC_INLINE uint32_t SF_CRYPTO_CIPHER_RSA_EB_SIZE_BYTES (uint32_t *key_size_bits*)

Routine to calculate and return the Encryption block size based on the key size.

Private Functions.

Parameters

[in]	key_size_bits	key size in bits.

◆ sf_crypto_cipher_rsa_final()

ssp_err_t sf_crypto_cipher_rsa_final (sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*, sf_crypto_data_handle_t const *const *p_data_in*, sf_crypto_data_handle_t *const *p_data_out*)

Routine to process the final encryption / decryption operation for RSA. This function is called by SF_CRYPTO_CIPHER_CipherFinal().

Return values

SSP_SUCCESS	The cipher update operation was successful.
SSP_ERR_UNSUPPORTED	The module does not support the algorithm bbased on the key type specified by the user.

Returns

See Common Error Codes for other possible return codes.

Clean up the data in the context buffer before exiting.

◆ sf_crypto_cipher_rsa_init()

ssp_err_t sf_crypto_cipher_rsa_init (sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*, sf_crypto_cipher_op_mode_t *cipher_operation_mode*, sf_crypto_key_t const *const *p_key*, sf_crypto_cipher_algorithm_init_params_t * *p_algorithm_specific_params*)

Routine to handle the cipherInit RSA operation.

Parameters

[in,out]	p_ctrl	Pointer to the cipher framework module control block used in the open() call.
[in]	cipher_operation_mode	The cipher operation mode - encrypt / decrypt.
[in]	p_key	Pointer to the key to be used for the cipher operations.
[in]	p_algorithm_specific_params	Pointer to the algorithm specific parameters.

Return values

SSP_SUCCESS	Cipher operation was updated successfully.
SSP_ERR_INVALID_SIZE	The out buffer is inadequate to hold the output data.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes.

All buffers within the context buffer are allocated at Open. Now just zeroise their contents.

Copy data into the control block / context buffer.

◆ sf_crypto_cipher_rsa_interface_get()

void sf_crypto_cipher_rsa_interface_get (sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*)

Subroutine to get a RSA HAL API instance. This function is called by sf_crypto_cipher_open_rsa().

Parameters

[in,out]	p_ctrl	Pointer to a Key framework control block, whose p_hal_api filled with HAL RSA interface. This indicates NULL, for not supported MCUs

Get a Crypto common control block and the HAL instance.

Check the RSA key type.

Check the RSA key type.

Get the HAL API instance for a selected algorithm type.

◆ SF_CRYPTO_CIPHER_RSA_PKCS_1_5_EB_DATA_SIZE_BYTES()

__STATIC_INLINE uint32_t SF_CRYPTO_CIPHER_RSA_PKCS_1_5_EB_DATA_SIZE_BYTES (uint32_t *key_size_bits*)

Routine to calculate and return the Encryption block size based on the key size.

Parameters

[in]	key_size_bits	key size in bits.

◆ sf_crypto_cipher_rsa_update()

ssp_err_t sf_crypto_cipher_rsa_update (sf_crypto_cipher_instance_ctrl_t *const *p_ctrl*, sf_crypto_data_handle_t const *const *p_data_in*, sf_crypto_data_handle_t *const *p_data_out*)

Subroutine to update the cipher RSA operation. This algorithm is only suitable for messages of limited length. The total number of input bytes processed during encryption may not be more than k-11, where k is the RSA key's modulus size in bytes. The encryption block(EB) during encryption with a Public key is built as follows: EB = 00 || 02 || PS || 00 || M :: M (input bytes) is the plaintext message :: PS is an octet string of length k-3-||M|| of pseudo random nonzero octets. The length of PS must be at least 8 octets. :: k is the RSA modulus size.

Parameters

[in,out]	p_ctrl	Pointer to the cipher framework module control block used in the open() call.
[in]	p_data_in	Pointer to the input data structure - has the pointer to input data and the data length
[in,out]	p_data_out	Pointer to the output data structure - has the pointer to output data and the buffer length on input. If data is filled the length is updated on output.

Return values

SSP_SUCCESS	Cipher operation was updated successfully.
SSP_ERR_UNSUPPORTED	Unknown cipher operation mode was passed in.
SSP_ERR_INVALID_SIZE	The out buffer is inadequate to hold the output data.

Returns

See Common Error Codes or HAL driver for other possible return codes or causes.

input parameters validation - done at the entry nothing to do here no output on update - so no checks for output buffer / length collect input up to the block size for encryption when no padding is selected. collect data up to block size -11 for encryption when padding is selected collect input up to the block size for decryption if it exceeds the above return error

Copy the data into the partial block

◆ SF_CRYPTO_CIPHER_VersionGet()

ssp_err_t SF_CRYPTO_CIPHER_VersionGet (ssp_version_t *const *p_version*)
Gets driver version based on compile time macros. **Return values** SSP_SUCCESS — The version is returned successfully. SSP_ERR_ASSERTION — The parameter p_version is NULL.

sf_crypto_cipher_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » SSP Crypto Cipher Framework

#include <sf_crypto_cipher.h>

Data Fields

sf_crypto_key_type_t	key_type Key type.
sf_crypto_key_size_t	key_size Key size.
sf_crypto_cipher_mode_t	cipher_chaining_mode Chaining mode specified for the cipher operation.
sf_crypto_cipher_state_t	status Module status.
crypto_algorithm_type_t	cipher_algorithm_type Cipher algorithm for the keys selected.
sf_crypto_instance_ctrl_t *	p_lower_lvl_fwk_common_ctrl Pointer to the Crypto Framework Common instance.

sf_crypto_api_t *	p_lower_lvl_fwk_common_api Pointer to the Crypto Framework Common API.
sf_crypto_trng_instance_ctrl_t *	p_lower_lvl_sf_crypto_trng_ctrl Pointer to the Crypto TRNG API.
sf_crypto_trng_api_t *	p_sf_crypto_trng_api Pointer to the Crypto TRNG API.
void *	p_hal_ctrl Pointer to HAL control structure for the Cipher operation.
void *	p_hal_api Pointer to HAL API structure for the cipher algorithm.
void *	p_cipher_context_buffer Cipher context buffer after DWORD alignment.

Detailed Description

SSP Crypto Cipher Framework instance control block. DO NOT INITIALIZE. Initialization occurs when SF_CRYPTO_CIPHER_Open is called

---

The documentation for this struct was generated from the following file:

- sf_crypto_cipher.h

5.1.3.16 SSP Crypto Hash Framework

Macro Definition Documentation

◆ SF_CRYPTO_HASH_CODE_VERSION_MAJOR

#define SF_CRYPTO_HASH_CODE_VERSION_MAJOR (2U)
The API version of SSP Crypto Framework

Function Documentation

◆ SF_CRYPTO_HASH_Close()

ssp_err_t SF_CRYPTO_HASH_Close (sf_crypto_hash_ctrl_t *const *p_api_ctrl*)

SSP Crypto HASH Framework Close operation.

Return values

SSP_SUCCESS	The module was successfully closed.
SSP_ERR_ASSERTION	NULL is passed through the argument.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.
SSP_ERR_UNSUPPORTED	HASH algorithms are not supported for the MCU part.

Returns

See Common Error Codes for other possible return codes.

Get a Crypto Framework common control block and the interface.

Check if the Crypto HASH Framework has been opened.

Delete memory resources used by this module and close the HASH HAL module.

Mark the module status as 'Closed'.

Decrement the open counter to enable users to close SF_CRYPTO module.

◆ SF_CRYPTO_HASH_MessageDigestFinal()

ssp_err_t SF_CRYPTO_HASH_MessageDigestFinal (sf_crypto_hash_ctrl_t *const *p_api_ctrl*, sf_crypto_data_handle_t *const *p_msg_digest*, uint32_t * *p_size*)

SSP Crypto HASH Framework - Hashes the last block of data and returns the message digest in the output buffer. Once this function is called, no additional function calls can be made but open function call can be made to initialize a new digest operation. The Output buffer will contain the message digest on success and the buffer length will be updated to reflect the size of the digest. On error, only the length is set to 0.This is a blocking call.

Return values

SSP_SUCCESS	The module updated a message Digest successfully.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_INVALID_SIZE	The memory size to store a message digest is not sufficient for the digest type.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.
SSP_ERR_UNSUPPORTED	HASH algorithms are not supported for the MCU part.
SSP_ERR_INVALID_CALL	Function call was made if the module state had not yet transitioned to SF_CRYPTO_HASH_DIGEST_UPDATED.

Returns

See Common Error Codes for other possible return codes.

Note

p_msg_digest->p_data must be WORD aligned. The memory allocation to store a message digest is user's responsibility.

Get a Crypto Framework common control block and the interface.

Check if the Crypto Framework has been in 'Digest Updated' status. If not, return an error.

Update the message digest.

We are all set now. A message digest is returned. Mark the module status as 'Opened'.

Unlock the module.

◆ SF_CRYPTO_HASH_MessageDigestInit()

ssp_err_t SF_CRYPTO_HASH_MessageDigestInit (sf_crypto_hash_ctrl_t *const *p_api_ctrl*)

SSP Crypto HASH Framework - Generates the initial message digest in an internal context buffer. Can be called once messageDigestFinal() is called to initialize a new digest operation. Unless a different HASH type is used, users do not need to close the module for new digest operation. This is a blocking call.

Return values

SSP_SUCCESS	The module updated a message Digest successfully.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.

Returns

See Common Error Codes for other possible return codes.

Note

When this function is called if SF_CRYPTO_HASH_DIGEST_INITIALIZED or SF_CRYPTO_HASH_DIGEST_UPDATED, the message digest will be initialized.

Check if the Crypto HASH Framework module has been opened. If not yet opened, return an error.

Create initial message digest code in the module context.

Mark the module status as 'Digest Initialized'.

◆ SF_CRYPTO_HASH_MessageDigestUpdate()

ssp_err_t SF_CRYPTO_HASH_MessageDigestUpdate (sf_crypto_hash_ctrl_t *const *p_api_ctrl*, sf_crypto_data_handle_t const *const *p_data_in*)

SSP Crypto HASH Framework - Hashes input data and saves it in an internal context buffer. Can be called multiple times for additional blocks of data. This is a blocking call.

Return values

SSP_SUCCESS	The module updated a message Digest successfully.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.
SSP_ERR_UNSUPPORTED	HASH algorithms are not supported for the MCU part.
SSP_ERR_INVALID_CALL	Function call was made if the module state had not yet transitioned to SF_CRYPTO_HASH_DIGEST_INITIALIZED.

Returns

See Common Error Codes for other possible return codes.

Get a Crypto Framework common control block and the interface.

Check if the Crypto Framework has been in 'Digest Initialized' status. If not, return an error.

Update the message digest.

Mark the module status as 'Digest Updated'.

Unlock the module.

◆ SF_CRYPTO_HASH_Open()

ssp_err_t SF_CRYPTO_HASH_Open (sf_crypto_hash_ctrl_t *const *p_api_ctrl*, sf_crypto_hash_cfg_t const *const *p_cfg*)

SSP Crypto HASH Framework Open operation.

Return values

SSP_SUCCESS	The module was successfully opened.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_CRYPTO_COMMON_NOT_OPENED	Crypto Framework Common Module has yet been opened.
SSP_ERR_ALREADY_OPEN	The module has been already opened.
SSP_ERR_UNSUPPORTED	HASH algorithms are not supported for the MCU part.

Returns

See Common Error Codes for other possible return codes.

Get a Crypto Framework common instance, the control block and interface.

Get a lower-level HASH instance.

Check if the Crypto Framework common instance has been opened. If not yet opened, return an error.

Check if the Crypto HASH Framework module has been opened.

Create memory resources used by this module and open a HASH HAL module.

Increment the open counter.

We have successfully processed the open procedures. Mark the module status as 'Opened'.

◆ SF_CRYPTO_HASH_VersionGet()

ssp_err_t SF_CRYPTO_HASH_VersionGet (ssp_version_t *const *p_version*)

Gets driver version based on compile time macros.

Return values

SSP_SUCCESS	Successful close.
SSP_ERR_ASSERTION	The parameter p_version is NULL.

sf_crypto_hash_instance_ctrl_t Struct Reference

Renesas Synergy Software Package Reference » Framework Layer » SSP Crypto Hash Framework

#include <sf_crypto_hash.h>

Data Fields

sf_crypto_hash_state_t	status Module status.
sf_crypto_hash_type_t	hash_type HASH algorithm type.
sf_crypto_hash_context_t	hash_context Context for calculating message digest.
sf_crypto_instance_t *	p_lower_lvl_crypto_common Pointer to a Crypto Framework common instance.
hash_instance_t *	p_lower_lvl_instance pointer to lower-level crypto module control structure

Detailed Description

SSP Crypto HASH Framework instance control block

Detailed Description

RTOS-integrated Crypto Key Framework Module.

Macro Definition Documentation

◆ SF_CRYPTO_KEY_CODE_VERSION_MAJOR

#define SF_CRYPTO_KEY_CODE_VERSION_MAJOR (2U)
The API version of SSP Crypto Framework

Function Documentation

◆ sf_crypto_key_aes_get_available_api_interface()

void sf_crypto_key_aes_get_available_api_interface (sf_crypto_key_instance_ctrl_t *const *p_ctrl*, crypto_interface_get_param_t * *p_param*)

Subroutine to get first available AES HAL API instance for ECB/CBC/CTR/GCM chaining modes. This function is called by sf_crypto_key_aes_interface_get(). Key framework control block's p_hal_api field is filled with HAL AES interface. This will be set to NULL if the API interface is not found on the particular MCU.

Parameters

[in,out]	p_ctrl	Pointer to a Key framework control block.
[in]	p_param	Interface get param. Algorithm type, key type and key size is set by the caller.

◆ sf_crypto_key_aes_interface_get()

void sf_crypto_key_aes_interface_get (sf_crypto_key_instance_ctrl_t *const *p_ctrl*)

Subroutine to get a AES HAL API instance. This function is called by sf_crypto_key_open_aes(). Key framework control block's p_hal_api field is filled with HAL AES interface. This will be set to NULL if the API interface is not found on the particular MCU.

Parameters

[in,out]	p_ctrl	Pointer to a Key framework control block. interface. This indicates NULL, for not supported MCUs

◆ sf_crypto_key_aes_verify_wrapped_xtskey_buffersize()

ssp_err_t sf_crypto_key_aes_verify_wrapped_xtskey_buffersize (sf_crypto_key_size_t *key_size*, uint32_t *buffer_length*)

Subroutine to verify that the provided num_words (indicates size of the secret AES Wrapped key for XTS AES chaining mode) is sufficient or not, before proceeding with key operations. This function is called by sf_crypto_key_aes_verify_wrappedkey_buffersize as an internal function call.

Parameters

[in]	key_size	Indicates AES key sizes - 128/256-bits, supported chaining mode - XTS
[in]	buffer_length	Length of the secret key which shall be filled by AES Key generation algorithm.

Return values

SSP_SUCCESS	Key length is successful, and proceed with AES Key Generation.
SSP_ERR_INVALID_SIZE	Failed, as the allocated key length is not sufficient for the Key generation operation of AES

Note

This function is not a user API but an internal function for SF_CRYPTO_KEY to verify whether passed buffer size is sufficient for Key to hold in Key Generate API call.

◆ sf_crypto_key_aes_verify_wrappedkey_buffersize()

ssp_err_t sf_crypto_key_aes_verify_wrappedkey_buffersize (sf_crypto_key_size_t *key_size*, uint32_t *buffer_length*)

Subroutine to verify that the provided buffer_length (indicates size of the secret AES Wrapped key) is sufficient or not, before proceeding with key Generate function. This function is called by AES Key Generate function before passing request to Crypto HAL Key generate API call.

Parameters

[in]	key_size	Indicates AES key sizes - 128/192/256-bits, supported chaining modes - CBC, ECB, GCM, CTR
[in]	buffer_length	Length of the secret key which shall be filled by AES Key generation algorithm.

Return values

SSP_SUCCESS	Key length is successful, and proceed with AES Key Generation.
SSP_ERR_INVALID_SIZE	Failed, as the allocated key length is not sufficient for the Key generation operation of AES

Note

This function is not a user API but an internal function for SF_CRYPTO_KEY to verify whether passed buffer size is sufficient for Key to hold in Key Generate API call.

◆ SF_CRYPTO_KEY_Close()

ssp_err_t SF_CRYPTO_KEY_Close (sf_crypto_key_ctrl_t *const *p_api_ctrl*)

SSP Crypto Key Framework Close operation.

Return values

SSP_SUCCESS	The module was successfully closed.
SSP_ERR_ASSERTION	NULL is passed through the argument.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.

Returns

See Common Error Codes for other possible return codes.

Get a Crypto common control block and the interface.

Check if the Crypto Framework has been opened. If not yet opened, return an error.

Close Crypto HAL module.

Decrement the open counter to enable users to close SF_CRYPTO module.

◆ sf_crypto_key_close_aes()

ssp_err_t sf_crypto_key_close_aes (sf_crypto_key_instance_ctrl_t * *p_ctrl*)

Subroutine to close a Crypto AES HAL module. This function is called by SF_CRYPTO_KEY_Close().

Parameters

[in]	p_ctrl	Pointer to a Crypto Key Framework module control block

Return values

SSP_SUCCESS	AES HAL module is successfully closed.

Returns

See Common Error Codes for other possible return codes.

◆ sf_crypto_key_close_ecc()

ssp_err_t sf_crypto_key_close_ecc (sf_crypto_key_instance_ctrl_t * *p_ctrl*)

Subroutine to close a Crypto ECC HAL module. This function is called by SF_CRYPTO_KEY_Close().

Parameters

[in]	p_ctrl	Pointer to a Crypto Key Framework module control block

Return values

SSP_SUCCESS	ECC HAL module is successfully closed.

Returns

See Common Error Codes for other possible return codes.

Close the Crypto HAL driver.

Release the control block memory back to byte pool

◆ sf_crypto_key_close_rsa()

ssp_err_t sf_crypto_key_close_rsa (sf_crypto_key_instance_ctrl_t * *p_ctrl*)

Subroutine to close a Crypto RSA HAL module. This function is called by SF_CRYPTO_KEY_Close().

Parameters

[in]	p_ctrl	Pointer to a Crypto Key Framework module control block

Return values

SSP_SUCCESS	RSA HAL module is successfully closed.

Returns

See Common Error Codes for other possible return codes.

◆ SF_CRYPTO_KEY_EcdhSharedSecretCompute()

ssp_err_t SF_CRYPTO_KEY_EcdhSharedSecretCompute (sf_crypto_key_ctrl_t *const *p_api_ctrl*, sf_crypto_key_t *const *p_local_secret_key*, sf_crypto_key_t *const *p_remote_public_key*, sf_crypto_key_t *const *p_shared_secret*)

SSP Crypto Framework ECDH Shared Secret Computation operation.

Return values

SSP_SUCCESS	The module created a key successfully.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.
SSP_ERR_UNSUPPORTED	The module does not support scalar multiplication operation.
SSP_ERR_INVALID_SIZE	The length of the buffer supplied for the key to be generated, is insufficient.

Returns

See Common Error Codes for other possible return codes.

Check if ECDH computation is used with ECC, otherwise return an error.

Check if the Crypto Framework has been opened. If not yet opened, return an error.

Lock the module to access to Crypto HAL module.

Perform the scalar multiplication.

Unlock the module.

◆ SF_CRYPTO_KEY_Generate()

ssp_err_t SF_CRYPTO_KEY_Generate (sf_crypto_key_ctrl_t *const *p_api_ctrl*, sf_crypto_key_t *const *p_secret_key*, sf_crypto_key_t *const *p_public_key*)

SSP Crypto Framework Key Generate operation.

Return values

SSP_SUCCESS	The module created a key successfully.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_NOT_OPEN	The module has yet been opened. Call Open API first.
SSP_ERR_UNSUPPORTED	The module does not support the key type specified by user.
SSP_ERR_INVALID_SIZE	The length of the buffer supplied for the key to be generated, is insufficient.

Returns

See Common Error Codes for other possible return codes.

Check if the Crypto Framework has been opened. If not yet opened, return an error.

Lock the module to access to Crypto HAL module.

Generate a key.

Unlock the module.

◆ sf_crypto_key_generate_aes()

ssp_err_t sf_crypto_key_generate_aes (sf_crypto_key_instance_ctrl_t * *p_ctrl*, sf_crypto_key_t *const *p_secret_key*)

Subroutine to generate a AES key. This function is called by SF_CRYPTO_KEY_Generate().

Parameters

[in]	p_ctrl	Pointer to a Crypto Key Framework module control block.
[out]	p_secret_key	Pointer to a secret key.

Return values

SSP_SUCCESS	The module created the AES Secret key successfully.
SSP_ERR_INVALID_SIZE	Failed, as the allocated key buffer length is not sufficient for the AES Key generation operation.
SSP_ERR_UNSUPPORTED	Procedure is not supported for the supplied parameters.

Returns

See Common Error Codes for other possible return codes.

◆ sf_crypto_key_generate_ecc()

ssp_err_t sf_crypto_key_generate_ecc (sf_crypto_key_instance_ctrl_t * *p_ctrl*, sf_crypto_key_t *const *p_secret_key*, sf_crypto_key_t *const *p_public_key*)

Subroutine to generate a ECC key. This function is called by SF_CRYPTO_KEY_Generate().

Parameters

[in]	p_ctrl	Pointer to a Crypto Key Framework module control block
[out]	p_secret_key	Pointer to a secret key
[out]	p_public_key	Pointer to a public key

Return values

SSP_SUCCESS	The module created a key successfully.
SSP_ERR_INVALID_SIZE	Failed, as the allocated key buffer length is not sufficient for the ECC Key generation operation.
SSP_ERR_UNSUPPORTED	Procedure is not supported for the supplied parameters.

Returns

See Common Error Codes for other possible return codes.

Verify the domain parameter input buffer size. The length has to be exactly as specified

Verify the public key buffer size that holds the generated public key.

Verify the secret key buffer size that holds the generated private key.

Local variable created to call the HAL API.

Note that the HAL driver requires data in WORDS

Call Crypto HAL driver.

◆ sf_crypto_key_generate_rsa()

ssp_err_t sf_crypto_key_generate_rsa (sf_crypto_key_instance_ctrl_t * *p_ctrl*, sf_crypto_key_t *const *p_secret_key*, sf_crypto_key_t *const *p_public_key*)

Subroutine to generate a RSA key. This function is called by SF_CRYPTO_KEY_Generate().

Parameters

[in]	p_ctrl	Pointer to a Crypto Key Framework module control block
[out]	p_secret_key	Pointer to a secret key
[out]	p_public_key	Pointer to a public key

Return values

SSP_SUCCESS	The module created a key successfully.
SSP_ERR_INVALID_SIZE	Failed, as the allocated key buffer length is not sufficient for the RSA Key generation operation.
SSP_ERR_UNSUPPORTED	Procedure is not supported for the supplied parameters.

Returns

See Common Error Codes for other possible return codes.

◆ SF_CRYPTO_KEY_Open()

ssp_err_t SF_CRYPTO_KEY_Open (sf_crypto_key_ctrl_t *const *p_api_ctrl*, sf_crypto_key_cfg_t const *const *p_cfg*)

SSP Crypto KeyFramework Open operation.

Return values

SSP_SUCCESS	The module was successfully opened.
SSP_ERR_ASSERTION	NULL is passed through an argument.
SSP_ERR_CRYPTO_COMMON_NOT_OPENED	Crypto Framework Common Module has yet been opened.
SSP_ERR_ALREADY_OPEN	The module has been already opened.
SSP_ERR_UNSUPPORTED	The module does not support the key type specified by user.
SSP_ERR_INVALID_SIZE	The buffer length of one of the configuration parameters is invalid.

Returns

See Common Error Codes for other possible return codes.

Get a Crypto common control block and the interface.

Check if the Crypto Framework has been opened. If not yet opened, return an error.

Check if the Crypto key framework module has been already opened. If yes, return an error.

Set a key type, size, domain and generator point. Generator point and domain are UNUSED for RSA and AES algorithms, applicable only for ECC.

Open Crypto HAL module.

◆ sf_crypto_key_open_aes()

ssp_err_t sf_crypto_key_open_aes (sf_crypto_key_instance_ctrl_t * *p_ctrl*, sf_crypto_key_cfg_t const *const *p_cfg*)

Subroutine to open a Crypto AES HAL module. This function is called by SF_CRYPTO_KEY_Open().

Parameters

[in,out]	p_ctrl	Pointer to a Crypto Key Framework module control block
[in]	p_cfg	Pointer to a Crypto Key Framework module configuration structure

Return values

SSP_SUCCESS	AES HAL module is successfully opened.
SSP_ERR_OUT_OF_MEMORY	Failed to allocate memory to store AES HAL module control block.
SSP_ERR_INTERNAL	RTOS service returned a unexpected error.

Returns

See Common Error Codes for other possible return codes.

◆ sf_crypto_key_open_ecc()

ssp_err_t sf_crypto_key_open_ecc (sf_crypto_key_instance_ctrl_t * *p_ctrl*, sf_crypto_key_cfg_t const *const *p_cfg*)

Subroutine to open a Crypto ECC HAL module. This function is called by SF_CRYPTO_KEY_Open(). The configuration parameters are validated before opening the HAL module.

Parameters

[in,out]	p_ctrl	Pointer to a Crypto Key Framework module control block
[in,out]	p_cfg	Pointer to a Crypto Key Framework module configuration structure

Return values

SSP_SUCCESS	ECC HAL module is successfully opened.
SSP_ERR_OUT_OF_MEMORY	Failed to allocate memory to store ECC HAL module control block.
SSP_ERR_INTERNAL	RTOS service returned a unexpected error.

Returns

See Common Error Codes for other possible return codes.
