Chapter 1 Renesas Synergy™ Software Package Introduction

1.1 Introduction to the SSP User's Manual

This manual describes how to use the Renesas Synergy Software Package for writing applications for the Synergy microcontroller series. In the figure below, the API Reference components of the SSP User's Manual are indicated in blue. Additional components such as the description of the e2 studio ISDE and tutorials and example applications are included in this manual to guide you through the steps of programming with the SSP.

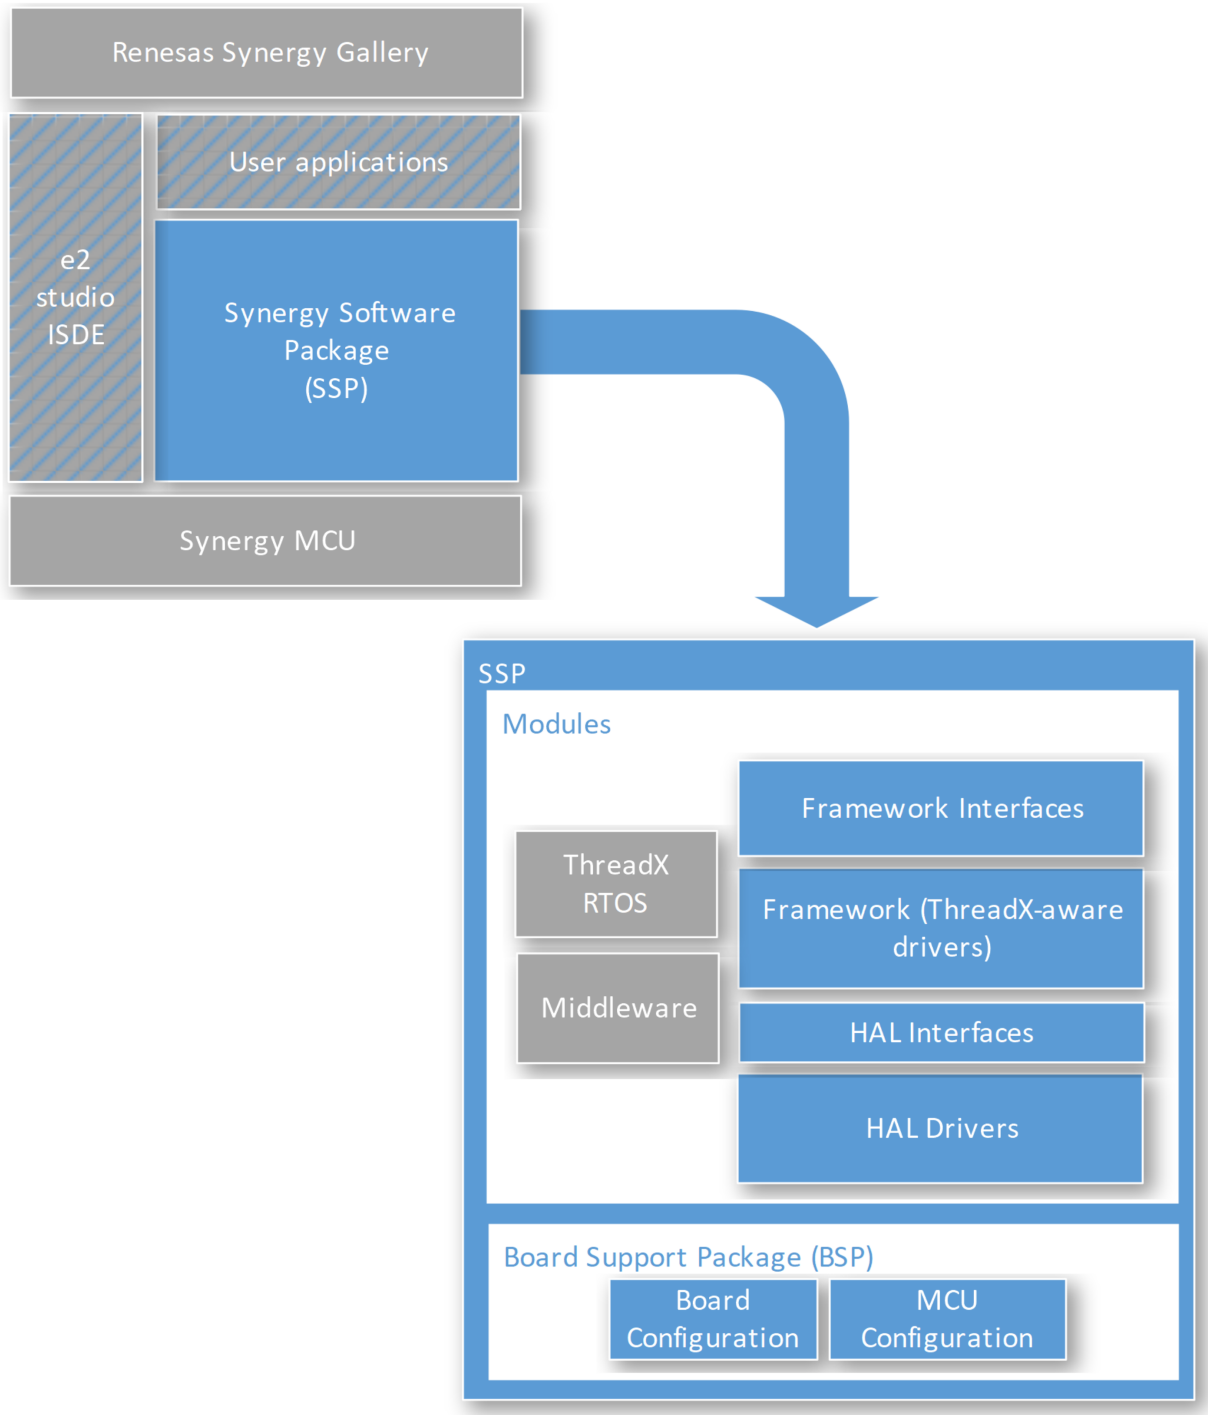

Figure 1: Synergy Software Package (SSP) Documentation

1.2 Subjects Covered in this Manual

To learn about the SSP architecture and about board and chip-level support included in the SSP see:

- SSP Architecture
- BSP Architecture

For programming with the SSP and an introduction to the e2 studio ISDE see:

e2 studio ISDE User Guide

For introductory tutorials and application examples see:

- Tutorial Blinky
- Application WDT

For Module Overviews describing the SSP Modules, see:

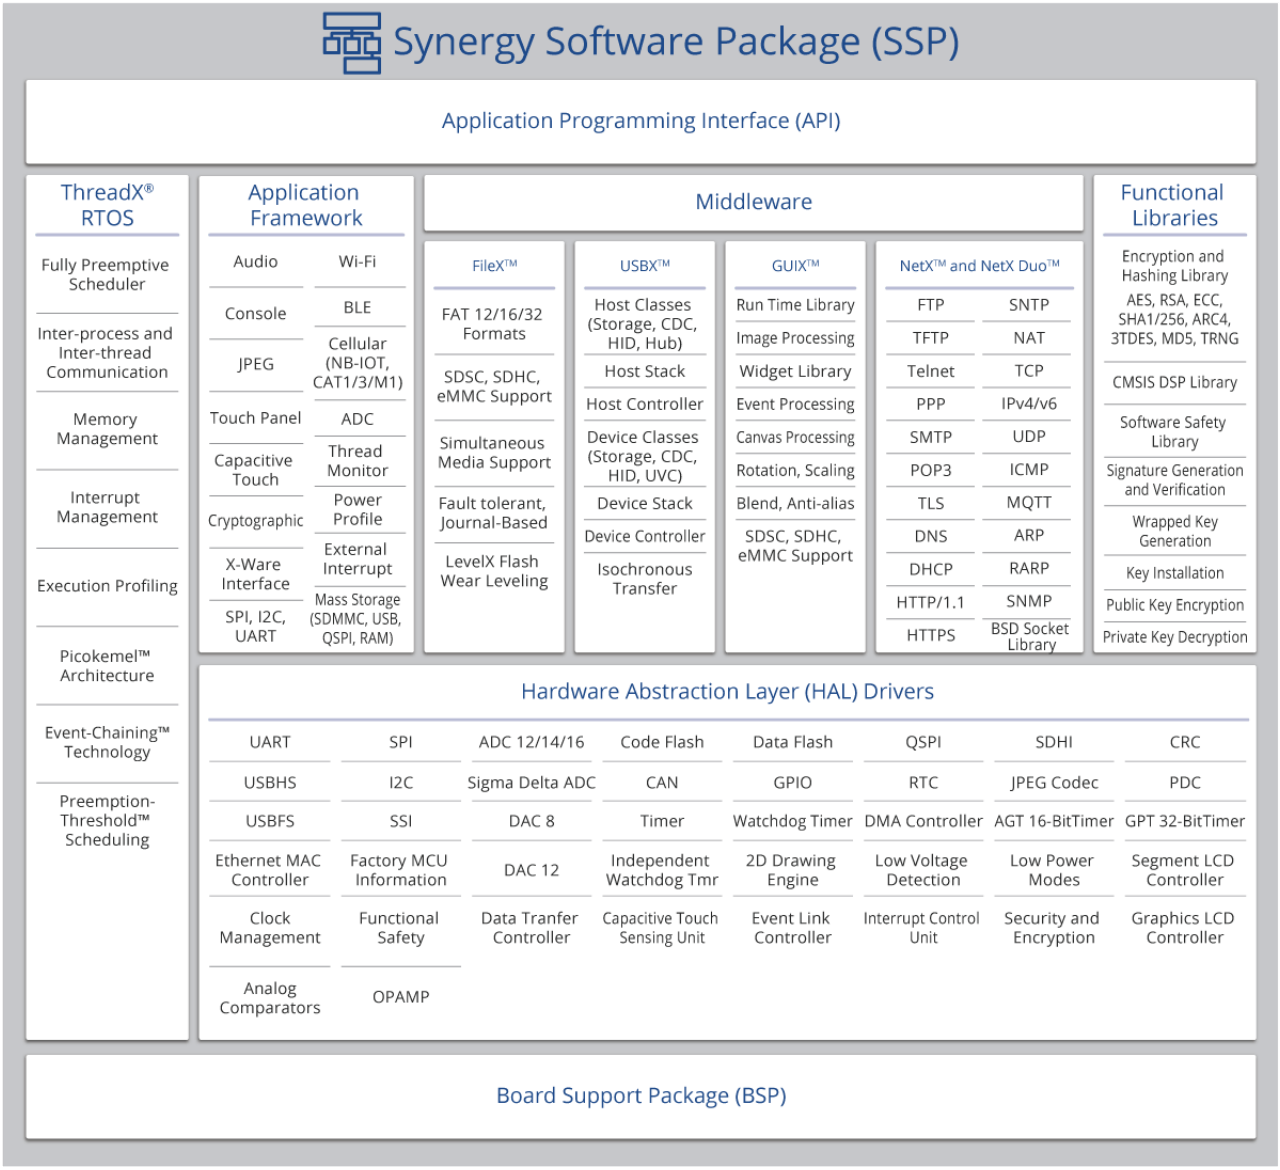
- Framework Layer
- HAL Layer

The API reference documentation of the following SSP components is included in this document:

- Framework Interfaces for Interfaces to the ThreadX-aware Framework Modules
- Framework Layer for ThreadX-aware Framework Driver Modules
- HAL Interfaces for Interfaces to the Hardware Abstraction Layer (HAL) Modules
- HAL Layer for the RTOS-independent HAL driver Modules
- Board Support Package for the Board Support Package (BSP) which includes board-specific and microcontroller-specific configuration modules

Chapter 2 SSP Overview

2.1 SSP Overview



Learn how to develop applications with the Synergy Software Package (SSP) using the SSP's module-based architecture and the functional software layers. Integrate SSP applications with multiple boards and Synergy devices using the Board Support Package (BSP).

The following pages describe the fundamental SSP architecture:

- SSP Architecture
- BSP Architecture

2.1.1 Introduction

2.1.1.1 Purpose

The Renesas Synergy™ Software Package (SSP), part of the Renesas Synergy™ Platform, is a complete integrated software package designed to provide easy to use, scalable, high quality software for embedded system design. Using the Synergy Software Platform will reduce time to market by providing a completely integrated and qualified embedded software platform comprising of an industry leading, completely optimized and hardened Real-time Operating System (RTOS), middleware, communication stacks, function libraries, application framework and hardware abstracted low-level device drivers.

2.1.1.2 Overview

The SSP is divided into four main layers:

- Framework Interfaces The Framework Library connects to Synergy hardware peripherals through common Interfaces, which abstract the hardware into functional use cases. The Interface layer is a group of header files with definitions of functions and parameters, so it consumes no code space.
- Framework Layer The Framework layer consists of RTOS integrated drivers and valuable application code.
- HAL Interfaces HAL layer Interfaces connect to RTOS-independent HAL-level drivers.
- HAL Layer The HAL layer drivers with hardware registers implement Interfaces.

2.1.1.3 Ease of Use

The SSP provides uniform and intuitive APIs that are well documented. Each module is supported with detailed user documentation and software datasheet including code size and execution time for each function.

2.1.1.4 Scalability

Users have the choice to integrate with the platform capabilities using either the Framework Interface or HAL layer, depending on which best meets the needs of the application. To further scale each module, build time options such as parameter checking may be compiled out for smaller, more efficient code.

2.1.2 SSP Architecture

2.1.2.1 Renesas Synergy Software Package (SSP) Architecture

This section describes the Renesas Synergy Software Package (SSP) architecture and how to use the SSP Application Programming Interface (API).

Introduction to the SSP

As microcontrollers increase in complexity, so does the breadth of knowledge required to make them

operate in the desired way. The SSP provides an innovative approach to embedded software for IoT applications. With the SSP, you have a new and extremely powerful software interface from the ground up, making coding fast and providing you with a robust development processes. With this software, you can create differentiated application code instead of spending months developing baseline code to interface at the hardware level.

SSP Terms

Term	Description	Reference
Module	Modules can be peripheral drivers, purely software, or anything in between. Each Module consists of a folder with source code, documentation, and anything else that the customer needs to use the code effectively. Modules are independent units, but they may depend on other Modules. Example SSP Modules are the UART driver (UART Interface), Audio Playback Framework, which relies on timer, DMA, and DAC drivers (Audio Framework Interface), or the Messaging Framework (Messaging Framework Interface). Applications can be built by combining multiple modules to provide the user with the features they need.	SSP Modules
BSP	Short for Board Support Package. In the SSP the BSP provides just enough foundation to allow other SSP modules to work together without issue.	BSP Architecture

Callback Function	This term refers to a function that is called when an event occurs. For example, the bus error interrupt handler is implemented in the r_bsp. The user will likely want to know when a bus error occurs. To alert the user, a callback function can be supplied to the r_bsp. When a bus error occurs the r_bsp will jump to the provided callback function and the user can handle the error. Interrupt callback functions should be kept short and be handled carefully because when they are called the MCU will still be inside of an interrupt and therefore will be delaying any pending interrupts.	-
Interface	See SSP Interfaces section: SSP Interfaces. All interfaces in the SSP are listed here: Framework Interfaces and HAL Interfaces	SSP Interfaces
Instance	See SSP Instances section: SSP Instances	SSP Instances
Module Instance	Single and independent configuration of a Module.	-
Application	Code that is owned and maintained by the user. Application code may be based off sample application code provided by Renesas, but is the responsibility of the user.	An example for a simple application is included as tutorial in this manual: ref application-wdt
Driver	A Driver is a specific kind of Module that directly modifies registers on the MCU.	-
Stacks	The SSP architecture is designed such that Modules work together to form a Stack. Starting with the uppermost Module and going to the bottommost dependency forms a specific Stack.	SSP Stacks

Layer/Level	Stacks are made of multiple layers of Modules. A Layer can consist of one or multiple Modules depending on the requirements of the next Layer up. Layer and Level are used interchangeably.	ref ssp-predefined-layers

2.1.2.2 SSP Modules

Modules are the core building block of SSP. Modules can do many different things, but all Modules share the basic concept of providing functionality upwards and requiring functionality from below.

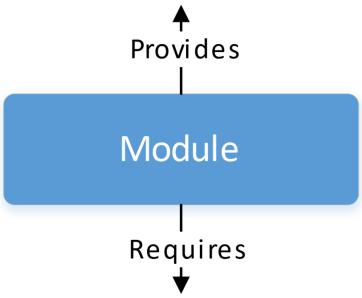


Figure 2: Modules

The amount of functionality provided by a Module is not limited though there are usually points where separation makes sense. If too much functionality is provided, then reuse of the Module can become difficult in the future. If not enough functionality is provided, then unnecessary complexity and overhead may be added in order to make the Modules work as expected.

The simplest SSP application consists of one Module with the user application on top.

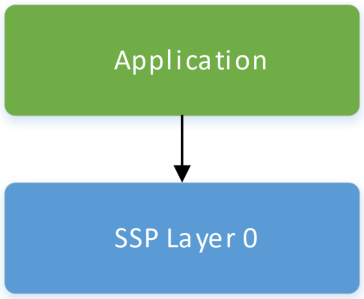

Figure 3: Module with application

For simplicity, ignore the Board Support Package (BSP) for now because it is a requirement of any

SSP project. In the picture above, the BSP is located underneath the bottom layer, SSP Layer 0.

2.1.2.3 SSP Stacks

When modules are layered atop one another, an SSP stack is formed. The stacking process is performed by matching what one module provides with what another module requires. For example, the Audio Playback Framework Module requires a Transfer Interface, which can be fulfilled by the Data Transfer Controller (DTC) Driver Module. Instead of including the DTC code in the Audio Playback Module, we split these into two modules. This allows for reuse of the underlying modules, which has many benefits.

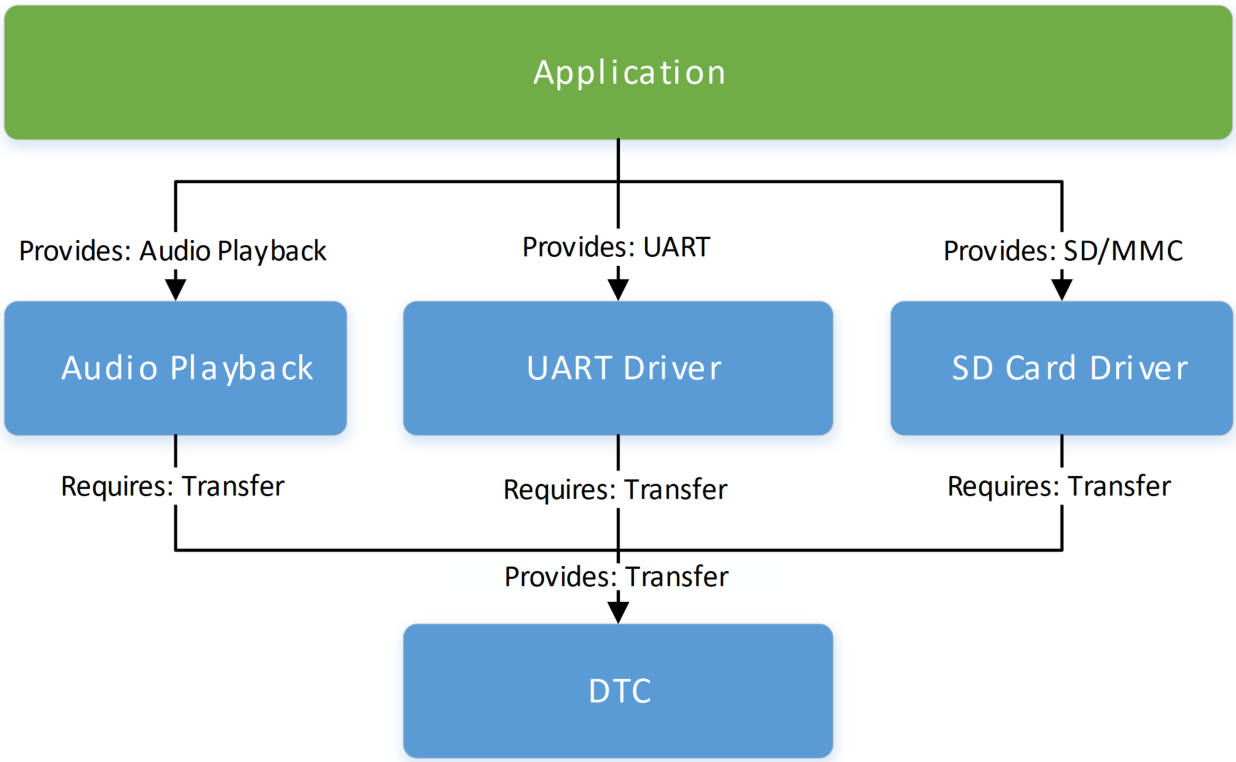

Figure 4: Stacks – Audio playback

By continuing to add layers to the Stack using SSP Modules, you can interface with the Synergy hardware at a high level.

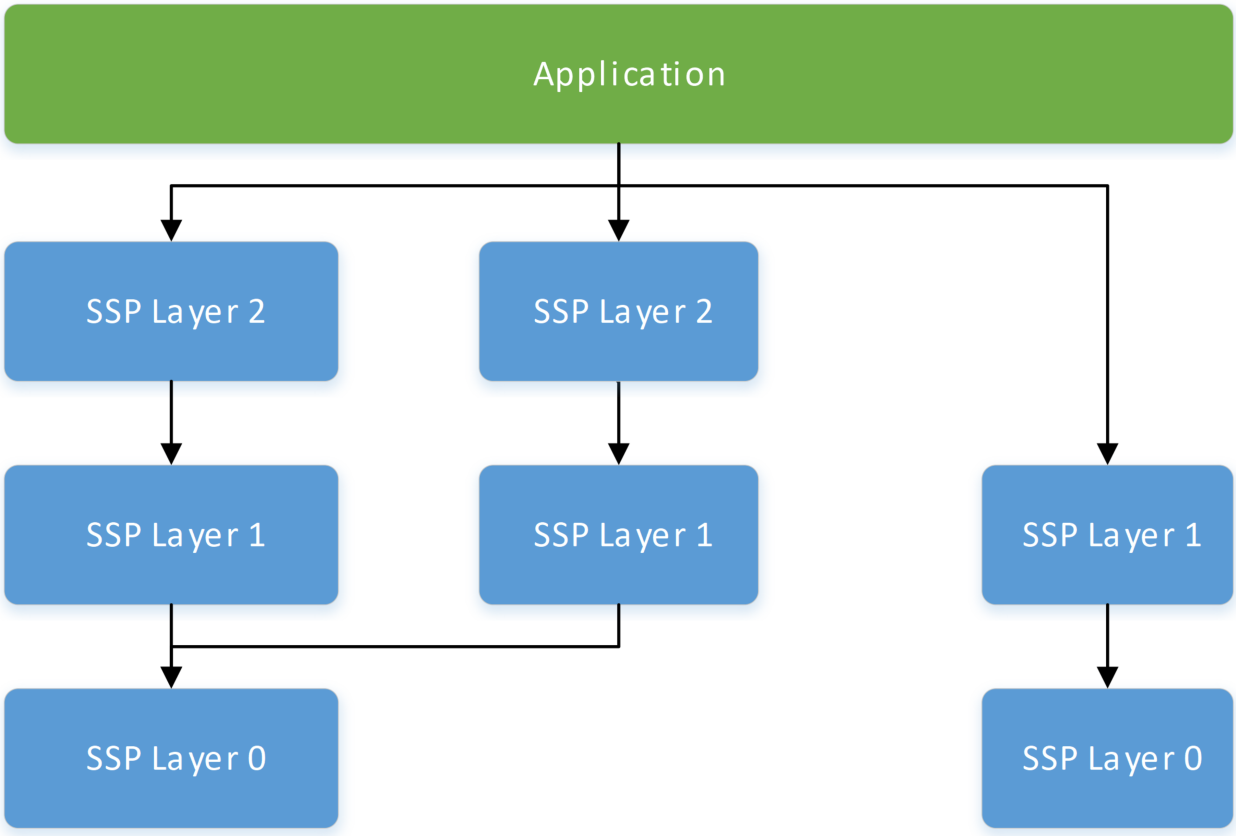

Figure 5: Stacks

The ability to stack modules has great benefit because it ensures the flexibility of the architecture as a whole. If modules are directly dependent upon other modules, then issues arise when application features must work across different user designs. To ensure that modules are reusable the modules must be capable of being swapped out for other modules that provide the same features. The SSP architecture provides this flexibility to swap modules in and out through the use of SSP Interfaces.

2.1.2.4 SSP Interfaces

At the architecture level, Interfaces are the way that Modules provide common features. This commonality allows Modules that adhere to the same Interface to be used interchangeably. Interfaces can be thought of as a contract between two Modules. The Modules agree to work together using the information that was agreed upon in the contract.

On Synergy hardware there is occasionally an overlap of features between different peripherals. For example, I2C communications can be achieved through use of the IIC peripheral or the SCI peripheral in its Simple I2C mode. There is a difference in the level of features provided by both peripherals. In I2C mode the SCI peripheral will only support a subset of the features of the full-featured IIC.

Interfaces aim to provide support for the common features that most users would expect. This means that some of the advanced features of a peripheral, such as the IIC, might not be available in

the Interface. In most cases these features are still available through Interface Extensions.

In design, Interfaces are implemented as header files. All Interface header filenames end with '_api.h'. The following sections detail what makes up an Interface.

SSP Interface Enumerations

Whenever possible, Interfaces use typed enumerations for function parameters and structure members.

```
typedef enum e_i2c_addr_mode
{
     I2C_ADDR_MODE_7BIT = 1, // Use 7-bit addressing mode
     I2C_ADDR_MODE_10BIT // Use 10-bit addressing mode
} i2c_addr_mode_t;
```

Enumerations remove any uncertainty when deciding what values are available for a parameter. Also note that enumeration options follow a strict naming convention where the name of the type is prefixed on the available options. Combining the naming convention with the autocomplete feature available in e^2 studio provides the benefits of rapid coding while maintaining highly readable code.

SSP Interface Data Structures

At a minimum, all SSP Interfaces include three data structures: a control structure, a configuration structure, and an instance structure.

The control structure is used as a unique identifier for using the module. If SSP modules were only peripheral drivers then this control structure might be replaced with a channel number. All function calls for that module would then take a channel number so that the code could determine which peripheral channel to operate on. SSP modules are not restricted to device drivers and therefore the control structure is used. The user allocates storage for a control structure and then sends a pointer to it into the open() call for a Module. At this point, the Module initializes the structure as needed. You must then send in a pointer to the control structure for all subsequent module calls. The contents of the control structure are used by the module and must not be altered. Reading data from a control structure should also be avoided as the data structure is not guaranteed to remain the same between SSP releases. In general, you should treat control structures like a black box.

The contents of a control structure are specific to an instance. This means that two instances of the same interface will have two completely different control structure types. The control structures that exist in an interface are named <interface>_ctrl_t. Below is an example of the interface control structure for I2C:

```
typedef void i2c_ctrl_t;
```

Since all interface control structures are of type void, they cannot be allocated. Instead, these types

are placeholders for instance control structures. Instance control structures are defined in instance header files and are named <instance>_instance_ctrl_t. Below are examples of I2C Instance control structures for the IIC (r_riic) and SCI (r_sci_i2c) peripherals:

```
/* riic Instance control structure to be used with I2C Interface. */
typedef struct st_riic_instance_ctrl
{
    i2c_cfg_t info; // Information describing I2C device
    uint32_t open; // Flag to determine if the device is open
    void * p_reg; // Base register for this channel

} riic_instance_ctrl_t;
/* sci_i2c Instance control structure to be used with I2C Interface. */
typedef struct st_sci_i2c_instance_ctrl
{
    i2c_cfg_t info; // Information describing I2C device
    uint32_t open; // Flag to determine if the device is open
    void * p_reg; // Base register for this channel
 /* More members specific to sci_i2c Instance. */
} sci_i2c_instance_ctrl_t;
```

When using an interface, the instance control structure should be allocated and used in place of the interface control structure. Using the example above, if the SCI-I2C Instance was being used then you would allocate a structure of type sci_i2c_instance_ctrl_t and use it wherever i2c_ctrl_t is referenced in the Interface. The ISDE will take care of allocating the correct control structure for you.

Dynamic memory allocation through use of the malloc() and free() functions are not used in SSP modules.

The configuration structure is used for the initial configuration of a module during the open() call. The structure consists of members such as: channel, interrupt priority, bitrate, and operating mode. The structure is used purely for input into the module. This structure does not have to be unique and could be discarded by you after initialization, if desired.

```
typedef struct st_i2c_cfg
{
    /* Generic configuration */
```

```
    uint8_t         channel;                                    // Identifier
recognizable by implementation
    i2c_rate_t      rate;                                       // Device's maximum
clock rate from enum i2c_rate_t
    uint16_t        slave;                                      // The address of the
slave device
    i2c_addr_mode_t addr_mode;                                  // Indicates how
slave fields should be interpreted
    uint16_t        sda_delay;                                  // The SDA output
delay
    uint8_t         rxi_ipl;                                    // Receive interrupt
priority
    uint8_t         txi_ipl;                                    // Transmit interrupt
priority
    uint8_t         tei_ipl;                                    // Transmit end
interrupt priority
    uint8_t         eri_ipl;                                    // Error interrupt
priority

    /* DTC/DMA support */
    transfer_instance_t const * p_transfer_tx;            // DTC instance for I2C
transmit.Set to NULL if unused.
    transfer_instance_t const * p_transfer_rx;            // DTC instance for I2C
receive. Set to NULL if unused.

    /* Parameters to control software behavior */
    void         (* p_callback)(i2c_callback_args_t * p_args);  // Pointer to
callback function
    void const    * p_context;                                  // Pointer to the
user-provided context

    /* Implementation-specific configuration */
    void const    * p_extend;                                   // Any configuration
data needed by the hardware
```

```
} i2c_cfg_t;
```

Above is an example configuration structure for the I2C Interface. The last three structure members (p_callback, p_context, and p_extend) are common to almost all module configurations.

The p_callback and p_context members are described in the SSP Interface Callback Functions section.

The p_extend member is used for extending the current Interface for a specific Instance. Interfaces are designed to support the most common features. There are cases where an Instance of an Interface requires extra information to properly configure itself. There are also cases where the extra information is not required, but users might need it to adjust the module for their specific application. When this is the case, the user can provide the underlying Instance with more configuration information by passing it through the p_extend member. The information that is passed through this member is defined by the underlying Instance, and therefore the user must adhere to its structure. If invalid information is passed to the underlying driver, then the Instance is not able to successfully use the data and proper operation cannot be guaranteed. Refer to the Interface Extensions section for more information.

It is also important that configuration structures only have members that apply to the current Interface. If multiple layers in the same stack define the same configuration parameters then it becomes difficult to know where to modify the option. For example, the baud rate for a UART is only be defined at the Driver layer. Any layers that use the UART Interface rely on the baud rate being provided at the Driver layer and do not offer it in their own configuration structures.

SSP Interface Callback Functions

Callback functions allow Modules to asynchronously alert the user application when an event has occurred. An example for an event is when a byte has been received over a UART channel. Callbacks are required to allow user application code to react to interrupts. SSP Modules define and handle the interrupts for Synergy MCU peripherals. If the user tries to define the interrupt service routine at the same time as a SSP Module, then the code does not build. Therefore SSP Modules allow the user application to respond to interrupts by registering a function to be called when an interrupt occurs.

Callback functions must be defined in the user application. They always return void and take a structure for their one parameter. The structure typedef is provided in the Interface for the Module and is named * _callback_args_t*. The contents of the structure may vary depending on the Interface, but two members are common: event and p_context.

The event member is used by the application to determine why the callback was called. Using the UART example again, the callback could have been triggered because a byte was received, all bytes had been transmitted, or a framing error has occurred. The event member is an enumeration provided by the Interface.

The p_context member is used for providing user-specified data to the callback function. In many cases a callback function is shared between multiple channels or Module Instances. When the callback occurs, the code handling the callback needs context information so that it can figure out which Module Instance the callback is for. For example, if the callback wanted to make a SSP API call in the callback, then at a minimum the callback must use the control structure. To make this easy, the user can provide a pointer to the control structure as the p_context. When the callback occurs,

the control structure is available as it will be passed in the callback structure.

Callback functions are called from within an interrupt service routine. For this reason callback functions should be kept as short as possible so they do not affect the real time performance of the user's system. An example skeleton function for the Flash Interface callback is shown below.

```
static void flash_callback (flash_callback_args_t * p_args)
{
    /* See what event caused this callback. */
 switch (p_args-&gt;event)
  {
        case FLASH_EVENT_ERASE_COMPLETE:
        /* Handle event. */
        break;
        case FLASH_EVENT_WRITE_COMPLETE:
        /* Handle event. */
        break;
        case FLASH_EVENT_BLANK:
        /* Handle event. */
        break;
        case FLASH_EVENT_NOT_BLANK:
        /* Handle event. */
        break;
        case FLASH_EVENT_ERR_DF_ACCESS:
        /* Handle error. */
        break;
        case FLASH_EVENT_ERR_CF_ACCESS:
        /* Handle error. */
        break;
        case FLASH_EVENT_ERR_CMD_LOCKED:
        /* Handle error. */
        break;
    }
}
```

When a Module is not directly used in the user application (it is not the top layer of the stack) then

its callback function will be handled by the Module above. If there is a Console Interface Module that requires a UART Interface Module then the Console Module will control and use the UART's callback function. In this case the user does not need to create a callback function for the UART Module in their application code.

SSP Interface API Structure

All Interfaces include an API structure which contains function pointers for all the supported Interface functions. An example structure, with the comments removed, for the Digital to Analog Convert (DAC) is shown below.

```
typedef struct st_dac_api
{
    ssp_err_t (* open)(dac_ctrl_t * p_ctrl, dac_cfg_t const * const p_cfg);
    ssp_err_t (* close)(dac_ctrl_t * p_ctrl);
    ssp_err_t (* write)(dac_ctrl_t * p_ctrl, dac_size_t * p_value);
    ssp_err_t (* start)(dac_ctrl_t * p_ctrl);
    ssp_err_t (* stop)(dac_ctrl_t * p_ctrl);
    ssp_err_t (* versionGet)(ssp_version_t * p_version);
} dac_api_t;
```

The API structure is what allows for Modules to easily be swapped in and out for other Modules that are Instances of the same Interface. Let's look at an example application using the DAC Interface above.

Synergy MCUs have an internal DAC peripheral. If the DAC API structure in the DAC Interface were not used, then the application could make calls directly into the module. In the example below the application is making calls to the R_DAC_Write function which is provided in the r_dac module.

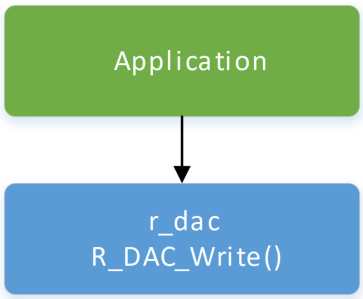

Figure 6: DAC Write example

Now let's assume that the user needs more DAC channels than are available on the MCU by adding a

new external DAC module named r_dac_external. The external DAC uses I2C for communications. The application must now distinguish between the two modules, which adds complexity and further dependencies to the application.

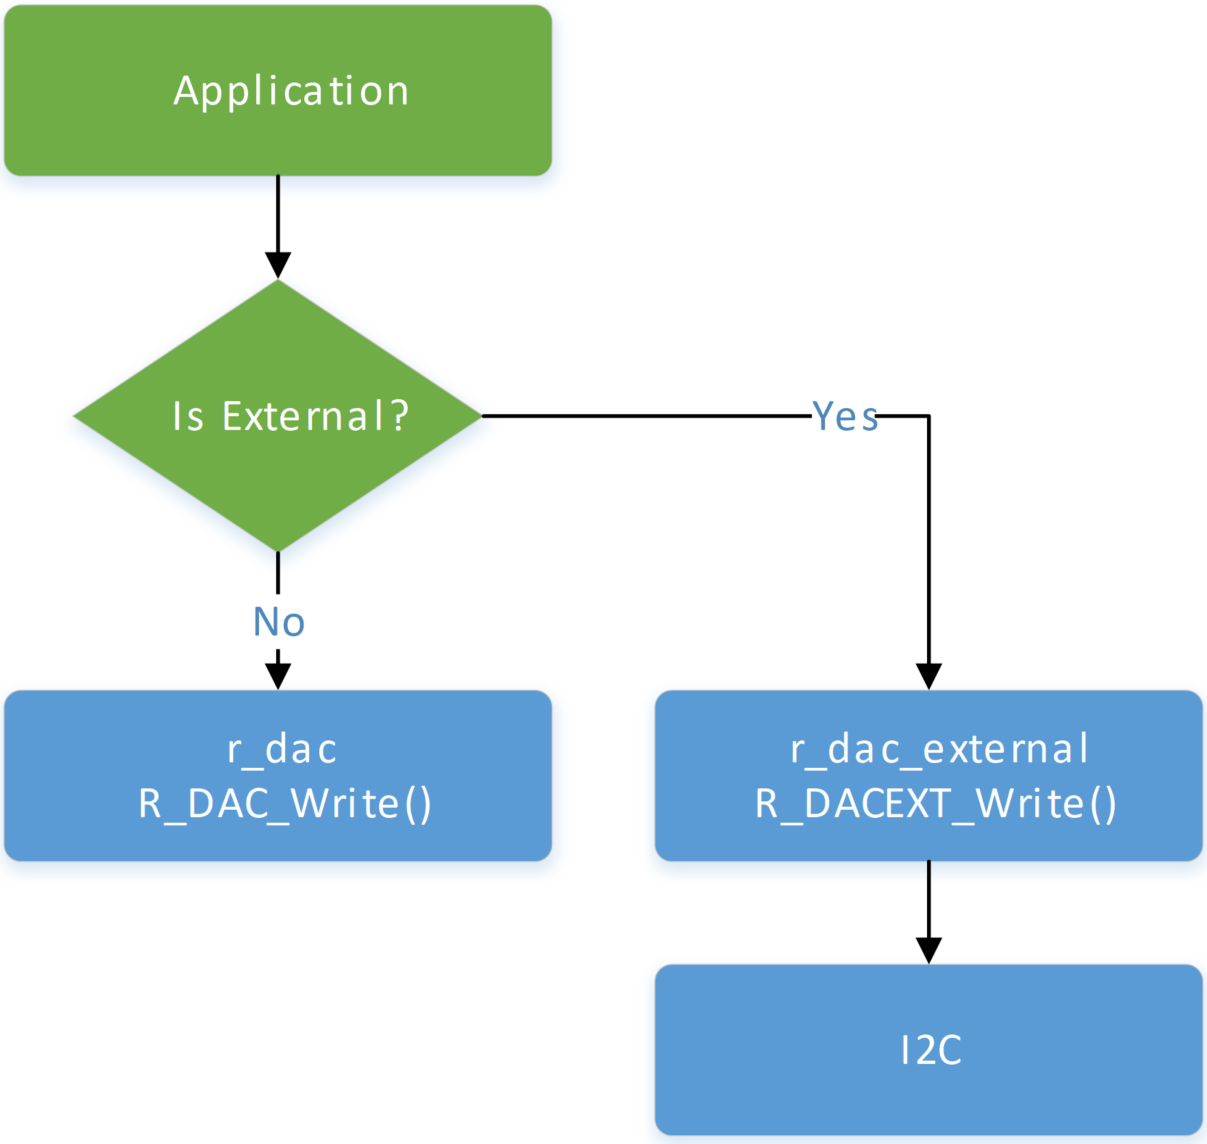

Figure 7: DAC Write with two write modules

The use of Interfaces and the API structure allows for the use of an abstracted DAC. This means that no extra logic is needed and the application no longer depends upon certain hard-coded Modules. Instead the application now depends on the DAC Interface API which can be implemented by any number of Modules.

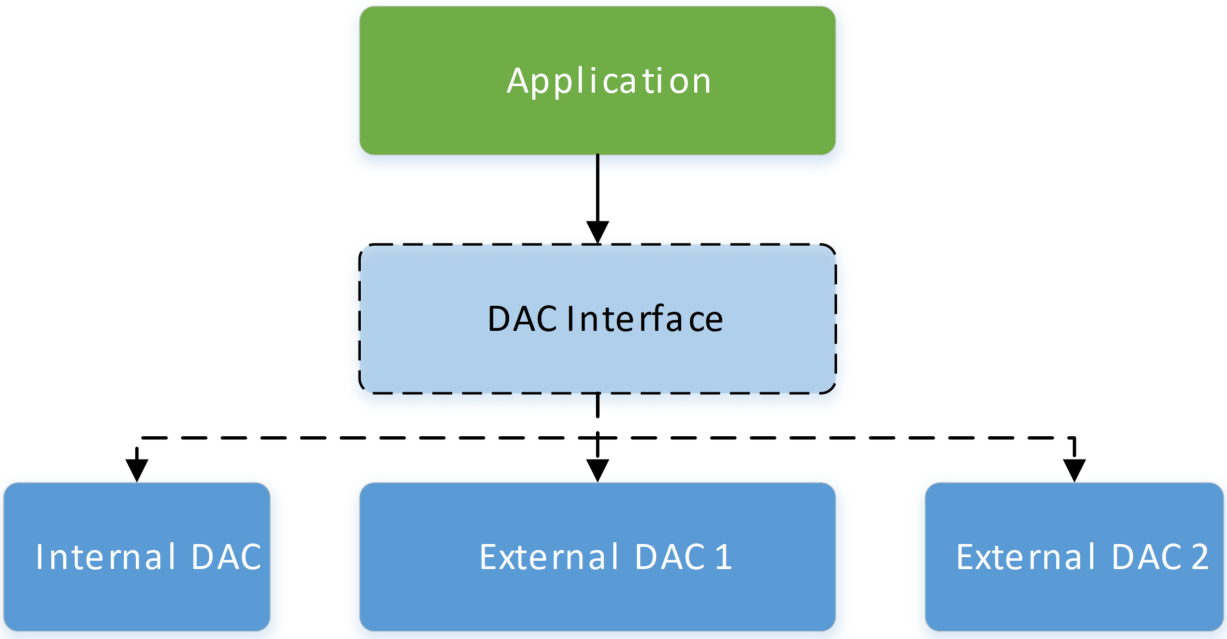

Figure 8: DAC Interface

Functions inside of the API structures follow common names. Most Modules will have a pair of open() and close functions. The open() function must be called before any of the other functions. The only exception is the versionGet() function which is not dependent upon any user provided information.

Other functions that will commonly be found are read(), write(), get(), and set(). Function names are designed to be a noun followed by a verb. Example names include:

- read(), write(), writeRead()
- statusGet()
- calendarAlarmSet(), calendarAlarmGet()
- accessWindowSet(), accessWindowClear()

SSP Interface Version Information

All Interfaces supply a versionGet() function. This function fills in a structure of type ssp_version_t. This structure is made up of two versions: one for the Interface (the API) and one for the underlying Instance that is currently being used.

```
/* Common version structure */
typedef union st_ssp_version
{
    /* Version id */
    uint32_t version_id;
```

```
    /* Code version parameters */
    struct
    {
    uint8_t code_version_major; //  Code major version
    uint8_t code_version_minor; // Code minor version
    uint8_t api_version_major; // API major version
    uint8_t api_version_minor; // API minor version
    };
} ssp_version_t;
```

The API version ideally never changes, and only rarely if it does. A change to the API may require users to go back and modify their code. The code version, the version of the current Instance, may be updated more frequently. Bug fixes, enhancements, and additional features may all bump the code version. Changes to the code version will only require changes to the user code if the user code is using extended features provided by the Instance.

SSP Instances

While Interfaces dictate the features that are provided, Instances actually implement those features. Each Instance is tied to a specific Interface. Instances use the enumerations, data structures, and API prototypes from the Interface. This allows for an application that uses an Interface to swap out the Instance when needed.

On Synergy MCUs some peripherals will have a one-to-one mapping between the Interface and Instance, while others will have a one-to-many. In the example below the IIC and SPI peripherals map to only one Interface each while the SCI peripheral implements three Interfaces.

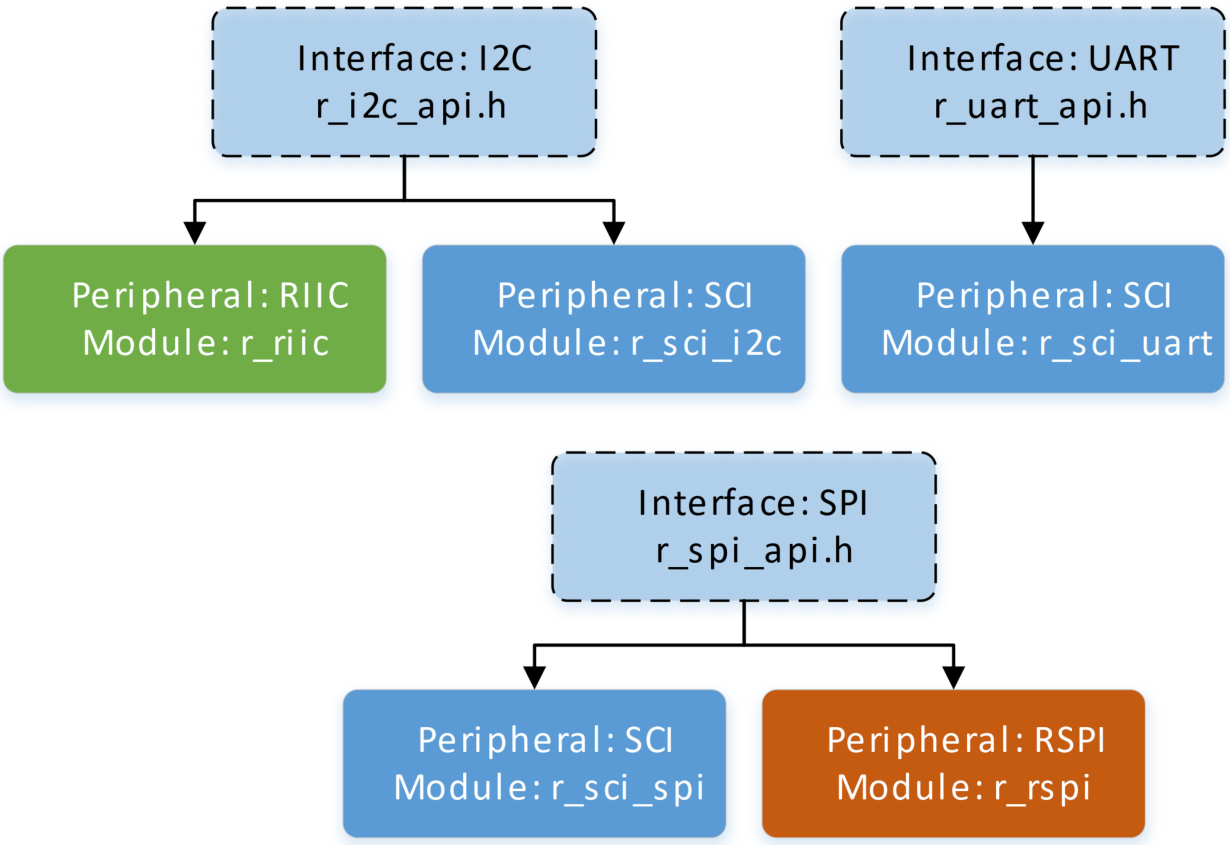

Figure 9: Instances

SSP Instances API Structure

Each Instance includes a constant global structure with its functions that implement the Interface's API. The name of this structure is standardized as g__on_. Examples include g_spi_on_spi, g_transfer_on_dtc, and g_adc_on_adc. This structure is available to be used through an extern in the instances header file (r_spi.h, r_dtc.h, and r_adc.h respectively).

2.1.2.5 Build Time Configuration

All modules have a build-time configuration header file. Most configuration options are supplied at run time. Some options that are rarely used, or apply to all instances of a module, may be moved to build time. The advantage of using a build-time configuration option is to potentially reduce code size reduction by removing an unused feature. Performance enhancements are also possible. All modules have at least one build time option, which is whether to enable or disable parameter checking for the module. SSP modules check function arguments for validity when possible. You may want to disable this feature when your testing has concluded to save code space and to speed up execution.

2.1.2.6 Interface Extensions

In some cases, Instances require more information than is provided in the Interface. This situation can occur in the following two cases:

- An Instance offers extra features that are not common to most Instances of the Interface.
- An Interface must be very generic out of necessity. As an Interface becomes more generic, the number of possible Instances increases. A prime example of this is the Block Media Interface.

```
typedef struct st_sf_block_media_cfg
{
    uint32_t block_size; // Block size in bytes
    void * p_extend; // Instance dependent configuration
} sf_block_media_cfg_t;
```

The configuration structure for the Block Media Interface is intentionally sparse. This allows for nearly endless Instances. Possible Instances include SD card, SPI Flash, SDRAM, USB, and many more. Different configuration information is needed for each Instance. This is accomplished by supplying the information through the p_extend parameter. While the configuration data provided in the p_extend is not the same between Instances, the API calls thereafter will be. This means that the change is only required in one place.

Use of Interface extensions is not always necessary. Some Instances do not offer an extension since all functionality is provided in the Interface. In many cases the p_extend member can be set to NULL. If NULL is provided and the Instance does offer an extension then the Instance will take this to mean that the default options should be used. The documentation for each Instance indicates whether an Interface extension is provided and whether its use is mandatory or optional.

2.1.2.7 SSP Predefined Layers

The SSP comes with two predefined layers: the Driver layer and the Framework layer. The layers are easily identifiable because the modules reside in different folders and have different prefixes. Driver layer modules are located in the ssp/src/driver folder, while Framework level modules are located in the ssp/src/framework folder. Modules in the Driver layer start with an r_ prefix, while Framework level modules start with a sf_ prefix.

The core difference in the functionality between the layers is that Driver layer modules are restricted to being peripheral drivers that are RTOS aware, but do not use any RTOS objects or make any RTOS API calls. This means that Driver layer modules can be used in applications with, or without, an RTOS.

Framework layer modules are free to use RTOS objects such as semaphores, mutexes, or event flags. Framework modules may also create their own when needed. Framework layer modules that need to access hardware typically do so through a Driver layer Interface. Exceptions can be granted in special cases where multiple peripherals need to be used together in a way that would not be practical through multiple individual Interfaces.

2.1.2.8 SSP File Structure

The high-level file structure of the SSP is shown below.

```
ssp
+---inc
\|  +---bsp
\|  \|  +---cmsis
\|  +---driver
\|  \|  +---api
\|  \|  \\---instances
\|  \\---framework
\|  +---api
\|  +---el
\|  +---instances
\|  \\---tes
---src
  +---bsp
  \|  +---cmsis
  \|  \\---mcu
  +---driver
  \|  \\---r_module
  \\---framework
  \\---sf_module
synergy_cfg
+---ssp_cfg
  +---bsp
  +---driver
  \\---framework
}
```

Directly underneath the base ssp folder the folders are split into the source and include folders. Include folders are kept separate from the source for easy browsing and easy setup of include paths. The same set of folders are located in the ssp/inc and ssp/src folders: bsp, driver, and framework.

Apart from the BSP, the SSP's two predefined layers, Driver and Framework, are present. Driver layer modules are located in the ssp/src/driver folder and Framework layer modules are located in ssp/src/framework. Under the include tree, the Driver and Framework layer folders contain two folders each: api and instances. The api folder contains the Interface header files for that layer. The instances folder contains the Instance header files for that layer. Both layers are flat internally which limits the number of include paths required for a project.

The ssp_cfg folder is where configuration header files are stored for each module. Its layout is the same as the ssp folder where the BSP, Driver, and Framework layers have separate flat directories. See the Build Time Configuration section for information on what is provided in these header files.

2.1.2.9 SSP Connecting Layers

SSP modules are meant to be both reusable and stackable. It is important to remember that modules are not dependent upon other modules, but upon other Interfaces. The user is then free to fulfill the Interface using the Instance that best fits their needs.

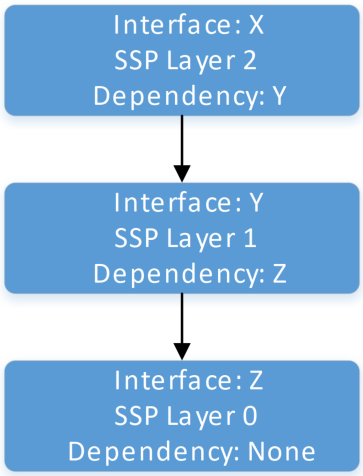

Figure 10: Connecting layers

In the image above Interface Y is a dependency of Interface X and has its own dependency on Interface Z. Interface X only has a dependency on Interface Y. Interface X has no knowledge of Interface Z. This is a requirement for ensuring that layers can easily be swapped out. This is shown in the diagram below:

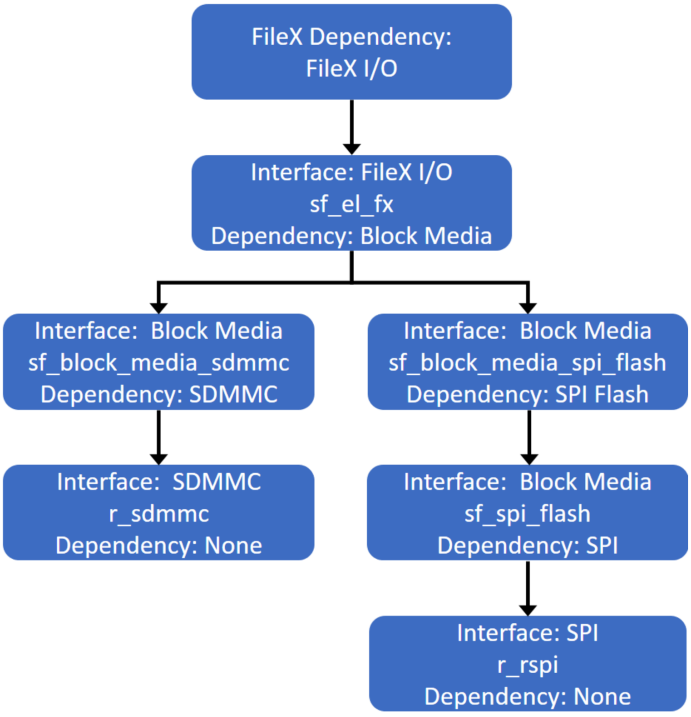

Figure 11: Connecting layers with the FileX interface

In this example we are using the Azure RTOS. FileX file system on two storage mediums: SDMMC and SPI Flash. The SPI Flash Interface takes care of the SPI flash protocol but requires a SPI Interface for actual SPI bus communications. The SDMMC Interface takes care of the protocol and the bus communications meaning that it does not have any dependencies.

2.1.2.10 SSP Architecture In Practice

Each layer in the SSP Stack is responsible for calling the API functions of its dependencies. This can also be described by saying that users are only responsible for calling the API functions at the layer at which they are interfacing. Using the FileX example above, the user is only responsible for calling FileX functions in the application code. Internally, FileX then calls FileX I/O, which in turn calls a Block Media Interface Module. The Block Media Interface can call multiple drivers. At a minimum an upper layer Module calls the open() function of the Interface it depends upon.

To write an application using a Module, you must determine the following:

1) Determine which open() function to call. Dependencies are based upon Interfaces which means that a Module must have some way of discerning which Instance to call.

2) Determine the configuration parameters. The Module also needs to know what configuration information to pass down. In some cases the Module requires certain configuration parameters to be set. If this is the case then the module sets these configuration structure members itself before passing on the rest of the structure. The rest of the configuration structure members must be provided outside of the Module.

3) Provide a control structure which is Module Instance specific and therefore can be allocated by the upper layer module.

Putting this all together means that to interact with a Module Instance, the following is needed:

- A pointer to the Instance's API structure
- A pointer to the Module Instance's configuration structure
- A pointer to the Module Instance's control structure

This information is sufficient to use any module. Notice that the API structure is the only structure that is Instance specific; not Module Instance specific. This is because the API structure will not vary between multiple uses of the same Instance. If SPI is being used on SCI channels 0 and 2 then both Module Instances will use the same API structure while the configuration and control structures will vary.

To make Module Instances easier to use, all of these pieces are encapsulated in instance structures found in each Interface. These structures have a standardized name of <interface>_instance_t. An example from the WDT interface is shown below.

```
typedef struct st_wdt_instance
{
    wdt_ctrl_t * p_ctrl; // Pointer to the control structure for this instance
    wdt_cfg_t const * p_cfg; // Pointer to the configuration structure for this
instance
 wdt_api_t const * p_api; // Pointer to the API structure for this instance
} wdt_instance_t;
```

Upper layer modules that have a dependency on an Interface can then use the instance structure to hold everything needed to interact with an Instance of that Interface. Continuing with the WDT example above, below is the Thread Monitor Framework Interface configuration structure. The Thread Monitor Interface is dependent upon the WDT Interface.

```
typedef struct st_sf_thread_monitor_watchdog_type
{
    wdt_instance_t * p_lower_lvl_wdt; // Pointer to lower level watchdog instance
    bool profiling_mode_enabled; // Enables or disables profiling mode
    UINT priority; // Priority of thread monitor thread
} sf_thread_monitor_cfg_t;
```

The Thread Monitor module has everything it needs to work with the WDT Interface in the *p_lower_lvl_wdt* structure member.

In some cases module dependencies are not be defined in the Interface, but instead in the Instance. An example is the Block Media Interface could be implemented on SDMCC, SPI Flash, or many other Instances (also see API Reference section). Because of the wide range of implementations, the instance structure for a particular Interface cannot be used directly in the Block Media Interface's configuration structure. The Block Media Interface's configuration structure is shown again below.

```
typedef struct st_sf_block_media_cfg
{
    uint32_t block_size; // Block size in bytes
    void * p_extend; // Instance dependent configuration
} sf_block_media_cfg_t;
```

Notice there are Instance structure pointers provided. The reason for this, as previously mentioned, is that the Block Media Interface is too generic to enforce a dependency upon a particular Interface. When a Module is an Instance of a generic Interface, such as Block Media, and it has dependencies on other Modules, the module puts the lower-layer pointers in an extension structure that is referenced through the Interface's *p_extend* configuration member. This is required to allow Module stacking while not forcing Interfaces to expand and have many optional configuration members.

```
typedef struct st_block_media_on_sdmmc_cfg
{
    sdmmc_instance_t const * const p_lower_lvl_sdmmc; // Pointer to SDMMC instance
structure
} sf_block_media_on_sdmmc_cfg_t;
```

2.1.2.11 Using SSP Modules

This section will give general information on how to use a SSP module.

Pick an Interface

Start by picking an Interface for the functionality that is required. For example, for UART communications use the UART Interface.

Find a suitable Instance of the Interface

After picking an Interface, choose a suitable Instance. The list of known Instances of an Interface is

listed in the documentation comments for an Interface. Include the header file of the selected Instance in the source file of the application that uses the Instance.

Allocate control and configuration structures

The e^2 studio ISDE provides a graphical user interface for setting the parameters of the Interface and Instance configuration structures. The ISDE also automatically includes those structures, once they are configured in the GUI, in application-specific header files that you can include into your application code.

To see how the ISDE handles the configuration, see Configuring a Project in the ISDE User's Guide: Using the e2 studio ISDE

The configuration and control structure types follow standard names of <interface>_ctrl_t and <interface>_cfg_t respectively. The ISDE allocates storage for both structures in the application specific header files, which the ISDE creates. Use the ISDE Properties view to set the values for the members of the configuration structure as needed. Many members will be typed enumerations in which case the enumeration can be referenced for available options.

If the Interface has a callback function option, then you first need to declare and define the function in their source code. The return value is always of type void and the parameter to the function is a typed structure of name <interface>_callback_args_t. Once the function has been defined, assign its name to the p_callback member of the configuration structure. If any context information is required in the callback, then the user can provide a pointer to the p_context member. You can assign callback function names through the ISDE Properties window for the selected Module.

Refer to the Instance documentation to see if an Interface extension is provided. If so, then it will be found in the Instance's header file and named <interface>_on__cfg_t. It may have several members just like the Interface's configuration structure. When you select a driver with a specific Instance, you can select any parameter in the configuration structure of the instance in the ISDE property.

Interact using Interface's Instance Structure

Once the instance structure has been defined, you can interact with the Instance as needed. Below is code that builds up an instance structure for the UART Interface as implemented on SCI. Please note that when using e^2 studio for Synergy, the following code is automatically generated for the user.

```
/* Include the header file of the Instance. */
#include "r_sci_uart.h" // This will in turn include the r_uart_api.h Interface
/* Allocate control structure. */
uart_ctrl_t my_uart_ctrl;
/* Setup extended UART configuration on SCI. */
uart_on_sci_cfg_t my_uart_extended_cfg =
{
    /* Set extended configuration members... */
};
/* Configure standard UART Interface. */
uart_cfg_t my_uart_cfg =
```

```
{
    .data_bits = UART_DATA_BITS_8,
    /* Continue configuring other members... */
    .p_extend = &my_uart_extended_cfg
};
/* Setup instance structure */
uart_instance_t my_uart = {
    .p_ctrl = &my_uart_ctrl,
    .p_cfg = &my_uart_cfg, //Extended configuration is brought through
in p_extend
    .p_api = &g_uart_on_sci //Defined in r_sci_uart.h
};
```

Now that the instance structure is ready, you can interact with the UART Interface. In e^2 studio, the name of the instance structure is the *Name* that you provide when configuring the Module Instance in the ISDE Properties window.

```
ssp_err_t err;
/* Initialize UART */
err = my_uart.p_api-&gt;open(my_uart.p_ctrl, my_uart.p_cfg);
/* Check return for errors. */
if (SSP_SUCCESS != err)
{
/* Handle error. */
}
/* Use other Interface functions. */
err = my_uart.p_api-&gt;write(my_uart.p_ctrl, ...);
err = my_uart.p_api-&gt;read(my_uart.p_ctrl, ...);
```

2.1.2.12 Coding Style

C99 Use

SSP uses the ISO/IEC 9899:1999 (C99) C programming language standard. Specific features introduced in C99 that are used include standard integer types (stdint.h), booleans (stdbool.h), designated initializers, and the ability to intermingle declarations and code.

Use of const in API parameters

The const qualifier is used with API parameters whenever possible. An example case is shown below:

```
ssp_err_t (* open)(flash_ctrl_t * const p_ctrl, flash_cfg_t const * const p_cfg);
```

While not fool-proof by any means, this does provide some extra checking inside the SSP code to ensure that arguments that should not be altered are treated as such.

Weak Symbols

Weak symbols are used occasionally in and with SSP. They are used to ensure that a project builds even when you have not defined an optional function.

2.1.3 BSP Architecture

This section describes the BSP or Board Support Package. For the API Reference see Board Support Package. The BSP is board specific and as a result also MCU specific.

2.1.3.1 What Does the BSP Do?

The BSP is responsible for getting the MCU from reset to the user's application (that is, the main() function). Before reaching the user's application the BSP sets up the stacks, heap, clocks, interrupts, and C runtime environment. The BSP also configures and sets up the port I/O pins and performs any board specific initializations.

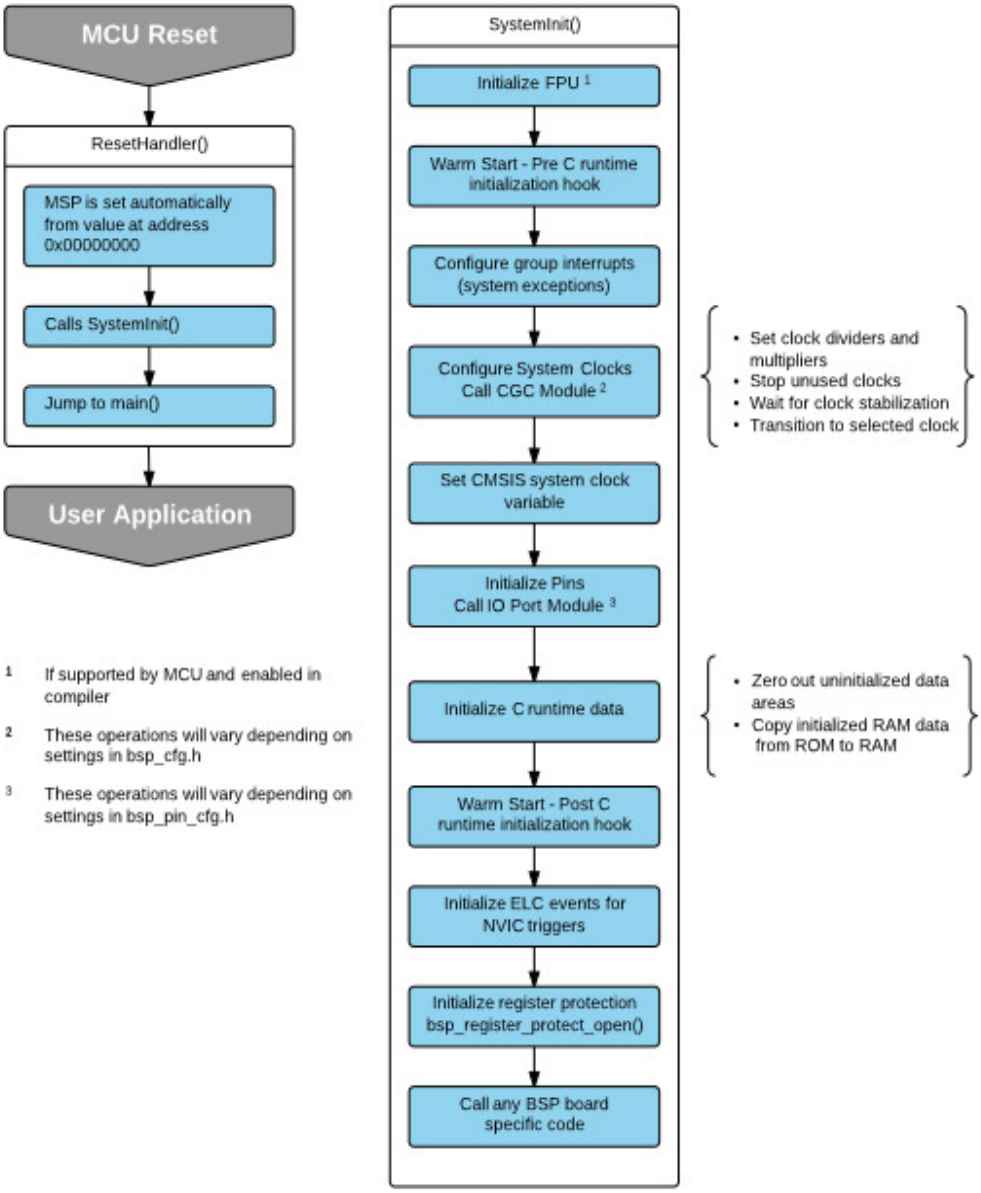

Figure 12: BSP flow

2.1.3.2 BSP Related Terminology

Term	Meaning
system_xxxx.c or startup_xxxx.c	The 'xxxx' refers to the MCU type. For example, system_S7G2.c when referencing the S7G2 MCU.
BSP	Short for Board Support Package. BSP's usually have source files related to a specific board.

Callback Function	This term refers to a function that is called when an event occurs. For example, the NMI interrupt handler is implemented in the BSP. The user will likely want to know when an NMI system exception occurs. To alert the user, a callback function can be configured for the group interrupts (a group of exceptions all of which are tied to the NMI). When an NMI occurs the BSP will jump to the provided callback function and the user can handle the error. Interrupt callback functions should be kept short and be handled carefully because when they are called the MCU will still be inside of an interrupt and therefore will be delaying any pending interrupts.

2.1.3.3 BSP Directory Structure

The BSP is organized into folders containing MCU, board specific and CMSIS information.

Synergy is CMSIS-compliant and based on the CMSIS-Core. This requires that we follow CMSIS requirements and naming standards.

- Standardized definitions for processor peripherals
- NVIC (Nested Vector Interrupt Controller)
- Systick (System Tick Timer)
- MPU (Memory Protection Unit)
- Standardized access functions to access processor features
- NVIC_SetPriority()
- NVIC_EnableIRQ
- Standardized function names for system exception handlers
- Reset_Handler()
- SysTick_Handler()
- Standardized functions for system initialization.
- SystemInit() – defined in system_S7G2.c for S7G2 MCUs
- Standardized software variables for clock speed information
- SystemCoreClock

The BSP directory structure is shown below:

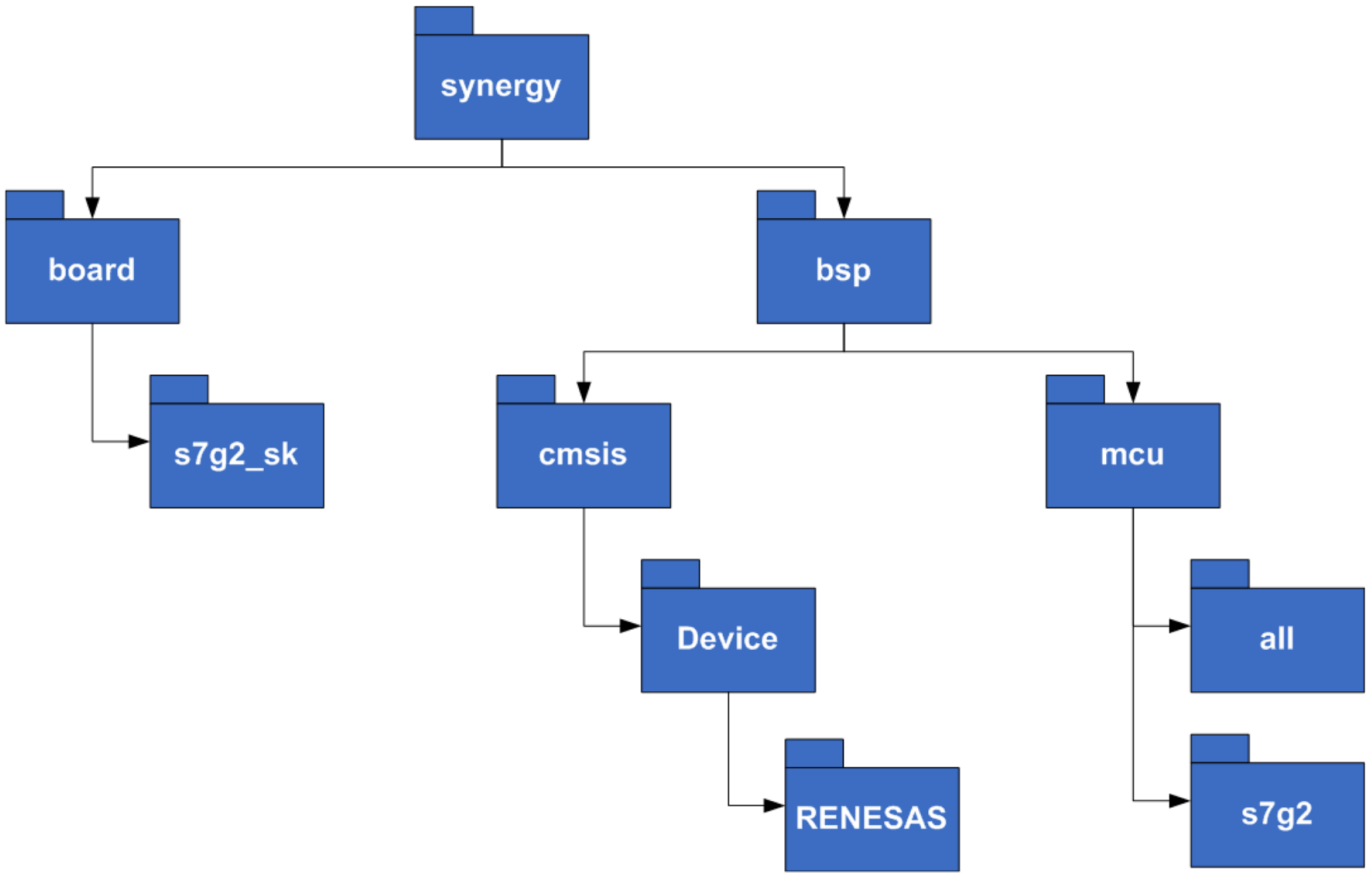

Figure 13: BSP directory structure

2.1.3.4 Configuring the BSP

The BSP is heavily data driven with most features and functionality being configured based on the content from configuration files. Configuration files represent the settings specified by the user and are generated by the ISDE when the Generate Project Content button is clicked.

2.1.3.5 BSP Configuration Settings

The table below describes each of the configurable BSP settings. Many of these settings are MCU specific and there are differences between the settings available for each of the supported MCUs.

Table: BSP Configuration options

BSP Property	Description
Part number	MCU part number
ram_size_bytes	Available RAM in this MCU package
rom_size_bytes	Available ROM in this MCU package
data_flash_size_bytes	Available Data Flash in this MCU package
package_style	Style of package (ie. BGA)
package_pins	Number of pins in this MCU package

series	MCU part series
Main stack size (bytes)	Size of the Main Stack. Must be > 0.
Process stack size (bytes)	Size of the Process Stack. Use of this stack is optional. If 0, then PSP use is disabled
Heap size (bytes)	Size of the heap in bytes. If 0, the heap is disabled.
OFS0 register settings: IWDT Start Mode, IWDT Timeout Period, IWDT Dedicated Clock Frequency Divisor, IWDT Window End Position, IWDT Window Start Position, IWDT Reset Interrupt Request Select, IWDT Stop Control, WDT Start Mode Select , WDT Timeout Period, WDT Clock Frequency Division Ratio, WDT Window End Position, WDT Window Start Position, WDT Reset Interrupt Request, WDT Stop Control	The option-setting memory determines the state of the MCU after a reset. It is allocated to the configuration setting area and the program flash area of the flash memory. See the MCU user manual for details.
OFS1 register settings: Voltage Detection 0 Circuit Start, Voltage Detection 0 Level, HOCO Oscillation Enable. S3 MPU has MPU configuration settings.	See the MCU user manual for details.
MPU - Enable or disable PC Region 0	Start block address for access window protection
MPU - PC0 Start, MPU - PC0 End, MPU - Enable or disable PC Region 1, MPU - PC1 Start, MPU - PC1 End, MPU - Enable or disable Memory Region 0, MPU -Memory Region 0 Start, MPU - Memory Region 0 End, MPU - Enable or disable Memory Region 1, MPU - Memory Region 1 Start, MPU - Memory Region 1 End, MPU - Enable or disable Memory Region 2, MPU - Memory Region 2 Start, MPU - Memory Region 2 End, MPU - Enable or disable Memory Region 3, MPU - Memory Region 3 Start, MPU - Memory Region 3 End	Secure MPU ROM register settings. See user manual for details.
ID code 1, ID code 2, ID code 3, ID code 4	Sets the ID Code for boot mode and debugger access protection.
MCU Vcc (mV)	Some Modules (e.g. LVD) need to know the voltage supplied to the MCU. This information is obtained from here.
Parameter checking	Defines whether the global setting for parameter checking is enabled or disabled. Local modules will take this value by default but can be locally overridden.
Assert Failures	Defines what happens when an assertion failure occurs.
Error Log	Defines whether or not errors are logged to ssp_error_log.

2.1.3.6 BSP Configuration Files

Configuration files are used by the BSP to set up ROM registers, clocks, interrupts, ELC events and initial pin configurations. These configuration files can be found in ssp_cfg\bsp.

Bsp_cfg.h

This configuration file contains the values for BSP system settings. These are the settings that can be modified from the ISDE BSP properties tab. They include ROM register settings, stack and heap size, parameter checking and control of error logging.

Some registers are located in ROM and therefore must be set at compile-time. These include some option-setting memory (OFS) registers as well as certain memory protection registers.

Option-setting memory determines the state of the MCU after a reset. For example, the IWDT can be configured and enabled, voltage detection can be enabled, and HOCO oscillation can be enabled. When these registers are set the operations are completed before the MCU's reset vector is fetched and execution begins.

Some Synergy MCUs include a Memory Protection Unit (MPU). The MPU is a programmable device that can be used to define memory access permissions (i.e. privileged access only or full access) and memory attributes (for example, bufferable, cacheable) for different memory regions. The MPU can support up to eight programmable memory regions, each with their own programmable starting addresses, sizes and settings.

The ISDE configures these memory areas by setting values for the provided MPU settings. You must be careful when setting these registers. Incorrect settings can prevent access to required memory areas or prevent access to the MCU entirely.

2.1.3.7 BSP Pin Configuration

You can configure the pins used in your application through the ISDE pin configurator. See Configuring Pins.

Bsp_pin_cfg.h

This configuration file contains an array of pin configurations. During start-up, and before main() is executed, the BSP iterates over this array and initializes the MCU's port pins based on the settings in the array. Initially, before any pin configuration by the user, the ISDE **Pins** tab displays the initial reference configuration defined for the selected board type (see Configuring Pins). Once the user modifies the pin configuration and clicks **Generate Project**, a new bsp_pin_cfg.h file is generated containing the new pin configuration. The BSP always uses the bsp_pin_cfg.h file from ssp_cfg\bsp as the source for its pin configuration information, but the pin information generated by clicking **Generate Project** is written to a bsp_pin_cfg.h file in the hidden folder ssp_cfg\bsp\.out.

In this way, the user can manually edit the bsp_pin_cfg.h in ssp_cfg\bsp without the fear of the file being overwritten by the project generation, while the Pin Configuration information generated by the ISDE also remains available for view or merging with the user's config file.

2.1.3.8 BSP Clock Configuration

All system clocks are set up during BSP initialization based on the settings in bsp_clock_cfg.h. These settings are derived from clock configuration information provided from the ISDE **Clocks** tab setting.

- Clock configuration is performed prior to initializing the C runtime environment to speed up

the startup process, as it is possible to start up on a relatively slow (for example, 32 kHz) clock.
- The BSP implements the required delays to allow the selected clock to stabilize.

Bsp_clock_cfg.h

This configuration file represents the values for system clock settings. These are the settings that can be modified from the ISDE **Clocks** tab. See: Configuring Clocks

2.1.3.9 System Interrupts

As Synergy MCU's are based on the Cortex-M ARM architecture, the NVIC Nested Vectored Interrupt Controller (NVIC) handles exceptions and interrupt configuration, prioritization and interrupt masking. In the ARM architecture, the NVIC handles exceptions. Some exceptions are known as System Exceptions. System exceptions are statically located at the top of the vector table and occupy vector numbers 1 to 15. Vector zero is reserved for the MSP Main Stack Pointer (MSP). The remaining 15 system exceptions are shown below:

- Reset
- NMI
- Cortex-M4 Hard Fault Handler
- Cortex-M4 MPU Fault Handler
- Cortex-M4 Bus Fault Handler
- Cortex-M4 Usage Fault Handler
- Reserved
- Reserved
- Reserved
- Reserved
- Cortex-M4 SVCall Handler
- Cortex-M4 Debug Monitor Handler
- Reserved
- Cortex-M4 PendSV Handler
- Cortex-M4 SysTick Handler

NMI and Hard Fault exceptions are enabled out of reset and have fixed priorities. Other exceptions have configurable priorities and some can be disabled.

2.1.3.10 Group Interrupts

Group interrupt is the term used to describe the 12 sources that can trigger the Non-Maskable Interrupt (NMI). When an NMI occurs the NMI Handler examines the NMISR (status register) to determine the source of the interrupt. NMI interrupts take precedence over all interrupts, are usable only as CPU interrupts, and cannot activate the Synergy peripherals Data Transfer Controller (DTC) or Direct Memory Access Controller (DMAC).

Possible group interrupt sources include:

- IWDT Underflow/Refresh Error
- WDT Underflow/Refresh Error
- Voltage-Monitoring 1 Interrupt
- Voltage-Monitoring 2 Interrupt
- VBATT monitor Interrupt
- Oscillation Stop is detected

- NMI pin
- RAM Parity Error
- RAM ECC Error
- MPU Bus Slave Error
- MPU Bus Master Error
- MPU Stack Error

A user may enable notification for one or more group interrupts by registering a callback using the BSP API function R_BSP_GroupIrqWrite. When an NMI interrupt occurs, the NMI handler checks to see if there is a callback registered for the cause of the interrupt and if so calls the registered callback function.

As mentioned earlier, the first 16 slots in the vector table are already accounted for by the system exceptions. Beginning with slot 16 are user configurable interrupts. These may be external, or peripheral generated interrupts.

The size of the NVIC interrupt table varies across Synergy MCU types (shown below).

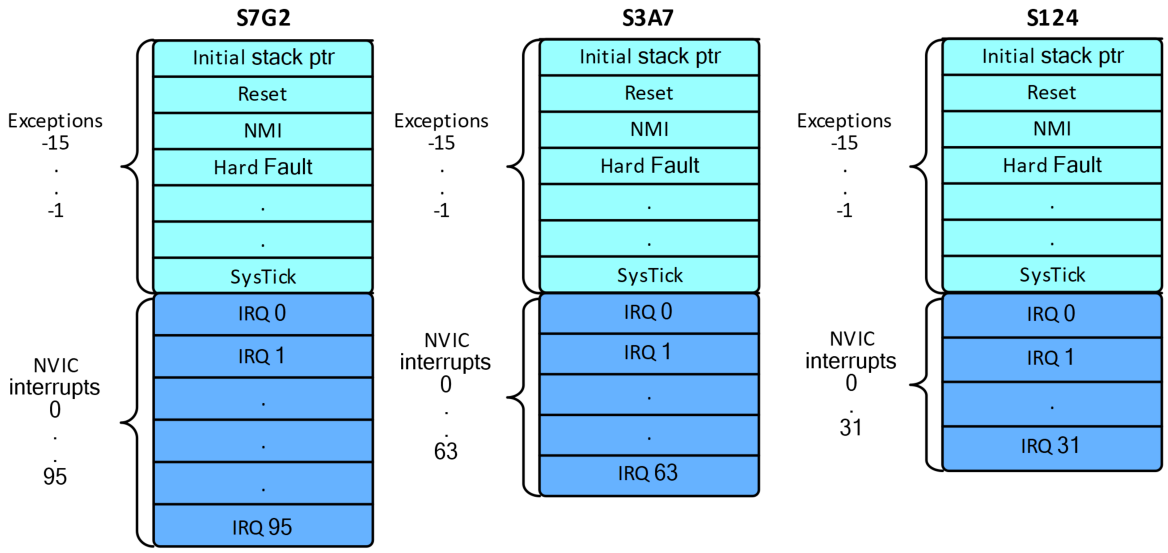

Figure 14: NVIC Interrupt vector table

Although the number of available slots for the NVIC interrupt vector table may seem small, the BSP defines up to 512 events that are capable of generating an interrupt. By using Event Mapping, the BSP maps user enabled events to NVIC interrupts. For an S7G2 MCU, only 96 of these events may be active at any one time, but the user has flexibility by choosing which events generate the active event.

The diagram below shows the interrupt vector table for the S7G2:

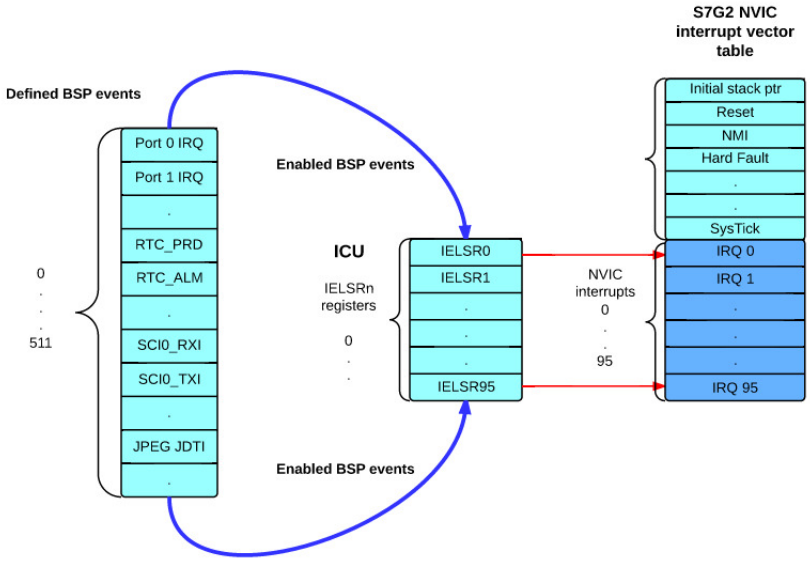

Figure 15: NVIC Interrupt vector table

By allowing the user to select only the events they are interested in as interrupt sources, we are able to provide an interrupt service routine that is fast and event specific.

For example, on other microcontrollers a standard NVIC interrupt vector table might contain a single vector entry for the SCI0 (Serial Communications Interface) peripheral. The interrupt service routine for this would have to check a status register for the 'real' source of the interrupt. In the Synergy implementation there is a vector entry for each of the SCI0 events that we are interested in. The difference between a standard NVIC table and the Synergy S7G2 NVIC table is shown below:

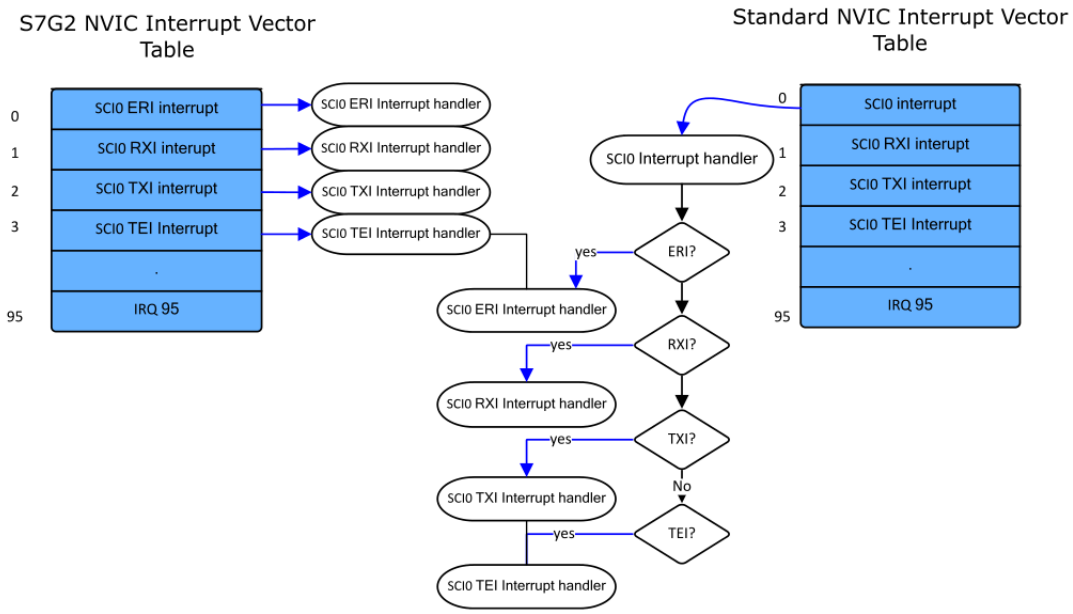

Figure 16: NVIC Interrupt vector table example

Configuration of interrupts is handled by the ISDE. Selecting an interrupt to be used by a module will generate the code necessary to allocate its entry in the vector table, as well as link it to the proper ICU ELC event.

When an interrupt occurs one of the very first operations must be to call R_BSP_IrqStatusClear() with the interrupt number corresponding to the NVIC interrupt slot that was assigned by the BSP. R_BSP_IrqStatusClear() clears the interrupt status flag (IR) for the given interrupt. When an interrupt is triggered the IR bit is set. If it is not cleared in the ISR then the interrupt will trigger again immediately.

Entries that have been assigned a priority (i.e. BSP_IRQ_CFG_ICU_IRQ0) in our example, have their corresponding 'weak handler' address placed in the next available vector slot. All of the possible interrupt sources are iterated over in this manner. Defined interrupts are entered into the vector table.

BSP Interrupt Configuration File

Bsp_irq_cfg.h is a legacy file that is no longer used and will be removed in the future. Interrupt configuration is now completely handled by the ISDE.

Vector table entries

System exceptions such as the HardFault_Handler, are defined as weak references. This allows the user to override the default handler for a particular exception and define their own handler.

All other entries in the vector table are generated by the ISDE using a macro which defines the vector and a corresponding vector information structure to generate an entries in ROM table linker sections (.vector.* for vectors and .vector_info.* for vector information).

Note that in CMSIS system_xxxx.c, there is also a weak definition (and a function body) for the Warm Start callback function R_BSP_WarmStart(). Because this function is defined in the same file as the weak declaration, it will be called as the 'default' implementation. The function may be overridden by you by copying the body into your application and modifying it as necessary. The linker identifies this as the 'strong' reference and uses it.

Warm start callbacks

As the BSP is in the process of bringing up the board out of reset, there are two points where the user can request a callback. These are defined as the 'Pre C' and 'Post C' warm start callbacks.

As described above, this function is already weakly defined as R_BSP_WarmStart(), so it is a simple matter of redefining the function or copying the existing body from CMSIS system_xxxx.c into the application code to get a callback. R_BSP_Warmstart() takes an event parameter which describes the type of warm start callback being made.

```
/* Different warm start entry locations in the BSP. */
typedef enum e_bsp_warm_start_event
{
    BSP_WARM_START_PRE_C = 0, // Called almost immediately after reset.
```

```
    /* No C runtime environment, clocks, or IRQs. */
    BSP_WARM_START_POST_C // Called after clocks and C runtime environment have been
set up.
} bsp_warm_start_event_t;
```

This function is not enabled/disabled and is always called for both events as part of the BSP startup. Therefore it needs a function body, which will not be called if the user is overriding it. The function body is located in system_xxxx. To use this function just copy this function into your own code and modify it to meet your needs.

Pre C Warm start callback

This callback occurs almost immediately after reset and at this point no C runtime environment, clocks, or IRQs have been setup.

Why would you be interested in a 'Pre C' warm start callback?

Below are a few examples.

- Execution of safety code (i.e. destructive memory tests) as part of the startup process.
- Examination of global memory as part of a crash dump investigation.
- Preventing re-initialization of an already running RTC.

Post C Warm start callback

This callback occurs after clocks and the C runtime environment have been setup.

Why would you be interested in a 'Post C' warm start callback?

Below are a few examples.

- Run tests that require that clocks have been setup.
- ADC diagnostics.
- ROM/External memory system checks.

2.1.3.11 Custom BSP Board support

Creating a Custom BSP for your own board is not supported in this version of the SSP. For information on creating a Custom BSP with earlier versions, see application note R11AN0071EU, *Creating a Custom Board Support Package for SSP v1.2.0 or Later*.

2.1.3.12 BSP API functions

The BSP provides public functions, available to any project using the BSP, that allow access to functionality that is common across BSP supported MCUs and boards.

- R_BSP_SoftwareLockInit: The BSP provides API functions to implement atomic locking. These locks can be used to protect critical areas of code as an RTOS semaphore or mutex normally would. This function simply initializes a defined lock structure to BSP_LOCK_UNLOCKED
- R_BSP_SoftwareLock: Attempts to acquire the lock that has been sent in. The Load-

Exclusive and Store-Exclusive instructions are being used to perform an exclusive read-modify-write on the input lock. This process is:
    - Use a load-exclusive (LDREXB) to read the value of the lock.
    - If the lock is available, then modify the lock value so it is reserved. If not available, then issue CLREX.
    - Use a store-exclusive to attempt to write the new value back to memory.
    - Test the returned status bit to see if the write was performed or not.
- R_BSP_SoftwareUnlock: Releases the hold on an existing software lock.
- R_BSP_HardwareLock: Hardware locks are similar to Software locks. In fact, the BSP Software lock functions are called by the Hardware lock functions. Hardware locks are specific to a particular peripheral, the list of available hardware locks being defined in bsp_hw_locks.h. Hardware locks can be used to prevent multiple threads from trying to use a peripheral that is already in use by a process or thread. For example, when the Flash API open() function is called, it takes the Flash Hardware lock and keeps it until the Flash API close is called.
- R_BSP_HardwareUnlock: Releases the hold on an existing hardware lock. In the Flash example above, the Flash API close function would call this function.
- R_BSP_GroupIrqWrite: Registers a callback function for one of supported group interrupts. As described earlier, there are 12 of these and they are all mapped to the NMI exception. When an NMI occurs, the NMI_Handler looks at the NMISR (status register) to determine the source of the interrupt. If a callback function has been registered for this group interrupt, it will be called. If NULL is passed for the callback argument, then any previously registered callbacks are unregistered.
- R_BSP_IrqStatusClear: Clears the interrupt status flag (IR) for a given interrupt. When an interrupt is triggered the IR bit is set. If it is not cleared in the ISR, then the interrupt will trigger again immediately.
- R_BSP_SoftwareDelay: Implements a blocking software delay. A delay can be specified in microseconds, milliseconds, or seconds. The delay is implemented based on the system clock rate.
- R_BSP_VersionGet: Returns the version of the BSP.
- R_BSP_LedsGet(): Returns information about the LEDs on the board.
- R_BSP_ModuleStop(): Specifies modules whose stop bit should be set.
- R_BSP_ModuleStart(): Specifies modules whose stop bit should be cleared.
- R_BSP_CacheOff(): Turns off the ROM cache, and return it's prior state.
- R_BSP_CacheSet(): Sets the cache state to a specific state (on or off).
- R_BSP_RegisterProtectEnable: Enables register protection. Registers that are protected cannot be written to. Register protection is enabled by using the Protect Register (PRCR) and the MPC's Write-Protect Register (PWPR). The registers that may be protected are grouped together into one of three groups.
    - BSP_REG_PROTECT_CGC - registers related to the clock generation circuit.
    - BSP_REG_PROTECT_OM_LPC_BATT - registers related to operating modes, low power consumption, and battery backup function.
    - BSP_REG_PROTECT_LVD – registers related to LVD (Low Voltage Detection)

The BSP register protection functions utilize reference counters to ensure that an application which has specified a certain register and subsequently calls another function does not have its register protection settings inadvertently modified.

- Each time RegisterProtectDisable() is called, the respective reference counter is incremented.
- Each time RegisterProtectEnable() is called, the respective reference counter is decremented.

Both functions will only modify the protection state if their reference counter is zero.

As the example below shows, without reference counters, MODULE2 would re-protect the registers that MODULE 1 had un-protected, preventing MODULE1 from writing them.

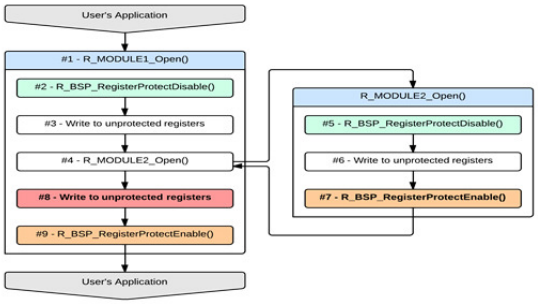

Figure 17: Register protection

- R_BSP_RegisterProtectDisable: Disables register protection. Registers that are not protected can be written to. Register protection is disabled by using the Protect Register (PRCR) and the MPC's Write-Protect Register (PWPR). The register groupings described above still apply.

2.1.4 Key Features

This section describes the key features

2.1.4.1 Azure RTOS ThreadX® RTOS

- Multithreaded, deeply embedded, real-time systems
- Small, fast Picokernel™ architecture
- Multitasking capabilities
- Preemptive and cooperative scheduling
- Flexible thread priority support (32-1024 priority levels)
- Small memory footprint and fast response times
- Optimized interrupt handling
- Stack Pointer Overflow Monitor

2.1.4.2 Azure RTOS GUIX™

- Supports 2D Graphics Acceleration in Hardware
- Unlimited objects (screens, windows, widgets)
- Dynamic object creation/deletion
- Alpha blending and anti-aliasing at higher color depths
- Canvas blending
- Dithering support
- Complete windowing support, including viewports and Z-order maintenance
- Multiple canvases and physical displays
- Window blending and fading
- Screen transitions, sprites, and dynamic animations
- Touchscreen and virtual keyboards
- Multilingual support with UTF8 string encoding
- Automatic size scaling

- 8-bit Color Lookup Table (CLUT) support
- Touch Rotation
- Radial Progress Bar
- Endian Neutral
- Monochrome through 32-bit true-color with alpha graphics formats
- Skinning and Themes
- Bitmap compression
- GUIX Studio desktop tool and Win32 simulation
- Integrated with hardware JPEG/MJPEG decoder

2.1.4.3 Azure RTOS USBX™

- USB 2.0 Full Speed and High-Speed support
- Device class: MSC, HID, CDC-ACM
- Host class: MSC, HID, CDC-ACM, UVC, HUB, Printer, Video
- Supports fast DMA and isochronous transfers

2.1.4.4 Azure RTOS FileX®

- MS-DOS compatible file system integrated with ThreadX
- FAT12-, 16-, 32-bit support
- exFAT
- Fault-tolerant file system (uses journaling)
- Multiple media instances
- LevelX Flash block media driver
- LevelX support for NOR Flash on QSPI

2.1.4.5 Azure RTOS NetX™

- Integrated with wired (Ethernet) and wireless (WiFi, Cellular) networking interfaces for Synergy
- IPv4 compliant TCP/IP Protocol Stack
- Integrated with ThreadX
- Zero-copy API
- UDP Fast Path Technology
- BSD-compatible socket layer
- RFC 791 Internet Protocol (IP)
- RFC 826 Address Resolution Protocol (ARP)
- RFC 903 Reverse Address Resolution Protocol (RARP)
- RFC 792 Internet Control Message Protocol (ICMP)
- RFC 3376 Internet Group Management Protocol (IGMP)
- RFC 768 User Datagram Protocol (UDP)
- RFC 793 Transmission Control Protocol (TCP)
- RFC 1112 Host Extensions for IP Multicasting

2.1.4.6 Application Frameworks

- ADC Periodic framework
- Audio Playback framework
- Audio Playback HW DAC framework
- Audio Playback HW I2S framework
- Audio Record framework
- Audio Recording HW ADC framework
- Block Media Interface for SD Multi Media Card
- Block Media LevelX NOR framework

- Block Media QSPI framework
- Block Media RAM framework
- Block Media SDMMC framework
- Bluetooth Low Energy (BLE) framework
- Deprecated – Capacitive Touch Sensing Unit framework
- Capacitive Touch Sensing Unit framework Version 2
- Deprecated – Capacitive Touch Sensing Unit Button framework
- Deprecated – Capacitive Touch Sensing Unit Slider framework
- Cellular framework
- Communications framework on NetX
- Communications framework on NetX Telnet
- Deprecated - Communications framework on USBX
- Communications Framework on USBX version2
- Console framework
- External Interrupt framework
- I2C framework
- Inter-Thread Messaging framework
- JPEG Decode framework
- Memory framework
- Port LevelX framework
- Periodic Sampling ADC framework
- Power Profile Version 2 framework
- SPI Framework
- Synergy FileX® Port Block Media Interface framework
- Synergy GUIX™ Interface framework
- Synergy NetX™ Port framework
- Synergy USBX™ Port framework
- Thread Monitor framework
- Deprecated - Touch Panel framework
- Touch Panel Version 2 framework
- UART framework
- Wi-Fi Framework

2.1.4.7 Security Cryptographic (SCE) Library

- True RNG (TRNG)
- SHA1, SHA224/SHA256
- ECC P-192, P-224, P-256 and P-384 curves. Includes APIs for scalar multiplication, key generation, ECDSA signature generation, and ECDSA signature verification operations
- AES 128, 192, and 256-bits ECB, CBC, CTR, GCM, XTS
- 3DES, 192-bit key, ECB, CBC, CTR
- ARC4
- RSA up to 2048-bit keys
- DLP, DSA up to 2048-bit keys
- Encryption/Decryption
- Key Generation (plaintext and wrapped keys) and Installation.
- Signature Generation and Verification
- MD5

2.1.4.8 CMSIS DSP Library

- Basic math functions
- Fast math functions
- Complex math functions
- Filters

- Convolution
- Matrix functions
- Transforms
- Motor control functions
- Statistical functions
- Support functions
- Interpolation functions
- Bayes functions
- Controller functions
- Distance functions
- Quaternion functions
- SVM functions

Detailed CMSIS library details can be found on
Github: https://github.com/ARM-software/CMSIS_5/releases/tag/5.8.0

2.1.4.9 CMSIS Neural Network Library

- Convolution functions
- Activation functions
- Fully-connected Layer functions
- Pooling functions
- Softmax functions
- Basic math functions
- Concatenation functions
- NN Support functions
- Reshape Functions
- SVD Functions

Detailed CMSIS library details can be found on
Github: https://github.com/ARM-software/CMSIS_5/releases/tag/5.8.0

2.1.4.10 AzureRTOS NetX Duo™

- IPv4 and IPv6 compliant TCP/IP Protocol Stack
- Integrated with ThreadX
- Integrated with wired (Ethernet) and wireless (WiFi, Cellular) networking interfaces for Synergy
- Zero-copy API
- UDP Fast Path Technology
- BSD-compatible socket layer
- RFC 2460 IPv6 Specification
- RFC 4861 Neighbor Discovery for IPv6
- RFC 4862 IPv6 Stateless Address
- RFC 1981 Path MTU Discovery for IPv6
- RFC 4443 ICMPv6
- RFC 791 Internet Protocol (IP)
- RFC 826 Address Resolution Protocol (ARP)
- RFC 903 Reverse Address Resolution Protocol (RARP)
- RFC 792 Internet Control Message Protocol (ICMP)
- RFC 3376 Internet Group Management Protocol (IGMP)
- RFC 768 User Datagram Protocol (UDP)
- RFC 793 Transmission Control Protocol (TCP)
- RFC 1112 Host Extensions for IP Multicasting
- RFC 1661 - The Point-to-Point Protocol (PPP)

2.1.4.11 Azure RTOS NetX™ Applications (IPv4 Networking Services)

- DHCP Client and Server
- DNS Client
- HTTP 1.0 Client and Webserver
- HTTP 1.1 Client
- FTP Client and Server
- TFTP Client and Server
- Telnet Client and Server
- Auto IP
- NAT
- SMTP Client
- POP3 Client and Server
- SNMP Agent
- SNTP Client
- PPP (Not currently supported by Synergy Configuration tool)

2.1.4.12 Azure RTOS NetX Duo™ Applications (IPv4/v6 Networking Services)

- DHCP Client and Server
- DNS Client
- HTTP 1.0 Client and Webserver
- HTTP 1.1 Client
- HTTPS Client and Server
- FTP Client and Server
- TFTP Client and Server
- Telnet Client and Server
- Auto IP
- NAT
- SMTP Client
- POP3 Client and Server
- SNMP Agent
- SNTP Client
- MDNS/DNS-SD
- PPP (Not currently supported by Synergy Configuration tool)

2.1.4.13 Azure RTOS NetX Secure

- TLS v1.2 (RFC 5246) and v1.3 (RFC 8446)
- DTLS v1.2 (RFC 6347)
- RFC 5280 Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile
- RFC 5280 X.509 PKI Certificates (v3)
- Supports X.509 extensions for Key Usage and Extended Key Usage
- RFC 3268 Advanced Encryption Standard (AES) Cipher suites for Transport Layer Security (TLS)
- RFC 3447 Public-Key Cryptography Standards (PKCS) #1: RSA Cryptography Specifications Version 2.1
- RFC 2104 HMAC: Keyed-Hashing for Message Authentication
- RFC 6234 US Secure Hash Algorithms (SHA and SHA-based HMAC and HKDF)
- RFC 8422 Elliptic Curve Cryptography (ECC) Cipher Suites for Transport Layer Security (TLS) Versions 1.2 and Earlier
- RFC 4279 Pre-Shared Key Cipher suites for TLS
- Supports TLS extensions for:
    - Secure Renegotiation Indication

    - Server Name Indication
    - Signature Algorithms
- Subject Alternative Name
- Integrated with hardware accelerated Cryptographic library on Synergy

2.1.4.14 Azure RTOS MQTT client for NetX Duo

- Compliant with OASIS MQTT Version 3.1.1
- Provides option to enable/disable TLS for secure communications using NetX Secure in SSP
- Supports QoS and provides the ability to choose the levels that can be selected while publishing the message
- Supports multiple Instances of MQTT Client Per Device

2.1.4.15 Memory Support

- Flash programming support via JTAG
- Code and Data Flash drivers
- External memory bus support

2.1.4.16 Human Machine Interface (HMI)

- Graphics LCD controller driver
- Segment LCD controller driver
- Capacitive Touch Sensing Unit (CTSU)

2.1.4.17 Hardware Abstract Layer (HAL) Driver Modules

- Analog Comparator High-Speed (ACMPHS)
- Analog Comparator Low Power (ACMPLP)
- Analog Connect Module (ACM)
- Analog to Digital Converter (ADC) (12-bit, 14-bit)
- Asynchronous General Purpose Timer (AGT)
- AGT Input Capture (AGT Input Capture)
- Capacitive Touch Sensing Unit (CTSU)
- Clock Frequency Accuracy Measurement (CAC)
- Clock Generation Circuit (CGC)
- Controller Area Network Interface (CAN)
- Cyclic Redundancy Check calculator (CRC)
- Data Operation Circuit (DOC)
- Data Transfer Controller (DTC)
- Digital to Analog converter (DAC)
- Digital to Analog converter 8-bit (DAC8)
- Direct Memory Access Controller (DMAC)
- Event Link Controller (ELC)
- Flash Memory-High Performance (FLASH_HP)
- Flash Memory-Low Power (FLASH_LP)
- General Purpose I/O Port (GPIO / IOPORT)
- General Purpose Timer (GPT)
- General PWM Timer with Input Capture (GPT_INPUT_CAPTURE)
- Graphics LCD Controller (GLCD)
- IEEE 1588 Precision Time Protocol (PTP)
- I2IC (RIIC)
- Independent Watchdog Timer (IWDT)
- Interrupt Controller Unit (ICU)
- JPEG Codec (JPEG_COMMON, JPEG_ENCODE, JPEG_DECODE)

- Keyboard Interrupt Interface (KINT)
- Deprecated – Low Power Mode (LPM)
- Low Power Mode Version 2 (LPMv2)
- Low Voltage Detection (LVD)
- Parallel Data Capture Unit (PDC)
- Quad SPI (QSPI)
- Real Time clock (RTC)
- SD Multi Media Card (SDMMC)
- Segment LCD (SLCD)
- Serial Communication Interface I2C (SCI_I2C)
- Serial Communication Interface SPI (SCI_SPI)
- Serial Communication Interface UART (SCI_UART)
- Sigma-Delta ADC (SDADC)
- Serial Peripheral Interface (SPI)
- Serial Sound Interface (SSI)
- Watchdog Timer (WDT)

2.1.4.18 GPIO and Key Interrupts

- GPIO module
- Key Interrupts module

Chapter 3 Starting Development

To start development with the Renesas Synergy Software Package (SSP), download and install e2 studio, obtain a target Synergy development or evaluation board, and run through the tutorials in this chapter. The e2 studio ISDE user guide and the tutorials include step-by-step instructions for getting started with a simple application. To get started with the SSP, refer to these pages:

- e2 studio ISDE User Guide
- Tutorial: Your First Synergy Project - Blinky
- Tutorial: Using HAL Drivers - Programming the WDT
- IAR Embedded Workbench for Renesas
- What is Synergy Standalone Configurator (SSC)?

3.1 e2 studio ISDE User Guide

3.1.1 Using the e2 studio ISDE

This section describes how to use the Renesas e^2 studio Integrated Solutions Development Environment (ISDE) to develop applications with the Renesas Synergy Software Package (SSP). The architecture of the SSP directly determines how you use the e^2 studio ISDE to develop a Synergy application. See the following documents for details on the SSP architecture included in this manual:

- SSP Architecture
- BSP Architecture

For simple example projects generated and built with e^2 studio, see:

- Tutorial: Using HAL Drivers - Programming the WDT
- Tutorial: Your First Synergy Project - Blinky

All User Guides in this manual show how to configure a driver and develop an application using the e^2 studio ISDE. See:

- HAL Layer for HAL layer user guides
- Framework Layer for Framework layer user guides

3.1.2 What is the e2 studio ISDE?

The Renesas e^2 studio ISDE, or Integrated Solution Development Environment, is a development tool encompassing code development, build, and debug. The ISDE is based on the open-source Eclipse IDE and the associated C/C++ Development Tooling (CDT). Specifically for Synergy MCUs, the ISDE provides a Graphical User Interface (GUI) with numerous wizards for configuring and auto-generating

code using the Synergy Software Package (SSP). The ISDE also incorporates a smart manual so that driver and device documentation is available in the form of tooltips right in the code.

Figure 18: e2 studio Splash Screen

Note

The e² studio screens shown in this manual are examples. Some details may differ between different releases of the e² studio ISDE and the SSP.

The e² studio ISDE and the Synergy Project Configurator have been developed to make it as easy as possible to quickly select the SSP modules required for a particular application, include them in a project, and configure them. The ISDE provides a graphical user interface to configure all elements of the SSP for the Synergy MCU applications. In addition to HAL and Framework modules, the ISDE can add and configure RTOS threads, semaphores, mutexes, event flags, and queues. This makes adding RTOS support to an application very straightforward. Once a project has been generated, you can go back and reconfigure any of the modules and settings if required. The ISDE generates the complete and correct configuration code from the selections in the configuration views, so you can focus on writing the application code.

The elements of the SSP are shown in the **Project Explorer** view of the e² studio ISDE. All SSP configuration structures and parameters are mapped to XML files. The XML files enable the ISDE to present a visual list of configurable options that you can select from. In addition to generating code to configure the modules, the XML also provides dependency information for modules.

When you add an SSP module to your project, the e² studio ISDE checks the dependencies of this module and adds all necessary drivers and framework modules to create the appropriate stack. If there is a dependency that requires you to make a choice, this module is highlighted in the Stack window and the ISDE guides your selection by showing the available options.

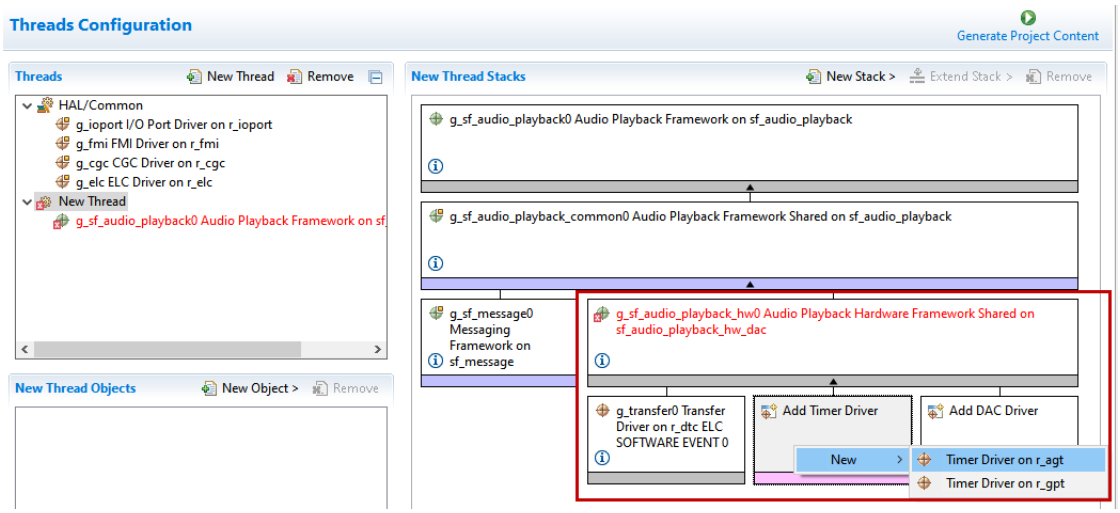

Figure 19: ISDE Dependency Checking

Errors are flagged next to the Driver name in the HAL/Common Modules or New Thread Modules pane. You can also review errors in the Problems window.

3.1.3 e2 studio ISDE Prerequisites

3.1.3.1 Obtaining a Synergy Kit

To develop applications with the SSP, start with one of the Renesas Synergy Kits. The Renesas Synergy Kits are designed to seamlessly integrate with the e^2 studio ISDE. Several types of kits are available:

- Development Kit (DK)
- Starter Kit (SK)
- Product Example (PE)
- Target Board (TB)

Ordering information, Quick Start Guides, User Manuals, and other related documents for all Synergy Kits are available at http://renesassynergy.com.

3.1.3.2 PC Requirements

To use the e^2 studio ISDE, ensure that your PC meets the following minimum requirements:

- Windows 7 with Intel i5 or i7, or AMD A10-7850K or FX
- Memory: 8 GB DDR3 or DDR4 DRAM (16 GB DDR4/2400 MHz RAM is preferred)
- Minimum 250 GB hard disk

3.1.3.3 Installing e2 studio and the SSP

Detailed installation instructions and installers for the e^2 studio ISDE and the SSP are available on the Renesas Synergy Gallery website https://synergygallery.renesas.com. Review the release notes for e^2 studio to ensure that the e^2 studio version supports the selected SSP version.

3.1.3.4 Choosing a Toolchain

The e^2 studio ISDE can work with several toolchains and toolchain versions such as the GNU ARM

compiler and the IAR toolchain. A version of the GNU ARM compiler is included in the e^2 studio installer and has been verified to run with the SSP version.

To use the IAR toolchain for ARM, install IAR Embedded Workbench for Renesas Synergy (EWSYN) (a license from IAR is required). Before starting a Synergy project with IAR, also install the IAR Embedded Workbench for ARM Eclipse plugin (using the IAR Embedded Workbench plugin manager in the 'Help' menu).

3.1.3.5 Adding the IAR Embedded Workbench for Renesas Synergy Compiler into e2 studio

The IAR Embedded Workbench for Renesas Synergy compiler (IAR compiler) can now be used from within ^{2} studio. This allows the developer to have the advantages provided by the IAR compiler without the need to also use the IAR EW for Renesas Synergy ISDE. The installation process involves installing IAR EW for Renesas Synergy, installing e^2 studio, and installing the associated IAR plugins for e^2 studio. The process is described in the application note found with this search: https://www.renesas.com/eu/en/document/apn/installing-iar-compiler-e2-studio-application-note

The application note also includes a description of how to migrate a project that originally used e^2 studio and GCC. It also includes a description of how to migrate a project from IAR 7.x to IAR 8.x so it will be successfully opened when using e^2 studio.

3.1.4 What is a Project?

In e^2 studio, all SSP applications are organized in Synergy projects. Setting up a Synergy project involves:

1. Creating the project
2. Configuring the project

The e^2 studio ISDE has many project wizards and configuration windows specifically for Synergy projects. You can create a new Synergy Project with the **Synergy Project Generator** or edit the configuration of an existing project in the **Synergy Project Editor**.

When you launch e^2 studio and select a workspace, all projects previously saved in the selected workspace are loaded and displayed in the **Project Explorer** view. Each project has an associated configuration file named configuration.xml which is located in the project's root directory.

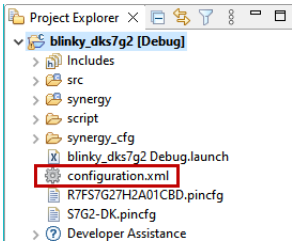

Figure 20: e2 studio Project Configuration File

Double-click on the configuration.xml file to open the Synergy Project Editor and view or modify all configuration settings associated with this project. To edit the project configuration, make sure that the **Synergy Configuration** perspective is selected in the upper right hand corner of the e^2 studio window.

Figure 21: e2 studio Synergy Configuration Perspective

Note

Whenever the Synergy project configuration (that is, the configuration.xml file) is saved, a verbose Synergy Project Report file (synergy_cfg.txt) with all the project settings is generated. The format is such that differences can be easily viewed using a textual difference tool. The generated file is located in the project root directory.

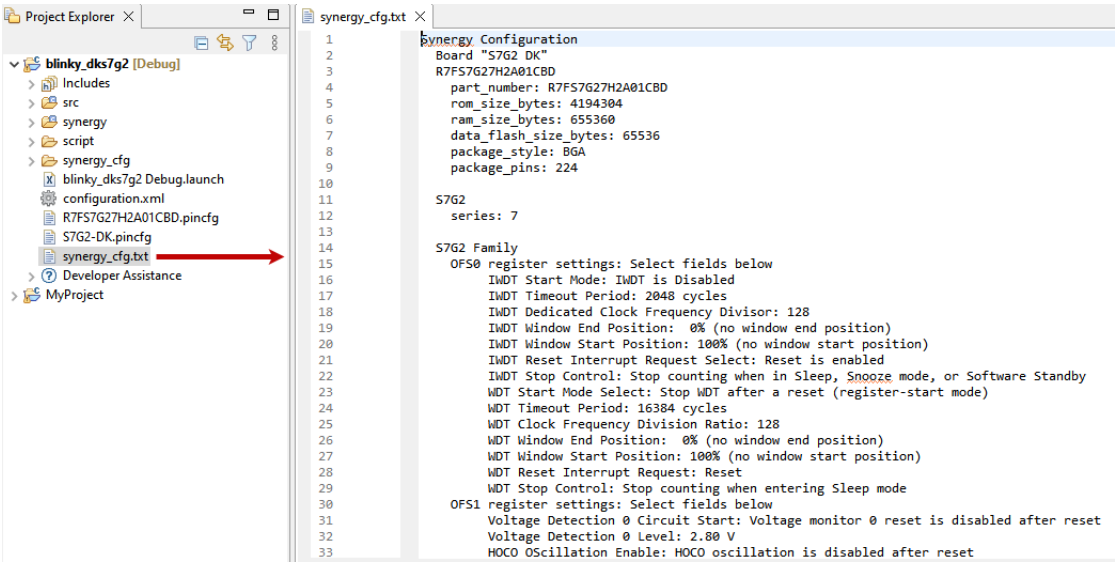

Figure 22: Synergy Project Report

The Synergy Project Editor has a number of tabs. The configuration steps and options for individual tabs are discussed in the following sections.

Note

Which tabs are available with the Synergy Project Editor depends on the e² studio version.

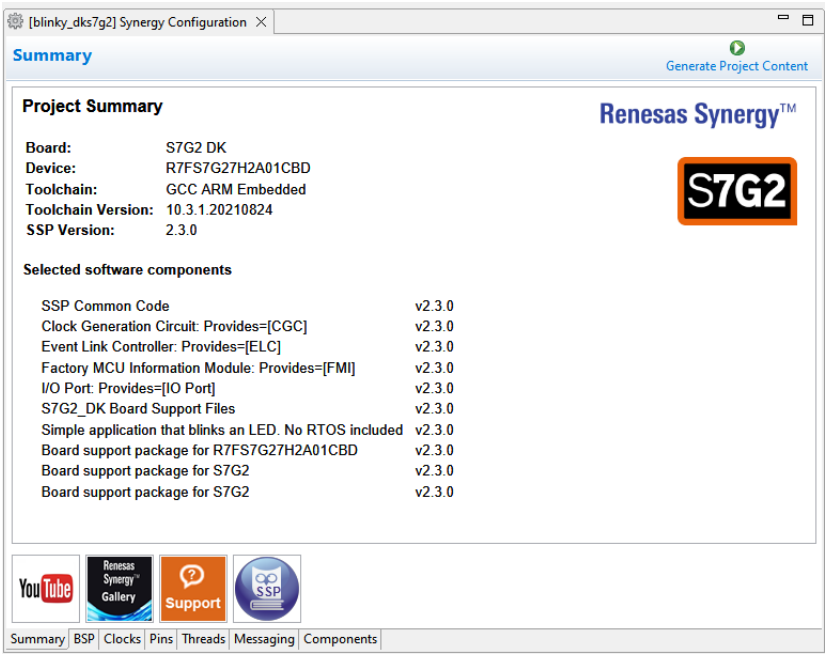

Figure 23: e2 studio Project Editor

3.1.5 Creating a Project

This section includes step-by-step instructions for creating a Synergy Project. Once you have created the project, you can easily configure the hardware (clocks, pins, interrupts) and the parameters of all modules that are part of your application.

To create a new Synergy Project with the Synergy Project Generator, select the project name, select the hardware for your application, select the toolchain and choose from preconfigured clock, pin, and MCU related settings by selecting a project template.

3.1.5.1 Creating a New Project

For Synergy applications, always generate a new project as a Synergy Project in the following way:

1. Click on **File > New > Synergy C/C++ Project**

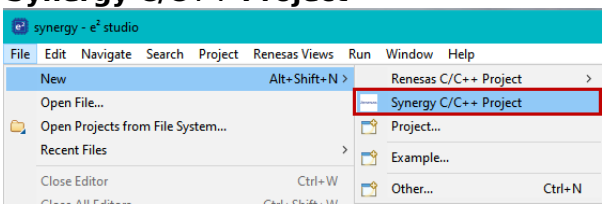

Figure 24: New Synergy Project

Then click on the type of template for the type of project you are creating.

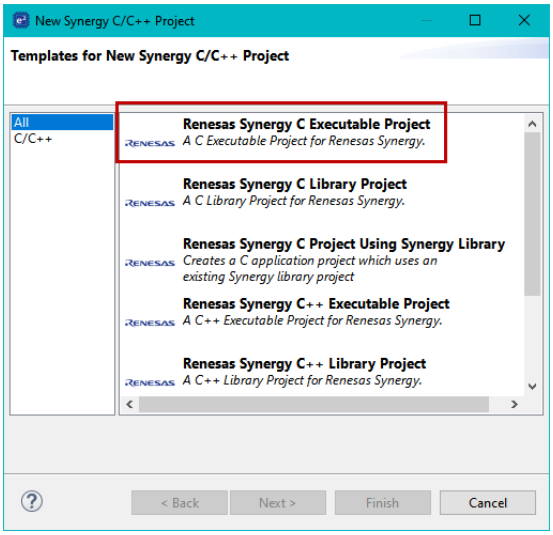

Figure 25: New Project Templates

2. Select a project name and location.

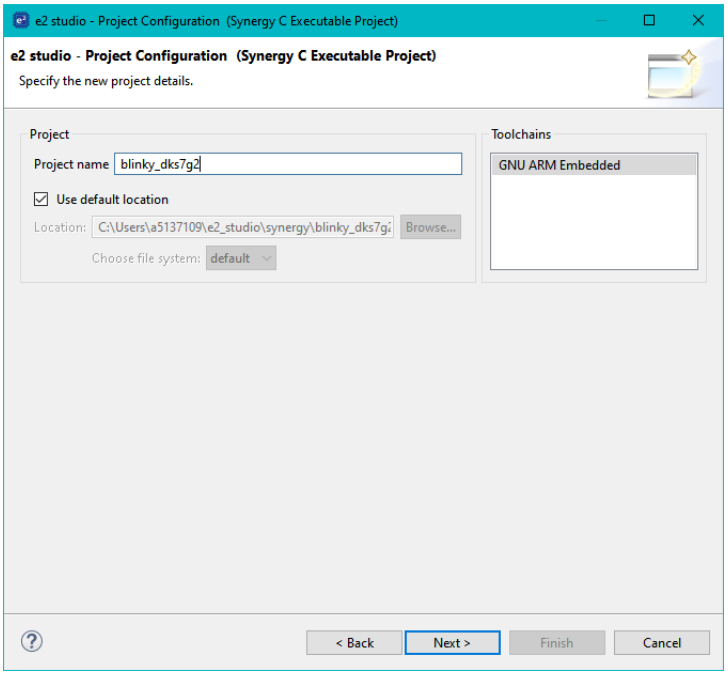

Figure 26: Synergy Project Generator (Screen 1)

3. Click **Next**.

3.1.5.2 Selecting a Board and Toolchain

In the next Project Configuration window select the hardware and software environment:

1. Select the **SSP version**.

2. Select the **Board** for your application. You can select an existing Synergy Kit or select Custom User Board for any of the Synergy devices with your own BSP definition.

Note

To develop your own BSP, see the following Application Note: "Creating a Custom Board Support Package" at http://renesassynergy.com.

3. Select the **Toolchain version**.
4. Select the **Debugger**. The J-Link ARM Debugger is preselected.
5. Click **Next**.

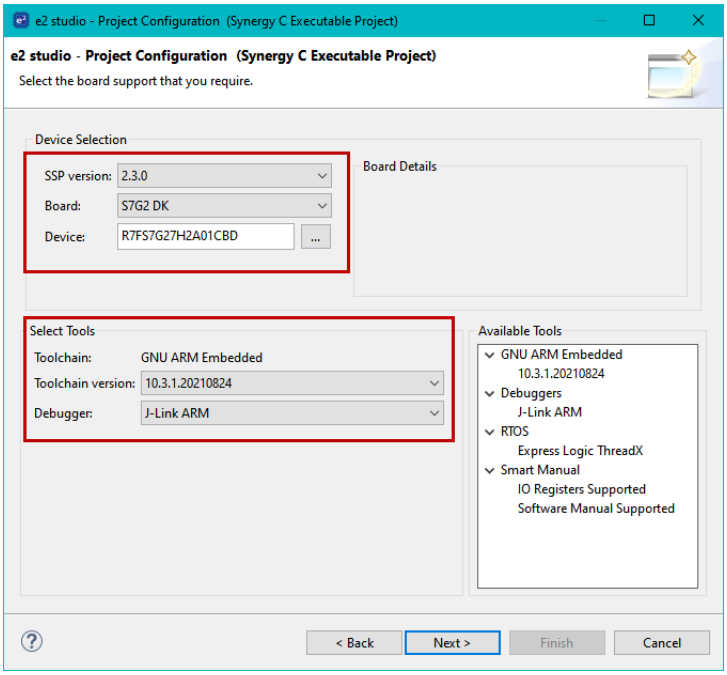

Figure 27: Synergy Project Generator (Screen 2)

3.1.5.3 Selecting a Project Template

In the next window, select a project template from the list of available templates and click **Finish**.

Note

If you want to develop your own application, select a basic template for your board, such as S7G2-DK BSP. You can add RTOS support at any time while you configure the modules for your project.

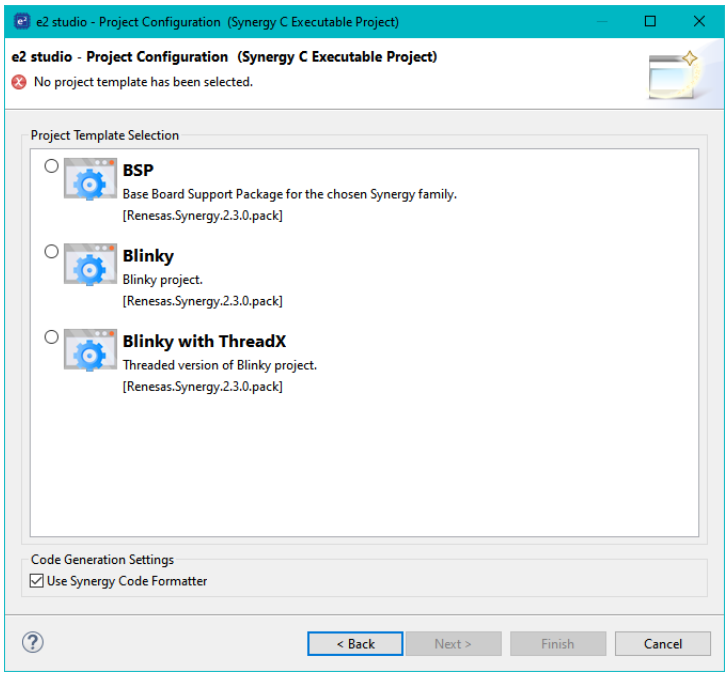

Figure 28: Synergy Project Generator (Screen 3)

By default, this screen shows the templates that are included in your current SSP pack.

When the project is created, the ISDE displays a summary of the current project configuration in the Synergy Project Editor.

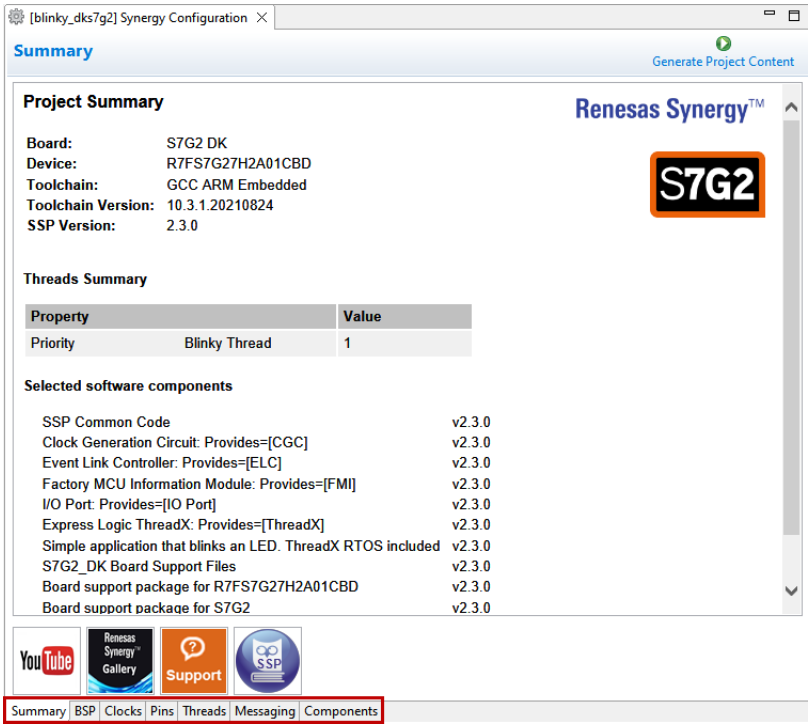

Figure 29: Synergy Project Editor and Available Editor Tabs

On the bottom of the Synergy Project Editor view, you can find the tabs for configuring multiple aspects of your project:

- With the BSP tab, you can change board specific parameters from the initial project selection.
- With the Clocks tab, you can configure the MCU clock settings for your project.
- With the Pins tab, you can configure the electrical characteristics and functions of each port pin.
- With the Threads tab, you can add SSP modules and drivers for RTOS and non-RTOS applications and configure the drivers. For each module or driver selected in this tab, the Properties window provides access to the configuration parameters, interrupt priorities, and pin selections.
- With the Messaging tab, you can configure the Messaging Framework for ThreadX-based projects. The Messaging tab is included in e^2 studio version 5.0 and higher.
- The Components tab provides an overview of the selected modules. You can also add drivers for specific SSP releases and application sample code here.

3.1.6 Configuring a Project

A project has two levels of configuration.

- The BSP, Clocks, and Pins tabs determine the initial configuration of the MCU after reset and before any user code is executed. By selecting a project template during project creation, the ISDE configures default values as appropriate for the selected board. You can change those default values as needed.
- The Threads allows you to add SSP modules to the project and set the configuration parameters of the module as needed by the application. Because the Messaging Framework is an integral part of many ThreadX-based applications, you can configure the Messaging Framework for each thread requiring messaging in the Messaging tab (for e^2 studio versions 5.0 and higher).

3.1.6.1 Configuring the BSP with the ISDE

The **BSP** tab shows the currently selected board (if any) and device. The **Properties** view is located in the lower left of the Project Configurations view as shown below.

Note

*If the Properties view is not visible, click **Window** > **Show View** > **Properties** in the top menu bar.*

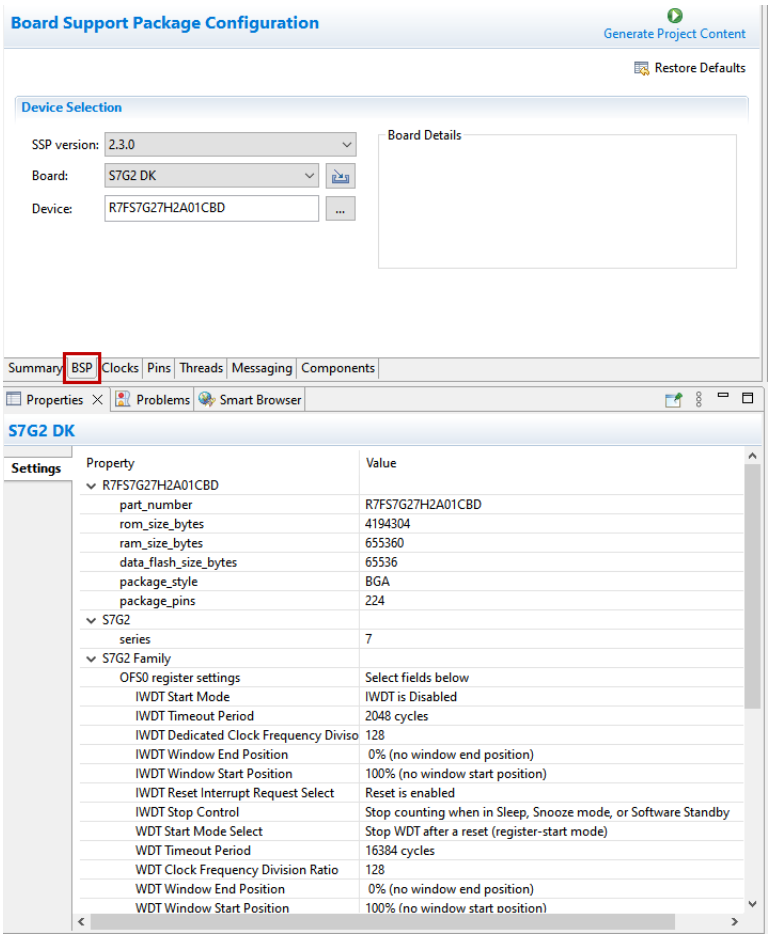

Figure 30: ISDE BSP Tab

The Properties view shows the configurable options available for the BSP. These can be changed as required. The BSP is the SSP layer above the MCU hardware. The ISDE checks the entry fields to flag invalid entries. For example, only valid numeric values can be entered for the stack size.

When you press the **Generate Project Content button**, the BSP configuration contents are written to

synergy_cfg/ssp_cfg/bsp/bsp_cfg.h

This file is created if it does not already exist.

Warning

Do not edit this file as it is overwritten whenever the **Generate Project Content** button is pressed.

3.1.6.2 Configuring Clocks

The **Clocks** tab presents a graphical view of the MCU's clock tree, allowing the various clock dividers and sources to be modified. If a clock setting is invalid, the offending clock value is highlighted in red. It is still possible to generate code with this setting, but correct operation cannot be guaranteed. In the figure below, the USB clock UCLK divider has been changed so the resulting clock frequency is 60 MHz instead of the required 48 MHz. This parameter is colored red.

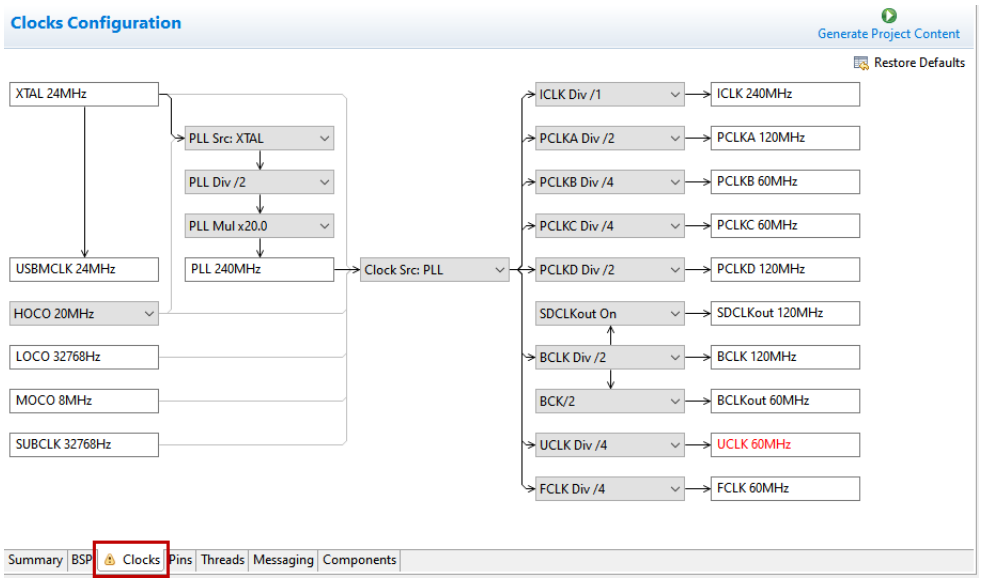

Figure 31: ISDE Clocks Tab

When you press the **Generate Project Content** button, the clock configuration contents are written to:

synergy_cfg/ssp_cfg/bsp/bsp_clock_cfg.h

This file will be created if it does not already exist.

Warning

Do not edit this file as it is overwritten whenever the **Generate Project Content** button is pressed.

3.1.6.3 Configuring Pins

The **Pins** tab provides flexible configuration of the MCU's pins. As many pins are able to provide multiple functions, they can be configured on a peripheral basis. For example, selecting a serial channel via the SCI peripheral offers multiple options for the location of the receive and transmit pins for that module and channel. Once a pin is configured, it is shown as green in the **Package** view.

Note

*If the Package view window is not open in the ISDE, select **Window** > **Show View** > **Pin Configurator** > **Package** from the top menu bar to open it.*

The **Pins** tab simplifies the configuration of large packages with highly multiplexed pins by highlighting errors and presenting the options for each pin or for each peripheral. If you selected a project template for a specific board such as the DK-S7G2, some peripherals connected on the board are preselected.

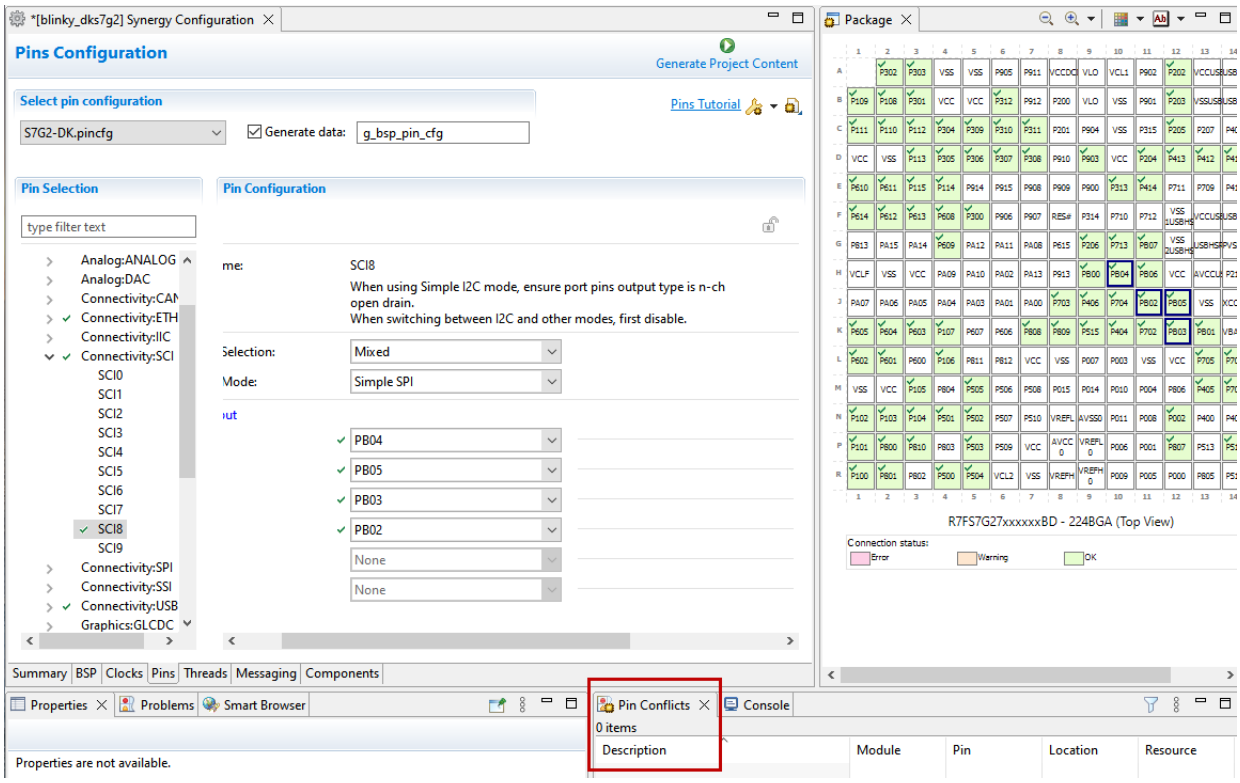

Figure 32: ISDE Pins Tab

The pin configurator includes a built-in conflict checker, so if the same pin is allocated to another peripheral or I/O function the pin will be shown as red in the package view and also with white cross in a red square in the **Pin Selection** pane and **Pin Configuration** pane in the main **Pins** tab. The **Pin Conflicts** view provides a list of conflicts, so conflicts can be quickly identified and fixed.

In the example shown below, port P105 is already used by the External Memory peripheral, and the attempt to connect this port to the Serial Communications Interface (SCI) results in a dangling connection error. To fix this error, select another port from the pin drop-down list or disable the External Memory peripheral in the **Pin Selection** pane on the left side of the tab.

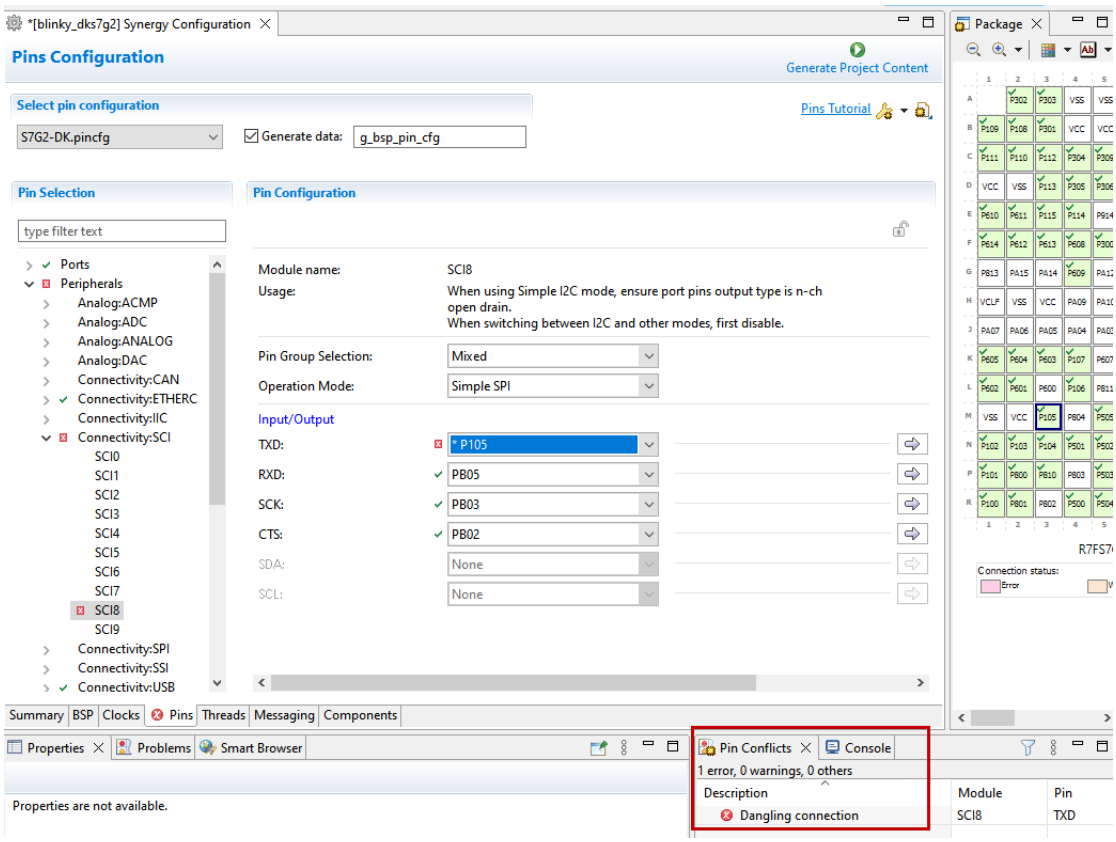

Figure 33: ISDE Pin Configurator

The pin configurator also shows a package view and the selected electrical or functional characteristics of each pin.

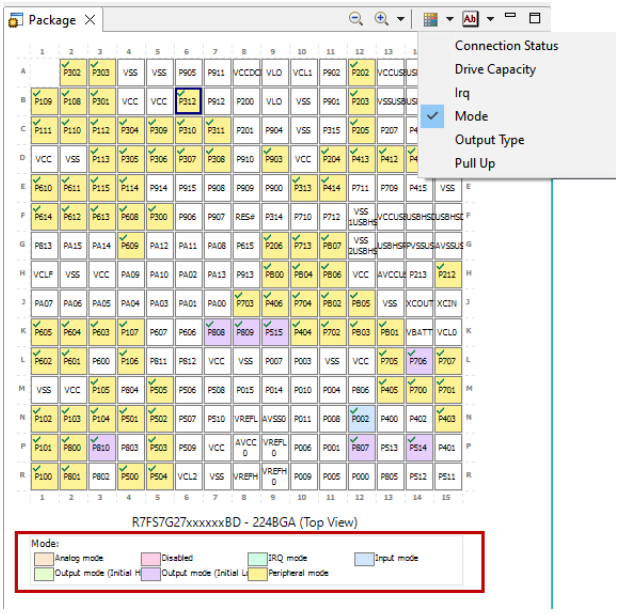

Figure 34: ISDE Pin Configurator

When you press the **Generate Project Content** button, the pin configuration contents are written to:

synergy_cfg/ssp_cfg/bsp/bsp_pin_cfg.h

This file will be created if it does not already exist.

Warning

Do not edit this file as it is overwritten whenever the **Generate Project Content** button is pressed.

To make it easy to share pinning information for your project, the ISDE exports your pin configuration settings to a csv format and copies the csv file to synergy_cfg/ssp_cfg/bsp/pincfg_<MCU package>.csv.

3.1.7 Adding Threads and Drivers

Every ThreadX-based Synergy Project includes at least one RTOS Thread and a stack of SSP modules running in that thread. The **Threads** tab is a graphical user interface which helps you to add the right modules to a thread and configure the properties of both the threads and the modules associated with each thread. Once you have configured the thread, the ISDE automatically generates the code reflecting your configuration choices.

For any driver or, more generally, any module that you add to a thread, the ISDE automatically resolves all dependencies with other modules and creates the appropriate stack. This stack is displayed in the Threads pane, which the ISDE populates with the selected modules and module options for the selected thread. If there is more than one module that can fulfill a dependency requirement, the ISDE prompts you to choose a module from a dropdown menu.

For example, when you add the Audio Playback Framework to a thread, you also must pick either the DAC or the I2S framework for playback:

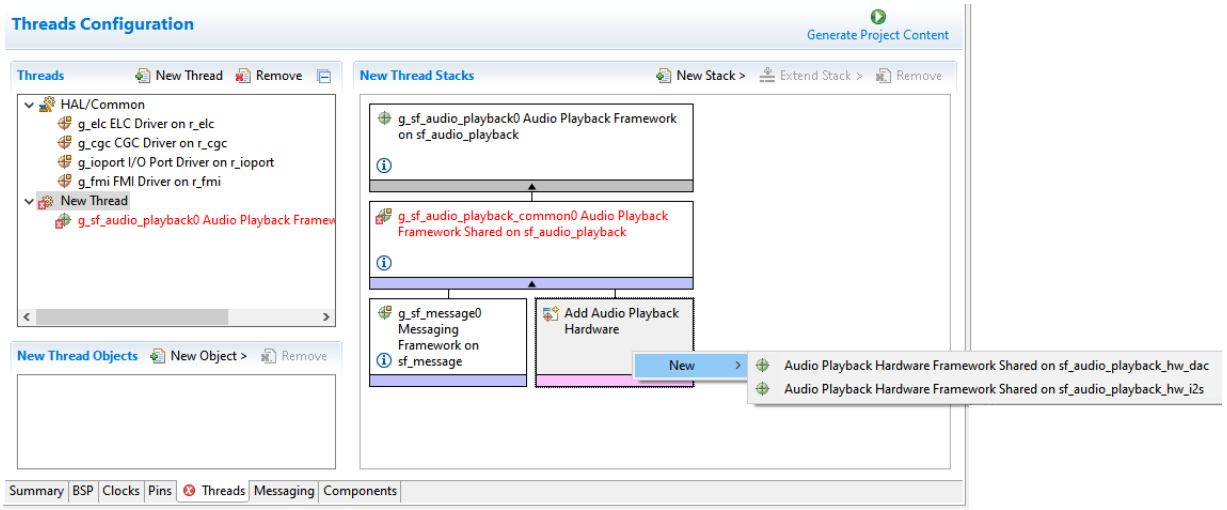

Figure 35: ISDE Project Configurator - Overview

The default view of the **Threads** tab includes a Common Thread called **HAL/Common.** This thread includes the drivers for I/O control (IOPORT), clock generation circuit (CGC), and the event link controller (ELC). The default stack is shown in the **HAL/Common Stacks** pane. The default modules added to the HAL/Common thread are special in that the SSP only requires a single instance of each,

which the ISDE then includes in every user-defined thread by default.

In applications that do not use an RTOS or run outside of the RTOS, the HAL/Common thread becomes the default location where you can add additional drivers to your application.

For a detailed description on how to add and configure modules and threads, see the following sections:

- Adding and Configuring HAL Drivers
- Adding Drivers to a Thread and Configuring the Drivers

Once you have added a module either to HAL/Common or to a new thread, you can access the driver's configuration options in the **Properties** view. If you added thread objects, you can access the objects configuration options in the **Properties** view in the same way.

You can find details about how to configure threads here: Configuring Threads

Note

Driver and module selections and configuration options are defined in the SSP pack and can therefore change when the SSP version changes.

3.1.7.1 Adding and Configuring HAL Drivers

For applications that run outside or without the RTOS, you can add additional HAL drivers to your application using the HAL/Common thread. To add drivers, follow these steps:

1. Click on the HAL/Common icon in the **Threads** pane. The Modules pane changes to **HAL/Common Stacks**.

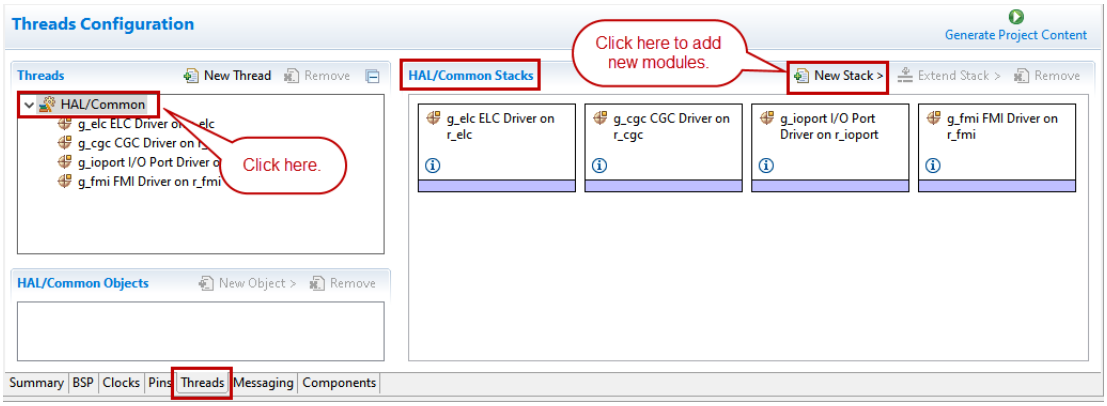

Figure 36: ISDE Project Configurator - Adding Drivers

2. Click **New Stack** to see a drop-down list of HAL level drivers available in the SSP.
3. Select a driver from the menu **New Stack > Driver**. In addition, you can select a subset of Framework modules for RTOS independent applications. All other modules can only be added to a thread when ThreadX is present.

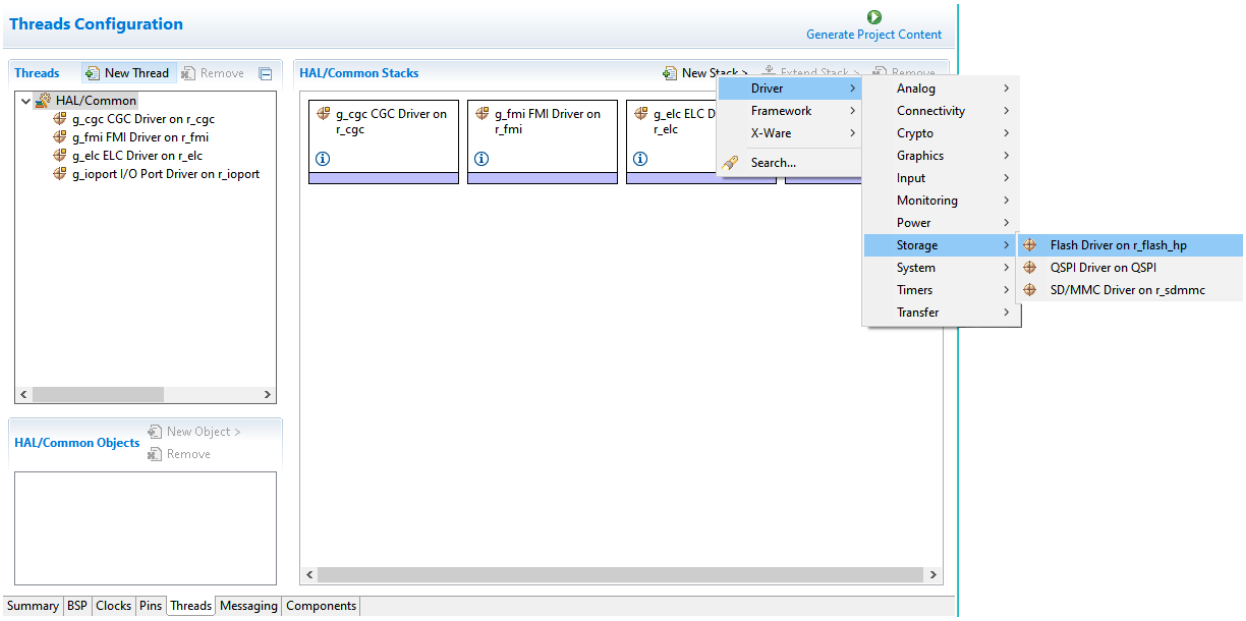

Figure 37: Select a Driver

The ISDE creates the stack for the selected driver and alerts you when the driver needs additional resources that must be enabled. In the case below, you can configure the interrupt in the **Properties** view.

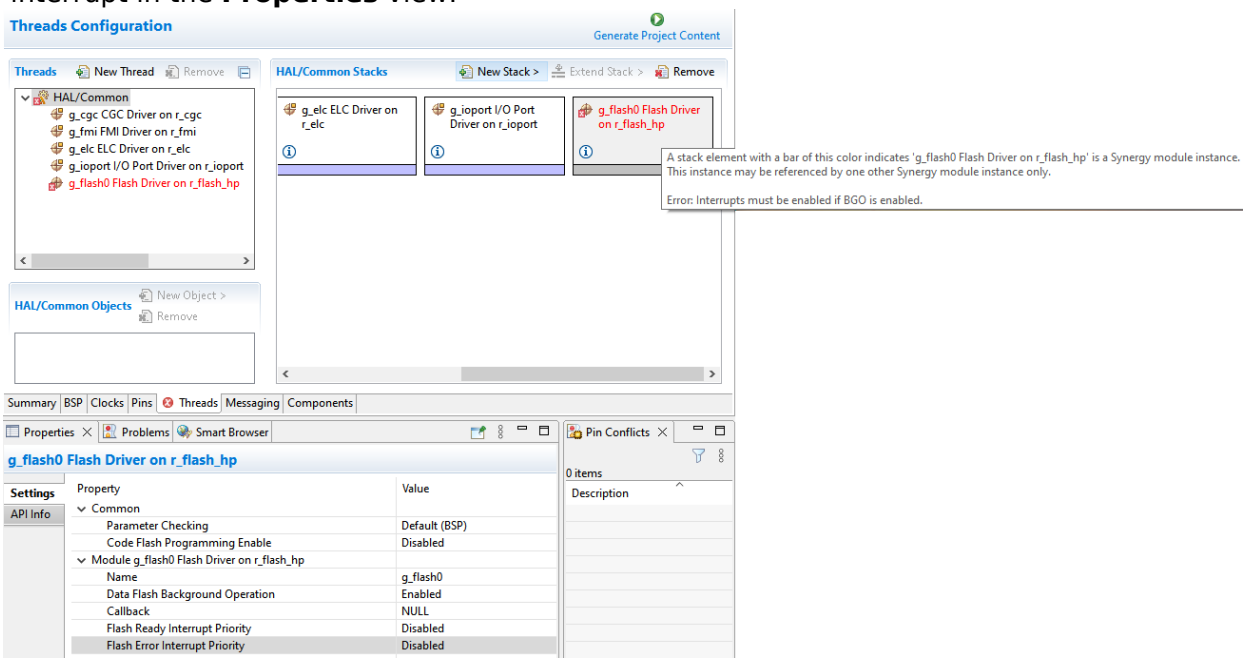

Figure 38: Dependency Checking on the Threads Tab

4. Select the driver module in the **HAL/Common Modules** pane and configure the driver properties in the **Properties** view.

The ISDE adds the following files when you click the **Generate Project Content** button:

- The selected driver module and its files to the synergy/ssp directory.
- The main() function and configuration structures and header files for your application as shown in the table below.

File	Contents	Overwritten by Generate Project Content?
src/synergy_gen/main.c	Contains main() calling generated and user code. When called, the BSP already has initialized the MCU.	Yes
src/synergy_gen/hal_data.c	Configuration structures for HAL Driver only modules.	Yes
src/synergy_gen/hal_data.h	Header file for HAL driver only modules.	Yes
src/hal_entry.c	User entry point for HAL Driver only code. Add your code here.	No

The configuration header files for all included modules are created or overwritten in this folder:

synergy_cfg/ssp_cfg/driver

3.1.7.2 Adding Drivers to a Thread and Configuring the Drivers

For an application that uses the ThreadX RTOS, you can add one or more threads, and for each thread at least one module that runs in the thread. You can select modules from either the Driver or Framework dropdown menu. To add modules to a thread, follow these steps:

1. In the **Threads** pane, click **New Thread** to add a Thread.

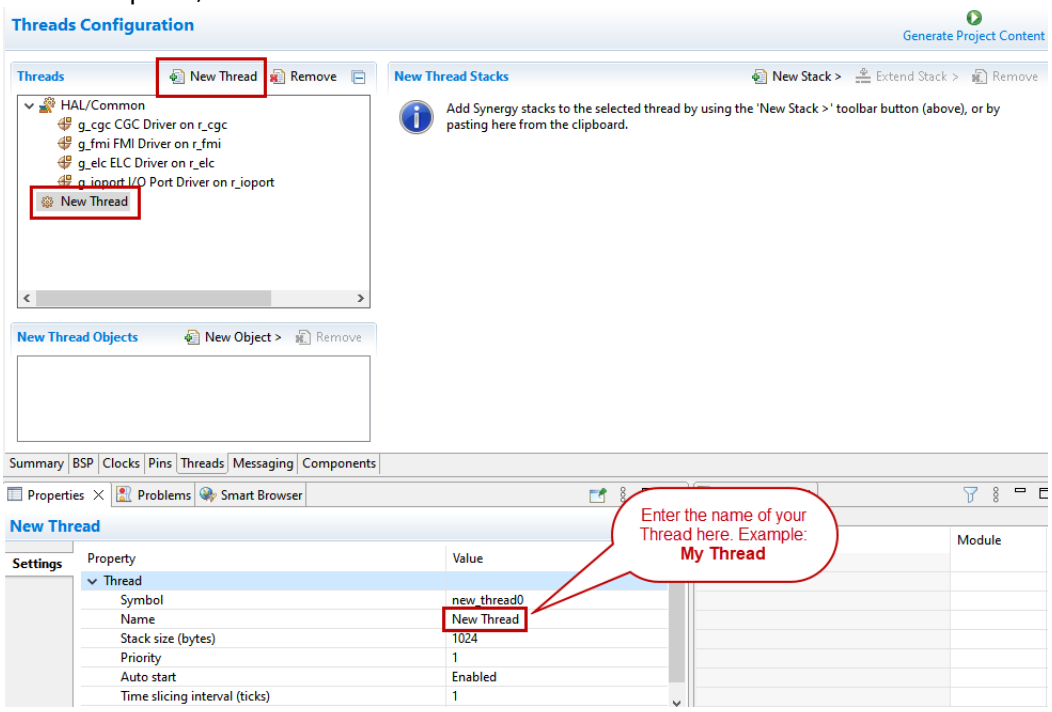

Figure 39: Adding a new RTOS Thread on the Threads Tab

2. In the **Properties** view, click on the **Name** and **Symbol** entries and enter a distinctive name and symbol for the new thread.

Note

*The ISDE updates the name of the thread stacks pane to **My Thread Stacks**.*

3. In the **My Thread Stacks** pane, click on **New** to see a list of modules and drivers. Both Framework-level Modules and HAL-level drivers can be added here.

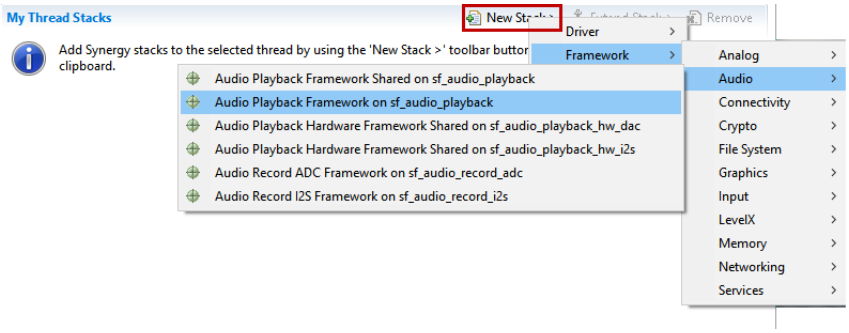

Figure 40: Adding Modules and Drivers to a Thread

4. Select a module or driver from the list.
5. If the module or driver indicates a dependency, select the missing resources.

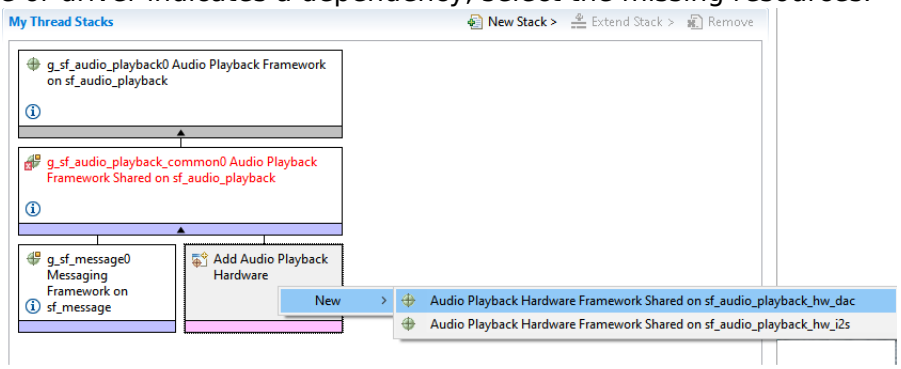

Figure 41: Identifying Module or Driver Dependencies on the Threads Tab

6. Click on the added driver and configure the driver as required by the application by updating the configuration parameters in the **Properties** view. To see the selected module or driver and be able to edit its properties, make sure the Thread containing the driver is highlighted in the **Threads** pane.

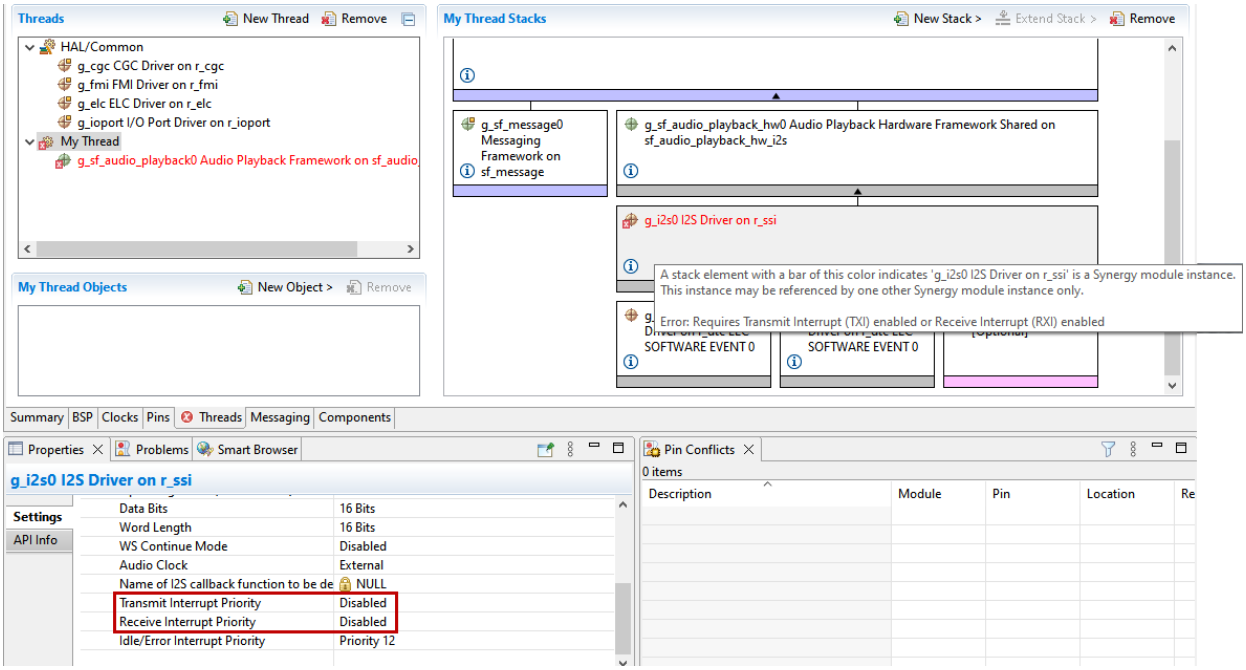

Figure 42: Configuring Module or Driver Properties

7. If needed, add another thread by clicking **New** in the **Threads** pane.

When you press the **Generate Project Content** button for the example above, the ISDE creates the files as shown in the following table:

File	Contents	Overwritten by Generate Project Content?
src/synergy_gen/main.c	Contains main() calling generated and user code. When called the BSP will have initialized the MCU.	Yes
src/synergy_gen/my_thread.c	Generated thread "my_thread" and configuration structures for modules added to this thread.	Yes
src/synergy_gen/my_thread.h	Header file for thread "my_thread"	Yes
src/synergy_gen/hal_data.c	Configuration structures for HAL Driver only modules.	Yes
src/synergy_gen/hal_data.h	Header file for HAL Driver only modules.	Yes
src/hal_entry.c	User entry point for HAL Driver only code. Add your code here.	No
src/my_thread_entry.c	User entry point for thread "my_thread". Add your code here.	No

The configuration header files for all included modules and drivers are created or overwritten in the following folders:

synergy_cfg/ssp_cfg/driver

synergy_cfg/ssp_cfg/framework

3.1.7.3 Configuring Threads

If the application uses the ThreadX RTOS, the **Threads** tab can be used to simplify the creation of ThreadX threads, semaphores, mutexes, and event flags.

The components of each thread can be configured from the **Properties** view as shown below.

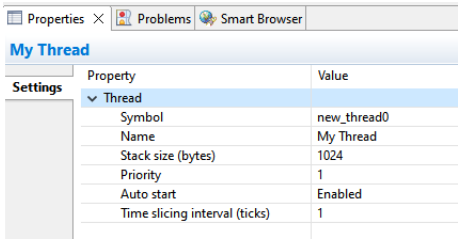

Figure 43: ISDE Thread Properties

The **Properties** view contains settings common for all Threads (**Common**) and settings for this particular thread (**Thread**).

For this thread instance, the thread's name and properties (such as priority level or stack size) can be easily configured. The ISDE checks that the entries in the property field are valid. For example, the ISDE ensures that the field **Priority**, which requires an integer value, only contains numeric values between 0 and 9.

To add ThreadX resources to a Thread, select a thread and click on **New Object** in the Thread Objects pane. The pane takes on the name of the selected thread, in this case **My Thread Objects**.

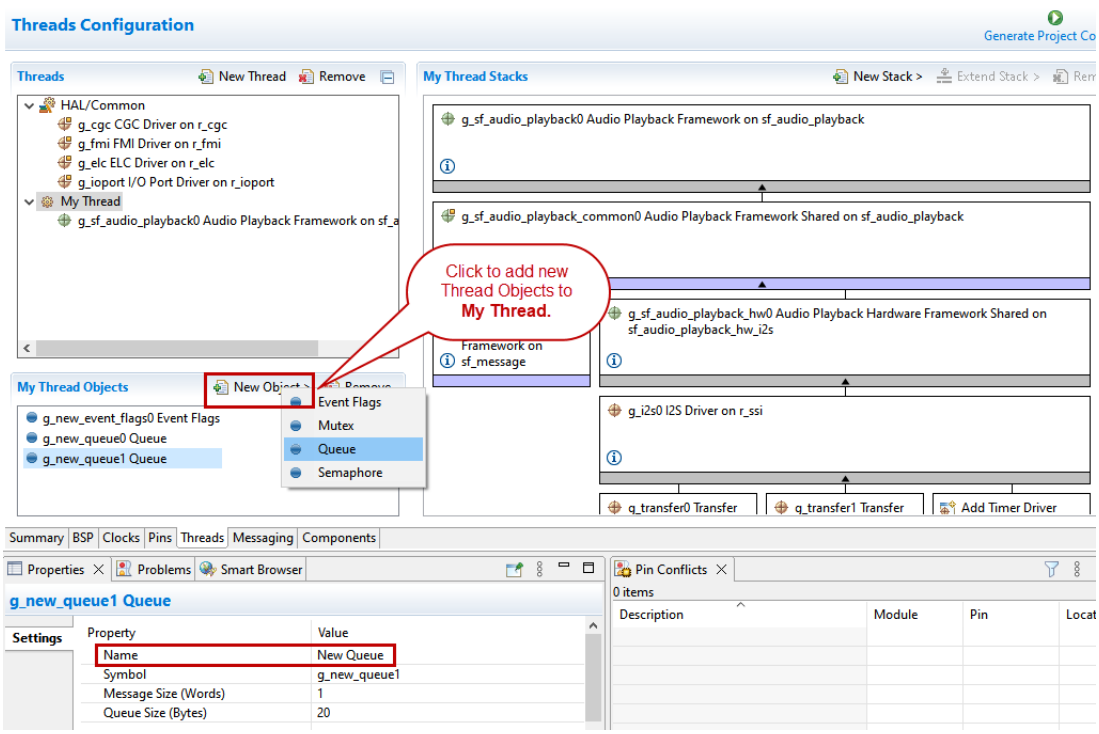

Figure 44: Configuring Thread Object Properties

Make sure to give each thread object a unique name and symbol by updating the **Name** and **Symbol** entries in the **Properties** view.

3.1.7.4 Configuring Interrupts

You can use the **Properties** view in the **Threads** tab to enable interrupts by setting the interrupt priority. Select the thread in the Threads pane to view and edit its properties.

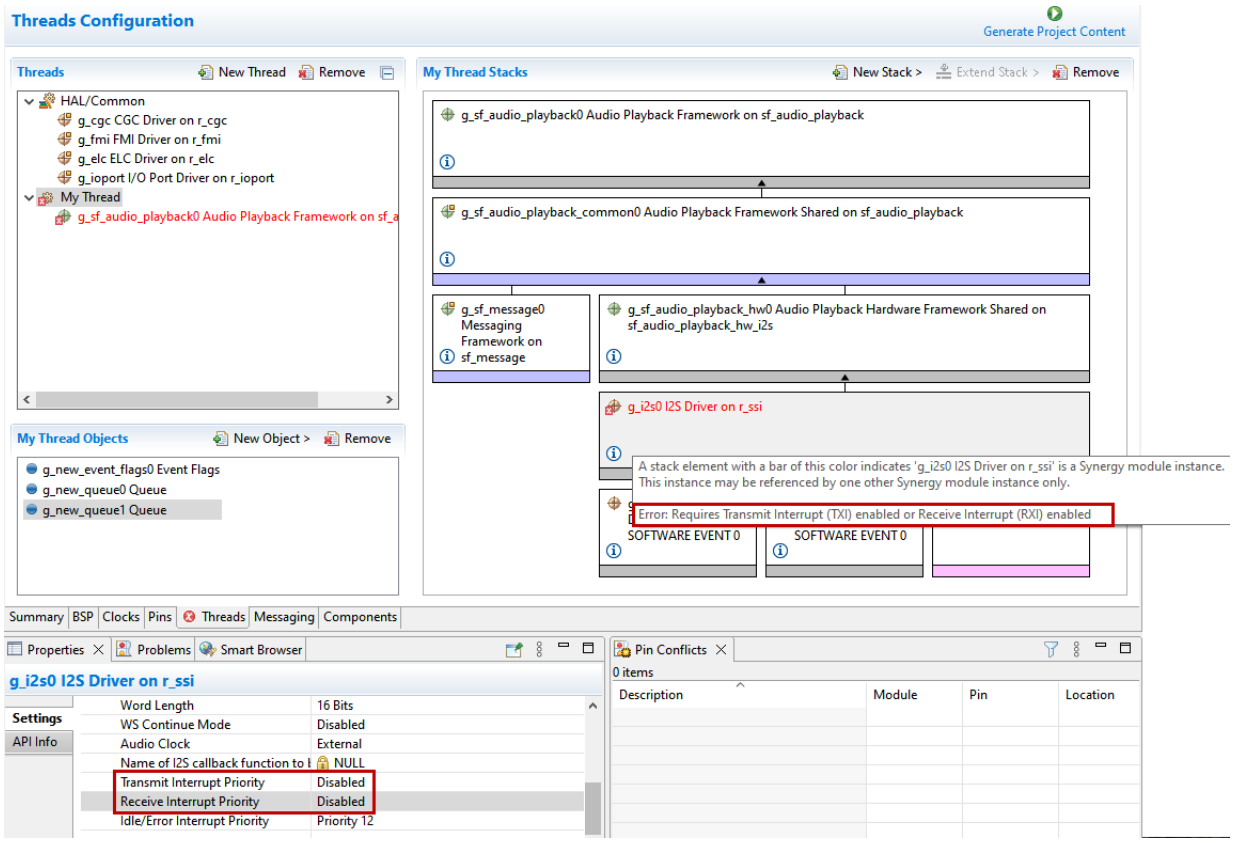

Figure 45: Configuring Interrupt on the Threads Tab

3.1.8 Configuring the SSP Messaging Framework

The Messaging Framework extends the ThreadX messaging queue functionality and is one of the most important SSP modules. It provides the mechanism for threads to communicate with each other through exchanging messages. The Messaging Framework allows threads to send (publish) or listen to (pend on) messages when preconfigured or user-configured Events happen. Any thread can publish a message with an attached Event Class that all threads subscribing to this Event class can listen to and act upon. The list of Threads that can listen to a specific Event Class is called the Subscriber List for that Event Class.

To use the Messaging Framework, you first must add one Messaging Framework instance in the **Threads** tab. You may add the Messaging Framework to any thread which is not the HAL/Common thread. All threads in your project can use this instance to communicate with each other. Some modules like the Audio Playback Framework require the Messaging Framework and add it automatically to the stack as shown below for the Audio Playback Framework. If your project includes a thread with such a module, you do not need to add another instance of the Messaging Framework even if you add more threads to your application. All threads can share one instance of the Messaging framework.

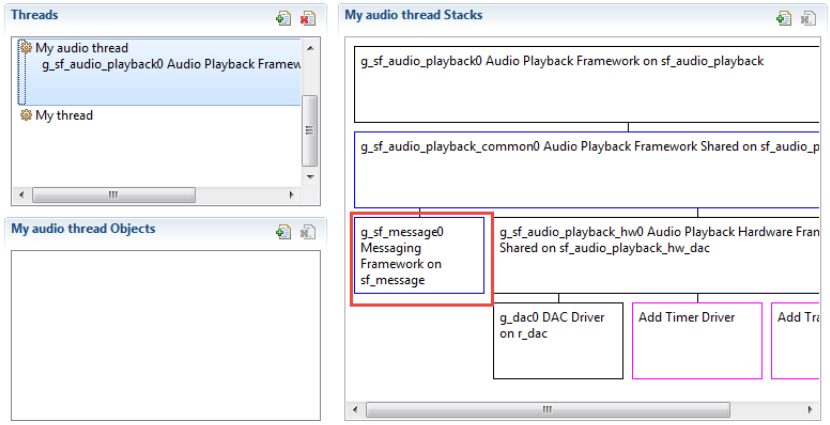

Figure 46: Adding the Messaging Module to a Thread

Once you have added a Messaging Framework instance in the **Threads** tab, you can use the **Messaging** tab to define your own event classes and events and determine which threads can listen to which event class. The SSP contains a predefined event class and events for the Audio Playback Framework module. If you have added the Audio Playback Framework module, the predefined event class and events appear in the Messaging tab as well, as shown below.

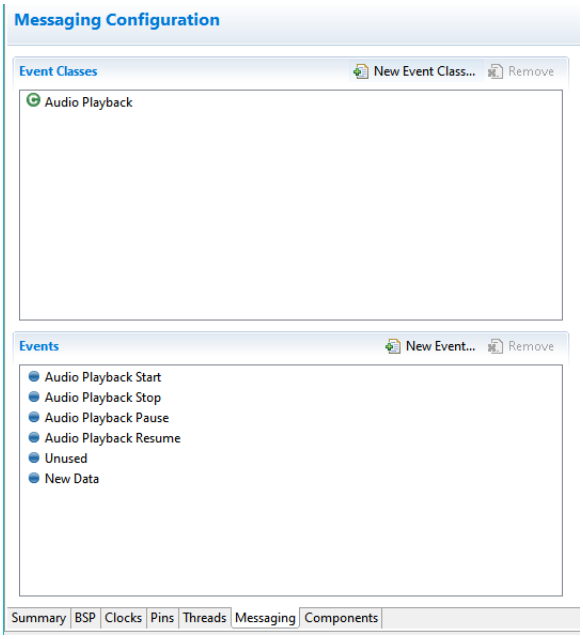

Figure 47: Audio Playback Framework Predefined Event Class

3.1.8.1 Adding an Event Class

To add your own user-defined Event Class to the messaging system, follow these steps:

1. In the **Messaging** tab, select the **Event Classes** Pane, and click the add button.
2. Enter a unique name for your event class.
3. Click **OK**.

Note

User-defined Event Classes are marked with a golden square on the upper right of the Event Class icon.

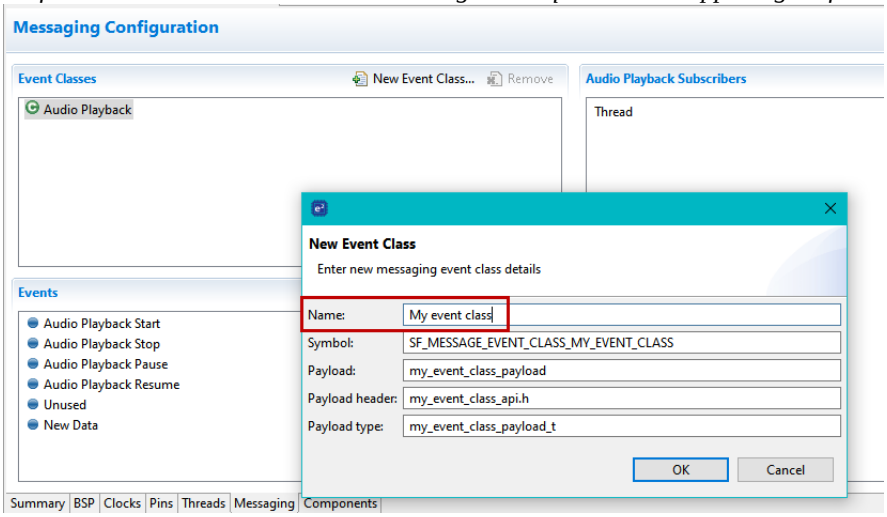

Figure 48: Messaging – Add an Event Class

3.1.8.2 Adding an Event

To add your own user-defined Event to the messaging system, follow these steps:

1. In the **Messaging** tab, select the **Event** Pane, and click the add button.
2. Enter a unique name for your event class.

3. Click **OK**.

Note

User-defined Events are marked with a golden square on the upper right of the Events icon.

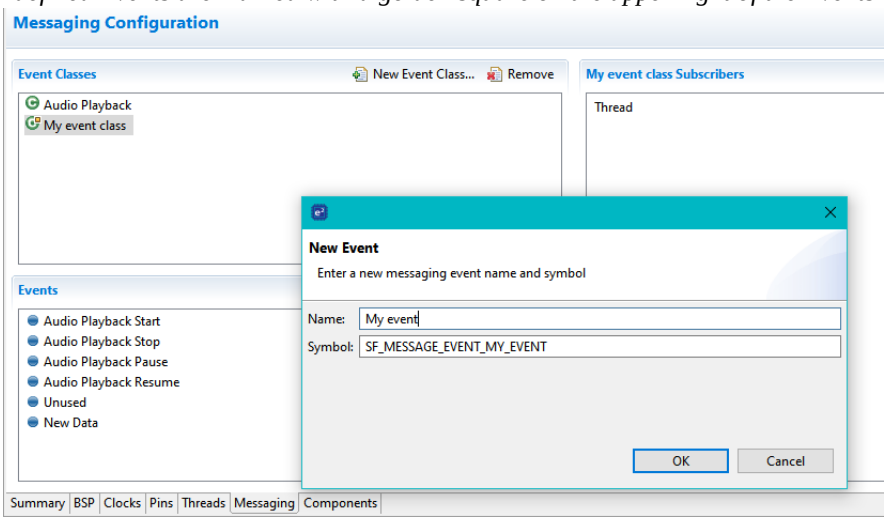

Figure 49: Messaging – Add an Event

3.1.8.3 Configuring the Messaging Subscriber List

In the Subscriber List, you select the threads that are listening to messages from the message publisher. The connection between the publishing thread and the listening thread is established through the Event Class. Therefore you define a subscriber list for each of the Event Classes in your project. All threads in the Subscriber List then can listen and act upon messages belonging to the selected Event Class.

To following assumes that you have two threads defined in the **Threads** tab, one of which uses the Audio Playback Framework:

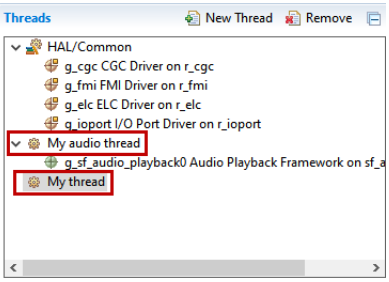

Figure 50: Messaging – Example Threads

To configure the Subscriber List for an Event Class, follow these steps:

1. In the **Messaging** tab, select the Event Classes in the Event Classes Pane.

   The Subscriber List pane takes its name from the selected Event Class.

2. Click the Add Icon.

   The New Subscriber Dialog box opens.

3. Select the Thread to add to the Subscriber List from the Thread dropdown menu.

4. Fill out the instance range by selecting Start and End.

   If you only have one instance of an Event Class, keep the Start and End values at their default value (0). See the Messaging Framework User Guide for selecting an instance range if you have more than one Event Class instance. Multiple Event Class instances can be useful in an application that uses the same Event Class multiple times for example for audio streaming on multiple channels.

5. Repeat steps 3 and 4 for each thread that you want to add to the Subscriber List for the selected Event Class.

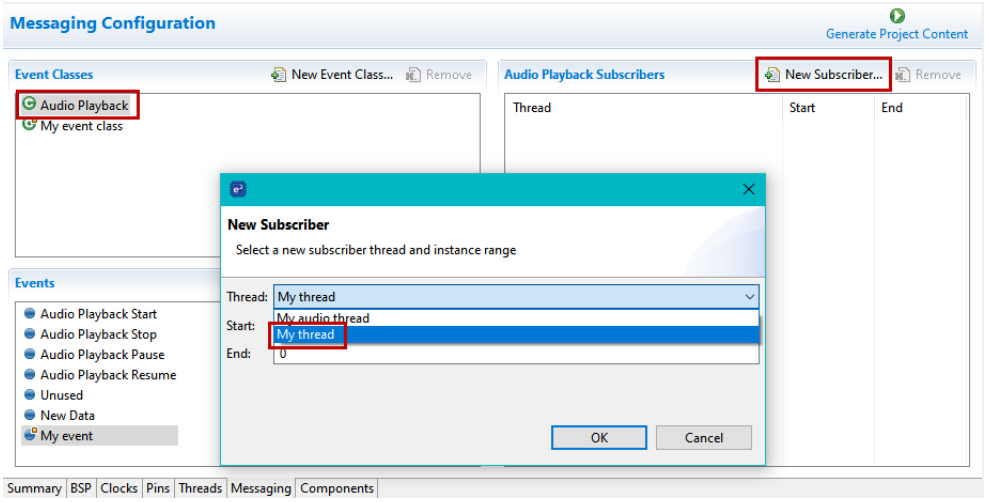

Figure 51: Messaging – Configuring the Subscriber List

3.1.8.4 Generating Files for the Messaging Framework

The ISDE generates the following files for the configured Messaging Framework when you click the Generate Project button:

File	Contents	Overwritten by Generate Project Content?
synergy_cfg/ssp_cfg/framework/sf_message_port.h	Contains the event class and event enumerations	Yes
synergy_cfg/ssp_cfg/framework/sf_message_payloads.h	Contains pointers to the event class payloads.	Yes
synergy_cfg/ssp_cfg/framework/sf_message_payloads.h	Compiler options for the Messaging Framework	Yes

3.1.9 Reviewing and Adding Components

The **Components** tab enables the individual modules required by the application to be included or excluded. Modules common to all Synergy projects are preselected (for example: BSP > BSP > Board-specific BSP and HAL Drivers > all > r_cgc). All modules that are necessary for the modules selected in the **Threads** tab are included automatically. You can include or exclude additional modules by ticking the box next to the required component.

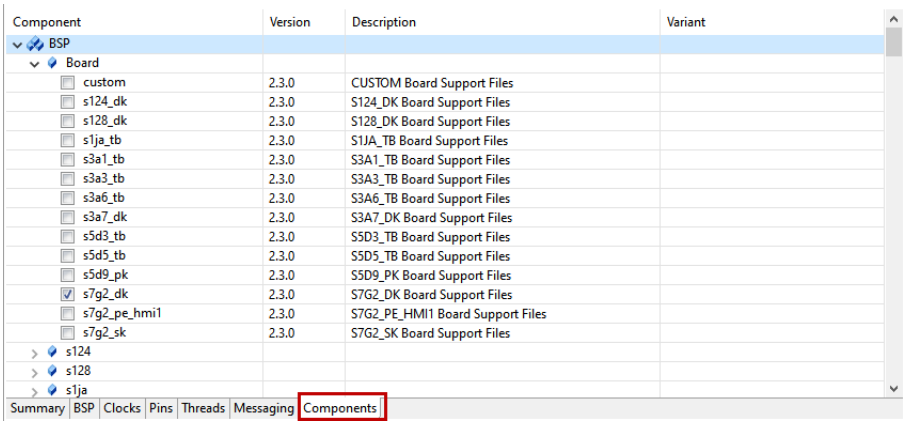

Figure 52: Components Tab

Components at the HAL and Framework layers are available as are components from Azure RTOS such as the RTOS ThreadX, file system FileX, TCP/IP networking NetX. In addition, you can select documentation to be added to a project or include complete projects.

While the components tab selects modules for a project, you must configure the modules themselves in the other tabs. Pressing the **Generate Project Content** button copies the .c and .h files for each component for a Pack file into the following folders:

synergy/ssp/inc/bsp

synergy/ssp/inc/driver

synergy/ssp/inc/framework

synergy/ssp/src/bsp

synergy/ssp/src/driver

synergy/ssp/src/framework

The ISDE also creates configuration files in the synergy_cfg/ssp_cfg folder with configuration options included from the remaining **Threads** tabs.

3.1.10 Writing the Application

Once you have added Modules and drivers and set their configuration parameters in the Threads tab, you can add the application code that calls the Modules and drivers.

Note

To check your configuration, build the project once without errors before adding any of your own application code.

3.1.10.1 RTOS-independent Applications

To write application code:

1. Add all drivers and modules in the **Threads** tab and resolve all dependencies flagged by the ISDE such as missing interrupts or drivers.
2. Configure the drivers in the **Properties** view.

3. In the Project Configuration view, press the **Generate Project Content** button.
4. In the **Project Explorer** view, double-click on the src/hal_entry.c file to edit the source file.

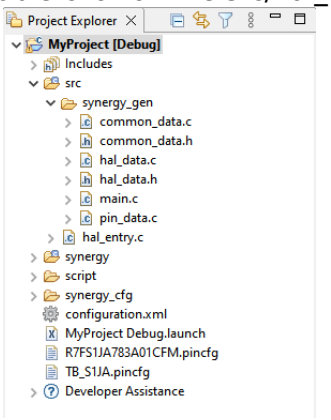

Figure 53: hal_entry.c

Note

All configuration structures necessary for the driver to be called in the application are initialized in src/synergy_gen/hal_data.c.
*Do not modify the files in the directory src/synergy_gen. These files are overwritten every time you push the **Generate Project Content** button.*

5. Add your application code here:

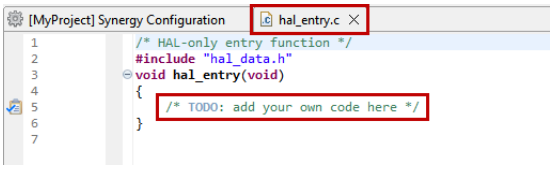

Figure 54: Adding User Code to hal_entry.c

6. Build the project without errors by clicking on **Project > Build Project**.

The following tutorial shows how execute the steps above and add application code: Tutorial: Using HAL Drivers - Programming the WDT

The WDT example is a HAL level application which does not use an RTOS. The user guides for each module also include basic application code that you can add to hal_entry.c.

3.1.10.2 ThreadX Applications

To write RTOS-aware application code using ThreadX, follow these steps:

1. Add a thread using the **Threads** tab.
2. Provide a unique name for the thread in the **Properties** view for this thread.
3. Configure all drivers and resources for this thread and resolve all dependencies flagged by the ISDE such as missing interrupts or drivers.
4. Configure the thread objects.
5. Provide unique names for each thread object in the **Properties** view for each object.
6. Add more threads if needed and repeat steps 1 to 5.
7. In the **Synergy Project Editor**, press the **Generate Project Content** button.
8. In the **Project Explorer** view, double-click on the src/my_thread_1_entry.c file to edit the source file.

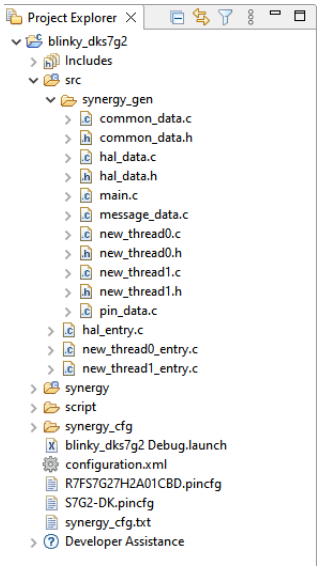

Figure 55: ISDE Generated Files for an RTOS Application

Note

All configuration structures necessary for the driver to be called in the application are initialized in synergy_gen/my_thread_1.c and my_thread_2.c
Do not modify the files in the directory src/synergy_gen. These files are overwritten every time you push the ***Generate Project Content*** *button.*

9. Add your application code here:

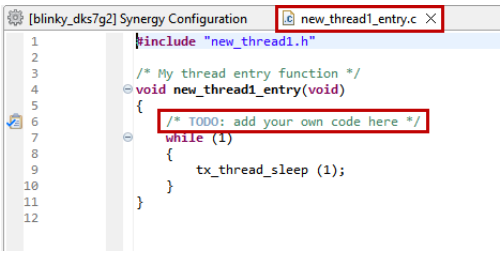

Figure 56: Adding User Code to my_thread_1.entry

10. Repeat steps 1 to 9 for the next thread.
11. Build your project without errors by clicking on **Project > Build Project**.

3.1.11 Debugging the Project

Once your project builds without errors, you can use the Debugger to download your application to the board and execute it.

To debug an application follow these steps:

1. click **Run > Debug Configurations**.

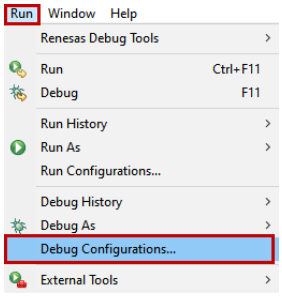

Figure 57: Invoking the Debug Configurations Dialog

2. In the **Debug Configurations** view, click on your project listed as **MyProject Debug**.

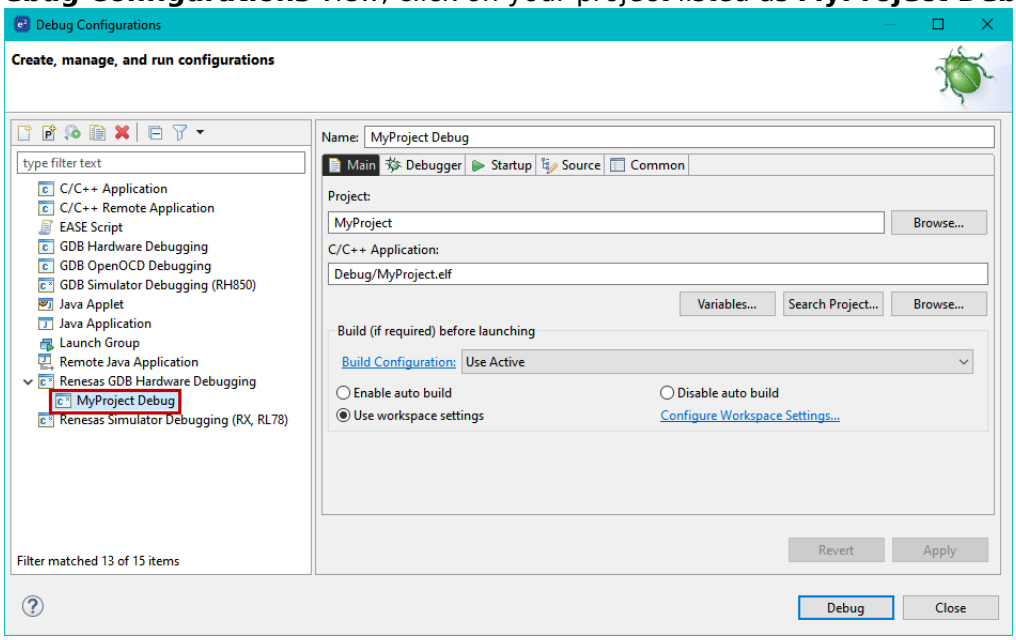

Figure 58: Debug Configuration

3. Connect the board to your PC via either a standalone Segger J-Link debugger or a Segger J-Link On-Board (included on all Synergy DKs and SKs) and click **Debug**.

Note

For details on using J-Link and connecting the board to the PC, see the Quick Start Guide included in the Synergy Kit.

3.1.12 Using TraceX with a Synergy Project

Precondition

Before you can use TraceX with your Synergy Project, you must download the TraceX executable file from the Microsoft Store.

TraceX™ is a host-based analysis tool that provides a graphical view of real-time system events. TraceX collects data on the target device and displays the data for inspection and analysis. A TraceX version for Synergy devices is available for downloading from the Microsoft Store.

To use TraceX, do the following:

1. In e^2 studio, add the ThreadX source code to your project by going to the **Threads** tab, clicking the **New Stack** button in the **Stacks** pane, and selecting **X-Ware > ThreadX > ThreadX Source**.

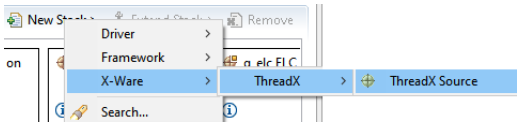

Figure 59: Add TraceX to your Source

2. Enable TraceX in the Properties Window of the Thread using the **Threads** tab. Keep the default name for the TraceX buffer as g_tx_trace_buffer.

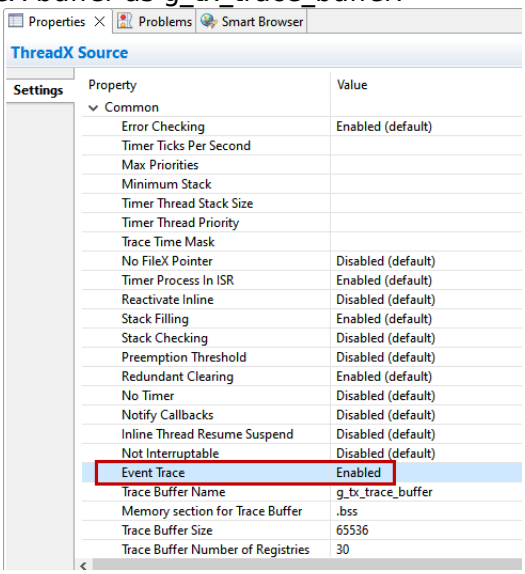

Figure 60: ISDE TraceX Configuration

3. Set the path to the TraceX application in **Window > Preferences > Renesas > TraceX**

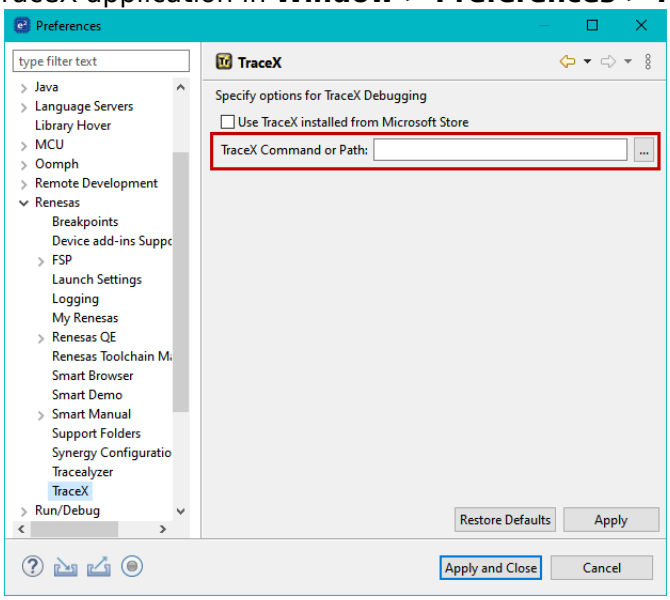

Figure 61: ISDE TraceX Path

4. Build your project (**Project > Build All**).

5. Connect your Synergy target board.
6. Start a debug session (**Run > Debug**)
7. In **Run > Renesas Debug Tools > TraceX**, select **Launch TraceX Debugging**.

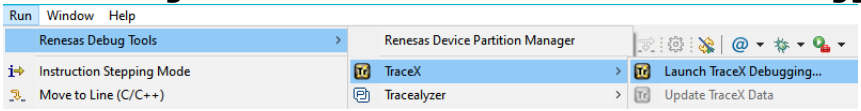

Figure 62: ISDE TraceX Launch

8. In the TraceX Debugging window, set **Buffer Start Address** to &g_tx_trace_buffer.

   In the TraceX Debugging window, set **Buffer Size (bytes)** to the buffer size selected in the Properties Window in step 2. The default is 65536.

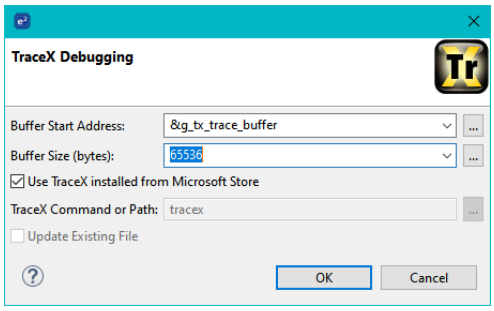

Figure 63: ISDE TraceX Debug

9. Click **OK**.
10. Run your code (**Run > Resume**) to collect TraceX data.
11. Suspend execution of your code (**Run > Suspend**).
12. Observe the collected data in TraceX.

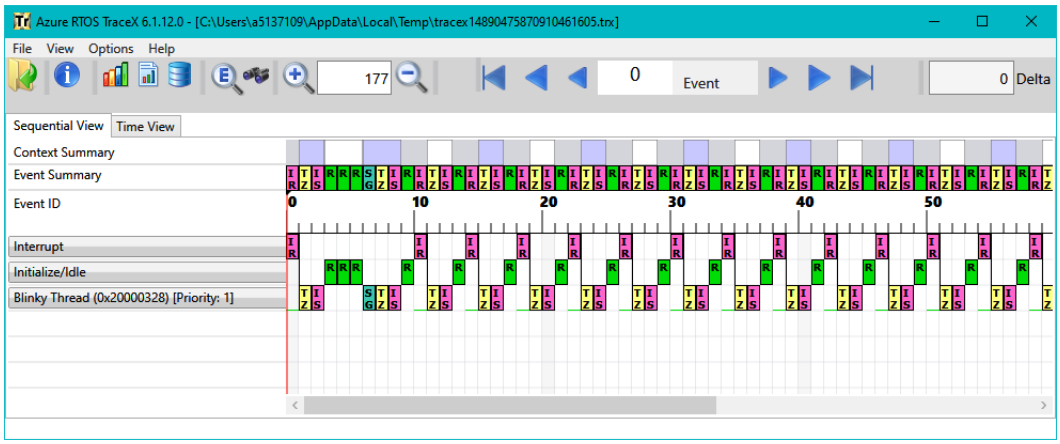

Figure 64: TraceX Collected Data

13. To collect further TraceX data:
    - Resume execution of your code
    - Suspend execution of your code
    - Click **Run > TraceX** and select **Update TraceX Data**.

You can find more information on using TraceX on the Renesas TraceX webpage

https://www.renesas.com/synergy/tracex.

3.1.13 Modifying Toolchain Settings

There are instances where it may be necessary to make changes to the toolchain being used (for example, to change optimization level of the compiler or add a library to the linker). Such modifications can be made from within the ISDE through the menu **Project > Renesas C/C++ Project Settings** when the project is selected. The following screenshot shows the settings dialog for the GNU ARM toolchain. This dialog will look slightly different depending upon the toolchain being used.

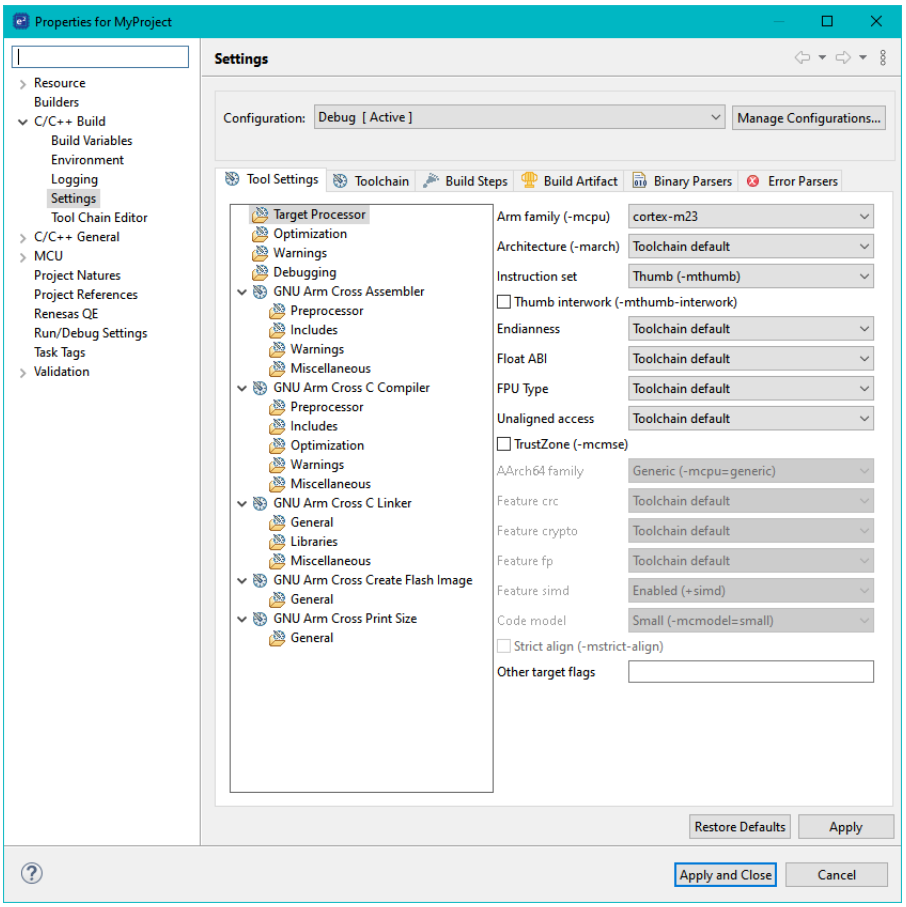

Figure 65: ISDE Project Toolchain Settings

The scope for the settings is project scope which means that the settings are valid only for the project being modified.

The settings for the linker which control the location of the various memory sections are contained in a script file specific for the device being used. This script file is included in the project when it is created and is found in the script folder (for example, /script/S7G2.ld).

3.1.14 e2 studio ISDE Usage Notes

3.1.14.1 Including ThreadX sources

You can use the **Theads** tab to include ThreadX source code in your project as follows:

1. Click on the HAL/Common icon in the **Threads** pane. The Modules pane changes to **HAL/Common Modules**.
2. Select **New Stack** > **X-Ware** > **ThreadX** > **ThreadX Source**.
3. Check the **Properties** window to configure the TheadX RTOS properties.
4. Click **Generate Project**.

The e^2 studio ISDE extracts the ThreadX source code into the following directory: synergy/ssp/src/framework/el/tx

Note

Extracting the ThreadX sources increases the compile time for your project.

3.1.14.2 Using Synergy Developer Assistance

This section describes a new feature, "Synergy Developer Assistance" included in e^2 studio.

Developer Assistance Node

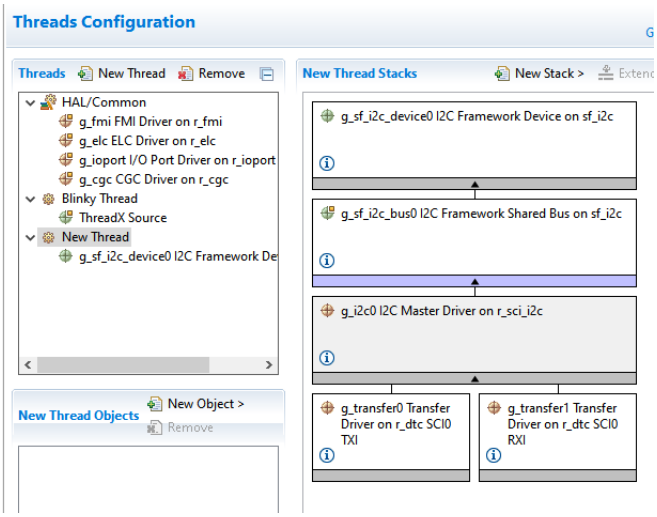
A new node **Developer Assistance** is now available in the project explorer. When expanded, the Developer Assistance tree shows you the threads and module stacks and their respective API information of the saved Synergy configuration.

The Developer Assistance node is available regardless of whether the Synergy Configuration Editor is open. This allows a user to easily consult the Developer Assistance for a project's stack modules while application code is being written. It assists by providing code templates and an autocompletion tool.

Configure Threads

Create a new project. In the Synergy configurator thread's tab create a thread and add a new stack.

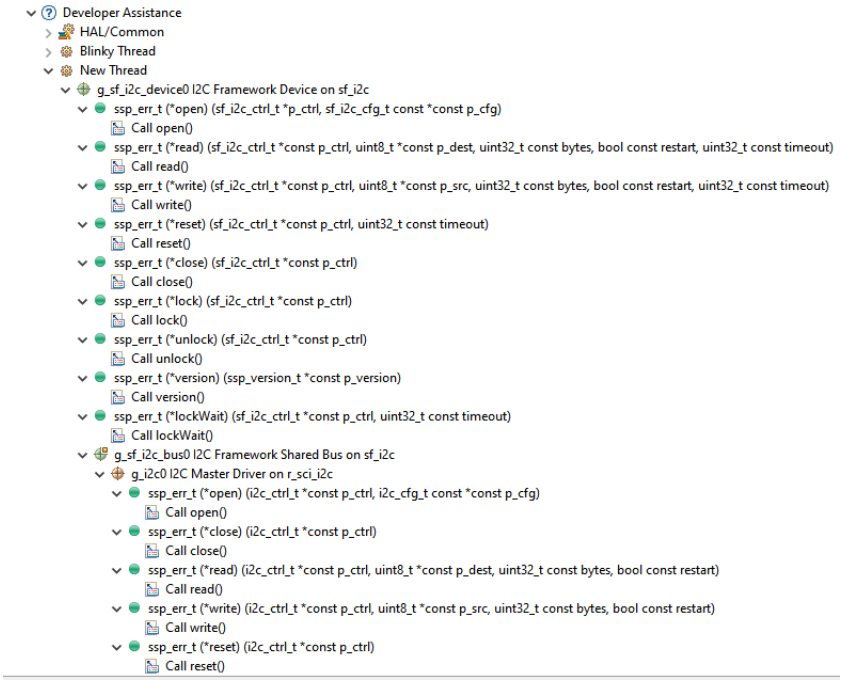
For example, Framework Device on sf_i2c:



Project Explorer View

Once the project is saved, expand the **Developer Assistance** node. Notice that the node is updated

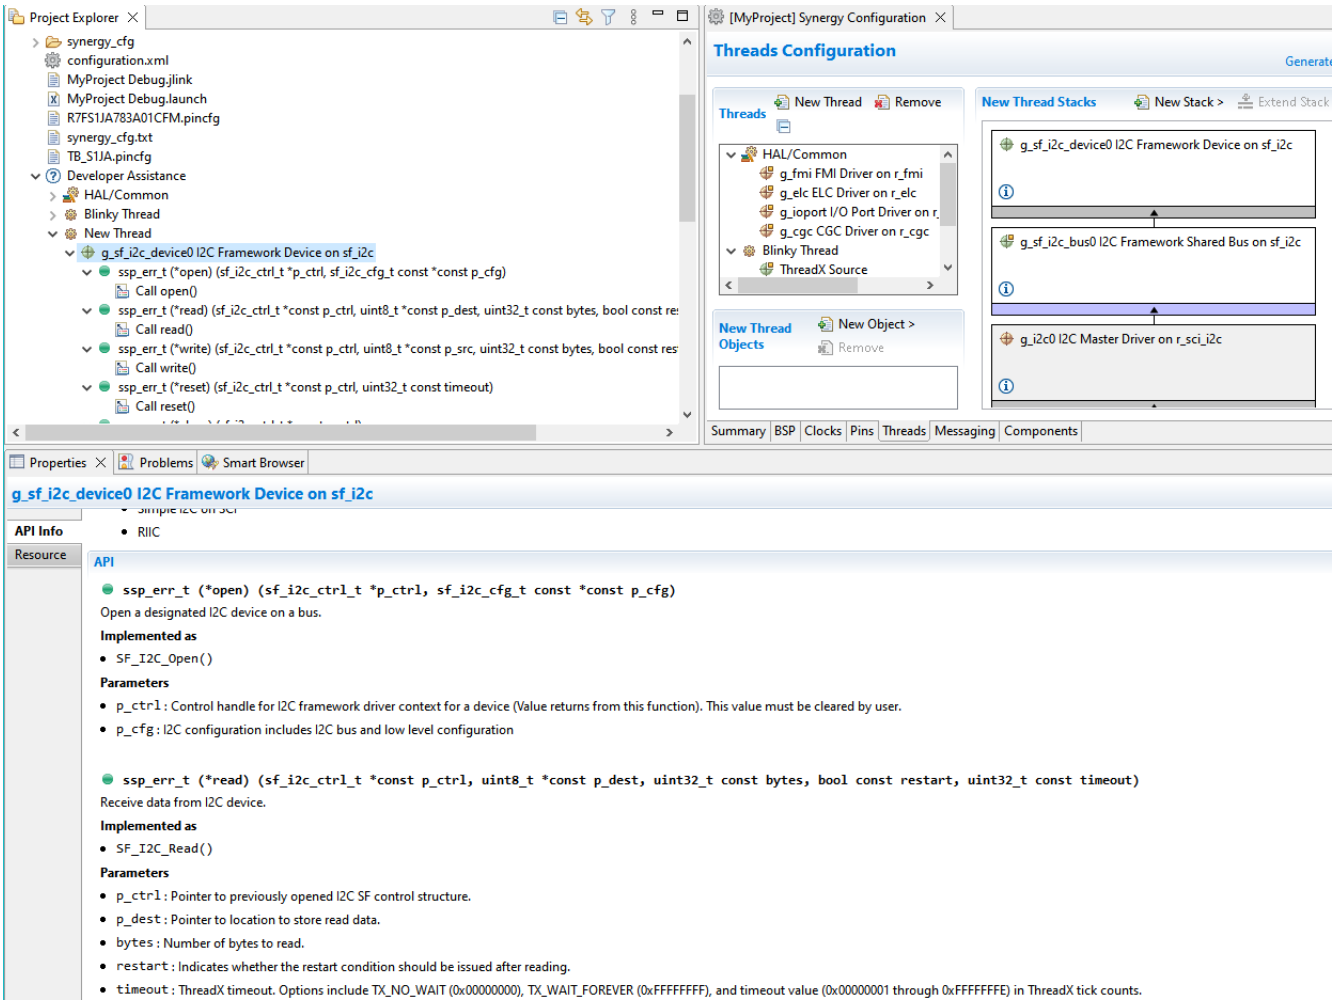
with the new thread **New Thread** Information. Clicking on the module instance under the thread will expand all the child nodes and show the API information of the modules.



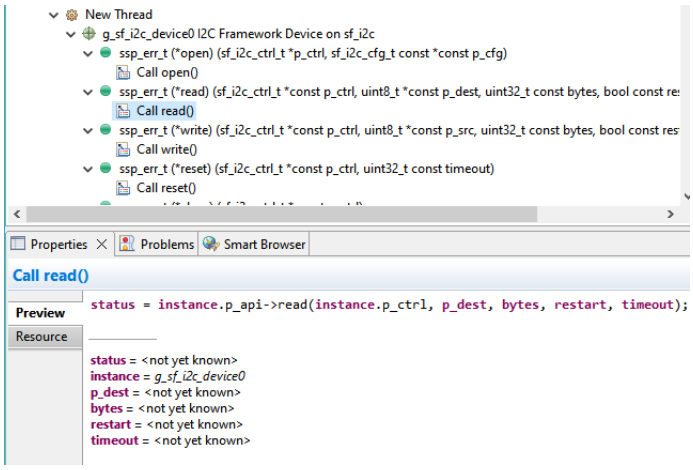
Properties View

Selecting the module instance in the thread tab or in the project explorer will show the module and module API information in the API info tab of properties view.

Tip: If the Properties view is not present in the current e^2 studio perspective, you can open it by selecting **Window** -> **Show View** -> **Properties**

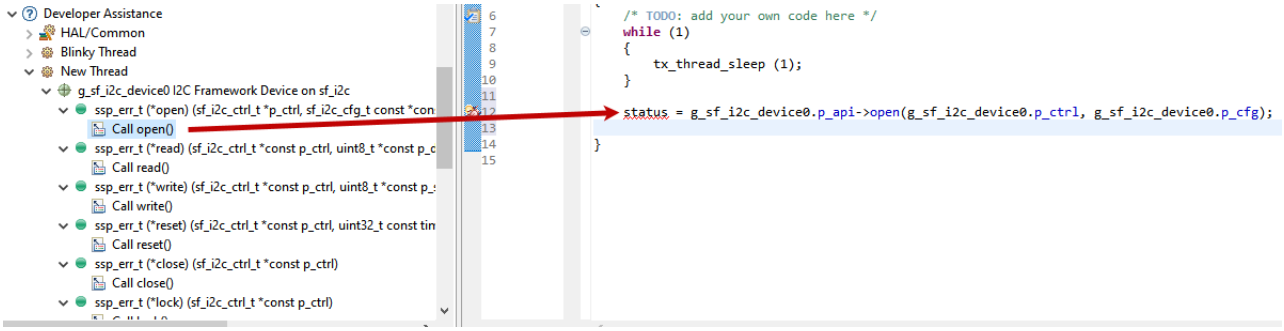


Selecting the code template node shows the preview of the function in the **Properties** view



Drag and drop to source File

The API function code templates or callbacks can be dragged and dropped to the source file. This will autofill the parameters and return type of the function



Please also refer to **Help**-> **Help Contents** -> **Synergy Contents** -> **Synergy Developer Assistance** page in e^2 studio for any further information.

3.2 Tutorial: Your First Synergy Project - Blinky

3.2.1 Tutorial Blinky

The goal of this tutorial is to quickly get acquainted with the Synergy Platform by moving through the steps of creating a simple application using e2 studio and running that application on a Synergy board.

3.2.2 What Does Blinky Do?

The application used in this tutorial is Blinky, traditionally the first program run in a new embedded development environment.

Blinky is the "Hello World" of microcontrollers. If the LED blinks you know that:

- The toolchain is setup correctly and builds a working executable image for your chip.
- The debugger has installed with working drivers and is properly connected to the board.
- The board is powered up and its jumper and switch settings are probably correct.
- The microcontroller is alive, the clocks are running, and the memory is initialized.

The Blinky example application used in this tutorial is designed to run the same way on all boards offered by Renesas that hold the Synergy microcontroller. The code in Blinky is completely board independent. It does the work by calling into the BSP (board support package) for the particular board it is running on. This works because:

- Every board has at least one LED connected to a GPIO pin.
- That one LED is always labeled LED1 on the silk screen.
- Every BSP supports an API that returns a list of LEDs on a board, and their port and pin

assignments.

3.2.3 Prerequisites

To follow this tutorial, you need:

- Windows based PC
- e^2 studio
- Synergy Software Package
- A Synergy board kit

3.2.4 Create a New Project for Blinky

The creation and configuration of a Synergy project is the first step in the creation of an application. The base SSP pack includes a pre-written Blinky example application that is simple and works on all Renesas Synergy boards.

Note

The e^2 studio screens shown in this manual are examples. Some details may differ between different releases of the e^2 studio ISDE and the SSP.

Follow these steps to create a Synergy project:

1. In e^2 studio ISDE, click **File > New > Synergy C/C++ Project**, select **Renesas Synergy C Executable Project**, and click **Next**.
2. Assign a name to this new project. Blinky is a good name to use for this tutorial.

3. Click **Next**. The Project Configuration window shows your selection.

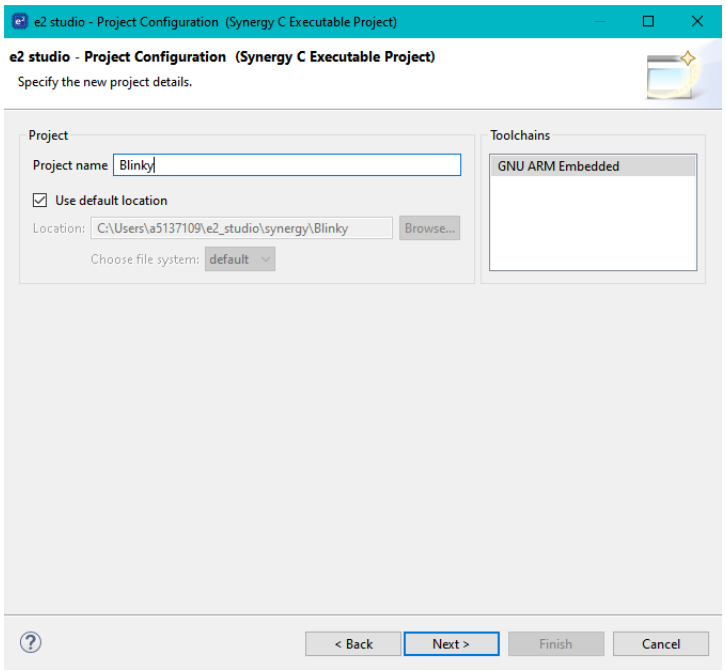


Figure 66: e2 studio ISDE Project Configuration Window (Part 1)

4. Select the board support package by selecting the name of your board from the **Device Selection** drop-down list and click **Next**.

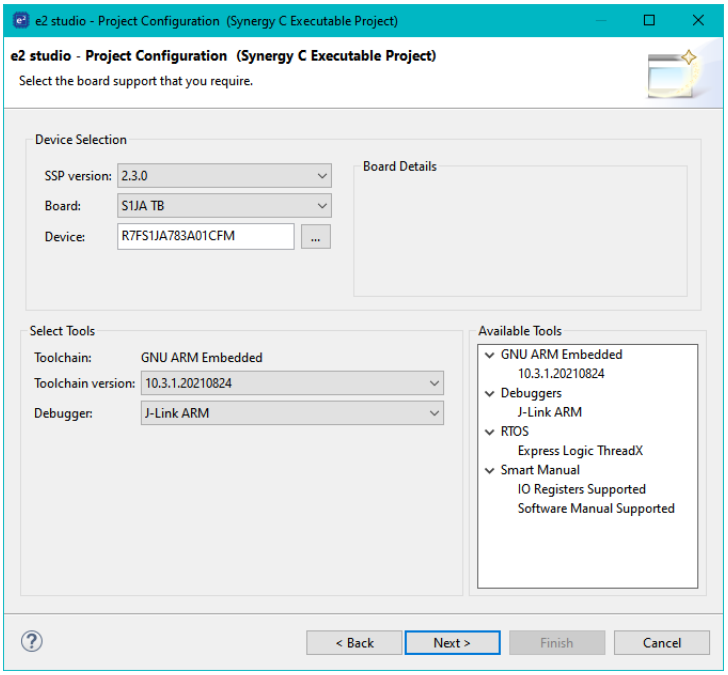

Figure 67: e2 studio ISDE Project Configuration Window (Part 2)

5. Select the Blinky template for your board and click **Finish**.

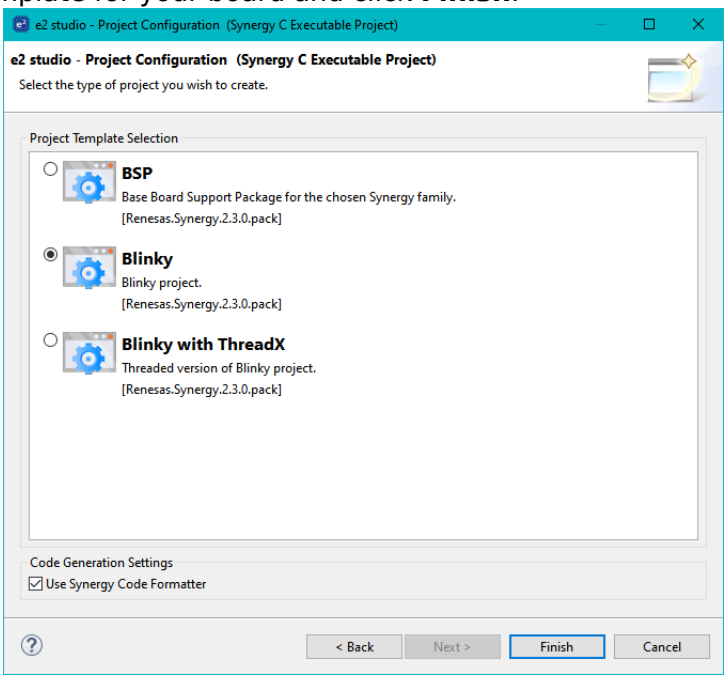

Figure 68: e2 studio ISDE Project Configuration Window (Part 3)

Once the project has been created, the name of the project will show up in the Project Explorer window of the ISDE. Now press the **Generate Project Content** button in the top right corner of the **Project Configuration** window to generate your board specific files.

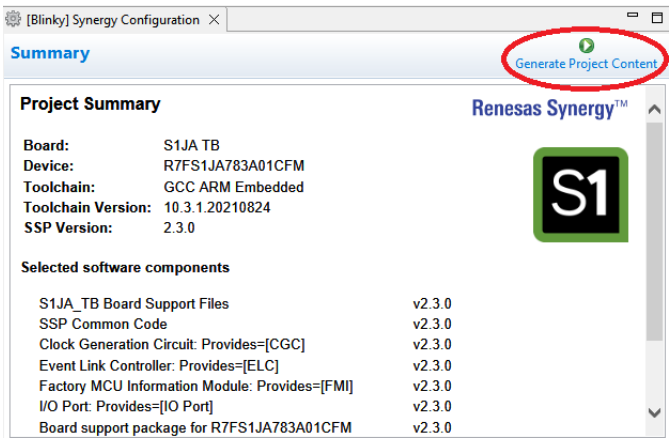

Figure 69: e2 studio ISDE Project Configuration Tab

Your new project is now created, configured, and ready to build.

3.2.4.1 Details about the Blinky Configuration

The **Generate Project Content** button creates configuration header files, copies source files from templates, and generally configures the project based on the state of the **Project Configuration** screen.

For example, if you check a box next to a module in the **Components** tab and press the **Generate Project Content** button all the files necessary for the inclusion of that module into the project will be copied or created. If that same check box is then unchecked those files will be deleted.

3.2.4.2 Configuring the Blinky Clocks

By selecting the Blinky template, the clocks are configured by the ISDE for the Blinky application. The ISDE clock configuration tab (see Configuring Clocks) shows the Blinky clock configuration. The Blinky clock configuration is stored in the BSP clock configuration file (see BSP Clock Configuration).

3.2.4.3 Configuring the Blinky Pins

By selecting the Blinky template, the GPIO pins used to toggle the LED1 are configured by the ISDE for the Blinky application. The ISDE pin configuration tab shows the pin configuration for the Blinky application (see Configuring Pins). The Blinky pin configuration is stored in the BSP configuration file (see BSP Pin Configuration).

3.2.4.4 Configuring the Parameters for Blinky Components

The Blinky project automatically selects the following HAL components in the ISDE Component:

- r_cgc
- r_elc
- r_fmi
- r_ioport

To see the configuration parameters for any of the components, check the Properties tab in the **HAL** window for the respective driver (see Adding and Configuring HAL Drivers).

3.2.4.5 Where is main()?

The main function is located in < project >/src/synergy_gen/main.c. It is one of the files that are generated during the project creation stage and only contains a call to hal_entry(). For more information on generated files Adding and Configuring HAL Drivers .

3.2.4.6 Blinky Example Code

The blinky application is stored in the hal_entry.c file. This file is generated by the ISDE when you select the Blinky Project template and is located in the project's src/ folder.

The application performs the following steps:

1. Get the LED information for the selected board by calling the BSP HAL function R_BSP_LedsGet().
2. Define the output level HIGH for the GPIO pins controlling the LEDs for the selected board.
3. Get the selected system clock speed and scale down the clock, so the LED toggling can be observed.
4. Toggle the LED by writing to the GPIO pin with

```
g_ioport.p_api->pinWrite()
```

3.2.5 Build the Blinky Project

Highlight your new project in the **Project Explorer** window and build it.

There are three ways to build a project:

a. Click on Project in the menu bar and select Build Project.

b. Click on the hammer icon.

c. Right-click on the project and select Build Project.

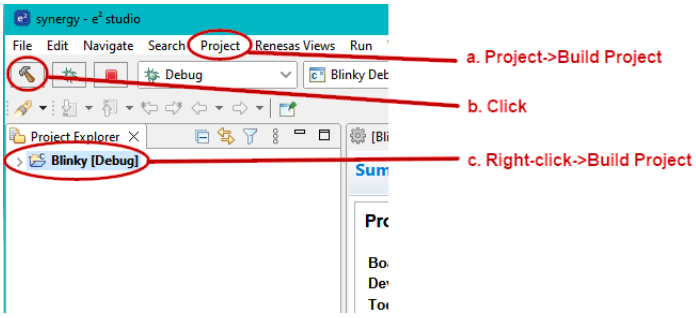

Figure 70: e2 studio ISDE Project Explorer Window

Once the build is complete a message is displayed in the build **Console** window that displays the final image file name and section sizes in that image.

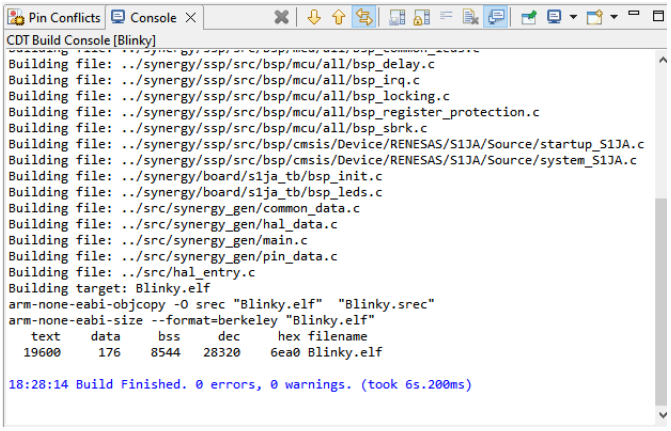

Figure 71: e2 studio ISDE Project Build Console

3.2.6 Debug the Blinky Project

3.2.6.1 Debug prerequisites

To debug the project on a board, you need:

- The board to be connected to the ISDE
- The debugger to be configured to talk to the board
- The application to be programmed to the microcontroller

Applications run from the internal flash of your microcontroller. To run or debug the application, the application must first be programmed to the microcontroller's flash. There are two ways to do this:

- JTAG debugger
- Built-in boot-loader via UART or USB

Some boards have an on-board JTAG debugger and others require an external JTAG debugger connected to a header on the board.

Refer to your board's user manual to learn how to connect the JTAG debugger to your ISDE.

3.2.6.2 Debug steps

To debug the Blinky application, follow these steps:

1. Configure the debugger for your project by clicking **Run > Debugger Configurations** ...

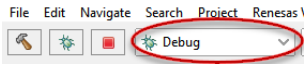

Figure 72: e2 studio ISDE Debug Icon

... or by selecting the drop-down menu next to the bug icon and selecting **Debugger Configurations** ...

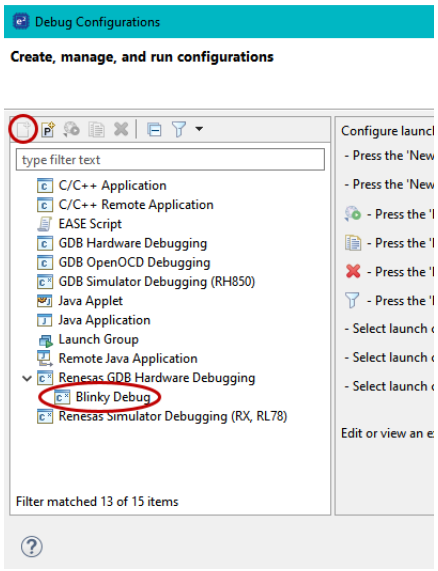

Figure 73: e2 studio ISDE Debugger Configurations Window

2. Select your debugger configuration in the window. If it is not visible then it must be created by clicking the **New** icon in the top left corner of the window. Once selected, the **Debug Configuration** window displays the Debug configuration for your Blinky project.

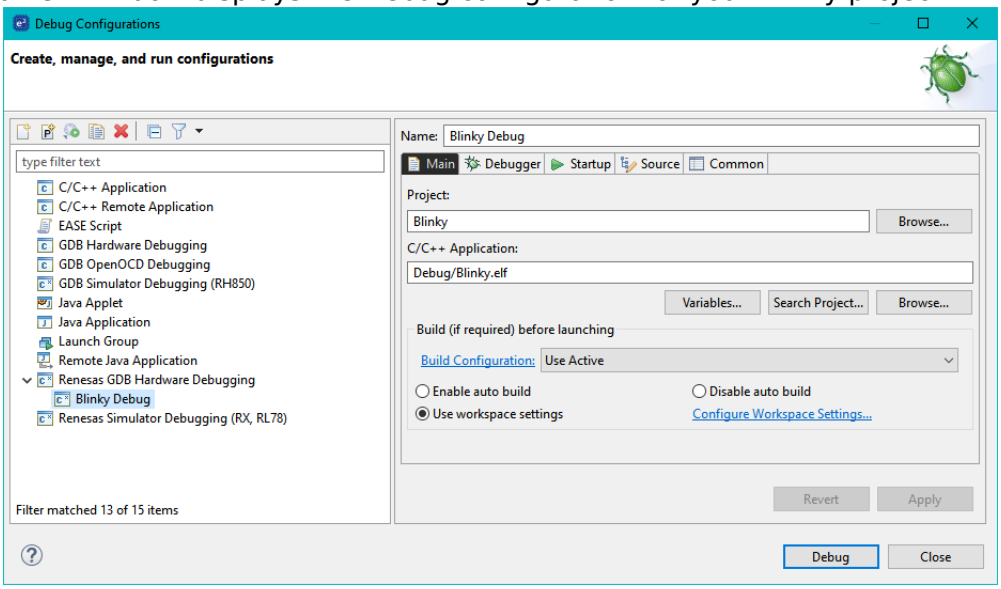

Figure 74: e2 studio ISDE Debugger Configurations Window with Blinky Project

3. Press **Debug** to begin debugging the application.

3.2.6.3 Details about the Debug Process

In debug mode, the ISDE executes the following tasks:

1. Downloading the application image to the microcontroller and programming the image to the internal flash memory.
2. Setting a breakpoint at main().
3. Setting the stack pointer register to the stack.
4. Loading the program counter register with the address of the reset vector.

5. Displaying the startup code where the program counter points to.

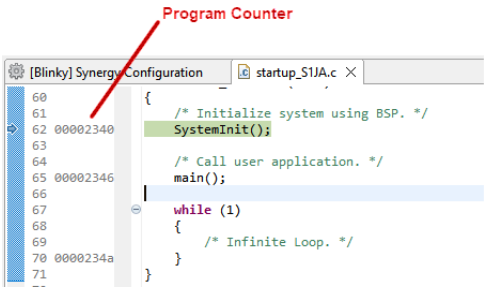

Figure 75: e2 studio ISDE Debugger Memory Window

3.2.7 Run the Blinky Project

While in Debug mode, click **Run > Resume** or click on the Play icon twice.

Figure 76: e2 studio ISDE Debugger Play Icon

The LED on the board marked LED1 should now be blinking.

3.3 Tutorial: Using HAL Drivers - Programming the WDT

3.3.1 Application WDT

This application uses the WDT Interface implemented by the WDT HAL Driver WDT. This document describes how to use the ISDE and SSP to create an application for the Synergy MCU Watchdog Timer (WDT) peripheral. This application makes use of the following SSP modules:

- Board Support Package (Board Support Package)
- CGC (Clock Generation Circuit)
- WDT (Watchdog Timer)
- IOPORT (GPIO)

3.3.2 Creating a WDT Application Using the Synergy SSP and ISDE

3.3.2.1 Using the SSP and the e2 studio ISDE

The Synergy Software Package (SSP) from Renesas provides a complete driver library for developing Synergy applications. The SSP provides Hardware Abstraction Layer (HAL) drivers, Board Support Package (BSP) drivers and higher level Framework applications for the developer to use to create applications. The SSP is integrated into the Renesas e2 studio Integrated Solution Development Environment (ISDE) based on eclipse providing build (editor, compiler and linker) and debug phases

with an extended GNU Debug (GDB) interface.

3.3.2.2 The WDT Application

The flowchart for the WDT application is shown below.

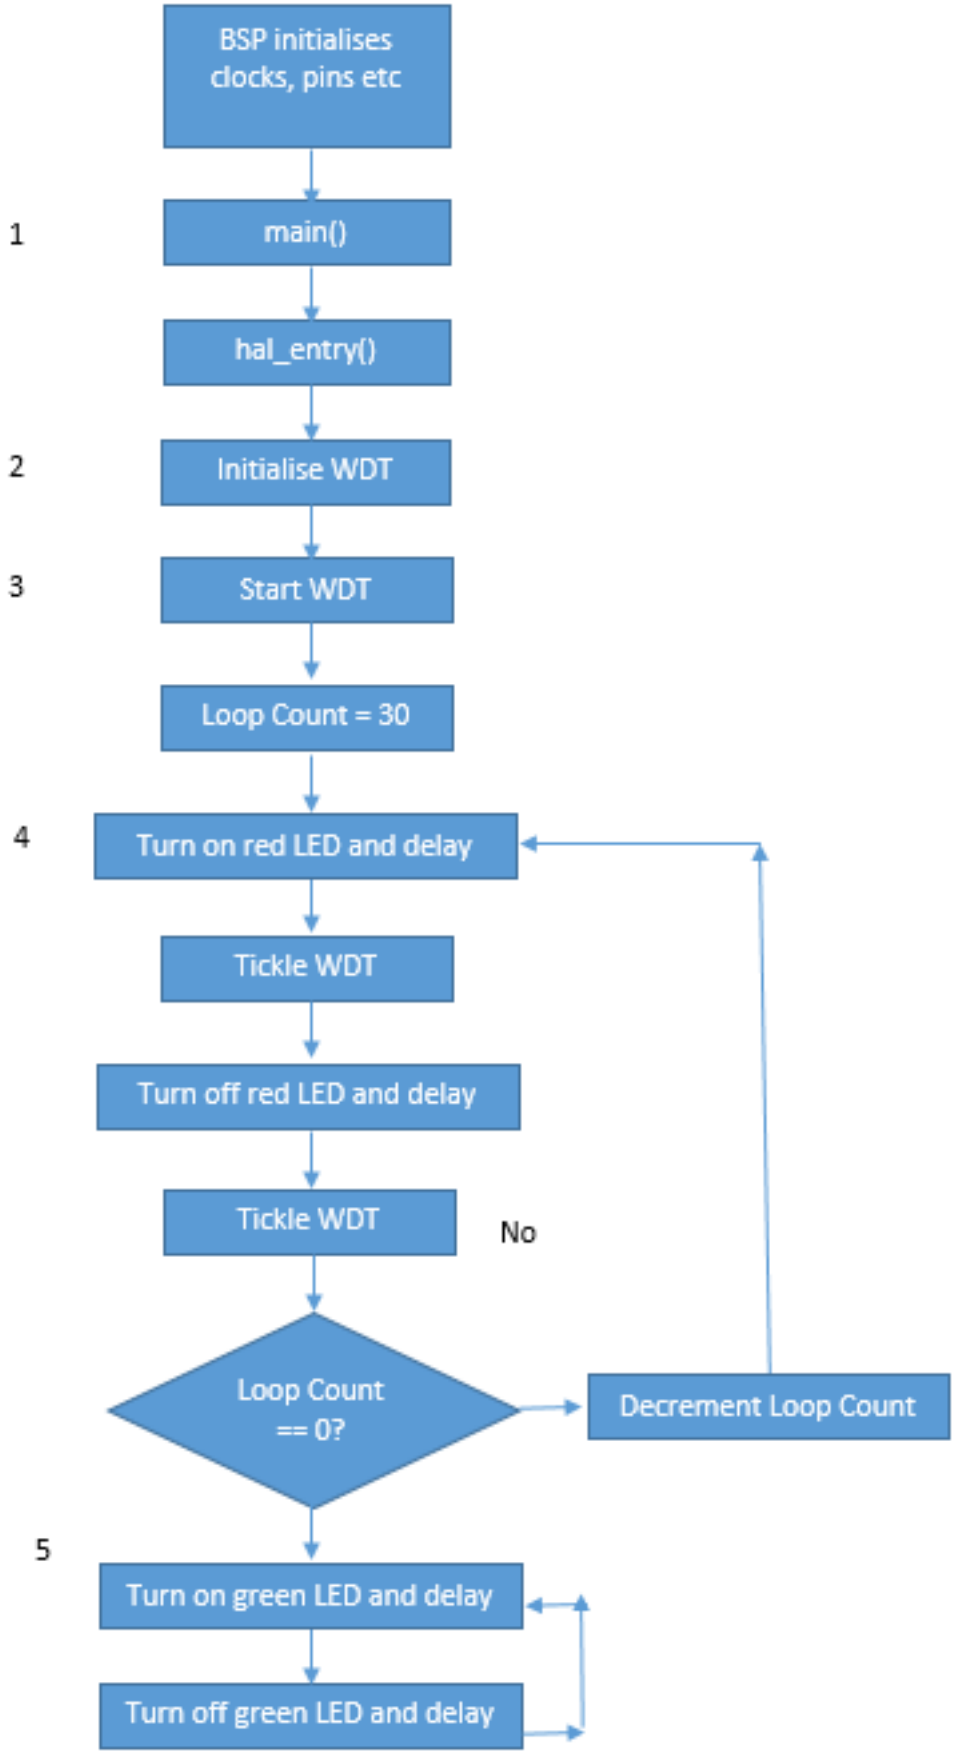

Figure 77: WDT Application Flow Diagram

3.3.2.3 WDT Application flow

These are the main parts of the WDT application:

1. main() calls hal_entry(). The function hal_entry() is created by the SSP with a placeholder for user code. The code for the WDT will be added to this function.
2. Initialize the WDT, but do not start it.
3. Start the WDT by refreshing it.
4. The red LED is flashed 30 times and refreshes the watchdog each time the LED state is changed.
5. Flash the green LED but DO NOT refresh the watchdog. After the timeout period of the watchdog the device will reset which can be observed by the flashing red LED again as the sequence repeats.

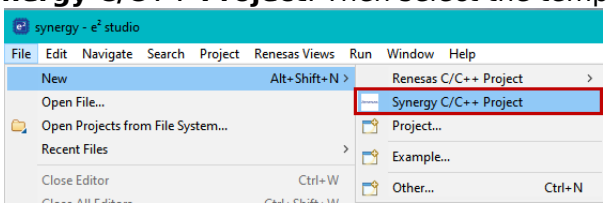
3.3.3 Creating the Project with the ISDE

Start the ISDE and choose a workspace folder in the Workspace Launcher. Configure a new Synergy project as follows.

Note

The e² studio screens shown in this manual are examples. Some details may differ between different releases of the e² studio ISDE and the SSP.

1. Select **File > New > Synergy C/C++ Project**. Then select the template for the project.



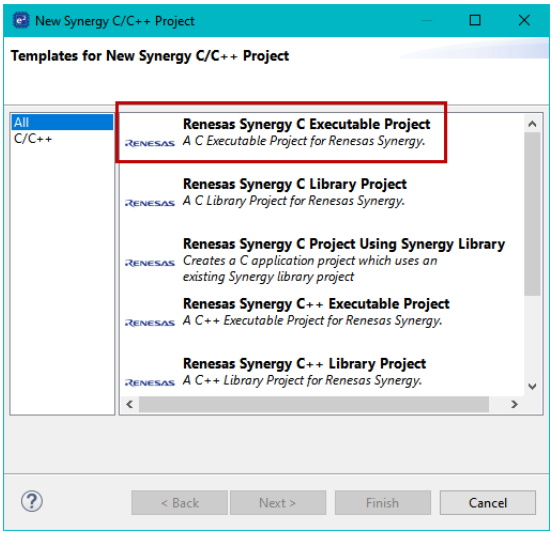


Figure 78: Creating a New Project

2. In the ISDE Project **Configuration (Synergy Project)** window, enter a project name (for

example, WDT_Application). Select the toolchain. If you want to choose a new location for the project, deselect **Use default location**. Click **Next**.

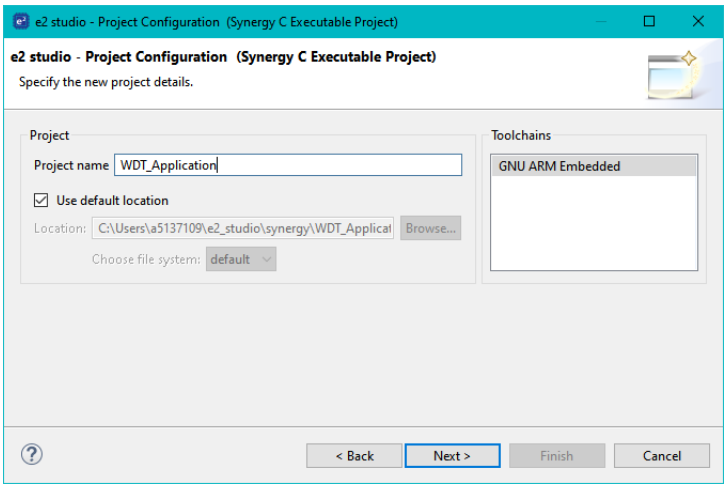

Figure 79: Project Configuration (Part 1)

3. This application runs on the Synergy S7G2 based DK-S7G2 board. So, for the **Board** select **S7G2 DK**.

   This will automatically populate the **Device** drop-down with the correct device used on this board. Select the **Toolchain** version. Select **J-Link ARM** as the **Debugger**. No **RTOS** is being used in this application but it can be left at the default. Click **Next** to configure the project.

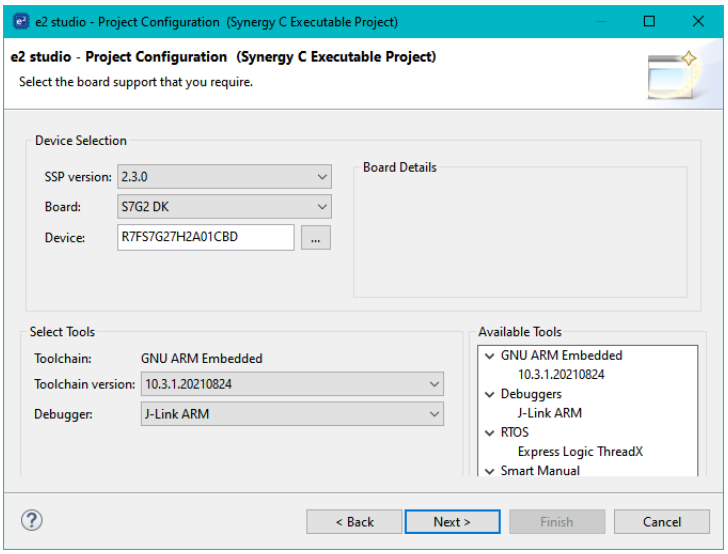

Figure 80: Project Configuration (Part 2)

The project template is now selected. As no RTOS is required select **BSP**.

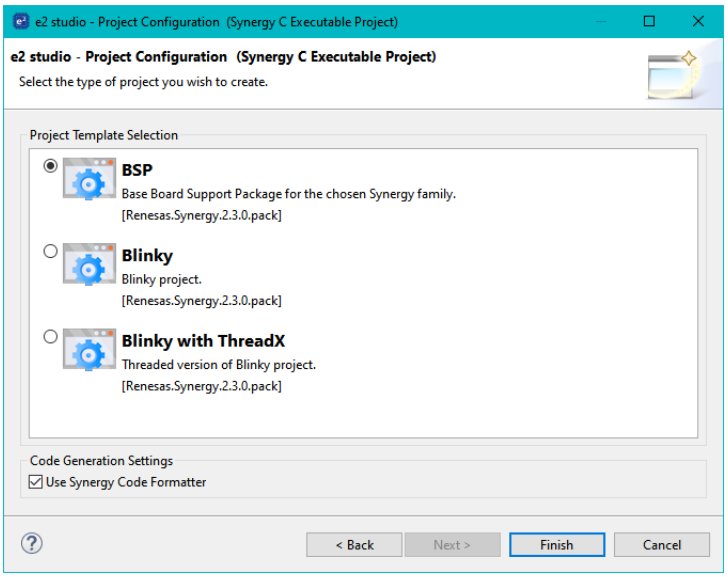

Figure 81: Project Configuration (Part 3)

4. Click **Finish**.

The ISDE creates the project and opens the **Project Explorer** and **Project Configuration Settings** views with the **Summary** page showing a summary of the project configuration.

3.3.4 Configuring the Project with the ISDE

The e2 studio ISDE simplifies and accelerates the project configuration process by providing a GUI interface for selecting the options to configure the project.

The ISDE offers a selection of perspectives presenting different windows to the user depending on the operation in progress. The default perspectives are **C/C++** , **Synergy Configuration** and **Debug**. The perspective can be changed by selecting a new one from the buttons at the top right of the ISDE.

Figure 82: Selecting a Perspective

The **C/C++** perspective provides a layout selected for code editing. The **Synergy Configuration** perspective provides elements for configuring a Synergy project, and the **Debug** perspective provides a view suited for debugging.

1. In order to configure the project settings ensure the **Synergy Configuration** perspective is selected.
2. Ensure the **Project Configuration [WDT Application]** is open. It is already open if the Summary information is visible. To open the Project Configuration now or at any time make sure the **Synergy Configuration** perspective is selected and double-click on the **configuration.xml** file in the Project Explorer pane on the right side of the ISDE.

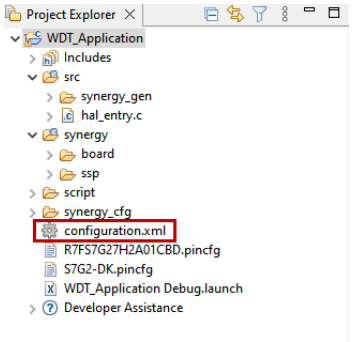

Figure 83: Synergy Project Configuration Settings

At the base of the Project Configuration view there are several tabs for configuring the project. A project may require changes to some or all of these tabs. The tabs are shown below.

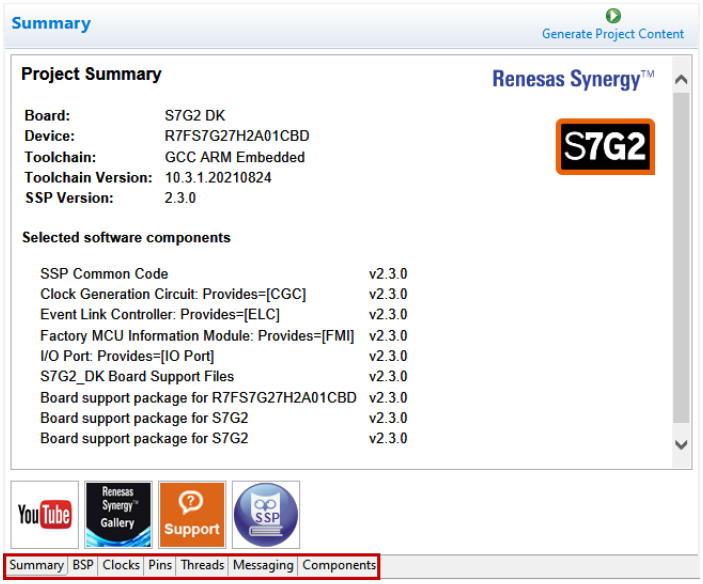

Figure 84: Project Configuration Tabs

3.3.4.1 BSP Tab

The BSP tab allows the Board Support Package (BSP) options to be modified from their defaults. For this particular WDT project no changes are required. However, if you want to use the WDT in auto-start mode, you can configure the settings of the OFS0 (Option Function Select Register 0) register in the BSP tab. See the Synergy Hardware User's Manual for details on the WDT autostart mode.

3.3.4.2 Clocks Tab

The clocks tab presents a graphical view of the clock tree of the device. Using the drop down boxes in the GUI enables configuration of the various clocks. The WDT uses PCLCKB. The default output frequency for this clock is 60 MHz. Ensure this clock is outputting this value.

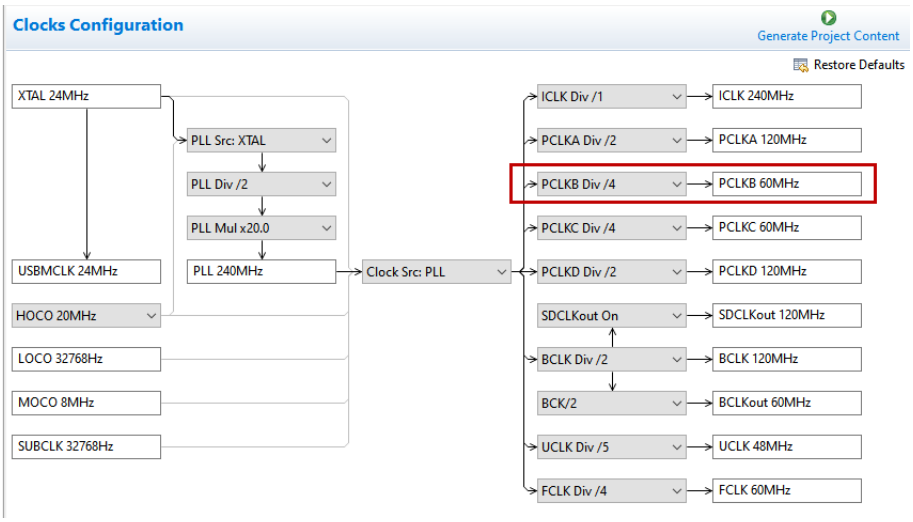

Figure 85: Clock Configuration

3.3.4.3 Pins Tab

The Pins tab provides a graphical tool for configuring the functionality of the pins of the device. For the WDT project no pin configuration is required. Although the project uses two LEDs connected to pins on the device, these pins are pre-configured as output GPIO pins by the BSP.

3.3.4.4 Threads Tab

You can add any driver to the project using the Threads tab. The HAL drivers for the Clock Generation Circuit, the Event Link Controller, and the IO port pins are added automatically by the ISDE when the project is configured. The WDT application uses no ThreadX Resources, so you only need to add the HAL WDT driver.

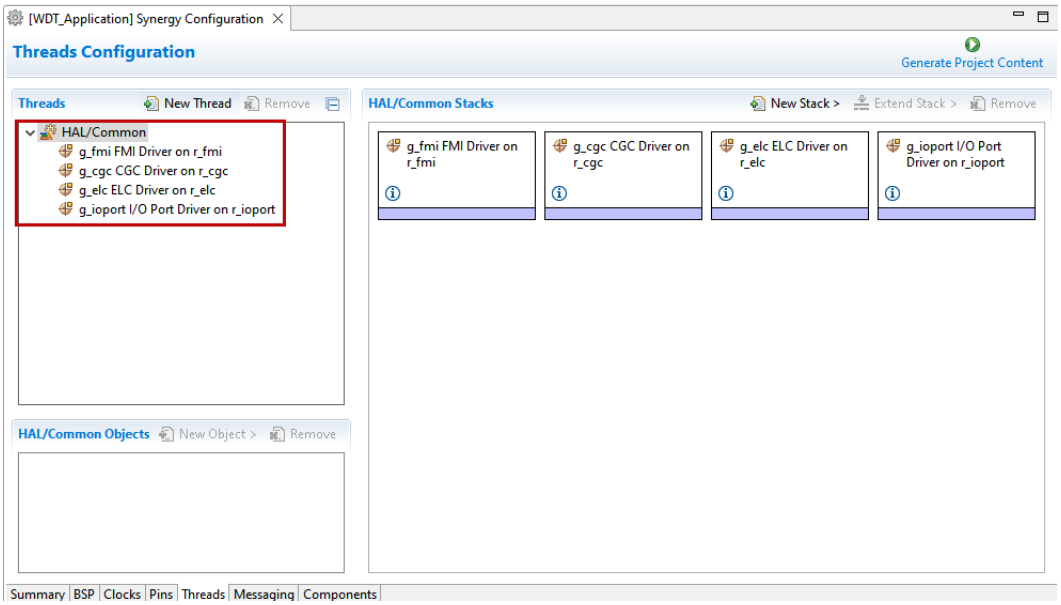

Figure 86: Threads Tab

The **HAL/Common Stacks** panel and is populated with the modules preselected by the ISDE.

1. Click on **New Stack** to find a pop-up window with the available HAL level drivers.
2. Select **Watchdog Driver on r_wdt**.

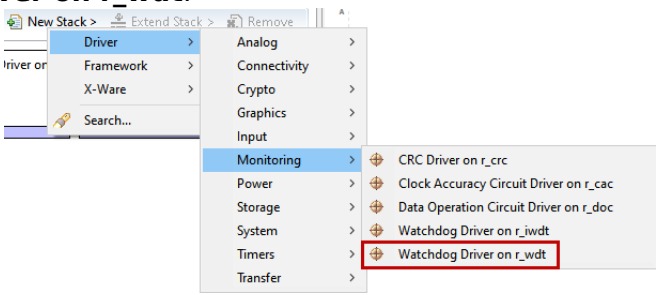

Figure 87: Module Selection

The selected HAL WDT driver is added to the **HAL/Common Stacks** Panel and the **Property** Window shows all configuration options for the selected module. The **Property** tab for the WDT should be visible at the bottom left of the screen. If it is not visible check that the **Synergy Configuration** perspective is selected.

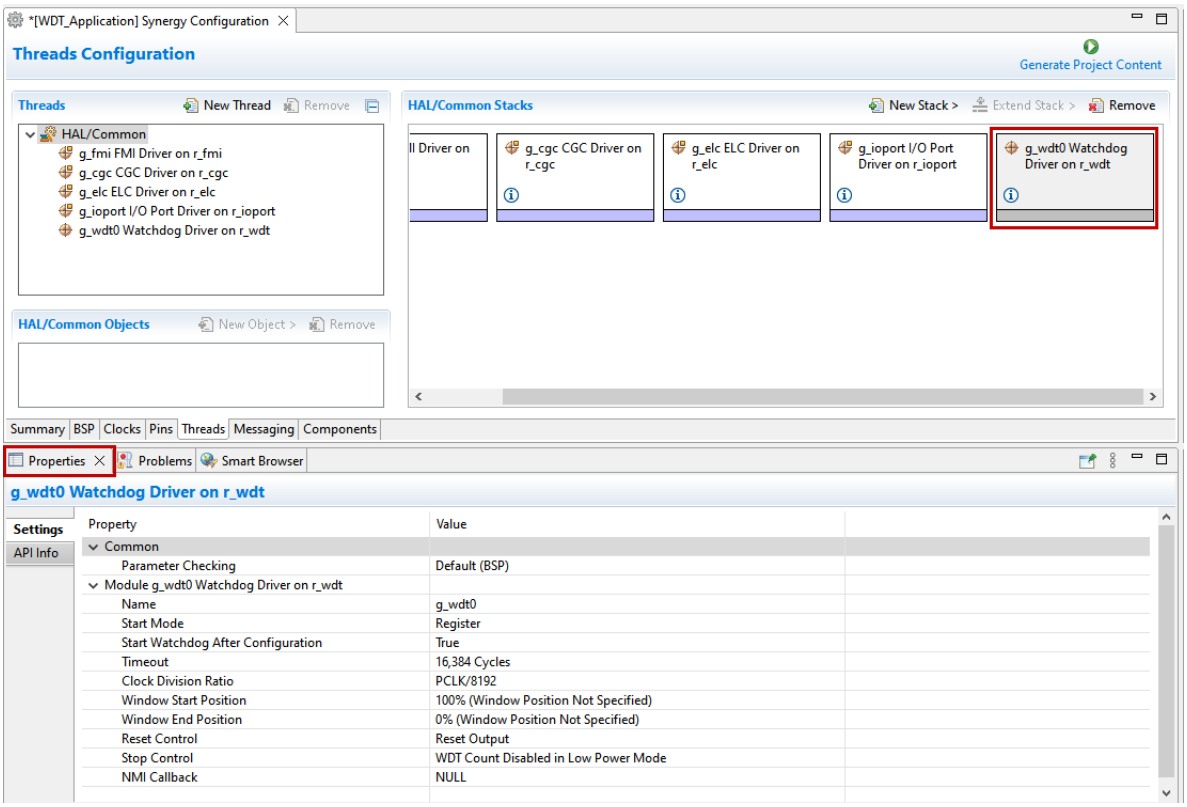

Figure 88: Module Properties

Change parameter **Start Watchdog After Configuration** from **True** to **False**. The other parameters can be left with their default values. Setting **Start Watchdog After Configuration** to **False** instructs the WDT driver (via its open API call) to configure the WDT but not to start it. It will be started later by refreshing it.

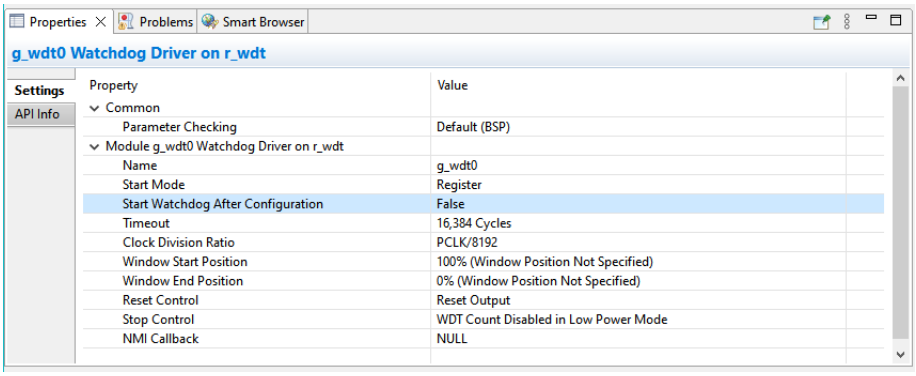

Figure 89: g_wdt Watchdog Driver on WDT Properties

With PCLKB running at 60 MHz the WDT will reset the device 2.23 seconds after the last refresh.

WDT clock = 60 MHz / 8192 = 7.32 kHz

Cycle time = 1 / 7.324 kHz = 136.53 us

Timeout = 136.53 us x 16384 = 2.23 seconds

Save the **Project Configuration** file and click the **Generate Project Content** button in the top right corner of the **Project Configuration** pane.

Figure 90: Generate Project Content Button

The ISDE generates the project files.

3.3.4.5 Components Tab

The components tab is included for reference to see which modules are included in the project. Modules are selected automatically in the Components view when after they are added in the Threads Tab.

For the WDT project ensure that the following modules are selected:

1. HAL_Drivers -> r_cgc
2. HAL_Drivers -> r_elc
3. HAL_Drivers -> r_ioport
4. HAL_Drivers -> r_wdt
5. HAL_Drivers -> r_fmi

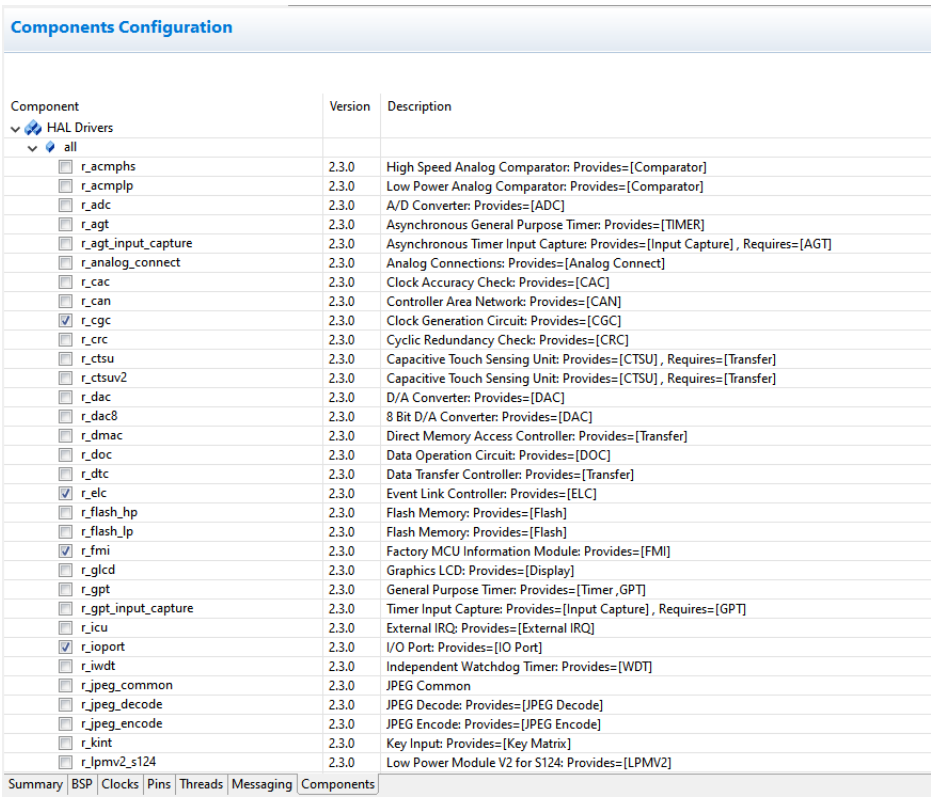

Figure 91: Component Selection

Note

The list of modules displayed in the Components tab depends on the installed SSP version.

3.3.5 WDT Generated Project Files

Pressing the Generate Project Content button performs the following tasks.

- r_wdt folder and WDT driver contents created at:
  - synergy/ssp/src/driver/
- r_wdt_api.h created in:
  - synergy/ssp/inc/driver/api
- r_wdt.h created in:
  - synergy/ssp/inc/driver/instances

The above files are the standard files for the WDT HAL module. They contain no specific project contents. They are the driver files for the WDT. Further information on the contents of these files can be found in the documentation for the WDT HAL module.

Configuration information for the WDT HAL module in the WDT project is found in:

- synergy_cfg/ssp_cfg/driver/r_wdt_cfg.h

The above file's contents are based upon the **Common** settings in the **g_wdt Watchdog Driver on WDT Properties** pane.

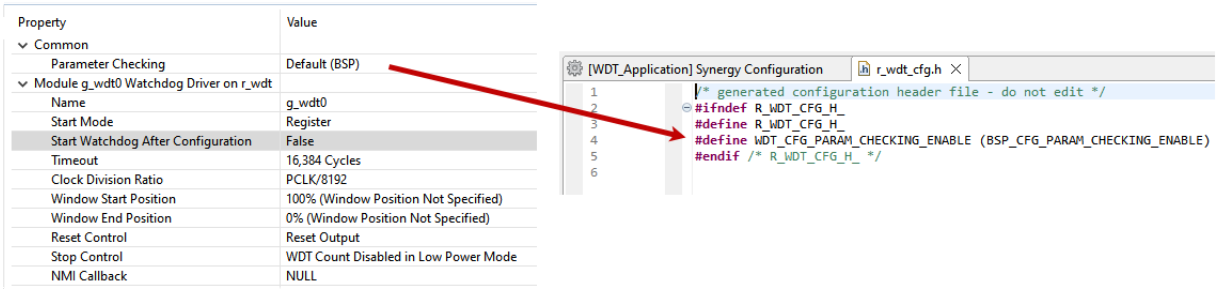

Figure 92: r_wdt_cfg.h Contents

Warning

Do not edit any of these files as they are recreated every time the Generate Project Content button is pressed and so any changes will be overwritten.

r_ioport folder is not created at ssp/src/driver as this module is required by the BSP and so already exists. It is included in the WDT project in order to include the correct header file in src/synergy_gen/hal_data.h – see later in this document for further details. For the same reason the other IOPORT header files – synergy/ssp/inc/api/r_ioport_api.h and synergy/ssp/inc/instances/r_ioport.h are not created as they already exist.

In addition to generating the HAL driver files for the WDT and IOPORT files the ISDE also generates files containing configuration data for the WDT and a file where user code can safely be added. These files are shown below.

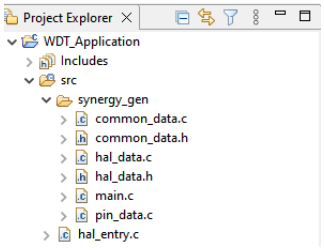

Figure 93: WDT Project Files

3.3.5.1 WDT hal_data.h

The contents of hal_data.h are shown below.

```
/* generated HAL header file - do not edit */
#ifndef HAL_DATA_H_
#define HAL_DATA_H_
#include <stdint.h>
#include "bsp_api.h"
#include "common_data.h"
#include "r_wdt.h"
#include "r_wdt_api.h"
```

```
#ifdef __cplusplus
extern "C"
{
#endif
extern const wdt_instance_t g_wdt0;
#ifndef NULL
void NULL(wdt_callback_args_t *p_args);
#endif
void hal_entry(void);
void g_hal_init(void);
#ifdef __cplusplus
} /* extern "C" */
#endif
#endif /* HAL_DATA_H_ */
```

hal_data.h contains the header files required by the ISDE generated project. In addition this file includes external references to the **g_wdt** instance structure which contains pointers to the configuration, control, api structures used for WDT HAL driver.

Warning

This file is regenerated each time Generate Project Content is pressed and must not be edited.

3.3.5.2 WDT hal_data.c

The contents of hal_data.c are shown below.

```
/* generated HAL source file - do not edit */
#include "hal_data.h"
static wdt_instance_ctrl_t g_wdt0_ctrl;
static const wdt_cfg_t g_wdt0_cfg =
{ .start_mode = WDT_START_MODE_REGISTER,
  .autostart = false,
  .timeout = WDT_TIMEOUT_16384,
  .clock_division = WDT_CLOCK_DIVISION_8192,
  .window_start = WDT_WINDOW_START_100,
  .window_end = WDT_WINDOW_END_0,
  .reset_control = WDT_RESET_CONTROL_RESET,
```

```
  .stop_control = WDT_STOP_CONTROL_ENABLE,
  .p_callback = NULL, };
/* Instance structure to use this module. */
const wdt_instance_t g_wdt0 =
{ .p_ctrl = &g_wdt0_ctrl, .p_cfg = &g_wdt0_cfg, .p_api = &g_wdt_on_wdt };
void g_hal_init(void)
{
    g_common_init ();
}
```

hal_data.c contains g_wdt_ctrl which is the control structure for this instance of the WDT HAL driver. This structure should not be initialised as this is done by the driver when it is opened.

The contents of **g_wdt_cfg** are populated in this file using the **g_wdt Watchdog Driver on WDT Properties** pane in the **ISDE Project Configuration HAL** tab. If the contents of this structure do not reflect the settings made in the ISDE, ensure the **Project Configuration** settings are saved in the ISDE before pressing the **Generate Project Content** button.

Warning
This file is regenerated each time Generate Project Content is pressed and so should not be edited.

3.3.5.3 WDT main.c

Contains main() called by the BSP start-up code. main() calls hal_entry() which contains user developed code (see next file). Here are the contents of main.c.

```
/* generated main source file - do not edit */
extern void hal_entry(void);
int main(void)
{
    hal_entry ();
 return 0;
}
```

Warning
This file is regenerated each time Generate Project Content is pressed and so should not be edited.

3.3.5.4 WDT hal_entry.c

This file contains the function hal_entry() called from main(). User developed code should be placed in this file and function.

For the WDT project edit the contents of this file to contain the code below. This code implements the flowchart in overview section of this document.

```
/* HAL-only entry function */
#include "hal_data.h"
#define RED_LED_NO_OF_FLASHES 30
#define RED_LED_PIN IOPORT_PORT_06_PIN_01 ? In case of SK-S7G2
#define GREEN_LED_PIN IOPORT_PORT_06_PIN_00 ? In case of SK-S7G2
#define RED_LED_DELAY_COUNT 1500000
#define GRN_LED_DELAY_COUNT 1200000
volatile uint32_t delay_counter;
volatile uint16_t loop_counter;
void hal_entry(void)
{
 /* TODO: add your own code here */
 /* Open the WDT */
    g_wdt0.p_api->open(g_wdt0.p_ctrl, (wdt_cfg_t *const)g_wdt0.p_cfg);
 /* Start the WDT by refreshing it */
    g_wdt0.p_api->refresh(g_wdt0.p_ctrl);
 /* Flash the red LED and tickle the WDT for a few seconds */
 for(loop_counter=0; loop_counter<RED_LED_NO_OF_FLASHES; loop_counter++)
    {
 /* Turn red LED on */
       g_ioport.p_api->pinWrite(RED_LED_PIN, IOPORT_LEVEL_HIGH);
 /* Delay */
 for(delay_counter=0; delay_counter<RED_LED_DELAY_COUNT; delay_counter++);
 /* Refresh WDT */
      g_wdt0.p_api->refresh(g_wdt0.p_ctrl);
 /* Turn red off */
       g_ioport.p_api->pinWrite(RED_LED_PIN, IOPORT_LEVEL_LOW);
 /* Delay */
 for(delay_counter=0; delay_counter<RED_LED_DELAY_COUNT; delay_counter++);
 /* Refresh WDT */
```

```
      g_wdt0.p_api->refresh(g_wdt0.p_ctrl);
    }
 /* Flash green LED but STOP tickling the WDT. WDT should reset the
  device */
 while(1)
    {
 /* Turn green LED on */
       g_ioport.p_api->pinWrite(GREEN_LED_PIN, IOPORT_LEVEL_HIGH);
 /* Delay */
 for(delay_counter=0; delay_counter<GRN_LED_DELAY_COUNT; delay_counter++);
 /* Turn green off */
       g_ioport.p_api->pinWrite(GREEN_LED_PIN, IOPORT_LEVEL_LOW);
 /* Delay */
 for(delay_counter=0; delay_counter<GRN_LED_DELAY_COUNT; delay_counter++);
    }
}
```

The WDT HAL driver is called through the interface **g_wdt_on_wdt** defined in **r_wdt.h**. The WDT HAL driver is opened through the open API call using the instance defined in **r_wdt_api.h**:

```
g_wdt0.p_api->open(g_wdt0.p_ctrl, (wdt_cfg_t *const)g_wdt0.p_cfg);
```

The first passed parameter is the pointer to the control structure **g_wdt_ctrl** instantiated in hal_data.c. The second parameter is the pointer to the configuration data **g_wdt_cfg** instantiated in the same hal_data.c file.

The WDT is started and refreshed through the API call:

```
g_wdt0.p_api->refresh(g_wdt0.p_ctrl);
```

Again the first (and only in this case) parameter passed to this API is the pointer to the control structure of this instance of the driver.

3.3.6 Building and Testing the Project

Build the project in the ISDE **Build > Build Project**. The project should build without errors.

To debug the project

1. Connect the JLink debugger between the target board and host PC. Apply power to the board.
2. In the **Project Explorer** pane on the right side of the ISDE right-click on the WDT project **WDT_Application** and select **Debug As > Debug Configurations**.
3. Under **Renesas GDB Hardware Debugging** select **WDT_Application Debug** as shown below.

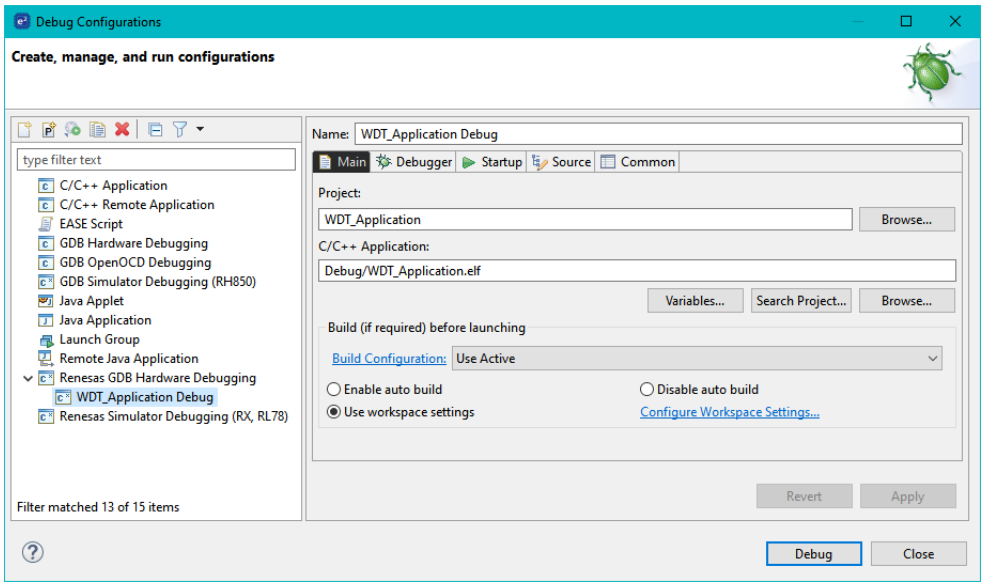

Figure 94: Debug Configuration

4. Press the **Debug** button. Switch (Yes) to the Debug perspective if asked.
5. The code should run to the Reset_Handler() function.
6. Resume execution via **Run > Resume**. Execution will stop in main() at the call to **hal_entry()**.
7. Resume execution again.

The red LED should start flashing. After 30 flashes the green LED will start flashing and the red LED will stop flashing.

While the green LED is flashing the WDT will underflow and reset the device resulting in the red LED to flash again as the sequence repeats. However, this sequence does not occur when using the debugger because the WDT does not run when connected to the debugger.

1. Stop the debugger in the ISDE via **Run > Terminate**.
2. Press the reset button on the target board. The LEDs begin flashing.

3.4 IAR Embedded Workbench for Renesas

3.4.1 Using IAR Embedded Workbench for Synergy

This section describes how to use the IAR Embedded Workbench for Renesas Synergy (IAR EW for Synergy) in combination with the Renesas Synergy Standalone Configurator (SSC) to develop

applications with the Renesas Synergy Software Package (SSP). The architecture of the SSP directly determines how you use the IAR EW for Synergy and SSC to develop a Synergy application. See the following documents for details on the SSP architecture included in this manual:

- SSP Architecture
- BSP Architecture

3.4.2 What is IAR EW for Synergy?

IAR Embedded Workbench is now completely integrated with the Renesas Synergy Platform. The new product IAR EW for Synergy provides add-on functionality to simplify and accelerate software development, and provide the best performance and smallest code size.

Just like e^2 studio, IAR EW for Synergy offers secure source-level visibility into the Synergy Software Package (SSP) as well as secure source-level debugging. The developer can see protected source code but not modify or save it. Once the application code is developed, IAR EW for Synergy includes IAR C-STAT® and C-RUN® analyzers, tools which help and guide to improve application code quality.

3.4.3 IAR EW Key Features

- Integrated development environment with project management tools and editor
- Highly optimizing C and C++ compiler and Linker for Renesas Synergy devices
- Integration support for Renesas Synergy Standalone Configurator (SSC)
- C-STAT and C-RUN code analysis tools included
- Extensive HW target system support
- Power debugging to visualize power consumption in correlation with source code
- C-SPY® Debugger with JTAG/SWD support and support for RTOS-aware debugging on hardware
- Support for ETM Trace
- Comprehensive user and reference guides and context-sensitive help function
- Compliant with ARM® Embedded Application Binary Interface (EABI) and ARM Cortex® Microcontroller Software Interface Standard (CMSIS)

For detailed instructions on how to download and install IAR EW for Synergy, see the IAR EW for Synergy Release Notes on the Synergy Gallery.

3.4.4 What is Synergy Standalone Configurator (SSC)?

The Synergy Standalone Configurator (SSC) is an Eclipse Rich Client Platform (RCP) application containing the Synergy Project Generator and the Synergy Project Editor as implemented in the Renesas e^2 studio ISDE. SSC includes configurators like the Clock Configurator, Pin Configurator, RTOS Configurator, SSP Module Selector/Configurator, and Interrupt Control Unit (ICU) Configurator for use with 3rd party IDEs such as IAR EW for Synergy.

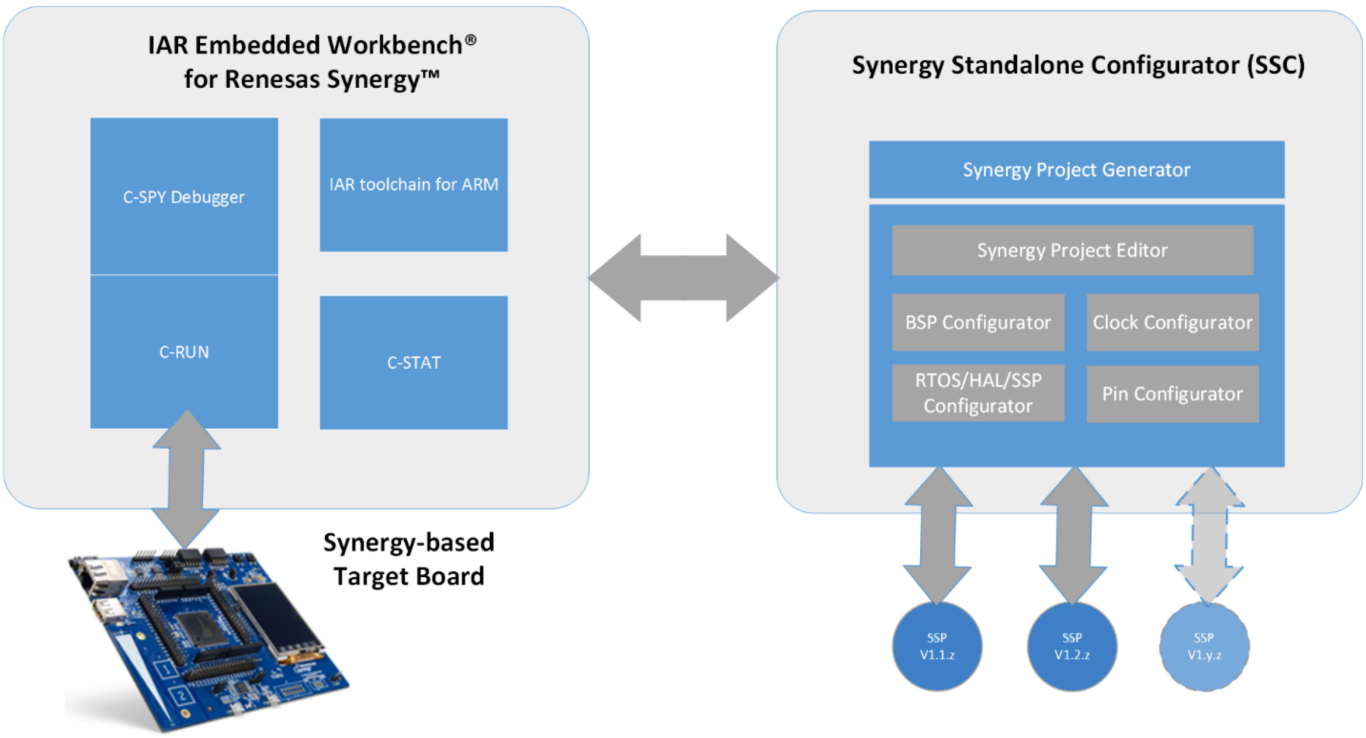

Figure 95: IAR EW for Synergy and SSC Functional Block Diagram

Since the functionality of the SSC is identical to the Synergy Project Generator and the Synergy Project Editor as implemented in the Renesas e^2 studio ISDE, refer to e2 studio ISDE User Guide for information on how to use it.

For detailed instructions on how to download and install the SSC and the SSP to use with IAR EW for Synergy, see the SSC Release Notes and the SSP Release notes on the Synergy Gallery.

3.4.5 Installing the Tools

To install the tools, follow the steps below:

1. Download and install the Renesas Synergy Standalone Configurator (SSC) from the Renesas Synergy Gallery. You can find it under Development Tools. The default installation directory is C:\Renesas\Synergy\SSC_<SSCversion>.
2. Download and install the Renesas Synergy Software Package (SSP) from the Renesas Synergy Gallery. During the installation you will be prompted to specify an installation directory for the SSP. Point the SSP installer to the directory where you just installed the SSC (for example C:\Renesas\Synergy\SSC_<SSCversion>).
3. Download and install IAR Embedded Workbench for Renesas Synergy from the Renesas Synergy Gallery. To install IAR Embedded Workbench:
    a. In your web browser, specify the URL https://synergygallery.renesas.com and download IAR Embedded Workbench for Renesas Synergy from the Renesas Synergy Gallery. You will also find information about how to obtain a license and get a license number.
    b. Execute the installer that is included in the downloaded file.
    c. Specify the license number when prompted for in the IAR License Manager.

Note

The IAR EW for Synergy license entitles you to use this specific edition of IAR Embedded Workbench, but not the Synergy Standalone Configurator for which separate licenses are required.

3.4.6 Creating a Renesas Synergy Project using IAR EW for Synergy and SSC

To create a Synergy Project using IAR EW for Synergy and SSC, follow the steps below:

1. In the IAR Embedded Workbench IDE, choose **Project>Create New Project**.

2. In the **Create New Project** dialog box, select **Renesas Synergy Project** and click **OK**.

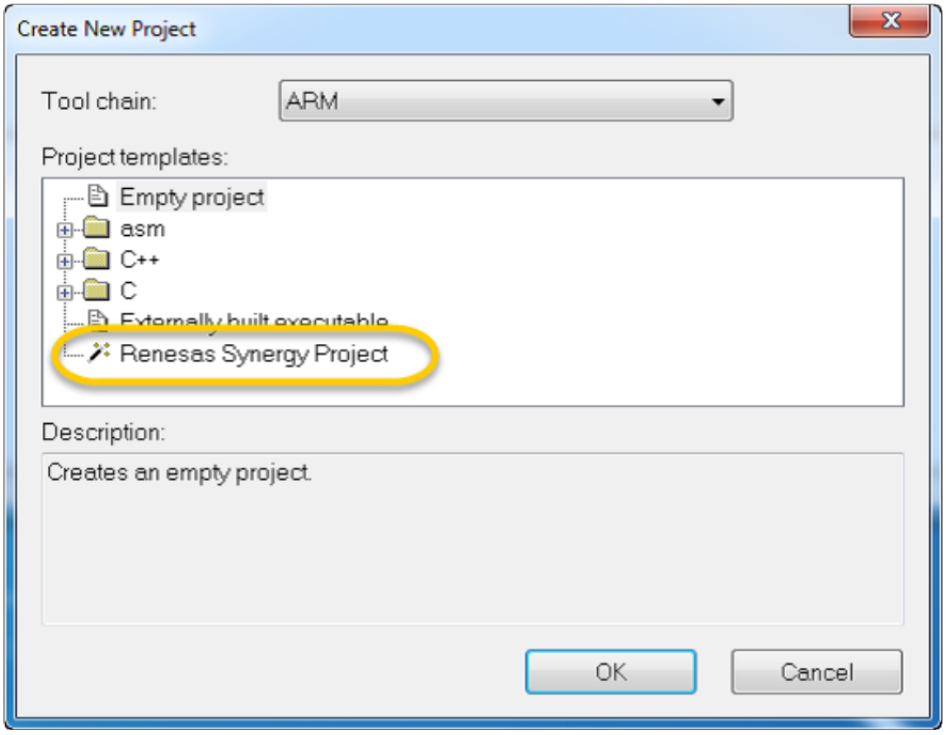

Figure 96: Creating a New Synergy Project using IAR EW for Synergy

3. In the **Save As** dialog box that appears, choose a suitable destination directory for your workspace (the container that holds your project), for example MyWorkspace, and click **Save**.

Note

Do not save your workspace in the root directory of your operating system (C:).

4. In the **Renesas Synergy Setting** dialog box that appears, specify the location of your installed Synergy Standalone Configurator (SSC), which by default is installed in C:\Renesas\Synergy\SSC_<SSCversion>.

Note

*You do not need to specify a license file. You can click **OK** with the **License file** field empty. An SSP license file is not required and the source files are not encrypted for SSP v2.0.0 and later.*

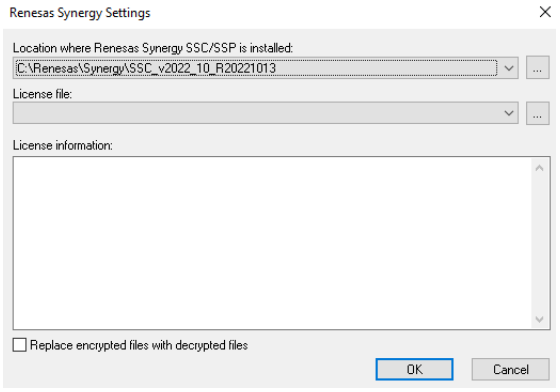

Figure 97: Renesas Synergy Settings in IAR EW for Synergy

5. Click **OK**.

6. In the **Save As** dialog box that appears, specify the name of your project, for example MyProject.

Note

Do not save your project in the root directory of your operating system (C:).

7. The IAR Embedded Workbench IDE now connects with the Renesas Synergy Standalone Configurator (SSC). Specify the board support you require:

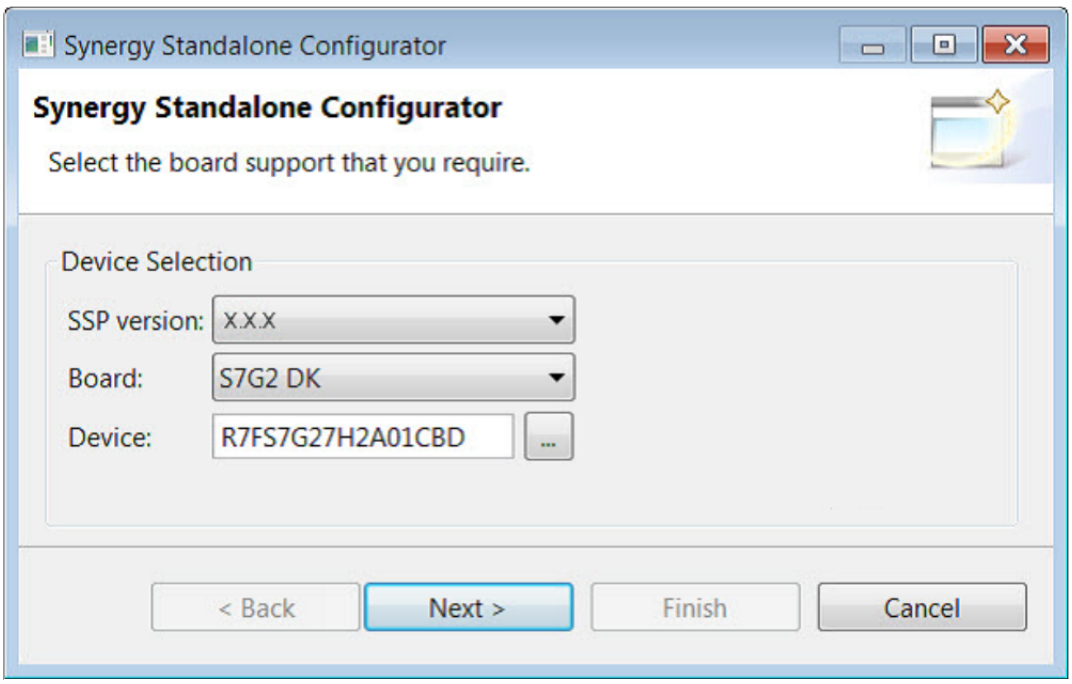

Figure 98: SSC selection Dialog for SSP, Board, and MCU to be used

Note

The SSP versions available in the drop-down list correspond to the versions you have previously

installed on your computer.

Click **Next**.

8. The Synergy Software Packages come with several example projects, which include source code files, header files, and linker configuration files, adapted for your device. Select the example packages that you want to add to your project:

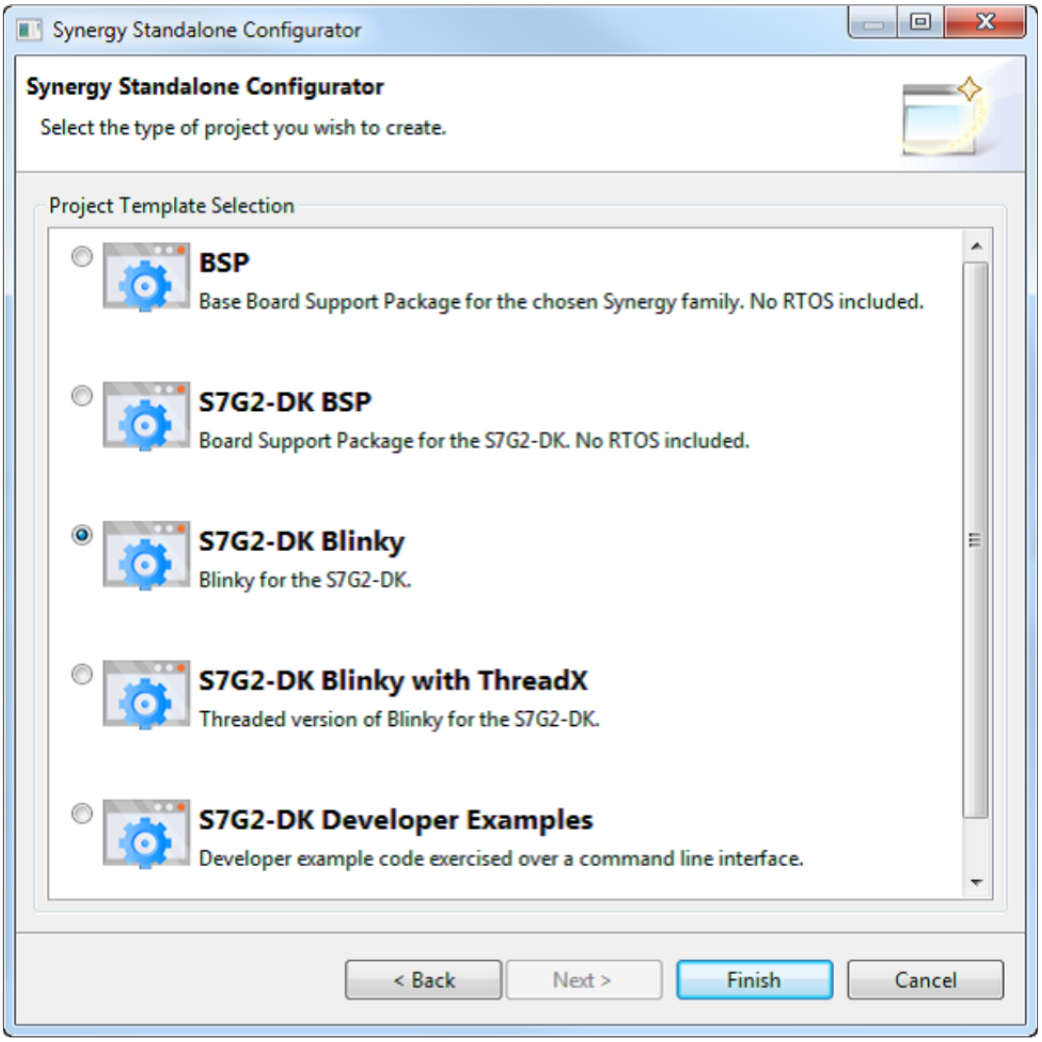

Figure 99: Project Template Selection Dialog

Click **Finish**.

9. In the Synergy Project Editor that opens up, you can now configure MCU pin function assignments, clock and peripheral settings, and interrupt source assignments. When finished configuring, click the **Generate Project Content** button. The source code is now generated.

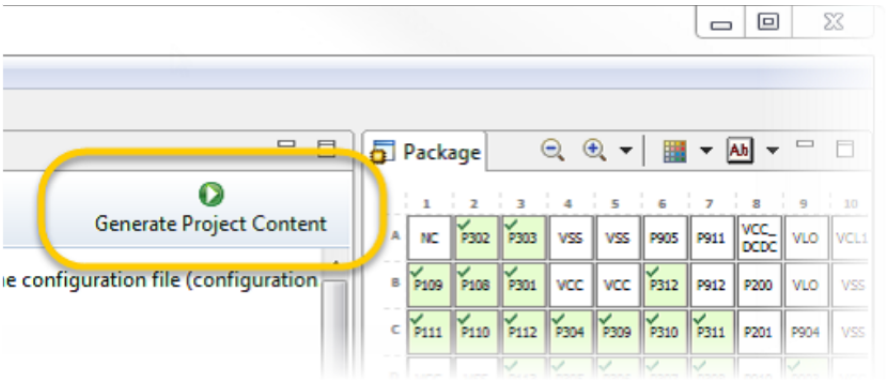

Figure 100: Generate Project Content Button

Note

You can always add or change the configuration of your Synergy project later on.

10. After a couple of seconds, your Renesas Synergy project is displayed in the IAR EW Workspace window:

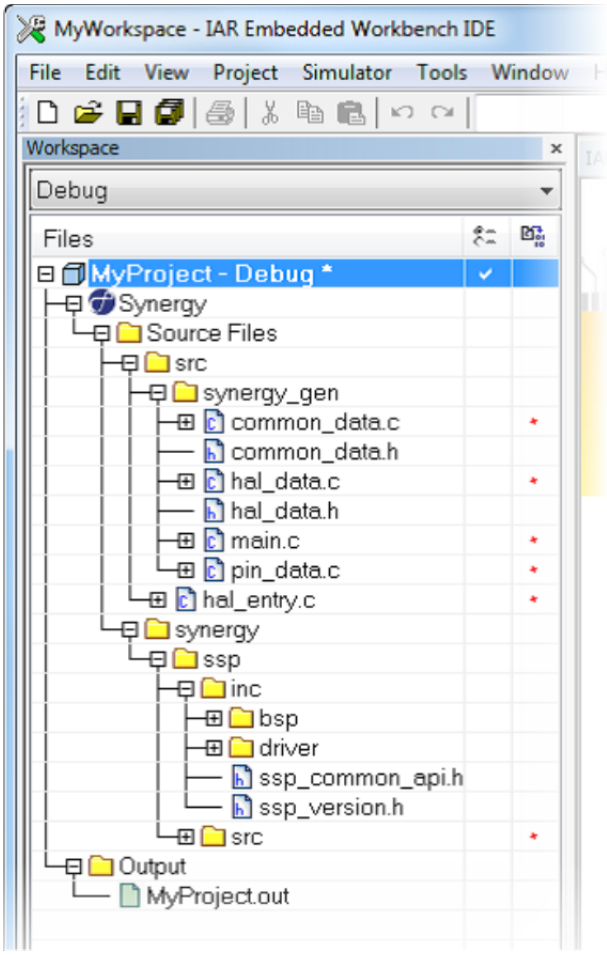

Figure 101: IAR EW for Synergy Workspace and Project Window

11. If you close the SSC, you can re-open it again by clicking the Synergy Configuration button

in the toolbar, or by selecting **Renesas Synergy > Configurator** from the menu.

12. Whenever you switch back to the SSC to change configuration settings, click the **Generate Project Content** button when finished. The affected source code files are now re-generated.

13. You can now continue building and debugging according to the standard routines in the IAR Embedded Workbench IDE, see the IAR Embedded Workbench® IDE User Guide on the IAR web site.

    As the SSC works just like the Synergy Project Editor in e^2 studio, refer to e2 studio ISDE User Guide for more details on how to use it.

    Note that the Synergy Project is by default configured for the J-Link debugging probe.

    If you have another debugging probe, for example I-jet or I-jet Trace, choose **Project>Options>Debugger** in the IDE and select I-jet/JTAGjet from the Driver drop-down list.

Chapter 4 Module Overviews

You can find a list of Module Overviews on the following pages:

- Framework Layer
- HAL Layer
- Azure RTOS Modules

The Module Overviews for each SSP module have been significantly improved since the last release. The new Module Overviews should provide all the information necessary for a developer to evaluate a specific modules fitness for use in a target application and significantly help with the development process. The intent of these notes is to provide all the information needed to begin develop0ment with the target module in one easy to find location.

Each Module Overview includes the following sections:

1. A short introduction to the module includes a short description, a block diagram of key module components, and a list of features
2. An API table lists all the available APIs, and example use of the API and a short description of the APIs function. A list of some of the key Status Return values is provided to help determine the result of the API call.
3. A functional overview describes key module operations and includes a list of important module limitations.
4. A step-by-step description of how to include the module in an application using the ISDE threads tab and stack selection process.
5. A set of tables showing the configuration parameters for the module and key lower level modules is provided so the developer can easily see the modules key capabilities. Note that these configurable properties vary by MCU series and by SSP Release. Treat the tables in these notes as illustrations and refer to the actual parameters available within the ISDE for your target MCU and for your chosen SSP release. Example pin and clock configuration and selection information is also provided to help guide development.
6. A simple implementation using the target module is provided and shows the steps used in a typical application, the associated flow diagram, and the API use at each step. This helps describe how APIs are commonly used and will give the developer a head start with their implementation.

Module Guide Application Notes

These six sections are also found in the Module Guide Application Notes for a specific module. In the Application Note additional sections provide detailed descriptions of the associated application project that demonstrates the module working in an actual design. Development can be dramatically simplified when the application project is used as a starting point or reference for a new design. Module guide application notes can be found with the following search: https://www.renesas.com/us/en/support/document-search?doc_file_all_types%5BApplication+Note%5D=Application+Note&doc_file_all_types%5BSample+Code+-+FIT+Module%5D=Sample+Code+-+FIT+Module&doc_file_all_types%5BSample+Code%5D=Sample+Code&doc_category_tier_1=467666&doc_category_tier_2=469306&doc_part_numbers=&keywords=&sort_order=DESC&sort_by=field_document_revision_date#documentation-tools-results. More module guide application notes are being added all the time so check back frequently to find when new ones have been released.

Using the Module Guide Module Overviews

The Module Overviews provide sufficient details to begin development, but there will be cases when additional information is useful in implementing a design. The SSP User Manual provides a wealth of information on the details of API implementation, structures, enumerations and more. Simply jump to the API reference section and find your module of interest to find any additional information you might need.

HAL modules have chapters that cover the above topics as well. It is highly recommended that you spend some time looking at the reference material available in ALL the reference chapters so you know where to look when an API implementation question, not answered in the module guide usage note or associated module guide application note, comes up.

4.1 Framework Layer

Some SSP framework modules are not included in the following list of Module Overviews. This is because some modules, although they can be selected and added to a thread, are only used as lower level modules and are not expected to be used by a developer separately. These modules are included in the Module Overview for the higher level module however. So if additional information is desired, just refer to the associated higher level Module Overview. The following list shows how to find these 'missing' modules:

Module	Included In
D/AVE 2D Port on sf_tes_2d_drw	GUIX Port on sf_el_gx under the Azure RTOS Modules section as GUIX Port
D/AVE 2D Driver on dave2d	GUIX Port on sf_el_gx under the Azure RTOS Modules section as GUIX Port

4.1.1 ADC Periodic Framework

4.1.1.1 ADC Periodic Framework Module Introduction

The ADC Periodic Framework provides a high-level API for signal processing applications. The module configures the ADC/SDADC to sample any of the available channels (using the single-scan mode) at a configurable rate and buffers the data for a configurable number of sampling iterations before notifying the application. The ADC Periodic Framework uses the ADC/SDADC, GPT or AGT and DTC peripherals on a Renesas Synergy™ Microcontroller. A user-defined callback can be created to

process the data each time a new sample is available.

ADC Periodic Framework Module Features

- 24-bit Sigma-Delta A/D Converter (S1JA only).
- 16-bit A/D Converter (S1JA)
- 14-bit A/D Converter (S3A7, S3A6, S3A3, S124, S128)
- 12-bit A/D Converter (S7G2, S5D9, S5D5)
- Multiple Operation Modes
  - Single Scan
  - Group Scan
  - Continuous Scan
- Multiple Channels
  - 1 channel (S1JA)
  - 13 channels (unit 0), 12 channels (unit 1) (S7G2 and S5D9)
  - 13 channels (unit 0), 9 channels (unit 1) (S5D5)
  - 18 channels (S124)
  - 21 channels (S128)
  - 25 channels (S3A6)
  - 28 channels (S3A7)
  - Temperature sensor channel
  - Voltage sensor channel

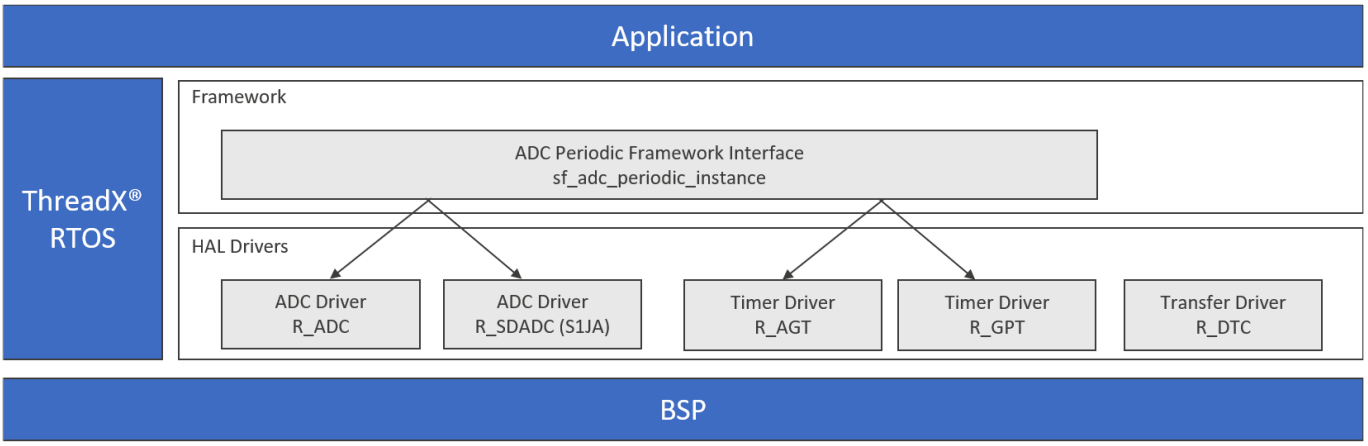

Figure 102: ADC Periodic Framework Module Block Diagram

4.1.1.2 ADC Periodic Framework Module APIs Overview

The ADC Periodic Framework defines APIs for opening, closing, starting and stopping the ADC scans. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

ADC Periodic Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_adc_periodic.p_api->open(g_sf_adc_periodic.p_ctrl, g_sf_adc_periodic.p_cfg); Acquires mutex, then initializes module at the HAL layer.

start	g_sf_adc_periodic.p_api->start(g_sf_adc_periodic.p_ctrl); Starts the scan.
stop	g_sf_adc_periodic.p_api->stop(g_sf_adc_periodic.p_ctrl); Stops the hardware trigger (timer) from triggering any more ADC scans.
close	g_sf_adc_periodic.p_api->close(g_sf_adc_periodic.p_ctrl); Releases channel mutex and closes channel at HAL layer.
versionGet	g_sf_adc_periodic.p_api->versionGet(&version); Retrieve the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_UNSUPPORTED	Command not found in the current menu.
SSP_ERR_NOT_OPEN	Driver control block not valid. CallSF_ADC_PERIODIC_Open to configure.
SSP_ERR_ASSERTION	Version get error- p_version was NULL.
SSP_ERR_INTERNAL	An internal ThreadX® error has occurred. This is typically a failure to create/use a mutex or to create an internal thread.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.1.3 ADC Periodic Framework Module Operational Overview

The ADC Periodic Framework module samples and buffers ADC data. The Framework notifies the application once the configured number of samples are buffered. The ADC Periodic Framework works as follows:

- After initial configuration and after the scan process is started, the framework uses a hardware timer to trigger an ADC scan in one-shot mode. Each scan can consist of one or more channels. When each scan is completed, the ADC interrupt is intercepted by the DTC, which moves the result of the scan into the user buffer.
- Each scan is defined as a sampling iteration, and the number of samples generated for each scan is equal to the number of channels. If the channels are sequential, for example, channels 1, 2, 3, 4, the data is captured in order. If the channels are not in sequence, for

example, channels 1, 3, 4, 5, then the samples generated by each scan also include data from the unused channels in between. Thus, in the second example, five samples are stored to the user buffer each time.
- The user specifies the total number of sample iterations that need to occur before being notified. When the specified number of sampling iterations have occurred and the data for each iteration has been stored into the user buffer, the user is notified via a callback with an index for the valid data in the buffer and an event indicating that sampling for the specified number of iterations is complete.

Unless the user stops the scan process, the scan continues to be triggered by the timer (using AGT or GPT) and data will be written into the user buffer, which is treated by the Framework as a circular buffer. The name and length of the buffer are specified via the ISDE configurator.

ADC Periodic Framework Module Important Operational Notes and Limitations

ADC Periodic Framework Module Operational Notes

1. At least one channel must be chosen while configuring the ADC/SDADC HAL driver to avoid an API return error.
2. When configuring the scan rate for the ADC Framework (the GPT or AGT timer period), make sure that the period is long enough to accommodate scanning of all selected channels (about 2 microseconds for each channel conversion on a Synergy S7G2 device).
3. The ADC Periodic Framework stores data for all the channels from each scan into the user specified buffer. When the specified number of sample iterations are completed, the user is notified. If five channels are selected (channels 1,2,3,4,5) and the sample count is set to 3, the user will be notified when 5 x 3 = 15 samples are available. The samples are ordered as follows:

Figure 103: ADC Periodic Framework Module Sample Order

When selecting the data buffer length in the ADC Periodic Framework configuration, make sure that the buffer length is at least twice the length of the number of samples that will be generated (15 x 2 = 30 in this example). This is because once the user application is notified that the data is available, the Framework will keep buffering in new data at the sample rate. Since the buffer is treated as a circular buffer, you can inadvertently overwrite the data. If the size is not larger than the number of samples generated, the data is overwritten before the application can use it.

The application callback has an index into the appropriate location in the buffer where valid data is present.

ADC Periodic Framework Module Limitations

- The ADC Periodic framework does not currently support the following features:
  - The use of Group Scan mode
  - The use of DMA
- When configuring the ADC channels to be used with this framework, the temperature or voltage sensors must not be selected if any of the other available channels are also selected. It is possible to use only the temperature sensor, only the voltage sensor, or any number of the regular ADC channels.
- ADC Periodic framework does not support DTC transfer when lower lever driver is SDADC.
- When using ADC Periodic framework with lower level SDADC of 24-bit, user should not

access output data through "p_args" in callback function. User should access output data only through user defined buffer.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.1.4 Including the ADC Periodic Framework Module in an Application

This section describes how to include the ADC Periodic Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the ADC Periodic Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the ADC Periodic Framework is g_adc_periodic0. This name can be changed in the associated Properties window.)

ADC Periodic Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_adc_periodic0ADC Periodic Framework on sf_adc_periodic	Threads	**New Stack**> **Driver**> **Analog**> **ADC Periodic Framework on sf_adc_periodic**

When the ADC Periodic Framework on sf_adc_periodic is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

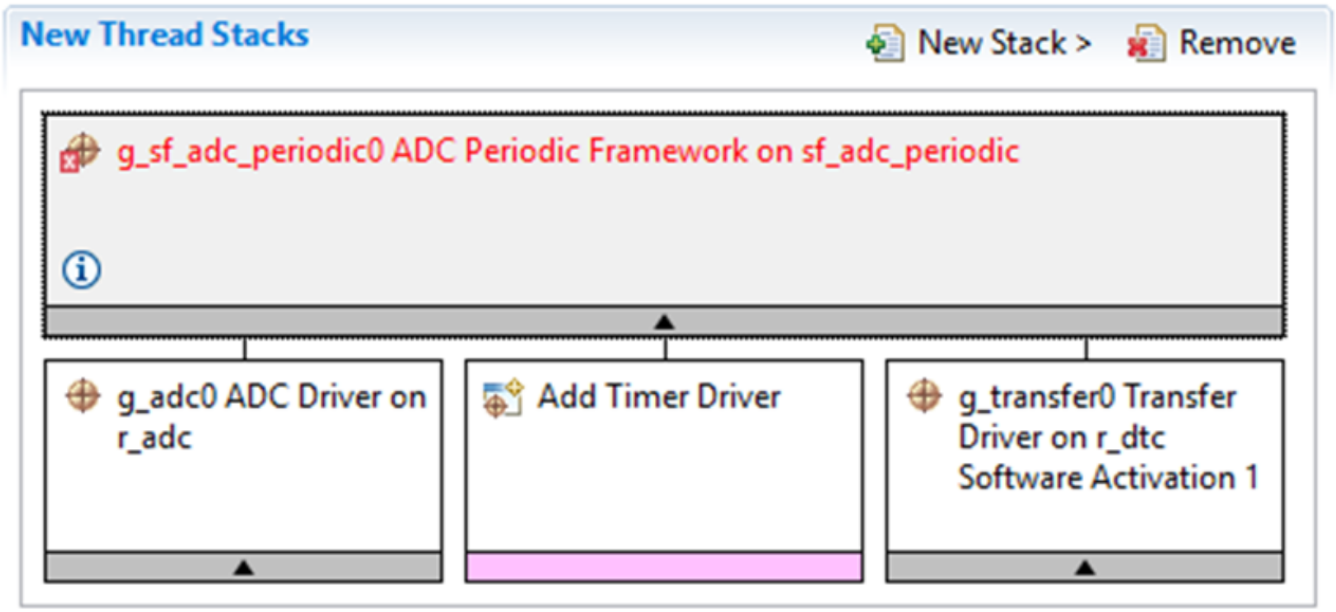

Figure 104: ADC Periodic Framework Module Stack

Note

The above diagram will have an "Add ADC Driver" block instead of the "g_adc0" block for the S1JA only.

4.1.1.5 Configuring the ADC Periodic Framework Module

The ADC Periodic Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the ADC Periodic Framework Module on sf_adc_periodic

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_adc_periodic0	Module name.
Name of the data-buffer to store samples	g_user_buffer	Name of the 16-bit data buffer to store samples.

Length of the data-buffer	128	Length of the buffer to which data is to be stored.
Number of sampling iterations	10	Priority of ADC Periodic Framework internal thread.
Callback	g_adc_framework_user_callback	User function that will be called once "sample_counts" number of data has been buffered.
Name of generated initialization function	sf_adc_periodic_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the ADC Periodic Framework Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the ADC HAL Module on r_adc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: Enabled	If selected code for parameter checking is included in the build.
Name	g_adc0	Module name.
Unit	0, 1 (S7G2 Only) Default: 0	Specify the ADC Unit to be used. The S7G2 has two units; 0 and 1.
Resolution	14-Bit (S3A7/S124 Only), 12-Bit, 10-Bit (S7G2) Default: 8-Bit (S7G2 Only)	Specify the conversion resolution for this unit.
Alignment	Right, Left Default: Right	Specify the conversion result alignment.

Clear after read	Off, On Default: On	Specify if the result register must be automatically cleared after the conversion result is read. Note: If this is enabled, then watching the result register using a debugger always results in a 0.
Mode	Single Scan	The ADC Framework preconfigures and locks this field.
Channels 0-6	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 7-10 (S3A7/S124 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 11-15 (S3A7 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 16-20	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.

Channel 21 (Unit 0 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 22 (S3A7/S124 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 23-27 (S3A7 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Temperature Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	Temperature sensor use selection for Channel Scan Mask.
Voltage Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	Voltage sensor use selection for Channel Scan Mask.
Normal/Group A Trigger	ELC Event	The ADC Framework preconfigures and locks this field.
Group B Trigger (Valid Only in Group Scan Mode)	ELC Event (The only valid trigger for either group in Group Scan Mode)	The ADC Framework preconfigures and locks this field.

Group Priority (Valid only in Group Scan Mode)	Group A cannot interrupt Group B, Group A can interrupt Group B; Group B scan restarts at next trigger, Group A can interrupt Group B; Group B scan restarts immediately, Group A can interrupt Group B; Group B scan restarts immediately and scans continuously Default: Group A cannot interrupt Group B	Do not use with ADC Framework since the mode is locked to Single Scan Mode.
Add/Average Count	Disabled, Add two samples, Add three samples, Add four samples, Add sixteen samples, Average two samples, Average four samples Default: Disabled	Specify if addition or averaging needs to be done for any of the channels in this unit. The actual channels are specified by using a channel mask adc_channel_cfg_t::add_mask.
Channels 0-27	Disabled, Enabled Default: Disabled	This field is valid only if adc_cfg_t::add_average_count is enabled. This field determines what channels results are to be averaged or summed.
Temperature Sensor	Disabled, Enabled Default: Disabled	Temperature sensor use selection for Addition/Averaging Mask.
Voltage Sensor	Disabled, Enabled Default: Disabled	Voltage sensor use selection for Addition/Averaging Mask.
Channels 0-2	Disabled, Enabled Default: Disabled	Determines which of channels 0, 1 and 2 are using the updated sample-and-hold states value specified in adc_channel_cfg_t::sample_hold_states. This field must only be set if it is desired to modify the default sample and hold count value for channels 0, 1 and 2.

Sample Hold States (Applies only to the 3 channels selected above)	24	Specifies the updated sample-and-hold count for the channel dedicated sample-and-hold circuit. This field is valid only if adc_channel_cfg_t::sample_hold_mask is not 0. Only channels 0, 1 and 2 have dedicated sample and hold circuits. Note: Use this to modify the default number of states (24) for which the value is sampled. Each state is equal to 1/ADCLK time.
Callback	NULL	The ADC Framework uses the callback internally.
Scan End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Scan End Interrupt Priority selection.
Scan End Group B Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Scan End Group B Interrupt Priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SDADC HAL Module on r_sdadc(Only for S1JA)

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_adc0	Module name.
Mode	Single Scan, Continuous Scan Default: Continuous Scan	In single scan mode, all channels are converted once per start trigger, and conversion stops after all enabled channels are scanned. In continuous scan mode, conversion starts after a start trigger, then continues until stopped in software.
Resolution	16 Bit, 24 Bit Default: 24 Bit	Select 24-bit or 16-bit resolution.

Alignment	Right, Left Default: Right	Select left or right alignment.
Trigger	ELC Hardware Event, Software Default: Software	Select conversion start trigger. Conversion can be started in software, or conversion can be started when a hardware event occurs if the hardware event is linked to the SDADC peripheral using the ELC API.
Vref Source	Internal, External Default: Internal	Vref can be sourced internally and output on the SBIAS pin, or Vref can be input from VREFI.
Vref Voltage	0.8 V, 1.0 V, 1.2 V, 1.4 V, 1.6 V, 1.8 V, 2.0 V, 2.2 V, 2.4 V Default: 1.0 V	Select Vref voltage. If Vref is input externally, the voltage on VREFI must match the voltage selected within 3%.
Internal Calibration During Open()	Enabled, Disabled Default: Enabled	Calibration is required for all channels configured for differential input. Internal calibration is performed automatically during open for these channels unless it is disabled here.
Callback	NULL	Enter the name of the callback function to be called when conversion completes or a scan ends.
Conversion End Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Select the interrupt priority for the conversion end interrupt. [Required]
Scan End Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for the scan end interrupt. [Required]
Calibration End Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for the calibration end interrupt. [Required]

Configuration Settings for the AGT HAL Module on r_agt

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables parameter checking.
Name	g_timer0	Module name.
Channel	0	Physical hardware channel.
Mode	Periodic	Warning: One-shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISRs must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation.
Period Unit	Raw Counts, Nanoseconds, Microseconds, Milliseconds, Seconds, Hertz, Kilohertz Default: Microseconds	See Timer Period Calculation.
Auto Start	False	Set to true to start the timer after configuring or false to leave the timer stopped until timer_api_t::start is called.
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	The clock source for the AGT counter.
AGTO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTO pin). Set to false for no output of the timer signal.
AGTIO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTIO pin). Set to false for no output of the timer signal.
Output Inverted	True, False Default: True	Set to false to start the output signal low. Set to true to start the output signal high.
Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection.

Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection.
Callback	NULL	A user callback function can be registered in timer_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Underflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Timer interrupt priority. 0 is the highest priority.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the GPT HAL Module on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_timer0	Module name.
Channel	0	The ADC Framework preconfigures and locks this field based on channel selected in the ADC Framework.
Mode	Periodic	The ADC Framework preconfigures and locks this field.
Period Value	10	Configure timer period to trigger ADC scans.
Period Unit	Raw Counts, Nanoseconds, Microseconds, Milliseconds, Seconds, Hertz, Kilohertz Default: Milliseconds	Configure units of the timer period set above.

Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection.
Auto Start	False	The ADC Framework preconfigures and locks this field.
GTIOCA Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
GTIOCB Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
Callback	NULL	The ADC Framework preconfigures and locks this field.
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.

Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Block	Mode selection.
Transfer Size	2 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	1	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	1	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

ADC Periodic Framework Module Pin Configuration

To access a channel, ADC channels must be set in the **Pins** tab of the ISDE. The following table illustrates the method for selecting the pins within the SSP configuration window:

Pin Selection for the ADC HAL Module on r_adc

Resource	ISDE Tab	Pin selection Sequence
ADC	Pins	Select **Peripherals** > **Analog: ADC > ADC0\1** > **AN_XX**

SDADC	Pins	Select **Peripherals** > **Analog: SDADC** > **SDADC0** > **AN_XX**

Note

In the cases of the internal temperature sensor and the internal voltage sensor, there are no pin configurations required.

4.1.1.6 Using the ADC Periodic Framework Module in an Application

The steps in using the ADC Periodic Framework module on sf_audio_record_adc in a typical application are:

1. Initialize the ADC using the sf_adc_periodic_api_t::open API.
2. Start the Scan of channels using the sf_adc_periodic_api_t::start API.
3. Stop the scan with the sf_adc_periodic_api_t::stop API.
4. Read the results of the conversion using the callback in application code.
5. Close the instance using the sf_adc_periodic_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

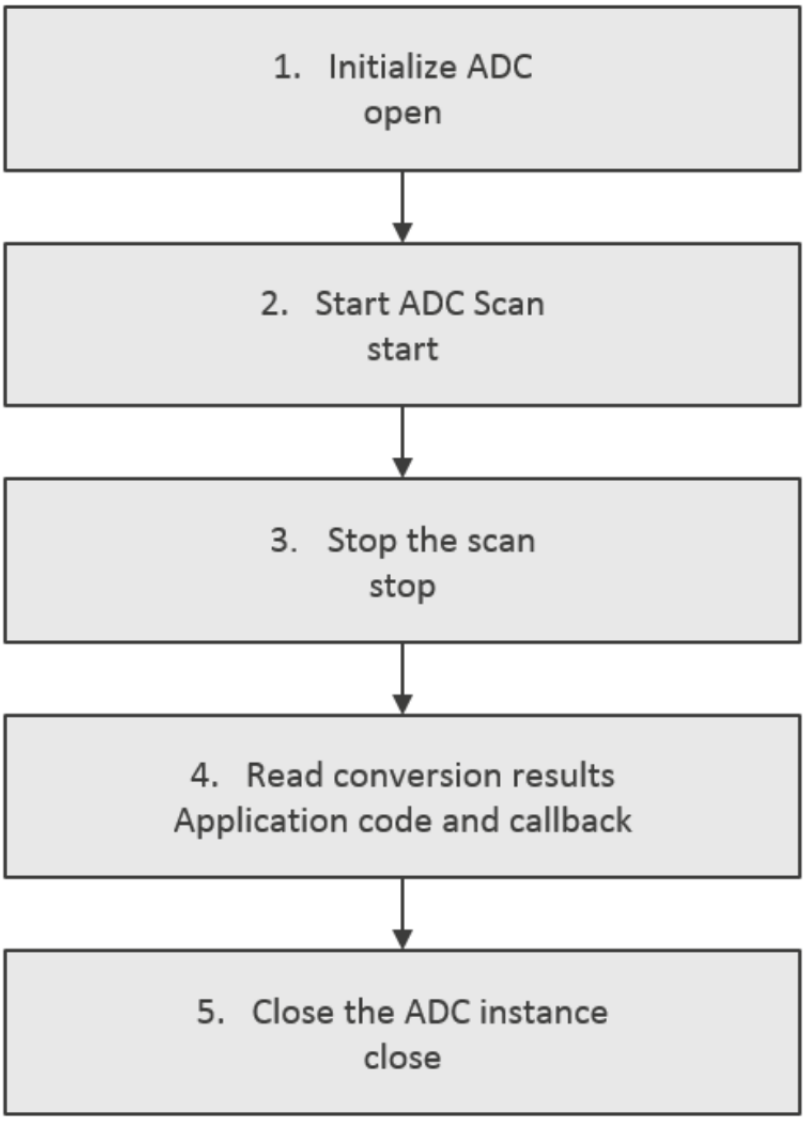

Figure 105: Flow Diagram of a Typical ADC/SDADC Periodic Framework Module Application

4.1.2 Audio Playback Framework

4.1.2.1 Audio Playback Framework Introduction

The Audio Playback Framework module provides a high-level API for audio playback applications and is implemented on either sf_audio_playback_hw_dac or sf_audio_playback_hw_i2s. The Audio Playback Framework handles the synchronization needed to play 16-bit and 8-bit pulse-code modulation (PCM) samples and uses the DAC (DAC12 or DAC8) or I2S, timer (AGT or GPT) and data-transfer (DMA or DTC) peripherals on a Synergy MCU. A user-defined callback can be created to respond to the need for additional data.

Audio Playback Framework Module Features

- Plays long buffers by splitting the data into manageable chunks.
- Repeats playback until a ThreadX timeout (for repeated audio like sine wave tones or looped background music).
- Requests next data using callback after last buffer playback begins.
- Software volume control.
- Pause and resume functions.
- Scaling, for example to move signed 16-bit PCM data into range of the unsigned 12-bit DAC or unsigned 8-bit DAC8.
- Basic mixing for multiple streams.

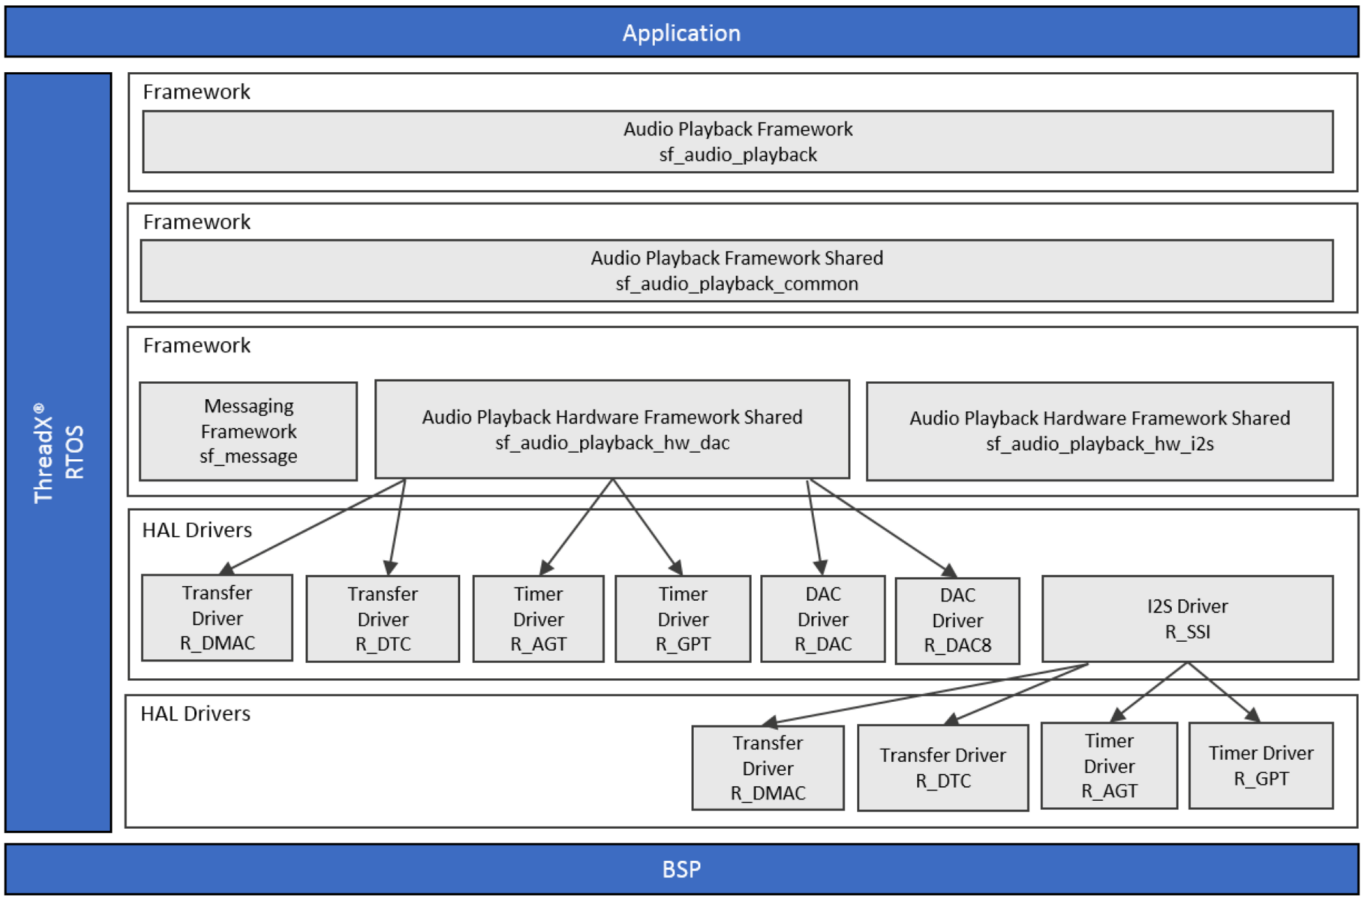

Figure 106: Audio Playback Framework Module Block Diagram

4.1.2.2 Audio Playback Framework Module APIs Overview

The Audio Playback Framework module defines APIs for operations such as opening, starting, playing and stopping. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Audio Playback Framework Module API Summary

Function Name	Example API Call and Description

open	g_sf_audio_playback0.p_api->open(g_sf_audio_playback0.p_ctrl, g_sf_audio_playback0.p_cfg); Open a device channel for read/write and control.
start	g_sf_audio_playback0.p_api->start(g_sf_audio_playback0.p_ctrl, p_data, Timeout); Start Audio Playback Hardware.
pause	g_sf_audio_playback0.p_api->pause(g_sf_audio_playback0.p_ctrl); Pause Audio Playback Hardware.
stop	g_sf_audio_playback0.p_api->stop(g_sf_audio_playback0.p_ctrl); Stop Audio Playback Hardware.
resume	g_sf_audio_playback0.p_api->resume(g_sf_audio_playback0.p_ctrl, &buffer, length); Resume playback.
volumeSet	g_sf_audio_playback0.p_api->volumeSet(g_sf_audio_playback0.p_ctrl, volume); Sets volume.
close	g_sf_audio_playback0.p_api->close(g_sf_audio_playback0.p_ctrl); Close the audio module.
versionGet	g_sf_audio_playback0.p_api->versionGet(&version); Return the version of the module using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	A pointer is NULL or a parameter is invalid.
SSP_ERR_OUT_OF_MEMORY	The number of streams open at once is limited to SF_AUDIO_PLAYBACK_CFG_MAX_STREAMS. If this number is exceeded, an out of memory error occurs.
SSP_ERR_TIMEOUT	Timeout occurred before playback finished.
SSP_ERR_NOT_OPEN	The stream control block p_ctrl is not initialized.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.2.3 Audio Playback Framework Module Operational Overview

The Audio Playback Framework module creates a thread internally to support audio playback. The following figure shows a flowchart of the audio playback framework thread and its interactions with public Audio Playback Framework API functions:

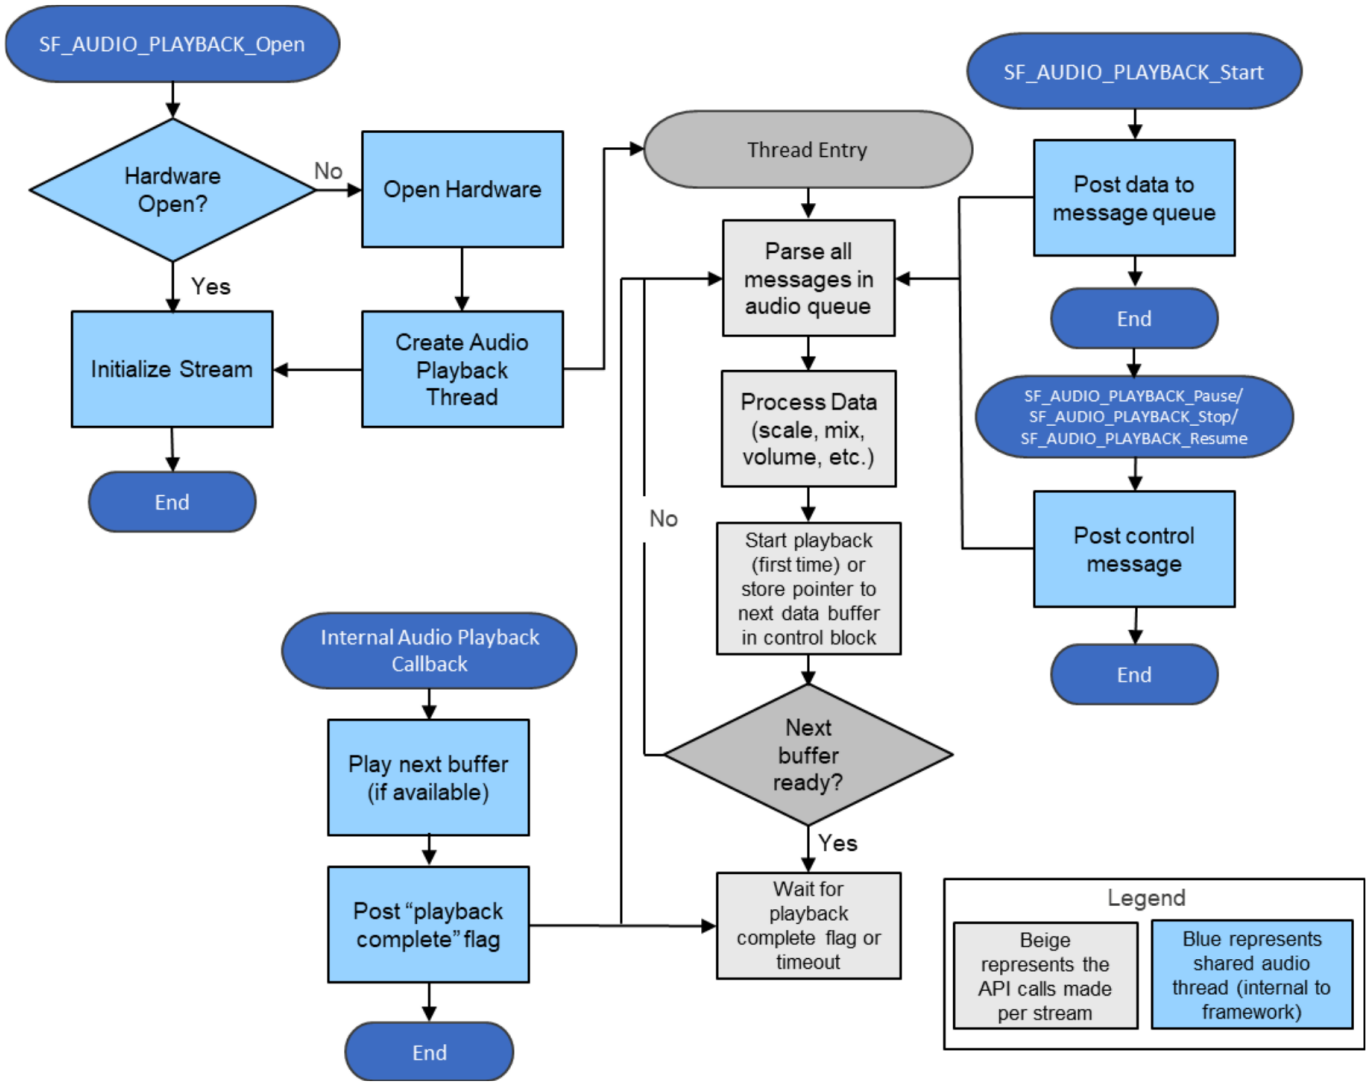

Figure 107: Audio Playback Framework Module Flow Chart

Suggested use of the audio playback framework:

- Create a semaphore (for example, g_sf_audio_playback_semaphore). This can be done on the **Threads** tab. Set the initial value to 2 (the audio playback framework can store up to two data messages per stream).
- Create a callback function (for example, sf_audio_playback_callback). Enter the name of your callback function in the Audio Playback Framework instance. The callback function will be called when the audio playback framework is done with the data. In the callback, put the semaphore created above.
- In your main loop, get the semaphore before playing data. To play data, first acquire a

buffer from the messaging framework, then create your audio playback data structure inside the buffer.

The Audio Playback Framework supports multiple audio streams on a single hardware port. A block diagram of the modules required if two streams are used is shown in the following figure:

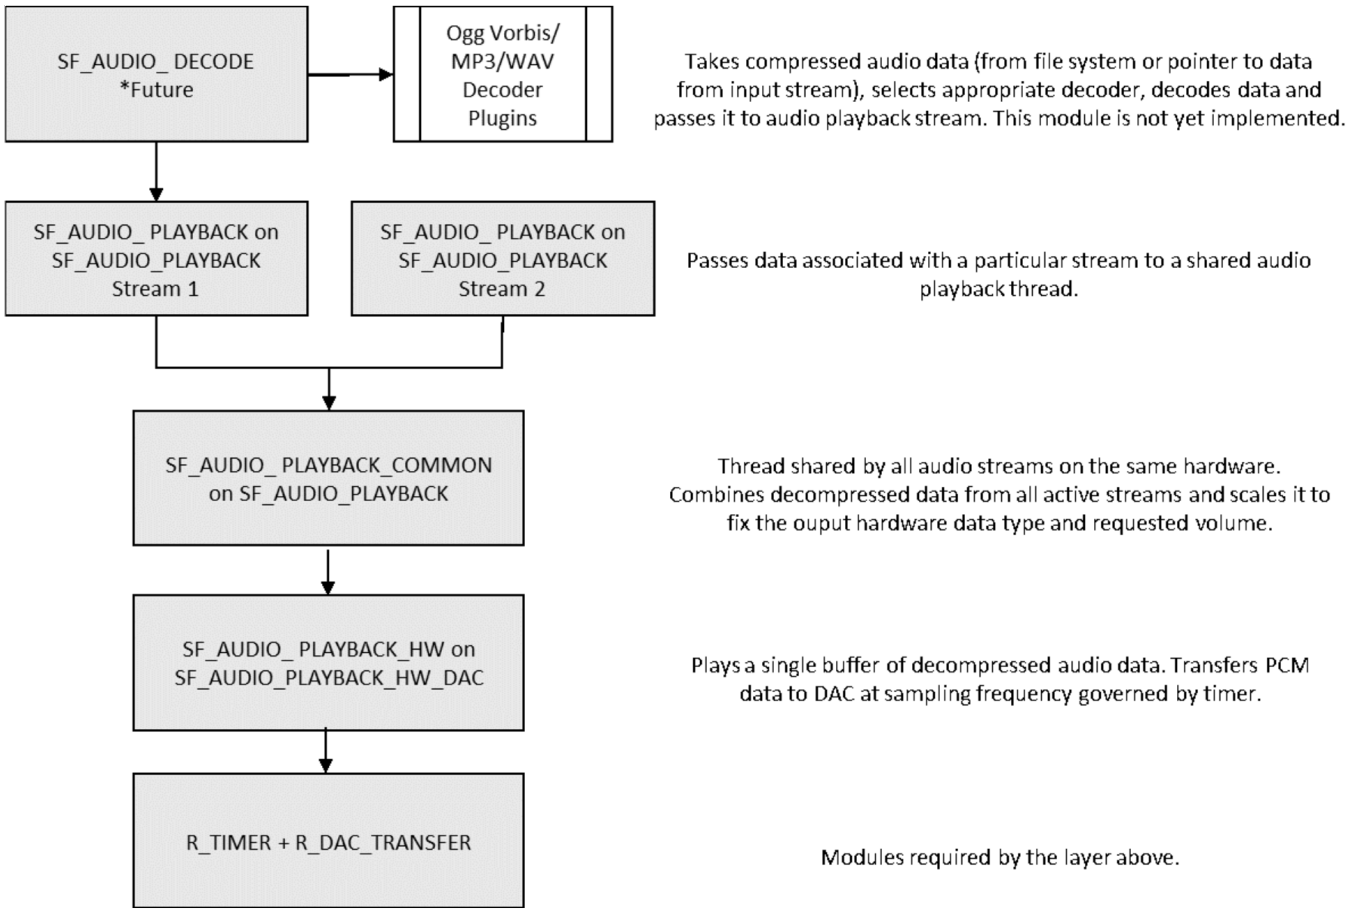

Figure 108: Audio Playback Framework Module Audio Streams

Audio Playback Framework Module Important Operational Notes and Limitations

Audio Playback Framework Module Operational Notes

Configuring Messages

Use the Messaging Framework configurator on the Messaging tab to configure the messaging framework:

1. Highlight the Audio Playback event class.
2. Add a new subscriber. Select the following configurations and make sure the Message Class Instance property set in the **Properties** tab of the Audio Playback Framework on sf_audio_playback module is between the Start and End instance.
    - Thread: Any thread in the application.
    - Start: First audio instance used in application.
    - End: Last audio instance used in application.
3. Highlight the new Subscriber in the Audio Playback Subscribers. Record the Symbol name.
4. Go back to the **Threads** tab.
5. Highlight the Audio Playback Framework Shared module in HAL/Common, and set the Audio

Message Queue Name to the Symbol name from the Audio Playback Subscriber.

Using the I2S Implementation

The audio framework I2S hardware port has dependencies on the I2S Driver module. The I2S driver module can be accelerated with DTC.

- Set the ISDE properties for the I2S driver module.
  - Set the Audio Clock Frequency (Hertz) to the frequency of the input audio clock used.
  - Set the Sampling Frequency (Hertz) to the sampling frequency of your audio data.
  - Set the Data Bits and Word Length to 16 bits (audio framework accepts 16 bit samples only).
  - Enable the SSIn TXI and SSIn INT interrupts.
- The Transfer module on r_dtc is added automatically.

Using the DAC Implementation

The audio framework DAC hardware port has dependencies on the Timer, DAC, and Transfer API modules.

- Add a Timer module.
  - Set the Frequency in Hz to the sampling frequency of your audio data.
  - Enable the interrupt if using DTC as the transfer module (recommended).
- Add a DAC (DAC12 or DAC8) module.
- Add a Transfer module on r_dtc.
  - Set Destination pointer to &R_DAC->DADRn[0] if using DAC channel 0 or &R_DAC->DADRn[1] if using DAC channel 1.
  - Set Destination pointer to &R_DAC8->DADRn[2] if using DAC8 channel 2 (S128) or &R_DAC8->DADRn[0] if using DAC8 channel 0 (S1JA).
  - Set the Activation source to the timer interrupt chosen above.

Other Operational Notes

The Queue used must match the name specified in Properties for Audio Playback Framework Shared on sf_audio_playback (default is g_sf_audio_playback_queue).

Audio Playback Framework Module Limitations

- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.1.2.4 Including the Audio Playback Framework Module in an Application

This section describes how to include the Audio Playback Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Audio Playback Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Audio Playback Framework module is g_sf_audio_playback0. This name can be changed in the

associated Properties window.)

Audio Playback Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_audio_playback Audio Playback Framework on g_sf_audio_playback	Threads	**New Stack> Framework> Audio> Audio Playback Framework on g_sf_audio_playback**

When the Audio Playback Framework module on sf_audio_playback is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

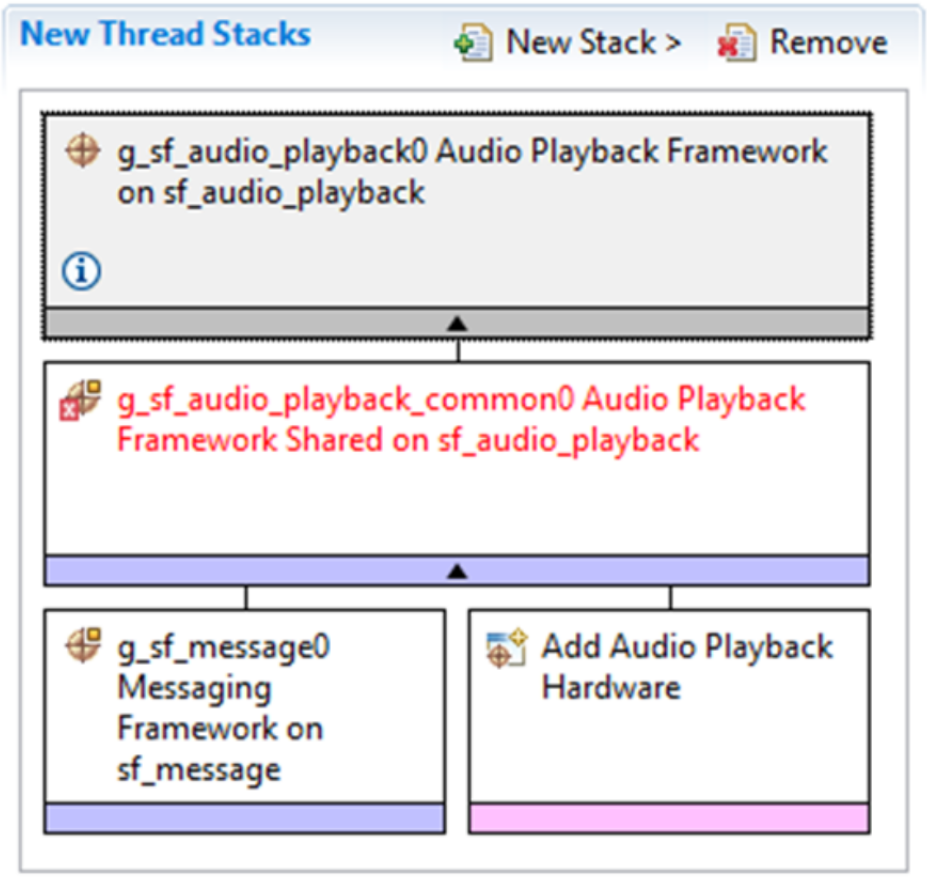

Figure 109: Audio Playback Framework Module Stack

4.1.2.5 Configuring the Audio Playback Framework Module

The Audio Playback Framework module must be configured by the user for the desired operation.

The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Audio Playback Framework Module on sf_audio_playback

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Buffer Size Bytes	512	Buffer size bytes selection.
Maximum Number of Streams	1	Maximum number of streams selection.
Thread Stack Size	512	Thread stack size selection.
Name	g_sf_audio_playback0	Module name.
Message Class Instance	0	Message class instance selection.
Callback	NULL	Callback selection.
Name of generated initialization function	sf_audio_playback_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

Increasing the buffer size will increase the RAM consumption of this module.
The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select the DAC Channel based on the target hardware implementation. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower level modules are fairly intuitive and can usually be determined by inspection of the associated Properties window from the SSP configurator.

Configuring the Audio Playback Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the Audio Playback Framework Shared on sf_audio_playback

ISDE Property	Value	Description
Name	g_sf_audio_playback_common0	Module name.
Thread Priority	3	Thread priority selection.
Audio Message Queue Name	g_sf_audio_playback_queue	Audio message queue name selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Messaging Framework on sf_message

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Message Queue Depth (Total number of messages to be enqueued in a Message Queue)	16	Specify the size of Thread X Message Queue in bytes for Message Subscribers. This value is applied to all the Message Queues.
Name	g_sf_message0	The name of Messaging Framework module control block instance.
Work memory size in bytes	2048	Specify the work memory size in bytes. Choosing a small number results in a small number of buffers, which can be allocated at the same time (you can confirm the total buffer number on sf_message_instance_ctrl_t::number_of_buffers). If the value is smaller than the peak number of messages to be posted at the same time, the Framework has a buffer allocation failure, affecting system performance.

Pointer to subscriber list array	p_subscriber_lists	Specify the name of pointer to the Subscriber List array.
name of the block pool internally used in the messaging framework	sf_msg_blk_pool	The name of memory block memory the Framework creates in the control block. This parameter might be useful for debugging purpose but NULL can be specified for saving memory.
Name of generated initialization function	sf_message_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Audio Playback Hardware Framework Shared on sf_audio_playback_hw_dac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
DMAC Support	Disabled, Enabled Default: Disabled	DMAC support selection.
Name	g_sf_audio_playback_hw0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dmac Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_transfer0	Module name.
Channel	0	Channel selection.
Mode	Normal	Mode selection.
Transfer Size	2 Bytes	Transfer size selection.

Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source	Software Activation, Peripheral Events Default: Software Activation	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback	NULL	Callback selection.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dmac Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	2 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.

Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Timer Driver on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables parameter checking.
Name	g_timer0	Module name.
Channel	0	Physical hardware channel.
Mode	Periodic	Warning: One-shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISRs must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation.

Period Unit	Hertz	See Timer Period Calculation.
Auto Start	False	Set to true to start the timer after configuring or false to leave the timer stopped until timer_api_t::start is called.
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	The clock source for the AGT counter.
AGTO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTO pin). Set to false for no output of the timer signal.
AGTIO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTIO pin). Set to false for no output of the timer signal.
Output Inverted	True, False Default: False	Set to false to start the output signal low. Set to true to start the output signal high.
Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection.
Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection.
Callback	NULL	A user callback function can be registered in timer_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Timer interrupt priority. 0 is the highest priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Timer Driver on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Warning: One-shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISRs must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation.
Period Unit	Hertz	See Timer Period Calculation.
Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection.
Auto Start	False	Set to true to start the timer after configuring or false to leave the timer stopped until timer_api_t::start is called.
GTIOCA Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
GTIOCB Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.

GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
Callback	NULL	A user callback function can be registered in timer_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DAC HAL Module on r_dac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_dac0	Module name.
Channel	0	Set to 0 for output DA0 or 1 for output DA1.
Synchronize with ADC	Enabled, Disabled Default: Disabled	Set to true for anti-interference synchronization with the Analog-to-Digital Converter (ADC) Module. Set to false if power supply interference between the analog modules is not a problem, or if asynchronous conversion by the DAC module is desired.

Data Format	Right Justified	Set to zero, if 12-bit data values are loaded in bits 11 through 0, or right justified. Set to one, if 12-bit data values are loaded in bits 15 through 4, or left justified.
Output Amplifier	Enable, Disable Default: Disable	Set to true, if output amplifier hardware function is desired. Set to false to bypass output amplifier hardware function.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Audio Playback Framework Shared on sf_audio_playback_hw_i2s

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_sf_audio_playback_hw0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2S HAL Module on r_ssi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_i2s0	Module name.
Channel	0	Physical hardware channel.
Audio Clock Frequency (Hertz)	2822400	Input audio clock frequency, used to generate the I2S clock. Must be a multiple between 1 and 128 of (sampling_freq_hz * word_length_in_bits).
Sampling Frequecy (Hertz)	44100	Sampling frequency of audio data.
Data Bits	8 bits, 16, 18, 20, 22, 24 Default: 16 bits	Bit depth of audio data, which is the size in bits of one sample of audio data.

Word Length	8 bits, 16, 24, 32 Default: 16 bits	Word length of audio data, must be at least the same size as the bit depth (Data Bits field).
WS Continue Mode	Enabled, Disabled Default: Disabled	Enable WS continue mode to continue to output the word select line when the peripheral is idle. Disable to stop outputting the word select line when the peripheral is idle.
Name of I2S callback function to be defined by user	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) when the transmission FIFO reaches the high watermark point after all data for transmission is transmitted or when reception is complete (the requested number of bytes have been received). Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Transmit interrupt priority selection.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Receive interrupt priority selection.
Idle/Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Idle/error interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activiation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC software event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activiation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC software event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Timer Driver on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC software event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Timer Driver on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Mode selection.
Period Value	2822400 *2	Period value selection.
Period Unit	Hertz	Period unit selection.
Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection.
Auto Start	FALSE	Auto start selection.
GTIOCA Output Enabled	True, False Default: False	GTIOCA output enabled selection.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCA stop level selection.
GTIOCB Output Enabled	True, False Default: False	GTIOCB output enabled selection.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCB stop level selection.
Callback	NULL	Callback selection.
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Audio Playback Framework Module Clock Configuration

The Audio Playback Framework hardware modules use the peripheral clocks available in the clock configuration window.

Audio Playback Framework Module Pin Configuration

The DAC or SSI peripheral module uses pins on the MCU to communicate with external devices. I/O pins must be selected and configured as required by the external device. The following tables illustrate the method for selecting the pins within the SSP configuration window, and show an example selection for the associated pins.

Pin Selection Sequence for the Audio Playback Framework Module

Resource	ISDE Tab	Pin selection Sequence
DAC	Pins	Select **Peripherals** > **Analog:DAC12** > **DAC120/121**
SSI	Pins	Select **Peripherals** > **Connectivity:SSI** > **SSI/0/1**

Note

The selection sequence assumes the DAC0/DAC1 or the SSI0/SSI1 is the desired hardware target of the driver.

Pin Configuration Settings for the DAC Driver on r_dac

Pin Configuration Property	Value	Description
Operation Mode	Enabled, Disabled	Operation selection.
DAC	None, P014 (Default: P014)	DAC pin selection.

Note

The example values are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.2.6 Using the Audio Playback Framework Module in an Application

The typical steps in using the Audio Playback Framework module in an application are:

1. Initialize an audio stream using the sf_audio_playback_api_t::open API.
2. Use the callback function to post to a semaphore with an initial count equal to the number of buffers required. This is implemented in the application code.
   - *Note*

     Get this semaphore in the application thread before calling sf_audio_playback_api_t::start API.
3. Acquire a buffer from the Messaging Framework using sf_message_api_t::bufferAcquire API.
   - *Note*

     Create the Audio Framework Data Structure using sf_audio_playback_data_t inside the buffer.
4. Start the Audio Playback Framework using the sf_audio_playback_api_t::start API.

Note

If multiple streams are desired, repeat steps 1-4 for any additional audio streams. A separate audio stream should only be used if the streams need to play simultaneously using mixing. If audio sounds are always played in

sequence and never overlap, the stream can be reused.

These common steps are illustrated in a typical operational flow in the following figure:

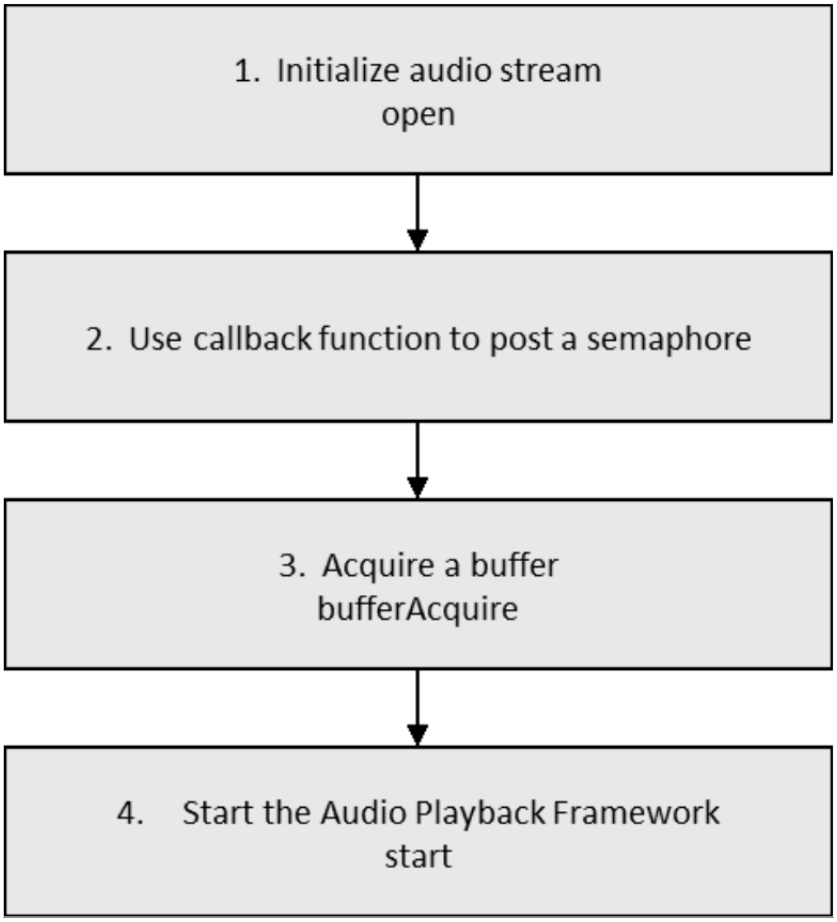

Figure 110: Flow Diagram of a Typical Audio Playback Framework Module Application

4.1.3 Audio Playback Hardware Framework Shared on sf_audio_playback_hw_dac

4.1.3.1 Audio Playback DAC Framework Introduction

The Audio Playback Framework DAC module provides a high-level API for audio playback applications and handles the synchronization needed to play 8-bit or 16-bit pulse-code modulation (PCM) samples. The Audio Playback DAC Framework uses the DAC/DAC8, timer (AGT or GPT) and data-transfer (DMA or DTC) peripherals on a Synergy MCU. A user-defined callback can be created to respond to the need for additional data.

Audio Playback DAC Framework Module Features

- Plays long buffers by splitting the data into manageable chunks.
- Repeats playback until a ThreadX timeout (for repeated audio like sine wave tones or

looped background music).
- Requests next data using callback after last buffer playback begins.
- Software volume control.
- Pauses and resumes functions.
- Scaling, for example, to move signed 16-bit PCM data into range of the unsigned 12-bit or 8-bit DAC.
- Basic mixing for multiple streams.

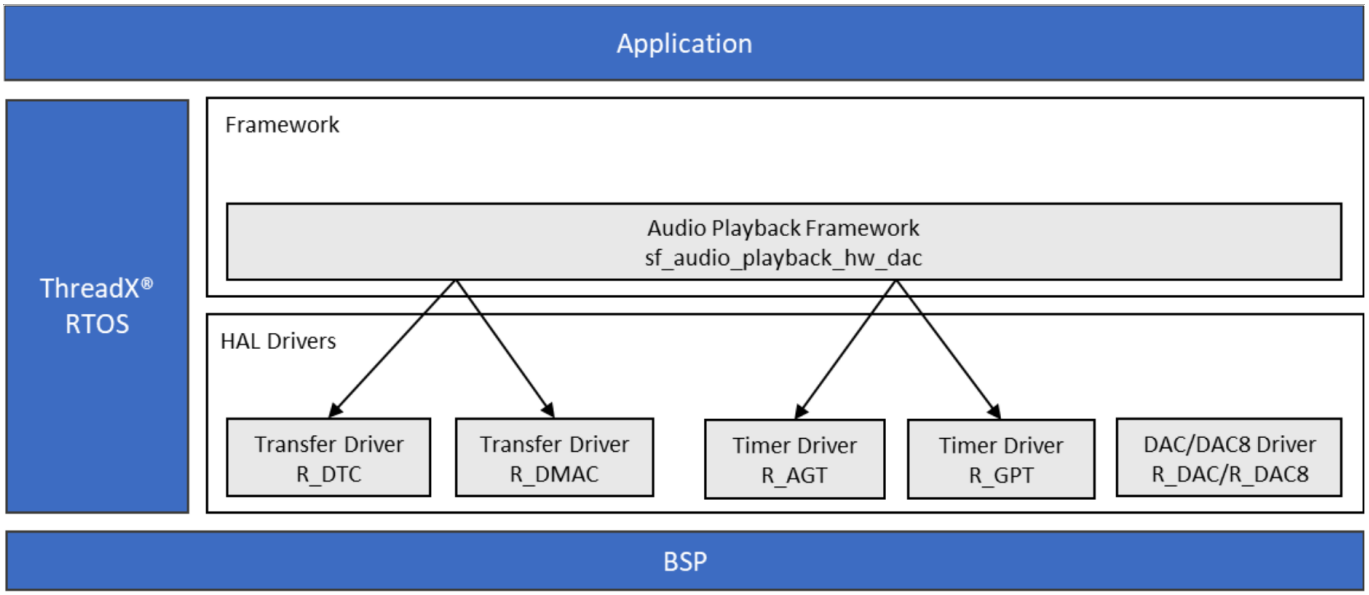

Figure 111: Audio Playback DAC Framework Module Block Diagram

Note

Selection options of DAC or DAC8 Driver is MCU specific.

4.1.3.2 Audio Playback DAC Framework Module APIs Overview

The Audio Playback DAC Framework module defines APIs for operations such as opening, starting, playing and stopping. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Audio Playback DAC Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_audio_playback_hw0.p_api->open(g_sf_audio_playback_hw0.p_ctrl, g_sf_audio_playback_hw0.p_cfg); Open a device channel for read/write and control.
start	g_sf_audio_playback_hw0.p_api->start(g_sf_audio_playback_hw0.p_ctrl, &p_data, Timeout); Start Audio Playback Hardware.

stop	g_sf_audio_playback_hw0.p_api->stop(g_sf_audio_playback_hw0.p_ctrl); Stop Audio Playback Hardware.
play	g_sf_audio_playback_hw0.p_api->play (g_sf_audio_playback_hw0.p_ctrl, p_buffer, length); Play audio buffer.
dataTypeGet	g_sf_audio_playback_hw0.p_api->dataTypeGet(g_sf_audio_playback_hw0.p_ctrl, p_data_type); Store expected data type in provided pointer p_data_type.
close	g_sf_audio_playback_hw0.p_api->close(g_sf_audio_playback_hw0.p_ctrl); Close the audio module.
versionGet	g_sf_audio_playback_hw0.p_api->versionGet(&version); Return the version of the module with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	A pointer is NULL or a parameter is invalid.
SSP_ERR_OUT_OF_MEMORY	The number of streams open at once is limited to SF_AUDIO_PLAYBACK_CFG_MAX_STREAMS. If this number is exceeded, an out of memory error occurs.
SSP_ERR_TIMEOUT	Timeout occurred before playback finished.
SSP_ERR_NOT_OPEN	The stream control block p_ctrl is not initialized.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.3.3 Audio Playback DAC Framework Module Operational Overview

The Audio Playback Framework DAC module creates a thread internally to support audio playback. The following figure shows a flowchart of the Audio Playback Framework thread and its interactions with public Audio Playback Framework APIs.

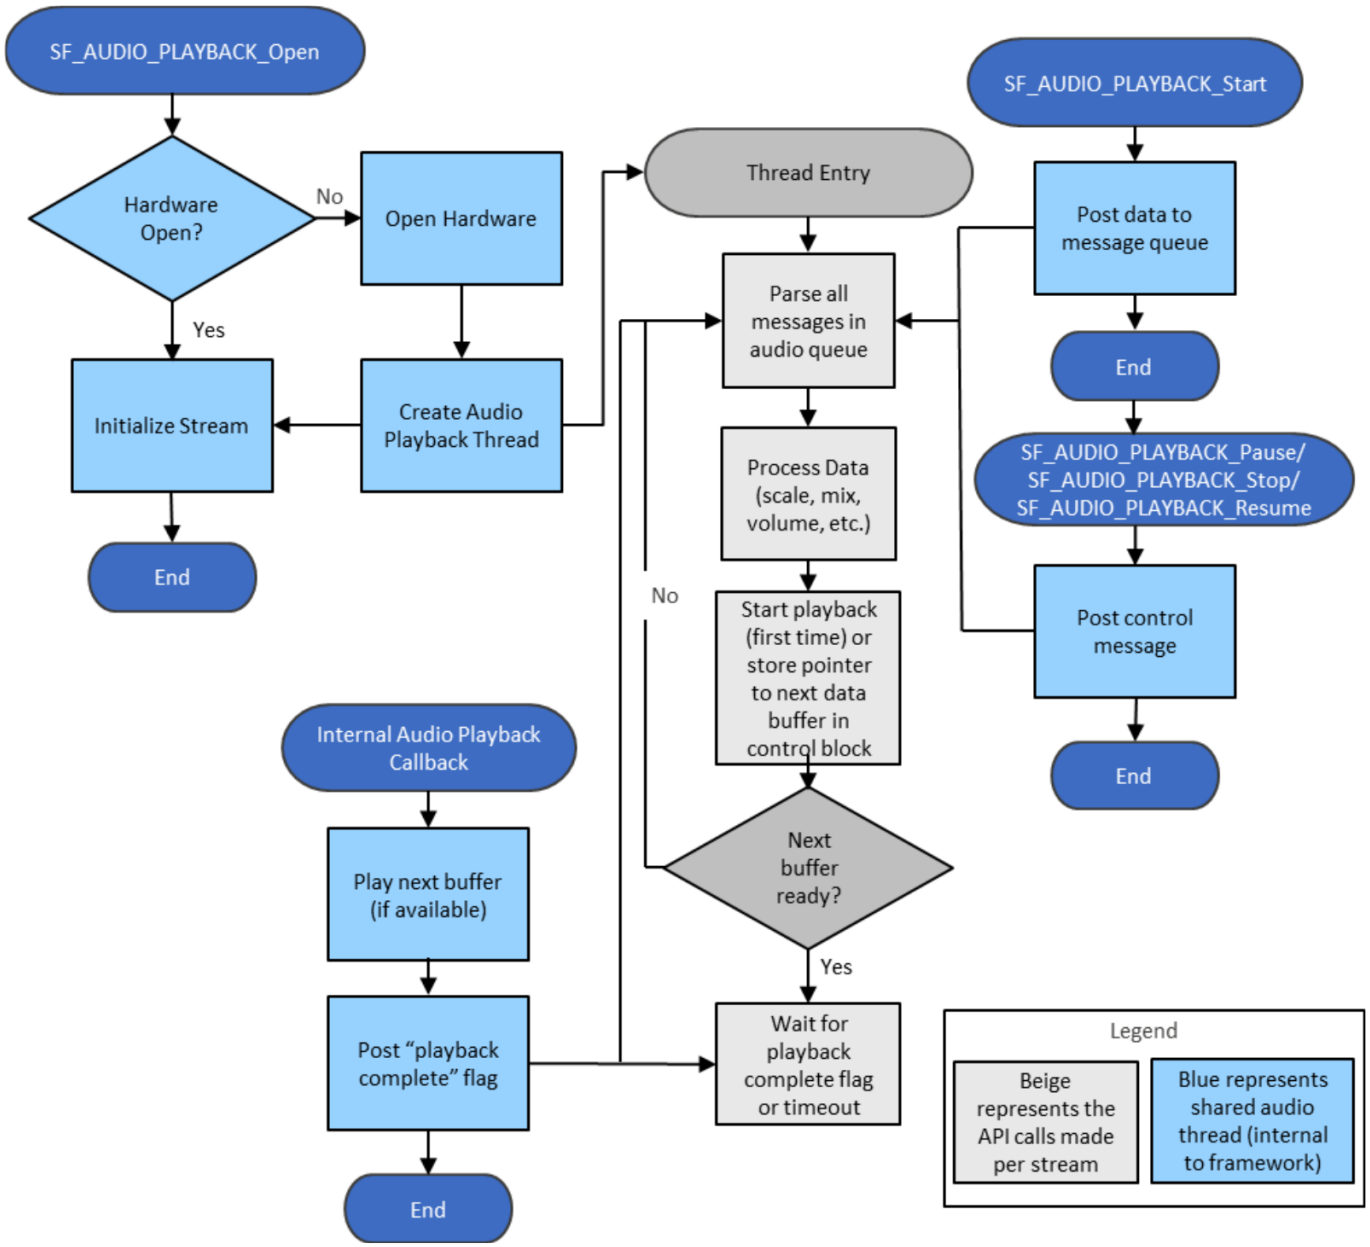

Figure 112: Audio Playback DAC Framework Module Flow Chart

Suggested use of the Audio Playback Framework:

- Create a semaphore (for example, 'g_sf_audio_playback_semaphore'). This can be done on the **Threads** tab. Set the initial value to 2 (the audio playback framework can store up to two data messages per stream).
- Create a callback function (for example, 'sf_audio_playback_callback)'. Enter the name of your callback function in the Audio Playback Framework instance. The callback function will be called when the Audio Playback Framework is done with the data. In the callback, put the semaphore created above.
- In your main loop, get the semaphore before playing data. To play data, first acquire a buffer from the messaging framework, then create your audio playback data structure inside the buffer.

The Audio Playback DAC Framework supports multiple audio streams on a single hardware port. A

block diagram of the modules required if two streams are used is shown in the following figure:

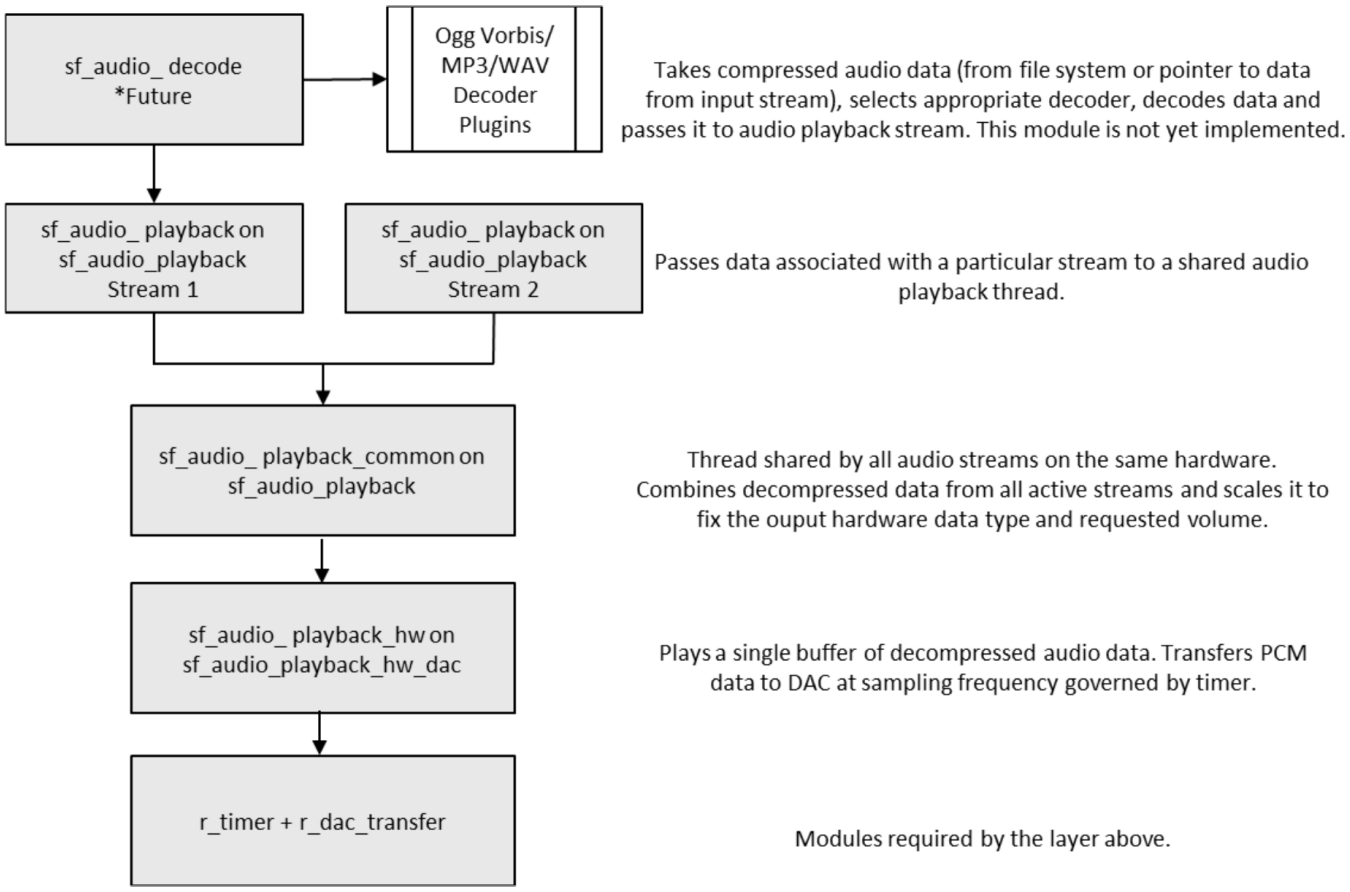

Figure 113: Audio Playback DAC Framework Implementing Multiple Audio Streams

Audio Playback DAC Framework Module Important Operational Notes and Limitations

Audio Playback DAC Framework Module Operational Notes

- The Audio Framework DAC hardware port uses the transfer API to transfer audio data from a playback buffer to DAC at a sampling frequency defined by an internal timer.
- The Audio Framework DAC hardware port has dependencies on the Timer, DAC/DAC8, and Transfer API modules.
- Add a Timer module.
    - Set the Frequency in Hz to the sampling frequency of your audio data.
    - Enable the interrupt if using DTC as the transfer module (recommended).
- Add a Transfer module: select either the DTC or DMAC.
- For DTC:
    - Set Destination pointer to &R_DAC->DADRn[0] if using DAC channel 0 or &R_DAC->DADRn[1] if using DAC channel 1.
    - Set Destination pointer to &R_DAC8->DADRn[2] if using DAC8 channel 2 (S128) or &R_DAC8->DADRn[0] if using DAC8 channel 0 (S1JA).
    - Set the activation source to the timer interrupt chosen above.
- For DMAC:
    - Enable the DMAC support
    - Set Destination pointer to &R_DAC->DADRn[0] if using DAC channel 0 or &R_DAC->DADRn[1] if using DAC channel 1.
    - Set Destination pointer to &R_DAC8->DADRn[2] if using DAC8 channel 2 (S128) or

&R_DAC8->DADRn[0] if using DAC8 channel 0 (S1JA).
    - Set the activation source to the timer interrupt chosen above.
- The Audio Playback DAC Framework is designed to support the following MCU families with no changes to the API:
    - S7G2
    - S3A3
    - S5D9
    - S3A7
    - S124
    - S3A6
    - S5D5
    - S3A1
    - S128
    - S1JA
    - S5D3

Audio Playback DAC Framework Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.3.4 Including the Audio Playback DAC Framework Module in an Application

This section describes how to include the Audio Playback DAC Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Audio Playback DAC Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Audio Playback DAC Framework module is g_sf_audio_playback_hw0. This name can be changed in the associated Properties window.)

Audio Playback DAC Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_audio_playback_hw0 Audio Playback Hardware Framework on g_sf_audio_playback_hw0	Threads	**New Stack> Framework> Audio> Audio Playback Hardware Framework on g_sf_audio_playback_hw_dac**

When the Audio Playback DAC Framework module on sf_audio_playback_hw_dac is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

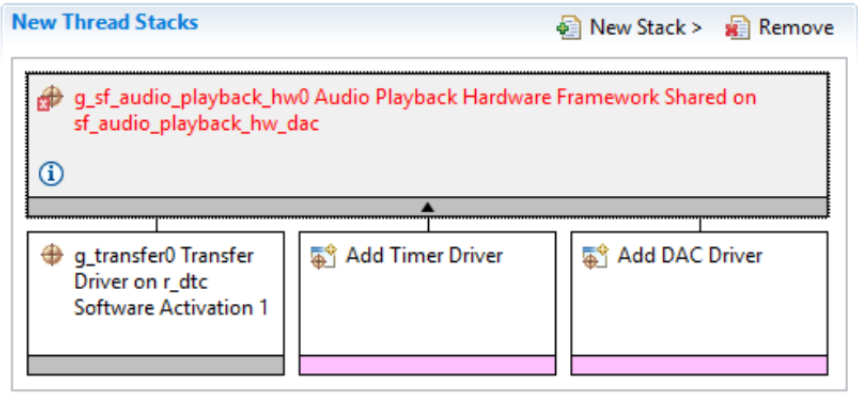

Figure 114: Audio Playback DAC Framework Module Stack

Note

Selection options of DAC or DAC8 Driver is MCU specific

4.1.3.5 Configuring the Audio Playback DAC Framework Module

The Audio Playback DAC Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Audio Playback DAC Framework Module on sf_audio_playback_hw_dac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
DMAC Support	Disabled, Enabled Default: Disabled	DMAC support selection.
Name	g_sf_audio_playback_hw0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. For example, it might be useful to select the DAC channel based on the target hardware implementation. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower level modules are fairly intuitive and can usually be determined by inspection of the associated Properties window from the SSP configurator.

Configuring the Audio Playback DAC Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the Transfer Driver on r_dmac Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_transfer0	Module name.
Channel	0	Channel selection.
Mode	Normal	Mode selection.
Transfer Size	2 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source	Software Activation, Peripheral Events Default: Software Activation	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback	NULL	Callback selection.

Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dmac Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	2 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.

ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Timer Driver on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables parameter checking.
Name	g_timer0	Module name.
Channel	0	Physical hardware channel.
Mode	Periodic	Warning: One-shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISRs must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation.
Period Unit	Hertz	See Timer Period Calculation.
Auto Start	False	Set to true to start the timer after configuring or false to leave the timer stopped until timer_api_t::start is called.
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	The clock source for the AGT counter.
AGTO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTO pin). Set to false for no output of the timer signal.
AGTIO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTIO pin). Set to false for no output of the timer signal.

Output Inverted	True, False Default: False	Set to false to start the output signal low. Set to true to start the output signal high.
Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection.
Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection.
Callback	NULL	A user callback function can be registered in timer_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Timer interrupt priority. 0 is the highest priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Timer Driver on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_timer0	Module name.
Channel	0	Channel selection.

Mode	Periodic	Warning: One-shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISRs must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation.
Period Unit	Hertz	See Timer Period Calculation.
Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection.
Auto Start	False	Set to true to start the timer after configuring or false to leave the timer stopped until timer_api_t::start is called.
GTIOCA Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
GTIOCB Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.

Callback	NULL	A user callback function can be registered in timer_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DAC HAL Module on r_dac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_dac0	Module name.
Channel	0	Set to 0 for output DA0 or 1 for output DA1.
Synchronize with ADC	Enabled, Disabled Default: Disabled	Set to true for anti-interference synchronization with the Analog-to-Digital Converter (ADC) Module. Set to false if power supply interference between the analog modules is not a problem, or if asynchronous conversion by the DAC Module is desired.
Data Format	Right Justified	Set to zero, if 12-bit data values are loaded in bits 11 through 0, or right justified. Set to one, if 12-bit data values are loaded in bits 15 through 4, or left justified.

Output Amplifier	Enable, Disable Default: Disable	Set to true, if output amplifier hardware function is desired. Set to false to bypass output amplifier hardware function.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DAC8 HAL Module r_dac8

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_dac8_0	Module name.
Channel	0	Channel selection.
Synchronize with ADC	Enabled, Disabled Default: Disabled	Choose whether to sync with the ADC module.
Data Format	Right Justified	Data format selection.
DAC Mode	Normal Mode, Real-time (Event Link) Mode Default: Normal Mode	DAC mode selection.
Charge Pump Enabled (Requires MOCO active)	Enabled, Disabled Default: Enabled	Enable or disable the charge pump.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Audio Playback DAC Framework Module Clock Configuration

The Audio Playback DAC Framework hardware modules use the peripheral clocks available in the Clocks configuration window.

Audio Playback DAC Framework Module Pin Configuration

The DAC or SSI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following tables illustrate the method for selecting the pins within the SSP configuration window and show an example selection for the associated pins.

Note

For some peripherals, the operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for the Audio Playback DAC Framework Module

Resource	ISDE Tab	Pin selection Sequence

DAC	Pins	Select **Peripherals** > **Analog:DAC12** > **DAC120/121**
SSI	Pins	Select **Peripherals** > **Connectivity:SSI** > **SSI/0/1**

Note

The selection sequence assumes the DAC0/DAC1 or the SSI0/SSI1 is the desired hardware target of the driver.

Pin Configuration Settings for the DAC HAL Module on r_dac

Pin Configuration Property	Value	Description
Operation Mode	Enabled, Disabled	Operation selection.
DAC	None, P014 Default: P014	DAC pin selection.

Note

The example values are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.3.6 Using the Audio Playback DAC Framework Module in an Application

The typical steps in using the Audio Playback DAC Framework module in an application are:

1. Initialize the Audio Playback DAC Framework using the sf_audio_playback_hw_api_t::open API
2. Start the low level hardware of the Audio Playback DAC Framework using the sf_audio_playback_hw_api_t::start API.
3. Play the PCM audio samples using the sf_audio_playback_hw_api_t::play API.
4. PCM audio samples supported by the hardware is provided by the sf_audio_playback_hw_api_t::dataTypeGet API.
5. Stop the low level hardware of the Audio Playback DAC Framework using sf_audio_playback_hw_api_t::stop API.
6. Close the Audio Playback DAC Framework using the sf_audio_playback_hw_api_t::close API.

These common steps are illustrated in a typical operational flow in the following figure:

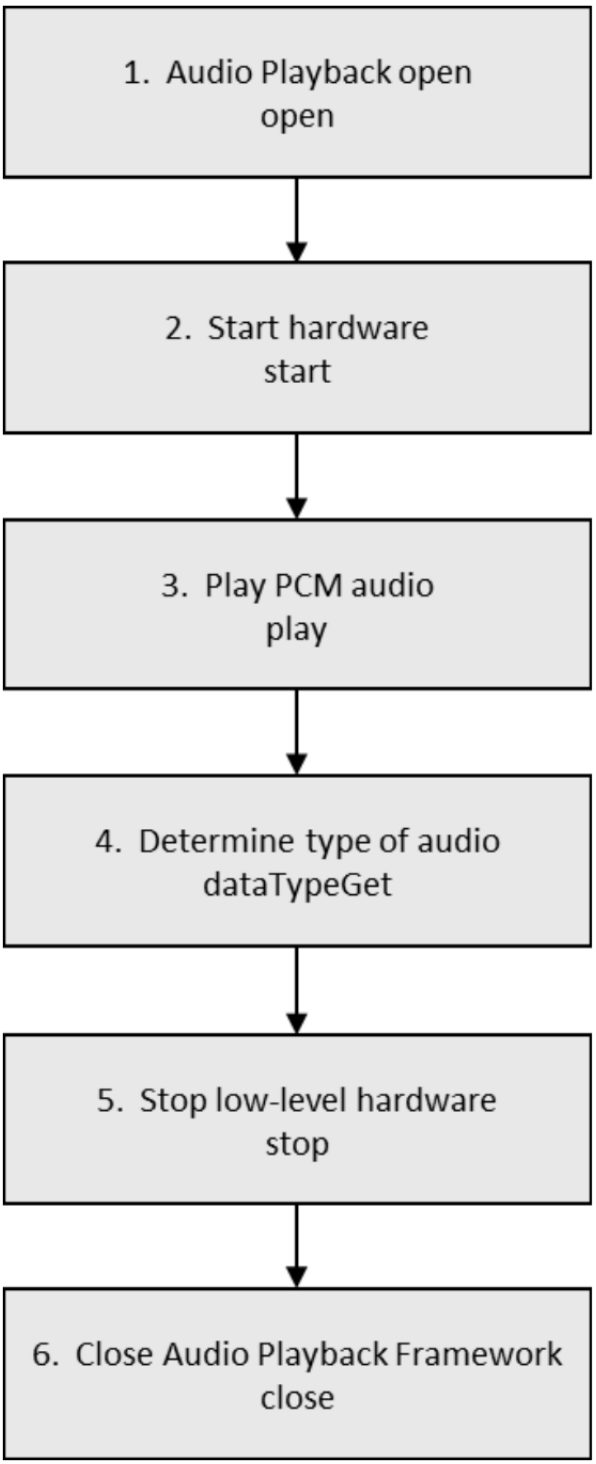

Figure 115: Flow Diagram of a Typical Audio Playback DAC Framework Module Application

4.1.4 Audio Playback Hardware Framework Shared on sf_audio_playback_hw_i2s

4.1.4.1 Audio Playback I2S Framework Introduction

The I2S Audio Playback Framework module provides a high-level API for Audio Playback applications and handles the synchronization needed to play 8-bit or 16-bit pulse-code modulation (PCM) samples. The Audio Playback Framework uses the I2S, Timer (AGT or GPT) and Data Transfer (DMA or DTC) peripherals on a Synergy MCU. A user defined callback can be created to respond to the need for additional data.

Audio Playback I2S Framework Module Features

- Plays long buffers by splitting the data into manageable chunks.
- Repeats playback until ThreadX timeout (for repeated audio like sine wave tones or looped background music).
- Requests next data using callback after last buffer playback begins.
- Software volume control.
- Pauses and resumes functions.
- Basic mixing for multiple streams.

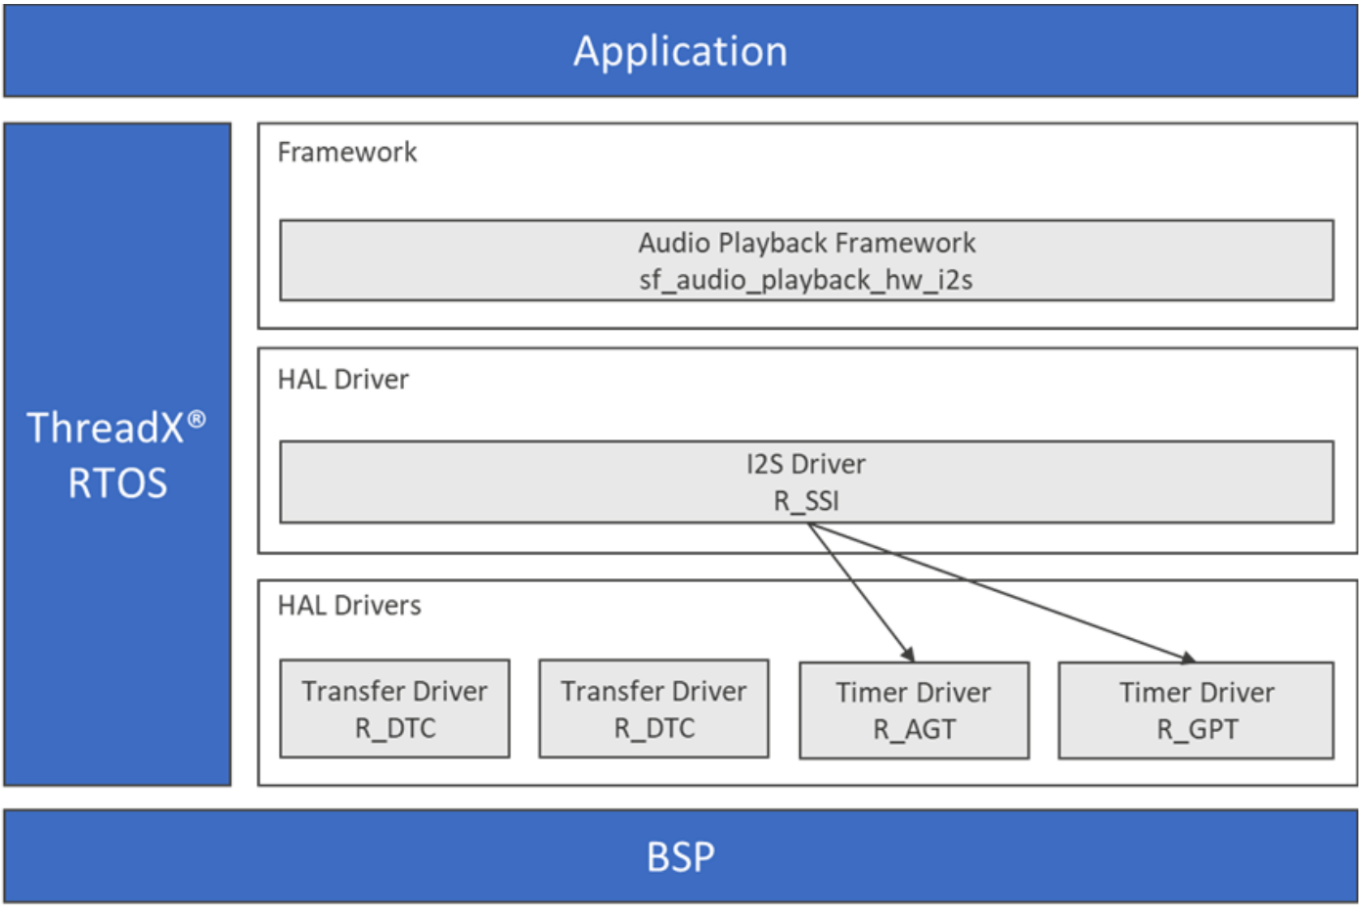

Figure 116: Audio Playback I2S Framework Module Block Diagram

4.1.4.2 Audio Playback I2S Framework Module APIs Overview

The Audio Playback I2S Framework module defines APIs for operations such as opening, starting, playing and stopping. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Audio Playback I2S Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_audio_playback_hw0.p_api->open(g_sf_audio_playback_hw0.p_ctrl, g_sf_audio_playback_hw0.p_cfg); Open a device channel for read/write and control.
start	g_sf_audio_playback_hw0.p_api->start(g_sf_audio_playback_hw0.p_ctrl, &p_data, Timeout); Start Audio Playback Hardware.
stop	g_sf_audio_playback_hw0.p_api->stop(g_sf_audio_playback_hw0.p_ctrl); Stop Audio Playback Hardware.
play	g_sf_audio_playback_hw0.p_api->play (g_sf_audio_playback_hw0.p_ctrl, p_buffer, length); Play audio buffer.
dataTypeGet	g_sf_audio_playback_hw0.p_api->dataTypeGet(g_sf_audio_playback_hw0.p_ctrl, p_data_type); Stores expected data type in provided pointer p_data_type.
close	g_sf_audio_playback_hw0.p_api->close(g_sf_audio_playback_hw0.p_ctrl); Close the audio module.
versionGet	g_sf_audio_playback_hw0.p_api->versionGet(&version); Return the version of the module with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_OUT_OF_MEMORY	The number of streams open at once is limited to SF_AUDIO_PLAYBACK_CFG_MAX_STREAMS. If thisnumber is exceeded, an out of memory error occurs.
SSP_ERR_TIMEOUT	Timeout occurred before playback finished.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.4.3 Audio Playback I2S Framework Module Operational Overview

The I2S Audio Playback Framework module creates a thread internally to support audio playback. The figure below shows a flowchart of the audio playback framework thread and its interactions with public Audio Playback Framework APIs.

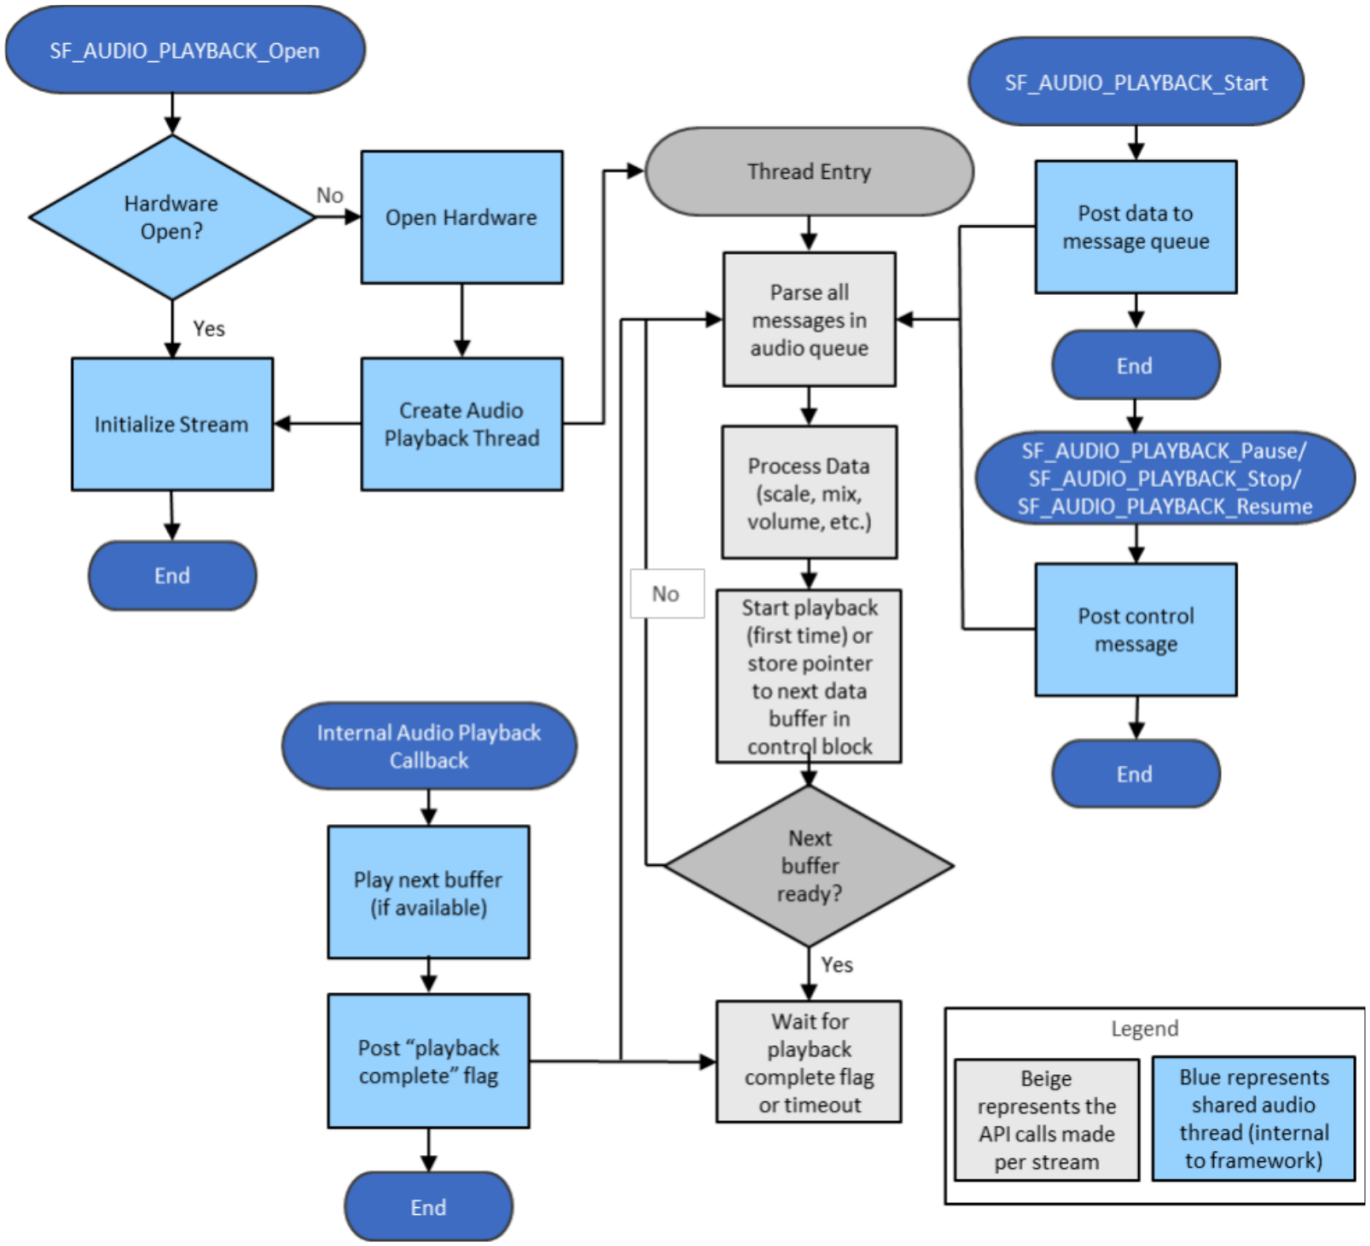

Figure 117: Audio Playback DAC Framework Module Flow Chart

Suggested use of the audio playback framework:

- Create a semaphore (for example g_sf_audio_playback_semaphore). This can be done on the **Threads** tab. Set the initial value to 2 (the audio playback framework can store up to two data messages per stream).

- Create a callback function (for example sf_audio_playback_callback). Enter the name of your callback function in the Audio Playback Framework instance. The callback function will be called when the audio playback framework is done with the data. In the callback, put the semaphore created above.
- In your main loop, get the semaphore before playing data. To play data, first acquire a buffer from the messaging framework, then create your audio playback data structure inside the buffer.

The Audio Playback Framework supports multiple audio streams on a single hardware port. A block diagram of the modules required if two streams are used is shown in following figure:

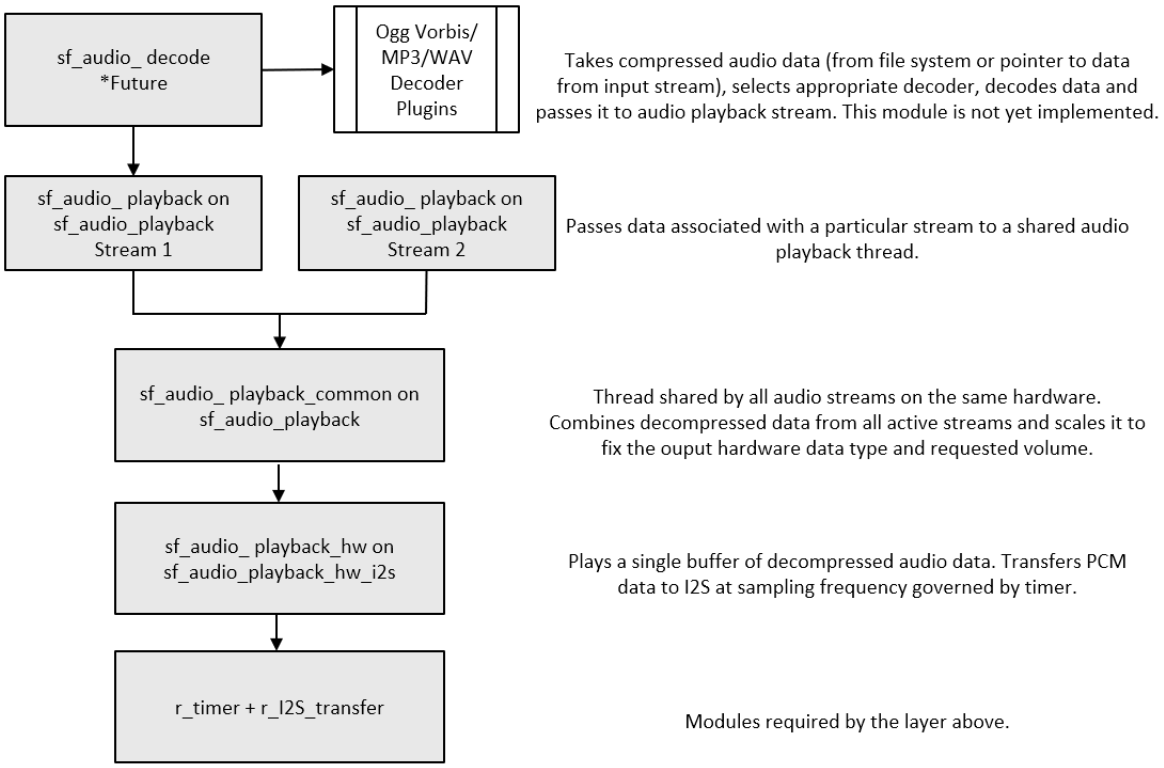

Figure 118: Audio Playback DAC Framework Implementing Multiple Audio Streams

Audio Playback I2S Framework Module Important Operational Notes and Limitations

Audio Playback I2S Framework Module Operational Notes

- The queue used must match the name specified in Properties for Audio Playback Framework Shared on sf_audio_playback (default is g_sf_audio_playback_queue).
- The audio framework I2S hardware port has dependencies on the I2S driver module. The I2S driver module can be accelerated with DTC (recommended).
- I2S driver module.
    - Set the Audio Clock Frequency (Hertz) to the frequency of the input audio clock used.
    - Set the Sampling Frequency (Hertz) to the sampling frequency of your audio data.
    - Set the Data Bits and Word Length to 16 bits (audio framework accepts 16 bit samples only).
    - Enable the SSIn TXI and SSIn INT interrupts.
- Transfer module on r_dtc (recommended).
- Set the activation source to the SSIn TXI interrupt.

- The Audio Playback I2S Framework is designed to support the following MCU families with no changes to the API:
  - S7G2
  - S3A7
  - S5D9
  - S3A3
  - S3A6
  - S5D5
  - S3A1
  - S5D3

Audio Playback I2S Framework Module Limitations

- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.1.4.4 Including the Audio Playback I2S Framework Module in an Application

This section describes how to include the Audio Playback I2S Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Audio Playback I2S Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Audio Playback I2S Framework module is g_sf_audio_playback_hw0. This name can be changed in the associated Properties window.)

Audio Playback I2S Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_audio_playback_hw0 Audio Playback Hardware Framework on sf_audio_playback_hw_i2s	Threads	**New Stack> Framework> Audio> Audio Playback Hardware Framework on sf_audio_playback_hw_i2s**

When the Audio Playback I2S Framework module on sf_audio_playback_hw_i2s is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

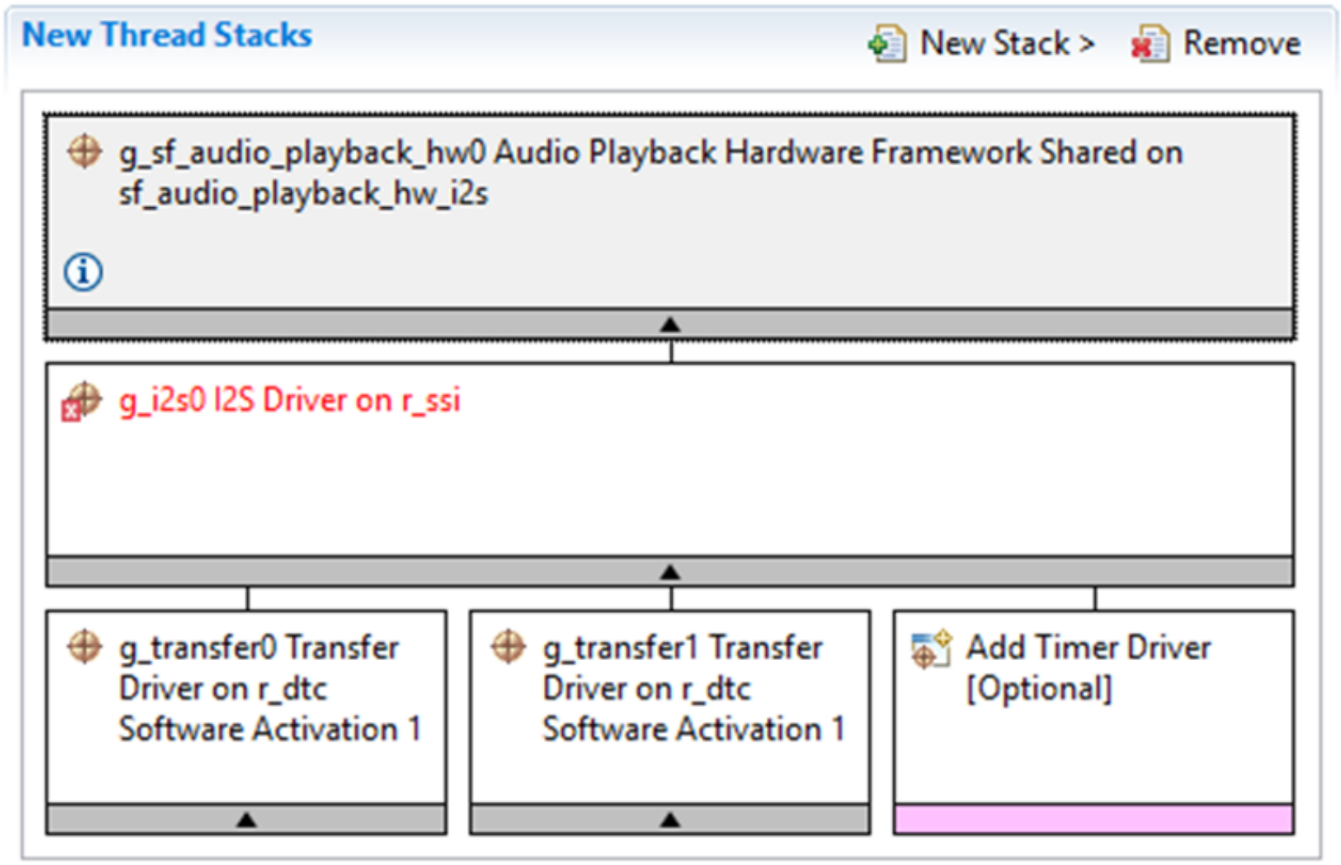

Figure 119: Audio Playback I2S Framework Module Stack

4.1.4.5 Configuring the Audio Playback I2S Framework Module

The Audio Playback I2S Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Audio Playback I2S Framework Module on sf_audio_playback_hw_i2s

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_sf_audio_playback_hw0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower level modules can be desirable. For example, it might be useful to select the DAC or I2S Channel based on the target hardware implementation. The configurable properties for the lower level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower level modules are fairly intuitive and can usually be determined by inspection of the associated Properties window from the SSP configurator.

Configuring the Audio Playback I2S Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the I2S HAL Module on r_ssi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_i2s0	Module name.
Channel	0	Physical hardware channel.
Audio Clock Frequency (Hertz)	2822400	Input audio clock frequency, used to generate the I2S clock. Must be a multiple between 1 and 128 of: (sampling_freq_hz * word_length_in_bits).
Sampling Frequecy (Hertz)	44100	Sampling frequency of audio data.
Data Bits	8 bits, 16, 18, 20, 22, 24 Default: 16 bits	Bit depth of audio data, which is the size in bits of one sample of audio data.
Word Length	8 bits, 16, 24, 32 Default: 16 bits	Word length of audio data, must be at least the same size as the bit depth (Data Bits field).

WS Continue Mode	Enabled, Disabled Default: Disabled	Enable WS continue mode to continue to output the word select line when the peripheral is idle. Disable to stop outputting the word select line when the peripheral is idle.
Name of I2S callback function to be defined by user	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) when the transmission FIFO reaches the high watermark point after all data for transmission is transmitted or when reception is complete (the requested number of bytes have been received). Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Transmit interrupt priority selection.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Receive interrupt priority selection.
Idle/Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Idle/error interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.

Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activiation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC software event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.

Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activiation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC software event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Timer Driver on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables parameter checking.

Name	g_timer0	Module name.
Channel	0	Physical hardware channel.
Mode	Periodic	Warning: One-shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISRs must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation.
Period Unit	Hertz	See Timer Period Calculation.
Auto Start	False	Set to true to start the timer after configuring or false to leave the timer stopped until timer_api_t::start is called.
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	The clock source for the AGT counter.
AGTO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTO pin). Set to false for no output of the timer signal.
AGTIO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTIO pin). Set to false for no output of the timer signal.
Output Inverted	True, False Default: False	Set to false to start the output signal low. Set to true to start the output signal high.
Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection.
Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection.

Callback	NULL	A user callback function can be registered in timer_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Timer interrupt priority. 0 is the highest priority.
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables parameter checking.
Name	g_timer0	Module name.
Channel	0	Physical hardware channel.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Timer Driver on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Mode selection.
Period Value	2822400 *2	Period value selection.
Period Unit	Hertz	Period unit selection.
Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection.

Auto Start	FALSE	Auto start selection.
GTIOCA Output Enabled	True, False Default: False	GTIOCA output enabled selection.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCA stop level selection.
GTIOCB Output Enabled	True, False Default: False	GTIOCB output enabled selection.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCB stop level selection.
Callback	NULL	Callback selection.
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Audio Playback I2S Framework Module Clock Configuration

The Audio Playback I2S Framework hardware modules use the peripheral clocks available in the clock configuration window.

Audio Playback I2S Framework Module Pin Configuration

The SSI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following tables illustrate the method for selecting the pins within the SSP configuration window and shows an example selection for the associated pins.

Pin Selection Sequence for the Audio Playback I2S Framework Module

Resource	ISDE Tab	Pin selection Sequence
I2S	Pins	Select **Peripherals** > **Connectivity:SSI** > **SSI0/SSI1**.

Note

The selection sequence assumes the ADC0/ADC1 or the SSI0/SSI1 is the desired hardware target of the driver.

Pin Configuration Settings for the I2S Driver on r_ssi

Pin Configuration Property	Value	Description
Pin Group Selection	_A only, _B only, Mixed	Pin group for I2S port.
Operation Mode	Enabled, Custom, Disabled	Operation selection.
SSISCK	None, P204 Default: None	SSI Serial clock.
SSIWS	None, P205 Default: None	SSI Stereo pin selection.
SSIDATA	None, P206 Default: None	SSI Data pin selection.

Note

The example values are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.4.6 Using the Audio Playback I2S Framework Module in an Application

The typical steps in using the Audio Playback I2S Framework module in an application are:

1. Initialize the Audio Playback I2S Framework using the sf_audio_playback_hw_api_t::open API.

2. Start the low level hardware of the Audio Playback I2S framework using the sf_audio_playback_hw_api_t::start API.

3. Play the PCM audio samples using the sf_audio_playback_hw_api_t::play API.

4. PCM audio samples supported by the hardware is provided by the sf_audio_playback_hw_api_t::dataTypeGet API.

5. Stop the low level hardware of the Audio Playback I2S Framework using sf_audio_playback_hw_api_t::stop API.

6. Close the Audio Playback I2S framework using the sf_audio_playback_hw_api_t::close API.

These common steps are illustrated in a typical operational flow in the following figure:

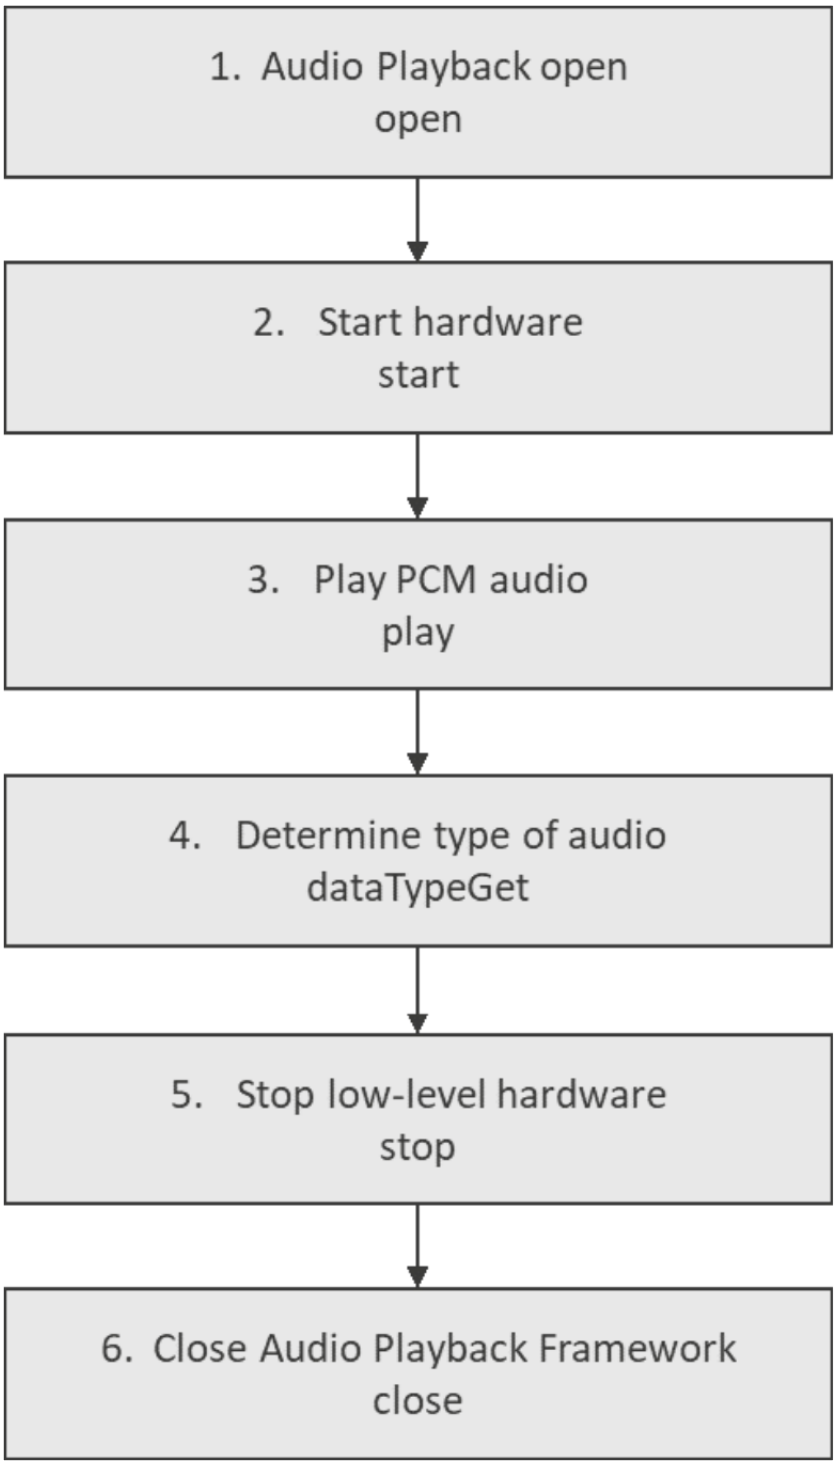

Figure 120: Flow Diagram of a Typical Audio Playback I2S Framework Module Application

4.1.5 Audio Record ADC Framework

4.1.5.1 Audio Record ADC Framework Module Introduction

The Audio Record ADC Framework module provides a high-level API for audio recording applications and uses the sf_adc_periodic and its lower layer ADC, GPT and DTC peripherals on the Synergy MCU. A user-defined callback can be created to indicate that the sample count has been completed.

Audio Record ADC Framework Module Features

- Currently supports 12-bit ADCs (supports 8, 10, and 12 bits) and 14-bit ADCs (supports 14 or 12-bit PCM data)
- Uses ADC Periodic Framework to simplify configuration and integration
- Uses a ThreadX object (for example, mutex) to protect hardware from improper access
- APIs for high-level functions simplify coding:
    - sf_audio_record_api_t::open, sf_audio_record_api_t::start
    - sf_audio_record_api_t::stop, sf_audio_record_api_t::infoGet
    - sf_audio_record_api_t::close

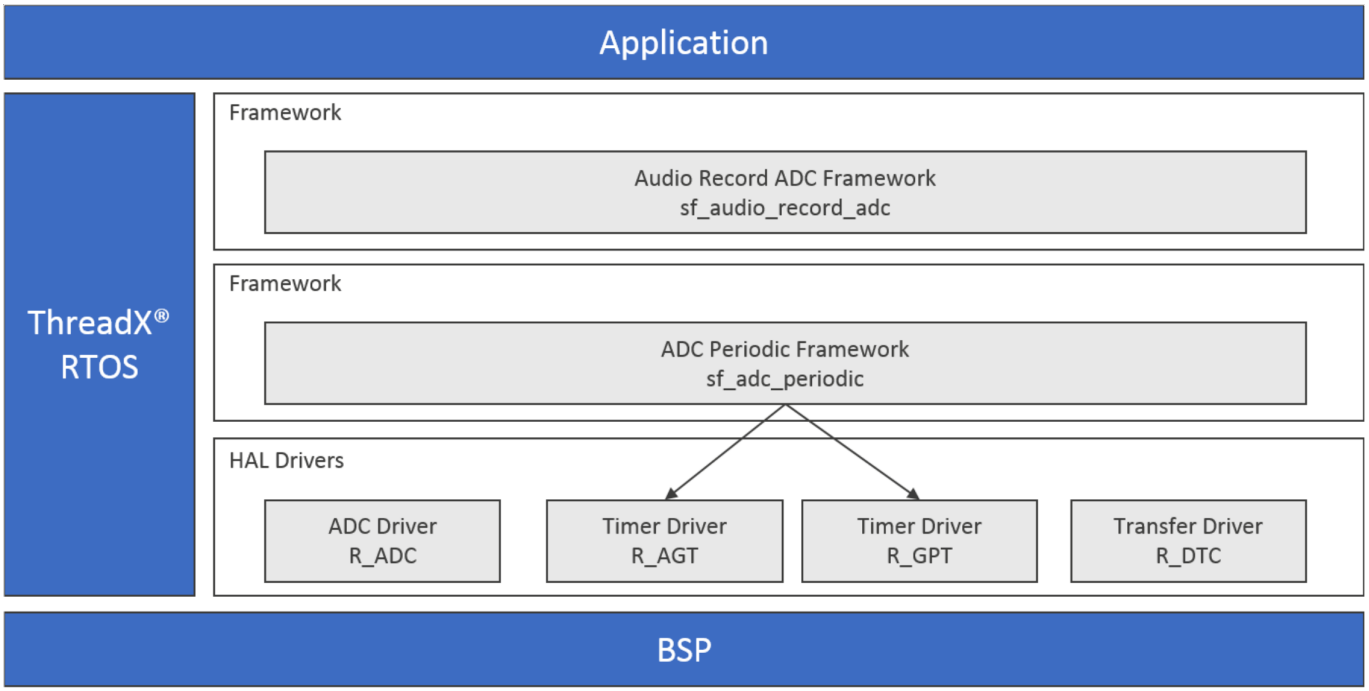

Figure 121: Audio Record ADC Framework Module Block Diagram

4.1.5.2 Audio Record ADC Framework Module APIs Overview

The Audio Record ADC Framework module defines APIs for opening, closing, starting and stopping the record process. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Audio Record ADC Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_audio_record_adc.p_api->open(g_sf_audio_record_adc.p_ctrl, g_sf_audio_record_adc.p_cfg); Initialize the module.

start	g_sf_audio_record_adc.p_api->start(g_sf_audio_record_adc.p_ctrl); Start audio recording.
stop	g_sf_audio_record_adc.p_api->stop(g_sf_audio_record_adc.p_ctrl); Stop audio recording.
infoGet	g_sf_audio_record_adc.p_api->infoGet(g_sf_audio_record_adc.p_api.p_ctrl; Get the channel information (mono or Stereo).
close	g_sf_audio_record_adc.p_api->close(g_sf_audio_record_adc.p_ctrl); Close the module.
versionGet	g_sf_audio_record_adc.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUME	Parameter has invalid value.
SSP_ERR_IN_USE	The adc periodic framework mutex may be unavailable for the unit requested. See HAL driver for other possible causes.
SSP_ERR_INTERNAL	An internal ThreadX error has occurred. This is typically a failure to create/use a mutex or to create an internal thread.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_UNSUPPORTED	This function is not supported by the HAL driver (p_ctrl->p_api->close is NULL).

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.5.3 Audio Record ADC Framework Module Operational Overview

The Audio Record ADC Framework Module samples audio analog data using the ADC Periodic Framework and the data samples captured are stored in the user buffer. The data is made available for further processing as needed by the application. The Audio Record ADC Framework has a configuration parameter that is initialized during the framework initialization, which also initializes

the underlying ADC periodic framework for data capture.

The captured data is stored in a user defined buffer and this is done in the callback function as illustrated below:

Assuming the name of the callback has been configured to be sf_audio_record_user_callback:

```
uint16_t * audio_record_buffer;
void sf_audio_record_user_callback (sf_audio_record_callback_args_t *p_args)
{
audio_record_buffer = ((uint16_t *)g_sf_audio_record_adc.p_cfg->
p_capture_data_buffer + (p_args->buffer_index/2)); }
```

Audio Record ADC Framework Module Important Operational Notes and Limitations

Audio Record ADC Framework Module Operational Notes

- The Audio Record ADC Framework Module configuration data can specify the length of the data buffer, data width, sampling rate and the number of sampling iterations.

Audio Record ADC Framework Module Limitations

- Currently, the Audio Record ADC only supports the ADC Periodic Framework as the lower level; recording via the I2S is not supported.
- The framework currently supports recording 8 bit or 12 bit PCM data.
- Currently, the Audio Record ADC only supports mono channel.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.5.4 Including the Audio Record ADC Framework Module in an Application

This section describes how to include the Audio Record ADC Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Audio Record ADC Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the ADC Audio Record ADC Framework is g_adc_record_adc0. This name can be changed in the associated Properties window.)

Audio Record ADC Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_audio_record_adc0 Audio Record ADC Framework on sf_audio_record_adc	Threads	**New Stack> Driver> Audio> Audio Record ADC Framework on sf_audio_record_adc**

When the Audio Record ADC Framework on sf_audio_record_adc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

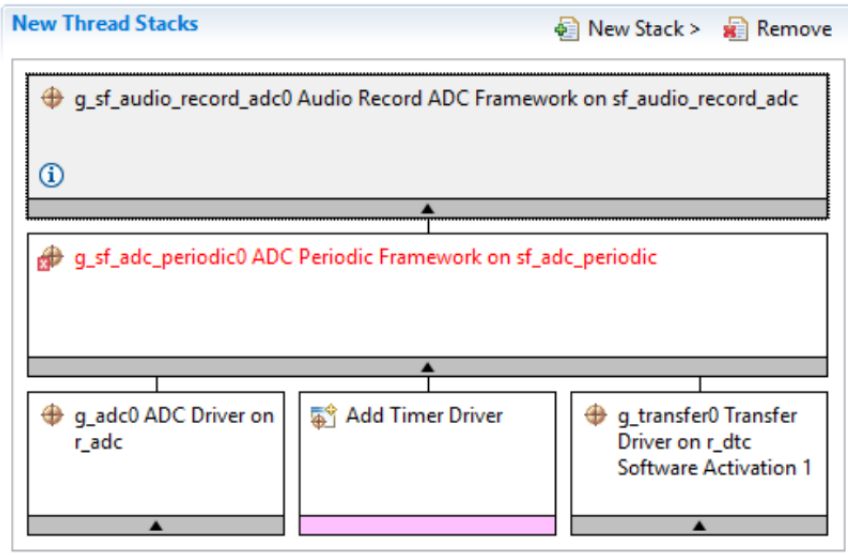

Figure 122: Audio Record ADC Framework Module Stack

4.1.5.5 Configuring the Audio Record ADC Framework Module

The Audio Record ADC Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Audio Record ADC Framework Module on sf_audio_record_adc

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_audio_record_adc0	Module name.
Name of the data-buffer to store samples	p_capture_data_buffer	Name of the 16-bit data buffer to store samples.
Length of the data-buffer	2048	Length of the buffer to which data is to be stored.
Audio Record Data Size	8-Bit, 16-Bit Default: 8-Bit	The data width of captured data 8 bit or 16 bit.
Sampling Rate in HZ	8000	Sampling rate to be used to capture data.
Number of sampling iterations	256	Samples to be captured.
Callback	g_audio_record_framework_user_callback	Callback to user after capturing the sample count.
Name of generated initialization function	sf_audio_record_adc_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Audio Record ADC Framework Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the ADC Periodic Framework on sf_adc_periodic

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_adc_periodic0	Module name.
Name of the data-buffer to store samples	g_user_buffer	Name of the 16-bit data buffer to store samples.
Length of the data-buffer	2048	Length of the buffer to which data is to be stored.

Number of sampling iterations	256	Priority of ADC Periodic Framework internal thread.
Callback	NULL	User function that will be called once "sample_counts" number of data has been buffered.
Name of generated initialization function	sf_adc_periodic_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the ADC HAL Module on r_adc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: Enabled	If selected code for parameter checking is included in the build.
Name	g_adc0	Module name.
Unit	0, 1 (S7G2 Only) Default: 0	Specify the ADC Unit to be used. The S7G2 has two units; 0 and 1.
Resolution	14-Bit (S3A7/S124 Only), 12-Bit, 10-Bit (S7G2) Default: 8-Bit (S7G2 Only)	Specify the conversion resolution for this unit.
Alignment	Right, Left Default: Right	Specify the conversion result alignment.
Clear after read	Off, On Default: On	Specify if the result register must be automatically cleared after the conversion result is read. Note: If this is enabled, then watching the result register using a debugger always results in a 0.
Mode	Single Scan	The ADC Framework preconfigures and locks this field.

Channels 0-6	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 7-10 (S3A7/S124 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 11-15 (S3A7 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 16-20	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 21 (Unit 0 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.

Channel 22 (S3A7/S124 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 23-27 (S3A7 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Temperature Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	Temperature sensor use selection for Channel Scan Mask.
Voltage Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	Voltage sensor use selection for Channel Scan Mask.
Normal/Group A Trigger	ELC Event	The ADC Framework preconfigures and locks this field.
Group B Trigger (Valid Only in Group Scan Mode)	ELC Event (The only valid trigger for either group in Group Scan Mode)	The ADC Framework preconfigures and locks this field.
Group Priority (Valid only in Group Scan Mode)	Group A cannot interrupt Group B, Group A can interrupt Group B; Group B scan restarts at next trigger, Group A can interrupt Group B; Group B scan restarts immediately, Group A can interrupt Group B; Group B scan restarts immediately and scans continuously Default: Group A cannot interrupt Group B	Do not use with ADC Framework since the mode is locked to Single Scan Mode.

Add/Average Count	Disabled, Add two samples, Add three samples, Add four samples, Add sixteen samples, Average two samples, Average four samples Default: Disabled	Specify if addition or averaging needs to be done for any of the channels in this unit. The actual channels are specified by using a channel mask adc_channel_cfg_t::add_mask.
Channels 0-27	Disabled, Enabled Default: Disabled	This field is valid only if adc_cfg_t::add_average_count is enabled. This field determines what channels results are to be averaged or summed.
Temperature Sensor	Disabled, Enabled Default: Disabled	Temperature sensor use selection for Addition/Averaging Mask.
Voltage Sensor	Disabled, Enabled Default: Disabled	Voltage sensor use selection for Addition/Averaging Mask.
Channels 0-2	Disabled, Enabled Default: Disabled	Determines which of channels 0, 1 and 2 are using the updated sample-and-hold states value specified in adc_channel_cfg_t::sample_hold_states. This field must only be set if it is desired to modify the default sample and hold count value for channels 0, 1 and 2.
Sample Hold States (Applies only to the 3 channels selected above)	24	Specifies the updated sample-and-hold count for the channel dedicated sample-and-hold circuit. This field is valid only if adc_channel_cfg_t::sample_hold_mask is not 0. Only channels 0, 1 and 2 have dedicated sample and hold circuits. Note: Use this to modify the default number of states (24) for which the value is sampled. Each state is equal to 1/ADCLK time.
Callback	NULL	The ADC Framework uses the callback internally.
Scan End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Scan End Interrupt Priority selection.

Scan End Group B Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Scan End Group B Interrupt Priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the AGT HAL Module on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables parameter checking.
Name	g_timer0	Module name.
Channel	0	Physical hardware channel.
Mode	Periodic	Warning: One-shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISRs must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation.
Period Unit	Raw Counts, Nanoseconds, Microseconds, Milliseconds, Seconds, Hertz, Kilohertz Default: Microseconds	See Timer Period Calculation.
Auto Start	False	Set to true to start the timer after configuring or false to leave the timer stopped until timer_api_t::start is called.
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	The clock source for the AGT counter.
AGTO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTO pin). Set to false for no output of the timer signal.

AGTIO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTIO pin). Set to false for no output of the timer signal.
Output Inverted	True, False Default: True	Set to false to start the output signal low. Set to true to start the output signal high.
Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection.
Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection.
Callback	NULL	A user callback function can be registered in timer_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Underflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Timer interrupt priority. 0 is the highest priority.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the GPT HAL Module on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_timer0	Module name.

Channel	0	The ADC Framework preconfigures and locks this field based on channel selected in the ADC Framework.
Mode	Periodic	The ADC Framework preconfigures and locks this field.
Period Value	10	Configure timer period to trigger ADC scans.
Period Unit	Raw Counts, Nanoseconds, Microseconds, Milliseconds, Seconds, Hertz, Kilohertz Default: Milliseconds	Configure units of the timer period set above.
Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection.
Auto Start	False	The ADC Framework preconfigures and locks this field.
GTIOCA Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
GTIOCB Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
Callback	NULL	The ADC Framework preconfigures and locks this field.
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Block	Mode selection.
Transfer Size	2 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	1	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	1	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have

different default values and available configuration settings.

Audio Record ADC Framework Module Clock Configuration

The ADC peripheral module uses the PCLKC as its clock source.

Audio Record ADC Framework Module Pin Configuration

The ADC peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. ADC pins must be configured as analog pins. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins.

Note

For some peripherals, the operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection for the Audio Record ADC Framework Module on sf_audio_record_adc

Resource	ISDE Tab	Pin selection Sequence
ADC	Pins	Select **Peripherals** > **Analog:ADC** > **ADC0**

Note

The selection sequence assumes KINT0 is the desired hardware target for the driver.

Pin Configuration Settings for the Audio Record ADC Framework Module on sf_audio_record_adc

Property	Value	Description
Operation Mode	Disabled, Custom Default: Custom	Select operating mode for ADC.
ADTRG	None, P407, P102 Default: None)	ADTRG pin.
AN00-19	None, Pnnn, Pmmm Default: None	Analog input pins.
PGAVSS0	None, P003 Default: None	PGAVSS pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.1.5.6 Using the Audio Record ADC Framework Module in an Application

The steps in using the Audio Record ADC Framework module on sf_audio_record_adc in a typical application are:

1. Open the module using the sf_audio_record_api_t::open API.
2. Start the recording using the sf_audio_record_api_t::start API.
3. Store data in a user buffer with the callback.

4. Operate on data as needed.
5. Close the module using the sf_audio_record_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

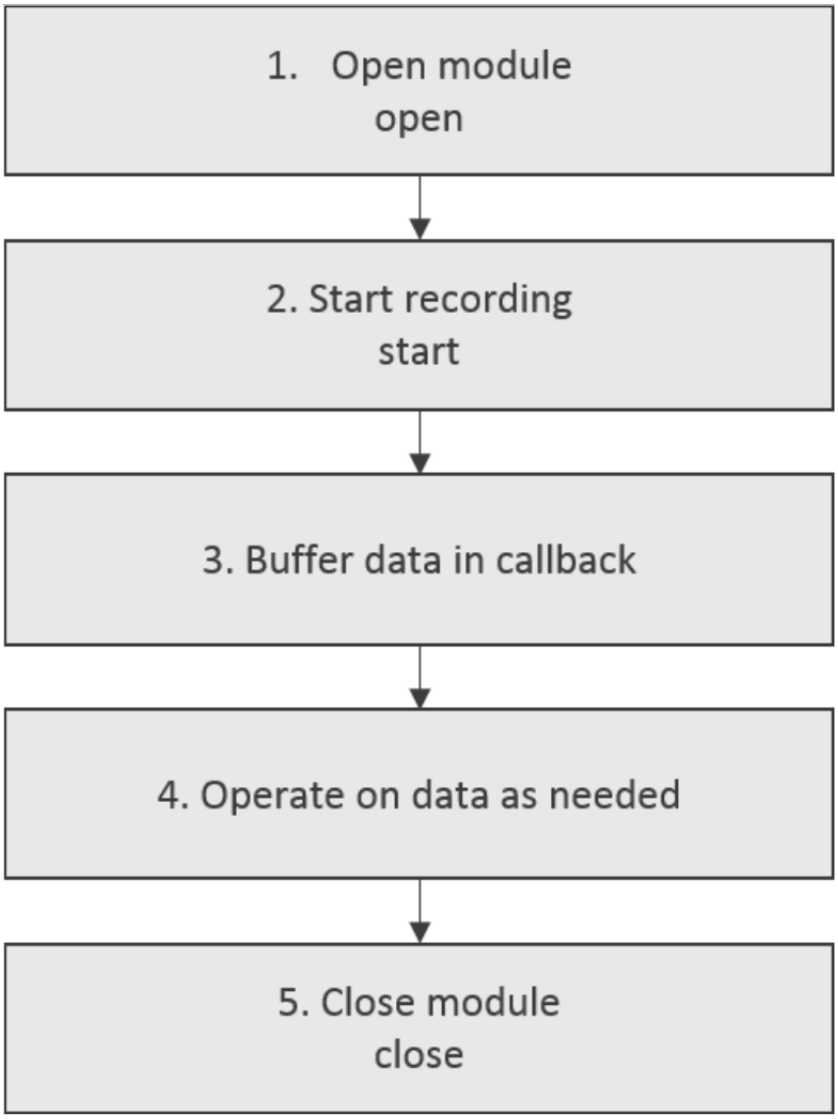

Figure 123: Flow Diagram of a Typical Audio Record ADC Framework Module Application

4.1.6 Audio Record I2S Framework

4.1.6.1 Audio Record I2S Framework Introduction

The Audio Record I2S Framework module provides a high-level API for audio recording applications and uses the I2S interface. The Audio Record I2S Framework module uses the SSI, GPT and DTC peripherals on the Synergy MCU. A user-defined callback can be created to indicate that new samples are stored in the user buffer.

Audio Record I2S Framework Module Features

- Thread safe
- Records data in 8 or 16-bit PCM
- Periodic callback function when new samples are available
- Configurable number of samples (sample count) per callback

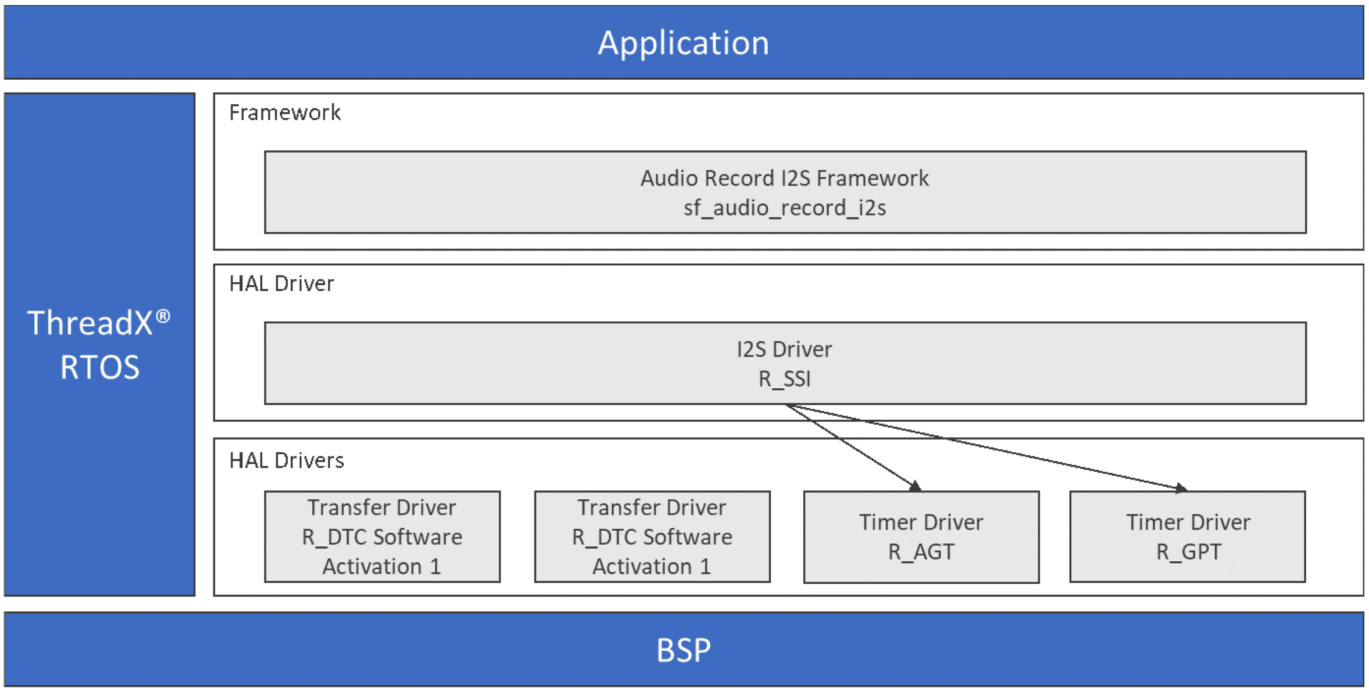

Figure 124: Audio Record I2S Framework Module Block Diagram

4.1.6.2 Audio Record I2S Framework Module APIs Overview

The Audio Record I2S Framework module defines APIs to open, start, stop and close the recording module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Audio Record I2S Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_audio_record_i2s0.p_api->open (g_sf_audio_record_i2s0.p_ctrl, g_sf_audio_record_i2s0.p_cfg); Initializes audio recording framework.
start	g_sf_audio_record_i2s0.p_api->start (g_sf_audio_record_i2s0.p_ctrl); Starts audio recording.
stop	g_ sf_audio_record_i2s0.p_api->stop (g_sf_audio_record_i2s0.p_ctrl); Stops audio recording.

infoGet	g_sf_audio_record_i2s0.p_api->infoGet (g_sf_audio_record_i2s0.p_ctrl, p_info); Gets channel information (Mono/Stereo).
close	g_sf_audio_record_i2s0.p_api->close (g_sf_audio_record_i2s0.p_ctrl); Releases channel mutex and closes channel at HAL layer.
versionGet	g_ sf_audio_record_i2s0.p_api->versionGet(&version); Gets version and stores it in provided version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INTERNAL	An internal TheadX error has occurred.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_IN_USE	Peripheral is still running in another mode; perform Close first.
SSP_ERR_UNSUPPORTED	Command not supported.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.6.3 Audio Record I2S Framework Module Operational Overview

The Audio Record I2S Framework Module uses the I2S HAL layer as the underlying interface for the audio data transfer and the data captured is stored in the user buffer. The data is made available for further processing as needed by the application.

The captured data is stored in a user defined buffer and this is done in the callback function as illustrated below:

Assuming the name of the callback has been configured to be sf_audio_record_user_callback.

```
uint16_t * audio_buffer;

void audio_record_user_callback (sf_audio_record_callback_args_t * p_args)
```

```
{
    audio_buffer = ((uint16_t *)sf_audio_record_i2s.p_cfg->p_capture_data_buffer
                   + (p_args->buffer_index));
}
```

Audio Record I2S Framework Module Important Operational Notes and Limitations

Audio Record I2S Framework Module Operational Notes

The Audio Record I2S Framework Module configuration data can specify the name of the data buffer, length of the data buffer, data size (8-bit or 16-bit samples), sampling iterations and the name of the callback.

Audio Record I2S Framework Module Limitations

- The framework currently supports recording 8-bit or 16-bit PCM data.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.6.4 Including the Audio Record I2S Framework Module in an Application

This section describes how to include the Audio Record I2S Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Audio Record I2S Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Audio Record I2S Framework module is g_sf_audio_record_i2s0. This name can be changed in the associated Properties window.)

Audio Record I2S Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_audio_record_i2s0 Audio Record I2S Framework on sf_audio_record_i2s	Threads	**New Stack> Framework> Audio> Audio Record I2S Framework on sf_audio_record_i2s**

When the Audio Record I2S Framework module on sf_audio_record_i2s is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink

banded modules brings up the New icon and displays possible choices.

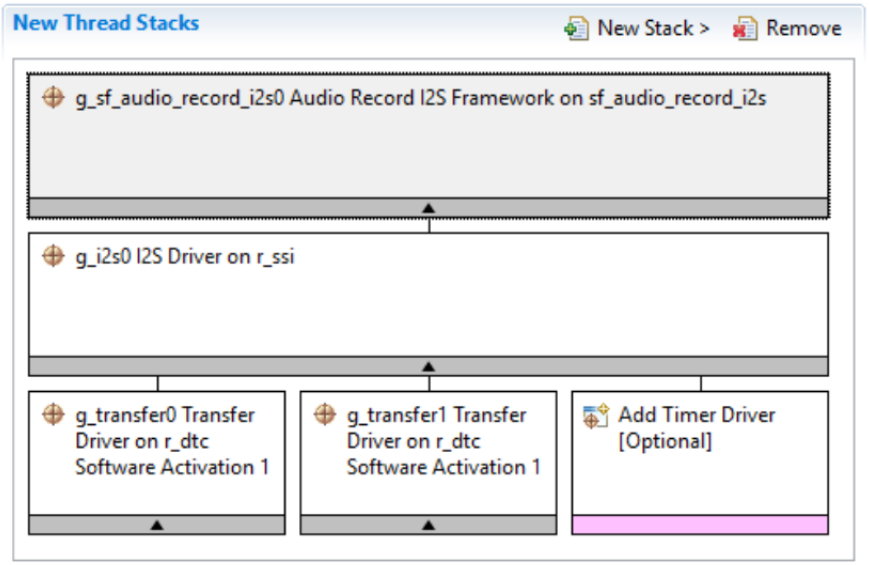

Figure 125: Audio Record I2S Framework Module Stack

4.1.6.5 Configuring the Audio Record I2S Framework Module

The Audio Record I2S Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Audio Record I2S Framework Module on sf_audio_record_i2s

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_audio_record_i2s0	Module name.
Name of the data-buffer to store samples	p_capture_data_buffer	Data-buffer name.
Length of the data buffer	2048	Length of the data buffer.

Audio Record Data Size	8-Bit, 16-Bit Default: 16-Bit	Audio record data size selection.
Number of sampling iterations	256	Number of sampling iterations.
Callback	g_audio_record_framework_user_callback	Callback name.
Name of generated initialization function	sf_audio_record_i2s_init0	Name of generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower level modules can be desirable. The configurable properties for the lower level stack modules are given in the below sections for completeness and as a reference.

Note

Most of the property settings for lower level modules are fairly intuitive and can usually be determined by inspection of the associated Properties window from the SSP configurator.

Configuring the Audio Record I2S Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the I2S HAL Module on r_ssi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_i2s0	Module name.
Channel	0	Physical hardware channel.
Audio Clock Frequency (Hertz)	2822400	Input audio clock frequency, used to generate the I2S clock. Must be a multiple between 1 and 128 of: (sampling_freq_hz * word_length_in_bits).
Sampling Frequency (Hertz)	44100	Sampling frequency of audio data.

Data Bits	8 bits, 16, 18, 20, 22, 24 Default: 16 bits	Bit depth of audio data, which is the size in bits of one sample of audio data.
Word Length	8 bits, 16, 24, 32 Default: 16 bits	Word length of audio data, must be at least the same size as the bit depth (Data Bits field).
WS Continue Mode	Enabled, Disabled Default: Disabled	Enable WS continue mode to continue to output the word select line when the peripheral is idle. Disable to stop outputting the word select line when the peripheral is idle.
Audio Clock Frequency (Hertz)	External, GTIOC1A Default: External	Select External for external signal to AUDIO_CLK input pin or GTIOCA1.
Name of I2S callback function to be defined by user	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) when the transmission FIFO reaches the high watermark point after all data for transmission is transmitted or when reception is complete (the requested number of bytes have been received). Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Transmit interrupt priority selection.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Receive interrupt priority selection.
Idle/Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Idle/error interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC software event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DTC HAL Module on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Driver name.
Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC software event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the AGT HAL Module on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Mode selection.
Period Value	2822400 *2	Period value selection.
Period Unit	Hertz	Period unit selection.
Auto Start	FALSE	Auto start selection.
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	Count source selection.
AGTO Output Enabled	True, False Default: False	AGTO output selection.
AGTIO Output Enabled	True, False Default: False	AGTIO output selection.
Output Inverted	True, False Default: False	Output inverted selection.
Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection.
Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection.
Callback	NULL	Callback selection.
Underflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have

different default values and available configuration settings.

Configuration Settings for the GPT HAL Module on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Mode selection.
Period Value	2822400 *2	Period value selection.
Period Unit	Hertz	Period unit selection.
Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection.
Auto Start	FALSE	Auto start selection.
GTIOCA Output Enabled	True, False Default: False	GTIOCA output enabled selection.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCA stop level selection.
GTIOCB Output Enabled	True, False Default: False	GTIOCB output enabled selection.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCB stop level selection.
Callback	NULL	Callback selection.
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Audio Record I2S Framework Module Clock Configuration

The Audio Record I2S Framework module uses the PCLKB as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

Audio Record I2S Framework Module Pin Configuration

To use the Audio Record I2S Framework module, the port pins for the peripheral inputs and outputs must be set in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the Audio Record I2S Framework Module

Resource	ISDE Tab	Pin selection Sequence
SSI	Pins	Select **Peripherals**> **Connectivity:SSI**> **SSI/SSI0/SSI1**

4.1.6.6 Using the Audio Record I2S Framework Module in an Application

The typical steps in using the Audio Record I2S Framework module in an application are:

1. Initialize the module using the sf_audio_record_api_t::open API.
2. Start the recording using the sf_audio_record_api_t::start API.
3. Operate on data from the periodic callback function as needed.
4. Close the module using the sf_audio_record_api_t::close API.

These common steps are illustrated in a typical operational flow in the following figure:

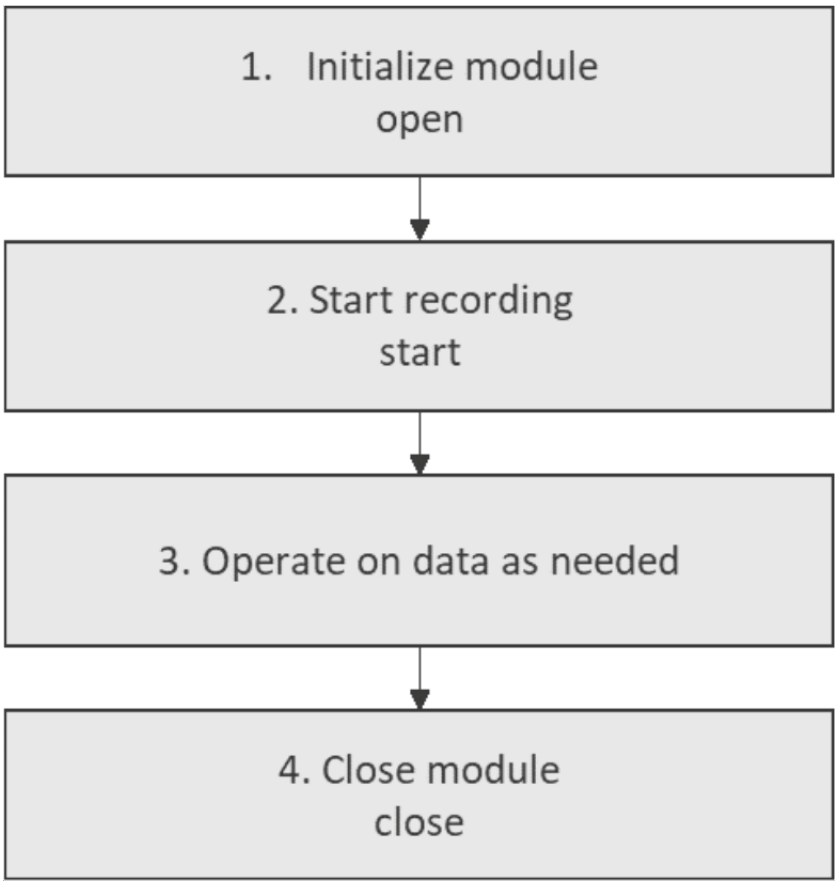

Figure 126: Flow Diagram of a Typical Audio Record I2S Framework Module Application

4.1.7 Block Media Framework on sf_block_media_lx_nor

4.1.7.1 Block Media Framework Module Introduction

The Block Media Framework on sf_block_media_lx_nor module provides a high-level API for interfacing with QSPI NOR flash memory devices. It provides API functions for reading, writing and controlling the QSPI NOR Flash memory. The framework includes the Azure RTOS wear leveling component LevelX NOR. The LevelX functions to support wear leveling are automatic and transparent to the developer. File system accesses, using the Azure RTOS FileX system, are also supported, making it easy to implement file system based applications.

Block Media Framework Module Features

- Supports Block Media Framework interface for NOR flash memory device.
- Supports file system access on NOR flash memory.
- Supports LevelX wear leveling functions transparently to the developer.

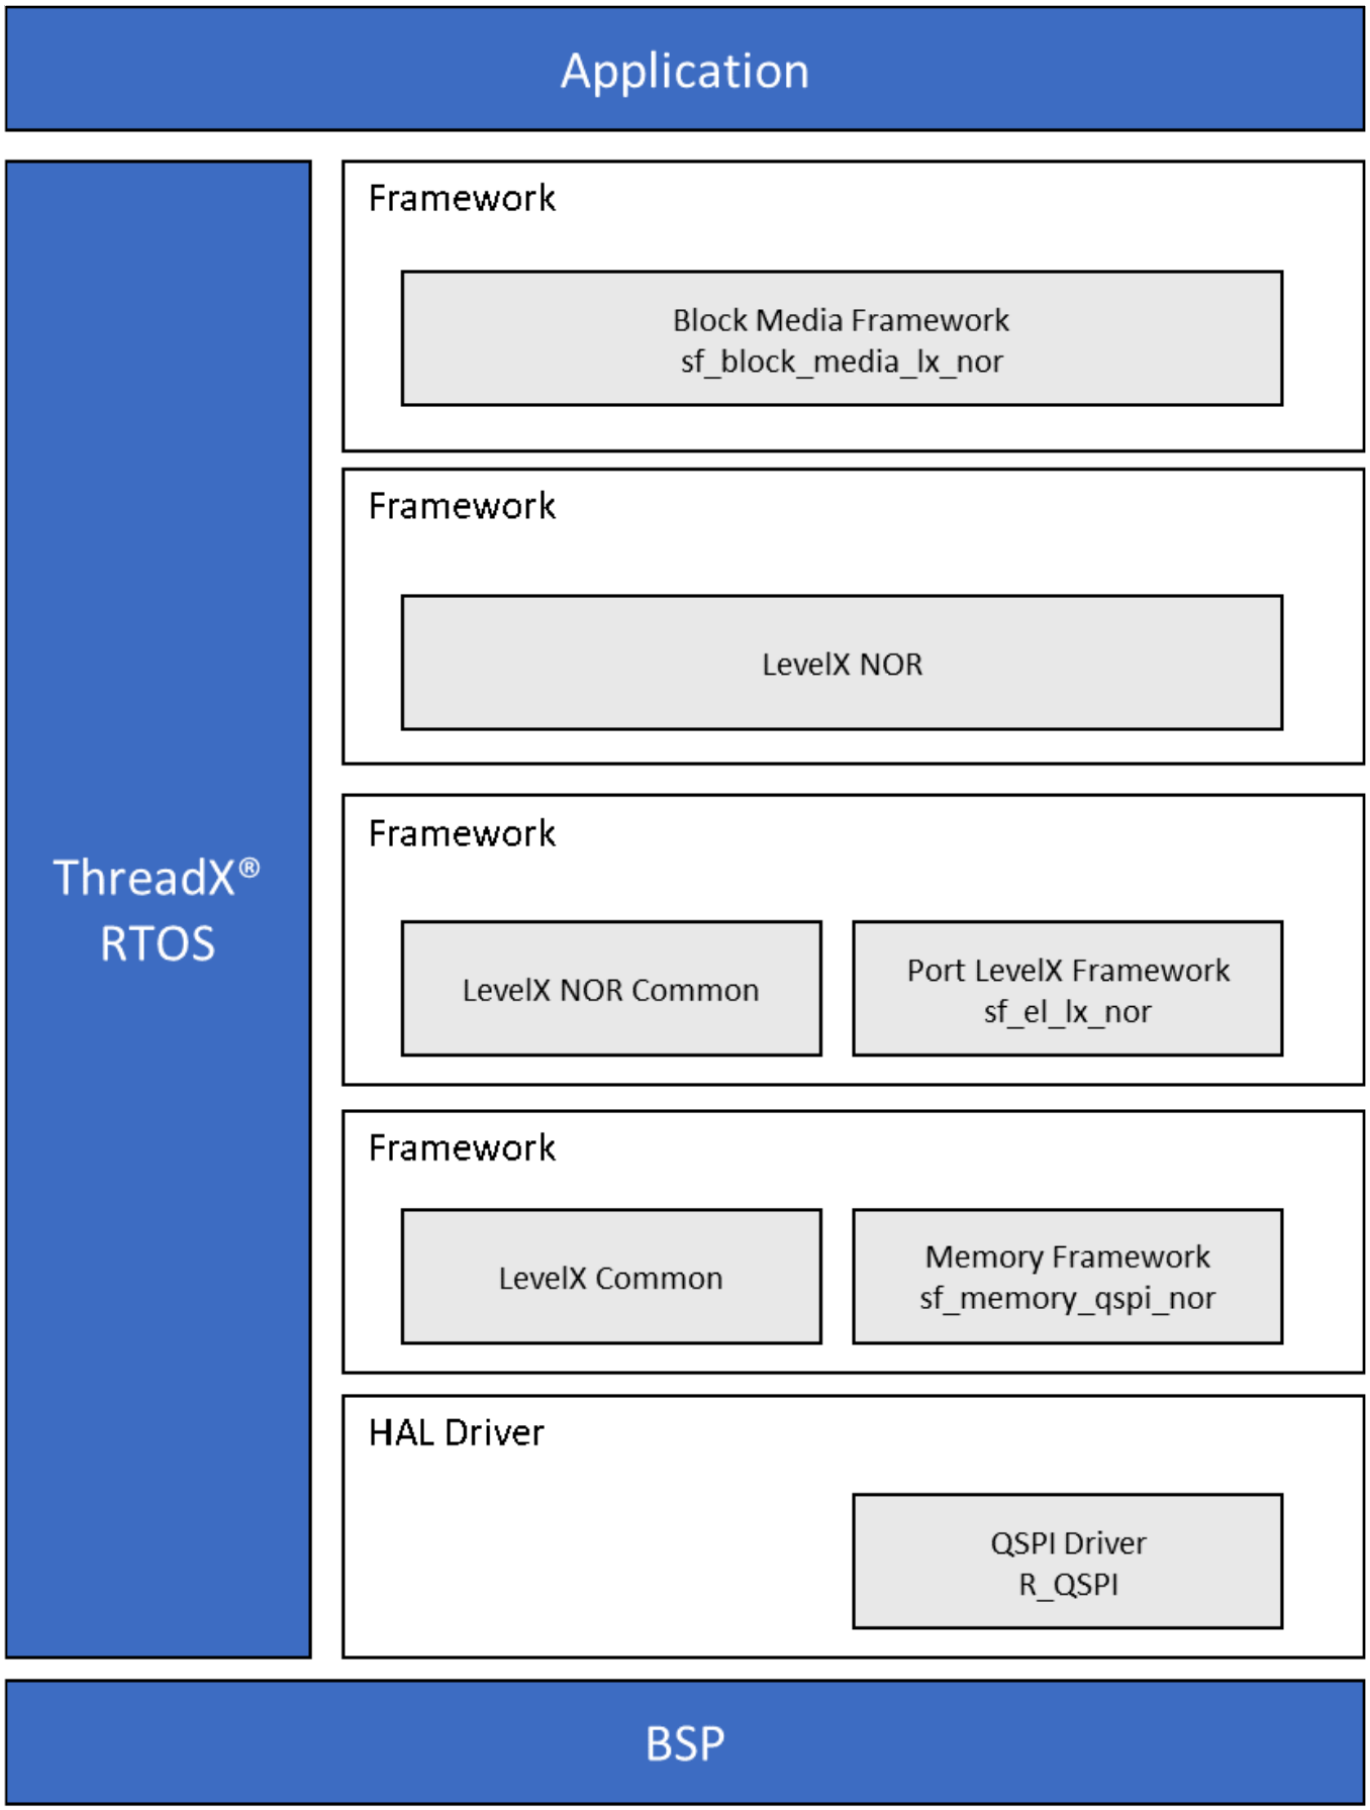

Figure 127: Block Media Framework Module Block Diagram

4.1.7.2 Block Media Framework Module APIs Overview

The Block Media Framework module defines API functions to open, read from, write to and close the module. A complete list of the available API functions, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Block Media Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_block_media_lx_nor0.p_api->open(g_sf_block_media_lx_nor0.p_ctrl, g_sf_block_media_lx_nor0.p_cfg); Open LevelX flash device for read/write and control. This function initializes the LevelX driver and hardware the first time it is called out of reset. The underlying flash needs to either be erased or already initialized with LevelX.
read	g_sf_block_media_lx_nor0.p_api->read(g_sf_block_media_lx_nor0.p_ctrl, p_dest, start_sector, sector_count); Read data from flash using LevelX.
write	g_sf_block_media_lx_nor0.p_api->write(g_sf_block_media_lx_nor0.p_ctrl, p_src, start_sector, sector_count); Write data to flash using LevelX.
ioctl	g_sf_block_media_lx_nor0.p_api->ioctl(g_sf_block_media_lx_nor0.p_ctrl, command, p_data); Send control commands to Block Media LevelX NOR driver.
close	g_sf_block_media_lx_nor0.p_api->close(g_sf_block_media_lx_nor0.p_ctrl); Close an open Block Media LevelX NOR driver.
versionGet	g_sf_block_media_lx_nor0.p_api->versionGet(&version); Return the version of the firmware and API using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	LevelX flash is available and is now open for read, write and control access.

SSP_ERR_ASSERTION	p_ctrl, p_cfg or an input pointer is NULL.
SSP_ERR_ALREADY_OPEN	The block media LevelX NOR instance has already been opened. No configurations were changed. Call the associated Close function or use associated Control commands to reconfigure the instance.
SSP_ERR_MEDIA_OPEN_FAILED	LevelX NOR or the underlying flash failed to open. The underlying flash needs to either be erased or already initialized with LevelX.
SSP_ERR_NOT_OPEN	The block media is not open.
SSP_ERR_READ_FAILED	Data read failed.
SSP_ERR_WRITE_FAILED	Data write failed.
SSP_ERR_UNSUPPORTED	This module does not support requested command.
SSP_ERR_SECTOR_RELEASE_FAILED	Sector release command failed.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.7.3 Block Media Framework Module Operational Overview

The Block Media Framework on sf_block_media_lx_nor framework module provides a high-level API for interfacing with QSPI NOR flash memory devices while supporting wear leveling and file system operations. Wear leveling is implemented, transparently to the developer, using the Azure RTOS LevelX component within the SSP. File system support is implemented using the Azure RTOS FileX component, integrated with the SSP. These components work together to make it easy to support embedded applications that require QSPI NOR Flash file system operations.

The Block Media Framework provides API functions for reading, writing and controlling the QSPI NOR Flash memory. In addition to these functions, all FileX related API functions become available once the Block Media Framework module is successfully opened and initialized. Refer to the FileX User's Manual for a complete description of these functions.

The Block Media Framework module uses a standard interface that is common to other SSP media modules. For example, the modules that support SDMMC, SPI Flash and SDRAM/RAM memories use the same API calls, so the programming interface remains the same for any media driver. These modules can be interchanged with one another easily. Device adaptation drivers, such as r_qspi, are accessed through the Memory Framework interface and provide device specific code needed to perform media I/O operations. Configuration and control structures passed through memory interface function calls are generally device specific as well.

Block Media Framework Module Important Operational Notes and Limitations

Block Media Framework Module Operational Notes

The media must be erased and formatted before using sf_block_media_lx_nor for creating, writing and reading files.

Block Media Framework Module Limitations

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.7.4 Including the Block Media Framework Module in an Application

This section describes how to include the Block Media Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Block Media Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Block Media Framework is g_sf_block_media_lx_nor. This name can be changed in the associated Properties window.)

Block Media Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_block_media_lx_nor0 Block Media Framework on sf_block_media_lx_nor	Threads	**New Stack> Framework> File System> Block Media Framework on sf_block_media_lx_nor**

When the Block Media Framework on sf_block_media_lx_nor is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description includes Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

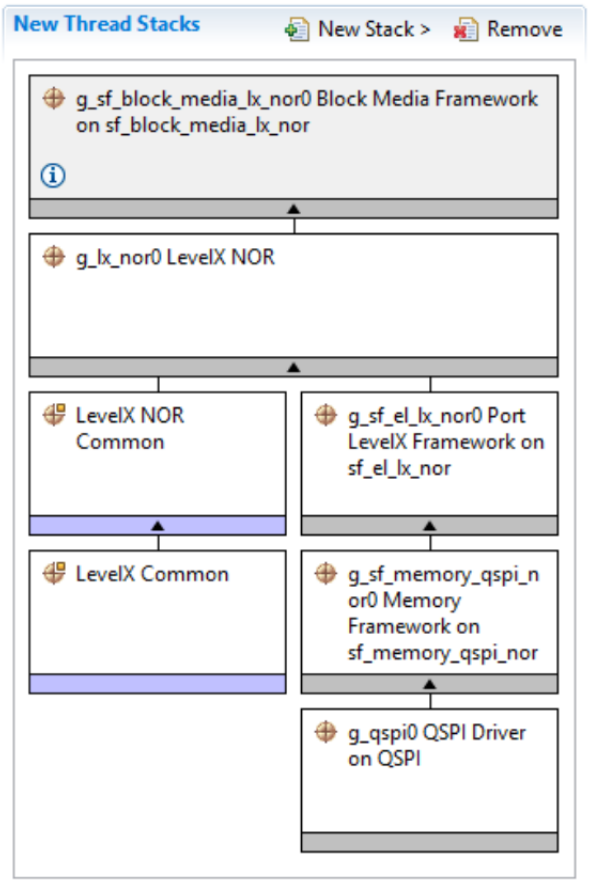

Figure 128: Block Media Framework Module Stack

4.1.7.5 Configuring the Block Media Framework Module

The Block Media Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Block Media Framework Module on sf_block_media_lx_nor

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.

Name	g_sf_block_media_lx_nor0	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Block Media Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the LevelX NOR Common Instance

ISDE Property	Value	Description
Name	g_lx_nor0	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the LevelX Common Instance

ISDE Property	Value	Description
Thread Safety	Enabled, Disabled Default: Disabled	If Enabled, this makes LevelX thread-safe by using a ThreadX mutex object throughout the API.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Port LevelX Framework Module on sf_el_lx_nor

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_sf_el_lx_nor0	Module name.
Event Callback	NULL	Name of the function to call when an event occurs.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Memory Framework on sf_memory_qspi_nor

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_sf_memory_qspi_nor0	Module name.
Write of Erase Timeout (in ticks)	30000	Timeout ticks for waiting on write or erase to complete.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the QSPI HAL Module on r_qspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_qspi0	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Block Media Framework Module Clock Configuration

The Block Media framework module uses the QSPI peripheral which uses PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

Block Media Framework Module Pin Configuration

To use the Block Media framework module, the port pins for the QSPI peripheral must be set as needed. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection for the Block Media Framework Module on sf_block_media_lx_nor

Resource	ISDE Tab	Pin selection Sequence
QSPI	Pins	Select **Peripherals**> **Storage:QSPI QSPI0**

4.1.7.6 Using the Block Media Framework Module in an Application

The typical steps in using the Block Media Framework module in an application are:

1. Initialize the media using the FileX API function fx_system_initialize (sf_el_fx calls it automatically).

2. Initialize the LevelX NOR using the API function lx_nor_flash_initialize (g_common_init calls it automatically).

3. Format the media using the FileX API function fx_media_format (sf_el_fx calls it automatically if "Format media during initialization" property is set to Enabled). This Format media is optional if media has already been formatted. Anything on the media will erase while media format. (Optional)

4. Open the media using the FileX API function fx_media_open (sf_el_fx opens the media automatically).

5. Read the media as required using the sf_block_media_api_t::read API function (Block Media Framework) or one of the FileX API functions, for example, fx_media_read(), fx_file_read().

6. Write to the media as required using the sf_block_media_api_t::write API function (Block Media Framework) or one of the FileX API functions, for example, fx_media_write(), fx_file_write().

Note

1. After a successful fx_media_open call, all FileX APIs can be used (not just read and write).
2. If the media has been formatted by FileX without LevelX earlier, erase it using the qspi_api_t::erase API function before initializing the file media. The erase size should be not less than the size of the memory FileX uses. Users can disable the "Format media during initialization" property in the project configuration, erase the FileX media and then format it in the application.

These common steps are illustrated in a typical operational flow diagram in the following figure:

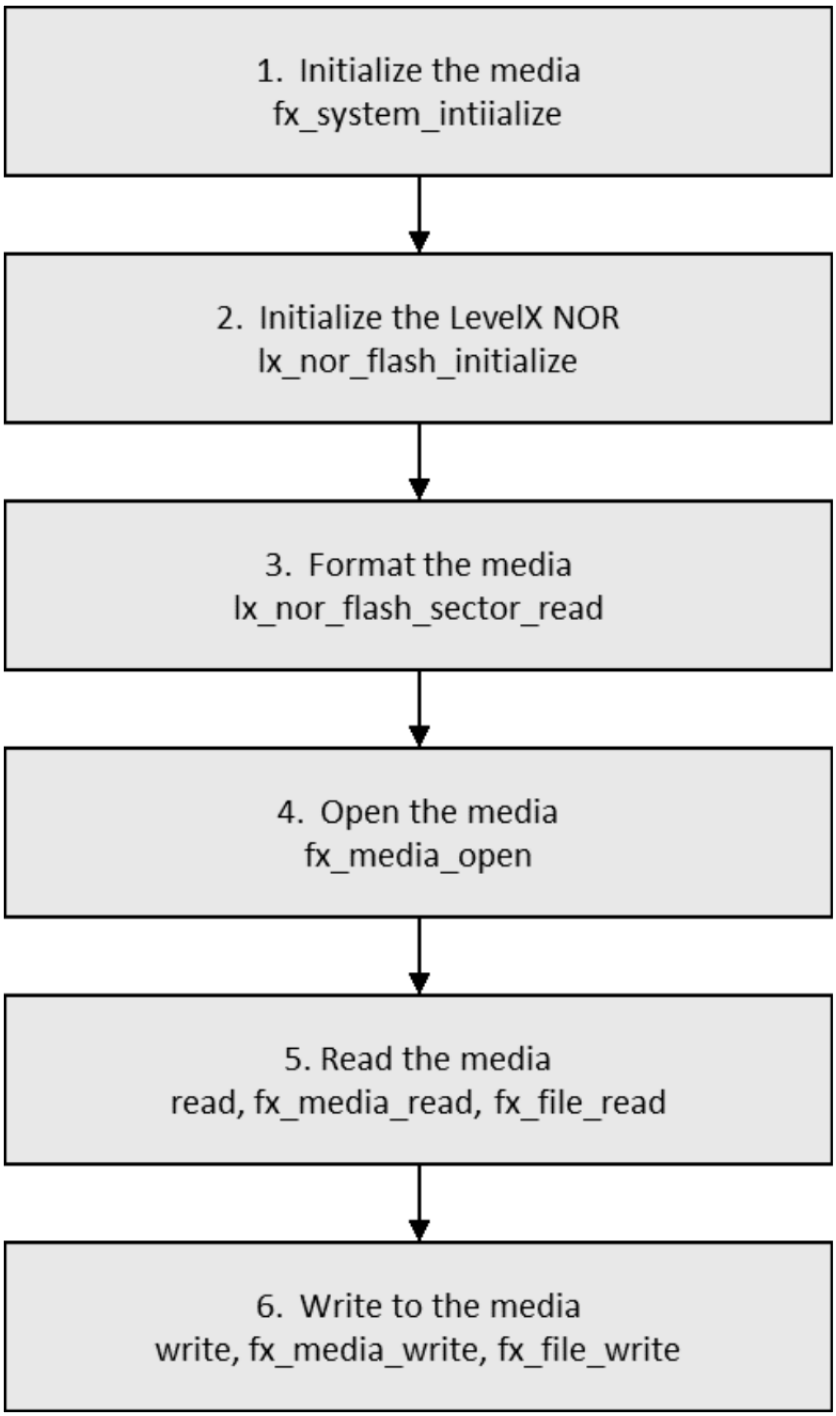

Figure 129: Flow Diagram of a Typical Block Media Framework Module Application

4.1.8 Block Media Framework on sf_block_media_qspi

4.1.8.1 Block Media QSPI Framework Module Introduction

The Block Media Framework Module can implement the QSPI channel for reading, writing and controlling the QSPI Flash memory peripheral through the r_qspi driver. The driver has all the functionality needed to interface with a file system through a block media interface.

Block Media QSPI Framework Module Features

- Supports QSPI channel interface for QSPI flash memory device.
- Support file system on QSPI flash memory.

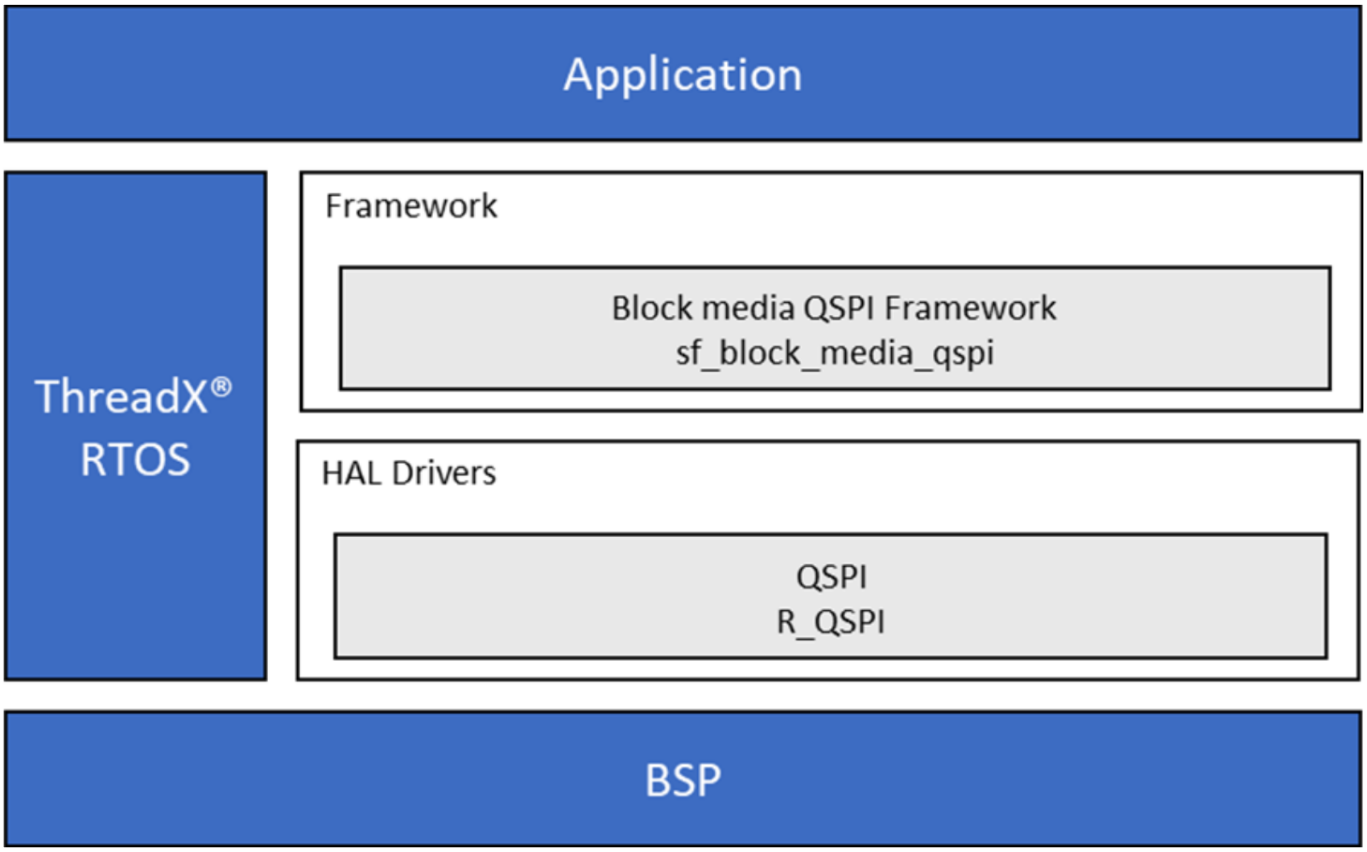

Figure 130: Block Media QSPI Framework Module Block Diagram

4.1.8.2 Block Media QSPI Framework Module APIs Overview

The Block Media QSPI Framework module defines APIs to open, control, read and write to the media. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Block Media QSPI Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_block_media_qspi0.p_api->open (g_sf_block_media_qspi0.p_ctrl, g_sf_block_media_qspi0.p_cfg); Open a device channel for read/write and control.

read	g_sf_block_media_qspi0.p_api->read (g_sf_block_media_qspi0.p_ctrl, p_dest, start_block, block_count); Read data from a media channel.
write	g_sf_block_media_qspi0.p_api->write (g_sf_block_media_qspi0.p_ctrl, p_src, start_block, block_count); Write data to a media channel.
ioctl	g_sf_block_media_qspi0.p_api->ioctl (g_sf_block_media_qspi0.p_ctrl, command, p_data); Send control commands to and receives the status from the media port.
close	g_sf_block_media_qspi0.p_api->close (g_sf_block_media_qspi0.p_ctrl); Close the open media channel.
versionGet	g_sf_block_media_qspi0.p_api->versionGet(&version); Return the version of the driver using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INTERNAL	An internal TheadX error has occurred.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_IN_USE	Peripheral is still running in another mode; perform Close first.
SSP_ERR_UNSUPPORTED	Command not supported.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.8.3 Block Media QSPI Framework Module Operational Overview

The Block Media Framework Interface is simply an abstract interface using function pointers instead of direct function calls. Functions are called between FileX and the SSP block media drivers, such as the SDMMC, SPI Flash and SDRAM/RAM. The interface remains the same for any media driver so all

media drivers appear functionally identical at file I/O layer and can be interchanged with one another without changing code. Device adaptation drivers, such as sf_block_media_qspi, are accessed through the Block Media Framework Interface and provide device specific code needed to perform media I/O operations. Configuration and control structures passed through block media function calls are generally device specific as well.

Block Media QSPI Framework Module Important Operational Notes and Limitations

Block Media QSPI Framework Module Operational Notes

- The media must be formatted at least once before you can begin creating, writing and reading files.

Block Media QSPI Framework Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.8.4 Including the Block Media QSPI Framework Module in an Application

This section describes how to include the Block Media QSPI Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Block Media QSPI Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Block Media QSPI Framework is g_sf_block_media_qspi0. This name can be changed in the associated Properties window.)

Block Media QSPI Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_block_media_qspi0Block Media Framework on sf_block_media_qspi	Threads	**New Stack> Framework> File System> Block Media Framework on sf_block_media_qspi**

When the Block Media QSPI Framework on sf_block_media_qspi is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

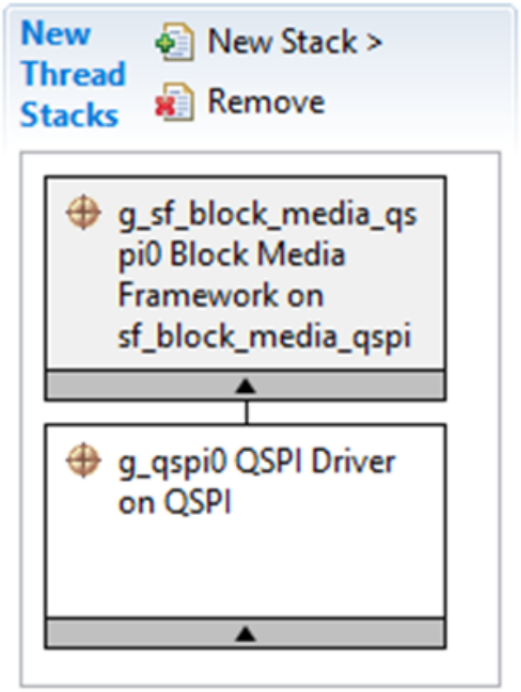

Figure 131: Block Media QSPI Framework Module Stack

4.1.8.5 Configuring the Block Media QSPI Framework Module

The Block Media QSPI Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Block Media QSPI Framework Module on sf_block_media_qspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_block_media_qspi	Module name.
Block size of media in bytes	4096	Block size selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Block Media QSPI Framework Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the QSPI HAL Module on r_qspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_qspi0	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Block Media QSPI Framework Module Clock Configuration

The Block Media QSPI Framework module uses the PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

Block Media QSPI Framework Module Pin Configuration

To use the Block Media QSPI Framework module, the port pins for the peripheral inputs and outputs must be set in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection for the Block Media QSPI Framework Module on sf_block_media_qspi

Resource	ISDE Tab	Pin selection Sequence
QSPI	Pins	Select **Peripherals**> **Storage:QSPI**> **QSPI0**

4.1.8.6 Using the Block Media QSPI Framework Module in an Application

The steps in using the Block Media QSPI Framework module on sf_block_media_qspi in a typical application are:

1. Initialize the media using the FileX API fx_system_initialize (sf_el_fx calls it automatically).
2. Format the media using FileX API fx_media_format (sf_el_fx calls it automatically if "Format media during initialization" property is set to Enabled). This Format media is optional if media has already been formatted. Anything on the media will erase while media format.

(Optional)
3. Open the media using the FileX API fx_media_open (sf_el_fx opens the media automatically).
4. Read the media as required using the sf_block_media_api_t::read API (Block Media Framework) or one of the FileX APIs, for example, fx_media_read(), fx_file_read().
5. Write to the media as required using the sf_block_media_api_t::write API (Block Media Framework) or one of the FileX APIs, for example, fx_media_write(), fx_file_write().

These common steps are illustrated in a typical operational flow diagram in the following figure:

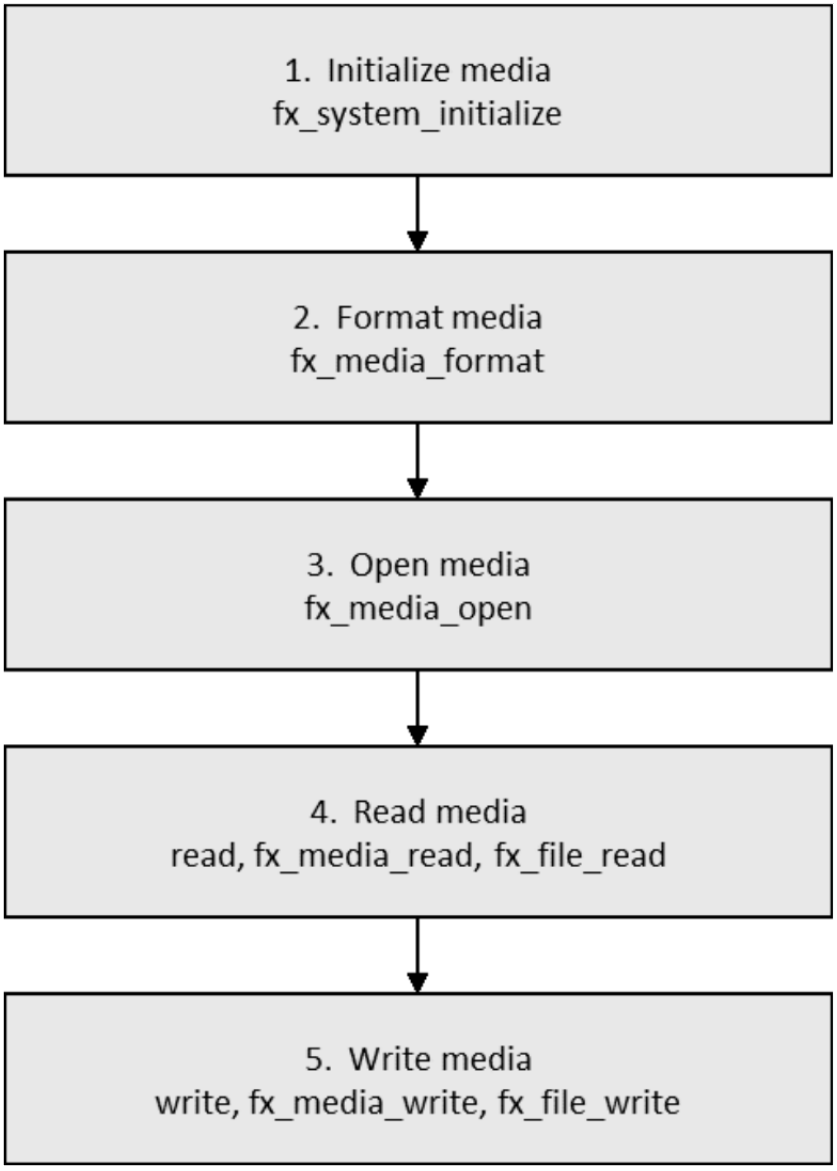

Figure 132: Flow Diagram of a Typical Block Media QSPI Framework Module Application

4.1.9 Block Media Framework on sf_block_media_ram

4.1.9.1 Block Media RAM Framework Module Introduction

The Block Media Framework Module can implement the file system on RAM for reading from, writing to and controlling the read/write region of the RAM memory. The framework has all the functionality needed to interface with a file system through a block media interface.

Block Media RAM Framework Module Features

- Enables FileX to be run on linear memory-mapped devices.
- Temporary and fast storage of data on RAM.

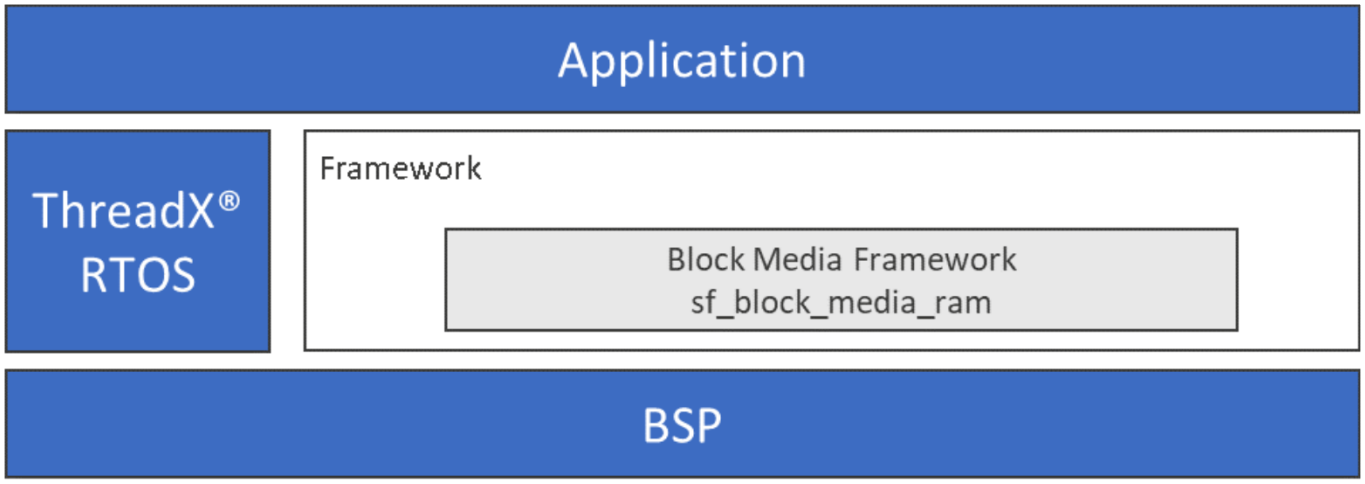

Figure 133: Block Media RAM Framework Module Block Diagram

4.1.9.2 Block Media RAM Framework Module APIs Overview

The Block Media RAM Framework module implements APIs to open, read from, write to and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Block Media RAM Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_block_media_ram0.p_api->open (g_sf_block_media_ram0.p_ctrl, g_sf_block_media_ram0.p_cfg); Open device for read, write and control.
read	g_sf_block_media_ram0.p_api->read (g_sf_block_media_ram0.p_ctrl, p_dest, start_block, block_count); Read data from RAM buffer.
write	g_sf_block_media_ram0.p_api->write (g_sf_block_media_ram0.p_ctrl, p_source, start_block, block_count); Write data to RAM buffer.

ioctl	g_sf_block_media_ram0.p_api->ioctl (g_sf_block_media_ram0.p_ctrl, command, p_data); Send control commands to and receive status of RAM buffer.
close	g_sf_block_media_ram0.p_api->close (g_sf_block_media_ram0.p_ctrl); Close the framework.
versionGet	g_sf_block_media_ram0.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_UNSUPPORTED	Command not supported.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	A parameter is NULL.
SSP_ERR_IN_USE	Framework is already open.
SSP_ERR_INVALID_BLOCKS	Invalid block passed.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.9.3 Block Media RAM Framework Module Operational Overview

The Block Media Framework Interface is simply an abstract interface using function pointers instead of direct function calls. Functions are called between the FileX and the SSP block media drivers, such as the SDMMC, SPI Flash and SDRAM/RAM. The interface remains the same for any media driver, so all media drivers appear functionally identical at the file I/O layer and can be interchanged with one another without changing code. Device adaptation drivers, such as the sf_block_media_ram, are accessed through the Block Media Framework Interface and provide device specific code needed to perform media I/O operations. Configuration and control structures passed through block media function calls are generally device specific as well.

Block Media RAM Framework Module Important Operational Notes and Limitations

Block Media RAM Framework Module Operational Notes

The media must be formatted before you can open the media and begin creating, writing to and reading from files. The memory area used must be directly readable and writable by the core. Internal SRAM or SDRAM size should be sufficient for the Block Media RAM and there will be no

persistence of data across the power cycles. Block count must be assigned by considering the boot record, FAT area, root directory and directory sector. If the File System is used on RAM then the minimum block count must be 4, as the first 3 sectors are reserved for boot record, FAT area and root directory and the 4th sector is used for data sector. The "Format media during initialization" property needs to be enabled to use RAM for FileX. The "File System is on block media" property needs to be true inorder to configure the block count and block size from the block media RAM.

Block Media RAM Framework Module Limitations

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.9.4 Including the Block Media RAM Framework Module in an Application

This section describes how to include the Block Media RAM Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Block Media RAM Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Block Media RAM Framework is g_sf_block_media_ram0. This name can be changed in the associated Properties window.)

Block Media RAM Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_block_media_ram0 Block Media Framework on sf_block_media_ram	Threads	**New Stack> Framework> File System> Block Media Framework on sf_block_media_ram**

When the Block Media RAM Framework on sf_block_media_ram is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description includes Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

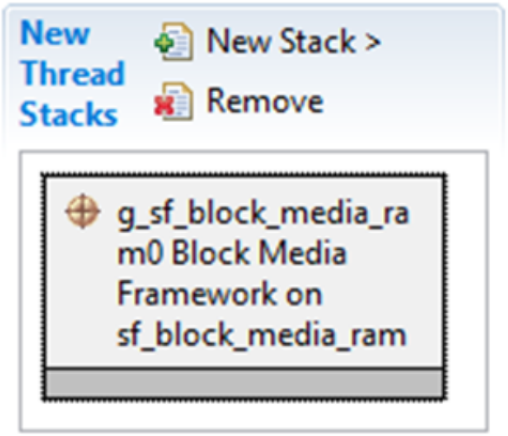

Figure 134: Block Media RAM Framework Module Stack

4.1.9.5 Configuring the Block Media RAM Framework Module

The Block Media RAM Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Block Media RAM Framework Module on sf_block_media_ram

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_block_media_ram0	Module name.
Block size of media in bytes	512	Block size of media in bytes selection.
Number of blocks to allocate	16	To make use of file system, block count must be assigned by considering the boot record, FAT area and root directory.
Enter the valid section for RAM buffer allocation	noinit	Enter the valid section for RAM buffer allocation.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Block Media RAM Framework Module Clock Configuration

The Block Media RAM Framework module uses the ICLK as the source for the internal RAM.

Block Media RAM Framework Module Pin Configuration

The Block Media RAM Framework module uses internal RAM so no external pins are required.

4.1.9.6 Using the Block Media RAM Framework Module in an Application

The steps in using the Block Media RAM Framework module on sf_block_media_ram in a typical application are:

1. Initialize the media using the FileX API, fx_system_initialize (sf_el_fx calls it automatically).
2. Format the media using FileX API, fx_media_format (sf_el_fx calls it automatically if "Format media during initialization" property is set to Enabled). This Format media is optional if media has already been formatted. Anything on the media will erase while media is formatted. (Optional)
3. Open the media using the FileX API fx_media_open (sf_el_fx opens the media automatically).
4. Read the media as required using the sf_block_media_api_t::read API (Block Media Framework) or one of the FileX APIs, for example, fx_media_read(), fx_file_read().
5. Write to the media as required using the sf_block_media_api_t::write API (Block Media Framework) or one of the FileX APIs, for example, fx_media_write(), fx_file_write().

These common steps are illustrated in a typical operational flow diagram in the following figure:

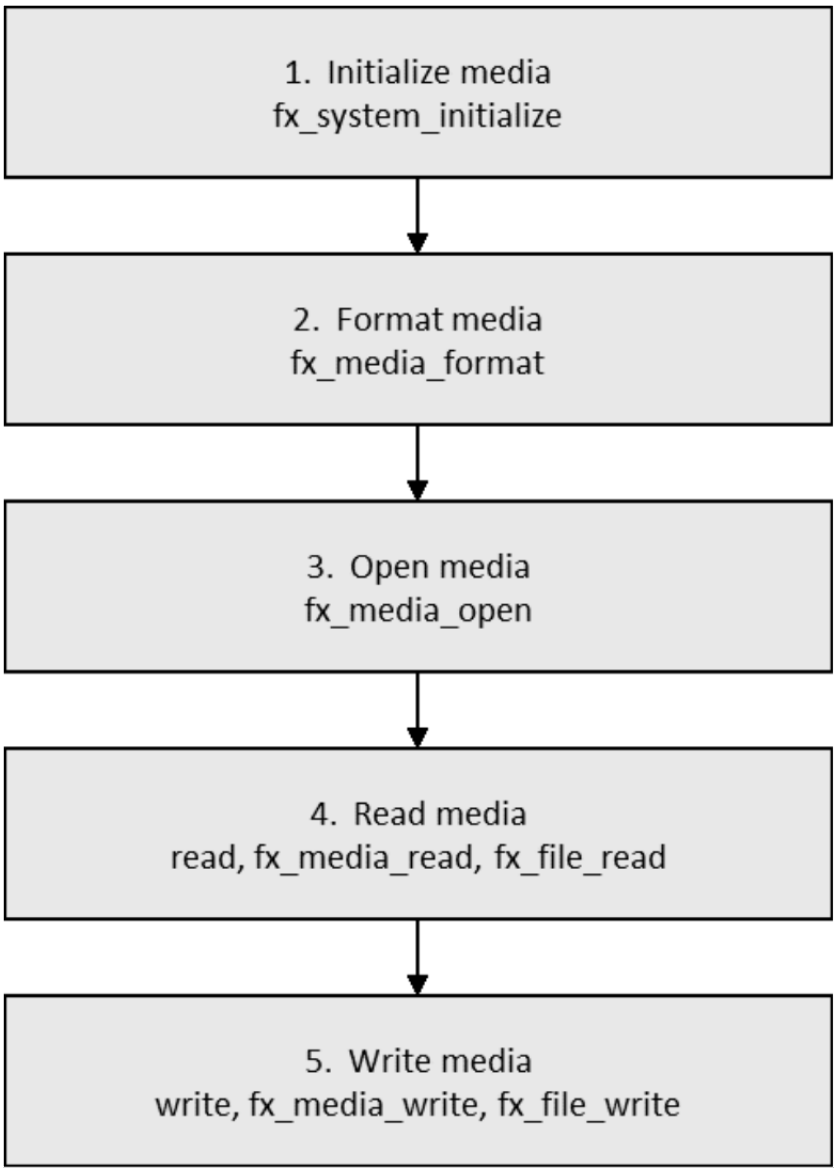

Figure 135: Flow Diagram of a Typical Block Media RAM Framework Module Application

4.1.10 Block Media Framework on sf_block_media_sdmmc

4.1.10.1 Block Media SDMMC Framework Module Introduction

The Block Media Framework module can implement the SD/MMC bus protocol for reading from, writing to and the control of SD cards and eMMC embedded devices through the SDHI (SD Host Interface) peripheral and the SD/MMC media driver. The driver has all the functionality needed to interface with a file system through a block media interface.

Block Media SDMMC Framework Module Features

- Supports SDHI host interface for SD/MMC.

- Supports SDSC (SD Standard Capacity), SDHC (SD High Capacity) and eMMC (embedded).
- Supports 1, 4 or 8-bit (eMMC only) data bus.

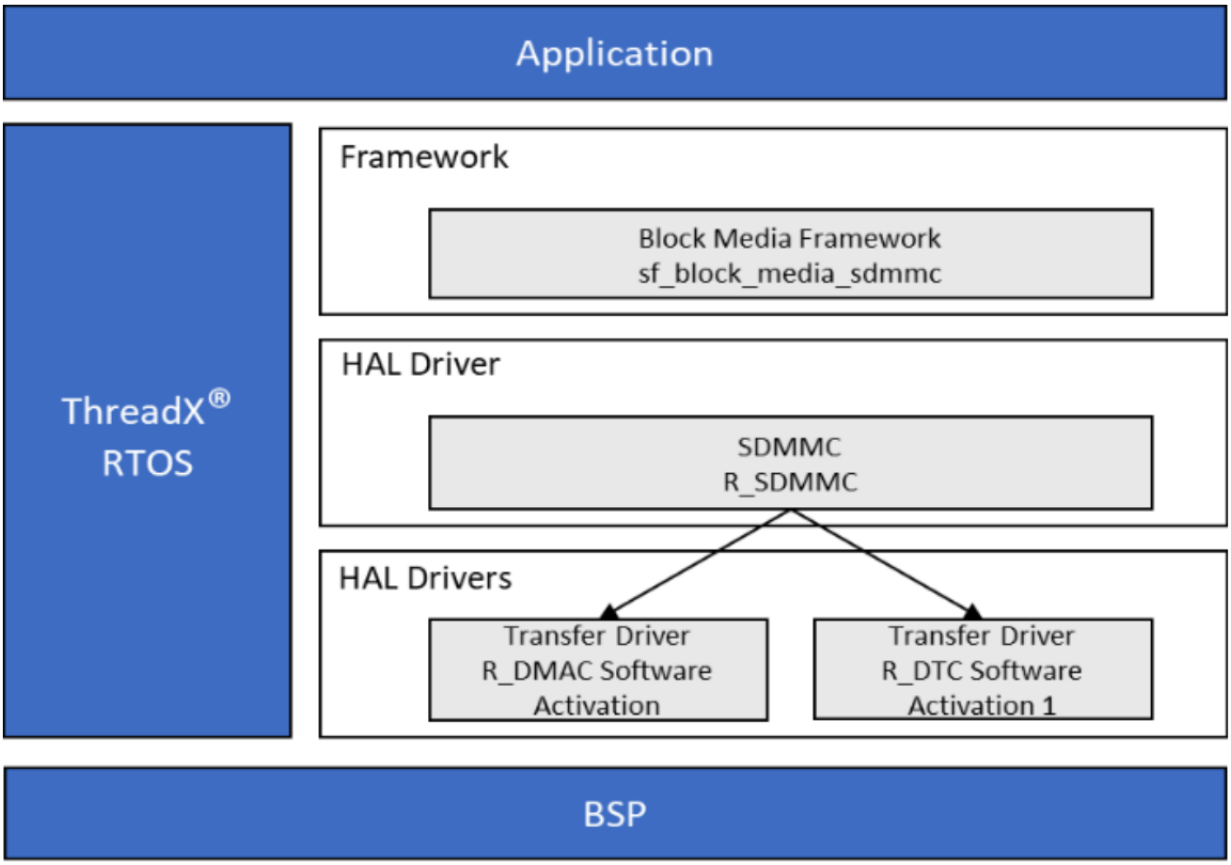

Figure 136: Block Media SDMMC Framework Module Block Diagram

4.1.10.2 Block Media SDMMC Framework Module APIs Overview

The Block Media Framework defines APIs for opening, reading from, writing to, controlling and closing the SDMMC. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Block Media SDMMC Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_block_media_sdmmc_api->open(g_sf_block_media_sdmmc.p_ctrl, g_sf_block_media_sdmmc.p_cfg); Open device for read/write and control.
read	g_sf_block_media_sdmmc_api->read(g_sf_block_media_sdmmc.p_ctrl, &destination, startsector, sectorcount); Read data from SD/MMC.

write	g_sf_block_media_sdmmc_api->write(g_sf_block_media_sdmmc.p_ctrl, &source, startsector, sectorcount); Write data to SDMMC channel.
ioctl	g_sf_block_media_sdmmc_api->ioctl(g_sf_block_media_sdmmc.p_ctrl, command, &data); Send control commands to the SD/MMC port and receive the status of the SD/MMC port.
close	g_sf_block_media_sdmmc_api->close(g_sf_block_media_sdmmc.p_ctrl); Close open device port.
versionGet	g_sf_block_media_sdmmc_api->versionGet(&version); Get version of Block Media SD/MMC driver.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_IN_USE	The channel specified has already been opened. No configurations were changed. Call the associated Close function or use associated control commands to reconfigure the channel.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_WRITE_PROTECTED	SD or MMC card is Write Protected.
SF_INFO_NOT_AVAILABLE	Information is not available possibly because card has been removed or is defective.
SSP_ERR_NOT_OPEN	The channel is not opened.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.10.3 Block Media SDMMC Framework Module Operational Overview

The Block Media Framework Interface is simply an abstract interface using function pointers instead of direct function calls. Functions are called between FileX and the SSP block media drivers, such as the SDMMC and the SPI Flash. The interface remains the same for any media driver, so all media drivers appear functionally identical at the file I/O layer and can be interchanged with one another without changing code. Device adaptation drivers, such as sf_block_media_sdmmc, are accessed through the Block Media Framework Interface and provide device specific code needed to perform

media I/O operations. Configuration and control structures passed through block media function calls are generally device specific as well.

Block Media SDMMC Framework Module Important Operational Notes and Limitations

Block Media SDMMC Framework Module Operational Notes

- The media must be formatted at least once before you can begin creating, writing and reading files.

Block Media SDMMC Framework Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.10.4 Including the Block Media SDMMC Framework Module in an Application

This section describes how to include the Block Media SDMMC Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Block Media SDMMC Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Block Media SDMMC Framework is g_sf_block_media_sdmmc0. This name can be changed in the associated Properties window.)

Block Media SDMMC Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_block_media_sdmmc0 Block Media Framework on sf_block_media_sdmmc	Threads	**New Stack> Framework> File system> Block Media Framework**

When the Block Media SDMMC Framework on sf_block_media_sdmmc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

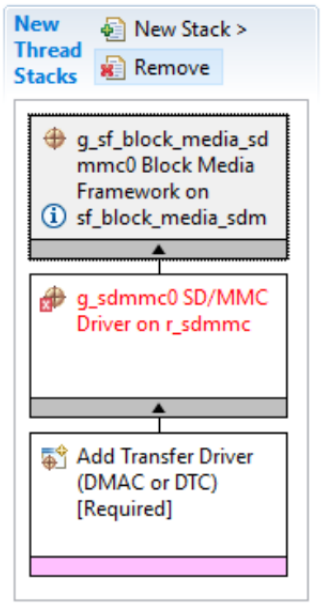

Figure 137: Block Media SDMMC Framework Module Stack

4.1.10.5 Configuring the Block Media SDMMC Framework Module

The Block Media SDMMC Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Block Media SDMMC Framework Module on sf_block_media_sdmmc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_block_media_sdmmc0	The name to be used for sf_block_media_sdmmc module control block instance.
Block size of media in bytes	512	Media Block size.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Block Media SDMMC Framework Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the SDMMC HAL Module on r_sdmmc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_sdmmc0	The name to be used for SDMMC module control block instance. This name is also used as the prefix of the other variable instances.
Channel	0, 1 Default: 1	Channel of SD/MMC peripheral, channel 0 or 1.
Media Type	Embedded, Card Default: Embedded	Media is a card or an embedded device. This allows to firmware to know whether to look for card insertion/removal and write protect pins.
Bus Width	1 Bit, 4 Bits, 8 Bits Default: 4 Bits	Data bus with as defined by hardware interface. (8 bits for eMMC only).
Block Size	512	Block size selection.
Card Detection	Not Used, CD Pin Default: CD Pin	Card detection selection.
Callback	NULL	(Not required if using Filex) Set to name of user callback function. Provides event that caused interrupt: SDMMC_EVENT_CARD_REMOVED, SDMMC_EVENT_CARD_INSERTED, SDMMC_EVENT_ACCESS, SDMMC_EVENT_SDIO, SDMMC_EVENT_TRANSFER_COMPLETE, SDMMC_EVENT_TRANSFER_ERROR

Access Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Access interrupt priority selection.
Card Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Card interrupt priority selection.
DMA Request Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	DMA request interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dmac Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Selects if code for parameter checking is to be included in the build.
Name	g_transfer0	Module name.
Channel	0	
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation	Activation source selection.
Auto Enable	False	Auto enable selection.

Callback (Only valid with Software start)	NULL	Callback selection.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.

ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Block Media SDMMC Framework Module Clock Configuration

The SDHI block (used to implement SDMMC and SDIO functions) uses the PCLKA for its clock source. There is no need to configure the clock specifically for the SDMMC peripheral unless you need to optimize the data rate. The SDMMC driver selects the appropriate built-in divider based on the PCLKA frequency and the maximum clock rate allowed by the SD, SDIO or eMMC device, obtained at media device initialization.

Block Media SDMMC Framework Module Pin Configuration

Use the e^2 studio pin configurator to configure the I/O pins for the SDMMC peripheral. The drive capacity for each pin should be set to "Medium" or "High" for most boards and high-speed memory and SDIO devices. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins.

Note

For some peripherals, the operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection for the Block Media SDMMC Framework Module on sf_block_media_sdmmc

Resource	ISDE Tab	Pin selection Sequence
SDHI	Pins	Select **Peripherals**> **Storage:SHDI**> **SDHI0**

Note

The selection sequence assumes SCI1 is the desired hardware target for the driver.

Pin Configuration Settings for the Block Media SDMMC Framework Module on sf_block_media _sdmmc

Property	Value	Description
Operation Mode	Disabled, Custom, SD_MMC 1 bit SD_MMC 4 bit MMC 8 bit	Select mode as per application.
CLK	None, P413 Default: None	Clock Pin.

CMD	None, P412 Default: None	Command Pin.
DAT0-7	None, PXXX Default: None	Data Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

Other Settings

The read and write media and extended read and write SDIO functions are non-blocking and require interrupts and a transfer function, either DMAC or DTC. The read and write functions return SSP_SUCCESS to indicate that the initial operations have started successfully. However, the user application must wait for the user callback and check for event SDMMC_EVENT_TRANSFER_COMPLETE or SDMMC_EVENT_TRANSFER_ERROR to indicate completion of the read or write.

4.1.10.6 Using the Block Media SDMMC Framework Module in an Application

The steps in using the Block Media SDMMC Framework module on sf_block_media_sdmmc in a typical application are:

1. Initialize media using the sf_block_media_api_t::open API.
2. Read media as required using the sf_block_media_api_t::read API.
3. Write media as required using the sf_block_media_api_t::write API.
4. Operate on data as required.
5. Close media as required using the sf_block_media_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

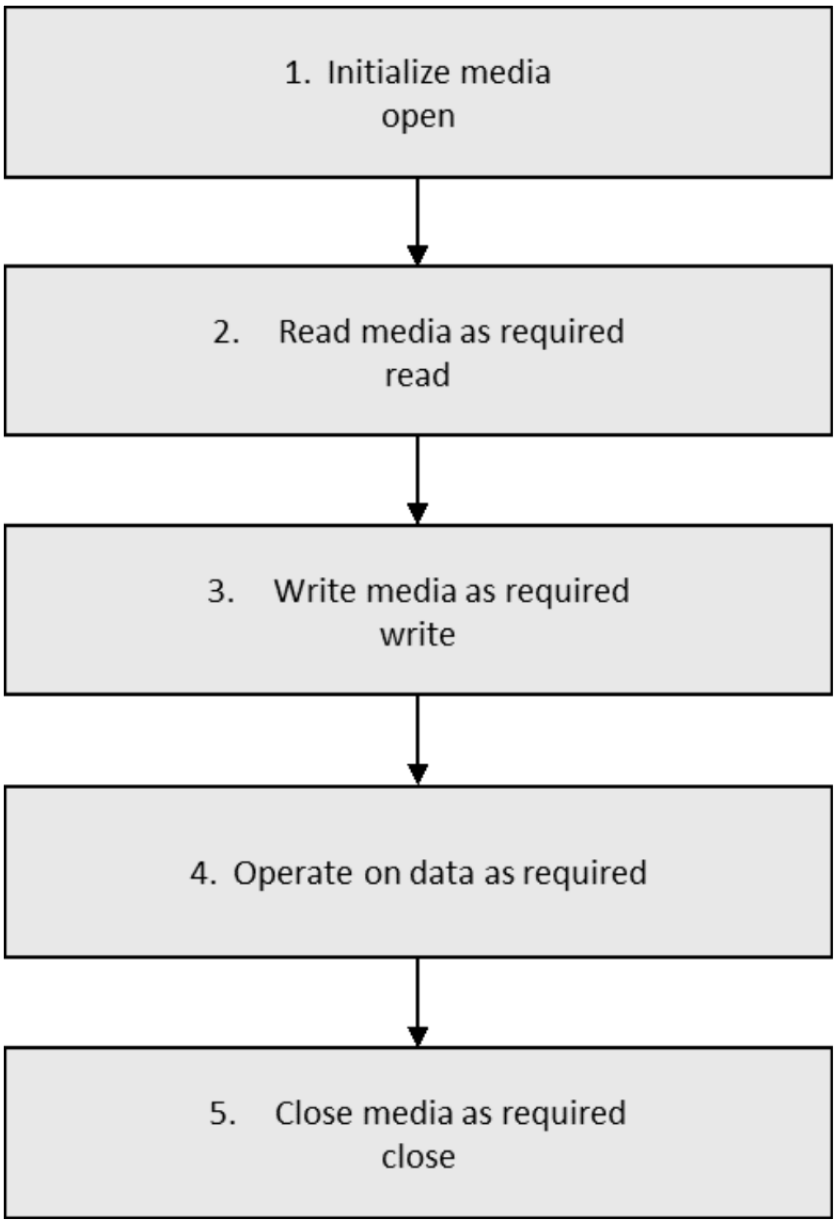

Figure 138: Flow Diagram of a Typical Block Media SDMMC Framework Module Application

The typical steps for using the sf_block_media_sdmmc using the sf_el_fx in an application are:

1. Initialize media using the FileX API, fx_system_initialize (sf_el_fx calls it automatically)
2. Format media using FileX API, fx_media_format (sf_el_fx calls it automatically if "Format media during initialization" property is set to Enabled)
3. Open the media using FileX API, fx_media_open (sf_el_fx opens the media automatically)
4. Read media as required using the sf_block_media_api_t::read API (Block Media Framework) or one of the FileX API, for example, fx_media_read(), fx_file_read()
5. Write to media as required using the sf_block_media_api_t::write API (Block Media Framework) or one of the FileX API, for example, fx_media_write(), fx_file_write().

Note

After successful fx_media_open call, all FileX APIs can be used (not only read and write).

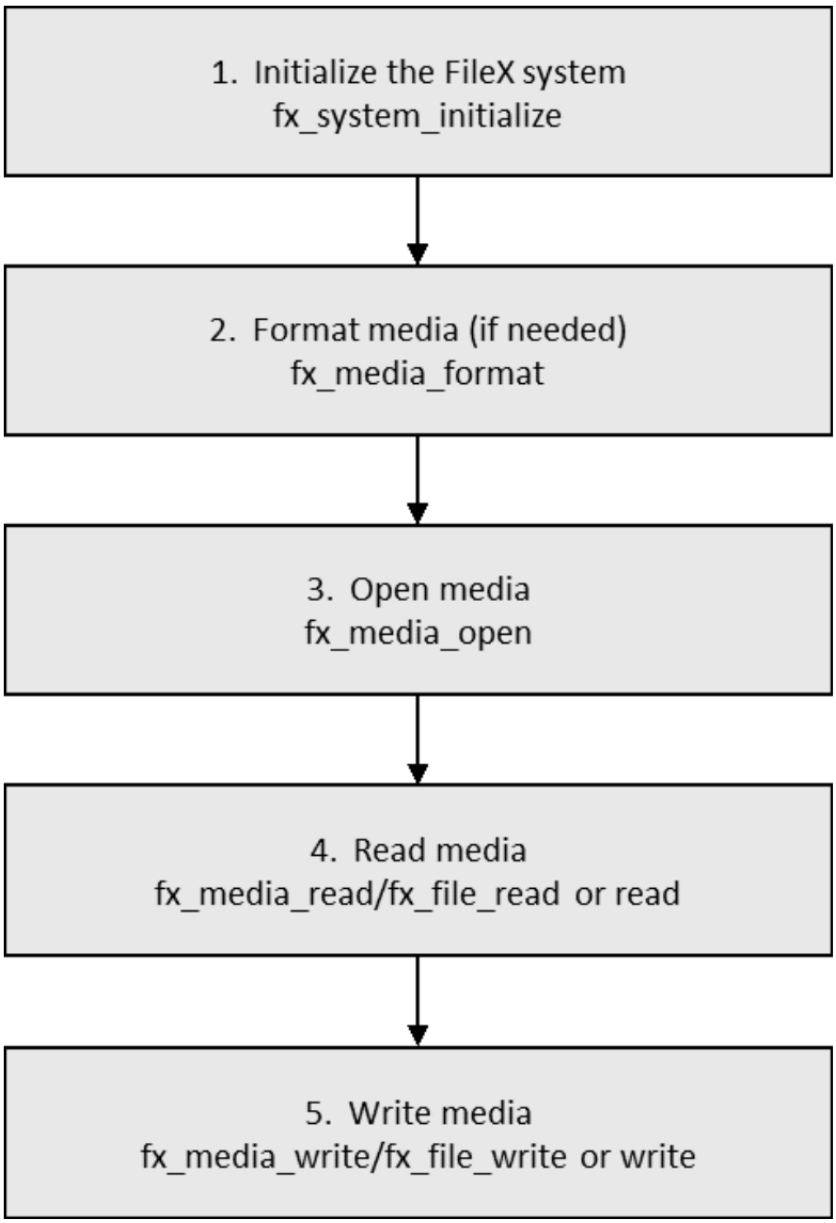

Figure 139: Flow Diagram of a Typical Block Media SDMMC Framework Module Application

4.1.11 BLE Framework

4.1.11.1 BLE Framework Introduction

Bluetooth® Low Energy (BLE), sometimes referred to as Bluetooth Smart, is a light-weight subset of Classic Bluetooth, and was introduced as part of the Bluetooth 4.0 core specification. In contrast to Classic Bluetooth, BLE is designed to provide significantly lower power consumption. This allows Internet of Thing (IoT) devices that have stricter power capacity to transfer small amounts of data between nearby devices.

Application developers access the functionality provided by the BLE stack using its APIs. The BLE stack APIs provided by different vendors are not standardized, and as a result, Application developers have to update their code when porting to different BLE stacks.

The Synergy BLE Framework handles this issue by providing a generic interface for the underlying BLE stack provided by various vendors, thereby preventing coupling between application and vendor-specific BLE stack code. The use of generic APIs makes application development simpler and portable.

The BLE Framework provides a high-level API for BLE applications and uses the Synergy Software Package (SSP) communication framework, which in turn enables the UART driver for communication to the underlying BLE module. It also integrates the generic BLE profile framework (g_sf_ble_onboard_profile), which provides a uniform interface to BLE profiles. For the RL78G1D BLE hardware module, the generic BLE profiles are implemented by the BLE module firmware.

BLE Framework Module Features

- ThreadX® RTOS Aware and thread safe
- Bluetooth v4.2 compliant framework
- Generic Access Profile (GAP) Features
    - User-defined advertising data
    - Security modes 1 and 2
    - Peripheral and central roles
    - White list support for up to 6 devices
    - Bonding support
- Generic Attribute Profile (GATT) features
    - GATT client and server
- Generic Attribute Profile (GATT) APIs
- Generic Access Profile (GAP) APIs
- Generic On-board Profiles APIs

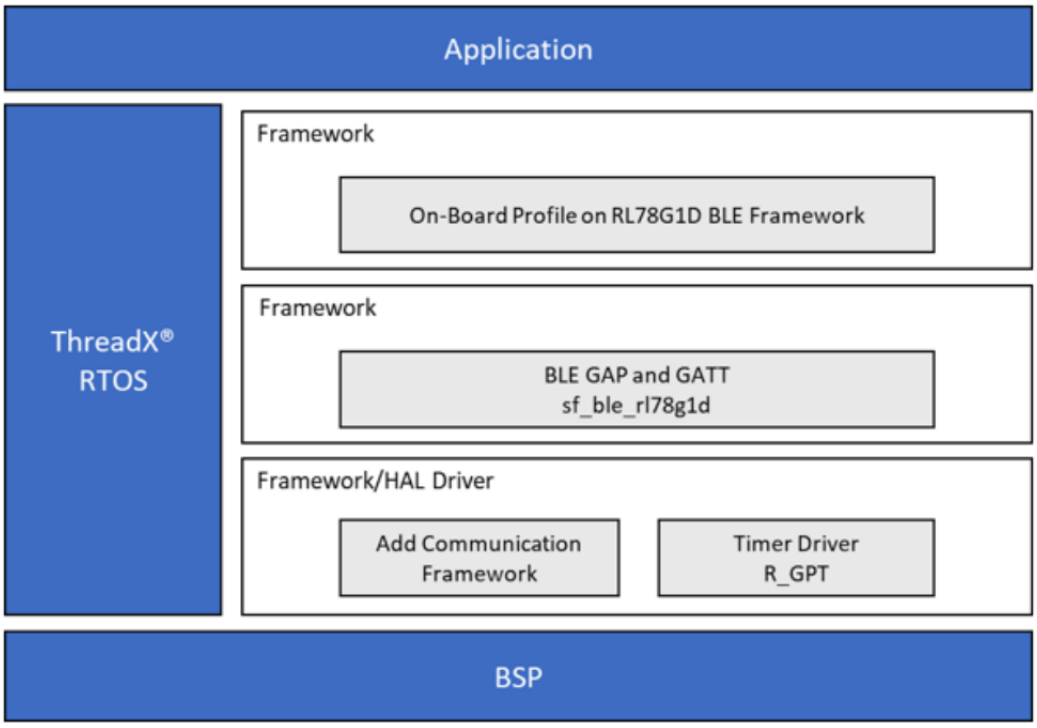

Figure 140: BLE Framework Module Block Diagram

Note

The BLE and GATT on sf_ble_rl78g1d can be used as a lower-level implementation of the On-Board Profile on RL789G1D BLE Framework or on its own.

4.1.11.2 BLE Framework Module APIs Overview

The BLE Framework defines APIs for initializing, setting and getting values, and stopping modules. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

BLE Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_ble0.p_api->open(g_ sf_ble_0.p_cfg); This function initializes and enables the BLE module. It accepts the BLE module configuration as an argument, which has the following parameters: - 48-bit Bluetooth Address - Device scan interval - Device scan window - Device discoverable time - Device connection interval - Slave latency - Supervision timeout - Own address type - Maximum slaves allowed to be connected
close	g_sf_ble0.p_api->close (g_ sf_ble0.p_cfg); This API de-initializes the interface and may put the BLE module in low power mode or power it off. It also closes the driver, disables the driver link, disables the interrupt in the BLE module driver.
infoGet	g_sf_ble0.p_api->infoGet (g_sf_ble_0.p_cfg, p_handle, p_ble_info); The infoGet API takes the BLE control structure as an argument. It returns the following information obtained from the BLE module: - Chipset/driver information string - RSSI value (unsigned integer 16 bits)
provisionGet	g_sf_ble0.p_api->provisionGet (g_sf_ble_0.p_cfg, p_ble_provisioning); The provisionGet API gets the BLE GAP provisioning information and takes the BLE control structure as an argument. It returns the following parameters: - Bonding Mode - Security Mode - GAP Role (Central/Master or Peripheral/Slave) - Security Keys

provisionSet	g_sf_ble0.p_api->provisionSet (g_sf_ble_0.p_cfg, p_ble_provisioning); The provisionSet() function provisions the BLE module. It takes the BLE control structure and the provisioning structure as an argument. - Bonding Mode - Security Mode - GAP Role (Central/Master or Peripheral/Slave) - Security Keys - GAP user event callback
scan	g_sf_ble0.p_api->scan (g_sf_ble_0.p_cfg, p_scan, p_cnt, p_scan_info); The scan() function takes BLE control structure as an argument. The scan() function returns a list of BLE devices scanned by the BLE module with below parameters. - Bluetooth address (48-bits) - RSSI - Scan data - Advertising Event type The scan() function takes device count as an argument, which acts as an in/out parameter. It specifies the size of the scan result array and the BLE framework sets it to count indicating the number of scan results stored in the array. The function takes scan type as an argument (active/passive).
advertisementStart	g_sf_ble0.p_api->advertisementStart (g_sf_ble_0.p_cfg, p_advt_info); The advertisementStart() function takes the following parameters: - Discovery mode (General/Limited) - Filter policy – Support for scan/connect request filtering combinations - Advertisement data - Connection mode - Advertisement intervals - Channel map - Address type - Advertising type - Scan response data
advertisementStop	g_sf_ble0.p_api->advertisementStop (g_sf_ble_0.p_cfg); Stops advertisement.
whitelistAdd	g_sf_ble0.p_api->whitelistAdd (g_sf_ble_0.p_cfg, p_bp_addr); The whitelistAdd() function adds devices to the whitelist for advertisements, scan requests and connection requests.

whitelistDel	g_sf_ble0.p_api->whitelistDel (g_sf_ble_0.p_cfg, p_bp_addr); The whitelistDel() function deletes devices from the whitelist for advertisements, scan requests and connection requests.
bondingStart	g_sf_ble0.p_api->bondingStart (g_sf_ble_0.p_cfg, p_handle, p_bp_addr, p_bonding_start); The bondingStart() function starts bonding with a remote device.
bondingResponse	g_sf_ble0.p_api->bondingResponse (g_sf_ble_0.p_cfg, p_handle, p_bp_addr, p_bonding_resp); The bondingResponse() function responds to a bonding request.
startEncryption	g_sf_ble0.p_api->startEncryption (g_sf_ble_0.p_cfg, p_enc_info); The startEncryption() function begins an encryption operation.
connect	g_sf_ble0.p_api->connect (g_sf_ble_0.p_cfg, p_handle, p_conn); The connect() function connects to a remote device.
disconnect	g_sf_ble0.p_api->disconnect (g_sf_ble_0.p_cfg, p_handle); The disconnect() function disconnects from a remote device.
listen	g_sf_ble0.p_api->listen (g_sf_ble_0.p_cfg); The listen() function listens for an incoming connect request from aremote device.
authorization	g_sf_ble0.p_api->authorization (g_sf_ble_0.p_cfg, &conhandle); The authorization() function authorizes a remote device after connection.
setTxPower	g_sf_ble0.p_api->setTxPower(g_sf_ble_0.p_cfg, &con_handle, &tx_power_info); The setTxPower() function sets the transmit power for the procedure specified by the connection handle.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

BLE Framework On-Board Profiles Module API Summary

Function Name	Example API Call and Description

open	g_sf_ble_onboard_profile0.p_api->open (g_sf_ble_onboard_profile0.p_cfg); This API initializes the interface for data transfers.
close	g_sf_ble_onboard_profile0.p_api->close (g_sf_ble_onboard_profile0.p_cfg); This API de-initializes the interface and may put it in low power mode or power it off. The API closes the driver, and disables the driver link and interrupt.
onbpEnable	g_sf_ble_onboard_profile0.p_api->onbpEnable (sf_ble_onboard_profile0.p_cfg, p_handle, profile, p_prf_cb, sec); Enables the profile in server mode or client mode.
onbpServerWriteData	g_sf_ble_onboard_profile0.p_api->onbpServerWriteData (sf_ble_onboard_profile0.p_cfg, p_handle, profile, characteristics, p_data); Updates the value of the characteristic in the local database.
onbpServerSendNotification	g_sf_ble_onboard_profile0.p_api->onbpServerSendNotification (sf_ble_onboard_profile0.p_cfg, p_handle, profile, characteristics, p_data); Sends notifications.
onbpServerSendIndication	g_sf_ble_onboard_profile0.p_api->onbpServerSendIndication (sf_ble_onboard_profile0.p_cfg, p_handle, profile, characteristics, p_data); Sends indications.
onbpClientWriteCCCD	g_sf_ble_onboard_profile0.p_api->onbpClientWriteCCCD (sf_ble_onboard_profile0.p_cfg, p_handle, profile, cccd_char, cccd_val); Sets the Client Configuration Control Descriptor on the remote device.
onbpDisable	g_sf_ble_onboard_profile0.p_api->onbpDisable (sf_ble_onboard_profile0.p_cfg, p_handle, profile); Disables the profile in server mode and clientmode.
onbpClientReadChar	g_sf_ble_onboard_profile0.p_api->onbpClientReadChar (sf_ble_onboard_profile0.p_cfg, p_handle, profile, characteristics); Reads a GATT characteristic associated with the profile or service.
onbpClientWriteChar	g_sf_ble_onboard_profile0.p_api->onbpClientWriteChar (sf_ble_onboard_profile0.p_cfg, p_handle, profile, characteristics); Writes a GATT characteristic associated with the profile or service.

versionGet	g_sf_ble_onboard_profile0.p_api-> versionGet(&version); Retrieves the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.
All the details related to BLE standard profiles can be found in BLE profile specifications.
BLE APIs will return SSP_ERR_UNSUPPORTED if the module does not support the feature.

BLE Framework GATT API Summary

Function Name	Example API Call and Description
gattAddCustomProfiles	g_sf_ble0.p_api->gattAddCustomProfiles (g_sf_ble_0.p_cfg, p_handle, p_sf_ble_svc_dscv_req, p_sf_ble_svc_dscv_rsp, p_rsp_cnt); This function adds custom profiles to the GATT database.
gattServiceDiscovery	g_sf_ble0.p_api->gattServiceDiscovery (g_sf_ble_0.p_cfg, p_handle, p_sf_ble_svc_dscv_req, p_sf_ble_svc_dscv_rsp, p_rsp_cnt); The gattServiceDiscovery() function performs service discovery.
gattCharDiscovery	g_sf_ble0.p_api->gattCharDiscovery (g_sf_ble_0.p_cfg, p_handle, p_sf_ble_svc_dscv_req, p_sf_ble_svc_dscv_rsp, p_rsp_cnt); The gattCharDiscovery() function performs the Char discovery operation.
gattCharDescDiscovery	g_sf_ble0.p_api->gattCharDescDiscovery (g_sf_ble_0.p_cfg, p_handle, start_handle, end_handle, p_sf_ble_svc_dscv_rsp, p_rsp_cnt); Discovers GATT characteristics descriptor on a remote device.
gattCharRead	g_sf_ble0.p_api->gattCharRead (g_sf_ble_0.p_cfg, p_handle, start_handle, p_char_read_req, p_char_read_rsp); Reads GATT characteristics on a remote device.
gattCharWrite	g_sf_ble0.p_api->gattCharWrite (g_sf_ble_0.p_cfg, p_handle, p_char_read_req); Writes GATT characteristics on a remote device.
gattCharExecuteWrite	g_sf_ble0.p_api->gattCharExecuteWrite (g_sf_ble_0.p_cfg, p_handle, execute_flag); Executes a write (commit) on GATT characteristics on a remote device.

gattCharWriteLocal	g_sf_ble0.p_api->gattCharWriteLocal (g_sf_ble_0.p_cfg, char_handle, data_length); Updates the local GATT database.
gattSendNotify	g_sf_ble0.p_api->gattSendNotify (g_sf_ble_0.p_cfg, p_handle, char_handle); Sends notifications from local GATT server to remote GATT client.
gattSendIndicate	g_sf_ble0.p_api->gattSendIndicate (g_sf_ble_0.p_cfg, p_handle, char_handle); Sends indications from local GATT server to remote GATT client.
gattWriteResponse	g_sf_ble0.p_api->gattWriteResponse (g_sf_ble_0.p_cfg, p_handle, char_handle); Responds to the write characteristic value request from the remote GATT client.
versionGet	g_sf_ble0.p_api->versionGet(&version); Retrieves the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	Parameter has invalid value.
SSP_ERR_INVALID_PTR	p_version is NULL.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.11.3 BLE Framework Module Operational Overview

This section provides the Synergy BLE Framework software architecture overview and highlights the major SSP modules used as part of BLE framework along with the operational flow sequence from the user's application level.

Note

A more comprehensive description of the operation of the BLE Framework module is available in the BLE Framework Application Project. The complete project and associated application note can be found by doing a search for "r30qan0309eu" in the search bar at the top of the www.renesas.com home page.

BLE Framework Module Important Operational Notes and Limitations

BLE Framework Module Operational Notes

The BLE framework provides a common interface for the application. The implementation of the interface is specific for each module. The Synergy BLE framework currently defines an interface implemented for RL78G1D BLE module. Each implementation interacts with the corresponding BLE device driver. The BLE device driver uses the underlying SSP communication framework (g_sf_comms), which in turn interacts with the SSP HAL components such as Universal Asynchronous Receiver/Transmitter (UART), Data Transfer Controller (DTC), and General PWM Timer (GPT) drivers to communicate with the BLE module. The following figure shows a high-level architectural description of the BLE Framework module.

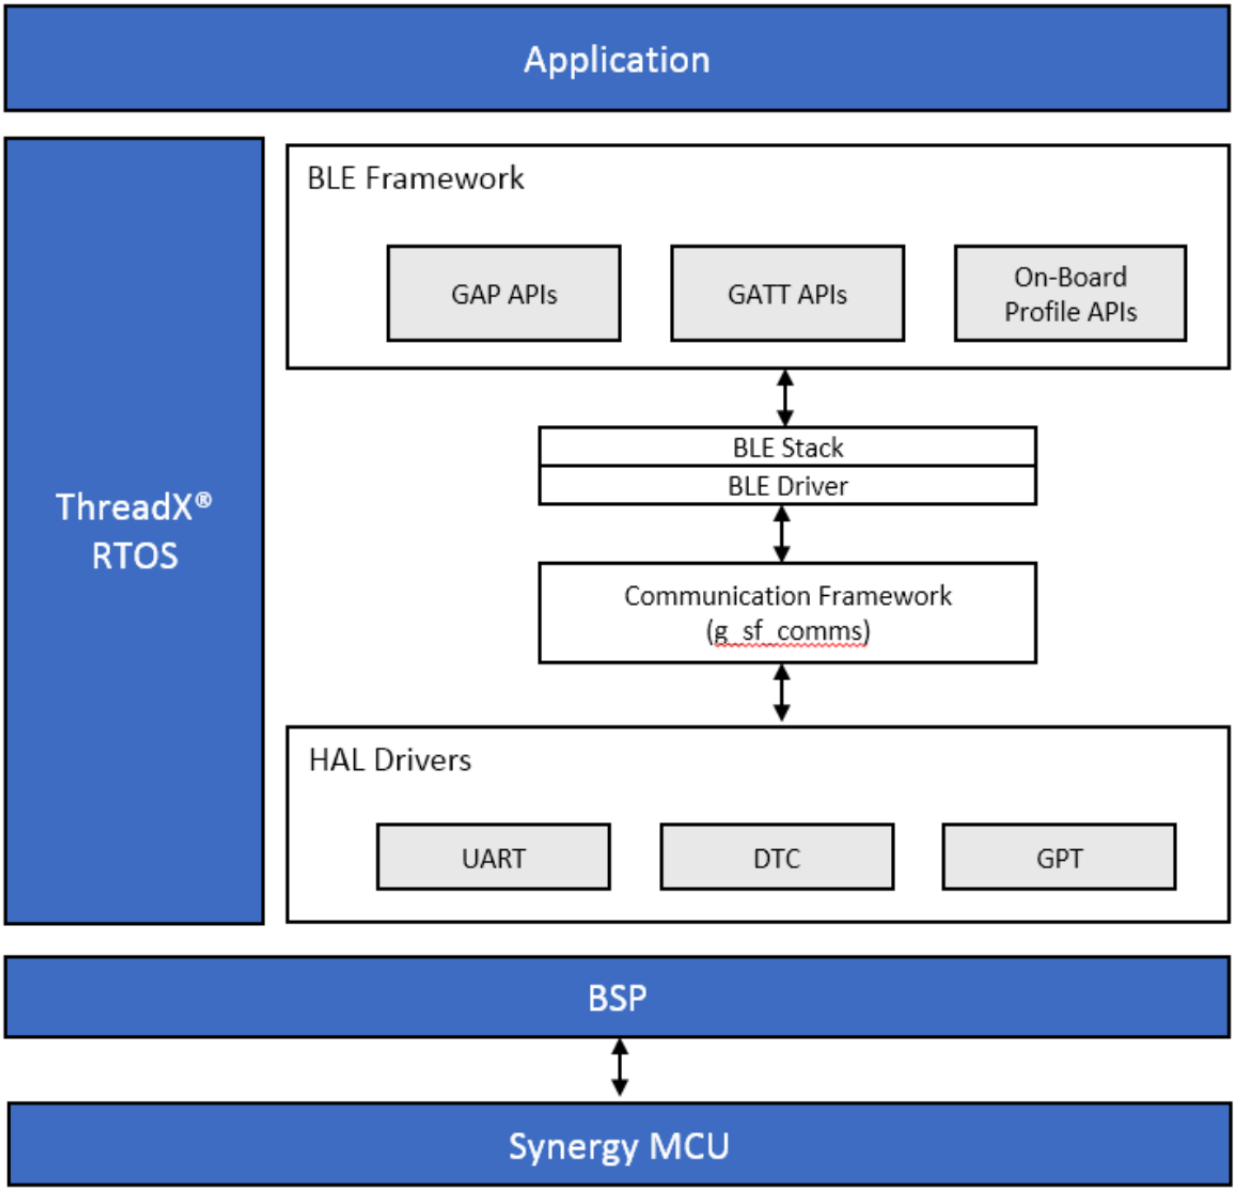

Figure 141: Typical BLE Module Architecture Types

GAP and GATT APIs

The BLE framework provides a generic interface for the application to configure and provision the BLE module. The BLE module has various configuration parameters as specified by the family of Bluetooth Smart standards. It is possible that individual device drivers and/or BLE modules might not support all configuration parameters. At a bare minimum, the provisioning API provides a mechanism

to set the operating mode, security mode, security keys, and bonding mode of the BLE interface. It also provides an API for the GAP/GATT layers.

On-Board Profiles APIs

The on-board profiles APIs provide a uniform interface to the BLE profiles implemented by the BLE module firmware.

BLE Stack

The BLE module host stack is typically provided by the BLE module vendor. The BLE module typically comes in three different flavors depending on the HW/SW partitioning between the host MCU and BLE module. The RL78G1D BLE module is part of the Network Controller Implementation architecture, where the BLE chipset includes all the implementation for the BLE link layer, GAP, GATT, and on-board profiles. The module interfaces with the MCU over the sf_comms framework provided by SSP.

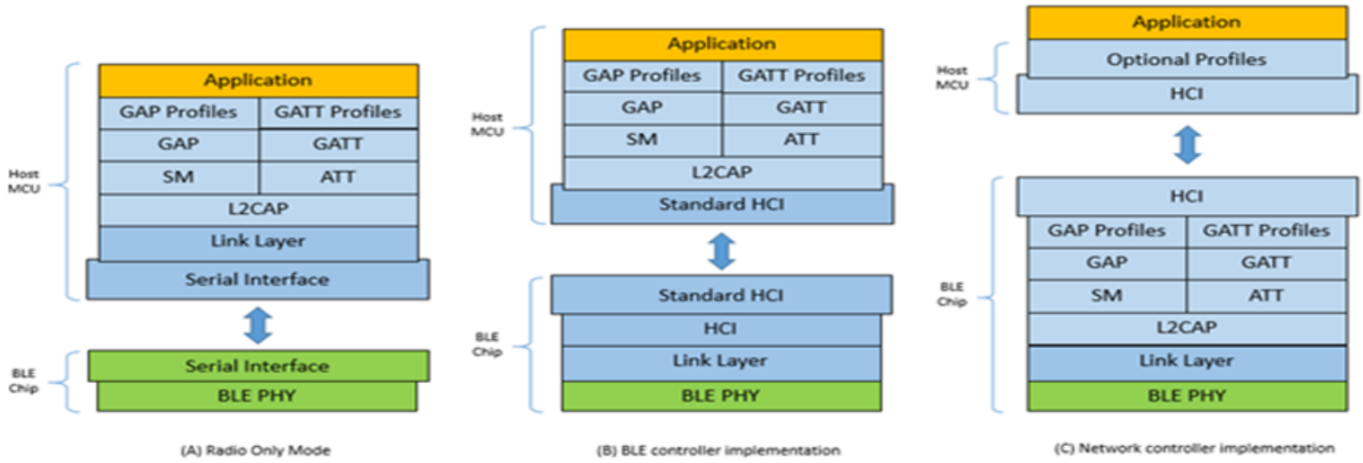

Figure 142: BLE Module Architecture Types

A: BLE radio-only mode

Link layer, L2CAP, GATT, GAP layers, profiles, and application run on the host MCU. Physical layer runs on BLE chipset.

B: BLE controller implementation

Link layer runs on BLE chipset, L2CAP, and higher BLE protocol (GATT, GAP) layers. Profiles and application run on the host MCU.

C: Network controller implementation

Link layer, L2CAP, GATT, GAP layers, and generic profiles run on the BLE chipset. Optional profiles and application run on the host processor.

BLE Framework Instances

An application must define the BLE Framework instance before using it. The instance is a structure that includes pointers to any of the following:

BLE Framework Control Structure

This structure is used in all BLE Framework APIs. This structure includes pointer to driver handle, which is used by the framework for storing the required information by the BLE device driver.

BLE Framework Configuration Structure

This structure is passed to sf_ble_api_t::open API and you can use this structure to configure the BLE module. This configuration is applied either during initialization, such as open or provisioning such as sf_ble_api_t::provisionSet API. Configuration parameters that are not supported by the BLE module are ignored by the framework.

BLE Framework APIs Structure

This structure contains pointers to the BLE Framework APIs that are specific to a given module. See Configuring the BLE Framework Module for more details on these APIs.

BLE Framework Module Operational Flow

The steps for using the BLE Framework module in an application are:

1. Initialize the BLE hardware module.
2. Select the GATT layer role such as GATT client or GATT server. It is most common for the slave (peripheral) device to be the GATT server and the master (central) device to be the GATT client.
3. The application controls operations using generic (on-board) profile APIs or GAP/GATT APIs.

Note

The GAP provisioning structure has a BLE user callback that runs in the driver thread context. An application should make sure that callback logic is as minimal as possible without any blocking calls. Print statements or blocking calls may introduce delays in BLE driver execution. Make sure that no BLE APIs are called in user callbacks as it may also lead to code failure.

BLE Module Initialization Flow Sequence

The following BLE module initialization sequence is part of the Synergy auto-generated code:

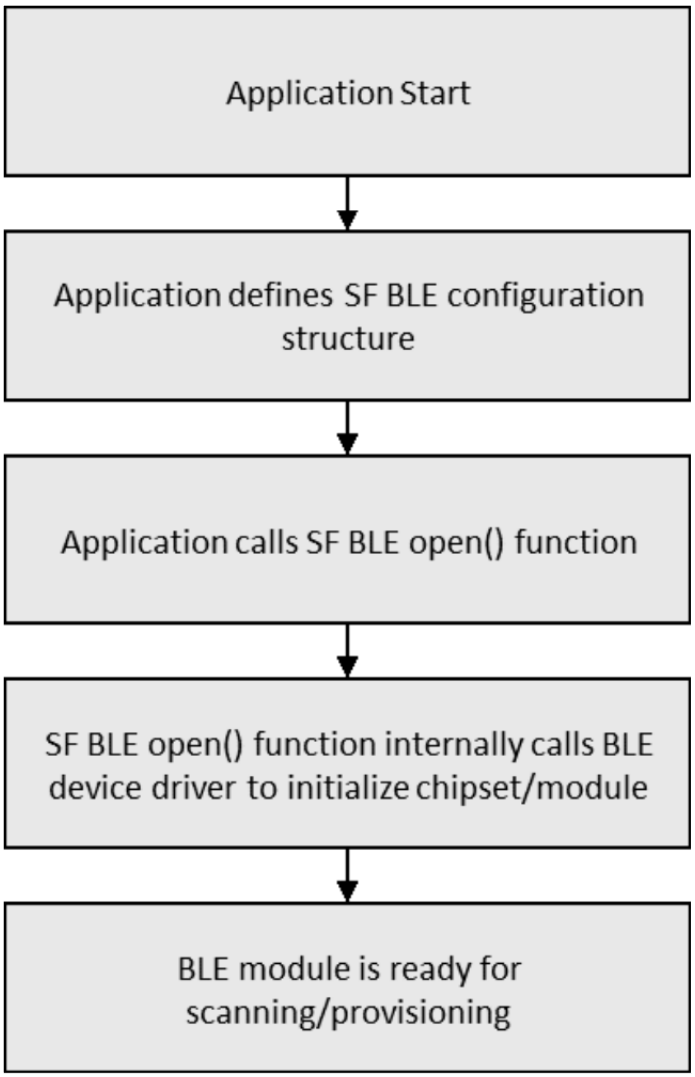

Figure 143: Auto-Generated Initialization Sequence Flow Chart

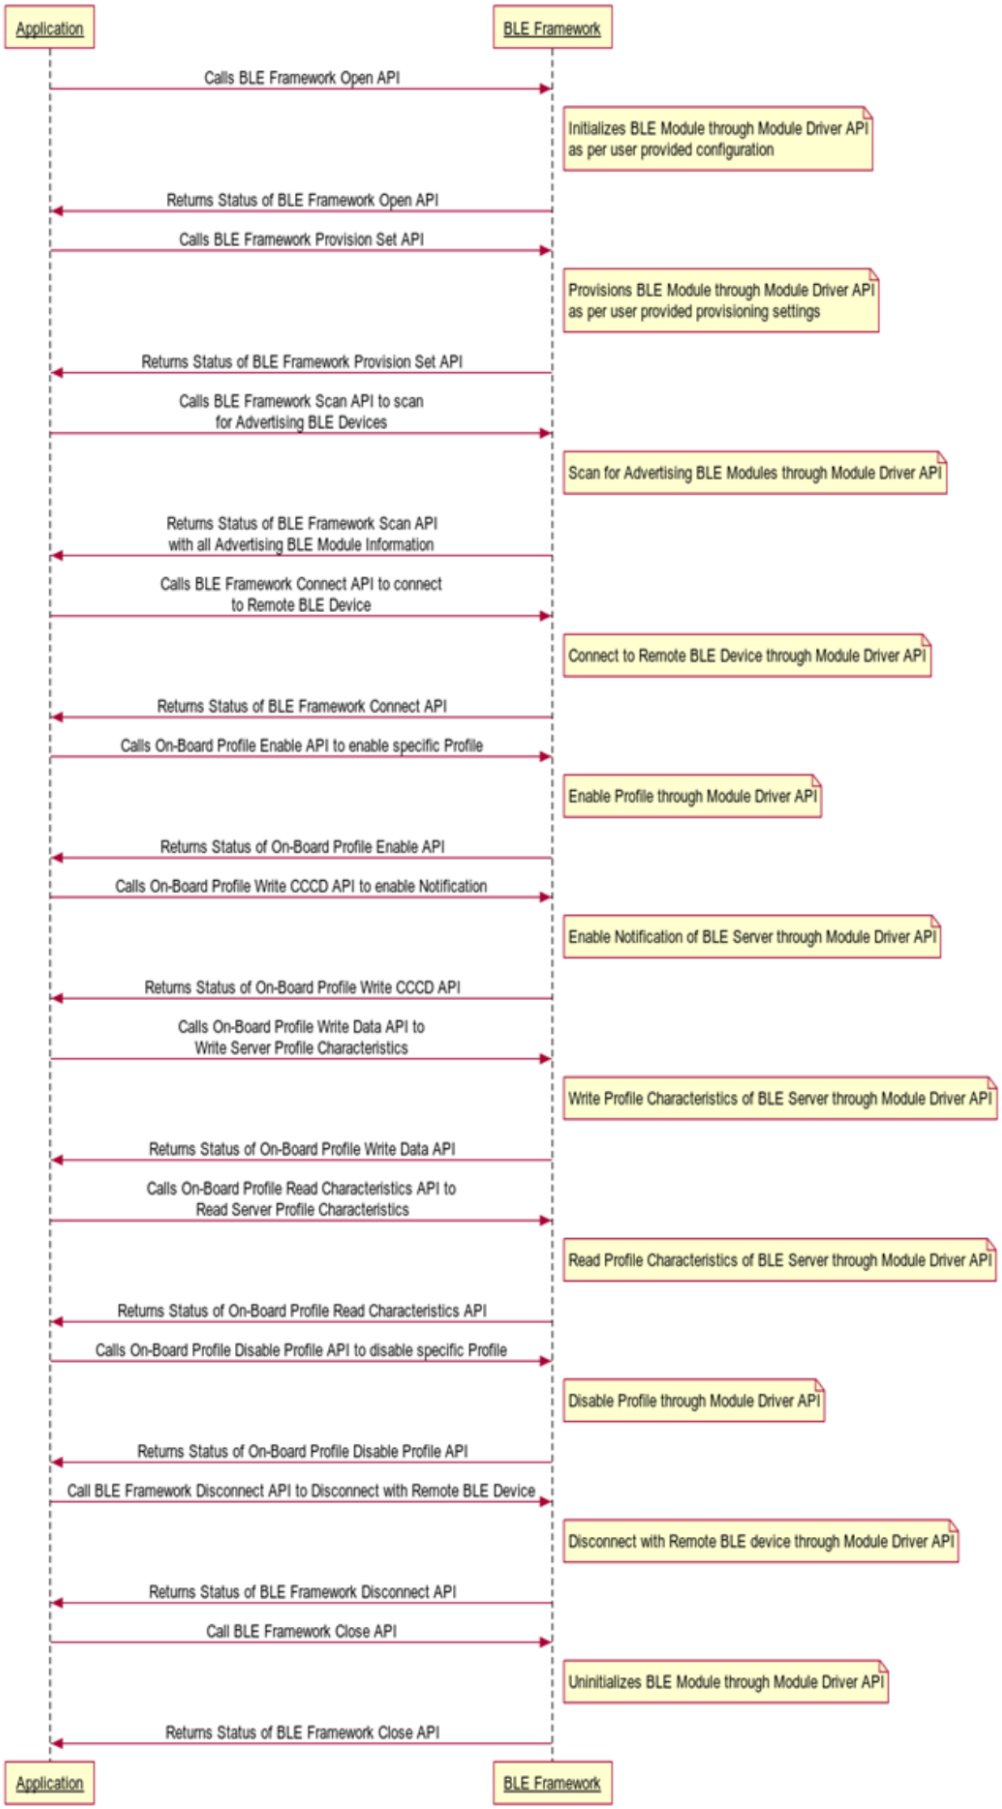
On-Board Profile-Based Client Application Flow Sequence



Application
BLE Framework
Calls BLE Framework Open API
Initializes BLE Module through Module Driver API as per user provided configuration
Returns Status of BLE Framework Open API
Calls BLE Framework Provision Set API
Provisions BLE Module through Module Driver API as per user provided provisioning settings
Returns Status of BLE Framework Provision Set API
Calls BLE Framework Scan API to scan for Advertising BLE Devices
Scan for Advertising BLE Modules through Module Driver API
Returns Status of BLE Framework Scan API with all Advertising BLE Module Information
Calls BLE Framework Connect API to connect to Remote BLE Device
Connect to Remote BLE Device through Module Driver API
Returns Status of BLE Framework Connect API
Calls On-Board Profile Enable API to enable specific Profile
Enable Profile through Module Driver API
Returns Status of On-Board Profile Enable API
Calls On-Board Profile Write CCCD API to enable Notification
Enable Notification of BLE Server through Module Driver API
Returns Status of On-Board Profile Write CCCD API
Calls On-Board Profile Write Data API to Write Server Profile Characteristics
Write Profile Characteristics of BLE Server through Module Driver API
Returns Status of On-Board Profile Write Data API
Calls On-Board Profile Read Characteristics API to Read Server Profile Characteristics
Read Profile Characteristics of BLE Server through Module Driver API
Returns Status of On-Board Profile Read Characteristics API
Calls On-Board Profile Disable Profile API to disable specific Profile
Disable Profile through Module Driver API
Returns Status of On-Board Profile Disable Profile API
Call BLE Framework Disconnect API to Disconnect with Remote BLE Device
Disconnect with Remote BLE device through Module Driver API
Returns Status of BLE Framework Disconnect API
Call BLE Framework Close API
Uninitializes BLE Module through Module Driver API
Returns Status of BLE Framework Close API
Application

BLE Framework

Figure 147: GAP/GATT Client Application Flow

BLE Framework Security

Security Manager provides BLE protocol stack the ability to generate and exchange security keys which is used to encrypt communication link. The Security Manager has two functions:

- Initiator - This is the GAP Master/Central device
- Responder - This is the GAP Slave/Peripheral device.

The initiator is the master device that initiate the security procedure, however the slave device can asynchronously request the initiator to begin the security procedure.

BLE Framework Security Modes

BLE Security provides modes with levels associated with each mode. Security mode and level is a combination of support for authenticated or unauthenticated pairing, encryption or data signing. Pairing is required to satisfy various security requirements. Two types of pairing are available:

Authenticated pairing where devices are protected from MITM (Man In The Middle) attacks

Unauthenticated pairing where they are not protected from MITM.

Security Mode 1

- Security Level 1: No Security
- Security Level 2: Unauthenticated pairing with encryption
- Security Level 3: Authenticated pairing with encryption
- Security Level 4: Authenticated LE secure connections pairing with encryption

Security Mode 2

- Security Level 1: Unauthenticated pairing with data signing
- Security Level 2: Authenticated pairing with data signing

Note

RL78G1D BLE module does not support Security Mode 1 with Security Level 4.

On-Board Profile Security Modes

No Security: If On-Board Profile security is set to No Security then Profile communication works in unsecured mode regardless of BLE GAP Security Mode and Level.

Unauthenticated: For this Profile Security method to work any of the BLE GAP Security Method other than Security Mode 1 Level 1 should be used. Module should have completed Pairing with the remote device.

Authenticated: For this Profile Security method to work any of the following BLE GAP Security Method should be used. Module should have completed Pairing with the remote device.

- Security Mode 1 Level 3
- Security Mode 2 Level 2

Authorization: For this Profile Security method to work the remote device should have been Authorized during GAP connection using BLE Framework authorization API. This On-Board profile security parameter is specific to server API only.

Encryption: In this Security procedure, the profile will use encrypted communication. For this Profile Security method to work, any of the BLE GAP Security methods other than Security Mode 1 Level 1 should be used. If any security method that does not use encryption is used, then the profile works in unencrypted mode.

1. On-Board Profile security can be set in the sf_ble_onboard_profile_api_t::onbpEnable function. The sf_ble_onboard_profile_api_t::onbpEnable API enables the profile in server mode or client mode. It is a generic API to enable client and server mode. But, the profile security parameter is specific to server API only. Security parameter can be set for server only in driver APIs. So, user needs to set profile security for server enable API.
2. Profile security enums are in bit pattern, so more than one profile security can be set using bitwise operators. There are a few points to keep in mind while setting the profile security:
    - If profile security is none, then other security bits should not be set.
    - Security bits should not be set to both authenticated and unauthenticated.

BLE Framework Security Procedure

BLE Security has the following procedures:

- Pairing: This procedure is used to generate temporary encryption key to encrypt communication link. Permanent encryption keys can be shared over this encrypted communication link for additional communication.
- Bonding: This is a combination of pairing and storing of permanent keys. After pairing, the permanent keys are stored in a non-volatile memory, which creates a permanent bond between two devices. For subsequent communication, it is not necessary for devices to perform the bonding procedure.
- Encryption Establishment: Communication is encrypted using permanent keys.

Pairing creates a secure link that lasts for the lifetime of the connection, whereas bonding creates a permanent association called bond.

BLE Security Phases

BLE Security goes through three phases. Two devices establish connection using the GAP connection procedure, followed by the three phases to establish a secure communication link:

- Phase 1 (Pairing Phase, Information Sharing): Initially in phase 1, all information required to generate the temporary keys are shared between two devices.
- Phase 2 (Pairing Phase, Temporary Key Sharing): In this phase, temporary encryption key (Short Term Key or STK) is generated on both devices. This is used to encrypt the connection. This encrypted link can be used for additional communication. This communication link remains encrypted until the peer devices stay connected.
- Phase 3 (Bonding, Sharing and Storage of Permanent keys): Devices enter this phase if bonding is required. In this phase, permanent keys (Long Term Key or LTK) are exchanged between two devices using the encrypted link, which was established in phase 2 using temporary keys. These permanent keys are then stored in non-volatile memory to be made available for the devices over each connection.

BLE Framework Module Limitations

1. The BLE framework is tested only on the RL78G1D BLE hardware module. Support for

different BLE modules will be added in later versions.
2. BLE Framework using RL78G1D will see compilation warnings. All the warnings are in the 3rd party RL78G1D driver code. The BLE framework files do not have any warning. These warnings should not impact the user applications.
3. The custom profile support in the BLE framework is limited to the RL78G1D type BLE hardware module only.
4. HID profile client mode, not supported by the RL78G1D BLE hardware module. As a result, the BLE framework implementation of the HID profile will also not support the HID profile client mode. Applications using BLE framework for RL78G1D will not be able to use the HID profile in client mode.
5. Multiple slave BLE devices cannot be connected to the RL78G1D BLE module.

The BLE framework is only tested on the following boards:

- DK-S7G2 Version 3.1
- DK-S3A7 Version 2.0
- PK-S5D9 Version 1.0
- ADK-S3A3
- TB-S5D5 Version 0.5D
- TB-S3A6 Version 0.5D
- DK-S128 Version 0.5b
- DK-S124 Version 3.1

Refer to the most recent SSP Release Notes for module limitations.

4.1.11.4 Including the BLE Framework Module in an Application

This section describes how to include the BLE Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the BLE Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the BLE Framework module is g_sf_ble0. This name can be changed in the associated Properties window.)

BLE Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_ble0 RL78G1D BLE GAP and GATT on sf_ble_rl78g1d	Threads	**New Stack> Framework> Networking> BLE> RL78G1D BLE GAP and GATT on sf_ble_rl78g1d**
g_sf_ble_onboard_profile0 On-Board Profile on RL78G1D BLE Framework	Threads	**New Stack> Framework> Networking> BLE> On-Board Profile on RL78G1D BLE Framework**

When the BLE Framework module on sf_ble is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing

additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

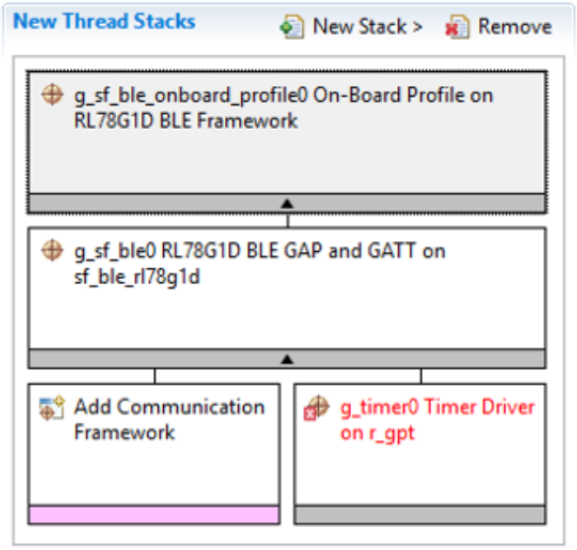

Figure 148: BLE Framework Module Stack

In the stack above, the Add Communication Framework block has not been populated yet. There are multiple possible selections for the Communication Frameowork; they are not all provided so as to not complicate needlessly, the figure and the following configuration tables. Typical options include:

- Communications Framework on sf_comms_telnet
- Communications Framework on sf_el_ux_comms_v2
- Communications Framework on sf_uart_comms

4.1.11.5 Configuring the BLE Framework Module

The BLE Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuring the On-Board Profile Profile on RL78G1D BLE Framework

Configuration Settings for the On-Board Profile on RL78G1D BLE Framework

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Heart Rate Profile	Enabled, Disabled Default: Enabled	Heart rate profile selection.
Alert Notification Profile	Enabled, Disabled Default: Disabled	Alert notification profile selection.
Blood Pressure Profile	Enabled, Disabled Default: Disabled	Blood pressure profile selection.
Find Me Profile	Enabled, Disabled Default: Disabled	Find me profile selection.
HID Over GATT Profile	Enabled, Disabled Default: Disabled	HID gatt profile selection.
Health Thermometer Profile	Enabled, Disabled Default: Disabled	Health thermometer profile selection.
Phone Status Alert Profile	Enabled, Disabled Default: Disabled	Phone alert profile selection.
Proximity Profile	Enabled, Disabled Default: Disabled	Proximity profile selection.
Scan Parameter Profile	Enabled, Disabled Default: Disabled	Scan parameter profile selection.
Time Profile	Enabled, Disabled Default: Disabled	Time profile selection.
Name	g_sf_ble_onboard_profile0	Module name.
Name of generated initialization function	sf_ble_rl78g1d_onboard_profile_init0	Name of generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the BLE GAP and GATT on sf_ble_rl78g1d

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_ble0	Module name.
Bluetooth Device Address (Restart Board after first run to see changed Address)	{0x0, 0x0, 0x0, 0x0, 0x0}	Bluetooth device address selection.
Address Type	Public Address, Random Address Default: Public Address	Address type selection.
Scan Interval	48	Scan interval selection.
Scan Window	48	Scan window selection.
Maximum Connection Interval	40	Maximum connection interval selection.
Connection Slave Latency	0	Connection slave latency selection.
Supervision Timeout	80	Supervision timeout selection.
BLE Driver Thread Priority	1	BLE Driver thread priority selection.
BLE Serial Thread Priority	1	BLE Serial thread priority selection.
Name of generated initialization function	sf_ble_rl78g1d_init0	Name of generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuring the On-Board Profile Profile on RL78G1D BLE Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the lower-

level modules.

Configuration Settings for the Timer Driver on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Warning: One-shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR, called when the period expires. For this reason, ISRs must be enabled for one-shot mode even if the callback is unused.
Duty Cycle Range (only applicable in PWM mode)	Shortest: 2 PCLK, Longest (Period-1) PCLK/Shortest: 1 PCLK, Longest: (Period-2) PCLK Default: Shortest 2 PCLK, Longest: (Period-1) PCLK	Select the duty cycle range. Due to hardware limitations, one PCLK is added before the output pin toggles after the duty cycle is reached. This extra clock cycle is added to the ON time (if Shortest: 2 PCLK is selected) or the OFF time (if Shortest: 1 PCLK is selected) based on this configuration.
Period Value	10	See Timer Period Calculation.
Period Unit	Milliseconds	See Timer Period Calculation.
Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts	Duty cycle unit selection.
Auto Start	True	Set to true to start the timer after configuring or false to leave the timer stopped until timer_api_t::start is called.
GTIOCA Output Enabled	False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low	Controls output pin level when the timer is stopped.

GTIOCB Output Enabled	False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCB Stop Level	Pin Level Low	Controls output pin level when the timer is stopped.
Callback	RBLE_Timer_cb	A user callback function can be registered in timer_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Overflow interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

BLE Framework Module Clock Configuration

The BLE Framework module uses the clocks specified by the lower-level modules.

BLE Framework Module Pin Configuration

The BLE Framework module uses the pins specified by the lower-level modules.

4.1.11.6 Using the BLE Framework Module in an Application

The steps in using the Bluetooth Low Energy Framework module in a typical application are:

1. Initialization- registration of callback functions, provisioning, and advertisement using the sf_ble_api_t::open API.

2. Provision the BLE module using the sf_ble_api_t::provisionSet API.

3. Scan for advertisement using the sf_ble_api_t::scan API.

4. Connect to remote BLE device using the sf_ble_api_t::connect API.

5. Enable the on-board profile using the sf_ble_onboard_profile_api_t::onbpEnable API.

6. Enable notification using the sf_ble_onboard_profile_api_t::onbpClientWriteCCCD API.

7. Write profile characteristics using the sf_ble_onboard_profile_api_t::onbpServerWriteData API.

8. Read profile characteristics using the sf_ble_onboard_profile_api_t::onbpClientReadChar API.

9. Disable the profile using the sf_ble_onboard_profile_api_t::onbpDisable API.

10. Disconnect from the remote BLE device using the sf_ble_api_t::disconnect API.

11. Close the BLE module using the sf_ble_api_t::close API.

The following figure illustrates common steps in a typical operational flow diagram:

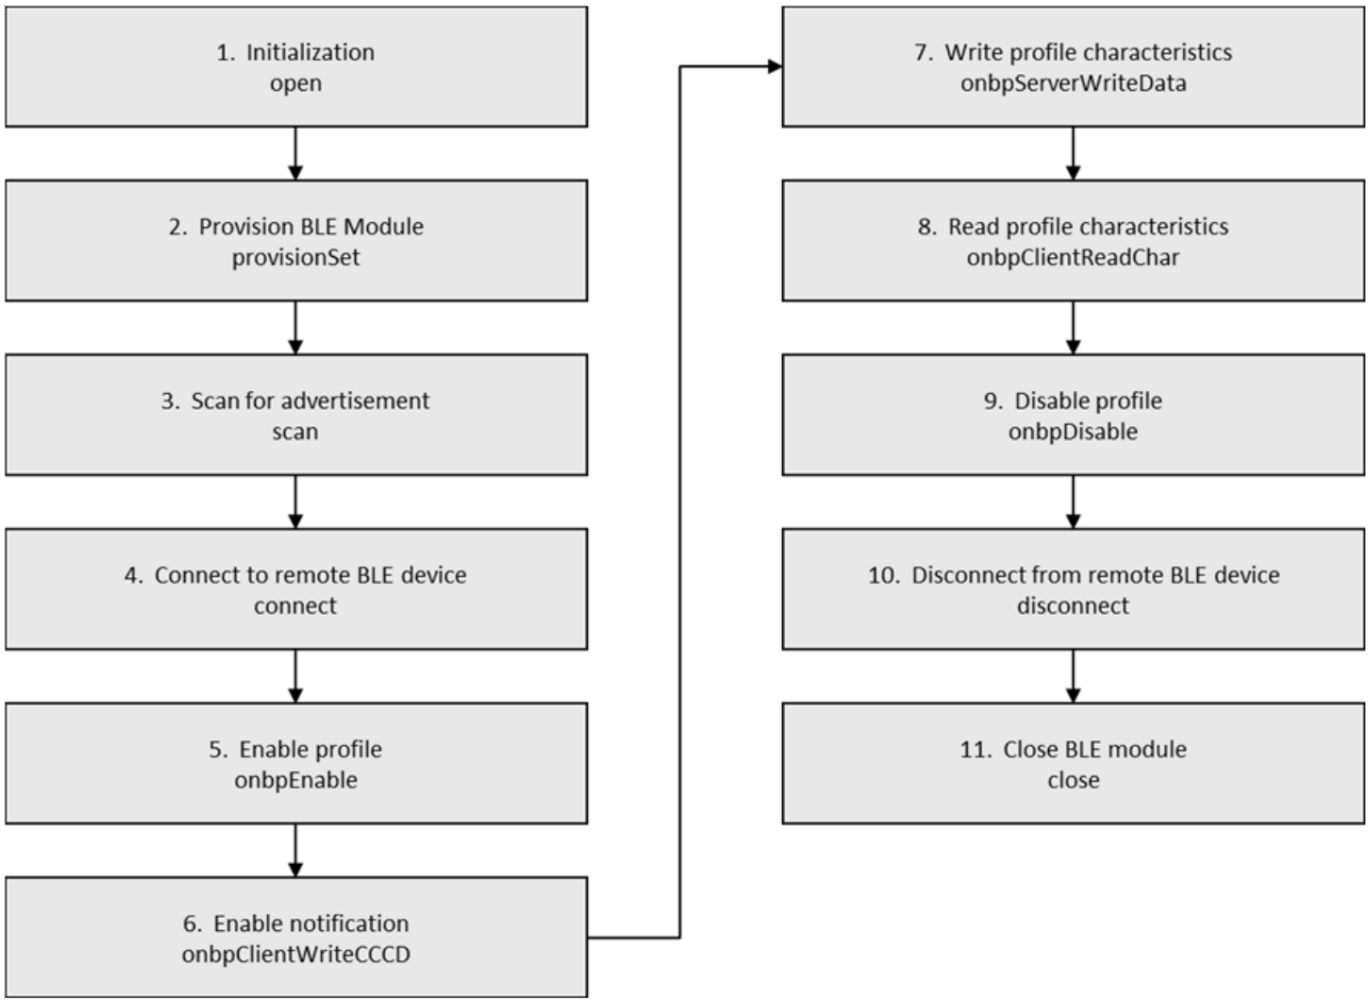

Figure 149: Application Control Flow using BLE Module Initialization

4.1.12 Cellular Framework

4.1.12.1 Cellular Framework Introduction

The Cellular Framework module provides a high-level application layer interface for cellular modem integration in SSP. The Cellular Framework provides a common interface for the applications to interface with the cellular modems from various vendors.

The Cellular Framework provides a set of APIs to provision, configure, and communicate with the cellular network for data communication. The Cellular Framework uses the UART Comms Framework to communicate with cellular modems over a serial interface by using AT commands. The Cellular framework creates the serial data pipe over a serial interface for the data communication, leveraging the PPP WAN protocol provided by NetX™. Data communication using TCP/IP can be established over this Wide Area Network (WAN) link using NetX Application protocols, sockets or IoT protocols such as MQTT.

The Cellular Framework also provides the framework-level socket APIs to communicate with the TCP/IP stack present on-chip (inside cellular hardware module) in certain cellular hardware modules and with the TCP/IP link for the network using socket APIs.

Cellular Framework Module Features

- Supports connectivity using:
  - BSD Socket interface for On-Chip stack present on the Cellular Module
  - NetX Stack on Synergy MCU (Host) using NSAL interface
- Supports a common a set of APIs to interface to the networking stack and a generic interface for the different Cellular hardware modules.
- Using generic APIs and abstraction, applications developed for the cellular hardware module can be easily migrated to work with another cellular hardware module.
- Supported Cellular modems:
  - RYZ014A CAT M1 (PMOD Expansion Board for RYZ014A) (For information on this kit, see: https://www.renesas.com/us/en/products/interface-connectivity/wireless-communications/cellular-iot-modules/rtkyz014a0b00000be-pmod-expansion-board-ryz014a)
  - Quectel BG96 (CAT M1, NB-IoT and GPRS) Rev F

Note

The following boards are obsolete and are no longer supported in SSP:

- NimbeLink CAT3 (NL-SW-LTE-TSVG, REVISION 17.01.571) Verizon-US
- NimbeLink CAT3 (NL-SW-LTE-TEUG, REVISION 17.01.571) India and Europe
- NimbeLink CAT1 (NL-SW-LTE-GELS3-B and NL-SW-LTE-GELS3-C, REVISION 4.3.3.0c) Verizon-US

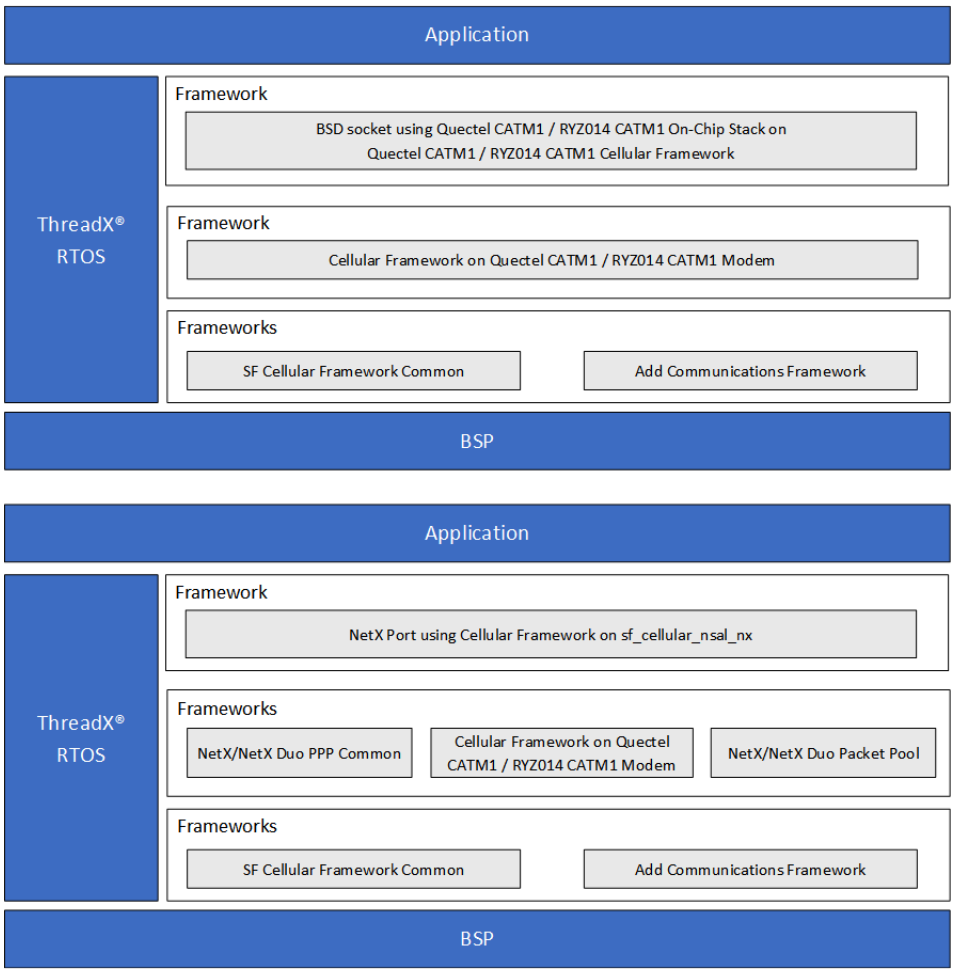

Figure 150: Cellular Framework Module Block Diagram

Note

Any of the four BSD Socket On-Chip stacks can implement any of the four Cellular Framework modules below it. Similarly, the NetX Port on sf_cellular_nsal_nx can implement any of the four Cellular Framework modules below it.

4.1.12.2 Cellular Framework Module APIs Overview

The Cellular Framework defines APIs for each of the related modules. The following descriptions explain the operation of each API.

Note

A more detailed description of the Cellular framework module APIs are available in the Cellular Application Note, downloadable from the Renesas web site. Just search, in the top search bar, for R30AN0311 and the application note and application project will be listed in the search results.

Cellular Framework Module APIs

Cellular Framework Module API Summary

Function Name	Example API Call and Description

open	g_sf_cellular0.p_api->open (g_sf_cellular0.p_ctrl, g_sf_cellular0.p_cfg); This API function initializes and enables the Cellular module. The open function returns the Cellular control structure, uniquely identifying the instance of the Cellular framework. The Cellular framework open function accepts the Cellular module configuration as an argument, with the following parameters: - Operator Selection Mode (enumeration) - Operator Name Format (enumeration) - Operator Name (string) - Preferred Operator List (array of structures) - Time zone update policy (enumeration)
close	g_sf_cellular0.p_api->close (g_sf_cellular0.p_ctrl); This API uninitializes the Cellular module and disables it. It takes the Cellular control structure as an argument.
infoGet	g_sf_cellular0.p_api->infoGet (g_sf_cellular0.p_ctrl, p_cellular_info); This API takes the Cellular control structure as an argument and returns the following information obtained from the Cellular module: - Chipset/driver information (string) - Manufacturer name (string) - Firmware version (string) - IMEI number (string) - RSSI value (unsigned integer 16 bits) - Bit Error Rate (unsigned integer 16 bits)
statisticsGet	g_sf_cellular0.p_api->statisticsGet (g_sf_cellular0.p_ctrl, p_stats); This API gets the data statistics from the Cellular module. It takes the Cellular control structure as an argument and returns the following statistics: - Received packets (unsigned integer 32 bits) - Transmitted packets (unsigned integer 32 bits) - Transmit packet errors (unsigned integer 32 bits)
transmit	g_sf_cellular0.p_api->transmit (g_sf_cellular0.p_ctrl, p_buffer, length); This API sends the data/packet out. It takes the Cellular control structure, the data buffer and the data buffer length as an argument. The Cellular framework transmit function passes the data buffer to the PPP driver for transmission.

provisioningGet	g_sf_cellular0.p_api->provisioningGet (g_sf_cellular0.p_ctrl, p_cellular_provisioninfo); This API takes the Cellular control structure as an argument and returns the following parameters: - Authentication type(enumeration) - Username (string) - Password (string) - APN Name(string) - PDP Context ID (integer) - PDP Context Type (enumeration) - Airplane mode (enumeration)
provisioningSet	g_sf_cellular0.p_api->provisioningSet (g_sf_cellular0.p_ctrl, p_cellular_provisioninfo); This API sets the authentication credential information. It takes the Cellular control structure and the following parameters as argument to provision the Cellular module: - Authentication type(enumeration) - Username (string) - Password (string) - APN Name(string) - PDP Context ID (integer) - PDP Context Type (enumeration) - Airplane mode (enumeration)
networkConnect	g_sf_cellular0.p_api-> networkConnect (g_sf_cellular0.p_ctrl); This API establishes the Network connection over Cellular Network, using which the application can communicate to remote host with the help of Network stack. It takes the Cellular control structure as an argument.
networkDisconnect	g_sf_cellular0.p_api->networkDisconnect (g_sf_cellular0.p_ctrl); This API terminates the Network connection established using networkConnect API. It takes the Cellular control structure as an argument.
simPinSet	g_sf_cellular0.p_api->simPinSet (g_sf_cellular0.p_ctrl, p_pin); This API allows the application/user to change the PIN required to register on Cellular Network. It takes the Cellular control structure, old PIN and New PIN as arguments.
simLock	g_sf_cellular0.p_api->simLock (g_sf_cellular0.p_ctrl, p_pin); This API locks the SIM. It takes the Cellular control structure and Sim PIN as arguments.

simUnlock	g_sf_cellular0.p_api->simUnlock (g_sf_cellular0.p_ctrl, p_pin); This API unlocks the SIM. It takes the Cellular control structure and Sim PIN as arguments.
simIDGet	g_sf_cellular0.p_api->simIDGet (g_sf_cellular0.p_ctrl, p_sim_id); This API reads the Sim ID from the Cellular module. It takes the Cellular control structure as argument and returns the SIM ID read from the Cellular module.
commandSend	g_sf_cellular0.p_api->commandSend (g_sf_cellular0.p_ctrl, p_input_at_commmand, p_output, timeout); Send AT command directly to Cellular Modem.
networkStatusGet	g_sf_cellular0.p_api-> networkStatusGet (g_sf_cellular0.p_ctrl, p_status); This API gets Cellular Module Network Status information. It takes the Cellular control structure as argument and returns following parameters: - Country code (integer) - Operator code (integer) - RSSI (integer) - Cell ID (string) - IMSI (string) - Operator name (string) - Service Domain (integer) - Active Band (integer).
versionGet	g_sf_cellular0.p_api->versionGet (p_version); This API retrieves the version for the API using the version pointer.
reset	g_sf_cellular0.p_api->reset (g_sf_cellular0.p_ctrl, reset_type); Reset the cellular hardware module.

Note

*** **When using commandSend API with RYZ014 cellular modem always give the exact size of the AT command in the p_input_at_commmand parameter.*
For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables review the SSP User's Manual API References for the associated module.

Cellular Framework Module Socket APIs Summary

These APIs can be used to configure the cellular module when using an on-chip networking stack, which helps to ping particular ip address, opening and closing of scokets and also to perform socket operations like TCP/UDP data transfer.

On-Chip Networking Stack Support Cellular Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_cellular_socket0.p_api->open (g_sf_cellular_socket0.p_ctrl, g_sf_cellular_socket0.p_cfg); This API calls the Cellular Framework's lower level open () API to Initialize the Cellular Device Driver.
close	g_sf_cellular_socket0.p_api->close (g_sf_cellular_socket0.p_ctrl); This API calls the Cellular Framework's lower level close () API to close the Cellular Device Driver.
versionGet	g_sf_cellular_socket0.p_api->versionGet (p_version); This API retrieves the version for the API using the version pointer.
ping	g_sf_cellular_socket0.p_api->ping (g_sf_cellular_socket0.p_ctrl, p_ip_address, count, interval_ms); This api pings the IP address provided by user.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

These API functions can be used by an application to perform data transfers using sockets. They include socket API functions which are compliant with these BSD API functions:

- socket
- close
- connect
- send
- recv
- sendto
- recvfrom
- select

Note

Ping functionality is supported only for RYZ014A CATM1 modem and is an unsupported feature for Quectel CATM1 modems.

Cellular Framework Error Codes

The following table lists the Cellular Framework specific error codes. These error codes are part of ssp_err_t.

Cellular Framework Error Codes

Error Codes	Description
SSP_SUCCESS	Call successful.

SSP_ERR_CELLULAR_CONFIG_FAILED	Configuration failed.
SSP_ERR_CELLULAR_INIT_FAILED	Initialization failed.
SSP_ERR_CELLULAR_TRANSMIT_FAILED	Transmit failed.
SSP_ERR_CELLULAR_FW_UPTODATE	Up to date.
SSP_ERR_CELLULAR_FW_UPGRADE_FAILED	Upgrade failed.
SSP_ERR_CELLULAR_FAILED	General failure.
SSP_ERR_CELLULAR_INVALID_STATE	Invalid state.
SSP_ERR_CELLULAR_REGISTRATION_FAILED	Registration failure.

4.1.12.3 Cellular Framework Module Operational Overview

The Cellular Framework provides a generic interface for applications to seamlessly communicate with the cellular hardware module from various vendors without the necessity of changing the applications. The framework mainly consists of a common set of APIs to interface to the networking stack and different cellular hardware modules. This section introduces the Cellular Framework's basic blocks and key features that enable you to determine whether the intended cellular application can be developed using the Cellular Framework.

Note

Additional operational descriptions of the Cellular Framework module are available in the Cellular Application Note, downloadable from the Renesas web site. Search (in the search bar at the top of the screen) for R30AN0311 and the application note and application project will be listed in the search results.

With the provided API and abstraction, the applications developed for the cellular hardware module can be easily ported to use another cellular hardware module. The networking stack NetX is also integrated with the framework using the Network Software Abstraction Layer (NSAL).

The Synergy Cellular Framework consists of the following logical blocks:

- Synergy Cellular Framework Application Interface.
- Network Stack Abstraction Layer (NSAL) for NetX TCP/IP stack.
- Cellular Device Driver (AT command interface for interacting with the cellular chipset).
- BSD Socket compatible APIs for interfacing with Cellular hardware module that supports on-chip networking stack.
- Synergy Software Package(SSP) HAL Interface.

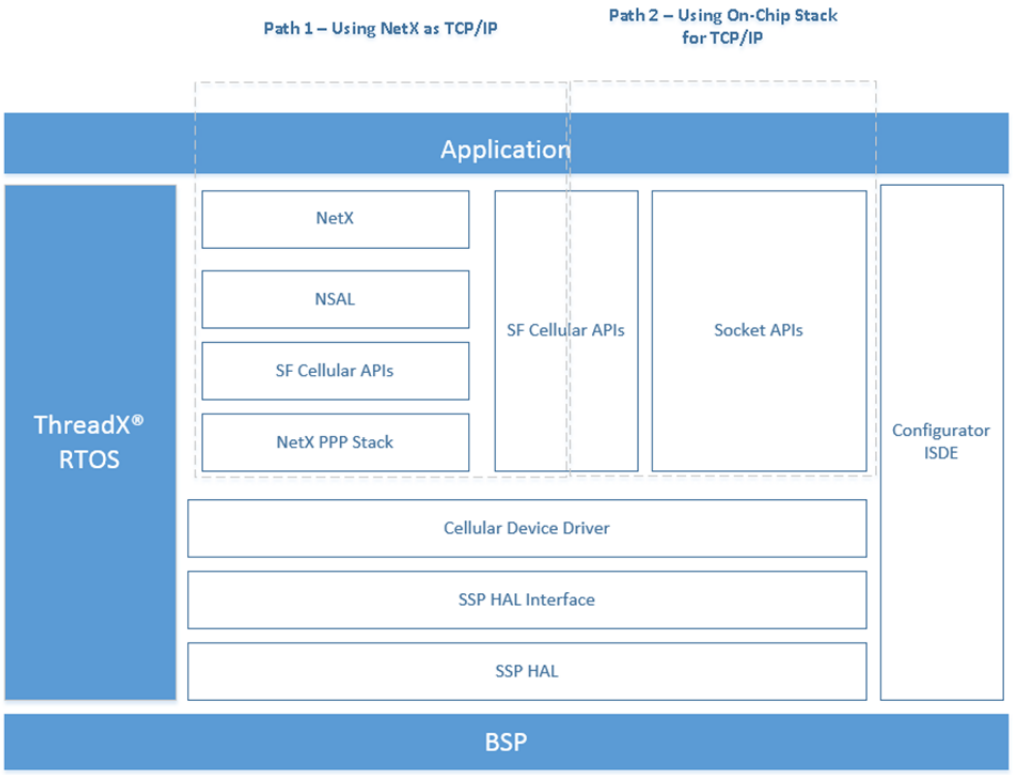

Figure 151: Cellular Framework Module Application Perspective

The Cellular Framework provides a common set of interfaces for the application to configure, provision and to communicate with the cellular hardware module. By using these generic interfaces, the user can develop a cellular-based application using Synergy MCUs. The cellular hardware module has various configuration parameters as specified by the family of 3GPP standards. It is possible that individual device drivers and/or cellular chipsets/modules will not support configuration of all parameters. At a bare minimum, the network operator, Access Point Name (APN) and security credentials are required to make the module functional.

Network Stack Abstraction Layer

The Cellular Framework provides a network stack abstraction layer (NSAL). The NSAL is layer that connects the NetX and the cellular driver by using a (PPP) stack that is used for data communication over a WAN link.

Socket Interface Layer

The Cellular Framework provides a socket-level API for the application to interact with the on-chip networking stack present on the cellular hardware module. This requires the cellular hardware module/driver to support an on-chip networking stack and socket interface. When the application uses these APIs, it uses the on-chip networking stack present on the cellular hardware module and does not use the NSAL or the NetX and its socket APIs and does not use the Networking stack running on the Synergy MCU Group.

PPP Stack

Point to point protocol (PPP) is a widely used WAN protocol in data communication. The PPP stack is a part of the NetX stack available in the SSP. The NSAL leverages the PPP stack to communicate over

the serial interface to the cellular service provider's network. PPP configuration provides options for authentication methods like PAP/CHAP; these authentication mechanisms are optional for the link establishment. The NSAL makes use of framework APIs to send/receive data from the cellular hardware module. The NSAL also allows the cellular device driver to be re-used without any specific changes to the network stack.

Cellular Device Driver (AT Command Interface For Interacting With The Cellular Chipset)

The Cellular Framework uses the AT command set to interact with the cellular modem using the serial driver. The serial interface used to interact with the modem is the UART. The UART speed used in the framework defaults ranges up to 115200 bits/sec.

Cellular Framework Module Important Operational Notes and Limitations

Cellular Framework Module Operational Notes

The application can be used in two different paths for the communication using the framework, depending on the support available on the cellular modems. Some modules provide options to use the TCP/IP stack at the host end and other modules provide options to use the TCP/IP stack present on the cellular modem itself. In some cases, the cellular hardware module provides both. When the host TCP/IP stack (NetX) is used, the logical layers of NetX, the NSAL and the PPP are used as described in the architecture diagram. When the on-chip stack is used, the socket APIs are used to communicate with the TCP/IP stack present on the cellular modem. However, the user cannot use both at the same time.

In the sf_cellular_qctlcatm1 framework, AT commands should be passed after the "APP RDY" string. However, in the current sf_cellular_qctlcatm1 framework, AT commands are being passed before the "APP RDY" string is received. There is no functional impact because, in the current sf_cellular_qctlcatm1 framework, instead of checking the "APP RDY" string, "OK" response is being checked in the BG 96 modem, which ensures that the modem is working.

Cellular Framework Module Initialization

As shown in the following control flow diagram, during the initialization using the configuration supplied by the user as required for the cellular modem, nx_ip_create is called. This API internally invokes the NSAL driver entry function that takes care of the link-level initialization and initializes the cellular hardware module. Additionally, it provisions the module and establishes the Network connection using the PPP interface.

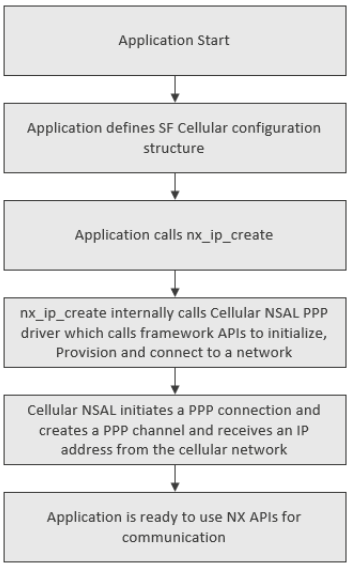

Figure 152: Cellular Framework Module Initialization Sequence

Cellular Hardware Module Provisioning

During the provisioning of the cellular modem, control structure and user configuration structures are passed as arguments. The details of the user arguments used for provisioning are the authentication, APN, username and password.

Application Flow Control Using the Socket Interface

The following flow diagram shows the flow for the on-chip stack path usage with the Cellular Socket interface.

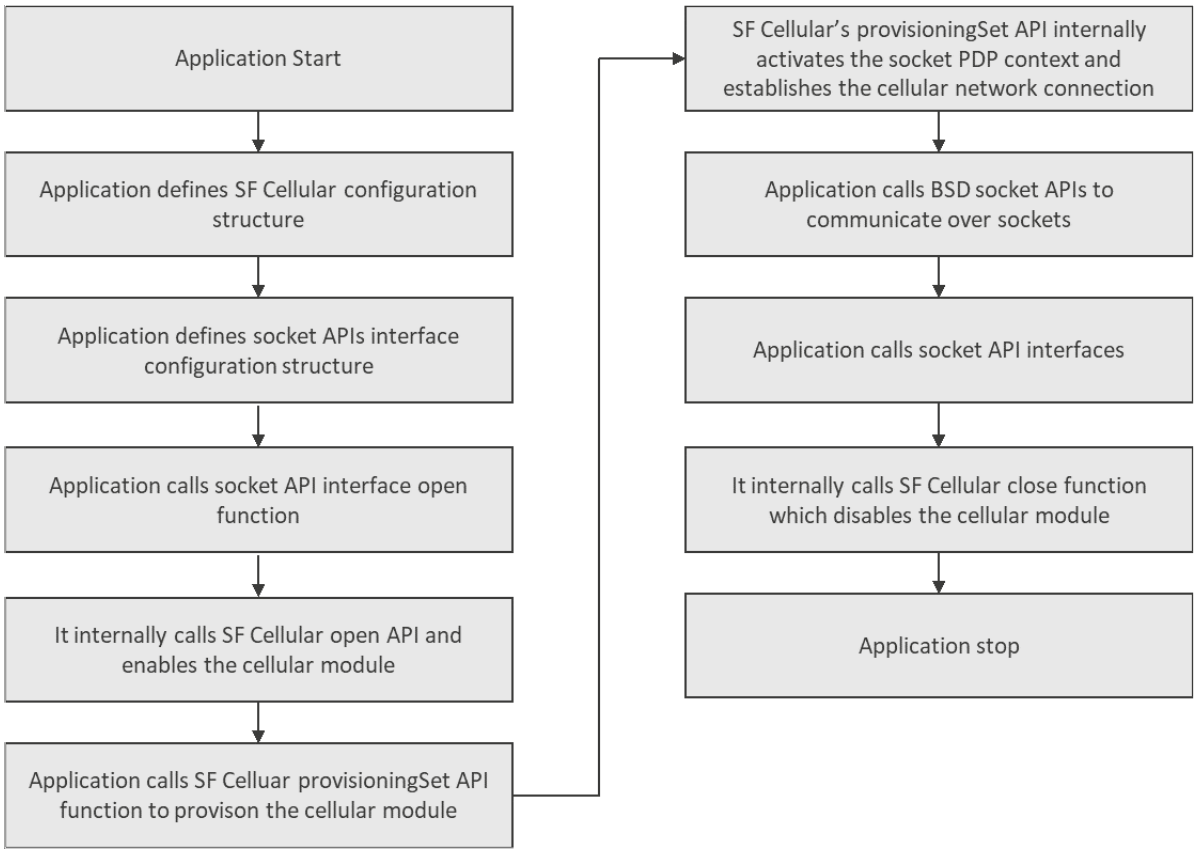

Figure 153: Cellular Framework Module Socket Interface

Cellular Packet Transmission

The following flow diagram shows the sequence of steps that the packet transmission uses for the NetX application.

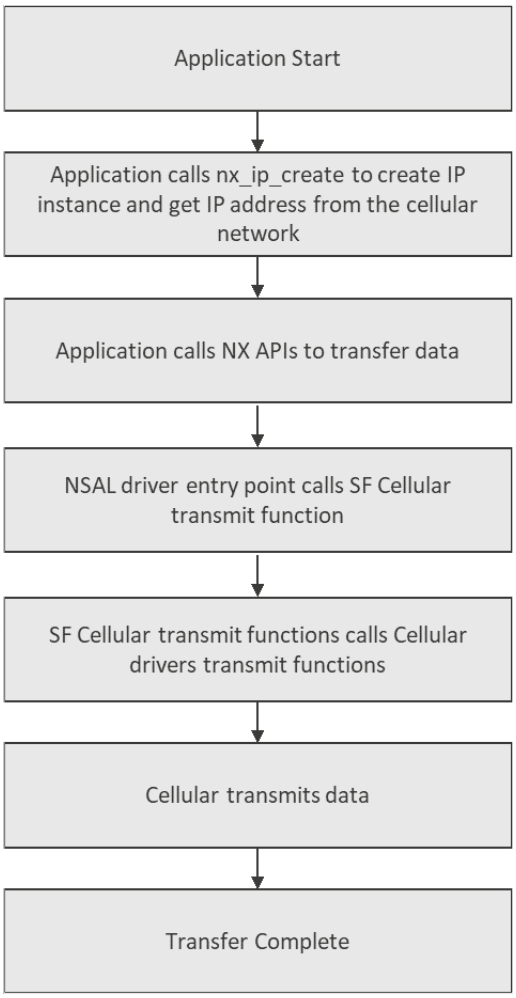

Figure 154: Cellular Framework Module Packet Transmission Sequence

Cellular Packet Reception

The following flow diagram shows the Packet reception for the Cellular Framework using NetX. In the case of a receive, when the data is received on the serial interface, the processing thread triggers the callback function and the callback functions handles the data and sends it to the NetX layers for further processing.

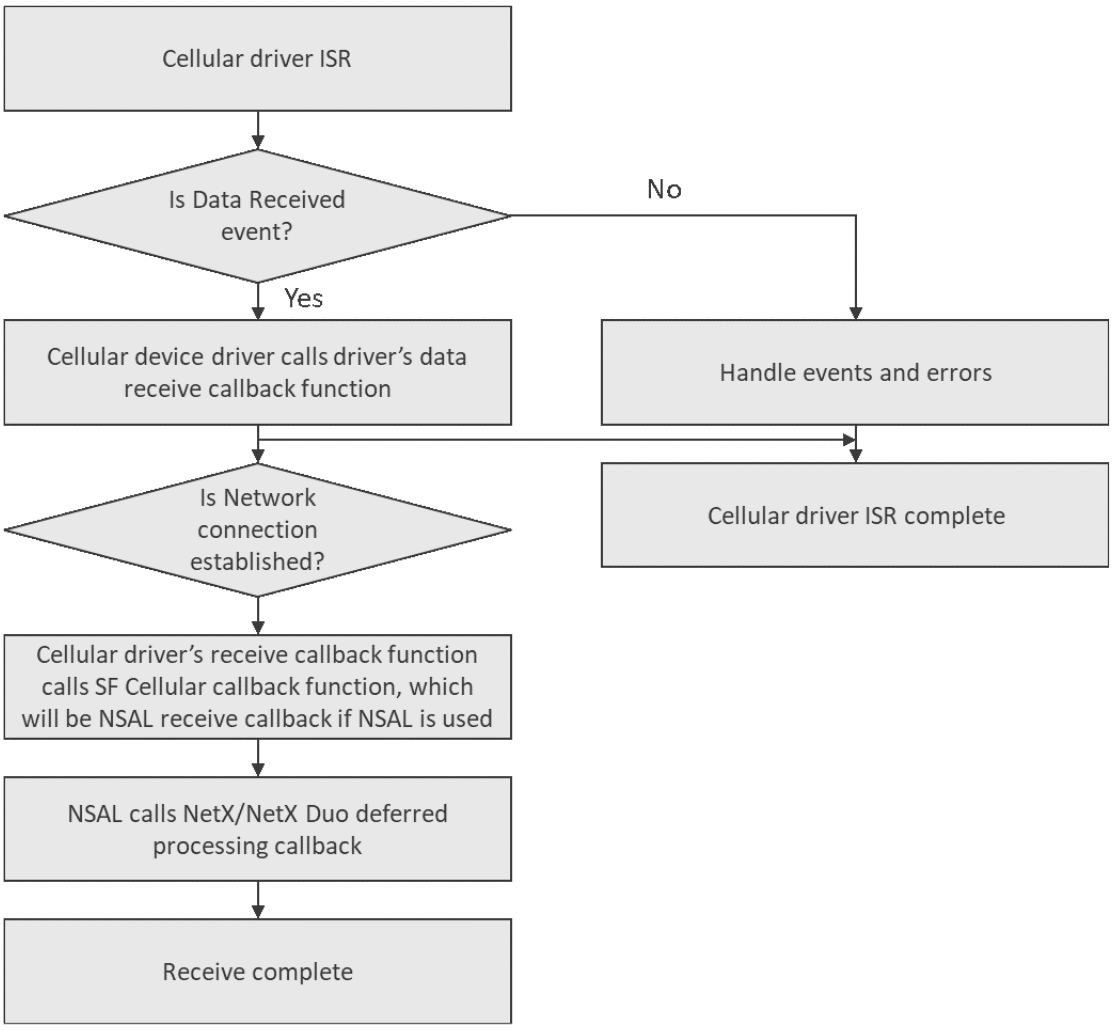

Figure 155: Cellular Framework Module Packet Reception Sequence

Cellular Module baud rate

The Cellular Framework baud rate update feature works in the following stages:

- Check if the modem is operating at the baud rate set by the user in ISDE. If so, proceed with modem initialization.
- If the modem is not responding over the user specified baud rate, auto detect the baud rate at which the modem is currently operating.
- Switch the modem to the baud rate configured by the user in the ISDE. (This baud rate is then saved on the module).

The developer can configure the Baud rate of the UART under SF_CELLULAR in ISDE configuration as shown in the below image. This is the baud rate at which user wants the Modem to operate.

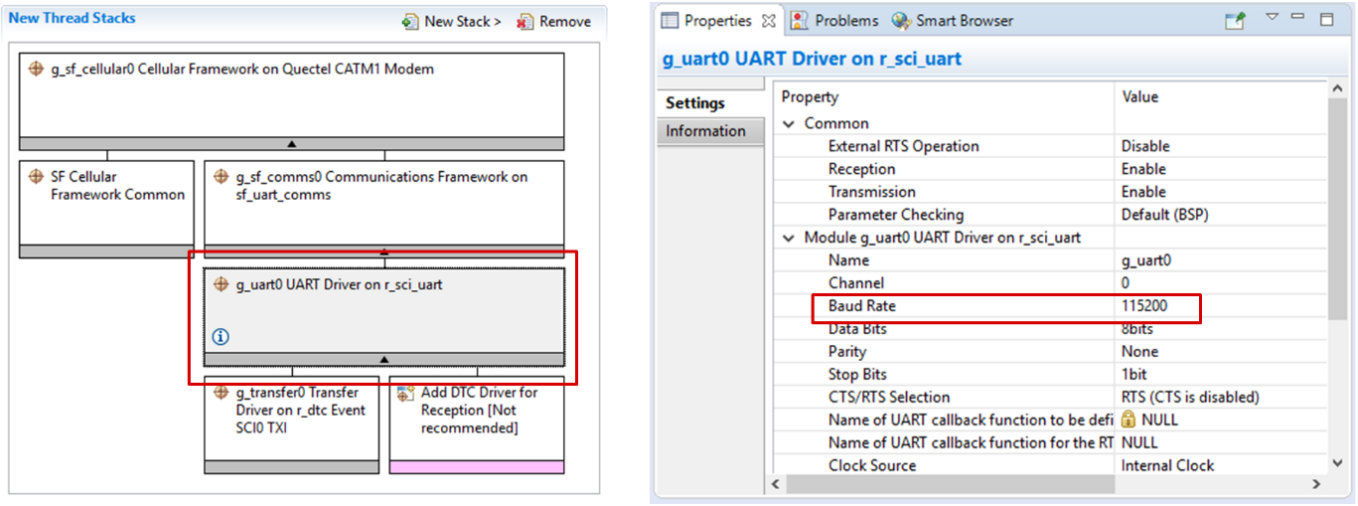

Figure 156: ISDE configuration for baud rate

Operational Steps

1. The Cellular Framework will try to communicate over the baud rate specified in the ISDE. If the module responds over that Baud rate, then the baud rate change feature will not be initiated.
2. If the Modem does not respond to the ISDE configured baud rate, then the Cellular Framework will detect the baud rate at which the Modem is operating currently. Once the baud rate is detected, the Cellular Framework will change the baud rate of the Modem to the user configured baud rate. The Framework will then save the baud rate configuration in the Modem.

    - *Note*

      The Cellular Framework will detect the baud rate of the Modem from the following list of baud rates {115200, 9600, 921600, 4800, 14400, 19200, 38400, 57600, 230400, 460800}. The baud rate configured in the ISDE will be skipped from the above list.
3. Once the Baud rate of the Modem is configured, the Cellular Framework will proceed with Modem initialization.

Framework close sequence

When using the Cellular framework with NSAL, that is, with NetX/NetX Duo, the application should call the NetX nx_ip_delete() API directly.

When using the On chip networking stack, the application shouldcall the sf_cellular_api_t::close API from the BSD socket interface, which internally calls the Cellular framework module sf_cellular_api_t::close API.

Runtime configuration support for SIM Properties

The cellular framework provides provision to set the SIM Pin and PUK value of SIM as a ISDE XML properties to unlock the SIM Card. These properties are used by SF Cellular framework to unblock the SIM access if SIM is in Lock state. In addition to these properties, Cellular framework also provides a callback function property to read the SIM Pin and PUK value at runtime. If user sets this callback function, and Cellular framework founds that SIM is in Locked state (either SIM Pin or SIM PUK Lock) then Cellular framework calls the callback function with the SIM Lock status. Based on the Sim Lock status, user should provide SIM Pin and/or SIM PUK information to callback function as mentioned

below:

1. If SIM Status is SF_CELLULAR_SIM_STATUS_PIN_REQUIRED, user should provide SIM Pin information.
2. If SIM Status is SF_CELLULAR_SIM_STATUS_PIN_PUK_REQUIRED then user should provide SIM Pin and PUK information in callback function.

Below is an illustrative code snippet for the callback function showing the configuration of the SIM Pin/PUK information at runtime.

```
uint8_t * const p_sim_pin = (uint8_t *)"1111";
uint8_t * const p_sim_puk = (uint8_t *)"12341234";

/** Sim Pin/PUK Read callback */
ssp_err_t sf_cellular_read_sim_pin_info_callback(sf_cellular_sim_pin_info_t  * p_args)
{
   if (p_args)
   {
      /** SIM Information found */
      switch(p_args->sim_status)
      {
         case SF_CELLULAR_SIM_STATUS_PIN_REQUIRED:
         p_args->p_sim_pin = (uint8_t *) p_sim_pin;
         break;

         case SF_CELLULAR_SIM_STATUS_PIN_PUK_REQUIRED:
         p_args->p_sim_puk = (uint8_t *) p_sim_puk;
         p_args->p_sim_pin = (uint8_t *) p_sim_pin;
         break;

         default:
         break;
      }
   }

   return SSP_SUCCESS;
}
```

Note

If SIM is in SIM Lock state and user entered invalid SIM Pin for 3 times, SIM get locked to SIM PUK state. SIM PUK pin is needed to collect from Cellular network providers. Entering invalid SIM PUK can block SIM permanently.

Cellular Framework Module Limitations

- The current framework supports the following Cellular modules:
  - RYZ014 CATM1 (RYZ014A PMOD).
  - Quectel BG96 (CAT M1, NB-IoT and GPRS) with firmware version BG96MAR02A07M1G_01.008.01.008
- RYZ014 does not support
  - NBIOT network band.
  - GSM network and GSM fallback sequence.
- The next section, Updating the Quectel BG96 firmware, includes instructions for downloading and updating the firmware for BG96 on the modules. Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

Updating the Quectel BG96 Firmware

To determine the current version of firmware on the module, issue the following commands:

- ATI

- AT+QGMR

To update (flash) the firmware for the Quectel BG96 (CAT M1, NB-IoT and GPRS), follow these instructions:

1. First, download the QFLASH firmware update utility from the Quectel BG96 product download page: https://www.quectel.com/ProductDownload/BG96.html. Click the Download button and open the zip file.
2. From the Tool folder, extract the QFLASH tool.
3. From the Driver folder, extract the Quectel LTE Windows USB Driverand follow the steps below to install the LTE Driver:

    a. Unzip and install the LTE Driver on your PC, then connect the USB port of the module to the PC with a USB cable. Check if the DM port of USB appears in device manager:

4. Download the firmware from https://support.quectel.com. For information on this process, see the Renesas Knowledge Base: https://en-support.renesas.com/knowledgeBase/18243404.
5. Upzip firmware and QFLASH file and follow these steps:

    a. Click Load FW Files and load the firmware path (shown as 1 in the figure below):

    b. Choose DM port (shown as 2 in the figure above).
    c. Choose 460800 baud rate (shown as 3 in the figure above).
    d. Click Start.
    e. Normally, it takes a while for the upgrade to complete and display the success message. Check module firmware with "ATI" command.

4.1.12.4 Including the Cellular Framework Module in an Application

This section describes how to include the Cellular Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Cellular Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Cellular Framework module is g_sf_cellular0. This name can be changed in the associated Properties window.)

Cellular Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_cellular_socket0 BSD Socket using RYZ014 CATM1 / Quectel CATM1 On-Chip Stack on RYZ014 CATM1 / Quectel CATM1 Cellular Framework	Threads	New Stack> Framework> Networking> Cellular> BSD Socket using RYZ014 CATM1 / Quectel CATM1 On-Chip Stack on RYZ014 CATM1 / Quectel CATM1 Cellular Framework
g_sf_cellular_0 Cellular Framework on RYZ014 CATM1 / Quectel CATM1 Modem	Threads	New Stack> Framework> Networking> Cellular> Cellular Framework on RYZ014 CATM1 /Quectel CATM1 Modem
g_sf_el_nx0 NetX Port using Cellular Framework on sf_cellular_nsal_nx	Threads	New Stack> Framework> Networking> Cellular> NetX Port using Cellular Framework on sf_cellular_nsal_nx

When the Cellular Framework module on sf_cellular is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

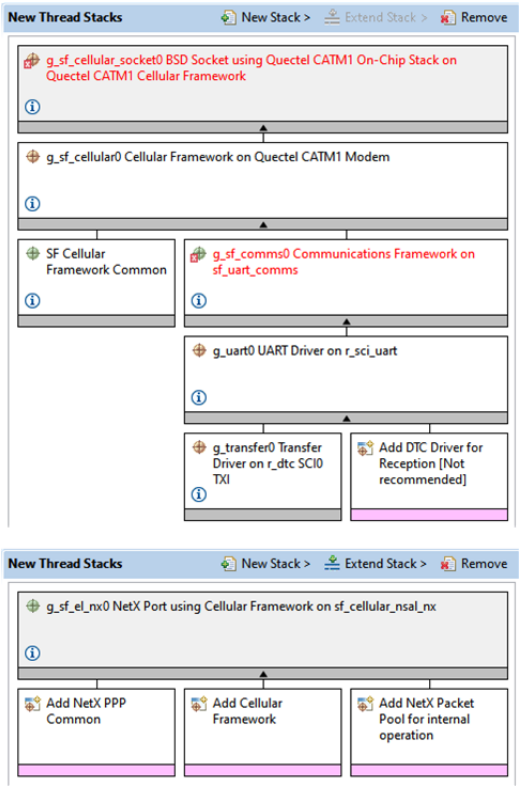

Figure 157: Cellular Framework Module Stack

In the stack above, the Add SF Communications Framework block has not been populated yet. There are multiple possible selections for the Communication Framework; they are not all provided so as not to needlessly complicate the figure and the following configuration tables. Communications Framework on sf_uart_comms should be used when using the sf_cellular framework.

4.1.12.5 Configuring the Cellular Framework Module

The Cellular Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the BSD Socket Using RYZ014 CATM1 On-Chip Stack on RYZ014 CATM1 Cellular Framework

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_cellular_socket0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the BSD Socket Using Quectel CATM1 On-Chip Stack on Quectel CATM1 Cellular Framework

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_cellular_socket0	Module name.
Name of generated initialization function	sf_cellular_qctcatm1_socket_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Cellular Framework on Quectel CATM1 Modem

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
On-Chip Stack Support	Enabled, Disabled Default: Disabled	On-chip stack support selection.
AT Command Retry Count	5	Modem selection.
Name	g_sf_cellular0	Module name.
SIM Pin (Used to Unlock SIM)	1111	SIM Pin selection.
SIM PUK Pin (Used to Unlock SIM)	12345678	SIM PUK Pin selection.
SIM Pin/PUK Callback to read SIM Pin/PUK value at runtimeNULL	NULL	SIM Pin/PUK read callback selection.
Number of Preferred Operator	0	Number of preferred operator selection.
Preferred Operator 1 Name	40422	Preferred operator 1 name selection.

Preferred Operator 1 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 1 name format selection.
Preferred Operator 2 Name	40424	Preferred operator 2 name selection.
Preferred Operator 2 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 2 name format selection.
Preferred Operator 3 Name	40422	Preferred operator 3 name selection.
Preferred Operator 3 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 3 name format selection.
Preferred Operator 4 Name	40424	Preferred operator 4 name selection.
Preferred Operator 4 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 4 name format selection.
Preferred Operator 5 Name	40422	Preferred operator 5 name selection.
Preferred Operator 5 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 5 name format selection.
Operator Select Mode	Auto, Manual, Deregister, Manual Fallback Default: Auto	Operator select mode selection.
Operator Name (Manual Mode Selection)	40422	Operator name selection.
Operator Name Format (Manual Mode Selection)	Long, Short, Numeric Default: Numeric	Operator name format selection.
Time Zone Update Policy	Enabled, Disabled Default: Enabled	Time zone update policy selection.
Receive Data Callback	sf_cellular_nsal_recv_callback	Receive data callback selection.
Provisioning Callback	celr_prov_callback	Provisioning callback selection.
Circular Queue Size in Bytes	256	Circular queue size selection.
SF Communications Framework Thread Stack Size	512	SF communications framework thread stack size selection.
Numerical priority of SF Communication Framework Thread. Legal values range from 0 through (TX_MAX_PRIORITIES-1), where a value of 0 represents the highest priority.	5	Numerical priority of SF communication framework thread selection.
Cellular Module Reset IO Pin	IOPORT_PORT_01_PIN_06	Cellular module reset IO pin selection.

Network Scan Sequence	LTE cat.M1-> LTE Cat.NB1-> GSM, LTE Cat.M1-> GSM-> LTE Cat.NB1, GSM-> LTE Cat.NB1-> LTE Cat.M1, GSM-> LTE Cat.M1-> LTE Cat.NB1, LTE Cat.NB1 -> LTE Cat.M1 -> GSM, LTE Cat.NB1 -> GSM -> LTE Cat.M1 Default: LTE cat.M1-> LTE Cat.NB1-> GSM	Network scan sequence selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Cellular Framework on RYZ014 CATM1 Modem

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
On-Chip Stack Support	Enabled, Disabled Default: Disabled	On-chip stack support selection.
AT Command Retry Count	5	Modem selection.
Name	g_sf_cellular0	Module name.
SIM Pin (Used to Unlock SIM)	1111	SIM Pin selection.
SIM PUK Pin (Used to Unlock SIM)	12345678	SIM PUK Pin selection.
SIM Pin/PUK Callback to read SIM Pin/PUK value at runtimeNULL	NULL	SIM Pin/PUK read callback selection.
Number of Preferred Operator	0	Number of preferred operator selection.
Preferred Operator 1 Name	40422	Preferred operator 1 name selection.
Preferred Operator 1 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 1 name format selection.
Preferred Operator 2 Name	40424	Preferred operator 2 name selection.
Preferred Operator 2 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 2 name format selection.
Preferred Operator 3 Name	40422	Preferred operator 3 name selection.
Preferred Operator 3 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 3 name format selection.

Preferred Operator 4 Name	40424	Preferred operator 4 name selection.
Preferred Operator 4 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 4 name format selection.
Preferred Operator 5 Name	40422	Preferred operator 5 name selection.
Preferred Operator 5 Name Format	Long, Short, Numeric Default: Numeric	Preferred operator 5 name format selection.
Operator Select Mode	Auto, Manual Default: Auto	Operator select mode selection.
Operator Name (Manual Mode Selection)	40422	Operator name selection.
Operator Name Format (Manual Mode Selection)	Long, Short, Numeric Default: Numeric	Operator name format selection.
Time Zone Update Policy	Enabled, Disabled Default: Enabled	Time zone update policy selection.
Receive Data Callback	sf_cellular_nsal_recv_callback	Receive data callback selection.
Provisioning Callback	celr_prov_callback	Provisioning callback selection.
Circular Queue Size in Bytes	256	Circular queue size selection.
SF Communications Framework Thread Stack Size	512	SF communications framework thread stack size selection.
Numerical priority of SF Communication Framework Thread. Legal values range from 0 through (TX_MAX_PRIORITIES-1), where a value of 0 represents the highest priority.	5	Numerical priority of SF communication framework thread selection.
Cellular Module Reset IO Pin	IOPORT_PORT_04_PIN_14	Cellular module reset IO pin selection.

Note

To use BSD Socket over RYZCATM1 on-chip stack, the "On-Chip Stack Support" property must be enabled. The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Cellular Framework Common Instance

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuring the NetX Port using the Cellular Framework

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the lower-level modules.

Configuration Settings for the NetX Port using the Cellular Framework on sf_cellular_nsal_nx

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_el_nx0	Module name.
PPP Stack Size in Bytes	2048	PPP stack size selection.
Name	g_nx_ppp0	Module name.
Numerical priority of PPP Thread	3	Specify the PPP thread priority. The priority must be lower than IP Helper thread. Legal values range from 0 through (TX_MAX_PRIORITIES-1), where a value of 0 represents the highest priority.
Authentication Method	None, PAP, CHAP Default: None	Authentication method selection.
Invalid Packet Handler Callback	NULL	Invalid packet handler callback selection.
Link Down Callback	ppp_link_down_callback	Link down callback selection.
Link Up Callback	ppp_link_up_callback	Link up callback selection.
PAP Login Callback	NULL	A user callback function can be provided.
PAP Verify Login Callback	NULL	A user callback function can be provided.
Get Challenges Values Callback	NULL	A user callback function can be provided.
Get Responder Values Callback	NULL	A user callback function can be provided.
Get Verification Callback	NULL	A user callback function can be provided.
Local IPv4 Address (use commas for separation)	0,0,0,0	Local IPv4 address selection.
Peer IPv4 Address (use commas for separation)	0,0,0,0	Peer IPv4 address selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX PPP Common Instance

ISDE Property	Value	Description
Name	g_nx_ppp_common0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name.
Packet Size (bytes)	1568	Packet size selection.
Number of Packets in Pool	16	Number of packets in pool selection.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection.
Auto initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Common on nx Instance

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection.
Auto initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.
Most of the property settings for modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration changes for file download over cellular framework

HTTP file download of up to 2 MB is tested on BG96. Following is the list of ISDE properties that must be updated for downloading of files over HTTP while using Cellular framework.

ISDE configuration parameters for HTTP download using BG96 RevF module

ISDE Property	Value	Description
Packet Size of NetX packet pool instance (bytes)	1568 Default: 1568	Packet size selection.
Number of Packets in Pool for NetX packet pool instance	64 Default:16	Number of packets in pool selection.
IP thread priority	2 Default: 3	Thread priority of IP helper thread for NetX IP instance.
Numerical priority of SF Communication Framework thread	3 Default: 5	Priority value of SF Comms thread in g_sf_cellular block.
TCP socket Window Size	16384 (for GSM network 8192) Default: 1024	TCP socket window size of g_http_client.

ISDE configuration parameters for HTTP download using RYZ014 module

ISDE Property	Value	Description
Packet Size of NetX packet pool instance (bytes)	1568 Default: 1568	Packet size selection.
Number of Packets in Pool for NetX packet pool instance	64 Default:16	Number of packets in pool selection.
IP thread priority	2 Default: 3	Thread priority of IP helper thread for NetX IP instance.
Numerical priority of SF Communication Framework thread	3 Default: 5	Priority value of SF Comms thread in g_sf_cellular block.
TCP socket Window Size	16384 Default: 1024	TCP socket window size of g_http_client.

Cellular Framework Module Clock Configuration

The Cellular Framework module uses the clocks required for the specific selections of the lower-level modules.

Cellular Framework Module Pin Configuration

The Cellular Framework module uses input and output pins depending on the selections of the lower-level modules.

4.1.12.6 Using the Cellular Framework Module in an Application

In a typical Cellular application, much of the work is done by SSP based on the configured cellular module stack. When the IP instance along with the Cellular framework is added using the configurator, it includes the PPP stack as part of the framework. In addition, it also includes the NSAL and cellular device driver code. The auto-generated code is responsible for cellular initialization.

The user added code is responsible for the data connections and the ICMP ping. It is responsible for

sending the ping request to the user entered Public IP address and for verifying the ping response. Callback functions can be implemented for PPP link down, PPP link up and cellular provisioning.

The steps in using the Cellular Framework in a typical application are:

1. Initialization from generated code.
2. Wait for link to come up using the nx_ip_status_check API.
3. Ping the network using the nx_icmp_ping API.
4. Check for Event flag using the nx_event_flags_set API.

The following figure illustrates common steps in a typical operational flow diagram:

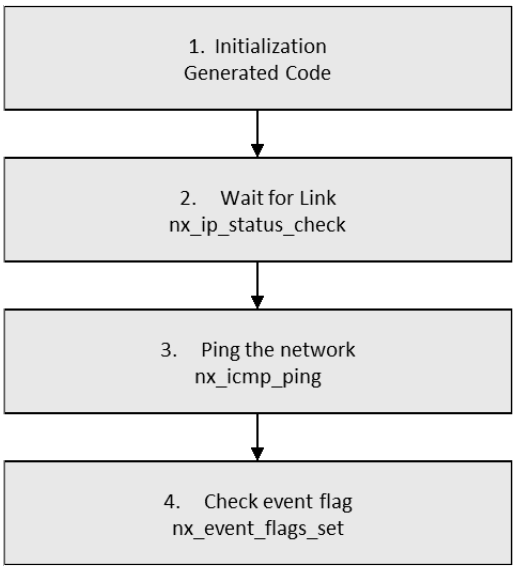

Figure 158: Application Control Flow using Cellular Module Initialization

4.1.13 Telnet Communications Framework on sf_comms_telnet

4.1.13.1 Telnet Communications Framework Introduction

The Communications Framework on NX provides a high-level API for communications framework applications and uses the Ethernet peripheral on the Synergy MCU.

Telnet Communications Framework Module Features

- High-level connectivity is supported on Ethernet but is easily changeable to UART and USB connectivity without API modification
- Supports channel locking for exclusive access
- Thread-aware implementation uses mutex and event flags internally

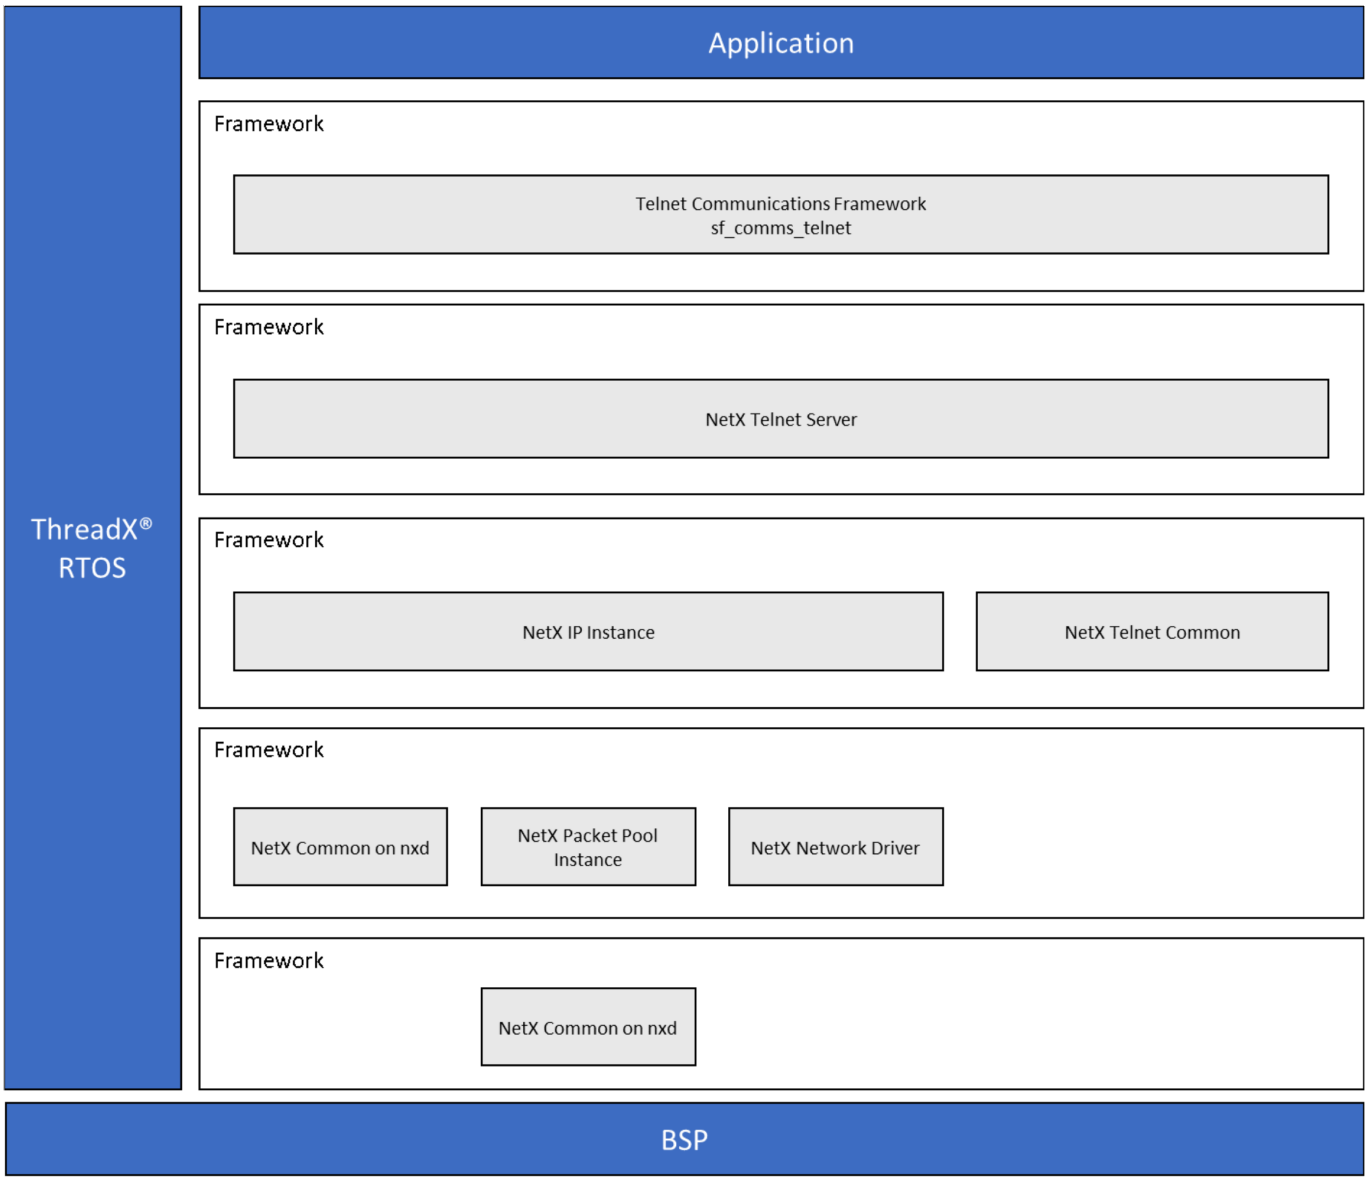

Figure 159: Telnet Communications Framework Module Block Diagram

4.1.13.2 Telnet Communications Framework Module APIs Overview

The Telnet Communications Framework module defines APIs to open, read from, write to, lock, unlock and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Telnet Communications Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_comms_telnet0.p_api->open (g_sf_comms_telnet0.p_ctrl, g_sf_comms_telnet0.p_cfg); Initialize the module.

read	g_sf_comms_telnet0.p_api->read (g_sf_comms_telnet0.p_ctrl, p_dest, bytes, timeout); Read a number of bytes of data into the destination.
write	g_ sf_comms_telnet0.p_api->write (g_sf_comms_telnet0.p_ctrl, P_src, bytes, timeout); Write a number of bytes from the source.
lock	g_sf_comms_telnet0.p_api->lock (g_sf_comms_telnet0.p_ctrl, locktype, timeout); Acquire lock type for the Telnet comms instance.
unlock	g_sf_comms_telnet0.p_api->unlock (g_sf_comms_telnet0.p_ctrl, locktype); Release the lock type for the Telnet comms instance.
close	g_sf_comms_telnet0.p_api->close (g_sf_comms_telnet0.p_ctrl); Disconnect Telnet server and clean up resources.
versionGet	g_ sf_comms_telnet0.p_api->versionGet(&version); Get version and store it in provided version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INTERNAL	An internal TheadX error has occurred.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	A parameter is NULL.
SSP_ERR_IN_USE	Peripheral is still running in another mode; perform Close first.
SSP_ERR_UNSUPPORTED	Command not supported.
SSP_ERR_OUT_OF_MEMORY	Cannot allocate pool memory.
SSP_ERR_TIMEOUT	An event timed out.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.13.3 Telnet Communications Framework Module Operational Overview

The Communications Framework using Telnet on NX provides an easy to use connection over an Ethernet port. The high-level APIs are compatible with other connection protocols, such as UART and USB, so that it is easy to switch from one implementation to another without changing APIs.

Operations supported by the framework include initializing the module using the sf_comms_api_t::open API, and closing the module using the sf_comms_api_t::close API. A communications read is implemented by the sf_comms_api_t::read API and a communications write by the sf_comms_api_t::write API. The sf_comms_api_t::read and sf_comms_api_t::write lock the module only until the called API is in action.

During a read operation, when using the TX_WAIT_FOREVER timeout, if the Ethernet link goes down, the sf_comms_api_t::read API will continue to wait for the data from the read queue. Once the Ethernet link is back up, the read operation resumes and exits. To exit the read operation during a link down event, the user must explicitly abort the read operation by calling the sf_comms_api_t::close API in the link status change callback function. The sf_comms_api_t::lock API locks the module until the sf_comms_api_t::unlock API is called on the same module instance. This helps ensure that processing is completed before moving to the next API function call.

A user defined disconnect callback function (Telnet client disconnect callback) can be defined by the user to handle the Telnet client disconnection due to Client inactivity timeout. This callback will be called when the configured Client inactivity timeout occurs.

The underlying NetX driver supports the configuration of the IP address, the Network mask, and the Ethernet channel. When a different communications implementation is used (like USB) different low-level module configuration settings are used to define its interface. Thus, no code needs to be changed in the application, only need changes to configuration settings. The same API calls are retained at the application level.

Telnet Communications Framework Module Important Operational Notes and Limitations

Telnet Communications Framework Module Operational Notes

- The Ethernet peripheral can use either RMII or MII depending on MCU capabilities.

Telnet Communications Framework Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.13.4 Including the Telnet Communications Framework Module in an Application

This section describes how to include the Telnet Communications Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Telnet Communications Framework module to an application, simply add it to a HAL

/Common thread using the stacks selection sequence given in the following table. (The default name for the Telnet Communications Framework module is sf_comms_telnet0. This name can be changed in the associated Properties window.)

Telnet Communications Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
sf_comms_telnet0 Telnet Communications Framework on sf_comms_telnet	Threads	**New Stack> Framework> Connectivity> Telnet Communications Framework on sf_comms_telnet**

When the Telnet Communications Framework module on sf_comms_telnet is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

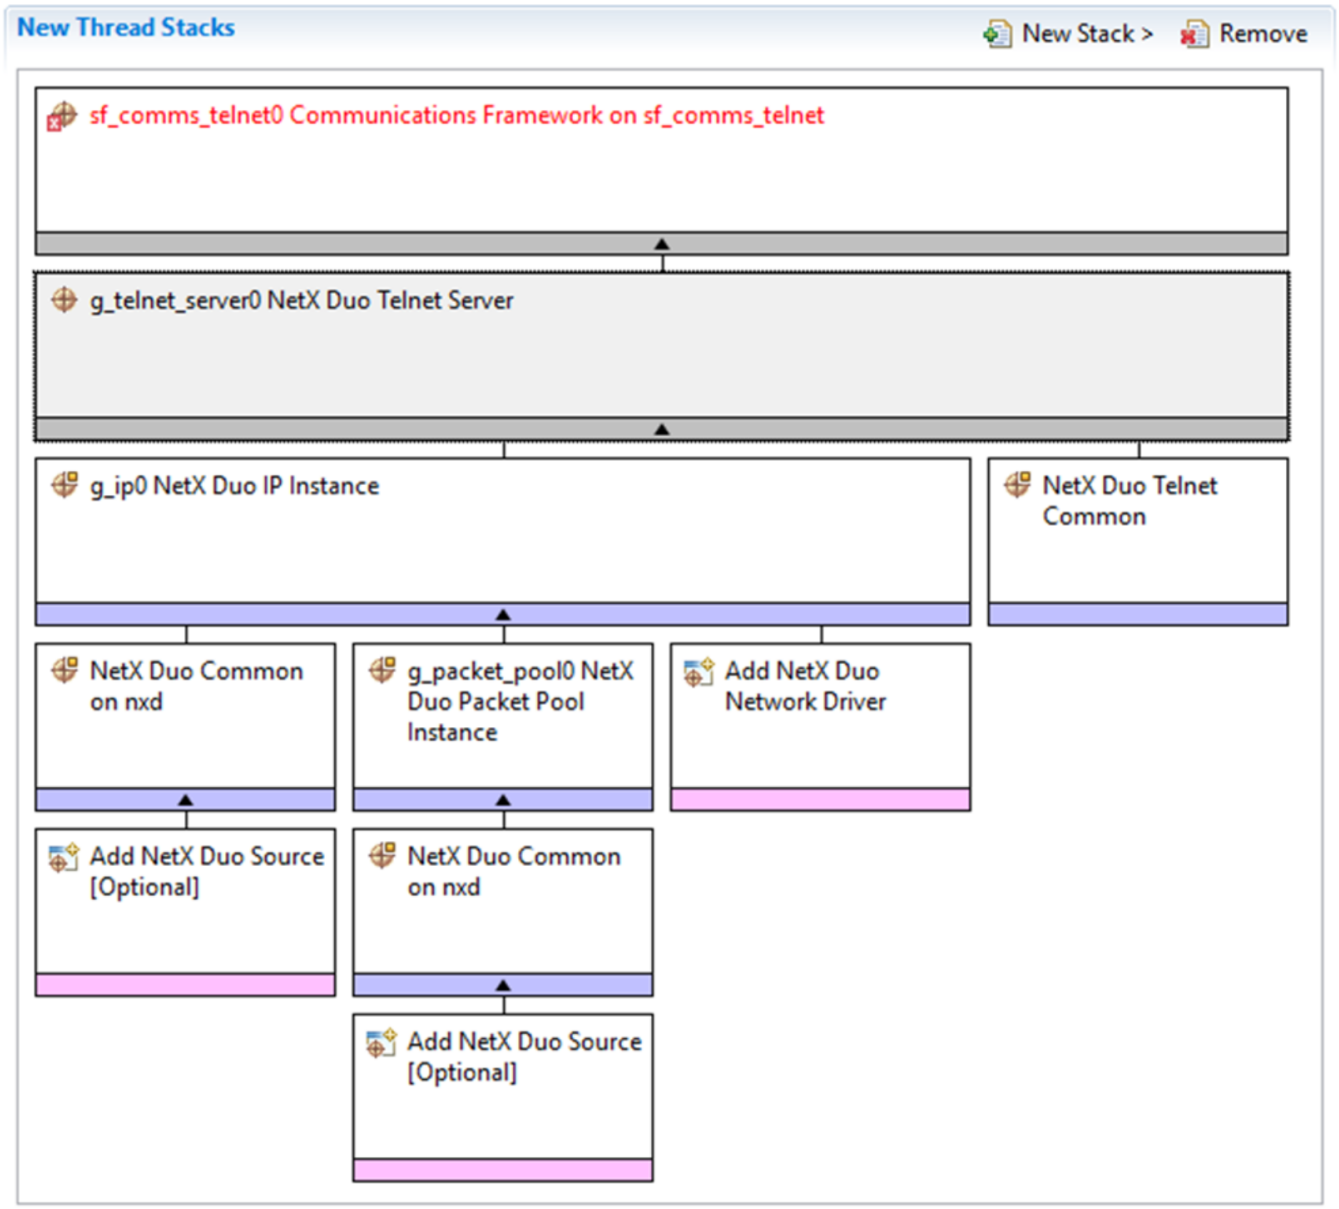

Figure 160: Telnet Communications Framework Module Stack

4.1.13.5 Configuring the Telnet Communications Framework Module

The Telnet Communications Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Telnet Communications Framework Module on sf_comms_telnet

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Packet size in pool memory (bytes)	1536	Packet size in pool memory selection.
Packets to allocate in pool memory (units)	5	Packets to allocate in pool memory selection.
Timeout for internal options (ticks)	10	Timeout for internal options selection.
Maximum number of instances	4	Maximum instances that can be open at any given time.
Name	sf_comms_telnet0	Module name.
Name of generated initialization function	sf_comms_telnet_init0	Name of generated initialization selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.
Telnet client disconnect callback	NULL	User defined callback invoked when the client is disconnected.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower-level modules can be desirable. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower level modules are fairly intuitive and can usually be determined by inspection of the associated Properties window from the SSP configurator.

Configuring the Telnet Communications Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the NetX/NetX Duo Telnet Server on telnet_server

ISDE Property	Value	Description
Internal thread priority	16	Internal thread priority selection.
Maximum clients to serve simultaneously	4	Maximum clients to serve simultaneously selection.
Socket window size (bytes)	2048	Socket window size selection.
Server time out (seconds)	10	Duration internal services will suspend for.
Client inactivity timeout (seconds)	600	Client inactivity duration for disconnection.
Timeout check period (seconds)	60	Client activity timeout check interval.
Option negotiation	Enable, Disable Default: Enable	Option negotiation selection.
Use application packet pool	Enable, Disable Default: Disable	Use application packet pool selection.
Packet size in the pool (bytes)	300	Telnet Server only creates this packet pool if 'Option negotiation' is enabled.
Total packet pool size (bytes)	2048	Telnet Server only creates this packet pool if NX_TELNET_SERVER_OPTION_DISABLE.
Name	g_telnet_server0	Module name.
Thread Stack Size (bytes)	2048	Thread stack size selection.
Name of Client Connect Callback Function	NULL	Name of client connect callback function selection.
Name of Receive Data Callback Function	NULL	Name of receive data callback function selection.
Name of Client Disconnect Callback Function	NULL	Name of client disconnect callback function selection.
Name of generated initialization function	telnet_server_init0	Name of generated initialization function selection.
Auto Initialization	Disable	Auto initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo IP Instance

ISDE Property	Value	Description

Name	g_ip0	Module name.
IPv4 Address (use commas for separation)	0,0,0,0	IPv4 Address selection.
Subnet Mask (use commas for separation)	255,255,255,0	Subnet Mask selection.
**IPv6 Global Address (use commas for separation)	0x2001, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x1	IPv6 global address selection.
**IPv6 Link Local Address (use commas for separation, All zeros means use MAC address)	0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0	IPv6 link local address selection.
IP Helper Thread Stack Size (bytes)	2048	IP Helper Thread Stack Size (bytes) selection.
IP Helper Thread Priority	3	IP Helper Thread Priority selection.
ARP	Enable	ARP selection.
ARP cache storage units	Bytes, Entries Default: Bytes	ARP cache storage units selection.
ARP Cache Size (in storage units)	520	ARP Cache Size in Bytes/Entries selection. Note: 1 Entry = 52 Bytes.
Reverse ARP	Enable, Disable Default: Disable	Reverse ARP selection.
TCP	Enable	TCP selection.
UDP	Enable, Disable Default: Enable	UDP selection.
ICMP	Enable, Disable Default: Enable	ICMP selection.
IGMP	Enable, Disable Default: Enable	IGMP selection.
IP fragmentation	Enable, Disable Default: Disable	IP fragmentation selection.
Name of generated initialization function	ip_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.
Link status change callback	NULL	Link status change callback selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

** Indicates properties that are only available in NetX Duo.

Configuration Settings NetX Telnet Common

ISDE Property	Value	Description
Type of Service for TCP requests	Normal, Minimum delay, Maximum data, Maximum reliability, Minimum cost Default: Normal	Type of service UDP requests selection.
Fragmentation option	Don't fragment, Fragment okay Default: Don't fragment	Fragment option selection.
Server TCP port number	23	Server TCP port number selection.
Time to live	128	Time to live selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Common on nxd

ISDE Property	Value	Description
Name of generated initialization function	nx_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX/NetX Duo Packet Pool Instance

ISDE Property	Value	Description
Name	g_packet_pool0	Module name.
Packet Size in Bytes	1568	Packet size selection.
Number of Packets in Pool	16	Number of packets in pool selection.
Name of generated initialization function	packet_pool_init0	Name of generated initialization function selection.

Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Port ETHER

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Channel 0 Phy Reset Pin	IOPORT_PORT_09_PIN_03	Channel 0 Phy reset pin selection.
Channel 0 MAC Address High Bits	0x00002E09	Channel 0 MAC address high bits selection.
Channel 0 MAC Address Low Bits	0x0A0076C7	Channel 0 MAC address low bits selection.
Channel 1 Phy Reset Pin	IOPORT_PORT_07_PIN_06	Channel 1 PHY reset pin selection.
Channel 1 MAC Address High Bits	0x00002E09	Channel 1 MAC address high bits selection.
Channel 1 MAC Address Low Bits	0x0A0076C8	Channel 1 MAC address low bits selection.
Number of Receive Buffer Descriptors	8	Number of receive buffer descriptors selection.
Number of Transmit Buffer Descriptors	32	Number of transmit buffer descriptors selection.
Ethernet Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Ethernet interrupt priority selection.
Link status monitoring method	PHY Interrupt (Uses LINKSTA Pin), PHY Polling Default: PHY Polling	Link status monitoring method selection.
Name	g_sf_el_nx	Module name.
Channel	0	Channel selection.
Callback	NULL	Callback selection.
Unknown packet receive Callback	NULL	Unknown packet receive callback selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Telnet Communications Framework Module Clock Configuration

The Telnet Communications Framework module uses the Ethernet peripheral which uses the PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

Telnet Communications Framework Module Pin Configuration

To use the Telnet Communications Framework module, the port pins for the peripheral inputs and outputs must be set in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection Sequence for the Telnet Communications Framework Module

Resource	ISDE Tab	Pin selection Sequence
SSI	Pins	Select **Peripherals**> **Peripherals**> **Connectivity:ETHERC**> **ETHERC0.RMI or ETHERC1.RMII**

4.1.13.6 Using the Telnet Communications Framework Module in an Application

The typical steps in using the Telnet Communications Framework module in an application are:

1. Initialize the Communications Framework on NX using the sf_comms_api_t::open API
2. Lock the channel for continuous communications using the sf_comms_api_t::lock API if needed
3. Receive data using the sf_comms_api_t::read API
4. Send data using the sf_comms_api_t::write API
5. Unlock the channel from continuous communication using the sf_comms_api_t::unlock command if needed
6. Close the channel using the sf_comms_api_t::close API

These common steps are illustrated in a typical operational flow in the following figure:

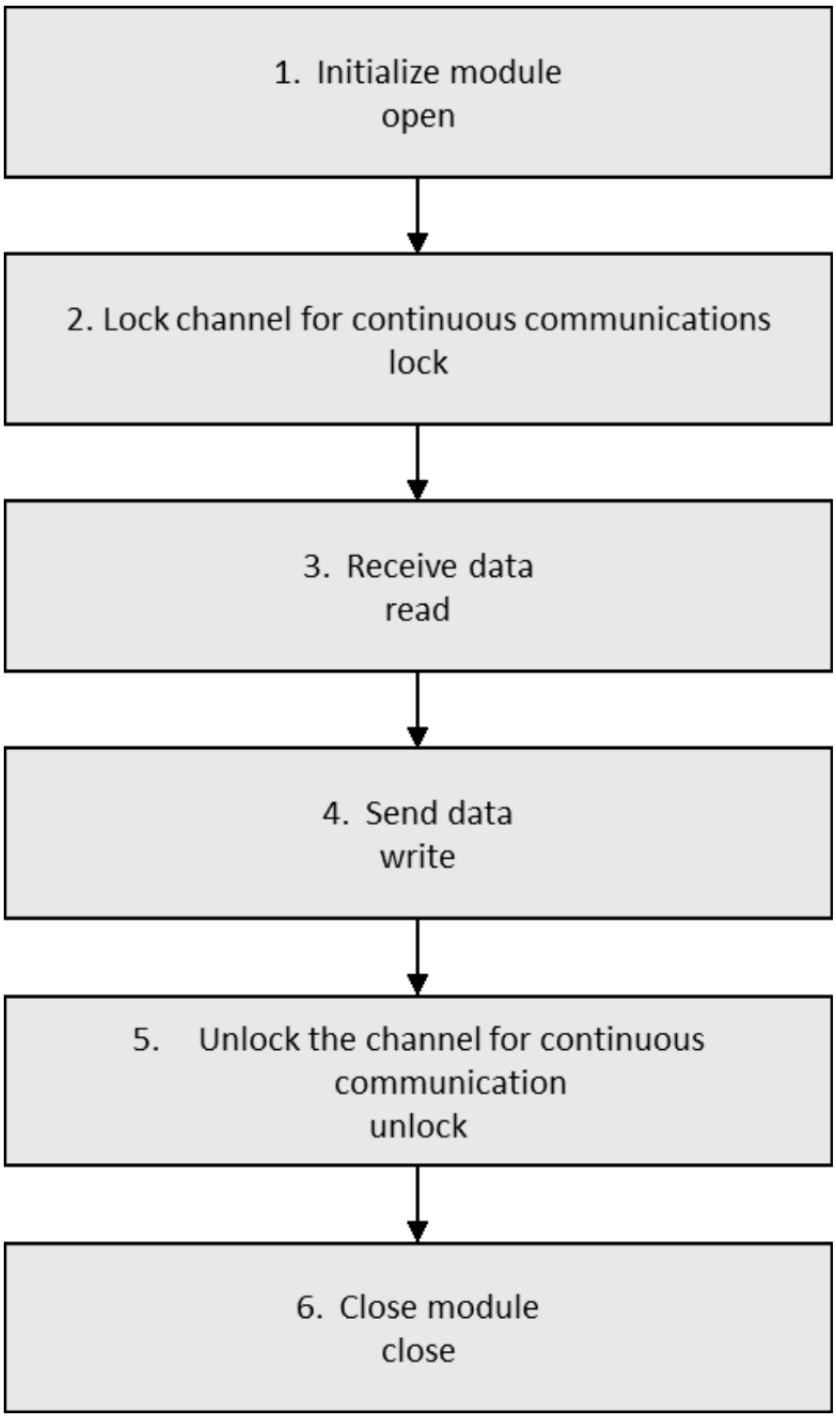

Figure 161: Flow Diagram of a Typical Telnet Communications Framework Module Application

4.1.14 Communications Framework on sf_el_ux_comms_v2

4.1.14.1 Communications Framework on USBX v2 Module Introduction

The Communications Framework on USBX™ (sf_el_ux_comms_v2) implements a high-level API for communications applications that provides an easy-to-use connection over the USB port. The high-level API functions in the framework are compatible with other connection implementations (such as UART and Ethernet), so it is easy to switch from one implementation to another without changing application code. The Communications Framework on USBX uses the USB peripheral on the Synergy MCU device.

Communications Framework on USBX v2 Module Features

- High-level connectivity is supported on USB but is easily changed to UART and Ethernet connectivity without API modification
- Supports channel locking for exclusive access
- Supports USB high speed (HS) or full speed (FS) operation
- Supports data-transfer (DMAC or DTC) peripherals on a Synergy MCU
- ThreadX®-aware implementation uses mutex

Note

Currently, DTC is not supported by both the host and device side driver (only DMAC is supported).

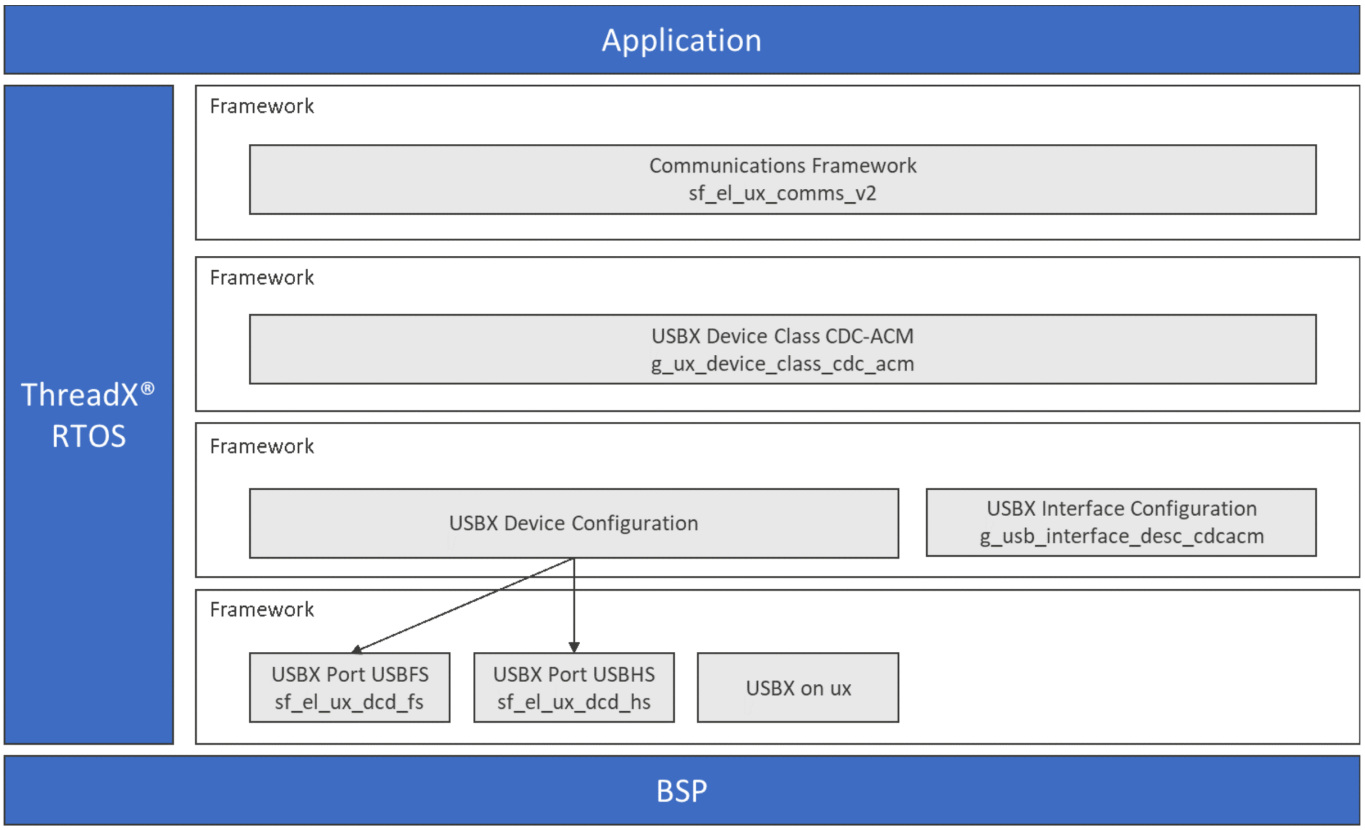

Figure 162: Communications Framework on USBX Module Block Diagram

4.1.14.2 Communications Framework on USBX v2 Module APIs Overview

The Communications Framework on USBX defines API functions for opening, closing, reading and writing over the USB connection. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows

the API summary table.

Communications Framework on USBX Module API Summary

Function Name	Example API Call and Description
open	g_sf_comms0.p_api->open(g_sf_comms0.p_ctrl, g_sf_comms0.p_cfg); Initialize communications driver.
close	g_sf_comms0.p_api->close(g_sf_comms0.p_ctrl); Clean up communications driver.
read	g_sf_comms0.p_api->read(g_sf_comms0.p_ctrl, &destination, bytes, timeout); Read data from communications driver. This call returns after the number of bytes requested is read or if a timeout occurs while waiting for access to the driver or read operation times out.
write	g_sf_comms0.p_api->write(g_sf_comms0.p_ctrl, &source, bytes, timeout); Write data to communications driver. This call returns after all bytes are written or if a timeout occurs while waiting for access to the driver or write operation times out.
lock	g_sf_comms0.p_api->lock(g_sf_comms0.p_ctrl, lock_type, timeout); Lock the communications driver. Reserve exclusive access to the communications driver.
unlock	g_sf_comms0.p_api->unlock(g_sf_comms0.p_ctrl , lock_type); Unlock the communications driver. Release exclusive access to the communications driver.
versionGet	g_sf_comms0.p_api->versionGet(&version); Retrieve the API version in the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Channel opened successfully.
SSP_ERR_IN_USE	Channel already in use.
SSP_ERR_ASSERTION	Pointer to UART control block or configuration structure is NULL.
SSP_ERR_INTERNAL	Internal error occurs.

SSP_ERR_TIMEOUT	Timeout error.
SSP_ERR_NOT_OPEN	Module is not opened.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.14.3 Communications Framework on USBX v2 Module Operational Overview

The Communications Framework on USBX provides an easy-to-use connection over the USB port. The high-level API functions in the framework are compatible with other connection implementations (such as UART and Ethernet), so it is easy to switch from one implementation to another without changing applications code. The module uses ThreadX objects like mutex for synchronization for the completion of a transaction. The USBX communication Framework module supports the locking functionality, meaning that the user can lock the communication framework to a thread so that multiple thread can use the same USBX port safely. The locking allows the application to reserve a USB port for a given period of time available between call made to sf_comms_api_t::lock API and sf_comms_api_t::unlock API. The high-level APIs are used to sf_comms_api_t::read API, sf_comms_api_t::write API to support receive or send data to host over USBX CDC-ACM communication interface.

Communications Framework on USBX v2 Module Important Operational Notes and Limitations

Communications Framework on USBX v2 Module Operational Notes

The USBX driver can be implemented on either the HS or FS USB peripherals, depending on the version supported by the target MCU.

A pre-defined weak callback function is available for the USBX CDC-ACM instance activate and another for the USBX CDC-ACM instance deactivate. The user can override these two callback functions if required, by defining a user function using the callback function name given in the Synergy configurator.

Communications Framework on USBX v2 Module Limitations

Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.1.14.4 Including the Communications Framework on USBX v2 Module in an Application

This section describes how to include the Communications Framework on USBX Module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Communications Framework on USBX Module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

Communications Framework on USBX Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence

g_sf_comms0 Communications Framework on sf_el_ux_comms_v2	Threads	**New Stack> Framework> Connectivity> Communications Framework on sf_el_ux_comms_v2**

When the Communications Framework on USBX Module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

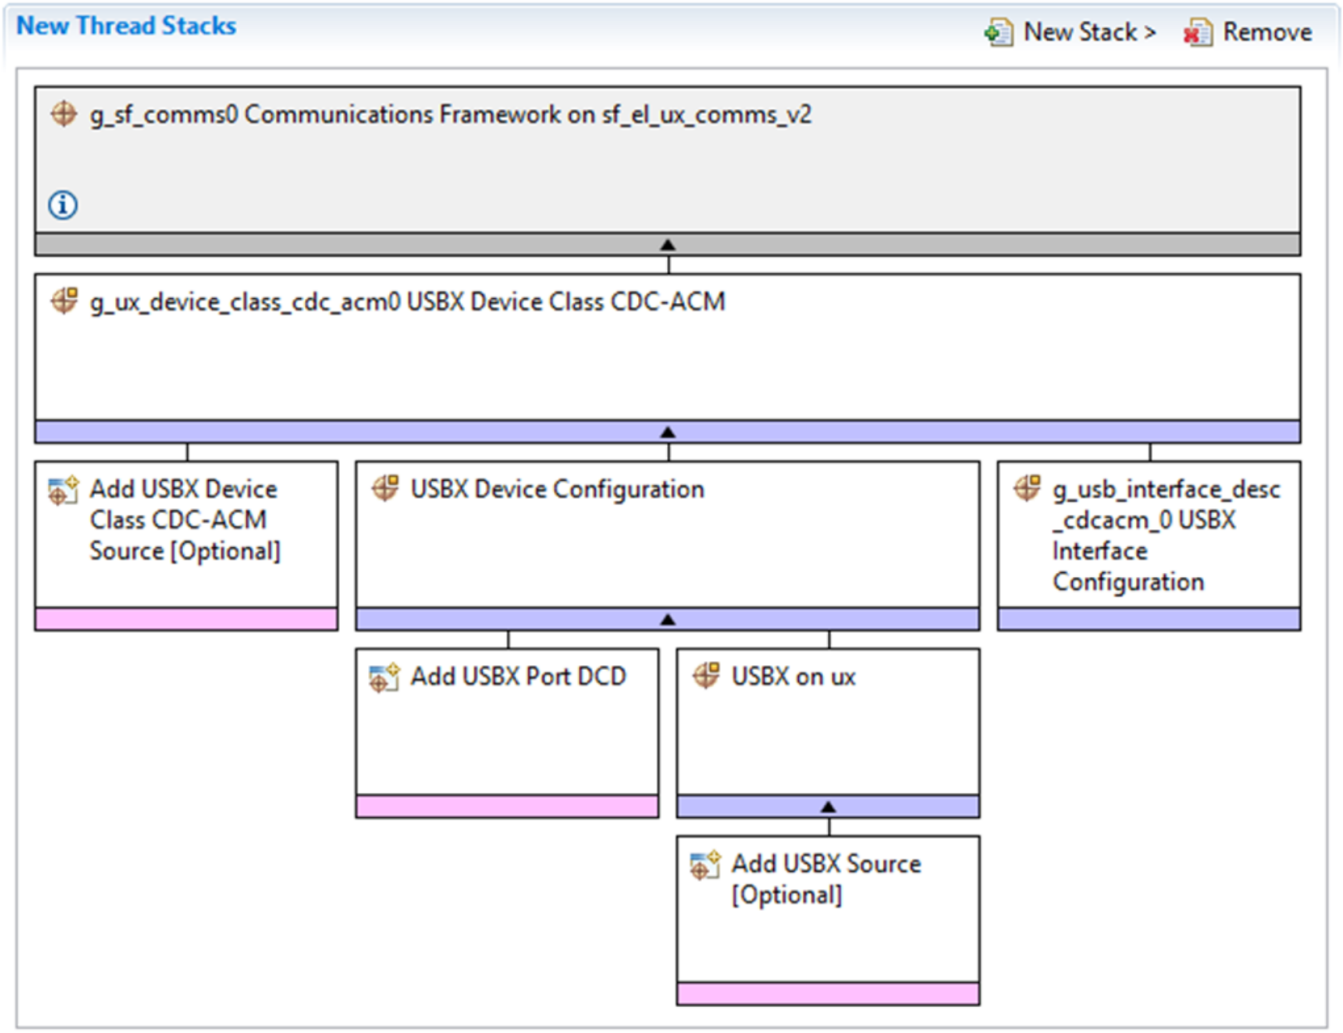

Figure 163: Communications Framework on USBX Module Stack

4.1.14.5 Configuring the Communications Framework v2 on USBX Module

The Communications Framework on USBX Module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Communications Framework on USBX Module

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Read Input Buffer Size (Bytes)	128	Maximum number of bytes that can be received at a time in the read() API.
Timeout in ticks	1000	Timeout value to suspend a USBX CDC instance creation in the open() API.
Name	g_sf_comms0	Module name.
Name of the generated initialization function	sf_comms_init0	Name of helper function to initialize Communications Framework. The function will be presented in the auto-generated code in the <xxx_thread>.c, where <xxx_thread> is the name of your thread symbol given to the Thread property. The function is to be called in the auto-generated code if Auto sf_comms Initialization property is Enabled. If Disabled, the function can be called in the user application.

Auto Initialization	Enable, Disable Default: Enable	Auto Initialization support of Communications Framework. The helper function above will be called in the auto-generated code if this configuration is enabled. Else, the function will not be called automatically and user can call it sometime later.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.
Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the Communications Framework on USBX v2 Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the USBX Device Class CDC-ACM Module

ISDE Property	Value	Description
Name	g_ux_device_class_cdc_acm0	Specify the name of the USBX Device CDC-ACM Class module instance. It must be a valid C symbol.
USBX CDC-ACM instance_activate Function Callback	ux_cdc_device0_instance_activate	Specify the name of the instance_activate user callback function for the USBX Device CDC-ACM Class module. Name must be a valid C symbol. See the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device CDC-ACM Class" for more information about the instance_activate callback function.

USBX CDC-ACM instance_deactivate Function Callback	ux-cdc_device0_instance_deactivate	Specify the name of the instance_deactivate user callback function for the USBX Device CDC-ACM Class module. Name must be a valid C symbol. Refer to the USBX Stack User's Manual "Chapter 5: USBX Device Class Considerations USB Device CDC-ACM Class" for more information about the instance_activate callback function.
Name of generated initialization function	ux_device_class_cdc_acm_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Device Configuration Instance

ISDE Property	Value	Description
Vendor ID	0x045B	Specify Vendor ID assigned by USB-IF. This configuration is a part of the USB Device Descriptor (idVendor).
Product ID	0x0000	Specify Product ID assigned by manufacturer. This configuration is a part of the Device Descriptor (idProduct).
Device Release Number	0x0000	Specify Device Release Number in binary-coded decimal. This configuration is a part of the USB Device Descriptor (bcdDevice).
Index of Manufacturing String Descriptor	0x00	Specify the Index of Manufacturer String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iManufacturer). Set zero if String Descriptor is not used. See section USBX-String-Framework-Configuration for more information.

Index of Product String Descriptor	0x00	Specify the Index of Product String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iProduct). Set zero if String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Index of Serial Number String Descriptor	0x00	Specify the Index of Serial Number String Descriptor defined in the USBX String Framework. This configuration is a part of the USB Device Descriptor (iSerialNumber). Set zero if the String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Class Code	Communications(CDC), HID, Mass Storage, Miscellaneous, Vendor specific Default: Communications(CDC)	Select the USB Device Class Code. This configuration is a part of the USB Configuration Descriptor (bDeviceClass).
Index of String Descriptor describing this configuration	0x00	Specify the Index of String Descriptor describing this configuration. This configuration is a part of the USB Configuration Descriptor (iConfiguration). Set zero if String Descriptor is not used. See section "USBX String Framework Configuration" for more information.
Size of USB Descriptor in bytes for this configuration (Modify this value only for Vendor-specific Class, otherwise set zero)	0x00	Specify the size of USB Descriptor in bytes. Modify the value for Vendor-specific Class, otherwise you can set zero to calculate the size automatically in the auto-generated code from Synergy Configuration tool. This configuration is a part of the USB Configuration Descriptor (wTotalLength).

Number of Interfaces (Modify this value only for Vendor-specific Class, otherwise set zero)	0x00	Specify the Number of interfaces supported by this configuration. Modify the value for Vendor-specific Class, otherwise you can set zero to calculate the value automatically in the auto-generated code from Synergy Configuration tool. This configuration is a part of the USB Configuration Descriptor (bNumInterfaces).
Self-Powered	Enable, Disable Default: Enable	Enable this configuration if your USB Device is a self- powered device. This configuration is a part of the USB Configuration Descriptor (bmAttributes bit6).
Remote Wakeup	Enable, Disable Default: Disable	Enable this configuration if your USB Device supports remote wakeup. This configuration is a part of the USB Configuration Descriptor (bmAttributes bit5).
Maximum Power Consumption (in 2mA units)	50	Set the maximum power consumption of your device to indicate the amount of bus power required. This configuration is 2 mA units, thus, the maximum 500 mA can be specified. This configuration is a part of the USB Configuration Descriptor (bMaxPower).
Supported Language Code	0x0409	Specify the Language ID Code. For example, 0x0409 English - United States. This configuration is used for Language ID Framework code generation. See section "USBX Language Framework Configuration" for more information.
Name of USBX String Framework	NULL	Specify the name of user defined USBX String Framework. This must be a valid C symbol. Set NULL if the String Descriptor is not used. See section "USBX String Framework Configuration" for more information.

Total index number of USB String Descriptors in USB String Framework	0	Specify the total number of index for String Descriptor. See section "USBX String Framework Configuration" for more information.
Name of USBX Language Framework	NULL	Specify the name of user defined USBX Language Framework. This must be a valid C symbol. If '0' is set to the property "Total Number of Language Support", this configuration is ignored. See section "USBX Language Framework Configuration" for more information.
Number of Languages to support (US English is applied if zero is set)	0	Specify the total number of languages to support. See section "USBX String Framework Configuration" for more information. If '0' is set here, US English (0x0409) is applied as the default language.
Name of generated initialization function	ux_device_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Interface Configuration CDC-ACM Instance

ISDE Property	Value	Description
Name	g_usb_interface_desc_cdcacm_0	Specify the name of USBX Interface Descriptor for CDC-ACM. It must be a valid C symbol.

Interface Number of Communications Class interface	0x00	Specify the index number of Communications Class interface. This configuration is a part of the USB Interface Descriptor (bInterface). The number must not be duplicated with the Interface Number of Data Class interface. Also must not be duplicated with any Interface Numbers if your USB device consists of a USB composite device.
Interrupt Transfer endpoint to use for Communications Class	Endpoint 1-9 Default: Endpoint 3	Specify the Endpoint Number of Interrupt Endpoint. It must not be duplicated with ones for the other Endpoints.
Polling period for Interrupt Endpoint (in mS/125us units for FS/HS)	0x0F	Specify the Interval for polling Endpoint transfers. This configuration is valid for Interrupt Endpoint and ignored for Bulk Endpoints. Value is in frame counts (1 ms units for FS mode and 125 us units for HS mode).
Interface Number of Data Class interface	0x01	Specify the index number of Data Class interface. This configuration is a part of the USB Interface Descriptor (bInterface). The number must not be duplicated with the Interface Number of Communications Class interface. Also must not be duplicated with any Interface Numbers if your USB device consists of a USB composite device.
Bulk In Transfer endpoint to use for Data Class	Endpoint 1-9 Default: Endpoint 1	Specify the Endpoint Number of Bulk In Endpoint. It must not be duplicated with ones for the other Endpoints.
Bulk Out Transfer endpoint to use for Data Class	Endpoint 1-9 Default: Endpoint 2	Specify the Endpoint Number of Bulk Out Endpoint. It must not be duplicated with ones for the other Endpoints.

Index of String Descriptor Describing Communications Class interface (Interface Descriptor: Interface)	0x00	Specify the index number of String Descriptor Describing Communications Class interface. This configuration is a part of the USB Interface Descriptor (iInterface). Set '0' if do not have String information for the interface.
Index of String Descriptor Describing Data Class interface (Interface Descriptor: Interface)	0x00	Specify the index number of String Descriptor Describing Data Class interface. This configuration is a part of the USB Interface Descriptor (iInterface). Set '0' if do not have String information for the interface.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on sf_el_ux for USBFS

ISDE Property	Value	Description
Full Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for full-speed USB.
LDO Regulator (Only for S3 and S1 part MCUs)	Enable, Disable Default: Disable	Select the LDO regulator will be enabled.
Name	g_sf_el_ux_dcd_fs_0	Module name.
USB Controller Selection	USBFS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX Port DCD on USBHS

ISDE Property	Value	Description
High Speed Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for high speed USB.

Name	g_sf_el_ux_dcd_hs_0	Module name.
USB Controller Selection	USBHS	Select the USB controller.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the USBX on ux Instance

ISDE Property	Value	Description
USBX Pool Memory Name	g_ux_pool_memory	Name must be a valid C symbol.
USBX Pool Memory Size	18432	See section "Azure RTOS USBX Memory Requirements" for the required memory size for each classes.
User Callback for Host Event Notification (Only valid for USB Host)	NULL	Name must be a valid C symbol. The name of User defined USBX Host event notification can be given to this property.
Name of generated initialization function	ux_common_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Communications Framework on USBX v2 Module Clock Configuration

The USB peripheral module uses the UCLK as its clock source; the UCLK should be configured for 48 MHz operation. In the SSP configuration window, select the **Clocks** tab to view the clock-source setting.

Communications Framework on USBX v2 Module Pin Configuration

The USB peripheral module uses MCU pins to communicate with external devices. Select I/O pins and configure to the external device requirements. The following table lists the pin selection method within the SSP Configuration Window and the subsequent tables demonstrate the selection process using USB pins as an example.

Note

The selected operation mode determines what peripheral signals are available and what MCU pins are required.

USBFS and USBHS Pin Selection Sequence

Resource	ISDE Tab	Pin selection Sequence

USBFS	Pins	Select **Peripherals**> **Connectivity: USBFS**> **USBFS0**
USBHS	Pins	Select **Peripherals**> **Connectivity: USBHS**> **USBHS0**

Note

The selection sequence assumes USBFS0 or USBHS0 is the desired hardware target for the driver.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select device as the Operation Mode.
USBDP	USBDP	USBDP pin.
USBDM	USBDM	USBDM pin.
OVRCURB	None	OVRCURB pin.
OVRCURA	None	OVRCURA pin.
VBUSEN	None	VBUSEN pin.
VBUS	None, P407 Default: P407	VBUS pin.
EXICEN	None	EXICEN pin.
ID	None	ID pin.
VCCUSB	VCCUSB	VCCUSB pin.
VSSUSB	VSSUSB	VSSUSB pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

USBHS Pin Configuration Settings

Property	Value	Description
Operation Mode	Disabled, Custom, Device, Host, OTG Default: Custom	Select Device as the Operation Mode.
USBHSDP	USBHSDP	USBHSDP pin.
USBHSDM	USBHSDM	USBHSDM pin.

OVRCURB	None	OVRCURB pin.
OVRCURA	None	OVRCURA pin.
VBUSEN	PB00	VBUSEN pin.
VBUS	PB01	VBUS pin.
EXICEN	None	EXICEN pin.
ID	None	ID pin.
USBHSRREF	USBHSRREF	USBHSRREF pin.
AVCCUSBHS	AVCCUSBHS	AVCCUSBHS pin.
AVSSUSBHS	AVSSUSBHS	AVSSUSBHS pin.
PVSSUSBHS	PVSSUSBHS	PVSSUSBHS pin.
VCCUSBHS	VCCUSBHS	VCCUSBHS pin.
VSS1USBHS	VSS1USBHS	VSS1USBHS pin.
VSS2USBHS	VSS2USBHS	VSS2USBHS pin.

Note

The example settings are for a project using the S7G2 Synergy MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and other Synergy Kits may have different available pin configuration settings.

4.1.14.6 Using the Communications Framework on USBX v2 Module in an Application

The typical steps in using the Communications Framework on USBX V2 module in an application are:

1. Initialize the Communications Framework on USBX V2 using the sf_comms_api_t::open API.

2. Lock the channel for continuous communications using the sf_comms_api_t::lock API if needed.

3. Receive data using the sf_comms_api_t::read API.

4. Send data using the sf_comms_api_t::write API.

5. Unlock the channel from continuous communication using the sf_comms_api_t::unlock command if needed.

6. Close the channel using the sf_comms_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

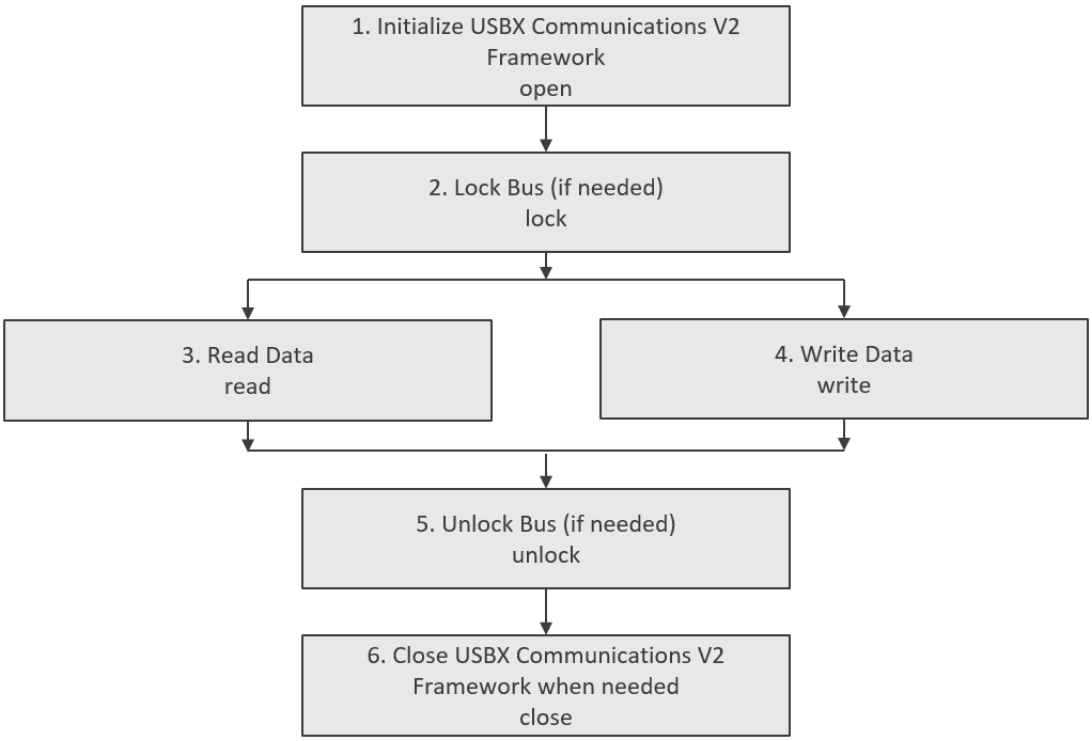

Figure 164: Flow Diagram of a Typical Communications Framework on USBX Module Application

4.1.15 Console Framework

4.1.15.1 Console Framework Introduction

The Console Framework provides a complete API implementation for a menu-driven console command line interface (CLI) using the ThreadX RTOS. The Console Framework module uses a lower-level communications interface, which connects to a hardware option for either UART, USB or Ethernet Telnet connectivity. The Console Framework module has a user-defined menu of commands and various APIs to present a prompt, identify and issue a callback for menu commands and read, write and parse input strings.

Console Framework Module Features

The console framework supports the following features:

- Creation of a menu-based command-line interface
- Submenus and navigation through multiple menus in a single call
- Menu navigation to go up to the parent menu or back to the root
- A help menu for each menu
- Writing NULL terminated strings and reading until return character is received
- An API to help parse arguments to the command line
- Case-insensitive inputs

The Console Framework module organization, as depicted in the thread stack window in the SSP configurator, is shown in the following figure. Each implementation choice, Ethernet, UART, and USB

has its own lower-level modules that are added automatically based on the developer's implementation choice. In most cases, all the needed configuration information is automatically added to the modules leaving the developer with just a few important configuration settings that need to be selected.

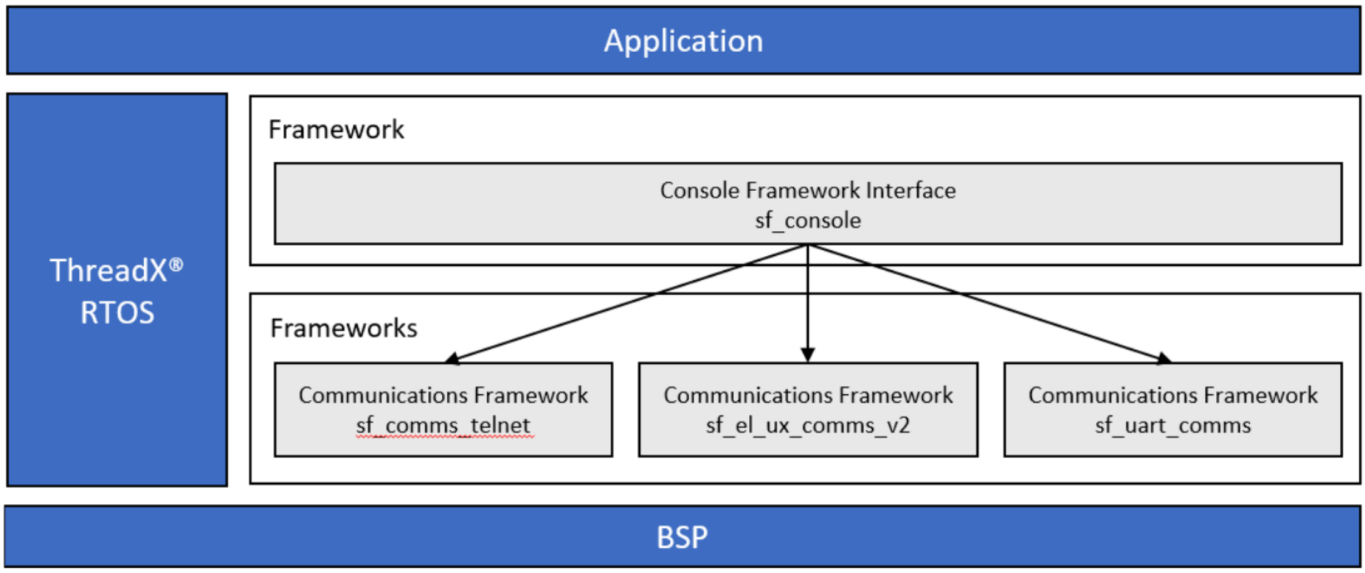

Figure 165: Console Framework Module Block Diagram

4.1.15.2 Console Framework Module APIs Overview

The Console Framework defines APIs for opening, closing, reading, writing and issuing an input prompt. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Console Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_console0.p_api->open(g_sf_console0.p_ctrl, g_sf_console0.p_cfg); The open API configures the console. This function must be called before any other console functions. *Note* *This call is made automatically during system initialization, prior to entering the users thread. Unless the user closes the console, open will not need to be called.*
close	g_sf_console0.p_api->close(g_sf_console0.p_ctrl); The close API handles the clean-up of internal driver data.

prompt	g_sf_console0.p_api->prompt(g_sf_console0.p_ctrl, NULL, TX_WAIT_FOREVER); The prompt API prints the prompt string from the menu, waits for input, parses the input based on the menu, and calls the appropriate callback function if a command is identified.
parse	g_sf_console0.p_api->parse(g_sf_console0.p_ctrl, commands, input, s_length); The parse API looks for an input string in the command menu and, if one is found, calls the appropriate callback function.
read	g_sf_console0.p_api->read(g_sf_console0.p_ctrl, ch, 1, TX_WAIT_FOREVER); The read API puts data into the destination, byte-by-byte and echoes the input to the console. Backspace, delete, and left/right arrow keys are supported. Read completes when a line ending with CR, CR+LF, or CR+NULL is received, or when the input exceeds the number of bytes allowed. If the buffer overflows SF_CONSOLE_MAX_INPUT_LENGTH, the read will return an error code.
write	g_sf_console0.p_api->write(g_sf_console0.p_ctrl, (uint8_t*)data_string, TX_WAIT_FOREVER); The write API gets the buffer mutex object and handles data transmission at the HAL layer. It obtains the event flag to synchronize the completion of a data transfer.
argumentFind	g_sf_console0.p_api->argumentFind("LED", p_args->p_remaining_string, NULL, &led_num); The argumentFind API locates a command line argument in an input string and returns the index of the character immediately following the argument. Any string numbers are converted to integers.
versionGet	g_sf_console0.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	p_ctrlis NULL.
SSP_ERR_UNSUPPORTED	Command not found in the current menu.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.15.3 Console Framework Module Operational Overview

The Console Framework module is a ThreadX-aware Command Line Interface (CLI). The module uses ThreadX objects like mutex for blocking and synchronization techniques like event flags for the completion of a transaction. The key operational elements of the Console Framework are initialization and input processing, each of which are described in the following sections.

Console Framework Module Initialization

The open call is automatically generated by the ISDE and is in the file where the module was added. The open call requires the application to define a root menu with a variable name that matches the one in the configurator (g_sf_console_root_menu) by default. By the time execution reaches the thread entry function the module is ready to use, provided the necessary hardware connection is established.

Console Framework Module Input Processing

The Console Framework module requires a set of menus, command structures, and callbacks. The Console Framework module typically operates from the prompt, often located within a while loop in the entry thread. The framework sf_console_api_t::prompt API will print the current menu as a prompt, then read input and echo it back to the console (unless echo is disabled in the properties.)

Following operations are performed against the user input:

While the console is accepting input,

- Backspace will remove characters before the cursor.
- Delete will remove characters after the cursor.
- The left and right arrow keys move the cursor.
- The up-arrow key will fill in the last command only when nothing else has been entered.

Note

There is no history beyond the last command; if the up-arrow key is pressed twice, the console does not know what command was entered prior to the last command and it will continue to display the last command.

When the console sees a return character on the read input, it parses the input string and calls the associated callback or switches to the next menu if SF_CONSOLE_CALLBACK_NEXT_FUNCTION is used in place of the callback for the command. The console will continue parsing until a callback function is called. If sf_console_api_t::prompt API is called again, it will prompt using the menu that contains the callback function. To navigate up to the parent menu, enter '^'. To navigate to the root menu from any submenu, enter '~'.

The parser will parse the input command till a white space or end of the string.

For example:

With the list of commands[2] = {"echo", "setbitrate"};

1. >echoIs valid
2. >echo<space>Is valid
3. >echo3Is an unsupported command

4. >setbitrateIs valid
5. >setbitrate 9600Results in the bit rate being set to 9600

Creating Console Framework Module Required Structures – The Menu

The Console Framework requires a menu and it is up to the developer to create the structure that is used by the Console Framework to implement the menu. The console menu structure (depicted in the following figure) includes a pointer to the previous menu, (for creating multi-level menus) a name for the menu, the number of commands in the menu, and a pointer to an array of command structures. As seen in the following figure, each entry in the array of commands includes pointers to the command name string, the help command description string, the associated command callback function, and a context parameter provided to the callback.

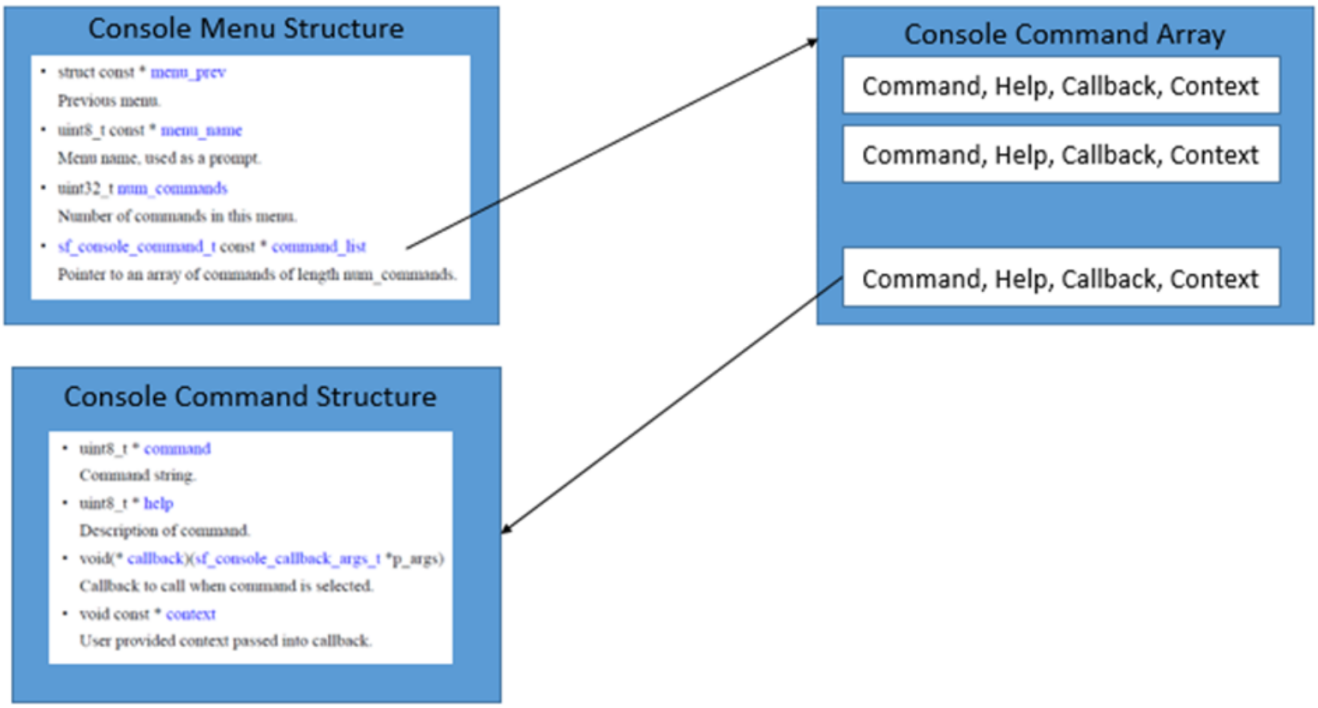

Figure 166: Console Framework Module Menu Structures

The application project example illustrates a Console Framework with a single menu; it controls the toggle of an LED from the CLI. The console command array (g_sf_console_commands, seen on the right in the following figure) stores the array of commands (in this case, just a single command.) The command structure defines the command as "LED TOGGLE", the help description as "Toggle an LED", the callback as led_toggle_callback, and the context as NULL, since it is unused for this example.

The root menu, seen on the left side of the following figure, is identified by the g_sf_console_root_menu structure. The structure defines the menu_prev entry as NULL, since there is only the single menu, the menu_name as "Root", the num_commands as the size of the array divided by the size of an entry (to determine the total number of entries) as "1", and the command_list starting address as "address", the location of the first entry in the command array.

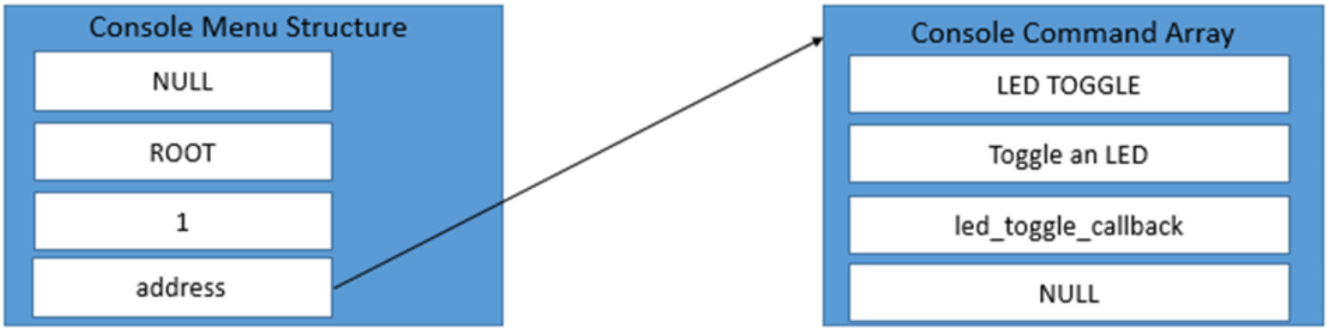

Figure 167: Console Framework Module Menu Structure Example Diagram

Console Framework Module Important Operational Notes and Limitations

Console Framework Module Operational Notes

- To use the Console Framework module sf_console_api_t::prompt API, first set up the menu, command structures and callbacks.

Console Framework Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.15.4 Including the Console Framework Module in an Application

This section describes how to include the Console Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Console Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Console Framework module is g_sf_console0. This name can be changed in the associated Properties window.)

Console Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_console0 Console Framework on sf_console	Threads	**New Stack> Framework> Services> Console Framework on sf_console**

When the Console Framework module on sf_console is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink

band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

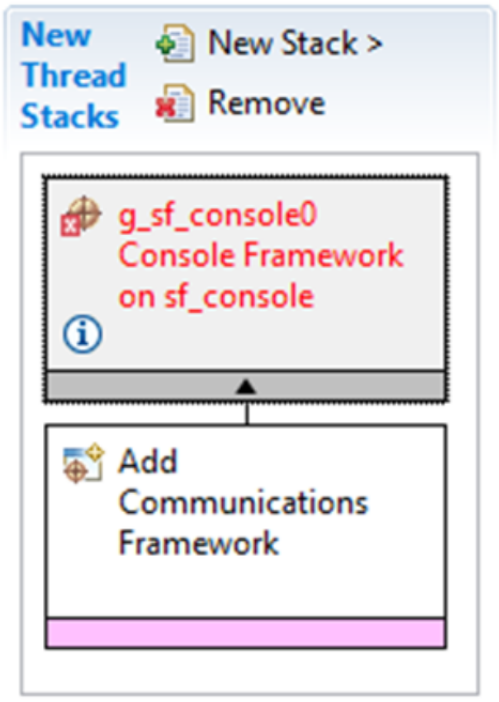

Figure 168: Console Framework Module Stack

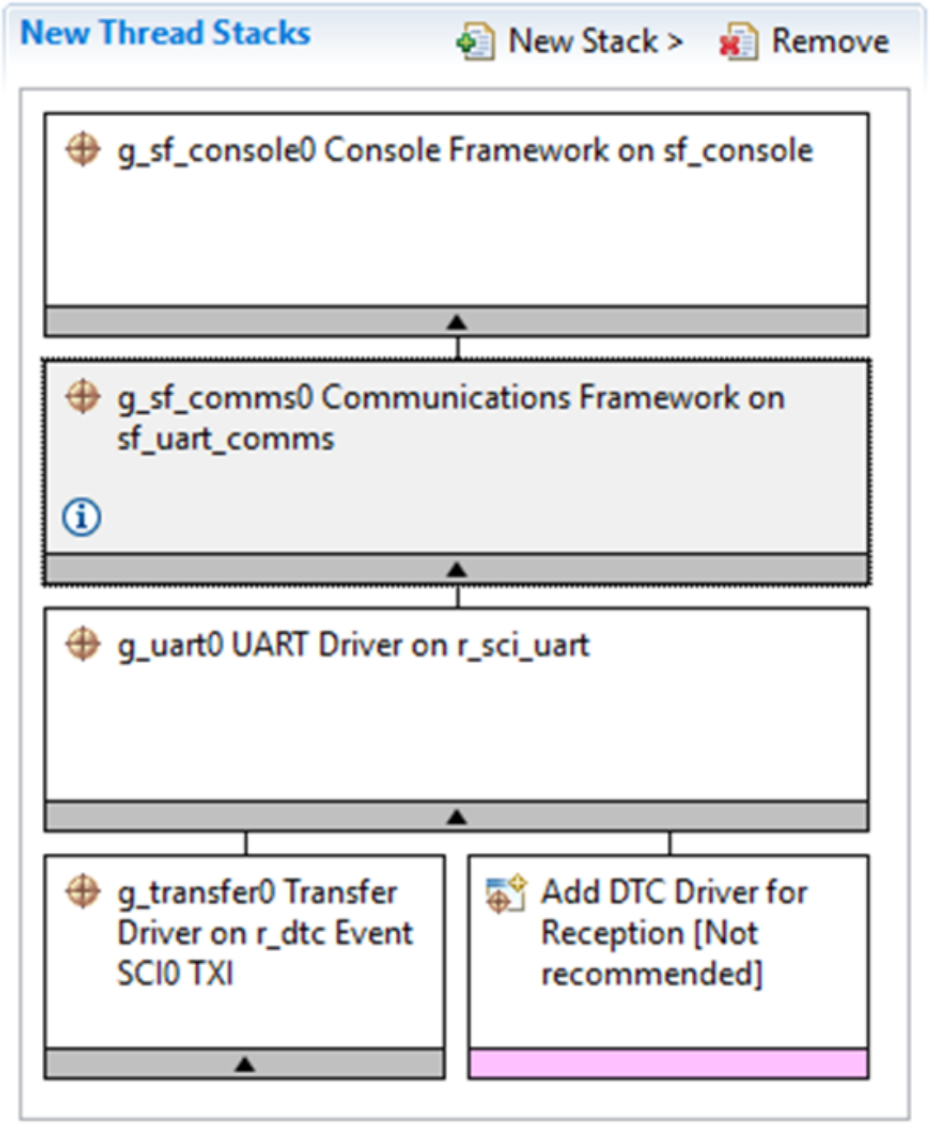

Figure 169: Example Console Framework with UART Communications Framework

4.1.15.5 Configuring the Console Framework Module

The Console Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Console Framework Module on sf_console

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Maximum Input String Length	128	Maximum input string length selection.
Maximum Write String Length	128	Maximum input string length selection.
Console print timeout value	0xFFFFFFFF	Console print timeout value selection.
Name	g_sf_console0	Module name.
Name of Initial Menu (Application Defined)	g_sf_console_root_menu	Initial menu name.
Echo	True, False Default: True	Echo selection.
Autostart	True, False Default: False	Autostart selection.
Name of generated initialization function	sf_console_init0	Name of generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Auto Initialization selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuring the Console Framework Lower-Level Modules

The Console Framework provides three different options for Communication Framework implementations: the Telnet Communications Framework, the Communications Framework on USBX v2, and the UART Communications Framework. Each of these frameworks have several lower-level module options themselves; configuration information for these frameworks is provided in the module overviews for the sf_comms_telnet, sf_el_ux_comms_v2, and sf_uart_comms modules.

4.1.15.6 Using the Console Framework Module in an Application

The typical steps in using the Console Framework module in an application are:

1. Create menu and command structures.
2. Implement needed callbacks.
3. Initialize the Console Framework using hte sf_console_api_t::open API.
4. Use the sf_console_api_t::prompt API to generate the prompt and process commands.
5. Use other APIs (sf_console_api_t::read, sf_console_api_t::write, sf_console_api_t::parse or sf_console_api_t::argumentFind) as needed to process commands.
6. Use sf_console_api_t::close API to close the module if desired.

These common steps are illustrated in a typical operational flow in the following figure:

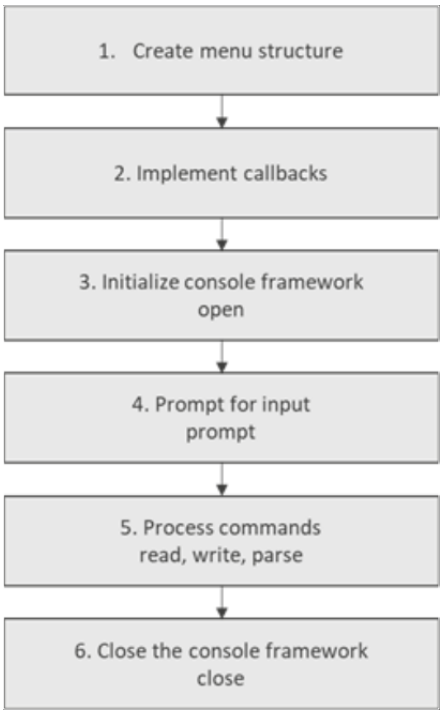

Figure 170: Flow Diagram of a Typical Console Framework Module Application

4.1.16 Crypto Framework

4.1.16.1 Crypto Framework Introduction

The Crypto Framework layer is composed of multiple Crypto modules providing varied cryptographic services. It includes:

SF_CRYPTO for resource synchronization between the crypto modules.

SF_CRYPTO_TRNG for true random number generation.

SF_CRYPTO_HASH for message digest generation. Provides support for MD5, SHA1, SHA 224, SHA 256 algorithms.

SF_CRYPTO_KEY for Key Generation services. Provides support for AES, ECC and RSA keys.

SF_CRYPTO_CIPHER for encryption and decryption services. Provides support for AES and RSA algorithms.

SF_CRYPTO_SIGNATURE for RSA signature generation and verification services.

SF_CRYPTO_KEY_INSTALLATION for key installation services. Provides support for AES, ECC and RSA keys.

Crypto Framework Module Features

The terms "key wrapping" and "key installation" in the context of SSP are defined as follows:

Key Wrapping: The APIs to generate symmetric keys or asymmetric key pairs on the Synergy platform where the private / secret key is a wrapped key (encrypted key).

Key Installation: User generated private /secret keys on a PC (system outside of the Synergy platform) will be installed (no storage) on the Synergy platform and the wrapped private /secret key returned to the user.

Wrapped keys provide the following advantages:

- The wrapped key can only be used on the Synergy platform (MCU) on which it was generated.
- It cannot be moved to another Synergy platform (MCU).
- Original Key cannot be recovered from the wrapped key.

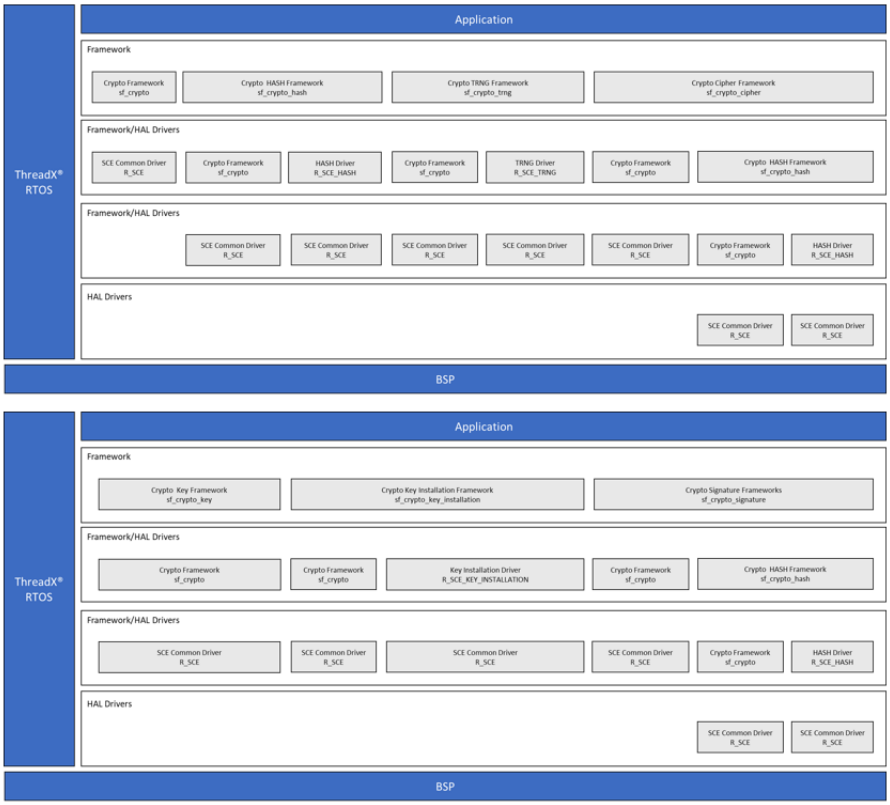

Figure 171: Crypto Framework Module Block Diagram

4.1.16.2 Crypto Framework Module APIs Overview

The Crypto Framework Module defines APIs for a variety of cryptographic services. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Crypto Framework Module API Summary

Function Name	Example API Call and Description

open	g_sf_crypto0.p_api->open(g_sf_crypto0.p_ctrl, g_sf_crypto0.p_cfg); This function is used to open the crypto framework module and the r_sce HAL module.
close	g_sf_crypto0.p_api->close(g_sf_crypto0.p_ctrl); This function is used to close the crypto framework module and the r_sce HAL module.
lock	g_sf_crypto0.p_api->lock(g_sf_crypto0.p_ctrl); This function locks shared resources for cryptography operations.
unlock	g_sf_crypto0.p_api->unlock(g_sf_crypto0.p_ctrl); Unlock shared resources for cryptography operations.
getStatus	g_sf_crypto0.p_api->statusGet(g_sf_crypto0.p_ctrl, &p_status); This function gets the status of the Crypto Framework common module.
versionGet	g_sf_crypto0.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Crypto HASH Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_crypto_hash0.p_api->open(g_sf_crypto_hash0.p_ctrl, g_sf_crypto_hash0.p_cfg); This function is used to open the crypto hash framework module.
close	g_sf_crypto_hash0.p_api->close(g_sf_crypto_hash0.p_ctrl); This function is used to close the crypto hash framework module.
hashInit	g_sf_crypto_hash0.p_api->hashInit(g_sf_crypto_hash0.p_ctrl); This function initializes the calculation of the hash function. It has to be invoked first and only once, at the beginning of each new calculation.
hashUpdate	g_sf_crypto_hash0.p_api->hashUpdate(g_sf_crypto_hash0.p_ctrl, &p_data_in); This function calculates the hash on the data pointed to by the p_data_in pointer.

hashFinal	g_sf_crypto_hash0.p_api->hashFinal(g_sf_crypto_hash0.p_ctrl, &p_data_in, &p_size); This function finalizes the hash operation on the data pointed to by the p_data_in pointer and stores the output size in the 32-bit word defined by the p_size pointer.
versionGet	g_sf_crypto_hash0.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Crypto TRNG Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_crypto_trng0.p_api->open(g_sf_crypto_trng0.p_ctrl, g_sf_crypto_trng0.p_cfg); This function is used to open the Crypto TRNG framework module.
close	g_sf_crypto_trng0.p_api->close(g_sf_crypto_trng0.p_ctrl); This function is used to close the Crypto TRNG framework module.
randomNumberGenerate	g_sf_crypto_trng0.p_api->randomNumberGenerate (&p_buffer); This function generates the random number and stores it in memory starting at the address defined by the p_buffer pointer.
versionGet	g_sf_crypto_trng0.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Crypto Key Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_crypto_key0.p_api->open(g_sf_crypto_key0.p_ctrl, g_sf_crypto_key0.p_cfg); This function is used to open the crypto key framework module.

keyGenerate	g_sf_crypto_key0.p_api->keyGenerate(g_sf_crypto_key0.p_ctrl, &p_secret_key, &p_public_key); This function is used to generate a key or key pair and store it at the p_secret_key and p_public_key pointers.
EcdhSharedSecretCompute	g_sf_crypto_key0.p_api->EcdhSharedSecretCompute(g_sf_crypto_key0.p_ctrl, &p_local_secret_key, &p_remote_public_key, &p_shared_secret); This function is used to perform ECC scalar multiplication
close	g_sf_crypto_key0.p_api->close(g_sf_crypto_key0.p_ctrl); This function is used to close the crypto key framework module and the r_sce HAL module.
versionGet	g_sf_crypto_key0.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Crypto Key Installation Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_crypto_key_installation.p_api->open(g_sf_crypto_key_installation.p_ctrl, g_sf_crypto_key_installation.p_cfg); This function is used to open the crypto key initialization framework module.
keyInstall	g_sf_crypto_key_installation.p_api->keyInstall(g_sf_crypto_key_installation.p_ctrl, p_user_key_input, p_install_key_input, p_key_data_out); This function is used to install a key using the p_user_key_input, p_install_key_input and p_key_data_out pointers.
close	g_sf_crypto_key_installation.p_api->close(g_sf_crypto_key_installation.p_ctrl); This function is used to close the crypto key installation framework module.
versionGet	g_sf_crypto_key_installation.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Crypto Cipher Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_crypto_cipher.p_api->open(g_sf_crypto_cipher.p_ctrl, g_sf_crypto_cipher.p_cfg); This function is used to open the crypto cipher framework module.
cipherInit	g_sf_crypto_cipher.p_api->cipherInit(g_sf_crypto_cipher.p_ctrl, mode, p_key, p_params); This function is used to initialize the crypto cipher framework module.
signUpdate	g_sf_crypto_cipher.p_api->cipherUpdate(g_sf_crypto_cipher.p_ctrl, p_datain, p_dataout); This function performs the cipher encrypt or decrypt operation. It can be called multiple times on additional blocks of data. Result is placed in p_dataout.
cipherFinal	g_sf_crypto_cipher.p_api->cipherFinal(g_sf_crypto_signature.p_ctrl, p_datain, p_dataout); This function performs the final encrypt or decrypt operation. Result is placed in p_dataout.
cipherAadUpdate	g_sf_crypto_cipher.p_api->cipherAadUpdate(g_sf_crypto_cipher.p_ctrl, p_aad); This function updates AAD (Additional Authenticated Data) for AES GCM operation using the p_aad pointer to the AAD data and length. It can be called multiple times on additional blocks of data.
close	g_sf_crypto_cipher.p_api->close(g_sf_crypto_cipher.p_ctrl); This function is used to close the crypto signature framework module.
versionGet	g_sf_crypto_cipher.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Crypto Signature Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_crypto_signature.p_api->open(g_sf_crypto_signature.p_ctrl, g_sf_crypto_signature.p_cfg); This function is used to open the crypto signature framework module.
contextInit	g_sf_crypto_signature.p_api->contextInit(g_sf_crypto_signature.p_ctrl, mode, p_params, p_key); This function is used to initialize the crypto signature framework module.
signUpdate	g_sf_crypto_signature.p_api->signUpdate(g_sf_crypto_signature.p_ctrl, p_message); This function performs the signature update operation. It can be called multiple times to accumulate the message to be signed.
verifyUpdate	g_sf_crypto_signature.p_api->verifyUpdate(g_sf_crypto_signature.p_ctrl, p_message); This function performs the signature verification update operation. It can be called multiple times to accumulate the message whose signature is to be verified.
signFinal	g_sf_crypto_signature.p_api->signFinal(g_sf_crypto_signature.p_ctrl, p_message, p_dest); This function generates the signature and writes it to the destination.
verifyFinal	g_sf_crypto_signature.p_api->verifyFinal(g_sf_crypto_signature.p_ctrl, p_signature, p_message); This function performs the signature verify operation.
close	g_sf_crypto_signature.p_api->close(g_sf_crypto_signature.p_ctrl); This function is used to close the crypto signature framework module.
versionGet	g_sf_crypto_signature.p_api->versionGet(&version); This function retrieves the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

The Framework APIs return common SSP error codes and in addition may return error codes from low level modules. Crypto Framework specific error codes can be found in the API Reference section for the specific function.

4.1.16.3 Crypto Framework Module Operational Overview

The following notes apply to SF_CRYPTO, SF_CRYPTO_TRNG, SF_CRYPTO_HASH, SF_CRYPTO_KEY, SF_CRYPTO_KEY_INSTALLATION, SF_CRYPTO_CIPHER and SF_CRYPTO_SIGNATURE modules.

Endianness configuration parameter

- In the Synergy Configurator (if *only* the Crypto HAL drivers are selected without the Crypto Framework modules), endianness is a configurable parameter and set to *big endian* by default. This is the mode that was supported in previous releases.
- In the Synergy Configurator, if Crypto Framework modules are selected (the respective HAL component is included automatically), the endianness flag is locked to the *little endian* mode where only the byte array format is supported.
- The Crypto Framework Layer APIs support only byte arrays for input and output data.
- The Crypto HAL APIs support WORD / 32-bit (uint32_t) arrays for input and output data.
- Users with data in byte array format should use the Crypto Framework modules.
- For any existing projects using the Crypto HAL API without the respective Framework API, Big Endian data may have been used and in that case, it needs to be converted to little Endian to use framework API or continue to use the existing HAL API directly.
- If using the HAL APIs directly, the user needs to make sure that the data cast as (uint32_t) matches the endianness of the HAL module used.

Alignment for data buffers

- All data buffers allocated to be passed in as input buffers must be aligned on WORD boundary.

Blocking calls

- All Crypto Framework APIs are blocking calls.

SF CRYPTO Framework Services

- The SF CRYPTO Framework modules include:
    - SF_CRYPTO for HW initialization and resource synchronization between the crypto modules.
    - SF_CRYPTO_TRNG for true random number generation.
    - SF_CRYPTO_HASH for message digest generation. Provides the ability to process data in chunks before finalizing the hash operation.
    - SF_CRYPTO_KEY for RSA, AES, ECC. Provides the option to generate wrapped keys in addition to plain text keys.
    - SF_CRYPTO_KEY_INSTALLATION provides key installation services for RSA, AES and ECC keys.
    - SF_CRYPTO_CIPHER provides encryption and decryption services for AES and RSA keys.
    - SF_CRYPTO_SIGNATURE provides RSA signature generation and verification services.

VersionGet API

This API can be called at any time, that is, even before a module is opened.

SF CRYPTO Framework Module Overview Description

The SF CRYPTO Framework provides a high-level API and is implemented on sf_crypto. The SF

CRYPTO Framework provides a foundation for the Framework Crypto services through the Secure Cryptographic Engine (SCE) HAL module.

SF CRYPTO Framework Module Features

- The SF CRYPTO Framework opens/ initializes the underlying HW Secure Crypto Engine.
- Provides services for access to shared resources for other Crypto Framework modules SF_CRYPTO_TRNG, SF_CRYPTO_HASH, SF_CRYPTO_KEY, SF_CRYPTO_CIPHER, SF_CRYPTO_SIGNATURE and SF_CRYPTO_KEY_INSTALLATION.

SF CRYPTO Framework Module Operational Notes

- sf_crypto_api_t::open API is called during initialization because the "Auto Initialization" configuration option is enabled by default.
- sf_crypto_api_t::lock API and sf_crypto_api_t::unlock API are for the SF_CRYPTO_XXX modules to to be used.

However, if the application is making a direct call to HAL APIs, use sf_crypto_api_t::lock API just before making the call to HAL module.

- Use sf_crypto_api_t::unlock API just after returning from the call to HAL module.
- sf_crypto_api_t::statusGet API requires the control block / p_ctrl as input parameter. Hence it should be called only after the open API of SF_CRYPTO module is called.

Configuration Settings for the SF CRYPTO Framework Module

Configuration parameter	Description
uint32_t wait_option	Wait option for RTOS service calls Defines how the service behaves if there is not enough memory available. The wait options are defined as follows: TX_NO_WAIT (0x00000000) T X_WAIT_FOREVER (0xFFFFFFFF) timeout value (0x00000001 through 0xFFFFFFFE) Selecting TX_NO_WAIT results in an immediate return from this service regardless of whether or not it was successful. This is the only valid option if the service is called from initialization. Selecting TX_WAIT_FOREVER causes the calling thread to suspend indefinitely until enough memory is available. Selecting a numeric value (1-0xFFFFFFFE) specifies the maximum number of timer-ticks to stay suspended while waiting for the memory. Default set through ISDE isTX_WAIT_FOREVER.
crypto_instance_t * p_lower_lvl_crypto	Pointer to a low-level Crypto engine HAL driver instance. Configured by Synergy Configurator.
void const * p_extend	Extension parameter for hardware specific settings. Configured by Synergy Configurator.

void const * p_context	Placeholder for user data. For future expansion.
void * p_memory_pool	Byte pool address. Configured by Synergy Configurator.
uint32_t memory_pool_size	Byte pool size. Default set by ISDE is 128 bytes. Caller to allocate pool based on the number of SF_CRYPTO_XXX module instances created. Recommended sizes: In addition to the default byte pool: *Note* *An additional 12 bytes per instance is needed for RTOS housekeeping.* *24 + 12 bytes per instance of SF_CRYPTO_KEY module if RSA Key is required.* *264 +12bytes per instance of SF_CRYPTO_KEY module if AES Key is required.* *SF_CRYPTO_KEY module if AES Key is required.* *112 +12 bytes per instance of SF_CRYPTO_HASH module.* *1200 bytes per instance of SF_CRYPTO_CIPHER module for RSA algorithm is required.* *600 bytes per instance of SF_CRYPTO_CIPHER module for AES algorithm is required.* *1450 bytes per instance of SF_CRYPTO_SIGNATURE module.*
sf_crypto_close_option_t close_option	Close option Selects how the SCE module can be closed. SF_CRYPTO_CLOSE_OPTION_DEFAULT - Close the module only if none of the other SF_CRYPTO_XXX modules are opened. *Note* *This is the default setting.* *SF_CRYPTO_CLOSE_OPTION_FORCE_CLOSE - Close the module regardless of SF_CRYPTO_XXX modules status.* *With either option, It is the responsibility of the caller to ensure that the SF CRYPTO module is not closed when any of the other Crypto Framework modules are open.*

SF CRYPTO Framework Module Limitations

It is the responsibility of the caller to ensure that the SF CRYPTO module is not closed when any of the other Crypto Framework modules are open.

Using the SF CRYPTO Framework Module in an Application

The typical steps in using the SF CRYPTO Framework module in an application are:

To use the SF CRYPTO module.

- Ensure that the configuration parameters (given in the previous table) are set as per the needs of the application.
- Use the sf_crypto_api_t::open API to Initialize the SF_CRYPTO and the SCE HAL module (R_SCE) through the SCE common driver. This is done by Synergy Configurator when the Auto Initialize setting is at default.
- The little endian mode is set by default. It is locked and not configurable.
- The open function cannot be called again until the module is closed.
- Use the sf_crypto_api_t::close API to close the Crypto Framework services and the HW SCE.

SF CRYPTO TRNG Framework Module Overview Description

The SF CRYPTO TRNG Framework provides a high-level API and is implemented on sf_crypto_trng. The SF CRYPTO TRNG Framework provides True Random Number Generation services through the Secure Cryptographic Engine (SCE) HAL module.

SF CRYPTO TRNG Framework Module Features

- The SF CRYPTO TRNG Framework module uses the TRNG HAL interfaces to the underlying Secure Crypto Engine.
- Access to shared resources through SF CRYPTO Framework module.

Configuration Settings for the SF TRNG CRYPTO Framework Module

Configuration Parameter	Description
sf_crypto_instance_t * p_lower_lvl_common;	Pointer to a low-level Crypto engine HAL driver instance. Configured by Synergy Configurator.
trng_instance_t * p_lower_lvl_instance;	Pointer to a TRNG HAL driver instance. Configured by Synergy Configurator.
void * p_extend;	Extension parameter for hardware specific settings. For future use.

The configuration is set through the ISDE for the TRNG HAL driver:

Configuration Parameter for the TRNG HAL Module on r_sce_trng

Configuration parameter	Description
uint32_t num_attempts	Number of attempts within which a true random number is to be generated. Set to 2 by default.

SF CRYPTO TRNG Framework Module Limitations

None.

SF CRYPTO HASH Framework Module Overview Description

The SF CRYPTO HASH Framework provides a high-level API and is implemented on sf_crypto_hash. The SF CRYPTO HASH Framework provides hash/message digest services through the Secure Cryptographic Engine (SCE) HAL module.

The hash functions supported are MD5, SHA-1, SHA-224 and SHA-256.

From FIPS Secure Hash Standard:

All of the algorithms are iterative, one-way hash functions that can process a message to produce a condensed representation called a *message digest*. These algorithms enable the determination of a message's integrity: any change to the message will, with a very high probability, result in a different message digest. This property is useful in the generation and verification of digital signatures and message authentication codes, and in the generation of random numbers or bits.

For the supported hash functions, the message size should be $< 2^{64}$ bits.

The message digest sizes are as follows:

MD5 : 16 bytes

SHA-1 : 20 bytes

SHA-224: 28 bytes

SHA-256: 32 bytes

SF CRYPTO HASH Framework Module Features

- The SF CRYPTO HASH Framework utilizes the underlying Secure Crypto Engine to provide HASH services.
- This module provides enhancements over the HAL Driver such as:
  - Initializing the HASH value.
  - Processing chunks of data through sf_crypto_hash_api_t::hashUpdate API before finalizing the hash operation.
  - Formatting the final block for the final HASH operation.

Configuration Settings for the SF CRYPTO HASH Framework Module

Configuration Parameter	Description
sf_crypto_hash_type_t hash_type;	HASH algorithm type. Select MD5, SHA1, SHA 224 or SHA256. See the header file for the definitions.
crypto_instance_t * p_lower_lvl_crypto	Pointer to a low-level Crypto engine HAL driver instance. Configured by Synergy Configurator.
hash_instance_t * p_lower_lvl_instance;	pointer to HASH lower-level module instance. Configured by ISDE.
void * p_extend	Extension parameter for hardware specific settings. Optional. Configured by Synergy Configurator.

SF CRYPTO HASH Framework Module Limitations

None

SF CRYPTO KEY Framework Module Overview Description

The SF CRYPTO KEY Framework provides a high-level API and is implemented on sf_crypto_key. The SF CRYPTO KEY Framework provides cryptographic key generation services through the Secure Cryptographic Engine (SCE) HAL module.

The wrapped keys are often referred to by different names, for example encrypted key, key handle, wrapped key. Key wrapping on Synergy platform is considered secure as those keys cannot be used outside of the platform.

SF CRYPTO KEY Framework Module Features

The following key types can be generated using the services of the SF CRYPTO KEY module:

- RSA 2048-bit, 1024-bit plain text / raw keys.
- RSA 2048-bit, 1024-bit standard format wrapped private keys (public keys in plain).
- AES 128-bit, 192-bit and 256-bit wrapped keys for ECB, CBC, CTR and GCM chaining modes.
- AES 128-bit and 256-bit wrapped keys for XTS chaining mode.
- ECC 192-bit, 224-bit, 256-bit, 384-bit plain-text and wrapped keys.

SF CRYPTO KEY Framework Module Operational Notes

AES Keys

AES wrapped key sizes are as follows:

```
/* Return Wrapped AES secret key size in bytes for a 128-bit AES Key */
#define AES128_WRAPPPED_SECRET_KEY_SIZE_BYTES  (36U)
/* Return Wrapped AES secret key size in bytes for a 192-bit AES Key */
#define AES192_WRAPPPED_SECRET_KEY_SIZE_BYTES  (52U)
/* Return Wrapped AES secret key size in bytes for a 256-bit AES Key */
#define AES256_WRAPPPED_SECRET_KEY_SIZE_BYTES  (52U)
/* Return Wrapped AES-XTS secret key size in bytes for a 128-bit AES XTS Mode Key */
#define AES_XTS_128_WRAPPPED_SECRET_KEY_SIZE_BYTES  (52U)
/* Return AES-XTS secret key size in bytes for a 256-bit AES XTS Mode Key */
#define AES_XTS_256_WRAPPPED_SECRET_KEY_SIZE_BYTES  (84U)
```

RSA Keys

The format of RSA plain text keys generated by the keyGenerate API is as follows:

RSA Public key

Byte 0 to Byte 3: Public key exponent

Byte 4 : Start of RSA modulus

(128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

RSA Private key in standard format

Byte 0: Private key exponent (128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

Followed by RSA modulus. (128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

RSA Private key in CRT format

The components are ordered in the following order with exponent2 at byte 0:

exponent2 // the second factor's CRT exponent, a positive integer

prime2 // the second factor, a positive integer

exponent1 // the first factor's CRT exponent, a positive integer

prime1 // the first factor, a positive integer

coefficient // the (first) CRT coefficient, a positive integer

The format of RSA wrapped keys generated by the keyGenerate API is as follows:

RSA Public key is always in plain text.

Byte 0 to Byte 3: Public key exponent

Byte 4 : Start of RSA modulus

(128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

RSA Private key in standard format

Byte 0: Private key exponent is wrapped. (Length is 148 bytes for RSA 1024-bit and 276 bytes for RSA 2048-bit keys)

Followed by RSA modulus in plain text. (Length is 128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

Configuration Settings for the SF CRYPTO KEY Framework Module

Configuration parameter	Description
sf_crypto_key_type_t key_type	Key type to be generated. Plain text or Wrapped keys. See the header file for the definitions.
sf_crypto_key_size_t key_size	Key size to be generated. See the header file for the definitions.

sf_crypto_data_handle_t domain_params;	Pointer to domain parameters for the requested key type. Structure contains, pointer to the data (contains the domain data) and data length. Structure contains the domain data in the order a||b||p||n for ECC as defined in FIPS186-3 and data length. To be filled appropriately for ECC and set to NULL for RSA and AES Key types, since this parameter only applies to the ECC function.
sf_crypto_data_handle_t generator_point	Pointer to the generator base point of curve in the order Gx||Gy for ECC (where Gx and Gy are x and y coordinates respectively) and data length. To be set to NULL for RSA and AES key types.
sf_crypto_instance_t * p_lower_lvl_crypto_common	Pointer to a Crypto Framework common instance. Configured by Synergy Configurator.
void const * p_extend	Extension parameter for hardware specific settings (Reserved for future use). Configured by Synergy Configurator.

SF Crypto Signature Framework Module Overview Description

The SF CRYPTO Signature Framework provides a high-level API and is implemented on sf_crypto_signature. This module is in the SSP framework layer that interfaces with Synergy HAL drivers for the hardware level cryptography operations. The module functions specified herein are used to sign / verify messagethat is provided as input.

SF Crypto Signature Module Features

- This module currently supports signature generation and signature-verification for RSA algorithm. There is support for both 1024-bits and 2048-bits key lengths for standard format plain-text, standard format wrapped private key and CRT plain-text keys.
- RSASSA-PKCS1 v1.5 is the supported signature scheme. The input message can be passed as raw message to be signed/verified or can be PKCS1 v1.5 encoded and padded before sign/verify.
- SHA1, SHA224, SHA256 are the supported hashing algorithms for PKCS1 v1.5 encoding /padding schemes.
- This module allows signature generation / verification on data which is smaller than a block size.
- If all of the data is not available at once, update APIs can be used to accumulate the incoming chunks of data and finally sign/verify the message only when all the message is gathered.
- Module allows to switching between sign and verify operations with less expensive API calls which are not involved in allocating and deallocating memory.

SF Crypto Signature Framework Module Operational Notes

1. Operation modes for Signature Framework Module:
    a. SF_CRYPTO_SIGNATURE_MODE_SIGN
    b. SF_CRYPTO_SIGNATURE_MODE_VERIFY
2. Input Message Format to the Signature Framework APIs to perform sign or verify operation:
    a. SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_NONE

b. SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_RSA_SHA1_PKCS1_1_5
c. SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_RSA_SHA224_PKCS1_1_5
d. SF_CRYPTO_SIGNATURE_MESSAGE_OPERATION_RSA_SHA256_PKCS1_1_5

Configuration Settings for SF CRYPTO Signature Framework Module

Configuration parameter	Description
sf_crypto_key_type_t key_type;	Type of Key RSA plain text or wrapped. See the header file for the definitions.
sf_crypto_key_size_t key_size	Size of Key RSA 1024-bit /2048-bit key. See the header file for the definitions.
sf_crypto_hash_instance_t * p_lower_lvl_sf_crypto_hash	Pointer to the Crypto Hash framework module instance structure. Configured by Synergy Configurator.
sf_crypto_instance_t * p_lower_lvl_crypto_common	Pointer to Crypto Common module instance. Configured by Synergy Configurator.
void const * p_extend	Extension parameter for hardware specific settings. Optional. Configured by Synergy Configurator.
void const * p_extend	Extension parameter for hardware specific settings (Reserved for future use). Configured by Synergy Configurator.

SF CRYPTO Signature Framework Module Limitations

None

SF Crypto Cipher Framework Module Overview Description

The SF CRYPTO Cipher Framework provides a high-level API and is implemented on sf_crypto_cipher. This module is in the SSP framework layer and provides encryption and decryption services through the Secure Cryptographic Engine (SCE) HAL module.

SF Crypto Cipher Module Features

- This module currently supports encryption and decryption for AES and RSA algorithms.
- This module allows encryption/ decryption of data when available in chunks through the sf_crypto_cipher_api_t::cipherUpdate API and final() when the last chunk /all the data is gathered.
- Once the module is opened for a specific key type and key size, the encrypt and decrypt modes can be switched by calling the sf_crypto_cipher_api_t::cipherInit API.

AES algorithm support:

- AES 128-bit, 192-bit and 256-bit plain text and wrapped keys for the following chaining modes:
    - ECB (Electronic Code Book)
    - CBC (Cipher Block Chaining)
    - CTR (Counter Mode)

    - GCM (Galois Counter Mode)
- AES 128-bit and 256-bit plain text and wrapped keys for XTS (XEX-based tweaked code-book mode with ciphertext stealing) are supported.
- IV provided for AES GCM operations can be either 96-bits or a 96-bit IV formatted to 128-bits.
    - Example:
        - 96-bit IV: 94c1935afc061cbf254b936f
        - 96-bit IV formatted to 128-bits: 94c1935afc061cbf254b936f00000001
- PKCS#7 padding scheme is supported for ECB and CBC modes. This scheme can be used when the data is of any block size from 1 to 255 bytes.
- No padding option is supported for all modes where the data is exactly a multiple of the AES block size.
    - For GCM, no padding option is to be selected even when the data is not a multiple of the block size.

RSA algorithm support:

- RSA 1024-bit and 2048-bit plain-text standard format, plain-text CRT format and standard format wrapped keys are supported.
- RSA encrypt operation requires RSA public key and RSA decrypt operation requires RSA private key.
- RSAES-PKCS1-v1_5 (RSA Encryption Scheme)
    - RSA-PKCS1 v1.5 encoding /padding scheme is supported.
    - The input raw message is encoded and formatted to be encrypted. It requires that the message be less than k-11 where k is the length of the modulus of the selected key.
- No padding option should be selected when an encoded and formatted block (exactly the size as the modulus of the selected key) needs to be encrypted / decrypted.

SF Crypto Cipher Framework Module Operational Notes

Configuration Settings for the SF Crypto Cipher Framework Module

Configuration Parameter	Description
sf_crypto_key_type_t key_type	Key type for cipher operation: AES or RSA plain text or wrapped. Please refer to the header file for the definitions.
sf_crypto_key_size_t key_size	Key size for cipher operation: AES 128-bit / 192-bit/256-bit key or RSA 1024-bit /2048-bit key. Please refer to the header file for the definitions.
sf_crypto_cipher_mode_t cipher_chaining_mode	Applicable only to AES algorithm: ECB, CBC, CTR, XTS or GCM chaining modes Set to ECB for RSA. Please refer to the header file for the definitions.
sf_crypto_instance_t * p_lower_lvl_crypto_common	Pointer to Crypto Framework Common module instance. Configured by Synergy Configurator.
sf_crypto_trng_instance_t * p_lower_lvl_crypto_trng	Pointer to Crypto Framework TRNG module instance. Configured by Synergy Configurator.

void	const	* p_extend	Extension parameter for hardware specific settings.Optional. Configured by Synergy Configurator.

SF CRYPTO Cipher Framework Module Limitations

- AES XTS mode only supports lengths which are a multiple of 32-bits / 4 bytes.

SF Crypto Key Installation Framework Module Overview Description

The SF Crypto Key Installation Framework provides a high-level API and is implemented on sf_crypto_key_installation. The SF Crypto Key Installation Framework Key Installation services through the Secure Cryptographic Engine (SCE) HAL module.

Note

1. The API returns the wrapped key (please refer to the SF CRYPTO KEY Module section for the wrapped key format and size details) to the user and does not store the key for future use. It is the responsibility of the application to store the wrapped key in non-volatile memory for future use.
2. This Framework module provides the same level of service as the Crypto HAL module without any enhancements. It is provided for thread safe operation and for completeness of Crypto support in the Framework layer.

SF Crypto Key Installation Framework Module Features

- The SF Crypto Key Installation Framework module uses the KEY INSTALLATION HAL interfaces to the underlying Secure Crypto Engine.
- Access to shared resources through SF CRYPTO Framework module.
- This module supports key installation for the following keys:
  - RSA:
    - 1024-bit and 2048-bit plain text standard format keys.
    - *Note*
      CRT keys are not supported.
  - AES:
    - 128-bit, 192-bit and 256-bit plain text keys for ECB, CBC, CTR and GCM chaining modes.
    - 128-bit and 256-bit plain text keys for XTS chaining mode.
  - ECC:
    - 192-bit and 256-bit plain text keys.
- The session key, iv and shared index must be provided to the key installation API in the specified format.
- Upon installation the key installation service returns a wrapped key to the caller for any future usage of installed key on that device.
- ECC 224-bit and 384-bit keys are supported by the HAL module and not by the framework.

Configuration Settings for the SF Crypto Key Installation Framework Module

Configuration parameter	Description

sf_crypto_key_type_t key_type;	Type of key to be installed. The prepared key will be of the encrypted type. Please refer to the header file for the definitions.
sf_crypto_key_size_t key_size;	Size of key to be installed. Please refer to the header file for the definitions.
sf_crypto_instance_t * p_lower_lvl_common;	Pointer to a Crypto Framework common instance. Configured by Synergy Configurator.
key_installation_instance_t * p_lower_lvl_instance;	Pointer to Crypto Key Install HAL instance Configured by Synergy Configurator.
void const * p_extend;	Extension parameter for hardware specific settings. For future use.

4.1.16.4 Including the Crypto Framework Module in an Application

This section describes how to include the Crypto Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Crypto Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Crypto Framework module is g_sf_crypto0. This name can be changed in the associated Properties window.)

Crypto Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_crypt0 Crypto Framework on sf_crypto	Threads	**New Stack> Framework> Crypto> Crypto Framework on sf_crypto**
g_sf_crypt_key0 Crypto Key Framework on sf_crypto_key	Threads	**New Stack> Framework> Crypto> Crypto Key Framework on sf_crypto_key**
g_sf_crypt0 Crypto TRNG Framework on sf_crypto_trng	Threads	**New Stack> Framework> Crypto> Crypto TRNG Framework**
g_sf_crypt0 Crypto HASH Framework on sf_crypto_hash	Threads	**New Stack> Framework> Crypto> Crypto HASH Framework**
g_sf_crypt_key0 Crypto Key Installation Framework on sf_crypto_key_installation	Threads	**New Stack> Framework> Crypto> Crypto Key Installation Framework on sf_crypto_key_installation**

g_sf_crypt0 Crypto cipher Framework on sf_crypto_cipher	Threads	**New Stack> Framework> Crypto> Crypto cipher Framework**
g_sf_crypt0 Crypto signature Framework on sf_crypto_signature	Threads	**New Stack> Framework> Crypto> Crypto signature Framework**

When the Crypto Framework module on sf_crypto is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

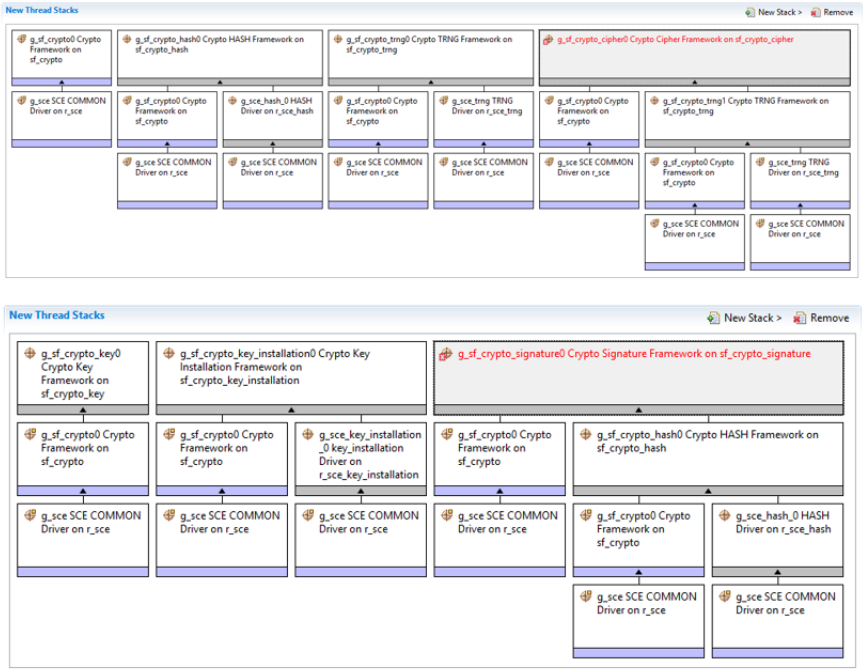

Figure 172: Crypto Framework Module Stack

4.1.16.5 Configuring the Crypto Framework Module

The Crypto Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Crypto Framework on sf_crypto

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Select if code for parameter checking is to be included in the build.
Name	g_sf_crypto0	Module name.
Wait time	TX_WAIT_FOREVER	Value must be a non-negative integer.
Byte Pool Size	128	Specify the size of the byte pool in bytes.
Auto Initialization	Enable, Disable Default: Enable	Select if sf_crypto will be initialized during startup.
Force Closure Support	Default, Force Close Default: Default	Select Force Close to close the crypto module regardless of the status of submodules.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Crypto HASH Framework on sf_crypto_hash

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Select if code for parameter checking is to be included in the build.
Instance Name	g_sf_crypto_hash0	Module name.
Name of generated initialization function	sf_crypto_hash_init0	Select the name of the generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Select if sf_crypto_hash will be initialized during startup.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Crypto TRNG Framework on sf_crypto_trng

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Select if code for parameter checking is to be included in the build.
Name	g_sf_crypto_trng0	Module name.
Name of generated initialization function	sf_crypt_trng_init0	Select the name of the generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Select if sf_crypto_trng will be initialized during startup.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Crypto Cipher Framework on sf_crypto_cipher

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Select if code for parameter checking is to be included in the build.
Name	g_sf_crypto_cipher0	Module name.
Key type	RSA Plain text, RSA CRT Plain text, RSA Wrapped, AES Wrapped, ECC Plain text, ECC Wrapped Default: RSA Plain text	Select the key type.
Key size	RSA 1024-bits, RSA 2048-bits, AES 128-bits, AES XTS 128-bits, AES 192-bits, AES 256-bits, AES XTS 256-bits, ECC 192-bits, ECC 256-bits Default: RSA 2048-bits	Select the key size.
Cipher chaining mode	ECB, CBC, CTR, GCM, XTS Default: ECB	Select the cipher chaining mode.
Name of generated initialization function	sf_crypto_cipher_init0	Select the name of the generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Select if sf_crypto_cipher will be initialized during startup.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Crypto Key Framework on sf_crypto_key

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Select if code for parameter checking is to be included in the build.
Name	g_sf_crypto_key0	Module name.
Key type	RSA Plain text, RSA CRT Plain text, RSA Wrapped, AES Wrapped, ECC Plain text, ECC Wrapped Default: RSA Plain text	Select the key type. For AES, the byte pool size defined in sf_crypto must be >= 280 bytes.
Key size	RSA 1024-bits, RSA 2048-bits, AES 128-bits, AES XTS 128-bits, AES 192-bits, AES 256-bits, AES XTS 256-bits, ECC 192-bits, ECC 224-bits, ECC 256-bits, ECC 384-bits Default: RSA 2048-bits	Select the key size.
Name of generated initialization function	sf_crypto_key_init0	Select the name of the generated initialization function.
Name of Domain Parameter (Applicable only for ECC)	sf_crypto_key_domain_params0	Specify the name of the ECC domain partner.
Name of Generator Point (Applicable only for ECC)	sf_crypto_key_generator_point0	Specify the name of the ECC generator point.
Auto Initialization	Enable, Disable Default: Enable	Select if sf_crypto_key_will be initialized during startup.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Crypto Key Installation Framework on sf_crypto_key_installation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Select if code for parameter checking is to be included in the build.
Name	g_sf_crypto_key_installation0	Module name.

Key type	Encrypted RSA Key, Encrypted AES Key, Encrypted ECC Key Default: Encrypted RSA Key	Select the key type.
Key size	RSA 1024-bits, RSA 2048-bits, AES 128-bits, AES XTS 128-bits, AES 192-bits, AES 256-bits, AES XTS 256-bits, ECC 192-bits, ECC 256-bits Default: RSA 2048-bits	Select the key size.
Name of generated initialization function	sf_crypto_key_installation_init0	Select the name of the generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Select if sf_crypto_key_installation will be initialized during startup.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Crypto Signature Framework on sf_crypto_signature

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Select if code for parameter checking is to be included in the build.
Name	g_sf_crypto_signature0	Module name.
Key type	RSA Plain text, RSA CRT Plain text, RSA Wrapped Default: RSA Plain text	Select the key type. Byte Pool size in sf_crypto must be > = 1450 bytes.
Key size	RSA 1024-bits, RSA 2048-bits Default: RSA 2048-bits	Select the key size.
Name of generated initialization function	sf_crypto_signature_init0	Select the name of the generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Select if sf_crypto_signature will be initialized during startup.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

4.1.16.6 Using the Crypto Framework Module in an Application

The typical steps in using the SF CRYPTO Framework module in an application are:

To use the SF CRYPTO module.

- Ensure that the configuration parameters (given in the previous table) are set as per the needs of the application.
- Use the sf_crypto_api_t::open API to Initialize the SF_CRYPTO and the SCE HAL module (R_SCE) through the SCE common driver. This is done by Synergy Configurator when the Auto Initialize setting is at default.
- The little endian mode is set by default. It is locked and not configurable.
- The open function cannot be called again until the module is closed.
- Use the sf_crypto_api_t::close API to close the Crypto Framework services and the HW SCE.

Using the SF CRYPTO HASH Framework Module in an Application

The typical steps in using the SF CRYPTO HASH Framework module in an application are:

Calling the APIs in this order: sf_crypto_hash_api_t::open -> sf_crypto_hash_api_t::hashInit -> sf_crypto_hash_api_t::hashUpdate -> sf_crypto_hash_api_t::hashFinal -> sf_crypto_hash_api_t::close.

Details:

- Add SF_CRYPTO HASH Framework module in the Synergy Configurator. The HASH algorithm for this instance is set to SHA 256 by default.
- The little endian mode is set by default. It is locked and not configurable. (Please refer to note on endianness and data format in the Module Operational Notes.)
- The SF CRYPTO Module has to be first opened. (The Synergy Configurator will do this provided the Auto start option set by default is retained.)
- Set the chosen HASH algorithm (specified in Table 4) as the configuration parameter for the module open API.
- Use the sf_crypto_hash_api_t::open API to initialize the SF CRYPTO HASH Framework module and the SCE HASH HAL module (R_SCE_HASH) through the SCE HASH driver. (The Synergy Configurator will do this provided the Auto init option set by default is retained.)
- The open function cannot be called again until the module is closed.
- Use the sf_crypto_hash_api_t::hashInit API to initialize the HASH operation for the chosen HASH algorithm.
    - The sf_crypto_hash_api_t::hashInit can be called after the sf_crypto_hash_api_t::open API, sf_crypto_hash_api_t::hashUpdate API or sf_crypto_hash_api_t::hashFinal API to initialize a new operation with the configured HASH algorithm.
- Use the sf_crypto_hash_api_t::hashUpdate API to hash input data. It can be called multiple times until all the data is completely used up.
- Use the sf_crypto_hash_api_t::hashFinal API to get the message digest for all the data hashed with the sf_crypto_hash_api_t::hashUpdate API.
    - Once the sf_crypto_hash_api_t::hashFinal API is called, either the sf_crypto_hash_api_t::hashInit can be called to initialize operation for the next set of data using the same HASH algorithm or the sf_crypto_hash_api_t::close API can be called to close the module. It can then be re-opened for a different HASH algorithm.
- Use the sf_crypto_hash_api_t::close API to close the Crypto HASH Framework services.

Note

In a particular thread, a single instance of the SF CRYPTO HASH module can be re-used for different HASH algorithms without having to create multiple instances.

Using the SF CRYPTO TRNG Framework Module in an Application

The typical steps in using the SF CRYPTO TRNG Framework module in an application are:

- Use the sf_crypto_trng_api_t::open API to initialize the SF_CRYPTO_TRNG and the SCE TRNG HAL module (R_SCE_TRNG). This is done by the ISDE when the auto initialization setting is set to default.
- The little endian mode is set by default. It is locked and not configurable. (Please refer to the note on endianness and data format in the module Operational Notes.)
- The open function cannot be called again until the module is closed.
- Use sf_crypto_trng_api_t::randomNumberGenerate API to generate random numbers. The minimum length of random number bytes that can be requested is 1.
- Use sf_crypto_trng_api_t::close API to close the Crypto Framework services and the SCE when the TRNG services are no longer required.

Note

In the rare event that the sf_crypto_trng_api_t::randomNumberGenerate API returns an error, all the CRYPTO Framework modules have to closed and SF CRYPTO module re-opened.
There will be only one instance of the TRNG HAL module, so the configuration parameters set for each instance of the Crypto TRNG Framework will be overwrite any previously configured instances. The last value configured is applicable to all instances.

Using the SF CRYPTO Cipher Framework Module in an Application

The typical steps in using the SF CRYPTO Cipher Framework module in an application are:

Calling the APIs in this order: sf_crypto_cipher_api_t::open -> sf_crypto_cipher_api_t::cipherInit -> sf_crypto_cipher_api_t::cipherUpdate -> sf_crypto_cipher_api_t::cipherFinal -> sf_crypto_cipher_api_t::close.

Details:

- Please refer to the note on endianness and data format in the module Operational Notes.
- The Crypto Framework module has to be opened first; the ISDE will do this provided the auto initialization option set by default is retained. Refer to the section regarding using the Crypto Framework module in an Application.
- Set the configuration parameters for the module sf_crypto_cipher_api_t::open API per the needs of the application.
- Use the sf_crypto_cipher_api_t::open API to open the Crypto Cipher Framework module (This is done by the ISDE when the auto start option is set to the default setting) and the SCE HAL modules through the SCE drivers.
- The open function cannot be called again until the module is closed.
- Use the sf_crypto_cipher_api_t::cipherInit API to initialize the context by assigning appropriate operation mode, key and padding scheme option and algorithm specific parameters.
- If the data for encrypt / decrypt operation is not available all at once but is available in chunks, use the sf_crypto_cipher_api_t::cipherUpdate API. The sf_crypto_cipher_api_t::cipherUpdate API can be called multiple times.

Note

For RSA operations, no data is outputted from the sf_crypto_cipher_api_t::cipherUpdate API. The message will only be accumulated until the sf_crypto_cipher_api_t::cipherFinal API is called.

- In order to complete the encrypt or decrypt operation call the sf_crypto_cipher_api_t::cipherFinal API. This API accepts last chunk of incoming data. In case

all the data has been passed through the sf_crypto_cipher_api_t::cipherUpdate APIs the length for last message chunk can be set to 0.
- In case all the data to be encrypted/decrypted is available at once, sf_crypto_cipher_api_t::cipherFinal API can be called directly without using the sf_crypto_cipher_api_t::cipherUpdate API.
- Use sf_crypto_cipher_api_t::close API to close the Crypto Cipher Framework Module services.

AES GCM operation specifics:

- For AES GCM encrypt / decrypt operations, AAD (Additional Authenticated Data) is optional. If it is to be used, it has to be provided for the cipher operation through the sf_crypto_cipher_api_t::cipherAadUpdate API after the sf_crypto_cipher_api_t::cipherInit is called and prior to calling the sf_crypto_cipher_api_t::cipherUpdate or sf_crypto_cipher_api_t::cipherFinal APIs.
- For AES GCM encrypt operation, the tag (Authentication Tag) will be generated when cipherFinal API is executed. The caller has to supply the buffer to hold the tag through the cipherInit API.
- For AES GCM decrypt operation, the tag has to be provided prior to providing any ciphertext data through the cipherUpdate / cipherFinal APIs. Hence the caller is required to provide the tag through the cipherInit API.
- The AES GCM decrypt operation may output plain text data through the cipherUpdate / cipherFinal APIs but it should not be consumed if the decrypt operation returns an error code. This is to ensure that the tag is verified before the data is used.

Note

In a particular thread, a single instance of the Crypto Cipher Framework module can be re-used for alternately performing encrypt or decrypt operations by appropriately setting/re-setting the operation mode and other related parameters. Two instances of the Crypto Cipher Framework module can also be used simultaneously.

Using the SF CRYPTO KEY Framework Module in an Application

The typical steps in using the SF CRYPTO KEY Framework module in an application are:

Calling the APIs in this order: sf_crypto_key_api_t::open -> sf_crypto_key_api_t::keyGenerate -> sf_crypto_key_api_t::EcdhSharedSecretCompute -> sf_crypto_key_api_t::close.

Details:

- Please refer to note on endianness and data format in the module Operational Notes.
- The Crypto Key Framework has to be opened first; the ISDE will do this provided the auto initialization option is set to the default setting. Refer to the Using the Crypto Framework Module in an Application section.
- Set the configuration parameters as per the needs of the application required for the module sf_crypto_key_api_t::open API.
- Use the sf_crypto_key_api_t::open API to initialize the Crypto Key Framework module; this is done by the ISDE when the auto start option is set to the default setting) and the SCE HAL modules through the SCE drivers.
- The open function cannot be called again until the module is closed.
- Use the sf_crypto_key_api_t::keyGenerate API to generate the cryptographic keys of the type and size set by the configuration parameters at the open call.
- Use sf_crypto_key_api_t::EcdhSharedSecretCompute API to perform scalar multiplication for ECC algorithms only.
- Use sf_crypto_key_api_t::close API to close the Crypto Key Framework Module services.

Note

In a particular thread, a single instance of Crypto Key Framework module can be re-used for generating different key types without having to create multiple instances.

Using the SF Crypto Key Installation Framework Module in an Application

The typical steps in using the SF Crypto Key Installation Framework module in an application are:

Calling the APIs in this order: sf_crypto_key_installation_api_t::open -> sf_crypto_key_installation_api_t::keyInstall -> sf_crypto_key_installation_api_t::close.

Details:

- Please refer to note on endianness and data format in the module Operational Notes.
- The Crypto Framework Module has to be opened first; the ISDE will do this provided the auto initialization option is set to the default setting. Refer to the Using the Crypto Framework Module in an Application section.
- Set the configuration parameters for the module sf_crypto_key_installation_api_t::open API per the needs of the application.
- Use the sf_crypto_key_installation_api_t::open API to open the Crypto Key Installation Framework module (This is done by the ISDE when the auto start option is set to the default setting) and the SCE HAL modules through the SCE drivers.
- The open function cannot be called again until the module is closed.
- Use the sf_crypto_key_installation_api_t::keyInstall API to install the user's key.
- Use sf_crypto_key_installation_api_t::close API to close the Crypto Key Installation Framework Module services.

Using the SF CRYPTO Signature Framework Module in an Application

The typical steps in using the SF CRYPTO Signature Framework module in an application are:

Calling the APIs in this order: sf_crypto_signature_api_t::open -> sf_crypto_signature_api_t::contextInit -> sf_crypto_signature_api_t::signUpdate -> sf_crypto_signature_api_t::signFinal -> sf_crypto_signature_api_t::close.

Calling the APIs in this order: sf_crypto_signature_api_t::open -> sf_crypto_signature_api_t::contextInit -> sf_crypto_signature_api_t::verifyUpdate -> sf_crypto_signature_api_t::verifyFinal -> sf_crypto_signature_api_t::close.

Details:

- Please refer to note on endianness and data format in the module Operational Notes.
- The Crypto Framework module has to be opened first; the ISDE will do this provided the auto initialization option is set to the default setting. Refer to the Using the Crypto Framework Module in an Application section.
- Set the configuration parameters per the needs of the application required for the module sf_crypto_signature_api_t::open API.
- Use the sf_crypto_signature_api_t::open API to open the Crypto Signature Framework module (This is done by ISDE when the auto start option is set to the default setting) and the SCE HAL modules through the SCE drivers.
- The open function cannot be called again until the module is closed.
- Use the sf_crypto_signature_api_t::contextInit API to initialize the context by assigning appropriate operation mode, key (public key for verify operation mode and private key for sign operation mode), message formatting option.
- If the data is coming in as smaller chunks for sign operation mode, use the

sf_crypto_signature_api_t::signUpdate API to accumulate the data for future signing operation or for verify operation mode use the sf_crypto_signature_api_t::verifyFinal API to accumulate the data for future signature verification.
- In order to complete the sign or verify operation call the sf_crypto_signature_api_t::signFinal or sf_crypto_signature_api_t::verifyFinal APIs, respectively. These APIs support accepting the last chunk of incoming data. In case all the data has been passed through, one of the update API parameters for last message chunk can be set to NULL.
- In case all the data to be signed or verified is available at once, sf_crypto_signature_api_t::signFinal or sf_crypto_signature_api_t::verifyFinal can be called directly without using either of the update APIs.
- Use sf_crypto_signature_api_t::close API to close the Crypto Signature Framework module services.

Note

In a particular thread, a single instance of the Crypto Signature Framework module can be re-used for alternately performing sign or verify operations by appropriately setting/re-setting the operation mode and other related parameters. In order to perform sign or verify operations simultaneously, two instances of the SF Crypto Signature Framework module need to be used.

4.1.17 Capacitive Touch v2 Framework

4.1.17.1 Capacitive Touch v2 Module Introduction

The Capacitive Touch v2 Framework uses the CTSU v2 Driver API and provides application-level APIs for scanning touch buttons, sliders, and wheels. This module is configured via the QE for Capacitive Touch.

4.1.17.2 Capacitive Touch v2 Module Features

- Supports touch buttons (Self and Mutual), sliders, and wheels
- Can retrieve the status of up to 64 buttons at once
- Software and external triggering
- Callback on scan end
- Collects and calculates usable scan results:
    - Slider position from 0 to 100 (percent)
    - Wheel position from 0 to 359 (degrees)
- Optional (build time) support for real-time monitoring functionality through the QE tool over UART

4.1.17.3 Capacitive Touch v2 Module Configuration

Note

This module is configured via the QE for Capacitive Touch. For information on how to use the QE tool, once the tool is installed click Help -> Help Contents in e2 studio and search for "QE".
Multiple configurations can be defined within a single project allowing for different scan procedures or button layouts.

The following build time configurations are defined in ssp_cfg/framework/sf_touch_ctsuv2_cfg.h:

Build Time Configurations for sf_touch_ctsuv2

Configuration	Options	Default	Description
Parameter Checking	- Default (BSP) - Enabled - Disabled	Default (BSP)	If selected code for parameter checking is included in the build.
Support for QE monitoring using UART	- Enabled - Disabled	Disabled	Enable SCI_UART support for QE monitoring.

This module can be added to the Stacks tab by selecting **New Stack > Framework > Input > Cap Touch Framework on sf_touch_ctsuv2**.

Capacitive Touch v2 Module Interrupt Configuration

Refer to the CTSU v2 Driver section for details.

Capacitive Touch v2 Module Clock Configuration

Refer to the CTSU v2 Driver section for details.

Capacitive Touch v2 Module Pin Configuration

Refer to the CTSU v2 Driver section for details.

4.1.17.4 Capacitive Touch v2 Module Usage Notes

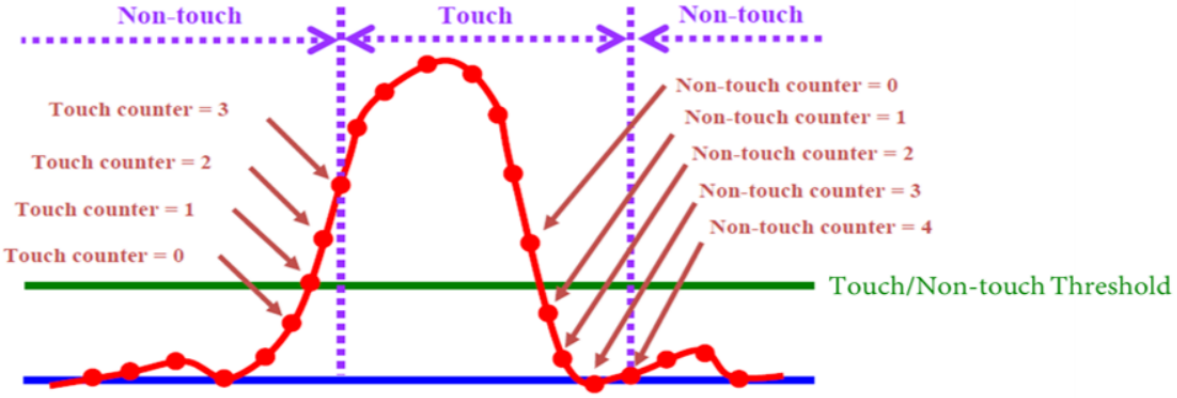
Capacitive Touch v2 Module Sliders and Wheels

Sliders and wheels are subject to some limitations:

	Slider	Wheel
Electrode type	Self capacitance only	Self capacitance only
Number of electrodes	3 to 10	4 or 8
Touch position output range	0-100	0-359
Default value (no touch)	0xFFFF	0xFFFF

Capacitive Touch v2 Module Touch Judgement

Touch data is judged as touched or not-touched based on the threshold and hysteresis values determined during the QE tool tuning process. Refer to the QE for Capacitive Touch tool documentation in e2 studio Help for details on how these values are set.



Measurement Count	Initialization	n	n+1	n+2	n+3	n+4	n+5	n+6	n+7	n+8	n+9	n+10	n+11
User-set touch/non-touch	Non-touch			Touch					Non-touch				
Touch counter buffer	0	0	0	1	2	3	3	3	0	0	0	0	0
Non-touch counter buffer	0	1	2	0	0	0	0	0	1	2	3	4	4
Touch/Non-touch judgement buffer	0	0	0	0	0	1	1	1	1	1	1	0	0
Actual touch/Non-touch judgement	Non-touch					Touch						Non-touch	

Figure 173: Touch/Non-touch judgement Image

4.1.17.5 Capacitive Touch v2 Module Examples

Capacitive Touch v2 Module Basic Example

This is a basic example of minimal use of the TOUCH in an application.

```
void touch_basic_example (void)
{
  ssp_err_t err = SSP_SUCCESS;

  err = SF_TOUCH_CTSU_Open(&g_touch_ctrl, &g_touch_cfg);

  /* Handle any errors. This function should be defined by the user. */
  handle_error(err);
  while (true)
  {
  SF_TOUCH_CTSU_ScanStart(&g_touch_ctrl);
  while (0 == g_flag)
  {
  /* Wait scan end callback */
  }
```

```
  g_flag = 0;
  err = SF_TOUCH_CTSU_DataGet(&g_touch_ctrl, &button, slider, wheel);
  if (SSP_SUCCESS == err)
  {
  /* Application specific data processing. */
  }
  }
}
```

Capacitive Touch v2 Module Multi-Mode Example

This is a optional example of using both Self-capacitance and Mutual-capacitance. Refer to the Multi Mode Example in CTSUV2 usage notes.

```
void touch_optional_example (void)
{
  ssp_err_t err = SSP_SUCCESS;
  err = SF_TOUCH_CTSU_Open(&g_touch_ctrl, &g_touch_cfg);
  handle_error(err);
  err = SF_TOUCH_CTSU_Open(&g_touch_ctrl_mutual, &g_touch_cfg_mutual);
  handle_error(err);
  while (true)
  {
  SF_TOUCH_CTSU_ScanStart(&g_touch_ctrl);
  while (0 == g_flag)
  {
  /* Wait scan end callback */
  }
  g_flag = 0;
  SF_TOUCH_CTSU_ScanStart(&g_touch_ctrl_mutual);
  while (0 == g_flag)
  {
  /* Wait scan end callback */
  }
```

```
  g_flag = 0;
  err = SF_TOUCH_CTSU_DataGet(&g_touch_ctrl, &button, slider, wheel);
  if (SSP_SUCCESS == err)
  {
  /* Application specific data processing. */
  }
  err = SF_TOUCH_CTSU_DataGet(&g_touch_ctrl_mutual, &button, slider, wheel);
  if (SSP_SUCCESS == err)
  {
  /* Application specific data processing. */
  }
  }
}
```

4.1.18 External IRQ Framework

4.1.18.1 External IRQ Framework Module Introduction

The External IRQ Framework provides a high-level API for applications using the external pin interrupts with the ThreadX RTOS and supports the external IRQ pins on the Synergy microcontroller. A callback function (sf_external_irq_callback) is available that will be called from the interrupt service routine (ISR) each time the IRQn triggers.

External IRQ Framework Module Features

- Responds to external interrupt inputs
- RTOS aware implementation using an internal semaphore for thread synchronization
    - Can signal internal threads
    - Can trigger transfers via the Event Link Controller (ELC)
- Uses the port pins available on Synergy MCUs
    - Pins may differ between MCUs so refer to MCU User's Manuals for specifics
- Supports several hardware features such as
    - Channel selection
    - Trigger conditions
    - Digital filtering
    - Auto-start

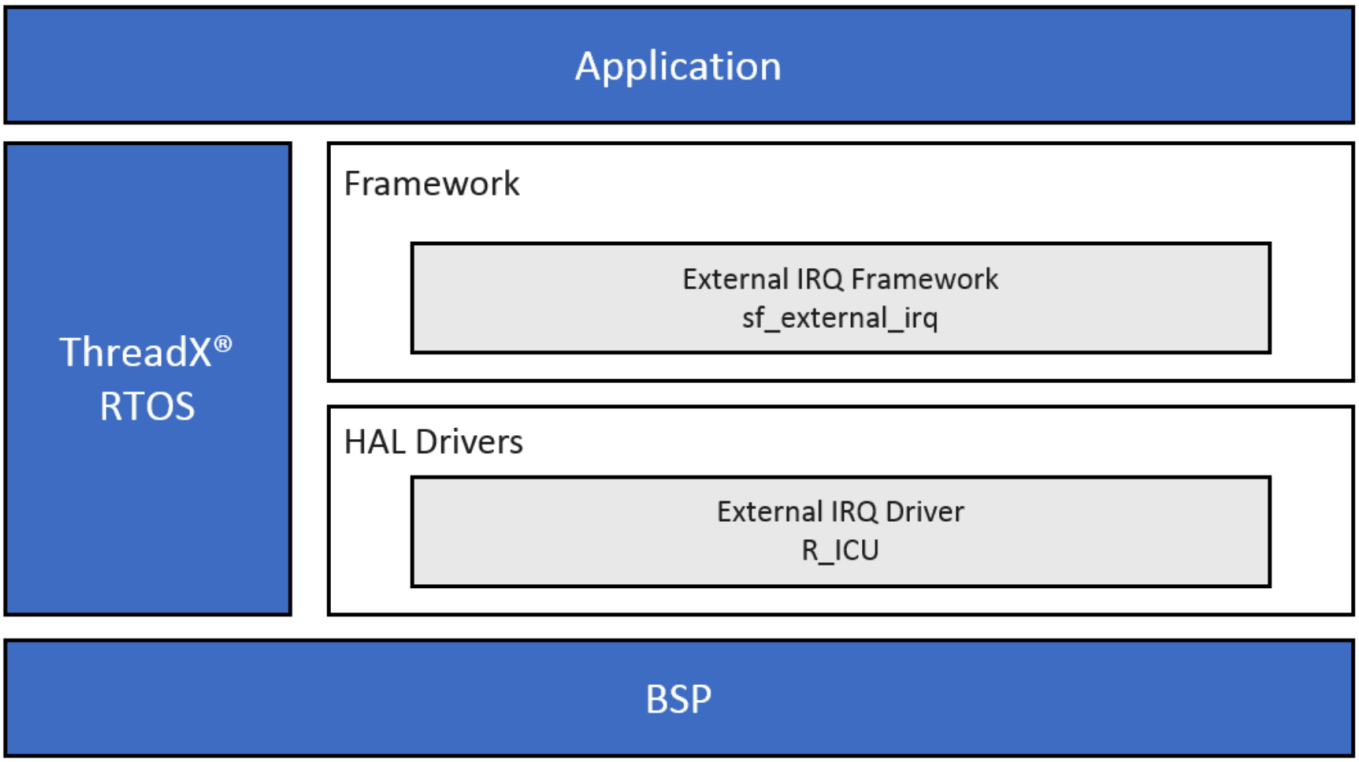


Figure 174: External IRQ Framework Module Block Diagram

4.1.18.2 External IRQ Framework Module APIs Overview

The External IRQ framework module defines APIs for opening, waiting or closing the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

External IRQ Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_external_irq.p_api->open(g_sf_external_irq.p_ctrl, g_sf_external_irq.p_cfg); Acquire mutex, then handle driver initialization at the HAL layer.
wait	g_sf_external_irq.p_api->wait(g_sf_external_irq.p_ctrl, TX_WAIT_FOREVER); Wait for the next external interrupt expiration, then return.
versionGet	g_sf_external_irq.p_api->versionGet(&version); Retrieve the API version and store it in the version pointer.
close	g_sf_external_irq.p_api->close(g_sf_external_irq.p_ctrl); Release channel mutex and close channel at HAL layer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_IN_USE	Device in use.
SSP_ERR_NOT_OPEN	Device unopened.
SSP_ERR_TIMEOUT	Timeout error.
SSP_ERR_WAIT_ABORTED	Suspension aborted.
SSP_ERR_UNSUPPORTED	Function unsupported by the HAL driver.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.18.3 External IRQ Framework Module Operational Overview

The External IRQ framework is a set of ThreadX-aware framework APIs. The External IRQ Framework external inputs can signal, via an internal semaphore, threads or trigger transfers via the Event Link Controller (ELC). Both the External IRQ framework module and the External IRQ HAL module need to be configured for proper operation. The HAL configuration settings allow control over hardware options such as triggering level and digital filtering settings.

External IRQ Framework Module Important Operational Notes and Limitations

External IRQ Framework Module Operational Notes

- Refer to the Datasheet for the Synergy device to be programmed to find the port pins which support the external interrupt functions and to obtain the External IRQ number for a given port pin.
- The External IRQ number corresponds to the channel setting in the ISDE Properties window for the External IRQ driver.

External IRQ Framework Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.18.4 Including the External IRQ Framework Module in an Application

This section describes how to include the External IRQ Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and

configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the External IRQ Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the External IRQ Framework is g_sf_external_irq0. This name can be changed in the associated Properties window.)

External IRQ Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_external_irq0 External IRQ Framework on sf_external_irq	Threads	**New Stack> Framework> Input> External IRQ Framework on sf_external_irq**

When the External IRQ Framework on sf_external_irq is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

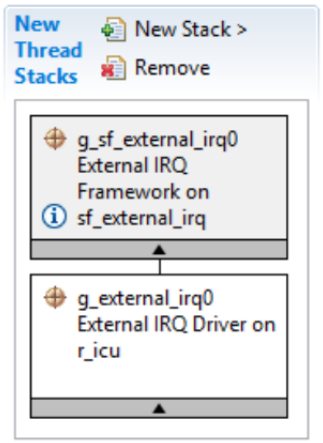

Figure 175: External IRQ Framework Module Stack

4.1.18.5 Configuring the External IRQ Framework Module

The External IRQ Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the External IRQ Framework Module on sf_external_irq

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Name	g_sf_external_irq0	Framework name.
Event	None, Semaphore Put Default: Semaphore Put	Event selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the External IRQ Framework Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the External IRQ HAL Module on r_icu

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter checking setting enables or disables the addition of parameter checking code.
Name	g_external_irq0	Module name.
Channel	0	Specifies the hardware IRQ channel used.
Trigger	Falling, Rising, Both Edges, Low Level Default: Rising	Configures edge or level triggering.
Digital Filtering	Enabled, Disabled Default: Disabled	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCLK/1, PLCK/8, PLCK/32, PCLK/64 Default: PCKL/64	Sets noise filter sampling period.

Interrupt enabled after initialization	True, False Default: True	Determines if the interrupt is enabled immediately after initialization.
Callback	NULL	A user callback function can be registered in external_irq_api_t::open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	An Interrupt priority can be registered in external_irq_cfg_t::irq_ipl.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

External IRQ Framework Module Clock Configuration

The External IRQ Framework does not require clock configuration.

External IRQ Framework Module Pin Configuration

The External IRQ Framework does not require pin configuration.

4.1.18.6 Using the External IRQ Framework Module in an Application

The steps in using the External IRQ Framework module in a typical application are:

1. Open the External IRQ Framework module with the sf_external_irq_api_t::open API.
2. Wait for an interrupt using the sf_external_irq_api_t::wait API.
3. Process External IRQ event.
4. Close the module using the sf_external_irq_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

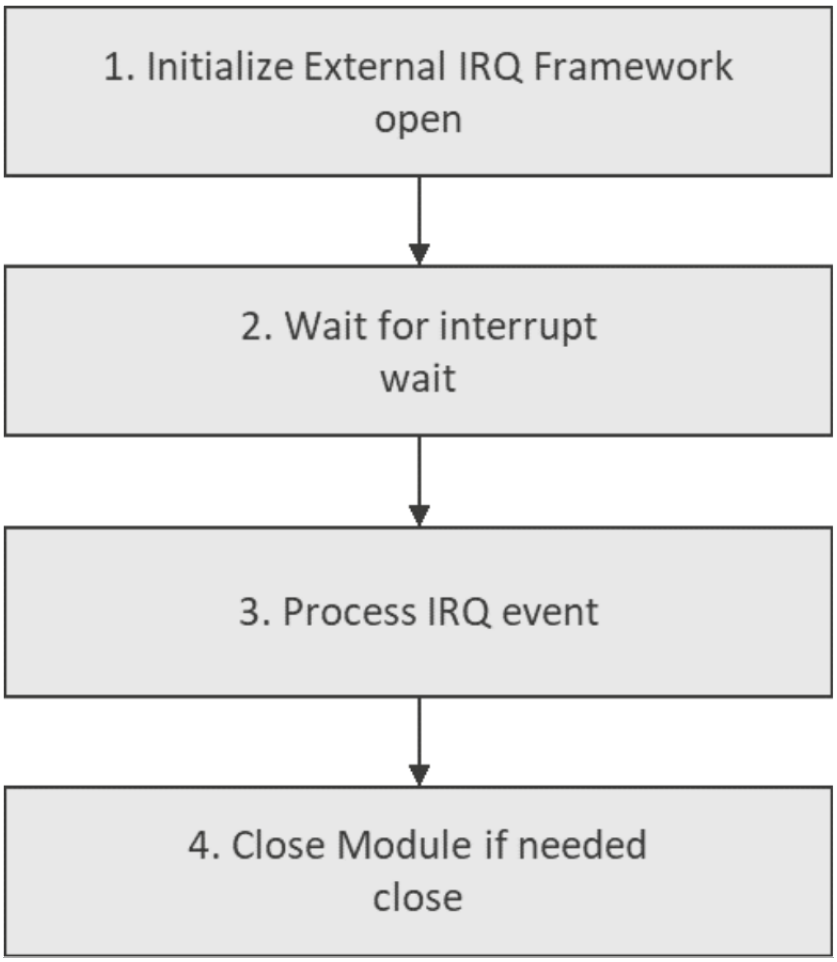

Figure 176: Flow Diagram of a Typical External IRQ Framework Module Application

4.1.19 I2C Framework

4.1.19.1 I2C Framework Introduction

The I2C Framework module provides a ThreadX-aware high-level API for I2C industry standard serial device communications and configures the I2C peripheral in order to enable serial communication to be used by the framework. The I2C Framework module uses the I2C and SCI peripherals on the Synergy MCU.

I2C Framework Module Features

- ThreadX-aware framework
- Handles integration and synchronization of multiple I2C peripherals on the I2C bus
- Provides a single interface to access both SCI I2C and RIIC drivers
- The I2C framework module configures I2C communication in master mode
- The I2C framework module supports three data rates: 100 kHz, 400 kHz, and 1 MHz
- The I2C framework module supports both 7-bit addressing and 10-bit addressing
- The I2C framework module also provides support for callbacks internally. User defined

callback is not used. The callback functions are called with the following events i2c_event_t
    - Transfer aborted
    - Transmit complete
    - Receive complete
- The callback structure i2c_callback_args_t also provides the number of bytes that were sent or received
- Implemented by:
    - Simple I2C on SCI
    - RIIC

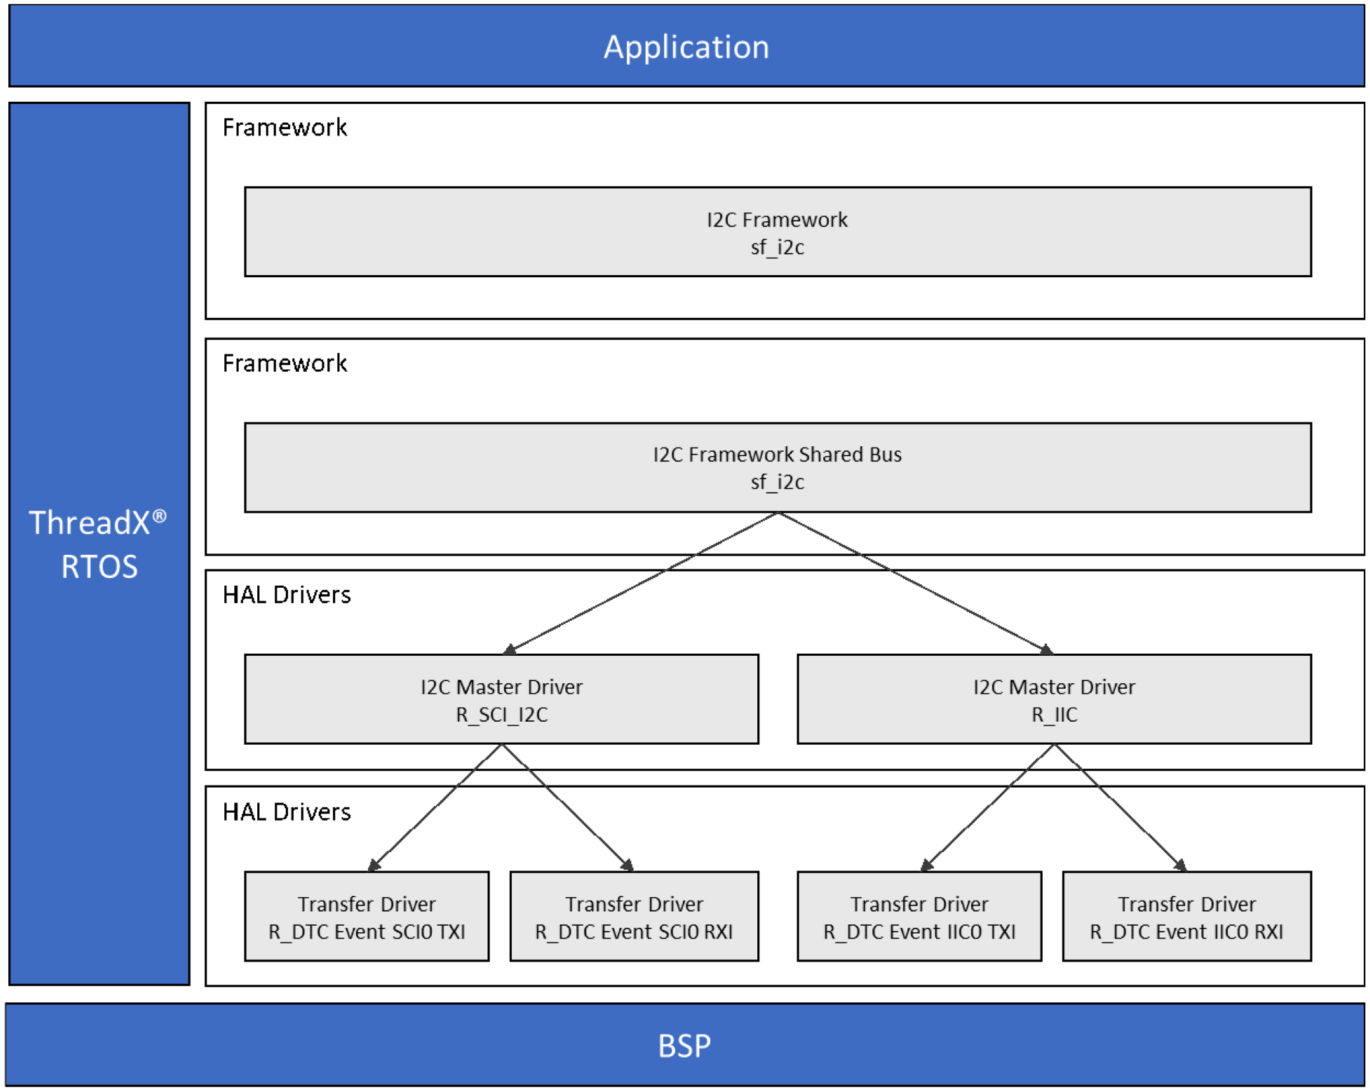

Figure 177: I2C Framework Module Block Diagram

4.1.19.2 I2C Framework Module APIs Overview

The I2C Framework interface defines APIs for opening, closing, reading, writing, locking, unlocking and resetting the bus using the I2C Framework. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

I2C Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_i2c_device.p_api->open(g_sf_i2c_device.p_ctrl, g_sf_i2c_device.p_cfg); Opens a designated I2C device on the bus.
close	g_sf_i2c_device.p_api->close (g_sf_i2c_device.p_ctrl); Disables I2C device designated by control handle. Closes the RTOS services used by the bus if no devices are connected to the bus.
read	g_sf_i2c_device.p_api->read (g_sf_i2c_device.p_ctrl, &destination, no_of_bytes_to_read, restart,timeout); Receives data from I2C device.
write	g_sf_i2c_device.p_api->write (g_sf_i2c_device.p_ctrl, &source, no_of_bytes_to_write , restart, timeout); Transmits data to I2C device
lock	g_sf_i2c_device.p_api->lock (g_sf_i2c_device.p_ctrl); Locks the bus for a device. Locking reserves the bus until unlocking and allows several reads and writes without interrupt.
unlock	g_sf_i2c_device.p_api->unlock (g_sf_i2c_device.p_ctrl); Unlocks the bus from a particular device and makes it available for other devices.
reset	g_sf_i2c_device.p_api->reset (g_sf_i2c_device.p_ctrl, timeout); Aborts any in-progress transfer and forces the I2C peripheral into ready state.
version	g_sf_i2c_device.p_api->version(version); Retrieves the version information using the version pointer.
lockWait	g_sf_i2c_device.p_api->lockWait (g_sf_i2c_device.p_ctrl, timeout); Locks the bus for a device. Locking reserves the bus until unlocking and allows several reads and writes without intervention from other devices on the same I2C bus. Timeout value is user configurable.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	I2C function performed successfully.
SSP_ERR_INVALID_MODE	Illegal I2C mode is specified.
SSP_ERR_IP_CHANNEL_NOT_PRESENT	Omitted I2C channel is specified.
SSP_ERR_IN_USE	I2C channel has already been opened.
SSP_ERR_INVALID_ARGUMENT	Argument is not one of the predefined values.
SSP_ERR_INTERNAL	Internal error has occurred.
SSP_ERR_ASSERTION	A critical assertion has failed or Null pointer(s) is (are) given.
SSP_ERR_NOT_OPEN	Device instance not opened.
SSP_ERR_TRANSFER_ABORTED	The data transfer was aborted.
SSP_ERR_INVALID_RATE	The requested rate cannot be set.
SSP_ERR_TIMEOUT	Timeout error occurs.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.19.3 I2C Framework Module Operational Overview

The I2C Framework module complies with the layered driver architecture of the SSP. It uses the lower-level I2C HAL modules to communicate with I2C peripherals and controls the I2C-capable peripherals on a Synergy microcontroller (as configured by a user). With the I2C Framework module, one or more I2C buses can be created and multiple I2C peripherals can be connected to each I2C bus. The I2C Framework module APIs use a ThreadX-Mutex to acquire and release the shared bus for I2C Slave devices. Acquire and release are implemented by sf_i2c_api_t::lock or sf_i2c_api_t::lockWait and sf_i2c_api_t::unlock APIs respectively in the I2C Framework module.

As I2C framework module configures I2C communication in master mode, this allows the user to:

- Initialize the driver
- Read from a slave device
- Write to a slave device
- Reset the MCU I2C peripheral
- Lock the I2C bus
- Unlock the I2C bus

The I2C Framework module works with the Synergy MCU I2C hardware modules; the RIIC and SCI HAL modules. Both I2C modules support the I2C fast-mode with bit rates of up to 400 kHz. The IIC peripheral and the RIIC HAL module support fast-mode plus with 1-MHz bit-rates. The module supports only master mode for both implementations.

Multiple Slave Devices on the Same Bus

The I2C Framework module uses a bus and device on bus architecture. If multiple slaves are connected to the I2C bus, each slave communicates with an associated and separate SF_I2C module instance. Each SF_I2C instance is created in a separate thread. Every slave device is linked to the

bus to which it will be connected and shares the bus with all other slave devices. The user must configure the framework shared-bus and the lower-level I2C HAL layer for each framework device connecting to the bus. The user can add the existing framework shared-bus when configuring multiple devices on the same bus. A common start and stop procedure is used for all I2C data-transfer operations. Only one device is configured to the lower level and the remaining devices perform read or write operations by switching the device address within the framework.

All I2C Framework devices on the same bus must use the same lower-level configuration settings, (for example, the I2C HAL module) except for the slave address and addressing mode. The framework will use the configuration of the first device that it opens in the application to configure the bus; this means that all I2C Framework devices on the same bus must have the same lower-level configuration settings (except for the slave address and addressing mode). If different configurations are used, proper operation cannot be guaranteed.

Bus Locking

The I2C Framework supports bus-locking functionality, meaning the bus can be locked for a given slave peripheral. The locking allows devices to reserve a bus to themselves for the period between the lock and unlock commands. This allows devices to complete several reads and writes on the bus without interruption (which can be required in some situations.)

The I2C bus is locked when sf_i2c_api_t::lock or sf_i2c_api_t::lockWait API is called. This API locks the I2C bus by acquiring the mutex for the thread in which the I2C Framework device is used. Once locked, the I2C bus can only be utilized by the associated device. The other I2C Framework devices or the same I2C Framework device from other threads, cannot acquire the mutex so they will not be able to access the bus. Once the bus is unlocked by calling the sf_i2c_api_t::unlock API from the sf_i2c device that locked it, the mutex will be released and the bus becomes available for other sf_i2c devices. The sf_i2c_api_t::lockWait API is similar to the sf_i2c_api_t::lock API except it provides user an option to set timeout value. The sf_i2c_api_t::lockWait API waits for the specified timeout period if the I2C bus is already locked by another device. In case of the sf_i2c_api_t::lock API, the thread waits forever, if the I2C bus is not released by the other device.

I2C Framework Module Important Operational Notes and Limitations

I2C Framework Module Operational Notes

- The closest possible baud rate that can be achieved (less than or equal to the requested rate) at the current PCLKB settings is calculated and used. If a valid clock rate could not be calculated, an error is returned.
- The I2C can trigger the start of other peripherals available from the ELC. See the ELC Module Guide for further information.
- The I2C Framework can support multiple I2C devices on the same bus if the clock rate remains the same for all the devices. That means multiple devices can be opened in the same bus if they are of the same clock rate. If devices have different clock rates, only one device can be opened at a time.
- SDA and SCL output pin type should be n-channel open drain when using I2C on SCI.
- In the I2C Framework configuration, the channel number given to this bus overrides the channel number given in the HAL module.
- Shared bus can be used by multiple slave devices with the respective configuration. The framework also handles mutual exclusion in lock and unlock APIs when multiple devices are using the same I2C channel.
- To configure multiple I2C devices on the same bus, add and configure the following modules for each device connecting to the bus:
    - I2C Framework device module
    - Configure the I2C shared bus module for the first device being configured, then

use the same bus for the remaining devices.
    - I2C HAL module
    - DTC module (Optional)
- Lock functionality will be effective for devices from different threads. If multiple devices connected to the bus are from the same thread, the I2C bus will be locked for all devices from that thread. In such cases, even if the bus is locked, all devices from the same thread can access the bus.
- In case a device is being used from multiple threads, and the device locks the I2C bus from one thread, the same device cannot access the I2C bus from other threads.

Note

Each I2C Framework device must be configured with a unique name in the ISDE configurator.
Provide the same configuration settings for all the devices connected on the same bus (except the slave address and addressing modes.)

I2C Framework Module Limitations

The I2C framework module does not currently support the following feature:

- The use of DMA

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.19.4 Including the I2C Framework Module in an Application

This section describes how to include the I2C Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the I2C Framework module to an application, simply add it to a HAL/Common thread using the stacks selection sequence given in the following table. (The default name for the I2C Framework module is g_sf_ i2c_device0. This name can be changed in the associated Properties window.)

I2C Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_i2c_device0 I2C Framework on sf_i2c	Threads	**New Stack> Framework> Connectivity> I2C Framework on sf_i2c**

When the I2C Framework module on sf_i2c is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

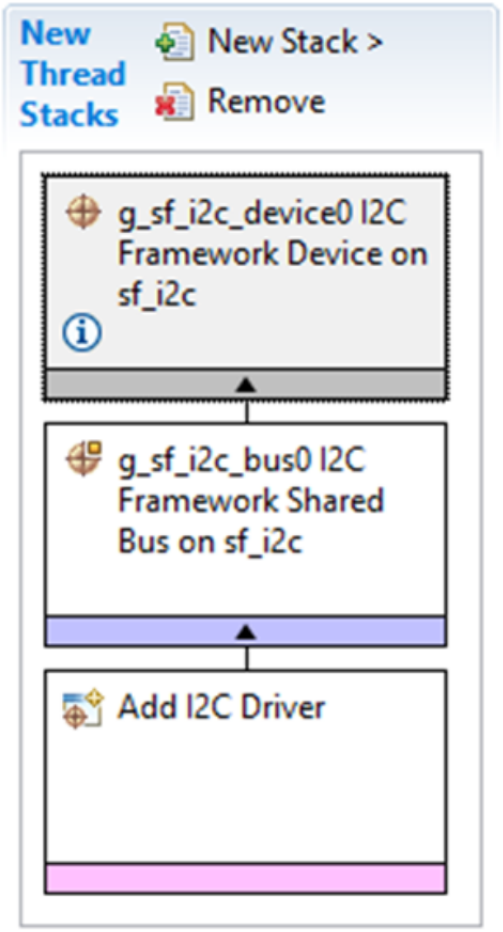

Figure 178: I2C Framework Module Stack

4.1.19.5 Configuring the I2C Framework Module

The I2C Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the I2C Framework Device Module on sf_ i2c

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: Enabled	Selects if code for parameter checking is to be included in the build.
Name	g_sf_i2c_device0	Give a name to identify the I2C Framework device. API, Config and Control instances will be created based on this name.
Slave Address	0x00	Specify the address of the I2C slave device.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Select the I2C address mode.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to select different byte ordering or pixel-color format. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower level modules are fairly intuitive and can usually be determined by inspection of the associated Properties window from the SSP configurator.

Configuring the I2C Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the lower-level modules:

Configuration Settings for the I2C Framework Shared Bus on sf_i2c

ISDE Property	Value	Description
Name	g_sf_i2c_bus0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2C Master Driver on r_riic

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Name	g_i2c0	Module name.

Channel	0	Specify the IIC channel to be used with this configuration.
Rate	Standard, Fast-mode, Fast-mode Plus Default: Standard	Standard, Fast, and Fast-plus. (See IIC Rate Calculation.)
Slave Address	0x00	Set the address of the slave device the I2C master will be communicating with.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
SDA Output Delay (nanoseconds)	Default: 300	SDA output delay in nanoseconds.
Timeout Mode	Short Mode, Long Mode Default: Short Mode	Select the timeout mode.
Callback	NULL	A user callback function can be registered in i2c_api_master_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. The exact hardware generated error event is also provided when i2c_event_t is I2C_EVENT_ABORTED. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Select the receive interrupt priority.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Select the transmit interrupt priority.

Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Select the transmit end interrupt priority.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Select the error interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event IIC0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Software Start	Enabled, Disabled Default: Disabled	Include code for software start in the build.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place the DTC vector table.
Name	g_transfer0	Module name.
Mode	Normal	Specify the hardware channel.
Transfer Size	1 Byte	Select the transfer mode.
Destination Address Mode	Fixed	Select the transfer size.
Source Address Mode	Incremented	Select the address mode for the destination.
Repeat Area (Unused in Normal Mode)	Source	Select the address mode for the source.
Interrupt Frequency	After all transfers have completed	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.

Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source (Must enable IRQ)	Event IIC0 TXI	Select the DTC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback (Only valid with Software start)	NULL	A user callback that is called at the end of the transfer.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event IIC0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Software Start	Enabled, Disabled Default: Disabled	Include code for software start in the build.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place the DTC vector table.
Name	g_transfer1	Module name.
Mode	Normal	Specify the hardware channel.
Transfer Size	1 Byte	Select the transfer mode.
Destination Address Mode	Incremented	Select the transfer size.
Source Address Mode	Fixed	Select the address mode for the destination.
Repeat Area (Unused in Normal Mode	Destination	Select the address mode for the source.

Interrupt Frequency	After all transfers have completed	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source (Must enable IRQ)	Event IIC0 RXI	Select the DTC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback (Only valid with Software start)	NULL	A user callback that is called at the end of the transfer.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2C Master Driver on r_sci_i2c

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Name	g_i2c0	Module name.
Channel	0 to 9	Specify the SCI channel to be used with this configuration. SCI has channels as follows: Series S7: 0 1 2 3 4 5 6 7 8 9; Series S3 : 0 1 2 3 4 - - - - 9; Series S1 : 0 1 - - - - - - - 9.

Rate	Standard, Fast-mode, Fast-mode plus Default: Standard	Select the I2C data rate.
Slave Address	0x00	Specify the slave address.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
SDA Output Delay (nano seconds)	300	SDA output delay in nanoseconds.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Enables bitrate modulation function.
Callback	NULL	A user callback function can be registered in i2c_api_master_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the receive interrupt priority.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the transmit interrupt priority.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the transmit end interrupt priority.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the error interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Software Start	Enabled, Disabled Default: Disabled	Include code for software start in the build.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place the DTC vector table.
Name	g_transfer0	Module name.
Mode	Block	Specify the hardware channel.
Transfer Size	1 Byte	Select the transfer mode.
Destination Address Mode	Fixed	Select the transfer size.
Source Address Mode	Incremented	Select the address mode for the destination.
Repeat Area (Unused in Normal Mode	Source	Select the address mode for the source.
Interrupt Frequency	After all transfers have completed	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source (Must enable IRQ)	Event SCI0 TXI	Select the DTC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback (Only valid with Software start)	NULL	A user callback that is called at the end of the transfer.

ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Software Start	Enabled, Disabled Default: Disabled	Include code for software start in the build.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place the DTC vector table.
Name	g_transfer1	Module name.
Mode	Normal	Specify the hardware channel.
Transfer Size	1 Byte	Select the transfer mode.
Destination Address Mode	Incremented	Select the transfer size.
Source Address Mode	Fixed	Select the address mode for the destination.
Repeat Area (Unused in Normal Mode	Destination	Select the address mode for the source.
Interrupt Frequency	After all transfers have completed	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.

Activation Source (Must enable IRQ)	Event SCI0 RXI	Select the DTC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback (Only valid with Software start)	NULL	A user callback that is called at the end of the transfer.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

I2C Framework Module Clock Configuration

The SCI peripheral module uses the PCLKB as its clock source. The PCLKB frequency is set by using the SSP configurator clock tab prior to a build or by using the CGC Interface at run-time. During configuration, the I2C transfer rate is calculated and set internally by the driver based on the user-selected PCLB rate and the user-selected transfer rate. If the PCLKB is configured in such a manner that the user-selected rate cannot be achieved, an error will be returned when initializing the driver.

I2C Framework Module Pin Configuration

The SCI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins.

Note

For some peripherals, the operation-mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for the I2C Framework Module

Resource	ISDE Tab	Pin selection Sequence
SCI	Pins	Select **Peripherals**> **SCI1_3_5_7_9**> **SCI1**

Note

The selection sequence assumes the SCI1 is the desired hardware target of the driver.

Pin Configuration Settings for the I2C Framework Module

Pin Configuration Property	Value	Description

Operation Mode	Disabled, Asynchronous UART, Synchronous UART, Simple I2C, Simple SPI, SmartCard Default: Disabled	Select Simple I2C as the Operation Mode for I2C on SCI.
RXD1_SCL1_MISO1	None, P212, P708 Default: None	SCL pin.
TXD1_SDA1_MOSI1	None, P213, P709 Default: None	SDA pin.

Note

The example values are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

I2C Framework Module Additional Settings

In addition to the SCL and SDA pins, an I2C RESET signal may be required to reset the I2C slave device. If this is the case, the RESET signal can be added using a GPIO pin and must be controlled directly by the application program. The external device reset function is not supported within the r_sci_i2c module.

4.1.19.6 Using the I2C Framework Module in an Application

A common application for the I2C framework module requires multiple slave devices on a single bus. The implementation for this common application is described below. (For an application where multiple busses are required, just duplicate the single bus example as needed for each separate bus.)

Implementation Steps for Two Slave Devices on the Same Shared Bus

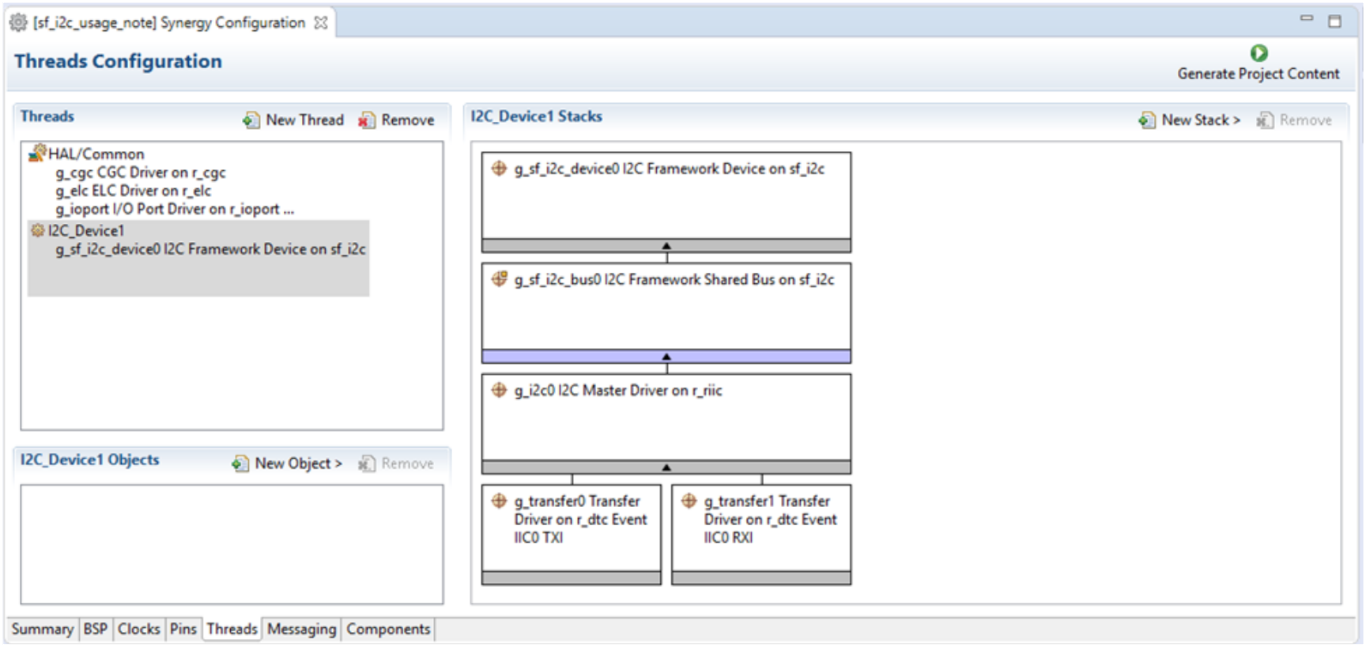
When using the I2C framework module to create a single bus with multiple slave devices, create two thread stacks each with an I2C framework instance. These instances will each use the same shared bus instance. Follow the steps below to see how this is done within the SSP Configurator.

Note

The following example puts both sf_i2c module instances in the same thread. If the bus locking function is needed, the sf_i2C modules should be put in different threads. Locking applies to all the devices within the locked thread. The following steps assume some familiarity with the use of the SSP development environment. If any of the following steps are confusing, read over the first few chapters of the SSP User's Manual to become familiar with the SSP development environment.

1. Add the first I2C framework device to a new or existing thread. This creates the I2C master stack. A shared bus on sf_i2c is added along with the I2C driver. The I2C driver can be selected for implementation on r_riic or r_sci_i2c. The DTC transfer driver is also added by default. This can be removed if the CPU transfer mode is needed instead.

The resulting module stack is shown in the following figure. Example configuration settings are given in the tables that follow the figure:



Example configuration setting for the first thread stack are given below:

Configuration Settings for the I2C Framework Device on sf_i2c (Slave #1)

Property	Value	Description
Parameter Checking	Default(BSP)	Enable Or Disable Parameter Checking.
Name	g_sf_i2c_device0	Give a name to identify the I2C Framework device. API, Config and Control instances will be created based on this name.
Slave Address	0x21	Specify the address of I2C slave 1.
Address Mode	7-bit	Select the I2C address mode.

Configuration Settings for the I2C Framework Shared Bus on sf_i2c

Property	Value	Description
Name	g_sf_i2c_bus0	Give a name to identify the I2C Framework shared bus. This shared bus will be shared by multiple I2C Framework Devices.

Configuration Settings for the I2C Master Driver on r_riic

Property	Value	Description

Parameter Checking	Default(BSP)	Enable Or Disable Parameter Checking.
Name	g_i2c0	Give a name to identify the I2C Driver device. This will be used internally by Framework.
Channel	0	Specify the I2C channel.
Rate	Standard	Select the speed of the I2C bus.
Slave Address	0	This field will be locked as slave address already configured in the I2C Framework Device on sf_i2c.
Address Mode	7-bit	This field will be locked as address mode already configured in the I2C Framework Device on sf_i2c.
Timeout Mode	Short Mode	Select Timeout mode: Short mode or Long mode.
Callback	NULL	This field will be locked as Framework does not provide callback handling to the user.
Receive Interrupt Priority	Priority 2	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 2	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 2	Error interrupt priority selection.

Configuration Settings for the I2C Master Driver on r_sci_i2c

Property	Value	Description
Parameter Checking	Default(BSP)	Enable Or Disable Parameter Checking.
Name	g_i2c0	Give a name to identify the I2C Driver device. This will be used by Framework internally.
Channel	0	Specify the address of I2C slave.
Rate	Standard	Select the speed of the I2C bus.
Slave Address	0	This field will be locked as slave address already configured in the I2C Framework Device on sf_i2c.

Address Mode	7-bit	This field will be locked as address mode already configured in the I2C Framework Device on sf_i2c.
Slave Output Delay	300	SDA output delay in nanoseconds.
Bit Rate Modulation Enable	Enable	Enables bitrate modulation function.
Callback	NULL	This field will be locked as Framework does not provide callback handling to the user.
Receive Interrupt Priority	Priority 2	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 2	Transmit end interrupt priority selection.

Configuration Settings for the Transfer Driver on r_dtc Event IIC0 TXI

Property	Value	Description
Parameter Checking	Default(BSP)	Enable Or Disable Parameter Checking.
Software Start	Disabled	
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection. This field is locked.
Transfer Size	1 Byte	Transfer size selection. This field is locked.
Destination Address Mode	Fixed	Destination address mode selection. This field is locked.
Source Address Mode	Incremented	Source address mode selection. This field is locked.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection. This field is locked.
Interrupt Frequency	After all transfers have completed	This field is locked.
Destination Pointer	NULL	Destination pointer selection. This field is locked.
Source Pointer	NULL	Source pointer selection. This field is locked.

Number of Transfers	0	Number of transfer selection. This field is locked.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection. This field is locked.
Activation Source (Must enable IRQ)	Event IIC0 TXI	Activation source selection. This field is locked.
Auto Enable	False	Auto enable selection. This field is locked.
Callback (Only valid with Software start)	NULL	Callback selection. This field is locked.
ELC Software Event Interrupt Priority	Disabled	ELC software event interrupt priority selection.

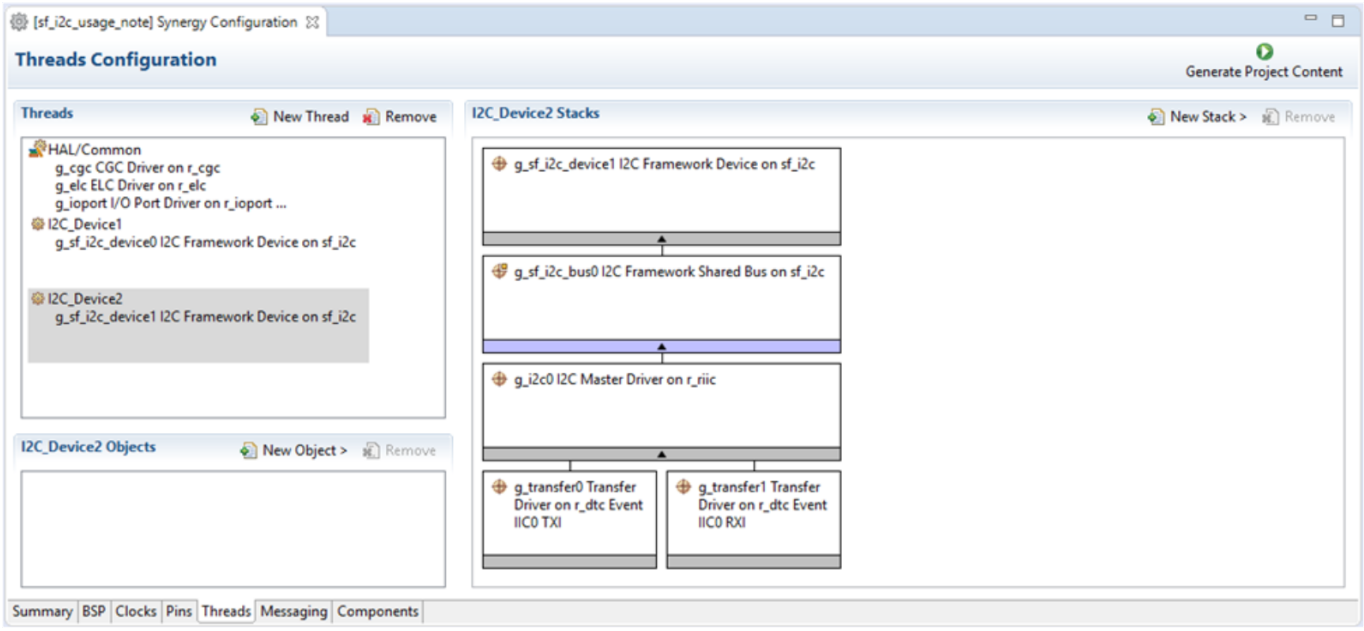
Configuration Settings for the Transfer Driver on r_dtc Event IIC0 RXI

Property	Value	Description
Parameter Checking	Default(BSP)	Enable Or Disable Parameter Checking.
Software Start	Disabled	Software Start Selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection. This field is locked.
Transfer Size	1 Byte	Transfer size selection. This field is locked.
Destination Address Mode	Incremented	Destination address mode selection. This field is locked.
Source Address Mode	Fixed	Source address mode selection. This field is locked.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection. This field is locked.
Interrupt Frequency	After all transfers have completed	This field is locked.
Destination Pointer	NULL	Destination pointer selection. This field is locked.
Source Pointer	NULL	Source pointer selection. This field is locked.
Number of Transfers	0	Number of transfer selection. This field is locked.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection. This field is locked.

Activation Source (Must enable IRQ)	Event IIC0 RXI	Activation source selection. This field is locked.
Auto Enable	False	Auto enable selection. This field is locked.
Callback (Only valid with Software start)	NULL	Callback selection. This field is locked.
ELC Software Event Interrupt Priority	Disabled	ELC software event interrupt priority selection.

2. Add the second I2C Framework Device to the same thread. The I2C Framework Shared Bus on sf_i2c will not get added automatically. Select the option to use the existing shared bus. Then Configurator will automatically add the I2C Framework Shared Bus on sf_i2c and remaining modules. The lower level modules will be added and configured automatically to be consistent with the previously defined settings from the first I2C framework instance. In fact, if any lower level settings are changed in on stack, they are automatically updated in the other.

The resulting module stack is shown in the following figure:



Example configuration settings for the second thread stack (Slave Device #2) are as follows:

Configuration Settings for the I2C Framework Device on sf_i2c (Slave #2)

Property	Value	Description
Parameter Checking	Default(BSP)	Enable Or Disable Parameter Checking.

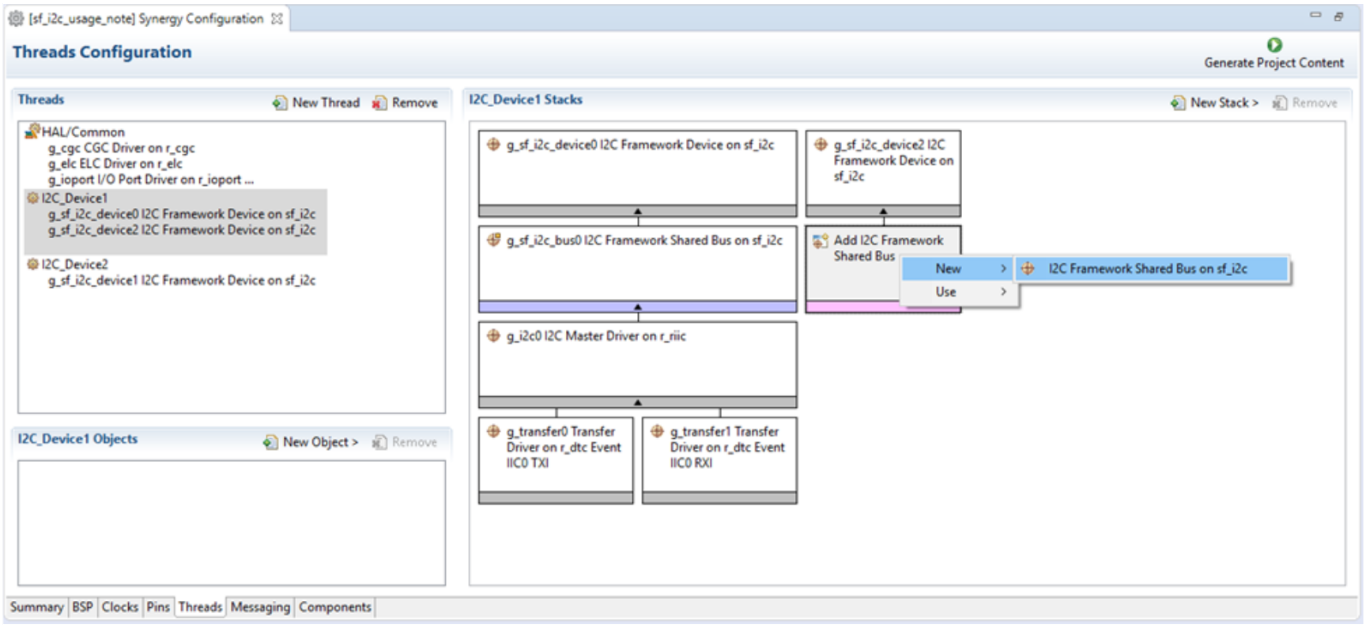
Name	g_sf_i2c_device1	Give a name to identify the I2C Framework device. API, Config and Control instances will be created based on this name.
Slave Address	0x28	Specify the address of I2C slave2.
Address Mode	7-bit	Select the I2C address mode.

The step above can be repeated as needed to add more slave devices to the same bus, if they share the same low-level settings.

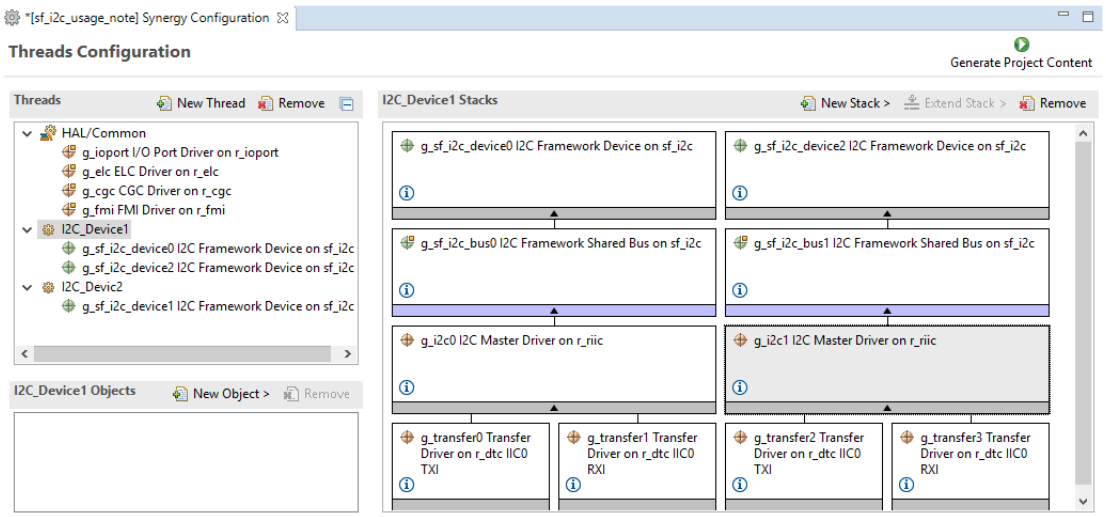
If a set of slave devices have different lower-level settings than another set, they must use a different bus and can be implemented by repeating the two steps outlined above- defining a different bus and the different lower-level characteristics for the set of slave devices.

Adding Another Shared Bus

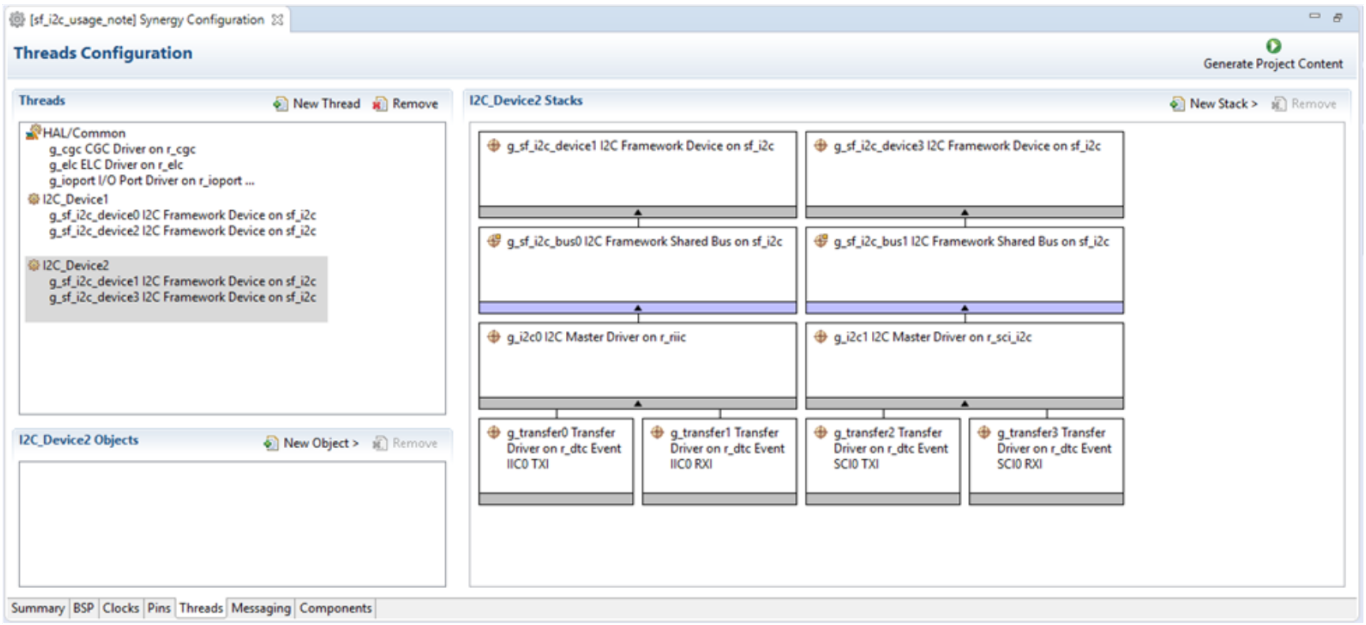
1. The I2C framework module which will use a second shared bus can be added to any thread. Starting with the previous example, if it is added to the I2C_Device1 thread, then the module stack would appear as shown below. Available options for the shared bus are **New** or **Use**.



2. Select **New** to and add another I2C Framework Shared Bus on sf_i2c module. Configure the shared bus properties as needed for the application. Select the desired low-level I2C driver. The channel number for the g_i2c1 I2C driver module, must be different from the channel number for the g_i2c0 I2C driver module. The resulting thread stack is shown below:



3. A second device can be added in the I2C_Device2 thread using the same steps described above. The resulting thread stack is shown below:



The typical steps in using the I2C Framework module in an application are:

1. Initialize the I2C Framework module using the sf_i2c_api_t::open API. Each I2C framework module needs to call sf_i2c_api_t::open API at least once before performing any operations on the bus.
2. Reset the I2C MCU peripheral using the sf_i2c_api_t::reset API (if needed)
3. Lock the bus using the sf_i2c_api_t::lock or sf_i2c_api_t::lockWait API for a particular framework module. Once the bus is locked by an I2C framework module it cannot be used by any other I2C framework module on the same bus. This ensures that ownership of the bus remains with the I2C framework module until it unlocks it. Any operation from other I2C

framework modules on the bus will fail while the bus is locked. It is not mandatory to lock the bus before any read/write operations on the bus. It is optional (if needed). If thread is not supposed to wait forever when locking the I2C bus, call sf_i2c_api_t::lockWait API with desired timeout value.

4. Write data to the slave using the sf_i2c_api_t::write API. The write operation will not be successful if the bus is already locked by any other I2C framework module.
5. Read data from the slave using sf_i2c_api_t::read API. The read operation will not be successful if the bus is already locked by any other I2C framework module.
6. Unlock the bus using the sf_i2c_api_t::unlock API if it is already locked by the same I2C framework module. Once the bus is unlocked other I2C framework modules can use it. It is necessary to unlock the locked bus after the protected read or write operations are over (if needed).
7. Close the I2C framework module using the sf_i2c_api_t::close API. Each I2C framework module can call the sf_i2c_api_t::close API after all its read and write operations on the bus are completed (if needed).

These common steps are illustrated in a typical operational flow in the following figure:

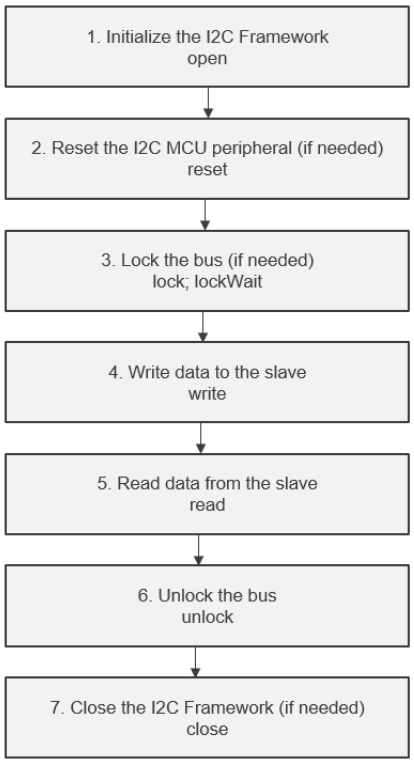


Figure 179: Flow Diagram of a Typical I2C Framework Module Application

4.1.20 JPEG Decode Framework

4.1.20.1 JPEG Decode Framework Module Introduction

The JPEG Decode HAL module provides a high-level API for industry standard JPEG image decode processing and supports the Renesas Synergy™ JPEG Codec peripheral. The JPEG Decode Framework

Module is a ThreadX®-aware implementation and provides thread-safe access to the Synergy JPEG hardware on a Synergy MCU. A user-defined callback can be created to detect hardware supported events.

JPEG Decode Framework Module Features

- Provides thread-safe access to the Synergy JPEG hardware.
- Supports JPEG decompression using the JPEG Decode HAL module.
- Supports a polling mode that allows an application to wait for the JPEG Decoder to complete.
- Supports an interrupt mode with user-supplied callback functions.
- Configures parameters such as horizontal and vertical subsample values, horizontal stride, decoded pixel format, input and output data format, and color space.
- Obtains the size of the image prior to decoding it.
- Supports putting coded data in an input buffer and an output buffer to store the decoded image frame.
- Supports streaming coded data into the JPEG Decoder module. This feature allows an application to read a coded JPEG image from a file or from a network without buffering the entire image.
- Configures the number of image lines to decode. This feature enables the application to process the decoded image on the fly without buffering the entire frame.
- Supports the input decoded formats YCbCr444, YCbCr422, YCbCr420 and YCbCr411.
- Supports the output formats ARGB8888 and RGB565.
- Returns an error when the JPEG image's size, height, and width do not meet the requirements.
- Supports the sf_jpeg_decode_api_t::wait API function to suspend/resume the thread for synchronizing with the JPEG hardware supported events.

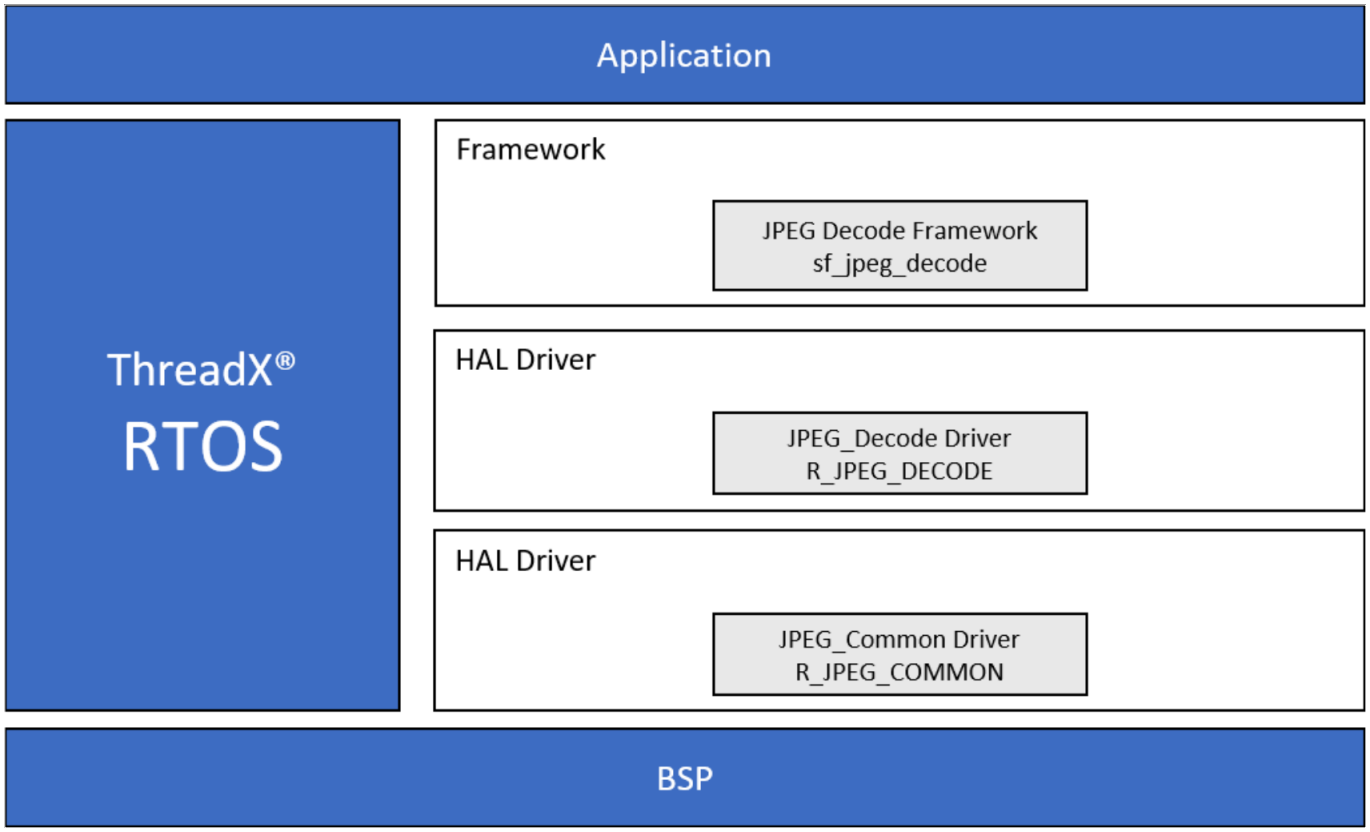

Figure 180: JPEG Decode Framework Module Block Diagram

4.1.20.2 JPEG Decode Framework Module APIs Overview

The JPEG Decode Framework module defines APIs for opening, closing, setting alarms and starting and stopping RTC operations. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

JPEG Decode Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_jpeg_decode0.p_api->open(g_sf_jpeg_decode0.p_ctrl, g_sf_jpeg_decode0.p_cfg); Open the JPEG Decode Framework.
inputBufferSet	g_sf_jpeg_decode0.p_api->close(g_sf_jpeg_decode0.p_ctrl); Close the JPEG Decode Framework.
outputBufferSet	g_sf_jpeg_decode0.p_api->outputBufferSet(g_sf_jpeg_decode0.p_ctrl, p_buffer, buffer_size); Assign output buffer to JPEG codec for storing output data.
linesDecodedGet	g_sf_jpeg_decode0.p_api->linesDecodedGet g_sf_jpeg_decode0.p_ctrl, p_lines); Return the number of lines decoded into the output buffer.
horizontalStrideSet	g_sf_jpeg_decode0.p_api->horizontalStrideSet(g_sf_jpeg_decode0.p_ctrl, stride); Configure the horizontal stride value.
imageSubsampleSet	g_sf_jpeg_decode0.p_api->imageSubsampleSet(g_sf_jpeg_decode0.p_ctrl, horizontal, vertical); Configure the horizontal and vertical subsample settings.
wait	g_sf_jpeg_decode0.p_api->wait(g_sf_jpeg_decode0.p_ctrl, p_status, timeout); Wait for the current JPEG codec operation to finish with a timeout value given in ThreadX ticks.
statusGet	g_sf_jpeg_decode0.p_api->statusGet(g_sf_jpeg_decode0.p_ctrl, p_status); Retrieve current status of the JPEG codec module.
imageSizeGet	g_sf_jpeg_decode0.p_api->imageSizeGet(g_sf_jpeg_decode0.p_ctrl, p_horizontal, p_vertical); Retrieve image size during decoding operation.
pixelFormatGet	g_sf_jpeg_decode0.p_api->pixelFormatGet(g_sf_jpeg_decode0.p_ctrl, p_color_space); Get the input pixel format.

close	g_sf_jpeg_decode0.p_api->close(g_sf_jpeg_decode0.p_ctrl); Cancel an outstanding operation.
versionGet	g_sf_jpeg_decode0.p_api->versionGet(&version); Get version and store it in provided pointer p_version.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	JPEG Decode driver is successfully opened.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_IN_USE	Module already in use.
SSP_ERR_TIMEOUT	The wait operation times out, the underlying driver did not respond in time.
SSP_ERR_WAIT_ABORTED	System internal error occurred.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.20.3 JPEG Decode Framework Module Operational Overview

The JPEG Decode Framework module implements the standard JPEG decode operation. It takes the data in an input buffer and applies the defined JPEG decode algorithm to the buffer, the output is then delivered to the defined output buffer location. A wait API function can be used to suspend/resume the thread for synchronization with JPEG hardware supported events.

JPEG Decode Framework Module Important Operational Notes and Limitations

JPEG Decode Framework Module Operational Notes

- Start decoding JPEG-encoded data by calling the sf_jpeg_decode_api_t::open API. To open the module, use the JPEG Decode Framework module instance, that includes the API function pointer, the pointer to the control block and static configuration that is generated through the Synergy Project configurator in the e^2 studio for ISDE.
- Stop the JPEG Decode Framework module by calling the sf_jpeg_decode_api_t::close API.
- An input buffer-streaming mode is available when an input-centric function is needed.
- An output buffer-streaming mode is available when an output-centric function is needed.
- Supports RGB565 and ARGBB888 output data-color formats.
- The JPEG Decode Framework module has a status flag in the control block, which provides the current status of the module through the sf_jpeg_decode_api_t::statusGet API. The status is also reported through a user-callback function when specific events occur in the module.
- The JPEG Decode Framework module supports buffer-streaming mode for the input buffer in

cases when the input buffer is smaller than the source image size. Set the next input frame as an input buffer every time there is a hardware-generated INPUT_PAUSE interrupt.
- The JPEG Decode Framework module supports buffer-streaming mode for the output buffer in cases when the resultant image is larger than the output buffer-size. Read and store data from the output buffer to make space for upcoming data every time there is a hardware generated OUTPUT_PAUSE interrupt.
- The input and output buffers should be 8-bytes aligned for the JPEG Decode Framework module to be successful. Otherwise, API functions will return error codes that indicate unsuccessful execution.

JPEG Decode Framework Module Limitations

- The JPEG Decode Framework module does not support JPEG-encode processing.
- Check for timeout error (SSP_ERR_TIMEOUT) using sf_jpeg_decode_api_t::wait API; if it returns timeout error, close the framework, re-open it and then perform the decoding operation.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.20.4 Including the JPEG Decode Framework Module in an Application

This section describes how to include the JPEG Decode Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the JPEG Decode Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the JPEG Decode Framework is g_sf_jpeg_decode0. This name can be changed in the associated Properties window.)

JPEG Decode Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_jpeg_decode0 JPEG Framework	Threads	**New Stack> Framework> Graphics> JPEG Decode Framework on sf_jpeg_decode**

When the JPEG Decode Framework on sf_jpeg_decode is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

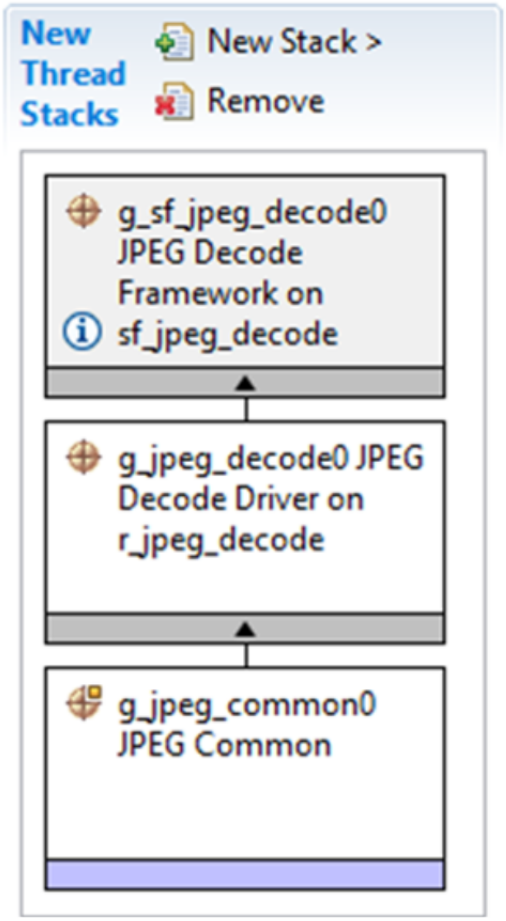

Figure 181: JPEG Decode Framework Module Stack

Decompression Process Interrupt (JEDI)

The JPEG decompression-process interrupt occurs when:

- The current decompression process is successfully completed.
- An error happens in the decompression process.
- Image size and pixel format are successfully read out.

Data Transfer Interrupt (JDTI)

The JPEG data-transfer interrupt occurs when:

- All the JPEG-coded data has successfully completed.
- The number of output image-data lines specified by sf_jpeg_decode_api_t::linesDecodedGet has been transferred.

The number of input image-data lines specified by sf_jpeg_decode_api_t::inputBufferSet has been transferred.

4.1.20.5 Configuring the JPEG Decode Framework Module

The JPEG Decode Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the

properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the JPEG Decode Framework Module on sf_jpeg_decode

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_jpeg_decode0	The name to be used for a JPEG Decode Framework module instance.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the JPEG Decode Framework Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the JPEG HAL Module on r_jpeg

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_jpeg_decode0	The name to be used for a JPEG Decode module instance.

Byte Order for Input Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) Default: Normal Byte order	Specify the byte order for input data. The order is swapped as specified in every 8-byte.
Byte Order for Output Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) Default: Normal Byte order	Specify the byte order for output data. The order is swapped as specified in every 8-byte.
Output Data Color Format	Pixel Data RGB565 format, Pixel Data ARGBB888 format Default: Pixel Data RGB565 format	Specify the output data format.
Alpha value to be applied to decoded pixel data (only valid for ARGB8888 format)	255	Specify the alpha value for the output data format (only valid for ARGB8888 format).
Name of user callback function	NULL	Specify the name of user callback function.
Decompression Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Decompression interrupt priority selection.

Data Transfer Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Data transfer interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the JPEG Common Module

ISDE Property	Value	Description
Name	g_jpeg_common0	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

JPEG Decode Framework Module Clock Configuration

The JPEG Framework module uses the peripheral module clock A (PCLKA) to run the internal logic.

JPEG Decode Framework Module Interrupt Configuration

To enable interrupts, set the priority of the decompression interrupt and the data-transfer interrupt in the **Properties** window of the JPEG Decode Framework module in the ISDE.

JPEG Decode Framework Module Pin Configuration

The JPEG Decode Framework module does not use any pins.

4.1.20.6 Using the JPEG Decode Framework Module in an Application

The steps in using the JPEG Decode Framework module in a typical application are:

1. Initialize the JPEG Decode peripheral using the sf_jpeg_decode_api_t::open API.
2. Set Image Subsample using the sf_jpeg_decode_api_t::imageSubsampleSet API.
3. Set Horizontal stride using the sf_jpeg_decode_api_t::horizontalStrideSet API.
4. Set output buffer using the sf_jpeg_decode_api_t::outputBufferSet API.
5. Set Input buffer using the sf_jpeg_decode_api_t::inputBufferSet API.
6. Wait for decode to complete with the sf_jpeg_decode_api_t::wait API.
7. Check decode status with the sf_jpeg_decode_api_t::statusGet API.
8. Close the instance with the sf_jpeg_decode_api_t::close API (if needed).

These common steps are illustrated in a typical operational flow diagram in the following figure:

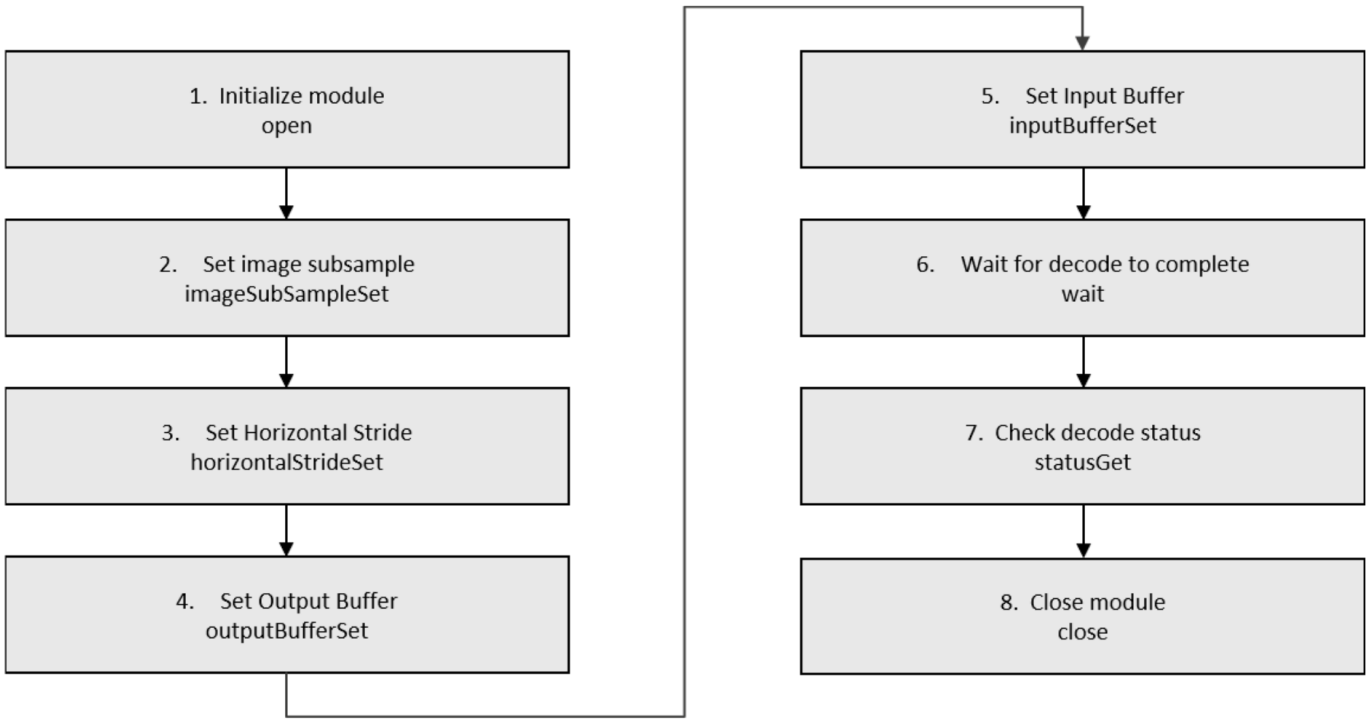

Figure 182: Flow Diagram of a Typical JPEG Decode Framework Module Application

4.1.21 Memory Framework on sf_memory_qspi_nor

4.1.21.1 Memory Framework Module Introduction

The Memory Framework on sf_memory_qspi_nor module provides a high-level API for interfacing with QSPI NOR memory devices. It provides API functions for reading, writing, and erasing data in QSPI NOR Flash memory. The Memory Framework on sf_memory_qspi_nor module is also used by the higher-level Port LevelX Framework on sf_el_lx_nor framework module when support for LevelX wear leveling is required.

Memory Framework Module Features

- Supports memory interface for QSPI NOR flash memory device.
- Supports I/O Operations on QSPI NOR flash memory device.
  - Read
  - Write
  - Erase

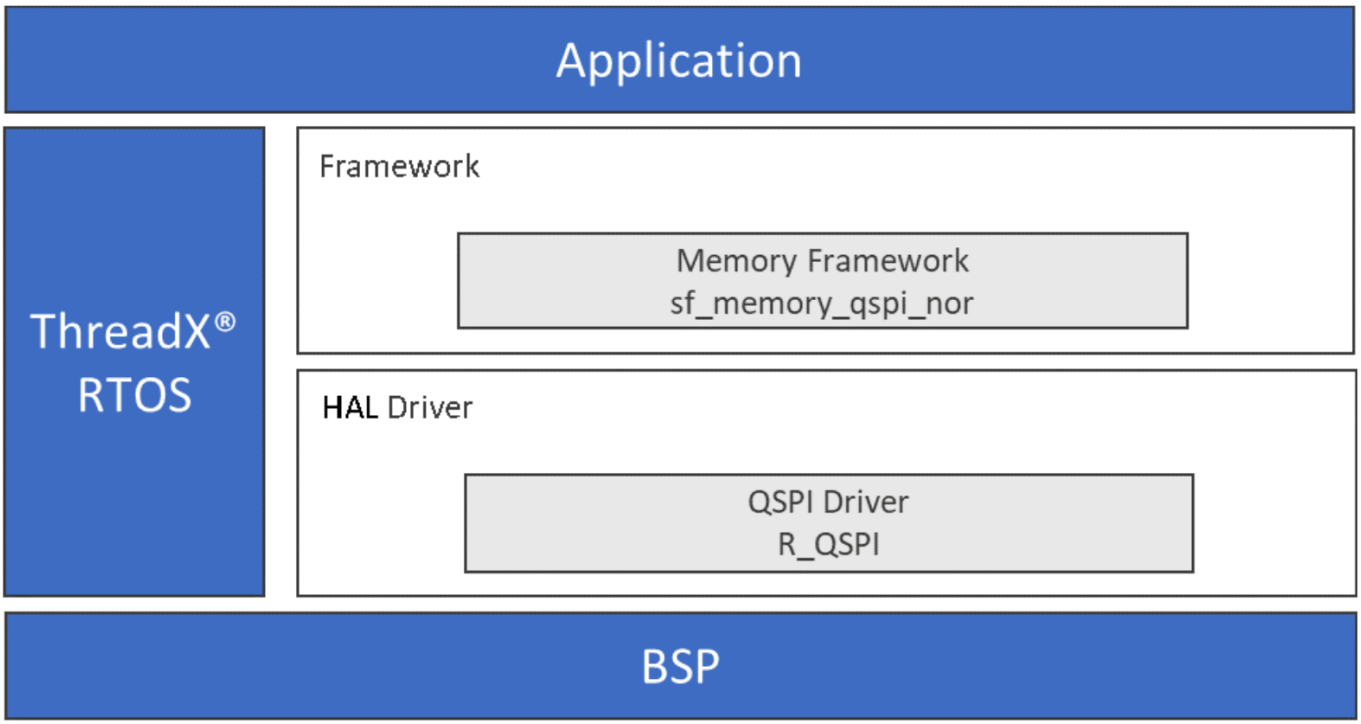

Figure 183: Memory Framework Module Block Diagram

4.1.21.2 Memory Framework Module APIs Overview

The Memory Framework module defines API functions to read, write and erase QSPI NOR flash memory devices. A complete list of the available API functions, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Memory Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_memory_qspi_nor0.p_api->open(g_sf_memory_qspi_nor0.p_ctrl, g_sf_memory_qspi_nor0.p_cfg); Open the SF Memory QSPI NOR driver module for the purposes of reading and writing flash memory.
close	g_sf_memory_qspi_nor0.p_api->close(g_sf_memory_qspi_nor0.p_ctrl); Close the Memory QSPI NOR driver module.
read	g_sf_memory_qspi_nor0.p_api->read(g_sf_memory_qspi_nor0.p_ctrl, p_dest_address, memory_address, num_bytes); Read specified number of bytes of data from a particular address on the QSPI flash device.

write	g_sf_memory_qspi_nor0.p_api->write(g_sf_memory_qspi_nor0.p_ctrl, p_src_address, memory_address, num_bytes); Program data to the flash.
flush	g_sf_memory_qspi_nor0.p_api->flush(g_sf_memory_qspi_nor0.p_ctrl); Flush any pending data to the disk. This is not required for QSPI NOR flash.
erase	g_sf_memory_qspi_nor0.p_api->erase(g_sf_memory_qspi_nor0.p_ctrl, memory_address, num_bytes); Erase a number of bytes from the flash.
infoGet	g_sf_memory_qspi_nor0.p_api->infoGet(g_sf_memory_qspi_nor0.p_ctrl, p_info); Returns the information about the flash.
versionGet	g_sf_memory_qspi_nor0.p_api->versionGet(&version); Get the driver version based on compile time macros.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Configuration was successful.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_cfg is NULL.
SSP_ERR_ALREADY_OPEN	Driver is already open.
SSP_ERR_NOT_OPEN	Driver is not opened.
SSP_ERR_INVALID_ARGUMENT	Number of bytes requested is invalid.
SSP_ERR_TIMEOUT	Wait timed out.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.21.3 Memory Framework Module Operational Overview

The Memory Framework module supports memory data transfers for a QSPI memory. High-level API functions are available to open, read, write, erase and close the module. If LevelX support is needed, the higher-level Port LevelX Framework on sf_el_lx_nor framework module can be used in conjunction with this module.

The Memory Framework module uses a standard interface that is common for other SSP media

modules. For example, the modules that support SDMMC, SPI Flash and SDRAM/RAM memories use the same API calls, so the programming interface remains the same for any media driver. These modules can be interchanged with one another easily. Device adaptation drivers, such as r_qspi, are accessed through the Memory Framework Interface and provide device specific code needed to perform media I/O operations. Configuration and control structures passed through memory interface function calls are generally device specific as well.

A user-defined delay callback function can be specified to fine tune the amount of time to wait before starting to poll the QSPI chip after a write or erase operation. This option is provided since there is a large variation in the delay that could be required for a QSPI operation to complete and it varies from chip to chip.

If the delay callback is not specified, then the QSPI driver sleeps for one tick, before polling the status again.

The number of ticks to wait before a timeout error occurs, on a chip erase or write, can be specified in the "Write or Erase Timeout" field. The default is set to 30,000 ticks.

Memory Framework Module Important Operational Notes and Limitations

Memory Framework Module Operational Notes

The media must be erased before using sf_memory_qspi_nor for I/O operations.

Memory Framework Module Limitations

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.21.4 Including the Memory Framework Module in an Application

This section describes how to include the Memory Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Memory Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Memory Framework is g_sf_memory_qspi_nor0. This name can be changed in the associated Properties window.)

Memory Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_memory_qspi_nor0 Memory Framework on sf_memory_qspi_nor	Threads	**New Stack> Framework> Memory> Memory Framework on sf_memory_qspi_nor**

When the Memory Framework on sf_memory_qspi_nor is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or

common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

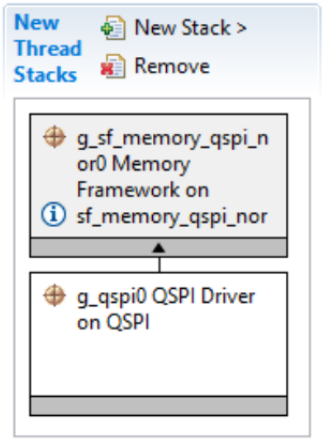

Figure 184: Memory Framework Module Stack

4.1.21.5 Configuring the Memory Framework Module

The Memory Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Memory Framework Module on sf_memory_qspi_nor

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_sf_memory_qspi_nor0	Module name.
Delay Callback (Optional)	NULL	Callback used to add a delay between polling the QSPI chip.
Write or Erase Timeout (in ticks)	30000	Timeout ticks for waiting on write or erase to complete.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Memory Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the QSPI HAL Module on r_qspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_qspi0	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Memory Framework Module Clock Configuration

The Memory Framework module uses the QSPI peripheral, which uses PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

Memory Framework Module Pin Configuration

To use the Memory Framework module, the port pins for the QSPI peripheral must be set as needed. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection for the Memory Framework Module on sf_memory_qspi_nor

Resource	ISDE Tab	Pin selection Sequence
QSPI	Pins	Select **Peripherals**> **Storage:QSPI QSPI0**

4.1.21.6 Using the Memory Framework Module in an Application

The typical steps in using the Memory Framework module in an application are:

1. Initialize the instance using sf_memory_api_t::open API function.

2. Write data to QSPI flash using sf_memory_api_t::write API function.

3. Read data from QSPI flash using sf_memory_api_t::read API function.

4. Erase data from QSPI flash using sf_memory_api_t::erase API function.

5. Read QSPI flash information using sf_memory_api_t::infoGet API function.

6. Close the instance using sf_memory_api_t::close API function.

These common steps are illustrated in a typical operational flow diagram in the following figure:

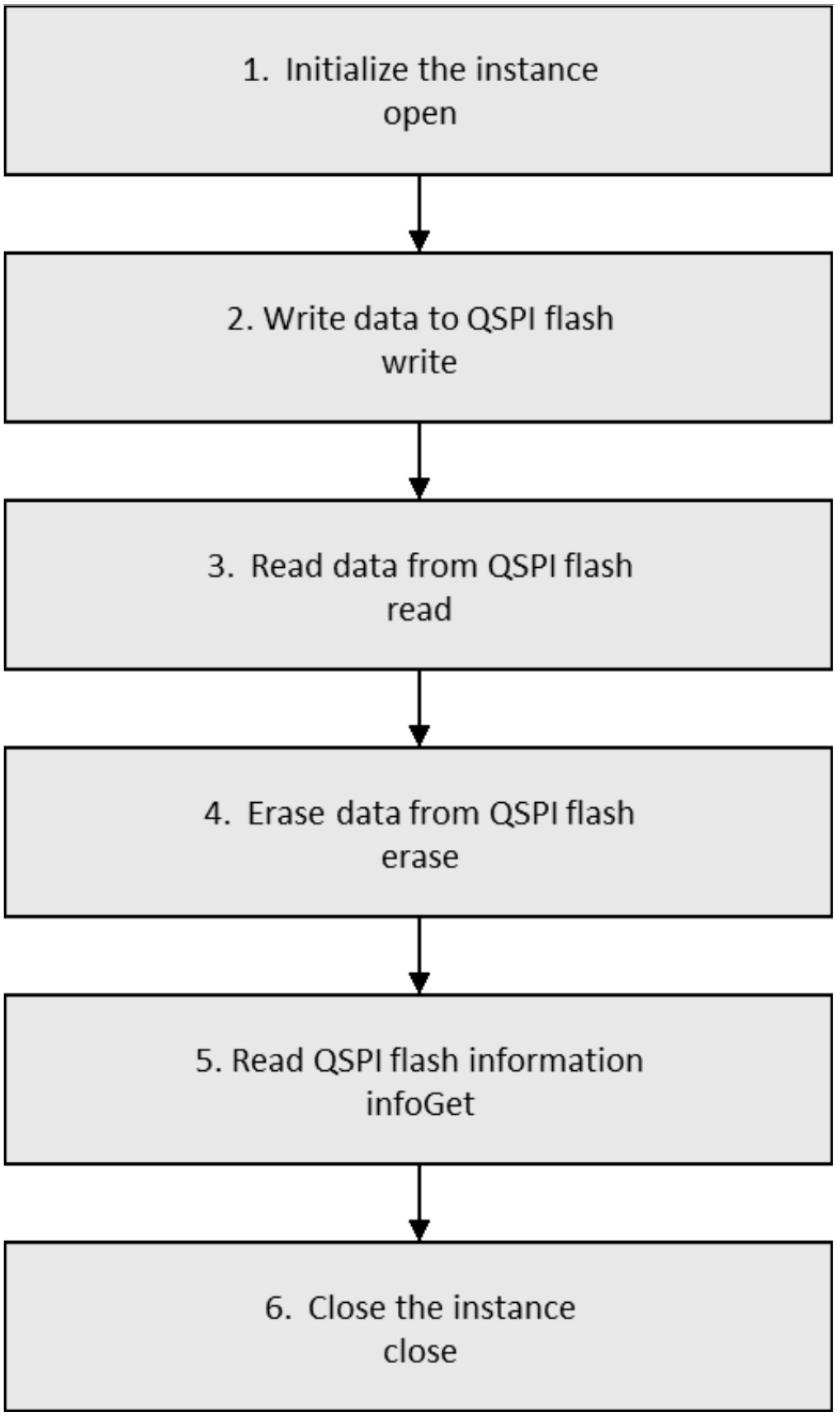

Figure 185: Flow Diagram of a Typical Memory Framework Module Application

4.1.22 Messaging Framework

4.1.22.1 Messaging Framework Module Introduction

The Messaging Framework implements a lightweight and event-driven API for passing messages between threads. The Messaging Framework module allows applications to communicate messages between two or more threads. The framework uses the ThreadX message-queue primitive for message passing and provides more benefits than the ThreadX RTOS message-queue services alone. The Messaging Framework API is purely a software API and does not access any hardware peripherals. The Messaging Framework callback is used to allow an event-producer thread and a message-subscriber thread to handshake after the message passing is done.

The **Messaging** tab is used to either create custom event classes, events and subscribers for the Messaging Framework module or to customize preconfigured events such as the touch event used by the Touch Panel Framework module.

Messaging Framework Module Features

The Messaging Framework module supports the following functions:

- Inter-Thread communication - The framework allows application threads which control disparate devices or manage subsystems to communicate with each other.
- Publishing/Subscribe scheme - The framework design is based on the loosely-coupled messaging paradigm. The design allows multiple threads to listen to an event class. The message producer thread does not need to know who is subscribing to a message for the event class. Subscribers do not need to know who produces the message.
- Message management - The framework supports buffer control blocks to manage each message including flags to control the buffer and a callback function pointer for handshaking.
- Message buffering - The framework manages buffer allocation and release for messaging. An application can make use of the allocated buffer to write a message and discard the message if it is no longer needed.
- Synchronous communication - The framework supports asynchronous messaging by using the ThreadX message-queue but also provides an option to create a handshake between a message producer and a subscriber thread. The handshake is implemented by invoking a user-callback function of the producer thread from a subscriber thread.
- Message formatting - The framework provides a predefined common message header. It also provides some typical payload structure templates as examples.
- Message Priority - The framework can send a high-priority message so that a subscriber thread can retrieve the message prior to other messages which are located in the message queue.

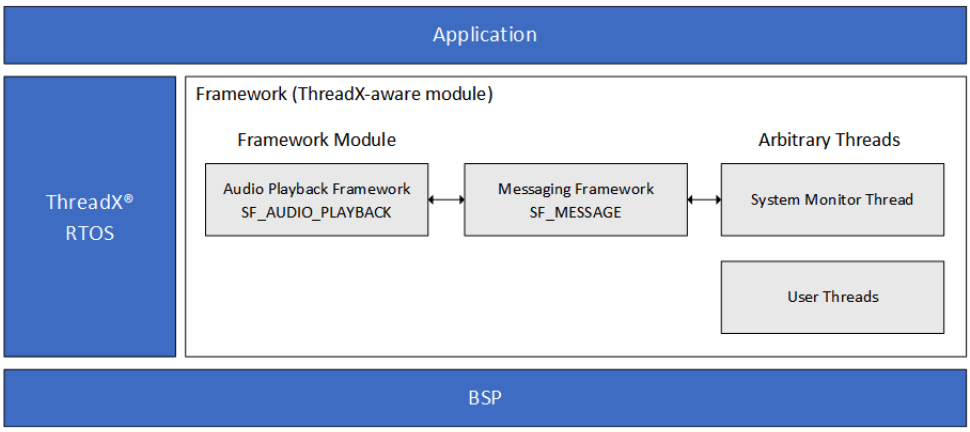

Figure 186: Messaging Framework Module Block Diagram

4.1.22.2 Messaging Framework Module APIs Overview

The Messaging Framework module defines APIs for opening and closing the framework, acquiring and releasing buffers, and posting messages to subscribers. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Messaging Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_message.p_api->open (g_sf_message.p_ctrl, g_sf_message.p_cfg); Initialize message framework. Initiate the messaging framework control block, configure the work memory corresponding to the configuration parameters.
close	g_sf_message.p_api->close (g_sf_message.p_ctrl); Finalize message framework.
bufferAcquire	g_sf_message.p_api->bufferAcquire (g_sf_message.p_ctrl, &p_buffer, &acquire_cfg, wait_option); Acquire buffer for message passing from the block.
bufferRelease	g_sf_message.p_api->bufferRelease (g_sf_message.p_ctrl, &p_buffer, option); Release buffer obtained from SF_MESSAGE_BufferAcquire.
post	g_sf_message.p_api->post (g_sf_message.p_ctrl, (sf_message_header_t *) p_payload, &post_cfg, &err_post, wait_option); Post message to the subscribers.

pend	g_sf_message.p_api->pend (g_sf_message.p_ctrl, &my_queue, (sf_message_header_t **)&p_buffer, &p_header, wait_option); Pend message.
versionGet	g_sf_message.p_api->versionGet (&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API call successful.
SSP_ERR_ASSERTION	Required pointer is NULL.
SSP_ERR_BUFFER_RELEASED	The buffer is released.
SSP_ERR_ILLEGAL_SUBSCRIBER_LISTS	Message subscriber lists is illegal.
SSP_ERR_IN_USE	The messaging framework is in use.
SSP_ERR_INTERNAL	OS service call fails.
SSP_ERR_INVALID_MSG_BUFFER_SIZE	Message buffer size is invalid.
SSP_ERR_INVALID_WORKBUFFER_SIZE	Invalid work buffer size.
SSP_ERR_MESSAGE_QUEUE_EMPTY	Queue is empty. (Timeout occurs before receiving a message if timeout option is specified.)
SSP_ERR_MESSAGE_QUEUE_FULL	Queue is full. (Timeout occurs before sending a message if timeout option is specified.)
SSP_ERR_NO_MORE_BUFFER	No more buffer found in the memory block pool.
SSP_ERR_NO_SUBSCRIBER_FOUND	No subscriber found.
SSP_ERR_NOT_OPEN	Message framework module has yet to be opened.
SSP_ERR_TIMEOUT	OS service call returns timeout.
SSP_ERR_TOO_MANY_BUFFERS	Too many message buffers.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.22.3 Messaging Framework Module Operational Overview

The following figure shows the overview of the messaging data flow between a message producer thread and subscriber thread(s) in the system making use of the Messaging Framework module.

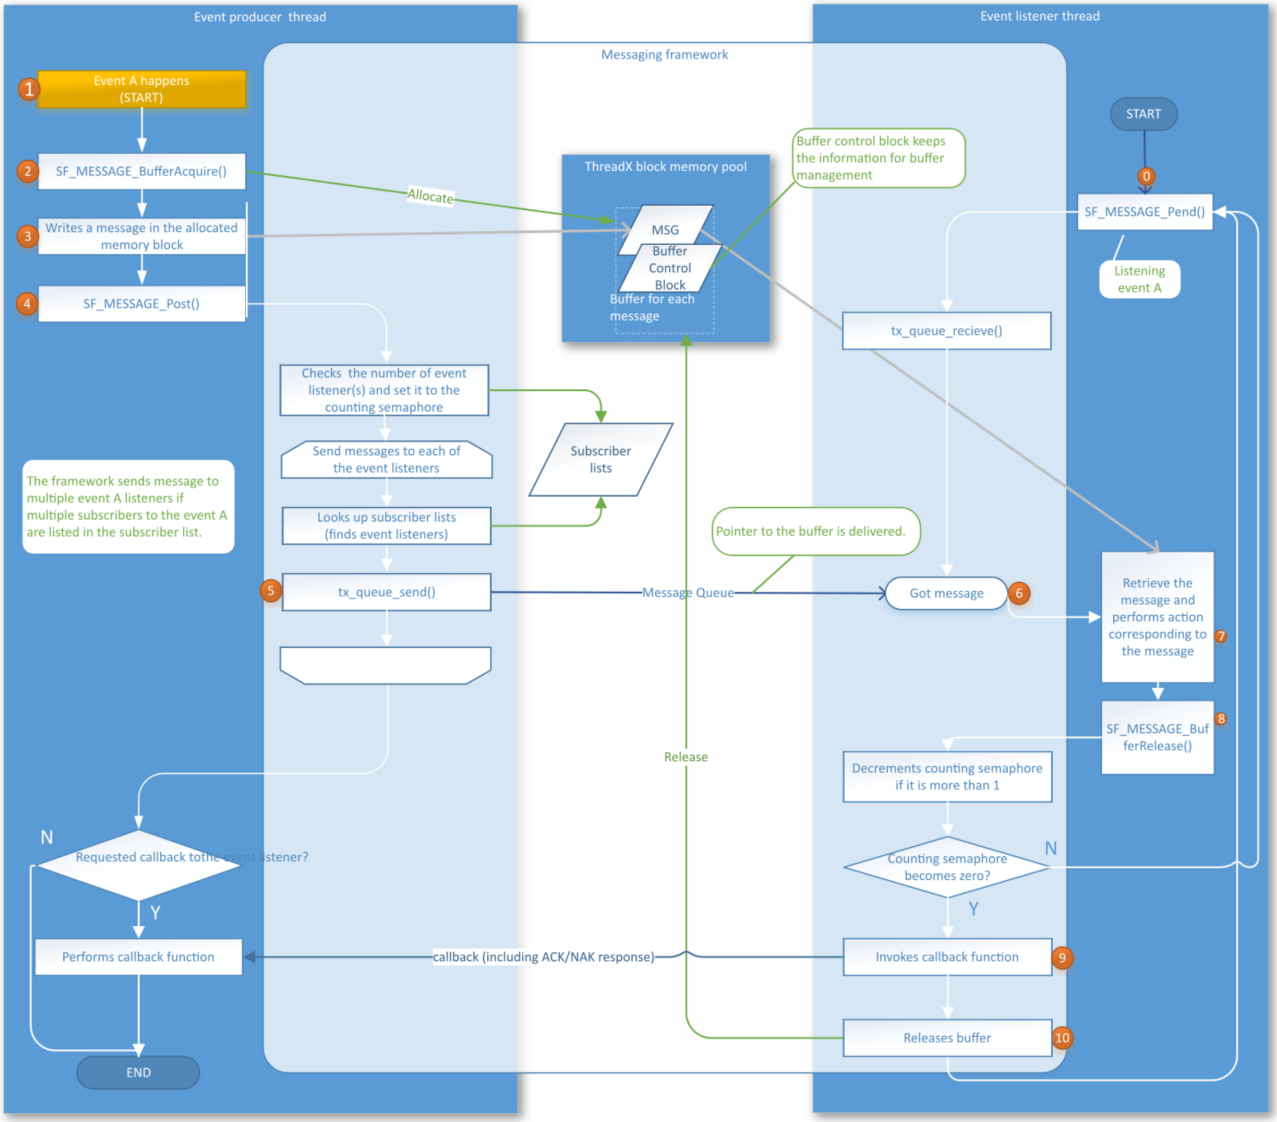

Figure 187: Messaging Framework Module Data Flow

The following is a description for each stage of the message passing procedure:

Note: A thread in the system has been called using the sf_message_api_t::open API and message subscriber threads have called the sf_message_api_t::pend API to pend on a message for the event class.

1. An event (Event A) happens on a message producer thread.
2. A message producer thread calls sf_message_api_t::bufferAcquire to acquire a buffer from the ThreadX memory pool managed by the Messaging Framework module; sf_message_api_t::bufferAcquire returns the address of allocated buffer.
3. A message producer writes the message to the allocated buffer.

4. A message producer calls sf_message_api_t::post to post the message.
5. The Messaging Framework module looks up the event subscriber list and sends a message to the message queue of the message subscriber threads using the ThreadX message-queue primitive. The framework just sends the pointer to the buffer but does not send the entire message, thereby performing lightweight message passing.
6. The message reaches the message queue of the message subscriber threads and the message subscriber threads return from sf_message_api_t::pend. The API function returns the buffer address where the message is stored to message subscriber threads.
7. The message subscriber threads receive the message and perform an action corresponding to the event.
8. The message subscriber threads call sf_message_api_t::bufferRelease to try to release the allocated buffer for the message. If the message subscriber thread is not the last one subscribing to the message, the framework does not release the buffer as the message has to be kept in the buffer until all subscribers have received the message.
9. The Messaging Framework module invokes a user-callback function which is specified by an event producer thread if the message subscriber thread is the last one in the message subscriber group.
10. The Messaging Framework module releases the buffer if all the subscribers in the group have notified the framework that they have consumed the message. (Note that the release option SF_MESSAGE_RELEASE_OPTION_FORCED_RELEASE in the sf_message_api_t::bufferRelease API function should not be used in a multiple subscriber scenario.)

Messaging Framework Module Message Producer and Subscribers

The Message Framework module is an inter-thread messaging system based on the publish/subscribe model. A message is posted with an event class code by an event producer thread. The message subscriber threads can check for pending messages which subscribe to the event class. Subscribers are registered in the subscriber list, which is referred to by the framework. The subscriber list allows the framework to deliver a message to multiple subscribers.

Every thread which joins the Messaging Framework module system network can send a message, and all threads in the network can listen to the message.

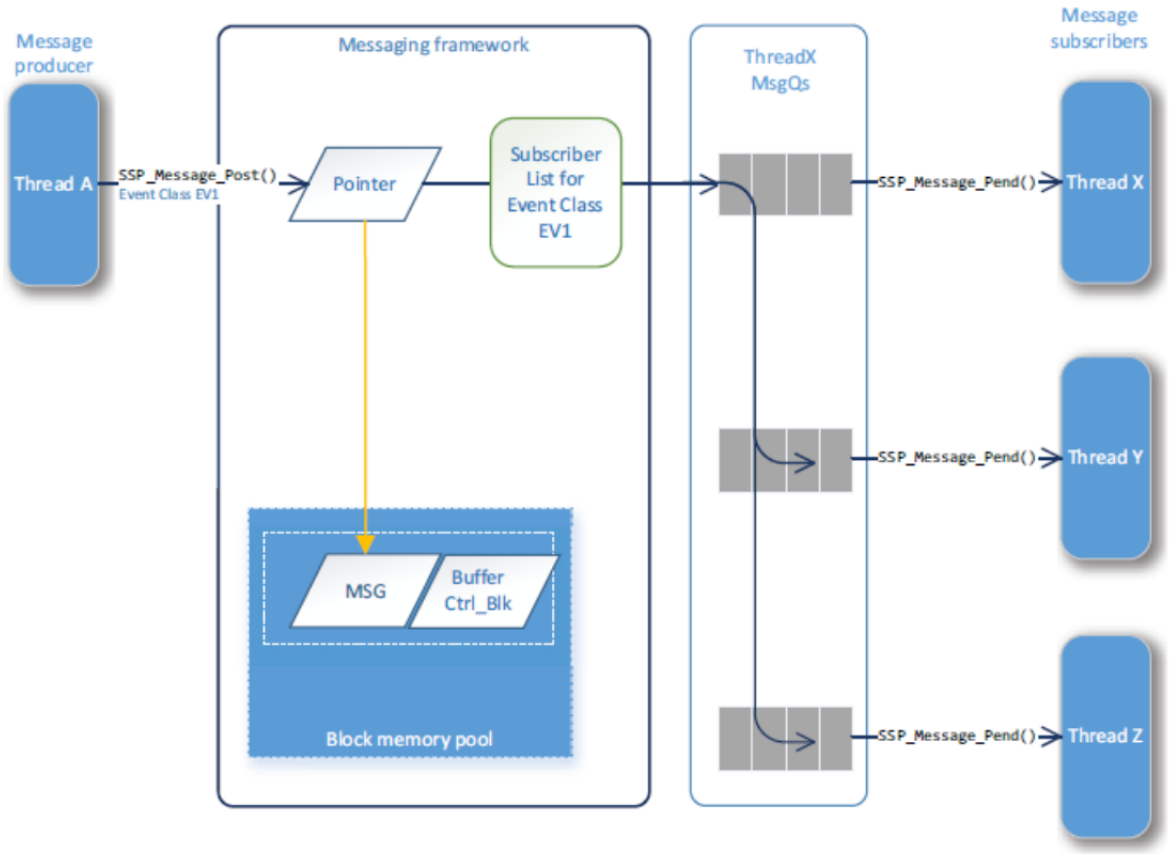

Figure 188: Messaging Framework Module Subscribing

Messaging Framework Module Events, Subscribers, and Messages

Messaging Framework Module Event Class Code

The event class code is the most important definition for the Messaging module. The Messaging module uses the event class code as the mechanism to connect a message producer with subscribers; the event class code is the class definition of the events which occur in the application. The classification of the event class relies on the user definition, but it is intended to be the group name of the particular events which can occur in a subsystem.

For example, you can use the 'Audio Playback' event class, which is part of the Audio Playback Framework module. The 'Audio Playback' Event Class is automatically loaded into the event classes window. This window is available on the Messaging tab in the Project Configurator when you add the Audio Playback Framework to your Synergy project.

The event class code is defined in the sf_message_event_class_t enumeration and has a prefix SF_MESSAGE_EVENT_CLASS_XXX. Since the definition of the event class code is different for each system, the framework does not provide a concrete event class code but instead provides a set of event class codes as examples. (See the Configuring the Messaging Framework Module section.) The maximum number for the event class is 255.

An application can use the event class code as follows:

- The message producer thread sets the event class code to the event_b.class_code bit fields in the sf_message_header_t type common message header before posting the message.
- The message subscriber-thread branches to the event processing corresponding to the event class code which is set to the message header after receiving the message.
- The subscribers for the event class code must be grouped and registered in the subscriber list so that the Message Framework can deliver the message to the subscribers.

The following figure shows how you can configure an event class using the ISDE:

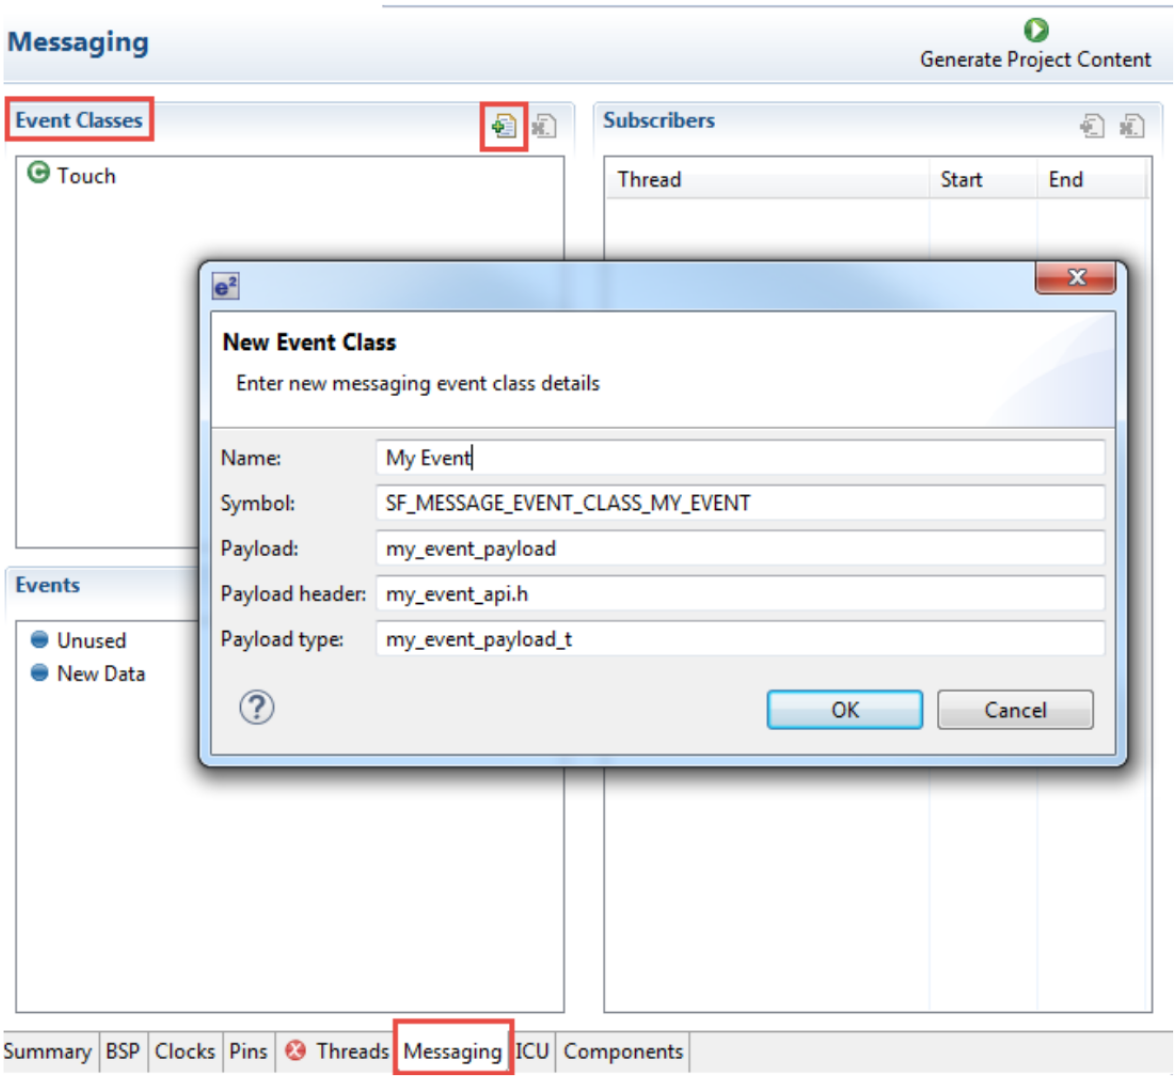

Figure 189: Messaging Framework Module ISDE Event Class Configuration

Messaging Framework Module Event Class Instance Number

The event class instance number is used when an application needs to have different event class instances. For example, the audio streaming event class can have instance *N* which represents the streaming channel N. Message subscribers can receive a message only if the event class instance number in the message common header matches to the number it owns.

In other words, messages for which the event class instance number is out of range for the subscriber are filtered out and not delivered to the subscriber even though it is the event class subscriber. The maximum for the event class instance number is 255.

Note

The Touch Panel Framework typically only has one instance, and therefore the event class instance number is 0 with the start and end values of the subscriber list set to 0.

An application can use the event class instance number as follows:

- The message producer thread sets the event class instance number to the event_b.class_instance bit fields in the sf_message_header_t type common message header before posting the message.
- Each subscriber instance in the Subscriber List has to specify the range of the event class instance numbers to receive the message (sf_message_subscriber_t::instance_range.start and sf_message_subscriber_t::instance_range.end).
- If there is no need for multiple instances for an event class, just specify zero to sf_message_header_t::event_b.class_instance, sf_message_subscriber_t::instance_range.start, and sf_message_subscriber_t::instance_range.end in the subscriber instance for the subscriber list.

Messaging Framework Module Event Code

The event code includes the details of the event definition. For instance, the event codes for the audio playback event class are "playback start" and "playback stop." Another example is 'set' or 'get' for the 'time' Event Class. The event code is enumerated in the sf_message_event_t and has a prefix SF_MESSAGE_EVENT_XXX. The definition of the event code relies on the user code as well as the event class code. The framework provides some code as examples. See Configuring the event class code and event code for configuring the event code. The maximum for the event class instance number is 65535.

An application can use the event code as follows:

The message producer thread sets the event code to the event_b.code bit fields in the sf_message_header_t type common message header before posting the message.

The message subscriber thread performs an action corresponding to the event code which is set to the message header after receiving the message.

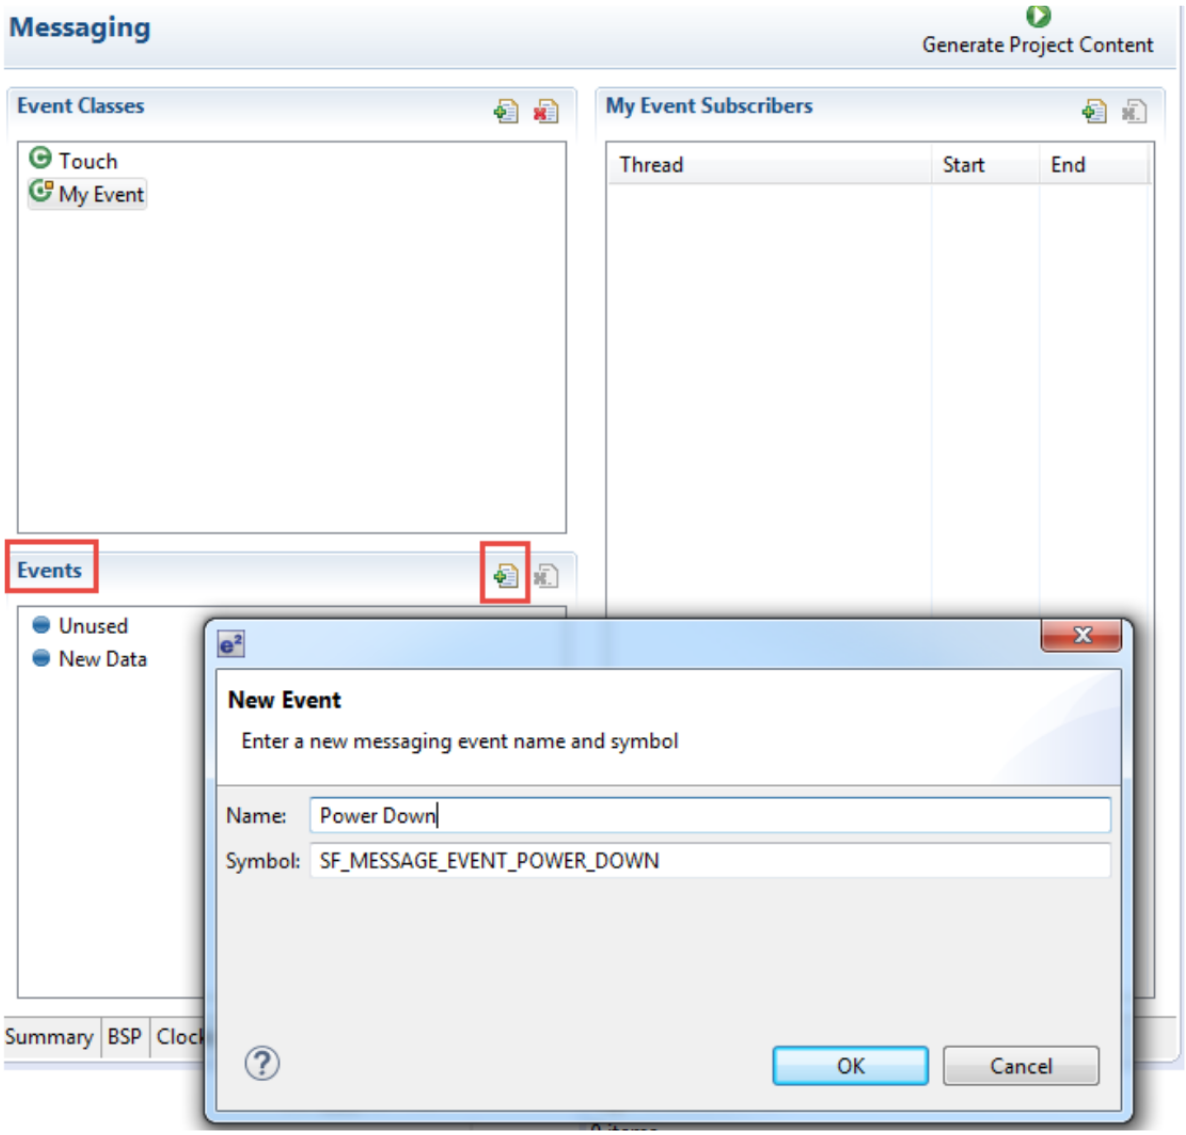

Figure 190: Messaging Framework Module ISDE Event Configuration

Messaging Framework Module Subscriber List

The subscriber list is used for message delivery and is looked up by the framework.

The framework starts to look up the message queues of each subscriber thread from the subscriber group listed in the head of the pointer array to the sf_message_subscriber_list_t instance. The important point of the subscriber list is that it is grouped by event class code (event_class).

When the framework looks up the subscriber list in the post API function at runtime, it compares the Event Class code in the message header (sf_message_header_t::event_b.class), which is included in the message payload data, with the one in the subscriber group instance (event_class). If there is a match, the Framework goes to the next level to get the message queue instance (sf_message_subscriber_t::queue) until the iterations reach number_of_nodes). If there is no match, the framework looks up the next subscriber group and continues until encountering a NULL in the pointer array to the sf_message_subscriber_list_t instance.

In the look-up procedure, the subscriber group listed at the head of the Subscriber List gets the

highest throughput for messaging, but lower subscriber groups encounter a penalty and get lower throughput for messaging.

The subscriber list is the look-up table for all message subscribers. The subscriber list is configured at compile time. It is statically mapped to the memory and looked up by the framework when the post API function is called. The subscriber list allows the framework to determine message queues to deliver a message to. The subscriber list consists of two structures sf_message_subscriber_list_t and sf_message_subscriber_t as shown in the following figure:

- A queue for a subscriber thread is registered in sf_message_subscriber_t instance.
- The instances above for the same event class code are grouped and listed in a pointer array.
- The pointer array for a subscriber group is registered in a sf_message_subscriber_list_t instance.
- The subscriber list is the pointer array to the subscriber group structures. Subscribers are grouped by the event class code.
- The pointer array must be terminated by NULL.

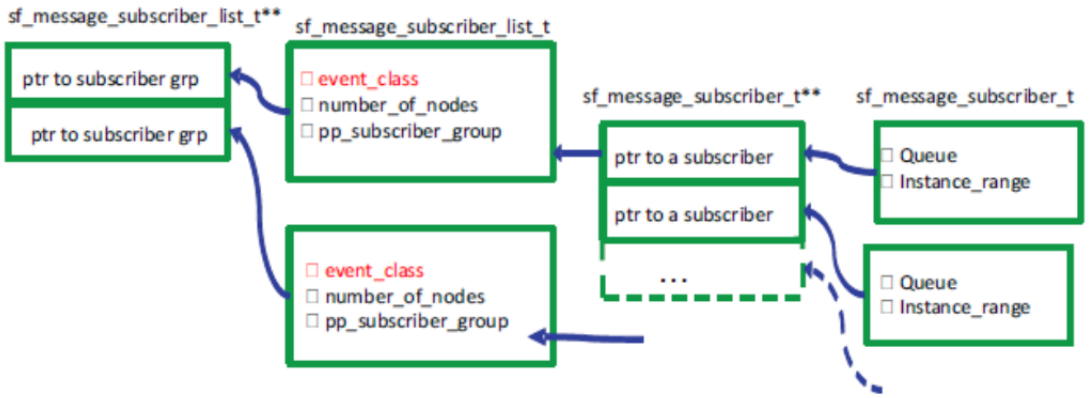

Figure 191: Messaging Framework Module Subscriber List

In the ISDE, you can configure a subscriber grouped by the event class for the thread you named in the **Threads** tab. In the following example, the thread is named "My Thread" in the **Threads** tab. The start and end values reflect the event class instance numbers this thread accepts.

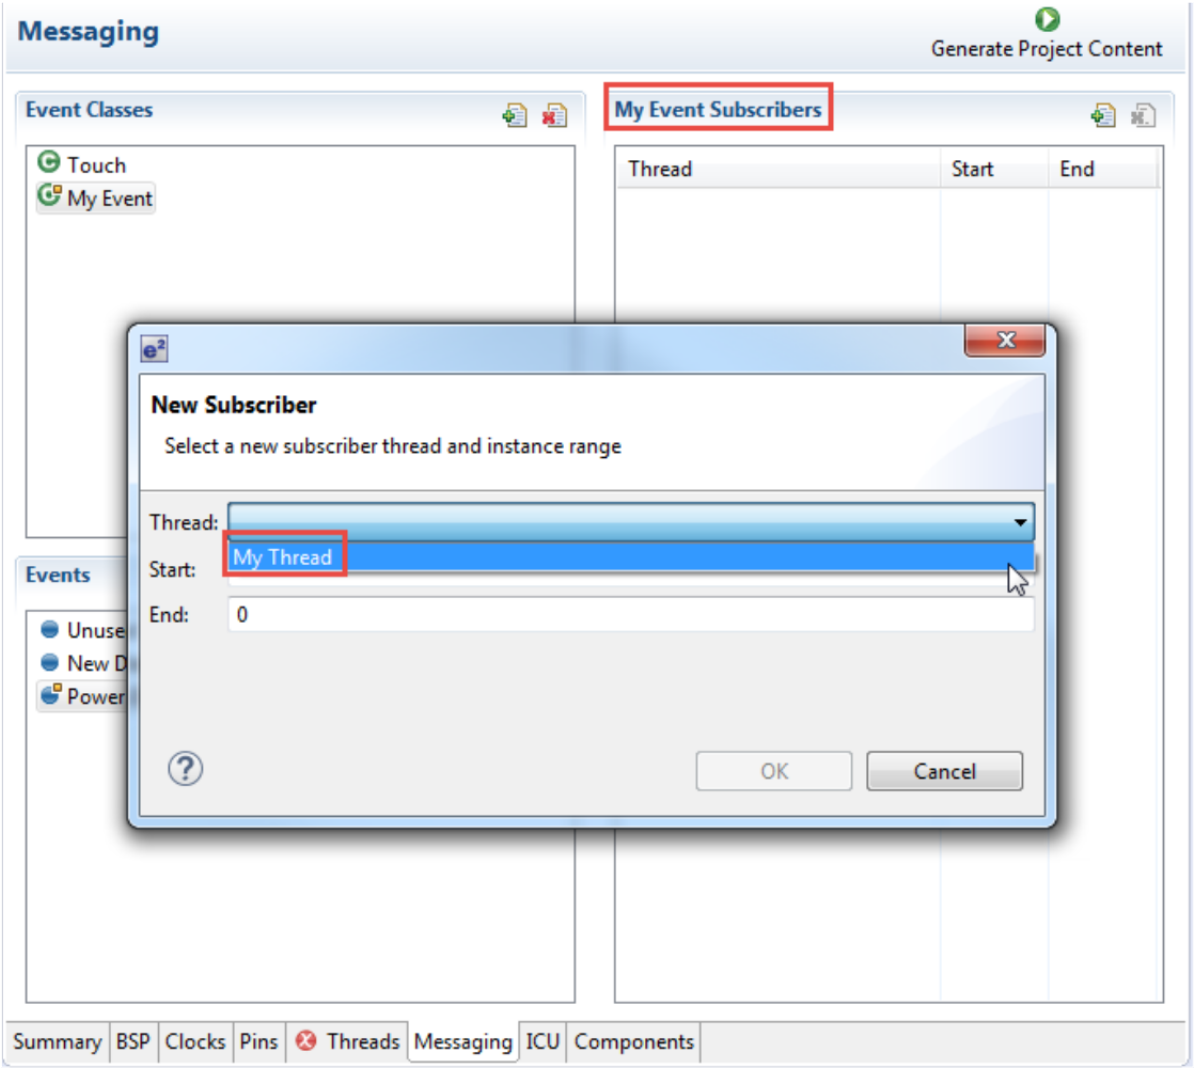

Figure 192: Messaging Framework Module ISDE Subscriber Configuration

Messaging Framework Module Message Payload

The message payload is structured data used by the message producer and the message subscribers to communicate with each other. The message payload contains event class and event code in the common header (sf_message_header_ttype data, see event class and event code) so that a message producer can post a message to the subscribers to inform the subscribers which event happened.

You must define a system specific message payload structure except for modules for which the SSP provides predefined structures such as the Audio Playback Framework module. The message payload can contain additional data, which are required for the event processing, in addition to the common header.

Messaging Framework Module SSP Predefined Payload

The SSP contains the predefined message payload structure sf_audio_playback_data_t type for the Audio Playback Framework module.

The Audio Playback Framework module uses the Messaging Framework internally and defines a

suitable message payload structures. An application thread that posts audio event messages to the Audio Playback Framework module can use sf_audio_playback_api.h.

Messaging Framework Module User-Defined Payload

You must define a message payload structure for each event class code; exceptions include the SSP predefined payloads described previously or payloads that require only the common header. To create a new message payload structure, add a common message header (sf_message_header_t type structure) at the head in the user-specific message payload structure. The size of the header is 4 bytes.

Note

The payload size must not be greater than the buffer size.

The buffer size limit is critical; oversized data written beyond the buffer may destroy data in the block memory pool, which is required by ThreadX kernel. Violating the size limit results in a hard fault exception. The buffer size can be configured insf_message_ctrl_t::buffer_size.

Messaging Framework Module Important Operational Notes and Limitations

Messaging Framework Module Operational Notes

Messaging Framework and OS Message Queue Service

The Messaging Framework module uses the ThreadX primitive-message queue and kernel services and supports some enhancement over the ThreadX RTOS features. For this reason, the Messaging Framework module does not work exactly the same as the ThreadX message-queue service. However, a messaging system with the Messaging Framework module can work simultaneously with the ThreadX message queue services in an application if the two messaging systems are separated.

API Calls Contexts

- The sf_message_api_t::open API can only be called from a thread; it can be called only once per the message framework control block instance. The behavior is undefined if the function is called twice.
- The sf_message_api_t::close API can only be called from a thread.
- The sf_message_api_t::bufferAcquire API can be called from a thread and an ISR.
- The sf_message_api_t::bufferRelease API can only be called from a thread.
- The sf_message_api_t::post API can be called from a thread and an ISR.
- The sf_message_api_t::pend API can be called from a thread and an ISR.

Estimating the Number of Buffers

The number of buffers available to be allocated in the work memory should be estimated properly when designing the messaging system. The number of buffers is estimated as follows:

$$N \approx \frac{W_m}{M_h + B_{ch} + T_v} = \frac{W_m}{M_h + 12\ bytes + 4\ bytes}$$

where:

- N – number of buffers,
- W_m – work memory size (in bytes),
- M_b – message buffer size (in bytes),
- Bcb = 12 bytes – size of buffer control block,
- T_x - 4 bytes – reserved bytes for ThreadX.

The maximum number possible for buffers allocated at the same time equals the total amount of depth of message queues in the system. Ideally, the number of buffers for a robust system should be the sum of the depths of the message queues in the system.

Message Queue Size and Depth Setting

The Messaging Framework module needs a 4-byte memory block on the message queue as it delivers the pointer to the buffer which contains a message payload. For this reason, the size of the message queue is fixed to 4 bytes.

The depth of the message queue is arbitrary, but it should accommodate the number of queued messages at runtime. As a guideline, estimate the value as follows:

$$D \approx \frac{P_{avg}}{S_{avg}}$$

where:

- D – queue depth,
- P_{avg} – average message delivery rate from producers,
- S_{avg} – average event loop completion time in the subscriber.

Messaging Framework Module Limitations

- In a multi-threaded and repeated message transfer application, keep the message Producer thread priority higher than the subscriber thread. So that the producer thread completes all its operation before the subscriber thread starts releasing the received buffer and avoid sending the message to the wrong queue.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.22.4 Including the Messaging Framework Module in an Application

This section describes how to include the Messaging Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Messaging Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Messaging Framework is g_sf_message0. This name can be changed in the associated Properties window.)

Messaging Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_message0 Messaging Framework on sf_message	Threads	**New Stack> Framework> Services> Messaging Framework on sf_message**

When the Messaging Framework on sf_message is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

Note: While using sf_message framework for communication between the multiple threads having different priorities,the priority of the thread in which sf_message stack is added should be kept high.

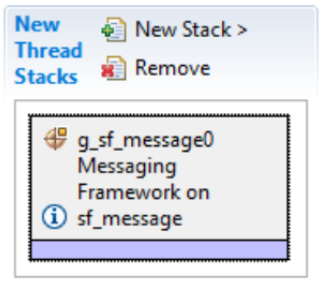

Figure 193: Messaging Framework Module Stack

4.1.22.5 Configuring the Messaging Framework Module

The Messaging Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Messaging Framework Module on sf_message

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Message Queue Depth (Total number of messages to be enqueued in a Message Queue)	16	Specify the size of Thread X Message Queue in bytes for Message Subscribers. This value is applied to all the Message Queues.
Name	g_sf_message0	The name of Messaging Framework module control block instance.
Work memory size in bytes	2048	Specify the work memory size in bytes. Choosing a small number results in a small number of buffers which can be allocated at the same time (You can confirm the total buffer number on: sf_message_ctrl_t:: number_of_buffers). If the value is smaller than the peak number of messages to be posted at the same time, the Framework has a buffer allocation failure affecting system performance.
Pointer to subscriber list array	p_subscriber_lists	Specify the name of pointer to the Subscriber List array.
name of the block pool internally used in the messaging framework	sf_msg_blk_pool	The name of the memory block memory the Framework creates in the control block. This parameter might be useful for debugging purpose but NULL can be specified for saving memory.
Name of generated initialization function	sf_message_init0	Name of generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Messaging Framework Module Creating a Messaging Queue

The messaging configurator automatically creates the message queue for the subscribers.

Messaging Framework Module Configuring an Event Class and Event

To use the Messaging Framework with your own event class, use the **Threads** tab and the **Messaging** tab of the project configurator in the ISDE.

In the **Threads** tab, do the following:

1. Add the Messaging Framework component in the Thread Stacks panel of the **Threads** window.
2. Add a new thread in the **Threads** window and give it a unique name.
3. In the **Messaging** tab (see event class code), do the following:
   a. In the **Event Class** window, add an event.

   b. Enter the name of the event class for your thread to subscribe to in the **New Event Class** dialog box.

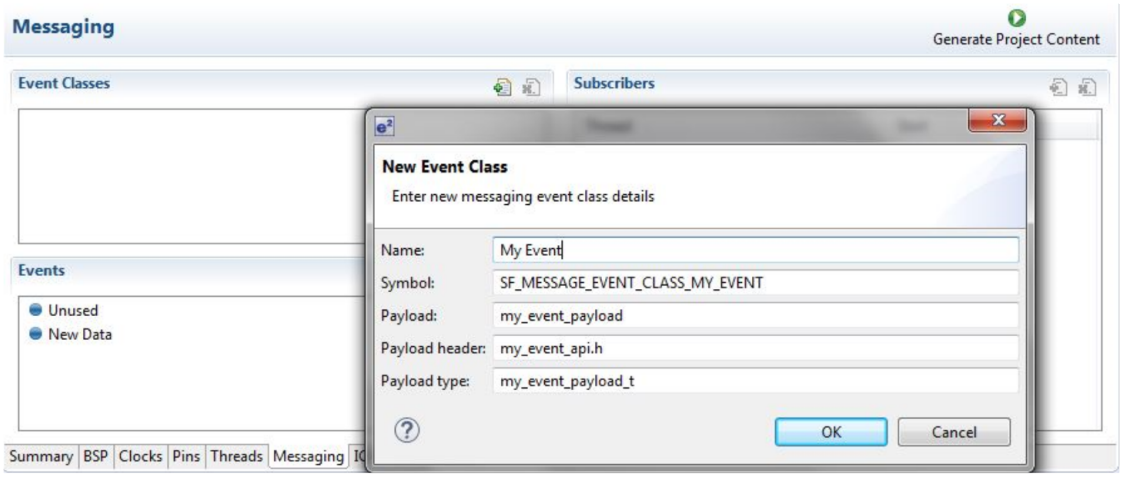

Figure 194: Messaging Framework New Event Class Configuration

4. In the **Events** window, add any events that your application may support (see event code).

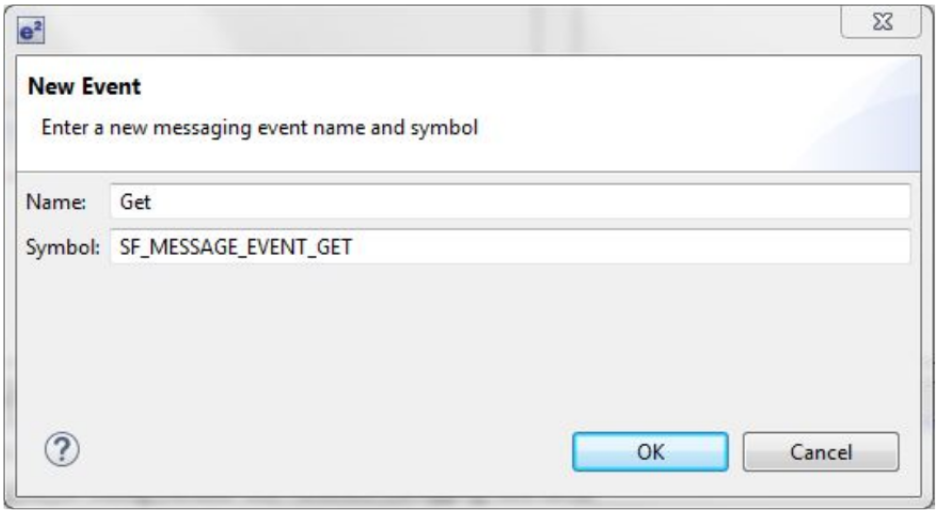

Figure 195: Messaging Framework New Event Configuration

Your custom event class code and event code are stored in a file named sf_message_port.h. The audio playback and the touch event classes are two predefined event classes in the SSP. The Touch Event Class only uses the new data event, SF_MESSAGE_EVENT_NEW_DATA.

Messaging Framework Module Configuring the Subscriber List

In the **Messaging** tab (see also Subscriber List), do the following:

1. Select the event class in the **Event Classes** window and configure a thread for the subscriber list in the event class **Subscribers** window.
2. Select your thread from the drop-down list in the **Threads** dialog box.
3. Next to Start, enter the start number of the event class instance(s). If your system does not use multiple event class instances for the event class, or you are not sure what number to specify, just keep the default number (0.) Allowed values range from 0 to 255.
4. Next to End, enter the last number of the event class instance(s). If your system does not use multiple event class instances for the event class, or you are not sure what number to specify, just keep the default number (0.) Allowed values range from 0 to 255.
5. Click **OK**. A subscriber for your specified event is added in the subscriber list.
6. Repeat these steps for all event class instances if there are more than one.

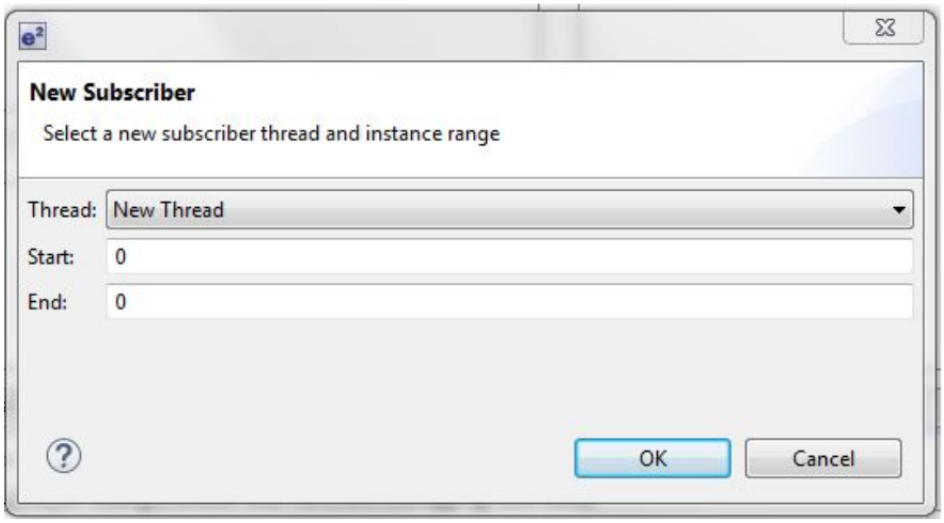

Figure 196: Messaging Framework New Subscriber Configuration

Messaging Framework Module Configuring the Event Class Code and Event Code

Messaging Framework Module Defining the Message Payload

You can define your own message payload structure. Every user-defined message structure must include the sf_message_header_t type structure as one of the members, but the other members are entirely user-definable. The Messaging Framework does not care where the message payload structures are defined. You can include the file which defines your own message payload structure in the source file for your message producer and subscriber threads.

Opening the Messaging Module in the Messaging Framework Module

Configure the sf_message_cfg_t type configuration parameters to match your system. You can generate code for the configuration structure through the Synergy Configuration tool. Add a Messaging Framework component to the thread stacks in the **Threads** tab and modify the properties for the Messaging Framework module in the Properties window. When you press the **Generate**

Project Content button, the code for the Messaging Framework module is generated on the thread code.

Messaging Framework Module Acquiring a Buffer

Before posting a message, an event producer thread must acquire a buffer for the message from the Messaging Framework module. An event producer thread can acquire the buffer by calling sf_message_api_t::bufferAcquire.

When the API function returns SSP_SUCCESS, the buffer with message buffer size in bytes configured on Synergy Configuration tool is allocated in the memory pool managed by the Messaging Framework. The maximum number allowed to be allocated depends on the configuration Work memory size in bytes specified on the Synergy Configuration tool. For the estimation of the maximum number, see *Estimating the Number of Buffers*.

The sf_message_api_t::bufferAcquire API has several options to change the message passing behavior:

- **buffer keep:** This option allows the application thread to hold the buffer not to be released by the API function sf_message_api_t::bufferRelease if set to true. Typically, the buffer is to be released by sf_message_api_t::bufferRelease when the message passing is done; however, in a scenario to have periodical or repeated message passing between threads, we can reuse the same buffer for the messaging without allocating and releasing the buffer each time. Enabling this option reduces the overhead in the buffer allocation/release operation and improve the system throughput.
- **wait_options:** This is the wait time option which is valid if all buffers have been acquired. Any arbitrary thread tick count, TX_WAIT_FOREVER, TX_NO_WAIT can be set for this option. For details, see the tx_block_allocate() description for the ThreadX service call in the *ThreadX User Guide*.

Messaging Framework Module Releasing a Buffer

After message subscriber threads receive a message posted by an event producer, the message subscriber threads must release the buffer to the framework. Buffer releasing is performed by calling sf_message_api_t::bufferRelease. Since the API function can be called multiple times if there are multiple event subscribers in the system, the actual buffer release is performed only by the last message subscriber thread in the event subscribers. For instance, if there were three subscribers in the subscriber group for the event class, the first and second thread which call sf_message_api_t::bufferRelease do not release the buffer. Only the third thread releases the buffer. Note, if the buffer keep option is specified by sf_message_api_t::bufferAcquire, the buffer is never being released except when option SF_MESSAGE_RELEASE_OPTION_FORCED_RELEASE is passed to the API function argument option. (Also see Messaging Framework callbacks for sf_message_api_t::bufferRelease API function usage.)

The API is also used for invoking a user-callback function to create a handshake between an event producer thread and a message subscriber thread.

Posting a message

1. After getting a buffer by sf_message_api_t::bufferAcquire, an event producer can write the message payload data to the buffer location.
2. **ATTENTION**: Writing data to the buffer is the user's responsibility and writing more data than the buffer size causes a fatal error in the Messaging Framework module.
3. Write an event class code to the sf_message_header_t::event_b.class_code in the payload structure.

4. Write an event code to the sf_message_header_t::event_b.code in the payload structure. It is not mandatory to specify this but necessary in most cases.
5. Write an event class instance number to sf_message_header_t::event_b.class_instance. Specify a number from 0 to 255 if your system has multiple instances for an event class. Specify 0 if your system simply uses single event class instance.
6. Post the message by the post API. Note that the pointer to the buffer needs to be casted with sf_message_header_t * type when given to the API. The message will be delivered to the message subscribers which are registered in the message subscriber list. The post API has several options to change the message passing behavior.
    - **Message priority:** Message can take two level message priority, SF_MESSAGE_PRIORITY_NORMAL or SF_MESSAGE_PRIORITY_HIGH. When SF_MESSAGE_PRIORITY_HIGH is specified, the message is queued at the front of the message queue of the message subscriber. This is typically used for the emergency message to make the message subscribers handle the event prior to the events which might have been queued in the message queue.
    - **User-callback function:** This function is registered in the buffer control block of the Messaging Framework module. The callback function is invoked by bufferRelease. This function can be used for handshaking between an event producer thread and a message subscriber thread.
    - **Wait_options:** This is the wait time option which is valid if a message queue of the message subscriber thread is full. Any arbitrary ThreadX tick count, TX_WAIT_FOREVER and TX_NO_WAIT can be set to this option. For details, see the description of tx_queue_send() ThreadX service call in ThreadX User Guide.

Checking for a Pending Message

1. After the Messaging Framework module is opened, the message subscriber threads can wait for a message by calling pend. In general use, the second API argument specifies the pointer to a message queue, which you configured for the message subscriber thread in the Thread Subscribers pane in the Messaging tab, but you can specify the other message queues instead if required.
2. When a message is delivered from an event producer, the thread returns from pend.
3. The API returns the pointer to the buffer which contains the message to the thread through the third argument of the API.
4. The message subscriber casts the pointer above with a pointer type for the user custom message payload structure and does the event processing corresponding to the Event Class code sf_message_header_t::event_b.class_code, Event code sf_message_header_t::event_b.code and the user defined arbitrary data in the message.

Note that pend has the wait_option to change the behavior of the API function:

The fourth argument of **pend** is the wait time option, which is only valid if the message queue of the message subscriber thread is empty. Any arbitrary ThreadX tick count, TX_WAIT_FOREVER, and TX_NO_WAIT can be set to this option. For details, see tx_queue_send()ThreadX service call in the ThreadX User Guide.

Messaging Framework Module Interrupts

The Messaging Framework module does not use any interrupts.

4.1.22.6 Using the Messaging Framework Module in an Application

The steps in using the Messaging Framework on sf_message module in a typical application are:

- Create a Message Queue
- Configure the Event Class and Event
- Configure the Subscriber List
- Configure the Event Class Code and Event Code

Once configuration is complete, the module's APIs can be used in the target application as follows:

1. Initialize the Messaging Framework with the sf_message_api_t::open API
2. Acquire a buffer with the sf_message_api_t::bufferAcquire API
3. Post a message with the sf_message_api_t::post API
4. Check for a pending message with the sf_message_api_t::pend API
5. Release a buffer using the sf_message_api_t::bufferRelease API
6. Close the Messaging Framework with the sf_message_api_t::close API

These common steps are illustrated in a typical operational flow diagram in the following figure:

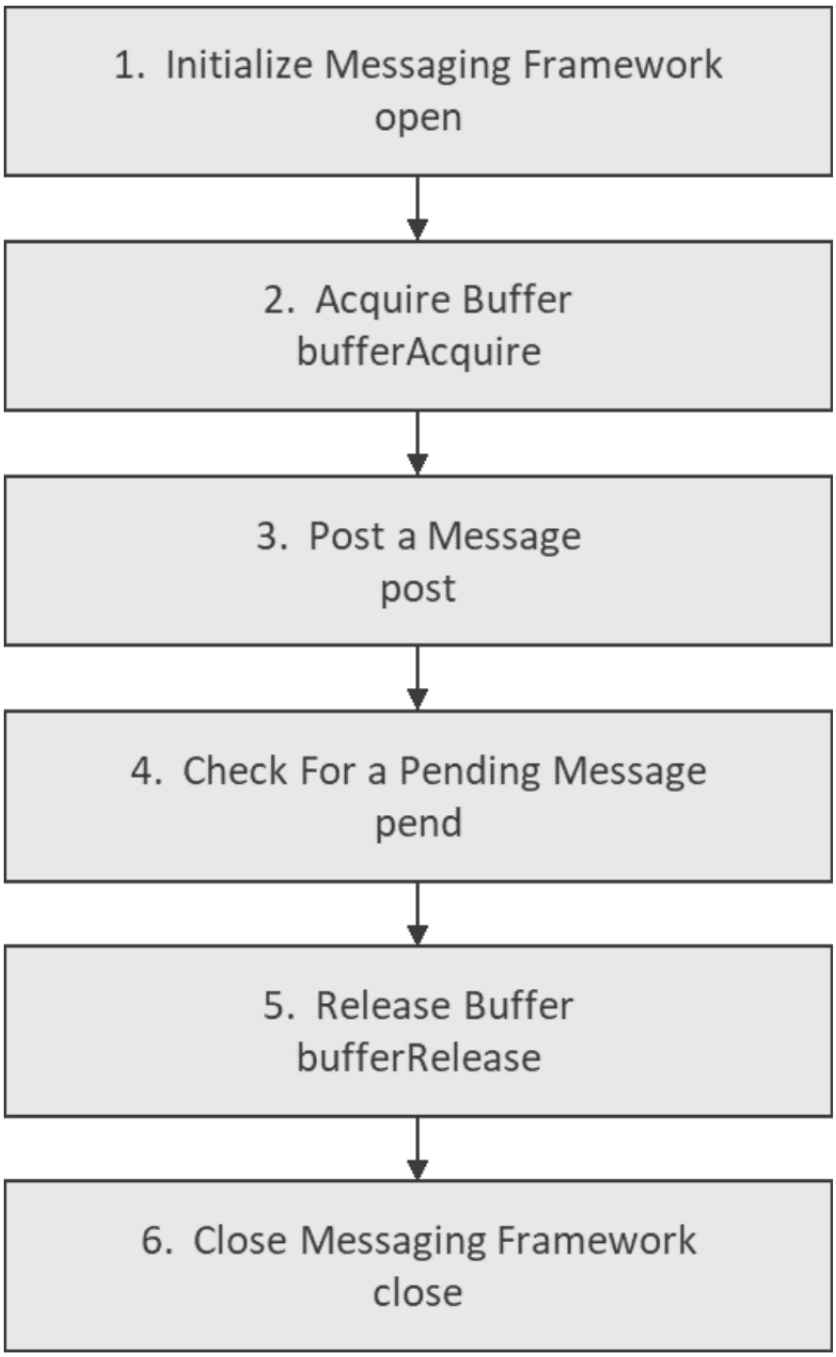

Figure 197: Flow Diagram of a Typical Messaging Framework Module Application

4.1.23 Power Profiles V2 Framework

4.1.23.1 Power Profiles V2 Framework Introduction

The Power Profiles V2 Framework provides a high-level API used to control the system clocks, the I/O ports, the operating modes (indirectly through the clock control) and the low power modes of the

MCU. The Power Profiles V2 Framework, when used with the LPM V2 Driver, CGC Driver and I/O Port Driver, gives the user advanced control over the power consumption of the MCU.

Power Profiles V2 Framework Module Features

- Uses Low Power Modes V2
- Sets CGC clock configuration and I/O Port pin configuration when entering and exiting the configured low power mode
- Supports both threaded and non-threaded operations

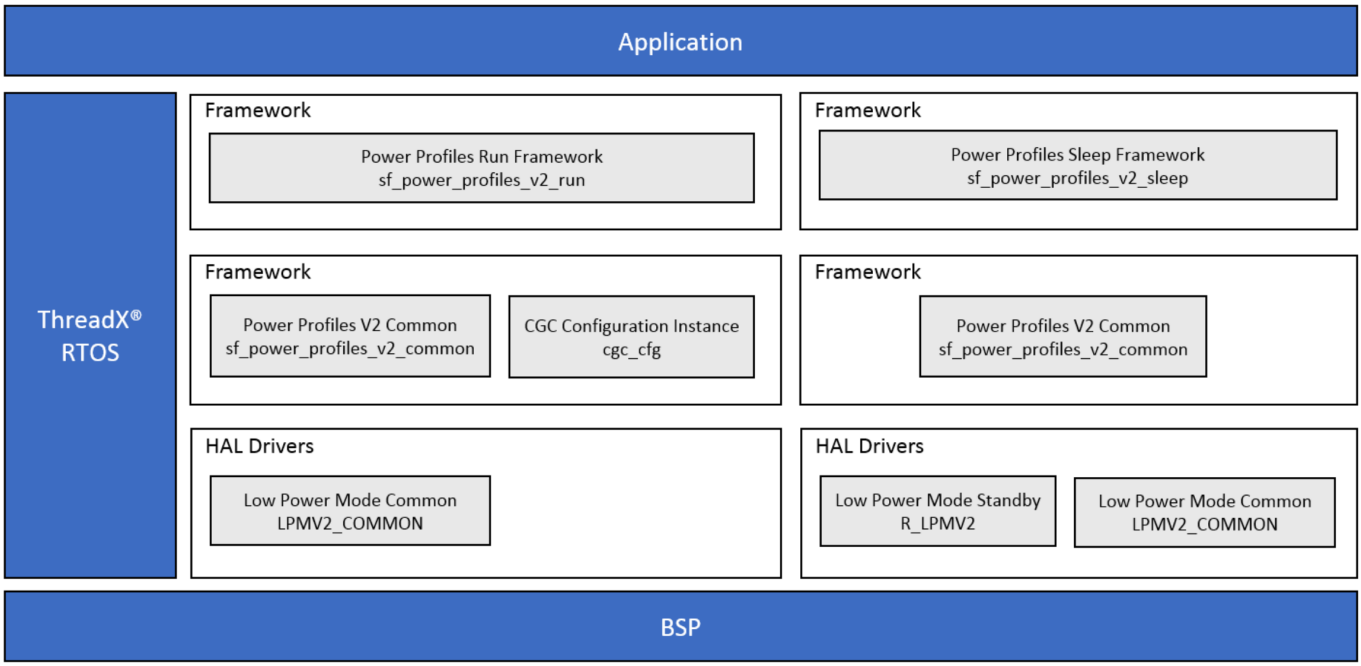

Figure 198: Power Profiles V2 Framework Module Block Diagram

4.1.23.2 Power Profiles V2 Framework Module APIs Overview

There are different low-level LPM V2 HAL modules used in the framework depending on the target MCU (as shown in the following table):

MCU	Driver
S124	S124 Low Power Mode Sleep on r_lpmv2
S124	S124 Low Power Mode Standby on r_lpmv2
S128	S128 Low Power Mode Sleep on r_lpmv2
S128	S128 Low Power Mode Standby on r_lpmv2
S3A3	S3A3 Low Power Mode Sleep on r_lpmv2
S3A3	S3A3 Low Power Mode Standby on r_lpmv2
S3A7	S3A7 Low Power Mode Sleep on r_lpmv2
S3A7	S3A7 Low Power Mode Standby on r_lpmv2
S5D9	S5D9 Low Power Mode Sleep on r_lpmv2

S5D9	S5D9 Low Power Mode Standby on r_lpmv2
S5D9	S5D9 Low Power Mode Deep Standby on r_lpmv2
S7G2	S7G2 Low Power Mode Sleep on r_lpmv2
S7G2	S7G2 Low Power Mode Standby on r_lpmv2
S7G2	S7G2 Low Power Mode Deep Standby on r_lpmv2

Because of the large number of lower level LPM V2 HAL modules available, it would be difficult to identify separate APIs and configuration settings. This module guide only goes into details for the S7G2 MCU. All the APIs and configuration settings are the same (except for those MCUs that do not support Deep Standby). It should be simple to extrapolate to any target MCU.

The Power Profiles defines APIs for common functions such as open, sleep and close. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Power Profiles V2 Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_power_profiles_v2_common.p_api->open(g_sf_power_profiles_v2_low_power_0.p_ctrl, g_sf_power_profiles0.p_cfg); Initialize the Power Profiles V2 Framework.
runApply	g_sf_power_profiles_v2_common.p_api->runApply(g_sf_power_profiles_v2_common.p_ctrl, &g_sf_power_profiles_v2_run_0); Apply the selected run power profile.
lowPowerApply	g_sf_power_profiles_v2_common.p_api->lowPowerApply(g_sf_power_profiles_v2_common.p_ctrl, &g_sf_power_profiles_v2_low_power_0); Apply the selected low power profile.
close	g_sf_power_profiles_v2_common.p_api->close(g_sf_power_profiles_v2_common.p_ctrl); Close the module.
versionGet	g_sf_power_profiles_v2_common.p_api->versionGet(&p_version); Get version and store it in provided pointer p_version.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description

SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_IN_USE	The framework has already been initialized.
SSP_ERR_INVALID_HW_CONDITION	Incompatible system clock configuration.
SSP_ERR_NOT_OPEN	Device not open.
SSP_ERR_UNSUPPORTED	The function is not supported by the module.
SSP_ERR_INTERNAL	Internal error.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.23.3 Power Profiles V2 Framework Module Operational Overview

The Power Profiles V2 Framework provides a high-level API used to control the system clocks, the I/O ports, the operating modes (indirectly through the clock control), and the low power modes of the MCU. The Power Profiles V2 Framework, when used with the LPM V2 Driver, CGC Driver, and I/O Port Driver, gives the user advanced control over the power consumption of the MCU.

The Power Profiles V2 Framework provides 2 main functions to control the MCU power consumption, sf_power_profiles_v2_api_t::runApply and sf_power_profiles_v2_api_t::lowPowerApply. The runApply() function uses a CGC Clocks configuration and an I/O Port pin configuration to set the system clocks and I/O Port pins of the MCU. The lowPowerApply() function uses a LPM V2 configuration and two I/O Port configuration to set the low power mode and I/O Port pins before entering the configured low power mode and after waking from the low power mode. See LPM V2 module overview and the MCU hardware manual for details about the available low power modes.

The Power Profiles V2 Framework uses the LPM V2, IOPORT, and CGC Drivers of the Synergy Software Package and provides an easy-to-use software interface to control the power consumption of the MCU.

Operational Description

The Power Profiles V2 Framework configures the system in both a Run state and a Low Power state. The system clocks, I/O pins, and low power mode of the MCU can all be handled and controlled using the Power Profiles V2 Framework.

The Power Profiles V2 Framework API function sf_power_profiles_v2_api_t::open initializes the Power Profiles V2 Framework internal variables, instance variables, and the LPM V2 Driver. If the project uses ThreadX, the Framework will ensure safe use in a multi-threaded environment.

The runApply() and lowPowerApply() functions optionally use I/O Port pin configurations to provide control of the MCU I/O Ports. The lowPowerApply() function can use 2 pin configurations: one to set the pins to a state appropriate for the low power mode when the MCU will not be executing instructions, and a second for after waking from the low power mode, when instruction execution resumes.

The Power Profiles V2 Framework runApply() function applies the user-defined optional pin configuration, then applies the user-defined CGC clocks configuration. The user can switch clocks on and off, change clock dividers, and switch the system clocks using the CGC Clocks configuration structure.

The Power Profiles V2 Framework API function runApply() performs the following tasks in order:

1. If the project uses ThreadX, the function will get the ThreadX mutex prior to calling any lower level driver.
2. Apply the user-specified optional pin configuration.
3. Apply the user-specified CGC Clocks configuration.
4. If the project uses ThreadX, the function will return the ThreadX mutex.

The lowPowerApply() function uses an LPM V2 configuration to set the low power mode, the triggers for waking from the low power mode, the state of bus pins, and other settings that are MCU specific. The lowPowerApply() function can optionally use an application callback function. The prototype can be found in /src/synergy_gen/hal_data.c or /src/synergy_gen/<thread name>.c.

The Power Profiles V2 Framework lowPowerApply() function performs the following tasks in order:

1. If the project uses ThreadX, the function will get the ThreadX mutex prior to calling any lower level driver.

2. Apply the optional user-specified low power entry pin configuration.

3. Call the user specified callback function with the enumeration SF_POWER_PROFILES_V2_EVENT_PRE_LOW_POWER.

4. Apply the user-specified low power mode configuration. Any valid LPM V2 configuration can be used.

5. Enter the low power mode.

6. If the low power mode chosen was other than Deep Standby the MCU will resume execution of code from the same point once the wakeup trigger is detected. (If the LPM V2 low power mode configuration was Deep Standby, the MCU will not resume code execution but will instead go through a soft reset once the wakeup trigger is detected.)

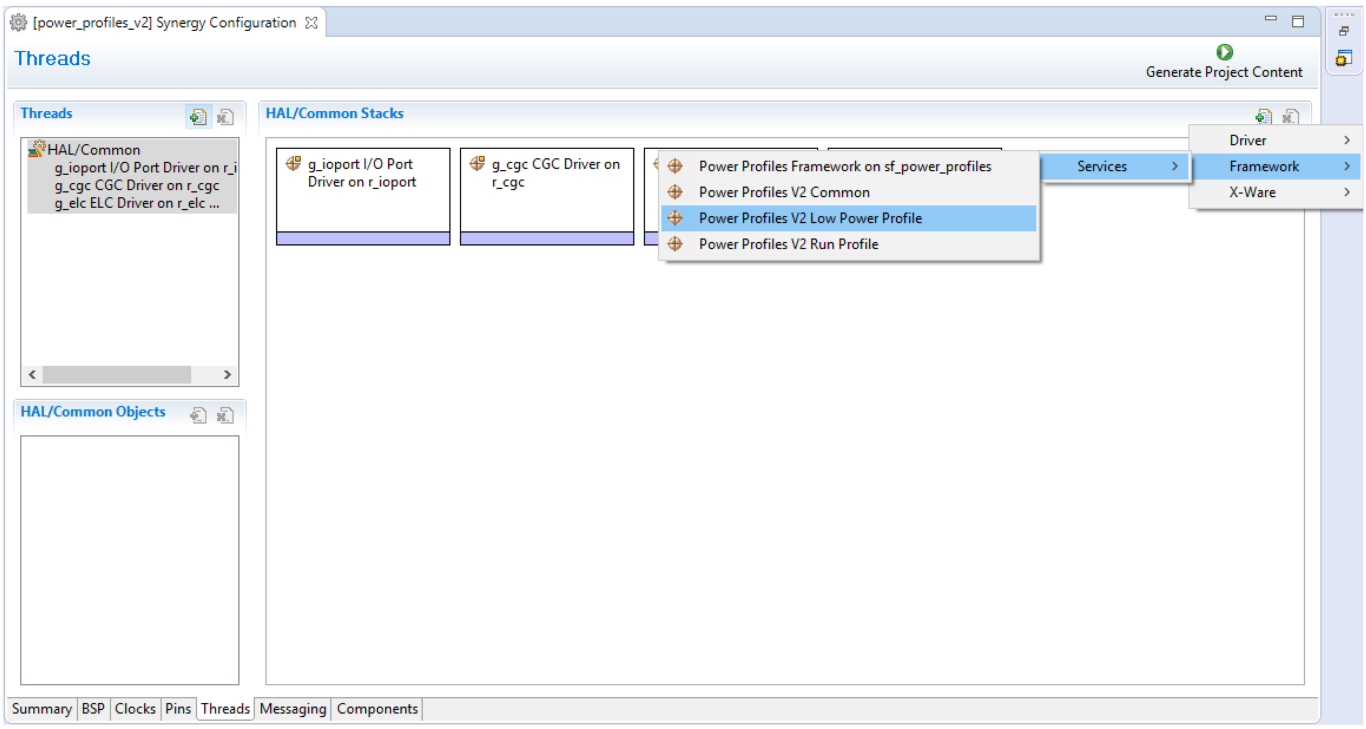
7. Apply the optional user-specified low power exit pin configuration.

8. Call the user specified callback function with the enumeration SF_POWER_PROFILES_V2_EVENT_POST_LOW_POWER.

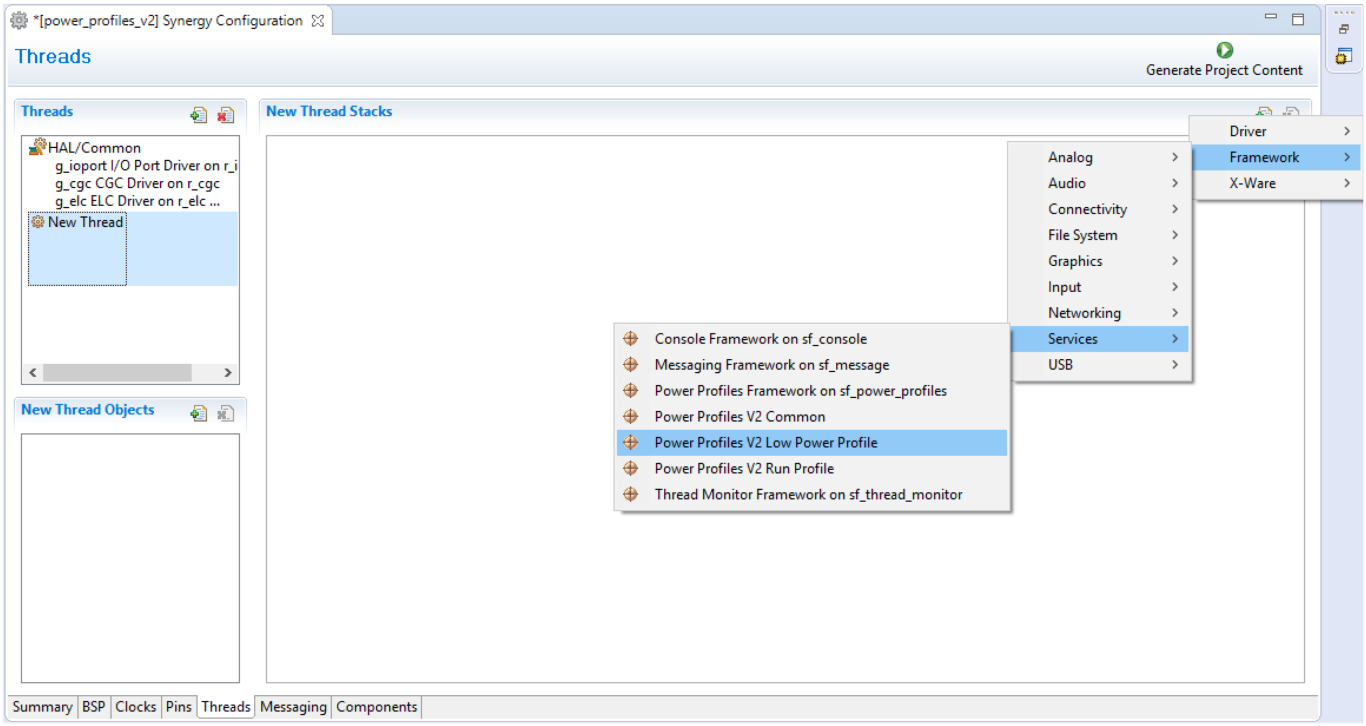
9. If the project uses ThreadX, the function will return the ThreadX mutex.

The Power Profiles V2 Run or Low Power profiles should be added to the project by the user. The Power Profiles V2 common module will be added automatically.

Outside of a thread:

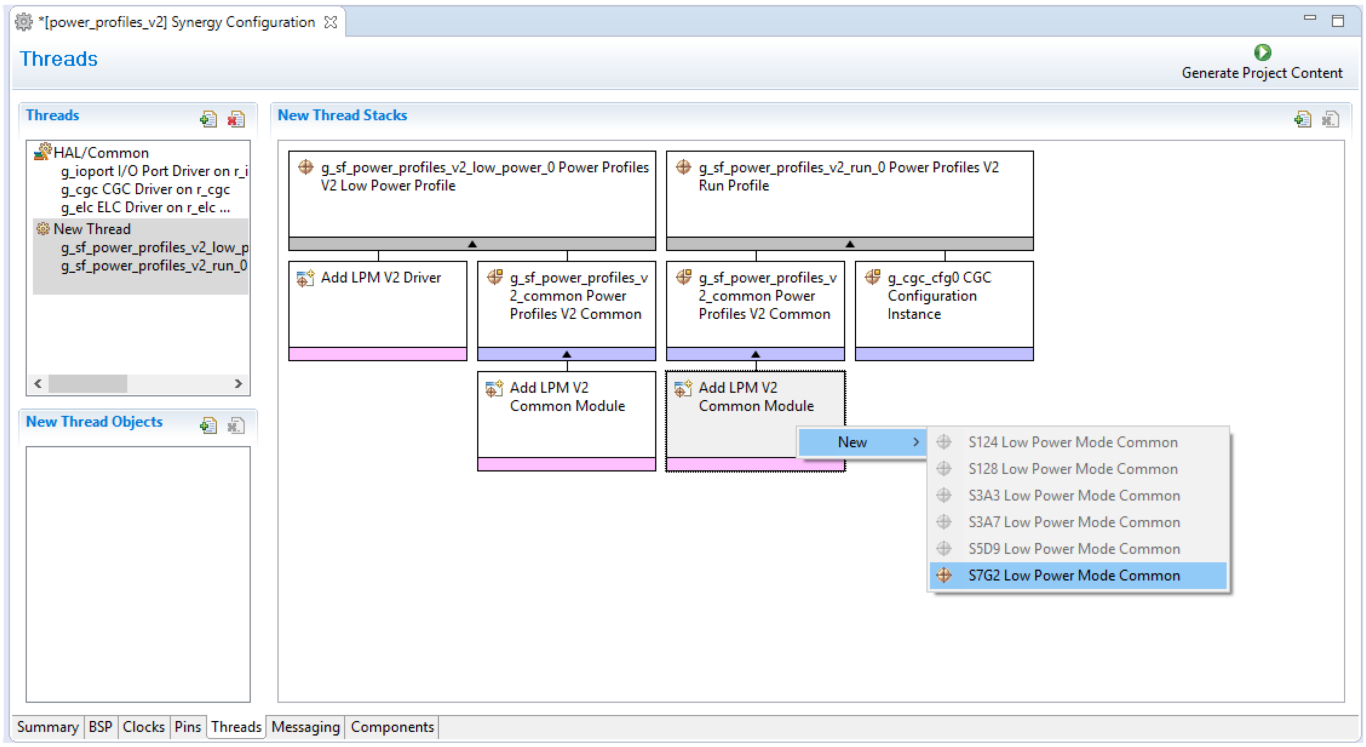


Within a thread:

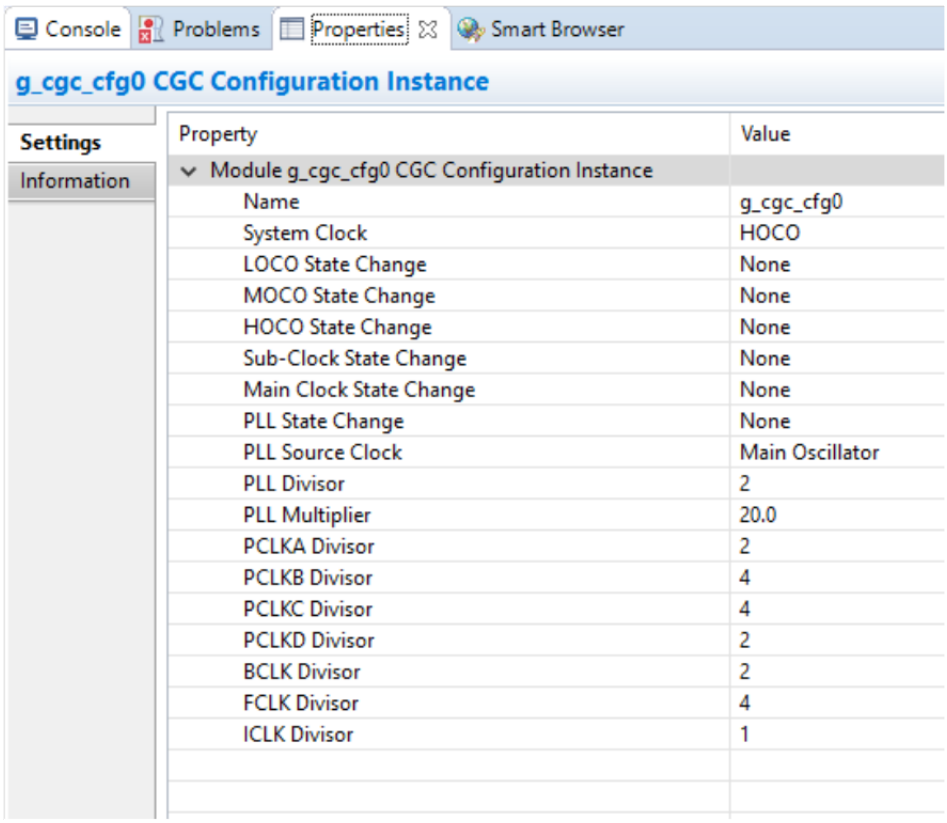


After adding a Power Profiles V2 Run or Low Power Profile, you will need to add an LPM V2 Common

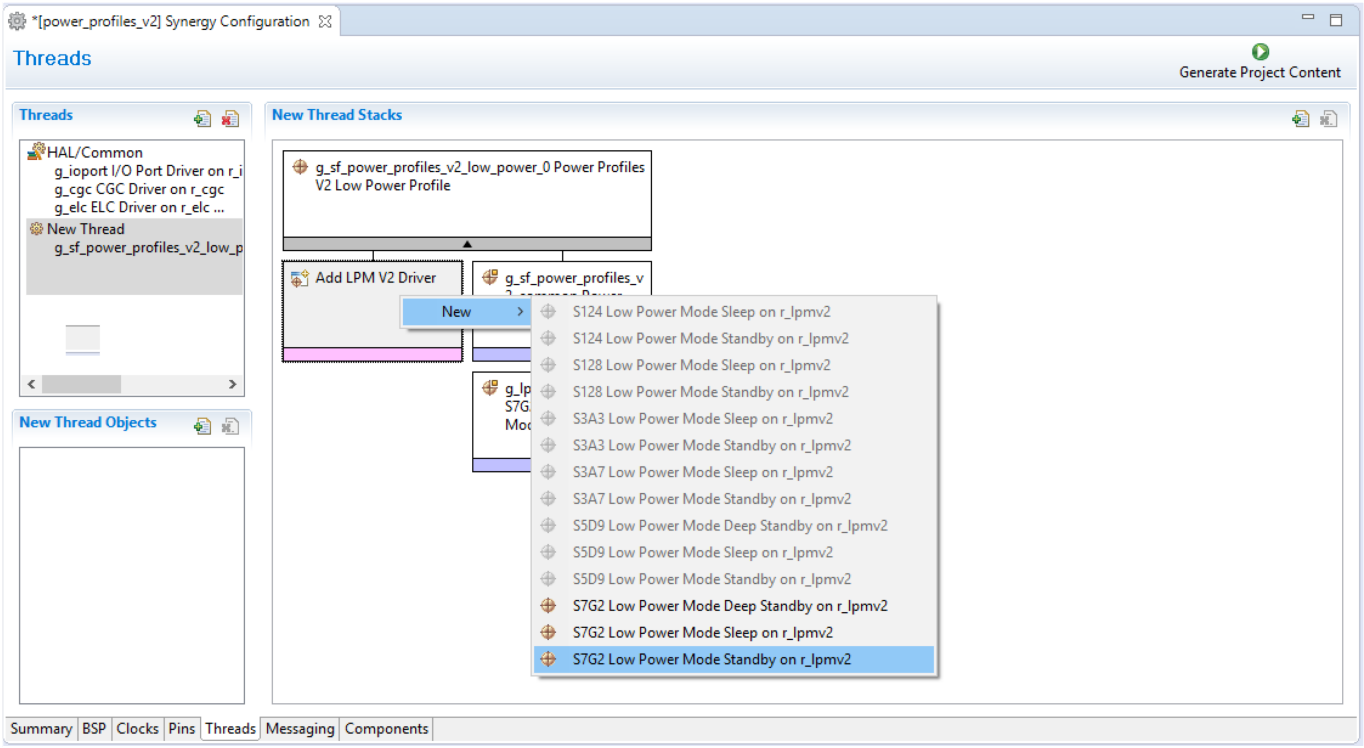
module. If an LPM V2 Common instance already exists in the project, it will be used. A Power Profiles V2 Run Profile does not directly use the LPM V2, but it is still a dependency for a successful build.



A Power Profiles V2 Run Profile depends upon a CGC Clocks Configuration. The configuration options of the CGC Clocks Configuration instance are provided below. If a CGC Clocks Configuration instance is not already present in the project, it will be automatically added. If one is present, it could be used instead. Controlling system clocks is a critical part of controlling power consumption of an MCU. See the CGC usage notes for more information.



The Power Profiles V2 Low Power Profile uses an LPM V2 standby instance, but an LPM V2 deep standby instance or LPM V2 sleep instance could be used instead depending on which MCU is currently being used.



The LPM V2 instance's properties can be configured by selecting the instance and reviewing the Properties pane.

Configuring the Pins for the Power Profiles V2 Framework

Optional: Create additional I/O Port pin configurations using the **Pins** tab as follows:

1. In the top-level directory of your project, find the file with file extension *.pincfg.

2. Make a copy of this file and rename it, keeping the new file in the same top-level directory of the project.

3. The new file is now available as an option on the Pins tab of the Synergy Configuration. Look for the file name in the drop down list on the Pins tab below "Select pin configuration".

4. Check the Generate data checkbox and type in a pin configuration name. The checkbox and text entry can be found to the right of the pin configuration drop down.

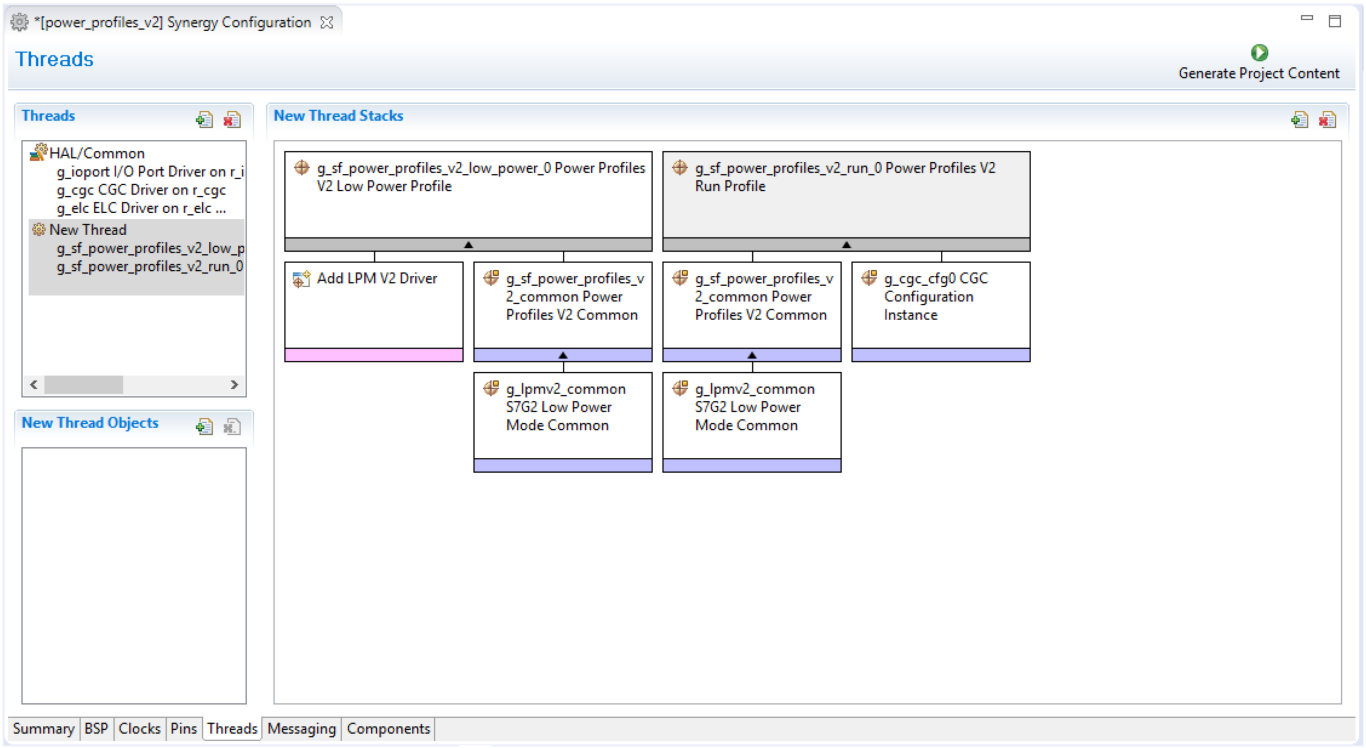
5. Configure the pins as desired for either a Run or Low Power Profile.

6. Save the project configuration and Generate Project Content.

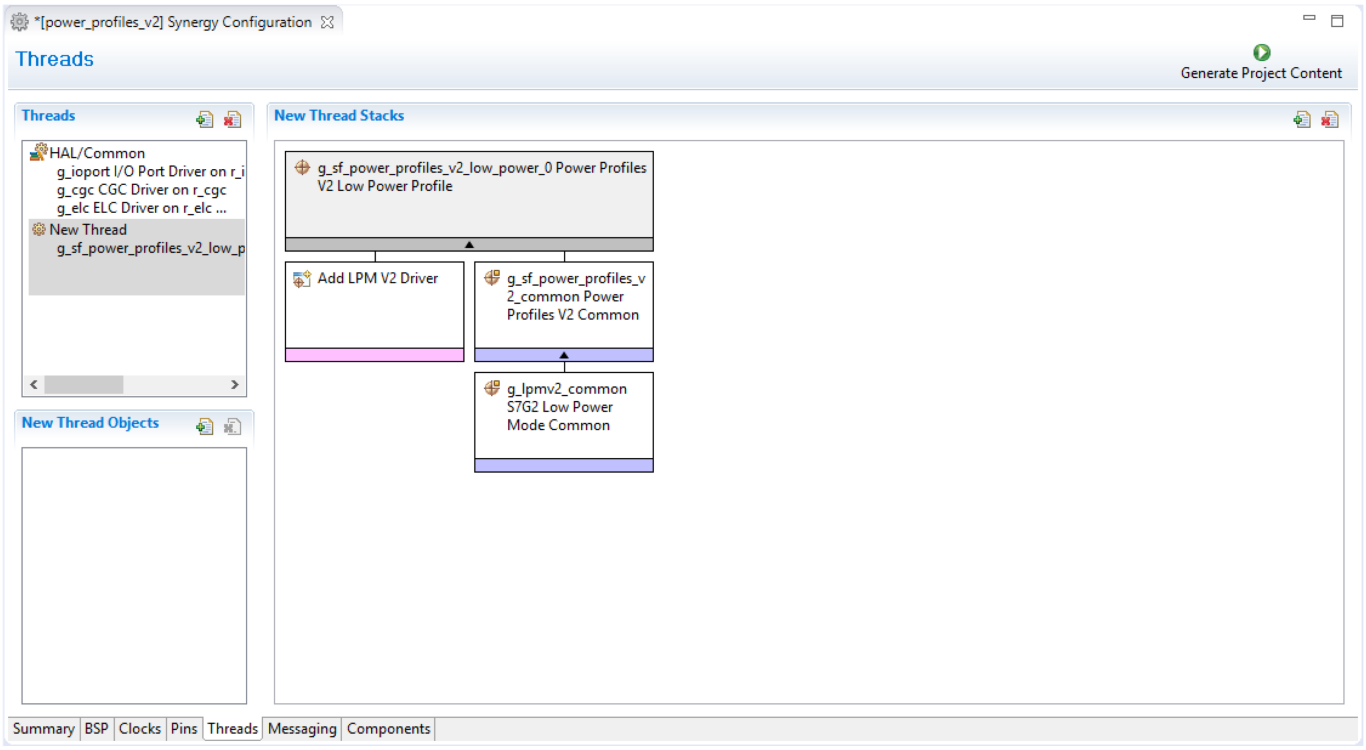
7. To view the pin configuration that was generated, look in the file {project_directory}/src/synergy_gen/pin_data.c for the ioport_cfg_t structure of the same name as entered in the text box.

8. Add the name of the ioport_cfg_t structure to one of the pin configuration table entries for a Run or Low Power Profile.

For a Power Profiles V2 Run Profile:



For a Power Profiles V2 Low Power Profile:



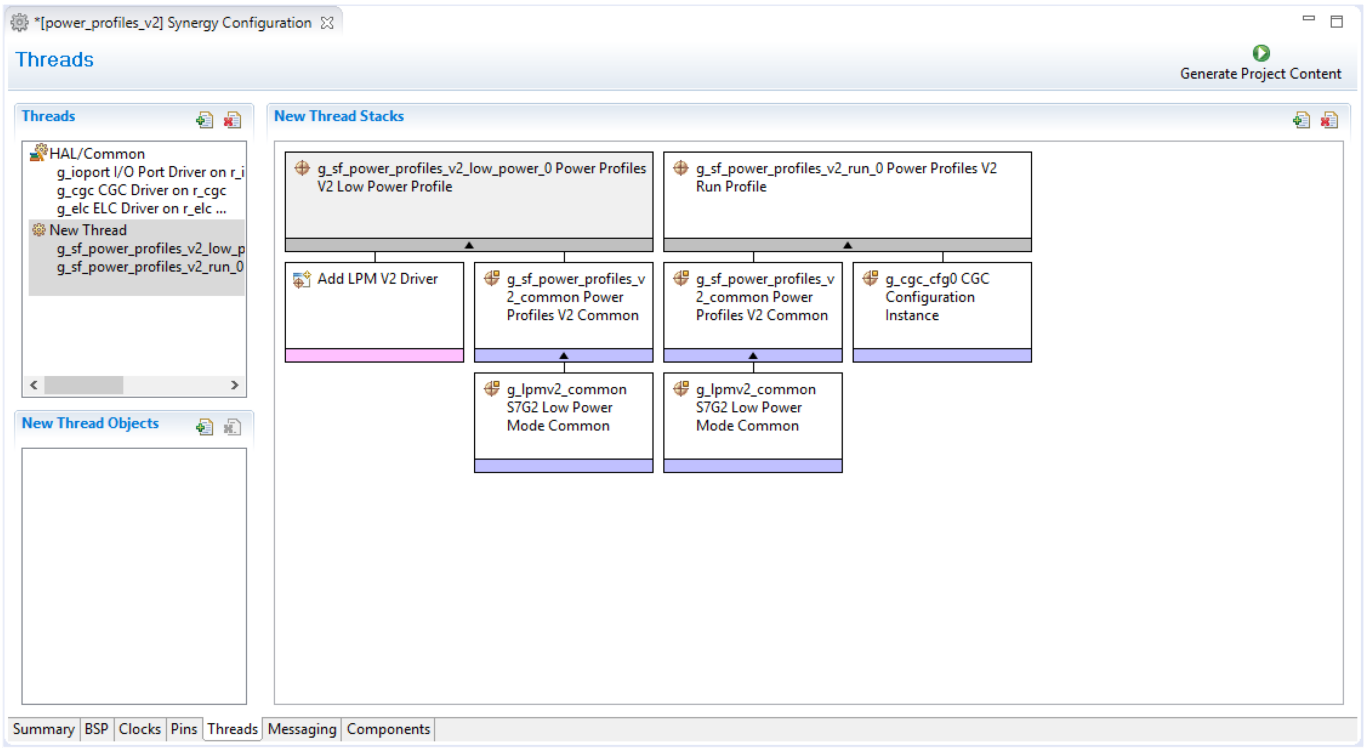
Configuring the Interrupts for the Power Profiles V2 Framework

The Power Profiles V2 Framework does not use any interrupts directly, although any interrupt is capable of waking the MCU while in Sleep mode. This is handled through the LPM V2 driver configuration.

Configuring the Power Profiles V2 Callbacks

Power Profiles V2 Low Power Profiles can notify the application before entering the low power mode and after waking from low power mode. The prototype can be found in /src/hal_data.c or /src/synergy_gen/<thread name>.c.

Fill in the callback used by the Power Profiles V2 Low Power Profile:



Configuring the Low Power Module Parameters

See the LPM V2 usage notes for an in depth description of how to use LPM V2.

Power Profiles V2 Framework Module Important Operational Notes and Limitations

Power Profiles V2 Framework Module Operational Notes

- An LPM V2 Driver instance is required to create Power Profiles V2 applications. The CGC driver is included in a Synergy project by default. To use the Power Profiles V2 runApply() function, another instance of the CGC Driver is required in order to create a CGC Clocks configuration. Since the CGC Driver is included in all Synergy projects by default, this does not add to the code size of the project.
- The I/O Port pin configurations can be created without adding an additional instance of the I/O Port driver.

- When used with ThreadX, this framework uses ThreadX intrinsic objects like mutexes. Operation with ThreadX is optional.
- Power Profiles V1 and Power Profiles V2 cannot be used in the same project. For all new projects, it is recommended that applications use Power Profiles V2.

Power Profiles V2 Framework Module Limitations

The Power Profiles V2 Framework does not handle starting or stopping MCU peripherals.

The Power Profiles V2 Framework open function will not be called automatically prior to main if the project does not use ThreadX. The initialization must be done explicitly by calling g_common_init() or by explicitly calling the sf_power_profiles_v2_api_t::open API. This is not a Power Profiles V2 limitation but a result of any Framework module that supports being used without an RTOS.

```
#include "hal_data.h"
void hal_entry(void)
{
    g_common_init();
    g_sf_power_profiles_v2_common.p_api->runApply(
        g_sf_power_profiles_v2_common.p_ctrl,
        &g_sf_power_profiles_v2_run_0);
    g_sf_power_profiles_v2_common.p_api->lowPowerApply(
        g_sf_power_profiles_v2_common.p_ctrl,
        &g_sf_power_profiles_v2_low_power_0);
    g_sf_power_profiles_v2_common.p_api->close(g_sf_power_profiles_v2_common.p_ctrl);
}
```

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.23.4 Including the Power Profiles V2 Framework Module in an Application

This section describes how to include the Power Profiles V2 Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Power Profiles V2 Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Power Profiles V2 Framework module is sf_power_profiles_v2_0. This name can be changed in the associated Properties window.)

Power Profiles V2 Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_power_profiles_low_power_0 Power Profiles V2 Low Power Profile	Threads	**New Stack> Framework> Services> Power Profiles V2 Low Power Profile**
g_sf_power_profiles_run_0 Power Profiles V2 Run Profile	Threads	**New Stack> Framework> Services> Power Profiles V2 Run Profile**

When the Power Profiles V2 Framework module on sf_power_profiles_v2 is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

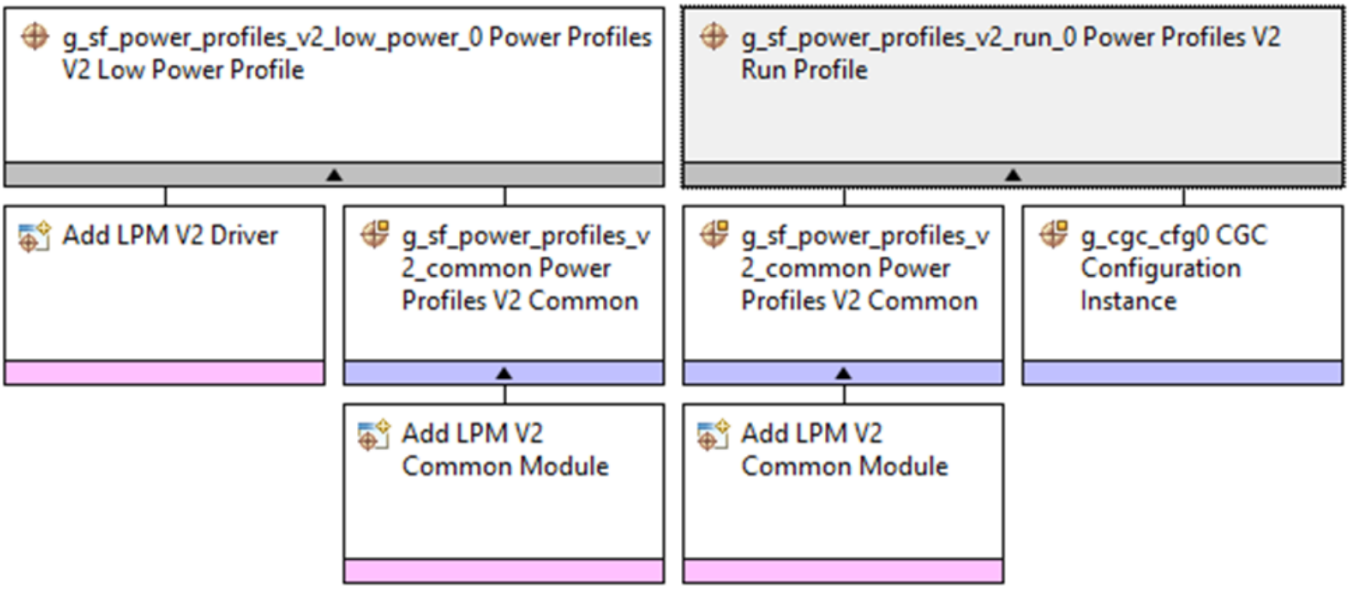


Figure 199: Power Profiles V2 Framework Module Stack

4.1.23.5 Configuring the Power Profiles V2 Framework Module

The Power Profiles V2 Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

There are two different stack selections for the Power Profiles V2 Framework, the Run Profile and the Low Power Profile. Their respective configuration settings will be covered separately in the following sections.

Configuring the Power Profiles V2 Run Profile

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module.

Configuration Settings for the Power Profiles V2 Run Profile

ISDE Property	Value	Description
Name	g_sf_power_profiles_v2_run_0	Module name.
Pin configuration table	NULL	Pin configuration table selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Power Profiles V2 Common

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_power_profiles_v2_common	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the CGC Configuration Instance

ISDE Property	Value	Description
Name	g_cgc_cfg0	Module name.
System Clock	HOCO, MOCO, LOCO, Main Oscillator, Sub Clock, PLL Default: HOCO	System clock selection.

LOCO State Change	None, Start, Stop Default: None	LOCO state change selection.
MOCO State Change	None, Start, Stop Default: None	MOCO state change selection.
HOCO State Change	None, Start, Stop Default: None	HOCO state change selection.
Sub-Clock State Change	None, Start, Stop Default: None	Sub-clock state change selection.
Main Clock State Change	None, Start, Stop Default: None	Main clock state change selection.
PLL State Change	None, Start, Stop Default: None	PLL state change selection.
PLL Source Clock	HOCO, MOCO, LOCO, Main Oscillator, Sub Clock, PLL Default: HOCO	PLL source clock selection.
PLL Divisor	1, 2, 3, 4 Default: 1	PLL divisor seiection.
PLL Multiplier	10.0, 10.5, 11.0, 11.5, 12.0, 12.5, 13.0, 13.5, 14.0, 14.5, 15.0, 15.5, 16.0, 16.5, 17.0, 17.5, 18.0, 18.5, 19.0, 19.5, 20.0, 20.5, 21.0, 21.5, 22.0, 22.5, 23.0, 23.5, 24.0, 24.5, 25.0, 25.5, 26.0, 26.5, 27.0, 27.5, 28.0, 28.5, 29.0, 29.5, 30.0, 31.0 Default: 10.0	PLL multiplier selection.
PCLKA Divisor	1, 2, 4, 8, 16, 64 Default: 1	PCLKA divisor selection.
PCKLB Divisor	1, 2, 4, 8, 16, 64 Default: 1	PCKLB divisor selection.
PCLKC Divisor	1, 2, 4, 8, 16, 64 Default: 1	PCLKC divisor selection.

PCLKD Divisor	1, 2, 4, 8, 16, 64 Default: 1	PCLKD divisor selection.
BCLK Divisor	1, 2, 4, 8, 16, 64 Default: 1	BCLK divisor selection.
FCLK Divisor	1, 2, 4, 8, 16, 64 Default: 1	FCLK divisor selection.
ICLK Divisor	1, 2, 4, 8, 16, 64 Default: 1	ICLK divisor selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Lower Power Mode Common

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_lpmv2_common	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Power Profiles V2 Low Power Profile

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the Thread Stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the Power Profiles V2 Low Power Profile

ISDE Property	Value	Description
Name	g_sf_power_profiles_v2_low_power_0	Module name.
Callback (Low Power Exit Event N/A when using Deep Software Standby)	NULL	Callback selection.
Low power entry pin configuration table	NULL	Low power entry pin configuration table selection.

Low power exit pin configuration table	NULL	Low power exit pin configuration table selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Low Power Mode Deep Standby

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_lpmv2_deep_standby	Module name.
Output port state in standby and deep standby, applies to address output, data output, and other bus control output pins	High impedance state, No change Default: No change	Output port state selection.
Maintain or reset the IO port states on exit from deep standby mode	Maintain the IO port states, Reset the IO port states Default: Maintain the IO port states	Maintain or reset the IO port states selection.
Internal power supply control in deep standby mode	Maintain the internal power supply, Cut the power supply to standby RAM, low-speed on-chip oscillator, AGTn, and USPFS/HS resume detecting unit, Cut the power supply to LVDn, standby RAM, low-speed on-chip oscillator, AGTn, and USBFS/HS resume detecting unit Default: Maintain the internal power supply	Internal power supply control selection.
IRQ0-15	Enabled, Disabled Default: Disabled	IRQ0-15 selection.
IRQ0-15 Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	IRQ0-15 Edge selection.
LVD1	Enabled, Disabled Default: Disabled	LVD1 selection.

LVD1 Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	LVD1 Edge selection.
LVD2	Enabled, Disabled Default: Disabled	LVD2 selection.
LVD2 Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	LVD2 Edge selection.
RTC Interval	Enabled, Disabled Default: Disabled	RTC Interval selection.
RTC Alarm	Enabled, Disabled Default: Disabled	RTC Alarm selection.
NMI	Enabled, Disabled Default: Disabled	NMI selection.
NMI Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	NMI Edge selection.
USBFS	Enabled, Disabled Default: Disabled	USBFS selection.
UBSHS	Enabled, Disabled Default: Disabled	UBSHS selection.
AGT1	Enabled, Disabled Default: Disabled	AGT1 selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Low Power Mode Sleep

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_lpmv2_sleep0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Low Power Mode Standby

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_lpmv2_standby0	Module name.
Choose the low power mode	Standby, Standby with snooze Enabled Default: Standby	Low power mode selection.
Output port state in standby and deep standby, applies to address output, data output, and other bus control output pins	High impedance state, No change Default: No change	Output port state selection.
IRQ1-15	Enabled, Disabled Default: Disabled	IRQ1-15 selection.
IWDT	Enabled, Disabled Default: Disabled	IWDT selection.
Key Interrupt	Enabled, Disabled Default: Disabled	Key Interrupt selection.
LVD1 Interrupt	Enabled, Disabled Default: Disabled	LVD1 Interrupt selection.
LVD2 Interrupt	Enabled, Disabled Default: Disabled	LVD2 Interrupt selection.
Analog Comparator High-speed 0 Interrupt	Enabled, Disabled Default: Disabled	Analog Comparator High-speed 0 Interrupt selection.
RTC Alarm	Enabled, Disabled Default: Disabled	RTC Alarm selection.
RTC Period	Enabled, Disabled Default: Disabled	RTC Period selection.
USB High-speed	Enabled, Disabled Default: Disabled	USB High-speed selection.

USB Full-speed	Enabled, Disabled Default: Disabled	USB Full-speed selection.
AGT1 underflow	Enabled, Disabled Default: Disabled	AGT1 underflow selection.
AGT1 Compare Match A	Enabled, Disabled Default: Disabled	AGT1 Compare Match A selection.
AGT1 Compare Match B	Enabled, Disabled Default: Disabled	AGT1 Compare Match B selection.
12C 0	Enabled, Disabled Default: Disabled	12C 0 selection.
Snooze Entry Source	RXD0 falling edge, IRQ0-IRQ15, KINT, ACMPHS0, RTC Alarm, RTC Period, AGT1 Underflow, AGT1 Compare Match A, AGT1 Compare Match B Default: RXD0 falling edge	Snooze Entry Source selection.
AGT1 Underflow	Enabled, Disabled Default: Disabled	AGT1 Underflow selection.
DTC Transfer Completion	Enabled, Disabled Default: Disabled	DTC Transfer Completion selection.
DTC Transfer Completion Negated Signal	Enabled, Disabled Default: Disabled	DTC Transfer Completion Negated Signal selection.
ADC0 Compare Match	Enabled, Disabled Default: Disabled	ADC0 Compare Match selection.
ADC0 Compare Mismatch	Enabled, Disabled Default: Disabled	ADC0 Compare Mismatch selection.
ADC1 Compare Match	Enabled, Disabled Default: Disabled	ADC1 Compare Match selection.
ADC1 Compare Mismatch	Enabled, Disabled Default: Disabled	ADC1 Compare Mismatch selection.
SCI0 Address Match	Enabled, Disabled Default: Disabled	SCI0 Address Match selection.

DTC state in Snoooze Mode	Enabled, Disabled Default: Disabled	DTC state in Snoooze Mode selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Power Profiles V2 Common

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_sf_power_profiles_v2_common	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Low Power Mode Common

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_lpmv2_common	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Power Profiles V2 Framework Module Clock Configuration

The Power Profiles V2 framework does not require any specific clock settings

Power Profiles V2 Framework Module Pin Configuration

The application may optionally maintain the I/OPort state during a low power mode.

4.1.23.6 Using the Power Profiles V2 Framework Module in an Application

The typical steps in using the Power Profiles V2 Framework module in an application are:

1. Define the body of the callback function configured in the Low Power profile. The callback function notifies the application when the MCU is about to enter a low power mode and when the MCU just woke up from a low power mode. Using a callback is optional, but if you define a callback in the Power Profiles V2 properties, then there must be a definition for it.
2. If ThreadX is used, the Power Profiles V2 Framework sf_power_profiles_v2_api_t::open function will be called by the Synergy generated code before the user application code is

reached. If ThreadX is not used, the application must call the open function.

3. Apply a Run Profile at any time using the runApply() function. The runApply() function accepts a Run Profile as its second parameter. The parameter can be any valid Run Profile, allowing the application to easily switch between Run Profiles. g_sf_power_profiles_v2_common.p_api->runApply(g_sf_power_profiles_v2_common.p_ctrl, &g_sf_power_profiles_v2_run_0);
4. Apply a Low Power Profile using the lowPowerApply() function. The lowPowerApply() function accepts a Low Power Profile as its second parameter. The parameter can be any valid Low Power Profile, allowing the application to easily switch between Low Power Profiles g_sf_power_profiles_v2_common.p_api->lowPowerApply(g_sf_power_profiles_v2_common.p_ctrl, &g_sf_power_profiles_v2_low_power_0);
5. Close the framework by calling the sf_power_profiles_v2_api_t::close function. [Optional] g_sf_power_profiles_v2_common.p_api->close(g_sf_power_profiles_v2_common.p_ctrl);

These common steps are illustrated in a typical operational flow in the following figure:

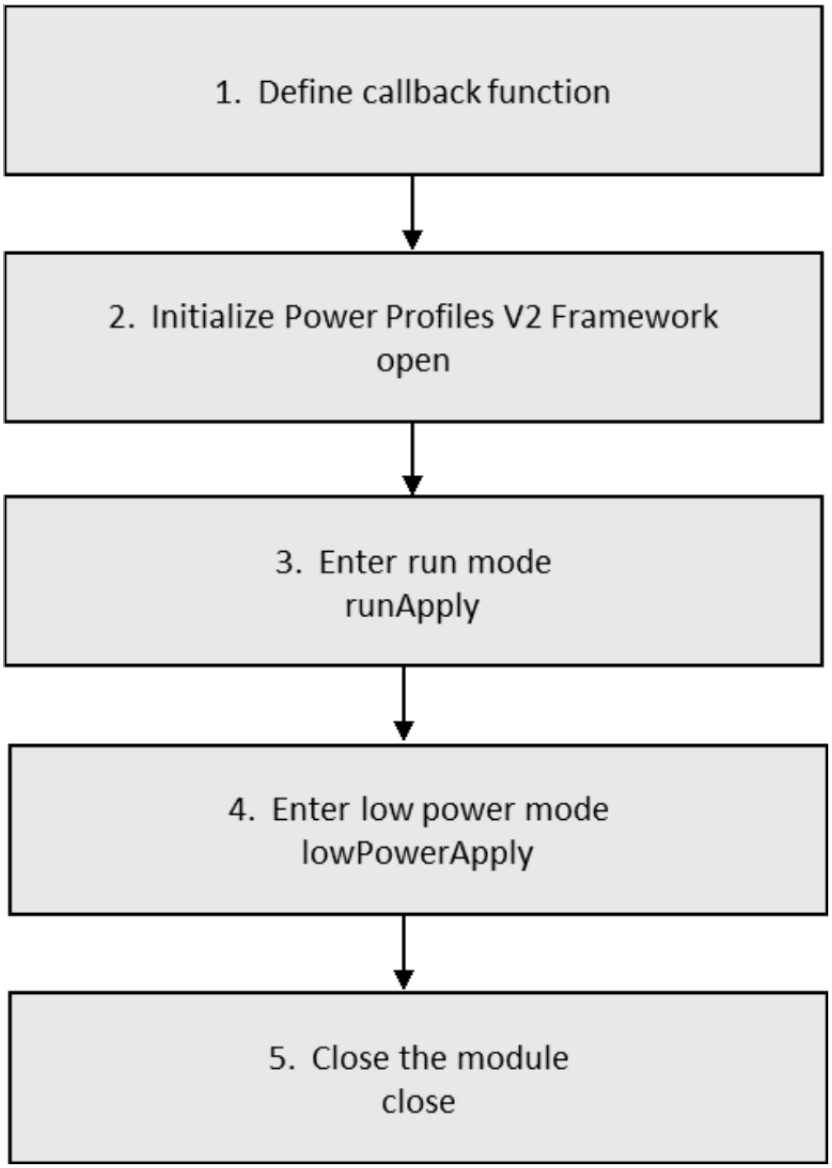

Figure 200: Flow Diagram of a Typical Power Profiles V2 Framework Module Application

4.1.24 SPI Framework

4.1.24.1 SPI Framework Introduction

The SPI Framework module provides a ThreadX-aware framework API and handles the integration and synchronization of multiple SPI peripherals on an SPI bus (including chip-select handling and its level activation). With the SPI Framework, one or more SPI buses can be created and multiple SPI peripherals can be connected to the SPI bus. The SPI Framework module uses a single interface to access both SCI SPI and RSPI drivers. The SPI Framework module uses the SCI and RSPI peripherals on the Synergy MCU.

SPI Framework Module Features

The SPI Framework module uses either the SCI in SPI mode (together with the SCI common lower-level modules) or the RSPI lower-level driver module to communicate with the SPI peripherals on the Synergy microcontroller.

- Supports multiple devices on a bus
- Provides high-level APIs for initialization, transfers and closing the module
- Supports synchronized transfers
- Supports chip-select operations
- Supports bus-locking

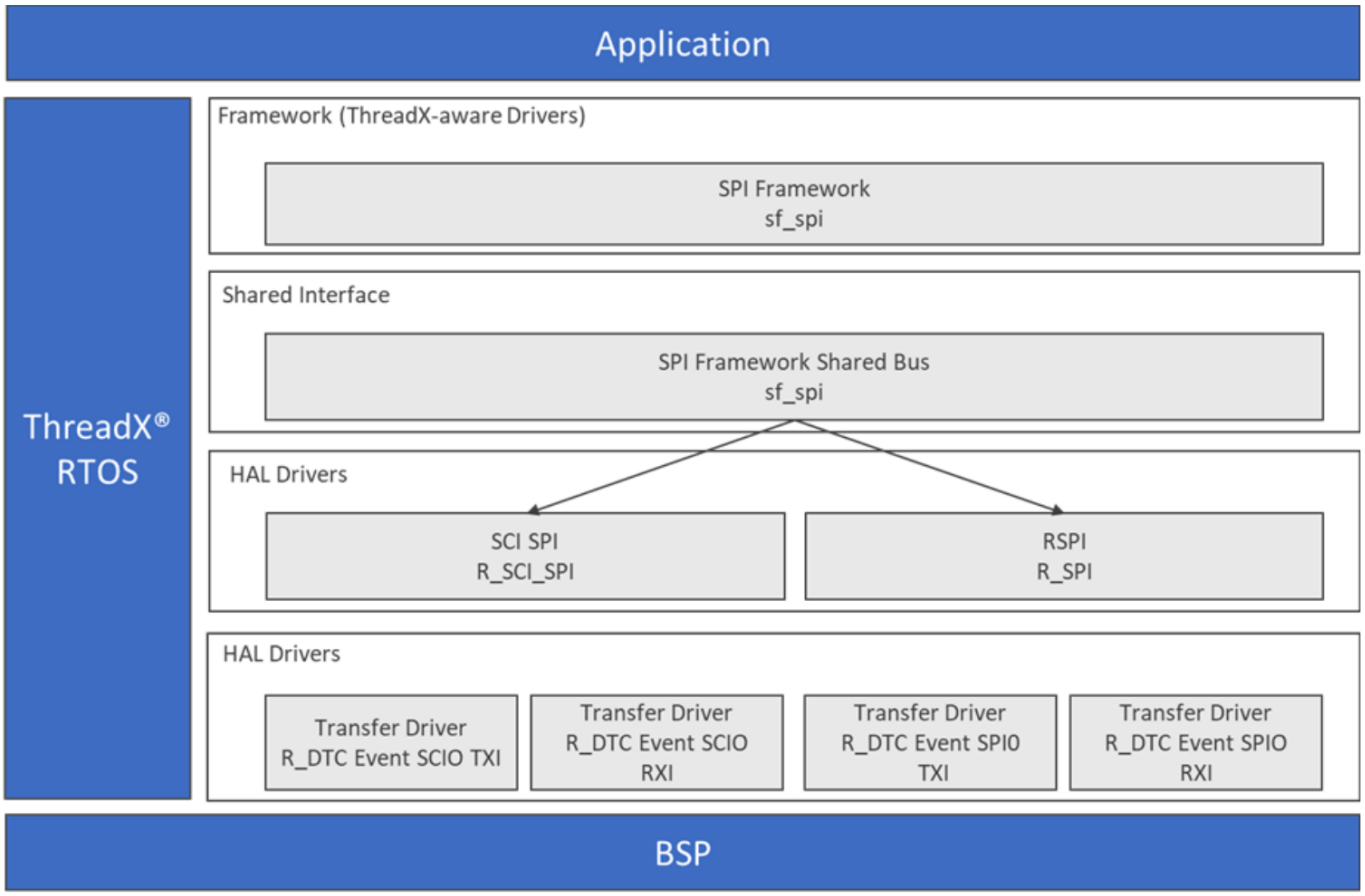

Figure 201: SPI Framework Module Block Diagram

4.1.24.2 SPI Framework Module APIs Overview

The SPI Framework module defines APIs for opening, closing, reading, writing and other useful functions. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

SPI Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_spi_device.p_api->open(g_sf_spi_device.p_ctrl, g_sf_spi_device.p_cfg); Open a designated SPI device on a bus.
read	g_sf_spi_device.p_api->read(g_sf_spi_device.p_ctrl, &destination, length, SPI_BIT_WIDTH_8_BITS, timeout); Receive data from SPI device.
write	g_sf_spi_device.p_api->write(g_sf_spi_device.p_ctrl, &source, length, SPI_BIT_WIDTH_8_BITS, timeout); Transmit data to SPI device.
writeRead	g_sf_spi_device.p_api->writeRead (g_sf_spi_device.p_ctrl, &source, &destination, length, SPI_BIT_WIDTH_8_BITS, timeout); Simultaneously transmits data to an SPI device while receiving data from an SPI device (full duplex). The writeread API gets a mutex object, handles the SPI data transmission at SPI HAL layer, and receives data from the SPI HAL layer. The API uses the event flag wait to synchronize to completion of data transfer.
close	g_sf_spi_device.p_api->close(g_sf_spi_device.p_ctrl); Disable the SPI device designated by the control handle and close the RTOS services used by the bus, if no devices are connected to the bus. This function removes power to the SPI channel designated by the handle and disables the associated interrupts.
lock	g_sf_spi_device.p_api->lock(g_sf_spi_device.p_ctrl); Lock the bus for a device. The locking allows devices to reserve a bus to themselves for a given period of time (such as between lock and unlock). This allows devices to complete several reads and writes on the bus without an interrupt.
unlock	g_sf_spi_device.p_api->unlock(g_sf_spi_device.p_ctrl); Unlock the bus for a particular device and make the bus usable for other devices.

version	g_sf_spi_device.p_api->version (&version); Retrieve the API version with the version pointer.
lockWait	g_sf_spi_device.p_api->lockWait(g_sf_spi_device.p_ctrl, timeout); Lock the bus for a device. The locking allows devices to reserve a bus to themselves for a given period of time (i.e. between lock and unlock). This allows devices to complete several reads and writes on the bus without interrupt. The wait option allows thread to wait for the specified timeout when acquiring the bus mutex.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function completed successfully.
SSP_ERR_INVALID_MODE	Invalid mode.
SSP_ERR_INVALID_CHANNEL	Invalid channel.
SSP_ERR_IN_USE	In-use error.
SSP_ERR_INVALID_ARGUMENT	Invalid argument.
SSP_ERR_QUEUE_UNAVAILABLE	Queue unavailable.
SSP_ERR_INVALID_POINTER	Invalid pointer.
SSP_ERR_INTERNAL	Internal error.
SSP_ERR_TRANSFER_ABORTED	Transfer aborted.
SSP_ERR_MODE_FAULT	Mode fault.
SSP_ERR_READ_OVF	Read overflow.
SSP_ERR_PARITY	Parity error.
SSP_ERR_OVERRUN	Overrun error.
SSP_ERR_UNDEF	Unknown error.
SSP_ERR_TIMEOUT	Timeout error.
SSP_ERR_NOT_OPEN	Device not opened.
SSP_ERR_ALREADY_OPEN	Requested channel is already open in a different configuration.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.24.3 SPI Framework Module Operational Overview

The SPI Framework module complies with the layered-driver architecture of the SSP. It uses either the SCI on SPI module or the RSPI module to communicate with the SPI peripherals on the Synergy microcontroller.

Multiple Slave Devices on the Same Bus

The SPI framework module uses a bus and device on bus architecture. Only one device is configured to the lower level driver at a time, and the other devices are reconfigured upon a read or write operation as required. The lower level driver can only be reconfigured when the bus is not locked. Every slave device is linked to the bus to which it will be connected and shares the bus with all other slave devices.

The user must configure the SPI framework shared-bus and the lower-level SPI HAL layer for each SPI framework module connecting to the bus. The user can add the existing framework shared-bus module when configuring multiple devices on the same bus. Each SPI framework module must be configured with a unique name in the ISDE configurator.

A common start and stop procedure is used for all SPI data-transfer operations (spi_api_t::read, spi_api_t::write and spi_api_t::writeRead). During the start process, the SPI framework module checks whether reconfiguration is required. Chip select is asserted during the transfer-start process and de-asserted during the transfer-end process if the bus is not locked. The user must configure the chip-select IO pin and the chip-select active level.

Bus Locking

The SPI Framework module supports bus-locking functionality, meaning that the bus can be locked for a given slave peripheral. The locking allows slave devices to reserve a bus to themselves for the period between the lock and unlock commands. This allows devices to complete several reads and writes on the bus without interruption (which can be required in some situations). The chip select becomes active during lock and becomes inactive when unlocked. Writes and reads in between the lock and unlock do not alter the chip-select line.

SPI Framework Module Important Operational Notes and Limitations

SPI Framework Module Operational Notes

- Multiple SPI devices can be configured to share a common bus. Once the SPI Framework bus module is configured, different SPI peripherals (devices) can be connected to that bus.
- For each SPI device connected to the bus, one SPI HAL module (new or shared) and one SPI Framework device module must be added.
- User defined Callback is not required as it has been internally taken care by framework.
- Setting the interrupts to different priority levels could result in improper operation.
- In the SPI Framework configuration, the channel number given to this bus overrides the channel number given in the HAL module.
- Shared bus can be used by multiple slave devices with the respective configuration. The framework also handles mutual exclusion in lock and unlock APIs when multiple devices are using the same SPI channel.
- Lock functionality will be effective for devices from different threads. If multiple devices connected to the bus are from the same thread, the SPI bus will be locked for all devices from that thread. In such cases, even if the bus is locked, all devices from the same thread can access the bus.
- In case a device used from multiple threads, and the device locks the SPI bus from one thread, the same device cannot access the SPI bus from other threads.

- The behavior of chip-select pin depends on the slave device. Chip-select pin can be utilized through framework or user can handle Chip-select pin in their application code based on the hardware specification of particular slave device.

SPI Framework Module Limitations

- Refer to the MCU specification manual for identifying SPI bus compatibility. Device compatibility with the SPI bus is not checked in the framework hence incompatible SPI device may result in improper operation.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.24.4 Including the SPI Framework Module in an Application

This section describes how to include the SPI Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the SPI Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the SPI Framework module is g_sf_spi_device0. This name can be changed in the associated Properties window.)

SPI Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_spi_device0 on sf_spi	Threads	**New Stack> Framework> Connectivity> SPI Framework Device on sf_spi**

When the SPI Framework module on sf_spi is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

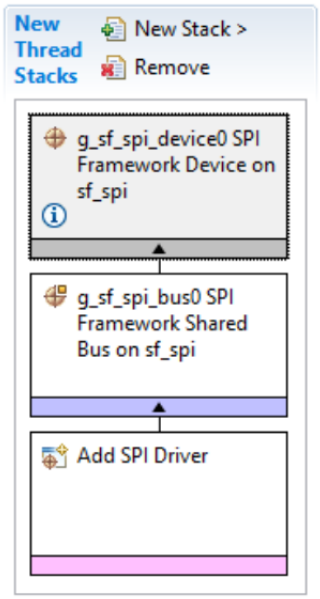

Figure 202: SPI Framework Module Stack

4.1.24.5 Configuring the SPI Framework Module

The SPI Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the SPI Framework Device Module on sf_ spi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_sf_spi_device0	Module name.

Clock Phase	Data sampling on odd edge, data variation on even edge/Data sampling on even edge, data variation on odd edge Default: Data sampling on odd edge, data variation on even edge	Select the clock phase.
Clock Polarity	Low when idle, High when idle Default: Low when idle	Select the clock polarity.
Chip Select Port	00 thru 11 Default: 00	Select GPIO port used for the chip select.
Chip Select Pin	00 thru 15 Default: 00	Select GPIO pin used for the chip select.
Chip Select Active Level	Low, High Default: Low	Polarity of the Chip Select signal, active High or Low.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to select different chip-select GPIOs or levels. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower level modules are fairly intuitive and can usually be determined by inspection of the associated Properties window from the SSP configurator.

Configuring the SPI Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the lower-level modules:

Configuration Settings for the SPI Framework Shared Bus on sf_spi

ISDE Property	Value	Description
Name	g_sf_spi_bus0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the RSPI HAL Driver on r_rspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Name	g_spi0	Module name.
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master, Slave Default: Master	Configure as a Master or Slave device. Note: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on odd edge, data variation on even edge	Data sampling on odd or even clock edge.
Clock Polarity	Low when idle	Clock level when idle.
Mode Fault Error	Enable, Disable Default: Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First, LSB First Default: MSB First	Select transmit order MSB/LSB first.
Bitrate	500000	Transmission or reception rate. Bits per second.
Callback	NULL	Optional Callback function pointer.
SPI Mode	SPI Operation, Clock synchronous operation Default: SPI Operation	Select spi or clock syn mode operation.
Slave Select Polarity(SSL0)	Active Low, Active High Default: Active Low	Select SSL0 signal polarity.
Slave Select Polarity(SSL1)	Active Low, Active High Default: Active Low	Select SSL1 signal polarity.
Slave Select Polarity(SSL2)	Active Low, Active High Default: Active Low	Select SSL2 signal polarity.
Slave Select Polarity(SSL3)	Active Low, Active High Default: Active Low	Select SSL3 signal polarity.

Select Loopback1	Normal, Inverted Default: Normal	Select the data mode for loopback 1.
Select Loopback2	Normal, Inverted Default: Normal	Select the data mode for loopback 2.
Enable MOSI Idle State	Enable, Disable Default: Disable	Select MOSI idle fixed value and selection.
MOSI Ildle State	MOSI Low, MOSI High Default: MOSI Low	Select mosi idle fixed value and selection.
Enable Parity	Enable, Disable Default: Disable	Enable/disable parity.
Parity Mode	Parity Odd, Parity Even Default: Parity Odd	Select parity.
Select SSL(Slave Select)	SSL0, SSL1, SSL2, SSL3 Default: SSL0	Select which slave to use; 0-SSL0; 1-SSL1; 2-SSL2; 3-SSL3.
Select SSL Level After Transfer	SSL Level Keep, SSL Level Do Not Keep Default: SSL Level Do Not Keep	Select SSL level after transfer completion; 0-negate; 1-keep.
Clock Delay Enable	Clock Delay Enable, Clock Delay Disable Default: Clock Delay Disable	Clock delay enable selection.
Clock Delay Count	Clock Delay 1 thru 8 RSPCK Default: Clock Delay 1 RSPCK	Clock delay count selection.
SSL Negation Delay Enable	Negation Delay Enable, Negation Delay Disable Default: Negation Delay Disable	SSL negation delay enable selection.
Negation Delay Count	Negation Delay 1 thru 8 RSPCK Default: Negation Delay 1 RSPCK	Negation delay count selection.
Next Access Delay Enable	Next Access Delay Enable, Next Access Delay Disable Default: Next Access Delay Disable	Next access delay enable selection.

Next Access Delay Count	Next Access Delay 1 thru 8 RSPCK Default: Next Access Delay 1 RSPCK	Next access delay count selection.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Error interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	2 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.

Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode)	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SPI0 TXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_transfer1	Module name.
Mode	Normal	Mode selection.
Transfer Size	2 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.

Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI Driver on r_sci_spi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name.
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master, Slave Default: Master	Configure as a Master or Slave device. Note: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on odd edge, data variation on even edge	Data sampling on odd or even clock edge.
Clock Polarity	Low when idle	Clock level when idle.
Mode Fault Error	Enable, Disable Default: Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First, LSB First Default: MSB First	Select transmit order MSB/LSB first.

Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable.
Callback	NULL	Optional Call back function pointer.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Bitrate Modulation Function enable or disable. Note: This is applicable only for SCI SPI.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Error interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.

Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer1	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.

Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SCI0 RXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

SPI Framework Module Clock Configuration

The SCI peripheral module uses the PCLKB as its clock source. The PCLKB frequency is set by using the SSP configurator **Clock** tab prior to a build or by using the CGC Interface at run-time.

SPI Framework Module Pin Configuration

The SPI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins.

Note

For some peripherals, the operation-mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for the SPI Framework Module

Resource	ISDE Tab	Pin selection Sequence
SCI	Pins	Select **Peripherals**> **Connectivity: SCI**> **SCI1**

RSPI	Pins	Select **Peripherals**> **Connectivity: SPI**> **SPI0**

Note

The selection sequences assume SCI1 and SPI0 are the desired hardware targets of the drivers.

Pin Configuration Settings for the SPI Framework Module

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Asynchronous UART, Synchronous UART, Simple I2C, Simple SPI, SmartCard Default: Disabled	Select Simple SPI as the Operation Mode for SPI on SCI.
CTS0_RTS0_SS0	None, P103, P413 Default: None	SS0 pin selection.
RXD0_SCL0_MISO0	None, P100, P410 Default: None	MISO0 pin selection.
SCK0	None, P102, P412 Default: None	SCK0 pin selection.
TXD1_SDA1_MOSI0	None, P213, P709 Default: None	MOSI0 pin selection.

Note

The example values are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

SPI Framework Module Additional Settings

If external chip selects are being used, configure the chip select pins as GPIO outputs.

4.1.24.6 Using the SPI Framework Module in an Application

A common application for the SPI framework module requires multiple slave devices on a single bus. The implementation for this common application is described below. A second implementation shows two buses each with two slave devices attached.

Implementation Steps for Two Slave Devices on a Single Shared Bus

When using the SPI framework module to create a single bus with multiple slave devices create two thread stacks each with an SPI framework instance. These instances will use the same shared bus instance. Follow the steps below to see how this is done within the SSP Configurator.

Note

The following steps assume some familiarity with the use of the SSP development environment. If any of the following steps are confusing, read over the first few chapters of the SSP User's Manual to become familiar with the SSP development environment.

Step 1: Add the first SPI framework device module to a new or existing thread. This creates the SPI master stack. A shared bus on sf_spi is added along with the SPI driver. The SPI driver can be selected for implementation on r_rspi or r_sci_spi. The DTC transfer driver is also added by default. This can be removed if the CPU transfer mode is needed instead.

The resulting module stack is shown in the following figure. Example configuration settings are given in the tables that follow the figure.

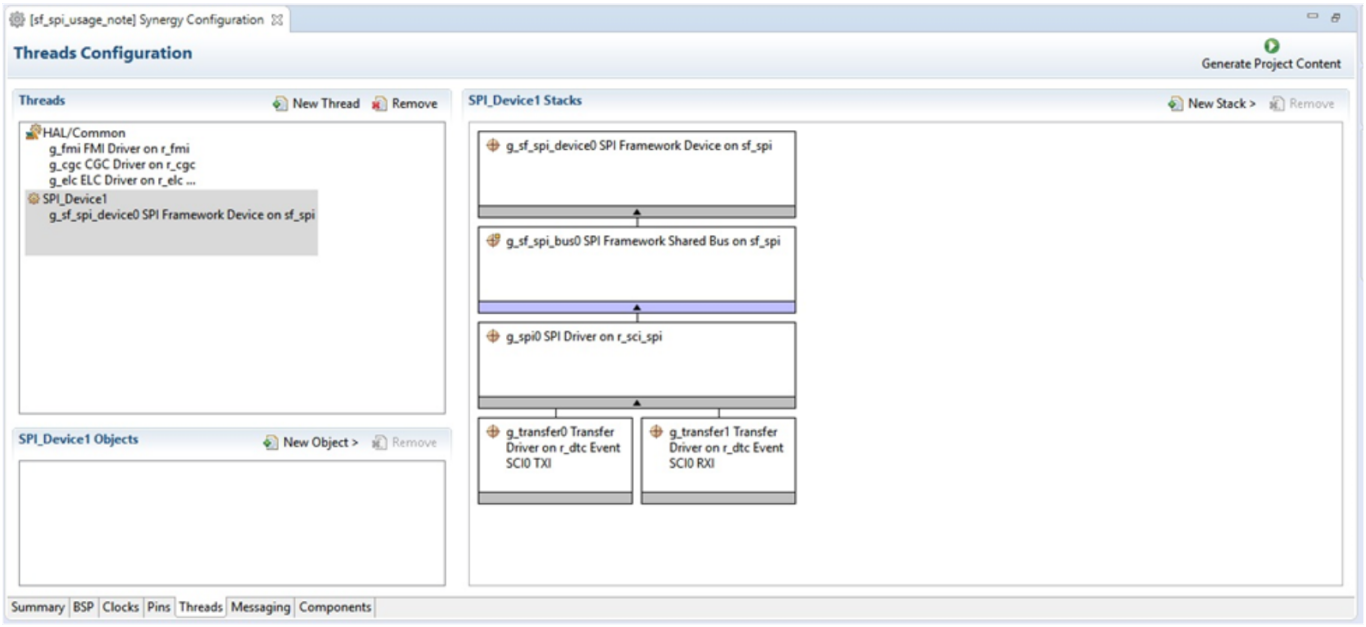

Figure 203: SPI Framework Module Stack 1

Example configuration settings for the key first thread stack modules for Slave Device #1 are as follows:

Configuration Settings for the SPI Framework Module on sf_spi

Property	Value	Description
Parameter Checking	Disabled	Enable or Disable Parameter Checking.
Name	g_sf_spi_device1	Give a name to identify the SPI Framework device. API, Config and Control instances will be created based on this name.
Clock Phase	Data sampling on odd edge	Specify the clock phase for data variation and data sampling
Clock Polarity	Low when idle	Select the clock polarity when clock is idle.
Clock Select Port	01	Select GPIO port used for the chip select.
Chip Select Pin	04	Select GPIO pin used for the chip select.

Chip Select Active Level	Low	Select Polarity of the chip select signal.

Configuration Settings for the SPI Framework Shared Bus on sf_spi

Property	Value	Description
Name	g_sf_spi_bus0	Give a name to identify the SPI Framework shared bus. This shared bus will be shared by multiple SPI Framework Devices.

Configuration Settings for the SPI Driver on r_rspi

Property	Value	Description
Parameter Checking	BSP	Enable or Disable Parameter Checking.
Name	g_spi0	Give a name to identify the SPI Driver device. This will be used by Framework internally.
Channel	0	Channel number.
Operating Mode	Master	Operating mode selection.
Clock Phase	Data sampling on odd edge/ data variation on edge	Clock phase selection. This field will be locked as these is already set in the SPI Framework Device on sf_spi module.
Clock Polarity	Low when idle	Clock polarity selection. This field will be locked as these is already set in the SPI Framework Device on sf_spi module.
Mode Fault Error	Enable	Mode fault error selection.
Bit Order	MSB First	Bit order selection.
Bitrate	500000	Bit rate selection.
Callback	NULL	Callback function name.
SPI Mode	SPI Operation	SPI mode selection.
SPI Communication Mode	Full Duplex	SPI communication mode selection.
Slave Select Polarity (SSL0)	Active Low	Slave select polarity selection 0.
Slave Select Polarity (SSL1)	Active Low	Slave select polarity selection 1.

Slave Select Polarity (SSL2)	Active Low	Slave select polarity selection 2.
Slave Select Polarity (SSL3)	Active Low	Slave select polarity selection 3.
Select Loopback 1	Normal	Loopback 1 selection.
Select Loopback 2	Normal	Loopback 2 selection.
Enable MOSI Idle	Disable	Enable MOSI idle selection.
MOSI Idle State	MOSI Low	Enable MOSI idle state selection.
Enable Parity	Disable	Enable parity selection.
Parity Mode	Parity Odd	Enable parity mode selection.
Select SSL (Slave Select)	SSL0	Select SSL selection.
Select SSL Level After Transfer	SSL Level Keep	Select SSL level after transfer selection.
Clock Delay Enable	Disable	Clock delay enable selection.
Clock Delay Count	Clock Delay 1 RSPCK	Clock delay count selection.
SSL Negation Delay Enable	Disable	SSL Negation Delay Enable selection.
Negation Delay Count	Clock Delay 1 RSPCK	Negation Delay Count selection.
Next Access Delay Enable	Disable	Next Access Delay Enable selection.
Next Access Delay Count	Clock Delay 1 RSPCK	Next Access Delay Count selection.
Receive Interrupt Priority	Priority 2	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 2	Transmit end interrupt priority selection.

Configuration Settings for the SPI Driver on r_sci_spi

Property	Value	Description
Parameter Checking	BSP	Enable or Disable Parameter Checking.
Name	g_spi0	Give a name to identify the SPI Driver device. This will be used by Framework internally.
Channel	0	Channel number.
Operating Mode	Master	Operating mode selection.

Clock Phase	Data sampling on odd edge/ data variation on even edge	Clock phase selection. This field will be locked as these is already set in the SPI Framework Device on sf_spi module.
Clock Polarity	Standard	Clock polarity selection. This field will be locked as these is already set in the SPI Framework Device on sf_spi module.
Mode Fault Error	Disable	Mode fault error selection.
Bit Order	MSB First	Bit order selection.
Bitrate	500000	Bit rate selection.
Bit Rate Modulation Enable	Enable	Enables/Disable the bit rate modulation.
Callback	NULL	Callback function name. This field will be locked as callback is handled internally in the framework.
Receive Interrupt Priority	Priority 2	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 2	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 2	Error interrupt priority selection.

Note

DTC configuration settings are not shown as a simplification.

Step 2: Add the second SPI Framework Device to a different thread. The SPI Framework Shared Bus on sf_spi is not added automatically. To add it, select the option to use the existing shared bus. The configurator will then automatically add the SPI Framework Shared Bus on sf_spi and the remaining modules. The lower level modules will automatically be configured to be consistent with the previously defined settings from the first SPI framework instance. This ensures that the SPI driver configurations are the same for both devices except for the Clock Phase, Clock Polarity, Chip Select Pin and Port, and Chip Select Active Level properties, as these are defined under the SPI Framework Device module and can be different for each slave device.

The resulting module stack is shown in the following figure:

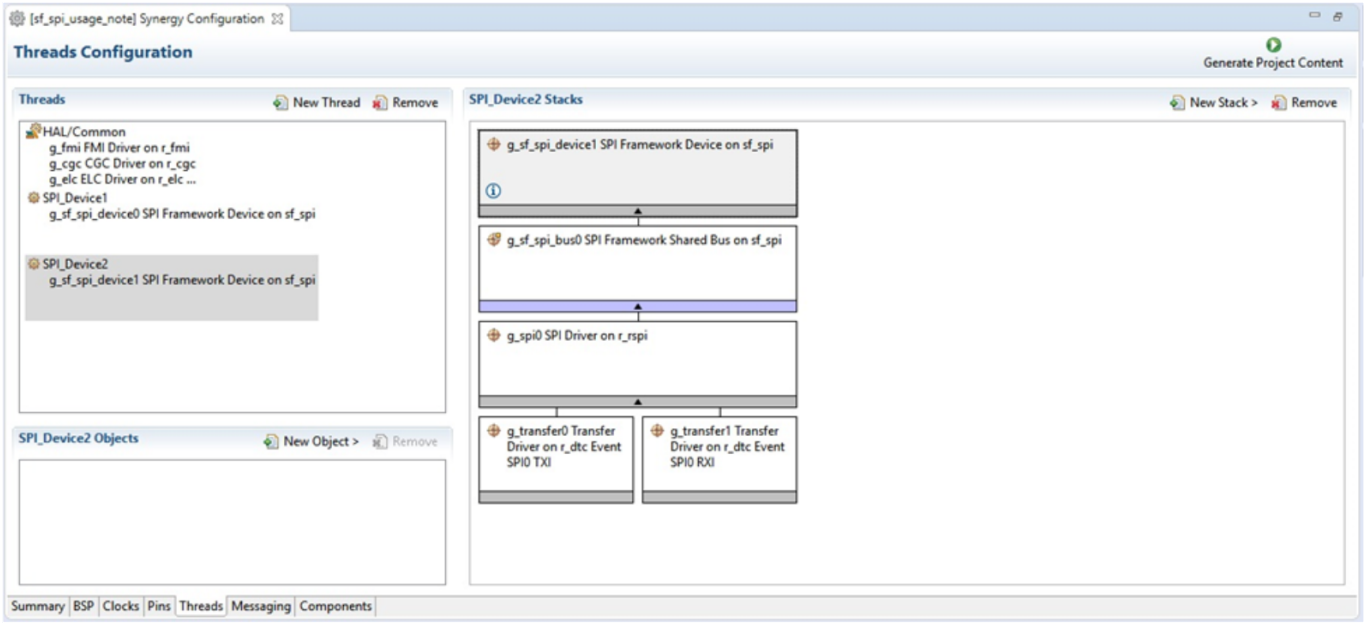

Figure 204: SPI Framework Module Stack 2

The only differences in the configuration parameters for the second stack are the name for the second SPI framework device module, and any differences in the non-shared slave settings (Clock Phase, Clock Polarity, Clock Select Port, Chip Select Pin and Chip Select Active Level). Example settings are shown in the following table:

Configuration Settings for the SPI Framework Device on sf_spi (Slave #2)

Property	Value	Description
Parameter Checking	BSP	Enable or Disable Parameter Checking.
Name	g_sf_spi_device2	Give a name to identify the SPI Framework device. API, Config and Control instances will be created based on this name.
Clock Phase	Data sampling on odd edge/ data variation on even edge	Specify the clock phase for data variation and data sampling
Clock Polarity	High when idle	Select the clock polarity when clock is idle.
Clock Select Port	05	Select GPIO port used for the chip select.
Chip Select Pin	01	Select GPIO pin used for the chip select.
Chip Select Active Level	Low	Select Polarity of the chip select signal.

Implementation Steps for Two Slave Devices on Two Shared Buses

When using the SPI framework module to create a single bus with multiple slave devices create two thread stacks each with an SPI framework instance. These instances will use the same shared bus instance. Follow the steps below to see how this is done within the SSP Configurator.

Note

The following steps assume some familiarity with the use of the SSP development environment. If any of the following steps are confusing, read over the first few chapters of the SSP User's Manual to become familiar with the SSP development environment.

Adding Another Shared Bus

To add another shared bus, just follow the below steps. The previous example is used as the starting point.

Step 3: The SPI framework module which will use a second shared bus can be added to any thread. Starting with the previous example, if it is added to the SPI_Device1 thread, then the module stack would appear as shown below. Available options for the shared bus are New or Use.

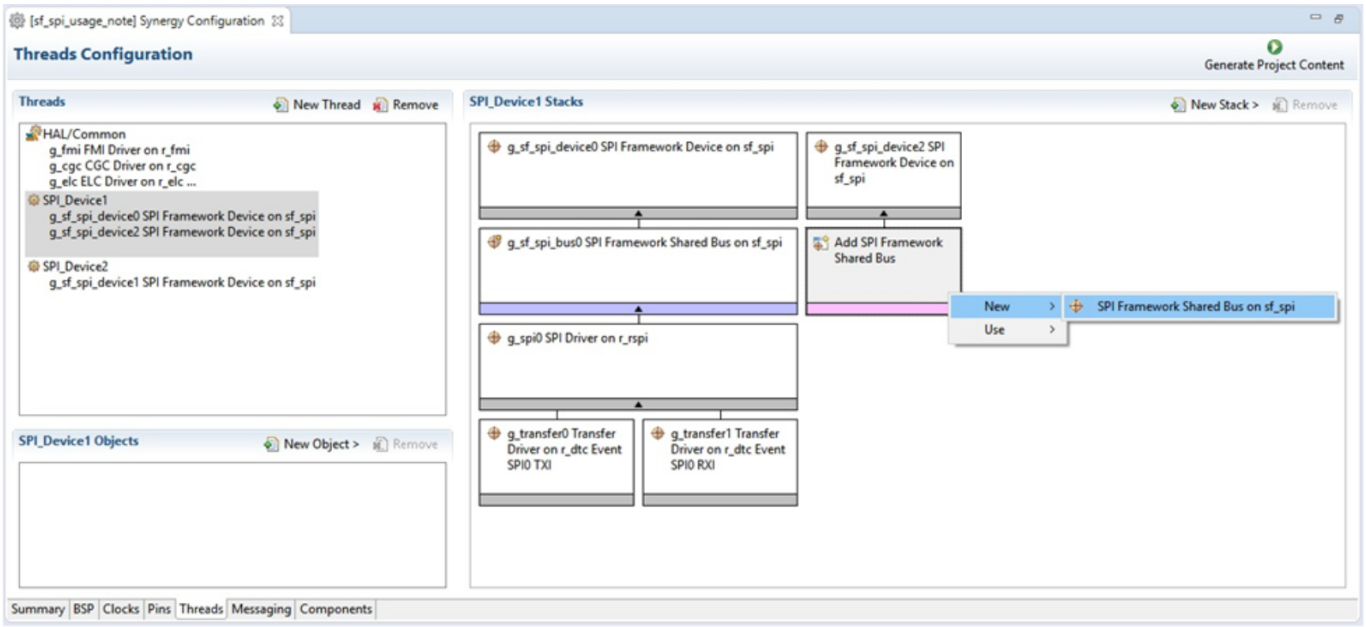

Figure 205: SPI Framework Module Stack 3

Step 4: Select New to and add another SPI Framework Shared Bus on sf_spi module. Configure the shared bus properties as needed for the application. Select the desired low-level SPI driver. The channel number for the g_spi1 SPI driver module, must be different from the channel number for the g_spi0 SPI driver module. The resulting thread stack is shown below:

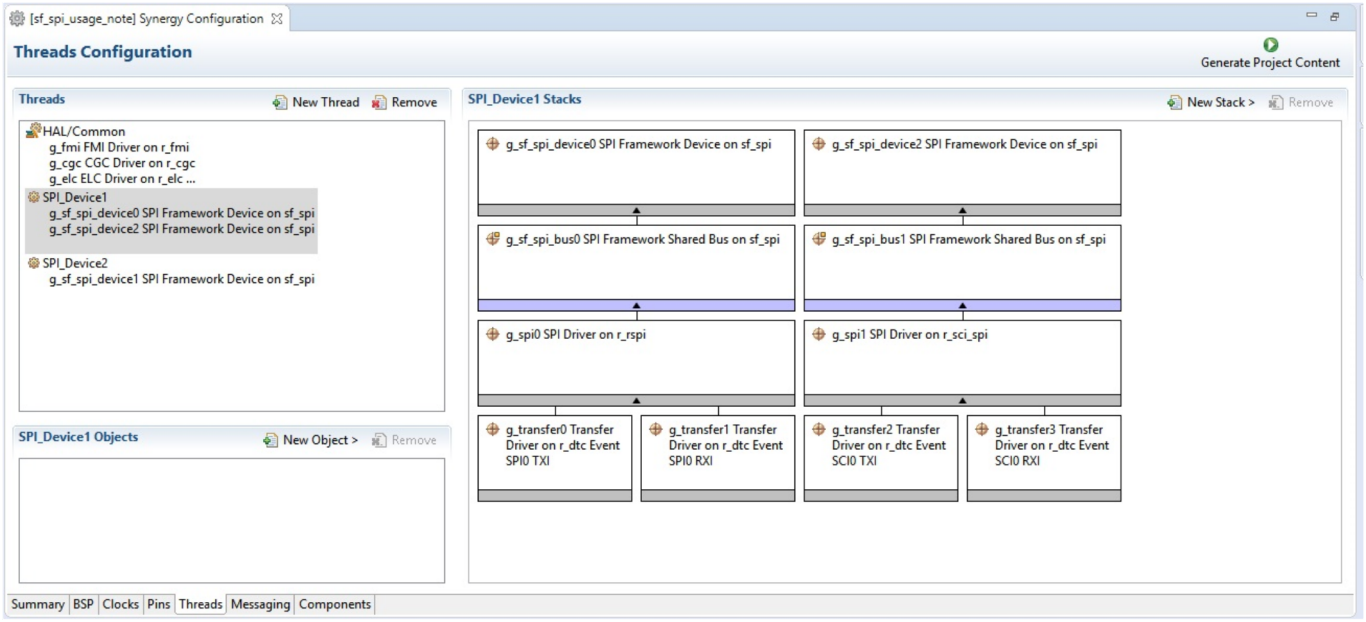

Figure 206: SPI Framework Module Stack 4

Step 5: A second device can be added in the SPI_Device2 thread using the same steps described above. The resulting thread stack is shown below:

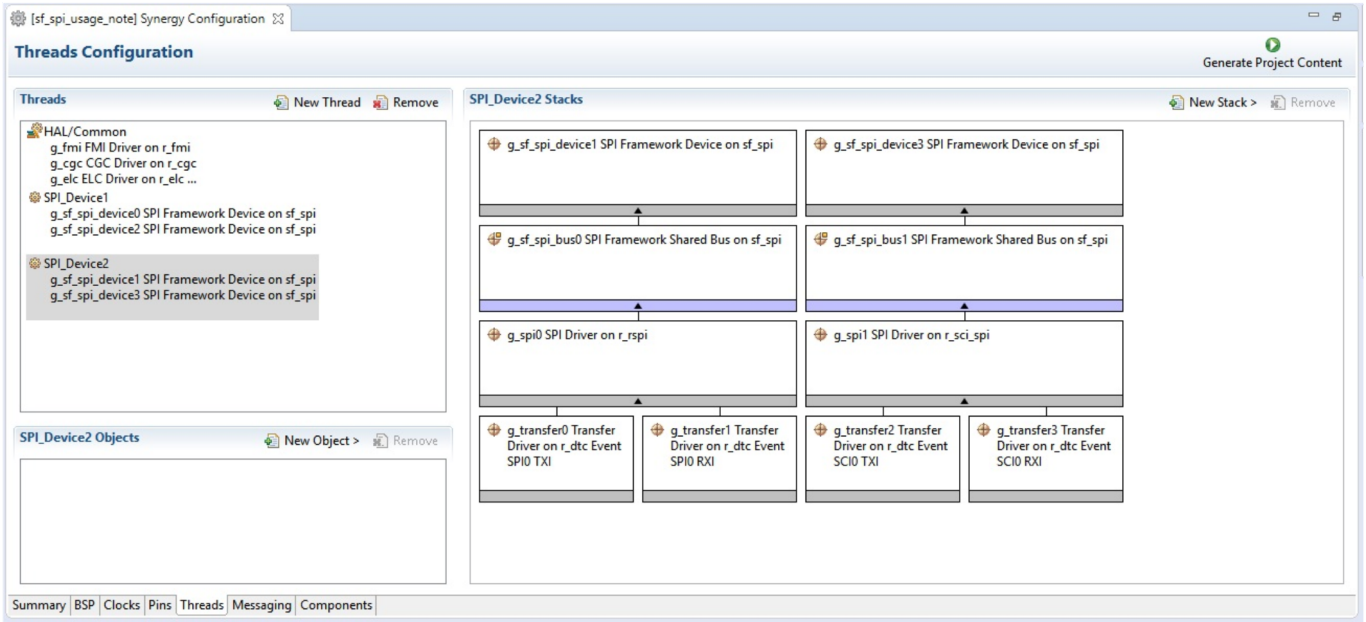

Figure 207: SPI Framework Module Stack 5

The typical steps in using the SPI Framework module in an application are:

1. Initialize the SPI Framework device module using the sf_spi_api_t::open API function. Each SPI framework device module needs to call the spi_api_t::open API function at least once before performing any operations on the bus.
2. Lock the bus for continuous transfer using the sf_spi_api_t::lock or sf_spi_api_t::lockWait API

function for a particular SPI Framework device module. Once the bus is locked by a particular SPI Framework device module, it cannot be used by any other SPI Framework device module on the bus. This ensures that ownership of the bus remains with the locked module until it explicitly unlocks it. Any kind of operation from other SPI Framework device modules on the bus will return a fail status during this period. It is not mandatory to lock the bus before any read/write operations on the bus. It is optional.

3. Read data using the sf_spi_api_t::read API function. The read operation will not be successful if the bus is already locked by any other SPI Framework device module.
4. Write data using the sf_spi_api_t::write API function. The write operation will not be successful if the bus is already locked by any other SPI Framework device module.
5. Write and read data simultaneously using the sf_spi_api_t::writeRead API function. The simultaneous read and write operation will not be successful if the bus is already locked by any other SPI Framework device module.
6. Unlock the bus from continuous transfer using the sf_spi_api_t::unlock API function if it is already locked by the same device. Once the bus is unlocked, other SPI Framework device modules can use it. It is necessary to unlock the locked bus after the intended read/write operation is completed.
7. Close the SPI Framework device module using the sf_spi_api_t::close API function. Each SPI Framework device module can call the sf_spi_api_t::close API function after all read/write operations on the bus are over.

These common steps are illustrated in a typical operational flow in the following figure:

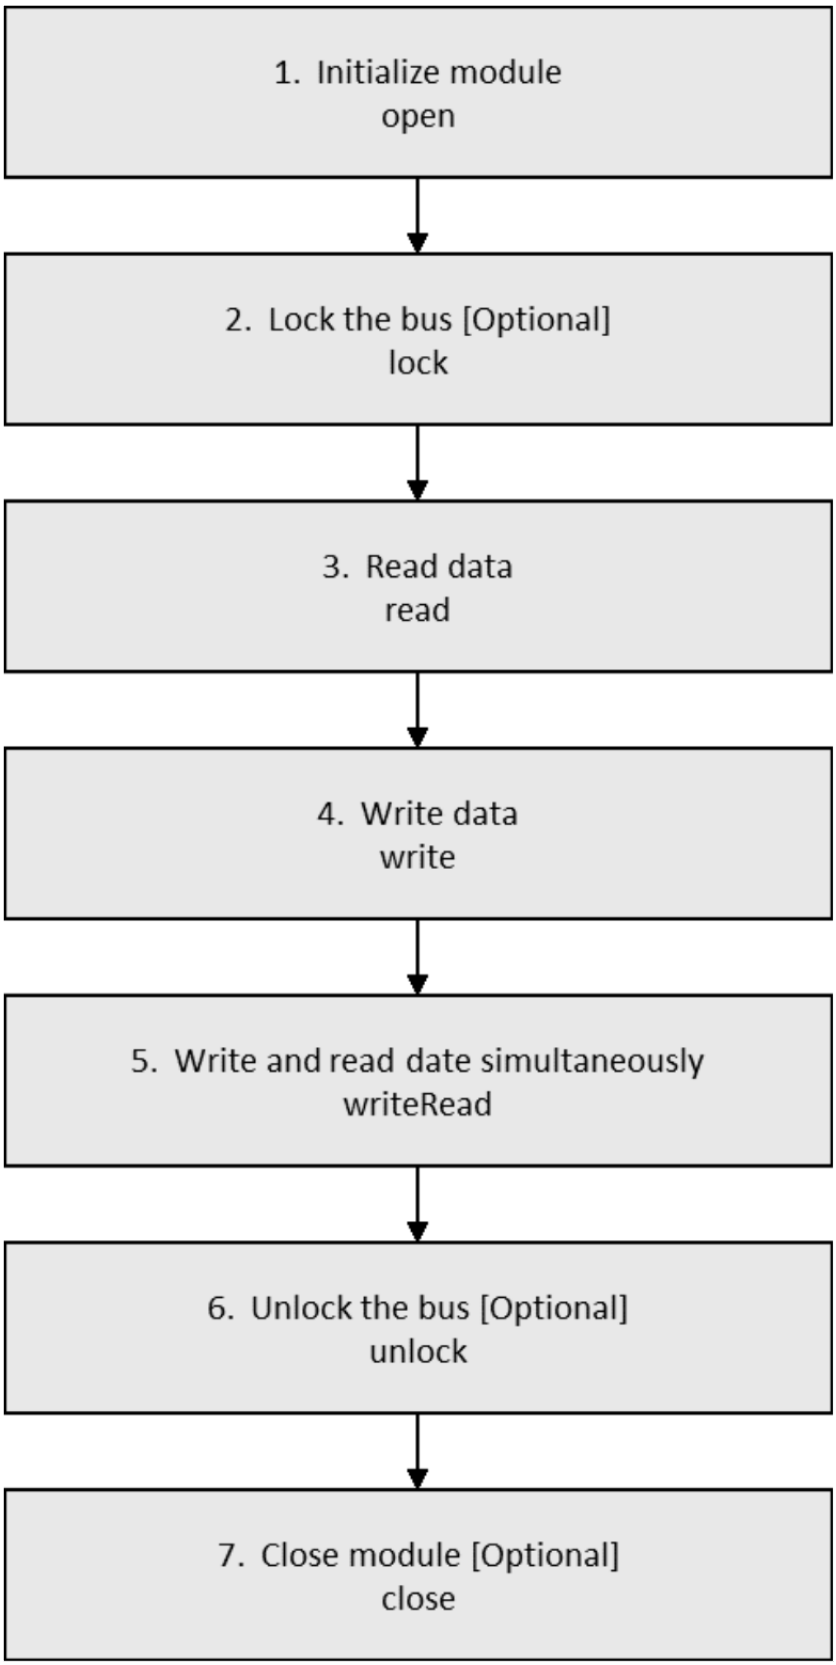

Figure 208: Flow Diagram of a Typical SPI Framework Module Application

4.1.25 Thread Monitor Framework

4.1.25.1 Thread Monitor Framework Module Introduction

The Thread Monitor Framework provides a high-level API for system monitoring applications using the watchdog timer (WDT) or independent watchdog timer (IWDT) to monitor program execution. The Thread Monitor Framework uses the WDT or IWDT peripherals on the Synergy MCU device.

Thread Monitor Framework Module Features

- The Thread Monitor Framework interface monitors RTOS threads using a watchdog timer. The Thread Monitor forces a watchdog reset of the microcontroller when any of the monitored threads do not behave as expected.
- The Thread Monitor is designed to support any Synergy device with either a WDT or IWDT peripheral and a HAL module with no changes to the API.
- In profiling mode, the minimum and maximum counter values for registered threads can be determined. When in profiling mode, the watchdog timer is always refreshed and does not reset the device.
- Both the WDT and IWDT HAL modules are supported by this framework module.

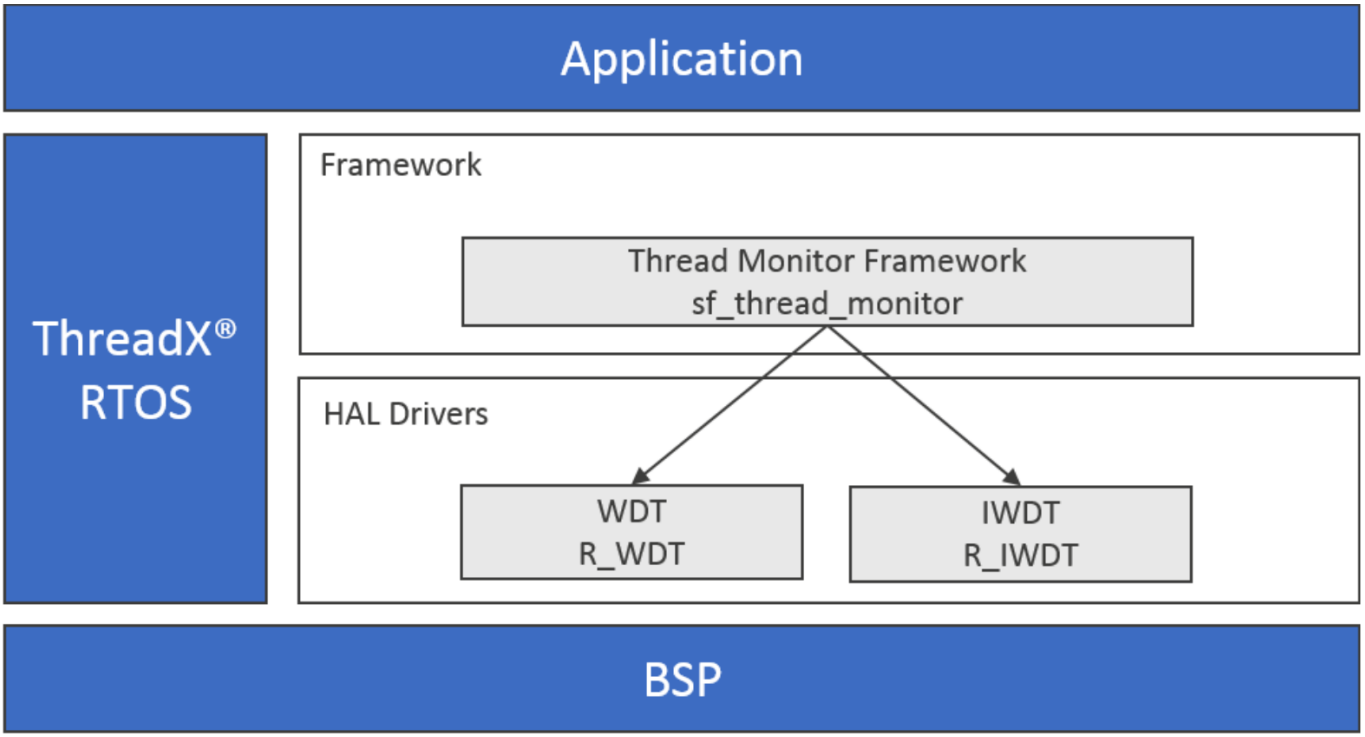

Figure 209: Thread Monitor Framework Module Block Diagram

4.1.25.2 Thread Monitor Framework Module APIs Overview

The Thread Monitor Framework defines APIs for opening and closing the framework and registering and unregistering threads for monitoring. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of return status values follows the API summary table.

Thread Monitor Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_thread_monitor.p_api->open (g_sf_thread_monitor.p_ctrl,g_sf_thread_monitor.p_cfg); Configures the WDT or IWDT module. From the configuration data, the timeout period of the WDT/IWDT is determined. A thread created to monitor registered threads.
close	g_sf_thread_monitor.p_api->close (g_sf_thread_monitor.p_ctrl); Suspends the thread monitoring thread. The watchdog peripheral no longer refreshes.
threadRegister	g_sf_thread_monitor.p_api-> threadRegister (g_sf_thread_monitor.p_ctrl, &p_min_max_struct); Registers a thread for monitoring.
threadUnregister	g_sf_thread_monitor.p_api-> threadUnregister (g_sf_thread_monitor.p_ctrl); Removes a thread from monitoring.
countIncrement	g_sf_thread_monitor.p_api-> countIncrement (g_sf_thread_monitor.p_ctrl); Safely increments a monitored thread's count value.
versionGet	g_sf_thread_monitor.p_api-> versionGet(&version); Retrieves the API version and stores it in the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	Pointer is null.
SSP_ERR_IN_USE	Thread monitor has already been opened.
SSP_ERR_INVALID_MODE	Low-level watchdog peripheral returns an error when opened.
SSP_ERR_UNSUPPORTED	Data structure could not be allocated.
SSP_ERR_INVALID_ARGUMENT	One or more configuration options is invalid for the low-level driver.

SSP_ERR_NOT_OPEN	sf_thread_monitor_api_t::open has either not been called or was not called successfully.
SSP_ERR_INSUFFICIENT_SPACE	Not enough entries in the threads-to-be-monitored array to add this thread. Increases the value of THREAD_MONITOR_CFG_MAX_NUMBER_OF_THREADS in sf_thread_moinitor_cfg.h.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.25.3 Thread Monitor Framework Module Operational Overview

The Thread Monitor performs as follows: a thread registers a counter variable with the thread monitor along with the minimum and maximum expected values for this counter variable. The thread which is monitored increments the counter variable while it runs. At a period of half the watchdog timeout period, the thread monitor checks the counter variables of registered threads. If any fall outside of the minimum and maximum values, the watchdog timer is allowed to reset the microcontroller. If all fall within their expected range, the watchdog timer is refreshed and the counter variables are cleared to zero.

Thread Monitor Framework Module Important Operational Notes and Limitations

Thread Monitor Framework Module Operational Notes

The following figure shows a flowchart for the operation of the Thread Monitor Framework module.

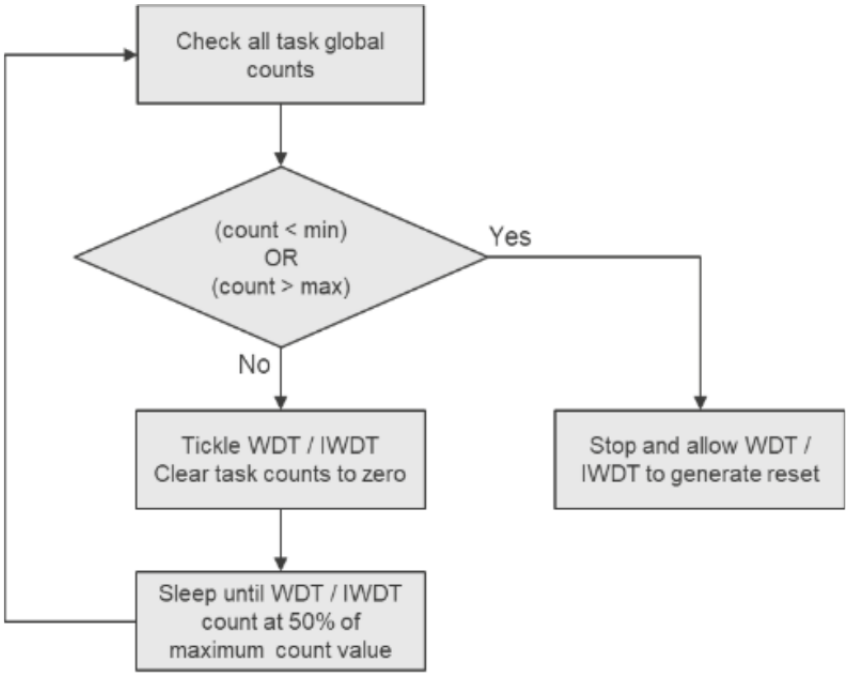

Figure 210: Thread Monitor Framework Operation Diagram

The following figure shows when the WDT/IWDT refreshes. Note that the valid refresh period is the central 50% of the count period, 25% on either side of the 50% count value.

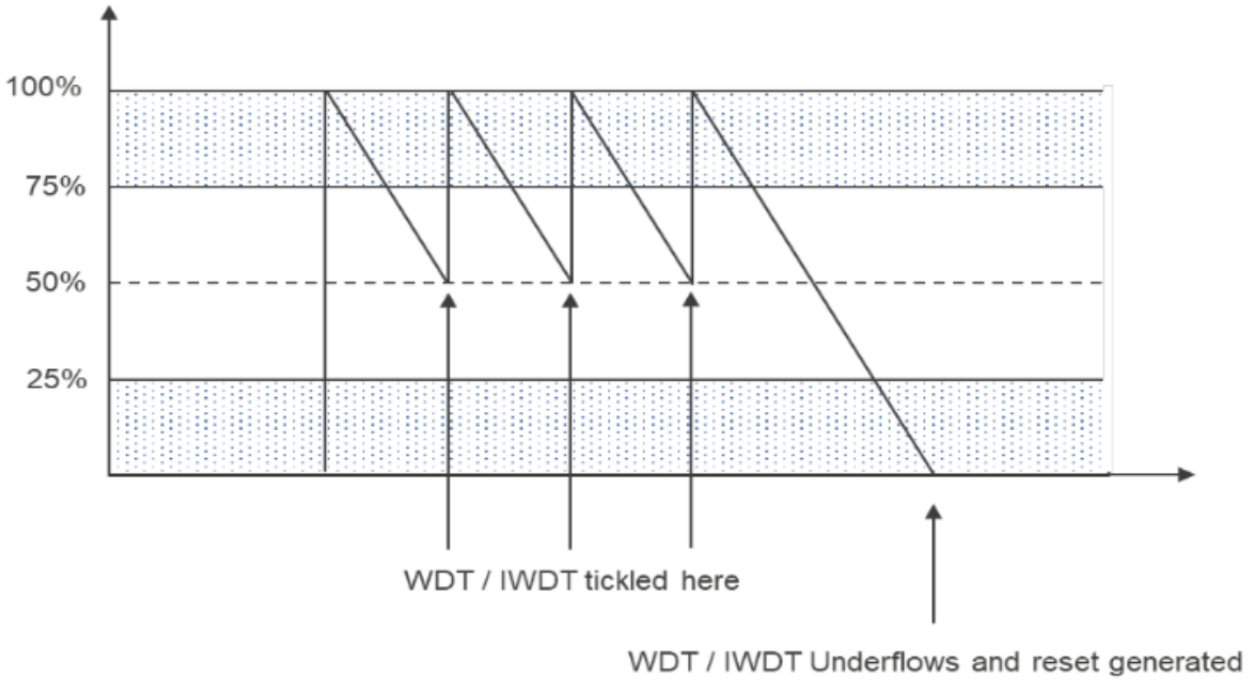

Figure 211: WDT/IWDT Refresh Operation

- The IWDT has its own clock source to improve safety.
- The WDT can be started from the application.
- When the thread is not executing sleep mode, set the stop-control property of the WDT to WDT Count Enabled in Low Power Mode. When the thread is not executing (asleep), the ThreadX® executes a WFI instruction effectively putting the device into soft sleep, which causes the WDT to stop counting.

Note

Do not open or refresh the WDT in a monitored thread file; it is done automatically by the Thread Monitor Framework.

Internally, the Thread Monitor Framework runs at the rate of half of the watchdog timer reset period. This rate ensures the Thread Monitor Framework runs at 50% of the watchdog count value-well within the valid refresh window. The Thread Monitor calculates the reset period internally by querying the lower-level watchdog driver.

Thread Monitor Framework Profiling Calculation

The thread monitor framework provides a method to keep track of the number of times a thread is registered. Any of the threads registered with the thread monitor framework need to call the sf_thread_monitor_api_t::countIncrement API to update a counter which is an indication of the number of times a specified thread was executed. A thread, which is part of the thread monitor framework would run at a predefined time interval and keeps the count value of the thread registered for monitoring. The monitor task will analyze count values taken over each interval and keeps track of the minimum and maximum counts obtained for each of the threads.

For example, consider a WDT configured with a time-out cycle of 16384 and clock division ratio of 8192. Assuming a PCLK of 60 MHz and time for a system tick to be 10 ms, the total number of ticks for WDT time out would be 223. Considering 50% of WDT time out, the thread monitor task would run at every 111 ticks to keep track of the threads registered for monitoring.

In a scenario where a simple thread executing a continuous loop with a sleep of 2 ticks in between each iteration, the max count value would be 56 (that is, 111/2).

When the thread monitor is run for the first time, it waits a full WDT time-out period of 111 counts (223 ticks) before activating the framework. This feature ensures proper working of WDT. In addition, whenever a new thread is registered, the max/min count value will not update unless the registered thread is activated from the thread monitor. This results in an additional delay of 56 counts (111 ticks).

Note

For the very first task registered with the thread monitor, a total delay of 111 + 56 counts would be introduced after which the Min/Max count is updated. The profiling calculation remains same for both WDT and IWDT clock sources except for the refresh time-out period.

Thread Monitor Framework Module Limitations

- The Thread Monitor Framework has a sf_thread_monitor_api_t::close API call. When WDT and IWDT are being used, it is not possible to stop them. If the Thread Monitor Framework is closed, some other provision for refreshing the watchdog must be made or the device resets.
- The Thread Monitor Framework has a sf_thread_monitor_api_t::threadUnregister API call which removes the calling thread from being monitored. The API would return SSP_SUCCESS for any thread that is not registered with the sf_thread_monitor framework and also for threads which were already unregistered.
- Debugging mode-support is required when running with a J-Link on some devices; WDT/IWDT does not count when using J-Link debugging hardware. The Thread Monitor Framework thread typically synchronizes to the WDT/IWDT counter, but skips this synchronization step when it is running with J-Link.
- Assign a high priority (low number in ThreadX) to the Thread Monitor Framework thread; any delays in running the Thread Monitor Framework could refresh the watchdog outside of the valid refresh window, causing the microcontroller to reset. The Thread Monitor Framework thread does not run for long and does not impact the performance of the system.
- Refer to the latest *SSP Release Notes* for any additional operational limitations for this module.

4.1.25.4 Including the Thread Monitor Framework Module in an Application

This section describes how to include the Thread Monitor Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Thread Monitor Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Thread Monitor Framework is g_sf_thread_monitor. This name can be changed in the associated Properties window.)

Thread Monitor Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence

g_thread_monitor0 Thread Monitor Framework	Threads	**New Stack> Framework> Services> Thread Monitor Framework on sf_thread_monitor**

When the Thread Monitor Framework on sf_thread_monitor is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

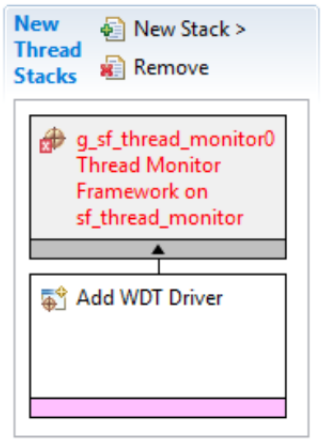

Figure 212: Thread Monitor Framework Module Stack

4.1.25.5 Configuring the Thread Monitor Framework Module

The Thread Monitor Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Thread Monitor Framework Module on sf_thread_monitor

ISDE Property	Value	Description

Parameter Checking	Enabled, Disabled, BSP Default: BSP	Controls whether to include code for API parameter checking.
Maximum Number of Monitored Threads	5	Maximum number of threads that can be monitored.
Name	g_sf_thread_monitor0	The name of the Thread Monitor instance.
Profiling Mode	Enabled, Disabled, Default: Disabled	Whether profiling mode should be enabled.
Thread Monitor Thread Priority	1	Priority of thread monitor internal thread.
Name of generated initialization function	sf_thread_monitor_init0	Name of generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Thread Monitor Framework Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the Independent Watchdog Timer on r_iwdt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_wdt0	Module name.

NMI Callback	NULL	Callback. A user callback function can be registered in external_irq_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Watchdog Timer on r_wdt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_wdt0	Module Name.
Start Mode	Register, Auto Default: Register	Configures the start mode as register start or auto-start.
Start Watchdog After Configuration	True, False Default: True	Controls whether WDT is started during initialization.
Timeout	1024 cycles, 4096 cycles, 8192 cycles, 16384 cycles Default: 16384 cycles	WDT timeout period.
Clock Division Ratio	PCLK/4, PCLK/64, PCLK/128, PCLK/512, PCLK/2048, PCLK/8192 Default: PCLK/8192	WDT clock divider.
Window Start Position	100% (Window Position Not Specified), 75%, 50%, 25% Default: 100% (Window Position Not Specified)	Permitted refresh period start postion.

Window End Position	0% (Window Position Not Specified), 25%, 50%, 75% Default: 0% (Window Position Not Specified)	Permitted refresh period end postion.
Reset Control	Reset Outpout, NMI Generated Default: Reset Output	Select whether WDT should reset the MCU or generate an NMI.
Stop Control	WDT Count Enabled in Low Power Mode, WDT Count Disabled in Low Power Mode Default: WDT Count Disabled in Low Power Mode	Select whether the WDT should stop counting in low power modes.
NMI Callback	NULL	Callback. A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Thread Monitor Framework Module Clock Configuration

Use the ISDE to configure the WDT clock using the **Clocks** tab.

The WDT is initially based on the PCLKB frequency. Set the PCLKB frequency in the ISDE using the clock configurator or the CGC Interface at run-time.

With the PCLKB running at 60 MHz, the WDT maximum timeout period is approximately 2.24 seconds.

The IWDT clock runs at 15 kHz resulting in a maximum possible timeout period of just under 35 seconds.

Thread Monitor Framework Module Pin Configuration

The Thread Monitor Framework does not require any pins for its operation.

Threads for the Thread Monitor Framework Module Application

Any thread monitored by the Thread Monitor Framework must be instrumented to work with the monitoring module. When a thread to be monitored is registered with the Thread Monitor, the expected minimum and maximum count values are passed via a pointer to a structure of type sf_thread_monitor_counter_min_max_tcontaining the values.

The thread's counter and minimum and maximum values must be registered with the Thread Monitor Framework by calling g_sf_thread_monitor.p_api->threadRegister().

Each time round the monitored thread's loop, the counter value should be updated by calling g_sf_thread_monitor.p_api->countIncrement().

Other Thread Monitor Framework Module Settings

The Thread Monitor Framework does not use any interrupts; the WDT/IWDT must be configured to generate a reset.

4.1.25.6 Using the Thread Monitor Framework Module in an Application

The steps in using the Thread Monitor Framework module on sf_thread_monitor in a typical application are:

1. Initialize the Thread Monitor using the sf_thread_monitor_api_t::open API.
2. Register thread that needs to be monitored with the sf_thread_monitor_api_t::threadRegister API.
3. Use the sf_thread_monitor_api_t::countIncrement API to increment the count every time the registered thread is executed.
4. Unregister the thread with the sf_thread_monitor_api_t::threadUnregister API when there is no longer a need to monitor the registered thread.
5. Close the Thread Monitor with the sf_thread_monitor_api_t::close API (only if the Thread Monitor is no longer required in an application).

These common steps are illustrated in a typical operational flow diagram in the following figure:

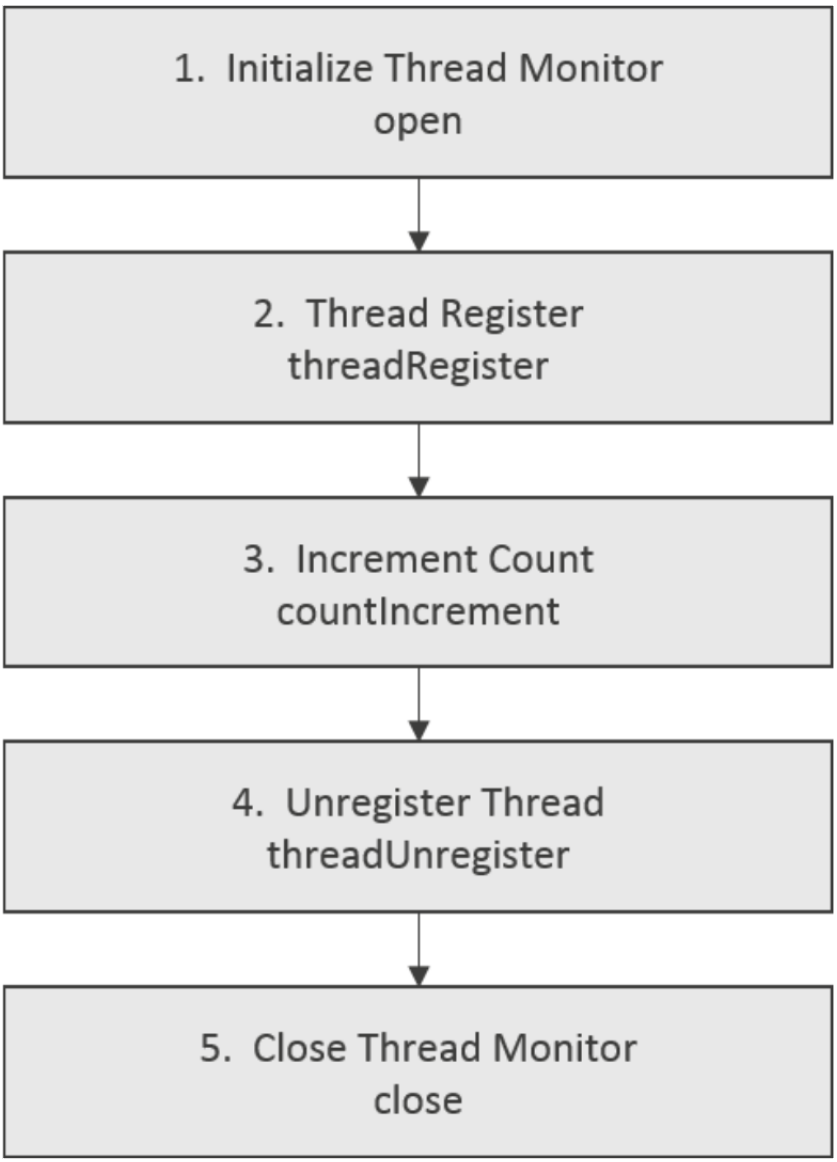

Figure 213: Flow Diagram of a Typical Thread Monitor Framework Module Application

4.1.26 Touch Panel V2 Framework

4.1.26.1 Touch Panel V2 Framework Introduction

The Touch Panel V2 Framework module provides a high-level API for obtaining touch data on coordinates and events from the touch controller. The Touch Panel V2 Framework module uses the touch chip driver SSP Supplement module for communication with the touch panel.

Touch Panel V2 Framework Module Features

- Provides position data (X and Y coordinates).
- Provides rotation of touch coordinates.

- Provides the touch event type (down, up, move, hold, or invalid).
- A callback can be registered or an API function can be used to get touch data.
- Supports calibration of the touch panel for key elements: scalar, rotation and mechanical shifts.
- Provides a common API interface to touch chip drivers.
- Supports an adjustable update frequency.

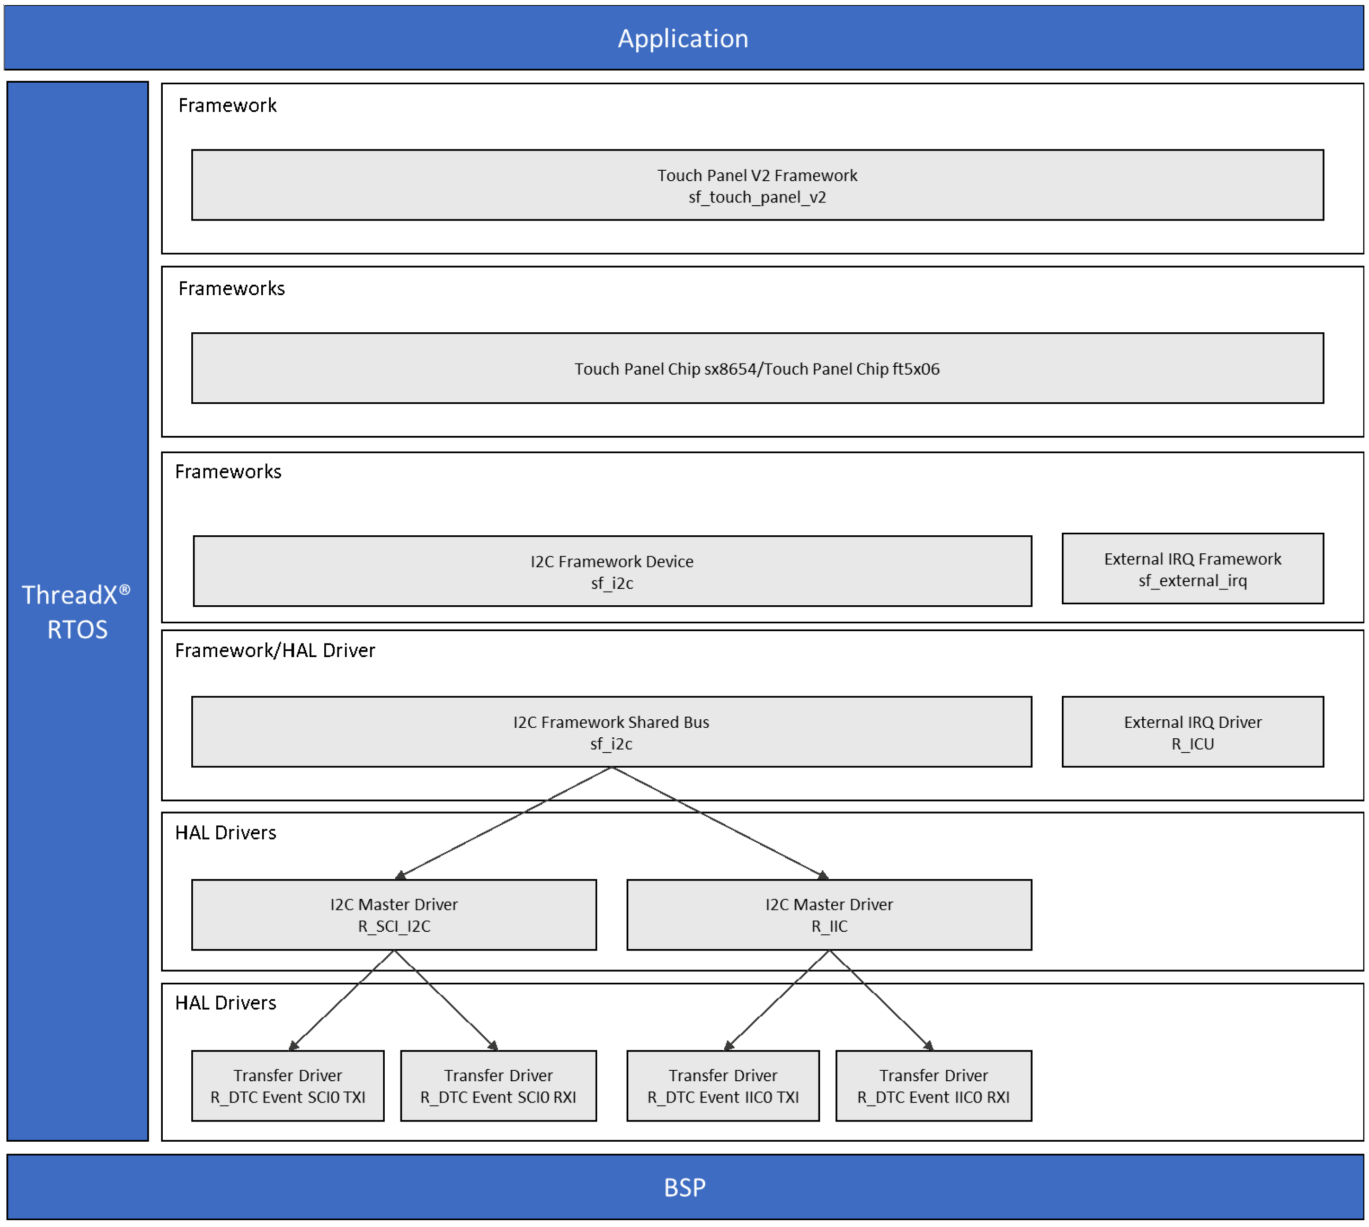

Figure 214: Touch Panel V2 Framework Module Block Diagram

4.1.26.2 Touch Panel V2 Framework Module APIs Overview

The Touch Panel V2 Framework module defines API functions such as opening, calibrating, starting, stopping or closing. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Touch Panel V2 Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_touch_panel_v2_0.p_api->open(g_sf_touch_panel_v2_0.p_ctrl, g_sf_touch_panel_v2_0.p_cfg); Create required RTOS objects, call a lower level module for hardware specific initialization and create a thread to post touch data to a user application.
calibrate	g_sf_touch_panel_v2_0.p_api->calibrate(g_sf_touch_panel_v2_0.p_ctrl, p_display, p_touchscreen, timeout); Begin calibration routine based on provided expected and actual coordinates.
start	g_sf_touch_panel_v2_0.p_api->start(g_sf_touch_panel_v2_0.p_ctrl); Start scanning for touch events.
stop	g_sf_touch_panel_v2_0.p_api->stop (g_sf_touch_panel_v2_0.p_ctrl); Stop scanning for touch events.
touchDataGet	g_sf_touch_panel_v2_0.p_api->touchDataGet (g_sf_touch_panel_v2_0.p_ctrl, p_payload, timeout); Reads the touch data and fills in the touch payload data.
reset	g_sf_touch_panel_v2_0.p_api->reset(g_sf_touch_panel_v2_0.p_ctrl); Resets touch controller if reset pin is provided.
close	g_sf_touch_panel_v2_0.p_api->close(g_sf_touch_panel_v2_0.p_ctrl); Terminates touch thread and closes channel at HAL layer.
versionGet	g_sf_touch_panel_v2_0.p_api->versionGet(g_sf_touch_panel_v2_0.p_version); Retrieves API version and stores it in the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API call successful.
SSP_ERR_ASSERTION	A pointer parameter was NULL, or a lower level driver reported this error.

SSP_ERR_INTERNAL	The touch panel thread or event flags could not be created, or a lower level driver reported this error.
SSP_ERR_CALIBRATE_FAILED	Actual touch value was not in expected range.
SSP_ERR_NOT_OPEN	Touch panel is not configured. Call SF_TOUCH_PANEL_V2_Open.
SSP_ERR_IN_USE	Mutex was not available, or a lower level driver reported this error.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.1.26.3 Touch Panel V2 Framework Module Operational Overview

The Touch Panel V2 Framework module scans data from a touch controller and invokes the user registered callback. If user callback is not registered the sf_touch_panel_v2_api_t::touchDataGet API function can be used to retrieve the data. The touch data contains touch coordinates (X and Y coordinates) and the touch event type (down, up, move, hold, or invalid). The Touch Panel V2 Framework uses an internal thread to read the touch controller.

Touch Panel V2 Framework Module Important Operational Notes and Limitations

Touch Panel V2 Framework Module Operational Notes

The key operational elements of the Touch Panel V2 Framework are described below:

Auto Initialization and Auto Start

The "Auto Initialization" property in the Synergy configurator window must be enabled to automatically initialize the framework. The "Auto start" property in the configurator window must be enabled to automatically receive touch data from the touch chip.

User Callback

The user callback must be registered to obtain touch data. If the user callback is registered then the framework will invoke the callback when touch events occur.

API to Get the Touch Data

The sf_touch_panel_v2_api_t::touchDataGet API function can be used to obtain touch data. This function will wait until new touch event data is available or it will timeout (based on the timeout argument passed to the API).

Update Frequency

The application will be notified with repeated touch events (like touch event down and touch event hold and touch event invalid) at the specified update frequency (Update Hz) configured in the Synergy configurator property window.

Note

The touch event UP and touch event DOWN will be notified regardless of the update frequency.

For example,

If the "Update Hz" property is set to 10 Hz, then only 10 repeated touch events will be notified to the application in a second.

Calibration

The touch panel V2 framework supports calibration of touch data to overcome the issues in the touch panel like: Scalar, rotation and Mechanical shifts.

To obtain the calibrated data the user needs to call the sf_touch_panel_v2_api_t::calibrate API function and pass 3 sets of expected coordinates and the obtained coordinated.

Note

The framework must be initialized before calling sf_touch_panel_v2_api_t::calibrate API.

For ex ample:

Consider a scenario where a touch panel with resolution 480 x 272 is being used. The touch panel is touched at upper left, upper right and lower right and the obtained coordinates (x, y) when touched at these touch panel locations and their expected coordinates are as illustrated below:

Table 3 Touch Panel Coordinates

Location on Touch Panel	Expected Coordinates	Obtained Coordinates
Upper left corner	(0, 0)	(17, 20)
Upper right corner	(480, 0)	(464, 17)
Lower right corner	(480, 272)	(463, 258)

These 3 sets of values (expected and obtained coordinates) are passed into the calibrate function in the expected format. Once the sf_touch_panel_v2_api_t::calibrate API function is called, the required calibration factors are calculated and stored in the control structure. The touch data now obtained will be calibrated.

Note

Once the sf_touch_panel_v2_api_t::close API function is called the stored calibration factors are erased and the calibrate API must be called again to obtain the calibrated touch data.

Create a Custom Touch Panel Chip Driver

To create your custom Touch Chip Driver, refer to the existing touch chip driver code in SSP which is located at synergy/ ssp_supplemental / touch_drivers .

Note

*This directory will only be visible if any existing touch chip driver touch_panel_chip_ft5x06 or touch_panel_chip_sx8654 is selected in the Synergy configurator . To do this go to the Synergy configurator and select **New** > **Framework** > **Input** > **Touch Panel V2 Framework on sf_touch_panel_v2** > **Add Touch Driver**. Select any existing touch driver for reference and generate project content .*
Refer to the SSP Module Development Guide document to learn more about creating a custom driver. The document can be found using this
link: https://www.renesas.com/us/en/document/apn/ssp-module-development-guide-application-note.

The following instructions can be used to connect a custom touch chip driver to the Touch Panel V2 Framework:

- Implement Touch Chip Driver Instance (synergy/ssp_supplemental/inc/framework/instances) and source file (synergy/ssp_supplemental/touch_drivers).
- Make sure the chip specific settings are configured based on the touch screen used and the applications use case.
- Implement the payloadGet function to obtain touch events and touch coordinates from the Touch Panel Controller.
- Implement a reset function reset to reset the touch chip.
- If the touch chip is using communication protocol other than I2C or if it doesn't support external IRQ then modify the open, payloadGet, reset and close functions. Also the touch chip driver Configuration XML (located under .module_descriptions folder) must be modified.

Configure the Custom Touch Panel Chip Driver

To configure a custom touch chip driver to a project, follow the steps below:

Step 1. Create a Synergy C project.

Step 2. Update existing touch driver XML for the custom touch driver by following these steps. Modify any existing touch XML as described below:

- Go to the .module_descriptions folder under the project root folder.
- Edit touch chip driver XML:
    - Renesas##HAL Drivers##touch panel##touch_panel_chip_ft5x06####<version>.xml Or
    - Renesas##HAL Drivers##touch panel##touch_panel_chip_sx8654####<version>.xml
- Change name of the instance structure with name of custom driver instance structure. For example "g_touch_panel_chip_xxxxx"
- Add the new instance declaration and api declaration in <header> tab. For example,

```
    <header>
  extern const sf_touch_panel_chip_instance_t g_touch_panel_chip_xxxxx;
  extern const sf_touch_panel_chip_api_t g_sf_touch_panel_chip_xxxxx;
    </header>
```

- Rename all touch chip number in the XML with custom touch chip number.
- If communication protocol other than I2C is used then change the interface and id under the <requires> tag. For example,

```
    <requires>
  id="module.external.ex_touch_panel_chip_ft5x06.requires.spi " interface="
interface.framework . sf_spi_v2_on_sf_spi " display="Add framework"
    </requires >
```

- Save and close the XML file

Step 3. Open project configurator and add Touch panel V2 framework, by selecting **New** > **Framework** > **Input** > **Touch Panel V2 Framework on sf_touch_panel_v2** (If the configurator was already opened, close and open it again).

Step 4. Configure all components.

Step 5. Add the custom touch panel chip driver to the "Add Touch Driver" box. (The custom touch driver open will be visible if XML is modified correctly).

Step 6. Generate Project Content and add new directory (for example, touch_panel_chip_xxxxxx) structure under synergy/ ssp_supplemental/ touch_drivers, the directory structure will look like this: synergy/ ssp_supplemental/ touch_drivers/ touch_panel_chip_xxxxxx (replace xxxxxx with touch controller part no).

Step 7. Add the custom driver code into this directory (ssp_supplemental/ touch_drivers/ touch_panel_chip_xxxxxx).

Step 8. Exclude existing driver from build if any (**right-click the .c file** > **Exclude from build...** > **Select all** > **OK**).

Step 9. Build the code.

Touch Panel V2 Framework Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.26.4 Including the Touch Panel V2 Framework Module in an Application

This section describes how to include the Touch Panel V2 Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Touch Panel V2 Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Touch Panel V2 Framework module is g_sf_touch_panel_v2_0. This name can be changed in the associated Properties window.)

Touch Panel V2 Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_touch_panel_v2_0 Touch Panel V2 Framework on sf_touch_panel_v2	Threads	**New Stack**> **Framework**> **Input**> **Touch Panel V2 Framework on sf_touch_panel_v2**

When the Touch Panel V2 Framework module on sf_touch_panel_v2 is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

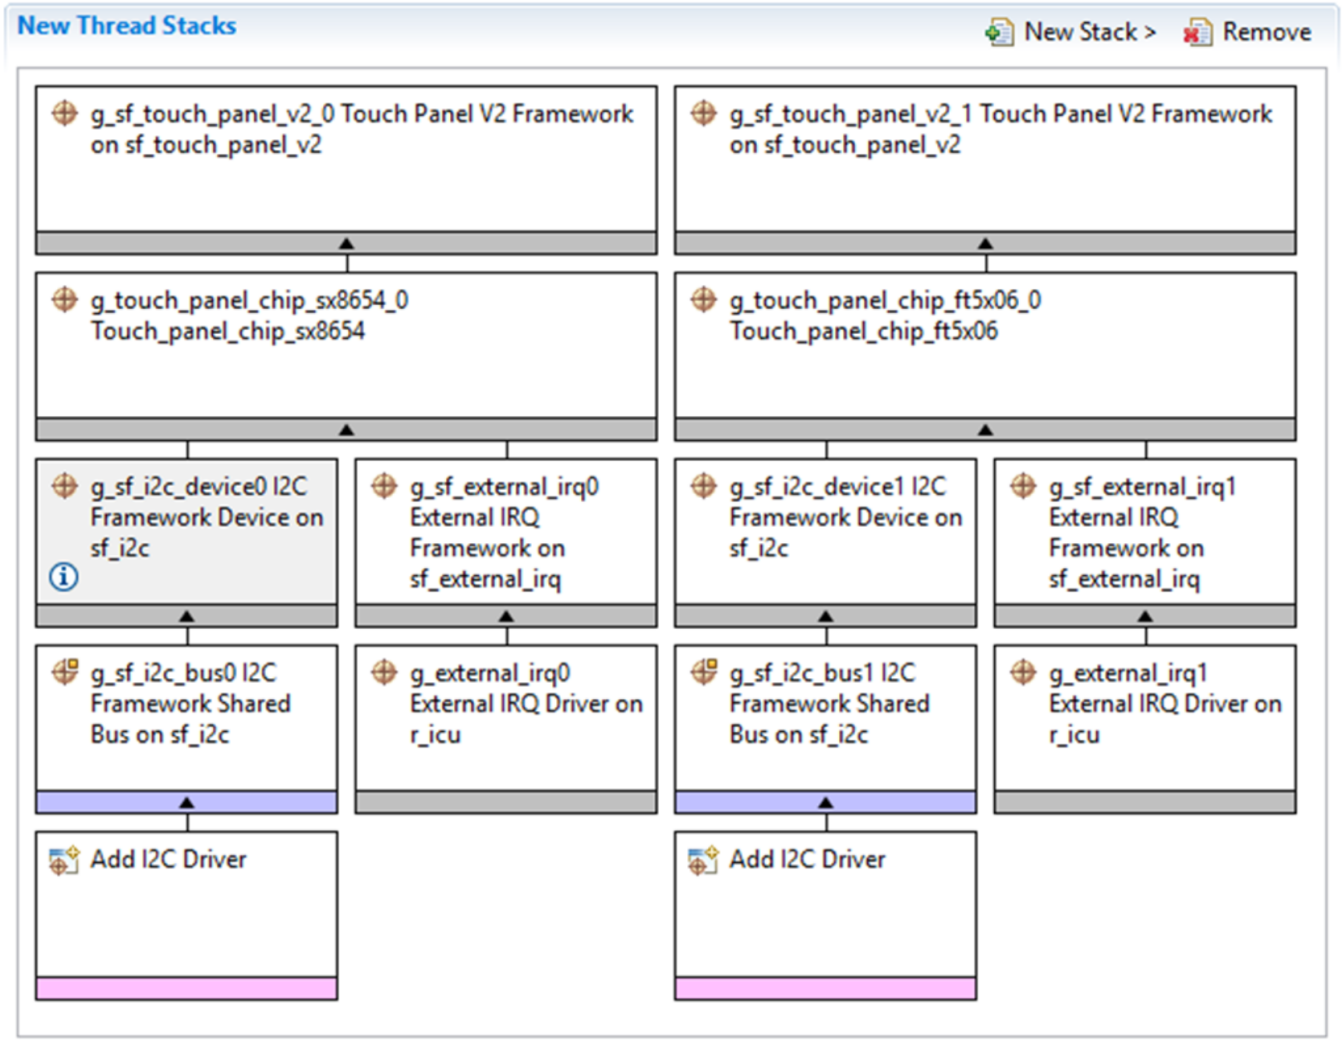

Figure 215: Touch Panel V2 Framework Module Stack

4.1.26.5 Configuring the Touch Panel V2 Framework Module

The Touch Panel V2 Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it

much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the Touch Panel V2 Framework Module on sf_touch_panel_v2

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Thread Stack Size	512	Specify the touch panel thread stack size.
Name	g_sf_touch_panel_v2_0	Module name.
Thread Priority	3	Specify the thread priority.
Update Hz	10	Specify the update rate in Hertz.
Touch Coordinate Rotation Angle (Clockwise)	0, 90 (Select this if 'Screen Rotation Angle' is 'CW' or '90'), 180 (Select this if 'Screen Rotation Angle' is FLIP or '180'), 270 (Select this if 'Screen Rotation Angle' is 'CCW' or '270') Default: 0	Select the touch coordinate rotation angle.
Name of generated initialization function	sf_touch_panel_v2_init0	Specify the name of the generated initialization function.
Auto Initialization	Enable, Disable Default: Enable	Select if sf_touch_panel_v2 will be initialized during startup.
Auto Start	Enable, Disable Default: Enable	Enabling this will start to get the touch data.
Name of touch panel callback function to be defined by user	NULL	Touch panel callback function name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower level modules are fairly intuitive and can usually be determined by inspection of the associated Properties window from the SSP configurator.

Configuring the Touch Panel V2 Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the lower-level modules:

Configuration Settings for the Touch Panel Chip sx8654

ISDE Property	Value	Description
Name	g_touch_panel_chip_sx8654_0	Module name.
Horizontal pixel count	480	Specify the number of horizontal pins.
Vertical pixel count	272	Specify the number of vertical pixels.
Reset Port	00:11 Default: 07	Select the chip reset port.
Reset Pin	00:15 Default: 11	Select the chip reset pin.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Touch Panel Chip ft5x06

ISDE Property	Value	Description
Name	g_touch_panel_chip_ft5x06	Module name.
Horizontal pixel count	800	Specify the number of horizontal pins.
Vertical pixel count	480	Specify the number of vertical pixels.
Reset Port	00:11 Default: 10	Select the chip reset port.
Reset Pin	00:15 Default: 02	Select the chip reset pin.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2C Framework Device on sf_i2c

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: Enabled	Selects if code for parameter checking is to be included in the build.
Name	g_sf_i2c_device0	Give a name to identify the I2C Framework device. API, Config and Control instances will be created based on this name.
Slave Address	0x00	Specify the address of the I2C slave device.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Select the I2C address mode.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2C Shared Bus on sf_i2c

ISDE Property	Value	Description
Name	g_sf_i2c_bus0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2C Master Driver on r_riic

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Name	g_i2c0	Module name.
Channel	0	Specify the IIC channel to be used with this configuration.
Rate	Standard, Fast-mode, Fast-mode Plus Default: Standard	Standard, Fast, and Fast-plus. (See IIC Rate Calculation.)

Slave Address	0x00	Set the address of the slave device the I2C master will be communicating with.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
Timeout Mode	Short Mode, Long Mode Default: Short Mode	Select the timeout mode.
Callback	NULL	A user callback function can be registered in i2c_api_master_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Select the receive interrupt priority.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Select the transmit interrupt priority.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Select the transmit end interrupt priority.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Priority 12	Select the error interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event IIC0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Software Start	Enabled, Disabled Default: Disabled	Include code for software start in the build.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place the DTC vector table.
Name	g_transfer0	Module name.
Mode	Normal	Specify the hardware channel.
Transfer Size	1 Byte	Select the transfer mode.
Destination Address Mode	Fixed	Select the transfer size.
Source Address Mode	Incremented	Select the address mode for the destination.
Repeat Area (Unused in Normal Mode)	Source	Select the address mode for the source.
Interrupt Frequency	After all transfers have completed	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source (Must enable IRQ)	Event IIC0 TXI	Select the DTC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback (Only valid with Software start)	NULL	A user callback that is called at the end of the transfer.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event IIC0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Software Start	Enabled, Disabled Default: Disabled	Include code for software start in the build.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place the DTC vector table.
Name	g_transfer1	Module name.
Mode	Normal	Specify the hardware channel.
Transfer Size	1 Byte	Select the transfer mode.
Destination Address Mode	Incremented	Select the transfer size.
Source Address Mode	Fixed	Select the address mode for the destination.
Repeat Area (Unused in Normal Mode	Destination	Select the address mode for the source.
Interrupt Frequency	After all transfers have completed	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source (Must enable IRQ)	Event IIC0 RXI	Select the DTC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback (Only valid with Software start)	NULL	A user callback that is called at the end of the transfer.

ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2C Master Driver on r_sci_i2c

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Name	g_i2c0	Module name.
Channel	0 to 9	Specify the SCI channel to be used with this configuration. SCI has channels as follows: Series S7: 0 1 2 3 4 5 6 7 8 9; Series S3 : 0 1 2 3 4 - - - - 9; Series S1 : 0 1 - - - - - - - 9.
Rate	Standard, Fast-mode, Fast-mode plus Default: Standard	Select the I2C data rate.
Slave Address	0x00	Specify the slave address.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
SDA Output Delay (nano seconds)	300	SDA output delay in nanoseconds.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Enables bitrate modulation function.

Callback	NULL	A user callback function can be registered in i2c_api_master_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the receive interrupt priority.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the transmit interrupt priority.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the transmit end interrupt priority.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the error interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Software Start	Enabled, Disabled Default: Disabled	Include code for software start in the build.

Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place the DTC vector table.
Name	g_transfer0	Module name.
Mode	Block	Specify the hardware channel.
Transfer Size	1 Byte	Select the transfer mode.
Destination Address Mode	Fixed	Select the transfer size.
Source Address Mode	Incremented	Select the address mode for the destination.
Repeat Area (Unused in Normal Mode	Source	Select the address mode for the source.
Interrupt Frequency	After all transfers have completed	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source (Must enable IRQ)	Event SCI0 TXI	Select the DTC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback (Only valid with Software start)	NULL	A user callback that is called at the end of the transfer.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Software Start	Enabled, Disabled Default: Disabled	Include code for software start in the build.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place the DTC vector table.
Name	g_transfer1	Module name.
Mode	Normal	Specify the hardware channel.
Transfer Size	1 Byte	Select the transfer mode.
Destination Address Mode	Incremented	Select the transfer size.
Source Address Mode	Fixed	Select the address mode for the destination.
Repeat Area (Unused in Normal Mode	Destination	Select the address mode for the source.
Interrupt Frequency	After all transfers have completed	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source (Must enable IRQ)	Event SCI0 RXI	Select the DTC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback (Only valid with Software start)	NULL	A user callback that is called at the end of the transfer.

ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the External IRQ Framework on sf_external_irq

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Name	g_sf_external_irq0	Framework name.
Event	None, Semaphore Put Default: Semaphore Put	Event selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the External IRQ Driver on r_icu

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter checking setting enables or disables the addition of parameter checking code.
Name	g_external_irq0	Module name.
Channel	0	Specifies the hardware IRQ channel used.
Trigger	Falling, Rising, Both Edges, Low Level Default: Rising	Configures edge or level triggering.
Digital Filtering	Enabled, Disabled Default: Disabled	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCLK/1, PLCK/8, PLCK/32, PCLK/64 Default: PCKL/64	Sets noise filter sampling period.

Interrupt enabled after initialization	True, False Default: True	Determines if the interrupt is enabled immediately after initialization.
Callback	NULL	A user callback function can be registered in external_irq_api_t::open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Pin Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	An Interrupt priority can be registered in external_irq_cfg_t::irq_ipl.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Touch Panel V2 Framework Module Clock Configuration

An example implementation of the I2C interface uses the SCI peripheral and is described here. Other implementation choices might have different selections and can be inferred from the following example. The SCI peripheral module uses the PCLKB as its clock source. The PCLKB frequency is set by using the SSP configurator **Clock** tab prior to a build, or by using the CGC Interface at run-time. During configuration, the I2C transfer rate is calculated and set internally by the driver based on the user selected PCLB rate and the user selected transfer rate. If the PCLKB is configured in such a manner that the user selected rate cannot be achieved, an error will be returned when initializing the driver.

Touch Panel V2 Framework Module Pin Configuration

An example implementation of the I2C interface uses the SCI peripheral and is described here. Other implementation choices might have different selections, but can be inferred from the below example. Synergy Kit specific settings for pins are shown in the following section. The SCI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the I2C pins:

Pin Selection Sequence for the Touch Panel V2 Framework Module

Resource	ISDE Tab	Pin selection Sequence

SCI0	Pins	Select **Peripherals**> **Connectivity:SCI**> **SCI0**

Note

The selection sequence assumes the SCI0 is the desired hardware target of the driver.

Pin Configuration Settings for the DAC Driver on r_dac

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Asynchronous UART, Synchronous UART, Simple I2C, Simple SPI, SmartCard Default: Disabled Simple I2C	Select Simple I2C as the Operation Mode for SPI on SCI.
RXD1_SCL1_MISO1	None, P212, P708 Default: None	SCL pin.
TXD1_SDA1_MOSI1	None, P213, P709 Default: None	SDA pin.

Note

The example values are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.1.26.6 Using the Touch Panel V2 Framework Module in an Application

The typical steps in using the Touch Panel V2 Framework module in an application are:

1. Register a user callback in application code to receive touch data (if needed).
2. Initialize the touch panel V2 framework module using the sf_touch_panel_v2_api_t::open API function (done automatically within SSP if "auto initialization" property is enabled).
3. Calibration of touch data can be done by using the sf_touch_panel_v2_api_t::calibrate API function (If required).
4. Start the touch panel framework module to begin scanning the touch data from the touch chip using the sf_touch_panel_v2_api_t::start API function (done automatically within SSP if the "auto start" property is enabled).
5. The registered user callback is invoked by the framework when a touch event occurs and is processed in application code.
6. Get the data using the sf_touch_panel_v2_api_t::touchDataGet API function (if the user callback is not registered).
7. Operate on the received touch data as needed using application code.
8. Stop receiving the touch data using the sf_touch_panel_v2_api_t::stop API function.
9. Close the module using the sf_touch_panel_v2_api_t::close API function (if required).

These common steps are illustrated in a typical operational flow in the following figure:

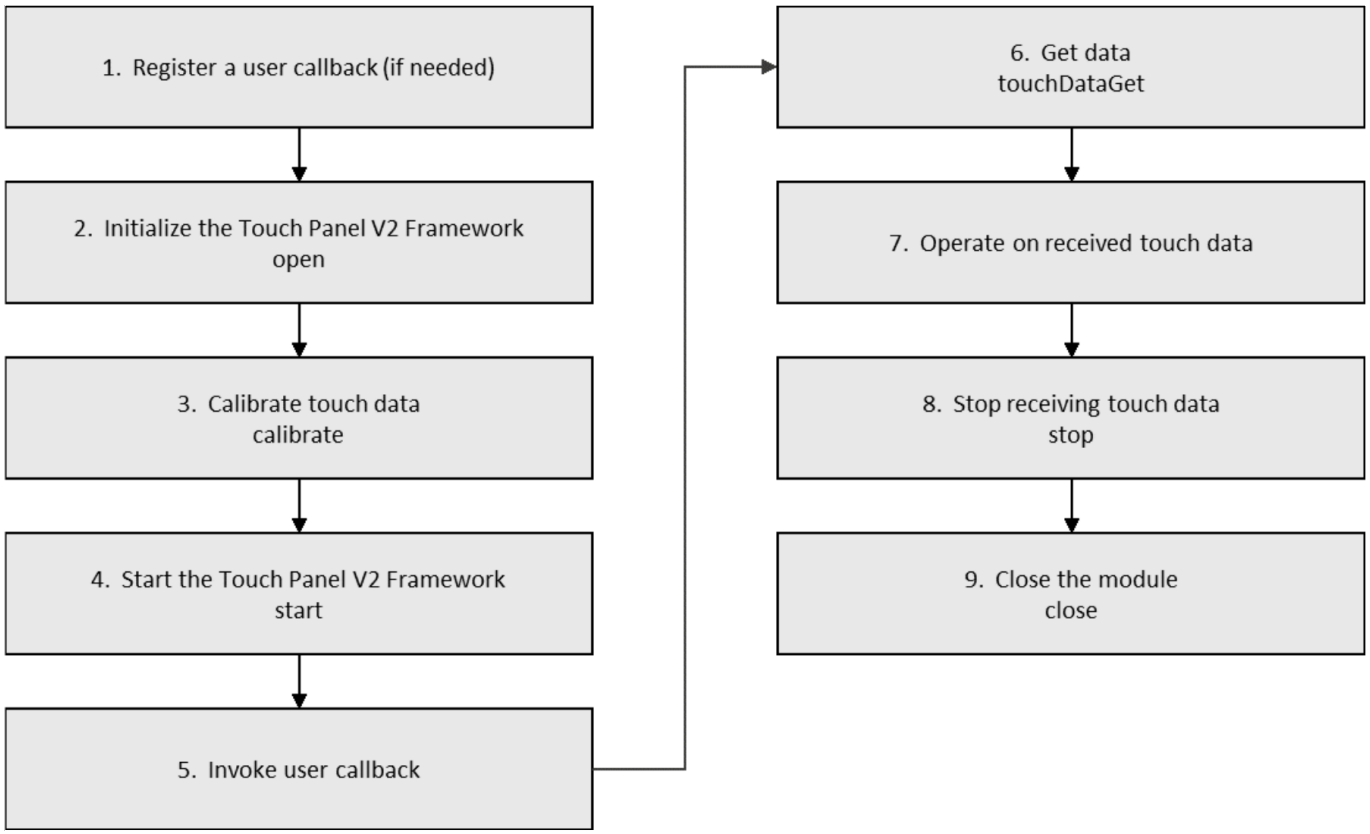

Figure 216: Flow Diagram of a Typical Touch Panel V2 Framework Module Application

4.1.27 UART Communications Framework

4.1.27.1 UART Communications Framework Module Introduction

The UART communications framework implements a high-level API for serial communications supporting the industry standard UART protocol on a UART-compliant Synergy MCU peripheral. It utilizes the r_sci_uart HAL driver to configure and operate the Synergy MCU SCI peripheral in the UART mode.

UART Communications Framework Module Features

This module is a ThreadX-aware communications framework; it uses ThreadX objects to ensure that the operations are thread safe.

Key features include:

- Support for UART Communications protocol
- Support for locking a channel to reserve exclusive access
- ThreadX-aware implementation

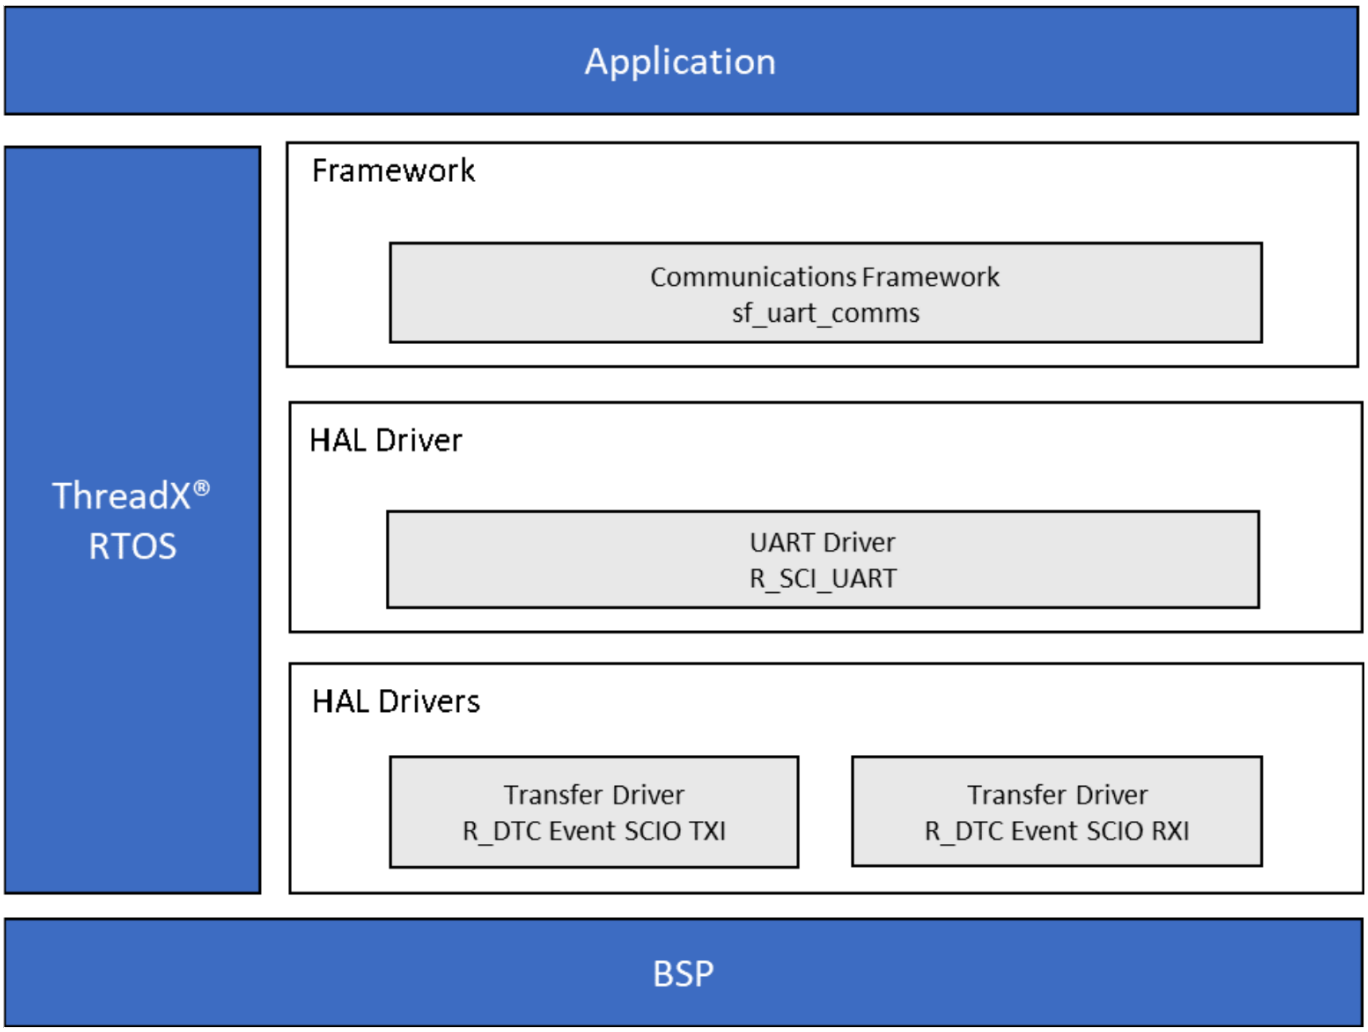

Figure 217: UART Communications Framework Module Block Diagram

4.1.27.2 UART Communications Framework Module APIs Overview

The UART Communications Framework module defines APIs for opening, closing, reading and writing to the communications channel. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

UART Communications Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_comms0.p_api->open(g_sf_comms0.p_ctrl, g_sf_comms0.p_cfg); Initialize communications driver.
close	g_sf_comms0.p_api->close(g_sf_comms0.p_ctrl); Clean up communications driver.

read	g_sf_comms0.p_api->read(g_sf_comms0.p_ctrl, &destination, bytes, timeout); Read data from communications driver. This call will return after the number of bytes requested is read or if a timeout occurs while waiting for access to the driver.
write	g_sf_comms0.p_api->write(g_sf_comms0.p_ctrl, &source, bytes, timeout); Write data to communications driver. This call will return after all bytes are written or if a timeout occurs while waiting for access to the driver.
lock	g_sf_comms0.p_api->lock(g_sf_comms0.p_ctrl, lock_type, timeout); Lock the communications driver. Reserve exclusive access to the communications driver.
unlock	g_sf_comms0.p_api->unlock(g_sf_comms0.p_ctrl, lock_type); Unlock the communications driver. Release exclusive access to the communications driver.
versionGet	g_sf_comms0.p_api->version(&version); Store the driver version in the provided version.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Channel opened successfully.
SSP_ERR_IN_USE	Channel already in use.
SSP_ERR_ASSERTION	Pointer to UART control block or configuration structure is NULL.
SSP_ERR_HW_LOCKED	Channel is locked.
SSP_ERR_INVALID_MODE	Channel is used for non-UART mode or illegal mode is set.
SSP_ERR_INVALID_ARGUMENT	Invalid parameter setting found in the configuration structure.
SSP_ERR_QUEUE_UNAVAILABLE	Cannot open transmit or receive queue or both.
SSP_ERR_INTERNAL	Internal error occurs.
SSP_ERR_TIMEOUT	Timeout error.
SSP_ERR_INSUFFICIENT_DATA	Not enough data in receive circular buffer.

SSP_ERR_RXBUF_OVERFLOW	Receive queue overflow.
SSP_ERR_OVERFLOW	Hardware overflow.
SSP_ERR_FRAMING	Framing error.
SSP_ERR_PARITY	Parity error.
SSP_ERR_INSUFFICIENT_SPACE	Not enough space in transmission circular buffer.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.1.27.3 UART Communications Framework Module Operational Overview

The UART Framework provides an easy-to-use communication framework using the standard UART protocol. In addition to the high-level API functions to read and write data from the UART device in a thread safe manner, the framework also provides API functions for applications to lock (and unlock) the UART channel to a thread. This is particularly useful when multiple application threads try to communicate with the same UART device and a context switch could upset the high-level application protocols and/or state machines implemented on top of the UART (like Kermit, for example).

UART Communications Framework Module Important Operational Notes and Limitations

UART Communications Framework Module Operational Notes

- The UART Framework module is reentrant for any channel.
- The UART Framework uses the UART Driver on r_sci_uart module for communicating with a UART device. The UART Driver can be augmented by adding DTC drivers (using the Synergy Platform configurator in the ISDE) to perform read or write transactions with a UART device without interrupting the CPU. When the UART Framework is used to read data from a UART device, it will rely on the UART Driver's callback feature to read data and will not use the DTC (even if the DTC module support is added to the UART Driver through the configurator). This is done to avoid any potential timing and synchronization issues that could arise when the driver uses the DTC to read data from the device. When using the UART Framework to write data to a UART device, it will use the DTC to perform the transaction (if the driver is configured to use the DTC).

UART Communications Framework Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.27.4 Including the UART Communications Framework Module in an Application

This section describes how to include the UART Communications Framework Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the UART Communications Framework to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the UART

Communications Framework is g_sf_comms0. This name can be changed in the associated Properties window.)

UART Communications Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_comms0 Communications Framework on sf_uart_comms	Threads	**Framework** > **Connectivity** > **Communications Framework on sf_uart_comms**

When the UART Communications Framework on sf_uart_comms is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

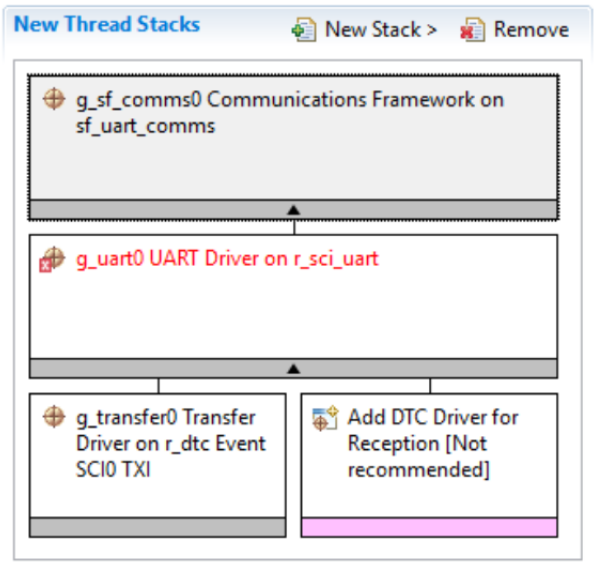

Figure 218: UART Communications Framework Module Stack

4.1.27.5 Configuring the UART Communications Framework Module

The UART Communications Framework Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the UART Communications Framework Module on sf_uart_comms

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if parameter checking is included.
Read Input Queue Size (4-Byte Words)	15	Buffer size for data reception queue. sf_uart_comms utilizes the ThreadX Queue for the queue management.
Name	g_sf_comms0	Name of UART communications framework module.
Name of generated initialization function	sf_comms_init0	Name of generated initialization function selection.
Auto Initialization	Enable, Disable Default: Enable	Auto initialization selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the UART Communications Framework Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configuration Settings for the UART HAL Module on r_sci_uart

ISDE Property	Value	Description
External RTS Operation	Enable, Disable Default: Disable	Enable an IOPORT pin to be used as RTS signal. For RTS functionality set this configuration parameter to "Enable" and specify the configuration "Name of UART callback function for the RTS external pin control".

Reception	Enable, Disable Default: Enable	Enable or disable UART reception for all UART channels on SCI. Setting this configuration parameter to "Disable" reduces code size because the portion of code for UART reception is not compiled. You cannot set this parameter for individual UART channels.
Transmission	Enable, Disable Default: Enable	Enable or disable UART transmission for all UART channels on SCI. Setting "Disable" to this configuration allows to get smaller code size due to the portion of code for UART transmission is compiled out, however, you can only set "Disable" to this configuration if any other SCI channels which work as UART ports do not perform the transmission.
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_uart0	The name to be used for UART on SCI module control block instance. This name is also used as the prefix of the other variable instances.
Channel	0	SCI channel number.
Baud Rate	9600	Baud rate selection.
Data Bits	7 bits, 8, bits, 9 bits Default: 8 bits	UART data bits.
Parity	None, Odd, Even Default: None	UART parity bits.
Stop Bits	1 bit, 2 bits Default: 1 bit	UART stop bits.

CTS/RTS Selection	CTS (Note that RTS is available when enabling External RTS Operation mode which uses 1 GPIO pin), RTS (CTS is disabled) Default: RTS (CTS is disabled)	Select CTS or RTS for the CTSn/RTSn pin of SCI channel n. The SCI hardware supports either the CTS or the RTS control signal on this pin but not both. For an application that uses both CTS and RTS, select "CTS" for this configuration parameter and enable the configuration "External RTS Operation" specifying the configuration "Name of UART callback function for the RTS external pin control".
Name of UART callback function to be defined by user	NULL	Name must be a valid C symbol.
Name of UART callback function for the RTS external pin control to be defined by user	NULL	Name must be a valid C symbol.
Clock Source	Internal Clock, External Clock 8x baudrate, External Clock 16x baudrate Default: Internal Clock	Selection of the clock source to be used in the baud-rate clock generator block.
Baudrate Clock Output from SCK pin	Enable, Disable Defaualt: Disable	Optional setting to output the baud-rate clock on the SCKn pin for the selected channel n.
Start bit detection	Fallling Edge, Low Level Default: Falling Edge	Start bit detection mode in the reception, usually set "Falling Edge" to this configuration.
Noise Cancel	Enable, Disable Defaualt: Disable	Enable the digital noise cancellation on RXDn pin. The digital noise filter block in SCI consists of two-stage flip-flop circuits. For detail, refer to the Noise cancellation section in the Renesas Synergy hardware manual.
Bit Rate Modulation Enable	Enable, Disable Defaualt: Enable	Bit rate modulation enable selection.
Receive FIFO Trigger Level	One, Max Default: Max	Receive FIFO trigger level selection.

Receive Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit interrupt priority selecition.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Error interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Defaualt: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.

Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_transfer1	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.

Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

UART Communications Framework Module Clock Configuration

The UART Communications Framework has no specific clock configuration requirements.

UART Communications Framework Module Pin Configuration

The UART Communications Framework uses pins on the MCU to communicate to external devices based on the lower level implementation selected. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the lower level implementation pins.

Note

For some peripherals, the operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection for the UART Communications Framework Module on sf_uart_comms

Resource	ISDE Tab	Pin selection Sequence
UART	Pins	Select **Peripherals**> **Connectivity: SCI**> **SCI8**

Note

The selection sequence assumes SCI0 is the desired hardware target for the driver.

Pin Configuration Settings for the UART Communications Framework Module on sf_uart_comms

Property	Value	Description
Pin Group Selection	Mixed, _A Only, _B Only	Pin group selection.

Operation Mode	Disabled, Custom, Asynchronous UART, Synchronous UART, Simple I2C, Simple SPI, SmartCard Default: Disabled	Select Asynchronous UART as the Operation Mode for a UART Receiver implementation.
TXD_MOSI	None, PB05, P105 Default: None	TXD pin P105.
RXD_MISO	None, PB05, P104 Default: None	RXD pin P104.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

Pin Selection Sequence for Communications Framework on UART, USB or Telnet (Transmitter)

Resource	ISDE Tab	Pin selection Sequence
UART	Pins	Select **Peripherals** > **Connectivity: SCI**> **SCI3**

Note

These selection sequences are examples for selected implementations. Others are also possible depending on the target hardware.

Pin Configuration Settings for UART

Pin Configuration Property	Settings	Description
Pin Group Selection	Mixed, _A Only, _B Only	Pin group selection.
Operation Mode	Disabled, Custom, Asynchronous UART, Synchronous UART, Simple I2C, Simple SPI, SmartCard Default: Disabled	Select Asynchronous UART as the Operation Mode for a UART Transmitter implementation.
TXD_MOSI	None, P707, P409 Default: None	TXD pin P707.
RXD_MISO	None, P706, P408 Default: None	RXD pin P706.

Note

These selection sequences are examples for selected implementations. Others are also possible depending on the target hardware.

4.1.27.6 Using the UART Communications Framework Module in an Application

The steps in using the UART Communications Framework module on sf_audio_record_adc in a typical application are:

1. Initialize the UART Communications Framework using the sf_comms_api_t::open API.
2. Lock the channel for continuous communications using the sf_comms_api_t::lock API if needed.
3. Receive data using the sf_comms_api_t::read API.
4. Send data using the sf_comms_api_t::write API.
5. Unlock the channel from continuous communication using the sf_comms_api_t::unlock API if needed.
6. Close the channel using the sf_comms_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

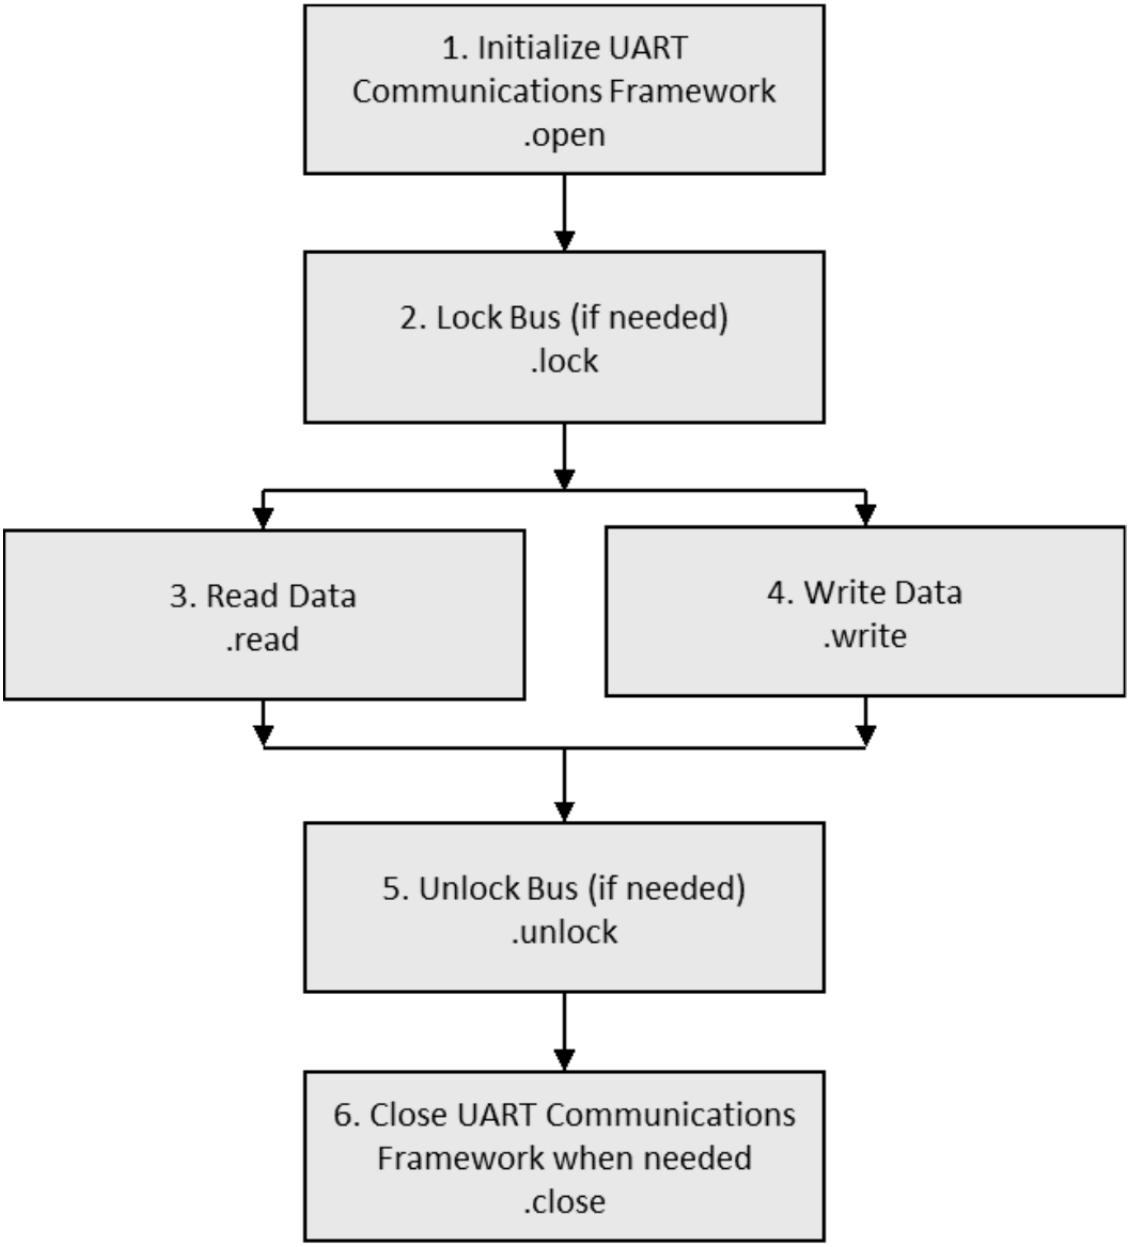

Figure 219: Flow Diagram of a Typical UART Communications Framework Module Application

4.1.28 Wi-Fi Framework

4.1.28.1 Wi-Fi Framework Introduction

The Wi-Fi framework provides a high-level API for configuring and provisioning Wi-Fi modules as well as performing data transfers with or without on-chip networking capability. Currently, only the Qualcomm GT202 module is supported. The Wi-Fi framework communicates through the SPI with the underlying GT202 module.

Wi-Fi Framework Module Features

- Provides high-level APIs to configure and provision a Wi-Fi module
- Provides four different implementations for:
    - A Wi-Fi device driver stack using the sf_wifi_gt202 framework.
    - An on-chip stack using the sf_wifi_onchip_stack framework.
    - A BSD socket stack using the sf_wifi_onchip_stack framework.
    - A NetX and NetX Duo port using the sf_wifi_nsal_nx framework.
- Using NetX and NASL:
    - Allows the same application code to be used across different Wi-Fi modules.
    - Allows for easy migration of the Ethernet-based application to a Wi-Fi based application.
    - Allows for debugging and fine-tuning the application and TCP/IP stack as required by the application.
    - The current NSAL implementation only provides NetX NSAL. Adding support for a new network stack requires implementing the appropriate NSAL.
- Using the On-chip networking stack:
    - Is beneficial when using MCUs with a small memory footprint.
    - Provides a BSD sockets interface to create socket-based applications with the On-chip TCP/UDP.
- Provides an option to integrate 3rd-party application protocols on top of TCP/IP such as MQTT and COAP without using the NetX stack.
- Provides support for Wi-Fi Protected Setup (**WPS**) router configuration using Push-Button and PIN methods.

Note

The On-Chip Stack on GT202 Wi-Fi Framework can be used as a lower-level implementation of the BSD Socket Framework or on its own. The GT202 Wi-Fi Device Driver and its lower-level modules is included below all other Wi-Fi Framework implementations.

4.1.28.2 Wi-Fi Framework Module APIs Overview

The Wi-Fi Framework defines API functions for each of the related modules. The following descriptions explain the operation of each API. A table of common return codes follows at the end of the section. Refer to the API reference section for the associated module for additional details.

Additionally, a more detailed API description, along with a working example application (which is too lengthy to include in this document), is available on the Renesas web site. Just search for the associated application note document number, r11an0226eu, in the top page search bar on www.Renesas.com. It is highly recommended that you use the application note to augment the summary descriptions found in this document.

Wi-Fi Framework Module APIs

WiFi Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_wifi0.p_api->open (g_sf_wifi0.p_ctrl, g_sf_wifi0.p_cfg); This API initializes and enables the Wi-Fi module. The open function returns the Wi-Fi control structure, uniquely identifying the instance of the Wi-Fi framework.
close	g_sf_wifi0.p_api->close(g_sf_wifi0.p_ctrl); This API un-initializes the Wi-Fi module and powers it off.
infoGet	g_sf_wifi0.p_api->infoGet (g_sf_wifi0.p_ctrl, wifi_info); This API takes the WiFi control structure as an argument and returns the following information obtained from the WiFi module: - Chipset/driver information string - RSSI value (unsigned integer 16 bits) - Noise level (unsigned integer 16 bits) - Link Quality (unsigned integer 16 bits)

statisticsGet	g_sf_wifi0.p_api->statisticsGet (g_sf_wifi0.p_ctrl, p_stats); This API gets the data statistics from the Wi-Fi module. It takes the Wi-Fi control structure as an argument and returns the following statistics: - Received packets (unsigned integer 32 bits) - Transmitted packets (unsigned integer 32 bits) - Transmit packet errors (unsigned integer 32 bits)
transmit	g_sf_wifi0.p_api->transmit (g_sf_wifi0.p_ctrl, p_buffer, length); This API sends the data/packet out. This function takes the Wi-Fi control structure as an argument. It takes the network packet buffer, and the network packet buffer length as arguments. The Wi-Fi framework transmit function passes the packet buffer to the Wi-Fi driver for transmission.
provisioningGet	g_sf_wifi0.p_api->provisioningGet (g_sf_wifi0.p_ctrl, &sf_wifi_provisioninfo); This API takes the Wi-Fi control structure as an argument and returns the following parameters: - Mode (enumeration, that is, AP or client) - Channel (unsigned integer 8 bits) - SSID (string) - Security type (enumeration) - Encryption type (enumeration) - Security key (string)
provisioningSet	g_sf_wifi0.p_api->provisioningSet (g_sf_wifi0.p_ctrl, &g_sf_wifi_provisioninfo); This API sets the Wi-Fi module in the given mode AP/Station. The provisioningSet function uses the following parameters to provision the WiFi module: - Mode (enumeration, that is, AP or client) - Channel (unsigned integer 8 bits), only used in AP mode - SSID (string) - Security type (enumeration) - Encryption type (enumeration) - Security key (sting). - Connection Status Notification Callback function: Used to get connection status change notification *See note at the end of this table.

scan	g_sf_wifi0.p_api->scan (g_sf_wifi0.p_ctrl, p_scan, p_count); This API scans the available SSIDs (that is, access points) in range. This function takes the Wi-Fi control structure as an argument and returns a list of SSIDs scanned by the WiFi module with the following parameters: - HW mode (enumeration a/b/g/n) - RSSI (unsigned integer 16 bits) - SSID (string) - BSSID (byte array of size 6 bytes) - Channel (unsigned integer 8 bits) - Security type (enumeration) - Encryption type(enumeration) - BSS type (enumeration) The Wi-Fi framework scan function takes the SSID count as an argument, which acts as an in/out parameter. It specifies the size of the scan result array and the Wi-Fi framework sets it to count the indicating number of scan results stored in the array.
ACLAdd	g_sf_wifi0.p_api->ACLAdd (g_sf_wifi0.p_ctrl, peer_device_mac); This API adds the given MAC address to the access control list. This function takes the Wi-Fi control structure and the MAC address as arguments.
ACLDelete	g_sf_wifi0.p_api->ACLDelete (g_sf_wifi0.p_ctrl, peer_device_mac); This API deletes the given MAC address from the access control list. This function takes the Wi-Fi control structure and MAC address as arguments.
multicastListAdd	g_sf_wifi0.p_api->multicastListAdd (g_sf_wifi0.p_ctrl, p_mac_addr); This API adds the given Multicast IP address to the multicast filer list. This function takes the Wi-Fi control structure and MAC address as arguments.
multicastListDelete	g_sf_wifi0.p_api->multicastListDelete (g_sf_wifi0.p_ctrl, p_mac_addr); This API deletes the given Multicast IP address from the multicast filer list. This function takes the Wi-Fi control structure and MAC address as arguments.
macAddressGet	g_sf_wifi0.p_api->macAddressGet (g_sf_wifi0.p_ctrl, p_mac); This API reads MAC address from WiFi module. This function takes the Wi-Fi control structure as argument and returns MAC address read from Wi-Fi module.

macAddressSet	g_sf_wifi0.p_api->macAddressSet (g_sf_wifi0.p_ctrl, p_mac); This API sets Wi-Fi module's MAC address. This function takes the Wi-Fi control structure and MAC address as arguments.
wpsStart	g_sf_wifi0.p_api->wpsStart(g_sf_wifi0.p_ctrl, &wps_data); This API starts WPS on device. The wpsStart function uses the following parameters passed to a structure to start WPS on device: - WPS method as Push-button or Pin - WPS pin. Used only with WPS pin method - WPS timeout value in seconds - Pointer to callback function to be called on change in client's connection status with AP or client connected/disconnected

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.
Provisioning: When the device is provisioned in client mode, the callback will be called when a connection with the AP is lost and then reestablished. When the device is provisioned in AP mode, this callback is called when any client connects or disconnects with the AP. When the device is provisioned in client mode, arguments passed to callback will have only the below valid field,

- event = SF_WIFI_EVENT_AP_CONNECT or SF_WIFI_AP_DISCONNECT

When device is provisioned in AP mode then arguments passed to callback will have only below valid fields,

- event = SF_WIFI_EVENT_CLIENT_CONNECT or SF_WIFI_CLIENT_DISCONNECT
- mac_addr = MAC address of client.

While calling the sf_wifi_api_t::provisioningSet API function to provision the device in client mode, the framework will not call the callback function on the successful association with the AP or on a failure. When the device is provisioned in AP mode, if the client tries to connect with the AP using the wrong password, the callback will be called twice; first with the connected event and then immediately after with the disconnected event.

On-Chip Networking Stack Support APIs

These APIs can be used to configure the Wi-Fi module when using an on-chip networking stack, which helps to configure the IP address for the interface and start/stop the DHCP server (when configured in the AP mode).

On-Chip Networking Stack Support Wi-Fi Framework Module API Summary

Function Name	Example API Call and Description

open	g_sf_wifi_onchip_stack0.p_api->open (g_sf_wifionchip_stack0.p_ctrl, g_sf_wifi_onchip_stack0.p_cfg); This API calls the WiFi framework open API which initializes the Wi-Fi module.
close	g_sf_wifi_onchip_stack0.p_api->close(g_sf_wifi_onchip_stack0.p_ctrl); This API calls the Wi-Fi framework close API which un-initializes the Wi-Fi module.
ipAddressCfg	g_sf_wifi_onchip_stack0.p_api->ipAddressCfg (g_sf_wifi_onchip_stack0.p_ctrl, p_cfg); This API configures the IP address of the interface using an on-chip networking stack. It provides facility to configure static IP address or using DHCP.
dhcpServerStart	g_sf_wifi_onchip_stack0.p_api->dhcpServerStart (g_sf_wifi_onchip_stack0.p_ctrl, p_start_ip, p_end_ip); This API starts the DHCP server on the interface (when configured in AP mode) using on-chip networking stack. It takes the range of IP addresses to be used by DHCP server.
dhcpServerStop	g_sf_wifi_onchip_stack0.p_api->dhcpServerStop (g_sf_wifi_onchip_stack0.p_ctrl); This API stops the DHCP server.
versionGet	g_sf_wifi_onchip_stack0.p_api->versionGet (&version); Retrieves the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

BSD Socket APIs

These APIs can be used for BSD socket support using the GT202 on-chip stack implementation.

BSD Socket using GT202 On-Chip Stack Wi-Fi Framework Module API Summary

Function Name	Example API Call and Description
open	g_sf_socket0.p_api->open (g_sf_socket0.p_ctrl, g_sf_socket0.p_cfg); This API initializes the networking interface.
close	g_sf_socket0.p_api->close(g_sf_socket0.p_ctrl); This API closes the network interface.

versionGet	g_sf_socket0.p_api->versionGet (&version); Retrieves the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Additionally, this implementation includes socket APIs which are compliant with BSD APIs. These APIs can be used by the application to perform data transfer using sockets. The following APIs are available:

- socket
- close
- bind
- listen
- accept
- connect
- send
- recv
- recvfrom
- sendto
- setsockopt
- getsockopt
- select

Note

While using on chip networking stack, application can use all BSD Socket APIs, all on chip Networking Stack support APIs and few Synergy Wi-Fi framework APIs. The Synergy Wi-Fi framework APIs which application can use are provisioningSet(), provisioningGet(), scan(), macAddressGet(), macAddressSet() and infoGet()

More information is available for these APIs as described in the NetX BSD 4.3 Sockets API Compliancy Wrapper for NetX User Guide which can be found on the Synergy Gallery on the SSP page under the documentation tab in the Azure RTOS Component Documents for Renesas Synergy zip file.

Wi-Fi NSAL

The Synergy Wi-Fi framework supports the NetX/NetX-Duo Network Services Abstraction Layer. This includes the NetX/NetX-Duo driver, packet transmit and receive callback functions implementation.

NetX/NetX-Duo Driver Function

The NetX/NetX-Duo driver function takes the NetX IP instance, Wi-Fi framework instance and NSAL configuration as arguments. The NSAL configuration controls the behavior of transmit and receive callback functions. The NSAL configuration includes flags which indicates zero-copy support is enabled or disabled in transmit and receive path. The NetX/NetX-Duo driver functions implement various IP driver commands used by NetX/NetX-Duo. The interface attach command calls the Wi-Fi framework open API to initialize the Wi-Fi module. The initialize command calls the Wi-Fi framework macAddressGet API to read MAC address from the Wi-Fi module. The multicast-join command calls the Wi-Fi framework multicastListAdd API to add the given MAC address to multicast list. The multicast-leave command calls the Wi-Fi framework multicastListDelete API to delete the given MAC address from the multicast list. The Send/Broadcast command calls the Wi-Fi framework transmit API to transmit a packet.

NSAL Transmit Function

The NSAL transmit function takes the NetX IP instance, the NetX packet, the Wi-Fi framework instance and the NSAL configuration as arguments. If zero-copy support is enabled, then the same NetX packet is transferred from NetX to the Wi-Fi driver. If zero-copy is not supported, then it copies data from the NetX packet to the driver buffer. It calls the Wi-Fi framework transmit API, which passes the buffer/packet to the Wi-Fi driver for further transmission.

NSAL Receive Callback

The NSAL receive callback function takes the NetX IP instance, the packet buffer, the packet buffer length and the NSAL configuration as arguments. This callback is called from the Wi-Fi device driver. If zero-copy support is enabled, then the same NetX packet is transferred from the Wi-Fi driver to NetX. If zero-copy is not supported, then it copies data from the driver buffer to the NetX packet and then passes the NetX stack for further processing. It calls the Wi-Fi framework transmit API, which passes the buffer to the Wi-Fi driver for further transmission.

More information is available for these APIs as described in the NetX User Guide which can be found on the Synergy Gallery on the SSP page under the documentation tab in the Azure RTOS Component Documents for Renesas Synergy zip file.

Wi-Fi Framework Error Codes

The following table lists the Wi-Fi Framework specific error codes. These error codes are part of ssp_err_t.

Wi-Fi Framework Error Codes

Error Codes	Description
SSP_ERR_WIFI_CONFIG_FAILED	Configuration failed.
SSP_ERR_WIFI_INIT_FAILED	Initialization failed.
SSP_ERR_WIFI_TRANSMIT_FAILED	Transmission failed.
SSP_ERR_WIFI_INVALID_MODE	Invalid mode specified.
SSP_ERR_WIFI_FAILED	WiFi failed.
SSP_ERR_WIFI_WPS_INVALID_START_INFO	Invalid input parameters.
SSP_ERR_WIFI_WPS_MULTIPLE_PB_SESSIONS	Another Push button session is already in progress.
SSP_ERR_WIFI_WPS_WALK_TIMER_TIMEOUT	WPS Timer expired.
SSP_ERR_WIFI_WPS_M2D_RECEIVED	M2D Error code received which means Registrar is unable to authenticate with the Enrollee.
SSP_ERR_WIFI_WPS_AUTHENTICATION_FAILED	WPS authentication failed.
SSP_ERR_WIFI_WPS_CANCELLED	WPS Request was not accepted by underlying driver.
SSP_ERR_WIFI_WPS_INVALID_PIN	Invalid WPS pin.

4.1.28.3 Wi-Fi Framework Module Operational Overview

The Wi-Fi framework provides a high-level interface for the application to configure the Wi-Fi module, provision the Wi-Fi module and perform data transfers. This simplifies application development and allows the same application code to be used across different Wi-Fi modules.

The following figure provides an overview of the Synergy Wi-Fi framework layered architecture:

- The Wi-Fi framework includes the enclosed 5 blocks in the middle of the architecture graph: NSAL, Wi-Fi Framework API, Wi-Fi on-chip Stack API, BSD Socket API, and the Wi-Fi Device Driver Interface.
- The vendor-provided Wi-Fi device drivers are included in the SSP package under SSP_Supplemental.

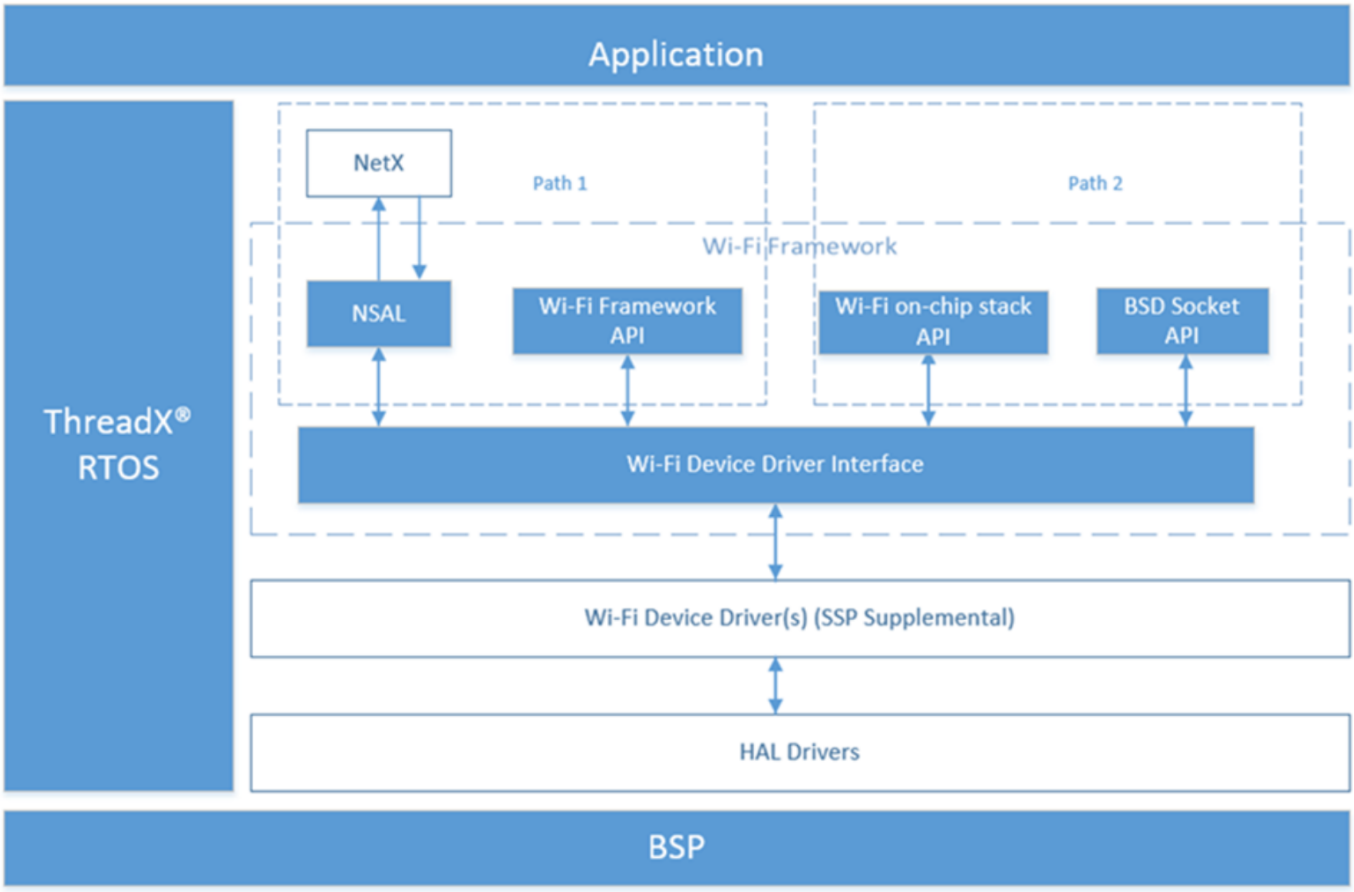

Figure 221: WiFi Framework Organization, Options and Stack Implementation

The Wi-Fi framework implementation allows Wi-Fi modules with or without On-chip networking stack support to be integrated with the SSP low-level support blocks.

- Path 1: Using NetX™/NetX Duo™, NSAL in addition to the Wi-Fi framework API blocks as shown in in the previous figure. To simplify the description, throughout this document, NetX refers to both NetX and NetX-Duo when the comment applies to both.
- Path 2: Using On-chip networking stack support API and the BSD Socket APIs as shown in the previous figure.

Wi-Fi Framework Module Important Operational Notes and Limitations

Wi-Fi Framework Module Operational Notes

- The Wi-Fi module has various parameters as specified by 802.11 standards. It is possible that individual device drivers and Wi-Fi chipsets might not support the configuration of all the functions.
- For the Wi-Fi interface to become active, at least the channel, Service Set Identifier (SSID), security scheme, and security credentials must be configured.
- The current NSAL implementation includes support for NetX (IPv4) and NetX-Duo (IPv6). NetX and NetX Duo support IPv4, however NetX Duo also supports IPv6. Adding support for a new network stack requires implementing the appropriate NSAL.
- For the security setting, WEP keys can be entered in either ASCII or Hex format and can be configured to use either 40 or 104-bit keys. A WEP key has a 24-bit initialization vector in addition to the secret key. Because of this and depending on the vendor, 64-bit WEP keys can be referred to as 40-bit keys and 128-bit WEP keys can be referred to as 104-bit keys. The Wi-Fi framework accepts 1 to 4 WEP keys of a specific format and type. In the provisioning structure, you must fill in the security type as SF_WIFI_SECURITY_TYPE_WEP and at least one (maximum is four) WEP key in the key buffer.

Wi-Fi Framework Module API Use Notes

Open:

When using the Wi-Fi framework module with NSAL, that is, with NetX/NeXDuo, the application should not call the Wi-Fi framework module sf_wifi_api_t::open API directly; instead, it should call the NetX nx_ip_create() API, which internally calls sf_wifi_api_t::open API from the NetX driver.

When using the On chip networking stack, the application should call the sf_wifi_api_t::open API from the BSD socket interface, which internally calls the Wi-Fi framework sf_wifi_api_t::open API.

Close:

When using the Wi-Fi framework module with NSAL, that is, with NetX/NetX Duo, the application should call the NetX nx_ip_delete() API directly.

When using the On chip networking stack, the application should call the sf_wifi_api_t::close API from the BSD socket interface, which internally calls the Wi-Fi framework module sf_wifi_api_t::close API.

ProvisioningSet:

When the device is provisioned in client mode, the callback will be called when the connection with the AP is lost and re-established. When the device is provisioned in AP mode, this callback is called when any client connects/disconnects with the AP. When the device is provisioned in client mode, the arguments passed to the callback will only have the following valid field:

event = SF_WIFI_EVENT_AP_CONNECT or SF_WIFI_AP_DISCONNECT

When the device is provisioned in AP mode, the arguments passed to the callback will only have the following valid fields:

event = SF_WIFI_EVENT_CLIENT_CONNECT or SF_WIFI_CLIENT_DISCONNECT

mac_addr = MAC address of client.

While calling the sf_wifi_api_t::provisioningSet API to provision the device in client mode, the framework will not call the callback function on successful association with the AP or on a failure.

When the device is provisioned in AP mode, if the client tries to connect with the AP using the wrong

password, the callback will be called twice, first with the connected event and then immediately after this, with the disconnected event.

InfoGet:

When the device is provisioned in the client mode, the RSSI value obtained using the sf_wifi_api_t::infoGet API call represents the SNR in dB. The noise_level and link_quality fields returned by the sf_wifi_api_t::infoGet API call do not contain any information - they are set to zero.

wpsStart:

If user wants to connect with Wi-Fi access-point, then user must know the SSID name, password and security type set on access-point. With this information, user can call Wi-Fi provisioning API to connect the device with given access-point. Wi-Fi Protected Setup (WPS) is a wireless network security standard that tries to make connections between a router and wireless devices faster and easier. WPS automatically configures the network name (SSID) and security key for the access point. User does not need to know the SSID and security key or passphrase when connecting WPS enabled devices.

There are 2 primary methods used in the WiFi Protected Setup:

- PIN entry – a mandatory method of setup for all WPS certified devices.
- Push button configuration – an actual push button on the hardware or through a simulated push button in the software.

Using the sf_wifi_api_t::wpsStart API, user can start WPS on device.

BSD Socket APIs:

While using the on-chip networking stack, applications can use all the BSD Socket APIs, all the On-Chip Networking Stack support APIs, and few Synergy Wi-Fi Framework APIs. The available Wi-Fi framework APIs are the sf_wifi_api_t::provisioningSet API, sf_wifi_api_t::provisioningGet API, sf_wifi_api_t::scan API, sf_wifi_api_t::macAddressGet, sf_wifi_api_t::macAddressSet API, and the sf_wifi_api_t::infoGet API.

Wi-Fi Framework Module Limitations

- The Wi-Fi framework does not support the Synergy S1 MCU Series due to memory constraints.
- Due to memory constraints, S3A6 and S128 MCUs will support only on-chip networking stack (that is, Path 2 for Wi-Fi use, where networking stack runs on Wi-Fi chipset).
- The Synergy Wi-Fi Framework APIs implemented for GT-202 are not re-entrant. All these APIs make calls to driver APIs to do the requested operation. If the GT-202 driver is working on behalf of any Wi-Fi Framework APIs and any other Wi-Fi Framework APIs are called, it will return SPP_ERR_IN_USE error until the ongoing operation is finished.
- The Synergy Wi-Fi framework sf_wifi_api_t::provisioningSet API for GT-202 may fail if the peripheral and IO pin drive capacity is not set to medium.
- While configuring the GT-202 with the SPI driver on r_rspi, set the drive capacity of the slave select pin, reset pin and SPI pins (that is, MISO, MOSI and RSPCK) to medium. While the configuring GT-202 with the SPI driver on r_sci_spi, set the drive capacity of the slave select pin, reset pin and SCI pins (that is, TXD_MOSI and RXD_MISO) to medium. Do not change the drive capacity of the SCK pin when the r_sci_spi driver is used.
- WiFi WPS functionality using GT-202 works only with WPA2 security in AP and Station mode.
- GT202 driver hangs if WPS session is terminated on peer device before session completion. However if user restarts WPS session on peer device and once WPS session is completed,

GT202 driver will exit from the loop and hanging issue will not be observed.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.1.28.4 Including the Wi-Fi Framework Module in an Application

This section describes how to include the Wi-Fi Framework module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Wi-Fi Framework module to an application, simply add it to a HAL /Common thread using the stacks selection sequence given in the following table. (The default name for the Wi-Fi Framework module is g_sf_wifi0. This name can be changed in the associated Properties window.)

Wi-Fi Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_wifi0 GT202 Wi-Fi Device Driver on sf_wifi_gt202	Threads	**New Stack> Framework> Networking> WiFi> GT202 Wi-Fi Device Driver on sf_wifi_gt202**
g_sf_wifi_onchip_stack0 On-Chip Stack on Gt202 Wi-Fi Framework	Threads	**New Stack> Framework> Networking> WiFi> On-Chip Stack on Gt202 Wi-Fi Framework**
g_sf_socket0 BSD Socket using On-Chip Stack on Gt202 Wi-Fi Framework	Threads	**New Stack> Framework> Networking> WiFi> BSD Socket using On-Chip Stack on Gt202 Wi-Fi Framework**
g_sf_el_nx0 NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx	Threads	**New Stack> Framework> Networking> WiFi> NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx**

When the Wi-Fi Framework module on sf_wifi is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description includes Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

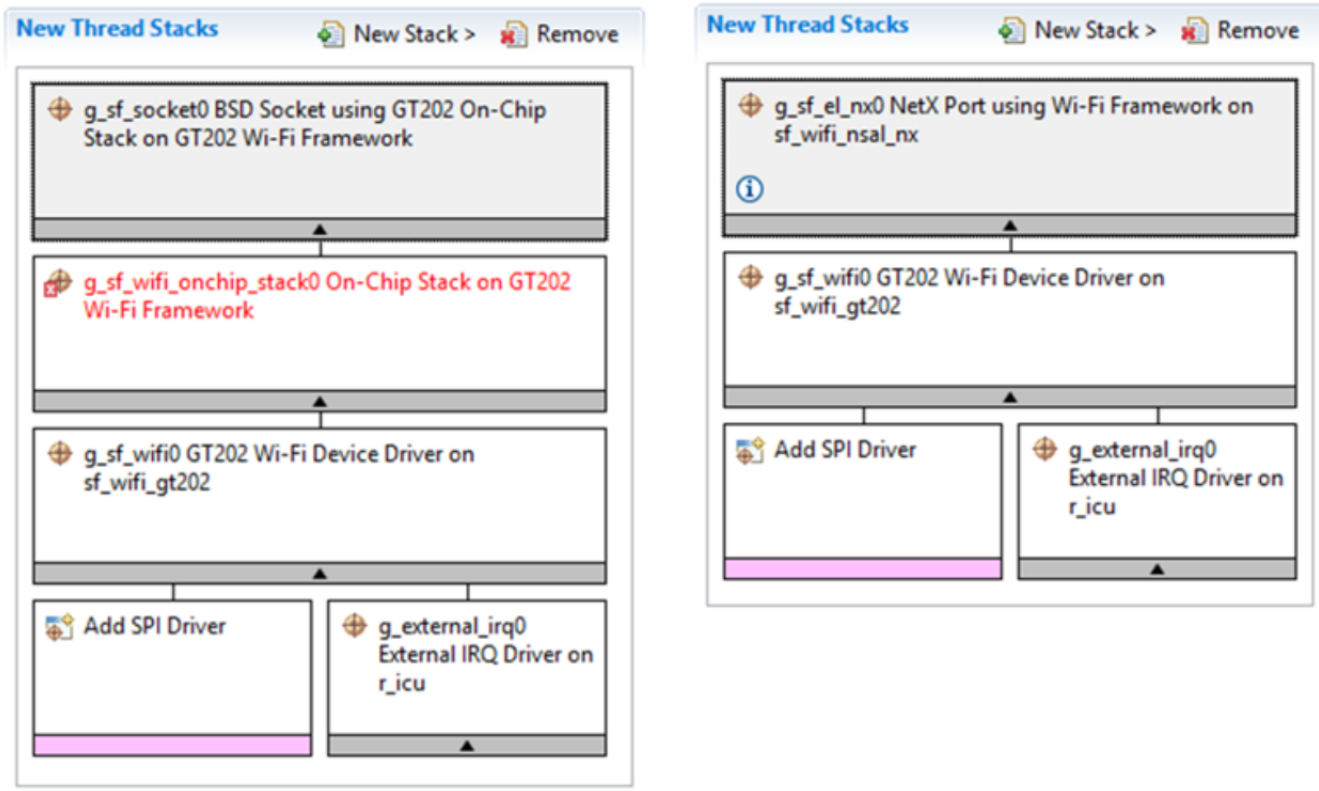

Figure 222: WiFi Framework Module Stack

4.1.28.5 Configuring the Wi-Fi Framework Module

The Wi-Fi Framework module must be configured by the user for the desired operation. The SSP configuration window will automatically identify (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules in order to ensure successful operation. Furthermore, only those properties that can be changed without causing conflicts are available for modification. Other properties are 'locked' and are not available for changes, and are identified with a lock icon for the 'locked' property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous 'manual' approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP configurator, and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings; this will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with the SSP.

Configuration Settings for the BSD Socket Using GT202 On-Chip Stack on GT202 Wi-Fi Framework

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.

Name (Must be a valid C Symbol)	g_sf_socket0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the On-Chip Stack on GT202 Wi-Fi Framework

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name (Must be a valid C Symbol)	g_sf_wifi_onchip_stack0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the NetX Port using Wi-Fi Framework on sf_wifi_nsal_nx

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name (Must be a valid C Symbol)	g_sf_el_nx0	Module name.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Wi-Fi Device Driver on sf_wifi_gt202

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
On-Chip Stack Support	Enabled, Disabled Default: Disabled	On-chip stack support selection.
Driver Heap Size in Bytes (Minimum 8192 bytes)	8192	Driver heap size selection.
Name (Must be a valid C symbol)	g_sf_wifi0	Module name.

Hardware Mode	802.11a, 802.11b, 802.11g, 802.11n Default: 802.11n	Hardware mode selection.
Transmit (TX) Power (Valid Range 1-17)	10	Transmit power selection.
Ready/Clear to Send (RTS/CTS) Flag	Enabled, Disabled Default: Enabled	Ready/Clear to send selection.
Delivery Traffic Indication Message (DTIM) Interval (Valid Range: 1-255)	3	Delivery traffic indication message interval selection.
Broadcast SSID (AP mode only)	Enabled, Disabled Default: Enabled	Broadcast SSID selection.
Beacon Interval in Microseconds (AP mode only and must be greater than 1023)	1024	Beacon interval in microseconds selection.
Station inactivity timeout in seconds (AP mode only and must be greater than 0)	100	Station inactivity timeout selection.
Requested High Throughput	Enabled, Disabled Default: Disabled	Requested high throughput selection.
Reset Pin (must be a valid C symbol)	IOPORT_PORT_06_PIN_00	Reset pin selection.
Slave Select Pin (SSL)(Must be a valid C symbol)	IOPORT_PORT_01_PIN_03	Slave select pin selection.
GT202 Driver Task Thread Priority (Modifying Task Thread Priority may cause Driver to malfunction)	5	GT202 driver task thread priority selection.
Callback	NULL	Callback selection.
Support NetX Packet Chaining	Enabled, Disabled Default: Enabled	Support NetX packet chaining selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to select different screen sizes. The configurable properties for the lower-level stack modules are given in the following sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are fairly intuitive and can usually be determined by

inspection of the associated Properties window from the SSP configurator.

Configuring the Wi-Fi Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated with red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the lower-level modules:

Configuration Settings for the SPI HAL Module on r_rspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name.
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device. Note: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first.
Bitrate	500000	Transmission or reception rate. Bits per second.
Callback	NULL	Optional Callback function pointer.
SPI Mode	Clock synchronous operation	Select spi or clock syn mode operation.
Slave Select Polarity(SSL0)	Active Low	Select SSL0 signal polarity.
Slave Select Polarity(SSL1)	Active Low	Select SSL1 signal polarity.
Slave Select Polarity(SSL2)	Active Low	Select SSL2 signal polarity.
Slave Select Polarity(SSL3)	Active Low	Select SSL3 signal polarity.
Select Loopback1	Normal	Select loopback1.
Select Loopback2	Normal	Select loopback2.

Enable MOSI Idle State	Disable	Select MOSI idle fixed value and selection.
MOSI Idle State	MOSI Low	Select mosi idle fixed value and selection.
Enable Parity	Disable	Enable/disable parity.
Parity Mode	Parity Even	Select parity.
Select SSL(Slave Select)	SSL0	Select which slave to use; 0-SSL0; 1-SSL1; 2-SSL2; 3-SSL3.
Select SSL Level After Transfer	SSL Level Do Not Keep	Select SSL level after transfer completion; 0-negate; 1-keep.
Clock Delay Enable	Clock Delay Disable	Clock delay enable selection.
Clock Delay Count	Clock Delay 1 RSPCK	Clock delay count selection.
SSL Negation Delay Enable	Negation Delay Disable	SSL negation delay enable selection.
Negation Delay Count	Negation Delay 1 RSPCK	Negation delay count selection.
Next Access Delay Enable	Next Access Delay Disable	Next access delay enable selection.
Next Access Delay Count	Next Access Delay 1 RSPCK	Next access delay count selection.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Error interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte, 2 Bytes, 4 Bytes Default: 2 Bytes	Transfer size selection. Note: For WiFi GT202 module, this property should be set to 1 Byte.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SPI0 TXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_transfer1	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte, 2 Bytes, 4 Bytes Default: 2 Bytes	Transfer size selection. Note: For WiFi GT202 module, this property should be set to 1 Byte.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SPI HAL Module on r_sci_spi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.

Name	g_spi0	Module name.
Channel	0	SCI or SPI Channel number to which the device has been connected.
Operating Mode	Master	Configure as a Master or Slave device. Note: Current version of SSP supports only SPI Master mode.
Clock Phase	Data sampling on even edge, data variation on odd edge	Data sampling on odd or even clock edge.
Clock Polarity	High when idle	Clock level when idle.
Mode Fault Error	Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First	Select transmit order MSB/LSB first.
Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable.
Callback	NULL	Optional Call back function pointer.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Bitrate Modulation Function enable or disable. Note: This is applicable only for SCI SPI.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Error interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have

different default values and available configuration settings.

Configuration Settings for the Transfer Driver on Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer1	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SCI0 RXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the External IRQ Driver on r_icu

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter checking setting enables or disables the addition of parameter checking code.
Name	g_external_irq0	Module name.
Channel	0	Specifies the hardware IRQ channel used.
Trigger	Falling	Selection for trigger event mode
Digital Filtering	Disabled	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCKL/64	Sets noise filter sampling period.
Interrupt enabled after initialization	TRUE	Determines if the interrupt is enabled immediately after initialization.
Callback	custom_hw_irq_isr	A user callback function can be registered in external_irq_api_t::open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Interrupt priority selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.
Most of the property settings for modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Wi-Fi Framework Module Clock Configuration

The Wi-Fi Framework module uses the clocks required for the specific selections of the lower-level modules (such as the SPI).

Wi-Fi Framework Module Pin Configuration

The Wi-Fi Framework module uses input and output pins depending on the selections of the low-level modules (such as the SPI or the IRQ).

4.1.28.6 Using the Wi-Fi Framework Module in an Application

The following description is a high-level overview of some typical Wi-Fi use cases. A more detailed description and a working application project (which is too lengthy to include in this document), is available on the Renesas web site. Just search for the associated application note document number, r11an0226eu, in the top page search bar on www.Renesas.com. It is highly recommended that you use the application note to augment the summary descriptions found in this document.

Each of the Wi-Fi framework implementations are treated differently in a target application. The typical control flow for initialization, packet transmission using NetX/NetX Duo, packet reception using NetX/NetX Duo and using an on-chip networking stack are of particular interest. Example flow diagrams for some typical implementations of these functions are shown as follows:

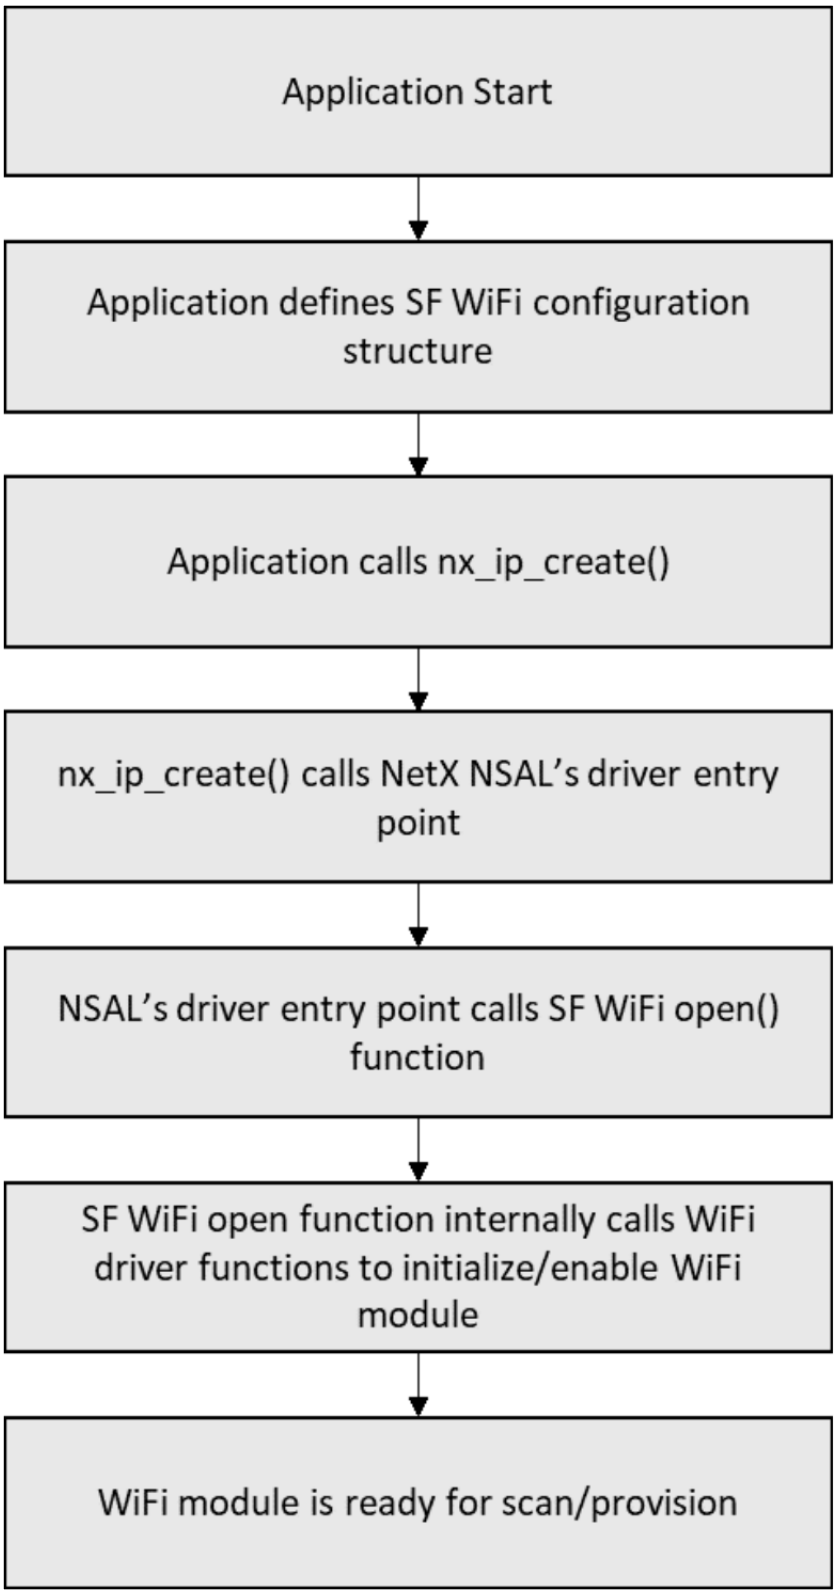

Figure 223: Application Control Flow using Wi-Fi Module Initialization

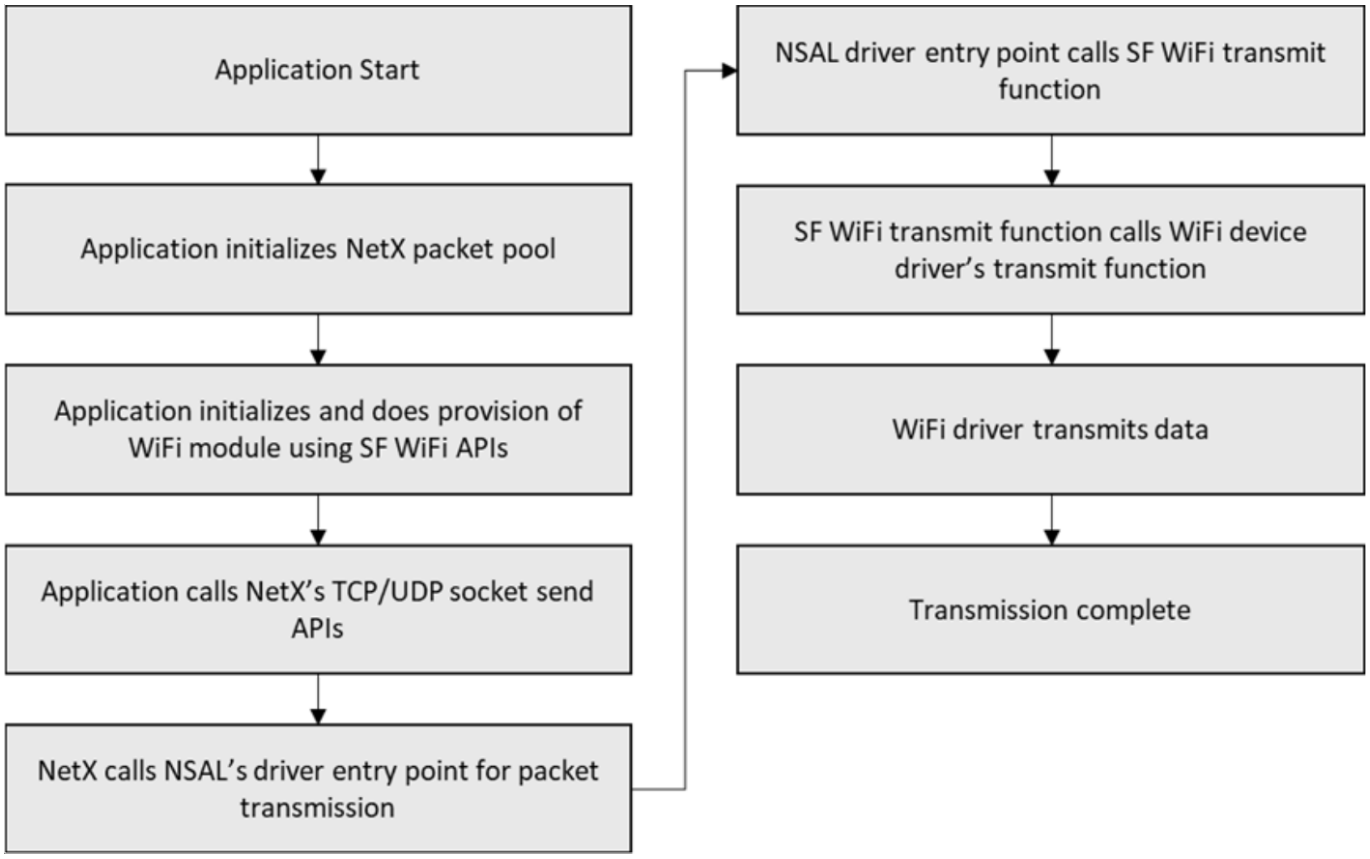

Figure 224: Application Control Flow Performing Packet Transmission using NetX

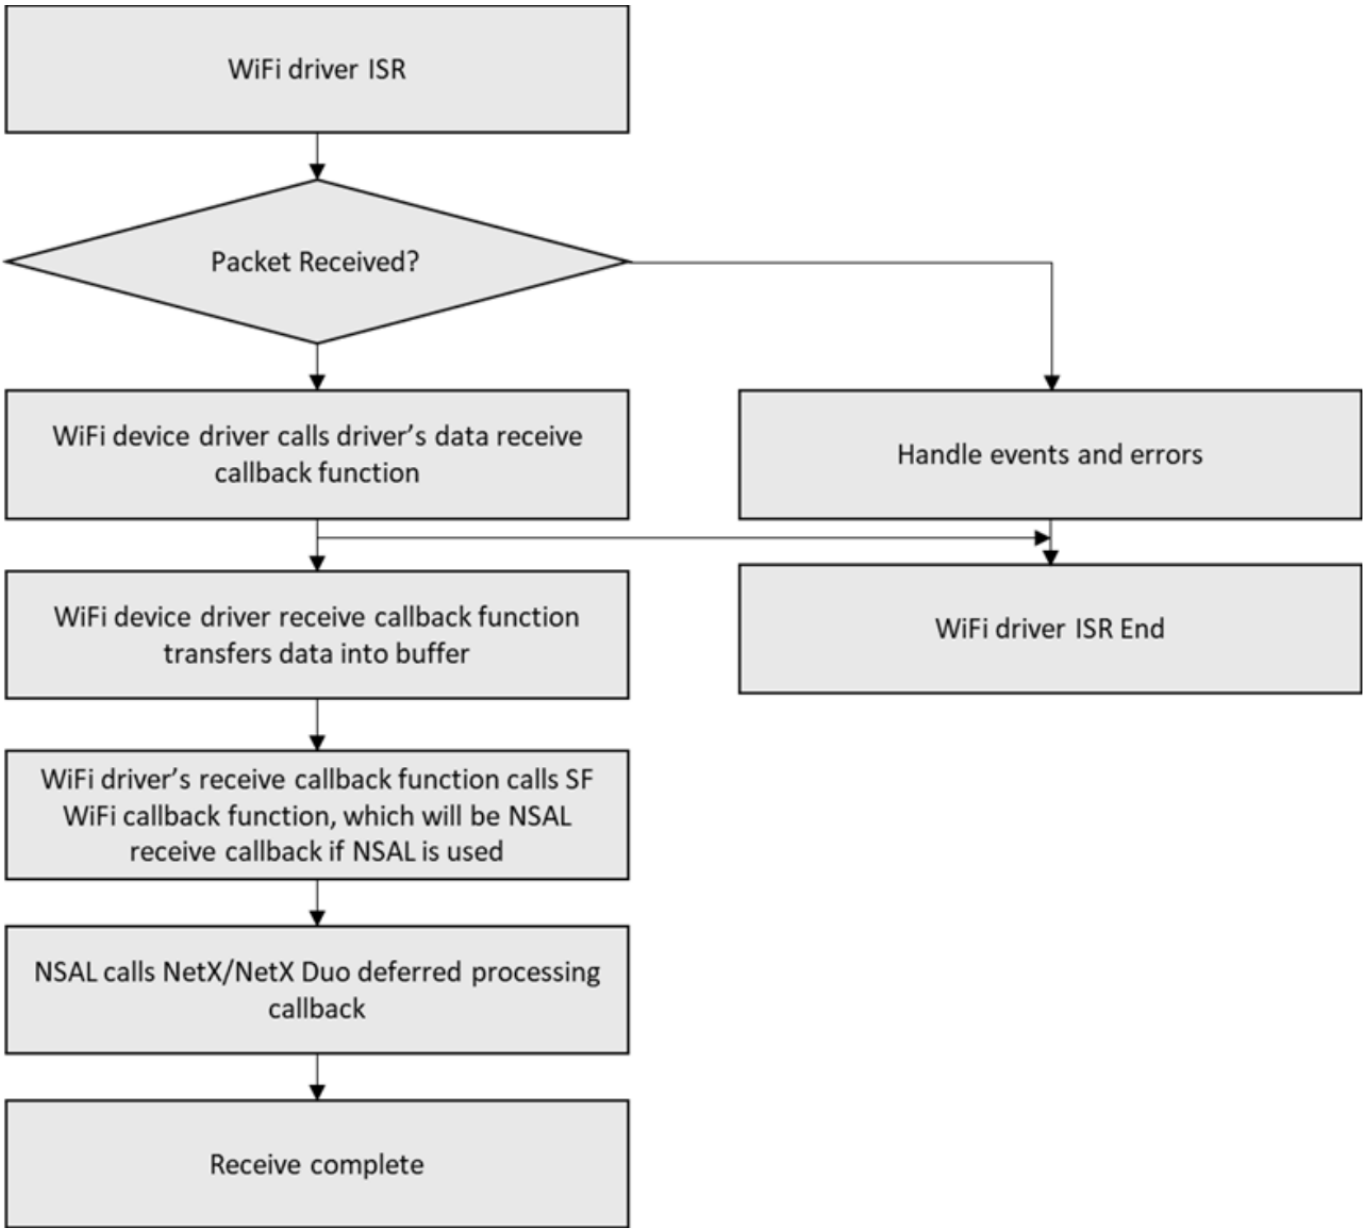

Figure 225: Application Control Flow Receiving Packets using NetX

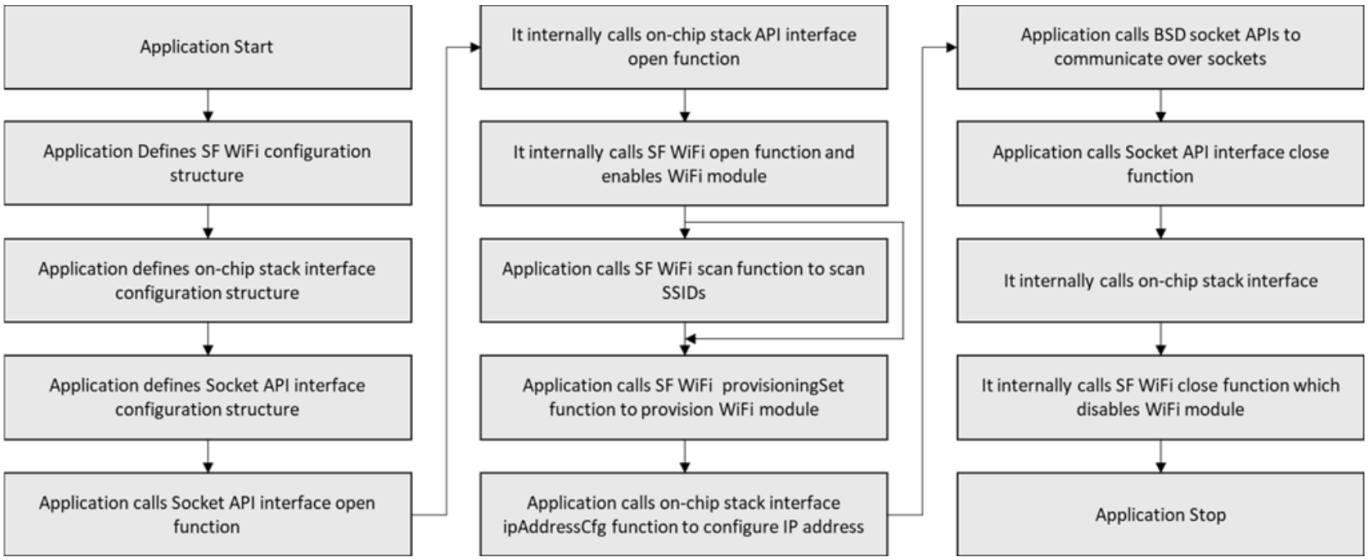

Figure 226: Application Control Flow using the On-Chip Networking Stack

Wi-Fi WPS Connection Methods

Flow diagrams for implementations of WPS connections for an application in both Station and AP modes for PIN and Button based connections are available in a Knowledge Base article here: https://en-support.renesas.com/knowledgeBase/18380440

4.1.29 Wi-Fi QCA4010 Framework

4.1.29.1 Wi-Fi QCA4010 Framework Introduction

The SX-ULPGN is a low-power, compact IEEE 802.11b/g/n 2.4GHz 1x1 Wireless LAN module equipped with the Qualcomm® QCA4010 Wireless SOC.

The Wi-Fi QCA4010 framework provides a high-level API for configuring and provisioning Silex QCA4010 ULPGN module as well as perform TCP and UDP data transfers with on-chip networking capability.

Wi-Fi QCA4010 Framework Module Features

- Provides high-level APIs to configure and provision a SX-ULPGN Wi-Fi module.
- Provides three different implementations for:
    - A Wi-Fi device driver stack using the sf_wifi_qca4010 framework.
    - An on-chip stack using the sf_wifi_qca4010_onchip_stack framework.
    - A socket stack using the sf_wifi_qca4010_socket framework.
- Provides a socket interface to create socket-based applications with the On-chip TCP/UDP.

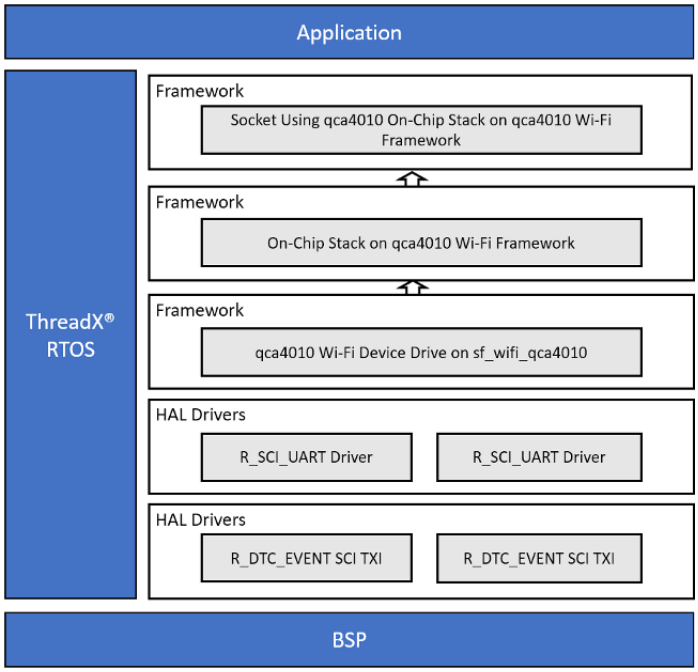

Figure 227: Wi-Fi QCA4010 Framework Module Block Diagram

Note

The On-Chip Stack on qca4010 Wi-Fi Framework, qca4010 Wi-Fi Device Driver on sf_wifi_qca4010 can be used as a lower-level implementation of the Socket Framework or on its own.

4.1.29.2 SF WIFI QCA4010 Framework APIs Overview

The QCA4010 Wi-Fi Framework provides APIs for features such as scanning, provisioning with access points, initialization of access point with different security types (WPA2, WPA, WEP, Open), enabling/disabling DHCP server in AP mode, sending AT commands directly to wifi module and obtain the response, creation of TCP and UDP sockets, TCP and UDP data transfers.

Complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Wi-Fi QCA4010 APIs

Wi-Fi QCA4010 APIs

API Name	Example API call and description
open	g_sf_wifi_qca4010.p_api->open(g_sf_wifi_qca4010.p_ctrl, g_sf_wifi_qca4010.p_cfg); Open lower level driver of Wi-Fi framework.
close	g_sf_wifi_qca4010.p_api->close(g_sf_wifi_qca4010.p_ctrl); Close lower level driver of Wi-Fi framework.

provisioningSet	g_sf_wifi_qca4010.p_api->provisioningSet(g_sf_wifi_qca4010.p_ctrl, &provisioning_info); Provision/Connect to Access Point or Initiate an access point with information provided by user such as mode (AP/station), channel, SSID, security type (WPA2/WPA/WEP/Open), WEP key index, encryption type(TKIP/CCMP), passphrase/key.
wifiStatusGet	g_sf_wifi_qca4010.p_api->wifiStatusGet(g_sf_wifi_qca4010.p_ctrl, &wifi_status); Get the status of connected or Initiated Access Point.
scan	g_sf_wifi_qca4010.p_api->scan(g_sf_wifi_qca4010.p_ctrl, scan_result, scan_count); San for available access points.
versionGet	g_sf_wifi_qca4010.p_api->versionGet(&version); Get the version based on compile time macros.
CommandSend	g_sf_wifi_qca4010.p_api->CommandSend(g_sf_wifi_qca4010.p_ctrl, &cmd, &resp, timeout); Send AT command directly to Wifi module and obtain the response.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.
For provisioningSet API, user has to provide information about the access point such as SSID, security type, Key(Password), encryption type, channel and mode. SSID and passphrase cannot contain commas. This is a current limitation of Silex module firmware.

Wi-Fi QCA4010 On chip Stack APIs

Wi-Fi QCA4010 On chip Stack APIs

API Name	Example API call and description
open	g_sf_wifi_qca4010_onchip_stack.p_api->open(g_sf_wifi_qca4010_onchip_stack.p_ctrl, g_sf_wifi_qca4010_onchip_stack.p_cfg); Open on-chip stack layer of Wi-Fi framework.
close	g_sf_wifi_qca4010_onchip_stack.p_api->close(g_sf_wifi_qca4010_onchip_stack.p_ctrl); Close on-chip stack layer of Wi-Fi framework.
ipAddressCfg	g_sf_wifi_qca4010_onchip_stack.p_api->ipAddressCfg(g_sf_wifi_qca4010_onchip_stack.p_ctrl, &ip_cfg); Set static IP or Enable DHCP based on user input.

ping	g_sf_wifi_qca4010_onchip_stack.p_api->ping(g_sf_wifi_qca4010_onchip_stack.p_ctrl, &ping_ip,0, 0); Ping the IP address provided by the user.
versionGet	g_sf_wifi_qca4010_onchip_stack.p_api->versionGet(&version); Get the version based on compile time macros.
dhcpServerStart	g_sf_wifi_qca4010_onchip_stack.p_api->dhcpServerStart (g_sf_wifi_qca4010_onchip_stack.p_ctrl, &start_ip, &end_ip) Start DHCP server in AP mode.
dhcpServerStop	g_sf_wifi_qca4010_onchip_stack.p_api->dhcpServerStop(g_sf_wifi_qca4010_onchip_stack.p_ctrl, &start_ip, &end_ip) Stop DHCP server in AP mode.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.
DHCP server has to be used in AP mode and not recommended to be used with station mode. User must set a fixed/static IP address to the AP using the API 'ipAddressCfg' and then start DHCP server.

Wi-Fi QCA4010 Socket APIs

Wi-Fi QCA4010 Socket APIs

API Name	Example API call and description
open	g_sf_wifi_qca4010_socket.p_api->open(g_sf_wifi_qca4010_socket.p_ctrl, g_sf_wifi_qca4010_socket.p_cfg); Open Socket layer of Wi-Fi Framework.
close	g_sf_wifi_qca4010_socket.p_api->close(g_sf_wifi_qca4010_socket.p_ctrl); Close Socket layer of Wi-Fi Framework.
versionGet	g_sf_wifi_qca4010_socket.p_api->versionGet(&version); Get the version based on compile time macros.
socketCreate	g_sf_wifi_qca4010_socket.p_api->socketCreate(g_sf_wifi_qca4010_socket.p_ctrl, 0, SOCK_STREAM, AF_INET); Create TCP/UDP socket
socketConnect	g_sf_wifi_qca4010_socket.p_api->socketConnect (g_sf_wifi_qca4010_socket.p_ctrl, 0, (structsockaddr*)&sock_addr,addrlen); Connect TCP/UDP client to Server.

socketDisconnect	g_sf_wifi_qca4010_socket.p_api->socketDisconnect(g_sf_wifi_qca4010_socket.p_ctrl, 0); Disconnect socket connection and close the network.
socketSend	g_sf_wifi_qca4010_socket.p_api->socketSend(g_sf_wifi_qca4010_socket.p_ctrl, 0, (uint8_t*)&data, length, 1000); Send data from TCP/UDP socket.
socketRecv	g_sf_wifi_qca4010_socket.p_api->socketRecv(g_sf_wifi_qca4010_socket.p_ctrl, 0, (uint8_t*)&data, 1024, 1000); Receive datafromTCP/UDPserver.
socketStatusGet	g_sf_wifi_qca4010_socket.p_api->socketStatusGet(g_sf_wifi_qca4010_socket.p_ctrl, 0, (uint32_t*)&socket_status); Check the status of socket created.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.
For socketCreate API, user has to pass parameter to select TCP or UDP socket, family (IPV4). The parameter socket number should be '0' for single socket and while creating multiple sockets, socket number of first socket has to be '0' and increments by 1 for the next socket.
For socketConnect API, user has to pass Server IP address, family (IPV4), Port number

Wi-Fi QCA4010 Framework Status Return Values

Wi-Fi QCA4010 Status Return Values

Name	Description
SSP_SUCCESS	API call successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_WIFI_FAILED	API call not successful.
SSP_ERR_ASSERTION	An input pointer is Null
SSP_ERR_ALREADY_OPEN	Unit is already opened
SSP_ERR_WIFI_INIT_FAILED	Driver initialization failed.
SSP_ERR_IN_USE	Module is already in use
SSP_ERR_NOT_OPEN	Unit is not open
SSP_ERR_INTERNAL	Internal error occurred
SSP_ERR_TIMEOUT	Timeout error
SSP_ERR_UNSUPPORTED	Functionality (IPV6) not supported

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the

associated module for a definition of all relevant status return values.

4.1.29.3 SF_WIFI_QCA4010 Framework Module Operational Overview

The Wi-Fi framework provides a high-level interface for the application to configure the Wi-Fi module, provision the Wi-Fi module in station or AP mode with different security types and perform TCP/UDP data transfers in server and client mode.

The following figure provides an overview of the QCA4010 Wi-Fi framework layered architecture.

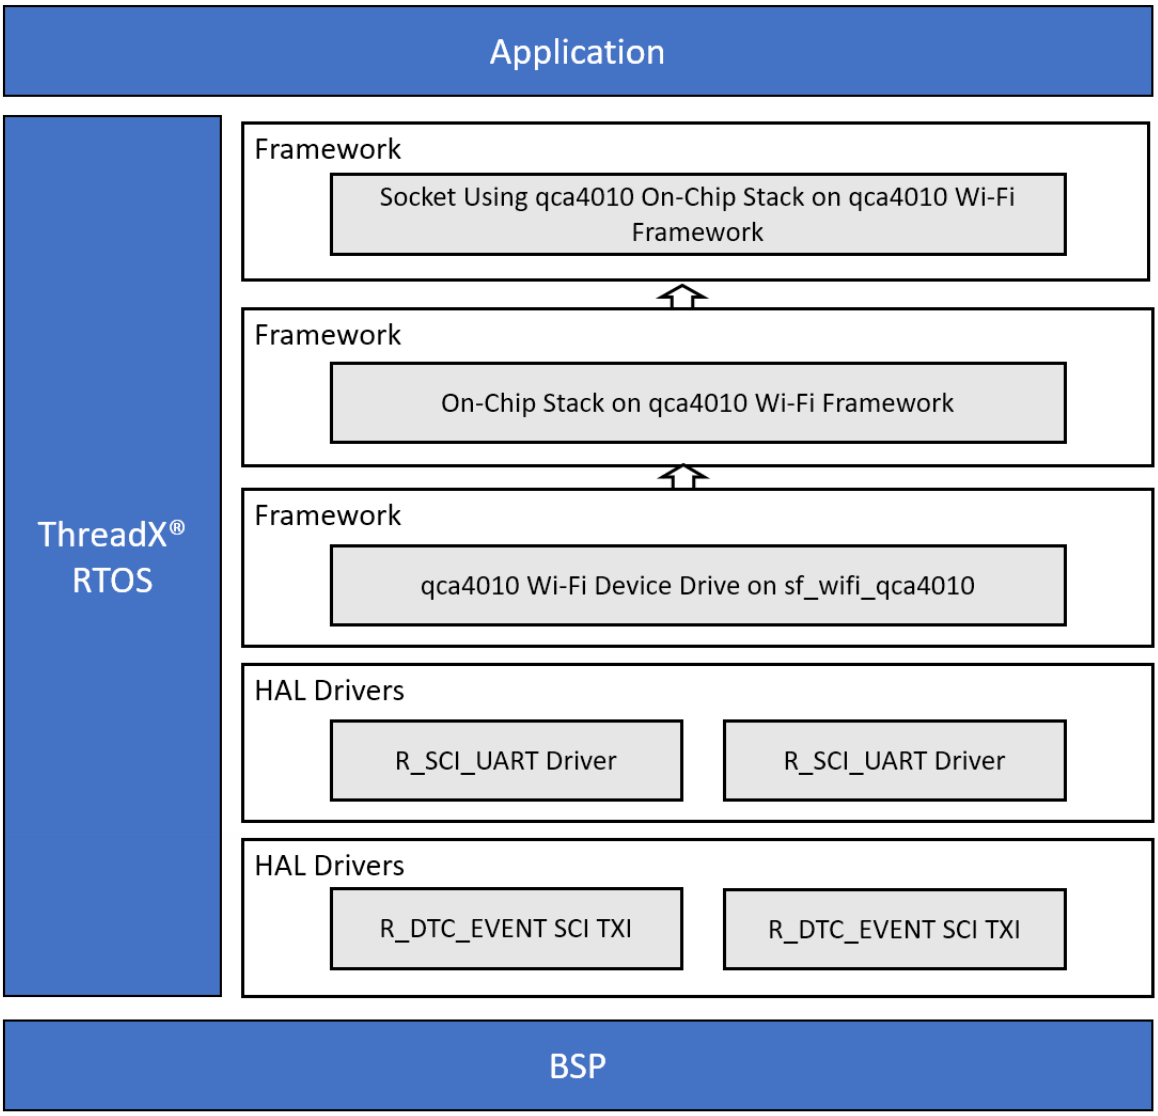

Figure 228: Wi-Fi QCA4010 Framework Module Stack Implementation

- Socket stack using the sf_wifi_qca4010_socket framework provides APIs to create, connect TCP/UDP sockets and perform data send and receive operations in client/server mode.
- On-chip stack using the sf_wifi_qca4010_onchip_stack framework provides APIs to configure static IP or enable DHCP, ping, Enable/Disable DHCP server.
- Wi-Fi device driver stack using the sf_wifi_qca4010 framework provides APIs to initialize Wifi module, provision the module in station or AP mode, scan for available access points, get

the status of connected or initiated access point, send AT commands directly to Wifi module.

Note

The On-Chip Stack on qca4010 Wi-Fi Framework, qca4010 Wi-Fi Device Driver on sf_wifi_qca4010 can be used as a lower-level implementation of the Socket Framework or on its own.

SF_WIFI_QCA4010 Framework Module Important Operational notes and Limitations

SF_WIFI_QCA4010 Framework Module Operational Notes

Operational Overview

SF_WIFI_QCA4010 Framework is used to:

1. Scan available access points.
2. Provision/connect to the desired access point with the information provided by user such as SSID, security type, Key, encryption type, WEP key index, channel, Mode.
3. Initiate an access point with different security types (WPA2/WPA/WEP/Open).
4. Enable/Disable DHCP server in AP mode.
5. Obtain the status of connected access point or initiated AP such as SSID, Phy Mode, MAC Address, Mode, Channel.
6. Set a static IP or enable DHCP and obtain information such as IP Address, NetMask and Gateway of the Wifi Module.
7. Ping the server IP address.
8. Send custom AT commands directly to wifi module and obtain the response.
9. Create single/multiple TCP/UDP sockets.
10. Connect TCP/UDP client to the server and vice-versa.
11. Obtain the current socket status.
12. Send or receive data from TCP/UDP server/client.
13. Disconnect the socket and close the connection.

Note

Wi-Fi framework supports 1 or 2 UARTs for interfacing with the SX-ULPGN module. The second UART is considered optional for single socket and is mandatory for multiple socket operation.
The number of sockets that can be created is based on the memory availability of board.
*SX-ULPGN supports WEP security with WEP key as **10 or 26 digit hexadecimal string**.*

SF_WIFI_QCA4010 Framework Module limitations

Wi-Fi QCA4010 Framework limitations

1. The Wi-Fi Framework does not support the Synergy S1 board series due to memory constraints.

2. Only IPV4 protocol version is supported as majority of the Silex AT commands does not support IPV6.

1. The SX-ULPGN chip does not support ethernet pass through. Hence NetX stack and related services are not supported. Only on-chip stack and related APIs are supported.

4. WPS (PUSH/PIN) method of station provisioning is not supported.

SX-ULPGN Hardware limitations:

1. SX-ULPGN chip doesn't support ethernet pass through.

2. WPA 2 Enterprise is not supported by SX-ULPGN.

3. SX-ULPGN supports only 2.4GHz frequency band, 5GHz band is not supported.

4.1.29.4 Including the SF_WIFI_QCA4010 Framework in an Application

This section describes how to include SF_WIFI_QCA4010 framework in an application using the SSP configurator.

Note

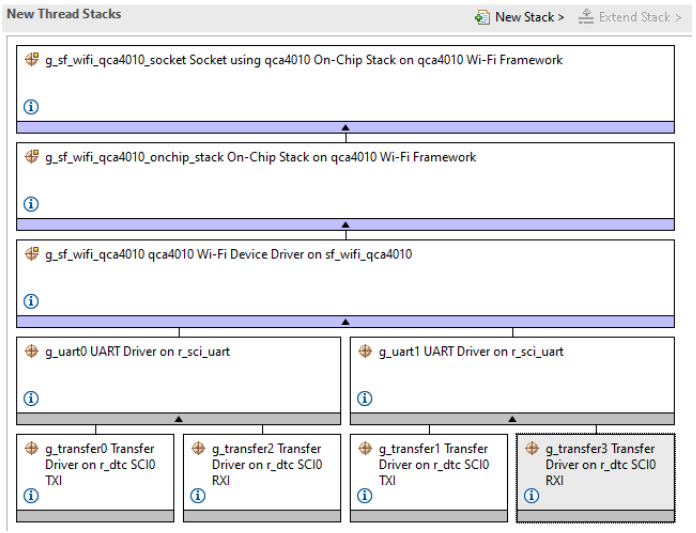
This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the sf_wifi_qca4010 Framework module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Wi-Fi QCA4010 Framework module is g_sf_wifi_qca4010_socket. This name can be changed in the associated Properties window.)

Wi-Fi QCA4010 Framework Module Selection Sequence

Resource	ISDE tab	Stack selection sequence
g_sf_wifi_qca4010_socket Socket using qca4010 On-Chip Stack on qca4010 Wi-Fi Framework	Threads	New Stack> Framework> Networking> Wi-Fi>Socket using qca4010 On-Chip Stack on qca4010 Wi-Fi Framework
g_sf_wifi_qca4010_onchip_stack On-Chip Stack on qca4010 Wi-Fi Framework	Threads	New Stack> Framework> Networking> Wi-Fi>On-Chip Stack on qca4010 Wi-Framework
g_sf_wifi_qca4010 qca4010 Wi-Fi Device Driver on sf_wifi_qca4010	Threads	New Stack> Framework> Networking> Wi-Fi>qca4010 Wi-Fi Device Driver on sf_wifi_qca4010

When the SF_WIFI_QCA4010 Framework is added to the thread stack as shown in the above figure, the configurator automatically adds any needed lower-level module. Any modules needing additional configuration information have the box text highlighted in Red (Here additional UART driver has to be added by the user for multiple socket operations). Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.



4.1.29.5 Configuring the Wi-Fi QCA4010 Framework

The Wi-Fi QCA4010 must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for g_sf_socket0 on qca4010 Wi-Fi Framework

ISDE Property	Value	Description
Parameter checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Number of supported socket instances	1 – 12 Default :1	Number of sockets to be created.
Name	g_sf_socket0	Name of upper level framework layer.
Name of generated initialization function	sf_socket_init0	Name of auto generated function.
Auto Initialization	Enable, Disable Default: Enable	Selects if code for auto-initialization to be included in the build.

Configuration Settings for g_sf_wifi_onchip_stack0 on Wi-Fi Framework

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_sf_wifi_onchip_stack0	Name of on-chip stack layer.

Configuration Settings for g_sf_wifi_qca40100 on qca4010 Wi-Fi Framework

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
AT command Retry count	5 – 255 Default: 10	Number of retries of issuing AT command in case of failure in response.
Hardware Mode	802.11b, 802.11g, 802.11n Default: 802.11n	Hardware mode of Wi-Fi Module.
Reset Pin	Default: IOPORT_PORT_10_PIN_05	Wi-Fi module reset IO pin selection.
Queue size in bytes	256 - 512 Default: 256	UART reception queue size.
Response Buffer size	256 - 4096 Default: 2048	Response Buffer size selection.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

Configuring the Wi-Fi QCA4010 Framework Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the lower-level modules:

Configuration Settings for r_sci_uart driver

ISDE Property	Value	Description

External RTS Operation	Disable, Enable Default: Disable	Enable an IOPORT pin to be used as RTS signal. For RTS functionality, set this configuration parameter to Enable and specify the configuration Name of UART callback function for the RTS external pin control.
Reception	Enable, Disable Default: Enable	Enable or disable UART reception for all UART channels on SCI. Setting this configuration parameter to Disable reduces code size because the portion of code for UART reception is not compiled. You cannot set this parameter for individual UART channels.
Transmission	Enable, Disable Default: Enable	Enable or disable UART transmission for all UART channels on SCI. Setting this configuration to Disable reduces code size because the portion of code for UART transmission is not compiled. However, you can only set this configuration to Disable if no other SCI channels which work as UART ports are transmitting.
Parameter checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_uart0	The name to be used for UART on SCI module control block instance. This name is also used as the prefix of the other variable instances.
Channel	0-9 Default : 0	SCI channel number.
Baud rate	Default : 9600	Baud rate selection.
Data bits	7 bits, 8, bits, 9 bits Default: 8 bits	UART data bits.
Parity	None, Odd, Even Default: None	UART parity bits.
Stop bits	1 bit, 2 bits Default: 1 bit	UART stop bits.

CTS/RTS selection	CTS (Note that RTS is available when enabling External RTS Operation mode which uses 1 GPIO pin), RTS (CTS is disabled) Default: RTS (CTS is disabled)	Select CTS or RTS for the CTSn/RTSn pin of SCI channel n. The SCI hardware supports either the CTS or the RTS control signal on this pin but not both. For an application that uses both CTS and RTS, select CTS for this configuration parameter and enable the configuration External RTS Operation specifying the configuration Name of UART callback function for the RTS external pin control.
Name of UART callback function	sf_wifi_qca4010_serial_uart_callback	UART callback to receive data/AT command response.
Name of UART callback function for the RTS external pin control to be defined by the user	NULL	Name must be a valid C symbol.
Clock Source	Internal Clock, External Clock 8x baudrate, External Clock 16x baudrate Default: Internal Clock	Selection of the clock source to be used in the baud-rate clock generator block.
Baudrate Clock Output from SCK pin	Enable, Disable Default: Disable	Optional setting to output the baud-rate clock on the SCKn pin for the selected channel n.
Start bit detection	Falling Edge, Low Level Default: Falling Edge	Start bit detection mode in the reception, usually set Falling Edge to this configuration.
Noise Cancel	Enable, Disable Default: Disable	Enable the digital noise cancellation on RXDn pin. The digital noise filter block in SCI consists of two-stage flip-flop circuits. For details, refer to the Noise cancellation section in the Renesas Synergy hardware manual.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bit rate modulation enable selection
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest- not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Receive interrupt priority selection.

Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest- not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest- not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest- not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	Error interrupt priority selection.
Baud rate Percent Error	Value must be greater than 0.0 and less than 15.0 Default; 2.0	Maximum baud rate percent error allowed in order for the module to function
UART Communication Mode	RS232, RS485 Default: RS232	UART communication mode selection, usually it is RS232 mode
UART RS485 Communication Mode	Half Duplex, Full Duplex Default: Half duplex	UART RS485 communication mode selection as half duplex or full duplex
RS485 DE Port	00 to 11 Default: 09	Select the port number of Driver Enable Pin
RS485 DE Pin	00 to 15 Default: 14	Select the pin number of Driver Enable Pin

Note

Additional UART is mandatory for multiple socket operation and is optional for single socket operation.

Configuration of second UART driver instance is same as first UART instance which is described above.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE	Property	Value Description
Parameter Checking	Enabled, Disabled Default: Disabled	Selects if code for parameter checking is to be included in the build
Software Start	Enabled, Disabled Default: Disabled	Set start mode
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section setting
Name	g_transfer0	Module name
Mode	Normal	Mode selection
Transfer Size	1 Bytes	Transfer size selection
Destination Address Mode	Fixed	Destination address mode selection
Source Address Mode	Incremented	Source address mode selection
Repeat Area (Unused in Normal Mode)	Source	Repeat area selection
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection
Destination Pointer	NULL	Destination pointer selection
Source Pointer	NULL	Source pointer selection
Number of Transfers	0	Number of transfers selection
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection
Auto Enable	True, False Default: True	Auto enable selection
Callback (Only valid with Software start)	NULL	Callback selection
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (CM4: valid, CM0+: lowest- not valid if using ThreadX), Priority 4:14 (CM4: valid, CM0+: invalid), Priority 15 (CM4 lowest - not valid if using ThreadX, CM0+: invalid) Default: Disabled	ELC Software Event interrupt priority selection

Addition of DTC driver for reception is not recommended.

Note

The example values and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

SF_WIFI_QCA4010 Framework Module Clock configuration

SF_WIFI_QCA4010 Framework has no specific clock configuration requirements.

SF_WIFI_QCA4010 Framework Module pin configuration

The SF_WIFI_QCA4010 Framework module uses input and output pins of the lower level UART driver.

4.1.29.6 Using the Wi-Fi QCA4010 Framework Module in an Application

Wi-Fi framework can be used to initialize access point (AP mode) or connect client to AP/router (station mode)

The typical steps of using the Wi-Fi Framework in an application for station mode are:

1. Initialize the Wi-Fi module using sf_wifi_qca4010_socket_api_t::open API.
2. Scan for the available access points using sf_wifi_qca4010_api_t::scan API.
3. Connect to the desired access point using sf_wifi_qca4010_api_t::provisioningSet API. User has to provide the information such as SSID, security type (WPA2/WPA/WEP/Open), Key, Mode, Channel, encryption type, WEP key index of the access point to be connected.
4. After connection is successful, obtain the status of the connected AP using sf_wifi_qca4010_api_t::wifiStatusGet API.
5. Configure IP address(static or Dynamic) using sf_wifi_qca4010_onchip_stack_api_t::ipAddressCfg API.
6. Ping the server IP using sf_wifi_qca4010_onchip_stack_api_t::ping API.
7. After ping is successful, create and connect single/multiple TCP/UDP sockets in client or server mode using sf_wifi_qca4010_socket_api_t::socketCreate and sf_wifi_qca4010_socket_api_t::socketConnect API's.
8. Send data from TCP/UDP client to server using sf_wifi_qca4010_socket_api_t::socketSend API.
9. Receive data from TCP/UDP server using sf_wifi_qca4010_socket_api_t::socketRecv API.
10. Disconnect single/multiple sockets using sf_wifi_qca4010_socket_api_t::socketDisconnect API to close the network connection.
11. De-Initialize the Wi-Fi module using sf_wifi_qca4010_socket_api_t::close API.

The typical steps of using the Wi-Fi Framework in an application for AP mode are:

1. Initialize the Wi-Fi module using sf_wifi_qca4010_socket_api_t::open API.
2. Initialize/provision access point using sf_wifi_qca4010_api_t::provisioningSet API. User has to provide the information such as SSID, security type (WPA2/WPA/WEP/Open), Key, Mode, Channel, encryption type, WEP key index to the access point.
3. Set a static IP address using sf_wifi_qca4010_onchip_stack_api_t::ipAddressCfg API.
4. Enable DHCP server using sf_wifi_qca4010_onchip_stack_api_t::dhcpServerStart API by specifying start and end IP address.
5. Once the above mentioned steps are successful, client can connect to the initiated access point and obtain the IP address in between the range set by DHCP server of AP.
6. After connection is successful, user can perform operations such as ping, TCP/UDP data transfers.

Note

*SX-ULPGN supports WEP security with either **10 or 26 digit hexadecimal string**.*

4.2.1 Analog Connection Driver on r_analog_connect

4.2.1.1 Analog Connection HAL Module Introduction

The analog connection HAL module implements the analog connect API on r_analog_connect to simplify the connection of the analog components that comprise the analog front end on select Synergy MCUs. Previously these connections needed to be made using low-level register-based configuration instead of using the Synergy configurator. The analog connection module supports the OPAMP (operational amplifier), ACMPHS (high speed analog comparator), and ACMPLP (low power analog comparator) peripherals, and their allowed interconnections, available on the Synergy microcontroller hardware.

Analog Connection HAL Module Features

- Simplifies the interconnection of internal analog connections
- Selection of interconnects is limited to those available to the target MCU, simplifying the configuration process and eliminating common configuration errors
- Uses the time saving and intuitive SSP configuration GUI

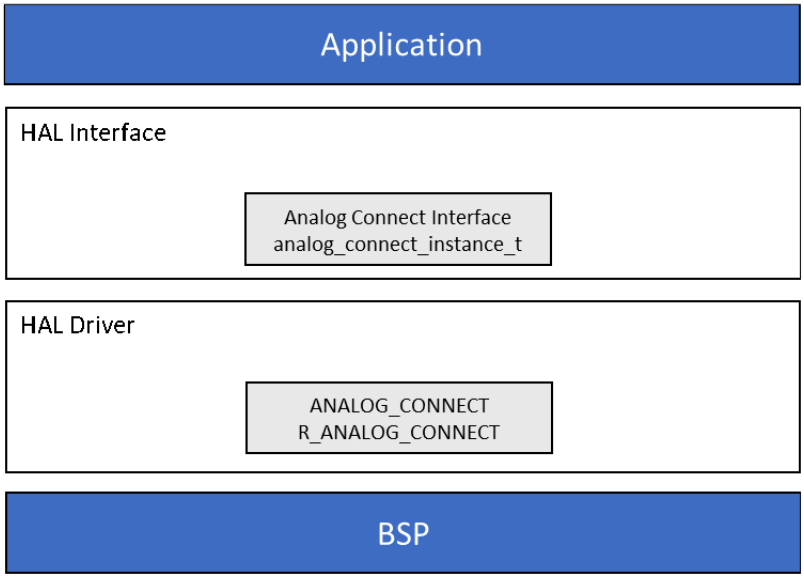

Figure 229: Analog Connection HAL Module Block Diagram

4.2.1.2 Analog Connection HAL Module APIs Overview

The Analog Connection HAL module defines API functions for making single or multiple connections. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Analog Connection HAL Module API Summary

Function Name	Example API Call and Description
init	g_analog_connect.p_api ->init(g_analog_connect.p_cfg); Initialize the analog connection module.

connect	g_analog_connect.p_api ->connect(ANALOG_CONNECT_OPAMP0_AMPP_TO_PORT0_P013); Make connection between specified analog module input and output using a connection option enum. Enum definitions are explained in the operational notes later in this document.
connectMultiple	g_analog_connect.p_api->connectMultiple(&connection_table); Make all connection between specified analog module input and output as specified in the connection table analog_connect_table_t.
versionGet	g_analog_connect.p_api ->versionGet (&version); Get the version information of the underlying driver.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Analog Connection HAL Module Status Return Values

Name	Description
SSP_SUCCESS	Function completed successfully
SSP_ERR_ASSERTION	Data table pointer is NULL or size is 0

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.1.3 Analog Connection HAL Module Operational Overview

The analog connection HAL module controls the internal analog connections for the OPAMP, ACMPLP, and ACMPHS peripherals on a Synergy microcontroller. It directly controls the hardware without using any RTOS elements and provides convenient APIs to simplify development.

Analog Connection HAL Module Important Operational Notes and Limitations

Analog Connection HAL Module Operational Notes

The following operational notes describe the available connections, the enumeration format used to describe connections, general notes and module specific notes on operations important when using the analog connect module in an application.

Available Connections

The list of connection options is unique for each MCU. This list is found in the analog_connect_t enumeration in synergy\ssp\src\bsp\mcu\<mcu_name>\bsp_analog.h, where <mcu_name> is the name of the MCU series, for example S7G2.

You can find the descriptions of the analog_connect_t enumeration for each MCU as follows:

- analog_connect_t for S124
- analog_connect_t for S128
- analog_connect_t for S1JA
- analog_connect_t for S3A1
- analog_connect_t for S3D3
- analog_connect_t for S3A6
- analog_connect_t for S3A7
- analog_connect_t for S5D5
- analog_connect_t for S5D9
- analog_connect_t for S7G2

The connection enum format is described below:

- ANALOG_CONNECT_<NODE>_TO_<NODE> is used to make a connection
  - <NODE> can be further divided into <PERIPHERAL><CHANNEL>_<SIGNAL>
  - <PERIPHERAL> is the peripheral name: ACMPHS, ACMPLP, or OPAMP
  - <CHANNEL> is the channel number
  - <SIGNAL> is the signal name. The signal name corresponds to the signal name in the hardware manual
- ANALOG_CONNECT_<NODE>_BREAK is used to break all connections to a node. This option is currently available for OPAMP connections only.

The connection options are grouped by peripheral, channel, and signal in the analog_connect_t enumeration. All signals should be configured for each peripheral/channel combination used. For example, if an application uses ACMPHS channel 0, then exactly one connection must be made for each node that begins with ACMPHS0. Exactly one connection must be made for ACMPHS0_IVREF and ACMPHS0_IVCMP. Likewise, if an application uses OPAMP channel 0, then a connection must be made for OPAMP0_AMPP, OPAMP0_AMPM, and OPAMP0_AMPO.

General Notes Regarding Connections

The analog connect module makes internal connections only. If an application interfaces to analog signals external to the MCU, it will also require pin configurations on the **Pins** tab in the Synergy Configuration Tool.

Calling analog_connect_api_t::connect or analog_connect_api_t::connectMultiple overwrites any existing connection and replaces it with the new connection.

The APIs in this module have no prerequisite. They can be called before or after the associated driver's comparator_api_t::open() or opamp_api_t::open(). If the analog_connect_api_t::connect or analog_connect_api_t::connectMultiple APIs are called before the open() of the associated driver, the module stop bit for the associated peripheral channel is cleared.

The analog_connect_api_t::connectMultiple API is most efficient when connections for the same peripheral/channel combination are grouped together in the list of connections.

Connection Aliases

Not all connection aliases are listed in the analog_connect_t enumeration. For example, take the S1JA connection to connect the IVCMP input of the ACMPHS comparator to P013 (ANALOG_CONNECT_ACMPHS0_IVCMP_TO_PORT0_P013). P013 can be used as the DAC8 channel 0 output. If P013 is used as the DAC8 channel 0 output, then making this connection connects the DAC8 channel 0 output to the ACMPHS0 IVCMP input. Refer to the Synergy Configuration tool **Pins** tab or the hardware manual I/O Ports chapter, "Peripheral Select Settings for each Product" section for pin aliasing options.

Multiple Connection Table

The table used to make multiple connections includes the number of connections followed by the list of connections. The multiple connection table structure follows the below definition:

```
typedef struct st_analog_connect_table_t
{
uint32_tnumber_of_connections;
analog_connect_tconst*p_connection_table;
} analog_connect_table_t;
```

ACMPLP Connections Operational Notes

ACMPLP connections should only be made before comparator_api_t::outputEnable() is called. To modify connections, call comparator_api_t::close() first.

On some MCUs, the ACMPLP peripheral has 2 internal nodes that can be configured. They are called ACMPLP0_IVREF0 and ACMPLP1_IVREF1. These nodes must be configured exactly once if they are used. Two enums must be used to make connections involving these nodes. For example, to connect ACMPLP channel 0 to the output of DAC8 channel 0, the following two connections must be made:

- To connect the - input of the comparator (IVREF) to the internal node IVREF0: ANALOG_CONNECT_ACMPLP0_IVREF_TO_ACMPLP0_IVREF0
- To connect the internal node IVREF0 to the output of DAC8 channel 0: ANALOG_CONNECT_ACMPLP0_IVREF0_TO_DAC80_DA

The node ACMPLP0_IVREF0 can be connected to the IVREF signal of either channel of the ACMPLP (ACMPLP0_IVREF or ACMPLP1_IVREF). The user should be aware when modifying this node that it may affect the setting of the other channel.

ACMPHS Connections Operational Notes

On MCUs that have an ADC PGA, the associated ADC PGA must be configured or bypassed to use IVCMP2 as the IVCMP input to the comparator. If the associated ADC unit is open, the PGA is bypassed. To enable the ADC PGA or bypass the PGA without opening the ADC driver, follow the instructions in the Usage Notes section of the ADC chapter of the hardware manual. This chapter typically starts with "Available Functions and Register Settings of AN000 to AN002".

ACMPHS connections can be reconfigured at runtime. If an ACMPHS connection is reconfigured after comparator_api_t::outputEnable() is called, the comparator will be disabled before reconfiguring the connection. If the comparator was already enabled, it will be re-enabled after a stabilization wait time of 48 ICLK.

OPAMP Connections Operational Notes

OPAMP connections are only supported on MCUs that have AMPnPS, AMPnMS, and AMPnOS registers. OPAMP connections are only listed in the analog_connect_t enumeration if they exist.

OPAMP connections require a change pump to be enabled if AVCC0 < 2.7 V. Make sure the setting

for MCU Analog Power Supply AVCC0 (mV) on the **BSP** tab of the Synergy Configuration tool is correct if OPAMP connections are used. If AVCC0 < 2.7 V, the MOCO must also be operating to use the charge pump. When using the charge pump for the amplifier:

- Turn on no more than a total of 5 connections for OPAMP0.
- Turn on no more than a total of 5 connections for OPAMP1.
- Turn on no more than a total of 2 connections for OPAMP2.

OPAMP connections can be reconfigured at runtime.

OPAMP connections can be combined by OR'ing connections for the same node. Connection enumerations that start with the same value up to the '_TO_' part of the enum name (ANALOG_CONNECT_<NODE>_TO_) can be OR'ed together. See the paragraph above regarding charge pump operation for limits on the total number of connections that can be made when the charge pump is operating. Any number of connections can be made if AVCC0 >= 2.7 V.

Warning

NEVER combine connections for different nodes. The analog connect module will not behave as expected if connections for different nodes are combined.

An illustration of combining connections is shown in the code snippet below:

```
/* Connect OPAMP0 AMP+ to the output of DAC12 channel 0 and P013. These connections
can be combined since both start with ANALOG_CONNECT_OPAMP0_AMPP_TO_. */
g_analog_connect.p_api->connect(ANALOG_CONNECT_OPAMP0_AMPP_TO_DAC120_DA |
ANALOG_CONNECT_OPAMP0_AMPP_TO_PORT0_P013);
/* Connect OPAMP0 AMP+ to just P013 (this disconnects the DAC12 channel 0 input). */
g_analog_connect.p_api->connect(ANALOG_CONNECT_OPAMP0_AMPP_TO_PORT0_P013);
```

If a connection must be broken before a new connection is made, use the _BREAK enumeration. This is illustrated by the code snippet that follows.

```
/* Connect OPAMP1 AMP+ to the output of DAC12 channel 0 and P002. */
g_analog_connect.p_api->connect(ANALOG_CONNECT_OPAMP1_AMPP_TO_PORT0_P002);
/* Break all connections to OPAMP1 AMP+ (in this case the connection to P002), then
establish a new connection to P003. */
g_analog_connect.p_api->connect(ANALOG_CONNECT_OPAMP1_AMPP_BREAK);
g_analog_connect.p_api->connect(ANALOG_CONNECT_OPAMP1_AMPP_TO_PORT0_P003);
```

Analog Connection HAL Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.1.4 Including the Analog Connection HAL Module in an Application

This section describes how to include the analog connection HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the analog connection HAL module to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the analog connect module is g_analog_connect0. This name can be changed in the associated Properties window.)

Analog Connection HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_analog_connect0 Analog Connection Driver on r_analog_connect	Threads	**New Stack> Driver> Analog> Analog ConnectionDriver on r_analog_connect<MCU>**

When the Analog Connection Driver on r_analog_connect is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

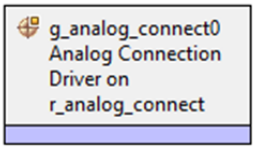

Figure 230: Analog Connection HAL Module Stack

4.2.1.5 Configuring the Analog Connection HAL Module

The Analog Connection HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Analog Connection HAL Module on r_analog_connect

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_analog_connect0	Module name.
Connection Table Name	g_analog_connect0_table	This connection table name is passed to the connectMultiple API function to make all configured connections.
ACMPHS0 IVCMP	No Connection, PORT5 P500, PORT0 P013, PORT1 P100 Default: No Connection	Select the connection for ACMPHS0 IVCMP.
ACMHS0 IVREF	No Connection, PORT5 P501, PORT0 P014, PORT1 P101, DAC80 DA, DAC120 DA, Analog0 VREF Default: No Connection	Select the connection for ACMPHS0 IVREF.
ACMPL0 IVREF0	No Connection, PORT1 P109, DAC80 DA Default: No Connection	Select the connection for ACMPL0 IVREF0.
ACMPLP1 IVREF1	No Connection, PORT1 P110, DAC81 DA Default: No Connection	Select the connection for ACMPLP1 IVREF1.
ACMPLP0 IVCMP	No Connection, PORT4 P400, OPAMP0 AMPO Default: No Connection	Select the connection for ACMPLP0 IVCMP.
ACMPLP0 IVREF	No Connection, ANALOG0 VREF, ACMPLP0 IVREF0 Default: No Connection	Select the connection for ACMPLP0 IVREF.
ACMPLP1 IVCMP	No Connection, PORT4 P408, OPAMP1 AMPO Default: No Connection	Select the connection for ACMPLP1 IVCMP.

ACMPLP1 IVREF	No Connection, ANALOG0 VREF, ACMPLP0 IVREF0, ACMPLP1 IVREF1 Default: No Connection	Select the connection for ACMPLP1 VREF.
OPAMP0 AMPO	No Connection, PORT0 P014, PORT0 P013, PORT0 P003, PORT0 P002 Default: No Connection	Select the connection for OAMP0 AMPO.
OPAMP0 AMPM	No Connection, PORT5 P501, PORT5 500, PORT0 P014, PORT0 P113, PORT0 P003, OPAMP0 AMPO Default: No Connection	Select the connection for OPAMP0 AMPM.
OPAMP0 AMPP	No Connection, PORT5 P500, PORT0 P014, PORT0 P013, PORT0 P002, DAC120 DA Default: No Connection	Select the connection for OPAMP0 AMPP.
OPAMP1 AMPM	No Connection, PORT0 P014, OPAMP1 AMPO Default: No Connection	Select the connection for OPAMP1 AMPM.
OPAMP1 AMPP	No Connection, PORT0 P014, PORT0 P013, PORT0 P003, PORT0 P002, DAC80 DA Default: No Connection	Select the connection for OPAMP1 AMPP.
OPAMP2 AMPM	No Connection, PORT0 P003, OPAMP2 AMPO Default: No Connection	Select the connection for OPAMP2 AMPM.
OPAMP2 AMPP	No Connection, PORT0 P003, PORT0 P002, DAC81 DA Default: No Connection	Select the connection for OPAMP2 AMPP.

Note

The example settings and defaults are for a project using the Synergy S1JA MCU Group. Other MCUs may have different default values and available configuration settings.

Analog Connection HAL Module Clock Configuration

The Analog Connection HAL module needs no clock. Clocks are supplied by the individual analog modules.

Analog Connection HAL Module Pin Configuration

The Analog Connection HAL module has no pins to configure. They are configured by the individual analog modules as needed.

4.2.1.6 Using the Analog Connection HAL Module in an Application

Once the analog connect module has been configured and the files generated, it is ready to be used in an application.

The typical steps in using the analog connect HAL module in an application are:

1. Initialize the analog connect module using analog_connect_api_t::init.
2. If analog connections are selected in the configurator, a connection table with a user configurable name (Connection Table Name) is generated. To make the configured connections with a module named g_analog_connect0 and a connection table named g_analog_connect0_tabl, call: g_analog_connect0.p_api->connectMultiple(&g_analog_connect0_table);
3. Before calling opamp_api_t::start or comparator_api_t::outputEnable, ensure that all required analog connections are set correctly using analog_connect_api_t::connect or analog_connect_api_t::connectMultiple.
4. [Optional] Connections for ACMPHS or OPAMP can be reconfigured at runtime using analog_connect_api_t::connect or analog_connect_api_t::connectMultiple. To reconfigure connections for ACMPLP after comparator_api_t::outputEnable has been called, first call comparator_api_t::close().

These common steps are illustrated in a typical operational flow diagram in the following figure:

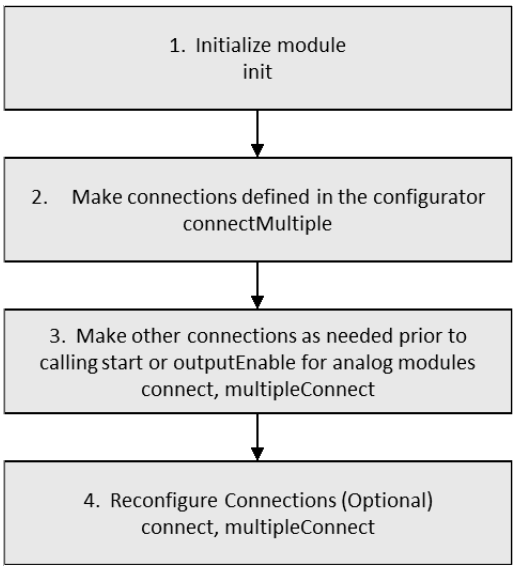

Figure 231: Flow Diagram of a Typical Analog Connect HAL Module Application

4.2.2 Comparator Driver on r_acmphs

4.2.2.1 ACMPHS HAL Module Introduction

The ACMPHS HAL module implements the comparator API for signal processing applications and supports the ACMPHS peripheral available on the Synergy microcontroller hardware. A callback is available to signal the user application on transition events.

ACMPHS HAL Module Features

- Callback on rising edge, falling edge or both
- Configurable debounce filter
- Option to include comparator output on VCOUT pin

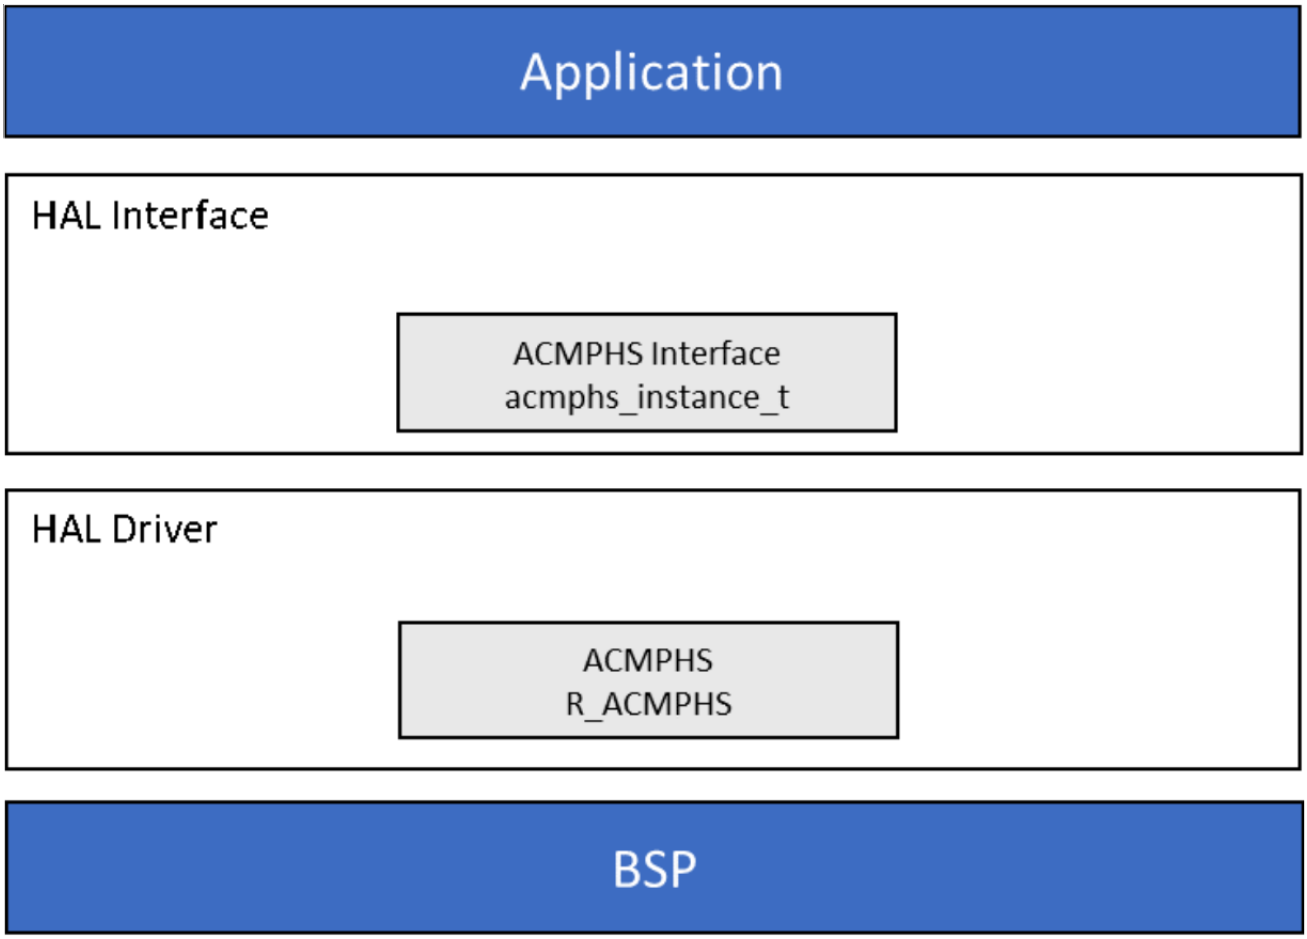

Figure 232: ACMPHS HAL Module Block Diagram

ACMPHS Hardware support details

The following hardware features are, or are not, supported by the SSP for the ACMPHS:

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

4.2.2.2 ACMPHS HAL Module APIs Overview

The ACMPHS HAL module defines APIs to open, enable, get status and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

ACMPHS HAL Module API Summary

Function Name	Example API Call and Description
open	g_comparator0.p_api->open(g_comparator0.p_ctrl, g_comparator0.p_cfg); Configures the comparator and starts operation. Callbacks and pin output are not active until outputEnable() is called. outputEnable() should be called after the output has stabilized.
outputEnable	g_comparator0.p_api->outputEnable(g_comparator0.p_ctrl); Enables the comparator output, which can be polled using statusGet(). Also enables pin output and interrupts as configured during open().
infoGet	g_comparator0.p_api->infoGet(g_comparator0.p_ctrl, p_info); Provides the minimum stabilization wait time in microseconds.
statusGet	g_comparator0.p_api->statusGet(g_comparator0.p_ctrl, p_status); Provides the operating status of the comparator.

close	g_comparator0.p_api->close(g_comparator0.p_ctrl); Close the module.
versionGet	g_comparator0.p_api->read(&version); Retrieves the version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IN_USE	Peripheral is in use or hardware lock is taken.
SSP_ERR_TIMEOUT	The debounce filter is off and 2 consecutive matching values were not read within 1024 attempts.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.2.3 ACMPHS HAL Module Operational Overview

The ACMPHS HAL module controls the high-speed analog comparator peripheral on a Synergy microcontroller. It directly controls the ACMPHS hardware without using any RTOS elements and provides convenient APIs to simplify development.

ACMPHS HAL Module Important Operational Notes and Limitations

ACMPHS HAL Module Operational Notes

Comparator Output on VCOUT Pin

The signal on the VCOUT pin is a logical 'OR' of the outputs of all comparators (ACMPHS and ACMPLP) with their output pin enabled.

Interrupts and Callbacks

When a comparator event occurs, the Comparator Driver on r_acmphs HAL module calls the callback (comparator_cfg_t::p_callback) with the callback argument (comparator_callback_args_t).

ACMPHS HAL Module Limitations

- This module only works for selected Synergy MCUs. Consult the release notes for your

current SSP release to see which MCUs are supported by this module. The MCU Hardware Manual shows which peripherals are available.
- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.2.4 Including the ACMPHS HAL Module in an Application

This section describes how to include the ACMPHS HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Comparator Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Comparator Driver is g_acmphs0. This name can be changed in the associated Properties window.)

ACMPHS HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_comparator0 Comparator Driver on r_acmphs	Threads	**New Stack> Driver> Analog> Comparator Driver on r_acmphs**

When the Comparator Driver on r_acmphs is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

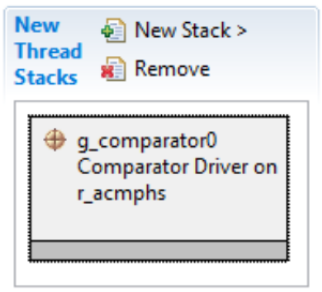

Figure 233: ACMPHS HAL Module Stack

4.2.2.5 Configuring the ACMPHS HAL Module

The ACMPHS HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only

properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the ACMPHS HAL Module on r_acmphs

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Name	g_comparator	Module name.
Channel	0	Select the hardware channel.
Trigger Edge	Rising, Falling, Both Edge Default: Both Edge	The trigger specifies when a comparator callback event should occur. Unused if the interrupt priority is disabled or the callback is NULL.
Debounce Filter	No Filter, 8, 16, 32 Default: No Filter	Select the PCLK divisor for the hardware digital debounce filter. Larger divisors provide a longer debounce and take longer for the output to update.
Invert	Not Inverted, Inverted Default: Not Inverted	Turns this on to invest comparator output. This affects the output read from StatusGet(), the pin output level, and the edge trigger.
Pin Output	Disabled, Enabled Default: Disabled	Turn this on to include the output from this comparator on VCOUT. The comparator output on VCOUT is ORed with output from all other ACMPHS and ACMPLP comparators.
Callback	NULL	Define this function in the application. It is called when the Trigger event occurs.

Comparator Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for the comparator interrupt.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

ACMPHS HAL Module Clock Configuration

The ACMPHS HAL module uses the PCLKB as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

ACMPHS HAL Module Pin Configuration

To use the ACMPHS HAL module, the port pins for the channels receiving the analog input must be set as input pins in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection for the ACMPHS HAL Module on r_acmphs

Resource	ISDE Tab	Pin selection Sequence
ACMPHS	Pins	Select **Peripherals**> **Analog:ACMP**

4.2.2.6 Using the ACMPHS HAL Module in an Application

The typical steps in using the ACMPHS HAL module in an application are:

1. Initialize the ACMPHSw using the comparator_api_t::open API.
2. Before enabling the output, consult the hardware manual to configure the internal connections by setting the COMPSELn registers directly. If the internal reference voltage is used, set COMPMDR.CiVRF.
3. After configuring the modules and internal connections, wait for the minimum stabilization wait time before enabling output. The minimum stabilization wait time can be queried using the comparator_api_t::infoGet API.
4. Enable the comparator output using the comparator_api_t::outputEnable API. This enables pin output, interrupts and the comparator_api_t::statusGet API as configured during the comparator_api_t::open API call.
5. [Optional] Use the comparator_api_t::statusGet API to poll comparator status.
6. [Optional] Use the comparator_api_t::close API to disable the comparator and power down the peripheral.

These common steps are illustrated in a typical operational flow diagram in the following figure:

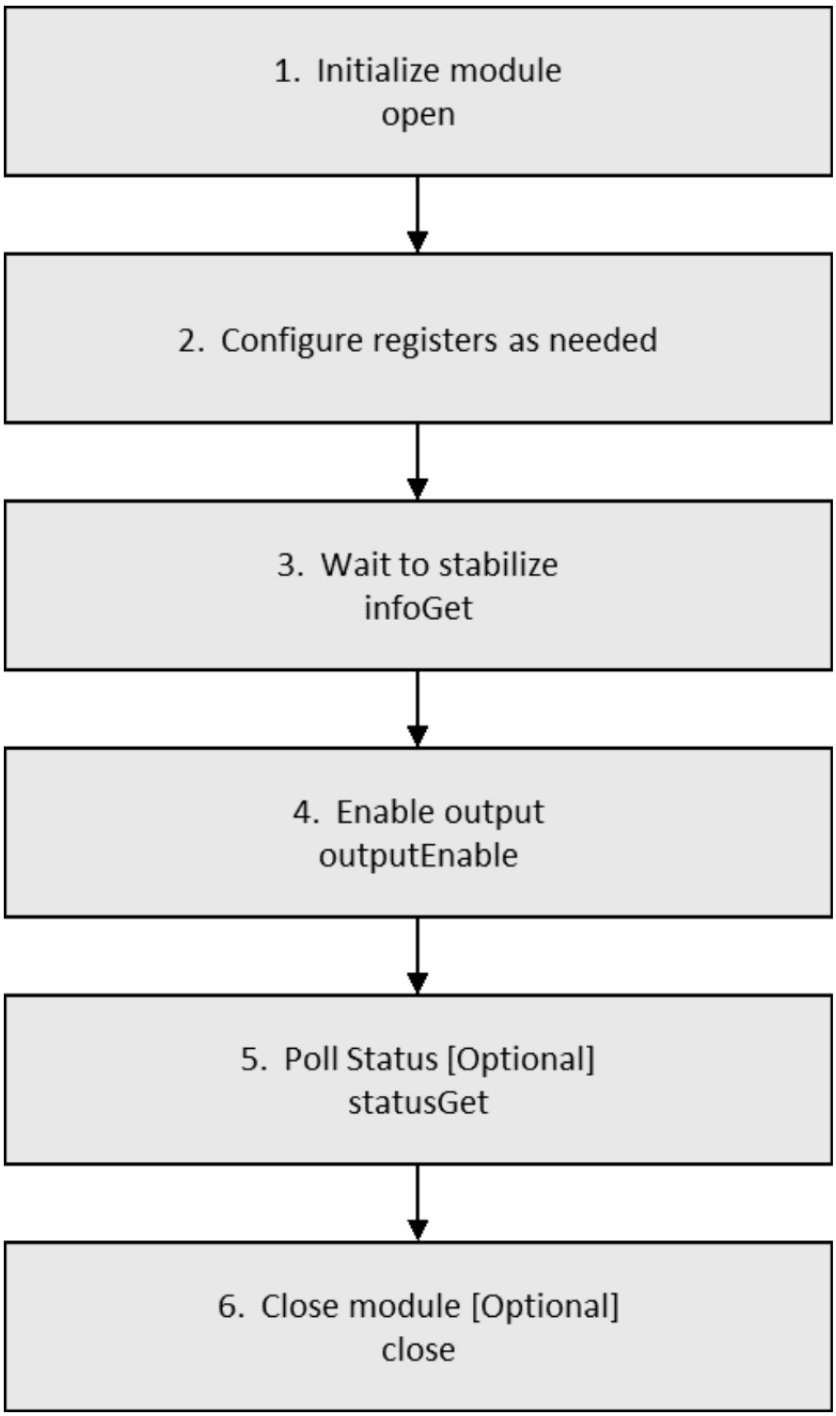

Figure 234: Flow Diagram of a Typical ACMPHS HAL Module Application

4.2.3 Comparator Driver on r_acmplp

4.2.3.1 ACMPLP HAL Module Introduction

The ACMPLP HAL module implements the comparator API for signal processing applications and supports the ACMPLP peripheral available on the Synergy microcontroller hardware. A callback is available to signal the user application on transition events.

ACMPLP HAL Module Features

- Normal mode or window mode
- Callback on rising edge, falling edge or both
- Configurable debounce filter
- Option to include comparator output on VCOUT pin

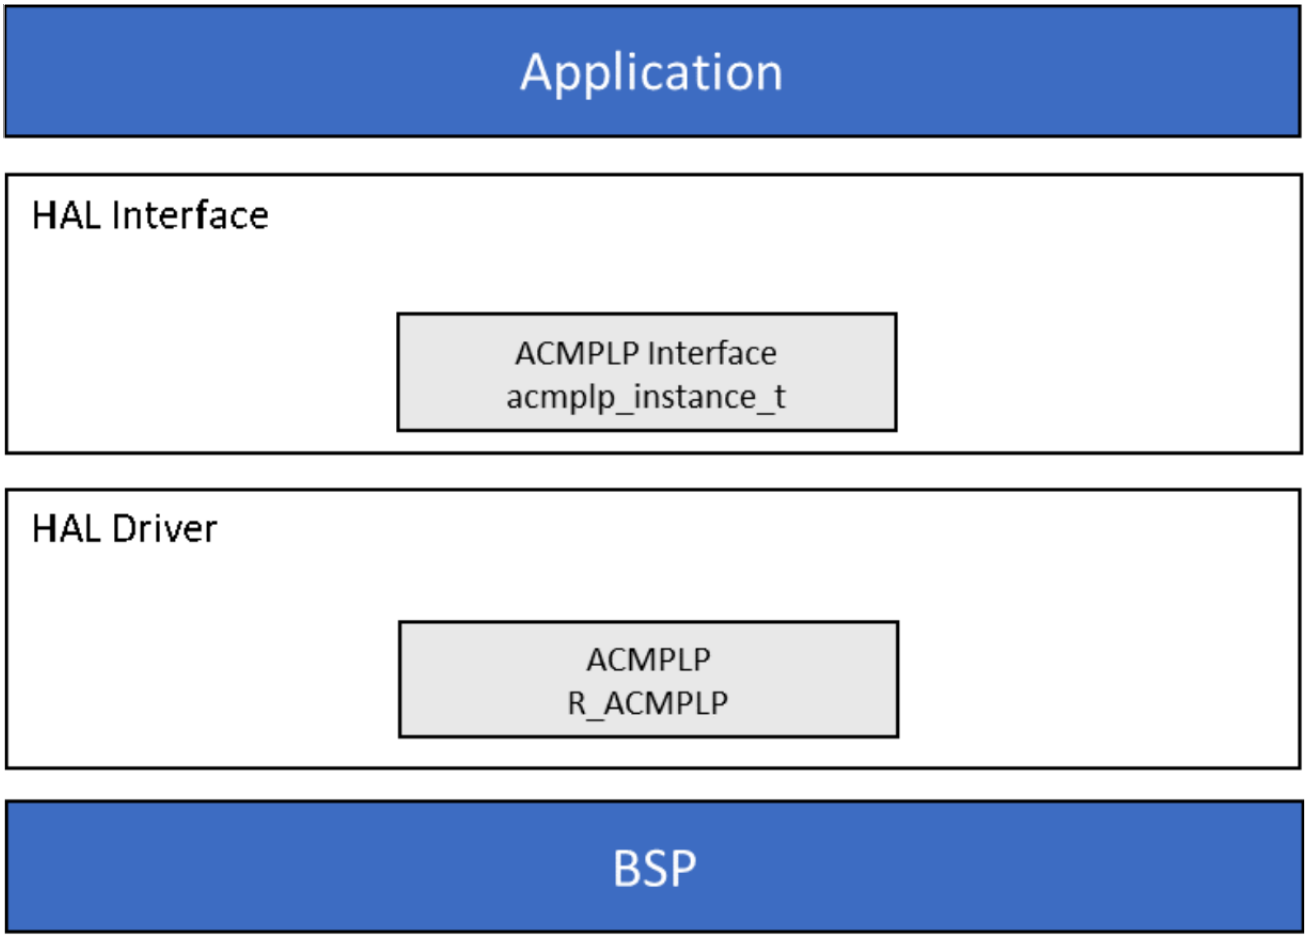

Figure 235: ACMPLP HAL Module Block Diagram

ACMPLP Hardware support details

The following hardware features are, or are not, supported by the SSP for the ACMPLP:

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

MCU Group	Normal or window mode	Callback on rising edge, falling edge, or both	Configurable debounce filter	Option to include comparator output on VCOUT

4.2.3.2 ACMPLP HAL Module APIs Overview

The ACMPLP HAL module defines API functions to open, enable, get status and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

ACMPLP HAL Module API Summary

Function Name	Example API Call and Description
open	g_comparator0.p_api->open(g_comparator0.p_ctrl, g_comparator0.p_cfg); Configures the comparator and starts operation. Callbacks and pin output are not active until comparator_api_t::outputEnable is called. comparator_api_t::outputEnable should be called after the output has stabilized.
outputEnable	g_comparator0.p_api->outputEnable(g_comparator0.p_ctrl); Enables the comparator output, which can be polled using statusGet(). Also enables pin output and interrupts as configured during open().
infoGet	g_comparator0.p_api->infoGet(g_comparator0.p_ctrl, p_info); Provides the minimum stabilization wait time in microseconds.
statusGet	g_comparator0.p_api->statusGet(g_comparator0.p_ctrl, p_status); Provides the operating status of the comparator.

close	g_comparator0.p_api->close(g_comparator0.p_ctrl); Close the module.
versionGet	g_comparator0.p_api->read(&version); Retrieves the version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IN_USE	Peripheral is in use or hardware lock is taken.
SSP_ERR_TIMEOUT	The debounce filter is off and 2 consecutive matching values were not read within 1024 attempts.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.3.3 ACMPLP HAL Module Operational Overview

The Comparator Driver (r_acmplp) HAL module controls the Low-Power Analog Comparator (ACMPLP) peripheral on a Synergy microcontroller. It directly controls the ACMPLP hardware without using any RTOS elements and provides convenient APIs to simplify development.

ACMPLP HAL Module Important Operational Notes and Limitations

ACMPLP HAL Module Operational Notes

Comparator Output on VCOUT Pin

The signal on the VCOUT pin is a logical 'OR' of the outputs of all comparators (ACMPHS and ACMPLP) with their output pin enabled.

Interrupts and Callbacks

When a comparator event occurs, the R_ACMPLP HAL module calls the callback (comparator_cfg_t::p_callback) with the callback argument (comparator_callback_args_t).

ACMPLP HAL Module Limitations

- This module does not support the Filter 16 option for PCLK divisor in the hardware digital

debounce filter.
- This module only works for selected Synergy MCUs. Consult the release notes for your current SSP release to see which MCUs are supported by this module. The MCU Hardware Manual shows which peripherals are available for each MCU.
- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.3.4 Including the ACMPLP HAL Module in an Application

This section describes how to include the ACMPLP HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Comparator Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Comparator Driver is g_acmplp0. This name can be changed in the associated Properties window.)

ACMPLP HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_comparator0 Comparator Driver on r_acmplp	Threads	**New Stack> Driver> Analog> Comparator Driver on r_acmplp**

When the Comparator Driver on r_acmplp is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

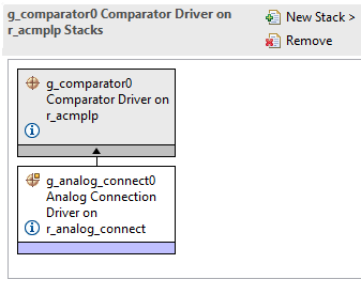

Figure 236: ACMPLP Module Stack

4.2.3.5 Configuring the ACMPLP HAL Module

The ACMPLP HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties

tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the ACMPLP HAL Module on r_acmplp

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Name	g_comparator	Module name.
Channel	0	Select the hardware channel.
Mode	Mode Normal, Mode Window Default: Mode Normal	In normal mode, comparator output is high if VCMP > VREF. In window mode, comparator output is high if VCMP is outside the range of VREF0 to VREF1.
Trigger	Trigger Rising, Trigger Falling, Trigger Both Edge Default: Trigger Both Edge	The trigger specifies when a comparator callback event should occur. Unused if the interrupt priority is disabled or the callback is NULL.
Filter	Filter Off, Filter 1, Filter 8, Filter 32 Default: Filter Off	Select the PCLK divisor for the hardware digital debounce filter. Larger divisors provide a longer debounce and take longer for the output to update.
Invert	Off, On Default: Off	Turns this on to invest comparator output. This affects the output read from StatusGet(), the pin output level, and the edge trigger.
Pin Output	Off, On Default: Off	Turn this on to include the output from this comparator on VCOUT. The comparator output on VCOUT is OR'd with output from all other ACMPHS and ACMPLP comparators.

Callback	NULL	Define this function in the application. It is called when the Trigger event occurs.
Comparator Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for the comparator interrupt.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the ACMPLP HAL Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the Red text in the Thread Stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the Analog Connection HAL Module on r_analog_connect

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_analog_connect0	Module name.
Connection Table Name	g_analog_connect0_table	This connection table name is passed to the connectMultiple API function to make all configured connections.
ACMPHS0 IVCMP	No Connection, PORT5 P500, PORT0 P013, PORT1 P100 Default: No Connection	Select the connection for ACMPHS0 IVCMP *Note* *Not required for ACMPLP Module.*

OPAMP0 AMPP	No Connection, PORT5 P500, PORT0 P014, PORT0P013, PORT0 P002, DAC120 DA Default: No Connection	Select the connection for OPAMP0 AMPP. *Note* *Not required for ACMPLP Module.*
OPAMP1 AMPM	No Connection, PORT0 P014, OPAMP1 AMPO Default: No Connection	Select the connection for OPAMP1 AMPM. *Note* *Not required for ACMPLP Module.*
OPAMP1 AMPP	No Connection, PORT0 P014, PORT0 P013, PORT0 P003, PORT0 P002, DAC80 DA Default: No Connection	Select the connection for OPAMP1 AMPP. *Note* *Not required for ACMPLP Module.*

OPAMP2 AMPM	No Connection, PORT0 P003, OPAMP2 AMPO Default: No Connection	Select the connection for OPAMP2 AMPM. *Note* *Not required for ACMPLP Module.*
OPAMP2 AMPP	No Connection, PORT0 P003, PORT0 P002, DAC81DA Default: No Connection	Select the connection for OPAMP2 AMPP. *Note* *Not required for ACMPLP Module.*

Note

The example settings and defaults are for a project using the Synergy S1JA MCU Group. Other MCUs may have different default values and available configuration settings.

4.2.3.6 Using the ACMPLP HAL Module in an Application

The typical steps in using the ACMPLP HAL module in an application are:

1. Initialize the ACMPLP using the comparator_api_t::open API.
2. Before VCOUT is enabled, the low level corresponding hardware register must be configured as mentioned below:
    a. Either directly configuring HW registers (COMPMDR/COMPSELn) in application.
    b. Or using Analog Connect module APIs which in turn configure low level registers.
3. After configuring the modules and internal connections, wait for the minimum stabilization wait time before enabling output. The minimum stabilization wait time can be queried using the comparator_api_t::infoGet API.
4. Enable the comparator output using the comparator_api_t::outputEnable API. This enables pin output, interrupts and the comparator_api_t::statusGet API as configured during the open API call.
5. [Optional] Use the comparator_api_t::statusGet API to poll comparator status.
6. [Optional] Use the comparator_api_t::close API to disable the comparator and power down the peripheral.

These common steps are illustrated in a typical operational flow diagram in the following figure:

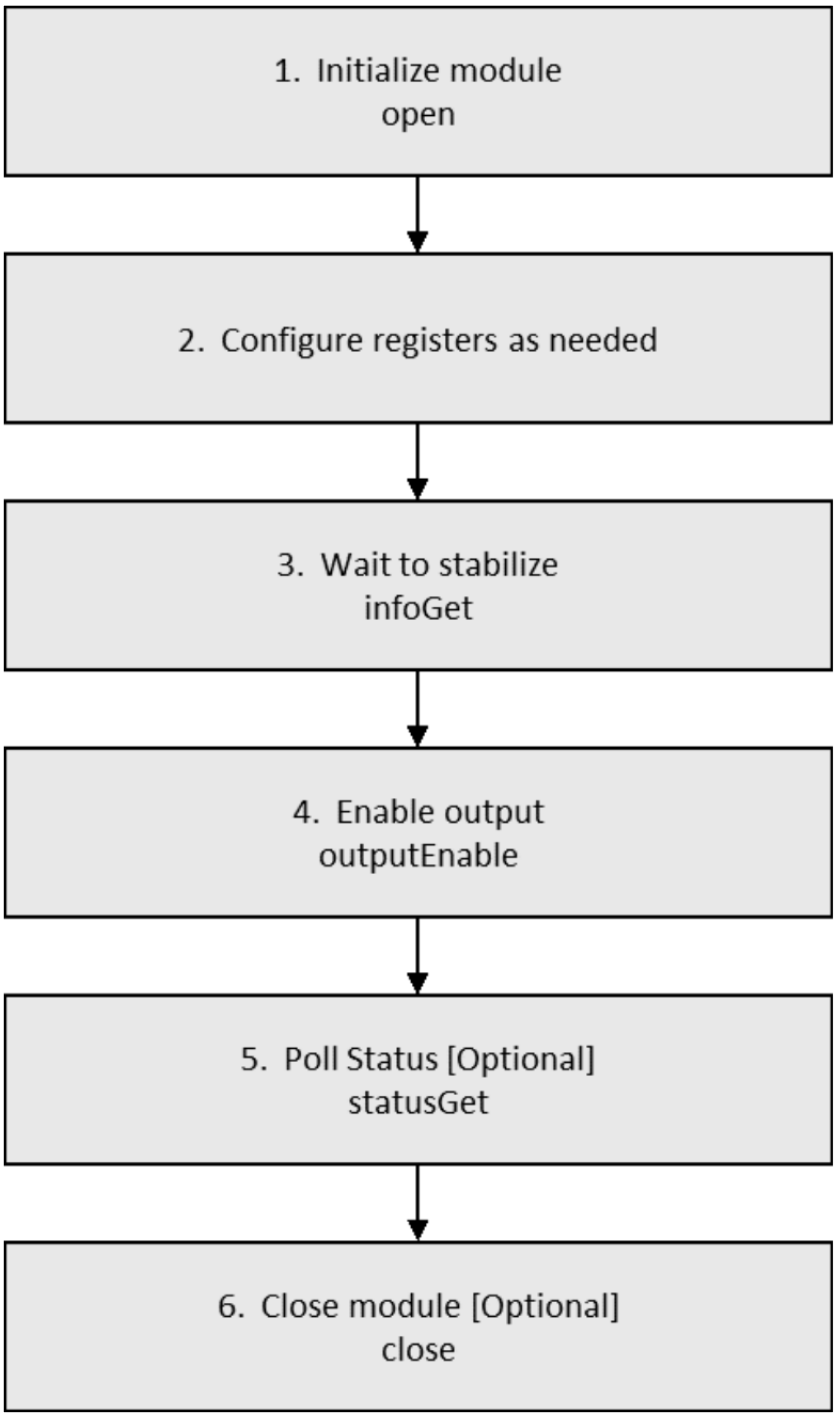

Figure 237: Flow Diagram of a Typical ACMPLP HAL Module Application

4.2.4 ADC Driver

4.2.4.1 ADC HAL Module Introduction

The ADC HAL module implements an API for analog-to-digital conversion applications. It supports the ADC12, ADC14, and ADC16 (for supported MCUs) for the associated peripherals available on Synergy MCUs. A user-defined callback can be used to process the data each time a new sample is complete.

ADC HAL Module Features

- 16-Bit A/D Converter (S1JA)
- 14-Bit A/D Converter (S3A7, S3A3, S3A6, S3A1, S128, S124)
- 12-Bit A/D Converter (S7G2, S5D9, S5D5)
- Multiple Operation Modes
    - Single Scan
    - Group Scan
    - Continuous Scan
- Multiple Channels
    - All analog channels on MCU
        - 13 channels (unit 0) or 12 channels (unit 1) for S7G2
        - 17 channels for S1JA
        - 18 channels for S124
        - 28 channels for S3A7
    - Temperature sensor channel
    - Voltage sensor channel
- Reference voltage selection on 16-Bit A/D Converter (S1JA).
- Programmable gain amplifier (PGA) (S7G2, S5D9, S5D3)
    - Single ended input mode
    - Differential input mode

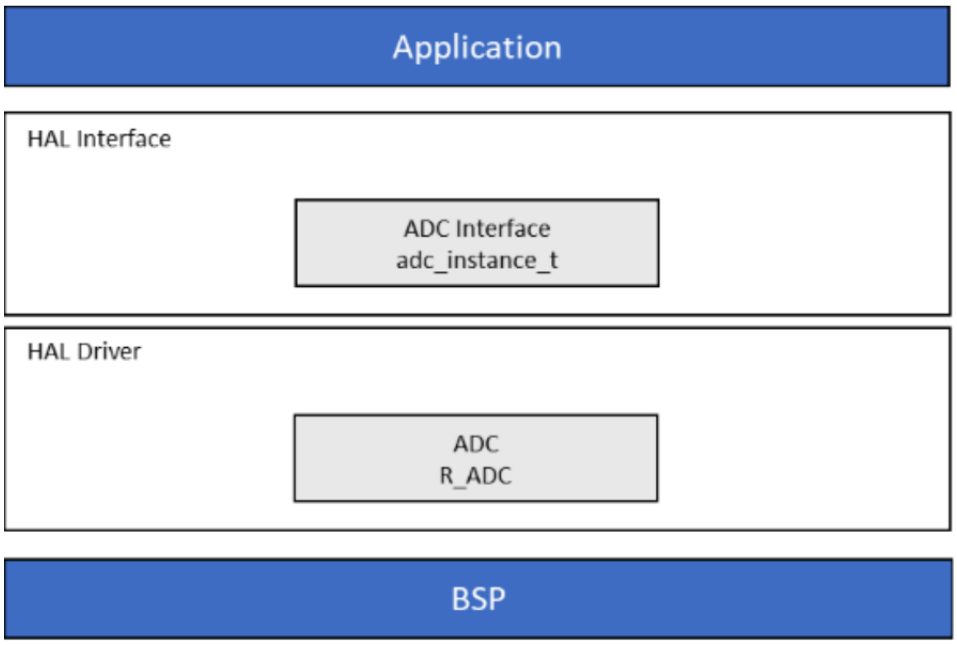

Figure 238: ADC HAL Module Block Diagram

ADC Hardware support details

The following hardware features are, or are not, supported by the SSP for the ADC:

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

MCU Group	Support for all Analog Channels (Unit 0 for all MCUs and Unit 0 & 1 for S5 and S7 series)	8-Bit	10-bit	12-Bit	14-bit	16-bit	Single scan Mode
S124	✓	N/A	N/A	✓	✓	N/A	✓

- Note: ELC is supported but only for Group mode. This must be set up manually by programming the Event Link Controller.

4.2.4.2 ADC HAL Module APIs Overview

The ADC HAL module defines APIs to open, configure scans, start scans, stop scans, read the conversion results of the ADC scans, and close the ADC unit. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. A table of status return values follows the API summary table.

ADC HAL Module API Summary

Function Name	Example API Call and Description
open	g_adc.p_api->open(g_adc.p_ctrl, g_adc.p_cfg); Initialize ADC Unit; apply power, set the operational mode, trigger sources, interrupt priority, and configurations common to all channels and sensors.
scanCfg	g_adc.p_api->scanCfg(g_adc.p_ctrl, g_adc.p_channel_cfg); Configure the scan including the channels, groups and scan triggers to be used for the unit that was initialized in the open call.
scanStart	g_adc.p_api->scanStart(g_adc.p_ctrl); Start the scan (in case of a software trigger), or enable the hardware trigger.
scanStop	g_adc.p_api->scanStop(g_adc.p_ctrl); Stop the ADC scan (in case of a software trigger), or disable the hardware trigger.
scanStatusGet	g_adc.p_api->scanStatusGet(g_adc.p_ctrl); Check scan status.
read	g_adc.p_api->read(g_adc.p_ctrl, ADC_REG_CHANNEL_13, &adc_data); Read ADC conversion result(s).
sampleStateCountSet	g_adc.p_api->sampleStateCountSet(g_adc.p_ctrl ,&adc_sample); Set the sample state count for the specified channel.
close	g_adc.p_api->close(g_adc.p_ctrl); Close the specified ADC unit by ending any scan in progress, disabling interrupts, and removing power to the specified A/D unit.

infoGet	g_adc.p_api->infoGet(g_adc.p_ctrl, &adc_info); Return the ADC data register address of the first (lowest number) channel and the total number of bytes to be read for the DTC/DMAC to read the conversion results of all configured channels.
versionGet	g_adc.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API call successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_IN_USE	Peripheral is still running in another mode; perform R_ADC_Close first.
SSP_ERR_INVALID_POINTER	The parameter p_data is NULL.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.4.3 ADC HAL Module Operational Overview

The ADC driver on r_adc HAL module controls the ADC peripherals on a Synergy microcontroller, as configured by the user. It directly controls the ADC hardware without using any RTOS elements. It provides convenient API functions to simplify development.

The driver supports three operation modes: single-scan, continuous-scan, and group-scan modes.

Single-scan Mode

In single scan mode, one or more specified channels are scanned once per trigger. A channel bit-mask is used in the channel properties configuration settings to indicate the scanned channels. Single-scan mode sequentially converts the analog inputs of the selected channels in the ascending order of the channel number. A callback event is generated after all selected channels have completed the conversion operation.

Continuous-scan Mode

Continuous-scan mode sequentially converts the analog inputs of selected channels continuously in the ascending order of the channel numbers. A single trigger is required to start the scan. No callback is used in this mode and interrupts must be disabled. The scanStatusGet API function is

used to determine when data is available.

Group-scan Mode

Group-scan mode allows the application to allocate channels to one of two groups (A and B). Analog inputs of the selected channels are converted for each group in the ascending order of the channel numbers. Conversion begins when the specified start trigger for that group is received. A callback interrupt is generated after all selected channels in the associated group have completed the conversion operation. The interrupt event indicates which group has completed conversion.

In group mode, only hardware triggers can be used, as opposed to normal mode, where software triggers or an external trigger can be used. With the priority configuration parameter, you can specify:

- Whether a trigger for one group can interrupt an ongoing scan for the other group.
- Whether an interrupted scan resumes or restarts or simply aborts the current scan and waits for the next trigger.

Interrupt and Callback Overview

When a scan or calibration (on supported MCUs) is complete and a callback is provided in the application code, (and if interrupts are enabled) the module invokes the defined callback and provides an argument that indicates the ADC unit, the event, the address of the converted data, and the channel.

The module supports two interrupts:

- The Normal/Group A Interrupt (Scan End Interrupt) fires when a scan is completed in single scan mode, when a Group A scan is completed in group mode, or at the end of calibration for supported MCUs.
- The Group B Interrupt (Scan End Group B Interrupt) fires when a group B scan is completed in group mode.

Interrupts function differently in each mode:

- In single-scan mode, the Normal interrupt (Scan End Interrupt) is triggered when the scan is completed.
- In continuous scan-mode, the hardware will constantly scan the selected channels. In this mode, the driver will return an error if interrupts are enabled, so they must be disabled in this mode.
- In group mode, the ADC unit provides two interrupts (when enabled). The Normal interrupt (called Group A interrupt in this mode, even though it is the same vector as the Normal interrupt) and the Group B interrupt. The Group A interrupt (Scan End Interrupt) is triggered when a Group A scan is completed. The Group B interrupt (Scan End Group B Interrupt) is triggered when a Group B scan is completed.

Note

You must change the Scan End Interrupt Priority and Scan End Group B Interrupt Priority configuration setting in the selected units' properties window from the default Disabled setting to the desired Priority level to Enable the associated interrupts.

When Interrupts Are Not Enabled

If interrupts are not enabled, the scanStatusGet API is used to poll the ADC to determine when the scan has completed. The read API function is used to access the converted ADC result.

For MCUs that support calibration, if interrupts are not enabled, the application program must wait 24 ms and then check the status of the calibration function using the infoGet API. Once calibration is complete, another API can be used.

ADC HAL Module Important Operational Notes and Limitations

ADC HAL Module Operational Notes

Sample-State Count Setting

The application program can modify the setting of the sample-state count by calling the adc_api_t::sampleStateCountSet API function. The application program only needs to modify the sample-state count settings from their default values to increase the sampling time. This can be either because the impedance of the input signal is too high to secure sufficient sampling time under the default setting or if the ADCLK is too slow. To modify the sample-state count for a given channel, set the channel number and the number of states when calling the adc_api_t::sampleStateCountSet API function. Valid sample state counts are 7-255.

Note

Although the hardware supports a minimum number of sample states of 5, some Synergy MCUs require 7 states, so the minimum is set to 7. At the lowest supported ADC conversion clock rate (1 MHz), these extra states will lead to, at worst case, a 2 microsecond increase in conversion time. At 60 MHz the extra states will add 33.4 ns to the conversion time.

If the sample state count needs to be changed for multiple channels, the application program must call the adc_api_t::sampleStateCountSet API function repeatedly, with appropriately modified arguments for each channel.

Triggering a Data Transfer with the ADC

To trigger a transfer of data when the ADC scan completes, configure the data transfer with the activation_source set to ELC_EVENT_ADCn_SCAN_END or ELC_EVENT_ADCn_SCAN_END_B (where n is the ADC channel number). The adc_api_t::infoGet API function can be called to retrieve the ADC unit-specific information to use with the transfer API. Refer to the ELC Module Overview for additional information.

Triggering ELC Events with the ADC

The ADC unit can trigger the start of other peripherals by using the ELC. Refer to the ELC Module Overview for additional information.

Using the Temperature Sensor with the ADC

The ADC HAL module supports reading the data from the on-chip temperature sensor. The value returned from the sensor can be converted into degrees Celsius or Fahrenheit in the application program using the following formula, T = (Vs – V1)/slope + T1, where:

- T: Measured temperature (°C)
- Vs: Voltage output by the temperature sensor at the time of temperature measurement (Volts)
- T1: Temperature experimentally measured at one point (°C)
- V1: Voltage output by the temperature sensor at the time of measurement of T1 (Volts)
- T2: Temperature at the experimental measurement of another point (°C)
- V2: Voltage output by the temperature sensor at the time of measurement of T2 (Volts)
- Slope: Temperature gradient of the temperature sensor (V/°C); slope = (V2 – V1)/ (T2 – T1)

Note

The slope value can be obtained from the hardware manual for each device in the Electrical Characteristics Chapter- TSN Characteristics Table, Temperature slope entry. The slope is positive for S7 and S5 devices and negative for S3 and S1 devices.

ADC HAL Module Limitations

When configuring the module, the temperature and voltage sensors must not be selected if any of the other available channels are also selected. The temperature sensor and the voltage sensor can both be used together, but neither can be used if any of the regular ADC channels are used.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.4.4 Including the ADC HAL Module in an Application

This section describes how to include the ADC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the ADC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the ADC Driver is g_adc0. This name can be changed in the associated Properties window.)

ADC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_adc0 ADC Driver on r_adc	Threads	**New Stack> Driver> Analog> ADC Driver on r_adc**

When the ADC Driver on r_adc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

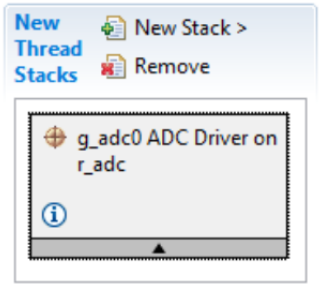

Figure 239: ADC HAL Module Stack

4.2.4.5 Configuring the ADC HAL Module

The ADC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module, and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the ADC HAL Module on r_adc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: Enabled	If selected, code for parameter checking is included in the build.
Name	g_adc0	Module name.
Unit	0, 1 (S7G2, S5D9 and S5D5) Default: 0	Specify the ADC Unit to be used. The S7G2 has two units; 0 and 1.
Resolution (resolution varies by MCU)	14-Bit, 12-Bit, 10-Bit, 8-Bit Default: 8-Bit	Specify the conversion resolution for this unit.
Alignment	Right, Left Default: Right	Specify the conversion result alignment.
Clear after read	Off, On Default: On	Specify if the result register must be automatically cleared after the conversion result is read. *Note* *If this is enabled, then watching the result register using a debugger always results in a 0.*
Mode	Single Scan, Continuous Scan, Group Scan Default: Single Scan	Specify the mode that this ADC unit is used in.
Internal Calibration During Open()	Disabled, Enabled Default: Enabled	Internal calibration during open selection.

Channel 0	- Unused, PGA 0: Configure gain from below field. - Use in Normal/Group A, - Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 1	- Unused, - Use in Normal/Group A, - Use in Group B PGA 1: Configure gain from below field. Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 2	- Unused, - Use in Normal/Group A, - Use in Group B PGA 2: Configure gain from below field. Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled.
Channels 3-13	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 14 (S3 Series Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.

Channel 15 (S3A7/S3A3 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 16-20	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 21 (Unit 0 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channels 22-24	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 25 (S3 series only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.

Channel 26 (S3A7/S3A3 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Channel 27 (S3A7/S3A3 Only)	Unused, Use in Normal/Group A, Use in Group B Default: Unused	In Normal mode of operation, this bitmask field is used to specify the channels that are enabled in that ADC unit. For example, if it is set to 0x101, then channels 0 and 2 are enabled. In group mode, this field is used to specify which channels belong to group A.
Temperature Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	Temperature sensor use selection for Channel Scan Mask.
Voltage Sensor	Unused, Use in Normal/Group A, Use in Group B Default: Unused	Voltage sensor use selection for Channel Scan Mask.
Normal/Group A Trigger	None, Asynchronous External Trigger 0, ELC Event, Software Default: Software	Specify the trigger type to be used for this unit. If group mode is used adc_cfg_t::mode, then this field is used to set the Group A trigger. *Note* *The only valid option in group mode is the ELC trigger.*
Group B Trigger (Valid Only in Group Scan Mode)	ELC Event (The only valid trigger for either group in Group Scan Mode)	Specify the group B trigger. This option is only valid if group mode is chosen in adc_cfg_t::mode.

Group Priority (Valid only in Group Scan Mode)	Group A cannot interrupt Group B, Group A can interrupt Group B; Group B scan restarts at next trigger, Group A can interrupt Group B; Group B scan restarts immediately, Group A can interrupt Group B; Group B scan restarts immediately and scans continuously Default: Group A cannot interrupt Group B	Determines whether an ongoing group B scan can be interrupted by a group A trigger, whether it should abort on a group A trigger, or if it should pause to allow group A scan and restart immediately after group A scan is complete. *Note* *This field is valid only in group mode.*
Add/Average Count	Disabled, Add two samples, Add three samples, Add four samples, Add sixteen samples, Average two samples, Average four samples, Average eight, Average sixteen Default: Disabled	Specify if addition or averaging needs to be done for any of the channels in this unit. The actual channels are specified by using a channel mask adc_channel_cfg_t::add_mask. Average eight and Average sixteen options are applicable only for S1JA. Add count option is not applicable for S1JA.
Channels 0-27	Disabled, Enabled Default: Disabled	This field is valid only if adc_cfg_t::add_average_count is enabled. This field determines what channels results are to be averaged or summed.
Temperature Sensor	Disabled, Enabled Default: Disabled	Temperature sensor use selection for Addition/Averaging Mask.
Voltage Sensor	Disabled, Enabled Default: Disabled	Voltage sensor use selection for Addition/Averaging Mask.
Sample and Hold Mask	Select channels for which individual sample and hold circuit is to be enabled	Sample and hold mask selection.
Channels 0-2	Disabled, Enabled Default: Disabled	Determines which of channels 0, 1 and 2 are using the updated sample-and-hold states value specified in adc_channel_cfg_t::sample_hold_states. This field must only be set if it is desired to modify the default sample and hold count value for channels 0, 1 and 2.

Sample Hold States (Applies only to the 3 channels selected above)	24	Specifies the updated sample-and-hold count for the channel dedicated sample-and-hold circuit. This field is valid only if adc_channel_cfg_t::sample_hold_mask is not 0. Only channels 0, 1 and 2 have dedicated sample and hold circuits. *Note* *Use this to modify the default number of states (24) for which the value is sampled. Each state is equal to 1/ADCLK time.*
Callback	NULL	A user callback function can be registered in adc_api_t::open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the ADC scan completes. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Scan End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Scan End Interrupt Priority selection.
Scan End Group B Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Scan End Group B Interrupt Priority selection.
Voltage reference (Only for S1JA)	- External VREFH0 - Internal VREF 1.5V - Internal VREF 2.0V - Internal VREF 2.5V	The ADC module will use the selected one as reference voltage.
Over-current protection (Only for S1JA)	- Enable - Disabled	Enables or disable over-current detection on sensor module.
Programmable Gain Amplifier	Select PGA channel from 'Channel Mask Scan' and Gain from below options	Select PGA channel from 'Channel Mask Scan' and Gain from below options.

PGA 0	- Disabled - Single Input_x2 - Single Input_x2.5 - Single Input_x_2.66 - Single Input_x_2.85 - Single Input_x_3.07 - Single Input_x_3.33 - Single Input_x_3.63 - Single Input_x_4.00 - Single Input_x_4.44 - Single Input_x_5.00 - Single Input_x_5.71 - Single Input_x_6.66 - Single Input_x_8.00 - Single Input_x_10.0 - Single Input_x_13.33 - Diff Input_x_1.5" - Diff Input_x_2.3" - Diff Input_x_4.0" - Diff Input_x_5.66"	Applicable only for S7G2, S5D9, S5D3.
PGA 1	- Disabled - Single Input_x2 - Single Input_x2.5 - Single Input_x_2.66 - Single Input_x_2.85 - Single Input_x_3.07 - Single Input_x_3.33 - Single Input_x_3.63 - Single Input_x_4.00 - Single Input_x_4.44 - Single Input_x_5.00 - Single Input_x_5.71 - Single Input_x_6.66 - Single Input_x_8.00 - Single Input_x_10.0 - Single Input_x_13.33 - Diff Input_x_1.5" - Diff Input_x_2.3" - Diff Input_x_4.0" - Diff Input_x_5.66"	Applicable only for S7G2, S5D9, S5D3.

PGA 2	- Disabled - Single Input_x2 - Single Input_x2.5 - Single Input_x_2.66 - Single Input_x_2.85 - Single Input_x_3.07 - Single Input_x_3.33 - Single Input_x_3.63 - Single Input_x_4.00 - Single Input_x_4.44 - Single Input_x_5.00 - Single Input_x_5.71 - Single Input_x_6.66 - Single Input_x_8.00 - Single Input_x_10.0 - Single Input_x_13.33 - Diff Input_x_1.5" - Diff Input_x_2.3" - Diff Input_x_4.0" - Diff Input_x_5.66"	Applicable only for S7G2, S5D9, S5D3.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

ADC HAL Module Clock Configuration

The ADC HAL module uses the PCLKC as its clock source (ADCLK.) The only restriction when configuring this clock is that it should be set to less than the max ADC clock; there is also a restriction on the ratio of the PCLKC and PCLKB clocks specified in the hardware manual.

The ADC-conversion time depends on the PCLKC setting.

To set the PCLKB and PCLKC frequencies, use the clock configurator in the ISDE.

To change the clock frequency at run-time, use the CGC Interface.

ADC HAL Module Pin Configuration

To use the ADC HAL module, the port pins for the channels receiving the analog input must be set as input pins in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection for the ADC HAL Module on r_adc

Resource	ISDE Tab	Pin selection Sequence
ADC	Pins	Select **Peripherals**> **Analog Pins**> **ADC0\1**> **AN_XX**

4.2.4.6 Using the ADC HAL Module in an Application

The typical steps in using the ADC HAL module in an application are:

1. Initialize the ADC using the adc_api_t::open API. (If calibration is enabled in the configuration, it will be performed as a part of the open call for the MCUs that support calibration.)
2. Configure the channels using the adc_api_t::scanCfg API. For MCUs that support calibration, if the calibration was not enabled in the configuration, then it must be performed before starting the first scan. Start the calibration (for supported MCUs) using the adc_api_t::calibrate API.
    a. If interrupts are disabled wait for at least 24 ms (for 32 MHz PCLKB), check status using the adc_api_t::infoGet API to insure the calibration is complete before using other ADC APIs.
    b. If interrupts are enabled, the callback will be invoked when the calibration is complete.
3. Start a conversion using the desired trigger with the adc_api_t::scanStart API.
    a. If a hardware trigger is used, this call enables the ADC unit to be triggered by the hardware trigger. If a software trigger is used, then this call starts the ADC scan.
4. If interrupts are disabled, use the adc_api_t::scanStatusGet API to determine if the scan is complete.
5. If interrupts are enabled, the callback will be invoked when the scan is complete.
6. Read the results of the conversion using the adc_api_t::read API.
7. Stop the ADC scan by calling the adc_api_t::scanStop API
    a. This prevents the ADC from being triggered by an external trigger or a hardware trigger; it also forces a stop of a software-triggered scan if one is ongoing.
8. Operate on the received data as needed by the application.
9. Use the adc_api_t::close API to power down the peripheral.

These common steps are illustrated in a typical operational flow diagram in the following figure:

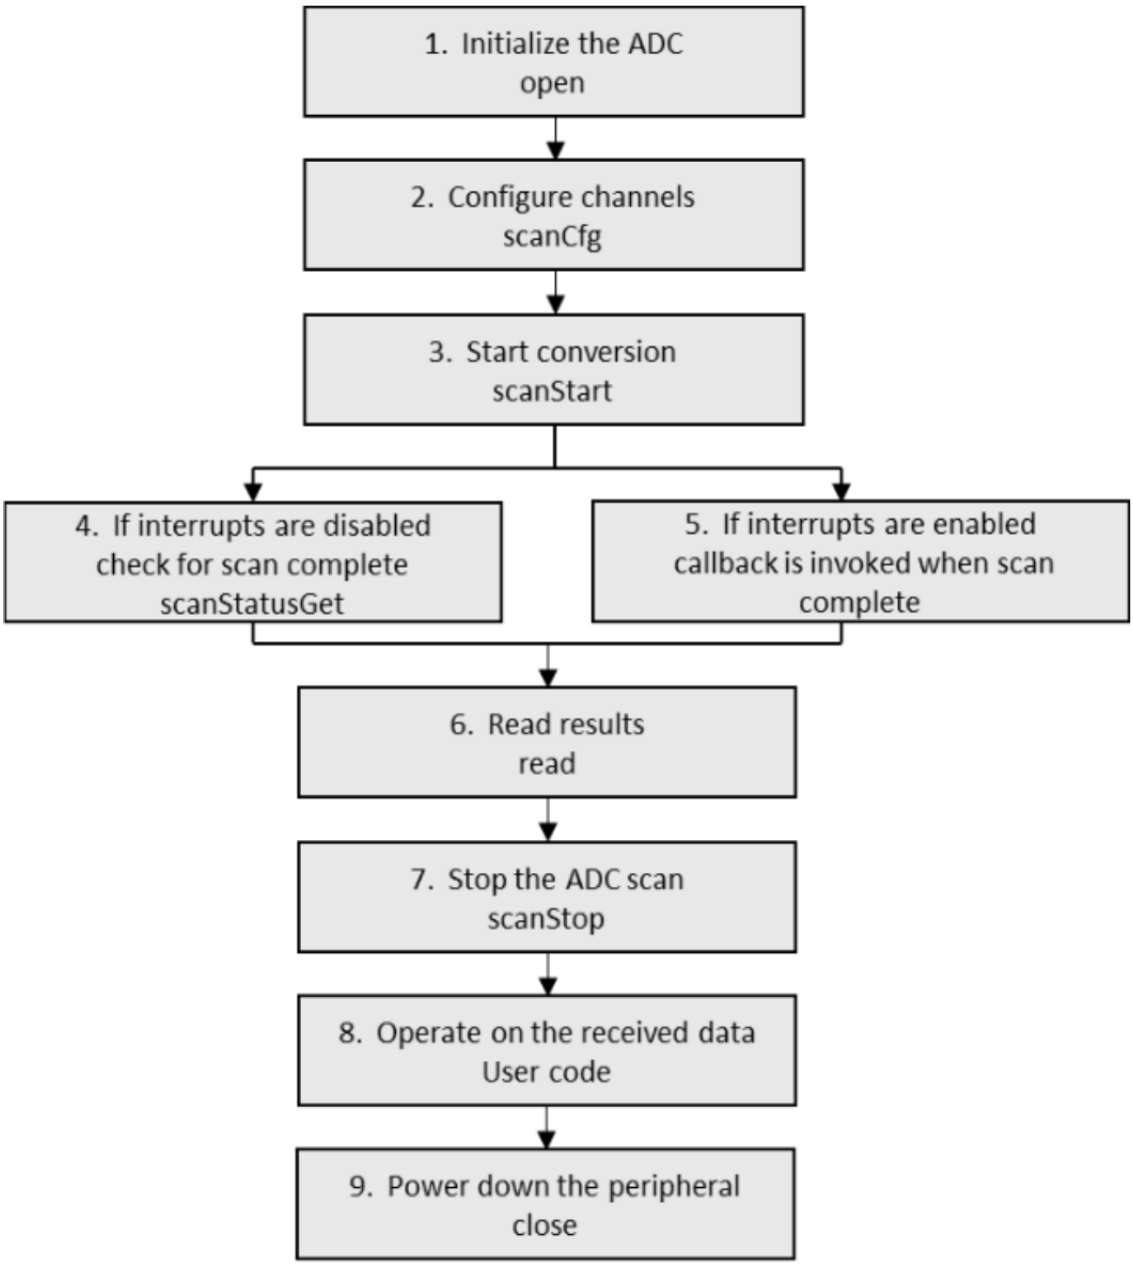

Figure 240: Flow Diagram of a Typical ADC HAL Module Application

4.2.5 Timer Driver on r_agt

4.2.5.1 AGT HAL Module Introduction

The AGT HAL module implements a high-level API for timing applications and uses the AGT peripheral on a Synergy MCU. A user-defined callback can be created to respond to a timer event.

AGT HAL Module Features

- Configures a timer for a set period and generates one of the following events when the period expires:
  - Interrupt the CPU, which calls a user-callback function (if provided)
  - Toggle a port pin
  - Transfer data using DMAC/DTC (if configured with transfer interface)
  - Start another peripheral (if configured with events and peripheral definitions)
- Multiple Channels: 16-bit x 2 channels
  - Channel 1 can be clocked by the channel 0 underflow, creating a cascaded 32-bit timer
- Core Clock: Can be clocked using PCLKB, LOCO, or Fsub. When clocked by LOCO or Fsub, it can be used to wake up the MCU from sleep modes

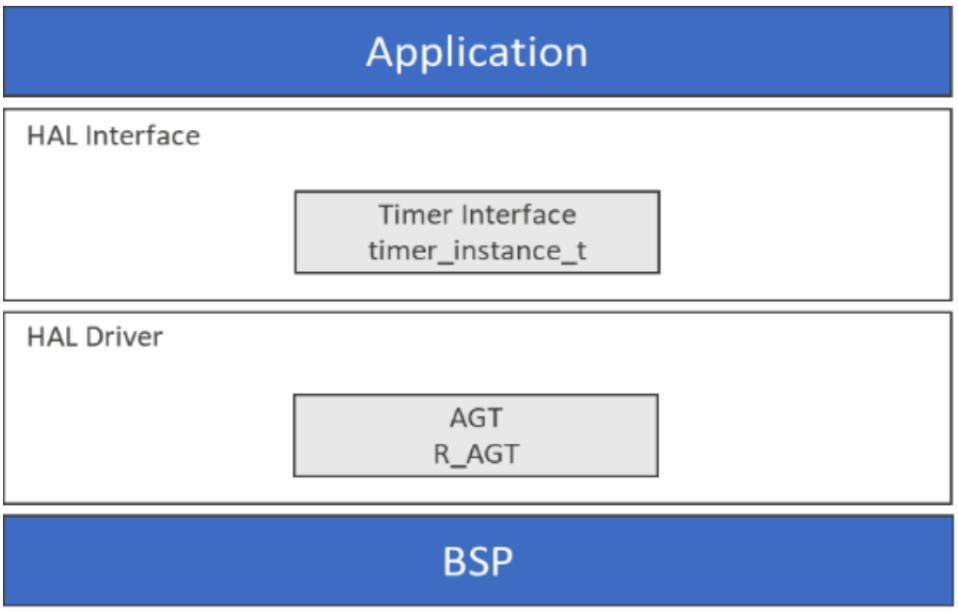

Figure 241: AGT HAL Module Block Diagram

AGT Hardware support details

The following hardware features are, or are not, supported by the SSP for the AGT.

4.2.5.2 AGT HAL Module APIs Overview

The AGT HAL module defines APIs for opening, closing, starting and stopping timers. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

AGT HAL Module API Summary

Function Name	Example API Call and Description
open	g_timer0.p_api->open(g_timer0.p_ctrl, g_timer0.p_cfg) Initial configuration.
stop	g_timer0.p_api->stop(g_timer0.p_ctrl) Stop the counter.
start	g_timer0.p_api->start(g_timer0.p_ctrl) Start the counter.

reset	g_timer0.p_api->reset(g_timer0.p_ctrl) Reset the counter initial value.
counterGet	g_timer0.p_api->counterGet(&value) Get current counter value and store it in the provided pointer, value.
periodSet	g_timer0.p_api->periodSet(g_timer0.p_ctrl, period, unit) Set the time until the timer expires.
dutyCycleSet	g_timer0.p_api->dutyCycleSet(g_timer0.p_ctrl, period, unit, pin) Sets the time until the duty cycle expires.
infoGet	g_timer0.p_api->infoGet(&info) Get the time until the timer expires in clock counts and store it in provided pointer, info.
close	g_timer0.p_api->close(g_timer0.p_ctrl) Allows driver to be reconfigured and may reduce power consumption.
versionGet	g_timer0.p_api->versionGet(g_timer0.p_ctrl, &version) Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Operation is successful.
SSP_ERR_ASSERTION	Parameter is NULL or configuration setting is not allowed.
SSP_ERR_IN_USE	The channel specified is already open.
SSP_ERR_IRQ_BSP_DISABLED	A required interrupt is not enabled in the BSP.
SSP_ERROR_NOT_OPEN	The channel is not open.
SSP_ERR_INVALID_ARG	Invalid argument provided.
SSP_ERR_INVALID_HW_CONDITION	Invalid hardware setting detected.
SSP_ERR_INVALID_PTR	A pointer parameter was NULL, but needed a non-NULL value.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.5.3 AGT HAL Module Operational Overview

The AGT HAL module configures a timer to a user-specified period. When the period elapses, the CPU can be interrupted, a port pin can be toggled, a transfer of data using the DMAC or DTC can be initiated, or another peripheral can be triggered to begin operation.

The following figure shows a flowchart for toggling a port pin or generating a CPU interrupt after a specified period. This flowchart is appropriate for both AGT and GPT counters. (Replace the GPT references with AGT references for AGT operation. AGT is a down counter so change overflow to underflow.)

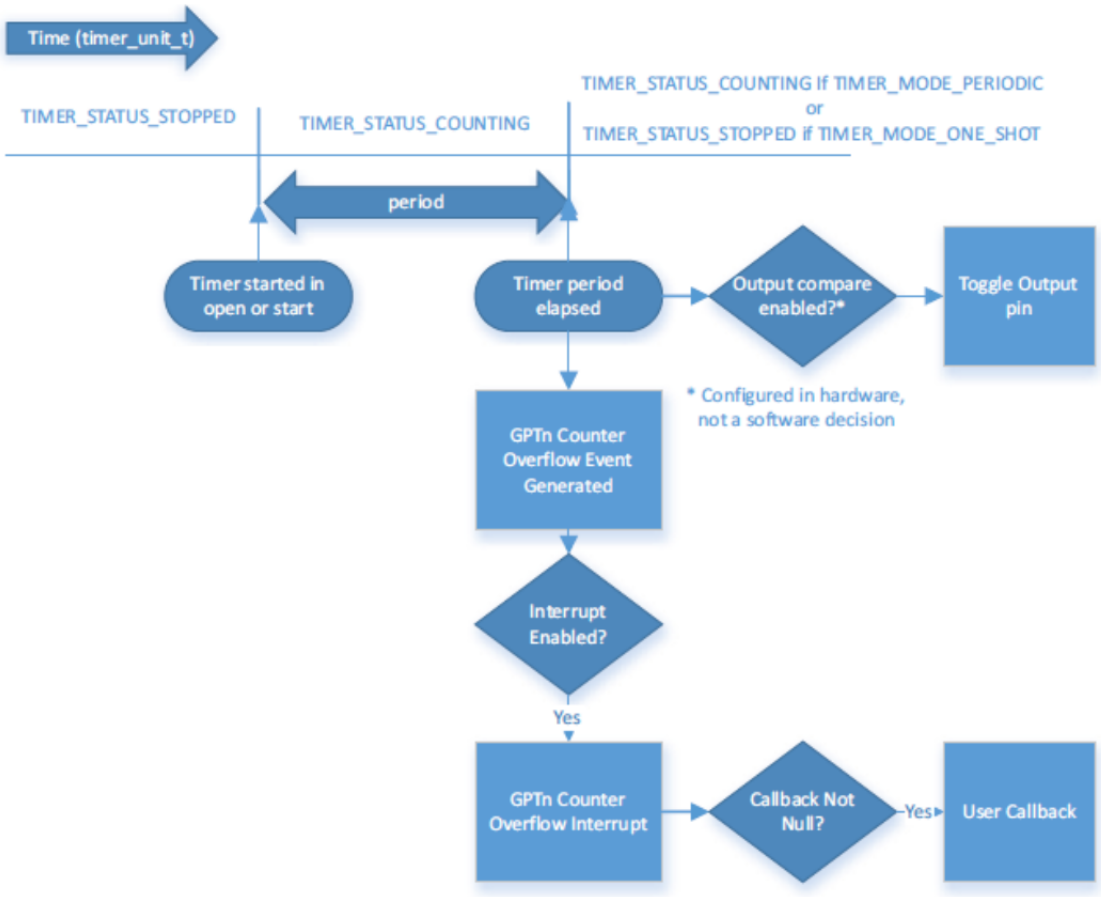

Figure 242: AGT HAL Module Flow Chart

Two different timer modules, the GPT and the AGT, are supported in the SSP. The following sections provide information on both modules so that the developer can compare and contrast the capabilities of each module for a particular application. For additional information on the GPT, refer to the GPT User's Guide.

The GPT module is recommended for most generic timer applications, but either module can be used for a basic timer functionality. The use cases in which one timer module would be preferred over the other are described as follows:

Selecting the GPT Timer Module

The GPT module uses a high-resolution 32-bit counter that can only be clocked by PCLKA. There are more GPT channels than AGT channels on Synergy devices, so using the GPT is less likely to cause a resource conflict.

Selecting the AGT Timer Module

The AGT module uses a 16-bit counter that can be clocked by PCLKB, LOCO or Fsub. If clocked by LOCO or Fsub, the AGT interrupt can be used to wake the MCU from sleep modes. There are two channels, and channel 1 can be clocked by channel 0 underflow, effectively creating a 32-bit cascaded timer.

AGT HAL Module Important Operational Notes and Limitations

AGT HAL Module Operational Notes

The maximum time period depends on the timer type and the input clock frequency.

- On a GPT with 32-bit resolution with PCLKA running at 120 MHz, the maximum period is approximately 36650 seconds, which is just over 10 hours.
- On a GPT with 16-bit resolution with PCLKA running at 32 MHz, the maximum period is approximately 2.09 seconds.
- On an AGT with 16-bit resolution with PCLKB running at 60 MHz, the maximum period is approximately 8.7 ms.
- On an AGT with 16-bit resolution with Fsub or LOCO at 32 kHz as its count source, the maximum period is approximately 262 seconds using pre-scalar up to 128.

The AGT counter underflow interrupt for the selected channel used must be enabled in the BSP in the following situations:

- To get a software interrupt when the timer period has elapsed.
- To use one-shot mode.

When the count source selected as AGTO Fsub or AGTO LOCO, turn on the count source using call cgc_api_t::clockStart API before calling timer_api_t::open.

When the AGTn AGTI interrupt is enabled in the BSP, the corresponding ISR is defined in the timer driver. The ISR calls a user-callback function if one was registered in open.

Note

Interrupts may be skipped when used with the DTC peripheral with the IRQ set to TRANSFER_IRQ_END.

AGT Output Timer Signal

If the timer output is configured, (AGTO Output Enabled set to true) the output pin starts at a high level if the output inverted is configured to True and a low level if it is configured to False. The output pin toggles every time the period elapses, beginning with the first time the period elapses after the timer is started.

In one-shot mode, the output is also configured to toggle when the timer starts counting. This generates a pulse - the timer toggles from the stop level when counting begins and toggles back to the stop level when counting ends.

Timer Period Calculation

The timer period is defined as the time until the timer expires. When output compare is used, the output pin toggles once per period, so the traditional period (from rising edge to rising edge) is twice the period specified in the software.

Runtime period calculation based on the current clock settings is available from timer_api_t::open

and timer_api_t::periodSet.

If the specified timer period is different than the raw counts, the period is calculated using the current timer clock frequency (see Configuring the GPT Clocks or Configuring the AGT Clocks). The current timer clock frequency is determined using systemClockFreqGet. This frequency is used in the appropriate formula from the following table as clk_freq_hz.

Timer Period Calculation

Timer Units	Description
TIMER_UNIT_PERIOD_NSEC	Counts = (period * clk_freq_hz)/ (1000000000 * channel_0_period)
TIMER_UNIT_PERIOD_USEC	Counts = (period * clk_freq_hz)/ (1000000 * channel_0_period)
TIMER_UNIT_PERIOD_MSEC	Counts = (period * clk_freq_hz)/ (1000 * channel_0_period)
TIMER_UNIT_PERIOD_SEC	Counts = (period * clk_freq_hz) / (channel_0_period)
TIMER_UNIT_FREQUENCY_HZ	Counts = (clk_freq_hz)/ (period * channel_0_period)
TIMER_UNIT_FREQUENCY_KHZ	Counts = (clk_freq_hz)/ (1000 * period * channel_0_period)

Note

In normal mode channel_0_period value will be 1 and in cascade mode channel_0_period value will be the timer T0 count value.

Timer Period Calculation

If the requested period is larger than the counter size (32-bit or 16-bit), the driver selects the smallest divisor that allows the result to fit in the counter size. If the counter value is larger than the counter size with the largest divisor (1024), an error code (SSP_ERR_INVALID_ARGUMENT) is returned.

Triggering DMAC/DTC with GPT

To trigger a transfer of data using the DMAC or DTC peripheral when the timer period elapses, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_GPTn_COUNTER_OVERFLOW (where n is the GPT channel number). See the DMAC or DTC guides for further information.

Note

If you use the timer in one-shot mode with the DTC, the entire transfer completes before the interrupt stops the timer if the IRQ is set to TRANSFER_IRQ_END. To generate only one transfer after the timer period elapses, set the IRQ to TRANSFER_IRQ_EACH or use the DMAC for the transfer.

Triggering ELC Events with GPT

The GPT timer can trigger the start of other peripherals. The ELC guide provides a list of all available peripherals.

Triggering DMAC/DTC with AGT

To trigger a transfer of data using the DMAC or DTC peripheral when the timer period elapses, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_AGTn_AGTI (where n is the AGT channel number). See the Transfer Interface for further information.

Note

If you use the timer in one-shot mode with the DTC, the entire transfer completes before the interrupt stops the timer if irq is set to TRANSFER_IRQ_END. To generate only one transfer after the timer period elapses, set irq to TRANSFER_IRQ_EACH, or use the DMAC for the transfer.

Triggering ELC Events with AGT

The AGT timer can trigger the start of other peripherals. The ELC guide provides a list of all available peripherals listed in elc_peripheral_t. (See events and peripheral definitions for further information.)

Cascading AGT Timers to Create a 32-bit timer

AGT Channel 1 can be clocked by the AGT Channel 0 underflow, creating a cascaded 32-bit timer. In this mode, the AGT Channel 0 output frequency will be the input frequency of AGT Channel 1. With cascaded operation, longer time periods are achievable:

- On a cascaded AGT with PCLKB running at 60 MHz, the maximum possible period is approximately 574.1 seconds.
- On a cascaded AGT with LOCO running at 32 kHz, the maximum possible period is approximately 1048560 seconds.

Cascaded Timer Period Calculation

AGT Channel 0 period calculation will be the same as normal timer period calculation as shown in the preceding table. If the requested period is larger than the counter size (32-bit or 16-bit), the driver selects the smallest divisor that allows the result to fit in the counter size.

AGT Channel 1 period calculation will be same as shown in the preceding table, except the "channel_0_period" value will be equal to AGT Channel 0's output period value (that is, after divisor selection).

Note

The cascaded timer output will have the granularity error of 1 / (clock source).

AGT HAL Module Limitations

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.5.4 Including the AGT HAL Module in an Application

This section describes how to include the AGT HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Timer Driver to an application, simply add it to a thread using the stacks selection

sequence given in the following table. (The default name for the Timer Driver is g_agt0. This name can be changed in the associated Properties window.)

AGT HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
r_agt0 Timer Driver on r_agt	Threads	**New Stack> Driver> Timers> Timer Driver on r_agt**

When the Timer Driver on r_agt is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

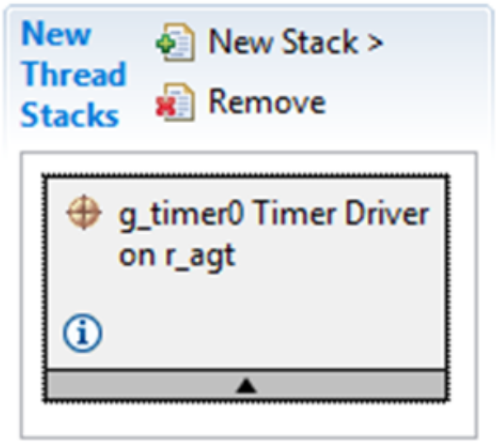

Figure 243: AGT HAL Module Stack

4.2.5.5 Configuring the AGT HAL Module

The AGT HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the AGT HAL Module on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables parameter checking.
Name	g_timer0	Module name.
Channel	0	Physical hardware channel.
Mode	Periodic, One Shot Default: Periodic	Warning: One Shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISR's must be enabled for one-shot mode even if the callback is unused.
Period Value	10	See Timer Period Calculation.
Period Unit	Raw Counts, Nanoseconds, Microseconds, Milliseconds, Seconds, Hertz, Kilohertz Default: Microseconds	See Timer Period Calculation.
Auto Start	True, False Default: True	Set to true to start the timer after configuring or false to leave the timer stopped until timer_api_t::start is called.
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	The clock source for the AGT counter.
AGTO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTO pin). Set to false for no output of the timer signal.
AGTIO Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for AGT (AGTIO pin). Set to false for no output of the timer signal.
Output Inverted	True, False Default: False	Set to false to start the output signal low. Set to true to start the output signal high.

Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection.
Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection.
Callback	NULL	A user callback function can be registered in timer_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Timer interrupt priority. 0 is the highest priority.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

AGT HAL Module Clock Configuration

The AGT timer is clocked based on the PCLKB, LOCO, Fsub or AGT Underflow frequency. The AGT clock is selectable in the **Properties** window in e^2 studio. You can set the clock frequencies using the clock configurator in e^2 studio or the CGC Interface at run-time.

AGT HAL Module Pin Configuration

The AGT peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the associated pins.

Note

The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection for the AGT HAL Module on r_agt

Resource	ISDE Tab	Pin selection Sequence
AGT	Pins	Select **Peripherals**> **Timer: AGT**> **AGT0**

Note

The selection sequence assumes AGT0 is the desired hardware target for the driver.

Pin Configuration Settings for the AGT HAL Module on r_agt

Property	Value	Description
Operation Mode	Disabled, Custom, Timer Output, Compare Match, Count Measurement, Gated Count Default: Disabled	Select timer operation mode.
AGTIO	None Default: None	AGTIO Pin.
AGTO	None, P102 Default: P102	AGTO Pin.
AGTOA	None Default: None	AGTOA Pin.
AGTOB	None Default: None	AGTOB Pin.
AGTEE	None, P101 Default: P101	AGTEE Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.2.5.6 Using the AGT HAL Module in an Application

The typical steps in using the AGT HAL Module in an application are:

1. Initialize the AGT HAL module using the timer_api_t::open API.
2. Start the AGT HAL module by calling the timer_api_t::start API.
3. Read the counter value by calling the timer_api_t::counterGet API.
4. Set the period value by using thetimer_api_t::periodSet API
5. Set the duty cycle by using timer_api_t::dutyCycleSet API
6. Get the timer information using timer_api_t::infoGet API
7. Respond to the AGT HAL module callback as needed.
8. Resets the counter value using the timer_api_t::reset API
9. Stop the AGT channel using timer_api_t::stop API
10. Use the timer_api_t::close call to power down the peripheral.

Note

The timer-period and duty-cycle parameters can be reconfigured based on the application's needs.

These common steps are illustrated in a typical operational flow diagram in the following figure:

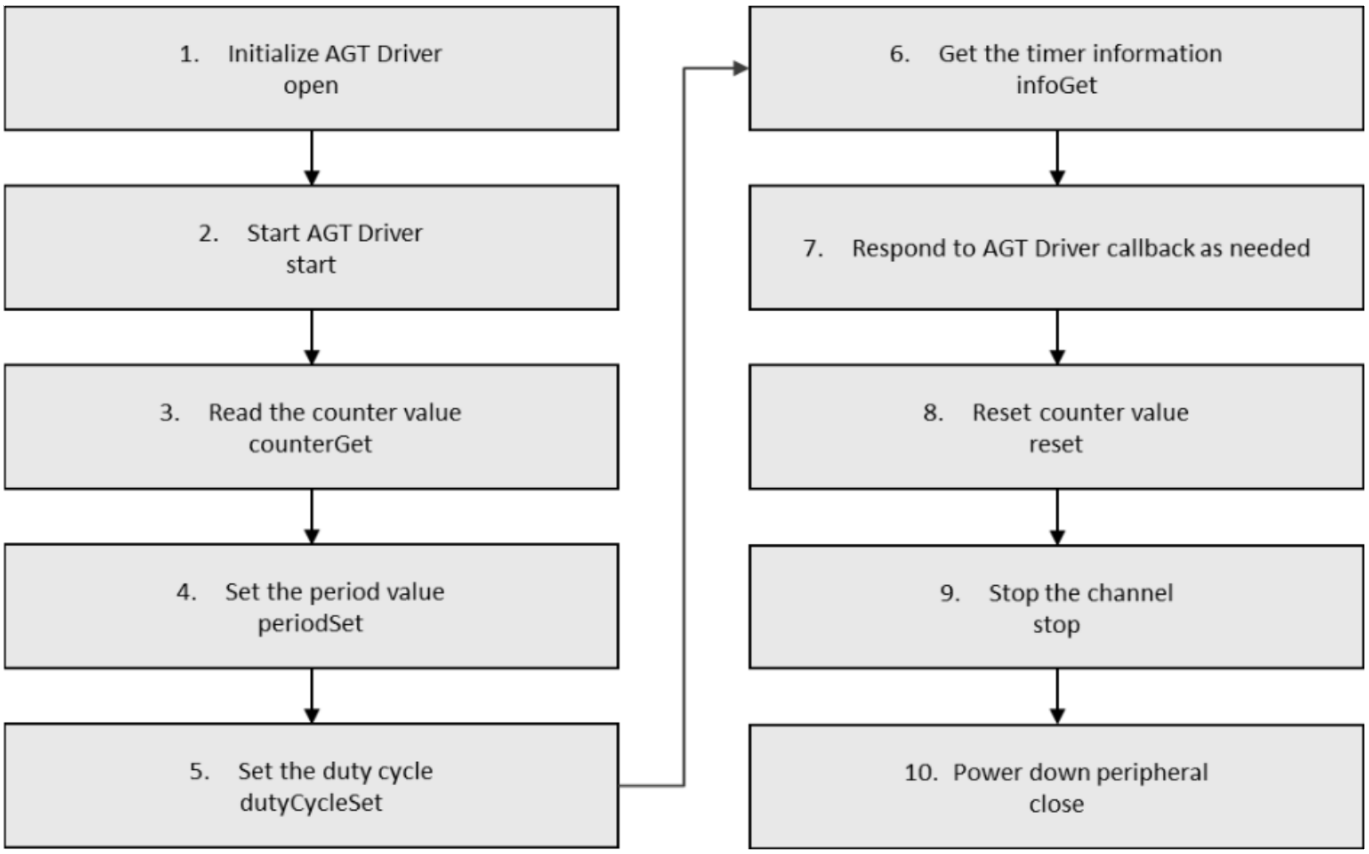

Figure 244: Flow Diagram of a Typical AGT HAL Module Application

4.2.6 AGT Input Capture Driver on r_agt

4.2.6.1 Input Capture HAL Module Introduction

The Input Capture HAL module provides an API for measuring input pulse-width, period measurement and event count measurement. The Input Capture HAL module also configures the input capture parameters to use with the AGT peripheral on the Synergy MCU. A user-defined callback can be created to acquire the value each time a new measurement is complete.

Input Capture HAL Module Features

The Input Capture HAL module configures the AGT for an input capture function.

- The Input Capture HAL allows the user to perform the following tasks:
  - Initialize the module
  - Enable input capture measurement
  - Disable input capture measurement
  - Get the status (running or not) of the measurement counter
  - Get the last captured timer/overflows counter value
  - Close the input capture operation
- The Input Capture HAL module supports:

    - Pulse-width measurement, period measurement and event count measurement
    - Rising-edge or falling-edge measurement start
    - One-shot or periodic mode
    - Callback function with the following events:
        - Measurement and overflow interrupt
        - Capture compare interrupt
- Callback structure (input_capture_callback_args_t) that provides data on the interrupting event, including which interrupt occurs and the associated counter values.

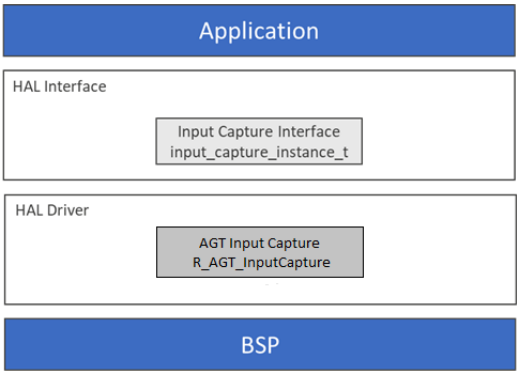

Figure 245: Input Capture HAL Module Block Diagram

4.2.6.2 Input Capture HAL Module APIs Overview

The Input Capture HAL module interface defines APIs for opening, closing, enabling, disabling, accessing status information, and accessing the last-capture value using the Asynchronous General-Purpose Timer (AGT) with Input Capture. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the HAL Module API Summary.

Input Capture HAL Module API Summary

Function Name	Example API Call and Description
open	g_input_capture.p_api->open(g_input_capture.p_ctrl, g_input_capture.p_cfg); Opens the Input Capture HAL and initializes configuration.
close	g_input_capture.p_api->close(g_input_capture.p_ctrl); Closes the input capture operation. Allow drive to be reconfigured, and may reduce power consumption.
enable	g_input_capture.p_api->enable(g_input_capture.p_ctrl); Enables input capture measurement.
disable	g_input_capture.p_api->disable(g_input_capture.p_ctrl); Disables input capture measurement.

infoGet	g_input_capture.p_api->infoGet(g_input_capture.p_ctrl, &input_capture_info); Gets the status (running or not) of the measurement counter.
lastCaptureGet	g_input_capture.p_api->lastCaptureGet(g_input_capture.p_ctrl, &input_capture_counter); Gets the last captured timer/overflows counter value.
versionGet	g_input_capture.p_api->versionGet(&input_capture_version); Retrieve the API version with the input_capture_version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	One of the parameters is NULL. Or the channel requested in the p_cfg parameter may not be available on the device selected in r_bsp_cfg.h. Or, p_cfg->mode is invalid.
SSP_ERR_IRQ_BSP_DISABLED	A required interrupt does not exist in the vector table.
SSP_ERR_IN_USE	Attempted to open an already open device instance.
SSP_ERR_NOT_OPEN	The channel is not opened.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.6.3 Input Capture HAL Module Operational Overview

The Input Capture HAL module controls the AGT HAL module units on a Synergy microcontroller (as configured by the user). It directly accesses the AGT hardware without using any RTOS elements and provides convenient APIs to simplify development.

When a normal measurement is complete and a callback is available (with interrupts enabled,) the Input Capture HAL module invokes the callback with the argument input_capture_callback_args_t.

The argument input_capture_callback_args_t indicates the channel, the event input_capture_event_t, the value of the timer captured when the interrupt occurred, and the number of counter overflows that occurred during this measurement.

If the interrupts are not enabled, the values read by the APIs would be the last captured timer/overflows counter value.

Input Capture HAL Module Important Operational Notes and Limitations

Input Capture HAL Module Operational Notes

AGT Input Capture Measurement and overflow

The input capture interface provides support for pulse-width, period measurement, and event count measurement. The input capture interface also provides support for one-shot measurement and periodic measurement. The AGT hardware does not natively support one-shot functionality. Code is automatically included in the interrupt service routine (ISR) to stop and clear the timer.

The AGT hardware doesn't have a hardware interrupt vector for event count measurement. Therefore, the compare match vector triggers a callback when the counter reaches the count value supplied by user.

AGT Input Capture Signal

The input capture measurement starts when the input capture signal edge (rising or falling) is detected on the input capture signal pin (AGTIO). The input could be captured in any one of the AGT input capture pin (such as AGTIO0_A, AGTIO0_B, or AGTIO0_C) as configured by user. The pin corresponding to this selection must also be configured in AGT peripheral in the configurator.xml (that is, under **configuration.xml > pins > peripherals > Timer:AGT).** The details on pins to be configured are in the user manual under the AGT block diagram and in the I/O ports section. Note that in the S3 and S5 series MCUs, AGTIO0_B is P402, AGTIO0_C is P403, and all other AGTIO pins are AGTIO0_A. The S1 MCU Series have only AGTIO0_A pins.

The noise filter samples the external signal at intervals of the PCLK divided by one of the values. When three consecutive samples are at the same level (high or low), then that level is passed on as the observed state of the signal.

For event count measurement, the module can be configured to count a single or both edges. That is, if it is configured as single edge, the signal edge as input by the user is counted, and if it is configured as both edges, pulses are counted on the starting edge of the pulse (either rising or falling edge). And the module will generate a callback when the pulse count reaches the event count value set by the user.

Event count measurement uses the capture compare interrupt to compare the counter value with the user expected value (and trigger a callback when they are the same), and uses the measurement and overflow interrupt to keep track of the overflow. Hence the priority of the measurement and overflow interrupt must be set higher than the latter, as the capturing of overflow takes precedence to compare match callback.

For pulse width measurement, if the input capture module is opened in the middle of an active level input by user, the module will start capturing the width from where it opened, and hence the captured width will not be the right width of the pulse.

Converting Measurement Counts to Time

When a measurement completes, the raw-count data and the number of overflows is returned to the user in the callback function.

If desired, the raw measurement data can be converted to logical time units in the callback or user

application. To convert the raw data, the current clock frequency and its pre-scaler value, number of overflows, maximum counter value, and measurement counts should be considered. The measurement counts and the number of overflows are provided in the callback arguments input_capture_callback_args_t.

The recommended method to obtain the current clock frequency is to use the cgc_api_t::systemClockFreqGet API. The input clock frequency is the clock frequency divided by the pre-scaler value and is represented as clk_freq_hz in the following Input Capture Time Calculation table. Note that pre-scaler are only available for AGTLCLK and AGTSCLK clocks

The maximum counter value for all boards is 0xFFFF. This maximum counter value plus one (since counter starts from zero) is represented as max_counts in the following table:

Input Capture Time Calculation

Desired Time Units	Formula
Nanoseconds (ns)	time_s = ((overflows * max_counts) + counter) * 1000000000 / clk_freq_hz
Microseconds (us)	time_s = ((overflows * max_counts) + counter) * 1000000 / clk_freq_hz
Milliseconds (ms)	time_s = ((overflows * max_counts) + counter) * 1000 / clk_freq_hz
Seconds (s)	time_s = ((overflows * max_counts) + counter) / clk_freq_hz

Input Capture HAL Module Limitations

- The input capture interface does not support the limited capture with Vbatt, that is, when running on battery power (which is available only for S3 MCU Series).
- Refer to the latest SSP Release Notes for any additional operational limitations for this module.
- When the count source selected is AGTSCLK or AGTLCLK, turn on the count source using call cgc_api_t::clockStart API before calling input_capture_api_t::open.

4.2.6.4 Including the Input Capture HAL Module in an Application

This section describes how to include the Input Capture HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Input Capture Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Input Capture Driver is g_input_capture0. This name can be changed in the associated Properties window.)

Input Capture HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence

g_input_captureInput Capture Driver on r_agt_input_capture	Threads->HAL/Common Stacks	**New Stack> Driver> Timers> Input Capture Driver on r_agt_input_capture**

When the Input Capture Driver on r_agt_input_capture is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

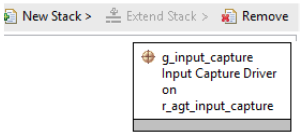

Figure 246: Input Capture HAL Module Stack

4.2.6.5 Configuring the Input Capture HAL Module

The Input Capture HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator. They are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Input Capture HAL Module on r_agt_input_capture

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_input_capture	Module name.
Channel	0	Physical hardware channel.
Mode	Pulse Width, Period, Event count Default: Pulse Width	Measures the input signal.

Signal Edge	Rising, Falling Default: Rising	Start measurement on rising or falling edge. Measurement stops on the opposite edge.
AGTIO Pin Select	AGTIO_A, AGTIO_B, AGTIO_C Default: AGTIO_A	Captures the input signal through one of these pins.
Event Edge Polarity	Single Edge, Both Edge Default: Both Edge	Counts the pulses on single edges (that is, on either rising or falling) or on both edges (that is, on either rising or falling) is received, in the event counter mode.
Repetition	Periodic, One Shot Default: Periodic	Capture a single measurement, then disable captures (one shot) until enable is called, or capture measurements continuously (periodic).
Auto Start	True, False Default: True	Set to true to enable measurements after configuring or false to leave the measurements disabled until enable is called.
Input Signal Filter	None, PCLK/1, PCLK/8, PCLK/32. Default: None	The noise filter samples the external signal at intervals of the PCLKB divided by one of the values. When 3 consecutive samples are at the same level (high or low), that level is passed on as the observed state of the signal.
Clock source	PCLKB, PCLKB/8, PCLKB/2, AGTLCLK, AGTSCLK Default: PCLKB	Input capture clock source.
Clock Divider	PCLK/1, PCLK/2, PCLK/4, PCLK/8, PCKL/16, PCLK/32, PCLK/64, PCLK/128 Default: PCLK/1	Clock divider used to scale the measurement counter.
Callback	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) each time the measurement or overflow occurs. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

Measurement and Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the measurement and overflow interrupt priority.
Capture Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the capture interrupt priority, captured interrupt is used only for event count mode.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Input Capture HAL Module Clock Configuration

The AGT HAL module uses the PCLKB, AGTLCLK and AGTSCLK as its clock source. The clock frequency is set using the SSP configurator **Clocks** tab prior to a build, or using the CGC Interface at run-time.

Input Capture HAL Module Pin Configuration

The AGT peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the associated pins.

Note

The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection for the AGT HAL Module on r_agt

Resource	ISDE Tab	Pin selection Sequence
AGT	Pins	Select **Peripherals** > **Timer: AGT**> **AGT0**

Note

The selection sequence assumes AGT0 is the desired hardware target for the driver.

Pin Configuration Settings for the Input capture HAL Module on r_agt_input_capture

Property	Value	Description
Operation Mode	Disabled, Custom, Timer Output, Compare Match, Count Measurement, Gated Count Default: Disabled	Select timer operation mode.
AGTIO	None, P100, P402, P403 Default: None	AGTIO pin.
AGTO	None Default: None	AGTO pin.

AGTOA	None Default: None	AGTOA pin.
AGTOB	None Default: None	AGTOB pin
AGTEE	None Default: None	AGTEE pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.2.6.6 Using the Input Capture HAL Module in an Application

The typical steps in using the Input Capture HAL module in an application are:

1. Initialize the module using the input_capture_api_t::open API.
2. The capture and overflow interrupt can be enabled and the timer started using the input_capture_api_t::enable API.
3. The status of the captured counter (running or stopped) can be queried using input_capture_api_t::infoGet API.
4. The desired value can be found either in the main loop routine using the input_capture_api_t::lastCaptureGet API or in the callback function.
5. The capture and overflow interrupt can be disabled and the timer stopped using theinput_capture_api_t::disable API.
6. The module can be closed using the input_capture_api_t::close API once done.

These common steps are illustrated in a typical operational flow diagram in the following figure:

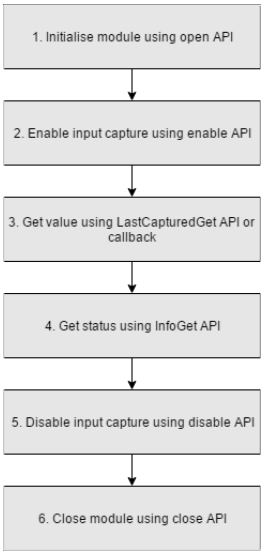

Figure 247: Flow Diagram of a Typical Input Capture HAL Module Application

4.2.7 Clock Accurate Circuit Driver

4.2.7.1 CAC HAL Module Introduction

The CAC HAL module provides a high-level API for clock accuracy control applications and uses the Clock Frequency Accuracy Measurement Circuit (CAC) peripheral on a Synergy MCU. This is particularly useful function when implementing a fail-safe mechanism for reliability-oriented applications. A user-defined callback can be created to respond to various error indications.

CAC HAL Module Features

- Supports clock frequency-measurement and monitoring based on a reference signal input.
- Reference can be either an externally supplied clock source or an internal clock sources.
- An interrupt request may optionally be generated by a completed measurement, a detected frequency error, or a counter overflow.
- A digital filter is available for an externally supplied reference clock, and dividers are available for both internally supplied measurement and reference clocks.
- Edge-detection options for the reference clock are configurable as rising, falling, or both.

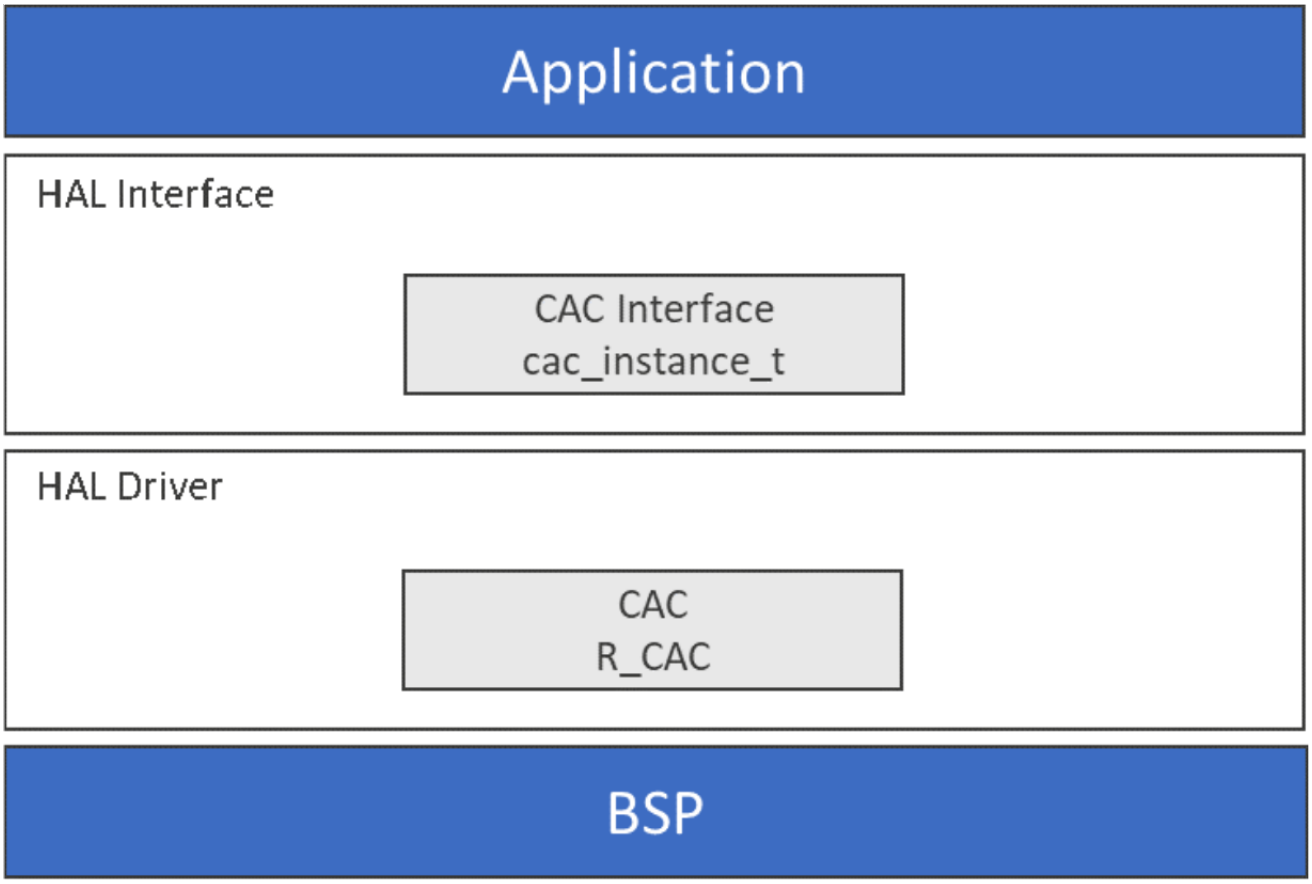

Figure 248: CAC HAL Module Block Diagram

4.2.7.2 CAC HAL Module APIs Overview

The CAC HAL module defines APIs for opening, closing, reading, starting, stopping and resetting the CAC. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

CAC HAL Module API Summary

Function Name	Example API Call and Description
open	g_cac0.p_api->open(g_cac0.p_ctrl, g_cac0.p_cfg) Open function for CAC device.
read	g_cac0.p_api->read(g_cac0.p_ctrl, &cac0_status, &cac0_counter) Read function for CAC peripheral.
close	g_cac0.p_api->close(g_cac0.p_ctrl) Close function for CAC device.
stopMeasurement	g_cac0.p_api->stopMeasurement(g_cac0.p_ctrl) Ends a measurement for the CAC peripheral.
startMeasurement	g_cac0.p_api->startMeasurement(g_cac0.p_ctrl) Begin a measurement for the CAC peripheral.
reset	g_cac0.p_api->reset(g_cac0.p_ctrl) Reset function for CAC device.
versionGet	g_cac0.p_api->versionGet(&cac0_version) Get the CAC API and code version information.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful
SSP_ERR_INVALID_ARGUMENT	One or more configuration options are invalid
SSP_ERR_NOT_OPEN	Open has not been successfully called
SSP_ERR_ASSERTION	Null provided for p_ctrl, p_cfg and others
SSP_ERR_INVALID_POINTER	Interrupt specified with NULL callback
SSP_ERR_HW_LOCKED	Hardware lock for CAC peripheral is already taken
SSP_ERR_INVALID_CAC_REF_CLOCK	Measured clock rate smaller than reference clock rate

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.7.3 CAC HAL Module Operational Overview

The CAC HAL module API interfaces with a clock frequency-measurement circuit capable of monitoring the clock frequency based on a reference signal input. The reference signal may be an

externally supplied clock source or one of several available internal clock sources. An interrupt request may optionally be generated by a completed measurement, a detected frequency error, or a counter overflow. A digital filter is available for an externally supplied reference clock, and dividers are available for both internally supplied measurement and reference clocks. Edge-detection options for the reference clock are configurable as rising, falling, or both.

The frequency of the following clocks can be measured:

- Clock output from main-clock oscillator (main clock)
- Clock output from sub-clock oscillator (sub clock)
- Clock output from high-speed on-chip oscillator (HOCO clock)
- Clock output from mid-speed on-chip oscillator (MOCO clock)
- Clock output from low-speed on-chip oscillator (LOCO clock)
- Clock output from IWDT-dedicated on-chip oscillator (IWDTCLK clock)
- Peripheral module clock (PCLKB)

The measurement clock is monitored using a reference clock. The reference clock may be an external clock (supplied on the CACREF input pin) or one of the following internal clocks:

- Clock output from main-clock oscillator (main clock)
- Clock output from sub-clock oscillator (sub clock)
- Clock output from high-speed on-chip oscillator (HOCO clock)
- Clock output from mid-speed on-chip oscillator (MOCO clock)
- Clock output from low-speed on-chip oscillator (LOCO clock)
- Clock output from IWDT-dedicated on-chip oscillator (IWDTCLK clock)
- Peripheral module clock (PCLKB)

Operational Description

The CAC HAL module measures the operation and accuracy of a selected clock. Once the measurement is requested, counting begins on the first valid edge detected for the reference clock and ends on the next valid edge. A valid edge can be configured to be rising, falling, or both. The count is incremented at each cycle of the measurement clock after it has passed through the divider circuit which is capable of dividing the clock by 1, 4, 8, or 32. An internally supplied reference clock also passes through a divider circuit which is capable of dividing the clock by 32, 128, 1024, or 8192. An externally supplied reference clock does not pass through a divider circuit, but may pass through a digital filter if it is configured to do so.

For example, if the sub-clock is specified as the measurement clock (32 kHz) and a divisor of 1 is specified, then the counter will increment at a 32 kHz rate. If a reference clock of 1 kHz is provided, then after one cycle of the reference clock you would expect the counter to be 32. This is where the CAC upper and lower-limit settings are examined. Part of the setup for a CAC measurement is the specification of an upper and lower limit for the measurement. When a measurement is complete, the CAC compares the counter contents to the limits configured for the measurement. If both the counter ≤ upper limit and the counter ≥ lower limit, then the measurement has completed without error and the measured frequency is operating within the defined limits. If the counter fails to meet these requirements, then a frequency error is indicated. A completed measurement may be identified by making API calls to poll the driver, or by establishing a callback function.

CAC HAL Module Important Operational Notes and Limitations

CAC HAL Module Operational Notes

Continuous Mode

The CAC module may be operated in either a single or continuous measurement mode. In continuous mode, the measuring process is restarted after each completed measurement. In non-continuous, or single measurement mode, measuring stops after the first completed measurement. The cac_cfg_t::continuous_mode configuration member controls this feature.

Interrupts and Callbacks

When a measurement is complete and a callback is provided by the user, (with one or more interrupts enabled) the CAC HAL module invokes the callback (cac_cfg_t::p_callback) with the argument cac_callback_args_t, indicating the event cac_event_t. If interrupts are not enabled, the API supports checking the measurement status to poll if the measurement is complete (cac_api_t::read), which will provide both the status of the measurement and the current value of the CAC counter register.

The CAC driver supports three interrupts:

- A frequency error interrupt occurs when a measurement completes and the CAC counter register value is outside of the range that was specified as part of the cac_api_t::open call. The configuration cac_cfg_t::ferr_interrupt_enabled member provided in the cac_api_t::open call must be enabled for this interrupt to be generated.
- An overflow error interrupt occurs when the CAC counter register overflows its maximum (0xFFFF) value. The configuration cac_cfg_t::ovf_interrupt_enabled member provided in the cac_api_t::open call must be enabled for this interrupt to be generated.
- A measurement complete interrupt occurs when a measurement completes and the CAC counter register value is within the range that was specified as part of the CAC driver cac_api_t::open. The configuration cac_cfg_t::mei_interrupt_enabled member provided in the cac_api_t::open call must be enabled for this interrupt to be generated.

Reset

The cac_api_t::reset API can be used to reset the overflow, measurement end and frequency error interrupt flags after measurement has been stopped to eliminate any false triggers.

CAC HAL Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.7.4 Including the CAC HAL Module in an Application

This section describes how to include the CAC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Clock Accuracy Circuit Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Clock Accuracy Circuit Driver is g_cac0. This name can be changed in the associated Properties window.)

CAC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence

g_comparator0 Comparator Driver on r_acmphs	Threads	**New Stack> Driver> Analog> Comparator Driver on r_acmphs**

When the Clock Accuracy Circuit Driver on r_cac is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

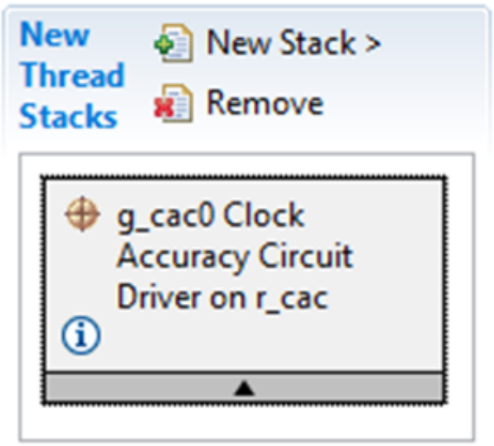

Figure 249: CAC HAL Module Stack

4.2.7.5 Configuring the CAC HAL Module

The CAC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the CAC HAL Module on r_cac

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Name	g_cac0	Identifies this instance.
Continuous Measurement Operation	Enabled, Disabled Default: Enabled	If Enabled, measurement will continuously restart after completing.
Measurement Complete Interrupt	Enabled, Disabled Default: Enabled	Enabling allows the CAC driver to generate an interrupt when a measurement is complete, providing the CAC MEASUREMENT END interrupt is enabled in the ICU.
Overflow Interrupt	Enabled, Disabled Default: Enabled	Enabling allows the CAC driver to generate an interrupt when a CAC overflow occurs, providing the CAC OVERFLOW interrupt is enabled in the ICU.
Frequency Error Interrupt	Enabled, Disabled Default: Enabled	Enabling allows the CAC driver to generate an interrupt when a frequency error occurs, providing the CAC FREQUENCY ERROR interrupt is enabled in the ICU.
Upper Limit Threshold	0	Top end of allowable range for measurement complete.
Lower Limit Threshold	0	Bottom end of allowable range for measurement complete.
Reference Clock Source	Main Oscillator, Sub-clock, HOCO, MOCO, LOCO, PCLKB, IWDT Default: Main Oscillator	Reference clock source.
Reference Clock Divider	32,128,1024,8192 Default:32	Reference clock divider.
Reference Clock Edge Detect	Rising, Falling, Both Default: Rising	Reference clock edge detection.
Reference Clock Digital Filter	Disabled, Sampling clock = measuring frequency, Sampling clock = measuring/4, Sampling clock = measuring/16 Default: Disabled	Reference clock digital filter.

Measurement Clock Source	Main Oscillator, Sub-clock, HOCO, MOCO, LOCO, PCLKB, IWDT Default: HOCO	Measurement clock source.
Measurement Clock Divider	1,4,8,32 Default: 1	Measurement clock divider.
Callback	NULL	Function name for callback.
Frequency Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	CAC Frequency Error interrupt priority selection.
Measurement End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	CAC Measurement End interrupt priority selection.
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	CAC Overflow interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

CAC HAL Module Clock Configuration

Clocks are selected from the **Clock** tab as needed by the application.

CAC HAL Module Pin Configuration

The pins for the CAC HAL module are selected as shown in the following table; the pin settings are shown in the subsequent table. If CACREF is used to the input pin of reference clock, you must configure this pin.

Pin Selection for the CAC HAL Module on r_cac

Resource	ISDE Tab	Pin selection Sequence
CAC HAL Module	Pins	**Peripherals> Monitoring: CAC> CAC0**

Note

The selection sequence assumes CAC0 is the desired hardware target for the driver

Pin Configuration Settings for the CAC HAL Module

Pin Configuration Property	Value	Description
Operation Mode	Disabled, External Reference Default: Disabled	Select **Enable** as the Operation Mode for CAC.
CACREF:	None, P204 Default: None	CACREF Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 kit. Other Synergy kits and MCUs may have different available pin configuration settings.

4.2.7.6 Using the CAC HAL Module in an Application

The typical steps in using the CAC HAL module in an application are:

1. Start reference clock and measurement clock using the CGC cgc_api_t::clockStart API if needed.
    a. For started clock, use the CGC cgc_api_t::clockCheck API to confirm oscillation stability or active state.
2. Get the API and code version information using the cac_api_t::versionGet if needed.
3. Initialize the CAC HAL module using the cac_api_t::open API.
4. Start a measurement using the cac_api_t::startMeasurement API.
5. Poll using the cac_api_t::read function to look for the measurement result or get measurement status and result using callback function called in ISR.
6. Stop the measurement using the cac_api_t::stopMeasurement API.
7. Reset the overflow, measurement end, and frequency error interrupt flags using the cac_api_t::reset API.
8. Close the CAC HAL module if no more measurements are needed using the cac_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

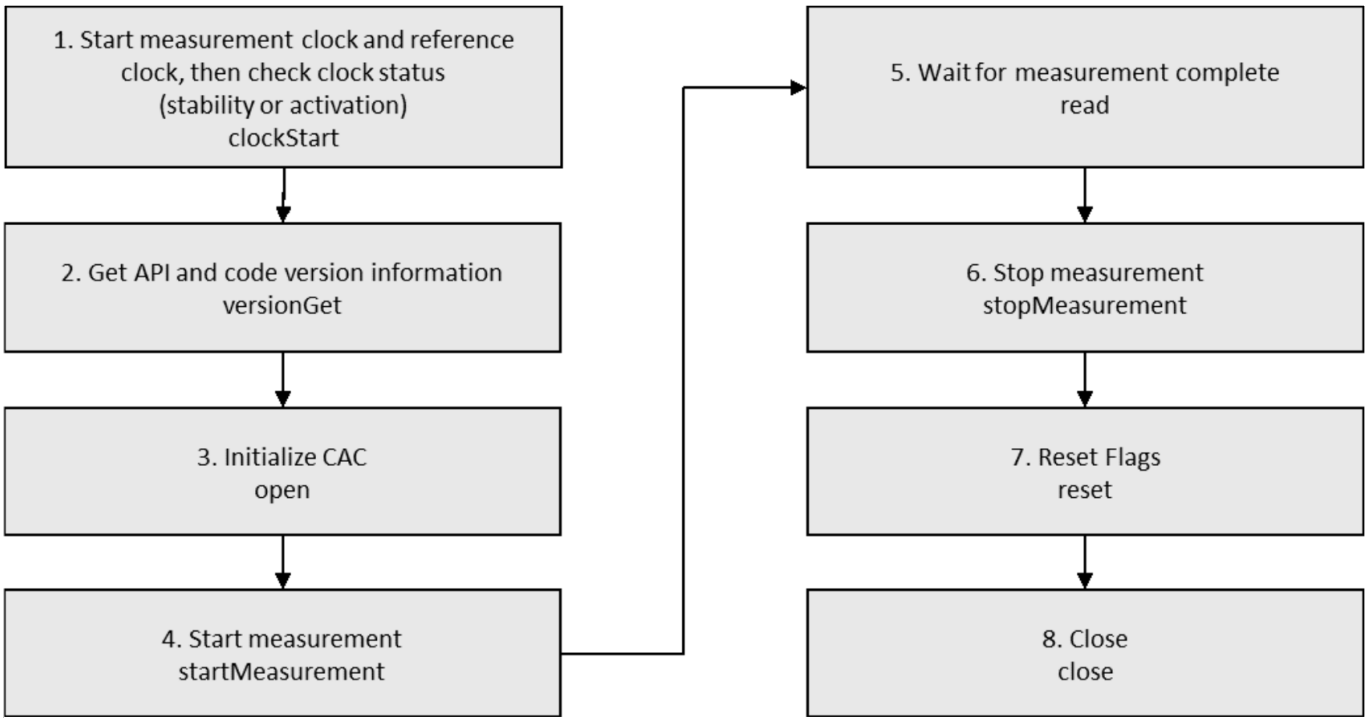

Figure 250: Flow Diagram of a Typical CAC HAL Module Application

4.2.8 CAN Driver

4.2.8.1 CAN HAL Module Introduction

The CAN HAL module provides a high-level API for CAN network applications and supports the CAN peripherals available on the Synergy microcontroller hardware. A user-callback function must be defined, which the driver will invoke when transmit, receive or error interrupts are received. The callback returns with a parameter which indicates the channel, mailbox and event.

CAN HAL Module Features

- Supports both standard (11-bit) and extended (29-bit) messaging formats
- Support for bit timing configuration as defined in the CAN specification
- Supports up to 32 transmit or receive mailboxes with standard or extended ID frames
- Receive mailboxes can be configured to capture either data or remote CAN Frames
- Receive mailboxes can be configured to receive a range of IDs using mailbox masks
- Supports a user-callback function when transmit, receive, or error interrupts are received

4.2.8.2 CAN HAL Module APIs Overview

The CAN HAL defines APIs for opening, closing, writing (transmitting) and reading (receiving) CAN data; it also provides some additional functions to assist in processing more complex commands. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

CAN HAL Module API Summary

Function Name	Example API Call and Description
open	g_can0.p_api->open(g_can0.p_ctrl, g_can0.p_cfg) The open API configures CAN Channel 0. This function must be called before any other CAN functions. Note: This call is made automatically during system initialization, prior to entering the users thread. Unless the user closes the module, open will not need to be called.
close	g_can0.p_api->close(g_can0.p_ctrl) The close API handles the clean-up of internal driver data.

read	g_can0.p_api->read (g_can0.p_ctrl, p_args->mailbox, &receiveFrame) The read API reads received CAN data.
write	g_can0.p_api->write (g_can0.p_ctrl, 0, &transmitFrame) The write API write data into the CAN transmit frame buffer and send it out.

control	g_can0.p_api->control(g_can0.p_ctrl, CAN_COMMAND_MODE_SWITCH, &mode);
	withcan_mode_t mode = CAN_MODE_LOOPBACK_INTERNAL;
	The control API will be able to change the CAN mode of operation.

infoGet	g_can0.p_api->infoGet(g_can0.p_ctrl, p_info) The infoGet API retrieves the CAN mode of operation.
versionGet	g_can0.p_api->versionGet(version) The versionGet API retrieves the module version information.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_HW_LOCKED	Lock already owned by another user.
SSP_ERR_CAN_MODE_SWITCH_FAILED	Channel failed to switch modes.
SSP_ERR_CAN_INIT_FAILED	Channel failed to initialize.
SSP_ERR_ASSERTION	Null pointer presented.
SSP_ERR_NOT_OPEN	Port is not open.
SSP_ERR_CAN_DATA_UNAVAILABLE	No data available.
SSP_ERR_CAN_TRANSMIT_MAILBOX	Mailbox is not setup for receive.
SSP_ERR_CAN_TRANSMIT_NOT_READY	Transmit in progress, cannot write data at this time.
SSP_ERR_CAN_RECEIVE_MAILBOX	Mailbox is setup for receive and cannot send.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.8.3 CAN HAL Module Operational Overview

The CAN HAL module controls the CAN peripherals on Synergy microcontrollers according to the user configuration. The API provides open, close, read, write, control and information functions. The driver allows for bit-timing configuration as defined in the CAN specification; it can be configured for up to 32 transmit or receive mailboxes with standard or extended ID frames. Receive mailboxes can be configured to capture either data or remote CAN frames. The user callback is invoked with the channel, mailbox and event information when a transmit, receive or error interrupt occurs.

Using the CAN IDs and Masks

Each CAN Mailbox configured to receive messages has an ID and Mask set. Incoming messages will be placed in the lowest mailbox where the following is true:

Incoming ID & Mailbox Mask == Mailbox ID & Mailbox Mask

Example 1: A mailbox with an ID of 0x25 and a mask of 0x1FFFFFFF can receive messages with IDs of 0x25.

Example 2: A mailbox with an ID of 0x25 and a mask of 0x1FFFFFF0 can receive messages with IDs of 0x20 through 0x2F.

Using the CAN HAL Module Test Modes

The CAN Module has three test modes, listen only, external loopback and internal loopback.

- In the listen only mode valid data frames and remote frames can be received. However, only recessive bits can be sent on the CAN bus. The ACK bit, overload flag, and active error flag cannot be sent. Listen only mode can be used for baud rate detection
- In the external loopback mode the protocol module treats its own transmitted messages as those received by the CAN transceiver and stores them into the receive mailbox. To be independent from external stimulation, the protocol module generates the ACK bit. Connect the CTX and CRX pins to the transceiver.
- The internal loopback mode is similar to the external loopback mode except the protocol controller performs internal loopback from the internal CTX pin to the internal CRX pin. The input value of the external CRX pin is ignored. The external CTX pin outputs only recessive bits. The CTX and CRX pins are not required to be connected to the CAN bus or any external device.

Changing the CAN HAL Module Operating Modes

The CAN Module can be switched between modes using the can_api_t::control API. Pass CAN_COMMAND_MODE_SWITCH and a pointer to a can_mode_t variable set to the desired mode into the can_api_t::control API.

Mode	can_mode_t value	Reason for use
Normal	CAN_MODE_NORMAL	Normal operation mode
Internal Loopback	CAN_MODE_LOOPBACK_INTERNAL	Internal loopback testing
External Loopback	CAN_MODE_LOOPBACK_EXTERNAL	External loopback testing
Listen Only	CAN_MODE_LISTEN	Baud rate detection

Halt	CAN_MODE_HALT	Mailbox configuration and test mode setting
Sleep	CAN_MODE_SLEEP	Stops the clock supply to the CAN module reducing current consumption
Exit Sleep	CAN_MODE_EXIT_SLEEP	Internal use only
Reset	CAN_MODE_RESET	Communication configuration

Example usage:

```
    /* Switch the device into internal loopback mode for easy testing. */
    can_mode_t mode = CAN_MODE_LOOPBACK_INTERNAL;
    ssp_err_t error = g_can0.p_api->control(g_can0.p_ctrl, CAN_COMMAND_MODE_SWITCH,
&mode);
```

CAN HAL Module Important Operational Notes and Limitations

CAN HAL Module Operational Notes

- The user application must start the main-clock oscillator (CANMCLK or XTAL) at run-time using the CGC Interface if it has not already started (for example, if it is not used as the MCU clock source.)
- For S7, S5, S3 and S1 MCUs, the following clock restriction must be satisfied for the CAN HAL module when the clock source is the main-clock oscillator (CANMCLK).fPCLKB >= fCANCLK (XTAL / Baud Rate Prescaler)
- For S7, S5 and S3 MCUs, the source of the peripheral module clocks must be PLL for the CAN HAL module when the clock source is PCLKB.
- For S3 MCUs, the clock frequency ratio of PCLKA and PCLKB must be 2:1 when using the CAN HAL module. Operation is not guaranteed for other settings.
- For S1 MCUs, the clock frequency ratio of ICLK and PCLKB must be 2:1 when using the CAN HAL module. Operation is not guaranteed for other settings.
- SJW (Synchronization Jump Width) is often given by the bus administrator. Select 1 <= SJW <= 4.
- Time segment and SJW settings must adhere to the following constraints: TS1 > TS2 >= SJW.

CAN HAL Module Limitations

- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.8.4 Including the CAN HAL Module in an Application

This section describes how to include the CAN HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of

the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the CAN Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the CAN Driver is g_can0. This name can be changed in the associated Properties window.)

CAN HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_can0 CAN Driver on r_can	Threads	**New Stack> Driver> Connectivity> CAN Driver on r_can**

When the CAN Driver on r_can is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

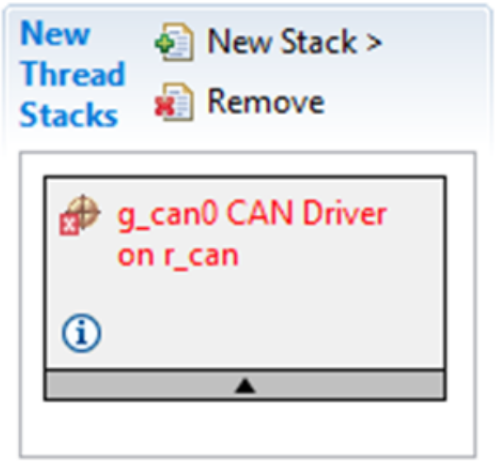

Figure 252: CAN HAL Module Stack

4.2.8.5 Configuring the CAN HAL Module

The CAN HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the CAN HAL Module on r_can

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_can0	Specify CAN Module instance name.
Channel	0	Specify if the CAN channel is to use 0 or 1 (S7G2 only).
Baud Rate Prescaler	5	Specify the baud rate prescaler (0-1023). See CAN Bit Rate Calculation.
Time Segment 1	4 Time Quanta thru 16 Time Quanta Default: 15 Time Quanta	Specify the time segment 1 value (4-16). See CAN Bit Rate Calculation.
Time Segment 2	2 Time Quanta thru 8 Time Quanta Default: 8 Time Quanta	Specify the time segment 2 value (2-8). See CAN Bit Rate Calculation.
Synchronization Jump Width	1 Time Quanta thru 4 Time Quanta Default: 2 Time Quanta	Specify the Synchronization Jump Width value (1-4). See CAN Bit Rate Calculation.
Clock Source	PCLKB (S7G2 and S3A7 only), CAN MCLK Default: CAN MCLK	CAN clock source, CANMCLK or PCLKB (S7G2 and S3A7 only).
Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time any interrupt occurs. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

Overwrite/Overrun Mode	Overwrite Mode, Overrun Mode Default: Overwrite Mode	Select whether receive mailbox will be overwritten or overrun if data is not read in time.
Standard or Extended ID Mode	Standard ID Mode, Extended ID Mode Default: Standard ID Mode	Select whether the driver will be using CAN standard or extended IDs.
Number of Mailboxes	4, 8, 16, 32 Mailboxes Default: 32 Mailboxes	Select 4, 8, 16 or 32 mailboxes.
Mailbox 0-31 ID	0-31	Select the receive ID for mailbox 0, between 0 and 0x7ff when using standard IDs, between 0 and 0x1FFFFFFF when using extended IDs. Value is not used when the mailbox is set as transmit type.
Mailbox 0 Type	Receive Mailbox, Transmit Mailbox Default: Transmit Mailbox	Select whether the mailbox is used for receive or transmit.
Mailbox 1-31 Type	Receive Mailbox, Transmit Mailbox Default: Receive Mailbox	Select whether the mailbox is used for receive or transmit.
Mailbox 0 Frame Type	Data Mailbox, Remote Mailbox Default: Remote Mailbox	Select whether the mailbox is used to capture data frames or remote frames (receive only).
Mailbox 1-31 Frame Type	Data Mailbox, Remote Mailbox Default: Data Mailbox	Select whether the mailbox is used to capture data frames or remote frames (receive only).
Mailbox 0-3 Group Mask	0x1FFFFFFF	Select the Mask for mailboxes 0-3. See Setting the Mailbox Group Masks.
Mailbox 4-7 Group Mask	0x1FFFFFFF	Select the Mask for mailboxes 4-7. See Setting the Mailbox Group Masks.
Mailbox 8-11 Group Mask	0x1FFFFFFF	Select the Mask for mailboxes 8-11. See Setting the Mailbox Group Masks.
Mailbox 12-15 Group Mask	0x1FFFFFFF	Select the Mask for mailboxes 12-15. See Setting the Mailbox Group Masks.
Mailbox 16-19 Group Mask	0x1FFFFFFF	Select the Mask for mailboxes 16-19. See Setting the Mailbox Group Masks.

Mailbox 20-23 Group Mask	0x1FFFFFFF	Select the Mask for mailboxes 20-23. See Setting the Mailbox Group Masks.
Mailbox 24-27 Group Mask	0x1FFFFFFF	Select the Mask for mailboxes 24-27. See Setting the Mailbox Group Masks.
Mailbox 28-31 Group Mask	0x1FFFFFFF	Select the Mask for mailboxes 28-31. See Setting the Mailbox Group Masks.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Specify the error interrupt priority 0-15 (required).
Receive Mailbox Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Specify the receive interrupt priority 0-15 (required).
Transmit Mailbox Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Specify the transmit interrupt priority 0-15 (required).

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

CAN HAL Module Clock Configuration

The CAN peripheral uses the CANMCLK (main-clock oscillator) or PCLKB (S7G2, S5D9, S5D5, S3A7 and S3A7 only) as its clock source (fCAN, CAN System Clock.) Using the PCLKB with the default of 60 MHz and the Synergy default, (S7G2 DK) CAN configuration will provide a CAN bit rate of 500 Kbit.

To set the PCLKB frequency, use the clock configurator in e^2 studio. To change the clock frequency at run-time, use the CGC Interface. Refer to the CGC module guide for more information on configuring clocks.

CAN HAL Module Pin Configuration

The CAN peripheral module uses the pins on the MCU to communicate to external devices connected on the CAN bus. Under Peripherals, select CAN and then CAN0 for channel 0 or CAN1 (S7G2 and S3A7 only) for channel 1. The operation mode for the channel must be enabled and the CRXn and CTXn pins must be selected to match your PC board layout. The pin configurator sets appropriate CAN pin configuration in the pin_cfg field for the associated pin. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the CAN pins.

Note

The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection for the CAN HAL Module on r_ can

Resource	ISDE Tab	Pin selection Sequence
CAN	Pins	Select **Peripherals**> **CAN**> **CAN0**

Note

The selection sequence assumes CAN0 is the desired hardware target for the driver.

Pin Configuration Settings for the CAN HAL Module on r_ can

Property	Value	Description
Operation Mode	Disabled, Enabled	Enable the mode to use CAN0.
CRX	None, P202, P402 Default: P402	CAN0_CRX0.
CTX	None, P203 P401 Default: P401	CAN0_CTX0.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

CAN Bit Rate Calculation

A time quanta (Tq) is one bit-time of the CAN communication clock, fCANCLK. This is not the CAN bit-time but the internal clock period of the CAN peripheral. The frequency is determined by the baud-rate prescaler value and the CAN source clock, fCAN (CANMCLK or PCLKB). One bit-time is divided into a number of time quanta, Tqtot. One time quantum is equal to the period of the fCANCLK. Each bitrate register is then given a certain number of Tq of the total of Tq that make up one CAN-bit period. The default ISDE bitrate setting (S7G2 DK template) is 500 Kbps for a fCAN at 60 MHz (using PCLKB.)

The formulas to calculate the bitrate register settings are as follows:

fCAN = (fPCLKB or fCANMCLK)

The baud-rate prescaler scales the CAN peripheral clock down.

fCANCLK = fCAN/ Baud Rate Prescaler = 60 MHz (default)/ 5(default) = 12 MHz

One time quantum is one clock period of the CAN clock.

Tqtot =1/fCANCLK

Tqtot is the total number of CAN peripheral clock cycles during one CAN bit time and is by the peripheral built by the sum of the "time segments" and "SS" which is always 1.

Tqtot = TSEG1 + TSEG2 + SS (TSEG1 must be > TSEG2) = 15 + 8 + 1 = 24 (default)

The bitrate is then:

Bitrate = fCANCLK/Tqtot = 12 MHz / 24 = 500 Kbps

Important notes:

- The user application must start the main-clock oscillator (CANMCLK or XTAL) at run-time using the CGC Interface if it is not already started (for example, if it is not used as the MCU clock source.)
- For S7G2, S3A7 and S124 MCUs, the following clock restriction must be satisfied for the CAN module when the clock source is the main-clock oscillator (CANMCLK): fPCLKB >= fCANMCLK
- For S7G2 and S3A7 MCUs, the source of the peripheral module clocks must be PLL for the CAN HAL module when the clock source is PCLKB.
- For S3A7 MCUs, the clock frequency ratio, PCLKA and PCLKB must be 2:1 when using the CAN HAL module. Operation is not guaranteed for other settings.
- For S124 MCUs, the clock frequency ratio of ICLK and PCLKB must be 2:1 when using the CAN HAL module. Operation is not guaranteed for other settings.
- SJW (Synchronization Jump Width) is often given by the bus administrator. Select 1 <= SJW <= 4.

Configurator sample values for different CAN bit-rate

fCAN (either PCLKB or CAN MCLK)	Baud Rate Prescalar	fCANCLK = fCAN / Baud Rate Prescalar	Time Segment 1 (TSEG1)	Time Segment 2 (TSEG2)	Synchronization Jump Width (SS)	Tqtot = TSEG1 + TSEG2 +SS	Bitrate = fCA NCLK / Tqtot
240	10	24	15	8	1	24	1 Mbps
60	5	12	15	8	1	24	500 kbps
240	48	5	16	2	2	20	250 kbps
240	96	2.5	16	2	2	20	125 kbps

Setting the Mailbox Group Masks

There are 8 mailbox group-masks, one for each group of 4 mailboxes. These masks allow the mailboxes to be configured to receive more than one ID. If the mask is all ones (0x7ff for standard IDs or 0x1FFFFFFF for extended ID) the mailboxes within the group do not mask any bits of the ID, requiring all bits of the mailbox ID to match the mailbox ID before a message is captured. If any bits of the mask are set to zero, those bits will not be necessary to match the same bits of the mailbox ID. For example, if Mailbox ID 1 is set to 0x7ff and Mailbox 0-3 Group Mask is set to 0x7ff, mailbox 1 will only capture messages with the ID of 0x7ff. If the mailbox 0-3 group mask is set to 0x7fe, mailbox 1 will still capture messages with IDs of 0x7f but will also capture messages with IDs of 0x7fe.

4.2.8.6 Using the CAN HAL Module in an Application

A CAN application requires a minimum of two nodes to demonstrate CAN communication. One node can be a transmitter, while the other can be a receiver (or both can behave as transmitter and receiver.)

The typical steps in using the CAN HAL Module in an application are:

1. Initialize the CAN HAL Module using the can_api_t::open API.

2. (Optional) Enter internal loopback or external loopback test modes using can_api_t::control API.
3. (Optional) Information about the module status, including bit rate, can be retrieved using the can_api_t::infoGet API.
4. To transmit a message:
    a. Create and configure the CAN frame ensuring correct ID and frame type.
    b. Write the CAN frame to a mailbox configured in transmit mode using the can_api_t::write API.
5. To receive a message:
    a. Read from a mailbox that has received a frame using the can_api_t::read API.
6. Close the CAN HAL Module using the can_api_t::close API (if needed).

These common steps are illustrated in a typical operational flow diagram in the following figure:

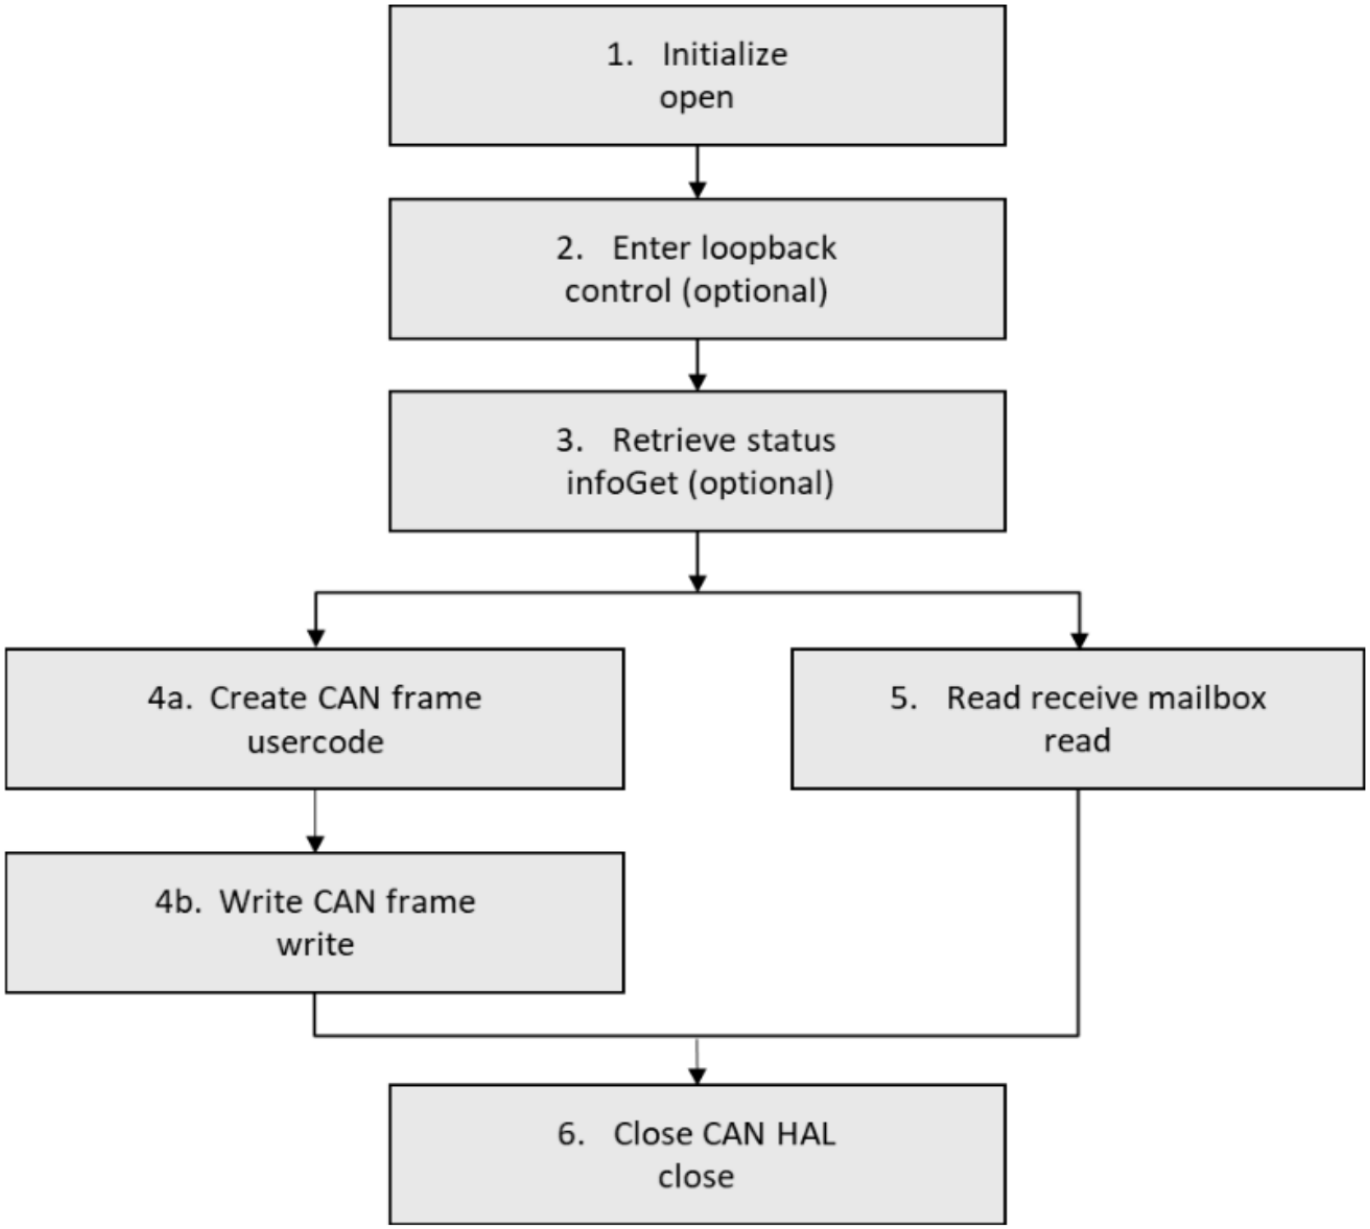

Figure 253: Flow Diagram of a Typical CAN HAL Module Application

4.2.9 CGC Driver

4.2.9.1 CGC HAL Module Introduction

The CGC HAL module provides a high-level API for clock-control applications and configures and controls the clock-control functions of a Synergy MCU using the clock-control peripheral. Since every project requires a clock function, the CGC HAL module is added to a project by default. (The module is configured in the ISDE.) A user-defined callback can be created to signal when the main oscillator has stopped.

CGC HAL Module Features

The CGC HAL module supports the configuration and control of the various clocking functions on the Synergy MCU. Key features include the following:

- Selects the system clock source

• HOCO (high-speed on-chip oscillator), MOCO (middle-speed on-chip oscillator), LOCO (low-speed on-chip oscillator), Main Clock, PLL, or Sub-Oscillator

- Configures internal clocks and turns them on or off
- Configures the output clocks
- Sets up the Oscillation Stop Detection feature
- Sets up clock divisors on each of the up to six clock domains
- Some Synergy MCUs also support controllable external clock outputs, which may have independent divisors

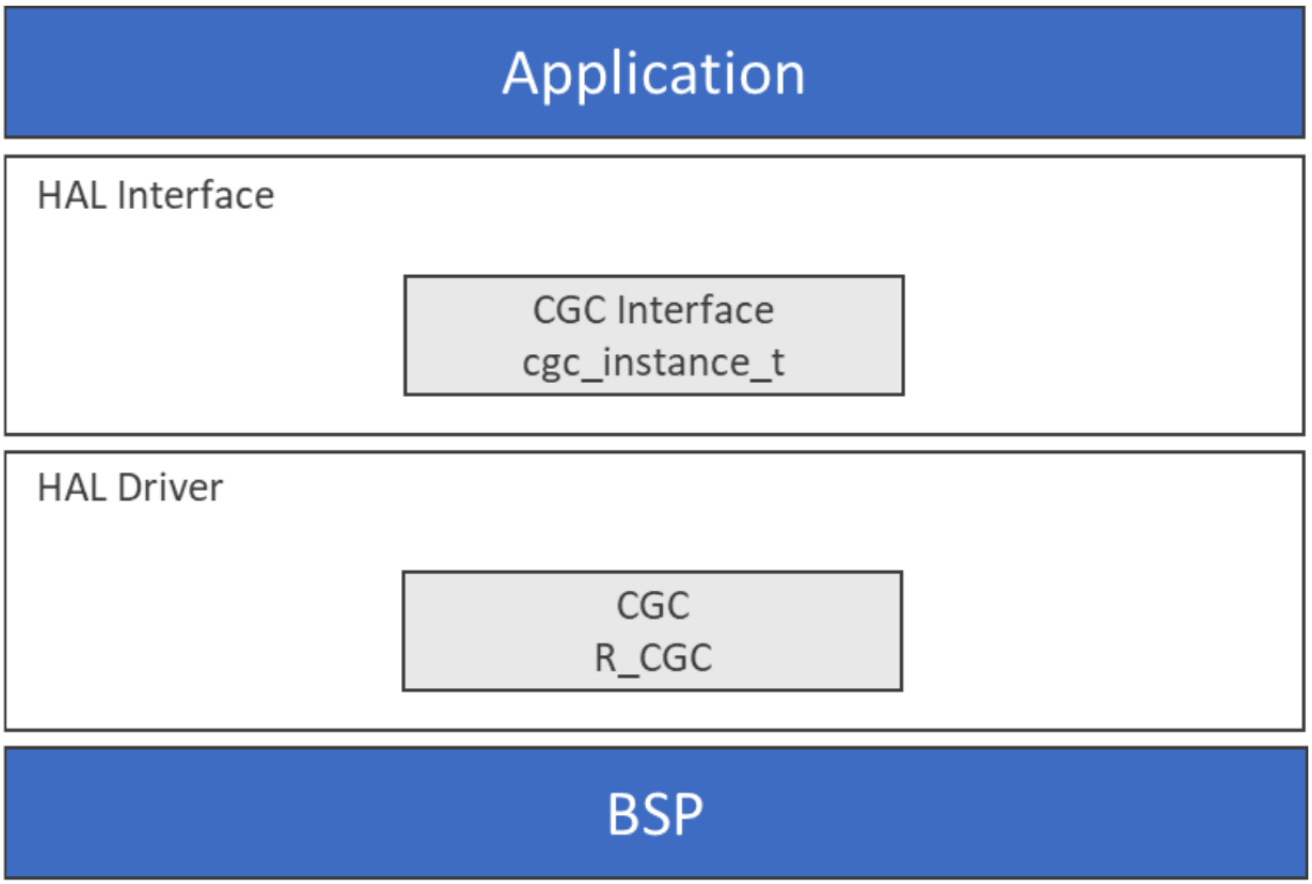

Figure 254: CGC HAL Module Block Diagram

CGC Hardware support details

The following hardware features are, or are not, supported by SSP for the Clock Generation Circuit specifications for the clock sources.

4.2.9.2 CGC HAL Module APIs Overview

The CGC HAL module defines APIs for initializing, starting, controlling and stopping the MCU clock. A complete list of the available APIs, an example API call and a short description of each can be found in the following API Summary table. A table of status return values are listed after the API summary.

CGC HAL Module API Summary

Function Name	Example API Call and Description
init	g_cgc.p_api->init(); Initial clock configuration called by BSP automatically.
clocksCfg	g_cgc.p_api->clocksCfg(&p_clock_cfg); The BSP calls this function at startup, but it can also be called from the application to change clocks at runtime.
clockStart	g_cgc.p_api->clockStart(clock_source, &p_clock_cfg); Start a clock.

clockStop	g_cgc.p_api->clockStop(clock_source); Stop a clock.
systemClockSet	g_cgc.p_api->systemClockSet(clock_source, &p_clock_cfg); Set the system clock.
systemClockGet	g_cgc.p_api->systemClockGet(&clock_source, &clock_config); Get the system clock information.
systemClockFreqGet	g_cgc.p_api->systemClockFreqGet(&clock_source, &frequency_hz); Return the frequency of the selected clock.
clockCheck	g_cgc.p_api->clockCheck(clock_source); Check the stability of the selected clock.
oscStopDetect	g_cgc.p_api->oscStopDetect(callback, enable); Configure the Main Oscillator stop detection.
oscStopStatusClear	g_cgc.p_api->oscStopStatusClear(); Clear the oscillator stop detection flag.
busClockOutCfg	g_cgc.p_api->busClockOutCfg (divider); Configure the bus clock output secondary divider. The primary divider is set using the BSP clock configuration and the systemClockSet function (S7G2 and S3A7 MCU only).
busClockOutEnable	g_cgc.p_api->busClockOutEnable (); Enable the bus clock output (S7G2 and S3A7 MCU only).
busClockOutDisable	g_cgc.p_api->busClockOutDisable (); Disable the bus clock output (S7G2 and S3A7 MCU only).
clockOutCfg	g_cgc.p_api->clockOutCfg(clock_source, clock_dividers); Configure clockOut.
clockOutEnable	g_cgc.p_api->clockOutEnable(); Enable clock output on the CLKOUT pin. The source of the clock is controlled by clockOutCfg.
clockOutDisable	g_cgc.p_api->clockOutDisable(); Disable clock output on the CLKOUT pin. The source of the clock is controlled by clockOutCfg.
lcdClockCfg	g_cgc.p_api->lcdClockCfg(clock); Configure the segment LCD Clock (S3A7 and S124 MCUs only).
lcdClockEnable	g_cgc.p_api->lcdClockEnable(); Enable the LCD clock (S3A7 and S124 MCUs only).

lcdClockDisable	g_cgc.p_api->lcdClockDisable(); Disables the LCD clock (S3A7 and S124 MCUs only).
sdadcClockCfg	g_cgc.p_api->sdadcClockCfg(clock); Configure the source for the SDADCCLK (S1JA only).
cgc_api_t::sdadcClockEnable	g_cgc.p_api->sdadcClockEnable(); Enable the SDADCCLK output (S1JA only)
cgc_api_t::sdadcClockDisable	g_cgc.p_api->sdadcClockDisable(); Disable the SDADCCLK output (S1JA only)
sdramClockOutEnable	g_cgc.p_api->sdramClockOutEnable(); Enables the SDRAM clock output (S7G2 MCU only).
sdramClockOutDisable	g_cgc.p_api->sdramClockOutDisable(); Disables the SDRAM clock (S7G2 only).
usbClockCfg	g_cgc.p_api->usbClockCfg(divider); Configures the USB clock (S7G2 only).
systickUpdate	g_cgc.p_api->systickUpdate(period_count, units); Update the Systick timer.
versionGet	g_cgc.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ABORTED	Attempt to update systick timer failed.
SSP_ERR_HARDWARE_TIMEOUT	Hardware timed out.
SSP_ERR_STABILIZED	Clock stabilized.
SSP_ERR_CLOCK_INACTIVE	Clock not turned on.
SSP_ERR_MAIN_OCO_INACTIVE	Main OCO off/unstable.
SSP_ERR_CLOCK_ACTIVE	Clock active.
SSP_ERR_NOT_STABILIZED	Clock source un-stabilized.
SSP_ERR_CLKOUT_EXCEEDED	Clock out exceeded.
SSP_ERR_NULL_PTR	Pointer null.
SSP_ERR_OSC_DET_ENABLED	Oscillation stop detection enabled.

SSP_ERR_OSC_STOP_DETECTED	The Oscillation stop detect status flag is set. Under this condition it is not possible to disable the Oscillation stop detection function.
SSP_ERR_OSC_STOP_CLOCK_ACTIVE	The Oscillation Detect Status flag cannot be cleared if the Main Osc or PLL is set as the system clock. Change the system clock before attempting to clear this bit.
SSP_ERR_INVALID_ARGUMENT	Invalid argument.
SSP_ERR_INVALID_MODE	Attempt to start a clock in a restricted operating power control mode.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.9.3 CGC HAL Module Operational Overview

The CGC HAL module interface provides the ability to configure and use all of the CGC HAL module's capabilities. Among those capabilities are the selection of several clock sources to use as the system clock source; additionally, the system clocks can be divided down to provide a wide range of frequencies for various system and peripheral needs.

Clock stability can be checked and clocks may also be stopped to save power when not needed. The API has a function to return the frequency of the system and system peripheral clocks at run time. There is also a feature to detect when the main oscillator has stopped, with the option of calling a user provided callback function.

The CGC HAL module can be used to:

- Configure any of the available clocks (HOCO, MOCO, LOCO, Main Clock, PLL, Sub-Oscillator) as the system clock source
- Configure the internal clocks (ICLK, PCLK, and so on)
- Switch the clocks on and off
- Configure the output clocks
- Set up the Oscillation Stop Detection feature

The Clock Generation Circuit peripheral features the following oscillators and clock generators:

- Main oscillator input of up to 24 MHz
- A 32.768 kHz sub-clock oscillator
- HOCO running at up to 64 MHz (depending on the device version)
- MOCO running at 8 MHz
- LOCO running at 32.768 kHz
- PLL circuit output running between 24 MHz and 240 MHz, depending on the device

The Synergy microcontrollers have six internal clock domains. Each of them has independent divisors but are dependent upon the clock input selected in the System Clock Control Register. These are:

- ICLK – The core clock, for CPU, DMAC, ROM and RAM (max 32/48/240 MHz)
- PCLKA – Peripheral clock for modules including EtherC, EDMAC, USB2.0 HS, QSPI and SCIF (max 32/48/120 MHz)

- PCLKB – Peripheral clock for modules like IIC, CAN, DAC12, RTC, USBFS, I/O Ports, WDT and IWDT (max 32/60 MHz)
- PCLKC – Peripheral clock for ADC12 conversion clock (max 64/60 MHz)
- PCLKD – Peripheral clock for GPT count clock (max 64/120 MHz)
- FCLK –Clock source for the flash memory (max 32/60 MHz)

In addition, some of the Synergy microcontrollers also support controllable external clock outputs, some of which have independent divisors. These are:

- CLKOUT – CLOCKOUT/BUZZER clock (max 24 MHz) (independent clock selector and divisor)
- BCLK – External bus clock to external bus controller (max 16/120 MHz)
- SDCLK – SDRAM clock (max 120 MHz)
- UCLK – USB clock (max 120 MHz) (independent divisor/selector on Synergy version 2)
- LCD_CLK – LCD Clock (independent clock selector but no divisor)

CGC HAL Module Changing the System Clock Peripheral Clock Divisors at Runtime

The CGC HAL module also has the option to change the system clock and clock tree settings at runtime via the cgc_api_t::clocksCfg API function. Choose **New Stack** > **System** > **CGC Configuration Instance** to create a configuration structure for use with the cgc_api_t::clocksCfg API function.

The cgc_api_t::clocksCfg function allows changes to the system clock, the peripheral clock dividers, the PLL multiplier and divider, and the state of the system clocks (stop/start) (HOCO, Main Oscillator, Subclock oscillator, and so on). The options in the following figure show an example where the system clock is being changed from HOCO to MOCO, and the peripheral clock dividers are also being updated. The options for each clock are Start, Stop, and None (meaning no change.) Not all clocks are available on all MCUs. Not all peripheral clocks are available on all MCUs.

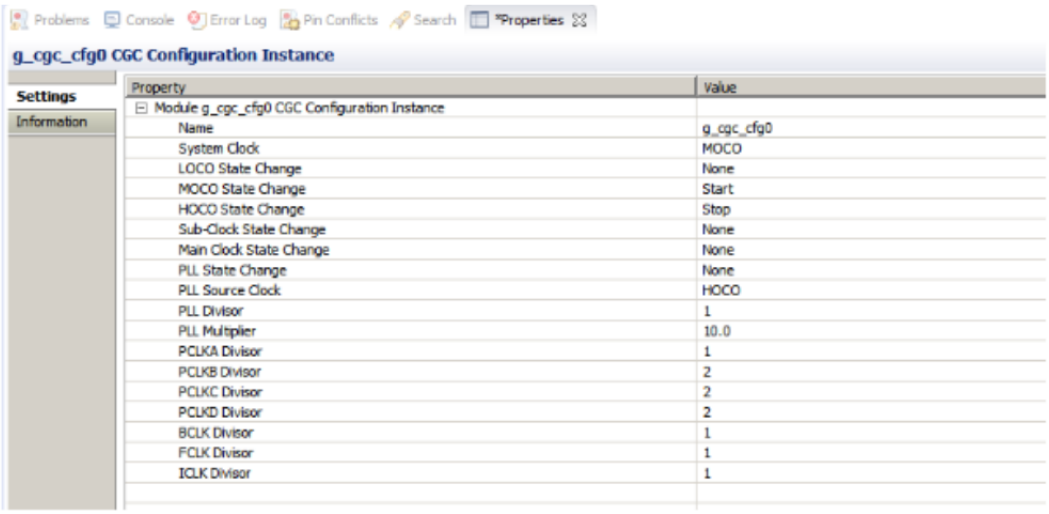

Figure 255: CGC Configuration Properties

The function call for the above example is:

```
g_cgc.p_api->clocksCfg(&g_cgc_cfg0);
```

CGC HAL Module Option Setting Memory

Synergy microcontrollers all include an Option-Setting Memory, this memory can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD and CGC HOCO. The following table lists CGC HOCO parameters that can be configured by OFS registers.

OFS register setting possibilities

Control	Description
HOCO oscillation enable	Automatically starts the HOCO after a Reset, if enabled.
HOCO Frequency	S7 and S5 Series - 16 MHz - 18 MHz - 20 MHz S3 and S1 Series - 24 MHz - 32 MHz - 48 MHz - 64 MHz

You can set the OFS register values through the properties dialog, the properties dialog is available on the Synergy Configuration editor when you select the **BSP** tab.

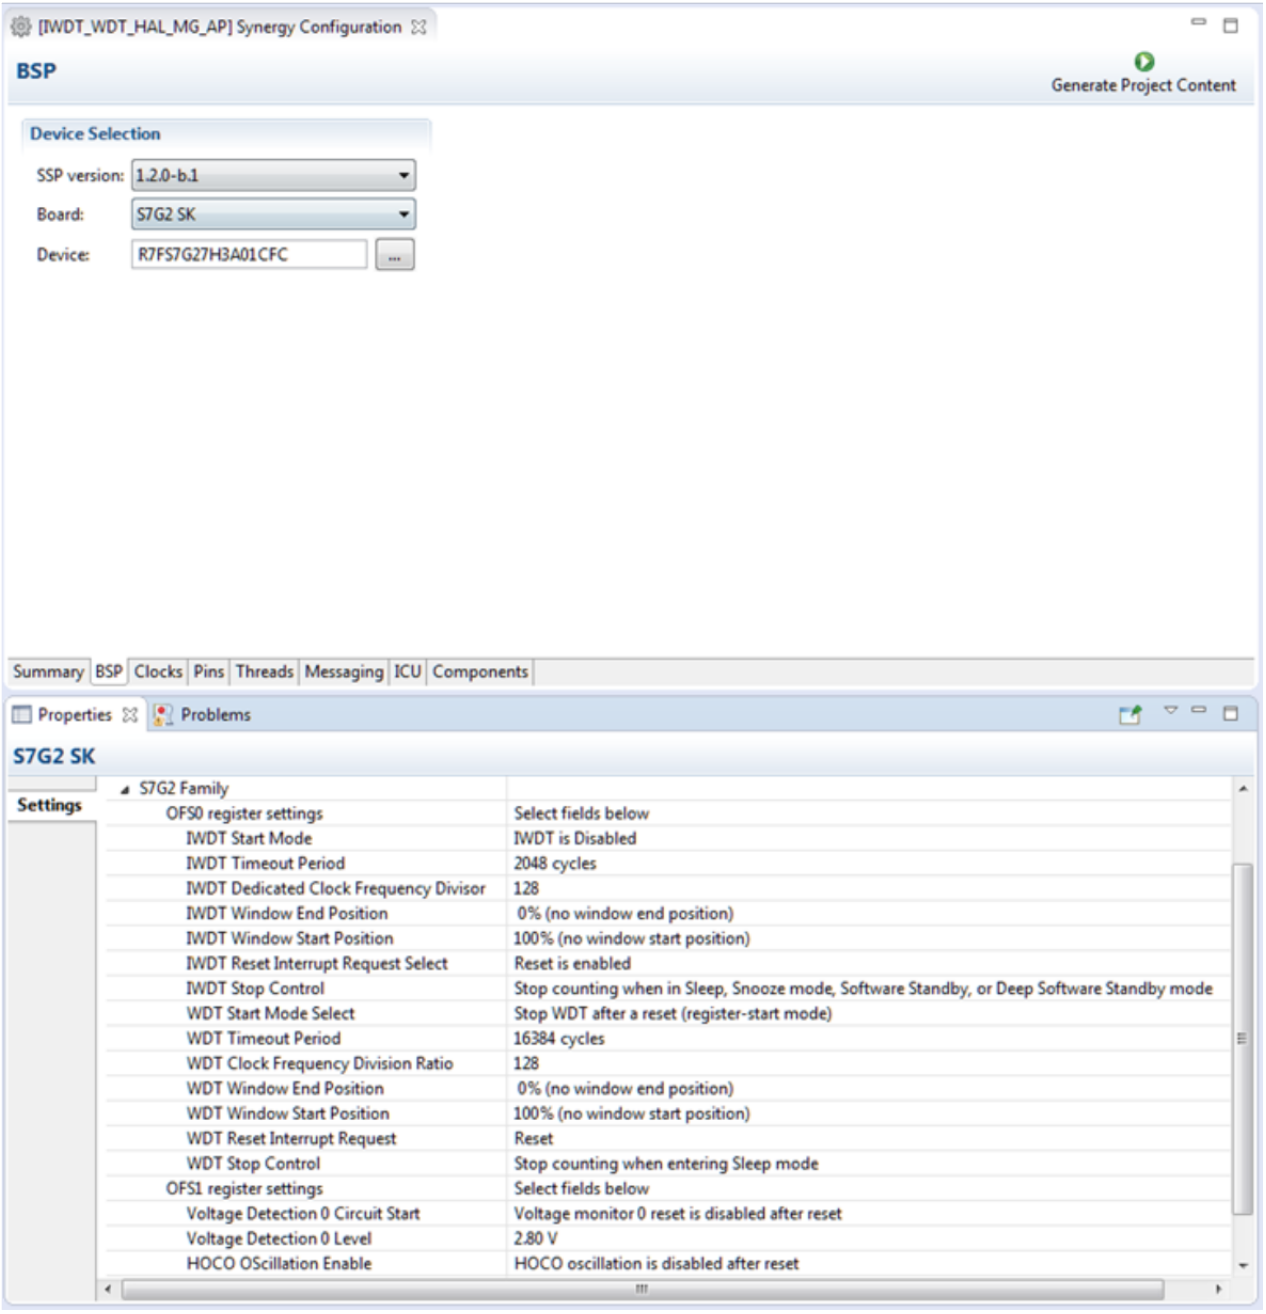

Figure 256: OFS Register Settings

Low Power Operation

The CGC HAL module also handles operating power control modes of the MCU since the Low Power Modes Version 2 HAL module will no longer handle operation-power control modes of the MCU.

When the operating power control mode is set to Sub-Oscillator Speed Mode, all system clocks except the Sub-Oscillator and the LOCO clock are turned off. To further lower the power consumption, the application program can call the clockStop API function to turn off the LOCO clock.

CGC HAL Module Important Operational Notes and Limitations

CGC HAL Module Operational Notes

- The CGC HAL module has no dependencies with respect to the ThreadX RTOS.
- The CGC HAL module is a core function of the MCU and is set after by the BSP initialization process. It is quite possible that the CGC can be left unchanged. However, the CGC HAL module provides functions that change the clock configuration that can balance the requirements of operating speed and power consumption, depending on application requirements.
- The CGC peripheral of the Synergy microcontrollers support Oscillator Stop Detection. If enabled in the application, the Oscillator Stop Detection function will automatically detect if the Main/PLL clock has stopped and switches operation to the MOCO. When enabling this functionality in the SSP a callback function has to be manually created by the user. The following steps detail this procedure.

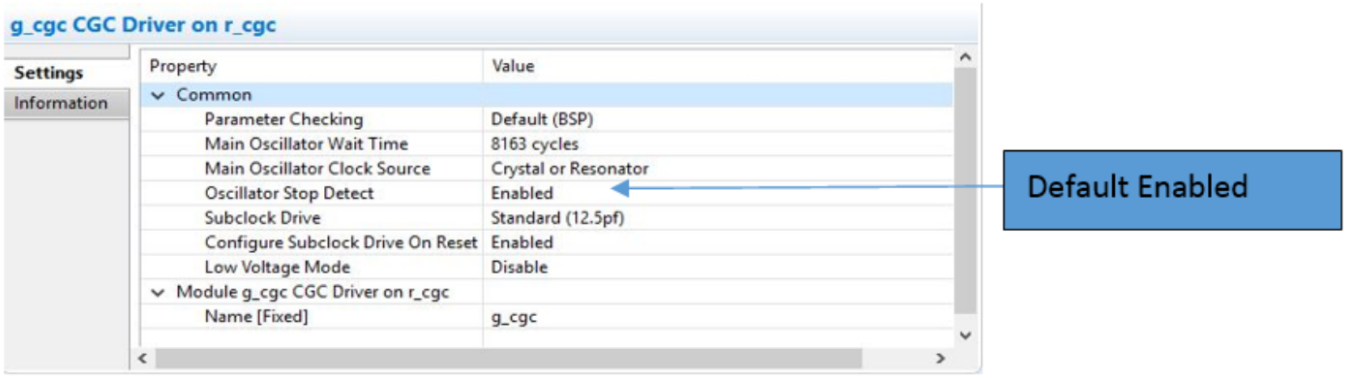

Figure 257: Oscillator Stop Detect Enable/Disable

Note

In SSP 1.4.0 and later, the Oscillator Stop Detect property is set to default as Enabled. Previous versions of SSP set the default to Disabled.

- If the Configure Subclock Drive on Reset is set to Disabled, then the subclock will not be configured at startup. In order to configure the subclock the user has to create a definition of a weakly linked function R_BSP_WarmStart(). In this function if the argument is "BSP_WARM_START_POST_C", the user can call the API cgc_api_t::clockStart clockStart to start the subclock.

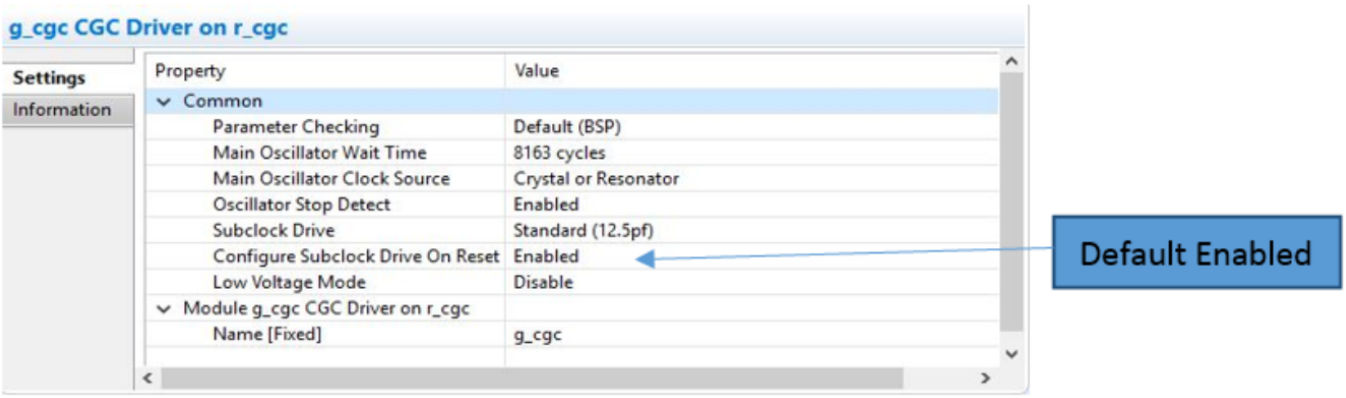

Figure 258: Configure Sub-Clock Drive on Reset

In the application code, create a callback function. In this example, it is called osc_stop_callback.

```
void osc_stop_callback(cgc_callback_args_t * p_args)
{
/* perform Oscillator Stop Detection processing */
}
```

Enable the oscillator stop detection by calling the API with the previously declared callback.

```
/* Enable the Osc Stop Detect functionality */
g_cgc.p_api->oscStopDetect( osc_stop_callback, true );
```

Enable the interrupt within the ICU

```
/* Osc Stop Detect is an NMI interrupt.  Enable the NMI in ICU */
R_ICU->NMIER_b.OSTEN = 1;
```

CGC HAL Module Limitations

Refer to the most recent SSP release notes for limitations on the use of this module.

4.2.9.4 Including the CGC HAL Module in an Application

This section describes how to include the CGC HAL module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

The CGC Driver is automatically added to the HAL/Common thread, so it only needs to be added to a new thread if it has been removed. (The default name for the CGC is g_cgc0. This name can be changed in the associated Properties window.)

CGC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_cgc CGC HAL on r_cgc	Threads	**New Stack> Driver> System> CGC Driver on r_cgc**

When the CGC Driver on r_cgc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are

individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

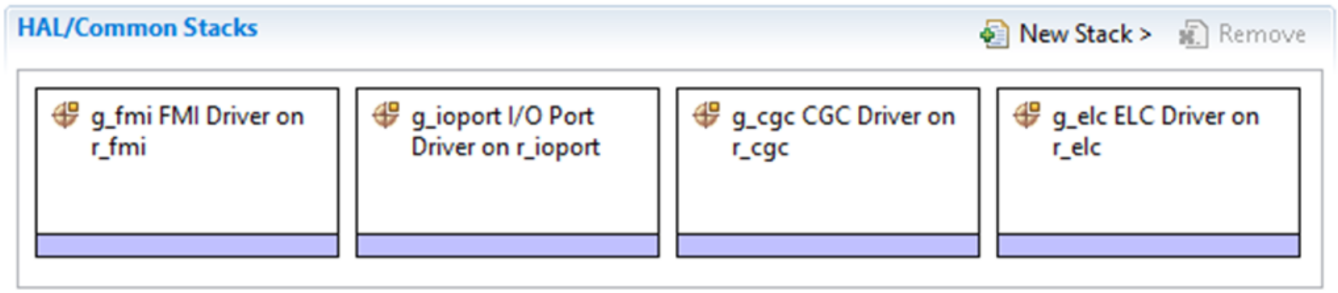

Figure 259: CGC HAL Module Stack

4.2.9.5 Configuring the CGC HAL Module

The CGC HAL module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the CGC HAL Module on r_cgc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Main Oscillator Wait Time	3,35,67,131,259,547,1059,2147,4291,8163 cycles Default: 8163 cycles	Set to 0 if a resonator, or crystal, is used. Set to 1 if an external oscillator input is used.

Main Oscillator Clock Source	External Oscillator, Crystal or Resonator Default: Crystal or Resonator	Set to one of these values. It should be at least as long as the main clock stabilization time. This delay will be configured only if #define CGC_CFG_MAIN_OSC_CLOCK_SOURCE is set to 0, indicating that a resonator/ crystal is used. Set the main clock oscillation stabilization time to longer than or equal to the stabilization time recommended by the oscillator manufacturer.
Oscillator Stop Detect	Enabled, Disabled Default: Enabled	This allows the R_CGC_OscStopDetect function code to be generated if enabled. The user must call this function with a callback pointer to use this feature.
Subclock Drive	Middle (4.4pf), Standard (12.5pf) Default: Standard (12.5pf)	This setting is for matching the subclock oscillator drive capacitance based on the crystal parameters #define CGC_CFG_SUBCLOCK_ DRIVE.
Low Voltage Mode	Enable, Disable Default: Disable	Low voltage mode selection.
Name	g_cgc	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for the CGC HAL module can be desirable. For example, it might be useful to selectively turn clocks on or off or change frequency to optimize power and performance characteristics.

Note

Most of the property settings for modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

CGC HAL Module Clock Configuration

The default CGC HAL module clock frequencies that will be set by the BSP initialization process are configurable in the ISDE by using the **Clocks** tab in the configurator. Invalid selections are indicated in red when selected.

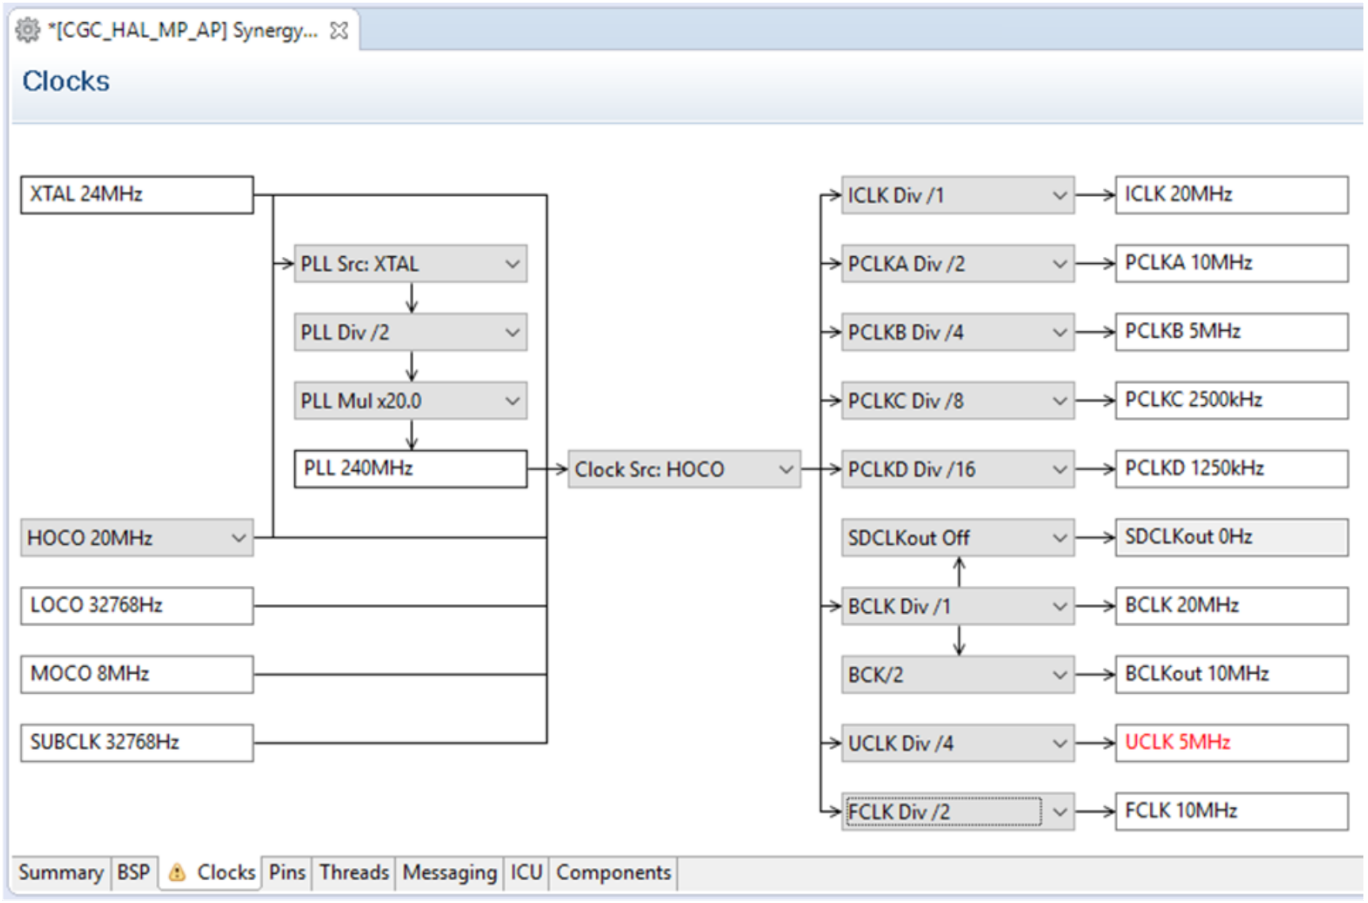

Figure 260: Default Clock Settings via the Clocks Tab

In this example, the Clock Source is HOCO, and various clock dividers are chosen for the peripheral clocks. If a valid USB Clock (UCLK) cannot be achieved, it is highlighted in RED. It should be noted that this is only advisory, and the project will still build, as such a clock frequency may be required.

CGC HAL Module Pin Configuration

The CGC peripheral module controls the output of BCLK and SDCLK signals. Use the **Clocks** tab to enable/disable this functionality. The BCLK_SDCLK I/O pin must be selected and configured as required via the **Pins** tab.

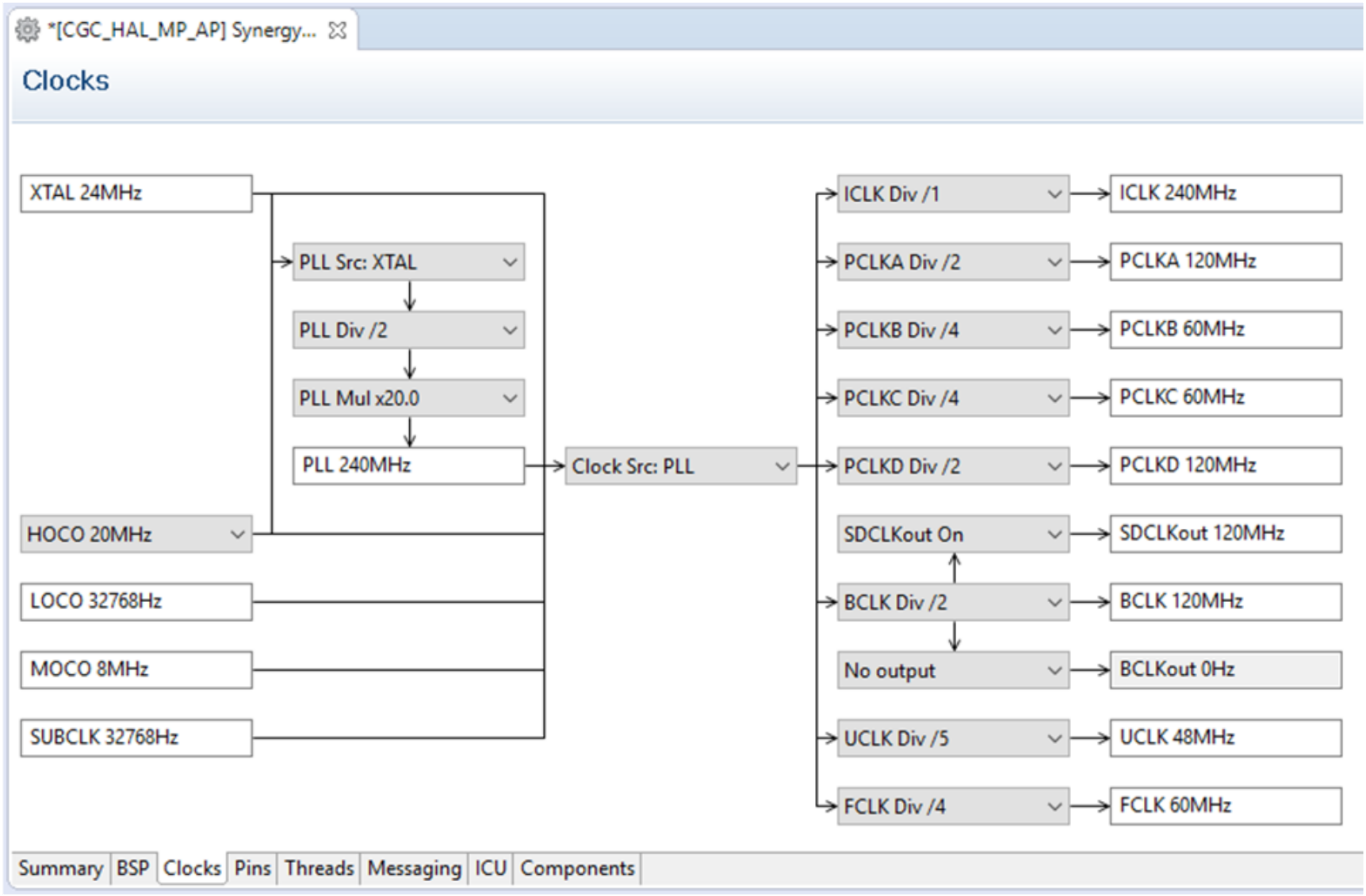

Figure 261: Enabling/Disabling SDCLK and BCLK via the Clock Tab

In this example, SDRAM Clock is enabled, BUS Clock is disabled.

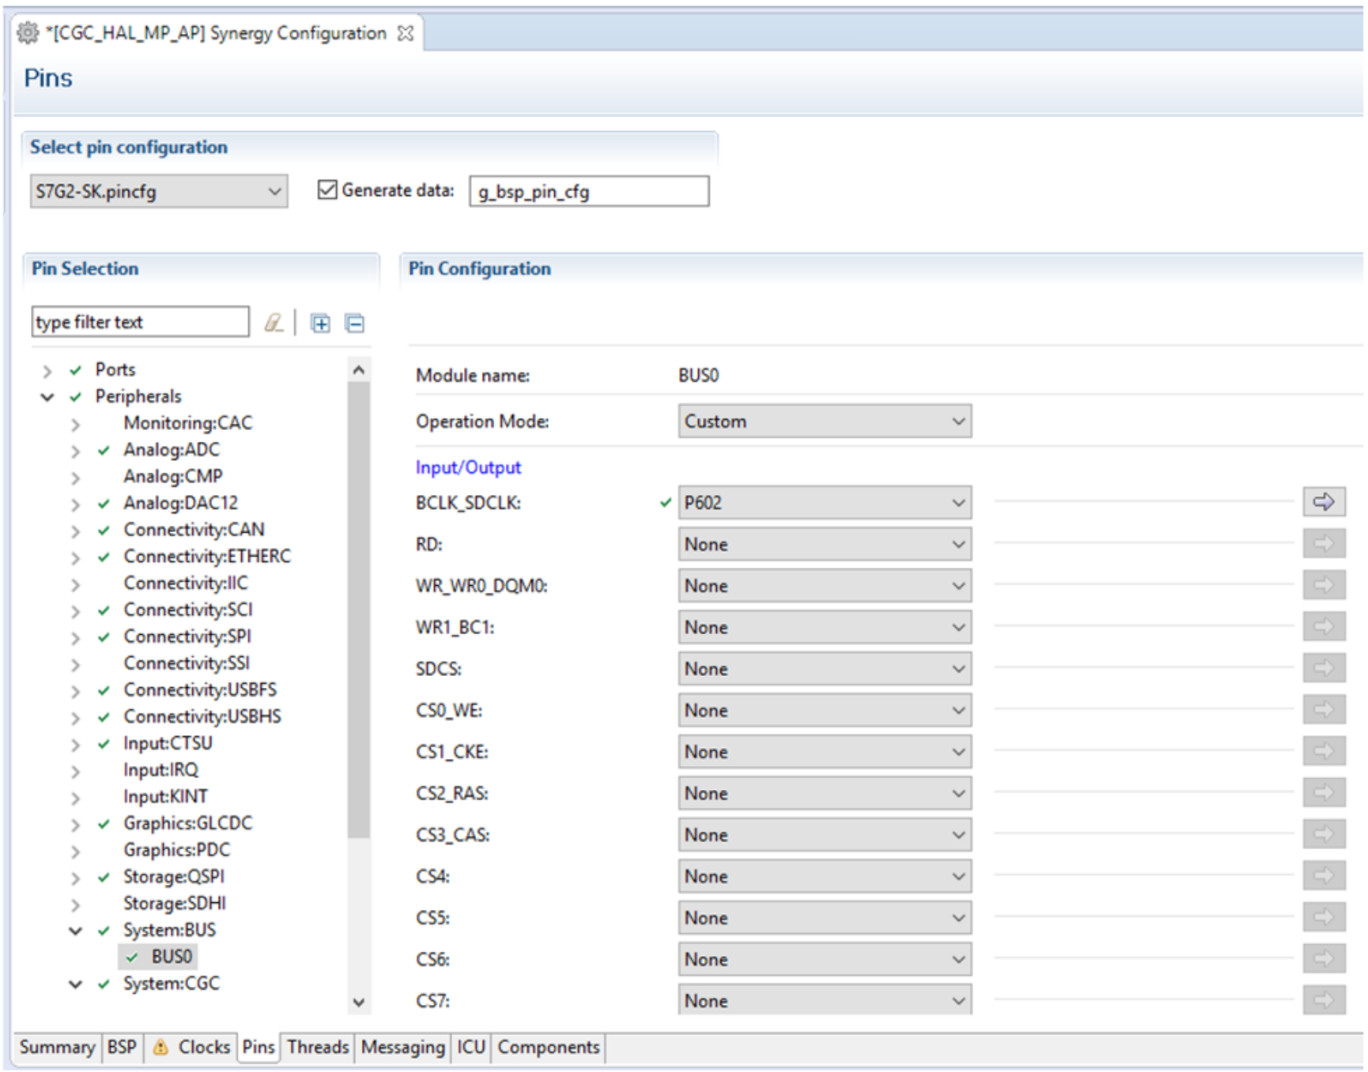

Figure 262: Enabling/Disabling SDCLK and BCLK via the Pins Tab

In this example, SDRAM Clock/BUS Clock is enabled on P602.

Additional pin settings associated with the CGC allow for the enabling/disabling of the external oscillator pins and the setting of the system Clock Out pin.

The Synergy devices can run from its on chip oscillators, in which case there is no requirement for the main clock external oscillator pins XTAL and EXTAL. These could be used as input pins by the application. The functionality of the sub clock external oscillator pins XCIN and XCOUT is fixed.

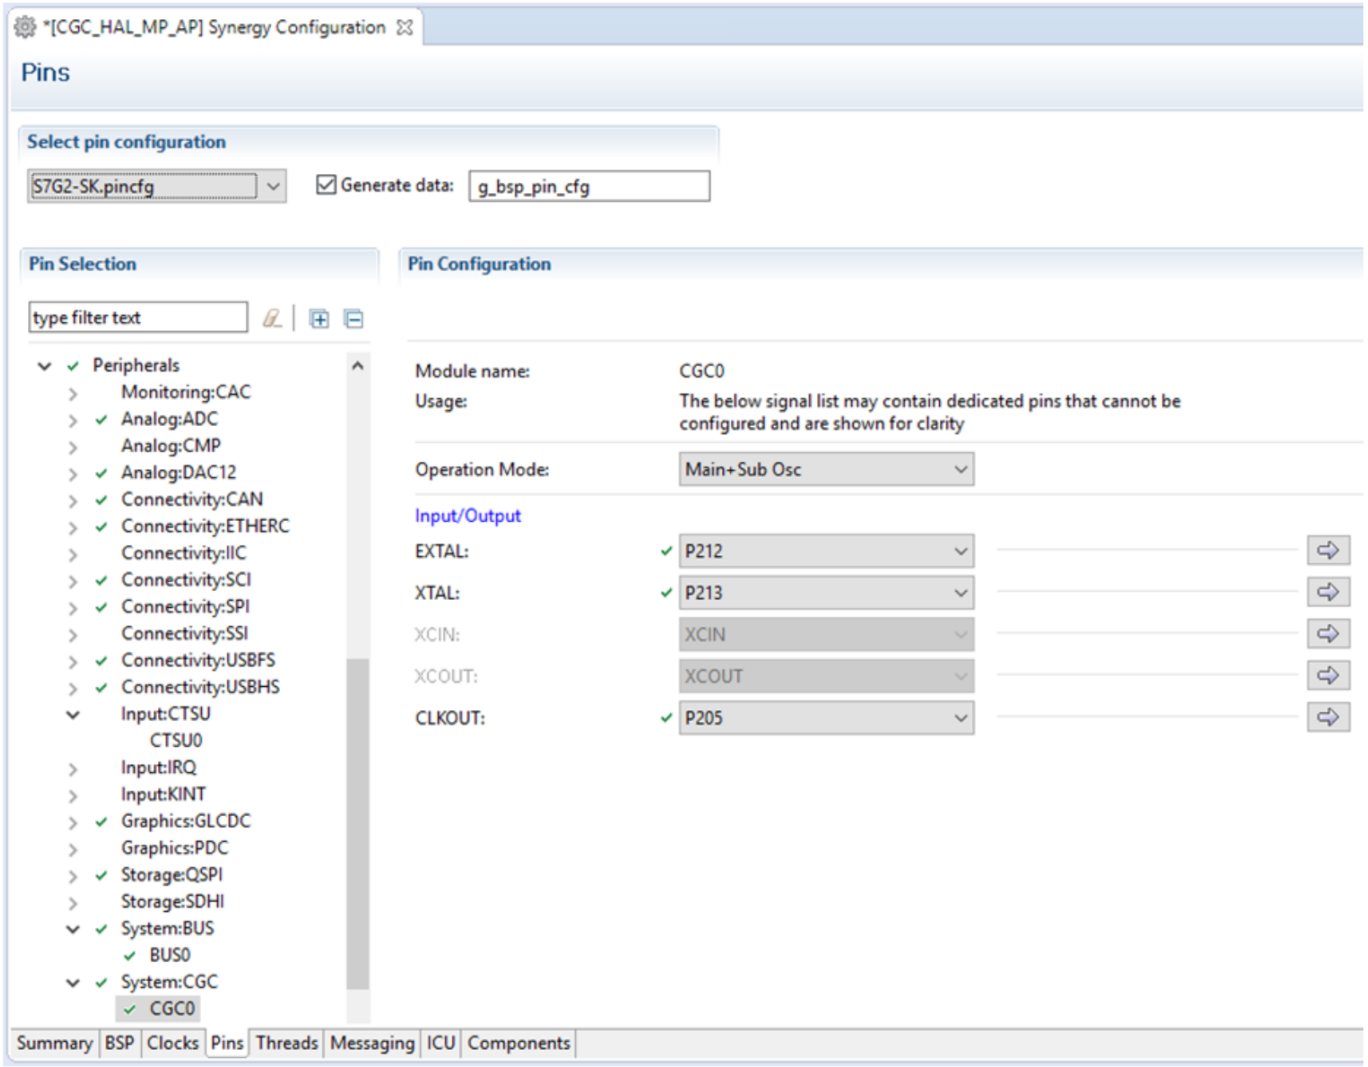

Figure 263: Enabling/Disabling EXTAL, XTAL and CLKOUT via the Pins Tab

In this example, an external Main Oscillator is used via pins P212 and P213 and the CLKOUT is enabled on P205.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and Synergy MCUs may have different available pin configuration settings.

4.2.9.6 Using the CGC Module in an Application

The typical steps in using the CGC HAL module in an application are:

1. The CGC is automatically set after the system reset.
2. Configure the clock as desired using the cgc_api_t::clocksCfg API.
3. Start clocks using the cgc_api_t::clockStart API if needed.
4. Stop clocks using the cgc_api_t::clockStop API if needed.
5. Other CGC functions as needed.

These common steps are illustrated in a typical operational flow diagram in the following figure:

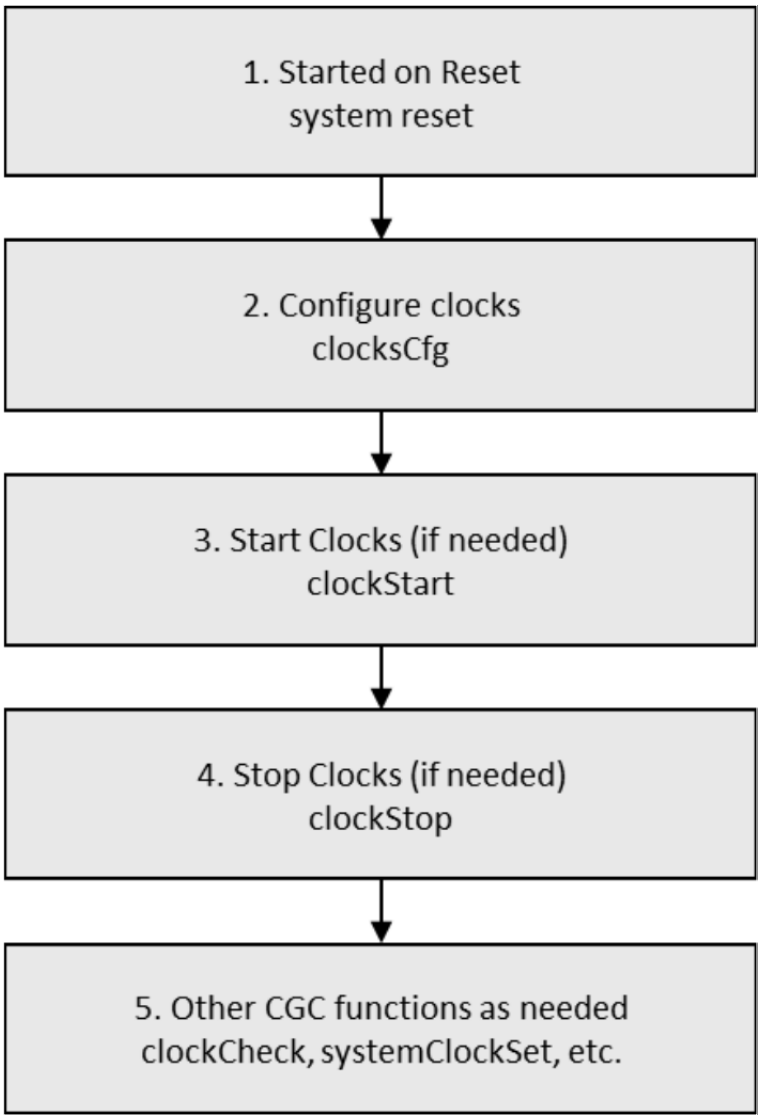

Figure 264: Flow Diagram of a Typical CGC HAL Module Application

4.2.10 CTSU v2 Driver

4.2.10.1 CTSU v2 HAL Module Introduction

The capacitive touch sensing unit version 2 HAL driver (r_ctsu v2) provides an API to control the CTSU peripheral. This module performs capacitance measurement based on various settings defined by the configuration. This module is configured via the QE for Capacitive Touch.

CTSU v2 HAL Module Features

- Supports both Self-capacitance multi scan mode and Mutual-capacitance full scan mode
- Scans may be started by software or an external trigger
- Returns measured capacitance data on scan completion

- Optional DTC support
- Built-in function that diagnoses its own circuit.

4.2.10.2 CTSU v2 HAL Module Configuration

Note

This module is configured via the QE for Capacitive Touch. For information on how to use the QE tool, once the tool is installed click Help -> Help Contents in e2 studio and search for "QE".

The following build time configurations are defined in ssp_cfg/r_ctsu_cfg.h:

Build Time Configurations for r_ctsu

Configuration	Options	Default	Description
Parameter Checking	- Default (BSP) - Enabled - Disabled	Default (BSP)	If selected code for parameter checking is included in the build.
Support for using DTC	- Enabled - Disabled	Disabled	Enable DTC support for the CTSU module.
Interrupt priority level	MCU Specific Options		Priority level of all CTSU interrupt (CSTU_WR,CTSU_RD,CTSU_FN)

This module can be added to the Stacks tab via New Stack > Driver > CapTouch > CTSU Driver on r_ctsu.

Configurations for Driver > CapTouch > CTSU Driver on r_ctsu

Configuration	Options	Default	Description
Scan Start Trigger	MCU Specific Options		CTSU Scan Start Trigger Select

CTSU v2 HAL Module Interrupt Configuration

The first R_CTSU_Open function call sets CTSU peripheral interrupts. The user should provide a callback function to be invoked at the end of the CTSU scan sequence. The callback argument will contain information about the scan status.

CTSU v2 HAL Module Clock Configuration

The CTSU peripheral module uses PCLKB as its clock source. You can set the PCLKB frequency using the **Clocks** tab of the RA Configuration editor or by using the CGC Interface at run-time.

Note

The CTSU Drive pulse will be calculated and set by the tooling depending on the selected transfer rate.

CTSU v2 HAL Module Pin Configuration

The TSn pins are sensor pins for the CTSU.

The TSCAP pin is used for an internal low-pass filter and must be connected to an external decoupling capacitor.

4.2.10.3 CTSU v2 HAL Module Usage Notes

CTSU v2 HAL Module Sensor ICO Correction

In order to improve the measurement accuracy, the correction coefficient is generated at the first R_CTSU_Open.

Therefore, the first R_CTSU_Open process takes about 40ms.

CTSU v2 HAL Module Initial Offset Tuning

CTSU v2 has a current offset mechanism to cancel the parasitic capacitance. This module automatically adjusts to be within the dynamic range of the Sensor ICO, taking into account the amount of current that changes with touch. This adjustment uses normal measurement process and requires several R_CTSU_ScanStart and R_CTSU_DataGet. R_CTSU_DataGet returns SSP_ERR_CTSU_INCOMPLETE_TUNING if it is being adjusted. The member "so" of ctsu_element_cfg_t is used as the starting point for adjustment, so if this value is appropriate, it can be completed quickly. Normally, this value uses the value adjusted by QE for Capacitive Touch.

CTSU v2 HAL Module Scan Trigger

Scanning of sensors may begin by either a software trigger or an external event initiated by the Event Link Controller (ELC). This trigger can be set with the member "cap" of ctsu_cfg_t. Typically, a software trigger is used. Common usage is to have a periodic timer initiate scans. For software triggers, a periodic timer such as the CMT is configured whose interval is large enough to allow for all sensors to be scanned and data to be updated. Software triggers are issued by calling R_CTSU_ScanStart. Using an external trigger is processed almost identically to using software triggers. Call R_CTSU_ScanStart before starting the timer to set the measurement and prepare for external trigger measurement. After that, when the timer is started, the measurement start trigger is applied.

CTSU v2 HAL Module Self-Capacitance Multi-Scan Mode

In self-capacitance mode each TS pin is assigned to one touch button. Electrodes of multiple TS pins can be physically aligned to create slider or wheel interfaces.

- Scan Order
  - The hardware scans the specified pins in ascending order.
  - For example, if pins TS05, TS08, TS02, TS03, and TS06 are specified in your application, the hardware will scan them in the order TS02, TS03, TS05, TS06, TS08.
- Element
  - -n element refers to the index of a pin within the scan order. Using the previous example, TS05 is element 2.
- Scan Time
  - Scanning is handled directly by the CTSU peripheral and does not utilize any main processor time.
  - It takes approximately 500us to scan a single sensor.
  - If DTC is not used additional overhead is required for the main processor to transfer data to/from registers when each sensor is scanned.

Set CTSU_MODE_SELF_MULTI_SCAN to "md" of ctsu_cfg_t. Also, add the number of terminals used for

this measurement to CTSU_CFG_NUM_SELF_ELEMENTS. For details, refer to the configuration and sample application output by QE for Capacitive Touch.

CTSU v2 HAL Module Mutual-Capacitance Full Scan Mode

In mutual-capacitance mode each TS pin acts as either a 'row' or 'column' in an array of sensors. As a result, this mode uses fewer pins when more than five sensors are configured. Mutual-capacitance mode is ideal for applications where many touch sensors are required, like keypads, button matrices and pads.

As an example, consider a standard phone keypad comprised of a matrix of four rows and three columns.

In mutual capacitance mode only 7 pins are necessary to scan 12 buttons. In self mode, 12 pins would be required.

- Scan Order
  - The hardware scans the matrix by iterating over the TX pins first and the RX pins second.
  - For example, if pins TS10, TS11, and TS03 are specified as RX sensors and pins TS02, TS07, and TS04 are specified as TX sensors, the hardware will scan them in the following sensor-pair order:
    TS03-TS02, TS03-TS04, TS03-TS07, TS10-TS02, TS10-TS04, TS10-TS07, TS11-TS02, TS11-TS04, TS11-TS07
- Element
  - An element refers to the index of a sensor-pair within the scan order. Using the previous example, TS10-TS07 is element 5.
- Scan Time
  - Because mutual-capacitance scans two patterns for one element it takes twice as long as self-capacitance (1ms vs 0.5ms per element).

Set CTSU_MODE_MUTUAL_FULL_SCAN to "md" of ctsu_cfg_t. Also, add the number of matrix used for this measurement to CTSU_CFG_NUM_MUTUAL_ELEMENTS. For details, refer to the configuration and sample application output by QE for Capacitive Touch.

CTSU v2 HAL Module Self Diagnosis

The CTSU peripheral has a built-in function that diagnoses its own inner circuit. The diagnostic requirements are providing 5 types of diagnosis. The diagnosis function is executed by calling the R_CTSU_Diagnosis() API function. This is executed independently from the other measurements and does not affect them.

Note

To enable the diagnosis function, set CTSU_CFG_DIAG_SUPPORT_ENABLE to 1.
A 27pF condenser should be connected externally.

4.2.10.4 CTSU v2 HAL Module Examples

CTSU v2 HAL Module Basic Example

This is a basic example of minimal use of the CTSU in an application.

```
volatile bool g_scan_flag = false;

void ctsu_callback (ctsu_callback_args_t * p_args)
```

```
{
  if (CTSU_EVENT_SCAN_COMPLETE == p_args->event)
  {
  g_scan_flag = true;
  }
}
void ctsu_basic_example (void)
{
  ssp_err_t err = SSP_SUCCESS;
  uint16_t data[CTSU_CFG_NUM_SELF_ELEMENTS];

  err = R_CTSU_Open(&g_ctsu_ctrl, &g_ctsu_cfg);

  /* Handle any errors. This function should be defined by the user. */
  handle_error(err);

  while (true)
  {
  err = R_CTSU_ScanStart(&g_ctsu_ctrl);
  handle_error(err);
  while (!g_scan_flag)
  {
  /* Wait for scan end callback */
  }
  g_scan_flag = false;
  err = R_CTSU_DataGet(&g_ctsu_ctrl, data);
  if (SSP_SUCCESS == err)
  {
  /* Application specific data processing. */
  }
  }
```

```
}
```

CTSU v2 HAL Module Multi-Configuration Example

This is a optional example of using both Self-capacitance and Mutual-capacitance configurations in the same project.

```
void ctsu_optional_example (void)
{
  ssp_err_t err = SSP_SUCCESS;
  uint16_t data[CTSU_CFG_NUM_SELF_ELEMENTS + (CTSU_CFG_NUM_MUTUAL_ELEMENTS * 2)];
  err = R_CTSU_Open(&g_ctsu_ctrl, &g_ctsu_cfg);
  handle_error(err);
  err = R_CTSU_Open(&g_ctsu_ctrl_mutual, &g_ctsu_cfg_mutual);
  handle_error(err);
  while (true)
  {
  R_CTSU_ScanStart(&g_ctsu_ctrl);
  while (!g_scan_flag)
  {
  /* Wait for scan end callback */
  }
  g_scan_flag = false;
  R_CTSU_ScanStart(&g_ctsu_ctrl_mutual);
  while (!g_scan_flag)
  {
  /* Wait for scan end callback */
  }
  g_scan_flag = false;
  err = R_CTSU_DataGet(&g_ctsu_ctrl, data);
  handle_error(err);
  if (SSP_SUCCESS == err)
  {
  /* Application specific data processing. */
  }
```

```
  err = R_CTSU_DataGet(&g_ctsu_ctrl_mutual, data);
  handle_error(err);
  if (SSP_SUCCESS == err)
  {
  /* Application specific data processing. */
  }
  }
}
```

CTSU v2 HAL Module Self Diagnosis Example

This is an example code of using self-diagnosis functionality.

```
ssp_err_t err;
uint16_t dummy;
/* Open the Diagnosis function */
R_CTSU_Open(g_qe_ctsu_instance_diagnosis.p_ctrl, g_qe_ctsu_instance_diagnosis.p_cfg);
/* Scan the Diagnosis function */
R_CTSU_ScanStart(g_qe_ctsu_instance_diagnosis.p_ctrl);
while (0 == g_qe_touch_flag) {}
g_qe_touch_flag = 0;
err = R_CTSU_DataGet(g_qe_ctsu_instance_diagnosis.p_ctrl,&dummy);
/* Call diagnosis function when the return value of R_CTSU_DataGet is SSP_SUCCESS. */
if (SSP_SUCCESS == err)
{
  err = R_CTSU_Diagnosis(g_qe_ctsu_instance_diagnosis.p_ctrl);
  if ( SSP_SUCCESS == err )
  {
   /* Diagnosis is done successfully */
  }
}
```

4.2.11 CRC Driver

4.2.11.1 CRC HAL Module Introduction

The CRC HAL module provides a high-level API to calculate 8, 16 and 32-bit CRC values on a block of data in memory or a stream of data over a Serial Communication Interface (SCI) channel using industry standard polynomials.

CRC HAL Module Features

- CRC HAL module can calculate CRC on a block of data in memory.
- CRC HAL module can calculate CRC on a stream of data being transmitted or received over a serial communication Interface (SCI) channel (snoop mode).
- CRC HAL module supports the following 8-and 16-bit CRC polynomials which operates on 8-bit data in parallel
  - $X^8 + X^2 + X + 1$ (CRC-8)
  - $X^{16} + X^{15} + X^2 + 1$ (CRC-16)
  - $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT)
- CRC HAL module supports the following 32 bit CRC polynomials which operates on 32-bit data in parallel
  - $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32)
  - $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C)
- CRC HAL module can calculate CRC with LSB first or MSB first bit order.

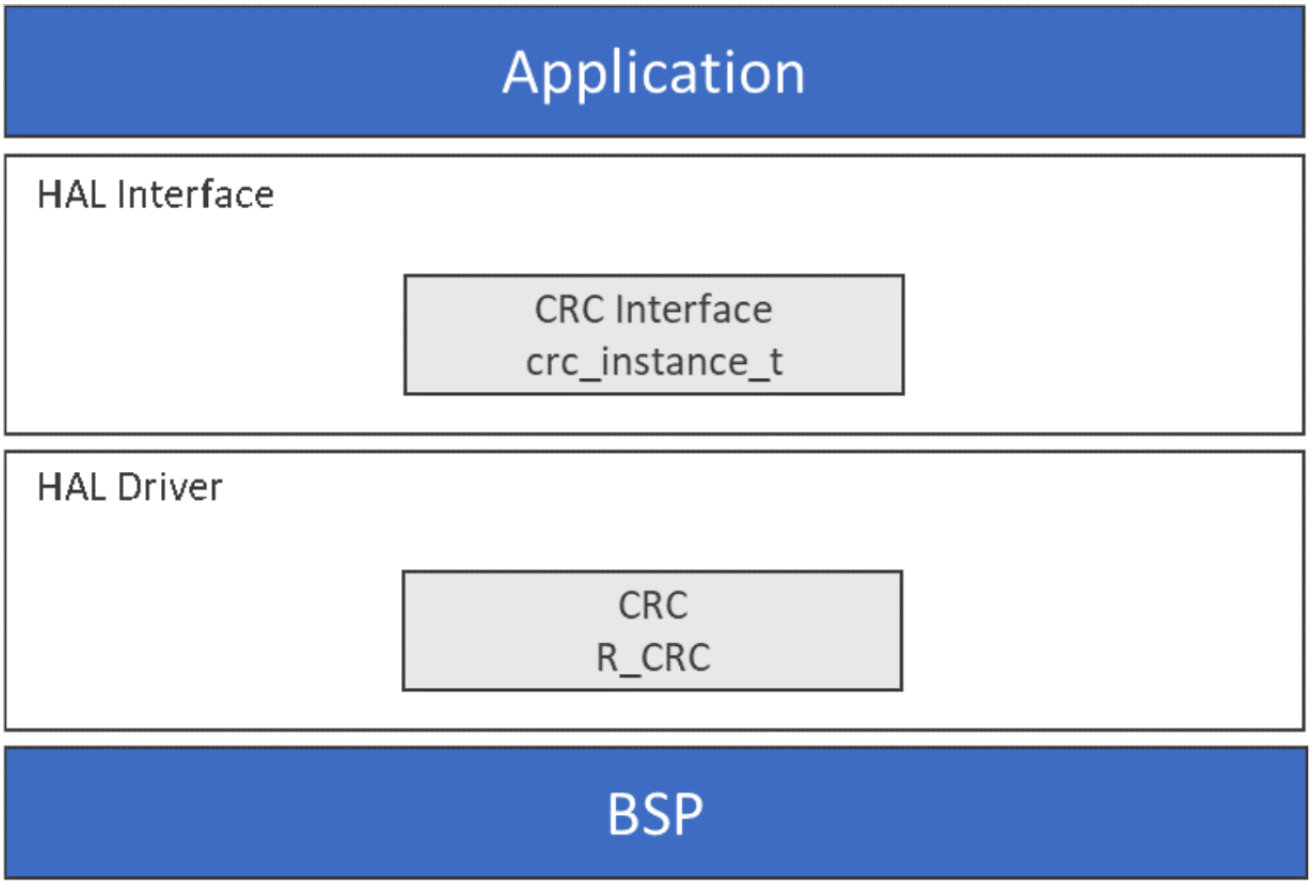

Figure 265: CRC HAL Module Block Diagram

CRC Hardware support details

The following hardware features are, or are not, supported by SSP for the CRC.

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

4.2.11.2 CRC HAL Module APIs Overview

The CRC HAL module defines APIs for opening, closing, enabling and calculating. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

CRC HAL Module API Summary

Function Name	Example API Call and Description
open	g_crc.p_api->open(g_crc.p_ctrl, g_crc.p_cfg); Open the CRC driver module.
close	g_crc.p_api->close(g_crc.p_ctrl); Close the CRC module driver.

crcResultGet	g_crc.p_api->crcResultGet(g_crc.p_ctrl, &result); Return the current calculated value.
snoopEnable	g_crc.p_api->snoopEnable(g_crc.p_ctrl, seed); Enable snooping.
snoopDisable	g_crc.p_api->snoopDisable(g_crc.p_ctrl); Disable snooping.
snoopCfg	g_crc.p_api->snoopCfg(g_crc.p_ctrl, g_crc.p_cfg); Configure the snoop channel and direction.
calculate	g_crc.p_api->calculate(g_crc.p_ctrl, &input_buffer, num_bytes, crc_seed, &crc_result); Perform a CRC calculation on a block of data.
versionGet	g_crc.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Configuration was successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_INVALID_ARGUMENT	Invalid argument error.
SSP_ERR_NOT_OPEN	The driver is not opened.
SSP_ERR_IN_USE	If driver is already open.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.11.3 CRC HAL Module Operational Overview

When the CRC HAL module is used to calculate the CRC value for a block of data in memory, the crc_api_t::calculate API can be used to take the input buffer pointer, length and the CRC seed value as input and outputs the calculated CRC value.

When the CRC HAL module is used to calculate the CRC on a stream of data being transmitted or received over a serial communication Interface (SCI) channel (snoop mode), then first the module should be configured to be in snoop mode by calling the crc_api_t::snoopCfg followed by the crc_api_t::snoopEnable APIs. After the requested number of data is transmitted or received on the SCI channel, the calculated CRC value can be polled from the module using crc_api_t::crcResultGet API.

CRC HAL Module Important Operational Notes and Limitations

CRC HAL Module Operational Notes

General CRC HAL Operational Notes

- The CRC block does not use any interrupts.
- There is no clock configuration for the CRC module.
- There are no callbacks for the CRC module.
- When using 32 bit CRC polynomials for calculating CRC values of data block in memory, the data block is interpreted using little-endian byte order.

CRC HAL Snoop Mode Operational Notes

- The CRC snoop function monitors reads from (receive) and writes to (transfer) a specified I/O register address.
- It performs a CRC calculation on the serial data read from (receive) and written to (transfer) the register address automatically.
- The CRC calculation is performed 1 byte at a time. When the target I/O register address is accessed in words (16 bits) or long words (32 bits), the CRC code is generated on the lower byte (1 byte) of data.
- The CRC snoop mode is useful in monitoring writes to the serial transmit buffer, and reads from the serial receive buffer. If the user is trying to write data through the SCI interface, then the data will be present in the TDR register of that particular channel. When the user enables the Snoop mode with the proper configuration then the CRC module will automatically calculate the CRC value for the data present in that TDR register and then stores the generated CRC value in the CRC Data output register.

CRC HAL Module Limitations

- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.11.4 Including the CRC HAL Module in an Application

This section describes how to include the CRC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the CRC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the CRC Driver is g_crc0. This name can be changed in the associated Properties window.)

CRC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
r_crc0 CRC Driver on r_crc	Threads	**New Stack**> **Driver**> **Monitoring**> **CRC Driver on r_crc**

When the CRC Driver on r_crc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional

configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

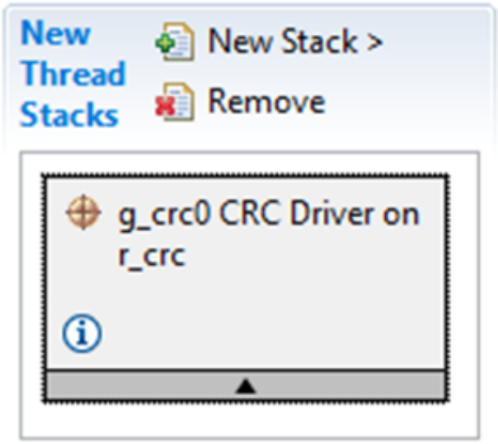

Figure 266: CRC HAL Module Stack

4.2.11.5 Configuring the CRC HAL Module

The CRC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the CRC HAL Module on r_crc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g-crc0	Module name.

CRC Polynomial	CRC-8, CRC-16, CRC-CCITT, CRC-32, CRC-32C Default: CRC-32C	Specify the polynomial to use for calculation.
Bit Order	LSB, MSB Default: MSB	Specify the bit order of the calculation.
FIFO Mode	Enable, Disable Default : Disable	Enable this property when using SCI_UART with FIFO mode during CRC snoop operation.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.
CRC snoop mode operation for SCI_UART with FIFO must be enabled when the SCI channel supports FIFO mode.

CRC HAL Module Clock Configuration

The CRC HAL module is clocked via the Peripheral Clock A (PCLKA.)

The CRC HAL module does not support any APIs for setting the frequency at which it operates.

CRC HAL Module Pin Configuration

The CRC HAL module does not have any configurable pins.

4.2.11.6 Using the CRC HAL Module in an Application

There are two main types of CRC implementations- normal mode and snoop mode. The typical steps for each mode are shown below.

The typical steps in using the CRC HAL module in an application are:

1. Initialize the CRC HAL module using the crc_api_t::open API.
2. Compute the CRC HAL module using the crc_api_t::calculate API.
3. Close the CRC HAL module using the crc_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

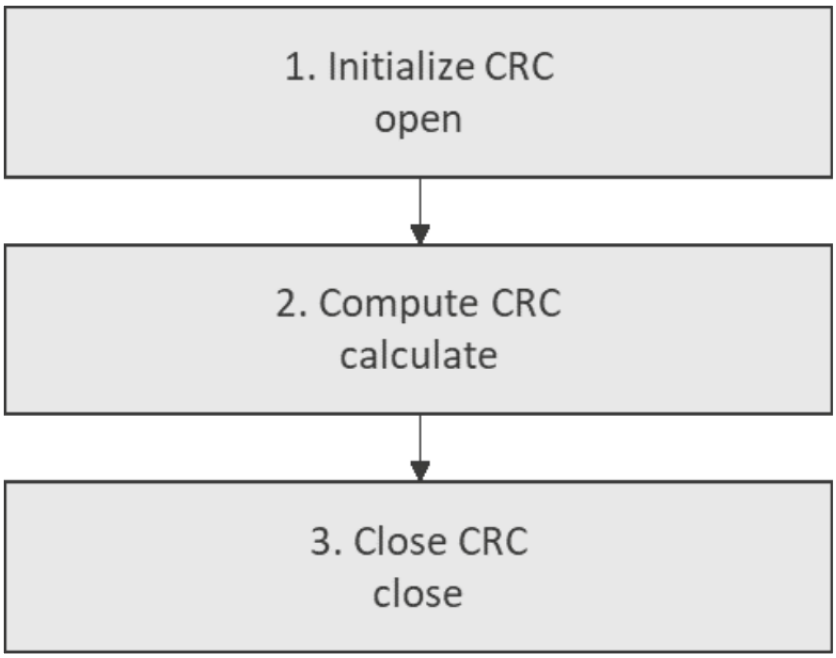

Figure 267: Flow Diagram of a Typical CRC HAL Module Application

The typical steps in using the CRC HAL module for computing in Snoop mode are:

1. Initialize the CRC HAL module using the crc_api_t::open API.
2. Snoop channel and snoop direction must be set manually by using snoop configuration structure crc_snoop_cfg_t.
3. Configure the CRC module to snoop an SCI channel (and its direction) using crc_api_t::snoopCfg API.
4. Enable snooping of the SCI channel using crc_api_t::snoopEnable API.
5. Once the required number of bytes are transmitted or received on the SCI channel, get the calculated CRC value using crc_api_t::crcResultGet API.
6. Disable the snooping operation using crc_api_t::snoopDisable API.
7. Close the CRC HAL module using the crc_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

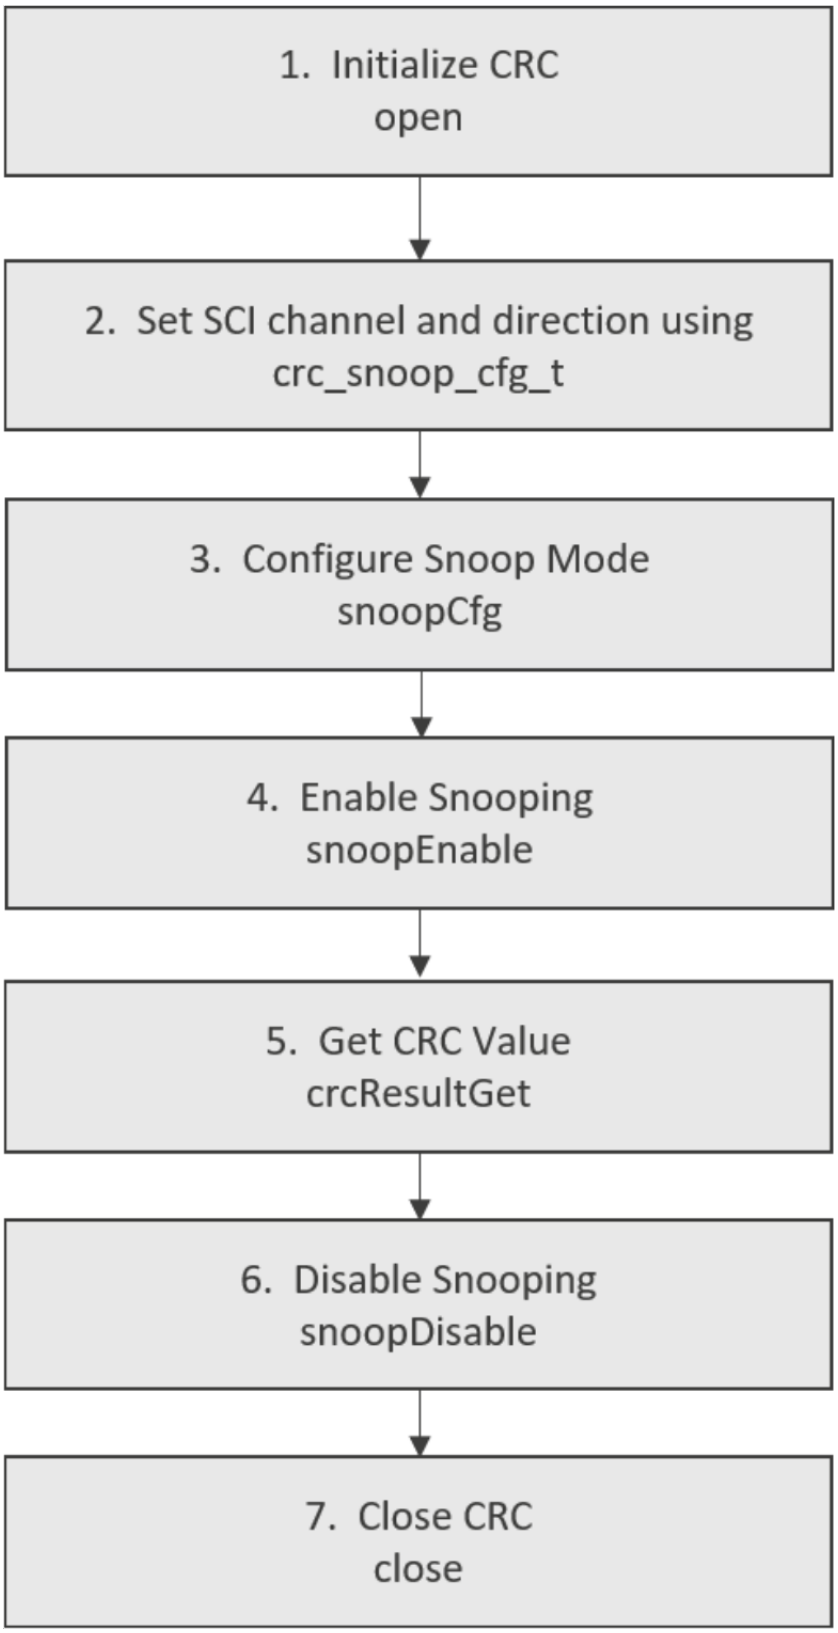

Figure 268: Flow Diagram of a Typical CRC HAL Module Application

4.2.12 DAC Driver

4.2.12.1 DAC HAL Module Introduction

The DAC HAL module provides a high-level API for digital-to-analog conversion applications and supports a dual-channel 12-bit D/A converter (DAC12) peripheral on Synergy MCUs.

DAC HAL Module Features

This module configures the dual-channel 12-bit D/A Converter (DAC12) to output one of 4096 voltage levels between the positive and negative reference voltages. The module includes configuration settings to:

- Set either a left-justified or right-justified 12-bit value format for the 16-bit input data registers
- Enable or disable output amplifiers
- Enable or disable charge pump
- Operate in synchronous anti-interference mode with the Analog-to-Digital Converter (ADC) module.

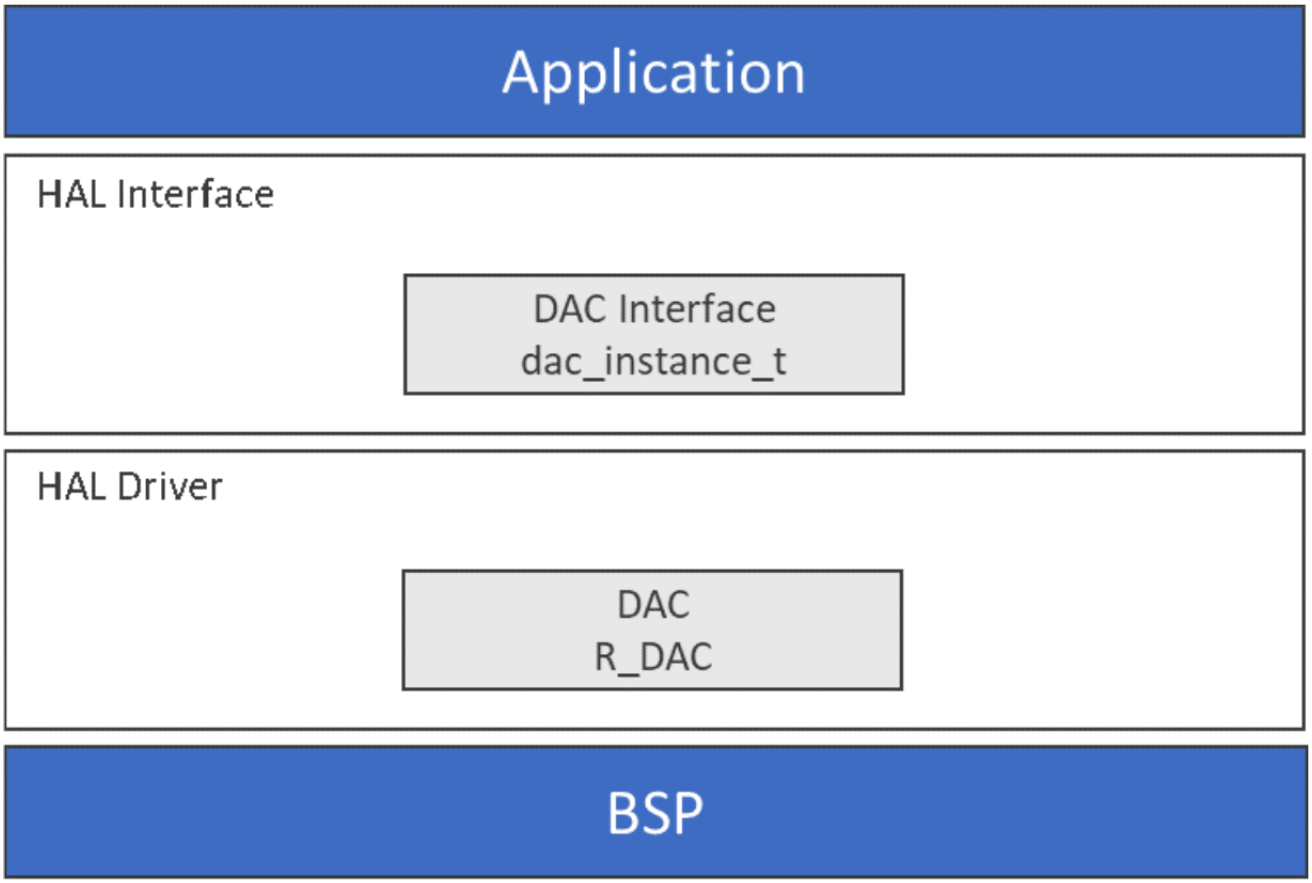

Figure 269: DAC HAL Module Block Diagram

DAC Hardware support details

The following hardware features are, or are not, supported by SSP for the DAC.

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

S7G2	✓	✓	✓	☒

- Note: The ELC event could be used instead of calling the DAC start() interface. This would have to be programmed by the user by setting up the link rather than using the ELC API.

4.2.12.2 DAC HAL Module APIs Overview

The DAC HAL module defines APIs to open, close, start, stop and write to the DAC. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

DAC HAL Module API Summary

Function Name	Example API Call and Description
open	g_dac.p_api->open(g_dac.p_ctrl, g_dac.p_cfg) Initial Configuration.
close	g_dac.p_api->close(g_dac.p_ctrl) Close the D/A Converter.
write	g_dac.p_api->write(g_dac.p_ctrl, val) Write Sample value to the D/A Converter.
start	g_dac.p_api->start(g_dac.p_ctrl) Start the D/A Converter if it has not been started yet.

stop	g_dac.p_api->stop(g_dac.p_ctrl) Stop the D/A Converter if the converter is running.
versionGet	g_dac.p_api->versionGet(&version) Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	Wrong parameter.
SSP_ERR_IN_USE	DAC resource is locked.
SSP_ERR_NOT_OPEN	The peripheral is not opened.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.12.3 DAC HAL Module Operational Overview

The DAC HAL module configures the dual-channel 12-bit D/A converter (DAC12) to output one of 4096 voltage levels between positive and negative reference voltages. The module can be used to configure the 12-bit output to left-or-right-justified format for 16-bit input data registers. The DAC HAL module can also enable or disable output amplifiers, or operate in synchronous anti-interference mode with the ADC HAL module.

DAC HAL Module Important Operational Notes and Limitations

DAC HAL Module Operational Notes

The DAC HAL module requires the following initialization steps:

- DAC module stop-bit cleared to zero.
- DAC channel output-enable set to one.

The DAC module stop-bit is cleared to zero at the time of an open call when the driver's instance counter is zero. The driver's instance counter is initialized to zero, incremented when a channel open returns successfully, and decremented when a channel close is called. The DAC module stop-bit is set to one when the driver's instance counter is decremented to zero on a close call.

The DAC channel output-enable is set to one when a channel write is called the first time after open was called successfully. The open call writes a zero to the dac_ctrl_t structure element channel_started. When write is called with channel_started cleared to zero, the DAC output-enable bit for that channel is set to one. The DAC output-enable for the channel is cleared to zero on close

and stop calls.

DAC HAL Module Limitations

- Pin configuration is not implemented for the DAC HAL module. Currently, DA0 and DA1 outputs are enabled by the reset values in the pin configuration control register's ASEL field.
- Voltage reference selection for the DAC HAL module is not implemented. Currently, no reference is selected by the reset values in the D/A VREF control register (DAVREFCR) which is a valid condition.
- Configuration of DAC input-event triggering for conversion is not currently implemented. The default reset value (zero) of the control register DAE bit allows individual triggering for each channel.
- Event signal input for synchronization of the DAC HAL module conversions is not currently implemented.
- The charge pump feature shall be disabled when DAC12 configured as ACMPHS or OPAMP input.
- Refer to the latest SSP Release Notes for operational limitations related to this module.

4.2.12.4 Including the DAC HAL Module in an Application

This section describes how to include the DAC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the DAC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the DAC Driver is g_dac0. This name can be changed in the associated Properties window.)

DAC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_dac0 DAC Driver on r_dac	Threads	**New Stack> Driver> Analog> DAC Driver on r_dac**

When the DAC Driver on r_dac is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

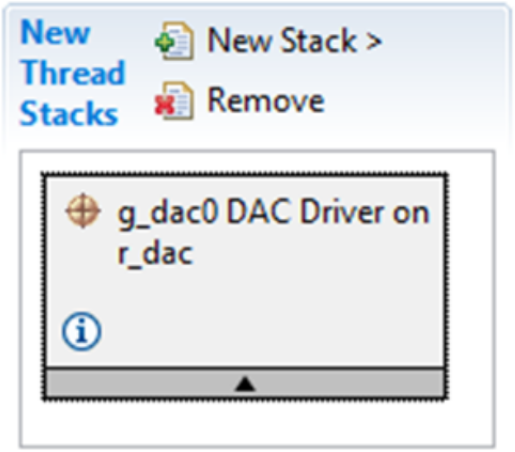

Figure 270: DAC HAL Module Stack

4.2.12.5 Configuring the DAC HAL Module

The DAC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the DAC HAL Module on r_dac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_dac0	Module name.
Channel	0	Set to 0 for output DA0 or 1 for output DA1.

Synchronize with ADC	Enabled, Disabled Default: Disabled	Set to true for anti-interference synchronization with the Analog-to-Digital Converter (ADC) Module. Set to false false if power supply interference between the analog modules is not a problem, or if asynchronous conversion by the DAC Module is desired.
Data Format	Right Justified, Left Justified Default: Right Justified	Set to zero, if 12-bit data values are loaded in bits 11 through 0, or right justified. Set to one, if 12-bit data values are loaded in bits 15 through 4, or left justified.
Output Amplifier	Enable, Disable Default: Disable	Set to true, if output amplifier hardware function is desired. Set to false to bypass output amplifier hardware function.
Charge Pump Enabled (Requires MOCO active)	Enable, Disable Default: Disable	Set to true, if charge pump hardware function is desired. Set to false to bypass charge pump hardware function.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

DAC HAL Module Clock Configuration

The DAC HAL module does not require any specific clock configuration.

DAC HAL Module Pin Configuration

To use the DAC HAL module, the port pins for the channels receiving the analog input must be set as analog pins in the pin configurator. The following table lists a method to select pins within the SSP configuration window and the subsequent table illustrates configuration settings for DAC pins:

Pin Selection for the DAC HAL Module on r_dac

Resource	ISDE Tab	Pin selection Sequence
DAC	Pins	Select **Peripherals**> **Analog: DAC12**> **DAC120.**

Pin Configuration Settings for the DAC HAL Module on r_dac

Property	Value	Description
Module Name	DAC120	DAC Peripheral Module.

Operation Mode	Enabled, Disabled Default: Enabled	DAC Peripheral operation mode.
DA0	None, DA0 Default: None	DAC Output Pin.
DA1	None, DA1 Default: None	DAC Output Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.2.12.6 Using the DAC HAL Module in an Application

The typical steps in using the DAC HAL module in an application are:

1. Initialize the DAC HAL module using the dac_api_t::open API.
2. Write a data value using the dac_api_t::write API.
3. Start writing data using the dac_api_t::start API.
4. Continue writing data values as needed using the dac_api_t::write API.
5. Stop writing data using the dac_api_t::stop API.
6. Close the DAC HAL module using the dac_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

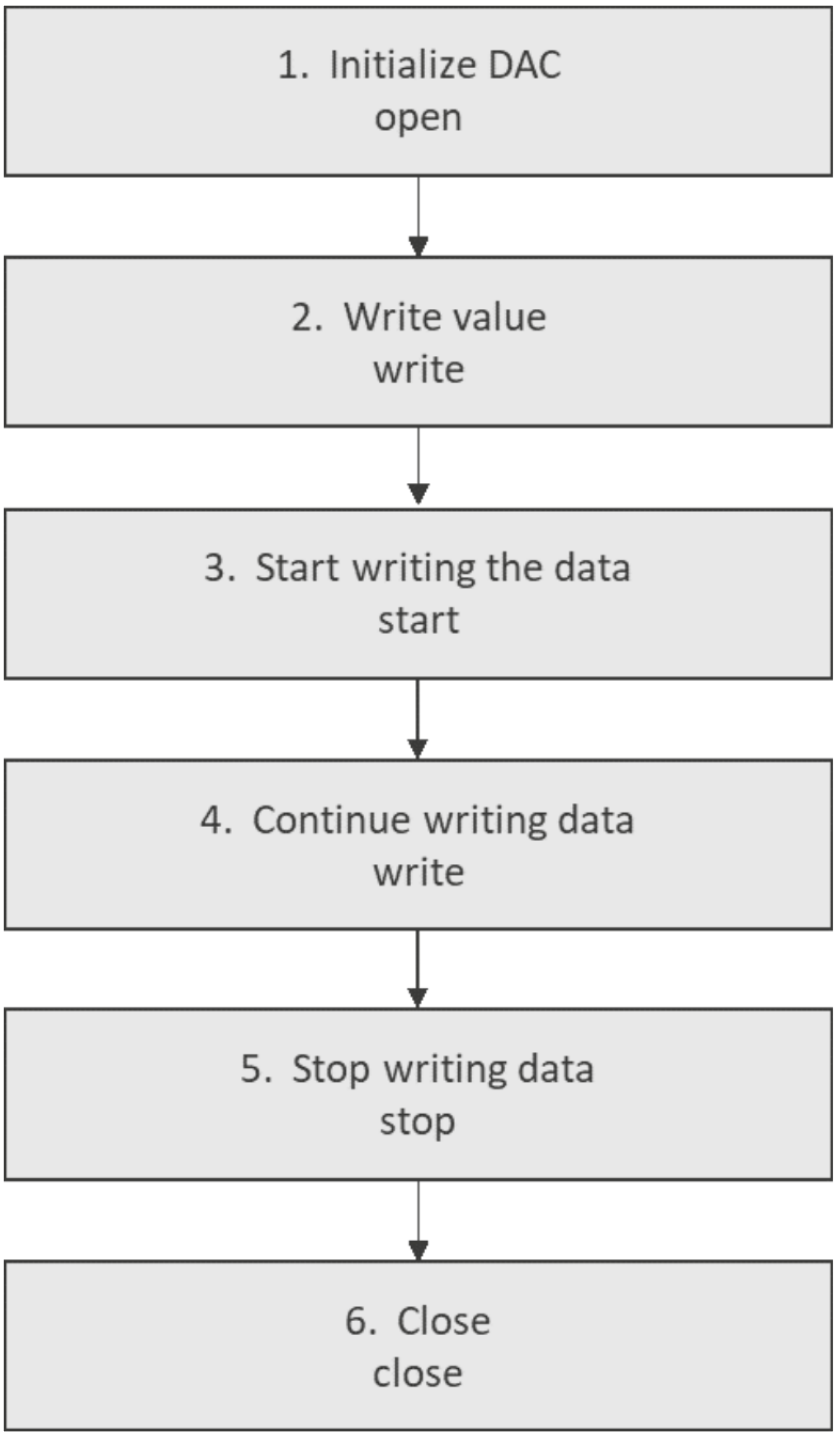

Figure 271: Flow Diagram of a Typical DAC HAL Module Application

4.2.13 DAC8 Driver

4.2.13.1 DAC8 HAL Module Introduction

The DAC8 HAL module provides a high-level API for digital-to-analog conversion applications and supports an 8-bit D/A converter (DAC8) peripheral on Synergy MCUs.

DAC8 HAL Module Features

- 8-Bit D/A Converter
- Left-Justified or Right-Justified Input Data Format
- Synchronization with the Analog-to-Digital Converter (ADC) module
- Multiple Operation Modes
    - Normal
    - Real-Time (Event Link)
    - Charge Pump Control

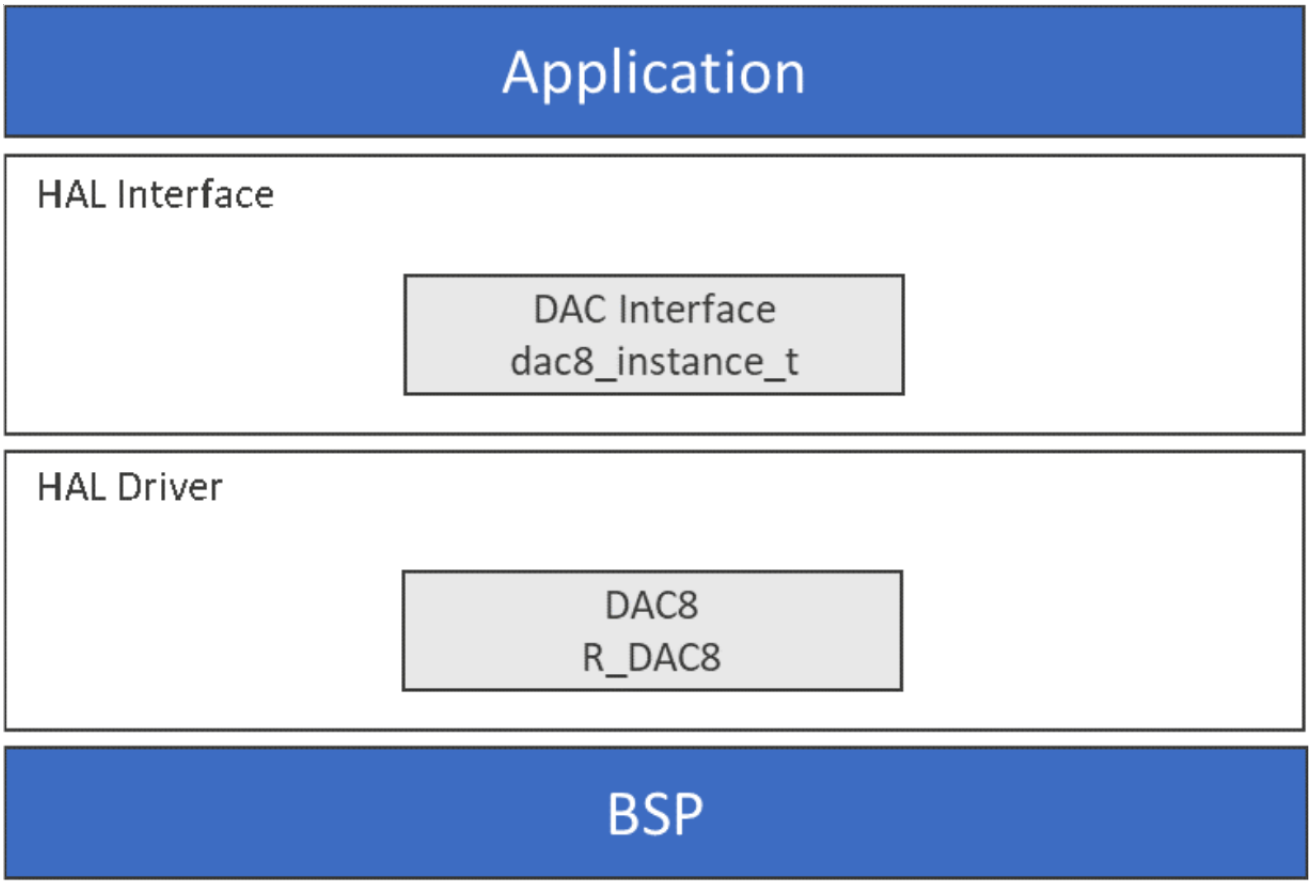

Figure 272: DAC8 HAL Module Block Diagram

DAC8 Hardware support details

The following hardware features are, or are not, supported by SSP for the DAC8.

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)

N/A			Not supported by MCU		
MCU Group	8-Bit	2 Channels Output	3-Channel Output	Module-Stop Function	Event link function through ELC HAL driver *
S124	N/A	N/A	N/A	N/A	N/A
S128	✓	✓	✓	✓	✓
S1JA	✓	✓	N/A	✓	✓
S3A1	☒	☒	N/A	☒	☒

S3A6	☒	☒	N/A	☒	☒
S3A7	N/A	N/A	N/A	N/A	N/A
S5D3	N/A	N/A	N/A	N/A	N/A
S5D5	N/A	N/A	N/A	N/A	N/A
S5D9	N/A	N/A	N/A	N/A	N/A
S7G2	N/A	N/A	N/A	N/A	N/A

- Note: The ELC event could be used instead of calling the DAC start() interface. This would have to be programmed by the user by setting up the link rather than using the ELC API.

4.2.13.2 DAC8 HAL Module APIs Overview

The DAC8 HAL module defines APIs for opening, closing, starting, stopping and writing to the DAC. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

DAC8 HAL Module API Summary

Function Name	Example API Call and Description
open	g_dac8.p_api->open(g_dac8.p_ctrl, g_dac8.p_cfg Initial Configuration.
close	g_dac8.p_api->close(g_dac8.p_ctrl) Close the D/A Converter.
write	g_dac8.p_api->write(g_dac8.p_ctrl, val) Write Sample value to the D/A Converter.
start	g_dac8.p_api->start(g_dac8.p_ctrl) Start the D/A Converter if it has not been started yet.
stop	g_dac8.p_api->stop(g_dac8.p_ctrl) Stop the D/A Converter if the converter is running.

versionGet	g_dac8.p_api->versionGet(&version) Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_HW_LOCKED	DAC resource is locked.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	Wrong parameter.
SSP_ERR_IP_CHANNEL_NOT_PRESENT	Wrong channel selected.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.13.3 DAC8 HAL Module Operational Overview

The DAC8 HAL module configures the 8-bit D/A converter (DAC8) to output one of 256 voltage levels between positive and negative reference voltages. The driver can be configured to accept the 8-bit output data in left-or-right-justified format in a 16-bit input data. The driver supports two modes for the DAC.

- Normal mode – The D/A output is updated on writes to the data register.
- Real-Time (Event Link) – The D/A output is updated on an Event Link event. While in this mode the data register can be written at any time. An Event Link event triggers the start of conversion. Refer to the "ELC Interface" in the SSP User's Manual for more information.

To reduce the noise present in ADC readings the driver can configure synchronous anti-interference mode with the ADC module. This reduces conversion noise by disabling the DAC charge while the ADC is sampling. Check the hardware manual to determine if this feature is supported.

For operation at low AVCC voltage the driver can enable or disable the hardware charge pump.

Real-Time Mode

In real-time mode the output voltage is only changed on a signal from the ELC peripheral. Note when using real time mode the first call to dac_api_t::write() will set the initial output voltage.

As an illustration, the following code shows how to link the DAC8 output on channel 0 to the ELC software event and trigger the output to change.

```
/* Open DAC8 driver.  */
g_dac8_0.p_api->open(g_dac8_0.p_ctrl, &g_dac8_0.p_cfg);
```

```
/* Link DAC8 output 0 to software event 0.
   In a real application, this feature would be used to link DAC8 output
   to a hardware event. A software event is used here for simplicity. */
g_elc_on_elc.linkSet(ELC_PERIPHERAL_DA80, ELC_EVENT_ELC_SOFTWARE_EVENT_0);
/* Set initial output voltage, the output is immediately updated
   because this is the first write since open. */
g_dac8_0.p_api->write(g_dac8_0.p_ctrl, initial_dac_value);
while (true) {
/* Set the next output value, the output voltage is not updated until
       an ELC event occurs. */
g_dac8_0.p_api->write(g_dac8_0.p_ctrl, next_dac_value);
/* Generate software ELC event to update DAC output. */
g_elc_on_elc.softwareEventGenerate(ELC_SOFTWARE_EVENT_0);
R_BSP_SoftwareDelay(10, BSP_DELAY_UNITS_MILLISECONDS);
}
```

DAC8 HAL Module Important Operational Notes and Limitations

DAC8 HAL Module Operational Notes

- The DAC8 channel output is enabled during dac_api_t::start() and dac_api_t::write() and disabled during dac_api_t::stop() and dac_api_t::close().

DAC8 HAL Module Limitations

- The DAC8 driver does not configure the ELC peripheral for real-time mode. The user will need to configure the Event Link Controller in addition to enabling real-time mode in the DAC8 module.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.13.4 Including the DAC8 HAL Module in an Application

This section describes how to include the DAC8 HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the DAC8 Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the DAC8 Driver is g_dac8_0. This name can be changed in the associated Properties window.)

DAC8 HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_dac8_0 DAC Driver on r_dac8	Threads	**New Stack> Driver> Analog> DAC Driver on r_dac8**

When the DAC8 Driver on r_dac8 is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

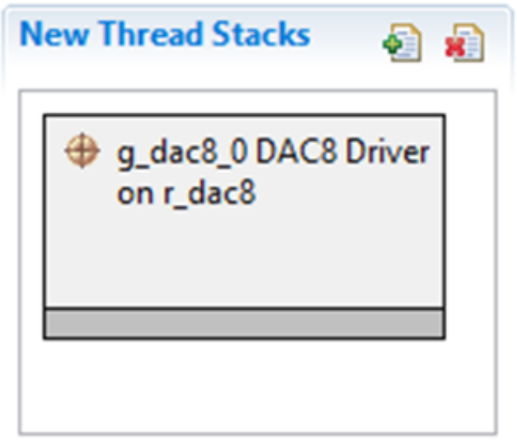

Figure 273: DAC8 HAL Module Stack

4.2.13.5 Configuring the DAC8 HAL Module

The DAC8 HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the DAC8 HAL Module on r_dac8

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_dac8_0	Module name.
Channel	0	Channel selection.
Synchronize with ADC	Enabled, Disabled Default: Disabled	Choose whether to sync with the ADC module.
Data Format	Right Justified, Left Justified Default: Right Justified	Data format selection.
DAC Mode	Normal Mode, Real-time (Event Link) Mode Default: Normal Mode	DAC mode selection.
Charge Pump Enabled (Requires MOCO active)	Enabled, Disabled Default: Enabled	Enable or disable the charge pump.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

DAC8 HAL Module Clock Configuration

The DAC8 HAL module does not require a specific clock configuration.

DAC8 HAL Module Pin Configuration

To use the DAC8 HAL module, the port pins for the channels receiving the analog input must be set as analog pins in the pin configurator. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the DAC pins:

Pin Selection for the DAC8 HAL Module on r_dac8

Resource	ISDE Tab	Pin selection Sequence
DAC8	Pins	Select **Peripherals**> **Analog:DAC8**> **DAC80.**

Note

The selection sequence assumes DAC80 is the desired hardware target for the driver.

Pin Configuration Settings for the DAC8 HAL Module on r_dac8

Property	Value	Description
Module Name	DAC80	DAC Peripheral Module.

Operation Mode	Enabled, Disabled Default: Enabled	DAC Peripheral operation mode.
DA0	None, DA0 Default: None	DAC Output Pin.
DA1	None, DA1 Default: None	DAC Output Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.2.13.6 Using the DAC8 HAL Module in an Application

The typical steps in using the DAC8 HAL module in an application are:

1. Initialize the DAC8 HAL module using the dac_api_t::open API.
2. Write a value using the dac_api_t::write API.
3. Start a conversion using the dac_api_t::start API.
4. Continue writing values as needed using the dac_api_t::write API.
5. Stop conversion using the dac_api_t::stop API.
6. Use the dac_api_t::close call to power down the peripheral.

These common steps are illustrated in a typical operational flow diagram in the following figure:

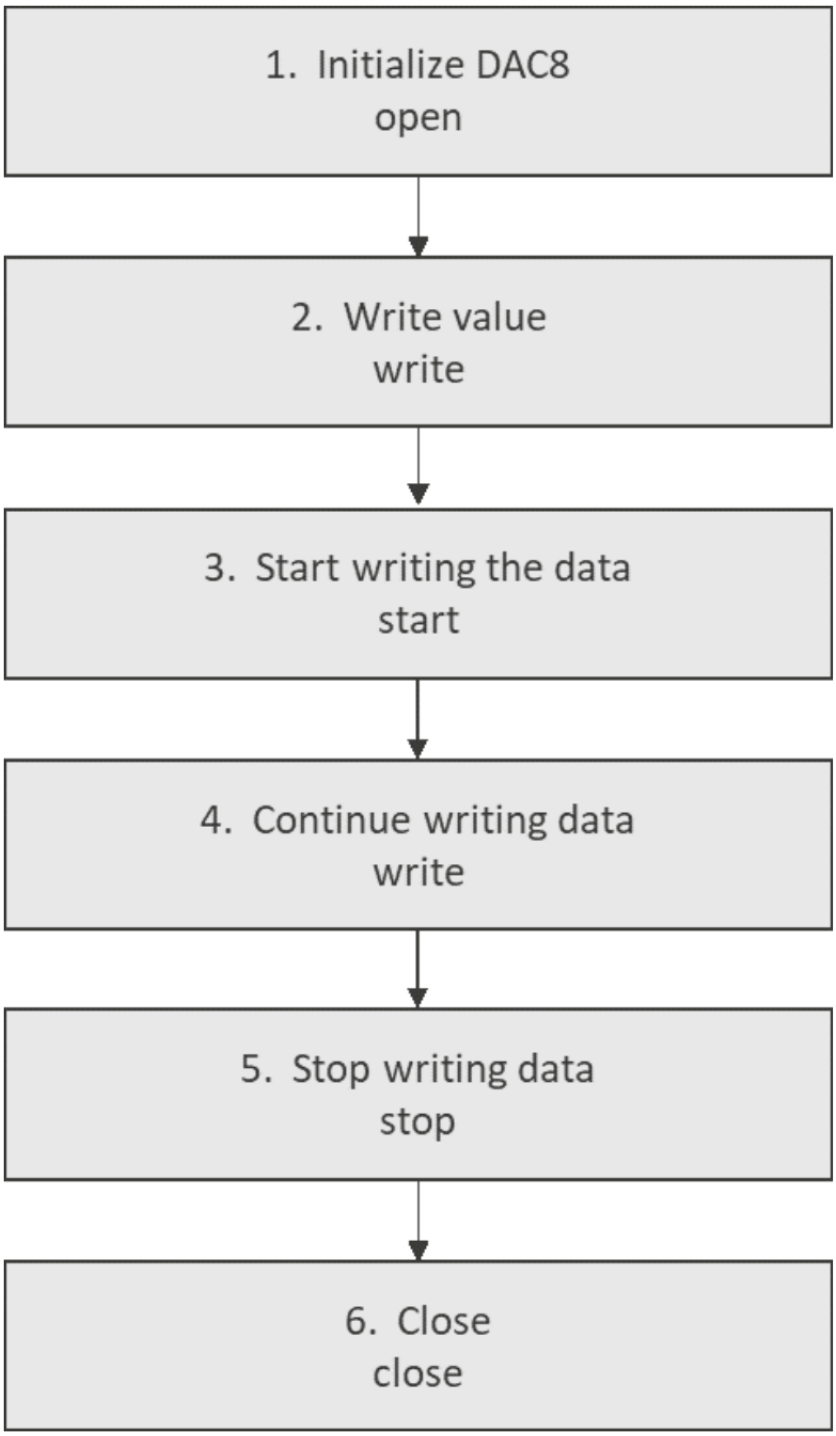

Figure 274: Flow Diagram of a Typical DAC8 HAL Module Application

4.2.14 Display Driver

4.2.14.1 GLCDC HAL Module Introduction

The Graphics LCD Controller (GLCDC) HAL module provides a high-level API for graphics display applications and uses the Graphics LCD Driver peripheral on the Synergy MCU. A user-defined callback can be created to handle frame buffer switching and underflow detection.

GLCDC HAL Module Features

The GLCDC HAL supports the following features:

- Supports LCD panels with RGB interface (up to 24 bits) and sync signals (HSYNC, VSYNC, and Data Enable (optional))
- Supports various color formats for input graphics planes (RGB888, ARGB888, RGB565, ARGB1555, ARGB4444, CLUT8, CLUT4, CLUT1)
- Supports the Color Look-Up Table (CLUT) usage for input graphics planes with 512 words (32 bits/word)
- Supports various color formats for output (RGB888, RGB666, RGB565, Serial RGB)
- Can input two graphics planes on top of the background plane and blend them on the screen
- Generates a dot clock to the panel. The clock source is selectable from internal or external (LCD_EXTCLK)
- Supports brightness adjustment, contrast adjustment, and gamma correction
- Supports GLCDC interrupts to handle frame buffer switching or underflow detection

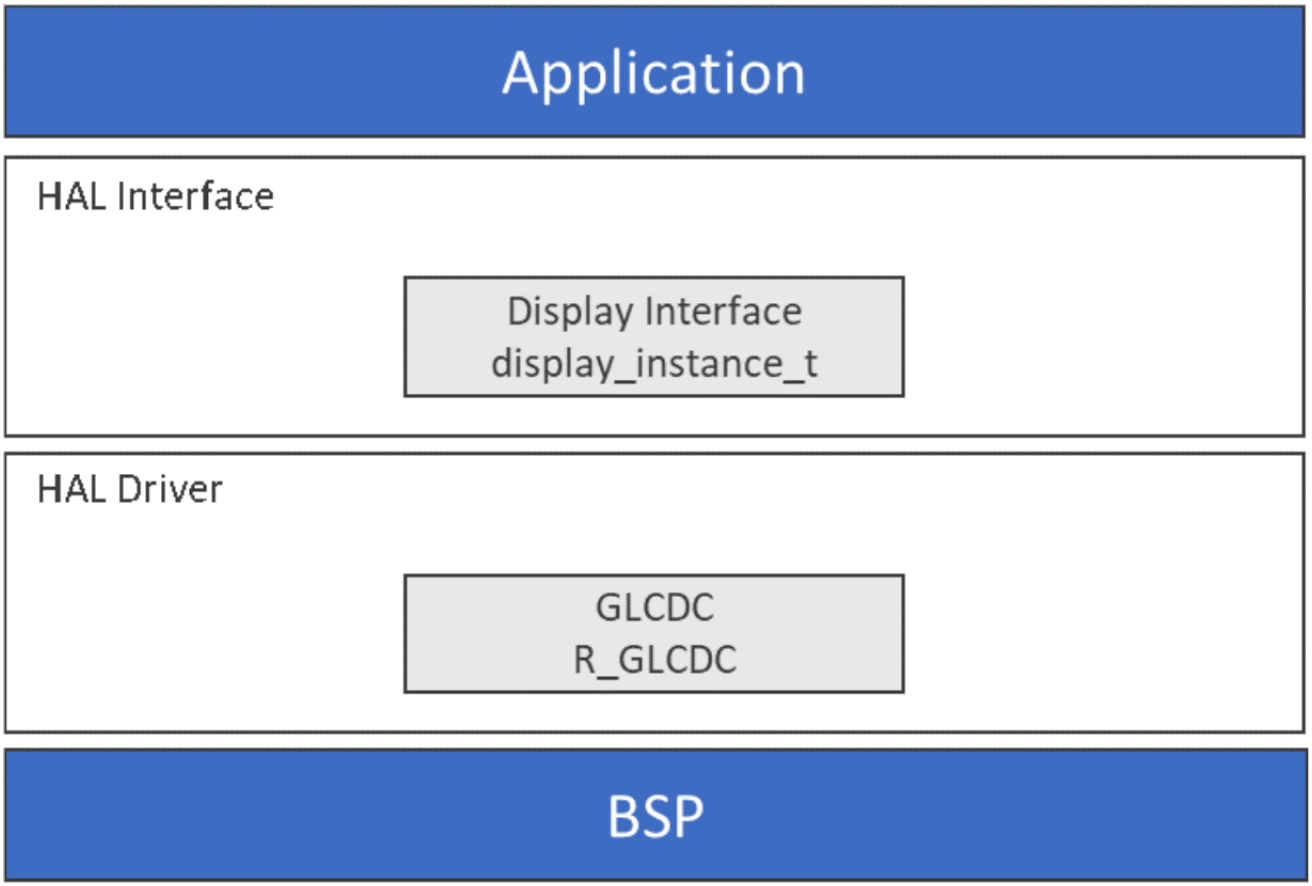

Figure 275: GLCDC HAL Module Block Diagram

GLCDC Hardware support details

The following hardware features are, or are not, supported by the SSP for the GLCDC:

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

MCU Group	Single Color Background Plane	Graphics 1 Plane	Graphics 2 Plane	Support 16 bit per pixel graphics	Support 32 bit per pixel graphics	Support 1-bit LUT

4.2.14.2 GLCDC HAL Module APIs Overview

The GLCDC HAL module defines APIs for opening, closing, starting, stopping and controlling the display of information on an LCD panel. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

GLCDC HAL Module API Summary

Function Name	Example API Call and Description
open	g_display.p_api->open (g_display.p_ctrl, g_display.p_cfg); Open display device.
close	g_display.p_api->close (g_display.p_ctrl); Close display device.

start	g_display.p_api->start(g_display.p_ctrl); Display start.
stop	g_display.p_api->stop(g_display.p_ctrl); Display stop.
layerChange	g_display.p_api->layerChange(g_display.p_ctrl, &layercng) Change layer parameters at runtime.
correction	g_display.p_api->correction(g_display.p_ctrl, &display_correction) Color correction.
clut	g_display.p_api->clut(g_display.p_ctrl, &clut) Set CLUT for display device.
statusGet	g_display.p_api->statusGet(g_display.p_ctrl, &status) Get status for display device.
versionGet	g_display.p_api->versionGet(&version) Retrieve the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API call successful.
SSP_ERR_ASSERTION	Parameter has invalid value.
SSP_ERR_INVALID_ARGUMENT	Invalid parameter in the argument.
SSP_ERR_HW_LOCKED	GLCDCC resource is locked.
SSP_ERR_CLOCK_GENERATION	Dot clock cannot be generated from clock source.
SSP_ERR_INVALID_TIMING_SETTING	Invalid panel timing parameter.
SSP_ERR_INVALID_LAYER_SETTING	Invalid layer setting found.
SSP_ERR_INVALID_LAYER_FORMAT	Invalid format is specified.
SSP_ERR_INVALID_GAMMA_SETTING	Invalid gamma correction setting found.
SSP_ERR_NOT_OPEN	The function call is performed when the driver state is not equal to DISPLAY_STATE_CLOSED.
SSP_ERR_INVALID_UPDATE_TIMING	A function call is performed when the GLCDC is updating register values internally.
SSP_ERR_INVALID_MODE	Function call is performed when the driver state is not DISPLAY_STATE_OPENED.

SSP_ERR_INVALID_CLUT_ACCESS	Illegal CLUT entry or size is specified.
p_version	The version number.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.14.3 GLCDC HAL Module Operational Overview

The GLCDC HAL module controls an LCD panel. The following figure shows an overview of the graphics data flow using the GLCDC HAL module. The module supports reading graphics frame image data from memory (up to two frames) and blending those images on top of the monochrome background screen. The driver supports CLUT memory and specifies the graphic frame format for the CLUT.

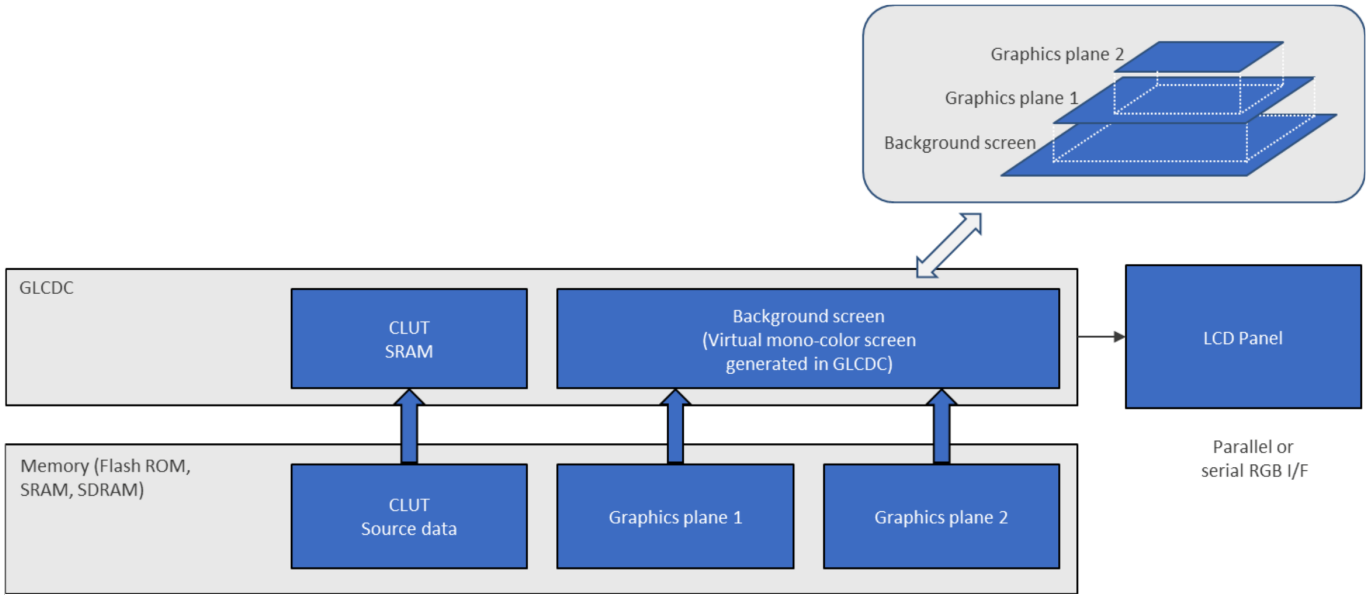

Figure 276: GLCDC HAL Module Data Flow

The following figure shows a display system with a ping-pong frame buffer. It is recommended to have more than two frame buffers in a display system to avoid image tearing, which happens in a single frame buffer display system. In such designs, the GLCDC hardware can read a graphics frame image from one of the frame buffers while the image drawing engines (for example, DRW and JPEG), CPU or DMAC/DTC transfer a graphics frame image to another frame buffer simultaneously. The module supports frame buffer toggling by the display_api_t::layerChange API at run-time.

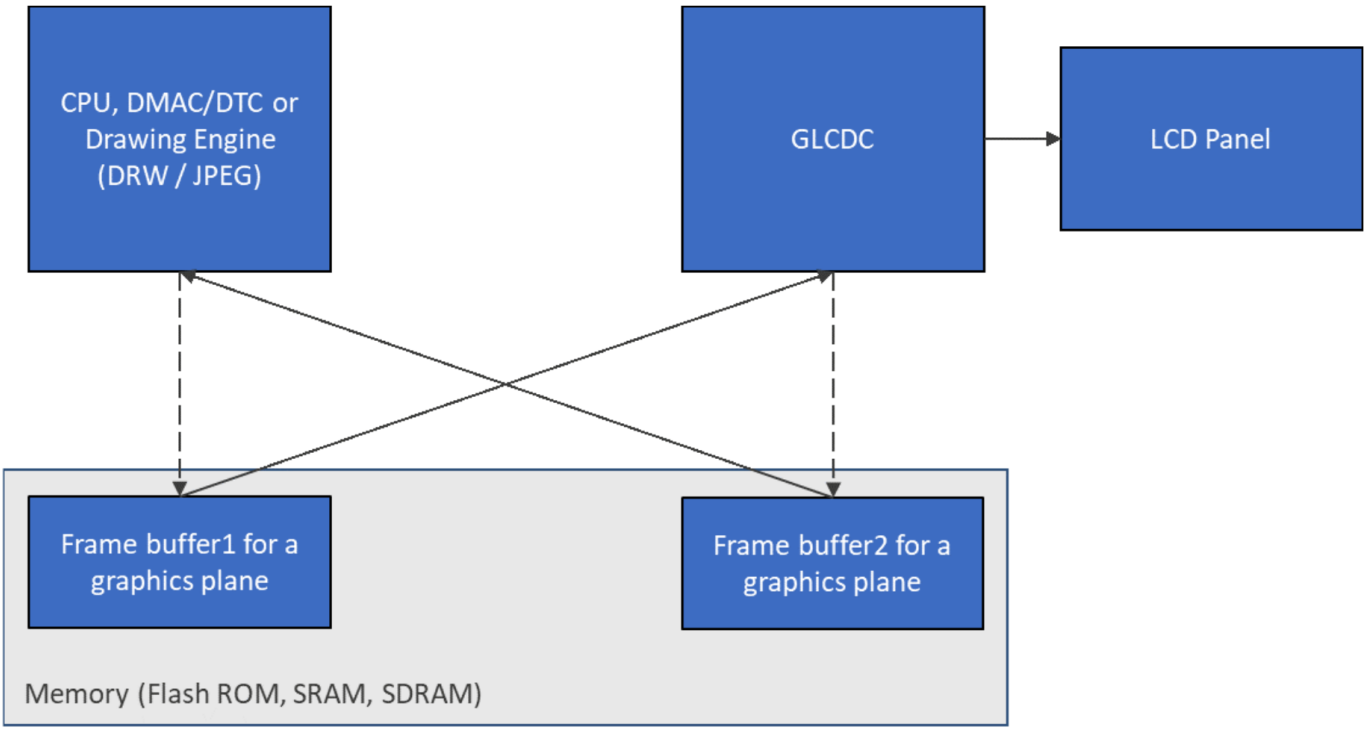

Figure 277: GLCDC HAL Module Ping-Pong Buffer System

Screen Format

The following figure shows the relationship between the LCD screen format and LCD timing parameters of the GLCDC module. The module has generic timing parameters for the LCD panel setting that support a variety of LCD panels.

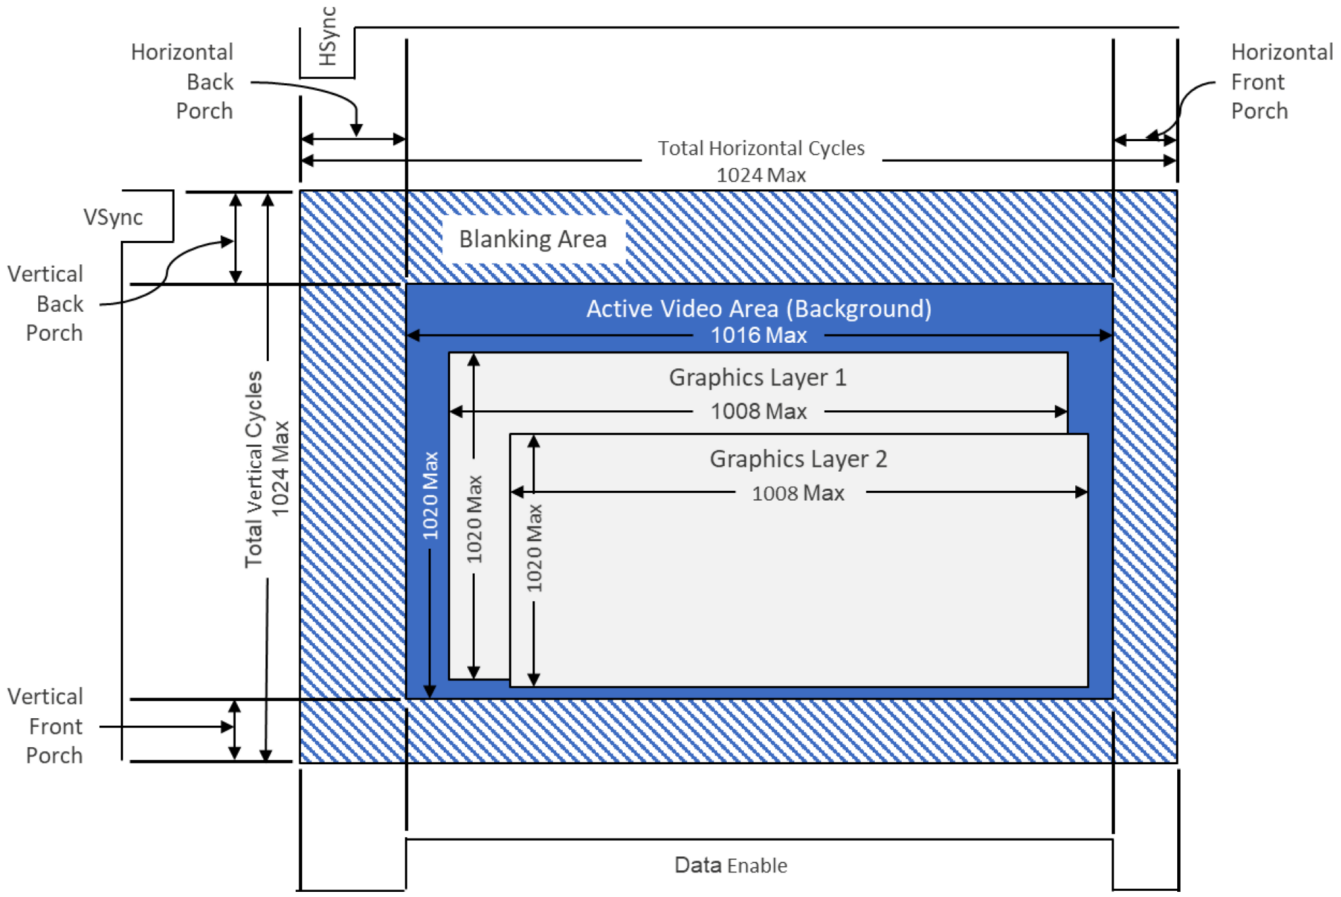

Figure 278: GLCDC HAL Module Screen Format

Front Porch Period

The GLCDC module does not have a setting for horizontal/vertical front porch cycles/lines. Those cycles/lines must be included in the total horizontal cycles/vertical lines setting.

Note

The module requires setting the back porch cycles/lines based on the GLCDC hardware specification. Since typical LCD panels have a greater number of back porch cycles/lines than described, this is not a true limitation of the module.

- Number of the horizontal back porch cycles >= 3
- Number of the vertical back porch lines >= 2

Example Parameter Settings

PE-HMI1 v2.0 board (LXD Research & Display, LLC, M7504A):

The following example adjusts the horizontal total cycles, vertical total lines, and panel clock division ratio to generate an LCD panel refresh rate of 60 Hz. Regarding symbols for the LCD panel, see the M7504A data sheet.

LCD Panel Parameter Settings - PE-HMI1 v2.0 Board

DK-S7G2 v3.0 board (LXD Research & Display, LLC, M7190A):

The following example adjusts the horizontal total cycles, vertical total lines and panel clock division ration to generate an LCD panel refresh rate of 60 Hz. Regarding symbols for the LCD panel, see the M7190A data sheet.

LCD Panel Parameter Settings - DK-S7G2 v3.0 Board

SK-S7G2 v2.0 board (ILI Technology Corp., IL9341C):

The following example sets the horizontal total cycles, and vertical total lines as large as allowed for the panel for an LCD panel refresh rate of about 76.8 Hz. Regarding symbols for the LCD panel, see the LIL9314V data sheet.

LCD Panel Parameter Settings - SK-S7G2 v2.0 Board

Note

The input horizontal size and stride are intentionally set to 256 pixels, even though the parameter should be 240 pixels for the panel. This is because a horizontal line has to be 64-byte aligned for GLCDC hardware. Only 240 pixels from the beginning in a line are valid and rest of pixels in the line (16 pixels) are don't care.

CLUT

The GLCDC module supports a Color Look-Up Table that is used if the color format is ARGB1555, CLUT8, CLUT4, or CLUT1. The CLUT API can update CLUT0/CLUT1 SRAM (implemented inside the GLCDC hardware) for each of the graphics foreground or background screens.

Note

Make sure to call the CLUT API if you select a color format that uses the CLUT, before using the display_api_t::start API; otherwise, CLUT0 and CLUT1 become an unknown condition and the graphics do not display properly.

You can also call the CLUT API at run-time to update CLUT SRAM.

Note

The API copies the source of CLUT data to the CLUT SRAM, which is not currently used (each CLUT SRAM consists of a ping-pong buffer). After completing the CLUT data update, the API automatically switches the CLUT SRAM to be read by the GLCDC hardware from the next frame to avoid tearing of the image.

Line Repeating Mode

Line Repeating is an important mode, especially for a system that does not have enough of memory. In this mode, the GLCDC module reads a raster image, which has fewer pixels than the LCD panel screen size, and displays the raster repeatedly on the screen. The following figure shows an example of a screen image constructed by reading a small raster image repeatedly in the background graphics plane.

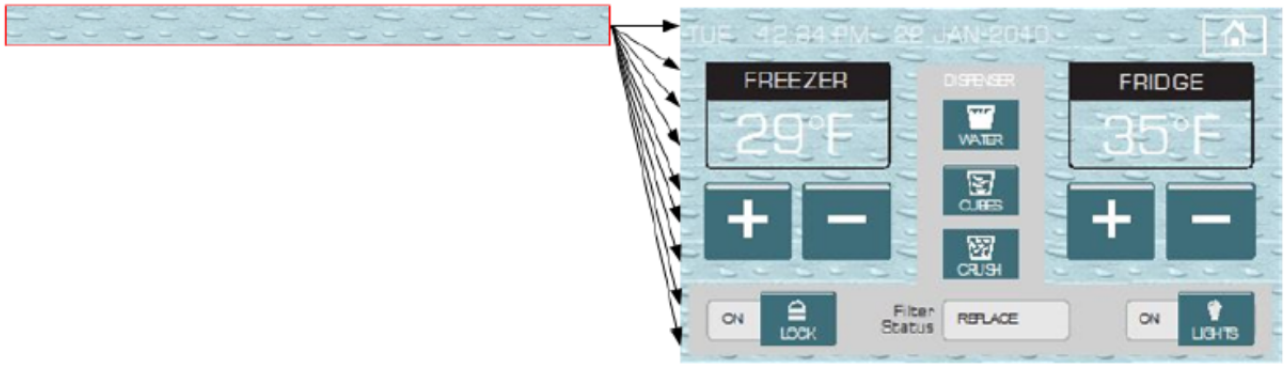

Figure 279: GLCDC HAL Module Line Repeating Mode

Note

To enable this mode, set the GLCDC module property "Input - Graphics screen N input lines repeat" (where N = 1 or 2) to ON with the Synergy configurator. Also, specify the repeat times to read a raster image to: "Input - Graphics screen N input lines repeat times". Specify the horizontal pixel size of the raster image in "Input - Graphics screen N input horizontal size" and "Input - Graphics screen N input horizontal stride," and then specify the vertical pixel size of the raster image in "Input - Graphics screen N input vertical size."

Gamma Correction

Gamma Correction is used to change the color characteristic of LCD panels to a flat characteristic. The following figure shows the gamma correction curve, which can be configured by the GLCDC module. The module supports 16 threshold values for the input color level for each (R, G, B) color and defines the gain level for each of 16 areas divided by thresholds.

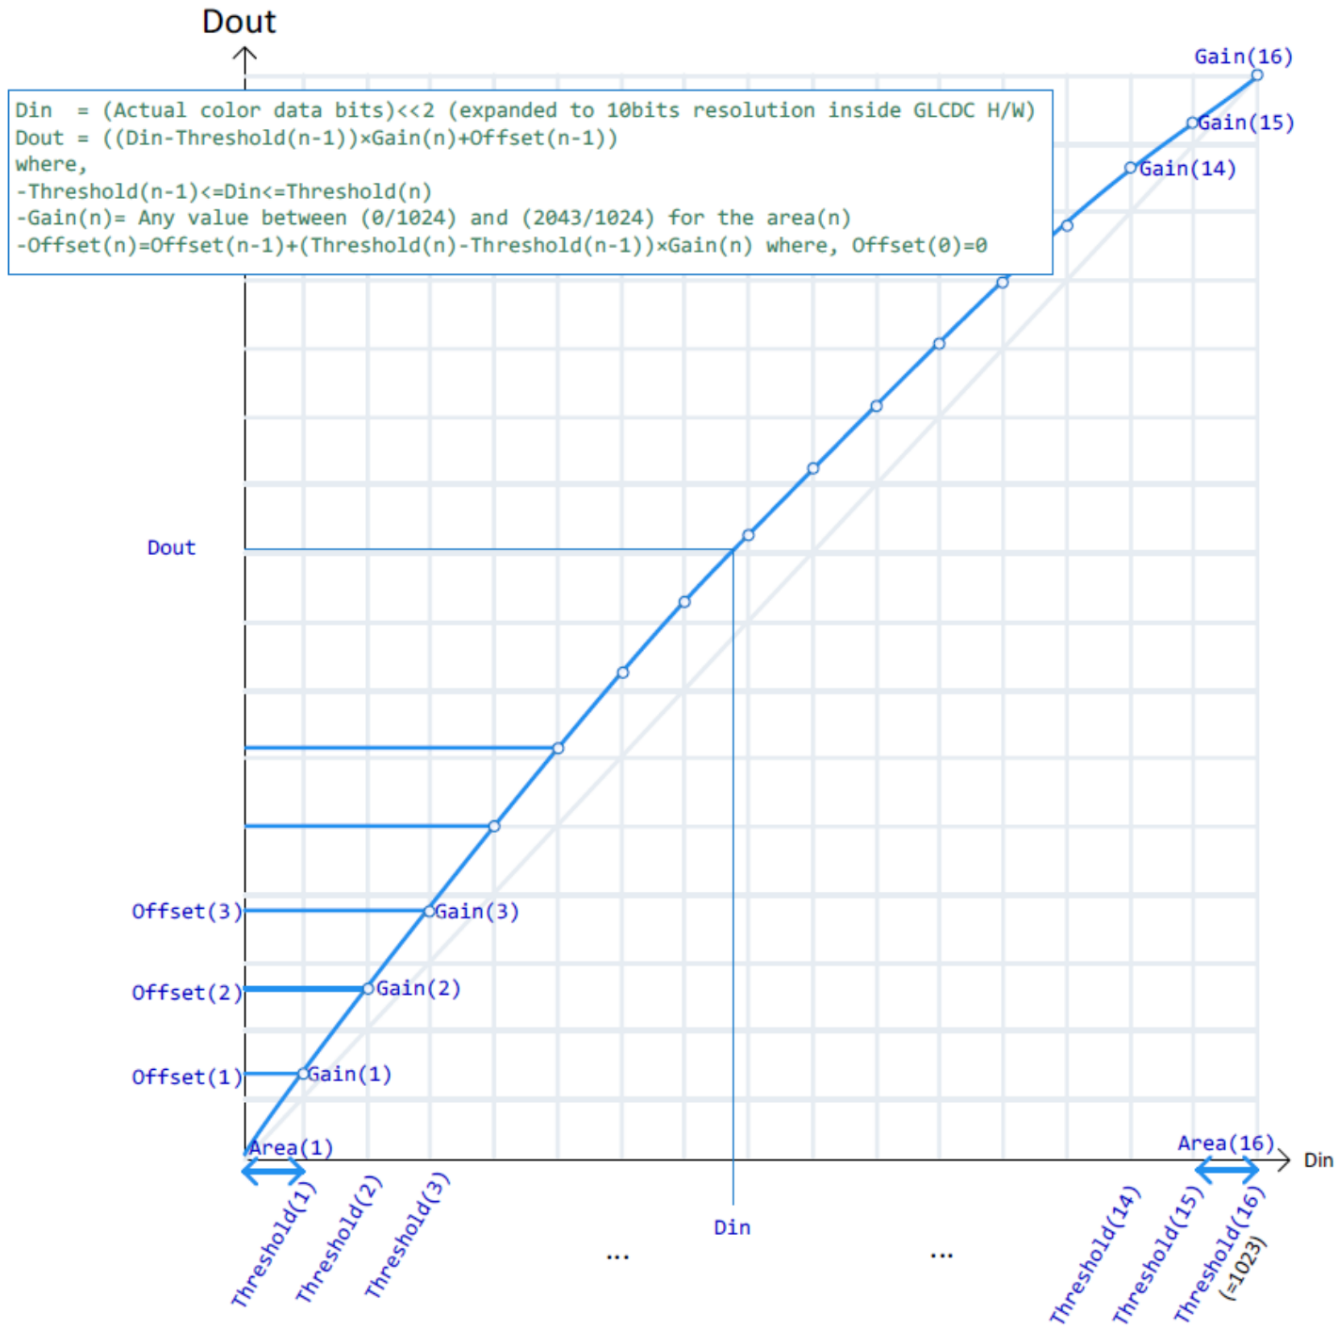

Figure 280: GLCDC HAL Module Gamma Correction Curve

Note

To enable the gamma correction for each channel (R, G, B), set the GLCDC module property "Color correction – Gamma correction (R, G, B)" to ON using the Synergy configurator. Thresholds (total 16) are set to "Color correction – Gamma correction threshold (R, G, B) [n]," where n=[0..15]. The gain value for each of areas are set to "Color correction – Gamma correction gain (R, G, B) \[n]," where n= [0..15].

GLCDC HAL Module Important Operational Notes and Limitations

GLCDC HAL Module Operational Notes

You have the option to configure multiple GLCDC interrupts covered in the following sections:

Line Detection Interrupt

The line detection interrupt is used to indicate when the GLCDC finishes outputting all lines to the LCD panel and goes into the blanking period. Use this interrupt to handle frame buffer switching in a graphics system and uses frame buffers with more than two frames.

Layer1 or Layer2 Line Buffer Underflow Interrupt

You can use the GLCDC layer1 or layer2 buffer underflow interrupt to detect lack of memory bandwidth in your system. The buffer underflow occurs when the graphics data transfer from memory (for example, SDRAM or SRAM) to the GLCDC internal line buffer is blocked by the other data transfer, and not enough against the data transfer from GLCDC line buffer to the LCD panel interface. You have to design the graphics system to prevent this interrupt from occurring.

GLCDC Callbacks

A user callback function can be registered in open. If a user callback function is provided, the callback function is called from the interrupt service routine (ISR) each time an interrupt happens. The argument of the callback function event can take the following enumerated value listed the table, so that a user can identify which event occurred in the graphics system. DISPLAY_EVENT_LINE_DETECTION event is used for switching frame buffers to update the screen, and DISPLAY_EVENT_GRn_UNDERFLOW event is used for error handling if an underflow occurs.

Event and Interrupt Summary

Name of Event	Name of Interrupt	Condition for the Event
DISPLAY_EVENT_LINE_DETECTION	Line detection	When GLCDC is done outputting the last line in the active video region
DISPLAY_EVENT_GR1_UNDERFLOW	Graphics 1 underflow	When GLCDC underflows during reading the data for graphics1 plane
DISPLAY_EVENT_GR2_UNDERFLOW	Graphics 2 underflow	When GLCDC underflows during reading the data for graphics2 plane

Note

Since the callback is called from an ISR, be careful not to use blocking calls or lengthy processing. Spending an excessive time in an ISR can affect the responsiveness of the system.

GLCDC HAL Module Limitations

- The Display driver on r_glcd does not support RGB-index chroma key.
- The Display driver on r_glcd does not support the event link function.

4.2.14.4 Including the GLCDC HAL Module in an Application

This section describes how to include the GLCDC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and

configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Display Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Display Driver is g_display0. This name can be changed in the associated Properties window.)

GLCDC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_display0 Display Driver on r_glcdc	Threads	**New Stack> Driver> Graphics> Display Driver on r_glcdc**

When the Display Driver on r_glcdc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

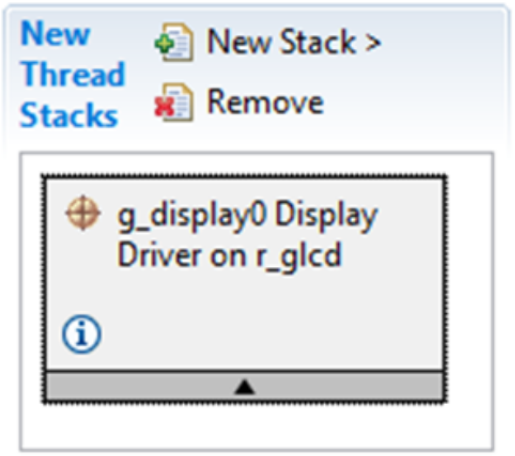

Figure 281: GLCDC HAL Module Stack

4.2.14.5 Configuring the GLCDC HAL Module

The GLCDC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the GLCDC HAL Module on r_glcdc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_display0	The name to be used for a GLCDC module control block instance. This name is also used as the prefix of the other variable instances.
Name of display callback function to be defined by user	NULL	Name must be a valid C symbol.
Input - Panel clock source select	Internal clock (GLCDCLK), External clock (LCD_EXTCLK) Default: Internal clock (GLCDCLK)	Choose the panel clock source depends on your system.
Input - Graphics screen1	Used, Not used Default: Used	Specify "Used" if the graphics screen N is used. Then the frame buffer named "display_fb_background" for graphics screen1 and "display_fb_foreground" for graphics screen2 is auto-generated by ISDE. If not using either of the graphics screens, specify "Not used". Then the frame buffer is not created. Note that there is no memory read access to the frame buffer when you specify "Not used", which reduces the consumption of bus bandwidth.
Input - Graphics screen1 frame buffer name	fb_background	Custom name for frame buffer.
Input - Number of Graphics screen1 frame buffer	2	Number of graphics selection.
Input - section where Graphics screen1 frame buffer allocated	sdram	Specify the section name to allocate the frame buffer. This is valid if "Input - Graphics screen1" is set as "Used."
Input - Graphics screen1 input horizontal size	800	Specify the number of horizontal pixels. Default value is the size for an image with 800x480 pixels

Input - Graphics screen1 vertical size	480	Specify the number of vertical pixels. Default value is the size for an image with 800x480 pixels.
Input - Graphics screen1 input horizontal stride (not bytes but pixels)	800	Specify the memory stride for a horizontal line. This value must be specified with the number of pixels, not actual bytes. Typically, this parameter is set to same number as parameter 'input horizontal size'. Default value is the size for an image with 800x480 pixels.
Input - Graphics screen1 input format	32bits ARGB888, 32bits RGB888, 16bits RGB565, 16bits ARGB1555, 16bits ARGB4444, CLUT 8, CLUT 4, CLUT 1 Default: 16bits RGB565	Specify the graphics screen Input format. If selecting CLUT formats, you must write CLUT data using clut before performing start. Default setting supports a RGB565 formatted image.
Input - Graphics screen1 input line descending	Used, Not used Default: Not used	Specify "On" if image data descends from the bottom line to the top line in the frame buffer. Usually "Off".
Input - Graphics screen1 input line repeat	On, Off Default: Off	Specify "On" if expecting to repeatedly read a raster image which is smaller than the LCD panel size. Usually "Off". For details, see the description of Line Repeating function.
Input - Graphics screen1 input line repeat times	0	Specify the number of repeating times for a raster image which is read repeatedly in a frame.
Input - Graphics screen1 layer coordinate X	0	Specify the horizontal offset in pixels of the graphics screen from the background screen.
Input - Graphics screen1 layer coordinate Y	0	Specify the vertical offset in pixels of the graphics screen from the background screen.
Input - Graphics screen1 layer background color alpha	255	Based on the alpha value, either the graphics screen2 (foreground graphics screen) is blended into the graphics screen1 (background graphics screen) or the graphics screen1 is blended into the monochrome background screen.

Input - Graphics screen1 layer background color Red	255	Specify the background color in the graphics screen N.
Input - Graphics screen1 layer background color Green	255	Specify the background color in the graphics screen N.
Input - Graphics screen1 layer background color Blue	255	Specify the background color in the graphics screen N.
Input - Graphics screen1 layer fading control	None, Fade-in, Fade-out Default: None	Specify "On" when performing a fade-in for the graphics screen. The transparent screen changes gradually to opaque. Specify "Off" when performing the fade-out for the graphics screen. The opaque screen changes gradually to transparent. Note that this processing is accelerated by the GLCDC hardware and cannot stop once started. The transition status can be monitored by statusGet.
Input - Graphics screen1 layer fade speed	0	Specify the number of frames for the fading transition to complete.
Input - Graphics screen2	Used, Not used Default: Not used	Specify "Used" if the graphics screen N is used. Then the frame buffer named "display_fb_background" for graphics screen1 and "display_fb_foreground" for graphics screen2 is auto-generated by ISDE. If not using either of the graphics screens, specify "Not used". Then the frame buffer is not created. Note that there is no memory read access to the frame buffer when you specify "Not used", which reduces the consumption of bus bandwidth.
Input - Graphics screen2 frame buffer name	fb_foreground	Custom name for frame buffer.
Input - Number of Graphics screen2 frame buffer	2	Number of graphics selection.
Input - section where Graphics screen2 frame buffer allocated	sdram	Specify the section name to allocate the frame buffer. This is valid if "Input - Graphics screen1" is set as "Used."

Input - Graphics screen2 input horizontal size	800	Specify the number of horizontal pixels. Default value is the size for an image with 800x480 pixels
Input - Graphics screen2 vertical size	480	Specify the number of vertical pixels. Default value is the size for an image with 800x480 pixels.
Input - Graphics screen2 input horizontal stride (not bytes but pixels)	800	Specify the memory stride for a horizontal line. This value must be specified with the number of pixels, not actual bytes. Typically, this parameter is set to same number as parameter 'input horizontal size'. Default value is the size for an image with 800x480 pixels.
Input - Graphics screen2 input format	32bits ARGB888, 32bits RGB888, 16bits RGB565, 16bits ARGB1555, 16bits ARGB4444, CLUT 8, CLUT 4, CLUT 1 Default: 16bits RGB565	Specify the graphics screen Input format. If selecting CLUT formats, you must write CLUT data using clut before performing start. Default setting supports a RGB565 formatted image.
Input - Graphics screen2 input line descending	On, Off Default: Off	Specify "On" if image data descends from the bottom line to the top line in the frame buffer. Usually "Off".
Input - Graphics screen2 input line repeat	On, Off Default: Off	Specify "On" if expecting to repeatedly read a raster image which is smaller than the LCD panel size. Usually "Off". For details, see the description of Line Repeating function.
Input - Graphics screen2 input line repeat times	0	Specify the number of repeating times for a raster image which is read repeatedly in a frame.
Input - Graphics screen2 layer coordinate X	0	Specify the horizontal offset in pixels of the graphics screen from the background screen.
Input - Graphics screen2 layer coordinate Y	0	Specify the vertical offset in pixels of the graphics screen from the background screen.

Input - Graphics screen2 layer background color alpha	255	Based on the alpha value, either the graphics screen2 (foreground graphics screen) is blended into the graphics screen1 (background graphics screen) or the graphics screen1 is blended into the monochrome background screen.
Input - Graphics screen2 layer background color Red	255	Specify the background color in the graphics screen N.
Input - Graphics screen2 layer background color Green	255	Specify the background color in the graphics screen N.
Input - Graphics screen2 layer background color Blue	255	Specify the background color in the graphics screen N.
Input - Graphics screen2 layer fading control	None, Fade-in, Fade-out Default: None	Specify "On" when performing a fade-in for the graphics screen. The transparent screen changes gradually to opaque. Specify "Off" when performing the fade-out for the graphics screen. The opaque screen changes gradually to transparent. Note that this processing is accelerated by the GLCDC hardware and cannot stop once started. The transition status can be monitored by statusGet.
Input - Graphics screen2 layer fade speed	0	Specify the number of frames for the fading transition to complete.
Output - Horizontal total cycles	1024	Specify the total cycles in a horizontal line. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Horizontal active video cycles	800	Specify the number of active video cycles in a horizontal line. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.

Output - Horizontal back porch cycles	46	Specify the number of back porch cycles in a horizontal line. Back porch starts from the beginning of Hsync cycles, which means back porch cycles contain Hsync cycles. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Horizontal sync signal cycles	20	Specify the number of Hsync signal assertion cycles. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches LCD panel on S7G2 PE-HMI1 board.
Output - Horizontal sync signal polarity	Low active, High active Default: Low active	Select the polarity of Hsync signal to match your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical total lines	525	Specify number of total lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical active video lines	480	Specify the number of active video lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical back porch lines	23	Specify the number of back porch lines in a frame. Back porch starts from the beginning of Vsync lines, which means back porch lines contain Vsync lines. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.

Output - Vertical sync signal lines	10	Specify the Vsync signal assertion lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical sync signal polarity	Low active, High active Default: Low active	Select the polarity of Vsync signal to match to your system. Default setting matches LCD panel on S7G2 PE-HMI1 board.
Output - Format	24bits RGB888, 18bits RGB666, 16bits RGB565, 8bits serial Default: 24bits RGB888	Specify the graphics screen output format to match to your LCD panel. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Endian	Little endian, Big endian Default: Little endian	Select data endian for output signal to LCD panel. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Color order	RGB, BGR Default: RGB	Select data order for output signal to LCD panel. The order of blue and red can be swapped if needed. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Data Enable Signal Polarity	Low active, High active Default: High active	Select the polarity of Data Enable signal to match to your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Sync edge	Rising Edge, Falling Edge Default: Rising Edge	Select the polarity of Sync signals to match to your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Background color alpha channel	255	Specify the background color of the background screens.
Output - Background color R channel	0	Specify the background color of the background screens.
Output - Background color G channel	0	Specify the background color of the background screens.
Output - Background color B channel	0	Specify the background color of the background screens.

CLUT	Used, Not used Default: Not used	Specify "Used" if selecting CLUT formats for a graphics screen input format. Then, a buffer named "CLUT_buffer" for the CLUT source data is generated in the ISDE auto-generated source file.
CLUT - CLUT buffer size	256	Specify the number of entries for the CLUT source data buffer. Each entries consumes 4 bytes (1 word). Words of CLUT source data specified by this parameter are generated in the ISDE auto-generated source file.
TCON - Hsync pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 Default: LCD_TCON0	Select the TCON pin used for the Hsync signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON - Vsync pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 Default: LCD_TCON1	Select TCON pin used for Vsync signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON - DataEnable pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 Default: LCD_TCON2	Select TCON pin used for DataEnable signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON - Panel clock division ratio	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8, 1/9, 1/12, 1/16, 1/24, 1/32 Default: 1/8	Select the clock source divider value. See the note at bottom of this table about the source clock for the pixel clock.
Color correction - Brightness	Off, On Default: Off	Specify "On" when performing brightness control. If specifying "Off", the setting below does not affect the output color.
Color correction - Brightness R channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each of R, G, B channels.
Color correction - Brightness G channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each of R, G, B channels.

Color correction - Brightness B channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each of R, G, B channels.
Color correction - Contrast	Off, On Default: Off	Specify "On" when performing contrast control. If specifying "Off", the setting below does not affect the output color.
Color correction - Contrast(gain) R channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each of R, G, B channels.
Color correction - Contrast(gain) G channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each of R, G, B channels.
Color correction - Contrast(gain) B channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each of R, G, B channels.
Color correction - Gamma correction(Red)	Off, On Default: Off	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off", the settings for gain and threshold do not affect the output color.
Color correction - Gamma gain R[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as follows: Output color level = Input color level / 1024 (/128).

Color correction - Gamma threshold R[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma correction(Green)	Off, On Default: Off	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off", the settings for gain and threshold do not affect the output color.
Color correction - Gamma gain G[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma threshold G[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma correction(Blue)	Off, On Default: Off	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off", the settings for gain and threshold do not affect the output color.

Color correction - Gamma gain B[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma threshold B[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Dithering	Off, On Default: Off	Dithering enable. Specify "On" when applying the dither effect to reduce the banding in case of selecting RGB666 or RGB565 output formats. Dithering can be applied when converting. If specified "Off", the settings for dithering below do not affect the output. For details on the dither effect, see Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Mode	Truncate, Round off, 2x2 Pattern Default: Truncate	Specify the dither mode. For detail, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Pattern A	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.

Dithering - Pattern B	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Pattern C	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Pattern D	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Misc - Correction Process Order	Brightness and Contrast then Gamma, Gamma then Brightness and Contrast Default: Brightness and Contrast then Gamma	Specify the color correction processing order if needed.
Line Detect Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Disabled	The driver needs valid interrupt priority setting and it will not work if disabled.
Underflow 1 Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Disabled	The driver needs valid interrupt priority setting and it will not work if disabled.
Underflow 2 Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Default: Disabled	The driver needs valid interrupt priority setting and it will not work if disabled.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

GLCDC HAL Module Clock Configuration

The GLCDC module can generate the pixel clock from either of the following clock sources (the source clock selection is available through Synergy Configuration in e^2 studio):

- Internal clock source (PLLOUT; 240 MHz)
- External clock source from the LCD_EXTCLK pin

Note

The internal clock is different in the S7G2 WS1 (Working Sample1) chip and the WS2 (Working Sample2) chip or later. The WS1 chip uses the PCLKB (max. 60 MHz), but WS2 or later chips use the PLLOUT (max. 240 MHz).

GLCDC HAL Module Pin Configuration

The GLCDC module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The pin selection table lists methods to select pins within the SSP configuration window and the configuration settings table lists an example depicting selection of GLCDC pins:

Pin Selection for the GLCDC HAL Module on r_glcdc

Resource	ISDE Tab	Pin selection Sequence
GLCDC	Pins	Select **Peripherals**> **Graphics: GLCDC**> **GLCDC0**

Note

The selection sequence assumes GLCDC0 is the desired hardware target for the driver.

Pin Configuration Settings for GLCDC HAL Module on r_glcd

Property	Value	Description
Pin Group Selection	Mixed, _A Only, _B Only Default: Mixed	Pin group selection.
Operation Mode	Disabled, Custom, RGB888, RGB666, RGB565 Default: Disabled	Select desired operation mode.
LCD_CLK	None, P900, P101 Default: None	LCD_CLK Pin.
LCD_DATA00:15	None, Pn, Pm Default: None	LCD_DATA Pins.
LCD_TCON0:3	None, Pn, Pm Default: None	LCD_TCON Pins.
LCD_EXTCLK	None, Pn, Pm Default: None	LCD_EXTCLK Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.
To use the GLCDC module on the S7G2 PE-HMI1 board, be sure to set up PORT10 pin3 (PA03) and pin5 (PA05) as IOPORT pins with the output level HIGH. Pin PA03 controls the DISP signal (Display on/off) and Pin PA05 controls the backlight of LCD panel. For details, see the schematics of S7G2 PE-HMI1 board.

4.2.14.6 Using the GLCDC HAL Module in an Application

- The typical steps in using the GLCDC HAL module in an application are:

1. Initialize the GLCDC HAL module with the display_api_t::open API.
2. Draw a primary image in the frame buffer with application code.
3. Start the image displaying using the display_api_t::start API.
4. Stop the image displaying using the display_api_t::stop API.
5. Copy the source CLUT data to CLUT SRAM using the display_api_t::clut API.

6. Draw a new image in the frame buffer to update the display with application code.

    - *Note*

      In a typical application a ping-pong frame buffer system is used, so the application will draw the image to another frame buffer, which is not used for displaying at this point.

7. Request frame buffer toggling to the GLCDC hardware with the display_api_t::layerChange API.

    - *Note*

      The GLCDC hardware toggles the frame buffer and displays a new image from the next frame.

8. Perform color correction using the display_api_t::correction API.
9. Get display status using the display_api_t::statusGet API.
10. Get the driver version using display_api_t::versionGet API. (Optional)
11. Close the GLCDC module by calling the display_api_t::close API.

To synchronize application code to the completion of drawing current frame buffer, use the Line Detection Interrupt and notify the timing to application code through the GLCDC callback.

These common steps are illustrated in a typical operational flow diagram in the following figure:

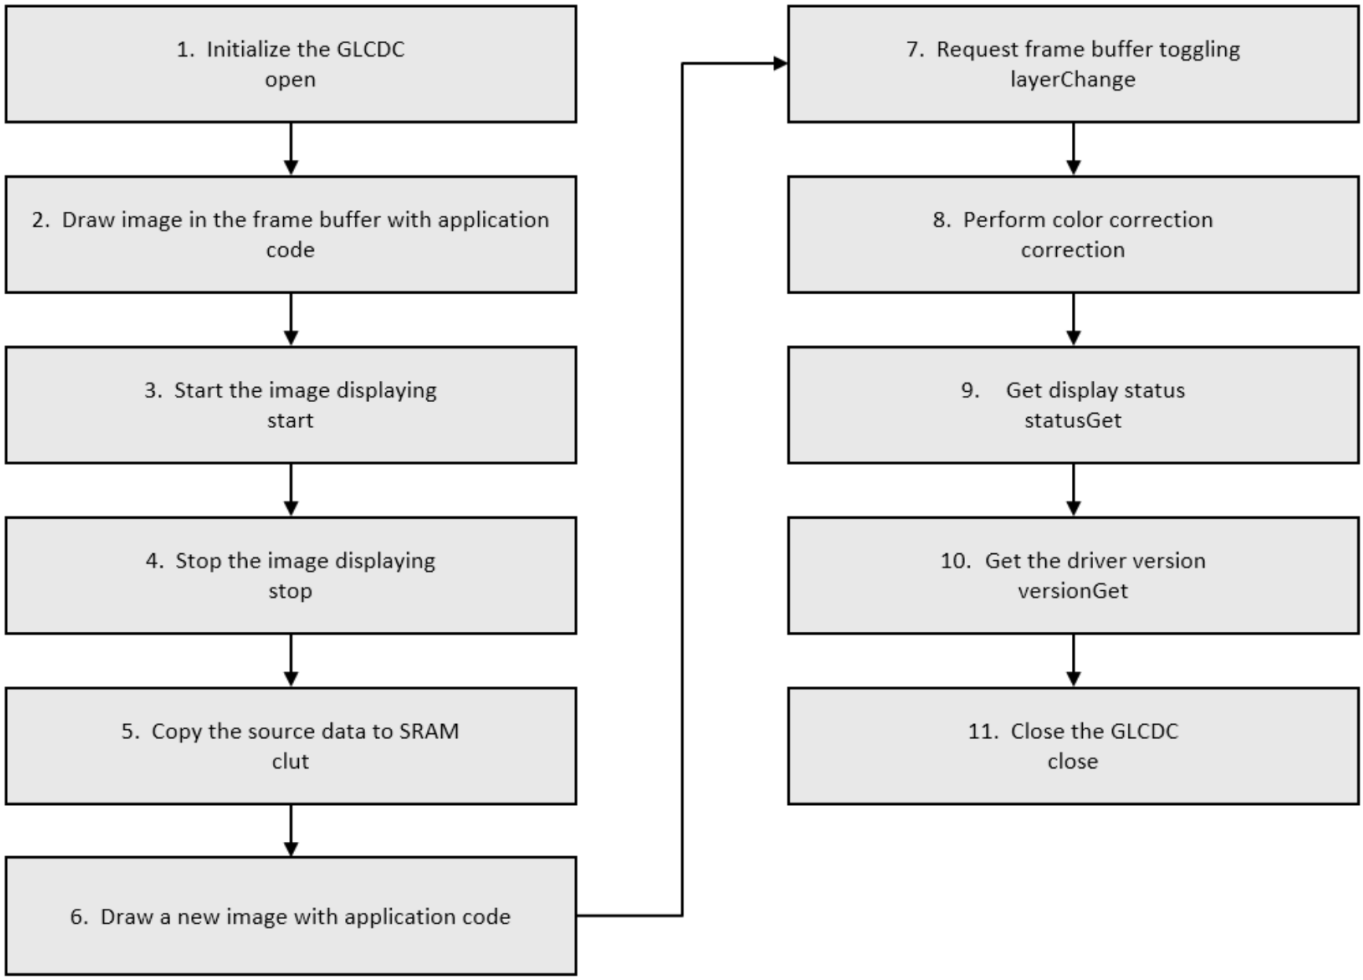

Figure 282: Flow Diagram of a Typical GLCDC HAL Module Application

4.2.15 Data Operation Circuit Driver

4.2.15.1 DOC HAL Module Introduction

The Data Operation Circuit (DOC) HAL module provides a high-level API for DOC applications and uses the DOC peripherals on the Synergy MCU. A user-defined callback can be created to inform the CPU when an event occurs.

DOC HAL Module Features

The DOC HAL module peripheral is used to compare 16-bit data and can detect the following events:

- A mismatch or match between data values
- Overflow of an addition operation
- Underflow of a subtraction operation

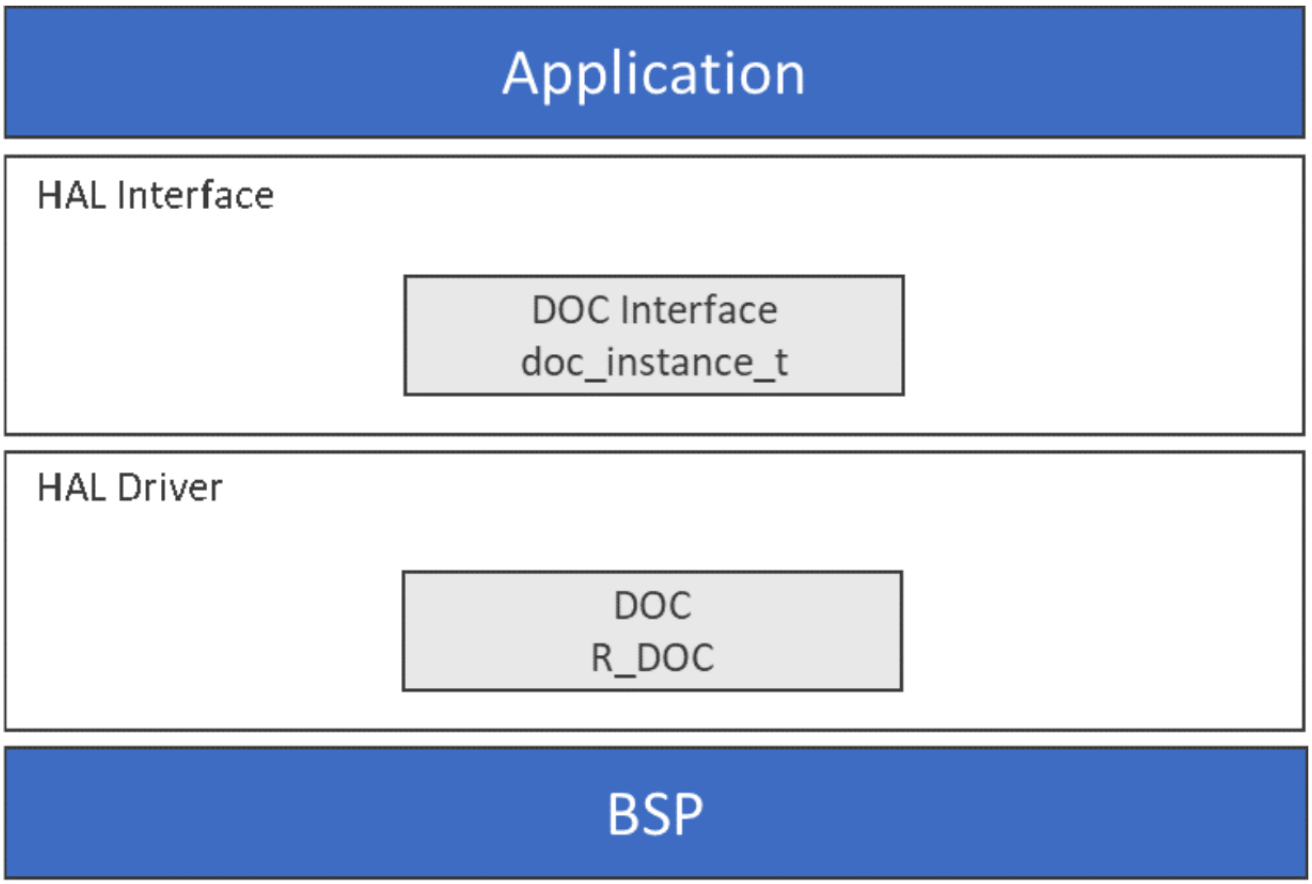

Figure 283: DOC HAL Module Block Diagram

DOC Hardware support details

The following hardware features are, or are not, supported by SSP for DOC.

4.2.15.2 DOC HAL Module APIs Overview

The DOC HAL module defines APIs for opening, closing, checking the status of and writing data to the data operation circuit. The DOC HAL module uses the DOC peripheral on the Synergy MCU. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

DOC HAL Module API Summary

Function Name	Example API Call and Description
open	g_doc.p_api->open(g_doc.p_ctrl, g_doc.p_cfg) Initial configuration.
close	g_doc.p_api->close(g_doc.p_ctrl) Allow the driver to be reconfigured. Will reduce power consumption.
statusGet	g_doc.p_api->statusGet(g_doc.p_ctrl, &my_Status) Get the DOC status and stores it in the provided pointer p_status.
statusClear	g_doc.p_api->statusClear(g_doc.p_ctrl) Clear DOPCF status flag.
write	g_doc.p_api->write(g_doc.p_ctrl, value) Write to the DODIR and DODSR registers.

inputRegisterWrite	g_doc.p_api->inputRegisterWrite(g_doc.p_ctrl, &doc_values) Write to the DODIR register.
versionGet	g_doc.p_api->versionGet(g_doc.p_ctrl, &version) Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	DOC successfully configured.
SSP_ERR_IN_USE	Module already open.
SSP_ERR_ASSERTION	One or more pointers point to NULL.
SSP_ERR_INVALID_ARGUMENT	ISR is not enabled. Enable the ISR in bsp_irq_cfg.h.
SSP_ERR_HW_LOCKED	DOC resource is locked.
SSP_ERR_NOT_OPEN	Driver not open.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.15.3 DOC HAL Module Operational Overview

The DOC HAL module controls the DOC peripheral on a Synergy MCU. It is used to compare 16-bit data and can detect a mismatch between data values, an overflow of an addition value, or an underflow of a subtraction operation. If a callback is available and the associated interrupt is enabled, the callback function will be called in response to a DOC event.

The DOC uses two data registers to perform operations: the DOC Data Input Register (DOCDIR) holds the data to be operated on and the DOC Data Setting Register (DOCDSR) holds the value that is used to operate on the input data. In the addition and subtraction modes, this register stores the results of data operations. (Both these registers are 16-bits wide.)

DOC HAL Module Important Operational Notes and Limitations

DOC HAL Module Operational Notes

The initial setting of comparison data is written to the DOC by calling the doc_api_t::write API. The doc_api_t::write API writes to the DOC DODSR and DODIR registers. The doc_api_t::write API use a variable of type doc_data_t, as illustrated below:

```
doc_data_t g_doc_values;

g_doc_values.dodir = 0x1000;
```

```
g_doc_values.dodsr = 0x1000;

g_doc.p_api->write(g_doc.p_ctrl, &g_doc_values);
```

If the data to be compared does not change, there is no need to re-write it each time a comparison is required. The input data value can be written to the DOC by using the doc_api_t::inputRegisterWrite API. The doc_api_t::inputRegisterWrite API writes only to the DOC data-input register.

DOC HAL Module Limitations

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.15.4 Including the DOC HAL Module in an Application

This section describes how to include the DOC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the DOC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the DOC Driver is g_doc0. This name can be changed in the associated Properties window.)

DOC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_doc0 Data Operation Circuit Driver on r_doc	Threads	**New Stack> Driver> Monitoring> Data Operation Circuit Driver on r_doc**

When the Key Matrix Driver on r_kint is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

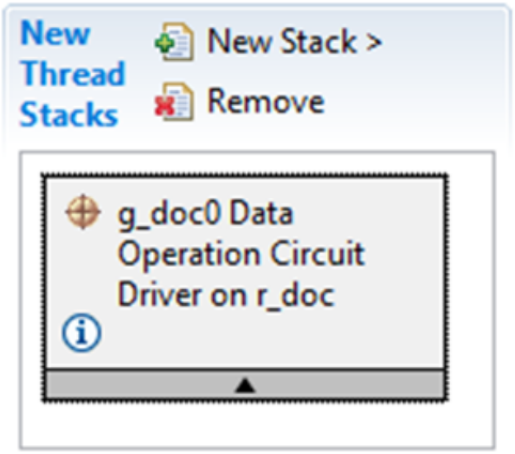

Figure 284: DOC HAL Module Stack

4.2.15.5 Configuring the DOC HAL Module

The DOC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the DOC HAL Module on r_doc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_doc0	Module name.
Event	Comparison mismatch, Comparison match, Addition overflow, Subtraction underflow Default: Comparison mismatch	Specify the event which will trigger the DOC interrupt.

Callback	NULL	A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) when the configured DOC event occurs. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
DOC Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Use the pull down to set the DOC interrupt priority.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

DOC HAL Module Clock Configuration

The DOC HAL module does not require a specific clock configuration.

DOC HAL Module Pin Configuration

The DOC HAL module does not require and specific pin configurations.

4.2.15.6 Using the DOC HAL Module in an Application

The typical steps in using the DOC HAL module in an application are:

1. Initialize the DOC using the doc_api_t::open API.
2. Set register values in DODIR and DODSR using the doc_api_t::write API.
3. Steam data to the DOC using the doc_api_t::inputRegisterWrite API.
4. Read the status of the comparison using the doc_api_t::statusGet API or in the callback if enabled.
5. Clear status flags using the doc_api_t::statusClear API.
6. Close the module using the doc_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

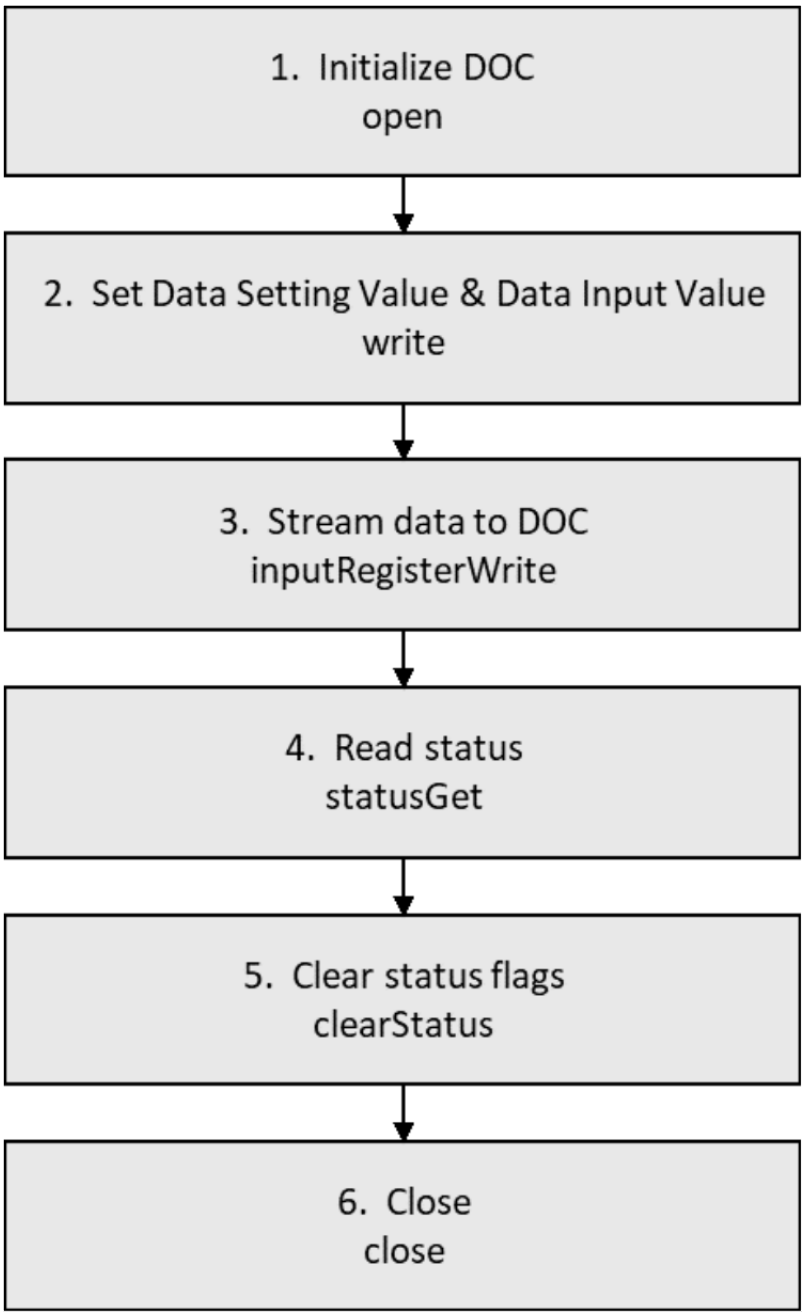

Figure 285: Flow Diagram of a Typical DOC HAL Module Application

4.2.16 Transfer Driver on r_dmac

4.2.16.1 DMAC HAL Module Introduction

The DMAC HAL module provides a high-level API for data-transfer applications and uses the DMAC peripheral on the Synergy MCU. A user-defined callback can be created to inform the CPU when transfer events occur.

DMAC HAL Module Features

The DMAC HAL module moves data from a user-specified source to a user-specified destination when an interrupt or event occurs. The DMAC HAL module supports the following:

- DMAC module on a Synergy MCU
- Interrupts, if desired
- Multiple transfer modes
    - Single Transfer
    - Repeat Transfer
    - Block Transfer
    - Address increment, decrement, offset addition, or fixed modes
- Multiple channels, with the number depending on the MCU used

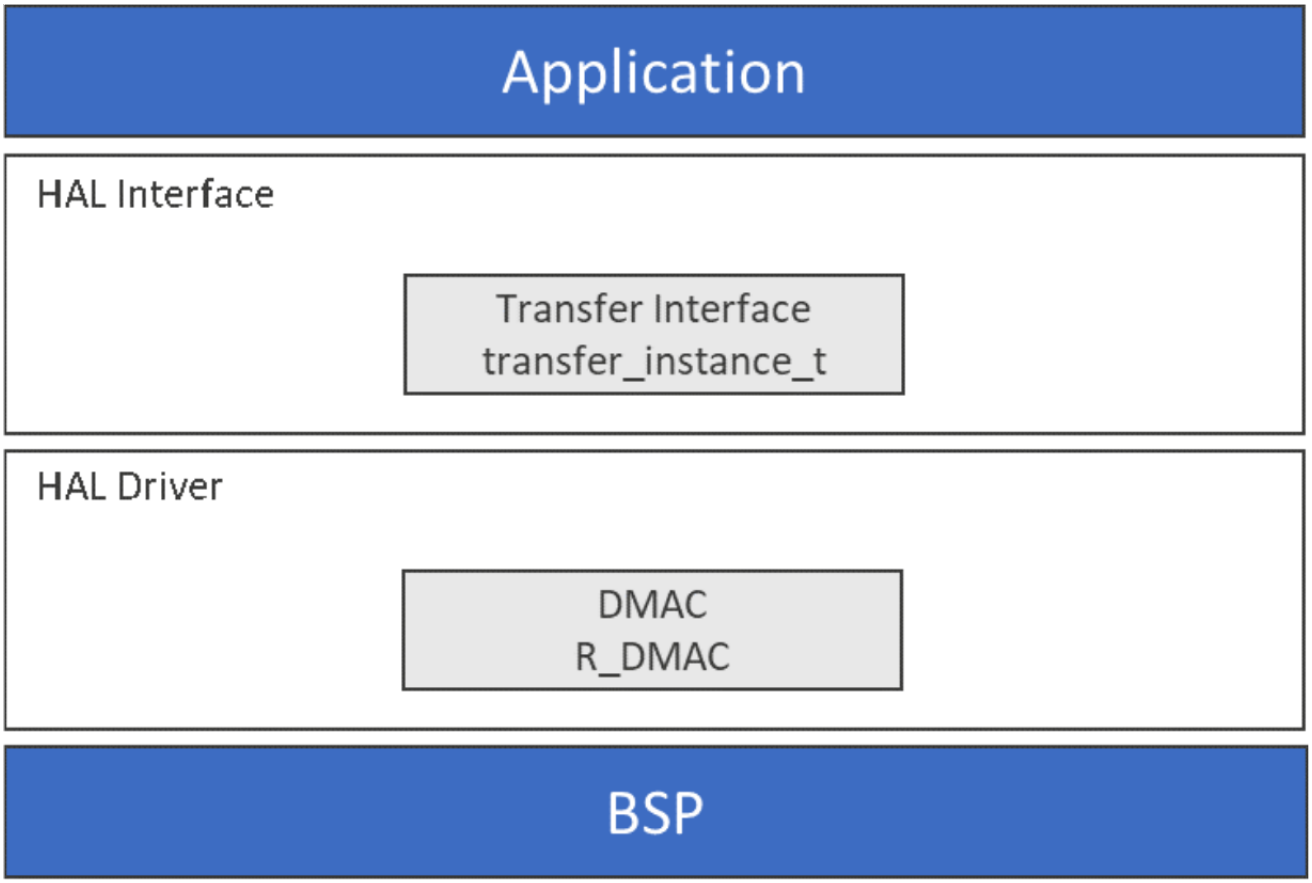

Figure 286: DMAC HAL Module Block Diagram

DMAC Hardware support details

The following hardware features are, or are not, supported by SSP for DMAC.

Legend:

Symbol	Meaning
✓	Available (Tested)

4.2.16.2 DMAC HAL Module APIs Overview

The DMAC HAL module defines APIs for opening, closing, starting and stopping timers. Note that the Data Transfer Controller (DTC) and the DMAC use the same transfer interface; sharing an interface makes it easier to change between DTC and DMA implementations. The API calls are the same independent of the lower level implementations. A complete list of the available APIs, an example API call and a short description of each function can be found in the following table. A table of status return values follows the API summary table.

DMAC HAL Module API Summary

Function Name	Example API Call and Description
open	g_transfer0.api->open(g_transfer0.p_ctrl, g_transfer0.p_cfg) Open device channel. Initialize driver and hardware on first call.
close	g_transfer0.api->close(g_transfer0.p_ctrl) Close device channel. Turns off hardware if last channel open.
reset	g_transfer0.api->reset(g_transfer0.p_ctrl, &source, &destination, number_of_transfers) Reset channel settings.

start	g_transfer0.api->start(g_transfer0.p_ctrl, mode) Start data transfer.
stop	g_transfer0.api->stop(g_transfer0.p_ctrl) Stop data transfer.
enable	g_transfer0.api->enable(g_transfer0.p_ctrl) Enable channel.
disable	g_transfer0.api->disable(g_transfer0.p_ctrl) Disable channel.
versionGet	g_transfer0.api->versionGet(&version) Retrieve the API version with the version pointer.
infoGet	g_transfer0.api->infoGet(g_transfer0.p_ctrl, &info) Get transfer channel info.
blockReset	g_transfer0.api->blockReset(g_transfer0.p_ctrl, &source, &destination, length, size, number_of_transfers) Reset Block Transfer parameters.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	Parameter has invalid value.
SSP_ERR_NOT_OPEN	The channel is not opened.
SSP_ERR_UNSUPPORTED	Operation not configured correctly.
SSP_ERR_IN_USE	The channel specified has already been opened. No configurations were changed. Call the associated Close function or use associated Control commands to reconfigure the channel.
SSP_ERR_IRQ_BSP_DISABLED	IRQ not enabled in BSP.
SSP_ERR_NOT_ENABLED	Operation failed.
SSP_ERR_NOT_OPEN	The channel is not opened.
SSP_ERR_INVALID_SIZE	Invalid Offset Value.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.16.3 DMAC HAL Module Operational Overview

The DMAC and the DTC can be used to move data within the Synergy MCU. There are a few considerations when selecting between these modules and you need to determine which implementation works best for your application. The DTC module is recommended for most generic transfer applications and is also available for data transfer operations. The following use cases describe operations within each transfer module.

Selecting the DTC Transfer Module

The DTC HAL module uses a RAM based vector table, with slots for every interrupt in the system. When the DTC transfer completes, the activation source interrupt is called. The activation source interrupt must be enabled to use the DTC. The activation source interrupt is generally muted by the DTC until the transfer completes, unless TRANSFER_IRQ_EACH is specified in the configuration. For example, if a normal mode transfer with a length of 16 is triggered by a timer, the timer interrupt does not fire the first 15 times while the transfer is in effect. After the 16th transfer, the timer interrupt fires. The DTC also allows chained transfers, meaning that more than one transfer can occur after a single activation source interrupt. This feature is supported by the driver but must be configured outside the ISDE.

Selecting the DMAC Transfer Module

The DMAC HAL module moves data from a user-specified source to a user-specified destination when an interrupt or event occurs. The DMAC HAL module uses DMAC peripheral registers, so the number of transfers in the system is limited to the number of DMAC channels on the device. The activation source does not have to be enabled to use the DMAC. When the DMAC transfer completes, a DMAC interrupt is called. If the activation source interrupt is enabled, it fires at the same time the transfer is triggered. If the DMAC interrupt is enabled, it fires after all transfers are complete. For example, if a normal mode transfer, with a length of 16 is triggered by a timer, the timer interrupt fires at the same time each transfer occurs and the DMAC interrupt fires after the 16th transfer completes. The DMAC does not support chained transfers.

DMAC HAL Module Important Operational Notes and Limitations

DMAC HAL Module Operational Notes

Normal Mode

In normal mode, a single transfer triggers each time an activation source event occurs. A single transfer is 1 byte, 2 bytes or 4 bytes, depending on the setting selected in the size parameter. Each time a transfer occurs, the transfer length decrements by 1. When the transfer length reaches 0, the transfer is complete.

Repeat Mode

In repeat mode, a single transfer triggers each time an activation source event occurs. A single transfer is 1 byte, 2 bytes or 4 bytes, depending on the setting selected in the size parameter. Each time a transfer occurs, the transfer length decrements by 1. When transfer length reaches 0, the transfer length reloads with its initial value and the transfer restarts. If the repeat area is set to source, the source register also reloads with its initial value when the transfer restarts. Alternatively, if the repeat area is set to destination, the destination register reloads with its initial value when the transfer restarts.

Block Mode

In block mode, the entire transfer length transfers each time an activation source event occurs. For example, if a transfer is configured in the block mode with a timer as the activation source, a 2-byte

size and 12-byte length, 24 bytes transfer each time the activation source event occurs. Each time a transfer occurs, the transfer length decrements by 1. When the length reaches 0, the transfer length reloads with its initial value and the transfer restarts. If the repeat area is set to source, the source register is also reloaded with its initial value when the transfer restarts. Alternatively, if the repeat area is set to destination, the destination register reloads with its initial value when the transfer restarts.

Address Mode

After each transfer of size (1 byte, 2 bytes, or 4 bytes), the source pointer and destination pointer adjust by transfer_info_t::src_addr_mode and transfer_info_t::dest_addr_mode, respectively.

For example, if transfer_info_t::src_addr_mode is set to TRANSFER_ADDR_MODE_INCREMENTED, and size is set to TRANSFER_SIZE_4_BYTE, the transfer_info_t::p_dest pointer is incremented by 4 (the transfer size) after each transfer.

For TRANSFER_ADDR_MODE_OFFSET, the pointer is incremented or decremented by the configured offset value.

The pointer does not change if set to TRANSFER_ADDR_MODE_FIXED.

DMAC HAL Module Limitations

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.16.4 Including the DMAC HAL Module in an Application

This section describes how to include the DMAC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Transfer Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Transfer Driver is g_dmac0. This name can be changed in the associated Properties window.)

DMAC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ transfer0 Transfer Driver on r_dmac	Threads	**New Stack> Driver> Transfer> Transfer Driver on r_dmac**

When the Transfer Driver on r_dmac is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and

displays possible choices.

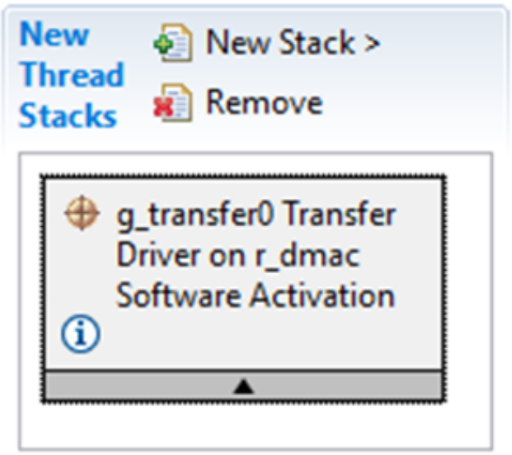

Figure 287: DMAC HAL Module Stack

4.2.16.5 Configuring the DMAC HAL Module

The DMAC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the DMAC HAL Module on r_dmac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_transfer0	Module name.
Channel	0	Channel selection.
Mode	Normal, Repeat, Block Default: Normal	Mode selection.
Transfer Size	1 Byte, 2 Bytes, 4 Bytes Default: 2 Bytes	Transfer size selection.

Destination Address Mode	Fixed, Incremented, Destination Default: Fixed	Destination address mode selection.
Source Address Mode	Fixed, Incremented, Destination Default: Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination, Source Default: Source	Repeat area selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Offset Addition (Valid only in Offset Addition mode)	-16777216 to 16777215 Default: 0	Offset value selection.
Activation Source	Software Activation, Peripheral Events Default: Software Activation	Activation source selection.
Auto Enable	True, False Default: True	Auto enable selection.
Callback	NULL	Callback selection.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

DMAC HAL Module Clock Configuration

The DMAC peripheral module use ICLK as the clock source. The ICLK frequency is set by using the SSP configurator clock tab, prior to a build, or by using the CGC Interface at run-time.

DMAC HAL Module Pin Configuration

The DMAC HAL Module is not associated with any pins.

4.2.16.6 Using the DMAC HAL Module in an Application

The typical steps in using the DMAC HAL module in an application are:

1. Initialize the DMAC HAL module using the transfer_api_t::open API.
2. Enable the DMAC HAL module using the transfer_api_t::enable API (if not auto enabled).
3. Manage transfers using other APIs as needed.
4. Close the DMAC HAL module using the transfer_api_t::close API when needed.

These common steps are illustrated in a typical operational flow diagram in the following figure:

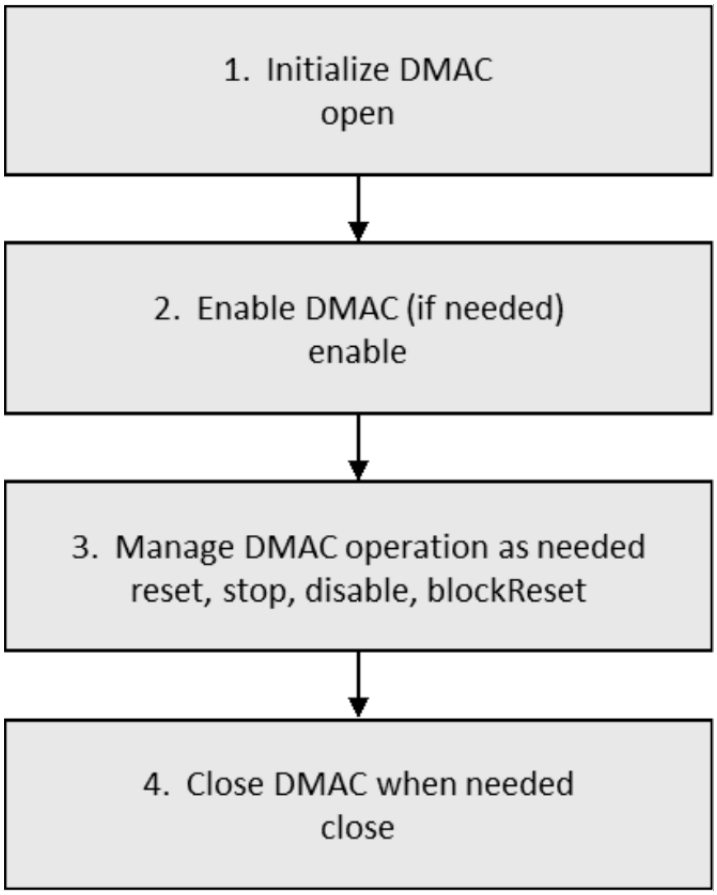

Figure 288: Flow Diagram of a Typical DMAC HAL Module Application

4.2.17 Transfer Driver on r_dtc

4.2.17.1 DTC HAL Module Introduction

The Data Transfer Controller (DTC) HAL module provides a high-level API for data-transfer applications and uses the DTC peripheral on the Synergy MCU. A user-defined callback can be created to inform the CPU when transfer events occur.

DTC HAL Module Features

The Data Transfer Controller (DTC) HAL module moves data from a user-specified source to a user-specified destination when an interrupt or event occurs.

- Supports the DTC module on a Synergy MCU
- Supports interrupts if desired
- Supports multiple transfer modes
    - Single transfer
    - Repeat transfer
    - Block transfer
    - Address increment or fixed modes
    - Chain transfers
- Supports multiple channels (depending on selected implementation)
    - Number of channels is limited only by the size of the RAM-based vector table

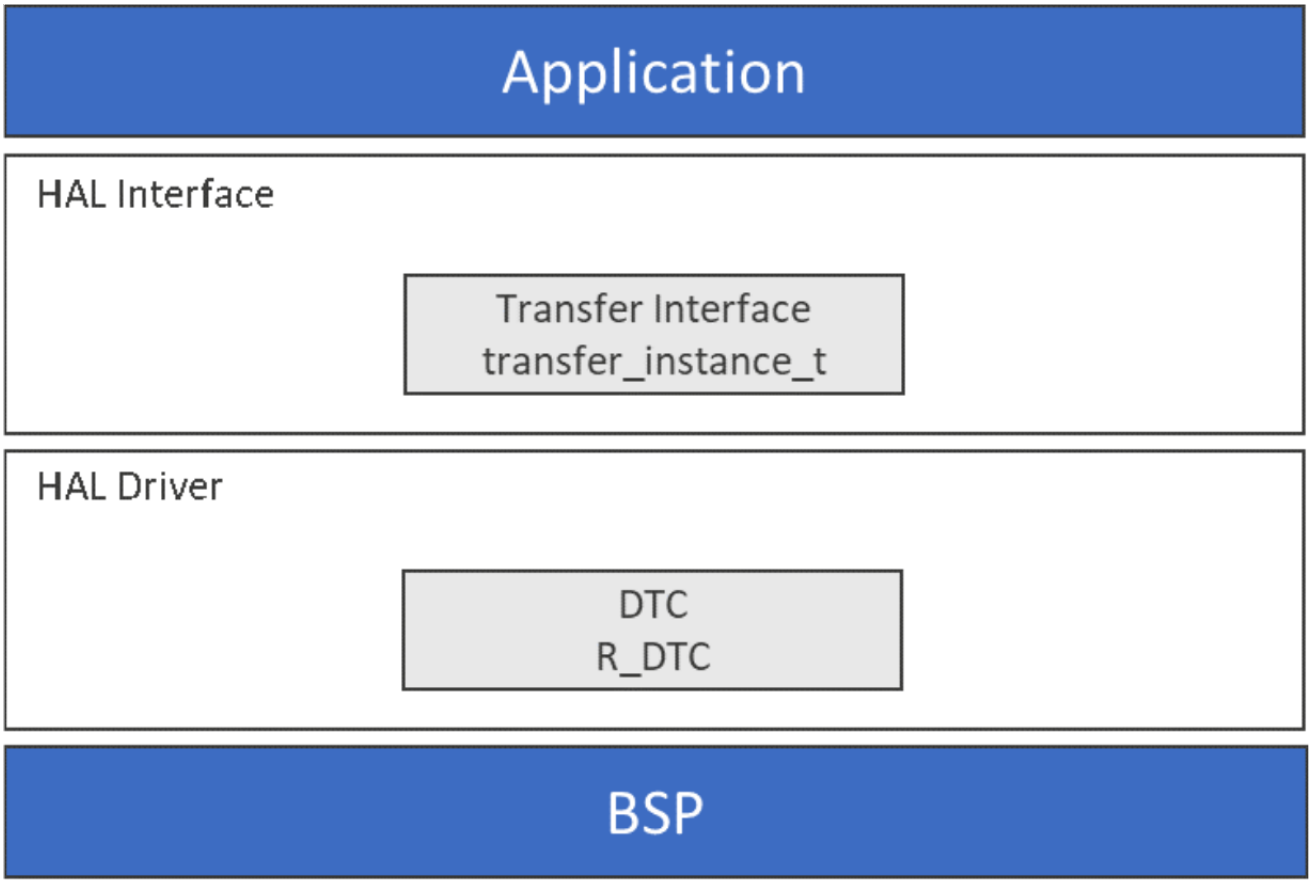

Figure 289: DTC HAL Module Block Diagram

DTC Hardware support details

The following hardware features are, or are not, supported by SSP for DTC.

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)

4.2.17.2 DTC HAL Module APIs Overview

The DTC HAL module defines APIs for opening, closing, resetting, enabling, disabling, starting and stopping. Note that the DTC and the DMAC use the same transfer interface to make it easier to change between DTC and DMA implementations. The API calls are the same independent of the lower-level implementations. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

DTC HAL Module API Summary

Function Name	Example API Call and Description
open	g_transfer0.api->open(g_transfer0.p_ctrl, g_transfer0.p_cfg) Initial configuration. Enables the transfer if auto_enable is true and p_src, p_dest, and length are valid. Transfers can also be enabled using enable or reset.
close	g_transfer0.api->close(g_transfer0.p_ctrl) Close device channel. Turns off hardware if last channel open.

reset	g_transfer0.api->reset(g_transfer0.p_ctrl, &source, &destination, number_of_transfers) Reset source address pointer, destination address pointer, and/or length, keeping all other settings the same. Enable the transfer if p_src, p_dest, and length are valid.
start	g_transfer0.api->start(g_transfer0.p_ctrl, mode) Start transfer in software.
stop	g_transfer0.api->stop(g_transfer0.p_ctrl) Stop transfer in software. The transfer will stop after completion of the current transfer.
enable	g_transfer0.api->enable(g_transfer0.p_ctrl) Enable transfer. Transfers occur after the activation source event (or when start is called if ELC_EVENT_ELC_SOFTWARE_EVENT_0 or ELC_EVENT_ELC_SOFTWARE_EVENT_0 is chosen as activation source).
disable	g_transfer0.api->disable(g_transfer0.p_ctrl) Disable transfer. Transfers do not occur after the transfer_info_t::activation source event (or when start is called if ELC_EVENT_ELC_SOFTWARE_EVENT_0or ELC_EVENT_ELC_SOFTWARE_EVENT_0 is chosen as transfer_info_t::activation_source).
versionGet	g_transfer0.api->versionGet(&version) Gets version and stores it in provided pointer version.
infoGet	g_transfer0.api->infoGet(g_transfer0.p_ctrl, &info) Provides information about this transfer.
blockReset	g_transfer0.api->blockReset(g_transfer0.p_ctrl, &source, &destination, length, size, number_of_transfers) Reset source address pointer, destination address pointer, and/or length, for block transfer keeping all other settings the same. Enable the transfer if p_src, p_dest, and length are valid.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	Parameter has invalid value.

SSP_ERR_NOT_OPEN	The channel is not opened.
SSP_ERR_UNSUPPORTED	Operation not configured correctly.
SSP_ERR_IN_USE	The channel specified has already been opened. No configurations were changed. Call the associated Close function or use associated Control commands to reconfigure the channel.
SSP_ERR_HW_LOCKED	The DTC hardware resource is locked.
SSP_ERR_IRQ_BSP_DISABLED	IRQ not enabled in BSP.
SSP_ERR_NOT_ENABLED	Operation failed.
SSP_ERR_NOT_OPEN	The channel is not opened.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.17.3 DTC HAL Module Operational Overview

The Direct Memory Access Controller (DMAC) and the Data Transfer Controller (DTC) can be used to move data within the Synergy MCU. There are some considerations when selecting between these implementations; the following operational overview includes information on each to help you determine which implementation is best for your application. The DTC module is recommended for most generic transfer applications, but either module can be used for basic transfer functionality. The use-cases for each transfer module are:

Selecting the DMAC HAL Module

The DMAC HAL module moves data from a user-specified source to a user-specified destination when an interrupt or event occurs. The DMAC HAL module uses DMAC peripheral registers, so the number of transfers in the system is limited to the number of DMAC channels on the device. The activation source does not have to be enabled to use the DMAC. When the DMAC transfer completes, a DMAC interrupt is called. If the activation source interrupt is enabled, it fires at the same time the transfer is triggered. If the DMAC interrupt is enabled, it fires after all transfers are complete. For example, if a normal-mode transfer with a length of 16 is triggered by a timer, the timer interrupt fires at the same time each transfer occurs and the DMAC interrupt fires after the 16th transfer completes. The DMAC HAL module does not support chained transfers.

Selecting the DTC HAL Module

The DTC HAL module uses a RAM-based vector table with slots for every interrupt in the system. When the DTC transfer completes, the activation source interrupt is called. The activation source interrupt must be enabled to use the DTC. The activation source interrupt is generally muted by the DTC until the transfer completes, unless TRANSFER_IRQ_EACH is specified in the configuration. For example, if a normal-mode transfer with a length of 16 is triggered by a timer, the timer interrupt does not fire the first 15 times while the transfer is in effect. After the 16th transfer, the timer interrupt fires. The DTC also allows chained transfers, meaning that more than one transfer can occur after a single activation-source interrupt. This feature is supported by the driver but must be configured outside the ISDE.

DTC HAL Module Important Operational Notes and Limitations

DTC HAL Module Operational Notes

Normal Mode

In normal mode, a single transfer is triggered each time an activation-source event occurs. A single transfer is 1 byte, 2 bytes or 4 bytes, depending on the setting selected in the size parameter. Each time a transfer occurs, the transfer length is decremented by 1. When the transfer length reaches 0, the transfer is complete.

Repeat Mode

In repeat mode, a single transfer is triggered each time an activation-source event occurs. A single transfer is 1 byte, 2 bytes or 4 bytes, depending on the setting selected in the size parameter. Each time a transfer occurs, the transfer length is decremented by 1. When the transfer length reaches 0, the transfer length is reloaded with its initial value and the transfer restarts. If the repeat area is set to source, the source register is also reloaded with its initial value when the transfer restarts. Alternatively, if the repeat area is set to destination, the destination register is reloaded with its initial value when the transfer restarts.

Block Mode

In the block mode, the entire transfer length is transferred each time an activation-source event occurs. For example, if a transfer is configured in block mode with the timer as the activation source, a 2-byte size, and a 12-byte length, 24 bytes are transferred each time the activation source event occurs. Each time a transfer occurs, the transfer length is decremented by 1. When the transfer length reaches 0, the transfer length is reloaded with its initial value and the transfer restarts. If the repeat area is set to source, the source register is also reloaded with its initial value when the transfer restarts. Alternatively, if the repeat area is set to destination, the destination register is reloaded with its initial value when the transfer restarts.

Address Mode

After each transfer of size (1 byte, 2 bytes, or 4 bytes), the source pointer and destination pointer are adjusted based on the configuration settings for Source Address Mode and Destination Address Mode, respectively. For example, if the Source Address Mode is set to TRANSFER_ADDR_MODE_INCREMENTED and the size is set to TRANSFER_SIZE_4_BYTES, the destination pointer is incremented by 4 (the transfer size) after each transfer. The pointer does not change if the configuration setting is TRANSFER_ADDR_MODE_FIXED.

Chained Transfers

Chained transfers are only supported by the DTC. To use a chained transfer, create an array of transfer_info_t structures. Configure transfer_chain_mode_t to TRANSFER_CHAIN_MODE_EACH or TRANSFER_CHAIN_MODE_END for all transfers except the last transfer. The last transfer must be TRANSFER_CHAIN_MODE_DISABLED.

Set transfer_cfg_t::p_info to the base of the first structure in the array for transfer_info_t structures.

DTC HAL Module Limitations

- Refer to the most SSP Release Notes for any additional operational limitations for this module.

4.2.17.4 Including the DTC HAL Module in an Application

This section describes how to include the DTC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Transfer Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Transfer Driver is g_transfer0. This name can be changed in the associated Properties window.)

DTC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ transfer0 DTC Driver on r_dtc	**Threads**> **HAL/Common**	**New Stack**> **Driver**> **Transfer**> **Transfer Driver on r_dtc**

When the Transfer Driver on r_dtc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

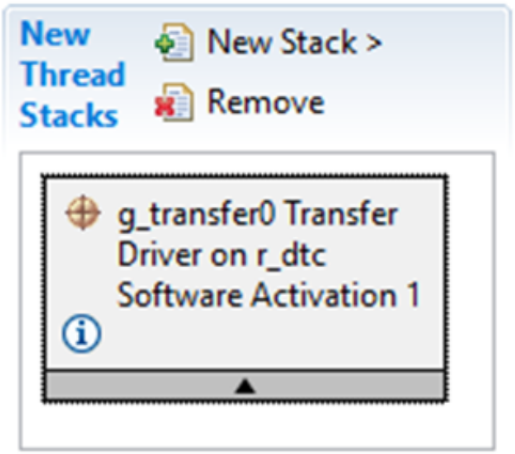

Figure 290: DTC HAL Module Stack

4.2.17.5 Configuring the DTC HAL Module

The DTC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties

tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the DTC HAL Module on r_dtc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Normal, Repeat, Block Default: Normal	Mode selection.
Transfer Size	2 Bytes	Transfer size selection.
Destination Address Mode	Fixed, Incremented, Destination Default: Fixed	Destination address mode selection.
Source Address Mode	Fixed, Incremented, Destination Default: Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination, Source Default: Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.

Auto Enable	True, False Default: True	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

DTC HAL Module Clock Configuration

The DTC peripheral module use ICLK as the clock source. The ICLK frequency is set by using the SSP configurator **Clocks** tab prior to a build, or by using the CGC Interface at run-time.

DTC HAL Module Pin Configuration

The DTC is not associated with any pins.

4.2.17.6 Using the DTC HAL Module in an Application

The typical steps in using the DTC HAL module in an application are:

1. Initialize the DTC using the transfer_api_t::open API.
2. Enable the DTC using the transfer_api_t::enable API (if not auto enabled).
3. Manage transfers using other APIs as needed.
4. Close the DTC with the transfer_api_t::close when needed.

These common steps are illustrated in a typical operational flow diagram in the following figure:

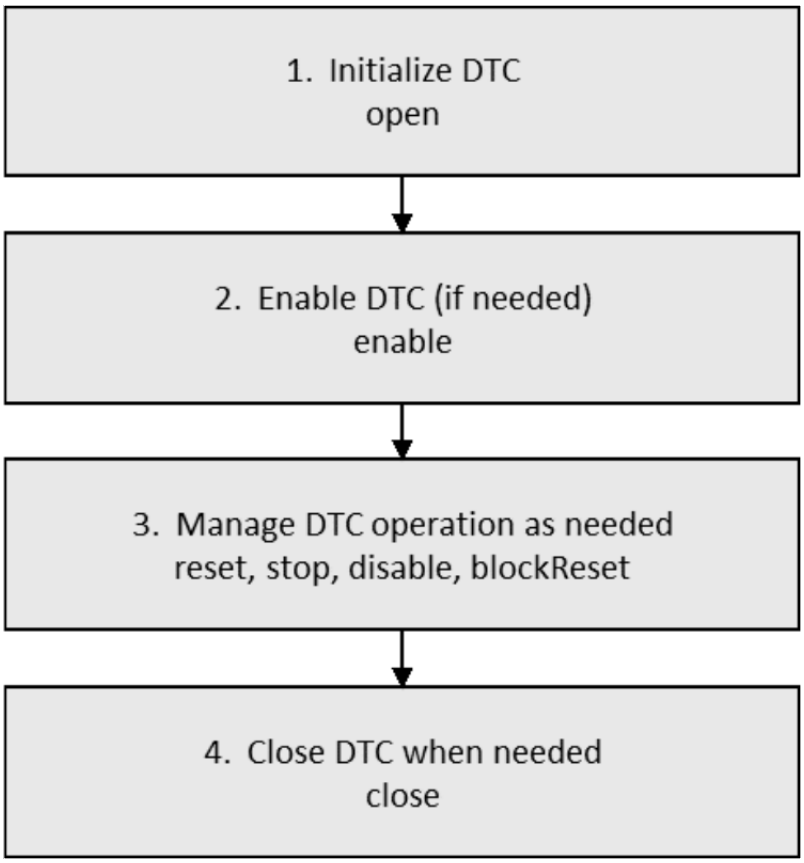

Figure 291: Flow Diagram of a Typical DTC HAL Module Application

4.2.18 ELC Driver

4.2.18.1 ELC HAL Module Introduction

The Event Link Controller (ELC) HAL module provides a high-level API for connecting various MCU peripherals for autonomous operation and uses the ELC peripheral on the Synergy MCU. There are no callbacks associated with the ELC HAL module. The project configurator in the e^2 studio Integrated Solution Development Environment (ISDE) includes the ELC HAL module in every project by default. To configure the ELC HAL module, select it in the HAL/Common module in the **Threads** tab and click on it in the HAL/Common Stacks window.

ELC HAL Module Features

The ELC HAL module can perform the following functions:

- Creates an event link between two blocks.
- Breaks that event link between two blocks.
- Generates one of two software events that interrupt the CPU.

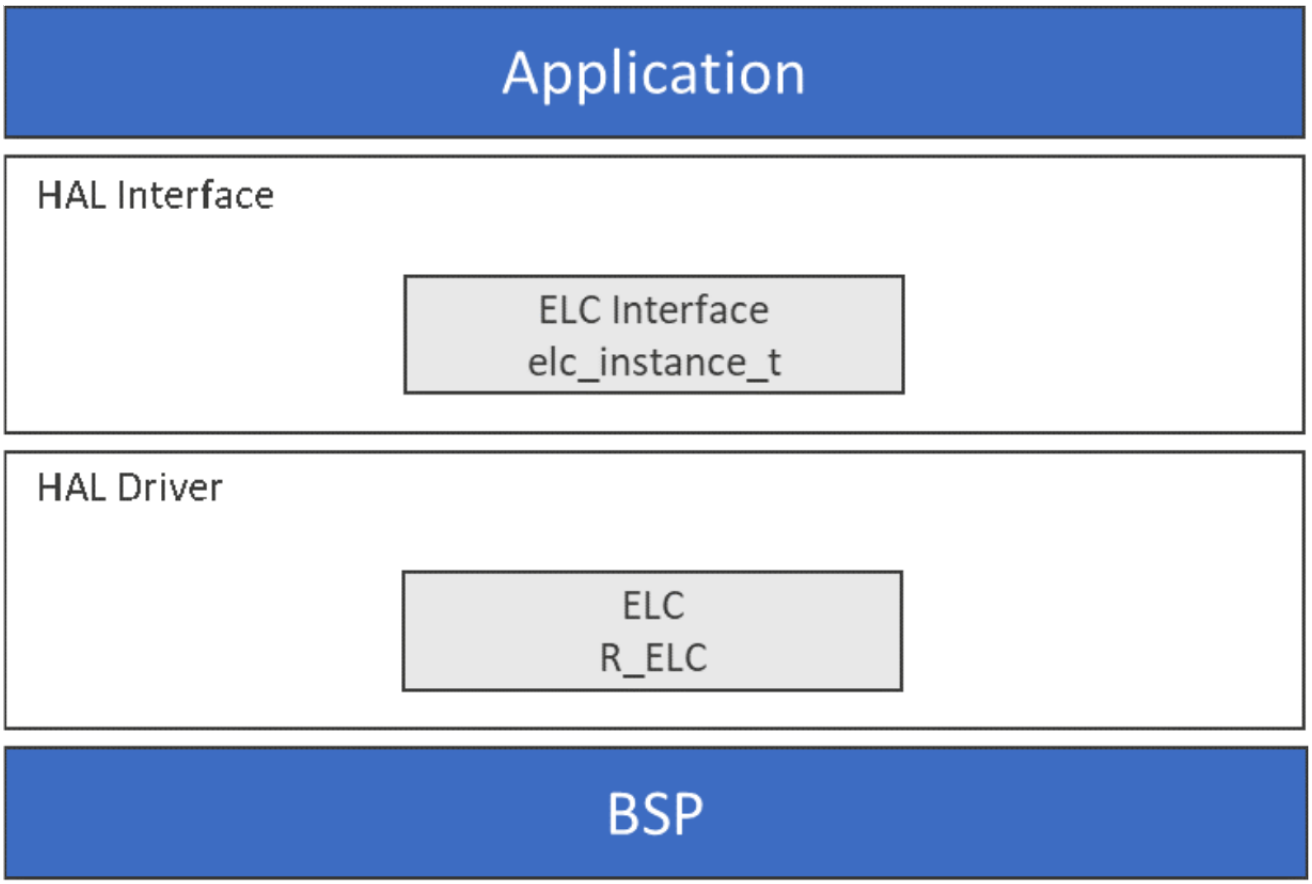

Figure 292: ELC HAL Module Block Diagram

ELC Hardware support details

The following hardware features are, or are not, supported by SSP for ELC.

Legend:

Symbol		Meaning	
✓		Available (Tested)	
☒		Not Available (Not tested/not functional or both)	
N/A		Not supported by MCU	
MCU Group	Create	Break	Generate

4.2.18.2 ELC HAL Module APIs Overview

The ELC HAL module defines APIs for initializing, enabling, disabling and creating or breaking event links between modules. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

ELC HAL Module API Summary

Function Name	Example API Call and Description
init	g_elc.p_api->init(g_elc.p_cfg) Initialize all links in the Event Link Controller.
softwareEventGenerate	g_elc.p_api->softwareEventGenerate(event_num) Generate a software event in the Event Link Controller.
linkSet	g_elc.p_api->linkSet(peripheral, signal) Create a single event link.
linkBreak	g_elc.p_api->linkBreak(peripheral) Break an event link.
enable	g_elc.p_api->enable() Enable the operation of the Event Link Controller.
disable	g_elc.p_api->disable() Disable the operation of the Event Link Controller.
versionGet	g_elc.p_api->versionGet(&version) Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successfully completed.
SSP_ERR_ASSERTION	p_version is NULL.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.18.3 ELC HAL Module Operational Overview

The ELC HAL module allows the developer to create events that link various peripheral operations by using events generated by one Synergy MCU peripheral to trigger the start of operation of another Synergy MCU peripheral. The ELC HAL module APIs make it easy to create a link between two blocks (for example, from a timer to an ADC to control a periodic scan interval). By connecting various peripherals in this way, intelligent functions can be constructed that require little, if any, CPU intervention.

The following figure shows a simplified block diagram of the ELC, showing the input event sources and the peripherals that can be triggered by these events. The number of input and output triggers is specific to the S7G2 MCU. Other Synergy devices support a different number of events.

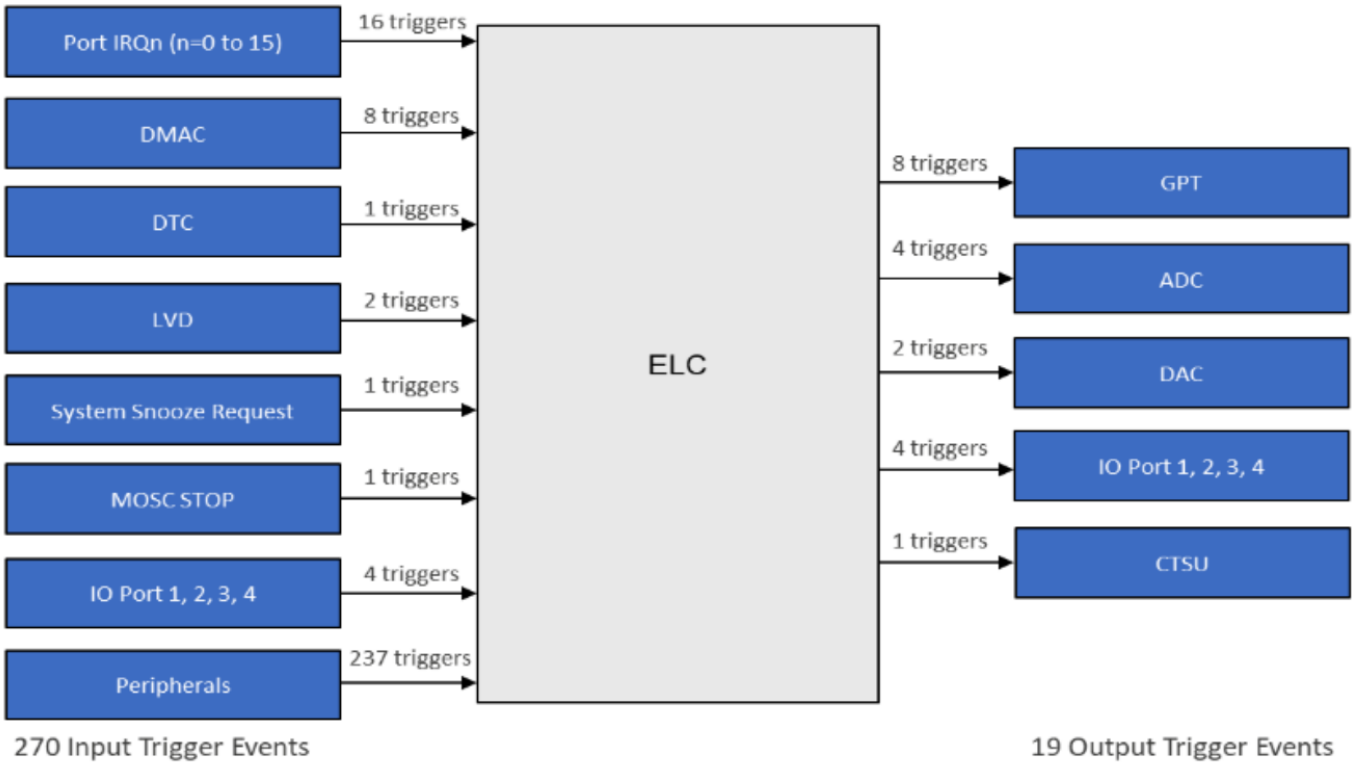

Figure 293: ELC HAL Module Trigger Events

It is possible to find the mapping of ELC peripherals in the file, bsp_elc.h, in the Synergy-generated code. The available peripherals and associated events for the S7G2 MCU are shown in the below figure. Additional information on ELC operation is also available in the associated MCU user's manual.

```
/** Possible peripherals to be linked to event signals */
typedef enum e_elc_peripheral
{
    ELC_PERIPHERAL_GPT_A                                    =    (0),
    ELC_PERIPHERAL_GPT_B                                    =    (1),
    ELC_PERIPHERAL_GPT_C                                    =    (2),
    ELC_PERIPHERAL_GPT_D                                    =    (3),
    ELC_PERIPHERAL_GPT_E                                    =    (4),
    ELC_PERIPHERAL_GPT_F                                    =    (5),
    ELC_PERIPHERAL_GPT_G                                    =    (6),
    ELC_PERIPHERAL_GPT_H                                    =    (7),

    ELC_EVENT_GLCDC_UNDERFLOW_2                             =  (508),
    ELC_EVENT_DRW_INT                                       =  (509),
    ELC_EVENT_JPEG_JEDI                                     =  (510),
    ELC_EVENT_JPEG_JDTI                                     =  (511),
} elc_event_t;
```

Figure 294: ELC HAL Peripheral Map

ELC HAL Module Important Operational Notes and Limitations

ELC HAL Module Operational Notes

The ELC HAL module needs no pin, clocking, or interrupt configuration. It is just a 'connect' mechanism between peripherals. However, if linking I/O Ports via the ELC, the I/O pins need to be configured as inputs or outputs.

ELC HAL Module Limitations

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.18.4 Including the ELC HAL Module in an Application

This section describes how to include the ELC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the ELC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the ELC Driver is g_elc0. This name can be changed in the associated Properties window.)

ELC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_elc ELC Driver on r_elc	Threads	**New Stack> Driver> System> ELC Driver on r_elc**

When the ELC Driver on r_elc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

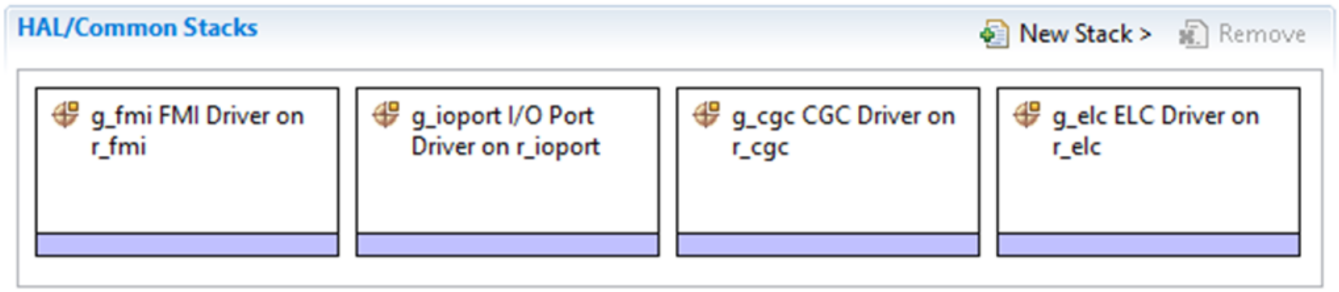

Figure 295: ELC HAL Module Stack

4.2.18.5 Configuring the ELC HAL Module

The ELC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the ELC HAL Module on r_elc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_elc	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

ELC HAL Module Clock Configuration

The ELC HAL module does not require a specific clock configuration.

ELC HAL Module Pin Configuration

There are no pins associated directly with the ELC HAL Module that require configuration.

4.2.18.6 Using the ELC HAL Module in an Application

The typical steps in using the ELC HAL module in an application are:

1. Initialize the ELC using the elc_api_t::init and enable APIs (automatically done by ISDE).
2. Link a peripheral with an event using elc_api_t::linkSet API.
3. Enable the linkage with the elc_api_t::enable API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

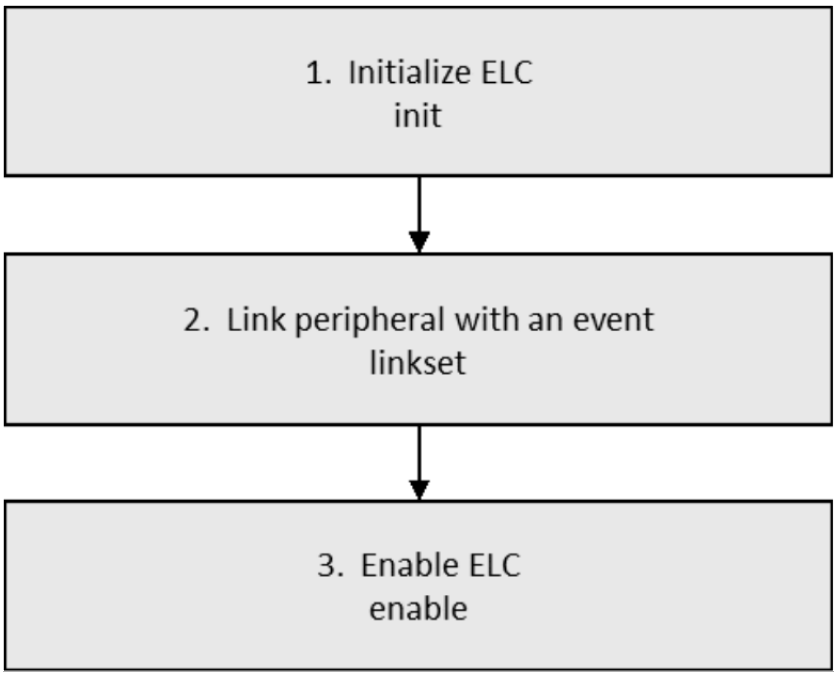

Figure 296: Flow Diagram of a Typical ELC HAL Module Application

4.2.19 External IRQ Driver

4.2.19.1 External IRQ HAL Module Introduction

The External IRQ HAL module provides an API for configuring and using external IRQ pins on Synergy MCUs. The External IRQ HAL module uses the Interrupt Controller Unit (ICU) of the Synergy MCU.

External IRQ HAL Module Features

- Supports the external interrupt pins available on the target Synergy MCU
- Supports multiple function options:
  - Enabling and disabling generation of an interrupt
  - Enabling and disabling the IRQ noise filter
  - Setting external pin IRQ trigger (Rising edge, falling edge or low level on the IRQ pin)
- Supports configuring a user callback function, which will be invoked by the HAL module when an external pin interrupt is generated.

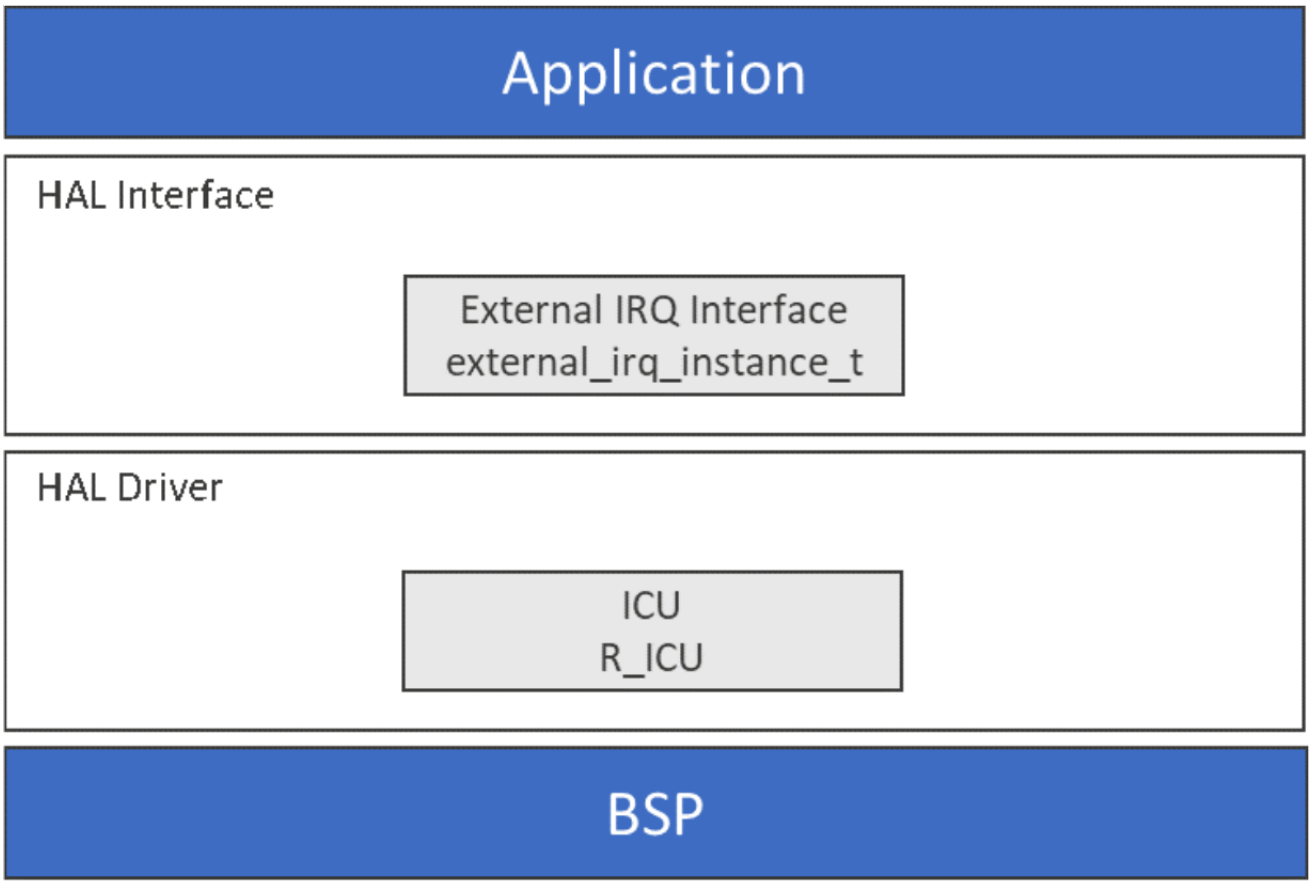

Figure 297: External IRQ HAL Module Block Diagram

The following hardware features are, or are not, supported by SSP for ICU.

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

MCU Group	Peripheral function interrupts	External pin interrupts	DTC and DMAC control	Interrupt sources for NVIC	Non-maskable interrupts (see notes)	Return from low power-mode (see notes)

S5D5	✓	✓	✓	✓	✓	✓
S5D9	✓	✓	✓	✓	✓	✓
S7G2	✓	✓	✓	✓	✓	✓

Notes: The ICU module in SSP (r_icu) handles only external pin interrupts and not the other features above. Peripheral function interrupts are controlled by BSPs for each MCU and each peripheral driver modules in SSP. DTC or DMA control is handled by DTC or DMAC module in SSP (r_dtc or r_dmac). Non-maskable interrupts supported in SSP are IWDT Underflow, WDT Underflow and Voltage Monitor Interrupts. Those NMIs are controlled by IWDT, WDT or LVD modules (r_iwdt, r_wdt, or r_lvd), respectively. LVD module (r_lvd) supports the Wake Up Interrupt Enable setting. For low power mode details, see the LPM section.

4.2.19.2 External IRQ HAL Module APIs Overview

The External IRQ HAL module defines APIs for opening, closing, and waiting for interrupt events from external pins. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

External IRQ HAL Module API Summary

Function Name	Example API Call and Description
open	g_external_irq.p_api->open(g_external_irq.p_ctrl, g_external_irq.p_cfg) Open instance and initialize.

enable	g_external_irq.p_api->enable(g_external_irq.p_ctrl) Enable callback when IRQ occurs.
disable	g_external_irq.p_api->disable(g_external_irq.p_ctrl) Disable callback when IRQ occurs.
triggerSet	g_external_irq.p_api->triggerSet(g_external_irq.p_ctrl, trigger) Set trigger.
filterEnable	g_external_irq.p_api->filterEnable(g_external_irq.p_ctrl) Enable noise filter.
filterDisable	g_external_irq.p_api->filterDisable(g_external_irq.p_ctrl) Disable noise filter.
close	g_external_irq.p_api->close(g_external_irq.p_ctrl); Close instance.
versionGet	g_external_irq.p_api->wait(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_INVALID_ARGUMENT	Callback is not NULL but ISR is not enabled.
SSP_ERR_IN_USE	Device in use.
SSP_ERR_NOT_OPEN	Device unopened.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.19.3 External IRQ HAL Module Operational Overview

The External IRQ HAL module provides a set of API functions for controlling external interrupts. Interrupts can be triggered on rising edge, falling edge, both edges or low level of the input signal on the external IRQ pin. A digital-filtering function can be enabled to eliminate some noise on the input signal. A user-callback function is supported and is triggered each time an IRQ event occurs.

To trigger a transfer of data using the DMAC or DTC peripheral when the configured external IRQ

event occurs, configure the DMAC or DTC transfer with the activation source set to ELC_EVENT_PORTn_IRQ (where n is the IRQ channel number.)

Other peripherals can be triggered to start from an external interrupt using the Event Link Controller (ELC.) Refer to the SSP User Manual User Guide for the ELC HAL module for more information.

External IRQ HAL Module Important Operational Notes and Limitations

External IRQ HAL Module Operational Notes

- Refer to the datasheet for the target Synergy device to find the port pins which support the external interrupt functions and to obtain the external IRQ number for a given port pin.
- The external IRQ number corresponds to the channel setting in the ISDE Properties window for the External IRQ HAL module.
- The PORTn (where n is the IRQ number) interrupt must be enabled in the BSP to notify the module that the anticipated hardware event has occurred.
- A user-callback function can be registered in the external_irq_api_t::open API. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the IRQn triggers.

    - *Note*

      Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can adversely affect the responsiveness of the system.

External IRQ HAL Module Limitations

- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.19.4 Including the External IRQ HAL Module in an Application

This section describes how to include the External IRQ HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the External IRQ Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the External IRQ Driver is g_icu0. This name can be changed in the associated Properties window.)

External IRQ HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
r_icu0 External IRQ Driver on r_icu	Threads	**New Stack> Driver> Input> External IRQ Driver on r_icu**

When the External IRQ Driver on r_icu is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need

only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

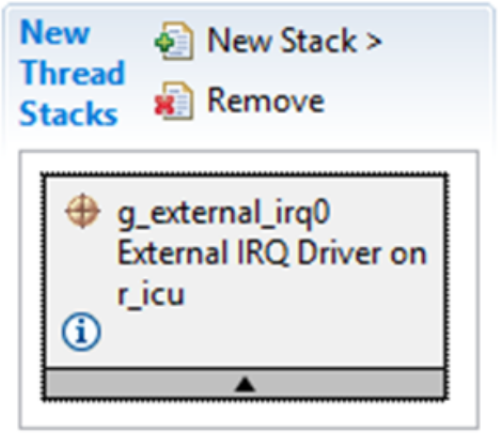

Figure 298: External IRQ HAL Module Stack

4.2.19.5 Configuring the External IRQ HAL Module

The External IRQ HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the External IRQ HAL Module on r_icu

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter checking setting enables or disables the addition of parameter checking code.
Name	g_external_irq0	Module name.
Channel	0	Specifies the hardware IRQ channel used.

Trigger	Falling, Rising, Both Edges, Low Level Default: Rising	Selection for trigger event mode
Digital Filtering	Enabled, Disabled Default: Disabled	Digital filter enable/disable.
Digital Filtering Sample Clock (Only valid when Digital Filtering is Enabled)	PCLK/1, PLCK/8, PLCK/32, PCLK/64 Default: PCKL/64	Sets noise filter sampling period.
Interrupt enabled after initialization	True, False Default: True	Determines if the interrupt is enabled immediately after initialization.
Callback	NULL	A user callback function can be registered in external_irq_api_t::open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Pin Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

External IRQ HAL Module Clock Configuration

The IRQ peripheral module does not require any specific clock settings.

External IRQ HAL Module Pin Configuration

The External IRQ peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the IRQ pins.

Pin Selection for the External IRQ HAL Module on r_icu

Resource	ISDE Tab	Pin selection Sequence
IRQ	Pins	Select **Peripherals**> **Input: IRQ**> **IRQ0**

Note

The selection sequence assumes IRQ0 is the desired hardware target for the driver.

Pin Configuration Settings for the External IRQ HAL Module on r_icu

Property	Value	Description
Operation Mode	Disabled, Enabled Default: Disabled	Select Enabled to enable interrupts.
NMI	None, P200 Default: None	Non-maskable interrupt Pin.
IRQ00:14	None, Pnn, Pmm Default: None	Interrupt request Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.2.19.6 Using the External IRQ HAL Module in an Application

The typical steps in using the External IRQ HAL module in an application are:

1. Initialize the External IRQ HAL module using the external_irq_api_t::open API.
2. Enable the IRQ (if needed) with the external_irq_api_t::enable API.
3. Enable the noise filter (if needed) with the external_irq_api_t::filterEnable API.
4. Change the trigger condition (only if the module is closed previously to avoid any false events) with the external_irq_api_t::triggerSet API.
5. Disable the noise filter (if enabled) with external_irq_api_t::filterDisable API.
6. Close the module (if needed) with the external_irq_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

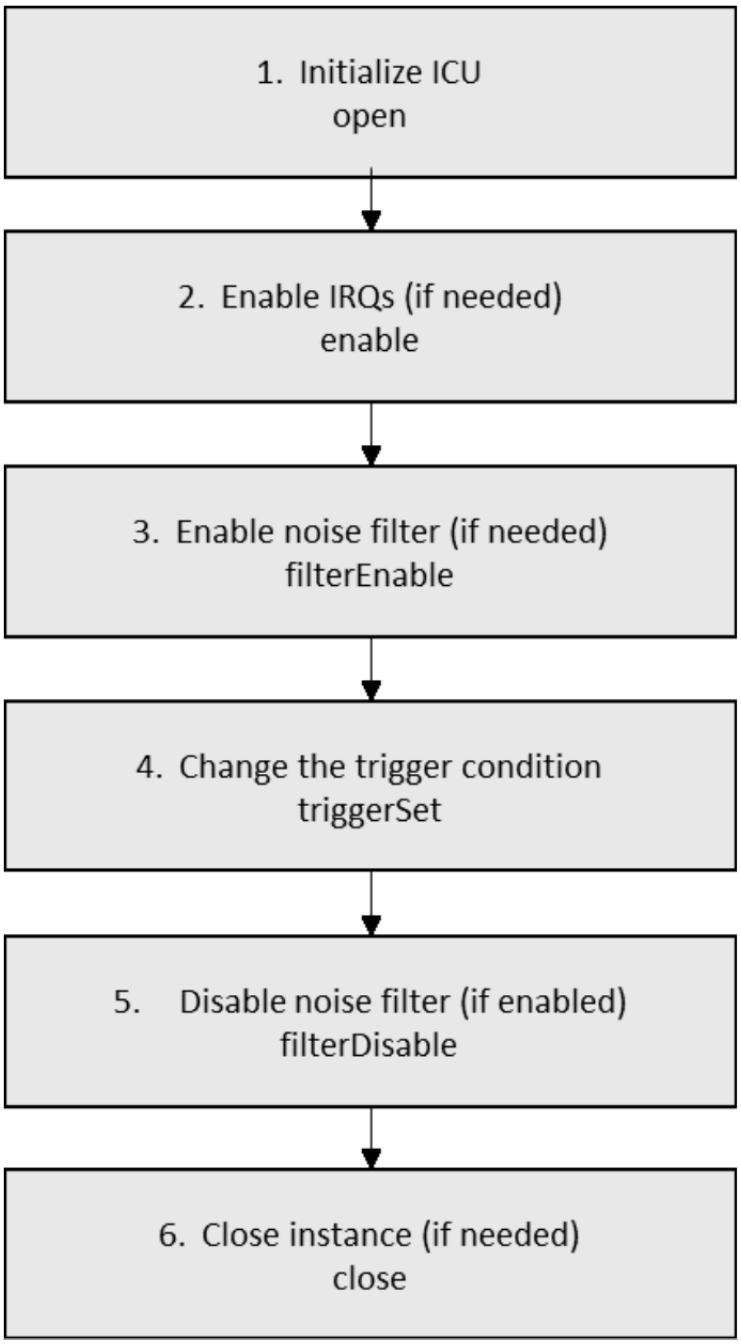

Figure 299: Flow Diagram of a Typical External IRQ HAL Module Application

4.2.20 Flash Driver

4.2.20.1 Flash HAL Module Introduction

There are two separate Flash modules: the r_flash_lp and the r_flash_hp. These modules implement a high-level API for flash memory programming applications. The High-Performance Flash module (Flash_HP) is used for programming the S7 and S5 family of MCUs. The Low-Power Flash module

(Flash_LP) is used for programming the S3 and S1 family of MCUs. The two are not interchangeable, although the APIs and other features of the modules are very similar.

Flash HAL Module Features

The Flash HAL modules APIs allow an application to read, write and erase both the data and ROM flash areas that reside within the MCU. The amount of flash memory available varies across MCU parts, but the API functions apply to all devices. Key features of the Flash HAL modules include:

- Support for both blocking and non-blocking erasing, reading, writing and blank-checking of data flash.
- Support for blocking erasing, reading, writing and blank checking of code flash.
- Support for callback functions for completion of non-blocking data-flash operations.
- Support for access window (write protection) for ROM Flash, allowing only specified areas of code flash to be erased or written.
- Support for boot block-swapping which allows safe rewriting of the startup program without first erasing it.

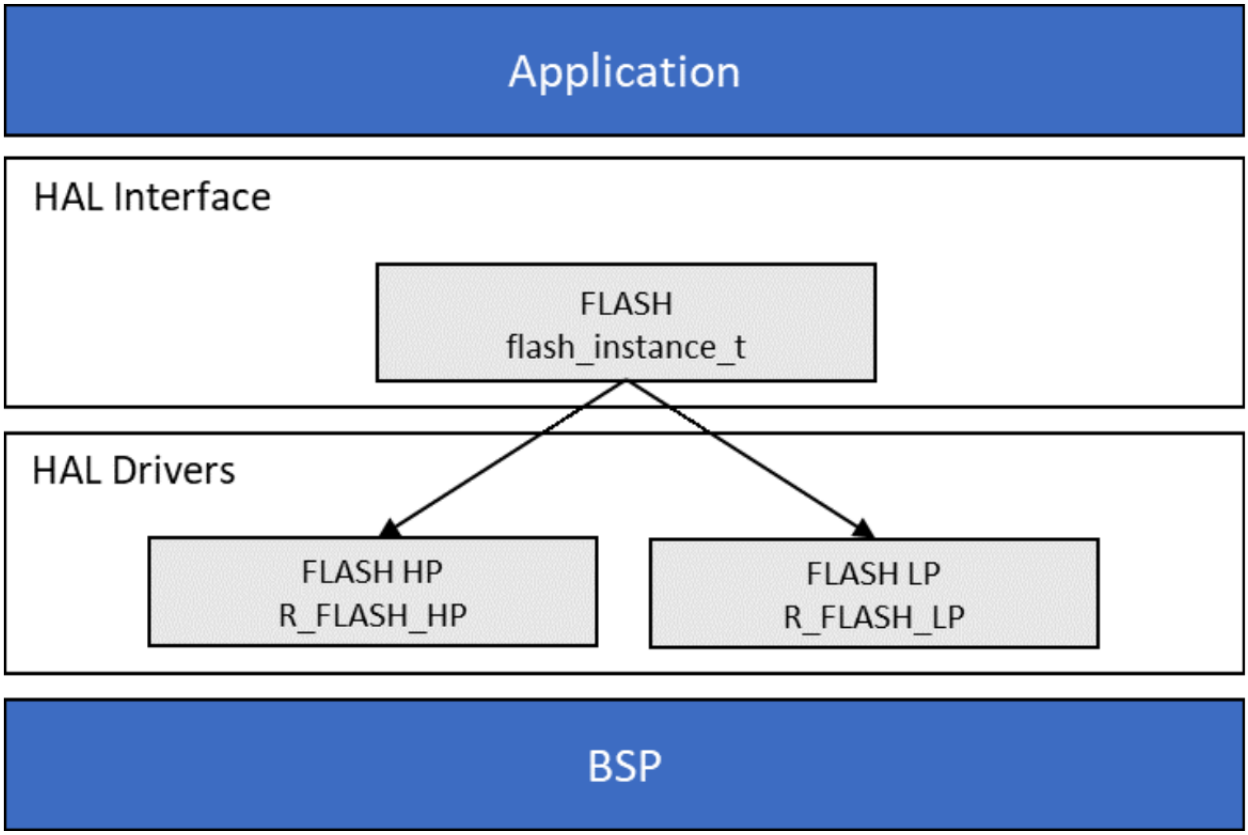

Figure 300: Flash HAL Module Block Diagram

4.2.20.2 Flash HAL Module APIs Overview

The Flash HAL module defines APIs for several operations including opening, reading, erasing and closing the flash memory. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Flash HAL Module API Summary

Function Name	Example API Call and Description
open	g_flash0.p_api->open(g_flash0.p_ctrl, g_flash0.p_cfg); Open FLASH device.
write	g_flash0.p_api->write(g_flash0.p_ctrl,(uint32_t) write_buffer, FLASH_CF_32KB_BLOCK55, CODE_BLOCK_SIZE_32KB); Write FLASH device.
read	g_flash0.p_api->read(g_flash0.p_ctrl, read_buffer, DATA_FLASH_ADDR, num_bytes); Read FLASH device.
erase	g_flash0.p_api->erase(g_flash0.p_ctrl, FLASH_CF_32KB_BLOCK55,num_sectors); Erase FLASH device.
blankCheck	g_flash0.p_api->blankCheck(g_flash0.p_ctrl, FLASH_CF_32KB_BLOCK55, FLASH_DATA_BLOCK_SIZE, &blankCheck); Blank check FLASH device.
close	g_flash0.p_api->close(g_flash0.p_ctrl); Close FLASH device.
statusGet	g_flash0.p_api->statusGet(g_flash0.p_ctrl); Get Status for FLASH device.

accessWindowSet	g_flash0.p_api->accessWindowSet(g_flash0.p_ctrl, FLASH_CF_32KB_BLOCK1, FLASH_CF_32KB_BLOCK3); Set Access Window for FLASH device.
accessWindowClear	g_flash0.p_api->accessWindowClear(g_flash0.p_ctrl); Clear any existing Code Flashcode-flash access window for FLASH device.
idCodeSet	g_flash0.p_api->idCodeSet(g_flash0.p_ctrl, id_bytes, mode) Write the ID code provided to the id code registers.
reset	g_flash0.p_api->reset(g_flash0.p_ctrl); Reset function for FLASH device.
updateFlashClockFreq	g_flash0.p_api-> updateFlashClockFreq (g_flash0.p_ctrl); Update Flash clock frequency (FCLK) and recalculate timeout values.
startupAreaSelect	g_flash0.p_api->startupAreaSelect(g_flash0.p_ctrl, FLASH_STARTUP_AREA_BLOCK1); Select which block - Default (Block 0) or Alternate (Block 1) is used as the start-up area block. Refer to the following table for all the possible values for parameter2.
versionGet	g_flash0.p_api->versionGet(&version); Retrieve the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

startupAreaSelect parameter2 options

Swap Type	Is_temporary	Operation
FLASH_STARTUP_AREA_BLOCK0	False	On next reset, Startup area will be Block 0.
FLASH_STARTUP_AREA_BLOCK0	False	On next reset, Startup area will be Block 0.
FLASH_STARTUP_AREA_BLOCK1	False	On next reset, Startup area will be Block 1.
FLASH_STARTUP_AREA_BLOCK1	True	Startup area is immediately, but temporarily switched to Block 1.

FLASH_STARTUP_AREA_BTFLG	True	Startup area is immediately, but temporarily switched to the Block determined by the Configuration BTFLG.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_IN_USE	Device in use error.
SSP_FLASH_ERR_FAILURE	Flash failure error.
SSP_ERR_FCLK	FCLK must be a minimum of 4 MHz for Flash operations.
SSP_ERR_TIMEOUT	Timeout error.
SSP_ERR_INVALID_SIZE	Invalid size error.
SSP_ERR_INVALID_ADDRESS	Invalid address error.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_INVALID_BLOCKS	Invalid number of blocks specified.
SSP_ERR_INVALID_ARGUMENT	Invalid argument error.
SSP_ERR_HW_LOCKED	Peripheral already in use.
SSP_ERR_CMD_LOCKED	FCU is in locked state, typically as a result of attempting to Erase an area that is protected by an Access Window.
SSP_ERR_NOT_OPEN	Flash has not yet been opened.
SSP_ERR_IRQ_BSP_DISABLED	Caller is requesting BGO (background mode operation) but the Flash interrupt is not enabled.
SSP_ERR_WRITE_FAILED	Write operation failed. This may be returned if the requested Flash area is not blank.
SSP_ERR_PE_FAILURE	Failed to enter P/E mode
false	Supplied address is valid flash address on this MCU.
true	Supplied address is valid and p_block info contains the details on this address's block.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.20.3 Flash HAL Module Operational Overview

The Flash API makes the process of programming and erasing on-chip flash areas easy. Both code (user ROM) and data-flash areas are supported. The API, in its simplest form, can be used to perform

blocking erase and program operations. The term "blocking" means that when a program or erase function is called, the function does not return until the operation has finished. This API supports blocking for both code and data-flash, with non-blocking operation (also known as BGO or Background Operation) available for data-flash operations only. When a code-flash operation is on-going, you cannot access that code-flash area. If you attempt to access the code-flash area while a code-flash operation is in progress, the flash-control unit will transition into an error state.

It is important to keep in mind that even though a code-flash operation is blocking, there are several situations where the code-flash could still end up being accessed while the operation is blocking and these must be prevented. This includes:

- Vector table access if the Vector table is located in ROM.
- ROM access by an interrupt vectoring to a ROM address, even if the vector table itself is not in ROM.

A multithreaded application where multiple threads are allowed to continue to run while a code-flash operation is blocking.

Flash HAL Module Important Operational Notes and Limitations

Flash HAL Module Operational Notes

Data-Flash BGO Precautions

When using the data-flash BGO, the user ROM, RAM and external memory can still be accessed. You must ensure that the data-flash is not accessed during a data-flash operation. This includes interrupts that may access the data-flash.

Code-Flash Precautions

BGO mode is not supported for code-flash, so a code-flash operation will not return before the operation has completed. By default, the vector table resides in the user ROM (code-flash.) If an interrupt occurs during the ROM operation, then ROM will be accessed to fetch the interrupt's starting address and an error will occur.

The simplest work-around is to disable interrupts during code-flash operations. Another option is to copy the vector table to RAM, update the VTOR (Vector Table Offset Register) accordingly and ensure that any interrupt service routines execute out of RAM. Similarly, you must insure that if in a multithreaded environment, threads running from ROM cannot become active while a code-flash operation is in progress.

Blank Checking

The flash_api_t::blankCheck API function checks whether code or data-flash contents are blank. Note that it is not possible to write to flash (code or data) without first erasing it. The flash_api_t::blankCheck function determines whether a specified area is blank and therefore writable. In almost all cases, it is not sufficient to compare flash contents to 0xFF to determine whether the area is blank. The one exception is Flash HP code-flash. A 0xFF in Flash_HP code-flash does indicate blank. Renesas strongly recommends using the flash_api_t::blankCheck API function in all cases.

Flash Status

The flash_api_t::statusGet API function allows the application to query the 'Ready' status of the flash. This is useful in data-flash BGO operations when you choose not to use a callback function, so there is no asynchronous notification of a completed data-flash operation. In this case, the data-flash is

configured to operate in BGO mode, so once the operation is started (an erase, for example), the call returns immediately with the operation executing in the background. By calling the flash_api_t::statusGet API function, you can determine when the operation has safely completed or generated an error, and it is now safe to proceed with another flash operation.

Swap Blocks

The flash_api_t::startupAreaSelect API function allows the user to select which block - default (Block 0) or alternate (Block 1) - is used as the startup-area block. The provided parameters determine which block will become the active startup block and whether that action will be immediate (but temporary) or permanent subsequent to the next reset.

Doing a temporary switch might appear to have limited usefulness; however, if there is an access window in place such that Block 0 is write-protected, then you could do a temporary switch, update the block, and switch them back without having to touch the access window.

Flash Clock (FCLK)

The FCLK is the clock used by the Flash peripheral in performing all Flash operations. It must be >= 4 MHz for successful flash operations. As part of the flash_api_t::open function the Flash clock is checked and if < 4 MHz flash_api_t::open will return SSP_ERR_FCLK. Once the Flash API has been opened, if the FCLK frequency is changed, the flash_api_t::updateFlashClockFreq API function must be called to inform the API of the change. Failure to do so could result in flash operation failures and possibly damage the part.

Interrupts

Enable the flash ready interrupt only if you plan to use the data-flash BGO. In this mode, the application can initiate a data-flash operation and then be asynchronously notified of its completion, or an error, using a user supplied-callback function. The callback function is passed a structure containing event information that indicates the source of the callback event (that is, flash_api_t::FLASH_EVENT_ERASE_COMPLETE)

When the FLASH FRDYI interrupt is enabled, the corresponding ISR will be defined in the flash driver. The ISR will call a user-callback function if one was registered with the flash_api_t::open API.

Note

The Flash HP supports an additional flash-error interrupt and if the BGO mode is enabled for the FLASH HP then both the Flash Ready Interrupt and Flash Error Interrupts must be enabled (assigned a priority).

Access Window

An access window defines a contiguous area in Code Flash for which programming/erase is enabled. This area is on block boundaries with a starting and ending address being provided to flash_api_t::accessWindowSet. The block containing the start address is the first block. The block containing the end address is the last block. The access window then becomes the first block – last block inclusive. Anything outside this range is write protected. Invalid address information provided to flash_api_t::accessWindowSet will return SSP_ERR_INVALID_ADDRESS. An access window may be removed by calling the flash_api_t::accessWindowClear API function

ID code set

Allows user to program the ID bytes rather than having the pre-programmed ID bytes with S-record.

Flash HAL Module Limitations

- The High-Performance Flash module (Flash_HP) is the API used for programming the S7 and S5 family of MCUs.
- The Low-Power Flash module (Flash_LP) is the API used for programming the S3 and S1 family of MCUs.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.20.4 Including the Flash HAL Module in an Application

This section describes how to include the Flash HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Flash Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Flash Driver is g_flash0. This name can be changed in the associated Properties window.)

Flash HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_flash0 Flash Driver on r_rflash_hp	Threads	**New Stack> Driver> Storage> Flash Driver on r_flash_hp**
g_flash0 Flash Driver on r_rflash_lp	Threads	**New Stack> Driver> Storage> Flash Driver on r_flash_lp**

When the Flash Driver on r_flash_hp or r_flash_lp is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

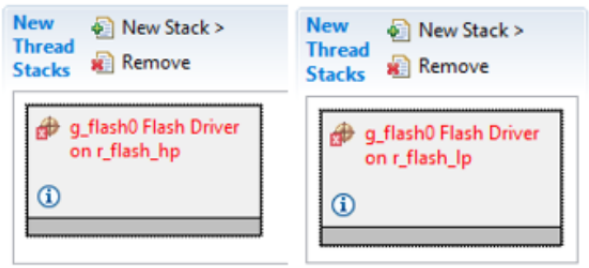

Figure 301: Flash HAL Module Stack

4.2.20.5 Configuring the Flash HAL Module

The Flash HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Flash HAL Module on r_flash_hp

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Code Flash Programming Enable	Enable, Disabled Default: Disabled	Controls whether or not Code Flash programming is enabled. Disabling reduces the amount of ROM used by the API.
Name	g_flash0	Module name.
Data Flash Background Operation	Enabled, Disabled Default: Enabled	Enabling allows Flash API calls that reference Data Flash to return immediately, with the operation continuing in the background.
Callback	NULL	Callback function called when a Data Flash BGO operation completes or errors. A user callback function can be registered in open. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Flash Ready Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Flash ready interrupt priority selection.

Flash Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Flash error interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Flash HAL Module on r_flash_lp

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
Code Flash Programming Enable	Enable, Disabled Default: Disabled	Controls whether or not Code Flash programming is enabled. Disabling reduces the amount of ROM used by the API.
Name	g_flash0	Module name.
Data Flash Background Operation	Enabled, Disabled Default: Enabled	Enabling allows Flash API calls that reference Data Flash to return immediately, with the operation continuing in the background.
Callback	NULL	Callback function called when a Data Flash BGO operation completes or errors. A user callback function can be registered in open. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Flash Ready Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Flash ready interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to disable code-flash programming to reduce the code size of the driver.

Flash HAL Module Clock Configuration

Enable the flash-ready interrupt only if you plan to use the data-flash BGO (background mode operation.) In this mode, the application can initiate a data-flash operation and then be asynchronously notified of its completion (or an error) using a user-supplied callback function. The callback function is passed a structure containing event information that indicates the source of the callback event (for example, FLASH_EVENT_ERASE_COMPLETE.)

To enable interrupts, set the priority of the FCU > FRDYI interrupt on the **ICU** tab of the Project Configurator in e^2 studio. This sets BSP_IRQ_CFG_FCU_FRDYI in synergy_cfg/ssp_cfg/bsp/bsp_irq_cfg.h to the priority level selected.

When the FLASH FRDYI interrupt is enabled in the BSP, the corresponding ISR will be defined in the Flash driver. The ISR will call a user-callback function if one was registered in open.

Note

The Flash HP supports an additional flash-error interrupt, and if BGO mode is enabled, then both FRDYI and FIFERR interrupts must be given a priority.

Flash HAL Module Pin Configuration

The flash circuit uses FCLK as its clock. FCLK must be <= 4 MHz. If this clock rate changes after the flash_api_t::open API is called, then you must call flash_api_t::updateFlashClockFreq API to inform the flash API of the change.

4.2.20.6 Using the Flash HAL Module in an Application

The typical steps in using the Flash HAL module in an application are:

1. Initialize the Flash HAL using the flash_api_t::open API.
2. Disable Interrupts.
3. Blank check a code flash area with flash_api_t::blankCheck API.
4. Erase one or more code-flash blocks with flash_api_t::erase API.
5. Write to code-flash with the flash_api_t::write API.
6. Enable Interrupts.
7. Blank check a data flash area with flash_api_t::blankCheck API.
8. Erase one or more data-flash blocks using the flash_api_t::erase API.
9. Write to data-flash using the flash_api_t::write API.
10. Enable Data Flash BGO mode and assign a callback function.
11. Erase one or more data-flash blocks using the flash_api_t::erase API.
12. Verify that the Erase has completed successfully by checking the event info passed to the callback.
13. Close using the flash_api_t::close API if finished with all Flash operations.

These common steps are illustrated in a typical operational flow diagram in the following figure:

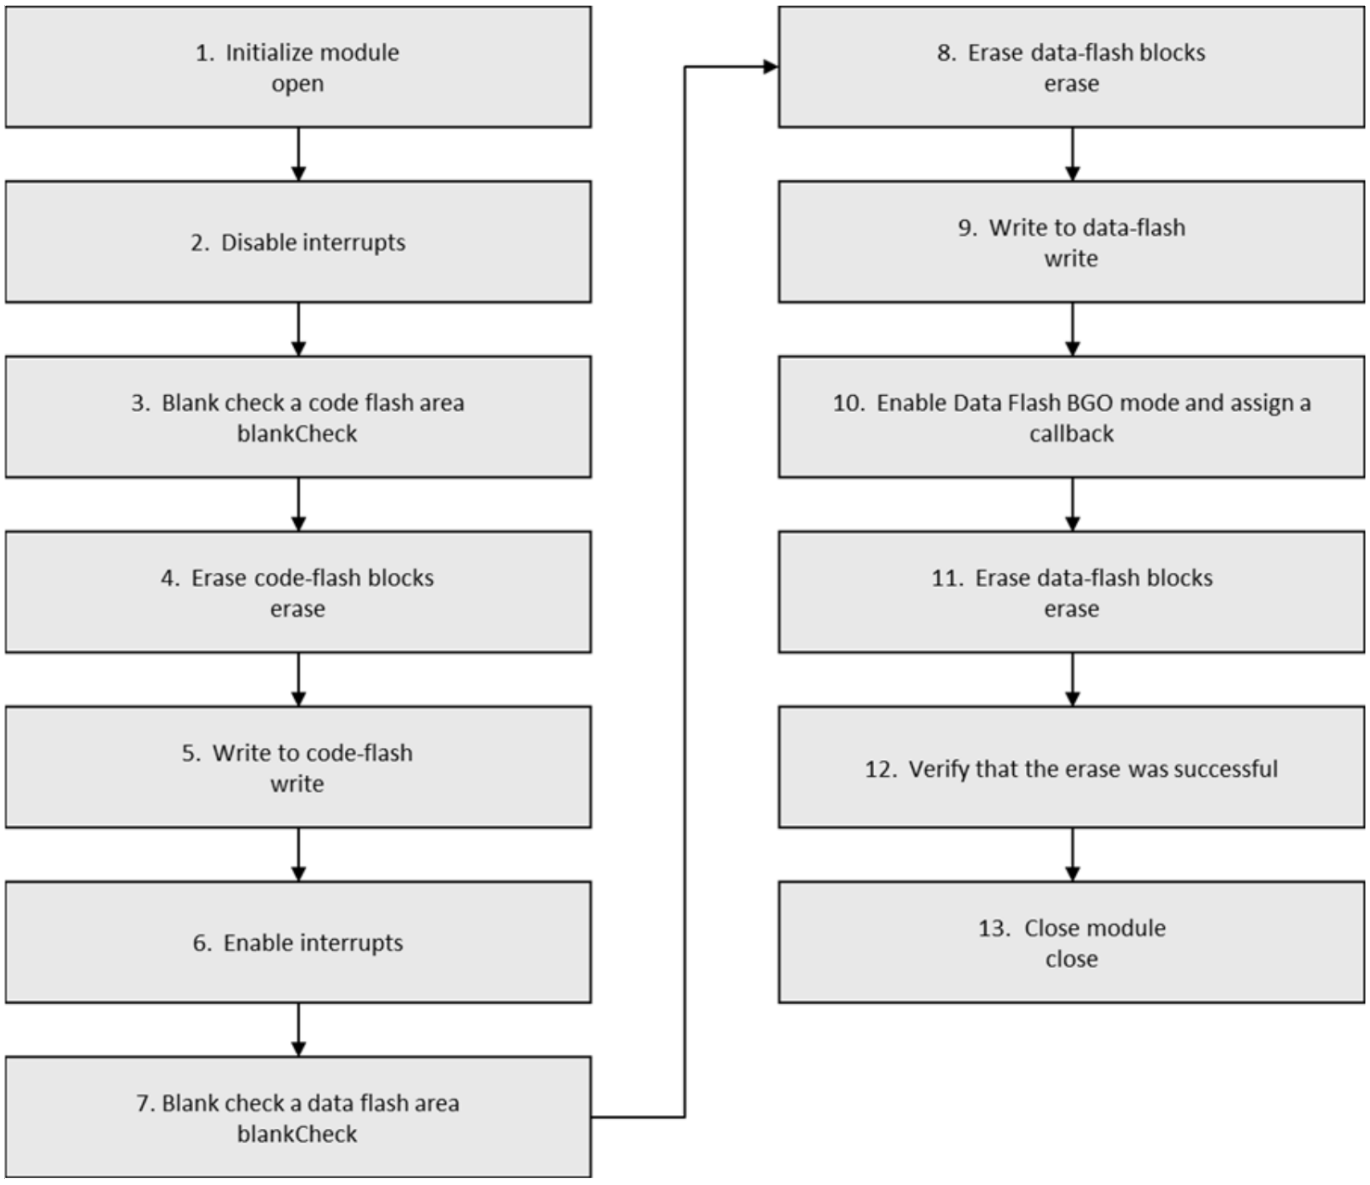

Figure 302: Flow Diagram of a Typical Flash HAL Module Application

4.2.21 FMI Driver

4.2.21.1 FMI HAL Module Introduction

The FMI HAL module provides a high-level API for applications that read records from the Factory MCU Information Flash Table and uses the Flash Interface on the Synergy MCU.

FMI HAL Module Features

The FMI HAL module reads the FMIFRT (Factory MCU Information Flash Root Table) on a Synergy microcontroller, looking up the address of the start of the table in flash. The module sets the caller's

pointer to the Product Information record from the table. This information may be used to determine the capabilities of features specific to this MCU package. Information available from the FMI HAL module includes:

- Product information (that is, product name, package, pin count and temperature range)
- Product features (version major, version minor and variant data)
- Event information such as interrupts and events

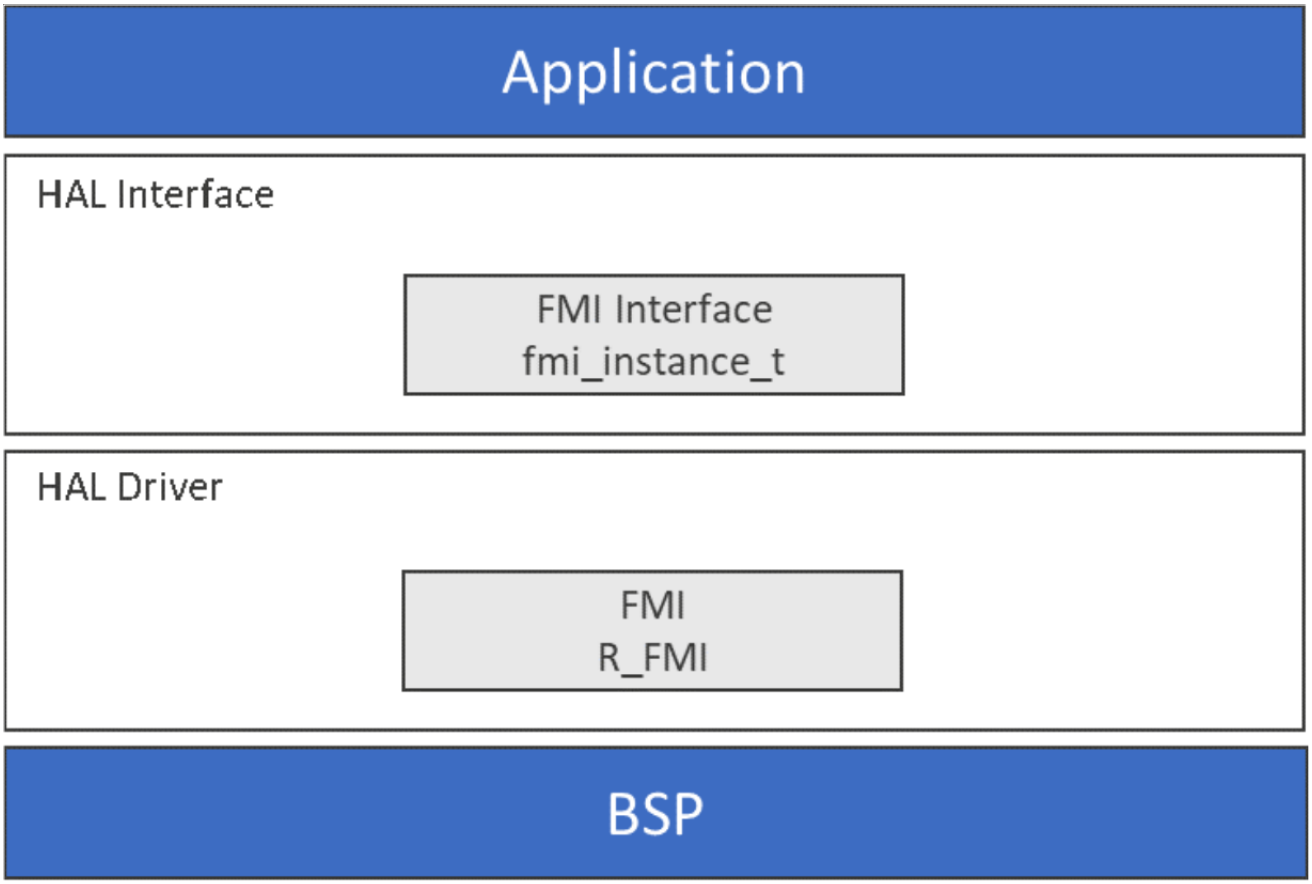

Figure 303: FMI HAL Module Block Diagram

4.2.21.2 FMI HAL Module APIs Overview

The FMI HAL module defines an API for accessing the FMIFRT. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

FMI HAL Module API Summary

Function Name	Example API Call and Description
init	g_fmi.p_api->init(); Initialize the FMI base pointer.
productInfoGet	g_fmi.p_api->productInfoGet(&g_pp_product_info); Get product information record address into g_pp_product_info pointer.

uniqueIdGet	g_fmi.p_api->uniqueIdGet(&g_p_unique_id); Copy the unique ID into the g_p_unique_id pointer.
productFeatureGet	g_fmi.p_api->productFeatureGet(&g_ssp_feature, &g_feature_info); Get feature information and store it in g_feature_info pointer.
eventInfoGet	g_fmi.p_api->eventInfoGet(&g_ssp_feature,SSP_SIGNAL_GPT_COUNTER_OVERFLOW, &g_event_info); Get event information and store it in g_event_info pointer.
versionGet	g_fmi.p_api->versionGet(&g_p_version); Get the driver version based on compile time macros.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_FMI_DATA	The FMI data table provided is not valid
SSP_ERR_IP_CHANNEL_NOT_PRESENT	Requested channel does not exist on this MCU
SSP_ERR_IP_UNIT_NOT_PRESENT	Requested unit does not exist on this MCU
SSP_ERR_INTERNAL	Requested feature is in a format not supported at this time
SSP_ERR_IRQ_BSP_DISABLED	Event information could not be found
SSP_ERR_ASSERTION	Caller's pointer is null
SSP_ERR_INVALID_FACTORY_FLASH	Factory flash is not valid

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.21.3 FMI HAL Module Operational Overview

The FMI HAL module retrieves the product information record address and populates the fmi_product_info_t structure using the fmi_api_t::productInfoGet API.

The FMI HAL module copies unique ID and populates the fmi_unique_id_t structure using the fmi_api_t::uniqueIdGet API.

The FMI HAL module gets feature information and populates the fmi_feature_info_t structure using

the fmi_api_t::productFeatureGet API.

The FMI HAL module fetches event information and populates the fmi_event_info_t structure using the fmi_api_t::eventInfoGet API.

The FMI HAL module gets code version and API version in ssp_version_t structure using the fmi_api_t::versionGet API.

For details, refer the FMI HAL module source code and SSP user manual.

FMI HAL Module Important Operational Notes and Limitations

FMI HAL Module Operational Notes

- The fmi_product_info_t::unique_id is deprecated. It does not contain a unique ID if the factory MCU information is linked in by the application code. Use fmi_api_t::uniqueIdGet for the unique ID.

FMI HAL Module Limitations

- For limitations of FMI HAL Interface and its implementation, see the latest SSP release notes.
- The FMI Driver has been tested on the S7G2 (WS2) Synergy microcontroller family using the FMIFRT peripheral register. It is the only Synergy MCU that is currently programmed with data in the Factory MCU Information Table.

4.2.21.4 Including the FMI HAL Module in an Application

This section describes how to include the FMI HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the FMI Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the FMI Driver is g_fmi0. This name can be changed in the associated Properties window.)

FMI HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_fmi FMI Driver on r_fmi	**Threads> HAL/Common**	**New Stack> Driver> System> FMI Driver on r_fmi**

When the FMI Driver on r_fmi is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and

displays possible choices.

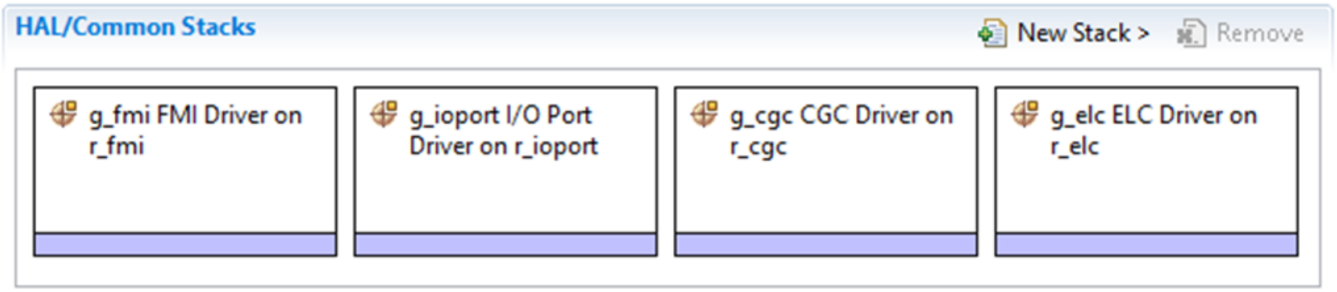

Figure 304: FMI HAL Module Stack

4.2.21.5 Configuring the FMI HAL Module

The FMI HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the FMI HAL Module on r_fmi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Controls whether to include code for API parameter checking.
SSP MCU Information Symbol Name	g_fmi_data	This symbol maps to the base address where the factory flash table information will be found. It should not be modified.

Part Number Mask	0xFE00	Each bit represents one character in the Synergy part number, where the MSB is the first character in the part number ('R'). Set bits to ensure the part number in the MCU factory flash matches the part number in the SSP MCU Information. The default mask checks everything except operating temperature, software ID, and quality ID.
Name	g_fmi	Module instance name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Family. Other MCUs may have different default values and available configuration settings.

FMI HAL Module Clock Configuration

No specific clock configurations are required for the FMI HAL Module.

FMI HAL Module Pin Configuration

No specific pin configurations are required for the FMI HAL Module.

4.2.21.6 Using the FMI HAL Module in an Application

The typical steps in using the FMI HAL Module in an application are:

1. Initialize the FMI using the fmi_api_t::init API, it is automatically initialized after Reset.
2. Use the fmi_api_t::productInfoGet API to get product information.
3. Use the fmi_api_t::uniqueIdGet API to get unique ID.
4. Use the fmi_api_t::productFeatureGet API to get feature information.
5. Use the fmi_api_t::eventInfoGet API to get event information.
6. Use the fmi_api_t::versionGet API to get driver version information.

These common steps are illustrated in a typical operational flow diagram in the following figure:

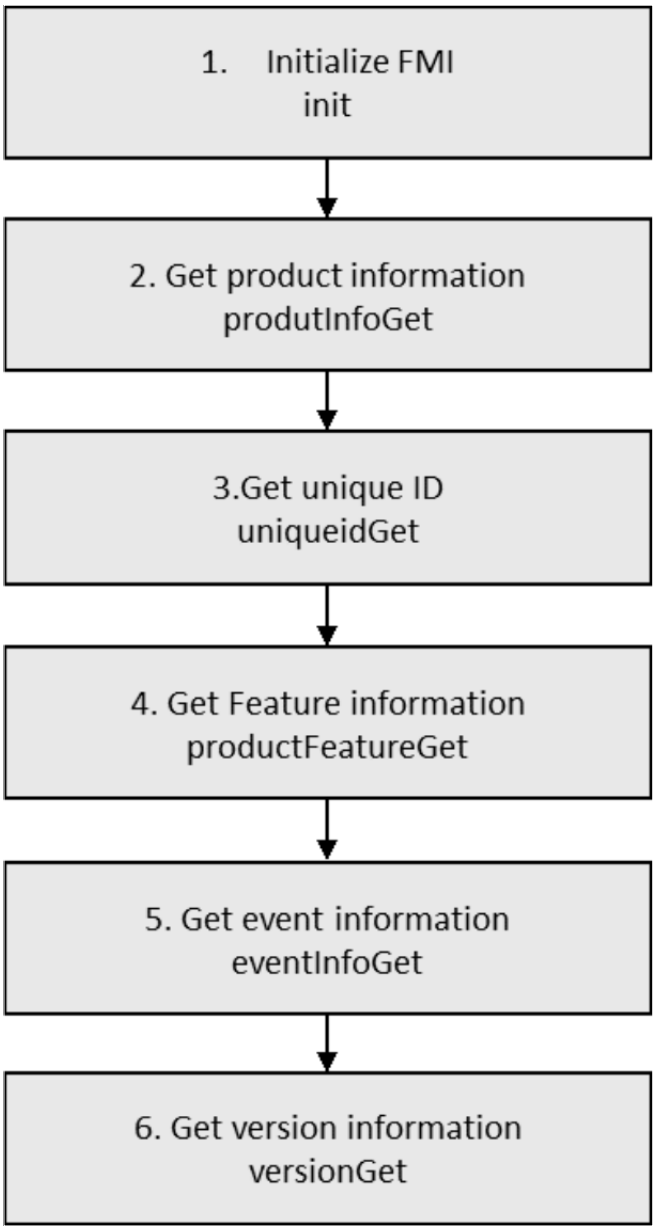

Figure 305: Flow Diagram of a Typical FMI HAL Module Application

4.2.22 Timer Driver on r_gpt

4.2.22.1 GPT HAL Module Introduction

The General PWM Timer (GPT) HAL module provides a high-level API for timer applications and uses the GPT peripheral on the Synergy MCU. A user-defined callback can be created to respond to a timer event.

GPT HAL Module Features

The GPT HAL module configures a timer to a user-specified period. When the period elapses, any of the following events can occur:

- CPU interrupt that calls a user callback function, if provided
- Toggle a port pin
- Data transfer using DMAC/DTC if configured with Transfer Interface
- Starting of another peripheral if configured with events and peripheral definitions

General PWM Timer (GPT)

- PCLKD as core clock
- Two I/O pins per channel

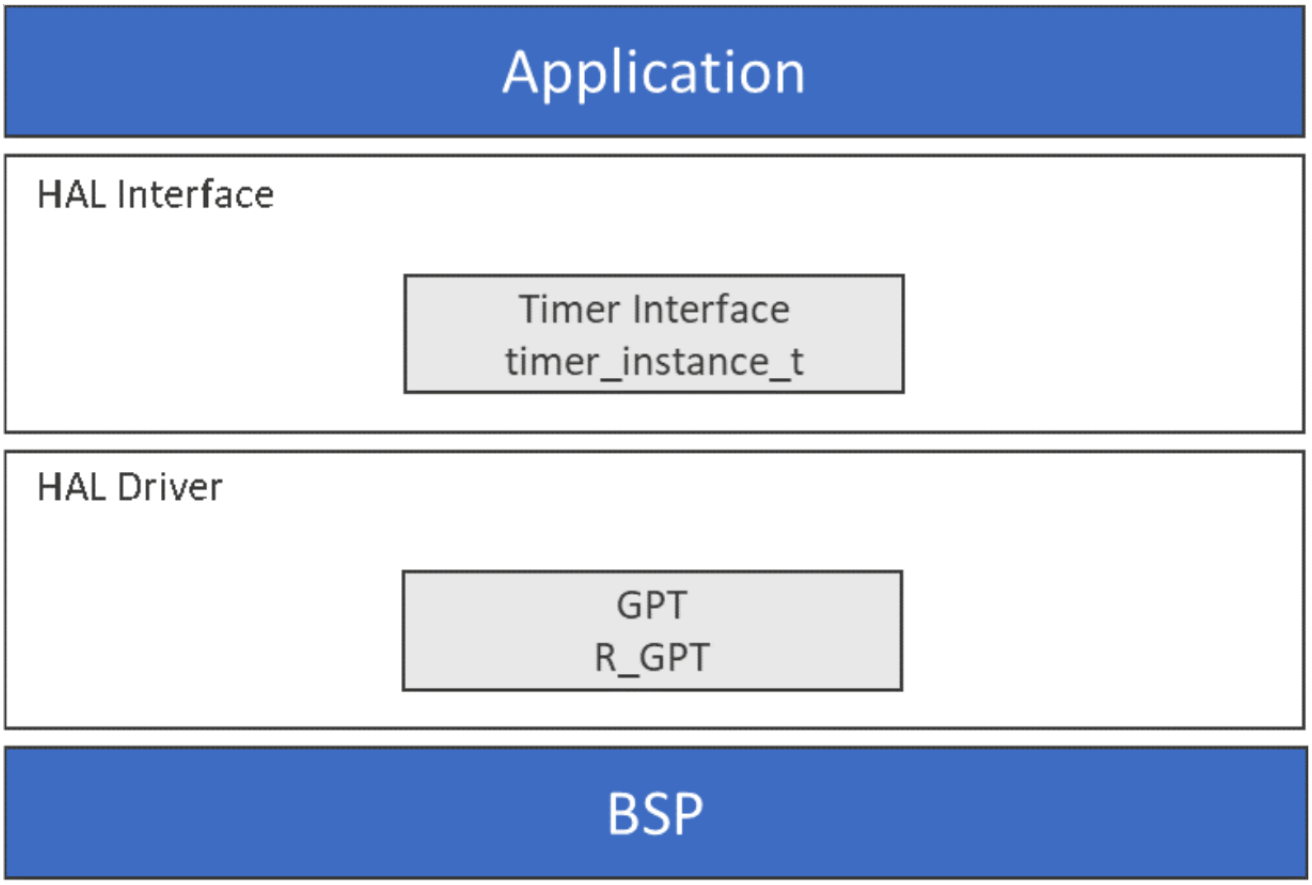

Figure 306: GPT HAL Module Block Diagram

GPT Hardware support details

The following hardware features are, or are not, supported by SSP for GPT.

Legend:

Symbol	Meaning

4.2.22.2 GPT HAL Module APIs Overview

The GPT HAL module defines APIs to open, start, stop, read status, trim and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

GPT HAL Module API Summary

Function Name	Example API Call and Description
open	g_timer0.p_api->open(g_timer0.p_ctrl, g_timer0.p_cfg) Initial configuration.
stop	g_timer0.p_api->stop(g_timer0.p_ctrl) Stop the counter.
start	g_timer0.p_api->start(g_timer0.p_ctrl) Start the counter.
reset	g_timer0.p_api->reset(g_timer0.p_ctrl) Reset the counter initial value.
counterGet	g_timer0.p_api->counterGet(&value) Get current counter value and store it in the provided pointer, value.
periodSet	g_timer0.p_api->periodSet(g_timer0.p_ctrl, period, unit) Set the time until the timer expires.
dutyCycleSet	g_timer0.p_api->dutyCycleSet(g_timer0.p_ctrl, period, unit, pin) Sets the time until the duty cycle expires.
infoGet	g_timer0.p_api->infoGet(&info) Get the time until the timer expires in clock counts and store it in provided pointer, info.
close	g_timer0.p_api->close(g_timer0.p_ctrl) Allows driver to be reconfigured and may reduce power consumption.
versionGet	g_timer0.p_api->versionGet(g_timer0.p_ctrl, &version) Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Operation is successful.

SSP_ERR_ASSERTION	Parameter is NULL or configuration setting is not allowed.
SSP_ERR_IN_USE	The channel specified has already been opened.
SSP_ERROR_NOT_OPEN	The channel is not open.
SSP_ERR_INVALID_ARGUMENT	Invalid argument provided.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.22.3 GPT HAL Module Operational Overview

The GPT HAL module configures a timer to a user-specified period. When the period elapses, the CPU can be interrupted, a port pin can be toggled, a transfer of data using the DMAC or DTC can be initiated, or another peripheral can be triggered to begin operation.

The following figure shows a flowchart for toggling a port pin or generating a CPU interrupt after a specified period:

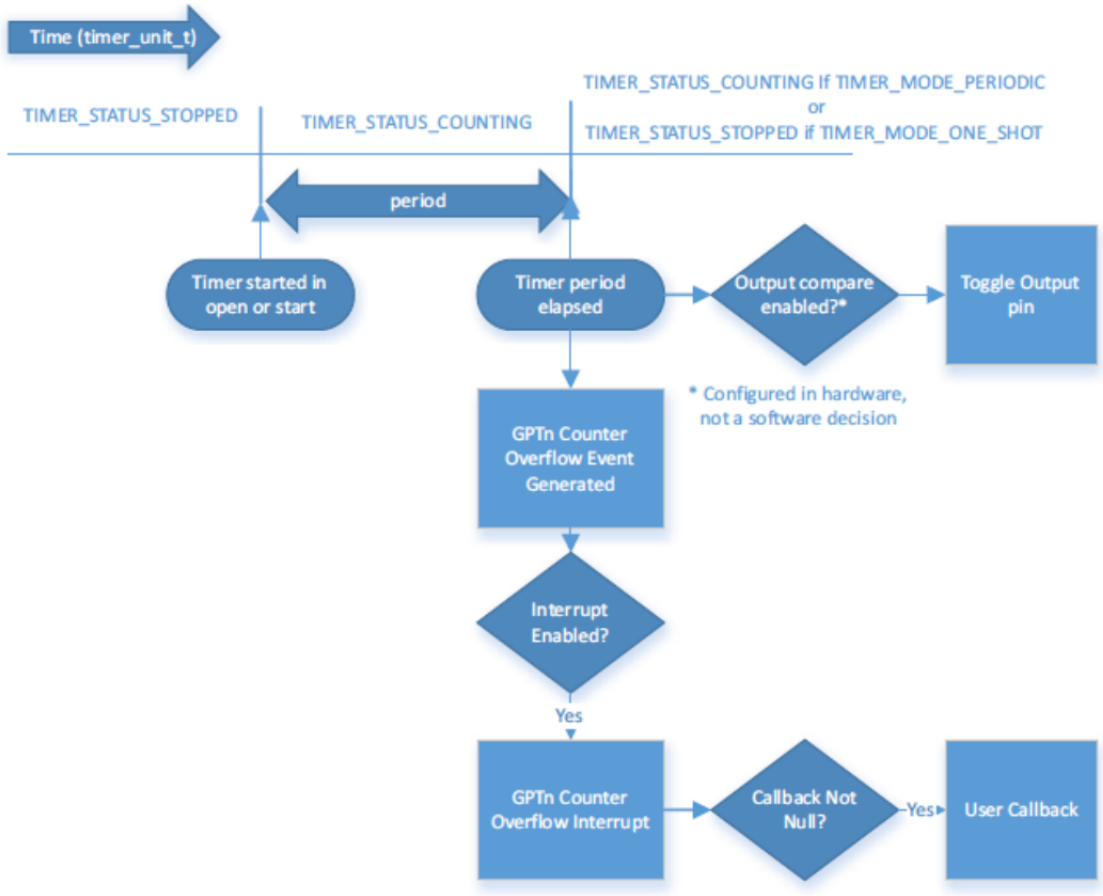

Figure 307: GPT HAL Module Timer-Periodic or One-Shot Mode

Two different timer modules, the GPT and the AGT, are supported in the SSP. The following sections

provide information on both modules so that the developer can compare and contrast the capabilities of each module for a particular application. For additional information on the AGT, refer to the AGT User's Guide.

The GPT module is recommended for most generic timer applications, but either module can be used for a basic timer functionality. The following use cases describe why one timer module would be preferred over the other.

Selecting the GPT Timer Module

The GPT module uses a high-resolution 32-bit counter that can only be clocked by PCLKD. There are more GPT channels than AGT channels on Synergy devices, so using GPT is less likely to cause a resource conflict.

Selecting the AGT Timer Module

The AGT module uses a 16-bit counter that can be clocked by PCLKB, LOCO, or Fsub. If clocked by LOCO or Fsub, the AGT interrupt can be used to wake the MCU from sleep modes. There are two channels, and channel 1 can be clocked by channel 0 underflow, effectively creating a 32-bit cascaded timer.

GPT HAL Module Important Operational Notes and Limitations

GPT HAL Module Operational Notes

The maximum time period depends on the timer type and the input clock frequency.

- On a GPT with 32-bit resolution with PCLKD running at 120 MHz, the maximum period is approximately 36650 seconds, which is just over 10 hours (GPT Count Clock is PCLKD/1024).
- On a GPT with 16-bit resolution with PCLKD running at 32 MHz, the maximum period is approximately 2.09 seconds (GPT Count Clock is PCLKD/1024).

The GPT counter overflow interrupt must be enabled in the following situations:

1. To get a software interrupt when the timer period has elapsed.
2. To use one-shot mode

When counter overflow interrupt is enabled, the corresponding ISR is linked in the vector table. The ISR calls a user callback function if one was registered in open.

Note: Interrupts may be skipped when used with the DTC peripheral with irq set to TRANSFER_IRQ_END.

GPT Output Timer Signal

If the timer output is configured (GTIOCA/B Output Enabled set to True), the output pin will start at the GTIOCA/B Stop Level and toggle every time the period elapses, beginning with the first time the period elapses after the timer is started.

In one-shot mode, the output is also configured to toggle when the timer starts counting. This generates a pulse - the timer toggles from the stop level when counting begins and toggles back to the stop level when counting ends.

Timer Period Calculation

The timer period is defined as the time until the timer expires. When output compare is used, the output pin will toggle once per period, so the traditional period (from rising edge to rising edge) is twice the period specified in the software.

Runtime period calculation based on the current clock settings is available from open and periodSet.

- If the specified Period Unit is different than the Raw Counts, the period is calculated using the current timer clock frequency. The current timer clock frequency is determined using the cgc_api_t::systemClockFreqGet API. This frequency will be used in the appropriate formula from the following table as clk_freq_hz.

Timer Period Calculation

Timer Units	Formula
TIMER_UNIT_PERIOD_NSEC	Counts = (period * clk_freq_hz) / 1000000000
TIMER_UNIT_PERIOD_USEC	Counts = (period * clk_freq_hz) / 1000000
TIMER_UNIT_PERIOD_MSEC	Counts = (period * clk_freq_hz) / 1000
TIMER_UNIT_PERIOD_SEC	Counts = (period * clk_freq_hz)
TIMER_UNIT_FREQUENCY_HZ	Counts = (clk_freq_hz) / period
TIMER_UNIT_FREQUENCY_KHZ	Counts = (clk_freq_hz) / 1000 * period

If the requested period is larger than the counter size (32-bit or 16-bit), the driver selects the smallest divisor that allows the result to fit in the counter size. If the counter value is larger than the counter size with the largest divisor (1024), an error code (SSP_ERR_INVALID_ARGUMENT) is returned.

Triggering DMAC/DTC with GPT

To trigger a transfer of data using the DMAC or DTC peripheral when the timer period elapses, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_GPTn_COUNTER_OVERFLOW (where n is the GPT channel number). See the DMAC or DTC guides for further information.

Note

If you use the timer in one-shot mode with the DTC, the entire transfer will complete before the interrupt stops the timer if irq is set to TRANSFER_IRQ_END. To generate only one transfer after the timer period elapses, set irq to TRANSFER_IRQ_EACH, or use the DMAC for the transfer.

Triggering ELC Events with GPT

The GPT timer can trigger the start of other peripherals. The ELC guide provides a list of all available peripherals.

Free Running Counter Mode

To use the GPT as a free running counter, set the Period to 0xFFFFFFFF for a 32-bit timer or 0xFFFF for a 16-bit timer and the Period Unit to Raw Counts in the Properties window of the Synergy Configuration tool. Stop and start the timer using the timer_api_t::stop API and the timer_api_t::start API. Check the counter value using the timer_api_t::counterGet API. Reset the timer using the timer_api_t::reset API. If the counter overflows, handle the counter overflow in the callback.

GPT PWM Mode

To use the GPT in PWM mode, set the Period and Duty cycle and select the duty cycle range.

The driver provides two options to select the duty cycle range:

1. Shortest duty cycle off: In this case, the lowest duty cycle obtained will be limited to 2 raw counts. But the configuration will be limited to 1 raw counts(because the hardware will add 1 extra clock cycle in ON time, hence if configured Dutycycle is 1 raw count, the user will be getting 2 raw counts in ON time).
2. Shortest duty cycle on: In this case, the lowest duty cycle of 1 raw count can be achieved and lowest duty cycle to configure will be limited to 1 raw counts and the longest will be (Period – 2). In this case, the 1 extra clock cycle will be added by hardware in OFF time.

GPT HAL Module Limitations

- For GPT Power Down, the GPT module does not set the Module Stop bit (MSTP) for GPT in the timer_api_t::close API. This is intentional because the GPT module stop bits control the power to multiple GPT channels, and the GPT module cannot know if other GPT modules are used in the application.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.22.4 Including the GPT HAL Module in an Application

This section describes how to include the GPT HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Timer Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Timer Driver is g_timer0. This name can be changed in the associated Properties window.)

GPT HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_timer0 Timer Driver on r_gpt	**Threads> HAL/Common**	**New Stack> Driver> Timers> Timer Driver on r_gpt**

When the Timer Driver on r_gpt is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

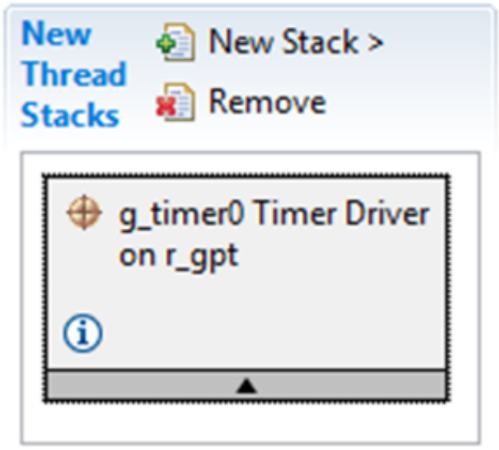

Figure 308: GPT HAL Module Stack

4.2.22.5 Configuring the GPT HAL Module

The GPT HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the GPT HAL Module on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic, One Shot, PWM Default: Periodic	Warning: One Shot functionality is not available in the GPT hardware, so it is implemented in software by stopping the timer in the ISR called when the period expires. For this reason, ISR's must be enabled for one-shot mode even if the callback is unused.

Period Value	10	See Timer Period Calculation.
Period Unit	Raw Counts, Nanoseconds, Microseconds, Milliseconds, Seconds, Hertz, Kilohertz Default: Milliseconds	See Timer Period Calculation.
Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection.
Auto Start	True, False Default: True	Set to true to start the timer after configuring or false to leave the timer stopped until timer_api_t::start is called.
GTIOCA Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
GTIOCB Output Enabled	True, False Default: False	Set to true to output the timer signal on a port pin configured for GPT. Set to false for no output of the timer signal.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	Controls output pin level when the timer is stopped.
Callback	NULL	A user callback function can be registered in timer_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Overflow interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

GPT HAL Module Clock Configuration

The GPT timer is clocked based on the PCLKD frequency. You can set the PCLKD frequency using the clock configurator in the ISDE Configuring Clocks tab, or the CGC Interface at run-time.

GPT HAL Module Pin Configuration

The GPT peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table lists the method used to select pins within the SSP configuration window and the subsequent table lists an example selection for the associated pins:

Pin Selection for the GPT HAL Module on r_gpt

Resource	ISDE Tab	Pin selection Sequence
GPT	Pins	Select **Peripherals**> **Timer: GPT**> **GPT0**

Note

The selection sequence assumes GPT0 is the desired hardware target for the driver.

Pin Configuration Settings for GPT HAL Driver

Property	Value	Description
Pin Group Selection	Mixed, _A Only, _B Only Default: Mixed	Select pin group mapping.
Operation Mode	Disabled, GTIOCA or GTIOCB, GTIOCA and GTIOCB Default: Disabled	Select timer operation mode.
GTIOCA:	None, P300, P512 Default: P512	GTIOCA Pin.
GTIOCB:	None, P108, P511 Default: P511	GTIOCB Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy

MCUs and Synergy Kits may have different available pin configuration settings.

4.2.22.6 Using the GPT HAL Module in an Application

The typical steps in using the GPT HAL module in an application are:

1. Initialize the GPT HAL module using the timer_api_t::open API.
2. Start the GPT HAL module by calling the timer_api_t::start API if the Auto Start property is False.
3. Respond to the timer callback as needed (application code).

Note

The GPT period and duty cycle parameters can be reconfigured based on the application needs using the timer_api_t::periodSet() and the timer_api_t::dutyCycleSet.

In PWM mode, there will be one extra PCLK added by the hardware in ON time if Duty cycle range is selected to GPT_SHORTEST_LEVEL_OFF and in OFF time if the Duty cycle range is selected to GPT_SHORTEST_LEVEL_ON.

These common steps are illustrated in a typical operational flow diagram in the following figure:

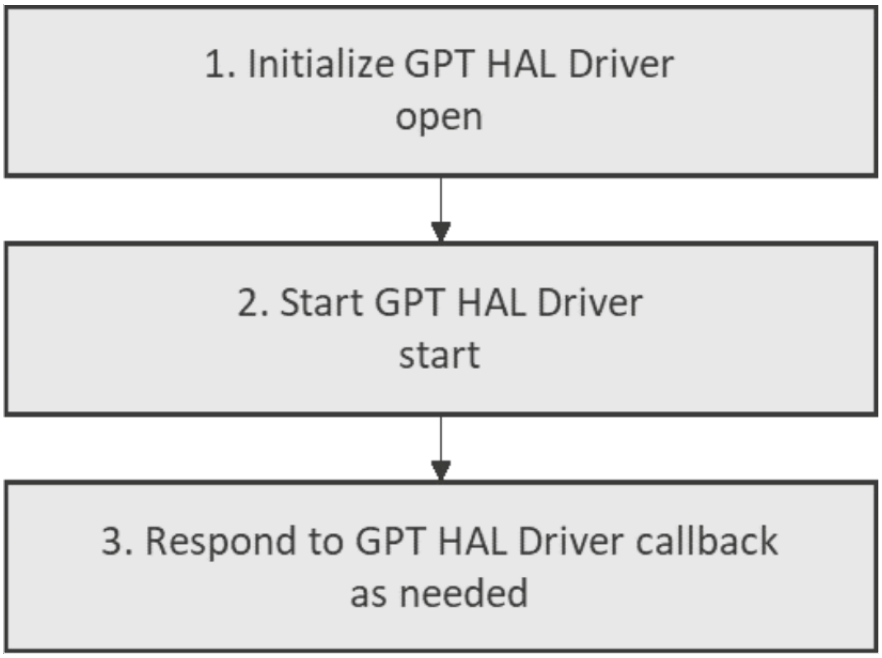

Figure 309: Flow Diagram of a Typical GPT HAL Module Application

4.2.23 I2C SCI Driver

4.2.23.1 I2C SCI HAL Module Introduction

The I2C SCI Master HAL module provides a high-level API for I2C industry standard serial device communication applications and uses the SCI peripheral on the Synergy MCU device. Callbacks are

provided for transmit complete and receive complete.

I2C SCI HAL Module Features

- Support for I2C SCI operations
- Supports following operations with a slave I2C SCI device
    - Read
    - Write
    - Reset
- Callback support
    - Transfer aborted
    - Transmit complete (number of bytes transmitted provided)
    - Receive complete (number of bytes received provided)

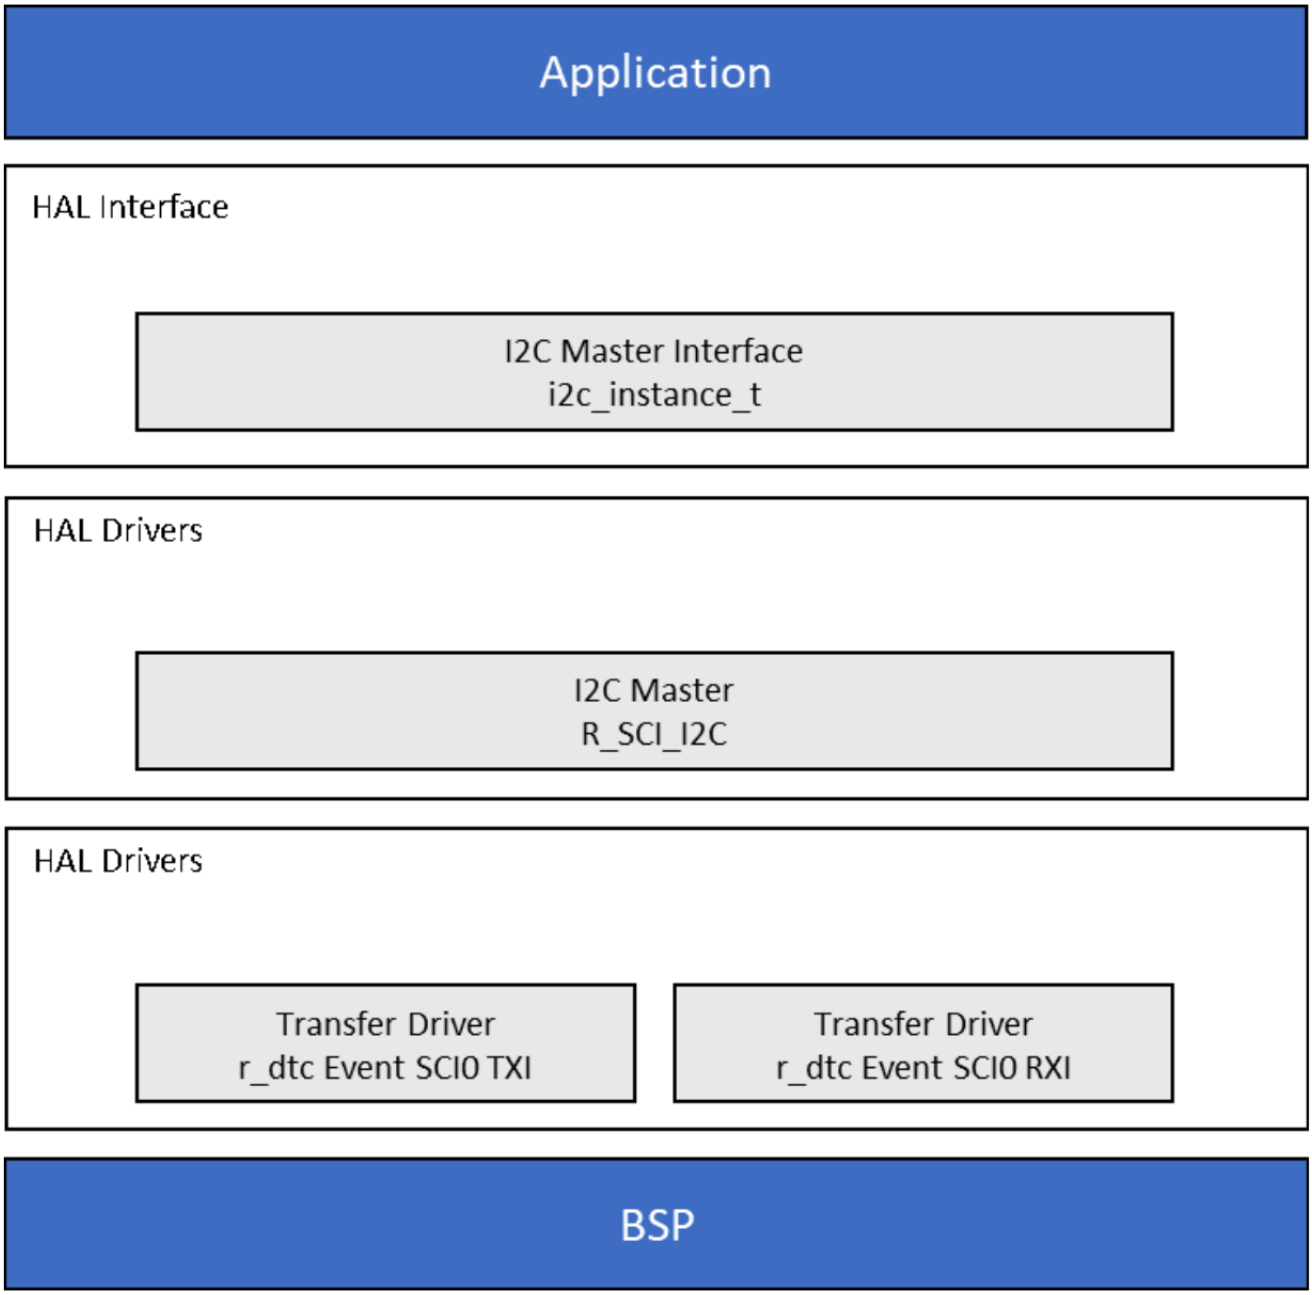

Figure 310: I2C SCI HAL Module Block Diagram

I2C SCI Hardware Support Details

The following hardware features are, or are not, supported by SSP for the I2C over SPI.

Legend:

Symbol	Meaning

4.2.23.2 I2C SCI HAL Module APIs Overview

The I2C SCI HAL module defines APIs for reading and writing using a master I2C device. A complete list of the available API functions, an example API function call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

I2C SCI HAL Module API Summary

Function Name	Example API Call and Description
open	g_i2c.p_api->open(g_i2c.p_ctrl, g_i2c.p_cfg); Open the instance and initialize the hardware.
close	g_i2c.p_api->close(g_i2c.p_ctrl); Closes the driver and releases the I2C device.
read	g_i2c.p_api->read(g_i2c.p_ctrl, &destination, bytes, restart); Performs a read operation on an I2C device.
write	g_i2c.p_api->write(g_i2c.p_ctrl, &destination, bytes, restart); Performs a write operation on an I2C device.
reset	g_i2c.p_api->reset(g_i2c.p_ctrl); Reset the peripheral.
slaveAddressSet	g_i2c.p_api->slaveAddressSet(g_i2c.p_ctrl, slave, addr_mode); Sets address of the slave device without reconfiguring the bus.
versionGet	g_i2c.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_IN_USE	Attempted to open an already open device instance.
SSP_ERR_ABORTED	Device was closed while a transfer was in progress.
SSP_ERR_INVALID_RATE	The requested rate cannot be set.
SSP_ERR_ASSERTION	The parameter p_ctrl is NULL.
SSP_ERR_NOT_OPEN	Device was not even opened.
SSP_ERR_IRQ_BSP_DISABLED	Event information could not be found.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.23.3 I2C SCI HAL Module Operational Overview

The I2C SCI Master HAL module supports transactions with an I2C slave device. Callbacks are provided to interrupt the CPU when a transmission has been completed or aborted, or receive completed. The I2C SCI HAL module invokes the callback with the argument i2c_callback_args_t, indicating the number of received or transmitted bytes in buffer, pointer to user provided context, and the event i2c_event_t.

I2C SCI HAL Module Important Operational Notes and Limitations

I2C SCI HAL Module Operational Notes

Interrupts

- The I2C interrupts (SCI Error (EEI), Receive Buffer Full (RXI), Transmit Buffer Empty (TXI), and Transmit End (TEI)) for the selected channel must be enabled in the board support package (BSP), without consideration of whether the user wants to use callbacks.
- Setting the interrupts to different priority levels could result in improper operation.

IIC Rate Calculation

- The I2C SCI HAL module calculates the internal baud-rate setting based on the configured transfer rate and passes this to open. The closest possible baud rate that can be achieved (less than or equal to the requested rate) at the current PCLKB settings is calculated and used.
- If a valid clock rate could not be calculated, an error is returned.

Triggering DMAC/DTC with the IIC

- DTC transfer support is added by default in the configurator, this can be removed for CPU transfer cases. The DTC is configured in the module. No user configuration is required for this.
- DMA transfer is not supported.

Triggering ELC Events with the IIC

- The I2C SCI HAL module can trigger the start of other peripherals. See the ELC User Guide for further information.

Multiple Devices on the Same Bus

When communicating with multiple slave devices on the same bus, if these slave devices have the same configuration settings the i2c_api_master_t::slaveAddressSet API function can be used to switch between slave devices without reconfiguring (no need to close and open). The control instance and bus configuration remains the same, but the slave address and addressing mode changes. A single instance of the I2C SCI HAL module is sufficient for this case.

When communicating with multiple slave devices on the same bus, if each slave device requires different configuration settings multiple instances of r_sci_i2c will be used- each configured as required for each slave device. Each instance of r_sci_i2c will be opened and closed when it is used to communicate with the target slave device.

A mix of the above two approaches can be used with a mix of slave devices. For example, if two slave devices share the same configuration settings, they can share the same instance of r_sci_i2c and the i2c_api_master_t::slaveAddressSet API function can be used to switch between them. If on the same bus, three other slave devices share the same configuration settings, but these settings are different from the first two, they will need a separate r_sci_i2c instance. Switching between each of these three slave devices can again use the i2c_api_master_t::slaveAddressSet API function. When switching between slave devices served by different instances of r_sci_i2c, the open and close technique must be used. In general, the configuration settings of the most recently slave device accessed are 'remembered' and can be re-used if appropriate. If a slave requires a different configuration than the most recently accessed slave, the r_sci_i2c module must be closed and then opened using the required configuration settings.

Applications using multiple devices connected on the same channel need to define the following macro in the pre-processor settings of the project (or the project may not build correctly):

SSP_SUPPRESS_ISR_<device_name>

Where <device_name> is the name of the additional device connected to the same channel.

I2C SCI HAL Module Limitations

- The I2C SCI HAL module in IRQ mode may not work with certain slave devices; you need to enable DTC transfer mode to work with such devices.
- To support high bit rate data transfers when operating in the IRQ mode it is highly recommended that the DTC transfer mode be enabled. This reduces the CPU overhead in responding to interrupts directly and thus removes a potential barrier in successfully implementing high bit-rate transfers.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.23.4 Including the I2C SCI HAL Module in an Application

This section describes how to include the I2C SCI HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the I2C Master Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the I2C Master Driver is g_i2c0. This name can be changed in the associated Properties window.)

I2C SCI HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_i2c0 I2C Master Driver on r_sci_i2c	Threads	**New Stack> Driver> Communications> I2C Master Driver on r_sci_i2c**

When the I2C Master Driver module on r_sci_i2c is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with

a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

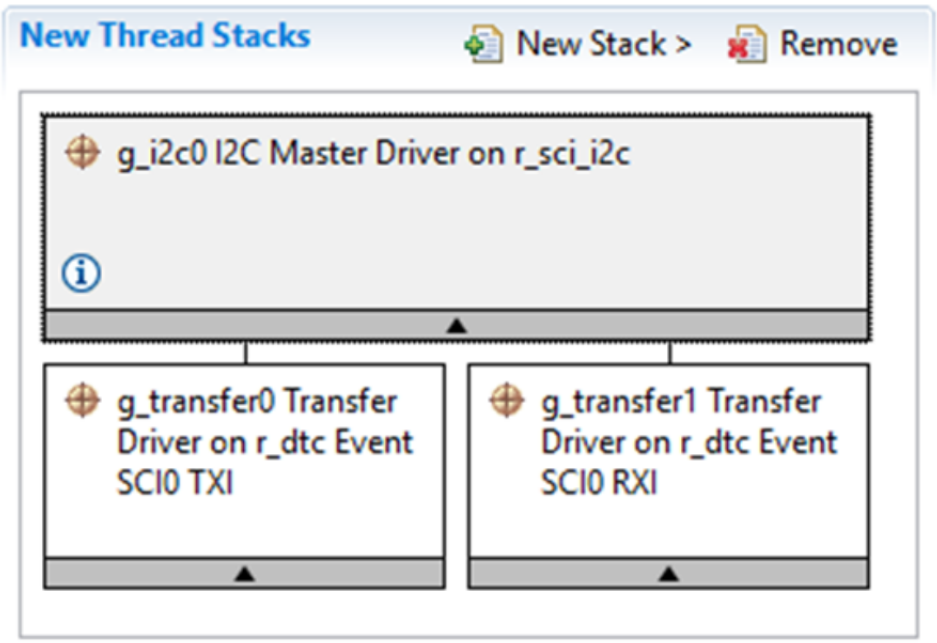

Figure 311: I2C SCI HAL Module Stack

4.2.23.5 Configuring the I2C SCI HAL Module

The I2C SCI HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the I2C SCI HAL Module on r_sci_i2c

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.

Name	g_i2c0	Module name.
Channel	0 to 9	Specify the SCI channel to be used with this configuration. SCI has channels as follows: Series S7 : 0 1 2 3 4 5 6 7 8 9; Series S3 : 0 1 2 3 4 - - - - 9; Series S1 : 0 1 - - - - - - - 9 .
Rate	Standard, Fast-mode Default: Standard	Select the I2C data rate.
Slave Address	0x00	Specify the slave address.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
SDA Output Delay (nano seconds)	300	SDA output delay in nanoseconds.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Enables bitrate modulation function.
Callback	NULL	A user callback function can be registered in i2c_api_master_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the receive interrupt priority.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the transmit interrupt priority.

Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the transmit end interrupt priority.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2C SCI HAL Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module:

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Software Start	Enabled, Disabled Default: Disabled	Include code for software start in the build.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place the DTC vector table.
Name	g_transfer0	Module name.
Mode	Block	Specify the hardware channel.
Transfer Size	1 Byte	Select the transfer mode.
Destination Address Mode	Fixed	Select the transfer size.
Source Address Mode	Incremented	Select the address mode for the destination.
Repeat Area (Unused in Normal Mode	Source	Select the address mode for the source.
Interrupt Frequency	After all transfers have completed	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.

Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source (Must enable IRQ)	Event SCI0 TXI	Select the DTC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback (Only valid with Software start)	NULL	A user callback that is called at the end of the transfer.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Software Start	Enabled, Disabled Default: Disabled	Include code for software start in the build.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Section to place the DTC vector table.
Name	g_transfer1	Module name.
Mode	Normal	Specify the hardware channel.
Transfer Size	1 Byte	Select the transfer mode.
Destination Address Mode	Incremented	Select the transfer size.
Source Address Mode	Fixed	Select the address mode for the destination.
Repeat Area (Unused in Normal Mode	Destination	Select the address mode for the source.

Interrupt Frequency	After all transfers have completed	Select the repeat area. Either the source or destination address resets to its initial value after completing Number of Transfers in Repeat or Block mode.
Destination Pointer	NULL	Specify the transfer destination pointer.
Source Pointer	NULL	Specify the transfer source pointer.
Number of Transfers	0	Specify the number of transfers.
Number of Blocks (Valid only in Block Mode)	0	Specify the number of blocks to transfer in Repeat or Block mode.
Activation Source (Must enable IRQ)	Event SCI0 RXI	Select the DTC transfer start event.
Auto Enable	False	Auto enable the transfer in open().
Callback (Only valid with Software start)	NULL	A user callback that is called at the end of the transfer.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the transfer end interrupt priority.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

I2C SCI HAL Module Clock Configuration

The SCI peripheral module uses the PCLKB as its clock source. The actual I2C transfer rate is calculated and set internally by the driver (depending on the selected transfer rate). If the PCLKB is configured in such a manner that the selected internal rate cannot be achieved, an error is returned when initializing the driver.

I2C SCI HAL Module Pin Configuration

The SCI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins:

Note

The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for I2C SCI HAL Module on r_sci_i2c

Resource	ISDE Tab	Pin selection Sequence
SCI	Pins	Select **Peripherals**> **Connectivity: SCI**> **SCI0**

Note

The selection sequence assumes SCI0 is the desired hardware target for the driver.

Pin Configuration Settings for the I2C SCI HAL Module on r_sci_i2c

Pin Configuration Property	Value	Description
Pin Group Selection	_A only, _B only, Mixed Default: _A only	Pin group selection.
Operation Mode	Enabled, Disabled Default: Disabled	Enable or disable peripheral module.
SDA	None, P401, P407 Default: None	SDA Pin.
SCL	None, P400, P204 Default: None	SCL Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.23.6 Using the I2C SCI HAL Module in an Application

The steps in using the I2C SCI HAL module in a typical application are:

1. Initialize and open the I2C SCI HAL module using the i2c_api_master_t::open API.
2. Transfer data to the slave using the i2c_api_master_t::write API.
3. Receive data from the slave using the i2c_api_master_t::read API.
4. Operate on the received data as needed by the application.
5. Reset the module with the i2c_api_master_t::reset API (Optional).
6. Perform transactions with slave device in the application code.
7. Change the slave address using the i2c_api_master_t::slaveAddressSet API (Optional).
8. Perform transactions with slave device in the application code (Optional).
9. Close the channel using the i2c_api_master_t::close API (Optional).

These common steps are illustrated in a typical operational flow diagram in the following figure:

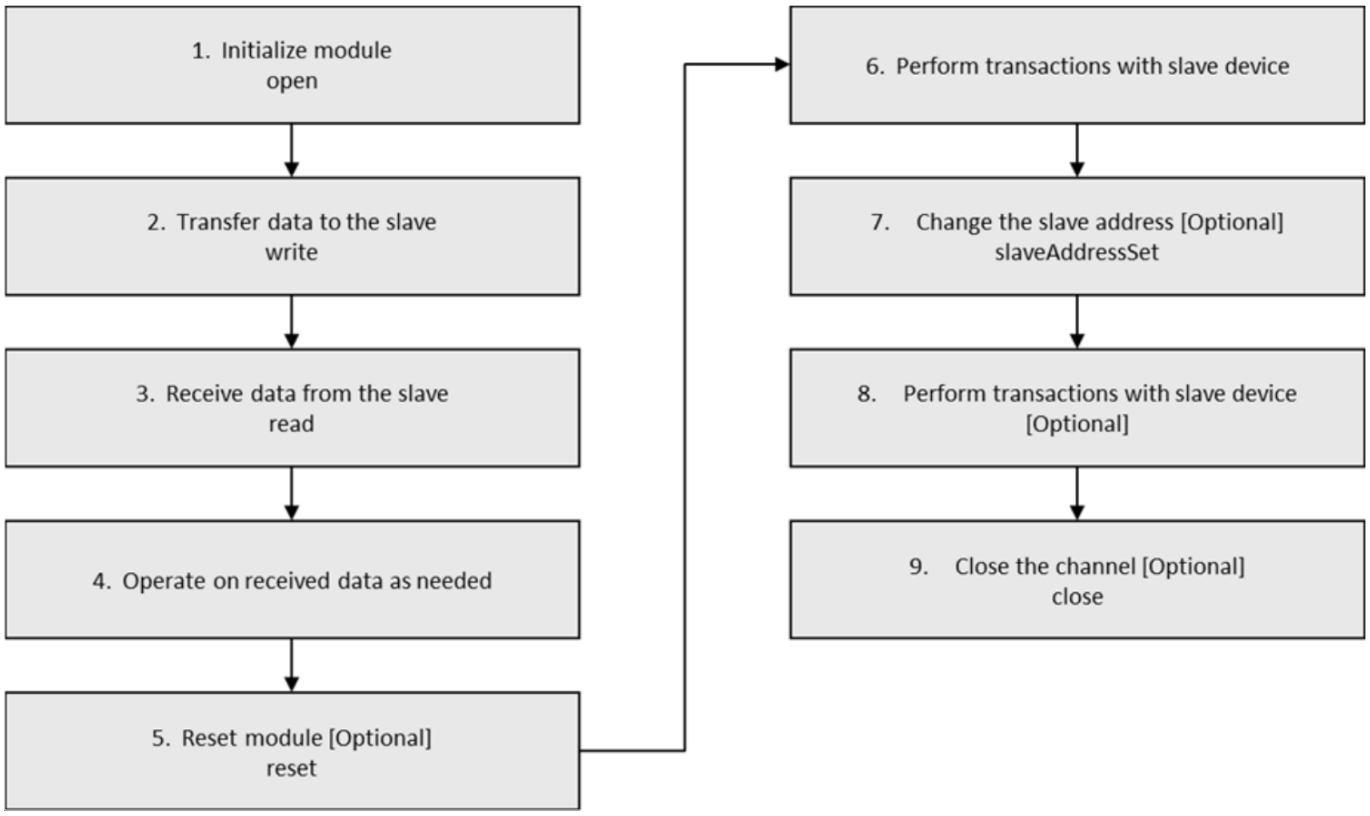

Figure 312: Flow Diagram of a Typical I2C SCI HAL Module Application

4.2.24 I2C Master Driver

4.2.24.1 I2C Master HAL Module Introduction

The I2C Master on RIIC HAL module provides a high-level API for industry standard I2C serial communications applications and uses the IIC peripheral on a Synergy MCU. Callbacks are provided for transmit complete and receive complete events notification.

I2C Master HAL Module Features

- Support for I2C RIIC operations
  - Standard (up to 100 kHz)
  - I2C fast-mode (up to 400 kHz)
  - I2C fast-mode plus (up to 1 MHz on channel 0 (SCL0-A, SDA0-A) of S7G2 and S5D9 MCU families)
- Initialization of the RIIC module
- Read from a slave device
- Write to a slave device
- Reset the MCUs I2C peripheral
- Set the address of the slave device
- Callback support
  - Transfer aborted (along with exact IIC hardware-generated error event)

- Transmit complete (number of bytes transmitted provided)
- Receive complete (number of bytes received provided)

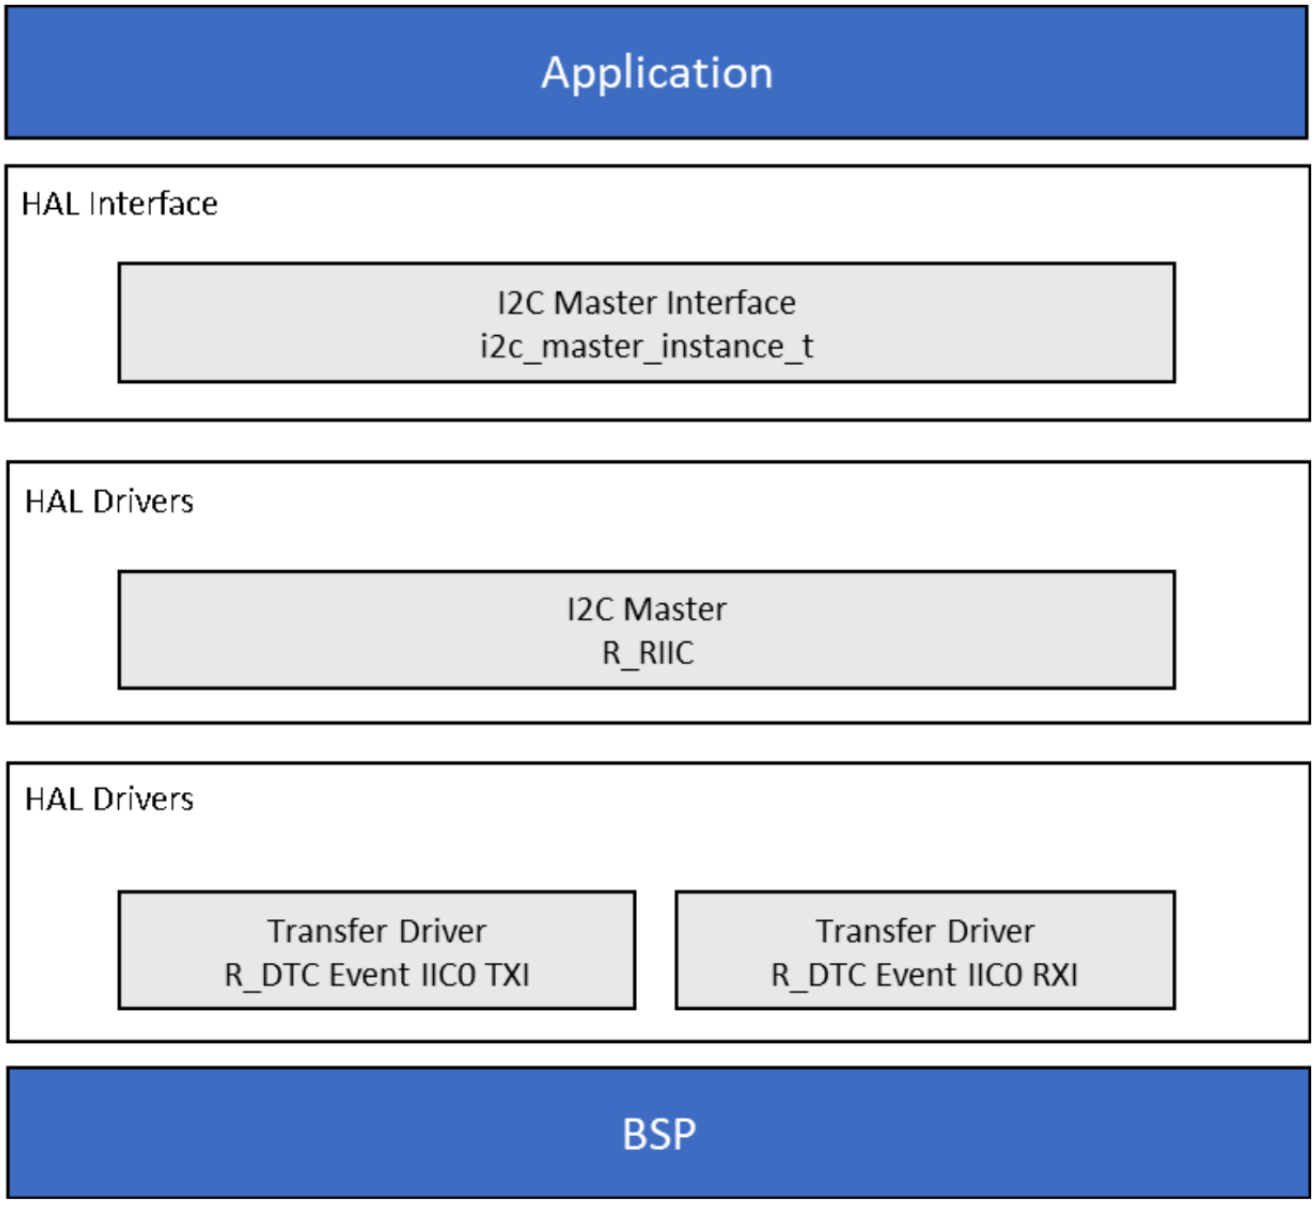

Figure 313: I2C Master HAL Module Block Diagram

4.2.24.2 I2C Master HAL Module APIs Overview

The I2C Master on RIIC (I2C RIIC) HAL module defines API functions including reading and writing using a master I2C device. A complete list of the available API functions, an example API function call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

I2C Master HAL Module API Summary

Function Name	Example API Call and Description
open	g_i2c.p_api->open(g_i2c.p_ctrl, g_i2c.p_cfg); Open the instance and initialize the hardware.
close	g_i2c.p_api->close(g_i2c.p_ctrl); Closes the driver and releases the I2C device.
read	g_i2c.p_api->read(g_i2c.p_ctrl, &destination, bytes, restart); Performs a read operation on an I2C device.
write	g_i2c.p_api->write(g_i2c.p_ctrl, &destination, bytes, restart); Performs a write operation on an I2C device.
reset	g_i2c.p_api->reset(g_i2c.p_ctrl); Reset the peripheral.
versionGet	g_i2c.p_api->versionGet(&version); Retrieve the API version with the version pointer.

slaveAddressSet	g_i2c.p_api->slaveAddressSet(g_i2c.p_ctrl, slave_addr, addr_mode); Reconfigures the slave address.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_POINTER	Pointer is NULL.
SSP_ERR_IN_USE	I2C bus busy state detected during I2C transaction operation or attempted to open an already open device instance only during open API call.
SSP_ERR_ABORTED	Device was closed while a transfer was in progress.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INVALID_RATE	The requested rate cannot be set.
SSP_ERR_HW_LOCKED	Driver busy doing riic operation.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.24.3 I2C Master HAL Module Operational Overview

The I2C master on RIIC HAL module supports transactions with an I2C Slave device. Callbacks are provided to interrupt the CPU when a transmission or receive has been completed. The RIIC HAL module invokes the callback with the argument i2c_callback_args_t, indicating the number of received or transmitted bytes in buffer, pointer to user provided context, and the event i2c_event_t.

I2C Master HAL Module Important Operational Notes and Limitations

I2C Master HAL Module Operational Notes

Interrupts

- The RIIC error (EEI), receive buffer full (RXI), transmit buffer empty (TXI) and transmit end (TEI) interrupts for the selected channel used must be enabled in the properties of the selected device irrespective of whether the user wants to use callbacks.
- Set equal priority levels for all the interrupts mentioned above. Setting the interrupts to different priority levels could result in improper operation.

IIC Rate Calculation

- The I2C Master module calculates the internal baud-rate setting based on the configured

transfer rate and passed to open. The closest possible baud-rate that can be achieved (less than or equal to the requested rate) at the current PCLKB settings is calculated and used.
- If a valid clock rate could not be calculated, an error is returned.

Triggering DMAC/DTC with the IIC

- DTC transfer support added by default in the configurator. This can be removed for CPU transfer cases. The DTC is configured in the module. No user configuration is required for this.
- DMA transfer is not supported.

Triggering ELC Events with the IIC

- The I2C Master module can trigger the start of other peripherals. See events and peripheral definitions in the ELC User Guide for further information.

Multiple Devices on the Bus

- If multiple devices are connected on the same bus, only one device can be opened at a time.
- If multiple slave devices are on the same bus, and they have different configurations, the application program should use multiple I2C master modules- one for each configuration.
- If the application wants to switch the device without opening and closing the bus, use the i2c_api_master_t::slaveAddressSet API where g_i2c.p_ctrl is the same control instance that was used in the last opened device. The module will use the same bus configuration to communicate with the new device when the application program subsequently calls the i2c_api_master_t::read or i2c_api_master_t::write API functions.

Usage of Restart Condition

- Passing the value 'true' to the restart parameter of the write/read API will generate restart condition after specified number (length) of bytes.The master will continue to hold the bus busy (low) without timeout so that current master can trigger the next write/read API.

Multi-Master Support

If multiple masters are connected on the same bus, the I2C Master is capable of detecting bus busy state before initiating the communication.

SDA Delay Support

The SDA Delay function delays SDA output from the detection of a falling edge of SCL signal to ensure that

the SDA signal is output within the interval during which the SCL is low.

I2C Master HAL Module Limitations

- Any of the supported IIC channel can be configured for either Master or Slave mode operation but not for both.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.24.4 Including the I2C Master HAL Module in an Application

This section describes how to include the I2C Master HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the I2C Master Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the I2C Master Driver is g_i2c0. This name can be changed in the associated Properties window.)

I2C Master HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_i2c0 I2C Master Driver on r_riic	Threads	**New Stack> Driver> Communications> I2C Master Driver on r_riic**

When the I2C Master HAL module on r_riic is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

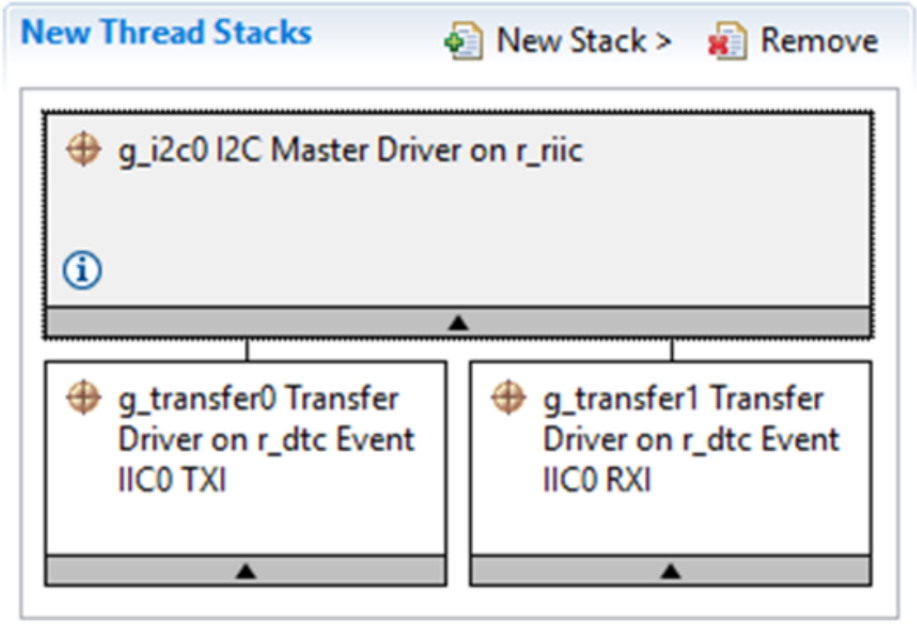

Figure 314: I2C Master HAL Module Stack

4.2.24.5 Configuring the I2C Master HAL Module

The I2C Master HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the I2C Master HAL Module on r_riic

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_i2c0	Module name.
Channel	0	Specify the IIC channel to be used with this configuration.
Rate	Standard, Fast-mode, Fast-mode Plus Default: Standard	Standard, Fast, and Fast-plus. (See IIC Rate Calculation.)
Slave Address	0x00	Set the address of the slave device the I2C master will be communicating with.
Address Mode	7-Bit, 10-Bit Default: 7-Bit	Only 7-bit addresses are currently supported.
SDA Output Delay(nanoseconds)	Default: 300	SDA output delay in nanoseconds.

Callback	NULL	A user callback function can be registered in i2c_api_master_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t*. *Exact hardware generated error event is also provided when i2c_event_t is I2C_EVENT_ABORTED. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Error interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the I2C Master HAL Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module:

Configuration Settings for the Transfer Driver on r_dtc Event IIC0 TXI

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event IIC0 TXI	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Disabled	ELC software event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event IIC0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.

Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event IIC0 RXI	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Disabled	ELC software event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

I2C Master HAL Module Clock Configuration

The IIC peripheral module uses the PCLKB as its clock source. The actual I2C transfer rate will be calculated and set internally by the driver depending on the selected transfer rate. If the PCLKB is configured in such a manner that the selected internal rate cannot be achieved, an error will be returned when initializing the driver.

I2C Master HAL Module Pin Configuration

The IIC peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the

method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins:

Note

The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for I2C Master HAL Module on r_riic

Resource	ISDE Tab	Pin selection Sequence
IIC	Pins	Select **Peripherals**> **Connectivity: IIC**> **IIC0**

Note

The selection sequence assumes IIC0 is the desired hardware target for the driver.

Pin Configuration Settings for the I2C Master HAL Module on r_sci_uart

Pin Configuration Property	Value	Description
Pin Group Selection	_A only, _B only, Mixed Default: _A only	Pin group selection.
Operation Mode	Enabled, Disabled Default: Disabled	Enable or disable peripheral module.
SDA	None, P401, P407 Default: None	SDA Pin.
SCL	None, P400, P204 Default: None	SCL Pin.
SCK	None, P412, P102 Default: P412	SCK Pin.
CTS_RTS_SS	None, P413, P103 Default: None	CTS Pin.
SDA	Disabled	SDA Pin (when Simple I2C is used).
SCL	Disabled	SCL Pin (when Simple I2C is used).

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.24.6 Using the I2C Master HAL Module in an Application

The steps in using the I2C Master HAL module in a typical application are:

1. Initialize and open the I2C RIIC HAL Module using the i2c_api_master_t::open API.
2. Transfer data to the slave using the i2c_api_master_t::write API.
3. Receive data from the slave using the i2c_api_master_t::read API.
4. Reset the module using the i2c_api_master_t::reset API. (Optional)
5. Change the slave address using i2c_api_master_t::slaveAddressSet API. (Optional)

6. Transfer data to the slave using the i2c_api_master_t::write API. (Optional)
7. Receive data from the slave using the i2c_api_master_t::read API. (Optional)
8. Close the module using the i2c_api_master_t::close API. (Optional)

These common steps are illustrated in a typical operational flow diagram in the following figure:

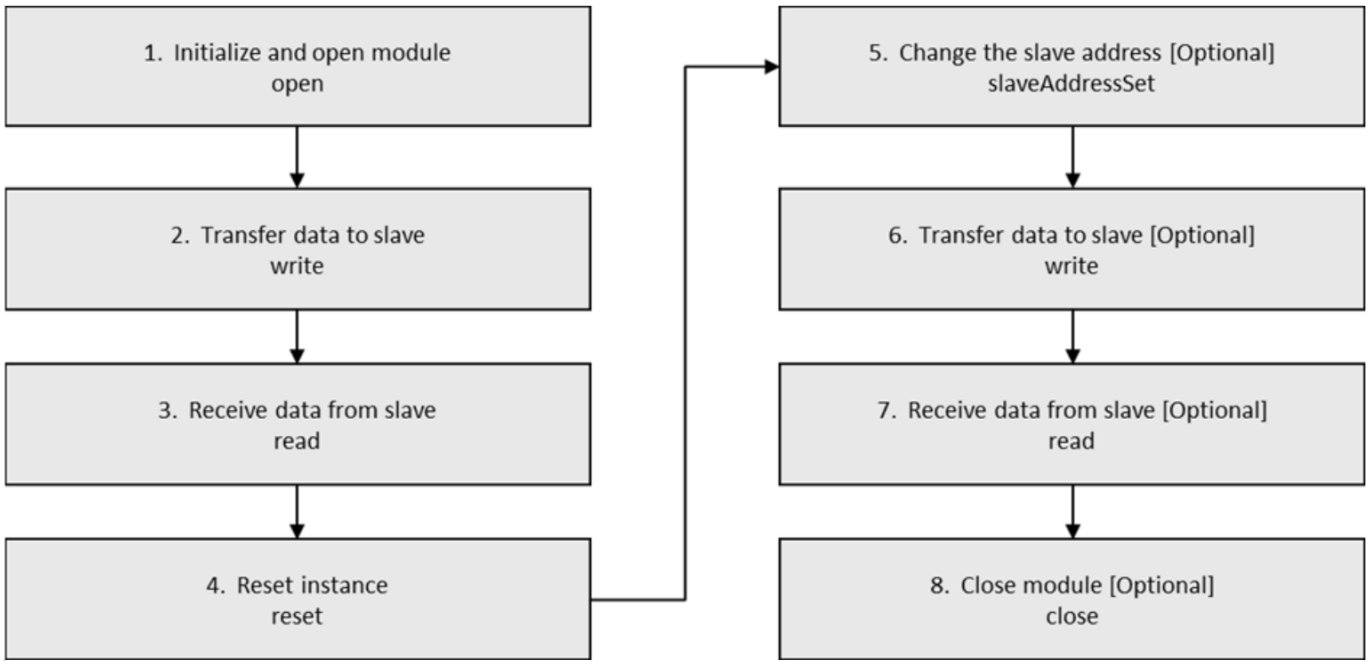

Figure 315: Flow Diagram of a Typical I2C Master HAL Module Application

4.2.25 I2C Slave Driver

4.2.25.1 I2C Slave HAL Module Introduction

The I2C Slave HAL Module provides a high-level API for I2C slave applications and uses the RIIC peripheral on the Synergy MCU. Callbacks are provided to signal read/write request received from master and transfer completion events.

I2C Slave HAL Module Features

- Support for I2C Slave operations
- Support transactions with a I2C master device
  - Read
  - Write
- Callback support
  - Transmit Request (notifies when a write operation is expected from slave)
  - Receive Request (notifies when a read operation is expected from slave)
  - Transmit more request (notifies when master requests more data than configured in slave write operation. Also provides number of bytes transmitted)
  - Receive more request (notifies when master tries to write more data than configured in slave read operation. Also provides number of bytes received)

- Transmit complete (provides number of bytes transmitted)
- Receive complete (provides number of bytes received)

4.2.25.2 I2C Slave HAL Module APIs Overview

The I2C RIIC Slave HAL Module defines APIs for reading and writing to a master I2C device. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

I2C Slave HAL Module API Summary

Function Name	Example API Call and Description
open	g_i2c.p_api->open(g_i2c.p_ctrl, g_i2c.p_cfg); Open the instance and initialize the hardware.
close	g_i2c.p_api->close(g_i2c.p_ctrl); Closes the driver and releases the I2C device.

masterWriteSlaveRead	g_i2c.p_api->masterWriteSlaveRead(g_i2c.p_ctrl, &destination, bytes); Performs a read operation on an I2C device.
masterReadSlaveWrite	g_i2c.p_api->masterReadSlaveWrite(g_i2c.p_ctrl, &source, bytes); Performs a write operation on an I2C device.
versionGet	g_i2c.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_POINTER	Pointer is NULL.
SSP_ERR_IN_USE	Attempted to open an already open device instance.
SSP_ERR_ABORTED	Device was closed while a transfer was in progress.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.25.3 I2C Slave HAL Module Operational Overview

The I2C RIIC Slave HAL Module supports transfers to an I2C Master device. Callbacks are provided to enable the application identify the occurrence of any of the following events.

- Read/write request with the slave address match is detected from master.
- Master requests more data than slave configured in read/write API.
- An ongoing transfer has been aborted.
- An ongoing transfer has completed.

I2C Slave HAL Module Important Operational Notes and Limitations

I2C Slave HAL Module Operational Notes

- The RIIC Error (EEI), Receive Buffer Full (RXI), Transmit Buffer Empty (TXI) and Transmit End (TEI) interrupts for the selected channel used must be enabled in the BSP irrespective of whether the user wants to use callbacks.
- Set equal priority levels for all the interrupts mentioned above. Setting the interrupts to different priority levels could result in improper operation.
- If using RIIC and RIIC_Slave modules on the same board, it is suggested to set equal interrupt priority for TXI, TEI and EI and set RXI interrupt priority higher than these.

I2C Slave HAL Module Limitations

This is the initial version of I2C RIIC Slave Driver with only basic functionality implemented. The following limitations are known:

1. For the driver provide to the application any information regarding the type of request received, the application has to implement/register for the appropriate callback. This limits in usage of the events provided by the driver in application. These events help in real-time master request processing.
2. When the driver is used in blocking mode, slave API has to be invoked with same number of bytes as configured in the master.
3. Any of the supported IIC channels can be configured for either Master or Slave mode operation but not for both.

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.25.4 Including the I2C Slave HAL Module in an Application

This section describes how to include the I2C Slave HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the I2C Slave Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the I2C Slave Driver is g_i2c0. This name can be changed in the associated Properties window.)

I2C Slave HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_i2c0 I2C Slave Driver on r_riic_slave	Threads	**New Stack> Driver> Communications> I2C Slave Driver on r_riic_slave**

When the I2C Slave Driver on r_riic_slave is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Grayband are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

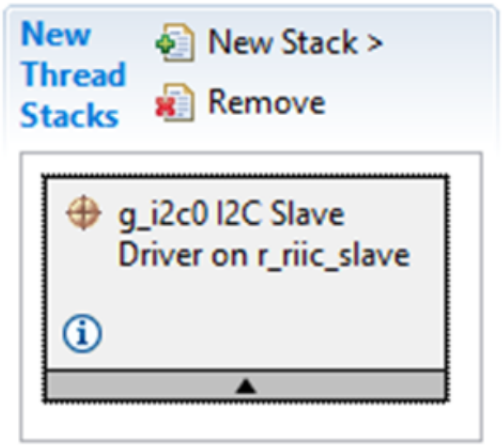

Figure 317: I2C Slave HAL Module Stack

4.2.25.5 Configuring the I2C Slave HAL Module

The I2C Slave HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the I2C Slave HAL Module on r_riic_slave

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_i2c0	Module name.
Channel	0	Specify the IIC channel to be used with this configuration.
Rate	Standard, Fast-mode, Fast-mode plus Default: Standard	Transfer rate to which the IIC peripheral should be configured to operate.
Slave Address	0x00	Set the address of the device as the I2C slave address. Both 7-bit and 10-bit addresses are supported.

Address Mode	7-Bit, 10 Bit Default: 7-Bit	Address mode selection.
Callback	NULL	A user callback function can be registered in i2c_api_master_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) for each of the conditions defined in i2c_event_t. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit End interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Error interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

I2C Slave HAL Module Clock Configuration

The RIIC peripheral module uses PCLKB as its clock source.

I2C Slave HAL Module Pin Configuration

The RIIC peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins:

Note

For some peripherals, the operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection for the I2C Slave HAL Module on r_riic_slave

Resource	ISDE Tab	Pin selection Sequence
I2C	Pins	Select **Peripherals**> **Connectivity: IIC**> **IIC0.**

Note

The selection sequence assumes that IIC0 is the desired hardware target for the driver.

Pin Configuration Settings for the I2C Slave HAL Module on r_riic_slave

Pin Configuration Property	Value	Description
Pin Group Selection	_A only, _B only, Mixed Default: _A only	Select Simple I2C as the Operation Mode for I2C on SCI.
Operation Mode	Enabled, Disabled Default: Disabled	Enable or disable peripheral module.
SDA	None, P401, P407 Default: None	SDA Pin.
SCL	None, P400, P204 Default: None	SCL Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and SK-S7G2 Kit. Other Synergy kits and MCUs may have different available pin configuration settings.

4.2.25.6 Using the I2C Slave HAL Module in an Application

The sequence for using the I2C Slave HAL module (blocking mode) in an application is:

1. Initialize and open the I2C Slave HAL Module using the i2c_api_slave_t::open API.

2. Transfer data to the master using the i2c_api_slave_t::masterReadSlaveWrite API.

3. Receive data from the master using the i2c_api_slave_t::masterWriteSlaveRead API.

4. Close the channel using the i2c_api_slave_t::close API.

These steps are illustrated in a typical operational flow diagram in the following figure:

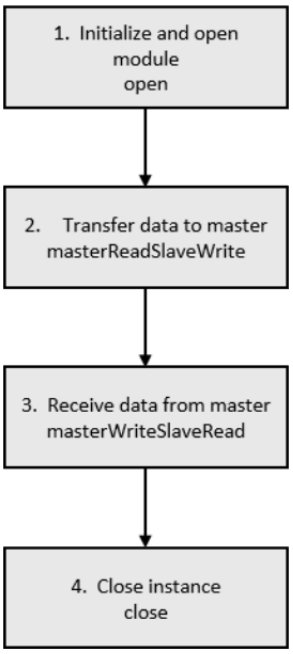

Figure 318: Flow Diagram of a Typical I2C Slave HAL Module Application without callback

The sequence for using the I2C Slave HAL module (non-blocking mode) in an application is:

1. Initialize and open the I2C Slave HAL Module using the i2c_api_slave_t::open API.
2. If callback event i2c_event_t generated indicates transmit request. Transfer data to the master using the i2c_api_slave_t::masterReadSlaveWrite API in callback.
3. If callback event i2c_event_t generated indicates transmit-more request (master tries to read more data than configured in slave write). Transfer data to the master using the i2c_api_slave_t::masterReadSlaveWrite API in callback with new transmit data buffer.
4. If callback event i2c_event_t generated indicates receive request. Receive data from the master using the i2c_api_slave_t::masterWriteSlaveRead API in callback.
5. If callback event i2c_event_t generated indicates a receive-more request (master tries to write more data than configured in slave read). Receive data from the master using the i2c_api_slave_t::masterWriteSlaveRead API in callback with new receive data buffer.
6. Close the channel using the i2c_api_slave_t::close API.

These steps above with registered callback are illustrated in a typical operational flow diagram in the following figure:

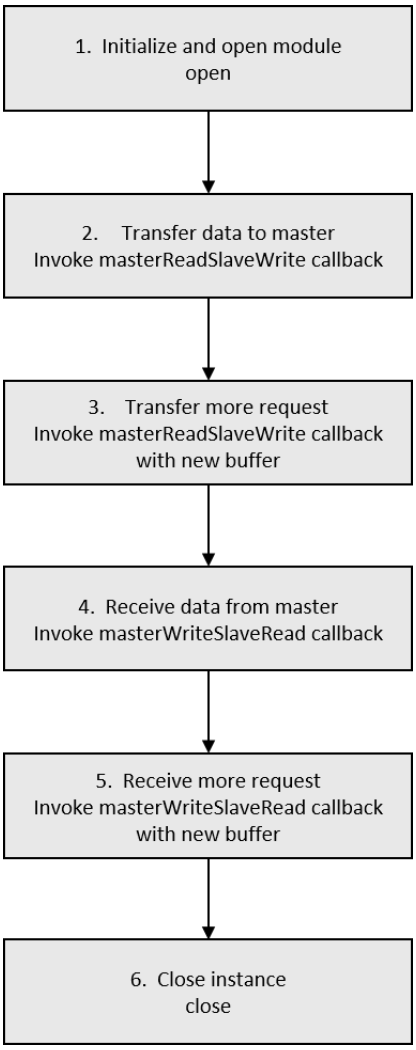

Figure 319: Flow Diagram of a Typical I2C Slave HAL Module Application with callback

4.2.26 I2S Driver

4.2.26.1 I2S HAL Module Introduction

The I2S HAL module provides a high-level API for the standard I2S audio serial communication protocol used to send or receive uncompressed audio data in master/slave mode.

I2S HAL Module Features

The I2S HAL module used with the SSI peripheral in I2S master/slave mode supports the following features (in addition to the standard I2S protocol):

- Full-duplex I2S communication (SSI channel 0 only)
- Interrupt driven data transmission and reception
- Integration with the DTC transfer module

- A user-defined callback created to respond to the need for additional data

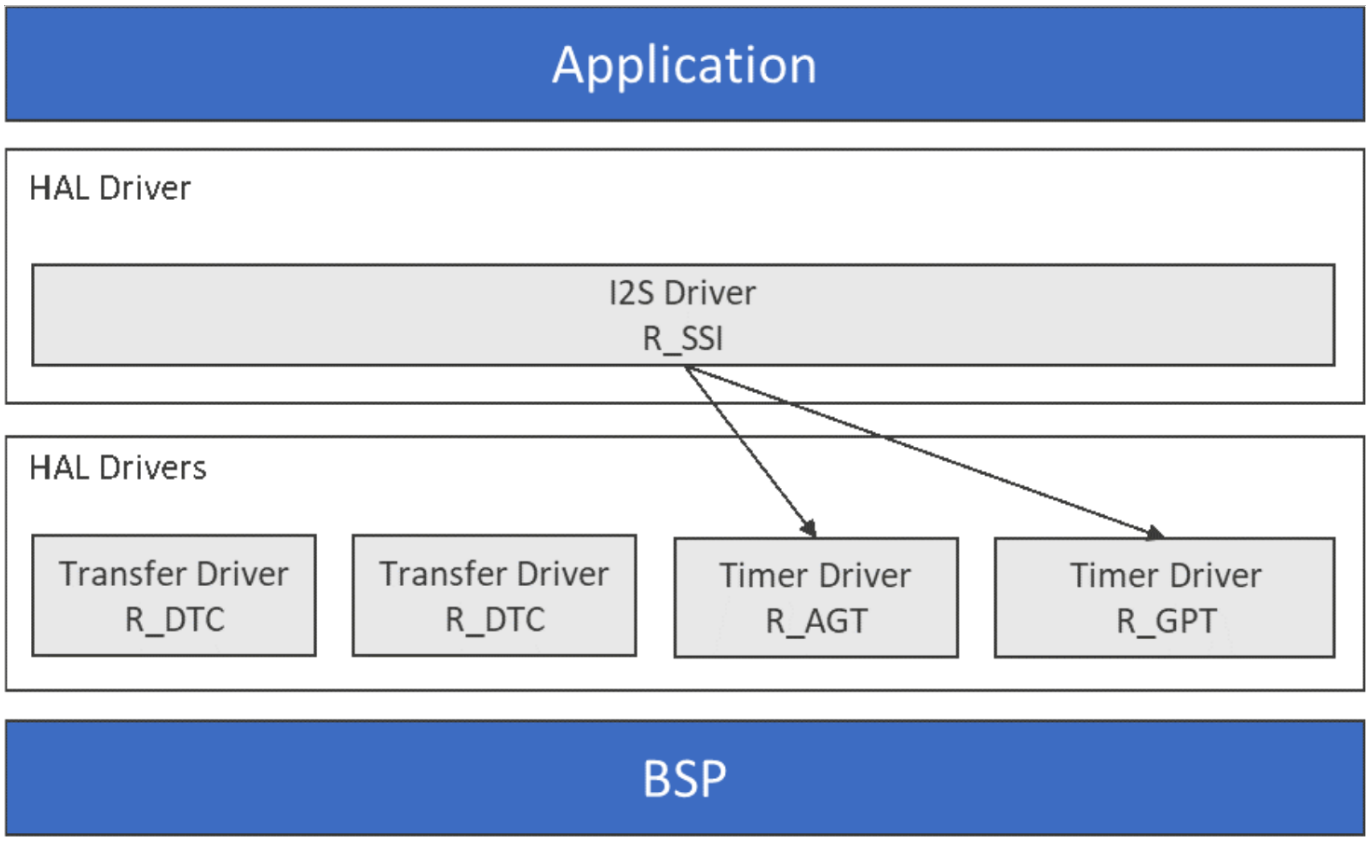

Figure 320: I2S HAL Module Block Diagram

I2S Hardware Support Details

The following hardware features are, or are not, supported by SSP for I2S:

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

MCU Group	Supports 2 Channels	SSI Format Support	MSB first Format Support	Serial bit clock configurable {16, 32, 48, and 64 sampling rates}	Master clock input from the master clock pin for audio (AUDIO_CLK)	Master clock input from the master clock pin for GPT output (GTIOC1A)

4.2.26.2 I2S HAL Module APIs Overview

The I2S HAL module defines APIs for operations such as opening, muting, writing and reading. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

I2S HAL Module API Summary

Function Name	Example API Call and Description
open	g_i2s0.p_api->open(g_i2s0.p_ctrl, g_i2s0.p_cfg); Initial configuration.

stop	g_i2s0.p_api->stop(g_i2s0.p_ctrl, direction_to_stop); Stop communication. Transmission is stopped when callback is called with I2S_EVENT_IDLE. Reception is stopped when callback is called with I2S_EVENT_RX_EMPTY.
mute	g_i2s0.p_api->mute(g_i2s0.p_ctrl, mute_enable); Enable or disable mute.
write	g_i2s0.p_api->write(g_i2s0.p_ctrl, &data, bytes); Write I2S data. All transmit data is queued when callback is called with I2S_EVENT_TX_EMPTY. Transmission is complete when callback is called with I2S_EVENT_IDLE.
read	g_i2s0.p_api->read(g_i2s0.p_ctrl, &data, bytes); Read I2S data. Reception is complete when callback is called with I2S_EVENT_RX_EMPTY.
writeRead	g_i2s0.p_api->writeRead(g_i2s0.p_ctrl, &source, &destination, bytes); Simultaneously write and read I2S data. Transmission and reception are complete when callback is called with I2S_EVENT_IDLE.
infoGet	g_i2s0.p_api->infoGet(g_i2s0.p_ctrl, &info); Get instance specific information and store it in provided pointer info.
close	g_i2s0.p_api->close(g_i2s0.p_ctrl); Allows driver to be reconfigured and may reduce power consumption.
versionGet	g_i2s0.p_api->versionGet(&version); Get version and store it in provided pointer version.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_OUT_OF_MEMORY	The number of streams open at once is limited to SF_AUDIO_PLAYBACK_CFG_MAX_STREAMS. If this number is exceeded, an out of memory error occurs.
SSP_ERR_TIMEOUT	Timeout occurred before playback finished.
SSP_ERR_ASSERTION	A critical assertion has failed.

SSP_ERR_IN_USE	Channel is running/busy.
SSP_NOT_OPEN	Requested channel is not configured or API not open.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.26.3 I2S HAL Module Operational Overview

The I2S HAL module supports audio communications using the I2S protocol. The driver supports the SSI Peripheral on a Synergy MCU in I2S master/slave mode. It can send and receive uncompressed audio data. It provides full-duplex I2S communication (SSI channel 0 only), interrupt-driven data transmission, reception, and integration with the DTC transfer module.

I2S HAL Module Important Operational Notes and Limitations

I2S HAL Module Operational Notes

To enable audio data reception on channel 0, enable the SSI0 RXI interrupt. To enable audio data transmission on channel 0, enable the SSI0 TXI interrupt. To enable both transmission and reception on channel 0, enable both the SSI0 TXI and SSI0 RXI interrupts. To enable transmission or reception on channel 1, enable the SSIn TXI RXI interrupt. In all cases, enable the SSIn INT interrupt.

When the interrupts are enabled in the BSP, the corresponding ISRs will be defined in the I2S driver. The ISR will call the user-callback function registered in open.

I2S HAL Module Limitations

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.26.4 Including the I2S HAL Module in an Application

This section describes how to include the I2S HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the I2S Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the I2S Driver is g_i2s0. This name can be changed in the associated Properties window.)

I2S HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_i2s0 I2S Driver on r_ssi	**Threads**> **HAL/Common Stacks**	**New Stack**> **Driver**> **Connectivity**> **I2S Driver on r_ssi**

When the I2S Driver on r_ssi is added to the thread stack as shown in the following figure, the

configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

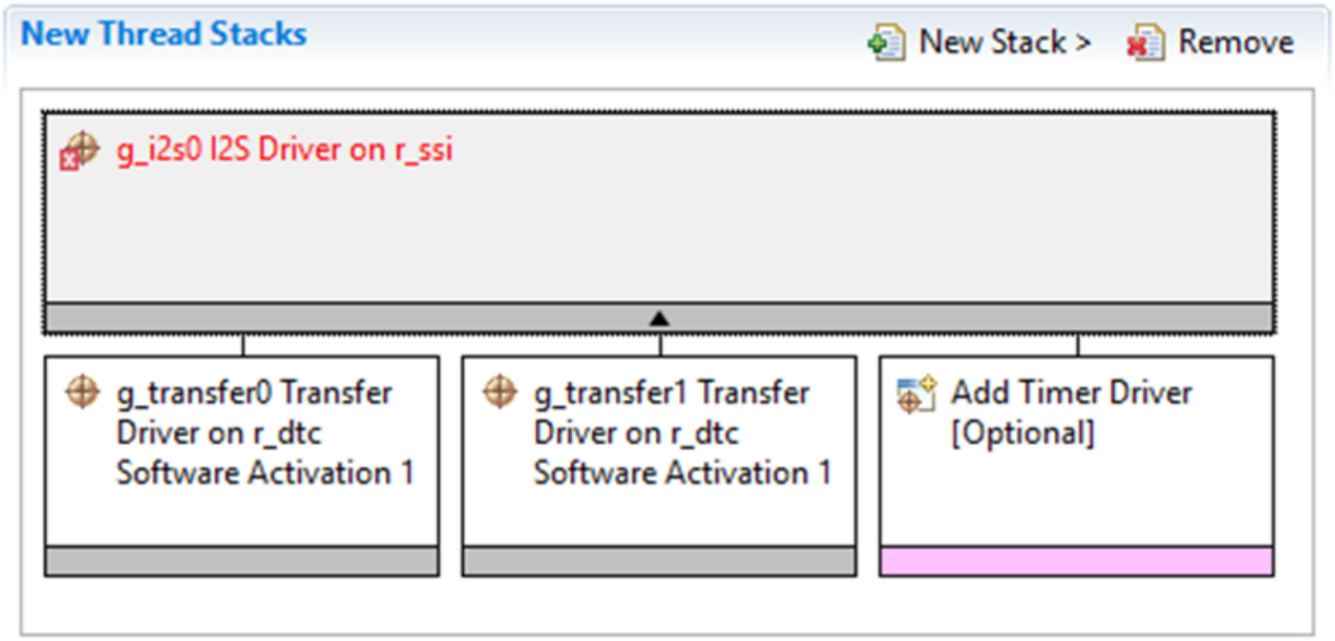

Figure 321: I2S HAL Module Stack

4.2.26.5 Configuring the I2S HAL Module

The I2S HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the I2S HAL Module on r_ssi

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_i2s0	Module name.
Channel	0	Physical hardware channel.
Audio Clock Frequency (Hertz)	2822400	Input audio clock frequency, used to generate the I2S clock. Must be a multiple between 1 and 128 of: (sampling_freq_hz * word_length_in_bits)
Sampling Frequency (Hertz)	44100	Sampling frequency of audio data.
Operating Mode	Master Mode, Slave Mode Default: Master Mode	Operating mode of communication (Master/Slave).
Data Bits	8 bits, 16, 18, 20, 22, 24 Default: 16 bits	Bit depth of audio data, which is the size in bits of one sample of audio data.
Word Length	8 bits, 16, 24, 32 Default: 16 bits	Word length of audio data, must be at least the same size as the bit depth (Data Bits field).
WS Continue Mode	Enabled, Disabled Default: Disabled	Enable WS continue mode to continue to output the word select line when the peripheral is idle. Disable to stop outputting the word select line when the peripheral is idle.
Name of I2S callback function to be defined by user	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) when the transmission FIFO reaches the high watermark point after all data for transmission is transmitted or when reception is complete (the requested number of bytes have been received). Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system

Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Transmit interrupt priority selection
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Receive interrupt priority selection
Idle/Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Priority 12	Idle/error interrupt priority selection

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults for lower level modules can be desirable. For example, it might be useful to select the DAC or I2S Channel based on the target hardware implementation. The configurable properties for the lower level stack modules are given in the below sections for completeness and as a reference.

Note

Most of the property settings for lower-level modules are fairly intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the I2S HAL Module Lower-Level Modules

Typically, only a small number of settings must be modified from the default for lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module.

Configurable Settings for the Transfer Driver on r_dtc Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer0	Driver name.
Mode	Normal	Mode selection.

Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC software event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table.
Name	g_transfer1	Driver name.

Mode	Normal	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1, Software Activation 2, Peripheral Events Default: Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC software event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configurable Settings for the Timer Driver on r_agt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Mode selection.
Period Value	2822400 *2	Period value selection.

Period Unit	Hertz	Period unit selection.
Auto Start	FALSE	Auto start selection.
Count Source	PCLKB, PCLKB/8, PCLKB/2, LOCO, AGT0 Underflow, AGT0 fSub Default: PCLKB	Count source selection.
AGTO Output Enabled	True, False Default: False	AGTO output selection.
AGTIO Output Enabled	True, False Default: False	AGTIO output selection.
Output Inverted	True, False Default: False	Output inverted selection.
Enable comparator A output pin	True, False Default: False	Enable comparator A output pin selection.
Enable comparator B output pin	True, False Default: False	Enable comparator B output pin selection.
Callback	NULL	Callback selection.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configurable Settings for the Timer Driver on r_gpt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Name	g_timer0	Module name.
Channel	0	Channel selection.
Mode	Periodic	Mode selection.
Period Value	2822400 *2	Period value selection.

Period Unit	Hertz	Period unit selection.
Duty Cycle Value	50	Duty cycle value selection.
Duty Cycle Unit	Unit Raw Counts, Unit Percent, Unit Percent x 1000 Default: Unit Raw Counts	Duty cycle unit selection.
Auto Start	FALSE	Auto start selection.
GTIOCA Output Enabled	True, False Default: False	GTIOCA output enabled selection.
GTIOCA Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCA stop level selection.
GTIOCB Output Enabled	True, False Default: False	GTIOCB output enabled selection.
GTIOCB Stop Level	Pin Level Low, Pin Level High, Pin Level Retained Default: Pin Level Low	GTIOCB stop level selection.
Callback	NULL	Callback selection.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

I2S HAL Module Clock Configuration

The SSI module uses the peripheral clock (PCLKB) available from the Clock configuration window. It also uses an external clock input to the AUDIO_CLK pin.

I2S HAL Module Pin Configuration

The SSI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device.

Configure the SSI RX and/or TX pins for the selected SSI channel (**Pins** tab > **Peripherals** > **SSI** > **SSIn** > **SSITXD0/SSIRXD0**). For channel 0, enable one or both of these pins. For channel 1, enable the SSIDATA1 pin.

Configure the word select and clock pins (**Pins** tab > **Peripherals** > **SSI** > **SSIn** > **SSITWSn** and **SSISCKn**). Both of these pins are required in most cases. Consult the datasheet of the I2S device

used for the required pins.

Configure the audio clock pin (**Pins** tab > **Peripherals** > **SSI** > **SSI0_SSI1_AUDIO_CLK**) for SSI. Connect an external audio clock to this clock input pin. If a GPT timer is used to generate the audio clock, configure the GPT timer output pin (**Pins** tab > **Peripherals** > **GPT1** > **GPTn** > **GTIOCx**) and connect the GPT output pin used to the audio clock input pin.

The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the associated pins:

Pin Selection for the I2S HAL Module on r_ssi

Resource	ISDE Tab	Pin selection Sequence
ACMPLP	Pins	Select **Peripherals**> **Analog:ACMP.**

Note

The selection sequence assumes SSI0 is the desired hardware target for the driver.

Pin Configurable Settings for the I2S Driver on SSI

Pin Configuration Property	Settings	Description
Pin Group Selection	_A only, Mixed	Pin group for I2S port.
Operation Mode	Custom, Disabled	Operation selection.
SSISCK	None, P400 Default: None	AUDIO_CLK pin(P400), used in this application

Note

The example values are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

Pin Configuration Settings for I2S Driver on SSI0

Pin Configuration Property	Settings	Description
Pin Group Selection	_A only, _B only, Mixed	Pin group for I2S port.
Operation Mode	Enabled, Custom, Disabled	Operation selection.
SSISCK	None, P112 Default: None	SSISCK pin (P112), used in this application.
SSIWS	None, P113 Default: None	SSIWS pin (P113), used in this application.
SSITXD	None, P115 Default: None	SSITXD pin (P115), used in this application.

SSIRXD	None, P114 Default: None	SSIRXD pin (P114), used in this application.

Note

The example values are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

Pin Configuration Settings for I2S Driver on SSI1

Pin Configuration Property	Settings	Description
Pin Group Selection	_A only, _B only, Mixed	Pin group for I2S port.
Operation Mode	Enabled, Custom, Disabled	Operation selection.
SSISCK	None, P204 Default: None	SSI Serial Clock, not used in this application.
SSIWS	None, P205 Default: None	SSI Stereo pin selection, not used in this application.
SSIDATA	None, P206 Default: None	SSI Data pin selection, not used in this application.

Note

The example values are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.26.6 Using the I2S HAL Module in an Application

The typical steps in using the I2S HAL module in an application are:

1. Open the I2S HAL module using the i2s_api_t::open API.
2. Use the i2s_api_t::write API to write audio data to the I2S bus.
3. Wait for a callback with I2S_EVENT_TX_EMPTY and free the source buffer.
4. Use the i2s_api_t::read API to read data from the I2S bus.
5. Wait for a callback with I2S_EVENT_RX_FULL before accessing the destination buffer or reading the next buffer.
6. Use other APIs as needed by the application.
7. Close the module with the i2s_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

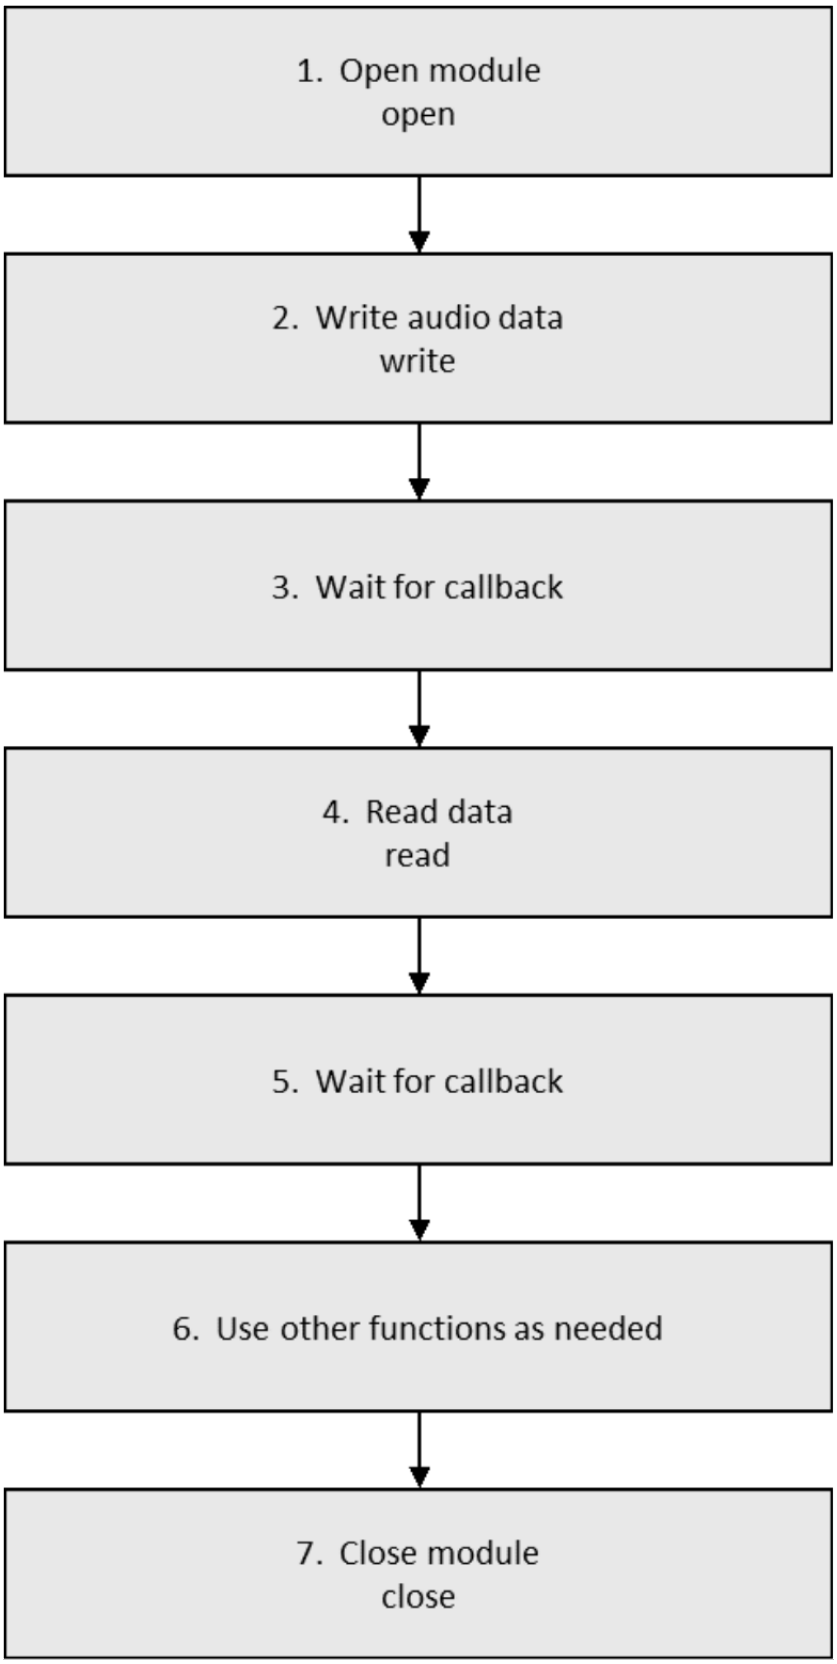

Figure 322: Flow Diagram of a Typical I2S HAL Module Application

4.2.27 GPT Input Capture on r_gpt Driver

4.2.27.1 GPT Input Capture HAL Module Introduction

The Input Capture HAL module provides an API for measuring input pulse-width and pulse-period measurement. The Input Capture HAL module also configures the input capture parameters to use with the GPT peripheral on the Synergy MCU. A user-defined callback can be created to acquire the value each time a new measurement is complete.

GPT Input Capture HAL Module Features

The Input Capture HAL module configures the GPT for an input capture function.

- The Input Capture HAL allows the user to perform the following tasks:
  - Initialize the module
  - Enable input capture measurement
  - Disable input capture measurement
  - Get the status (running or not) of the measurement counter
  - Get the last captured timer/overflows counter value
  - Close the input capture operation
- The Input Capture HAL module supports:
  - Pulse-width measurement and pulse-period measurement
  - Rising-edge or falling-edge measurement start
  - One-shot or periodic mode
  - Hardware-enable signals to enable captures (low enable/high enable)
  - Callback function with the following events:
    - Counter overflow
    - Input capture occur
  - Callback structure (input_capture_callback_args_t) that provides data on the interrupting event, including which interrupt occurs and the associated counter values.

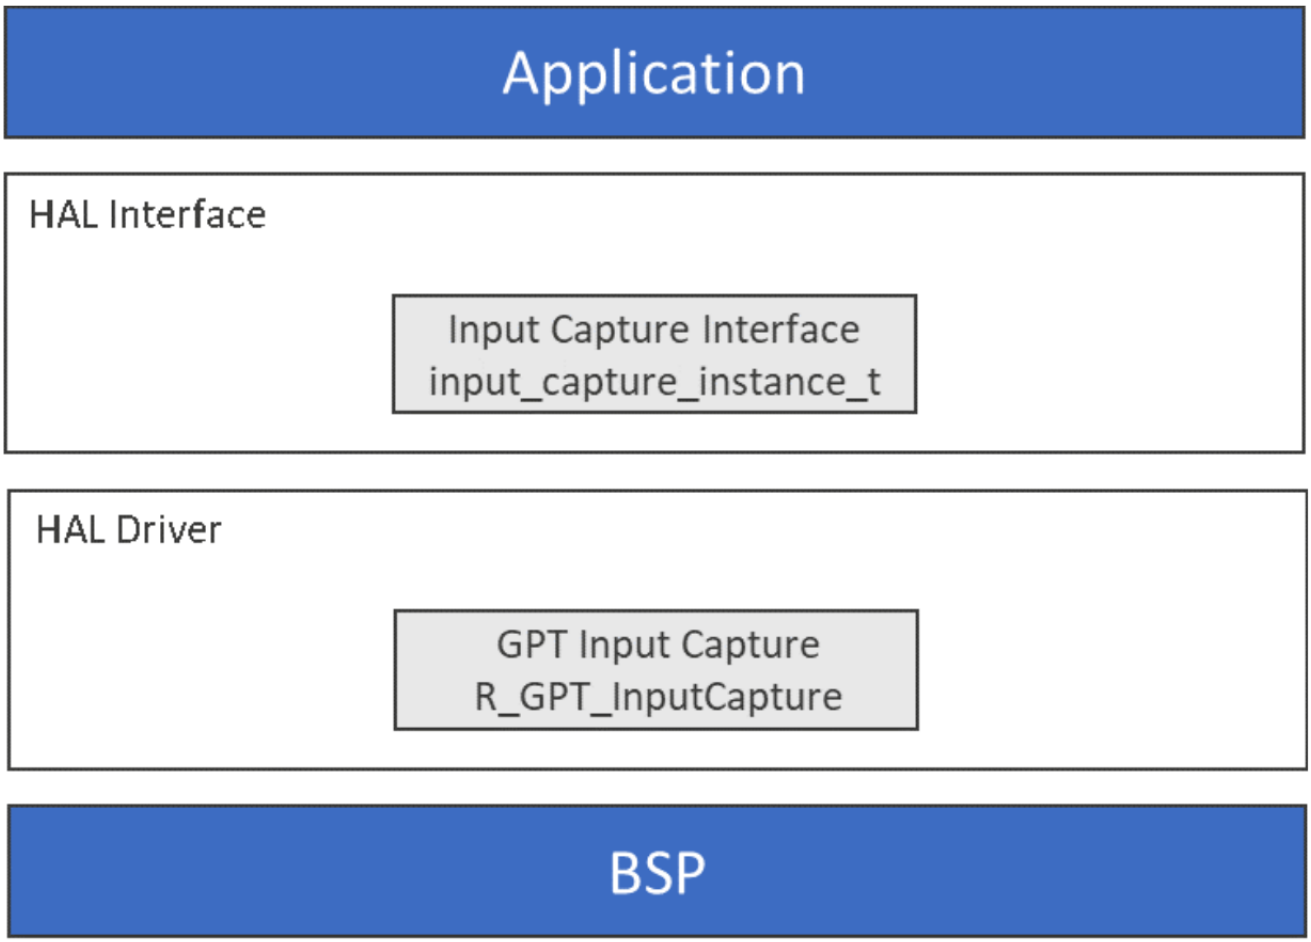

Figure 323: Input Capture HAL Module Block Diagram

GPT Input Capture Hardware support details

The following hardware features are, or are not, supported by SSP for GPT_INPUT_CAPTURE.

Legend:

4.2.27.2 GPT Input Capture HAL Module APIs Overview

The Input Capture HAL module interface defines APIs for opening, closing, enabling, disabling, accessing status information and last-capture value accessing using the General PWM Timer (GPT) with Input Capture. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the HAL Module API Summary.

Input Capture HAL Module API Summary

Function Name	Example API Call and Description
open	g_input_capture.p_api->open(g_input_capture.p_ctrl, g_input_capture.p_cfg); Opens the Input Capture HAL and initializes configuration.

close	g_input_capture.p_api->close(g_input_capture.p_ctrl); Closes the input capture operation. Allow drive to be reconfigured, and may reduce power consumption.
enable	g_input_capture.p_api->enable(g_input_capture.p_ctrl); Enables input capture measurement.
disable	g_input_capture.p_api->disable(g_input_capture.p_ctrl); Disables input capture measurement.
infoGet	g_input_capture.p_api->infoGet(g_input_capture.p_ctrl, &input_capture_info); Gets the status (running or not) of the measurement counter.
lastCaptureGet	g_input_capture.p_api->lastCaptureGet(g_input_capture.p_ctrl, &input_capture_counter); Gets the last captured timer/overflows counter value.
versionGet	g_input_capture.p_api->versionGet(&input_capture_version); Retrieve the API version with the input_capture_version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	One of the parameters is NULL. Or the channel requested in the p_cfg parameter may not be available on the device selected in r_bsp_cfg.h or p_cfg->mode is invalid.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value or ISR is not enabled.
SSP_ERR_IN_USE	Attempted to open an already open device instance.
SSP_ERR_NOT_OPEN	The channel is not opened.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.27.3 GPT Input Capture HAL Module Operational Overview

The Input Capture HAL module controls the GPT HAL module units on a Synergy microcontroller (as configured by the user). It directly accesses the GPT hardware without using any RTOS elements and provides convenient APIs to simplify development.

When a normal measurement is complete and a callback is available (with interrupts enabled,) the Input Capture HAL module invokes the callback with the argument input_capture_callback_args_t.

The argument input_capture_callback_args_t indicates the channel, the event input_capture_event_t, the value of the timer captured when the interrupt occurred, and the number of counter overflows that occurred during this measurement.

If the interrupts are not enabled, the values read by the APIs would be the last captured timer/overflows counter value.

GPT Input Capture HAL Module Important Operational Notes and Limitations

GPT Input Capture HAL Module Operational Notes

GPT Input Capture Measurement Mode

The input capture interface provides support for one-shot measurement and periodic measurement. The GPT hardware does not natively support one-shot functionality. Code is automatically included in the interrupt service routine (ISR) to stop and clear the timer. For this reason, ISRs must be enabled for one-shot mode, even when the callback is unused.

GPT Input Capture Signal

The input capture measurement starts when the input capture signal edge (rising or falling) is detected on the input capture signal pin (GTIOCA/GTIOCB) and the enable condition is met. The enable condition is defined by the enable level and can be disabled (none), or a specified low or high level on the input capture enable pin (GTIOCA/GTIOCB). The input capture enable pin is the pin not used as the input capture signal pin.

Converting Measurement Counts to Time

When a measurement completes, the raw-count data and the number of overflows is returned to the user in the callback function.

If desired, the raw measurement data can be converted to logical time units in the callback or user application. To convert the raw data, the current PCLKD clock frequency and its pre-scaler value, number of overflows, maximum counter value, and measurement counts should be considered. The measurement counts and the number of overflows are provided in the callback arguments input_capture_callback_args_t.

The recommended method to obtain the current PCLKD frequency is to use the cgc_api_t::systemClockFreqGet API. The input clock frequency is the PCLKD frequency divided by the pre-scalar value and is represented as clk_freq_hz in the following Input Capture Time Calculation table.

The maximum counter value on the S7G2 (all channels), S3A7 (all channels), and S124 (channel 0) is 0xFFFFFFFF. The maximum counter value for S124 (channels 1 - 6) is 0xFFFF. This maximum counter value plus one (since counter starts from zero) is represented as max_counts in the following table:

Input Capture Time Calculation

Desired Time Units	Formula
Nanoseconds (ns)	time_ns = ((overflows * max_counts) + counter) * 1000000000 / clk_freq_hz
Microseconds (us)	time_ns = ((overflows * max_counts) + counter) * 1000000 / clk_freq_hz
Milliseconds (ms)	time_ns = ((overflows * max_counts) + counter) * 1000 / clk_freq_hz
Seconds (s)	time_ns = ((overflows * max_counts) + counter) / clk_freq_hz

GPT Input Capture HAL Module Limitations

- Currently, the Input Capture HAL module supports only pulse-width measurement and pulse-period measurement.
- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.27.4 Including the GPT Input Capture HAL Module in an Application

This section describes how to include the Input Capture HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Input Capture Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Input Capture Driver is g_input_capture0. This name can be changed in the associated Properties window.)

Input Capture HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_input_captureInput Capture Driver on r_gpt_input_capture	**Threads**> **HAL/Common Stacks**	**New Stack**> **Driver**> **Timers** > **Input Capture Driver on r_gpt_input_capture**

When the Input Capture Driver on r_gpt_input_capture is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

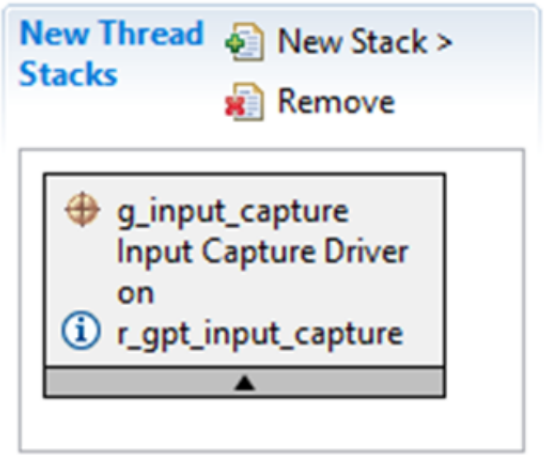

Figure 324: Input Capture HAL Module Stack

4.2.27.5 Configuring the GPT Input Capture HAL Module

The Input Capture HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Input Capture HAL Module on r_gpt_input_capture

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_input_capture	Module name.
Channel	0	Physical hardware channel.
Mode	Pulse Width, Period Default: Pulse Width	Measures inputs from the Signal edge until the opposite edge.
Signal Edge	Rising, Falling Default: Rising	Start measurement on rising or falling edge. Measurement stops on the opposite edge.

Repetition	Periodic, One Shot Default: Periodic	Capture a single measurement, then disable captures (one shot) until enable is called, or capture measurements continuously (periodic).
Auto Start	True, False Default: True	Set to true to enable measurements after configuring or false to leave the measurements disabled until enable is called.
Callback	NULL	A user callback function must be registered in open. The callback will be called from the interrupt service routine (ISR) each time the timer period elapses. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Input Capture Signal Pin	GTIOCA, GTIOCB Default: GTIOCA	Select the input pin used to trigger the start of a measurement.
GTIOCx Signal Filter	PCLK/1, PCLK/4, PCLK/16, PCLK/64 Default: PCLK/1	The noise filter samples the external signal at intervals of the PCLK divided by one of the values. When 3 consecutive samples are at the same level (high or low), that level is passed on as the observed state of the signal.
Clock Divider	PCLK/1, PCLK/4, PCLK/16, PCLK/64, PCKL/256, PCLK/1024 Default: PCLK/1	Clock divider used to scale the measurement counter.

Input Capture Enable Level	None, Low, High Default: None	Each GPT channel has 2 I/O pins (GTIOCA and GTIOCB). One must be selected as the Input Capture Signal Pin. The other GPT I/O pin can be used as a hardware enable signal to enable captures. Select None and captures are always enabled, select low and captures are enabled only while the enable input pin is low, select high and captures are enabled only while the enable input pin is high.
Input Capture Enable Filter	Enable, Disable Default: Disable (No filtering)	Enable/Disable the input noise filter for input on GTIOCx pin
Capture Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Capture interrupt priority selection.
Overflow Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Overflow interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

GPT Input Capture HAL Module Clock Configuration

The GPT HAL module uses the PCLKD as its clock source. The PCLKD frequency is set using the SSP configurator clocks tab prior to a build, or using the CGC Interface at run-time.

GPT Input Capture HAL Module Pin Configuration

To access a particular channel and pin, the GTIOCx pins must be set in the **Pins** tab of the ISDE. The following table provides the method for selecting the pins within the SSP configuration window and the subsequent table provides an example selection for GTIOCx pins.

Pin Selection for the Input Capture HAL Module on r_gpt_input_capture

Resource	ISDE Tab	Pin selection Sequence
GPT Input Capture	Pins	Select **Peripherals**> **Timer: GPT**> **GPT0**

Note

The selection sequence assumes GPT0 is the desired hardware target for the driver.

Pin Configuration Settings for the Input Capture HAL Module on r_kint

Property	Value	Description
Pin Group Selection	Mixed, _A Only, _B Only Default: Mixed	Pin grouping selection.
Operation Mode	Disabled, GTIOCA or GTIOCB, GTIOCA and GTIOCB Default: Disable	Select GTIOCA or GTIOCB as the Operation Mode for Input Capture on GPT.
GTIOCA	None, P300, P512 Default: None	GTIOCA Pin.
GTIOCB	None, P108, P511 Default: None	GTIOCB Pin.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.2.27.6 Using the GPT Input Capture HAL Module in an Application

The typical steps in using the Input Capture HAL module in an application are:

1. Initialize the module using the input_capture_api_t::open API.
2. The desired value can be found either in the main loop routine using the input_capture_api_t::lastCaptureGet API or in the callback function.
3. The capture and overflow interrupt can be disabled and the timer stopped using theinput_capture_api_t::disable API.
4. The capture and overflow interrupt can be enabled and the timer started using the input_capture_api_t::enable API.
5. The status of the captured counter (running or stopped) can be queried using input_capture_api_t::infoGet API.
6. The module can be closed using the input_capture_api_t::close API once done.

These common steps are illustrated in a typical operational flow diagram in the following figure:

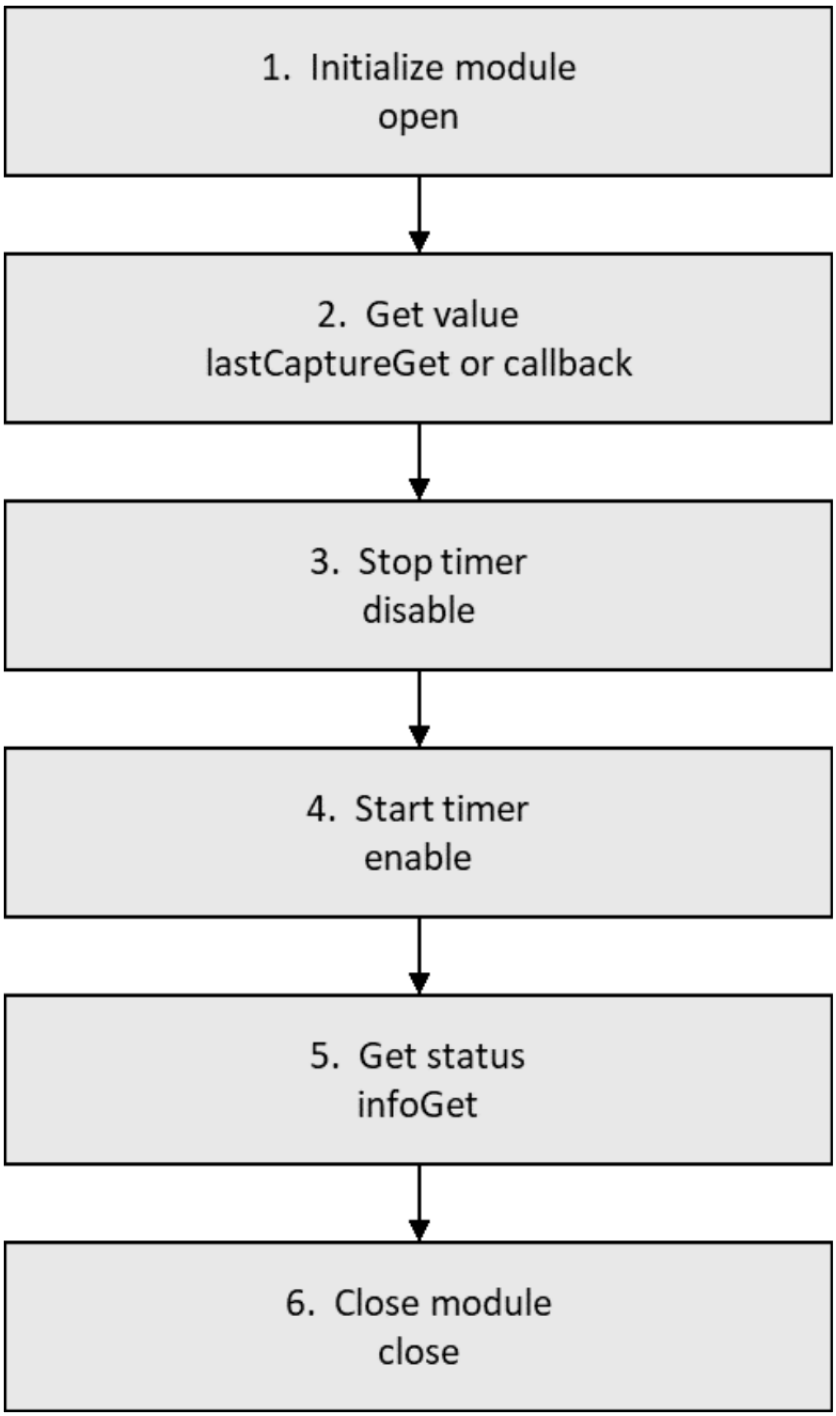

Figure 325: Flow Diagram of a Typical Input Capture HAL Module Application

4.2.28 I/O Port Driver

4.2.28.1 I/O PORT HAL Module Introduction

The I/O Port HAL module implements a high-level API for controlling I/O pins, configuring the board's pins and manipulating I/O pins. The operating state of an I/O pin can be set via the Synergy configurator. When the Synergy project is built, a pin configuration file is created. When the application runs, the BSP will configure the MCU IO port accordingly, using the same API functions described in this document.

I/O PORT HAL Module Features

The I/O PORT HAL module can perform the following functions:

- Create an event link between two blocks.
- Break that event link between two blocks.
- Generate one of two software events that interrupt the CPU.

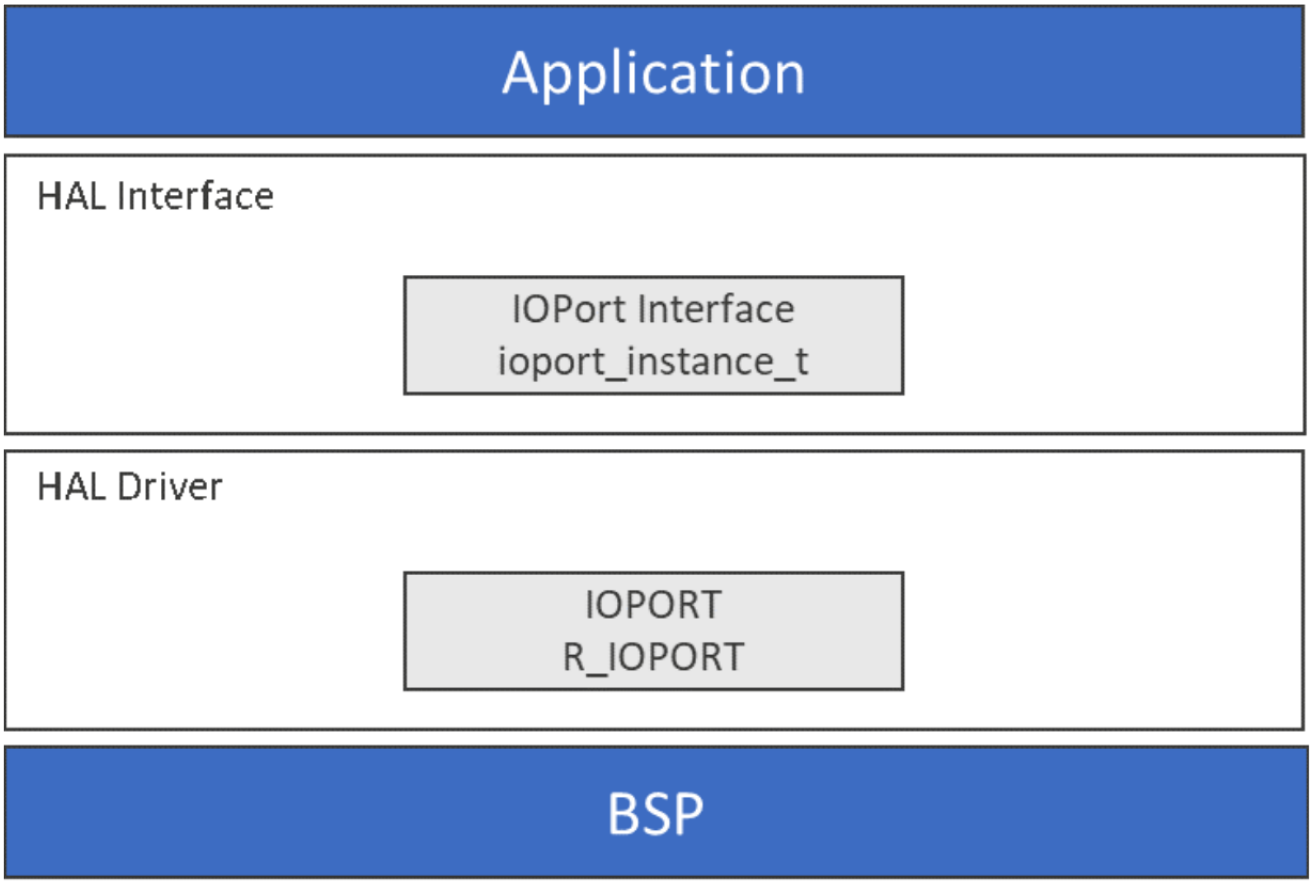

Figure 326: I/O PORT HAL Module Block Diagram

I/O Port Hardware support details

The following hardware features are, or are not, supported by SSP for GPIO.

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)

- Note: Event Linking would have to be set up by the user, rather than using the ELC API.

4.2.28.2 I/O PORT HAL Module APIs Overview

The I/O Port HAL module defines APIs for reading and writing from particular pins and ports. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

I/O PORT HAL Module API Summary

Function Name	Example API Call and Description
init	g_ioport.p_api->init(g_ioport.p_cfg); Initialize configuration of multiple pins.
pinCfg	g_ioport.p_api->pinCfg(IOPORT_PORT_00_PIN_00, IOPORT_CFG_IRQ_ENABLE | IOPORT_CFG_PORT_DIRECTION_INPUT); Configure settings for an individual pin.
pinDirectionSet	g_ioport.p_api->pinDirectionSet(IOPORT_PORT_00_PIN_00, IOPORT_DIRECTION_INPUT); Set the pin direction of a pin.
pinEventInputRead	g_ioport.p_api->pinEventInputRead(IOPORT_PORT_00_PIN_00, &pin_level); Read the event (ELC) input data of the specified pin and return the level.

pinEventOutputWrite	g_ioport.p_api->pinEventOutputWrite(IOPORT_PORT_00_PIN_00, IOPORT_PIN_LEVEL_HIGH); Write pin event (ELC) data.
pinEthernetModeCfg	g_ioport.p_api->pinEthernetModeCfg(IOPORT_ETHERNET_CHANNEL_0, IOPORT_ETHERNET_MODE_MII); Configure the PHY mode of the Ethernet channels.
pinRead	g_ioport.p_api->pinRead(IOPORT_PORT_00_PIN_00, &pin_level); Read level of a pin.
pinWrite	g_ioport.p_api->pinWrite(IOPORT_PORT_00_PIN_00, IOPORT_PIN_LEVEL_HIGH); Write specified level to a pin.
portDirectionSet	g_ioport.p_api->portDirectionSet(IOPORT_PORT_00, direction_values, mask); Set the direction of one or more pins on a port.
portEventInputRead	g_ioport.p_api->portEventInputRead(IOPORT_PORT_00, &pin_levels); Read captured event (ELC) data for a port.
portEventOutputWrite	g_ioport.p_api->portEventOutputWrite(IOPORT_PORT_00, pin_levels, mask); Write event (ELC) output data for a port.
portRead	g_ioport.p_api->portRead(IOPORT_PORT_00, &pin_levels); Read states of pins on the specified port.
portWrite	g_ioport.p_api->portWrite(IOPORT_PORT_00, pin_levels, mask); Write to multiple pins on a port.
versionGet	g_ioport.p_api->versionGet(&version); Retrieve version information using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	The port/pin/mask/direction/level (and so forth) not valid.
SSP_ERR_ASSERTION	Unexpected null pointer.

SSP_ERR_UNSUPPORTED	Feature not supported – for instance Ethernet configuration not supported on the device.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.28.3 I/O PORT HAL Module Operational Overview

The I/O Port HAL module provides the ability to access the I/O ports of a device at both bit and port level; both port and pin direction can be changed. In addition, a number of configuration APIs are provided to change the functionality of individual pins.

The I/O Port HAL module provides the following operations for configuring pins:

- Initializes the driver – performed by calling ioport_api_t::init API:
  - Performs parameter checking and processes error conditions.
  - Handles VBATT domain pin configuration.
  - Writes PFS registers for pins.
- Configures pin – performed by calling ioport_api_t::pinCfg API:
  - Performs parameter checking and processes error conditions (checks pin number pin, VBATT support).
  - Writes PFS register for the pin.
- Reads pin level – performed by calling ioport_api_t::pinRead API:
  - Performs parameter checking and processes error conditions (checks pin number pin).
  - Reads PFS register for the pin.
- Reads all pin levels on a port – performed by calling ioport_api_t::portRead API:
  - Performs parameter checking and processes error conditions (checks port number port).
  - Reads current value of PCNTR register value for the specified port.
- Writes pin level – performed by calling ioport_api_t::pinWrite API:
  - Performs parameter checking and processes error conditions (check pin number pin and written level level).
  - Write to PFS register for the pin.
- Write multiple pin levels on a port – performed by calling ioport_api_t::portWrite API:
  - Performs parameter checking and processes error conditions (checks port number port and pin mask mask).
  - Reads current configuration from the PCNTR register for the specified port.
  - Writes the pin levels to the PCNTR register for the specified port accordingly to the mask, preserving pin levels out of the scope.
- Sets the direction of multiple pins on a port – performed by calling ioport_api_t::portDirectionSet API:
  - Performs parameter checking and processes error conditions (checks port number port and pin mask mask).
  - Reads current configuration from the PCNTR register for the specified port.
  - Writes the pin levels to the PCNTR register for the specified port accordingly to the mask, preserving pin directions out of the scope.
- Writes pin direction – performed by calling ioport_api_t::pinDirectionSet API:
  - Performs parameter checking and processes error conditions (checks pin number pin and written direction direction).
  - Writes to the PFS register for the pin.
- Reads event (ELC) port input – performed by calling ioport_api_t::portEventInputRead API:
  - Performs parameter checking and processes error conditions (checks port number

port).
    - Reads current value of the PCNTR register value for the specified port.
- Reads event (ELC) pin input – performed by calling ioport_api_t::pinEventInputRead API:
    - Performs parameter checking and processes error conditions (checks pin number pin).
    - Reads current value of the PCNTR register value for the specified pin's port.
    - Gets the pin level by applying a pin mask to the PCNTR register value.
- Writes event (ELC) port output – performed by calling the ioport_api_t::portEventOutputWrite API:
    - Performs parameter checking and processes error conditions (checks port number port and pin mask mask_value).
    - Reads current configuration from the PCNTR register for the specified port.
    - Writes the pin levels to the PCNTR register for the specified port accordingly to the mask preserving pin levels out of the event scope.
- Writes event (ELC) pin output – performed by calling ioport_api_t::pinEventOutputWrite API:
    - Performs parameter checking and processes error conditions (checks pin number pin and written level ioport_api_t::pinRead).
    - Writes the pin level to the PCNTR register for the specified pin's port accordingly to the mask that is preserving pin levels out of the event scope.
- Configures Ethernet channel PHY mode – performed by calling ioport_api_t::pinEthernetModeCfg API:
    - Performs parameter checking and processes error conditions (checks Ethernet channel channel and mode mode).
    - Updates the Ethernet Control Register (PFENET).

I/O PORT HAL Module Important Operational Notes and Limitations

I/O PORT HAL Module Operational Notes

- A bit mask of 16 bits needs to be applied in order to read and write to a specific pin on a port; ports are numbered from 0 (LSB) to 15 (MSB).
- Configuring the Ethernet port (selection of the RMII or MII output format) using the ioport_api_t::pinEthernetModeCfg API function on MCUs without an Ethernet Port will return an Unsupported Error message. To avoid this, the developer should verify the target MCU has an Ethernet port available. This information is easily found in the target MCU hardware user's manual. Simply verify that an Ethernet peripheral is available on the target MCU before beginning development.

I/O PORT HAL Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.28.4 Including the I/O PORT HAL Module in an Application

This section describes how to include the I/O PORT HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the I/O Port Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the I/O Port Driver is g_ioport0. This

name can be changed in the associated Properties window.)

I/O PORT HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_ioport I/O Port driver on r_ioport	Threads	**Highlight HAL/Common and select New> Driver> System> I/O Port Driver on r_ioport**

When the I/O Port Driver on r_ioport is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

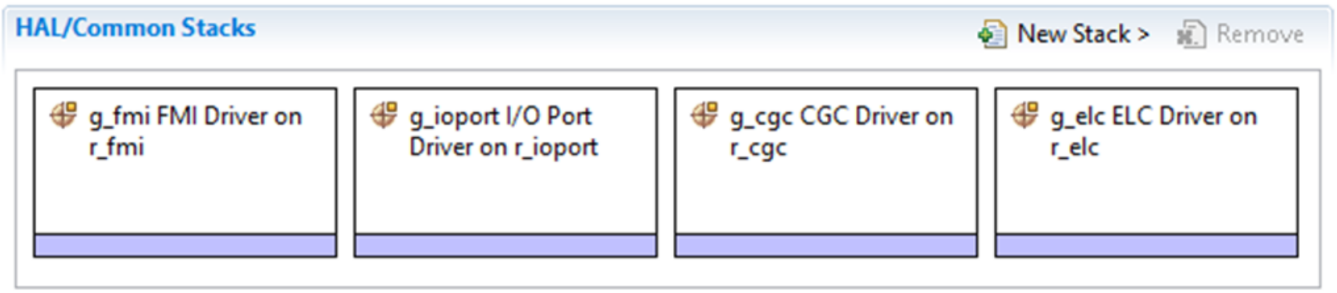

Figure 327: I/O PORT HAL Module Stack

4.2.28.5 Configuring the I/O PORT HAL Module

The I/O PORT HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the I/O PORT HAL Module on r_ioport

ISDE Property	Value	Description

Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_ioport	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

I/O PORT HAL Module Clock Configuration

The I/O PORT HAL module does not require a specific clock configuration.

I/O PORT HAL Module Pin Configuration

There are no pins associated directly with the I/O PORT HAL Module that require configuration.

4.2.28.6 Using the I/O PORT HAL Module in an Application

The typical steps in using the I/O PORT HAL module in an application are:

1. Initialize the driver using the ioport_api_t::init API.
2. Configure the pins using the ioport_api_t::pinCfg API.
3. Read from specified pins and ports using the ioport_api_t::pinRead and ioport_api_t::portRead APIs.
4. Write to specified pins and ports using the ioport_api_t::pinWrite and ioport_api_t::portWrite APIs.

These common steps are illustrated in a typical operational flow diagram in the following figure:

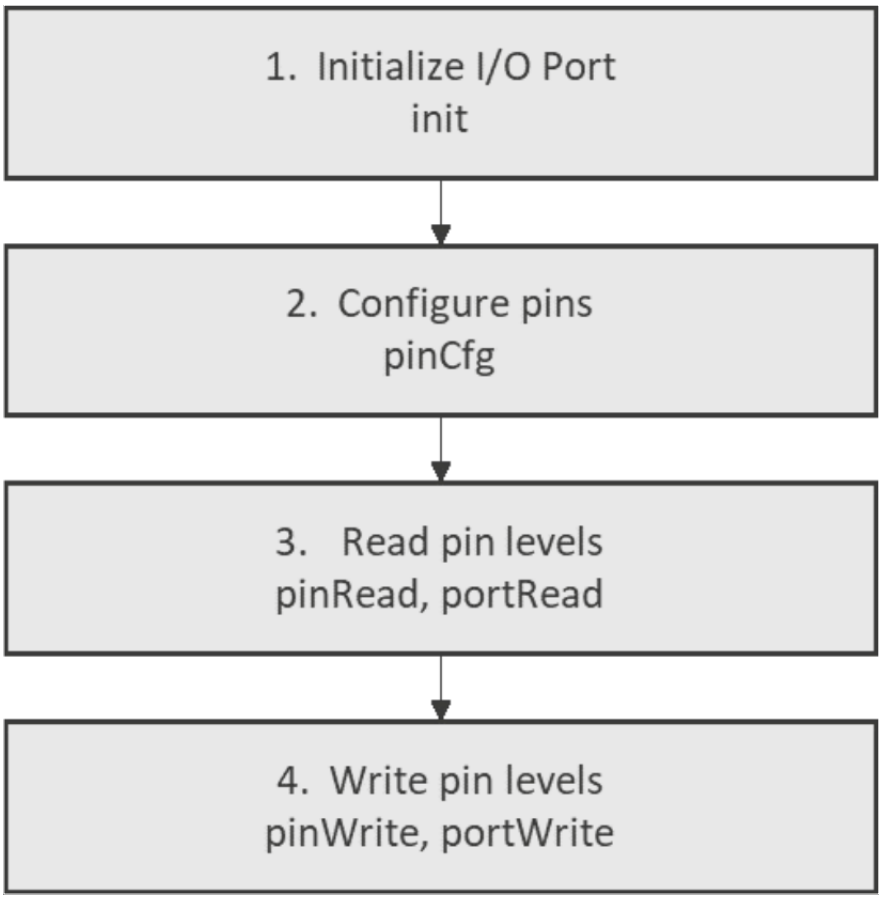

Figure 328: Flow Diagram of a Typical I/O PORT HAL Module Application

4.2.29 Watchdog Driver on r_iwdt

4.2.29.1 Independent Watchdog Timer HAL Module Introduction

The Independent Watchdog Timer (IWDT) HAL module provides a high-level API for watchdog timer applications and uses the IWDT peripheral on the Synergy MCU. A user-defined callback can be created to respond to event notifications.

Independent Watchdog Timer HAL Module Features

The IWDT HAL module supports the following key features:

- When the WDT underflows or is refreshed outside of the permitted refresh window, one of the following events can occur:
  - Resetting of the device
  - Generation of an NMI
- Supports the internal Watchdog timer peripheral (IWDT), which has its own clock source which improves safety.
- Supports automatic hardware configuration after reset.

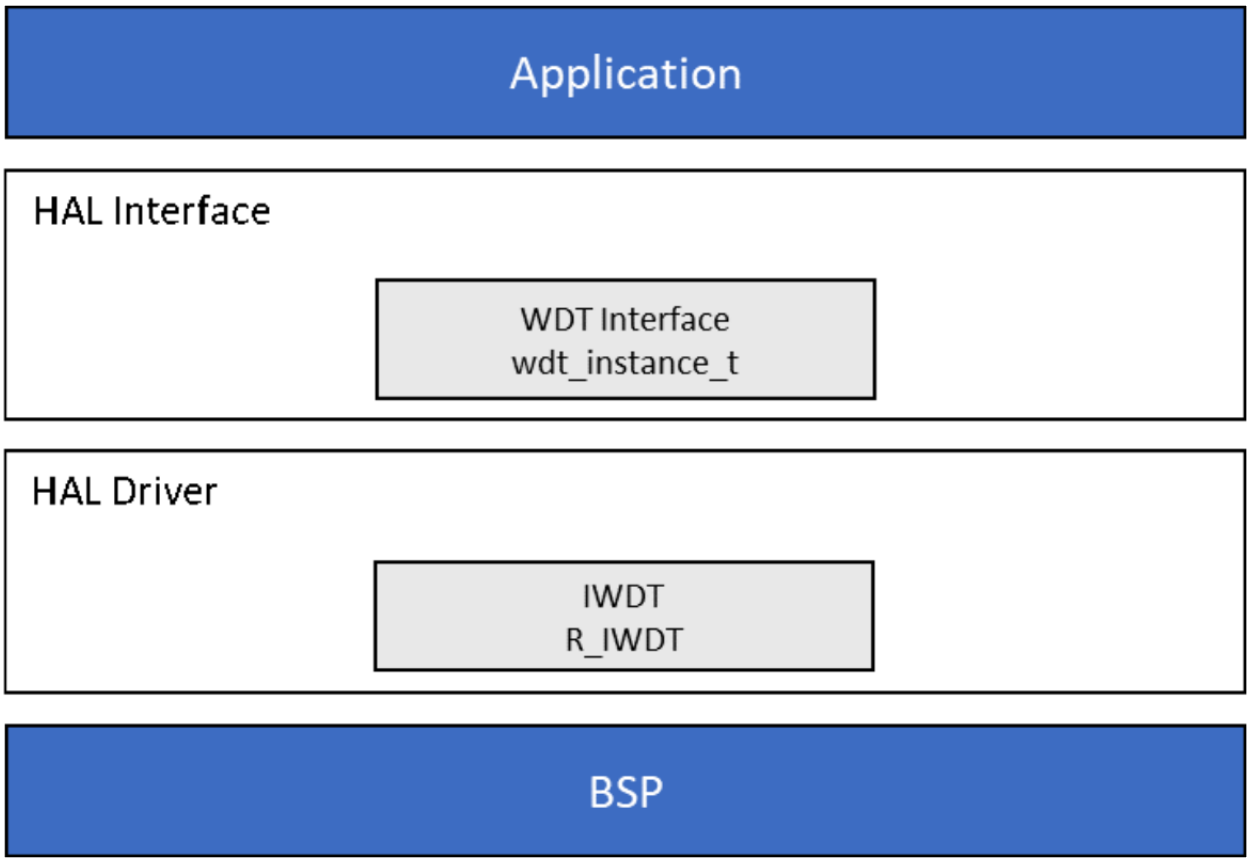

Figure 329: Independent Watchdog Timer HAL Module Block Diagram

Independent Watchdog Timer Hardware Support Details

The following hardware features are, or are not, supported by SSP for IWDT:

Legend:

4.2.29.2 Independent Watchdog Timer HAL Module APIs Overview

The IWDT HAL module defines APIs for open, refresh, read and get status. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Independent Watchdog Timer HAL Module API Summary

Function Name	Example API Call and Description
cfgGet	g_wdt0.p_api->cfgGet(g_wdt0.p_ctrl, g_wdt0.p_cfg); Initialize the iWDT in register start mode. In auto-start mode with NMI output it registers the NMI callback.
open	g_wdt0.p_api->open(g_wdt0.p_ctrl, g_wdt0.p_cfg); Initialize the iWDT in register start mode. In auto-start mode with NMI output it registers the NMI callback.
refresh	g_wdt0.p_api->refresh(g_wdt0.p_ctrl); Refresh the watchdog timer.
statusGet	g_wdt0.p_api->statusGet(g_wdt0.p_ctrl, &status); Read the status of the iWDT.
statusClear	g_wdt0.p_api->statusClear(g_wdt0.p_ctrl, clear); Clear the status flags of the iWDT.
counterGet	g_wdt0.p_api->counterGet(g_wdt0.p_ctrl, &counter); Read the current iWDT counter value.
tiimeoutGet	g_wdt0.p_api->timeoutGet(g_wdt0.p_ctrl, &timeout); Read the watchdog timeout values.

versionGet	g_wdt0.p_api->versionGet(&version); Retrieve the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successfully executed.
SSP_ERR_ASSERTION	Null Pointer(s).
SSP_ERR_INVALID_ARGUMENT	One or more configuration options is invalid.
SSP_ERR_INVALID_MODE	An attempt to open the WDT in register-start mode when the OFS0 register is configured for auto-start mode. Or to open the WDT in auto-start mode when the OSF0 is configured for register start mode.
SSP_ERR_ABORTED	Invalid clock divider for this watchdog.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.29.3 Independent Watchdog Timer HAL Module Operational Overview

The IWDT HAL module configures the IWDT Interface. When the IWDT underflows or is refreshed outside of the permitted refresh window, one of the following events can occur:

- Resetting of the device
- Generation of an NMI

The following figure shows an example of the operation of the IWDT. When refreshed in the valid refresh period of the counter the timer count value is reset. If the count is allowed to underflow or refresh occurs outside of the valid refresh period, the IWDT resets the device or generates an NMI.

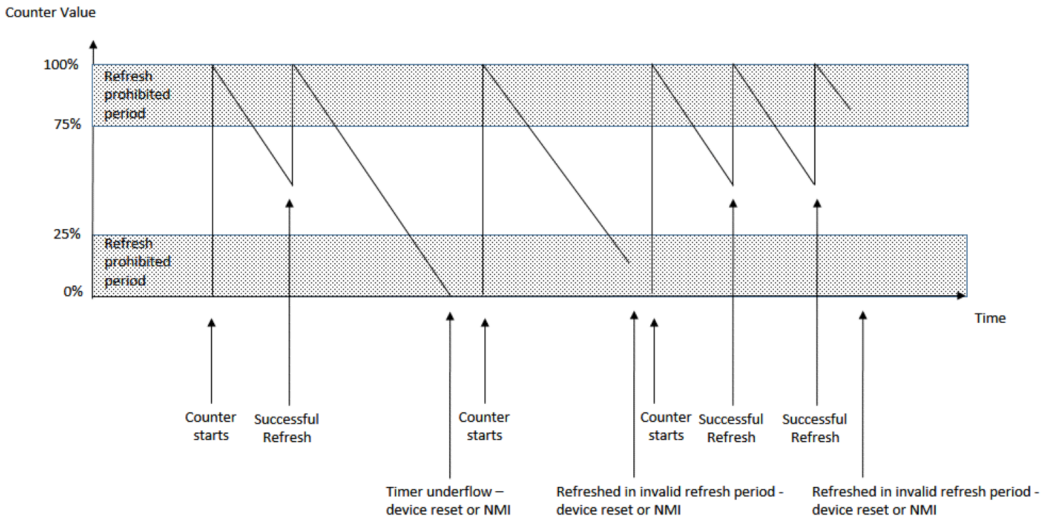

Figure 330: Independent Watchdog Timer HAL Module Operational Diagram

All series of Synergy microcontrollers have an option-setting Memory which can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD and CGC HOCO.

The following table details which parameters of the IWDT can be configured by the OFS registers.

Note

The IWDT can only be configured via the OFS registers. The IWDT does not support Register Start mode.

Control	Description
IWDT Start Mode Select	Automatically starts the IWDT after a Reset, if enabled.
IWDT Timeout Period	Specifies the IWDT timeout (number of clock cycles) 128 cycles 512 cycles 1024 cycles 2048 cycles
IWDT-Dedicated Clock Frequency Division Ratio	1 1/16 1/32 1/64 1/128 1/256

IWDT Window End Position	25 %50 %75 %100% (no window end position set)
IWDT Window Start Position	25 %50 %75 %100% (no window start position set)
IWDT Reset Interrupt Request	The IWDT can either generate an Interrupt Signal or a Reset signal.
IWDT Stop Control	The IWDT can continue to count or Stop counting in Low Power Mode.

Note

For further information on the contents of the OFS0 register, see the Synergy MCU hardware manual.

The OFS register values are set via the properties dialog of the **BSP** tab of Synergy Configuration editor as shown in the following figures:

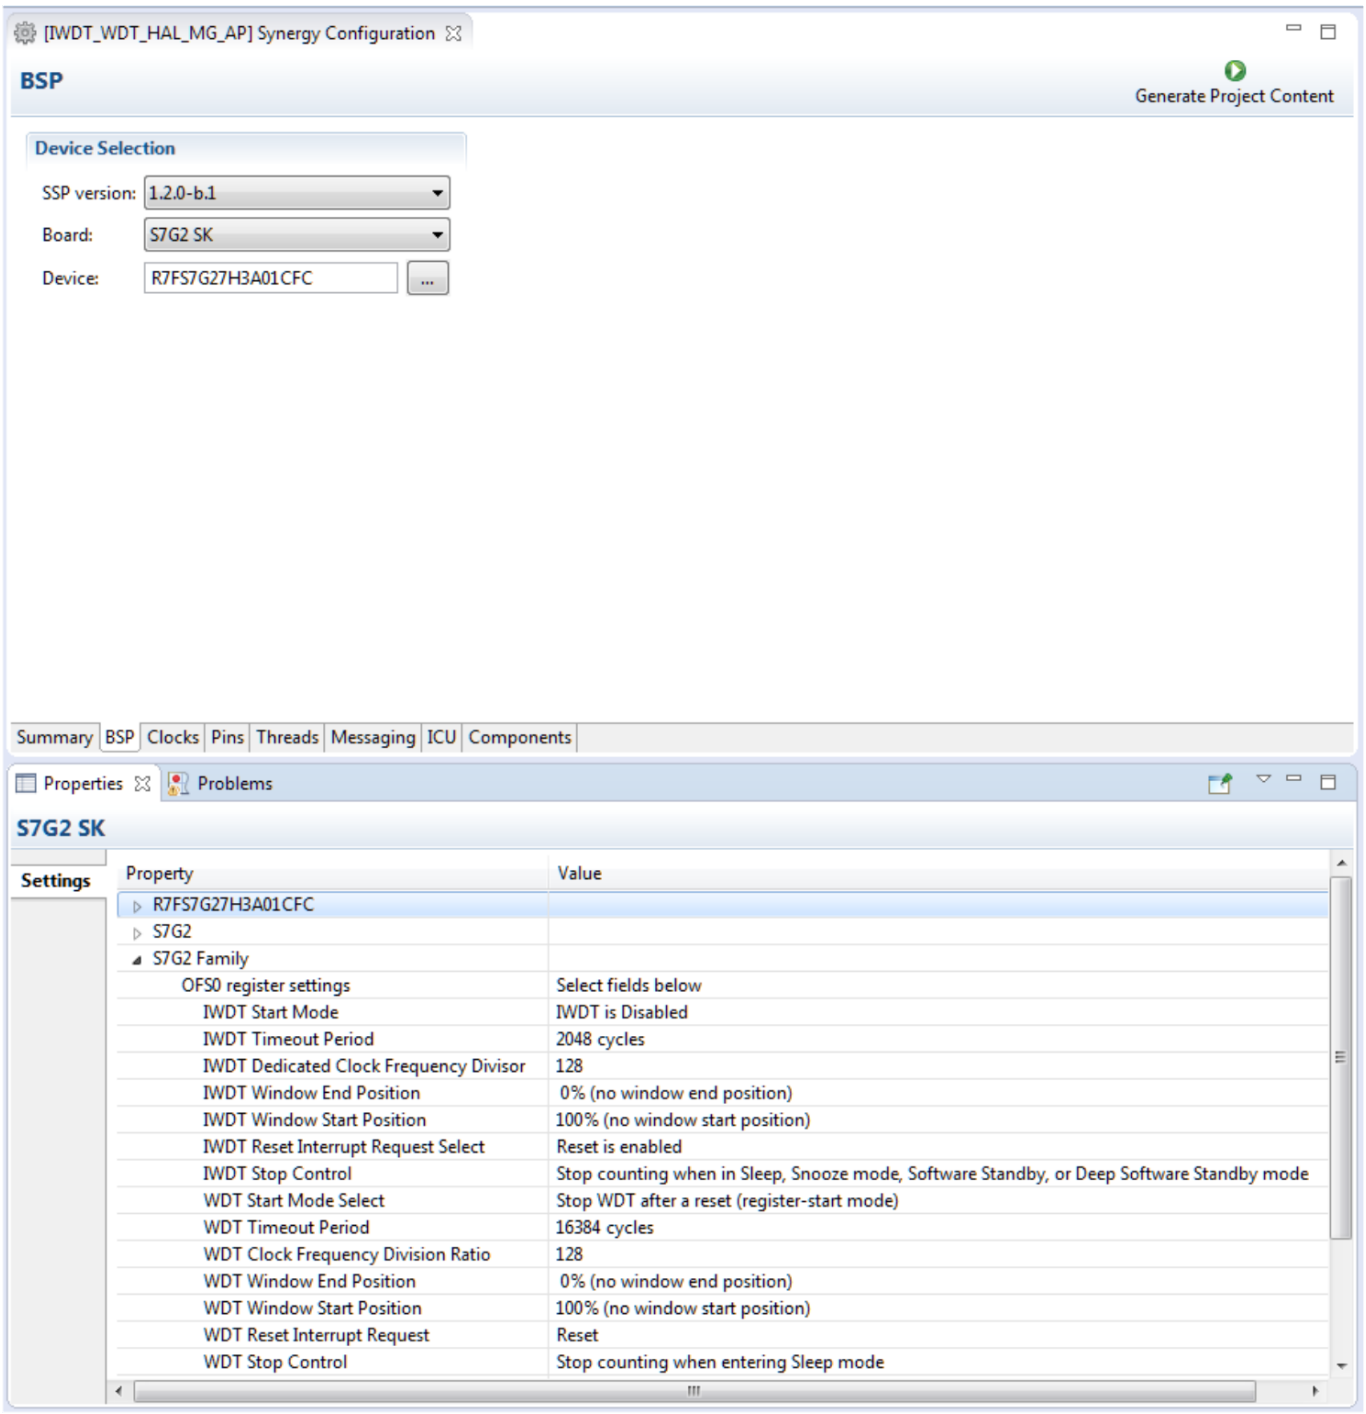

Figure 331: Independent Watchdog Timer HAL Module Configuration Screens

Independent Watchdog Timer HAL Module Important Operational Notes and Limitations

Independent Watchdog Timer HAL Module Operational Notes

IWDT HAL Module Period Calculation

The IWDT operates from IWDTCLK. Assuming largest parameters for the WDT and an IWDTCLK frequency of 15 kHz, the time from the last refresh to device reset or NMI generation will be just under 35 seconds as detailed below.

IWDTLCK = 15 kHz

Clock division ratio = IWTCLK/256

Timeout period = 2048 cycles

IWDT clock frequency = 15 kHz / 256 = 58.59 Hz

Cycle time = 1 / 58.59 Hz = 17.07 ms

Timeout = 17.07 ms x 2048 cycles = 34.95 seconds

Triggering DMAC/DTC with the IWDT HAL Module

To trigger a transfer of data using the DMAC or DTC peripheral when the watchdog counter underflows or when a refresh is attempted outside of the valid refresh period, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_IWDT_UNDERFLOW. See the appropriate module guide for additional information.

Triggering ELC Events with the IWDT HAL Module

The IWDT can trigger the start of other peripherals as available with the Event Link Controller (ELC). See the ELC HAL module guide for additional information.

Independent Watchdog Timer HAL Module Limitations

- When using a J-Link debugger, the IWDT counter does not count and therefore will not reset the device or generate an NMI.
- When there is no active task ready to run, ThreadX puts the MCU into sleep mode. If the IWDT is configured to stop the counter in low-power mode, then your application must restart the timer when used with the ThreadX RTOS.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.29.4 Including the Independent Watchdog Timer HAL Module in an Application

This section describes how to include the Independent Watchdog Timer HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Independent Watchdog Timer Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Independent Watchdog Timer Driver is g_iwdt0. This name can be changed in the associated Properties window.)

Independent Watchdog Timer HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_wdt0 IWDT HAL on r_iwdt	Threads	**New Stack> Driver> Monitoring> IWDT HAL on r_iwdt**

When the Independent Watchdog Timer Driver on r_iwdt is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

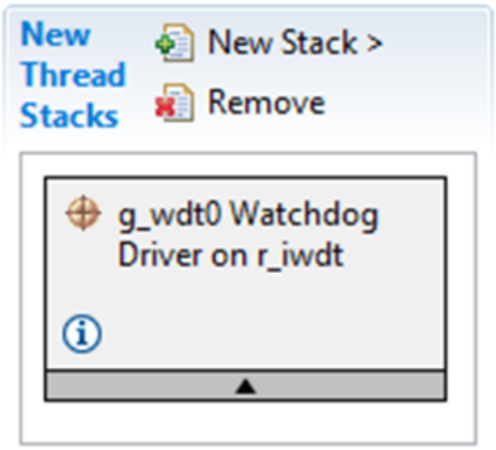

Figure 332: Independent Watchdog Timer HAL Module Stack

4.2.29.5 Configuring the Independent Watchdog Timer HAL Module

The Independent Watchdog Timer HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Independent Watchdog Timer HAL Module on r_iwdt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_wdt0	Module name.

NMI Callback	NULL	Callback. A user callback function can be registered in external_irq_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configure Option Function Select Register 0 (OFS0) for the IWDT HAL Module

All series of Synergy microcontrollers have an Option-Setting Memory which can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD and CGC HOCO.

Configure the Interrupts for the IWDT HAL Module

Use the ISDE to configure the IWDT interrupts in the same way as configuring the other options for the IWDT module. If the IWDT is configured to generate an NMI interrupt on underflow or invalid refresh the interrupt must be enabled in the BSP.

Note

To enable interrupts, set the priority of the IWDT > IWDT NMIUNDF N. This sets BSP_IRQ_CFG_IWDT_UNDERFLOW in ssp_cfg/bsp/bsp_irq_cfg.h to the priority level selected.

When the IWDT NMIUNDF N interrupt is enabled in the BSP, the corresponding ISR will be defined. The ISR will call a user callback function if one was registered in the wdt_api_t::open API.

Independent Watchdog Timer HAL Module Clock Configuration

The IWDT has its own dedicated clock operating at a set frequency which cannot be modified.

Independent Watchdog Timer HAL Module Pin Configuration

The IWDT does not require pins for its operation.

4.2.29.6 Using the Independent Watchdog Timer HAL Module in an Application

The typical steps in using the Independent Watchdog Timer HAL module in an application are:

1. Register the IWDT NMI callback using the wdt_api_t::open API.
2. Read the configuration of the IWDT HAL module using the wdt_api_t::cfgGet API.
3. Refresh the independent watchdog timer using the wdt_api_t::refresh API.

4. Read the IWDT status flags using the wdt_api_t::statusGet API.
5. Clear the IWDT Status and error flags using the wdt_api_t::statusClear API.
6. Read the current count value of the IWDT using the wdt_api_t::counterGet API.
7. Read the timeout values of the IWDT HAL module using the wdt_api_t::timeoutGet API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

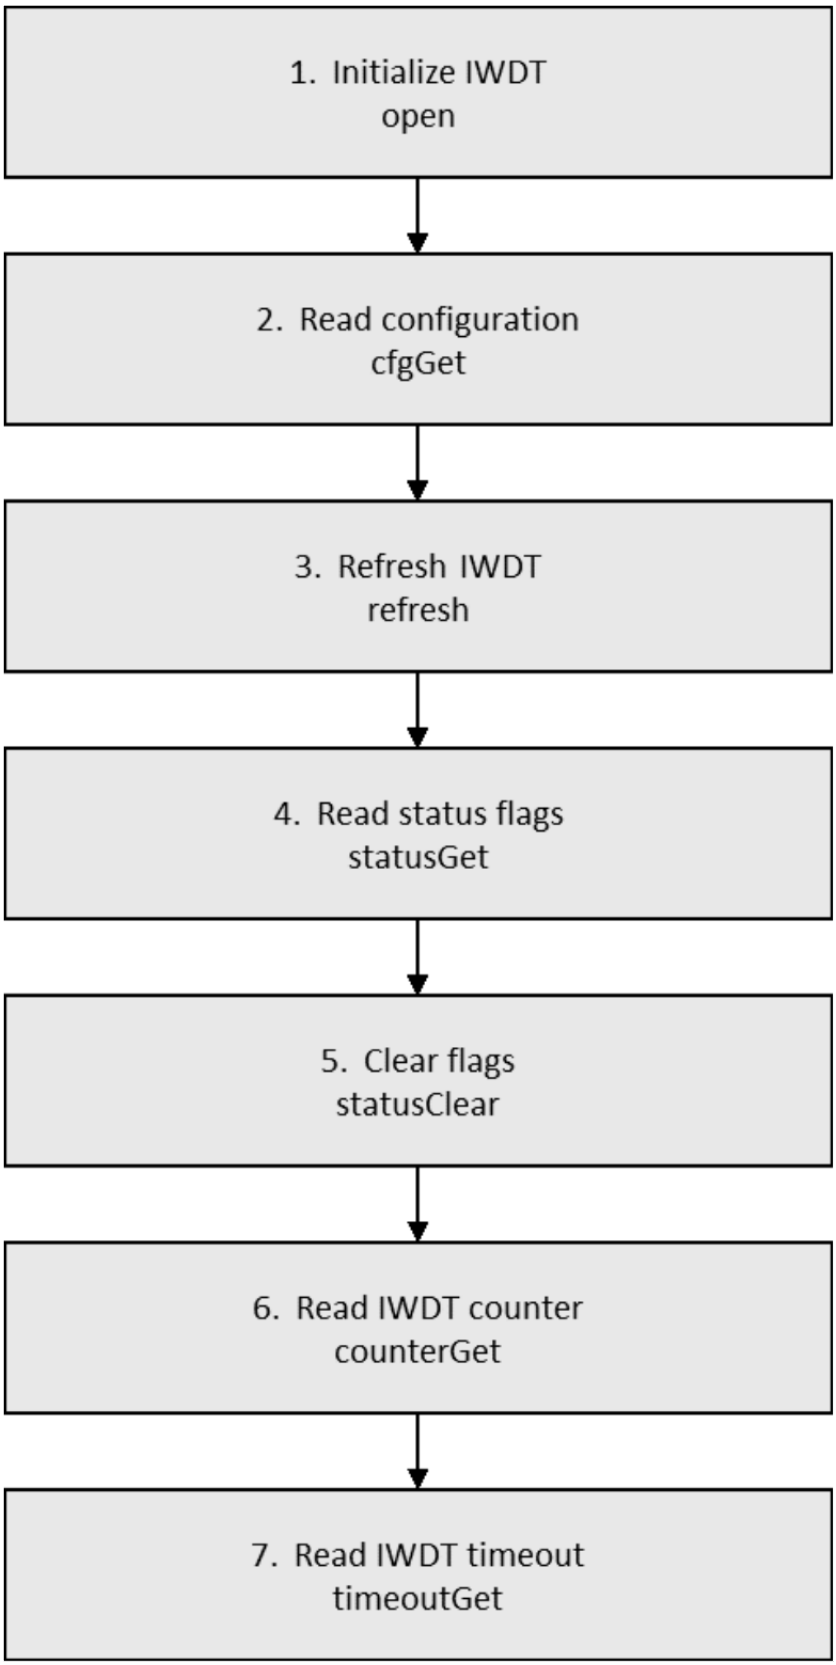

Figure 333: Flow Diagram of a Typical Independent Watchdog Timer HAL Module Application

4.2.30 JPEG Decode Driver

4.2.30.1 JPEG Decode HAL Module Introduction

The JPEG Decode HAL module provides high-level APIs for JPEG Decode image processing. The JPEG Decode HAL module uses the Synergy MCU JPEG Codec peripheral. A user callback function is available to inform the application program of key processing events.

JPEG Decode HAL Module Features

- Supports JPEG decompression.
- Supports polling mode that allows an application to wait for JPEG Decoder to complete.
- Supports interrupt mode with user-supplied callback functions.
- Configures parameters such as horizontal and vertical subsample values, horizontal stride, decoded pixel format, input and output data format, and color space.
- Obtains the size of the image prior to decoding it.
- Supports putting coded data in an input buffer and an output buffer to store the decoded image frame.
- Supports streaming coded data into JPEG Decoder module. This feature allows an application to read coded JPEG image from a file or from network without buffering the entire image.
- Configures the number of image lines to decode. This feature enables the application to process the decoded image on the fly without buffering the entire frame.
- Supports the input decoded format YCbCr444, YCbCr422, YCbCr420, YCbCr411.
- Supports the output format ARGB8888, RGB565.
- Returns error when the JPEG image's size, height and width do not meet the requirements.

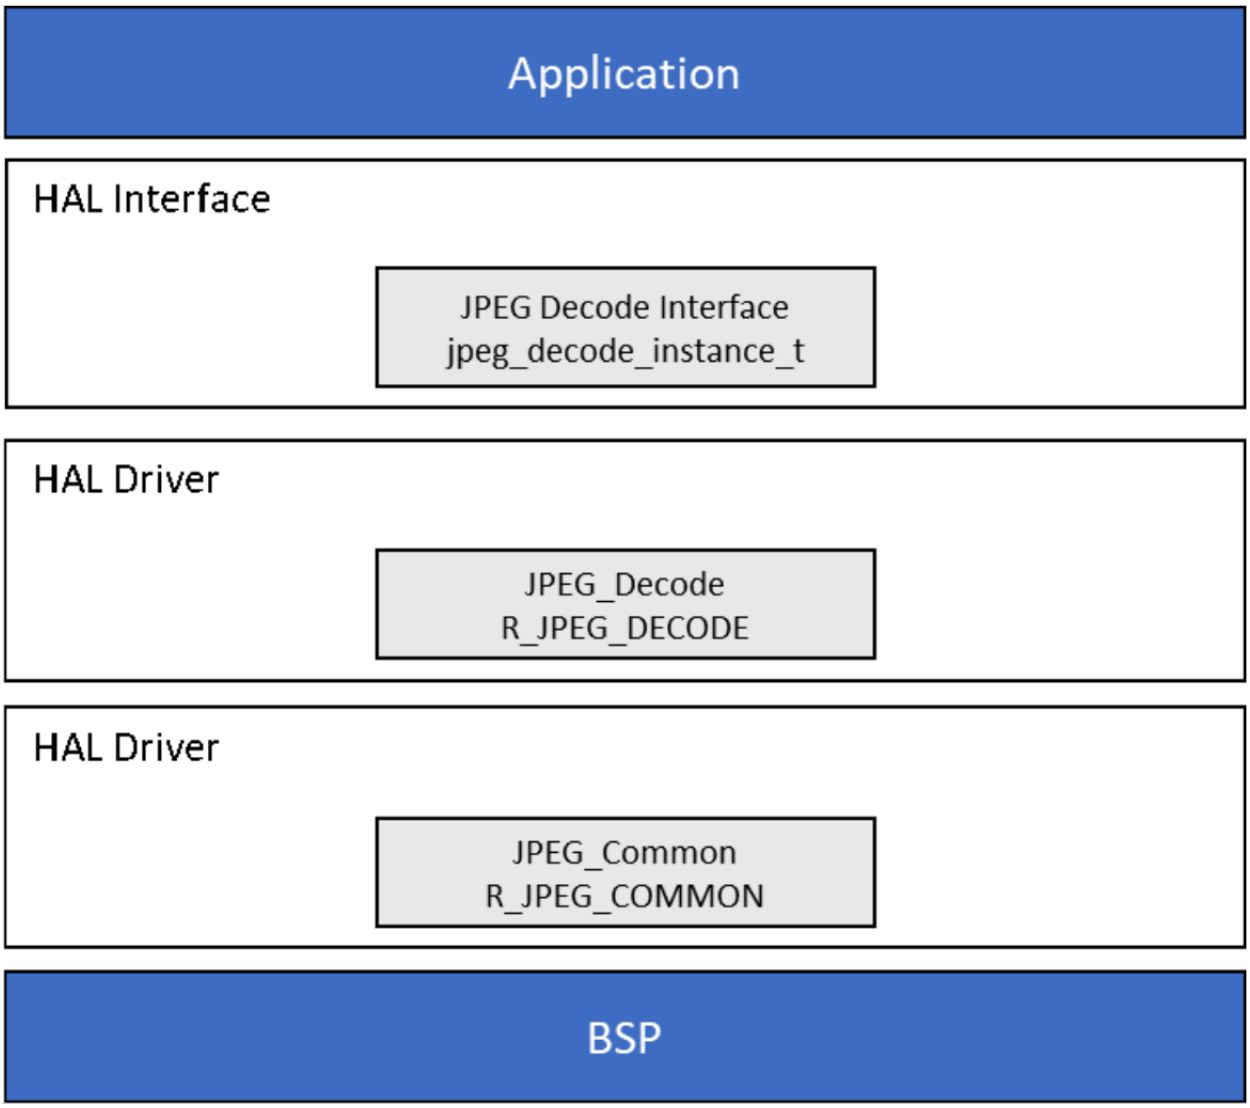

Figure 334: JPEG Decode HAL Module Block Diagram

JPEG Decode Hardware support details

The following hardware features are, or are not, supported by SSP for JPEG.

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

MCU Group	8 lines by 8 pixels in YCbCr444	8 lines by 16 pixels in YCbCr422	8 lines by 32 pixels in YCbCr411	16 lines by 16 pixels in YCbCr420	Output decoded format ARGB8888	Output decoded format RGB565

4.2.30.2 JPEG Decode HAL Module APIs Overview

The JPEG Decode HAL Module implements APIs to open, set processing parameters, start processing, get processing status and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

JPEG Decode HAL Module API Summary

Function Name	Example API Call and Description
open	g_jpeg_decode0.p_api->open(g_jpeg_decode0.p_ctrl, g_jpeg_decode0.p_cfg); Initial configuration.
outputBufferSet	g_jpeg_decode0.p_api->outputBufferSet(g_jpeg_decode0.p_ctrl, p_buffer, buffer_size); Assign output buffer to JPEG codec for storing output data.
horizontalStrideSet	g_jpeg_decode0.p_api->horizontalStrideSet(g_jpeg_decode0.p_ctrl, stride); Configure the horizontal stride value.
imageSubsampleSet	g_jpeg_decode0.p_api->imageSubsampleSet(g_jpeg_decode0.p_ctrl, horizontal, vertical); Configure the horizontal and vertical subsample settings.
inputBufferSet	g_jpeg_decode0.p_api->inputBufferSet(g_jpeg_decode0.p_ctrl, p_buffer, size); Assign input data buffer to JPEG codec.

linesDecodedGet	g_jpeg_decode0.p_api->linesDecodedGet g_jpeg_decode0.p_ctrl, p_lines); Return the number of lines decoded into the output buffer.
imageSizeGet	g_jpeg_decode0.p_api->imageSizeGet(g_jpeg_decode0.p_ctrl, p_horizontal, p_vertical); Retrieve image size during decoding operation.
statusGet	g_jpeg_decode0.p_api->statusGet(g_jpeg_decode0.p_ctrl, p_status); Retrieve current status of the JPEG codec module.
close	g_jpeg_decode0.p_api->close(g_jpeg_decode0.p_ctrl); Cancel an outstanding operation.
versionGet	g_jpeg_decode0.p_api->versionGet(&version); Get version and store it in provided pointer p_version.
pixelFormatGet	g_jpeg_decode0.p_api->pixelFormatGet(g_jpeg_decode0.p_ctrl, p_color_space); Get the input pixel format.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INVALID_ALIGNMENT	Horizantal stride is not 8-byte aligned.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IN_USE	Peripheral is in use or hardware lock is taken.
SSP_ERR_HW_LOCKED	JPEG Codec resource is locked.
SSP_ERR_INVALID_CALL	An invalid call has been made, Codec output buffer address is attempted to change during codec operation. Or set output buffer first.
SSP_ERR_JPEG_IMAGE_SIZE_ERROR	Image size is not supported by JPEG codec.
SSP_ERR_JPEG_BUFFERSIZE_NOT_ENOUGH	Invalid buffer size.
SSP_ERR_INVALID_MODE	JPEG Codec module is not decoding.

SSP_ERR_IMAGE_SIZE_UNKNOWN	The image size is unknown. More input data may be needed.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.30.3 JPEG Decode HAL Module Operational Overview

The JPEG Decoder HAL module can be used in the Input Buffer Streaming mode or JPEG Output Buffer Streaming mode.

Input Buffer Streaming Mode Operational Description

In this scenario the JPEG image data resides on a file, or is received from network. The HAL-layer driver is able to handle this scenario without requiring the input data to be stored in memory first.

Output Buffer Streaming Mode Operational Description

In this scenario the application needs to write the decoded image data to a file or to a network. The HAL-layer driver does not require the application to allocate memory for the entire frame. Instead the application may choose to decode one or more lines at a time. With this feature the amount of memory needed for the output data is greatly reduced.

MJPEG Decode Operational Description

In this scenario the application needs to display a continuous stream of JPEG images on the native display. The JPEG images can reside on a file or can be received from the network. The HAL driver handles this scenario by using the Input Buffer Streaming Mode feature of the JPEG Decode module.

The basic flow to achieve this would be:

1. Open the JPEG Decode driver.
2. Set the image parameters: horizontal stride, image sub-samples.
3. Set the input buffer which holds the jpeg image frame.
4. Set the output buffer to hold the raw image.
5. Display the decoded image.
6. Close the jpeg driver.
7. Repeat the process from step 1 as needed.

JPEG Decode HAL Module Important Operational Notes and Limitations

JPEG Decode HAL Module Operational Notes

JPEG Decode Callbacks A user callback function can be registered in the open API. If a user callback function is provided, the callback function will be called from the interrupt service routine (ISR) each time an interrupt happens. The argument of the callback function status can take the enumerated values listed below so that user can identify which event occurred in the decoding procedure.

Event Name	Event Condition
JPEG_DECODE_STATUS_ERROR	JPEG Decode module encountered an error.

JPEG_DECODE_STATUS_IMAGE_SIZE_READY	JPEG Decode obtained the image size of data to be decoded, and paused.
JPEG_DECODE_STATUS_INPUT_PAUSE	JPEG Decode paused waiting for more input data.
JPEG_DECODE_STATUS_OUTPUT_PAUSE	JPEG Decode paused after decoded the number of lines specified by user.
JPEG_DECODE_STATUS_DONE	JPEG Decode operation has successfully completed.

Note

Since a user callback function is called from an ISR, be careful not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

JPEG Decode HAL Module Limitations

- The JPEG Decode HAL module only support JPEG decoding processing. For encoding, use the JPEG Encode Driver.
- If both drivers are in use, the JPEG Encode driver needs to be closed in order to use the JPEG Decode Driver (or vice versa, as both drivers share the same IP).
- Ensure timeout detection logic is implemented (as in sf_jpeg_decode_api_t::wait API of SF_JPEG_DECODE). If timeout error occurs while decoding the image, close the driver, re-open it and then perform the decoding operation.
- Refer to the most recent SSP Release notes for the most up to date limitations for this module.

4.2.30.4 Including the JPEG Decode HAL Module in an Application

This section describes how to include the JPEG Decode HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the JPEG Decode Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the JPEG Decode Driver is g_jpeg_decode0. This name can be changed in the associated Properties window.)

JPEG Decode HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_jpeg_decode0 JPEG Decode Driver on r_jpeg_decode	Threads	**New Stack> Driver> Graphics> JPEG Decode Driver**

When the JPEG Decode Driver on r_jpeg_decode is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink

band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

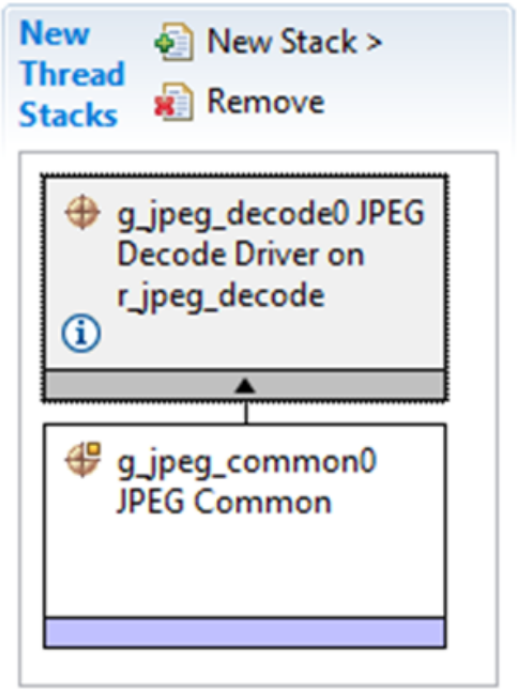

Figure 335: JPEG Decode HAL Module Stack

4.2.30.5 Configuring the JPEG Decode HAL Module

The JPEG Decode HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the JPEG Decode HAL Module on r_jpeg_decode

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.

Name	g_jpeg_decode0	The name to be used for a JPEG Decode module instance.
Byte Order for Input Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word-Byte Swap (8)(7)(6)(5)(4)(3)(2)(1) Default: Normal Byte order	Specify the byte order for input data. The order is swapped as specified in every 8-byte.
Byte Order for Output Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word-Byte Swap (8)(7)(6)(5)(4)(3)(2)(1) Default: Normal Byte order	Specify the byte order for output data. The order is swapped as specified in every 8-byte.
Output Data Color Format	Pixel Data RGB565 format, Pixel Data ARGBB888 format Default: Pixel Data RGB565 format	Specify the output data format.
Alpha value to be applied to decoded pixel data (only valid for ARGB8888 format)	255	Specify the alpha value for the output data format (only valid for ARGB8888 format).
Name of user callback function	NULL	Specify the name of user callback function.
Decompression Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Decompression interrupt priority selection.

Data Transfer Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Data transfer interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the JPEG Common Module

ISDE Property	Value	Description
Name	g_jpeg_common0	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

JPEG Decode HAL Module Clock Configuration

The JPEG Decode HAL Module uses the PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

JPEG Decode HAL Module Pin Configuration

The JPEG Decode HAL Module has no configurable input or output pins.

4.2.30.6 Using the JPEG Decode HAL Module in an Application

The typical steps in using the JPEG Decode HAL module in an application are:

1. Initialize the JPEG Decode using the jpeg_decode_api_t::open API.
2. Set the horizontal stride using the jpeg_decode_api_t::horizontalStrideSet API.
3. Set vertical and horizontal image sub-sample using the jpeg_decode_api_t::imageSubsampleSet API.
4. Set the input buffer address (which contains the JPEG image) using the jpeg_decode_api_t::inputBufferSet API.
5. Set the output buffer (should be large enough to hold the raw image data) using the jpeg_decode_api_t::outputBufferSet API.
6. The jpeg_decode_api_t::statusGet API can be used to get the JPEG operation. It returns an enumerated value (described above) to notify the user.
    a. The status JPEG_DECODE_STATUS_DONE returned from the jpeg_decode_api_t::statusGet API shows that the Decode operation is complete.
    b. The status JPEG_DECODE_STATUS_INPUT_PAUSE or JPEG_DECODE_STATUS_OUTPUT_PAUSE returned from the jpeg_decode_api_t::statusGet API shows that the decode operation is not complete.
    c. Implement a timeout detect function as part of this step. Refer to the wait function used for the JPEG Decode Framework if an illustration is required.
7. Operate on the received raw image data as needed by the application.
8. Close the module using the jpeg_decode_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

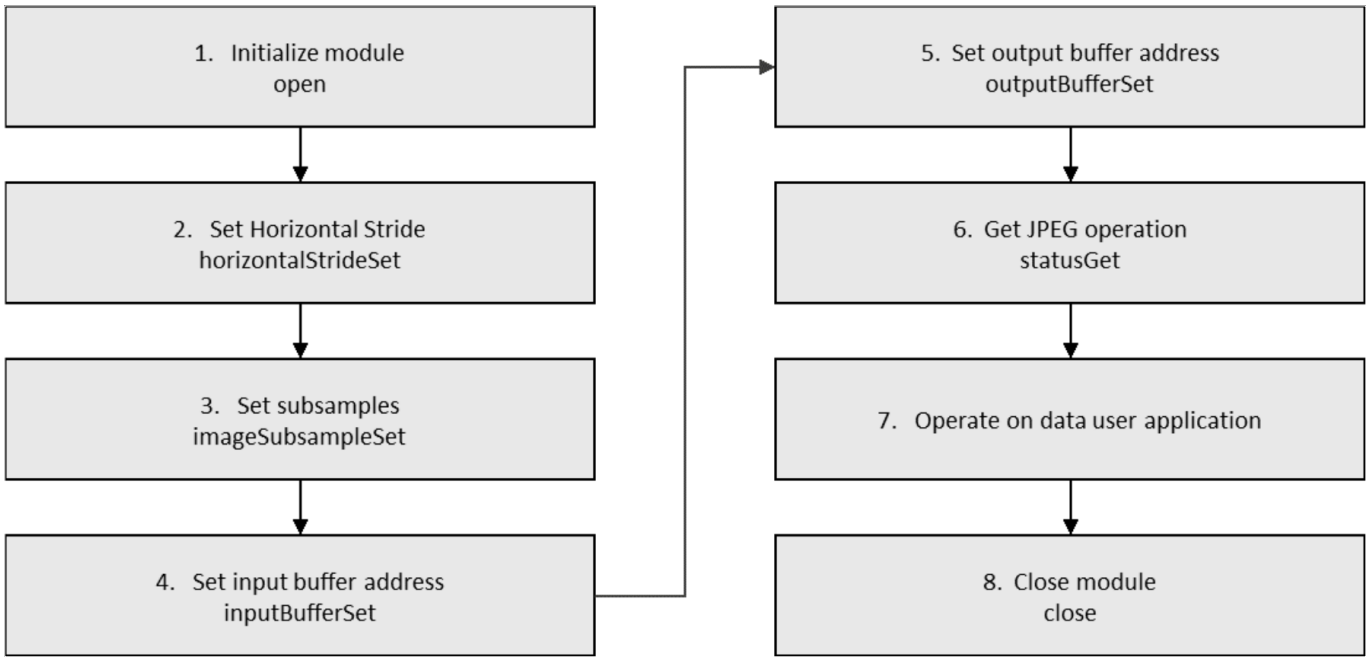

Figure 336: Flow Diagram of a Typical JPEG Decode HAL Module Application

4.2.31 JPEG Encode Driver

4.2.31.1 JPEG Encode HAL Module Introduction

The JPEG Encode HAL module provides a high-level API for industry standard JPEG image encode processing (compression) and uses the Synergy MCU JPEG Codec peripheral. A user callback function is available to inform the application program of key processing events.

JPEG Encode HAL Module Features

- Supports JPEG Compression.
- Supports polling mode that allows an application to wait for JPEG Encoder to complete.
- Supports interrupt mode with user-supplied callback functions.
- Configures parameters such as horizontal and vertical resolution, horizontal stride, and Quality factor.
- Supports putting raw image data in an input buffer and an output buffer to store the encoded/compressed jpeg image.
- Supports streaming raw image data into JPEG Encoder module. This feature allows an application to read coded raw image from a capture device or camera or from network without buffering the entire image.
- Only supports the YCbCr422 color space to input.
- Supports DRI Maker for RTP streaming application.
- Supports quality factor configuration: The quality factor value determines the quality of output image.

4.2.31.2 JPEG Encode HAL Module APIs Overview

The JPEG Encode HAL Module defines APIs to open, set up processing parameters for, process, get status from and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the HAL Module API Summary.

JPEG Encode HAL Module API Summary

Function Name	Example API Call and Description
open	g_jpeg_encode0.p_api->open(g_jpeg_encode0.p_ctrl, g_jpeg_encode0.p_cfg); Initial configuration.
imageParameterSet	g_jpeg_encode0.p_api->imageParameterSet(g_jpeg_encode0.p_ctrl, p_image_parameters); Set image parameters to JPEG Codec.
outputBufferSet	g_jpeg_encode0.p_api->outputBufferSet(g_jpeg_encode0.p_ctrl, p_buffer); Assign output buffer to JPEG Codec for storing output data.
inputBufferSet	g_jpeg_encode0.p_api->inputBufferSet(g_jpeg_encode0.p_ctrl, p_buffer, buffer_size); Assign input data buffer to JPEG Codec.
statusGet	g_jpeg_encode0.p_api->statusGet(g_jpeg_encode0.p_ctrl, p_status); Retrieve current status of the JPEG Codec module.
close	g_jpeg_encode0.p_api->close(g_jpeg_encode0.p_ctrl); Cancel an outstanding operation.

versionGet	g_jpeg_encode0.p_api->versionGet(&version); Get version and store it in the provided pointer version.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_INVALID_ALIGNMENT	Horizontal stride is not 8-byte aligned.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IN_USE	Peripheral is in use or hardware lock is taken.
SSP_ERR_HW_LOCKED	JPEG Codec resource is locked.
SSP_ERR_INVALID_CALL	An invalid call has been made, Codec output buffer address is attempted to change during codec operation. Or set output buffer first.
SSP_ERR_JPEG_IMAGE_SIZE_ERROR	Image size is not supported by JPEG codec.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.31.3 JPEG Encode HAL Module Operational Overview

The JPEG Encoder HAL module can be used in the input buffer streaming mode or normal mode.

Input Buffer Streaming Mode Operational Description

In this mode the raw image data arrives from the network, file or capturing device in separate data 'chunks'. The HAL-layer driver handles this mode without requiring the input data to be stored in memory first.

Normal Operational Description

In this mode raw image data arrives from the network, file or capturing device as a complete frame. The HAL-layer driver handles this mode and can compress the entire raw image frame.

JPEG Encode HAL Module Important Operational Notes and Limitations

JPEG Encode HAL Module Operational Notes

Motion JPEG

There is no defined standard for Motion JPEG (MJPEG), but the basic concept is to continuously project JPEG images to the rendering device. The basic application steps to implement an MJPEG function using the JPEG Encoder HAL module are as follows:

1. Open the JPEG Encoder driver with the desired quality factor value (default = 50).
2. Setup the image resolution (optional if already configured in Thread stack window).
3. Initialize the capturing device for capturing a YCbCr422 image.
4. Set the output buffer to hold the jpeg image using the jpeg_encode_api_t::outputBufferSet API function.
5. Capture the image.
6. Set the input buffer which holds the RAW YCbCr 422 image captured from the capturing device using jpeg_encode_api_t::inputBufferSet API function.
7. Check the status of the encode operation and if DONE send the image to the rendering device.
8. Continue the process from step 5 as needed.

JPEG Encode Callbacks

A user callback function can be registered in the open API. If a user callback function is provided, the callback function will be called from the interrupt service routine (ISR) each time an interrupt happens. The argument of the callback function status can take the enumerated values listed below so that user can identify which event occurred in the encoding procedure.

Event Name	Event Condition
JPEG_ENCODE_STATUS_INPUT_PAUSE	JPEG Encode paused waiting for more input data.
JPEG_ENCODE_STATUS_DONE	JPEG Encode operation has successfully completed.

Note

Since a user callback function is called from an ISR, be careful not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

JPEG Encode HAL Module Limitations

- The JPEG Encode HAL module only support JPEG Encode processing. For decoding please use the JPEG Decode HAL module.
- In an Application where both the encode and decode modules are used, JPEG Decode module needs to be closed for the application to use JPEG Encode driver (or vice versa) as both modules share the same MCU peripheral.
- The JPEG Encode HAL module only supports the "Normal byte order" in the thread stack window. Other option may result in an invalid image.

4.2.31.4 Including the JPEG Encode HAL Module in an Application

This section describes how to include the JPEG Encode HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the JPEG Encode Driver to an application, simply add it to a thread using the stacks selection

sequence given in the following table. (The default name for the JPEG Encode Driver is g_jpeg_encode0. This name can be changed in the associated Properties window.)

JPEG Encode HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_jpeg_encode0 JPEG Encode Driver on r_jpeg_encode	Threads	**New Stack> Driver> Graphics> JPEG Encode Driver**

When the JPEG Encode Driver on r_jpeg_encode is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

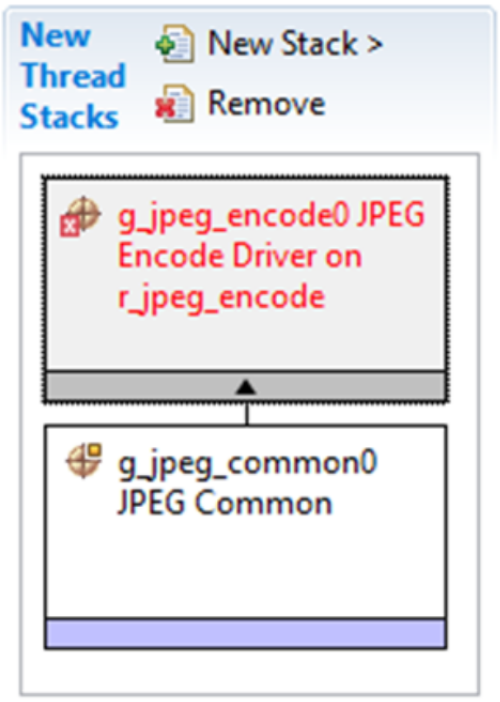

Figure 338: JPEG Encode HAL Module Stack

4.2.31.5 Configuring the JPEG Encode HAL Module

The JPEG Encode HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and

makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the JPEG Encode HAL Module on r_jpeg_encode

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_jpeg_encode0	Module name.
RAW Image Vertical Resolution	800	RAW image vertical resolution selection.
RAW Image Horizontal Resolution	480	RAW image horizontal resolution selection.
Byte Order for Input Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word-Byte Swap (8)(7)(6)(5)(4)(3)(2)(1) Default: Normal Byte order	Byte order for input data format selection.

Byte Order for Output Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word-Byte Swap (8)(7)(6)(5)(4)(3)(2)(1) Default: Normal Byte order	Byte order for output data format selection.
Define Restart Marker	512	Define restart marker selection.
Quality Factor	50	Quality factor selection.
Name of user callback function	NULL	Name of user callback function selection.
Decompression Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Decompression interrupt priority selection.
Data Transfer Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Data transfer interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the JPEG Common Module

ISDE Property	Value	Description
Name	g_jpeg_common0	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

JPEG Encode HAL Module Clock Configuration

The JPEG Encode HAL Module uses the PCLKA as its clock source.

To change the clock frequency at run-time, use the CGC Interface.

JPEG Encode HAL Module Pin Configuration

The JPEG Encode HAL module has no configurable input or output pins on the device.

4.2.31.6 Using the JPEG Encode HAL Module in an Application

The typical steps in using the JPEG Encode HAL module in an application are:

1. Initialize the JPEG Encode using jpeg_encode_api_t::open API.
    a. Configures the quality factor, horizontal stride, horizontal and vertical resolution.
2. Set the output buffer address (should be large enough to hold compressed jpeg image) using the jpeg_encode_api_t::outputBufferSet API.
3. Set the input buffer to start the encoding operation (address of raw image data and size) using thejpeg_encode_api_t::inputBufferSet API.
4. The jpeg_encode_api_t::statusGet API can be used to get the JPEG operation, thejpeg_encode_api_t::statusGet API return an enumerated value (described above) to notify user.
    a. Status JPEG_ENCODE_STATUS_DONE from the jpeg_encode_api_t::statusGet API shows that the encode operation is complete.
    b. Status JPEG_ENCODE_STATUS_INPUT_PAUSE from the jpeg_encode_api_t::statusGet API shows that driver is waiting for more input – Go to step 3 and set the input buffer with remaining data.
5. Operate on the received JPEG image data as needed by the application.
6. Close the module using the jpeg_encode_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

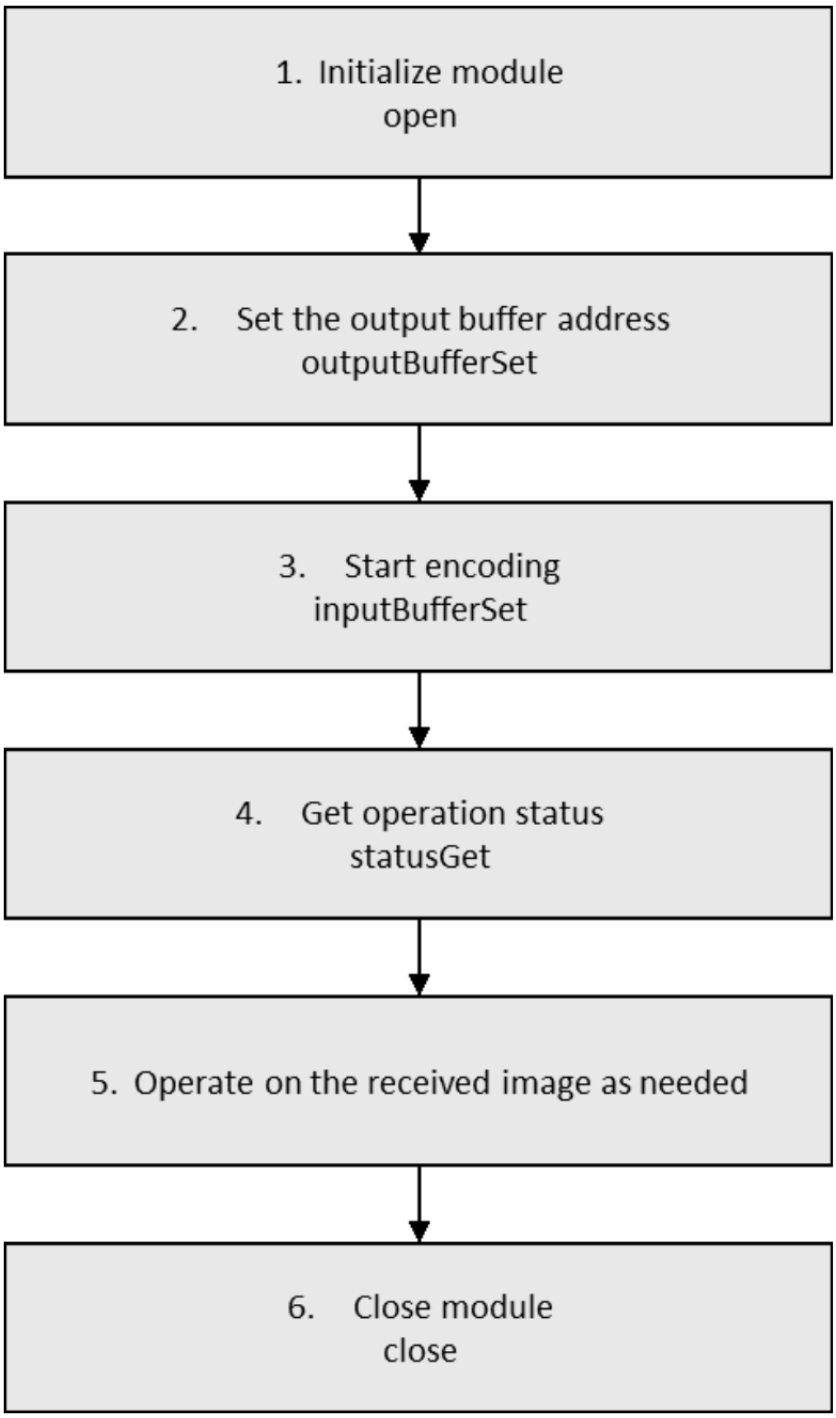

Figure 339: Flow Diagram of a Typical JPEG Encode HAL Module Application

4.2.32 Key Matrix Driver

4.2.32.1 Key Matrix HAL Module Introduction

The Key Matrix HAL module provides a high-level API for key input applications and uses the key-interrupt function peripheral on the Synergy MCU. A user-defined callback can be created to inform the CPU of a key press event.

Key Matrix HAL Module Features

This Key Matrix HAL module configures and controls the Key Interrupt (KINT) peripheral. It implements the following key functions:

- Supports both rising and falling edges on KINT channels
- Supports interrupt-based event notification
- Supports a bit-masking function to capture multiple events efficiently
- Supports a matrix keypad with edges on any two channels

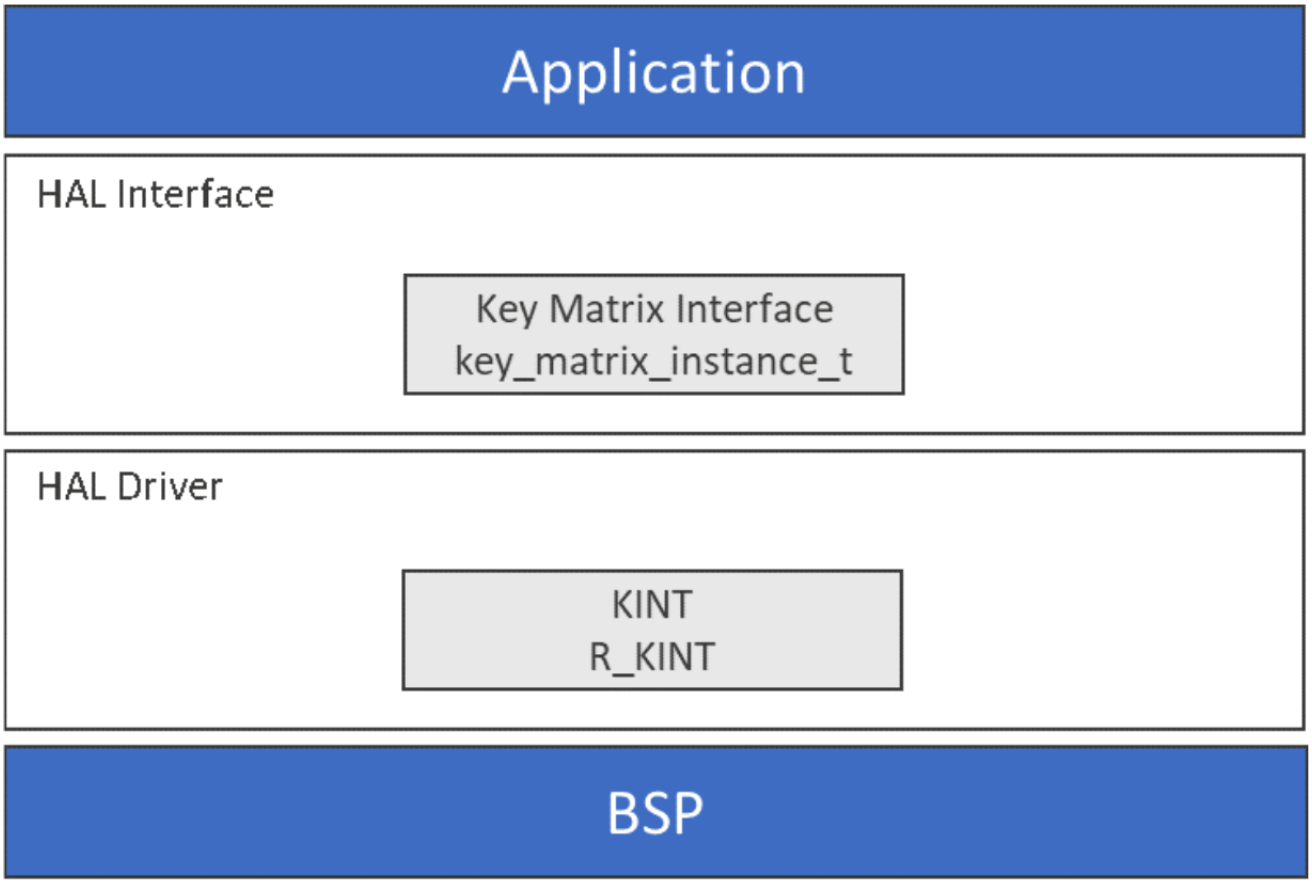

Figure 340: Key Matrix HAL Module Block Diagram

KINT Hardware support details

The following hardware features are, or are not, supported by SSP for KINT.

4.2.32.2 Key Matrix HAL Module APIs Overview

The Key Matrix HAL module defines APIs for opening, closing, enabling and disabling key-interrupt functions. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Key Matrix HAL Module API Summary

Function Name	Example API Call and Description
open	g_keymatrix_on_kint.p_api->open(g_kint.p_ctrl, g_kint.p_cfg_cfg) Initial configuration.
enable	g_keymatrix_on_kint.p_api->enable(g_kint.p_ctrl) Enable Key interrupt.
disable	g_keymatrix_on_kint.p_api->disable(g_kint.p_ctrl) Disable Key interrupt.
triggerSet	g_keymatrix_on_kint.p_api->triggerSet() Set trigger for Key interrupt.
close	g_keymatrix_on_kint.p_api->close(&g_keymatrix) Allow driver to be reconfigured. May reduce power consumption.

versionGet	g_keymatrix_on_kint.p_api->versionGet(&version) Get version and store it in provided pointer version.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successfully completed.
SSP_ERR_ASSERTION	Parameter has invalid value.
SSP_ERR_INVALID_ARGUMENT	Argument is invalid.
SSP_ERR_HW_LOCKED	The API has already been opened. It must be closed before it can be opened again.
SSP_ERR_NOT_OPEN	The peripheral is not opened.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.32.3 Key Matrix HAL Module Operational Overview

The Key Matrix HAL module configures the Key Interrupt (KINT) peripheral to detect rising or falling edges on any of the KINT channels. When such an event is detected on any of the configured pins, the module generates an interrupt; the interrupt then calls the user callback (p_callback) with the callback argument keymatrix_callback_args_t that specifies the channel(s) on which the edge was detected using a bitmask.

Even though detection of an edge on any one channel generates the interrupt, the callback returns a bitmask keymatrix_channels_t of all the pins that were triggered at that time (if any other pins also detected an edge). Thus, an interrupt is not necessarily generated for edge detection on each pin if an edge was also detected on another pin before the callback was called. If a new edge is detected after the callback was called, then the interrupt is triggered again, resulting in a new callback. The bit mask in the user callback should be checked to identify the interrupt source channels.

This module can be used to implement a matrix keypad with edges on any two channels indicating the actual key that was pressed; alternatively, the module can be used as a single input to detect an edge on an input pin.

Key Matrix HAL Module Important Operational Notes and Limitations

Key Matrix HAL Module Operational Notes

- To trigger a transfer of data using the DMAC or DTC peripheral when a trigger edge is detected, configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_KEY_INT.
- The KINT module can trigger the start of other peripherals available to the ELC. For details,

see the ELC User's Guide in the SSP User's Manual.
- You must enable the KINT (INTKR) interrupt in the BSP for this module to operate, regardless of whether a callback is used in the keymatrix_api_t::open call.

Key Matrix HAL Module Limitations

- This module does not support polling-mode operation.
- Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.32.4 Including the Key Matrix HAL Module in an Application

This section describes how to include the Key Matrix HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Key Matrix Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Key Matrix Driver is g_kint0. This name can be changed in the associated Properties window.)

Key Matrix HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_kint0 Key Matrix Driver on r_kint	Threads	**New Stack**> **Driver**> **Input**> **Key Matrix Driver on r_kint**

When the Key Matrix Driver on r_kint is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

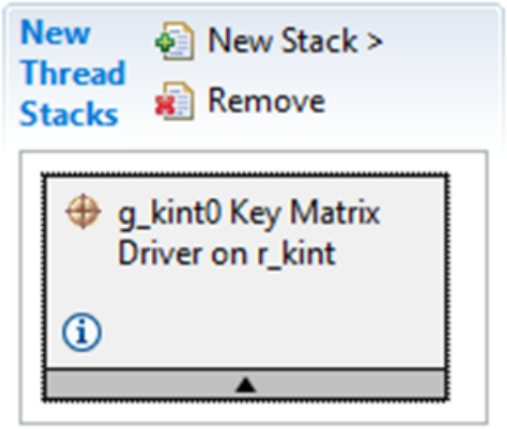

Figure 341: Key Matrix HAL Module Stack

4.2.32.5 Configuring the Key Matrix HAL Module

The Key Matrix HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the properties window; the interrupt settings are often toward the bottom of the properties list, so scroll down until they become available.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Key Matrix HAL Module on r_kint

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_kint0	Module name.
Channel 0-7	Unused, Used Default: Unused	This is a bit-mask with each bit specifying if that channel is to be enabled or not. Select the channels to be used.

Trigger Type	Rising Edge, Falling Edge Default: Rising Edge	Specify if the enabled channels detect a rising edge or a falling edge. Note: Either all channels detecting a rising edge or all channels detecting a falling edge.
Interrupt enabled after initialization	True, False Default: False	Specify if the module interrupts must be enabled as part of the open call.
Callback	NULL	A user callback function can be registered in keymatrix_api_t::open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time a configured edge is detected on any of the channels. Note: Without callback, the application cannot determine whether an event has occurred. Warning: Since the callback is called from an ISR, do not use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Key Matrix HAL Module Clock Configuration

The Key Matrix HAL module does not require a specific clock configuration.

Key Matrix HAL Module Pin Configuration

The KINT peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the KINT pins:

Pin Selection for the Key Matrix HAL Module on r_kint

Resource	ISDE Tab	Pin selection Sequence
KINT	Pins	**Select Peripherals> Input:KINT> KINT0.**

Note

The selection sequence assumes KINT0 is the desired hardware target for the driver.

Pin Configuration Settings for the Key Matrix HAL Module on r_kint

Property	Value	Description
Operation Mode	Disabled, Custom Default: Disabled	Select Custom as the Operation Mode.
KRM0:7	None, Pnn Default: None	Key Interrupt Pin selection.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.2.32.6 Using the Key Matrix HAL Module in an Application

The typical steps in using the Key Matrix HAL module in an application are:

1. Initialize the Key Matrix HAL module using the keymatrix_api_t::open API.
2. If the autostart configuration setting is true, the module starts operation immediately.
    a. If the autostart is not set, use keymatrix_api_t::enable API to enable operation.
3. Respond to key inputs.
4. Disable operation using the keymatrix_api_t::disable API.
5. To modify trigger edge after initialization, use the keymatrix_api_t::triggerSet API.
6. Close the module by using the keymatrix_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

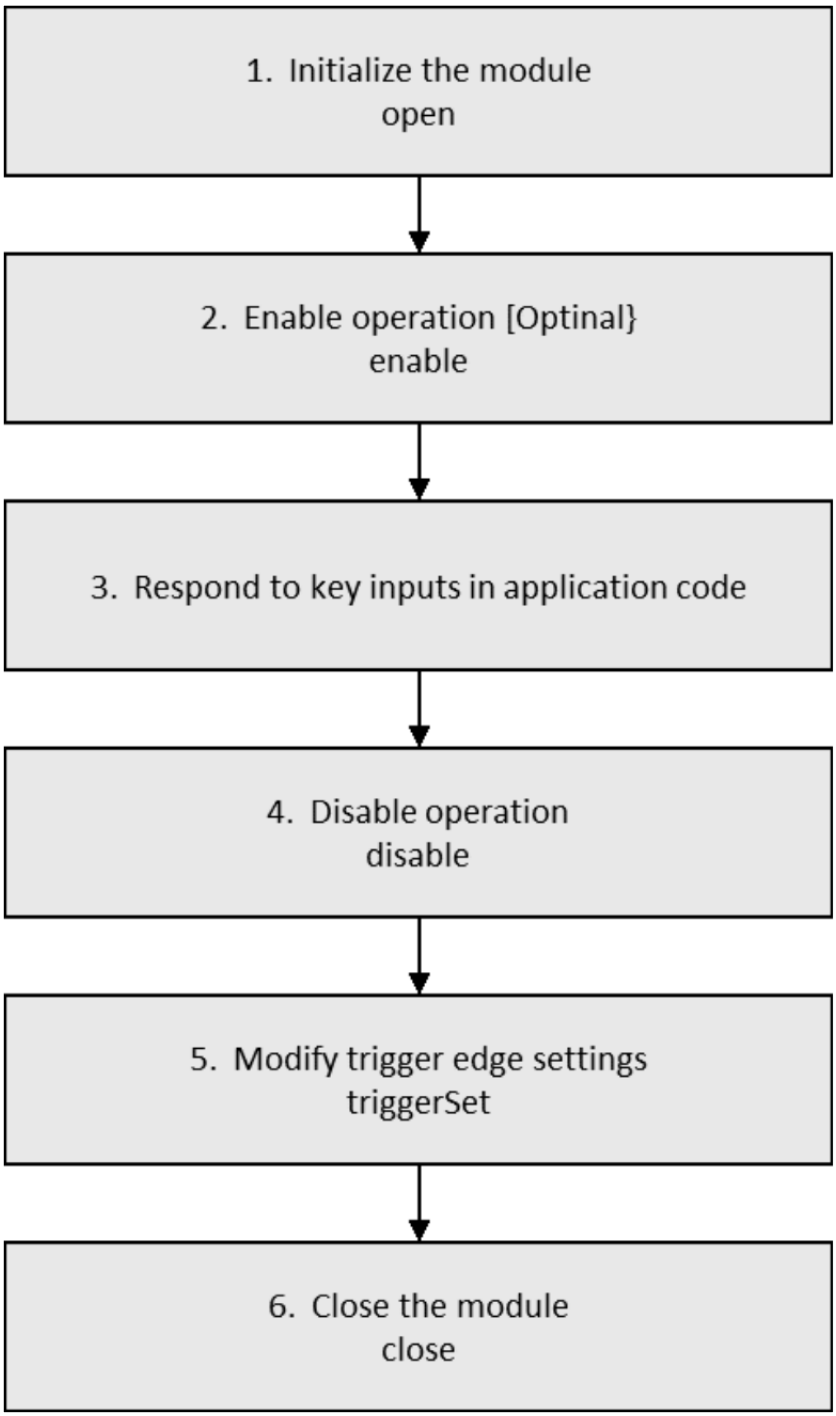

Figure 342: Flow Diagram of a Typical Key Matrix HAL Module Application

4.2.33 Low Power Modes Driver on r_lpmv2

4.2.33.1 LPM V2 HAL Module Introduction

The Low Power Modes V2 HAL module provides a high-level API for low-power mode applications and uses the low-power mode hardware peripheral on the Synergy MCU.

LPM V2 HAL Module Features

- Supports configuration of MCU operating power-control modes and MCU low-power modes
- Supports the following low power modes:
  - Deep Software Standby mode
  - Software Standby mode
  - Sleep mode
  - Snooze mode
- Supports reducing power consumption when in deep stand-by mode through internal power-supply control and by resetting the states of I/O ports.
- Supports disabling and enabling of the MCU's other hardware peripherals.

Note

Not all low-power V2 modes are available on all MCU Groups.

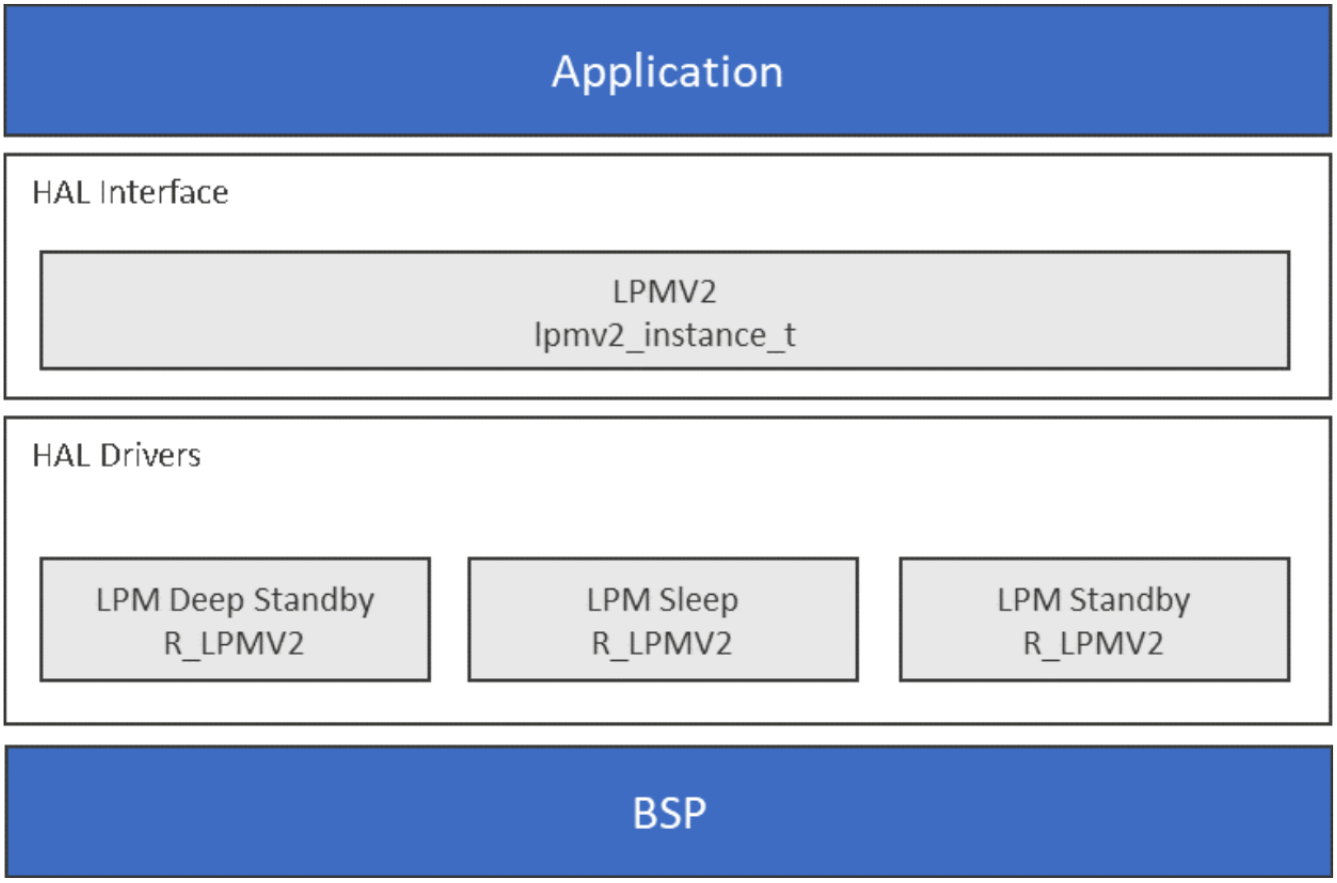

Figure 343: LPM V2 HAL Module Block Diagram

4.2.33.2 LPM V2 HAL Module APIs Overview

The Low Power Modes V2 HAL module defines APIs for configuring operations and enabling and disabling low-power operations. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

Note

The Low Power Modes V2 HAL module will no longer handle operating power-control modes of the MCU; these are now handled by the CGC HAL module.

The following API examples illustrate sleep-mode use; "deep_standby" and "standby" can be substituted for "sleep" in the API examples to create examples for those modes.

LPM V2 HAL Module API Summary

Function Name	Example API Call and Description
init	g_lpmv2_sleep0.p_api->init(g_lpmv2_sleep0.p_cfg); Open the LPM driver module Initialized the LPM block according to the passed in config structure.
lowPowerCfg	g_lpmv2_sleep0.p_api->lowPowerCfg(power_mode, output_port_enable, power_supply, io_port_state); Configure a low power mode.
lowPowerModeEnter	g_lpmv2_sleep0.p_api->lowPowerModeEnter(void); Enter low power mode (sleep/standby/deep standby) using WFI macro. Function will return after waking from low power mode.
versionGet	g_lpmv2_sleep0.p_api->versionGet(&version); Get the driver version and place it at the pointer version.
clearIOKeep	g_lpmv2_sleep0.p_api->clearIOKeep(void); Clear the IOKEEP bit after deep software stand by mode exit

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.

SSP_ERR_INVALID_POINTER	Pointer is NULL.
SSP_ERR_INVALID_MODE	Invalid settings for specified mode.
SSP_ERR_INVALID_HW_CONDITION	OPCMTSF and SOPCMTSF flags are not cleared within internally set timeout.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.33.3 LPM V2 HAL Module Operational Overview

LPM V2 Initialization

The LPM V2 API function lpmv2_api_t::init should be called before calling any other LPM V2 function. The init function handles initialization of internal variables and locks.

Sleep Low-Power Mode

By default, at power on, sleep mode is enabled as the low-power mode. Sleep mode is the most convenient low-power mode available, as it does not require any special configuration (other than configuring and enabling a suitable interrupt or event to wake the MCU from sleep) to return to normal program-execution mode. Any interrupt wakes the MCU device from sleep low-power mode. The states of the SRAM, the processor registers, and the hardware peripherals are all maintained in sleep mode, and the time needed to enter and wake from sleep is minimal. Any interrupt causes the MCU device to wake from sleep mode, including the Systick interrupt used by the ThreadX® thread scheduler. The LPM API function lpmv2_api_t::init should be called before any other function. The LPM API function, lpmv2_api_t::lowPowerCfg, can be used to configure the MCU to use sleep as its low-power mode. The LPM API function lpmv2_api_t::lowPowerModeEnter should be used to directly enter sleep mode.

The following code illustrates configuring sleep as a low-power mode and entering the low-power sleep mode. In this illustration, the LPM V2 sleep module uses the name g_lpmv2_sleep0:

```
/* HAL-only entry function */
#include "hal_data.h"
void hal_entry(void)
{
    ssp_err_t error = SSP_SUCCESS;
    /* Initialize the LPM V2 Driver */
    error = g_lpmv2_sleep0.p_api->init();
    /* Handle error if any */
    /* Configure LPM peripheral for sleep mode */
    error = g_lpmv2_sleep0.p_api->lowPowerCfg(g_lpmv2_sleep0.p_cfg);
    /* Handle error if any */
    /* Entry sleep mode */
```

```
    error = g_lpmv2_sleep0.p_api->lowPowerModeEnter();
    /* Handle error if any */
}
```

Software Standby Mode for LPM V2

In software-standby mode, the CPU, as well as most of the on-chip peripheral functions and all of the internal oscillators, are stopped. Retained are the contents of the CPU internal registers and SRAM data, the states of on-chip peripheral functions, and I/O Ports. Software-standby mode allows significant reduction in power consumption, because most of the oscillators are stopped in this mode. Like Sleep mode, Standby mode requires an interrupt or event be configured and enabled to wake from Standby mode.

The possible triggers for waking from standby mode are enumerated in the Properties window for convenience; multiple triggers can be enabled.

The following code illustrates configuring standby as the low-power mode and entering the low-power standby mode. In this illustration, the LPM V2 standby module with nameg_lpmv2_standby0 is used. A version of this illustration using the Standby module with snooze enabled would be identical:

```
/* HAL-only entry function */
#include "hal_data.h"
void hal_entry(void)
{
    ssp_err_t error = SSP_SUCCESS;
    /* Initialize the LPM V2 Driver */
    error = g_lpmv2_standby0.p_api->init();
    /* Handle error if any */
    /* Configure LPM peripheral for standby mode */
    error = g_lpmv2_standby0.p_api->lowPowerCfg(g_lpmv2_standby0.p_cfg);
    /* Handle error if any */
    /* Entry standby mode */
    error = g_lpmv2_standby0.p_api->lowPowerModeEnter();
    /* Handle error if any */
}
```

Snooze Mode with Software Standby Mode for LPM V2

Snooze mode is available through the standby mode LPM V2 instance. Choose "Standby with Snooze Enabled" for "Choose the low power mode" in the Properties window. Snooze mode can be used with

some MCU peripherals to execute basic tasks, while keeping the MCU in a low-power state. The snooze settings are below the standby settings in the Properties window. The ADC, DTC, and other peripherals can be enabled in snooze mode. All the settings for snooze are available through configuration properties for the standby instance Snooze is considered an advanced feature.

There are three ways to exit from Snooze mode:

1. Select **Snooze Exit Sources** from the configurator (Transit from Snooze to Software Standby mode).
2. Select **Standby/Snooze Exit Sources** from the configurator (Transit from Snooze to Normal mode).
3. Select **Additional snooze exit sources** from the configurator (Transit from Snooze to Normal mode).

The **Snooze Mode Settings** are only used if the low-power mode choice is **Standby with Snooze Enabled**,"as shown in the following screen capture:

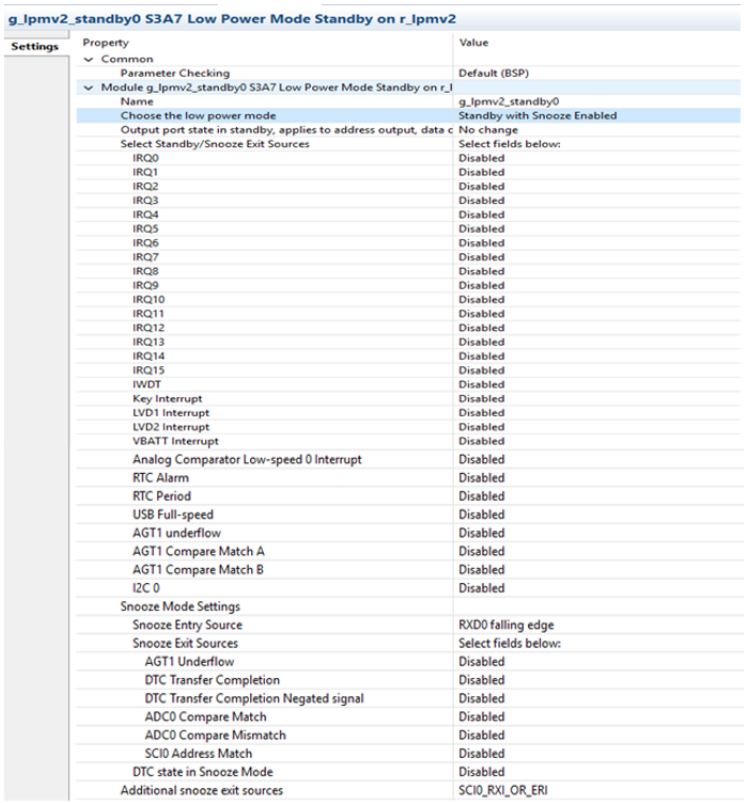

Figure 344: LPM V2 HAL Module Standby Mode With Snooze Setting Enabled

Snooze is a feature of Standby mode that allows some peripherals to run even though the MCU core is not executing instructions. The low-power mode peripheral options related to Snooze mode are shown in the following image. Only one snooze-entry source can be enabled; multiple snooze-exit sources can be enabled. The DTC peripheral can be enabled in snooze mode as well.

Snooze Mode Settings	
Snooze Entry Source	RXD0 falling edge
Snooze Exit Sources	Select fields below:
AGT1 Underflow	Disabled
DTC Transfer Completion	Disabled
DTC Transfer Completion Negated signal	Disabled
ADC0 Compare Match	Disabled
ADC0 Compare Mismatch	Disabled
SCI0 Address Match	Disabled
DTC state in Snooze Mode	Disabled

Figure 345: LPM V2 HAL Module Snooze Mode Settings

Deep Software Standby Mode for LPM V2

Deep Software Standby Mode is only available on some MCU devices. The MCU device always wakes from Deep Software Standby Mode by going through reset, either by the negation of the reset pin or by one of a set of wake up events displayed in the configuration Properties window for the LPM deep standby instance.

The possible triggers for waking from deep standby mode are enumerated in the Properties window for convenience. Multiple triggers can be enabled. Some triggers have an associated edge type, falling or rising. These options are enumerated also as shown above and below.

The following illustration is for configuring deep standby as the low power mode and entering low power Deep Standby mode. In this illustration, the LPM V2 Deep Standby module with nameg_lpmv2_deep_standby0 is used:

```
/* HAL-only entry function */
#include "hal_data.h"
void hal_entry(void)
{
    ssp_err_t error = SSP_SUCCESS;
    /* Initialize the LPM V2 Driver */
    error = g_lpmv2_deep_standby0.p_api->init();
    /* Handle error if any */
    /* Configure LPM peripheral for deep sleep mode */
    error = g_lpmv2_deep_standby0.p_api->lowPowerCfg(g_lpmv2_deep_standby0.p_cfg);
    /* Handle error if any */
    /* Entry deep sleep mode */
    error = g_lpmv2_deep_standby0.p_api->lowPowerModeEnter();
    /* Handle error if any */
```

LPM V2 HAL Module Important Operational Notes and Limitations

LPM V2 HAL Module Operational Notes

Using this driver to configure the LPM peripheral to wake the MCU from standby mode through interrupts requires the interrupt to be configured and enable by the peripheral driver or framework that uses that interrupt. For example, to wake from standby through AGT1 underflow, that interrupt must be enabled through the configuration of the AGT timer module.

If the main oscillator or PLL with main-oscillator source is used for the system clock, the wake time from standby mode can be affected by the Main Oscillator Wait Time Setting in the MOSCWTCR register. This register setting is available to be changed through the Main Oscillator Wait Time setting in the CGC HAL module properties. See the Wakeup Timing and Duration table in Electrical Characteristics for more information.

When a project uses ThreadX and the low-power mode standby, deep standby, or standby with snooze enabled, the call to the lpmv2_api_t::lowPowerCfg API function should occur immediately before the call to the lpmv2_api_t::lowPowerModeEnter API function. This is necessary since ThreadX also uses low-power modes in its idle loop and tx_thread_sleep function; ThreadX expects the MCU device to be configured for the low-power mode sleep.

When a project uses ThreadX and the low-power mode standby or standby with snooze enabled, the low-power mode should be reverted to sleep after the MCU device wakes from standby after returning from the lpmv2_api_t::lowPowerModeEnter function. This is necessary since ThreadX also uses low-power modes in its idle loop and tx_thread_sleep function; ThreadX expects the MCU device to be configured for the low-power mode sleep. The API function lpmv2_api_t::lowPowerCfg needs to be called again before lpmv2_api_t::lowPowerModeEnter to re-configure the low-power mode to sleep, if tx_thread_sleep() is used in the project, or if there may not always be a thread ready to run.

If the deep software standby mode is used, the configurator provides a property to select whether to reset the IO Ports or maintain the status of IO Ports while coming out of deep software standby. If the property is configured to maintain the status of IO port the status of IO Ports will be maintained, however the application code will have to clear the IOKEEP bit in the DSPBYCR register through an API call to clearIOKeep(), after coming out of the deep software standby mode, to allow the operation on IO Ports thereafter.

Detailed information about the expected power consumption of the MCU device in operating states and in Low Power Modes V2 can be found in the Operating and Standby Current section within the Electrical Characteristics section of the MCU Synergy Hardware User's Manual.

LPM V2 HAL Module Limitations

- Flash stop (code flash disable) is not supported. See the section "Flash Operation Control Register (FLSTOP)" of the S1/S3 Synergy MCU Series Hardware User's Manual.
- Reduced SRAM retention area in software standby mode is not supported. See the section "Power Save Memory Control Register (PSMCR)" of the S3 MCU Series Synergy Hardware User's Manual.
- The MCU may not enter or stay in Software Standby and Deep Software Standby modes with the debugger attached. Instead, the MCU may be woken from Software Standby and Deep Software Standby modes by the debugger. To properly test and verify Software Standby and Deep Software Standby modes, the debugger must not be attached.
- If the main oscillator or PLL with main oscillator source is used for the system clock, the wake time from standby mode can be affected by the Main Oscillator Wait Time Setting in the MOSCWTCR register. This register setting is available to be changed through the Main Oscillator Wait Time setting in the CGC HAL module properties. See the "Wakeup Timing and Duration" table in Electrical Characteristics for more information.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.33.4 Including the LPM V2 HAL Module in an Application

This section describes how to include the LPM V2 HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the LPM V2 Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the LPM V2 Driver is g_lpm2_<mode>0. This name can be changed in the associated Properties window.)

LPM V2 HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_lpmv2_deep_standby0 S7G2 Low Power Mode Sleep on r_lpmv2	Threads	**New Stack> Driver> Power> Low Power Mode Deep Standby on r_lpmv2**
g_lpmv2_sleep0 S7G2 Low Power Mode Sleep on r_lpmv2	Threads	**New Stack> Driver> Power> Low Power Mode Sleep on r_lpmv2**
g_lpmv2_standby0 S7G2 Low Power Mode Sleep on r_lpmv2	Threads	**New Stack> Driver> Power> Low Power Mode Standby on r_lpmv2**

When the LPM V2 Driver on r_lpm2 is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

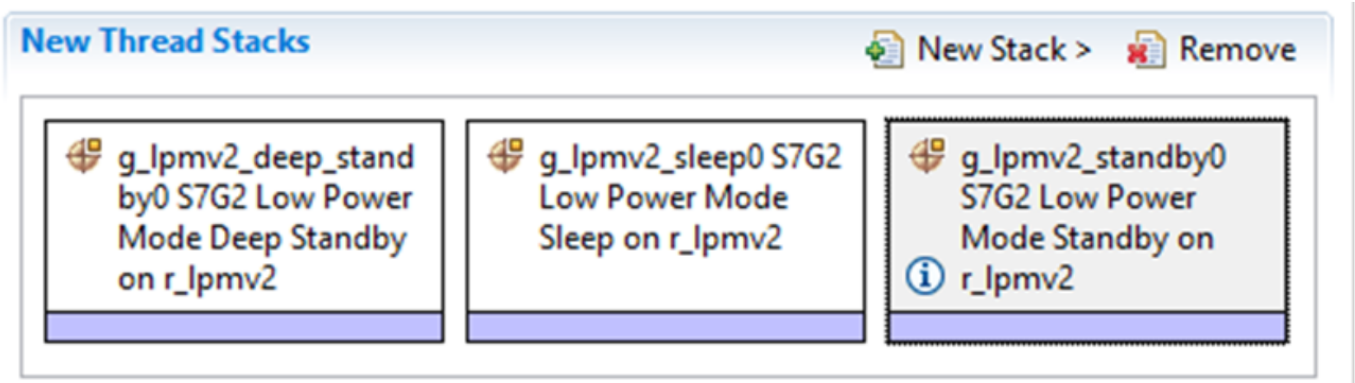

Figure 346: LPM V2 HAL Module Stack

4.2.33.5 Configuring the LPM V2 HAL Module

The LPM V2 HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the LPM Deep Standby Module on r_lpm2

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_lpmv2_deep_standby	Module name.
Output port state in standby and deep standby, applies to address output, data output, and other bus control output pins	High impedance state, No change Default: No change	Output port state selection.
Maintain or reset the IO port states on exit from deep standby mode	Maintain the IO port states, Reset the IO port states Default: Maintain the IO port states	Maintain/reset I/O port states selection.
Internal power supply control in deep standby mode	Maintain the internal power supply, Cut the power supply to standby RAM, low-speed on-chip oscillator, AGTn, and USPFS/HS resume detecting unit, Cut the power supply to LVDn, standby RAM, low-speed on-chip oscillator, AGTn, and USBFS/HS resume detecting unit Default: Maintain the internal power supply	Internal power supply control selection.
IRQ0-15	Enabled, Disabled Default: Disabled	IRQ0-15 selection.

IRQ0-15 Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	IRQ0-15 Edge selection.
LVD1	Enabled, Disabled Default: Disabled	LVD1 selection.
LVD1 Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	LVD1 Edge selection.
LVD2	Enabled, Disabled Default: Disabled	LVD2 selection.
LVD2 Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	LVD2 Edge selection.
RTC Interval	Enabled, Disabled Default: Disabled	RTC Interval selection.
RTC Alarm	Enabled, Disabled Default: Disabled	RTC Alarm selection.
NMI	Enabled, Disabled Default: Disabled	NMI selection.
NMI Edge	Disabled, Rising Edge, Falling Edge Default: Disabled	NMI Edge selection.
USBFS	Enabled, Disabled Default: Disabled	USBFS selection.
UBSHS	Enabled, Disabled Default: Disabled	UBSHS selection.
AGT11	Enabled, Disabled Default: Disabled	AGT11 selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the LPM Sleep Module on r_lpm2

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled (Default: BSP)	Enables or disables the parameter checking.
Name	g_lpmv2_sleep0	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the LPM Standby Module on r_lpm2

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_lpmv2_standby0	Module name.
Choose the low power mode	Standby, Standby with snooze Enabled Default: Standby	Low power mode selection.
Output port state in standby and deep standby, applies to address output, data output, and other bus control output pins	High impedance state, No change Default: No change	Output port state selection.
Select Standby/Snooze Exit Sources	Select fields below:	Transit from Standby to Normal or Snooze to Normal mode.
IRQ1-15	Enabled, Disabled Default: Disabled	IRQ1-15 selection.
IWDT	Enabled, Disabled Default: Disabled	IWDT selection.
Key Interrupt	Enabled, Disabled Default: Disabled	Key Interrupt selection.
LVD1 Interrupt	Enabled, Disabled Default: Disabled	LVD1 Interrupt selection.
LVD2 Interrupt	Enabled, Disabled Default: Disabled	LVD2 Interrupt selection.
Analog Comparator High-speed 0 Interrupt	Enabled, Disabled Default: Disabled	Analog Comparator High-speed 0 Interrupt selection.

RTC Alarm	Enabled, Disabled Default: Disabled	RTC Alarm selection.
RTC Period	Enabled, Disabled Default: Disabled	RTC Period selection.
USB High-speed	Enabled, Disabled Default: Disabled	USB High-speed selection.
USB Full-speed	Enabled, Disabled Default: Disabled	USB Full-speed selection.
AGT1 underflow	Enabled, Disabled Default: Disabled	AGT1 underflow selection.
AGT1 Compare Match A	Enabled, Disabled Default: Disabled	AGT1 Compare Match A selection.
AGT1 Compare Match B	Enabled, Disabled Default: Disabled	AGT1 Compare Match B selection.
12C 0	Enabled, Disabled Default: Disabled	12C 0 selection.
Snooze Entry Source	RXD0 falling edge, IRQ0-IRQ15, KINT, ACMPHS0, RTC Alarm, RTC Period, AGT1 Underflow, AGT1 Compare Match A, AGT1 Compare Match B Default: RXD0 falling edge	Snooze Entry Source selection.
AGT1 Underflow	Enabled, Disabled Default: Disabled	AGT1 Underflow selection.
DTC Transfer Completion	Enabled, Disabled Default: Disabled	DTC Transfer Completion selection.
DTC Transfer Completion Negated Signal	Enabled, Disabled Default: Disabled	DTC Transfer Completion Negated Signal selection.
ADC0 Compare Match	Enabled, Disabled Default: Disabled	ADC0 Compare Match selection.
ADC0 Compare Mismatch	Enabled, Disabled Default: Disabled	ADC0 Compare Mismatch selection.

ADC1 Compare Match	Enabled, Disabled Default: Disabled	ADC1 Compare Match selection.
ADC1 Compare Mismatch	Enabled, Disabled Default: Disabled	ADC1 Compare Mismatch selection.
SCI0 Address Match	Enabled, Disabled Default: Disabled	SCI0 Address Match selection.
DTC state in Snooze Mode	Enabled, Disabled Default: Disabled	DTC state in Snooze Mode selection.
Additional snooze exit sources	SCI0_RXI_OR_ERI Default: SCI0_RXI_OR_ERI	Transit from Snooze to Normal mode.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

In some cases, settings other than the defaults can be desirable. For example, it might be useful to select different states for entering or exiting low-power states.

LPM V2 HAL Module Clock Configuration

The LPM V2 peripheral module does not have any selectable clock sources.

LPM V2 HAL Module Pin Configuration

The LPM V2 peripheral module does not need pin assignments. Pin function selections are done in the properties configuration window.

4.2.33.6 Using the LPM V2 HAL Module in an Application

The typical steps in using the LPM V2 HAL module in an application are:

1. Initialize the Low Power Modes V2 HAL module using the lpmv2_api_t::init API.
2. Configure a low-power mode with the lpmv2_api_t::lowPowerCfg API.
3. Enter a low-power mode with the lpmv2_api_t::lowPowerModeEnter API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

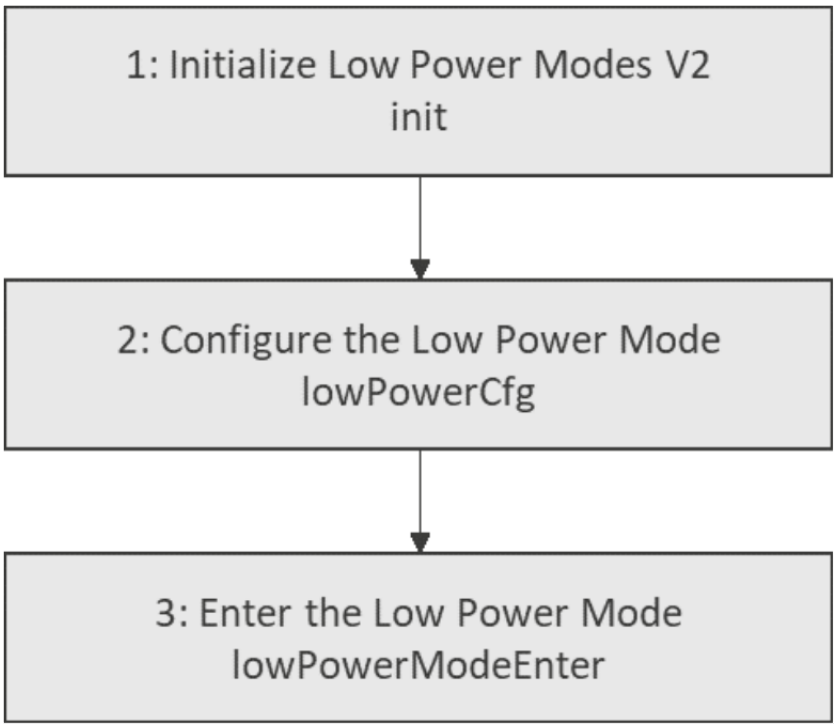

Figure 347: Flow Diagram of a Typical LPM V2 HAL Module Application

4.2.34 Low Voltage Detection Driver

4.2.34.1 LVD HAL Module Introduction

The Low Voltage Detection (LVD) HAL module provides a high-level API for voltage-detection applications and uses the LVD peripheral on the Synergy MCU. A user-defined callback can be created to notify the CPU when a voltage-detection event is triggered. The VCC is the source for all voltage-detection functions.

LVD HAL Module Features

The LVD HAL module supports the following functions:

- V_{CC} as the voltage-detection input
- One build-time configurable low-voltage detector (via OFS1 register)
- Two run-time configurable low-voltage detectors
- Two result flags; one for a threshold check and one for the current state
- Support for both interrupt or polling-event checking

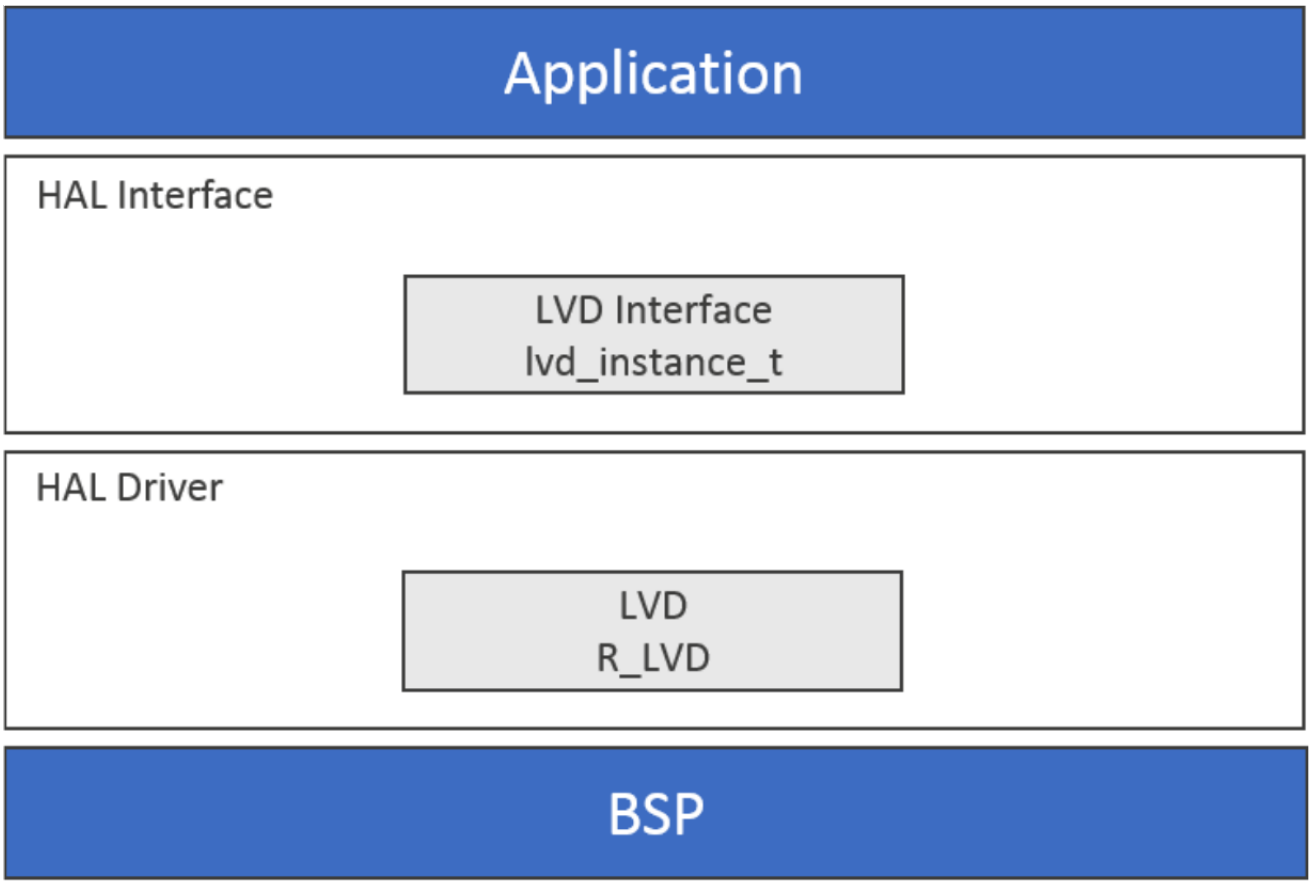

Figure 348: LVD HAL Module Block Diagram

4.2.34.2 LVD HAL Module APIs Overview

The LVD HAL module defines APIs for opening, closing, statusGet and statusClear. The following table includes a complete list of the available APIs, an example API call and a short description of each API. A table of status return values follows the API summary table.

LVD HAL Module API Summary

Function Name	Example API Call and Description
open	g_lvd.p_api->open(g_lvd.p_ctrl, g_lvd.p_cfg; Initializes a low voltage detection driver according to the passed in configuration structure. Enables an LVD peripheral based on configuration structure.

StatusGet	g_lvd.p_api->statusGet(g_lvd.p_ctrl, &monitor_status); Get the current state of the monitor, (threshold crossing detected, voltage currently within range) Can be used to poll the state of the LVD monitor at any time. Must be used if the peripheral was initialized with the lvd_response_tset to LVD_RESPONSE_NONE.
StatusClear	g_lvd.p_api->statusClear(g_lvd.p_ctrl); Clears the latched status of the monitor. Must be used if the peripheral was initialized with lvd_response_t set to LVD_RESPONSE_NONE.
close	g_lvd.p_api->close(g_lvd.p_ctrl, g_lvd.p_cfg); Disables the LVD peripheral. Closes the driver instance.
versionGet	g_lvd.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_IN_USE	Driver already open or unable to acquire hardware lock.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	Invalid configuration value.
SSP_ERR_INVALID_MODE	If the attempted mode is invalid for this configuration.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.34.3 LVD HAL Module Operational Overview

The LVD HAL module supports the configuration and operation of the LVD monitors in the Synergy MCUs. The LVD HAL module provides configuration structures that provide all the information needed to fully configure a single LVD monitor. One instance of the LVD HAL module is needed per instance of an LVD monitor, with the exception of the LVD0 monitor. The LVD0 monitor is not configurable at runtime and must be configured at compile time via the OFS1 register.

The LVD1 and LVD2 monitors are both configurable at runtime and are configured by this module. The lvd_api_t::open function allows the user to configure and enable an LVD monitor with a single function call; the lvd_api_t::close function disables the LVD monitor. The lvd_api_t::statusGet function

returns the current status of the LVD monitor. The lvd_api_t::statusGet function should be used if the module is in polling mode, that is, without the LVD monitor interrupt enabled.

The monitor status consists of two flags. The first flag is a latched flag called lvd_status_t::crossing_detected, which indicates if the voltage being monitored has crossed the voltage threshold. In polling mode, this flag must be cleared via a call to lvd_api_t::statusClear. The flag does not need to be cleared explicitly if the LVD interrupt is in use, it will be cleared in the LVD interrupt by the driver code after the user-callback function is called. The second flag, lvd_status_t::current_state, is the instantaneous status of the monitored voltage with respect to the voltage threshold; this flag is not latched and will change as the monitored voltage changes.

The LVD HAL module can be configured to enable one or several of the LVD peripheral interrupts. If an interrupt is to be used, the user should provide a callback function for that monitor. Separate callback routines should be provided for each LVD monitor.

The LVD HAL module requires functionality provided by the BSP; this driver makes use of hardware locks provided by the BSP for register locks as well as enabling and clearing interrupts.

LVD HAL Module Important Operational Notes and Limitations

LVD HAL Module Operational Notes

- Once the appropriate values are chosen for these settings, you should add the code to call the LVD HAL module lvd_api_t::open API function to your project. This function should be called once early in the application.
- The module can be closed and reopened whenever the configuration of an LVD monitor needs to be changed. Calling the LVD lvd_api_t::open API function configures and enables the LVD hardware peripheral for the specified LVD monitor.
- The close function disables the LVD monitor and closes the driver.
- Using this module to configure the LVD peripheral to generate an interrupt requires the corresponding interrupt to be enabled in the module properties tab.
- A callback function is not required when using the LVD interrupts, but is recommended.
- A unique callback function for each LVD interrupt is not required, but is recommended.
- Clock system initialization, configuration, and runtime modification are handled outside this module. This driver only makes changes to the digital filter sample clock based on the user's choice of sample clock divisor. The digital filter sample clock is derived from the LOCO system clock.
- Not all voltage thresholds are available on all MCUs.
- Digital filtering of the VCC input to the LVD monitor is not available on all MCUs.
- The LVD driver requires functionality provided by the BSP; it makes use of hardware locks provided by the BSP for register locks as well as enabling and clearing interrupts.

LVD HAL Module Limitations

- The process of configuring and enabling a Low Voltage Detection monitor has very specific timing constraints and register write ordering. Because of these constraints, the entire process of configuring and enabling a voltage monitor is most effectively performed by a single function. The open API function performs configuration and enables the monitor in order to properly enforce the timing and register write ordering constraints.
- All series of Synergy microcontrollers have an Option-Setting Memory which can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD, and CGC HOCO.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.34.4 Including the LVD HAL Module in an Application

This section describes how to include the LVD HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the LVD Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the LVD Driver is g_lvd0. This name can be changed in the associated Properties window.)

LVD HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_lvd Low Voltage Detection Driver on r_lvd	Threads	**New Stack> Driver> Power> Low Voltage Detection Driver on r_lvd**

When the LVD Driver on r_lvd is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone.

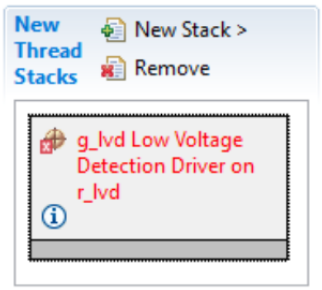

Figure 349: LVD HAL Module Stack

4.2.34.5 Configuring the LVD HAL Module

The LVD HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

One of the properties most often identified as requiring a change is the interrupt priority; this configuration setting is available with the Properties window of the associated module. Simply select the indicated module and then view the properties window; the interrupt settings are often toward

the bottom of the properties list, so scroll down until they become available. Also note that the interrupt priorities listed in the Properties window in the ISDE will include an indication as to the validity of the setting based on the MCU targeted (CM4 or CM0+). This level of detail is not included in the following configuration properties tables, but is easily visible with the ISDE when configuring interrupt priority levels.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the LVD HAL Module on r_lvd

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_lvd	Module name.
Monitor number	1	Monitor number selection.
Digital filter, enable by selecting a valid sample clock rate (S7G2 only).	Digital filter is disabled, Digital filer is enabled (sampling clock is LOCO/2), Digital filer is enabled (sampling clock is LOCO/4), Digital filer is enabled (sampling clock is LOCO/8), Digital filer is enabled (sampling clock is LOCO/16) Default: Digital filter is disabled	Digital filter selection.
Voltage Threshold	Default: 2.85V (Vdet1_13)(S7G2 only).	Voltage threshold selection.
Detection Response, either reset, interrupt, non-maskable interrupt, or no response (polling mode).	Maskable interrupt triggered when voltage crosses the detection threshold, Non-maskable interrupt triggered when voltage crosses the detection threshold, Reset MCU when voltage falls below the detection threshold, No response driver will be in polled mode (using statusGet and statusClear functions). Default: Maskable interrupt triggered when voltage crosses the detection threshold	Detection response selection.

Voltage slope, rising or falling or both	Threshold crossing detected with decreasing voltage, Threshold crossing with increasing voltage, Threshold crossing detected with increasing or decreasing voltage Default: Threshold crossing detected with decreasing voltage	Indicates the direction of voltage change detection in relation to the threshold.
Negation of the monitor signal can be either be delayed from the reset event or from voltage returning to normal range	Negation of reset signal is based on delay from reset, Negation of reset signal is based on delay from voltage returning to normal range Default: Negation of reset signal is based on delay from reset	Negation of the monitor signal selection.
Monitor Interrupt Callback	NULL	Monitor interrupt callback selection.
LVD Monitor Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	LVD monitor interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

LVD HAL Module Clock Configuration

Clock system clock initialization, configuration, and runtime modification are handled outside this module. This module only makes changes to the digital filter sample clock based on the user's choice of sample clock divisor. The digital filter sample clock is derived from the LOCO system clock.

LVD HAL Module Pin Configuration

The LVD HAL module measures the voltage on the VCC pin only and does not need to be configured.

4.2.34.6 Using the LVD HAL Module in an Application

The typical steps in using the LVD HAL module in an application are:

1. Initialize the LVD HAL module using the lvd_api_t::open API.
2. If using software polling, monitor the LVD status flags with the lvd_api_t::statusGet API and process accordingly. If using the interrupt mode, process accordingly within the callback function which will return both the monitor number as well as the status.
3. Process as needed.
4. Close the LVD Instance with the lvd_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

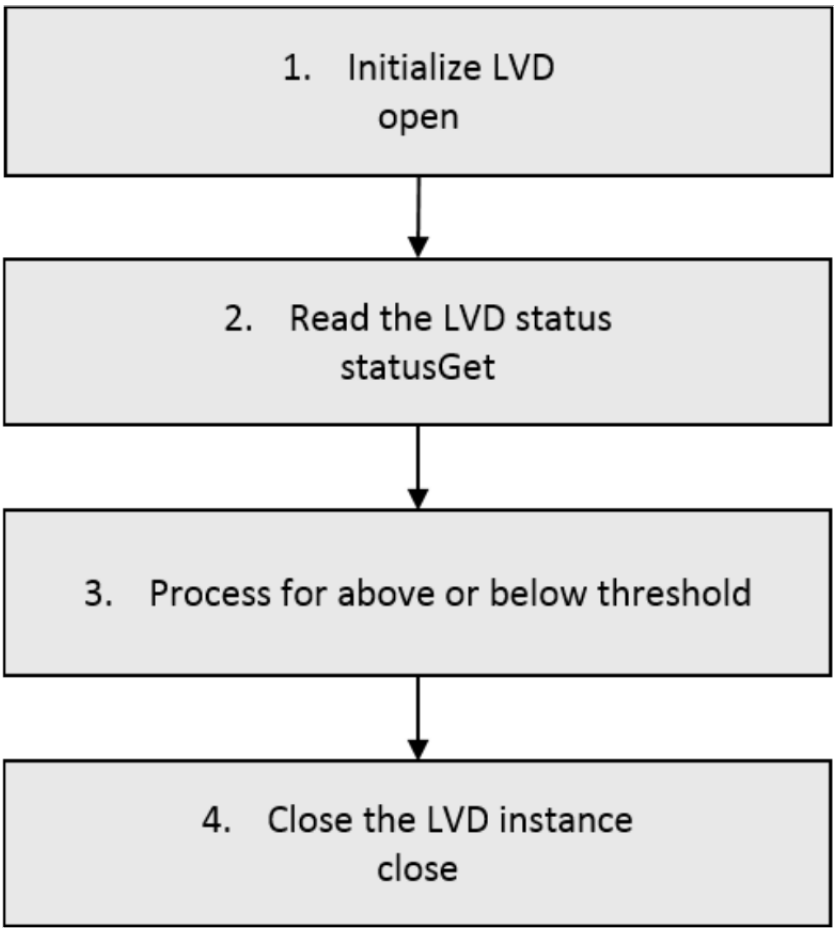

Figure 350: Flow Diagram of a Typical LVD HAL Module Application

4.2.35 OPAMP Driver

4.2.35.1 OPAMP HAL Module Introduction

The OPAMP HAL module provides a high level API for signal amplification applications and supports the OPAMP peripheral available on Synergy MCUs.

OPAMP HAL Module Features

- Low power or high-speed mode
- Start by software or AGT compare match
- Stop by software or ADC conversion end (stop by ADC conversion end only supported on op-amp channels configured to start by AGT compare match)
- Trimming available on some MCUs (see hardware manual)

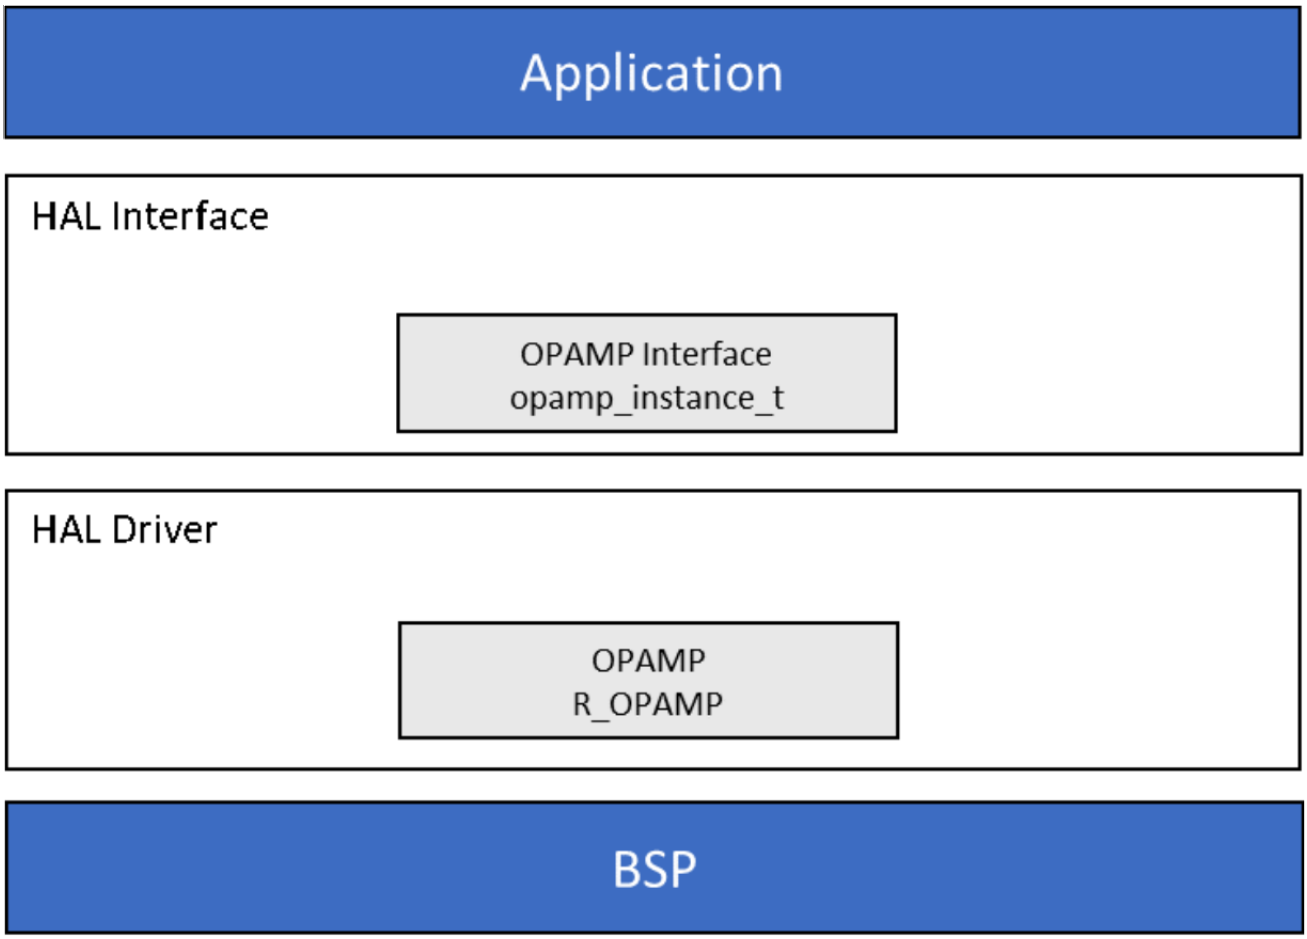

Figure 351: OPAMP HAL Module Block Diagram

OPAMP Hardware Support Details

The following hardware features are, or are not, supported by SSP for OPAMP:

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

4.2.35.2 OPAMP HAL Module APIs Overview

The OPAMP HAL module defines API functions to open, start, stop, read status, trim and close the module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

OPAMP HAL Module API Summary

Function Name	Example API Call and Description
open	g_opamp0.p_api->open(g_opamp0.p_ctrl, g_opamp0.p_cfg); Applies power to the OPAMP and initializes the hardware based on the user configuration.
start	g_opamp0.p_api->start(g_opamp0.p_ctrl, channel_mask); If the OPAMP is configured for hardware triggers, enables hardware triggers. Otherwise, starts the op-amp.
stop	g_opamp0.p_api->stop(g_opamp0.p_ctrl, channel_mask); Stops the op-amp. If the OPAMP is configured for hardware triggers, disables hardware triggers.
trim	g_opamp0.p_api->trim(g_opamp0.p_ctrl, cmd, p_args); On MCUs that support trimming, the op-amp trim register is set to the factory default after open(). This function allows the application to trim the operational amplifier to a user setting, which overwrites the factory default factory trim values. See Operational Notes for important details.
infoGet	g_opamp0.p_api->infoGet(g_opamp0.p_ctrl, p_info); Provides the minimum stabilization wait time in microseconds.

statusGet	g_opamp0.p_api->statusGet(g_opamp0.p_ctrl, p_status); Provides the operating status for each op-amp in a bitmask. This bit is set when operation begins, before the stabilization wait time has elapsed.
close	g_opamp0.p_api-> close(g_opamp0.p_ctrl); Stops the op-amps.
versionGet	g_opamp0.p_api->versionGet(&version); Retrieve the module version using the version pointer

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IN_USE	Peripheral is in use or hardware lock is taken.
SSP_ERR_INVALID_POINTER	The parameter p_data is NULL.
SSP_ERR_INVALID_STATE	The command is not valid for the current state of the trim function.
SSP_ERR_INVALID_MODE	Trim is not allowed in low power mode.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.35.3 OPAMP HAL Module Operational Overview

The OPAMP HAL module controls the OPAMP peripheral on a Synergy microcontroller. It directly controls the OPAMP hardware without using any RTOS elements and provides convenient APIs to simplify development.

OPAMP HAL Module Important Operational Notes and Limitations

OPAMP HAL Module Operational Notes

Trimming the OPAMP

On MCUs that support trimming, the op-amp trim register is set to the factory default after the opamp_api_t::open API is called).

This function allows the application to trim the operational amplifier to a user setting, which overwrites the factory default factory trim values.

Not supported on all MCUs. See hardware manual for details. Not supported if configured for low power mode (OPAMP_MODE_LOW_POWER).

This function is not reentrant. Only one side of one op-amp can be trimmed at a time. Complete the procedure for one side of one channel before calling the opamp_api_t::trim API with the command OPAMP_TRIM_CMD_START again.

The trim procedure works as follows:

- Call the opamp_api_t::trim API for the Pch (+) side input with command OPAMP_TRIM_CMD_START.
- Connect a fixed voltage to the Pch (+) input.
- Connect the Nch (-) input to the op-amp output to create a voltage follower.
- Ensure the op-amp is operating and stabilized.
- Call the opamp_api_t::trim API for the Pch (+) side input with command OPAMP_TRIM_CMD_START.
- Measure the fixed voltage connected to the Pch (+) input using the SAR ADC and save the value (referred to as A later in this procedure).
- Iterate over the following loop 5 times:
    - Call the opamp_api_t::trim API for the Pch (+) side input with command OPAMP_TRIM_CMD_NEXT_STEP.
    - Measure the op-amp output using the SAR ADC (referred to as B in the next step).
    - If A <= B, call the opamp_api_t::trim API for the Pch (+) side input with command OPAMP_TRIM_CMD_CLEAR_BIT.
- Call the opamp_api_t::trim API for the Nch (-) side input with command OPAMP_TRIM_CMD_START.
- Measure the fixed voltage connected to the Pch (+) input using the SAR ADC and save the value (referred to as A later in this procedure).
- Iterate over the following loop 5 times:
    - Call the opamp_api_t::trim API for the Nch (-) side input with command OPAMP_TRIM_CMD_NEXT_STEP.
    - Measure the op-amp output using the SAR ADC (referred to as B in the next step).
    - If A <= B, call the opamp_api_t::trim API for the Nch (-) side input with command OPAMP_TRIM_CMD_CLEAR_BIT.

The following status return values are associated with the opamp_api_t::trim API:

SSP_SUCCESS	Conversion result in p_data
SSP_ERR_UNSUPPORTED	Trimming is not supported on this MCU.
SSP_ERR_INVALID_STATE	The command is not valid in the current state of the trim state machine.
SSP_ERR_INVALID_ARGUMENT	The requested channel is not operating or the trim procedure is not in progress for this channel/input combination.
SSP_ERR_INVALID_MODE	Trim is not allowed in low power mode.
SSP_ERR_ASSERTION	An input pointer was NULL.
SSP_ERR_NOT_OPEN	Instance control block is not open. Trimming is not supported on all MCUs.

OPAMP HAL Module Limitations

This module only works for selected Synergy MCUs. Refer to the release notes for your current SSP release to see which MCUs are supported by this module. Additionally, the MCU Hardware Manual shows which peripherals are available.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.35.4 Including the OPAMP HAL Module in an Application

This section describes how to include the OPAMP HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the OPAMP Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the OPAMP Driver is g_opamp0. This name can be changed in the associated Properties window.)

OPAMP HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_opamp0 OPAMP Driver on r_opamp	Threads	**New Stack> Driver> Analog> OPAMP Driver on r_opamp**

When the OPAMP Driver on r_opamp is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

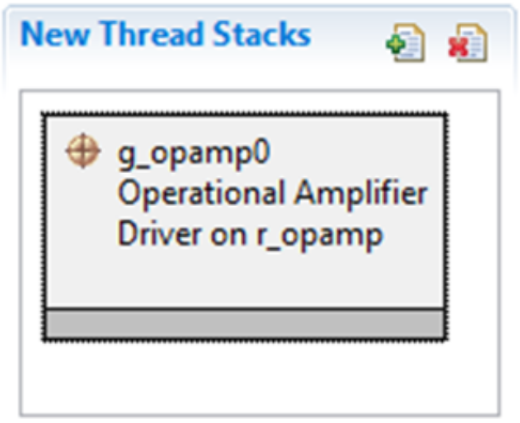

Figure 352: OPAMP HAL Module Stack

4.2.35.5 Configuring the OPAMP HAL Module

The OPAMP HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the OPAMP HAL Module on r_opamp

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_opamp	Module name.
AGT Start Trigger Configuration (N/A unless AGT Start Trigger is Selected for the Channel)	AGT1 Compare Match Starts OPAMPs 0 and 2 if configured for AGT Start/AGT0 Compare Match Starts OMPAMPs 1 and 3 if configured for AGT Start, AGT1 Compare Match Starts OPAMPs 0 and 1 if configured for AGT Start/AGT0 Compare Match Starts OPAMPs 2 and 3 if configured for AGT Start, AGT1 Compare Match Starts all OPAMPs configured for AGT Start Default: AGT1 Compare Match Starts all OPAMPs configured for AGT Start	Configure which AGT channel event triggers op-amp channel. The AGT compare match event only starts the op-amp channel if the AGT Start trigger is selected in the Trigger configuration for the channel.
Power Mode	Low Power, Middle Speed, High Speed Default: High Speed	Configure the op-amp based on power or speed requirements. This setting affects the minimum required stabilization time. Middle speed is not available for all MCUs.

Trigger Channel 0	Software Start Software Stop, AGT Start Software Stop, AGT Start ADC Stop Default: Software Start Software Stop	Select the event triggers to start or stop op-amp channel 0. If the event trigger is selected for start, the opamp_api_t::start API enables the event trigger for this channel. If the event trigger is selected for stop, the opamp_api_t::stop API disables the event trigger for this channel.
Trigger Channel 1	Software Start Software Stop, AGT Start Software Stop, AGT Start ADC Stop Default: Software Start Software Stop	Select the event triggers to start or stop op-amp channel 1. If the event trigger is selected for start, the opamp_api_t::start API enables the event trigger for this channel. If the event trigger is selected for stop, the opamp_api_t::stop API disables the event trigger for this channel.
Trigger Channel 2	Software Start Software Stop, AGT Start Software Stop, AGT Start ADC Stop Default: Software Start Software Stop	Select the event triggers to start or stop op-amp channel 2. If the event trigger is selected for start, the opamp_api_t::start API enables the event trigger for this channel. If the event trigger is selected for stop, the opamp_api_t::stop API disables the event trigger for this channel.
Trigger Channel 3	Software Start Software Stop, AGT Start Software Stop, AGT Start ADC Stop Default: Software Start Software Stop	Select the event triggers to start or stop op-amp channel 3. If the event trigger is selected for start, the opamp_api_t::start API enables the event trigger for this channel. If the event trigger is selected for stop, the opamp_api_t::stop API disables the event trigger for this channel.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

OPAMP HAL Module Clock Configuration

The OPAMP HAL module does not require a specific clock configuration.

OPAMP HAL Module Pin Configuration

To use the OPAMP HAL module, the port pins for the channels receiving the analog input must be set

as input pins in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection for the OPAMP HAL Module on r_opamp

Resource	ISDE Tab	Pin selection Sequence
OPAMP	Pins	Select **Peripherals**> **Analog: OPAMP 0/1/2**

4.2.35.6 Using the OPAMP HAL Module in an Application

The typical steps in using the OPAMP HAL module in an application are:

1. Initialize the OPAMP module using the opamp_api_t::open API.
   Note
   Before starting any op-amp, consult the hardware manual to determine if the MCU used has internal connections switches in the OPAMP peripheral. If the OPAMP peripheral does have internal connection switches, configure the internal connections by setting the AMPnMS, AMPnPS, and AMP0OS registers directly.
2. Start the OPAMP channel(s) using the desired trigger with the opamp_api_t::start API.
   Note
   If the AGT compare match start is used, this call enables the OPAMP to be triggered by the AGT compare match. If a software trigger is used, then this call starts the OPAMP channel(s).
3. Wait for the OPAMP to stabilize. The stabilization time can be found in the hardware manual or by using the opamp_api_t::infoGet API.
4. Stop the OPAMP channel(s) by calling the opamp_api_t::stop API. (Optional)
   Note
   This stops the OPAMP regardless of if ADC conversion end triggers are enabled to stop the OPAMP.
5. Close the module and power down the peripheral using the opamp_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

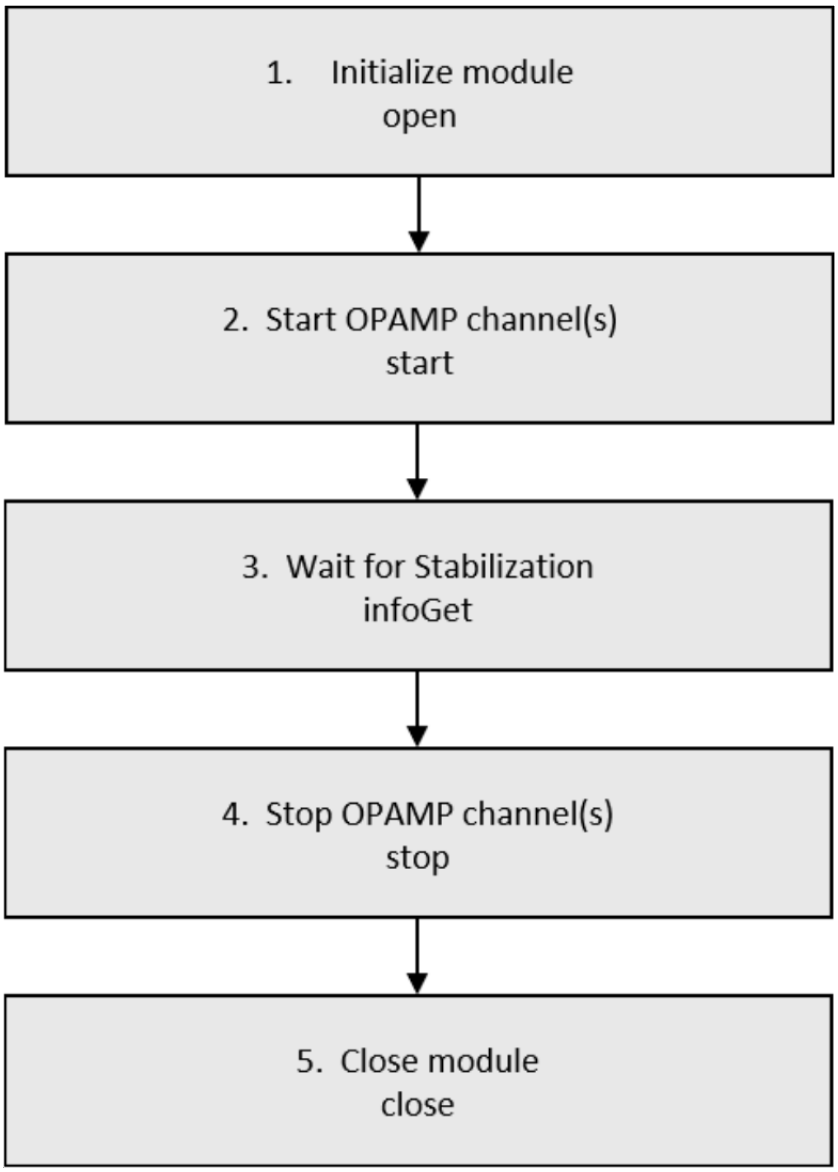

Figure 353: Flow Diagram of a Typical OPAMP HAL Module Application

4.2.36 PDC Driver

4.2.36.1 PDC HAL Module Introduction

The Parallel Data Capture Unit (PDC) HAL module provides a high-level API to capture images from a camera application and uses the PDC peripheral on the Synergy MCU. A user-defined callback can be created to inform the CPU when a capture has been completed.

PDC HAL Module Features

- Supports capture from a connected and configured camera.
- Supports a callback that informs the CPU when a capture is complete.

- Provides a pointer to the capture buffer.
- Provides an indication of the event triggering the callback.

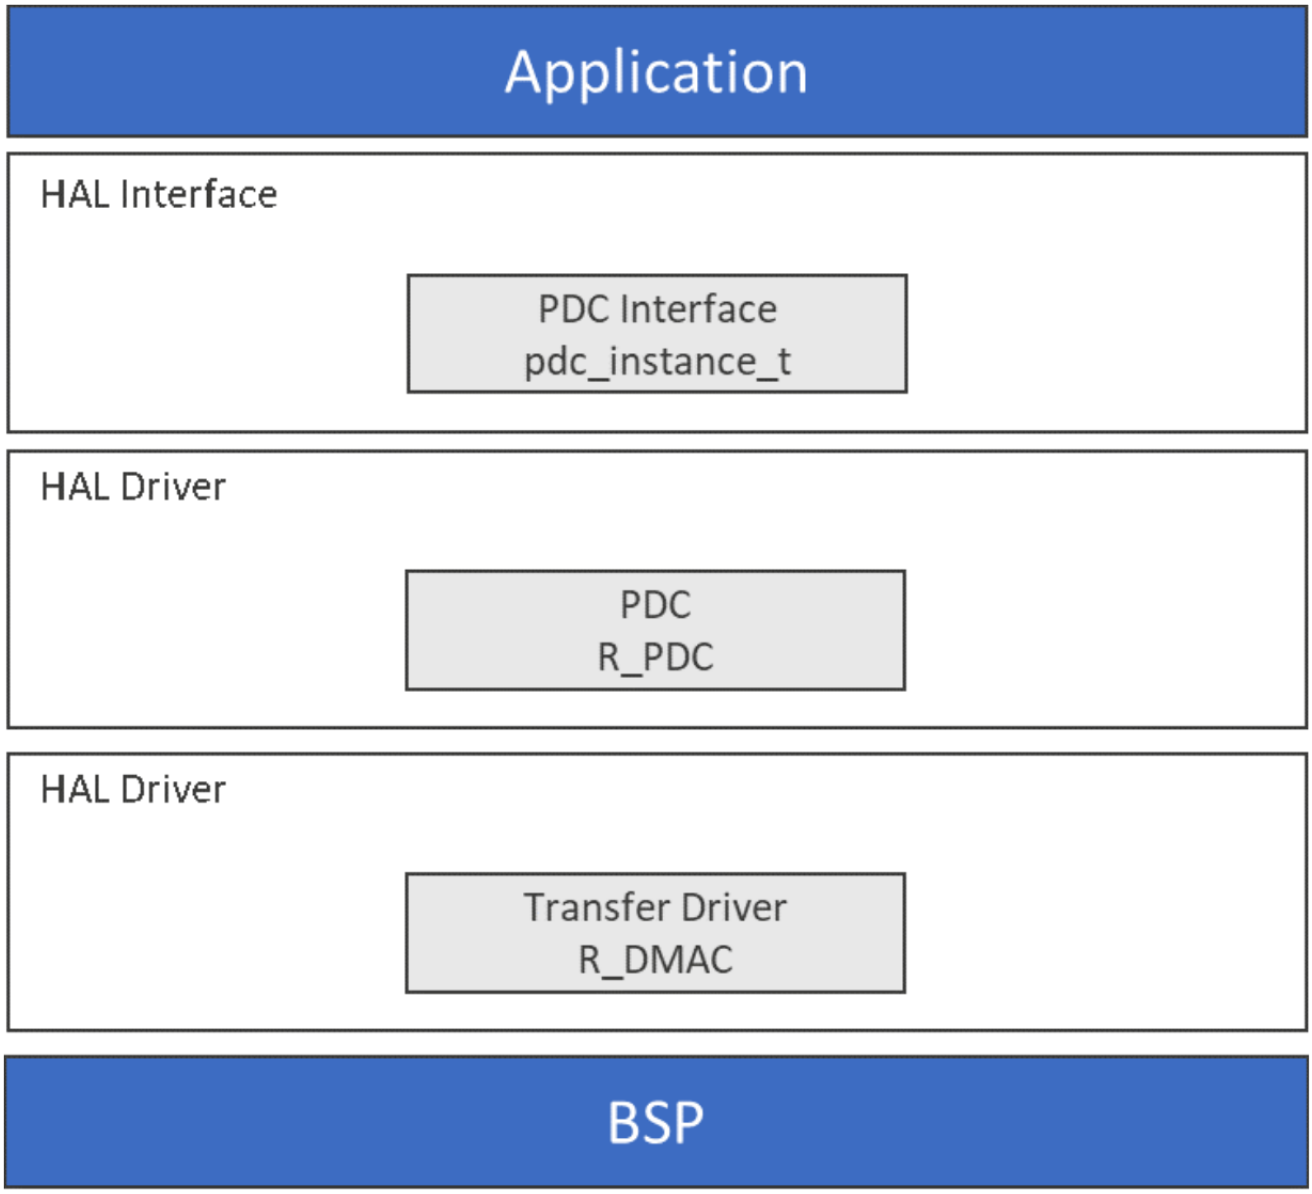

Figure 354: PDC HAL Module Block Diagram

PDC Hardware Support dDetails

The following hardware features are, or are not, supported by SSP for PDC:

Legend:

4.2.36.2 PDC HAL Module APIs Overview

The PDC HAL module defines APIs for opening, closing and starting data capture. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

PDC HAL Module API Summary

Function Name	Example API Call and Description
open	g_pdc.p_api->open(g_pdc.p_ctrl, g_pdc.p_cfg) Initial configuration.
close	g_pdc.p_api->close(g_pdc.p_ctrl)) Closes the driver and allows reconfiguration. May reduce power consumption.
captureStart	g_pdc.p_api->captureStart(g_pdc.p_ctrl, NULL) Start a capture.
stateGet	g_pdc.p_api->stateGet(g_pdc.p_ctrl, &state_data) Get the state of VSYNC and HSYNC pins.
versionGet	g_pdc.p_api->versionGet(&version) Return the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ALREADY_OPEN	Unit is already open.
SSP_ERR_HW_LOCKED	Unable to reserve BSP hardware lock.
SSP_ERR_TIMEOUT	Reset Operation timed out.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.36.3 PDC HAL Module Operational Overview

The capture operation requires a configured external camera connected to the Synergy microcontroller. Before performing a capture, the camera must be configured and it must generate a PIXCLK-clock input into the microcontroller. In some instances, a camera requires a running-clock input before it can be configured.

Use the call pdc_api_t::open API (which configures and starts the PCKO-clock output from the PDC into the camera) before initializing the camera. Once the camera is configured, the pdc_api_t::captureStart can be called to capture an image. Configuration of a camera module may require the use of an I^2C or SPI interface.

PDC HAL Module Important Operational Notes and Limitations

PDC HAL Module Operational Notes

In most instances, the data rate from a camera or the PDC peripheral is too fast to be serviced by the CPU in an interrupt service routine (ISR). Therefore, this module requires an implementation of the transfer driver on the DMAC to perform a high-speed transfer from the PDC peripheral and memory.

Both the PDC frame-end and PDC error interrupts must be used to generate interrupts in the following situations:

- An interrupt when an image is captured (frame end)
- An interrupt when an error occurs

Data Buffer Setting

If p_buffer is set to anything other than NULL, one or more data buffers are created to store image data. The size of each buffer is calculated using the following formula:

Buffer size (bytes) = x_capture_pixels x y_capture_pixels x bytes_per_pixel

For large resolution cameras, the captured image could result in a large amount of data. It may be necessary to locate the buffer(s) in external memory (such as, SDRAM). Consideration should be

given to bus bandwidth when using external memory.

For example, when using a high frame-rate camera to do an image capture via the PDC into SDRAM, and using SDRAM to hold the display buffer for an LCD display with a high refresh rate, may cause a data bottleneck from the PDC to memory that results in an overrun-error condition.

Note

If p_buffer is set to NULL, no memory is allocated to store the captured image data. The application must ensure that there is suitable memory of sufficient size available to the PDC. The PDC could capture directly into the display buffer of a connected LCD panel.

PDC HAL Module Limitations

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4.2.36.4 Including the PDC HAL Module in an Application

This section describes how to include the PDC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the PDC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the PDC Driver is g_pdc0. This name can be changed in the associated Properties window.)

PDC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_pdc0 PDCDriver on r_pdc	Threads	**New Stack> Driver> Graphics> PDC Driver on r_pdc**

When the PDC Driver on r_pdc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

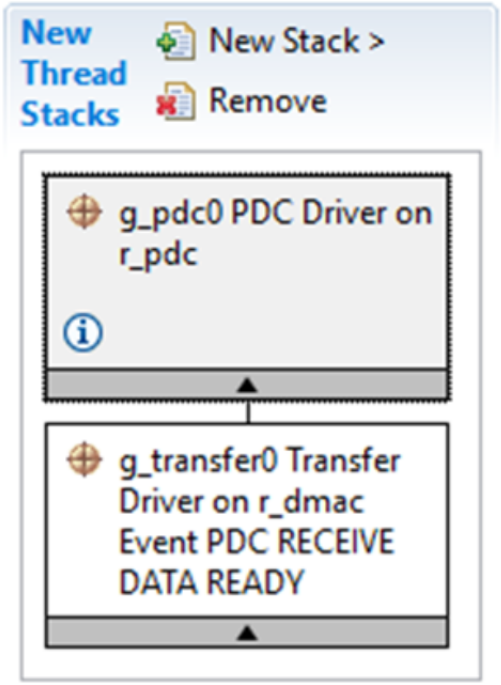

Figure 355: PDC HAL Module Stack

4.2.36.5 Configuring the PDC HAL Module

The PDC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the PDC HAL Module on r_pdc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_pdc0	The name of the PDC module instance. Specify arbitrary C symbol.

Name of the data buffer to store image data	g_user_buffer	Specify the name of the data buffer to create or set to NULL if it is to be created by the user external to the PDC driver.
Section where data buffer is allocated	sdram	Specify the RAM section for the image data buffer. Typically bss (internal RAM) or sdram.
Number of bytes per pixel	2	Specify the number of bytes per pixel of the captured image data.
Number of image data buffers	1	Specify the number of buffers to create.
Clock Divider	CLK/2, CLK/4, CLK/6, CLK/8, CLK10, CLK12, CLK14, CLK16 Default: CLK/2	Specify the clock divider of the clock input to the PDC peripheral.
Endian of image data	Little, Big Default: Little	Specify the endian of the captured image data.
HYSNC signal polarity	High, Low Default: High	Specify the active polarity of the HSYNC signal.
VSYNC signal polarity	High, Low Default: High	Specify the active polarity of the VSYNC signal.
Number of pixels to capture horizontally	640	Number of horizontal pixels to capture.
Number of pixels to capture vertically	480	Number of vertical lines to capture.
Horizontal pixel to start capture from	0	Horizontal pixel to start capturing image data from. Allows an image smaller than the native resolution of a camera to be captured.
Line to start capture from	0	Vertical line to start capturing image data from. Allows an image smaller than the native resolution of a camera to be captured.

Callback	g_pdc_user_callback	A user callback function can be registered in open. If this callback function is provided, it is called from the interrupt service routine (ISR) each time a frame is captured and ready to be processed. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.
Frame End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	The driver needs a valid interrupt priority setting. It will not function if disabled.
PDC Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	The driver needs a valid interrupt priority setting. It will not function if disabled.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the PDC HAL Module Lower-Lever Module

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the Red text in the Thread Stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the Transfer Driver on r_dmac Event PDC RECEIVE DATA READY

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Parameter selection.
Name	g_transfer0	Driver name.
Mode	Block	Mode selection.
Transfer Size	4 Bytes	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.

Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	8	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	1	Number of blocks selection.
Activation Source (Must enable IRQ)	Event PDC RECEIVE DATA READY	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

PDC HAL Module Clock Configuration

The PDC uses the PCLKB as its clock source. The only restriction when configuring this clock is that the PIXCLCK should be less than 0.6 x PCLKB so the PCLKB frequency should be set accordingly.

PDC HAL Module Pin Configuration

The PDC peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table depicts the method to select pins within the SSP configuration window and the subsequent table gives an example selection for PDC pins:

Pin Selection for the PDC HAL Module on r_pdc

Resource	ISDE Tab	Pin selection Sequence
PDC	Pins	Select **Peripherals**> **Graphics: PDC**> **PDC0**

Note

The selection sequence assumes KINT0 is the desired hardware target for the driver.

Pin Configuration Settings for the PDC HAL Module on r_pdc

Property	Value	Description

Pin Group Selection	Mixed, _A Only Default: Mixed	Pin group selection.
Operation Mode	Disabled, Custom, Enabled Default: Disabled	Select Enabled as the Operation Mode for PDC.
HSYNC	None, P704 Default: None	HSYNC Pin.
PCKO	None, P511 Default: P511	PCKO Pin.
PIXCLK	None, P705 Default: None	PIXCLK Pin.
VSYNC	None, P512 Default: P512	VSNC Pin.
PIXD0:7	None, Pnnn Default: None	PIX Data0:7 Pins.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.2.36.6 Using the PDC HAL Module in an Application

The typical steps in using the PDC HAL module in an application are:

1. Initialize the PDC HAL module using the pdc_api_t::open API.
2. Configure the camera as needed.
3. Start image capture using the pdc_api_t::captureStart API.
4. Callback is called when image is captured.
5. Read state of HSYNC and VSTNC using pdc_api_t::stateGet API.
6. Process data as needed.
7. Close using the pdc_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

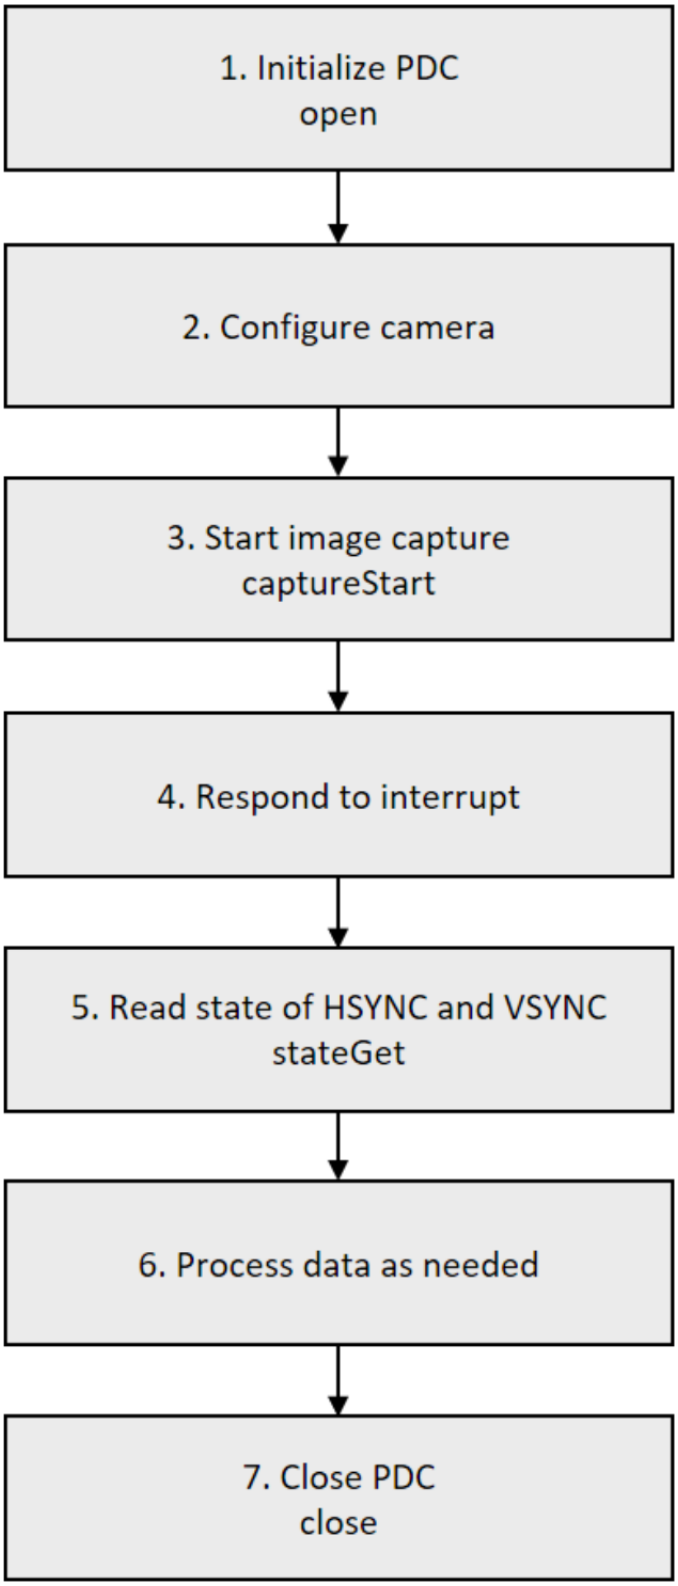

Figure 356: Flow Diagram of a Typical PDC HAL Module Application

4.2.37 PTP Driver on r_ptp

4.2.37.1 Precision Time Protocol HAL Module Introduction

The PTP HAL Module provides high-level APIs for the time synchronization using the PTP function of the EPTPC peripheral module (EPTPC) on the synergy MCU. A user callback can be created to indicate the occurrence of pulse output timer event or the state change of Synchronous Frame Processing units(SYNFP0 and SYNFP1), Statistical Time Correction Algorithm(STCA), or Packet Relation Controller unit(PRC-TC).

Precision Time Protocol HAL Module Features

The PTP HAL module configures the PTP for time synchronization functionality.

The PTP HAL allows the user to perform the following operations:

- Set and get local clock counter value.
- Set and get master port ID.
- Set and get PTP message reception configuration.
- Update PTP message information.
- Get offset from master and mean path delay values.
- Collecting gradient differences and extracting the worst ten values by hardware and software.
- Set start time, period, and pulse width of pulse output timer.
- Indicate and auto-clear pulse output event signals to the ELC.
- Enable and disable INFABT status notification.

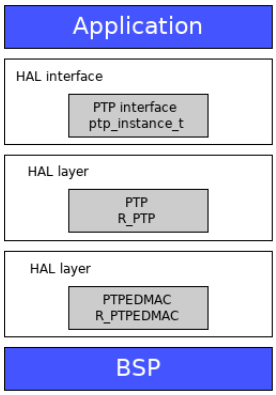

Figure 357: PTP HAL Module Block Diagram

Precision Time Protocol Hardware Support Details

The following hardware features are, or are not, supported by SSP for PTP.

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

MCU Group	Ordinary clock	Boundary clock	Transparent clock	E2E delay mechanism	P2P delay mechanism	Pulse output timer operation

S7G2	✓	✓	✓	✓	✓	✓

4.2.37.2 Precision Time Protocol HAL Module APIs Overview

The PTP HAL module interface defines APIs for key features such as initializing, starting, stopping, getting and setting of synchronous information, setting start time for pulse output timer, setting ELC event indication, and updating PTP message flags. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

PTP HAL Module API Summary

PTP API functions

Function Name	Example API Call and Description
open	g_ptp.p_api->open(g_ptp.p_ctrl, g_ptp.p_cfg); Open the PTP driver module.
close	g_ptp.p_api->close(g_ptp.p_ctrl); Close the PTP driver module.
configure	g_ptp.p_api->configure(g_ptp.p_ctrl, ip_address, physical_address_msw, physical_address_lsw); Configures the PTP driver module.
setExtPromiscuous	g_ptp.p_api->setExtPromiscuous(g_ptp.p_ctrl, 1, false); Sets or clears the extended promiscuous mode
setLocalClock	g_ptp.p_api->setLocalClock(g_ptp.p_ctrl, &lc_clk); Sets local clock counter

getLocalClock	g_ptp.p_api->getLocalClock(g_ptp.p_ctrl, &lc_clk, 20); Gets local clock counter.
getMasterPortID	g_ptp.p_api->getMasterPortID(g_ptp.p_ctrl, 1, curClkId, &curPortId); Gets master port ID.
setMasterPortID	g_ptp.p_api->setMasterPortID(g_ptp.p_ctrl, 1, curClkId, &curPortId); Sets master port ID.
getSyncInfo	g_ptp.p_api->getSyncInfo(g_ptp.p_ctrl, 1, &master_offset, &path_delay); Get current offsetFromMaster and meanPathDelay.
start	g_ptp.p_api->start(g_ptp.p_ctrl, 100); Starts the time synchronization.
stop	g_ptp.p_api->stop(g_ptp.p_ctrl, 100); Stops the time synchronization.
checkWorst10Values	g_ptp.p_api->checkWorst10Values(g_ptp.p_ctrl, 40000); Checks worst 10 values acquired by hardware and set as gradient limits.
setWorst10Values	g_ptp.p_api->setWorst10Values(g_ptp.p_ctrl, 32); Sets the time interval for collecting worst 10 values.
getWorst10Values	g_ptp.p_api->getWorst10Values(g_ptp.p_ctrl, p_lim, m_lim, 40000); Gets the worst 10 values acquired by software.
setGradientLimit	g_ptp.p_api->setGradientLimit(g_ptp.p_ctrl, p_lim, m_lim); Sets the gradient limits for positive and negative worst 10 values.
updateClockID	g_ptp.p_api->updateClockID(g_ptp.p_ctrl, 1, clock_id); Updates clock identity field.
updateDomainNumber	g_ptp.p_api->updateDomainNumber(g_ptp.p_ctrl, 1, domain_num); Updates domain number field in the message header.
updateAnnounceFlags	g_ptp.p_api->updateAnnounceFlags(g_ptp.p_ctrl, 1, &p_flag); Updates announce message's flag field.
updateAnnounceMsgs	g_ptp.p_api->updateAnnounceMsgs(g_ptp.p_ctrl, 1, &p_message); Updates announce message's message field.

updateSyncAnnounceMsgInterval	g_ptp.p_api->updateSyncAnnounceMsgInterval(g_ptp.p_ctrl, 1, &p_sync_interval, &p_ance_interval); Updates transmission interval and logMessageInterval of Sync and Announce messages.
updateDelayMsgInterval	g_ptp.p_api->updateDelayMsgInterval(g_ptp.p_ctrl, 1, &p_interval, &p_timeout); Updates transmission interval, logMessageInterval and timeout values of Delay message.
getMessageReceptionConfig	g_ptp.p_api->getMessageReceptionConfig(g_ptp.p_ctrl, 1, &p_ptp_message_reception); Gets PTP message reception synchronous configuration.
setMessageReceptionConfig	g_ptp.p_api->setMessageReceptionConfig(g_ptp.p_ctrl, PTP_TEST_CHANNEL, &p_ptp_message_reception); Sets PTP message reception synchronous configuration.
disableTimer	g_ptp.p_api->disableTimer(g_ptp.p_ctrl, PTP_STCA_TIMER_CHANNEL_0));Disables the specified timer event interrupt.
indicateEvent	g_ptp.p_api->indicateEvent(g_ptp.p_ctrl, cyc_ch, PTP_STCA_TIMER_PULSE_EDGE_RISING, true); Sets or clears ELC interrupt indication.
autoClearEvent	g_ptp.p_api->autoClearEvent(g_ptp.p_ctrl, cyc_ch, PTP_STCA_TIMER_PULSE_EDGE_RISING, true); Sets or clears ELC interrupt auto clear mode.
setTimer	g_ptp.p_api->setTimer(g_ptp.p_ctrl, 0U, start_time, 200000, 100000);Sets start time, pulse period and pulse width for the pulse output timer.
setMINTevent	g_ptp.p_api->setMINTevent(g_ptp.p_ctrl, PTP_EVENT_STCA, 0x03, false);Sets EPTPC MINT interrupt event.
enableINFABTnotification	g_ptp.p_api->enableINFABTnotification(g_ptp.p_ctrl, 1); Enables EPTPC INFABT notification of the specified PTP channel.
disableINFABTnotification	g_ptp.p_api->disableINFABTnotification(g_ptp.p_ctrl, 1); Disables EPTPC INFABT notification of the specified PTP channel.

checkINFABTstatus	g_ptp.p_api->checkINFABTstatus(g_ptp.p_ctrl, &status); Checks the status of INFABT flag of the specified PTP channel.
clearINFABTstatus	g_ptp.p_api->clearINFABTstatus(g_ptp.p_ctrl, 1); Clears INFABT interrupt occurrence flag of the specified PTP channel.
versionGet	g_ptp.p_api->versionGet(&ptp_version); Get the driver version based on compile time macros.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.
While calling configure API, make sure that IP address and MAC address are assigned to respective index when using ordinary clock 0 and ordinary clock 1.
checkWorst10Values API should be called only when STCA synchronous mode is set to Mode 2 - Gradient collection by hardware in the configurator.
getWorst10Values and setGradientLimit APIs should be called only when STCA synchronous mode is set to Mode 2 - Gradient collection by software in the configurator.
linkProcess API should be called after configure API and ensure that there is no delay between the API calls.
While calling setTimer API, user needs to pass half the required pulse output period and pulse high width.

PTP HAL Module Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_CHANNEL	Attempt to use invalid PTP channel
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IRQ_BSP_DISABLED	A required interrupt does not exist in the vector table.
SSP_ERR_TIMEOUT	Timeout error.
SSP_ERR_INVALID_MODE	Attempt to use unsupported or incorrect mode.
SSP_ERR_IN_USE	Unit is already opened.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.37.3 Precision Time Protocol HAL Module Operational Overview

The PTP driver on r_ptp HAL module controls the on-chip Precision Time Protocol (PTP) module for the Ethernet Controller (EPTPC) on a Synergy microcontroller, as configured by the user. It directly controls the EPTPC hardware without using any RTOS elements. It provides convenient API functions to simplify development.

Precision Time Protocol HAL Module Important Operational Notes and Limitations

Precision Time Protocol HAL Module Operational Notes

PTP HAL module can be used for the synchronization of clocks.

Clock state

- **Master**: EPTPC peripheral sends announce and sync message to slave devices which contain local clock time in UNIX Timestamp format
- **Slave**: EPTPC peripheral receives and corrects the local time in accordance to master clock time.

Clock mode

- **Ordinary clock**: PTP messages are transmitted and received through one Ethernet port in operation as an ordinary clock. An ordinary clock operates as either master or slave.
- **Boundary clock**: PTP messages are transmitted and received through both ports in operation as a boundary clock. One port operates as a slave in synchronization with the master and the other operates as the master that delivers time information synchronized with the master clock. Both ports can also operate as masters.
- **Transparent clock**: A transparent clock does not act as a master or slave, instead relays PTP messages from the master to the slave.

Delay correction mechanism

- **E2E delay correction mechanism**: It involves message exchange between master and slave. The slave sends a delay request to the master, which in turn responds with a delay response back to the requested slave.
- **P2P delay correction mechanism**: This mechanism uses a port-based peer delay message mechanism. Each port on a PTP device sends peer delay request messages to the port it is directly connected to. The connected port then responds with a peer delay response message.

Statistical time correction algorithm (STCA): When configured as a slave, the synchronized state can be identified by the offset from master value staying below a threshold specified in advance or calculated statistically from collected positive and negative gradient values by hardware or software (worst-10 acquisition).

STCA clock can be used as the clock source for generating pulse signals from pulse output timer m (m = 0 to 5). PCLKA is used as a source clock at a frequency of 20 MHz.

The generated pulse signals can be linked through event link (ELC) to get triggered when a rising or falling edge is detected.

Interrupts and callback: The user callback must be registered to handle pulse output timer event or state change of SYNFP0, SYNFP1, STCA or PRC-TC. If the user callback is registered then the PTP driver will invoke the callback (ptp_cfg_t::p_callback) with argument ptp_callback_args_t, indicating the event ptp_event_t.

PTPEDMAC supports the following interrupts:

1. Rising edge detected on the periodic pulse signal from pulse output timer
2. Change in state of SYNFP0
3. Change in state of SYNFP1

4. Change in state of STCA
5. Change in state of PRC-TC

Initialization: Ethernet initialization should be done and Ethernet link should be up before calling PTP APIs.

Precision Time Protocol HAL Module Limitations

PTP HAL module limitations:

1. PTP HAL module does not support the setting of inter-port transfer mode for standard ethernet frames.
2. PTP HAL module does not support the setting of multicast frame filter for standard ethernet frames.

EPTPC hardware limitations:

1. PTP message frames are not supported over IPv6 format.

4.2.37.4 Including the Precision Time Protocol HAL Module in an Application

This section describes how to include the PTP HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

PTP HAL driver is used as a lower level module for Ethernet and is not available to add as a separate stack. It is available as optional driver under sf_el_nx. PTPEDMAC is added as a lower level module for PTP automatically. An example is illustrated in the following figure where a module must be selected to Add PTP Driver. The following figure shows the selection of the PTP driver to complete the stack for the module.

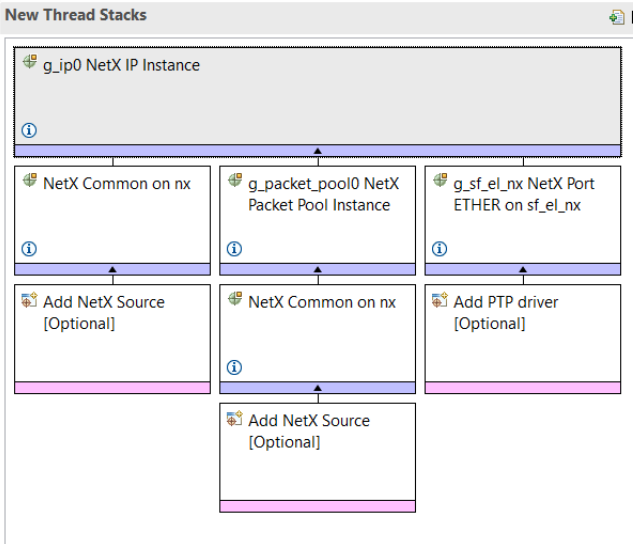

Figure 358: PTP HAL Module Stack 1

When the PTP Driver on r_ptp is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

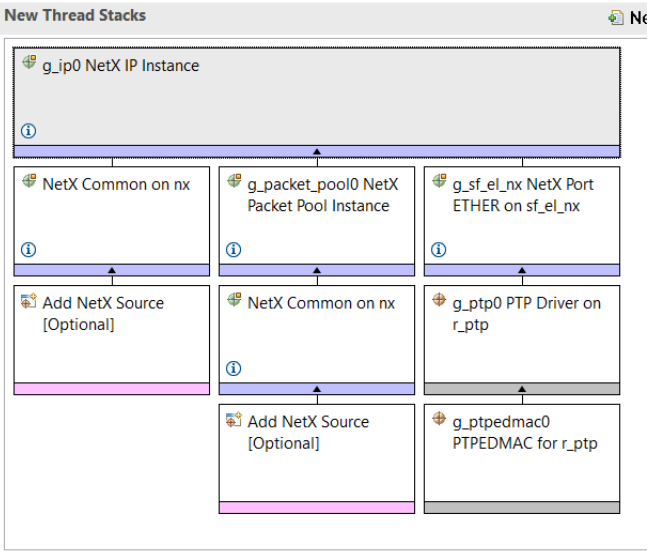

Figure 359: PTP HAL Module Stack 2

4.2.37.5 Configuring the Precision Time Protocol HAL Module

The PTP HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the PTP HAL Module on r_ptp

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.

Name	g_ptp	Module name.
Clock mode	Ordinary clock 0, Ordinary clock 1, Boundary clock, Transparent clock Default: Ordinary clock 0	PTP clock mode selection.
STCA synchronous mode	Mode 1- No gradient collection, Mode 2- Gradient collection by hardware, Mode 2- Gradient collection by software Default: Mode 2- Gradient collection by hardware	STCA synchronous mode selection.
MINT callback	Default: NULL	PTP MINT interrupt callback selection.
MINT interrupt priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the MINT interrupt priority.
Clock state	Slave, Master Default: Slave	PTP clock state selection.
Delay correction mechanism	E2E (End to end), P2P (Peer to peer) Default: End to end delay correction mechanism	Delay correction mechanism selection.
Frame format	Ethernet II, Ethernet 802.3, Ethernet II over UDP4, Ethernet 802.3 over UDP4 Default: Ethernet II	PTP message frame format selection.

Note

While using ordinary clock mode, make sure the Ethernet channel selected for sf_el_nx and r_ptp are the same.

Other MCUs may have different default values and available configuration settings.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group.

Precision Time Protocol HAL Module Clock Configuration

No specific clock configurations are required for the PTP HAL Module.

Precision Time Protocol HAL Module Pin Configuration

No specific pin configurations are required for the PTP HAL Module.

4.2.37.6 Using the Precision Time Protocol HAL Module in an Application

Note

User shall proceed with time synchronization operations only after Ethernet is initialized, link is up and PTP is configured with IP and MAC address.

The typical steps in using the PTP HAL module in an application are:

PTP master application:

1. Initialize the PTP HAL module using ptp_api_t::open, ptp_api_t::configure, ptpedmac_api_t::open APIs.

2. Set PTP host interface for PTP message transfer using the ptpedmac_api_t::linkProcess API.

3. Set the local clock value using the ptp_api_t::setLocalClock API.

4. Start time synchronization using the ptp_api_t::start API.

5. Stop synchronization using the ptp_api_t::stop API.

6. Use the ptp_api_t::close call to close the peripheral.

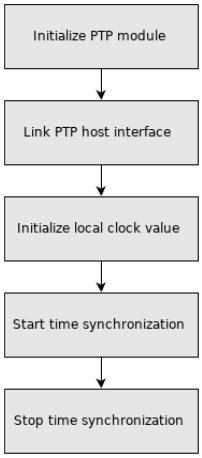

Figure 360: Flow Diagram of a PTP HAL Module Application as master

PTP slave application:

1. Initialize the PTP HAL module using ptp_api_t::open, ptp_api_t::configure, ptpedmac_api_t::open APIs.
2. Set the interval for getting worst 10 values using the ptp_api_t::setWorst10Values API.
3. Set PTP host interface for PTP message transfer using the ptpedmac_api_t::linkProcess API.
4. Wait till PINT interrupt occurs. Receive PTP message using ptpedmac_api_t::read API through ptpedmac_cfg_t::p_callback.
5. Start time synchronization using the ptp_api_t::start API.
6. Get worst 10 value acquired by software or hardware using ptp_api_t::getWorst10Values or ptp_api_t::checkWorst10Values and set as gradient limit.
7. Get local clock counter value using the ptp_api_t::getLocalClock API.
8. Get master offset and path delay using ptp_api_t::getSyncInfo API.
9. Stop time synchronization using the ptp_api_t::stop API.
10. Use the ptp_api_t::close call to close the peripheral.

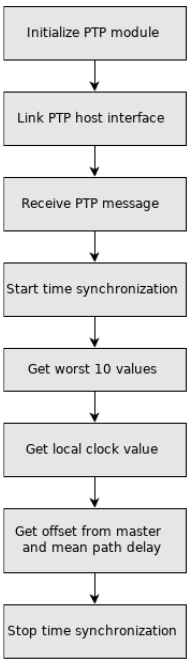

Figure 361: Flow Diagram of a PTP HAL Module Application as slave

Application for setting pulse output timer:

1. Configure PTP clock state as master and register a callback function for MINT ISR.
2. Initialize the PTP HAL module using ptp_api_t::open, ptp_api_t::configure APIs.
3. Configure PTP module to indicate and auto-clear event using ptp_api_t::indicateEvent, ptp_api_t::autoClearEvent APIs.
4. Set the start time, period, and pulse width for pulse output timer using ptp_api_t::setTimer API
5. Set the local clock value using the ptp_api_t::setLocalClock API.
6. Start time synchronization using the ptp_api_t::start API.
7. Wait till the MINT timer event occurs. Start counting by pulse output timer through ptp_cfg_t::p_callback.
8. Stop synchronization using the ptp_api_t::stop API.
9. Use the ptp_api_t::close call to close the peripheral.

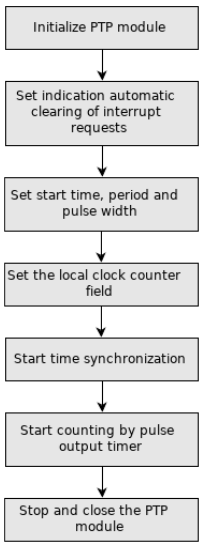

Figure 362: Flow Diagram of a PTP HAL Module Application for setting pulse output timer

Note

As per hardware user manual, time synchronization will not start immediately after starting the PTP module by calling start API. It might take about 3 seconds to get synchronized.

4.2.38 PTPEDMAC Driver on r_ptpedmac

4.2.38.1 PTPEDMAC HAL Module Introduction

The PTPEDMAC HAL Module provides high-level APIs for message transmission using a DMA controller for EPTPC peripheral in synergy MCU. A user callback can be created to indicate the occurrence of frame receive complete event, frame transmit complete event, or error event.

PTPEDMAC HAL Module Features

The PTPEDMAC HAL module configures PTPEDMAC for data transmission and reception of PTP messages.

The PTPEDMAC HAL allows the user to perform the following operations:

- Link the PTP host interface to transmit and receive PTP messages.
- Check the communication status.
- Read PTP messages.

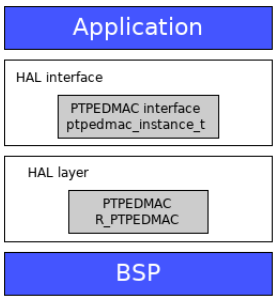

Figure 363: PTPEDMAC HAL Module Block Diagram

PTPEDMAC Hardware Support Details

The following hardware features are, or are not, supported by SSP for PTPEDMAC.

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

MCU Group	Linking PTP host Interface	Read PTP message
S124	N/A	N/A

4.2.38.2 PTPEDMAC HAL Module APIs Overview

The PTPEDMAC module interface defines APIs for key features such as opening, closing, reading, linking host interface. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

PTPEDMAC HAL Module API Summary

PTPEDMAC API functions

Function Name	Example API Call and Description
open	g_ptpedmac.p_api->open(g_ptpedmac.p_ctrl, g_ptpedmac.p_cfg); Open the PTPEDMAC driver module for reception of PTP messages.
close	g_ptpedmac.p_api->close(g_ptpedmac.p_ctrl); Close the PTPEMAC module.
linkProcess	g_ptpedmac.p_api->linkProcess(g_ptpedmac.p_ctrl); Sets host interface to transfer PTP messages
linkCheck	g_ptpedmac.p_api->linkCheck(g_ptpedmac.p_ctrl); Checks host interface communication status
read	g_ptpedmac.p_api->read(g_ptpedmac.p_ctrl, &read_ch, P_BUF, &num_recvd); Receives PTP message.
versionGet	g_ptpedmac.p_api ->versionGet (&ptpedmac_version); Get the driver version based on compile time macros.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.
PTPEDMAC open API should be called after PTP open API call is successful.

PTPEDMAC HAL Module Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	An input pointer is NULL.
SSP_ERR_IRQ_BSP_DISABLED	A required interrupt does not exist in the vector table.
SSP_ERR_NOT_ENABLED	PTP host interface is not enabled.
SSP_ERR_TIMEOUT	Timeout error.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.38.3 PTPEDMAC HAL Module Operational Overview

The PTPEDMAC HAL module provides DMA controller for message transmission and reception for the on-chip Ethernet PTP Controller (EPTPC) on a Synergy microcontroller, as configured by the user. It provides convenient API functions to simplify development.

PTPEDMAC HAL Module Important Operational Notes and Limitations

PTPEDMAC HAL Module Operational Notes

The PTPEDMAC controls data transmission and reception based on EPTPC configuration.

The PTPEDMAC transfers data according to the information written in the descriptor. A descriptor includes the buffer size, address, and transmit or receive status.

The user callback must be registered to indicate PTPEDMAC communication status. If the user callback is registered then the PTPEDMAC driver will invoke the callback (ptpedmac_cfg_t::p_callback) with argument ptpedmac_callback_args_t, indicating the event ptpedmac_event_t.

PTPEDMAC supports the following interrupts:

1. Frame receive complete event - this event occurs when PTP message frame is received successfully

    1. Frame transmit complete event - this event occurs when the PTP message frame is transmitted successfully
    2. Error event - this event occurs when an error occurs during the transfer of PTP message

PTPEDMAC HAL Module Limitations

PTPEDMAC write functionality is not supported as EPTPC hardware automatically handles analysis and transmission of PTP messages for time synchronization.

4.2.38.4 Including the PTPEDMAC HAL Module in an Application

This section describes how to include the PTPEDMAC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

PTPEDMAC HAL driver is used as a lower-level module for PTP driver and is not available to add as a separate stack. PTPEDMAC is added as a lower-level module for PTP driver automatically.

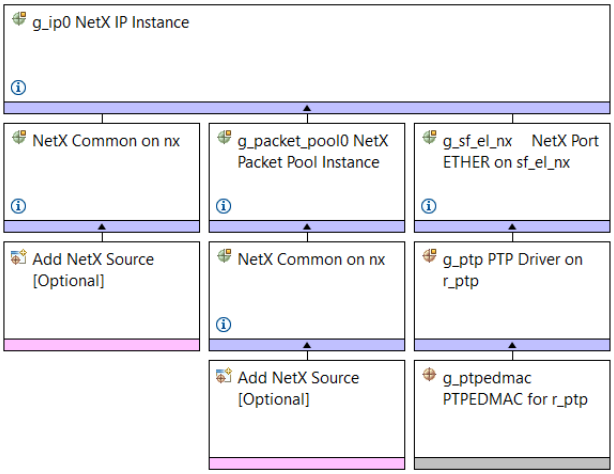

Figure 364: PTPEDMAC HAL Module Stack

When the PTPEDMAC Driver on r_ptpedmac is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

4.2.38.5 Configuring the PTPEDMAC HAL Module

The PTPEDMAC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the PTPEDMAC HAL Module on r_ptpedmac

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Number of RX descriptors	Range: 1 to 8 Default: 1	Number of receive buffer descriptors selection.

PTPEDMAC buffer size	Range: 64 to 1536 Default: 1536	Buffer size.
Name	g_ptpedmac0	Module name.
Callback	Default: NULL	PINT interrupt callback selection.
PINT interrupt priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Select the PINT interrupt priority.

Other MCUs may have different default values and available configuration settings.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group.

PTPEDMAC HAL Module Clock Configuration

No specific clock configurations are required for the PTPEDMAC HAL Module.

PTPEDMAC HAL Module Pin Configuration

No specific pin configurations are required for the PTPEDMAC HAL Module.

4.2.38.6 Using the PTPEDMAC HAL Module in an Application

Note

PTPEDMAC APIs are to be used along with PTP APIs for message transmission and reception.
User shall call ptpedmac_api_t::open API only after ptp_api_t::open API call is successful.

The typical steps in using the PTPEDMAC HAL module in an application are:

1. Initialize the PTP HAL module using ptp_api_t::open API.
2. Initialize the PTPEDMAC module using ptpedmac_api_t::open API.
3. Configure the PTP module with IP and MAC address using ptp_api_t::configure API.
4. Link PTPEDMAC to receive and transfer PTP message transfer using the ptpedmac_api_t::linkProcess API.
5. Start time synchronization using the ptp_api_t::start API.
6. Receive PTP message using ptpedmac_api_t::read API through ptpedmac_cfg_t::p_callback.

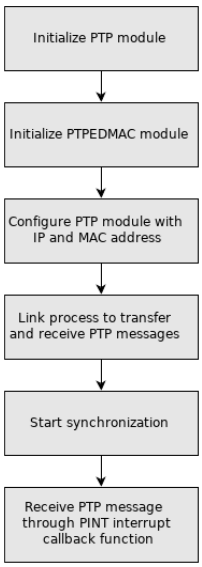

Figure 365: Flow Diagram of a PTPEDMAC HAL Module Application

4.2.39 QSPI Driver

4.2.39.1 QSPI HAL Module Introduction

The Quad SPI (QSPI) HAL module provides a high-level API for erasing and programming the contents of a QSPI flash device connected to the microcontroller. Unlike many other modules, there is no callback function for the QSPI.

QSPI HAL Module Features

The QSPI HAL Module is used to initialize the QSPI peripheral that allows erasing and programming the contents of a QSPI flash device connected to the microcontroller over the Quad SPI interface. Key features include:

- Accessing Quad SPI flash devices using Direct Communication Mode
- Reading data from a QSPI flash device
- Programming the page of a QSPI flash device
- Erasing sectors of a QSPI flash device
- Selecting a bank to control access to a QSPI flash device
- Accessing Quad SPI flash devices using 3-byte/4-byte Addressing Mode

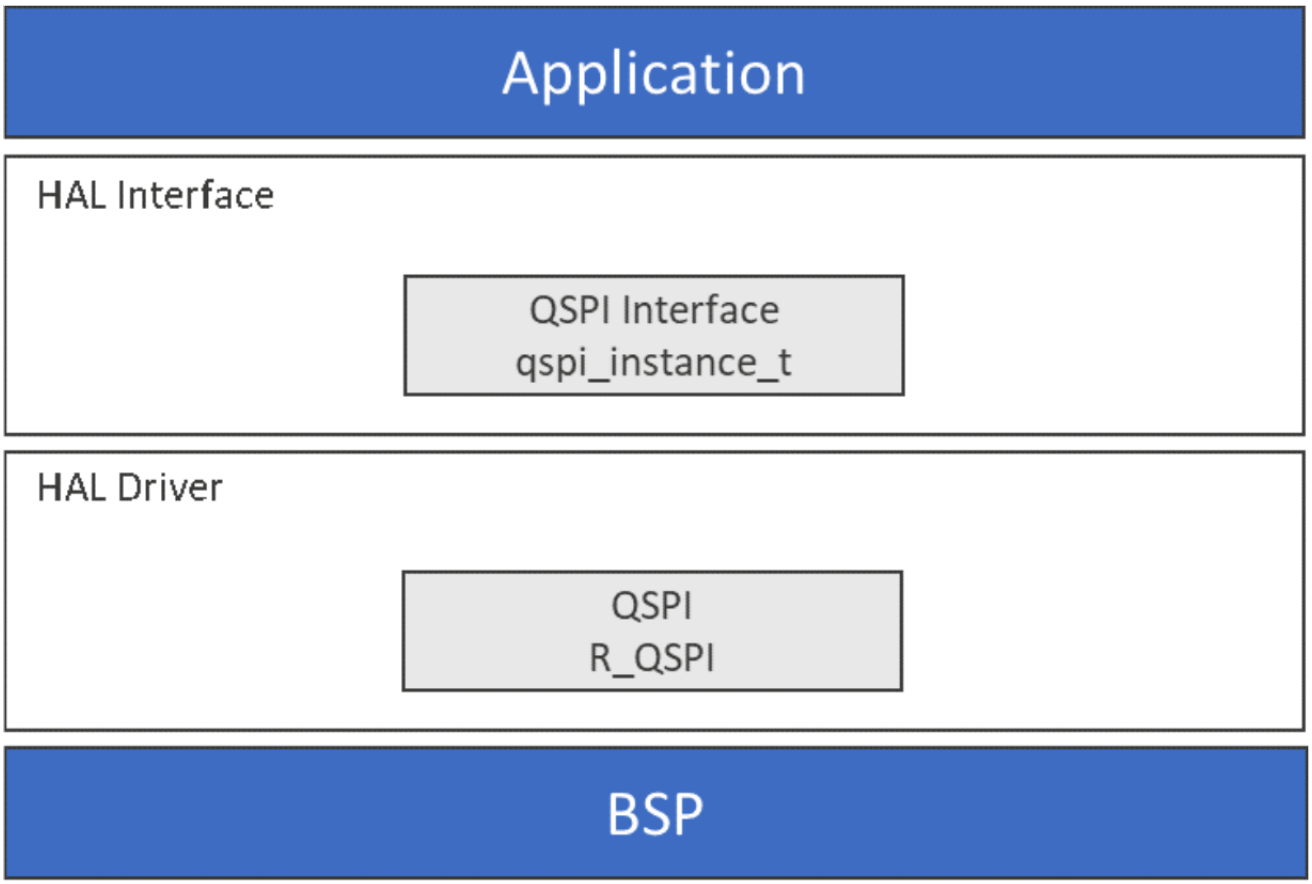

Figure 366: QSPI HAL Module Block Diagram

QSPI Hardware Support Details

The following hardware features are, or are not, supported by SSP for the QSPI.

Legend:

4.2.39.2 QSPI HAL Module APIs Overview

The QSPI interface defines API functions for opening, closing, reading, writing, erasing, and device bank selection using the QSPI HAL module. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

QSPI HAL Module API Summary

Function Name	Example API Call and Description
open	g_qspi0.p_api->open(g_qspi0.p_ctrl, g_qspi0.p_cfg); Open the QSPI HAL module.
close	g_qspi0.p_api->close(g_qspi0.p_ctrl); Close the QSPI HAL module.
read	g_qspi0.p_api->read(g_qspi0.p_ctrl, (uint8_t *) QSPI_DEVICE_ADDRESS, readBuffer, BUFFER_LENGTH); Read data from the flash.
pageProgram	g_qspi0.p_api->pageProgram(g_qspi0.p_ctrl, (uint8_t *) QSPI_DEVICE_ADDRESS, writeBuffer, BUFFER_LENGTH); Program a page of data to the flash.
sectorErase	g_qspi0.p_api->sectorErase(g_qspi0.p_ctrl, (uint8_t *) QSPI_DEVICE_ADDRESS); Erase a sector on the flash.

erase	g_qspi0.p_api->erase(g_qspi0.p_ctrl, (uint8_t *) QSPI_DEVICE_ADDRESS, BYTE_COUNT); Erase a block of memory depending on the input argument "byte_count"
statusGet	g_qspi0.p_api->statusGet(g_qspi0.p_ctrl, &in_progress); Get the write or erase status of the flash.
bankSelect	g_qspi0.p_api->bankSelect(0); Select the bank to access.
infoGet	g_qspi0.p_api->infoGet(g_qspi0.p_ctrl, &qspi_info); Provides information about the underlying QSPI flash, as specified in bsp_qspi.c
versionGet	g_qspi0.p_api->versionGet(& ssp_version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Invalid parameter is passed.
SSP_ERR_ASSERTION	p_cfg was NULL.
SSP_ERR_NOT_OPEN	Driver is not opened.
SSP_ERR_UNSUPPORTED	Driver not able to query the following information from the flash manufacturer id, memory capacity and memory type.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.39.3 QSPI HAL Module Operational Overview

The QSPI HAL module is used to initialize the QSPI peripheral so that the Synergy device can communicate (read, write and erase data) with a QSPI serial flash device.

The driver supports three operation modes: page program (write), read and erase.

- The Page program operation programs a single page of data to the flash device. Page size is specific to flash memory and may vary with the vendor to vendor. The typical page size of flash are 128, 256 or 512 bytes. Use qspi_api_t::infoGet API to get the supported page size by the underlying flash device.
- The Read operation will read the data from the flash and store it to the user provided

buffer.
- The Erase operation will erase the block of data from the flash. Use qspi_api_t::infoGet API to get the supported erase size by the underlying flash device.

Note

1. After any Erase/Write operation and before starting the next operation, it is advisable to use the qspi_api_t::statusGet API to poll the status of operation. Not doing so may corrupt user data.
2. For above mentioned operations, the value of function parameter p_device_address should be in the range 0x60000000 – 0x63FFFFFF. Accessing the addresses beyond this range will cause data wrap around. To access the addresses beyond this range, select the valid and appropriate bank using qspi_api_t::bankSelect.

QSPI HAL Module Important Operational Notes and Limitations

QSPI HAL Module Operational Notes

In the case of using a board supported by the SSP and a BSP based project (for example the SK-S7G2 and DK-S7G2) and the board having a QSPI memory device pre-installed, the BSP initializes and places the QSPI peripheral in ROM access mode with XIP (execute in place) enabled. This process enables the memory to be read like standard memory, meaning the QSPI HAL Module is only needed when erasing and programming the QSPI flash device.

Page programming by default uses only one line (D0). To use multiple lines during page program, define the command QSPI_PAGE_PROGRAM_DATA_LINES as one of the following macros in bsp_qspi.h:

- QSPI_COMMAND_PAGE_PROGRAM_QUAD
- QSPI_COMMAND_4BYTE_PAGE_PROGRAM_QUAD
- QSPI_COMMAND_PAGE_PROGRAM_DUAL
- QSPI_COMMAND_4BYTE_PAGE_PROGRAM_DUAL

Also, define QSPI_PAGE_PROGRAM_ADDRESS_ONE_LINE to 1 if the address should be sent on D0 only during dual input page program and quad input page program commands. An example of this can be found in bsp_qspi.h for S7G2-DK starting in SSP version 1.5.0.

The accompanying code to this module guide demonstrates both modes of operation: access via the QSPI HAL Module and ROM access mode with XIP enabled.

The typical QSPI application programs or erases data on the QSPI flash device. When this driver is not open, the QSPI flash device contents get mapped to 0x60000000 and can be read as if ordinary memory.

This driver has been tested on the Micron N25Q256A QSPI flash device.

To configure a QSPI flash memory with 4-byte addressing mode on customized boards, follow the steps below:

1. Make sure QSPI chip supports 4-byte addressing mode by referring the user manual of the flash device.
2. Configure the following in bsp_qspi.c and bsp_qspi.h, referring to the user manual of the flash device.
    - bsp_qspi.c file:

        - Macros:
            - Dummy cycles required
            - Delay timings
            - Page size
        - Global variables:
            - Erase size
            - Erase commands (sector, block, and chip)
    - bsp_qspi.h file:
        - Manufacturer ID
        - Memory Type
        - Memory Capacity
    - Enum definitions:
        - qspi_command (if required)
3. In configuration window select addressing mode as 4-byte.

To use a QSPI flash memory on customized boards, follow the steps below:

1. Configure the following in bsp_qspi.c and bsp_qspi.h, referring to the user manual of the flash device.
    - bsp_qspi.c file:
        - Macros:
            - Dummy cycles required
            - Delay timings
            - Page size
        - Global variables:
            - Erase size
            - Erase commands (sector, block, and chip)
    - bsp_qspi.h file:
        - Manufacturer ID
        - Memory Type
        - Memory Capacity
    - Enum definitions:
        - qspi_command (if required)
2. Calculation of memory capacity in bsp qspi.c file by user (if required).
    - Memory capacity varies for different QSPI flash chips and it should be handled accordingly in bsp_qspi_config_get() function
    - Example: For MT23QL512QSPI FLASH memory capacity calculation should be:

```
uint8_t actual_ memory_capacity = n25_device_characteristics.memory_capacity;
if(actual_ memory_capacity > 0x1F)
{
actual_ memory_capacity = 0x19 + (actual_ memory_capacity - 0x1F);
*p_memory_capacity    = actual_ memory_capacity;
}
else
{
*p_memory_capacity    = n25_device_characteristics.memory_capacity;
}
```

QSPI HAL Module Limitations

Refer to the latest SSP Release Notes for any additional operational limitations for this module.

4-Byte supported MCU/board list:

Sl No.	Board	QSPI Flash Part No.	QSPI Memory Size	3-byte hardware support	3-byte software support	4-byte hardware support	4-byte software support	4-byte bsp changes	XIP Mode support	Remarks
1	s7g2_dk (v4.0, v4.1)	MX25L12835F (Macronix)	16MB	YES	YES	NO	NO	YES	YES	4-byte addressing not supported by device
2	s7g2_dk (v3.95 & below)	N25Q256A13E40 (Micron)	32MB	YES	YES	YES	NO	YES	YES	4-byte command is only for part numbers N25Q256A83ESF40x, N25Q256A83E1240x, and N25Q256A83ESFA0F
3	s7g2_sk	W25Q64FV (Winbond)	8MB	YES	YES	NO	NO	YES	YES	4-byte addressing not supported by device
4	s5d3_tbb	MX25L12835F (Macronix)	16MB	YES	YES	NO	NO	YES	YES	4-byte addressing not supported by device

5	s5d5_tbb	N25Q256A13E40 (Micron)	32MB	YES	YES	YES	NO	YES	YES	4-byte command is only for part numbers N25Q256A83ESF40x, N25Q256A83E1240x, and N25Q256A83ESFA0F
6	s5d9_pk	W25Q64FV (Winbond)	8MB	YES	YES	NO	NO	YES	YES	4-byte addressing not supported by device
7	s3a7_dk	N25Q256A83E40 (Micron)	32MB	YES	YES	YES	YES	YES	YES	
8	s3a3_adk	N25Q256A83E40 (Micron)	32MB	YES	YES	YES	YES	YES	YES	
9	s3a1_adk	N25Q256A83E40 (Micron)	32MB	YES	YES	YES	YES	YES	YES	

Note

S1 MCU Series does not support QSPI.

4.2.39.4 Including the QSPI HAL Module in an Application

This section describes how to include the QSPI HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the QSPI Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the QSPI Driver is g_qspi0. This name can be changed in the associated Properties window.)

QSPI HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_qspi0 QSPI Driver on r_qspi	Threads	**New> Driver> Storage> QSPI Driver on r_qspi**

When the QSPI Driver on r_qspi is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

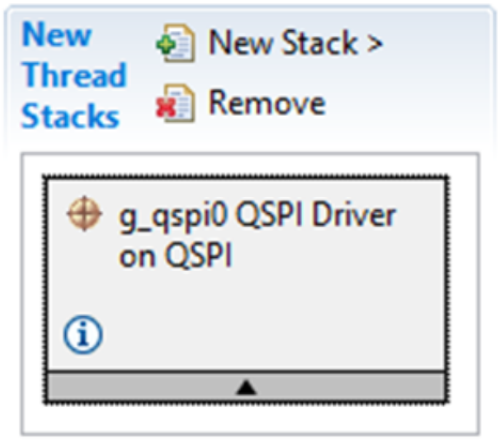

Figure 367: QSPI HAL Module Stack

4.2.39.5 Configuring the QSPI HAL Module

The QSPI HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the QSPI HAL Module on r_qspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	If selected code for parameter checking is included in the build.
Name	g_qspi0	Module name.
Addressing Mode	3-Byte, 4-Byte Default: 3-Byte	Addressing modes of flash memory For memory > 16 MB, 4-Byte addressing mode should be selected

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

QSPI HAL Module Pin Configuration

The QSPI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table indicates the method for selecting pins within the SSP configuration window and the subsequent table lists an example selection sequence for the QSPI pins.

Pin Selection Sequence for the QSPI HAL Module on r_qspi

Resource	ISDE Tab	Pin selection Sequence
QSPI	Pins	Select **Peripherals**> **Storage:QSPI**> **QSPI0**

Note

The selection sequence assumes the QSPI0 is the desired hardware target for the driver.

Pin Configuration Settings for the QSPI HAL Module

Property	Value	Description
Pin Group Selection	- Mixed - _A only	Pin group selection.
Operation Mode	- Disabled - Custom - Single or Dual - Quad	Operation mode.
QSPCLK	None, P500	QSPI clock output pin.
QSSL	None, P501	QSPI slave select pin.
QIO0	None, P502	Data 0 input/output.
QIO1	None, P503	Data 1 input/output.

QIO2	None, P504	Data 2 input/output.
QIO3	None, P505	Data 3 input/output.

Note

The example settings come from a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.39.6 Using the QSPI HAL Module in an Application

The typical steps in using the QSPI HAL module in an application are:

1. Initialize the QSPI HAL module using the qspi_api_t::open API call.
2. Read a block of data using the qspi_api_t::read API call.
3. Erase a sector of data using the qspi_api_t::sectorErase API call.
4. Erase n bytes of data using the qspi_api_t::erase API call.
    a. qspi_api_t::infoGet can be used to get the supported erase sizes by the underlying flash.
    b. qspi_api_t::statusGet API can be used to poll the status of ease operation applicable for sectorErase API also.
5. Program a page of data using the qspi_api_t::pageProgram API call.
    a. Use qspi_api_t::infoGet API to get the page size supported by the underlying flash.
    b. qspi_api_t::statusGet API can be used to poll the status of write operation.
6. Close the QSPI HAL module using the qspi_api_t::close API call.

Note

It is advisable to use the qspi_api_t::erase API instead of the qspi_api_t::sectorErase API as a Sector is not a standard size for flash device and it varies with different vendors.

These common steps are illustrated in a typical operational flow diagram in the following figure:

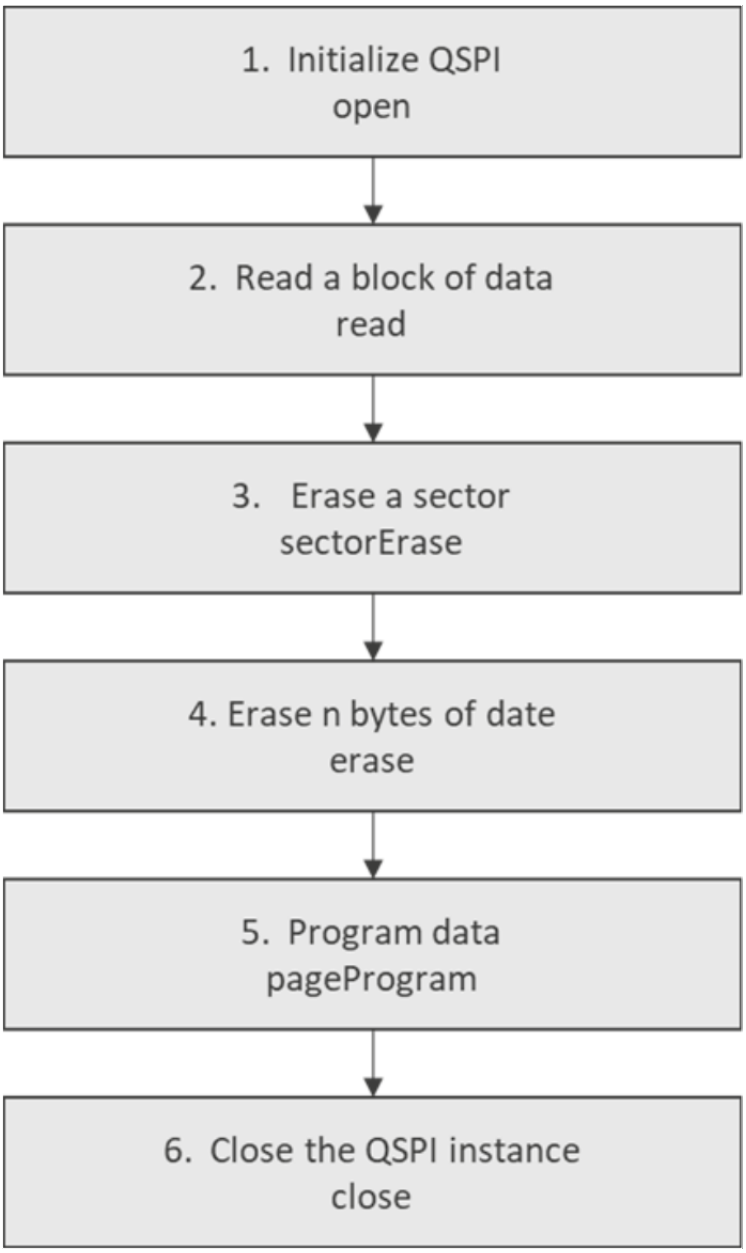

Figure 368: Flow Diagram of a Typical QSPI HAL Module Application

4.2.40 RTC Driver

4.2.40.1 RTC HAL Module Introduction

The Real-Time Clock (RTC) HAL module implements a high-level API for real-time timing applications and uses the real-time clock module on a Synergy MCU. The RTC HAL module configures the RTC module and controls clock, calendar and alarm functions. A callback can be used to respond to any of the three supported interrupt types: alarm, periodic, or carry.

RTC HAL Module Features

- RTC peripheral configuration.
- RTC time and date get and set.
- RTC time and date alarm get and set.
- RTC time counter start and stop.
- RTC alarm, periodic, and carry event notification.
- RTC event type enable and disable.
- RTC event rate configuration.
- RTC clock source set and get.
- RTC sub-clock error adjustment.
- RTC status get.

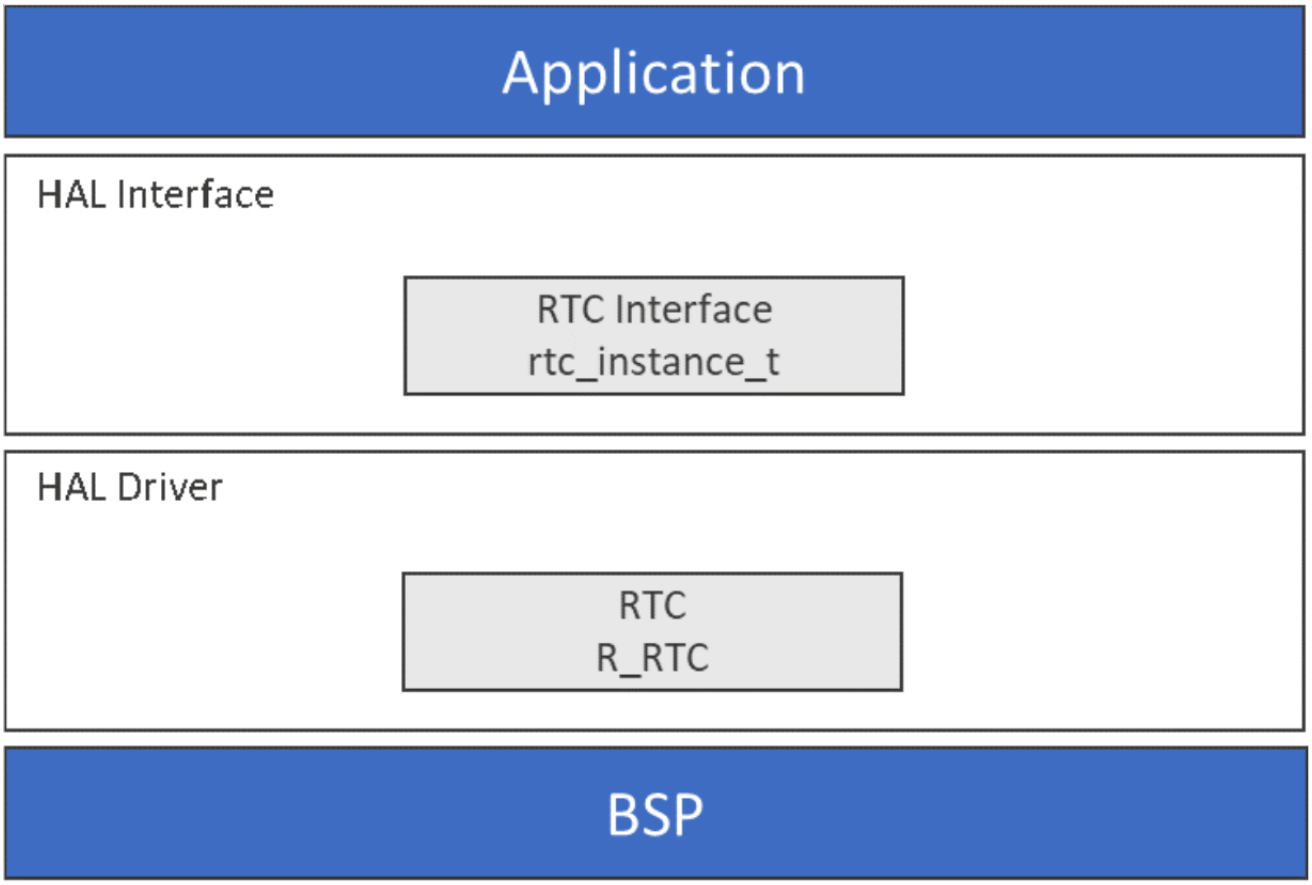

Figure 369: RTC HAL Module Block Diagram

RTC Hardware Support Details

The following hardware features are, or are not, supported by SSP for the RTC.

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)

N/A	Not supported by MCU

4.2.40.2 RTC HAL Module APIs Overview

The RTC HAL module defines APIs for opening, closing, setting alarms and starting and stopping RTC

operations. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

RTC HAL Module API Summary

Function Name	Example API Call and Description
open	g_rtc0.p_api->open(g_rtc0.p_ctrl, g_rtc0.p_cfg); Open the RTC HAL.
close	g_rtc0.p_api->close(g_rtc0.p_ctrl); Close the RTC HAL.
configure	g_rtc0.p_api->configure(g_rtc0.p_ctrl, p_extend);
calendarTimeSet	g_rtc0.p_api->calendarTimeSet(g_rtc0.p_ctrl, &start_time_struct_in, true); Set the calendar time.
calendarTimeGet	g_rtc0.p_api->calendarTimeGet(g_rtc0.p_ctrl, &current_time_struct_out); Get the calendar time.
calendarAlarmSet	g_rtc0.p_api->calendarAlarmSet(g_rtc0.p_ctrl, &in_alarm_time_struct_in, true); Set the calendar alarm time.
calendarAlarmGet	g_rtc0.p_api->calendarAlarmGet(g_rtc0.p_ctrl, &get_alarm_time_struct_out); Get the calendar alarm time.
calendarCounterStart	g_rtc0.p_api->calendarCounterStart(g_rtc0.p_ctrl); Start the calendar counter.
calendarCounterStop	g_rtc0.p_api->calendarCounterStop(g_rtc0.p_ctrl); Stop the calendar counter.
irqEnable	g_rtc0.p_api->irqEnable(g_rtc0.p_ctrl, CALLBACK); Enable the alarm irq.
irqDisable	g_rtc0.p_api->irqDisable(g_rtc0.p_ctrl, CALLBACK); Disable the alarm irq.
periodicIrqRateSet	g_rtc0.p_api->periodicIrqRateSet(g_rtc0.p_ctrl, Rate); Set the periodic irq rate.
infoGet	g_rtc0.p_api->infoGet(g_rtc0.p_ctrl, clk_src); Return the currently configure clock source for the RTC.
errorAdjustmentModeSet	
errorAdjustmentSet	

versionGet	g_rtc0.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function executed successfully.
SSP_ERR_ASSERTION	API dependent error.
SSP_ERR_INVALID MODE	Invalid mode.
SSP_ERR_INVALID_PTR	Invalid parameter.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.40.3 RTC HAL Module Operational Overview

The RTC HAL module controls the operation of the real-time clock module on a Synergy MCU. The typical RTC application configures the real-time clock controller periodically based on a system configuration driven by the user. Common operations include setting the time, setting an alarm, configuring a periodic interrupt, and starting or stopping operation. An RTC application usually consists of calls to the RTC HAL module and an optional callback from ISR handler.

- The RTC HAL module can use two main clock sources
  - A Low Speed On-Chip Oscillator (LOCO) with lower power, but with less accuracy
  - A sub-clock oscillator with higher power, increased accuracy, and more cost (external crystal required)
- The RTC HAL module supports three different interrupt types
  - An alarm interrupt generated on a match of any combination of year, month, day, day of the week, hour, minute or second
  - A periodic interrupt generated every 2, 1, ½, ¼, 1/8, 1/16, 1/32, 1/64 ,1/128 or 1/256 second(s)
  - A carry interrupt when either a carry to the second counter occurs or when a carry to the R64CNT counter occurs during a read access to the 64 Hz counter

A user-defined callback function can be registered (in the rtc_api_t::open API call) and will be called from the interrupt service routine (ISR) for any supported interrupt type. When called, it is passed a pointer to a structure (rtc_callback_args_t) that holds a user-defined context pointer and an indication of which type of interrupt was fired.

Note

The carry interrupt priority must be set to avoid an incorrect time returned from the rtc_api_t::calendarTimeGet API during roll-over.

RTC HAL Module Important Operational Notes and Limitations

RTC HAL Module Operational Notes

The RTC HAL module must be opened before any of the other RTC module APIs can be called. A configuration structure is passed to the open call which specifies the clock source, the name of the user callback from ISR handler, and a user-specified context for the callback. Configuration structures can be either manually defined or generated by the ISDE based on user input during the configuration process.

Functions in the driver can be accessed by either making direct calls to the HAL layer or by using the RTC interface structure. The name of this interface structure is based on the name setting entered in the module's configuration. For example, if the name is g_rtc, then the interface structure is called g_rtc_api.

RTC HAL Module Limitations

- The rtc_api_t::calendarTimeGet API must not be called with interrupts disabled globally, as this API internally uses carry interrupt for its processing. The API may return incorrect time if this is done.
- This module has no support for the following functions:
    - Binary-count mode
    - Binary alarm set and get
    - Binary time get and set.
    - LOCO clock-error correction
    - 1-Hz/64-Hz clock output
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.40.4 Including the RTC HAL Module in an Application

This section describes how to include the RTC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the RTC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the RTC Driver is g_rtc0. This name can be changed in the associated Properties window.)

RTC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_rtc0 RTC HAL on r_rtc	Threads	**New Stack> Driver> Timers> RTC HAL on r_rtc**

When the RTC Driver on r_rtc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and

displays possible choices.

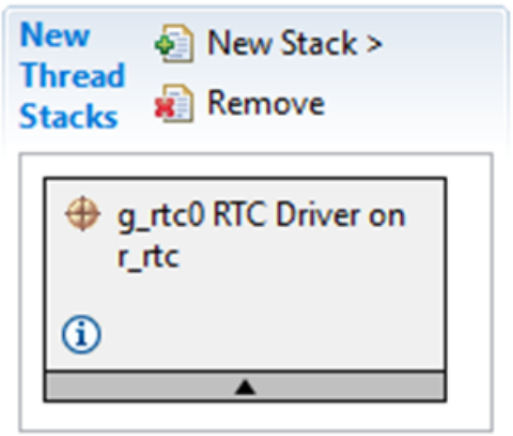

Figure 370: RTC HAL Module Stack

4.2.40.5 Configuring the RTC HAL Module

The RTC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the RTC HAL Module on r_rtc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_rtc0	The name to be used for the RTC module control block instance. This name is also used as the prefix of the other variable instances. See the example code below.
Clock Source	LOCO, Sub-clock Default: LOCO	Clock source for the RTC block.

Configure RTC hardware in open() call	Yes, No Default: Yes	If enabled, the RTC registers and clock source will be initialized in the open() call. If disabled, the user call must call the configure() api to initialize the hardware.
Error Adjustment Value	0	Warning: Deprecated configuration field. Must be 0.
Error Adjustment Type	None	Warning: Deprecated configuration field. Must be 0.
Callback	NULL	The name of the ISR that is called when one of the three interrupts fire. The argument passed into this ISR has an indication of which interrupt caused it to be called. See the example code below.
Alarm Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Alarm interrupt priority selection.
Period Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Period interrupt priority selection.
Carry Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Carry interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

RTC HAL Module Clock Configuration

The RTC HAL module can use the following clock sources:

- LOCO (Low Speed On-Chip Oscillator)
  - Lower-power consumption
  - Less accurate
- Sub-clock oscillator
  - Higher-power consumption
  - More accurate
  - More cost (requires a crystal)

The LOCO is the default selection during configuration.

RTC HAL Module Pin Configuration

The RTC does not currently support outputs, so no output pin selections are available.

4.2.40.6 Using the RTC HAL Module in an Application

General Usage

The typical RTC application configures the real-time clock controller periodically based on a system configuration driven by the user. Examples include setting the time, setting an alarm, configuring a periodic interrupt, etc. An RTC application consists of calls to the RTC module and an optional callback.

The RTC module must be opened before any of the other APIs can be called. A configuration structure is passed to the open call which specifies the clock source, the name of the callbacks, and user-specified context for the handler. Configuration structures can be either manually defined or generated by the ISDE based on user input during the configuration process. Functions in the module can be accessed by using the RTC interface structure. The name of this interface structure is based on the name setting entered in the module's configuration.

Avoid Drift Issue After Reset

To avoid drift in RTC time across MCU reset, the application needs to follow the following steps:

Make these changes to module configuration settings:

1. Disable the "Configure Subclock Drive On Reset" option in the CGC stack element of the ISDE configurator.
2. Disable the "Configure RTC hardware in open() call" option in the RTC stack element of the ISDE configurator.

Make these calls in the application code:

1. Call the rtc_api_t::open API as usual.
2. Call the RTC rtc_api_t::configure API only on a cold start. This will initialize the RTC only in a cold start condition.

These two steps can be performed by using the following initialization sequence in the application:

```
    g_rtc.p_api->open(g_rtc.p_ctrl,g_rtc.p_cfg);
    g_rtc.p_api->infoGet(g_rtc.p_ctrl,&info1);
    /* initialize RTC if its status is stopped state i.e. on cold start */
    if(RTC_STATUS_STOPPED == info1.status)
    {
/* if the RTC clock source is sub-clock, stop it so that the sub-clock drive capacity
is set correctly in the configure API */
          g_cgc.p_api->clockStop(CGC_CLOCK_SUBCLOCK);
          g_rtc.p_api->configure(g_rtc.p_ctrl, NULL);
          g_rtc.p_api->calendarTimeSet(g_rtc.p_ctrl,&rt_time,true);
                }
```

An alternative way to determine cold start condition (instead of status) is to obtain the information from the reset status registers (RSTSRx).

Date and Time Validation

The "Parameter Checking" setting needs to be enabled in the ISDE configurator if date and time validation is required for the rtc_api_t::calendarTimeSet and rtc_api_t::calendarAlarmSet APIs. If "Parameter Checking" is enabled, the 'day of the week' field is automatically calculated and updated by the driver for the provided date. When using rtc_api_t::calendarAlarmSet API, only the fields which have their corresponding match flag set are written to the registers, other register fields are reset to default value.

Sub-Clock Error Adjustment

The rtc_api_t::errorAdjustmentModeSet and rtc_api_t::errorAdjustmentSet APIs can be used to correct the error in the RTC sub-clock source. These APIs can only be used after the RTC is configured and time is set.

The error adjustment is reset every time the RTC is reconfigured or time is set.

There are two common application uses for the RTC HAL module. The first simply uses the RTC to supply the current time as required by the application. A second use of the RTC HAL modules uses the periodic interrupt capability to initiate a process at a regular period. Examples of both uses are provided below.

Note

The configuration property 'Configure RTC hardware in open() call' in the RTC stack of the ISDE configurator controls the behavior of the rtc_api_t::open API. If enabled, the RTC peripheral is configured in the rtc_api_t::open API. If disabled, it is the responsibility of the application to make sure that RTC is configured before usage by using the rtc_api_t::configure API.

The typical steps in using the RTC HAL module in a timing application are:

1. Initialize the RTC using the rtc_api_t::open API
2. Set the time using the rtc_api_t::calendarTimeSet API
3. Set the alarm using the rtc_api_t::calendarAlarmSet API (If required)
4. Start the calendar counter using the rtc_api_t::calendarCounterStart API
5. Get the current time using the rtc_api_t::calendarTimeGet API (as required)

These common steps are illustrated in a typical operational flow diagram in the following figure:

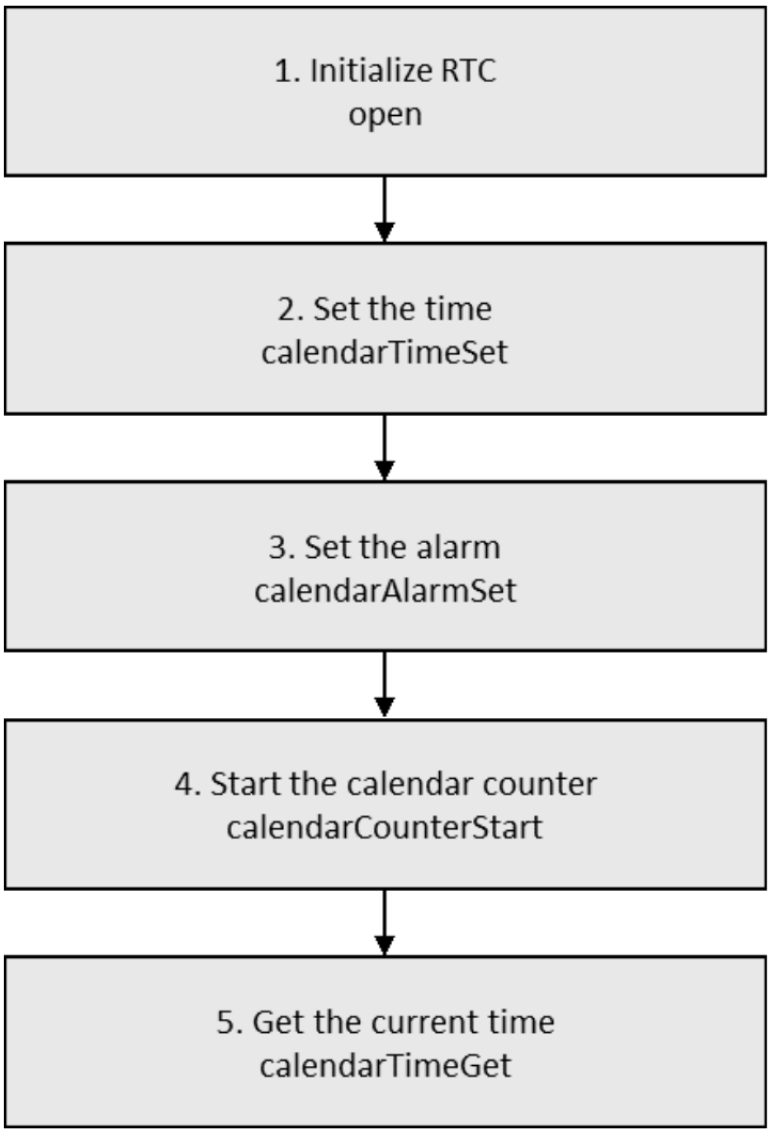

Figure 371: Flow Diagram of a Typical RTC HAL Module Timing Use Application

The typical steps in using the RTC periodic IRQ in an application are:

1. Initialize the RTC using the rtc_api_t::open API.
2. Set periodic IRQ rate using the rtc_api_t::periodicIrqRateSet API.
3. Start calendar counter using the rtc_api_t::calendarCounterStart API.
4. Enable interrupt using the rtc_api_t::irqEnable API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

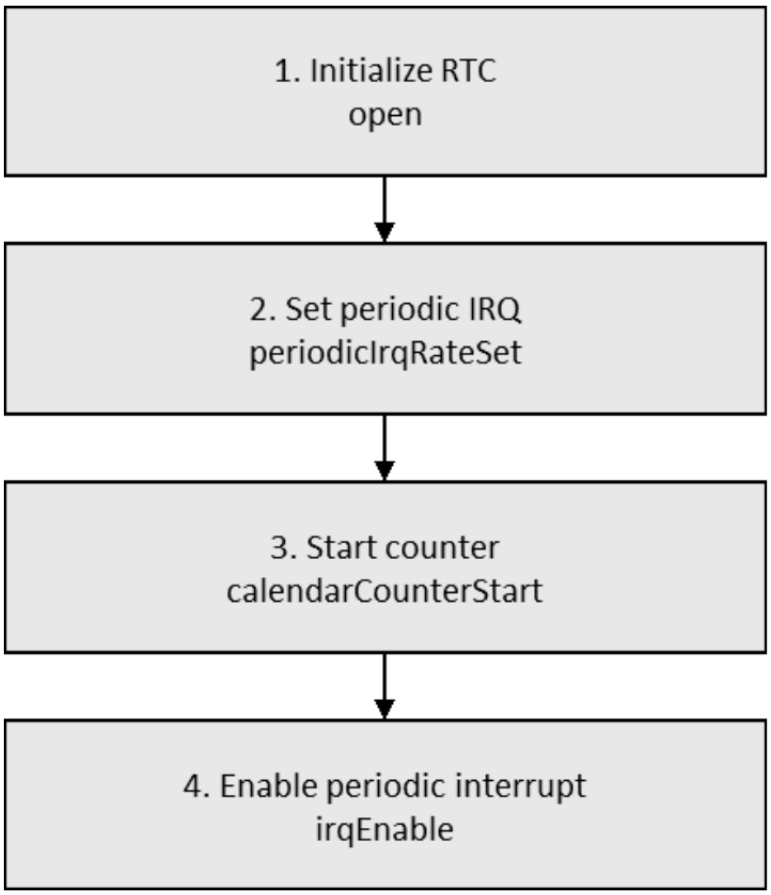

Figure 372: Flow Diagram of a Typical RTC HAL Module Application

4.2.41 SCE Crypto Driver

4.2.41.1 SCE HAL Module Introduction

The Secure Cryptographic Engine (SCE) HAL module provides high-level API functions for random number generation, digest computation (hash), data encryption and decryption, digital signing and verification, key generation (using RSA, AES and ECC algorithms), ECC scalar multiplication and key installation (for RSA, AES and ECC keys). The SCE is a dedicated hardware block and the functionality provided by the SCE varies across the supported MCUs.

SCE HAL Module Features

The SCE HAL module configures the cryptographic module, which allows user to build cryptographic protocols for security with the following cryptographic primitives:

- Random-number generation
- Data encryption and decryption using AES or Triple DES (3DES) or ARC4 algorithms
- Signature generation and verification using the ECC, RSA or DSA algorithms
- Scalar multiplication support for ECDH key agreement operations.
- Message-digest computation using HASH algorithms MD5, SHA1, SHA224, or SHA256

- Key generation - AES wrapped keys, RSA plain text and wrapped keys, ECC plain text and wrapped keys
- Installing the encrypted user key on to the Synergy platform.

The terms "key wrapping" and "key installation" in the context of SSP are defined as follows:

Key Wrapping: The APIs to generate symmetric keys or asymmetric key pairs on the Synergy platform where the private/secret key is a wrapped key (encrypted key).

Key Installation: User generated private /secret keys on a PC (system outside of the Synergy platform) will be installed (no storage) on the Synergy platform and the wrapped private /secret key returned to the user.

Wrapped keys provide the following advantages:

- The wrapped key can only be used on the Synergy platform (MCU) on which it was generated.
- It cannot be moved to another Synergy platform (MCU).
- The original key cannot be recovered from the wrapped key.

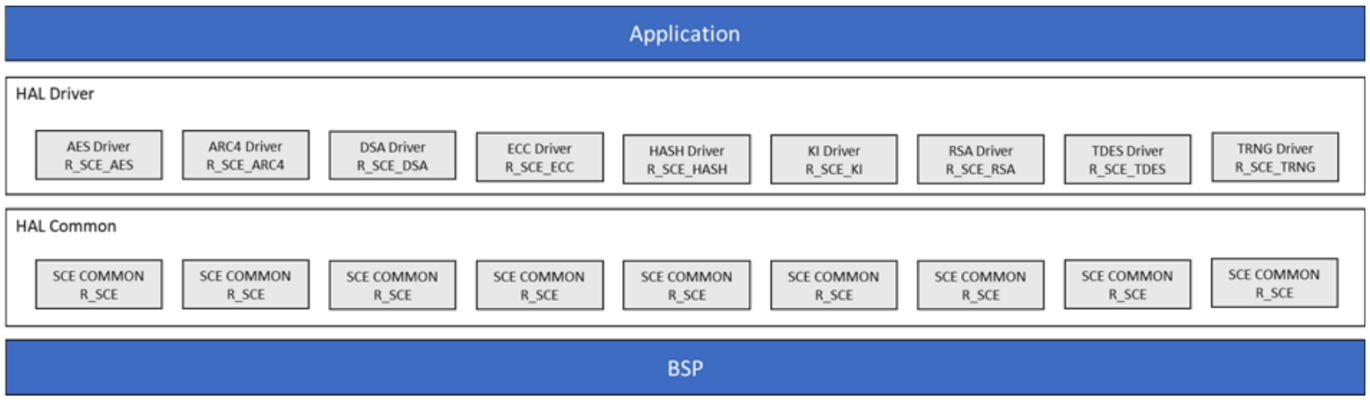

Figure 373: SCE HAL Module Block Diagram

*KI is an abbreviation for Key Installation

SCE Hardware Support Details

Note: The prior figure shows all nine available crypto modules. The SCE COMMON module is repeated for each one since it is included when the module is added to a thread stack. Common modules can be referenced by multiple other module instances across multiple Synergy stacks.

Support of MCU Groups: SCE Driver

Function	S7G2, S5D9, S5D5, S5D3	S3A1, S3A3, S3A7, S3A6	S1JA, S124, **S128**	Notes
TRNG	Generate and read random number	Generate and read random number	Generate and read random number	Generate and read random number

AES	Encryption, decryption, key generation - wrapped keys	Encryption, decryption, key generation - wrapped keys	Encryption, decryption	Symmetric key encryption based on AES standard
AES Key Size	128-bit, 192-bit, 256-bit	128-bit, 256-bit	128-bit, 256-bit	
AES Key Type	Plain text/raw key, wrapped key	Plain text/raw key, wrapped key	Plain text/raw key	
AES Chaining Modes	ECB, CBC, CTR, GCM, XTS††	ECB, CBC, CTR, GCM, XTS	ECB, CBC, CTR	
ARC4	Encryption, decryption	NA	NA	
TDES	Encryption, decryption	NA	NA	
TDES Key Size	192-bit	NA	NA	
TDES Chaining Modes	ECB, CBC, CTR	NA	NA	
RSA	Signature Generation, Signature Verification, Public-key Encryption, Private-key Decryption, Key Generation - plain text and wrapped keys	NA	NA	Supports CRT keys and standard keys for private key operations for both plain-text and wrapped key types
Function	**S7G2, S5D9, S5D5, S5D3**	**S3A1, S3A3, S3A7, S3A6**	**S1JA, S124,** **S128**	**Notes**
RSA Key Size	1024-bit, 2048-bit	NA	NA	
RSA Key Type	Plain text/raw standard format and CRT keys, wrapped standard format and wrapped CRT keys	NA	NA	
Key Installation	AES, ECC, RSA keys	AES keys	NA	

ECC	Key Generation – plain text and wrapped keys, Scalar Multiplication, ECDSA – Signature Generation, ECDSA – Signature Verification	NA	NA	
ECC Key Size (in bits)	192, 224, 256, and 384	NA	NA	
ECC Key Type	Plain text/ raw keys and wrapped keys	NA	NA	
DSA	Signature Generation, Signature Verification	NA	NA	
DSA Key Size	(1024, 160)-bit, (2048, 224)-bit, (2048, 256)-bit	NA	NA	
HASH	MD5, SHA1, SHA224, SHA256	NA	NA	Message digest algorithms

†† XTS is supported for 128-bit and 256-bit keys only.

4.2.41.2 SCE HAL Module APIs Overview

The SCE interface provides a common API for SCE HAL modules. The SCE interface supports multiple operations depending on the chosen module (AES, ARC4, RSA, DSA, HASH, TDES or TRNG).

The AES interface defines APIs for opening, closing, generating wrapped keys, encrypting and decrypting data using the AES algorithm. It uses a 128-bit, 192-bit or 256-bit key and ECB, CBC, CTR, GCM or XTS chaining-mode options. A complete list of the available APIs, an example API call, and a short description of each can be found in the following table. For return status values, refer to the SCE API reference section of the SSP User's Manual.

SCE Common Instance API Summary

Function Name	Example API Call and Description
open	g_sce.p_api->open(g_sce.p_ctrl, g_sce.p_cfg); SCE Common module open function. Must be called before performing any other crypto operations.
close	g_sce.p_api->close(g_sce.p_ctrl); Close the SCE Common module.

interfaceGet	g_sce.p_api->interfaceGet(g_sce_aes.p_ctrl, p_interface_info, p_interface); Get the interface structure for the interface info provided.
statusGet	g_sce.p_api->statusGet (g_sce.p_ctrl, p_status); Get status of SCE initialization.
versionGet	g_sce.p_api->versionGet(&version); Gets the module code and API version and stores it in provided version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

AES HAL Module API Summary

Function Name	Example API Call and Description
open	g_sce_aes.p_api->open(g_sce_aes.p_ctrl, g_sce_aes.p_cfg); AES module open function. Must be called before performing any encrypt/decrypt operations.
createKey	g_sce_aes.p_api->createKey(g_sce_aes.p_ctrl, num_words, p_key); Generate an AES key for encrypt/decrypt operations.
encrypt	g_sce_aes.p_api->encrypt(g_sce_aes.p_ctrl, p_key, p_vi, num_words, p_source, p_dest); AES encryption using the chaining mode and padding mode specified in the open() function call.
addAdditionalAuthenticationData	g_sce_aes.p_api->addAdditionalAuthenticationData (g_sce_aes.p_ctrl, p_key, p_vi, num_words, p_source); Add additional authentication data (called before starting an encryption or decryption operation).
encryptFinal	g_sce_aes.p_api->encryptFinal(g_sce_aes.p_ctrl, p_key, p_iv, input_num_words, p_source, output_num_words, p_dest); AES final encryption using the chaining mode and padding mode specified in the open() function call.
decrypt	g_sce_aes.p_api->decrypt(g_sce_aes.p_ctrl, p_key, p_iv, num_words, p_source, p_dest); AES decryption.

setGcmTag	g_sce_aes.p_api->setGcmTag(g_sce_aes.p_ctrl,num_words, p_source); Set authentication tag data.
getGcmTag	g_sce_aes.p_api->getGcmTag(g_sce_aes.p_ctrl,num_words, p_dest); Get authentication tag data.
zeroPaddingEncrypt	g_sce_aes.p_api->zeroPaddingEncrypt(g_sce_aes.p_ctrl, p_key, p_iv, num_bytes, p_source, p_dest) AES zero padding encryption using the chaining mode and padding mode specified. Implementation for GCM mode only API usage - 1. To provide any Add Authentication Data (AAD): set p_dest = NULL 2. Encryption: set p_source to input data and p_dest will return encrypted data 3. Get/Compute Tag: set p_source = NULL
zeroPaddingDecrypt	g_sce_aes.p_api->zeroPaddingDecrypt(g_sce_aes.p_ctrl, p_key, p_iv, num_words, p_source, p_dest); AES zero padding decryption< using the chaining mode and padding mode specified. Implementation for GCM mode only API usage - 1. Set expected tag value using the setGcmTag() function 2. To provide any Add Authentication Data (AAD), invoke this API using p_dest = NULL 3. Decryption: set p_source to input encrypted data, decrypted data will be returned in p_dest 4. To verify the tag, invoke this API using p_source = NULL and p_dest = NULL, the return value indicates authentication tag verification status.
versionGet	g_sce_aes.p_api->versionGet(&version); Gets the module code and API version and stores it in provided version pointer.
close	g_sce_aes.p_api->close(g_sce_aes.p_ctrl); Close the AES module.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

The ARC4 interface defines APIs for opening, closing, setting a key and processing data. A complete list of the available APIs, an example API call and a short description of each can be found in the following table:

ARC4 HAL Module API Summary

Function Name	Example API Call and Description
open	g_sce_arc4.p_api->open(g_sce_arc4.p_ctrl, g_sce_trng.p_cfg); Open the ARC4 module.
keySet	g_sce_arc4.p_api->keySet(g_sce_arc4.p_ctrl, &rngbuf, nbytes); Set the key to be used by the ARC4 module.
arc4Process	g_sce_arc4.p_api->arc4Process(g_sce_arc4.p_ctrl, nbytes, &source, &destination); Encrypt or decrypt data using the ARC4 module.
close	g_sce_arc4.p_api->close(g_sce_arc4.p_ctrl); Close the ARC4 module.
versionGet	g_sce_arc4.p_api->versionGet (&version); Retrieve the version using the provided version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

The DSA interface defines APIs for opening, closing, digital-signing and verification. Available options include a 1024-bit public key and a 160-bit private key, a 2048-bit public key and a 224-bit private key or a 2048-bit public key and a 256-bit private key. A complete list of the available APIs, an example API call and a short description of each can be found in the following table:

DSA HAL Module API Summary

Function Name	Example API Call and Description
open	g_sce_dsa.p_api->open(g_sce_dsa.p_ctrl, g_sce_dsa.p_cfg); DSA module open function. Must be called before performing any sign/verify operations.
verify	g_sce_dsa.p_api->verify(p_key, p_domain, num_words, p_signature, p_paddedHash); DSA signature verification using given DSA public key. This function is deprecated. The function hashVerify should be used instead.
hashVerify	g_sce_dsa.p_api->hashVerify(g_sce_dsa.p_ctrl, p_key, p_domain, num_words, p_signature, p_paddedHash); DSA signature verification using given DSA public key.

sign	g_sce_dsa.p_api->sign(p_key, p_domain, num_words, p_padded_hash, p_dest); DSA Signature generation using DSA private key. This function is deprecated. The function hashSign should be used instead.
hashSign	g_sce_dsa.p_api->hashSign(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_padded_hash, p_dest); DSA Signature generation using DSA private key.
close	g_sce_dsa.p_api->close(g_sce_dsa.p_ctrl); Close the DSA module.
versionGet	g_sce_dsa.p_api->versionGet(p_version); Gets version and stores it in provided pointer p_version.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

ECC HAL Module API Summary

Function Name	Example API Call and Description
open	g_sce_ecc.p_api->open(g_sce_ecc.p_ctrl, g_sce_ecc.p_cfg); Open the ECC driver. This API must be called before performing any ECC operations.
close	g_sce_ecc.p_api->close(g_sce_ecc.p_ctrl); Close the ECC module.
scalarMultiplication	g_sce_ecc.p_api->scalarMultiplication(g_sce_ecc.p_ctrl, p_domain, p_k, p_p, p_r); This API calculates R=kP.
keyCreate	g_sce_ecc.p_api->keyCreate(g_sce_ecc.p_trl, p_domain, p_generator_point, p_key_private, p_key_public); This API generates key pair for ECC.
sign	g_sce_ecc.p_api->sign(g_sce_ecc.p_ctrl, p_domain, p_generator_point, p_key_private, msg_digest, signature_r, signature_s); This API generates signature of ECDSA.
verify	g_sce_ecc.p_api->verify(g_sce_ecc.p_ctrl, p_domian, p_generator_point, p_key_public, msg_digest, signature_r, signature_s); This is a procedure for signature verification of ECDSA.

versionGet	g_sce_ecc.p_api->versionGet(&version); Gets version and stores it in provided version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

The HASH interface defines APIs for calculating hash values for a given data-set. Available options include SHA1 and SHA256 algorithms. A complete list of the available APIs, an example API call and a short description of each can be found in the following table:

HASH HAL Module API Summary

Function Name	Example API Call and Description
open	g_sce_hash.p_api->open(g_sce_hash.p_ctrl, g_sce_hash.p_cfg); HASH module open function. Must be called before performing any sign/verify operations.
updateHash	g_sce_hash.p_api->updateHash(p_source, num_words, p_dest); Update hash for the num_words words from source buffer p_source. This function is deprecated. The function hashUpdate should be used instead.
hashUpdate	g_sce_hash.p_api->hashUpdate(g_sce_hash.p_ctrl, p_source, num_words, p_dest); Update hash for the num_words words from source buffer p_source.
close	g_sce_hash.p_api->close(g_sce_hash.p_ctrl); HASH module close function.
versionGet	g_sce_hash.p_api->versionGet(p_version); Gets version and stores it in provided pointer p_version.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Key Installation HAL Module API Summary

Function Name	Example API Call and Description
open	g_sce_key_installation.p_api->open(g_sce_key_installation.p_ctrl, p_cfg); Open the Crypto Key Installation framework for subsequent call/Key installation.

close	g_sce_key_installation.p_api->close(g_sce_key_installation.p_ctrl); Close the Crypto Key Installation framework.
keyInstall	g_sce_key_installation.p_api->keyInstall (g_sce_key_installation.p_ctrl, p_user_key_input, p_user_key_rsa_modulus, p_install_key_input, p_key_data_out); Install a key version 2. This function takes the RSA modulus of the user's RSA private key as one of the input parameters to return the RSA wrapped key in a format that is compatible with other Crypto APIs. For all other key types the functionality remains the same as the earlier keyInstall API.
versionGet	g_sce_key_installation.p_api->versionGet(&version); Get version of the Crypto Key Installation framework and stores it in the provided version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

The RSA interface defines APIs for opening, closing, encrypting and decrypting data using an RSA algorithm as well as digitally signing and verifying the algorithm. The RSA interface employs a 1024-bit or 2048-bit key. A complete list of the available APIs, an example API call and a short description of each can be found in the following table:

RSA HAL Module API Summary

Function Name	Example API Call and Description
open	g_sce_rsa.p_api->open(g_sce_rsa.p_ctrl, g_sce_rsa.p_cfg); RSA module open function. Must be called before performing any encrypt/decrypt or sign/verify operations.
encrypt	g_sce_rsa.p_api->encrypt(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_source, p_dest); Encrypt source data from p_source using an RSA public key from p_key and write the results to destination buffer p_dest.
decrypt	g_sce_rsa.p_api->decrypt (g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_source, p_dest); Decrypt source data from p_source using an RSA private key from p_key and write the results to destination buffer p_dest.

decryptCrt	g_sce_rsa.p_api->decryptCrt(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_source, p_dest); Decrypt source data from p_source using an RSA private key from p_key and write the results to destination buffer p_dest. RSA private key data is specified in CRT format.
verify	g_sce_rsa.p_api->verify(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_signature, p_padded_hash); Verify signature given in buffer p_signature using the RSA public key p_key for the given padded message hash from buffer p_padded_hash.
sign	g_sce_rsa.p_api->sign(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_padded_hash, p_dest); Generate signature for the given padded hash buffer p_padded_hash using the RSA private key p_key. Write the results to the buffer p_dest.
signCrt	g_sce_rsa.p_api->signCrt(g_sce_rsa.p_ctrl, p_key, p_domain, num_words, p_padded_hash, p_dest); Generate signature for the given padded hash buffer p_padded_hash using the RSA private key p_key. RSA private key p_key is assumed to be in CRT format. Write the results to the buffer p_dest.
close	g_sce_rsa.p_api->close(g_sce_rsa.p_ctrl); Close the RSA module.
keyCreate	g_sce_rsa.p_api->keyCreate(g_sce_rsa.p_ctrl, p_private_key, p_public_key); Generates an RSA key pair.
versionGet	g_sce_rsa.p_api->versionGet(p_version); Gets version and stores it in provided pointer p_version.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

The TDES interface defines APIs for encrypting and decrypting data according to the TDES standard. A complete list of the available APIs, an example API call and a short description of each can be found in the following table:

TDES HAL Module API Summary

Function Name	Example API Call and Description
open	g_sce_tdes.p_api->open(g_sce_tdes.p_ctrl, g_sce_tdes.p_cfg); Open the TDES module.

encrypt encrypt	g_sce_tdes.p_api->encrypt(g_sce_tdes.p_ctrl, &key, &iv, nwords, &source, &destination); Encrypt the data.
decrypt	g_sce_tdes.p_api->decrypt(g_sce_tdes.p_ctrl, &key, &iv, nwords, &source, &destination); Decrypt the data.
close	g_sce_tdes.p_api->close(g_sce_tdes.p_ctrl); Close the TDES module.
versionGet	g_sce_tdes.p_api->versionGet(p_version); Gets version and stores it in provided pointer p_version.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

The TRNG interface defines APIs for computing the random-number generator. A complete list of the available APIs, an example API call and a short description of each can be found in the following table.

TRNG HAL Module API Summary

Function Name	Example API Call and Description
open	g_sce_trng.p_api->open(g_sce_trng.p_ctrl, g_sce_trng.p_cfg); Open the TRNG driver for reading random data from the hardware TRNG module.
read	g_sce_trng.p_api->read(g_sce_trng.p_ctrl, p_rngbuf, nbytes); Generate nbytes of random number bytes and store them in p_rngbuf buffer.
close	g_sce_trng.p_api->close(g_sce_trng.p_ctrl); Close the TRNG interface driver.
versionGet	g_sce_trng.p_api->versionGet(&version); Gets version and stores it in provided version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

4.2.41.3 SCE HAL Module Operational Overview

Different cryptographic functions are available for different target MCUs; the following table shows the functionality that is available for each individual MCU-series:

Function	S7G2, S5D9, S5D5, S5D3	S3A1, S3A3, S3A7, S3A6	S124, S128, S1JA	Notes
TRNG	Generate and read random number	Generate and read random number	Generate and read random number	Generate and read random number.
AES	Encryption, decryption, Key Generation - wrapped keys	Encryption, decryption, Key Generation - wrapped keys	Encryption, decryption	Symmetric Key Encryption based on AES standard.
AES Key Size	128-bit, 192-bit, 256-bit	128-bit, 256-bit	128-bit, 256-bit	
AES Key Type	Plain text/raw key, Wrapped key	Plain text/raw key, Wrapped key	Plain text/raw key	
AES Chaining Modes	ECB, CBC, CTR, GCM, XTS Note: XTS is supported for 128-bit and 256-bit keys only	ECB, CBC, CTR, GCM, XTS	ECB, CBC, CTR	
ARC4	Encryption, decryption	NA	NA	
TDES	Encryption, decryption	NA	NA	
TDES Key Size	192-bit	NA	NA	
TDES Chaining Modes	ECB, CBC, CTR	NA	NA	
RSA	Signature Generation, Signature Verification, Public-key Encryption, Private-key Decryption, Key Generation - plain text and wrapped keys	NA	NA	Supports CRT keys and standard keys for private key operations for both plain-text and wrapped key types.
RSA Key Size	1024-bit, 2048-bit	NA	NA	
RSA Key Type	Plain text/raw standard format and CRT keys, wrapped standard format and wrapped CRT keys	NA	NA	

DSA	Signature Generation, Signature Verification	NA	NA	
DSA Key Size	(1024, 160)-bit, (2048, 224)-bit, (2048, 256)-bit	NA	NA	
HASH	MD5, SHA1, SHA224, SHA256	NA	NA	Message digest algorithms.
ECC	Key Generation – plain text and wrapped keys, Scalar Multiplication, ECDSA- Signature Generation, ECDSA -Signature Verification,	NA	NA	
ECC Key Size	192-bit, 224-bit, 256-bit and 384-bit	NA	NA	
ECC Key Type	Plain Text/Raw Key, Wrapped Key			
Key Installation	AES, ECC, RSA keys	AES keys	NA	

Configuration Settings for the R_SCE Module

The endianness of the SCE is set to big endian by default. It can be set to little endian mode.

Please refer to the operational notes on endianness configuration parameter usage.

Configuration Settings for the TRNG Module

Random number-generation can be configured for the maximum number of attempts it makes to the underlying hardware to generate a unique 16-byte random number that differs from the previously-generated random number. On reaching the maximum number of attempts, the read API will return an error code to the caller, otherwise a success code is returned and the generated random number will be transferred to the caller-supplied data buffer.

Configuration Settings for the AES Module

The AES module can be configured for a user-specified key-length, key type (plain text or wrapped key) and chaining modes.

Configuration Settings for the RSA Module

The RSA module can be configured for a user-specified key length and key type: plain text or wrapped keys.

Configuration Settings for the DSA Module

The DSA module can be configured for a user-specified key length.

Configuration Settings for the HASH Module

The HASH module can be configured for a user specified HASH algorithm (depending on the target MCU.)

Configuration Settings for the TDES Module

The TDES module can be configured for a user-specified chaining mode.

Configuration Settings for the Key Installation Module

The Key Installation module can be configured to install the user's encrypted key.

Configuration Settings for the ECC Module

The ECC module can be configured for a user-specified key length and key type.

SCE HAL Module Important Operational Notes and Limitations

SCE HAL Module Operational Notes

- Synergy S7 and S5 devices have the SCE7 and therefore support AES, TRNG, RSA, HASH, DSA, ECC and Key Installation.
- Synergy S3 devices have the SCE5 and therefore support AES, TRNG, & GHASH. GHASH is supported as part of the AES GCM mode. Key Installation is supported as part of AES GCM, ECB, CTR, XTS, CBC chaining modes. Synergy S3 devices do not support MD5, SHA1/SHA256 HASH functionality.
- Synergy S1 devices only support AES and TRNG.
- If an unsupported module is added to the project, then a compiler warning will be generated indicating this fact.
- All modules support the versionGet API which can be called even before a module is opened.
- R_SCE module crypto_api_t::interfaceGet API is provided for use by the Framework layer SF CRYPTO modules.

The InterfaceGet API is used to request a crypto HAL interface. The example below shows usage of this API:

```
crypto_instance_t         * p_crypto;  /* R_SCE  instance */
void * p_interface = NULL;    /* Declare a pointer to hold the output interface
structure object */
crypto_interface_get_param_t     param;
param.hash_type = CRYPTO_TYPE_HASH_256; /* Requesting SHA 256 interface*/
/* It is mandatory for the address of the p_interface pointer be passed to the API */
p_crypto->p_api->interfaceGet(&param, &p_interface);
```

- All crypto APIs may return SSP_ERR_ASSERTION on null pointer input or invalid input parameters. All APIs return error codes documented in sf_crypto_err_t or ssp_err_t which are within the width of the type uint32_t.
- Crypto hardware engine does not support reentrancy. When the crypto hardware engine is busy performing a task, any new request will receive a status error code SSP_ERR_CRYPTO_SCE_RESOURCE_CONFLICT.

Endianness configuration parameter usage:

- The default mode is big endian where the input and output parameters (example: keys, payload and IV) are required to be in uint32_t data type.
- The little endian mode allows the user to have uint8_t/byte array for input and output parameters (example: keys, payload and IV) and they should be cast to (uint32_t *).
- The endianness configuration is set at the initialization of the SCE module and remains in effect until the module is closed. Hence all data should be formatted accordingly.

Example:

- Select the Big endian mode when the data is in uint32_t and big endian format:

uint32_t test_data[5] = {0x84983E44, 0x1C3BD26E, 0xBAAE4AA1, 0xF95129E5, 0xE54670F1};

- Select the Little endian mode when the same data is in byte array format

```
uint8_t  test_data_byte_array[20] =
{0x84, 0x98, 0x3E, 0x44, 0x1C, 0x3B, 0xD2, 0x6E, 0xBA, 0xAE, 0x4A, 0xA1, 0xF9, 0x51,
0x29, 0xE5, 0xE5, 0x46, 0x70, 0xF1};
```

AES Keys:

AES wrapped key sizes are as follows:

```
/* Return Wrapped AES secret key size in bytes for a 128-bit AES Key */
#define AES128_WRAPPPED_SECRET_KEY_SIZE_BYTES  (36U)
/* Return Wrapped AES secret key size in bytes for a 192-bit AES Key */
#define AES192_WRAPPPED_SECRET_KEY_SIZE_BYTES  (52U)
/* Return Wrapped AES secret key size in bytes for a 256-bit AES Key */
#define AES256_WRAPPPED_SECRET_KEY_SIZE_BYTES  (52U)
/* Return Wrapped AES-XTS secret key size in bytes for a 128-bit AES XTS Mode Key */
#define AES_XTS_128_WRAPPPED_SECRET_KEY_SIZE_BYTES  (52U)
/* Return AES-XTS secret key size in bytes for a 256-bit AES XTS Mode Key */
#define AES_XTS_256_WRAPPPED_SECRET_KEY_SIZE_BYTES  (84U)
```

The format of RSA keys generated by the rsa_api_t::keyCreate API is as follows:

Note: The endianness is the same as that set during SCE initialization.

RSA Key Format:

RSA Public Key Format:

WORD 0 : Public key exponent

WORD 1: Start of RSA modulus

(128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

RSA Private Key in Plain Text Standard Format:

WORD 0: Private key exponent (128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

Followed by RSA modulus. (128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

RSA Private Key in Plain Text CRT Format:

The components are ordered in the following order with exponent2 at byte 0:

exponent2 // the second factor's CRT exponent, a positive integer

prime2 // the second factor, a positive integer

exponent1 // the first factor's CRT exponent, a positive integer

prime1 // the first factor, a positive integer

coefficient // the (first) CRT coefficient, a positive integer

The format of RSA wrapped keys generated by the rsa_api_t::keyCreate API is as follows:

RSA Public key is always in plain text.

Byte 0 to Byte 3: Public key exponent

Byte 4 : Start of RSA modulus

(128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

RSA Private key in standard format

Byte 0: Private key exponent is wrapped.(Length is 148 bytes for RSA 1024-bit and 276 bytes for RSA 2048-bit keys)

- Followed by RSA modulus in plain text. (Length is 128 bytes for RSA 1024-bit and 256 bytes for RSA 2048-bit keys)

SCE HAL Module Limitations

- The AES encrypt() and decrypt() functions do not support data padding. These functions

operate on data lengths that are multiples of 16 bytes. (Data padding needs to be handled by the user application.) AES GCM mode may require support for authentication data that may not be a multiple of 16 bytes. To support this, zeroPaddingEncrypt() and zeroPaddingDecrypt() function APIs are provided only for the AES GCM mode.
    - For AES GCM, when using uint32_t arrays in big endian mode, if the number of bytes of data is not a multiple of 4 (WORD length) it should be zero-padded.
- AES encryption/ decryption API with XTS chaining mode supports data input lengths which are multiples of AES block size. Arbitrary input data lengths will work only when the input data is zero-padded in the user application. (Data padding needs to be handled by the user).
- The TDES encrypt() and decrypt() functions do not support data padding. These functions operate on data lengths that are multiples of 8 bytes. (Data padding needs to be handled by the user application.)
- Disable the unused interfaces in the r_sce module configuration in ISDE properties which will reduce the code memory. This will help in reducing code/text memory size in low memory devices like S5D3 MCUs.

HASH Module - MD5

- MD5 requires byte swapping of the final message digest output. Intermediate updates (partial updates) are not required to be byte swapped.
- MD5 also requires the length field within the formatted final block to be in big endian format before calling the hash_api_t::hashUpdate API.

Refer to the most recent SSP release notes for the most up-to-date limitations on this module.

4.2.41.4 Including the SCE HAL Module in an Application

This section describes how to include the SCE HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Crypto Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table.

SCE HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sce_aes_0 AES Driver on r_sce_aes	Threads	**New Stack> Driver> Crypto> AES Driver on r_sce_aes**
g_sce_arc4_0 ARC4 Driver on r_sce_arc4	Threads	**New Stack> Driver> Crypto> ARC4 Driver on r_sce_arc4**
g_sce_dsa_0 DSA Driver on r_sce_dsa	Threads	**New Stack> Driver> Crypto> DSA Driver on r_sce_dsa**

g_sce_ecc_0 ECC Driver on r_sce_ecc	Threads	**New Stack> Driver> Crypto> ECC Driver on r_sce_ecc**
g_sce_hash_0 HASH Driver on r_sce_hash	Threads	**New Stack> Driver> Crypto> HASH Driver on r_sce_hash**
g_sce_key_initialization_0 Key Initialization Driver on r_sce_key_initialization	Threads	**New Stack> Driver> Crypto> Key Initialization Driver on r_sce_key_initialization**
g_sce_rsa_0 RSA Driver on r_sce_rsa	Threads	**New Stack> Driver> Crypto> RSA Driver on r_sce_rsa**
g_sce_tdes TDES Driver on r_sce_tdes	Threads	**New Stack> Driver> Crypto> TDES Driver on r_sce_tdes**
g_sce_trng TRNG Driver on r_sce_trng	Threads	**New Stack> Driver> Crypto> TRNG Driver on r_sce_trng**

When a Crypto HAL module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

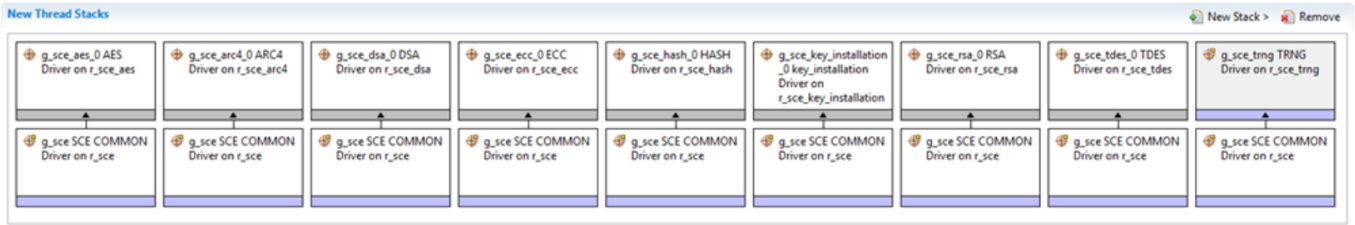

Figure 374: SCE HAL Module Stack

4.2.41.5 Configuring the SCE HAL Module

The SCE HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties

tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the AES HAL Module on r_sce_aes

ISDE Property	Value	Description
Name	g_sce_aes_0	Module name.
Key Length	128, 192, 256 Default: 128	Key length used for encryption/decryption operations by this instance of the driver.
Chaining Mode	ECB, CBC, CTR, GCM, XTS Default: CBC	Block cipher chaining mode used for encryption/decryption operations by this instance of the driver.
Key Format	Plain Text Key, Wrapped Key (Not available for S1 MCU series) Default: Plain Text Key	Key format selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the ARC4 HAL Module on r_sce_arc4

ISDE Property	Value	Description
Name (for S7G2, S5D9, S5D5 devices only)	g_sce_arc40	Module name.
Key Length in number of bytes	0	Key length selection.
Key Name, this symbol must be defined as uint8_t array type data in user code	g_arc4_0_key	Key name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the DSA HAL Module on r_sce_dsa

ISDE Property	Value	Description
Name	g_sce_dsa_0	Module name.

Key Length	(1024, 160), (2048, 224), (2048, 256) Default: (2048, 256)	Key length used for signing/verification operations by this instance of the driver.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the ECC HAL Module on r_sce_ecc

ISDE Property	Value	Description
Name (for S7G2, S5D9, S5D5 devices only)	g_sce_ecc0	Module name.
Key Length	192, 224, 256, 384 Default: 256	Key length used for encryption/decryption operations by this instance of the driver.
Key Format	Plain Text Key, Wrapped Key Default: Plain Text Key	Key format selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the HASH Driver on r_sce_hash

ISDE Property	Value	Description
Name (for S7G2, S5D9, S5D5 devices only)	g_sce_hash_0	Module name.
Algorithm	SHA1, MD5, SHA224 SHA256 Default: SHA256	Algorithm used for computing the message digest/hash on the message data.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the RSA HAL Module on r_sce_rsa

ISDE Property	Value	Description
Name	g_sce_rsa_0	Module name.
Key Length	1024, 2048 Default: 2048	Key length used for signing/verification/encryption/decryption operations by this instance of the driver.
Key Format	Plain Text Key, Wrapped Key Default: Plain Text Key	Key format selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the TDES HAL Module on r_sce_tdes

ISDE Property	Value	Description
Name	g_sce_tdes_0	Module name.
Chaining Mode	EBC, CBC, CTR Default: CBC	Chaining mode selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the TRNG HAL Module on r_sce_trng

ISDE Property	Value	Description
Name	g_sce_trng	Module name.
Max. Attempts	2	Sets the maximum number of attempts when a newly generated random number differs from the previously generated random number.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Key Installation on r_sce_key_installation

ISDE Property	Value	Description
Name (Not Supported for S1 Series MCUs)	g_sce_key_installation_0	Module name.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

4.2.41.6 Using the SCE HAL Module in an Application

The SCE Driver on r_sce HAL module makes several APIs available for various cryptographic functions. The steps to use each function are illustrated as follows, but a flow diagram is not provided due to the large number of steps.

The steps in using the SCE Driver on r_sce HAL module in a typical application are:

1. To use the SCE module:
    - Initialize the SCE and the SCE HAL module (R_SCE) using the crypto_api_t::open API through the SCE common driver. This initializes the module as defined in the

associated configuration parameters.

- *Note*

  Configure the endianness (little-endian or big-endian) for the input /output data for all the HAL APIs. The big-endian mode is configured by default. See the above operational notes for details on endianness configuration.

  - All interfaces supported on the selected MCU are available at run-time by calling the crypto_api_t::interfaceGet API. This is available for use by the Crypto framework.
  - If the crypto_api_t::interfaceGet API function is used by the HAL module, disable the unused interfaces. This will exclude them from the build to save code/text space.
  - If the application is using the Crypto frameworks, disable only the interfaces which will not be used at run-time. Make sure to keep all the used interfaces enabled.
  - If the crypto_api_t::interfaceGet API is not used directly by the HAL application project and if none of the Crypto Framework modules are being used, disable all the interfaces. This will reduce the code/text space significantly.
  - Note that disabling the interfaces will only exclude them from being requested through the crypto_api_t::interfaceGet API function. These interfaces can still be used by the HAL project by including the appropriate module in ISDE.
  - Call the crypto_api_t::open API function before using the crypto_api_t::interfaceGet API.

- *Note*

  The open function cannot be called again until the module is closed.

2. To use the AES functions:
   - Initialize the selected AES module with the aes_api_t::open API. This initializes the module as defined in the associated configuration parameters.

     - *Note*

       AES available key sizes are 128-bit, 192-bit or 256-bit. Chaining modes supported are ECB, CBC, CTR, GCM and XTS.

       - Encrypt data with the aes_api_t::encrypt API.
   - Decrypt data with the aes_api_t::decrypt API.
   - Generate keys using the aes_api_t::createKey API.

     - *Note*

       The aes_api_t::createKey API in AES module creates AES wrapped keys. AES plain text keys can be generated with the services of the TRNG module.

   - Close the interface instance using the aes_api_t::close API.

     - *Note*

       Subtle difference exist in GCM operations as follows.

   - IV provided for AES GCM operations must be a 96-bit IV formatted to 128-bits.

Example:

- 96-bit IV formatted to 128-bits: e0e00f19fed7ba0136a797f300000001
- 96-bit IV: e0e00f19fed7ba0136a797f3

AES GCM operations:

The IV will be updated after each operation and that value should be used for each subsequent operation.

AES GCM encryption:

1. AAD (Additional Authenticated Data) is optional. If it is to be used, it has to be provided prior to encrypting/decrypting any data by setting p_dest = NULL
2. Encryption: set p_source to input data and p_dest will return encrypted data
3. Get/Compute Tag: set p_source = NULL.

AES GCM decryption:

1. Set expected tag value using the setGcmTag() function
2. Provide any Add Authentication Data (AAD), invoke this API using p_dest = NULL
3. **Decryption**: set p_source to input encrypted data, decrypted data will be returned in p_dest
4. To verify the tag, invoke this API using p_source = NULL and p_dest = NULL, the return value indicates authentication tag verification status.The decrypted data is to be used only if the tag is verified successfully. zeroPaddingEncrypt/zeroPaddingDecrypt APIs can be used for GCM operations when the data is not a multiple of the block size.
5. To use the TDES functions:
    - Initialize the selected TDES module with the tdes_api_t::open API. This initializes the module as defined in the associated configuration parameters.

    - *Note*

      The TDES chaining mode can be specified as ECB, CBC or CTR.
        - *Encrypt data using the tdes_api_t::encrypt API.*
        - *Decrypt data using the tdes_api_t::decrypt API*
        - *Close the interface instance with tdes_api_t::close API.*
6. To use the ARC4 functions:
    - Initialize the selected ARC4 module with the arc4_api_t::open API. This initializes the module as defined in the associated configuration parameters.

        - *Note*

          The ARC4 key can be specified by length (anywhere from 64-bits, 2048-bits) and location.
    - Set the key with the arc4_api_t::keySet API.
    - Encrypt or decrypt data using the arc4_api_t::arc4Process API.
    - Close the module using the arc4_api_t::close API.
7. To use the RSA functions:
    - Initialize the selected module with the rsa_api_t::open API. This initializes the module as defined in the associated configuration parameters.

        - *Note*

          For rsa_api_t::encrypt API, rsa_api_t::decrypt API, rsa_api_t::decryptCrt API, rsa_api_t::sign and rsa_api_t::signCrt API, the size of the data buffer is indicated in num_words. It must be 32 words /128 bytes/1024-bits for 1024-bit keys and 64 words /256 bytes/2048-bits for the 2048-bit keys.

        - *Note*

          Supported key-formats are Standard Key and CRT Key.

        - *Note*

          Supported key-types are plain-text and wrapped private keys.

- *Note*

  Supported key-lengths are 1024-bits and 2048-bits.

  - Encrypt data with the RSA public Key using the rsa_api_t::encrypt API .
  - Decrypt data with the RSA private Key using the rsa_api_t::decrypt API.
  - Decrypt data with the RSA private Key, in the CRT format, using the rsa_api_t::decryptCrt API.
  - Generate the signature for a given padded hash using the RSA private Key, in the standard format, using the rsa_api_t::sign API.
  - Generate the signature for a given padded hash using the RSA private Key, in the CRT format, using the rsa_api_t::signCrt API.
  - Verify the signature for a given padded hash using the RSA public Key, in the standard format, using the rsa_api_t::verify API.
  - Generate keys using the rsa_api_t::keyCreate API.

    - *Note*

      The rsa_api_t::keyCreate API in the RSA module creates RSA plain-text keys or wrapped keys based on the input parameters to the API.

  - Close the interface instance with the rsa_api_t::close API.

8. To use the DSA functions:
   - Initialize the selected DSA module with the dsa_api_t::open API. This initializes the module as defined in the associated configuration parameters.

     - *Note*

       Supported key-lengths are (1024,160)-bits, (2048,224)-bits and (2048,256)-bits

   - Generate the signature with the DSA private key using the dsa_api_t::hashSign API.
   - Verify the signature with the DSA public key using the dsa_api_t::hashVerify API.
   - Close the module using the dsa_api_t::close API.
9. To use the HASH algorithms:
   - Initialize the selected HASH module with the hash_api_t::open API. This initializes the module as defined in the associated configuration parameters.

     - *Note*

       MD5, SHA1 and SHA256 hash methods are supported.

   - Compute the message digest using the hash_api_t::hashUpdate API.
   - Close the module with hash_api_t::close API.
10. To use the True Random Number Generator functions:
    - Initialize the TRNG module using the trng_api_t::open API.
    - Generate a random number using the trng_api_t::read API.
    - Close the interface instance using the trng_api_t::close API.
11. To use the Key Installation API:
    - Initialize the Key Installation module using the sf_crypto_key_installation_api_t::open API. This initializes the module as defined in the associated configuration parameters.

      - *Note*

        Specify Output key structure with pointer to buffer and buffer length.

      - *Note*

        Specify Key installation key structures for the user's encrypted key and Renesas provided key index (key size, key format, pointer to buffer and buffer length).

    - Install the key using the sf_crypto_key_installation_api_t::keyInstall API.
    - Close the module using the sf_crypto_key_installation_api_t::close API.
12. To use the ECC functions:
    - Initialize the selected ECC module using the ecc_api_t::open API. This initializes the

module as defined in the associated configuration parameters.

- *Note*

  To generate the domain parameters for NIST curves, use OpenSSL command to generate curves as shown below.
  - *ECC P-384: openssl ecparam -name secp384r1 -param_enc explicit -text | more*
  - *ECC P-256: openssl ecparam -name secp256r1 -param_enc explicit -text | more*
  - *ECC P-224: openssl ecparam -name secp224r1 -param_enc explicit -text | more*
  - *ECC P-192: openssl ecparam -name secp192r1 -param_enc explicit -text | more*

- *Note*

  Supported key sizes are 192 bits, 224 bits, 256 bits, and 384 bits.

- *Note*

  For the ecc_api_t::scalarMultiplication API, the ecc_api_t::keyCreate, the ecc_api_t::sign and the ecc_api_t::verify API:
  - *The size of the data buffer is indicated in the data_length field of r_crypto_data_handle_t. The actual buffer must be pointed to by p_data field of the r_crypto_data_handle_t.*

  - Perform ECC Scalar Multiplication using the ecc_api_t::scalarMultiplication API.
  - Generate the signature for a given padded hash using the ECC private Key, in the standard format, using the ecc_api_t::sign API.
  - Verify the signature for a given padded hash using the ECC public Key, in the standard format, using the ecc_api_t::verify API.
  - Generate the ECC keys using the ecc_api_t::keyCreate API.
  - Close the module with the ecc_api_t::close API.

13. Close the SCE and the SCE HAL moduleusing the crypto_api_t::close API.

4.2.42 SDADC Driver

4.2.42.1 SDADC HAL Module Introduction

The SDADC HAL module provides a high level API for analog-to-digital conversions and supports the SDADC24 24-bit analog-to-digital converter peripheral available on the Synergy microcontroller hardware. A user-defined callback can be created to process the data each time a new sample is available.

SDADC HAL Module Features

- 24-bit sigma delta A/D Converter
- Single scan or continuous scan operation mode
- Single-ended or differential input
- Gain of up to 32 on differential inputs
- Oversampling ratio configurable on differential inputs

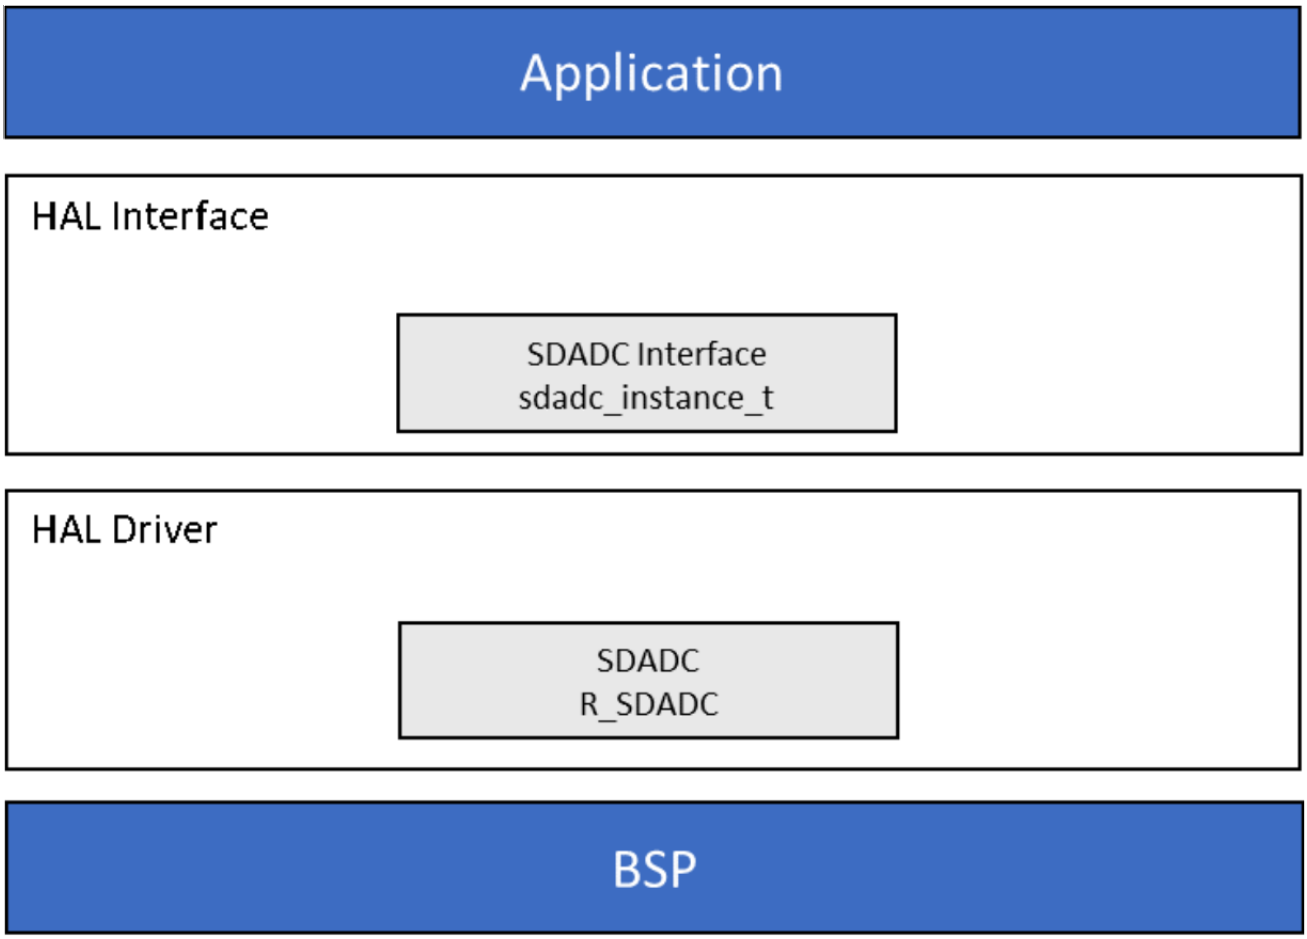

Figure 375: SDADC HAL Module Block Diagram

SDADC Hardware Support Details

The following hardware features are, or are not, supported by SSP for SDADC:

Legend:

Symbol	Meaning
✓	Available (Tested)

4.2.42.2 SDADC HAL Module APIs Overview

The SDADC HAL module defines API functions to open, configure scans, start scans, stop scans, read the conversion results the ADC scans and close the ADC unit. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

SDADC HAL Module API Summary

Function Name	Example API Call and Description
open	g_adc.p_api->open(g_adc.p_ctrl, g_adc.p_cfg); Initialize ADC unit; apply power, set the operational mode, trigger sources, interrupt priority, and configurations common to all channels and sensors.
scanCfg	g_adc.p_api->scanCfg(g_adc.p_ctrl, g_adc.p_channel_cfg); Configure the scan including the channels, groups and scan triggers to be used for the unit that was initialized in the open call.

scanStart	g_adc.p_api->scanStart(g_adc.p_ctrl); Start the scan (in case of a software trigger), or enable the hardware trigger.
scanStop	g_adc.p_api->scanStop(g_adc.p_ctrl); Stop the ADC scan (in case of a software trigger), or disable the hardware trigger.
scanStatusGet	g_adc.p_api->scanStatusGet(g_adc.p_ctrl); Check scan status.
read	g_adc.p_api->read(g_adc.p_ctrl, ADC_REG_CHANNEL_13, &adc_data); Read ADC conversion result.
read32	g_adc.p_api->read32(g_adc.p_ctrl, ADC_REG_CHANNEL_13, &adc_data); Read ADC conversion result into a 32-bit word.
sampleStateCountSet	g_adc.p_api-> sampleStateCountSet(g_adc.p_ctrl,&adc_sample); Set the sample state count for the specified channel.
calibrate	g_adc.p_api-> calibrate(g_adc.p_ctrl, reg_id, offset); Calibrate ADC or associated PGA (programmable gain amplifier). The driver may require implementation specific arguments to the p_extend input.
offsetSet	g_adc.p_api-> offsetSet(g_adc.p_ctrl, p_extend); Set offset for input PGA configured for differential input.
close	g_adc.p_api->close(g_adc.p_ctrl); Close the specified ADC unit by ending any scan in progress, disabling interrupts, and removing power to the specified A/D unit.
infoGet	g_adc.p_api->infoGet(g_adc.p_ctrl, &adc_info); Return the ADC data register address of the first (lowest number) channel and the total number of bytes to be read for the DTC/DMAC to read the conversion results of all configured channels.
versionGet	g_adc.p_api->versionGet(&version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description

SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_NOT_OPEN	Unit is not open.
SSP_ERR_ASSERTION	The parameter p_ctrl or p_sample is NULL.
SSP_ERR_IN_USE	Peripheral is still running in another mode; perform R_ADC_Close first.
SSP_ERR_INVALID_POINTER	The parameter p_data is NULL.
SSP_ERR_CALIBRATION_FAILED	Calibration failed.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.42.3 SDADC HAL Module Operational Overview

The SDADC HAL module controls the SDADC peripheral on a Synergy microcontroller. It directly controls the SDADC hardware without using any RTOS elements and provides convenient APIs to simplify development.

In this document, the term 'scan' refers to the AUTOSCAN feature of the SDADC, which works as follows:

1. Conversions are performed on enabled channels in ascending order of channel number. All conversions required for a single channel are completed before the sequencer moves to the next channel.
2. Conversions are performed at the rate (in Hz) of the SDADC oversampling clock frequency / oversampling ratio (configured per channel). The SSP uses the normal mode SDADC oversampling clock frequency.
3. If averaging is enabled for the channel, the number of conversions to average are performed before each conversion end interrupt occurs.
4. If the number of conversions for the channel is more than 1, performs the number of conversions requested. If averaging is enabled for the channel, each averaged result counts as a single conversion.
5. Continues to the next enabled channel only after completing all conversions requested.
6. After all enabled channels are scanned, a scan end interrupt occurs.

The driver supports single-scan and continuous scan operation modes.

- Single-scan mode performs one scan per trigger (hardware trigger or software start using adc_api_t::scanStart).
- In continuous scan mode, the scan is restarted after each scan completes. A single trigger is required to start continuous operation of the SDADC.

Interrupts and Callbacks

When a conversion is complete and a callback is provided by the user, the SDADC HAL module calls the callback (adc_cfg_t::p_callback) with the argument adc_callback_args_t, indicating the unit and the event adc_cb_event_t.

The SDADC driver supports the following callback events:

- ADC_EVENT_CONVERSION_COMPLETE to notify the application that new conversion data is available.
- ADC_EVENT_SCAN_COMPLETE to notify the application when a scan is complete.
- ADC_EVENT_CALIBRATION_COMPLETE to notify the application that the calibration process is complete.

SDADC HAL Module Important Operational Notes and Limitations

SDADC HAL Module Operational Notes

Triggering a Data Transfer with the SDADC

To trigger a transfer of data when the SDADC scan completes, configure the data transfer with transfer_cfg_t::activation_source set to ELC_EVENT_SDADCn_SCAN_END. The ELC events are listed under elc_event_t. To retrieve the SDADC specific information to use with the Transfer Interface API, use the adc_api_t::infoGet function call.

Triggering ELC Events with the SDADC

The SDADC unit can trigger the start of other peripherals listed in elc_peripheral_t. Refer to the "ELC Interface" in the SSP User's Manual for more information.

SDADC HAL Module Limitations

This module only works for selected Synergy MCUs. Consult the release notes for your current SSP release to see which MCUs are supported by this module. Additionally, the MCU Hardware Manual shows which peripherals are available.

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.42.4 Including the SDADC HAL Module in an Application

This section describes how to include the SDADC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the SDADC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the SDADC Driver is g_sdadc0. This name can be changed in the associated Properties window.)

SDADC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sdadc0 SDADC Driver on r_adc	Threads	**New Stack> Driver> Analog> SDADC Driver on r_sdadc**

When the SDADC Driver on r_sdadc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are

individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

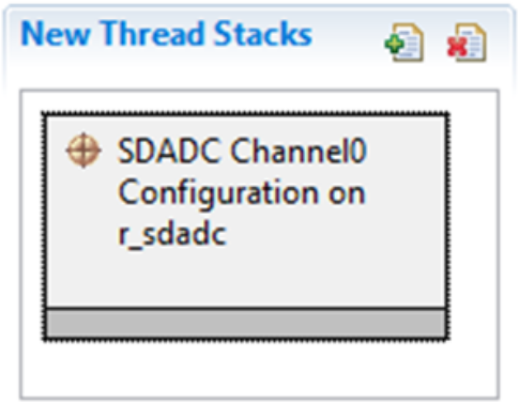

Figure 376: SDADC HAL Module Stack

4.2.42.5 Configuring the SDADC HAL Module

The SDADC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the SDADC HAL Module on r_sdadc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_adc0	Module name.

Mode	Single Scan, Continuous Scan Default: Continuous Scan	In single scan mode, all channels are converted once per start trigger, and conversion stops after all enabled channels are scanned. In continuous scan mode, conversion starts after a start trigger, then continues until stopped in software.
Resolution	16 Bit, 24 Bit Default: 24 Bit	Select 24-bit or 16-bit resolution.
Alignment	Right, Left Default: Right	Select left or right alignment.
Trigger	ELC Hardware Event, Software Default: Software	Select conversion start trigger. Conversion can be started in software, or conversion can be started when a hardware event occurs if the hardware event is linked to the SDADC peripheral using the ELC API.
Vref Source	Internal, External Default: Internal	Vref can be sourced internally and output on the SBIAS pin, or Vref can be input from VREFI.
Vref Voltage	0.8V, 1.0V, 1.2V, 1.4V, 1.6V, 1.8V, 2.0V, 2.2V, 2.4V Default: 1.0V	Select Vref voltage. If Vref is input externally, the voltage on VREFI must match the voltage selected within 3%.
Internal Calibration During Open()	Enabled, Disabled Default: Enabled	Calibration is required for all channels configured for differential input. Internal calibration is performed automatically during open for these channels unless it is disabled here.
Callback	NULL	Enter the name of the callback function to be called when conversion completes or a scan ends.
Conversion End Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Select the interrupt priority for the conversion end interrupt. [Required]
Scan End Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for the scan end interrupt. [Required]

Calibration End Interrupt Priority	Priority 0 (highest), Priority 1, Priority 2, Priority 3 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Select the interrupt priority for the calibration end interrupt. [Required]

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

SDADC HAL Module Clock Configuration

The SDADC HAL module uses the SDADCCLK as its clock source and it must be set to 4 MHz.

SDADC HAL Module Pin Configuration

To use the SDADC HAL module, the port pins for the channels receiving the analog input must be set as input pins in the pin configurator in the ISDE. The following table illustrates the method for selecting the pins within the ISDE configuration window:

Pin Selection for the SDADC HAL Module on r_sdadc

Resource	ISDE Tab	Pin selection Sequence
SDADC	Pins	Select **Peripherals**> **Analog:SDADC**> **SDADCn,** where n is the channel number.

4.2.42.6 Using the SDADC HAL Module in an Application

The typical steps in using the SDADC HAL module in an application are:

1. Initialize the SDADC using adc_api_t::open. Calibration is performed on all channels configured for differential input during this function unless calibration during open is disabled in the configuration.
2. If calibration during open is disabled in the configuration, calibrate each channel configured for differential input using adc_api_t::calibrate. Wait for a calibration complete interrupt after calibrating each channel. See R_SDADC_Calibrate for details regarding the calibration procedure.
3. Configure active channels using adc_api_t::scanCfg. (Optional)
4. Start a conversion using the desired trigger with adc_api_t::scanStart.
    a. If a hardware trigger is used, this call enables the ADC unit to be triggered by the hardware trigger. If a software trigger is used, then this call starts the ADC scan.
5. The callback will be called after each conversion, and when the entire scan is complete.
6. Read the results of the conversion using adc_api_t::read.
7. Stop the ADC scan by calling adc_api_t::scanStop. (Optional)
    a. This prevents the ADC from being triggered by an external trigger or a hardware trigger; it also forces a stop of a software-triggered scan if one is ongoing.
8. Operate on the received data as needed by the application.
9. Close the module and power down the peripheral using the adc_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

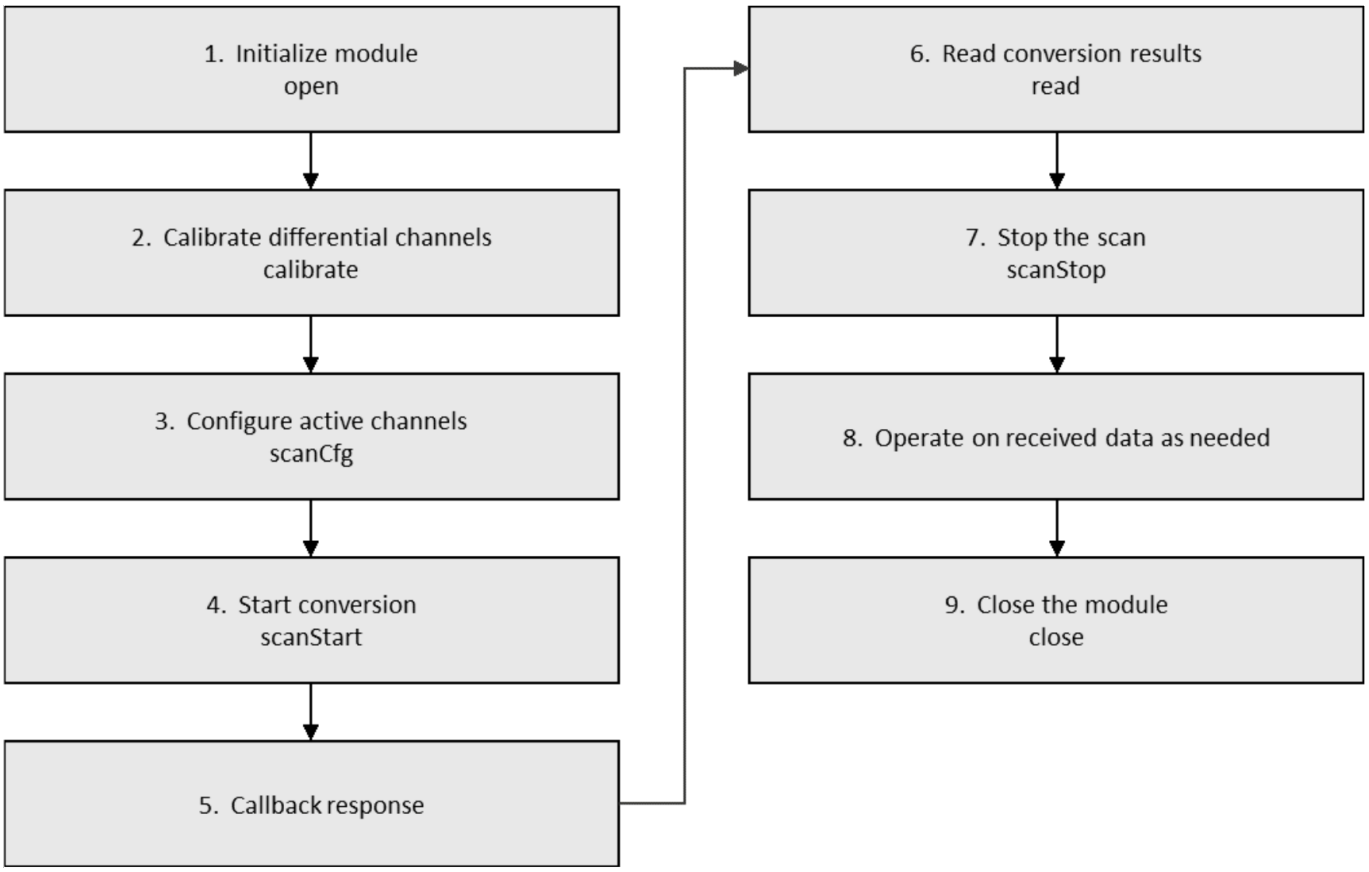

Figure 377: Flow Diagram of a Typical SDADC HAL Module Application

4.2.43 SD/MMC Driver and SDIO Driver

4.2.43.1 SDMMC HAL Module Introduction

The SDMMC (SD/MMC and SDIO) HAL module is used to read/write and control SDMMC media devices and SDIO cards. The SDMMC module can be used as a standalone SD card, eMMC or media driver, or it can be used with FileX and other compatible file systems. The SDMMC HAL module uses the SDMMC peripheral on the Synergy MCU.

SDMMC HAL Module Features

- Supports the following memory devices: SDSC (SD Standard Capacity), SDHC (SD High Capacity), SDXC (SD Extended Capacity) and eMMC (embedded Multi Media Card)
    - Supports reading, writing and erasing SD and eMMC memory devices
    - Supports 1, 4 or 8-bit data busses (8-bit bus is supported for eMMC only)
    - Supports detection of hardware write protection (SD cards only)
    - Automatically selects between backwards compatible mode and high speed SRD mode (eMMC)
- Supports SDIO
    - Supports SDIO single register access (CMD52)
    - Supports SDIO multiple register access (CMD53)

- Supports SDIO interrupts
- Automatically configures the clock to the maximum clock rate supported by both host (MCU) and device

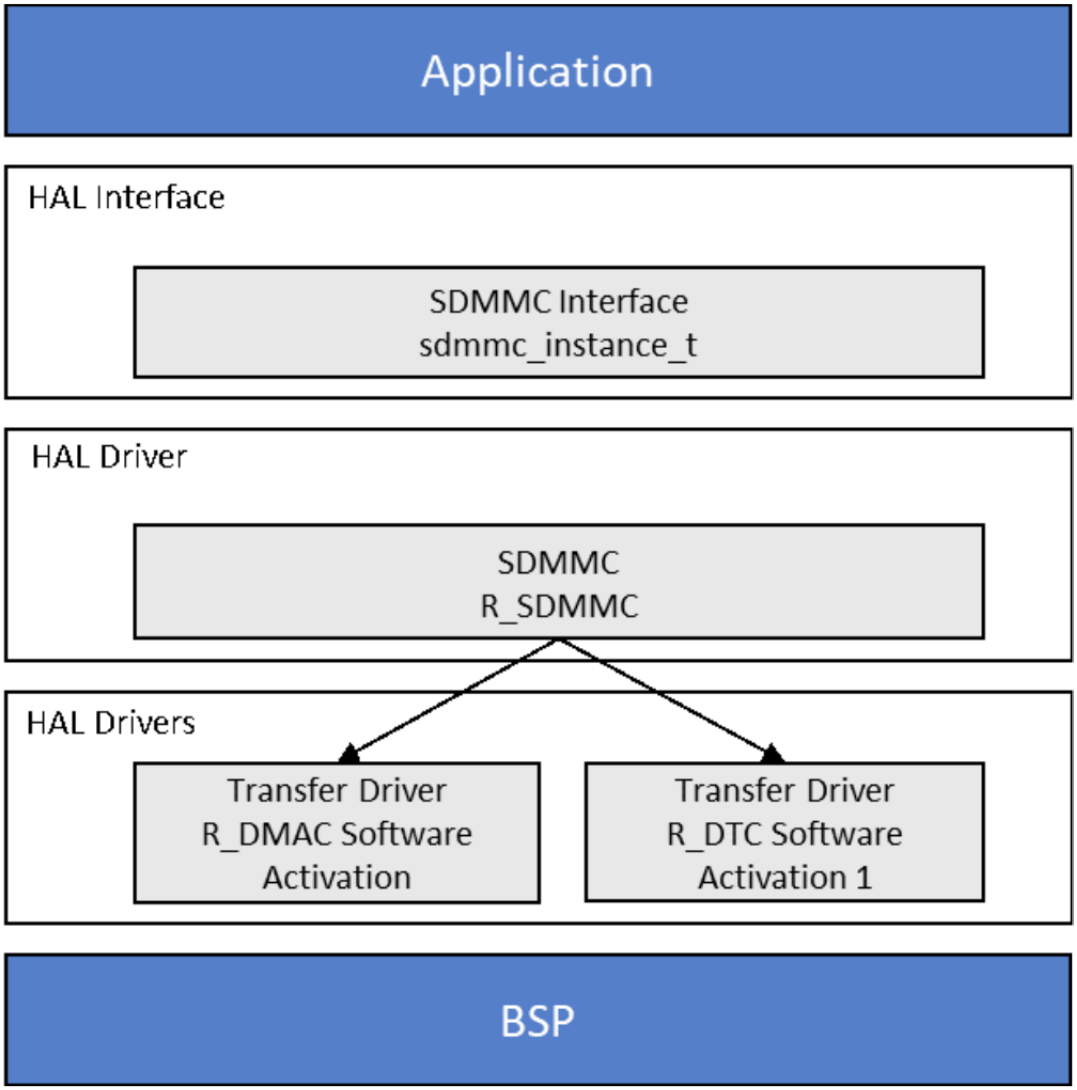

Figure 378: SDMMC HAL Module Block Diagram

4.2.43.2 SDMMC HAL Module APIs Overview

The SDMMC HAL module defines API functions including opening, reading, writing and closing. A complete list of the available API functions, an example API function call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

SDMMC HAL Module API Summary

Function Name	Example API Call and Description
open	g_sdmmc.p_api->open(g_sdmmc.p_ctrl, g_sdmmc.p_cfg); Open device channel for read/write and control. Initialize driver and hardware on first call.
read	g_sdmmc.p_api->read(g_sdmmc.p_ctrl, &destination, start, count); Read data from SD/MMC channel.
write	g_sdmmc.p_api->write(g_sdmmc.p_ctrl, &source, start, count); Write data to SDMMC channel.
control	g_sdmmc.p_api->control(g_sdmmc.p_ctrl, command, &data); Send control commands to the SD/MMC port and receive the status of the SD/MMC port.
close	g_sdmmc.p_api->close(g_sdmmc.p_ctrl); Close open SDMMC channel. Turns off hardware if last channel open.
versionGet	g_sdmmc.p_api->versionGet(&version); Get version of Block Media SD/MMC driver.
readIo	g_sdmmc.p_api->readIo(g_sdmmc.p_ctrl, &data, function, address); Read I/O data from an SDMMC channel.
writeIo	g_sdmmc.p_api->writeIo(g_sdmmc.p_ctrl, &data, function, address, read_after_write); Write I/O data to SDMMC channel.

readIoExt	g_sdmmc.p_api->readIoExt(g_sdmmc.p_ctrl, &destination, function, address, count, transfer_mode, address_mode); Read I/O data, extended, from an SDMMC channel.
writeIoExt	g_sdmmc.p_api->writeIoExt(g_sdmmc.p_ctrl, &source, function, address, count, transfer_mode, address_mode); Write I/O data, extended, to SDMMC channel.
IoIntEnable	g_sdmmc.p_api->IoIntEnable(g_sdmmc.p_ctrl, enable); Enables SDIO interrupt for SDMMC channel.
infoGet	g_sdmmc.p_api->infoGet(g_sdmmc.p_ctrl, &info); Get SDMMC channel info.
erase	g_sdmmc.p_api->erase(g_sdmmc.p_ctrl, start, count); Erase SDMMC sectors.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_INVALID_ARGUMENT	Parameter has invalid value.
SSP_ERR_IN_USE	The channel specified has already been opened. No configurations were changed. Call the associated Close function or use associated Control commands to reconfigure the channel.
SSP_ERR_ASSERTION	The pointer is NULL.
SSP_ERR_WRITE_PROTECTED	SD or MMC card is Write Protected.
SF_INFO_NOT_AVAILABLE	Information not available possibly because card has been removed or is defective.
SSP_ERR_NOT_OPEN	The channel is not opened.
SSP_ERR_HW_LOCKED	The hardware lock has already been acquired.
SSP_ERR_TRANSFER_BUSY	The transfer is in progress.
SSP_ERR_CARD_NOT_READY	The card is not ready yet.
SSP_ERR_NOT_ENABLED	SDIO interrupt enable failed.
SSP_ERR_READ_FAILED	Read operation failed.

SSP_ERR_WRITE_FAILED	Write operation failed.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.43.3 SDMMC HAL Module Operational Overview

The following descriptions cover the operational functions and requirements when using the SDMMC HAL module:

Interrupt Configurations:

Using SD/MMC with DTC:

- Access Interrupt
- DTC Interrupt

Using SD/MMC with DMAC:

- Access Interrupt
- DMAC Interrupt (in DMAC instance)

Using SDIO with DTC:

- Access Interrupt
- SDIO Interrupt
- DTC Interrupt

Using SDIO with DMAC:

- Access Interrupt
- SDIO Interrupt
- DMAC Interrupt (in DMAC instance)

The Card interrupt is optional and only available on MCU packages that have the SDHIn CD pin (n = channel number) available on the **Pins** tab of the Synergy Configuration tool.

Block Size Configuration

Block size configuration is provided for use with SDIO cards only. For SDIO cards, block size may be configured to 1-512 bytes. Block size must remain at the default 512 bytes for SD cards and e/MMC memory devices.

Card Detection Configuration

See *Card Detection Limitations* before using card detection in the SDMMC HAL driver. If card detection is not available or not desired for the application, Card Detection must be set to Not Used in the Properties for the r_sdmmc instance in the Synergy Configuration tool. To enable card detection, set Card Detection to CD Pin and Media Type to Card in the Properties for the r_sdmmc instance in the Synergy Configuration tool.

Access Interrupt Priority

When data transfers are not 4-byte aligned or not a multiple of 4 bytes, a software copy of the block size (up to 512 bytes) is done in the access interrupt. This blocks other interrupts that are a lower or equal priority to the access interrupt until the software copy is complete.

General Timing Notes

Several functions in this driver block. sdmmc_api_t::open() and sdmmc_api_t::erase() block until the entire operation is complete. sdmmc_api_t::read(), sdmmc_api_t::write(), sdmmc_api_t::readIo(), sdmmc_api_t::writeIo(), sdmmc_api_t::readIoExt(), and sdmmc_api_t::writeIoExt() block for a single command response cycle. In a multithreaded system, care should be taken to use this driver in a lower priority thread if other threads require a response time faster than the time this driver could block for during one of these function calls.

Timing Notes for Open

The sdmmc_api_t::open() API completes the entire device identification and configuration process. This involves several command-response cycles at a bus width of 1-bit and a bus speed of 400 kHz or less.

Timing Notes for Read, Write, ReadIoExtand WriteIoExt

The read and write media (sdmmc_api_t::read() and sdmmc_api_t::write()) and extended read and write SDIO APIs (sdmmc_api_t::readIoExt() and sdmmc_api_t::writeIoExt()) block until the response is received from the device. The data transfer operation is non-blocking and requires interrupts and a transfer instance, either DMAC or DTC. These APIs return SSP_SUCCESS to indicate that the initial operations have started successfully. The application must wait for a callback with the event SDMMC_EVENT_TRANSFER_COMPLETE or SDMMC_EVENT_TRANSFER_ERROR to indicate completion of the read or write.

Timing Notes for ReadIo and WriteIo

The SDIO sdmmc_api_t::readIo() and sdmmc_api_t::writeIo() APIs block until the response is received from the device. The read or write operation is complete when these APIs return.

Timing Notes for Erase

The sdmmc_api_t::erase() API blocks until the erase operation is complete. This may be several seconds or more depending on how many sectors are being erased.

SDIO Interrupts

Many SDIO cards use level interrupts, meaning the interrupt is not de-asserted until the interrupt is cleared on the device. In order to ensure SDIO interrupts are cleared appropriately, one of the following methods are recommended:

- Ensure the SDIO interrupt is cleared on the device before exiting the callback function with the event SDMMC_EVENT_SDIO. If this method is chosen and any SDIO API must be used in the interrupt, the access interrupt must be a higher priority than the SDIO interrupt.
- Disable the SDIO interrupt in the callback function with the event SDMMC_EVENT_SDIO using sdmmc_api_t::IoIntEnable(). Clear the SDIO interrupt elsewhere in the application, then re-enable SDIO interrupts if desired using sdmmc_api_t::IoIntEnable().

SDMMC HAL Module Important Operational Notes and Limitations

SDMMC HAL Module Operational Notes

SD HALA Compliance

When developing host devices that are compliant with the SD Specifications, the host must comply with the SD Host/Ancillary Product License Agreement (SD HALA).

SDMMC HAL Module Limitations

Data Alignment and Size

Data transfers should be 4-byte aligned and a multiple of 4 bytes in size whenever possible. This recommendation applies to the read(), write(), readIoExt(), and writeIoExt() APIs. When data transfers are 4-byte aligned and a multiple of 4-bytes, the r_sdmmc driver is zero copy and takes full advantage of hardware acceleration by the DMAC or DTC. When data transfers are not 4-byte aligned or not a multiple of 4 bytes an extra CPU interrupt is required for each block transferred (see Access Interrupt Priority).

Card Detection Limitations

Card detection support in the r_sdmmc driver is limited. Card detection is only available after sdmmc_api_t::open() is complete, and open() cannot be completed unless a card is inserted. Card detection in the r_sdmmc driver is therefore only useful to detect card removal and reinsertion. After reinsertion is detected, the driver must be closed and reopened, and card detection will not be available until the reopen is complete. Card detection is available only on MCU packages that have the SDHIn CD pin (n = channel number) available on the Pins tab of the Synergy Configuration Tool. If the MCU does not have the SDHIn CD pin, or card detection is not desired for the application, card detection must be disabled in the Properties for the r_sdmmc instance in the Synergy Configuration Tool. An alternative to using the card detection feature of the r_sdmmc driver is to use an External IRQ instance and handle card detection at the application layer. If card detection is handled at the application layer, the sdmmc_api_t::open() should be called after card insertion is detected, and the sdmmc_api_t::close() should be called after card removal is detected.

Refer to the most recent SSP Release notes for the most up to date limitations for this module.

4.2.43.4 Including the SDMMC HAL Module in an Application

This section describes how to include the SDMMC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the SD/MMC Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the SD/MMC Driver is g_sdmmc0. This name can be changed in the associated Properties window.)

SDMMC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sdmmc0 SD/MMC driver on r_sdmmc	Threads	**New Stack> Driver> Storage> SD/MMC Driver on r_sdmmc**

When the SDMMC HAL module on r_sdmmc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

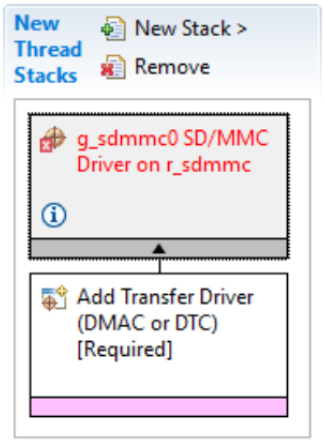

Figure 379: SDMMC HAL Module Stack

4.2.43.5 Configuring the SDMMC HAL Module

The SDMMC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

ConfigurationSettings for the SDMMC HAL Module on r_sdmmc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.

Name	g_sdmmc0	The name to be used for SDMMC module control block instance. This name is also used as the prefix of the other variable instances.
Channel	0	Select the channel.
Media Type	Embedded, Card Default: Embedded	Media is a card or an embedded device. This allows to firmware to know whether to look for card insertion/removal and write protect pins.
Bus Width	1 Bit, 4 Bits, 8 bits Default: 4 Bits	Data bus with as defined by hardware interface. (8 Bits for eMMC only).
Block Size	512	Select the media block size.
Card Detection	Not Used, CD Pin Default: CD Pin	Select the card detection method.
Write Protection	WP Pin, Not Used Default: WP Pin	Select whether or not to use the write protect pin. Select Not Used if the MCU or device does not have a write protect pin.
Callback	NULL	(Required if not using FileX) Set to name of user callback function. Provides event that caused interrupt: SDMMC_EVENT_CARD_REMOVED, SDMMC_EVENT_CARD_INSERTED, SDMMC_EVENT_ACCESS, SDMMC_EVENT_SDIO, SDMMC_EVENT_TRANSFER_COMPLETE, SDMMC_EVENT_TRANSFER_ERROR.
Access Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Access interrupt priority selection.
Card Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Card interrupt priority selection.
DTC Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	DTC interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SDMMC HAL Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module:

Configuration Settings for the Transfer Driver on r_dmac Software Activation

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Name	g_transfer0	Module name.
Channel	0	Channel selection.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Software Activation 1

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Software Activation 1	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

SDMMC HAL Module Clock Configuration

The SDMMC MCU peripheral (SDHI) uses the PCLKA for its clock source. There is no need to configure the clock specifically for the SDMMC peripheral unless you need to optimize the data rate. The SDMMC driver selects the appropriate built-in divider based on the PCLKA frequency and the maximum clock rate allowed by the SD, SDIO or eMMC device obtained at media device initialization.

SDMMC HAL Module Pin Configuration

Use the ISDE pin configurator to configure the I/O pins for SDMMC peripheral (SDHI). The drive capacity for each pin should be set to "Medium" or "High" for most boards and high-speed memory and SDIO devices. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins:

Note

The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for SDMMC HAL Module on r_riic

Resource	ISDE Tab	Pin selection Sequence
SDHI	Pins	Select **Peripherals**> **Storage:SHDI**> **SDHI0**

Note

The selection sequence assumes SCI1 is the desired hardware target for the driver.

Pin Configuration Settings for the SDHI Peripheral

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Custom, SD_MMC 1 bit SD_MMC 4 bit MMC 8 bit Default: Custom	Select mode as per application.
CLK	None, P413 Default: P413	Clock pin.
CMD	None, P412 Default: P412	Command pin.
DAT0-7	None, PXXX Default: PXXX	Data pin.
CD	None, P903 Default: P903	Card detection pin.
WP	None, P414 Default: P414	Card write protection pin.
SDA	Disabled	SDA Pin (when Simple I2C is used).
SCL	Disabled	SCL Pin (when Simple I2C is used).

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.43.6 Using the SDMMC HALModule in an Application

The steps for using the SDMMC HAL module in a typical application are:

1. Open the driver using the sdmmc_api_t::open() API.
2. Read data from the card using the sdmmc_api_t::read() API or write data to the card using sdmmc_api_t::write() API.
3. Wait for a callback with the event SDMMC_EVENT_TRANSFER_COMPLETE (meaning the operation completed successfully) or SDMMC_EVENT_TRANSFER_ERROR (meaning the operation did not complete successfully) after each time the sdmmc_api_t::read() API or the sdmmc_api_t::write() API is called.

These common steps are illustrated in a typical operational flow diagram in the following figure:

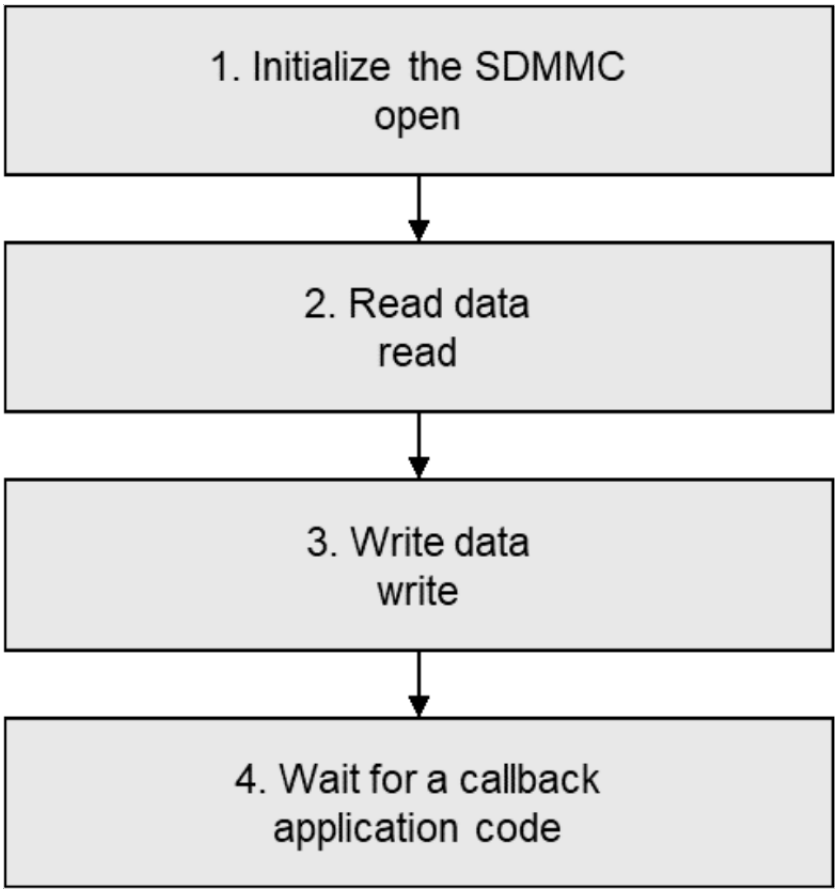

Figure 380: Flow Diagram of a Typical SDMMC HAL Module Application

The steps for using the SDMMC HAL module with an SDIO card in a typical application are:

1. Open the driver using the sdmmc_api_t::open() API.
2. Set or read back single registers using the sdmmc_api_t::readIo() API or the sdmmc_api_t::writeIo() API. The operation is complete immediately after these calls and there is no need to wait for a callback.
3. Set or read back multiple registers using the sdmmc_api_t::readIoExt() API or the sdmmc_api_t::writeIoExt() API. The block size can be changed using the sdmmc_api_t::control() API between calls if necessary.
4. Wait for a callback with the event SDMMC_EVENT_TRANSFER_COMPLETE (meaning the operation completed successfully) or SDMMC_EVENT_TRANSFER_ERROR (meaning the operation did not complete successfully) after each time the sdmmc_api_t::readIoExt() API

or the sdmmc_api_t::writeIoExt() API is called.

5. If the card requests an interrupt, the callback is called with the event SDMMC_EVENT_SDIO. Handle the SDIO interrupt as described in the documentation for the card (see the SDIO Interrupts section of this documentation). SDIO interrupts from the card can be enabled or disabled at any time using the sdmmc_api_t::IoIntEnable() API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

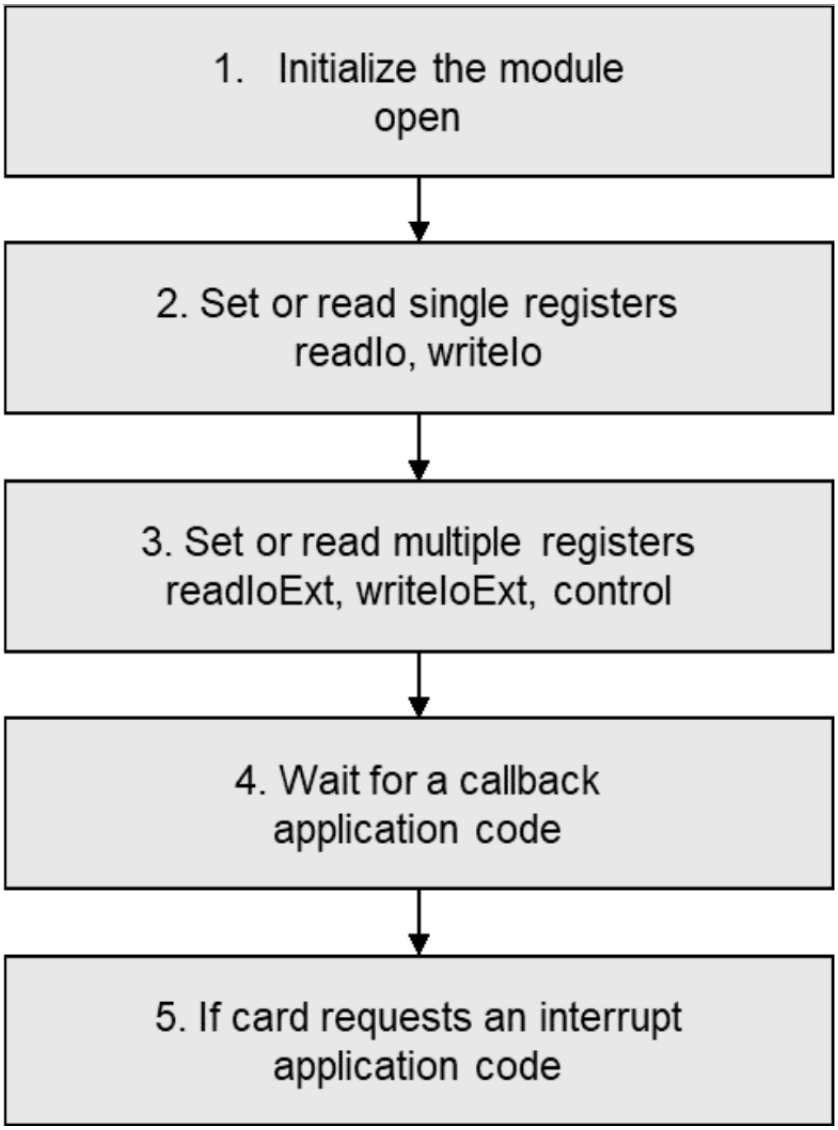

Figure 381: Flow Diagram of a Typical SDMMC HAL Module Application

4.2.44 Segment LCD Driver

4.2.44.1 SLCDC HAL Module Introduction

The Segment LCD HAL module provides a high-level API for Segment LCD applications and displays

and modifies data on a Segment LCD. The Segment LCD HAL module uses the Segment LCD Controller module on a Synergy MCU.

SLCDC HAL Module Features

- Internal voltage-boosting for the LCD driver voltage generator: select the capacitor split method or the external resistance division.
- Display bias: select the 1/2 bias method, 1/3 bias method, or 1/4 bias method.
- Time slice of the display: select static, 2-time slice, 3-time slice, 4-time slice, or 8-time slice.
- Display waveform: select waveform A or waveform B.
- Display data area: select A-pattern, B-pattern, or blinking. You can switch the display data area.
- Use the RTC periodic interrupt (PRD) to generate a blinking display with A-pattern and B-pattern.
- Adjust the reference voltage which is generated when operating the voltage boost circuit in 16 steps (contrast adjustment.)

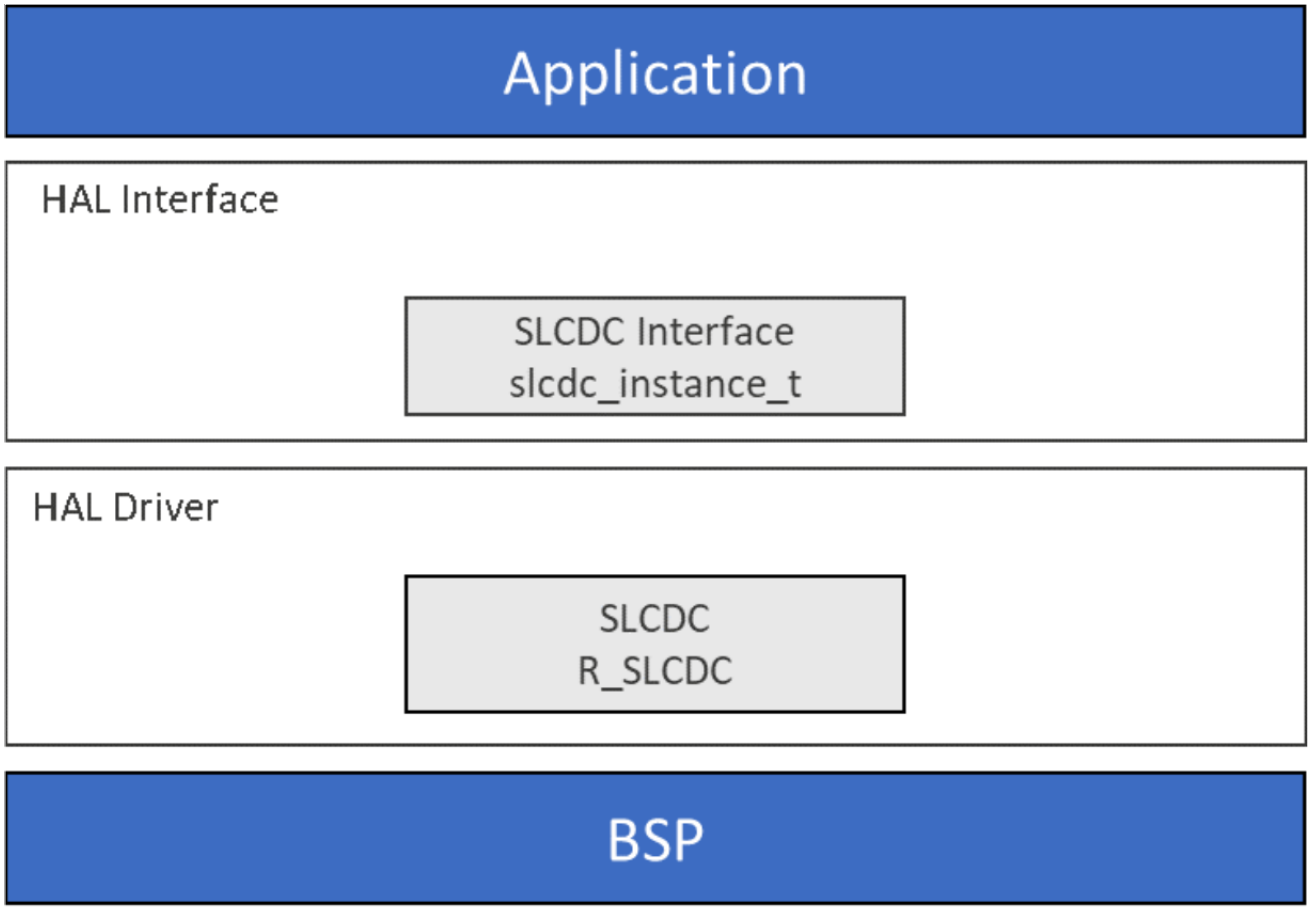

Figure 382: SLCDC HAL Module Block Diagram

SLCDC Hardware Support Details

The following hardware features are, or are not, supported by SSP for the SLCD.

Legend:

Symbol	Meaning

4.2.44.2 SLCDC HAL Module APIs Overview

The Segment LCD Controller HAL module defines APIs for functions such as opening, writing, starting, modifying and closing. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

SLCDC HAL Module API Summary

Function Name	Example API Call and Description
open	g_slcdc.p_api->open(g_slcdc.p_ctrl, g_slcdc.p_cfg); Open SLCD device.
write	g_slcdc.p_api->write(g_slcdc.p_ctrl, start_segment, &data, segment_count); Write data to SLCD segments. Specifies the initial display data. The data parameter is a pointer to an array of bytes consisting at least segment_count items, in which each byte is associated with one segment data register. When the number of time slices is static, 2, 3 or 4, the lower 4 bits of the data become an A-pattern area and the upper 4 bits become a B-pattern area. See slcdc_api_t::setdisplayArea for setting a display area.
modify	g_slcdc.p_api->modify(g_slcdc.p_ctrl, segment, data_mask, data); Rewrite data in the SLCD segment. Rewrites the LCD display data in 1-bit units. If a bit is not specified for rewriting, the value stored in the bit is held as it is. Specifies the data to rewrite.
start	g_slcdc.p_api->start(g_slcdc.p_ctrl); Enable display on the SLCD. Displays the specified data on the LCD. Before that data should be written to the segments.
stop	g_slcdc.p_api->stop(g_slcdc.p_ctrl); Disable display on the SLCD. Stops displaying data on the SLCD.
contrastIncrease	g_slcdc.p_api->contrastIncrease(g_slcdc.p_ctrl); Increase the display contrast. Increase by 1 unit. This function can be selected when the internal voltage boosting method is used for the drive voltage generator.

contrastDecrease	g_slcdc.p_api->contrastDecrease(g_slcdc.p_ctrl); Decrease the display contrast. Decrease by 1 unit. This function can be selected when the internal voltage boosting method is used for the drive voltage generator.
setdisplayArea	g_slcdc.p_api->setdisplayArea(g_slcdc.p_ctrl, display_area); Set LCD display area. This function sets a specified display area, A-pattern or B-pattern. This function can be used to set blink on where A-pattern and B-pattern area data will be alternately displayed. When using blinking, the RTC is required to operate before this function is executed. To configure the RTC, follow the steps below. 1. Open RTC 2. Set Periodic interrupt request, ½ second 3. Start RTC counter 4. Enable IRQ, RTC_EVENT_PERIODIC_IRQ Refer to the User's Manual: Microcontrollers for the detailed procedure.
close	g_slcdc.p_api->close(g_slcdc.p_ctrl); Close display device.
versionGet	g_slcdc.p_api->versionGet(&version); Retrieve the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successful.
SSP_ERR_ASSERTION	Assertion error.
SSP_ERR_INVALID_ARGUMENT	Invalid Argument.
SSP_ERR_HW_LOCKED	SLCDC resource is locked.
SSP_ERR_NOT_OPEN	Device is not opened or initialized.
SSP_ERR_UNSUPPORTED	Unsupported operation.
SSP_ERR_NOT_ENABLED	RTC not enabled for blink operation.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.44.3 SLCDC HAL Module Operational Overview

This module uses the Segment LCD controller (SLCDC) to display data on a Segment LCD. The driver initializes the LCD for displaying data and configures the drive-voltage generator, display waveform, number of time slices and bias methods to drive the LCD. This module provides functions to display data to a specified set of segments, to modify existing segment data, to enable and disable display, to set the display area and to adjust the contrast. The contents displayed on the LCD can be changed by changing the contents of the LCD display data registers.

SLCDC HAL Module Important Operational Notes and Limitations

SLCDC HAL Module Operational Notes

- This driver is a HAL driver and has no dependencies with the ThreadX RTOS. You can add the Segment LCD HAL module to a thread in the ThreadX RTOS if it is desirable.
- To write to a sequence of segments, give the start segment number and number of segments to be written in the slcdc_api_t::write API.

SLCDC HAL Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.44.4 Including the SLCDC HAL Module in an Application

This section describes how to include the SLCDC HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Segment LCD Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Segment LCD Driver is g_timer0. This name can be changed in the associated Properties window.)

SLCDC HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_slcdc0 Segment LCD Driver on r_slcdc	Threads	**New Stack> Driver> Graphics> Segment LCD Driver on r_slcdc**

When the Segment LCD Driver on r_slcdc is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

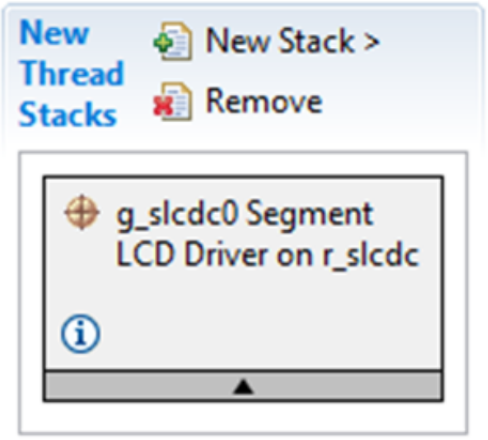

Figure 383: SLCDC HAL Module Stack

4.2.44.5 Configuring the SLCDC HAL Module

The SLCDC HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the SLCDC HAL Module on r_slcdc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Select if extra code will be added to check parameter values.
Name	g_slcdc0	Module name.
Slcdc Clock	Clock Loco, Clock Sosc, Clock Mosc, Clock Hoco Default: Clock Hoco	SLCD clock source (LCDSCKSEL).

Slcdc Clock Divisor	Clk Divisor Loco 4, Clk Divisor Loco 8, Clk Divisor Loco 16, Clk Divisor Loco 32, Clk Divisor Loco 64, Clk Divisor Loco 128, Clk Divior Loco 256, Clk Divisor Loco 512, Clk Divisor Loco 1024, Clk Divisor Hoco 256, Clk Divisor Hoco 512, Clk Divisor Hoco 1024, Clk Divisor Hoco 2048, Clk Divisor Hoco 4096, Clk Divisor Hoco 8192, Clk Divisor Hoco 16384, Clk Divisor Hoco 32768, Clk Divisor Hoco 65536, Clk Divisor Hoco 131072, Clk Divisor Hoco 262144, Clk Divisor Hoco 524288 Default: Clk Divisor Hoco 16384	LCD clock setting (LCDC0), clock divisor.
Bias Method	Bias 2, Bias 3, Bias 4 Default: Bias 2	LCD display bias method select (LBAS bit).
Time Slice	Static, Slice 2, Slice 3, Slice 4, Slice 8 Default: Static	Time slice of LCD display select (LDTY bit).
Wave Form	Wave A, Wave B Default: Wave A	LCD display waveform select (LWAVE bit).
Slcdc Drive Voltage Generator	External resistance division, Internal voltage boosting, Capacitor split Default: External resistance division	LCD Drive Voltage Generator Select (MDSTET bit).

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

SLCDC HAL Module Clock Configuration

Configure the SLCDC Hal module clock in the properties window of the g_slcdc driver. The operating clock of the SLCDC HAL Module is specified by the SLCDC Clock and SLCDC Clock Divisor settings in the Properties window. The Segment LCD HAL module-source clock can be configured as the Main (MOSC), HOCO (High-speed Clock Oscillator), LOCO (Low-speed Clock Oscillator) or Sub-clock (SOSC) using the ISDE configurator. For HOCO and LOCO settings, several clock divisors are available.

SLCDC HAL Module Pin Configuration

The SLCDC peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates

the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the pins.

Note

For some peripherals, the operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection for the SLCDC HAL Module on r_slcdc

Resource	ISDE Tab	Pin Selection Sequence
SLCDC	Pins	Select **Peripherals**> **Graphics: SLCDC**> **SLCDC0**

Note

The selection sequence assumes SLCDC0 is the desired hardware target for the driver.

Pin Configuration Settings for SLCDC HAL Module

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Custom, Static, 2x Slice, 3x Slice, 4x Slice, 8x Slice Default: Custom	Select operation mode enable or disable.
CAPH	None, P111 Default: None	Capacitor connection pin.
CAPL	None, P112 Default: P112	Capacitor connection pin.
COM0:3	None, Pn Default: P104:107	Common pins.
COM4:7	None, Pn Default: None	Common pins.
VL1:4	None, Pn Default: P100:103	Power supply pins.
SEG00:02, SEG06:07, SEG16:17, SEG21:25, SEG46:51	None, Pn Default: None	Segment pins.
SEG03	None, P303 Default: P303	Segment pin.

SEG04:05	None, Pn Default: P314:315	Segment pins.
SEG08	None, P902 Default: P902	Segment pin.
SEG09:15	None, Pn Default: P312:306	Segment pins.
SEG18:19	None, Pn Default: P808:809	Segment pins.
SEG20	None, P313 Default: P313	Segment pin.
SEG26:27	None, Pn Default: P806:807	Segment pins.
SEG28:34	None, Pn Default: P608:614	Segment pins.
SEG35:41	None, Pn Default: P606:600	Segment pins.
SEG42:43	None, Pn Default: P805:804	Segment pins.
SEG44:45	None, Pn Default: P800:801	Segment pins.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy MCUs and Synergy Kits may have different available pin configuration settings.

4.2.44.6 Using the SLCDC HAL Module in an Application

The typical steps in using the SLCDC HAL module in an application are:

1. Initialize the SLCD HAL module using the slcdc_api_t::open API.
2. Write a sequence of segments using the slcdc_api_t::write API.
3. Modify the content of the segment data using the slcdc_api_t::modify API if needed.
4. Change the display area or blinking display using the slcdc_api_t::setdisplayArea API.
5. Enable the display by using the slcdc_api_t::start API.
6. Adjust contrast using the slcdc_api_t::contrastIncrease or slcdc_api_t::contrastDecrease APIs.
7. Disable the display by using the slcdc_api_t::stop API.
8. Close the driver using the slcdc_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

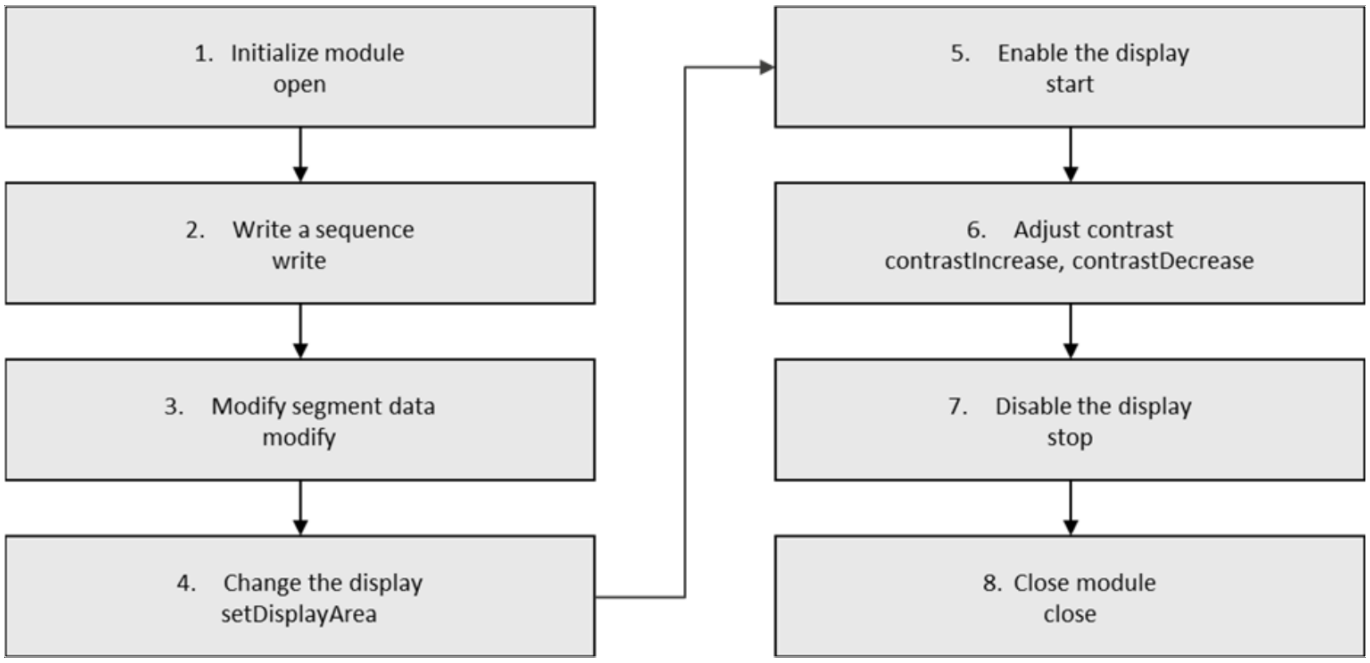

Figure 384: Flow Diagram of a Typical SLCDC HAL Module Application

4.2.45 SCI SPI Driver

4.2.45.1 SCI SPI HAL Module Introduction

The SCI SPI HAL module provides a high-level API for master/slave-based industry standard SPI serial communications and configures and uses the SCI (Serial Communications Interface) peripheral on a Synergy MCU. A user-defined callback can be created to signal when the SPI has transmitted data, aborted a data transfer or detected an error condition.

The SCI SPI HAL module is enabled with a data transfer function support by incorporating the Data Transfer Controller module of the MCU. This performs SPI transfers through the DTC without intervention of the CPU.

SCI SPI HAL Module Features

The SCI SPI HAL module supports the configuration and control of the SPI functions on the Synergy MCU. Key features include the following:

- Driver initialization
- Serial communication through SPI operation using 8-bit data transfers
- Configurable among four clock phase and clock polarity settings
- Support for callbacks. The callback functions are called with the following events:
    - Transfer aborted
    - Transfer complete
    - Over run error

- SPI communication in master and slave mode.

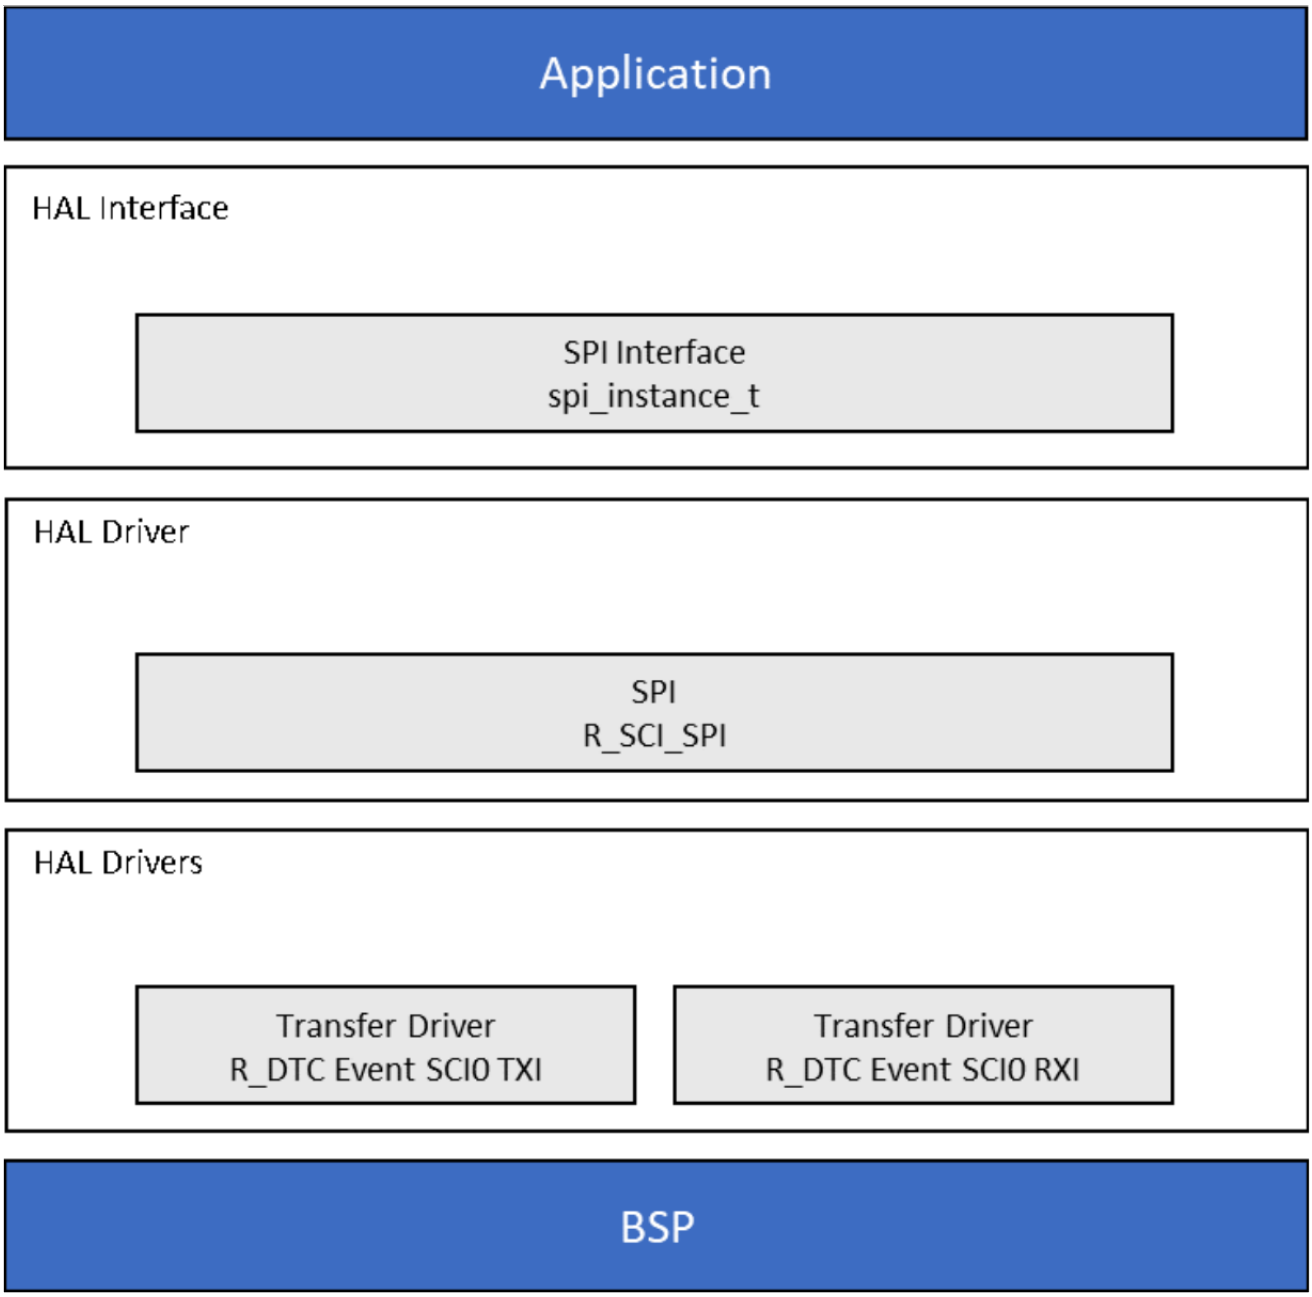

Figure 385: SCI SPI HAL Module Block Diagram

SCI SPI Hardware Support Details

4.2.45.2 SCI SPI HAL Module APIs Overview

The SPI defines APIs for opening and closing the SCI peripheral and transmitting and receiving data. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

SCI SPI HAL Module API Summary

Function Name	Example API Call and Description
.open	g_spi.p_api ->open(g_spi.p_cntl, g_spi.p_cfg); Open a designated SPI device.
.read	g_spi.p_api->read(g_spi.p_ctrl, dst16, length, SPI_BIT_WIDTH_16_BITS); Receive data from SPI device.
.write	g_spi.p_api->write (g_spi.p_ctrl, source, length, SPI_BIT_WIDTH_8_BITS); Transmit data to SPI device
.writeRead	g_spi.p_api ->writeRead (g_spi.p_cntl, &source, &destination, length, SPI_BIT_WIDTH_8_BITS, TX_WAIT_FOREVER); Simultaneously transmits data to an SPI device, while receiving data from an SPI device (full duplex). The writeRead API fetches the mutex object, handles SPI data transmission at SPI HAL layer, and receives data from the SPI HAL layer. The API uses the event flag wait to synchronize to complete the data transfer.
.close	g_spi.p_api->close(g_spi,p_ctrl) Disable the SPI device designated by the control handle and close the RTOS services used by the bus if no devices are connected to the bus. This function removes power to the SPI channel designated by the handle and disables the associated interrupts.
.versionGet	g_spi.p_api ->versionGet (&version); Get the version information of the underlying driver.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API Call Successful.
SSP_ERR_IN_USE	Attempted to open an already open device instance OR Another transfer was in progress.
SSP_ERR_INVALID_POINTER	p_version is NULL.
SSP_INVALID_ARGUMENT	Channel number invalid.
SSP_ERR_HW_LOCKED	The lock could not be acquired. The channel is busy.

SSP_ERR_CH_NOT_OPEN	The channel has not been opened. Open channel first.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.45.3 SCI SPI HAL Module Operational Overview

The SCI SPI HAL module provides the ability to configure and use the SPI capabilities of the Synergy MCU. The SCI SPI HAL module enables communication with a peripheral device using the SPI communications protocol. After opening the SCI SPI HAL module instance, the SCI SPI module handle is used to perform various transfer operations. The device control handle will be used within the API calls to indicate the specific SCI SPI device to communicate with.

The SCI SPI HAL module allows the user to:

- Initialize the module.
- Serial Communication through SPI operation. Read from and write to (and simultaneous read/write – full duplex) a SPI device – performed by calling the spi_api_t::read, spi_api_t::write and spi_api_t::writeRead APIs.

The Driver also provides support for callbacks. The callback functions are called with the following events:

- Transfer aborted
- Transfer complete
- Overrun error

The SCI SPI module supports only 8-bit data transfer operations. The SCI SPI module uses GPIO pins configured as chip selects.

Clock Settings

The SCI SPI uses PCLKA as its clock source. You can set the PCLKA frequency using the clock configurator in e^2 studio or the CGC Interface at run-time.

I/O Port Settings

To use with the SPI, the I/O port pin(s) used as output pins must be configured as SCI SPI peripheral pins in the pin configurator. For external chip select, configure Chip select pin as GPIO output.

SCI SPI Interrupts

To enable the interrupts of the SCI SPI, highlight the driver module and set the priority of the SCI RXI, TXI, TEI and ERI interrupts on the **Threads** tab of the Project Configurator in e^2 studio: Configuring Interrupts.

This sets the corresponding interrupts in ssp_cfg/bsp/bsp_irq_cfg.h to the priority level selected.

Note

Setting the interrupts to different priority levels could result in improper operation.

SCI SPI HAL Module Important Operational Notes and Limitations

SCI SPI HAL Module Operational Notes

- Chip select outputs are supported using GPIOs
- The SCI SPI HAL module uses only 8-bit data transfers.
- Setting the interrupts to different priority levels could result in improper operation.
- The SCI SPI HAL module is enabled with a data transfer support by incorporating the Data Transfer Controller module of the MCU. This performs an SPI transfer through the DTC without intervention of the CPU. The DTC transfer is enabled by default; the user has to remove it from the configurator for an IRQ mode transfer.

SCI SPI HAL Module Limitations

- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.45.4 Including the SCI SPI HAL Module in an Application

This section describes how to include the SPI HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the SPI Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the SPI Driver is g_spi0. This name can be changed in the associated Properties window.)

SCI SPI HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_spi0 SPI Driver on r_sci_spi	Threads	**New Stack> Driver> Connectivity> SPI Driver on r_sci_spi**

When the SPI Driver on r_sci_spi is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

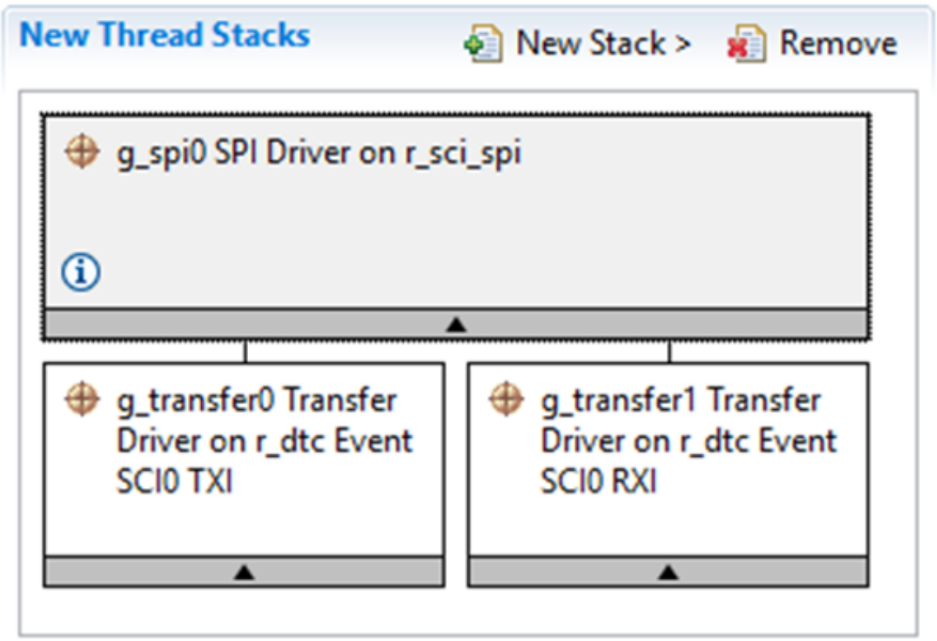

Figure 386: SPI HAL Module Stack

4.2.45.5 Configuring the SCI SPI HAL Module

The SPI HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the SCI SPI HAL Module on r_sci_spi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name.
Channel	0	SCI or SPI Channel number to which the device has been connected.

Operating Mode	Master, Slave Default : Master	Configure as a Master or Slave device.
Clock Phase	Data sampling on odd edge, data variation on even edge/Data sampling on even edge, data variation on odd edge Default: Data sampling on odd edge, data variation on even edge	Data sampling on odd or even clock edge.
Clock Polarity	Low when idle, High when idle Default: Low when idle	Clock level when idle.
Mode Fault Error	Enable, Disable Default: Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First, LSB First Default: MSB First	Select transmit order MSB/LSB first.
Bitrate	100000	Transmission or reception rate. Bits per second.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bitrate Modulation Function enable or disable.
Callback	NULL	Optional Call back function pointer.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Error interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SCI SPI HAL Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module:

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency seleciton.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.

ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer1	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SCI0 RXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.

ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Disabled	ELC software event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

SCI SPI HAL Module Clock Configuration

The SCI peripheral is clocked via the Peripheral Clock A (PCLKA.) The clock frequencies are configurable in the ISDE by using the Clocks tab in the configurator. Invalid selections are indicated in red when selected. Ensure that desired SPI bitrate can be achieved with the stated value of PCLKA. The ISDE will not be indicated if the specified bitrate is not achievable. At run time, the SPI HAL module will attempt to configure the SCI peripherals to the correct bitrate and will return an error if the desired bitrate cannot be set. The bitrate is calculated via the equations in the following table. If the result of the equation (N) is in the range of 0 to 255, then the bit rate can be achieved.

Baud Rate Calculation Equations

SPI HAL	Bitrate calculation	Description
SPI on SCI	$N = \frac{PCLKA\ (MHz)}{8 * 2^{(2n-1)} * \left(256/M\right) * B} - 1$	N = Peripheral register value. This must be in the range of 0 to 255 PLCKA = value of PLCKA in MHz n = 0, 1, 2 or 3 M = Bit Rate Modulation Index 128 < M < 256 *If the Bit Rate Modulation is disabled, then M=256* B = Desired Bit Rate

SCI SPI HAL Module Pin Configuration

The SCI peripheral use pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the SPI pins:

Note

The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for SCI SPI HAL Module on r_sci_spi

Resource	ISDE Tab	Pin Selection Sequence
SPI on SCI	Pins	Select **Peripherals**> **Connectivity:SCI**> **SCIx,** where x is the required SCI peripheral channel.

Note

The selection sequence assumes SCI0 is the desired hardware target for the driver.

Pin Configuration Settings for the SCI SPI HAL Module on r_sci_spi

Pin Configuration Property	Value	Description
Pin Group Selection	Mixed, _A only, _B only	Synergy devices support peripheral functionality via multiple pins location, identified by _A, _B. Selecting Mixed allows the user to select any combination of locations (_A and _B). Selecting _A allows the user to select only _A locations. Selecting _B allows the user to select only _B locations.
Operation Mode	Disabled Custom Asynchronous UART Simple SPI Simple I2C Synchronous UART Smart Card	Set the operating mode to: Simple SPI.
TXD_MOSI	None, P411, P101	Specify the port pin to be used as MOSI.
RXD_MISO	None, P410, P100	Specify the port pin to be used as MISO.
SCK	None, P412, P102	Specify the port pin to be used as CLK.
CTS_RTS_SS	None, P413, P103	Specify the port pin to be used as SS.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.*

4.2.45.6 Using the SCI SPI HAL Module in an Application

The steps in using the SCI SPI HAL module in a typical application are:

Note

The spi_api_t::open API function must be called first. The rest of the calls may be used in any order depending on the application requirements:

1. Initialize an SPI instance using the spi_api_t::open API function. (g_spi.p_api->open (g_spi.p_ctrl, g_spi.p_cfg) where p_ctrl and p_cfg are the instances of control and configuration structures autogenerated after the configuration step).
2. Initiate a write to a slave device using the spi_api_t::write API function. (g_spi.p_api->write (g_spi.p_ctrl, source, length, SPI_BIT_WIDTH_8_BITS); where g_spi.p_ctrl is the same control instance that was used in the spi_api_t::open call).

3. Initiate a read from a slave device using the spi_api_t::read API function. (g_spi.p_api->read(g_spi.p_ctrl, dst, length, SPI_BIT_WIDTH_8_BITS); where g_spi.p_ctrl is the same control instance that was used in the spi_api_t::open call).
4. Initiate a data transfer in both directions with a slave device using the spi_api_t::writeRead API function. (g_spi.p_api->writeRead(g_spi.p_ctrl, source, s_length, destination, d_length, SPI_BIT_WIDTH_8_BITS); where g_spi.p_ctrl is the same control instance that was used in the spi_api_t::open call).
5. Use the spi_api_t::close API function to close the instance. (g_spi.p_api->close(g_spi,p_ctrl) where g_spi.p_ctrl is the same control structure that was used in the spi_api_t::open call).

These common steps are illustrated in a typical operational flow diagram in the following figure:

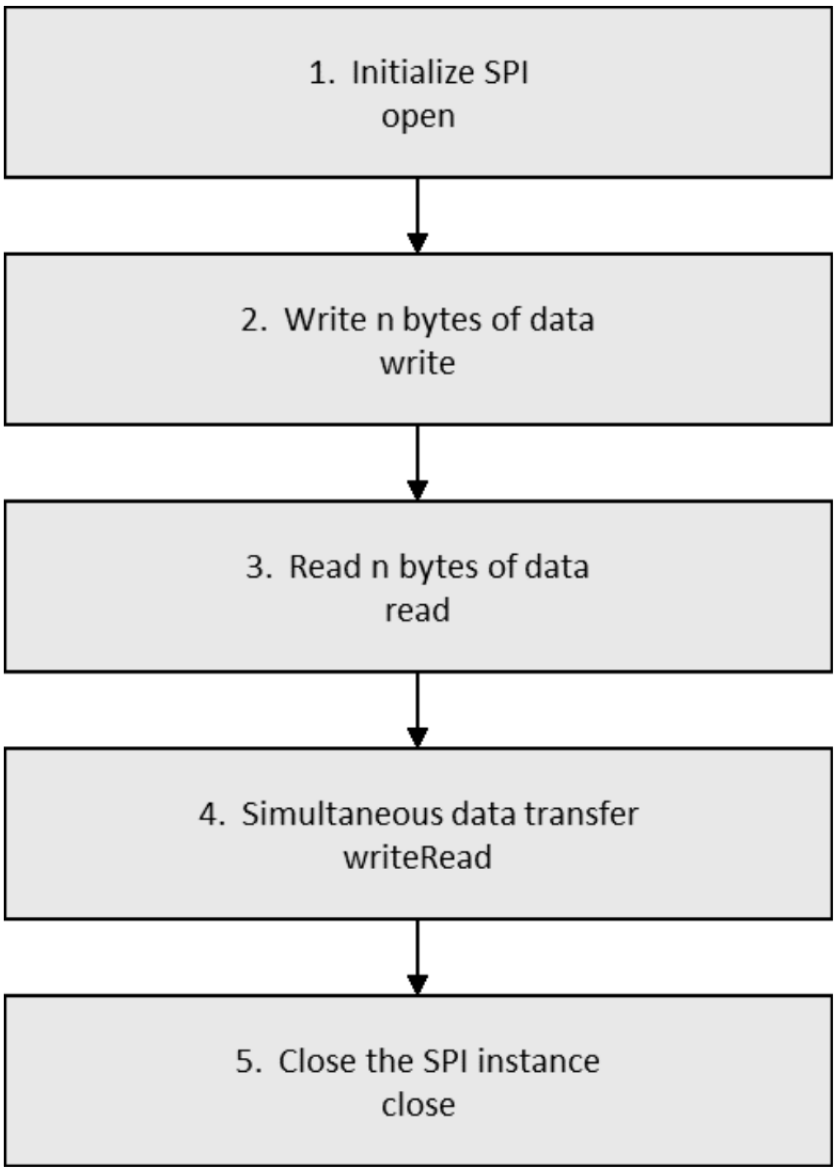

Figure 387: Flow Diagram of a Typical SPI HAL Module Application

4.2.46 SPI Driver

4.2.46.1 RSPI HAL Module Introduction

The RSPI HAL module provides a high-level API for serial communication using the SPI protocol. The module supports the SPI (formerly known as RSPI) peripheral available on the Synergy microcontroller hardware. The RSPI HAL module supports standard SPI master and Slave mode communications functions. Callbacks are provided for transfer events. The RSPI HAL module is enabled with data transfer support by incorporating the data transfer controller module of the MCU; this performs SPI transfers through the DTC without requiring interrupt processing for each frame.

RSPI HAL Module Features

- Initialization of the driver
- SPI transfer functions:
    - Allows serial communication through the SPI operation using the four-wire method
    - Capable of serial communication in master and slave modes
    - Switching the polarity of the serial transfer clock
    - Switching the phase of the serial transfer clock
- Data Format
    - MSB-first/LSB-first selectable
    - Transfer bit length is selectable as 8, 16 and 32 bits
    - 16-bit and 32-bit byte swapping for both received and transmitted data register
- Error Detection
    - Mode fault detection
    - Overrun error detection
    - Parity error detection
- SSL control functions
    - External hardware slave select can be used in master mode
- Interrupts
    - RSPI receive interrupt (receive buffer full)
    - RSPI transmit interrupt (transmit buffer empty)
    - RSPI error interrupt (mode fault, overrun and parity error)
- Delays
    - Add SPI clock delay
    - Add slave select negation delay
    - Add next-access delay

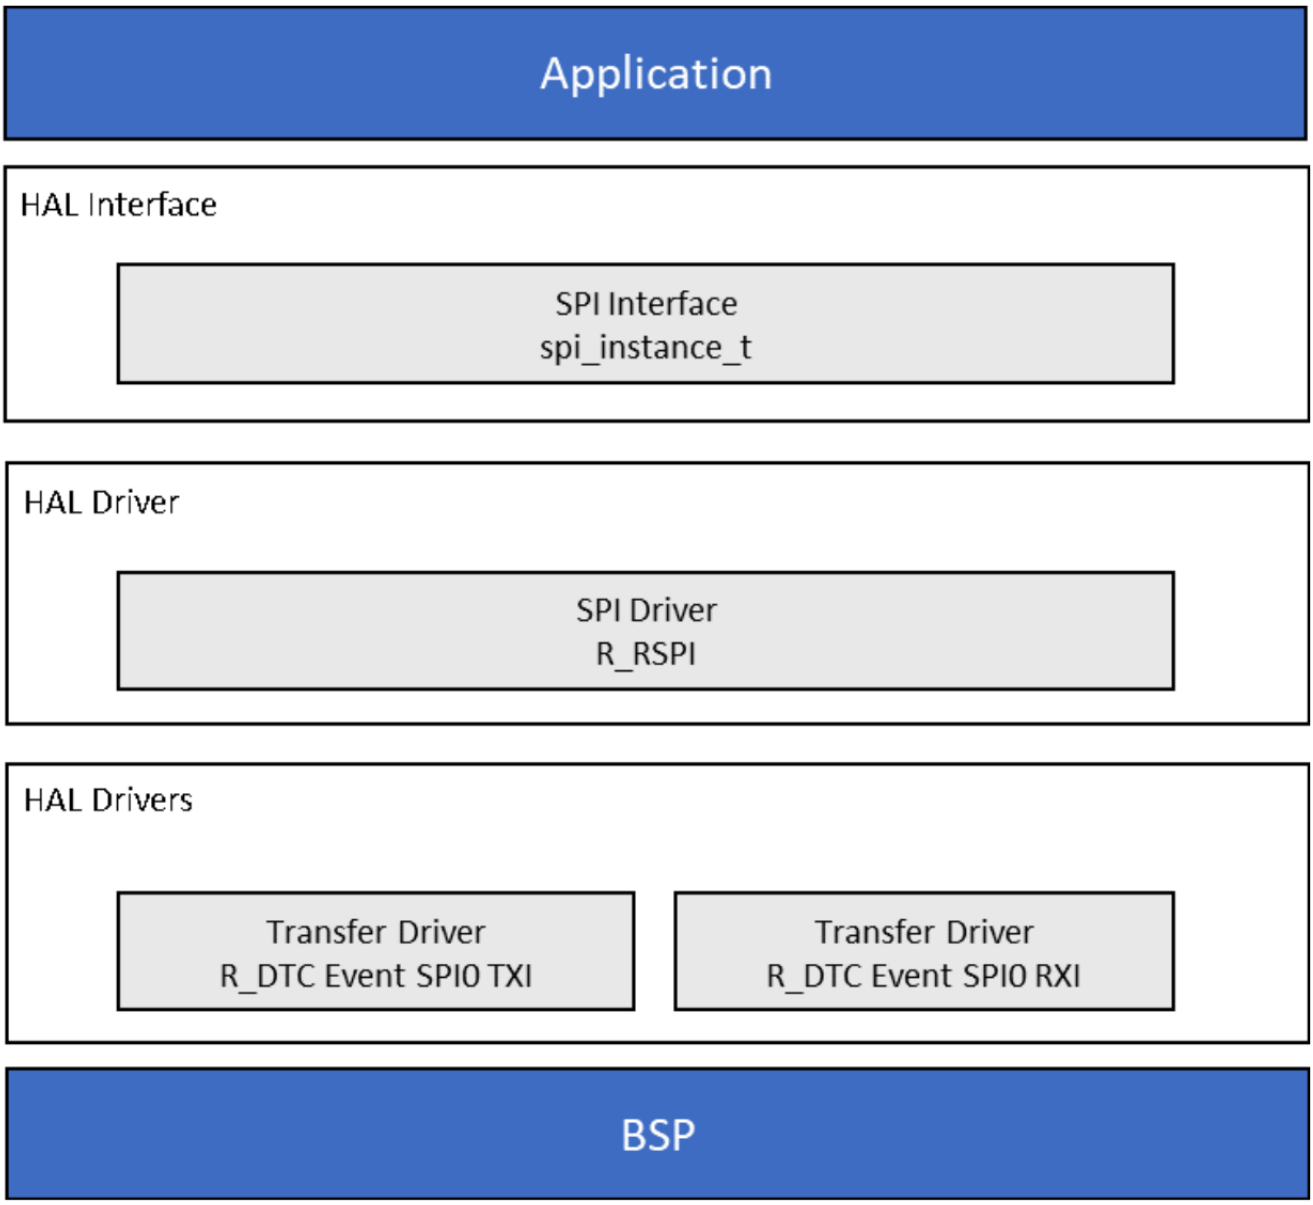

Figure 388: RSPI HAL Module Block Diagram

RSPI Hardware Support Details

The following hardware features are, or are not, supported by SSP for the RSPI.

4.2.46.2 RSPI HAL Module APIs Overview

The RSPI HAL module defines API functions for opening, closing, reading, writing and other useful functions. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

RSPI HAL Module API Summary

Function Name	Example API Call and Description
.open	g_spi.p_api ->open(g_spi.p_cntl, g_spi.p_cfg); Open a designated SPI device.
.read	g_spi.p_api->read(g_spi.p_ctrl, dst16, length, SPI_BIT_WIDTH_16_BITS); Receive data from SPI device.
.write	g_spi.p_api->write (g_spi.p_ctrl, source, length, SPI_BIT_WIDTH_8_BITS); Transmit data to SPI device
.writeRead	g_spi.p_api ->writeRead (g_spi.p_cntl, &source, &destination, length, SPI_BIT_WIDTH_8_BITS, TX_WAIT_FOREVER); Simultaneously transmits data to an SPI device, while receiving data from an SPI device (full duplex). The writeRead API fetches the mutex object, handles SPI data transmission at SPI HAL layer, and receives data from the SPI HAL layer. The API uses the event flag wait to synchronize to complete the data transfer.
.close	g_spi.p_api->close(g_spi,p_ctrl) Disable the SPI device designated by the control handle and close the RTOS services used by the bus if no devices are connected to the bus. This function removes power to the SPI channel designated by the handle and disables the associated interrupts.
.versionGet	g_spi.p_api ->versionGet (&version); Get the version information of the underlying driver.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function completed successfully
SSP_ERR_INVALID_MODE	Invalid mode
SSP_ERR_INVALID_CHANNEL	Invalid channel
SSP_ERR_IN_USE	In-use error
SSP_ERR_INVALID_ARGUMENT	Invalid argument
SSP_ERR_QUEUE_UNAVAILABLE	Queue unavailable

SSP_ERR_INVALID_POINTER	Invalid pointer
SSP_ERR_INTERNAL	Internal error
SSP_ERR_TRANSFER_ABORTED	Transfer aborted
SSP_ERR_MODE_FAULT	Mode fault
SSP_ERR_READ_OVF	Read overflow
SSP_ERR_PARITY	Parity error
SSP_ERR_OVERRUN	Overrun error
SSP_ERR_UNDEF	Unknown error
SSP_ERR_TIMEOUT	Timeout error
SSP_ERR_NOT_OPEN	Device not opened

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.46.3 RSPI HAL Module Operational Overview

The RSPI HAL module enables communication with a peripheral device using the SPI communications protocol. After opening the module instance, the module handle is used to perform various transfer operations. The device control handle will be used within the API calls to indicate the specific SPI device with which to communicate.

The Driver allows the application program to:

- Initialize the driver.
- Implement serial communication through SPI operation.

The module also provides support for callbacks. The callback functions are called with the following events spi_event_t

- Transfer aborted
- Transfer complete
- Mode fault
- Error events

The RSPI HAL module supports 8, 16 and 32-bit data transfers. The module supports GPIO pins configured as chip selects. In addition, the SPI peripheral supports dedicated chip select signal, SSL. When the SSL pin is enabled in the SPI peripheral, chip select handling is performed by the hardware.

Clock settings:

The SPI peripheral uses the PCLKA as its clock source. You can set the PCLKA frequency using the clock configurator in e^2 studio or the CGC Interface at run-time.

Note

For S1 devices the SPI peripheral clock source is PCLKB.

IO Port settings:

To use with the SPI peripheral, the I/O port pin(s) used as output pins must be configured as SPI peripheral pins in the pin configurator. If you are using an external chip select, configure Chip select pin as GPIO output.

Extended configuration:

A number of extended hardware specific configurations are present for SPI Driver.

Note

All extended hardware specific configuration parameters are set in the extended driver configuration structure spi_on_rspi_cfg_t.

RSPI HAL Module Important Operational Notes and Limitations

RSPI HAL Module Operational Notes

While configuring the RSPI HAL drivers, setting the interrupts to different priority levels could result in improper operation.

The module is enabled with a data transfer support by incorporating the Data Transfer Controller module of the MCU. This performs SPI transfers through the DTC without the intervention of the CPU.

In the application, data transfers over the DTC are used in the same way as normal SPI transfers. To enable DTC transfers, add the DTC module under the RSPI HAL module.

The RSPI HAL module supports 8-, 16-, and 32-bit data transfers in both CPU and DTC-based transfer modes. 16- and 32-bit transfers will be endian swapped.

The RSPI HAL drivers also provide supports swapping oftransmit/receive data in byte units for both 16-bit and 32-bit data transfer (big endian to little endian).This feature is applicable only for S5 series MCUs.

The RSPI HAL module supports run time configuration of 8-, 16- and 32-bit data transfers for both CPU and DTC data transfer modes. The DTC transfer size can be any irrespective of user API bit-width.

Performance Notes

The RSPI HAL module can be configured for several different modes, each with different performance characteristics. DTC transfers take slightly longer to setup than CPU-based transfers due to resetting the DTC, but DTC transfers offer greater performance for transfers larger than 1 frame because no intervention is required from the CPU.

Write operations will configure the module for transmit-only mode, disabling the receive interrupt and ignoring incoming data. CPU-based write operations at high bitrates can result in the transmit ISR being constantly called, blocking other code from running. spi_api_t::writeRead and spi_api_t::read operations will configure the module for full duplex mode.

There is a lower limit of 3 SPI clock cycles between transfers resulting in an effective bitrate slower than configured. At high bitrates, the time between transfers can be longer, especially for CPU-based transfers.

The module will wait for the hardware to enter an idle state when in master mode, or all data to be transmitted or received when in slave mode, before invoking the callback.

RSPI HAL Module Limitations

- When the RSPI HAL module is used in slave mode, either the data must be sampled on the even clock edge (that is, CPHA=1) or the master must de-assert the slave select line between the frames when data is sampled on the odd clock edge (that is, CPHA=0). This is a hardware limitation.
- The S124, S128, and S3A6 do not support SSL Level Keep.
- Once the driver has been opened using the DTC or CPU, all transfers must use the bit width configured by the user.
- 16- and 32-bit transfers will be endian swapped.
- The R_RSPI bit rate value must be a positive integer less than 30 MHz or PCLK/2, whichever is smaller.
- r_rspi data transfers will be incomplete when DMAC is used simultaneously by another module. User callback will occur before the data is completely transferred.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.46.4 Including the RSPI HAL Module in an Application

This section describes how to include the SPI HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the SPI Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the SPI Driver is g_spi0. This name can be changed in the associated Properties window.)

RSPI HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_spi0 SPI Driver on r_rspi	Threads	**New Stack> Driver> Connectivity> SPI Driver on r_rspi**

When the SPI Driver on r_rspi is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

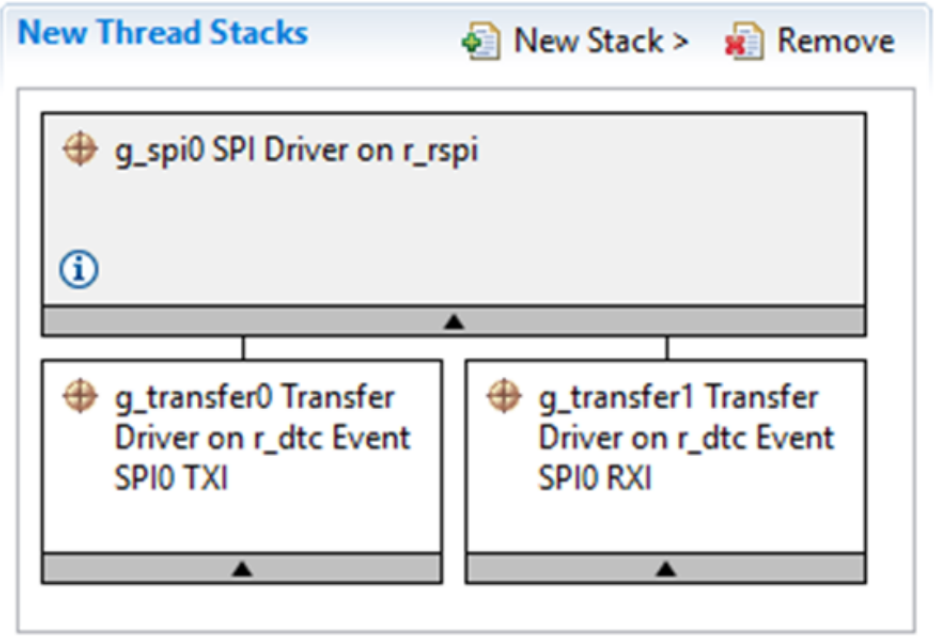

Figure 389: SPI HAL Module Stack

4.2.46.5 Configuring the RSPI HAL Module

The SPI HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the RSPI HAL Module on r_rspi

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_spi0	Module name.
Channel	0	SCI or SPI Channel number to which the device has been connected.

Operating Mode	Master, Slave Default: Master	Configure as a Master or Slave device.
Clock Phase	Data sampling on odd edge, data variation on even edge/Data sampling on even edge, data variation on odd edge Default: Data sampling on odd edge, data variation on even edge	Data sampling on odd or even clock edge. Note: If CPHA is set to 0 in slave mode, slave select should not be fixed at active state and burst transfer should not be performed.
Clock Polarity	Low when idle, High when idle Default: Low when idle	Clock level when idle.
Mode Fault Error	Enable, Disable Default: Disable	Indicates Mode fault error (master/slave conflict) flag.
Bit Order	MSB First, LSB First Default: MSB First	Select transmit order MSB/LSB first
Bitrate	500000	Transmission or reception rate. Bits per second.
Callback	NULL	Optional Callback function pointer.
SPI Mode	SPI Operation, Clock synchronous operation Default: SPI Operation	Select spi or clock syn mode operation.
SPI Communication Mode	Full Duplex, Transmit Only Default: Full Duplex	Select full-duplex or transmit-only communication.
Slave Select Polarity(SSL)	Active Low, Active High Default: Active Low	Select SSL signal polarity.
Select Loopback1	Normal, Inverted Default: Normal	Select loopback1.
Select Loopback2	Normal, Inverted Default: Normal	Select loopback2.
Enable MOSI Idle State	Enable, Disable Default: Disable	Select MOSI idle fixed value and selection.

MOSI Idle State	MOSI Low, MOSI High Default: MOSI Low	Select mosi idle fixed value and selection.
Enable Parity	Enable, Disable Default: Disable	Enable/disable parity.
Parity Mode	Parity Odd, Parity Even Default: Parity Odd	Select parity.
Select SSL Level After Transfer	SSL Level Keep, SSL Level Do Not Keep Default: SSL Level Do Not Keep	Select SSL level after transfer completion; 0-negate; 1-keep. Note: If CPHA = 0 in slave mode, slave select level after transfer should not be set to SSL level Keep.
Clock Delay Enable	Clock Delay Enable, Clock Delay Disable Default: Clock Delay Disable	Clock delay enable selection.
Clock Delay Count	Clock Delay 1 thru 8 RSPCK Default: Clock Delay 1 RSPCK	Clock delay count selection.
SSL Negation Delay Enable	Negation Delay Enable, Negation Delay Disable Default: Negation Delay Disable	SSL negation delay enable selection.
Negation Delay Count	Negation Delay 1 thru 8 RSPCK Default: Negation Delay 1 RSPCK	Negation delay count selection.
Next Access Delay Enable	Next Access Delay Enable, Next Access Delay Disable Default: Next Access Delay Disable	Next access delay enable selection.
Next Access Delay Count	Next Access Delay 1 thru 8 RSPCK Default: Next Access Delay 1 RSPCK	Next access delay count selection.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Receive interrupt priority selection.

Transmit Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Priority 2	Error interrupt priority selection.
Byte Swap(Only for S5 series MCUs)Disable	Enable, Disable Default: Disable	Enable byte swapping (applicable only for S5 series MCUs).

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.
RSPI driven slave select currently supports SSL0 only.

Configuration Settings for the SPI HAL Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module:

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte, 2 Bytes, 4 Bytes Default: 2 Bytes	Transfer size selection.

Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SPI0 TXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SPI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer1	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte, 2 Bytes, 4 Bytes Default: 2 Bytes	Transfer size selection.

Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection.
Auto Enable	FALSE	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.
ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:2, Priority 3 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

RSPI HAL Module Clock Configuration

The SPI peripheral is clocked via Peripheral Clock A (PCLKA). The clock frequencies are configurable in the ISDE by using the Clocks Tab in the configurator. Invalid selections are indicated in red when selected. Ensure that desired SPI bitrate can be achieved with the stated value of PCLKA. The ISDE will not be indicated if the specified bitrate is not achievable. At run time, the SPI driver will attempt to configure the SPI peripheral to the correct bitrate and will return an error if the desired bitrate cannot be set. The bitrate is calculated via the equations in the table below. If the result of the equation (n) is in the range of 0 to 255, then the bit rate can be achieved.

Baud Rate Calculation Equations

SPI HAL	Bitrate calculation	Description
SPI on SPI	$n = \frac{PCLKA\ (MHz)}{2 * 2^N * B} - 1$	n = Peripheral register value. This has to be in the range of 0 to 255 PLCKA = value of PLCKA in MHz N = 0, 1, 2 or 3 B = Desired Bit Rate

RSPI HAL Module Pin Configuration

The SPI peripheral module uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example listing a selection for SPI pins:

Note

The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for SPI HAL Module on r_riic

Resource	ISDE Tab	Pin selection Sequence
RSPI	Pins	Select **Peripherals**> **RSPI**> **SPI0_Pin_Option_A/B.**

Note

The selection sequence assumes SPI0 is the desired hardware target for the driver.

Pin Configuration Settings for the SPI HAL Module on r_sci_uart

Pin Configuration Property	Value	Description
Operation Mode	Disabled, Custom, Enabled Default: Disabled	Select Enabled for SPI Operation.
MISO	None, P100, P410 Default: None	MISO Pin selection.
MOSI	None, P101, P411 Default: None	MOSI Pin selection.
RSPCLK	None, P102, P412 Default: None	RSPCLK Pin selection.
SSL0:3	None, P103:106, P413:415 Default: None	SSL0:3 Pin selections.

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.46.6 Using the SPI HAL Module in an Application

The steps in using the SPI HAL module in a typical application are:

Note

The spi_api_t::open API must be called first, but the rest of the calls may be used in any order depending on the application requirements.

1. Initialize the module using the spi_api_t::open API.
2. Write to a slave device by using the spi_api_t::write API.
3. Read from a slave device using the spi_api_t::read API.
4. Close the module by calling the spi_api_t::close API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

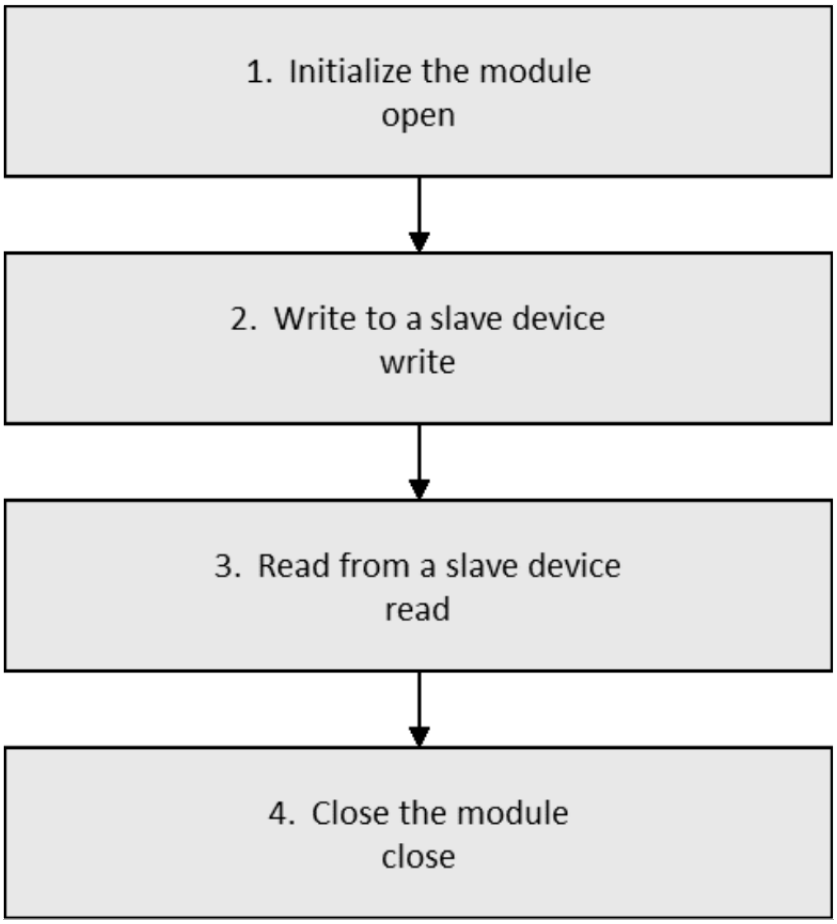

Figure 390: Flow Diagram of a Typical SPI HAL Module Application

4.2.47 UART Driver

4.2.47.1 UART HAL Module Introduction

The UART HAL Module provides a high-level API for industry standard UART serial communications applications and uses the SCI peripherals on the Synergy MCU. A user-defined callback can be created to manage hardware-handshake and data operation, if needed.

UART HAL Module Features

The UART HAL module supports the standard UART protocol. The UART HAL module used in concert with the SCI peripheral in UART mode (UART on SCI) supports the following features (in addition to

the standard UART protocol):

- Full-duplex UART communication
- Simultaneous communication with multiple channels
- Interrupt-driven data transmission and reception
- Invoking the user-callback function with an event code in the argument
- Baud-rate change at run-time
- Hardware resource locking during UART transaction
- CTS/RTS hardware flow control (with an associated IOPORT pin and supported by user-defined callback function)
- Integration with the DTC transfer module
- Abort in-progress read/write operations

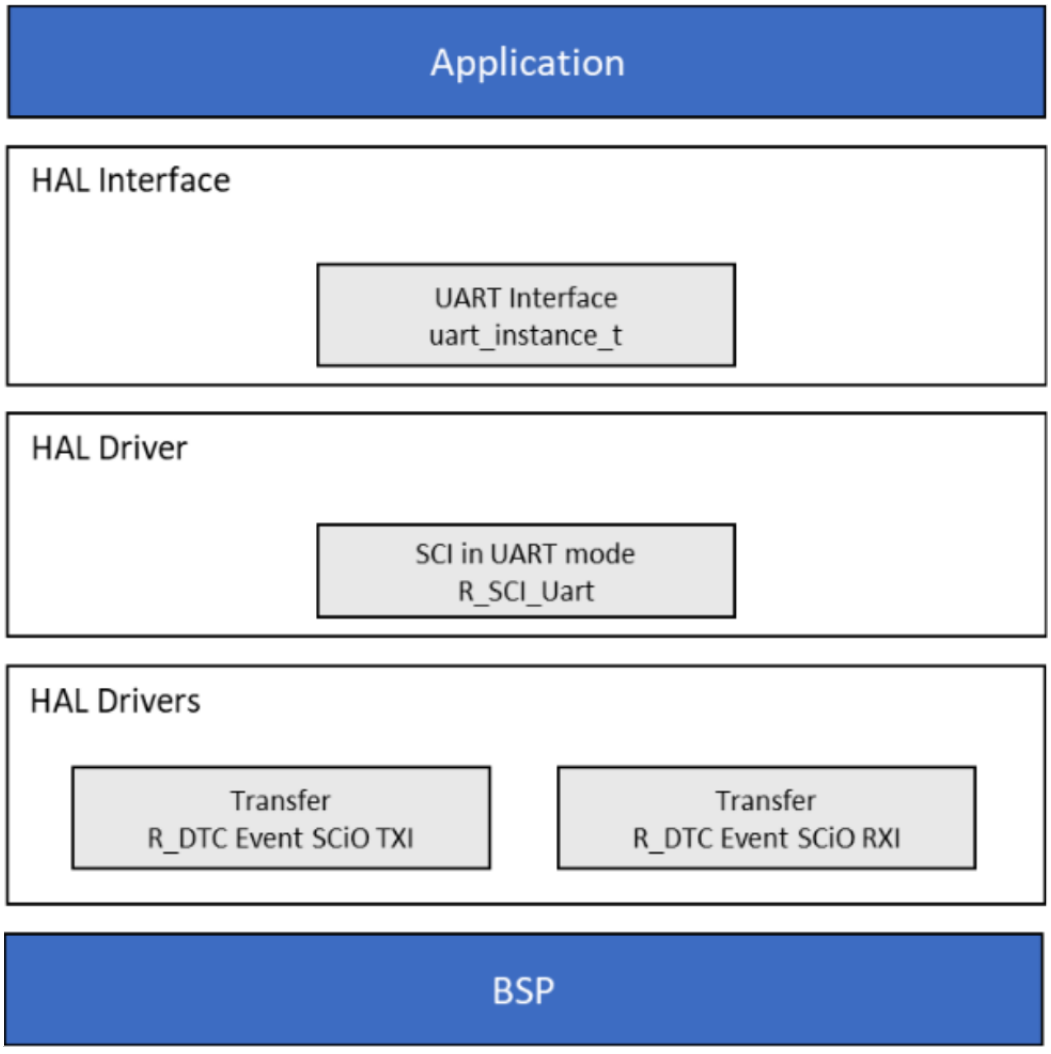

Figure 391: UART HAL Module Block Diagram

UART Hardware Support Details

The following hardware features are, or are not, supported by SSP for the UART (SCI).

4.2.47.2 UART HAL Module APIs Overview

The UART HAL module interface defines APIs for key features such as opening, closing, reading, writing and setting the baud rate. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

UART HAL Module API Summary

Function Name	Example API Call and Description
open	g_uart0.p_api->open(g_uart0.p_ctrl, g_uart0.p_cfg); Open UART device.

read	g_uart0.p_api->read(g_uart0.p_ctrl, uart0_buf, uart0_rcv_num); Read from UART device. The received bytes are stored directly in the read input buffer, uart0_buf. When a transfer is complete/expected bytes are received, the callback is called with event UART_EVENT_RX_COMPLETE. When the uart_api_t::read API is not called then the bytes will be received in the callback function with event UART_EVENT_RX_CHAR for each byte.
write	g_uart0.p_api->write(g_uart0.p_ctrl, uart0_buf, uart0_send_num) Write to UART device. The write buffer is used until write is complete. Do not overwrite write buffer contents until the write is finished. When the write is complete (all bytes are fully transmitted on the wire), the callback called with event UART_EVENT_TX_COMPLETE.
baudSet	g_uart0.p_api->baudSet(g_uart0.p_ctrl, (uint32_t)9600); Change baud rate.
infoGet	g_uart0.p_api->infoGet(g_uart0.p_ctrl, &uart_info); Get the driver specific information.
close	g_uart0.p_api->close(g_uart0.p_ctrl); Close UART device.
versionGet	g_uart0.p_api->versionGet(version); Retrieve the API version with the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Channel operates successfully.
SSP_ERR_IN_USE	Control block has already been opened or channel is being used by another instance.
SSP_ERR_ASSERTION	Pointer to UART control block is NULL or configuration structure is NULL.
SSP_ERR_HW_LOCKED	Channel is locked.
SSP_ERR_INVALID_MODE	Channel is used for non-UART mode or illegal mode is set.

SSP_ERR_INVALID_ARGUMENT	Invalid parameter setting found in the configuration structure. Or source/destination address or data size is invalid against data length.
SSP_ERR_NOT_OPEN	The control block has not been opened.
SSP_ERR_UNSUPPORTED	SCI_UART_CFG_RX_ENABLE is set to 0.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.47.3 UART HAL Module Operational Overview

The UART HAL Module manages data flow using the standard UART protocol. The high-level APIs are used to read, write and set the baud rate for the UART interface. In addition, interrupts are typically used to simplify the management of low-level activities.

Note

Interrupts need to be enabled for the following functions to operate successfully.

UART on SCI RXI Interrupt

The RXI interrupt is used to control the flow of data received from the UART port. When the amount of received data reaches the expected read length, the ISR invokes a user-defined callback (sci_uart_instance_ctrl_t::p_callback) with the argument uart_callback_args_t to indicate that the received data is complete. When the External RTS Operation option is enabled, the ISR invokes the UART callback function for the RTS external pin control twice: once at the top of ISR and once at the bottom. You can use the callback function to emulate the RTS function (see the UART on SCI hardware flow-control section); this interrupt is activated as long as reception is enabled in the SCI_UART_CFG_RX_ENABLE configuration parameter.

UART on SCI TXI Interrupt

The TXI interrupt handles consecutive transmissions of data to the UART port as requested by the uart_api_t::write API. When no data is left in the transmit circular buffer, the ISR deactivates the TXI interrupt and activates the TEI interrupt to handle the last sequence in the data transmission. This interrupt is activated in the uart_api_t::write API as long as the transmission is enabled by the SCI_UART_CFG_TX_ENABLE configuration parameter.

UART on SCI TEI Interrupt

The TEI interrupt is used to handle a last data transmission to the UART port requested by uart_api_t::write API; this interrupt is activated by TXI ISR and deactivates itself. The ISR invokes a user-defined callback (sci_uart_instance_ctrl_t::p_callback) with the argument uart_callback_args_t to indicate that the end of data istransmit.

UART on SCI ERI Interrupt

The ERI interrupt is used to handle errors that occur in the UART reception. This interrupt is activated in the uart_api_t::open API as long as the reception is enabled by the SCI_UART_CFG_RX_ENABLE configuration parameter. The ISR invokes a user-defined callback (sci_uart_instance_ctrl_t::p_callback) with the argument uart_callback_args_t to indicate uart_event_t cause of an error.

UART HAL Module Important Operational Notes and Limitations

UART HAL Module Operational Notes

UART on SCI Hardware Flow Control

The SCI hardware module supports hardware flow-control for only one of the RTS or CTS signals at a time. CTS and RTS are multiplexed on the CTSn/RTSn pin so that one of the hardware flow-control signals can be used exclusively depending on the use-case. The UART HAL module expands this specification and allows control of both the CTS and the RTS signal by enabling an additional pin for the RTS signal. To enable this mode, set the UART on SCI configurations as follows:

- Set SCI_UART_CFG_EXTERNAL_RTS_OPERATION to Enable.
- Set uart_cfg_t::ctsrts_en to CTS (true).
- Specify a user-callback function name to "Name of UART callback function for the RTS external pin control" in uart_on_sci_cfg_t::p_extpin_ctrl.

The UART on SCI HAL module invokes the user-callback function from the RXI ISR at the top and at the end of processing.

The callback function argument "level" refers to the signal level on the RTS pin for the selected SCI channel.

Note

The HAL module does not handle the GPIO pin-initialization or control it; instead, the user needs to initialize the GPIO pin before starting the UART reception.

The following figure shows the timing diagram of CTS/RTS hardware flow-control with an external GPIO pin used as the RTS signal:

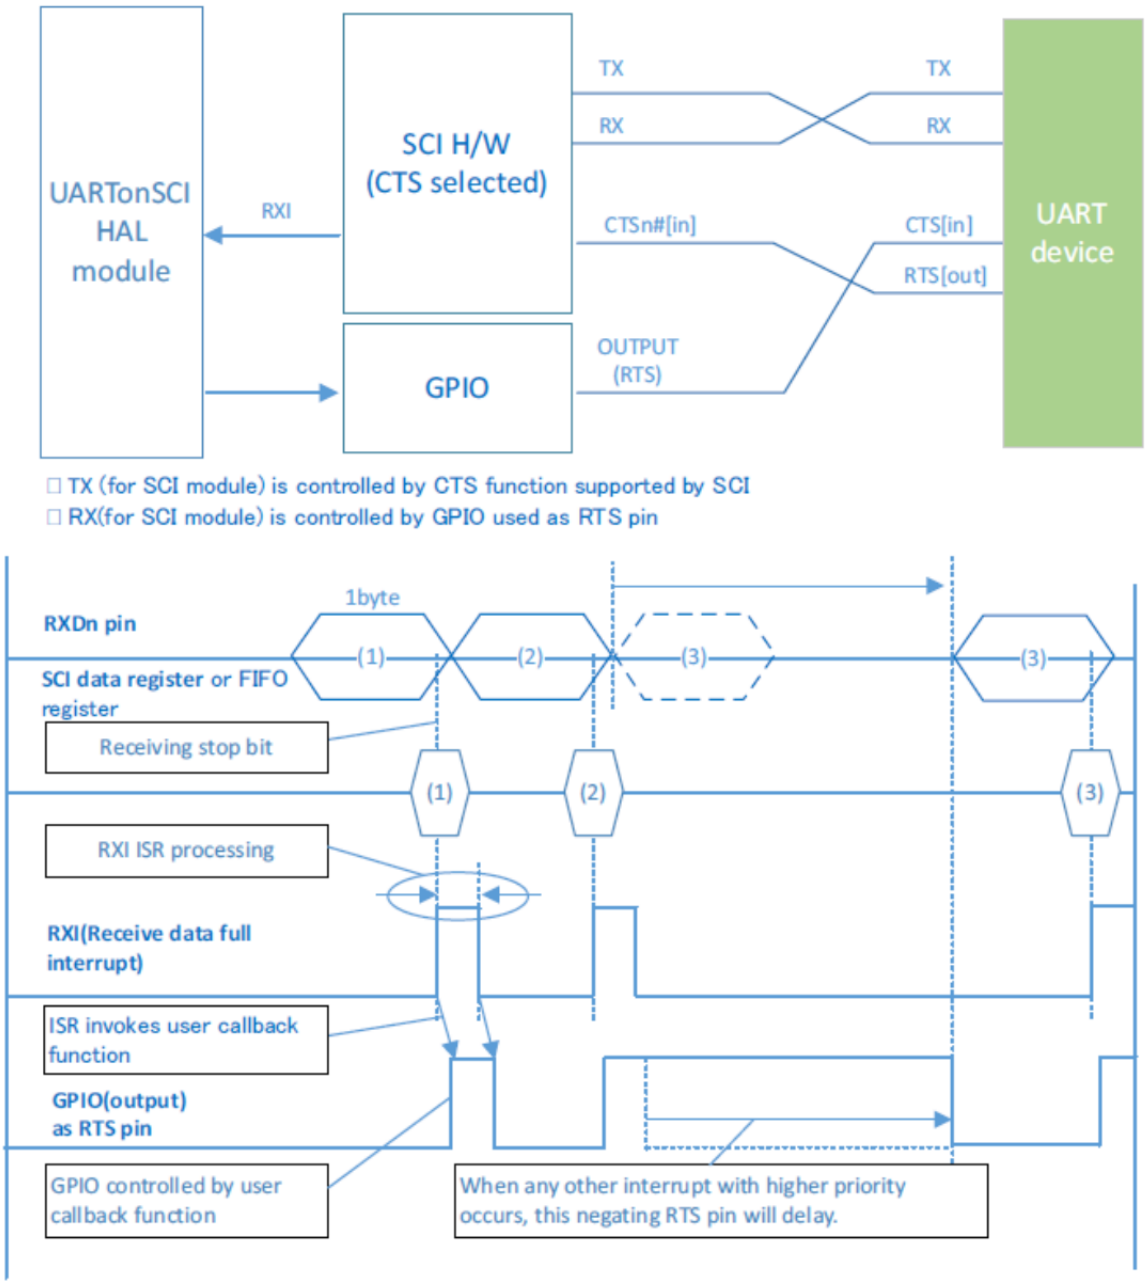

Figure 392: UART HAL Module CTS/RTS Hardware Control with an External GPIO

Note

The UART on SCI module on the SK-S7G2 board uses PORT8 pin0 (pin P800) and J8 to activate the RS232C port on the RS-232C transceiver. Connect pin 1 and pin 2 of J8. Configure pins P800 as IOPORT pins and set its level for the desired operation.

Notes on RS485 Implementations

- For RS485 communication mode, ON pin and RXEN pin should be controlled from the application
- In the case of RS485 Full Duplex communication, configuration of ON pin is not required and in the case of RS485 half-duplex communication, ON should be configured as level Low

- RXEN pin is usually DIP switch (HALF or HD/FD) in Synergy MCUs and is made LOW (ON) for RS485 half-duplex and made HIGH (OFF) for RS485 Full Duplex communication

UART HAL Module Limitations

- The module supports interrupt-based operation but does not support a polled UART mode.
- The module does not support non-buffered UART mode.
- The module does not support Event Link functionality.
- Transfer size must be less than or equal to 64K bytes if DTC interface is used for transfer. uart_api_t::infoGet API can be used to get the max transfer size allowed.
- Reception is still enabled after uart_api_t::communicationAbort API is called. Any characters received after abort and before the next call to read, will arrive via the callback function with event UART_EVENT_RX_CHAR.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.47.4 Including the UART HAL Module in an Application

This section describes how to include the UART HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the UART Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the UART Driver is g_uart0. This name can be changed in the associated Properties window.)

UART HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_uart0 UART on r_sci_uart	Threads	**Threads> Driver> Connectivity> UART Driver on r_sci_uart**

When the UART HAL module on r_sci_uartis added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

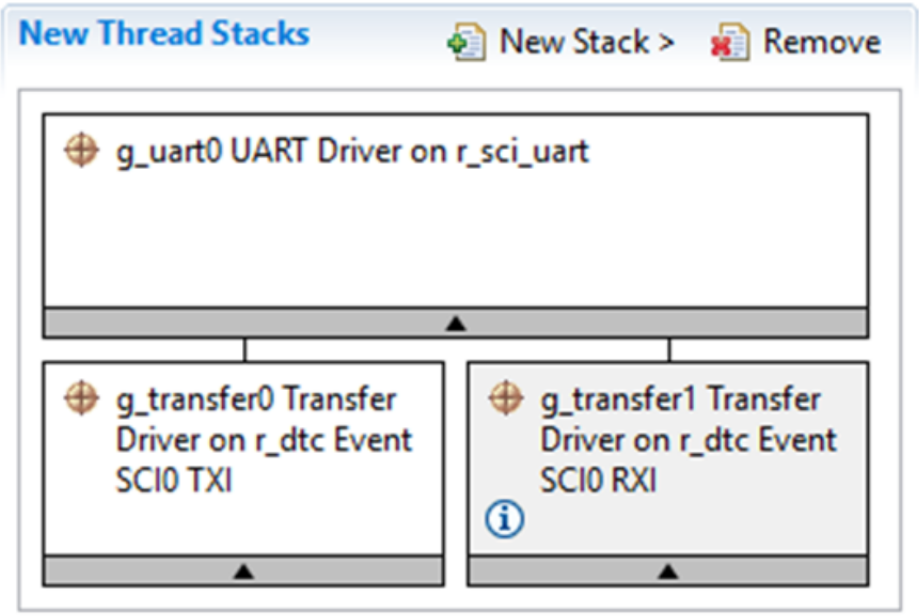

Figure 393: UART HAL Module Stack

4.2.47.5 Configuring the UART HAL Module

The UART HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

ConfigurationSettings for the UART HAL Module on r_sci_uart

ISDE Property	Value	Description
External RTS Operation	Enable, Disable Default: Disable	Enable an IOPORT pin to be used as RTS signal. For RTS functionality set this configuration parameter to "Enable" and specify the configuration "Name of UART callback function for the RTS external pin control".

Reception	Enable, Disable Default: Enable	Enable or disable UART reception for all UART channels on SCI. Setting this configuration parameter to "Disable" reduces code size because the portion of code for UART reception is not compiled. You cannot set this parameter for individual UART channels.
Transmission	Enable, Disable Default: Enable	Enable or disable UART transmission for all UART channels on SCI. Setting "Disable" to this configuration allows to get smaller code size due to the portion of code for UART transmission is compiled out, however, you can only set "Disable" to this configuration if any other SCI channels which work as UART ports do not perform the transmission.
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_uart0	The name to be used for UART on SCI module control block instance. This name is also used as the prefix of the other variable instances.
Channel	0	SCI channel number.
Baud Rate	9600	Baud rate selection.
Data Bits	7 bits, 8, bits, 9 bits Default: 8 bits	UART data bits.
Parity	None, Odd, Even Default: None	UART parity bits.
Stop Bits	1 bit, 2 bits Default: 1 bit	UART stop bits.

CTS/RTS Selection	CTS (Note that RTS is available when enabling External RTS Operation mode which uses 1 GPIO pin), RTS (CTS is disabled) Default: RTS (CTS is disabled)	Select CTS or RTS for the CTSn/RTSn pin of SCI channel n. The SCI hardware supports either the CTS or the RTS control signal on this pin but not both. For an application that uses both CTS and RTS, select "CTS" for this configuration parameter and enable the configuration "External RTS Operation" specifying the configuration "Name of UART callback function for the RTS external pin control".
Name of UART callback function to be defined by user	user_uart_callback	Name must be a valid C symbol.
Name of UART callback function for the RTS external pin control to be defined by user	NULL	Name must be a valid C symbol.
Clock Source	Internal Clock, External Clock 8x baudrate, External Clock 16x baudrate Default: Internal Clock	Selection of the clock source to be used in the baud-rate clock generator block.
Baudrate Clock Output from SCK pin	Enable, Disable Default: Disable	Optional setting to output the baud-rate clock on the SCKn pin for the selected channel n.
Start bit detection	Falling Edge, Low Level Default: Falling Edge	Start bit detection mode in the reception, usually set "Falling Edge" to this configuration.
Noise Cancel	Enable, Disable Default: Disable	Enable the digital noise cancellation on RXDn pin. The digital noise filter block in SCI consists of two-stage flip-flop circuits. For detail, refer to the Noise cancellation section in the Renesas Synergy hardware manual.
Bit Rate Modulation Enable	Enable, Disable Default: Enable	Bit rate modulation enable selection.

Receive FIFO Trigger Level	One, Max Default: Max	Receive FIFO trigger level selection: One: an interrupt occurs for every byte received. Max: an interrupt will be triggered if either of the below conditions are met: a) The FIFO is filled to the Max level (15). b) 15bit times have occurred with no data received.
Receive Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Receive interrupt priority selection.
Transmit Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit interrupt priority selection.
Transmit End Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Transmit end interrupt priority selection.
Error Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	Error interrupt priority selection.
Baud rate Percent Error	Value must be greater than 0.0 and less than 15.0 Default; 2.0	Maximum baudrate percent error allowed in order for the module to function.
UART Communication Mode	RS232, RS485 Default: RS232	UART communication mode selection, usually it is RS232 mode.
UART RS485 Communication Mode	Half Duplex, Full Duplex Default: Half duplex	UART RS485 communication mode selection as half duplex or full duplex.
RS485 DE Port	00 to 11 Default: 09	Select the port number of Driver Enable Pin.
RS485 DE Pin	00 to 15 Default: 14	Select the pin number of Driver Enable Pin.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the UART HAL Module Lower Level Modules

Typically, only a small number of settings must be modified from the default for lower level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and will be locked to prevent user modification. The following tables identify all the settings within the properties section for the module:

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 TXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer0	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Bytes	Transfer size selection.
Destination Address Mode	Fixed	Destination address mode selection.
Source Address Mode	Incremented	Source address mode selection.
Repeat Area (Unused in Normal Mode	Source	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SCI0 TXI	Activation source selection.
Auto Enable	True, False Default: True	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.

ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the Transfer Driver on r_dtc Event SCI0 RXI

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Selects if code for parameter checking is to be included in the build.
Software Start	Enabled, Disabled Default: Disabled	Software start selection.
Linker section to keep DTC vector table	.ssp_dtc_vector_table	Linker section to keep DTC vector table selection.
Name	g_transfer1	Module name.
Mode	Normal	Mode selection.
Transfer Size	1 Byte	Transfer size selection.
Destination Address Mode	Incremented	Destination address mode selection.
Source Address Mode	Fixed	Source address mode selection.
Repeat Area (Unused in Normal Mode	Destination	Repeat area selection.
Interrupt Frequency	After all transfers have completed	Interrupt frequency selection.
Destination Pointer	NULL	Destination pointer selection.
Source Pointer	NULL	Source pointer selection.
Number of Transfers	0	Number of transfers selection.
Number of Blocks (Valid only in Block Mode)	0	Number of blocks selection.
Activation Source (Must enable IRQ)	Event SPI0 RXI	Activation source selection.
Auto Enable	False	Auto enable selection.
Callback (Only valid with Software start)	NULL	Callback selection.

ELC Software Event Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Disabled	ELC Software Event interrupt priority selection.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

When using the UART with CTS and RTS function simultaneously, the transfer driver cannot be used; please delete all transfer drivers on the low level. After being deleted, the optional transfer driver will display in pink, meaning the driver is recommended but optional.

UART HAL Module Clock Configuration

The SCI UART peripheral uses PCLKA as its clock source (PCLKB for S124) or an external clock from the SCKn pin for the selected channel n.

UART HAL Module Pin Configuration

The SCI UART peripheral uses pins on the MCU to communicate to external devices. I/O pins must be selected and configured as required by the external device. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table illustrates an example selection for the UART pins.

Note

The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for UART HAL Module on SCI

Resource	ISDE Tab	Pin selection Sequence
SCI	Pins	Select **Peripherals> Connectivity: SCI > SCI0**

Pin Configuration Settings for the UART HAL Module on r_sci_uart

Pin Configuration Property	Value	Description
Pin Group Selection	Mixed, _A Only, _B Only (Default: Mixed)	Pin grouping selection.
Operation Mode	Disabled, Custom, Asynchronous UART, Simple SPI, Simple I2C, Synchronous UART, SmartCard (Default: Simple SPI)	Select Operation Mode for UART on SCI.
TXD_MOSI	None, P411, P101 (Default: P411)	TXD Pin.
RXD_MISO	None, P410, P100 (Default: P410)	RXD Pin.

SCK	None, P412, P102 (Default: P412)	SCK Pin.
CTS_RTS_SS	None, P413, P103 (Default: None)	CTS Pin.
SDA	Disabled	SDA Pin (when Simple I2C is used).
SCL	Disabled	SCL Pin (when Simple I2C is used).

Note

The example settings are for a project using the Synergy S7G2 MCU Group and the SK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.2.47.6 Using the UART HAL Module in an Application

The steps in using the UART HAL module in a typical application are:

1. Initialize the UART HAL Module using the uart_api_t::open API.
2. Set Baud Rate with the uart_api_t::baudSet API (if needed.)
3. Read and Write data as needed using the uart_api_t::read and uart_api_t::write APIs and callbacks.
4. Read or Write operations can be aborted using uart_api_t::communicationAbort API if required.
5. Close the UART HAL module using the uart_api_t::close API as needed.

These common steps are illustrated in a typical operational flow diagram in the following figure:

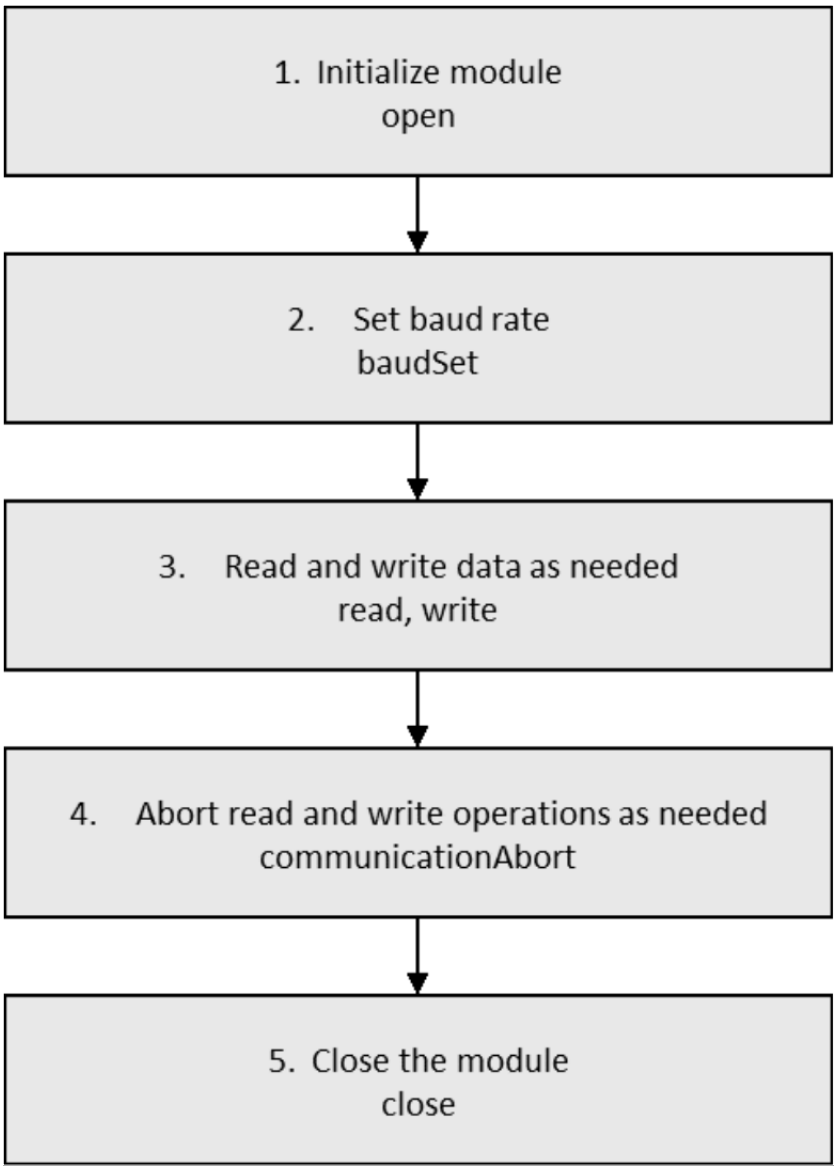

Figure 394: Flow Diagram of a Typical UART HAL Module Application

4.2.48 Watchdog Driver

4.2.48.1 Watchdog Timer HAL Module Introduction

The WDT (Watchdog Timer) HAL module provides a high-level API for critical timing applications and uses the WDT peripheral on the Synergy MCU. A user-defined callback can be created to respond to event notifications.

Watchdog Timer HAL Module Features

The WDT HAL module has the following key features:

- When the WDT underflows or is refreshed outside of the permitted refresh window, one of the following events can occur:
    - Resetting of the device
    - Generation of an NMI
- Supports the Watchdog Timer (WDT) peripheral, which uses an external clock.
- The WDT can be configured in register start mode through the WDT registers.
- Supports automatic hardware configuration after reset.
- The WDT can be started from the application.

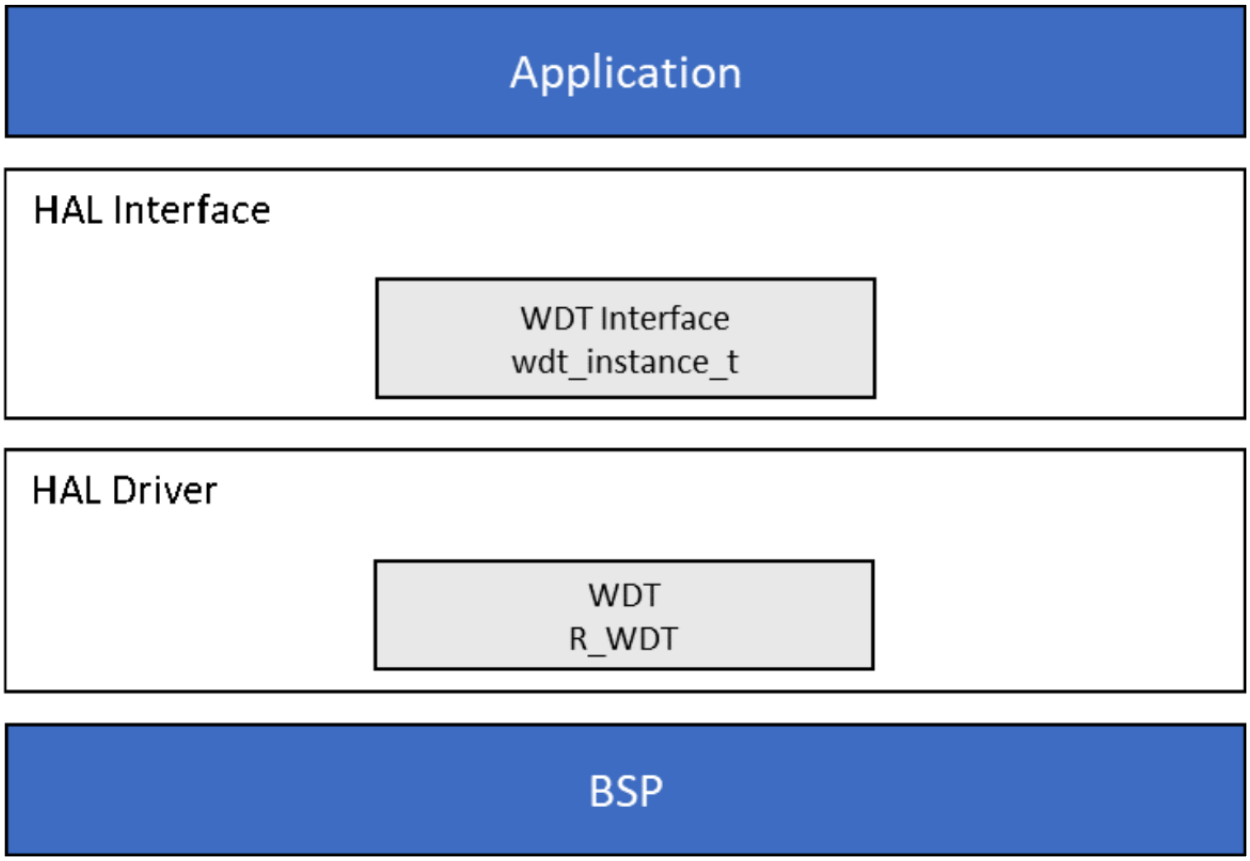

Figure 395: Watchdog Timer HAL Module Block Diagram

Watchdog Timer Hardware Support Details

The following hardware features are, or are not, supported by SSP for WDT:

Legend:

Symbol	Meaning
✓	Available (Tested)
☒	Not Available (Not tested/not functional or both)
N/A	Not supported by MCU

4.2.48.2 Watchdog Timer HAL Module APIs Overview

The WDT HAL module defines APIs for opening, refreshing, reading and getting status. A complete list of the available APIs, an example API call and a short description of each can be found in the

following table. A table of status return values follows the API summary table.

Watchdog Timer HAL Module API Summary

Function Name	Example API Call and Description
cfgGet	g_wdt0.p_api->cfgGet(g_wdt0.p_ctrl, g_wdt0.p_cfg); Initialize the WDT in register start mode. In auto-start mode with NMI output it registers the NMI callback.
open	g_wdt0.p_api->open(g_wdt0.p_ctrl, g_wdt0.p_cfg); Initialize the WDT in register start mode. In auto-start mode with NMI output it registers the NMI callback.
refresh	g_wdt0.p_api->refresh(g_wdt0.p_ctrl); Refresh the watchdog timer.
statusGet	g_wdt0.p_api->statusGet(g_wdt0.p_ctrl, &status); Read the status of the WDT.
statusClear	g_wdt0.p_api->statusClear(g_wdt0.p_ctrl, clear); Clear the status flags of the WDT.
counterGet	g_wdt0.p_api->counterGet(g_wdt0.p_ctrl, &counter); Read the current WDT counter value.
timeoutGet	g_wdt0.p_api->timeoutGet(g_wdt0.p_ctrl, &timeout); Read the watchdog timeout values.
versionGet	g_wdt0.p_api->versionGet(&version); Retrieve the API version using the version pointer.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures, and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	Function successfully executed.
SSP_ERR_ASSERTION	Null Pointer(s).
SSP_ERR_INVALID_ARGUMENT	One or more configuration options is invalid.

SSP_ERR_INVALID_MODE	An attempt to open the WDT in register-start mode when the OFS0 register is configured for auto-start mode. Or to open the WDT in auto-start mode when the OSF0 is configured for register start mode.
SSP_ERR_ABORTED	Invalid clock divider for this watchdog

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status return values.

4.2.48.3 Watchdog Timer HAL Module Operational Overview

Synergy MCUs have two watchdog peripherals- the watchdog timer (WDT) and the independent watchdog timer (IWDT). When selecting between them, consider these factors:

- The WDT can be started from the application.
- The WDT can be configured in register start mode through the WDT registers. The WDT can also be configured by hardware automatically after reset using parameters stored in Option Function Select Register 0 (OFS0).
- The IWDT has its own clock source which improves safety.
- The IWDT is configured by hardware automatically after reset using parameters stored in the Option Function Select Register 0 (OFS0).

Watchdog Timer HAL Module Important Operational Notes and Limitations

Watchdog Timer HAL Module Operational Notes

The WDT HAL module configures the WDT Interface. When the WDT underflows or is refreshed outside of the permitted refresh window, one of the following events can occur:

- Resetting of the device
- Generation of an NMI

The following figure shows an example of the operation of the WDT. When refreshed in the valid refresh period of the counter the timer count value is reset. If the count is allowed to underflow or refresh occurs outside of the valid refresh period, the WDT resets the device or generates an NMI.

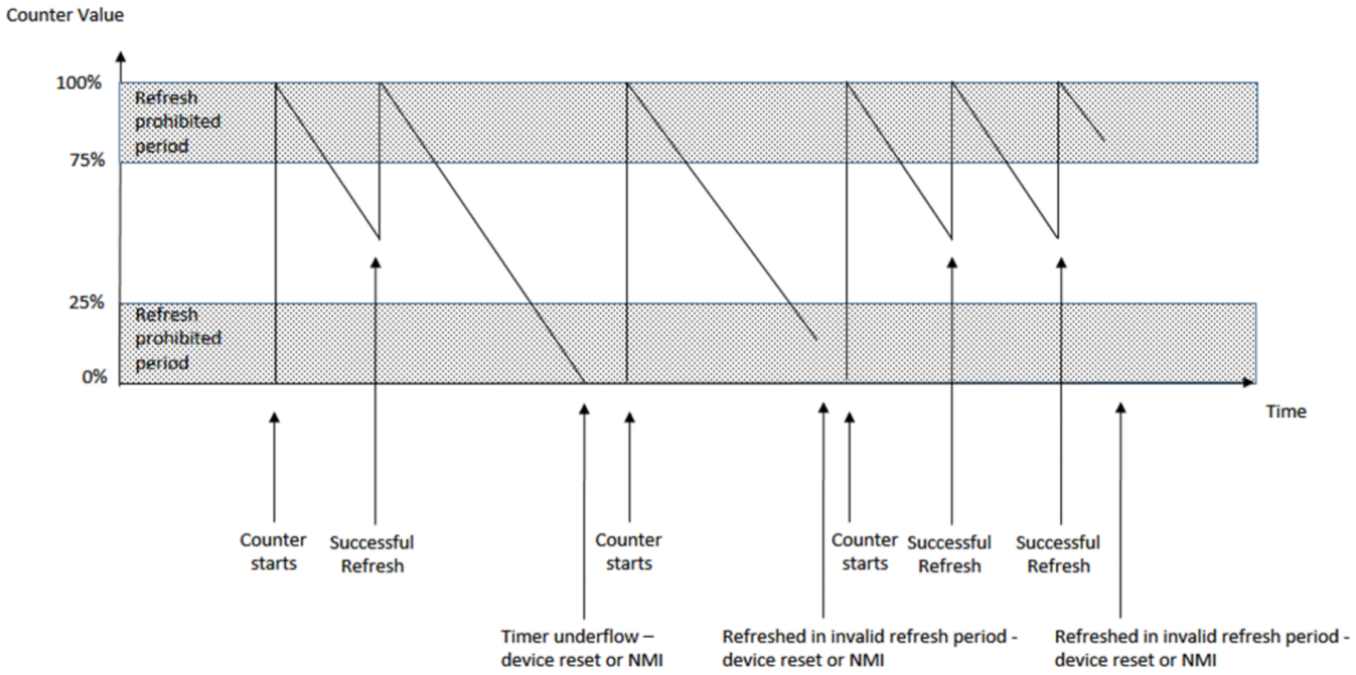

Figure 396: Watchdog Timer HAL Module Operational Diagram

The WDT can be configured in register start mode through the WDT registers. The WDT can also be configured by hardware automatically after reset using parameters stored in Option Function Select Register 0 (OFS0) as displayed in the following table.

All series of Synergy microcontrollers have an option-setting Memory which can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD and CGC HOCO.

The following table details which parameters of the IWDT can be configured by the OFS registers.

Note

The IWDT can only be configured via the OFS registers. The IWDT does not support Register Start mode.

Control	Description
IWDT Start Mode Select	Automatically starts the IWDT after a Reset, if enabled.
IWDT Timeout Period	Specifies the IWDT timeout (number of clock cycles) 128 cycles 512 cycles 1024 cycles 2048 cycles
IWDT-Dedicated Clock Frequency Division Ratio	1 1/16 1/32 1/64 1/128 1/256

IWDT Window End Position	25% 50% 75% 100% (no window end position set)
IWDT Window Start Position	25% 50% 75% 100% (no window start position set)
IWDT Reset Interrupt Request	The IWDT can either generate an Interrupt Signal or a Reset signal.
IWDT Stop Control	The IWDT can continue to count or Stop counting in Low Power Mode.

Note

For further information on the contents of the OFS0 register, see the Synergy MCU hardware manual.

The OFS register values are set via the properties dialog of the **BSP** tab of Synergy Configuration editor as shown in the figures below.

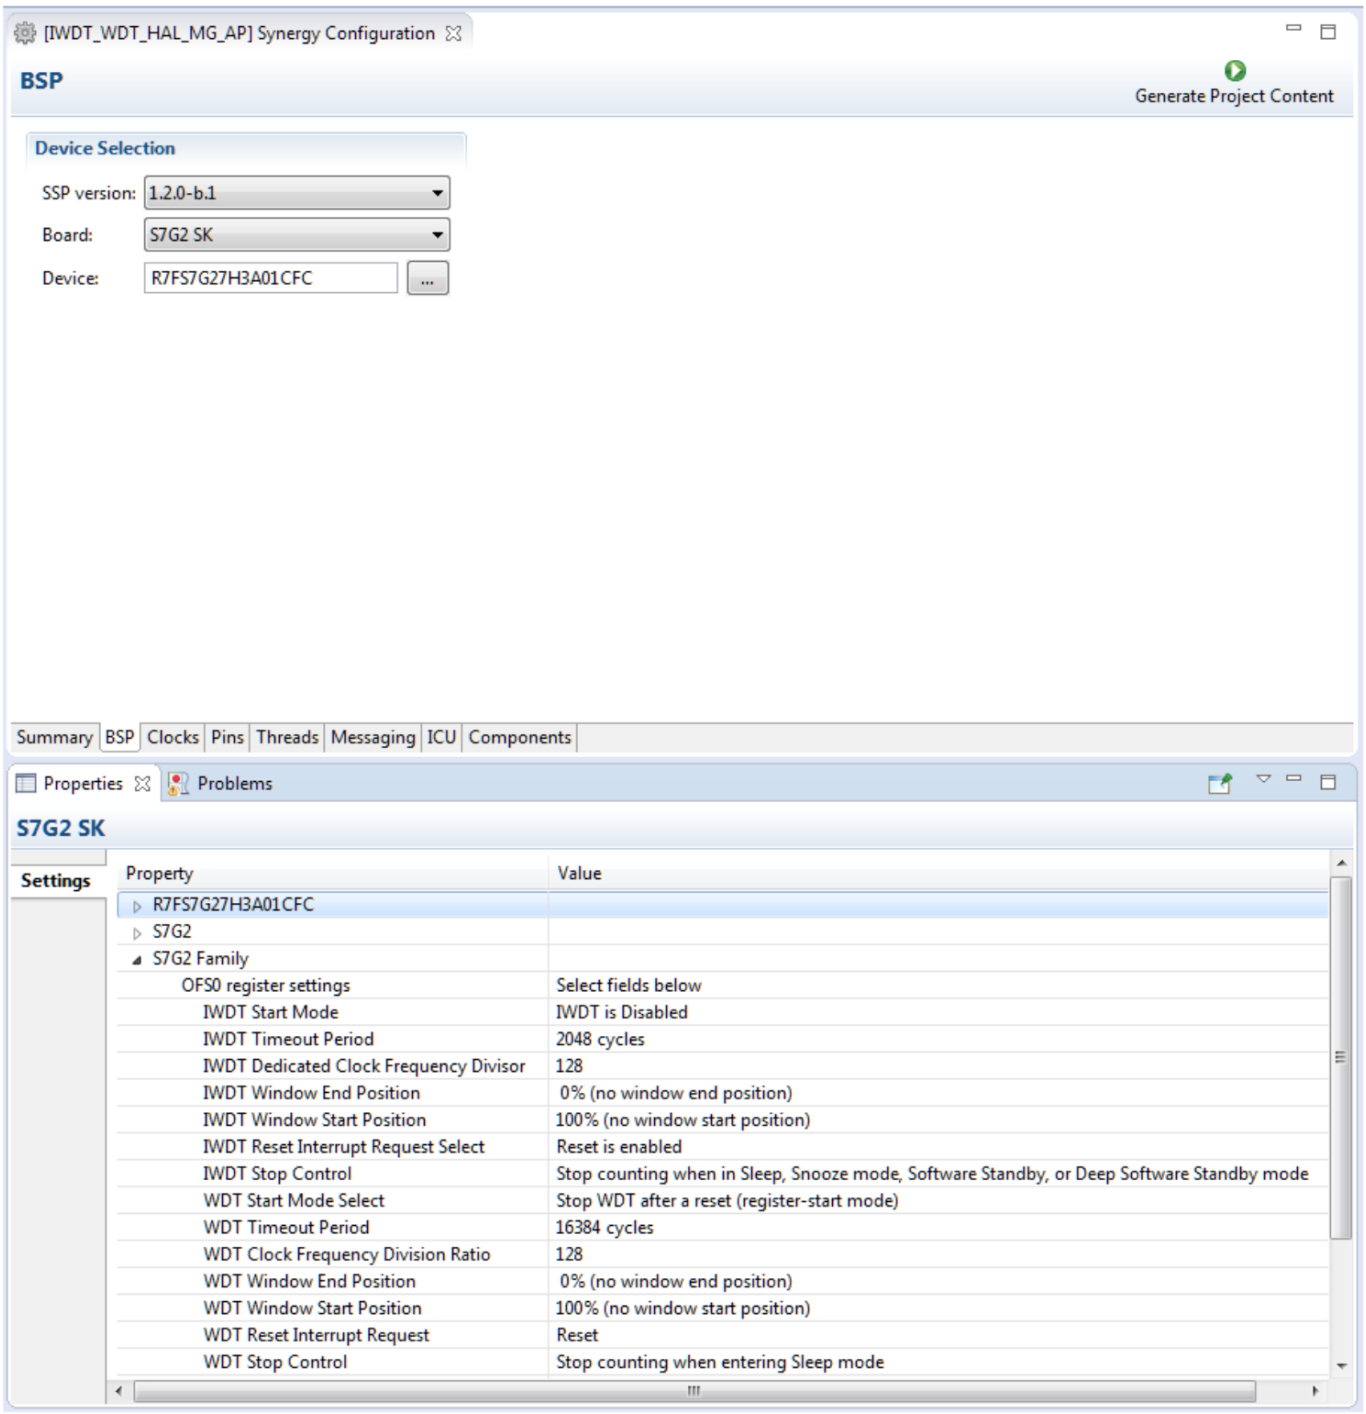

Figure 397: Watchdog Timer HAL Module Configuration Screens

WDT HAL Module Period Calculation

The WDT operates from PCLKB. Assuming largest parameters for the WDT and a PCLKB of 60 MHz, the time from the last refresh to device reset or NMI generation will be just over 2.2 seconds as detailed below.

PLCKB = 60 MHz

Clock division ratio = PCLKB/8192

Timeout period = 16384 cycles

WDT clock frequency = 60 MHz / 8192 = 7.324 kHz

Cycle time = 1 / 7.324 kHz = 136.53 us

Timeout = 136.53 us x 16384 cycles = 2.23 seconds

Triggering DMAC/DTC with the WDT HAL Module

To trigger a transfer of data using the DMAC or DTC peripheral when the WDT counter underflows or when a refresh is attempted outside of the valid refresh period, configure the WDT to generate an NMI and configure the DMAC/DTC transfer with activation_source set to ELC_EVENT_WDT_UNDERFLOW. See the associated User Guide (DMAC, DTC) for further information.

Triggering Event Link Controller Events with the WDT HAL Module

The WDT can trigger the start of another peripheral using the Event Link Controller (ELC). Refer to the ELC User Guide for a complete list of available peripherals.

Watchdog Timer HAL Module Limitations

- When using a J-Link debugger the WDT counter does not count and therefore will not reset the device or generate an NMI.
- When there is no active task ready to run, ThreadX puts the MCU into sleep mode. If the WDT is configured to stop the counter in low power mode, then your application must restart the timer when used with the ThreadX RTOS.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.2.48.4 Including the Watchdog Timer HAL Module in an Application

This section describes how to include the Watchdog Timer HAL Module in an application using the SSP configurator.

Note

This section assumes you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the Watchdog Timer Driver to an application, simply add it to a thread using the stacks selection sequence given in the following table. (The default name for the Watchdog Timer Driver is g_wdt0. This name can be changed in the associated Properties window.)

Watchdog Timer HAL Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_wdt0 Watchdog Driver on r_wdt	Threads	**New Stack>Driver> Monitoring> Watchdog Driver on r_wdt**

When the Watchdog Timer Driver on r_wdt is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band

are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

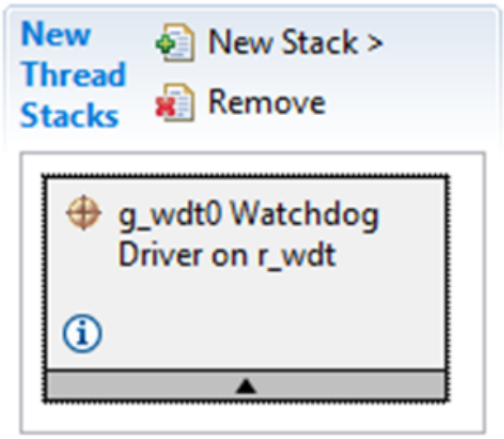

Figure 398: Watchdog Timer HAL Module Stack

4.2.48.5 Configuring the Watchdog Timer HAL Module

The Watchdog Timer HAL Module must be configured by the user for the desired operation. The available configuration settings and defaults for all the user-accessible properties are given in the properties tab within the SSP configurator and are shown in the following tables for easy reference. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table settings. This will help orient you and can be a useful 'hands-on' approach to learning the ins and outs of developing with SSP.

Configuration Settings for the Watchdog Timer HAL Module on r_wdt

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enables or disables the parameter checking.
Name	g_wdt0	Module name.
Start Mode	Register, Auto Default: Register	Configures the start mode as register start or auto-start.

Start Watchdog After Configuration	True, False Default: True	Controls whether WDT is started during initialization.
Timeout	1024 cycles, 4096 cycles, 8192 cycles, 16384 cycles Default: 16384 cycles	WDT timeout period.
Clock Division Ratio	PCLK/4, PCLK/64, PCLK/128, PCLK/512, PCLK/2048, PCLK/8192 Default: PCLK/8192	WDT clock divider.
Window Start Position	100% (Window Position Not Specified), 75%, 50%, 25% Default: 100% (Window Position Not Specified)	Permitted refresh period start postion.
Window End Position	0% (Window Position Not Specified), 25%, 50%, 75% Default: 0% (Window Position Not Specified)	Permitted refresh period end postion.
Reset Control	Reset Outpout, NMI Generated Default: Reset Output	Select whether WDT should reset the MCU or generate an NMI.
Stop Control	WDT Count Enabled in Low Power Mode, WDT Count Disabled in Low Power Mode Default: WDT Count Disabled in Low Power Mode	Select whether the WDT should stop counting in low power modes.
NMI Callback	NULL	Callback. A user callback function can be registered in open. If this callback function is provided, it will be called from the interrupt service routine (ISR) each time the IRQn triggers. Warning: Since the callback is called from an ISR, care should be taken not to use blocking calls or lengthy processing. Spending excessive time in an ISR can affect the responsiveness of the system.

Note

The example settings and defaults are for a project using the Synergy S7G2 MCU Group. Other MCUs may have different default values and available configuration settings.

Configure Option Function Select Register 0 (OFS0) for the WDT HAL Module

All series of Synergy microcontrollers have an Option-Setting Memory which can be used to set the operating state of peripherals after a reset. The OFS can be used to set the state of the IWDT, WDT, LVD and CGC HOCO. See the description in the operational overview section earlier in this document.

Configuring the Interrupts for the WDT HAL Module

Configure the WDT interrupts in the same way as configuring the other options for the WDT module. If the WDT is configured to generate an NMI interrupt on underflow or invalid refresh, the interrupt must be enabled in the BSP.

To enable interrupts, set the priority of the **CWDT**> **CWDT NMIUNDF N n**. This sets BSP_IRQ_CFG_WDT_UNDERFLOW in ssp_cfg/bsp/bsp_irq_cfg.h to the priority level selected.

When the CWDT NMIUNDF N interrupt is enabled in the BSP, the corresponding ISR will be defined. The ISR will call a user callback function if one was registered in the wdt_api_t::open API.

Watchdog Timer HAL Module Clock Configuration

The WDT clock is based on the PCLKB frequency. You can set the PCLKB frequency using the clock configurator in the ISDE or using the CGC Interface at run-time. The maximum timeout period with PCLKB running at 60 MHz is approximately 2.2 seconds.

Watchdog Timer HAL Module Pin Configuration

The WDT does not require pins for its operation.

4.2.48.6 Using the Watchdog Timer HAL Module in an Application

The typical steps in using the Watchdog Timer HAL module in an application are:

1. Initialize the WDT HAL module in either register start mode or auto-start mode using the wdt_api_t::open API.
2. Read the configuration of the WDT HAL module in either register start mode or auto start mode with the wdt_api_t::cfgGet API.
3. Refresh the watchdog timer using the wdt_api_t::refresh API.
4. Read the WDT status flags using the wdt_api_t::statusGet API.
5. Clear the status flags and error flags of the WDT HAL module using the wdt_api_t::statusClear API.
6. Read the current WDT counter value using the wdt_api_t::counterGet API.
7. Read the watchdog timeout values using the wdt_api_t::timeoutGet API.

These common steps are illustrated in a typical operational flow diagram in the following figure:

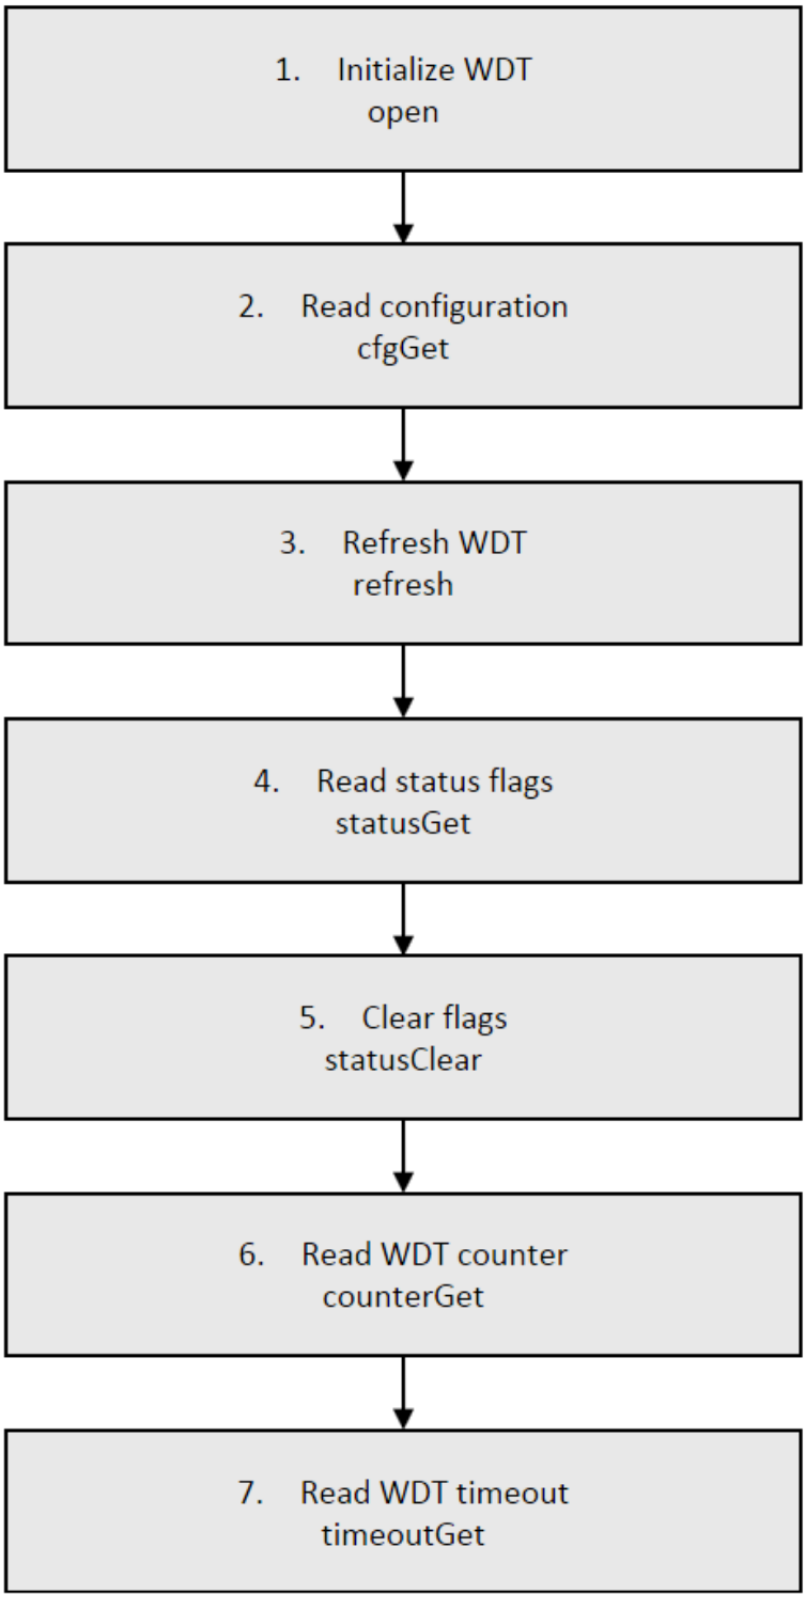

Figure 399: Flow Diagram of a Typical Watchdog Timer HAL Module Application

4.3 Azure RTOS Modules

The following documents for Renesas SSP Azure RTOS modules cover a wide range of topics and are organized to make it easy to find the specific information needed to accelerate your development process. Follow the below pointers to more quickly find the information you are looking for:

- Azure RTOS components are organized by key application functions: ThreadX RTOS support, FileX file system support, GUIX graphics user interface support, USBX Universal Serial Bus interface support, NetX and NetX Duo networking protocol support. The below articles are organized using these same key applications areas.
- Some Azure RTOS components have an Overview document that describes many of the key elements and concepts. The Overview document can also include common information that would be redundant to include in all the separate Module Overviews.
- Some Azure RTOS components have a Source module document that describes the configurable options available within the source module. These documents, and the associated Azure RTOS User's Manuals, (available in the X-Ware Component Documents package at the bottom of this web page: https://www.renesas.com/synergy/ssp) should be understood before attempting to modify any source configuration settings).
- Some Azure RTOS components have a Port Framework document that describes the details of the interface between SSP and an Azure RTOS Component. For example, the NetX Port Ethernet module (sf_el_nx) interfaces the NetX and Net Duo software with the Synergy hardware.
- Some Azure RTOS components have a variety of protocols or similar lower level functions. These are typically included in SSP as separate modules and each has a Module Overview document that explains their operation. For example, there are separate Module Overviews for DHCP, FTP and Telnet.
- Some Azure RTOS networking components have a Module Overview that covers more than one protocol. Often this is because the NetX and NetX Duo implementations are very similar and any differences can be easily identified in the combined document- thus eliminating unneeded duplication. (NetX Duo supports both IPv4 and IPv6- while NetX supports only IPv4. Operational differences can be easily explained where needed.) For example, the NetX/NetX Duo HTTP Server, NetX/NetX Duo HTTP Client Module Overviews cover both the NetX and NetX Duo implementations of these standard functions.

4.3.1 ThreadX Overview

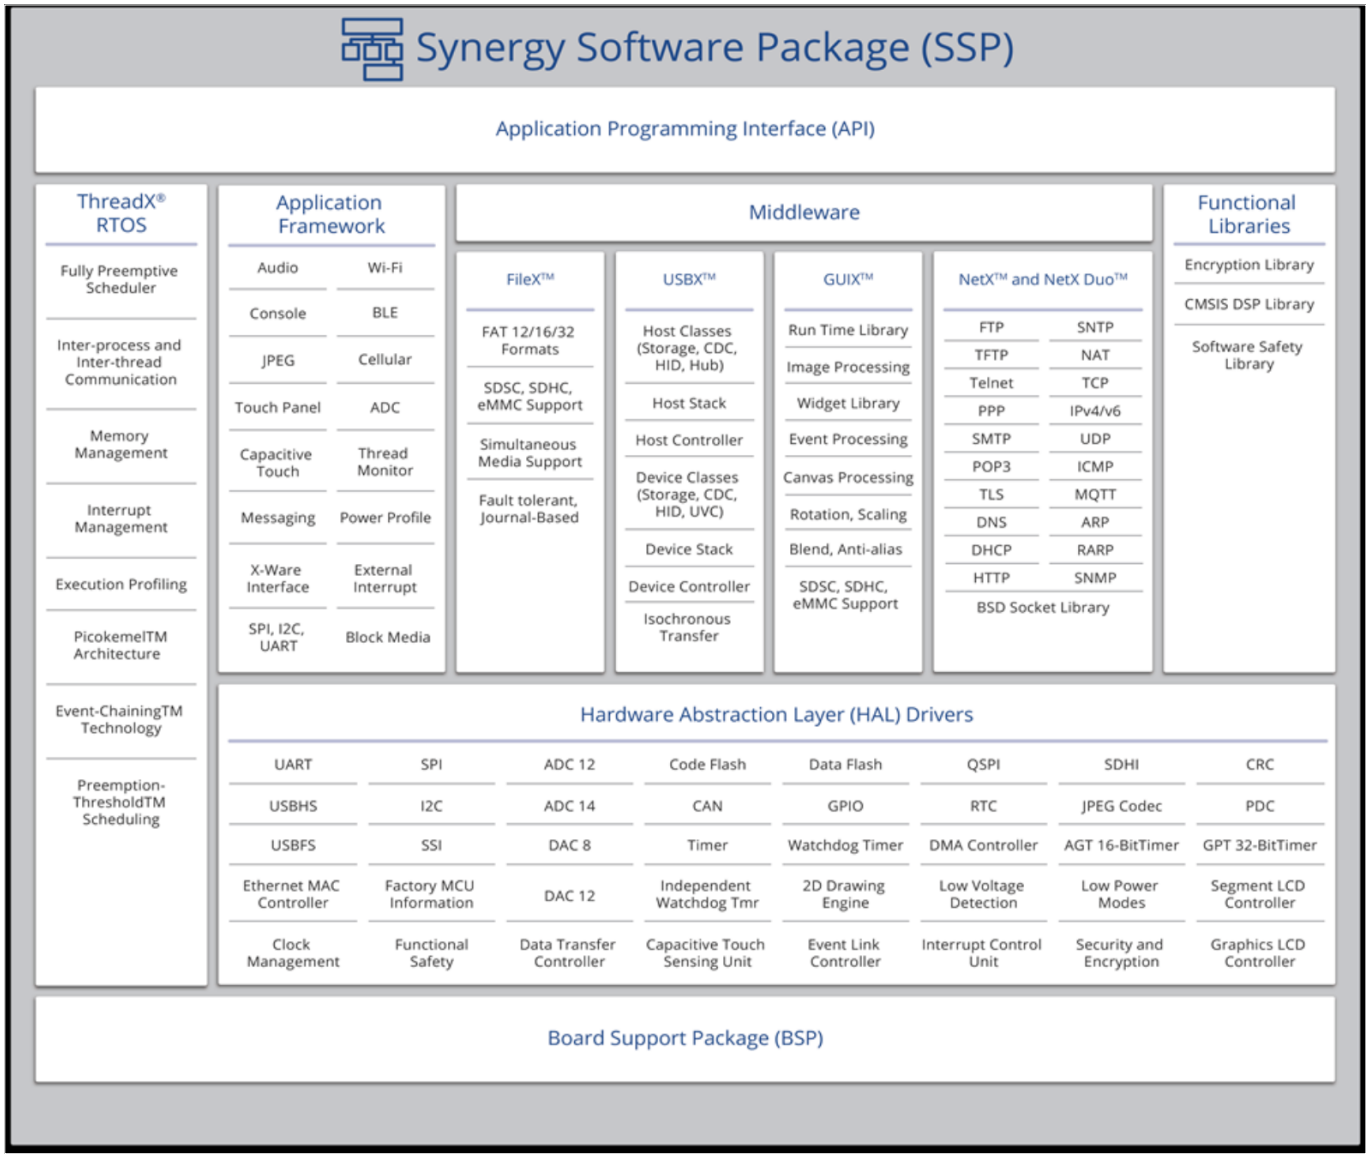
4.3.1.1 Azure RTOS ThreadX Module Introduction

The Azure RTOSThreadX kernel (tx) is integrated into the SSP. The Azure RTOS ThreadX kernel is the foundation of multi-threaded SSP applications. It provides thread creation and synchronization services, including message queues, counting semaphores, mutexes, event flags, memory block pools, memory byte pools, and application timers.

Azure RTOS ThreadX Module Features

- Implements the ThreadX RTOS in the Synergy Platform
- Automatically added when a thread is created
- Source code can be added using the ThreadX source module
- Provides threaded services for:

    - Synchronization
    - Messaging queues
    - Counting semaphores
    - Mutexes
    - Event flags
    - Memory block and byte pools
- Application timers



4.3.1.2 Azure RTOS ThreadX Module Operational Overview

The Azure RTOS ThreadX on tx module implements the ThreadX RTOS kernel within the Synergy Software Package. It provides all the scheduling, inter-process communications, memory management, interrupt management and a variety of other RTOS related functions. Typically, application code simply makes use of the functions provided by the kernel. The following operational notes outline some of the areas where the application may benefit from a more detailed interaction with ThreadX and ThreadX source.

Azure RTOS ThreadX Module Important Operational Notes and Limitations

Azure RTOS ThreadX Module Operational Notes

Preemption Threshold

The preemption threshold feature is disabled in the provided ThreadX library to reduce code size. If preemption support is needed, then ThreadX source should be included in the project and **Preemption Threshold** should be set to **Enabled** in the ThreadX source properties. The preemption threshold for a thread is initially set by the configurator to the thread priority. It can be changed by the tx_thread_preemption_change function.

IAR Library Support (IAR Only)

Thread-safe support for the IAR tools is easily enabled by making the following setting in the **Properties** of the ThreadX Source Module. In the table, ISDE Property refers to the **Properties** tab name in the e^2 studio ISDE.

ThreadX Source IAR Library Support Configuration

ISDE Property	Setting	Description
IAR Library Support	Enabled, Disabled (Default: Disabled)	If enabled, defines TX_ENABLE_IAR_LIBRARY_SUPPORT to provide thread safe access to IAR standard library functions such as malloc() and printf().

Also, add the following line to the linker control file (if not already in place):

@ code

initialize by copy with packing = none { section __DLIB_PERTHREAD };

// Required in a multi-threaded application.

@endcode

Note

*Make sure the ThreadX Source module is added to the **Threads** tab (HAL/Common) before modifying TX_ENABLE_IAR_LIBRARY_SUPPORT.*
*The TX_ENABLE_IAR_LIBRARY_SUPPORT macro enables thread creation and destruction extensions which are required for thread safe access to the IAR runtime library. The TLS (Thread Local Storage) memory is allocated from the heap for each instance. Currently, SSP **does not** implement the synchronization mechanisms that are required to use the library functions in a thread safe manner. Using the library with just the features provided is safe only if the library functions are accessed in a non-reentrant manner, that is, only a single thread makes calls to this library. To get full multithreaded support, refer to the IAR Dlib Thread Support document from IAR for more information on how to implement the synchronization mechanisms. The implementation will need to be done in the tx_src_user.h file which is an SSP generated file.*

ThreadX Source Advanced Configurations

If the ThreadX Source module is added to the project, the Properties window provides advanced configurations for the ThreadX source library. Highlight a configuration option to view a description of the option in the bottom left corner of the e^2 studio GUI. If the configuration option entry field is

empty, the default value will be used. Refer to the Configuration Options chapter of the *ThreadX User Guide* for more information.

At the end of the advanced properties, there are TX_<COMPONENT>_EXTENSION macros, where <COMPONENT> identifies the type of extension. These extension macros are for advanced use cases only. In most projects, they are not modified. Some cases, such as BSD support for NetX, require use of extension macros and explicitly describe how they should be used.

Azure RTOS ThreadX Module Limitations

- Hardware stack monitoring is not supported for the ARM CM23 and CM0+ MCUs. If the ThreadX Source is used with these MCUs, use the SSP configurator to set the Enable Hardware Thread Stack Monitoring property to Disabled.
- Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.1.3 Using the Azure RTOS ThreadX Module in an Application

During the configuration of the project, ThreadX is added automatically when a new Thread is created.

ThreadX objects, including mutexes, semaphores, event flags and queues can be added to Threads in the <Thread Name> Objects section, where <Thread Name> represents the name of an application thread. For example, to add a new queue to a thread, highlight the thread and select New Object > Queue.

To access the queue from a different thread, include the header file of the thread where the queue is defined. For example, if an application has a thread named main_thread with a queue named message_queue, a file named main_thread.h will be generated with an extern for message_queue. If the application also has a thread named background_thread, and the background_thread requires access to the message_queue, main_thread.h should be included in background_thread_entry.c to ensure background_thread_entry.c has access to the definition of message_queue.

Threadx Source configurator property **Memory section for Trace Buffer** relocates the trace buffer to the memory section indicated by the property. This requires enabling the property **Event Trace**. By default the trace buffer will be placed in the .bss section of memory

To relocate the trace buffer:

1. Enable the **Event Trace** property
2. Input the memory section where you want to put trace buffer

Note

It is the developer's responsibility not to relocate the trace buffer to the restricted memory sections. Developers are responsible for inputting the appropriate memory section if they want to relocate the trace buffer.

If the selected device is from a family of MCUs that have less memory, please resize the trace buffer from default size = 65536 to a lesser size so as to avoid RAM overflows by using configurator property **Trace Buffer Size** before enabling the **Event Trace**.

To restart a user defined thread created by Synergy

Applications trying to restart a thread after tx_thread_terminate/tx_thread_reset/tx_thread_resume call have to use tx_semaphore_put (&g_ssp_common_initialized_semaphore) before restarting.

4.3.2 FileX on Block Media

4.3.2.1 FileX On Block Media Framework Module Introduction

The FileX Port on Media Framework module supports the Azure RTOS FileX system, a complete FAT and exFAT format media and a file management system for deeply embedded applications. FileX is highly optimized for both size and performance.

FileX On Block Media Framework Module Features

Single Partition (Uses total available memory size):

- Supports FAT32, FAT16, FAT12 and exFAT filesystems
- Supports single FAT and exFAT partition operations in all SSP block media, that is, sf_block_media_lx_nor, sf_block_media_sdmmc, sf_block_media_qspi and sf_block_media_ram.
- Multiple FileX objects (that is, media, directories, and files, only limited by available memory)
- Dynamic FileX object creation/deletion
- Flexible memory usage
- Size scales automatically
- Small footprint
- Complete integration with ThreadX

Multi Partition:

- Supports FAT32, FAT16 and exFAT filesystem.
- Supports the creation of any number of partition on single physical media, and supports all other fileX operations on them, for underlying block media sf_block_media_lx_nor and sf_block_media_sdmmc.
- MBR/EBR support with visibility of partitions under Windows OS environment.
- Each partition can be operated-on independently of other partitions.
- Provides following operations on synergy platform for FAT and exFAT filesystem:
    1. Format/re-format
    2. open
    3. close
    4. write
    5. read

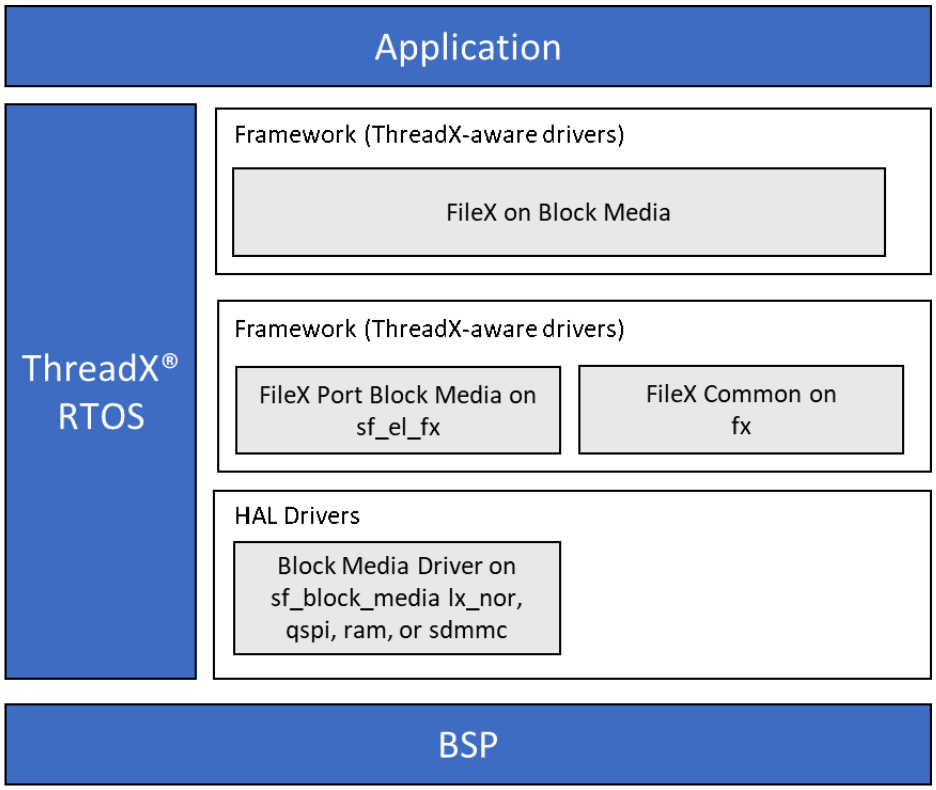


Figure 400: FileX On Block Media Framework Module Block Diagram

4.3.2.2 FileX On Block Media Framework Module APIs Overview

The FileX On Block Media Framework provides access to all the FileX APIs used to create the file system, access files and directories and manage the file system. The full set of FileX API functions, their parameters, operation and example use can be found in the FileX User's Manual. Some examples are shown below to provide some background for better understanding the rest of the descriptions of the FileX on Block media framework module.

FileX On Block Media Framework Module API Summary (Selected Examples Only)

Function Name	Example API Call and Description
fx_directory_attributes_read	fx_directory_attributes_read(&my_media, "mydir", &attributes); Reads the directory's attributes from the specified media.
fx_file_open	fx_file_open(&my_media, &my_file, "myfile.txt", FX_OPEN_FOR_READ); Open "myfile.txt" file for read.
fx_file_create	fx_file_create(&my_media, "myfile.txt"); Create file with name "myfile.txt"
fx_media_read	fx_media_read(&my_media, 22, my_buffer); Read the logic sector (in this example from sector 22) from media specified by &my_media, and places it into the buffer my_buffer.

Note

For more complete descriptions refer to the FileX User's Manual available as described in the Reference Section later in this document.

4.3.2.3 FileX On Block Media Framework Module Operational Overview

- FileX is a complete File Allocation Table (FAT) and exFAT format media and file management system for deeply embedded applications.
- FileX supports an unlimited number of media devices at the same time, like sdmmc, FLASH managers, RAM disks & Multiple other physical devices
- FileX is highly optimized for both size and performance.
- FileX provides support to following media & file operations for single and multiple partitions on the synergy platform: Format/re-format, open, close, write, read
- The user will able to view the SSP created FAT and exFAT partitions and files in windows OS environment.
- In fileX, when the exFAT support is enabled, the FAT functionalities would still be available

For single partition:

- FileX supports contiguous file allocation and FAT12, FAT16 FAT32 & exFAT formats.
- All underlying ssp block media ie sf_block_media_lx_nor, sf_block_media_sdmmc sf_block_media_qspi & sf_block_media_ram are supported

For multiple partitions:

- FileX supports the creation of any number of partition on given single physical media
- FileX supports only FAT16, FAT32 and exFAT formats.
- The following underlying block medias are supported: sf_block_media_lx_nor & sf_block_media_sdmmc.

FileX On Block Media Framework Module Important Operational Notes and Limitations

FileX On Block Media Framework Module Operational Notes

For Single Partition (Uses total available memory size):

The media must be formatted to either a FAT12, FAT16, FAT32 or exFAT file system before it can be opened, And media Format can be done prior to inserting the media (ie in a windows OS environment) or at project run time (using the "Format media" option in fileX properties in configurator).

For multi-partition:

- The following media partition format are supported: FAT16, FAT32 or exFAT file system, and the multiple partition must be created in synergy platform first before it can be used in windows environment.
- MBR sector i.e. sector 0 of the media must be erased (to erase all the existing partitions in the media), before creating new partitions in the media.
- At least one sector must be left before each EBR partition offset to accommodate the EBR sector, and at least one sector must be left before the first partition to accommodate the MBR sector.
- The auto-initialization for all the partitions must be disabled, and the partitions must be formatted and opened in the main entry function in application.

FileX On Block Media Framework Module Limitations

For Single partition:

- The exFAT file system is not supported on the sf_block_media_qspi framework (note: the user can use the sf_block_media_lx_nor instead to use the same qspi flash memory)
- For certain "total sectors" values in fileX properties, the media format in SSP application returns success, but the formatted media fails to open in the SSP application and in the windows OS environment (the user workaround for this is to increase the "Sector per cluster" value in filex properties).
- For exFAT single partition, If the block media is partially exfat formatted (ie fileX configurator option "total_sectors"<the total sectors in block media), the sd card media opens fine in the board, file operation in the board also works fine, but the media open fails in a PC windows environment (the user workaround for this is to filex format the media in the multiple of 1gb or the complete block media)

For Multiple partition:

- Partitions that are created, formatted, deleted or re-sized in any OS (for example the sd card partitions created/formatted in windows environment), when this media partitions is used with synergy platform, the SSP application will give undesired results
- Interface to below block media drivers is not supported:
    - sf_block_media_qspi (Users can alternately use sf_block_media_lx_nor)
    - sf_block_media_ram
- Auto initialization option in fileX properties is not supported, and must be disabled.
- USBX mass storage is not supported.
- The "Bytes per sector" in fileX properties is only supported for default value ie 512 bytes

Refer to the most recent SSP Release Notes for any additional operational limitations for this module.

4.3.2.4 Including the FileX On Block Media Framework Module in an Application

This section describes how to include the FileX on Block Media Framework module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

Following steps should be followed by the user for Single Partition (Used total available memory size): partitions:

To add the FileX on Block Media Framework module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

FileX On Block Media Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_fx_media0FileXonBlock Media	Threads	**New Stack**> **X-Ware** > **FileX on Block Media**

When the FileX on Block Media Framework module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or

common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

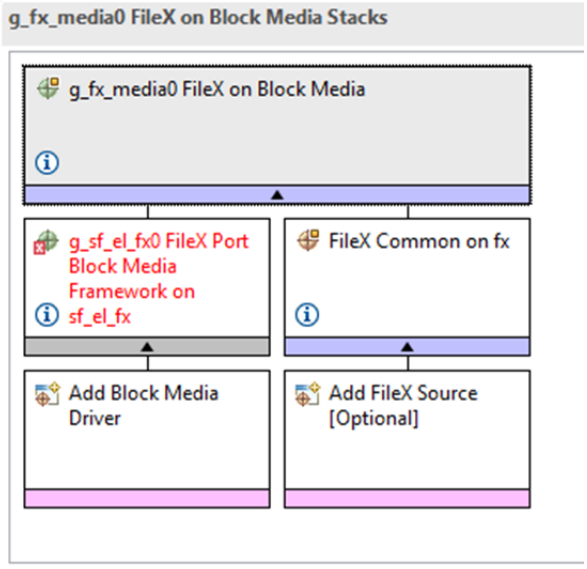

Figure 401: FileX on Block Media Stacks

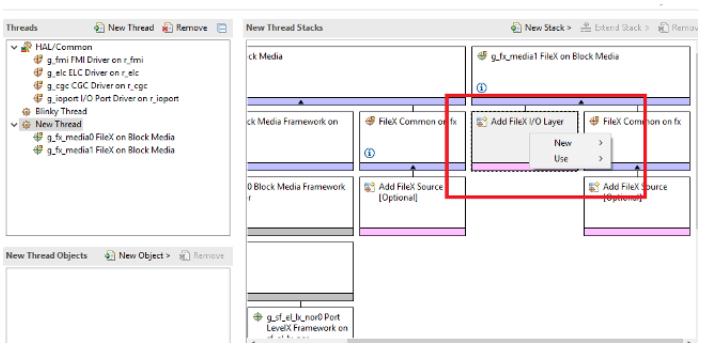
The Add Block Media Driver block must be filled in prior to generating the Synergy project code. There are multiple selections possible depending on the physical media targeted. Currently available media include RAM, LX NOR, QSPI, and SDMMC. Options may be different depending on what your target board and associated board support package (BSP) supports.

To enable the exFAT file system support in SSP, the user has to add the fileX source files to the project, and enable the “FileX Source" -> “exFAT support" option in the fileX source configurator properties, and re-build the FileX project.

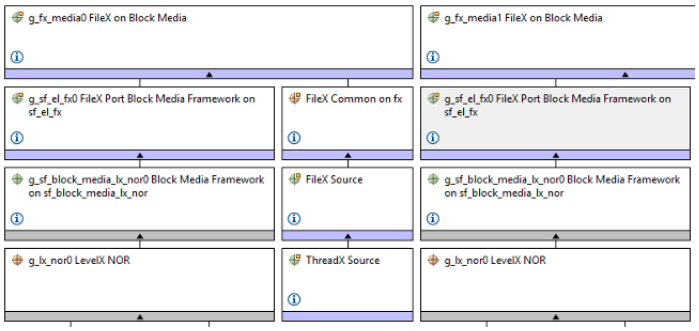
The following steps should be followed by the user for multiple partitions on the same/different media type:

1. Select FileX from X-Ware
2. Select FileX on Block Media
3. Select Block media framework - sf_block_media_lx_nor or sf_block_media_sdmmc. For example, FileX instance g_fx_media0 is created and it selects lx_nor media type.
4. Select the second Filex media instance. For example,g_fx_media1 created. For example, g_fx_media0 and g_fx_media1 represent the two partitions.

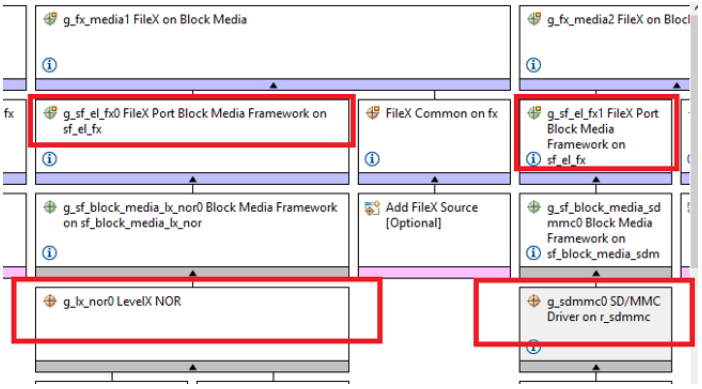
5. From the second instance and onward, selecting SF_EL_FX module instance gives two options **New** and **Use.**



6. **Use:** If the user selects **Use**, the partition will be made on the media previously selected by FileX media instance (g_sf_el_fx0 selected lx_nor). For example, g_fx_media0 and g_fx_media1 represent partitions on the same media type lx_nor.



7. **New:** If the user selects New, a new instance of SF_EL_FX is created. The user will have the choice to select the different media type. If the new instance of SF_EL_FX is chosen, a different media has to be selected for making the partition. For example: Select a third FileX media instance. Here g_fx_media2 is created. Here g_fx_media0 and g_fx_media1 have partitions on same media type with same instance of SF_EL_FX (g_sf_el_fx0). For g_fx_media2, a different instance of SF_EL_FX is selected (g_sf_el_fx1). g_fx_media2 selects a new instance of SF_EL_FX module (g_sf_el_fx1) which selects SDMMC block media framework. Here, g_fx_media0 and g_fx_media1 have partitions on media type qspi memory. g_fx_media2represents the partition on SDMMC framework.)



8. For g_fx_media3, the user has the choice to select **Use** (for SF_EL_FX module) or **New** for a different media type.

4.3.2.5 Configuring the FileX On Block Media Framework Module

The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the FileX On Block Media Framework Module

ISDE Property	Value	Description
Name	g_fx_media0	Module name.
Format media during initialization	Enable, Disable Default: Disabled	Select to automatically format the media during initialization.
File System is on block media	True, False Default: True	This setting will use code that reads sector size and count from the media device before formatting, if true. If set to false, the format function will use the sector size and count from configuration below.
Formatting Options		

Volume Name	Volume 1	This is the volume name to use when formatting the media device. It should be no longer than 11 characters.
Number of FATs	1	Number of File Allocation Tables.
Directory Entries	Default: 256	Number of directory entries in the root directory.
Hidden Sectors	0	Number of hidden sectors.
Total Sectors	3751936	Total number of sectors in the media. *Note* *When "File System is on Block media" property is set to false, enter appropriate total sector.*
Bytes per Sector	512	Sector size to format, when using the format function. "File System is on SDMMC" must be disabled for this value to be used. *Note* *When selected QSPI as media, Bytes per sector must be at least 4096.*
Sectors per Cluster	1	Sectors per cluster. This value is not used if "File System is on SDMMC" disabled.
Volume Serial Number	12345	Serial number to be used for this volume. Only used if Format media during initialization is enabled. Used in exFAT media format only.
Boundary unit	128	Physical data area alignment size, in number of sectors. Only used if Format media during initialization is enabled. Used in exFAT media format only.

Working media memory size	512	This is the number of bytes FileX uses to read and write to the media. It should be at least the size of one sector. *Note* *'Working media memory size' must be equal to or greater than 'Block size of media in bytes'. When selected QSPI as media, then working media memory size must be at least 4096 or greater.*
Name of generated initialization function	fx_media_init0	Name of the initialization function that is generated by SSP.
Auto Initialization	Enable, Disable Default: Enable	Select to enable or disable auto initialization.

Note

For multi partition Auto initialization and media format during initialization should be disabled.
For multi partition, "Bytes per sector" in filex properties is only supported for default value ie 512 bytes
The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.
Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

For Multi partitions:

sf_el_fx user configuration settings are require for multi-partition operation.

ISDE Property	Value	Description
Name	g_sf_el_fx0	Module name.
Partition info callback	A callback can be NULL or the name of the user-defined function.	If partitions exist and the system got reset, user callback specifies the partition offset/base address. This callback is called while opening the partition.
Total partitions	>1	The number of partitions users wanted to make on the media.

1. **Partition info callback:** Partition will be open as per user requirement by setting partition info callback to user define function or by setting it to NULL value it will open partitions in linear manner.
2. **Total partitions:** Total partition specifies the desired number of partitions. Values 0 and 1 represent a single partition. Any value more than 1 indicates the required partition.

Configuration Settings for the FileX On Block Media Framework Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the Block Media Framework on sf_block_media_sdmmc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_block_media_sdmmc0	Module name.
Block size of media in bytes	512	Specify the size of a block in bytes.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the SDMMC HAL Module on r_sdmmc

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable parameter error checking.
Name	g_sdmmc0	The name to be used for SDMMC module control block instance. This name is also used as the prefix of the other variable instances.
Channel	0	Select the channel.
Media Type	Embedded, Card Default: Embedded	Media is a card or an embedded device. This allows to firmware to know whether to look for card insertion/removal and write protect pins.
Bus Width	1 Bit, 4 Bits, 8 Bits Default: 4 Bits	Data bus with as defined by hardware interface. (8 Bits for eMMC only)
Block Size	512	Block size selection.
Card Detection	Not Used, CD Pin Default: CD Pin	Card detection selection.

Callback	NULL	(Not required if using Filex) Set to name of user callback function. Provides event that caused interrupt: SDMMC_EVENT_CARD_REMOVED, SDMMC_EVENT_CARD_INSERTED, SDMMC_EVENT_ACCESS, SDMMC_EVENT_SDIO, SDMMC_EVENT_TRANSFER_COMPLETE, SDMMC_EVENT_TRANSFER_ERROR
Access Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Access interrupt priority selection.
Card Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	Card interrupt priority selection.
DTC Interrupt Priority	Priority 0 (highest), Priority 1:14, Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	DTC interrupt priority selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

FileX Port Block Media Framework Module Clock Configuration

The SDHI uses the PCLKA for its clock source. There is no need to configure the clock specifically for the SDMMC peripheral unless you need to optimize the data rate. The SDMMC driver selects the appropriate built-in divider based on the PCLKA frequency and the maximum clock rate allowed by the SD, SDIO or eMMC device obtained at media device initialization.

FileX Port Block Media Framework Module Pin Configuration

Use the e^2 studio pin configurator to configure the I/O pins for the target media peripheral. The following description applies to the SDHI peripheral used for SDMMC media. Other media will require similar pin settings, and these are easily determined using their associated pin selection sequence in the Synergy Configurator. Consult the appropriate HAL driver section in the SSP User's Manual for additional details.

For SDMMC media, the drive capacity for each pin should be set to "Medium" or "High" for most boards and high-speed memory and SDIO devices. The following table illustrates the method for selecting the pins within the SSP configuration window and the subsequent table provides an example selection for the module pins.

Note

The operation mode selection determines what peripheral signals are available and what MCU pins are required.

Pin Selection Sequence for the SDHI Peripheral

Resource	ISDE Tab	Pin selection Sequence
SDHI	Pins	Select **Peripherals**> **Storage:SHDI**> **SDHI0**

Note

The selection sequence assumes that the SDHI0 is the desired hardware target for the driver.

Pin Configuration Settings for the SDHI Peripheral

Pin Configuration Property	Settings	Description
Operation Mode	Disabled, Custom, SD_MMC 1 bit SD_MMC 4 bit MMC 8 bit Default: Custom	Select mode as per application.
CLK	None, P413 Default: P413	Clock pin.
CMD	None, P412 Default: P412	Command pin.
DAT0-7	None, PXXX Default: PXXX	Data pin.
CD	None, P903 Default: P903	Card detection pin.
WP	None, P414 Default: P414	Card write protection pin.

Note

The example values are for a project using the Synergy S7G2 MCU Group and the DK-S7G2 Kit. Other Synergy Kits and other Synergy MCUs may have different available pin configuration settings.

4.3.2.6 Using the FileX on Block Media Framework Module in an Application

The steps in using the FileX on Block Media Framework module in a typical application are:

1. Initialize the media using the FileX API fx_system_initialize (FileX on Block Media calls it automatically if **Auto Initialization** property is set to Enabled in **FileX Common on fx**)
2. Optionally, format/create a FAT media using the FileX API "fx_media_format", (or)

format/create a exFAT media using the FileX API "fx_media_exFAT_format" (FileX on Block Media automatically formats the media using the auto-generated initialization function if its **Format media during initialization** property is set to Enabled).
3. Open the media using the FileX API fx_media_open (FileX on Block Media opens the media automatically if its **Auto Initialization** property is set to Enabled)
4. Create and delete files and directories as required using one of the FileX APIs (for example, fx_file_create, fx_file_delete, fx_directory_create, fx_directory_delete)
5. Read from and write to files on the media as required using one of the FileX API (for example, fx_file_read or fx_file_write)
6. Read from and write to the media directly as required using one of the FileX API (for example, fx_media_read or fx_media_write)
7. Close the physical media using the FileX API fx_media_close

Note

After a successful fx_media_open call, all FileX file and directory related APIs can be used. Refer to the FileX User Guide for documentation on all available functions.

These common steps are illustrated in a typical operational flow in the following figure:

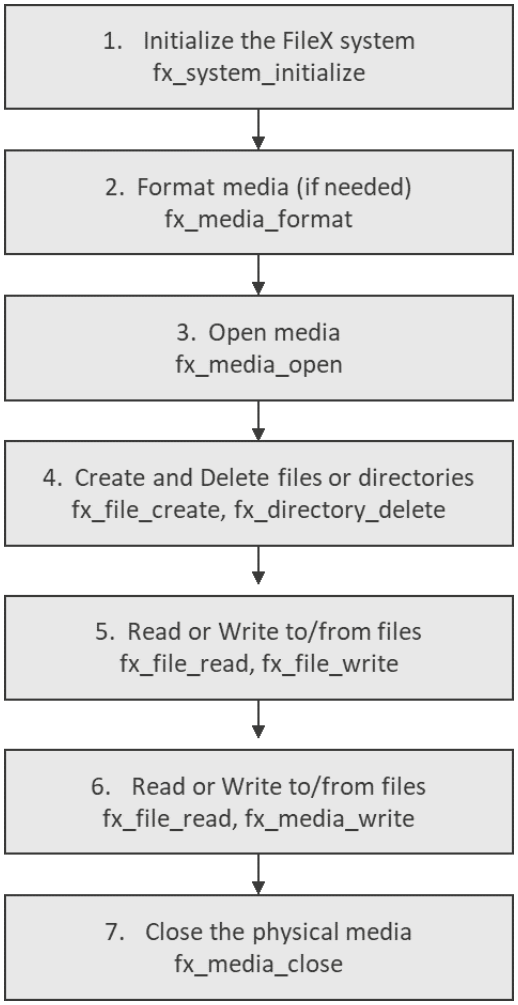


Figure 402: Flow Diagram of a Typical FileX On Block Media Framework Module Application

4.3.3 FileX Source

4.3.3.1 FileX Source Component Module Introduction

The purpose of this document is to provide an easy reference for the FileX source component in e^2 studio. The properties are explained in greater detail than the footer comment supplied with each property. Context specific usage is included to help understand when to change the default values. This document should make it easier to use the FileX source component without having to cross reference with the Azure RTOS FileX User Guide, and help the developer become familiarized, more quickly, with FileX features.

4.3.3.2 When to Include the FileX Source Component

Adding the FileX source component enables the developer in the Synergy configurator environment to customize the FileX library, change values from default settings, and enable or disable certain features. Otherwise, they must use the prebuilt FileX library. In most projects beyond the simplest, the developer will typically want to customize their FileX environment. Note that the ThreadX source component is automatically added whenever FileX is added as a higher-level source component.

Without adding the FileX source component, the e^2 studio configurator will use a prebuilt library with the FileX default settings.

4.3.3.3 Adding the FileX Source Component

In the e^2 studio configurator, add the ThreadX source component by selecting any thread from the Threads list and pressing the **New Stack** button and navigating the menu to **X-Ware** > **FileX**> **FileX Source**. Often the FileX source is available as an option when a high-level framework is created. For example, the FileX source module is available as an option for the FileX on USB Mass Storage framework module as seen in the below thread stack diagram.

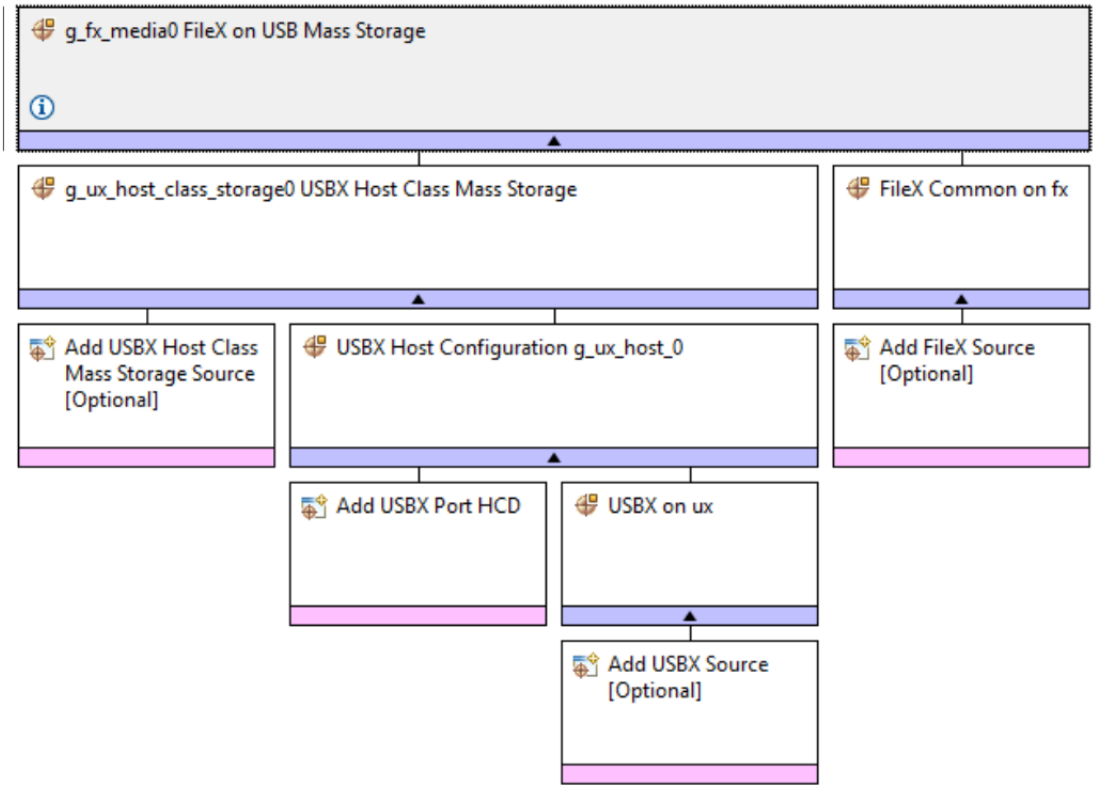

Figure 403: FileX Source Module Stack

4.3.3.4 Changing the FileX Source Component Properties

After changing FileX property settings, the developer must click on the Generate Project Content button to update the project configurator in e^2 studio and then the FileX library **must** be rebuilt (for example, rebuild the project). Simply changing a property (or applying a #define in the preprocessor list) without rebuilding the project will not affect any change since e^2 studio will use the previously built library.

The default settings are often the choice needed for the most common use cases.

4.3.3.5 FileX Source

The properties of the FileX Source component are given in the order they appear in the properties window of the Synergy configurator.

Error Checking – default value enabled – Generally enabled during development and debugging phase, and disabled when a release version is being built. When enabled, FileX include error checking services that will check input and other parameters before calling the actual API. Some of the things it checks for are:

- NULL pointer input
- Invalid non-pointer parameters, such as an invalid file or directory names.
- Required configurable option must be enabled. For example, performance information must be enabled to call the get services.
- The data structure IDs must match what is expected. For example,
    - file_ptr -> fx_file_id != FX_FILE_ID // check the file instance structure
- Size of the data structure, the FileX file for example, matches the size of the data structure

in the FileX library.

These last two checks guard against an application using a different version of the FileX library than the application is using.

Disabling the FileX error checking API results in improved performance (as much as 30%) and smaller code size.

Max Long Name Len – Maximum Long Name Length – default value not displayed, 33 characters is used – Defines the maximum size of long file names supported by FileX. The default value is 33. The minimum value is 13 and the maximum value is 256.

Max Last Name Len – Maximum Last Name Length – default value not displayed, 256 characters is used – Defines the maximum size of last opened file names supported by FileX. The default value is 256. The minimum value is 13 and the maximum value is 256. Must be as large as or larger than Max Long Name Len.

Max Sector Cache – Maximum Sector Cache Size - default value not displayed, 256 is used – Defines the maximum number of logical sectors that can be cached by FileX. The cache memory supplied to FileX at fx_media_open determines how many sectors can actually be cached. Minimum value is 2, all other values must be a power of 2.

Fat Map Size – FAT Map Size - default value not displayed, 128 is used – Defines the size in bytes of the bit map used to update the secondary FAT sectors. Larger the value result in fewer unnecessary secondary FAT sector writes. Minimum value is 1, no maximum value.

Max Fat Cache – Maximum FAT Cache - default value not displayed, 16 is used – Defines the number of entries in the internal FAT cache. The minimum value is 8, all values must be a power of 2.

Update Rate (seconds) - **default value not displayed, 10 seconds used** - Specifies rate at which the system time in FileX is adjusted. The default value 10 means that the FileX system time is updated every 10 seconds.

__Max exFAT Cache Size - default value not displayed, 512 is used. -__ Defines bitmat cache size for exFAT. Size should be minimum one sector size and maximum 4096. For applications using multiple media devices with varying sector size, the value should be set to the size of largest sector size.

No Timer – default value disabled – When enabled, FileX is built without update to the time parameters. Eliminates the ThreadX timer setup to update the FileX system time and date. Doing so causes default time and date to be placed on all file operations.

Single Thread – default value disabled – When enabled, FileX is running in a single-threaded environment and does not need thread protection. Eliminates ThreadX protection logic from the FileX source. It should be used if FileX is being used only from one thread or if FileX is being used without ThreadX.

Don't Update Open Files – default value disabled – When enabled, FileX does not update already opened files.

Media Search Cache – default value enabled – When enabled, a cache is used for optimization when searching for open media. Disabling this option will remove this optimization, reducing code size and memory footprint at the expense of performance.

Direct Data Read Cache Fill – default value enabled – When enabled, data sector reads are cached for faster access. Disabling this feature will reduce code size and memory footprint at the expense of performance.

Media Statistics – default value enabled – Determine if media statistics are kept and gathered. When disabled, no media statistics are available. This improves performance slightly and reduces code size; each instance of the FX_MEDIA_STRUCT structure is considerably smaller.

Single Open Legacy – default value disabled – When enabled, legacy single open logic for the same file is used. This may be necessary to make the fx_file_open behave in the same way as older versions of FileX, when migrating old FileX application code.

Rename Path Inherit – default value disabled – When enabled, renaming inherits path information. In other words, prepend the path in the new file name, then override the old file name with the new one on the renamed file.

No Local Path – default value disabled – When enabled, the local path logic is disabled. When disabled, a local path is kept for each thread; all operations performed with a relative path, will be relative to this local path.

Fault Tolerant Data – default value disabled – When enabled, data sector write requests are flushed immediately to the driver. This will increase the likelihood that data is not lost in case of power loss or a reset, but it will impact performance.

Fault Tolerant – default value disabled – When enabled, system sector write requests (including FAT and directory entry requests) are flushed immediately to the driver. This will increase the likelihood that data is not lost in case of power loss or a reset, but it will impact performance.

64-bit LBA – default value enabled – When enabled, 64-bits sector addresses are used in the I/O driver. This allows bigger media and bigger files.

Fault Tolerant Service – default value disabled – Enables or disables the FileX fault tolerant service. The FileX Fault Tolerant Module is designed to prevent file system corruption caused by interruptions during the file or directory update. For example, when appending data to a file, FileX needs to update the content of the file, the directory entry, and possibly the FAT entries. If this sequence of update is interrupted (such as by a power glitch, or if the media is ejected in the middle of the update), the file system is in an inconsistent state, which may affect the integrity of the entire file system, leading towards corruption of other files.

Fault Tolerant Boot Index – default is 16 – Defines byte offset in the boot sector where the cluster for the fault tolerant log is. By default, this value is 116. This field takes 4 bytes. Bytes 116 through 119 are chosen because they are marked as reserved by FAT 12/16/32/exFAT specification.

Fault Tolerant Minimal Cluster Size – default is 3072 – Defines the requirement for minimal size of a cluster in bytes. It must be a multiple of the sector size. The default value is 3072, which works with the worst case for long file renaming.

exFAT Support – default value disabled – When enabled, the logic for handling the exFAT file system is enabled in FileX source code

Standalone enable – default value is disabled – When enabled, Filex will be used in standalone mode (without ThreadX).

Disable cache – default value is disabled – When enabled, cache is disabled.

Disable file close – default value is disabled – When enabled, file close is disabled.

Disable fast open – default value is disabled – When enabled, fast open is disabled.

Disable force memory operation – default value is disabled – When enabled, force memory operations are disabled.

Disable build option – default value is disabled – When enabled, build option is disabled.

Disable one line function – default value is disabled – When enabled, one line function is disabled.

Disable fat entry refresh – default value is disabled – When enabled, FAT entry refresh is disabled.

Disable consecutive detect – default value is disabled – When enabled, consecutive detect is disabled.

4.3.3.6 FileX Fault Tolerant Module

When an application writes data into a file, FileX updates both data clusters and system information. These updates must be completed as an atomic operation to keep information in the file system coherent. For example, when appending data to a file, FileX needs to find an available cluster in the media, update the FAT chain, update the length filed in the directory entry, and possibly update the starting cluster number in the directory entry. Either a power failure or media ejection can interrupt the sequence of updates, which will leave the file system in an inconsistent state. If the inconsistent state is not corrected, the data being updated can be lost, and because of damage to the system information, subsequent file system operation may damage other files or directories on the media.

The FileX Fault Tolerant Module works by journaling steps required to update a file before these steps are applied to the file system. If the file update is successful, these log entries are removed. However, if the file update is interrupted, the log entries are stored on the media. Next time the media is mounted, FileX will detect these log entries from the previous (unfinished) write operation. In such cases, FileX can recover from a failure by either rolling back the changes already made to the file system, or by reapplying the required changes to complete the previous operation. In this way, the FileX Fault Tolerant Module maintains file system integrity if the media loses power during an update operation.

Note

The FileX Fault Tolerant Module is not designed to prevent file system corruption caused by physical media corruption with valid data in it.

After the FileX Fault Tolerant module protects a media, the media must not be mounted by anything other than FileX with Fault Tolerant enabled. Doing so can cause the log entries in the file system to be inconsistent with system information on the media. If the FileX Fault Tolerant module attempts to process log entries after the media is updated by another file system, the recovery procedure may fail, leaving the entire file system in an unpredictable state.

The FileX Fault Tolerant feature is available to all FAT file systems supported by FileX, including FAT12, FAT16, FAT32, and exFAT. To enable the fault tolerant feature, FileX must be built with the option "Fault tolerant service" enabled. At run time, the application starts the fault tolerant service by calling fx_fault_tolerant_enable() immediately after the call to fx_media_open. After fault tolerant is enabled, all file write operations to the designated media are protected. By default, the fault tolerant module is not enabled.

The application needs to make sure the file system is not being accessed prior to fx_fault_tolerant_enable() being called. If application writes data to the file system prior to fault tolerant enable, the write operation could corrupt the media if prior write operations were not completed, and the file system.

The FileX fault tolerant log takes up one logical cluster in flash. The index to the starting cluster number of that cluster is recorded in the boot sector was not restored using fault tolerant log entries. For further details on the log format refer to the FileX user guide.

4.3.3.7 About exFAT Support

To enable the exFAT file system support in SSP, the user has to add the fileX source files to the project, and enable the “FileX Source" -> “exFAT support" option in the fileX source configurator properties, and re-build the FileX project.

4.3.4 GUIX Port

4.3.4.1 GUIX Synergy Port Framework Introduction

The SF_EL_GX (GUIX Port) module is the Azure RTOS GUIX adaptation layer for Synergy MCU groups, which have graphics engines GLCDC, DRW (2DG engine) or a JPEG decode engine. The API supports graphics hardware engine setup for GUIX and supports graphics rendering and displaying accelerated by hardware engines. The module defines full-set of GUIX low-level display driver functions which draw graphics accelerated by the DRW (2DG engine) or the JPEG or displays graphics with the GLCDC (See the GUIX User Guide Chapter 5: GUIX Display Drivers). The module encourages the hardware acceleration for graphics rendering, but also allows software processing without hardware support.

Supported and Unsupported Features

The following GUIX features are supported in SSP:

- RGB565 Pixel Format
- CLUT8 Pixel Format
- ARGB888 Pixel Format
- ARGB8888 Pixel Format
- Rotation Of Screen: Supported in SSP v2.0.0
- Dynamic Loading of Binary Resources
- Hardware and Software JPEG Support

The following features are not supported:

- ARGB4444 Format
- Multiple Canvases: GUIX allows use of multiple canvases but SSP supports only a single canvas

GUIX Synergy Port Framework Module Features

- Adapts GUIX on top of the SSP

- Attaches the SSP Display Interface driver to GUIX Display Driver Interface
- Allows GUIX to draw widgets accelerated by the Synergy D2W (2DG) engine
- Allows GUIX to draw widgets accelerated by the Synergy JPEG engine
- Supports double-buffer toggling control for screen transitions without tearing
- Supports screen rotation (90/180/270 degree)
- Supports various output color formats
    - 32bpp (ARGB8888, RGB-888)
    - 16bpp (RGB565)
    - 8bpp (8bit Palette (CLUT))
- Supports user callback functions

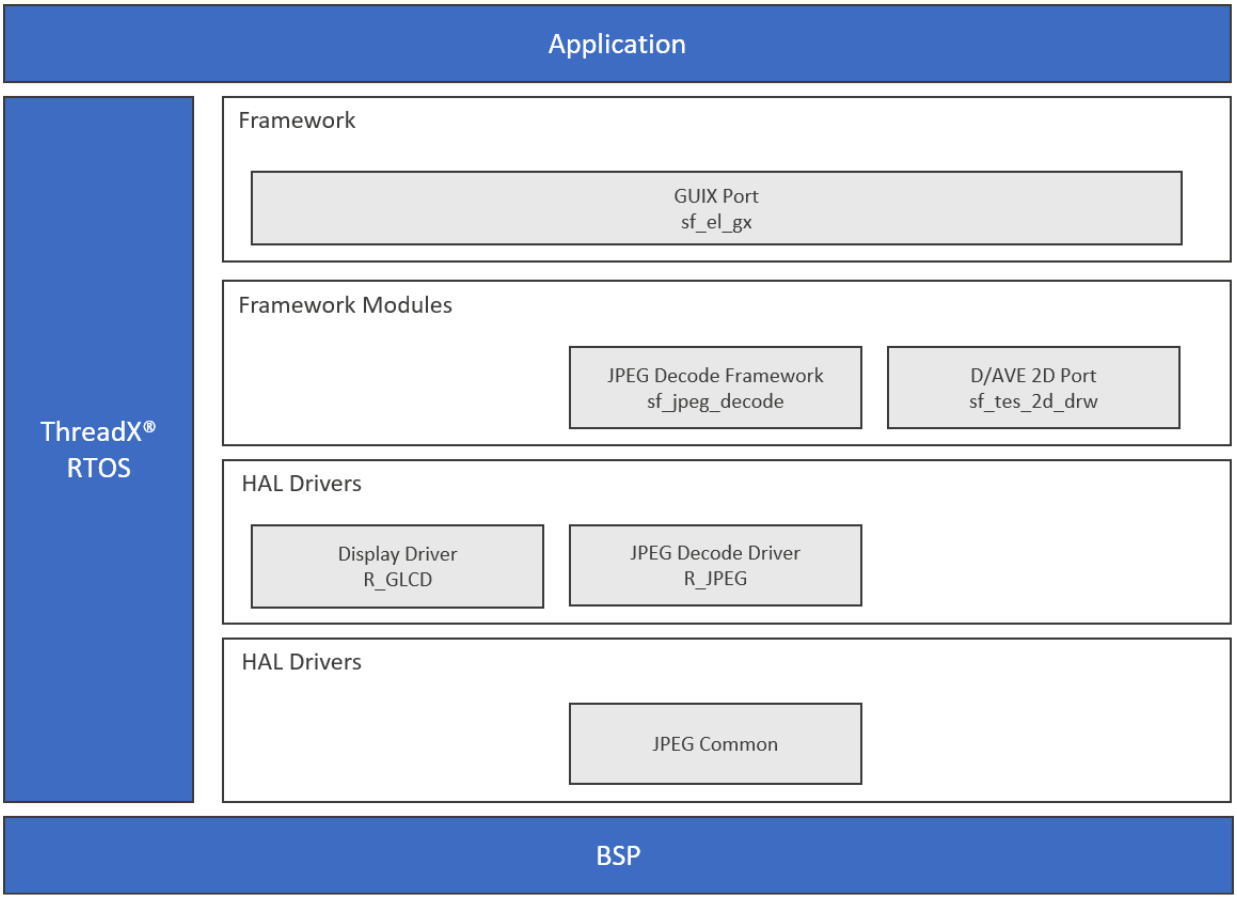

Figure 404: GUIX Synergy Port Framework Module Block Diagram

4.3.4.2 GUIX Synergy Port Framework Module APIs Overview

The GUIX Synergy Port Framework defines APIs for opening, closing, setup and initialization. A complete list of the available APIs, an example API call and a short description of each can be found in the following table. A table of status return values follows the API summary table.

GUIX Synergy Port Framework Module API Summary

Function Name	Example API Call and Description

open	g_sf_el_gx.p_api->open(g_sf_el_gx.p_ctrl, g_sf_el_gx.p_cfg); Opens the SF_EL_GX Module. The API can only be called from a thread. The API passes the configuration pointer to define low-level graphics device drivers and frame buffers and register the user callback function. This function does not actually initialize low-level drivers. Instead, the API setup initializes the low-level drivers.
close	g_sf_el_gx.p_api->close(g_sf_el_gx.p_ctrl); Closes the SF_EL_GX Module. This API closes the low-level drivers. Normally, the API is not called since GUIX will not be closed once initialized.
versionGet	g_sf_el_gx.p_api->versionGet(&version); Returns the version of the Module in the version pointer.
setup	gx_studio_display_configure (MAIN_DISPLAY, g_sf_el_gx.p_api->setup, LANGUAGE_ENGLISH, MAIN_DISPLAY_THEME_1, &p_window_root); This is the interface to initialize low-level graphics device drivers and must be passed to GUIX through GUIX (Studio) service call gx_studio_display_configure() as the function pointer. GUIX then calls the API back and, at that moment, the API configures the SSP device drivers based on the configuration passed by open. The reason for this procedure to initialize low-level drivers is that the API has the GUIX-compliant argument (GX_DISPLAY *) type and does not allow applying the detailed configuration of the SSP graphics device drivers generated from e^2 studio.
canvasInit	g_sf_el_gx.p_api->canvasInit(g_sf_el_gx.p_ctrl, p_window_root); This is the GUIX helper API to determine the memory address of GUIX canvas. The API has an argument with (GX_WINDOW_ROOT *) type and the API provides GUIX the start address of canvas memory, which is needed for the low-level graphics device drivers to draw/display images.

Note

For more complete descriptions of operation and definitions for the function data structures, typedefs, defines, API data, API structures and function variables, review the SSP User's Manual API References for the associated module.

Status Return Values

Name	Description
SSP_SUCCESS	API call successful.

SSP_ERR_ASSERTION	NULL pointer error happens.
SSP_ERR_IN_USE	SF_EL_GX is in-use.
SSP_ERR_INTERNAL	Error happen in Kernel service calls.
SSP_ERR_NOT_OPEN	SF_EL_GX is not opened.
SSP_ERR_TIMEOUT	A task times out (or exceeds retry limit) before completion in display driver.
SSP_ERR_D2D_ERROR_DEINT	Error occurred in D/AVE 2D driver.
GX_SUCCESS	Device driver setup is successfully done.
GX_FAILURE	Device driver setup failed.
SSP_ERR_INVALID_CALL	Function call was made when the driver is not in SF_EL_GX_CONFIGURED state.
SSP_ERR_D2D_RENDERING	The D/AVE 2D returns error at opening a display list buffer.
SSP_ERR_INVALID_ARGUEMENT	Invalid non-pointer (for example, parameter) input.
SSP_ERR_UNSUPPORTED	Specified color format is not supported.
SSP_ERR_D2D_ERROR_INIT	The D/AVE 2D returns error at the initialization.

Note

Lower-level drivers may return common error codes. Refer to the SSP User's Manual API References for the associated module for a definition of all relevant status-return values.

4.3.4.3 GUIX Synergy Port Framework Module Operational Overview

The following block diagram shows how the sf_el_gx module interfaces with the other Synergy components at the operational level. It also shows the layers at which the callback and low-level modules communicate with the rest of the system. Refer to this diagram while reading the operational overview and operational notes descriptions provided below.

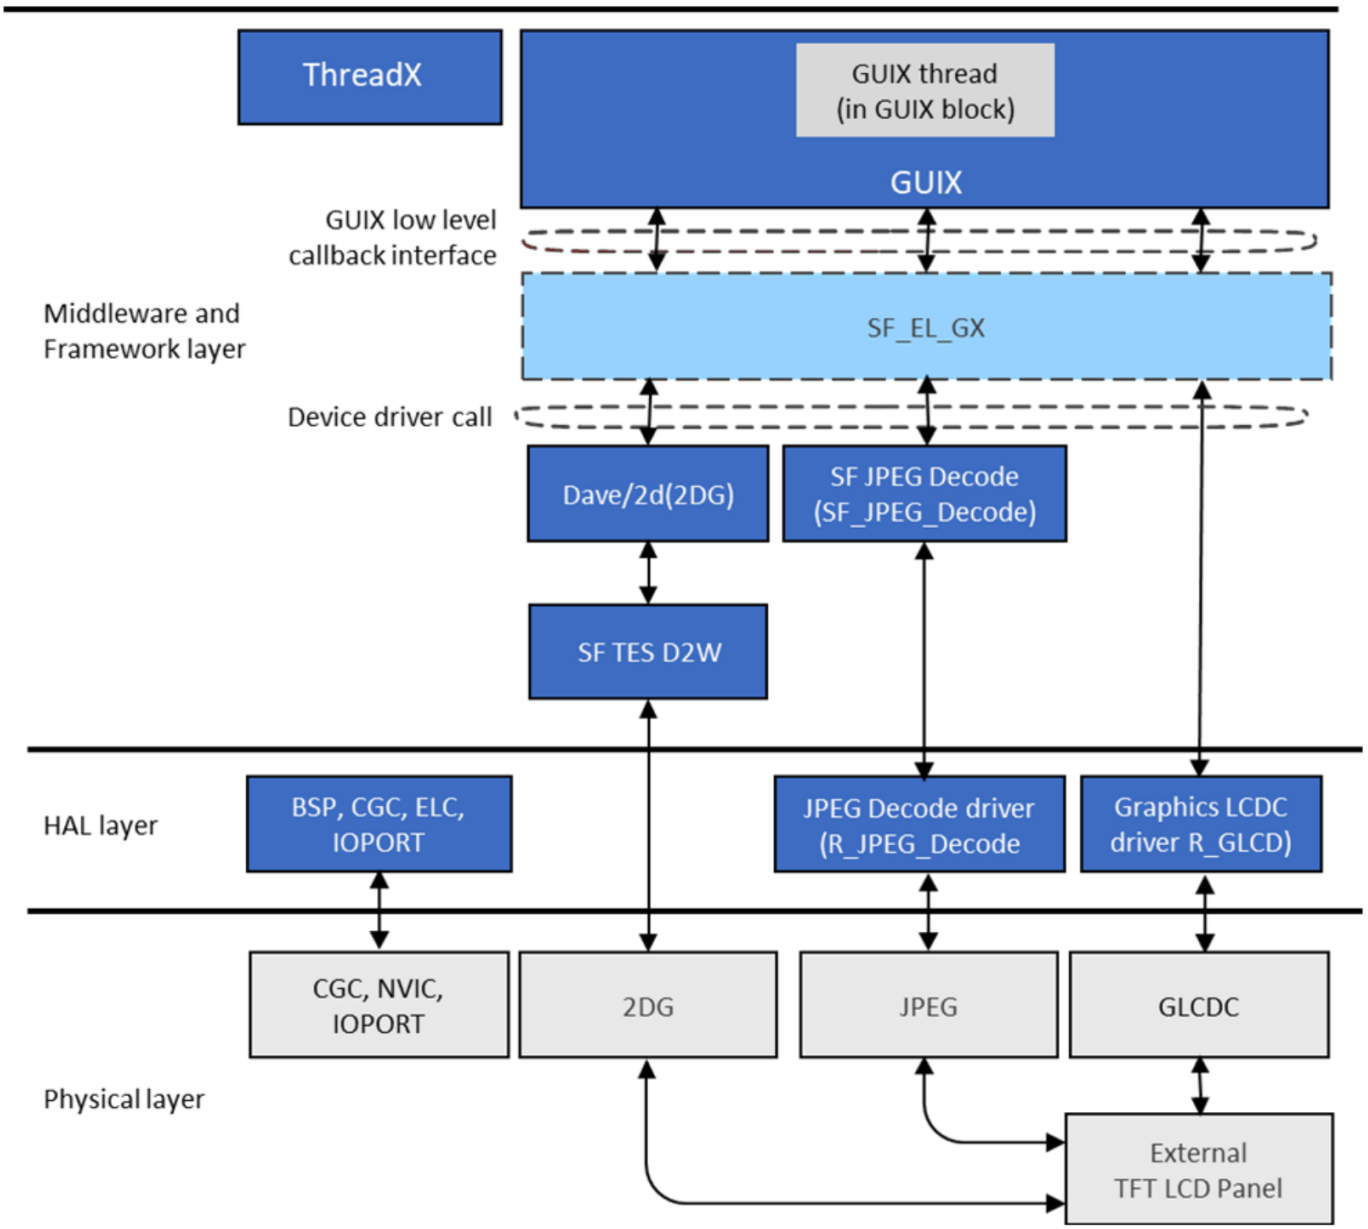

Figure 405: GUIX Synergy Port Framework Module Flow Chart

Module Initialization

The SF_EL_GX supports the Synergy graphics hardware setup, which is required to run the GUIX system. The module has a dependency with Azure RTOS GUIX™ and GUIX Studio™ generated code. The GUIX system initialization needs to follow the sequence below as a general guidance.

1. open SF_EL_GX module to initialize SF_EL_UX control block and pass module configurations.
2. Initialize GUIX Display object by GUIX Studio generated API gx_studio_display_configure. Through this API, SF_EL_GX setup API is input to GUIX and Synergy graphics hardware setup will complete. Also, the root window initialized by GUIX is output to a user application.
3. Initialize the primary memory address of a GUIX Canvas Buffer by canvasInit API.
4. Create the root window by GUIX Studio generated the gx_studio_named_widget_create API.
5. Show the root window with the GUIX gx_window_show API.
6. Start the GUIX system withe GUIX gx_system_start API.

Ping-Pong Frame Buffer Management

The SF_EL_GX module manages the buffer toggling operation in the graphics system with a ping-pong frame buffer. The figure below shows a ping-pong buffer graphics system managed by the SF_EL_GX module. The module uses GUIX and the low-level display driver functions to draw an image (2D Drawing engine(DRW) or JPEG) and display the image (DISPLAY module, for example: GLCDC). A design with a single frame buffer is also possible in the SF_EL_GX configuration. However, it is encouraged to use two frame buffers to avoid the tearing issue that could occur in a single frame buffer system.

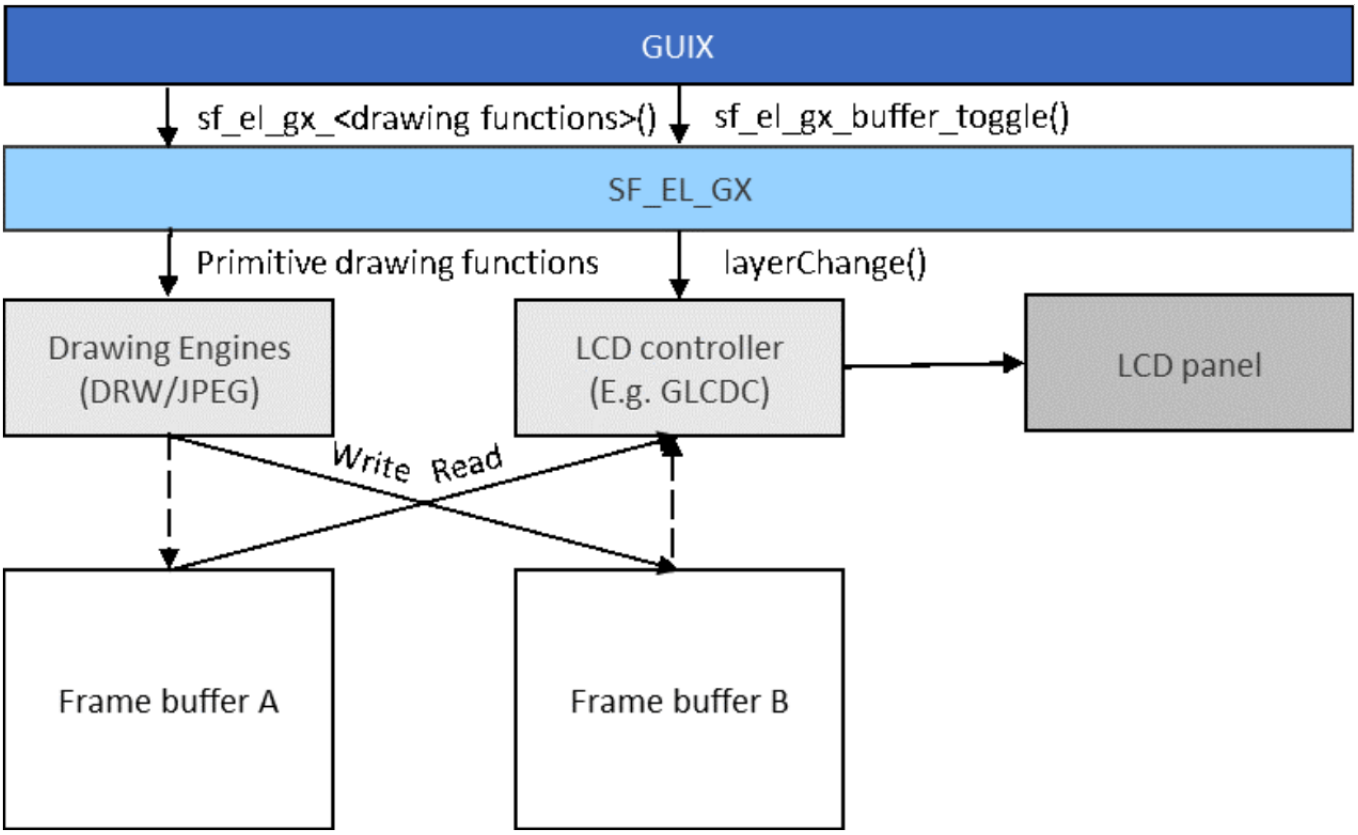

Figure 406: GUIX Synergy Port Framework Ping Pong Frame Buffer System

GUIX Synergy Port Framework Module Important Operational Notes and Limitations

GUIX Synergy Port Framework Module Operational Notes

Synergy 2D Drawing Engine Support

The module can draw graphics image accelerated by 2D Drawing engine (DRW) to get better graphics performance. Users can enable 2D Drawing engine with following configurations. The configuration is available through Synergy Configurator.

- Define GX_USE_SYNEGY_DRW (1) in gx_user.h
- Set DRW (SF_TES_2D_DRW) interrupt priority

Make sure to select **Renesas Synergy** in **Target CPU** setting in the **Configure Project** window and check **Enable Graphics Accelerator** in the **Synergy Advanced Settings** window on the Azure RTOS GUIX Studio (v5.2.8 or later). For the Pixelmap Output Format in the **Edit Pixel map** window (Right-click on **pixelmap**->**edit settings** to open the window), select **Compress Output**.

Do not select **Raw Format**. This configuration allows the GUIX Studio to generate Targa RLE formatted encoded image resource data. The 2D Drawing engine hardware can read this format and decode and draw the image on the frame buffer.

Synergy JPEG Support

The module can draw graphics image accelerated by JPEG engine to get better graphics performance if a JPEG encoded image is used as a GUIX image resource. Users can enable JPEG engine with following configurations. The configuration is available through Synergy Configurator.

- Define GX_USE_SYNEGY_JPEG (1) in gx_user.h
- Set JPEG (R_JPEG_DECODE) interrupt priority

Make sure to select **Renesas Synergy** in **Target CPU** setting in the **Configure Project** window and select **Hardware JPEG Decoder** in the **Decoder Types JPEG:** drop-down menu on the Azure RTOS GUIX Studio (v5.2.8 or later). For the Pixelmap Output Format in the **Exit Pixel map** window (Right-click on **pixelmap**->**edit settings** to open the window), select "Raw Format". This configuration allows the GUIX Studio to generate raw JPEG encoded image resource data. JPEG hardware can read this format and decode and draw the image on the frame buffer.

GUIX 5.4.0 API Compatibility Support

The Certain GUI APIs were modified post GUIX 5.4.0 to add support for disabled test colors and to improve the accuracy of certain math functions by using fixed point match parameters. To support existing applications which use the legacy APIs, configure following property in Synergy Configurator. The Legacy APIs can be used by enabling the property.

- Enable GUI Legacy API Support

The new version of these APIs should be preferred while creating a new application. In order to use new version of these APIs, the GUIX Source should be included in the project and the above property should be disabled.

GUIX Canvas Buffer

With SSP v2.0.0 or later,, the canvas buffer is required only for 180 (or Flip) degree screen rotation. For 180 screen rotation operation, the GUIX first draws the image on a Canvas buffer and then image is flipped and stored in the frame buffer. The size of GUIX Canvas Buffer must be exactly same as a frame buffer for the DISPLAY module. Note that, the use of a GUIX Canvas impacts to the graphics performance because of additional graphics image processing being required. Therefore, GUIX Canvas buffer should be only used if the 180 degree screen rotation is required. Otherwise set NULL to sf_el_gx_cfg_t::p_canvas to let GUIX draw an image directly to frame buffers.

Screen Rotation

The module supports the screen rotation. Supported rotation angle is either of 90, 180, 270 degree in clockwise way and must be set in the GUIX Studio. With SSP v2.0.0 or later, the canvas buffer is not required for the 90 and 270 degree screen rotation and must not be set. However, to enable the 180 degree screen rotation feature, a GUIX Canvas Buffer is still required and should be set in sf_el_gx configuration property. In this case, GUIX draws screen update on a canvas first and then GUIX Port processes the screen copy to a frame buffer with rotating the image by 180 degree. Dynamic screen rotation is not supported. If *Synergy 2D Drawing Engine Support* is enabled (GX_USE_SYNEGY_DRW = 1), the 180 screen rotation is processed by 2D Drawing engine with texture mapping. If not enabled (GX_USE_SYNEGY_DRW = 0), it is processed by software copy.

Note that starting with the SSP 2.0.0 the configuration option sf_el_gx_cfg_t::rotation_angle is not available. The rotation angle must be set in GUIX Studio project. Make sure to select rotation angle**(**either **None, CW, CCW or FLIP**) in **Rotation** setting in the **Configure Project** window on the Azure RTOS GUIX Studio (v6.1.6.2 or later). The earlier 90 degree Counter Clock wise rotation angle option in sf_el_gx_cfg_t::rotation_angle is now replaced with CCW option in GUIX Studio. Similarly, earlier 180 and 270 degree rotation options are replaced with FLIP and CW options in GUIX Studio. The (sf_el_gx_cfg_t::p_canvas = non-NULL value) is allowed for rotation angle other than 180 degree, but should not be done. This configuration just consumes extra bus bandwidth for screen image copy from a GUIX Canvas buffer to frame buffers. Therefore, set NULL to sf_el_gx_cfg_t::p_canvas to not use a GUIX Canvas buffer.

Size of JPEG Work Buffer

The JPEG work buffer trades off the JPEG decode speed against the buffer size. When a widget on the screen is formatted in JPEG, the JPEG work buffer is used as a temporary storage memory to create the decoded image. If the buffer size is not large enough for decoding an entire image, JPEG decoding is performed in the output buffer streaming mode. BitBLT operation by 2D Drawing engine decodes a piece of JPEG raster image in the buffer, then transfers it to the frame buffer. The minimum size of JPEG work buffer is {(The number of pixels in the horizontal line) x (bpp (bytes per pixel) of the display format) x 8 (lines)}. For instance, if the decoded image is 800 pixels in a horizontal line and RGB565 format, the number is 800 x 2 x 8= 12 800 (byte). If the buffer size was smaller than this number, JPEG decoding will not be processed. To get better throughput, parameter "Size of the JPEG Work Buffer" should be set as much as larger because it improves the JPEG decode throughput. The JPEG output buffer streaming mode repeats partial JPEG decode operations and the repletion comes to be overhead.

D/AVE 2D Buffer Cache

The D/AVE 2D buffer cache can be enabled or disabled through following configuration in Synergy Configurator. Disable it when images with high resolution and 32 bit ARGB8888 color format are used.

- D/AVE 2D Frame Buffer Cache (Valid if D/AVE 2D Drawing Engine is enabled)

Screen Tearing in Single Buffer Designs

Screen tearing is a visual artifact in video display where a display device shows information from multiple frames in a single screen draw. In general, a system with a single frame buffer can cause the screen tearing issue on a LCD panel. The module allows users to have single frame buffer (set NULL to sf_el_gx_cfg_t::p_framebuffer_b) but does not care for the screen tearing. It is recommended to have a ping-pong frame buffer system to consist of two frame buffers.

GUIX Synergy Port Framework Module Limitations

SF_EL_GX is only applicable for the Synergy MCU with GLCDC (mandatory), 2D Drawing engine or JPEG engine (optional)

Refer to the most recent *SSP Release Notes* for any additional operational limitations for this module.

4.3.4.4 Including the GUIX Synergy Port Framework Module in an Application

This section describes how to include the GUIX Synergy Port Framework module in an application using the SSP configurator.

Note

It is assumed you are familiar with creating a project, adding threads, adding a stack to a thread and configuring a block within the stack. If you are unfamiliar with any of these items, refer to the first few chapters of the SSP User's Manual to learn how to manage each of these important steps in creating SSP-based applications.

To add the GUIX Synergy Port Framework module to an application, simply add it to a thread using the stacks selection sequence given in the following table.

GUIX Synergy Port Framework Module Selection Sequence

Resource	ISDE Tab	Stacks Selection Sequence
g_sf_el_gx0 GUIX Port on sf_el_gx	Threads	**New Stack> Framework> Graphics> GUIX Port on sf_el_gx**

When the GUIX Synergy Port Framework module is added to the thread stack as shown in the following figure, the configurator automatically adds any needed lower-level modules. Any modules needing additional configuration information have the box text highlighted in Red. Modules with a Gray band are individual modules that stand alone. Modules with a Blue band are shared or common; they need only be added once and can be used by multiple stacks. Modules with a Pink band can require the selection of lower-level modules; these are either optional or recommended. (This is indicated in the block with the inclusion of this text.) If the addition of lower-level modules is required, the module description include Add in the text. Clicking on any Pink banded modules brings up the New icon and displays possible choices.

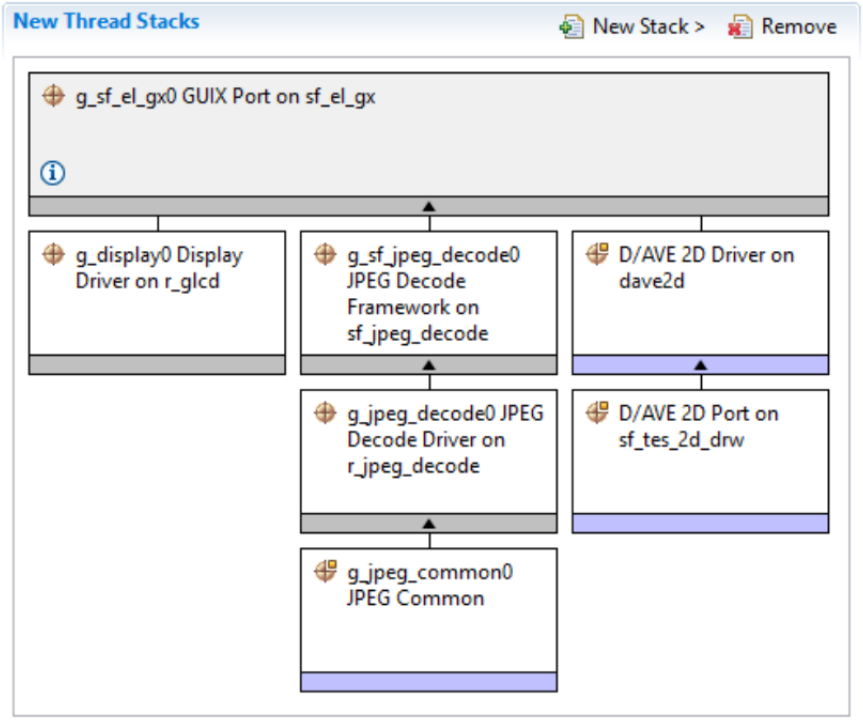

Figure 407: GUIX Synergy Port Framework Module Stack

4.3.4.5 Configuring the GUIX Synergy Port Framework Module

The GUIX Synergy Port Framework module must be configured by the user for the desired operation. The SSP configuration window automatically identifies (by highlighting the block in red) any required configuration selections, such as interrupts or operating modes, which must be configured for lower-level modules for successful operation. Only properties that can be changed without causing conflicts are available for modification. Other properties are locked and not available for changes and are identified with a lock icon for the locked property in the Properties window in the ISDE. This approach simplifies the configuration process and makes it much less error-prone than previous manual approaches to configuration. The available configuration settings and defaults for all the user-accessible properties are given in the Properties tab within the SSP Configurator and are shown in the following tables for easy reference.

Note

You may want to open your ISDE, create the module and explore the property settings in parallel with looking over the following configuration table values. This helps to orient you and can be a useful hands-on approach to learning the ins and outs of developing with SSP.

Configuration Settings for the GUIX Synergy Port Framework on sf_el_gx

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_el_gx0	Name of SF_EL_GX instance which will be generated by ISDE. Specify the instance name of this module. Name must be a valid C symbol.
Display Driver Configuration Instance	Inherit Graphics Screen 1, Inherit Graphics Screen 2 Default: Inherit Graphics Screen 1	Display drive configuration instance selection.
Name of User Callback function	NULL	Name of User Callback function invoked by the Module when events happen. It must be a valid C symbol and NULL is allowed.
GUIX Canvas Buffer (required only if rotation angle is FLIP or 180 degree)	Used, Not used Default: Not used	A canvas buffer must be used for FLIP or 180 degree screen rotation. The size of canvas buffer must be exactly the same as a frame buffer for the display module.
Size of JPEG Work Buffer (valid if JPEG hardware acceleration enabled)	768000	The JPEG work buffer size in bytes. Value must be a valid integer value and zero is allowed to be set if JPEG acceleration is not used. Larger buffer size shortens the drawing time. See Size of JPEG Work Buffer.

Memory section for GUIX Canvas Buffer	sdram	Name of memory section where you want to allocate the GUIX Canvas Buffer. Enter a valid section name defined in the linker script file. Name must be a valid C symbol.
Memory section for JPEG Work Buffer	sdram	Name of memory section where you want to allocate the JPEG Work Buffer. Enter a valid section name defined in the linker script file. Name must be a valid C symbol.
D/AVE 2 2D Frame Buffer Cache (Valid if D/AVE 2D Drawing Engine is enabled)	Enable, Disable Default: Enable	If Synergy 2D Drawing Engine (DRW) Support is enabled, the rotation is processed by Synergy DRW with texture mapping. If not enabled, the rotation is processed by software copy.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.
Most of the property settings for lower-level modules are intuitive and usually can be determined by inspection of the associated properties window from the SSP configurator.

Configuration Settings for the GUIX Synergy Port Framework Lower-Level Modules

Only a small number of settings must be modified from the default for the IP layer and lower-level drivers as indicated via the red text in the thread stack block. Notice that some of the configuration properties must be set to a certain value for proper framework operation and are locked to prevent user modification. The following table identifies all the settings within the properties section for the module:

Configuration Settings for the GLCD HAL Module on r_glcd

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_display0	The name to be used for a GLCDC module control block instance. This name is also used as the prefix of the other variable instances.
Name of display callback function to be defined by user	NULL	Name must be a valid C symbol.

Input - Panel clock source select	Internal clock(GLCDCLK), External clock(LCD_EXTCLK) Default: Internal clock (GLCDCLK)	Choose the panel clock source depends on your system.
Input - Graphics screen1	Used, Not used Default: Used	Specify "Used" if the graphics screen N is used. Then the frame buffer named "display_fb_background" for graphics screen1 and "display_fb_foreground" for graphics screen2 is auto-generated by ISDE. If not using either of the graphics screens, specify "Not used". Then the frame buffer is not created. Note that there is no memory read access to the frame buffer when you specify "Not used", which reduces the consumption of bus bandwidth.
Input - Graphics screen1 frame buffer name	fb_background	Custom name for frame buffer.
Input - Number of Graphics screen1 frame buffer	2	Number of graphics selection.
Input - section where Graphics screen1 frame buffer allocated	sdram	Specify the section name to allocate the frame buffer. This is valid if "Input - Graphics screen1" is set as "Used."
Input - Graphics screen1 input horizontal size	800	Specify the number of horizontal pixels. Default value is the size for an image with 800x480 pixels
Input - Graphics screen1 vertical size	480	Specify the number of vertical pixels. Default value is the size for an image with 800x480 pixels.
Input - Graphics screen1 input horizontal stride (not bytes but pixels)	800	Specify the memory stride for a horizontal line. This value must be specified with the number of pixels, not actual bytes. Typically, this parameter is set to same number as parameter 'input horizontal size'. Default value is the size for an image with 800x480 pixels.

Input - Graphics screen1 input format	32bits ARGB888, 32bits RGB888, 16bits RGB565, 16bits ARGB1555, 16bits ARGB4444, CLUT 8, CLUT 4, CLUT 1 Default: 16bits RGB565	Specify the graphics screen Input format. If selecting CLUT formats, you must write CLUT data using clut before performing start. Default setting supports a RGB565 formatted image.
Input - Graphics screen1 input line descending	Used, Not used Default: Not used	Specify "On" if image data descends from the bottom line to the top line in the frame buffer. Usually "Off".
Input - Graphics screen1 input line repeat	On, Off Default: Off	Specify "On" if expecting to repeatedly read a raster image which is smaller than the LCD panel size. Usually "Off". For details, see the description of Line Repeating function.
Input - Graphics screen1 input line repeat times	0	Specify the number of repeating times for a raster image which is read repeatedly in a frame.
Input - Graphics screen1 layer coordinate X	0	Specify the horizontal offset in pixels of the graphics screen from the background screen.
Input - Graphics screen1 layer coordinate Y	0	Specify the vertical offset in pixels of the graphics screen from the background screen.
Input - Graphics screen1 layer background color alpha	255	Based on the alpha value, either the graphics screen2 (foreground graphics screen) is blended into the graphics screen1 (background graphics screen) or the graphics screen1 is blended into the monochrome background screen.
Input - Graphics screen1 layer background color Red	255	Specify the background color in the graphics screen N.
Input - Graphics screen1 layer background color Green	255	Specify the background color in the graphics screen N.
Input - Graphics screen1 layer background color Blue	255	Specify the background color in the graphics screen N.

Input - Graphics screen1 layer fading control	None, Fade-in, Fade-out Default: None	Specify "On" when performing a fade-in for the graphics screen. The transparent screen changes gradually to opaque. Specify "Off" when performing the fade-out for the graphics screen. The opaque screen changes gradually to transparent. Note that this processing is accelerated by the GLCDC hardware and cannot stop once started. The transition status can be monitored by statusGet.
Input - Graphics screen1 layer fade speed	0	Specify the number of frames for the fading transition to complete.
Input - Graphics screen2	Used, Not used Default: Not used	Specify "Used" if the graphics screen N is used. Then the frame buffer named "display_fb_background" for graphics screen1 and "display_fb_foreground" for graphics screen2 is auto-generated by ISDE. If not using either of the graphics screens, specify "Not used". Then the frame buffer is not created. Note that there is no memory read access to the frame buffer when you specify "Not used", which reduces the consumption of bus bandwidth.
Input - Graphics screen2 frame buffer name	fb_foreground	Custom name for frame buffer.
Input - Number of Graphics screen2 frame buffer	2	Number of graphics selection.
Input - section where Graphics screen2 frame buffer allocated	sdram	Specify the section name to allocate the frame buffer. This is valid if "Input - Graphics screen1" is set as "Used."
Input - Graphics screen2 input horizontal size	800	Specify the number of horizontal pixels. Default value is the size for an image with 800x480 pixels
Input - Graphics screen2 vertical size	480	Specify the number of vertical pixels. Default value is the size for an image with 800x480 pixels.

Input - Graphics screen2 input horizontal stride (not bytes but pixels)	800	Specify the memory stride for a horizontal line. This value must be specified with the number of pixels, not actual bytes. Typically this parameter is set to same number as parameter 'input horizontal size'. Default value is the size for an image with 800x480 pixels.
Input - Graphics screen2 input format	32bits ARGB888, 32bits RGB888, 16bits RGB565, 16bits ARGB1555, 16bits ARGB4444, CLUT 8, CLUT 4, CLUT 1 Default: 16bits RGB565	Specify the graphics screen Input format. If selecting CLUT formats, you must write CLUT data using clut before performing start. Default setting supports a RGB565 formatted image.
Input - Graphics screen2 input line descending	On, Off Default: Off	Specify "On" if image data descends from the bottom line to the top line in the frame buffer. Usually "Off".
Input - Graphics screen2 input line repeat	On, Off Default: Off	Specify "On" if expecting to repeatedly read a raster image which is smaller than the LCD panel size. Usually "Off". For details, see the description of Line Repeating function.
Input - Graphics screen2 input line repeat times	0	Specify the number of repeating times for a raster image which is read repeatedly in a frame.
Input - Graphics screen2 layer coordinate X	0	Specify the horizontal offset in pixels of the graphics screen from the background screen.
Input - Graphics screen2 layer coordinate Y	0	Specify the vertical offset in pixels of the graphics screen from the background screen.
Input - Graphics screen2 layer background color alpha	255	Based on the alpha value, either the graphics screen2 (foreground graphics screen) is blended into the graphics screen1 (background graphics screen) or the graphics screen1 is blended into the monochrome background screen.
Input - Graphics screen2 layer background color Red	255	Specify the background color in the graphics screen N.
Input - Graphics screen2 layer background color Green	255	Specify the background color in the graphics screen N.

Input - Graphics screen2 layer background color Blue	255	Specify the background color in the graphics screen N.
Input - Graphics screen2 layer fading control	None, Fade-in, Fade-out Default: None	Specify "On" when performing a fade-in for the graphics screen. The transparent screen changes gradually to opaque. Specify "Off" when performing the fade-out for the graphics screen. The opaque screen changes gradually to transparent. Note that this processing is accelerated by the GLCDC hardware and cannot stop once started. The transition status can be monitored by statusGet.
Input - Graphics screen2 layer fade speed	0	Specify the number of frames for the fading transition to complete.
Output - Horizontal total cycles	1024	Specify the total cycles in a horizontal line. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Horizontal active video cycles	800	Specify the number of active video cycles in a horizontal line. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Horizontal back porch cycles	46	Specify the number of back porch cycles in a horizontal line. Back porch starts from the beginning of Hsync cycles, which means back porch cycles contain Hsync cycles. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.

Output - Horizontal sync signal cycles	20	Specify the number of Hsync signal assertion cycles. Set to the number of cycles defined in the data sheet of LCD panel sheet in your system. Default value matches LCD panel on S7G2 PE-HMI1 board.
Output - Horizontal sync signal polarity	Low active, High active Default: Low active	Select the polarity of Hsync signal to match your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical total lines	525	Specify number of total lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical active video lines	480	Specify the number of active video lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical back porch lines	23	Specify the number of back porch lines in a frame. Back porch starts from the beginning of Vsync lines, which means back porch lines contain Vsync lines. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical sync signal lines	10	Specify the Vsync signal assertion lines in a frame. Set to the number of lines defined in the data sheet of LCD panel sheet in your system. Default value matches the LCD panel on S7G2 PE-HMI1 board.
Output - Vertical sync signal polarity	Low active, High active Default: Low active	Select the polarity of Vsync signal to match to your system. Default setting matches LCD panel on S7G2 PE-HMI1 board.

Output - Format	24bits RGB888, 18bits RGB666, 16bits RGB565, 8bits serial Default: 24bits RGB888	Specify the graphics screen output format to match to your LCD panel. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Endian	Little endian, Big endian Default: Little endian	Select data endian for output signal to LCD panel. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Color order	RGB, BGR Default: RGB	Select data order for output signal to LCD panel. The order of blue and red can be swapped if needed. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Data Enable Signal Polarity	Low active, High active Default: High active	Select the polarity of Data Enable signal to match to your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Sync edge	Rising Edge, Falling Edge Default: Rising Edge	Select the polarity of Sync signals to match to your system. Default setting matches the LCD panel on S7G2 PE-HMI1 board.
Output - Background color alpha channel	255	Specify the background color of the background screens.
Output - Background color R channel	0	Specify the background color of the background screens.
Output - Background color G channel	0	Specify the background color of the background screens.
Output - Background color B channel	0	Specify the background color of the background screens.
CLUT	Used, Not used Default: Not used	Specify "Used" if selecting CLUT formats for a graphics screen input format. Then, a buffer named "CLUT_buffer" for the CLUT source data is generated in the ISDE auto-generated source file.
CLUT - CLUT buffer size	256	Specify the number of entries for the CLUT source data buffer. Each entries consumes 4 bytes (1 word). Words of CLUT source data specified by this parameter are generated in the ISDE auto-generated source file.

TCON - Hsync pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 Default: LCD_TCON0	Select the TCON pin used for the Hsync signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON - Vsync pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 Default: LCD_TCON1	Select TCON pin used for Vsync signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON - DataEnable pin select	Not used, LCD_TCON0, LCD_TCON1, LCD_TCON2, LCD_TCON3 Default: LCD_TCON2	Select TCON pin used for DataEnable signal to match to your system. Default setting is for LCD panel on S7G2 PE-HMI1 board.
TCON - Panel clock division ratio	1/1, 1/2, 1/3, 1/4, 1/5, 1/6, 1/7, 1/8, 1/9, 1/12, 1/16, 1/24, 1/32 Default: 1/8	Select the clock source divider value. See the note at bottom of this table about the source clock for the pixel clock.
Color correction - Brightness	Off, On Default: Off	Specify "On" when performing brightness control. If specifying "Off", the setting below does not affect the output color.
Color correction - Brightness R channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each of R, G, B channels.
Color correction - Brightness G channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each of R, G, B channels.
Color correction - Brightness B channel	512	Output color level is calculated as follows: Output color level = Input color level +/ - 512. Set the value for each of R, G, B channels.
Color correction - Contrast	Off, On Default: Off	Specify "On" when performing contrast control. If specifying "Off", the setting below does not affect the output color.
Color correction - Contrast(gain) R channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each of R, G, B channels.

Color correction - Contrast(gain) G channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each of R, G, B channels.
Color correction - Contrast(gain) B channel	128	Output color level is calculated as follows: Output color level = Input color level x (/128). Set the value for each of R, G, B channels.
Color correction - Gamma correction(Red)	Off, On Default: Off	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off", the settings for gain and threshold do not affect the output color.
Color correction - Gamma gain R[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma threshold R[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma correction(Green)	Off, On Default: Off	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off", the settings for gain and threshold do not affect the output color.

Color correction - Gamma gain G[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma threshold G[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma correction(Blue)	Off, On Default: Off	Control for each channel R/G/B. Specify "On" when performing gamma correction for the red channel. If specifying "Off", the settings for gain and threshold do not affect the output color.
Color correction - Gamma gain B[0-15]	0	Set the gain value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between ((Gamma threshold R[N-1])<<2) and ((Gamma threshold R[N])<<2). The output value is calculated as follows: Output color level = Input color level / 1024 (/128).
Color correction - Gamma threshold B[0-15]	0	Set the threshold value for the red channel in the area N on the gamma correction curve. The gain setting for area N is applied to the input data with a color level between Gamma threshold R[N-1] and Gamma threshold R[N]. The output value is calculated as follows: Output color level = Input color level / 1024 (/128).

Dithering	Off, On Default: Off	Dithering enable. Specify "On" when applying the dither effect to reduce the banding in case of selecting RGB666 or RGB565 output formats. Dithering can be applied when converting. If specified "Off", the settings for dithering below do not affect the output. For details on the dither effect, see Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Mode	Truncate, Round off, 2x2 Pattern Default: Truncate	Specify the dither mode. For detail, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Pattern A	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Pattern B	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Pattern C	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Dithering - Pattern D	Pattern 00, Pattern 01, Pattern 10, Pattern 11 Default: Pattern 11	Specify the dither pattern for 2X2 pattern mode. For details, see the Output Control Block Panel Dither Correction Register (OUT_PDTHA) in the hardware manual.
Misc - Correction Process Order	Brightness and Contrast then Gamma, Gamma then Brightness and Contrast Default: Brightness and Contrast then Gamma	Specify the color correction processing order if needed.

Line Detect Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	The driver needs valid interrupt priority setting and it will not work if disabled.
Underflow 1 Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	The driver needs valid interrupt priority setting and it will not work if disabled.
Underflow 2 Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX), Disabled Default: Disabled	The driver needs valid interrupt priority setting and it will not work if disabled.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the JPEG Decode Framework on sf_jpeg_decode

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter checking.
Name	g_sf_jpeg_decode0	The name to be used for a JPEG Decode Framework module instance.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the JPEG Decode Driver on r_jpeg_decode

ISDE Property	Value	Description
Parameter Checking	BSP, Enabled, Disabled Default: BSP	Enable or disable the parameter error checking.
Name	g_jpeg_decode0	The name to be used for a JPEG Decode module instance.

Byte Order for Input Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) Default: Normal Byte order	Specify the byte order for input data. The order is swapped as specified in every 8-byte.
Byte Order for Output Data Format	Normal byte order (1)(2)(3)(4)(5)(6)(7)(8), Byte Swap (2)(1)(4)(3)(6)(5)(8)(7), Word Swap (3)(4)(1)(2)(7)(8)(5)(6), Word-Byte Swap (4)(3)(2)(1)(8)(7)(6)(5), Longword Swap (5)(6)(7)(8)(1)(2)(3)(4), Longword-Byte Swap (6)(5)(8)(7)(2)(1)(4)(3), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2), Longword-Word Swap (7)(8)(5)(6)(3)(4)(1)(2) Default: Normal Byte order	Specify the byte order for output data. The order is swapped as specified in every 8-byte.
Output Data Color Format	Pixel Data RGB565 format, Pixel Data ARGBB888 format Default: Pixel Data RGB565 format	Specify the output data format.
Alpha value to be applied to decoded pixel data (only valid for ARGB8888 format)	255	Specify the alpha value for the output data format (only valid for ARGB8888 format).
Name of user callback function	NULL	Specify the name of user callback function.
Decompression Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Decompression interrupt priority selection.

Data Transfer Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	Data transfer interrupt priority selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

JPEG Common Instance

ISDE Property	Value	Description
Name	g_sf_jpeg_common	Module name.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the D/AVE 2D Driver on dave2d

ISDE Property	Value	Description
No configurable parameters.		

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

Configuration Settings for the D/AVE 2D Port sf_tes_2d_drw

ISDE Property	Value	Description
Work memory size for display lists in bytes	32768	Work memory size for display lists selection
DRW Interrupt Priority	Priority 0 (highest), Priority 1:14 Priority 15 (lowest - not valid if using ThreadX) Default: Priority 12	DRW INT selection.

Note

The example settings and defaults are for a project using the S7G2 Synergy MCU Group. Other MCUs may have different default values and available configuration settings.

GUIX Synergy Port Framework Module Clock Configuration

The GUIX Synergy Port Module is a logical module and therefore does not require any hardware setting except setting the ARM Cortex-M core SysTick timer.

GUIX Synergy Port Framework Module Pin Configuration

The GUIX Synergy Port Module is a logical module and therefore does not require pin settings.

4.3.4.6 Using the GUIX Synergy Port Framework Module in an Application

These important settings are made in the Synergy Configurator and are used to initialize the module:

- Setup GLCDC configurations including the module clock setting and GLCDC interrupt priority. Typically, the configuration can be auto-generated through Synergy Configurator.
- Setup 2D Drawing engine or JPEG engine configurations including the module clock setting and hardware interrupt priorities. Typically, the configuration can be auto-generated through Synergy Configurator.

The steps in using the GUIX Port on sf_el_gx module in a typical application are:

Step 1. Initialize the SF_EL_GX control block and pass module configuration settings by calling the sf_el_gx_api_t::open API.

Step 2. Complete initialization by calling the GUIX Studio generated gx_studio_display_configure API and pass the SF_EL_GX setup function as shown in the illustration below. This function call completes the initialization of Synergy graphics hardware accelerators. Obtain the address of the root window initialized by GUIX through the call.

```
gx_studio_display_configure (MAIN_DISPLAY,
                             g_sf_el_gx0.p_api->setup,
                             LANGUAGE_ENGLISH,
                             MAIN_DISPLAY_THEME,
                             &p_window_root);
```

Step 3. Initialize the primary memory address GUIX Canvas buffer by calling the sf_el_gx_api_t::canvasInit API.

Step 4. Create the root window by calling the GUIX Studio generated gx_studio_named_widget_create API.

Step 5. Show the root screen by calling the GUIX gx_widget_show API.

Step 6. Start the GUIX system by calling the GUIX gx_system_start API.

Once GUIX system is started, the SF_EL_GX module is driven under GUIX control. The application need not execute any operations after this.

These common steps are illustrated in a typical operational flow in the following figure:

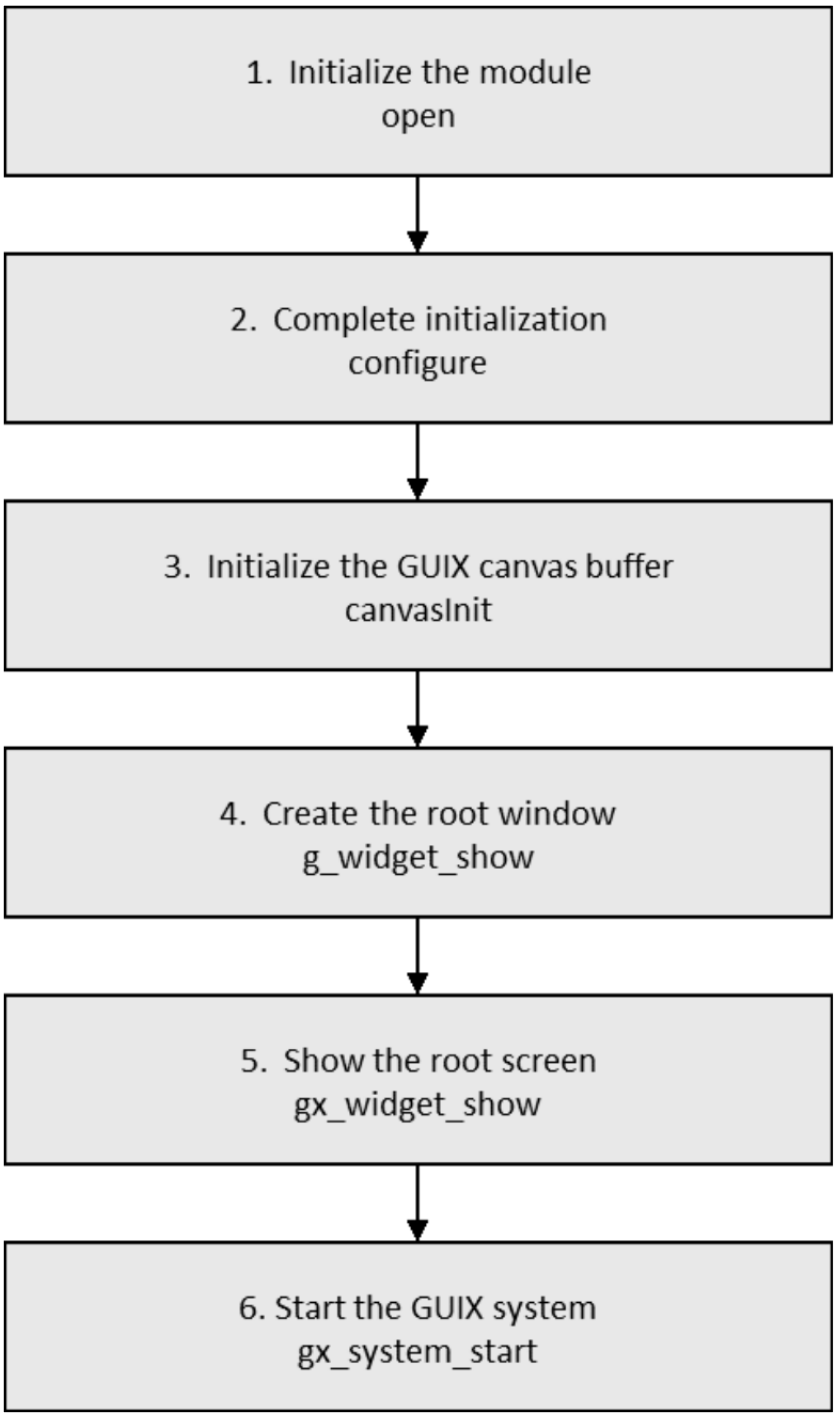

Figure 408: Flow Diagram of a Typical GUIX Synergy Port Framework Module Application

4.3.5 GUIX Source

4.3.5.1 GUIX GX_SRC Framework Introduction

The Azure RTOS GUIX Source component (GX_SRC) is the list of properties available in GUIX to modify the RTOS components of GUIX (for example, the system timer). See the GUIX User Guide Chapter 3: GUIX System Components for a list of GUIX components. The GUIX service calls have mutual exclusion for protection built in so that the application can use GUIX services while the GUIX 'engine' is managing the graphics. GUIX uses ThreadX threads, timers and message queues to manage display events and render screens.

GUIX GX_SRC Framework Module Features

The GUIX GX_SRC Framework module includes the following options:

- Disables multithread support
- Disables UTF8 Support
- Sets the system timer to match the hardware

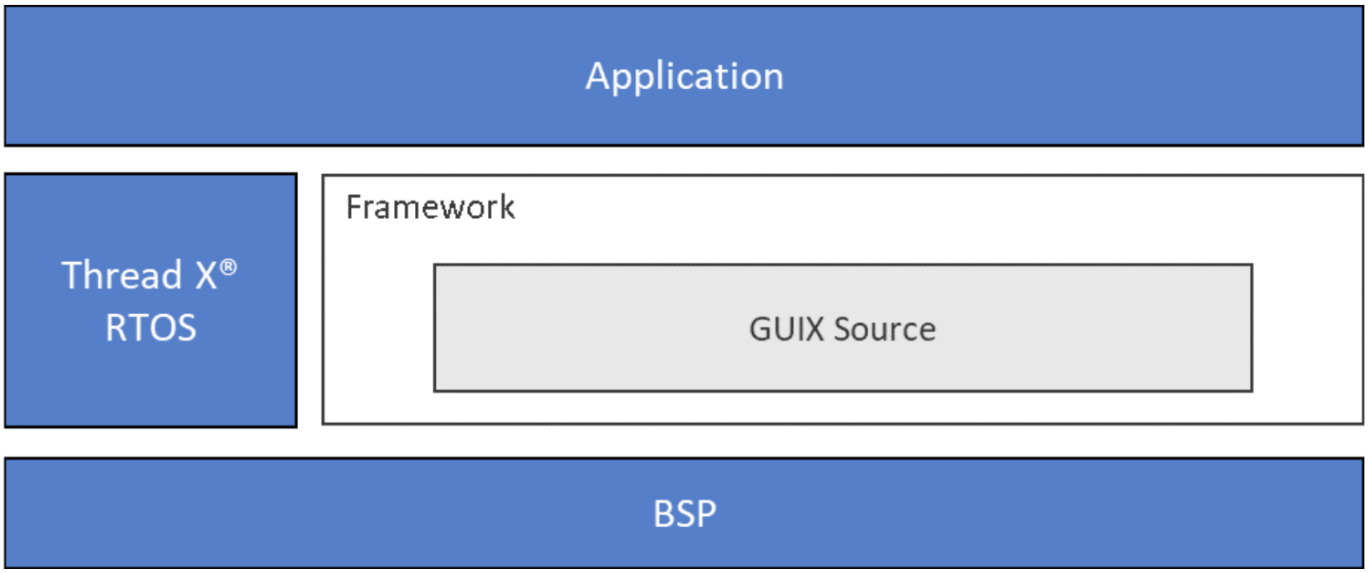

Figure 409: GUIX GX_SRC Framework Module Block Diagram

4.3.5.2 GUIX GX_SRC Framework Components Overview

The number of API functions available in GUIX in the current release is over 300 and the reader is referred to the GUIX User Guide for detailed API listings and descriptions. A list of GUIX components is discussed as follows:

GUIX Components

GUIX SYSTEM – Timers, threads and any internal objects the GUIX engine requires to run

GX_CANVAS* – Set by gx_canvas_create. In the simple GUIX design case, this function is called by the specification file from GUIX Studio so it is handled automatically.

GUIX CONTEXT – All the components that make up what GUIX is drawing into, that is, screen, canvas, brush and so on.

GX_DISPLAY* – All the components, including drawing functions that GUIX needs to draw on a canvas. GUIX display drivers are responsible for all interaction with the underlying physical screen. The display drivers have three basic functions: initialization, drawing and frame buffer display.

Initialization is responsible for preparing the physical display hardware, informing GUIX of the properties of the physical display hardware, and for informing GUIX which specific drawing functions should be used. The main display driver initialization is called from the GUIX gx_display_create API. This function is called from gx_studio_display_configure in applications that use the resource and specification.

In GUIX Studio, the specification files will set up the display driver automatically. If 16bpp is chosen in the Configure Displays dialog box in GUIX Studio, _gx_display_driver_565rgb_setup is used. If 32bpp is chosen you get _gx_display_driver_32argb_setup, and so on.

GUIX in Synergy supports the following formats:

- 32bpp (ARGB8888, RGB-888)
- 16bpp (RGB565)
- 8bpp (8bit Palette (CLUT))

The display driver function is set up in the GUIX Studio specification files if the target CPU is set to Synergy in GUIX Studio (see the IOTSG-782 module guide document for more details on setting up GUIX Studio for Synergy):

```
UINT _gx_synergy_display_driver_setup(GX_DISPLAY *display)
{
_gx_display_driver_565rgb_setup(display, GX_NULL, _gx_dave2d_buffer_toggle);
```

In the user application, the gx_studio_display_configure API configures the main display including specifying the display driver. Synergy has already tied the display driver to the SF_EL_GX instance. The SF_EL_GX driver setup function pointer supplies the display driver:

```
gx_studio_display_configure (MAIN_DISPLAY,
                             g_sf_el_gx0.p_api->setup,...
```

GX_WIDGET* – any visible thing you place on a screen; may or may not generate events

GUIX UTILITY – essentially a tool box for utility functions

- Defined as a struct data type in GUIX

4.3.5.3 GUIX GX_SRC Framework Module Operational Overview

Setting up GUIX in the Configurator

The GUIX Source component is optional. If not using the GUIX source, the prebuilt GUIX library with default settings is used. If the GUIX source component is added or any of its properties modified, the developer must click on Generate Project Content in the configurator pane and rebuild the project, or the prebuilt GuiX (gx.a) library is used with none of its properties modified.

GUIX at Startup

The following steps need to be performed before rendering any GUIX images:

- Call the gx_system_initialize API to initialize the GUIX system.
- Initialize the GUIX driver (g_sf_el_gx.p_api->open).
- Create and configure the display instance (gx_studio_display_configure called with g_sf_el_gx.p_api->setup as the driver input).
- Create and initialize the canvas for the display (g_sf_el_gx.p_api->canvasInit API).
- Prepare the display of the main screen (gx_studio_display_configure API) if using GUIX Studio specification and resource files.
- [Optionally] create any other windows or widgets if not created (gx_widget_create).
- Show the root window (gx_window_show API).
- Start the GUIX engine (gx_system_start API).

In the gx_system_initialize API, GUIX creates its own thread, event queue and timer necessary for performing all drawing, timer and GUIX related tasks. It also creates a mutex for multithreaded environments. Application threads have access to the same resources as GUIX; for example, if GUIX is doing a refresh operation, the mutex protections prevents other threads that try to access visible widgets during the refresh of a screen.

The open, setup and canvasInit API are accessible by function pointer fields of the sf_el_gx instance. One need only supply any other details except for the language and display screen name in the gx_studio_display_configure call.

GX_SRC Properties

GUIX Configurable Options for GX_SRC

ISDE property	Default value	Description
GUIX Stack Size	4096 bytes	GUIX internal thread stack size in bytes.
System Timer	20 ms	Used to calculate GX_SYSTEM_TIMER_TICKS. See explanation that follows. Equivalent option in Azure RTOS is GX_SYSTEM_TIMER_MS.
Disable Multithread Support	No (Disabled)	If not defined, ThreadX can support multiple threads by defining and using locking and unlocking functions to define critical sections. Equivalent option in Azure RTOS is GUIX_DISABLE_MULTITHREAD_SUPPORT.
Disable UTF8 Support	No (Disabled)	If defined, this disables UTF8 format string encoding in GUIX and allows only 8-bit ASCII character plus Latin-1 code page character encoding. Equivalent option in Azure RTOS is GX_UTF8_SUPPORT.

GUIX Event Queue Size	48	Size of GUIX Event Queue Size. Must be greater than zero or empty.
GUIX Thread Priority	16	Priority of GUIX Internal Thread. The value must be between 0 to 31.
GUIX Thread Time Slice	10	Time Slice value of GUIX Internal Thread. The value must be between 0(TX_NO_TIME_SLICE) to 0xFFFFFFFF.
Use User Data Field in GX_WIDGET Structure	No(default)	GUIX allows users to use gx_widget_user_data member in GX_WIDGET Structure if you say yes.
Enable partial canvas frame buffer	No (Disabled)	Enabling this option will define the GX_ENABLE_CANVAS_PARTIAL_FRAME_BUFFER to use the partial canvas frame buffer feature.
Enable horizontal canvas refresh direction	No (Disabled)	Specify the canvas refresh directions for the partial canvas frame buffer feature. By default, the canvas refreshes its dirty areas one by one. If the application requires refreshing the canvas in horizontal direction to mitigate tearing effects,this can be used.
Enable vertical canvas refresh direction	No (Disabled)	Specify the canvas refresh directions for the partial canvas frame buffer feature. By default, the canvas refreshes its dirty areas one by one. If the application requires refreshing the canvas in vertical direction to mitigate tearing effects,this option can be used.
